Effectiveness and Safety of Apremilast in Biologic-Naive versus Biologic-Experienced Patients with Psoriatic Arthritis in Real-World Clinical Practice Settings in Germany: Interim Analysis of an Ongoing, Multicenter, Prospective, Non-interventional Study

Jurgen Wollenhaupt[1], Christian Bach[2] and Josefine Roemmler-Zehrer[3], [1]Rheumatologie im Struenseehaus, Hamburg, Germany, [2]Amgen GmbH, München, Germany, [3]Amgen GmbH, München

SESSION INFORMATION
Session Date: Friday, November 6, 2020
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Treatment Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

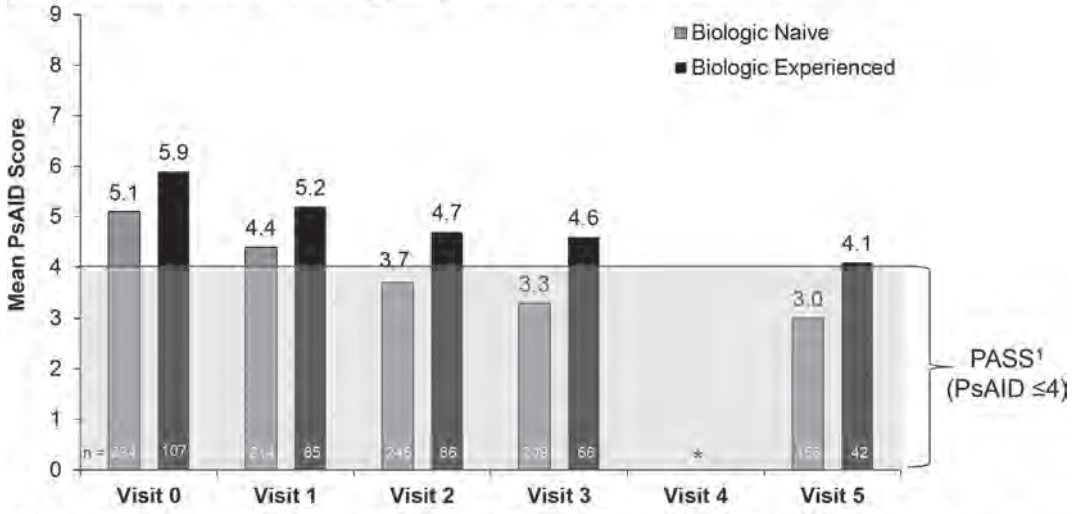
Background/Purpose: Apremilast (APR) was associated with improvements in physician-assessed and patient-reported outcomes in a large cohort of patients with PsA based on a 1-year interim analysis of LAPIS-PsA, a real-world study conducted in clinical practice settings in Germany. The current interim analysis of LAPIS-PsA evaluated the effectiveness and safety of APR in patients with and without prior biologic therapy.

Table 1. Physician- and Patient-Reported Outcomes With APR Treatment at Baseline and Follow-up

Outcome	Biologic Naive						Biologic Experienced					
	Visit 0 (n = 306)	Visit 1 (n = 232)	Visit 2 (n = 269)	Visit 3 (n = 229)	Visit 4 (n = 193)	Visit 5 (n = 170)	Visit 0 (n = 110)	Visit 1 (n = 92)	Visit 2 (n = 88)	Visit 3 (n = 69)	Visit 4 (n = 53)	Visit 5 (n = 43)
PhGA of 0 or 1, %	0	35	65	75	71	78	0	34	49	64	64	74
PtGA of 0 or 1, %	9	20	34	41	46	48	4	11	17	21	15	20
LEI score of 0*, %	0	36	51	51	61	53	0	44	51	50	45	71
Dactylitis count of 0†, %	0	49	75	77	84	87	0	42	59	70	67	90
Mean (95% CI) SJC	4.3 (3.8, 4.8)	2.3 (1.9, 2.8)	1.4 (1.1, 1.7)	0.6 (0.4, 0.8)	1.0 (0.6, 1.4)	0.7 (0.4, 1.1)	5.0 (4.0, 5.9)	3.0 (2.2, 3.9)	2.9 (1.7, 4.1)	1.4 (0.8, 2.1)	1.5 (0.7, 2.2)	1.3 (0.5, 2.2)
Mean (95% CI) TJC	11.4 (9.9, 12.9)	7.7 (5.9, 9.5)	5.0 (3.7, 6.3)	3.8 (2.3, 5.2)	3.5 (2.0, 4.9)	3.0 (1.7, 4.3)	11.3 (8.7, 14.0)	8.6 (6.0, 11.3)	8.3 (5.3, 11.3)	7.1 (3.7, 10.4)	4.6 (1.7, 7.6)	5.0 (1.3, 8.7)

*In patients with LEI >0 at baseline. †In patients with dactylitis at baseline. The n represents the total sample; the number of patients with data available may vary. CI = confidence interval; LEI = Leeds Enthesitis Index; PhGA = Physician's Global Assessment; PtGA = Patient's Global Assessment; SD = standard deviation; SJC = swollen joint count; TJC = tender joint count.

Figure 1. Lower Mean PsAID Scores Observed Over Time in Biologic-Naive Patients Compared With Biologic-Experienced Patients



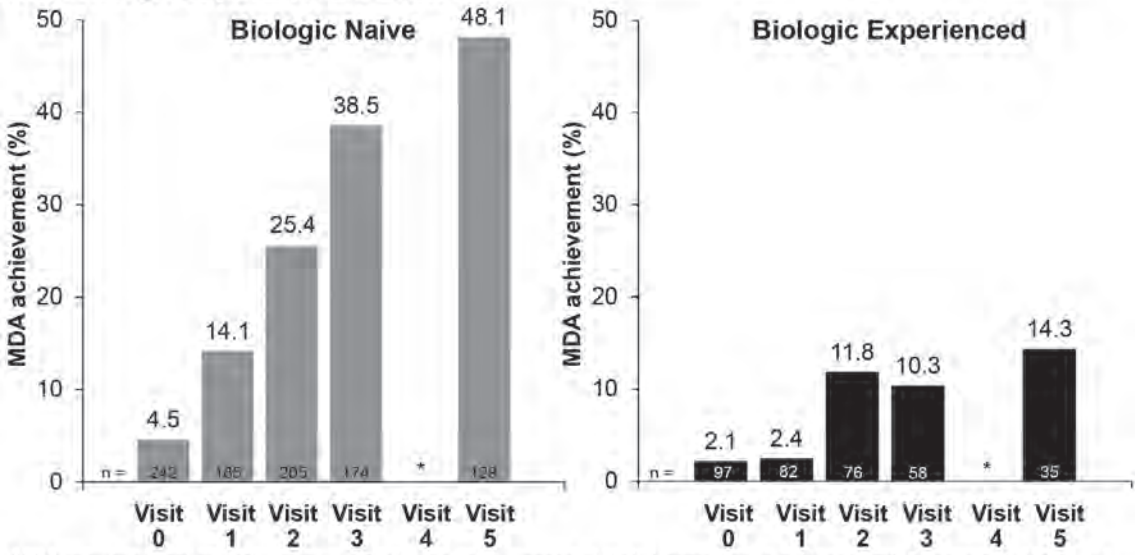
*PsAID score was not assessed at Visit 4 according to the protocol. Visit 0 (baseline); Visit 1 (~1 month after baseline); Visit 2 (~4 months after baseline); Visit 3 (~7 months after baseline); Visit 4 (~10 months after baseline); Visit 5 (~13 months after baseline). PASS = Patient-Acceptable Symptom State; PsAID = Psoriatic Arthritis Impact of Disease.

1. Gossec L, et al. *Ann Rheum Dis.* 2014;73:1012-1019.

Methods: LAPIS-PsA is a multicenter, prospective, non-interventional study enrolling patients with PsA under routine care in Germany who initiated APR according to the summary of product characteristics. Assessments included the Physician's Global Assessment of Disease Activity (PhGA), Patient's Global Assessment of Disease Activity (PtGA), Leeds Enthesitis Index (LEI), dactylitis count, swollen and tender joint counts (SJC/TJC), and Psoriatic Arthritis Impact of Disease (PsAID). Efficacy was examined descriptively at baseline and Visit 1 (~1 month), Visit 2 (~4 months), Visit 3 (~7 months), Visit 4 (~10 months) and Visit 5 (~52 weeks). Safety was evaluated based on adverse events (AEs) in the safety population (all patients who received ≥1 dose of APR).

Results: Of the 418 patients who were enrolled in the full analysis set, 306 were biologic naive and 110 were biologic experienced. For biologic-naive vs biologic-experienced patients, mean (SD) age was 54.6 (11.0) vs 55.3 (10.6) years, mean (SD) body mass index was 29.5 (5.7) kg/m^2 vs 29.6 (5.7) kg/m^2, and 56.4% vs 65.1% were women. Biologic-naive vs biologic-experienced patients had similar baseline (mean [SD]) duration of psoriasis (24.9 [17.4] vs 27.7 [17.5] years), duration of PsA (17.0 [19.6] vs 19.7 [18.2] years), enthesitis counts (LEI count: 3.0 [1.7] vs 2.9 [1.7]), and dactylitis counts (2.3 [2.2] vs 2.0 [1.4]). During follow-up, early and sustained improvements were observed in PhGA,

Figure 2. Greater MDA Achievement Over Time in Biologic-Naive Patients Compared With Biologic-Experienced Patients



*MDA calculation not possible because FFbH was not assessed at Visit 4 according to protocol. Visit 0 (baseline); Visit 1 (~1 month after baseline); Visit 2 (~4 months after baseline); Visit 3 (~7 months after baseline); Visit 4 (~10 months after baseline); Visit 5 (~13 months after baseline). FFbh = Funktionsfragebogen Hannover questionnaire; MDA = minimal disease activity.

PtGA, enthesitis, dactylitis, SJC, and TJC assessments in both groups (Table 1); achievement of PtGA score of 0 or 1 was higher in biologic-naive vs biologic-experienced patients at all study visits (Table 1). Mean PsAID scores were lower for biologic-naive vs biologic-experienced patients at all study visits; biologic-naive patients achieved mean PsAID scores exceeding the Patient-Acceptable Symptom State (PASS; PsAID ≤4) as early as Visit 2 and maintained PsAID PASS up to Visit 5 (Figure 1). A greater proportion of patients in the biologic-naive vs biologic-experienced group achieved minimal disease activity (MDA) over visits (Figure 2). Rates of AEs commonly reported (≥5%) in APR clinical trials were similar in biologic-naive (n = 358) vs biologic-experienced (n = 128) patients in the safety analysis population of LAPIS-PsA (diarrhea: 31 [8.7%] vs 17 [13.3%]; nausea: 22 [6.1%] vs 8 [6.3%]; headache: 10 [2.8%] vs 5 [3.9%]; upper respiratory tract infection: 3 [0.8%] vs 1 [0.8%]).

Conclusion: In this real-world study of patients with PsA, APR demonstrated early and sustained effectiveness in patients with and without prior biologic therapy. More biologic-naive patients achieved PtGA 0-1 and PsAID PASS at all study visits vs biologic-experienced patients and were more likely to achieve early and sustained MDA. AEs were consistent with the known safety profile of APR.

Abstract Number: 0346

Safety Profiles of Ixekizumab versus Adalimumab: 52-Week Results from a Head-to-Head Comparison in Patients with Active Psoriatic Arthritis

Philip Mease[1], Josef Smolen[2], Arthur Kavanaugh[3], Peter Nash[4], Gaia Gallo[5], Soyi Liu-Leage[5], Christophe Sapin[5] and Mark Genovese[6], [1]Seattle Rheumatology Associates, P.L.L.C., Seattle, WA, [2]Division of Rheumatology, Department of Medicine III, Medical University of Vienna, Vienna, Austria, [3]UC San Diego Health System, San Diego, CA, [4]School of Medicine Griffith University, Brisbane, Queensland, Australia, [5]Eli Lilly and Company, Indianapolis, IN, [6]Stanford University Medical Center, Palo Alto, CA

SESSION INFORMATION
Session Date: Friday, November 6, 2020
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Treatment Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Ixekizumab (IXE) was shown to be superior to adalimumab (ADA) in achievement of simultaneous improvement of joint and skin disease (American college of Rheumatology [ACR]50 and Psoriasis Area and Severity Index [PASI]100) in patients with active psoriatic arthritis (PsA) and inadequate response to conventional synthetic disease-modifying anti-rheumatic drugs (csDMARDs).[1] The objective of this study was to compare the safety and tolerability profile of vs ADA in patients with PsA up to 52 weeks of treatment.

Methods: SPIRIT-H2H (NCT03151551) was an open-label, head-to-head, blinded assessor clinical trial which included patients with active PsA (≥3 tender joint count + ≥3 swollen joint count) and plaque psoriasis (body surface area ≥3%) who were inadequate responders to csDMARD therapy but naïve to biologic DMARDs. Patients were randomized (1:1) to approved dosing of IXE or ADA. Safety events were assessed at each patient visit up to Week 52. Frequencies of adverse events (AEs) were based on the number of patients in the safety population (patients who received ≥1 dose of study drug). Cases of inflammatory bowel disease (IBD) and cerebro-cardiovascular events were adjudicated by external committees. Kaplan-Meier analysis of time to onset of serious adverse events (SAEs) was performed.

Table: Safety results at 52 weeks

	IXE N=283 n (%)	ADA N=283 n (%)
TEAEs	209 (74)	194 (69)
Severe[a]	9 (3.2)	20 (7.1)
Related to study treatment[b]	98 (35)	87 (31)
Serious adverse events	12 (4.2)	35 (12)***
Deaths	0	0
Discontinuation due to AE	12 (4.2)	21 (7.4)
Serious infections	3 (1.1)	4 (1.4)
Injection-site reactions[c]	30 (11)	10 (3.5)**
Severe	0	1 (0.4)
Resulted in discontinuation	2 (0.7)	3 (1.1)
Anaphylaxis	0	0
Inflammatory bowel disease	2 (0.7)	0
Ulcerative colitis	1 (0.4)[d]	0
Crohn's disease	1 (0.4)	0
Cerebro-cardiovascular events	5 (1.8)	7 (2.5)
MACE	0	2 (0.7)
Malignancies	0	4 (1.4)
Depression	5 (1.8)	9 (3.2)
Interstitial lung disease	0	1 (0.4)
Cytopenias	9 (3.2)	12 (4.2)
Hepatic events	18 (6.4)	20 (7.1)

[a]Patients with multiple occurrences of the same event are counted under the highest severity. [b]The treatment-emergent adverse event 's relationship to study treatment was judged by the investigator. [c]Medical Dictionary for Regulatory Activities (MedDRA) high-level term. [d]This event was adjudicated but it was not a confirmed inflammatory bowel disease. ***p<0.001; **p<0.01 by Fisher's exact test. ADA=adalimumab, AE=adverse event; IBD=inflammatory bowel disease; IXE=ixekizumab; MACE=major adverse cardiovascular event.

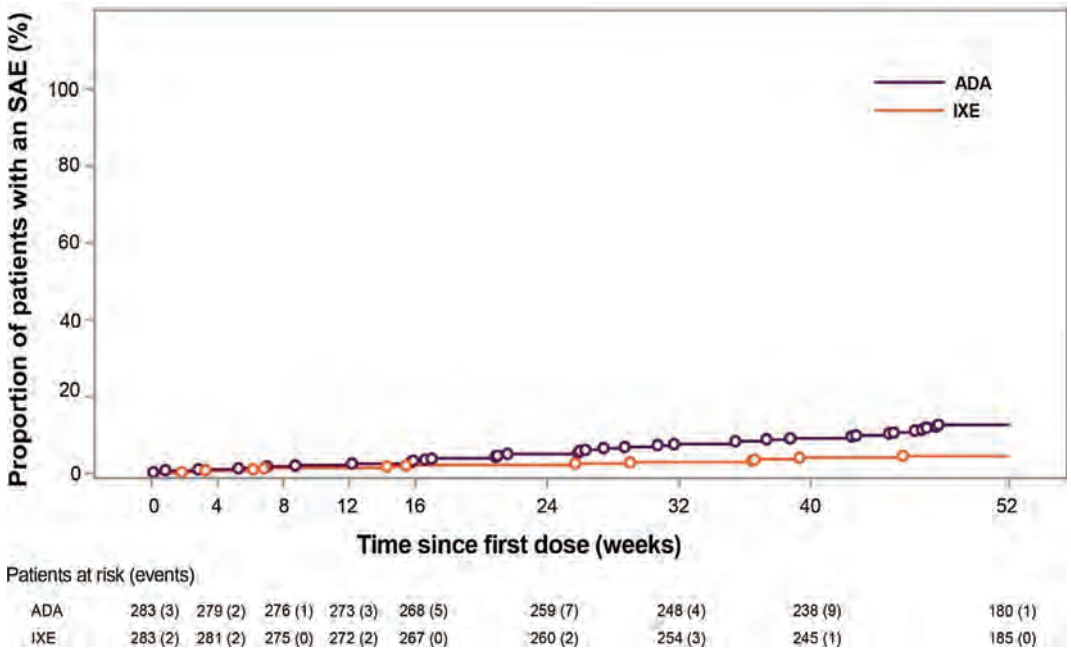

Figure 1. Time to onset of first SAE. Numbers below x-axis represent patients at risk at each time point. Open circles represent events. p<0.001 by log rank test. ADA=adalimumab; IXE=ixekizumab; SAE=serious adverse event.

Results: Of the 283 patients randomized to each treatment, 87% (246/283) of patients who received IXE and 84% (237/283) of patients who received ADA, completed 52 weeks of treatment. The frequency of treatment-emergent AEs (TEAEs) was similar between the groups (74% IXE vs 69% ADA), however fewer severe TEAEs were reported in the IXE group (3.2% IXE vs 7.1% ADA) (Table). SAEs were significantly more frequent in the ADA group compared to the IXE group (12% vs 4.2%; p< 0.001), and the time to develop a patient's first SAE was significantly shorter for ADA versus IXE (p< 0.001; Figure). Discontinuations due to AEs were numerically more frequent in the ADA group versus the IXE group (7.4% vs 4.2%; p=0.15). IXE-treated patients reported more injection-site reactions (ISR) than ADA-treated patients (11% vs. 3.5%; p=0.002). Study withdrawals due to ISR were comparable, and only one injection-site reaction was severe on ADA (Table). There were two IBD cases reported for IXE; one case was confirmed as IBD.

Conclusion: Safety results were consistent with previous trials with IXE and ADA. Compared with IXE, patients with PsA treated with ADA had significantly more serious AEs.

SESSION INFORMATION

Session Date: Friday, November 6, 2020

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Treatment Poster I

Session Type: Poster Session A

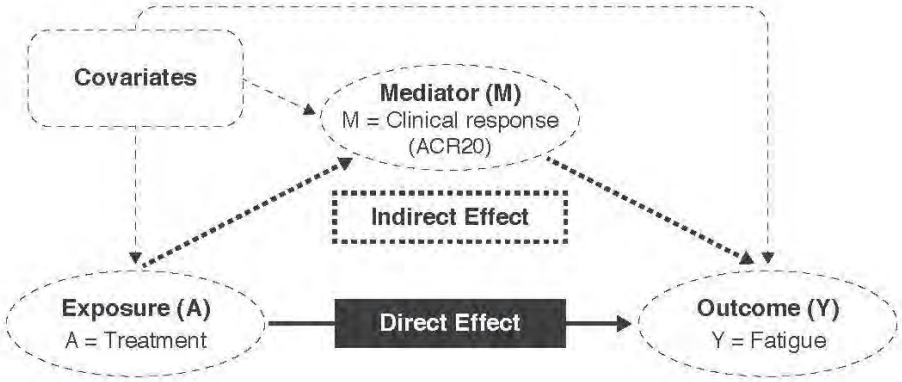
Session Time: 9:00AM–11:00AM

Background/Purpose: DISCOVER 1 & 2 are phase-3 trials of guselkumab (GUS, an IL-23 inhibitor) in patients with psoriatic arthritis (PsA). In both trials, treatment with GUS led to significantly more improvement than placebo (PBO) in the primary endpoint (ACR20) and in other measures of arthritis and psoriasis at week (w) 24,[1,2] and these improvements were maintained through 1 year of active treatment.[3,4] Here we evaluate the effect of GUS on fatigue in DISCOVER 1 & 2 using the patient reported outcome (PRO) FACIT-Fatigue, which has demonstrated content validity and strong psychometric properties in clinical trials.[5]

Methods: DISCOVER 1 & 2 enrolled patients with active PsA, despite non-biologic DMARDS or NSAIDS, who were biologic naïve except ~30% of patients in DISCOVER 1 who had received 1-2 TNFi. Patients were randomized (1:1:1) in a blinded fashion to subcutaneous GUS 100 mg at w0, w4, then every (q) 8w; GUS 100 mg q4w; or matching PBO. At w24, PBO patients were switched to GUS q4w. Concomitant treatment with select non-biologic DMARDS, oral corticosteroids, and NSAIDs was allowed. The FACIT-Fatigue is a 13-item PRO assessing fatigue and its impact on daily activities and function over the past 7 days, total score ranging from 0 to 52, higher score denoting less fatigue. A change of ≥4 points is considered clinically meaningful.[5] The change from baseline in FACIT-Fatigue presented below is based on observed data. Mediation analysis[6] was applied to the treatment effect of GUS on FACIT-Fatigue to estimate the natural direct and indirect effects, after adjusting for ACR20 response (Figure 1).

Results: At baseline in DISCOVER 1 & 2, the mean FACIT-fatigue scores (SD) were 30.4 (10.4) and 29.7 (9.7), respectively, indicating that patients with PsA experienced fatigue worse than the general population. At w24 in the DISCOVER trials, treatment with GUS led to significant improvements in FACIT-Fatigue scores compared with PBO, as early as w16 in DISCOVER 1 and w8 in DISCOVER 2. Improvements in fatigue were similar between GUS q4w and q8w doses, and the improvements at w24 were maintained through w52 (Figure 2). After a switch to GUS q4w at w24, PBO patients achieved FACIT-Fatigue scores that were comparable to those of GUS patients (Figure 2). 54%-63% of GUS patients compared with 35%-46% of PBO patients achieved clinically meaningful improvement (≥4 points) in FACIT-Fatigue at w24 ($P \leq 0.003$). At w52, 61%-70% of both GUS and PBO-to-GUS groups reached this improvement. As evaluated by mediation analysis at w24, GUS had independent positive treatment effects on fatigue (12%-36% in the q8w GUS dosing group and 69%-70% in the q4w GUS group) after adjustment for ACR20 response (Figure 1).

Figure 1. Mediation Analysis: Guselkumab has Direct Effects and Indirect Effects (mediated through ACR 20) on Fatigue in PsA.



Mediation Analysis			
	Effect	**GUS 100 mg q8W vs. PBO (95% CI)**	**GUS 100 mg q4W vs. PBO (95% CI)**
DISCOVER-1	Total Effect	3.1 (1.0, 5.2) ($p < 0.02$)	3.8 (1.9, 5.4) ($p < 0.02$)
	% Direct Effect	11.7%	68.5%
	% Indirect Effect mediated by ACR20	88.3%	31.5%
DISCOVER-2	Total Effect	4.0 (2.4, 5.5) ($p < 0.02$)	3.6 (2.1, 5.0) ($p < 0.02$)
	% Direct Effect	36.3%	69.7%
	% Indirect Effect mediated by ACR 20	63.7%	30.3%
The mediation analysis shows that for total treatment effect on fatigue, 11.7%-36.3% with GUS 100 mg q8w and 68.5%-69.7% with GUS 100 mg q4w are direct effects, indicating additional patient benefit beyond clinical response.			

3000_v3

Conclusion: In 2 phase-3 trials, GUS treatment improved fatigue when compared to PBO during PBO-controlled periods and maintained improvements through 1 year of active treatment. Substantial proportions of those effects were independent of the effects on ACR 20, especially for the q4W dosing group.

SESSION INFORMATION

Session Date: Friday, November 6, 2020

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Treatment Poster I

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: Golimumab (**GLM**) is the latest anti-TNFα to be indicated for treating rheumatoid arthritis (**RA**), psoriatic arthritis (**PsA**) and axial spondyloarthritis (**axSpA**). The post-registration GO-PRACTICE study was performed at the request of the French Health Authorities, for the reevaluation of **GLM** in real-life.

Methods: The primary objective was to estimate **GLM** persistence at 2 years from initial prescription which was defined as the time to **GLM** discontinuation. This abstract focuses on a *post-hoc* analysis of the factors linked to **GLM** discontinuation in **axSpA** patients.

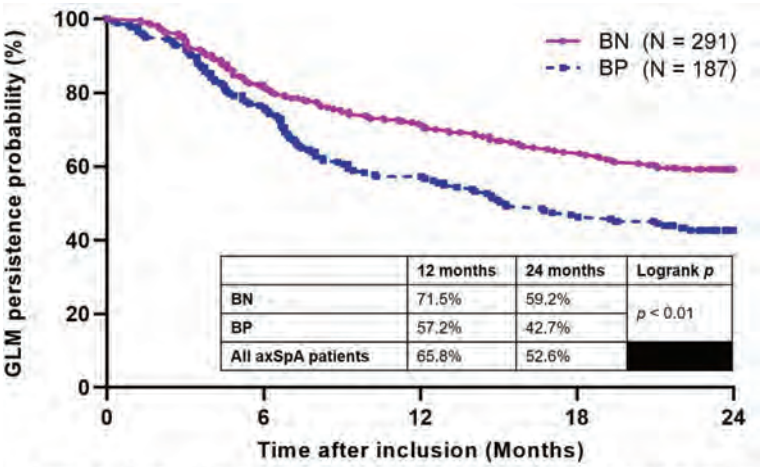

Figure 1: Kaplan-Meier curve of golimumab persistence in biologic-naïve (BN) and biologic-pretreated (BP) patients with axSpA

Figure 1. Kaplan-Meier curves of golimumab persistence in biologic-naïve and biologic-pretreated patients with axSpA

Table 1. Cox proportional hazard model results for variables of interest and their link to golimumab discontinuation in axSpA

Table 1: Cox proportional hazard model results for variables of interest and their link to GLM discontinuation in axSpA

Factor	Modalities	*p*-value	Hazard ratio (HR)	95% CI
HR for variables of interest following univariate analysis ($p > 0.20$)				
Age	Continuous variable	0.5200	1.00	0.99–1.02
Disease duration		0.5187	1.00	0.98–1.01
Inflammatory bowel disease	Yes vs. No	0.2771	0.74	0.43–1.28
Gastrointestinal disease		0.3440	1.27	0.78–2.06
Uveitis		0.2374	0.80	0.55–1.16
Psoriasis		0.2376	0.92	0.64–1.31
HR following multivariate analysis (all variables with $p < 0.20$ at univariate analysis)				
Gender	Female vs. Male	0.0065	1.59	1.14–2.23
Biologics history	Pretreated vs. naïve	0.0034	1.63	1.18–2.26
Serum CRP	Continuous variable	0.5367	1.00	0.99–1.01
DMARD history	Yes vs. No	0.2007	1.25	0.89–1.75
Ongoing corticosteroids		0.7518	1.07	0.71–1.60
Anemia		0.1002	2.06	0.87–4.88
Asthma		0.9384	0.98	0.57 – 1.68
Kidney Disease		0.6359	1.34	0.40–4.41
Other physical illness		0.5331	1.21	0.66–2.24

Observational, prospective, multicenter study, that consecutively recruited adult patients with **RA**, **PsA** and **axSpA** who were newly prescribed **GLM**. Patients were followed-up for 2 years and outcomes data were collected at baseline, 1 and 2 years. Patients' sociodemographic characteristics, disease history, comorbidities and treatment history were also collected at baseline. Persistence was estimated with the Kaplan-Meier method. Cox proportional hazard models were used to assess factors associated with persistence. Selected baseline characteristics were studied in univariate models, where those associated with *p*-value < 0.20 were included in multivariate analysis. Significance level was set at $p < 0.05$.

Results: Patients with **axSpA** (n=478) were included from Jan 2015 to Mar 2016. Mean age was 43 years and 55% were female; 61% of patients were biologic-naïve (**BN**, n=291) and 39% (n=187) were biologic-pretreated (**BP**). Median time-elapsed in years since **axSpA** diagnosis was 1.7 (range 0–45.1) and 6.9 (range 0.2–51.8) in **BN** and **BP** patients, respectively ($P < 0.001$); 97% patients were prescribed 50 mg GLM monthly and co-treatments included **DMARD** (34%), corticosteroids (17%) and **NSAIDs**/analgesics (90%).

The cumulative persistence probability of **GLM** at 2-years was 52.6% (Fig 1). Table 1 details the binary variables associated with GLM discontinuation at $p < 0.20$. Among continuous variables, baseline **CRP** level was associated with $p < 0.20$. A multivariate analysis of these factors revealed that being female (Hazard Ratio 1.59, 95%CI 1.14–2.23, $P = 0.0065$) and being **BP** (Hazard ratio 1.63, 95%CI (1.18–2.26), $P = 0.0034$) were risk factors for earlier **GLM** discontinuation (Table 1).

Conclusion: The persistence of golimumab at 2-years was 52.6% in patients with axial spondyloarthritis. Females and those who were biologics-pretreated were at greater risk for earlier golimumab discontinuation.

†Combined GUS q8w and q4w treatment groups.
‡For subjects in PBO group who changed treatment from PBO to GUS, only data on and after first administration of guselkumab were included in this group.
AE, adverse event; CI, confidence interval; PY, patient year; q4w, every 4 weeks; q8w, every 8 weeks

Background/Purpose: DISCOVER 1 & 2, two double-blind, phase 3, psoriatic arthritis (PsA) trials of guselkumab (GUS, an IL-23 inhibitor), demonstrated significant improvement with GUS vs placebo (PBO) in signs and symptoms of PsA, with good tolerability, at week (w) 24 during the PBO-controlled period.[1,2] Beyond w24, all patients switched to GUS. Continued treatment maintained efficacy through w52.[3,4] Here, we describe pooled safety results from the DISCOVER 1 & 2 trials through 1-year of GUS treatment.

Methods: Adults with active PsA (≥3 tender/swollen joints and C-Reactive protein [CRP] ≥0.3 mg/dL in DISCOVER 1; ≥5 tender/swollen joints and CRP ≥0.6 mg/dL in DISCOVER 2) were enrolled. Patients were biologic naive except ~30% patients in DISCOVER 1 had taken 1-2 TNF inhibitors. Patients were randomized to subcutaneous GUS 100 mg at w0, w4, then every 8 w (q8w); GUS 100 mg q4w; or PBO. At w24, PBO patients were switched to GUS 100 mg q4w. Adverse events (AEs), laboratory investigations, and AEs of interest (Table 3) through w60 (end of trial) in DISCOVER 1 and through w52 in DISCOVER 2 were reported.

Results: Baseline characteristics were similar between treatment groups in the pooled studies (Table 1). Through w24 and 1 year, time adjusted results (per 100 patient years [PY]) for numbers of patients with ≥1 event were similar among treatment groups for AEs, serious AEs, infections, serious infections, and discontinuations due to an AE (Table 2). For events of interest at 1 year (Table 3), there were no cases of active tuberculosis or opportunistic infections (including *Candida*); no inflammatory bowel disease in GUS-treated patients; 2 deaths in PBO patients; and low incidences that were similar across treatment groups for malignancy, major adverse cardiac events, and injection-site reactions. Incidence of anti-GUS antibodies was 4.5%, and most were not neutralizing. Mild elevations in serum hepatic transaminases and decreases in neutrophil counts were consistent at 1 year with the results at w24 (Table 3).

*Through week 60 for DISCOVER 1 and week 52 for DISCOVER 2. **National Cancer Institute toxicity grades †Combined GUS q8w and q4w treatment groups. ‡For subjects in PBO group who changed treatment from PBO to GUS, only data on and after first administration of guselkumab were included in this group.
ALT, alanine aminotransferase; AST. Aspartate aminotransferase; IBD, inflammatory bowel disease; MACE, major adverse cardiac events (cardiovascular death, non-fatal myocardial infarction, or non-fatal stroke); NA, not applicable; PBO, placebo; q4w, every 4 weeks; q8q, every 8 weeks

Conclusion: GUS regimens of q8w and q4w were well tolerated in PsA patients through 1 year of treatment in the phase 3 DISCOVER trials, consistent with the w24 results. There were no meaningful differences between incidences of AEs reported in the q8w and q4w groups. The safety profile of GUS in PsA patients is generally comparable with the previously established safety profile of GUS.

SESSION INFORMATION

Session Date: Friday, November 6, 2020

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Treatment Poster I

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: Ankylosing spondylitis (AS) is a chronic inflammatory disease involving the sacroiliac joints and spine and associated with pain, stiffness, and disability.[1] A previous analysis of 16-wk data from the phase 3 MEASURE studies showed that secukinumab (SEC), a selective inhibitor of interleukin 17A, led to significant improvements in efficacy outcomes vs placebo, regardless of age or time since diagnosis (TSD).[2] Younger patients (pts) reported better responses, possibly due to shorter TSD and higher rates of biologic inexperience. However, the relative importance of these factors was not clear.

In this hypothesis-generating analysis of pooled 52-wk data, we investigated the impact of age, TSD, TNFi exposure, and other baseline factors on responses in pts with AS treated with SEC in the MEASURE studies.

Methods: Pts with active AS from MEASURE 1 (NCT01358175), 2 (NCT01649375), 3 (NCT02008916), and 4 (NCT02159053) were included.[3-8] Pts received subcutaneous (SC) SEC every 4 wk at doses of 300 mg with an intravenous (IV) loading dose (MEASURE 3 only) or 150 mg with or without an IV or SC loading dose. Pooled efficacy outcomes (ASAS20/40; ASDAS-CRP inactive disease [ID]; change from baseline [BL] in BASDAI, BASFI, and BASMI)

at wk 52, were analyzed using logistic regression or ANCOVA with TSD and age at BL as continuous predictors along with key binary factors (eg, TNFi exposure). No adjustments were made for multiple comparisons.

Results: This analysis included 460 pts (SEC 300 mg, n = 76; SEC 150 mg, n = 384) (**Table 1**); data were available at BL and wk 52 for 393 pts (85.4%). Regression analyses (**Table 2**) revealed that ASAS20 responses were less likely with older age and prior TNFi exposure; ASAS40 responses were more likely in nonsmokers vs smokers and less likely with older age. ASDAS-CRP ID responses were more likely to occur in pts with BMI < 30 vs ≥ 30 kg/m^2. Reductions in BASDAI and BASFI were greater in nonsmokers vs smokers, and in TNFi-naive vs -treated pts (**Table 2**). Reductions in BASFI were also greater in pts with BMI < 30 vs ≥ 30 kg/m^2. TSD was not a significant covariate. Age at BL was a significant factor for reductions in BASDAI, BASFI, and BASMI scores.

Conclusion: ASAS20/40 responses at wk 52 were more likely to occur in younger pts, and age at BL was a significant covariate for predicting reductions in disease activity measures. Better outcomes in younger pts demonstrate the importance of early treatment. It is possible that the effect of age was due to longer disease duration in older pts (which would also support the importance of early treatment) and that TSD was not predictive of outcomes due to the variable time between onset of symptoms and diagnosis; age might therefore be a better surrogate for disease duration than TSD.

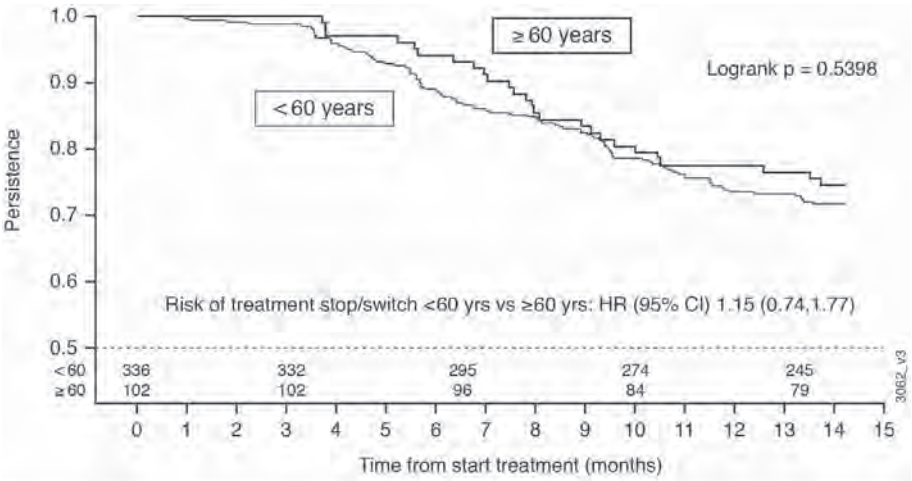

Figure 2. Kaplan-Meier Plot of Treatment Duration: ≥60 vs. <60 Years of Age in Patients Treated with UST.

Background/Purpose: In the PsABio study (NCT02627768), real-world data from patients with PsA showed comparable clinical results after treatment with ustekinumab (UST, an anti-p40 IL-12/23 inhibitor) versus TNF inhibitors (TNFi).[1,2] Patients of all ages may acquire psoriatic arthritis (PsA) and may require prolonged treatment. In general, treatment persistence is a function of effectiveness, safety, convenience, and treatment satisfaction. Elderly patients may be at increased risk of treatment interruption due to adverse events (AEs), increased comorbidities, and/or polypharmacy. Here we report PsABio results in younger versus older patients treated with UST.

Methods: PsABio is a multinational, prospective, observational study in patients with PsA prescribed either UST or TNFi (as 1st, 2nd or 3rd line treatment) at the discretion of the treating rheumatologist. This post-hoc analysis compared the effectiveness and safety in UST-treated patients by age subgroup (< 60 vs ≥60 years old). Drug persistence was compared by means of Kaplan-Meier plots and the log-rank test. Cox-regression analysis was used to compare the risk of stopping treatment before 15 months of follow-up between the age subgroups.

Results: 458 of 930 patients in PsABio received UST (77.1% were < 60 years of age; 22.9% were ≥60). Baseline characteristics (Table) were comparable across the older vs younger subgroups, except that older patients had more cardiovascular disease and trended towards greater PsA disease duration. Effectiveness after treatment with UST for 6 months and 1 year was generally comparable across age subgroups. The similarities included components of the ACR response criteria (Swollen 66-joint Count, Tender 68-joint Count, C-Reactive Protein, Health Assessment Questionnaire-Disease Index [HAQ-DI], Physician's Global Assessment, Patient's Global Assessment, and Patient's Pain Assessment) (Figure 1A) and composite measures (clinical Disease Activity Index for Psoriatic Arthritis and Minimal Disease Activity) (Figure 1B). Numerically fewer older patients reached the goals measured in the composite endpoints. Incidence of AEs, but not withdrawal due to an AE, was somewhat higher in the older patient subgroup (data not shown). Observed treatment persistence did not differ between older and younger patients (Log Rank p value=0.54), confirmed by Cox-regression analysis showing similar risk for stop/switch within the first year (Figure 2).

Conclusion: In a real-world setting, no clinically meaningful differences were observed in UST effectiveness and safety in PsA patients who were < 60 compared with ≥60 years of age. These results were generally maintained from 6 months to 1 year of treatment. Additionally, no significant differences were observed in treatment persistence over one year when comparing younger or older populations treated with UST, indicating that UST appears safe and effective in the aged PsA population.

SESSION INFORMATION

Session Date: Friday, November 6, 2020

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Treatment Poster I

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: Ixekizumab (IXE), a high-affinity monoclonal antibody selectively targeting IL-17A, was superior to adalimumab (ADA) at Week (Wk) 24 for simultaneous achievement of ACR50 and 100% improvement from baseline in Psoriasis Area and Severity Index (PASI 100); (primary endpoint) in patients (pts) with active PsA from SPIRIT-H2H. SPIRIT-H2H had 2 major secondary endpoints and achieved both: noninferiority of IXE to ADA for ACR50 and superiority of IXE to ADA for PASI 100, at Wk 24.The aim was to determine how concomitant conventional synthetic (cs) DMARD use affects safety and efficacy of IXE and ADA in prespecified subgroups defined by biologic monotherapy, concomitant MTX use, and concomitant csDMARD use through Wk 52 in SPIRIT-H2H.

Methods: SPIRIT-H2H was a 52-wk, multicenter, randomized, open-label, assessor-blinded, parallel-group study evaluating the efficacy and safety of IXE vs ADA in adults with PsA and naïve to biologic DMARDs. Pts were required to have active PsA fulfilling Classification for Psoriatic Arthritis (CASPAR) criteria and ≥3/68 tender and ≥3/66 swollen joints, ≥3% plaque psoriasis (PsO) body surface area (BSA) involvement, no prior treatment with biologic DMARDs, and with prior inadequate response to ≥1 csDMARD (but not necessarily current treatment with csDMARDs). Randomization (1:1) was stratified by concomitant use of csDMARD and the presence/absence of moderate-to-severe PsO (baseline: BSA≥10% + PASI≥12, + static Physician's Global Assessment≥3). Pts (N=566) received IXE/ADA through 52 wks according to the labelled dose dependent on presence/absence of moderate-to-severe PsO. In this prespecified subgroup analysis by presence/absence of csDMARDs, efficacy outcomes through Wk 52 were com-

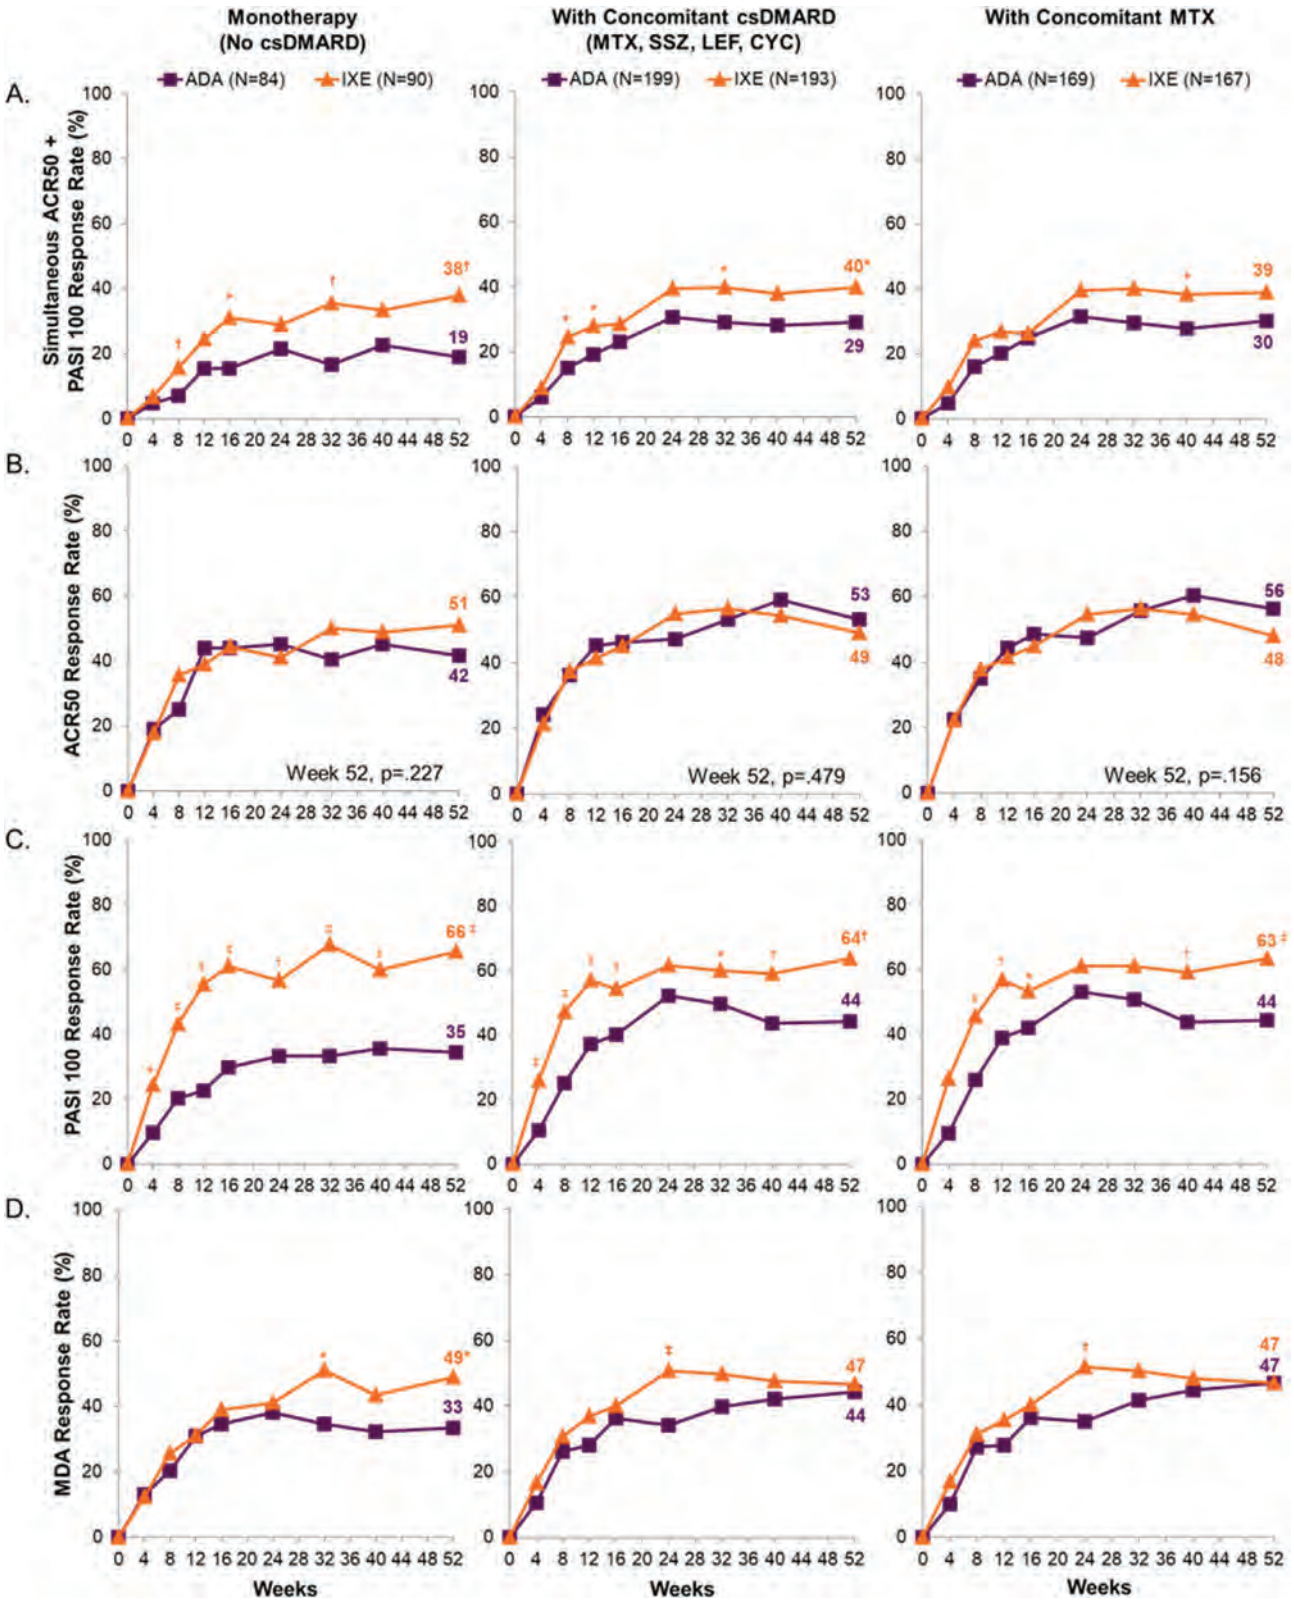

Figure 1. Proportion patients through 52 weeks with simultaneous achievement of ACR50 + PASI 100, ACR50, PASI 100, and MDA-18 Entheseal Points. Nine patients with active PsO and BSA≥3% were assessed as PASI=0 at baseline, a medical inconsistency that was resolved using medical judgement. These patients were considered PASI 100 responders if PASI=0 and BSA=0 at post baseline visit. *p≤.05 vs. ADA; †p<.01 vs. ADA; ‡p≤.001 vs. ADA. ACR=American College of Rheumatology; ADA=adalimumab; BSA=body surface area; csDMARD=conventional synthetic disease modifying anti-rheumatic drugs; CYC=cyclophoshamide; Ixe=ixekizumab; LEF=leflunomide; MDA=minimal disease activity PASI=Psoriasis Area and Severity Index; PsO=psoriasis; MTX=methotrexate; SSZ=sulfasalazine.

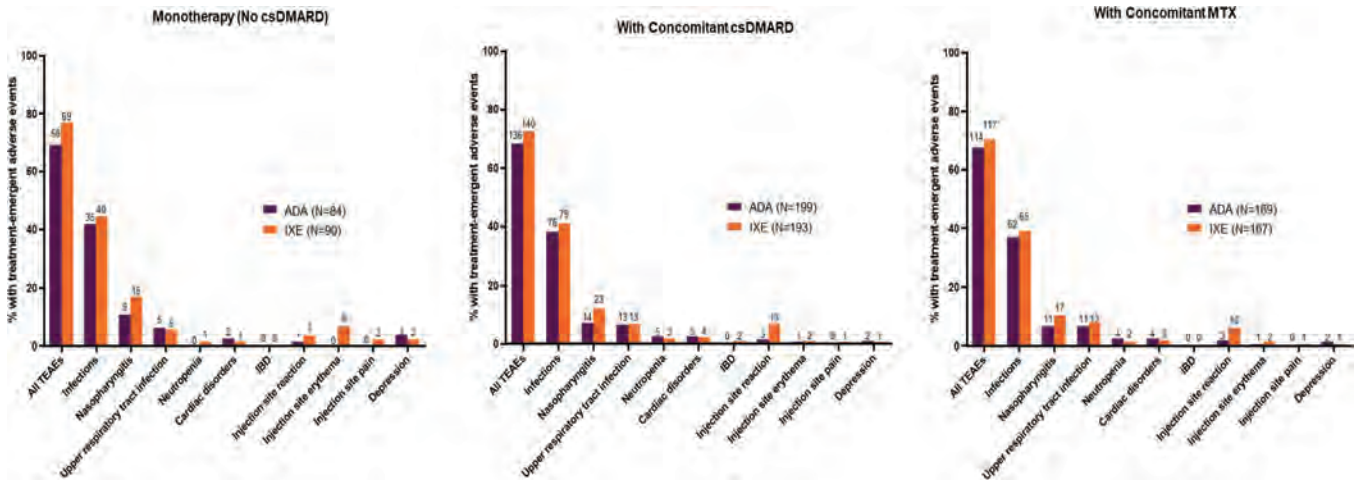

Figure 2. Safety data for patients through 52 weeks. Two events of IBD were reported in the ixekizumab treatment arm but only 1 case met the adjudication criteria of confirmed inflammatory bowel disease. ADA=adalimumab; csDMARD=conventional synthetic disease modifying anti-rheumatic drugs; IBD=inflammatory bowel disease; Ixe=Ixekizumab; MTX=methotrexate; TEAE=treatment emergent adverse event.

pared between IXE and ADA using logistic regression models and Fisher's exact tests. Missing data were imputed using non-responder imputation.

Results: At baseline, 167/283 IXE- and 169/283 ADA-treated pts had concomitant MTX use. Of these, 9.0% (15/167) and 7.1% (12/169) treated with IXE and ADA, respectively, were taking an additional csDMARD (sulfasalazine, cyclosporine, or leflunomide). A significantly greater proportion of pts on IXE vs ADA achieved the primary endpoint or PASI 100 when used as monotherapy or in combination with csDMARD (Figs. 1A and 1C). At Wk 52, the proportion of pts achieving ACR50 was not statistically different between IXE and ADA, regardless of monotherapy or concomitant csDMARD use (Fig. 1B). A significantly higher proportion of pts achieved minimal disease activity (MDA) on IXE compared to ADA in the monotherapy subgroup (49% vs 33%), while the response rates were similar in both combination subgroups (Fig. 1D). These data support consistent ACR50, PASI 100, and MDA response for IXE across all 3 subgroups. There were no significant differences in safety data across the 3 subgroups for either IXE or ADA (Fig. 2).

Conclusion: As with prior studies, consistent efficacy across multiple PsA disease-specific endpoints was observed with IXE in SPIRIT-H2H, regardless of whether IXE was taken as monotherapy or in combination with MTX or another csDMARD. Both agents were well tolerated, with no unexpected safety signals.

SESSION INFORMATION

Session Date: Friday, November 6, 2020

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Treatment Poster I

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: A treat-to-target approach in psoriatic arthritis (PsA) was recommended by EULAR and GRAPPA to achieve remission (REM) or low disease activity (LDA), by regular disease activity assessment and therapeutic adjustment.[1,2] Disease activity index for psoriatic arthritis (DAPSA) or the minimal disease activity (MDA) are considered for defining REM/LDA in secukinumab (SEC) treated patients (pts) with PsA.[3] Very low disease activity (VLDA) is a more stringent measure compared to MDA in defining REM/LDA.[4] Currently, limited reports are available on pts with PsA achieving sustained REM in clinical trials or real-world evidence, using these stringent criteria. Here, we report an exploratory analysis on sustained REM/LDA in pts with PsA treated with SEC and its impact on health-related quality of life (QoL) and physical function, in the FUTURE 5 study (NCT02404350).

Methods: FUTURE 5 is a randomized, double-blind, placebo-controlled 2-year phase 3 trial in pts with active PsA. The study design has been previously reported.[5] Pts randomized to SEC 150 mg could be escalated to 300 mg from Week (Wk) 52 to 104, based on investigators' judgement. The pts were categorized as either achieving REM/LDA once only or sustained REM/LDA, which was defined as pts who achieved REM/LDA between Wk 24-52 and maintained the same response at least 2 of the next 6 visits (visit every 8 wks). Of pts who achieved REM/LDA (VLDA, DAPSA REM, MDA, DAPSA LDA+REM) between Wk 24 and 52, the relationship between REM/LDA, sustained REM/LDA and physical function (health assessment questionnaire disability index [HAQ-DI]), QoL (short form-36 physical component score [SF-36 PCS]) were assessed. To assure that sustainability of responses were uniformly assessed for all pts at the same time period, only pts who completed the 2-year study with no missing REM/LDA assessment at Wks 24 and 104 were evaluated.

Results: In total, 996 pts were randomized to one of 4 treatment groups: SEC 300 mg loading dose (LD; N=222), SEC 150 mg LD (N=220), SEC 150 mg no loading dose (NL; N=222), and placebo (N=332). The baseline clinical characteristics were comparable across treatment groups. A total of 48-62% and 19-36% of all SEC-treated groups, respectively achieved sustained LDA (DAPSA LDA+REM or MDA) and sustained REM (DAPSA REM or VLDA) in at least three visits (**Table 1**). Higher improvements in QoL (SF-36 PCS) (**Table 2**) and physical function (HAQ-DI) were observed from baseline to Wk 104 in pts who had achieved sustained REM or LDA when compared with pts who had not achieved this or who had achieved this only once.

Table 1. Proportion of patients achieving remission or low disease activity

REM and LDA composite indices, %	Treatment group	REM/LDA only once	Sustained REM/LDA
MDA	SEC 150 mg LD (N=184)	10.9	47.8
	SEC 150 mg NL (N=169)	11.2	49.7
	SEC 300 mg LD (N=191)	10.5	55.5
VLDA	SEC 150 mg LD (N=184)	9.8	18.5
	SEC 150 mg NL (N=169)	9.5	20.7
	SEC 300 mg LD (N=191)	9.4	23.6
DAPSA REM	SEC 150 mg LD (N=167)	8.4	29.9
	SEC 150 mg NL (N=162)	8.0	35.2
	SEC 300 mg LD (N=179)	8.4	36.3
DAPSA LDA + REM	SEC 150 mg LD (N=167)	11.4	56.9
	SEC 150 mg NL (N=162)	12.3	61.7
	SEC 300 mg LD (N=179)	14.0	60.9

Sustained REM/LDA was defined if the same response was achieved at least 2 out of the next 6 visits (every 8 weeks), respectively.
DAPSA, Disease activity in Psoriatic Arthritis; LD, loading dose; LDA, Low Disease Activity; MDA, Minimal Disease Activity; N, number of randomized patients assessed at both Week 24 and 104; NL, without loading dose; REM, remission; SEC, secukinumab; VLDA, Very Low Disease Activity.

Table 2 Summary of change from baseline in SF36-PCS at Week 104 by REM/LDA and sustained REM/LDA status

REM and LDA composite indices, Mean ± Standard Deviation (n)	Treatment group	REM/LDA only once	Sustained REM/LDA
MDA	SEC 150 mg LD	6.36 ± 9.54 (20)	9.45 ± 8.70 (87)
	SEC 150 mg NL	6.35 ± 8.78 (19)	11.38 ± 9.19 (84)
	SEC 300 mg LD	8.58 ± 6.61 (19)	10.40 ± 8.75 (104)
VLDA	SEC 150 mg LD	10.18 ± 9.12 (17)	11.14 ± 9.25 (34)
	SEC 150 mg NL	7.56 ± 9.25 (16)	13.28 ± 10.02 (35)
	SEC 300 mg LD	13.11 ± 7.08 (17)	11.67 ± 8.21 (43)
DAPSA REM	SEC 150 mg LD	3.48 ± 6.24 (14)	9.84 ± 8.57 (50)
	SEC 150 mg NL	7.71 ± 6.45 (13)	12.01 ± 9.52 (57)
	SEC 300 mg LD	9.11 ± 9.19 (15)	11.58 ± 9.05 (64)
DAPSA LDA + REM	SEC 150 mg LD	2.76 ± 6.05 (19)	7.00 ± 7.71 (94)
	SEC 150 mg NL	8.26 ± 7.92 (20)	7.82 ± 9.23 (100)
	SEC 300 mg LD	7.13 ± 8.10 (25)	8.43 ± 9.23 (107)

Sustained REM/LDA was defined if the same response was achieved at least twice out of the next 6 visits (every 8 weeks), respectively.
DAPSA, Disease Activity in Psoriatic Arthritis; LD, loading dose; LDA, Low Disease Activity; MDA, Minimal Disease Activity; n, number of evaluable patients; NL, without loading dose; REM, remission; SEC, secukinumab; SF-36 PCS, Short Form-36 Physical Component Score; VLDA, Very Low Disease Activity.

Conclusion: The majority of pts treated with SEC were able to achieve sustained REM/LDA. Sustained LDA/REM was associated with higher improvement of QoL and physical function compared to pts who achieved this response at only one visit.

How Do TNF-alpha-Inhibitors in Medical History Affect Patient Reported Outcomes and Retention in Ankylosing Spondylitis Patients Treated with Secukinumab in Real World? – German Observational Study

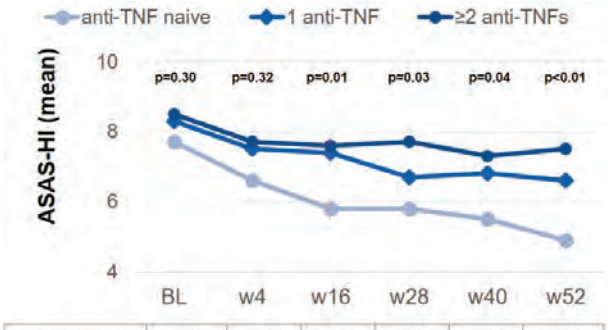
Uta Kiltz[1], Jan Brandt-Jürgens[2], Peter Kästner[3], Elke Riechers[4], Daniel Peterlik[5] and Hans-Peter Tony[6], [1]Rheumazentrum Ruhrgebiet, Ruhr-University Bochum, Herne, Germany, [2]Rheumatologische Schwerpunktpraxis Berlin, Berlin, Germany, [3]Ambulantes Rheumazentrum, Erfurt, Germany, [4]Hannover Medical School, Hannover, Germany, [5]Novartis Pharma GmbH, Nürnberg, Germany, [6]Rheumatology/Clinical Immunology, Department of Internal Medicine II, Würzburg, Germany

SESSION INFORMATION
Session Date: Friday, November 6, 2020
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Treatment Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Secukinumab (SEC), a fully human monoclonal antibody that selectively inhibits interleukin 17A, is approved for treatment of patients with ankylosing spondylitis (AS). However, there is lack of real-world evidence on SEC treatment outcomes, disease activity, physical functioning and on its retention, especially in anti-tumor necrosis factor (anti-TNF) naïve patients and patients pretreated with different anti-TNFs in medical history.[1]

The aim of this interim analysis is to evaluate SEC treatment outcomes on disease activity, physical functioning and retention rates in AS patients stratified by number of anti-TNFs (naive, 1 or ≥2) in medical history.

Methods: AQUILA is an ongoing, multi-center, non-interventional study. AS and psoriatic arthritis patients treated with SEC in daily practice are enrolled and observed from baseline (BL, d0 or d1 of study start) up to week 52 accord-



anti-TNF naive	n=79	n=69	n=75	n=60	n=59	n=56
1 anti-TNF	n=72	n=53	n=64	n=58	n=52	n=41
≥2 anti-TNFs	n=125	n=89	n=114	n=83	n=65	n=59

Figure 1. Change of health in AS patients treated with SEC stratified by anti-TNF pretreatment

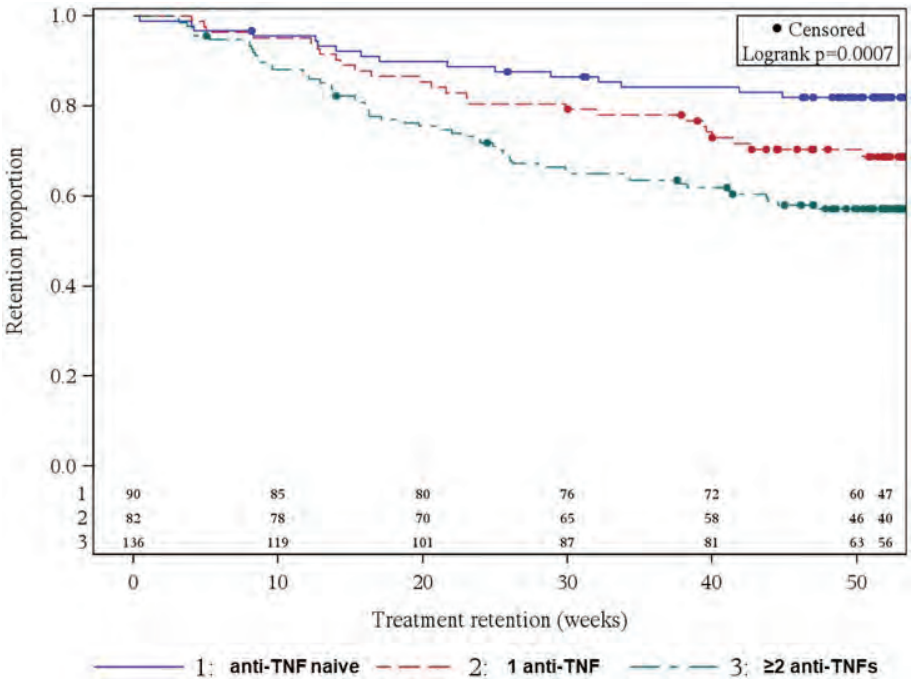


Figure 2. SEC treatment retention depending on anti-TNF pretreatment (Kaplan-Meier plot)

ing to clinical routine. Real-world effectiveness of SEC was assessed prospectively and analyzed as observed. Here, we report interim results of SEC effectiveness on different treatment outcomes in AS patients by means of validated questionnaires such as patient´s global assessment (PGA), Bath Ankylosing Disease Activity Index (BASDAI), and Assessment of Spondyloarthritis Health Index (ASAS-HI). In addition, retention rates (time from study inclusion until premature SEC treatment discontinuation) were assessed through Kaplan-Meier plots. This interim analysis focuses on *anti-TNF naïve* and AS patients treated with *1 anti-TNF* or *≥2 anti-TNFs* in medical history. Wilcoxon tests were conducted to show significant differences between the subgroups.

Results: At BL, 311 AS patients were included; 72 (23.2%) of them received SEC already for more than 1 day up to more than 6 months before BL. Most AS patients were anti-TNF-experienced (71.1%): 82 (26.4%) and 139 (44.7%) AS patients had 1 or ≥2 prior anti-TNF treatments, respectively. BL scores for PGA, BASDAI and ASAS-HI were similar between the different anti-TNF subgroups. Constant improvement was shown in all parameters from BL up to week 52, irrespective of prior anti-TNF treatment (PGA-*anti-TNF naïve*: 5.9 to 3.5, PGA-*1 anti-TNF:* 6.1 to 4.2 and PGA-*≥2 anti-TNFs:* 6.7 to 5.1; BASDAI-*anti-TNF naïve*: 5.3 to 3.4, BASDAI-*1 anti-TNF:* 5.5 to 3.7 and BASDAI-*≥2 anti-TNFs:* 5.7 to 4.7). However, overall better improvement was observed in *anti-TNF naïve* patients, as seen by the example of ASAS-HI (Fig. 1). Between 30% and 40% of patients prematurely discontinued SEC treatment in the subgroups *1 anti-TNF* and *≥2 anti-TNFs*, respectively, while only about 20% did so in the *anti-TNF naïve* AS patients (Fig. 2).

Conclusion: SEC has shown to improve disease activity, physical functioning and QoL in anti-TNF-naïve and pre-treated AS patients in a real-world setting. The benefits of SEC were numerically more distinct in anti-TNF-naïve patients. Moreover, SEC demonstrated high retention rate, particularly in anti-TNF-naïve patients, thereby confirming previously reported real-world data on SEC from EuroSpA research collaboration network.[2]

SESSION INFORMATION

Session Date: Friday, November 6, 2020

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Treatment Poster I

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: Guselkumab (GUS), an interleukin-23p19-subunit monoclonal antibody, demonstrated efficacy compared to placebo (PBO) in reducing skin and musculoskeletal signs and symptoms in patients with active

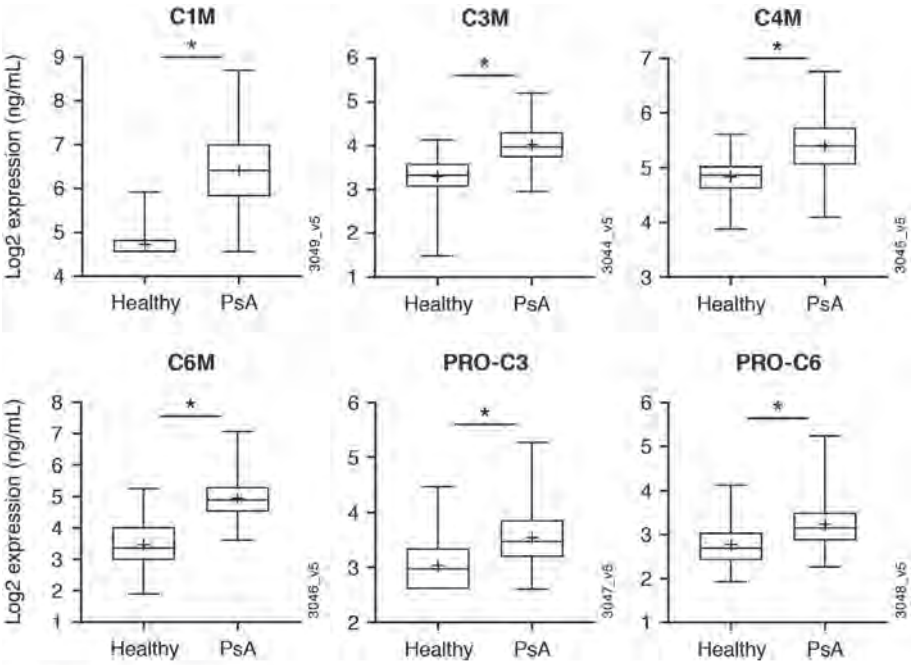

Figure 1. Upregulation of collagen degradation/formation biomarkers is detected in the serum of PsA subjects compared to healthy controls.

Healthy controls have been demographically matched (age, sex, race/ethnicity) to the PsA cohort. Median values (+ marks mean). Boxes represent the interquartile range, whiskers the minimum and maximum.

* Indicates significance defined by |fold change| ≥1.25 and FDR adjusted $p < 0.05$.

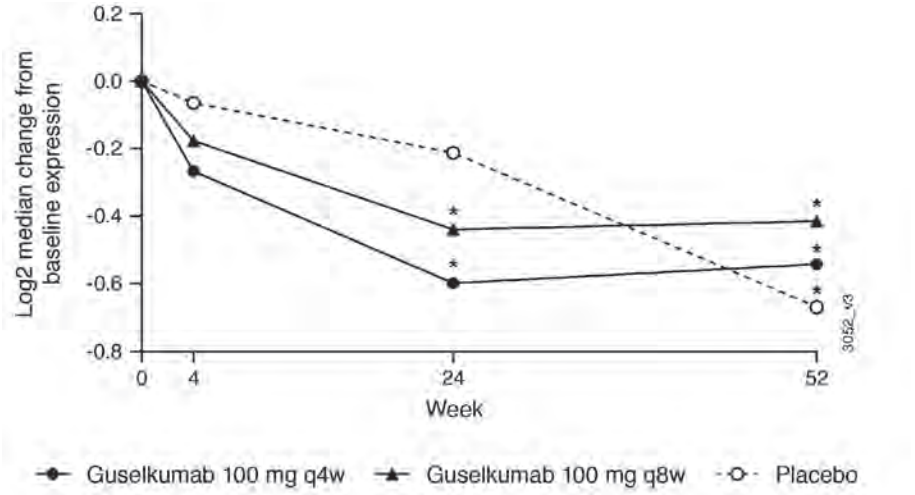

Figure 2. Collagen degradation marker C1M decreases with guselkumab treatment.
* Significant change from baseline defined by $p < 0.05$ and |fold difference| ≥1.25

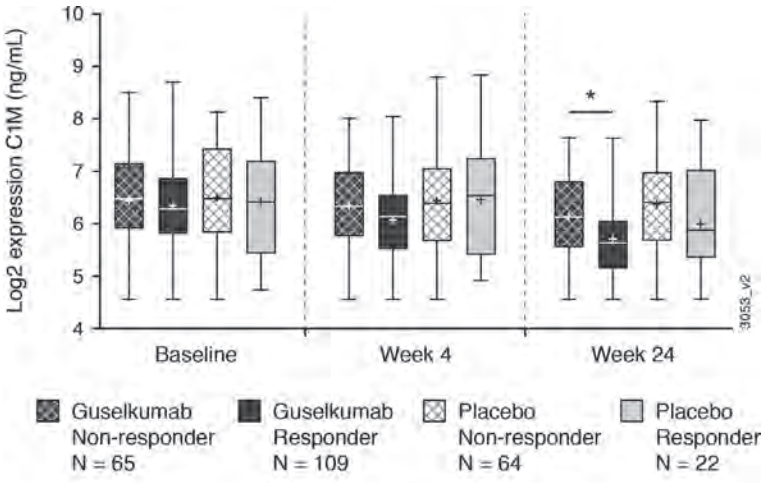

Figure 3. C1M Reductions by ACR20 Response.
Response defined by ACR20 at Week 24. Median values (+ marks mean). Boxes represent the interquartile range, whiskers the minimum and maximum.
* p=0.0065, significance between responder and non-responder defined by $p < 0.05$ and |fold difference| ≥1.25.

psoriatic arthritis (PsA) in two phase-3 studies, DISCOVER 1 & 2, and in retarding structural damage in DISCOVER 2.[1,2] Here we evaluate tissue-derived extracellular matrix (ECM) products[3,4] in serum of PsA patients in the DISCOVER 2 study and their relationship with radiographic damage, clinical response, and impact of treatment.

Methods: In DISCOVER 2, patients were treated with GUS 100 mg at Week (w) 0, 4, then every 8w (q8w); GUS 100mg every 4w (q4w); or matching PBO. At w24, PBO subjects were crossed-over to GUS q4w. 11 serum biomarkers of ECM collagen formation (PRO-C1, PRO-C2, PRO-C3, PRO-C4, PRO-C6) and degradation (C1M, C2M, C3M, C4M, C6M, and COL10) were measured (by Nordic Bioscience) in a subset of 260 patients from the DISCOVER 2 program at Weeks 0, 4, 24, & 52 and in 76 healthy controls matched for age, sex, and ethnicity. PsA patients were selected randomly, though enriching for subjects with greatest radiographic changes, at Weeks 24 and 52. Significance defined by $P < 0.05$ and $|\text{fold difference}| \geq 1.25$.

Results: At baseline, collagen degradation markers C1M, C3M, C4M, C6M and collagen formation markers PRO-C3 and PRO-C6 were significantly higher in PsA patients compared to matched healthy controls (Figure 1). Baseline C3M, C4M, and C6M were positively correlated to baseline skin and joint disease; baseline C1M, C3M, C4M, C6M, and PRO-C1 were positively correlated to baseline radiographic damage (data not shown). Levels of C1M (a maker indicating breakdown of collagen type I, the major collagen subtype in the bone) were significantly decreased after 24w treatment with GUS (Figure 2), reaching significant differences from placebo with the GUS 100 mg q4w group. For the PBO patients who crossed over to GUS at w24, there was also a reduction in this marker observed at w52 (Figure 2). In patients treated with GUS or PBO, there were not significant differences in baseline expression levels of the analytes in responders (patients achieving ACR20 at w24) compared with non-responders. However, ACR20 responders in the combined GUS group had a significantly greater reduction in C1M levels compared to non-responders (Figure 3).

Conclusion: This work provides evidence that collagen biomarkers in serum are dysregulated in patients with PsA compared to healthy controls, and that GUS impacts levels of these proteins. Importantly, C1M serves as a biomarker that tracks with joint response. We observed a greater reduction in C1M in ACR responders compared to non-responders, providing insight into how GUS may be working to protect from degradation of bone in PsA.

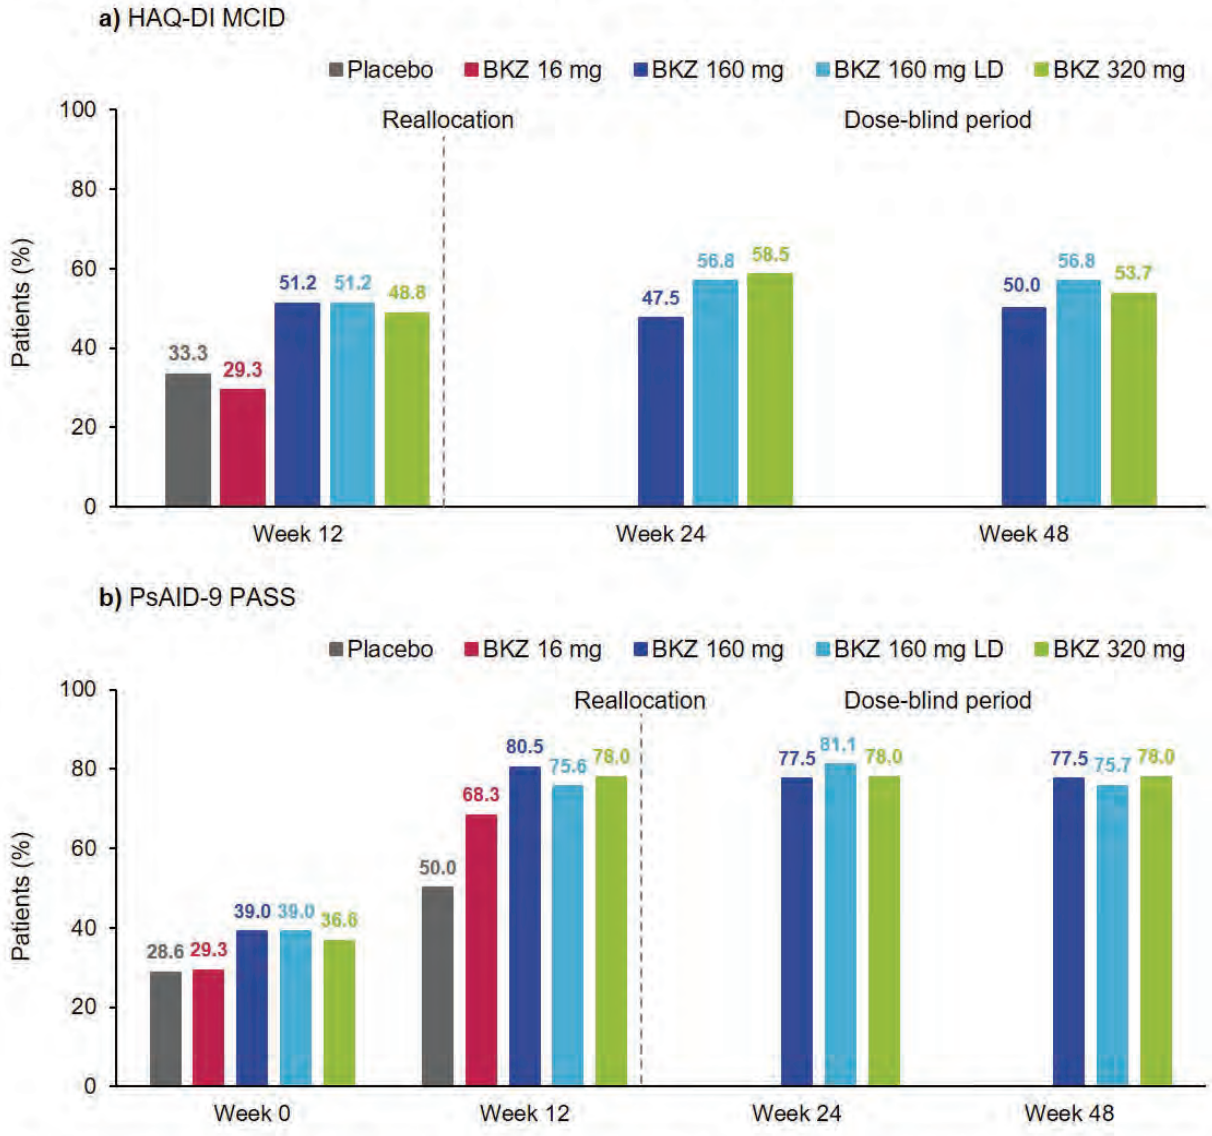
Bimekizumab Improves Patient-Reported Outcomes in Psoriatic Arthritis: 48-Week Results from a Phase 2b Study and Association Between Patient-Reported Outcomes and Disease Activity

Laure Gossec[1], Philip Mease[2], Alice Gottlieb[3], Deepak Assudani[4], Jason Coarse[5], Barbara Ink[6] and Laura Coates[7], [1]Sorbonne Université and Hôpital Universitaire Pitié Salpêtrière, Paris, France, [2]Seattle Rheumatology Associates, P.L.L.C., Seattle, WA, [3]Department of Dermatology, Icahn School of Medicine at Mount Sinai, New York, NY, [4]UCB Pharma, Slough, United Kingdom, [5]UCB Pharma, Raleigh, NC, [6]UCB Pharma, Slough, [7]University of Oxford, Oxford, United Kingdom

SESSION INFORMATION
Session Date: Friday, November 6, 2020
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Treatment Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Bimekizumab (BKZ), a humanized monoclonal IgG1 antibody that selectively neutralizes interleukin (IL)-17A and IL-17F, has shown clinical improvements in joint and skin outcomes and a favorable safety profile in patients (pts) with active psoriatic arthritis (PsA).[1] Here we report the impact of BKZ treatment over 48 weeks

Figure 1: Proportion of patients with HAQ-DI MCID and PsAID-9 PASS



The study was double-blind and placebo-controlled to Wk 12 and dose-blind to Wk 48. Patients were randomized at baseline to receive either placebo Q4W or 1 of 4 dosing regimens of BKZ Q4W (16 mg, 160 mg, 160 mg with 320 mg LD at baseline, or 320 mg). After Wk 12, patients receiving placebo or 16 mg BKZ were reallocated (1:1) to receive either 160 mg or 320 mg BKZ, while all other patients continued their original dosing regimen. Data are shown by randomized dose at baseline. FAS up to Wk 12 and DBS Wks 12–48; DBS consists of all patients who received ≥1 dose of BKZ in dose-blind period. patients with missing values were counted as non-responders. The HAQ-DI MCID is a ≥0.35 decrease from baseline. Lower PsAID-9 score corresponds to better quality of life in patients. PASS is defined as having a PsAID-9 total score ≤4. BKZ: bimekizumab; DBS: Dose-Blind Set; FAS: Full Analysis Set; HAQ-DI: Health Assessment Questionnaire Disability Index; LD: loading dose; MCID: minimal clinically important difference: PASS: patient acceptable symptom state; PsAID-9: Psoriatic Arthritis Impact of Disease-9; Q4W: every four weeks; Wk: Week.

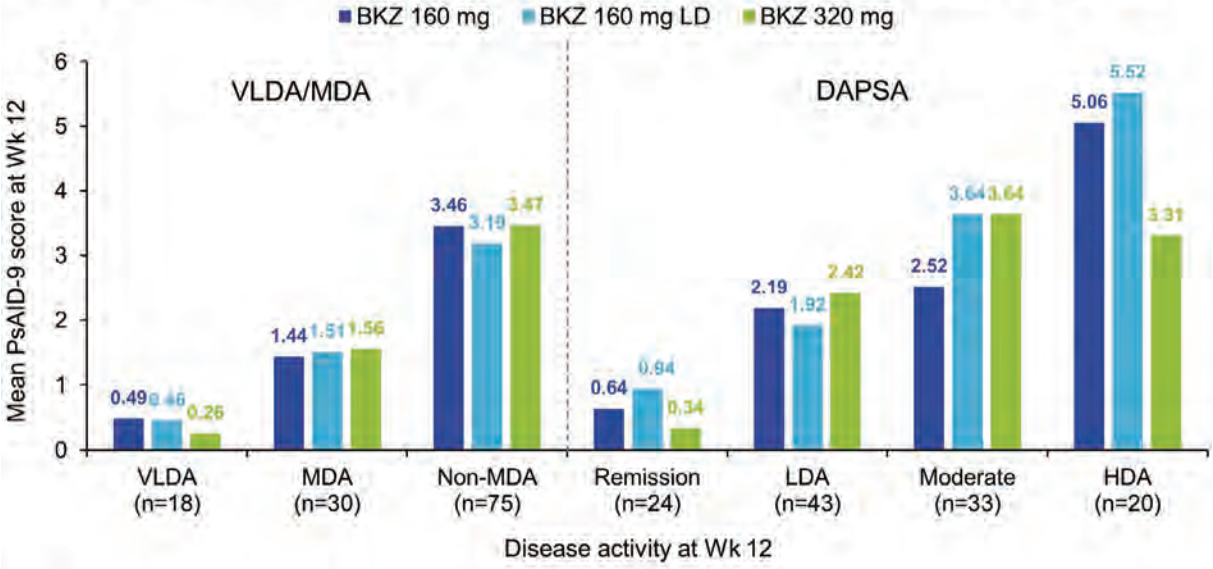
on two patient-reported outcome (PRO) measures: Health Assessment Questionnaire Disability Index (HAQ-DI) and Psoriatic Arthritis Impact of Disease-9 (PsAID-9). The PsAID-9 is a questionnaire specifically developed to assess the impact of PsA on pts' lives.[2, 3] We also examine the association between achieving high disease control states (very low disease activity [VLDA], minimal disease activity [MDA] or Disease Activity in PSoriatic Arthritis [DAPSA] remission) and PsAID-9 score.

Table: VLDA, MDA and DAPSA responder rates

Treatment arm (FAS n, DBS n)	VLDA (%) [a]			MDA (%) [a]			DAPSA remission (%) [b]		
	Wk 12	Wk 24	Wk 48	Wk 12	Wk 24	Wk 48	Wk 12	Wk 24	Wk 48
Placebo (n=42)	2.4			14.3			2.4		
BKZ 160 mg (n=41, n=40)	14.6	22.5	37.5	46.3	50.0	60.0	19.5	35.0	45.0
BKZ 160 mg LD (n=41, n=37) [c]	19.5	32.4	29.7	41.5	59.5	54.1	29.3	48.6	37.8
BKZ 320 mg (n=41, n=41)	9.8	14.5	22.0	29.3	36.6	46.3	12.2	19.5	34.1

FAS for Wk 12 and DBS for Wks 24 and 48. Data are shown by randomized dose at baseline. [a] DBS, patients with missing data were counted as non-responders; [b] DBS, missing data are imputed using last observation carried forward; [c] 160 mg with 320 mg LD at baseline. BKZ: bimekizumab; DAPSA: Disease Activity Index for Psoriatic Arthritis; DBS: Dose-Blind Set; FAS: Full Analysis Set; LD: loading dose; MDA: minimal disease activity.

Figure 2: Association between VLDA, MDA, and DAPSA disease states and PsAID-9 at Wk 12



FAS; values of n are the number of patients on the 160 mg, 160 mg LD, and 320 mg doses with the specified disease activity outcome. Missing data are imputed using multiple imputation based on the Markov-Chain Monte Carlo method for the intermittent missing data, followed by monotone regression for the monotone missing data assuming missing at random. Lower PsAID-9 score corresponds to better quality of life in patients. BKZ: bimekizumab; DAPSA: Disease Activity in Psoriatic Arthritis; FAS: Full Analysis Set; HDA: high disease activity; LD: loading dose; LDA: low disease activity; MDA: minimal disease activity; PsAID-9: Psoriatic Arthritis Impact of Disease-9; VLDA: very low disease activity; Wk: Week.

Methods: In this phase 2b dose-ranging study (BE ACTIVE; NCT02969525), PsA pts received BKZ or placebo.[1] Here we report improvements in PROs over 48 weeks using the proportion of pts who achieved a Minimal Clinically Important Difference (MCID) in the functional score HAQ-DI (≥0.35 decrease from baseline). We also show the rate of pts reporting a PsAID-9 Patient Acceptable Symptom State (PASS), which for the PsAID-9 has been proposed as a score ≤4,[2] and examine the association of VLDA/MDA (binary disease control states) or DAPSA (where remission is

0–4, low: 5–14, moderate: 15–28, and high disease activity is >28) with PsAID-9 score at Wk 12. The Full Analysis Set (FAS) is used up to and including Wk 12; the Dose-Blind Set (DBS) is used from Wk 12 to Wk 48.

Results: Across 206 randomized pts at baseline, 66.5% had psoriasis body surface area (BSA) ≥3%, 18.9% had prior tumor necrosis factor inhibitor (TNFi) exposure, and 63.6% received concomitant methotrexate. Mean baseline HAQ-DI scores were comparable across all treatment arms (including placebo), ranging from 0.9–1.0; PsAID-9 scores ranged from 4.3–4.8. The proportion of pts achieving HAQ-DI MCID for BKZ 160 mg, 160 mg plus loading dose (LD), and 320 mg treatment arms was 47.5–58.5% across Wks 12, 24 and 48 (**Figure 1a**). Additionally, more than 75% of pts receiving BKZ 160/160 LD/320 mg achieved PsAID-9 PASS across Weeks 12, 24 and 48 (**Figure 1b**). Furthermore, a substantial proportion of pts within these BKZ treatment arms also achieved VLDA, MDA and/or DAPSA remission at Wk 12; this generally increased through to Wk 24 and 48 (**Table**). PsAID-9 score at Wk 12 was consistently lower for pts with VLDA/MDA or in DAPSA remission (**Figure 2**).

Conclusion: This patient population with active PsA demonstrated rapid and sustained improvements in patient-reported physical function and psychological wellbeing over 48 weeks of BKZ treatment. Achievement of VLDA/MDA or DAPSA remission was associated with lower mean PsAID-9 scores, reinforcing evidence that achievement of higher disease control in pts with PsA is important for improved quality of life.

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Treatment Poster I

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

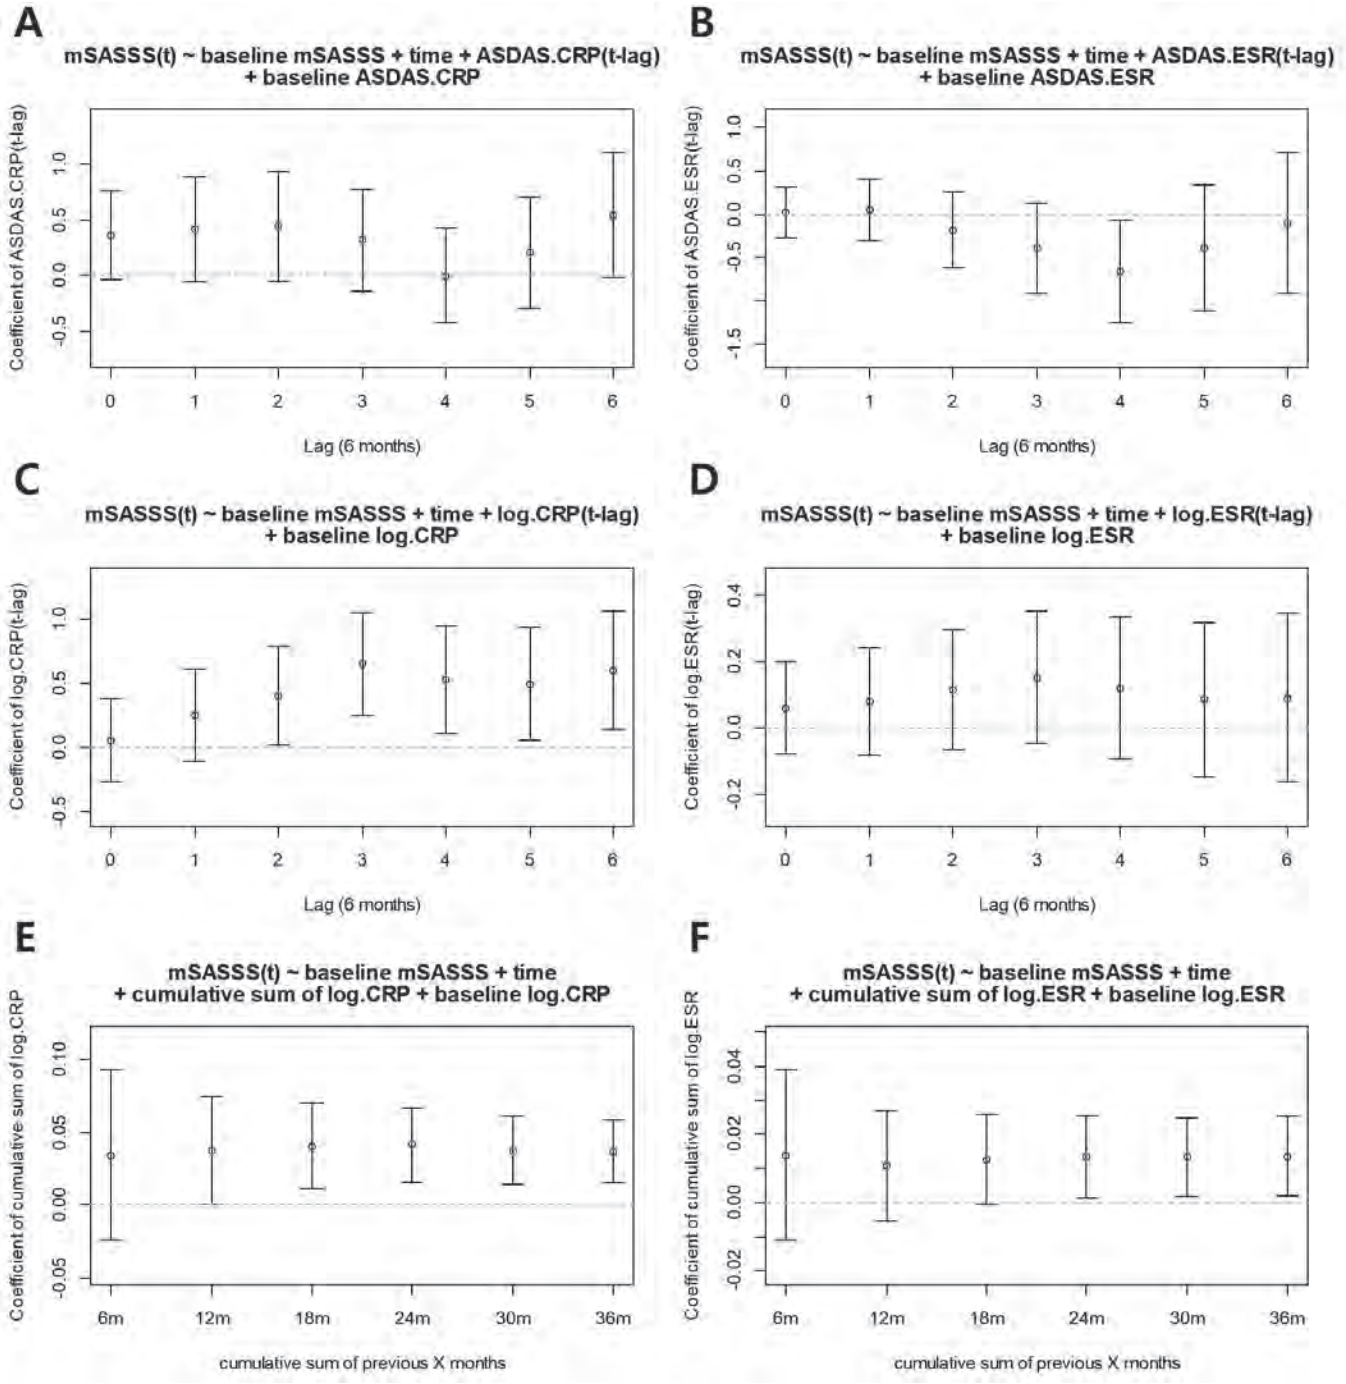

Figure 1. Relationship between mSASSS and inflammatory markers and disease activities over time using an autoregressive model

Background/Purpose: Treatment with tumor necrosis factor (TNF) inhibitors has the effect of slowing radiographic progression by improving symptoms and reducing inflammation in patients with ankylosing spondylitis (AS). However, the inflammation is still not controlled in some patients even if their symptoms improve with the TNF inhibitor treatment. The purpose of this study was to analyze the relationship between inflammation and radiographic progression in patients with AS, whose symptoms were well controlled by a TNF inhibitor treatment in a real-world observational data.

Table 1. Linear mixed model with the cumulative sum of log CRP up to 24 months as main independent variable and mSASSS at 24 months as outcome

X	Beta estimate	95% CI		p-value
		LB	UB	
Baseline mSASSS	1.047	1.013	1.080	<0.001
Time	0.466	0.433	0.500	<0.001
Cumulative sum of previous 24 months' log CRP	0.043	0.014	0.071	0.004
Female	-0.649	-2.658	1.359	0.525

Methods: Of the 1,280 patients who were followed-up for 18 years in a single center, the electronic medical data of 590 patients treated with TNF inhibitors were included. Among them, 333 patients with bath ankylosing spondylitis disease activity Index (BASDAI) < 4 measured at all the time points following the first TNF inhibitor dosing were included. From these patients, 898 intervals were obtained, which was the period of administration of the TNF inhibitor. To determine the relationship between the modified stoke ankylosing spondylitis spinal score (mSASSS) and inflammatory markers such as c-reactive protein (CRP), erythrocyte sedimentation rate (ESR), and disease activities such as Ankylosing Spondylitis Disease Activity Score (ASDAS)-ESR and ASDAS-CRP over time, we fitted linear mixed models with mSASSS as response variable, baseline mSASS and inflammatory marker with different lag times as fixed effects, and patients as random effects. With the inflammatory marker and the lag time with statistically significant beta coefficient, , its association with the mSASSS was further investigated with linear mixed model that includes additional clinical variables.

Results: The relationship between mSASSS and past inflammatory markers and disease activities were examined for up to 36 months using linear mixed models (Fig. 1). The cumulative sums of log CRP for the previous 18, 24, 30, and 36 months showed significantly positive correlation with mSASSS (Fig. 1E). From these results, the cumulative sum of the previous 24 months' log CRP as the main independent variable was used in the linear mixed model with mSASSS at 24 months as the outcome (Table 1). Baseline mSASSS (b=1.047, 95% CI: 1.013 to 1.080, p< 0.001), time (b=0.466, 95% CI: 0.433 to 0.500 p< 0.001), and cumulative sum of the previous 24 months' log CRP (b=0.043, 95% CI: 0.014 to 0.071, p=0.004) were significantly associated with mSASSS at 24 months.

Conclusion: The symptoms were well controlled because BASDAI was maintained below 4; however, those with a high cumulative sum of CRP showed an increased mSASSS change. In order to slow the radiographic progression in patients with AS, inflammation rather than disease activity should be targeted and actively controlled during treatment with TNF inhibitors.

Does Smoking Affect Secukinumab Treatment Outcomes and Safety in Patients with Ankylosing Spondylitis? – Real World Data from German Observational Study

Elke Riechers[1], **Uta Kiltz**[2], Jan Brandt-Jürgens[3], Peter Kästner[4], Daniel Peterlik[5] and Hans-Peter Tony[6], [1]Hannover Medical School, Hannover, Germany, [2]Rheumazentrum Ruhrgebiet, Ruhr-University Bochum, Herne, Germany, [3]Rheumatologische Schwerpunktpraxis Berlin, Berlin, Germany, [4]Ambulantes Rheumazentrum, Erfurt, Germany, [5]Novartis Pharma GmbH, Nürnberg, Germany, [6]Rheumatology/Clinical Immunology, Department of Internal Medicine II, Würzburg, Germany

SESSION INFORMATION
Session Date: Friday, November 6, 2020
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Treatment Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: There is growing body of evidence that smoking is associated with more active and severe disease in patients (pts) with ankylosing spondylitis (AS)[1,2]. The German non-interventional study AQUILA provides real-world data on the influence of smoking on therapeutic effectiveness and safety under secukinumab (SEC), a fully human monoclonal antibody that selectively inhibits interleukin-17A.

The aim of this interim analysis is to describe selected baseline (BL) demographics, to evaluate SEC effectiveness on disease activity and global functioning and health, and to report safety profile depending on smoking status of AS pts.

Methods: AQUILA is an ongoing, multi-center, non-interventional study including up to 2700 pts with active AS or psoriatic arthritis. Pts were observed from BL up to week (w) 52. Real-world data was assessed prospectively and analyzed as observed. Assessment of CRP and validated questionnaires were used to collect data on disease activity (Bath Ankylosing Spondylitis Disease Activity Index, BASDAI), global functioning and health (Assessment of

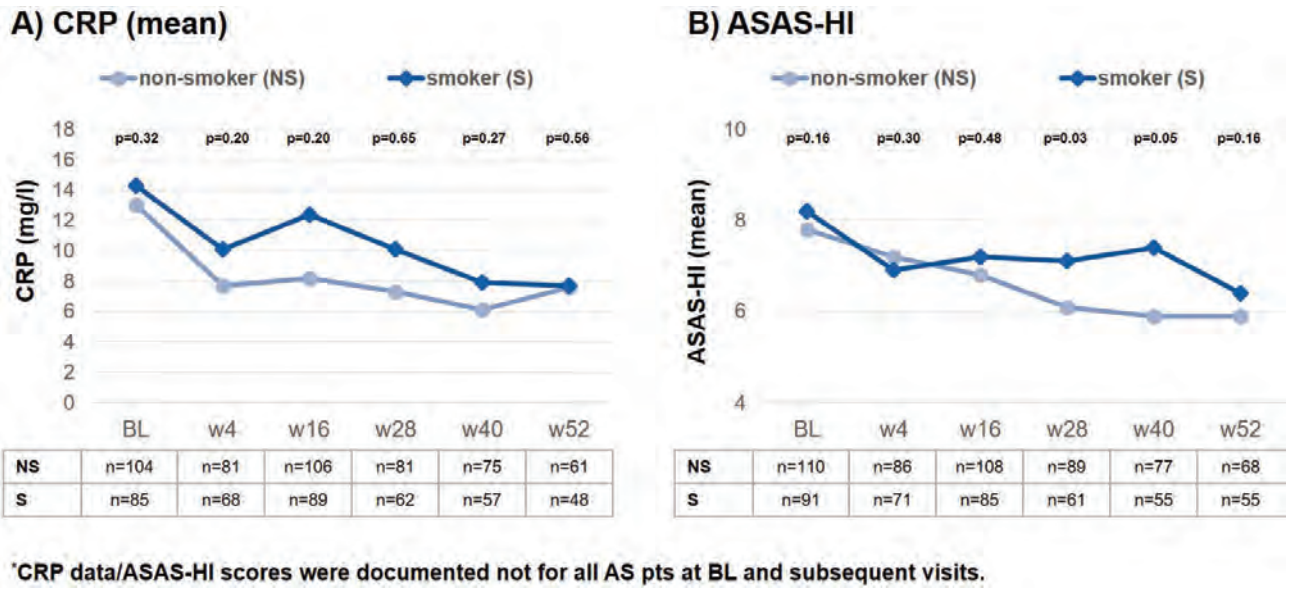

Figure 1. CRP and global functioning and health in AS pts treated with SEC depending on smoking status*

Table 1 Overview of AEs (and SAEs) under SEC treatment depending on smoking status in AS pts

Number of pts with	NS (N=140), n (%)	S (N=110), n (%)	P value
AE	95 (67.9)	78 (70.9)	0.80
AE with suspected relationship to SEC	66 (47.1)	41 (37.3)	0.29
SAE	39 (27.9)	30 (27.3)	0.95
SAE with suspected relationship to SEC	15 (10.7)	10 (9.1)	0.87

SpondyloArthritis-Health Index, ASAS-HI) and depressive mood (Beck´s Depression Inventory version II, BDI-II). For calculation of proportion of pts who experienced (serious) adverse events ((S)AEs), all AS pts were included who received at least one dose of SEC irrespective of further documentation of any study visit. This analysis focuses on the subgroups non-smoker (NS) and smoker (S).

Results: At BL, 311 AS pts were included: 42.1% (n=131) NS and 32.8% (n=102) S. Remaining subgroups were 15.1% (n=47) ex-smoker and 10.0% (n=31) of unknown smoking status. About half of AS pts in NS were male, while in S (69.6%) portion of men was more than twice as high as of women. S were slightly younger than NS (mean age: 43.9/49.0 years). During the study, CRP value decreased irrespective of smoking status with numerically higher fluctuations in S (Fig. 1A). BASDAI (NS: 5.2 at BL to 3.7 at w52, S: 5.6 at BL to 4.1 at w52) and ASAS-HI (Fig. 1B) scores numerically improved best in NS, whereas more variations were seen in S; the same was observed for BDI-II score values (NS: 11.8 at BL to 9.2 at w52, S: 13.0 at BL to 12.1 at w52). Although no major significant differences in mean values existed between NS and S, S displayed – except in w4 – overall higher mean values in the parameters mentioned above. Regarding the occurrence of AEs/SAEs with or without suspected relationship to SEC, there was no significant difference between NS and S (Table 1).

Conclusion: In a real-world setting, SEC improved disease activity and global functioning and health in AS pts with slight (mostly non-significant) differences between NS and S. Overall, this interim analysis shows that SEC is an effective treatment with a favorable safety profile up to 52 weeks, irrespective of the pts' smoking status. Further progress of the AQUILA study will reveal whether this trend will continue.

SESSION INFORMATION

Session Date: Friday, November 6, 2020

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Treatment Poster I

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: Axial disease in psoriatic arthritis (PsA) has been reported to occur in anywhere from 25% to 75% of PsA patients (pts). It can be associated with more severe disease characteristics.[1] Our objective was to describe the characteristics of clinical registry PsA pts with physician-identified spondylitis, at treatment initiation and 6 months post-treatment with biologic (b) or targeted synthetic (ts) disease modifying anti-rheumatic drugs (DMARDs), and to determine whether treatment response differs by HLA-B27 status.

Methods: The Corrona Psoriatic Arthritis/Spondyloarthritis Registry is a prospective, multicenter, observational disease-based registry launched in March 2013 that currently has information on over 3000 enrolled pts. Pt assessments are completed at approximately 6-month intervals. The PsA pts included in this analysis initiated treatment with either bDMARDs or tsDMARDs at a Corrona visit (baseline) and had a 6-month follow-up, fulfilled Classification Criteria for Psoriatic Arthritis (CASPAR), had physician-reported spondylitis with Bath Ankylosing Spondylitis Disease Activity Index (BASDAI) scores ≥4 at baseline, and had known HLA-B27 genotype. Disease characteristics at baseline and

*Data are mean (SD) unless otherwise stated. **Some entries have missing patient values; observations are based on unique therapy initiations, thus patients may contribute ≥1 observation
ASDAS-CRP, Ankylosing Spondylitis Disease Activity Score-C-reactive protein (<1.3:inactive, ≥1.3-<2.1:moderate, ≥2.1-≤3.5:high, >3.5:very high); BASDAI, Bath Ankylosing Spondylitis Disease Activity Index (0-10cm, ≥4 active disease); mBASDAI, modified BASDAI (excludes Q#3); BSA, body surface area; HAQ-DI, The Stanford Health Assessment Questionnaire Disability Index (0 -1 mild to moderate difficulty, 1-2 moderate to severe disability, and 2-3 severe to very severe disability); HAQ-S, Health Assessment Questionnaire for the Spondylarthropathies; VAS, visual analog scale

6-months are described via means (SD) and counts (%) by HLA-B27 status (+/–). A multivariable-adjusted linear mixed model was used to test for association (regression coefficient) of HLA-27 status with outcomes at 6-months.

Results: Among the 173 initiations, 31% were HLA B27+ and 69% were HLA B27–. Baseline demographics, comorbidities (Table 1), and disease characteristics (Table 2) were similar between HLA-B27+ and HLA-B27– groups. Axial disease-related outcome measures, including BASDAI, BASDAI Q#2, modified BASDAI (mBASDAI, Q#3 removed), and ASDAS-CRP, all consistently indicated either active disease or high disease activity at baseline. In HLA-B27+ and HLA-B27– pts, respectively, 85% and 80% initiated a bDMARD, while 15% and 20% initiated a tsDMARD. Six-months post-treatment, axial disease-related measures reflected only mild improvement and were still indicative of active disease or high disease activity, irrespective of HLA-B27 status (Table 2). There were no statistically significant differences between HLA B27+ and HLA B27– pts in changes from baseline in the axial disease-related outcome measures assessed (Table 3). In an exploratory analysis of a subgroup of these pts with radiologic confirmation of axial involvement (n=21), similar outcomes were observed (data not shown).

Conclusion: In this registry study of PsA pts with physician-reported axial disease, after 6 months of treatment with bDMARD or tsDMARD therapy, only mild improvements in axial disease-related outcome measures were observed.

Table 3. Adjusted* Difference Between HLA-B27+ and HLA-B27– Initiators in Outcomes (Mean Change from Baseline to 6 Months)		
Disease Characteristic	**β Estimate (95% CI)**	**p-value**
Tender Joint Count (68 joints)	-0.368 (-2.926, 2.190)	0.777
Swollen Joint Count (66 joints)	-0.136 (-1.431, 1.159)	0.835
Physician Global Assessment of PsA, VAS	2.287 (-6.385, 10.959)	0.603
Patient-reported Pain VAS	1.881 (-6.562, 10.324)	0.660
HAQ-DI	-0.004 (-0.161, 0.153)	0.960
BSA, %	-1.262 (-3.231, 0.707)	0.207
BASDAI (0-10)	0.040 (-0.584, 0.665)	0.898
BASDAI Q2: Spine Pain	0.863 (-6.729, 8.455)	0.822
mBASDAI	0.077 (-0.561, 0.714)	0.812
HAQ-S	0.006 (-0.147, 0.158)	0.941
Patient-reported Spine Pain VAS	-0.269 (-8.61, 8.076)	0.949
Patient-reported Nocturnal Spine Pain VAS	3.012 (-6.376,12.399)	0.527
*Linear regression model estimates adjusted for baseline value and other potential risk factors: (age at initiation, insurance, alcohol use, history of cardiovascular disease, prior cDMARD, prior bDMARD, and prior tsDMARD). The HLA-B27– group is the reference group for this comparison. BASDAI, Bath Ankylosing Spondylitis Disease Activity Index; mBASDAI, modified BASDAI (excludes Q3); BSA, body surface area; HAQ-DI, The Stanford Health Assessment Questionnaire Disability Index; HAQ-S, Health Assessment Questionnaire for the Spondylarthropathies; VAS, visual analog scale		

Furthermore, response did not differ based on HLA-B27 status. The continued high disease activity of these pts reflects a critical unmet need for additional safe and effective therapies for PsA axial disease.

SESSION INFORMATION
Session Date: Friday, November 6, 2020
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Treatment Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Several studies have shown an negative association between smoking status and psoriatic arthritis (PsA) clinical outcomes[1,2]. The German non-interventional study AQUILA provides real-world data on the influence of smoking on therapeutic effectiveness and safety issues under secukinumab (SEC), a fully human monoclonal antibody that selectively inhibits interleukin-17A.

The aim of this interim analysis is to describe selected baseline (BL) demographics, to evaluate SEC effectiveness on disease activity and depressive mood and to report the safety profile depending on smoking status of PsA patients.

Methods: AQUILA is an ongoing, multi-center study including up to 2700 patients with active PsA or ankylosing spondylitis. Patients were observed from BL up to week (w) 52. Real-world data was assessed prospectively and analyzed as observed. In addition to the assessment of C-reactive protein (CRP), data was collected on patient´s disease activity (tender/swollen joint counts, TJC/SJC), skin disease activity (Psoriasis Area and Severity Index, PASI) and depressive mood (Beck´s Depression Inventory version II, BDI-II). For calculation of the proportion of patients who experienced (serious) adverse events ((S)AEs), all PsA patients were included who received at least one dose of SEC irrespective of further documentation of any study visit. This interim analysis focuses on subgroups non-smoker (NS) and smoker (S).

Results: At BL, 641 PsA patients were included: 49.8% (n=319) non-smokers (NS) and 24.3% (n=156) smokers (S). 17.5% (n=112) were ex-smoker and 8.4% (n=54) of unknown smoking status. In both, NS and S, the proportion of women was higher (58.0% in NS and 67.3% in S). NS were slightly older than S (mean age: 53.8/49.7 years). There were no significant differences between NS and S in mean CRP within the 52 weeks (Fig. 1A). Both TJC and SJC improved over time and were similar between NS and S (Fig. 1B). Although mean absolute PASI value was worse in S at BL, a similar temporal improvement was seen in both groups (NS: 7.0 at BL to 1.0 at w52; S: 9.2 at BL to 1.0 at w52). BDI-II scores decreased in both groups with overall higher values in S (NS: 10.9 at BL to 9.1 at w52; S: 12.8 at BL and 10.8 at w52). Regarding the occurrence of AEs and SAEs with or without suspected relationship to SEC,

	BL	w4	w16	w28	w40	w52
NS	n=267	n=195	n=247	n=210	n=194	n=146
S	n=134	n=103	n=120	n=102	n=79	n=63

	BL	w4	w16	w28	w40	w52
NS/S, tender	n= 215/120	n= 155/82	n= 203/105	n= 160/87	n= 138/66	n= 118/50
NS/S, swollen	n= 215/121	n= 155/83	n= 203/105	n= 162/87	n= 140/66	n= 119/50

*CRP data/ACR joint counts were documented not for all PsA patients at BL and subsequent visits.

Figure 1 Disease activity in PsA patients treated with SEC depending on the smoking status*

Table 1. Overview of AEs (and SAEs) under SEC treatment depending on smoking status in PsA patients

Number of patients with	NS (N=333), n (%)	S (N=161), n (%)	P value
AE	233 (70.0)	118 (73.3)	0.11
AE with suspected relationship to SEC	129 (38.7)	72 (44.7)	0.10
SAE	74 (22.2)	45 (28.0)	0.06
SAE with suspected relationship to SEC	29 (8.7)	18 (11.2)	0.37

NS had percentagewise less events than S (Table 1). In addition, percentage of PsA patients who discontinued SEC treatment due to an AE was lower for NS compared to S.

Conclusion: In a real-world setting, SEC improved disease activity and depressive mood of PsA patients with no obvious differences between NS and S. Overall, this interim analysis shows that SEC is an effective and reliable treatment, irrespective of the PsA patients' smoking status. Further progress of the AQUILA study as well as long-term data from other real-world observational studies with SEC, such as SERENA, will reveal whether this trend will continue.

Abstract Number: 0361

Response to Treatment with Ixekizumab in Patients with Active Non-Radiographic Axial Spondyloarthritis Based on HLA-B27 Status and Disease Duration

Victoria Navarro-Compán[1], Jose Maldonado-Cocco[2], Proton Rahman[3], Andris Kronbergs[4], David Sandoval[4], So Young Park[4], Theresa Hunter[4] and **Marina Magrey**[5], [1]Hospital Universitario La Paz IdiPaz, Madrid, Pais Vasco, Spain, [2]University of Buenos Aires School of Medicine, Buenos Aires, Argentina, [3]Memorial University of Newfoundland, Department of Medicine, St John's, Canada, [4]Eli Lilly and Company, Indianapolis, [5]Case Western Reserve University School of Medicine, Cleveland, OH

SESSION INFORMATION
Session Date: Friday, November 6, 2020
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Treatment Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: In this analysis, we evaluate the efficacy of ixekizumab at week 16 in patients with non-radiographic axial spondyloarthritis (nr-axSpA) with or without baseline HLA-B27 positivity and disease duration using a 5 year cutoff.

Methods: COAST-X (NCT02757352) was a phase 3, randomized, double-blind, placebo-controlled study of eligible patients with active nr-axSpA who received 80 mg ixekizumab every 4 weeks (IXE Q4W, N=96) or every 2 weeks (IXE Q2W, N=102), or placebo (PBO, N=105) up to 52 weeks. Post hoc analysis was performed on the intent-to-treat population at week 16 and included two subpopulations of patients based on baseline HLA-B27 status (positive or negative) or disease duration (< 5 or ≥5 years). Outcomes reported here are achievement of Assessment of Spondy-

loArthritis international Society 40% response (ASAS40) and Bath Ankylosing Spondylitis Disease Activity Index 50% response (BASDAI50) at week 16. Missing data were imputed using non-responder imputation. Treatment comparison was performed using Fisher's exact test.

Results: Of patients treated with IXE Q4W, IXE Q2W, and PBO through week 16, 74.0% (n=71), 71.6% (n=73), and 73.3% (n=77) respectively were HLA-B27+, and 25.0% (n=24), 27.5% (n=28), and 25.7% (n=27) respectively were HLA-B27-. Of patients treated with IXE Q4W, IXE Q2W, and PBO through week 16, 42.7% (n=41), 40.2% (n=41), 37.1% (n=39) respectively had disease duration < 5 years and 57.3% (n=55), 59.8% (n=61), 62.9% (n=66) had disease duration ≥5 years. ASAS40 and BASDAI50 response rates were higher with IXE Q4W and IXE Q2W vs. PBO at week 16 regardless of HLA-B27 status or disease duration < 5 or ≥5 years **(Figure)**. Patients who were HLA-B27+ showed a significant difference over PBO for ASAS40 response (IXE Q4W, p=.047; IXE Q2W, p=.005) and BASDAI50

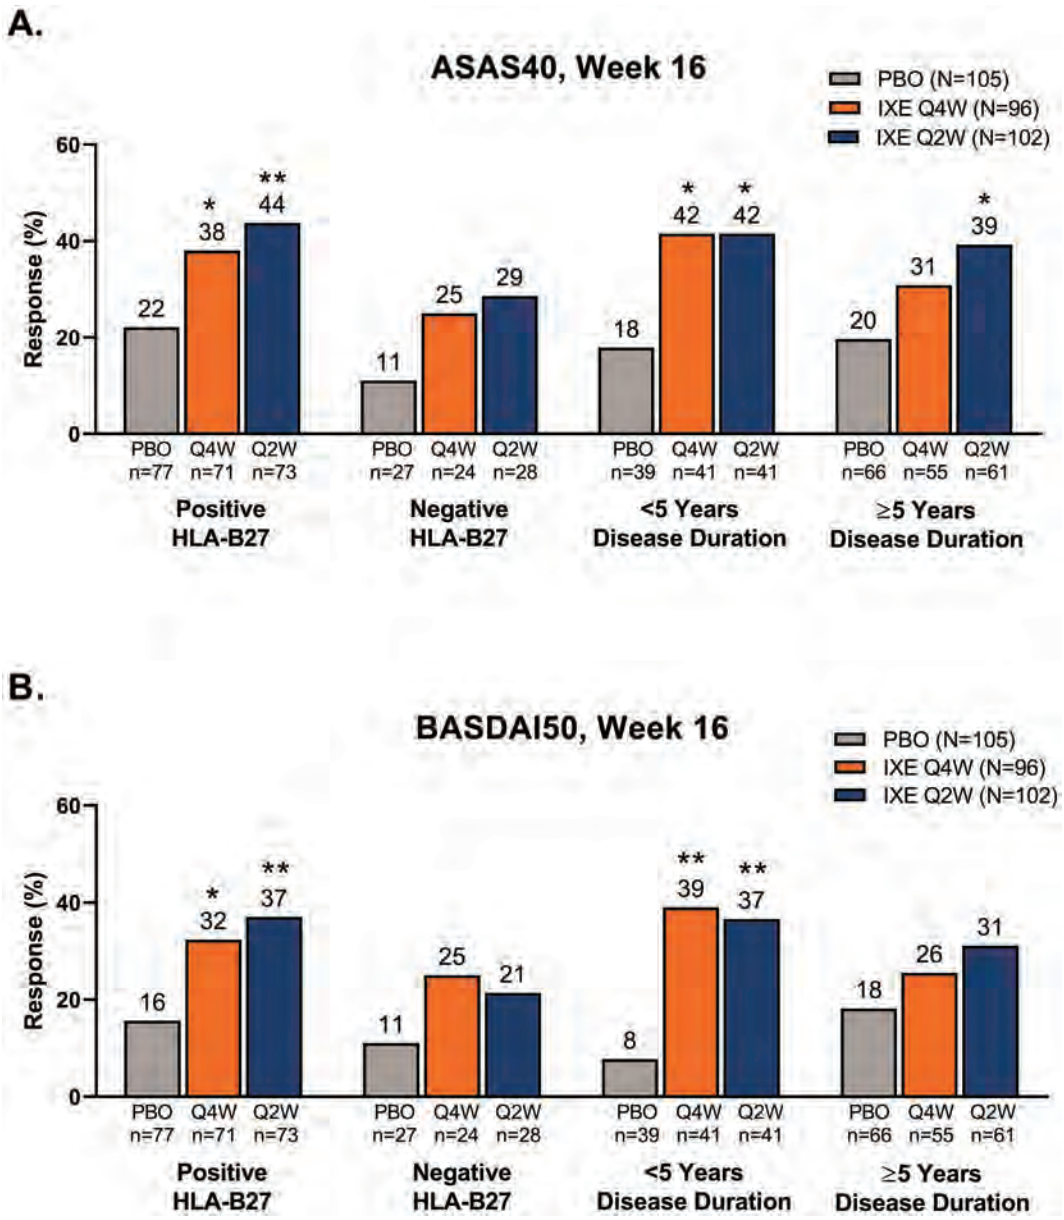

Figure. ASAS40 (A) and BASDAI50 (B) response rates at week 16 with IXE versus PBO in subpopulations of patients with non-radiographic axial spondyloarthritis. ASAS40, Assessment of SpondyloArthritis international Society 40% response, BASDAI50, Bath Ankylosing Spondylitis Disease Activity Index 50% response, IXE, ixekizumab; N, number of patients in the analysis population; n, number of patients in the specified category; PBO, placebo; Q2W, every 2 weeks; Q4W, every 4 weeks. *p<.05, **p<.01 vs. PBO

response (IXE Q4W, p=.020; IXE Q2W, p=.003) at week 16. Patients who had disease duration < 5 years showed a significant difference over PBO for ASAS40 response (IXE Q4W, p=.029; IXE Q2W, p=.029) and BASDAI50 response (IXE Q4W, p=.001; IXE Q2W, p=.003) at week 16, and patients who had disease duration ≥5 years showed a significant difference over PBO for ASAS40 response for IXE Q2W (p=.019) at week 16.

Conclusion: Patients treated with ixekizumab saw improvement in signs and symptoms of nr-axSpA as assessed by ASAS40 and BASDAI50 responses regardless of HLA-B27 status (positive or negative) or disease duration (< 5 or ≥5 years). However, the responses with IXE Q4W and IXE Q2W were significant over placebo for the HLA-B27+ patients and those with < 5 years of disease.

Abstract Number: 0362

Patients with Psoriatic Arthritis Treated with Guselkumab Achieved Psoriasis-Related Symptom-Free State and Had No Skin Condition Impact on Their Health Related Quality of Life

Jan Dutz[1], Joseph Merola[2], Chenglong Han[3], Alexa Kollmeier[4], Bei Zhou[3], Prasheen Agarwal[3], Ya-Wen Yang[5], May Shawi[6] and Atul Deodhar[7], [1]Vancouver General Hospital, Vancouver, Canada, [2]Brigham and Women's Hospital, Harvard Medical School, Boston, MA, [3]Janssen Research & Development, LLC, Spring House, PA, [4]Janssen Research & Development, LLC, La Jolla, CA, [5]Janssen Global Services, LLC, Malvern/Horsham, PA, [6]Janssen Global Services, LLC, Toronto, ON, Canada, [7]Oregon Health & Science University, Portland, OR

SESSION INFORMATION
Session Date: Friday, November 6, 2020
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Treatment Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Guselkumab (GUS), a monoclonal antibody that specifically binds to the p19 subunit of IL-23, is approved for psoriasis. In the DISCOVER-2 Phase 3 trial in patients with psoriatic arthritis (PsA), the treatment effect of GUS on patient-reported symptoms and Health Related Quality of Life (HRQOL) as related to psoriatic skin was assessed.

Methods: For DISCOVER-2, adults with active PsA (≥5 swollen + ≥5 tender joints; CRP ≥0.6 mg/dL) despite standard therapies (eg, non-biologic DMARDs, apremilast, or NSAIDs) were eligible. Patients in the HRQOL analyses also had baseline ≥3% Body Surface Area (BSA) of psoriatic involvement and an Investigators Global Assessment (IGA) Score ≥2 (mild). Patients were randomized 1:1:1, stratified by Week 0 DMARD use (Yes/No) and the most recent CRP value prior to randomization (< 2.0 mg/dL vs ≥2.0 mg/dL), to GUS 100 mg every 4 weeks (Q4W); GUS 100 mg at Week 0, Week 4, then every 8 weeks (Q8W); or Placebo. Concomitant stable use of select non-biologic DMARDs, oral corti-

Table 1. Least squares mean change from baseline in DLQI subscore through Week 24 among subjects with ≥3% Body Surface Area (BSA) of psoriatic involvement and an Investigators Global Assessment (IGA) Score ≥2 (mild) at Baseline[a]

DLQI subscores	Placebo (n=183) LS mean (range)[b]	Guselkumab

DLQI=Dermatology Life Quality Index; LS=least squares; MRMM=Mixed Model Repeated Measures; Q4W=every 4 weeks; Q8W=every 8 weeks

[a] The DLQI measures the impact of psoriasis on a patient's health related quality of life. The score is calculated based on a 10-item questionnaire that assesses 6 aspects (symptoms and feelings, daily activities, leisure, work or school performance, personal relationships, and treatment). A higher score indicates more severe disease.

[b] The LS means and p-values are based on the MMRM analysis.

Table 2. Mean change (SD) from baseline in total DLQI score and domain subscores at Week 52[a]

Subjects Evaluable	Placebo → 100 mg Q4W (n=173)	Guselkumab	
		100 mg Q8W (n=170)	100 mg Q4W (n=174)
Total DLQI score	-8.82 (7.27)	-9.24 (7.38)	-9.84 (6.88)

Treatment	-0.80 (0.90)	-0.85 (0.93)	-0.85 (0.90)

DLQI=Dermatology Life Quality Index; SD=standard deviation

[a] The DLQI measures the impact of psoriasis on a patient's health related quality of life. The score is calculated based on a 10-item questionnaire that assesses 6 aspects (symptoms and feelings, daily activities, leisure, work or school performance, personal relationships, and treatment). A higher score indicates more severe disease.

costeroids, and NSAIDs was allowed. At Week 16, patients with < 5% improvement in tender+swollen joints could initiate or increase the dose of permitted medications while continuing study treatment. Dermatology Life Quality Index (DLQI), a validated endpoint, assessed skin-related symptoms and HRQOL at Weeks 8, 16, 24, and 52. Skin-related symptom-free was defined as a DLQI item-1 score=0, and no impact of skin condition on HRQOL was defined as total DLQI score=0 or 1.

Results: Among 738 treated patients (248 GUS Q8W, 245 GUS Q4W, and 245 Placebo), baseline mean (standard deviation [SD]) DLQI score was 9.9 (7.5), indicating the great impact of skin disease on patients' HRQOL. Baseline

mean (SD) % BSA (n=736) was 17.4% (20.4%) and IGA score ≥2 (n=738) was reported for 82% of patients. A greater proportion of patients treated with GUS 100 mg Q8W (54.3%) or 100 mg Q4W (49.6%) was observed for psoriasis symptom-free at Week 24 vs Placebo (16.9%) (each nominal p< 0.001). A greater mean change from baseline was observed for DLQI total score at Week 24 in patients treated with GUS 100 mg QW8 (n=175) (-8.95 [95% CI -9.691, -8.218]) or 100 mg Q4W (n=184) (-8.85 [95% CI -9.581, -8.124]) vs placebo (n=182) (-2.13 [95% CI -2.854, -1.404]) (each nominal p< 0.001), and the least squares mean difference was observed as early as Week 8 (each nominal p< 0.001). At Week 24, a greater proportion of patients treated with GUS 100 mg Q8W (101 [63.9%]) or 100 mg Q4W (102 [59.0%]) achieved a DLQI score of 0 or 1 vs Placebo (20 [11.8%]) (each p< 0.001), indicating no impact of skin disease on their HRQOL. Similarly, greater improvements in each of the 6 DLQI domain subscores at Week 24 were observed in GUS-treated patients vs Placebo (Table 1). The greater mean changes from baseline in DLQI total and subscores observed at Week 24 were sustained through Week 52 (Table 2). Placebo-treated patients who switched to GUS 100 mg Q4W at Week 24 achieved improvement in DLQI score, which was comparable with originally randomized patients who received GUS.

Conclusion: The majority of GUS-treated patients with PsA achieved skin-related symptom-free and no impact of skin condition on their HRQOL.

SESSION INFORMATION

Session Date: Friday, November 6, 2020

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Treatment Poster I

Session Type: Poster Session A

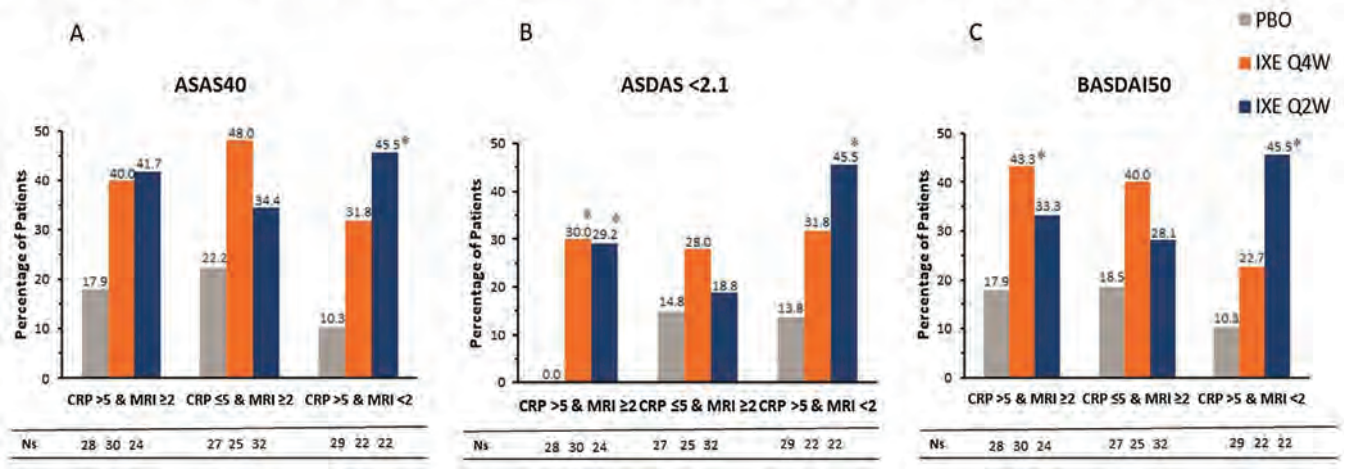
Session Time: 9:00AM–11:00AM

Background/Purpose: Ixekizumab (IXE), a high-affinity anti-interleukin-17A monoclonal antibody, is effective in patients (pts) with active non-radiographic axial spondyloarthritis (nr-axSpA), who had elevated C-reactive protein (CRP) and/or active sacroiliitis on magnetic resonance imaging (MRI).[1] The objective was to determine if disease activity and patient-reported outcomes at Week 16 were similar between groups after stratifying pts by CRP/sacroiliac joint (SIJ) MRI status at baseline.

Methods: COAST-X (NCT02757352) included pts with active nr-axSpA and objective signs of inflammation, that is, presence of sacroiliitis on MRI (Assessment of Spondyloarthritis International Society [ASAS]/Outcome Measures in Rheumatology criteria) or elevation of serum CRP (>5.0 mg/L). Pts were randomized 1:1:1 to receive subcutaneous 80 mg IXE every 4 weeks (Q4W) or every 2 weeks (Q2W), or placebo (PBO). Depending on the baseline values of CRP and MRI SIJ (Spondyloarthritis Research Consortium of Canada [SPARCC] score), pts in the intent-to-treat population (N=239) were divided into 3 subgroups (CRP >5 and MRI ≥2; CRP ≤5 and MRI ≥2; CRP >5 and MRI < 2). Logistic regression analysis with treatment, subgroup, and treatment-by-subgroup interaction was used to detect treatment group differences in ASAS40, Ankylosing Spondylitis Disease Activity Score (ASDAS) < 2.1 (low disease activity), and Bath Ankylosing Spondylitis Disease Activity Index 50 (BASDAI50) responses at Week 16. Analysis of covariance model with baseline value, treatment, subgroup, and treatment-by-subgroup interaction was used to detect the treatment group difference in change from baseline in Short Form-36 physical component score (SF-36 PCS).

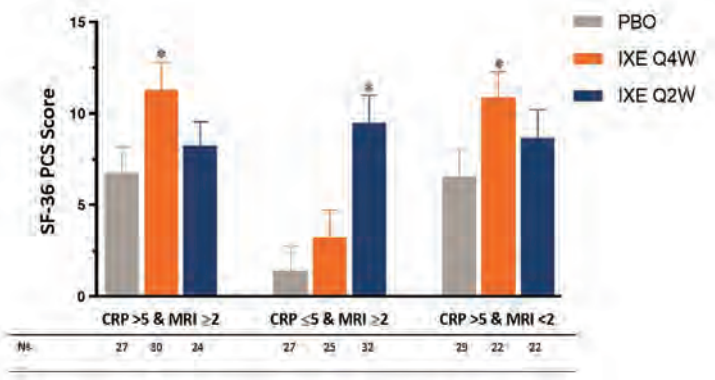
Results: The proportion of pts achieving ASAS40 (primary endpoint), ASDAS < 2.1, and BASDAI50 (secondary endpoints) was higher in IXE treatment groups compared to PBO at Week 16 (Figure 1). The response rates in IXE-treated subjects were higher in all subgroups (CRP >5 and MRI ≥2; CRP ≤5 and MRI ≥2; CRP >5 and MRI < 2) without consistent differences in efficacy between the subgroups. Similarly, pts in the IXE groups showed improvement in SF-36 PCS scores (secondary endpoint) versus pts on PBO at Week 16 (Figure 2).

Figure 1: Disease Activity and Patient Reported Outcomes (NRI) at Week 16 by baseline CRP and MRI SIJ SPARCC Score



*p<0.05 as compared to PBO. Data from ITT population in 3 subgroups, N=239. Baseline CRP is defined as the last CRP value prior to first study injection. ASAS40=Assessment of Spondyloarthritis International Society 40; ASDAS=Ankylosing Spondylitis Disease Activity Score; BASDAI50=Bath Ankylosing Spondylitis Disease Activity Index 50; CRP=C-Reactive Protein; ITT=intent-to-treat; IXE Q4W=ixekizumab every 4 weeks; IXE Q2W=ixekizumab every 2 weeks; MRI=magnetic resonance imaging; N=number of patients in the analysis population; NRI=non-responder imputation; Ns=number of patients in each subgroup; PBO=placebo; SIJ=sacroiliac joints; SPARCC=Spondyloarthritis Research Consortium of Canada Score.

Figure 2: Change from Baseline in SF-36 PCS Score at Week 16 by Baseline CRP and MRI SIJ SPARCC Score



*p<0.05 as compared to PBO. mBOCF data provided as least square mean ± standard error from ITT population in 3 subgroups, N=239. Baseline CRP is defined as the last CRP value prior to first study injection. CRP=C-Reactive Protein; ITT=intent-to-treat; IXE Q4W=ixekizumab every 4 weeks; IXE Q2W=ixekizumab every 2 weeks; mBOCF=modified baseline observation carried forward; MRI=magnetic resonance imaging; N=number of patients in the analysis population; Ns=number of patients in each subgroup; PBO=placebo; SF-36 PCS=Short Form-36 physical component score; SIJ=sacroiliac joints; SPARCC=Spondyloarthritis Research Consortium of Canada Score.

Conclusion: Pts with active nr-axSpA and objective signs of inflammation at baseline who were treated with IXE showed an overall improvement in the signs and symptoms of the disease. The efficacy was not different between pts with both elevated CRP and active sacroiliitis on MRI and pts with either elevated CRP or active sacroiliitis on MRI.

SEC 150 mg, N = 72 and placebo, N = 74
MCID definition: total and nocturnal back pain, defined as improvement of ≥50%; overall level of spinal pain, defined as improvement of ≥22.5%; BASDAI average, defined as improvement of ≥22.5%; SF-36 PCS, defined as improvement of ≥2.5 points; BASFI, defined as improvement of ≥17.5%; Overall level of fatigue/tiredness, defined as improvement of ≥22.5% (on a VAS scale of 0-10); FACIT-Fatigue: defined as improvement of ≥4 points; ASDAS-CRP, defined as improvement of ≥1.1 points
MCID, minimal clinically important difference; M, number of evaluable pts; N, number of randomized pts; n, number of pts with response.

Background/Purpose: Patients (pts) with ankylosing spondylitis (AS) report pain (70–80%), stiffness (20–40%), and fatigue (50–60%) as the most troubling symptoms. Early diagnosis and sustained improvement in these symptoms are essential for effective management of AS. Here, we report the effect of subcutaneous (s.c.) secukinumab (SEC) 150mg on these symptoms through 5 years (end-of-study) from MEASURE 2.

Methods: The MEASURE 2 study design has been reported previously. This post hoc analysis assessed the mean change from baseline to Week (Wk) 260 in total and nocturnal back pain scores (Visual analogue scale [0–100]), overall level of spinal pain (neck, back, or hip) from BASDAI score, and morning stiffness (overall level; mean of questions 5 and 6 of BASDAI score). Additionally, the SF-36 physical component summary (PCS) score, BASFI score, overall level of fatigue (BASDAI question 1), FACIT-Fatigue, ASDAS-CRP scores, and proportion of pts meeting minimal clinically important difference (MCID) criteria across multiple clinical domains were also assessed. Data are shown for pts originally randomized to SEC 150mg and placebo. Data are reported as observed for overall population and by prior tumor necrosis factor inhibitor (TNFi) therapy status (naïve vs inadequate response/intolerance [IR]).

Results: Baseline clinical characteristics were generally comparable across the treatment groups; SEC 150mg (N=72) and placebo (N=74). 73.6% (n=53) of pts originally randomized to SEC 150 mg completed 5 years of treatment. The most frequent reason of discontinuation was adverse events reported 9.7% (n=7) pts. Improvements were sustained through 5 years in pts treated with SEC 150mg in pain, morning stiffness, physical function (SF-36 PCS and BASFI), fatigue (overall level of fatigue and FACIT-Fatigue), and ASDAS-CRP (Table 1). 48.1% and 25.0% of SEC 150mg treated pts met MCID criteria for ASDAS-CRP Low Disease Activity and ASDAS-CRP Inactive Disease at 5 years, respectively (Table 2). Improvements were observed in both TNFi-naïve and -IR pts, with numerically higher improvement in TNFi-naïve pts.

Conclusion: Secukinumab 150mg provided clinically meaningful improvements in total back pain, nocturnal back pain, morning stiffness, fatigue and low disease activity through 5 years of treatment in pts with active AS.

SESSION INFORMATION
Session Date: Friday, November 6, 2020
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Treatment Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Apremilast is the one targeted immune modulating (TIM) treatment for psoriatic arthritis (PsA) that may be combined with csDMARDs, biologic therapies, or used as a monotherapy. Here we describe the utilization of and experience with apremilast in a large network of community rheumatologists.

Methods: The ARN-TRIO Rheumatology registry consists of EMR (fielded and open text), lab, procedure, infusion, medical claims, and specialty pharmacy data generated in care of >75,000 patients by ARN, a network of independent practices with >200 rheumatologists across the US. For this study, registry data were limited to patients diagnosed with PsA who initiated apremilast or TNF inhibitors between Jan 2014 to Nov 2019 with ≥6 months follow-up. Disease Assessment Scores (DAS) were calculated using CDAI or RAPID3 and analyzed categorically using 4 grade scale. Comparisons between groups used Fisher's Exact Test for categorical variables. As a surrogate for clinical effectiveness, we examined time from apremilast monotherapy initiation to modification or discontinuation, defined as either drug discontinuation or addition of a csDMARD or TIM drug. Time to event analyses were conducted via KM curves and associated Log-Rank Test for difference in Hazard.

Results: Of the 581 apremilast-treated patients in the study, 325 (56%) had no prior observed PsA treatment, 129 (22%) previously were treated with csDMARDs but not TIM drugs, and 127 (22%) had previously received TIM therapies. Two or more of the apremilast treatment groups were significantly different for gender, race, age, payer, and prior

therapies; groups were not different by baseline disease severity. [Table 1] Across these groups, 227 (48%) received apremilast as a monotherapy without prior TIM therapies. A comparator group of 1662 patients who received a TNF inhibitor (TNFi) as a monotherapy and without prior TIM was identified. Characteristics for the apremilast monotherapy and TNFi monotherapy groups differed significantly for gender and race but not for baseline disease severity. [Table 2] Median time from monotherapy start to modification or discontinuation was significantly different between apremilast (19.3 months) and TNFi (30.4 months, p=0.018). In subset analyses, differences in time to modification persisted between apremilast and TNFi monotherapy groups among males (p = 0.037) and patients with severe baseline DAS (p=0.009), but not among females or non-severe baseline DAS. [Figure 1]

Conclusion: The use of apremilast in US community practice is predominantly as a monotherapy. When examined as a first TIM monotherapy, time to modification or discontinuation was significantly less than comparator TNFi monotherapy-treated group. However, when stratified by gender and baseline DAS, female patients and those with low DAS had no difference in time to modification between apremilast and TNFi. These results should be viewed in light of the limitations of the study, which include potential prior treatments or other confounding variables not present in the collected data.

Table 2. Patient Characteristics for patients with qualifying first TIM monotherapy with apremilast or TNFi

Category	Characteristic	(1)	(2)	p

SESSION INFORMATION
Session Date: Friday, November 6, 2020
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Treatment Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Ankylosing spondylitis (AS) is a chronic inflammatory disease of the axial skeleton associated with pain, stiffness, and disability.[1] Up to 66% of patients (pts) with AS may also have peripheral involvement, including swollen and tender joints (STJs),[2,3] which are associated with worse overall disease activity.[4] A previous analysis showed that secukinumab, a selective inhibitor of interleukin 17A, led to significant improvements in efficacy outcomes vs placebo, regardless of peripheral joint involvement.[3] However, the effect of secukinumab on symptoms of peripheral arthritis in pts with AS was not assessed.

The objective of this analysis was to assess changes in peripheral symptoms in pts with AS treated with secukinumab vs placebo.

Methods: Data from pts with active AS and peripheral symptoms who were enrolled in MEASURE 1 (NCT01358175), 2 (NCT01649375), 3 (NCT02008916), and 4 (NCT02159053) were pooled in this hypothesis-generating analysis. No adjustments for multiple comparisons were made. Pts with peripheral symptoms were identified by the presence

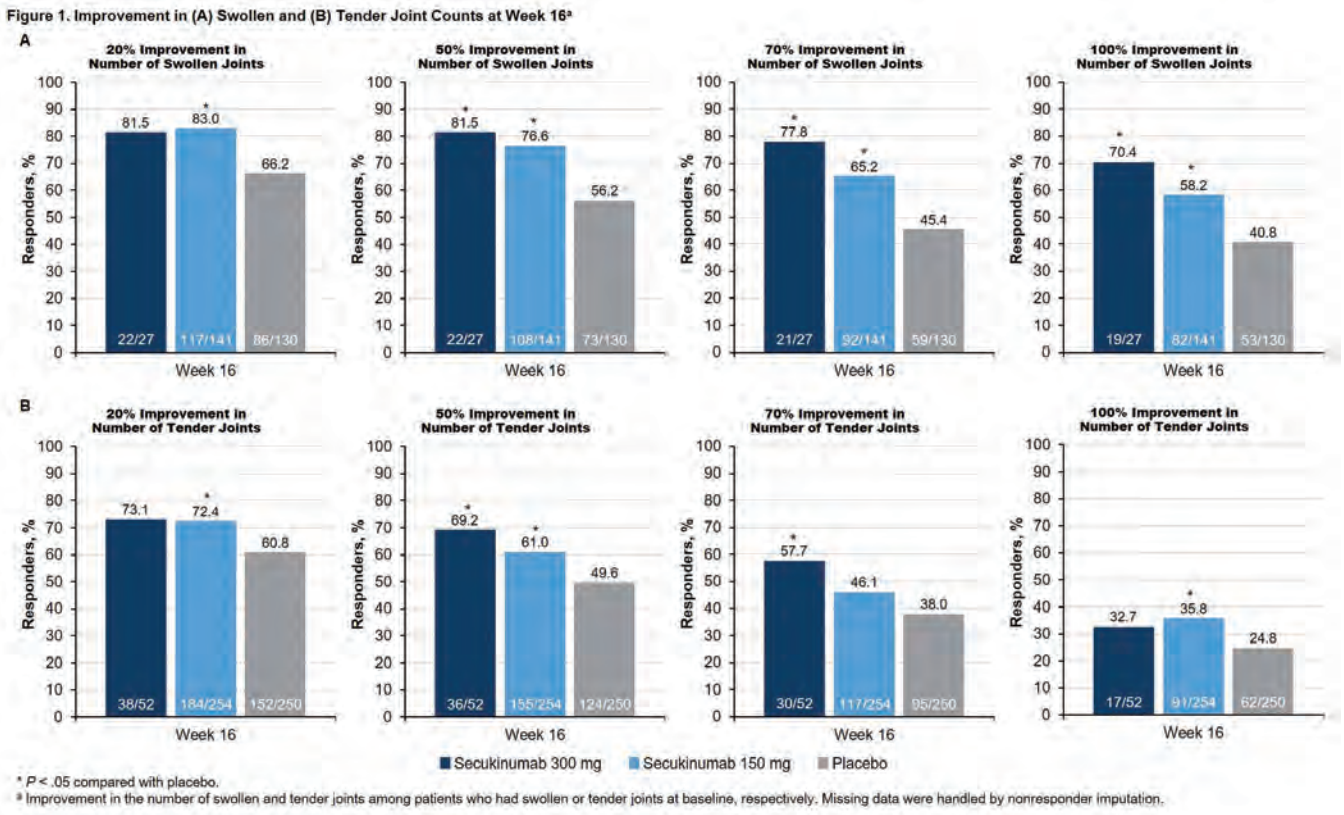
Unknown	1 (1.9)	0	0
BMI, mean (SD), kg/m^2	27.8 (5.9)	27.6 (6.1)	27.4 (5.4)
Current smoker at baseline, n (%)	14 (26.9)	82 (32.0)	72 (28.6)
Time since diagnosis, mean (SD), years	5.6 (7.4)	7.2 (8.9)	7.3 (9.0)
Previous TNFi use, n (%)	15 (28.8)	79 (30.9)	79 (31.3)
BASDAI, mean (SD)	7.0 (1.5)	7.0 (1.4)	6.9 (1.3)
BASDAI question 3, mean (SD)	6.3 (2.5)	6.6 (2.2)	6.4 (2.1)
hs C-reactive protein, mean (SD), mg/L	12.0 (14.7)	18.5 (32.4)	15.4 (20.5)
Patient Global Assessment (VAS 0-100), mean (SD)	73.4 (15.8)	71.7 (17.2)	70.1 (16.1)
Swollen 44-joint count, mean (SD)	1.9 (2.8)	2.6 (4.2)	2.5 (4.4)
Tender 44-joint count, mean (SD)	7.1 (7.1)	7.8 (7.5)	7.9 (8.0)

BASDAI, Bath Ankylosing Spondylitis Disease Activity Index; BMI, body mass index; hs, high-sensitivity; SD, standard deviation; TNFi, tumor necrosis factor-α inhibitor; VAS, visual analog scale.
[a] Includes black or African American, American Indian or Alaskan Native, and other.



of STJs, based on 44-joint counts at baseline (BL). Pts received subcutaneous (SC) secukinumab every 4 weeks at doses of 300 mg with an intravenous (IV) loading dose (MEASURE 3 only), 150 mg with an IV or SC loading dose, or placebo. Treatment response through Week 16 was assessed based on the proportions of pts who achieved improvements of 20%, 50%, 70%, or 100% in the number of swollen and number of tender joints and improvements in the BASDAI score for question 3 and Patient Global Assessment (PGA). Changes in the number of swollen and number of tender joints were assessed in pts with swollen or tender joints at BL, respectively.

Results: This pooled analysis included 560 pts with AS and STJs at BL (**Table**). At Week 16, treatment with secukinumab led to significantly greater proportions of pts achieving reductions in the number of swollen (**Fig 1A**) or tender (**Fig 1B**) joints compared with placebo; the treatment effect was more pronounced in reduction of swollen joints. Furthermore, a greater proportion of secukinumab-treated pts achieved complete resolution of swollen or tender joints vs placebo (**Fig 1**). Secukinumab also led to significant improvements in peripheral pain/swelling (**Fig 2A**) and disease activity (**Fig 2B**) vs placebo, as assessed using BASDAI question 3 and the PGA, respectively.

Conclusion: In parallel with its previously reported efficacy in axial symptoms,[3] secukinumab led to significant improvements in symptoms of peripheral arthritis in pts with AS. Significant improvements were seen in both tender and swollen joints.

SESSION INFORMATION

Session Date: Friday, November 6, 2020

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Treatment Poster I

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: Guselkumab (GUS), an IL-23 inhibitor monoclonal antibody (MAb) that specifically binds the IL-23p19 subunit, demonstrated efficacy compared to placebo (PBO) in reducing skin & musculoskeletal signs & symptoms in patients (pts) with active PsA in two Ph3 studies, DISCOVER 1 & 2.[1,2] Results from a GUS PsA Ph2 trial[3] & Ustekinumab (UST, anti-IL12/23p40 MAb) PsA Ph3 trials (PSUMMIT 1 & 2)[4] showed associations of baseline IL-17A, IL-17F, & CRP with baseline disease characteristics, & associations of GUS-induced cytokine reductions with clinical responses. We investigated cytokine expression in PsA & changes post GUS therapy.

Methods: In DISCOVER 1 & 2, pts received GUS 100 mg at Week (Wk) 0, 4, then every 8Wks (q8w); GUS 100 mg q4w; or matching PBO. 21 serum biomarkers were measured in 300 PsA pts from DISCOVER at Wks 0, 4, & 24, & in 34 healthy controls matched for age, sex, & ethnicity. Serum proteins measured were acute phase reactants: CRP & SAA & inflammatory cytokines/chemokines: Th17 effector cytokines IL-17A, IL-17F, IL-22, soluble ICAM-1, soluble VCAM-1, IL-6, CXCL-8, IL-10, IL-13, IL-12p70, CCL22, IFN-γ, CCL2, CCL4, TNF-α, IL-1β, IL-2, IL-4 (MSD), & YKL-40. Serum IL-17A, IL-17B, & CRP measured in PSUMMIT[4] were compared with GUS.

Results: Baseline serum levels of CRP, SAA, IL-6, IL-17A, & IL-17F were elevated in PsA pts vs healthy controls ($p< 0.05$, geometric mean [GM] ≥40% higher, FIG 1). No significant dysregulation in other cytokines in PsA pts vs healthy controls. Baseline IL-17A, IL-17F, IL-22, & CCL22 were significantly associated with baseline psoriasis disease activity (Body Surface Area & Psoriatic Area & Severity Index, Spearman Signed Rank $p< 0.05$, $r >0.25$). Baseline CRP, SAA, IL-6, & YKL40 were significantly associated with baseline joint disease (Disease Activity Score 28-CRP, Spearman $p< 0.05$, $r >0.25$). Baseline SAA, IL-6, IL-17A, & IL-17F were higher in pts with prior TNF inhibitor exposure than without ($p< 0.05$, GM ≥40% higher), although PsA pts with/without prior TNF inhibitor had higher levels vs healthy controls. GUS treatment resulted in decreases in serum CRP, SAA, IL-6, IL-17A, IL-17F, & IL-22 that were significantly greater than PBO as early as Wk 4 (FIG 1). These protein levels continued to decrease through Wk 24 in GUS-treated pts with both regimens ($p< 0.05$, GM decrease from baseline ≥ 33%). No significant difference in Wk 24 IL-17A & IL-

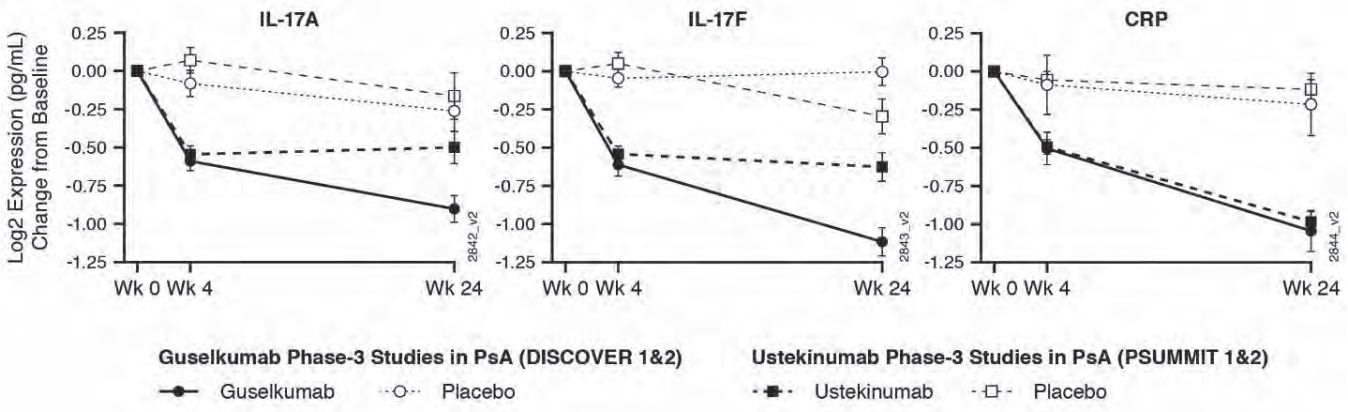
FIGURE 2.



Error bars represent standard error of the mean
Wk=Week

17F levels for GUS vs healthy controls suggests a normalization of peripheral effector cytokines associated with the IL-23/Th17 axis post GUS treatment. Effects on IL-17A/IL-17F were greater in GUS vs UST treated pts, while CRP levels were similar in both programs (FIG 2).

Conclusion: Comprising a strong pharmacodynamic effect, GUS reduced serum protein levels of acute phase & Th17-effector cytokines (whose elevations at baseline were associated with PsA disease characteristics) & achieved comparable levels to those in healthy controls. In PsA pts, reductions of IL-17A & IL-17F by GUS were of greater magnitude than those by UST.

Comparable Impact and Burden of Disease of Psoriatic Arthritis Patients with Limited Joint Involvement vs. Those with More Extensive Joint Involvement: Interim Results from a Prospective, Multicenter, Real-World Study in Patients Treated with Apremilast

Tim Jansen[1], Arie van Vliet[2] and Marijn Vis[3], [1]Viecuri MC, Venlo, Netherlands, [2]Amgen B.V., Breda, Netherlands, [3]Erasmus UMC, Rotterdam, Netherlands

SESSION INFORMATION

Session Date: Friday, November 6, 2020

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Treatment Poster I

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: Psoriatic arthritis (PsA) is associated with a high burden of disease and an increased risk of comorbidities. Recent data suggest that patients with moderate PsA benefit most from apremilast (APR) treatment (Mease PJ, et al. *Arthritis Care Res [Hoboken].* 2020 Jan 7. [Epub ahead of print]). Results from an earlier analysis of the REWARD study suggest that patients with limited joint involvement may benefit from APR treatment, with improvements in the perceived impact of disease (Jansen TL, et al. *Ann Rheum Dis*. 2019;78:913 [abstract FRI0442]). Patients with limited joint involvement or comorbidities are underrepresented in randomised controlled trials; therefore, evidence from real-world patient cohorts is needed to assess and compare the impact and burden of disease on patients with limited vs. extensive joints who may also have comorbidities. This study compared the burden of disease and comorbidities in patients with PsA who have limited joint involvement with patients with PsA who have extensive joint involvement.

Methods: The prospective, multicenter, observational REWARD study assessed the impact of using the Psoriatic Arthritis Impact of Disease (PsAID) questionnaire (score range: 0-10), presence of domains of PsA (enthesitis, dactylitis, skin psoriasis, nail psoriasis, axial involvement), and ongoing or history of comorbidities of interest on patients with

Table 1. Patient Characteristics

Demographics	SJC ≤4 (n=53)	SJC >4 (n=24)

Figure 1. Baseline SJC vs PsAID vs Pain VAS

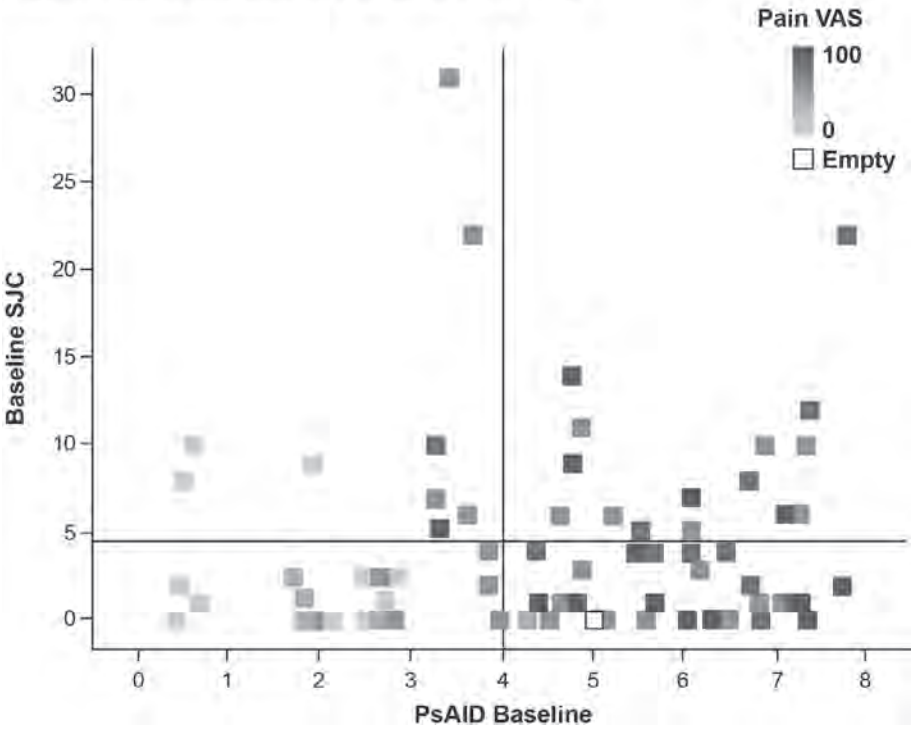

Figure 2. Baseline PsAID by Domain

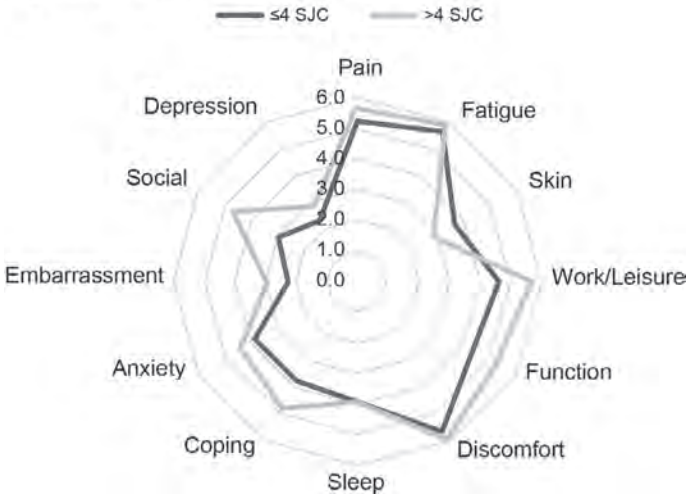

PsA considered for apremilast treatment in The Netherlands. This interim analysis compared results in patients with limited joint involvement (swollen joint count [SJC] ≤4) vs. more extensive joint involvement (SJC >4).

Results: Currently, 77 patients have been included in the analysis (SJC ≤4: n=53; SJC >4: n=24) (Table 1). Mean baseline PsAID scores were 4.4 vs. 4.8 for the SJC ≤4 vs. SJC >4 groups (Figure 1). The proportions of patients who were not in the PsAID-defined Patient Acceptable Symptom State (PASS) were 58.7% for the SJC ≤4 group and 62.5% for the SJC >4 group. Mean pain visual analog scale (VAS) scores (0-100 mm) were 45.9 vs. 53.4 for the SJC ≤4 group vs. for the SJC >4 group. Mean scores for the individual PsAID domains for the SJC ≤4 vs. SJC >4 groups were generally comparable (Figure 2). Presence of specific manifestations of PsA for patients in the SJC ≤4 group vs. the SJC >4 group, respectively, were: moderate to severe psoriasis (psoriasis-involved body surface area [BSA]

>3: 31.4% vs. 21.7%), nail psoriasis (45.3% vs. 41.7%), enthesitis (Leeds Enthesitis Index >0: 43.4% vs. 45.8%), dactylitis (18.9% vs. 33.3%), and axial involvement (3.8% vs 8.3%). Comorbidities in ≥5% of either group (SJC ≤4 vs. SJC >4) included hypertension (30.2% vs. 37.5%), hypercholesterolemia (13.2% vs. 16.7%), uveitis (1.9% vs. 8.3%), malignancy (0.0% vs. 8.3%), heart failure (5.7% vs. 8.3%), and depression (5.7 vs. 4.2%).

Conclusion: In this real-world study, no strong associations between SJC and patient-reported impact of disease or pain were observed. Similar to patients with more extensive joints involvement, patients with limited joint involvement had an associated substantial burden of disease, with more than half not achieving PsAID PASS.

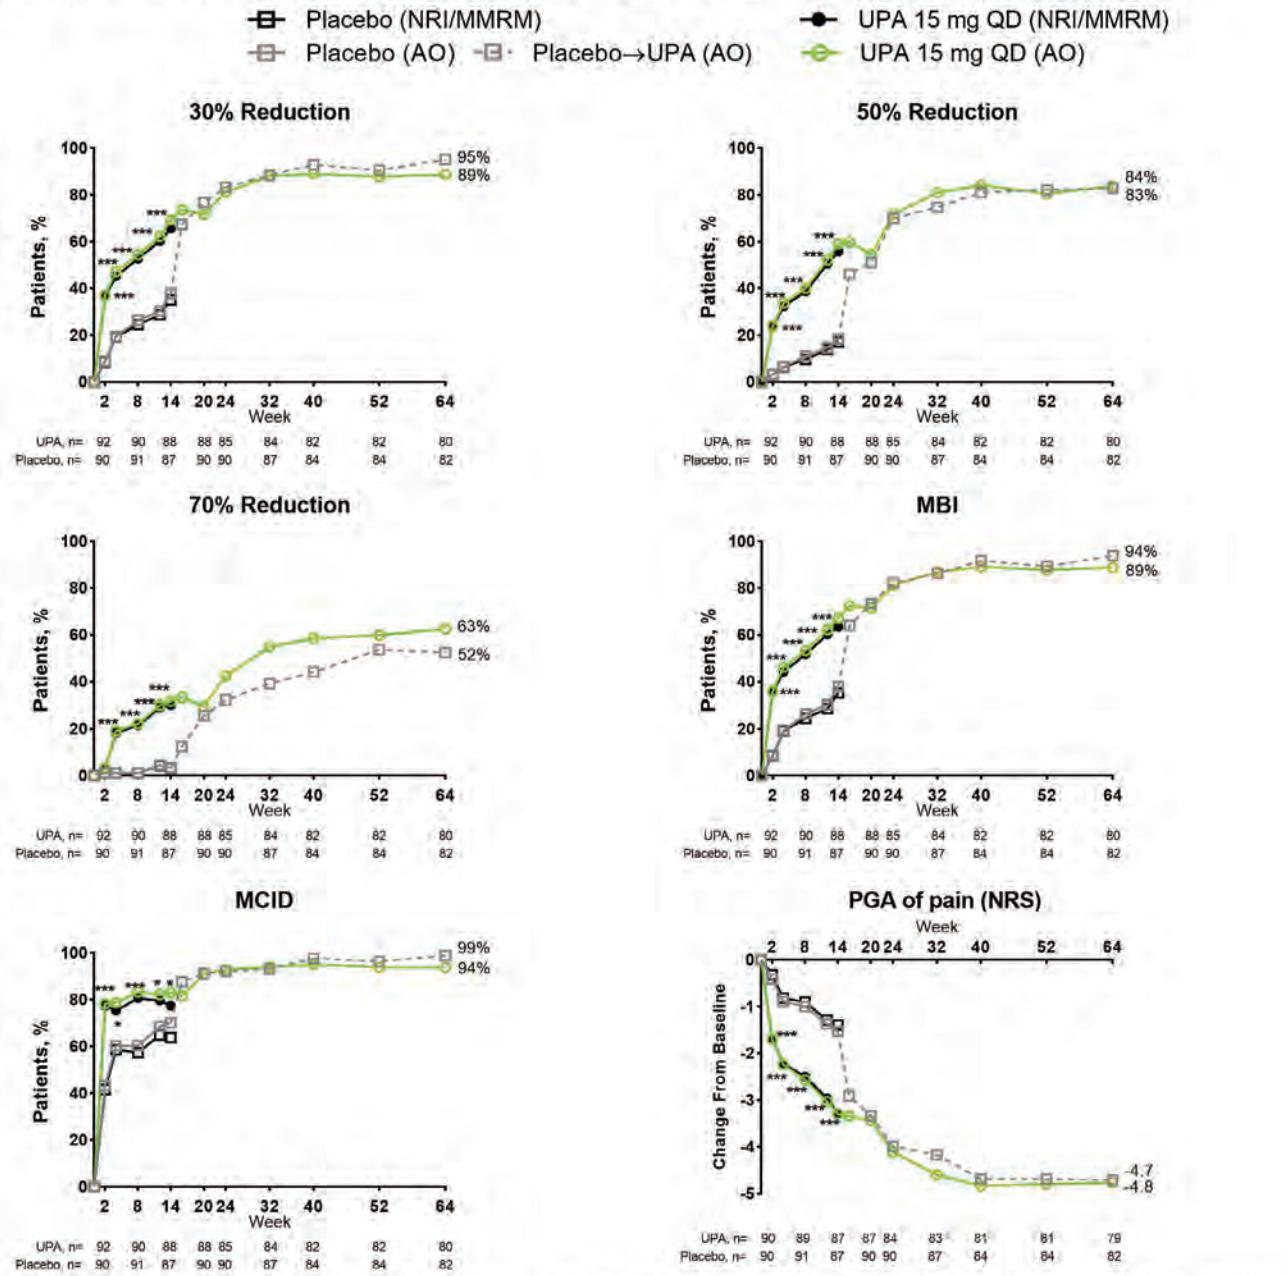
SESSION INFORMATION
Session Date: Friday, November 6, 2020
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Treatment Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Pain is a debilitating symptom of ankylosing spondylitis (AS) and negatively impacts patient (pt) lives. Upadacitinib (UPA), a Janus kinase (JAK) inhibitor engineered for increased selectivity for JAK1 over JAK2, JAK3, and tyrosine kinase 2, [1] showed significant efficacy vs placebo (PBO) in the randomized phase 2/3 SELECT-AXIS 1 study in active AS.[2] The objective of this analysis was to evaluate the efficacy of UPA on multiple pain assessments through 64 weeks (wks).

Methods: SELECT-AXIS 1 (NCT03178487) enrolled adults with active AS, who had an inadequate response, intolerance or contraindications to ≥2 NSAIDs, were biologic DMARD naive and met the modified New-York Criteria. Pts were randomized 1:1 to UPA 15 mg once daily (QD, n=93) or PBO (n=94) for 14 wks (Period 1), followed by open-label UPA 15 mg QD during 90-wk extension (Period 2); reported here are data through wk 64. Pain endpoints included the proportion of pts achieving ≥30%/≥50%/≥70% reduction in Pt's Global Assessment (PGA) of pain on a 0–10 numeric rating scale (NRS), minimal clinically important difference (MCID, defined as ≥1 point reduction or ≥15% reduction from baseline [BL]) in PGA of pain, and much better improvement (MBI, defined as ≥2 point reduction and ≥33% reduction from BL) in PGA of pain. In addition, mean change from baseline in PGA of pain, BASDAI questions 2 (neck/back/hip pain) and 3 (peripheral pain/swelling), and pt's assessment of total back pain and nocturnal back pain NRS scores (NRS 0–10) were assessed. Non-responder imputation (binary endpoints) and mixed-effects model for repeated measurements (continuous endpoints) were used for missing data/dropouts in Period 1; as-observed analysis was used for Period 2.

Figure 1. Proportion of Patients with ≥30%/50%/70% Reduction from Baseline, MBI, or MCID in PGA of Pain and Mean Change from Baseline in PGA of Pain NRS Score Through 64 Weeks

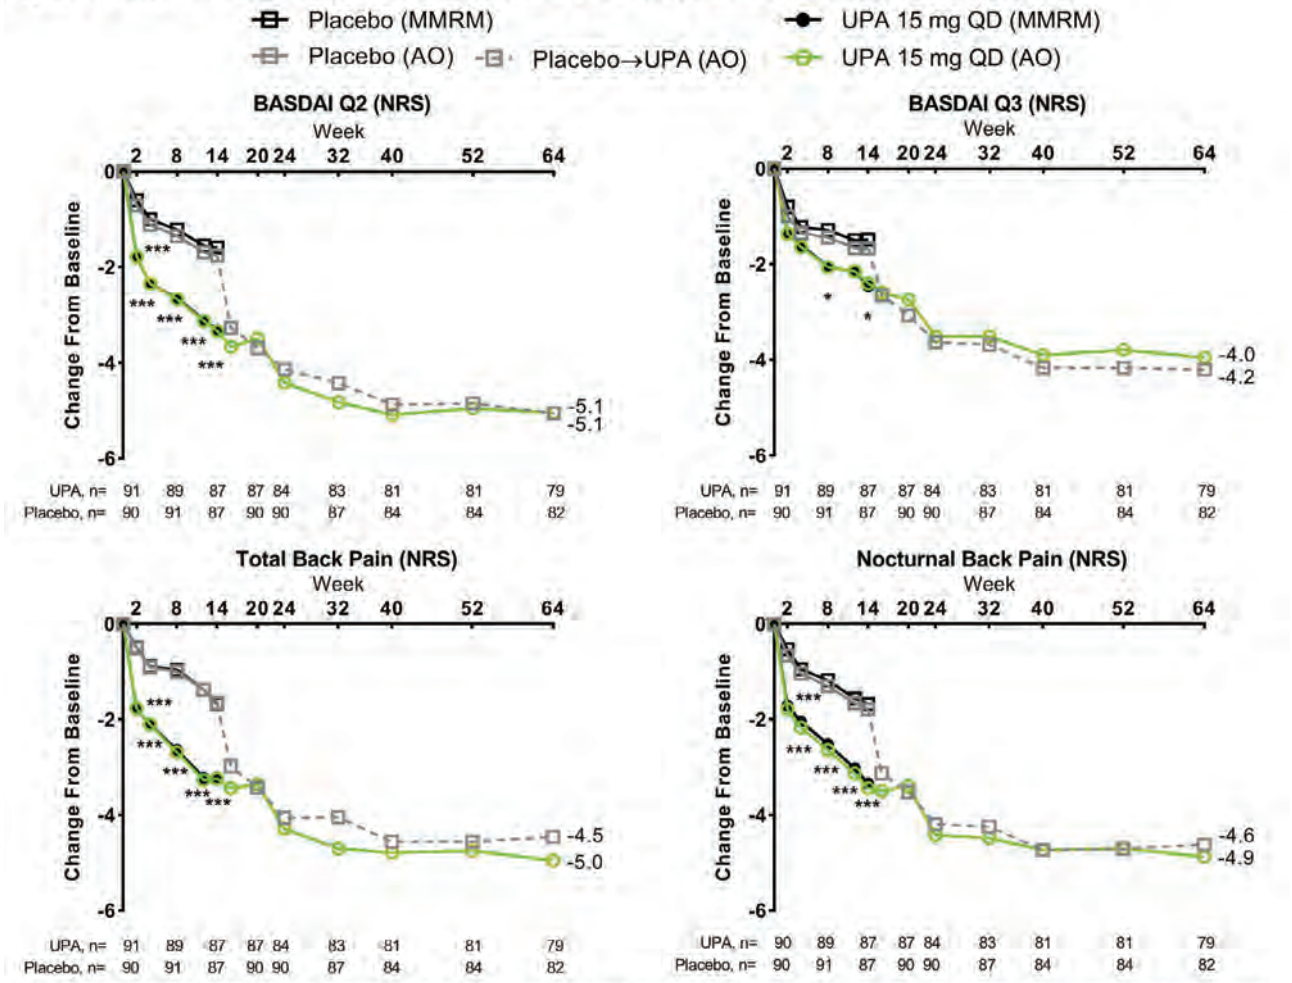


AO, as observed; MBI, much better improvement; MCID, minimal clinically important difference; MMRM, mixed-effects model for repeated measurements; NRI, non-responder imputation; NRS, numeric rating scale; PGA, patient's global assessment; UPA, upadacitinib.
Dashed line: all patients randomized to placebo received open-label UPA starting from week 14.
UPA vs PBO comparison was calculated using Cochran-Mantel-Haenszel test adjusting for stratification factor of high-sensitivity CRP level; nominal *P* values: ***$P<0.001$, *$P<0.05$.
Patient's Global Assesment of Pain based on: "How much pain have you had because of your condition during the last week?"

Figure 1

Results: A significantly higher proportion of pts receiving UPA vs PBO achieved reductions in all PGA of pain assessments as early as wk 2 that was sustained at all time points in Period 1; the only exception was ≥70% reduction in PGA of pain that was significant at wk 4 and sustained thereafter (**Fig. 1**). For ≥30%/≥50%/≥70% reduction and MBI, the response rate increased over time with UPA; the difference for UPA vs PBO also continued to increase over time for ≥50% and ≥70% reduction endpoints. For MCID, an increase from BL to wk 2 was observed and plateaued there-

Figure 2. Mean Change from Baseline in Other Pain NRS Scores Through 64 Weeks



AO, as observed; MBI, much better improvement; MCID, minimal clinically important difference; MMRM, mixed-effects model for repeated measurements; NRS, numeric rating scale; UPA, upadacitinib.
Dashed line: all patients randomized to placebo received open-label UPA starting from week 14.
UPA vs PBO comparison was calculated using Cochran-Mantel-Haenszel test adjusting for stratification factor of high-sensitivity CRP level; nominal *P* values: ***$P<0.001$, *$P<0.05$.
BASDAI Q2 based on a question: "How would you describe the overall level of AS neck, back or hip pain you have had?"
BASDAI Q3 based on a question: "How would you describe the overall level of pain/swelling in joints other than neck, back or hips you have had?"
Patient's assessment of total back pain based on question: "What is the amount of back pain that you experienced at any time during the last week?
Patient's assessment of nocturnal back pain based on a question:"What is amount of back pain at night that you experienced during the last week?"

Figure 2

after. The mean change from BL in PGA of pain, BASDAI Q2, total back pain, and nocturnal back pain NRS scores were significantly greater for UPA vs PBO at all time points in Period 1; BASDAI Q3 was significant at wk 8 and 14 (**Figs 1-2**). The effect of UPA on pain reduction was sustained through wk 64. PBO pts who switched to open-label UPA at wk 14 generally reached the same level of pain reduction as those initially randomized to UPA (**Figs 1-2**).

Conclusion: In pts with active AS and an inadequate response/contraindication to NSAIDs, a greater proportion of patients treated with UPA achieved rapid, significant, and clinically meaningful reductions in pain vs PBO through 14 wks across multiple pain assessments. The reductions in pain were sustained over time, and pts who switched from PBO to UPA reached the same level of improvement as the continuous UPA group.

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Treatment Poster I

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: Patients with psoriatic arthritis (PsA) experience broad systemic symptoms including pain, fatigue, depression, sleep disturbance, poor physical function, and diminished social participation. DISCOVER 1 is a Phase 3 trial (NCT03162796) evaluating the efficacy and safety of guselkumab (GUS), an interleukin 23 inhibitor that binds to the p19-subunit of IL-23, in patients with active PsA. In this study, PROMIS-29 (Patient-Reported Outcomes Measurement Information System-29), a validated generic health instrument,[1] assessed the treatment effect of GUS on symptoms in patients with PsA.

Methods: Patients with active PsA despite nonbiologic DMARDs were enrolled, and ~30% of patients could have previously received ≤2 TNFi. Patients were randomized (1:1:1) to subcutaneous GUS 100 mg at Week 0 (W0), W4 then q8W (n=127), GUS 100 mg q4W (n=128), or PBO (n=126). Concomitant stable use of select csDMARDs, oral steroids, and NSAIDs was allowed. PROMIS-29 consists of 7 domains (Depression, Anxiety, Physical Function, Pain Interference, Fatigue, Sleep Disturbance, and Social Participation) and a pain intensity 0-10 numeric rating scale (NRS). The raw score of each domain is converted into a standardized T-score with a mean of 50 (general population mean) and a standard deviation (SD) of 10. Higher PROMIS scores represent more of the concept being measured. A ≥5-point improvement (1/2 SD of T-score) is defined as clinically meaningful.[1]

Table. PROMIS-29 Domain T-Scores Least Square (LS) Mean Change from Baseline

Table. PROMIS-29 Domain T-Scores Least Square (LS) Mean Change from Baseline			
	LS Mean Change from Baseline		
	PBO	GUS q8W	GUS q4W
Anxiety	-1.37	-3.23*	-2.92
Depression	-0.85	-3.4**	-2.67*
Fatigue	-1.86	-4.79**	-5.08**
Pain interference	-2.30	-5.49**	-5.69**
Physical function	1.34	3.89**	5.05**
Sleep disturbance	-1.17	-3.48**	-2.46
Social participation	1.45	4.90**	4.52**
Pain intensity	-0.56	-1.98**	-2.32**
Nominal p-values vs placebo: *<0.05, **<0.01			
GUS, guselkumab; q4W, every 4 week; q8W, every 8 week			

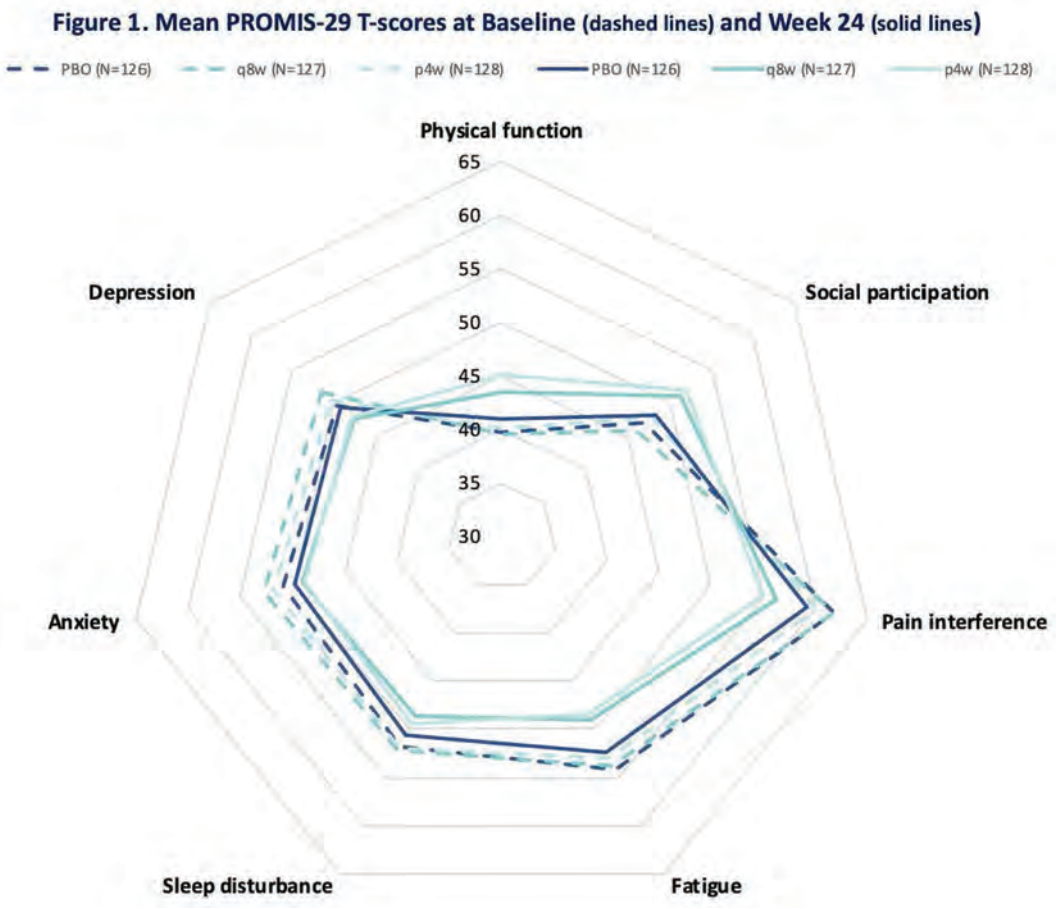

Figure 1. Mean PROMIS-29 T-Scores at Baseline (dashed lines) and Week 24 (solid lines)

Results: At baseline, mean PROMIS-29 T-scores for physical function, social participation, sleep disturbance, pain, and fatigue were worse than the general US population. At W24, GUS q8W-treated patients achieved greater improvements from baseline in all PROMIS-29 domains vs PBO ($p< 0.05$) (Table and Fig 1). Results were consistent

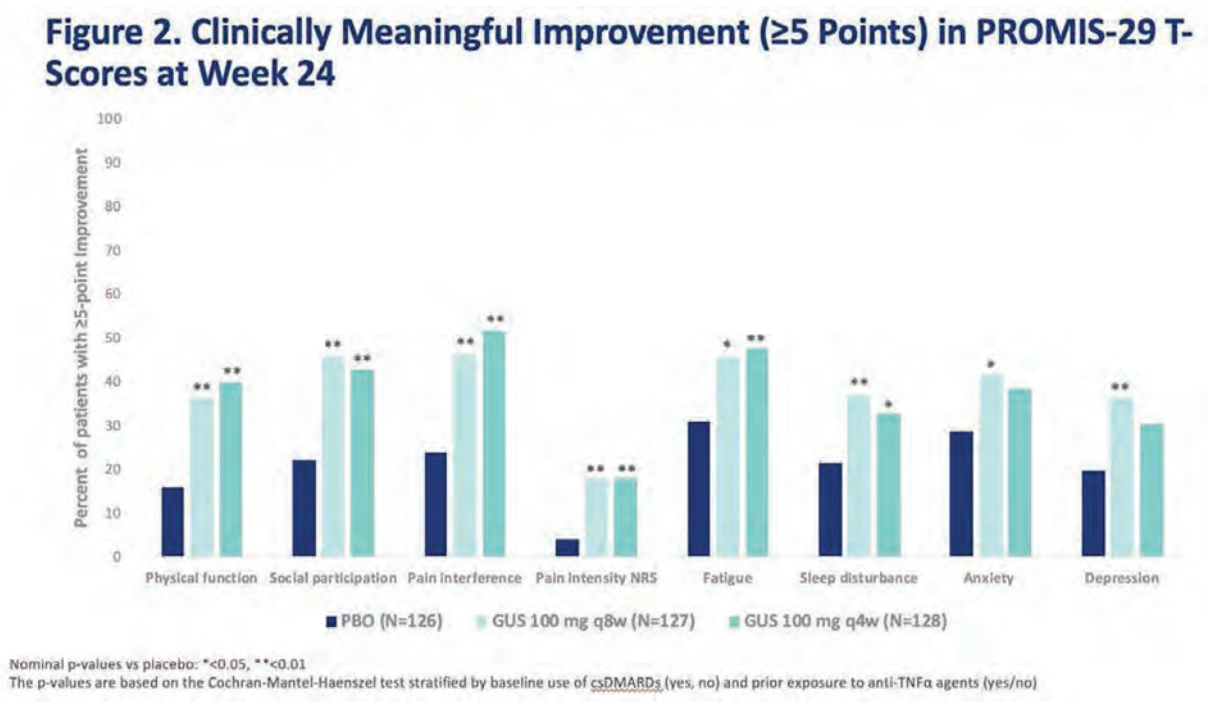

Figure 2. Clinically Meaningful Improvement (>=5-Points) in PROMIS-29 T-Scores at Week 24

in the GUS q4W group except for anxiety and sleep disturbance. More patients receiving GUS achieved clinically meaningful improvement vs PBO except for depression and anxiety in the GUS q4W group, which were numerically improved (Fig 2).

Conclusion: Active PsA patients treated with GUS achieved clinically meaningful reduction in symptoms and improvement in physical function and social participation vs PBO at W24

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Treatment Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: The purpose of this analysis was to assess the frequency of inadequate response (IR) over 1 year from biologic initiation among ankylosing spondylitis (AS) patients in the United States using a claims-based algorithm that was originally developed and validated for rheumatoid arthritis[1]. Baseline factors associated with IR to biologic were also analyzed.

Methods: This was a retrospective cohort study using claims data from the HealthCore Integrated Research Database (HIRD®). Adult patients with AS who initiated a biologic (TNFi: adalimumab, certolizumab, etanercept, golimumab, infliximab; IL-17: secukinumab) from 7/1/2016 to 8/31/2018 and had continuous enrollment ≥6 months before and ≥12 months after index date (date of first biologic claim) were included. The index biologic was defined as the first biologic prescribed during the study time period. Patients were identified as having IR to their index biologic if during the 12 months after index date they had one or more of the following: low adherence (defined as proportion of days covered (PDC)< 80%), switched/added new biologic, added a new conventional disease modifying anti-rheumatic drugs (cDMARDs) (methotrexate and/or sulfasalazine), increased dose/frequency of biologic, >1 glucocorticoid injection/infusion, addition or dose increase of oral glucocorticoids, used a new pain medication, or had a spinal procedure. Baseline patient characteristics were compared between responders and IRs using Chi-square tests for categorical variables and t-tests for continuous variables. A multivariable logistic regression model was constructed to identify baseline characteristics associated with IR to index biologic.

Results: A total of 646 AS patients were included in this analysis. Mean age was 43 years, 58% were male, 93% initiated a TNFi, and 7% initiated an IL-17 as their index biologic (Table 1). Over the 1-year follow-up period, 69% of AS patients had an IR to their biologic: 56% of patients had low adherence, 14% switched/added a new biologic, 8% added a new cDMARD, 4% had a dose/frequency increase of their index biologic, 8% had >1 glucocorticoid injection/infusion, 6% had an addition/dose increase of oral glucocorticoids, 12% used a new pain medication, and 2% had a spinal procedure (Table 2). Inadequate responders were more likely to be female (odds ratio (OR)=2.05; p< 0.001), have anxiety or depression (OR=1.91; p=0.014) and other mental health issues (OR=4.57; p< 0.001), and live in the South (OR=1.61; p=0.017); while patients with baseline use of methotrexate were more likely to be responders (OR=0.48; p=0.018) (Table 3). Prior exposure to TNFi was associated with a 3.89-fold greater odds of non-response (p=0.001).

Conclusion: Over 68% of AS patients had an inadequate response to their index biologic 1 year after initiation, mostly driven by low adherence. Health plan claims data appears useful to classify inadequate responders in AS and additional research should be done to further validate this claims-based algorithm in a clinical setting.

Table 1. Demographic and Baseline Characteristics of AS Patients at Biologic Index Date

	AS Patients N=646	Responders N=203	Inadequate Responders N=443	p-value

Tumor Necrosis Factor-α Receptor 2 Polymorphisms and Response to TNF Inhibitor Therapy in Patients with Psoriatic Arthritis

Sarah Rasheed[1], MacKenzie Dunlap[1], Jennifer Harvey[1], Connery Brennan[1], Yuxuan Jin[2], Unnikrishnan Chandrasekharan[3] and M. Elaine Husni[2], [1]Cleveland Clinic Foundation, Cleveland, [2]Cleveland Clinic, Cleveland, OH, [3]Cleveland Clinic Foundation, Cleveland, OH

SESSION INFORMATION
Session Date: Friday, November 6, 2020
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Treatment Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Tumor necrosis factor inhibitors (TNFi) have significantly improved the prognosis of patients with psoriatic arthritis (PsA); however, approximately 40% of patients do not achieve complete treatment response. There is an unmet clinical need to predict which psoriatic arthritis patients have an increased likelihood of responding to TNFi therapies. Recently published studies have demonstrated that the presence of a TNFR2 gene polymorphism (rs1061622) is linked to TNFi response in patients with immune-mediated diseases, including psoriasis. Presence of the TNFR2 gene with T/T genotype shows a significantly higher rate of response to TNFi compared to G/G genotype in these patients. However, the relationship between this specific TNFR2 gene polymorphism and TNFi response in PsA patients is not known. The aim of this study was to test the association of 3 genotypes (T/T genotype as compared to the T/G and G/G genotypes) with anti TNF response in a cohort of psoriatic arthritis patients.

Methods: Patients treated with TNFi were identified from the PsA longitudinal cohort. Genomic DNA isolated from the buffy coats of these patients were used to perform restriction fragment length polymorphism (RFLP) analysis to identify T/T, T/G or G/G genotypes. TNFi response was then evaluated through chart review by two board certified rheumatologists. Non-response was defined as change of TNFi treatment due to lack of achieving low disease activ-

	Odds Ratio (95% CI)	P-value
Genotype: T/T vs. T/G	6.4 (1.12, 36.44)	0.036
Genotype: G/G vs. T/G	0.8 (0.13, 5.09)	0.810
Genotype: T/T vs G/G	8 (0.91, 70.27)	0.061

ity in skin or joint symptoms. Response rate was studied retrospectively and groups were matched for age, gender and BMI.

Continuous variables were summarized using means and standard deviations. Categorical variables were summarized using counts and percentages. Univariable logistic regression with each genotypes as a single predictor was built to investigate the relationship between genotypes and non-response to TNFi. Results were represented using odds ratios and 95% confidence intervals. Data management and analysis were done in R software (Version 3.5; Vienna, Austria). All tests were two-sided, with an alpha level of 0.05.

Results: 42 patients were included (50.0% female, mean age 53.6 years, mean BMI 29.7) in the analyses. Our results demonstrated that 89% of patients with T/T genotype (n=18) were responders to TNFi, as compared to only 56% of patients with T/G genotype (n=18) and 50% of patients with G/G genotype (n=6) (Figure 1). The main finding in our study was that the odds of having a response in the T/T genotype is 6.4 times the odds of having a response in the T/G genotype (OR = 6.4 (1.12, 36.44), p = 0.036) (Table 1).

Conclusion: Our results suggest that PsA patients homozygous for T genotype (T/T), as compared to the T/G or G/G genotypes, show a stronger likelihood of response to TNFi. Identifying the association between these TNFR2 gene polymorphisms and TNFi response can potentially be a valuable guide in a more personalized approach to treatment options for PsA patients. Our study suggests the potential role of pharmacogenomics profiling in predicting treatment response.

SESSION INFORMATION
Session Date: Friday, November 6, 2020
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Treatment Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Recreational legalization of cannabis has influenced the medical use by patients. When only legal medical access was available in Canada, 4.3% of all rheumatology patients reported medical use, with this number increasing to 12.6% following recreational legalization. In this study we examine the prevalence of medical cannabis use and explore factors associated with medical use in patients with ankylosing spondylitis (AS).

Methods: During a two-month period (April-May 2019), consecutive patients attending an academic, community-based rheumatology clinic staffed by 3 rheumatologists participated in an onsite survey comprising 2 questionnaires: 1) demographic and disease information completed by the rheumatologist, 2) patient anonymous questionnaire of health status, cannabis use (recreational and/or medicinal) and characteristics of use.

Table 1. Demographic and ankylosing spondylitis disease related information (part 1)

Table 1. Demographic and ankylosing spondylitis disease related information

		All patients (n=72)	Never medical cannabis users (n=55)	Ever medical cannabis users (n=17)	p-value
Demographics	Age, years, mean (SD)	50.4 (14.4)	49.3 (14.7)	53.9 (13.1)	0.252
	Female gender, n (%)	42 (58.3)	33 (60.0%)	9 (52.9%)	0.779
	Employment				
	Full-time, n (%)	36 (50.0%)	28 (50.9%)	8 (47.1%)	0.750
	Part-time, n (%)	6 (8.3%)	5 (9.1%)	1 (5.9%)	
	Disabled, n (%)	15 (20.8%)	10 (18.2%)	5 (29.4%)	
	Student, n (%)	3 (4.2%)	3 (5.5%)	0 (0.0%)	
	Retired, n (%)	12 (6.7%)	9 (16.4%)	3 (17.6%)	
	Employment: unemployed/disabled, n (%)	15 (20.8%)	10 (18.2%)	5 (29.4%)	0.325
	Fibromyalgia, n (%)	13 (18.1%)	7 (12.7%)	6 (35.3%)	0.065
Comorbid conditions	Cardiovascular, n (%)	13 (18.1%)	9 (16.4%)	4 (23.5%)	0.490
	Pulmonary, n (%)	0 (0.0%)	0 (0.0%)	0 (0.0%)	N/A
	Gastrointestinal, n (%)	17 (23.6%)	12 (21.8%)	5 (29.4%)	0.527
	Neurological, n (%)	5 (6.9%)	2 (3.6%)	3 (17.6%)	*0.082*
	Endocrine, n (%)	9 (12.5%)	5 (9.1%)	4 (23.5%)	0.201
	Mood disorder, n (%)	15 (20.8%)	11 (20.0%)	4 (23.5%)	0.742
	Other psychiatric disorder, n (%)	1 (1.4%)	0 (0.0%)	1 (5.9%)	0.236
	Other comorbid condition, n (%)	2 (2.8%)	1 (1.8%)	1 (5.9%)	0.419
Medications for	Number of medication types for rheumatic disease, mean (SD)	1.5 (1.0)	1.2 (0.7)	2.4 (1.5)	**<0.001**
	Non-steroidal anti-inflammatory drug use, n (%)	31 (43.1%)	22 (40.0%)	9 (52.9%)	0.407

Results: In a cohort of 1000 rheumatology attendees (73% females; mean age 64 ± 14 yrs), medical cannabis (MC) had ever been used by 12.6% (95% CI: 10.7%-14.8%) with half continuing use. Inflammatory arthritis was diagnosed in 621 (62%), with 72 (7.2%) diagnosed with AS. Characteristics of AS patients are shown in Table 1. Of the 72 AS patients, 17 (24%) had used MC (95% CI: 14.4-35.1), with 9 (53%) continuing medical use. Past and current recreational cannabis use for all AS patients was 31 (43.1%) and 8 (11.1%) respectively, with no difference in ever recreational rates for medical users. AS users vs. AS non users did not differ for demographic or employment data; there was a trend for users to have more concomitant FM 35.3% vs 12.7% (p=0.065), used significantly more medication types 2.4 vs. 1.2 (p< 0.001), used more opioids 23.5% vs. 5.5% (p=0.049), had a poorer patient global assessment 5.3 vs. 3.6 (p=0.022) and had more pain 6.5 vs 4.4 (p=0.015). Inhalation was the most common method of medical cannabis use. Symptom relief was 5.1±2.1 on a 10 cm VAS.

Conclusion: AS patients had double the rate of medical cannabis use compared to other rheumatology patients. Poorly controlled pain may be the driver for an increased MC in AS, although the effect was perceived as modest.

SESSION INFORMATION
Session Date: Friday, November 6, 2020
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Treatment Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Psoriasis (PsO) is a chronic immune-mediated skin disease. Around 30% of patients diagnosed with PsO will develop psoriatic arthritis (PsA). Patients with PsA may develop irreversible joint damage, therefore optimized screening methods identifying the patients with PsO in risk of developing PsA have become a medical priority. In the interstitial matrix of bone and soft tissue, type I collagen is the most abundant collagen and secreted by fibroblasts. During extracellular matrix (ECM) remodeling, proteases cleave type I collagen resulting in the release of metabolites into the circulation. These collagen metabolites can be quantified in serum as biomarkers of tissue remodeling and give insight to pathological process at tissue level. In this study we investigated type I collagen turnover by measuring synthesis (PRO-C1) and degradation (C1M) biomarkers in a preclinical Scar-in-a-Jar (SiaJ) model and in serum from patients with PsO or PsA.

Methods: In the SiaJ model, primary human healthy dermal fibroblasts were grown for up to 17 days in DMEM medium containing 0.4% fetal calf serum, Ficoll (to produce a crowded environment) and ascorbic acid. Cells were treated with tumor necrosis factor β1 (TGF-β1) [1 nM] and a range of Tofacitinib concentrations [0-100 nM]. Media and treatments were changed twice a week and untreated cell were used as control. PRO-C1 was quantified in the tissue culture supernatant by ELISAs (Nordic Bioscience). Furthermore, patients with PsO (n=30, mean age 41.1) and patients with PsA (n=30, mean age 50.3) were recruited through St. Vincent's University Hospital, Ireland. Study was ethically approved by their local ethics committee. Clinical disease parameters were recorded. PRO-C1 and C1M were measured in serum by ELISAs (Nordic Bioscience). Statistical analysis included one-way ANOVA on data from SiaJ model and Mann Whitney test on clinical data from patients with PsO or PsA.

Results: In the dermal fibroblasts, TGF-β1 significantly increased PRO-C1 levels compared to w/o (p<0.001). Moreover, above a concentration of 12.5nM, Tofacitinib decreased TGF-β1 induced type I collagen formation in a dose-dependent manner. The highest treatment concentration of Tofacitinib (100 nM) significantly decreased PRO-C1 to the level of controls (p< 0.001). In the clinical study, PRO-C1 levels were not different between patients with PsO and PsA (p=0.123). However, levels of C1M were elevated in patients with PsA (p=0.029) compared to PsO. The tissue turnover of type I collagen in the interstitial network-system was analyzed (PRO-C1/C1M). Patients with PsO demonstrated increased formation of type I collagen (p=0.007) compared to PsA.

Conclusion: We demonstrated that Tofacitinib decreased collagen type I production in dermal fibroblasts. Moreover, the tissue turnover profile of type I collagen in PsO patients was significantly increased compared to PsA patients, with balance toward tissue formation. The increased type I collagen formation may be due to the dermal fibroblast

activity in PsO producing extensive amounts of PRO-C1. These results suggest that serological biomarkers may be used to separate PsO and PsA patients and potentially be used to identify the 30% of PsO patients that progress to PsA.

Efficacy of Disease Modifying Anti-Rheumatic Drugs for Enthesitis in a Prospective Longitudinal Psoriatic Arthritis Cohort

Ashish Mathew[1], Mitchell Sutton[2], Daniel Pereira[2], Vinod Chandran[3] and Dafna Gladman[3], [1]University Health Network, Vellore, Tamil Nadu, India, [2]Centre for Prognosis Studies in the Rheumatic Diseases, Krembil Research Institute, Toronto Western Hospital, University Health Network, Toronto, Canada, [3]Krembil Research Institute, Toronto Western Hospital, Toronto, ON, Canada

SESSION INFORMATION
Session Date: Friday, November 6, 2020
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Treatment Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Enthesitis is a common clinical feature of psoriatic arthritis (PsA). There is limited evidence on the effect of treatment on enthesitis. Our purpose was to study the effectiveness of conventional and targeted (c and t) DMARDs in treating clinical enthesitis in an observational PsA cohort.

Methods: Patients enrolled into a large PsA cohort from 1 January 2000 to 6 May 2020, with clinical enthesitis were included in this study. Enthesitis was defined as tenderness over at least 1 of the 29 sites described by validated enthesitis scoring indices, including spondyloarthritis research consortium of Canada (SPARCC) enthesitis index, Leeds enthesitis index (LEI), and Maastricht ankylosing spondylitis enthesitis score (MASES). Baseline medications, including non-steroidal anti-inflammatory drugs (NSAIDs) and/or c/t DMARDs at the diagnosis of enthesitis, were recorded for each patient. Complete resolution of enthesitis at 12 months was the primary outcome. The pharmacological treatment prescribed was divided into the following mutually exclusive ordinal categories: I- No treatment/NSAIDs; II- cDMARDs±NSAIDs, without tDMARD; III- tDMARDs±cDMARDs/NSAIDs. Univariable and multivariable logistic regression models were created to determine the association between medication category and complete resolution of enthesitis after controlling for age, sex, body mass index (BMI), PsA duration and baseline enthesitis score. A global p-value was calculated to evaluate the overall effect of medication categories on enthesitis resolution. The results are expressed as odds ratios (OR) with a 95% confidence interval (CI).

Results: Of the 1270 patients, 628 (49.4%) had enthesitis. After excluding 102 patients for inadequate follow-up data, 526 patients (51.7% males) with a mean age of 49.02 years (sd=13.12) years were included. The mean tender entheses count was 2.13 (sd=2.16). The mean duration of PsA at baseline was 10.74 years (sd=10.73), and the mean BMI was 29.13 (sd=6.25). The proportion of patients treated with each category of medications is presented in Table 1. Complete resolution of enthesitis was noted in 453 (86%) patients, within a mean of 8.9 months. The results of the regression analysis are shown in Table 2. The global p-value for medication categories was not significant in uni-

Table 1: Number of patients on each drug category

Individual medications in each category	Number (%) (N = 526)	Numbers on the individual drug (%)
Category I	**142 (27)**	
• No medication		52 (36.7)
• NSAIDs		90 (63.3)
Category II	**196 (37.3)**	
• Methotrexate		158 (80.6)*
• Leflunomide		29 (14.8)
• Sulphasalazine		32 (16.3)
• Azathioprine		10 (5.1)
• Cyclosporine		2 (1)
Category III	**188 (35.7)**	
• Tumor necrosis factor inhibitors (TNFi)		155 (82.4)
• Interleukin-17 inhibitors (IL-17i)		14 (7.4)
• Others (IL-12/23i, IL-23i, Tofacitinib, Apremilast)		19 (10.1)

* Percentage of individual drugs do not add to 100 since some patients were treated with a combination of cDMARDs

Table 2: Association between treatment and resolution of enthesitis

	Univariable models		Multivariable Model	
Variable	**OR (95% CI)**	**P value**	**OR (95% CI)**	**P value**
Sex (Male vs. Female)	1.61 (0.97 – 2.68)	0.07	1.61 (0.96 – 2.70)	0.07
Baseline age in years	1.00 (0.98 – 1.02)	0.85	1.00 (0.98 – 1.02)	0.90

Category II	1.40 (0.74 – 2.63)	0.30	1.37 (0.72 – 2.60)	0.34
Category III	1.24 (0.67 – 2.31)	0.50	1.27 (0.67 – 2.41)	0.47

*global p value

variate and multivariable models. The models showed a trend for males to achieve complete resolution of enthesitis regardless of the medication category (OR 1.71; 95% CI 0.96-2.70; p=0.07).

Conclusion: In an observational setting resolution of clinical enthesitis occurs regardless of the treatment used. Future effectiveness studies may require evaluating patients with severe enthesitis using advanced imaging.

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Treatment Poster I

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: Diet has been described as a factor influencing the course of rheumatic diseases, such as rheumatoid arthritis and systemic lupus erythematosus (SLE). In addition, it has been previously reported that dietary sugar intake may contribute to subclinical inflammation and disease activity in SLE. However, no studies have been performed to investigate the possible association of nutritional parameters on disease activity in patients with spondyloarthritis (SpA).

Methods: Patients with radiographic axSpA (ankylosing spondylitis fulfilling the modified New York criteria) and starting a bDMARD therapy were recruited between 2015 and 2019 in an extension of the prospective German Spondyloarthritis Inception Cohort (GESPIC). Dietary habits were collected at baseline using the country-specific validated food frequency questionnaire (FFQ) developed for the use in the German Health examination Survey for Adults 2008-2011. The FFQ includes questions about the frequency and amount of 53 food items, consumed during the past 4 weeks, and enabled to compute individual mean consumptions of foods in grams per day. Total energy intake (in Kcal per day) and nutritional parameters: carbohydrates, free sugars, total fats, saturated fats, mono and poly-unsaturated fats, proteins and dietary fiber, were calculated for each patient using Prodi® software (version 6.10, Basis, Nutri-Science, Stuttgart/Germany) and the database of Federal Food Code (Bundeslebensmittelschlüssel), version 3.02. Disease activity measures (BASDAI, CRP and ASDAS), as well as height, weight and body mass index (BMI) were assessed at baseline before bDMARD treatment.

Results: A total of 129 patients with axSpA were included in this cohort. FFQ with the consequent nutritional analysis was performed in 104 patients. There were 68.3% males, and 86.5% were HLA-B27 positive. At baseline, patients presented BMI of 25.1±4.3 kg/m^2, BASDAI 5.6±1.4, CRP 14.0±18.2 mg/l, and ASDAS 3.5±1.0.

In the univariable analysis, a higher energy intake and carbohydrates at baseline were associated with higher disease activity, measured by ASDAS, BASDAI and CRP (tables 1-3). This association was attributable to the full intake of carbohydrates and specifically to the total of free sugars (monosaccharides and disaccharides) and the decrease

Evaluation of Sex Differences in the Efficacy and Safety of Tofacitinib in Patients with Active Psoriatic Arthritis: A Post Hoc Analysis of Two Phase 3 Randomized Controlled Trials

Lihi Eder[1], Dafna Gladman[2], Sibel Zehra Aydin[3], Alexis Ogdie[4], Harry Shi[5], Pierre-Alexandre Landry[6] and Rayana Luna[6], [1]Women's College Research Institute, University of Toronto, Toronto, ON, Canada, [2]Krembil Research Institute, Toronto Western Hospital, Toronto, ON, Canada, [3]Ottawa Hospital Research Institute, University of Ottawa, Ottawa, Canada, [4]Division of Rheumatology, Department of Medicine, Perelman School of Medicine, University of Pennsylvania, Philadelphia, PA, [5]Pfizer Inc, Collegeville, PA, [6]Pfizer Canada ULC, Kirkland, Canada

SESSION INFORMATION
Session Date: Friday, November 6, 2020
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Treatment Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

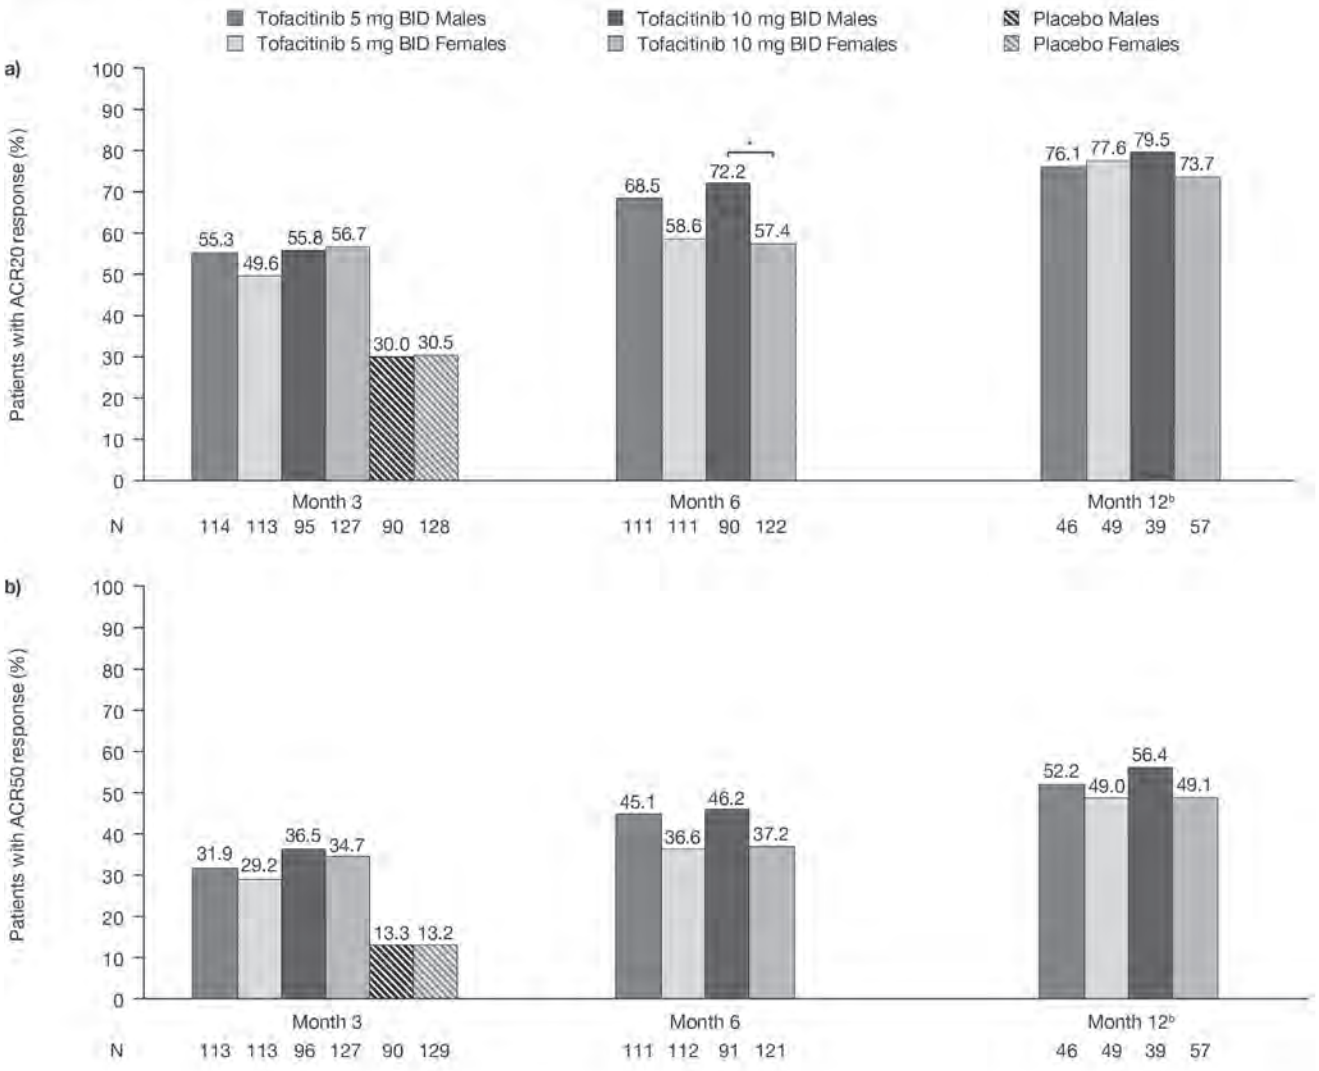
Background/Purpose: Studies indicate that sex (male vs female) is predictive of outcomes with PsA treatments, such as TNF inhibitors (TNFi).[1] Tofacitinib is an oral JAK inhibitor for the treatment of PsA. This post hoc analysis evaluated the impact of sex on tofacitinib efficacy and safety in PsA.

Methods: Data were pooled from two Phase 3, randomized, placebo-controlled studies of tofacitinib (OPAL Broaden [NCT01877668]; OPAL Beyond [NCT01882439]) in patients (pts) with active PsA and an inadequate response to ≥ 1 conventional synthetic DMARD (and were TNFi-naïve; OPAL Broaden) or ≥ 1 TNFi (OPAL Beyond). Analyses included pts randomized to tofacitinib 5 mg twice daily (BID), tofacitinib 10 mg BID, or placebo (switching to tofacitinib 5 or 10 mg BID at Month [M]3). Efficacy endpoints included ACR20/50 response rates; change from baseline (Δ) in Leeds Enthesitis Index (LEI), ΔDactylitis Severity Score (DSS), and ΔFunctional Assessment of Chronic Illness Therapy-Fatigue (FACIT-F); and proportion of pts achieving a minimal clinically important difference (MCID) for HAQ-Disability Index (HAQ-DI) (≥ 0.35). Safety outcomes were assessed up to M6. Demographic and baseline disease characteristics were tested using one-way analysis of variance for continuous parameters and chi-squared test for categorical parameters. Analyses are based on observed cases and presented without p-value multiplicity adjustment.

Results: Overall, 710 pts (317/393, male/female) were included (tofacitinib 5 mg BID, 117/121; tofacitinib 10 mg BID, 100/136; placebo, 100/136, respectively). Baseline characteristics were broadly similar between sexes; exceptions included higher Composite Psoriatic Disease Activity Index in females (tofacitinib 5 mg), higher FACIT-F total score (less fatigue) in males, higher HAQ-DI in females (tofacitinib 5 mg BID and placebo), and higher DSS in males (placebo). ACR20/50 response rates were similar between sexes at M3. At M6, ACR20 response rates were numerically higher for males (Figure a), with a significant difference seen for tofacitinib 10 mg BID (72.2% males vs 57.4% females; p=0.0163); no significant differences in ACR50 response rates were observed (Figure b). ACR20/50 response rates were similar between sexes by M12 (OPAL Broaden). In general, no significant differences between sexes were shown in ΔLEI, ΔDSS, ΔFACIT-F, or HAQ-DI MCID at M3, 6, and 12 in all groups. Up to M6, numerically more females vs males had adverse events (AEs), serious AEs, severe AEs, discontinuations due to AEs, gastrointestinal, nervous, respiratory, thoracic and mediastinal system disorders (system organ class) with tofacitinib 5 and 10 mg BID (Table). Rates of vascular disorders were numerically higher in males.

Conclusion: In general, no clinically meaningful differences between sexes were observed in the efficacy of tofacitinib 5 and 10 mg BID up to M12. Some numerical differences in safety outcomes with tofacitinib were seen between sexes. Results further characterize the efficacy and safety of tofacitinib in pts with PsA.

Figure. a) ACR20 and b) ACR50 response rates, by sex (FAS; no imputation[a])



*p<0.05 male vs female
[a]Analyses were based on observed cases. Results of the analyses with NRI are not presented as they were similar to results without imputation; [b]OPAL Broaden only
The FAS included all patients who received ≥1 dose of study medication and had ≥1 post-baseline assessment; differences in the proportion of responders between males and females, and associated p values were estimated using the Cochran-Mantel-Haenszel approach, adjusted for study
ACR20/50, American College of Rheumatology ≥20/50% response criteria; BID, twice daily; FAS, full analysis set; N, number of patients with non-missing data; NRI, non-responder imputation

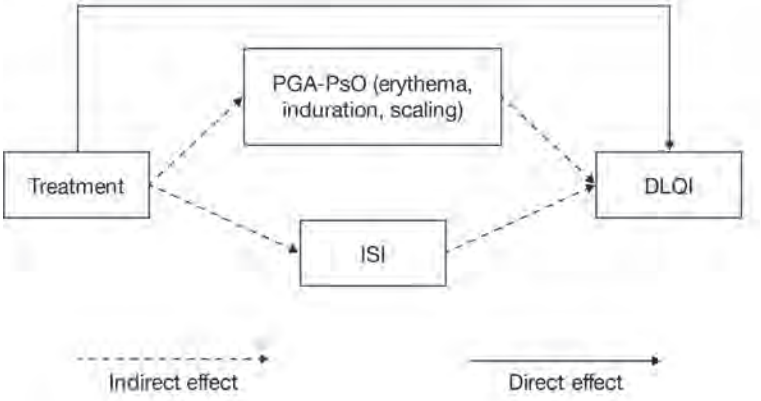
Itch as the Major Mediator of the Effect of Tofacitinib on Health-Related Quality of Life in Psoriatic Arthritis: A Mediation Analysis

Joseph Merola[1], Peter Taylor[2], Andrew Bushmakin[3], Joseph Cappelleri[3], Pamela Young[4], Rebecca Germino[5] and Gil Yosipovitch[6], [1]Brigham and Women's Hospital, Harvard Medical School, Boston, MA, [2]Botnar Research Centre, Nuffield Department of Orthopaedics, Rheumatology and Musculoskeletal Sciences, University of Oxford, Oxford, United Kingdom, [3]Pfizer Inc, Groton, CT, [4]Pfizer Inc, Collegeville, PA, [5]Pfizer Inc, New York, NY, [6]University of Miami, Miami, FL

SESSION INFORMATION
Session Date: Friday, November 6, 2020
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Treatment Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

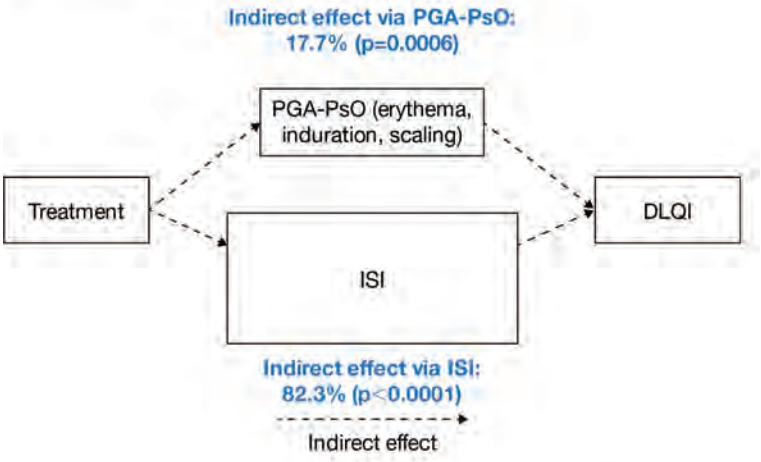
Background/Purpose: Psoriatic arthritis (PsA) is a chronic, systemic inflammatory disease with signs and symptoms across multiple domains, including cutaneous manifestations, which can impact health-related quality of life (HRQoL). Tofacitinib is an oral Janus kinase inhibitor for the treatment of PsA. In two Phase 3 randomized studies, patients (pts) with active PsA treated with tofacitinib experienced greater improvements in various dermatologic endpoints, compared with placebo. As pruritus is a bothersome symptom of skin disease in pts with PsA, we sought to determine how tofacitinib treatment affects pt-reported HRQoL via clinical improvements in dermatologic symptoms including itch.

Figure 1. Initial mediation model



Treatment is represented by a binary variable (tofacitinib 5 mg BID vs placebo).
DLQI, Dermatology Life Quality Index; ISI, Itch Severity Index;
PGA-PsO, Physician Global Assessment of Psoriasis

Figure 2. Revised mediation model



Treatment is represented by a binary variable (tofacitinib 5 mg BID vs placebo).
DLQI, Dermatology Life Quality Index; ISI, Itch Severity Index;
PGA-PsO, Physician Global Assessment of Psoriasis

Methods: Analyses used data (mean scores from Months 1 and 3) from two Phase 3 studies (OPAL Broaden [NCT01877668]; OPAL Beyond [NCT01882439]) of pts with active PsA treated with tofacitinib 5 mg twice daily or placebo; pts were tumor necrosis factor inhibitor (TNFi)-naïve or had previous inadequate response to ≥1 TNFi. All pts were treated continuously with a single conventional synthetic DMARD. Mediation modeling, a statistical method used to assess mechanisms underlying observed relationships between different variables via other explanatory variables (mediators), was applied. The mediation model included: treatment, as the independent (explanatory) binary variable (tofacitinib 5 mg BID vs placebo); HRQoL, measured by Dermatology Life Quality Index (DLQI), as the dependent (outcome) variable; and two mediators, pt-reported Itch Severity Index (ISI) and Physician's Global Assessment of Psoriasis (PGA-PsO) (a latent variable represented by erythema, induration, and scaling). The initial model designated the treatment effect on DLQI mediated via ISI and PGA-PsO as an indirect effect, and treatment effects not attributable to ISI or PGA-PsO as a direct effect (Figure 1).

Results: Data were collected from 468 pts, pooled from both studies. In the initial model (pooled data), the effect of tofacitinib treatment on DLQI was largely mediated by itch (measured by ISI) and PGA-PsO (indirect effect) ($p< 0.0001$); the effect of treatment attributable to factors other than ISI and PGA-PsO (direct effect) was not statistically significant ($p=0.66$). Results were consistent for pooled and individual study data. Because the direct effect was small and not statistically significant, the model was re-specified to exclude the direct effect of tofacitinib treatment on DLQI. In the revised model (pooled data), 17.7% of the indirect effect of treatment on DLQI was attributable to PGA-PsO ($p=0.0006$) and 82.3% was attributable to itch ($p< 0.0001$) (Figure 2). Analyses of individual studies using the revised model gave results generally consistent with pooled data.

Conclusion: Dermatology-focused mediation modeling showed that the majority of the effect (~80%) of tofacitinib treatment on DLQI is mediated by improvements in itch, with ~20% mediated via improvements in PGA-PsO.

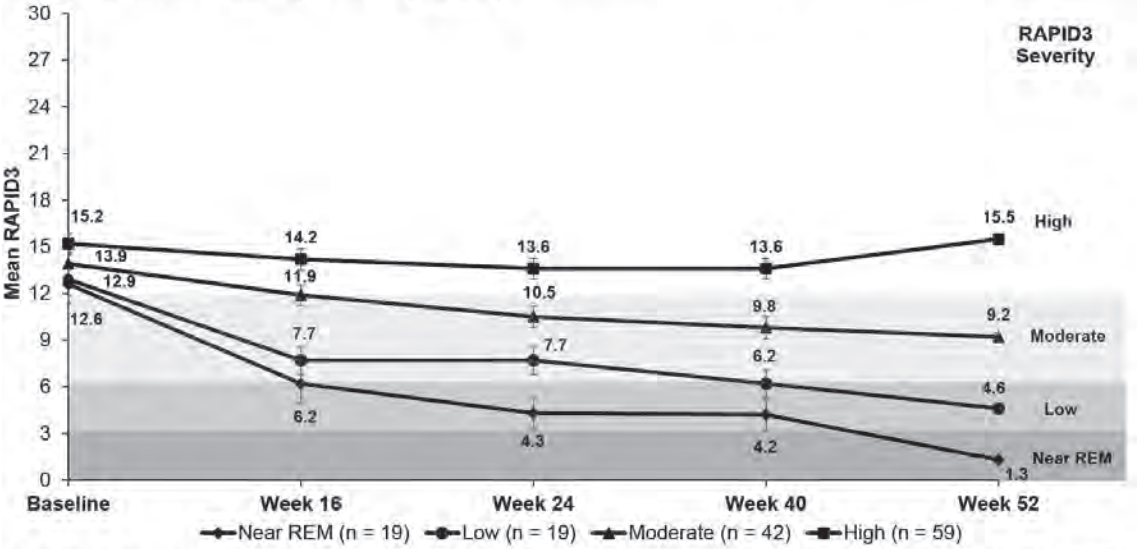
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Treatment Poster I

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

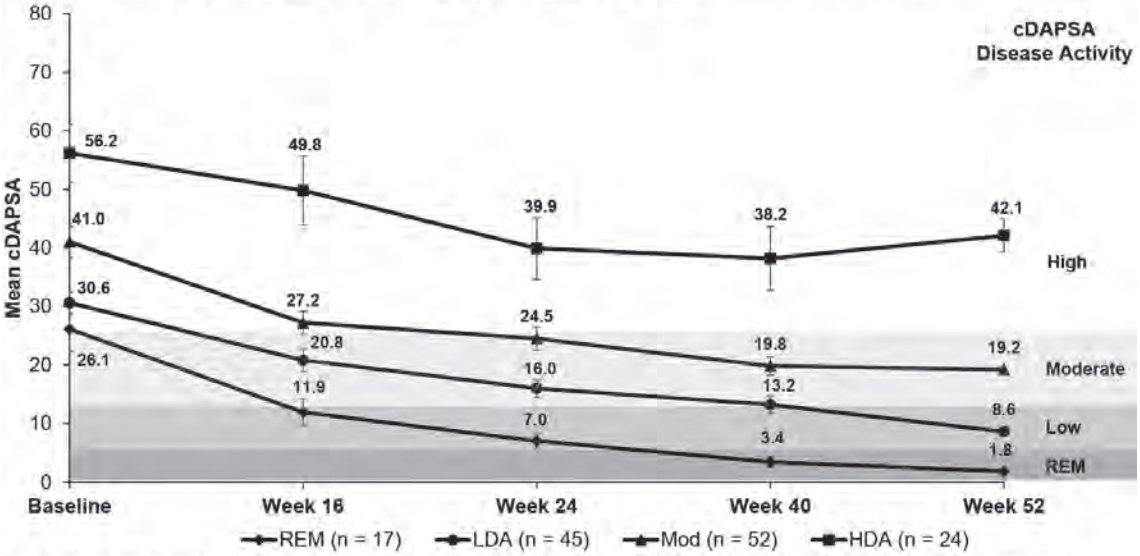
Background/Purpose: Phase III PALACE 4 (NCT01307423) assessed the efficacy of apremilast (APR) in DMARD-naive patients with PsA. The Routine Assessment of Patient Index Data 3 (RAPID3 [0-30]) evaluates disease activity derived from patients' self-reported measures, including HAQ-DI or multidimensional HAQ, Pain visual analog scale

Figure 1. RAPID3 Scores (0–30) Through Week 52 by RAPID3 Category at Week 52 in cDMARD-Naive Patients Randomized to Apremilast (N = 139)



Includes patients randomized at baseline who had RAPID3 components available at Week 52; data are as observed. RAPID3 near REM: ≤3; low severity: >3 to ≤6; moderate severity: >6 to ≤12; and high severity: >12 to ≤30. Error bars represent standard error of the mean.

Figure 2. cDAPSA Scores (0–154) Through Week 52 by cDAPSA Category at Week 52 in cDMARD-Naive Patients Randomized to Apremilast (N = 138)



Includes patients randomized at baseline who had cDAPSA components available at Week 52; data are as observed. REM: cDAPSA ≤4; low: cDAPSA >4 to ≤13; moderate: cDAPSA >13 to ≤27; high: cDAPSA >27. Error bars represent standard error of the mean.

Articular and Extra-articular Disease Activity in Patients Achieving RAPID3 and cDAPSA Treatment Targets at Week 52

*Includes patients randomized at baseline who had RAPID3 components available at Week 52. RAPID3 near REM: ≤3; RAPID3 low severity: >3 to ≤6. †Includes patients randomized at baseline who had cDAPSA components available at Week 52. REM: cDAPSA ≤4; low: cDAPSA >4 to ≤13. ‡Patients with baseline psoriasis body surface area involvement ≥3%. §Patients with pre-existing enthesitis at baseline. ¶Patients with pre-existing dactylitis at baseline. MASES = Maastricht Ankylosing Spondylitis Enthesitis Score; PAP = Patient's Assessment of Pain; PASI = Psoriasis Area and Severity Index; PhGA = Physician's Global Assessment of Disease Activity.

(VAS), and Patient's Assessment of Disease Activity (PtGA) VAS. The Clinical Disease Activity Index for Psoriatic Arthritis (cDAPSA [0-154]) includes objective and subjective physician assessments (ie, swollen and tender joints counts [SJC and TJC]) and the Patient's Assessment of Pain and PtGA VAS scores. Among patients receiving APR in the DMARD-naive PALACE 4 trial, we examined trajectories for improving RAPID3 scores for those achieving RAPID3 near remission (REM) or low severity, cDAPSA scores among those achieving cDAPSA REM or low disease activity (LDA), and PsA manifestations not measured by either outcome by Wk 52.

Methods: DMARD-naive patients in PALACE 4 who were randomized to receive APR 30 mg BID at baseline with available scores on RAPID3 and/or cDAPSA components at Wk 52 were included and grouped according to RAPID3 categories at Wk 52 using RA cutoffs (near REM: ≤3; low severity: >3-≤6; moderate severity: >6-≤12; and high severity: >12-30) and cDAPSA categories at Wk 52 (REM: ≤4; LDA: >4-≤13; moderate disease activity: >13-≤27; high disease activity: >27). Mean RAPID3 and cDAPSA scores were assessed from baseline through Wk 52. Other measures of PsA disease activity were reported longitudinally by RAPID3 and cDAPSA categories at Wk 52.

Results: The RAPID3 analysis included 139 APR patients; the cDAPSA analysis included 138 APR patients. Achievement of near REM or low severity (RAPID3) or REM or LDA (cDAPSA) by Wk 52 with APR were associated with improvements over time in mean RAPID3 (Figure 1) and cDAPSA (Figure 2) trajectories, with observable improvement at Wk 16. Patients achieving RAPID3 or cDAPSA treatment targets at Wk 52 had mild or resolved articular involvement at Wk 52. Achievement of treatment targets was also associated with improvements in extra-articular disease activity at Wk 52, although not all manifestations were as well controlled in patients achieving RAPID3 treatment targets (Table). In the RAPID3 and cDAPSA analyses, improvements in SJC and TJC were observed for patients with REM or low severity (RAPID3) or REM or LDA (cDAPSA) at Wk 52. In the RAPID3 analysis, mean TJC was higher than expected at Wk 52 in patients achieving low severity. The Psoriasis Area and Severity Index score was the only measure for which a pattern of greater improvement for the near RAPID3 REM/cDAPSA REM group vs the RAPID3 low severity/cDAPSA LDA group was not observed; it was numerically lower in cDAPSA REM vs LDA and numerically higher in RAPID3 REM vs low severity.

Conclusion: DMARD-naive patients achieving RAPID3 and cDAPSA targets with APR showed early and sustained improvements to Wk 52 with continued treatment. Achievement of treatment targets was associated with improvements in other domains not captured directly by RAPID3 or cDAPSA (eg, dactylitis, enthesitis). As shown in a prior analysis, RAPID3 LDA was associated with higher residual TJC than what would be expected from this categorization.

Efficacy and Safety of Ixekizumab in Patients with Psoriatic Arthritis and Inadequate Response to TNF Inhibitors: 3 Year Results from a Phase 3 Study

Jordi Gratacós[1], Anthony Turkiewicz[2], Eva Dokoupilova[3], Amanda Gellett[4], Aubrey Sprabery[4], Vladimir Geneus[5] and **Arnaud Constantin**[6], [1]University Hospital Parc Tauli Sabadell, Barcelona, Spain, [2]Rheumatology Associates PC, Birmingham, AL, [3]MEDICAL PLUS s.r.o., Uherske Hradiste; University of Veterinary and Pharmaceutical Sciences, Faculty of Pharmacy, Department of Pharmaceutics, Brno, Czech Republic, [4]Eli Lilly and Company, Indianapolis, IN, [5]Eli Lilly and Company, Indianapolis, [6]Hospital Pierre Paul Riquet, Toulouse, France

SESSION INFORMATION

Session Date: Friday, November 6, 2020

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Treatment Poster I

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: Ixekizumab (IXE) is a high affinity monoclonal antibody that selectively targets interleukin-17A. In the SPIRIT-P2 study, IXE every 4 (Q4W) or 2 (Q2W) weeks was superior to placebo (PBO) in improving the signs and symptoms of psoriatic arthritis (PsA) at Week 24 in patients (pts) with prior inadequate response or intolerance to 1 or 2 tumor necrosis factor inhibitors (TNFi). The objective of this study was to determine efficacy and safety of IXE treatment up to 3 years in pts with PsA.

Methods: In SPIRIT-P2 (NCT02349295), 310 pts entered the extension period where pts maintained their original ixekizumab dose, and placebo pts received IXEQ4W or IXEQ2W (1:1). Pts failing to demonstrate ≥20% improvement in both tender and swollen joint counts at Week 32, or any subsequent visit, were discontinued (mandatory discontinuation criteria). Efficacy outcomes were ACR20/50/70 response, Psoriasis Area and Severity Index (PASI) 75/90/100 response, Leeds Enthesitis Index (LEI), Leeds Dactylitis Index-Basic (LDI-B), minimal disease activity (MDA), and Disease Activity in Psoriatic Arthritis (DAPSA). Ad-hoc efficacy data are presented for intent-to-treat (ITT) pts initially randomized to IXE at Week 0. Observed and modified non-responder imputation (mNRI; missing data treated as non-response for pts discontinued due to lack of efficacy or adverse events [AEs]) was applied to categorical

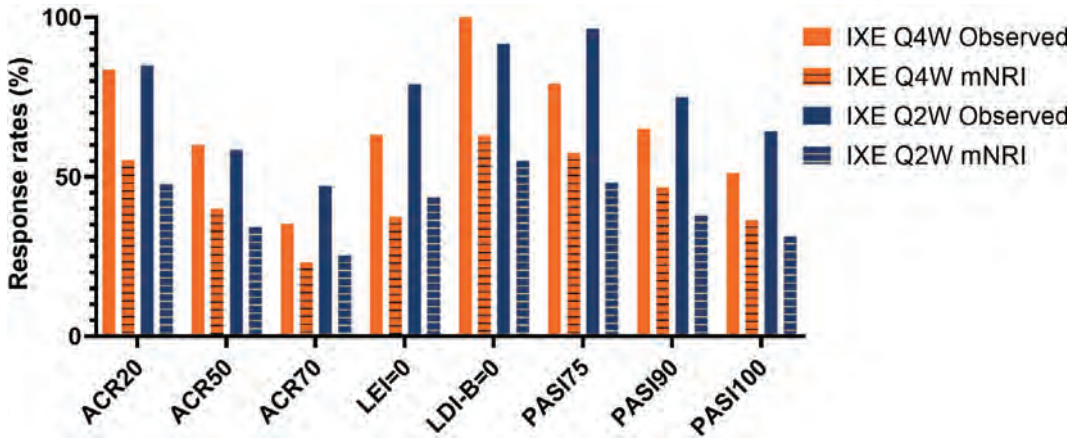

Figure 1. Efficacy Outcome Measures at Week 156 (Intent-to-treat Population). ACR=American College of Rheumatology; IXE=ixekizumab; LEI=Leeds Enthesitis Index; LDI-B=Leeds Dactylitis Index-Basic; mNRI=modified non-responder imputation; PASI=Psoriasis Area and Severity Index; Q2W=every two weeks; Q4W=every four weeks.

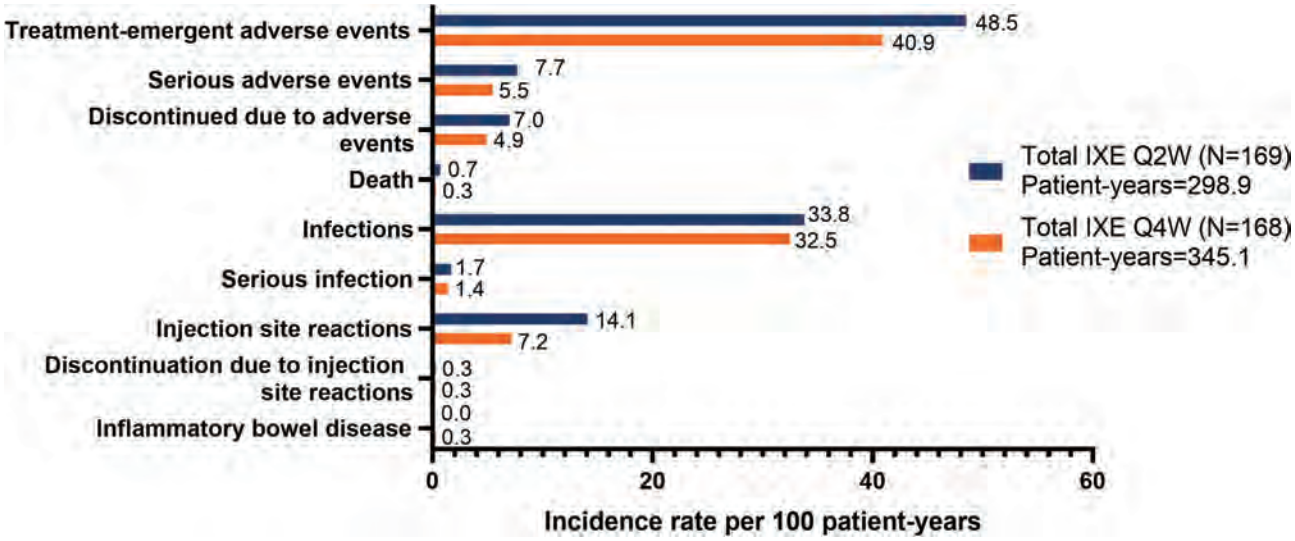

Figure 2. Safety Outcome Measures (Weeks 0-156). Safety was analyzed in patients exposed to at least one dose of ixekizumab. During the double-blind treatment period (Weeks 0-24), one patient reported serious adverse events of anal fistula and anal abscess, which were considered by the sponsor to be inflammatory bowel disease (IBD); however, an independent adjudication committee of external experts reviewed the case and determined the events to be "Not IBD." IXE=ixekizumab; Q2W=every two weeks; Q4W=every four weeks.

measures. Observed and modified baseline observation carried forward (mBOCF) was applied to continuous efficacy measures. Safety was analysed in pts exposed to at least one dose of IXE.

Results: Of the 245 pts initially randomized to IXE at Week 0 (ITT), 64 (26.1%) pts discontinued due to lack of efficacy and 22 (9.0%) pts due to mandatory discontinuation criteria. Efficacy results are summarized below (Figure 1). Pts in SPIRIT-P2 who received IXEQ4W and IXEQ2W for 156 weeks reported sustained improvement in ACR responses and manifestations of PsA, including enthesitis, dactylitis, and skin outcomes. Treat-to-target measures such as MDA and DAPSA (Low Disease Activity or Remission) were achieved by 30.8% and 47.7% of pts, respectively on IXEQ4W, and by 29.2% and 40.7% of pts, respectively on IXEQ2W. Incidence rates (IR) of treatment-emergent adverse events (TEAEs) are provided below (Figure 2). Most TEAEs were mild or moderate in severity, and 38 out of 337 (5.9%) pts (safety population) discontinued due to AEs. The most common TEAEs were infections (IR=33.1) and injection site reactions (IR=5.4). Three deaths were reported in the study.

Conclusion: In pts treated with IXE who had prior inadequate response or intolerance to 1 or 2 TNFi, improvements in the signs and symptoms of PsA persisted up to 3 years. No unexpected safety signals were observed, and the safety profile was consistent with previous studies of IXE.

Efficacy of Tofacitinib on Dactylitis in Individual Digits in Patients with Active Psoriatic Arthritis

Ana-Maria Orbai[1], Philip Mease[2], Philip Helliwell[3], Oliver FitzGerald[4], Mohamed Bedaiwi[5], Dona Fleishaker[6], Rajiv Mundayat[6] and Pamela Young[7], [1]Division of Rheumatology, Johns Hopkins University School of Medicine, Baltimore, MD, [2]Seattle Rheumatology Associates, P.L.L.C., Seattle, WA, [3]Leeds Institute of Rheumatic and Musculoskeletal Medicine, University of Leeds, Leeds, United Kingdom, [4]Conway Institute for Biomolecular Research, University College Dublin, Dublin, Ireland, [5]Division of Rheumatology, College of Medicine, King Saud University Medical City, King Saud University, Riyadh, Saudi Arabia, [6]Pfizer Inc, Groton, CT, [7]Pfizer Inc, Collegeville, PA

SESSION INFORMATION

Session Date: Friday, November 6, 2020

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Treatment Poster I

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: Dactylitis, a hallmark of psoriatic arthritis (PsA), is a uniformly diffuse and sometimes painful swelling of the fingers and/or toes.[1] Up to 50% of patients (pts) with PsA may experience dactylitis;[1,2] as such, dactylitis is an accepted domain of PsA that should be considered in treatment decisions.[3] In PsA, dactylitis typically involves feet more than hands; dactylitic joints more frequently have erosive damage, compared with non-dactylitic joints.[2] There remains a need for effective therapies to treat dactylitis in pts with PsA. Improvements in dactylitis have been associated with tofacitinib, an oral Janus kinase inhibitor for the treatment of PsA.[4,5] Here, we assessed the effect of tofacitinib on dactylitis by location (hands/feet) and individual digit involvement in pts with PsA.

Methods: These post hoc analyses used data pooled from two Phase 3 studies (12-month OPAL Broaden [NCT01877668];[5] 6-month OPAL Beyond [NCT01882439][4]) in pts with active PsA treated with tofacitinib 5 mg twice daily (BID; approved dose; to Month [M]6), tofacitinib 10 mg BID (to M6), or placebo (PBO; to M3); pts were treated continuously with a single conventional synthetic DMARD. Pts were categorized by the presence of dactylitis at baseline (BL) in the hands and/or feet. Endpoints included change from BL (CFB) in Dactylitis Severity Score (DSS),[6] the number of dactylitic digits, and the proportion of pts with dactylitis in individual digits at M1, M3, and M6. Descriptive statistics were generated by visit and treatment arm.

Results: Data were pooled from 373 pts with DSS > 0 at BL. BL characteristics were similar across dactylitis groups, except pts with dactylitis in both hands and feet had higher DSS at BL, compared to those with dactylitis in hands only or feet only, likely due to having more dactylitic digits (Table). Regardless of location, pts treated with tofacitinib

had cumulative improvements from BL to M6 in DSS (Figure 1a) and in the number of dactylitic digits (Figure 1b); improvements were greater at M1 and M3, compared with PBO. Pts treated with tofacitinib 10 mg BID typically had numerically greater improvements in DSS, compared with pts treated with tofacitinib 5 mg BID (Figure 1a). Most pts treated with tofacitinib experienced improvement of dactylitis across all fingers and toes (Figure 2); mean dactylitis presence was ≤ 15% at M6 in pts treated with tofacitinib for all digits. Generally, at M1 and M3, fewer pts treated with tofacitinib had dactylitis in any digit, compared with PBO (Figure 2).

Conclusion: Among pts with pre-existing dactylitis, treatment with tofacitinib resulted in improvements in dactylitis in hands, feet, or both, and in all digits as early as M1, and up to M6.

Table. Baseline demographics and disease characteristics in patients with DSS >0, treated with tofacitinib 5 mg BID (green), tofactinib 10 mg BID (blue), and placebo (purple), stratified by BL location of dactylitis (pooled from OPAL Broaden and OPAL Beyond).

Multiparous	3 (17.5)	46 (27.1)	

Table 2. Conditional logistic regression analysis comparing SSc cases with controls matched on maternal age and year of delivery.

Table 2. Conditional logistic regression analysis comparing SSc cases with controls matched on maternal age and year of delivery.

Variable	Cases (N=17), %	Controls (N=170), %	OR (95% CI)
Hypertensive disorder of pregnancy	13 (17.7)	16 (9.4)	2.1 (0.5-8.4)
Premature rupture of membranes	2 (11.8)	7 (4.1)	3.6 (0.6-22.9)
Intrauterine growth restriction	1 (5.9)	3 (1.8)	3.3 (0.4-32.0)
Maternal infection	5 (29.4)	24 (14.2)	2.5 (0.8-7.6)
Neonatal intensive care unit admission	4 (23.5)	13 (7.7)	4.7 (1.2-18.8)
Preterm birth<37 weeks	2 (11.8)	17 (10.0)	1.2 (0.3-5.8)
Mode of delivery: assisted vaginal delivery or C-section*	9 (52.9)	59 (34.7)	2.3 (0.8-6.4)

*Compared to normal spontaneous vaginal deliveries.

Background/Purpose: Vasculopathy and immune dysfunction likely precede the diagnosis of systemic sclerosis (SSc) by years as evidenced by longstanding Raynaud's phenomenon prior to diagnosis. Poor obstetric outcomes may also reflect underlying vascular and immune system abnormalities in patients who later develop SSc. We investigated whether obstetric complications prior to SSc diagnosis are more common compared to the general obstetric population.

Methods: A retrospective case-control study was conducted among Kaiser Permanente Northern California (KPNC) pregnant women with subsequent SSc diagnosis (2013 ACR-EULAR classification criteria confirmed by chart review) from 2007-2016. Controls from the general obstetric population were matched 10:1 by maternal age and year of delivery. Exposures of interest included hypertensive disorders of pregnancy (including pre-eclampsia, eclampsia, and gestational hypertension), premature rupture of membranes (PROM), intrauterine growth restriction (IUGR), maternal infections, neonatal intensive care unit (NICU) admission, and preterm birth. Fischer's exact tests were used to compare categorical variables. Conditional logistic regression models estimated the odds ratio (OR) and corresponding 95% confidence intervals for the outcome SSc.

Results: Median maternal age at delivery was 34 years (range 23-46 years) for 17 SSc cases and 170 matched controls (Table 1). Median time from delivery to SSc diagnosis was 2 years (range 0.2-7.3 years), with 13/17 developing limited cutaneous disease. Compared to controls, SSc cases were more likely to be Hispanic and Black. Obstetric complications were non-significantly higher in women with an eventual SSc diagnosis compared to controls, including hypertensive disorders (17.7% vs. 9.4%), PROM (11.8% vs. 4.1%), IUGR (5.9% vs 1.8%), maternal infection (29.4% vs. 14.1%), NICU admissions (23.5% vs. 7.7%), and preterm birth (29.4% vs. 21.8%). Women with a subsequent diagnosis of SSc were found to have twice the odds of having hypertensive disorders of pregnancy compared with controls, but the results were not statistically significant). Cases had a significantly higher odds of delivering infants requiring NICU admission (Table 2).

Conclusion: Women who eventually develop SSc appeared to have more pregnancy complications, particularly NICU admissions, before overt diagnosis. Larger studies are needed to validate these findings.

SESSION INFORMATION

Session Date: Friday, November 6, 2020

Session Title: Systemic Sclerosis & Related Disorders – Clinical Poster I

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: Although systemic sclerosis (SSc) disproportionately affects females compared with males [1], observational studies have demonstrated higher mortality rates in males with SSc [2]. This may be due to a higher prevalence of interstitial lung disease (ILD) in males [2], or external factors, such as delayed SSc diagnosis in males. The objective of this study was to compare short- and long-term outcomes of male and female participants of two RCTs for SSc: Scleroderma Lung Studies (SLS) I [3] and II [4].

Methods: SLS I randomized 158 SSc participants (47 Males) with ILD to 1 year of oral cyclophosphamide (CYC) versus placebo, followed by 1 year off treatment. SLS II randomized 142 SSc-ILD participants (37 Males) to 1 year of oral CYC, followed by 1 year of placebo, versus 2 years of mycophenolate (MMF). Both studies measured the FVC every 3 months during the study and performed HRCT scans at baseline and 12 (SLS I) and 24 (SLS II) months. Up to 12 (SLS I) and 8 (SLS II) years after randomization, we assessed morbidity and mortality outcomes. Joint models evaluated progression of ILD based on the course of the FVC and linear regression models evaluated radiographic changes in ILD. We compared survival using a log-rank test and used Cox proportional hazard modeling to determine the variables associated with survival.

Results: Baseline demographic and disease characteristics were similar for males and females of SLS I and II, with the exception of a higher prevalence of Caucasians in SLS I males (79% versus 58%, respectively). Additionally, males demonstrated more restrictive physiology in SLS I (lower FVC, TLC, DLCO) and II (lower DLCO) compared

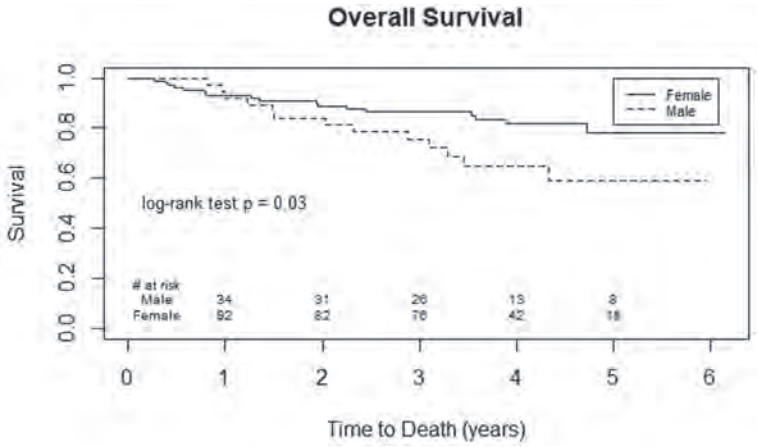

Figure 1. Time to death in males (dotted line) versus females (solid line) in SLS I.

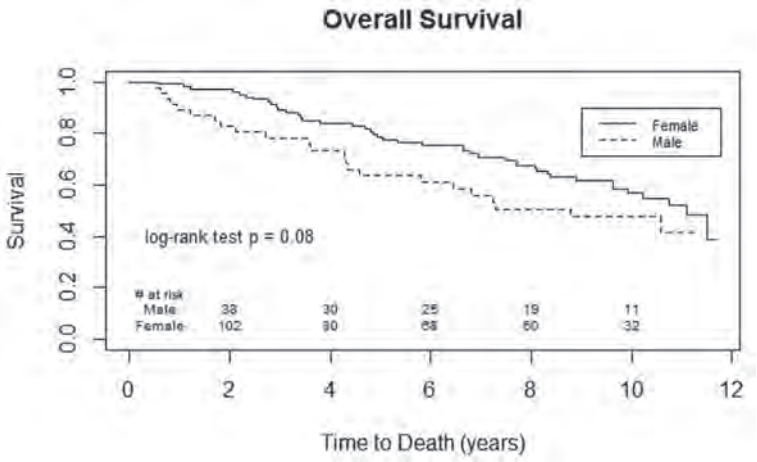

Figure 2. Time to death in males (dotted line) versus females (solid line) in SLS II.

with females. In the placebo arm of SLS I, there was a trend for increased worsening of the FVC in males compared with females from 3 to 12 months (P=0.14). In the CYC arm of SLS I, there was no difference in the course of the FVC from 3 to 12 months (P=0.84). In the CYC arm of SLS II, males experienced a decline in the FVC from 3 to 12 months, whereas females experienced an improvement (P=0.0006). In the MMF arm of SLS II, males experienced less of an improvement in the FVC from 3 to 12 months compared with females (P=0.005). In SLS II (but not SLS I), males had increased radiographic progression of ILD based on quantitative imaging analysis, even after adjusting for treatment arm. Long-term survival was worse in males compared with females in both SLS I and II (Log Rank Test: P=0.08, P=0.03, respectively). After adjustment for baseline disease severity (FVC, skin score) and age, male sex was independently associated with increased mortality compared with females in SLS II (HR 2.42; P=0.01), but not SLS I (HR 1.14; P=0.63).

Conclusion: Data from two large RCTs in SSc-ILD demonstrated that males with SSc-ILD had evidence of increased ILD severity at baseline. Males also appeared to have increased progression of ILD both with and without treatment, as well as worse long-term survival. These findings are consistent with prior observational studies, and future studies are needed to understand the genetic and hormonal underpinnings for these important sex differences.

Serum Neutrophil Count Predicts Progression of Interstitial Lung Disease and Mortality in Patients with Systemic Sclerosis Related Interstitial Lung Disease

Nancy Wareing[1], Ning Li[2], Elizabeth Volkmann[3], Marka Lyons[4], Michael Roth[2], Donald Tashkin[2] and Shervin Assassi[1], [1]University of Texas Houston McGovern Medical School, Division of Rheumatology and Clinical Immunogenetics, Houston, TX, [2]University of California, Los Angeles, Los Angeles, [3]University of California, Los Angeles, Los Angeles, CA, [4]University of Texas Houston, McGovern Medical School, Division of Rheumatology and Clinical Immunogenetics, Houston, TX

SESSION INFORMATION
Session Date: Friday, November 6, 2020
Session Title: Systemic Sclerosis & Related Disorders – Clinical Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Systemic sclerosis (SSc) patients have a prominent neutrophil gene expression signature. However, investigations into the pathophysiologic role of neutrophils in SSc are lacking. This is predominantly due to their limited survivability *in vitro* and the significantly lower proportion of neutrophils in rodent serum compared to humans. These limitations highlight the need to directly study the role of neutrophils in SSc using human specimens. In this study, we examined the prognostic significance of neutrophil count in the Scleroderma Lung Study (SLS) II.

Methods: Neutrophil counts were prospectively obtained at the baseline visit of SLS II. All subjects had clinically significant SSc related interstitial lung disease (ILD) and had a disease duration less than 7 years. Baseline neutrophil count was log-transformed with a base of 2 in all analyses. A joint model combining mixed effects and survival models was used to examine the relationship between baseline blood neutrophil count and serially obtained % predicted forced vital capacity (FVC%) as well as modified Rodnan skin scores (mRSS) from 3-12 month visits after adjustment

Table 1. Baseline neutrophil count as a predictor of worsening SSc-ILD in SLS II

	β (95% CI)	P-value
Baseline neutrophil count*	-1.11 (-1.15, -1.08)	0.030
Baseline FVC%	0.90 (0.90, 0.90)	<0.001
Time variable	0.07 (0.07, 0.08)	0.004
Treatment arm #	0.88 (0.83, 0.93)	0.185

* Neutrophil count was log-transformed using a base of 2.

Mycophenolate compared to cyclophosphamide treatment groups

Table 2. Mortality risk in SLS II patients as a function of baseline neutrophil count

	Hazard Ratio	95% CI	P-value
Baseline neutrophil count*	2.02	1.02, 4.01	0.045
Age at enrollment	1.09	1.05, 1.14	<0.001
Treatment arm #	0.73	0.34, 1.55	0.415

* Neutrophil count was log-transformed using a base of 2. This indicates that the risk of mortality increases 102% with doubling of the baseline neutrophil count.

Mycophenolate compared to cyclophosphamide treatment groups

for baseline disease severity and treatment arm. Cox proportional hazards models were created to evaluate the association between neutrophil count and long-term mortality.

Results: Of the 142 patients enrolled in SLS II, 134 (94.3%) had an available baseline neutrophil count. The majority of patients had diffuse cutaneous disease (59%) and mean disease duration was 2.6 years (±1.7). Higher neutrophil count predicted worsening of SSc-ILD based on the course of the FVC% from 3-12 months (p=0.030 – Table 1). Neutrophil count did not predict changes in mRSS. Baseline neutrophil count predicted an increased risk of mortality after adjustment for age (HR=2.02, 95% CI [1.02, 4.01], p=0.045-Table 2). The median follow-up time was 3.4 years with IQR (2.9, 4.6) for the mortality analysis. Both findings were independent of treatment arm.

Conclusion: Higher neutrophil count predicted worse ILD course and higher long-term mortality in patients with SSc-ILD. Our findings were independent of treatment with cyclophosphamide or mycophenolate. Neutrophils, largely under-investigated in SSc, might play a role in pathogenesis of SSc and warrant further mechanistic studies. Furthermore, baseline neutrophil counts may serve as a useful prognostic marker of disease progression.

A Pilot Study to Evaluate the Safety and Efficacy of Treprostinil in the Treatment of Calcinosis in Patients with Systemic Sclerosis

Melody Chung[1], Antonia Maria Valenzuela Vergara[2], Benjamin Catanese[1], Shufeng Li[1], Kate Stevens[1] and Lorinda Chung[3], [1]Stanford University, Stanford, CA, [2]Pontificia Universidad Catolica de Chile, Santiago de Chile, Chile, [3]Stanford University School of Medicine and Palo Alto VA Health Care System, Palo Alto, CA

SESSION INFORMATION
Session Date: Friday, November 6, 2020
Session Title: Systemic Sclerosis & Related Disorders – Clinical Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Calcinosis is characterized by calcium deposition in skin and subcutaneous tissues and progresses over one year in the majority of systemic sclerosis (SSc) patients. Since vascular hypoxia may contribute to calcinosis pathophysiology, we evaluated the safety and efficacy of oral treprostinil in preventing progression of SSc-associated calcinosis.

Methods: We performed a prospective, open-label, single-institution study in 12 SSc patients meeting 2013 ACR/EULAR classification criteria with confirmed radiological and physical examination evidence of ≥1 subcutaneous calcium deposit in the hands (ClinicalTrials.gov Identifier: NCT02663895). Patients received oral treprostinil for 1 year with evaluations every 3 months. Primary endpoints were safety/tolerability and percentage of patients without radiographic progression of calcinosis at 1 year assessed by the Scleroderma Clinical Trials Consortium radiographic score. Progression of calcinosis was defined as >25% increase in score, improvement as >25% decrease, and stabilization as values in-between. Radiographs were scored by a radiologist blinded to treatment history and sequence of images. Secondary endpoints included 1-year changes in the Scleroderma HAQ (SHAQ), Cochin Hand Functional Scale, SF-36, Raynaud Condition Score, and patient and physician assessment of calcinosis severity. Endpoints were assessed using Wilcoxan signed rank test.

a median follow-up of 5 months (range 0.25-10 months) due to the following: intolerable side effects (n=3, diarrhea, headaches), withdrawn by investigator for intercurrent illness unrelated to drug (n=2, cirrhosis, cancer), progressive SSc (n=1), and personal reasons (n=1). Most patients developed headaches and gastrointestinal side effects, consistent with the known side effect profile of treprostinil **(Table 2).** No serious adverse events occurred. Four of the 12 (33%) patients experienced progression of calcinosis at 1 year. Of the 5 patients who completed 12 months of treatment, 4 had stability and 1 had progression of calcinosis (1-year median % score change: 22.2%, range: 5.3-85.5%, p=0.06). Of the 6 patients who withdrew but had 1-year follow-up radiographs, 3 had stability/improvement of calcinosis while 3 progressed (1-year median % score change: 38.4%, range: -38.9%-111%, p=0.16). Including all 12 enrolled patients, worsening of the SHAQ-VAS-GI score was observed (median change/month: 0.03, range 0-0.25, p=0.016); there were no significant changes in other secondary endpoints.

Conclusion: Oral treprostinil was poorly tolerated in SSc patients with calcinosis, with most patients developing headaches and gastrointestinal side effects. Of patients who were able to complete the treatment period, most (80%) had stability of calcinosis on hand radiographs at 1 year.

Phase 1 Clinical Study of MGTA-145 in Combination with Plerixafor Shows Rapid Single-Day Mobilization and Collection of CD34+ Hematopoietic Stem Cells Without G-CSF

John DiPersio[1], **Jonathan Hoggatt**[2], Steven Devine[3], David Scadden[2], Haley Howell[4], Veit Schmelmer[4], Glen Raffel[4], Pat Falahee[4], Kevin Goncalves[4], William Savage[4] and John Davis[4], [1]Washington University, Saint Louis, [2]Massachusetts General Hospital, Boston, [3]National Marrow Donor Program, Minneapolis, [4]Magenta Therapeutics, Cambridge

SESSION INFORMATION

Session Date: Friday, November 6, 2020

Session Title: Systemic Sclerosis & Related Disorders – Clinical Poster I

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: Autologous hematopoietic stem cell (HSC) transplantation is a recommended therapeutic option for selected patients with scleroderma and other autoimmune diseases. HSC transplant requires collection

of HSCs via mobilization by G-CSF, which consists of 4-7 days of injections that are associated with significant side effects and potential for severe complications including disease flares (e.g., scleroderma and multiple sclerosis). MGTA-145 is a biologic that activates CXCR2 on neutrophils, and with plerixafor (a CXCR4 antagonist) rapidly mobilizes HSCs in mice and non-human primates. The combination promises to be a same-day, G-CSF-free mobilization regimen.

Methods: This healthy volunteer study consisted of four parts- Part A: single-agent MGTA-145 or placebo; Part B: MGTA-145 or placebo given immediately or 2 hours after plerixafor; Part C: MGTA-145 or placebo given 2 hours after plerixafor on 2 consecutive days; Part D: MGTA-145 given 2 hours after plerixafor, just prior to apheresis cell collection.

Results: Monotherapy of MGTA-145 mobilized CD34+ cells within minutes and peaked within 1-hour post MGTA-145 (median 11 CD34+ cells/μL, a 7-fold increase vs baseline). White blood cells and neutrophils followed a similar pattern. Importantly, markers of neutrophil activation were relatively unchanged (≤2-fold vs baseline, Fig 1).

MGTA-145 combined with plerixafor increased CD34+ cell mobilization, whether given simultaneously or 2h after plerixafor (Fig. 2). Mobilization was highly enriched for CD34+CD90+CD45RA- HSCs. At the 0.03 mg/kg dose with

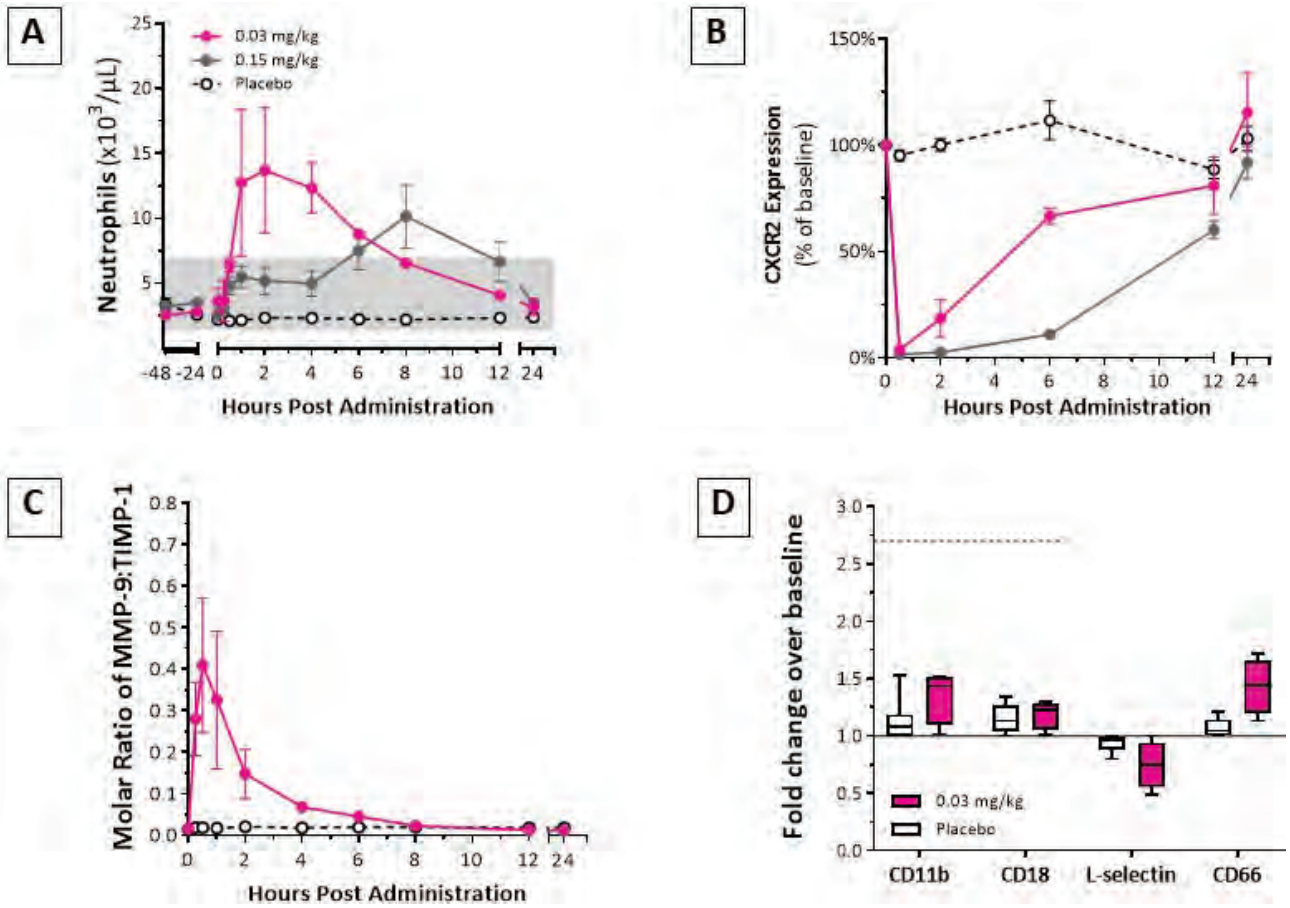

Figure 1. MGTA-145 has rapid, on-target neutrophil pharmacodynamics with minimal activation. (A) A single dose of MGTA-145 elicits dose-dependent mobilization of neutrophils into peripheral blood. (B) MGTA-145 monotherapy leads to rapid downregulation of its target receptor, CXCR2, on peripheral blood neutrophils. (C) MGTA-145 monotherapy leads to an increase in the molar ratio of the neutrophil protease, MMP-9, to its inhibitor, TIMP-1, in plasma. (D) MGTA-145 monotherapy elicits only modest changes in peripheral blood neutrophil activation markers (median ≤ 2-fold) after administration. Data represent at least 4 subjects per dose level and are expressed as mean ± SEM (A-C) or median + 10-90 percentile range (D). The shaded region in (A) represents the normal reference range for healthy subjects. The dotted line in (D) represents the anticipated effect of 5 days of G-CSF based on published data (Falanga et al, Blood. 1999).

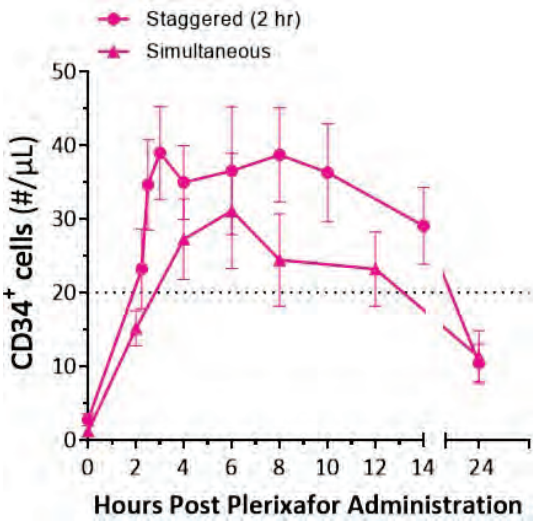

Figure 2. Peripheral blood mobilization after plerixafor + 0.03 mg/kg MGTA-145 in healthy subjects with simultaneous and 2h stagger dosing after plerixafor. Dotted line: previously reported CD34+ counts with plerixafor alone mobilization (Chen et al, Blood Advances. 2018).

Table. Single-day Mobilization and Apheresis Cell Yields in Part D

MGTA-145 dose (mg/kg)	Subjects (n)	Total CD34+ Yield (x10⁶) Median (range)	CD34+ / kg (x10⁶)			CD90+ / kg (x10⁶)a			CD90+ (% of CD34+)
			Mean	Median	Range	Mean	Median	Range	
0.015	4	310 (118-525)	4.0	3.7	1.5 - 7.0	1.4	1.2	0.5 – 2.8	37%
0.03	4	321 (239-500)	4.1	4.3	2.7 – 5.3	1.3	1.5	0.5 – 1.8	31%

2h stagger, median peak CD34+ peripheral blood mobilization was ≥40 cells/µL in Part B. On a second consecutive day of dosing, MGTA-145 + plerixafor mobilized HSCs to levels comparable to day 1. Apheresis cell collection yields in Part D showed that sufficient numbers of cells (median 4.3 x 10^6 CD34+ cells/kg) for transplant were collected in a single day. Notably, MGTA-145 + plerixafor mobilized 3-fold higher numbers of CD34+CD90+CD45RA- HSCs and demonstrated >10-fold higher engraftment in NSG mice compared to cells mobilized by G-CSF.

MGTA-145 monotherapy was well tolerated with no significant adverse events (AEs). Grade 1, transient lower back pain that dissipated within minutes was reported. The combination of MGTA-145 with plerixafor was well tolerated, with some subjects experiencing grade 1/2 gastrointestinal AEs commonly observed with plerixafor and one grade 2 back pain with MGTA-145 at 0.075 mg/kg that resolved within minutes.

Conclusion: MGTA-145 was well-tolerated and induced rapid mobilization of significant numbers of HSCs. CD34+ cell mobilization with MGTA-145 + plerixafor was immediate and superior to plerixafor alone. These data suggest that the combination enables the collection of sufficient HSCs for transplant in one day without the need for G-CSF. Further clinical development as a first line mobilization agent is warranted in scleroderma and other autoimmune diseases, as well as in gene therapy and hematologic malignancies.

Altered Iron Homeostasis and Pulmonary Haemodynamics in Systemic Sclerosis Associated Pulmonary Arterial Hypertension

Alper Sari[1], Christopher Denton[2], Svetlana Nihtyanova[3], Benjamin Schreiber[4] and Voon Ong[3], [1]Hacettepe University, Division of Rheumatology, Department of Internal Medicine, Faculty of Medicine, Ankara, Turkey, [2]University College London, London, United Kingdom, [3]Centre for Rheumatology, Royal Free Campus, UCL Division of Medicine, UK, London, United Kingdom, [4]UCL, London, United Kingdom

SESSION INFORMATION
Session Date: Friday, November 6, 2020
Session Title: Systemic Sclerosis & Related Disorders – Clinical Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Iron deficiency (ID) is more frequent in systemic sclerosis (SSc) patients with pulmonary hypertension (PH) than those without and associated with worse prognosis. There is paucity of data on the relationship between serum iron parameters and pulmonary haemodynamics.

Methods: Right heart catheterisation (RHC) reports of SSc patients were retrospectively reviewed. Subjects were included in the study if they had serum iron studies done within 12 months of RHC and were either diagnosed as 1) pulmonary arteral hypertension (PAH, group 1 PH), defined as mean pulmonary artery pressure (mPAP) ≥25 mmHg at rest with pulmonary artery wedge pressure ≤15 mmHg; or 2) no PH. Patients with gastrointestinal disorders that may cause low iron levels and glomerular filtration rate below 60 ml/min/1.73m^2 were excluded. We recorded serum iron concentration (µmol/L), total iron-binding capacity (TIBC, µmol/L), transferrin saturation (TS, %), ferritin (µg/L), red cell distribution width (RDW, %), as well as mPAP (mmHg) and pulmonary vascular resistance (PVR, dynes/sec/cm^{-5}). Univariable associatıons were assessed using Mann-Whitney test and Spearman's correlation as appropriate. Multiple regression of log-transformed mPAP and PVR and Cox regression were used to compare iron and RDW association with haemodynamics and survival.

Results: We included 122 subjects in the analysis, 84% were female and mean age at RHC was 57 years. The majority (73%) had limited cutaneous SSc and 34% carried anti-centromere antibodies, followed by 18% with anti-Scl70 and 8% with anti-U3RNP.

At RHC, 53/122 (43%) of the patients were diagnosed with PAH. Among them we observed substantially lower levels of serum iron (8.7 vs. 12.1 µmol/L, p< 0.001), TS (15.3% vs. 22.5%, p< 0.001), ferritin (68.1 vs. 112.5 µg/L, p=0.07), significantly higher RDW (16.4% vs. 14.8%, p< 0.001) and no difference in TIBC (57.4 vs. 54.3 µmol/L, p=0.163), compared to subjects in whom PH was excluded.

mPAP showed moderately strong negative correlation with iron concentration (Spearman's rho=-0.35, p< 0.001) and TS (Spearman's rho=-0.39, p< 0.001) and positive correlation with RDW (Spearman's rho=0.46, p< 0.001).

PVR was significantly inversely correlated with iron concentration (Spearman's rho=-0.30, p=0.001), TS (Spearman's rho=-0.37, p< 0.001 and ferritin (Spearman's rho=-0.22, p=0.016), while it showed positive correlation with TIBC (Spearman's rho=0.28, p=0.003) and RDW (Spearman's rho=0.37, p< 0.001).

Compared to serum iron indices, RDW is a better predictor of mPAP and PVR. In addition, iron levels did not demonstrate any association with survival, while risk of death was significantly higher for patients with higher RDW (HR=1.18, p=0.002) and the association remained after adjusting for presence of PH (HR=1.16, p=0.013).

Conclusion: To our knowledge, this is the first study to demonstrate a significant relationship between ID state and haemodynamic measures of SSc-PAH. Our data also support RDW, as an indicator for functional iron deficiency, may serve as a biomarker for severity of pulmonary vasculopathy in SSc.

Session Title: Systemic Sclerosis & Related Disorders – Clinical Poster I

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: The progression of SSc-ILD is variable and unpredictable. However, observational studies have identified patient characteristics that may be prognostic of a greater rate of decline in forced vital capacity (FVC) in patients with SSc-ILD. We used data from the placebo group of the SENSCIS trial to conduct a preliminary analysis of whether baseline variables were prognostic of a greater rate of decline in FVC over 52 weeks.

Methods: Patients with SSc-ILD with onset of first non-Raynaud symptom ≤7 years before screening, extent of fibrotic ILD ≥10% on HRCT and FVC ≥40% predicted were enrolled in the SENSCIS trial. Patients on prednisone ≤10 mg/day (or equivalent) and/or stable therapy with mycophenolate or methotrexate for ≥6 months prior to randomization were allowed to participate. Patients were randomized to receive nintedanib or placebo until the last patient had reached week 52 but for ≤100 weeks. We used data from the placebo group to investigate baseline characteristics as prognostic factors for a greater rate of decline in FVC (mL/year) over 52 weeks (Table). Our analyses were based on

Table. Baseline characteristics as prognostic factors for a greater rate of decline in FVC (mL/year) over 52 weeks in the placebo group of the SENSCIS trial

Baseline characteristic		N analyzed	Rate of decline in FVC (mL/year) over 52 weeks		
			Adjusted rate (SE)	Difference (95% CI)	p-value†

ATA, anti-topoisomerase I antibody. *Assessed visually in the whole lung to nearest 5%. The assessment did not include pure (non-fibrotic) ground glass opacities. †p-value for subgroup-by-time interaction.

a random coefficient regression model with effects of anti-topoisomerase I antibody status, sex, time, baseline FVC (mL), age and height, and subgroup-by-time and baseline-by-time interactions.

Results: A total of 288 patients received placebo, of whom 73.6% were female, 61.5% were ATA-positive, and 50.7% had diffuse cutaneous SSc. At baseline, mean (SD) age was 53.4 (12.6) years, FVC was 72.7 (16.6) % predicted and modified Rodnan skin score was 10.9 (8.8); median time since onset of first non-Raynaud's symptom was 3.5 years. Almost half (48.6%) of patients were taking mycophenolate at baseline. In the primary analysis, the adjusted rate (SE) of decline in FVC in the placebo group was -93.3 (13.5) mL/year. None of the baseline factors investigated in this patient population was prognostic ($p< 0.05$) of a greater rate of decline in FVC (mL/year) over 52 weeks, but baseline FVC ≤70% predicted and not taking mycophenolate at baseline showed trends toward being prognostic factors (Table).

Conclusion: Among patients with SSc-ILD who received placebo in the SENSCIS trial, no baseline characteristic was found to be prognostic of a greater rate of decline in FVC over 52 weeks, although baseline FVC ≤70% predicted

and not taking mycophenolate at baseline showed trends toward being prognostic factors. These findings support previous studies suggesting that the course of SSc-ILD is difficult to predict, that prognostic factors identified in certain populations may not apply to all populations of patients with SSc-ILD, and that new parameters or a combination of factors from different disease domains might be needed to predict the course of SSc-ILD.

Abstract Number: 0389

Organ Specific Treatment Patterns of a Real-World, Electronic Health Record Cohort of Patients with Systemic Sclerosis

Kyle Kidwell[1], Leslie J. Crofford[1] and April Barnado[1], [1]Vanderbilt University Medical Center, Nashville, TN

SESSION INFORMATION
Session Date: Friday, November 6, 2020
Session Title: Systemic Sclerosis & Related Disorders – Clinical Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Assembling large cohorts of patients with rare diseases is difficult and limits the power to assess outcomes in systemic sclerosis (SSc) studies. Treatment in SSc varies significantly and is tailored to a patient's disease manifestations. To investigate this variability, we identified a cohort of SSc patients in the EHR to examine real-world disease presentations and treatment practices.

Methods: We analyzed data from a de-identified EHR that contains over 3 million subjects with longitudinal clinical data. We identified potential SSc patients using a previously validated algorithm requiring ^{3} 4 SSc ICD-9 (710.1) or ICD-10-CM codes (M34.0, M34.1, M34.8, M34.9). We performed chart review to determine case status, disease manifestations, autoantibodies, and medication use. Patients were confirmed to have SSc if diagnosed by a rheumatologist, pulmonologist, or dermatologist. Disease manifestations were included if documented in inpatient or outpatient notes. Immunosuppressants and medications for gastroesophageal reflux disease (GERD), Raynaud's phenomenon, and pulmonary hypertension (PH) were assessed through inpatient and outpatient notes and counted if ever used.

Results: Of 223 patients identified by the algorithm, 196 were confirmed on chart review as SSc patients with an additional 4 mixed connective tissue disease patients. Of these 200, patients were predominantly female (84%) and

SSc: Systemic Sclerosis
MCTD: Mixed connective tissue disease

Caucasian (87%) (Table 1). Of patients with available tests, 95% had a positive antinuclear antibody (titer ≥ 1:160). Most were of the limited cutaneous subtype (83%). Overall, 22% had interstitial lung disease (ILD), 36% PH, and 3% renal crisis. The most common disease manifestations were Raynaud's phenomenon (82%) and GERD (78%). Of the patients with Raynaud's phenomenon, 45% were ever on a calcium channel blocker and 34% were not on any medications (Table 2). Almost all patients with GERD were on acid suppression therapy (97%) with 89% on a proton pump inhibitor. Overall, immunosuppressant use varied widely, with the most commonly used medications being prednisone at any dose (40%) and methotrexate (17%). Only 16% of patients on prednisone were on doses higher than 30 mg daily, and a majority (69%) had co-existing ILD or arthritis. For the ILD patients, 91% were on immunosuppressants with the most frequently used medications being prednisone (70%) and cyclophosphamide (50%). Of the PH patients, 79% were on disease specific treatment with 21% not on therapy or on diuretics alone. A majority (60%) of the PH patients were managed with combination therapy.

Conclusion: We identified a large, real-world EHR cohort of SSc patients. The majority of SSc patients were on medications for GERD, PH, and ILD. This trend may reflect our EHR cohort being based at a tertiary care center with access to multi-disciplinary care. Despite high percentages of treatment, immunosuppressant treatments and

SESSION INFORMATION

Session Date: Friday, November 6, 2020

Session Title: Systemic Sclerosis & Related Disorders – Clinical Poster I

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: Interstitial lung disease (ILD) is the leading cause of death in SSc. Several international observational studies have evaluated characteristics of ILD in their SSc patient populations, however these studies do not necessarily reflect the US SSc patient population. The purpose of this analysis was to assess the baseline characteristics of SSc patients with and without restrictive lung disease (RLD) in a US based longitudinal registry.

Methods: The Collaborative National Quality and Efficacy Registry (CONQUER) for Systemic Sclerosis is a multicenter US based registry of patients with early SSc within 5 years of first non-Raynaud's symptom enrolled at 13 expert centers. All patients are >18 years old and fulfill the 2013 ACR/EULAR Classification Criteria for SSc. All patients who had a pulmonary function test (PFT) at baseline on or before April 1, 2020 were included in this analysis. As a high-resolution computed tomography (HRCT) Chest at baseline was not available to characterize ILD for all patients, patients were characterized as RLD based on force vital capacity (FVC) % predicted < 80% or total lung capacity (TLC) % predicted < 80%. Chi-squared test and Fisher's Exact test were performed for categorical variables. T-test was performed for continuous variables. Multivariable modeling with stepwise selection was performed to predict RLD. A p-value < 0.05 was considered significant.

Results: 329 patients underwent PFTs at baseline with 147 (45%) patients characterized as RLD. There was no significant difference in age, sex or disease duration between patients with and without RLD. Patients with RLD had a mean disease duration of 2.6 years and a mean FVC of 67% at baseline. RLD patients compared to no RLD were more likely to be non-white (African American, Asian or other) and have diffuse disease, a higher modified Rodnan skin score, digital pitting scars and abnormal GI symptoms including gastric antral vascular ectasia (GAVE), esophageal dysmotility, small bowel dysfunction or malabsorption (Table 1). RLD patients who underwent HRCT also were more likely to have a patulous esophagus on HRCT compared to those patients without RLD (Table 2). In multivariable analysis, non-white race, crackles on exam, DLCO< 60%, and higher physician global health assessment scores were found to be independently associated with RLD (Table 3).

Physician global damage[7]: Mean (SD)	4.0 (7.23)	4.3 (2.17)	3.7 (9.52)	0.419[1]
SHAQ breathlessness score[8]: Mean (SD)	3.4 (11.87)	5.4 (15.70)	1.9 (7.32)	0.020[1]
mMRC dyspnea scale[9]				<.001[2]
0	117 (40.6%)	34 (27.2%)	83 (50.9%)	
1	108 (37.5%)	50 (40.0%)	58 (35.6%)	
2-4	63 (21.9%)	41 (32.8%)	22 (13.5%)	
FACIT dyspnea score: Mean (SD)	6.6 (6.95)	8.5 (7.65)	5.1 (5.96)	<.001[1]

[1] T-test with unpooled variance estimates.
[2] Chi-squared test.
[3] Class I (No symptoms and no limitation to physical activity), to Class IV (severe limitations, symptoms at rest)
[4] P-values are not calculated for FVC and TLC because those variables were used to derive the outcome of RLD.
[5] How was your overall health in the last week? 0 (Excellent) to 10 (Extremely poor).
[6] How would you rate the participants overall health for the past week? 0 (Excellent) to 10 (Very poor).
[7] How much damage do you think the participant has from his/her scleroderma? 0 (No damage) to 10 (Very severe damage).
[8] In the past week how much have your breathing problems interfered with your daily activities? 0 (No interference) to 10 (Very severe interference).
[9] Describe your shortness of breath: 0 (I only get breathless with strenuous exercise) 1 (I get short of breath when hurrying on level ground or walking up a slight hill) to 4 (I am too breathless to leave the house or I am breathless when dressing).
HRCT = high resolution computed tomography of the chest; SHAQ = Scleroderma Health Assessment Questionnaire; mMRC = Modified Medical Research Council; FACIT = Functional Assessment of Chronic Illness Therapy; FVC = forced vital capacity; FEV1 = forced expiratory volume in 1 second; TLC = total lung capacity; DLCO = diffusion capacity for carbon monoxide

Conclusion: We found that SSc patients with RLD enrolled in CONQUER had more diffuse disease and significant GI manifestations compared to patients without RLD. Non-white race was independently associated with RLD. Interestingly, patients with RLD had early disease yet already significant restrictive defects on PFTs, suggesting that even

Defining the Optimal Disease Duration of Early Diffuse Systemic Sclerosis for Clinical Trial Design

Robyn Domsic[1], Shiyao Gao[2], Maureen Laffoon[2], Steven Wisniewski[3], Yuqing Zhang[4], Robert Lafyatis[5], Virginia Steen[6] and Thomas Medsger[7], [1]University of Pittsburgh School of Medicine, Pittsburgh, PA, [2]University of Pittsburgh, Pittsburgh, PA, [3]University of Pittsburgh Graduate School of Public Health, Pittsburgh, PA, [4]Massachusetts General Hospital, Harvard Medical School, Boston, [5]University of Pittsburgh, Arlington, MA, [6]Division of Rheumatology, Department of Medicine, MedStar Georgetown University Hospital, Washington, DC, [7]University of Pittsburgh School of Medicine, Verona, PA

SESSION INFORMATION
Session Date: Friday, November 6, 2020
Session Title: Systemic Sclerosis & Related Disorders – Clinical Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

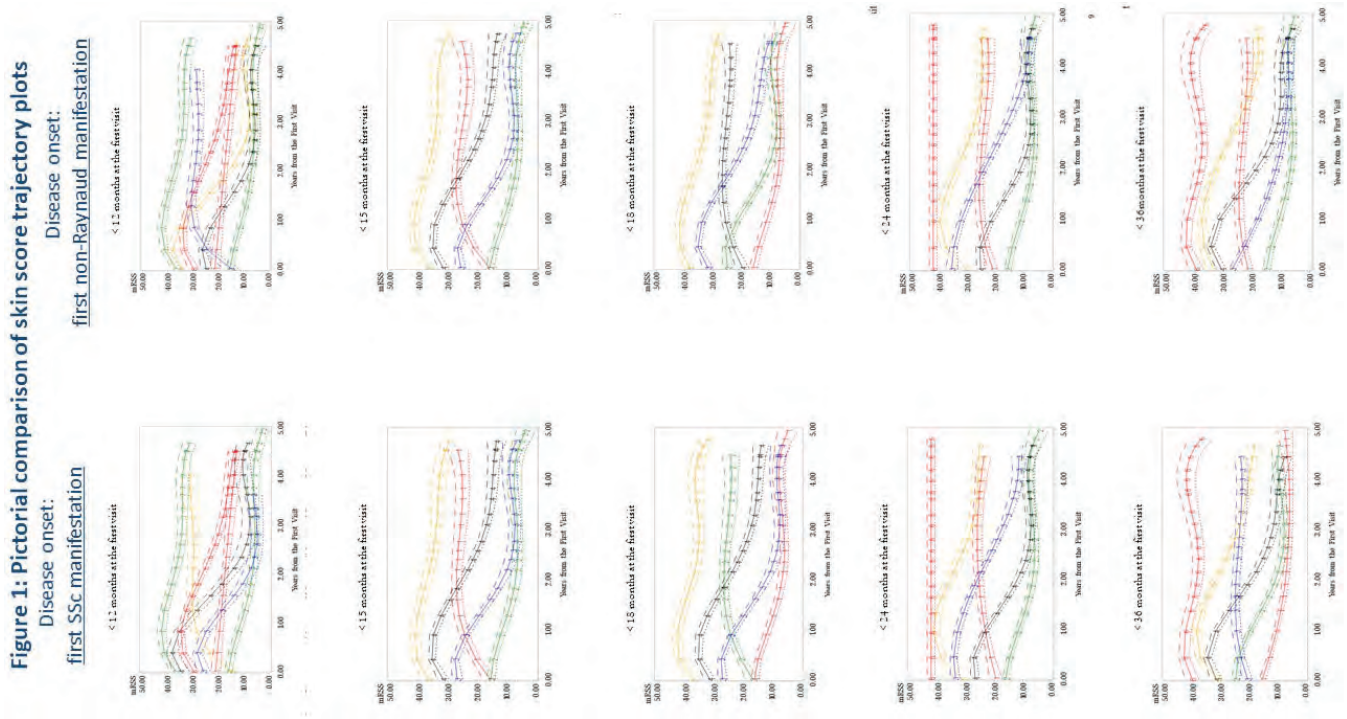
Background/Purpose: Clinical trials in early diffuse cutaneous systemic sclerosis (SSc) have historically used the modified Rodnan skin score (mRSS) as the primary outcome measure. These trials have persistently been unable to show any significant improvement in the mRSS between placebo and comparison groups. What has been demonstrated in many trials are declines in the mRSS in both groups; suggesting regression to the mean occurring in both the treatment and the comparison group. We wanted to assess how the definition of disease onset (first SSc manifestation versus first non-Raynaud manifestation), and how varying lengths of disease duration at trial entry as an inclusion criteria functioned with respect to mRSS trajectory. Our objective was to optimize trial inclusion criteria.

Methods: We used a prospective, observational cohort from a large US university, tertiary-care referral Scleroderma Center cohort. We identified early diffuse SSc patients first seen between 1980 and 2015. All had < 3 years from first SSc (n=481) or first non-Raynaud manifestation (n=514) and ≥3 mRSS scores during follow-up. We used descriptive, time to event and group-based trajectory analyses to model: 1) the two different definitions of disease onset (first SSc and first non-Raynaud manifestation), and 2) varying lengths of disease duration as inclusion criteria for clinical trials. Disease duration definitions assessed included < 12 months, < 15 months, < 18 months, < 24 months and < 36 months using both definitions of disease onset.

Results: Baseline characteristics are in Table 1. There was no appreciable difference in mRSS trajectory patterns between using first SSc manifestation compared to first non-Raynaud manifestation as the definition of disease onset

Table 1: Baseline characteristics of first SSc and first non-Raynaud manifestation onset cohorts

	First SSc manifestation <36 months (n=481)	First non-Raynaud manifestation <36 months (n=514)
Mean age at first visit (±SD)	49.8 ±13.7	49.4 ± 13.8
Female	355 (74%)	382 (74%)
Caucasian	435 (90%)	468 (91%)
Median disease duration (years) from first SSc manifestation (IQR)	0.97 (0.66, 1.53)	1.04 (0.70, 1.84)
Median follow-up time in years (IQR)	9.6 (4.3, 16.2)	10.2 (4.5, 16.3)
Median number of clinic visits (IQR)	7 (4, 14)	14 (8, 23)
SKIN CHARACTERISTICS		
Mean mRSS (±SD) at 1st visit	24.6 ± 10.7	24.5 ± 10.6
Maximum mRSS during follow-up (mean ±SD)	31.2 ± 11.2	31.1 ± 11.1
Skin Thickness Progression Rate rapid	169 (35%)	194 (38%)
intermediate	158 (33%)	163 (32%)
slow	151 (32%)	154 (30%)
NON-CUTANEOUS DISEASE CHARACTERISTICS		
Tendon friction rubs present	219 (46%)	231 (46%)
Gastrointestinal involvement	215 (45%)	235 (46%)
Fibrosis on chest imaging	95/411 (23%)	103/440 (23%)
Renal crisis	42 (9%)	50 (10%)
Joint/tendon involvement	456 (92%)	484 (92%)
Myopathy	20 (4%)	22 (4%)
Pulmonary hypertension	9 (2%)	9 (2%)
AUTOANTIBODIES		
anti-RNA polymerase III	269 (56%)	273 (53%)
anti-Scl-70	121 (25%)	137 (27%)



(Figure 1). Compared to other disease durations, < 18 months of disease had >70% of patients fitting into trajectories with worsening cutaneous disease over the first six months of follow-up. Longer disease durations demonstrated that the majority of patients had trajectories showing an improvement in mRSS (regression to the mean) over six months.

Conclusion: Regardless of whether the first SSc or first non-Raynaud manifestation is used to define disease onset, duration of < 18 months at enrollment is preferable, despite the difficulty in identifying such patients. Longer disease duration criteria more frequently results in regression to the mean of the mRSS score, and may have contributed to prior negative trials. Given the weight of the mRSS in the combined response index (CRISS), this analysis likely applies to trials using the CRISS as an outcome.

Prevalence and Survival of Systemic Sclerosis (SSc) and Associated Interstitial Lung Disease (ILD) in Ontario, Canada over 10 Years

Janet Pope[1], Kobina Quansah[2], Martin Kolb[3], Jason Flavin[4], Hassan Shazia[5] and Soo Jin Seung[5], [1]Department of Medicine, University of Western Ontario, St. Joseph's Health Centre, London, ON, Canada, [2]Boehringer Ingelheim (Canada) Limited, Burlington, ON, Canada, [3]McMaster University and Firestone Institute for Respiratory Health, St Joseph's Healthcare, Hamliton, ON, Canada, [4]Boehringer Ingelheim, Corporate Headquarters, Burlington, ON, Canada, [5]HOPE Research Centre, Sunnybrook Health Sciences Centre, Toronto, ON, Canada

SESSION INFORMATION
Session Date: Friday, November 6, 2020
Session Title: Systemic Sclerosis & Related Disorders – Clinical Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Systemic sclerosis (SSc) is an autoimmune disease characterized by skin thickening, vascular lesions and fibrotic changes in various organs, mainly the lungs, heart, intestinal tract, kidneys, muscles and joints. Pulmonary complications of SSc are one of the leading causes of morbidity and mortality. Interstitial lung disease (ILD) is among the most common forms of lung disease associated with SSc. To date, no published study has generated population-based estimates of the prevalence of SSc-ILD in Canada. The objective of this study was to develop prevalence and survival estimates of SSc and SSc-ILD in Ontario, Canada using administrative data over 10 years.

Methods: Adult patients diagnosed with SSc between April 1, 2008 and March 31, 2018 were identified from the National Ambulatory Care Reporting System (NACRS) and Discharge Abstract Database (DAD) administrative databases, using ICD 10 CA codes. Patients with SSc were identified first, using M34 ICD-10 CA codes (M34.0, M34.1, M34.2, M34.8, and M34.9). SSc-ILD patients were identified if an additional one of J84.1, J84.8, J84.9 or J99.1 codes for lung disease was used after the SSc diagnosis. Prevalence estimates were determined for both SSc and SSc-ILD, based on the population of all eligible Ontario adults (~11.0 million as of fiscal 2017). Descriptive statistics and Kaplan Meier survival curves were generated.

Results: There were 3,111 unique patients identified as having SSc over 10 years. Of those, 559 (18%) were further identified as having SSc-ILD. At the start of fiscal year 2017/18 (final year of the cohort), there were 2,114 prevalent SSc cases for a cumulative prevalence of 19.12 per 100,000 persons from 2008/9 to 2017/18. Over the same time frame, there were 257 prevalent cases of SSc-ILD, generating a prevalence of 2.32 cases per 100,000 persons. At index date, mean age was approximately 57 and 58 years of age for SSc and SSc-ILD patients with 84% and 80% females in the groups. The survival rates at one, five and ten years after diagnosis for the SSc group were 84.96%, 64.45% and 44.88%, respectively. The SSc-ILD group survival rates at one, five and ten years were lower, at 77.12%, 44.41% and 22.02%, respectively.

Conclusion: This study provides the first population based estimates of SSc-ILD in Canada. Results confirm that the prevalence of SSc-ILD may fall within a Canadian threshold for drugs for 'other' rare disease. It also demonstrates the poor survival in SSc and especially when SSc-ILD is present.

SESSION INFORMATION

Session Date: Friday, November 6, 2020

Session Title: Systemic Sclerosis & Related Disorders – Clinical Poster I

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: Diffuse cutaneous Systemic Sclerosis (dcSSc) is a morbid disease involving the skin and internal organs. The American College of Rheumatology has provisionally approved a Composite Response Index in dcSSc (CRISS) (1) as a global endpoint for trials in dcSSc. Based on changes after 1 year, a CRISS score of ≥0.6 is considered improved and < 0.6 not improved. While the CRISS has been adopted in several trials, it lacks definite validation. Our goal is to assess the agreement between the CRISS score and physicians' evaluation of dcSSc patient profiles. We hypothesized that there will be agreement on whether a patient has improved after 1 year. This would further validate the CRISS.

Methods: Patient profiles were created for 100 randomly selected dcSSc patients with < 5 years disease duration from a multicenter cohort. Patients were selected such that after 1 year of observation, 50 had improved and 50 had non-improved CRISS. The profiles described features used during the development of the CRISS at baseline and 1 year: patient and physician global; HAQ; modified Rodnan skin score; forced vital capacity; body mass index; patient assessed score (0-10) of their breathing, gastrointestinal symptoms, Raynaud's, pain, digital ulcers; number of digital ulcers; presence of renal crisis and tendon friction rubs; SF-36 Vitality and Physical component scores. A total of 15 physicians with SSc expertise were involved and each patient profile was rated by 3 different physicians. The majority opinion determined consensus on whether a patient was improved (physician rated "improved") or not improved (physician rated "stable", "worsened", or "unable to tell"). Kappa agreement between the CRISS and physician ratings was calculated.

Results: The mean age of patients was 51.8 ± 12.3 years with mean disease duration of 2.2 ± 1.3 years. Physician consensus was obtained in all patient profiles. All CRISS non-improvers were also rated as non-improved by physician consensus (Table 1). 12 CRISS improvers were rated as non-improved by physician consensus because their profiles were rated as "stable" or "unable to tell". The kappa agreement was substantial, κ (95%CI) =0.76 (0.64, 0.88). The agreement between physician assessment prior to consensus and the CRISS remained substantial, κ (95%CI) = 0.70 (0.62, 0.78).

Table 1: Agreement of physician consensus rating with CRISS score

	Improved CRISS ≥ 0.6	Not improved CRISS < 0.6	Total
Improved by physician consensus (n)	38	0	38
Not improved by physician consensus (n)	12	50	62
Total (n)	50	50	100

Kappa (95%CI) = 0.76 (0.64, 0.88)

Table 1. Agreement of physician consensus rating with CRISS score; Kappa (95%CI) = 0.76 (0.64, 0.88)

Conclusion: There was substantial agreement between the dichotomous CRISS rating and physician assessment of dcSSc patients after 1 year. This supports the use of a dichotomous CRISS cut-off at 0.6 for improvement versus non-improvement. All CRISS non-improvers were also rated as not improved by physicians, although the CRISS was less conservative than physicians in assessing improvement. Physicians were more likely to report patients as stable or report that improvement was difficult to determine.

a. n is the number of patients with available test results. Percentage = n / total number of enrolled subjects (348).
b. *p* values were calculated from chi-squares test.
c. High dose of corticosteroids treatment is defined as greater than 7.5 mg of prednisone equivalent daily.

Background/Purpose: This study aims to determine the prevalence of a diagnosis of osteopenia/osteoporosis (OP) in systemic sclerosis (SSc) patients and to identify the clinical and serologic features independently associated with OP in SSc patients.

Methods: This is a cross-sectional study of 348 adult patients who visited the Stanford Rheumatologic Dermatology Clinic from January 2006 to March 2016 and were diagnosed with SSc according to the revised 2013 ACR/EULAR criteria for SSc. We compared the clinical characteristics, autoantibodies, and treatment of SSc patients with a diagnosis of OP to those without a diagnosis of OP. We used logistic regression analyses to identify clinical characteristics and autoantibodies associated with a diagnosis of OP in SSc patients.

Results: The prevalence of a diagnosis of OP in our SSc cohort was 41.4% (144/348, 95% CI: 36.2%, 46.6%) and was significantly higher in female patients and those >50 years of age (Table 1). Patients with a diagnosis of OP had longer disease duration and were more likely to have sclerodactyly, telangiectasias, interstitial lung disease (ILD), and gastroesophageal reflux. Patients with a diagnosis of OP were more commonly treated with corticosteroids and

Abbreviations: mRSS = modified Rodnan skin score, ILD = interstitial lung disease, PAH = pulmonary artery hypertension, GERD = gastroesophageal reflux, ACA = anti-centromere antibody, RNP = ribonucleoprotein, PPI = proton-pump inhibitor

a. Model adjusted for common risk factors including age, gender, race, smoking history, BMI, and corticosteroids treatment.

non-corticosteroids immunosuppressants (Table 2). Longer disease duration and non-corticosteroid immunosuppressant use were significantly associated with a higher odds of diagnosis of OP in logistic regression models adjusted for common risk factors for OP including age, race, gender, smoking history, body mass index, and corticosteroid treatment (Table 3).

Conclusion: More than 40% of SSc patients have a diagnosis of OP during the course of disease. Longer disease duration and non-corticosteroid immunosuppressant use increased the odds of diagnosis of OP in SSc patients.

SESSION INFORMATION

Session Date: Friday, November 6, 2020

Session Title: Systemic Sclerosis & Related Disorders – Clinical Poster I

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: African American (AA) patients have a higher prevalence of SSc than European Americans (EA). Adding to this health disparity, AA SSc patients are more likely to present with pulmonary involvement leading to significant morbidity and mortality. Samples from the Genome Research in African American Scleroderma Patients (GRASP) cohort were used for a genome-wide association analysis (GWAS) study in AA SSc patients. Intronic variants within the intraflagellar transport 43 (*IFT43)* gene were identified as the top non-*HLA* loci that were significant at the genome-wide level. These variants were in tight linkage disequilibrium with each other and were African-ancestry specific.

Methods: Expression quantitative trait loci (eQTL) analysis of fibroblast data from the Genotype-Tissue Expression (GTEx) project was performed for the *IFT43* variants. Assay for transposase-accessible chromatin with high-throughput sequencing (ATAC-seq) and DNase I hypersensitive sites sequencing (DNase-Seq) sample data from the GEO and ENCODE databases were downloaded and filtered to exclude poor-quality samples. 251 samples from primary cells and tissues, covering 76 distinct primary tissues and cell types, were analyzed further. Real-time PCR (RT-PCR) was performed on primary fibroblast cells with and without the *IFT43* risk variants. Two fibroblast cell lines, BJ and IMR-90, were obtained and processed for ATAC-Seq and RNA-Seq.

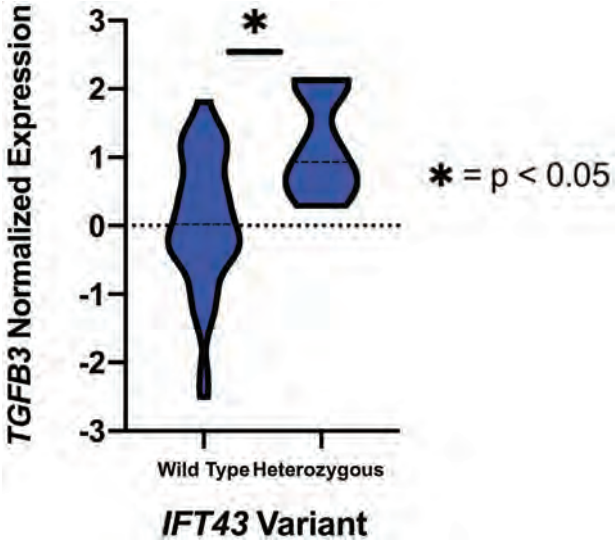

Figure 1. GTEx TGFB3 Expression.

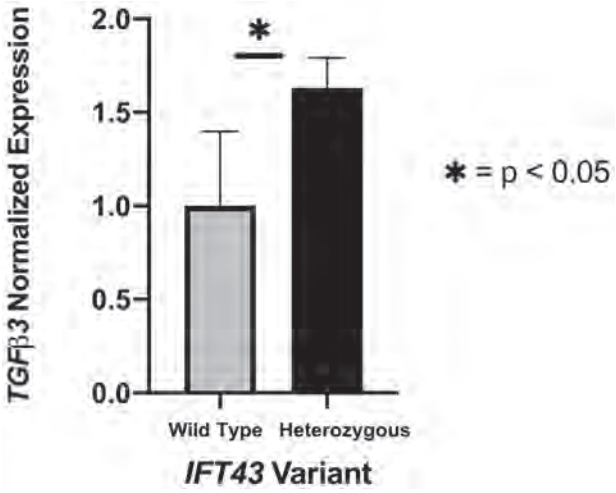

Figure 2. RT-PCR for TGFB3 expression.

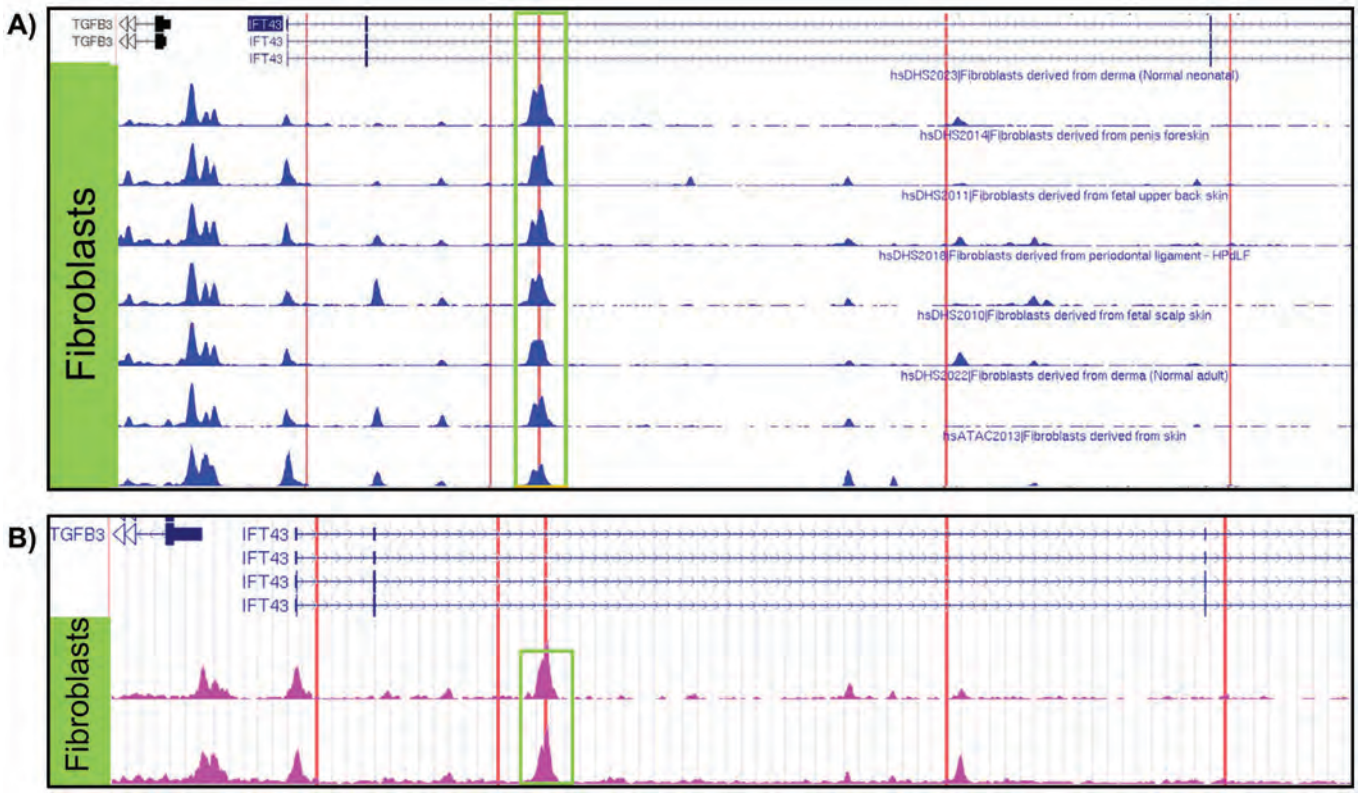

Figure 3. A) ATAC-Seq and DNAse-Seq tracks from ENCODE database showing accessible chromatin in fibroblasts. B) ATAC-Seq results from obtained BJ and IMR-90 fibroblast cell lines. Red lines represent location of IFT43 variants.

Results: eQTL analysis of fibroblast data from GTEx revealed increased expression of *TGFB3* in samples with the *IFT43* minor variants, suggesting that *TGFB3* expression was likely being regulated by these *IFT43* intronic variants (Figure 1). RT-PCR for *TGFB3* expression was performed on fibroblasts cells from healthy AA individuals. Individuals heterozygous for the *IFT43* minor variant had 1.6-fold higher *TGFB3 expression* compared to wildtype individuals (Figure 2). Bioinformatic analysis of ATAC-Seq and DNase-Seq data for fibroblasts showed that one of the SSc-associated *IFT43* variants was within an open, accessible chromatin region (Figure 3A). ATAC-Seq analysis of the BJ and IMR-90 fibroblast cell lines confirmed accessible chromatin at the site of one of the *IFT43* variants (Figure 3B).

Conclusion: Based on these results, we hypothesize that the *IFT43* variants overlap *cis*-regulatory modules (i.e. enhancer elements) and disrupt transcription factor binding, leading to altered *TGFB3* gene expression and function in SSc patients. TGFB3 could be regulating fibrosis via the canonical TGFB pathway or be inducing pathogenic Th17 cell development. Future directions include deletion of these *IFT43 cis*-regulatory modules in fibroblast cell lines utilizing CRISPR-Cas9 and assessing for changes in *TGFB3* gene expression. ChIP-Seq will be used for identifying transcription factor binding at the site of SSc-associated variants. This work implicates *TGFB3* as a novel therapeutic target in SSc, especially with regard to regulating fibrosis and autoimmunity. An isoform-selective TGFB inhibitor (blocking TGFB1 and -B3) is in early phase clinical trials in SSc. Identifying SSc patients based on variants increasing TGFB3 expression would provide an ideal target population for such a therapeutic agent.

Safety and Efficacy of Subcutaneous Tocilizumab in Systemic Sclerosis: Results from the Open-Label Period of a Phase 3 Trial

Dinesh Khanna[1], Celia J. F. Lin[2], Helen Spotswood[3], Jeffrey Siegel[2], Daniel Furst*[4] and Christopher Denton[5], [1]University of Michigan, Ann Arbor, MI, [2]Genentech, South San Francisco, CA, [3]Roche Products Ltd, Welwyn Garden City, United Kingdom, [4]Department of Medicine, Division of Rheumatology, University of California at Los Angeles, Los Angeles, California, USA, Los Angeles, CA, [5]University College London, London, United Kingdom

SESSION INFORMATION
Session Date: Friday, November 6, 2020
Session Title: Systemic Sclerosis & Related Disorders – Clinical Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: The anti–interleukin-6 (IL-6) receptor-α antibody tocilizumab (TCZ) demonstrated skin score improvement and forced vital capacity (FVC) preservation in patients with systemic sclerosis (SSc) in a phase 2 randomized controlled trial.[1,2] Data from the 48-week, double-blind (DB), placebo (PBO)-controlled period of the focuSSced phase 3 trial were previously presented,[3] and open-label (OL) data up to week 96 are presented to assess the long-term safety and efficacy of TCZ in SSc patients.

Methods: Adult patients with active SSc (≤60-month duration, modified Rodnan skin score [mRSS] 10-35, and elevated acute-phase reactants) treated with PBO or TCZ in the DB period received OL TCZ 162 mg SC weekly from weeks 48 to 96 in the OL period (PBO→OL TCZ and TCZ→OL TCZ, respectively). Exploratory analysis of data up to week 96 included no formal statistical analyses. Changes in mRSS and percent predicted FVC (ppFVC) were assessed. The study was conducted in accordance with the principles of the Declaration of Helsinki and received IRB approval.

Results: Overall, 92 of 105 TCZ (88%) and 89 of 107 PBO (83%) patients entered the OL TCZ treatment period at week 48, and 85 of 105 TCZ→OL TCZ (81%) and 82 of 107 PBO→OL TCZ (77%) patients completed treatment up to week 96. Continued decline in mRSS was observed in the OL period for PBO→OL TCZ and TCZ→OL TCZ patients (Table). Change in ppFVC for patients who switched from PBO to TCZ (PBO→OL TCZ) was comparable between weeks 48 and 96 (OL period) to the change in patients who received TCZ from BL to week 48 in the DB period (Table). Rates (95% CI) of serious adverse events from weeks 48 to 96 were 15.8 (8.6, 26.5) per 100 PY for TCZ→OL TCZ patients, 14.8 (7.9, 25.3) per 100 PY for PBO→OL TCZ patients, and 15.4 (11.0, 20.9) for all-TCZ exposure over 96 weeks (n = 193). Rates (95% CI) of serious infections were 2.3 (0.3, 8.1) per 100 PY for TCZ→OL TCZ patients, 3.4

Table 1. Change in Efficacy From Baseline

	Baseline to Week 48		Baseline to Week 96		Week 48 to Week 96	
	PBO	TCZ	PBO→OL TCZ	TCZ→OL TCZ	PBO→OL TCZ	TCZ→OL TCZ
mRSS, mean (95% CI)[a]	–5.3 (–6.9, –3.7) n = 92	–6.7 (–8.0, –5.4) n = 97	–8.4 (–10.0, –6.8) n = 83	–9.6 (–10.9, –8.4) n = 85	–2.5 (–3.3, –1.6) n = 82	–2.3 (–3.2, –1.5) n = 85
ppFVC, mean (95% CI) [median]	–4.1 (–5.8, –2.4) [–3.9] n = 92	–0.2 (–1.6, 1.2) [–0.7] n = 94	–3.3 (–5.1, –1.5) [–3.1] n = 79	–0.5 (–2.4, 1.3) [–1.4] n = 84	0.6 (–0.7, 1.9) [0.3] n = 78	–0.3 (–1.7, 1.1) [0.0] n = 82
Decline in ppFVC ≥10%, n/N (%)[a]	15/91 (16.5)	5/93 (5.4)	14/79 (17.7)	11/84 (13.1)	2/78 (2.6)	8/82 (9.8)
Improvement in ppFVC >0% change, n/N (%)[a]	26/91 (28.6)	43/93 (46.2)	22/79 (27.8)	35/84 (41.7)	39/78 (50.0)	40/82 (48.8)
Improvement in ppFVC ≥10% change, n/N (%)[a]	1/91 (1.1)	8/93 (8.6)	4/79 (5.1)	9/84 (10.7)	4/78 (5.1)	3/82 (3.7)

*Observed data. NA, not assessed.

(0.7, 10.0) per 100 PY for PBO→OL TCZ patients, and 3.0 (1.3, 5.9) for all TCZ exposure over 96 weeks. One death occurred during the OL period in each arm (TCZ→OL TCZ, pulmonary hypertension; PBO→OL TCZ, brain injury).

Conclusion: Although OL data have to be interpreted with caution, results from OL TCZ treatment show numeric improvements in mRSS and FVC preservation similar to those of the DB period, with a beneficial effect on trajectory of FVC decline in patients who switched from PBO to TCZ. Long-term safety results were consistent with the known safety profile of TCZ, and no new or unexpected events were observed.

Assessing Adherence to Screening of Systemic Sclerosis-Related Lung Disease

Matthew Herrmann[1] and Zineb Aouhab[1], [1]Loyola University Medical Center, Maywood, IL

SESSION INFORMATION
Session Date: Friday, November 6, 2020
Session Title: Systemic Sclerosis & Related Disorders – Clinical Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Feared complications of systemic sclerosis (SSc) affect the pulmonary system, with pulmonary hypertension and interstitial lung disease being common causes of mortality. Baseline and annual transthoracic echocardiography (TTE) screening for pulmonary hypertension in asymptomatic patients is recommended by experts

Table 1: Baseline Demographics and Clinical Characteristics

Variable	*n* (%)
Sex	
Female	57 (87.69)
Male	8 (12.31)
Race

Chart 1: Primary Outcome

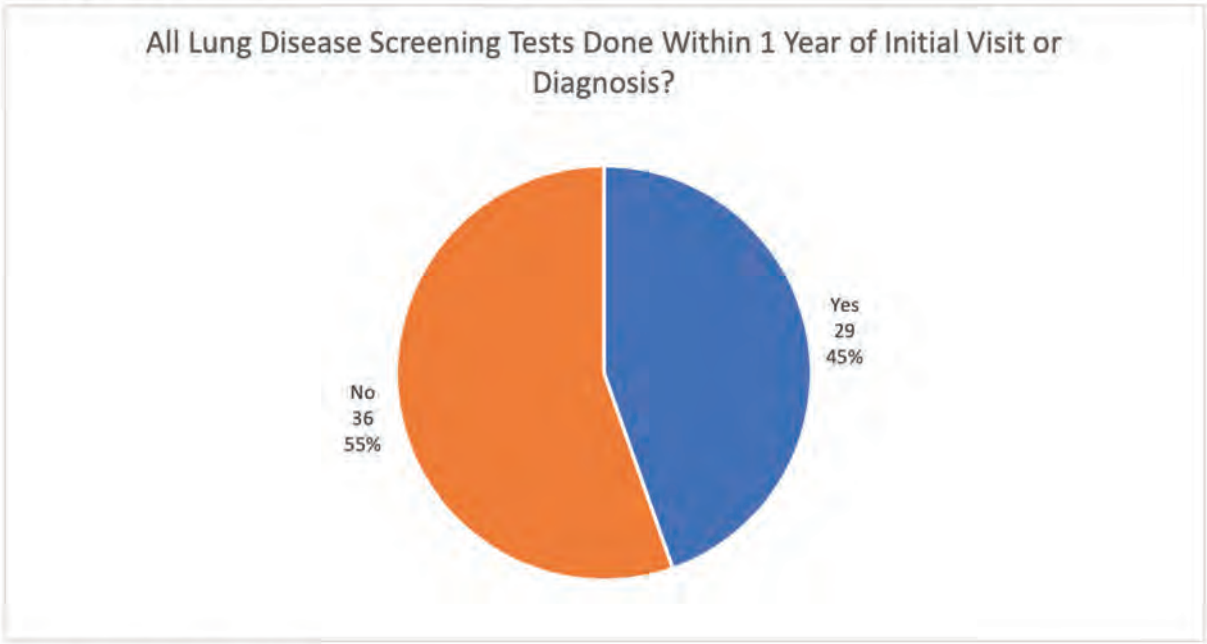

Chart 2: Secondary Outcome

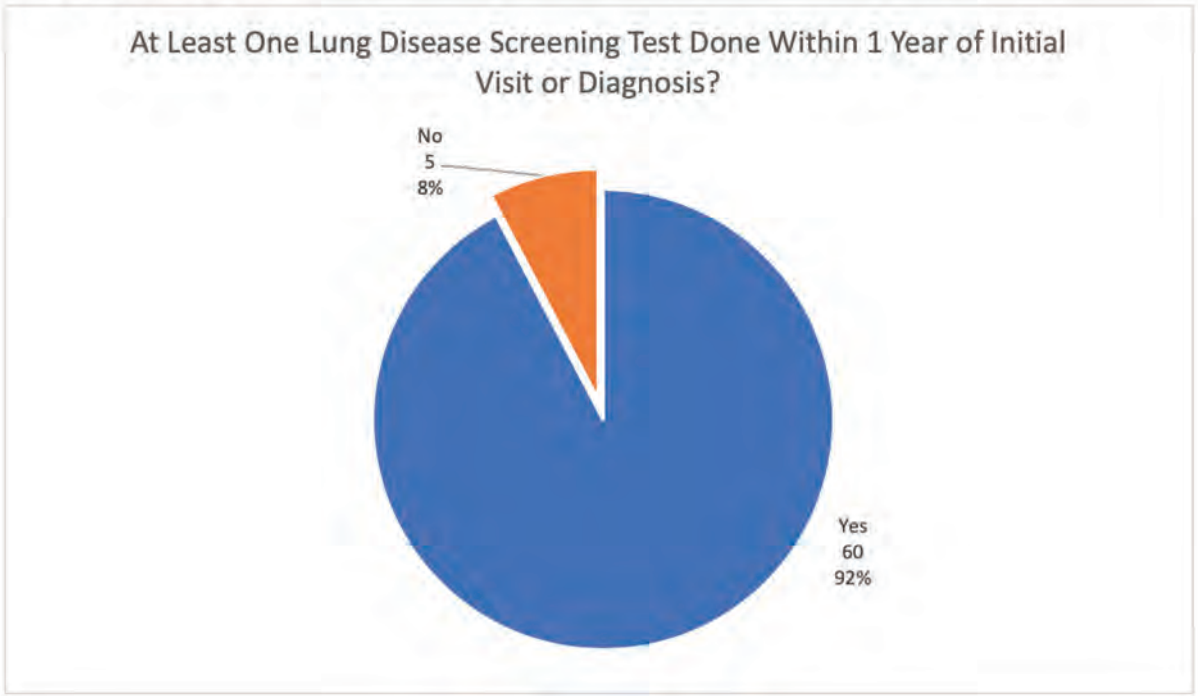

from the American College of Cardiology, American Heart Association, European Society of Cardiology, and European Respiratory Society.[1] For screening of interstitial lung disease (ILD) in SSc, it is recommended that computed tomography (CT) of the chest in addition to pulmonary function tests (PFTs) be obtained at baseline. Based on expert opinion, PFTs should then be obtained every two years in asymptomatic patients with normal diffusing capacity.[2]

The aim of our quality improvement study was to assess the compliance rate of the Division of Rheumatology at Loyola University Medical Center in screening patients for SSc-related lung disease within one year of diagnosis, or at the initial encounter in those patients with a preexisting diagnosis of SSc.

Table 2: Secondary Outcomes

Variable	Median Frequency of Tests/Patient Years (IQR)
Pulmonary Function Tests	0.83 (0.19-1.0)
Transthoracic Echocardiogram	1.0 (0.41-1.75)

Methods: Patients with a diagnosis of SSc at Loyola University Medical Center between January 1, 2010 and June 1, 2019 were screened for study inclusion. Medical records were retrospectively reviewed and data collected included demographic information and dates of PFTs, TTEs, and chest CT scans. The primary endpoint was the proportion of patients who have all three lung disease screening tests done within one year of diagnosis or at the initial encounter in patients with a preexisting diagnosis of SSc. Secondary endpoints included the proportion of patients having at least one screening test done within this same time frame, as well as the frequency of follow-up PFTs and TTEs. Nonparametric univariate statistics were used to quantify the frequency in which SSc patients had PFTs and TTEs performed.

Results: A total of 122 patients were screened, and 65 fulfilled inclusion criteria. The primary outcome was reached in 29 patients (44.62%), and not reached in 36 patients (55.38%). At least one lung disease screening test was performed within one year of diagnosis or initial visit in 60 patients (92.31%), and not performed in 5 patients (7.69%). Of the three lung disease screening tests CT of the chest was obtained the most infrequently, with 35 patients (53.85%) having the test performed, and 30 patients (46.15%) not having the test performed. The median number of PFTs per patient years was 0.83 (IQR 0.19-1.0), while the median number of TTEs per patient years was 1.0 (IQR 0.41-1.75).

Conclusion: Our study showed that while the majority of SSc patients have at least one lung disease screening test within one year of diagnosis or initial visit, only about half of the patients had CT of the chest performed. Several cohorts involving SSc patients have suggested that more than half of patients may have ILD at diagnosis despite an absence of symptoms. Therefore, efforts should be made to obtain CT scans as early as possible in the course of diagnosis, and further quality improvement measures should be instituted to help achieve this goal.

SESSION INFORMATION

Session Date: Friday, November 6, 2020

Session Title: Systemic Sclerosis & Related Disorders – Clinical Poster I

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: Interstitial lung disease (ILD) is the leading cause of death in patients with systemic sclerosis (SSc). Although pulmonary function tests (PFTs) are commonly used to screen for ILD in patients with SSc, studies have shown that they lack sensitivity for the detection of ILD. Moreover, although high resolution computed tomography (HRCT) scan of the chest is the gold standard test for detection of ILD, there is no consensus among rheumatologists regarding the use of HRCT to screen for ILD in their SSc patients. The aims of this study were to describe the HRCT ordering practices at expert SSc centers in the US, and to determine which patient characteristics are associated with HRCT ordering.

Methods: We performed a retrospective cohort study of patients enrolled in the Collaborative National Quality and Efficacy Registry (CONQUER) at 13 sites in the US between June 6, 2018, and February 1, 2020. CONQUER is a US-based, multicenter cohort of adults with SSc who met 2013 ACR/EULAR Classification Criteria and had a disease duration ≤5 years from the 1st non-Raynaud's symptom at enrollment. We used the Student's t test, chi square test, and Fisher's exact test, as appropriate, to compare baseline characteristics between participants who did and did not undergo HRCT. We performed univariate logistic regression (LR) followed by multivariable LR to determine which patient characteristics were associated with HRCT ordering. Each variable that attained a p-value< 0.1 in the univariate analysis was included in the final multivariable LR model, as were age and sex. Statistical significance in the univariate and multivariable models was defined as a p-value< 0.05.

Results: 356 SSc patients were enrolled in CONQUER, of whom 285 (80%) underwent HRCT at some point during their SSc disease course. Among those who underwent HRCT compared to those who did not, a smaller proportion were centromere positive (9.5% vs. 22.5%) and a greater proportion had crackles on exam (23.5% vs. 9.9%). SSc patients who underwent HRCT had lower forced vital capacity (FVC), forced expiratory volume in 1 second (FEV1), and diffusion capacity for carbon monoxide (DLCO) than those who did not (Table 1). In univariate analyses, the following variables were statistically significantly associated with HRCT ordering: crackles on pulmonary exam, FVC< 80%, FEV1< 80%, total lung capacity (TLC)< 80%, missing TLC%, and DLCO< 60% (Table 2). A positive centromere antibody was negatively associated with HRCT ordering. In the final multivariable LR model, positive centromere

Results are based on a multivariable model, adjusting for each of the predictors in this table.
HRCT = high resolution computed tomography of the chest; SHAQ = Scleroderma Health Assessment Questionnaire; FVC = forced vital capacity; TLC = total lung capacity; DLCO = diffusion capacity for carbon monoxide

antibody remained negatively associated and missing TLC% remained positively associated with HRCT ordering (Table 3).

Conclusion: 80% of SSc patients enrolled in CONQUER at 13 expert SSc centers in the US underwent HRCT. Abnormal PFTs and crackles were associated with HRCT ordering in univariate analyses. However, in the multivariable analysis, only a positive centromere antibody remained associated with a decreased odds of HRCT ordering and a

missing TLC% remained associated with an increased odds of HRCT ordering. Given the poor sensitivity of PFTs for the detection of SSc-ILD, research is needed about how to increase rheumatologists' HRCT ordering practices in their SSc patients.

A Heavy Burden of Calcinosis Reflects Cumulative Disease Damage in Scleroderma

Carrie Richardson[1], Jamie Perin[2], Scott Zeger[3], Fredrick Wigley[4], Laura Hummers[5], Livia Casciola-Rosen[6], Antony Rosen[7] and Ami Shah[8], [1]Rush University Medical Center, Chicago, IL, [2]JHUSPH, Baltimore, [3]Johns Hopkins University, Baltimore, [4]Johns Hopkins University School of Medicine, Baltimore, MD, [5]Johns Hopkins Univerisity, Ellicott City, MD, [6]Johns Hopkins University, Johns Hopkins University, MD, [7]Johns Hopkins University, Baltimore, MD, [8]Johns Hopkins University School of Medicine, Ellicott City, MD

SESSION INFORMATION
Session Date: Friday, November 6, 2020
Session Title: Systemic Sclerosis & Related Disorders – Clinical Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Ectopic calcification, or calcinosis, is a common complication of scleroderma. However, a subset of scleroderma patients has a heavy burden of calcinosis, which may have unique risk factors compared to a light burden of calcinosis.

Methods: We determined calcinosis burden of patients in the Johns Hopkins Scleroderma Center cohort database through chart review. A heavy burden was defined as calcinosis deposits in three or more body areas excluding the hands and fingers, mass-like or bulky deposits, and/or sheet-like or plaque-like deposits on physician exam. A light burden was defined as calcinosis present but not meeting the criteria for heavy burden by chart review. No calcinosis was defined as calcinosis recorded as absent in the Scleroderma Center database. We performed exploratory analyses comparing clinical, demographic, and serologic parameters by burden status. We then performed latent class analysis to identify scleroderma phenotypic classes followed by multinomial logistic regression to determine whether latent phenotypic classes and autoantibodies are independent risk factors for a light burden or a heavy burden of calcinosis.

Results: 29.4% (997/3388) of patients with scleroderma had calcinosis. 13.5% (130/963) had a heavy burden. The phenotypic class (Class 3 in Table 1) with predominantly diffuse skin disease as well as the greatest overall disease

Table. Association between calcinosis burden, phenotypic class, and autoantibodies among 3388 scleroderma patients, adjusting for race, disease duration, and sex*

Class 2	0.00	0.40	1.00	(0.45, 2.20)	0.992
Class 3	1.84	0.31	6.29	(3.42, 11.57)	<0.001

*Light burden and heavy burden are each compared to the group without calcinosis. Phenotypic classes 1-3 are assessed relative to the reference class 4.

Table 3: Multivariable model

severity was associated with an increased risk of both a heavy burden of calcinosis (OR 6.29, 95% CI 3.42-11.57; p< 0.001) and a light burden of calcinosis (OR 2.71, 95% CI 2.01-3.65; p< 0.001) compared to the reference class with predominantly limited skin disease (Class 4). The phenotypic class with predominantly sine skin disease (Class 1) was associated with a decreased risk of a light burden of calcinosis (OR 0.26, 95% CI 0.16-0.42; p< 0.001) compared to Class 4 but was not significantly associated with a high burden. The phenotype with predominantly diffuse skin disease but less severe extra-cutaneous disease compared to Class 3 (Class 2) was not associated with either a light or heavy burden of calcinosis. Autoantibodies to PM100 (OR 4.04, 95% CI 1.53 to 10.68; p=0.005) and PM75 (OR 3.07, 95% CI 1.23 to 7.68; p=0.024) were associated with an increased risk of a heavy burden of calcinosis.

Conclusion: Calcinosis burden may reflect cumulative scleroderma-related tissue damage. Independent of disease activity, autoantibodies to the PM/Scl complex are associated with a high burden of calcinosis, indicating the possibility of excess subclinical disease activity or aberrant tissue repair in patients with this unique immunologic response.

Outcomes of Systemic Sclerosis Hospitalizations by Hospital Teaching Status: Analysis of the National Inpatient Sample

Ehizogie Edigin[1], Precious Eseaton[2] and Pius Ojemolon[3], [1]John H Stroger Jr. Hospital of Cook County, Chicago, IL, [2]University of Benin Teaching Hospital, Benin, [3]St. George's University, St. George's, Grenada

SESSION INFORMATION
Session Date: Friday, November 6, 2020
Session Title: Systemic Sclerosis & Related Disorders – Clinical Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Systemic sclerosis (SSc) is a chronic autoimmune connective tissue disease that results in hospitalizations in different hospital settings. It is unclear if outcomes of SSc hospitalizations differ between teaching and non-teaching hospitals. This study aims to compare outcomes of SSc hospitalizations between teaching and nonteaching hospitals.

Methods: Data were abstracted from the National Inpatient Sample (NIS) Database. NIS is the largest inpatient admission database in the United States. It is a nationally representative sample of 20% of hospitalizations from approximately 1000 hospitals. The numbers in the databases are weighted to optimize national estimates. The NIS was searched for SSc hospitalizations in 2016 using ICD-10 code "M34" as the principal or secondary diagnosis. Only hospitalizations for patients aged ≥ 18 years were included. The primary outcome was inpatient mortality. Multivariate logistic regression analysis was used to adjust for confounders for the primary outcome. Secondary outcomes were hospital length of stay (LOS) and total hospital charges. Multivariate linear regression analysis was used to adjust for confounders for the secondary outcomes. Confounders adjusted for include age, sex, race, median income expected for zip code, Charleston comorbidity index, insurance status, hospital location/region, and bed size. STATA software was used to analyze the data.

Results: There were over 35 million discharges included in the 2016 NIS database. 30,965 hospitalizations were for patients aged ≥18 years, who had either a principal or secondary ICD 10 code for SSc. 22,280 of these hospitalizations (72%) were in teaching hospitals, while 8,685 hospitalizations (28%) were in nonteaching hospitals. The mean age for teaching hospital hospitalizations was 61.45 vs 64.56 for nonteaching hospitals (P< 0.0001). 1,395 (4.5%) hospitalizations resulted in inpatient mortality. Inpatient mortality occurred in 4.7% of hospitalizations in teaching hospitals vs 4.1 % in nonteaching hospitals (P=0.3164). The adjusted odds ratio (AOR) of inpatient mortality in teaching hospitals compared to nonteaching hospitals was 1.05 (95% CI 0.78-1.42, P=0.75). Mean LOS for hospitalizations in teaching hospitals was 6.67 vs 5.18 days for nonteaching hospitals. Hospitalizations in teaching hospitals have a mean increase in Adjusted LOS of 1.12 days (95% CI 0.69-1.54, P< 0.0001) compared to nonteaching hospitals. Total hospital charges for hospitalizations in teaching hospital was $75,943.58 vs $51,611.54 for nonteaching hospitals. Hospitalizations in teaching hospitals have an increase in adjusted total hospital charges of $16,333 compared to nonteaching hospitals (95% CI 9,005-23,660, P< 0.0001).

Conclusion: There was no statistically significant difference in inpatient mortality for SSc hospitalizations in teaching compared to nonteaching hospitals. SSc hospitalizations in teaching hospitals had younger patients, more LOS, and total hospital charges compared to nonteaching hospitals.

Methods: A single-center, retrospective study of SSc patients was performed. A previously described cohort (Moore 2019) composed of African American and non-African American SSc patients matched 1:1 by sex, age, date of first visit, disease duration at first visit, and limited vs. diffuse cutaneous disease was used. The 2013 ACR/EULAR Classification Criteria for SSc were fulfilled in 91% of these patients. Patient data were re-abstracted to evaluate specifically for fulfillment of the 2019 EULAR/ACR Classification Criteria for SLE and the 2012 SLICC Criteria for the Classification of SLE. Demographic, laboratory, and clinical features and mortality were compared among SSc-SLE overlap and non-overlap SSc patients.

Results: 402 patients with SSc were analyzed. 40 (10%) of patients fulfilled the 2019 EULAR/ACR SLE criteria, 41 (10%) fulfilled the 2012 SLICC criteria, and 33 (8.2%) fulfilled both sets of criteria. Table 1 shows the frequencies of the criteria items among patients who fulfilled the EULAR/ACR criteria. Neuropsychiatric and renal involvement were rare. Table 2 compares the features of overlap and non-overlap SSc patients. An initial diagnosis of SLE was purported in 43% of the overlap patients and 7% of non-overlap patients ($p < 0.001$). Overlap patients were more likely to be female, be African American, and have limited cutaneous SSc. Anti-U1RNP antibody positivity prevalence was only 30% among overlap patients, and lower at 6.6% among non-overlap patients ($p < 0.001$). Overlap and non-overlap patients were similar in the prevalence of other SSc-specific autoantibodies, Raynaud's phenomenon, scleroderma renal crisis, pulmonary fibrosis per CT scan, and pulmonary hypertension by right heart catheterization. Overlap patients were more likely to have received treatment with prednisone or hydroxychloroquine at any point. Death during follow-up occurred in 12 (30%) of SSc-SLE overlap patients and in 81 (22%) of non-overlap patients, but there was no difference in survival among the groups per log rank test ($p = 0.404$).

Conclusion: Approximately 10% of SSc patients fulfill the 2019 EULAR/ACR Classification Criteria for SLE. These SSc-SLE overlap patients comprise a distinct demographic, serologic, and clinical phenotype but sustain similar severe SSc-specific end-organ damage and mortality as non-overlap SSc patients. SLE patients with Raynaud's should be evaluated for SSc-specific autoantibodies and clinical features.

Session Date: Friday, November 6, 2020
Session Title: Systemic Sclerosis & Related Disorders – Clinical Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: The Very Early Diagnosis Of Systemic Sclerosis (VEDOSS) study has shown that more than 80% of patients with Raynaud's Phenomenon, specific ANA positivity and scleroderma pattern at nailfold video-capillaroscopy will fulfill classification criteria within 5 years. This is suggesting that there is a subclinical window of opportunity to diagnose systemic sclerosis (SSc) before clinical manifestations occur. In this scenario, a non-invasive tool to diagnose SSc in clinically unaffected skin might improve the early detection of disease in at risk-patients. Optical coherence tomography (OCT) of the skin has been shown to be a sensitive and accurate biomarker of skin fibrosis in SSc. Here we aimed to assess the ability of skin OCT to "detect SSc" in clinically unaffected skin from a multicenter cohort.

Methods: Dorsal forearm skin of SSc patients and matched-healthy controls (HC) was evaluated using VivoSight scanner (Michelson Diagnostics). Mean A-scans (mean OCT signal plotted against depth-in-tissue) were derived as previously described. Minimum Optical Density (MinOD), Maximum OD (MaxOD) and OD at 300 micron-depth (OD300) were calculated. Clinical involvement was assessed by an operator blinded to OCT findings using the mRSS. Receiver-operating characteristic (ROC) curve analysis was carried out for MinOD, MaxOD, and OD300 to evaluate their ability to discriminate between SSc and HC. Statistical analysis was performed using GraphPad Prism software V.7.0.

Results: One hundred seventy four OCT images were collected from 87 subjects [43 SSc (39 Female, mean age 49.7 ± 9.1 years) and 44 gender/age-matched healthy controls (HC) (36 Female, mean age 50.2 ± 8.3 years)] in two different SSc centers. All patients fulfilled classification criteria for SSc. OCT measures demonstrated discriminative ability in SSc skin detection with any clinical skin involvement (0-3 at site of analysis) with an AUC of 0.73 (MinOD, 95%CI 0.64-0.81), 0.77 (MaxOD, 95%CI 0.7-0.85) and 0.82 (OD300, 95%CI 0.76-0.89); $p < 0.0001$ for all as previously indicated. Most importantly, all three measures showed comparable performance in detecting scleroderma also in clinically unaffected skin (mRss=0 at site of analysis), with an AUC of 0.7 (95%CI 0.6-0.81, p=0.001), 0.72 (95%CI 0.61-0.83, p=0.0003) and 0.72 (95%CI 0.61-0.83, p=0.0003) for MinOD, MaxOD and OD300 respectively.

Conclusion: Virtual biopsy by OCT recognises clinically unaffected skin of SSc patients from the HC skin. This is in line with gene array data showing that scleroderma specific signatures are consistent in affected and clinically unaffected skin. These results inform future studies on at risk patients with clinically unaffected skin which may define a role for OCT in detecting subclinical SSc.

Comparison of Immediate Post-Operative and Long-Term Outcomes in Aortitis and Non-Inflammatory Thoracic Aortic Aneurysms Undergoing Open Surgical Repair

Adam Mayer[1], Alexandra Sperry[2], Laarni Quimson[3] and Rennie Rhee[4], [1]University of Pennsylvania, Internal Medicine/Pediatrics Residency Program, Philadelphia, PA, [2]Perelman School of Medicine at the University of Pennsylvania, Philadelphia, PA, [3]Division of Rheumatology at the University of Chicago, Chicago, IL, [4]University of Pennsylvania, Philadelphia, PA

SESSION INFORMATION
Session Date: Friday, November 6, 2020
Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Around 2-12% of patients who undergo open thoracic aortic aneurysm repair are incidentally found to have aortitis on pathology. There is no standardized approach to the post-operative care of patients with incidentally-found aortitis nor extensive data on post-operative and long-term outcomes. A better understanding of the risk for recurrent vascular disease and surgical complications in this population could inform clinical surveillance and treatment. This study compared immediate post-operative and long-term outcomes between patients with pathology-diagnosed aortitis and those with non-inflammatory aortic aneurysms after undergoing open thoracic aortic aneurysm repair.

Methods: This is a single-center matched cohort study. Patients with aortitis were identified by histopathology following open thoracic aortic aneurysm repair in the University of Pennsylvania Health System between 2007 and 2017 and lacked any evidence of infection or known prior diagnosis of rheumatic disease. Two comparators who lacked significant inflammation on pathology were matched to each aortitis case by year of surgical repair. Outcomes included length of hospital stay, surgical complications, formation of new vascular abnormalities on CT/MRI imaging, and death. Differences between groups were compared using conditional logistic, Cox proportional hazards, or conditional Poisson regression models accounting for matching.

Results: For the analysis, 162 patients were included: 53 patients with aortitis and 109 matched comparators with similar follow-up time between groups (median follow-up 3.7 vs 3.3 years) (**Table 1**). Aortitis patients were more likely to be older, female and less likely to have a history of coronary artery disease. 93% of each group had an ascending thoracic aortic aneurysm that was repaired **(Table 1)**. Patients with aortitis had a significantly longer hospital length of stay even after adjusting for perioperative glucocorticoid use and referral to rheumatology (adjusted IRR 1.35 (1.19 to 1.53), $P < 0.01$). There was no difference in rates of post-operative complications or surgical revision between groups (**Table 1**). On long-term surveillance imaging, no difference was seen in new or worsening aortic aneurysms between groups, but there were significantly more vascular abnormalities in the thoracic aortic branch arteries (carotid, subclavian, brachiocephalic, and celiac arteries) in the aortitis group (39% vs. 11%, $P < 0.01$)(**Table 2, Figure**).

Conclusion: Among patients who underwent open surgical repair of a thoracic aortic aneurysm, patients with incidentally-discovered aortitis were more likely than non-inflammatory comparators to have a longer hospital length of stay and develop vascular anomalies in major aortic branch arteries. The higher rate of arterial abnormalities in patients with aortitis may reflect ongoing inflammatory changes from an underlying vasculitic process and suggest that more frequent surveillance imaging and involvement of a rheumatologist are needed in the long-term care of these patients.

Table 1. Immediate post-operative outcomes in patients with aortitis vs non-inflammatory comparators.

Isolated Aortitis: Single Centre Experience of Clinical Spectrum and Management

Nadia Ahmad[1], Ayna Verdiyeva[2], Raashid Luqmani[2] and Shirish Dubey[2], [1]Oxford University Hospitals NHS Foundation Trust, Reading, United Kingdom, [2]Oxford University Hospitals NHS Foundation Trust, Oxford, United Kingdom

SESSION INFORMATION
Session Date: Friday, November 6, 2020
Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Aortitis was previously regarded as a rare form of large vessel vasculitis (LVV), but is now increasingly being recognised. It may occur in the context of primary systemic vasculitis, as a part of systemic autoimmune disease or in isolation. Positron emission tomography (PET) has facilitated the diagnosis of LVV which is often a challenge as the presenting clinical features are often nonspecific. The outcome and optimal management remain uncertain; EULAR 2018 recommendations on LVV have helped to address some of these issues [EULAR 2018 guidelines (Hellmich B, et al. Ann Rheum Dis 2020;79:19–30)]

We aimed to assess the presenting features, time to diagnosis, imaging methods utilized, treatment and complications in a cohort of patients with isolated aortitis.

Methods: We identified patients diagnosed with isolated aortitis presenting at our centre over the last 10-years. Patients were identified using a specifically designed database, which prospectively phenotyped all patients attending a single rheumatology department. Their medical notes were retrospectively reviewed using the electronic patient record system.

Results: We identified 63 patients who had been diagnosed with isolated aortitis (IA) over the last 10 years; 5 were excluded due to incomplete data.

Demographic data and main results are presented in Table 1. The median age at diagnosis of aortitis was 68 years (range 32 - 88); 36 (62%) were females. The median duration of symptoms was 7 months (range 2-120). The commonest presenting feature was systemic inflammatory syndrome in 28 patients (49%) followed by back/abdominal pain in 8, chest symptoms in 6 and weight loss in 4. Acute presentation with dissection/aneurysm was seen in 6 patients who also had histological confirmation of aortitis.

Patients had elevated inflammatory markers (median CRP 81 [range16-249]; median ESR 79 [range 11-139]) at presentation. 43 patients (74%) were diagnosed on PET CT with aortitis, 12 (21%) on CT angiogram aorta (CTA) and 3 (5%) on CT chest/full body performed to rule out other diagnoses. Follow up imaging included MRA in 60, CTA in 56 and PET CT in 30 patients.

Prednisolone and disease modifying anti-rheumatic drugs (DMARDs) were used in the majority of patients (90% and 93% respectively), with methotrexate being the commonest DMARD. Cyclophosphamide was used in 11 patients and 4 patients received tocilizumab.

Parameter	Overall Population (n=58)
Age at Diagnosis (yr.), mean, (S.D.)	68, (13)
Sex, Female	36 (62%)
Ethnicity	
White	49 (85%)
South Asian	7 (12%)
Others	2 (3%)
Risk Factors	
Smoker	27 (47%)
Hypertension	26 (45%)
Hyperlipidaemia	13 (22%)
Coronary artery disease	7 (12%)
Diabetes mellitus	3 (5%)
Atherosclerosis	3 (5%)
Underlying carcinoma	4 (7%)
Presentation	
Systemic inflammatory syndrome	28 (49%)
Back/Abdominal pain	8 (14%)
Chest Symptoms	6 (10%)
Dissection	5 (9%)
Weight loss	4 (7%)
Headache	2 (3%)
Neurological Symptoms	2 (3%)
Claudication	2 (3%)
Aneurysmal disease	1 (2%)
Treatment	
Corticosteroids	52 (90%)
Immunosuppressive	
First line	
Methotrexate	45 (78%)
Leflunomide	3 (5%)
Cyclophosphamide	5 (9%)
Mycophenolate	1 (2%)
Biologics	
Tocilizumab	4 (7%)

The median duration of follow up was 3 years (range 0.30 - 10). 17 patients developed vascular complications, including aneurysms (8 patients), vascular stenosis/ischaemic complications (9 patients) with 4 patients requiring subsequent vascular/surgical interventions.

Drug free remission was achieved in 13 (23%) patients and they remain in remission whilst off treatment for a median duration of 11 months (range 2-40). 4 patients died during follow up, 3 due to sepsis and 1 to unknown cause.

Conclusion: We have reviewed the clinical features, treatment and complications of a cohort of patients with isolated aortitis. Diagnostic delay remains an issue, highlighting the need for increasing awareness of this condition. Vascular complications are high in this group, despite aggressive immunosuppression and only a minority achieve sustained drug free remission.

SESSION INFORMATION

Session Date: Friday, November 6, 2020

Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster I

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: Recurrent, painful oral ulcers (OU) are common symptoms of Behçet's syndrome that can impact daily activities and impair quality of life (QoL) (Kokturk A. *Patholog Res Int*. 2012;2012:690390; Hatemi G, et al. *Ann Rheum Dis*. 2018;67:808-818). Apremilast (APR), an oral phosphodiesterase 4 inhibitor, demonstrated efficacy in the treatment of OU associated with Behçet's syndrome, including improvements in OU pain, disease activity, and QoL, in the phase III RELIEF study (Hatemi G, et al. *N Engl J Med*. 2019;381:1918-1928). We describe outcomes in APR-treated patients in the RELIEF study who achieved complete response of OU (ie, OU-free) by Week 6 and remained OU-free for at least an additional 6 weeks compared with those who did not.

Methods: RELIEF was a phase III, multicenter, randomized, double-blind, placebo (PBO)-controlled study (BCT-002; NCT02307513). Adult patients (≥18 years of age) with active Behçet's syndrome and ≥3 OU at randomization or ≥2 OU at screening and randomization, without active major organ involvement, were randomized (1:1) to APR 30 mg BID or PBO during the 12-week PBO-controlled phase. In patients who received APR, a post hoc analysis compared outcomes in patients who achieved an OU-free response by 6 weeks and remained OU-free for at least 6 weeks thereafter (6+6 achiever) with outcomes in those who did not achieve an OU-free response at any time point, or those who did but were not able to remain OU-free for at least 6 weeks thereafter (non-6+6 achiever). Outcomes assessed at Week 12 included OU pain visual analog scale (VAS; 0-100 mm), disease activity measures (components of the Behçet's Disease Activity Index Form: Behçet's Disease Current Activity Index [BDCAI], Patient's Perception of Dis-

Changes From Baseline at Week 12 in Efficacy Outcomes With APR 30 mg BID Treatment in 6+6 Achievers and Non-6+6 Achievers in the RELIEF Study

Outcome	APR 6+6 Achiever n = 31	APR Non-6+6 Achiever n = 73
OU pain VAS, LS mean change (SE)	−49.5 (1.8)	−35.3 (4.2)
BDCAI, LS mean change (SE)	−1.4 (0.4)	−0.7 (0.2)
Patient's Perception of Disease Activity, LS mean change (SE)	−2.4 (0.3)	−1.4 (0.2)
Clinician's Overall Perception of Disease Activity, LS mean change (SE)	−2.3 (0.2)	−1.3 (0.2)
BSAS, LS mean change (SE)	−23.9 (2.1)	−14.1 (2.2)
BDQoL, LS mean change (SE)	−5.6 (1.3)	−2.7 (0.8)

Intent-to-treat population. Last-observation-carried-forward analysis.
6+6 Achiever = patients who achieved OU-free response by 6 weeks and remained OU-free for at least 6 weeks thereafter. Non-6+6 Achiever = patients who did not achieve OU-free response by 6 weeks or did but were not able to remain OU-free for at least 6 weeks thereafter.

ease Activity, Clinician's Overall Perception of Disease Activity, and Behçet's Syndrome Activity Scale [BSAS]), and a QoL measure (Behçet's Disease Quality of Life [BDQoL]). OU pain VAS scores, disease activity measures, and BDQoL scores were analyzed using an analysis of covariance model.

Results: Of the 207 patients who were randomized and received ≥1 dose of study medication, 104 received APR; of these, 31 (29.8%) were 6+6 achievers and 73 (70.2%) were non-6+6 achievers. 6+6 achievers, as defined above, showed greater improvements from baseline in outcomes beyond OU count, such as OU pain VAS score, measures of disease activity, and QoL measures, compared with non-6+6 achievers (Table).

Conclusion: In RELIEF, patients who achieved an OU-free response by Week 6 and remained OU-free for an additional 6 weeks with APR treatment showed greater improvements in clinically relevant outcomes, including OU pain, overall disease activity, and QoL, than those who did not achieve or maintain an OU-free response.

- **Relapses, median (IQR)**	0 [0-1]	0 [0-2]	0.46
- **Remission, %**	100	75.6	0.02
- **Severe side effects, n (per 100 patients/year)**	0 (0)	3 (0.78)	0.55
- **Cost (mean), euros per year**	4826.52	9854.13	-

Background/Purpose: Biologic therapy has improved prognosis of Behçet Disease (BD) uveitis. Although infliximab (IFX) is approved in Japan, most data in Caucasian patients comes from small series and no data on IFX optimization has been published. In the present study we assessed: **a)** long-term efficacy and safety of IFX and **b)** IFX optimization when ocular remission was achieved

Methods: Multicenter study of IFX-treated patients with BD uveitis refractory to conventional immunosuppressants.103 patients were treated with IFX as 1st biologic as follows: 3-5 mg/kg i.v. at 0, 2, 6 and every 4-8 weeks. The main outcomes were anterior chamber cells, vitritis, retinal vasculitis, macular thickness, best corrected visual acuity, and the glucocorticoids sparing effect that were analysed at baseline, 1st week, 1st and 6th months and 1st and 2nd years. After remission, based on a shared decision between patient and clinician, IFX optimization was performed. Efficacy, safety, and IFX cost were evaluated

Results: In whole series (n=103), main outcomes showed a rapid and maintained improvement, reaching remission in 78 patients after a mean IFX duration of 31.5 months. Severe side-effects were observed in 9 patients.

In the optimization subanalysis, comparative study between optimized and non-optimized groups showed: **a)** no differences in clinical baseline characteristics; **b)** similar maintained improvement in most ocular outcomes; **c)** lower severe adverse events and **d)** lower IFX cost in optimized group (4826.52 vs. 9854.13 euros/patient/year) **(Table)**

Conclusion: IFX seems effective and relatively safe in Caucasian patients with refractory BD uveitis. IFX optimization is also effective, safe, and cost-effective

Main general features and follow-up of a subgroup of patients (n= 60) with Refractory Uveitis Due to BD who Achieved Remission after the standard dose of IFX therapy (5 mg/kg at 0, 2, 6 and then every 8 weeks). Differences between Optimized and Non-optimized patients

Achievement of Early and Sustained Complete Response of Oral Ulcers with Apremilast Compared with Placebo in Patients with Active Behçet's Syndrome

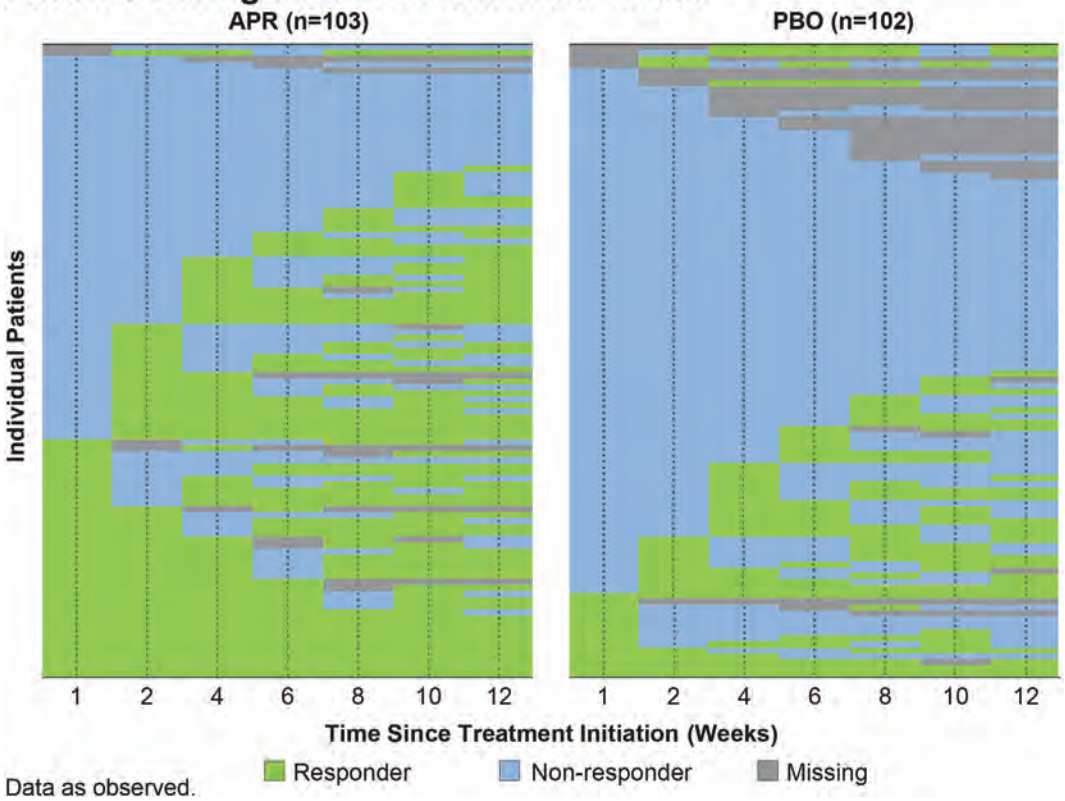
Gülen Hatemi[1], Alfred Mahr[2], Mitsuhiro Takeno[3], Doyoung Kim[4], Melike Melikoğlu[1], Sue Cheng[5], Sven Richter[5], Michele Brunori[6], Maria Paris[5], Mindy Chen[5] and Yusuf Yazici[7], [1]Istanbul University−Cerrahpaşa, Cerrahpaşa Medical School and Behçet's Disease Research Center, Istanbul, Turkey, [2]Cantonal Hospital St. Gallen, St. Gallen, Switzerland, [3]Nippon Medical School, Graduate School of Medicine, Tokyo, Japan, [4]Yonsei University College of Medicine and Severance Hospital, Seoul, Republic of Korea, [5]Amgen Inc., Thousand Oaks, [6]Amgen Europe GmbH, Rotkreuz, Switzerland, [7]New York University School of Medicine, New York

SESSION INFORMATION
Session Date: Friday, November 6, 2020
Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Painful and recurring oral ulcers (OU) are a common manifestation of Behçet's syndrome that can interfere with eating and have a negative impact on quality of life (Ozguler Y, et al. *Clin Exp Rheumatol*. 2019;37[6 Suppl 121]:28-34). Apremilast (APR), an oral phosphodiesterase 4 inhibitor, has demonstrated efficacy in the treatment of OU in the phase 3 RELIEF study (Hatemi G, et al. *N Engl J Med*. 2019;381:1918-1928). In RELIEF, 53% of patients treated with APR 30 mg BID and 22% who received placebo (PBO) achieved OU complete response at Week 12 (Hatemi G, et al. *N Engl J Med*. 2019;381:1918-1928). Here, we describe the achievement of OU complete response over different time points during the PBO-controlled period in RELIEF.

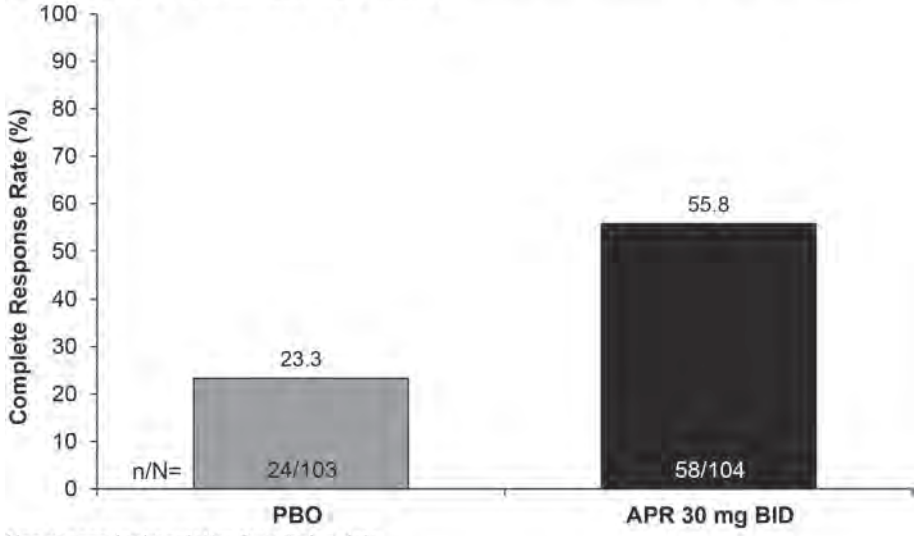
Methods: This multicenter, randomized, double-blind, PBO-controlled study (BCT-002; NCT02307513) enrolled adult patients (≥18 years of age) with active Behçet's syndrome and ≥3 OU at randomization or ≥2 OU at screening and randomization, without active major organ involvement. Patients were randomized (1:1) to receive APR or PBO during the 12-week PBO-controlled period. The current post hoc analysis assessed the proportion of individual patients who achieved OU complete response (ie, were OU-free) at any point during the PBO-controlled period and the proportion of patients who achieved complete response for OU as early as Weeks 1 or 2. The number of patients achieving OU complete response by Week 6 who remained OU-free for ≥6 additional weeks was also evaluated. Data are summarized descriptively.

Figure 1. Achievement of OU Complete Response for Individual Patients During the PBO-Controlled Period



Data as observed.

Figure 2. Achievement of Early OU Complete Response During Weeks 1 or 2 of the PBO-Controlled Period



Non-responder imputation for missing data.

Results: A total of 207 patients were randomized and received ≥1 dose of study medication, including 104 who received APR and 103 who received PBO. At baseline, the mean (SD) number of OU was 4.2 (3.7) in the APR group and 3.9 (2.7) in the PBO group. Mean (SD) duration of Behçet's syndrome at baseline was 6.7 (7.4) years in the APR group and 6.9 (8.0) years in the PBO group. The proportion of individual patients who achieved OU complete response at any time point during the 12-week PBO-controlled period was higher with APR than with PBO (Figure 1). Greater proportions of patients achieved early OU complete response during Weeks 1 or 2 with APR compared with PBO

(Figure 2). In total, 44/104 patients receiving APR and 24/103 patients receiving PBO had OU complete response by Week 6; of these, 33 patients in the APR group and 12 in the PBO group maintained OU-free response for ≥6 additional weeks.

Conclusion: In the RELIEF study, a higher proportion of patients with active Behçet's syndrome achieved OU complete response with APR treatment compared with PBO during the PBO-controlled period. Similarly, a greater proportion of patients achieved early OU complete response and maintained OU-free response with APR compared with PBO.

Epidemiology and Treatment of Behçet's Disease Insights from the Rheumatology Informatics System for Effectiveness (RISE) Registry

Nevin Hammam[1], Jinoos Yazdany[2] and Gabriela Schmajuk[3], [1]UCSF, San Francisco, CA, [2]University of California, San Francisco, San Francisco, CA, [3]University of California, San Francisco, Atherton, CA

SESSION INFORMATION
Session Date: Friday, November 6, 2020
Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Behçet's disease (BD), a rare multisystem vasculitis, is prevalent among Middle Eastern populations but remains rare in North America. Data for patients with BD in the U.S. are based on cohorts from single centers and limited by small sample sizes. Therefore, we sought to characterize BD in the U.S., analyzing patient characteristics and medication use across the RISE registry. We also compared the characteristics of U.S. patients with those from the Egyptian College of Rheumatology (ECR) registry, which represents one of the largest cohorts of BD patients to date (Gheita TA, et al. *Clin Rheumatol*. 2019).

Methods: We conducted a cross-sectional study using data from the RISE Registry (2014-2018). RISE contains patient data collected during routine clinical care through EHRs of participating rheumatology practices. As of 2018, RISE held validated data from 1,113 providers in 226 practices, representing ~32% of the US clinical rheumatology workforce. Patients aged ≥ 18 years with ≥ 1 diagnosis codes (ICD-9 or ICD-10) for BD were included. Sociodemographic, laboratory, and treatment information was extracted when available. The ECR BD registry, a population-based multicenter cohort, included adults aged ≥ 18 years who fulfilled the 2014 International Study Group diagnostic criteria for BD who presented to one of the included rheumatology centers during 2017-2018. Patients' demographic, clinical, and laboratory data in the ECR were collected and entered into a standardized data abstraction form. Data were summarized with descriptive statistics and comparisons were performed using t-tests and chi-square tests, as appropriate.

Table 1. Characteristics of patients with Behçet's disease in the RISE registry

Characteristics mean±SD / N (%)			Total patients (N=1323)

Abbreviations: RISE: Rheumatology Informatics System for Effectiveness, GC: glucocorticoid, csDMARDs: conventional disease modifying anti-rheumatic drugs, TNFi: tumor necrosis factor inhibitors. # Prednisone or equivalent included prednisone and other oral and intravenous steroids. *Other race: Asian, Not determined OMB race, and AMERICAN INDIAN OR ALASKA, NATIVE HAWAIIAN, # Other insurance: include Veteran, §include Rituximab, Abatacept, Tocilizumab, Ustekinumab, and Secukinumab. IQR: interquartile range.

Results: A total of 1323 subjects with BD from the RISE registry were included. The mean ± SD age was 48.7 ± 16.3 years, female to male ratio was 3.8:1, with 66.7% being White (Table 1). The most frequently used medications included glucocorticoids (67.6%) and colchicine (55.0%). Infliximab and adalimumab were the most commonly used biologics (14.5% and 14.1%, respectively); 3.2% of patients used apremilast.

In comparison to the ECR cohort, the RISE cohort had more women (49.0% in RISE vs. 27.8% in ECR, $p < 0.001$, Table 2) and patients were older (mean age (SD); 48.7 (16.3) in RISE vs. 35.7 (9.84) in ECR, $p < 0.001$). There were also significant differences in medication use, with methotrexate and TNFi used more commonly in RISE (21.8% and

Table 2 Comparison of BD characteristics between RISE and Egyptian college of rheumatology cohorts

Characteristics mean±SD / N (%)	RISE (N=1323)	ECR (N=1526)	P value
Demographics			
Age	48.7 (16.3)	35.7 (9.84)	<0.001
Female	1049 (79.3%)	424 (27.8%)	<0.001
Medication use			
Colchicine	728 (55.0%)	611 (82.7%)	<0.001
Prednisone or equivalent#	895(67.6%)	947 (90.2%)	0.002

Cyclophosphamide	8 (0.6%)	208 (20.1%)	<0.001
TNFi	491 (37.1%)	83 (8.3%)	<0.001

Abbreviations: RISE: Rheumatology Informatics System for Effectiveness, TNFi: tumor necrosis factor inhibitors.

37.1%) compared to the ECR (7.2% and 8.3%, $p < 0.001$) whereas colchicine, glucocorticoids, cyclosporine and cyclophosphamide had more widespread use in the ECR cohort.

Conclusion: We report on the largest population-based BD cohort in the U.S. using the RISE registry. Our findings suggest that U.S. patients with BD are predominantly female, which is in contrast to cohorts in the Middle East. Differences in medication use may be due to practice patterns or differences in the manifestations of BD. Further research is needed to explore the reasons for the increased prevalence of BD among women in the U.S. and its possible impact on disease severity and management.

Clinical Characteristics, Brain MRI Findings, and Diagnostic Approach of the Central Nervous System Vasculitis by Affected Vessel Size

Takashi Shimoyama[1], Ken Uchino[2], Leonard Calabrese[3] and **Rula Hajj-ali**[3], [1]Nippon Medical School, Nippon, Japan, [2]Cleveland Clinic, Cleveland, [3]Cleveland Clinic, Cleveland, OH

SESSION INFORMATION

Session Date: Friday, November 6, 2020
Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Diagnosis of the central nervous system vasculitis (CNS-V) is made on the basis of image findings or brain biopsy. Recently, two different subtypes of the disease have been postulated, the small (SVV) and large-medium vessel variant (LMVV). We hypothesized that the image profiles and diagnostic approaches would vary

between the LMVV and the SVV in patients with CNS-V. The aim of this study was to clarify the clinical characteristics, brain MRI findings, and diagnostic accuracy for high-resolution vessel wall image (HR-VWI) and brain biopsy according to affected vessel size in CNS-V patients from our prospective CNS vasculopathy registry.

Methods: We extracted CNS-V patients from our prospective CNS vasculopathy registry (n=201) from 2012-2019. Arterial involvement was assessed by digital subtraction angiography (DSA) or MR angiography (MRA). LMVV was defined as patients with cerebral vasculature indicating vasculitis in proximal or middle arterial segments. SVV was diagnosed with vessel involvements in only smaller distal branch or normal angiography. We compared clinical demographics, MRI findings including high-resolution vessel wall image (HR-VWI), and diagnostic accuracy for brain biopsy between two variants.

Results: We identified 34 cases who underwent cerebral vascular studies (DSA: n=26, MRA: n=32). Among them, 11 (32.4%) were LMVV and 23 (67.6%) were SVV based on angiographical findings. LMVV had more infarcts (LMVV: 100.0 % vs. SVV: 60.9%, P=0.017) and were more likely to have concentric vessel wall enhancement on HR-VWI (LMVV: 90.0% (9/10) vs. SVV: 7.1% (1/14), P< 0.001); summary in Table1.

By contrast, meningeal/parenchymal contrast enhancement lesion was more frequently observed in the SVV group (SVV: 87.0% vs. LMVV 45.5%, P=0.006) and the majority of SVV was diagnosed by brain biopsy (SVV: 78.3% vs. LMVV: 30.8%, P=0.022). The diagnostic accuracy of the brain biopsy was 100 % (18/18) in the SVV and 57.1% (4/7) in the LMVV, respectively (P=0.015); summary inTable 2.

Pleocytosis *	10 (90.9) [n=11]	12 (60.0) [n=20]	0.106
Elevated protein*	8 (72.7) [n=11]	13 (65.0) [n=20]	1.000

CSF; cerebral spinal fluid, LMVV; large/medium vessel variant, SVV; small vessel variant, CNS-V; central nervous system vasculitis.*Abnormal CSF is defined by either leukocyte counts >5 cells/mm^3 (pleocytosis) or protein level >45 mg/dl (elevated protein).

Brain biopsy and CSF findings between LMVV and SVV in CNS-V patients

Conclusion: Clinical and image characteristics of CNS-V seem to differ concerning the affected vessel size. LMVV is more likely to develop ischemic stroke and HR-VWI is useful for diagnosis of CNS-V with LMVV. Higher prevalence rate of mass lesion and leptomeningeal/parenchymal contrast enhancement lesion is associated with SVV; Brain biopsy is of high yield and thus should be considered in suspected CNS-V; higher yield of biopsy is associated with SVV variant but still positive in almost one third of LMVV variant

Exploring Gene Expression Profile of Primary Central Nervous System Vasculitis

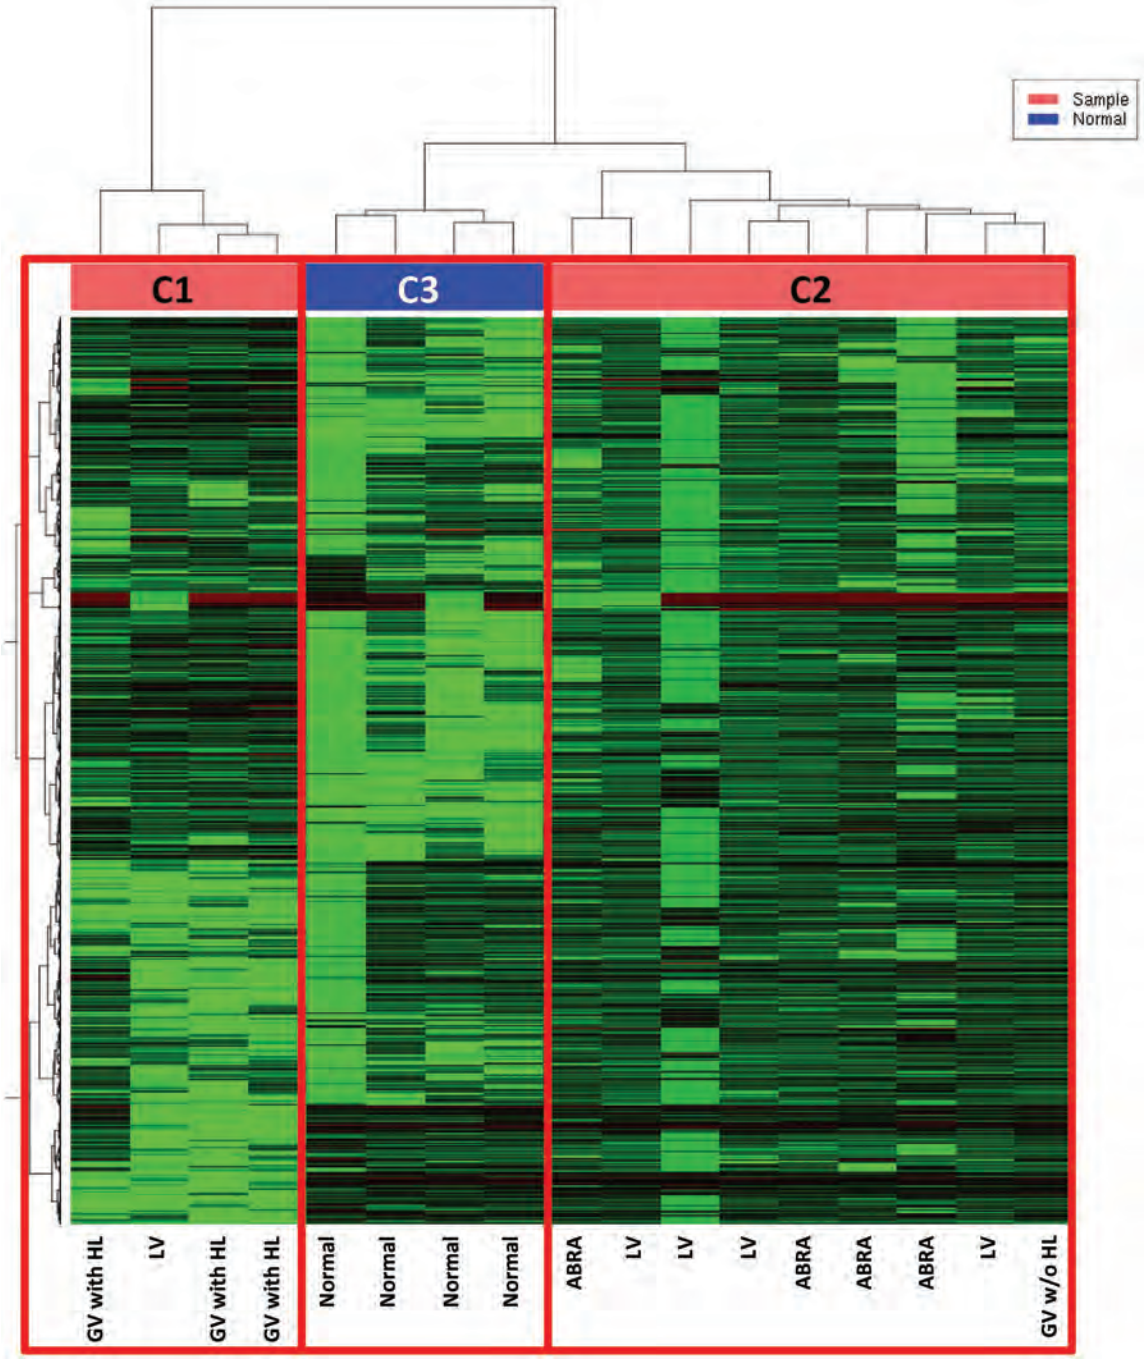
Carlo Salvarani[1], Robert Brown[2], Jonas Paludo[2], Stefania Croci[3], Stephen Ansell[4], Caterina Giannini[2], Joseph Parisi[2], Kenneth Warrington[2] and Gene Hunder[2], [1]Azienda USL-IRCCS di Reggio Emilia e Università di Modena e Reggio Emilia, Reggio Emilia, Italy, [2]Mayo Clinic, Rochester, MN, [3]Azienda USL-IRCCS di Reggio Emilia, Reggio Emilia, Italy, [4]Mayo Clinic, Rochester

SESSION INFORMATION
Session Date: Friday, November 6, 2020
Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Primary CNS vasculitis (PCNSV) is an uncommon and poorly understood disease that affects the brain and spinal cord. It includes heterogeneous histopathological patterns, clinical subsets, outcomes, and re-

sponse to treatment. PCNSV has also been associated with lymphoma suggesting an immunological paraneoplastic mechanism. The molecular hallmarks of PCNSV are still unknown. We investigated the gene expression profile of granulomatous vasculitis (GV) including with Hodgkin lymphoma (HL), lymphocytic vasculitis (LV) and amyloid β-related angiitis (ABRA).

Methods: Formalin fixed paraffin embedded (FFPE) brain biopsy samples were cut for histology and RNA extraction (n=3 GV with HL, n=1 GV without HL, n=5 LV, n=4 ABRA, n=4 normal brain). RNA-sequencing was performed using Illumina® Hiseq-4000 platform and the Illumina® TruSeq® Total-RNA library. Student's t-test and false discovery



Unsupervised Clustering by RNAseq: 3 clusters are clearly defined. No cases clustered with normal samples

rate (FDR) tests were performed for each of the differentially expressed transcripts. Ingenuity Pathway Analysis® was used for the pathway expression analysis.

Results: Samples clustered in three groups by unsupervised analysis of gene expression profile. Cluster 1 (C1) included all samples of GV with HL plus one of the samples of LV. Cluster 2 (C2) included all ABRA samples plus 4/5 LV samples and the GV not associated with HL. Normal brain samples clustered together in cluster 3 (C3). Results indicated that PCNSV has specific transcriptomes compared to normal brain and GV with HL have a distinct profile from the other types of PCNSV. Pathway analysis revealed upregulation of dendritic cell maturation and antigen processing, T helper type 1 lymphocyte activation and neuroinflammation in PCNSV versus normal brain. The comparison of the different kinds of PCNSV showed that GV expressed CD28 at lower levels than LV (FDR < 0.01) suggesting a lower activation of lymphocytes. The top differentially expressed genes between GV and ABRA were TRAJ13 and CD27 suggesting an expansion of naïve and memory T cells in GV. Finally, only one gene, namely CD163, was expressed at lower levels in LV than in ABRA (FDR < 0.05) suggesting a lower presence of macrophages or the presence of anti-inflammatory mediators.

Conclusion: RNA sequencing revealed pathways deregulated in PCNSV and genes differentially expressed between the different kinds of PCNSV increasing the knowledge on PCNSV pathogenesis. It also sugested that GV with HL has an distinct gene expression profile compared to other types of PCNSV.

Abstract Number: 0411

Serial Vessel Wall Enhancement Change on High-Resolution MRI Vessel Wall Imaging in Primary Central Nervous System Vasculitis

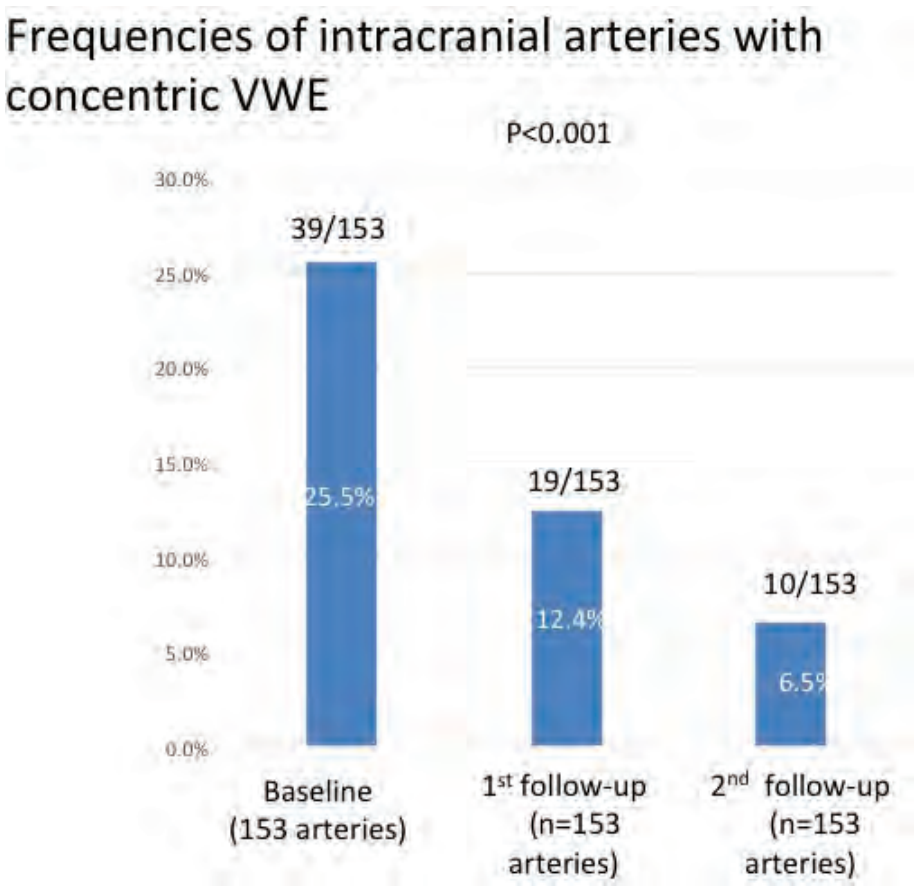
Takashi Shimoyama[1], Ken Uchino[2], Leonard Calabrese[2] and **Rula Hajj-ali**[2], [1]Nippon Medical School, Nippon, Japan, [2]Cleveland Clinic, Cleveland, OH

SESSION INFORMATION
Session Date: Friday, November 6, 2020
Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: High-resolution vessel wall imaging (HR-VWI) is emerging as a tool of notable utility in the diagnosis of central nervous system vasculitis (CNS-V). However, little is known about monitoring the response to treatments in these patients. The aim of this study was to investigate the temporal vessel wall enhancement (VWE) pattern and its clinical practice through the management of patients with CNS-V

Methods: We extracted 9 patients with primary CNS-V who underwent serial high-resolution MRI vessel wall image (HR-VWI) from Cleveland Clinic prospective CNS vasculopathy registry. Visibility and VWE were analyzed in 17 intracranial artery segments (Bilateral ICA, M1, M2, A1, A2, P1, P2, VA, and BA). Intraluminal enhancement was classified into 3 categories (none, eccentric VWE, and concentric VWE).

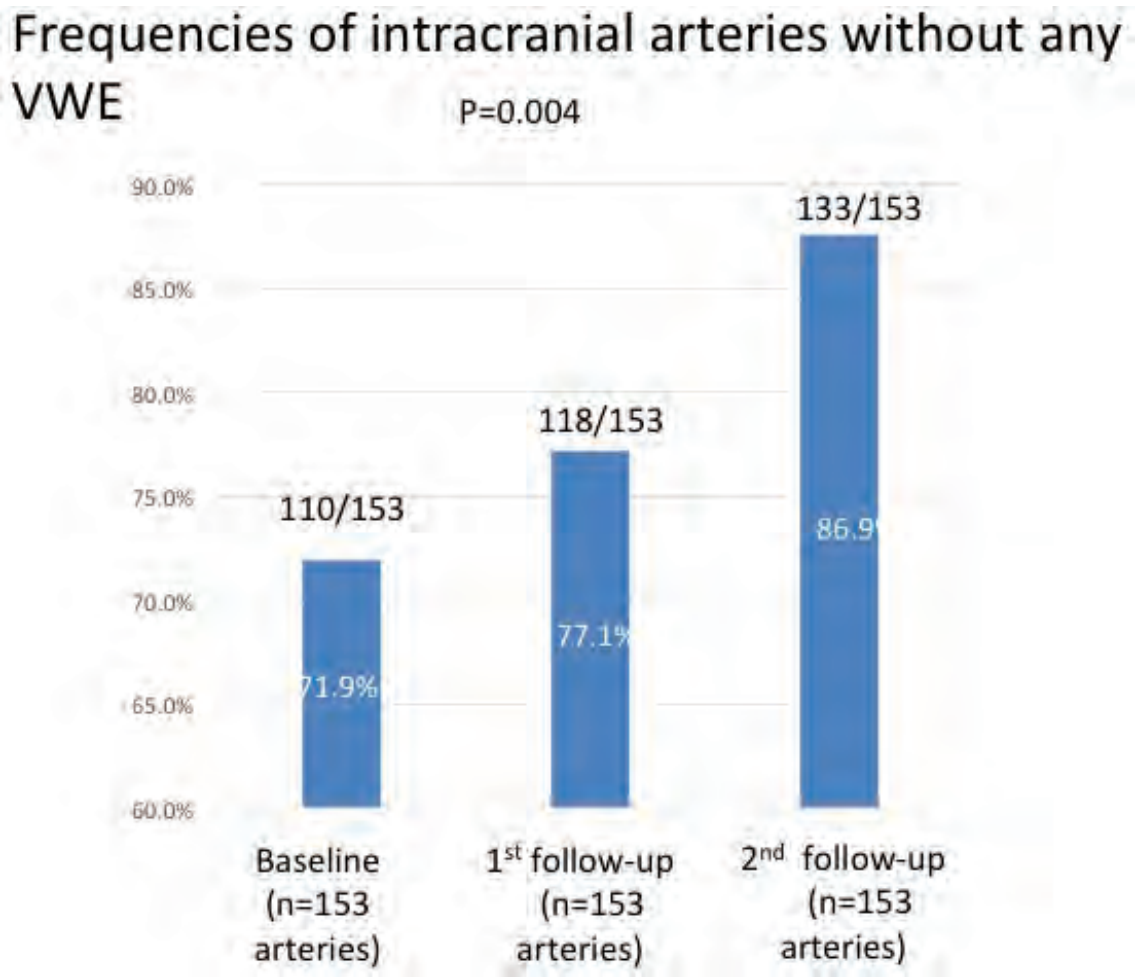
Results: In unique 153 intracranial arterial segments, 39 arteries (25.5%) had concentric VWE on baseline HR-VWI. The frequencies of intracranial arteries with concentric VWE have decreased to 12.4% (19 of 153 arteries) at 1st follow-up image and 6.5% (10 of 153 arteries) at 2nd follow-up image, respectively (P< 0.001), [figure 1]. By contrast, the



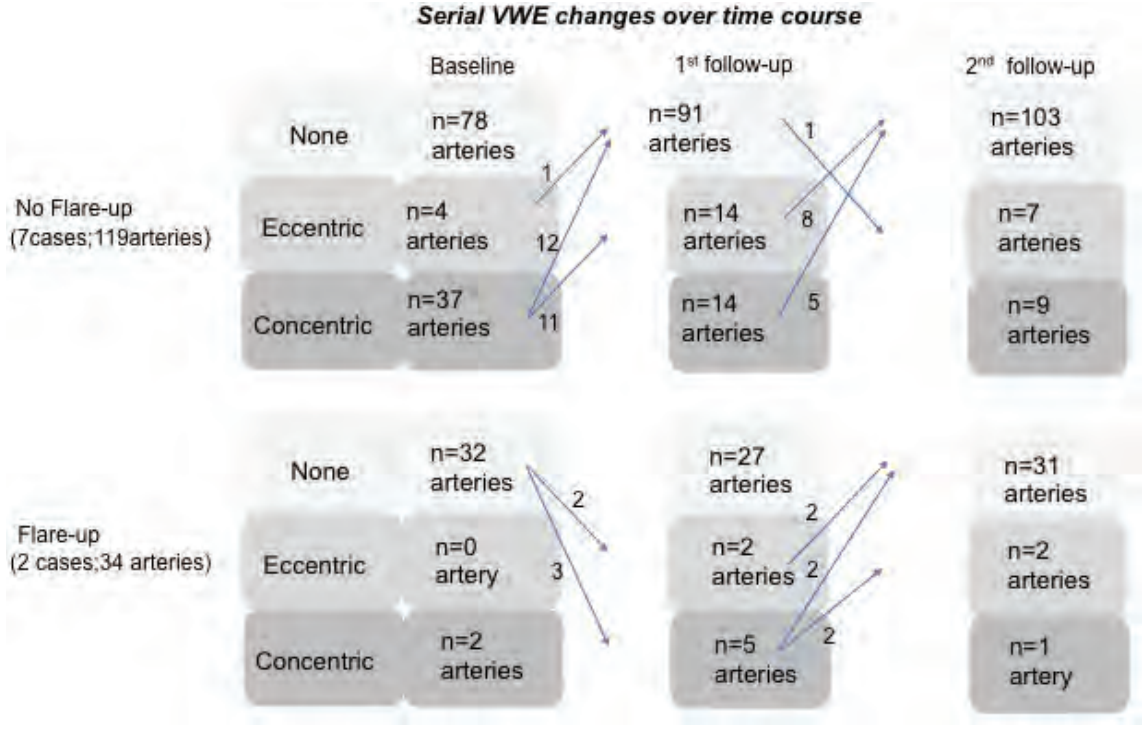
Frequencies of intracranial arteries with concentric vessel wall enhancement (VWE)

prevalence of intracranial arteries without VWE increased over time course (Baseline; 71.9% (110 of 153 arteries), 1st follow-up; 77.1% (118 of 153 arteries), and 2nd follow-up; 86.9% (133 of 153 arteries), P=0.004), [figure 2]. During the follow-up (mean follow-up 15.9 months), two patients had clinical flare-up at 1st follow-up image. New intraluminal enhancements were identified in 5 intracranial artery segments (Eccentric VWE: 0 to 2 arteries, Concentric VWE: 2 to 5 arteries). After intensive immunosuppressive treatment, VWE changes were improved at 2nd follow-up image (None: 27 to 31 arteries, Concentric VWE: 5 to 1 artery), [figure 3].

Conclusion: Decreasing contrast VWE at follow-up images were frequently observed in CNS-V patients after treatment. Patients with flare-up had temporal VWE worsening during the clinical course. Serial vessel wall enhancement pattern on HR-VWI may be useful for monitoring the response to treatment in patients with CNS-V. Larger studies are needed to validate our observation.



Frequencies of intracranial arteries without any vessel wall enhancement (VWE)



Serial vessel wall enhancement (VWE) changes over time

SESSION INFORMATION

Session Date: Friday, November 6, 2020

Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster I

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: Advanced age and cardiovascular diseases are recognized as major comorbidities associated with severe forms of coronavirus disease 2019 (COVID-19) caused by the severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2). Patients with large vessels vasculitis (LVV) could be considered at-risk for severe COVID-19 due to frequent age over 65 years in patients with giant cell arteritis (GCA), severe hypertension in patients with Takayasu arteritis (TAK) and current use of immunomodulating therapies in both LVV. The aim of this study was to determine the prevalence, clinical presentation and outcome of COVID-19 among LVV patients.

Methods: We retrospectively collected symptoms compatible with COVID-19 reported during SARS-CoV-2 pandemic in France, and severity, therapeutic management and outcomes of COVID-19 infection in all LVV patients followed for GCA or TAK in a single-tertiary centre.

Results: Between 04 and 20 may 2020, 148 patients with LVV were enrolled, including 84 GCA and 64 TAK. Median age at inclusion was 73 (67-82) years vs. 48 (42-62) for GCA and TAK, respectively, $p < 0.001$. Comorbidities such as hypertension, diabetes, obesity, and smoking habit were not significantly different between GCA and TAK group, except for the presence of solid cancer (19% vs 3% for GCA and TAK, respectively, $p = 0.004$). Seventy-seven percent of LVV patients were currently receiving glucocorticoids, 33% DMARDs and 20% biotherapies. Sixteen (11%) LVV patients presented a COVID-19 infection, including 9/84 (11%) GCA patients and 7/64 (11%) TAK patients. COVID-19 infections in LVV patients were confirmed by nasal PCR (n=3) and/or thoracic CT scan (n=3) and/or serological tests (n=3). Pneumonia occurred in 5 (31%) COVID-19 positive LVV patients, all requiring hospitalization and 4 oxygen therapy. LVV-COVID$^+$ patients had a more active vasculitis disease than LVV-COVID$^-$ patients ($p = 0.044$). Over a two-month period contemporary with the SARS-CoV-2 pandemic, in our LVV cohort we observed 3 COVID-19 related deaths (2 TAK and 1 GCA), leading to a mortality rate of 3/16 (18.8%).

Conclusion: Severe COVID-19 may occur in LVV requiring hospitalization in up to 30% of patients and frequent fatal issue. Active LVV or recent remission appear to increase the risk of COVID-infection.

Abstract Number: 0413

Coronavirus Infection and Vasculitis: Identifying Associations Mining the Biomedical Literature

Alicia Rodriguez Pla[1] and Rodrigo Cartin-Ceba[2], [1]Rheumatology. Mayo Clinic Arizona, Scottsdale, [2]Pulmonary. Mayo Clinic Arizona, Scottsdale, AZ

SESSION INFORMATION
Session Date: Friday, November 6, 2020
Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Based on recent publications suggesting an association between COVID-19 and vascular inflammation, our aim was to explore new associations between coronavirus infections and vasculitis utilizing semantic mining of PubMed results.

Methods: The following literature search string: "(vasculitis OR vascular inflammation OR vascular damage) AND (coronavirus OR SARS virus OR MERS-CoV OR Covid-19)" was used to retrieve abstracts from the whole PubMed database, using Semantic MEDLINE 2 on 6/7/2020. This application represents a network of semantic predications (triples of the form subject-predicate-object, e.g. COVID-19 *causes* Disease) on a knowledge graph. The system allows for choosing the maximum number of nodes represented, the central topic, and the length of the network. For our network we chose to display all relations, COVID-19 (31 edges) as the central term, 3 lengths, and selecting the most informative nodes. Automatic summarization eliminated the less informative predications.

Results: The search string retrieved 152 citations from PubMed and identified 1,028 predications. The network (Figure 1), displayed using COVID-19 as the central term, consisted of 72 nodes and 140 edges. The 5 most connected nodes were 'Patients: 19 nodes', COVID-19: 13', 'Inflammation: 13', 'Lung: 11', and 'Disease: 11'.

Multiple links have been found between coronavirus and vasculitis. Animal coronaviruses, including the one causing feline infectious peritonitis (FIP), the murine coronavirus mouse hepatitis virus (MHV), the SARS-CoV in transgenic mice and coronavirus in ferrets, are known to cause vasculitis in animals. It is known that coronaviruses that infect animals can evolve and become new human coronaviruses. SARS produces inflammation in blood vessels. In 2005, a link between the coronavirus HCoV-NL63 or New Haven Coronavirus (HCoV-NH) and Kawasaki Disease (KD) was reported, although later studies concluded that HCoV-NH did not play a dominant role in the etiology or pathogenesis of KD. In 2014, serological testing suggested the possible involvement of HCoV-229E in the development of KD. There has also been a report of KD patients being infected by coronavirus OC43/HKU1. SARS-CoV2 may infect the vessels and trigger inflammatory reactions like those of vasculitis, including vasculitis-like cutaneous lesions. Some COVID-19 patients develop thrombosis, and increased risk of thrombosis is also present in primary vasculitic syndromes. Children, many of whom tested positive for COVID-19 antibodies, developed Multisystem Inflammatory Syndrome (MIS-C), an inflammatory condition similar to KD.

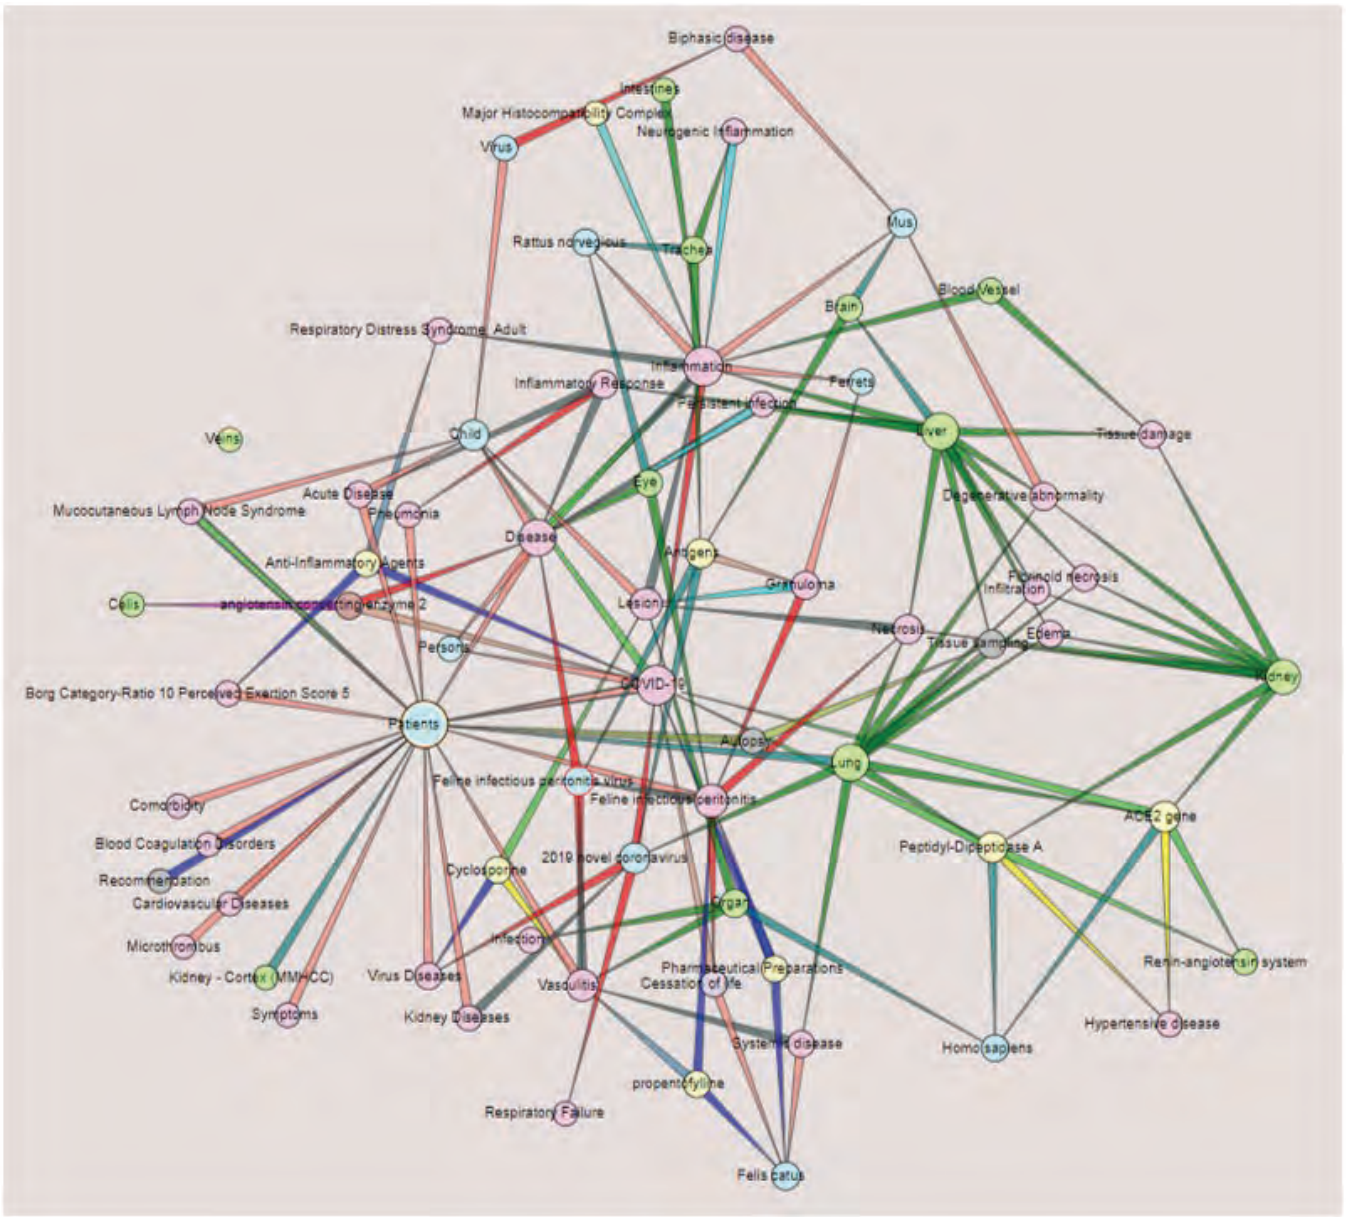

Figure 1. Semantic Network Resulting from PubMed Results

Conclusion: Knowledge integration and discovery methods are an efficient and powerful way of retrieving and analyzing relevant information from multiple papers. Their main advantages are finding relations among biomedical concepts, generating new hypotheses, and opening them to literature-based discovery.

SARS-CoV-2 may cause vasculitis or vasculitis-like syndromes. The KD-like syndrome reported mainly in children with COVID-19 revives the previous suspicion of coronavirus as a possible triggering agent of KD and the decades-old hypothesis of infection involvement in the pathogenesis of vasculitis.

Clinical Characteristics of an Internet-Based Cohort of Participants with a Self-Reported Diagnosis of Cryoglobulinemic Vasculitis or IgA Vasculitis

Jason Springer[1], Tanaz Kermani[2], Dianne Shaw[3], Kalen Young[4], Cristina Burroughs[5] and Peter Merkel[6], [1]University of Kansas Medical Center, Overland Park, KS, [2]David Geffen School of Medicine / University of California, Los Angeles, CA, [3]Vasculitis Foundation, North Carolina, [4]Vasculitis Foundation, Kansas City, [5]University of South Florida, Tampa, [6]University of Pennsylvania, Philadelphia, PA

SESSION INFORMATION
Session Date: Friday, November 6, 2020
Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Cyroglobulinemic vasculitis (CV) and IgA vasculitis are forms of small-vessel vasculitis characterized by immune complex deposition. The purpose of this study was to a) describe the characteristics of an international internet-based cohort of patients with a self-reported diagnosis of CV or IgA vasculitis and b) determine the extent to which these diagnoses agreed with established definitions of disease or classification criteria.

Methods: Participants with self-reported diagnoses of CV or IgA vasculitis were included in a prospective, internet-based, longitudinal registry from November 2014 to May 2020. All information was self-reported including diagnosis, symptoms at onset, and diagnostic testing.

Results: CV: 117 participants reported a diagnosis of CV (79% female). The racial/ethnic distribution was: 86% Caucasian/White, 3% Asian, 3% Hispanic/Latino and 2% African American/Black. Mean age at diagnosis was 48.7

Table 1: Comparison of Childhood and Adult onset IgA vasculitis

	Childhood onset*	Adult onset*	P-value
Female	17/26 (65%)	60/77 (78%)	0.203
Onset in summer	5/24 (21%)	30/74 (41%)	0.080
Manifestations			
Fevers	8/20 (40%)	19/57 (33%)	0.591
Purpura	26/26 (100%)	72/77 (94%)	0.183
Intussusception	2/25 (8%)	1/75 (1%)	0.091
GI bleed	7/23 (30%)	28/71 (39%)	0.438
Joint pains	24/25 (96%)	61/68 (89%)	0.337
Myalgia	22/23 (96%)	57/70 (81%)	0.098
Numbness	8/22 (36%)	46/65 (71%)	0.004
Hearing loss	3/23 (13%)	8/73 (11%)	0.784
Kidney involvement	17/25 (68%)	46/70 (66%)	0.836
ESRD	0/27 (0%)	1/76 (1%)	0.550
Thrombocytopenia	0/9 (0%)	10/31 (32%)	0.049

***Responses of "I don't know" were excluded from analysis.**
ESRD: end-stage renal disease

± 2.6 years. 22% had a history of hepatitis C and 13% of hematologic malignancy. 96% reported positive serum cryoglobulins. Common clinical manifestations included: purpura (94%), peripheral nerve involvement (93%), joint involvement (91%), and kidney involvement (27%). The establishment of the diagnosis was by laboratory testing (84%), symptoms (60%), and biopsy (37%). 108 participants (92%) met the Chapel Hill Consensus Conference (CHCC) definition.

IgA vasculitis: 103 participants reported a diagnosis of IgA vasculitis (75% female). The racial/ethnic distribution was: 88% Caucasian/White, 5% Asian, 5% Hispanic/Latino, 2% American Indian/Alaska Native, and 1% African American/Black. Mean age at diagnosis was 42.7 ± 3.2 years, with 77 (75%) developing symptoms in adulthood (≥18 years); there were few differences in clinical manifestations based on age of presentation (**Table 1**). 52% reported onset after an upper respiratory infection. Common clinical manifestations included: purpura (99%), joint involvement (93%), gastrointestinal pain/bleeding (70%), and kidney involvement (66%). Patients reported their diagnosis was established by biopsy results (68%), symptoms (62%), and serum laboratory testing (52%). 96 participants (93%) met the 1990 American College of Rheumatology criteria while 70 (68%) met the CHCC definition.

Conclusion: Self-reported clinical manifestations of CV and IgA vasculitis are similar to cohorts utilizing the traditional center-based approach. In addition, most patients with these diseases met established criteria or definitions for their disease. The diagnosis of CV appears to be more commonly reliant on laboratory testing as opposed to IgA vasculitis in which the diagnosis is more heavily based on biopsy results. Patients with adult-onset IgA vasculitis were more likely to develop peripheral neuropathy and thrombocytopenia. Patient-derived data from online registries is a feasible option for the conduct of future clinical trials in these rare and understudied diseases.

Abstract Number: 0415

Characteristics of Arthritis in Adult IgA Vasculitis

Alojzija Hocevar[1], Vesna Jurcic[2], Matija Tomsic[1] and Ziga Rotar[1], [1]University Medical Center Ljubljana, LJUBLJANA, Slovenia, [2]Institute of Pathology, Medical Faculty, University of Ljubljana, LJUBLJANA, Slovenia

SESSION INFORMATION
Session Date: Friday, November 6, 2020
Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Arthritis is one of the main clinical features in IgA vasculitis (IgAV). In children, joint involvement represents the second most common manifestation with the prevalence of ≈75%, and predilection for the knees and ankles. The aim of our study was to describe the characteristics of arthritis in adult IgAV.

Methods: We analysed medical records of histologically proven adult IgAV cases, diagnosed between January 2010 and May 2020 at our secondary/tertiary rheumatology centre. The frequency, temporal occurrence and the localization of arthritis was recorded. Additionally, we explored potential differences in other clinical features of acute IgAV between patients with and without arthritis.

Table 1. Clinical characteristics of IgA vasculitis patients with and without arthritis

Clinical characteristics	Arthritis IgAV (48)	Non-arthritis IgAV (265)	P value
Male gender (%)	56.3	61.5	0.523
Age (years)*	49.9 (36.1-66.9)	65.6 (49.0;78.2)	<0.001
Ever smoker (%)	50.0	41.9	0.343
Prior infection (%)	43.8	30.2	0.092
Generalized purpura	50.0	49.8	1.0
Skin necroses (%)	35.4	50.2	0.062
GI involvement (%)	47.9	26.4	0.005
Renal involvement (%)	47.9	46.8	1.0
Elevated serum IgA (%)	33.3 (11/33)	53.4 (111/208)	0.039

Legend: * median and IQR; GI gastrointestinal;

Results: During the 125-month observation period we identified 313 new IgAV cases (60.7 % males, median (IQR) age 64.6 (45.6; 77.1) years). Arthritis developed in 48 (15.3%) patients and was the first IgAV manifestation in 16 (5.1%) patients. Arthritis was mono-, oligo- and poly- articular (involving up to 15 joints) in 13 (4.2%), 25 (8%) and 10 (3.2%) patients, respectively. Arthritis was most common in wrists and ankles (each in 18 (37.5%) patients); metacarpophalangeal joints and knees (each in 11 (22.9%)); proximal interphalangeal joints (9 (18.8%)); elbows (8 (16.7%)) and metatarsophalangeal joints (4 (8.3%)). Table 1 shows clinical differences between IgAV patients with and without arthritis. Patients with arthritis were significantly younger, more commonly had gastrointestinal tract involvement and less frequently elevated serum IgA. Arthritis remitted in all with immunomodulatory treatment (given predominantly for necrotic skin purpura or visceral involvement). Follow up (FU) data accessible for 40/48 (83.3%) patients with arthritis showed that IgAV relapsed in 10 (25%) patients during a median (IQR) 24.6 (11.2; 41.8) month FU. Relapses were limited to skin and/or kidneys, there were no relapses of arthritis.

Conclusion: Arthritis more commonly affected younger adults with IgAV, was frequently oligoarticular, involved large and small joints of both upper and lower extremities and unlike skin lesions or renal involvement was not prone to chronic course and recurrence.

Background/Purpose: The spectrum of IgG4-related disease (IgG4-RD) includes many diseases that were thought to be confined to a single organ, as the retroperitoneal fibrosis. Many patients identified with idiopathic retroperitoneal fibrosis (IRF) could be reclassified as IgG4-RD, due to immunohistochemistry techniques. Classification criteria have

Table 2. Histopathological features of IgG4- related and non - IgG4- related retroperitoneal fibrosis

	IgG4-RD (n=8)	Non IgG4-R(n=8)	*p*
Biopsy area (mm^2)*	144 (75.5 - 258)	42 (13 - 108)	0.16
Storiform fibrosis*	8 (100%)	1 (12.5%)	0.01
Non storiform fibrosis*	0	7 (87.5%)	0.01
Dense lymphocytic infiltrate*	8 (100%)	5 (62.5%)	0.46
Obliterative phlebitis*	3 (37.5%)	1 (12.5%)	0.56
Non-obliterative phlebitis*	2 (25%)	1 (12.5%)	1
Eosinophils*	6 (75%)	1 (12.5%)	0.04
Germinal centers*	3 (37.5%)	2 (25%)	1
Fat necrosis*	0	0	-
IgG4+ cells/hpf*	17.8 (15.5 - 22.8)	1 (0.75 - 9.5)	0.01
IgG4/IgG ratio*	41 (18 - 59.5)	12.5 (10.2 - 14)	0.03
*Absolute frequency (%), *median (IQR_{25-75})			

not been uniform during last years and IgG4-related retroperitoneal fibrosis frequency is unknown in our country. We aim to describe IgG4-related retroperitoneal fibrosis (IgG4-RF) frequency using last published criteria and compare clinical, histopathologic and radiologic features with non-Ig4-RF

Methods: A dynamic retrospective cohort involving 16 adults with histopathological diagnosis of IRF at Hospital Italiano de Buenos Aires since january 2010 to february 2020 was studied. Pathology slides were reviewed, and immunohistochemistry for IgG4 and IgG was performed and assessed for each case. 2019 American College of Rheumatology (ACR)/ European League Against Rheumatism (EULAR) classification criteria were used to identify IgG4-RD cases. Mann Whitney U test and the Fisher exact test were used to compare continuous and categorical variables respectively

Results: 8 (50%) patients met criteria for IgG4-RF. The median age was similar in the two subsets (61 years old in IgG4-RF versus 54, p = 0.2) and both had male predominance. 3 patients presented other manifestations of IgG4-RD in IgG4-RF group. None had either high serum IgG4 levels or eosinophilia. All of the IgG4-RF had infrarenal and circumferential retroperitoneal extension along the aorta on computed tomography but there were not significant differences with non-IgG4-RF (p= 0.4 and 0.1). Hydronephrosis, renal failure and requirement of renal replacement therapy did not differ between groups. Corticosteroids were mostly used as drug therapy, followed by azathioprine but most of the patients did not receive specific treatment. 7 (87.5%) patients needed surgical or endoscopic intervention in each group. 7 patients in each subset were admitted to hospital with a similar median number of hospitalizations (3 in IgG4-RF versus 2, p=0.07). All of Ig4-RF patients had a dense lymphocytic infiltrate and storiform fibrosis (p=0.01) and 75% presented eosinophils (p=0.04). IgG4+ cells/hpf and IgG4/IgG ratio were significantly higher than patients with non-Ig4-RF (p = 0.01 and 0.03, respectively)

Conclusion: Half of patients in our IRF retrospective cohort met criteria of IgG4-RF, first data in our region. ACR/ EULAR new criteria may be helpful in order to homogenize the identification of Ig4-RD. These findings may motivate further evaluation of this condition, increasing early recognition, accurate treatment and integral follow-up

Different Immunophenotypes Characterized IgG4-Related Disease Clinical Phenotypes

Eduardo Martin-Nares[1], Janette Furuzawa-Carballeda[1], Ángel Alexis Priego-Ranero[1], Isela Chan-Campos[1], Gladys Sulikey Herrera-Noguera[1], Fidel López-Verdugo[1] and Gabriela Hernandez-Molina[1], [1]Department of Immunology and Rheumatology, Instituto Nacional de Ciencias Médicas y Nutrición Salvador Zubirán, Mexico City, Distrito Federal, Mexico

SESSION INFORMATION
Session Date: Friday, November 6, 2020
Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Patients with IgG4-related disease (IgG4-RD) can be classified in clinical phenotypes which differ in terms of demographics, clinical and serological features. Whether there are also differences in the immunophenotype of each phenotype is unknown. Our aim was to characterize the immunophenotype of IgG4-RD patients according to their clinical phenotype.

Methods: We included consecutive patients with a diagnosis of IgG4-RD according to the Comprehensive Diagnostic Criteria for IgG4-RD who attended our Institution from Aug 2018 to Nov 2019. Healthy subjects were included as controls. We obtained peripheral blood for isolation of peripheral mononuclear cells and through negative selection, CD4+ memory T cells were obtained. We determined the percentage of the following cell subsets by flow cytometry:

- Th2 (CD4+/CD45RO+/CD14-/IL-4+; CD4+/CD45RO+/CD14-/IL-13+, CD4+/CD45RO+/CD14-/IL-5+);
- CD4+IL-21 T cells (CD4+/CD45RO+/CD14-/IL-21+);
- CD4+ cytotoxic T cells (CTLs) (CD4+/CD45RO+/SLAMF7+/IL-1β+/TGF-β1+);
- Th9 (CD3+/CD4+/ CD45RO+/IL-9);
- T follicular helper cells (Tfh) (CD4+/CD45RO+/CCR7-/ICOS+/CCCR5+/Bcl6+);
- Tfh1 (CD4+/CD45RO+/CCR7-/ICOS+/CCCR5+/Bcl6+/IFN-γ+);
- Tfh2 (CD4+/CD45RO+/CCR7-/ICOS+/CCCR5+/Bcl6+/IL-4+);
- Tfh17 (CD4+/CD45RO+/CCR7-/ICOS+/CCCR5+/Bcl6+/IL-17+);
- Tfr (CD4+/CD45RO+/CCR7-/ICOS+/CCCR5+/Bcl6+/Foxp3+);
- Tregs (CD4+/CD25hi/CD127-/Foxp3+);
- Tr1 (CD4+/CD25low/Foxp3-/IL-10+);
- Th3 (CD4+/CD25-/Foxp3-/TGF-β1+);
- Bregs (CD19+/CD24hi/CD38hi/IL-10+);
- Plasmocitoid dendritic cells (pDC) (CD86+/CD163hi/IL-10+);
- M1 macrophages (CD86+/CD127+/TNF-α+);
- M2 macrophages (CD163+/CD14+/TGF-β1+/IL-33+).

Results: We recruited 43 patients with a mean age of 52.3±16.4 years, 48.8% were male. Twelve controls were included. Eight (18.6%) patients belong to the pancreato-hepatobiliary, 7 (16.3%) to the retroperitoneal-aorta, 16 (37.2%) to the head and neck limited and 12 (27.9%) to the Mikulicz/Systemic phenotypes. Twenty two (51.2%) had active disease. The percentages of all cell subsets were statistically higher in patients vs controls, with the exception

of Tr1 cells. The percentages of the following cell subsets were different among clinical phenotypes: Th2 (CD4+/IL-4+) (p=0.029), Th2 (CD4+/IL-5+) (p=0.047), CD4+ CTLs, (p=< 0.001), Tfh17 (p=0.005), Tregs FOXP3+ (p=0.008), Th3 (p=0.02), Bregs (p=0.005) and pDC IL-10 (p=0.016). In a sensitive analysis including only the 22 patients with active disease, the same cell subsets remained significant and we also observed differences in Tfh1 (p=0.03), Tfh2 (p=0.009), Tr1 (p=0.034), and M1 macrophages (p=0.03). Patients with active IgG4-RD had higher proportions of Tfh (< 0.001), Tfh17 (p< 0.001), Tr1 (p=0.001), Th3 (p=0.01), pDC IL-10 (0.005) and M1 macrophages (p=0.017). There were no differences according to the presence of atopy or immunosuppressive treatment at recruitment.

Conclusion: Our study showed that the clinical heterogeneity of IgG4-RD might be driven by the participation of different immune cell subsets.

SESSION INFORMATION
Session Date: Friday, November 6, 2020
Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Previous studies have reported higher risk of thyroid disease in patients with giant cell arteritis (GCA) and ANCA-associated vasculitis (AAV) compared to age- and sex-matched controls. The aim of this study was to compare the risk of hypothyroidism or hyperthyroidism in patients with large-vessel vasculitis (giant cell arteritis, GCA and Takayasu's arteritis, TAK), polyarteritis nodosa (PAN), and AAV.

Methods: Patients GCA, TAK, PAN, granulomatosis with polyangiitis (GPA), microscopic polyangiitis (MPA), and eosinophilic granulomatosis with polyangiitis (EGPA) enrolled in a prospective, multicenter, longitudinal study were included. All patients were followed with standardized data collection. Information on type of thyroid disease was systematically collected for each form of vasculitis. Odds ratios (OR) and 95% confidence intervals (CI) for risk of thyroid diseases were calculated between clinical subgroups.

Results: The study included 2,087 patients, 63% female, 90% White, mean age 54.6 (±17.2) years. Diagnoses were: GCA (427, 20%), TAK (225, 11%), PAN (108, 5%), GPA (873, 42%), MPA (170, 8%), and EGPA (285, 14%).

Thyroid disease was present in 246 patients (12% overall cohort), 83% female, mean (±SD) age 59.2 (14.8) years. The majority of the cases were hypothyroidism; 217 patients (88% with thyroid disease). The frequency of thyroid

Table 1: Thyroid Disease by Type of Vasculitis

Hyperthyroidism, N (%)	4 (1)	6 (3)	1 (1)	14 (2)	1 (1)	3 (1)
Any thyroid disease, OR* (95% CI)	0.58 (0.40, 0.85)	0.72 (0.43, 1.20)	0.60 (0.27, 1.32)	1.54 (1.16, 2.05)	1.70 (1.12, 2.59)	0.77 (.050, 1.20)
Hypothyroidism, OR* (95% CI)	0.61 (0.41, 0.90)	0.57 (0.31, 1.03)	0.59 (0.25, 1.38)	1.51 (1.12, 2.05)	1.81 (1.18, 2.80)	0.82 (0.52, 1.30)
Hyperthyroidism, OR* (95% CI)	0.40 (0.13, 1.30)	1.80 (0.65, 4.97)	0.69 (0.09, 5.16)	1.52 (0.72, 3.21)	0.78 (0.18, 3.33)	0.76 (0.23, 2.52)

GCA=giant cell arteritis, TAK=Takayasu arteritis, PAN=polyarteritis nodosa, GPA=granulomatosis with polyangiitis, MPA=microscopic polyangiitis, EGPA=eosinophilic granulomatosis with polyangiitis, N=number of patients, SD=standard deviation, OR=odds ratio, CI=confidence intervals

* age- and sex-adjusted

disease by type of vasculitis, and, age- and sex-adjusted OR for thyroid disease is in **Table 1.** Adjusting for age and sex, patients with LVV had lower risk of hypothyroidism (OR 0.59, 95% CI 0.42, 0.81) while risk of hypothyroidism was higher in patients with AAV (OR 1.80, 95% CI 1.31, 2.47). Patients with GCA had the lowest risk compared to the other forms of vasculitis while patients with GPA and MPA had the highest risk (**Table 1**). There were no differences in age- and sex-adjusted risk of hyperthyroidism between the different forms of vasculitis (**Table 1**).

Conclusion: There are important differences in the risk of hypothyroidism, but not hyperthyroidism, between the different forms of vasculitis. Patients with GCA have the lowest age- and sex- adjusted risk of hypothyroidism while patients with GPA and MPA had the highest risk. Possible explanations for these findings include differences in genetic susceptibilities, immune responses, or treatment exposures between the forms of vasculitis. The interplay of thyroid disease and vasculitis warrants further investigation.

SESSION INFORMATION
Session Date: Friday, November 6, 2020
Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: There is limited information on mortality in patients with polymyalgia rheumatica (PMR), and on prevalent comorbidity at the time of diagnosis of PMR. The purpose of this study was to investigate survival in a community-based sample of patients with PMR diagnosed in primary health care (PHC) compared to the general population. Furthermore, we assessed comorbidities diagnosed prior to PMR diagnosis, and their impact on mortality.

Methods: A community-based cohort of consecutive patients with a validated diagnosis of PMR at two PHC centres (1) between 2000 and 2013 was investigated. Validation was based on a review of the electronic records by an experienced rheumatologist, taking into account the disease course and differential diagnoses. Four controls, matched for age, sex and municipality were retrieved from the regional health care database. The index date was defined as the date of PMR diagnosis in cases and the corresponding date in the matched controls. Cases and controls were censored at death, emigration, 10 years of follow-up or the end date of the study (December 31, 2018). Prevalent comorbidity was defined as ≥1 ICD-code indicating a predefined condition prior to the index date. Survival in PMR cases and controls was estimated using the Kaplan-Meier method (log rank test). The impact of PMR and comorbidities was investigated in Cox regression models.

Table 1. Registered comorbidities before index date; n (%)

	PMR cases N=113	Controls N=452	p
Coronary artery disease (CAD)	8 (7.0)	55 (12.1)	0.12
Cerebrovascular disease (CeVD)	9 (7.9)	37 (8.1)	0.94
Peripheral artery disease (PAD)	4 (3.5)	21 (4.6)	0.61
Cardiovascular disease (CVD)	18 (15.9)	102 (22.5)	0.12
Hypertension	28 (24.7)	167 (36.9)	0.02
Diabetes	10 (8.8)	102 (22.5)	0.001
Malignancy	12 (10.6)	102 (22.5)	0.005
COPD	6 (5.3)	39 (8.6)	0.24

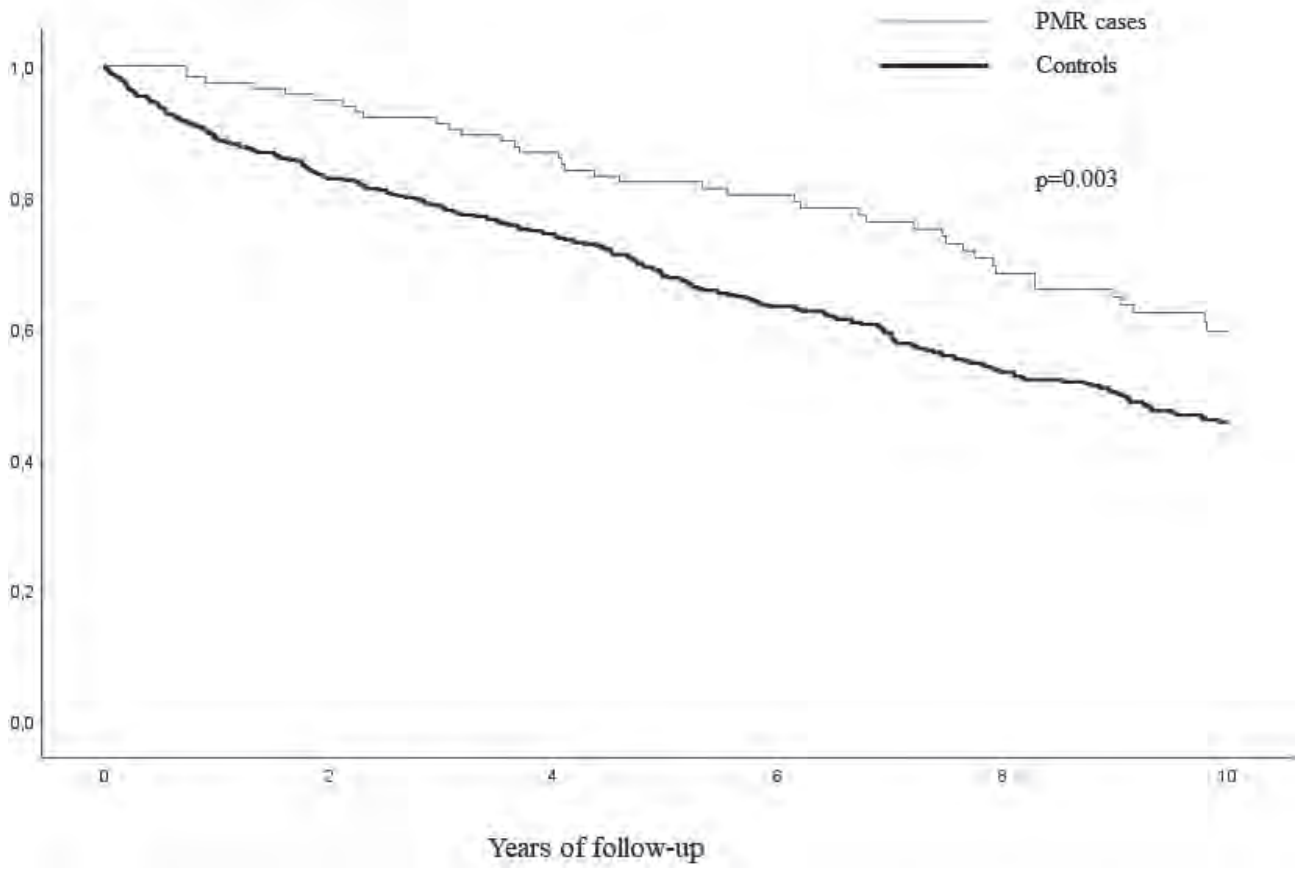
CVD: CAD and/or CeVD and/or PAD. COPD: Chronic obstructive pulmonary disease

Table 2. Predictors of mortality (Cases and controls combined)
Cox regression, univariate analyses

	Hazard ratio (95 % CI)
PMR	0.62 (0.45-0.84)
Coronary artery disease (CAD)	1.30 (0.94-1.79)
Cerebrovascular disease (CeVD)	1.49 (1.02-2.17)
Peripheral artery disease (PAD)	2.14 (1.34-3.41)
Cardiovascular disease (CVD)	1.51 (1.17-1.94)
Hypertension	1.15 (0.92-1.45)
Diabetes	1.79 (1.39–2.32)
Malignancy	1.86 (1.45-2.40)
COPD	2.36 (1.66-3.36)

CVD: CAD and/or CeVD and/or PAD.
COPD: Chronic obstructive pulmonary disease

Figure 1. Survival in cases with PMR and age-sex matched controls



Results: One hundred and thirteen patients with verified PMR (68 % women, mean age at diagnosis 75.3 years) and 452 matched controls were included. There were 40 (35.4%) deaths among the PMR cases, and 252 (55.7%) among the controls. Survival was significantly higher in PMR cases compared to controls (Figure 1). There was not a single

death during the first 0.7 years after diagnosis among the patients with PMR (Figure 1). Among the investigated comorbidities, diabetes, malignancy and hypertension were diagnosed in significantly lower proportions prior to the index date in patients with PMR compared to controls (Table 1). Prevalent malignancy, diabetes and cardiovascular disease (CVD) were all associated with increased mortality in pooled analysis of cases and controls (Table 2). In analysis adjusted for malignancy, diabetes and CVD, PMR was associated with reduced mortality (adjusted hazard ratio (HR) 0.66; 95 % CI 0.48-0.90). In a sensitivity analysis, excluding the first 0.7 years of follow-up to avoid short term survival bias after PMR diagnosis, the association between PMR and reduced mortality did not reach statistical significance (adjusted HR 0.75; 95 % CI 0.55-1.04).

Conclusion: Patients with PMR diagnosed in PHC had an improved survival compared to the background population, and were less likely to have been diagnosed with several comorbidities. The reduced mortality in PMR may be partly due to a tendency to regard PMR as a diagnosis of exclusion, and a reluctance to make a diagnosis of PMR in patients with serious comorbidities and a poor prognosis. Alternatively, factors that predispose to PMR may protect from other conditions, in particular diabetes and malignancy.

Prospective Analysis of the Prevalence of Giant Cell Arteritis in Consecutive Newly Diagnosed Patients with Polymyalgia Rheumatica

Lara Burg[1], Peter Brossart[2], Charlotte Behning[3] and **Valentin Schaefer**[4], [1]Clinic for Internal Medicine III, Department of Oncology, Haematology, Rheumatology and Clinical Immunology, University Hospital Bonn, Germany, Bonn, Nordrhein-Westfalen, Germany, [2]Clinic for Internal Medicine III, Department of Oncology, Hematology and Rheumatology, University Hospital Bonn, Germany, Bonn, Nordrhein-Westfalen, Germany, [3]Institute for Medical Biometry, Informatics and Epidemiology, University Hospital Bonn, Germany, Bonn, Nordrhein-Westfalen, Germany, [4]Clinic of Internal Medicine III, Department of Oncology, Hematology and Rheumatology, University Hospital Bonn, Germany, Bonn, Nordrhein-Westfalen, Germany

SESSION INFORMATION
Session Date: Friday, November 6, 2020
Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Giant cell arteritis (GCA) is the most common form of systemic vasculitis affecting people aged 50 years and older.[1] Although it is known, that GCA often coexists with polymyalgia rheumatica (PMR)[2], to this point, the prevalence of GCA in consecutive newly diagnosed patients with PMR has not been investigated.

Methods: Consecutive patients with newly diagnosed PMR fulfilling the ACR /EULAR classification criteria[3] were included. Vascular US examination of the extracranial arteries typically involved in GCA, such as axillary arteries, vertebral arteries, common carotid arteries, superficial temporal arteries with both frontal and parietal branches, occipital arteries, facial arteries and the central retinal arteries was performed in all PMR patients. Typical symptoms of GCA and PMR were recorded. Diagnosis of GCA was made, if intima-media thickness (IMT) was above respective cut-off values.[4]

Symptoms	Group	
	PMR-group	GCA-PMR-group
Morning stiffness	22 (95%)	23 (85%)
=1 shoulder with synovits or bursitis trochanterica	12 (52%)	13 (48%)
=1 shoulder or hip with synovitis or bursitis	11 (48%)	14 (51%)
Absence of RF/ anti-CCP	5 (21%)	11 (40%)
Hip pain	23 (100%)	23 (85%)
No other joints affected	22 (95%)	26 (96%)

PMR-group: patients with diagnosis of polymyalgia rheumatica only
GCA-PMR-group: patients with diagnosis of polymyalgia rheumatica and giant cell arteritis

Table 1. Number of patients fulfilling ACR/EULAR classification criteria for polymyalgia rheumatica

Results: Fifty patients with newly diagnosed PMR were included. In 27 PMR patients, GCA was diagnosed by vascular ultrasound (GCA-PMR group), while 23 PMR patients showed no evidence of GCA (PMR-group). Mean age of the PMR-GCA group was 74 years (SD ± 9) with ten (37%) females, while mean age in the PMR-GCA group was 71 years (SD ± 10.1) with seventeen (73%) females. Mean C-reactive protein (CRP) values were 29.4 mg/l (SD±24.5) in the PMR-group and 52.2 mg/l (SD±43.2) in the GCA-PMR group. CRP values were not found to be significant between groups (p = 0.1432). Forty-five of all patients (90%) described morning stiffness. Ten patients (37%) in the GCA-PMR group did not complain of any GCA symptoms, GCA was only detected by ultrasound examination. Every patient with diagnosis of PMR had shoulder or hip inflammation on US. Characteristic symptoms of PMR and GCA and the number of patients with respective symptoms are depicted in table 1 and 2.

Conclusion: Prevalence of GCA in patients with PMR in our cohort was 54%. CRP was higher in the GCA-PMR group compared to the PMR-group. Ten (37%) patients with GCA and PMR did not have any GCA symptoms. Performing vascular US in patients with PMR can be useful to diagnose a clinical inapparent GCA. Prompt onset of the respective therapy could prevent complications of GCA, glucocorticoid therapy and probably improve disease outcome.

Polymyalgia Rheumatica Is Associated with Later Menopause: An Observational Study

Sarah Dyball[1], Christopher Saleh[2] and Marwan Bukhari[1], [1]Rheumatology Department, University Hospitals of Morecambe Bay NHS Trust, Lancaster, United Kingdom, [2]Rheumatology Department, University Hospitals of Morecambe Bay NHS Trust, Manchester, United Kingdom

SESSION INFORMATION
Session Date: Friday, November 6, 2020
Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Oestrogen exposure leads to an increase in peak bone mass whereas menopause is associated with rapid bone loss. Numerous studies have linked rheumatoid arthritis (RA), systemic lupus erythematosus (SLE) and osteoarthritis to an earlier menopause; however, there are paucity of data in polymyalgia rheumatica (PMR). This study aims to establish whether PMR is associated with a later self-reported age of menopause.

Methods: Post menopausal patients who were referred for bone mineral density (BMD) estimation in a scanner in the North West of England between June 2004 and October 2015 were included in the analysis. All patients had their baseline demographics recorded at time of scan as well as risk factors for fracture including presence of PMR, RA, SLE and coeliac disease, excess alcohol intake, corticosteroid use, smoking history and parental family history of hip fracture. Bone mineral density (BMD) was measured at the left neck of femur and the lumbar spine. Patients were grouped into those with a clinician made diagnosis of PMR and those without; and initially compared using student's T-test. Univariate and multivariate linear regression models were then fitted to examine associations with age of menopause in this group. All statistical analysis was performed using STATA v13, with results expressed as coefficients with 95% confidence intervals (95%CI).

Results: We recruited 14481 post-menopausal patients with a mean (SD) age of menopause of 65.5 years (10.8). 407 patients (2.8%) had a diagnosis of PMR, 63 (0.44%) patients with SLE, 832 (5.8%) with RA and 272 (1.9%) with coeliac disease. In this cohort, 4742 (32.8%) patient had a smoking history, 810 (5.6%) drank an excess of alcohol, 3157 (21.8%) were taking corticosteroids and 2428 (16.8%) had a parental family history of hip fracture. The mean age (SD) of patients was 65.5 (10.8) years. Mean age of menopause was later in patients with PMR (49.3 vs 48.2 years, mean difference 1.1 years, p=< 0.001). Results of the univariate analysis are shown in table 1. This analysis showed that PMR, increasing age and increased BMD in the lumbar spine are associated with a later age of menopause. Smoking and SLE, however, were associated with an earlier age of menopause. In the multivariable model when adjusting for

Table 1. Linear regression analysis of patient's parameters with 95% confidence interval (CI). BMD, bone mineral density.

Predictor of menopause	Beta co-efficient	95% CI	P value
Age	0.07	0.09, 0.10	<0.001
Previous smoker	-0.95	-1.14, -0.77	<0.001
Body mass index	-0.00	-0.02, 0.01	0.756
Polymyalgia rheumatica	1.15	0.63, 1.68	<0.001
Systemic lupus erythematosus	-3.03	-4.35, -1.72	<0.001
Coeliac disease	-0.08	-0.72, 0.55	0.797
Rheumatoid arthritis	-0.19	-0.56, 0.18	0.315
History of fragility fracture	0.11	-0.07, 0.28	0.246
Parental history of hip fracture	-0.03	-0.27, 0.20	0.770
BMD left femoral neck	-0.63	-1.28, 0.02	0.06
BMD lumbar spine	0.96	0.51, 1.41	<0.001

all of the above, delayed menopause was still significantly associated with PMR (beta co-efficient 1.34 95% CI 0.72, 1.96, p< 0.001).

Conclusion: In this large observational study, women with PMR have a later onset of self reported menopause. This is the first study to establish this association between the age of menopause and PMR. Further studies will be required to confirm this association and review whether the age of menopause is a risk factor for PMR.

Frailty and Health-Related Quality of Life in Patients with Polymyalgia Rheumatica

Sebastian Sattui[1], Deanna Jannat-Khah[2], Lindsay Lally[1], Sarah Lieber[1], Lisa Mandl[1] and Robert Spiera[3], [1]Hospital for Special Surgery, New York, NY, [2]Hospital for Special Surgery, New York City, NY, [3]Division of Rheumatology, Hospital for Special Surgery, New York, New York, USA, New York, NY

SESSION INFORMATION
Session Date: Friday, November 6, 2020
Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Frailty is a syndrome characterized by an increased vulnerability to stressors. Frailty and pre-frailty have been reported in 10% and 44%of community dwelling elderly, respectively.[1] Chronic inflammation is a risk factor for frailty. Patients with PMR represent a population at high risk for frailty; however, there are no data on the prevalence and impact of frailty in PMR patients. The objective of this study is to describe the prevalence of frailty in a single center cohort of patients with PMR and to determine the association of frailty with health-related quality of life (HRQoL), cognition and sarcopenia.

Methods: Patients with an ICD-10 diagnosis of PMR were identified between 03/2019-03/2020. Patients fulfilling 2012 EULAR/ACR Provisional Classification Criteria, ≤ 12 months from diagnosis and on glucocorticoids (≥ 3 mg of prednisone) were included. Disease activity was measured with the PMR-activity score. Frailty and pre-frailty were

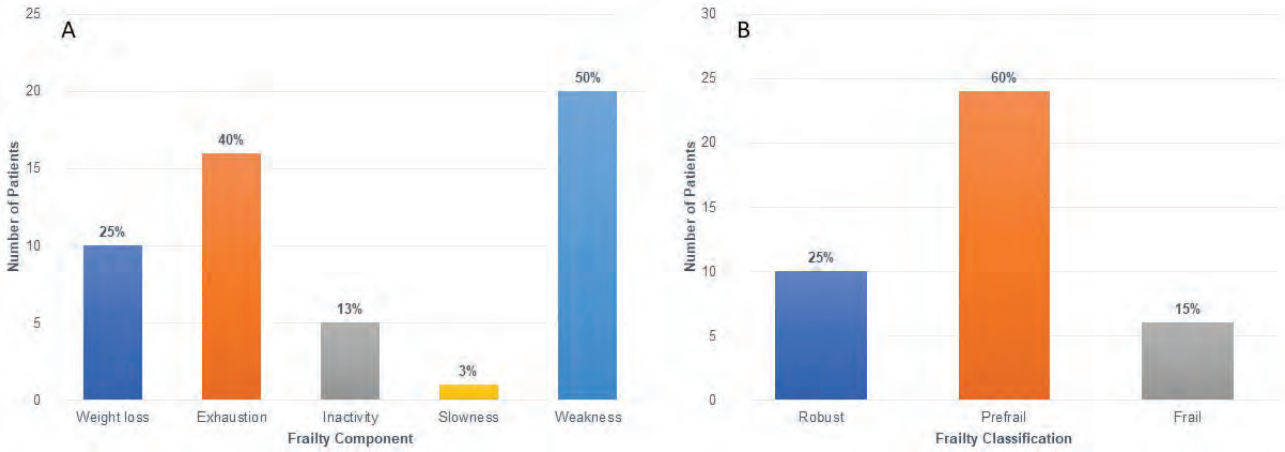

Figure 1. Fried Frailty Classification

defined according to Fried Frailty Criteria[2]. HRQoL was assessed using global Patient-Reported Outcomes Measurement Information System (PROMIS) computerized adaptive tests where 50 is the population mean. Cognition was assessed using the Mini-Mental Standard Examination (MMSE) and sarcopenia was assessed by DXA[3]. Fisher's exact test, chi-square tests and Kruskal-Wallis tests were used to describe differences among groups as appropriate. Univariate and multivariate linear regressions were used to describe the associations with frailty.

Results: 40 patients were enrolled. Overall, patients had a low burden of comorbidities and high education level (Table 1). Prevalence of frailty, pre-frailty and robustness was 15%,60% and 25%, respectively. Frail patients were older and had longer duration of disease; however, these differences were not statistically significant. Of 27 patients with

MMSE = Mini-Mental Standard Examination

body composition analysis, 26% were sarcopenic. Frail patients had worse physical function (lower scores) and more fatigue, pain behavior and interference (higher scores) compared to pre-frail and robust patients (Table 2). In the multivariate analysis, frail patients were more likely to have worse physical function, more fatigue, and more pain behavior and pain interference. No significant associations between either cognition or sarcopenia and frailty were observed.

Conclusion: In this cohort of PMR patients, we found a higher prevalence of frailty and pre-frailty than community dwelling elderly. Frailty was associated with worse physical function and increased fatigue, pain behavior and pain interference, differences that were clinically meaningful and statistically significant. Study limitations include the relatively small, homogenous sample size and missing data regarding sarcopenia. These data suggest that frailty is common in PMR and that it is associated with clinical phenotypes. Further assessment of frailty and its impact on PMR outcomes in a larger prospective cohort is warranted.

Abstract Number: 0423

Defining Ear Chondritis: Data from 685 Patients with Relapsing Polychondritis

Marcela Ferrada[1], Nathalie Costedoat-Chalumeau[2], Guillaume Moulis[3], Nancy Linn[4], Emily Rose[1] and Peter C. Grayson[5], [1]Systemic Autoimmunity Branch, Vasculitis Translational Research Program, National Institute of Arthritis and Musculoskeletal and Skin Diseases, National Institutes of Health, Bethesda, MD, [2]APHP, Université de Paris, Paris, France, [3]Toulouse University hospital, Toulouse, France, [4]Relapsing Polychondritis Foundation, Palos Verdes Estates, CA, [5]Systemic Autoimmunity Branch, National Institutes of Health, NIAMS, Bethesda, MD

SESSION INFORMATION
Session Date: Friday, November 6, 2020
Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Ear chondritis is often considered the pathognomonic feature of relapsing polychondritis (RP). Although painful redness and swelling of the pinna and a resultant cauliflower ear are universally recognized as chondritis, the complete spectrum of symptoms associated with ear chondritis have not been well described. The study objective was to seek patient input to help characterize ear chondritis.

Methods: An online survey was administered in English or Spanish to participants with self-reported RP. Participants were asked questions about their ear pain, including quality, location, duration, aggravating/alleviating factors, timing of onset and duration. Participants were included who reported age ≥ 18 years, a diagnosis of RP confirmed by a physician, and sufficient symptoms to meet McAdams or Damiani's diagnostic criteria. Participants were categorized as having "typical ear chondritis" if they reported ear pain localized to the pinna with associated redness and swelling. Atypical presentations of ear chondritis were also considered.

Results: A total of 685 participants from five continents completed the survey. Among them, 659 met inclusion criteria for subsequent analysis. Most participants were female (n=574; 87%), white (n=548; 83%) and from the United States (n=484;74%). The median age was 50 years (interquartile range = 41-58). In total, 593 (90%) patients reported ear pain, 227 (38%) had "typical ear chondritis", and 98 (16%) had cauliflower ear.

Ear pain was most commonly described as burning (n=334, 56%) or throbbing (n=295, 50%). The most common location of pain was the pinna (n=373, 63%). Participants reported ear redness (n=454, 76%) and swelling (n=349, 53%). Some patients experienced isolated redness (n=130, 22%) or swelling (n=25, 4%). The most common aggravating factors were minor trauma (n=371, 62%) and stress (n=358, 60%). The most common alleviating factor was avoidance of touching the ear (n=374, 63%). Pain was most frequently reported during the daytime (n=355, 60%) and most likely to occur in either ear at different times (n=310, 52%). Onset could be gradual (n=198, 33%) or sudden (n=155, 26%). Pain typically lasted a few hours (n=175, 30%) or 2-3 days (n=130, 22%). The majority of patients who had pinna pain also had pain in other parts of the ear (e.g. mastoid process, inner ear, whole ear) at some point (n=394, 67%). In patients with cauliflower ear, the most common location of pain was the pinna (n=57, 58%) followed by pain inside the ear (n=53, 54%). Most participants reported at least two different types of pain (n=420, 64%).

Conclusion: Ear chondritis in patients with RP has a wide range of clinical presentations and characteristics beyond the typical triad of redness, swelling, and pain localized to the pinna. The description of pain often significantly varies within the same patient. Knowledge of the various distinct characteristics of ear involvement in RP may help physicians recognize and monitor the disease more effectively.

Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster I

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: Relapsing polychondritis (RP) is a highly heterogenous systemic inflammatory disorder that affects many organ systems, in particular, cartilaginous structures. Clinical presentations in RP are variable, making recognition and diagnosis of the disease challenging. Testing for anti-collagen II (CII) antibodies is sometimes used to confirm the diagnosis of RP; however, the data remains inconclusive as to what percentage of RP patients have anti-CII antibodies in their serum. Our objectives were to evaluate the utility of anti-CII antibody as a diagnostic tool and as a possible objective measure of disease activity in a large cohort of patients with RP.

Methods: Patients 18 years and older were recruited into a prospective observational cohort of RP. All patients met McAdams or Damiani's diagnostic criteria for RP. Anti-CII antibodies were assayed via a clinically certified ELISA test (Mayo Clinic, Rochester, MN) in all patients evaluated from July 2019 to March 2020. Clinical features were compared between patients with RP stratified by presence of anti-CII antibody results using Fisher's exact test or Wilcoxon rank sum test as appropriate. Linear regression was used to determine if antibody titer correlated to Physician Global Assessment (PGA) score of disease activity. Clinical ELISA test results were compared to results using a different ELISA test platform (cat. no. 2065, Chondrex Inc., Redmond, WA, USA).

Results: Forty-six patients were tested, and six patients (13%) had elevated levels of anti-CII antibodies. Of four patients (8%) who had repeat testing, anti-CII antibodies were persistently negative in 3 patients and discordant positive/negative in 1 patient. Patients with elevated anti-CII antibodies compared to those without elevated antibodies were female (100 vs 63%, $p = 0.02$) with a significantly higher prevalence of oral ulcers (50 vs 15%, $p = 0.04$), genital ulcers (33 vs 5%, $p = 0.02$), costochondritis (66 vs 25%, $p = 0.048$), and Sicca symptoms (83 vs 33%, $p = 0.03$) and with a significantly lower prevalence of eye inflammation (0 vs 40%, $p = 0.018$), as well as lower absolute monocyte (median 0.33 vs 0.51 K/uL, $p = 0.02$) and white blood cell counts (median 4.54 vs 6.95 K/ul, $p = 0.049$). There was no correlation between antibody titer and PGA ($r= 0.18$; $p = 0.33$). A total of 24 patients were tested on both ELISA platforms. Twenty-three patients tested negative on both platforms, but 1 patient that tested positive by the Mayo Clinic ELISA tested negative by the Chondrex ELISA. Thus, there was little concordance between platforms.

Conclusion: Anti-CII antibodies likely have a limited role as a diagnostic test or biomarker of disease activity in RP. Few patients with RP have detectable anti-CII antibodies, and detection of these antibodies is dependent on testing platform. Presence of anti-CII antibodies may be associated with specific clinical symptoms and may be enriched in a subset of patients with RP who have mucocutaneous disease. This subset is commonly referred to as MAGIC syndrome (mouth and genital ulcers with inflamed cartilage). Whether anti-CII antibodies provide pathogenic insight for a smaller subset of patients with RP remains to be determined.

SESSION INFORMATION

Session Date: Friday, November 6, 2020

Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster I

Session Type: Poster Session A

Session Time: 9:00AM–11:00AM

Background/Purpose: Mouth and genital ulcers with inflamed cartilage (MAGIC) syndrome is an extremely rare condition that encompasses symptoms of relapsing polychondritis (RP) and Behcet's disease (BD). Little is known about the prevalence of clinical symptoms in patients with MAGIC and to what extent patients with MAGIC are similar to other patients with RP. The study objectives were to determine the frequency of patients with MAGIC syndrome and BD in a cohort of patients with RP and compare the clinical, laboratory and radiographic characteristics as well as treatment and outcomes.

Methods: Patients who met McAdams or Damiani's diagnostic criteria for RP and were 18 years old or older were included in this analysis. The International Criteria for Bechet's Disease (ICBD) was used for the diagnosis of BD. MAGIC syndrome was defined by presence of recurrent oral and genital ulcers plus chondritis. Categorical and continuous variables were compared using the Fisher's exact test and Kruskal-Wallis test, respectively.

Results: Eighty-four patients were included in this analysis. Most of the patients were female (n=72, 86%) and white (n=73, 87%). Median age of symptom onset was 36 years (IQR 28-42). Among patients with RP, 13 (15%) met diagnostic criteria for BD, all of whom had MAGIC syndrome. Although referred for RP, MAGIC syndrome was not recognized by any of the referring care providers. When comparing patients with RP and MAGIC syndrome, there were no significant differences between race or sex (white, 85% vs 87%, p=0.68; female 83% vs 100%, p=0.20). Patients with MAGIC syndrome were more likely compared to RP to have diagnostic delay (median 10.1 years (IQR 3-18) vs 6.9 years (IQR 1-9.75), p=0.04), a higher prevalence of Raynaud's phenomena (54% vs 11%, p = 0.002), uveitis or retinal vasculitis (23% vs 4%, p =0.04), chronic GI symptoms (54% vs 13%, p = 0.002), and elevated anti-collagen II antibodies (60% vs 9 %, p=0.03). Although not statistically significant, patients with MAGIC syndrome also had a higher percentage of pulmonary embolism (15% vs 3%), unprovoked DVT (15 vs 3%), aortitis (8% vs 1%), airway chondritis (69% vs 41%), GI ulcers or inflammation (15% vs 4%) and erythema nodosum or pseudofolliculitis (8% vs 1%). There were no significant differences in the prevalence of ear or nose chondritis, costochondritis, hearing loss, joint involvement, neurologic disease, elevated inflammatory markers, or HLA-B51 status. There were no significant

differences in treatment or outcome measures including mortality, ICU admissions and tracheotomy between MAGIC and RP.

Conclusion: Fifteen percent of patients with RP meet diagnostic criteria for MAGIC syndrome and BD. Patients with MAGIC syndrome have distinct clinical and laboratory characteristics including prevalent vascular symptoms such as Raynaud's, thromboembolic disease, and aortitis. Recognizing the wide pattern of organ involvement and clinical characteristics in patients with MAGIC syndrome may help identify these patients earlier. Larger studies to determine whether anti-collagen II antibodies in patients with MAGIC play a causal role in disease and/or function as a diagnostic biomarker are warranted.

SESSION INFORMATION
Session Date: Friday, November 6, 2020
Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Relapsing polychondritis (RP) is a rare, systemic inflammatory disease characterized by recurrent inflammation of cartilaginous structures, including the nose/ears, joints, and trachea. The etiology of this life-threatening and disabling disease is currently unknown and little is known about its pathogenesis. HLA association evidence supports T-cell involvement in RP; however, the extent of T-cell involvement is incompletely understood. Previous studies demonstrate that TCR repertoire diversity is decreased in individuals with autoimmune diseases, such as rheumatoid arthritis and type 1 diabetes. Here we study the TCR repertoire of individuals with RP to identify potential disease-causing clones, which may provide critical knowledge in uncovering disease etiology, serve as a biomarker, or influence treatment decisions.

Methods: Peripheral blood leukocyte DNA was collected from 13 patients with highly active RP, and TCR-β chains were sequenced by Adaptive Biotechnologies. 3 samples containing a dominant clone were re-sequenced at a time of reduced disease activity. 13 age and sex matched healthy controls were obtained from the ImmuneACCESS public database. Data was analyzed using ImmunoSEQ Analyzer to quantify Productive Entropy, Max Productive Frequencies, Differential Abundance, and TCR- β chain V family gene usage. Frequencies were compared using the Mann-Whitney U test. Physician global assessment (PGA) was used to determine disease activity in a subset of the patients.

Results: Productive Entropy values were significantly lower in patients with RP compared to healthy controls (median 15.73 vs 16.86, P=0.0015), indicating a less diverse TCR repertoire in patients with RP. 3 patients had unique dominant clones with Max Productive Frequencies over 5 % (range 5.68-10.71%). In 2 of these patients Productive Entropy values increased in parallel with improvement in PGA scores (12.316 to 12.8916 and 14.1600 to 15.5207 respectively) and Max Productive Frequencies of dominate clones decreased (5.675% to 4.961% and 10.712% to 7.476% respectively). Additionally, 3 TCR- β chain variable (V) expansions were detected for Vβ9, Vβ19, and Vβ20 families that were not expanded in controls.

Conclusion: TCR repertoire is less diverse in patients with RP compared to healthy controls. Expanded TCR- β chain V families and dominant clones not expressed in healthy controls may provide insights to antigenic drivers of RP. Further, the TCR repertoire may be less diverse during active disease compared to lower disease activity. Based upon these findings, we intend to confirm the trends in a larger cohort of patients, make comparisons to immunopheno-

types and clinical associations, and detect possible antigens by clustering TCRs with conserved CDR3 and V family motifs.

Validation of Physician Global Assessment as an Outcome Measure in Relapsing Polychondritis

Emily Rose[1], Marcela Ferrada[1], Kaitlin Quinn[2], Wendy Goodspeed[1], Laurent Arnaud[3] and Peter C. Grayson[4], [1]Systemic Autoimmunity Branch, Vasculitis Translational Research Program, National Institute of Arthritis and Musculoskeletal and Skin Diseases, National Institutes of Health, BETHESDA, MD, [2]Systemic Autoimmunity Branch, National Institutes of Health, NIAMS, Washington, DC, [3]Department of rheumatology, University Hospitals of Strasbourg and French National Reference Center for Rare Auto-immune diseases, Strasbourg, Alsace, France, [4]Systemic Autoimmunity Branch, National Institutes of Health, NIAMS, Bethesda, MD

SESSION INFORMATION
Session Date: Friday, November 6, 2020
Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Relapsing polychondritis (RP) is a rare systemic inflammatory disorder of cartilage that lacks validated disease activity measures. Physician global assessment (PhGA) is a measure of disease activity frequently used in a variety of rheumatologic diseases to track treatment response and categorize disease states. PhGA has not been studied specifically in a cohort of patients with RP. The objective was to characterize the reliability and utility of PhGA for RP.

Methods: Adult patients in an ongoing observational cohort who meet existing diagnostic criteria for RP underwent a standardized comprehensive evaluation at approximately 6-month intervals. PhGA was scored by consensus of 3 raters on a scale of 0 (no clinical activity) to 10 (maximum disease activity) at each study visit. Ratings were considered discordant if any two ratings differed by three or more points. Change in immunosuppressive treatment between consecutive visits was recorded as increased, decreased or unchanged. Intraclass correlation coefficients (ICC) (2, 1), Spearman's correlation, Fisher's exact test and Wilcoxon signed rank were used to characterize the reliability and utility of PhGA as a measure of disease activity.

Results: 78 patients were evaluated over visits. The ICC for the ratings by the 3 raters was 0.79 (95 % confidence interval:0.73-0.84), indicating good reliability. For 6 out of 164 visits (3.7%) the ratings by the 3 raters were discordant. After adjudicating the discordant ratings, the assigned PhGA ranged from 0-7 with a median of 3 (interquartile range 2-3). PhGA was 0 at 4 visits (2%), 1 or 2 at 76 visits (46%), 3 or 4 at 63 visits (38%), and more 5 or more at 22 visits (13%). PhGA was weakly correlated with CRP ($r= 0.30$, $P< 0.001$) but not with ESR ($r=0.13$, $P=0.10$). Between the baseline and the first follow-up visit there was decrease in PhGA from median of 3 (interquartile range 2-5) to median of 2 (interquartile range of 1-3) ($P< 0.001$). There was no further change in PhGA over subsequent consecutive follow-up visits. Between consecutive visits in which there was an increase in immunosuppressive treatment, the median PhGA decreased from 3 (interquartile range 2-4) to 2 (interquartile range 2-3) ($P< 0.001$) but rarely went to 0. Between consecutive visits in which there was no change or a decrease in treatment, there were no corresponding changes in PhGA.

Conclusion: PhGA is a reliable measure to quantify disease activity and monitor treatment response in RP. Even with treatment, few patients with RP have a PhGA of 0, suggesting that a state of no clinical activity is difficult to achieve or that damage may be masquerading as low disease activity in some patients. These data provide insight into the burden of disease activity in RP and highlight a need for improved treatments.

Enrichment of Clinical Trial Recruitment Using Advanced Molecular Imaging in Takayasu's Arteritis

Kaitlin Quinn[1], Mark Ahlman[2], Emily Rose[3], Peter Merkel[4] and Peter C. Grayson[5], [1]Systemic Autoimmunity Branch, National Institutes of Health, NIAMS, Bethesda, [2]National Institutes of Health, Clinical Center, Radiology and Imaging Sciences, Bethesda, MD, [3]Systemic Autoimmunity Branch, Vasculitis Translational Research Program, National Institute of Arthritis and Musculoskeletal and Skin Diseases, National Institutes of Health, Bethesda, MD, [4]University of Pennsylvania, Philadelphia, PA, [5]Systemic Autoimmunity Branch, National Institutes of Health, NIAMS, Bethesda, MD

SESSION INFORMATION
Session Date: Friday, November 6, 2020
Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster I
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Definitions of disease activity are not standardized in Takayasu's arteritis (TAK), which can lead to difficulty in determining whether a patient should be enrolled into a randomized controlled trial (RCT). FDG-PET can complement clinical assessment of disease activity. Two prior RCTs in TAK (AGATA, North American study of abatacept[1] and TAKT, Japanese study of tocilizumab[2]) used different definitions of disease activity. Neither trial considered FDG-PET findings in these definitions.

The objectives of this study were to: 1) Evaluate physician agreement about patient enrollment based on study inclusion criteria from AGATA and TAKT and 2) Determine if vascular FDG-PET impacts decision-making about trial inclusion.

Methods: Patients with TAK were recruited from an observational cohort. Each patient underwent clinical assessment and an FDG-PET-CT scan during a single study visit. A nuclear medicine physician reviewed all PET scans, blinded to clinical data, and interpreted the scans as active, indeterminate, or inactive. Two rheumatologists independently rated whether each patient met inclusion criteria for AGATA[1] and/or TAKT[2]. In Round 1, determination of disease activity was based on clinical and laboratory data only. In Round 2, determination of disease activity was based on the same data plus PET scan results. In both rounds, each reviewer recorded certainty about the decision to enroll/exclude a patient. Inter-rater reliability (IRR) was calculated using Fleiss' Kappa.

Results: 76 patients with TAK were evaluated. Using AGATA enrollment criteria, the raters agreed to enroll 31 patients (41%), exclude 33 patients (43%), and disagreed for 12 patients (16%). Using TAKT enrollment criteria, the raters agreed to enroll 34 patients (45%), exclude 29 patients (38%), and disagreed for 13 patients (17%). Disagreement was frequently driven by fatigue/malaise and/or elevated acute phase reactants, and raters were uncertain in 92%

Table: Certainty of Disease Activity Assessment for Trial Enrollment Based on Clinical and Laboratory Data (Blinded to FDG-PET Scan)

			Certain to Enroll in Round 1	Certain to Exclude in Round 1	Uncertain in Round 1
NIH Cohort N = 76	AGATA	*Rater 1* *PET Active* *PET Indeterminate* *PET Inactive*	Total n=16 n=16 (100%) n= 0 (0%) n=0 (0%)	Total n=24 n= 11 (46%) n= 5 (21%) n= 8 (33%)	Total n=36 n= 22 (61%) n= 9 (25%) n= 5 (14%)
		Rater 2 *PET Active* *PET Indeterminate* *PET Inactive*	Total n=18 n=17 (94%) n=1 (6%) n=0 (0 %)	Total n=25 n= 12 (48%) n= 6 (24%) n= 7 (28%)	Total n=33 n= 20 (61%) n= 7 (21%) n= 6 (18%)
	TAKT	*Rater 1* *PET Active* *PET Indeterminate* *PET Inactive*	Total n=20 n=19 (95%) n=1 (5%) n=0 (0 %)	Total n=25 n= 12 (48%) n= 6 (24%) n= 7 (28%)	Total n=31 n= 19 (61%) n= 7 (23%) n= 5 (16%)
		Rater 2 *PET Active* *PET Indeterminate* *PET Inactive*	Total n=21 n=19 (90%) n=2 (10%) n=0 (0%)	Total n=23 n= 11 (48%) n= 5 (22%) n= 7 (30%)	Total n=32 n= 18 (56%) n= 7 (22%) n= 7 (22%)

of these cases. Availability of PET scan results significantly improved agreement between raters (Round 1 IRR= 0.68 [95% CI (0.67-0.69)]; Round 2 IRR=0.88 [CI 0.87-0.89]; p< 0.01).

Of patients whom the rater was certain in Round 1 to enroll, no patient had an inactive PET. Conversely, of patients whom the rater was certain to exclude, approximately half of these patients had abnormal subclinical PET activity (TABLE). For patients whom the rater noted uncertainty about enrollment in Round 1, certainty improved in both raters once PET data was incorporated [Rater 1: 56% to 86% certainty, Rater 2: 57% to 87% certainty].

Conclusion: Physicians are frequently uncertain about disease activity assessment in TAK. This uncertainty leads to disagreement about which patients meet RCT requirements for enrollment. Consideration of FDG-PET findings in addition to clinical assessment improves confidence about disease activity assessment and significantly reduces disagreement about trial eligibility. Incorporation of PET findings into the definition of disease activity identifies a substantial number of patients with subclinical inflammation, which could increase the number of eligible participants for treatment trials in TAK.

Prothrombotic Antiphospholipid Antibodies in COVID-19

Yu Zuo[1], Shanea Estes[2], Alex Ghandi[3], Srilakshmi Yalavarthi[3], Ramadan Ali[3], Shi Hui[3], Gautam Sule[3], Kelsey Gockman[3], Jacqueline Madison[3], Melanie Zuo[3], Wrenn Woodard[3], Sean Lezak[3], Njira Lugogo[3], Yogendra Kanthi[4] and Jason Knight[1], [1]Division of Rheumatology, University of Michigan, Ann Arbor, MI, [2]University of Michigan, Ann Arbor, MI, [3]University of Michigan, Ann Arbor, [4]Division of Cardiovascular Medicine, Ann Arbor

SESSION INFORMATION
Session Date: Friday, November 6, 2020
Session Title: Plenary Session I
Session Type: Plenary Session
Session Time: 11:30AM–1:00PM

Background/Purpose: Patients with coronavirus disease 19 (**COVID-19**) are at high risk for thrombosis of arteries and veins. At the same time, COVID-19 lung histopathology has revealed fibrin-based occlusion of small vessels. Antiphospholipid syndrome (**APS**) is an acquired thrombophilia in which patients develop pathogenic autoantibodies (**aPL**) targeting phospholipids and phospholipid-binding proteins. Small case series have recently detected aPL in patients with COVID-19. Here, we endeavored to comprehensively measure aPL in a large cohort of patients hospitalized with COVID-19. We also asked whether purified IgG fractions from these patients had prothrombotic properties in vitro and in vivo.

Methods: Sera from 172 patients hospitalized with COVID-19 were evaluated for eight different types of aPL: anti-cardiolipin IgG/IgM/IgA, anti-beta-2 glycoprotein I IgG/IgM/IgA, and anti- phosphatidylserine/prothrombin (**PS/PT**) IgG/IgM. IgG fractions were purified from COVID-19 patients with various aPL profiles. The prothrombotic potential of the purified IgG fractions were evaluated in neutrophil extracellular trap (**NET**) assays and in two mouse models of inferior vena cava thrombosis.

Results: We detected anticardiolipin IgM antibodies in 23% of COVID-19 patients, anti-PS/PT IgG in 24%, and anti-PS/PT IgM in 18%. Any aPL was present in 52% of patients based upon the manufacturer's threshold and in 30% using a more stringent cutoff (≥40 units) (**Table 1**). High aPL levels tended to track with more severe COVID-19. For example, anti-PS/PT IgM levels were significantly correlated with neutrophil activation (calprotectin, r=0.23, p=0.002), circulating NETs (myeloperoxidase/**MPO**-DNA complexes, r=0.23, p=0.003), and more severe respiratory disease (SpO_2/FiO_2, r=-0.16, p=0.03). Similar correlations were also seen for anticardiolipin IgM (calprotectin r=0.28, p=0.0002; MPO-DNA r=0.25, p=0.001; SpO_2/FiO_2 r=-0.19, p=0.01). Furthermore, positive testing for any aPL predicted impaired kidney function as defined by estimated glomerular filtration rate (p=0.03). Purified IgG fractions from aPL-positive COVID-19 patients (either anti-β_2GPI IgG or anti-PS/PT IgG) promoted NET release from control neutrophils, similar to IgG isolated from individuals with established APS. Furthermore, injection into mice of COVID-19 IgG fractions (isolated from four different patients with high levels of anti-PS/PT IgG) more than doubled thrombus extension and accretion in two separate models of inferior vena cava thrombosis. Administration of the COVID-19 IgG also significantly increased circulating NET remnants in mice (p=0.0004), similar to IgG from patients with catastrophic antiphospholipid syndrome (p=0.001).

Conclusion: These data demonstrate that a significant percentage of patients with COVID-19 become at least transiently positive for aPL and that these aPL are potentially pathogenic.

Table 1: Prevalence of antiphospholipid antibodies in COVID-19 patients (n=172)

aPL	Number positive (factory cut-off)	%	Number positive (titer ≥40)	%
aCL IgG	8	4.7%	2	1.2%
aCL IgM	39	23%	13	7.6%
aCL IgA	6	3.5%	1	0.58%
aβ_2GPI IgG	5	2.9%	3	1.7%
aβ_2GPI IgM	9	5.2%	7	4.1%
aβ_2GPI IgA	7	4.1%	3	1.7%
aPS/PT IgG	42	24%	21	12%
aPS/PT IgM	31	18%	21	12%
any positive aPL	89	52%	52	30%

aPL=antiphospholipid antibodies; aCL= anticardiolipin;
aβ_2GPI=anti-beta-2 glycoprotein I; aPS/PT=anti-phosphatidylserine/prothrombin
Factory cut-offs:

- aCL IgG/M/A=20 GPL/MPL/APL
- aβ2GPI IgG/M/A=20 GPL/MPL/APL
- aPS/PT IgG/M=30 units

Outcomes of Coronavirus Disease 2019 Infection Among Patients Living with Rheumatic Diseases: A Matched Cohort Study from a US Multi-Center Research Network

Kristin D'Silva[1], April Jorge[1], Na Lu[2], Yuqing Zhang[3], Zachary Wallace[4] and Hyon Choi[5], [1]Massachusetts General Hospital, Boston, MA, [2]Arthritis Research Canada, Vancouver, BC, Canada, [3]Massachusetts General Hospital, Quincy, MA, [4]Massachusetts General Hospital, Newton, MA, [5]Massachusetts General Hospital, Department of Medicine, Division of Rheumatology, Lexington, MA

SESSION INFORMATION
Session Date: Friday, November 6, 2020
Session Title: Plenary Session I
Session Type: Plenary Session
Session Time: 11:30AM–1:00PM

Background/Purpose: Whether patients living with systemic autoimmune rheumatic diseases (SARDs) suffer from more severe complications of Coronavirus Disease 2019 (COVID-19) infection remains unknown.

Methods: We conducted a matched cohort study to examine COVID-19 infection outcomes of patients with SARDs using the TriNETX Research Network, which contains real-time electronic health record data from >52 million patients across 35 healthcare organizations. COVID-19 infections were identified by International Classification of Diseases

Table 1. Baseline characteristics of COVID-19 infected patients with SARD versus 1:1 age-sex-race-matched comparators without SARD.

	COVID-19 with SARD (N=716)	COVID-19 without SARD (N=716)
Age, years	57 ± 16	57 ± 16
Female	569 (79%)	569 (79%)
Race/ethnicity		
White	388 (54%)	388 (54%)
Black/African American	241 (34%)	241 (34%)
Asian	13 (2%)	13 (2%)
Latinx	47 (7%)	47 (7%)
Body mass index, kg/m^2	31 ± 8	32 ± 9
Creatinine, mg/dL	1.2 ± 1.4	1.0 ± 0.8
Hypertension	349 (49%)	228 (32%)
Diabetes mellitus	173 (24%)	120 (17%)
Asthma	129 (18%)	67 (9%)
Chronic obstructive pulmonary disease	25 (3%)	13 (2%)
Chronic kidney disease	136 (19%)	47 (7%)
Congestive heart failure	104 (15%)	38 (5%)

Continuous variables are expressed as mean ± standard deviation and categorical variables are expressed as number (percentage). COVID-19 = Coronavirus Disease 2019; SARD = systemic autoimmune rheumatic disease.

Table 2. Outcomes of COVID-19 infection in patients with SARD versus 1:1 age-sex-race-matched comparators without SARD.

COVID-19 Infection Outcome	Risk in People with SARD, N(%) (N=716)	Risk in People without SARD, N(%) (N=716)	Risk Difference, % (95% CI)	Risk Ratio (95% CI)	p-value
Hospitalization	175 (24.4%)	142 (19.8%)	4.6 (0.3, 8.9)	1.23 (1.01, 1.50)	**0.04**
Intensive care unit admission	49 (6.8%)	28 (3.9%)	2.9 (0.6, 5.3)	1.75 (1.11, 2.75)	**0.01**
Mechanical ventilation	39 (5.5%)	22 (3.1%)	2.4 (0.3, 4.5)	1.77 (1.06, 2.96)	**0.03**
Acute kidney injury*	42 (5.9%)	23 (3.2%)	2.7 (0.5, 4.8)	1.83 (1.11, 3.00)	**0.02**
Congestive heart failure	49 (6.8%)	16 (2.2%)	4.6 (2.5, 6.8)	3.06 (1.76, 5.33)	**<0.01**
Death	36 (5.0%)	31 (4.3%)	0.7 (-1.5, 2.9)	1.16 (0.73, 1.86)	0.53

COVID-19 = Coronavirus Disease 2019; SARD = systemic autoimmune rheumatic disease; CI = confidence interval.
*Includes ICD-10 codes for acute kidney injury and procedure codes for initiation of renal replacement therapy.

10th Revision (ICD-10) codes or positive COVID-19 testing by polymerase chain reaction between January 20, 2020, and June 1, 2020. Patients with SARDs (including rheumatoid arthritis [RA], systemic lupus erythematosus [SLE], Sjogren's syndrome, systemic sclerosis [SSc], idiopathic inflammatory myositis [IIM], mixed or undifferentiated connective tissue disease, systemic vasculitis, psoriatic arthritis [PsA], and ankylosing spondylitis [AS]) were identified by two ICD-10 codes for rheumatic disease greater than two months apart. For the comparison cohort, we matched one individual without SARDs based on age, sex, and race/ethnicity. Baseline characteristics were assessed in the 1 year prior to COVID-19 infection, and outcomes were assessed between 2 weeks and 3 months after COVID-19 infection. We calculated the risk difference and risk ratio (RR) for the association of SARD with each outcome.

Results: There were 716 patients with COVID-19 infection and SARD and 716 age-sex-race-matched comparators with COVID-19 infection but without SARD. After matching, the average age was 57 years, 79% were female, 54% were white, and 34% were Black or African American (**Table 1**). Patients with SARDs had higher rates of comorbidities than comparators, including hypertension, asthma, chronic kidney disease, and heart failure. Among patients with SARDs, the distribution of rheumatic disease was: 325 (45%) RA, 128 (18%) SLE, 71 (10%) Sjogren's syndrome, 25 (3%) SSc, 20 (3%) IIM, 34 (5%) mixed or undifferentiated connective tissue disease, 61 (9%) systemic vasculitis, 44 (6%) PsA, and 22 (3%) AS. Of patients with SARDs, 289 (40%) were on prednisone, 140 (20%) were on hydroxychloroquine, and 84 (12%) were on tumor necrosis factor inhibitors. Patients with SARDs had higher risk of hospitalization (RR 1.23), intensive care unit admission (RR 1.75), mechanical ventilation (RR 1.77), acute kidney injury (RR 1.83), and congestive heart failure (RR 3.06) versus comparators without SARDs (all $p < 0.05$, **Table 2**). Mortality was numerically higher in patients with SARDs than comparators, although not statistically significant.

Conclusion: Patients with SARDs who develop COVID-19 infection may have higher risks of end-organ failure (including mechanical ventilation, acute kidney injury, and heart failure) compared to matched comparators without SARDs. Further studies are needed to identify risk factors associated with severe COVID-19 infection in patients living with SARDs.

Abstract Number: 0431

Hydroxychloroquine Use Was Not Associated with QTc Length in a Large Cohort of SLE and RA Patients

Elizabeth Park[1], Jon Giles[2], Thania Perez-Recio[1], Paloma Pina[3], Christopher Depender[1], Joan Bathon[1] and Laura Geraldino-Pardilla[4], [1]Division of Rheumatology, Columbia University Vagelos College of Physicians and Surgeons, New York, NY, [2]Columbia University, New York, NY, [3]Cardiac Electrophysiology, Northwestern Medicine, Chicago, IL, [4]Division of Rheumatology, Columbia University Vagelos College of Physicians and Surgeons, New York

SESSION INFORMATION
Session Date: Friday, November 6, 2020
Session Title: Plenary Session I
Session Type: Plenary Session
Session Time: 11:30AM–1:00PM

Background/Purpose: Hydroxychloroquine (HCQ) is a cornerstone therapy for systemic lupus erythematosus (SLE), and is used as monotherapy and combined with other DMARDs in rheumatoid arthritis (RA). However, its use in the treatment of COVID-19 has raised concerns for the possibility of QTc prolongation and development of arrhythmia. We therefore assessed QTc length in a large SLE and RA cohort and its association with HCQ use.

Figure 1.

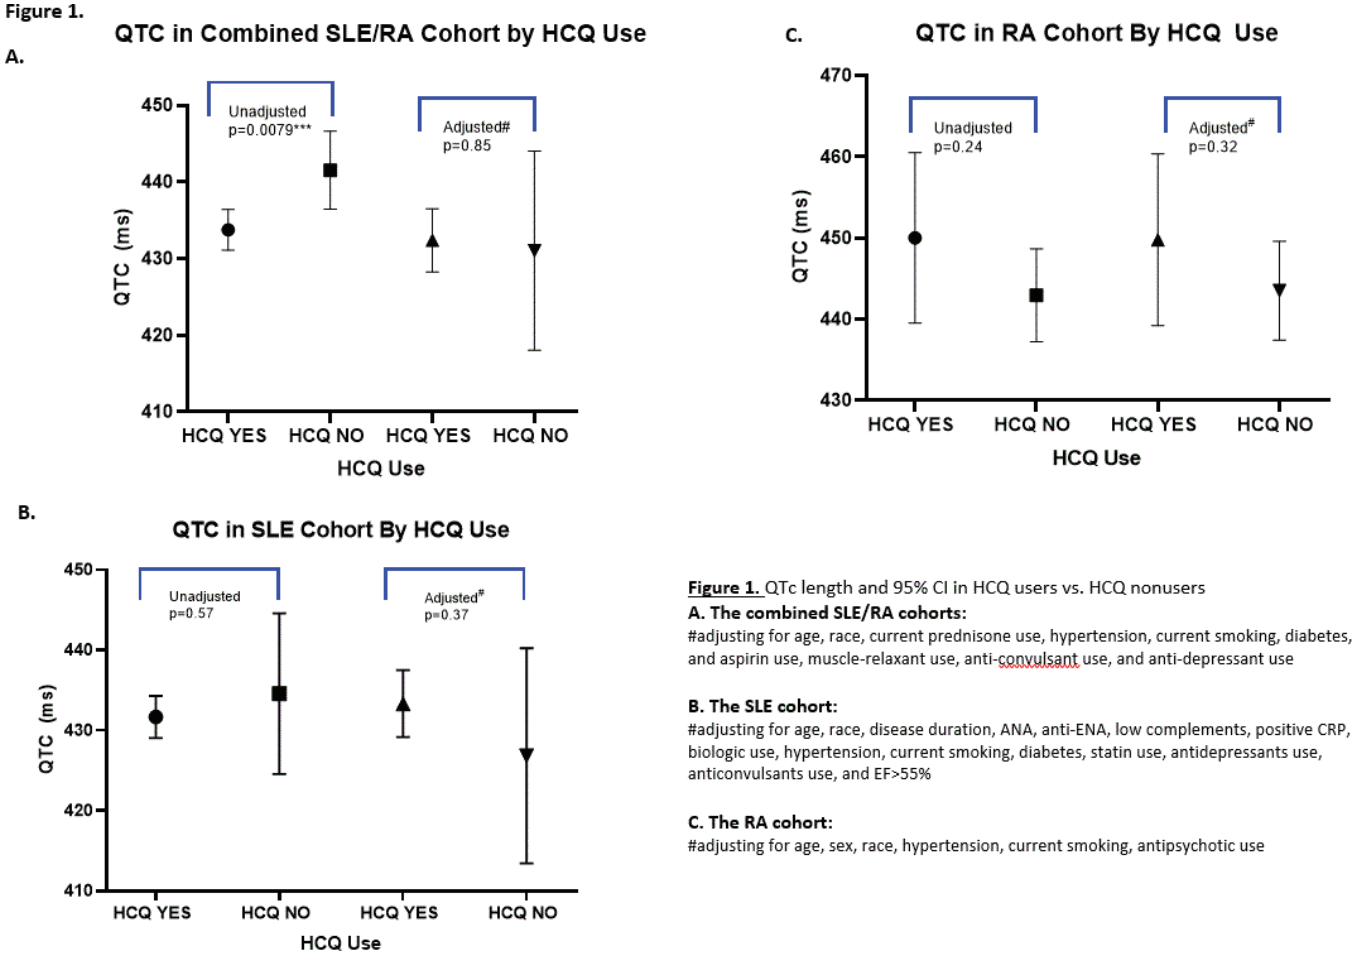

Figure 1. QTc length and 95% CI in HCQ users vs. HCQ nonusers

A. The combined SLE/RA cohorts:
#adjusting for age, race, current prednisone use, hypertension, current smoking, diabetes, and aspirin use, muscle-relaxant use, anti-convulsant use, and anti-depressant use

B. The SLE cohort:
#adjusting for age, race, disease duration, ANA, anti-ENA, low complements, positive CRP, biologic use, hypertension, current smoking, diabetes, statin use, antidepressants use, anticonvulsants use, and EF>55%

C. The RA cohort:
#adjusting for age, sex, race, hypertension, current smoking, antipsychotic use

Figure 1A-C

Methods: A total of 681 SLE and RA patients without clinical cardiovascular disease (CVD) were analyzed from two prospective RA cohorts with EKGs as part of study data collection (n=307), and one retrospective SLE cohort (n=374) with EKGs performed as part of standard of care. The participants from all three cohorts were recruited from tertiary referral centers. The association between QTc length and HCQ use was explored in regression models and adjusted for disease-specific characteristics and CVD risk factors.

Results: Of the entire (SLE+RA) cohort, 54% were HCQ users and 44% had a QTc > 440 ms. The mean QTc length was 437± 28 ms. In the entire cohort, adjusted QTc length in HCQ users was comparable to that of non-HCQ users (*Figure 1*). In multivariate logistic modeling, HCQ use was *not* a significant predictor of prolonged QTc > 440 or >500 ms for the entire cohort (OR 0.89; CI 0.25-3.2, & OR 0.11; CI 0.007-1.7, respectively), nor for the RA cohort (OR 1.1; CI 0.54-2.2, & OR 0.80; CI 0.23-2.8, respectively). HCQ use was not a significant predictor of a QTc >440 ms in the SLE subset (OR 2.0; CI 0.46-8.8). However, 9/11 SLE patients with a QTc >500 ms were on HCQ, yet these observations were too small to detect statistically significant differences between the HCQ groups. Importantly, QTc >500 ms was *not* associated with arrhythmias or deaths. No significant interactions were found between HCQ use and other QTc prolonging medications in the entire cohort. In fact, use of HCQ combined with any QTc prolonging medication was associated with a comparable QTc length (434 ms; CI 430-439) vs. use of HCQ alone (433 ms; CI 429-437). A significant interaction (p=*0.014*) was found between HCQ use and antipsychotic use in the SLE cohort, with QTc length being *longer* (441 ms; CI 428-454) for those on both vs. those only on HCQ (432 ms; CI 428-436).

Conclusion: This study demonstrates that in a large combined cohort of SLE and RA patients, QTc length does not significantly differ in HCQ users compared with non-HCQ users even while adjusting for potential clinical confound-

ers. Importantly, HCQ use was not associated with a prolonged QTc (>440 ms) in the combined and individual SLE and RA cohorts, nor was HCQ use a significant predictor of QTc length.

The Effect on Renal Function of the Complement C5a Receptor Inhibitor Avacopan in ANCA-Associated Vasculitis

Peter Merkel[1], Pirow Bekker[2], Huibin Yue[2], Catherine Kelleher[2], Thomas Schall[2] and David Jayne[3], [1]University of Pennsylvania, Philadelphia, PA, [2]ChemoCentryx, Mountain View, CA, [3]Department of Medicine, Vasculitis and Lupus Research Group, University of Cambridge, Cambridge, UK, Cambridge, United Kingdom

SESSION INFORMATION

Session Date: Friday, November 6, 2020

Session Title: Plenary Session I

Session Type: Plenary Session

Session Time: 11:30AM–1:00PM

Background/Purpose: Avacopan, a novel, orally-administered selective antagonist of C5aR, was recently evaluated in a pivotal Phase 3 randomized clinical trial where its use in patients with ANCA-associated vasculitis, also receiv-

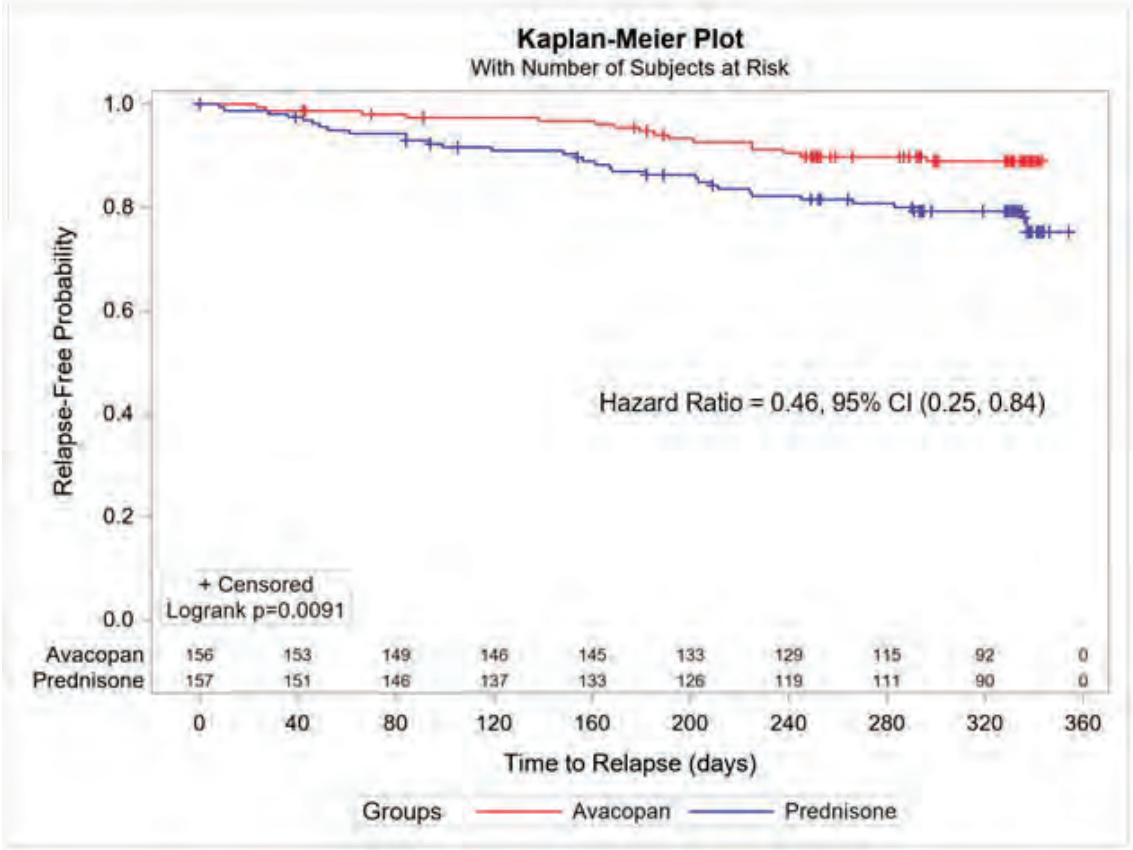

Figure 1. Time to Relapse in the ADVOCATE Study

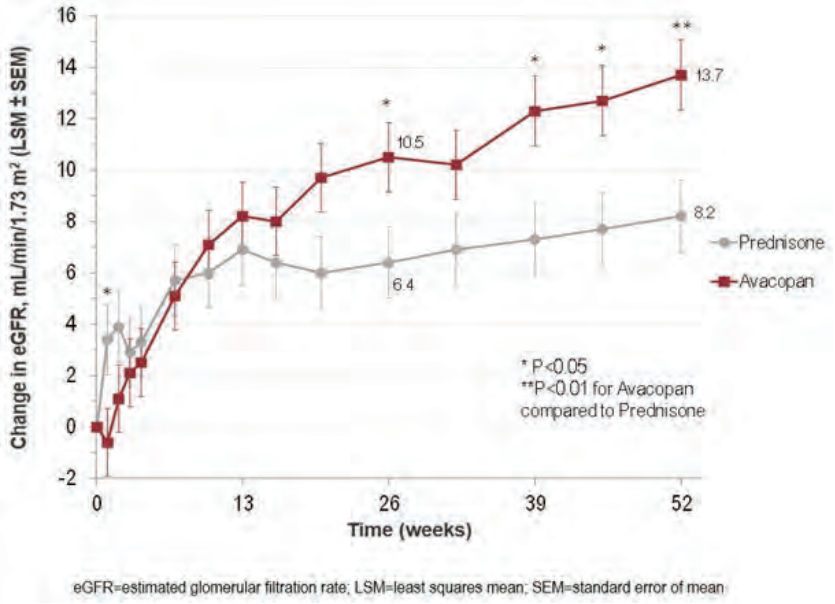

Change in Estimated Glomerular Filtration Rate (eGFR) in Subjects with eGFR <30mL/min/1.73 m2 at Baseline

ing cyclophosphamide/azathioprine or rituximab, demonstrated superiority compared with the prednisone group. Eighty-one percent of subjects had renal vasculitis, with renal function being a major outcome predictor. This analysis focuses on changes observed in renal function during the trial.

Methods: Subjects were randomized 1:1 to receive either standard prednisone therapy or avacopan 30 mg twice daily. Both treatment groups received either cyclophosphamide followed by azathioprine, *or* rituximab. The primary efficacy endpoints were the proportion of subjects achieving disease remission at Week 26, and sustained disease remission at Week 52 as measured by the Birmingham Vasculitis Activity Score (BVAS). Renal function was assessed based on the estimated glomerular filtration rate (eGFR), and albuminuria, based on the albumin:creatinine ratio.

Results: 330 subjects were dosed: 164 in the prednisone group, 166 in the avacopan group. Primary endpoints, remission Week 26: avacopan 72.3% vs. prednisone 70.1% (P< 0.0001 non inferiority); avacopan 65.7% vs. prednisone 54.9% at Week 52 (avacopan statistically superior P=0.0066). Time to relapse from time of remission (BVAS=0) was longer for the avacopan group (P=0.0091 Log-rank test of difference). The hazard ratio of time to relapse for avacopan:prednisone was 0.46, (95% confidence interval: 0.25, 0.84), **Figure 1**. Efficacy was observed across newly-diagnosed vs. relapsed disease, PR3- vs. MPO-ANCA, granulomatosis with polyangiitis vs. microscopic polyangiitis, cyclophosphamide vs. rituximab, and men vs. women.

In subjects with renal disease at baseline, the avacopan group had a greater increase in eGFR vs. the prednisone group (7.3 mL/min/1.73 m^2 vs. 4.1 mL/min/1.73 m^2) (P=0.029). The difference was greatest in subjects with a baseline eGFR < 30 mL/min/1.73 m^2 **(Figure 2)**. There was a more rapid reduction in albuminuria in the avacopan group (-40%) compared to no change in the prednisone group at 4 weeks; the overall reduction at Week 52 was similar between groups.

The avacopan group had a favorable safety profile compared to the prednisone group. There were 166 serious adverse events in the prednisone group compared to 116 in the avacopan group, and 31 serious infections vs. 25 in the avacopan group. SAEs of WBC count decreases occurred in 4.9% of subjects in the prednisone group vs. 2.5% in the avacopan group, and liver function test increases in 3.7% vs. 5.4%, respectively.

Conclusion: Avacopan offers a new treatment option in ANCA-associated vasculitis. In addition to an improved sustained remission outcome, the avacopan group had greater improvement in renal function compared to standard prednisone therapy. These findings suggest the potential for better long-term outcomes with avacopan for patients with renal disease than current standard of care treatment and provide intriguing insights into subclinical renal disease activity in ANCA-associated vasculitis.

Racial Disparities and New SLE-Specific Predictors of Stroke and Ischemic Heart Disease in Patients with Lupus

Shivani Garg[1], Christie Bartels[2], Gaobin Bao[3], Cristina Drenkard[4] and S. Sam Lim[3], [1]UW Madison, Madison, WI, [2]University of Wisconsin School of Medicine and Public Health, Department of Medicine, Division of Rheumatology, Madison, WI, [3]Emory University, Atlanta, GA, [4]Division of Rheumatology, Department of Medicine, Emory School of Medicine, Atlanta, GA

SESSION INFORMATION
Session Date: Friday, November 6, 2020
Session Title: Plenary Session I
Session Type: Plenary Session
Session Time: 11:30AM–1:00PM

Background/Purpose: In the US, cardiovascular disease (CVD) is the leading cause of disparities in life expectancy between black and white populations. We recently reported a 19-fold higher occurrence of CVD in blacks with SLE compared to non-blacks and noted disproportionately high stroke-related events around the time of SLE diagnosis. This study measured the risk and predictors of stroke and ischemic heart disease (IHD) in a predominantly black, population-based, incident cohort.

Methods: The Georgia Lupus Registry (GLR) is a population-based registry of SLE patients from Atlanta, Georgia. Incident patients in 2002-04 met ≥4 ACR SLE criteria or 3 criteria with a final diagnosis of SLE by their board-certified rheumatologist. Patients were matched to the Georgia Hospital Discharge Database and National Death Index from 2000-13. Stroke- and IHD-related hospitalizations and deaths were classified by the first three admission or cause of death codes. Stroke also included transient ischemic attack, and IHD included myocardial infarction and angina. Predictors of strokes and IHD were examined using Cox proportional hazards models.

Results: Among 336 incident SLE patients, 87% were female, 75% were black patient with a mean age at SLE diagnosis of 40 ± 17 years. There were 38 stroke-related and 25 IHD-related events or deaths, from the period 2 years before through 14 years after SLE diagnosis.

ACR criteria total >4	0.8 (0.58-1.2)	0.32

*p <0.1 on univariable analysis included in multivariable cox proportional hazards model; *includes ACR renal disorder at time of SLE diagnosis and/or end-stage renal disease after SLE diagnosis; All ACR criteria were within 1 year of SLE diagnosis. ESRD was through Year 2002-2015; ESRD=end stage renal disease. Ref=reference. p-values <0.05 are in bold.*

In the 11% with strokes, the mean age at first stroke was 48 years, with 78% occurring in females and 90% in blacks. The peak number of strokes occurred during the 2nd year after SLE diagnosis. We noted 8% had IHD, the mean age at first IHD was 52 years, with all occurring in females and 96% in blacks. The peak number of IHD occurred in the 14th year after SLE diagnosis.

Table 2. Predictors of Incident Ischemic Heart Disease (IHD) Occurrence

Table 2. Predictors of Incident Ischemic Heart Disease (IHD) Occurrence

Variable	HR (95% CI)	p value
Age <19 years	ref	ref
Age 19-<35 years	2.7 (0.31-24)	0.36
Age 35-<50 years	5.8 (0.63-54)	0.12
Age 50-<65 years	3.9 (0.36-41)	0.26
Age ≥65 years	**61 (5.8-647)**	**0.0007**
Non-black race	ref	ref
Black race	**24 (2.7-206)**	**0.004**

No oral ulcers	ref	ref
Oral ulcers	2.2 (0.81-5.8)	0.12
No neurologic disorder	ref	ref
Neurologic disorder	**4.0 (1.3-13)**	**0.018**
No immunologic disorder	ref	ref
Immunologic disorder	**4.7 (1.3-18)**	**0.02**
No discoid rash	ref	ref
Discoid rash	2.1 (0.69-6.5)	0.21
ACR criteria total of 4 or 3 ACR criteria with a rheumatologist diagnosis of SLE	ref	ref
ACR criteria total >4	0.97 (0.67-1.3)	0.83

p <0.1 on univariable analysis included in multivariable cox proportional hazards model and discoid rash; Gender not included in multivariable model as all IHD events occurred in females; All ACR criteria were within 1 year of SLE diagnosis. Ref=reference. p-values <0.05 are in bold.

Blacks had a 3-fold higher risk for stroke (HR 3.4, 95% CI 1.2-10, p 0.03) and a 24-fold higher risk for IHD (HR 24, 95% CI 3-206, p 0.004) (Table 1 & 2). Discoid rash at SLE diagnosis predicted a 5-fold (HR 4.6, 95% CI 1.7-13, p 0.003) and renal disorder predicted a 2-fold higher risk for stroke (HR 2.4, 95% CI 1.1-2.5, p 0.04) (Table 1). Neither impacted IHD (Table 2). Neurologic (HR 4.0, 95% CI 1.3-13, p 0.02) and immunologic disorder (HR 4.7, 95% CI 1.3-18, p 0.02) (Table 2) were strong predictors of IHD but not stroke.

Race stratified Cox proportional hazard models showed significantly accelerated stroke and IHD events in black compared to non-black patients ($p \leq 0.001$) (Figure 1A & B).

Conclusion: We found a 3-fold higher risk of stroke and 24-fold higher risk of IHD in blacks with SLE. We found different SLE-specific predictors of stroke and IHD: discoid rash and renal disorder predicted stroke, and neurologic and

Figure 1 Race Stratified: Panel A) Stroke-Event Free Survival, Panel B) IHD-Event Free Survival

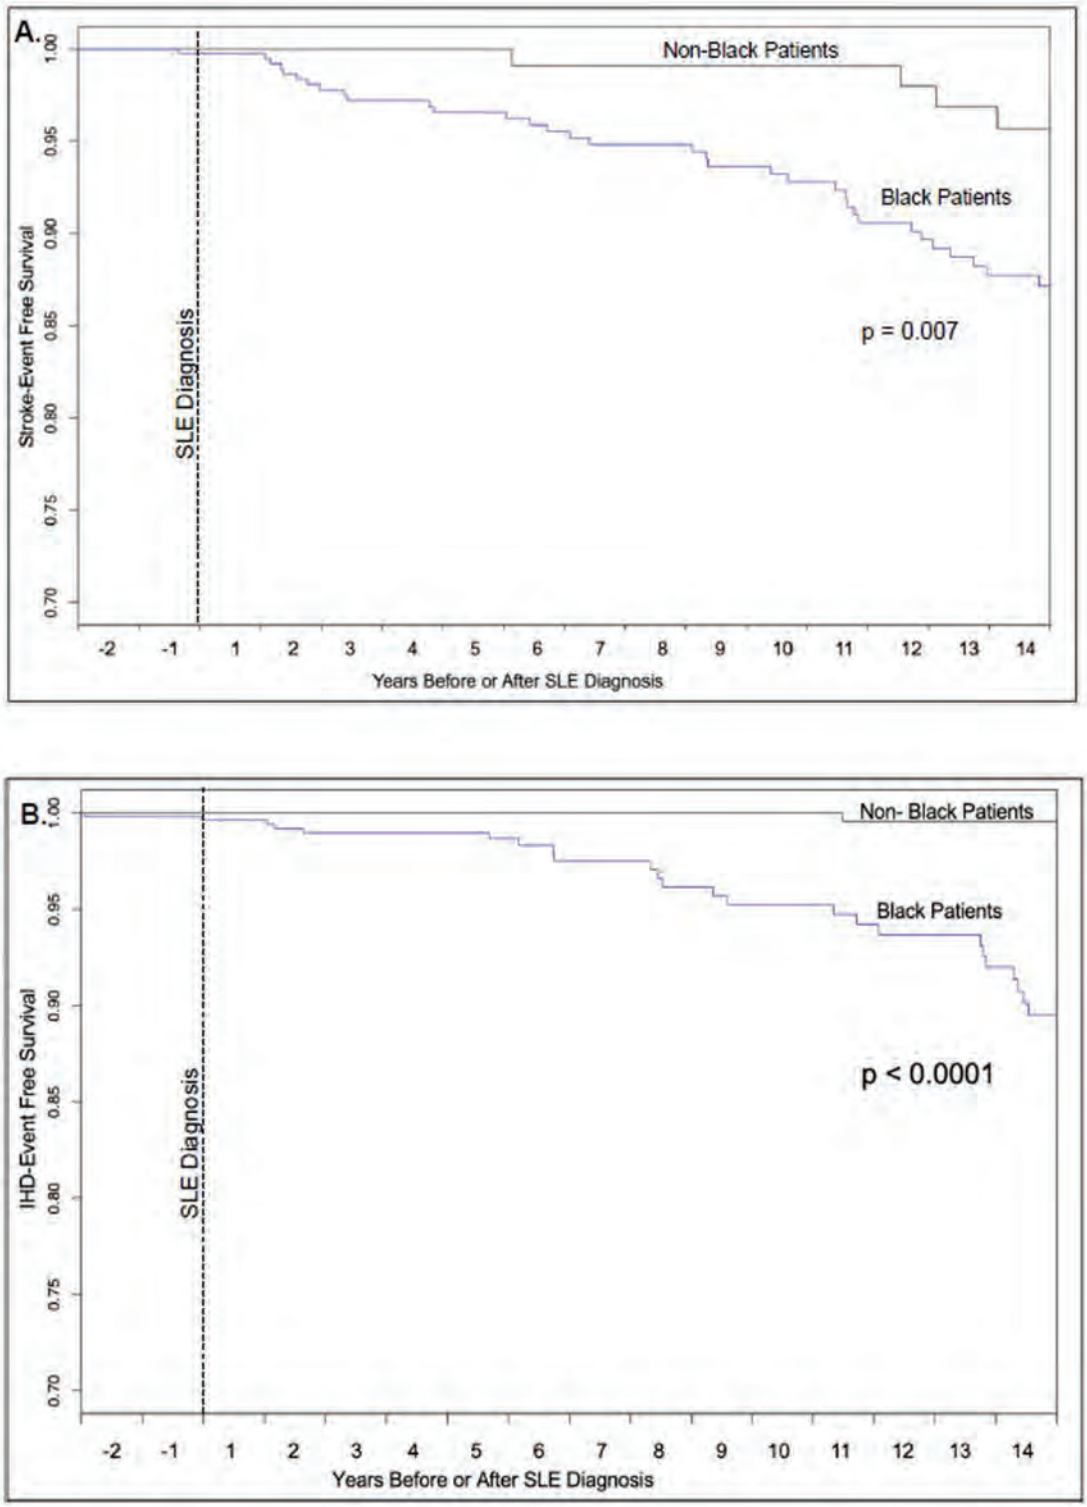

Figure 1. Race Stratified: Panel A) Stroke-Event Free Survival, Panel B) IHD-Event Free Survival

immunologic disorder strongly predicted IHD. This study provides unique insights on significantly different SLE-disease related predictors, timing and racial disparities in stroke compared to IHD in SLE. Hence, we highlight the need to consider different preventive strategies for stroke and IHD in SLE.

Changes in Mental Health During the COVID-19 Pandemic Among Individuals with Rheumatic Disease

Patricia Katz[1], Sofia Pedro[2], Kristin Wipfler[3], Teresa Simon[4], Yomei Shaw[5], Adam Cornish[6] and Kaleb Michaud[7], [1]University of California, San Francisco, Novato, CA, [2]FORWARD-The National Data Bank for Rheumatic Diseases, Wichita, [3]FORWARD, The National Databank for Rheumatic Diseases, Omaha, NE, [4]Bristol-Myers Squibb Company (at time of analysis), Princeton, NJ, [5]Forward, The National Databank for Rheumatic Diseases, East Lansing, MI, [6]FORWARD, 68134, NE, [7]University of Nebraska Medical Center, Omaha, NE

SESSION INFORMATION
Session Date: Friday, November 6, 2020
Session Title: Clinical Practice I
Session Type: Abstract Session
Session Time: 4:00PM–4:50PM

Background/Purpose: Symptoms of both depression and anxiety are often elevated among individuals with rheumatic conditions, and stress levels may play a role in each. Depression, anxiety, and stress have also been linked to worse outcomes. We examined changes in symptoms of anxiety and depression from pre-pandemic to during the pandemic, with a focus on the role of stress.

Table 1. Characteristics of Participants

	Total (n = 1504)	RA (n=1126)	OA (n=277)	SLE (n=101)
Age	66.1 ± 10.6	65.4 ± 10.7	70.4 ± 8.5	61.9 ± 11.9
Female	85.7 (1289)	84.6 (953)	(86.6) 240	95.1 (96)
Education (yrs)	15.3 ± 2.0	15.3 ± 2.0	15.4 ± 2.1	15.3 ± 2.0
Rural residence	21.6 (325)	22.2 (250)	19.1 (53)	21.8 (22)
Disease duration (yrs)	23.2 ± 12.5	22.7 ± 12.7	23.4 ± 11.0	27.7 ± 12.0
Pre-COVID Global severity rating	3.2 ± 2.4	3.1 ± 2.3	3.3 ± 2.4	3.8 ± 2.7
Stress				
COVID-19-specific	6.1 ± 1.9	6.1 ± 1.9	5.9 ± 1.8	6.4 ± 2.0
General (PSS)	2.5 ± 1.8	2.4 ± 1.8	2.4 ± 1.7	2.8 ± 1.9
PHQ4 depression				
Pre-COVID-19	0.79 ± 1.25	0.78 ± 1.25	0.66 ± 1.12	1.28 ± 1.46
During COVID-19	0.84 ± 1.24	0.84 ± 1.27	0.73 ± 1.07	1.20 ± 1.36
% with increase*	7.9 (119)	8.0 (90)	6.9 (19)	9.9 (10)
PHQ4 anxiety				
Pre-COVID-19	0.66 ± 1.18	0.67 ± 1.18	0.52 ± 1.04	0.97 ± 1.47
During COVID-19	0.99 ± 1.35	1.01 ± 1.39	0.84 ± 1.15	1.23 ± 1.47
% with increase*	10.6 (159)	10.7 (120)	8.7 (24)	14.9 (15)

PHQ4 DEP and ANX: score range = 0 – 6. Increase defined as change ≥2.
Global severity rating range 0 – 10
Both stress measures re-scaled for range 0 – 10.

Table 2. Association of stress with increases in anxiety and depression			
	Model 1	Model 2	Model 3
Increase in DEP			
COVID-19-specific	1.8 (1.6, 2.1)	---	1.6 (1.4, 1.9)
General PSS	---	1.8 (1.6, 2.1)	1.6 (1.4, 1.9)
Increase in ANX			
COVID-19-specific	2.1 (1.8, 2.3)	---	1.9 (1.7, 2.2)
General PSS	---	1.7 (1.5, 1.9)	1.5 (1.3, 1.7)
Values are odds ratio (95% confidence interval) from multiple logistic regression analyses adjusting for age, sex, education, race, rural residence, and pre-COVID global severity rating, hydroxychloroquine use, and PHQ4 depression or anxiety score. Model 1 includes PSS only, Model 2 includes COVID-19-specific stress only, Model 3 includes both			

Methods: Data are from FORWARD, The National Databank for Rheumatic Diseasesa longitudinal registry of individuals with rheumatic diseases. Data are regularly collected via semi-annual questionnaires. Participants with active emails were asked to respond to 5 COVID-19-specific questionnaires from March 25 through June 2, 2020. Both regular and COVID-19 questionnaires included the PHQ4, a validated screening measure for symptoms of anxiety (ANX) and depression (DEP). The COVID-19 questionnaire also include an item about COVID-19-specific stress ("how much stress or worry has the COVID-19 pandemic caused you? None, a little, moderate amount, great deal) and the 4-item Perceived Stress Scale (PSS), which assesses general stress. Both stress scale scores were transformed to 0 – 10 scores to facilitate comparison. Participant characteristics were taken from the most recent semi-annual (pre-COVID-19) questionnaire. Analyses examined the frequency of increases in ANX and DEP, defined as score change ≥2. Predictors of ANX and DEP increases among respondents with rheumatoid arthritis (RA), osteoarthritis (OA), and lupus (SLE) were identified using multiple logistic regression, focusing on the role of COVID-19-specific stress and PSS, and controlling for age, sex, race, education, rural residence, disease duration, and pre-COVID-19 global disease severity rating, and DEP and ANX scores.

Results: A total of 7217 participants were invited; 2000 (28%) responded at ≥1 COVID-19 questionnaire. Only those reporting diagnoses of RA, OA, or SLE (n=1504) are included in analyses. Respondent characteristics are shown in Table 1. COVID-specific stress ratings were twice as high as general stress ratings. Correlation between the two was 0.40. Increases in ANX were more common than increases in DEP (ANX: 10.6%; DEP: 7.9%), with no significant differences in frequency of increases among condition groups. Both COVID-19-specific and general stress were significantly associated with increases in DEP and ANX (Table 2).

Conclusion: Substantial increases in symptoms of both anxiety and depression were found when comparing scores from pre-pandemic to during the pandemic. Both COVID-19-specific and general stress levels were significantly associated with those changes. While the impact on disease outcomes remains to be seen, results suggest the need for assessment of stress in clinical settings and identification of effective stress management techniques.

Abstract Number: 0435

Low Incidence of Coronavirus Disease 2019 (COVID-19) Infection in Patients on Biologic Infusion Therapies at a Community Rheumatology Practice

Julie Keegan Strosser[1], Ronald Yglesias[2] and Norman Gaylis[1], [1]Arthritis & Rheumatic Disease Specialties, Aventura, FL, [2]Arthritis & Rheumatic Disease Specialties, Hialeah, FL

SESSION INFORMATION
Session Date: Friday, November 6, 2020
Session Title: Clinical Practice I
Session Type: Abstract Session
Session Time: 4:00PM–4:50PM

Background/Purpose: Following the first documented Florida case of COVID-19 on March 1, 2020, our community rheumatology practice continued to administer biologic infusion therapy with concern as to the outcome of exposure to COVD-19 in this patient population.

Methods: Point-of-care COVID-19 antibody testing was initiated prior to all infusions from April 28, 2020, using the RayBiotech or Healgen COVID-19 IgM/IgG Rapid Test Kit. During this three month period a review of the medical records revealed a total of 255 unique infusion patients screened for COVID-19, 185 females and 70 males, age 16 to 92 with a mean age of 58. Underlying diagnoses included AS, GCA, hidradenitis suppurativa, IBD, MS, myasthenia gravis, PSA, RA, and SLE. Treatments included infliximab (51.8%), rituximab (12.9%), golimumab (10.2%), abatacept, belimumab, ocrelizumab, tocilizumab, ustekinumab, and vedolizumab.

IgM positive patients were not infused and were asked to get confirmatory PCR testing done, quarantine for two weeks, and needed to test negative for IgM before infusions were restarted. All staff wore appropriate PPE, had daily body temperatures checked, and were tested for COVID weekly.

Results: On April 28, 2020 there were 11,831 confirmed COVID-19 cases in Dade County (the county in which this practice resides)[1], and by June 16, 2020 Dade County reported 22,741 confirmed cases of COVID-19, with 3,497 hospitalizations (16% of all cases) and 847 reported deaths (4% of all cases)[2].

Of the 255 unique infusion patients screened in this period, six tested positive for both COVID-19 IgM and Ig G antibodies (2.67% of patients) while four patients (1.57%) tested positive for COVID-19 IgG antibodies alone. None of these patients required hospitalization and none had experienced severe COVID-19 symptoms or disease. All experienced negligible or only mild symptoms when questioned by the provider about current or historical diagnosis following their positive test results.

Conclusion: Considering the level of community spread occurring in our area, we were surprised to find how few of our patients on biologic therapy tested positive for COVID-19 antibodies, and furthermore, how few of those who tested positive experienced symptoms. This appears to support the concept that cytokine inhibition from the use of biologic infusion therapy and possibly may in fact provide some protective mechanism to this group of patients and may arguably reduce the clinical consequences following infection[3,4]. To be noted, background steroids were utilized in a high percentage of our patients. In the past, this facility, amongst others, has reported a potential benefit and lack of toxicity with the use of biologic therapies in the face of HIV and Hepatitis C infections.[5] Further investigation would

be warranted to determine if there is any anti-COVID-19 benefit prophylactically and therapeutically from the various immune modulators currently used in the clinical rheumatology space.

SESSION INFORMATION
Session Date: Friday, November 6, 2020
Session Title: Clinical Practice I
Session Type: Abstract Session
Session Time: 4:00PM–4:50PM

Background/Purpose: The Addressing Lupus Pillars for Health Advancement (ALPHA) Project is a global consensus effort to identify, prioritize and address top barriers in lupus impacting diagnosis, care, treatment and research. Prior publications outlined mixed methodology of expert interviews and surveys to identify and prioritize barriers across drug development, clinical care and access to care among global lupus stakeholders including: clinicians, researchers, biopharmaceutical and government representatives, patients and caregivers.[1,2] This abstract details methodology used to develop a roadmap of specific recommendations to address the barriers.

Methods: An in-person stakeholder meeting of ALPHA Global Advisory Committee (GAC) members and a 2-round scoring survey were used to elicit recommendations. Prior to the meeting, held in Jan. 2020 in Washington, DC, GAC members (n=15) defined 'success' across drug development, clinical care and access to care using prior identified barriers as a framework. The meeting included 14 GAC members, 2 patients, an added clinician-researcher and Lupus Foundation of America and Tufts Center for the Study of Drug Development staff. Participants were divided into 3 breakout groups, with patient and specialty representation in each group, and identified at least 1 actionable solution to achieve 'success' per pillar. After full group discussion, participants voted on 1 top solution per pillar. Post-meeting, solutions were evaluated by feasibility, impact and timeline for implementation (FIT; **Table 1**). Each meeting

Table 1. Feasibility, Impact, and Timeline (FIT) Scoring Guide

Score	Feasibility	Impact	Timeline
1	Low feasibility: Item implementation faces **many** internal and external economic, technical, legal, and operational constraints that hinder achievability	Low impact: If implemented, the item will have a **minimal to no effect** on lupus communities, practices, organizations, and systems, and the impact will be short-term.	Long timeline: Item implementation will take **more than 5 years.**
2	Moderate feasibility: Item implementation faces **some** internal and external economic, technical, legal, and operational constraints that hinder achievability	Moderate impact: If implemented, the item will have a **modest effect** on lupus communities, practices, organizations, and systems, and the impact may be short term.	Moderate timeline: Item implementation will take **between 1-5 years.**
3	High feasibility: Item implementation faces **few to no** internal and external economic, technical, legal, and operational constraints that hinder achievability	High impact: If implemented, the item will have **maximum effect** on lupus communities, practices, organizations, and systems, and the impact will last for years to come.	Short timeline: Item implementation will take **less than 1 year.**

participant completed 2 rounds of scoring in Qualtrics software. Potential FIT component values were between 1-3 and total scores between 3-9. Higher scores represent higher achievability based on the composite of the 3 criteria.

Results: Table 2 shows ranked solutions per pillar based on in-person voting, and **Table 3** shows FIT scores. Simplifying and standardizing outcomes measures, such as steroid-sparing (drug development), and defining the lupus spectrum (clinical care) ranked as the highest priority solutions during the GAC meeting and received high FIT scores.

Table 2. Ranked Solutions per Pillar Identified During GAC In-Person Meeting

Priority	Drug Development	Clinical Care	Access to Care
#1	Simplify and standardize outcomes measures, including steroid-sparing as an outcome *(10 votes)*	Define the lupus spectrum (9 votes)	Build the case for World Health Organization prioritization (9 votes)
#2	Develop data sharing approaches related to biomarkers, clinical data, and lab samples *(5 votes)*	Perform longitudinal studies of prognostic and diagnostic biomarkers (5 votes)	Develop standardized and specialized, expert-driven care pathways (5 votes)
#3	Drive quality of life driven studies (e.g. fatigue) *(3 votes)*	Drive clinical and lab-based measures for individualized treatments (3 votes)	Drive telehealth advances and reimbursement, and build upon current infrastructures (3 votes)
#4	Increase representativeness in trials (e.g. minority, pediatric) *(1 vote)*	Identify and support development of adherence strategies that work for lupus and communicate them to patients and providers (3 votes)	(0 votes) • Explore broader partnering • Leverage social media • Develop evidence base for interventions, including standardized endpoints / outcomes • Payer education and alignment

Table 3. Feasibility, Impact, and Timeline Scoring Results, Listed by Highest Average Score

Consensus Item	Feasibility 1 = low 2 = moderate 3 = high		Impact 1 = low 2 = moderate 3 = high		Timeline 1 = long 2 = moderate 3 = short		TOTAL		
	Round 1	Round 2	Round 1	Round 2	Round 1	Round 2	Round 1	Round 2	Average
Drug Development – Average Scores									
Simplify and standardize outcomes measures, including steroid-sparing as an outcome	2.44	2.61	2.72	2.94	2.11	2.11	**7.28**	**7.67**	**7.48**
Increase representativeness in trials (e.g. minority, pediatric)	2.17	2.11	2.61	2.61	1.89	1.83	**6.67**	**6.56**	**6.62**
Drive quality of life driven studies (e.g. fatigue)	2.28	2.22	2.39	2.39	1.72	1.94	**6.39**	**6.56**	**6.48**
Develop data sharing approaches related to biomarkers, clinical data, and lab samples	1.78	1.78	2.72	2.78	1.50	1.50	**6.00**	**6.06**	**6.03**
Clinical Care – Average Scores									
Identify and support development of adherence strategies that work for lupus and communicate them to patients and providers	2.44	2.39	2.72	2.67	2.00	2.17	**7.17**	**7.22**	**7.20**
Define the lupus spectrum	2.50	2.56	2.44	2.56	2.00	2.33	**6.94**	**7.44**	**7.19**
Drive clinical and lab-based measures for individualized treatments	2.00	1.78	2.61	2.78	1.44	1.33	**6.06**	**5.89**	**5.98**
Perform longitudinal studies of prognostic and diagnostic biomarkers	2.11	1.89	2.67	2.61	1.39	1.00	**6.17**	**5.50**	**5.84**
Access to Care – Average Scores									
Leverage social media	2.71	2.89	2.47	2.06	2.76	2.83	**7.94**	**7.78**	**7.86**
Explore broader partnering	2.47	2.56	2.18	2.11	2.06	2.22	**6.71**	**6.89**	**6.80**
Payer education and alignment	2.00	2.06	2.59	2.50	1.76	1.89	**6.35**	**6.44**	**6.40**
Develop standardized and specialized, expert-driven care pathways	2.12	2.17	2.53	2.44	2.00	1.83	**6.28**	**6.44**	**6.36**
Develop evidence base for interventions, including standardized endpoints / outcomes	2.12	1.83	2.71	2.72	1.53	1.44	**6.36**	**6.00**	**6.18**
Drive telehealth advances and reimbursement, and build upon current infrastructures	2.06	2.00	2.53	2.11	2.00	1.89	**6.22**	**6.00**	**6.11**
Build the case for World Health Organization prioritization	1.76	1.67	2.29	2.06	1.47	1.39	**5.52**	**5.11**	**5.32**

Leveraging social media (access to care) received the highest FIT score across all pillars. Cross-cutting themes included leveraging digital technology and applying specific considerations for pediatric populations, as drug development has been limited and outcomes may differ from adults.

Conclusion: ALPHA has developed a roster of actionable solutions to barriers collectively impacting drug development, clinical care and access to care, and assessed achievability of each to improve the quality of life of adults and children with lupus. Simplifying and standardizing outcome measures, including steroid-sparing, may be pivotal to advance lupus drug development. Further clarifying the lupus spectrum may improve time to diagnosis and aid both provider and patient understanding of lupus. These findings are also an important indicator of patient preferences, highly relevant in patient-focused drug development.

Integrating Reproductive Health in Systemic Lupus Erythematosus in a Tertiary Care Setting

Jun Chu[1], Sarthak Gupta[1], Zerai Manna[2], Michael Davis[1], Yenealem Temesgen-Oyelakin[1], Elaine Poncio[1], Isabel Ochoa[1], Laura Lewandowski[3], Mariana Kaplan[4], Alan Decherney[1] and Sarfaraz Hasni[2], [1]National Institutes of Health, Bethesda, MD, [2]Lupus Clinical Trials Unit, NIAMS/NIH, Bethesda, MD, [3]NIAMS, NIH, Rockville, MD, [4]National Institute of Arthritis and Musculoskeletal and Skin Diseases, Bethesda, MD

SESSION INFORMATION
Session Date: Friday, November 6, 2020
Session Title: Clinical Practice I
Session Type: Abstract Session
Session Time: 4:00PM–4:50PM

Background/Purpose: Systemic Lupus Erythematosus (SLE) predominantly affects women of childbearing age. Women affected by SLE have higher risk for infertility, miscarriages, and other pregnancy complications due to dis-

Gender	Subjects	SLE, N(%)
Female	900 (85.1%)	777 (89.1 %)
Male	158 (14.9%)	95 (10.9 %)
female patients age between 18-50	465 (44.0%)	372 (42.7 %)
female patients seen the last two years only	325 (30.7%)	281 (32.2 %)
female patients seen last two years age between 18-50	203 (19.2%)	166 (19.0 %)
Total number of subjects	1058	872 (82.4 %)

Table 1A (Demographic History of protocol 94-AR-0066):

Female Subjects	N	Percent %
Seen in the past two years between 18-50	203.0	
Healthy Volunteers	39	19.2%
Age above 45 years old	39	19.2%
SLE patients age between 18-45 years old	122	60 %

Table 1B (Demographic History of female subjects seen in the past two years between ages 18-50):

ease activity, renal involvement, medications (like cyclophosphamide), and presence of certain autoantibodies (like anti- Ro/SSA, anti-La/SSB, antiphospholipid antibodies). Active SLE at the time of conception is a strong predictor of adverse maternal and fetal outcomes; current recommendations include attempting disease quiescence for 6 months before trying to conceive. Our goal is to improve reproductive health in patients with SLE following the ACR Guidelines. We embark on this study by assessing our current practice of addressing and documenting reproductive health issues and to develop a quality improvement process to address any deficiencies.

Methods: A retrospective chart review was conducted of the NIAMS Lupus Natural History Cohort on female patients of childbearing age with at least one clinic visit in the preceding two years were included in the study (Table 1B) to identify current practice. Data collected included documentation of obstetrics history, discussion on reproductive health, fertility preservation, and autoantibody history (anti-Ro/SSA, anti-La/SSB, and antiphospholipid antibodies).

Results: Our cohort comprises of 85% (N=900) females, with 44% (n=465) in childbearing age (Table 1A). The mean age of SLE women studied was 35 years old with a range of 21-45 years of age. Autoantibody history was documented in 98%. Contraception was documented in 92%. Out of the 112 patients, documentation of pre-pregnancy counseling occurred in only 4%. There was no documentation of discussion on fertility preservation (Table 2).

Conclusion: Reproductive health is an important topic that should be a shared decision-making process between SLE patients and providers. Studies have shown that patients desire an active role from their rheumatologist regarding initiating family planning conversations and sexual/reproductive health education. The current study reveals that, while certain aspects of reproductive health (such as autoantibodies and contraception) are documented, discussions on pre-pregnancy counseling and fertility preservation are lacking. Furthermore, although there were documentations on disease activity, there was no discussion on how disease activity may affect future pregnancy. Based on the current study, we will implement the HOP-STEP program which provides a guideline in helping providers address pre-pregnancy counseling, and acceptable options for contraception. We plan to modify our progress note template to incorporate elements from ACR reproductive health guidelines. Lastly, with our colleagues in reproductive health

Data Collection:	Percentage:
Serological History Documentation	98%
Contraception Documentation	92%
Intrauterine device (IUD)	33%
Abstinence/None	15.1%
Oral Contraception	12.5%
Tubal Ligation/Hysterectomy	10.7%
Barrier Method	10.7%
Medroxyprogesterone injection	4.4%
Etonogestrel implant	3.5%
Ovarian Failure	2.6%
Patient/Provider Pre-Pregnancy Counseling	4.4%
Patient/Provider Fertility Preservation	0

Table 2 (Retrospective Chart Review on 100% (N=112) of all females seen within the last two years between the ages of 18-45 years old):

we will develop a fertility preservation resource for our patients. With these interventions put in place, we believe will greatly impact and improve reproductive health in SLE.

Pharmacist-Led Multidisciplinary Approach to Opioid Tapering in a Large Private Rheumatology Practice

Jessica Farrell[1], Mitchell Miller[1], Kelsey Hennig[2], Kelley Powers[3], Sooyeon Kwon[4], Denae Moyer[5], Kathryn French[5], Angela Citta[5] and Jacqueline Cleary[1], [1]Albany College of Pharmacy and Health Sciences, Albany, NY, [2]Albany College of Pharmacy and Health Sciences, New Lebanon, NY, [3]The Center for Rheumatology, Delanson, NY, [4]Albany Stratton VA Hospital, Loudonville, NY, [5]Albany College of Pharmacy and Health Sciences, Albany

SESSION INFORMATION

Session Date: Friday, November 6, 2020

Session Title: Clinical Practice I

Session Type: Abstract Session

Session Time: 4:00PM–4:50PM

Background/Purpose: With the evolution of DMARDs, the need for opioids in the treatment of rheumatic diseases has decreased. However, rheumatology professionals are often presented with patients in whom chronic opioid ther-

apy was started prior to the availability of newer DMARDs. Current guidelines suggest opioid tapering should be considered in patients with chronic noncancer pain on ≥90 mg morphine equivalent dose (MED) daily or in combination with other high-risk medications. The aims of our project are to assess provider perspective and baseline knowledge on opioid taper regimens, provide education and support related to opioid management, and demonstrate improved patient outcomes when a pharmacist is part of the multidisciplinary team in a rheumatology practice.

Methods: The pharmacy team at a private rheumatology practice developed a three phased program including provider and staff education, updates to office workflows, and implementation of individualized patient taper plans. A baseline survey was administered to providers to characterize current practices and perspectives regarding practice-wide opioid use and confidence in managing opioids. The pharmacy team held training sessions to teach providers to appropriately identify circumstances when opioid tapering is indicated, develop individualized opioid taper regimens, recognize and manage withdrawal symptoms, and apply risk mitigation strategies during a chronic opioid therapy taper. Patients identified by providers as candidates are enrolled in the pharmacy service. The pharmacy team serves as a continuous resource to providers and works directly with patients enrolled in the service. Baseline characteristics, historical data on opioid related efficacy and side effects, and daily morphine equivalents are collected and tracked for each patient.

Results: All providers (n=10) reported having patients on chronic opioids; 70% felt they had at least one patient who would benefit from tapering. Reported barriers to tapering included time, comfort, and lack of confidence in managing withdrawal. Eighty percent of providers rated their comfort level a 5 or lower in tapering or discontinuing an opioid, on a scale of 0 to 10, with 0 being not comfortable at all and 10 being very comfortable. Nine providers stated they were hesitant or very hesitant in developing an opioid tapering plan. As of June 2020, 16 patients have been enrolled in the opioid taper service, and 2 withdrew. Five have reduced their daily MED somewhere between 25 and 100%. The remainder of patients are at stage where the focus is optimizing non-opioid analgesics, limiting high-risk concomitant medications, and minimizing use of existing opioids. A follow-up provider survey is planned. Patient survey data will also be collected.

Conclusion: Successful opioid tapering is a time intensive process and requires a multidisciplinary approach. This provides an opportunity for pharmacists to play an essential role as part of a team-based approach to ensure a successful opioid taper or discontinuation while minimizing adverse events. Our pharmacist-led opioid taper protocol can serve as an innovative model for rheumatology practices to include a clinical pharmacist as part of their healthcare team.

Hurried Communication and Low Patient Self-Efficacy Are Associated with Persistent Non-Adherence to SLE Medications

Ann Cameron Barr[1], Megan Clowse[2], Amanda Eudy[3], Jennifer Rogers[4], Rebecca Sadun[3], Lisa Criscione-Schreiber[5], Jayanth Doss[3], Lena Eder[6], Mithu Maheswaranathan[3], Amy Corneli[7], Hayden Bosworth[7] and Kai Sun[3], [1]Duke University Hospital, Durham, NC, [2]Duke University, Chapel Hill, NC, [3]Duke University, Durham, NC, [4]Duke, Durham, NC, [5]Duke University School of Medicine, Durham, NC, [6]Duke University Hospital, Chapel Hill, NC, [7]Duke University, Durham

SESSION INFORMATION

Session Date: Friday, November 6, 2020

Session Title: Healthcare Disparities in Rheumatology

Session Type: Abstract Session

Session Time: 4:00PM–4:50PM

Background/Purpose: Medication non-adherence is common among SLE patients and contributes to poor outcomes. Underrepresented racial minorities have disproportionately lower rates of medication adherence and often have more severe manifestations of SLE. In this longitudinal analysis, we aimed to identify modifiable factors associated with persistent medication non-adherence.

Table 1. Comparing those with Persistent Adherence, Inconsistent Adherence, and Persistent Non-Adherence based on the Composite Adherence measure at baseline and follow-up.

Table 1. Comparing those with Persistent Adherence, Inconsistent Adherence, and Persistent Non-Adherence based on the Composite Adherence measure at baseline and follow-up.

* Interpersonal Processes of Care survey, score ranges 1-5, with higher score indicating more of the domains. 1 is best score for Hurried Communication and its sub-domains. Scores of other domains of this survey (Elicited concerns, Explained results, Patient-centered decision making, Discrimination, and Disrespectful office staff) were not significantly different between adherence groups.

‡ Subdomains of Hurried Communication, as reflected by answers to the questions "how often did doctors speak too fast?" and "how often did doctors use words that were hard to understand?"

^ Patient Reported Outcomes Measurement Information System (PROMIS®) measures, general population mean score is 50, clinically significant difference is ≥ 5

Methods: Consecutive SLE patients taking ≥1 SLE medications at a tertiary lupus clinic were enrolled. Baseline data collected 7/2018-1/2019 included demographics, patient-provider communication as measured by the Interpersonal Processes of Care survey, self-efficacy, and SLICC damage scores. Follow-up data collected 9/2019-1/2020 included SLEDAI and physician global assessment (PGA) of disease activities. Adherence data obtained at both baseline and follow-up included: 1) self-reported adherence in the preceding month from 0-100%, with ≥90% indicating High Self-Reported Adherence; and 2) pharmacy refill data in the preceding 3 months, with a medication possession ratio (MPR) of ≥80% indicating High Refills. High Composite Adherence was defined as having both High Self-reported Adherence and High Refills. Those with High Composite Adherence at both baseline and follow-up were considered to have Persistent Adherence, those with Low Composite Adherence at both time points were considered to have Persistent Non-Adherence, and the rest were considered to have Inconsistent Adherence. We compared characteristics of adherence groups.

Results: Data from 77 SLE patients were analyzed (43% white, 53% African-American, and 4% other). Median age was 44 years, 96% were female, 60% had ≥ college education, and 51% had private insurance. On average, patients were prescribed 2 SLE medications, with 84% prescribed HCQ, 57% prescribed a DMARD, and 4% prescribed Belimumab. At baseline, 73% had High Self-Reported Adherence, 51% High Refills, and 43% High Composite Adherence. Longitudinally, 32% had Persistent Adherence, 47% had Persistent Non-Adherence, and 21% had Inconsistent Adherence. Comparing adherence groups, those with Persistent Non-Adherence were younger, more likely to be African-American, took more SLE medications, and had higher PGA scores. Patients with Persistent Non-Adherence also rated more hurried communication with providers – specifically with respect to speaking fast and using hard words – and had lower self-efficacy in managing treatments and medications (Table 1).

Conclusion: Our results show that adherence rates to SLE medications are low, and persistent non-adherence is disproportionately more common among African-Americans. Potential areas for intervention in order to improve adherence include optimizing patient-provider communication, specifically avoiding difficult vocabulary and fast speech, and enhancing patient self-efficacy, particularly among young African-Americans with SLE who are at higher risk for non-adherence.

Session Title: Healthcare Disparities in Rheumatology
Session Type: Abstract Session
Session Time: 4:00PM–4:50PM

Table. Proportion of articles according to author gender.

		First author gender, women		Senior author gender, women	
	Number of articles, N	n	% [95% CI]	n	% [95% CI]
All	7651	3939	51.5% [50.4%, 52.6%]	2699	35.3% [34.2%, 36.4%]
Research design					
Basic science	1801	931	51.5% [49.4%, 54.0%]	542	30.1% [28.0%, 32.2%]
Randomised controlled trial	603	201	33.3% [29.7%, 37.2%]	159	26.4% [23.0%, 30.0%]
Systematic literature review/meta-analysis	449	227	50.6% [45.9%, 55.2%]	178	39.6% [35.2%, 44.2%]
Other clinical	4798	2580	53.7% [52.4%, 55.2%]	1820	37.9% [36.6%, 39.3%]
Funding source					
Industry-funded/industry-initiated	724	284	39.2% [35.7%, 42.8%]	224	30.9% [27.7%, 34.3%]
Industry-funded/investigator-initiated	734	369	50.3% [46.7%, 53.9%]	261	35.6% [32.2%, 39.1%]
Not industry-funded	6193	3286	53.1% [51.8%, 54.3%]	2214	35.8% [34.6%, 37.0%]

Background/Purpose: In academic medicine, journal article authorship is central to career advancement and promotion. This study aimed to examine the contemporary representation of women as first and senior authors of rheumatology-related original research articles.

Methods: The gender of first and senior author, disease category, research design and funding source were extracted from rheumatology original research articles published in high impact rheumatology and general medical journals between 2015 and 2019.

Results: 7,651 original research articles were included in the analysis. In total, there were 51.5% [95% CI 50.4%, 52.6%] articles with women first authors and 35.3% [95% CI 34.2%, 36.4%] with women senior authors. Women were significantly less likely to be first and senior authors of articles reporting randomized controlled trials compared with other clinical research designs ($P < 0.001$), and of articles reporting industry-funded/industry-initiated studies compared with studies not funded by industry ($P \leq 0.01$). For articles reporting industry-funded/industry-initiated randomized controlled trials, women were first authors in 18.5% [95% CI 13.8%, 24.0%] and senior authors in 23.9% [95% CI 18.6%, 29.8%].

Conclusion: In rheumatology journal articles, there is gender parity for first authorship, but women are under-represented in senior authorship positions. Under-representation of women in authorship is particularly apparent in articles reporting randomized controlled trials, especially those that are initiated by industry.

Abstract Number: 0441

Use of an Integrated Care Management Program to Uncover and Address Social Determinants of Health for Individuals with Lupus

Kreager Taber[1], Jessica Williams[1], Weixing Huang[2], Katherine McLaughlin[1], Christine Vogeli[3], Rebecca Cunningham[1], Lisa Wichmann[1] and Candace Feldman[4], [1]Brigham and Women's Hospital, Boston, MA, [2]Division of Rheumatology, Inflammation, and Immunity; Brigham and Women's Hospital and Harvard Medical School, Boston, [3]Massachusetts General Hospital, Boston, MA, [4]Brigham and Women's Hospital, Boston

SESSION INFORMATION
Session Date: Friday, November 6, 2020
Session Title: Healthcare Disparities in Rheumatology
Session Type: Abstract Session
Session Time: 4:00PM–4:50PM

Background/Purpose: The burden of systemic lupus erythematosus (SLE) falls disproportionately on racial/ethnic minorities and individuals of lower socioeconomic status who often receive fragmented, inconsistent care. The Integrated Care Management Program (iCMP) enrolls patients at high risk for acute care use and adverse outcomes and connects them with a nurse and care team who help coordinate their medical care. We studied SLE patients enrolled in iCMP to understand whether social determinants of health (SDoH) needs such as food insecurity, housing instability, and financial constraints were prevalent in this population. We hypothesized iCMP teams would uncover and address SDoH issues that while likely present, would not have been documented before enrollment.

Methods: The iCMP enrolls the top 2% of medically and psychosocially complex patients within our multihospital primary care practices. Patients are identified by a system that incorporates clinical complexity, healthcare utilization

Figure. Social Determinants of Health-related Issues Documented Before and During Integrated Care Management Program (iCMP) Enrollment

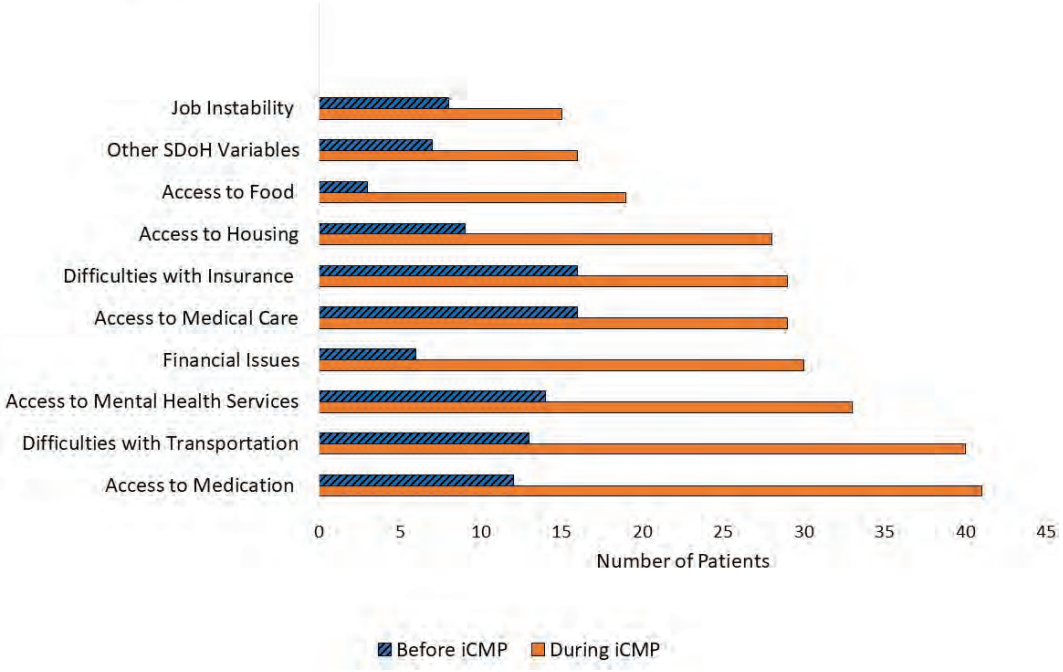

Table. Social determinants of health needs uncovered by the integrated care management program (iCMP) team and examples of strategies used to address these needs			
Social Determinants of Health (SDoH) Factors	SLE patients with issues addressed (n=56)	Example of issue	Examples of strategies used by iCMP team* to address issue
Medication Access	66%	Patient could not afford copays for medications	Connected patient with new insurance plan to make medications more affordable
Transportation Needs	61%	Patient needed transportation to medical appointments	Coordinated door-to-door transportation to appointments
Insurance Difficulties	50%	Patient's health insurance was revoked	Connected to financial services to reinstate insurance
Mental Health Service Access	48%	Patient would like to see mental health services but has significant difficulty leaving her home	Referred to at-home psychiatrist
Financial Issues	48%	Patient could not pay utility bill	Utility protection letter composed for patient
Housing Instability	46%	Patient given eviction notice from apartment after unable to pay rent	Connected with emergency housing and helped during appeal of eviction
Food Instability	32%	Patient couldn't afford to eat	Referred to Elder services and Meals-on-Wheels
Other SDoH Variables (Access to child care, personal/neighborhood safety, education access, job instability)	32%	Patient had no resources to support children while she was admitted Patient experienced domestic violence Patient not able to start school on time due to illness Patient reported difficulty finding work after catastrophic medical event	Connected with services to help with child care and home upkeep while admitted Family helped while finding a long-term care facility for patient Helped patient contact her academic advisor for assistance delaying her enrollment Helped patient search for jobs that could accommodate her functional needs
*iCMP Team includes iCMP Nurse, Social Workers, Care Coordinators, Community Resource Specialists, and Pharmacists			

indicators, and consultation with primary care providers, but does not explicitly factor in SDoH. Individuals with SLE enrolled in iCMP were identified with a validated machine learning algorithm (PPV=90%) and verified by chart review. We reviewed patients' electronic health record encounters to identify SDoH needs prior to iCMP enrollment primarily using notes from physicians and social workers, and throughout enrollment using notes from iCMP nurses and team members.

Results: There were 69 patients with SLE enrolled in iCMP. Of these, 93% were female, 55% were white, 25% black, 3% Asian/Pacific Islander, 16% other/unknown race, and 21% were Hispanic. The mean duration of iCMP enrollment was 3.8 (SD 2.4) years. Prior to iCMP enrollment, 57% of the patients had documentation of ≥1 SDoH factor, compared to 94% during enrollment **(Figure).** The iCMP nurses addressed ≥1 SDoH factor for 81% of the SLE patients and completed high risks assessments for each patient. For these patients, iCMP nurses discussed and addressed multiple SDoH issues including medication access (66%), transportation (61%), insurance (50%), financial issues (48%), housing concerns (46%) and food insecurity (32%) **(Table).** The iCMP nurses connected 75% of these patients with additional resources, including social workers/mental health resources (58%), home health (43%) and elder care (14%) services, pharmacists (14%) and substance abuse programs (6%).

Conclusion: While SDoH-related issues were not used to identify patients for iCMP, the majority of enrolled high-risk, medically complex SLE patients had these needs. The iCMP nurses and care team members uncovered and addressed numerous SDoH-related concerns that while likely present, had not been documented prior to iCMP participation. As SDoH directly impact the care that patients access and the disproportionate burden of adverse out-

comes among vulnerable populations, the healthcare system must develop and expand sustainable strategies like this integrated care management program to identify, document, and address these issues.

Abstract Number: 0442

Disparities in CoronaViridae Infection Are Readily Apparent in Rheumatology Patients Despite Use of Hydroxychloquine And/or Methotrexate

Maria Antonelli[1] and Nora Singer[2], [1]MHMC/CWRU, Cleveland, OH, [2]The MetroHealth System, Case Western Reserve University School of Medicine, Cleveland, OH

SESSION INFORMATION
Session Date: Friday, November 6, 2020
Session Title: Healthcare Disparities in Rheumatology
Session Type: Abstract Session
Session Time: 4:00PM–4:50PM

Background/Purpose: In the initial months of the SARS CoV2/COVID19 pandemic, broad use of off-label therapy with hydroxychloroquine (HCQ) was prescribed to reduce CoV2-related morbidity and mortality. Disparity in infection rates in non-Caucasians were observed even when other co-morbidities such as diabetes, obesity and smoking were accounted for. We hypothesized that if HCQ was effective against CoV2, then the rates of CoV2 infections in patients treated with HCQ for both African Americans and non-African Americans, would be lower than in those using patients methotrexate (MTX) as a control drug that was not postulated, at the time, to protect against CoV2.

Methods: A retrospective observational analysis utilizing IBM Watson Health Explorys data was performed. The Explorys database contains pooled de-identified clinical data. Explorys aggregates, standardizes and normalized clinical data from diverse electronic health records. Patient records are mapped into a systematized nomenclature of medicine- clinical terms (SNOMED-CT) hierarchy. To determine if chronic use of HCQ prevented CoV2 infection, individuals prescribed HCQ or MTX at least twice in the preceding 12 months were included. Incident disease was identified using the term SNOMED-CT diagnosis of “Disease caused by Coronoviridae” (CorV) to calculate infection rates. Cohorts were analyzed accordingly: African American (AA) or not AA, male sex, age >65, presence of obesity, cardiovascular disease (CVD), chronic kidney disease (CKD), and diabetes (DM). Rates of infection were calculated and compared to the reference populations using odds ratios (OR).

Results: At time of data collection in May 2020, Explorys included data from 68,569,460 patients. There were 14,490 total infections of CoV; Infection rates for the general population are shown in table 1, 34% were in AA patients. Table 2 shows infection rates in patients who used either HCQ or MTX . Table 3 shows a comparison of rates of infection in AA in those treated with HCQ or MTX. AA were more likely to be diagnosed with a CorV than nonAA overall in all the analyses: the odds ratio (OR) of having a corona virus ranged from 3.31-5.27 (all statistically significant). In both HCQ and MTX users, AA were more likely to be diagnosed with a CorV infection as compared with nonAA ranging from 4.43 to 7.37 in HCQ users and, 3.42-8.89 in MTX users. Comparing AA, there was a trend towards HCQ users being more likely than MTX users to be diagnosed with a CorV infection, but none of these comparisons were statistically significant. Death rates in each cohort were also calculated but too low to report (0 or < 10 each).

Conclusion: Of total CoV infections through May 2020, a higher proportion of those with a diagnosis of CorV were AA. When variables were analyzed separately, the ORs were elevated in AA with the following comorbidities: male sex, age >65, presence of obesity, CVD, CKD, DM. AA lupus and rheumatoid arthritis (RA) patients were more likely to be diagnosed with an infection compared to non-AA with lupus/RA. The data suggest that the disparities are exaggerated in rheumatology patients who contract CoV and that infection rates are not reduced in either in AA or non-AA on chronic HCQ. In contrast, rates of diagnosis of CoV were lower for patients on MTX.

Table 1. General Population	**Total COVID Infection Rate % (n)**	**African American COVID Infection Rate % (n)**	**Non-African COVID American Infection Rate % (n)**	**AA vs nonAA Odds Ratio (CI)**	***p*-value (AA v non-AA)**

SESSION INFORMATION
Session Date: Friday, November 6, 2020
Session Title: Healthcare Disparities in Rheumatology
Session Type: Abstract Session
Session Time: 4:00PM–4:50PM

Background/Purpose: The COVID-19 pandemic has exacerbated structural and systematic barriers in access to healthcare for racial and ethnic minorities. The impact of these increased barriers on patients with rheumatic disease has not been studied. We describe the clinical characteristics and COVID-19 disease burden among racial and ethnic minority participants in an international survey of patients with rheumatic disease.

Methods: The COVID-19 Global Rheumatology Alliance (C19-GRA) Patient Experience Survey is an international, self-reported survey for adults and parents of children with rheumatic disease, with or without COVID-19 infection. The survey was distributed online by patient support organizations and social media platforms. Responses of participants living in Canada, the United States, and Europe were analyzed to compare outcomes between minority and non-minority groups. Descriptive statistics were used to describe patient characteristics and COVID-19 related outcomes.

Results: We report data on 6,581 respondents to the Patient Experience Survey. There were 5,703 (86.7%) respondents who identified as White, and 878 (13.3%) belonged to all other racial or ethnic groups (Table 1). Respondents from ethnic minority groups were mostly female (92.3%) with a mean age of 44.0 (SD 12.4). The most common rheumatic diseases include systemic lupus erythematosus (47.8%) and rheumatoid arthritis (37.2%).

A total of 455 (6.9%) participants reported a diagnosis of COVID-19; of these, 66 (14.5%) self-identified as a racial or ethnic minority including 12 (2.6%) who were Black. Among ethnic minorities, 24 patients diagnosed themselves based on symptoms and 42 were diagnosed by a physician according to symptoms or a lab result. Of patients who were hospitalized with COVID-19, 33 (73.3%) were White and 12 (26.7%) belonged to other ethnic groups.

Conclusion: This international survey reports data related to the impact of COVID-19 on racial and ethnic minorities with rheumatic disease. There were differences in high risk comorbidities, yet no difference in incidence of COVID-19 and severity of disease among various racial and ethnic groups compared to White participants. Racial and ethnic minorities were underrepresented in our survey, likely a consequence of systemic barriers that prohibit their engagement within the healthcare community.This reinforces the importance of collecting race-related data, particularly where there are concerns of inequities influencing health outcomes, and the need to implement targeted recruitment strategies to enhance representation of minority groups in research.

Chronological Order of Decrease of Synovitis, Osteitis and Tenosynovitis in Early Arthritis Patients Receiving First DMARD-treatment

Xanthe Matthijssen[1], Ellis Niemantsverdriet[1], Saskia le Cessie[1] and Annette van der Helm - van Mil[2], [1]Leiden University Medical Center, Leiden, Netherlands, [2]Leiden University Medical Center, Erasmus Medical Center, Leiden, Netherlands

SESSION INFORMATION
Session Date: Friday, November 6, 2020
Session Title: Imaging of Rheumatic Diseases
Session Type: Abstract Session
Session Time: 10:00AM–10:50AM

Background/Purpose: Advanced imaging modalities have shown that not only joints but also bones and tendon sheaths can be inflamed at diagnosis of rheumatoid arthritis. We aimed to better understand the time order in which the inflamed tissues respond to DMARD-treatment and whether this differs between ACPA-subgroups.

Methods: 216 consecutive patients presenting with undifferentiated or rheumatoid arthritis, who received DMARD-treatment, were studied. 1.5T contrast-enhanced hand and foot MRIs were performed before treatment and after 4, 12 and 24-months. Cross-lagged models evaluated the influence of two time-patterns: a simultaneous pattern ("change in one inflammatory feature associated with change in another feature") and a subsequent pattern ("change in one inflammatory feature preceded change in another feature"). ACPA-stratification was performed.

Results: All pairs of inflammatory features decreased simultaneously in all time-intervals (0–4/4–12/12–24m; $p< 0.05$). Moreover, time orders were identified: synovitis decrease preceded tenosynovitis decrease (0-4m- >4-12m; $p=0.02$ & 4-12m- >12-24m; $p=0.03$). Similar results were obtained in both ACPA-subgroups. Additionally, in ACPA-positive but not ACPA-negative patients, synovitis decrease preceded osteitis decrease (4-12m- >12-24m; $p=0.002$).

Conclusion: This study increased the understanding of the response to treatment on tissue level. Additional to simultaneous decrease of inflammation, synovitis decrease preceded tenosynovitis decrease. Differences in time order of inflammation decrease between ACPA-subgroups suggest differences in underlying inflammatory pathways.

Dual-Energy CT in Gout Patients: Do All Color-Coded Lesions Actually Represent Monosodium Urate Crystals?

Sara Christiansen[1], Felix Müller[2], Mikkel Østergaard[3], Ole Slot[1], Jakob Møller[2], Henrik Børgesen[2], Kasper Gosvig[2] and Lene Terslev[4], [1]Copenhagen Center for Arthritis Research, Center for Rheumatology and Spine Diseases, Rigshospitalet, Glostrup., Glostrup, Denmark, [2]Department of Radiology, Herlev and Gentofte Hospital, Herlev, Denmark, [3]Rigshospitalet, University of Copenhagen, Copenhagen, Denmark, [4]Copenhagen Center for Arthritis Research, Center for Rheumatology and Spine Diseases, Rigshospitalet, Glostrup., Copenhagen, Denmark

SESSION INFORMATION

Session Date: Friday, November 6, 2020

Session Title: Imaging of Rheumatic Diseases

Session Type: Abstract Session

Session Time: 10:00AM–10:50AM

Background/Purpose: Dual-Energy CT (DECT) can acknowledge differences in tissue compositions and can color-code tissues with specific features including monosodium urate (MSU) crystals. However, when evaluating gout patients DECT frequently color-codes material not truly representing MSU crystals and this might lead to misinterpretations if the reader is not aware of these potential pitfalls. The variations in properties of color-coded DECT lesions in gout patients have not yet been systematically investigated.

The objective was to evaluate the properties and locations of color-coded DECT lesions in gout patients.

Methods: DECT of the hands, knees and feet were performed in patients with suspected gout using factory default gout-settings. Location-relevant colour-coded lesions were registered. For each lesion properties [mean density (mean of Hounsfield Units (HU) at 80kV and Sn150kV), mean DECT ratio and size] and location were determined.

Subgroup analysis was performed post-hoc evaluating differences in locations of lesions when divided into definite MSU deposits and possibly other lesions. Division were made according to lesion properties: 1) *Size*—to separate small volume artefacts (*possible image noise artefacts*), 2) *DECT ratios*—to separate calcium-containing material

Figure 1: Properties of color-coded DECT lesions in gout and non-gout patients

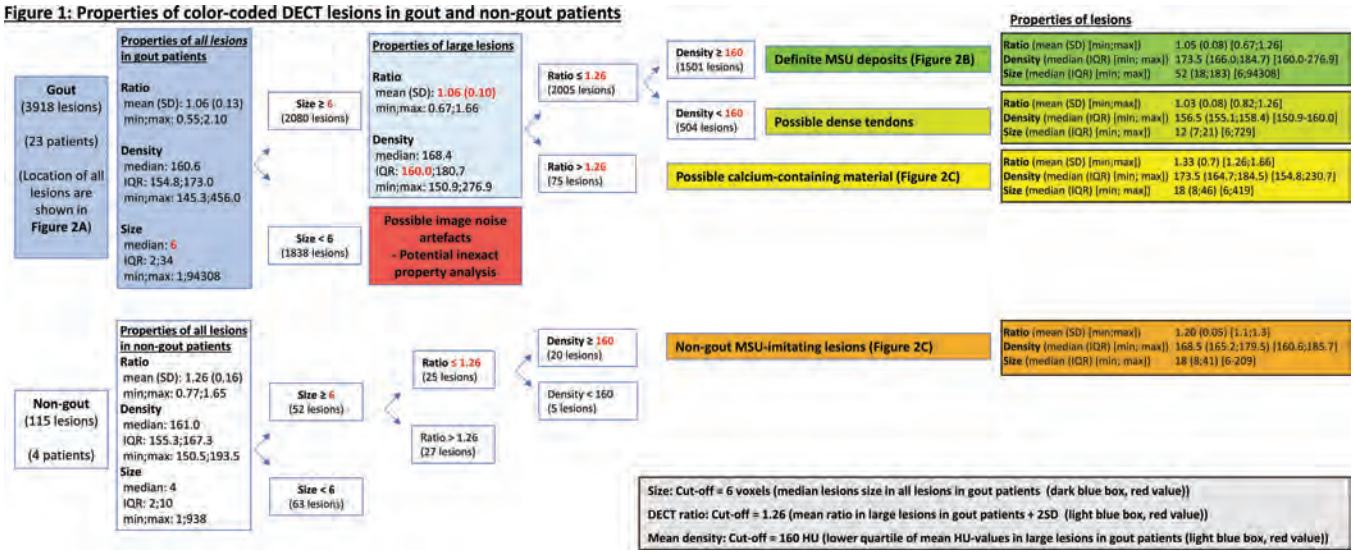

Figure 2: Distributions of DECT ratios. Evaluation of large color-coded DECT lesions in gout patients.

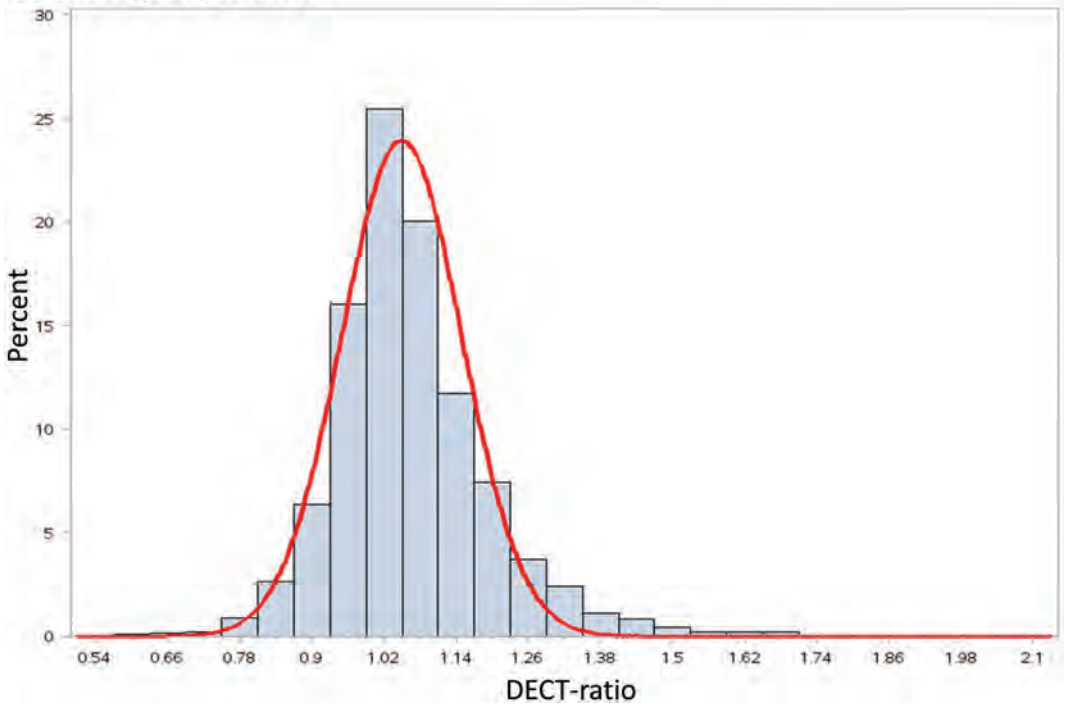


characterised by high DECT ratio (*possible calcium-containing material*). 3) *Density*—to separate dense tendons characterised by low DECT ratio and low HU values (*possible dense tendons*). Lesion fulfilling all MSU characteristics (large volume, low DECT ratio, high density) were labelled *definite MSU deposits*. Finally, for non-gout patients, properties of *non-gout MSU-imitating lesions* (properties as *definite MSU deposits*) were analysed.

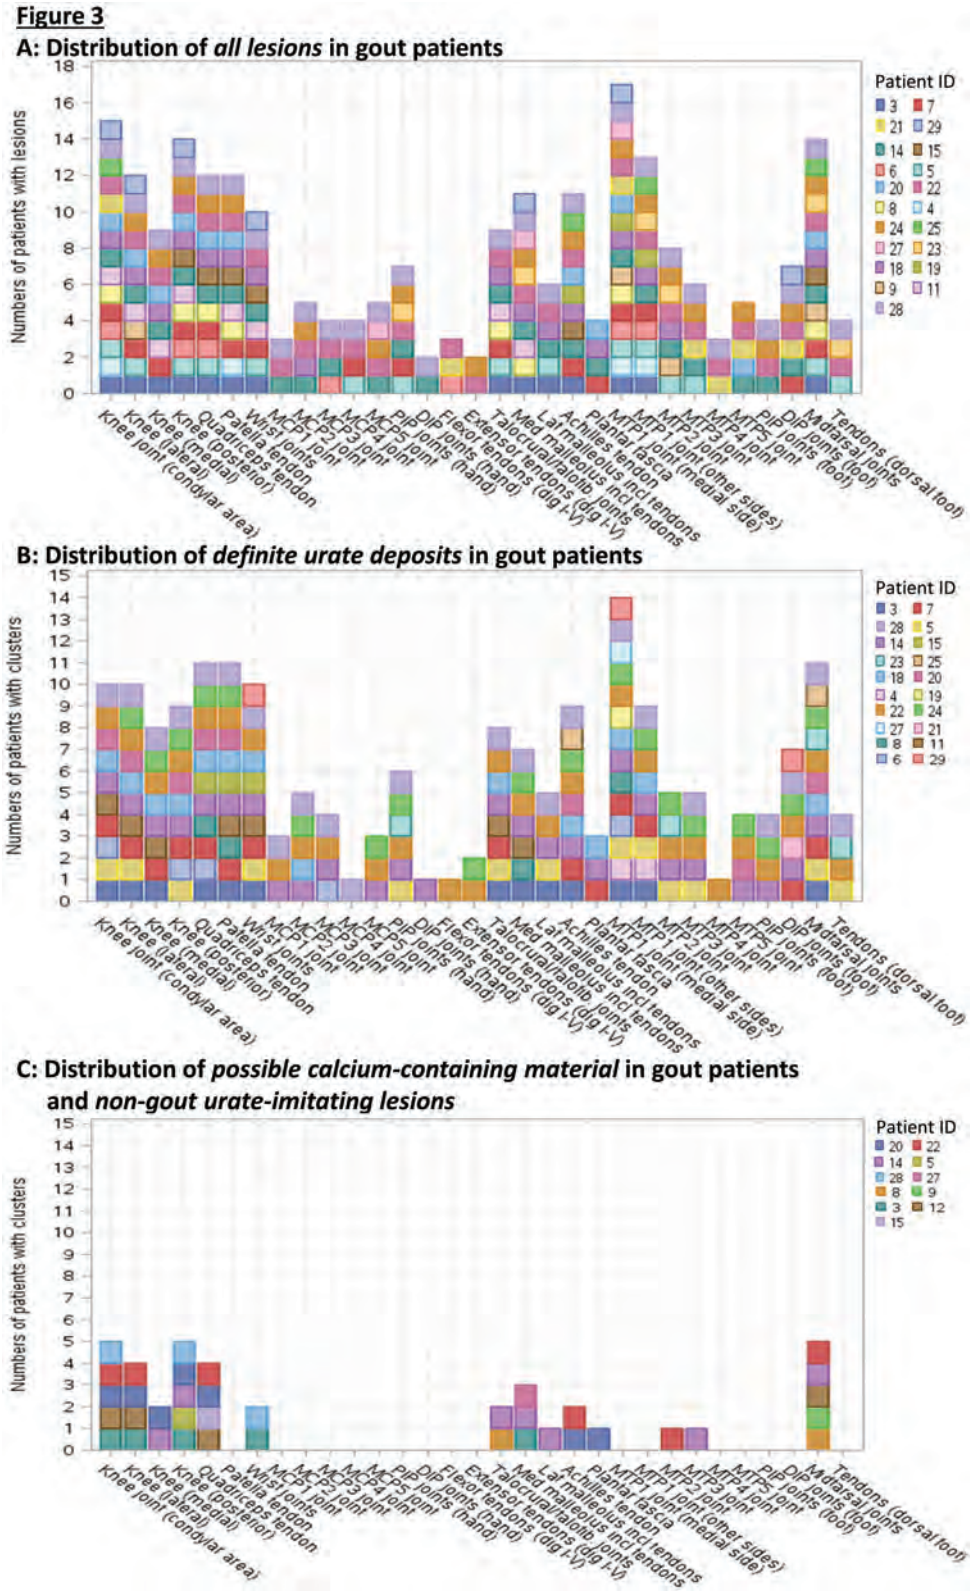
Results: In total, 3918 lesions (*all lesions*) were registered in 23 gout patients with median density of 160.6HU and median size of 6 voxels (Figure 1). DECT ratios of large lesions showed an approximated normal distribution, but with a right heavy tail consistent with presence of smaller amounts of calcium-containing lesions (Figure 2). The most common locations of *all lesions* were MTP1, knee and midtarsal joints along with quadriceps and patella tendons (Figure 3A).

Subgroup analyses showed that *definite MSU deposits* had a similar distribution pattern as *all lesion* with the same five most common locations (Figure 3B). This was also the case for *possible dense tendon* (data not shown), indicating that these lesions primarily consisted of true MSU deposits. In contrast, *possible calcium-containing material* and *non-gout MSU-imitating lesions* had distinctly different properties (DECT ratios 1.33 and 1.20, respectively) (Figure 1) and furthermore showed different distribution pattern as they were primarily found in some larger joints (knee, midtarsal and talocrural) and tendons (Achilles and quadriceps), whereas non were found in either MTP1 joints or patella tendons (figure 3C).

Conclusion: Color-coded DECT lesions in gout patients showed heterogenicity in properties and locations. MTP1 joints and patella tendons exclusively showed definite MSU deposits. Hence, a sole focus on these regions in the evaluation of gout patients may improve the specificity of DECT scans.

DECT, dual energy CT ; HU, Hounsfields Units ; ratios, DECT ratios (HU a 80kV / HU at sn150kV) ; density, (HU at 80kV+HU at sn150kV) / 2 ; size, numbers of pixels; SD, standard deviation ; IQR, interquartile range ; SD standard deviation.

Figure 3



The distributions of DECT ratios have been overlaid with a normal distribution curve with a mean at the local maxima at a DECT ratio of 1.06 and a standard deviation estimated from points below this mean to be 0.10. Notice that the right tail on the DECT ratios are heavy with more lesions having a high DECT ratio than expected by a Gaussian

distribution in agreement with a mixture of monosodium-urate deposits and calcium-containing material. DECT, Dual-Energy computed tomography; DECT ratio, HU at 80kV / HU at 150kV (with tin filter).

MCP, metacarpophalangeal joints; PIP, proximal interphalangeal joints; DIP, distal interphalangeal joints; MTP, metatarsophalangeal joints.

SESSION INFORMATION
Session Date: Friday, November 6, 2020
Session Title: Imaging of Rheumatic Diseases
Session Type: Abstract Session
Session Time: 10:00AM–10:50AM

Background/Purpose: The clinical decision-making process in pediatric arthritis lacks an objective, reliable bedside imaging tool. Although increasingly used for children, there is a need for reliable ultrasound (US) scanning protocols and scoring systems to provide objective assessments of various inflammatory lesions. The aim of this study was to develop a scanning protocol and assess the reliability of B-Mode and Doppler scoring systems for the pediatric ankle.

Methods: As part of the Childhood Arthritis and Rheumatology Research Alliance (CARRA) US group, 19 pediatric rheumatologists developed through a comprehensive literature review a set of standard views to assess inflammatory lesions of the synovial recesses as well as tendons of the pediatric ankle. The views included in the final acquisition protocol reached at least 80% agreement following a nominal group technique. Subsequently, a B-mode and Doppler scoring system was developed through a comprehensive literature review, then a consensus process. Three rounds of scoring of still-images were followed by one practical exercise. Agreement between raters determined using two-way single score intraclass correlation coefficients (ICC).

Results: Following published standardized guidelines, we examined the available evidence for using sonographic views to assess presence of synovitis in the tibiotalar (TTJ), subtalar (STJ) and talonavicular joints (TNJ), as well as tenosynovitis of the anterior, medial and lateral tendon compartments of the ankle. We identified 37 possible views to assess the presence of ankle synovitis and tenosynovitis in children. We further considered different positions of the ankle (extension, neutral and flexion). Following a practical exercise, a total of 9 views were chosen for each B-mode and Doppler in a nominal group technique (Table 1). The scanning protocol was feasible with a scanning time of 12-15 minutes. Scoring protocols for each structure based upon anatomic variability among the joints and tendons of interest were developed. An initial scoring exercise included 124 images. There was good to excellent agreement for B-mode on the anterior TTJ: medial and lateral views ICC 0.69 (CI 0.61-0.75) and midline view ICC 0.75 (CI 0.71-0.79). The ICC for the TNJ was fair at 0.51 (CI 0.40-0.61). Views assessing the medial and lateral aspects of the STJ had good to fair reliability 0.67 (CI 0.57-0.75) and 0.51 (CI 0.43-0.59) respectively. ICC for tendon images was 0.49 (CI 0.37-0.59). The observations from this scoring exercise are elucidating which modifications are necessary to reach good to excellent reliability of the scoring systems. Additional scoring exercises and consensus rounds will be necessary to refine the individual scores.

Conclusion: A novel pediatric ankle US scanning protocol and scoring system for the assessment of arthritis were successfully developed. Preliminary results from practical exercises indicate overall good reliability but also illustrate the challenges in certain views especially the STJ, TNJ and tendons. With further refinement and validation, this scoring system may serve as an assessment tool and outcome measure for both clinical and research applications

BM: B-mode, PD: Power Doppler, TTJ: Tibiotalar Joint, STJ: subtalar joint. Note: It is recommended to slide the probe medially to laterally and capture the area of maximal distention.

Table 1. Ankle Scanning Protocol

	View (BM/PD)		View Description
	BM	PD	
Anterior compartment: ankle in a neutral position: knee flexed at 90˚, foot flat on table.			
Midline TTJ	1a	1b	Probe is placed in line with the 3rd toe. Move the probe laterally and medially to obtain the area of maximal pathology while ensuring visualization of the joint recess, talar dome, and talar neck.
Antero-Medial TTJ	2a	2b	Probe just anterior to the medial malleolus.
Antero-Lateral TTJ	3a	3b	Probe just anterior to the lateral malleolus.
Talonavicular	4a	4b	Start midline. Obtain a longitudinal view with the proximal end of the probe on the talus and distal end of the probe over the navicular bone.
Anterior Tendon Compartment	5a	5b	Place the probe in a transverse position over the top of the talar dome visualizing the bone cortex and the cartilage covering it. Move the probe proximally and distally to find the area of maximal distension of each abnormal tendon sheath and obtain an image representing abnormality. If tendons are normal, obtain an image at the level of the talar dome.
Medial compartment: hold the leg straight with slight external rotation. For the scanning of the anterior STJ hold foot in slight eversion.			
Medial Flexor Tendons	6a	6b	Place the proximal probe tip on medial malleolus and distal end perpendicular to Achilles to visualize PTT, FDT, FHL (*heel-toe distal end of probe to observe the FHL well).* Sweep distally along the tendons to find the area of maximal distension of each abnormal tendon sheath and obtain an image. If tendons are normal, obtain an image at the level of the sustentaculum tali
Medial aspect of the Anterior STJ	7a	7b	Probe will be positioned with proximal end anterior to the medial malleolus and distal end pointing towards the heel of the foot with the sustentaculum tali in view. Move the probe just distal to the sustentaculum tali where the anterior medial STJ is visible and obtain images at the site of maximal distention.
Lateral compartment: hold the leg straight with slight internal rotation. For the scanning of the lateral STJ hold foot in slight inversion			
Lateral Tendon Compartment	8a	8b	Place the proximal end of the probe on the lateral malleolus and distal end perpendicular to the Achilles to visualize PB/PL tendons. Sweep distally along the tendons to find the area of maximal distension of each abnormal tendon sheath and obtain an image. If tendons are normal, obtain an image at the level of the lateral view of the posterior STJ.
Lateral view of the Posterior STJ	9a	9b	Place the probe perpendicular to the sole over the sinus tarsi. Slide the probe posteriorly following the lateral STJ. Obtain image at the level of maximal distention. If no pathology obtain image just anterior to the lateral malleoli.

Mean score (SD)	PsA N = 128	axSpA N = 76	Total N = 204
Bone edema	0.4 (0.65)	0.7 (0.87)	0.5 (0.75)
Bone erosion	0.4 (0.63)	0.4 (0.69)	0.4 (0.65)
Composite Score (PsAMRIS)	1.0 (1.09)	1.3 (1.34)	1.1 (1.20)
Bone edema score was based on 0 = absent, 1 = 1-33%, 2 = 34-66%, 3 = >67% of bone edematous; Bone erosion score was based on 0 = absent, 1 = 1-10%, 2 = 11-20%, …, 10 = 90-100%; and composite score was a total of Periarticular inflammation 0 = absent, 1 = present + bone edema score + bone erosion score N, total number of pts in a group with MRI parameter present			

tween pain and objective signs of inflammation at entheseal sites.[2] ACHILLES (NCT02771210) is the largest prospective randomized controlled trial so far, investigating both clinical and imaging endpoints, with blinded and centrally read MRI data on heel enthesitis in pts with SpA.[3] Here, we report MRI characteristics at screening in pts clinically diagnosed with heel enthesitis (N=204) from the ACHILLES trial.

Methods: ACHILLES included pts (≥18 years) with active PsA (CASPAR criteria and ≥1 tender joint count and swollen joint count) or axSpA (ASAS axSpA criteria with objective signs of inflammation at screening and/or hsCRP >5mg/L and total BASDAI ≥4), with clinical (presence of pain and tenderness) and STIR-MRI positive heel enthesitis, refractory to standard treatment (either NSAIDs or TNF-inhibitors). MRI-positive heel enthesitis was confirmed for all pts by local investigators and was defined as tendinitis and/or bone marrow edema (BME) in the insertional area of the Achilles' tendon and/or the plantar aponeurosis. After randomization, all MRI were re-evaluated by two blinded central readers in a consensus read fashion for a priori defined qualitative and quantitative MRI parameters (based on PsAMRIS)[4].

Results: According to central reading, 114/204 (55.9%) pts presented with MRI-positive heel enthesitis. The most frequently observed MRI feature was tendinitis, affecting 46.1% (94/204) of the population (**Table 1**). A total of 61 pts (29.9%) presented with BME affecting 1-33% of the heel (PsAMRIS category 1); out of these 40/61 (65.6%) had an edema length of ≤0.5 cm and 21/61 (34.4%) had an edema length of >0.5 cm. There was no bone erosion affecting more than 40% of the calcaneus; therefore, no erosions reported in the PsAMRIS categories 5 to 10 (**Table 2**). AxSpA pts presented with more severe edema compared to PsA pts (more pts having edema in category 2 or 3), resulting in a higher bone marrow edema score based on PsAMRIS categories and a higher composite score (**Table 3**).

Conclusion: Despite clinical assessment of enthesitis, only 56% of the ACHILLES patients presented with MRI-positive heel enthesitis according to central reading. These results indicate discrepancies in MRI evaluations between

local and trained central readers. Furthermore, clinically assessed enthesitis might not necessarily correlate with imaging features of heel inflammation or chronic changes.

SESSION INFORMATION
Session Date: Friday, November 6, 2020
Session Title: Imaging of Rheumatic Diseases
Session Type: Abstract Session
Session Time: 10:00AM–10:50AM

Background/Purpose: Cardiovascular (CV) mortality and morbidity is increased in ankylosing spondylitits (AS) due to a process of accelerated atherosclerosis. The disease-related factors involved in this process are not yet well known. The aim of this study is to identify factors associated with subclinical atherosclerosis in the largest series of axial spondyloarthritis (axSpA) studied so far, and to analyze possible differences in this regard between AS and non-radiographic axial spondyloarthritis (nr-axSpA).

Methods: This is a transversal observational study from the AtheSpAin cohort, a Spanish multicenter cohort to study atherosclerosis in axSpA. We included patients older than 18 years old diagnosed with axSpA according to ASAS criteria. Carotid ultrasound (US) examination was done in all patients, included the measurement of carotid intima-media wall thickness (cIMT) in the common carotid artery and the detection of plaques in the extracranial carotid tree bilaterally, according to the Mannhein consensus.

Results: 639 AS patients and 167 nr-axSpA were recruited. Baseline characteristics and clinical features are shown in **table 1**

Table 2 shows the association between three surrogate markers for subclinical atherosclerosis (unilateral and bilateral carotid plaques and cIMT) with disease features, analyzed in an unadjusted model. As expected, cardiovascular risk factors (CRF) were associated with the presence of carotid plaques and cIMT.

Concerning disease related data, a very high disease activity according to ASDAS-CPR was related with both unilateral and bilateral plaques as well as an increased cIMT. BASDAI was associated only with cIMT. The three surrogate markers for atherosclerosis were also associated with CPR and ESR at time of diagnosis. The severity of the disease measured by BASMI, BASFI or hip involvement and the radiographic damage were strongly associated with subclinical atherosclerosis. History of synovitis and extraarticular manifestations as well as the use of prednisone and DMARDs were found to be related with IMT.

After adjustment for age, sex and CRF, associations with surrogate markers for atherosclerosis remained statistically significant for BASFI (unilateral plaques: OR 1.13, p=0.01), BASMI (bilateral plaques: OR 1.22, p=0.01), use of prednisone and DMARDs (bilateral plaques: OR 2.42, p=0.03; OR 2.10, p=0.02 respectively), CRP and ESR at time of diagnosis (IMT: beta coefficient 0,31, p=0,047 and 0.77, p=0,002 respectively), and inflammatory bowel disease (bilateral plaques: OR 3.48, p=0.01).

Differences, between AS and nr-axSpA, in the effect of CV riks factors on cIMT/carotid plaque were assessed including interaction factors in the regression models. In this sense, no differences were found between both subtypes of patients in the effects of CV risks factors over CIMT/carotid plaque.

Conclusion: Apart from CRF, the atherosclerotic disease in axSpA is associated with disease-related factors such as the inflammatory response, the severity of the disease or extraarticular manifestations, without differences between AS and nr-axSpA.

TABLE 1. Association between unilateral/bilateral carotid plaques and IMT with the main clinical, analytical (unadjusted model) and radiological features in axSpA patients.

Cytotoxic T Cells with a Chronic Antigen Exposure Phenotype Drive Immune Checkpoint Inhibitor Sicca

Blake Warner[1], Billel Gasmi[2], David Kleiner[3], Paola Perez Riveros[4], Daniel Barber[5], Shunsuke Sakai[5] and Alan Baer[6], [1]National Institute of Dental and Craniofacial Research, Bethesda, [2]National Cancer Institute, Bethesda, MD, [3]National Cancer Institute, Bethesda, [4]National Institute of Dental and Craniofacial Research, Bethesda, MD, [5]National Institute of Allergy and Infectious Disease, Bethesda, MD, [6]Johns Hopkins University School of Medicine, Baltimore, MD

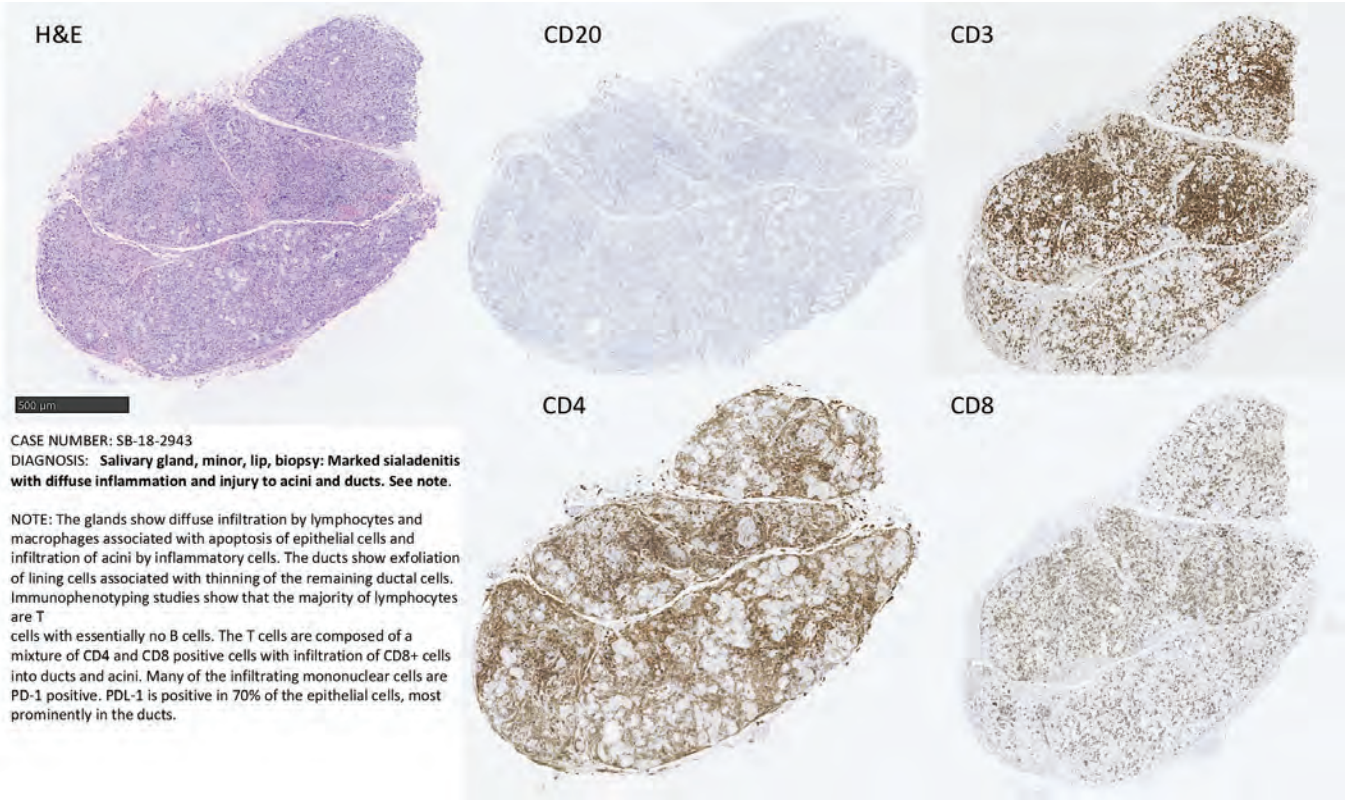
SESSION INFORMATION
Session Date: Friday, November 6, 2020
Session Title: Immunological Complications of Therapy
Session Type: Abstract Session
Session Time: 3:00PM–3:50PM

Background/Purpose: Immune checkpoint inhibitors (ICI) have advanced the field of cancer therapeutics. By blocking the negative co-stimulation of T cells, ICI augment the anti-tumor immune response. However, ICI can elicit inflammatory reactions termed immune-related adverse events (irAEs). We previously reported that ICI therapy is associated an abrupt onset, oftentimes severe irAE resembling Sjögren's syndrome (Warner et al., 2019). Herein we aimed to characterize the inflammatory infiltrate of labial salivary gland biopsies (LSGB) from patients with ICI sicca.

Methods: Patients with ICI sicca (ICI, n=21) and healthy volunteers (HV, n=9) underwent saliva assessments, medical workup, and LSGBs. We measured the surface area of acini and fibrosis with histochemical stains and the density of IHC stains in LSGB using QuPath_2.0. Transcriptional profiling of immune markers was determined using RNA sequencing. Dissociated LSGB were subjected to 4h PMA/ionomycin stimulation and subsequent flow cytometry analysis. In patients with available dissociated tissues, single cell (sc)RNA sequencing was performed.

Results: LSGB form ICI sicca patients demonstrated architectural distortion including the most common findings of reduced density of acini (p=0.01), variable fibrosis (p= 0.07), and mild-to-severe sialadenitis composed chiefly of T lymphocytes. In some patients, destruction of PD-L1$^+$ epithelia with marked effacement of gland architecture was observed. IHC demonstrated the ICI inflammatory infiltrate was composed increased numbers of CD8$^+$ (p=0.039), CD4$^+$ (p=0.078), and CD3$^+$ (p=0.05) T lymphocytes. RNA sequencing exhibited significantly higher PD-1 expression in the ICI LSGB (p=0.02) with higher CD8 and CD39 expression (p=0.05). CD3, CD4, 4-1BB, TIM3, GzmB, FOXP3 and PDL1 were all upregulated in the ICI group but did not reach statistical significance. Flow cytometry confirmed increased infiltration with CD3$^+$ with significant increases in activated cytotoxic T cells (CD8$^+$CD107a$^+$). scRNAseq and confocal immunofluorescence microscopy confirmed increased density of CD8$^+$PD-1$^+$CD39$^+$ T cells in the ICI LSGB.

Conclusion: The histopathology of ICI induced sialadenitis consists primarily of a T cell infiltrate with parenchymal destruction with patchy fibrosis. IHC analysis combined with the transcriptional data show the presence of cytotoxic T-cell population (CD8, 4-1BB, TIM3, GrzB) with a chronic antigen exposure phenotype (PD-1, CD39). Further investigation is necessary to determine if this T-cell population is causing the sicca or if it constitutes a reactive population.



Example of severe sialadenitis induced by anti-PD-L1 therapy . Total effacement of the gland architecture with injury to the acini and ducts is evident. The infiltrate is composed chiefly of T cells without B cells. CD4 cells predominate, although infiltration of the acini and ducts is seen.

In Vitro Characterization of Inflammatory Arthritis Associated with Immune Check Point Inhibition

Anne Sofie Sørensen[1], Morten Nørgaard Andersen[1], Kristian Juul-Madsen[2], Cæcilie Deisting Skejø[1], Henrik Schmidt[1], Thomas Vorup-Jensen[1] and Tue Wenzel Kragstrup[1], [1]Aarhus University, Aarhus, Denmark, [2]Aarhus University, Aarhus, Midtjylland, Denmark

SESSION INFORMATION
Session Date: Friday, November 6, 2020
Session Title: Immunological Complications of Therapy
Session Type: Abstract Session
Session Time: 3:00PM–3:50PM

Background/Purpose: During treatment with immune checkpoint inhibitors (ICI) such as the anti-PD-1 antibody pembrolizumab, 2-4% of cancer patients develop inflammatory arthritis as an immune-related adverse event (IRAE). These IRAEs show striking similarities with inflammatory arthritis and are linked with immune activation. However, the underlying immunological mechanisms are not well characterized.

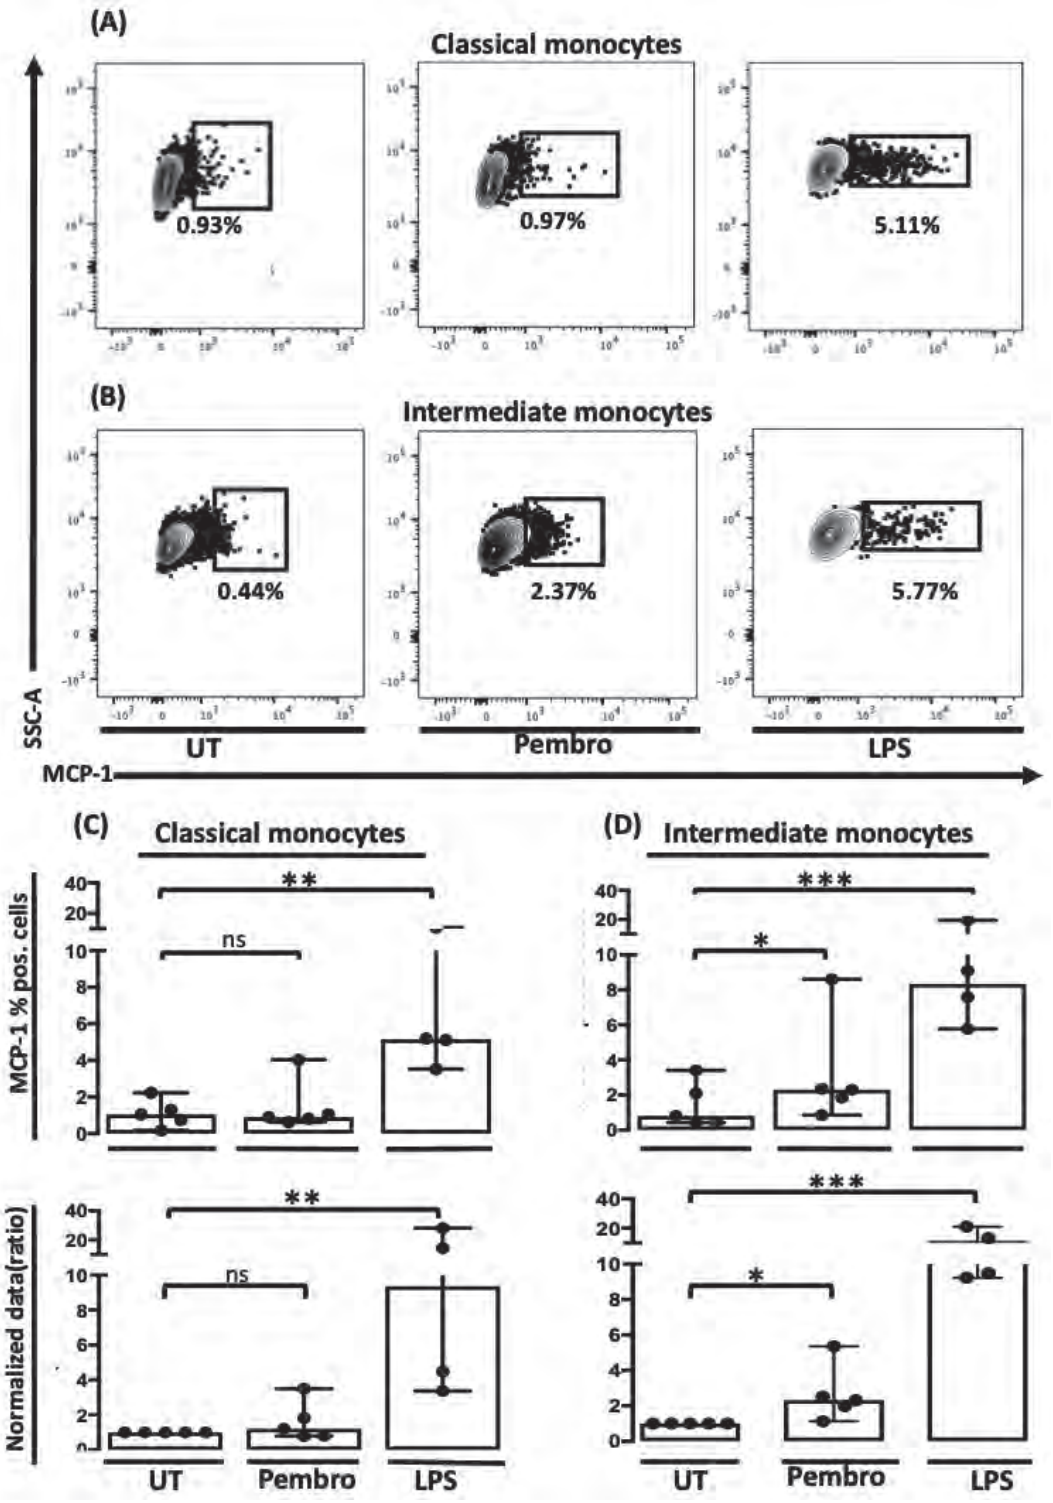

Figure 1. MCP-1 production in the monocyte subsets following treatment with pembrolizumab. (A) Representative dotplots of MCP-1 production in classical monocytes. (B) Representative dotplots of MCP-1 production in intermediate monocytes. (C) Upper panel: Frequency of MCP-1+ cells in classical monocytes in each culture. Lower panel: Data were normalized and expressed as ratios. (D) Upper panel: Frequency of MCP-1+ cells in intermediate monocytes in each culture. Lower panel: Data were normalized and expressed as ratios. All data are expressed as median + 95% Confidence interval. * p-value < 0.05, ** p-value < 0.01, *** p-value < 0.001. UT, untreated; Pembro, Pembrolizumab ; CM, Classical monocytes ; IM, intermediate monocytes.

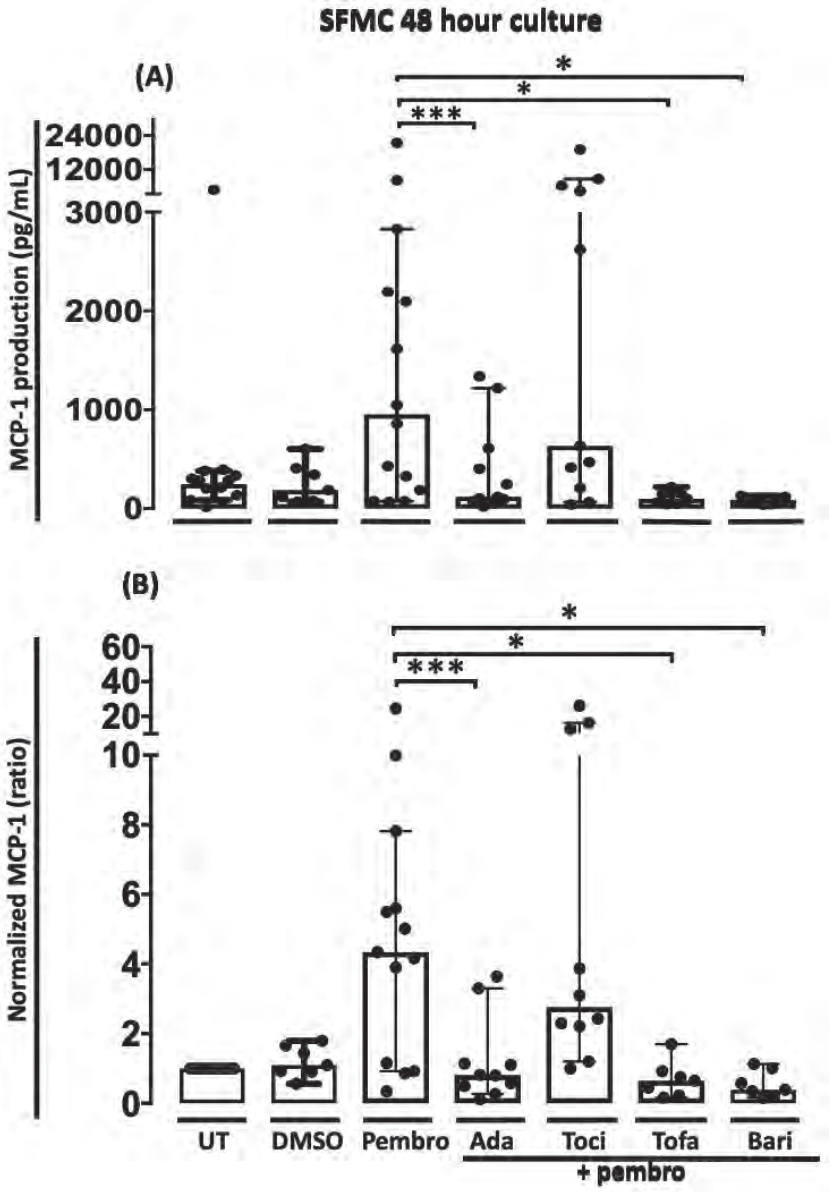

Figure 2. MCP-1 production in SFMC cultures treated with pembrolizumab combined with different DMARDs A) MCP-1 production in SFMCs cultured for 48 h untreated (UT)(n=13) or treated with DMSO (n=7), pembrolizumab (n=13), pembrolizumab + adalimumab (n=10), pembrolizumab + tocilizumab (n=10), pembrolizumab + tofacitinib (n=7) or pembrolizumab + baricitinib(n=7). B) Data were normalized to untreated cultures and expressed as ratios.

Methods: We included synovial fluid mononuclear cells (SFMCs, n=31) and peripheral blood mononuclear cells (PBMCs, n=6) from patients with rheumatoid arthritis and peripheral spondyloarthritis and PBMCs from healthy controls (n=6).Pembrolizumab-treated cells were analyzed using flowcytometry and pro-inflammatory multiplex assays. The mitigation of the effects of pembrolizumab treatment was compared for the disease modifying anti-rheumatic drugs (DMARDs) adalimumab, tocilizumab, tofacitinib, and baricitinib.

Results: Pembrolizumab significantly increased MCP-1 production by arthritis SFMCs (P=0.0031) but not by PBMCs from patients or healthy controls (P=0.77 and P=0.43). In SFMCs, pembrolizumab increased the production of TNFα(P=0.049), IFNγ (P=0.047), and IL-12p70 (P=0.031), but did not change the production of IL-6 (P=0.98). The SFMCs treated with pembrolizumab showed an increased frequency of intermediate monocytes (P=0.044) and increased the

MCP-1 production only within the intermediate monocyte subset (P=0.028) (Figure 1). Lastly, adalimumab, baricitinib, and tofacitinib treatment were able to attenuate the pembrolizumab-induced MCP-1 production (P=0.0004, P=0.033, and P=0.025, respectively) while this was not seen with tocilizumab treatment (P=0.75) (Figure 2).

Conclusion: We have established an in vitro model to study the immunological reactions caused by pembrolizumab. In this model, pembrolizumab specifically activated intermediate monocytes and induced TNFα, IFNγ, and IL-12p70 production, whereas IL-6 was unchanged.

Data is expressed as median + 95% Confidence interval. * p-value < 0.05, ** p-value < 0.01, *** p-value < 0.001. DMSO, Dimethyl sulfoxide; Pembro, Pembrolizumab; Ada, Adalimumab; Toci, Tocilizumab ; Tofa, Tofacitinib ; Bari, Baricitinib.

Prevalence, Therapy and Tumor Response in Patients with Rheumatic Immune-related Adverse Events Following Immune Checkpoint Inhibitor Therapy: A Single-Centre Analysis

Sophia Verspohl[1], Tobias Holderried[1], Charlotte Behning[2], Peter Brossart[1] and **Valentin Schaefer**[3], [1]Clinic for Internal Medicine III, Department of Oncology, Hematology and Rheumatology, University Hospital Bonn, Germany, Bonn, Nordrhein-Westfalen, Germany, [2]Institute for Medical Biometrics, Informatics and Epidemiology (IMBIE), University Hospital Bonn, Bonn, Germany, Bonn, Nordrhein-Westfalen, Germany, [3]Clinic of Internal Medicine III, Department of Oncology, Hematology and Rheumatology, University Hospital Bonn, Germany, Bonn, Nordrhein-Westfalen, Germany

SESSION INFORMATION
Session Date: Friday, November 6, 2020
Session Title: Immunological Complications of Therapy
Session Type: Abstract Session
Session Time: 3:00PM–3:50PM

Background/Purpose: Immune checkpoint inhibitors (ICIs) have improved cancer therapy [1] by inducing a higher immune system activity and subsequent attack of tumor cells. However, this effect can cause rheumatic immune-related adverse events (rh-irAE), which have not yet been extensively studied.

Methods: We analysed 437 patients between January 2014 and October 2019, treated with ipilimumab (anti-CTLA-4) and / or nivolumab (anti-PD-1) or pembrolizumab (anti-PD-1) at the Department of Oncology, Hematology and Rheumatology at the University Hospital in Bonn, Germany.

Results: Of the 437 patients, 260 (60%) were males, 177 (40%) were females with a mean age of 64 years (SD ± 14) at the beginning of the ICI-therapy. 163 patients (37.3%) displayed at least one irAE, including rh-irAE. Most common other non-rheumatic irAE (non-rh-irAE) were rash, colitis and hepatitis.

We identified 19 patients (4.3%) with a minimum of one rh-irAE due to ICI-therapy, three of those had a pre-existing rheumatological disease. Clinical characteristics of patients with rh-irAE, including types of rh-irAE and therapy, are displayed in table 1. Rh-irAE occurred in one patient (2.6%) with ipilimumab, in ten patients (5.3%) with nivolumab

	Number of patients (%)
Patients with rh-irAE	19 (100)
Median onset time of rh-irAE	109.0 days (IQR 40 – 420 days)
Types of rh-irAE	
Arthralgia only[1]	8 (42.1)
Arthritis	7 (36.8)
Rheumatoid arthritis	3
Psoriatic arthritis	2
Juvenile idiopathic arthritis	1
Undifferentiated arthritis	1
Myalgia	2 (10.5)
Myositis	3 (15.8)
Immunosuppressive treatment	
Glucocorticosteroids (GC) only	11 (57.9)
GC plus MTX	3 (15.8)
GC plus tocilizumab	1 (5.3)
Other treatments	
NSAIDs	6 (31.6)
Opioids	1 (5.3)

Table 1. Clinical characteristics of rheumatic immune-related adverse events (rh-irAE). 1= Excluding patients with arthritis. IQR: interquartile range, MTX: methotrexate, NSAIDs: non-steroidal anti-inflammatory drugs

	Patients without irAE n=200 (%)	Patients with non-rh-irAE n=135 (%)	Patients with rh-irAE n=18 (%)
Responders*	65 (32.5)	82 (60.7)	17 (94.4)
Non-responders*	135 (67.5)	53 (39.3)	1 (5.6)

Table 2. Comparison of best tumor response to immune checkpoint inhibitors (ICIs) in patients without immune-related adverse events (irAE), patients with non-rheumatic irAE (non-rh-irAE) and in patients with rheumatic irAE (rh-irAE). *Response to ICI-therapy includes complete response, partial response and stable disease. Non-responders were affected by progressive disease. Patients who suffered from rh-irAE and non-rh-irAE were classified as rh-irAE cohort.

and in eight patients (5.0%) with pembrolizumab. Thirteen patients with rh-irAE received ICI-therapy (percentage within each malignancy given in brackets) for melanoma (6.2%), three patients for lung cancer (3.8%), two patients for head and neck tumor (5.9%) and one patient for gastrointestinal carcinoma (8.3%). Most rh-irAE were classified as moderate severe (CTCAE [Common Terminology Criteria of Adverse Events] grade 2: 68.4%). Even though patients benefited from ICI treatment, therapy had to be discontinued in six of them as a consequence of rh-irAE.

Interestingly, patients with rh-irAE had a significantly higher tumor response rate compared to patients without irAE (94.4% vs. 32.5%; $p< 0.0001$). The comparison of best tumor response in different cohorts (patients without irAE, with non-rh-irAE and with rh-irAE) is listed in table 2. In order to calculate progression-free survival (PFS), we performed a Kaplan-Meier analysis (Fig. 1) and compared thereby the PFS in the three cohorts mentioned above. Using the log-rank test, a significant difference in PFS was found in these three cohorts ($p=0.003$).

Conclusion: Rh-irAE occur under ICI-therapy and in patients with higher tumor response. However, they are not the most frequent irAE after ICI exposure: 9.3% of all irAE were rheumatic (20 rh-irAE cases in 19 patients of a total of

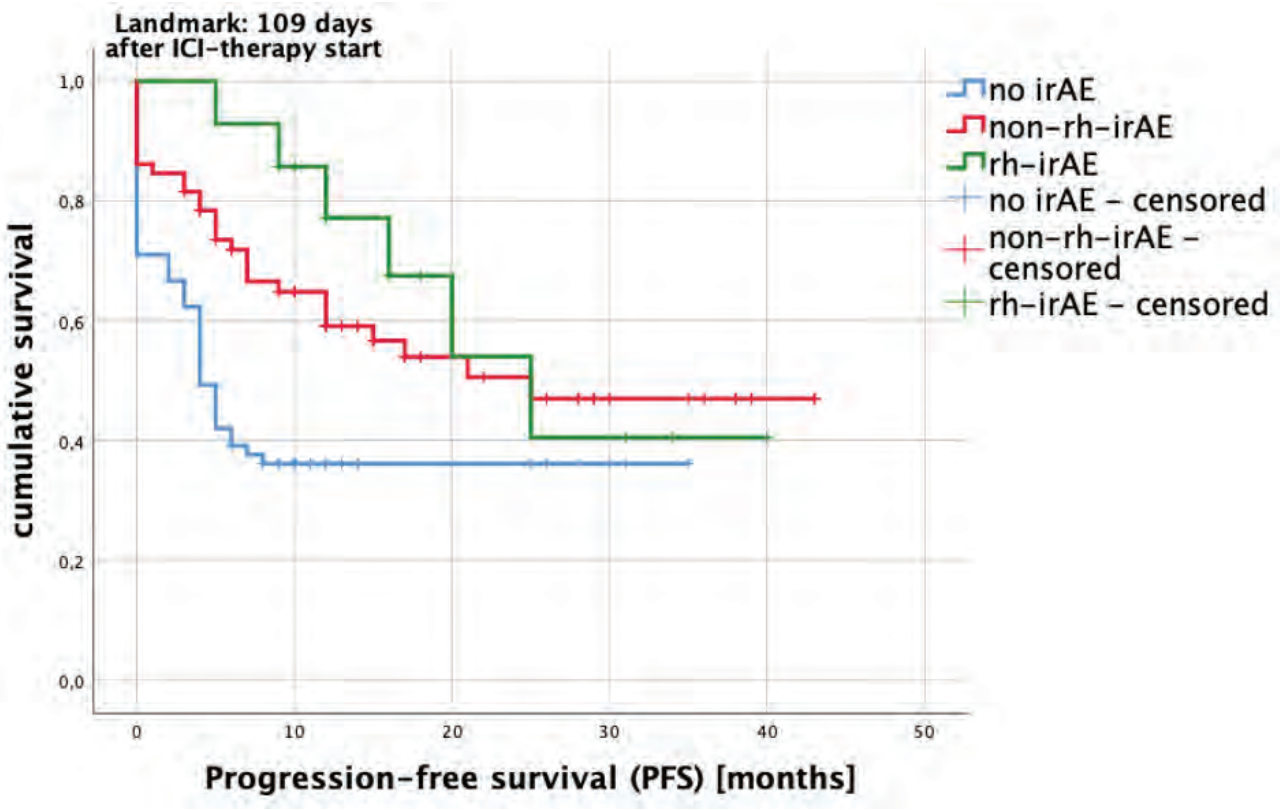

Figure 1. Kaplan-Meier analysis estimated PFS (progression-free survival) after immune checkpoint inhibitor (ICI) therapy. Compared were patients with no side effects (no irAE=blue line), patients with other non-rheumatic immune-related adverse events (non-rh-irAE=red line) and patients with rheumatic immune-related adverse events (rh-irAE=green line). Patients who suffered from rh-irAE and non-rh-irAE were classified as rh-irAE cohort. Patients with a therapy duration of 109 days or more were included in the analysis (landmark 109 days after ICI-therapy start). Log rank test: p=0.003.

215 irAE cases in 163 patients). As the use of ICIs is increasing for different malignancies the incidence of rh-irAE can be expected to increase.

Recombinant Zoster Vaccine in Patients with Rheumatic Diseases: A Retrospective Study of 622 Patients

Tiphaine Lenfant[1], Elizabeth Kirchner[2], Rula Hajj-ali[3], Leonard Calabrese[3] and Cassandra Calabrese[3], [1]Cleveland Clinic Foundation, Rocky River, OH, [2]Cleveland Clinic Foundation, Cleveland, [3]Cleveland Clinic, Cleveland, OH

SESSION INFORMATION

Session Date: Friday, November 6, 2020

Session Title: Immunological Complications of Therapy

Session Type: Abstract Session

Session Time: 3:00PM–3:50PM

Background/Purpose: The recombinant herpes zoster vaccine (RZV) was FDA-approved in 2017 but patients with rheumatic diseases were excluded from initial pivotal trials because of theoretical risk of flares given the vaccine's potent immunogenicity. Its use in patients with RA, SLE and vasculitis raises particular concern.

Methods: Patients followed in the Cleveland Clinic Rheumatology Department who received RZV between February 2018 and March 2020 were identified and retrospectively included in this study. Inclusion criteria were: age > 18 years, at least one RZV dose during the study period, available data on the clinical status before and after the vaccine. Data were collected from the electronic medical record. An immune mediated inflammatory disease (IMID) flare was defined as a) a documentation of flare in the rheumatology office notes, telephone encounter or patient portal communication or b) new prednisone prescription, occurring in the 12 week period following each dose. Adverse events (AE) attributed to RZV and occurrence of herpes zoster (HZ) were also assessed. The statistical analysis was performed with R studio v.1.2.5042. Categorical variables were compared using chi-square tests and multivariable analysis were performed using logistic regression and Cox model (tests were two-sided, significance level was 0.05).

Results: In the study period, 622 patients met the inclusion criteria; the majority were female (67%), and median age was 67 years. Of the group, 15% reported a history of HZ and 43% had previously received live attenuated zoster vaccine. 147 patients (24%) received 1 dose of RZV, while 475 (76%) received both dsoses with a median interval of

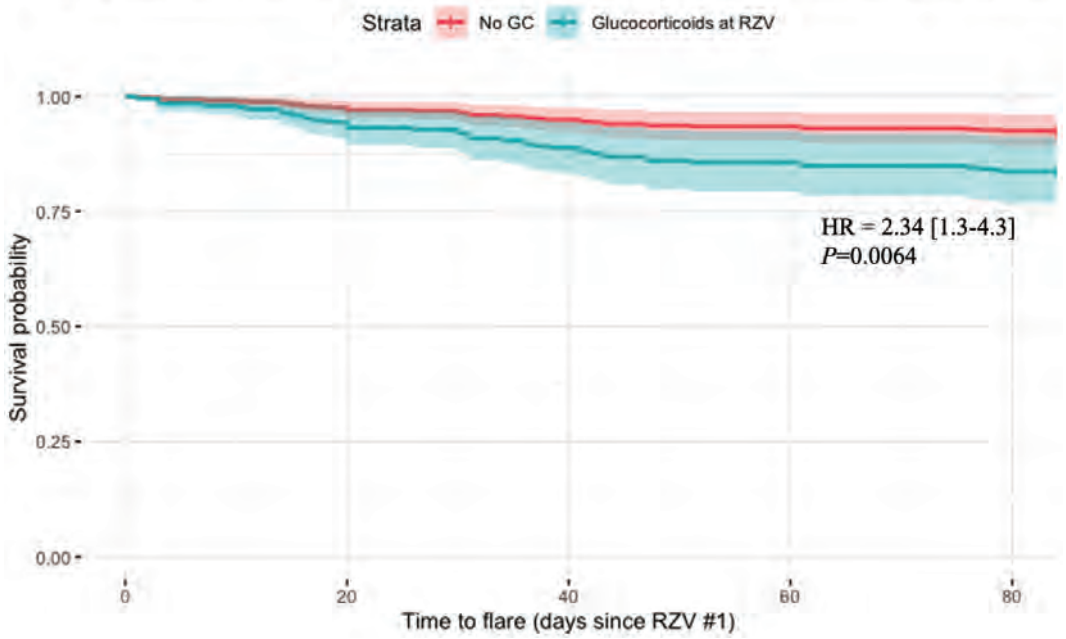
Legend. IMID: Immune Mediated Inflammatory Disease; RZV: Recombinant Zoster Vaccine; RA: Rheumatoid Arthritis; SLE: Systemic Lupus Erythematosus; GC: Glucocorticoids; MTX: Methotrexate; HCQ: Hydroxychloroquine; SSA: Sulfasalazine; Jak-i: Jak-inhibitors; TNF-i: TNF inhibitors; Other biologic: abatacept, apremilast, belimumab, mepolizumab, rituximab, secukinumab, tocilizumab, ustekinumab; Other IS: Other Immunosuppressant, azathioprine, leflunomide, ciclosporine, mycophenolate mofetil, tacrolimus; IVIG: Intravenous Immunoglobulin.

Figure 2. Glucocorticoid use at time of vaccine was associated with a higher risk of IMID flare after the first RZV dose



Legend: This figure shows a survival analysis of the time-to-flare with estimated risk of being on glucocorticoids at the time of first RZV dose (multivariate Cox-model). IMID: Immune Mediated Inflammatory Disease; RZV: Recombinant Zoster Vaccine; GC: Glucocorticoids; HR: Hazard Ratio

2.9 months. The AE rate was 8.5% with mostly mild events (71%). After a median 35.8 weeks of follow-up, the HZ incidence was 0.6%.

Of 358 IMID patients the most common were RA (n=88, 25%), vasculitis (n=50, 14%), and PMR (n=29, 8%). Baseline treatment in this group included glucocorticoids (GC) (35%, median dose 5 mg/day), conventional and biologic DMARDs (Fig 1). Fifty-seven (16%) experienced a flare: 34 (60%) after the first dose, 16 (28%) after the second, and 7 (12%) flared after both. RA patients had the highest flare rate (n=21, 24%). Flares occurred in temporal relation to a treatment change in 18 cases (31%). Flares were most often treated with GC (44%, median dose 20 mg/day) and 14 (25%) required a change in immunosuppressive therapy. Among IMID patients, univariate analysis revealed more flares in patients on GC and Jak-inhibitors (p=0.002 and 0.025 respectively), and in RA patients (p=0.019) (Table 1). A multivariate analysis showed that only GC use at time of vaccine remained significantly associated with flares (OR = 2.31 [1.29-4.15], p=0.005). A time-to-flare survival analysis was conducted with a multivariate Cox-model: glucocorticoids remained the only significant predictor of the first IMID flare (HR = 2.34 [1.3-4.3], p=0.006) (Fig 2).

Conclusion: In this retrospective cohort of rheumatic disease patients, we found the incidence of AEs and HZ after RZV to be consistent with the existing literature. GC at time of RZV was associated with a significantly higher rate of flares, suggesting that delaying RZV administration in patients with active disease may be prudent

Monitoring of BK Reactivation and Long-term Safety on JAK1/2 Inhibition with Baricitinib

Kader Cetin Gedik[1], Gema Souto Adeva[2], Jenna Wade[1], Gina Montealegre Sanchez[3], Adriana de Jesus[4] and Raphaela Goldbach-Mansky[5], [1]Translational Autoinflammatory Disease Section (TADS)/NIAID/NIH, Bethesda, MD, [2]Translational Autoinflammatory Disease Section (TADS)/NIAID/ NIH, Bethesda, [3]Translational Autoinflammatory Disease Section (TADS)/NIAID/NIH, Rockville, MD, [4]Translational Autoinflammatory Disease Section (TADS)/NIAID/NIH, Silver Spring, MD, [5]Translational Autoinflammatory Disease Section (TADS)/NIAID/NIH, Potomac, MD

SESSION INFORMATION
Session Date: Friday, November 6, 2020
Session Title: Immunological Complications of Therapy
Session Type: Abstract Session
Session Time: 3:00PM–3:50PM

Background/Purpose: Baricitinib has been used to treat pediatric patients (pts) with Type 1 Interferonopathies[1]. Safety profile including BK viral reactivation in urothelium and pharmacokinetic model have been reported[1,2]. Given the association of BK nephropathy with BK viremia[3], we assessed long term safety and consequences of chronic BK viruria on renal function.

Methods: Between October 2011 and August 2018, 25 pts [10 CANDLE (Chronic atypical neutrophilic dermatosis with lipodystrophy and elevated temperatures), 7 SAVI (Stimulator of IFN genes–associated [STING-associated] vasculopathy with onset in infancy) and 8 other interferonopathies] were enrolled in an institutional review board

Table 1: Severe Adverse Events[A]

Severe Adverse Events	CANDLE (n=10), number of SAEs	Other (n=8),[B] number of SAEs	SAVI (n=7), number of SAEs	Total (n=25), number of SAEs

approved protocol (NCT01724580). Safety was longitudinally assessed during study period (cut off May 2020). After detection in an index pt in June 2015, BK viral load and renal function were monitored longitudinally, with baseline assessments in 7 additionally enrolled pts. Dichotomous adverse events (AEs and SAEs) were descriptively analyzed, for continuous outcomes (BK viral load) paired t-tests were used.

Results: The mean age at enrollment was 11.5 years [range 1.2-24.2]. The mean baricitinib exposure was 4.2 years [104.6 pt.-years]. Of 25 pts, 1 CANDLE (azotemia in the context of BK viremia) and 4 pts with undifferentiated disease discontinued (4/4 inadequate response; 1/4 osteonecrosis). Nine pts are receiving commercial baricitinib and discontinued from study. During the study period, 114 SAEs were reported [66 were treatment related] (Table 1). Of 23 pts monitored, 20 developed BK viruria (1/20 pre-baricitinib). All except the index pt. had stable renal function over a mean of 4.9±2.4 years on baricitinib. Out of 8 pts with no BK viruria at baseline, 5 (63%) developed viruria after a mean of 8.3±10.3 months on baricitinib at a mean age of 5.8±2.3 years. Two pts had BK viremia prior to baricitinib (1 on tacrolimus and 1 azathioprine) and 10 additional pts developed viremia [mean 3.08±1.1 log copy/ml] after a mean of 1.7±1.4 years on baricitinib. The mean urine BK load was 7.7±2 log copy/ml at the time of first viremia (Table 2). Herpes zoster developed in 2 pts and resolved without holding baricitinib. The most frequent treat-

Table 2: BK viral reactivation in interferonopathy patients with baricitinib treatment

BK viral load [A] n=23	Pre-baricitinib Baseline Screening n (%) (Mean±SD)	On-baricitinib June 2015 n (%) (Mean±SD)	On-baricitinib May 2020 n (%) (Mean±SD)	p-value
BK viremia [log copy/ml] (n=12/23)	2/23 (8%) 0.21±0.72		9/23 (39%) 1.55±2.08	0.012[B]
BK viruria[C] [log copy/ml] (n=15/16)	Not tested in 16/23 pts prior to baricitinib	14/16 (88%) 5.56±3.17	15/16 (94%) 6.11±2.66	ns[D]
BK viruria[E] [log copy/ml] (n=5/7)	1/7 (14%) 2.88±1.02		4/7 (57%) 4.57±3.65	ns[F]

[A]Results reported in [log_{10}] copies/mL; n (%) represents the number and (percentage) of patients who tested positive for BK virus.
[B]The BK viral load in blood at baseline (prior to baricitinib) was compared to the last visit (n=23)
[C]Baseline urine samples had not been collected and therefore baseline BK urine viral load could not be obtained. Of 23 patients enrolled, 16/23 had their first evaluation of BK viral load in urine in/around June 2015, while already on baricitinib.
[D]The first BK titer assessment in urine at the time of the identification of the first case (post-baricitinib - June 2015) was compared to the last visit (n=16)
[E]Of 23 patients, 7 patients who enrolled after June 2015 had BK assessment in blood and urine prior to baricitinib.
[F]The BK titer assessment in urine at baseline (prior to baricitinib) was compared to the last visit (n=7).

ment-emergent infectious AEs were upper respiratory tract infections, gastroenteritis, sinusitis and pneumonia (in 76%, 36%, 36%, 28% of the pts respectively).

Conclusion: Overall, baricitinib was well tolerated. BK reactivation in urine occurred or was present in 20/23 (87%) pts. In 19/23 who were prospectively monitored, baricitinib dose adjustments to keep BK viremia negative or low were made and renal function remained unchanged during the study period. Our data suggest that BK viral load should be monitored on baricitinib. The presence of BK viremia/ viruria prior to baricitinib treatment suggests evaluation of BK viral load in pts on other chronic immunosuppressive regimens.

Abstract Number: 0454

Anticytokine Therapies for Inflammatory Rheumatic Disease (IRD) Are Associated with Reduced Hospitalisation Following Community COVID-19 Infection; Results of the Trinity Rheumatology and Covid-19 Registry - TRACR

Rachael Flood[1], Richard Conway[2], David Kane[1] and Ronan Mullan[1], [1]Tallaght University Hospital, Dublin, Ireland, [2]St James's Hospital, Dublin, Ireland

SESSION INFORMATION
Session Date: Friday, November 6, 2020
Session Title: Infection-related Rheumatic Disease
Session Type: Abstract Session
Session Time: 10:00AM–10:50AM

Background/Purpose: Anticytokine biological disease modifying anti-rheumatic drugs (bDMARD), which are widely prescribed for Inflammatory Rheumatological Diseases (IRD) are currently undergoing clinical trials for the treatment of Covid-19. Despite indicators that bDMARDs ought to reduce adverse outcomes through inhibition of hyperinflammatory cytokine storm events, only one global registry of 600 Covid-19 IRD patients has indicated that pre-treatment with the tumour necrosis factor inhibitor class of bDMARD protects against hospitalisation. Furthermore global registry reports of admission rates of 46% in IRD are at variance with lower rates recently published in the NEJM,

suggesting a potential reporting bias in registry data towards hospitalised patients, including those who may only become infected during hospitalisation for an unrelated condition.

Methods: To eliminate reporting bias we contacted 7,500 patients comprising 4,524 with IRDs and 2,976 with non-inflammatory disease (nIRDs) attending Trinity College Dublin aligned academic Rheumatology centres, collecting data up to the end of the 1st pandemic wave in Ireland on 03rd June 2020. Cross-referencing with test-centre positive polymerase chain reaction (PCR) results and mortality data was performed to ensure complete collation of cases.

Results: We identified 77 cases of PCR or physician diagnosed COVID-19, of whom 68 were community acquired (supplementary table 1) and 9 were hospital acquired. No differences were seen in cumulative incidence/100,000 of COVID-19 between IRD (884), non-inflammatory rheumatic disorders (nIRD, 940), or incidence rates for metropolitan Dublin (887). In subgroup analysis of community acquired infection, hospitalisation was statistically less likely in patients receiving long-term anticytokine biological therapies ($P< 0.05$). This significance was lost when hospital acquired cases were included. In further analysis of the 40 IRD and 28 nIRD community acquired cases, hospitalisation was more likely to occur in those receiving glucocorticosteroids ($p< 0.01$) or those diagnosed with type 2 diabetes ($p< 0.05$). Lower hospitalisation rates for community acquired Covid-19 in IRD (15%), equivalent to national figures (13%) were observed.

Conclusion: Unintentional bias in reporting hospitalised COVID-19 cases to IRD registries and the inclusion of hospital acquired cases during data analysis, may lead to spurious overestimates of overall morbidity while masking critically important information on the role of anticytokine therapies in preventing hospitalisation. Although our dataset is

small, these results suggest a much more powerful role for anticytokine therapies in treating COVID-19 than existing published registry data indicate. Further analysis using existing datasets on community acquired cases, are likely to more rapidly identify existing drugs to treat COVID-19, which are urgently required to improve health outcomes.

HLA-B27 and Host Immune Response: Lessons from Reactive Arthritis

Sophie Wojcik[1], Davina Morris[2], Gillian Fitzgerald[3], Steve Ramkissoon[4], Nigil Haroon[2] and Robert Inman[5], [1]UHN, Montreal, QC, Canada, [2]University of Toronto, Toronto, ON, Canada, [3]Toronto Western Hospital, Toronto, ON, Canada, [4]UHN, Toronto, ON, Canada, [5]University Health Network, Toronto, ON, Canada

SESSION INFORMATION
Session Date: Friday, November 6, 2020
Session Title: Infection-related Rheumatic Disease
Session Type: Abstract Session
Session Time: 10:00AM–10:50AM

Background/Purpose: The natural history of reactive arthritis (ReA) remains poorly understood. Certain patients with ReA will go on to develop a chronic course while others will have a self-limited course. The goal of this study is to identify prognostic factors for chronicity of disease.

Methods: ReA patients were identified via two methods; from a Spondyloarthritis clinic database and from an urgent Rheumatology clinic, both located within the University Health Network in Toronto, Canada. Baseline data at presentation, including history, physical exam, X-rays and clinical laboratory results were collected. Patients whose arthritis resolved and were discharged from clinic were defined as self-limited ReA, whereas patients with persisting arthritis with long term follow-up in the clinic were defined as chronic ReA.

Results: A total of 57 patients with ReA were identified. Of these patients, 23 were classified as self-limited ReA (mean disease duration 2.5 years +/- 4.0) and 34 were classified as chronic ReA (disease duration 14.2 years +/- 10.7), $p < 0.01$. The most striking difference was the presence of HLA-B27: 82.4% in the chronic group *vs*45.0% in the self-limited ($p= 0.004$). The nature of the antecedent infection was not a prognostic marker. There was a difference in the presence of inflammatory back pain at disease onset (59.4% *vs* 30.0% $p= 0.04$) and in CRP (15.0 mg/L *vs* 1.5, $p = 0.04$) in the chronic *vs* self-limited group, respectively. In multivariate analysis, the presence uveitis *trended* towards an increased risk of chronic ReA (OR 6.71 (95% CI 0.44-102.12) as did male gender (OR 3.22 (95% CI 0.59- 16.67), but neither reached statistical significance. A subgroup analysis of chronic ReA patients revealed an increased incidence of both uveitis and SI joint involvement over time; 25.8% patients presented with uveitis; however over time, 53.9% developed uveitis. Similarly, 38.9% of chronic ReA patients initially presented with sacroiliitis vs. 56.3% over time.

Conclusion: HLA-B27 is the predominant risk factor for chronicity in ReA, as it is for ankylosing spondylitis (AS). In contrast, the type of antecedent infection is not a prognostic factor for the course of ReA. This suggests that host immune response orchestrated by HLA-B27, rather than a particular antigenic specificity, determines outcome in ReA by setting stage for chronic inflammation. This may have direct relevance to deciphering the inciting events in AS.

Table 1: Clinical features of combined groups, self-limited ReA and chronic ReA group at presentation of disease

SESSION INFORMATION
Session Date: Friday, November 6, 2020
Session Title: Infection-related Rheumatic Disease
Session Type: Abstract Session
Session Time: 10:00AM–10:50AM

Background/Purpose: The aim was to examine the rates of putative pneumococcal infections up to 10 years before and after administration of heptavalent conjugated pneumococcal vaccine (PCV7) in patients with inflammatory arthritis compared to non-vaccinated arthritis patients.

Methods: Adult patients with rheumatoid arthritis (RA) and spondylarthropathy (SpA) including psoriatic arthritis (PsA) patients, at the Department of Rheumatology at Skåne University Hospital, Sweden were offered one single

Table. Relative risk (RR) and ratio of relative risk (RRR) of pneumonia and all serious pneumococcal infections among vaccinated and non-vaccinated individuals before and after date of vaccination.

	Vaccinated patients (n=595)	Non-vaccinated references (n=2379)
Events of pneumonia, *before* vaccination, n	42	77
Events of pneumonia *after* vaccination, n	76	263
Risk ratio (after/before) (95% CI)	1.74 (1.14-2.64)	3.65 (2.70-4.93)
RRR of pneumonia (vaccinated /non-vaccinated) (95% CI): 0.47 (0.28-0.77)		
Events of serious infection, *before* vaccination, n	48	103
Events of serious infection *after* vaccination, n	85	307
Risk ratio (after/before) (95% CI)	1.72 (1.12-1.63)	3.09 (2.33-4.10)
RRR of serious pneumococcal infection, vaccinated /non-vaccinated (95% CI): 0.54 (0.33-0.89)		

RRR, ratio of relative risk

intramuscular dose of PCV7 between May 2008 and February 2012. 595 patients participated (RA=342; 80% women, and SpA=253; 45% women). Mean age was 62 and 51 years, mean disease duration was 16 and 14 years respectively. For each patient, 4 reference subjects were identified, matched for arthritis diagnosis, age, sex, and geographical area, and date of vaccination of the patient was also used as index date for its references. References were presumed to be non-vaccinated for pneumococci, following the current national guidelines.

At the time of vaccination, 420 patients were treated with bDMARDs including anti-TNF agents (n=330), tocilizumab (n=15), abatacept (n=18), anakinra (n=1) and rituximab (n=56). Methotrexate (MTX) was given as monotherapy (n=86), or in combination with bDMARD (n=220). Eighty-nine of the SpA patients were treated with NSAIDs without DMARD. Thirty percent (n=176) of the patients were treated with prednisolone, mean weekly dose 41 (1-140) mg.

The Skåne Healthcare Register was searched for ICD-10 diagnostic codes for serious putative pneumococcal infections between January 2000 and December 2018 for both patients and reference subjects. The outcome events included community acquired pneumonia, lower respiratory tract infection, septicemia, meningitis, and septic arthritis. We compared the frequency of outcome events after vs before date of vaccination by calculating relative risks (RRs). The ratio of relative risk (RRR) was calculated comparing the RR of vaccinated patients vs non-vaccinated references. A generalized estimated equation (GEE) was used to handle correlated data for several events in the same individual and included time of follow up as a covariate. We also did a survival analysis (Kaplan-Meier) and Cox regression to investigate time to first event after vaccination.

Results: The point estimate of RRR for pneumonia only was 0.47, 95% CI 0.28-0.77 and for all serious putative pneumococcal infections the RRR was 0.54, 95% CI 0.33-0.89 (Table). Time to first pneumonia or other serious infection after vaccination was significantly shorter among vaccinated patients compared to references (Figure), but after adjusting for number of the same type of infection before vaccination, there was no longer a statistically significant difference after vaccination (p=0.12) and (p=0.09), respectively.

Conclusion: A single dose of heptavalent pneumococcal conjugate vaccine may decrease the risk of putative serious pneumococcal infection up to 10 years after vaccination in adult patients with inflammatory arthritis receiving immunomodulating treatment. However, the vaccine does not seem to prolong the time to first serious infection.

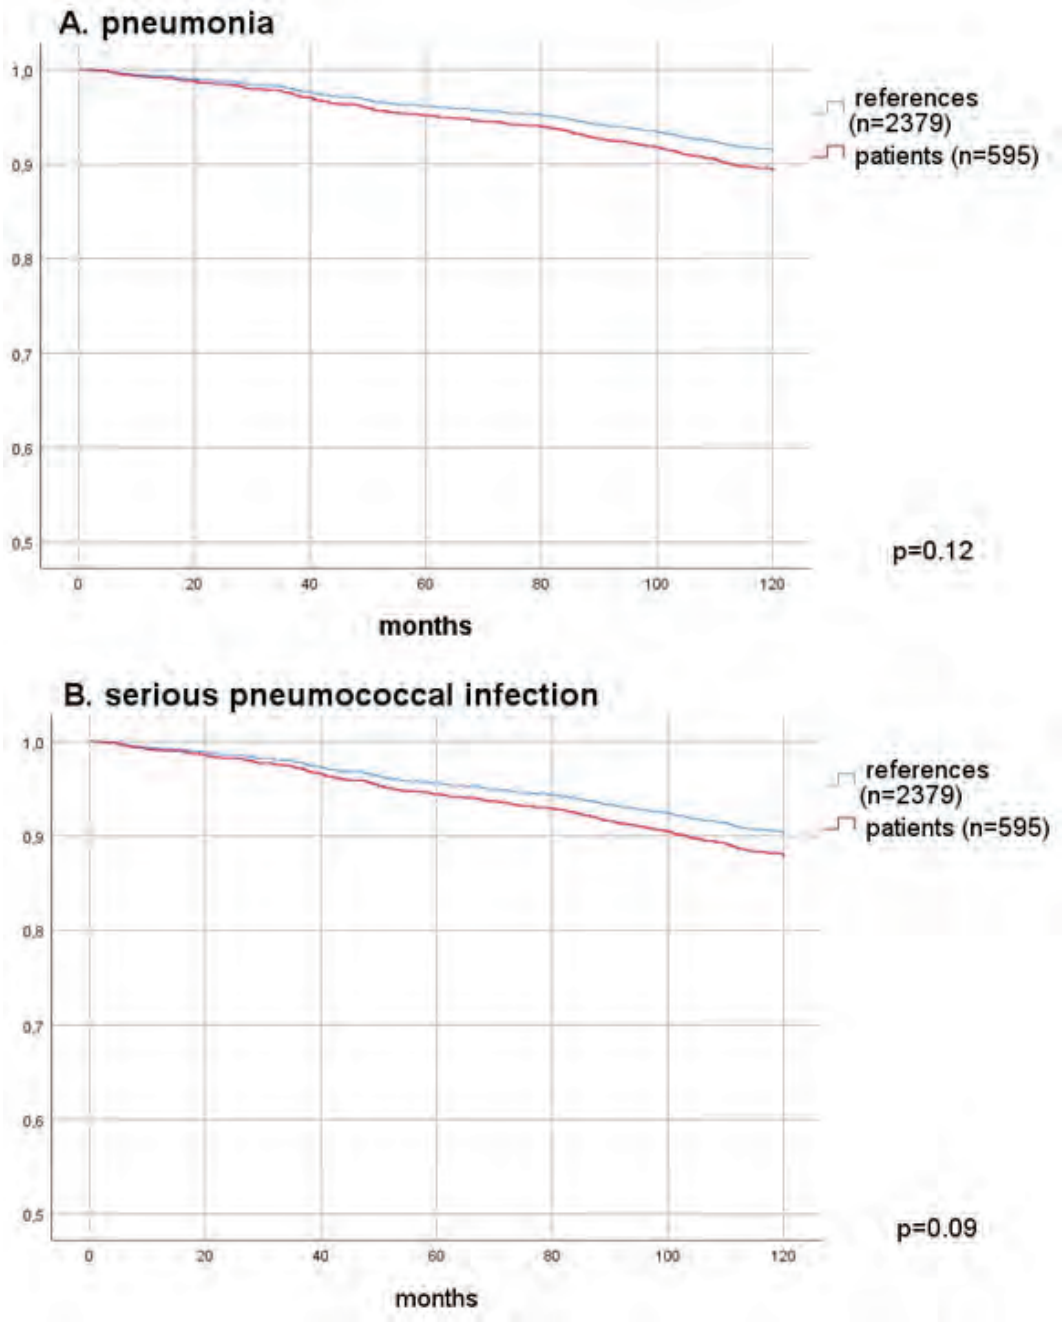

Figure. Cox regression; Time to first event, death or loss of follow-up after date of vaccination for pneumonia only (A), all serious pneumococcal infections (B), adjusted for number of events before date of vaccination.

Abstract Number: 0457

Improving Pneumococcal Vaccination Rates in Immunosuppressed Rheumatology Patients

Julia Harris[1], Michael Holland[2], Emily Fox[2], Amy Ivy[3], Maria Ibarra[2], Cara Hoffart[2], Jordan Jones[2], Leslie Favier[4] and Ashley Cooper[2], [1]Children's Mercy Kansas City, Overland Park, KS, [2]Children's Mercy Kansas City, Kansas City, MO, [3]Children's Mercy Kansas City, Kansas City, [4]Children's Mercy Kansas City, Leawood, KS

SESSION INFORMATION

Session Date: Friday, November 6, 2020

Session Title: Infection-related Rheumatic Disease

Session Type: Abstract Session

Session Time: 10:00AM–10:50AM

Background/Purpose: The Centers for Disease Control and Prevention recommends pneumococcal vaccination of high-risk patients, including patients on iatrogenic immunosuppression. Many patients seen in the rheumatology clinic are at increased risk of invasive pneumococcal infection secondary to primary or acquired immunodeficiencies. A quality improvement project to increase pneumococcal vaccination rates in patients with systemic lupus erythematosus (SLE) and mixed connective tissue disease (MCTD) was started in September 2016. After increasing the

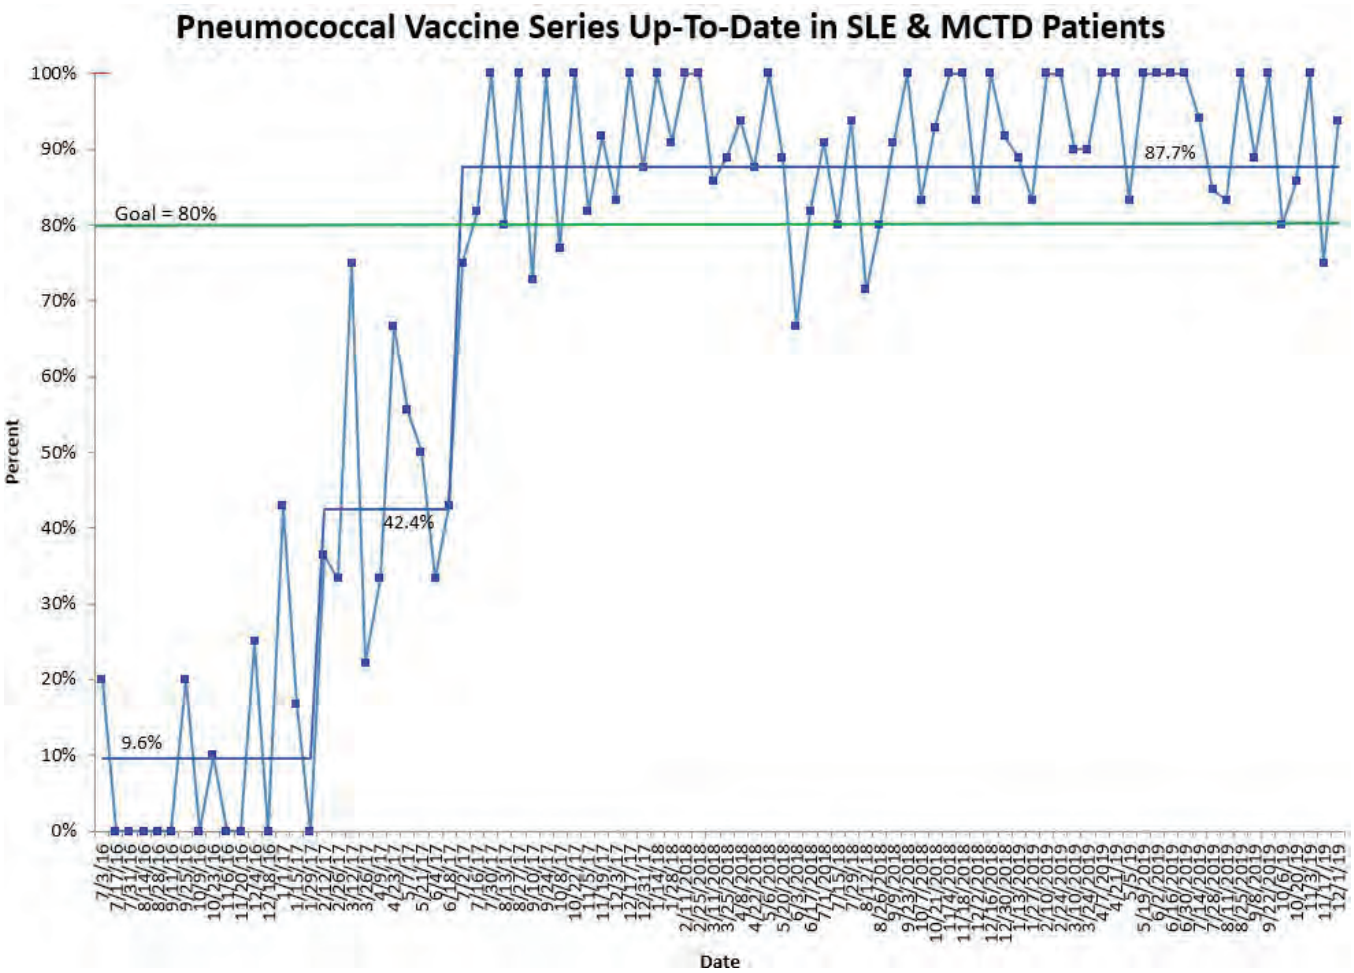

Figure 1. Pneumococcal vaccine series up-to-date in SLE and MCTD patients.

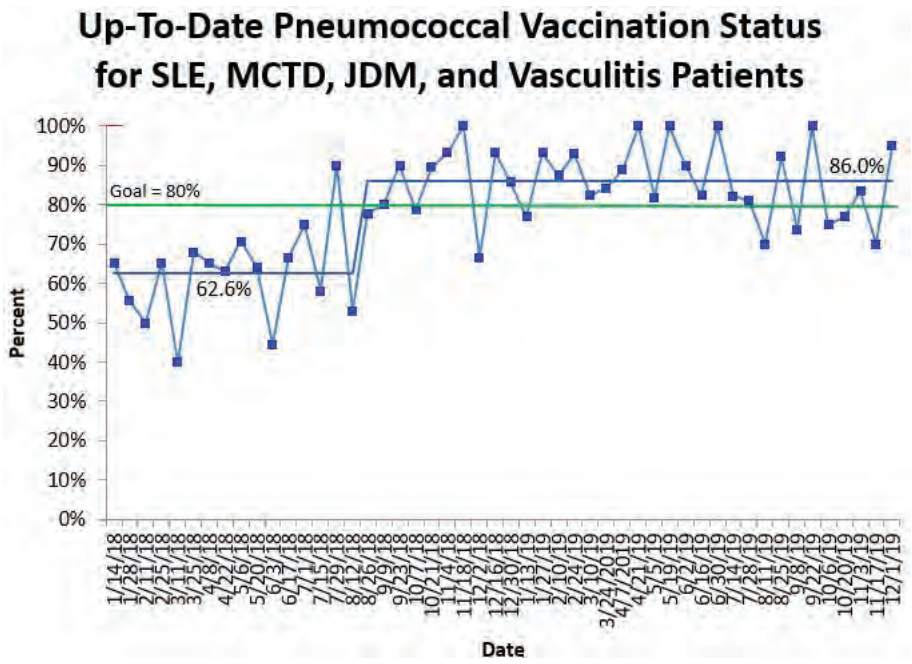

Figure 2. Pneumococcal vaccinations up-to-date in SLE, MCTD, JDM and vasculitis patients on immunosuppression.

combined pneumococcal vaccination rate to 87.7% for those with SLE and MCTD, our new aim in July 2018 was to have 80% of patients on immunosuppression with SLE, MCTD, juvenile dermatomyositis (JDM) and systemic vasculitis up-to-date on pneumococcal vaccinations by July 2019.

Methods: Our division established a project team and utilized quality improvement methodology including a driver diagram, process map, fishbone diagram, and plan-do-study-act cycles. Two process measures were created: 1) being up-to-date on the 13-valent pneumococcal conjugated vaccine (PCV13) and 2) being up-to-date on the 23-valent pneumococcal polysaccharide vaccine (PPSV23). Our outcome measure was being completely up-to-date on pneumococcal vaccinations. Eligible patients from September 2016 to June 2018 were all SLE and MCTD patients. From July 2018 onward, JDM and vasculitis patients on immunosuppression were eligible along with all SLE and MCTD patients. Interventions included: generating an immunization algorithm, creating a report of eligible patients, providing physician and nurse education, sending email reminders, and performing pre-visit planning. Control charts were made to evaluate for change over time.

Results: Data collection of pneumococcal immunization rates began in July 2016 and is ongoing. There were shifts in the center line for all three quality measures in both phases of our project indicating a significant increase in vaccination rates. Average PCV13 rate for SLE and MCTD patients increased from 32.1% to 91.5%, and PPSV23 rate went from 17.1% to 89.9%. Combined pneumococcal vaccination rate for SLE and MCTD patients increased from 9.6% to 87.7%, and this mean has been sustained for over two years (**Figure 1**). Pneumococcal vaccination rates also significantly increased for phase 2 with SLE, MCTD, JDM, and vasculitis patients: 70.5% to 92.2% for PCV13, 63.8% to 86% for PPSV23, and 62.6% to 86% for the combined pneumococcal vaccination rate (PCV13 and PPSV23) (**Figure 2**). There have been no significant known adverse events related to the vaccinations.

Conclusion: Using quality improvement methodology, pneumococcal vaccination rates significantly increased and have been sustained in our immunosuppressed pediatric rheumatology patients. We continue to prioritize this important initiative through a multi-specialty project and through pre-visit planning by identifying additional rheumatology patients on immunosuppression that are eligible for pneumococcal vaccination.

Abstract Number: 0458

Rapid Implementation of a Multidisciplinary COVID-19 Cytokine Storm Syndrome Task Force

Bibi Ayesha[1], Anand Kumthekar[1], Ruchi Jain[2], Sneha Patel[3], Manish Ramesh[1], Denisa Ferastraoaru[4], Golda Hudes[4], Merhunisa Karagic[4], Sheema Zafar[1], Rachel Bartash[4], Natalia Vasquez-Canizares[5], Elizabeth Kitsis[6], Clement Tagoe[7], Dawn Wahezi[5], Tamar Rubinstein[8] and Anna Broder[3], [1]Montefiore Medical Center, Bronx, NY, [2]Montefiore Medical Center, Irvington, NY, [3]Albert Einstein College of Medicine/Montefiore Medical Center, Bronx, NY, [4]Montefiore Medical Center, Bronx, [5]Albert Einstein College of Medicine, Bronx, NY, [6]Albert Einstein College of Medicine, New York, NY, [7]Albert Einstein College of Medicine, Fresh Meadows, NY, [8]Albert Einstein College of Medicine / Montefiore Medical Center, White Plains, NY

SESSION INFORMATION

Session Date: Friday, November 6, 2020

Session Title: Infection-related Rheumatic Disease

Session Type: Abstract Session

Session Time: 10:00AM–10:50AM

Background/Purpose: Coronavirus disease (COVID-19) infected patients present with a state of ongoing inflammation and an exaggerated inflammatory state due to unregulated cytokine release called the cytokine storm syndrome (CSS).Early identification and timely, management of CSS is needed for avoiding an untoward outcome. Multi-disciplinary involvement is needed because of the complexity of the syndrome and the multi-systemic presentation. We summarize a novel approach and our experience in the formation and functioning of multidisciplinary COVID-19 CSS task force at Montefiore Medical Center in the Bronx, New York City (NYC).

Methods: As adult and pediatric rheumatologists, allergy and immunologists (AI) are well versed with managing inflammatory disorders, after input of infectious disease (ID) and critical care team (CCM) specialists, with consensus developed a set of 4 clinical and 6 laboratory parameters to potentially help in early identification of COVID 19 patients progressing towards CSS

Every consulted patient was reviewed by a sub-specialist and discussed in daily multidisciplinary virtual conference. A consensus recommendation was made regarding steroid therapy or biologic therapy if deemed appropriate. All

Clinical Parameters	Laboratory Parameters
Persistent Fever ≥ 101°F for 48 hours	Ferritin ≥1000 ug/L
Systolic BP ≤ 90 (not responding to IV fluids)	CRP ≥ 30 mg/dl or change in CRP ≥ 15 mg/dl
PaO2/FiO2 ≤ 200 in intubated patients or Increasing oxygen requirement in non-intubated patients.	AST ≥ 150 IU/L
	Hemoglobin ≤ 9 g/L
	Platelets ≤ 100 K/ul
	Absolute neutrophil count ≤ 7.7 K/ul

Abbreviations: BP: Blood pressure, CRP: C-reactive protein, AST: Aspartate Amino transferase

Table 1. Clinical and Laboratory Parameters based on consensus recommendations of the COVID-19 CSS Task Force.

Variable	Total (N=288)	Biologic Therapy (N=31)	No Biologic Therapy (N=257)	P value
Age, years- Median (IQR)	62 (51-70)	53 (32-63)	62.5 (52-70)	0.01
Male - no (%)	197 (68)	22 (71)	175 (68)	0.75
Ethnicity - no (%)				0.63
Non-Hispanic	149 (52)	15 (48)	134 (52)	
Hispanic	122 (42)	13 (42)	109 (42)	
Race - no (%)				0.56

Asian	24 (8)	2 (6)	22 (9)	
Presenting Symptoms - No/Total no (%)				
Subjective Fever	197 (68)	26 (84)	171 (67)	0.05
Cough	188 (65)	20 (65)	168 (65)	0.86
Dyspnea	245 (85)	27 (87)	218 (85)	0.74
Hyperglycemia	109 (38)	16 (52)	94 (37)	0.21
Acute Kidney Injury	116 (40)	13 (42)	103 (40)	0.86
Diarrhea	230 (80)	5 (16)	51 (20)	0.81
DVT	20 (7)	1 (3)	19 (7)	0.39
PE	9 (3)	2 (7)	7 (3)	0.26
CVA	15 (5)	1 (3)	14 (5)	0.60
Required ICU Admission	177 (61)	26 (84)	151 (59)	0.01
New Onset Dialysis	60 (21)	6 (19)	54 (21)	0.83
Anoxic Brain Injury	8 (3)	0	8 (3)	0.32

Table 2. Characteristics of COVID-19 patients evaluated by the CSS Task Force

biological therapy recommended by the CSS task force required a final approval from designated physician from ID or CCM.

Results: Between April 4,2020 and May 7,2020, the CSS consult service evaluated a total of 288 patients. Patients who received biologic therapy were younger with a median age of 53 years (IQR= 32-63 years) versus 62.5 years (52-70 years) in the no-biologic group (p=0.008). A higher proportion of patients receiving biologics were in the critical care setting {26 (84%) vs 151 (59%), p= 0.006}, were on mechanical ventilation {26 (84%) vs 146 (57%), p=0.003} and on vasopressors {22 (71%) vs 111 (43%), p=0.003}. Patients who received biologics were more likely to have a longer median duration of steroid therapy 12.5 days (IQR= 6-15 days) vs 8 days (IQR= 5-12 days) (p=0.01).

Conclusion: To our knowledge, this is the first multi-disciplinary team model collaborative effort to provide consensus recommendations for COVID-19 patients at risk of developing CSS, which is a unique experience at our institution where multiple sub-specialities came together to create a consult service to help early identify and treat patients with COVID-19 CSS, at a time of unparalleled COVID-19 surge with limited resources in NYC.

Variable	Total (N=288)	Biologic Therapy- Yes (N=31)	BiologicTherapy- No (N=257)	P value

Median Follow-up (months)	48 (6-252)	0

ATG : Anti Thymocyte Globulin, BEAM : BCNU – Etoposide- Cytarabine- Melphalan, CR = Complete Remission : no evidence for disease activity in patients with daily prednisolone equivalent dosage ≤ 7.5mg and absence of disease-modifying drugs, DVT : Deep Venous Thrombosis, DDPR : Drug-Dependent Partial Response *ig* any documented clinical and/or laboratory response in patients receiving glucocorticoids ≥7.5mg daily prednisolone dosage and/or disease-modifying drugs.

Background/Purpose: Behçet's Disease (BD) is a rare autoimmune disease mostly presenting with recurrent oral and genital aphtosis, ulcers, and uveitis. Rare patients are refractory to conventional treatments. Autologous hematological stem cell transplantation (AHSCT) is a standard of care in other autoimmune diseases. Some patients with BD have been treated with AHSCT based on compassionate use.

Methods: Evaluate the outcome of AHSCT in adult patients with BD treated in member centers of the European Society for Blood and Marrow Transplantation (EBMT). Adults who received AHSCT primarily for BD were identified retrospectively in the EBMT registry and/or in published literature. Data were extracted from either medical records of the patient or from publications.

Results: Eight out of 9 cases reported to the registry and extracted data of 2 further patients from literature were analyzed. Four were female, median age at onset of BD was 24y (range 9-50). Median age at AHSCT was 32y (27-51). Patients had received median 4 (2-11) prior lines of therapy (89% corticosteroids, 50% methotrexate, anti-TNFa or cyclophosphamide). All patients had active disease before mobilization. Conditioning regimen was heterogeneous. Median follow-up was 48 months (range 6-240 months). No treatment-related mortality was reported. At last

Lymphocyte Clonal Expansion Distinguishes Different Forms of Uveitis

Michael Paley[1], Lynn Hassman[1], Philip Ruzycki[1], Ekaterina Esaulova[1], Grace Paley[1], Jennifer Laurent[1], Luke Springer[1], Lacey Feigl[1], Maxim Artyomov[1] and Wayne Yokoyama[2], [1]Washington University, Saint Louis, [2]Washington University, St Louis, MO

SESSION INFORMATION
Session Date: Friday, November 6, 2020
Session Title: Miscellaneous Rheumatic & Inflammatory Diseases I: Mechanisms of Disease
Session Type: Abstract Session
Session Time: 10:00AM–10:50AM

Background/Purpose: Anterior uveitis is a form of ocular inflammation associated with rheumatologic disease and can be categorized as granulomatous or non-granulomatous. Whether different ocular manifestations are associated with distinct immune responses, however, remains unclear. Here, we evaluated lymphocyte clonal expansion in granulomatous and non-granulomatous uveitis to determine whether putative antigen-driven T or B cell responses distinguish clinical presentations of ocular inflammation.

Methods: We performed single cell RNA-sequencing (scRNAseq) to obtain an unbiased gene expression survey of aqueous and blood immune cells in subjects with different forms of uveitis. This analysis allowed quantification, cell type identification, and transcriptional profiling of individual lymphocytes within the inflamed eye as compared to cells in circulation, along with T cell receptor and B cell receptor sequencing to determine clonotype distribution.

Results: The majority of aqueous immune cells were CD4 T cells, with smaller contributions of CD8 T cells, B cells, NK cells, and myeloid cells. Analysis of clonal expansion in granulomatous uveitis revealed highly expanded lymphocyte clonotypes, but only in one T or B cell lineage. Coincident with the clonal expansion were transcriptional signatures of T cell receptor signaling and effector differentiation. In contrast, non-granulomatous uveitis was not associated with robust clonal expansion in any T or B cell lineage analyzed.

Conclusion: Here, these data suggest that the clinical presentation of uveitis may be the result of distinct pathogenic mechanisms, with granulomatous inflammation arising from a select few antigen-specific T or B cells. Furthermore, this extensive clonal expansion was seen in a different lymphocyte lineage for each individual, suggesting a distinct antigen-specific response in each patient and highlighting the potential to identify personalized therapeutic targets.

High-Throughput Single-Cell Analysis Reveals Unique Lung Cellular Subsets in a Murine Model of Rheumatoid Arthritis-Inflammatory Lung Disease

Rohit Gaurav[1], Ted Mikuls[1], Geoffrey Thiele[1], Amy Nelson[1], Meng Niu[1], Chittibabu Guda[1], James Eudy[1], Austin Barry[1], Debra Romberger[1], Michael Duryee[1], Bryant England[1] and Jill Poole[1], [1]University of Nebraska Medical Center, Omaha, NE

SESSION INFORMATION

Session Date: Friday, November 6, 2020

Session Title: Miscellaneous Rheumatic & Inflammatory Diseases I: Mechanisms of Disease

Session Type: Abstract Session

Session Time: 10:00AM–10:50AM

Background/Purpose: Rheumatoid arthritis (RA)-associated inflammatory lung disease is an extra-articular manifestation of RA associated with increased morbidity and mortality, whose precise molecular mechanisms remain undetermined. We established a novel mouse model of combining the collagen-induced arthritis (CIA) model with the organic dust extract (ODE)-induced airway inflammatory disease model to demonstrate that combined exposures (CIA+ODE) increased arthritis, autoantibody levels, and polarized the lung towards pre-fibrotic inflammatory processes. Utilizing this animal model, we aimed to identify relevant cellular and protein mediators through high-throughput single-cell analysis.

Methods: Arthritis-prone DBA/1J mice were assigned to 1 of 4 treatment groups: Sham, CIA, ODE, and CIA+ODE for 5 weeks. Whole lung cells were processed for single cell RNA-sequencing (scRNA-seq). In separate studies, 4 defined myeloid-derived immune cell populations consisting of macrophages, monocytes/macrophages, monocytes, and neutrophils were isolated from whole lung of exposed mice by fluorescence activated cell sorting (FACS) with gene expression determined by NanoString (771 genes). Data are represented as fold-change compared to Sham from 3 experiments (2-3 mice/group/experiment) using two-way ANOVA.

Results: By scRNA-seq, 14 discrete lung immune cell populations were identified through unsupervised clustering and respective gene expression. Cell populations included 3 neutrophils (inflammatory, resident/transitional, autoreactive/myeloid derived suppressor), 5 macrophages (airspace, differentiating/recruited, recruited, resident/interstitial, and proliferative airspace), 2 T-cells (differentiating and effector), and a population of inflammatory monocytes, dendritic cells, B-cells and natural killer cells (**Figure 1)**. Inflammatory monocytes, autoreactive/suppressor neutrophils, and recruited/differentiating macrophage subpopulations were predominantly ascribed to arthritis induction (CIA and

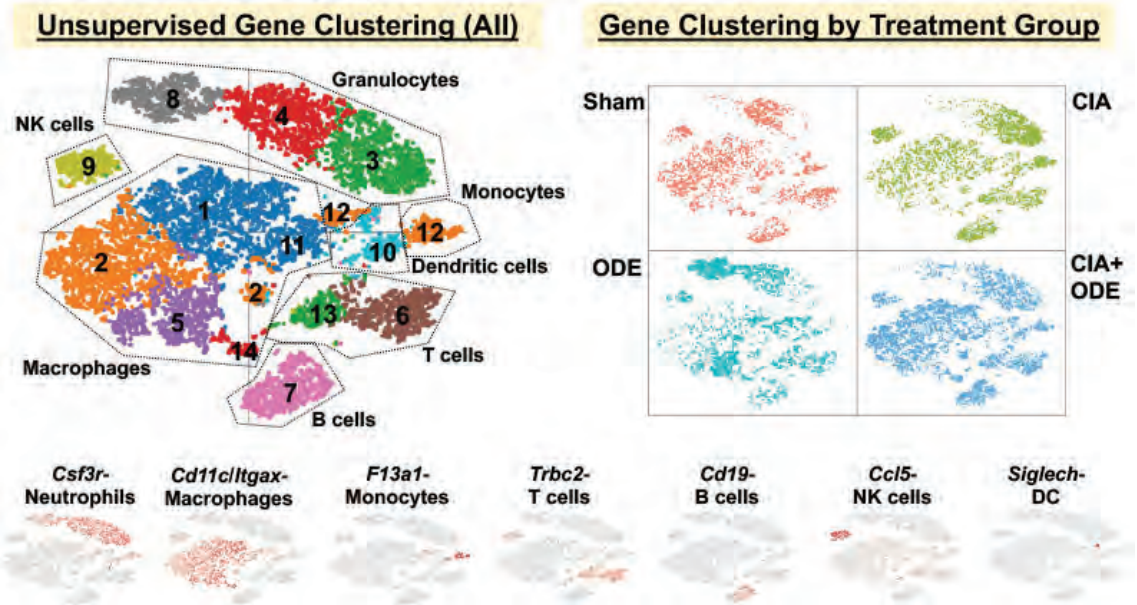

Figure 1. Single-cell RNA-sequencing analysis. Top left panel shows unsupervised gene clustering of all CD45+ gene expressing lung cells when all treatment groups are aggregated. Cell names are ascribed based upon gene expression (bottom panel). Top right panel depicts clustering of the defined aggregated clustering across treatment groups with dotted circles highlighting macrophages, monocytes, and granulocytes. Arbitrary numbers (1, 2, etc.) designate unique gene clusters determined by unsupervised clustering.

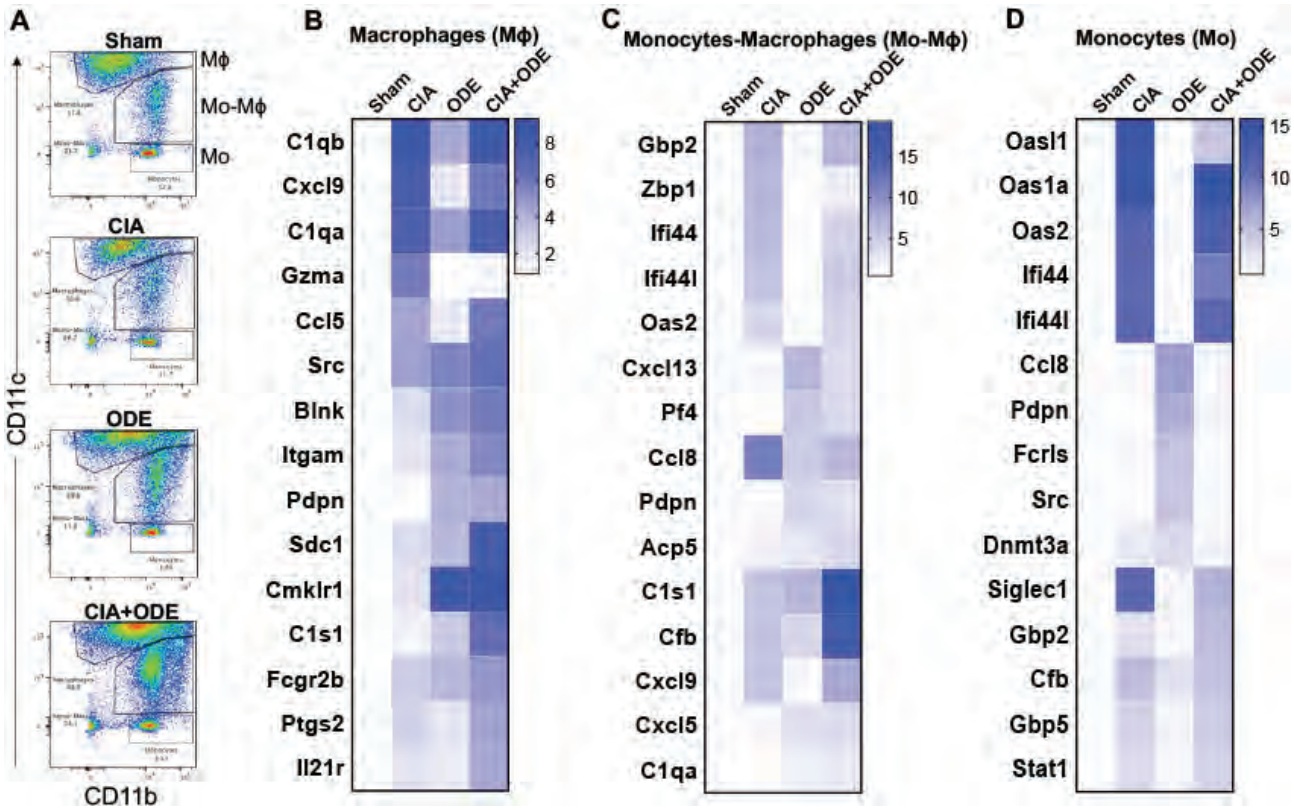

Figure 2. Lung cell populations of macrophages (MΦ) and monocytes (Mo) isolated by FACS and gene expression analysis among treatment groups. A, Representative dot plots of macrophages (CD11chigh CD11bvariable), monocytes-macrophages (CD11cintermediate CD11bhigh), and monocytes (CD11c– CD11bhigh) from each treatment of Sham, CIA, ODE, and CIA+ODE shown. B, C, and D Heatmaps of each cell population depicting the fold-change of top 5 genes/treatment group (CIA, ODE and CIA+ODE), normalized to 20 housekeeping genes and compared to Sham.

CIA+ODE). Genes highly expressed with arthritis induction across lung cell populations of myeloid origin included interferon-related, autoimmunity, and suppressive genes (e.g. *Ifit3b*, *Ifit3*, *S100a8*, and *S100a9*). NanoString analysis of the 4 isolated lung myeloid-derived populations were consistent with scRNA-seq findings (**Figure 2,3**). Several immunosuppressive and autoimmune genes (e.g. *Oasl1*, *Oas2*, *Ifit3*, *Gbp2*, *Ifi44*, *Ifi44l*, *Zbp1*, and *Ifit1*) were disproportionately expressed in lung cell populations of neutrophils and macrophages/monocytes among CIA and CIA+ODE groups. Complement cascade genes (e.g. *C1s1*, *Cfb*, *C1qa*, and *C1ra*) were uniquely increased in the co-exposure (CIA+ODE) across all 4 cell populations.

Conclusion: Recruited and inflammatory macrophages/monocytes and neutrophils expressing suppressive and autoimmune genes in systemic autoimmunity might contribute towards pro-fibrotic inflammatory responses in the lung following airborne biohazard exposures. Targeting these cellular features and/or signature genes could lead to novel approaches in RA-associated inflammatory lung disease.

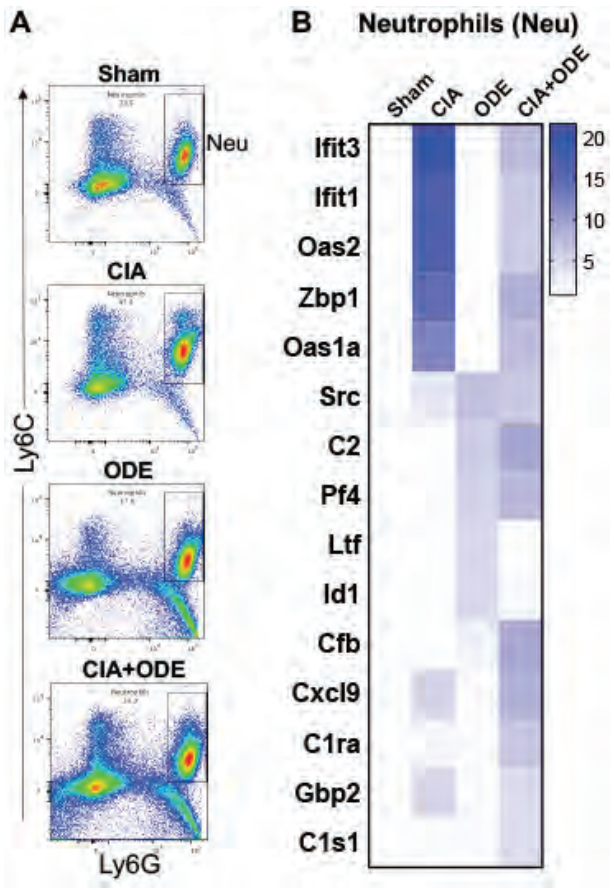

Figure 3. Lung cell populations of neutrophils (Neu) isolated by FACS and gene expression analysis among treatment groups. A, Representative dot plots of neutrophils (Ly6C+ Ly6G+) from each treatment of Sham, CIA, ODE, and CIA+ODE shown. B, Heatmap depicting the fold-change of top 5 genes/treatment group (CIA, ODE and CIA+ODE), normalized to 20 housekeeping genes and compared to Sham.

Abstract Number: 0462

Lupus-like Autoimmunity and Increased Interferon Response in Patients with STAT3-deficient Hyper-IgE Syndrome

Brian Dizon[1], Rishi Goel[2], Shuichiro Nakabo[2], Amanda Urban[2], Meryl Waldman[2], Lilian Howard[2], Dirk Darnell[2], Munir Buhaya[2], Sarfaraz Hasni[3], Mariana Kaplan[4], Alexandra Freeman[2] and Sarthak Gupta[1], [1]National Institutes of Health, BETHESDA, MD, [2]National Institutes of Health, Bethesda, [3]Lupus Clinical Trials Unit, NIAMS/NIH, Bethesda, MD, [4]National Institute of Arthritis and Musculoskeletal and Skin Diseases, Bethesda, MD

SESSION INFORMATION

Session Date: Friday, November 6, 2020

Session Title: Miscellaneous Rheumatic & Inflammatory Diseases I: Mechanisms of Disease

Session Type: Abstract Session

Session Time: 10:00AM–10:50AM

Background/Purpose: Autosomal dominant hyper-IgE syndrome (AD-HIES), also known as Job's syndrome, is a rare primary immunodeficiency caused by dominant-negative loss-of-function (LOF) mutations in signal transducer and activator of transcription 3 (STAT3). STAT3 LOF patients develop dermatitis, recurrent infections, and elevated serum IgE. Autoimmunity and auto-inflammation are common complication of primary immune deficiencies; however, systemic autoimmune features and the role of innate immune system are not well-characterized in AD-HIES.

Methods: A retrospective chart review of patients with STAT3 LOF seen at the National Institutes of Health was performed to identify patients who also had clinical and serologic features of systemic lupus erythematosus (SLE), as defined by American College of Rheumatology (ACR) 1997 classification criteria. To characterize lupus-associated innate immune dysregulation, type I interferon (IFN) stimulated genes (ISGs) were quantified by RT-PCR in neutrophils, *in vitro* neutrophil extracellular trap (NET) formation was measured by immunofluorescence, and serum anti-NET IgG autoantibodies were quantified by ELISA.

Results: We identified 10 out of 158 individuals (prevalence ~6.3%) with genetically confirmed STAT3 LOF mutations who developed systemic lupus erythematosus (SLE) or SLE-like manifestations, including immune complex glomerulonephritis (40%), cytopenias (50%), cutaneous disease (40%), and arthritis (40%). STAT3 LOF patients with SLE features were predominantly female (70%), and the onset of lupus and lupus-like disease features occurred between 12-24 years of age. All patients had positive ANA (100%), with a majority having anti-double-stranded DNA antibodies (90%), and hypocomplementemia (70%). Other lupus-associated-autoantibodies were also detected (**Table 1**). Immunosuppressive medications were required in 8 patients with systemic autoimmune features, which were well-tolerated and led to improvement in clinical symptoms. STAT3 LOF subjects with and without clinical features of SLE had increased expression of ISGs in neutrophils when compared to healthy controls. Increased spontaneous NET formation and anti-NET autoantibodies were observed in LOF STAT3 subjects, independent of the presence or absence of lupus-like symptoms and at higher levels than healthy controls (**Figure 1**).

Conclusion: Although autoimmunity is not a common finding in STAT3 LOF patients, we have identified SLE or SLE-like disease in about 6% of our cohort, with a high incidence of kidney involvement. These findings are associated

Table 1. Clinical characteristics of STAT3 LOF patients with lupus and lupus-like autoimmunity. Patients (n=10) with STAT3 LOF mutations were identified to have clinical and serologic features of lupus. Demographic information, disease manifestations, clinical laboratory data, and historic treatment protocols are shown. Diagnosis of lupus and lupus-like disease was made on the basis of fulfilling ACR 1997 classification criteria. Updated classification criteria for systemic lupus, SLICC 2012 and ACR 2017, are shown for comparison. Abbreviations are the following: W= white, AA= African-American, L= Latino, PI= Pacific Islander, ESRD= end-stage renal disease, ITP= idiopathic thrombocytopenic purpura, AIHA= autoimmune hemolytic anemia, IVIG= intravenous immunoglobulin, IVIG= intravenous immunoglobulin. 1Age at onset of lupus symptoms. 2Delineation of lupus and non-lupus symptoms is unclear at this time.

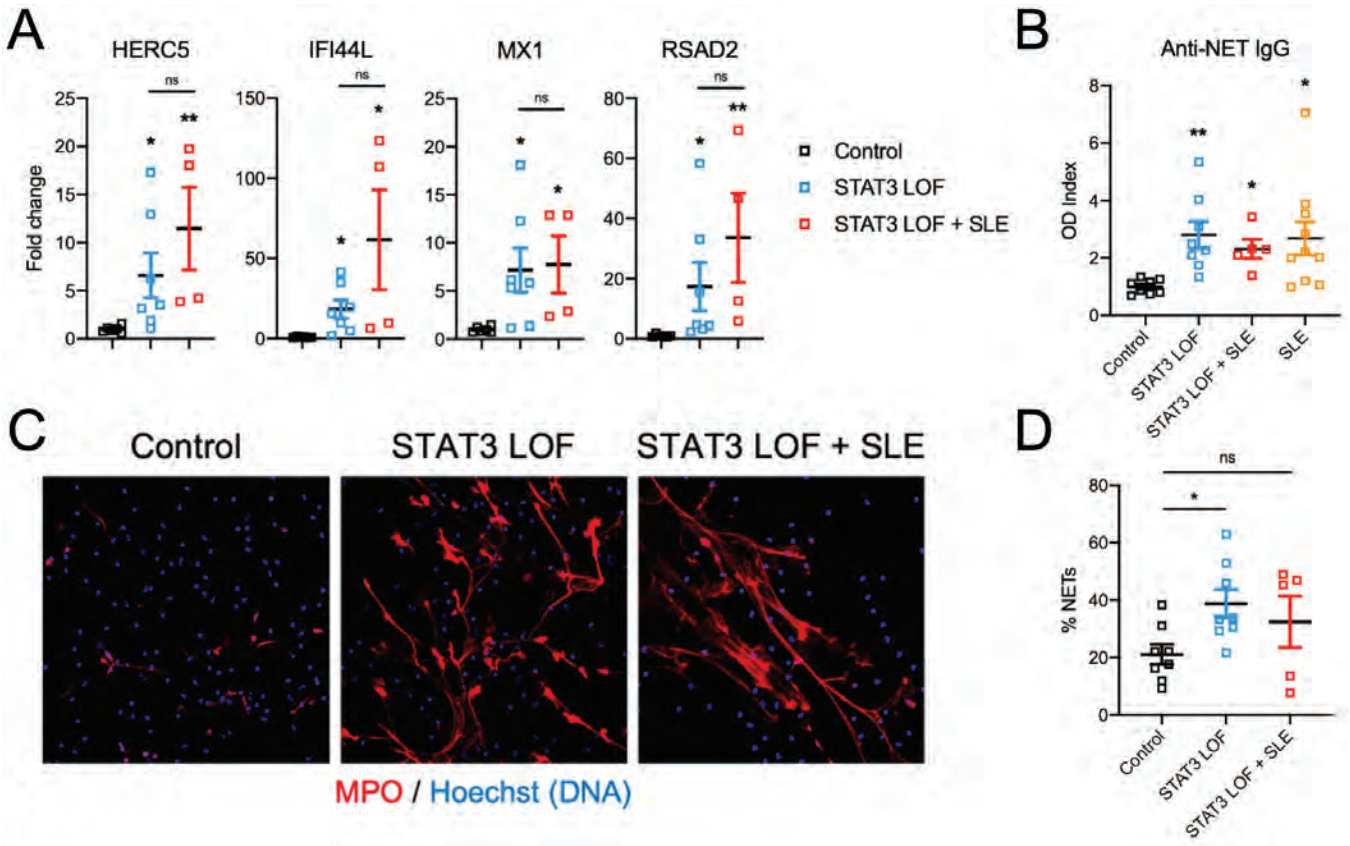

Figure 1. Increased interferon response, neutrophil extracellular trap (NET) formation, and anti-NET antibodies in patients with AD-HIES. (A) RT-PCR for interferon-stimulated gene expression in neutrophils from healthy controls (n=6), STAT3 LOF (n=7), and STAT3 LOF + SLE (n=4) patients. (B) Anti-NET IgG antibodies were measured in serum by ELISA in healthy controls (n=8), STAT3 LOF (n=8), STAT3 LOF + SLE (n=5), and SLE (n=10) patients. (C) Immunofluorescence for spontaneous NET formation in healthy controls (n=8), STAT3 LOF (n=7), and STAT3 LOF + SLE (n=5) patients; MPO (red), DNA (Hoechst, blue). (D) NETs were further quantified as percentage of neutrophils forming extracellular traps. Statistics were calculated by non-parametric Kruskal-Wallis test with Dunn's correction (A,B,C) or non-parametric Mann-Whitney test (D). *p>0.05, **p>0.01, ns=not significant.

with immune dysregulation characteristic of SLE including an increased IFN signature, NET formation, and various autoantibodies, including anti-NET antibodies. Significant immune dysregulation associated with dominant-negative STAT3 LOF mutations may explain the increased prevalence of systemic autoimmunity in these patients. Given this association, we recommend that patients with STAT3 LOF mutations be considered for rheumatology consultation for early recognition and treatment of SLE. The increased IFN signature also raises the potential for JAK-STAT modulation for therapy in these patients.

Abstract Number: 0463

Molecular Diagnosis of Childhood Immunodysregulation, Endocrinopathy and Enteropathy X-linked (IPEX)-Like Syndrome and Implications for Clinical Management

Sarah Baxter[1], Tom Walsh[1], Silvia Casadei[1], Suleyman Gulsuner[1], Eric Allenspach[2], David Hagin[3], Gesmar Segundo[4], Troy Torgerson[5] and Mary-Claire King[1], [1]University of Washington, Seattle, [2]Seattle Children's Research Institute, Seattle, [3]Tel Aviv Medical Center, Tel Aviv, Israel, [4]Universidade Federal de Uberlandia, Uberlandia, Brazil, [5]Allen Institute, Seattle

SESSION INFORMATION
Session Date: Friday, November 6, 2020
Session Title: Miscellaneous Rheumatic & Inflammatory Diseases I: Mechanisms of Disease
Session Type: Abstract Session
Session Time: 10:00AM–10:50AM

Background/Purpose: Patients with early-onset immunodysregulation, endocrinopathy and enteropathy but without identified mutations in *FOXP3* are termed "IPEX-like," and undergo trial-and-error immunosuppressive treatment with highly variable outcomes. The scope of genetic variation in these patients has not been well studied, even though genetic diagnosis can be critical to determining appropriate medical treatment.

We sought to investigate the prevalence and breadth of genetic diagnoses in patients with early-onset immune dysregulation, polyendocrinopathy, and/or enteropathy who had previously normal *FOXP3* sequencing, in order to determine the clinical utility of broad panel sequencing in these patients.

Methods: Patients with IPEX-like disease who were referred from around the world for analysis of *FOXP3* but who had apparently normal sequencing were re-evaluated using an extensive targeted sequencing panel encompassing 464 genes associated with innate disorders of immunity. Prediction pipelines were used to identify potentially damaging mutations, including copy number variants (CNVs) and splice site alterations, which were validated by whole genome sequencing (WGS) and RT-PCR, respectively.

Results: A likely genetic diagnosis was identified in 59 of 131 (44%) patients. Seven patients were found to have *FOXP3* mutations not previously detected. Likely damaging variants in alternative genes were identified in 52 of the 124 (42%) remaining patients with intact *FOXP3.* Twenty-one patients had variants in genes known to cause IPEX-like Syndrome. The remaining genes belong to a wide array of phenotypic categories and biologic pathways. Within the patients carrying a known or candidate gene, over 75% had diagnoses which would have significantly altered therapeutic recommendations.

Conclusion: Patients with severe and early-onset immune dysregulation, polyendocrinopathy and/or enteropathy but without *FOXP3* mutations (IPEX-like syndrome) have a high mutational burden with a very high rate of clinically actionable findings. These patients should undergo broad genetic screening for innate diseases of immunity, with technologies capable of detecting coding variants, splice-site variants, and CNVs.

Abstract Number: 0464

Assessment of the COVID-19 Pandemic from the Perspective of People with Rheumatic Musculoskeletal Diseases in Europe. Preliminary Results from the REUMAVID Study

Marco Garrido-Cumbrera[1], Helena Marzo-Ortega[2], José Correa-Fernández[3], Sergio Sanz-Gomez[4], Laura Christen[5] and Victoria Navarro-Compán[6], [1]Health & Territory Research (HTR), Universidad de Sevilla / Spanish Federation of Spondyloarthritis Associations, Sevilla, Spain, [2]The University of Leeds, Leeds Institute for Rheumatic and Musculoskeletal Medicine, NIHR Leeds Biomedical Research Centre, Leeds Teaching Hospitals Trust, Leeds, UK, Leeds, United Kingdom, [3]Health & Territory Research (HTR), Universidad de Sevilla, Sevilla, Spain, [4]Health & Territory Research, Seville, Spain, [5]Novartis Pharma AG, Basel, Switzerland, [6]Hospital Universitario La Paz IdiPaz, Madrid, Pais Vasco, Spain

SESSION INFORMATION
Session Date: Friday, November 6, 2020
Session Title: Patient Outcomes, Preferences, & Attitudes I: COVID-19
Session Type: Abstract Session
Session Time: 5:00PM–5:50PM

Background/Purpose: The COVID-19 pandemic is an unprecedented public health crisis affecting people worldwide, including those with rheumatic and musculoskeletal diseases (RMDS). REUMAVID aims to assess the impact of the COVID-19 pandemic and lockdown on the wellbeing, mental health, disease activity and function, access to healthcare and treatment, support services, and hopes and fears of people RMDs.

Methods: REUMAVID is an international collaboration led by the Health & Territory Research group at University of Seville, Spain, together with a multidisciplinary team including patient organizations and rheumatologists. The study consists of an online survey gathering data from patients with a diagnosis of 15 RMDs in Cyprus, France, Greece, Italy, Portugal, Spain, and the United Kingdom. Participants are recruited by patient organizations. Data is collected in two phases: 1) during the first peak of the COVID-19 pandemic (Spring 2020), and 2) either during the predicted second peak, or as a follow-up if a second peak does not occur (Fall 2020). This analysis presents preliminary descriptive results of the aggregated data, summarizing continuous and categorical variables.

Results: A total of 1,707 RMD patients have participated in Phase 1 so far (from early April to mid-June 2020). The most frequent reported diagnosis were axial spondyloarthritis (47.5%), 618 (36.2%), rheumatoid arthritis (36.2%) and osteoarthritis (22.0%). Mean age was 50.9±17.1 years, 78.2% were female, 68.8% were in a relationship or married and 28.4% had university studies. In total, 1.4% had tested positive for COVID-19, 11.5% reported symptoms but were not tested, while 87.0% did not experience symptoms. 45.0% reported worsening health during the pandemic. 59.7% perceived their health status to be “fair to very bad” and 52.4% reported poor wellbeing according to the WHO-5 scale. Psychological health during the pandemic was also poor, with 55.3% marking as anxiety and 44.3% as depression in the HADS scale. Access to care was limited with 60.6% being unable to keep the rheumatologist appointment, of which 92.5% were cancelled by the provider. 15.3% changed their medication, for which 60.4% were changed by the provider and 28.1% own decision. Reported wellbeing and psychological health during the pandemic was poor, with 52.4% reporting poor wellbeing according to the WHO-5 scale, 55.3% marking as anxiety and 44.3% as depression in the HADS scale. During the pandemic, 25.0% smoked and 17.2% drank more than before and 42.9% were unable to exercise at home.

Conclusion: Preliminary results show disturbance of the healthcare quality, substantial changes to harmful health behaviors and an unprecedented impairment of mental health in REUMAVID participants. REUMAVID will continue

to collect information in order to assess the impact of the COVID-19 pandemic in people affected by RMDs across Europe.

Abstract Number: 0465

The COVID-19 Pandemic and Its Effect on Patients with Chronic Rheumatologic Disease Regarding the Value of Vaccination Recommendations

Rebecca Overbury[1], Gregory Stoddard[2] and Tracy Frech[3], [1]University of Utah and Primary Children's Hospital, Salt Lake City, UT, [2]University of Utah, Salt Lake City, UT, [3]University of Utah and Salt Lake Veterans Affair Medical Center, Salt Lake City, UT

SESSION INFORMATION
Session Date: Friday, November 6, 2020
Session Title: Patient Outcomes, Preferences, & Attitudes I: COVID-19
Session Type: Abstract Session
Session Time: 5:00PM–5:50PM

Background/Purpose: Vaccinations are an important component of care in rheumatology as many patients are immunocompromised by treatment therapies. Patients are sometimes reticent to receive recommended vaccinations for various reasons. A contributing reason could be an under-appreciation of the positive protective benefit of vaccinations. We hypothesize that patients' experience with the COVID-19 pandemic may shift this understanding.

Methods: On April 15, 2020, a link to an anonymous online survey was sent to patients cared for in an academic outpatient rheumatology clinic (RO) via the protected electronic medical record email communication system. Formal institutional review board (IRB) approval was obtained for completion of anonymous surveys. As this research was low risk, this study qualified for IRB exemption. Statistical analysis included two-tailed Fisher exact test and binary Poisson regression.

Results: A total of 83 patients responded to the survey. Most were female. The majority had "rheumatoid arthritis or other autoimmune arthritis" (Table 1). 34.9% (n = 29) had been, or knew someone who had been, affected by COVID-19. 14.5% (n = 12) reported that COVID-19 had changed their opinion on the importance of vaccinations. There was no association between age group, gender, or diagnosis and having a changed opinion on the importance of vaccinations. Those who were affected or knew someone affected by COVID-19 were less likely to change their opinion on the importance of vaccinations due to COVID-19 (p=0.049). However, those who had ever declined a vaccination recommend by their doctor were almost three times more likely to change their opinion on the importance of vaccinations due to the COVID-19 pandemic (RR = 2.96, 95% CI [1.05 - 8.36]). 85.5% (n = 71) reported full compliance with previous vaccination recommendations by their doctor and 97.8% (n = 76) reported that they were now "likely" or "very likely" to have a vaccine recommended by their doctor; there was not a statistically significant difference when comparing these responses (p = 0.059). When asked if participants would want a COVID-19 vaccine were it available today, 8.4% (n = 7) would decline. When asked if participants would want a COVID-19 vaccine for their child, were it available today, 3.6% (n = 3) would decline (Figure 1).

Table 1. Demographics *(n = 83)*

Variables	%
Ages	
18-24 (n=8)	9.6
25-34 (n=12)	14.5
35-44 (n=14)	16.9
45-54 (n=14)	16.9
55-64 (n=14)	16.9
65-74 (n=17)	20.5
75-84 (n=4)	4.8
85+ (n=0)	0
Gender	
Male (n=20)	24.1
Female (n=63)	75.9
Diagnosis	
Rheumatoid arthritis or other autoimmune arthritis (n=47)	56.6
Lupus or other autoimmune connective tissue disease (n=16)	19.3
Gout, pseudo-gout, osteoarthritis (n=3)	3.6
Vasculitis (n=2)	2.4
Periodic fever syndromes (n=3)	3.6
Fibromyalgia (n=1)	1.2
Other or I don't know (n=11)	13.3

Table 1. Demographics

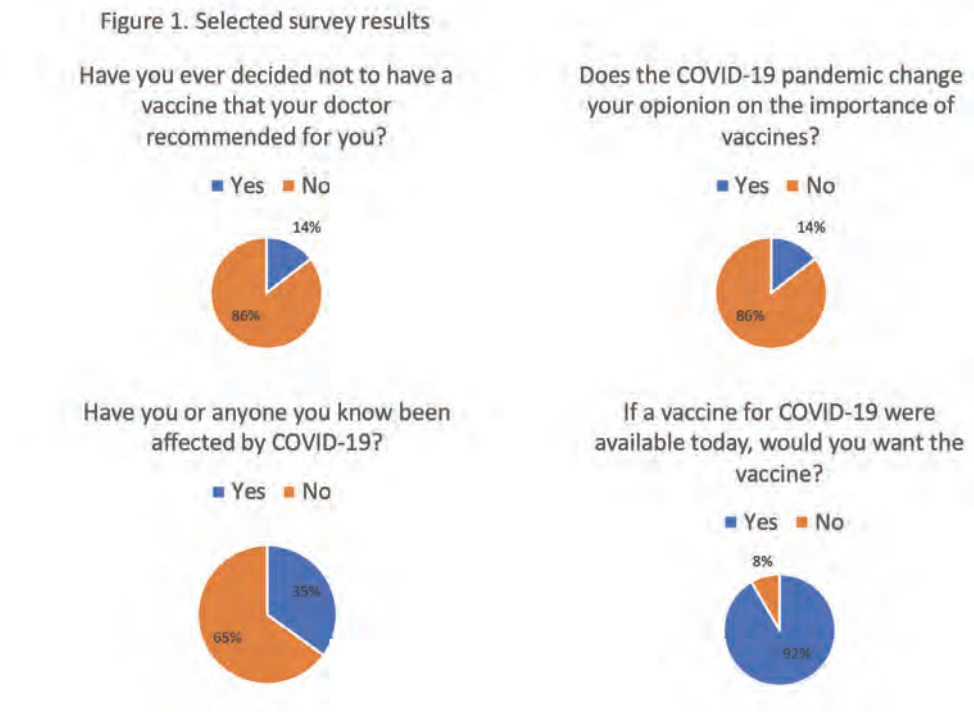

Figure 1. Selected survey results

Conclusion: Based on this research, most patients in an academic rheumatology clinic would desire a COVID-19 vaccination were it available today, both for themselves and for their children. Personal experiences or exposure to COVID-19 did not change opinions on the importance of vaccinations. However, patients who had previously opted to forgo vaccinations, were more likely to change their opinion on the importance of vaccinations due to the COVID-19 pandemic. Although it did not reach statistical significance, there is a trend towards patient expressed intention of compliance with vaccination recommendations after the COVID-19 pandemic. This research suggests that the COVID-19 pandemic may positively affect the likelihood of patients with chronic rheumatologic disease to value and comply with vaccination recommendations offered by their doctor.

Dosage Modification of Immunomodulatory Medications by Rheumatology Patients in New York City During the Peak of the COVID-19 Pandemic

Marianna Frey[1], Gregory Vitone[2], Candace Feldman[3], Lindsay Lally[1], Anne Bass[4], Jane Salmon[1], Mary Crow[1], Michael Lockshin[5], Vivian Bykerk[1], Lisa Mandl[1] and Medha Barbhaiya[5], [1]Hospital for Special Surgery, New York, NY, [2]Hospital for Special Surgery, New York, [3]Brigham and Women's Hospital, Boston, [4]Hospital for Special Surgery/Weill Cornell Medicine, New York, NY, [5]Hospital for Special Surgery, Barbara Volcker Center for Women and Rheumatic Diseases, New York, NY

SESSION INFORMATION
Session Date: Friday, November 6, 2020
Session Title: Patient Outcomes, Preferences, & Attitudes I: COVID-19
Session Type: Abstract Session
Session Time: 5:00PM–5:50PM

Background/Purpose: Due to concerns about underlying immune dysregulation and immunosuppression, patients with systemic rheumatic diseases living in COVID-19 "hot spots" may have modified their immunomodulatory medications during the peak of the pandemic in an effort to minimize risk and severity of infection. We aimed to assess the degree of immunomodulatory medication modification at a large specialty hospital.

Methods: We emailed a secure web-based survey to 26,045 patients aged ≥18 years evaluated at least once by a rheumatologist between April 1, 2018-April 21, 2020 at a tertiary care academic center in New York City. Patients were invited to complete the survey by email or phone between April 24, 2020 and May 26, 2020. Detailed information was collected, including potential COVID-19 exposure, symptoms, and outcomes, as well as rheumatic disease history and medications. Patients were asked to report any immunomodulatory medication use in the previous six months and to indicate whether they increased, decreased or discontinued the medication during the COVID-19 pandemic, as well as reasons for reduction or discontinuation.

Results: 6,908/26,045 patients (26.5%) responded to the survey. Mean age was 59.6±15.6 years, 76.3% were female, 86.7% were white, and 7.4% were Hispanic/Latinx. 3,230 patients (46.8% of respondents) reported any use of antimalarial drugs, biologic therapies, conventional DMARDs), and/or corticosteroids in the previous six months. 1275/6,908 (18.5%) patients used antimalarials, 1033 (15.0%) used biologic therapies, 1208 (17.5%) used conventional DMARDs, and 1100 (15.9%) used corticosteroids. Among 3,230 patients, there were 4,701 individual reports of immunomodulatory drug use (2,109 used 1 medication, 843 used 2 medications, 278 used ≥2 medications). Medication dosages were increased 156 times (3.3% of reports), decreased 523 times (11.1%), unchanged 3,382 times

* Taken for COVID-19 prevention or treatment, or due to side effects
** Side effects, short-term or tapered prescription

(71.9%), and discontinued 560 times (11.9%) **(Table 1).** We collected only one modification per medication during the study time period. Among dosage reduction reports, 35.6% were corticosteroids, 30.2%r biologics, 19.7% conventional DMARDs, and 14.5% antimalarials. Medication discontinuation was highest for corticosteroids (56.6%), less for conventional DMARDs (18.6%) and biologics (17.5%), and lowest for antimalarials (7.3%). 19.2% of reported increases in medication doses were for antimalarials. Medication reductions were advised >50% of the time by a physician, whereas up to a third of discontinuations were self-directed **(Table 2)**.

Conclusion: During the peak of the COVID-19 pandemic, nearly a quarter of immunomodulatory drugs used by surveyed rheumatology patients at a large, tertiary care, specialty center in NYC were reduced or discontinued. These findings provide insight into real-world medication management of patients with rheumatic disease during an infectious disease pandemic. Understanding patient and physician behavior during this public health crisis will help guide planning for a second Sars-CoV-2 spike or future pandemic. Longitudinal studies will evaluate the impact of changes to routine medications on disease activity among these patients.

SESSION INFORMATION
Session Date: Friday, November 6, 2020
Session Title: Patient Outcomes, Preferences, & Attitudes I: COVID-19
Session Type: Abstract Session
Session Time: 5:00PM–5:50PM

Background/Purpose: The prevalence of anti-SARS-CoV-2 IgG infection was estimated at 9.7% in the Geneva population end of April 2020. (1) Immunosuppressed patients may be at increased risk of developing severe forms of COVID-19. It is unknown whether the increasing risk is due to immune-mediated diseases by themselves or to specific immunosuppressive therapies. We postulated that long-lasting cell-depleting therapies may increase the risk of severe COVID-19 more than targeted anti-cytokine therapies.

Methods: We included all patients who received infliximab or rituximab at the Rheumatology Division of the Geneva University Hospitals between September 1st 2019 and February 29, 2020 (last 6 months). We called each patient and administrated a questionnaire with predefined questions on incident COVID-19 symptoms and COVID-19 diagnosis between March 1st, 2020 and end of May 2020, which represents the first wave of the COVID 19 pandemic in Switzerland.

Table 1: Patient characteristics by treatment group

Characteristics	Infliximab (n=64)	Rituximab (n =78)	p value
Age (yr, median [IQR]))	49.17 [39.67, 56.85	56.92 [47.2, 67.4]	0.005
Sex (male)	31(48.4)	15 (19.2)	<0.001
Tobacco consumption (ever, n(%))	7 (13.7)	5 (19.2)	0.526
Comorbidities, n(%)	23 (45.1)	14 (53.8)	0.428
Type of immune-mediated disease			
RA (n=33)	14 (21.6)	54 (96.2)	<0.001
SpA (n=44)	45(70.3)	0 (0.0)	
Other (n=10)	5(7.8)	22(28.2)	

We compared patient characteristics using Wilcoxon test for continuous variables and Fisher test for categorical variables. We calculated prevalence, incidence and their crude and adjusted prevalence and incidence ratio with generalised estimating equations using a Poisson distribution. We adjusted the prevalence and incidence ratio by quartiles of a propensity score based on age, gender, disease (rheumatoid arthritis (RA) vs other), smoking and presence of a comorbidity.

Results: During the study period, 151 patients received either rituximab (RTX, n=86) or infliximab (IFX, n=65). We were able to retrieve complete COVID-19 information from 142 (94.0%) patients. RTX patients were older than IFX patients with an average of 56.6 (47.2, 67.4), and significant different in the underlying diagnoses (more RA on RTX and more spondyloarthritis (SpA) on IFX) (Table 1).

Overall, 15 (10.5%) patients have reported symptoms of plausible COVID-19; 9 (13.8%) on IFX and 6 (7.0%) on RTX (p= 0.18). All 15 patients (RTX=7, IFX=8) were tested for Sars-Cov2 using nasopharyngeal swab PCR. Three patient developed severe pulmonary manifestations requiring hospitalisation (two hospitalized in intensive care units, one died). These patient's were 74, 62, 45 years of age respectively, without any of the established at risk comorbidities, but tobacco smoking.

During this first wave of COVID-19 epidemic, the prevalence of plausible COVID-19 in these immunosuppressed patients was 13.8% (95%CI: 7.5-25.4) on IFX, compared to 7.0% (95%CI: 3.2-15.1) on RTX (crude p=0.17, adjusted p=0.03). The incidence rate of COVID-19 was 2.10 (95% CI: 0.94-3.92) cases/1000 patients-days on IFX, compared to 0.97 (0.35-2.10) cases/1000 patients-days on RTX, a significantly increased rate with IFX compared to RTX (crude p< 0.001, adjusted p=0.03).

The incidence rate of severe COVID-19 was null on IFX (95%CI: 0.0-0.76) compared to 0.47 (0.10-1.38) cases/1000 patients-days on RTX. On RTX, tree out of six patients had a severe evolution compared to zero out of 9 patients on IFX (p=0.04).

Conclusion: The incidence of severe COVID-19 tended to be higher in patients on RTX compared to IFX. The study is ongoing, with an analysis of a broader patient sample.

SESSION INFORMATION
Session Date: Friday, November 6, 2020
Session Title: Patient Outcomes, Preferences, & Attitudes I: COVID-19
Session Type: Abstract Session
Session Time: 5:00PM–5:50PM

Background/Purpose: Patients with autoimmune rheumatic diseases (ARD) may be particularly concerned about COVID-19. We aimed to compare concerns and health-related behaviors of patients with common autoimmune rheumatic conditions versus patients with non-autoimmune rheumatic conditions during the COVID-19 pandemic.

Methods: Adults cared for by members of a multi-state rheumatology provider network (AARA) were invited to complete an online survey (completed April 22 to May 27, 2020). Demographics and rheumatic diagnoses were obtained from the electronic health record data warehouse (Columbus) and linked to the survey. Analyses were restricted to patients with primary diagnoses of common ARD (rheumatoid arthritis, psoriatic arthritis, ankylosing spondylitis, or systemic lupus erythematosus) or patients with non-autoimmune rheumatic disease (osteoarthritis or osteoporosis) who had no ARD diagnoses or DMARD use. Concerns about COVID-19 and health-related behaviors were compared in patients with autoimmune versus non-autoimmune disease using logistic regression, adjusting for demographics, rural residence, and zip-code based measures of COVID-19 activity, income, and education.

Results: Among 18219 respondents with completed surveys, 9004 met criteria for a primary diagnosis of interest, 7176 with and 1828 without autoimmune disease. Patients with ARD were younger (mean age 58 vs. 69) and less commonly female (78% vs. 85%) (Table 1). Respiratory illnesses were reported by 353 (3.9%) and COVID-19 diagnoses by 66 (0.7%). After multivariable adjustment, patients with and without autoimmune disease expressed similar concerns about COVID-19 and similar social distancing behaviors (Figure 1). Older age, female sex, Black race, urban residence, and higher county COVID-19 cases per capita were associated with higher levels of concern (all $p< 0.001$). Patients with ARD had greater concerns related to their rheumatic condition (Figure 1, $p < 0.001$). Among patients with ARD, those with lupus and those treated with biologics/janus kinase inhibitors (JAKi) or glucocorticoids had greater COVID-19-related concerns (all $p < 0.01$). Among the 5543 patients receiving a DMARD, 571 (10.3%) stopped a medication because of concerns about COVID-19. Patients with ARD were less likely to avoid a doctor's visit or laboratory tests and were more likely to have had a telehealth visit (38% versus 33%, Figure 2, all $p < 0.01$) compared to those with non-autoimmune disease.

Conclusion: Concerns about COVID-19 and degree of social distancing were similar in patients with ARD vs. those with non-autoimmune rheumatic disease. Those with ARD had more concerns specific to their rheumatic condition, especially patients with lupus and those treated with biologics/JAKi or glucocorticoids. Patients with ARD were less likely to

DMARD: disease modifying anti-rheumatic drug; JAKi: Janus kinase inhibitor; NSAIDs: non-steroidal anti-inflammatory drugs

avoid office visits and testing and more likely to have telehealth visits, perhaps reflecting the need for closer monitoring of these conditions. These results emphasize the impact of the pandemic across patients with rheumatic disease and the need to ensure adequate follow-up and address concerns specific to patients with autoimmune disease as the pandemic continues.

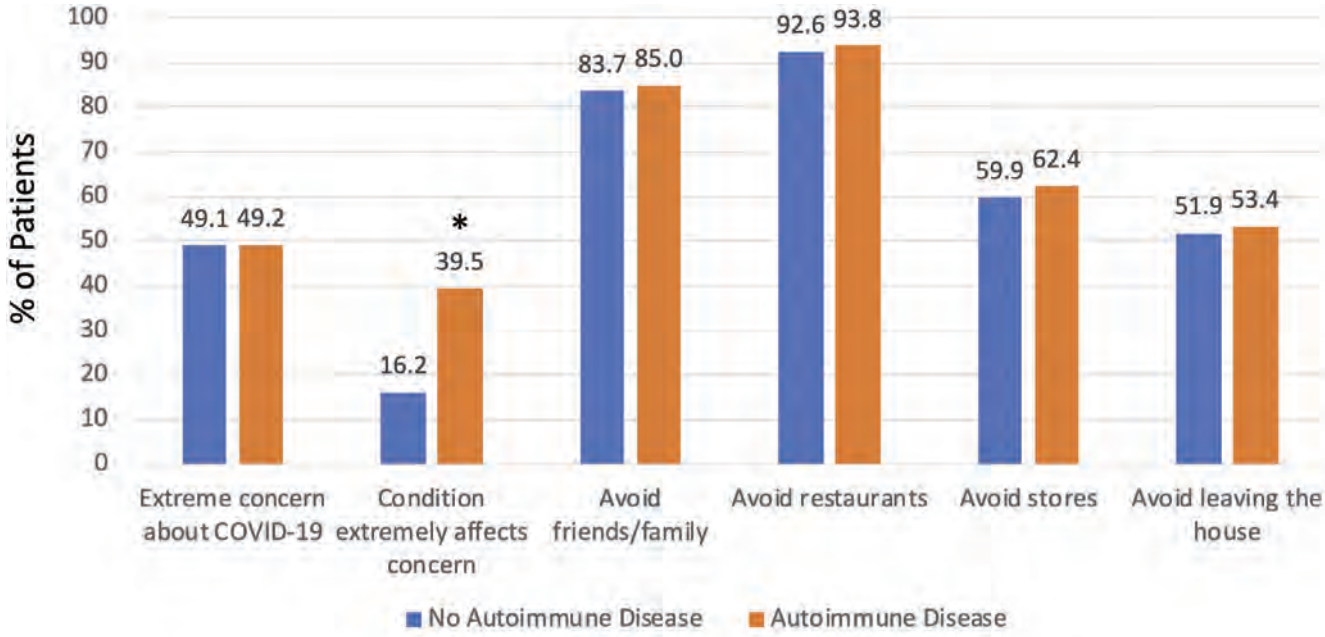

Figure 1: Comparison of concerns about COVID-19 and social distancing behaviors in patients with autoimmune disease (rheumatoid arthritis, psoriatic arthritis, ankylosing spondylitis, or systemic lupus erythematosus) compared to those without autoimmune disease (osteoarthritis or osteoporosis). Proportions shown are based on predicted probabilities from multivariable logistic regression to adjust for age, sex, race, rural residence, tertiles of county-based COVID-19 activity, and tertiles of zip-code based median household income and education. Concerns about COVID-19 and degree to which the patient's autoimmune/rheumatic condition affects these concerns were based on a 5-point Likert scale ranging from 1 (not at all) to 5 (extremely). Patients who indicated "not applicable" for questions about each social distancing measure were excluded

* $p < 0.05$

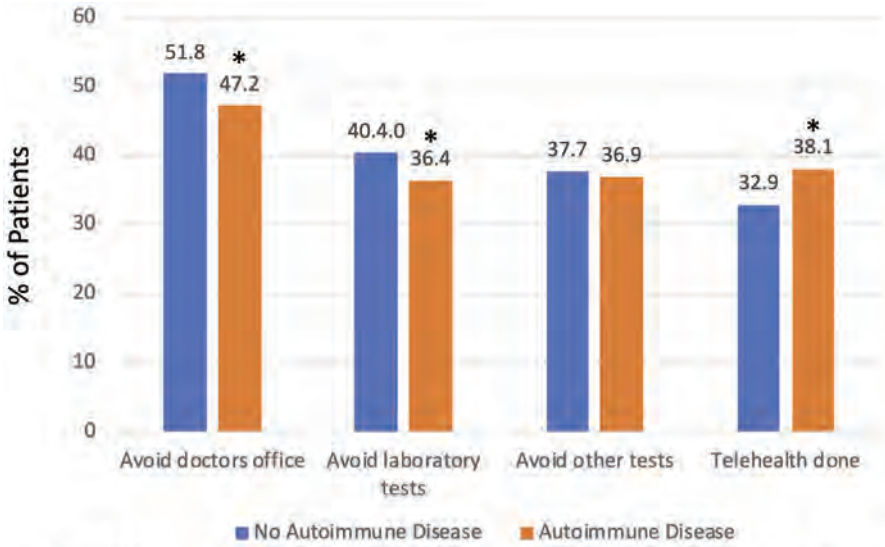

Figure 2: Comparison of health-related behaviors in patients with autoimmune disease (rheumatoid arthritis, psoriatic arthritis, ankylosing spondylitis, or systemic lupus erythematosus) compared to those without autoimmune disease (osteoarthritis or osteoporosis). Proportions shown are based on predicted probabilities from multivariable logistic regression to adjust for age, sex, race, rural residence, tertiles of county-based COVID-19 activity, and tertiles of zip-code based median household income and education. Patients who indicated "not applicable" for each question were excluded.

IFNγ Is Essential for Alveolar Macrophage Driven Lung Inflammation in Macrophage Activation Syndrome

Denny Gao[1], Maggie Henderlight[1], Christopher Woods[1], Alexei Grom[1], Sherry Thornton[1], Michael Jordan[1], Katheryn Wikenheiser-Brokamp[1] and **Grant Schulert**[2], [1]Cincinnati Children's Hospital Medical Center, Cincinnati, OH, [2]PRCSG, Cincinnati Children's Hospital Medical Center, Cincinnati, OH

SESSION INFORMATION
Session Date: Friday, November 6, 2020
Session Title: Pediatric Rheumatology – Basic Science
Session Type: Abstract Session
Session Time: 5:00PM–5:50PM

Background/Purpose: Macrophage activation syndrome (MAS) is a life-threatening cytokine storm syndrome frequently complicating systemic juvenile idiopathic arthritis (SJIA) and driven by IFNγ. MAS is also associated with an emerging and severe inflammatory lung disease (SJIA-LD). The causes and pathogenesis of SJIA-LD are unknown, but have been proposed to include introduction of anti-cytokine therapies, allergic reactions, or other environmental factors, along with recurrent MAS. Our recent work supports activation of IFNγ pathways in the lungs of children with SJIA-LD, supporting a pathologic link between pulmonary inflammation and MAS. The objective of this study was to mechanistically define the novel observation of pulmonary inflammation in the TLR9 mouse model of MAS.

Methods: Pulmonary inflammation was examined by histopathology, cytokine/chemokine levels and alveolar macrophage gene expression profiling. IFNγ signaling was inhibited through neutralizing antibodies as well as using mice with macrophages insensitive to IFNγ.

Results: In acute MAS, lungs exhibit mild but diffuse lymphocyte-predominant, primarily perivascular interstitial inflammation with elevated IFNγ, elevated levels of the IFN-induced chemokines CXCL9 and CXCL10, and alveolar macrophage expression of IFNγ-induced genes. We have further developed the TLR9 model system by for the first time characterizing the resolution phase of MAS. MAS resolution was associated with alveolar macrophage expansion and increased interstitial mononuclear cell infiltration. Alveolar macrophage microarrays confirmed IFNγ-induced proinflammatory polarization during acute MAS. However, this switches towards an anti-inflammatory phenotype during MAS resolution with activation of STAT6-induced genes and repression of STAT1-induced genes. As many patients with SJIA-LD have repeated episodes of MAS, we retreated mice with CpG to model recurrent MAS. Interestingly, recurrent MAS led to increased alveolar inflammation, and reset alveolar macrophage polarization towards a persistent proinflammatory state. Furthermore, using both direct IFNg blockade and macrophages insensitive to IFNγ (MIIG) mice, both systemic feature of MAS and pulmonary inflammation were markedly attenuated.

Conclusion: These findings demonstrate that experimental MAS induces IFNγ-driven pulmonary inflammation that replicates key features of children with SJIA-LD. These findings support a model whereby MAS induces IFNγ-driven pulmonary inflammation and dynamic changes in alveolar macrophage polarization, contributing to development of SJIA-LD.

SESSION INFORMATION
Session Date: Friday, November 6, 2020
Session Title: Pediatric Rheumatology – Basic Science
Session Type: Abstract Session
Session Time: 5:00PM–5:50PM

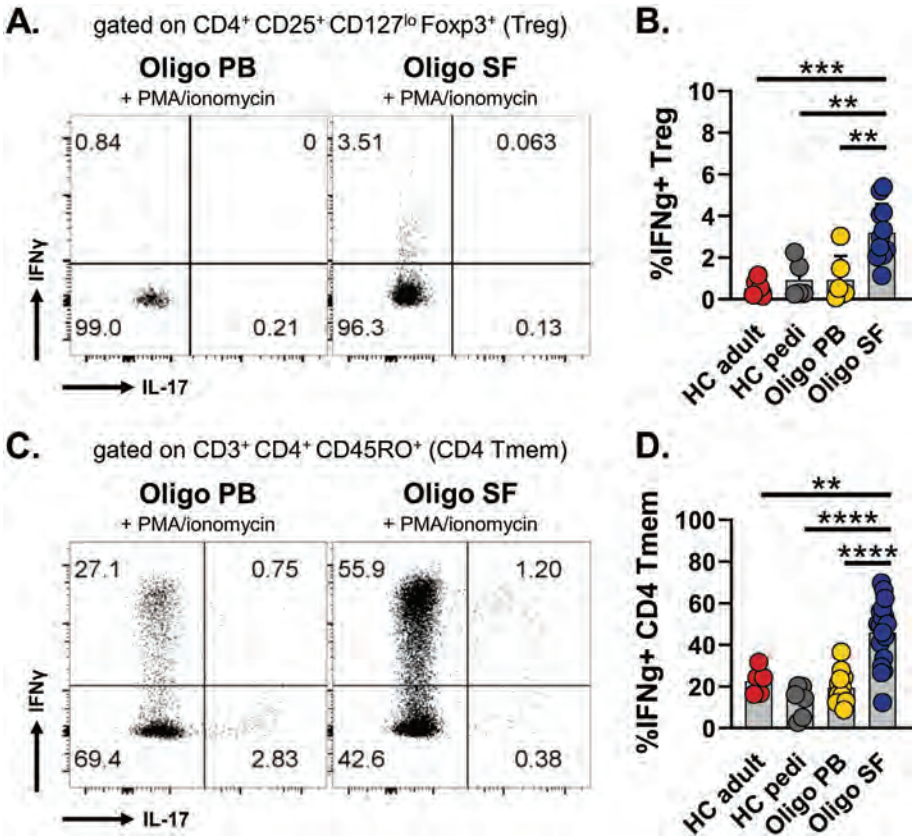
Background/Purpose: Oligoarticular juvenile idiopathic arthritis (oligo JIA) is defined by limited joint involvement at disease onset. Some children achieve long-term remission while others continue to have chronic arthritis in a few joints or extend to a polyarticular course. The mechanisms driving persistent or extended disease in a subgroup of patients are unknown. To better understand how $CD4^+$ T cell responses evolve in oligo JIA, we characterized regulatory (Treg) and effector (Teff) T cells found in the joints of patients at disease onset and during recurrent arthritic flares.

Methods: Synovial fluid (SF) and paired peripheral blood (PB) samples were collected from oligo JIA patients, defined by ILAR criteria. PB was also obtained from healthy controls (HC). Tregs ($CD3^+CD4^+CD25^+CD127^{lo}$) and Teffs ($CD3^+CD4^+CD25^-$) were sorted from SF and PB, and processed for bulk RNA sequencing, single-cell RNA sequencing coupled with T cell receptor (TCR) repertoire analysis (10x genomics), DNA methylation studies (EpigenDx), or *in vitro* Treg suppression assays. PB and SF mononuclear cells were evaluated with flow cytometry.

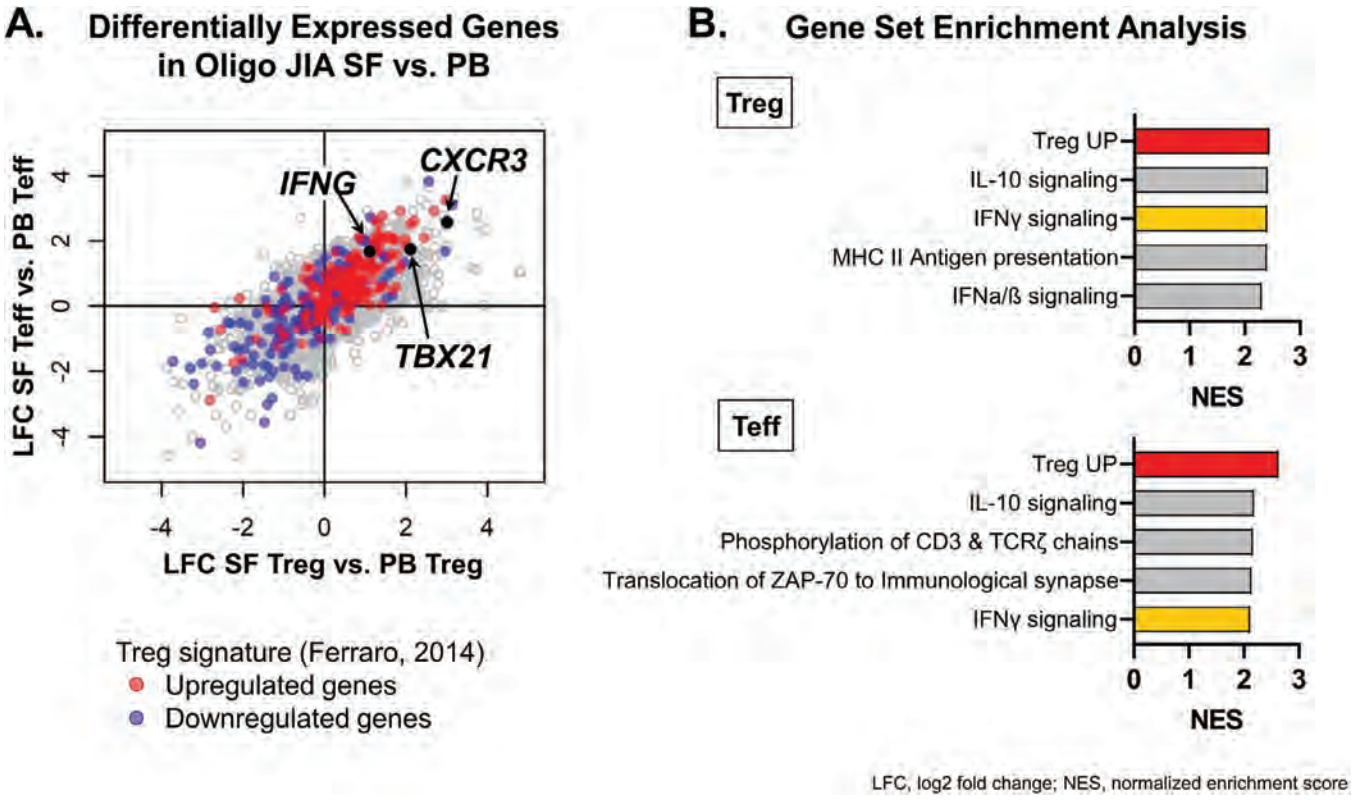
Results: 34 oligo JIA patients and 15 controls were studied. In SF, flow cytometry demonstrated significantly increased frequencies of memory $CD4^+$ T cells ($CD3^+CD4^+CD45RO^+$) expressing Th1 related cytokines (IFNγ) and chemokine receptors (CXCR3). Th17 cells were not enriched in the joint. SF Tregs ($CD4^+CD25^+CD127^{lo}Foxp3^+$) were markedly skewed to a Th1 phenotype: 76.3% ± 6.0% (SEM) expressed CXCR3, and 3.2% ± 0.4% secreted IFNγ after stimulation *in vitro* (Fig1). Bulk RNA sequencing confirmed a Th1 signature in SF Tregs and SF Teffs at disease onset and relapse, with elevated levels of *TBX21* (T-bet, master regulator of the Th1 fate), *CXCR3* and *IFNG* transcripts in oligo JIA SF compared to oligo JIA PB and HC PB. Gene set enrichment analysis uncovered IFNγ signaling as one of the most enriched pathways in SF Tregs and SF Teffs (Fig2). The Treg transcriptional signature was preserved in

SF Tregs. In addition, *FOXP3* locus demethylation and Treg suppressive capacity was maintained in Th1-like Tregs (CXCR3^{+} Tregs), confirming the regulatory identity of this population. Single-cell RNA sequencing uncovered heterogeneity in oligo JIA SF Tregs, with 5 distinct subsets: (1) 'classical' Tregs, (2) IL2RA^{low} Tregs, (3) activated, HLA-DR^{hi} Tregs, (4) Th1-like Tregs expressing *FOXP3* and *IL2RA* jointly with *TBX21* and *IL12RB2*, and (5) Tregs expressing other IFNγ induced genes. Except for IL2RA^{lo} Tregs, all other Treg clusters were enriched in expanded TCR clones, with 22.0 to 37.0% of cells per cluster having at least 3 clonal copies across the single-cell dataset.

Conclusion: Our results identify a strong Th1 polarization in the joints of oligo JIA patients that encompasses both regulatory and effector CD4^{+} T cells and persists longitudinally. While the majority of SF Tregs display Th1 features, this population is heterogeneous with at least 5 subpopulations. Th1-like Tregs retain their regulatory gene expression signature, methylation patterns and functional capacity. These results suggest that augmenting the function of Th1-like Tregs may be key in controlling Th1 mediated inflammation in the joint and restoring tolerance in oligo JIA.



CD4+ T cells from oligo JIA SF express IFNγ upon stimulation in vitro. A) and C) Representative flow cytometry dot plots for Tregs (A) and memory CD4+ T cells (C). B) and D) Mean frequencies +SD of IFNγ+ Tregs (B) and memory CD4+ T cells (D), as measured by flow cytometry (ANOVA with correction for multiple comparisons, **p<0.01, ***p<0.001, ****p<0.0001). PB, peripheral blood; SF, synovial fluid; HC, healthy control; pedi, pediatric.



Oligo JIA SF Treg and SF Teff show markers of a Th1 transcriptomic profile. A) Log2 fold change vs. Log2 fold change plot of the outcomes from the differential expression analysis of oligo JIA SF (n=14, including 7 new-onset and 7 persistent oligo JIA) versus PB (n = 22, including 8 oligo JIA and 14 HC) in Tregs and Teffs. Genes upregulated (red) and downregulated (blue) in the Treg signature described in Ferraro (2014) are highlighted. Th1-related genes (CXCR3, TBX21, IFNG) are labeled. B) Top enriched gene sets in oligo JIA SF Tregs vs. PB Tregs and oligo JIA SF Teffs vs. PB Teffs based on the normalized enrichment score (NES) from the gene set enrichment analysis against the Reactome Database (Immune system and Metabolism subsets) and the Treg signature (Ferraro, 2014).

SESSION INFORMATION

Session Date: Friday, November 6, 2020

Session Title: Pediatric Rheumatology – Basic Science

Session Type: Abstract Session

Session Time: 5:00PM–5:50PM

Background/Purpose: The Inhibitor of Kappa-B Kinase Regulatory Subunit Gamma (*IKBKG*) is located on the X chromosome and encodes the NF-κB essential modulator (NEMO). Loss-of-function mutations in *IKBKG* cause immunodeficiency with ectodermal dysplasia in males and incontinentia pigmenti in females. We have recently reported 4 patients (pts) with gain-of-function (GOF) splice site variants in *IKBKG* causing an autoinflammatory disease (AID) that mimics chronic atypical neutrophilic dermatosis with lipodystrophy and elevated temperature (CANDLE)[1]. This AID has been called NEMO-deleted exon 5 autoinflammatory syndrome (NDAS). The presence of an *IKBKG* pseudogene (*IKBKGP1*) makes the genetic diagnosis of NEMO-associated diseases challenging. We sought to develop a customized bioinformatics approach as screening tool to facilitate the discovery of disease-causing splice site variants.

Methods: Pts enrolled in an IRB-approved protocol underwent whole exome/genome sequencing (WES/WGS) and trio analysis. A bioinformatics pipeline was developed to computationally mask the *IKBKGP1* pseudogene and improve sensitivity of the discovery of splice site mutations. An interferon (IFN) response gene (IRG) score was assessed by Nanostring.

Results: Eight female pts with 5 different de novo splice-site variants in *IKBKG* were identified. The clinical phenotype of the 8 female pts was similar and, in some cases, more severe than the clinical phenotype of male pts with GOF *IKBKG* mutations previously reported. All female pts had early disease onset (2 days to 6 months-old) with nodular skin rashes, fever and increased inflammatory markers (ESR and CRP). Other frequent clinical manifestations included failure to thrive (8/8), lipodystrophy (4/8), hepatosplenomegaly (5/7), anemia (8/8), thrombocytopenia (6/8) and B-cell lymphopenia (5/7). All pts were cortico-dependent and partially responded to anti-TNF (n=5) or JAK inhibitor (n=5) therapies, and one pt deceased due to opportunistic infections (3 years-old). Analysis of pts' WES/WGS data using

a custom approach to mask *IKBKG* pseudogene revealed that two pts had variants in intron 5 (*IKBKG* NM_003639.4 c.671+5G >A in Pt1 and c.671+1G >A in Pt2); and 6 pts had variants in intron 4 (c.519-2A >G in Pt3-Pt6, c.519-22_519-14delGTCTGCTCT in Pt7 and c.519-7_519-6insGGCCCTGG in Pt8). None of the *IKBKG* variants had previously been detected by pts' WES/WGS using standard analysis methods. Reverse transcription followed by cDNA sequencing showed exon 5 skipping in the 7 pts tested and Western blot confirmed the splice product in 2/2 pts. All 8 pts had high 28-gene IFN scores with a relatively higher expression of IRG's that have transcription factor binding sites for NF-κB (*CXCL10*, *GBP1* and *SOCS1*) and a high 3 NF-κB/25 IFN-gene ratio[1].

Conclusion: We describe de novo splice-site variants in the X chromosome gene, *IKBKG* (encoding NEMO), in 8 female pts with a CANDLE-like phenotype. Analysis of WES/WGS masking the *IKBKG* pseudogene provided a remarkably better diagnostic yield than standard methods, and could be used for the diagnosis of pts with NEMO-NDAS.

ApoB:ApoA1 Ratio Could Predict Atherosclerotic Risk in Juvenile-SLE Patients Associated with Altered Interferon Signalling in CD8+ T-cells

George Robinson[1], Kirsty Waddington[2], Leda Coelewij[2], Junjie Peng[2], Meena Naja[2], Chris Wincup[2], Anna Radziszewska[2], Hannah Peckham[2], David Isenberg[2], Yiannis Ioannou[2], Ines Pineda Torra[2], Coziana Ciurtin[2] and Elizabeth Jury[2], [1]University College London, Hertford, United Kingdom, [2]University College London, London, United Kingdom

SESSION INFORMATION
Session Date: Friday, November 6, 2020
Session Title: Pediatric Rheumatology – Basic Science
Session Type: Abstract Session
Session Time: 5:00PM–5:50PM

Background/Purpose: Systemic lupus erythematosus (SLE) is an autoimmune rheumatic disease characterised by immune-dysregulation, chronic inflammation, type-I interferon (IFN) signatures and increased cardiovascular disease (CVD) risk (CVR); CVD is a major cause of morbidity and mortality in SLE. Juvenile-SLE (JSLE) has a more severe disease phenotype and CVR than adult SLE. All patients with SLE should receive careful monitoring and treatment of modifiable CVR factors. However, no guidelines exist for CVR management in SLE and it is not possible to predict the CVR of patients using traditional factors. This study used a multi-omic approach to investigate CVR in JSLE patients.

Methods: NMR-based serum metabolomic biomarker analysis (including 113 lipoprotein measures assessing size/lipid content) was performed on a discovery cohort of JSLE patients (n=31, median age 19). Data were analysed using cluster, receiver operating characteristic (ROC) and logistic regression analysis. Results were validated in a second

JSLE cohort (n=31, median age 19). All patients were assessed clinically over 3-6 years of follow up. Flow cytometry evaluated 28 immune cell subsets and RNAseq assessed gene expression in matched patient samples.

Results: Unbiased hierarchical clustering of metabolomic data identified 2 JSLE patient groups, each with a complex and unique lipoprotein profile. Group-1 had decreased high density lipoproteins (HDL) and increased very low and low density lipoproteins (VLDL/LDL) and Group-2 had elevated HDL but reduced VLDL/LDL, indicating an association with high and low CVR respectively. This pattern was verifed by the measurement of lipid biomarkers associated with pre-clinical atherosclerotic plaque in adult SLE patients. The groups were validated the second JSLE cohort and the Apolipoprotein(Apo)B:A1 ratio was identified as a predictive and longitudinally stable biomarker of CVR (ROC area under the curve >0.99).

Patients with a high ApoB:A1 ratio had significantly increased circulating CD8+ T-cells. Transcriptomic and pathway enrichment analysis of differentially expressed genes (DEGs) from isolated JSLE CD8+ T-cells identified significantly increased interferon (IFN) signaling pathways in high ApoB:A1 ratio patients which overlapped with CD8+ T-cells from human and mouse atherosclerotic plaque. When DEGs associated with disease activity were removed from the analysis, we observed a unique dysregulation of the IFN-stimulated gene factor 3 transcription complex (ISGF3), including significantly increased expression of JAK2, STAT1/2 and IRF9.

Finally, a higher baseline ApoB:A1 ratio predicted an increased average Systemic Lupus Erythematosus Disease Activity Index (SLEDAI) over an average of 5 years (p=0.0009), suggesting worsened clinical outcome.

Conclusion: Multi-omic analysis identified a putative predictive biomarker (ApoB:A1 ratio) and novel immunopathogenic pathways, involving CD8+ T-cells and ISGF3 signalling, associated with increased CVR in JSLE. Patient stratification using the measurement of ApoB:A1 may therefore provide an opportunity for tailored disease treatments using lipid modification therapy and/or diet modification to control disease severity and CVR outcome.

Abstract Number: 0473

Characterization of *DOCK8* as a Novel Gene Associated with Cytokine Storm Syndrome

Mingce Zhang[1], Remy Cron[2], Devin Absher[3], Prescott Atkinson[1], Winn Chatham[1] and **Randy Cron**[1], [1]University of Alabama at Birmingham, Birmingham, AL, [2]University of Alabama at Birmingham, Birmingham, [3]HudsonAlpha Institute for Biotechnology, Huntsville, AL

SESSION INFORMATION
Session Date: Friday, November 6, 2020
Session Title: Pediatric Rheumatology – Basic Science
Session Type: Abstract Session
Session Time: 5:00PM–5:50PM

Background/Purpose: Cytokine storm syndrome (CSS), also known as macrophage activation syndrome (MAS) or secondary hemophagocytic lymphohistiocytosis (HLH), is a life threatening condition that commonly presents with unremitting fever and shock like multi-organ dysfunction (MOD). Laboratory studies show pancytopenia, elevated liver enzymes, elevated ferritin, and hemophagocytosis. Familial forms of HLH result from homozygous defects in

Table. DOCK8 rare mutations and polymorphisms identified in CSS patients.

Table. *DOCK8* rare mutations and polymorphisms identified in CSS patients.

#	Age (yrs)	Sex	Disease	Trigger	Mutation	Frequency
1	16	M	?	*Bartonella*	c.782C>T, p.Ala261Val	novel
2	19	M	T cell leukemia	?	c.54-1G>T (splice acceptor)	0.03%
3	24	M	Still disease	?	c.187G>A, p.Asp63Asn	12%
4	36	F	Polyarteritis nod.	*Streptococcus*	c.187G>A, p.Asp63Asn	12%

genes involved in perforin mediated cytolysis by NK cells and CD8 T cells. As many as 30-40% of CSS patient cohorts studied have heterozygous defects in the same HLH genes resulting in decreased cytolytic function, prolonged interaction with antigen presenting cells, and subsequent increased pro-inflammatory cytokines resulting in MOD. Since NK cell dysfunction is common in CSS, there are likely other genes that contribute to CSS via decreased cytolysis. Using gene sequencing, mutations in potentially novel HLH genes present in 2 or more CSS patients were explored.

Methods: Pediatric and adult patients with CSS at UAB were screened for genetic mutations, potentially contributing to CSS, via whole genome sequencing or a commercial immunodeficiency exomic genetic panel of 207 genes. Four patients were noted to have mutations in the guanine nucleotide exchange factor *DOCK8* critical to NK cell function. *DOCK8* mutations from this CSS cohort, or wild-type (WT) sequence controls, were introduced exogenously into human NK-92 NK cell lines by foamy virus (FV) transduction. Alternatively, the endogenous NK-92 *DOCK8* genes were cut and repaired to express WT sequence or patient derived *DOCK8* mutations by CRISPR/Cas9 technology. WT and mutant *DOCK8* expressing NK-92 cells were incubated with K562 target cells and compared for cytolytic activity, degranulation (CD107a), and cytokine [interferon-g (IFNg), tumor necrosis factor (TNF)] production by flow cytometry.

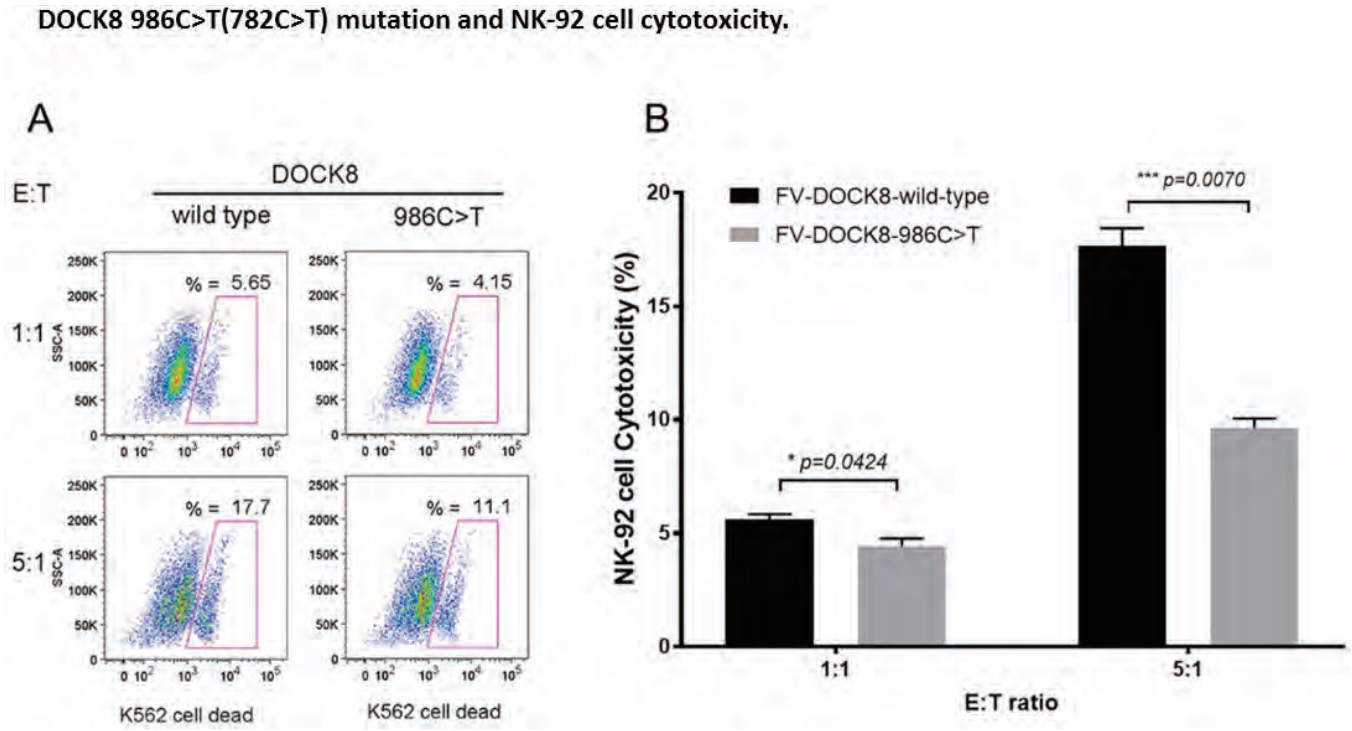

Figure 1. Cytolytic activity of patient #1 DOCK8 missense mutation in NK-92 cells. NK-92 cells were transduced with WT or patient mutation DOCK8-expressing FV and incubated with K562 target cells. A. K562 lysis detected by near-IR fluorescence at 2 E:T ratios. B. N=3, means +/- SEMs.

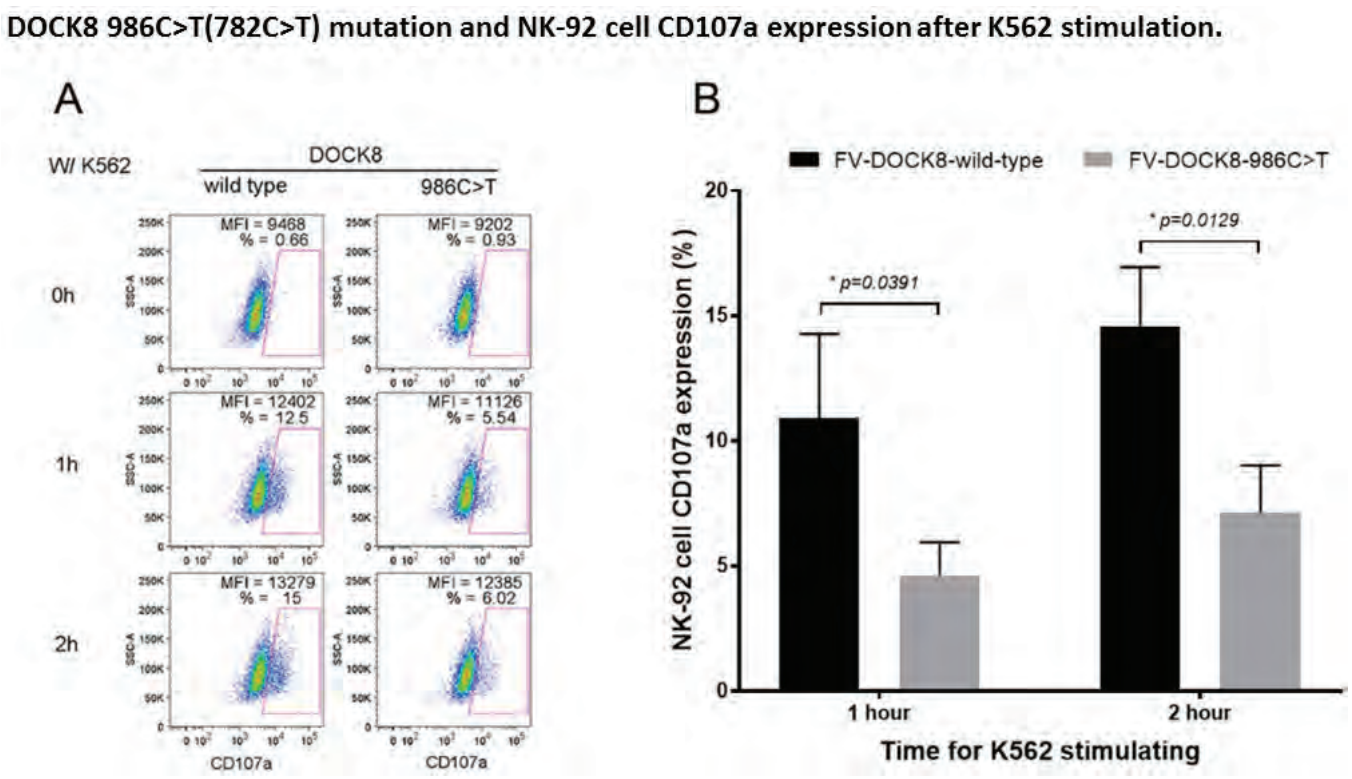

Figure 2. Degranulation of patient #1 DOCK8 missense mutation in NK-92 cells. NK-92 cells were transduced with WT or patient mutation DOCK8-expressing FV and incubated with K562 target cells. A. NK-92 cell degranulation detected by CD107a surface expression at 3 time points. B. N=3, means +/- SEMs.

Results: Two CSS patients were identified with rare heterozygous *DOCK8* mutations, and 2 others with CSS were noted to have the same *DOCK8* polymorphism (c.187G >A, p.Asp63Asn) present in 12% of the population (Table). One of the rare mutations was missense (c.782C >T, p.Ala261Val – novel), and one was a splice acceptor variant (c.54-1G >T, 0.03%). The novel *DOCK8* mutant consistently decreased NK cell lytic activity when introduced by either CRISPR/Cas9 (n=2) or FV (n=3, decreased by ~50% compared to WT, p=0.007) (Fig. 1). Similarly, the novel mutant decreased degranulation by >50% (n=3, p=0.013) (Fig. 2). During the incubation of the NK-92 cells with K562 targets, NK cells expressing the novel *DOCK8* mutant increased expression of IFNg and TNF by >200% (p=0.019 & p=0.003, respectively). The *DOCK8* polymorphism decreased lysis and degranulation to a lesser degree. The *DOCK8* splicing mutation disrupted RNA splicing by an exon trapping assay and a novel assay developed in the lab.

Conclusion: Heterozygous mutations in *DOCK8*, a novel CSS associated gene, likely contribute to CSS pathology through a partial dominant-negative or hypomorphic effect resulting in decreased cytolysis and increased pro-inflammatory cytokine production.

Abstract Number: 0474

Assessment of Teaching Behavior and Knowledge Among Faculty to Inform an Active Teaching Intervention Within a Rheumatology Fellowship Curriculum

Stefanie Wade[1], Vasileios Kyttaris[1], Jason Freed[2] and Jonathan Hausmann[3], [1]Beth Israel Deaconess Medical Center, Harvard Medical School, Boston, MA, [2]Beth Israel Deaconess Medical Center / Harvard Medical School, Boston, MA, [3]Boston Children's Hospital / Beth Israel Deaconess Medical Center, Cambridge, MA

SESSION INFORMATION
Session Date: Friday, November 6, 2020
Session Title: Professional Education
Session Type: Abstract Session
Session Time: 10:00AM–10:50AM

Background/Purpose: The science of learning has provided us with evidence-based tools to enhance learning. Studies show that greater learning occurs in interactive workshops that tackle real-life problems, as compared to traditional lectures. We sought to determine the use of active learning techniques during fellowship didactics and to assess faculty knowledge regarding active teaching strategies.

Methods: We assessed faculty use of active learning strategies during the "Introduction to Rheumatology" curriculum by using a cognitive learning assessment tool that was created by Saunders S and Freed JA (manuscript in progress). An "Active Learning Score" was calculated based on questions that measured active learning (Table 1). A pair of observers (JSH, VCK, or SDW) scored each of the lectures, which took place from July to September 2019. We surveyed faculty knowledge and behavior regarding current teaching practices. Unprecedented teaching challenges brought on by the COVID-19 pandemic prompted us to survey faculty comfort teaching within a virtual learning environment. This project was determined to be exempt by the Beth Israel Deaconess Medical Center IRB.

Results: We surveyed 14 faculty members within the Division of Rheumatology. Faculty demographics are shown in Table 2. Faculty placed the highest value on "understanding concepts" and "applying information to new cases" as

Active Learning Score Items	Score
1. Uses questions in the beginning to determine prior knowledge related to the topic	0 or 3
2. Uses questions periodically during lecture to revisit key concepts	0 to 3
3. Encourages audience participation (i.e., through non-rhetorical questions to group or audience response systems)	0 to 3
4. Asks learners to explain their reasoning with follow-up questions	0 to 3
5. Creates hypothetical situations or asks "what if" questions	0 or 3
6. Utilizes techniques such as "think-pair-share" to facilitate discussion	0 to 3
7. Asks audience to share experiences of taking care of patients with 'x' (i.e., "how many of you have ever taken care of a patient with RA")	0 or 3
8. Asks learners to identify or share with a neighbor key take-home points or concepts	0 or 3
	/24

Table 1. Active Learning Score items from a cognitive learning lecture assessment tool designed by Saunders S, Freed JA (manuscript in progress).

Faculty Surveyed, n	14
Response Rate, n (%)	14 (100)
Years since fellowship, n (%)	
0 to 5	3 (21.4)
6 to 9	2 (14.3)
10 to 19	3 (21.4)

Professor	1

Table 2. Faculty Demographics.

opposed to "remembering facts." A minority of faculty (42.9%) were familiar with the concept of a flipped classroom. Only 50% of faculty felt that virtual teaching could be as effective as in-classroom teaching.

A total of 12 faculty members delivered 16 lectures on core rheumatology topics. 93.8% of lectures incorporated case-based examples that fellows could relate to. Mean baseline Active Learning Scores were 7.8 +/- 5.3 out of 24. We had strong agreement between raters as measured by intraclass correlation (0.86, 95% CI: 0.64-0.95). Faculty asked learners to explain their reasoning with follow up questions an average of 1.25 +/- 1.14 times per lecture. Techniques to facilitate small-group discussion, such as "think-pair-share," were used in 1 out of the 16 lectures (6.25%). Learners were asked to identify or share key take-home points or concepts in 1 out of 16 (6.25%) lectures.

Conclusion: Faculty use of active teaching techniques in fellowship didactics was low. A minority of faculty were familiar with the flipped classroom, and the majority of faculty expressed hesitancy regarding teaching in a virtual environment. Based on these results, we plan to use a multifaceted approach to improve the use of active teaching strategies in the "Introduction to Rheumatology" curriculum (Figure 1). We designed a faculty development workshop to provide strategies for increasing active learning in a virtual environment and will seek input from the department regarding how best to implement these educational changes. We will compare Active Learning Scores pre- versus post-intervention.

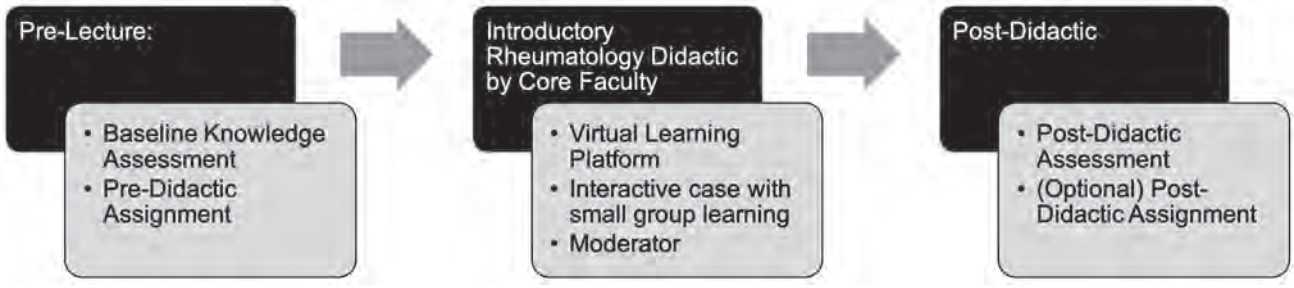

Figure 1. Proposed framework for increasing active teaching within the "Introduction to Rheumatology Curriculum" via virtual learning environment.

Abstract Number: 0475

To Attend or Note to Attend; The Medical Student's Dilemma

Benjamin Widener[1], Amy Cannella[1] and Sarah McBrien[1], [1]University of Nebraska Medical Center, Omaha, NE

SESSION INFORMATION
Session Date: Friday, November 6, 2020
Session Title: Professional Education
Session Type: Abstract Session
Session Time: 10:00AM–10:50AM

Background/Purpose: We present a comparison of student's outcomes with remote video-based learning versus lecture attendance in pre-clinical medical students during a musculoskeletal curriculum, thus allowing insight to optimizing educational formats for pre-clinical medical students. Our purpose was to assess academic outcomes (Rheumatology exam, overall course exam, and overall second year rank) among second year medical students in a musculoskeletal course at the University of Nebraska Medical Center College of Medicine (UNMC COM) varying by percentage of remote learning versus attended lecture for this musculoskeletal block. As remote learning becomes increasingly common during the ongoing COVID-19 pandemic, it is prudent to understand how this may impact medical student's acquisition of pre-clinical knowledge of Rheumatology.

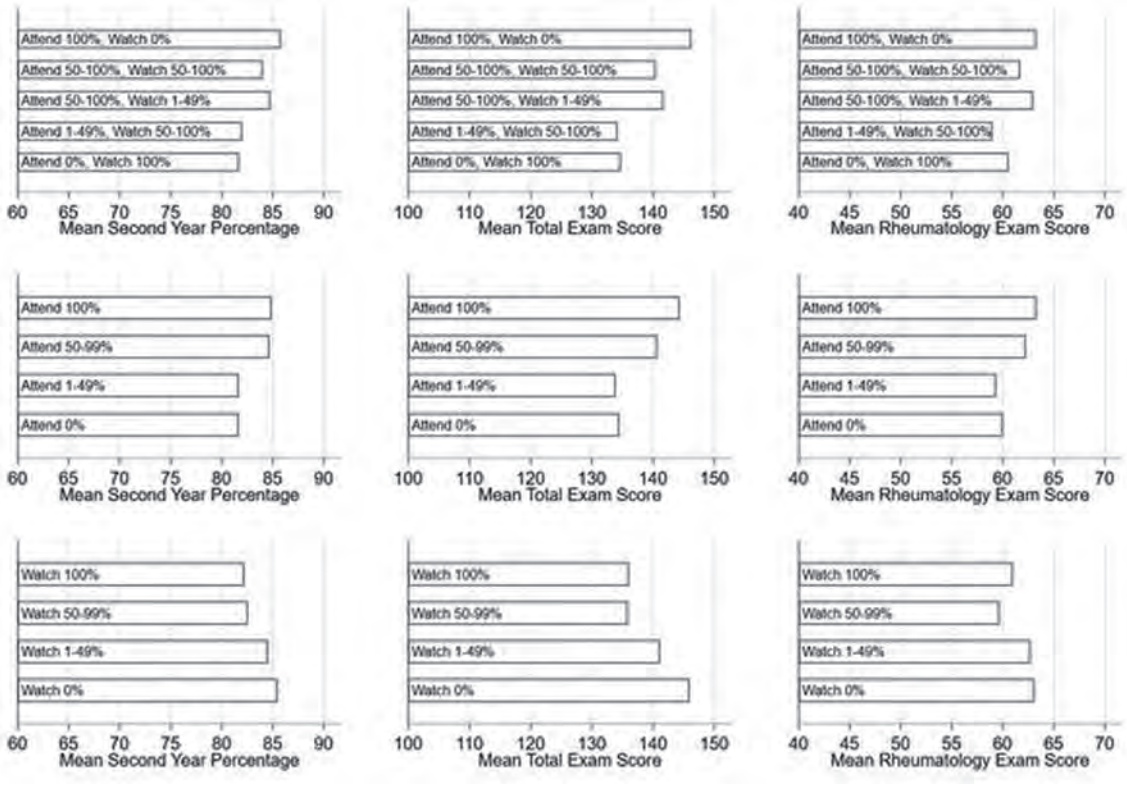

Figure 1 Outcomes 2nd year percentage, Mean total exam (overall course) and mean rheumatology Exam Score.

Methods: Our study is a prospective cohort study conducted at UNMC COM during the M-ID-640 Musculoskeletal, Dermatology & BLS Core from March 23, 2015 to April 10, 2015. We compared the outcomes of 126 second year medical students during this time period. Outcomes were compared based upon confirmed variations in percentage of class attendance and remote lecture viewing. We directly took lecture attendance and had automated record of remote viewing of the material using Echo 360. Our outcomes of interest were the Rheumatology subject exam score, M-ID-640 (course) overall exam score, and the second year cumulative GPA. Investigators reviewed the attendance and echo 360 viewing data and assigned each student to one of the following groups 1) Attend 100%, Watch 0%; 2) Attend 50-100%, Watch 50-100%; 3) Attend 50-100%, Watch 1-49%; 4) Attend 1-49%, Watch 50-100%; 5) Attend 0%, Watch 100%. The outcomes or these groups were compared by regression analysis.

Results: Increased lecture attendance when compared to remote viewing of the lectures, correlated with improved scores in all three of the measured academic outcomes (overall second year percentage, mean overall course grade and mean rheumatology exam score.) There was no statistical difference in undergraduate GPA's among the cohorts that would help explain the outcome differences we observed.

Conclusion: Increased lecture attendance had a positive correlation with multiple scholastic measures in a pre-clinical musculoskeletal course at the UNMC COM when compared to remote video learning. As remote learning is becoming increasingly commonplace, particularly in the setting of the current COVID-19 pandemic, careful consideration of medical school curricula delivery should be undertaken to best achieve academic success and knowledge acquisition in pre-clinical medical students.

Abstract Number: 0476

Using Consensus Building to Guide Rheumatology Curriculum Development for Internal Medicine Residents

Sarah Goglin[1] and Jennifer Babik[2], [1]University of California San Francisco, Burlingame, CA, [2]University of California San Francisco, San Francisco, CA

SESSION INFORMATION
Session Date: Friday, November 6, 2020
Session Title: Professional Education
Session Type: Abstract Session
Session Time: 10:00AM–10:50AM

Background/Purpose: In spite of the increasing burden of rheumatic diseases in the United States, many patients have limited access to rheumatologists. As a result, internists provide much of the care for these patients. However, the current state of rheumatology education for internal medicine (IM) residents is inadequate. No national rheumatology curriculum exists for IM residents. At the University of California San Francisco (UCSF), 20% of IM residents report dissatisfaction with their clinical and didactic experience in rheumatology and in-training exam scores in rheumatology are consistently in the bottom 3 specialties. The purpose of this study was to determine expert consensus on the most important topics to include in a curriculum for UCSF IM residents.

Methods: We conducted a modified, 2-round Delphi process to develop consensus on rheumatology topics that all graduating IM residents should know. Through review of the literature for common diagnoses and the ABIM Blueprint

Topics Meeting Consensus		
	Clinical Features/Diagnostics	Treatment
Gout	x	x
CPPD	x	x
Osteoarthritis	x	x
Psoriatic arthritis	x	
Rheumatoid arthritis	x	x
Infectious arthritis	x	x
Systemic lupus	x	
Drug induced lupus	x	
Antiphospholipid antibody syndrome	x	
Sjogren's syndrome	x	
Raynaud's phenomenon	x	
Inflammatory myopathies	x	
Giant cell arteritis	x	x
Polyarteritis nodosa	x	
ANCA-associated vasculitis	x	
Leukocytoclastic vasculitis	x	
Polymyalgia rheumatica	x	x
Osteoporosis	x	x
Avascular necrosis	x	
Occupational/sports-related overuse syndromes	x	x
Adverse effects of non-biologic antirheumatic drugs	x	
Adverse effects of biologic drugs used by rheumatologists	x	
New topics suggested for Round 2 only		
Indications for a rheumatology consult/referral	x	
How to initiate a rheumatologic work up in cost effective way	x	
Rheumatologic emergencies	x	
Approach to patient with inflammatory arthritis	x	

Table 1. Topics meeting consensus after Round 2 of Delphi process categorized as either clinical features/diagnostics or treatment of specific rheumatologic condition

in rheumatology, we generated an initial list of 78 topics. We surveyed 50 expert faculty educators from general internal medicine, hospital medicine, and rheumatology, and asked them to rate each topic's importance using a 4-point Likert scale (0 = absolutely do not include, 1 = not very important, 2 = kind of important, 3 = important, 4 = very important). We considered a content validity index (the percentage of respondents who rated the topic as ≥3 in Round 2) of at least 80% as our definition for having reached consensus.

Results: 35 of 50 (70%) completed Round 1 of the survey, and 27 of 35 (77%) completed Round 2 (total response rate 54%). In Round 1, 63.6% of topics were scored as ≥3, with a significant difference in scoring between rheumatologists and general medicine faculty (56.2% vs. 69%, p=0.009). 30 of 78 topics met our consensus definition (scored as ≥3 by at least 80% of respondents), with 21 of 78 meeting consensus by rheumatologists compared with 31 of 78 by general internists (p=0.09). 8 additional topics proposed by participants in Round 1 were included in Round 2. Af-

ter Round 2, 35 of 86 topics met the consensus definition, with rheumatologists reaching consensus on fewer topics than general internists (33.7% versus 44.2% of topics, p=0.16). 74.2% of the topics meeting consensus addressed clinical features and/or diagnostics of rheumatologic conditions, while the remainder focused on treatment.

Conclusion: The Delphi consensus method was used to determine which topics should be included in a rheumatology curriculum for IM residents. This process can be used as a blueprint for development of curricula in other medicine specialties in our and other residency programs. Interestingly, rheumatologists considered more topics to be of lower importance to include in a curriculum for IM residents compared with ratings by general internists. The potential differences in opinion between rheumatologists and general internists highlights the need to include both specialists and general medicine physicians in developing subspecialty curricula.

Rheumatology Fellowship Program Directors in the United States: Analysis of Demographics, Educational and Scholarly Achievements

Aakanksha Khanna[1], Dawid Czarny[2], Vibhor Wadhwa[3] and Alysia Kwiatkowski[4], [1]Department of Medicine, University at Buffalo, Jacobs School of Medicine and Biomedical Sciences, Buffalo, NY, [2]University at Buffalo, Amherst, NY, [3]Department of Radiology, University of Arkansas for Medical Sciences, Little Rock, AR, [4]State University of New York at Buffalo, Clarence, NY

SESSION INFORMATION
Session Date: Friday, November 6, 2020
Session Title: Professional Education
Session Type: Abstract Session
Session Time: 10:00AM–10:50AM

Background/Purpose: Rheumatology program directors (PDs) play a vital role in developing, improving and overseeing the fellowship programs. Although PDs have an important role to play in the education and training of future rheumatologists, there is paucity of literature about the educational and demographic background of the current PD workforce in the United States (US). The main aim of the study was to analyze the demographic variables, educational background, and scholarly achievements of rheumatology fellowship PDs in the US.

Methods: The Accreditation Council for Graduate Medical Education (ACGME) website was accessed to obtain a list of all accredited rheumatology fellowships, and PDs of all programs were included. Publicly available sources including individual program/institutional websites, HealthGrades© and Doximity© websites, and the Scopus© database were accessed. Each PD's age, gender, educational background, appointment age, interval between fellowship completion and appointment as PD, additional degrees, and scholarly metrics (publications, citations, h-index) were recorded. Nonparametric statistics including Mann-Whitney U and Kruskal-Wallis tests were used to compare differences between groups and P-value of < 0.05 was considered significant.

Results: A total of 121 PDs were included in the study, of which 61 (50.4%) were females. The average age was 52.69±9.17 years (median 52, range 33-). There was no statistical difference in of male versus female PDs (p=0.112). The average age at appointment was 46.06±7.9 years (range 32-71) and mean tenure duration was 6.53±5.71 years (median 4.8, range 0.17-27.42). International medical graduates comprised 42 (34.7%) of the PDs, with the most common country of international medical school being India (13, 10.7%). Six (5%) received a Doctor of Osteopathic Medicine (DO) degree. The mean (and median) number of publications, citations and h-index for PDs were

31.98±45.47 (median 14), 1344.21±3035.96 (median 384) and 11.94±13.05 (median 8). There was no statistical difference between male and female PDs with regards to distribution of publications (p=0.108), citations (p=0.204) and h-index (p=0.12). There was no statistical difference between PDs from American and international medical schools with regards to distribution of publications (p=0.261), citations (p=0.367) and h-index (p=0.337).

Conclusion: Rheumatology fellowship PD positions demonstrate gender equality with 50% being female, and with no significant difference in scholarly metrics between male and female PDs. International medical graduates comprise thirty five percent, a sizeable minority. This study provides a single snapshot of the current rheumatology PD workforce in the US in 2020, and will be helpful for those interested in an academic career, with a focus on medical education. Furthermore, this study will serve as a baseline for future comparative studies.

Abstract Number: 0478

Increasing Awareness of Advocacy During Early Career – a Web-Based Educational Program

Sirisha Gokaraju[1], Angus Worthing[2], Katherine Maher[3], Grace Wright[4] and Gail Kerr[5], [1]Georgetown University hospital, Bethesda, MD, [2]Arthritis & Rheumatism Associates, PC, Washington, DC, [3]Arthritis & Rheumatism Associates, PC, Alexandria, VA, [4]Association of Women in Rheumatology, New York, NY, [5]Washington DC VA Medical Center, Washington, DC

SESSION INFORMATION

Session Date: Friday, November 6, 2020
Session Title: Professional Education
Session Type: Abstract Session
Session Time: 10:00AM–10:50AM

Background/Purpose: In 2015, the American College of Rheumatology (ACR) began Advocacy 101 in person-education for Fellows in Training (FIT) and physicians to encourage participation in federal regulatory and legislative issues that relate to access to care, research funding, and contemporaneous matters. However, FIT participation has

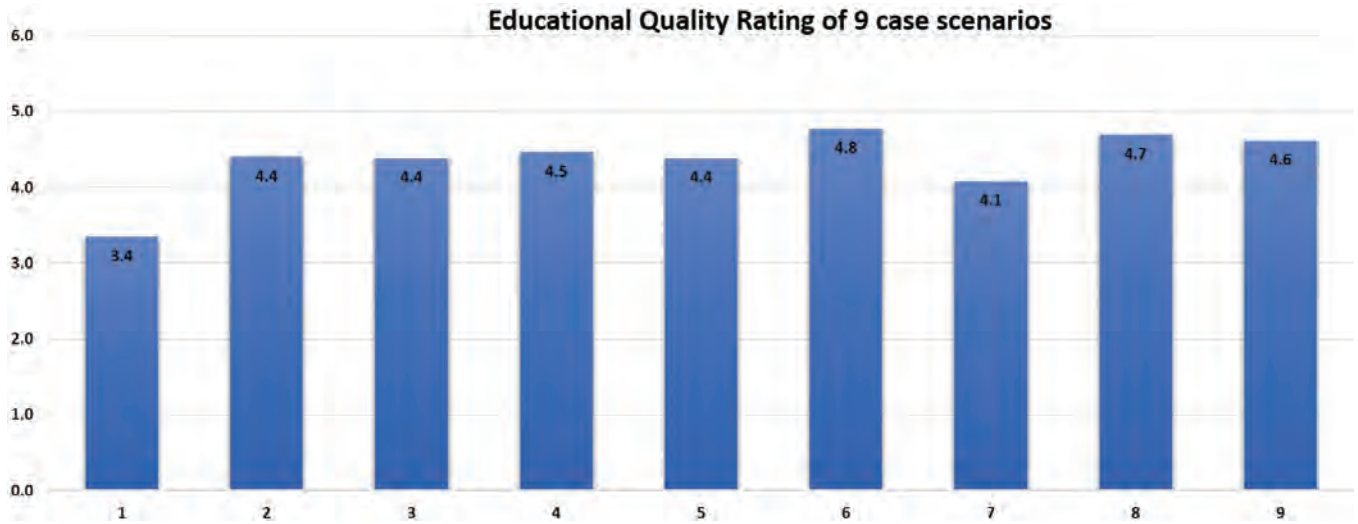

Table 1. Rating of Educational Quality of 9 case scenarios

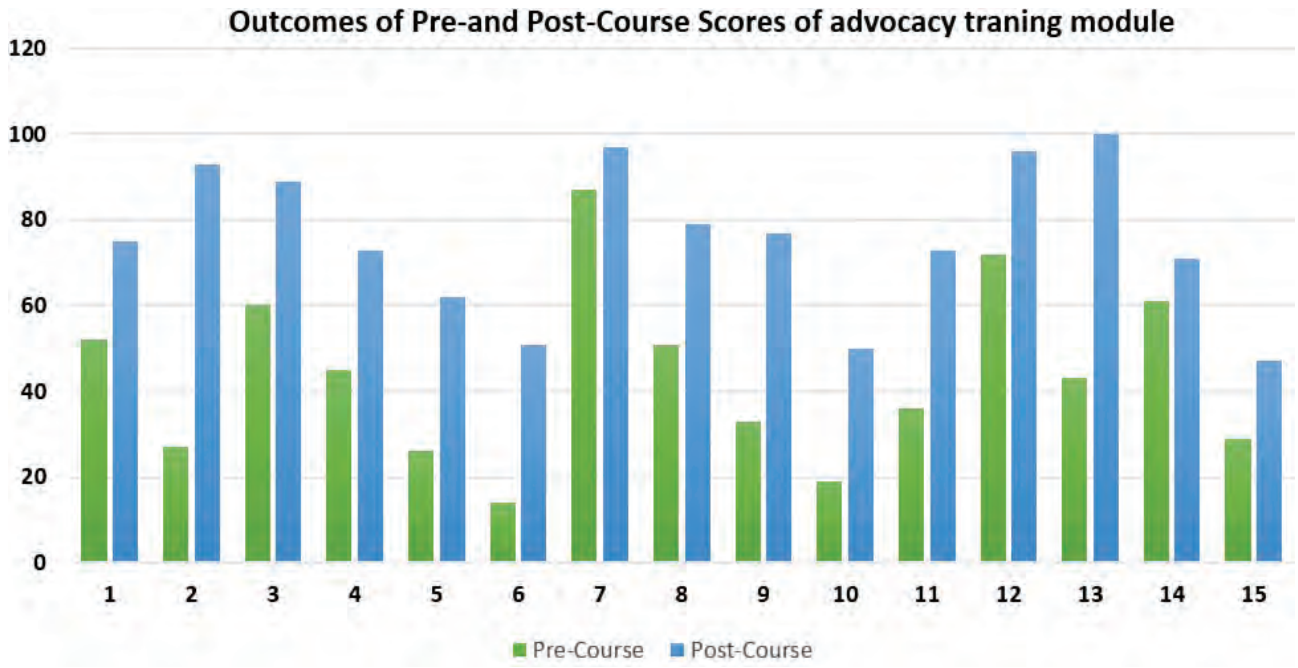

Table 2. Pre- and Post-course Questionnaire scores for Advocacy Training

been undersubscribed, with 50% - 80% of adult and pediatric trainees unexposed, particularly in single-Fellow programs. Though knowledge of the Advocacy process improved by 30%, there was minimal increase in ACR Advocacy awareness (5%), or increased investment in the Rheum PAC® (3%). FIT reported that while in-person training was acceptable, 48% were receptive to on-line training. To date, no web-based Advocacy Training tool exists.

Objective: To evaluate the impact of a web-based Rheumatology Advocacy Training tool on Increasing Awareness in Early Career.

Methods: Early career rheumatologists who attended the 2019 ACR-Advocacy 101 were invited to participate. Email notification for the 9-step, case-based, web-hosted Advocacy training program was sent every 28 days. Content included ACR and other sources of legislative and regulatory material. Tasks related to improving access to care, writing letters of appeals were included. Single multiple-choice questions were assigned to each case scenario, with continuing medical education credit. Participants were invited to 2 web-based teleconferences; 1) at mid-point - to clarify technical questions, 2) at completion - to review and discuss cases, responses, and obtain feedback from participants. Outcomes of pre- and post-questionnaires, completed, correct answers, narrative summations of responses, and suggestions for improvement were collected.

Results: Early Career Rheumatology physicians (≤ 2years) from 9 academic institutions accepted the invitation to participate. Of 20 trainees who started the program, 75% completed all 9 cases. Correct CME answers were scored on 85% of cases. Overall educational quality of content received a mean rating of 4.3 (Likert scare: 1-5). Seven of the 9 cases achieved positive ratings related to relevance of case content, achievement of training goal, objectivity and helping improve competence. Cases relevant to Medicare drug coverage structures, Tele-Health, Biosimilars, Medicare Sequestration, Prior Authorization, and how to translate Advocacy training into action, were rated as having the greatest impact. All cases were assessed free of bias. Feedback indicated ~ 30 minutes was dedicated for completion of each case, and that a combination of skill set and content learning to be most effective. Pre- and post-questionnaire scores indicated significant improvement in knowledge of advocacy matters ($p < 0.0001$,Table).

Conclusion: A web-based, case-scenario Advocacy tool permitted access to training, increased participation and awareness of pertinent federal regulatory and legislative issues related to the care of rheumatic patients. A follow-up evaluation 2 years post-training to assess enduring Advocacy engagement is planned.

Abstract Number: 0479

Early DAS Response After DMARD-start Increases Probability of Achieving Sustained DMARD-free Remission in Rheumatoid Arthritis

Marloes Verstappen[1], Ellis Niemantsverdriet[2], Xanthe Matthijssen[2], Saskia le Cessie[2] and Annette van der Helm - van Mil[3], [1]Leiden University Medical Center, Leiden, Zuid-Holland, Netherlands, [2]Leiden University Medical Center, Leiden, Netherlands, [3]Leiden University Medical Center, Erasmus Medical Center, Leiden, Netherlands

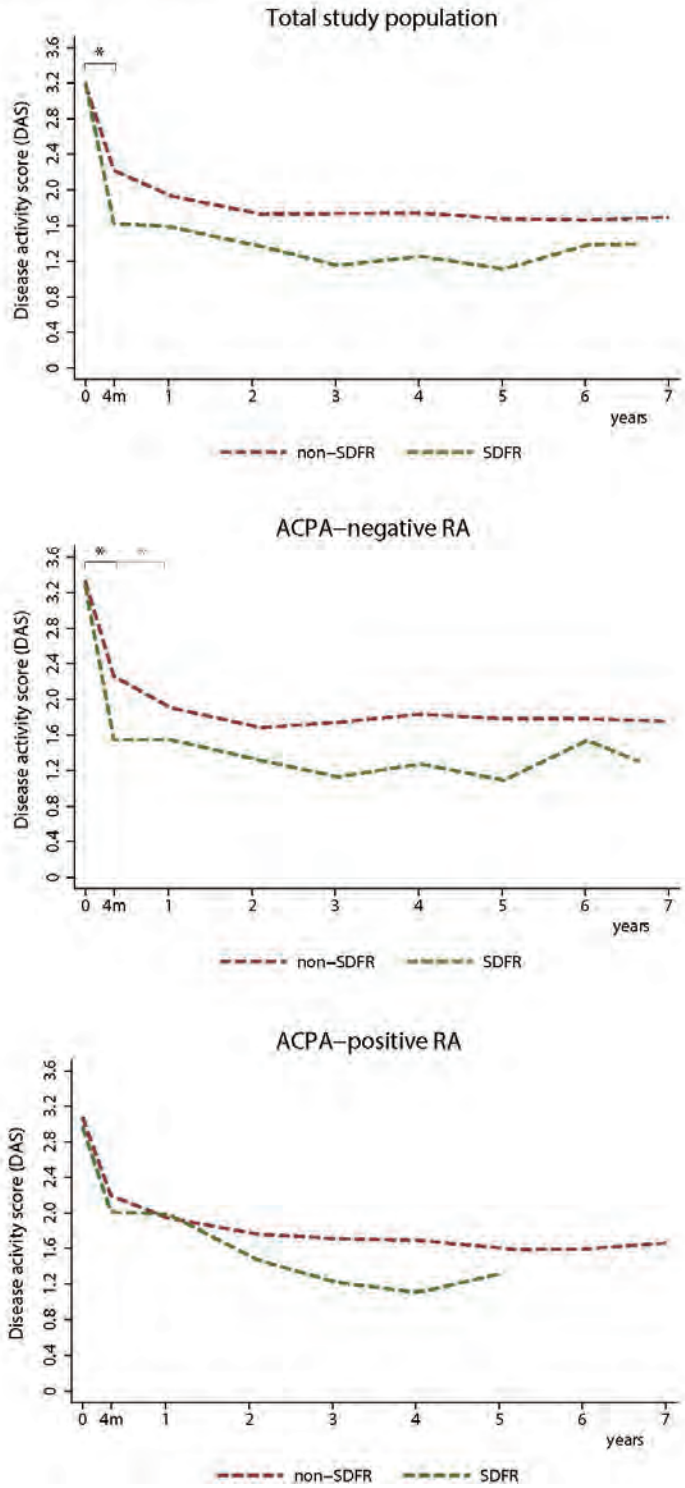
SESSION INFORMATION
Session Date: Friday, November 6, 2020
Session Title: RA – Diagnosis, Manifestations, & Outcomes I: Pre-Onset & Early RA
Session Type: Abstract Session
Session Time: 3:00PM–3:50PM

Background/Purpose: Sustained DMARD-free remission (SDFR) is increasingly achievable. The pathogenesis underlying SDFR-development is unknown and patient-characteristics at diagnosis poorly explain whether SDFR will be achieved. To increase the understanding, we studied the course of disease activity scores (DAS) over time in relation to SDFR-development. Subsequently, we explored whether DAS-course could be helpful identifying patients likely to achieve SDFR.

Methods: 772 consecutive RA-patients, promptly treated with csDMARDs (mostly methotrexate and treat-to-target treatment adjustments), were studied for SDFR-development (absence of synovitis, persisting minimally 12-months after DMARD-stop). The course of disease activity scores (DAS) were compared between patients with and without SDFR-development within 7-years, using linear mixed models, stratified for ACPA. The relation between 4-months DAS and the probability of SDFR-development was studied with logistic regression. Cumulative incidence of SDFR within DAS-categories (< 1.6, 1.6-2.4, 2.4-3.6, ≥3.6) at 4-months was visualized using Kaplan-Meier-curves.

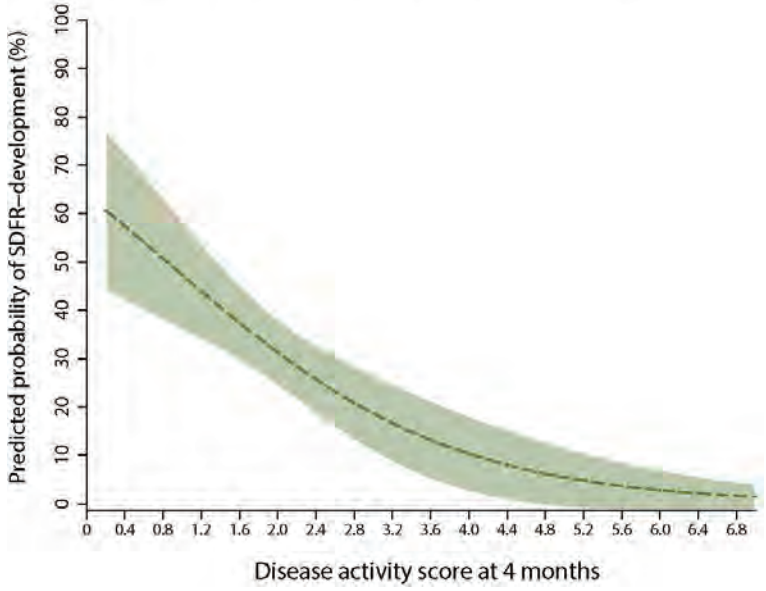
Results: In ACPA-negative patients, those achieving SDFR showed a remarkably stronger DAS-decline within the first 4-months, compared to patients without SDFR; -1.73 units (95%CI,1.28-2.18) versus -1.07 units (95%CI,0.90-1.23) (p< 0.001). In APCA-positive patients such a difference was not observed. In ACPA-negative RA, DAS-decline in the first 4-months and absolute DAS-levels at 4-months (DAS4months) were equally predictive for SDFR-development. Incidence of SDFR in ACPA-negative patients was high (70.2%) when DAS4months was < 1.6, whilst SDFR was rare (7.1%) when DAS4months was ≥3.6. In ACPA-negative patients, those achieving SDFR showed a remarkably stronger DAS-decline within the first 4-months, compared to patients without SDFR; -1.73 units (95%CI,1.28-2.18) versus -1.07 units (95%CI,0.90-1.23)(p< 0.001). In APCA-positive patients such a difference was not observed. In ACPA-negative RA, DAS-decline in the first 4-months and absolute DAS-levels at 4-months ($DAS_{4months}$) were equally predictive for SDFR-development. Incidence of SDFR in ACPA-negative patients was high (70.2%) when $DAS_{4months}$ was < 1.6, whilst SDFR was rare (7.1%) when $DAS_{4months}$ was ≥3.6.

Figure 1. Course of DAS over time for the SDFR and non-SDFR group in the total RA population studied, and for ACPA-negative RA and ACPA-positive RA separately.



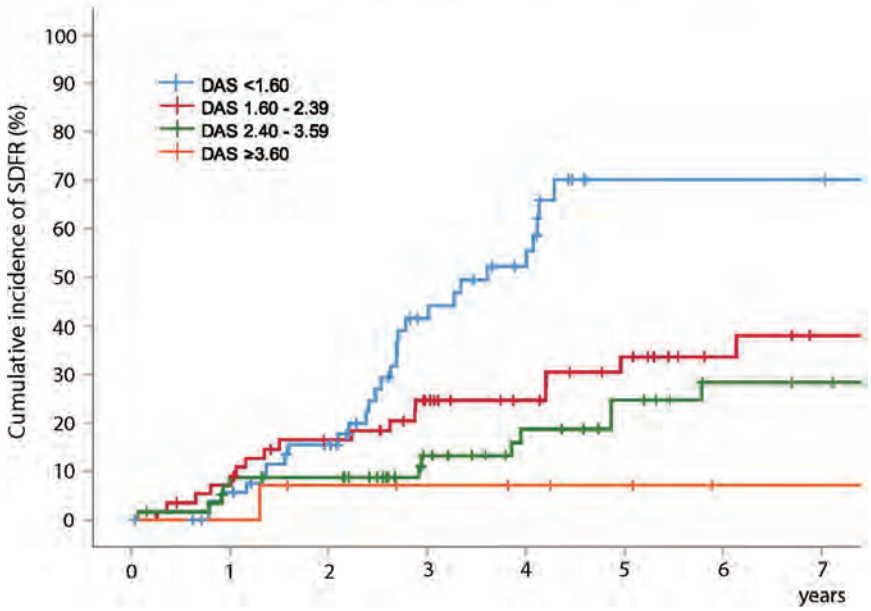
Legend: Course of DAS over time of patients achieving sustained DMARD-free remission (SDFR) within 7 years of follow-up (n=149), and those not (n=623). In ACPA-positive patients, the line of the SDFR-group was restricted to 5 years follow-up because of insufficient data thereafter. Statistically significant differences in course of DAS over time, between the SDFR-group and non-SDFR-group, were indicated by with: * ACPA: anti-citrullinated protein antibody, DAS: Disease activity scores, RA: Rheumatoid arthritis, SDFR: Sustained DMARD-free remission.

Figure 2. Predicted probability of SDFR-development in ACPA negative RA in relation to DAS at 4 months.



Legend: Predicted probability of achieving SDFR during follow-up in ACPA-negative RA, based on multivariate logistic model including DAS at 4 months, age, gender and symptom duration (table 2). For this graph, age, gender and symptom duration were set at the mean value of each covariable. An inverse relation is seen between DAS at 4-months and the predicted probability of achieving SDFR (within 7 years). ACPA: anti-citrullinated protein antibody, DAS: Disease Activity Score, SDFR: Sustained DMARD-free remission.

Figure 3. Kaplan-Meier curves for SDFR-development within 7-years follow-up based on disease activity scores at 4 months in ACPA-negative RA



Legend: Time-to-event was defined as time from 4-months visit until SDFR-development (yes/no), i.e. the absence of clinical arthritis for minimally 12-months after DMARD-stop. ACPA: anti-citrullinated protein antibody, DAS: Disease activity score, SDFR: sustained DMARD-free remission.

Conclusion: In ACPA-negative RA, early response to treatment, i.e. a strong DAS-decline within the first 4-months, is associated with a higher probability of SDFR-development. DAS-values at 4-months could be useful for later decisions to stop DMARDs.

Abstract Number: 0480

Impact of Targeting Remission or Low Disease Activity on 10-year Severity in Rheumatoid Arthritis: Data from ESPOIR Cohort

Julia Dupont[1], Gregory Guernec[2], Yannick Degboé[3], Frédéric Lioté[4], Olivier Vittecoq[5], Arnaud Constantin[6] and Adeline Ruyssen Witrand[7], [1]University Hospital of Thoulouse, Toulouse, [2]Inserm UMR 1027, TOULOUSE CEDEX 9, France, [3]University Hospital of Toulouse, Toulouse, [4]AP-HP, Paris, France, [5]University Hospital of Rouen, Rouen, France, [6]Rheumatology Department, Toulouse University Hospital, Toulouse, France, [7]Rheumatology center, University Hospital of Toulouse, Inserm 1027, University Paul Sabatier, Toulouse, France, Toulouse, France

SESSION INFORMATION
Session Date: Friday, November 6, 2020
Session Title: RA – Diagnosis, Manifestations, & Outcomes I: Pre-Onset & Early RA
Session Type: Abstract Session
Session Time: 3:00PM–3:50PM

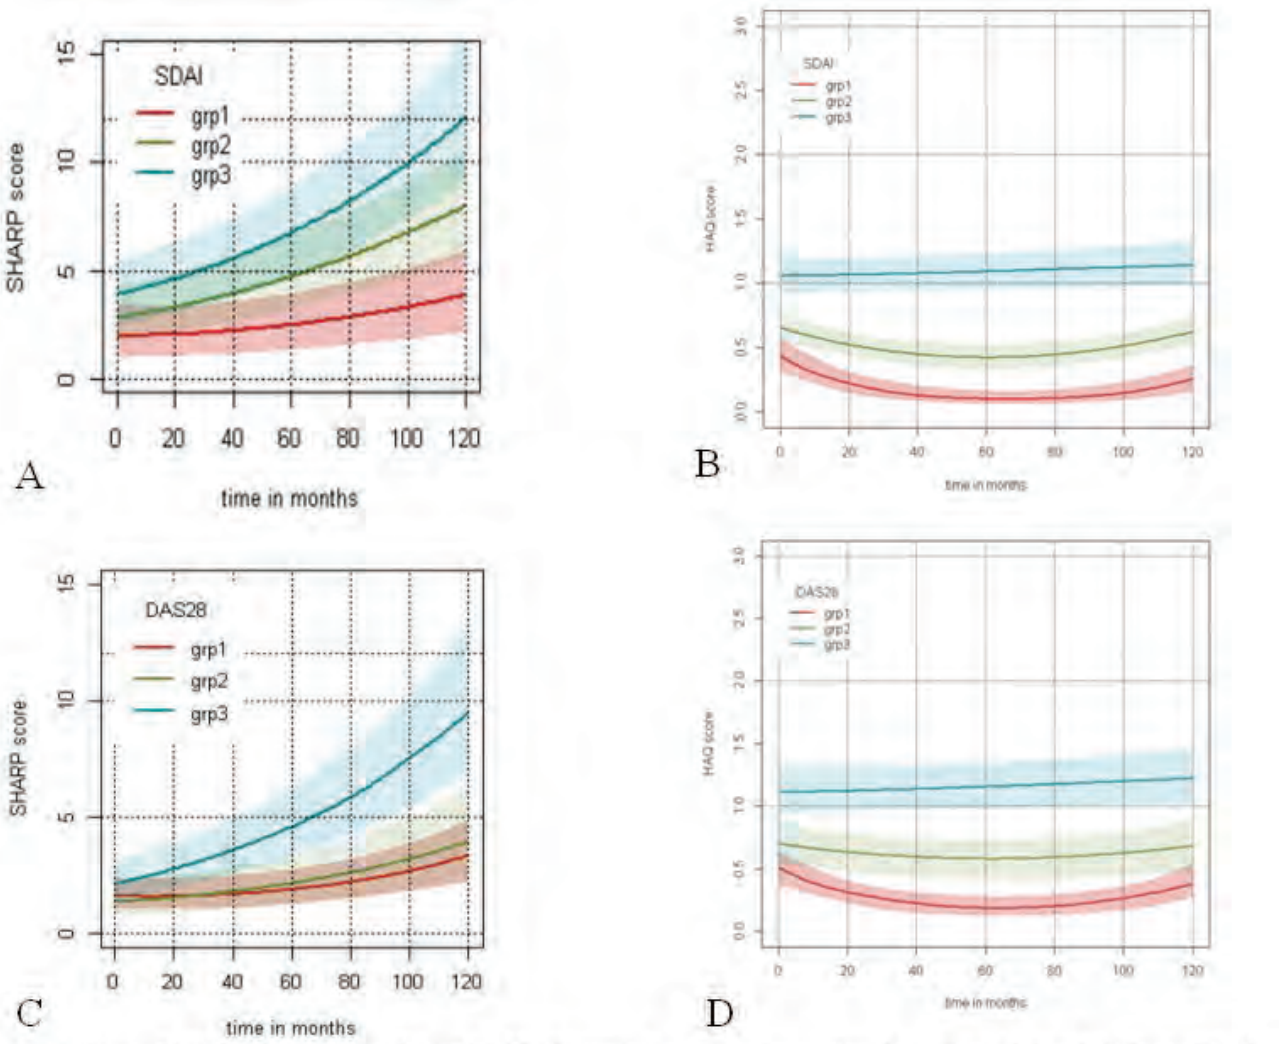
Background/Purpose: The aim of rheumatoid arthritis (RA) treatment is to target remission or at least low disease activity (LDA). We previously showed that SDAI remission at one year decreased the risk of 3-year structural progression in RA compared to patients in LDA.

The aim of the study was to compare 10-year severity outcomes including structural progression, function and orthopaedic surgery in RA patients with sustained remission versus patients with sustained LDA.

Methods: *Patients:* 813 patients with DMARDs-naïve early arthritis were included in the ESPOIR cohort and followed for 10 years. We analyzed data from with disease activity scores available at least at 6 visits out of 11 (n=523 with SDAI scores and n=527 with DAS28 scores).

Data analyzed: Remission was defined by SDAI ≤ 3.3 or DAS28< 2.6; LDA by 3.3 < SDAI score ≤ 11 or 2.6 ≤ DAS28 ≤ 3.2. Radiographs were centrally scored using the Total Sharp Score modified by Van der Heijde (mTSS) at baseline and at 10-year visits. Health Assessment Questionnaires (HAQ) and RA orthopaedic procedures were collected at each visit.

Analysis: patients were classified in 3 groups according to the SDAI at each visit between 1-year and 10-year visits. Group 1: patients with sustained SDAI remission. Group 2: patients with sustained SDAI LDA. Group 3: patients with moderate or high sustained disease activity. Patient with instable disease activity over time were excluded. A process latent mixed model were used to assess the impact of SDAI status over time on mTSS progression and mHAQ-DI evolution until 10-year visit was performed. A Cox proportional model was used to assess the impact of SDAI status over time on the risk of surgery. The following cofounding factors were included in the model: age, gender, disease duration, clinical center, erosions at baseline, ACPA positivity and titer , smoking habits, DMARDs use, time to start



A: predicted means of mTSS over time according to the SDAI groups (1=sustained remission, 2= sustained LDA, 3=MDA or HDA)
B : predicted means of HAQ over time according to SDAI groups (1=sustained remission, 2=sustained LDA, 3=MDA or HDA)
C: predicted means of mTSS over time according to the DAS28 groups (1=sustained remission, 2= sustained LDA, 3=MDA or HDA)
D: predicted means of HAQ over time according to DAS28 groups (1=sustained remission, 2=sustained LDA, 3=MDA or HDA)

DMARD, biologic agents use and glucocorticoid use. Comparisons between remission and LDA fort the 3 outcomes over 10 years were obtained from the multivariate model with contrasts method. Analyses were repeated using DAS28.

Results: After classification of patients according to SDAI over time, group 1 included 48 patients in remission (9.2%), and group 2 included 135 patients in LDA (25.8%), while 79 patients (14.9%) could be classified in remission group 1 and 53 patients (10.1%) could be classified in LDA group 2 using the DAS28.

Patients with sustained SDAI remission had lower 10-year structural progression compared to patients in LDA ($p=0.0014$) and lower 10-year HAQ means ($p< 0.0001$). After 10 year follow-up only 53 patients have undergone orthopaedic procedures (10%) of whom 3 were in the group 1 according to SDAI and 14 in group 2 ($p=0.14$). When

using DAS28 as disease activity score to classify patients, we identified a lower structural progression in the sustained DAS28 remission group compared to the LDA group (p=0.02) and patients in remission had lower 10-year HAQ means (p=0.0008) (figure), while no difference was observed for the risk of orthopaedic procedures between groups.

Conclusion: Aiming for SDAI or DAS28 remission rather than LDA during monitoring leads to better radiographic and functional outcomes at 10 years in early RA patients.

Subclinical Synovitis in Arthralgia: How Often Does It Result in Clinical Arthritis? A Longitudinal Study to Reflect on Starting Points for DMARD Treatment

Cleo Rogier[1], Fenne Wouters[2], Laurette van Boheemen[3], Dirkjan van Schaardenburg[4], Pascal de Jong[1] and Annette van der Helm - van Mil[5], [1]Erasmus MC, Rotterdam, Netherlands, [2]Leiden University Medical Center, Leiden, Netherlands, [3]Amsterdam Rheumatology and immunology Center | Reade, Amste, Netherlands, [4]Amsterdam Rheumatology and immunology Center | Reade and Amsterdam UMC, Amsterdam, Netherlands, [5]Leiden University Medical Center, Erasmus Medical Center, Leiden, Netherlands

SESSION INFORMATION
Session Date: Friday, November 6, 2020
Session Title: RA – Diagnosis, Manifestations, & Outcomes I: Pre-Onset & Early RA
Session Type: Abstract Session
Session Time: 3:00PM–3:50PM

Background/Purpose: According to guidelines, clinical arthritis is mandatory for diagnosing rheumatoid arthritis (RA). However, in the absence of clinical synovitis, imaging-detected subclinical synovitis is increasingly used instead, and considered as starting point for DMARD-therapy. We searched for evidence of the natural course and determined in arthralgia-patients with subclinical synovitis from three longitudinal cohorts the frequencies of non-progression to clinically apparent inflammatory arthritis (IA) (i.e 'false-positives').

Methods: Subclinical synovitis in hands or feet of arthralgia-patients was visualized with ultrasound (two cohorts, subclinical synovitis definition: greyscale≥2 and/or power doppler≥1) or MRI (one cohort, subclinical synovitis: synovitis score ≥1 by two readers). Patients were followed for 1-year on IA-development; two cohorts also had 3-year data. Analyses were stratified for anti-citrullinated protein antibody (ACPA).

Results: Subclinical synovitis at presentation was present in 36%, 41% and 31% in the three cohorts. Of the ACPA-positive arthralgia-patients with subclinical synovitis 54%, 44% and 68%, respectively, did not develop IA (Figure 1A). These percentages were even higher in the ACPA-negative arthralgia-patients: 66%, 85% and 89% (Figure 1A). Similar results were seen after 3-years follow-up (Figure 1B).

Conclusion: Replacing clinical arthritis by subclinical synovitis to identify RA introduces a high false positive rate (44-89%). DMARD-initiation in absence of clinical arthritis may lead to considerable overtreatment.

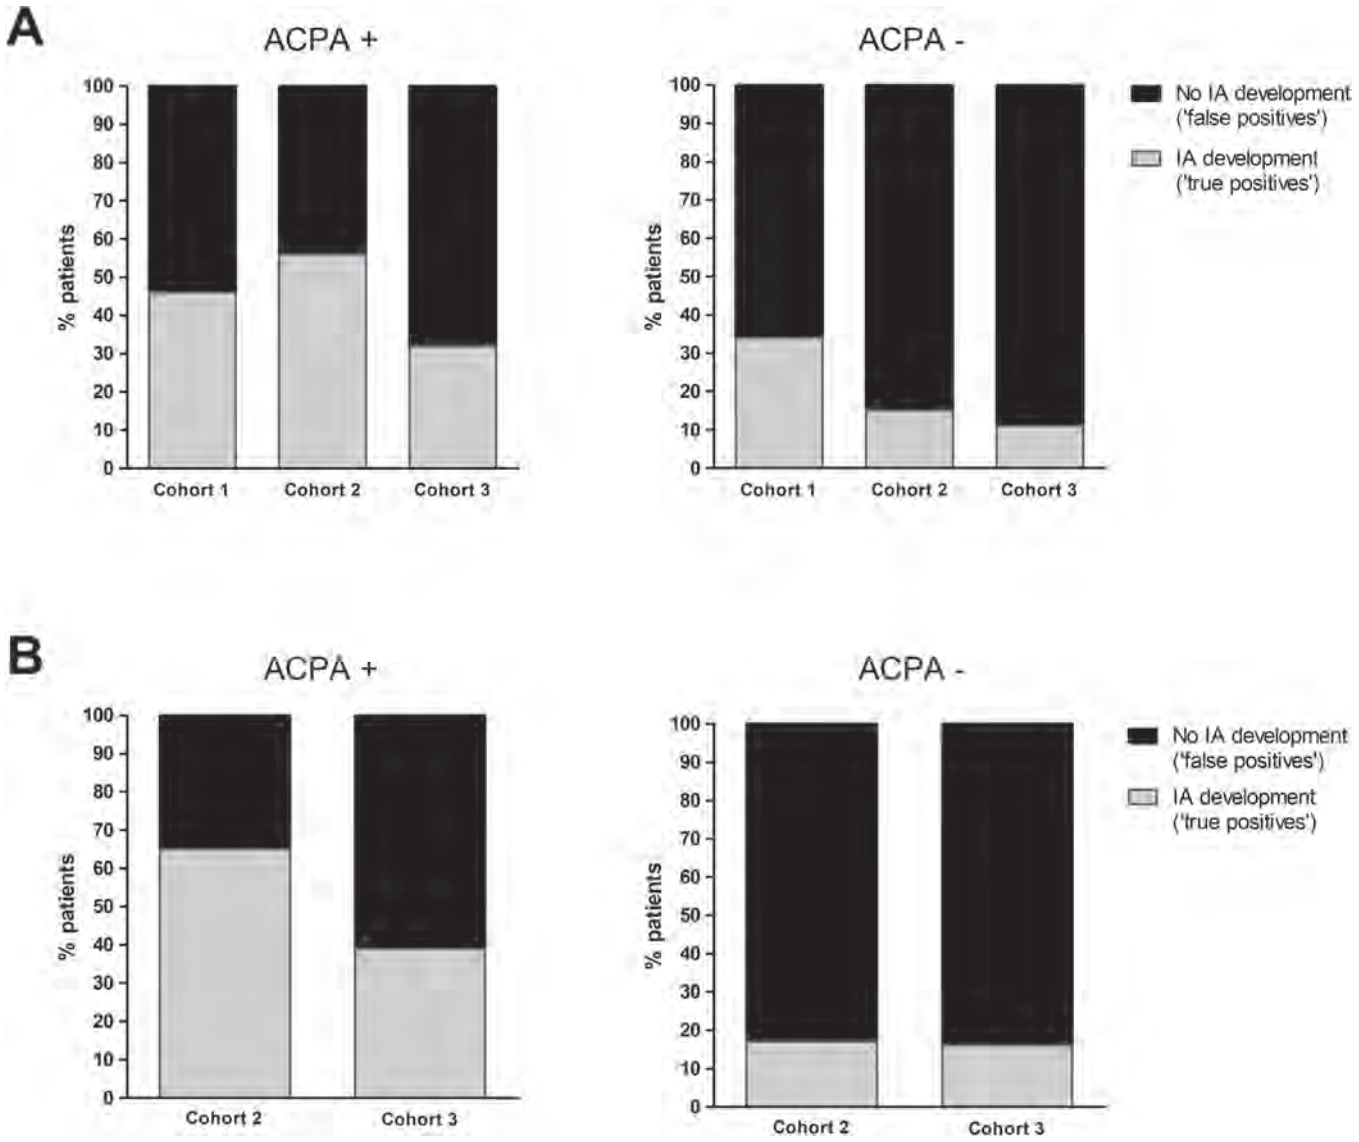

Figure 1 Percentage of arthralgia-patients with subclinical synovitis at baseline that did and did not develop inflammatory arthritis after 1-year (A) and 3-years follow-up (B), stratified for ACPA-status. Legend: (A) Percentage of patients with subclinical synovitis at baseline that did and did not progress to inflammatory arthritis after one year follow-up in three independent cohorts (ACPA-positive patients n=13, n=36, n=31, respectively; ACPA-negative patients n=47, n=157, n=19, respectively). (B) Percentage of patients with subclinical synovitis at baseline that did and did not progress to inflammatory arthritis after three year follow-up, in two independent cohorts (ACPA-positive patients n= 26, n=31, respectively; ACPA-negative patients n=121, n=19, respectively).

Abstract Number: 0482

Differential Influence of CDAI Components Based on Disease State in Rheumatoid Arthritis Patients: Real World Results from a Rheumatoid Arthritis Cohort

Edward C Keystone[1], Mohammad Movahedi[2], Angela Cesta[3], Claire Bombardier[4], John Sampalis[5] and **Emmanouil Rampakakis**[5], [1]Mount Sinai Hospital, Toronto, ON, Canada, [2]Toronto General Hospital Research Institute, University Health Network, Toronto, ON, Canada, [3]Toronto General Hospital Research Institute, Toronto, ON, Canada, [4]Institute for Work and Health, Toronto, ON, Canada, [5]JSS Medical Research, St-Laurent, QC, Canada

SESSION INFORMATION
Session Date: Friday, November 6, 2020
Session Title: RA – Diagnosis, Manifestations, & Outcomes I: Pre-Onset & Early RA
Session Type: Abstract Session
Session Time: 3:00PM–3:50PM

Background/Purpose: Treat-to-target recommendations for rheumatoid arthritis (RA) dictate that remission or low disease activity should be aimed. Although numerous composite indices are available, the clinical disease activity index (CDAI) is commonly used in routine clinical care due to its simplicity and non-reliance on acute phase reactants. The purpose of this analysis was to evaluate the CDAI properties both cross-sectionally and longitudinally in a cohort of RA patients followed in Canadian routine care.

Methods: RA patients enrolled in the Ontario Best Practices Research Initiative (OBRI), with available follow-up for ≥6 months and data on CDAI, disease activity score based on 28 joints (DAS28), health assessment questionnaire (HAQ), and ACR/EULAR Boolean remission were included. For both the CDAI score and its change from baseline to 6 months, construct validity was assessed with principal component analysis, internal consistency with the Cronbach's alpha coefficient (α), correlational validity with the Spearman's rho coefficient, agreement in disease state classification with percent concordant pairs and the kappa statistic. Stratified analysis by presence of CDAI low disease activity (LDA) or remission was performed.

Results: 1,582 patients met the inclusion criteria. Principal component analysis showed that CDAI could be reduced to a single component when CDAI is >10 with SJC28 accounting for most variance in score and patient global assessment (PtGA) the least; whereas, when CDAI is ≤10, two distinct components were identified, the first comprising PtGA and physician global assessment (PhGA) and the second SJC28 and TJC28. In terms of internal consistency, high levels were observed for both CDAI at baseline (α=0.83) and its change from baseline to 6 months (α=0.81); however, the consistency between CDAI components was very low when CDAI is ≤10 (α=0.23).

Overall, a strong positive correlation was observed between CDAI and DAS28 (rho=0.86) and their changes (rho=0.87) while its correlation with HAQ was weak. When stratifying by CDAI levels, the correlation of CDAI with DAS28 was moderate when CDAI is ≤10 and very weak when CDAI is ≤2.8. Similarly, agreement in the classification of LDA between CDAI and DAS28 or HAQ was fair to moderate, and agreement in classification of remission was poor to fair.

Conclusion: CDAI and DAS28 correlate well when disease activity is moderate or high and poorly in LDA or remission. PtGA had a stronger influence on CDAI at LDA or remission state compared to moderate or high disease state. Thus, careful interpretation of PtGA is necessary particularly in patients who are identified as CDAI non-remitters.

SESSION INFORMATION
Session Date: Friday, November 6, 2020
Session Title: RA – Diagnosis, Manifestations, & Outcomes I: Pre-Onset & Early RA
Session Type: Abstract Session
Session Time: 3:00PM–3:50PM

Background/Purpose: COVID-19 mitigation strategies have forced rheumatologists to shift from in-person clinical visits to telemedicine, limiting their ability to carry out complete joint exams needed to score disease activity and provide target based-care for RA patients. The purpose of this study was to estimate agreement between the validated Clinical Disease Activity Index (CDAI), and an alternative patient-based CDAI (PT-CDAI) scored using patient-reported joint counts.

Methods: Data were from early RA patients (sx < 1 year) enrolled in 2 North American prospective cohort studies, CATCH (Canadian early ArThritis CoHort) and CATCH-US (Consortium of early ArThritis Cohorts-USA), from Mar 2017-Jan 2020 and Jan 2015-Feb 2020 with complete data needed to calculate the MD-CDAI and PT-CDAI including concurrently measured patient (PT) and physician (MD) assessed 28-tender and 28-swollen joints counts (28-TJC/28-SJC) using a homunculus, MD and PT global assessments (NRS 0-10) and other PROs (pain, stiffness, fatigue, function and mental health) at baseline, 6- and 12-months follow up. MD-CDAI and PT-CDAI were scored by summing (28-TJC and 28-SJC, MD and PT global assessments) though the former was scored using MD assessed joint counts and the latter with PT assessed joint counts. The established CDAI cut-off of 10 was applied to both scores to classify patients in REM/LDA vs. MDA/HDA disease states. Descriptive statistics were used to summarize and compare baseline cohort characteristics. Bland-Altman plots were used to estimate agreement between the MD-CDAI and the PT-CDAI. Cohen's Kappa was used to estimate agreement between scores at classifying patients into controlled (REM/LDA) vs. active (MDA/ HDA) disease states. Mixed-effects linear regression was used to identify potential predictors of greater discrepancies between MD-CDAI and PT-CDAI.

Results: Baseline characteristics of 358 ERA patients enrolled in CATCH and 102 ERA patients enrolled in CATCH-US are summarized in Table 1. Mean differences in PT vs. MD assessments were lower for swollen than tender joints (Figure). Both studies showed higher agreement at lower ranges of the CDAI and more spread in scores at higher

Data comparing MD / PT joint Counts and MD and PT-CDAI are from all visits (baseline, 6 months, 12 months combined, mean (SD))
Active RA is defined using MD-CDAI DA states combining those who are in moderate and high disease activity (MDA/HDA) and controlled RA as those in low disease activity and remission (LDA/REM)

Table 2. Comparisons of MD vs. PT Joint Counts and CDAI Scores

in mixed-effects linear regression were greater tender joints and worse stiffness in CATCH and tender joints, obesity and male sex in CATCH-US.

Conclusion: The newly calculated PT-CDAI had good agreement with the MD-CDAI at identifying active vs. controlled RA disease activity. Results suggested that PT-based swollen joints were more consistent with MD assessments than PT tender joint counts. Moreover, predictors of higher discrepancies between PT-CDAI and MD-CDAI may help identify patient subsets that could benefit most from more MD guided training at joint self-assessments and/or more probing questioning during a telehealth visit to confirm active synovitis. Although there are other validated PROs to assess disease activity, none directly assess joint involvement which is critical to informing treatment decisions.

SESSION INFORMATION
Session Date: Friday, November 6, 2020
Session Title: RA – Diagnosis, Manifestations, & Outcomes II: The Heart of the Matter
Session Type: Abstract Session
Session Time: 4:00PM–4:50PM

Background/Purpose: Paraoxonase 1 (PON1) is a high-density lipoprotein (HDL)-associated enzyme with paraoxonase, lactonase, and arylesterase activities. PON1 contributes to the antioxidant properties of HDL, and is being investigated for its atheroprotective properties.[1] Patients (pts) with RA that are homozygous for the RR genotype of the Q192R gene polymorphism on PON1 (rs662) have increased paraoxonase activity, and a lower risk of carotid plaques, vs those with QQ or QR genotypes.[2] Tofacitinib is an oral Janus kinase inhibitor for the treatment of RA. This post hoc analysis investigated the relationship between PON1 genotype/activity and risk of major adverse cardiovascular events (MACE) in the tofacitinib RA clinical program.

Methods: Data were pooled from pts enrolled in nine Phase 2/3 studies of tofacitinib in RA. Enzyme activities in pt plasma samples were measured at individual study baseline (BL) and at follow-up visits using three substrates: paraoxon (paraoxonase activity), dihydrocoumarin (lactonase activity), and phenylacetate (arylesterase activity). The effect of the PON1 Q192R genotype (QQ, QR, or RR) on BL paraoxonase/lactonase/arylesterase activity was determined using linear regression for each study with age and sex as covariates, and then fixed-effect meta-analysis assessed effects across studies. The risk of MACE by enzyme activity was determined using Cox proportional hazards regression stratified by clinical studies. Univariate regression against BL enzyme activity and other risk factors, as well as both minimally and fully adjusted multivariable regressions against time-varying enzyme activity, are presented.

Results: The analysis included 1,969 pts with RA who received ≥ 1 dose of tofacitinib and had PON1 activity measures available at BL; 39 pts had ≥ 1 MACE event. Compared with the QQ genotype, the RR genotype had a highly significant positive association with BL paraoxonase activity, and a highly significant negative association with BL

Figure 1

lactonase and arylesterase activity (Figure 1). A univariate analysis identified several BL covariates significantly associated with risk of MACE (Figure 2a). Time-varying models found a highly significant association of increased paraoxonase activity over time with lower risk of future MACE, even after controlling for low-density lipoprotein or HDL cholesterol levels, and other traditional cardiovascular (CV) risk factors identified in univariate analysis (Figure 2b), with similar findings for lactonase and arylesterase (data not shown).

Conclusion: Higher activity of the HDL-associated protein, PON1, over time was associated with a significantly reduced risk of future MACE in pts with RA receiving tofacitinib, after controlling for traditional CV risk factors and cholesterol levels. Further investigation of PON1 as a novel functional lipid biomarker to assess CV risk in RA pts is warranted.

*p≤0.05, **p<0.01, ***p<0.001
[a]All paraoxonase activities were standardized (mean = 0, SD = 1); [b]All lipids were log transformed and standardized (mean = 0, SD = 1); [c]All lipids analyzed were time-varying, log transformed and then standardized (mean = 0, SD = 1).
Risk of MACE by BL enzyme activity was determined using Cox proportional hazards regression stratified by clinical studies. BL univariate regression models included BL paraoxonase/lactonase/arylesterase activities and pt demographic/disease characteristics. Time-varying univariate regression models included time-varying PON1 activity. Minimally and fully adjusted multivariable regression models included time-varying PON1 activity and additional covariates of significance/interest in univariate models.
After FDR multiplicity adjustment, age, BMI, diabetes mellitus, and smoking status were significant or nominally significant and included in the fully adjusted model; tofacitinib dose was also included. Heterogeneity was measured using the Cochran Q test. In the event of significant heterogeneity, random-effect (DerSimonian and Laird) meta-analysis was also conducted.

Abstract Number: 0485

Non-obese Rheumatoid Arthritis Patients with Low Low-density Lipoprotein Have Higher Coronary Atherosclerosis Burden, Greater Plaque Progression and Cardiovascular Event Risk

George Karpouzas[1], Sarah Ormseth[1], Elizabeth Hernandez[1] and Matthew Budoff[1], [1]Harbor-UCLA Medical Center and the Lundquist Institute, Torrance, CA

SESSION INFORMATION
Session Date: Friday, November 6, 2020
Session Title: RA – Diagnosis, Manifestations, & Outcomes II: The Heart of the Matter
Session Type: Abstract Session
Session Time: 4:00PM–4:50PM

Background/Purpose: RA patients with low body weight incur higher mortality than obese patients. Paradoxically, RA patients in the lowest low-density lipoprotein group (LDL < 70 mg/dl) also experience unexpectedly high cardiovascular disease (CVD) risk. We here explored whether abdominal obesity (waist-to-height ratio >0.58 in females and >0.63 in males) might moderate the effect of low LDL (< 70mg/dl) on coronary atherosclerosis burden, progression and long-term CVD event risk in RA.

Methods: One hundred fifty patients without symptoms or diagnosis of CVD underwent coronary computed tomography angiography. Plaque progression was evaluated 6.9±0.3 years later in 101 patients. Coronary artery calcium, number of segments with plaque (segment involvement score), and extensive (>4 segments with plaque) or obstructive disease (>50% stenosis) were assessed. CVD events were prospectively recorded, including cardiac death, myocardial infarction, unstable angina, revascularization, stroke, claudication, and heart failure hospitalization over 6.0±2.4 years of follow-up. Lipoprotein classes were directly measured. Oxidized LDL (oxLDL) was assessed with monoclonal antibody E06. Adjusted robust linear regression evaluated interactions between abdominal obesity and LDL groups on plaque outcomes. Per segment, adjusted robust logistic regression models explored obesity x LDL group interactions on new plaque formation and stenotic progression of prevalent plaques. Robust Cox regression models stratified by abdominal obesity evaluated the effect of LDL group (< 70 vs. >70mg/dl) on CVD events.

Results: Non-obese patients with low LDL had the highest plaque burden (Figure 1A, all $p < 0.02$). Obesity further moderated the effect of LDL on likelihood of extensive/obstructive disease (*P* for interaction = 0.061); specifically, LDL< 70 associated with an increased likelihood of extensive/obstructive plaque in non-obese (adjusted OR 4.75 [95% CI 1.18-19.07], *P* = 0.028) but not obese patients (adjusted OR 1.55 [95% CI 0.39-6.08], *P* = 0.532). No differences in disease activity or inflammatory markers were seen across groups. Compared to LDL >70 mg/dl, low LDL predicted an increased likelihood of high oxLDL (>median) in non-obese patients (adjusted OR 5.10 [95% CI 1.46-17.75], *P* = 0.011) but not obese patients (adjusted OR 0.50 [95% CI 0.11-2.21], *P* = 0.36). In non-obese patients, low LDL further associated with a greater likelihood of plaque forming in coronary segments without baseline plaque (adjusted OR 4.68 [95% CI 2.26-9.66], *P* < 0.001) and worsening stenotic severity in segments with prevalent plaque (OR 5.35 [95% CI 1.62-17.67], *P* = 0.006). This was not observed in obese patients (Figure 1B). Notably, in non-obese patients, low LDL associated with higher CVD event risk compared to those with LDL >70 mg/dl (HR 7.94 [95% CI 1.52-41.36], *P* = 0.015). This was not the case in obese patients (HR 0.32 [95% CI 0.04-2.40], *P*= 0.27, Figure 1C).

Conclusion: In non-obese RA patients, LDL< 70 mg/dl may reflect higher LDL oxidation and was associated with higher baseline coronary atherosclerosis burden, new plaque formation, stenotic plaque progression and greater CVD risk than LDL >70 mg/dl.

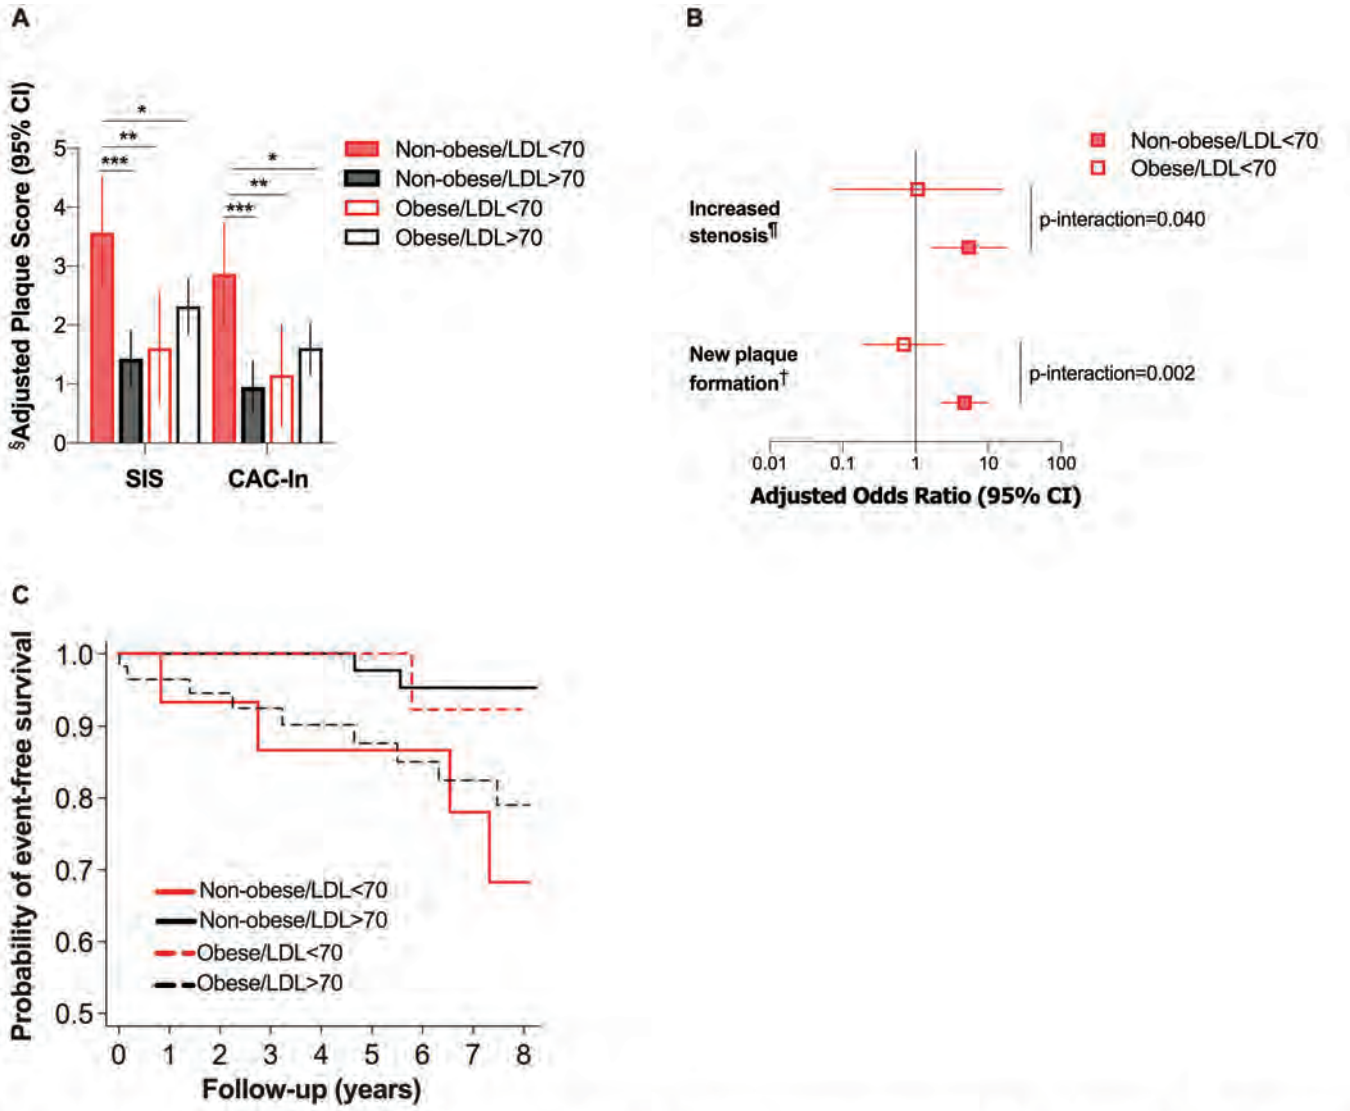

Figure 1. Abdominal obesity moderates the effect of low LDL (<70mg/dl) on **(A)** coronary atherosclerosis burden at baseline. §Model adjusted for age, gender, diabetes and statin use. **(B)** Effect on coronary plaque progression over time. ¶Stenotic severity model adjusted for age, time between scans, segment location, time-averaged CRP, prednisone dose and statin duration. †New plaque formation model adjusted for age, time between scans, segment location, prednisone dose, statin duration and bDMARD duration. **(C)**. Differences in Low-density Lipoprotein (LDL) Particle Composition and Oxidation May Underlie the Paradoxical Association of Low LDL with Higher Coronary Atherosclerosis Burden in Rheumatoid Arthritis

George Karpouzas[1], Sarah Ormseth[1], Elizabeth Hernandez[1] and Matthew Budoff[1], [1]Harbor-UCLA Medical Center and the Lundquist Institute, Torrance, CA

SESSION INFORMATION
Session Date: Friday, November 6, 2020
Session Title: RA – Diagnosis, Manifestations, & Outcomes II: The Heart of the Matter
Session Type: Abstract Session
Session Time: 4:00PM–4:50PM

Background/Purpose: Rheumatoid arthritis (RA) patients in the lowest LDL group (< 70mg/dl) experience unexpectedly high cardiovascular risk. We first explored whether this group (Group 1) had higher coronary atherosclerosis burden compared to other LDL groups (Group 2: 70≤ LDL ≤130 and Group 3: LDL >130). We then evaluated whether differences in LDL particle composition, oxidation, or inflammation associated with low LDL in Group 1.

Methods: One hundred fifty RA patients without cardiovascular disease underwent coronary atherosclerosis evaluation with computed tomography angiography. Coronary artery calcium, number of segments with plaque (segment involvement score), stenotic severity (segment stenosis score), and extensive (>4 segments with plaque) or obstructive disease (>50% stenosis) were assessed. Lipoprotein classes and subclasses were directly measured. Oxidized LDL (oxLDL) was measured with monoclonal antibody E06. Chemiluminescence Elisa quantified IgG and IgM antibodies to oxLDL (anti-oxLDL) and apoB100 immune complexes. Proinflammatory cytokines were measured with Erenna Immunoassay. Robust linear and logistic regression models- adjusted for Framingham D'Agostino score and statin treatment- evaluated associations between LDL groups and plaque outcomes. Similar models evaluated adjusted differences in LDL subclasses, oxLDL, anti-oxLDL, ApoB100 immune complexes, and cytokines across LDL groups.

Results: Patients in Group 1 had higher coronary plaque burden (Figure 1A) and 2.8 times greater likelihood of extensive or obstructive disease (adjusted OR 2.82 [95% CI 1.12-7.17], *P* = 0.031) compared to LDL >70 groups. Group 1 had higher anti-oxLDL IgG and ApoB100 IgG immune complexes compared to other groups (Figure 2A). Among statin naïve patients, those with LDL< 70 also had higher oxLDL (Log transformed EMM 2.55 [95%CI 2.34-2.77] vs.

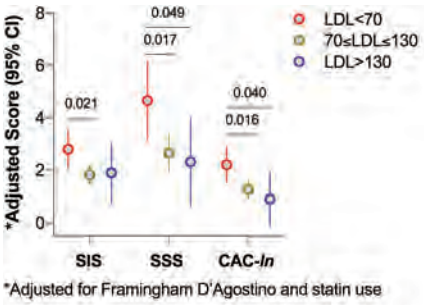

Figure 1. Coronary atherosclerosis burden across different LDLgroups. SIS=segment involvement score, SSS= segment stenosis score, CAC-ln=log-transformed coronary artery calcium score.

Figure 1. Coronary attherosclerosis burden across different LDLgroups. SIS=segment involvement score, SSS= segment stenosis score, CAC-ln=log-transformed coronary artery calcium score.

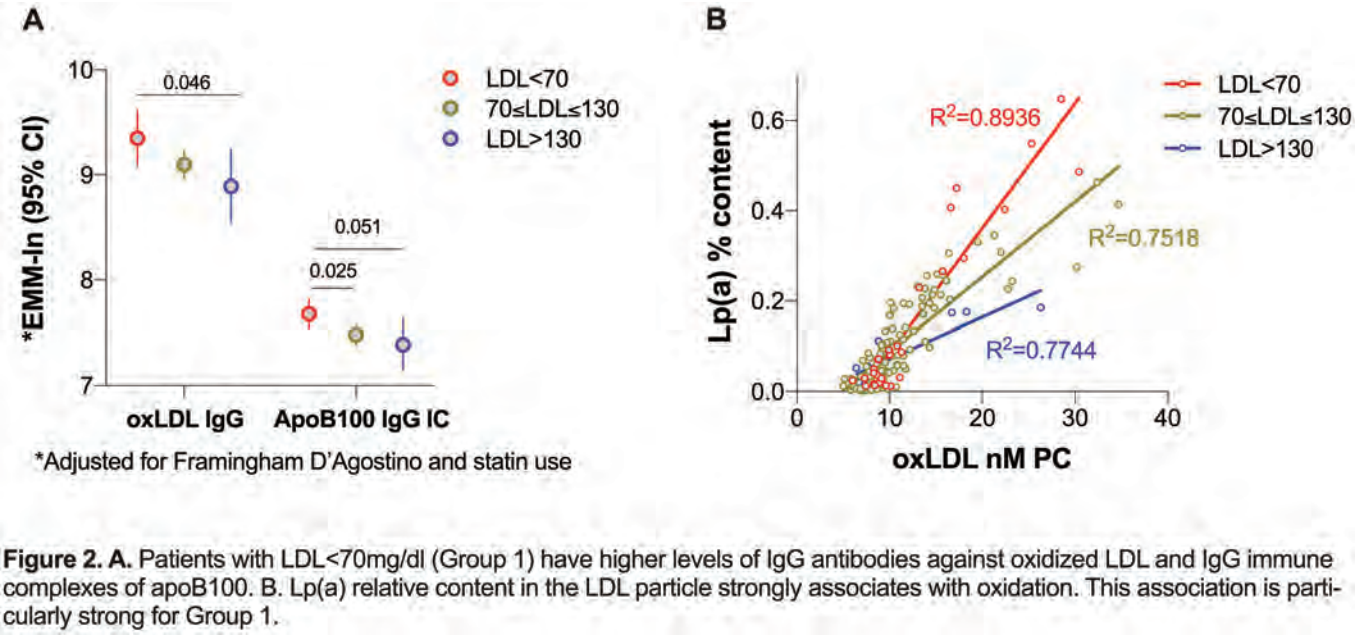

Figure 2. A. Patients with LDL<70mg/dl (Group 1) have higher levels of IgG antibodies against oxidized LDL and IgG immune complexes of apoB100. B. Lp(a) relative content in the LDL particle strongly associates with oxidation. This association is particularly strong for Group 1.

Figure 2. A. Patients with LDL<70mg/dl (Group 1) have higher levels of IgG antibodies against oxidized LDL and IgG immune complexes of apoB100. B. Lp(a) relative content in the LDL particle strongly associates with oxidation. This association is parti- cularly strong for Group 1.

2.27 [95%CI 2.19-2.36], P = 0.018 for LDL >70). LDL subclass relative content in the LDL particle differed across groups. Lp(a) was higher in LDL particles in Group 1 (EMM 16.04% [95% CI 11.75-20.33], vs. 10.48% [95% CI 8.20-12.75] in Group 2, p = 0.026 and 7.41% [95% CI 0.77-14.04] in Group 3, p = 0.033). Notably, Lp(a) content strongly associated with oxLDL overall (r = 0.83, p< 0.0001). This association was stronger for Group 1 compared to others (p< 0.005, Figure 2B). No differences in RA activity, CRP, TNF-α, IL-17A, or IL-17F were seen across groups. However, Group 1 had higher IL-6 (log-transformed EMM= 1.98 [95% CI 1.64- 2.32] vs. 1.57 [1.45-1.70],*P* = 0.028 in Group 2 and 1.32 [95% CI 0.84-1.80],

P = 0.031 in Group 3). IL-6 associated with both IgG anti-oxLDL (p=0.015) and apoB100 immune complexes (p=0.016). IL-6 further associated with higher CAC (adjusted B 0.41 [95% CI 0.01-0.81], *P*= 0.049).

Conclusion: RA patients with LDL< 70 had higher coronary atherosclerosis burden. Low circulating LDL in that group may reflect higher oxidation; this was mostly linked to the larger Lp(a) relative content of LDL and its significantly higher oxidation potential in that group. Greater oxLDL further associated with higher IL-6 elaboration which may in turn augment atherosclerosis burden in Group1.

Abstract Number: 0487

Association Between an Extended Lifestyle Score and Adverse Health-related Outcomes in People with Rheumatoid Arthritis: A Study of 5295 UK Biobank Participants

Jordan Canning[1], Stefan Siebert[2], Bhautesh Jani[1], Frances Mair[1] and Barbara Nicholl[1], [1]University of Glasgow, Glasgow, Scotland, United Kingdom, [2]University of Glasgow, Glasgow, United Kingdom

SESSION INFORMATION
Session Date: Friday, November 6, 2020
Session Title: RA – Diagnosis, Manifestations, & Outcomes II: The Heart of the Matter
Session Type: Abstract Session
Session Time: 4:00PM–4:50PM

Background/Purpose: Rheumatoid arthritis (RA) is a chronic autoimmune disorder characterised by inflammation of the synovial joints. Traditional lifestyle factors, such as smoking and poor diet, have been associated with adverse outcomes in people with RA. However, the effect of emerging lifestyle factors, such as sleep duration and sedentary behaviour, remain unclear as does their combined effect. We examined the association between an extended lifestyle score (based on traditional and emerging lifestyle factors) and all-cause mortality and major adverse cardiac events (MACE) in an RA population.

Methods: Data were sourced from the population-based cohort, UK Biobank (N = 502,503). Data were collected from 2006 to 2010 and linked to mortality and hospital admissions records. Participants with RA were assigned one point for each unhealthy lifestyle behaviour: frequent alcohol intake, four poor dietary habits (low fruit and vegetable or oily fish intake, and high processed or red meat intake), physical inactivity, short/long sleep duration, current smoker and prolonged television viewing time, giving a lifestyle score of 0-9. Participants were categorised as most healthy (score 0-2), moderately healthy (score 3-5) and least healthy lifestyle (score 6-9). Cox proportional hazards models were used to examine the association between lifestyle score categories and all-cause mortality and MACE (including myocardial infarction and stroke). All analyses were adjusted for age, sex, socioeconomic status, body mass index and other long-term conditions count.

Results: 5295 participants with RA and a lifestyle score (aged between 40 and 70; mean age (SD) 59.19 (7.10); 69.97% Female) were included in this study. There were 390 deaths and 290 MACE recorded. The adjusted hazard ratio (HR) for all-cause mortality in the least healthy category, compared with the most healthy (reference) category, was 2.42 (95% confidence interval (CI) 1.42-4.12) and 2.04 (95% CI 1.03-4.06) for MACE. The adjusted HR in the moderately healthy category, compared with the most healthy (reference) category, was 1.23 (95% CI 0.99-1.51) for all-cause mortality and 1.39 (95% CI 1.09-1.77) for MACE.

Conclusion: Combinations of unhealthy lifestyle factors are associated with higher risk of adverse health-related outcomes in people with RA. People in the least healthy category experience over twice the risk of all-cause mortality or MACE compared to those in the most healthy category. Examining the impact of combined traditional and emerging lifestyle factors may inform health policy reducing avoidable adverse health-related outcomes.

Incidence of Dementia in Patients with Rheumatoid Arthritis and Association with DMARDs – Analysis of a National Claims Database

Sebastian Sattui[1], Iris Navarro-Millan[2], Fenglong Xie[3], Mangala Rajan[2], Huifeng Yun[4] and Jeffrey R Curtis[4], [1]Hospital for Special Surgery, New York, NY, [2]Weill Cornell Medicine, New York, [3]University of Alabama at Birmingham, Birmingham, AL, [4]Division of Clinical Immunology and Rheumatology, University of Alabama at Birmingham, Birmingham, AL

SESSION INFORMATION

Session Date: Friday, November 6, 2020

Session Title: RA – Diagnosis, Manifestations, & Outcomes II: The Heart of the Matter

Session Type: Abstract Session

Session Time: 4:00PM–4:50PM

Background/Purpose: There is growing interest regarding the role of neuroinflammation in the development of dementia and the potential role for anti-inflammatory therapy, including TNF-inhibitors (TNFi), in its prevention. Previous studies suggest that inflammatory diseases like rheumatoid arthritis (RA) can increase risk for dementia, yet the effect of DMARDs on reducing this risk is unclear. The objective of this study was to evaluate the risk of incidence dementia associated with the use of biologics or targeted synthetic DMARDs (b/tsDMARD) compared to csDMARDS only in RA patients.

Methods: This longitudinal analysis used 2006-2017 Medicare claims data. Patients must have had continuous enrollment >12 months in Medicare Part A, B, and D, be ≥40 years old and have no prior diagnosis of dementia. RA

Characteristics	Incident Dementia During Follow-up Period	
	No N = 229,477	Yes N = 3794
Age, years, n (%)		
40-54	30,774 (13.4)	56 (1.5)
55-64	40,280 (17.6)	212 (5.6)
64-74	107,873 (47.0)	1,346 (35.5)

*Define as history myocardial infarction, heart failure, stroke, peripheral vascular disease, history of coronary artery bypass graft, history of percutaneous coronary intervention and history of carotid endarterectomy. ** Defined as hypertension, diabetes mellitus, hyperlipidemia, obesity.
ACEI = angiotensin converting enzyme inhibitor; ARB = angiotensin receptor blocker.

Table 1. Characteristics of Patients with RA and Incident Dementia

RA Medication	N	No. of events	Person years	Crude IR per 100 person-years (95% CI)	Crude HR (95% CI)	Adjusted HR (95% CI)*
csDMARDs	121,010	1711	85,268.0	2.0 (1.9-2.1)	REF	REF
b/tsDMARDS	112,261	2083	159,809.3	1.3 (1.2-1.4)	0.63 (0.59-0.67)	0.83 (0.78-0.89)
TNFi-bDMARDs	62,717	1210	91,115.1	1.3 (1.3-1.4)	0.64 (0.59-0.69)	0.88 (0.81-0.94)
Non-TNFi-bDMARDs	42,667	816	62,167.9	1.3 (1.2-1.4)	0.63 (0.58-0.69)	0.78 (0.72-0.85)
tsDMARDs	6877	57	6256.4	0.9 (0.7-1.1)	0.46 (0.35-0.59)	0.68 (0.52-0.89)

* Adjusted for age, sex, race, cardiovascular disease, cardiovascular risk factors, cardiovascular medications, any hospitalizations, number of physician visits, dual eligibility and original reason for Medicare enrollment.

Table 2. Events, person-years, crude, and age-adjusted incidence rates (IRs), and crude and adjusted hazard ratios (HRs) for incident dementia

defined as: two RA diagnoses (ICD-9-CM 714.xx/ICD-10 M0.5.x or M06.x) by a rheumatologist > 7 and < 365 days apart. Patients had to meet RA definition on or before DMARD initiation. Person-time was classified as either: 1) b/tsDMARD exposed, which included TNFi-bDMARDs, non-TNFi-bDMARDs or tsDMARDs with or without csDMARDs; 2) csDMARD-exposed: any csDMARD without b/tsDMARD. Patients could contribute time to different exposure groups if they changed medications. Incident dementia was defined as: 1 inpatient claim for dementia (ICD-9-CM codes for 290.xx, 294.1x, or 331.xx and ICD-10 codes for F00.x, F01.x, F03.x,G30.x, G31.x) OR 2 outpatient claims for dementia OR prescription of a dementia specific medication (rivastigmine, galantamine, memantine, donepezil, tacrine). Incidence rates (IR) were estimated using Poisson models. Cox proportional hazard models (HR) were used to examine the risk for incident dementia among patients receiving b/tsDMARDs compared to those receiving csDMARD, adjusting for the competing risk of death. A sensitivity analysis was done that re-grouped the b/tsDMARD category as TNFi-bDMARDs, non-TNFi-bDMARDs and tsDMARDs.

Results: We identified 141,326 eligible RA patients; 80% female and 75.3% white, median age 67 years and a mean (SD) exposure time of 1.1 (1.5) years. Censoring events included incident dementia, death, change in bDMARD and discontinuation of fee for service. There were 233,271 initiations of c/b/tsDMARDS and 3,794 events of incident dementia (Table 1). The crude IR of dementia was 2.0 (95% CI 1.9-2.1) per 100 person-years for patients on csDMARDs and 1.3 (95% CI 1.2-1.4) for patients on any bDMARD (Table2). Patients on b/tsDMARDs had an adjusted 17% lower risk for dementia than patients on csDMARDs [HR 0.83 (95% CI 0.78-0.89)]. Sensitivity analysis found comparable risks between TNFi, non-TNFi, and tsDMARDs on the risk of dementia (Table 2).

Conclusion: The incidence of dementia in patients with RA was lower in patients receiving b/tsDMARDs when compared to patients on csDMARD only. No differences were observed between different classes of b/tsDMARDs, suggesting that decreased risk is possibly explained by the overall decrease in inflammation rather than a specific mechanism of action.

Abstract Number: 0489

Prevalence, Incidence, and Cause-Specific Mortality of Rheumatoid Arthritis-Associated Interstitial Lung Disease Among Older Patients with Rheumatoid Arthritis: A Nationwide Cohort Study

Jeffrey Sparks[1], Yinzhu Jin[1], Soo-Kyung Cho[2], Seanna Vine[1], Rishi Desai[1], Tracy J. Doyle[3] and Seoyoung Kim[1], [1]Brigham and Women's Hospital, Boston, MA, [2]Hanyang University Hospital for Rheumatic Diseases, Seoul, Republic of Korea, [3]Brigham and Women's Hospital, West Roxbury, MA

SESSION INFORMATION
Session Date: Friday, November 6, 2020
Session Title: RA – Diagnosis, Manifestations, & Outcomes III: Major Comorbidities in RA
Session Type: Abstract Session
Session Time: 5:00PM–5:50PM

Background/Purpose: Rheumatoid arthritis-associated interstitial lung disease (RA-ILD) is one of the most serious extra-articular RA manifestations and is more common in older patients. Registry-based RA-ILD studies have been limited to investigate incident RA-ILD and cause-specific mortality due to small sample size. Previous nationwide studies were limited due to the previous lack of a validated RA-ILD algorithm in administrative data. Therefore, we aimed to investigate prevalence, incidence, and cause-specific mortality of RA-ILD using a recently validated claims-based algorithm.

Methods: We performed a retrospective cohort study using US nationwide claims data from Medicare (2008-2017). RA was identified using a previously validated algorithm (2+ ICD-9/10 codes for RA separated by 7+ days and DMARD prescription [PPV 86%]; RA date [index date] was the date these criteria were met). RA-ILD was identified using a recently validated algorithm (2+ ICD-9/10 codes for ILD by a rheumatologist or pulmonologist separated by 7+ days [PPV 72%]; ILD date was the 2nd ILD code). We identified prevalent RA-ILD and covariates as of 365 days prior to index date. Among RA without ILD at baseline, Cox regression estimated HRs for incident RA-ILD by baseline covariates. We compared the risk for total mortality between patients with RA-ILD to RA without ILD using multivariable Cox regression adjusting for baseline covariates. For cause-specific mortality, Fine and Gray subdistribution hazard ratios (sdHR) were estimated to handle competing risks of alternative causes of mortality.

Results: Among a total of 509,787 patients with RA in Medicare (mean age 72.6 years; 76.2% female), 10,306 (2.0%) had prevalent RA-ILD at initial RA observation. Among RA without ILD at baseline, 13,372 (2.6%) developed RA-ILD during 1,873,127 person-years of follow-up (median 3.0 years/person). The incidence rate of RA-ILD was 7.14 per 1,000 person-years. Several baseline factors were associated with incident RA-ILD: male sex (HR 1.31, 95%CI 1.26-1.36), smoking (HR 1.35, 95%CI 1.29-1.41), biologic/targeted DMARD use (HR 1.34, 95%CI 1.29-1.40), and glucocorticoid use (HR 1.45, 95%CI 1.39-1.50, Table 1). During follow-up, 38.7% of RA-ILD died compared to 20.7% of RA without ILD (unadjusted HR 2.36, 95%CI 2.28-2.45). After multivariable adjustment that included confounders and possible mediators (such as comorbidities after RA-ILD onset), the association of RA-ILD with total mortality remained significant (HR 1.66, 95%CI 1.60-1.72, Table 2). Accounting for competing risk of other causes of death, RA-ILD had a sdHR of 4.39 (95%CI 4.13-4.67) for respiratory mortality and a sdHR of 1.56 (95%CI 1.43-1.71) for cancer mortality compared to RA without ILD.

Baseline characteristic	Incident RA-ILD cases	Person-years	RA-ILD incidence rate*	Incidence rate* 95% CI	Multivariable** HR (95%CI)

RA without ILD	1.00 (Ref)	1.00 (Ref)	1.00 (Ref)	1.00 (Ref)	1.00 (Ref)	1.00 (Ref)
RA-ILD	1.66 (1.60-1.72)	1.01 (0.93-1.09)	1.56 (1.43-1.71)	4.39 (4.13-4.67)	1.19 (0.97-1.45)	1.30 (1.21-1.40)

*Adjusted for age, sex, US region, smoking, methotrexate use, hydroxychloroquine use, tumor necrosis factor inhibitor use, other biologic or targeted DMARD use, glucocorticoid use, combined comorbidity score, and number of physician visits.

Table 2. Hazard ratios (HRs) for total mortality and subdistribution hazard ratios (sdHRs) for cause-specific mortality comparing RA-ILD to RA without ILD in Medicare (n=509,787).

Conclusion: RA-ILD was present or developed in nearly 5% in this nationwide study of older patients with RA. RA-ILD was associated with excess total mortality that was not explained by measured factors. Male sex, smoking, biologic/targeted DMARD use, and glucocorticoid use were associated with incident RA-ILD. RA-ILD was strongly associated with increased respiratory mortality compared to RA without ILD. The novel association of RA-ILD with increased cancer mortality requires further investigation.

SESSION INFORMATION

Session Date: Friday, November 6, 2020

Session Title: RA – Diagnosis, Manifestations, & Outcomes III: Major Comorbidities in RA

Session Type: Abstract Session

Session Time: 5:00PM–5:50PM

Background/Purpose: Seropositivity for anti-citrullinated protein antibodies (ACPA) has been shown to increase risk for RA-associated interstitial lung disease (RA-ILD). However, RA-related autoantibodies used in clinical care are unable to accurately predict future RA-ILD. Previous investigations of specific ACPA and RA-ILD were cross-sectional and had inconsistent results. Therefore, we aimed to investigate fine specificity ACPA and subsequent risk of RA-ILD.

Methods: We performed a nested case-control study among patients with RA in a single center prospective registry. Three radiologists/pulmonologists confirmed RA-ILD through research review of the images of chest computed tomography imaging (index date). We matched each incident RA-ILD case to three RA controls (without patient/physician report or billing codes for ILD) on age, sex, RA duration, rheumatoid factor (RF) status, and time from blood draw to index date. Reactivities to three isotypes of 26 different fine specificity ACPA were measured from serum using a previously developed multiplex bead-based platform. The primary analysis investigated log-transformed levels of IgG ACPA. Secondary analyses considered IgA1 and IgA2 isotypes. Covariates at time of blood draw included smoking pack-years, BMI, and RA clinical factors. Conditional logistic regression estimated ORs for RA-ILD, adjusting for matching factors and covariates. We accounted for multiple comparisons using a 10% false discovery rate.

Results: We identified 84 incident RA-ILD cases and 243 RA controls without ILD. Mean age was 65.8 years, 79.2% were female, 89.0% were seropositive for ACPA/RF, and median RA duration was 19 years. Blood was drawn a medi-

	IgG ACPA biomarker by targeted protein and epitope position	OR (95%CI) per log-transformed unit conditioned on matching factors[1]	Multivariable[2] OR (95%CI) per log-transformed unit

[1]All models were conditioned on matching factors (age, sex, RA duration, RF status, and time from blood draw to index date).
[2]Additionally adjusted for smoking pack-years (continuous) and body mass index (continuous).

Table 1. Associations of log-transformed IgG fine specificity ACPA with incident RA-ILD in 84 RA-ILD cases and 243 RA controls without ILD.

an of 1.7 years prior to the index date of RA-ILD. After accounting for multiple comparisons, four IgG ACPA biomarkers were significantly associated with subsequent risk of RA-ILD (Table 1). Filaggrin_48_65_cit2_cyclic was strongly associated with increased risk for incident RA-ILD (multivariable OR 3.08 per each log-transformed unit, 95%CI 1.63-5.84) adjusted for matching factors, smoking pack-years, and BMI. Clusterin_231_250_cit_cyclic (OR 1.24, 95%CI 1.04-1.48), fibronectin_cit_1035_1036 (OR 1.20, 95%CI 1.02-1.42), and H4_33_48_cit39_40 (OR 1.23, 95%CI 1.04-1.46) were also associated with incident RA-ILD. The association of filaggrin_48_65_cit2_cyclic with RA-ILD was also observed in the IgA1 (OR 1.83, 95%CI 1.03-3.26) and IgA2 (OR 4.36, 95%CI 1.13-16.90) isotype analyses.

Conclusion: We identified several fine specificity ACPA associated with subsequent risk of RA-ILD that may inform pathogenesis. In particular, autoimmunity to a specific citrullinated epitope of filaggrin was associated with RA-ILD across all isotypes investigated and is potentially a novel predictive biomarker for RA-ILD. External replication is in process, but these results suggest that fine specificity ACPA biomarkers may have utility in RA-ILD prediction.

Session Date: Friday, November 6, 2020

Session Title: RA – Diagnosis, Manifestations, & Outcomes III: Major Comorbidities in RA

Session Type: Abstract Session

Session Time: 5:00PM–5:50PM

Background/Purpose: Established pulmonary manifestations of RA include restrictive processes such as interstitial lung disease and obstructive processes such as bronchiectasis, but clinically detected forms of these diseases are relatively uncommon. Emerging research suggests that airways disease may be common in RA and not explained by smoking. However, prior studies investigating the relationship of RA with restriction or obstruction were limited by small sample size, insufficient smoking data, or lack of a control group without RA. Therefore, we aimed to investigate the relationship of RA with type and severity of pulmonary function test (PFT) abnormalities compared to the general population, accounting for smoking.

Methods: We performed a cross-sectional study investigating the association of RA and PFT abnormalities among subjects who had PFTs performed for research purposes in the UK Biobank. RA cases were identified by self-report and current DMARD use (as previously published in this dataset). We compared RA cases to general population controls in the UK Biobank that denied RA and other systemic rheumatic disease. Outcomes were: continuous PFT results, type of PFT abnormality (restrictive pattern, obstructive pattern, and either abnormality), and level of severity (mild, moderate, and severe) according to standard clinical PFT cutpoints from population prediction equations. Covariates included age, sex, smoking status, and pack-years. We used linear regression to compare RA cases to

CI, confidence interval; FEV_1, forced expiratory volume in 1 second; FVC, forced vital capacity; OR, odds ratio; RA, rheumatoid arthritis.

Table 2. Odds ratios for pulmonary function test abnormalities, comparing rheumatoid arthritis to general population controls (n=319,288).

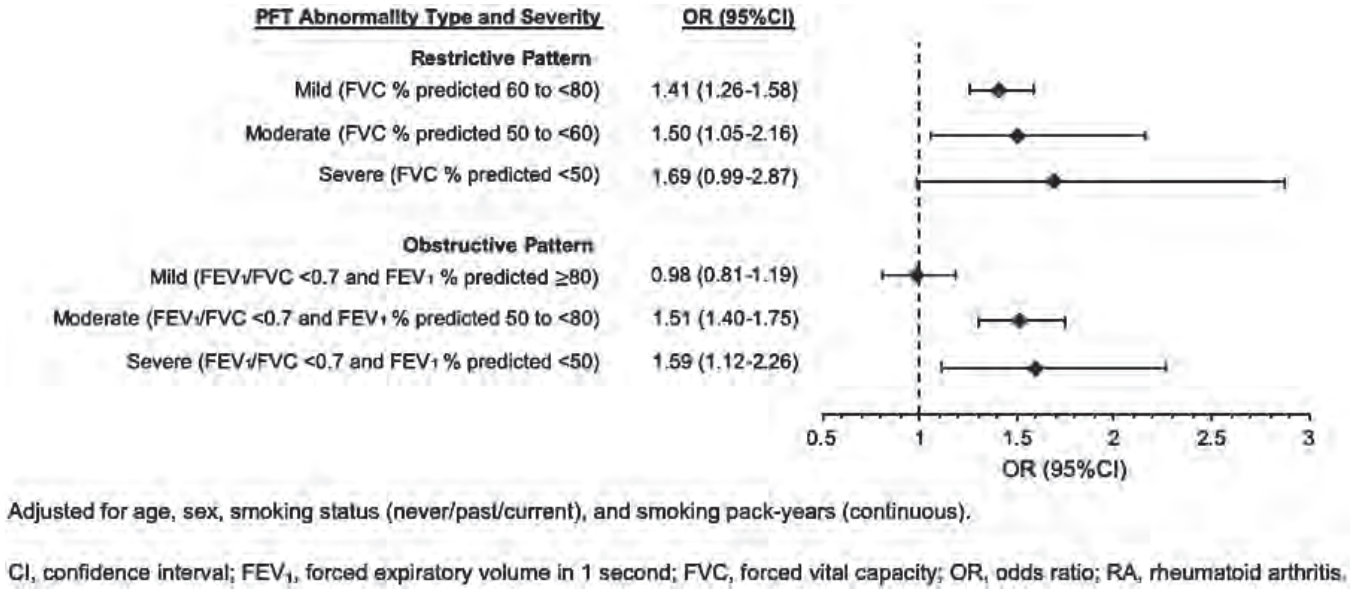

Figure 1. Multivariable odds ratios for level of severity of pulmonary function test abnormalities, comparing rheumatoid arthritis to general population controls (n=319,288).

controls for continuous PFT results. We used logistic regression to estimate adjusted ORs for type and severity of PFT abnormality, comparing RA cases to controls.

Results: Among 319,288 analyzed subjects with PFTs performed (mean age 56.4 years, 56% female, and 46% ever smokers), we identified 1,853 (0.6%) cases of treated RA. Among RA cases, 72% were female and 84% were RF+. Among the entire sample, 16% had restrictive pattern and 14% had obstructive pattern on PFTs. RA was strongly associated with lower % predicted forced expiratory volume 1 second (FEV_1), % predicted forced vital capacity (FVC), and FEV_1/FVC results than general population controls, independent of smoking and other confounders (**Table 1**). RA

was also associated with increased odds of restrictive (multivariable OR 1.42, 95%CI 1.27-1.59) and obstructive (OR 1.28, 95%CI 1.14-1.45) patterns (**Table 2**). RA was associated with increased odds of either PFT abnormality (OR 1.41, 95%CI 1.28-1.56) compared to controls. RA was associated with higher odds of restrictive pattern across all severity levels and higher odds of moderate and severe, but not mild, obstructive pattern (**Figure 1**). Findings were similar among never smokers.

Conclusion: RA cases were more likely than general population controls to have restrictive or obstructive pattern abnormalities on PFTs obtained for research purposes, and this relationship was not explained by smoking and other measured confounders. The independent association of RA with obstructive pattern adds to the growing literature implicating RA and airways disease. In addition to restrictive lung disease, clinicians should also be aware that obstructive lung diseases may be a pulmonary manifestation of RA independent of smoking history.

Microbiota-induced Intestinal Barrier Dysfunction Initiates the Shuttling of Immune Cells from the Gut to the Joints

Narges Tajik[1], Michael Frech[2], **Carolin Brandl**[1], Juan Cañete[3], Francesco Ciccia[4], Georg Schett[5] and Mario Zaiss[6], [1]Department of Internal Medicine 3, Rheumatology and Immunology, Friedrich-Alexander-University Erlangen-Nürnberg (FAU) and Universitätsklinikum Erlangen, Erlangen, Germany; 2 Deutsches Zentrum für Immuntherapie (DZI), Erlangen, Germany, [2]Department of Internal Medicine 3, Rheumatology and Immunology, Friedrich-Alexander-University Erlangen-Nürnberg (FAU) and Universitätsklinikum Erlangen, Erlangen, Germany; 2 Deutsches Zentrum für Immuntherapie (DZI), Erlangen, [3]Departamento de Reumatología, Hospital Clínic de Barcelona e IDIBAPS, Barcelona, Spain, Barcelona, Spain, [4]Dipartimento Biomedico di Medicina Interna e Specialistica, University of Palermo, Palermo, Italy, Palermo, Italy, [5]Friedrich-Alexander-Universität Erlangen- Nuremberg, Erlangen, Germany, [6]Department of Internal Medicine 3, Friedrich-Alexander University (FAU) Erlangen-Nuremberg and Universitätsklinikum Erlangen, Erlangen, Germany

SESSION INFORMATION
Session Date: Friday, November 6, 2020
Session Title: RA – Diagnosis, Manifestations, & Outcomes III: Major Comorbidities in RA
Session Type: Abstract Session
Session Time: 5:00PM–5:50PM

Background/Purpose: While it is known that microbial dysbiosis is associated with the onset of rheumatoid arthritis, mechanistic insights how it facilitates the development of arthritis remained largely elusive to date. It is especially interesting how microbial dysbiosis affects the transition from asymptomatic autoimmunity to arthritis. We speculated that a breakdown of intestinal barrier function caused by microbial dysbiosis allows immune cells to shuttle from the gut to the joints. The purpose of this study was to test whether intestinal barrier function is impaired before the onset of human RA and experimental arthritis and to seek for evidence that immune cells from the gut migrate to the joints.

Methods: In a longitudinal cohort of RA-at risk individuals markers of disturbed intestinal barrier function, such as zonulin, were analyzed and linked to RA onset. Furthermore, new-onset RA patients were assessed for gut leakiness and their intestinal biopsies for the expression of tight junction proteins and immune cell infiltration. In the murine model of collagen-induced arthritis, sequential analysis of intestinal dysbiosis, intestinal barrier function and arthritis onset was carried out. Additionally, barrier function was assessed on intestinal organoids exposed to faecal super-

natants from eu- and dysbiotic mice with and without inhibition of zonulin. Furthermore, three types of interventions restoring intestinal barrier function were carried out for testing their effects on the inhibition of arthritis onset. Finally, photo- converted cells from the gut were traced in the joints and further identified in more detail to test for cellular trafficking from one to the other compartment.

Results: Zonulin, a potent regulator for intestinal tight junctions, was elevated in autoimmune mice and men before the onset of arthritis and predicted the onset of human RA. Intestinal barrier functions as well as epithelial tight junctions were decreased before the onset of experimental arthritis and at onset of human RA. In mice, induction of autoimmunity was followed by rapid intestinal dysbiosis followed by gut leakiness before arthritis started. Faecal supernatants of arthritic mice induce epithelial barrier dysfunction in intestinal organoids in zonulin dependent manner. Restoration of the intestinal barrier in the pre-phase of arthritis using butyrate, CB1R agonist or zonulin antagonist larazotide inhibited the development of arthritis. Finally, using photoconvertible mice, gut-borne immune cells were identified that homed to the joints when barrier function was impaired.

Conclusion: In summary, these data show the intestinal barrier dysfunction precedes the onset of RA and allows the trafficking of immune cells from the gut to the joints. Targeting of intestinal tight junction function may therefore allow preventing the onset of RA.

Automatic Joint Space Assessment in Hand Radiographs with Deep Learning Among Patients with Rheumatoid Arthritis

Yun-Ju Huang[1], Chang-Fu Kuo[1], Fakai Wang[2], Shun Miao[2], Kang Zheng[2] and Le Lu[2], [1]Chang Gung Memorial Hospital, Taoyuan, Taiwan (Republic of China), [2]PAII labs, Bethesda, MD

SESSION INFORMATION
Session Date: Friday, November 6, 2020
Session Title: RA – Diagnosis, Manifestations, & Outcomes III: Major Comorbidities in RA
Session Type: Abstract Session
Session Time: 5:00PM–5:50PM

Background/Purpose: Assessment of joint space is the fundamental radiographic task to diagnose rheumatoid arthritis (RA) and to assess the severity and progression of the disease. The clinical assessment of joint space is a visual task, and the current scoring systems, such as the modified Sharp's score, generally follow the semiquantitative grading.(1) The inter- and intra-observer variation impede the development of computer-aided detection and diagnosis software to help physicians.(2) This exploratory study aims to assess the performance of a deep-learning model for detecting and scoring joint space automatically and compare it with the physician's performance.

Methods: We collected 1,397 conventional hand radiographs from 450 RA patients (training: 309; validation, 141) whose diagnoses were based on the 2010 ACR/EULAR criteria for RA. Three rheumatologists assessed the joint space independently according to the van der Heijde-modified Sharp scoring method. The consensus was the ground truth for training data. We trained a model to detect joints automatically using the Deep Adaptive Graph (a landmark detection technique based on graph convolutional network; figure 1). The extracted region of interest was fed into the joint space assessment algorithm to predict the joint space score and compare it with rheumatologists'

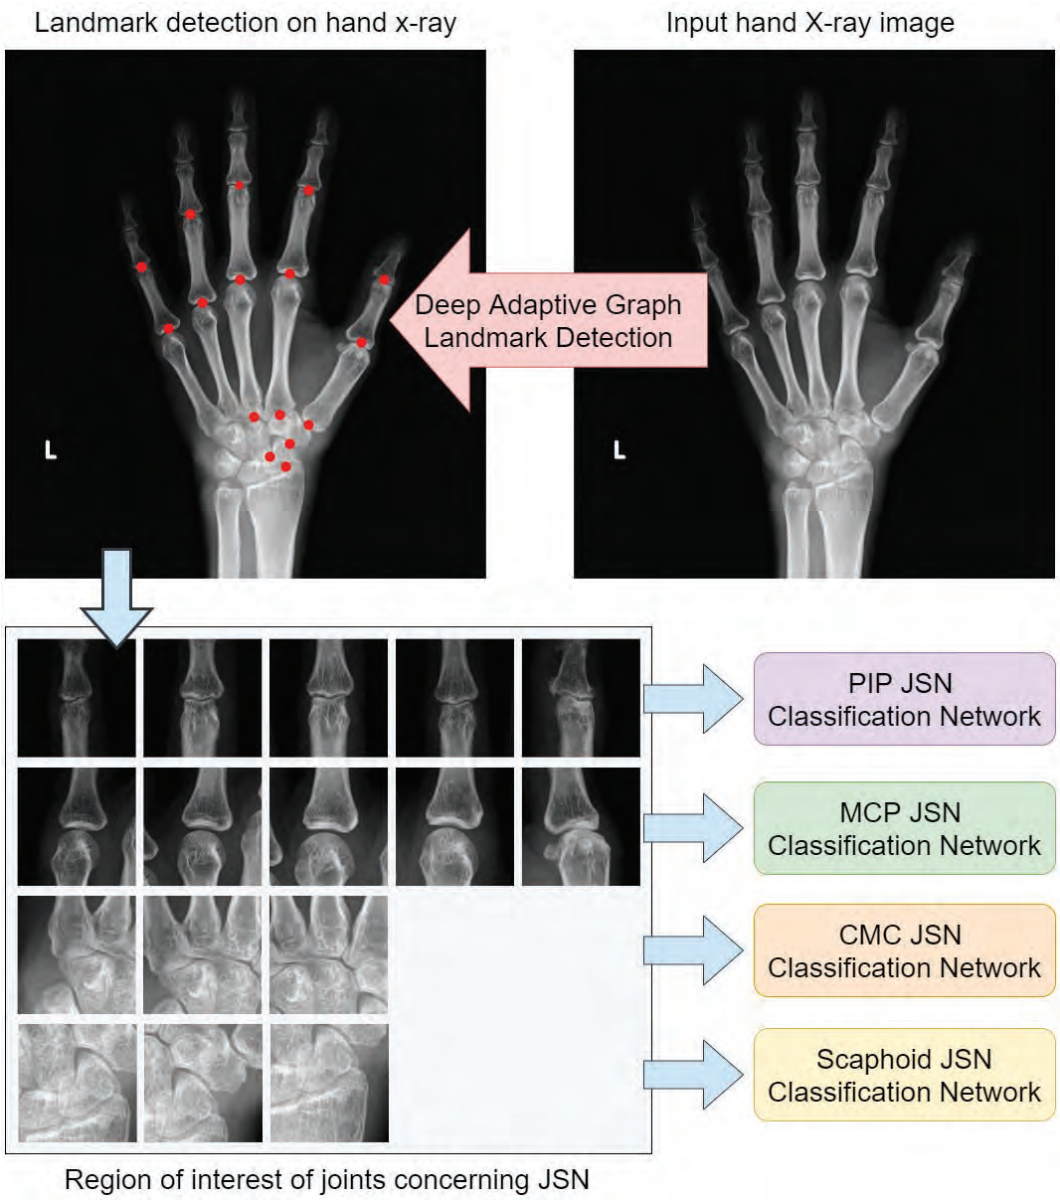

Figure 1. Flow chart for the development of joint detection and joint space scoring algorithms.

scoring. The model-rheumatologist agreement was compared to the inter-rater agreement between rheumatologists as an assessment for model performance. The accuracy of the model to predict an exact joint space score of rheumatologist consensus, a joint space score of rheumatologist consensus by one score, and score a joint space score ≥ 2 were also performed.

Results: Among 141 RA patients in the validation set, the mean age was 57.9 years, and 82.3% were female. The overall model-rater agreement was similar to the inter-rater agreement with Kappa statistics of 0.568 and 0.565, respectively. The accuracy to predict exact the joint space score of rheumatologist consensus and to predict the joint space score of rheumatologist consensus by one score were 0.674 and 0.973. The model sensitivity, specificity, and positive predictive value to detect a joint space score ≥ 2 were 0.808, 0.919, and 0.884, respectively. The performance was consistent across different joint areas as shown in Table 1.

Joint areas	Model performance			Comparison of model-rater and inter-rater reliability	
	Exact accuracy*	One-score accuracy**	PPV for a score≥2	Inter-rater Kappa statistic	Model-rater Kappa statistic
PIP	0.698	0.986	0.855	0.578	0.589
MCP	0.764	0.987	0.900	0.629	0.674
CMC	0.570	0.946	0.877	0.434	0.426
Wrist	0.594	0.952	0.906	0.537	0.477
All	0.675	0.972	0.884	0.565	0.568

* Predicted score matched rheumatologist consensus exactly.

** Predicted score matched rheumatologist consensus by one score.

Table 1. Performance of joint space scoring algorithm.

Conclusion: This study indicates that deep learning models are useful to detect specific joint area and score the joint space with performance comparable with rheumatologists.

Genetic-epigenetic Interaction and the Relationship Between DNA Methylation Patterns and Disease Activity in a Longitudinal Cohort of Lupus Patients

Patrick Coit[1], Lourdes Ortiz-Fernandez[2], Emily Lewis[3], W. Joseph McCune[3], Kathleen Maksimowicz-McKinnon[4] and Amr Sawalha[2], [1]University of Pittsburgh and University of Michigan, Pittsburgh, PA, [2]University of Pittsburgh, Pittsburgh, PA, [3]University of Michigan, Ann Arbor, MI, [4]Henry Ford Hospital, Detroit

SESSION INFORMATION
Session Date: Friday, November 6, 2020
Session Title: SLE – Etiology & Pathogenesis
Session Type: Abstract Session
Session Time: 5:00PM–5:50PM

Background/Purpose: Genetic factors and epigenetic dysregulation are implicated in the pathogenesis of lupus. We performed a longitudinal analysis of DNA methylation in lupus patients for the first time. We assessed epigenetic changes over time and across disease activity status. Combining genomic and epigenomic analyses, we also examined ancestry-specific DNA methylation and DNA methylation changes influenced by genetic variants across the genome.

Methods: A total of 54 female lupus patients, including 32 European-American and 22 African-American, were followed over a period of up to 43 months. Blood samples were obtained at routine follow up visits and during disease flares, with a total of 229 samples collected. Disease activity at each blood draw was determined by SLEDAI. Granulocytes were isolated and DNA extracted. Genotyping was performed using the Infinium Global Screening Array v2.0, and genome-wide DNA methylation was assessed at each time-point using the Infinium MethylationEPIC array. Ancestry-specific DNA methylation changes were determined, and methylation quantitative trait loci (meQTL) analysis was performed. A linear mixed effects model was implemented to identify DNA methylation alterations that vary with disease activity.

Results: We identified 487 hypomethylated and 420 hypermethylated CpG sites in African-American compared to European-American lupus patients, annotated to 391 and 316 unique genes, respectively. Differentially methylated genes include type I interferon-response genes such as *IRF7* and *IFI44,* and genes related to the NFkB pathway. After adjusting for age, medications, and genetic background, DNA methylation levels in 142 (15.7%) differentially methylated sites were found to be allele-specific and influenced by at least one genetic variant located within 1kb. *TREML4*, which plays a vital role in toll-like receptor signaling, was hypomethylated in African-American patients and demonstrated a strong *cis*-meQTL association (R^2=0.91). The associated genetic variant (rs9369265) significantly differs in allele frequencies between African-American and European-American patients, and is located within an active enhancer region in neutrophils and modifies *TREML4* expression. Interestingly, the DNA methylome was highly stable across different disease activity levels and over time. Methylation levels in *SNX18* and *FGD1* showed correlation with disease activity in African-American patients (P= 4.6 x 10^{-8} and P= 3.7 x 10^{-7}, respectively). FGD1 is a guanine nucleotide exchange factor that activates the GTPase Cdc42 which has been shown to regulate neutrophil morphology during migration and apoptotic response to immune complex signaling.

Conclusion: Lupus granulocytes demonstrate significant differences in DNA methylation patterns between African-American and European-American patients. DNA methylation profiles in lupus patients are influenced by ancestry-specific genetic variants and are highly stable over time independent of disease activity levels. Progressive demethylation in *SNX18* and *FGD1* was observed with increasing disease activity in granulocytes from African-American lupus patients.

Epstein Barr Virus (EBV), an Etiologic Factor for Systemic Lupus Erythematosus (SLE), Interacts with SLE Risk Loci Through EBV-encoded Transcription Co-factors (co-TFs)

Viktoryia Laurynenka[1], Xiaoting Chen[1], Sreeja Parameswaran[1], Shruti Eswar[2], Kenneth Kaufman[3], Bahram Namjou[4], Matthew Weirauch[5], Leah Kottyan[4] and John Harley[6], [1]Cincinnati Children's Hospital Medical Center, Cincinnati, OH, [2]Cincinnati Children's Hospital Medical Center, Cincinnati, [3]Cincinnati Children's Hospital Medical Center;US Department of Veterans Affairs Medical Center, Cincinnati, OH, [4]Cincinnati Children's Hospital Medical Center/Univ of Cincinnati, Cincinnati, OH, [5]Cincinnati Children's Hospital Medical Center/Univ of Cincinnati, 535 Terrace Ave, [6]Cincinnati Children's Hospital Medical Center/Univ of Cincinnati College of Medicine, Cincinnati, OH

SESSION INFORMATION
Session Date: Friday, November 6, 2020
Session Title: SLE – Etiology & Pathogenesis
Session Type: Abstract Session
Session Time: 5:00PM–5:50PM

Background/Purpose: SLE affects millions worldwide. The etiology of this complex autoimmune disease is the consequence of both strong genetic and environmental components. Genome-wide association studies (GWAS) have identified many variants associated with SLE that mostly localize to incompletely understand regulatory regions. EBV has been nominated as potential triggering environmental factors in SLE from immunochemical, virologic, epidemiologic and genomic studies. Recent work reveals a possible mechanism via the concentration of the EBV-encoded transcription cofactor (co-TF), Epstein-Barr virus nuclear antigen 2 (EBNA2) at SLE risk loci (Nat Genet 50:699 2018).

Methods: In 124 GWAS and candidate-gene studies ~500 variants have been associated with SLE at p< 5E-08. By literature curation and linkage disequilibrium pruning, we identify 187 independent SLE loci when requiring r^2< 0.2 or regression modeling to separate loci. Most loci (132, 71%) are ancestry specific. The most studied ancestries, European (100 loci) and East Asian (94 loci), share only 31 loci.

The simulation algorithm, RELI, first presented in (Nat Genet 50:699, 2018), has been improved and applied to 53 viral and 11,781 human ChIP-seq (chromatin immunoprecipitation with DNA sequencing) datasets, a collection 8-times larger than previously available, to assess DNA binding of 1,467 regulatory proteins (TFs & co-TFs).

Results: We confirm association with EBNA2 DNA binding complexes (OR=2.4, Pc= $3.1x10^{-12}$) and discover association with EBV Latency III genes EBNA3C (OR=2.7, Pc= $1.44x10^{-23}$) and EBNA-LP (OR=2.0, Pc= $3.18x10^{-15}$) that bind 33% to 51% of the 187 SLE loci. Among human TFs & co-TFs 193 significantly associated (Pc< 10^{-6}) with SLE risk loci. In GO Enrichment Analysis these 193 human TFs & co-TFs show involvement in JAK/STAT, Toll receptor, interleukin, apoptosis signaling pathways, oxidative stress response and transcription regulation pathways and enriched in such biological processes as T and B cell regulation and differentiation, dendritic cell, megakaryocyte and erythrocyte differentiation, cellular response to interleukin-6, -7, -9, 15, type I interferon, positive regulation of interleukin-10 and -12 biosynthetic processes, chromatin modification, mitosis, and viral transcription.

The EBV co-TFs EBNA2, EBNA3C, and EBNA-LP and human regulatory proteins, tend to cluster together at the same subset of the SLE risk loci (p< 10^{-300}). The associated human TFs have a powerful tendency to be from EBV transformed B cells (OR≈56, P< E-100) and to be known components of the super-enhancer complexes that form upon EBV infection and transformation of B cells (OR >30, p< 10^{-25}). Meanwhile, genetic associations for many other diseases, such as depression, anxiety, and schizophrenia and other complex genetic phenotypes (n >400) show no such relationships.

Conclusion: These new results confirm previous results and extend evidence supporting an etiologic role for EBV in SLE. At this moment, the most attractive hypothesis of mechanism is that the EBV alters a substantial proportion of SLE genetic risk through gene expression changes that occur in EBV transformed B cells as a consequence of the action of the Latency III EBV gene expression program.

Abstract Number: 0496

A Role of Lipid-Peroxidation in Systemic Lupus Erythematosus-Associated Cardiovascular Disease

David Patrick[1], Justin van Beusecum[1], Michelle Ormseth[2], Leslie J. Crofford[2], Sean Davies[3], Sergey Dikalov[1] and David Harrison[1], [1]Vanderbilt University Medical Center, Nashville, [2]Vanderbilt University Medical Center, Nashville, TN, [3]Vanderbilt University, Nashville

SESSION INFORMATION
Session Date: Friday, November 6, 2020
Session Title: SLE – Etiology & Pathogenesis
Session Type: Abstract Session
Session Time: 5:00PM–5:50PM

Background/Purpose: In SLE, cardiovascular complications are a significant contributor to morbidity and death. Importantly, there is an increased prevalence of hypertension in SLE patients compared to healthy controls. We have identified a critical role of isolevuglandins (isoLGs) as activators of the immune system in essential hypertension. IsoLGs are peroxidized products of fatty acids that form as a result of reactive oxygen species. These isoLG adducts participate in the activation of T-cells and contributed. We hypothesize that isoLGs are important for the development of hypertension and systemic immune activation in SLE.

Methods: To determine the presence of isoLG's in monocytes of human subjects we recruited 11 subjects with SLE and 10 controls subjects. IsoLG adduct accumulation within antigen presenting cells was performed by flow cytometry and mass spectrometry. Superoxide was measured by incubation with dihydroethidium and subsequent high performance liquid chromatography. Flow cytometry was performed with a single chain antibody that recognizes isoLG adducted lysine residues independent of the peptide backbone. $CD11c^+$ and $CD14^+$ monocytes were analyzed for the presence of isoLG adducts. To determine a causative role of isoLG adducts in immune activation and hypertension in SLE, we employed the *B6.SLE123* and *NZBWF1* mouse models of SLE. Animals were treated with the specific isoLG scavenger 2-hydroxybenzylamine (2-HOBA) or vehicle beginning at 7 weeks. Animals were sacrificed at 32 weeks of age and *C57BL/6* and *NZW* were used as controls. Blood pressure was analyzed by radiotelemetry. Immune cell accumulation was determined by flow cytometry and the presence of anti-isoLG adduct antibodies was determined by a capture enzyme linked immunosobent assay (ELISA).

Results: By flow cytometry and mass spectrometry we found marked accumulation of isoLG adducts within $CD11c^+$ and $CD14^+$ antigen presenting cells in SLE subjects compared to control. This was accompanied by an increase in superoxide production in $CD14^+$ monocytes. In animals, treatment with 2-HOBA attenuated blood pressure in both mouse models. Immune cell accumulation in primary and secondary lymphoid organs is significantly attenuated by 2-HOBA. Moreover, treatment with 2-HOBA reduced albuminuria and renal injury in the *B6.SLE123* model of SLE as measured by urinary albumin/creatinine ratio and histologic scoring. Similarly, there is a significant reduction in bone marrow plasma cell accumulation and anti-double stranded DNA (anti-dsDNA) titers in treated animals. Finally we have detected anti-isoLG-adduct IgG in serum collected from both mouse models.

Conclusion: These studies define a critical role of isoLG adduct accumulation in both systemic immune activation and hypertension in SLE. Moreover, they suggest a potential therapeutic strategy for the treatment of SLE and associated cardiovascular disease.

Interleukin-23 Acts Directly on Podocytes and Contributes to the Development of Glomerulonephritis

Shui Lian Yu[1], Hao Li[1], Abhigyan Satyam[1], Shawn Rose[2], Jarrat Jordan[3] and George Tsokos[4], [1]Division of Rheumatology & Clinical Immunology/Beth Israel Deaconess Medical Center/Harvard Medical School, boston, [2]Rheumatology & Autoimmunity Translational Medicine at Janssen Pharmaceuticals, boston, [3]Janssen Research & Development, LLC, Spring House, PA, [4]Division of Rheumatology & Clinical Immunology/Beth Israel Deaconess Medical Center/Harvard Medical School, Boston, MA

SESSION INFORMATION

Session Date: Friday, November 6, 2020

Session Title: SLE – Etiology & Pathogenesis

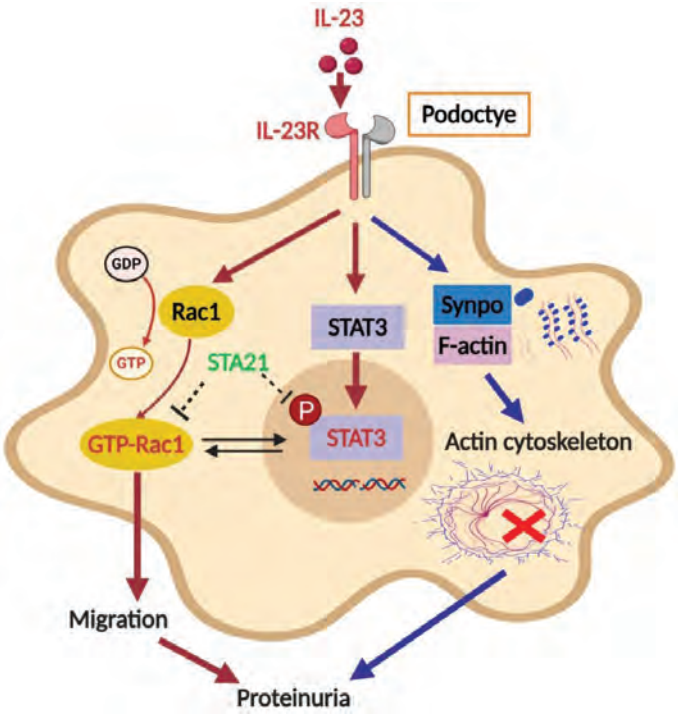
Session Type: Abstract Session

Session Time: 5:00PM–5:50PM

Background/Purpose: Interleukin (IL)-23 is central in the advancement of an inflammatory response and has been shown to be involved in the pathogenesis of autoimmune diseases. Therapeutic targeting of IL-23-mediated signaling is being exploited for therapeutic purposes. It is still unknown whether IL-23 can affect the function of tissue resident cells and promote organ damage. Disruption of podocyte structure and function represents a common feature of several inflammatory kidney diseases.

Methods: Podocytes were cultured on an advanced decellularized matrix (doi.org/10.1002/adfm.201908752).

Results: Using podocytes cultured on an advanced decellularized matrix, we demonstrated that in the presence of IL-23 the expression of IL-23 receptor on the surface membrane of podocytes increases significantly followed by increased levels of phosphorylated STAT3. We found that phosphorylated STAT3 associated with Rac1 and this re-



sulted in decreased actin and synaptopodin, two proteins which are important in the structure of podocytes. Using a wound healing assay we showed that the presence of IL-23 increases the motility of podocytes. The presence of a small drug inhibitor of STAT3 prevented all aspects of IL-23-induced podocyte injury.

To determine the role of IL-23-instigated signaling in podocytes in the development of glomerulonephritis we constructed a mouse which lacked IL-23 receptor in podocytes (*Il-23*$^{f/f}$*.Nphs2*^{cre}*)* and exposed it to a nephrotoxic serum. *Il-23*$^{f/f}$*.Nphs2*^{cre}mice, unlike control mice, developed minimal proteinuria, histologically defined glomerulonephritis and maintained normal levels of synaptopodin in their podocytes.

Conclusion: Our results present first evidence that IL-23 acts directly on tissue resident cells and contributes directly to the development of kidney disease. We propose that approaches to block IL-23 signaling should benefit people with glomerulonephritis.

Abstract Number: 0498

Exploring the Role of Lipocalin-2 in Neuropsychiatric SLE Pathogenesis

Chaim Putterman[1], Elise Mike[1] and **Sayra Garcia**[1], [1]Albert Einstein College of Medicine, Bronx, NY

SESSION INFORMATION
Session Date: Friday, November 6, 2020
Session Title: SLE – Etiology & Pathogenesis
Session Type: Abstract Session
Session Time: 5:00PM–5:50PM

Background/Purpose: While the etiology of neuropsychiatric lupus (NPSLE) is not fully understood, blood brain barrier (BBB) disruption and localized neuroinflammation are potential mechanisms that contribute to disease progression. Lipocalin-2 (LCN2) is a multi-functional acute phase protein known to affect immune cell function, BBB integrity, and glial cell activation. Previous studies in our laboratory demonstrated the amelioration of behavioral deficits in a LCN2 deficient, lupus-prone mouse model, B6.Sle1.Sle3 (Sle1,3), indicating a potential role of LCN2 in NPSLE. At the transcriptional level, we found that LCN2 deficiency restored genes involved in cognitive function that were down-regulated in Sle-1,3 mice. Moreover, LCN2 regulated *MMP-9* and *Plp1,* genes involved in blood brain barrier function

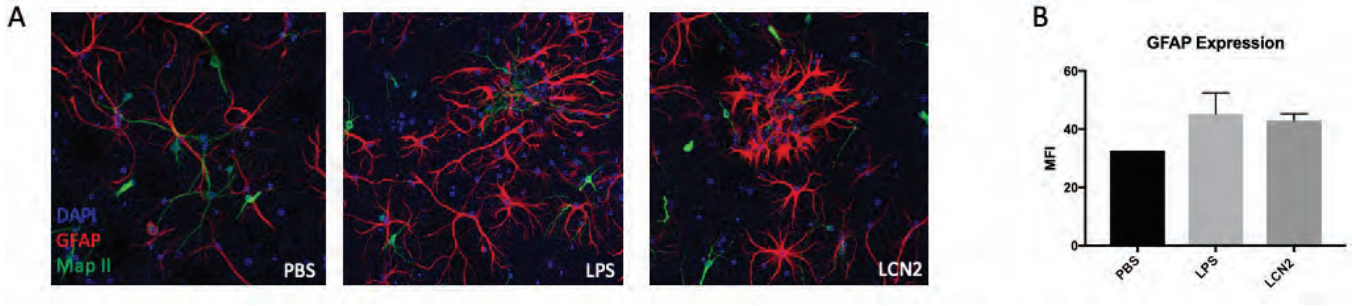

Figure 1. Immunofluorescent staining of neuron-astrocyte co-cultures stimulated with LCN2, LPS, and PBS revealed that LCN2 stimulation leads to activated astrocyte morphology. We observed increased cell volume and cell process extension, indicating higher levels of astrocyte activation in the LPS treated positive control and in the LCN2 experimental group (1A). GFAP mean fluorescence intensity (MFI) was measured using ImageJ software (1B). Green = MAP-II (neurons), Red = GFAP(astrocytes), Blue = DAPI.

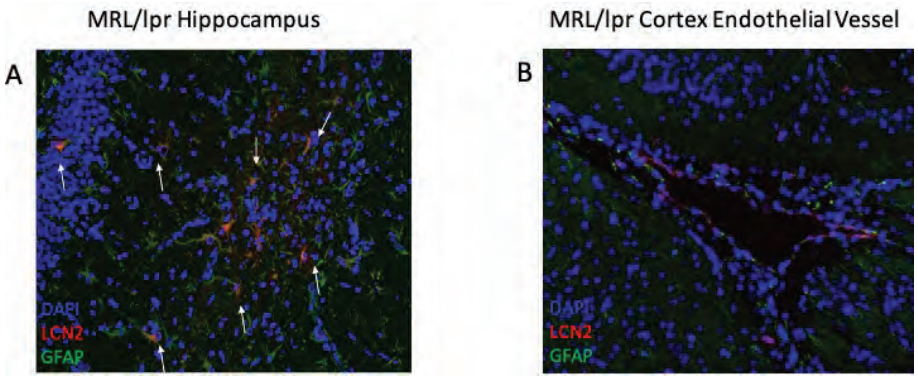

Figure 2. Immunofluorescent staining of MRL/lpr cortex and hippocampus reveals astrocyte-LCN2 co-staining (indicated by white arrows) in MRL/lpr mice injected with LPS, suggesting that under inflammatory stimulus, astrocytes are the main source of LCN2 in MRL/lpr brains. We observed co-staining of astrocytes with LCN2 in the hippocampus (2A) and localization of LCN2 and astrocytes around cortical endothelial vessels (2B). Green = GFAP (astrocytes), Red = LCN2, Blue = DAPI.

and glial cell activation in the brain. In the following studies we examined the role of LCN2 in the neuroinflammation present in the well established MRL/lpr lupus prone strain, as well as the potential role of astrocytes in NPSLE

Methods: Astrocytes and neurons from P1 C57BL/6 pups were isolated and co-cultured for 13 days. On day 14, the co-cultures were treated with either LPS at 100 ng/mL, LCN2 at 5 mcg/ml, or PBS. After 8 hours the cells were fixed and stained for neuron and astrocyte markers by immunofluorescence. Astrocyte activation was analyzed by measuring glial fibrillary acid protein (GFAP) expression through mean fluorescence intensity. For the *ex vivo* experiments, female 10 week old MRL/lpr mice received an intraperitoneal LPS injection to accelerate systemic inflammation. Eight hours post injection, mice were sacrificed, and their brains paraffin embedded for immunofluorescent staining.

Results: To examine astrocyte activation by LCN2 in the *in vitro* studies, we analyzed astrocyte morphology and GFAP expression in stimulated cells. Measurement of mean fluorescence intensity showed an increase in GFAP expression with LCN2 stimulation that was similar to the increase seen in the positively treated LPS stimulated cells when compared to the control (Fig. 1B). Additionally, astrocyte morphology in LPS and LCN2 treated cultures showed a similar increase in cellular processes as well as total cell volume size, both indicators of an activated astrocyte morphology (Fig. 1A). Next, we examined the brains of MRL/lpr mice. We found co-staining of LCN2 with GFAP, an astrocyte marker, in the hippocampus and cortex in injected MRL/lpr mice. Additionally, LCN2 was localized around brain endothelial vessels (Fig. 2).

Conclusion: These preliminary results begin to shed light on the significant behavioral improvement we saw in previous experiments in LCN2 deficient mice. Our *in vitro* results suggest that LCN2 can promote astrocyte activation. Moreover, astrocytes may be the primary source of LCN2 in the brain of MRL/lpr mice. Increased astrocyte LCN2 expression *in vivo* was mainly localized to the cortex and hippocampus, brain regions that are involved in cognitive function and emotional behaviors, respectively. Our findings of astrocyte activation by LCN2 and the colocalization of LCN2 and astrocytes suggest astrocyte derived LCN2 acting in an autocrine manner to promote pathological neuroinflammation in this NPSLE model.

SESSION INFORMATION

Session Date: Friday, November 6, 2020

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes I: Psoriatic Arthritis

Session Type: Abstract Session

Session Time: 5:00PM–5:50PM

Background/Purpose: Delays in diagnosis of psoriatic arthritis (PsA) are common and impair quality of life and function. The study objective was to identify phenotypes, genetic variants, and plasma biomarkers that may predict PsA in patients with psoriasis.

Table 1. Demographics and baseline characteristics

	Phenotype analysis¥		Gene analysis (WES)		Protein analysis (PEA)	
	Psoriasis only (n= 506)	Psoriasis + PsA ¶ (n= 132)	Healthy Controls (n= 1176)	Early onset PsA £ (n= 247)	Psoriasis only (n= 162)	Psoriasis + PsA (n= 65)
Demographics						
Age	45.9 (17.0)	46.9 (12.7)	45.7 (17.4)	47.4 (14.3)	46.2 (16.7)	48.5 (13.3)
Male gender	275 (54.3%)	58 (43.9%)	463 (39.5%)	117 (47.4%)	71 (43.8%)	31 (47.7%)
Age at psoriasis onset	28.3 (17.5)	29.0 (14.9)	NA	32.8 (15.4)	28.5 (17.4)	31.2 (16.7)
Age at PsA diagnosis*	NA	52.9 (13.2)	NA	45.4 (15.9)	NA	49.3 (14.3)
PsA prior to psoriasis onset	NA	11 (8.3%)	NA	73 (29.6%)	NA	12 (19.4%)
BMI at age 18	22.3 (4.1)	22.2 (4.6)	NA	22.9 (4.5)	22.7 (4.7)	22.4 (5.0)
Psoriatic fingernails	208 (41.4%)	85 (65.4%)	NA	134 (57.5%)	63 (39.4%)	33 (53.2%)
Worst-ever induration	2.0 (1.2)	2.5 (1.2)	NA	2.2 (1.3)	2.6 (1.2)	2.9 (1.1)
Worst-ever erythema	3.1 (1.0)	3.4 (1.1)	NA	3.4 (1.2)	3.3 (1.1)	3.4 (1.1)
Worst-ever desquamation	3.0 (1.2)	3.3 (1.2)	NA	3.2 (1.2)	3.2 (1.2)	3.3 (1.1)
Worst-ever BSA	17.9 (24.2)	22.6 (27.3)	NA	19.1 (25.1)	20.2 (25.9)	18.8 (26.1)
Koebner phenomenon	178 (37.8%)	70 (57.4%)	NA	100 (45.2%)	59 (40.4%)	29 (49.2%)
Pustular psoriasis	15 (3.1%)	15 (11.7%)	NA	21 (8.6%)	9 (5.9%)	8 (12.7%)

Numbers in this table are mean (standard deviation) for continuous variables or number of observations (percentage) for binary variables. ¥ Phenotype analysis included psoriasis patients who reported no diagnosis of PsA at the time of phenotyping. ¶ Psoriasis+PsA patients in the phenotype analyses were diagnosed with PsA after the date of phenotyping. £ Early onset PsA was defined as the PsA patients with the shortest time tertile between patient-reported psoriasis onset and PsA onset. *PsA or ankylosing spondylitis diagnosed by a rheumatologist per patient report. WES = whole exome sequencing. PEA = Proximity Extension Assay. Worst ever induration, erythema, and desquamation were estimated by patients on a scale of 0-5.

Table 2. Phenotypes in psoriasis patients associated with subsequent PsA diagnosis

	Univariate		Multivariate	
Phenotype	Hazard Ratio [95% CI]	p-value	Hazard Ratio [95% CI]	p-value
Worst-ever induration	1.46 [1.27-1.68]	**<0.001** *	1.37 [1.19-1.58]	**<0.001** *
Psoriatic fingernails	2.54 [1.75-3.68]	**<0.001** *	2.20 [1.50-3.23]	**<0.001** *
Pustular psoriasis	3.32 [1.92-5.77]	**<0.001** *		
Palmoplantar pustulosis	3.30 [1.57-6.93]	0.002		
Generalized pustular Ps	3.14 [1.43-6.90]	0.004		
Koebner phenomenon	2.15 [1.49-3.11]	**<0.001** *		
Depression	1.72 [1.18-2.51]	0.005		
Inflammatory bowel disease	3.59 [1.43-9.01]	0.006		
Worst-ever desquamation	1.23 [1.06-1.42]	0.006		

Table 3. Gene and protein associations with PsA.

Phenotype	Populations	# Genes/ proteins	Pathway or name	p-value
Genes (Whole exome sequencing)				
Early onset PsA[£]	Early onset PsA vs. Healthy controls	12 genes	Glycosphingolipid metabolic process	**$2x10^{-6}$** *
Early onset PsA	Early onset PsA vs. Healthy controls	34 genes	Upregulation of genes in CD4 T helper cells Th0	$7x10^{-6}$
Early onset PsA	Early onset PsA vs. Healthy controls	2 genes	Hepatocyte growth factor (HGF) and HGF activator	**$2x10^{-6}$** *
PsA before Ps	PsA before psoriasis vs. Healthy controls	2 genes	Hepatocyte growth factor (HGF) + HGF activator	**$3x10^{-7}$** *
Proteins (Plasma Extension Assay)[£]				
PsA	PsA vs. PsC	1 protein	Hepatocyte growth factor (HGF)	0.03
PsA duration	PsA	1 protein	Tumor necrosis factor	**$6x10^{-5}$** **
PsA duration	PsA	1 protein	PI3 (Elafin)	0.02
PsA duration	PsA	1 protein	MCP-3	0.03

Whole exome sequencing results were selected by p<0.00001, without filtering based on biology of the genes or pathways. [£]Early onset PsA was defined as the PsA patients with the shortest time tertile between patient-reported psoriasis onset and PsA onset. *Significant after Bonferroni correction for the number of genes or pathways. **Significant after Bonferroni correction for the number of proteins. PsC = psoriasis without PsA. [£]PEA analyses were adjusted for age, sex and body mass index.

Methods: Clinical data and specimens were collected from 1360 psoriasis patients participating in the Utah Psoriasis Initiative (UPI) between 2002 and 2014. Three concurrent analyses were performed for identifying 1) phenotypes,

2) genes, and 3) plasma protein biomarkers associated with PsA. For the phenotype analysis, proportional hazard Cox regression was used to identify variables associated with an increased risk of developing PsA in the subset of patients with psoriasis phenotyping prior to PsA diagnosis. For the genotype analysis, whole exome sequencing (WES) and primary data analysis were performed by the Regeneron Genetics Center. Variant filtering was completed with the deleterious score BayesDel. Participants with early-onset PsA were compared to healthy controls using an in-house software suite PERCH. Cox regression was also used to assess genotype associations in PsA patients vs. psoriasis patients. For the biomarker analysis, 273 proteins were quantified with Proximity Extension Assay (PEA) and compared in psoriasis subsets with and without PsA.

Results: The mean ages of the phenotype, genotype, and biomarker populations ranged from 45.9 to 48.5 and 39.5% to 54.3% were male (Table 1). Phenotypes associated with a subsequent diagnosis of PsA in the multivariate analysis included worst-ever induration and fingernail involvement (Table 2). With WES analysis, early-onset PsA had a significantly higher burden of deleterious or loss-of-function variants in the glycosphingolipid metabolic process pathway and the gene set hepatocyte grow factor (*HGF*) and HGF activator (*HCFAC*) than healthy controls (Table 3). The association of *HGF*+*HGFAC* was genome-wide significant among the subset of patients who developed PsA before psoriasis. Cox regression in PsA (n=402) vs. psoriasis patients (n=1019) also demonstrated that *HGF* and *HGFAC* associated with an increased risk of PsA (p=0.01). With PEA, associations were newly discovered between 1) PsA and HGF and 2) PsA duration and TNF, P13, MCP-3 proteins.

Conclusion: Multiple phenotypes, genes, and proteins associate with PsA. Patient-reported psoriatic nails and worst-ever induration associate with the subsequent development of PsA in psoriasis patients. Genetic analyses demonstrate the newly discovered associations with *HGF* and *HGFAC* genes that differentiated between PsA and cutaneous psoriasis. The association between PsA and plasma HGF concentration also suggests that HGF may be a useful protein biomarker for PsA. Additional plasma protein biomarkers for PsA may include TNF, PI3, and MCP-3. After validation and additional discovery of phenotypes, genotypes, and biomarkers, we anticipate using these variables to develop a predictive model for identifying psoriasis patients at high risk for PsA.

SESSION INFORMATION

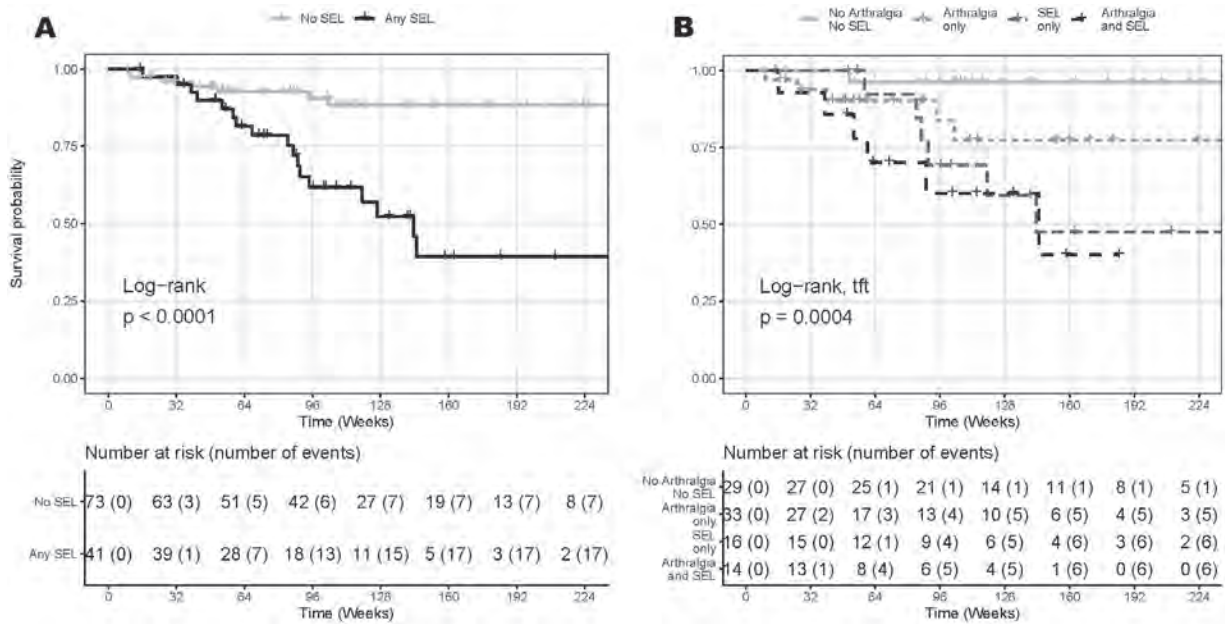
Session Date: Friday, November 6, 2020

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes I: Psoriatic Arthritis

Session Type: Abstract Session

Session Time: 5:00PM–5:50PM

Background/Purpose: We have previously reported that the presence of musculoskeletal pain in psoriasis patients is associated with a higher risk of developing psoriatic arthritis (PsA) (1). Furthermore, a subset of psoriasis patients shows evidence for structural entheseal lesions (SEL) in their hand joints (2), sometimes also referred as “Deep Koebner Phenomenon”, which are highly specific for psoriatic disease and virtually absent in healthy controls, rheumatoid arthritis and hand osteoarthritis patients (2-4). However, it remains unclear whether SEL alone or in combination with



(A) Kaplan-Meier plots of psoriatic arthritis-free survival by presence/absence of structural entheseal lesions (SEL) at baseline. P value by log-rank test;, (B) Kaplan-Meier plots of psoriatic arthritis-free survival by four groups; 1, no arthralgia and no SEL at baseline; 2, arthralgia but no SEL (Arthralgia only) ; 3, no arthralgia but SEL(SEL only) ; 4, arthralgia and SEL

musculoskeletal pain are associated with the development of PsA. Therefore, we aimed to test whether the presence of SEL in psoriasis patients increases the risk for progression to PsA and how this is related to the presence of musculoskeletal pain.

Methods: Psoriasis patients without evidence of PsA were enrolled in a prospective cohort study between 2011 and 2018. All patients underwent baseline assessment of SEL in their 2nd and 3rd MCP joints by high-resolution peripheral quantitative computed tomography (HR-pQCT). The risk of PsA development associated with SEL and arthralgia was explored using survival analyses and multivariable Cox regression models.

Results: 114 psoriasis patients (72 men/42 women) with a mean (SD) follow-up duration of 28.2 (17.7) months were included, 24 of whom developed PsA (9.7 /100 patient-years, 95%CI 6.2 to 14.5) during the observation period. Patients with SEL (N=41) were at higher risk of developing PsA compared to patients without such lesions (21.4/100 patient-years, 95%CI 12.5 to 34.3, HR 5.10, 95%CI 1.53 to 16.99, p=0.008) (Kaplan Meier plot A). Furthermore, while patients without arthralgia and without SEL had a very low progression rate to PsA (1/29; 3.4%), patients with arthralgia but no SEL showed higher progression (5/33; 15.2%), which was in line with previous observations (1) (Kaplan Meier plot B). Presence of SEL further enhanced the risk for progression to PsA both in the absence (6/16; 37.5%) and presence (6/14; 42.8%) of arthralgia with the highest progression rate in those subjects with both arthralgia and SEL ($p< 0.001$ by log rank test for trend) (Kaplan Meier plot B).

Conclusion: Presence of SEL is associated with an increased risk of developing PsA in patients with psoriasis. If used together with pain, SEL allow defining subsets of psoriasis patients with very low and very high risk to develop PsA.

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes I: Psoriatic Arthritis

Session Type: Abstract Session

Session Time: 5:00PM–5:50PM

Background/Purpose: Psoriatic Arthritis (PsA) is a progressive inflammatory arthritis that occurs in about 24% of psoriasis patients. Early diagnosis of PsA is associated with better outcomes. Since almost 90% of patients develop PsA either simultaneously or after the onset of cutaneous psoriasis, careful evaluation of psoriasis patients may increase early identification of PsA. Although several candidate protein markers have been demonstrated to be associated with PsA, individually the power to discriminate between PsA and psoriasis without PsA (PsC) is poor. Here, we have developed a computational approach to identify 9 alternative signatures by combining clinical and protein markers to improve discrimination between PsA and PsC.

Methods: Serum samples were obtained from 192 PsA and 191 PsC patients (Table 1). Sixteen protein markers identified in previous studies were assayed in serum samples using ELISA and combined with four clinical features associated with PsA and easily identified by non-rheumatologists (Table 1). To classify patients, we used Support Vector Machines (SVM). To identify the best performing signatures (markers and classifier parameters) we used a three-layer approach. In the first two layers, for training and testing classifiers, we used data only from patients with polyarticular PsA (tender or swollen joint count > 4), while in the third layer, we used all PsA samples. Evaluation of signatures was done using 10-fold cross-validation. First, using a greedy algorithm we identified 41 signatures with accuracy above 75%. Next, we identified 9 signatures using four different measures based on frequency of features and AUCs of these 41 signatures. In the third layer, we used three sample sets for training and testing 2700 classifiers: all samples, only oligoarticular (tender or swollen joint count ≤ 4) PsA, and only polyarticular PsA. All 9 classifiers were trained and tested on similar training and testing sets. Finally, we prioritized the 9 signatures based on their AUC ranks (Table 2).

Results: Demographics and clinical features of patients are provided in Table 1. We propose 9 signatures as alternative signatures to use for distinguishing PsA from PsC, depending on available data, all of which share four features:

List of sixteen measured protein markers		
LEP, SPP1, SOST, POSTN, TNFSF11, TFCP2_CPII, TFCP2_C2C, COMP, TNFSF14, DEFA1, S100A8, ITGB5, LGALS3BP, TNFRSF11B, CXCL10, CRP		
Clinical features	**PsC**	**PsA**
Number of patients	191	192
***Sex (% female)**	28%	56%
Age at psoriasis diagnosis in years - Mean (S.D)	27.53 (14.41)	31.32 (16.77)
***Psoriasis duration in years - Mean (S.D)**	15.69 (14.35)	20.74 (13.61)
***PASI - Mean (S.D)**	4.76 (8.35)	4.75 (6.76)
***Presence of nail psoriasis**	59%	56%
Tender or swollen joint count - Mean (S.D)	-	7.16 (7.63)

* Clinical features used for classifying patients

Table 1. Clinical and demographic information about samples

	Score based on rank of AUC using each feature set in 100 runs of the classifier			
Signature	**All samples**	**oligoarticular**	**polyarticular**	**Total**
Nail psoriasis, CRP, DEFA1, LEP, SOST, SPP1, TFCP2_CPII, TNFRSF11B	669	607	636	1912
Nail psoriasis, CRP, LEP, PASI, SOST, SPP1, TFCP2_CPII, TNFRSF11B, TNFSF11	548	604	551	1703
Nail psoriasis, CRP, ITGB5, LEP, SOST, SPP1, TFCP2_CPII	538	591	510	1639
Nail psoriasis, CRP, ITGB5, LEP, SOST, SPP1, TFCP2_CPII, TNFRSF11B, TNFSF11	531	546	510	1587
Nail psoriasis, CRP, CXCL10, DEFA1, LEP, S100A8, SOST, SPP1, TNFRSF11B	553	454	543	1550
Nail psoriasis, PASI, COMP, CRP, DEFA1, LEP, SOST, SPP1, TNFRSF11B	572	414	563	1549
Nail psoriasis, CRP, ITGB5, LEP, SOST, SPP1, TFCP2_CPII, TNFSF11	459	561	481	1501
Nail psoriasis, CRP, CXCL10, DEFA1, ITGB5, LEP, SOST, TFCP2_CPII, TNFSF11	325	435	350	1110
Nail psoriasis, PASI, COMP, CRP, DEFA1, ITGB5, LEP, SOST, TFCP2_CPII	305	288	356	949

Table 2. 9 identified feature sets sorted based on their score (the higher the score, the better) We used same combinations of samples to train and test all 9 classifiers. To obtain the scores, for each training and testing set, we ranked all of the 9 classifiers from 1 to 9 (1 for the lowest and 9 for the highest AUC). Next, for each signature, we multiplied its frequency at each rank by the rank. The scores in this table are the sum up of these 9 values for each of the three categories of samples.

nail psoriasis, LEP, CRP, and SOST (Table 2). Importantly, the lowest ranked signatures were those without SPP1, suggesting its importance in classifying patients. Our top feature set (Table 2) obtained AUC of up-to 90% on polyarticular samples (median 75%). Performance slightly dropped when we considered all samples, or only oligoarticular samples (Figure 1). Median AUC of 68% (max AUC = 86%) for distinguishing oligoarticular PsA cases from PsC is significant considering high similarity between patients of these two groups.

Conclusion: Integration of clinical and biomarker data through machine learning improves discrimination of PsA from PsC patients. Nail psoriasis and CRP followed by SPP1 are the most important features influencing performance of classifiers. *Nail psoriasis, CRP, DEFA1, LEP, SOST, SPP1, TFCP2_CPII, TNFRSF11B* provided best discrimination between PsA and PsC and needs further validation.

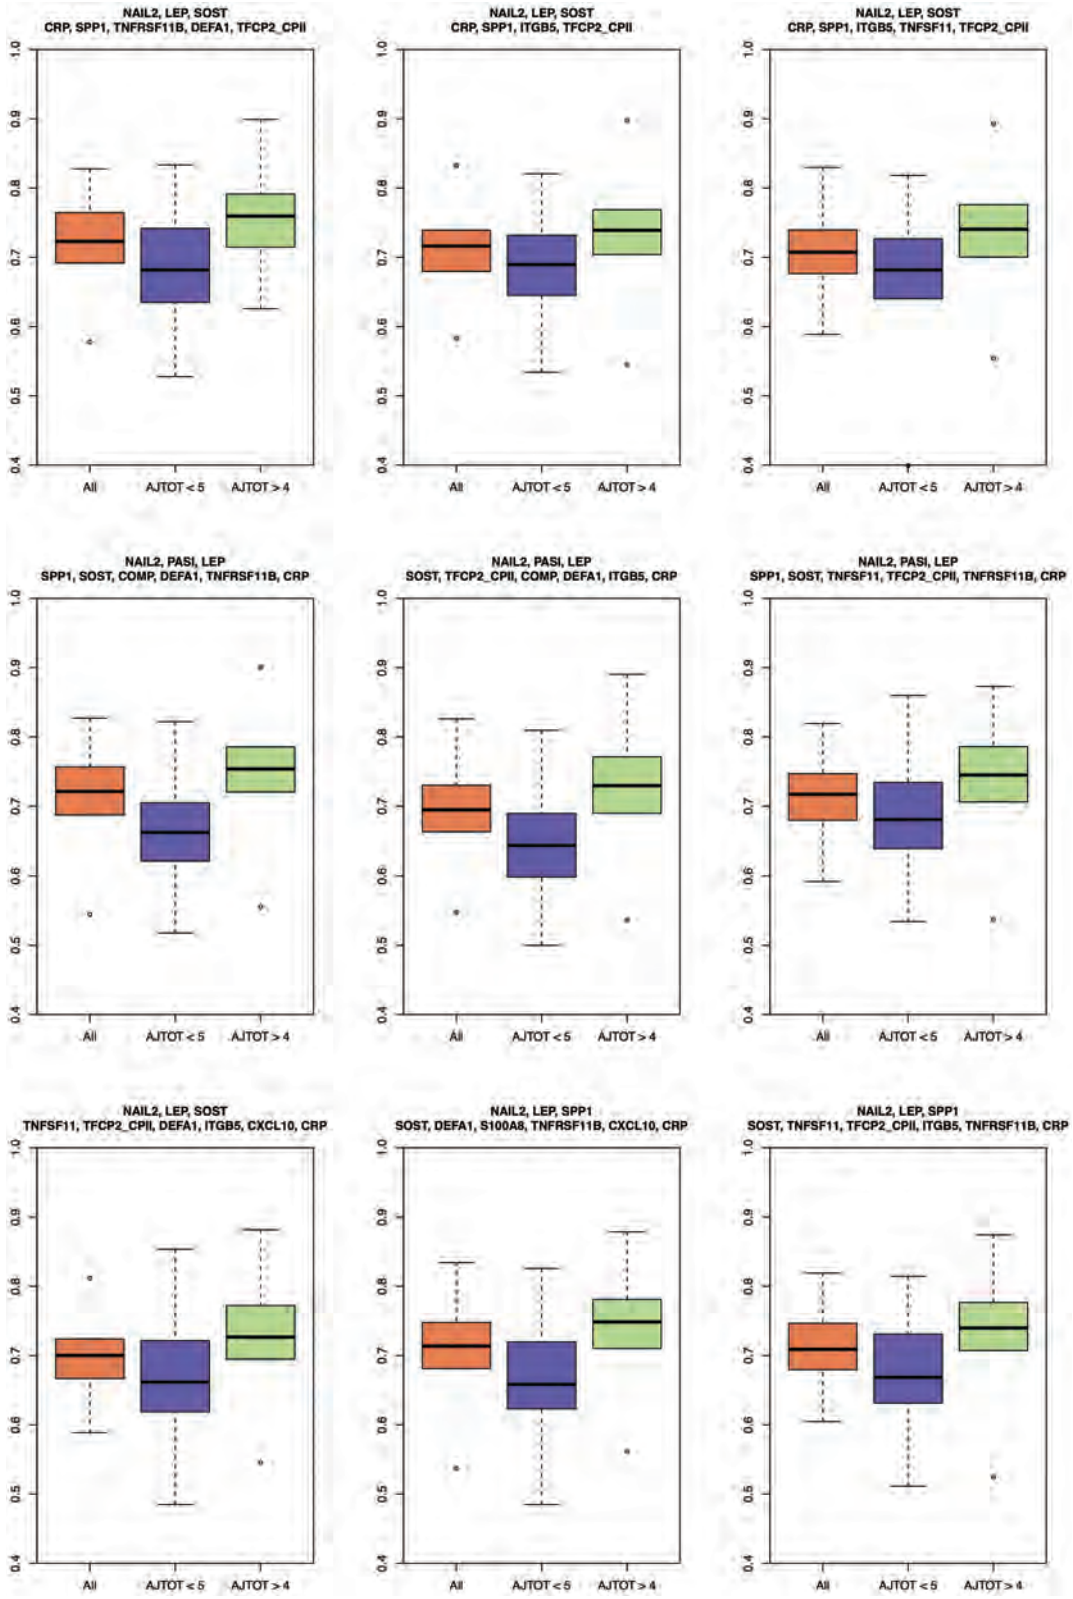

Figure 1. Distribution of AUC of SVMs (y-axis) using each of the 9 identified signatures (listed above each panel) as their feature sets. Each classifier was trained and tested 100 times using three different samples sets: all PsC samples and 1) only polyarticular samples; 2) only oligoarticular samples; 3) all samples. Three boxplots in each panel shows AUC distribution relevant to these three sample sets. For all 9 classifiers, similar training and testing sets were used, making their performance comparable. While all 9 signatures are among high performing signatures, the top left panel was the highest rank in our list.

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Diagnosis, Manifestations, & Outcomes I: Psoriatic Arthritis

Session Type: Abstract Session

Session Time: 5:00PM–5:50PM

Background/Purpose: Psoriatic arthritis and psoriasis, collectively termed psoriatic disease (PsD), are associated with increased cardiovascular (CV) risk. Metabolites comprise biomarkers that may add predictive value over traditional CV risk factors. We aimed to identify metabolites associated with CV events (CVEs) and to determine whether they could improve CV risk prediction beyond traditional CV risk factors.

Methods: Patients from a longitudinal PsD cohort without a prior history of CVEs were included. In the first available serum sample, a targeted nuclear magnetic resonance (NMR) metabolomics platform was used to quantify 64 metabolite measures comprised of lipoprotein subclasses, fatty acids, glycolysis precursors, ketone bodies and amino acids. The study outcome included any of the following CVEs occurring within the first 10 years of biomarker assessment: angina, myocardial infarction, congestive heart failure, transient ischemic attack, cerebrovascular accident, revascularization procedures and CV death. The association of each metabolite with incident CVEs were analyzed separately using Cox proportional hazards regression models first adjusted for age and sex, and subsequently for traditional CV risk factors. Variable selection was performed using penalization with boosting after adjusting for age and sex. The added predictive value of the selected metabolites to improve risk prediction beyond traditional CV risk factors was assessed using the area under the receiver operator characteristic curve (AUC).

Selected Serum Metabolite	Cross-validation coefficient
Acetate	0.0853
Acetoacetate	0.0984
Albumin	0.0781
Average diameter for LDL particles	0.0077
Beta-hydroxybutyrate	0.0091
Glucose	0.0678
Glycoprotein acetyls	0.1692
Phenylalanine	0.0311
Triglycerides in IDL	0.1878
Concentration of large HDL particles	-0.0290
Concentration of medium HDL particles	-0.0238
Degree of unsaturation	-0.1233
Glycine	-0.0071
HDL_3 cholesterol	-0.0384
Lactate	-0.2487
Ratio of DHA to total fatty acids	-0.0845
Tyrosine	-0.1303

DHA, docosahexaenoic acid; HDL, high-density lipoprotein; IDL, intermediate-density lipoprotein; LDL, low-density lipoprotein.

Table 1. Selected serum metabolites associated with incident cardiovascular events, based on 5-fold cross-validation and a proportional subdistribution hazard model adjusted for age and sex.

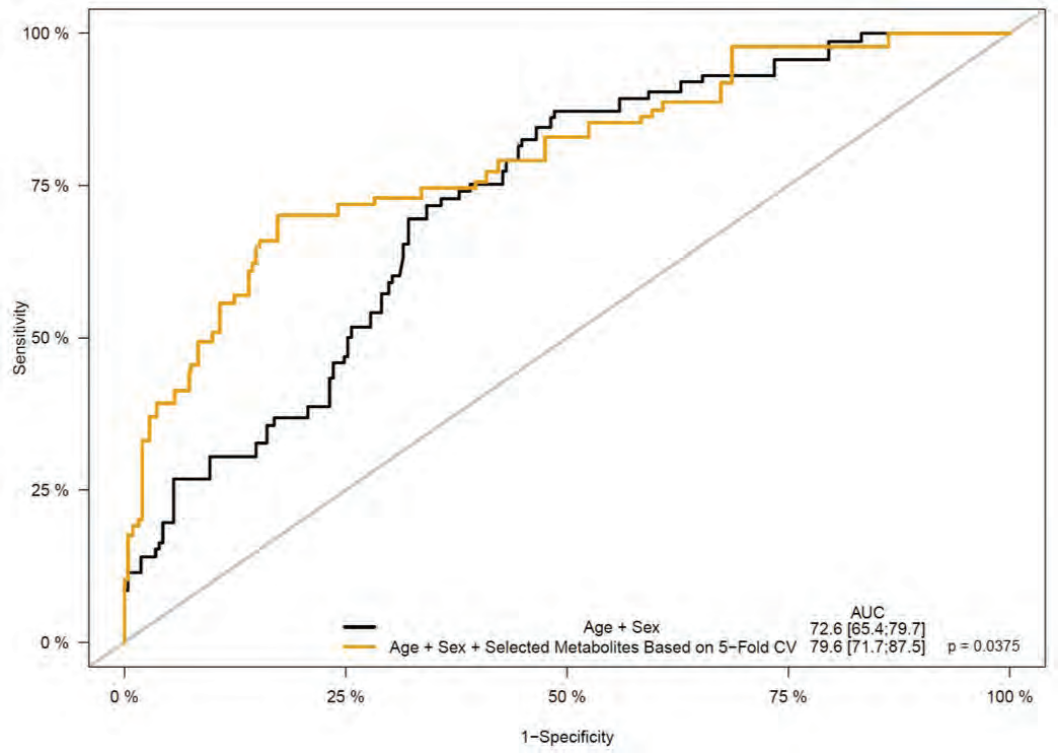

Figure 2. Comparison of the predictive performance of the base model (age and sex alone) and expanded model (age and sex plus selected metabolites) for prediction of cardiovascular events in patients with psoriatic disease. AUC indicates area under the receiver operator characteristic curve; CV, cross-validation.

Results: A total of 977 patients with PsD, followed between 2005 and 2019, were analyzed (mean age 49.1 ± 12.6 years, 45.1% female). During a mean follow-up of 7.1 years, 70 (7.2%) patients developed incident CVEs. In Cox regression models adjusted for CV risk factors, alanine, tyrosine, lactate, degree of unsaturation, high-density lipoprotein (HDL) cholesterol, and medium and large HDL particles were significantly associated with decreased CV risk. Acetate, glycoprotein acetyls, apolipoprotein B, remnant cholesterol, very low-density lipoprotein (VLDL) cholesterol, and very small VLDL particles were associated with an increased CV risk (**Figure 1**). In proportional sub-distribution hazards regression models adjusted for age and sex, 17 metabolites were selected (**Table 1**). The age- and sex-adjusted expanded model (base model + 17 metabolites) significantly improved prediction of CVEs beyond the base model (only age and sex) with an AUC of 79.6 vs. 72.6, respectively (p=0.038) (**Figure 2**).

Conclusion: Using NMR metabolomics profiling, we identified a variety of metabolites associated with a lower and higher risk of developing CVEs in patients with PsD. Further study of their underlying association with CVEs is needed to clarify the clinical utility of these biomarkers to guide CV risk assessment in this population.

SESSION INFORMATION
Session Date: Friday, November 6, 2020
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Treatment I: Psoriatic Arthritis
Session Type: Abstract Session
Session Time: 3:00PM–3:50PM

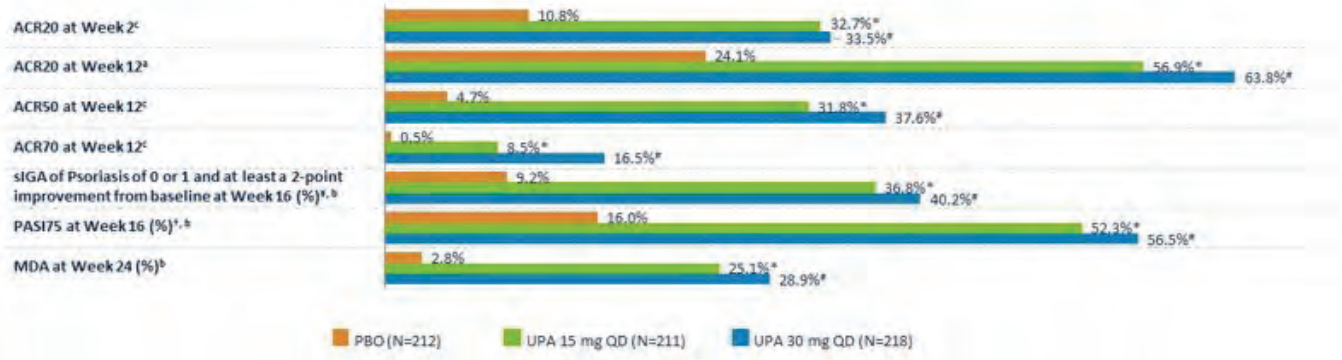
Background/Purpose: Upadacitinib (UPA) is an oral, reversible, JAK inhibitor approved for treatment of moderate to severe rheumatoid arthritis (RA) and currently under evaluation for treatment of psoriatic arthritis (PsA). We assess the efficacy and safety of UPA versus placebo (PBO) in patients (pts) with PsA and prior inadequate response or intolerance to ≥1 biologic disease-modifying anti-rheumatic drug (bDMARD).

Methods: In SELECT-PsA-2, pts were randomized 1:1:1 to once daily UPA 15 mg (UPA15), UPA 30 mg (UPA30), or PBO. Pts were stratified by baseline DMARD use, number of prior failed bDMARDs, and extent of psoriasis. The primary endpoint was the proportion of pts achieving ACR20 response at Wk 12. Multiplicity controlled secondary endpoints included change in HAQ-DI, FACIT-Fatigue (FACIT-F), and SF-36 Physical Component Summary (PCS) at Wk 12; static Investigator Global Assessment (sIGA) of Psoriasis of 0 or 1 and at least a 2-point improvement from baseline, PASI75, and change in Self-Assessment of Psoriasis Symptoms (SAPS) at Wk 16; and proportion of pts achieving MDA at Wk 24. Additional key secondary endpoints were ACR50 and ACR70 at Wk 12, and ACR20 at Wk 2. Treatment-emergent adverse events (TEAEs) are reported for pts who received ≥1 dose of study drug.

Results: 641 pts were randomized and received study drug; 54.3% were female with mean age of 53.4 years, and mean duration since PsA diagnosis of 10.1 years. 61% of pts failed 1 bDMARD, 18% failed 2 bDMARDs, and 13% failed ≥3 bDMARDs. 543 (84.6%) pts completed Wk 24 study drug.

At Wk 12, a significantly greater proportion of pts receiving UPA15 and UPA30 vs PBO achieved ACR20 (56.9% and 63.8% vs 24.1%; $p < .0001$ for both comparisons). Statistically significant improvements were observed in the UPA15 and UPA30 arms vs PBO in all multiplicity controlled secondary endpoints, including ΔHAQ-DI (PBO, -0.10; UPA15, -0.30; UPA30, -0.41), ΔSF-36 PCS (PBO, 1.6; UPA15, 5.2; UPA30, 7.1), ΔFACIT-F (PBO, 1.3; UPA15, 5.0; UPA30, 6.1), and ΔSAPS (PBO, -1.5; UPA15, -24.4; UPA30, -29.7; $p < .0001$ for all endpoints; **Figure 1**). In addition, a greater proportion of pts achieved ACR50 and ACR70 at Wk 12 with UPA vs PBO.

Figure 1. Efficacy Endpoints



[a] Primary endpoint; [b] Multiplicity controlled ranked secondary endpoints; [c] Additional key secondary endpoints.
[d] for patients with baseline sIGA ≥2; [e] for patients with ≥ 3% body surface area psoriasis at baseline
PBO, placebo; UPA, upadacitinib; QD, once daily; ACR, American College of Rheumatology; sIGA, static Investigator Global Assessment; PASI, Psoriasis Area Severity Index; MDA, Minimal Disease Activity; *, p < 0001 for UPA15 vs. PBO; #, p < .0001 for UPA30 vs. PBO. Nominal p-value is provided for ACR50/70 at Week 12 and ACR20 at Week 2. Multiplicity adjustments were applied to the primary and ranked key secondary endpoints.

Results for binary endpoints are based on non-responder imputation (NRI) analysis; each of the two UPA arms was compared to PBO using the Cochran-Mantel-Haenszel (CMH) test, adjusting for the main stratification factor of current use of at least 1 DMARD.
Results for MDA at week 24 are based on NRI with additional rescue handling, where patients rescued at Week 16 are imputed as non-responders.
A graphical multiple testing procedure is used to control the overall type I error rate at the 0.05 level for all primary and ranked key secondary endpoints.

Figure 2. Safety Summary Through Week 24

	PBO; N=212; n (%)	UPA 15mg QD; N=211; n (%)	UPA 30mg QD; N=218; n (%)
Any Adverse Event	139 (65.6)	135 (64.0)	170 (78.0)
Serious AE	4 (1.9)	12 (5.7)	18 (8.3)
AE Leading to Discontinuation of Study Drug	11 (5.2)	15 (7.1)	20 (9.2)
Infection	73 (34.4)	71 (33.6)	108 (49.5)
• Serious Infection	1 (0.5)	1 (0.5)	6 (2.8)
• Opportunistic Infection excl. tuberculosis and herpes zoster[a]	0	0	2 (0.9)
• Herpes Zoster[b]	2 (0.9)	3 (1.4)	8 (3.7)
• Active Tuberculosis	0	0	0
Hepatic Disorder	3 (1.4)	4 (1.9)	18 (8.3)
Creatine Phosphokinase elevation	4 (1.9)	4 (1.9)	12 (5.5)
Anemia	2 (0.9)	4 (1.9)	14 (6.4)
Neutropenia	1 (0.5)	2 (0.9)	6 (2.8)
Lymphopenia	0	2 (0.9)	2 (0.9)
Malignancy (including NMSC)[c]	0	3 (1.4)	3 (1.4)
MACE (adjudicated)[d]	0	1 (0.5)	0
VTE (adjudicated)[e]	0	1 (0.5)	0
Deaths[f]	1 (0.5)	0	0

NMSC, non-melanoma skin cancer; MACE, major adverse cardiovascular event; VTE, venous thromboembolic events

[a]Opportunistic infections: UPA30: 1 candidiasis of the trachea, 1 oropharyngeal candidiasis; [b]Herpes zoster: All events of herpes zoster were mild or moderate in severity with the exception of 1 severe event of herpes zoster involving 2 dermatomes in 1 pt on UPA30. Three pts had involvement of 3 dermatomes (1 on UPA15 and 2 on UPA30); [c]Malignancies: UPA15: 1 pt basal cell carcinoma, 1 pt prostate cancer, 1 pt rectal cancer; UPA30: 1 pt rectal adenocarcinoma, 1 pt ovarian cancer and endometrial cancer, 1 pt basal cell carcinoma; [d]MACE (includes CV death, non-fatal myocardial infarction [MI], non-fatal stroke): UPA15: 1 non-fatal myocardial infarction; [e]VTE: UPA15: 1 pulmonary embolism; [f]Deaths: PBO: 1 motor vehicle accident

Generally, TEAEs were reported at similar frequencies in the PBO and UPA15 arms and at a higher frequency in the UPA30 arm (**Figure 2**). Numerically higher rates of serious AEs were reported in the UPA arms. Herpes zoster was more frequent with UPA30. Three malignancies occurred in each of the UPA arms. One adjudicated non-fatal myocardial infarction and one adjudicated pulmonary embolism were reported with UPA15.

Conclusion: In this bDMARD-IR PsA population, UPA15 and UPA30 demonstrated significant improvements across PsA domains including improvements in joint and skin signs and symptoms vs PBO through Wk 24 with improvement

observed by Wk 2. A greater percentage of pts treated with UPA achieved MDA and ACR50/70, stringent composite measures of disease control. No new safety signals were identified compared to what has been observed with UPA in RA.

SESSION INFORMATION

Session Date: Friday, November 6, 2020

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Treatment I: Psoriatic Arthritis

Session Type: Abstract Session

Session Time: 3:00PM–3:50PM

Background/Purpose: Axial disease may affect up to 25–70% of psoriatic arthritis (PsA) patients, depending on the definition used. Current evidence on efficacy of biologics in the treatment of axial manifestations is limited,[1] particularly as validated classification criteria for this subtype of PsA are not yet available. MAXIMISE (NCT02721966); the first randomized controlled trial evaluating the efficacy of a biologic drug in the management of the axial manifestations of PsA, showed that secukinumab (SEC) 300 and 150 mg provided rapid and significant improvement in ASAS20 responses through Week (Wk) 12.[2] Here, we report the effect of SEC on clinical and imaging outcomes through 52 wks from the MAXIMISE trial.

Criteria	SEC 300 mg s.c. (N = 164)	SEC 150 mg s.c. (N = 157)	Placebo to SEC 300 mg s.c. (N = 81)	Placebo to SEC 150 mg s.c. (N = 80)
Clinical endpoints				
ASAS20, % Responders (n/M)*	75.5 (123/163)	77.3 (119/154)	74.1 (60/81)	74.7 (59/79)

BASDAI50, % Responders (n/M)#	68.3 (95/139)	58.5 (83/142)	55.6 (40/72)	54.1 (40/74)
Spinal pain VAS, mean change from BL (SD), n#	-42.4 (27.0), 140	-43.8 (26.2), 142	-43.1 (25.0), 72	-36.4 (25.2), 74
Imaging endpoint				
Berlin MRI score for Entire Spine, mean change from BL (SD), n#	-0.6 (2.3), 121	-0.3 (1.3), 124	-0.8 (2.7), 63	-0.4 (1.3), 60
Berlin MRI score for SIJ, mean change from BL (SD), n#	-0.7 (2.2), 122	-0.5 (1.7), 122	-0.9 (2.4), 63	-1.0 (2.7), 59

N, total number of patients in the group; n, number of patients with response; M, number of evaluable patients
*Intermediate missing data as well as any data missing in the case of study discontinuation is imputed using LOCF; #observed data
Patients with initial placebo treatment were re-randomized to SEC 300 mg or 150 mg at Wk 12
ASAS, Assessment of Spondyloarthritis International Society criteria ankylosing spondylitis; BASDAI, Bath Ankylosing Spondylitis Disease Activity Index; BL, baseline; LOCF, Last observation carried forward; MRI, magnetic resonance imaging; s.c., subcutaneous; SEC, secukinumab; SIJ, sacroiliac joints; VAS, visual analogue scale, Wk, week.

Table. Endpoints at Wk 52

Methods: This phase-3, double-blind, placebo-controlled, multicentre trial included 498 patients (≥18 years) diagnosed with PsA and fulfilling CASPAR criteria presenting with spinal-pain VAS-score ≥40/100 and BASDAI-score ≥4 and inadequate response to ≥2 NSAIDs. Patients were randomized to SEC 300 mg (N=167); 150 mg (N=165) or placebo (N=166) wkly for 4 wks and every 4 wks thereafter. At Wk 12, placebo patients were re-randomized to SEC 300/150 mg. The primary endpoint was ASAS20 response with SEC 300 mg at Wk 12. Assessments at Wk 52 were exploratory and included ASAS20/40, BASDAI50, spinal pain (VAS), and improvement in Berlin MRI score for the spine and the sacroiliac joints. Multiple imputation and last observation carried forward (LOCF) were used to account for missing data for analysis of ASAS20/40 at Wk 12 and Wk 52, respectively. All other data were reported as observed.

Results: The primary endpoint was met.[2] ASAS20/40 responses at Wk 12 were 62.9%/43.6% (SEC 300 mg) and 66.3%/39.5% (SEC 150 mg) versus 31.2%/12.2% (placebo), respectively (P< 0.0001). ASAS20/40 responses improved further with SEC 300/150 mg treatment from baseline through 52 wks. 74.1%/75.0% and 63.0%/50.0% of placebo patients re-randomized at Wk 12 to SEC 300/150 mg, achieved ASAS20/40 response at Wk 52. At baseline, 59.5% (SEC 300 mg), 53.5% (SEC 150 mg) and 64.2% (placebo) of the pts had positive MRI scores for the sacroiliac joints and/or the spine. The reductions of Berlin MRI score for entire spine and sacroiliac joints were sustained with SEC 300/150 mg from baseline through 52 wks (**Table**). 64.6%, 69.1% and 33.6% of patients with inflammatory back pain at baseline as confirmed by the ASAS, Calin et al. and Berlin criteria in the secukinumab 300 mg, 150 mg and placebo groups, respectively, achieved an ASAS20 response at Wk 12.

Conclusion: Secukinumab provided further improvement in signs and symptoms of axial disease as assessed by ASAS20/40 through 52 wks and showed reduced inflammatory MRI lesions in the spine and sacroiliac joints in patients with PsA with axial manifestations. Efficacy responses at Wk 52 were comparable in patients who switched at Wk 12 from placebo to SEC 300/150 mg.

SESSION INFORMATION

Session Date: Friday, November 6, 2020

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Treatment I: Psoriatic Arthritis

Session Type: Abstract Session

Session Time: 3:00PM–3:50PM

Background/Purpose: Guselkumab (GUS), a monoclonal antibody that specifically binds to the p19-subunit of IL-23, is approved to treat psoriasis. Through Week24 (W24) of the Ph3, double-blind, placebo (PBO)-controlled trial in biologic-naïve pts with active PsA (DISCOVER-2), GUS every 4 or 8 weeks (Q4W or Q8W) demonstrated efficacy for joint & skin symptoms and inhibition of structural damage progression (Q4W), and was well tolerated. This study assessed GUS efficacy and safety through W52.

Methods: Biologic-naïve adults with active PsA (≥5 swollen+≥5 tender joints; CRP ≥0.6mg/dL) were randomized (1:1:1) to GUS 100 mg Q4W; GUS 100 mg at W0, W4, Q8W; or PBO. At W24, PBO pts switched to GUS 100 mg Q4W (PBO X Q4W). ACR response rates at W52, based on nonresponder imputation (NRI) for missing data and as observed in pts who continued study agent at W24, are shown. Observed data for additional endpoints, including PsA-modified van der Heijde Sharp (vdH-S) scores derived from blinded radiographic images collected at W0, W24, W52 (or at d/c) and scored in a new Read Campaign, are shown.

Results: 712/739 (96.3%) randomized & treated pts continued study agent at W24; 689/739 (93.2%) completed Wk52. NRI ACR20 response rates continued to increase after W24, and at W52 were 70.6% for GUS Q4W and 74.6% for GUS Q8W (Fig1A). Similar response patterns were observed for the more stringent ACR50/70 criteria

Table 1. Observed Efficacy[1]	GUS Q4W		GUS Q8W		PBO (W0-24) X	GUS Q4W (W24-52)
Data are % unless otherwise stated	W24	W52	W24	W52	W24	W52
Dactylitis at W0, n	116	111	107	105	95	93
Resolution	68.1	81.1	60.7	81.9	41.1	78.5
Enthesitis at W0, n	165	160	151	148	172	168
Resolution	45.5	60.0	57.6	65.5	32.6	67.3
≥3% BSA psoriasis, IGA ≥2 at W0, n	176	173	172	170	176	172
IGA 0/1 + ≥2-grade decrease	71.0	84.4	72.1	77.1	19.9	84.3

PASI100	46.6	61.3	46.5	54.7	2.8	55.2
HAQ-DI, n	234	229	238	234	237	230
Mean change	-0.4	-0.5	-0.4	-0.5	-0.2	-0.4
SF-36 scores, n (mean change)	234	229	238	234	237	230
Physical Component - PCS	7.2	9.0	7.8	9.5	3.8	8.1
Mental Component - MCS	4.1	4.1	4.5	4.5	2.2	4.3
MDA/VLDA, n	234	228	238	234	238	231
MDA	19.7	36.8	26.5	32.9	6.3	31.6
VLDA	5.1	12.2[2]	4.6[3]	17.1	1.3	6.9

[1]Randomized pts still on study agent at W24; [2]N=229; [3]N=237

Table 1. Observed Efficacy

(Fig1C,E). Observed ACR (Fig, 1B,D,F), IGA, PASI & MDA/VLDA responses; dactylitis & enthesitis resolution; and mean improvements in HAQ-DI and SF-36 PCS/MCS scores were also sustained through W52 in pts receiving Q4W & Q8W; W52 data for PBO X Q4W pts were generally consistent with other GUS-treated pts (Fig1, Table1). Changes in vdH-S scores were similar for W24-52 (0.62) and W0-24 (0.46) for Q4W; less radiographic progression occurred from W24-52 v W0-24 for Q8W (0.23 v 0.73) & PBO X Q4W (0.25 v 1.00). In 731 GUS-treated pts, 4.2% had SAEs; 1.2% had serious infections; no pt died; and no pt had IBD, opportunistic infections or active TB, or anaphylactic or serum sickness-like reactions.

Conclusion: In biologic-naïve pts with active PsA, GUS elicited sustained improvements in joint & skin symptoms; inhibition of radiographic progression & improvements in physical function, quality of life & composite indices through W52. GUS safety in PsA was similar at W24[1] & W52 and consistent with GUS safety in psoriasis.

Fig 1. NRI and Observed ACR20 (**A & B**), ACR50 (**C & D**), and ACR70 (**E & F**) responses through W52 (Note: patients randomized to PBO crossed over to GUS Q4W at W24)

SESSION INFORMATION
Session Date: Friday, November 6, 2020
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Treatment I: Psoriatic Arthritis
Session Type: Abstract Session
Session Time: 3:00PM–3:50PM

Background/Purpose: Lower efficacy to anti-tumor necrosis factor treatment has been reported in female patients with psoriatic arthritis (PsA) as compared to males in clinical registries.[1] The EXCEED study (NCT02745080) evaluated efficacy and safety of secukinumab (SEC) *versus* adalimumab (ADA) as first-line monotherapy in biologic-naïve patients with PsA. Here, we report the impact of sex on efficacy outcomes with SEC *versus* ADA at Week 52 from the EXCEED study.

Methods: Eligible patients were randomized 1:1 to receive SEC 300 mg subcutaneous at baseline, Week 1-4, followed by dosing every 4 weeks until Week 48 or ADA 40 mg subcutaneous at baseline followed by same dosing

every 2 weeks until Week 50. The detailed study design and objectives have been previously described.[2] The primary analysis was to demonstrate superiority of SEC *versus* ADA on ACR20 response at Week 52 using logistic regression model with treatment as a factor and baseline weight as a covariate. A *post-hoc* analysis for ACR20 response was performed using the same model with treatment, sex and smoking status as factors to adjust for imbalances observed in the baseline characteristics. Comparative *post-hoc* analysis was performed with SEC *versus* ADA by sex for other efficacy outcomes through Week 52.

Results: A total of 853 patients were randomized to receive SEC (N=426) or ADA (N=427) with similar baseline demographics except for higher proportion of females (51% in SEC; 46% in ADA) and smokers (21·8% in SEC; 17·8% in ADA) in the SEC group.[2] The primary endpoint for ACR20 response at Week 52 was not met. ACR20 response at Week 52 was, SEC (67·4%) *versus* ADA (61·4%); p=0·0227, after adjusting for sex and smoking status. The female patients had higher tender joint count, patient global assessment, HAQ-DI, PsA pain and enthesitis compared to males (**Table 1**). A greater proportion of patients with SEC (83·0% females; 91·3% males) completed Week 52 *versus* ADA (74·2% females; 83·4% males). SEC was associated with numerically higher efficacy on joints in females at Week 52 without any notable differences in the ACR core components *versus* ADA. Overall, higher efficacy was demonstrated in males versus females at Week 52 (**Table 2**).

Conclusion: Females had greater baseline disease severity than males. Secukinumab was associated with higher retention rate in both males and females at Week 52. Secukinumab provided numerically higher clinical responses in females *versus* adalimumab in musculoskeletal and skin endpoints and physical function at Week 52. In males, similar efficacy on musculoskeletal endpoints for both treatments and greater efficacy on skin with secukinumab were observed. These interesting findings warrant further investigation for reproducibility or uniqueness.

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Treatment I: Psoriatic Arthritis

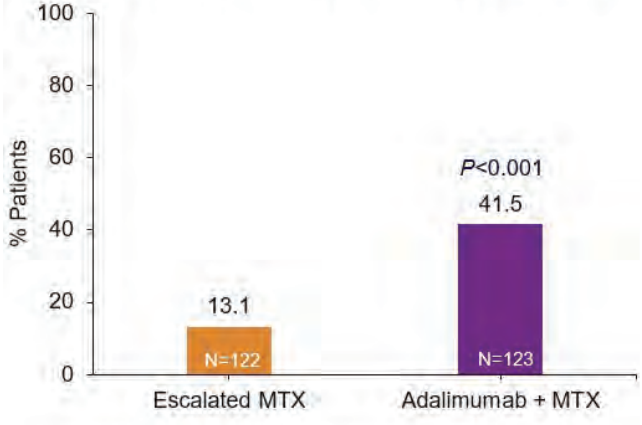
Session Type: Abstract Session

Session Time: 3:00PM–3:50PM

Background/Purpose: Minimal Disease Activity (MDA) is suggested as an appropriate treat-to-target outcome for patients (pts) with PsA. Results from Part 1 of the CONTROL study demonstrated that the introduction of adalimumab (ADA) after an initial course of MTX 15 mg resulted in significantly higher MDA rates at week (wk) 16 compared with escalating MTX dose (**Fig 1**).[1] Here we present results from Part 2 of the CONTROL study, in which therapy was either maintained or modified based upon MDA response at wk 16.

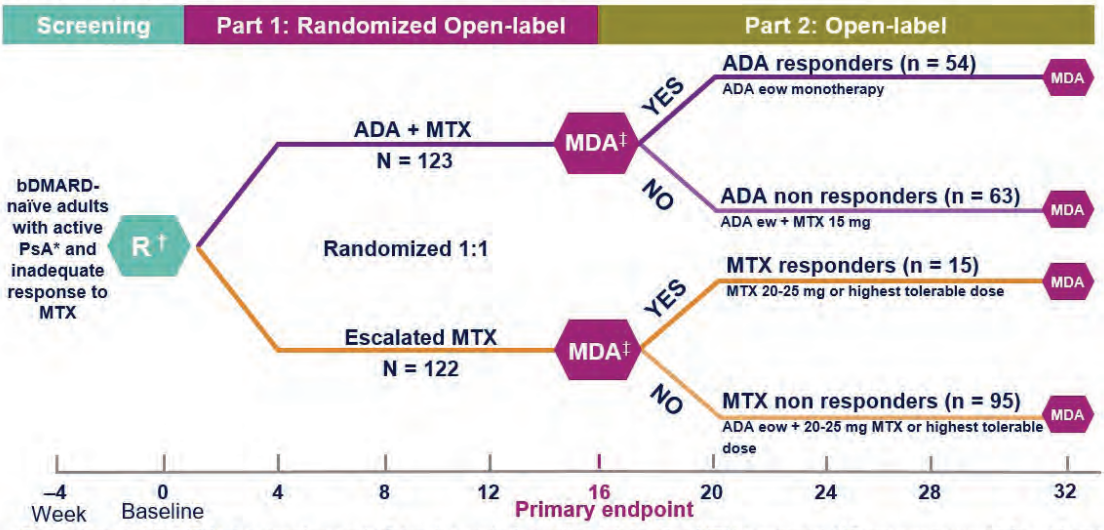
Methods: The open-label, 2-part CONTROL study enrolled bDMARD-naive adult pts with active PsA (not in MDA at screening and ≥3 tender and ≥3 swollen joints) despite MTX 15 mg every wk (ew) for ≥4 wks.[1] During Part 1, pts were randomized to ADA 40 mg every other wk (eow) + MTX 15 mg (ADA + MTX) or escalated MTX to 20–25 mg ew or highest tolerable dose for 16 wks (**Fig 2**). In Part 2 (wk 16 through 32), pts initially randomized to ADA + MTX who

Figure 1. MDA at Week 16 (Primary Endpoint)



MDA, minimal disease activity; MTX, methotrexate.

Figure 2. Study Design

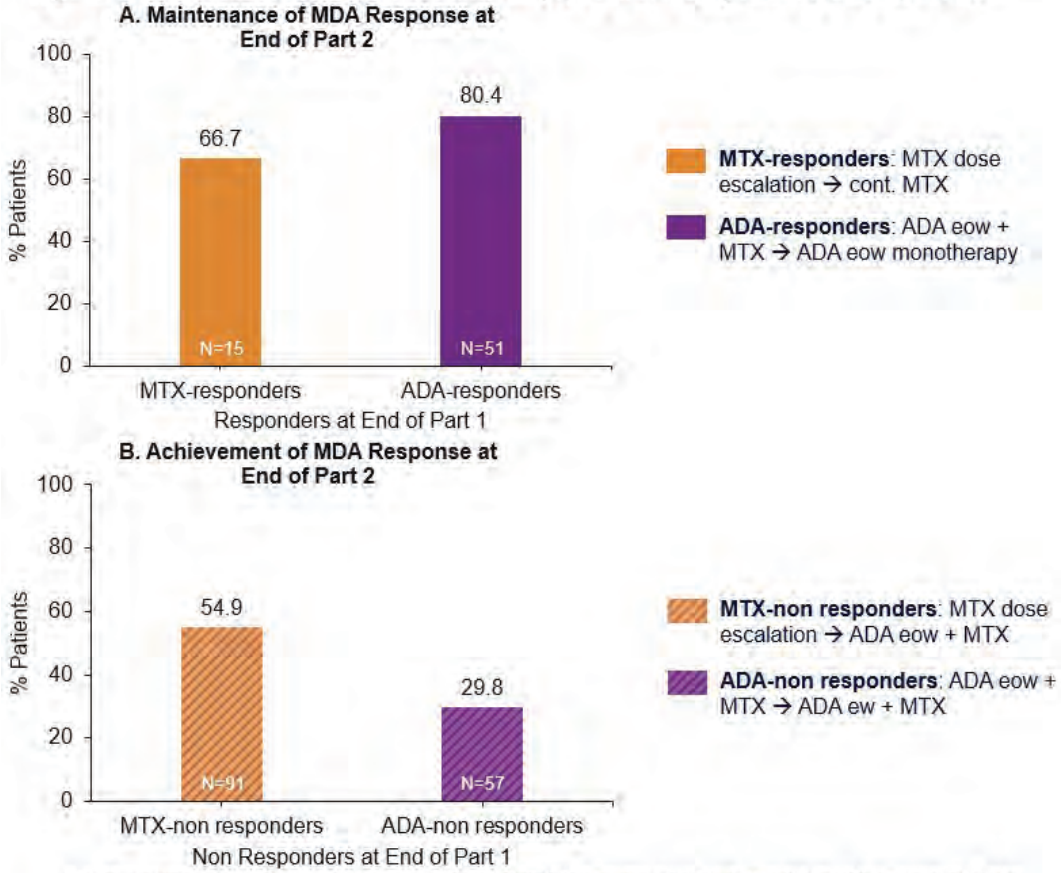


*Defined as not in MDA at screening and ≥3 tender and ≥3 swollen joints after MTX treatment (15 mg every week) for at least 4 weeks.
†Patients stratified by duration of prior MTX (MTX 15 mg/week for ≤3 months or >3 months).
‡Patients were assigned to treatment arms based on their MDA status.

ADA-responders: ADA eow + MTX → ADA eow monotherapy
ADA-non responders: ADA eow + MTX → ADA ew + MTX
MTX-responders: MTX dose escalation → cont. MTX
MTX-non responders: MTX dose escalation → ADA eow + MTX

ADA, adalimumab; bDMARD, biologic disease-modifying antirheumatic drug; eow, every other week; ew, every week; MDA, minimal disease activity; MTX, methotrexate; PsA, psoriatic arthritis.

Figure 3. Maintenance (A) or Achievement (B) of MDA Response at End of Part 2[a]



[a]MDA status was inaccurately identified by the investigator at wk 16 for 6 patients (MTX-responders, n=1; MTX-non responders, n=2; ADA-responders; n=3). Rescue therapy was available starting at wk 24; patients who were rescued were considered non responders for MDA analysis.
ADA, adalimumab; eow, every other week; ew, every week; MDA, minimal disease activity; MTX, methotrexate.

achieved MDA at wk 16 (ADA responders) discontinued MTX and continued ADA 40 mg eow as monotherapy; those initially randomized to ADA + MTX who did not achieve MDA (ADA-non responders) escalated therapy to ADA 40 mg ew + MTX 15 mg ew. For pts initially randomized to escalated MTX, if MDA was achieved at wk 16 (MTX responders), weekly MTX (20-25 mg or highest tolerable dose ew) was continued; if MDA was not achieved (MTX non-responders), pts were switched to ADA 40 mg eow + MTX 20-25 mg or highest tolerable dose ew. Data are reported as observed.

Results: At wk 16, 54 and 15 pts achieved MDA on ADA + MTX or escalated MTX (ADA responders and MTX responders, respectively) (**Fig 2**). There were 63 ADA-non responders and 95 MTX-non responders who did not achieve MDA at wk 16. In the responder groups, 80% of ADA responders were in MDA state at the end of Part 2 after switching from ADA + MTX to ADA monotherapy; whereas 67% of MTX responders were in MDA after maintaining their escalated MTX therapy during Part 2 (**Fig 3A**). Among MTX-non responders who switched from escalated MTX to ADA eow + MTX in Part 2, 55% achieved MDA at the end of Part 2 (**Fig 3B**). Thirty percent of ADA-non responders who did not respond to ADA eow + MTX in Part 1 were able to achieve MDA following escalation of therapy to ADA ew + MTX (**Fig 3B**). In Part 2, the proportion of pts with treatment-emergent adverse events (AE) was as follows: ADA responders: 44.4% (24/54); ADA-non responders: 66.7% (42/63); MTX responders: 33.3% (5/15); MTX-non responders: 56.8% (54/95). Serious AEs were reported infrequently (< 5%) across all groups. Two malignancies were reported: one each in the ADA responder and ADA-non responder groups. There were no opportunistic infections, tuberculosis, or deaths or new safety signals identified in Part 2.

Conclusion: Patients who achieved MDA response in Part 1 generally maintained efficacy through Part 2 despite a reduction in or maintenance of current therapy, with numerically higher proportions of patients achieving MDA response in ADA responders vs MTX responders at wk 32. For patients who did not achieve MDA after 16 wks in Part 1, modification of therapy by addition or escalation of ADA resulted in increased proportions of patients achieving MDA at the end of Part 2. The safety profile of ADA was consistent with the known safety profile.

SESSION INFORMATION

Session Date: Friday, November 6, 2020

Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders I: GCA, Behçet's, & Relapsing Polychondritis

Session Type: Abstract Session

Session Time: 3:00PM–3:50PM

Background/Purpose: Relapsing polychondritis (RP) is a rare, heterogenous, systemic inflammatory disease with a predilection for cartilaginous structures. Recently we discovered myeloid-restricted somatic mutations in *UBA1* in patients with a spectrum of adult-onset inflammatory diseases, and 60% of these patients were diagnosed with RP. Hematologic mosaicism for variants within a single residue of *UBA1* now defines a novel syndrome called VEXAS (vacuoles, E1 enzyme, X-linked, autoinflammatory,somatic). The study objectives were to determine the prevalence of VEXAS in a cohort of patients with RP, to compare their clinical, laboratory, and immunologic features and to develop a clinical algorithm to inform genetic screening for VEXAS among patients with RP.

Methods: Patients that met diagnostic criteria for RP and were ≥18 years old were included. All patients were screened by whole-exome sequencing and *UBA1* variants of interest were confirmed by Sanger sequencing. To determine prevalence of VEXAS within RP, *UBA1* variants were tested in all patients enrolled in a large, prospective, observational cohort of RP. Additional patients with VEXAS were recruited from other cohorts and included in subsequent analyses. Immune populations were quantified by multipanel flow cytometry. Categorical and continuous variables were compared using the chi square or Kruskal-Wallis test. Random forest was used to create an algorithm to identify patients with VEXAS based on key clinical features. $P < 0.05$ defined statistical significance.

Results: Within a prospective cohort of 92 patients with RP, 7 patients were confirmed to have *UBA1* variants consistent with VEXAS (prevalence=8%). Six additional patients with VEXAS from other cohorts were included for subsequent analyses. Compared to RP, patients with VEXAS were all male, older at disease onset, and more likely to have fever, ear chondritis, periorbital edema, skin involvement, deep vein thrombosis, and pulmonary infiltrates. Patients with RP as compared with VEXAS had a significantly higher prevalence of airway chondritis, costochondritis, tenosynovitis/arthralgias, and vestibular symptoms (**Table**). Mortality was significantly greater in VEXAS than RP (27% vs 2% p=0.01). Maximum ESR, CRP, and mean corpuscular volume (MCV) values were significantly greater in VEXAS. Absolute monocyte, lymphocyte, and platelet counts were significantly lower in VEXAS. Reduction of B lymphocytes

Table 1. Clinical Characteristics of Patients with RP vs VEXAS

	All Patients n=98	RP n=85	VEXAS n=13	p value
Demographic Characteristics				
Race, White n (%)	90 (92)	77 (91)	13 (100)	0.59
Sex, Male n (%)	26 (27)	13 (15)	13 (100)	<0.0001
Age, Current visit, years, Median (IQR)	47 (38-57)	45 (36-55)	62 (56-70)	<0.0001
Disease Duration, years, Median (IQR)	8 (3.25-13)	8 (4-15)	4 (2-5)	0.0068
Age, Symptom onset, years, Median (IQR)	38 (30-47)	37 (28-43)	56 (54-64)	<0.0001
Clinical Symptoms				
Fever n (%)	33 (34)	20 (24)	13 (100)	<0.0001
Ear chondritis n (%)	61 (62)	48 (56)	13 (100)	0.0015

Need for transfusion n (%)	6 (6)	0 (0)	6 (46)	<0.0001
Unprovoked DVT n (%)	12 (12)	4 (5)	8 (62)	<0.0001
Medications				
Prednisone dose, (mg), mean (IQR)	7.25 (0-20)	5 (0-20)	17.5 (5-30)	0.065
Prednisone n (%)	61 (63)	51 (60)	10 (91)	0.045
Number of steroid sparing agents ever, mean (IQR)	3 (2-4)	2 (2-4)	4 (3-7)	0.0043

N = number; IQR = interquartile range

and nonclassical monocytes (CD14-/CD16+) relative to healthy controls was observed in both RP and VEXAS, but was more marked in VEXAS. Increased Th17 cells was observed only in RP. A decision tree based on 1) Male sex or age at onset >50, 2) MCV >100 and 3) platelet count< 200 classified between VEXAS and RP with 100% sensitivity and 96% specificity.

Conclusion: Mutations in *UBA1* are causal for disease in 8% of patients with RP. These patients have unique clinical characteristics that readily distinguish them from other patients with RP. A screening algorithm based on four, easily measurable clinical variables differentiates between VEXAS and RP with near-perfect accuracy. Early disease detection and improved clinical management is important in VEXAS given the high rate of mortality in this genetic subset of RP.

SESSION INFORMATION

Session Date: Friday, November 6, 2020

Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders I: GCA, Behçet's, & Relapsing Polychondritis

Session Type: Abstract Session

Session Time: 3:00PM–3:50PM

Background/Purpose: Giant cell arteritis (GCA) is a large and medium size-vessel granulomatous vasculitis that predominantly affects the aorta and its major branches. The renin-angiotensin-aldosterone system (RAAS) is a multiple-step cascade of vasoactive peptides that plays a major role in the regulation of blood pressure and electrolyte balance. Angiotensin II (ATII), the major effector molecule of the RAAS, has emerged as a powerful pro-inflammatory peptide and pharmacological blockade of this system results in anti-inflammatory effects. In this line, a previous observational study suggested that treatment with angiotensin II blockers (ARB) was associated with lower relapse rate and glucocorticoid (GC)-sparing effect in patients with GCA (Alba MA, Semin Arthritis Rheum. 2014). Our objective was to investigate the expression and functional activity of the ATII system in GCA temporal arteries (TA).

Methods: 40 involved TA from patients with GCA and 18 normal arteries from controls were included. Angiotensinogen (AGT), angiotensin-converting enzyme (ACE), ATII receptor 1 (ATR1), and counter-regulatory ACE2 expression was investigated by quantitative real-time PCR in TA. Distribution of ATII system components was assessed by confocal microscopy. The effect of ATII and ATR1-blockade on pro-inflammatory cytokine production was investigated in a co-culture system of peripheral blood mononuclear cells (PBMC) and TA-derived vascular smooth muscle cells (VSMC). In addition, modulation of the ATII system by GC was addressed using an *ex vivo* model of cultured TA.

Results: A local ATII system, mainly characterized by constitutive expression of ATG, overexpression ACE mRNA transcripts and a down-regulation of ACE2 was identified in GCA inflamed arteries (figure 1). By confocal microscopy, ATII, ACE, and ATR1 expression was identified to be qualitatively higher in GCA sections in comparison with a control TA. The local ATII system appears to require multi-cellular cooperation as VSMC were the main cells expressing ATII and ATR1 while ACE was predominantly expressed by inflammatory infiltrating cells. *In vitro*, ATII was able to induce a pro-inflammatory phenotype in PBMC and co-cultured VSMC: IL-1β, IL-6, TNF-α, CCL-2, ICAM-1, and VCAM-1 mRNA expression measured by real-time quantitative PCR was increased in PBMC whereas IL-1β, IL-6, CCL-2, ICAM-1, and VCAM transcripts increased in VSMC co-cultured with PBMC. Losartan, an ARB, was able to reverse

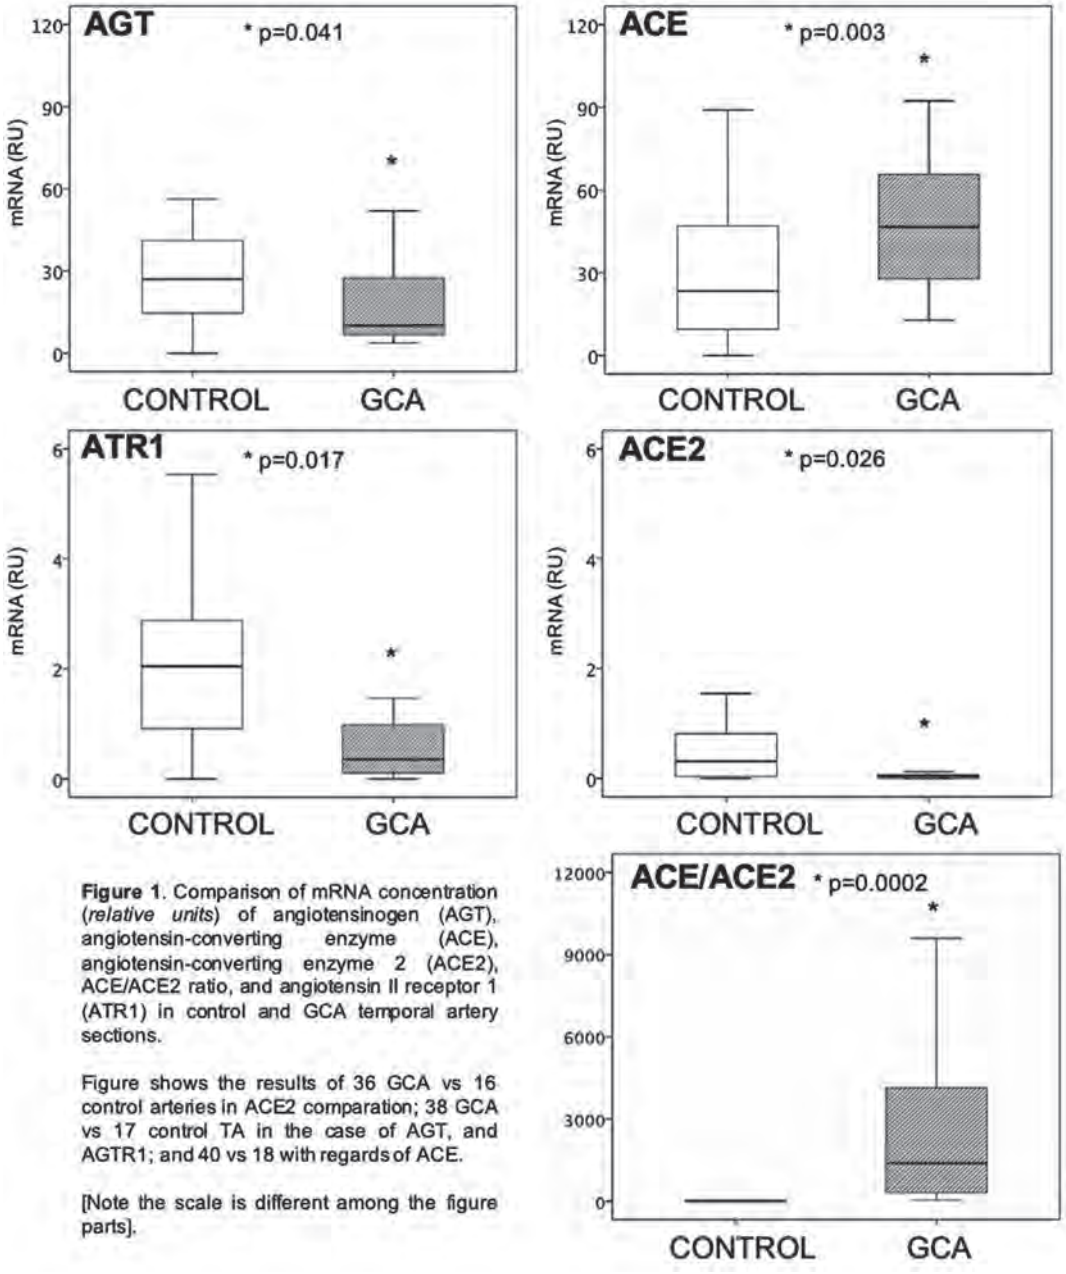

Figure 1. Comparison of mRNA concentration (*relative units*) of angiotensinogen (AGT), angiotensin-converting enzyme (ACE), angiotensin-converting enzyme 2 (ACE2), ACE/ACE2 ratio, and angiotensin II receptor 1 (ATR1) in control and GCA temporal artery sections.

Figure shows the results of 36 GCA vs 16 control arteries in ACE2 comparation; 38 GCA vs 17 control TA in the case of AGT, and AGTR1; and 40 vs 18 with regards of ACE.

[Note the scale is different among the figure parts].

these changes and interestingly, it reduced basal expression of IFN-γ, CCL-2, ICAM-1, and VCAM-1 in PBMC. Finally, we observed that dexamethasone was able to modulate the expression of the ATII system by reducing ACE gene expression and increasing ATR1 and ACE2 in an *ex-vivo* model of cultured temporal arteries.

Conclusion: Our findings suggest that the ATII system may play a role in vascular inflammatory lesions of GCA. Thus, interference of the RAAS system may be a potential adjunctive therapeutic option for patients with GCA.

MA Alba and E Planas-Rigol contributed equally to this study. Supported by Ministerio de Economía y Competitividad (SAF 2017/88275-R). MA Alba was supported by BITRECS.

Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders I: GCA, Behçet's, & Relapsing Polychondritis

Session Type: Abstract Session

Session Time: 3:00PM–3:50PM

Background/Purpose: HLA-B51 is a definite risk factor for Behçet's disease (BD). A coding variant of ERAP1, Hap10 – with low peptide-trimming activity – vastly potentiates this risk, but is mechanistically unclear. Here, we aimed to test the hypothesis that low or absent ERAP1 activity alters CD8 T cell immunogenicity through changes in the HLA-B51 peptidome and shapes the CD8 T cell immune response in affected subjects.

Methods: We generated HLA-B51^{+}ERAP1 KO LCL clones using CRISPR-Cas9, performed mass spectrometry of the immunoprecipitated MHC-class I peptidome with subsequent computational deconvolution for HLA-B51-binding peptides. We then assessed single cell (ICS), bulk (ELISA) and proliferative (CFSE) CD8 effector (IFNG, granzyme-B, perforin) T cell responses through stimulation of allogeneic donor cells with WT vs KO LCL and determined ERAP1 haplotypes in 49 untreated Turkish BD subjects with ocular and/ or vascular involvement as well as healthy donors (HD) whose PBMC were profiled using 6 multicolor flow cytometry panels.

Results: WT and KO peptidomes differed significantly ($p< 0.0005$ Fisher's exact test) with a distinct shift of peptide length frequencies exceeding 9-mer (binding optimum) in the KO vs WT. This held true for computationally deconvoluted HLA-B51 binders. IFNG secretion from CD8 T cells stimulated with KO LCL was significantly different from WT (ICS, $p=0.0006$; ELISA, $p=0.0059$) as were CD8 T cell proliferation and ICS of perforin/ granzyme-B^{+} CD8 T cells. Analysis of 133 T, B, NK, and monocyte cell populations revealed a predominance of CD8 T and NKT cell subset in HLA-B51+/Hap10+ BD vs HLA-B51+/Hap10- BD and HD, accounting for 80% of all populations reaching significance ($p< 0.05$, Mann-Whitney). Naive and effector memory CD8 T cell subsets were inversely correlated. Cohen's effect sizes were large (>0.8) or very large (>1.2).

Conclusion: We show that the absence of functional ERAP1 alters human CD8 T cell immunogenicity. This is mediated by an HLA-class I peptidome with a propensity for longer peptides above 9mer and suggests a loss or de-novo presentation of peptide-HLA-B51 complexes to cognate CD8 TCR. The reciprocal changes in antigen-experienced vs naive CD8 T cell subsets in affected subjects point to the biologic significance of HLA-B51/Hap10 in BD. Collectively, our findings suggest that an altered HLA-B51 peptidome modulates the immunogenicity of CD8 effector T cells in ERAP1-Hap10 carriers with BD and identifies targets for future drug development.

Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders I: GCA, Behçet's, & Relapsing Polychondritis

Session Type: Abstract Session

Session Time: 3:00PM–3:50PM

Background/Purpose: Behçet's syndrome is a chronic, multi-system inflammatory disorder characterized by painful and recurrent oral ulcers (OU) and other manifestations, such as skin lesions and arthritis, that have a significant impact on quality of life (Hatemi G. *Ann Rheum Dis*. 2018;77:808-818). Apremilast, an oral phosphodiesterase 4 inhibitor, demonstrated efficacy in the treatment of OU in the phase 3 RELIEF study (Hatemi G, et al. *N Engl J Med*. 2019;381:1918-1928). We describe outcomes for non-OU manifestations of Behçet's syndrome in patients (pts) treated with apremilast (APR) 30 mg BID vs placebo (PBO) in RELIEF.

Methods: RELIEF was a multicenter, randomized, double-blind, PBO-controlled study (BCT-002; NCT02307513). Eligible pts were adults with active Behçet's syndrome and ≥3 OU at randomization or ≥2 OU at screening and randomization, without active major organ involvement. Pts were randomized (1:1) to receive APR or PBO up to Week 12 and stratified by region (Japan/other). The proportions of pts with ≥1 new, recurrent, or worsening non-OU manifestations

Weeks	1	2	4	6	8	10	12
PBO, n	98	98	94	92	88	83	82
APR, n	102	101	101	97	95	94	97

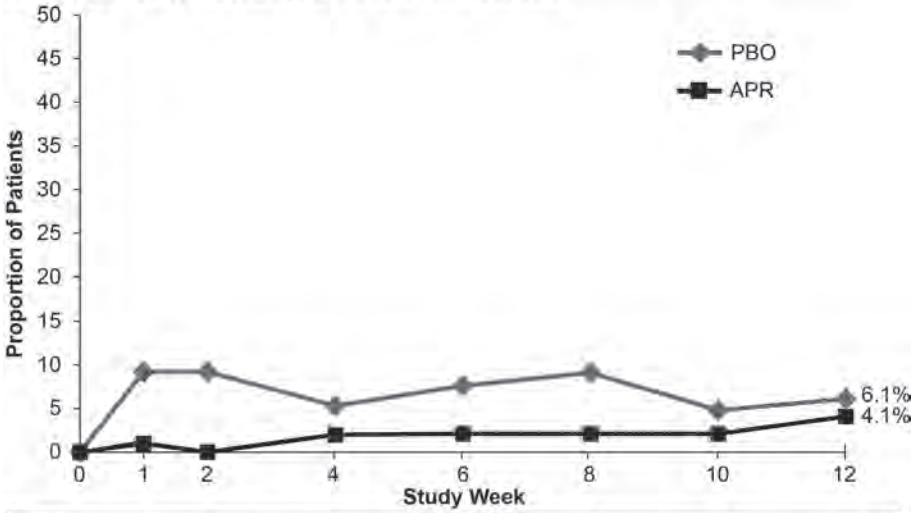
Intent-to-treat population. Data as observed. n = number of patients.

Figure 3. Proportion of Patients in the Overall Population With ≥1 New, Recurrent, or Worsening Arthritis From Baseline



Weeks	1	2	4	6	8	10	12
PBO, n	98	98	94	92	88	83	82
APR, n	102	101	101	97	95	94	97

Intent-to-treat population. Data as observed. n = number of patients.

(ie, skin lesions, arthritis, uveitis, and gastrointestinal, CNS, or vascular manifestations) were assessed up to Week 12 in the overall population and in a Japanese subgroup. Change from baseline (BL) at Week 12 in scores on the Physician's Global Assessment (PGA) of skin lesions, swollen joint count (SJC), and tender joint count (TJC) in pts with skin lesions, SJC >0, and TJC >0 at BL, respectively, were assessed in the overall and Japanese subgroup populations.

Results: A total of 207 pts were randomized and received ≥1 dose of study medication in the overall population (APR: n=104; PBO: n=103), including 39 pts in the Japanese subgroup (APR: n=19; PBO: n=20). During the 12-week PBO-controlled period, the proportions of pts with ≥1 new, recurrent, or worsening non-OU manifestations (Figure 1), skin lesions (Figure 2), or arthritis (Figure 3) were lower in pts treated with APR vs PBO in the overall population. In

the Japanese subgroup, lower proportions of pts in the APR vs PBO group had new, recurrent, or worsening non-OU manifestations (5.9% [1/17] vs 31.3% [5/16]), skin lesions (5.9% [1/17]) vs 18.8% [3/16]), and arthritis (0.0% [0/17] vs 6.3% [1/16]) at Week 12. In the overall population treated with APR vs PBO, mean (SD) BL values were 3.4 (3.1) vs 5.7 (7.1) for SJC and 6.5 (8.5) vs 6.0 (8.0) for TJC; LS mean (95% CI) changes from BL at Week 12 were –0.9 (–1.1, –0.6) vs –0.8 (–1.0, –0.5) for PGA of skin lesions, –3.1 (–5.2, –1.0) vs –2.9 (–5.0, –0.8) for SJC, and –4.4 (–6.3, –2.4) vs –2.7 (–4.5, –0.9) for TJC. In the Japanese subgroup treated with APR vs PBO, mean (SD) BL values were 1.5 (0.7) vs 3.7 (3.8) for SJC and 6.4 (10.5) vs 4.3 (4.8) for TJC; LS mean (95% CI) changes from BL at Week 12 were –0.7 (–1.4, –0.1) vs –0.5 (–1.1, 0.2) for PGA of skin lesions, –3.0 (–9.6, 3.6) vs –2.3 (–8.6, 4.0) for SJC, and –3.7 (–6.1, –1.2) vs –2.4 (–4.4, –0.5) for TJC.

Conclusion: Pts with active Behçet's syndrome in the overall population and the Japanese subgroup of RELIEF achieved lower rates of new, recurrent, or worsening non-OU manifestations, including skin lesions and arthritis, and numerically greater improvements in PGA of skin lesions, SJC, and TJC with APR vs PBO over 12 weeks.

Mass Spectrometry Identifies Novel Biomarkers in Giant Cell Arteritis, Useful in Patients on Interleukin-6 Receptor Blockade

Sebastian Unizony[1], Robert Morris[2], Johannes Kreuzer[2], Wilhelm Haas[2] and John H. Stone[1], [1]Massachusetts General Hospital Rheumatology Unit, Harvard Medical School, Boston, MA, [2]Massachusetts General Hospital, Boston, MA

SESSION INFORMATION
Session Date: Friday, November 6, 2020
Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders I: GCA, Behçet's, & Relapsing Polychondritis
Session Type: Abstract Session
Session Time: 3:00PM–3:50PM

Background/Purpose: We aimed to identify biomarkers of disease activity in giant cell arteritis (GCA) patients treated with prednisone monotherapy and with prednisone in combination with tocilizumab (TCZ)

Methods: We mapped the serum proteome of GCA patients with active and inactive disease in an unbiased manner using high-throughput multiplexed mass spectrometry. Proteomic analyses were performed in 5 µl serum samples with 11-plexed tandem mass tag (TMT) technology using an Orbitrap Lumos mass spectrometer. A SEQUEST-based database search engine was employed for peptide identification. Quantification was based on TMT reporter ion intensities. All patients were sampled during their participation in the GiACTA trial,[1] in which they received TCZ plus 26 weeks of prednisone (TCZ group) or placebo plus 26 or 52 weeks of prednisone (PRED group). Active disease was defined as the presence of cranial or PMR symptoms requiring treatment intensification regardless of ESR and CRP levels. Samples were selected if patients were in clear states of active or inactive disease at GiACTA systematic sample collection timepoints (baseline and weeks 4, 12, 24, 48). An exhaustive leave-2-out strategy was used to identify classification markers. Proteins with an absolute log2 fold concentration difference ≥0.5 between active and inactive samples and a P-value < 0.1 were retained and sorted based on the metric -log10(P-value)*absolute(log2

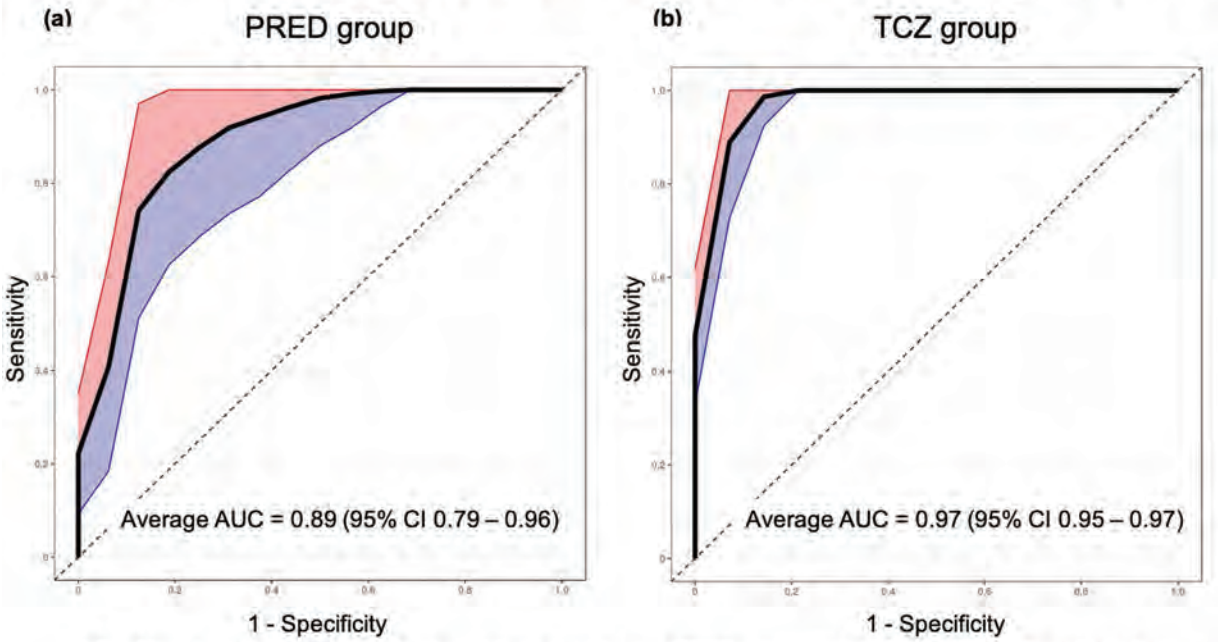
Figure 1. Differentially expressed serum proteins in giant cell arteritis patients with active and inactive disease

	log2 fold change	P-value
Serum amyloid A2 (SAA2)	4.8	0.0054
Complement factor H (CFH)	4.1	0.0003
Serum amyloid A1 (SAA1)	2.9	0.0005
C-reactive protein (CRP)	2	0.0650
Pregnancy zone protein (PZP)	1.5	0.0028
Immunoglobulin Kappa Variable 1-5 (IGKV1-5)	1.5	0.0746
Alpha-1-acid glycoprotein 1 (ORM1)	0.8	0.0033
Serum amyloid A4 (SAA4)	0.7	0.0005
Alpha 1-antichymotrypsin (SERPINA3)	0.7	0.0009
Leucine-rich alpha-2-glycoprotein 1 (LRG1)	0.6	0.0026

	log2 fold change	P-value
Haptoglobin precursor (pHP)	2.3	0.0006
Haptoglobin (HP)	1.9	0.0001
Serum amyloid A2 (SAA2)	1.6	0.0165
Complement factor 4A (C4A)	1	0.0079
Alpha-1-acid glycoprotein 2 (ORM2)	0.8	0.0016
Alpha 1-antichymotrypsin (SERPINA3)	0.8	0.0001
Complement factor 8A (C8A)	0.7	0.0001
Complement factor 5 (C5)	0.6	<0.0001
Complement factor 6 (C6)	0.5	<0.0001
Peptidase Inhibitor 16 (PI16)	-1	0.0055

(a) Top 10 markers in patients treated with prednisone monotherapy (PRED group); (b) top 10 markers in patients treated with tocilizumab and prednisone (TCZ group)

Figure 2. Accuracy of top biomarkers for discrimination between active and inactive giant cell arteritis



(a) Top 10 markers in patients treated with prednisone monotherapy (PRED group); (b) top 10 markers in patients treated with tocilizumab and prednisone (TCZ group)

fold change). The accuracy of the top 10 biomarkers for classification of active versus inactive disease in each group was evaluated by determining areas under the curves (AUC) of receiver operator characteristic (ROC) curves.

Results: The PRED group included 21 patients (active, n = 16; inactive, n = 5) and the TCZ group included 21 patients (active, n = 14; inactive, n = 7). Compared to inactive PRED-treated patients, active PRED-treated patients showed significant overexpression of several acute phase reactants including serum amyloid A1 and 2 (SAA1, SAA2) and complement factor H (CFH) (**Fig. 1a**). The magnitude of concentration change and the level of statistical significance observed for SSA1, SSA2 and CFH in PRED-treated patients were higher than those of CRP (**Fig. 1a**). Compared to inactive TCZ-treated patients, active TCZ-treated patients demonstrated significant overexpression of multiple biomarkers including haptoglobin, haptoglobin precursor, SSA2 and complement factor 4A, and underexpression of peptidase inhibitor 16 (**Fig. 1b**), a protein involved in vascular and regulatory T cell biology. Sets of 10 biomarkers resulted in a classification of active versus inactive disease with ROC AUCs of 0.89 (95% CI 0.79-0.96) in the PRED group (**Fig. 2a**) and 0.97 (95% CI 0.95-0.97) in the TCZ group (**Fig. 2b**).

Conclusion: We identified several differentially expressed serum proteins in GCA patients with active and inactive disease receiving prednisone monotherapy or TCZ-based treatment regimens. In both treatment groups, a signature of biomarkers classified disease activity status with high accuracy. Haptoglobin, a readily available laboratory test, may be useful in monitoring disease activity in GCA patients receiving IL-6 blockade therapy.

Feasibility of 18F-fluorodeoxyglucose Positron Emission Tomography to Monitor the Effect of Tocilizumab on Vascular Inflammation in Giant Cell Arteritis: A Prospective Observational Cohort Study

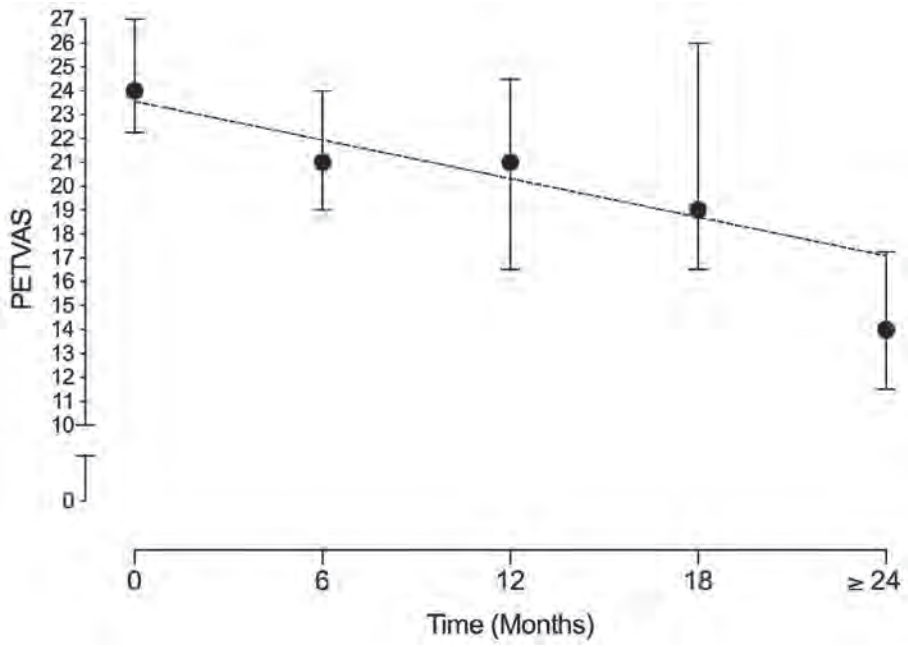
Kaitlin Quinn[1], Himanshu Dashora[2], Mark Ahlman[3], Elaine Novakovich[2] and Peter C. Grayson[2], [1]Systemic Autoimmunity Branch, National Institutes of Health, NIAMS, Bethesda, [2]Systemic Autoimmunity Branch, National Institutes of Health, NIAMS, Bethesda, MD, [3]National Institutes of Health, Clinical Center, Radiology and Imaging Sciences, Bethesda, MD

SESSION INFORMATION
Session Date: Friday, November 6, 2020
Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders II: GCA Clinical & Epidemiology
Session Type: Abstract Session
Session Time: 4:00PM–4:50PM

Background/Purpose: Two randomized controlled trials have demonstrated the clinical efficacy of tocilizumab for treatment of giant cell arteritis (GCA) (1,2). In these trials, response to treatment was defined by improvement in clinical and laboratory-based assessment of disease activity, but direct assessment of the large arteries by vascular imaging was not systematically evaluated.

The objective of this study was to evaluate the longitudinal effects of tocilizumab on vascular inflammation as measured by ^{18}F-fluorodeoxyglucose positron emission tomography (FDG-PET) in giant cell arteritis (GCA).

Methods: Patients with GCA treated with tocilizumab were selected from an ongoing prospective, observational cohort. All patients fulfilled modified 1990 American College of Rheumatology (ACR) Classification Criteria for GCA.



Patients underwent FDG-PET computed tomography (CT) at the baseline visit prior to the initiation of tocilizumab and at subsequent follow-up visits. In a subset of patients in whom tocilizumab was discontinued due to established remission, a repeat FDG-PET scan was obtained after therapy discontinuation.

A single reader reviewed all PET scans, blinded to clinical data. Qualitative assessment of FDG uptake relative to liver uptake by visual assessment (scale 0-3) was assessed in 9 arterial territories. A summary score, PET Vascular Activity Score (PETVAS), was calculated (scale 0-27).

Wilcoxon signed rank test was used to compare change in PETVAS between study visits. Linear regression was used to determine change in PETVAS over multiple timepoints.

Results: Twenty-five patients with GCA were included. All patients had clinically active disease with associated active vasculitis by FDG-PET imaging at the baseline visit. PETVAS was significantly reduced in association with tocilizumab treatment from the baseline to the most recent follow-up visit [24.0 (IQR 22.3-27.0) vs. 18.5 (IQR 15.3-23.8); $p< 0.01$]. A significant reduction in PETVAS was observed over a two-year treatment period ($p< 0.01$ for linear trend), with a similar degree of improvement in both the first and the second years of treatment (Figure).

In a subset of six patients who discontinued tocilizumab due to established remission [median PETVAS 18.5 (16.5-21.0) at time of remission], a repeat FDG-PET scan at least 6 months after treatment discontinuation showed worsening PET activity in 5 out of 6 patients [median PETVAS 21.5 (17.3-23.0)]. Two of these patients subsequently experienced a clinical relapse.

Conclusion: Treatment of patients with GCA with tocilizumab was associated with both clinical improvement and reduction of vascular inflammation as measured by serial FDG-PET. There was continued improvement of vascular inflammation at both year 1 and year 2 of treatment, and this preliminary evidence suggests a rebound of vascular inflammation when tocilizumab was discontinued. These data support the use of FDG-PET as a novel outcome measure in clinical trials in GCA.

SESSION INFORMATION

Session Date: Friday, November 6, 2020

Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders II: GCA Clinical & Epidemiology

Session Type: Abstract Session

Session Time: 4:00PM–4:50PM

Background/Purpose: Two randomized controlled trials [Villiger et al. Lancet 2016; Stone et al. NEJM 2017] demonstrated a glucocorticoid (GC)-sparing effect of tocilizumab (TCZ) of at least 50%. The GUSTO (GCA treatment with Ultra-Short GC and TCZ) trial was set up to unravel the efficacy and safety of TCZ-monotherapy after ultra-short GC treatment in new-onset GCA. Data up to week 24 are presented.

Methods: In this investigator-initiated, single-arm, single-center, open-label clinical trial with Simon's two stage design, 18 patients with newly diagnosed GCA were enrolled (NCT03745586). Patients received 500mg methylprednisolone intravenously for three consecutive days. Thereafter, GC treatment was discontinued and TCZ (8mg/kg body-weight) was administered intravenously, followed by weekly subcutaneous TCZ injections (162mg) from day 10 until week 52. The primary endpoints included the proportion of patients (i) achieving remission within 31 days and (ii) without relapse at week 24. Remission was defined as disappearance of GCA symptoms; partial remission included the presence of mild symptoms (defined as non-ischemic with NRS < 5/10, reported as mild, not occurring on most days of the week). An interim analysis of the primary endpoint was performed after the first 12 patients reached the primary endpoint, analysis of the 24-week outcome after all patients reached 24 weeks.

Results: Baseline characteristics include 12/18 female patients with a median age of 72 (range 64-78) years, 11/18 with median 1 (range 1-7) day of prior GC-treatment, 15/18 with cranial symptoms (10/18 with jaw claudication, 6/18 with visual involvement), 10/18 with PMR-symptoms, 16/18 with positive cranial ultrasound, 14/18 with aortitis on MRI, 14/18 with vasculitis on cranial MRI and 13/18 with GCA-findings in temporal biopsy.

At the interim analysis, 3/12 patients achieved remission at 31 days and stayed relapse-free until week 24 (25%, 95% confidence interval (CI) 5-57%), i.e. less than necessary to continue to the second stage. We could therefore not reject the null hypothesis that the proportion of responders is smaller than 40% (p=0.92). 11/12 patients achieved remission within 24 weeks after a mean of 74 days (95% CI 50-98) and 10 stayed relapse-free up to 24 weeks (83%, 95% CI 52-98%).

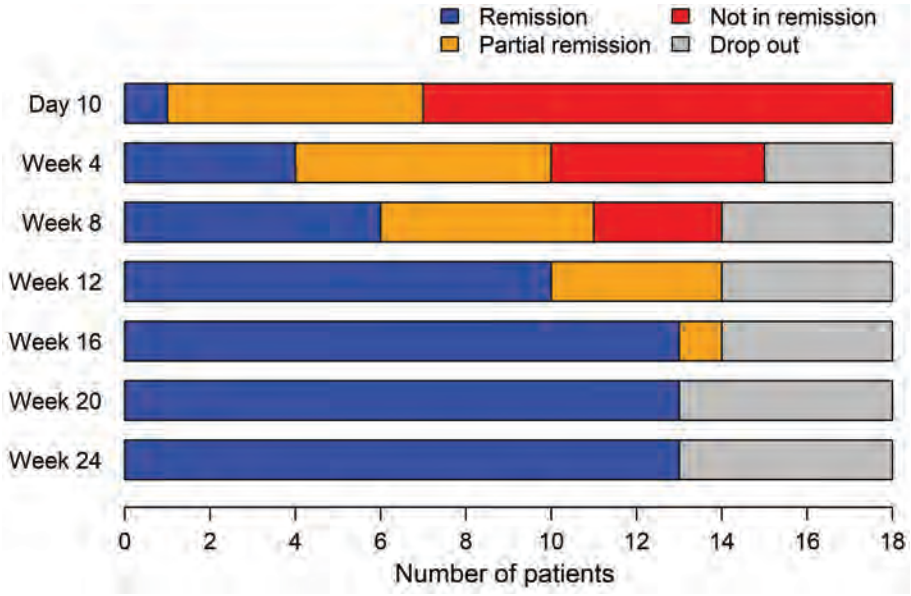

Figure 1. Disease status of patients at each visit (Day 0 - week 24, n=18).

Of the 18 patients recruited up to the time point of the interim analysis, 14 achieved remission within 24 weeks after a mean of 78 days (95% CI 58-97) and 13 stayed relapse-free up to 24 weeks (72%, 95% CI 47-90%).

3/18 patients (17%) were non-responders and started on rescue GC-treatment (2/3 with persistent cranial symptoms including one new-onset anterior ischemic optic neuropathy (AION); 1/3 with persistent PMR symptoms), 2/18 (11%) discontinued the study due to an adverse event (hepatopathy and diverticulitis, respectively; 1/2 after induction of remission). Figure 1 demonstrates remission status over time.

Conclusion: After a 3-days pulse of methylprednisolone, ensuing TCZ monotherapy induced and maintained remission until week 24 in 13/18 patients. Although the primary end-point was not met, the data add an important piece of evidence regarding the potency of blocking the IL-6 pathway in GCA.

Abstract Number: 0516

Characteristics of Giant Cell Arteritis Flares After Successful Treatment with Tocilizumab: Results from the Long-Term Extension of a Randomized Controlled Phase 3 Trial

Sebastian Unizony[1], Shalini V. Mohan[2], Jian Han[2] and John H. Stone[1], [1]Massachusetts General Hospital Rheumatology Unit, Harvard Medical School, Boston, MA, [2]Genentech, South San Francisco, CA

SESSION INFORMATION
Session Date: Friday, November 6, 2020
Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders II: GCA Clinical & Epidemiology
Session Type: Abstract Session
Session Time: 4:00PM–4:50PM

Background/Purpose: To investigate the characteristics of disease flare after successful treatment with tocilizumab (TCZ) in patients with giant cell arteritis (GCA).

Methods: We performed a post hoc analysis of data from part 2 of the GiACTA trial. GiACTA consisted of a 52-week, double-blind, randomized controlled treatment period (part 1) and a 2-year long-term follow-up (part 2). In part 1, patients received TCZ 162 mg subcutaneously every week or every other week with a 26-week prednisone taper (TCZ+Pred) or placebo plus a 26-week or a 52-week prednisone taper. Patients who achieved the primary outcome of sustained remission through week 52 while adhering to the protocol prednisone taper entered part 2 on no treatment. Any treatment during part 2 was administered open-label at the investigator's discretion. We analyzed the characteristics of first disease flare in patients originally assigned to the TCZ+Pred arms who were in sustained remission at the end of part 1 (week 52) and experienced flare in part 2. Flare was defined as the reappearance of cranial symptoms (headaches, jaw claudication, visual manifestations, scalp tenderness) or polymyalgia rheumatica (PMR) symptoms or as the elevation of erythrocyte sedimentation rate (ESR) ≥30 mm/h that was attributable to GCA and necessitated treatment. ACR GCA classification criteria were fulfilled by 78% of patients

Results: Among 149 patients treated with TCZ+Pred in part 1, 81 (54%) were in sustained remission at week 52 upon entering part 2 (Table 1). Of these 81 patients, 37 (46%) experienced at least one flare during part 2, including 17 patients with new-onset GCA and 20 patients with relapsing GCA at the start of the trial. Flares among patients with new-onset GCA presented with cranial symptoms (53%) more often than PMR symptoms (18%). In contrast, the incidence of cranial (60%) and PMR (60%) symptoms was balanced in patients with relapsing GCA. Visual manifestations occurred in two patients (5%) who experienced flare (Table 2). ESR and CRP were elevated in 68% and 36% of patients, respectively, at the time of flare. Median ESR and CRP values around the time of flare were 37.0 mm/h and 5.44 mg/L, respectively, in patients with new-onset GCA and 35.0 mm/h and 8.6 mg/L, respectively, in patients with relapsing GCA. Only three (8%) of the flares were identified as ESR elevation without cranial or PMR symptoms.

Conclusion: Overall, 46% of GCA patients successfully treated with TCZ for 12 months experienced disease flare within the following 2 years. Flares in patients with new-onset disease at the time of TCZ initiation occurred more often with cranial symptoms than PMR symptoms. Visual manifestations were rare at the time of flare, and no cases of blindness occurred. ESR was within the normal range in one-third of the patients who experienced flare.

Table 1. Baseline Demographics and Disease Characteristics

Characteristic	Part 1 Treatment[a]	
	TCZ QW+Pred n = 56	TCZ Q2W+Pred n = 25
Age, mean (SD)	68.4 (8.3)	70.0 (8.6)
Female, n (%)	44 (78.6)	14 (56.0)
Race white, n (%)	56 (100)	24 (96.0)
Positive TAB, n (%)	29 (82.9)	18 (85.7)
Positive vascular imaging, n (%)	30 (53.6)	12 (48.0)
New onset GCA, n (%)	28 (50.0)	14 (56.0)
Prednisone dose, mg/day, mean (SD)	34.8 (12.1)	37.4 (12.8)

TAB, temporal artery biopsy.

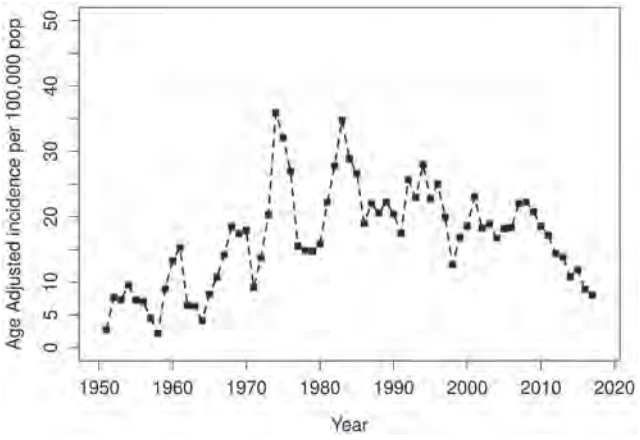
Trends in the Incidence and Use of Diagnostic Modalities for Giant Cell Arteritis over Seven Decades: A Population-based Study

Thomas Garvey[1], Cynthia Crowson[2], Matthew J. Koster[3] and Kenneth Warrington[3], [1]Mayo Clinic Rochester, Apple Valley, MN, [2]Mayo Clinic, Rochester, Minnesota, USA, Rochester, MN, [3]Mayo Clinic, Rochester, MN

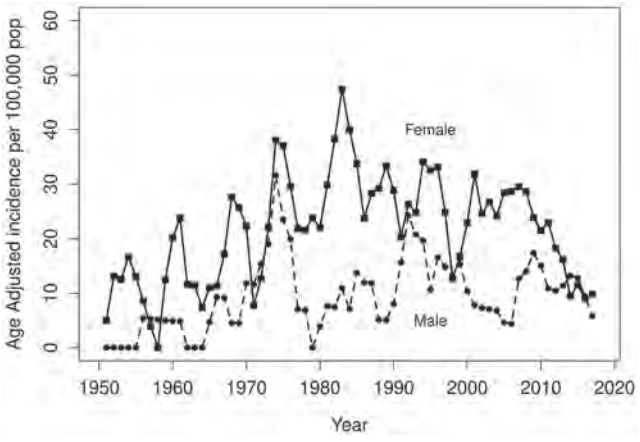
SESSION INFORMATION
Session Date: Friday, November 6, 2020
Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders II: GCA Clinical & Epidemiology
Session Type: Abstract Session
Session Time: 4:00PM–4:50PM

Background/Purpose: Diagnostic methods for giant cell arteritis (GCA) have evolved over recent decades, and large vessel imaging plays an increasing role in disease detection. The purpose of this study is to examine the incidence of GCA in recent decades, and to analyze trends in the frequency of GCA subsets according to diagnostic modalities.

Methods: A pre-existing population-based cohort of patients diagnosed with GCA between 1950 and 2009 was extended with incident cases from 2010 to 2018. The diagnosis of GCA was confirmed by review of medical records



Trends in the incidence of GCA in Olmsted County (1950-2018)



Trends in the incidence of GCA in Olmsted County by sex (1950-2018)

of patients with ICD9/10 codes for GCA between 1/1/2010 and 12/31/2018. Incident cases that met either one of the following sets of inclusion criteria were added to the cohort: one, American College of Rheumatology 1990 GCA classification criteria; or two, patients aged ≥50 years with elevation of erythrocyte sedimentation rate or C-reactive protein and radiographic evidence of large vessel vasculitis attributed to GCA. Incident cases were classified into one of three groups: group 1, temporal artery biopsy (TAB) positive; group 2, TAB negative or not done with positive large-vessel imaging; or group 3, clinical diagnosis of GCA.

Results: The study cohort included 302 patients diagnosed with GCA from 1950 until 2018. Fifty-two incident cases were diagnosed between 2010 and 2018; 34 females (65%) and 18 males (35%). The age and sex adjusted incidence rates (95% CI) per 100,000 between 2010 and 2018 for females, males, and the total population were 13.6 (9.0, 18.1), 9.8 (5.2, 14.3), and 11.6 (8.4, 14.7), respectively. The corresponding incidence rates from 2000-2009 were 28.1 (21.0, 35.2), 10.2 (5.0, 15.5), and 20.5 (15.9, 25.1), respectively. This represents a significant decline in the incidence rates in females ($p< 0.001$) and the total group ($p< 0.001$) between the 2000-2009 and 2010-2018 cohorts but no change in males ($p=0.92$). Of the 52 patients diagnosed between 2010 and 2018, there were 35 (67%) in group 1, 10 (19%) in group 2, and 7 (13%) in group 3. In contrast, of the 250 patients diagnosed between 1950 and 2009 there were 209 (84%) in group 1, 4 (2%) in group 2, and 37 (15%) in group 3. There was a significant difference between the 1950-2009 and 2010-2018 cohorts in the composition of these groups ($p< 0.001$).

Conclusion: In this population-based cohort of patients with GCA diagnosed over a 69-year period, the incidence of GCA has declined in recent years. The total decline is driven by a decline in females but not in males. The reasons for this are unclear but should be followed over time and investigated in other population-based cohorts. There has also been a shift in the diagnostic modalities for GCA. In recent years, there are fewer TAB positive patients, and more patients diagnosed with large vessel imaging. This is the first population-based incidence cohort demonstrating a trend towards increased use of large vessel imaging for the diagnosis of GCA.

Abstract Number: 0518

The Impact of Large Vessel Vasculitis of the Axillary Artery on Cumulative Glucocorticoid Dose and Relapse Rate in Giant Cell Arteritis

Philipp Bosch[1], Christian Dejaco[2], Wolfgang Schmidt[3], Andreas Krause[3], Kenny-Davis Schlüter[3], Gudrun Pregartner[4] and Valentin Schaefer[5], [1]Department of Rheumatology and Immunology, Medical University Graz, Graz, Austria, Graz, Austria, [2]Department of Rheumatology and Immunology, Medical University Graz, Graz, Austria and Rheumatology Service, Hospital of Bruneck, Bruneck, Italy, Bruneck, Italy, [3]Immanuel Krankenhaus Berlin, Medical Center for Rheumatology Berlin-Buch, Berlin, Germany, [4]Institute for Medical Informatics, Statistics and Documentation, Medical University of Graz, Graz, Austria, Graz, Austria, [5]Clinic of Internal Medicine III, Department of Oncology, Hematology and Rheumatology, University Hospital Bonn, Germany, Bonn, Nordrhein-Westfalen, Germany

SESSION INFORMATION
Session Date: Friday, November 6, 2020
Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders II: GCA Clinical & Epidemiology
Session Type: Abstract Session
Session Time: 4:00PM–4:50PM

Background/Purpose: Prognostic markers for clinical outcomes in giant cell arteritis (GCA) are urgently needed. While large vessel GCA (LV-GCA) has been associated with higher glucocorticoid (GC) dose and increased relapses, data are still controversial (Muratore et al. 2015). The axillary artery is almost always affected in LV-GCA patients (axG-

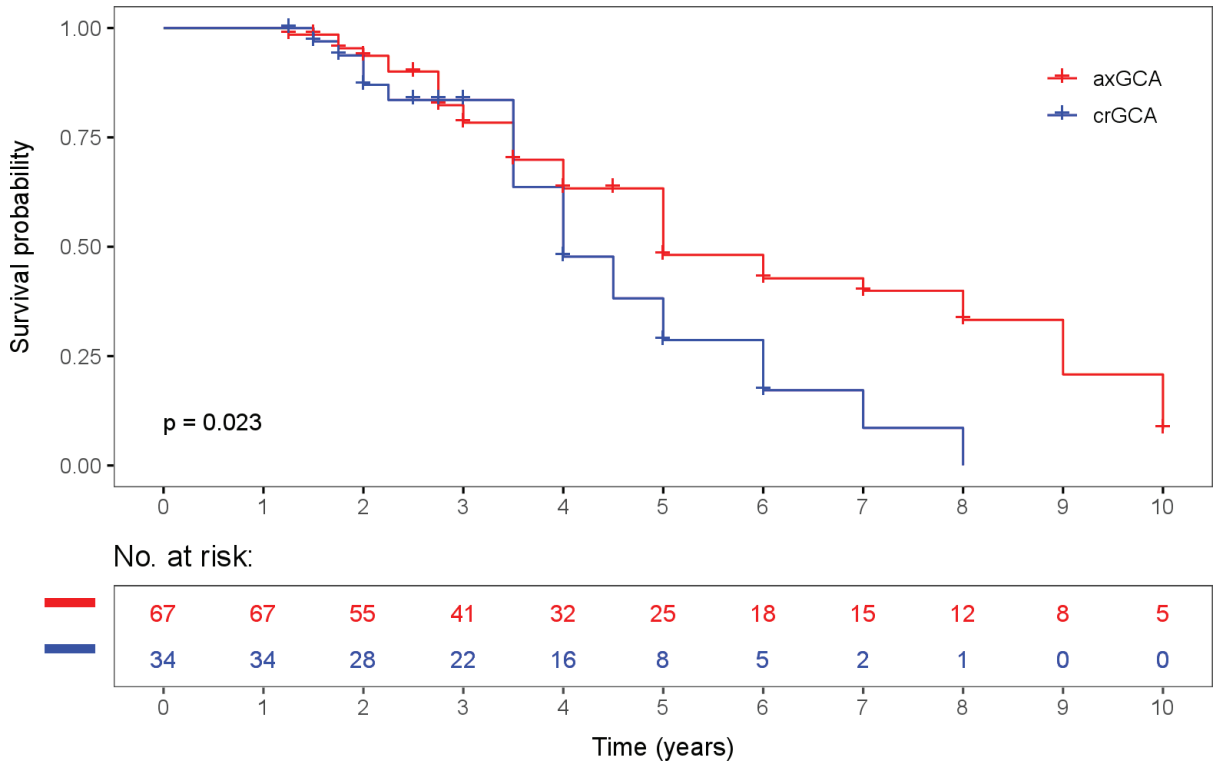

Figure 1. Kaplan-Meier curves assessing time until cessation of glucocorticoid treatment in patients with giant cell arteritis with (axGCA) and without (crGCA) vasculitis of the axillary artery.

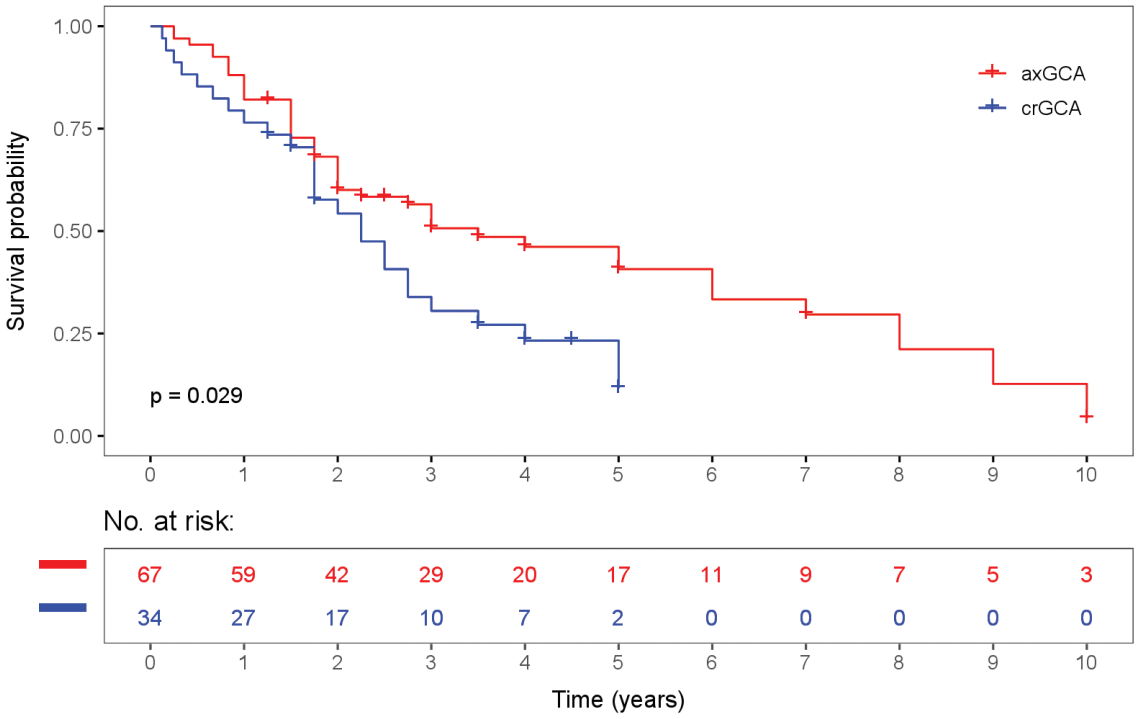

Figure 2. Kaplan-Meier curves assessing the time until the first clinical relapse in patients with giant cell arteritis with (axGCA) and without (crGCA) axillary artery involvement.

CA) (Schmidt et al. 2008; Czihal et al. 2012), however, it is not yet clear whether axGCA patients have more relapses and a higher GC need, compared to GCA with exclusive cranial vessel involvement (crGCA).

The aim of this study was to determine the prognostic value of axillary artery involvement in GCA in respect to cumulative GC doses and relapse rates.

Methods: Ultrasound (US) of the axillary arteries was performed in GCA patients at the time of diagnosis and at multiple follow-up visits. Patients with US signs of axillary artery vasculitis at the time of diagnosis were compared with patients in whom US was exclusively positive in cranial arteries. Cumulative GC doses and relapse rates were calculated for the most recent study visit and survival analysis was performed to determine differences between the groups concerning the time until the first relapse and the cessation of GC treatment. Linear mixed models were used to assess the effect of GC and relapses on the axillary artery wall in axGCA patients.

Results: Sixty-seven patients had US signs of vasculitis of the axillary arteries at baseline (=axGCA group), while 34 patients had exclusively signs of vasculitis in the cranial arteries (=crGCA group). Mean (SD) age at diagnosis was 68.0 (7.3) years in the axGCA group and 72.4 (6.5) years in the crGCA group; 72% and 56% were female, respectively. Time from diagnosis was 48 months in both groups (range: axGCA: 16-137, crGCA: 16-102). Median time until GC cessation was 60 months (95% CI: 60-108) in the axGCA group compared to 48 months (95% CI: 42-72) in the crGCA group (p=0.0239), while median time until the first relapse was 42 months (95% CI: 24-84) vs 27 months (95% CI: 21-42; p=0.029), as depicted in figure 1 and 2. Median cumulative GC doses were higher in the axGCA group with 6801mg (range: 1748-34169), compared to the crGCA group with 5633mg (range: 2553-19967; p=0.052), while median cumulative number of relapses were similar with 2 (range: 0-16) and 1 (range: 0-13) in the axGCA and crGCA group, respectively (p=0.67). While we observed a continuous decline of the intima media thickness (IMT) over the entire study period, the cumulative GC dose had no significant effect on IMT decrement. In contrast, a clinical relapse resulted in an increase of the IMT by 0.18mm (95% CI: 0.07-0.30; p=0.003).

Conclusion: GCA patients with vasculitis of the axillary artery have longer GC treatment and higher cumulative GC doses compared to GCA patients without vasculitis of axillary arteries. Relapse rates are similar between the groups but occur later in patients with axillary artery involvement. Also, relapses lead to an IMT increase of axillary arteries.

Thrombotic and Obstetric Associations of Non-Criteria Antiphospholipid Immunoassays That Detect Antibodies to Neutral and Negatively-Charged Phospholipid

Rohan Willis[1], E Nigel Harris[2], Vijaya Murthy[3], Zurina Romay-Penabad[1], Alvaro Schleh[4], Monica Smikle[2], Karel De Ceulaer[2], Anne Tebo[5], Troy Jaskowski[6], Marta Guerra[7], David Ware Branch[8], Jane Salmon[7], Michelle Petri[9] and Emilio Gonzalez[1], [1]University of Texas Medical Branch, Galveston, TX, [2]University of the West Indies, Kingston, Jamaica, [3]University of Texas Medical Branch, League City, TX, [4]Antiphospholipid Standardization Laboratory, GALVESTON, TX, [5]Department of Pathology, University of Utah, Salt Lake City, [6]ARUP Laboratories, Salt Lake City, UT, [7]Hospital for Special Surgery, New York, NY, [8]University of Utah, Salt Lake City, [9]Johns Hopkins University School of Medicine, Baltimore

SESSION INFORMATION

Session Date: Saturday, November 7, 2020
Session Title: Antiphospholipid Syndrome Poster
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Criteria antiphospholipid (aPL) antibodies that identify antiphospholipid syndrome (APS) patients, anticardiolipin (aCL) and anti-β2glycoprotein-I (anti-β2GPI), have demonstrated inconsistent specificity and sensitivity in this regard respectively. The purpose of this study was to evaluate the performance characteristics of non-criteria anti-phosphatidic acid (anti-PA), anti-phosphatidylglycerol (anti-PG) and anti-phosphatidylethanolamine (anti-PE) assays (IgG/IgM) in identifying APS related clinical manifestations in a large group of patients with aPL-related diseases.

Methods: Serum samples from 520 patients from the Hopkins (n=344) and Jamaican SLE cohorts (n=42), the PROMISSE cohort (n=77), as well as APS patients (n=29) and healthy controls (n=28) from the Antiphospholipid Standardization Laboratory were examined for IgG/IgM positivity in aCL (in-house), anti-β2GPI (INOVA Diagnostics), anti-PA, anti-PG and anti-PE (Louisville APL) ELISA assays. Assay cut-offs were aCL IgG/IgM (10GPL/10MPL), anti-β2GPI (20SGU/20SMU), anti-PA, anti-PG, anti-PE (15GPL/15MPL). Correlation of assay positivity with clinical manifestations expressed as odds ratio (OR) with 95%CI, the effect of increasing antibody titers, logistic regression multivariate analysis, quantitative and qualitative inter-assay agreement, and various analytical measures of assay performance including sensitivity, specificity, positive (PPV) and negative (NPV) predictive values were evaluated.

Results: The prevalence of IgG/IgM anti-PA positivity was 30.4%, anti-PG was 27.7%, anti-PE was 30.8%, aCL was 24.2% and anti-β2GPI was 18.3%. The IgG isotypes of all assays were associated with at least one or more thrombotic and/or obstetric manifestation, while IgM isotypes of non-criteria assays were associated with obstetric manifestations. All criteria and non-criteria assays (IgG/IgM) were associated with APS diagnosis (Table 1). There was a 3 to 10-fold increased risk for thrombotic manifestations, particularly venous thrombosis, associated with high

*p-value <0.05. ** p-value <0.01.

Table 1. Association of antiphospholipid assay positivity with APS-related clinical manifestations – Odds Ratios with 95% Confidence Intervals

vs low positive titers in IgG assays. There was moderate to excellent quantitative and qualitative agreement among most assays of corresponding isotypes. Overall, sensitivity (26.3-39.5%), specificity (85.3-94.1%), PPV (39.3-68.0%) and NPV (70.4-76.1%) for APS diagnosis were relatively similar among IgG assays, which performed better than their IgM counterparts. IgG aCL was the only independent predictor for venous thrombosis OR 3.6(2.1-6.1) and arterial thrombosis OR 1.9(1.1-3.4) while IgG anti-PA was the only independent predictor for placental insufficiency due to pre-eclampsia/eclampsia OR 2.4(1.3-4.6) and recurrent miscarriage OR 1.9(1.2-3.0).

Conclusion: IgG anti-PA, anti-PG and anti-PE antibodies were associated with thrombotic and obstetric APS-related manifestations, while their IgM counterparts were associated with mainly obstetric manifestations. Increasing titers of IgG assays imparted an increased risk, particularly for venous thrombosis. These non-criteria PL assays are promising biomarkers for particular APS manifestations and their independent value in APS classification requires further investigation.

SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: Antiphospholipid Syndrome Poster
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: A high prevalence of thrombotic events has been reported in critically ill COVID-19 patients but data on the prevalence of thrombosis in ward patients are scarce. The presence of antiphospholipid antibodies (aPL) and whether aPL are involved in the risk of thrombosis in this setting has not been addressed.

Our objective was to study the prevalence of aPL in non-ICU COVID-19-patients and their relationship with thrombotic events.

Methods: This is a prospective single-center observational cohort study of COVID-19 patients admitted in the Internal Medicine and Clinical Immunology Department of a tertiary care university hospital (Paris, France). Included patients were older than 18 years with an initial requirement for hospitalization in a medical ward and a positive SARS-CoV-2 RT-PCR assay from nasal swabs. Patients were tested for the presence of aPL antibodies. Limit of

positivity was fixed at 15 and 10 units/mL (99th percentile of a control population) for aCL and aβ2GPI antibodies respectively. Continuous variables are presented as median (interquartile range, IQR) and were compared using Wilcoxon's- test. Categorical variables are presented as count (percent) and were compared using Fisher's-test.

Table 1 (...)				
Anti-phospholipid Ab markers				
IgG anticardiolipin Ab	8 (7.7)	5 (5.4)	3 (27.3)	**0.037**
IgG titer (fold UNL)	1.5 [1.3-2]	1.6 [1.2-2]	1.3 /1.5 / 2.3*	0.786
IgM anticardiolipin Ab	8 (7.7)	3 (3.2)	5 (45.5)	**< 0.001**
IgM titer(fold UNL)	1.6 [1.4-2.2]	1.2 / 1.5 / 1.6 *	1.7 [1.5-2.5]	0.143
IgA anticardiolipin Ab	31 (28)	26 (28)	5 (45.5)	0.297
IgA titer (fold UNL)	1.5 [1.4-1.7]	1.4 [1.3-1.7]	1.7 [1.6-2.6]	0.081
IgG anti-β2-GPI Ab	5 (4.8)	4 (4.3)	1 (9.1)	0.435
IgG titer (fold UNL)	4.5 [1.8-14]	6.9 [1.6-15.1]	4.5*	-
IgM anti-β2-GPI Ab	3 (2.9)	2 (2.2)	1 (9.1)	0.287
IgM titer(fold UNL)	1 / 4 / 26 *	4 / 26*	1*	-
IgA anti-β2-GPI Ab	6 (5.8)	3 (3.2)	3 (27.3)	**0.015**
IgA titer (fold UNL)	10 [3.1-13]	2.6 / 3.3 / 15.2	10/10/12	0.7
Lupus anticoagulant, yes/nb tested	21/53 (39.6)	18/48 (37.5)	3/5 (60)	0.374
Anti-phospholipid markers positivity#				
Single positivity	35 (33.7)	31 (33.3)	4 (36.4)	0.740
Double positivity	12 (11.5)	11 (11.8)	1 (9.1)	1
Triple positivity	2 (1.9)	0 (0)	2 (18.2)	**0.01**

*IQR : InterQuartil Range ; BMI : Body Mass Index ; CRP : C reactive protein ; Ab : antibody. # Positivity of anti-phospholipid marker among anticardiolipin Ab, anti-β2-GPI Ab and lupus anticoagulant. * when n≤3, singles values are given*

Results: A total of 104 patients (57.7% males, 71 years) were included. Eleven (10.6%) patients had a thrombotic event (9 acute pulmonary embolisms, 1 deep vein thrombosis and 1 aortic thrombus). They had more frequently a history of venous thrombosis, and increased C- reactive protein and D-Dimer levels versus patients without thrombotic events. Overall, 49/104 (47.1%) patients had a least one positive aPL marker while double or triple antiphospholipid seropositivity was found in 11.1% and 1.9%, respectively. Anticardiolipin (aCL) and anti-beta2 glycoprotein I (aβ2GPI) were noted in 35/104 (33.7%) and 9/104 (8.7%) patients. A lupus anticoagulant was found in 21 out of 53 (39.6%) patients. IgG aCL, IgM aCL, IgA β2-GPI and triple positivity were significantly associated with the occurrence of thrombotic events (details are shown in table 1).

If we consider only highly positive aPL (cut off > 30 U/mL), 27/103 (26.2%) non-ICU patients had at least one positive aPL [5/11 (45%) vs 22/91 (24%) patients with or without thrombosis, p=0.051]. The presence of at least two positive aPL (>30 U/ml) was associated with thrombosis [3/11 (27.3%) vs 1/93 (1.1%), p =0.003].

Conclusion: Although aPL are frequently found in Covid-19 non-ICU patients, their role in thrombotic events needs dedicated studies.

Abstract Number: 0521

Avoiding Misclassification of Primary Antiphospholipid Syndrome as Systemic Lupus Erythematosus: What Are the Best-performing SLE Classification Criteria?

Flavio Signorelli[1], Gustavo Balbi[2], Eloisa Bonfa[3], Eduardo Borba[4] and Danieli Andrade[5], [1]Universidade de São Paulo, Rio de janeiro, Rio de Janeiro, Brazil, [2]Universidade de São Paulo, Juiz de Fora, Minas Gerais, Brazil, [3]Hospital das Clínicas, Faculdade de Medicina da Universidade de Sao Paulo (HCFMUSP), Sao Paulo, Sao Paulo, Brazil, [4]Rheumatology Division, Hospital das Clinicas HCFMUSP, Faculdade de Medicina, Universidade de São Paulo, São Paulo, Brazil, [5]University of Sao Paulo, Sao Paulo, Brazil

SESSION INFORMATION

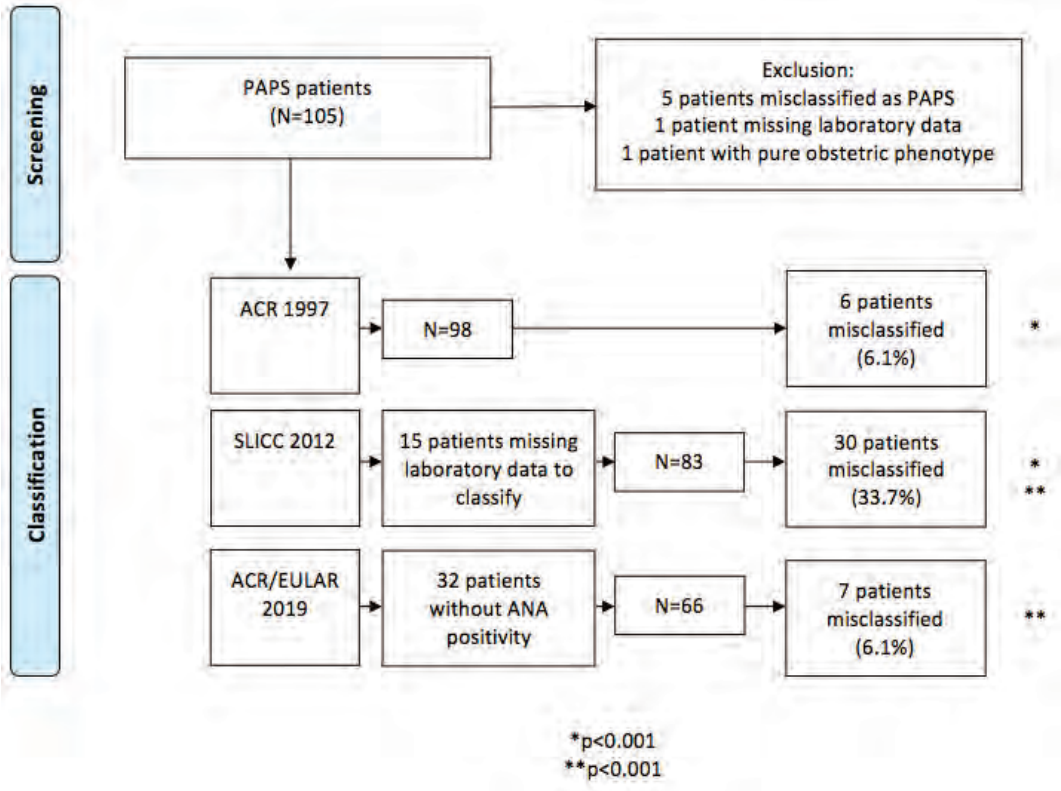
Session Date: Saturday, November 7, 2020

Session Title: Antiphospholipid Syndrome Poster

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: Primary Antiphospholipid Syndrome (PAPS) patients, when submitted to Systemic Lupus Erythematosus (SLE) classification criteria, can be misclassified. The new 2019 ACR/EULAR classification criteria have never been applied for PAPS patients. The main objective of this study is to evaluate the risk of misclassifying thrombotic PAPS (Sidney) as SLE in a cohort of a tertiary Hospital.



Data	
Female sex, n (%)	86 (87.8)
Age at diagnosis (years), n (median, IQ)	29 (23-26)
Age at study (years), n (median, IQ)	46 (37.8-56)
Time since APS diagnosis (years), n (median, IQ)	14 (10-21)
Arterial thrombosis, n (%)	39 (39.8)
Venous thrombosis, n (%)	68 (68.4)
Obstetric criteria, n=72, n (%)	40 (55.6)
Valvulopathy, n (%) (MD)	16 (16.3) (59)
Nephropathy, n (%)	10 (10.2)
Livedo, n (%) (MD)	44 (52.4) (14)
Thrombocytopenia, n (%)	7 (7.1)
LA positivity, n (%) (MD)	91 (93.8) (1)
aCL positivity, n (%)	63 (63.4)
aB2GP1 positivity, n (%)	50 (51.0)
Triple positivity, n (%)	41 (41.8)
Anticoagulation therapy (warfarin/LWH)*, n (%)	96 (98)
Antiaggregating therapy**, n (%)	12 (12.4)
Hydroxychloroquine, n (%)	43 (43.9)

Legend: n (%)= number (%), IQ- interquartile range, (MD)= missing data, LA=lupus anticoagulant, aCL= anticardiolipin, aB2GPI= antibeta2 glycoprotein 1,LWH= low weight heparin. *warfarin, n=93 and LWH=3, **acid acetylsalicylic, n=9 and clopidogrel, n=3.

Methods: A retrospective analysis of our PAPS cohort was performed using electronic chart database. The three current classification criteria for SLE (ACR 1997, SLICC 2012 and 2019 ACR/EULAR) were applied in parallel focusing on the latter. Flowchart of the study is shown in Figure 1. Categorical variables were analyzed by x^2 or two-tailed Fisher's exact test, and continuous variables were analyzed by Student's T test or Mann–Whitney-U test, as applicable. The misclassification rates of the three different criteria were compared using McNemar's test. A p-value of < 0.05 was considered statistically significant.

Results: All patients had thrombotic PAPS and 55.6% presented obstetric criteria manifestations. Venous and arterial thrombosis were detected in 69.4% and 39.8%, respectively. Ninety-eight PAPS patients were submitted to ACR 1997 and 2019 ACR/EULAR. SLICC 2012 was applied in only 83 patients due to missing data (lack of direct Coombs test). Our patients were mostly female (87.8%), with a median age at study inclusion of 46 years (38-56) and median disease duration of 14 years (10-21). LA was the most frequent antiphospholipid antibody, identified in 91 patients (93.8%). Main characteristics of the studied patients are shown in Table 1. The comparison of different criteria two-by-two according to their rates of misclassification found that 2019 ACR/EULAR and ACR 1997 performed similarly (N=98; 6.1 vs. 6.1%, p=1.00). On the other hand, SLICC 2012 demonstrated a poor performance compared to both 2019 ACR/EULAR (N=83, 36.1 vs. 6.1%, p< 0.001) and ACR 1997 criteria (N=83, 36.1 vs. 6.1%, p< 0.001). When the 3 classification criteria were used simultaneously, only 1 patient was misclassified as SLE. Hematological manifestations were the most frequent criteria related to misclassification in PAPS patients, encompassing 100% of misclassified patients (vs. 52.2%, p=0.025) in ACR 1997, 90% (vs. 11.3%, p< 0.001) in SLICC 2012 and 71.4% (vs. 18.6%, p=0.01) in 2019 ACR/EULAR.

Conclusion: 2019 ACR/EULAR is very accurate in differentiating PAPS from SLE, with only 6.1% of misclassification rates (similar to those observed in ACR 1997 and lower than those found in SLICC 2012).

Development of New International Classification Criteria for Antiphospholipid Syndrome: Phase III Case Collection Results

Medha Barbhaiya[1], Stephane Zuily[2], Yasaman Ahmadzadeh[3], Karen Costenbader[4], Raymond Naden[5] and Doruk Erkan[6], [1]Hospital for Special Surgery, Barbara Volcker Center for Women and Rheumatic Diseases, New York, NY, [2]Nancy Academic Hospital, Vandoeuvre-l□Nancy, France, [3]Hospital for Special Surgery, New York, [4]Brigham and Women's Hospital and Harvard Medical School, Boston, MA, [5]Department of Medicine, Middlemore Hospital, Auckland, Auckland, New Zealand, [6]Hospital for Special Surgery, New York, NY

SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: Antiphospholipid Syndrome Poster
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: An international multi-disciplinary effort is underway to develop rigorous, new, consensus- and evidence-based classification criteria for Antiphospholipid Syndrome (APS). The methodological approach includes four phases; we have previously presented Phase I (item generation) and II (item reduction), resulting in 27 candidate criteria organized into laboratory and clinical domains. Phase III (item weighting/threshold identification) is currently underway; here we report initial Phase III case collection results.

Methods: We used REDCap, a secure web-based data system, for Phase III international case collection. The 27 candidate criteria items from Phase II were represented in a standardized case collection form. We asked 17 physicians specializing in APS from Europe, North and South America to provide cases and to rate them using a Likert scale from +3 to -3 (highly likely to highly unlikely to be APS). Cases with higher scores (+2 or +3) were categorized as "highly likely" APS based on treating physician assessment, whereas lower scores (+1 to -3) were categorized as "equivocal or unlikely" APS. We calculated risk ratios to represent the probability that a laboratory or clinical candidate criterion would be associated with a "highly likely" compared to "equivocal or unlikely" APS case.

Results: We collected 314 potential APS cases (mean age 43.8 +/- 14.4 years; 79% female; and 77% white) between 6/2019-8/2019 from 17 sites in Europe (n=8, 47%), North America (n=7, 41%), and South America (n=2, 11%). Majority of cases were potential primary APS (n=201, 64%). Out of 314 cases, 137 (44%) were rated as "highly likely" and 177(56%) as "equivocal or unlikely" APS. The table demonstrates frequency of laboratory and clinical manifestations of potential APS cases (overall and categorized by physician assessment) as well as the risk ratios; the three criteria with the lowest risk ratios (< 1.5) were superficial vein thrombosis, transient ischemic attack, and embryonic loss < 10 weeks 0 days.

Conclusion: In Phase III of the development of new APS classification criteria, a large international collection of cases spanning the spectrum of "highly likely" to "equivocal or unlikely" APS was used to identify the observation frequency of each of the candidate criterion from Phase II in real world clinical settings. In next steps, these proposed candidate criteria will be further refined and weighted using multi-criteria decision analysis methodology, and a preliminary threshold for APS classification will be determined.

Characterization of Antiphospholipid Antibody-Associated Nephropathy: An International Survey of Renal Pathology Society Members

Medha Barbhaiya[1], Doruk Erkan[2], Stephane Zuily[3], Tektonidou Maria[4] and Surya Seshan[5], [1]Hospital for Special Surgery, Barbara Volcker Center for Women and Rheumatic Diseases, New York, NY, [2]Hospital for Special Surgery, New York, NY, [3]Nancy Academic Hospital, Vandoeuvre-l□Nancy, France, [4]National and Kapodistrian University of Athens, Athens, Greece, [5]Weill Cornell Medical College, New York, NY

SESSION INFORMATION

Session Date: Saturday, November 7, 2020

Session Title: Antiphospholipid Syndrome Poster

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: Antiphospholipid antibody (aPL)-associated nephropathy (aPL-N) is recognized as a distinct complication of APS. However, it remains unclear whether pathologists worldwide use uniform diagnostic criteria to distinguish aPL-N from other forms of thrombotic microangiopathy. In parallel with international efforts to develop new classification criteria for antiphospholipid syndrome (APS), we conducted a pilot study to assess the renal pathologic features used by academic pathologists to diagnose aPL-N.

Methods: We conducted a web-based survey of 780 members of an international Renal Pathology Society in 50 countries. We asked respondents to determine whether two acute and eight chronic aPL-N features were consistent with acute or chronic aPL-N without providing aPL serology. and rate each item using a Likert scale (from +5 to -5): "Please consider two renal biopsies which are exactly the same except that one has the pathologic feature presented below and the other does not. Please rate how specific each feature is in differentiating "acute" or "chronic" aPL nephropathy from other diagnoses. They were also asked to rate their confidence in diagnosing aPL nephropathy on renal biopsy in two scenarios: 1) without aPL laboratory test results, or 2) with known lupus.

Results: Survey response rate was 14% (111/780) and 91% of participants self-identified as renal pathologists from 33 countries and in clinical practice for a mean (SD) of 19.1 (15.1) years. Over 92% of respondents agreed that thrombotic microangiopathy lesions in the glomeruli, arterioles, or arteries were consistent acute aPL-N, and >75% gave a positive Likert scale score (>0), with >50% indicating Likert score +3 to +5. For chronic aPL-N, >83% agreed with the pathologic features of organized arterial or arteriolar microthrombi with or without recanalization, organized

Table. Laboratory and Clinical Manifestations of 314 International Potential APS Cases, Overall and Categorized by Physician Assessment

glomerular thrombi, and fibrous and fibrocellular (arterial or arteriolar) occlusions, and >50% indicated a positive Likert score (>0), while there was less consensus for other chronic features (Table). The majority of respondents (76%) reported either an equivocal (Likert score of 0, 18%) or lack of confidence (score from -1 to -5, 58%) in diagnosing aPL-N on renal biopsy without of aPL laboratory test results. However, 80% indicated confidence (Likert score >0) in diagnosing aPL-N with concomitant lupus (69%) indicated Likert score +3 to +5.

Conclusion: Consensus exists among over 90% of pathologists worldwide that the following renal pathologic features are most specific for aPL-N: 1) non-inflammatory glomerular or small arterial microthrombi and 2) organized microvascular thrombi with recanalization. However, in the absence of serologic aPL status, over 75% of pathologists indicated lack of specificity of chronic glomerular or small arterial changes for aPL-N. Over 80% of pathologists indicated high confidence in diagnosing aPL nephropathy in patient with concomitant lupus. These findings indicate the importance of aPL serologic test results in biopsy interpretation and suggest higher specificity for certain acute or chronic features.

Session Title: Antiphospholipid Syndrome Poster
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Antiphospholipid syndrome (APS) is a heterogeneous disease, with different phenotypes which may widely vary from classical thrombotic or obstetrical manifestations to catastrophic antiphospholipid syndrome (CAPS). APS can be associated with other auto-immune diseases, such as systemic lupus erythematosus (SLE). We aimed to determine distinct homogenous phenotypes among APS patients, using a non-supervised hierarchical cluster analysis.

Methods: We performed an observational, retrospective study on APS patients satisfying Sydney classification criteria and enrolled in the French multicentre “APS and SLE” registry. The clustering process involved an unsupervised multiple correspondence analysis followed by hierarchical ascendant clustering analysis, using 27 selected variables

Data are expressed as number (% of available data) unless stated otherwise.
Comparisons between different subgroups were performed with Chi-2 tests and ANOVAs.
¶Percentage of obstetrical manifestations were calculated among women only.
*Other autoimmune diseases included Sjögren syndrome, systemic sclerosis, rheumatoid arthritis, or chronic lymphocytic thyroiditis.
Abbreviations: N=number; wg= weeks of gestation; PE= preeclampsia; SLE=systemic lupus erythematosus; ANA=anti-nuclear antibody.

Table 1. Main characteristics according to devised cluster (N=509).

to widely cover APS clinical and biological manifestations. Comparisons between different subgroups were performed with Chi-2 tests and ANOVAs.

Results: We included 509 patients in the analyses, mainly women (78%). Mean (± SD) age at APS diagnosis was 36.3 ± 14.7 years, and mean follow-up duration after APS diagnosis was 10.3 ± 8.5 years. Cluster hierarchical classification yield in four homogenous groups of patients. Their main characteristics are described in *Table 1*.

1. Cluster 1 (n=181) included mostly patients with venous thrombosis (78%) and premature births due to placenta insufficiency (14%) history, without associated auto-immune disease (only 2.2%).
2. Cluster 2 (n=130) included older patients (mean 45.8 years), less frequently women (65% of women), with arterial events history (89%). Valvular involvement (21%), migraine (21%), livedo (35%), arterial hypertension (49%), and cardiovascular risk factors were relatively frequent.
3. Cluster 3 (n=102) included younger patients, frequently women (mean 30.7 years; 92% women), with associated SLE (76%) or other autoimmune diseases (30%). They frequently had history of venous thrombosis (74%) and of pregnancy morbidity (36%). Thrombocytopenia (48%), haemolytic anaemia (14%), and lupus anticoagulant (84%) were frequent.
4. Cluster 4 (n=96) included mainly patients with a history of CAPS (77%) and/or APS-associated nephropathy (93%), and pregnancy morbidity (36%). Renal hypertension (61%), livedo (36%), seizures (14%), valvular involvement (44%) and triple positivity (66%) were relatively frequent.

Conclusion: Using an unsupervised clustering method, our study highlighted four distinct homogenous subgroups of APS patients that were predominantly venous; arterial; associated with SLE or other autoimmune disease; and microthrombotic. It confirms the underlying idea of heterogeneous pathophysiological mechanisms.

Abstract Number: 0525

Epidemiology of Thromboembolic Complications Among Hospitalized Patients with Antiphospholipid Syndrome in the United States

Lauren Mathias[1], Aditya Mantha[2], Kristen Mathias[3] and Glenn Ehresmann[1], [1]University of Southern California, Division of Rheumatology, Los Angeles, CA, [2]University of Southern California, Department of Medicine, Los Angeles, CA, [3]University of Chicago, Department of Medicine, Chicago, IL

SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: Antiphospholipid Syndrome Poster
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Antiphospholipid syndrome (APLS) is characterized by arterial and venous thrombosis, often in the setting of an underlying systemic disease. Few studies have described the varied clinical presentations of this disease. This study aims to characterize healthcare expenditure and inpatient clinical outcomes of APLS using a nationally representative sample.

Methods: Patients with a diagnosis of APLS admitted to U.S. hospitals were identified using the ICD 10 CM classification system. The NIS is an all-payer inpatient database that estimates over 37 million annual U.S. hospitalizations

Table 1. In hospital thrombotic complications among hospitalized APLS patients in the United States, NIS 2016-2017		
Complication	**N (weighted)**	**%**
Venous Thromboembolism	6100	7.6
Stroke, ischemic	4445	5.6
Pulmonary Embolism	4015	5
Myocardial Infarction	2320	2.9
Stroke, hemorrhagic	1035	1.3
Portal and hepatic thrombosis	814	1
Mesenteric Ischemia	640	<1
Thrombophlebitis	619	<1
Renal Infarction	590	<1
Splenic Infarction	510	<1
Retinal Occlusion	116	<1
Intrauterine Demise	100	<1

and is maintained by the Healthcare Cost and Utilization Project. The primary outcomes were prevalence of APLS among hospitalized patients. Secondary outcomes included mortality, rate of acute thrombotic complications, and cost of care. Multivariate hierarchical regression analysis was used adjusting for demographics, hospital factors, and comorbid conditions.

Results: Of 79,835 patients identified in this retrospective cohort, 915 were primarily admitted for APLS. Patients were most commonly admitted for cardiovascular (22%), pregnancy-related (10.5%), gastrointestinal (9.3%) and infectious (6.5%) etiologies. Most patients were female (71.1%), white (66.5%) and had a mean age of 51.9 (51.5-52.2, 95% CI) years. Most patients were admitted to urban academic centers (77.7%) and had an average length of stay of 6.5 (6.3-6.6, 95% CI) days. The average hospitalization cost was $18,776 ($18,093-$19,458, 95% CI). 1,720 (2.2%) deaths occurred. The rates of acute arterial and venous thrombotic complications are summarized in Table 1. 21.7% of patients were diagnosed with systemic lupus erythematosus (SLE).

Conclusion: Acute thrombotic events remain a significant cause of morbidity and mortality among patients admitted for APLS. The prevalence of life-threatening thrombotic complications including pulmonary embolism, stroke, myocardial infarction and fetal demise were lower than previously reported [1,2]. These results may reflect overall improvements in disease detection and anticoagulation practices in the community setting and merit further investigation.

Patient-Reported Outcomes in Antiphospholipid Syndrome

Julia Weiner[1], Kelsey Gockman[1], Jacqueline Madison[1], Yu Zuo[2], Emily Briceño[1], Vivek Nagaraja[3] and Jason Knight[2], [1]University of Michigan, Ann Arbor, [2]Division of Rheumatology, University of Michigan, Ann Arbor, MI, [3]University of Michigan, Ann Arbor, MI

SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: Antiphospholipid Syndrome Poster
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: PROMIS® (Patient-Reported Outcome Measurement Information System) is a set of person-centered measures that evaluates and monitors the physical, emotional, and social aspects of health. PROMIS® measures have been used to assess health-related quality of life (HRQoL) in patients with rheumatic diseases1 and cut-points of severity in impairments have been identified for specific domains (like physical function). These measures have not been carefully evaluated in patients with persistent antiphospholipid antibodies (**aPL**) or with antiphospholipid syndrome (**APS**).

Methods: At an academic medical center, patients (n = 78) with persistent aPL seen in the rheumatology clinic prospectively completed PROMIS® Physical Function (**PF**) Short Form 10A v2.0, Cognitive Function (**CF**) Short Form 8A, and self-perceived pain intensity (**PI**, the scale of 1-10, with 10 being the most pain). Of the 78 patients, 51 had primary APS, 17 had secondary APS, and 10 had persistent aPL without a history of thrombotic event or pregnancy loss. Data regarding serologies and clinical manifestations associated with APS were captured; also, medications taken for mental health, pain, or seizures were recorded. Groups were compared by unpaired t-tests or one-way ANOVA; correlations were tested by Pearson's method.

Results: For the general United States population, the T-score average is standardized at 50 ± 10 for PF and CF. For the 78 patients studied here, the average T-scores for PF and CF were 45.0 ± 9.8 and 47.5 ± 10.9, respectively; the average score for PI was 3.2 ± 2.6. Patients who endorsed more impairment on one measure endorsed more impairment on another measure (PF vs. CF, r=0.51, p< 0.0001; PF vs. PI, r=-0.55, p< 0.0001; and CF vs. PI, r=-0.33, p=0.004). About a third of the patients endorsed moderate to severe impairment in PF (**Table 1**). A quarter of the patients had a T-score of < 40 for CF. While clinical markers of disease (specific aPL, previous thrombotic events, etc.) did not predict PROMIS® scores, several general health and lifestyle factors (especially sedentary lifestyle) were predictive of impairments in PF and CF (**Table 2**). The use of medications for mental health or pain was associated with more endorsed impairments in PF and CF (**Table 3**).

Conclusion: In this single-center cohort of patients with positive aPL (most of whom have APS), a large minority of patients endorsed impairments in PF and CF. Health and lifestyle factors such as sedentary lifestyle and smoking and

Table 1: Physical and cognitive PROs for 78 persistently aPL-positive individuals

Rituximab for Refractory Manifestations of the Antiphospholipid Syndrome: A Multicenter Israeli Experience

Nancy Agmon-Levin[1], **Mark Berman**[2], Liora Harel[3], Merav Lidar[4], Soad Hajyahia[1] and Daphna Paran[5], [1]Clinical Immunology, Angioedema and Allergy Unit, Center for Autoimmune Diseases, Sheba Medical Center, Tel Hashomer, Ramat Gan, Israel, [2]Tel Aviv Sourasky Medical Center, Tel Aviv, Israel, [3]Scheider Children's Medical Center of Israel, Tel Aviv University, Tel Aviv, Israel, Petach Tikva, Israel, [4]Rheumatology unit, Center for Autoimmune Diseases, Sheba Medical Center, Tel Hashomer, Hod Hasharon, Israel, [5]Department of Rheumatology, Tel Aviv Medical Center, Tel Aviv, Israel

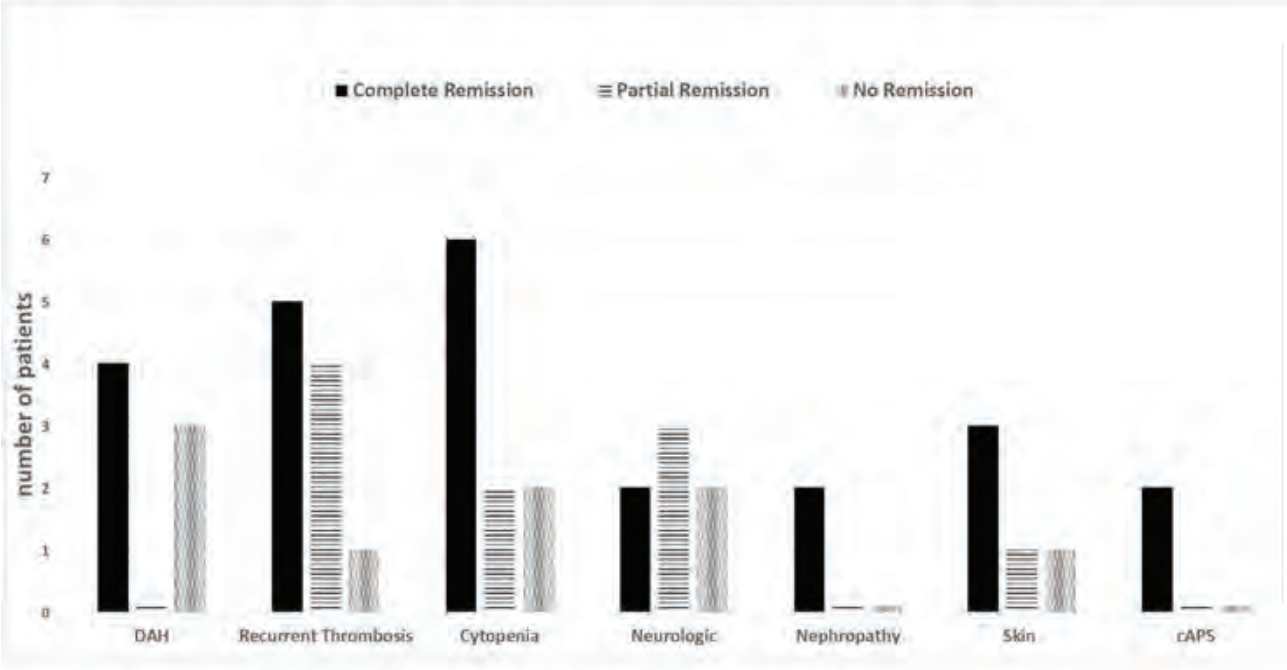
SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: Antiphospholipid Syndrome Poster
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: The clinical manifestations of the antiphospholipid syndrome (APS) are heterogeneous and related to anti-phospholipid antibodies (aPL). There is some evidence that B cells are involved in the pathogenesis of this condition. Thus the ability of rituximab (RTX) to deplete B cells makes it an appealing potential therapy for refractory antiphospholipid syndrome (APS). Real world data on RTX treatment of APS is still lacking. This study was conducted to report outcomes of RTX administration in the treatment of different aspects of APS.

Methods: This is a retrospective case series study on APS patients from 3 medical centers in Israel who were treated with RTX during 2010-2019 for refractory manifestations of APS including diffuse alveolar hemorrhage, recurrent thrombosis, thrombocytopenia, neurological and skin manifestations. Medical records were reviewed regarding the clinical indication for RTX treatment, concomitant medications, RTX protocol, aPL status and response to treatment. Outcomes were defined as complete response if full resolution of the "indicated manifestation" was achieved and maintained for at least 12 months, partial response or no response

Results: We identified 40 patients who were treated with RTX for refractory APS, 31 patients had primary APS (78%), 24 (60%) were female, mean age was 40 years. A favorable response to RTX was documented in 32 patients (80%) including complete response in 22 (55%). A RTX regimen of 375mg/m2 X 4 was more effective than a regimen of 1000 mgx2 (100% vs. 65%; p=0.01).

Fig. 1 Response to treatment with Rituximab according to APS manifestations



DAH – diffuse alveolar hemorrhage; cAPS- catastrophic APS.

Complete response was associated with a decrease in aPL titers 4-6 months post treatment. No significant change in aPL titers was observed in patients with partial or no response.

Conclusion: Consistent with previous small case series, we report a good therapeutic response to RTX in patients with difficult to treat manifestations of APS. In this cohort, treatment protocols were associated with outcomes. Although further studies are required to verify our observations, our data support a plausible role for B cell depletion in refractory APS.

The Complex Relationship Between C4b Binding Protein, Warfarin and Antiphospholipid Antibodies

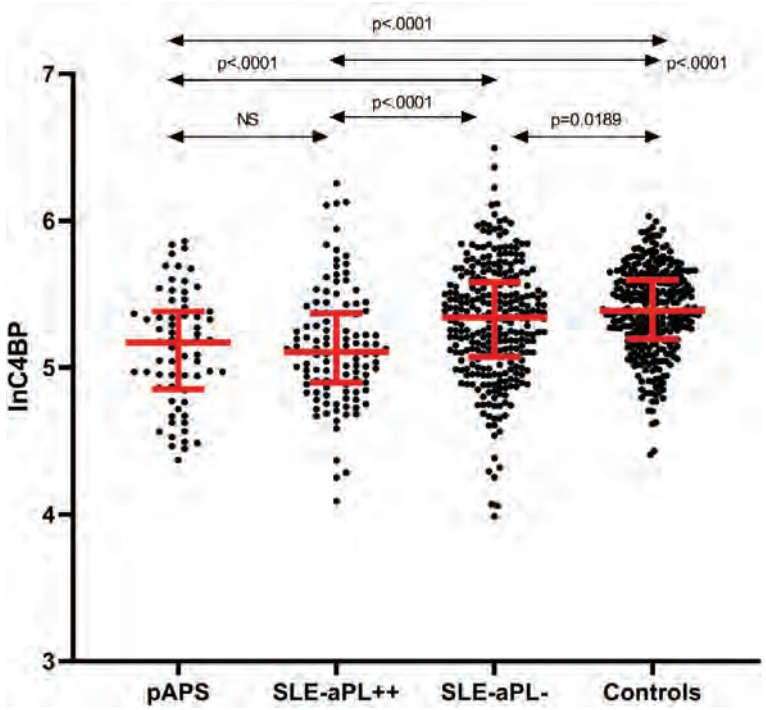
Giorgia Grosso[1], Kerstin Sandholm[2], Aleksandra Antovic[1], Iva Gunnarsson[1], Agneta Zickert[1], Anna Vikerfors[3], Lennart Truedsson[4], Maria Bruzelius[1], Bo Nilsson[5], Kristina Nilsson Ekdahl[5] and Elisabet Svenungsson[1], [1]Karolinska University Hospital, Stockholm, Sweden, [2]Linnaeus Center for Biomaterials Chemistry, Linnaeus University, Kalmar, Sweden, [3]Swedish Medical Products Agency, Uppsala, Sweden, [4]Lunds University, Lund, Sweden, [5]Uppsala University, Uppsala, Sweden

SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: Antiphospholipid Syndrome Poster
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

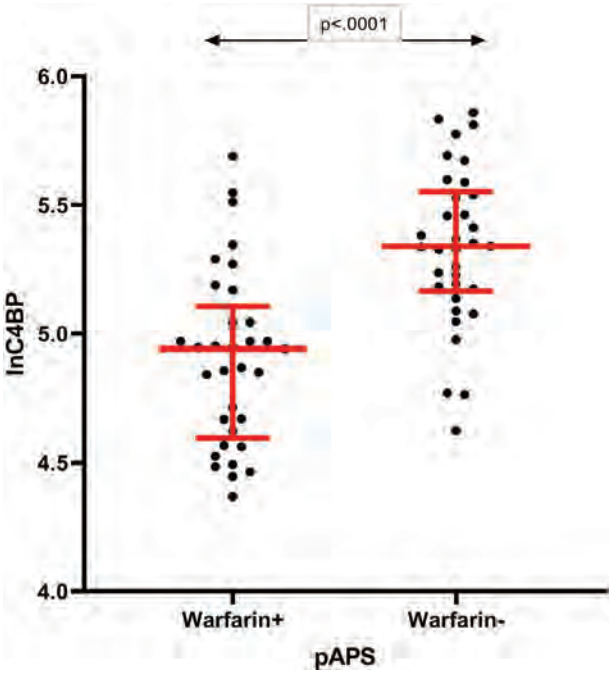
Background/Purpose: C4b Binding Protein (C4BP) is the main inhibitor of the classical complement pathway. Both β2glycoprotein-I (β2GPI), the main antigen in the antiphospholipid syndrome (APS), and C4BP, belong to the Complement Control protein (CCP) family. C4BP binds to protein S (PS) in circulation. Low C4BP levels are reported in the presence of antiphospholipid antibodies (aPL) and during treatment with vitamin K antagonists (VKA). / To investigate if levels of C4BP vary with aPL profile, clinical manifestations and anticoagulant treatment in primary (p) and secondary (s) APS.

Methods: C4BP, complement proteins and PS were investigated in 67 patients with pAPS, 67 age and sex matched controls and 15 individuals with repeated positivity (++) for aPL (nonSLE-aPL++) without clinical manifestations. Moreover, 118 SLE-aPL++, of which 56 with sAPS, 291 aPL negative SLE patients (SLE-aPL-) and 322 controls were included. Clinical characteristics, including treatment, were tabulated. C4BP was determined with a magnetic bead-beased sandwich immunoassay. Additional proteins in the complement cascade (C1q, C2, C3, C4, C3a, C3dg, sC5b-9, Factor I) were measured.

Results: C4BP is 20% decreased in aPL++ patients, independently of SLE or clinical manifestations (fig. 1). We report positive associations between C4BP and complement proteins C1q, C2, C3, C4, whereas C4BP associates negatively with complement activation products (C3a, C3dg) ($p < 0.05$ for all). Treatment with warfarin contributes to C4BP reduction by 9% (fig.2) according to mediation analysis performed in the SLE group: since warfarin is mostly prescribed to aPL+ patients, it is considered a mediator in the reducing effect of aPL on C4BP.



Levels of C4BP in different subgroups of patients: pAPS (n=67), SLEaPL++ (n=118), SLEaPL- (n=291) and controls (n=322)



C4BP in 67 pAPS patients, 33/67 on warfarin

Conclusion: Both the presence of aPL and warfarin treatment are associated with decreased levels of C4BP. Furthermore, higher complement degradation products are observed in patients with low C4BP levels, indicating that depressed levels of C4BP may, through reduced inhibition, contribute to complement activation in APS.

A Prospective Study on the Incidence of a First Thrombo-embolic Event in Patients with Systemic Lupus Erythematosus and Anti-phosphatidylserine/prothrombin Antibodies

Savino Sciascia[1], Massimo Radin[1], Irene Cecchi[1], Daniela Rossi[1] and Dario Roccatello[2], [1]University of Torino, Torino, Italy, [2]S Giovanni Hospital, Univ of Turin, Turin, Italy

SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: Antiphospholipid Syndrome Poster
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

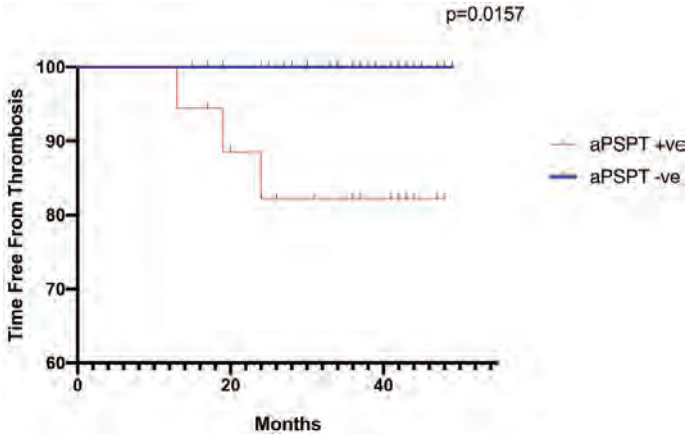
Background/Purpose: Prospective data confirming the role of anti-phosphatidylserine/prothrombin antibodies **(**aPS/PT) in the absence of other aPL tested by β2–glycoprotein I-depend assays are missing.

Methods: Since 2015 aPSPT was implemented as part of the routine testing in our SLE patients as part of the autoantibody screening. Patients with the revised criteria for SLE and fulfilling the following criteria were included in this study and prospectively followed-up.

- No previous TEs
- No concomitant anticoagulant therapy
- Negative tests aCL, anti-β2GPI (confirmed at least twice, at least 12 weeks apart)

All included patients were tested for aPS/PT at study inclusion. Positivity aPS/PT was defined as having at least two positive test results (IgG and/or IgM), at least 12 weeks apart.

Reports for objectively diagnosed TEs during follow-up had to include type, site, and the status of antithrombotic treatment at the time of event.



Results: This study included a total of 52 patients with SLE (42, 80.8% women). Of those 18 patients (34.6%) were found to be positive for aPS/PT (IgG and/or IgM). During a total follow-up of 238 years, there were 3 TEs (1.26% per year). The overall cumulative incidence of TEs was 5.8% after 2 years, being up to 16.7% when focusing on aPS/PT+ve patients (Figure 1). All the TEs events (2 cerebrovascular events and 1 thrombotic kidney microangiopathy) occurred in the aPS/PT+ve group. TEs not included among end-points were superficial thrombophlebitis in 2 subjects. No patient died and no pregnancy was recorded during the follow-up. The 3 patients with TEs were compared with the controls who did not have this complication. All patients tested negative for aB2GPI Domain 1 IgG.

aPS/PT was found to be associated with a trend in conferring an increased risk for TE (HR 12.9, 95% CI 0.70 to 236.74 p= 0.0851). When focusing on IgG aPS/PT we found that patients tested positive were at a significant higher risk for TEs (HR 19.6, 95% CI 1.0741 to 357.6416 p= 0.0446) when compared to controls.

Patients with TEs had a higher GAPSS when compared to those without, even if it failed to reach a statistically significance [6±2.64 Vs. 2±5.37, p=0.0971], probably due to sample size.

On multivariate analysis of considered variables (demographic factors, SLE features, arterial and venous risk factors), no factors was found to be statistically associated with the TEs.

Conclusion: Our prospective data validated previous retrospective studies demonstrating that aPS/PT, especially IgG, confers an increased risk for TEs in SLE patients.

Pediatric APS: Clinical Features, Therapeutic Interventions, and Damage in a Series of 22 Cases

Jacqueline Madison[1], Kelsey Gockman[1] and Jason Knight[2], [1]University of Michigan, Ann Arbor, [2]Division of Rheumatology, University of Michigan, Ann Arbor, MI

SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: Antiphospholipid Syndrome Poster
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Pediatric antiphospholipid syndrome (APS) is a thromboinflammatory disease classically defined by the presence of circulating antiphospholipid antibodies and either thrombotic events or pregnancy morbidity. Despite its potential to cause significant morbidity in children, pediatric APS is an understudied condition that lacks classification criteria specific to the pediatric age group. The objective of this study was to review a large institution's experience with pediatric APS in pursuit of a better understanding of the characteristics of children with APS.

Methods: We conducted a retrospective review of pediatric APS at a tertiary referral center. The electronic medical record system was queried for patients aged 21 and younger with a diagnosis of APS from 2000 through 2019. Fifty cases were evaluated further, and 22 were ultimately included in this study based on meeting the revised Sapporo Classification criteria by age 18 or younger.

Table 1: Demographics and clinical manifestations of pediatric APS patients

Characteristics	APS patients (n=22)
Median age at diagnosis	16 years (range 8-18)
Median duration of follow-up	5.8 years (range 0.8-15.3)
Sex, N (%)	
Male	6 (27.3%)
Female	16 (72.7%)
Primary APS	10 (45.5%)
Secondary APS	12 (54.5%)
SLE	10 (45.5%)
Ulcerative colitis	1 (4.5%)
Microscopic polyangiitis	1 (4.5%)
Type of APS	
Obstetric	1 (4.5%)
Thrombotic	21 (95.5%)

[1] Damage Index in Patients with Thrombotic APS

Results: Twenty-two patients were included with a median age at diagnosis of 16 years and median follow-up of 5.8 years (**Table 1**). Of the cases, 72.7% were in female patients (**Table 1**). Secondary APS was slightly more common than primary APS (12 versus 10 cases) and was primarily diagnosed in the context of SLE (10/12 cases). With regards to clinical features, 1 patient had obstetric APS and 21 patients had thrombotic APS (**Table 1**). Many patients (both primary and secondary APS) had so-called "non-criteria" manifestations of APS includingthrombocytopenia, autoimmune hemolytic anemia, and livedo reticularis/racemosa (**Table 2**). Patients had durably positive anti-beta-2-glycoprotein I antibodies in 73% of cases, anticardiolipin antibodies in 77%, and lupus anticoagulant in 55%. Secondary

APS patients were more likely to be positive for ANA, anti-double-stranded DNA, and anti-chromatin antibodies (**Table 2**). Two patients were tested for anti-phosphatidylserine/prothrombin antibodies, and both were positive. Both primary and secondary groups had recurrent thromboses without any significant difference in rates between the groups (**Table 2**), often when patients were subtherapeutic foranticoagulation. Although two patients were treated with aspirin alone, the majority (86%) received anticoagulation with warfarin or heparinoids; 41% (9/22) were treated with both aspirin and anticoagulation. Direct oral anticoagulants and fondaparinux were used in four patients each. The Damage Index in Patients with Thrombotic APS (DIAPS) scores indicate a significant burden of disease (**Table 2**).

Conclusion: This is the largest case series to date of pediatric APS in a United States population, and thereby provides important context regarding potential phenotypes displayed by children with APS. There was a high prevalence of non-criteria clinical manifestations, highlighting the need to consider these additional characteristics when developing pediatric-specific classification criteria and, most importantly, when considering this rare diagnosis in pediatric practice.

The Prevalence of Systemic Sclerosis, Dermatomyositis/Polymyositis, and Giant Cell Arteritis in the United States by Race and Ethnicity: An Analysis Using Electronic Health Records

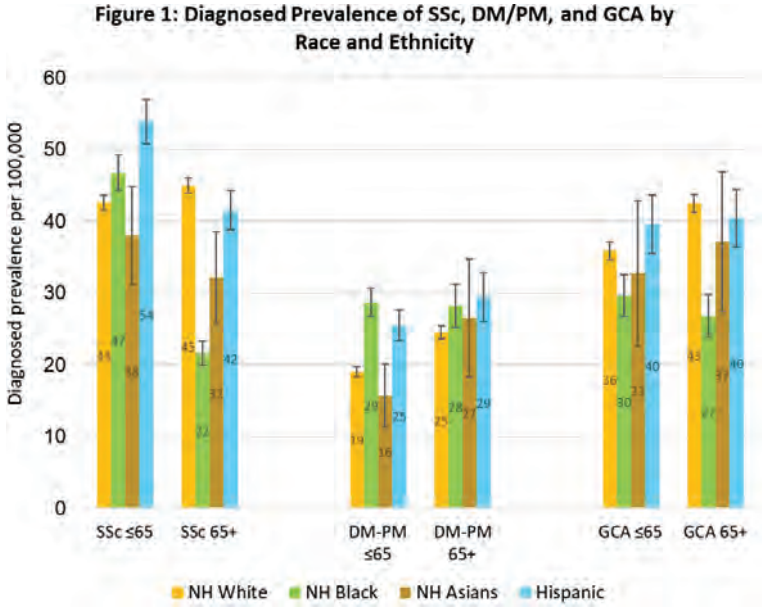
Sunali Goonesekera[1], Ankit Bansal[1], Swarali Tadwalkar[2] and Alison Isherwood[3], [1]Decision Resources Group, Part of Clarivate, Boston, MA, [2]Decision Resources Group, part of Clarivate, Bangolore, India, [3]Decision Resources Group, part of Clarivate, London, United Kingdom

SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: Epidemiology & Public Health Poster II: OA, Osteoporosis, & Other Rheumatic Disease
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Epidemiological studies suggest differences in the prevalence and disease severity of certain autoimmune diseases by race and ethnicity. In this study, we evaluate the distribution of three rare connective-tissue diseases i.e., systemic sclerosis (SSc), dermatomyositis/polymyositis (DM/PM), and giant cell arteritis (GCA), in different racial/ethnic groups in the United States using data from electronic health records (EHR).

Methods: We restricted the study population to patients aged 20 or older, who had submitted at least two insurance claims in 2018 (Real World Data. Decision Resources Group, 2020), and had no missing information in their EHR regarding age, gender, and race/ethnicity. We categorized the patients with respect to age (≤65 versus 65+ for SSC and DM/PM; 50-65 versus 65+ for GCA) and race/ethnicity (non-Hispanic White (NHW), non-Hispanic Black (NHB), Hispanic, and non-Hispanic Asian (NHA)). To be considered a case, a patient was required to have at least two diagnoses recorded for each autoimmune disease in 2018. For each racial/ethnic category, we estimated the age-group-specific diagnosed prevalence of SSc, DM/PM, and GCA, and calculated the diagnosed prevalence ratios for NHBs, Hispanics, and NHAs using NHWs as the referent population.

Results: In persons aged ≤65, we observed a significantly increased risk of SSc in NHBs (RR=1.10; 95% CI = 1.04-1.16) and Hispanics (RR = 1.26, 95% CI = 1.19-1.35) as compared to the NHW population, but not in NHAs (RR =



Diagnosed prevalence of SSc, DM/PM, and GCA by race and ethnicity

Table 1: Risk Ratios (95% Confidence Intervals) for SSc, DM/PM, and GCA _ minority ethnicities versus non-Hispanic Whites

	SSc ≤65	SSc 65+	DM/PM ≤65	DM/PM 65+	GCA ≤65	GCA 65+
Non-Hispanic White (Referent)	1.0	1.0	1.0	1.0	1.0	1.0
Non-Hispanic Black	1.1 (1.0-1.2)*	0.5 (0.4-0.5)***	1.5 (1.4-1.6)***	1.2 (1.0-1.3)*	0.8 (0.7-0.9)**	0.6 (0.6-0.7)***
Non-Hispanic Asian	0.9 (0.7-1.1)	0.7 (0.6-0.9)**	0.8 (0.6-1.1)	1.1 (0.8-1.5)	0.9 (0.7-1.2)	0.9 (0.7-1.1)
Hispanic	1.3 (1.2-1.4)***	0.9 (0.9-1.0)*	1.3 (1.2-1.5)***	1.2 (1.1-1.4)*	1.1 (1.0-1.2)	1.0 (0.9-1.1)

*$p < 0.05$; **$p < 0.001$; ***$p < 0.0001$

Risk ratios (95% confidence intervals) for SSc, DM/PM, and GCA _ minority ethnicities versus non-HIspanic Whites

0.89, 95% CI = 0.74-1.07). Interestingly, the pattern was reversed in NHBs aged 65+, with a significantly lower diagnosed prevalence of SSc (RR = 0.48; 95% CI = 0.44-0.52) as compared to NHWs. We also observed a reduced risk of SSc in Hispanics (RR=0.92, 95% CI = 0.86-0.99) and in NHAs (RR = 0.71; 95% CI = 0.58-0.87) in the older age-group. The risk of DM/PM in both age-groups was elevated in NHBs (ages ≤65: RR = 1.51, 95% CI = 1.40-1.63; ages 65+: RR = 1.15, 95% CI = 1.03-1.29) and Hispanics (ages ≤65: RR = 1.34, 95% CI = 1.22-1.47; ages 65+ RR = 1.20, 95% CI = 1.06-1.35) as compared to NHWs, but not in NHAs (ages ≤65: RR = 0.83, 95% CI = 0.62-1.10; ages 65+: RR = 1.08, 95% CI = 0.79-1.48). We observed a significantly reduced risk of GCA in NHBs in both age groups (ages ≤65: RR = 0.83, 95% CI = 0.75-0.92; ages 65+: RR = 0.63, 95% CI = 0.56-0.71) as compared to NHWs, while no significant difference was observed in Hispanics (ages ≤65: RR = 1.10, 95% CI = 0.99-1.23; ages 65+: RR = 0.95, 95% CI = 0.86-1.05) and in NHAs (ages ≤65: RR = 0.91, 95% CI = 0.67-1.25; ages 65+: RR = 0.87, 95% CI = 0.67-1.14).

Conclusion: Our results concur with findings of other epidemiological studies that have observed a higher prevalence of SSc and DM/PM and a lower prevalence of GCA in certain ethnic groups as compared to NHWs. However,

the lower prevalence of SSC observed in NHBs and Hispanics aged 65+ warrants further investigation, as it may indicate early mortality in these patients known to experience more severe disease.

Abstract Number: 0532

State-Specific Percentage of Adults with Arthritis Who Report Both Severe Joint Pain and Physical Inactivity and Their Characteristics, United States, Behavioral Risk Factor Surveillance System, 2017

Dana Guglielmo[1], Louise Murphy[1], Jennifer Hootman[1], Michael Boring[1], Kristina Theis[1], Charles Helmick[1], Susan Carlson[1], Yong Liu[1], Hua Lu[1] and Janet Croft[1], [1]Centers for Disease Control and Prevention, Atlanta, GA

SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: Epidemiology & Public Health Poster II: OA, Osteoporosis, & Other Rheumatic Disease
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: About one in four (27%) US adults with arthritis have severe joint pain, and only 36% meet the Physical Activity Guidelines for Americans. While low-impact physical activity can relieve arthritis pain, improve physical functioning, and prevent or delay arthritis-related disability, pain itself is the most frequently reported barrier to physical activity among adults with arthritis. The study purpose was to estimate, among adults with arthritis, percentages of reporting both severe joint pain and physical inactivity: 1) for each of the 50 states and District of Columbia, and 2) overall by selected sociodemographic and health-related characteristics.

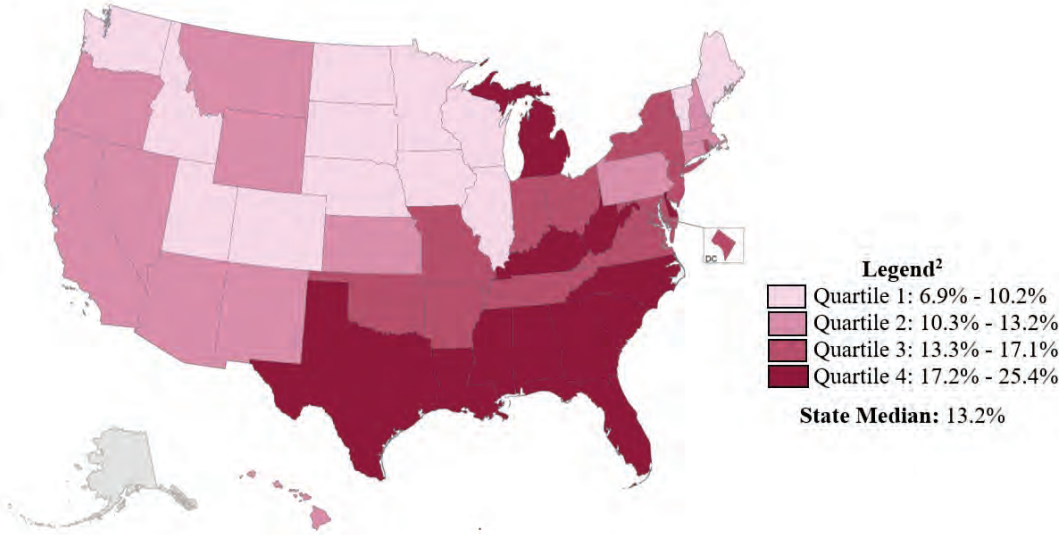
Methods: We analyzed 2017 Behavioral Risk Factor Surveillance System data (unweighted n=134,405 adults with arthritis). We used standard definitions of arthritis, severe joint pain, and physical inactivity (Table). We generated age-specific or age-adjusted percentages with 95% confidence intervals (CIs) for all outcomes. Differences between subgroups were assessed using t-tests and linear patterns in ordinal variables using tests for trends (i.e., orthogonal linear contrasts) (α=0.05). We accounted for the complex survey design by applying sampling weights and adjusting variance.

Results: In 2017, the median state age-adjusted percentage of reporting both severe joint pain and physical inactivity among adults with arthritis was 13.2% (range: 6.9% [Wisconsin]-25.4% [Mississippi]), with higher percentag-

Table. Variable Definitions

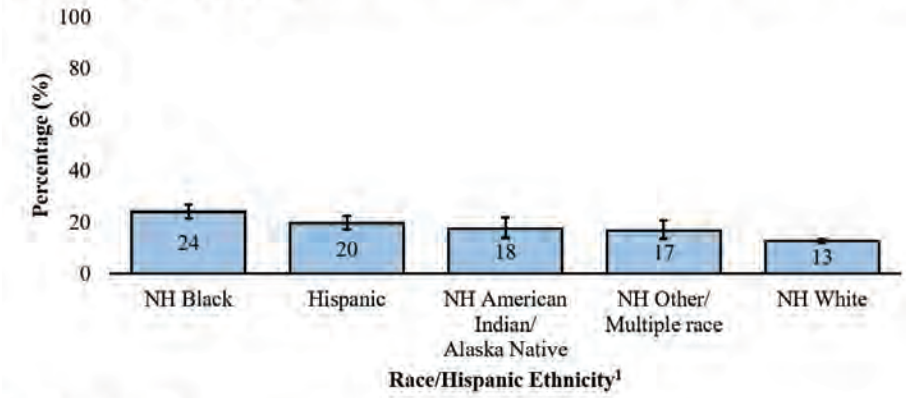
Variable	Definition
Arthritis	Response of "yes" to "Have you ever been told by a doctor or other health care professional that you have arthritis, rheumatoid arthritis, gout, lupus, or fibromyalgia?"
Severe Joint Pain	Response of "7," "8," "9," or "10" to "Please think about the past 30 days, keeping in mind all of your joint pain or aching and whether or not you have taken medication. On a scale of 0 to 10 where 0 is no pain or aching and 10 is pain or aching as bad as it can be, during the past 30 days, how bad was your joint pain on average?"
Physical Inactivity	Response of "no" to "During the past month, other than your regular job, did you participate in any physical activities or exercises such as running, calisthenics, golf, gardening, or walking for exercise?"

Figure 1. Age-Adjusted[1] State-Specific Percentage of Adults Aged ≥18 Years with Arthritis who Report Both Severe Joint Pain and Physical Inactivity — Behavioral Risk Factor Surveillance System, 50 states and District of Columbia, 2017



[1]Estimates were age-standardized to the 2000 projected U.S. population aged ≥18 years using three groups (18–44 years, 45–64 years, and ≥65 years).
[2]Estimates for Nevada and Hawaii were unreliable (relative standard error 20-30%); estimate for Alaska was suppressed (relative standard error >30%).

Figure 2. Age-Adjusted Percentage of Adults with Arthritis who Report Both Severe Joint Pain and Physical Inactivity, by Race/Hispanic Ethnicity, Behavioral Risk Factor Surveillance System, 50 States and District of Columbia



NH: Non-Hispanic
[1]Estimate for non-Hispanic Asians was suppressed (relative standard error >30%).

es in South and Southeast states (Figure 1). Age-specific percentage was higher among those aged 45-64 years (17.3% [95% CI: 16.6-18.1]) compared with those aged 18-44 years (14.2% [95% CI: 12.9-15.6]) and those aged >65 years (13.2% [95% CI: 12.6-13.9]). Age-adjusted percentages were highest in their respective subgroups for females (17.2% [95% CI: 16.1-18.3]), those with < high school graduation (27.9% [95% CI: 25.0-31.0]), non-Hispanic blacks (24.2% [95% CI: 21.5-27.0]) (Figure 2), Hispanics (19.7% [95% CI: 17.3-22.4]) (Figure 2), and those with obesity (18.5% [95% CI: 17.2-19.9]). Age-adjusted percentage for those unable to work/disabled (36.7% [95% CI: 34.4-39.0]) was more than four times higher than for those employed/self-employed (8.8% [95% CI: 8.0-9.6]). Age-adjusted percentage was similar across urban/rural geographic areas, ranging from 14.9%–17.1% in all areas, except for a slightly lower prevalence (13.1%) in large fringe metro areas.

Conclusion: Across states, about 1-in-8 adults with arthritis reported both severe joint pain and physical inactivity. The percentage was even higher among specific subgroups (e.g., 1-in-3 adults unable to work/disabled, 1-in-4 non-Hispanic blacks), making them an important target for evidence-based physical activity programs. These programs, available in most states, can safely reduce the compound effects of severe joint pain and physical inactivity by helping adults with arthritis reduce pain and increase physical functioning and quality-of-life.

Characterization of Older Male Patients with a Fragility Fracture

Setareh A Williams[1], Shanette G Daigle[2], Richard Weiss[1], Yamei Wang[1], Tarun Arora[2] and **Jeffrey R Curtis**[3], [1]Radius Health, Inc., Waltham, MA, Waltham, MA, [2]University of Alabama at Birmingham, Birmingham, AL, Birmingham, AL, [3]Division of Clinical Immunology and Rheumatology, University of Alabama at Birmingham, Birmingham, AL

SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: Epidemiology & Public Health Poster II: OA, Osteoporosis, & Other Rheumatic Disease
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Osteoporosis is associated with significant burden in terms of adverse patient outcomes, mortality, and cost; and is particularly common in the older Medicare population. Approximately a quarter of patients with fractures are male. Emerging evidence suggests worse outcomes related to osteoporotic fractures in male compared to female patients.The objective of this study was to examine baseline characteristics of male Medicare patients who experienced a fragility fracture.

Methods: We studied Medicare fee-for-service (FFS) beneficiaries with a closed fragility (or osteoporosis-related) fracture between 01 January 2010 and 30 September 2014 (identification period). Additional inclusion criteria included age ≥65 years as of the index date, continuous enrollment in Medicare FFS with medical and pharmacy benefits (parts A+B+D-C) for a minimum of one year prior to the index date, through at least 1 month after (i.e. beneficiaries were excluded if they died within 30 days of the index date). Patients with Paget's disease or malignancy (except for non-melanoma skin cancer) at baseline were excluded. Patients were classified into four cohorts based on the observed diagnoses and/or treatment of osteoporosis at baseline. Diagnoses of osteoporosis could be in any position on any medical claim.

Results: A total of 9,876 beneficiaries met eligibility criteria. Sixty-one percent were ≥75 years of age and 90.3% were white. Fewer than 6% had undergone bone mineral density testing with DXA in the 2 years prior to their fracture. 62.8% had a history of musculoskeletal pain and 48.5% had a history of opioid use 1 year prior to index fracture. The most commonly observed fracture sites were spine (n=3,060; 31.0%), hip (n=2,759; 27.9%), and ankle (n=965; 9.8%). Of all patients with a qualifying fracture, approximately 92.8% (n=9,163) did not have a claim for diagnosis or treatment of osteoporosis at baseline. 2.8% (n=279) were diagnosed but not treated, 2.3% (n=227) were treated but not diagnosed, and only 2.1% (n=207) were diagnosed and treated. There was a trend in declining DXA scans from 2012 to 2014 (65-69 years; 6.3 to 5.5% AND 70-74 years; 4.7 to 4.0%) especially pronounced in the ≥75 age group (6.0 to 4.3%).

Conclusion: Our findings suggest a high level of underdiagnosis and undertreatment of osteoporosis in the older male population who experience fracture. Further documentation of cost of illness following an osteoporosis-related fracture, including identification of drivers of high costs and earlier identification high risk patients who may benefit from more targeted screening and osteoporosis therapies, will be of value.

National Variation and Factors Associated with Long-term Opioid Use for Non-cancer Pain in the First Year of Use

Meghna Jani[1], Belay Yimer[1], Therese Sheppard[1], Mark Lunt[1] and William Dixon[1], [1]Centre for Epidemiology Versus Arthritis, University of Manchester, Manchester, United Kingdom

SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: Epidemiology & Public Health Poster II: OA, Osteoporosis, & Other Rheumatic Disease
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Physician prescribing behaviour has been described as a key driver of rising opioid prescriptions and long-term opioid use. However, the effect of prescribers requires interpretation within context. No studies have investigated the extent to which regions, practices, prescribers, vary in opioid prescribing by considering this hierarchy together, whilst accounting for case-mix. Objectives: (i) quantify and identify risk factors for the transition from new-users to long-term opioid users (ii) quantify variation of long-term use attributed to region, practice, prescriber, accounting for patient mix and chance variation.

Methods: We conducted a retrospective observational study between 2006-2017 using Clinical Practice Research Datalink. New users of opioids, ≥18 years, without cancer were identified. Long-term opioid use was defined as ≥3 opioid prescriptions within a 90-day period from index date, or ≥1 opioid prescription lasting at least 90-days in the first year. A multi-level random-effects logistic regression model was used to examine the association of patient characteristics with the odds of becoming a long-term opioid-user. To examine variation in opioid use amongst prescribers, GP-practices and region after adjusting for case-mix, we used a nested random-effect structure. A 'high-risk' region, prescriber or practice was defined as those where the entire adjusted 95% CI lay above population average.

Results: 1,968,742 new opioid users were included; 14.6% transitioned to long-term use. In the fully-adjusted model, factors associated with higher-odds of long-term use included older-age, deprivation, fibromyalgia, rheumatological conditions, higher morphine milligram equivalents (MME)/day at initiation and prior surgery (Table). After adjustment for case-mix, the North-West, Yorkshire and South-West were found to be high-risk regions for long-term use. 103 practices (25.6%) and 540 prescribers (3.5%) were associated with a significantly higher-risk of long-term use. The odds of becoming a long-term user for patients belonging to these prescribers reached up to >3.5 times than the population average.

Individual factors	Adjusted Odds Ratio (95% CI) *
Prescribing factors	
Index daily MME >200	7.59 (6.29, 9.16)
Index daily MME 100-200	1.12 (1.03, 1.21)
Index daily MME 50-100	1.58 (1.49, 1.68)
Index daily MME <50	Ref
Gabapentinoid use	2.51 (2.43, 2.60)
Psychotropic use	1.28 (1.17, 1.40)
Age	
>75	4.35 (4.26, 4.45)
65-75	3.57 (3.50, 3.65)
55-65	3.03 (2.96, 3.09)
35-55	1.91 (1.88, 1.95)

Rheumatological conditions Ψ	1.54 (1.49, 1.59)
Alcohol abuse	1.50 (1.45, 1.55)
Depression	1.28 (1.26, 1.30)
Major Surgery	1.09 (1.06, 1.13)
Abbreviations: MME, Morphine Milligram Equivalent; *p<0.05. Index daily MME/day is the MME/day at first prescription (MME= daily dose in milligrams X opioid conversion ratio). Ψ Defined by Charlson score including rheumatoid arthritis, SLE, myositis.	

Factors associated with long term opioid use using a multi-level model accounting for clustering of individuals within prescriber, practice and region

Conclusion: Prescribing factors, age, deprivation and conditions including fibromyalgia and rheumatological conditions were associated with higher odds of long-term opioid use. In the first UK study evaluating long-term opioid prescribing with patient-level characteristics adjustment, variation in regions, especially practices and prescribers were observed. Our findings support greater calls for action to reduce practice/prescriber variation by promoting safe practice in opioid-prescribing.

Session Date: Saturday, November 7, 2020

Session Title: Epidemiology & Public Health Poster II: OA, Osteoporosis, & Other Rheumatic Disease

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: To assess rheumatologists' views and practices related to shared decision making (SDM) in gout treatment.

Methods: We performed a cross-sectional electronic survey of rheumatologists at U.S. Veterans Affairs (VA) medical centers, assessing views and practices related to SDM in gout.

Table 1. Characteristics of survey respondents (n=90 providers)

	N (%) unless specified otherwise*
Female Sex	45 (58%)
Age in years, mean (standard deviation)	51 (9.6)
Age group	
≤ 50 years	34 (47%)
>50 to 65 years	34 (47%)
>65 years	4 (6%)
U.S. region	
Northeast	18 (27%)
West	15 (22%)
Midwest	12 (18%)
South	68 (34%)
Years in Practice	
0-5 years	6 (11%)
6-10 years	12 (16%)
11-20 years	23 (31%)
21-30 years	23 (31%)
>30 years	9 (12%)
*Missing: Sex, n=13; age, n=18; Region, n=22; years in practice, n=15	

Table 1. Characteristics of survey respondents (n=90 providers)

Appendix 1. Provider practices for choice for the patient regarding gout treatment decisions

	Yes	No
Do you routinely offer your gout patients a choice regarding the following?		
1. Starting urate-lowering therapy (ULT) vs. doing nothing?	70%	30%
2. Choosing among non-steroidal anti-inflammatory drugs (NSAIDs), steroids, or colchicine for the treatment of acute flares?	67%	33%
3. Choosing among NSAIDs, steroids, or colchicine for prophylaxis when starting ULTs	51%	49%
4. Choosing allopurinol vs. febuxostat as a first ULT?	16%	84%
5. Choosing whether to take daily ULT and continue taking it long-term vs. intermittently (e.g., during a flare)?	15%	85%

Appendix 1. Provider practices for choice for the patient regarding gout treatment decisions

Table 2. Provider view of patient difficulties and their role in shared decision-making (SDM) process in gout

	Often	Sometimes	Rarely	Never	Don't know
Q1. How common is it for your patients to have difficulty starting urate-lowering therapy vs. doing nothing…					
a. Unsure about the best choice for them?	11 (14%)	41 (51%)	25 (31%)	2 (2%)	1 (1%)
b. Uninformed about both benefits and risks?	28 (36%)	23 (29%)	22 (28%)	5 (6%)	0 (0%)
c. Unclear about the personal importance of the benefits and risks?	32 (58%)	26 (33%)	16 (20%)	4 (5%)	1 (1%)
d. Unsupported in decision-making?	8 (10%)	29 (37%)	25 (32%)	11 (14%)	5 (6%)
Q2. How common is it for your patients to have difficulty choosing between non-steroidal anti-inflammatory drugs (NSAIDs), steroids or colchicine for the treatment of acute flares…					
a. Unsure about the best choice for them?	20 (26%)	35 (45%)	23 (18%)	9 (6%)	4 (5%)
b. Uninformed about both benefits and risks?	22 (28%)	28 (36%)	18 (23%)	7 (9%)	3 (4%)
c. Unclear about the personal importance of the benefits and risks?	22 (28%)	33 (42%)	12 (15%)	7 (9%)	4 (5%)
d. Unsupported in decision-making?	10 (13%)	27 (35%)	19 (25%)	12 (16%)	8 (10%)
Q3. How common is it for your patients to have difficulty choosing between NSAIDs, steroids, or colchicine for prophylaxis when starting ULTs…					
a. Unsure about the best choice for them?	22 (28%)	32 (42%)	13 (17%)	5 (7%)	4 (5%)
b. Uninformed about both benefits and risks?	25 (33%)	22 (29%)	16 (21%)	9 (12%)	4 (5%)
c. Unclear about the personal importance of the benefits and risks?	26 (35%)	23 (32%)	14 (19%)	7 (9%)	4 (5%)

Table 2. Provider view of patient difficulties and their role in shared decision-making (SDM) process in gout

Results: Of the 154 VA rheumatology providers eligible, 90 responded (response rate, 58%). Fifty-eight percent were female, the mean age was 51 years (standard deviation, 9.6), 42% had >20 years of experience in medical practice (**Table 1**).

Rheumatologists reported routinely offering a choice to their patients for: (1) starting urate-lowering therapy (ULT) for gout vs. doing nothing (70%); (2) choosing NSAIDs, corticosteroids, or colchicine for the treatment of acute flares (67%); and (3) choosing NSAIDs, corticosteroids, or colchicine for anti-inflammatory prophylaxis when starting ULT (51%; **Appendix 1**). Very few rheumatologists offered choice regarding: (4) choosing allopurinol vs. febuxostat as the first ULT (16%); and (5) taking daily ULT long-term vs. intermittently (15%).

Rheumatologists perceived that large proportion of patient were often or sometimes unsure of the best choice for these five decisions, respective proportions were 34%, 76%, 76%, 52%, and 54%. Similar proportions were often or sometimes uninformed about both medication benefits and risks, unclear about the personal importance of the benefits and risks, and unsupported in decision-making (**Table 2**). The rheumatologists reported that 44-64% of the patients were uninformed about both benefits and risks, 52-73% were unclear about the personal importance of the benefits and risks, and 36-52% were unsupported in decision-making (**Table 2**).

Conclusion: The majority of VA rheumatologists incorporated SDM in several gout treatment decisions. Rheumatologists also recognized that patients need better support to participate in SDM in gout.

Systematic Geriatric Assessment in Older Patients with Rheumatic Diseases - The RheuMAGIC Pilot Study

Bjoern Buehring[1], Anna Berrisch[2], Ioana Andreica[3], Styliani Tsiami[4], David Kiefer[3], Uta Kiltz[2], Xenofon Baraliakos[2] and Juergen Braun[2], [1]Rheumazentrum Ruhrgebiet, Ruhr-University Bochum, Velbert, Germany, [2]Rheumazentrum Ruhrgebiet, Ruhr-University Bochum, Herne, Germany, [3]Rheumazentrum Ruhrgebiet, Ruhr-University Bochum, Herne, [4]Rheumazentrum Ruhrgebiet Herne, Ruhr-University Bochum, Herne, Germany

SESSION INFORMATION

Session Date: Saturday, November 7, 2020

Session Title: Epidemiology & Public Health Poster II: OA, Osteoporosis, & Other Rheumatic Disease

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: Current demographic data predict that the number of older adults with rheumatic diseases will considerably increase in the coming years. Geriatric patients differ from younger adults in many ways including their clinical presentation, co-morbidities and response to medication. The management of such patients is often

Geriatric Problem	% present
Problems with Daily Activities	67
Problems with Vision	28
Problems with Hearing	38
Problems with Falls	11
Problems with Urinary Incontinence	38
Problems with Depression	57
Lack of Social Support	10
Incomplete Vaccinations	53
Problems with Cognition	31
Problems with Chronic Pain	90
Problems with Dizziness	44
Problems with Mobility	41
Problems with Unintentional Weight Loss	30
Inappropriate Medications present	17
Polypharmacy present	81
Frailty present	46
Short Physical Performance Battery low	57

Table 1. Frequency of Geriatric Problems

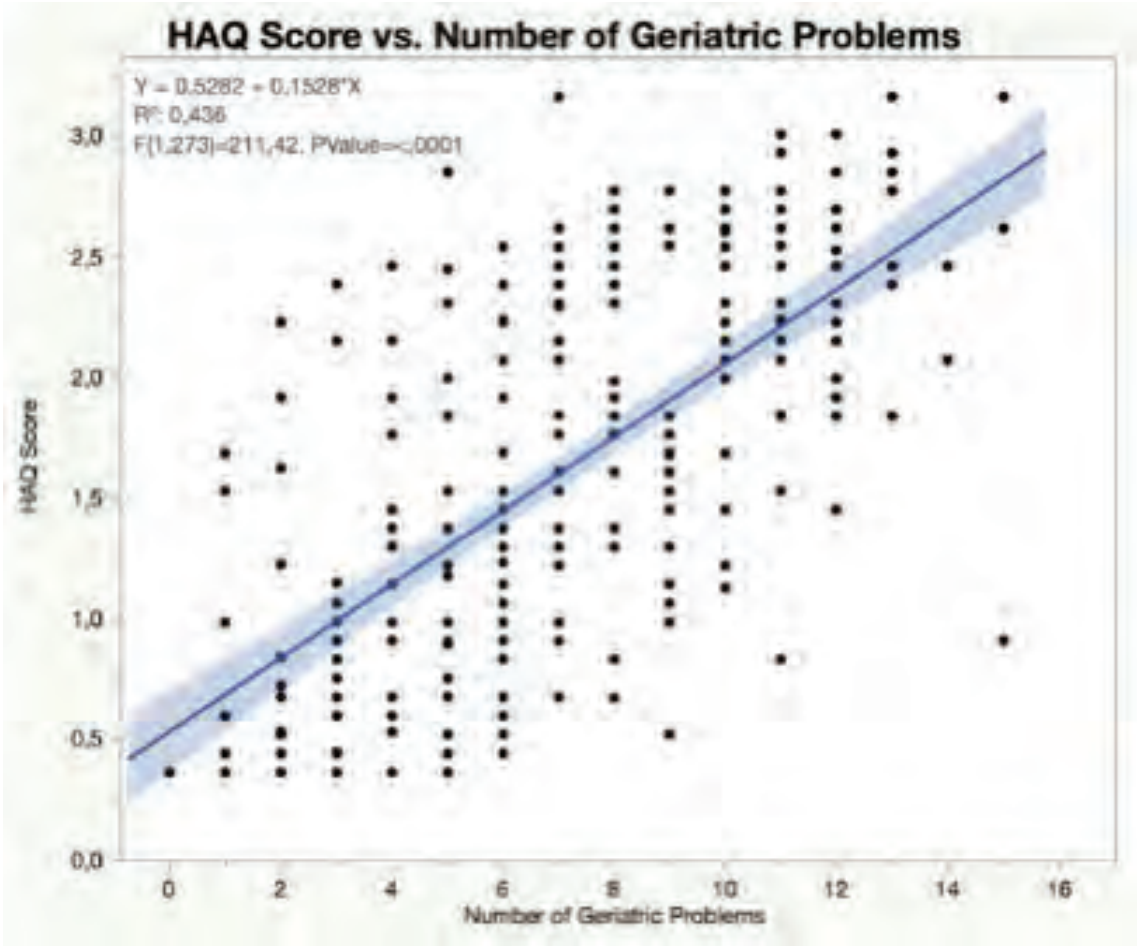

Figure 1. Relationship of Number of Geriatric Problems and Health Assessment Questionnaire (HAQ) Score. A significant linear relationship was found between the number of geriatric problems and HAQ score indicating that a higher number of geriatric problems is associated with greater difficulty in daily function

challenging due to the presence of multimorbidity, polypharmacy and geriatric syndromes (i.e. conditions in which symptoms result from impairments in multiple systems rather than a discrete disease). To systematically assess geriatric patients, specific tools have been developed; however, they are not routinely utilized by rheumatologists. Using these tools could improve patient management and satisfaction in rheumatologic care. The aim of this study was to examine the prevalence of 17 common geriatric health problems using validated geriatric assessment tools in older patients with rheumatic and musculoskeletal diseases.

Methods: Adults 65 years and older who presented to a tertiary rheumatologic hospital were included after informed consent. All patients recruited were assessed using the MAngable GeriatrIC Assessment (MAGIC) which addresses 14 common geriatric health problems. In addition, polypharmacy (≥ 5 medication), muscle function using the Short Physical Performance Battery and frailty applying the Fried definition were assessed. Disability was quantified with the "Funktionsfragebogen Hannover" (FFbH), a validated tool for patients with rheumatologic diseases that can be easily converted to Health Assessment Questionnaire (HAQ) scores. Primary outcome was the frequency of the selected 17 geriatric health problems; the correlation of the total number of problems with HAQ scores was a secondary outcome.

Results: Of the 300 individuals included 67% were female with a mean age of 73±6.6 years; 85% (> 50% with rheumatoid arthritis) had a rheumatologic diagnosis. The remaining participants had either a chronic pain syndrome or degenerative joint/spine disease. On average participants had 7 out of 17 assessed geriatric problems. Females had

more such problems than males (8 vs. 6, p< 0.0001). Chronic pain and polypharmacy were most common but several others were also seen in more than 50% of patients (see Table). The mean HAQ Score was 1.67±0.79. There was a positive correlation (see Graph) between the number of problems and the HAQ Score (R2 0.44, p< 0.0001).

Conclusion: A systematic geriatric assessment can be successfully used to discover and quantify geriatric health problems in older patients with rheumatic and musculoskeletal diseases. These problems appear to be very common and importantly, patients with more problems had poorer functional status. Frailty, depression, incomplete vaccination status, cognitive impairment or polypharmacy are all known to negatively impact patient care. Recognizing and addressing geriatric problems has the potential to lead to health care improvements including adherence and medication side effects and might increase patient satisfaction and functional status independent of disease activity.

Hip Abductor Strength and Its Association with New or Worsening Knee Pain: The MOST Study

Cara Lewis[1], Neil Segal[2], Joshua Stefanik[3], Xiaoyang Chen[4], Glenn Williams[5], Michael Nevitt[6], Cora Lewis[7] and David Felson[8], [1]Boston University, Brookline, MA, [2]University of Kansas Medical Center, Iowa City, IA, [3]Northeastern University, Boston, MA, [4]Boston University, Boston, MA, [5]Drexel University, Philadelphia, PA, [6]Department of Epidemiology and Biostatistics, University of California San Francisco, Orinda, CA, [7]University of Alabama Birmingham, Birmingham, AL, [8]Boston University School of Medicine, Boston, MA

SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: Epidemiology & Public Health Poster II: OA, Osteoporosis, & Other Rheumatic Disease
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Hip abductors are important for controlling pelvic orientation and rotation of the femur during gait, both of which affect knee mechanics. Thus hip abductor weakness may influence the development or worsening of knee pain. The purpose of this study was to evaluate the relation of hip abductor strength to worsening or new onset of frequent knee pain, with and without adjusting for quadriceps strength.

Methods: We used data from the Multicenter Osteoarthritis Study (MOST). For the existing cohort, the 144-month study visit was considered baseline for the current analysis. At this visit, a new cohort was recruited, with their initial visit considered as the baseline. Participants had hip abductor and quadriceps muscle strength measured in each limb. Strength was measured as maximal isometric torque with hip abduction and isotonic torque with knee extension, respectively. Sex-specific quartiles were created for both hip and knee strength. Participants also filled out the WOMAC questionnaire and answered questions about frequent knee pain at baseline, 8, 16 and 24 months later.

We characterized two knee pain outcomes. First, using the WOMAC questionnaire, we defined worsening as an increase in pain score by at least 2 on the 0-20 scale. We characterized each knee as having worsening pain if worse pain was reported at 2 or more of the 3 follow-ups. For those who did not report frequent knee pain (FKP) at baseline, we characterized the knee as having new FKP if they responded ‘yes’ to the frequent knee pain question at greater

Table 1: Cohort characteristics: mean (standard deviation) or percent of participants.

Variables		n = 2259 participants
Age (years)		63.4 (10.3)

Women (%)		56.5
Clinic Site = Iowa (%)		52.9
Depressive Symptoms (%)		11.1
Race (%)	Black or African-American	16.5
	White or Caucasian	80.7
	Other	2.7
WOMAC Pain Worsening (%)		13.7
New Frequent Knee Pain (%)		9.8
Hip Abductor Torque (Nm/kg)		1.10 (0.40)

Table 2: Odds ratios and 95% confidence intervals (CI) for each quartile of hip abductor strength. Analyses adjusted for age, sex, race, BMI, depressive symptoms, and baseline WOMAC pain score.

	WOMAC Pain Worsening		New Frequent Knee Pain	
Hip Abductor Strength Quartiles	Odds Ratio (95% CI)	Odds Ratio adjusted for Quadriceps Strength (95% CI)	Odds Ratio (95% CI)	Odds Ratio adjusted for Quadriceps Strength (95% CI)
Q1 (Weakest)	1.47 (1.03, 2.09) P = 0.03	1.27 (0.87, 1.85) P = 0.22	1.84 (1.11, 3.06) P = 0.02	1.52 (0.87, 2.66) P = 0.14
Q2	1.24 (0.90, 1.69) P = 0.19	1.14 (0.81, 1.59) P = 0.45	1.48 (0.94, 2.34) P = 0.09	1.30 (0.79, 2.14) P = 0.31
Q3	1.14 (0.84, 1.54) P = 0.40	1.10 (0.80, 1.50) P = 0.55	1.37 (0.86, 2.19) P = 0.18	1.27 (0.77, 2.09) P = 0.35
Q4 (Strongest)	1 (referent)	1 (referent)	1 (referent)	1 (referent)
P for Trend	0.031	0.228	0.018	0.161

than 50% of 2 or more follow-ups. Non-cases were those with no reports of worsening or new FKP on follow-up. We carried out hip and knee specific analyses testing hip abductor strength as a risk factor for ipsilateral worsening and new knee pain, accounting for the correlation between limbs with GEE and adjusting for age, sex, race, body mass index (BMI), depressive symptoms, and baseline WOMAC pain score in that knee. After initial analyses, we added quadriceps strength as a covariate.

Results: Of 2391 participants with hip abductor strength measurements, sufficient follow-up data were available from 2259 participants for WOMAC pain worsening and 1891 participants for incident frequent knee pain. Characteristics of the participants are in Table 1. In analyses unadjusted for quadriceps strength, hip abductor strength demonstrated a significant association with worsening WOMAC knee pain and new onset FKP (Table 2). However, when we adjusted additionally for quadriceps strength, the associations between hip abductor strength and knee pain became much weaker and nonsignificant. Quadriceps strength was associated with pain outcomes; trend tests were significant for WOMAC pain worsening (p=0.023) and for new onset frequent knee pain (p=0.038).

Conclusion: Hip abductor strength is not independently associated with worsening or incident knee pain in this cohort. Instead, the relation of abductor strength with knee pain appears to be substantially due to its association with quadriceps strength.

Autoimmune Disease Outcomes of Women with Breast Implants: A Population-Based Study

Madeline Peterson[1], Thomas O'Byrne[1], John Davis[1], Vanessa Kronzer[1], Lynne Peterson[1], Michael Weisman[2] and Cynthia Crowson[3], [1]Mayo Clinic, Rochester, MN, [2]Distinguished Professor of Medicine Emeritus, David Geffen School of Medicine at UCLA, LOS ANGELES, CA, [3]Mayo Clinic, Rochester, Minnesota, USA, Rochester, MN

SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: Epidemiology & Public Health Poster II: OA, Osteoporosis, & Other Rheumatic Disease
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: The long-term safety of breast implants has been a debated topic; two recent studies have raised new concerns about their potential negative health effects (Watad A et al., *Int J Epidemiol.* 2018; Coroneos C et al., *Annals of Surgery.* 2018). While these reports suffer from methodological weaknesses, previous studies indicating no association between silicone breast implants and systemic disease may have been under-powered for rare outcomes. Since disease diagnostic criteria have been expanded in modern times, we felt these recent reports required a re-examination of whether autoimmune conditions occurred more frequently in women after silicone and saline breast implantation compared to those with no history of implants.

Methods: In this retrospective cohort study, all women who received a breast implant in a geographically defined region between January 1, 1998 and December 31, 2017 were identified. Implant cases were individually reviewed to confirm implant status and determine implant date, type, and reason. Each subject was matched to 3 women of the same age and region with no history of implants. Index date was defined as date of implantation or matched date. Both cohorts were screened for 26 autoimmune conditions using diagnostic codes (Table 1). Using a previously validated method, confirmed autoimmune conditions were defined by the presence of ≥1 inpatient encounter as the primary diagnosis, or ≥2 codes ≥30 days and ≤2 years apart (Ong MS et al., *JAMA Neurol.* 2014). Comparisons of autoimmune disease occurrence in women with and without implants were performed using Cox models adjusted for age and calendar year.

Results: We identified 835 women who received breast implants during the study period and 2505 comparators with no history of implants. Women with implants were 89.2% white with a mean age of 41.4 years at implantation. Roughly half the implants were for cosmetic reasons (n = 422; 50.5%), with 310 (37.1%) for breast cancer, and 103 (12.3%) for prophylaxis or reasons related to another condition. The median length of prior medical history for implant patients was 24.9 years (IQR: 11.3, 36.1). After implant placement, these women had a median follow-up of 9.3 years (IQR: 4.8, 14.2). Prior to receiving implants, 129 (15.4%) women had an autoimmune condition compared to 381 (15.2%) comparators (p = 0.87). Excluding women with prior autoimmune disease, 74 women with implants (cumulative incidence at 10 years: 11.0%; 95% CI: 8.5-14.1%) and 222 comparators (cumulative incidence at 10 years: 11.3%; 95% CI: 9.8-13.0%) developed an autoimmune condition during follow-up. We found no evidence of an increase in the risk of autoimmune disease for women with implants compared to those without (HR: 0.98; 95% CI: 0.75-1.27). When assessing the risk of autoimmune disease for implant reason subtypes, we did not observe any differences (Table 2).

Table 1. Diagnostic codes for autoimmune conditions

Autoimmune Disease	ICD-9	ICD-10
Addison's disease	255.4	E27.1, E27.2
Ankylosing spondylitis	720	M45.x, M08.1

SESSION INFORMATION

Session Date: Saturday, November 7, 2020

Session Title: Epidemiology & Public Health Poster II: OA, Osteoporosis, & Other Rheumatic Disease

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: Sports that require the use of a racket or bat to propel a ball (e.g., baseball, softball, tennis) expose the thumb-base to repetitive high-velocity loading. However, it remains unclear if these sports increase the risk of thumb-base osteoarthritis (OA). We aimed to determine if a history of participation in racket or bat sports is associated with prevalent thumb-base OA.

Methods: We studied men and women from the Osteoarthritis Initiative (OAI) – a multicenter cohort study recruited from the community. Eligible participants had dominant hand radiographic readings, hand symptom assessments, and historical physical activity survey data. A history of participation in racket or bat sports (i.e., baseball/softball, racquetball/squash, badminton, table tennis, tennis [doubles/singles]) was based on self-reported recall data covering 3 age ranges (teens: 12-18 years, young adult: 19-34 years, adult: 35-49 years). As a sensitivity analysis, we examined people who indicated that participation in these sports was among their top 3 commonly performed physical activities during each age range. Prevalent radiographic thumb-base OA was defined as Kellgren-Lawrence grade≥2 in the first carpometacarpal joint or scaphotrapezoidal joint at the OAI baseline visit. Symptomatic thumb-base OA was defined as the presence of radiographic OA and hand symptoms. We used a series of logistic regression models to assess the association between a history of racket or bat sports within each age range with prevalent radiographic thumb-base OA (primary outcome) or symptomatic thumb-base OA (secondary outcome). These models were performed stratified by sex and completed with and without adjusting for confounders (see Tables).

Results: The 2309 participants tended to be 60 (9) years of age, female (55%), white (80%), and educated with at least some college experience (87%). Among 1049 men, 355 (34%) and 56 (5%) had radiographic or symptomatic

Note. * adjusted for age, race, and education.
Further adjusting for other physical activities related to racket or bat sports and rTBOA led to similar results (data not shown).
OR = odds ratio, 95% CI = 95% confidence interval.

Table 2

thumb-base OA, respectively. Among 1260 women, 525 (42%) and 170 (13%) had radiographic or symptomatic thumb-base OA, respectively. After adjusting for age, race, and education level, we found no significant associations between a history of any racket or bat sport participation and thumb-base OA (radiographic or symptomatic; odds ratios range from 0.84 to 1.34; Tables 1 and 2). Sensitivity analyses among people who listed racket/bat sports among their top 3 sports in each age range supported the primary analyses (Tables 1 and 2).

Conclusion: Within a community-based cohort, a self-reported history of participation in racket or bat sports was not associated with having radiographic or symptomatic thumb-base OA in the dominant hand.

Session Date: Saturday, November 7, 2020

Session Title: Epidemiology & Public Health Poster II: OA, Osteoporosis, & Other Rheumatic Disease

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: Hydroxychloroquine (HCQ) is used in the treatment of a wide variety of autoimmune diseases. HCQ retinopathy is a feared complication of long-term use. The reported prevalence of this complication increased with the advent of optical coherence tomography (OCT) or visual field assessment (VFA), and is estimated

Table 1. Selected Study Population and Case Characteristics

Characteristic	Study Population N=372	Cases N= 8
Age at First HCQ Prescription in years (Mean (SD); Range)	54.3 (15.6); 16.9-84.4	55.7 (11.5); 38.8-70.9

Time to Retinopathy in Years (N=372, Events=8)	Cumulative incidence (risk), % (95% CI)
5	0
6	0.3 (0.0-2.3)
7	0.6 (0.2-2.6)
8	1.3 (0.5-3.5)
9	2.0 (0.9-4.5)
10	2.5 (1.2-5.2)

Table 2. HCQ Retinopathy Rates

Table 3. Risk factors for HCQ Retinopathy

Risk factor	HR (95% CI)	p-value
Age at HCQ start, years	1.01 (0.97, 1.06)	0.58
Male sex	—	0.99
BMI at 4 years HCQ, kg/m^2	0.96 (0.86, 1.07)	0.43
Daily HCQ dose per 100mg	1.19 (0.69, 2.06)	0.54
Cumulative HCQ dose per 100,000 mg	1.65 (0.98, 2.80)	0.061
Daily dose mg/kg*	1.28 (0.88, 1.87)	0.20
Daily dose =5mg/kg* (vs. < 5)	2.59 (0.64, 10.43)	0.18
CKD	0.86 (0.11, 7.02)	0.89
*Actual body weight; Kg, kilogram; HCQ, hydroxychloroquine; CKD, chronic kidney disease; BMI, Body Mass Index.		

Table 3. Risk factors for HCQ Retinopathy

to be approximately 7.5% after five years of use. This led to guideline recommendation of using lower doses of HCQ. However, the reliance on prevalence rather than on incidence to predict the risk of developing a non-fatal and irreversible condition such as retinopathy leads to risk overestimation. To better estimate the risk of this complication, we estimated the incidence (risk) of retinopathy among new HCQ users.

Methods: A cohort of new HCQ users in a geographically defined 27-county region was identified using population-based research infrastructure. Prescription data was available starting in 2003 for one county and since 2010 for the rest of the counties. The patients were followed until HCQ toxicity incidence, migration out of the region, death or December 31, 2018. Medical records of these patients were reviewed for the development of HCQ retinopathy. HCQ

retinopathy was defined based on characteristic paracentral visual field defects and parafoveal retinal photoreceptor layer changes on OCT. Indication for HCQ, demographics and risk factors for retinopathy were abstracted. Incidence rates were age- and/or sex-adjusted to the estimated 2010 white population of the US. To compute 95% confidence intervals for incidence rates, it was assumed that the number of incident cases followed a Poisson distribution. The cumulative incidence rates after 4 years of HCQ use were estimated adjusting for the competing risk of death. Risk factors for HCQ retinopathy were estimated using Cox models.

Results: The study cohort identified 372 new HCQ users who had taken HCQ for four or more years. The average age was 54 years and 79% were female. The most common indications for HCQ were RA and SLE. The average follow up was 9.6 years after the first HCQ prescription (range 4.2 to 17.1). The mean dose in mg was 358.9, while the mean daily dose per weight was 4.6 mg/kg. Eight patients developed HCQ retinopathy, all were females and 88% were white. The majority used HCQ for RA treatment. The mean daily dose per weight was 5.9 mg/kg (Table 1). Table 2 references the risk of HCQ retinopathy. After five years of use, the risk was 0% and progressively increased up to 2.5% at ten years. Age at onset of therapy, daily dose per 100 mg, male sex, and presence of CKD did not increase the risk of retinopathy (Table 3). Those taking ≥5mg/kg of HCQ had a hazard ratio of 2.6 (0.64, 10.43) compared to those who took less than 5mg/kg, however this did not reach statistical significance.

Conclusion: The risk of HCQ retinopathy at ten years of use is lower compared to previous prevalence-based estimations. The number of cases was low for risk factor assessment; however, a dose higher than 5mg/kg may be associated with higher HCQ retinopathy risk.

Suboptimal Vaccination Coverage with Influenza, Pneumococcal and Herpes Zoster Vaccines Among Adult Patients with Autoimmune Inflammatory Rheumatic Diseases in a Nationwide Health Care Plan

Victoria Furer[1], Clara Weil[2], Melanie Orin[2], Gabriel Chodick[2], Varda Shalev[2], Yonit Fisher Shoval[3], Raanan Cohen[3] and Ori Elkayam[4], [1]Tel Aviv Sourasky Medical Center, Tel Aviv, Israel, [2]Maccabitech Institute for Research and Innovation, Maccabi Healthcare Services, Tel Aviv, Israel, [3]Abbvie, Hod Hasharon, Israel, [4]Tel Aviv Sourasky Medical Center, Tel-Aviv, Israel

SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: Epidemiology & Public Health Poster II: OA, Osteoporosis, & Other Rheumatic Disease
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Autoimmune inflammatory rheumatic diseases (AIIRD) increase the susceptibility to infections. Immunisation against vaccine-preventable diseases is recommended for patients with AIIRD by most international medical societies. Yet, evidence points to a suboptimal adherence to vaccination recommendations among the AIIRD population.[1-3]

The purpose of this study is to assess the vaccination coverage with influenza, pneumococcal and herpes zoster (HZ) vaccines among adult patients with AIIRD in a real-world setting.

Table 1. Vaccination coverage with influenza, pneumococcal and herpes zoster vaccines among adults diagnosed with autoimmune inflammatory rheumatic diseases (30/4/2019).

Vaccine	Coverage (look-back)	RA	PsA	SLE	Mixed AIIRD	Total AIIRD
Age ≥18y: Total N		6,932	4,395	1,951	1,250	14,528
Influenza	Past year*	45.1%	36.2%	33.7%	46.0%	41.0%
	Ever	74.2%	65.8%	65.8%	74.7%	70.6%
PCV13	Past 5y*	5.1%	4.1%	4.0%	6.6%	4.8%
	Ever	5.2%	4.1%	4.2%	6.6%	4.8%
PPSV23	Past 5y*	19.6%	16.2%	12.6%	17.7%	17.5%
	Ever	49.4%	31.1%	29.3%	42.6%	40.6%
PCV13+	Past year	0.8%	0.8%	0.5%	0.6%	0.7%
PPSV23**	Past 5y*	2.9%	2.3%	2.1%	2.8%	2.6%
	Ever	4.4%	3.0%	3.3%	5.0%	3.9%
Age ≥50y: Total N		5,514	2,954	962	912	10,342
HZ	Past 5y*	4.0%	3.6%	2.0%	3.1%	3.6%

AIIRD, autoimmune inflammatory rheumatic diseases; HZ, herpes zoster; Mixed AIIRD, >1 diagnosed AIIRD (defined here as RA, PsA, SLE); PCV13, pneumococcal conjugate vaccine; PPSV23, pneumococcal polysaccharide vaccine; PsA, psoriatic arthritis; RA, rheumatoid arthritis; SLE, systemic lupus erythematosus. *Defined as optimal vaccination coverage. **Prime boost vaccination strategy – consecutive vaccination with PCV13 followed by PPSV23

Table 1. Vaccination coverage with influenza, pneumococcal and herpes zoster vaccines among adults diagnosed with autoimmune inflammatory rheumatic diseases (30/4/2019).

Methods: A retrospective cross-sectional study was performed using the databases of Maccabi Healthcare Services (MHS), a large healthcare provider in Israel. The AIIRD population was defined as adults (≥ 18 years old) alive on 30/04/2019, with ≥12 months of continuous enrolment, diagnosed with rheumatoid arthritis (RA), psoriatic arthritis (PsA) and systemic lupus erythematosus (SLE). Point prevalence rates among MHS members were age-adjusted. Optimal coverage was defined as vaccination documented in the past year for influenza and 5 years for pneumococcal (PPSV23 and/or PCV13) and HZ vaccines.

Results: A total of 14,528 AIIRD patients were included. Overall, 41.0%, 17.5%, 4.8%, and 3.6% of AIIRD patients had optimal influenza, PPSV23, PCV13 and HZ vaccination coverage, respectively (Table 1). The highest age-specific

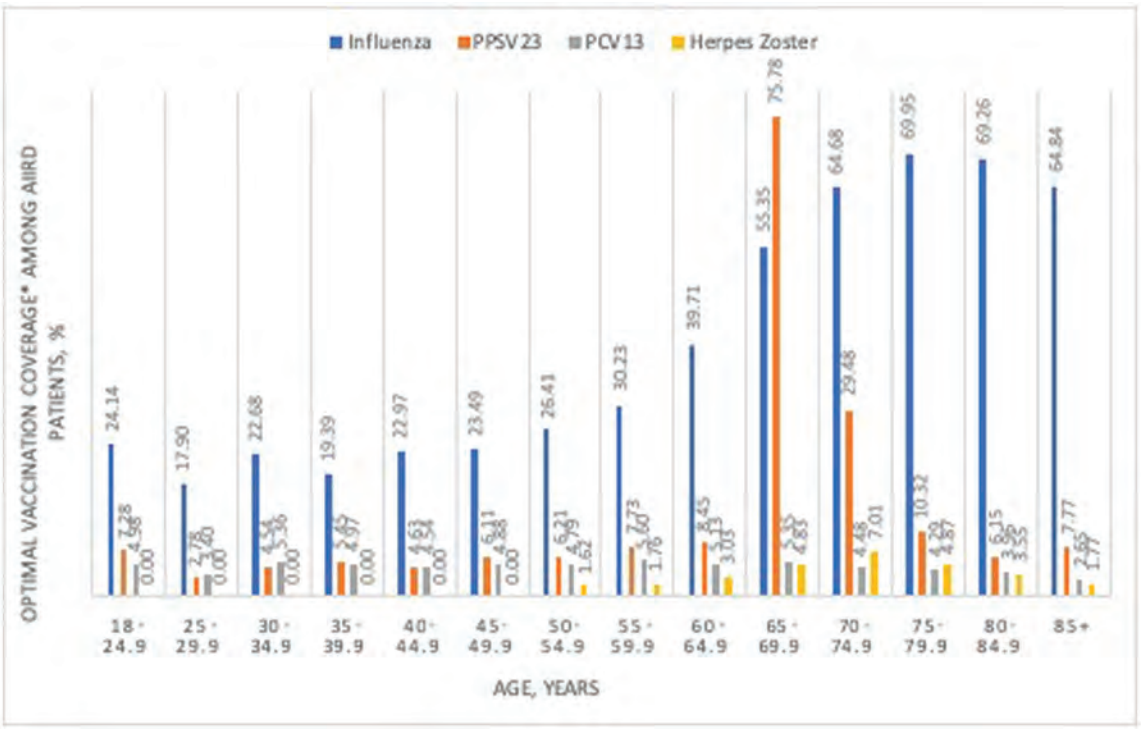

Figure 1. Age-specific optimal vaccination coverage with influenza, pneumococcal and herpes zoster vaccines among adults diagnosed with autoimmune inflammatory rheumatic diseases (30/4/2019). AIIRD, autoimmune inflammatory rheumatic diseases (defined here as rheumatoid arthritis, psoriatic arthritis, and/or systemic lupus erythematosus); PCV13, pneumococcal conjugate vaccine; PPSV23, pneumococcal polysaccharide vaccine. *Optimal coverage defined as vaccination in the past year for influenza, and vaccination in the past 5 years for pneumococcal and herpes zoster vaccines.

vaccination rates were observed in age group 75-79y for influenza, 65-69y for PPSV23, 55-59y for PCV13, and 70-74y for HZ respectively (Figure 2). Influenza vaccination was significantly ($p< 0.05$) associated with older age (≥60y) after adjusting for patient characteristics and potential confounders. Among the elderly (≥65y), AIIRD patients had comparable vaccine coverage rates to those reported in the general population in Israel[4] for influenza (past year: 63.2% vs. 61.0%) and PPSV23 (past 5y or at least once since age 65y: 83.4% vs. 77.7%). The uptake of PCV13 and HZ vaccines was remarkably low in all age groups.

Conclusion: This study provides real-world evidence of suboptimal influenza, pneumococcal, and HZ vaccination coverage of patients with AIIRD, in particular among younger adults. There remains significant scope to improve uptake of vaccinations in patients with AIIRD.

Table 1. Baseline characteristics for 2,525 study participants stratified by rheumatic and musculoskeletal diseases

Background/Purpose: Chronic pain is common in rheumatic and musculoskeletal diseases (RMDs), yet the patterns and the extent of variability over time are poorly understood. Real-time longitudinal capture of pain symptoms using smartphones enables the assessment of temporal patterns of pain, which are important indicators of disease activity. We examined the day-to-day pain variability in inflammatory and non-inflammatory RMDs using *Cloudy With a Chance of Pain*, a national U.K. smartphone study.

Methods: 10,584 study participants (aged ≥18 years; chronic pain for ≥3 months) entered their daily pain using a downloaded smartphone app (on a five-point ordinal scale of 1 - no pain/ 2 - mild pain/ 3 - moderate pain/ 4 - severe pain/ 5 - very severe pain). 2,525 participants diagnosed with single RMD (rheumatoid arthritis - RA, axial spondyloarthropathy - axSpA, osteoarthritis - OA, chronic widespread pain/fibromyalgia - CWP/FM) were included (median symptom entry days: 165 [IQR 82-284]). Long-term and short-term day-to-day pain variability for the first one-month period were analyzed using multilevel and Markov transition models respectively.

Results: From 29,705 daily pain scores (83% female; mean age 48 years; median symptom entry days: 24 [IQR 15-29]), the average pain scores for the first one-month period were higher in participants with axSpA and OA compared with participants with RA (2.74±0.98, 2.61±0.96, and 2.53±0.98 respectively), although participants with CWP/FM had the highest average pain score of 3.06±1.04. In addition, participants with CWP/FM had the highest overall pain

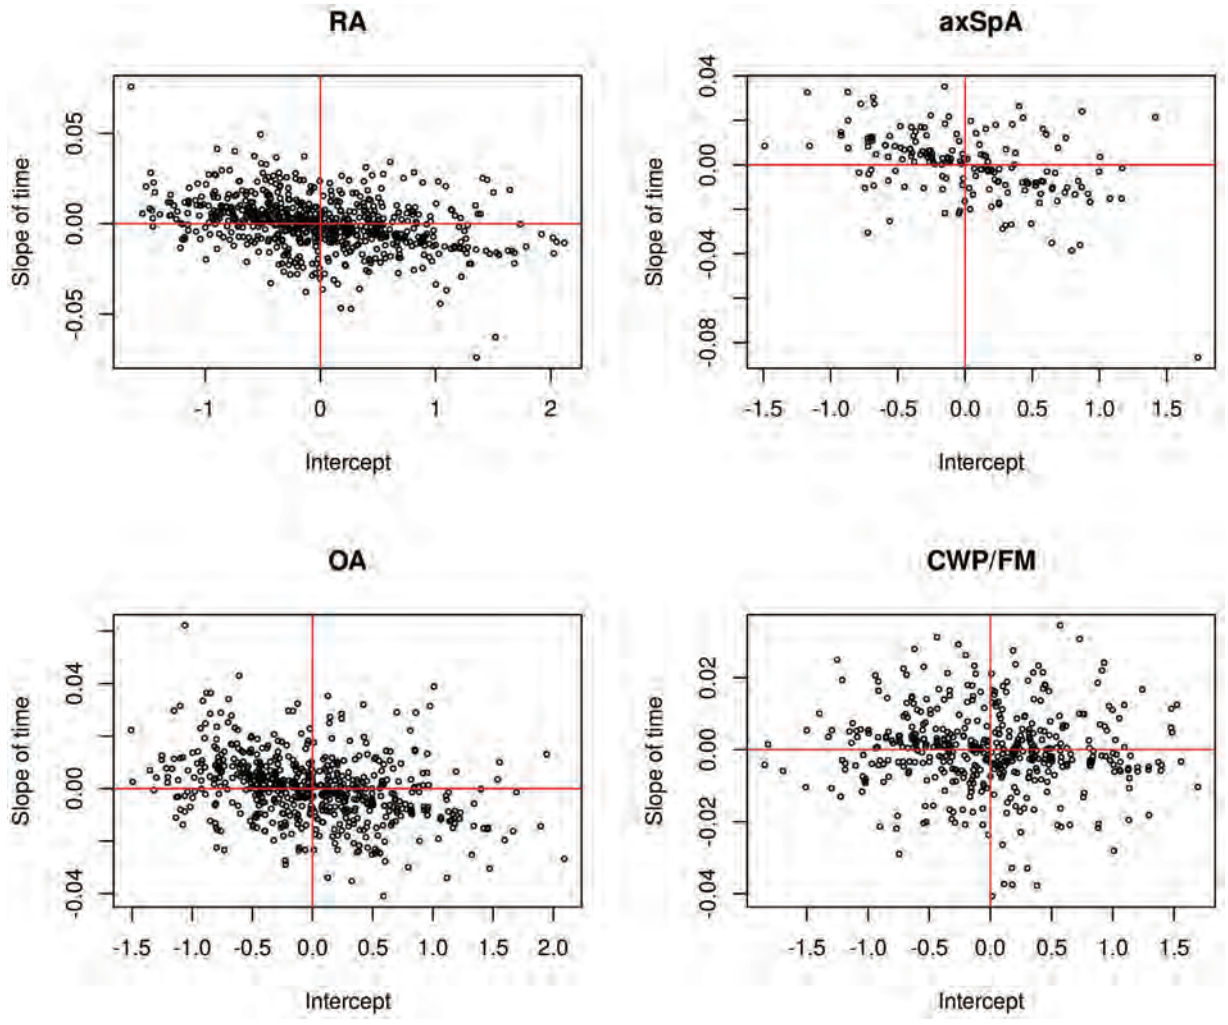

Figure 1. Slope-intercept plots for the multilevel model stratified by rheumatic and musculoskeletal diseases

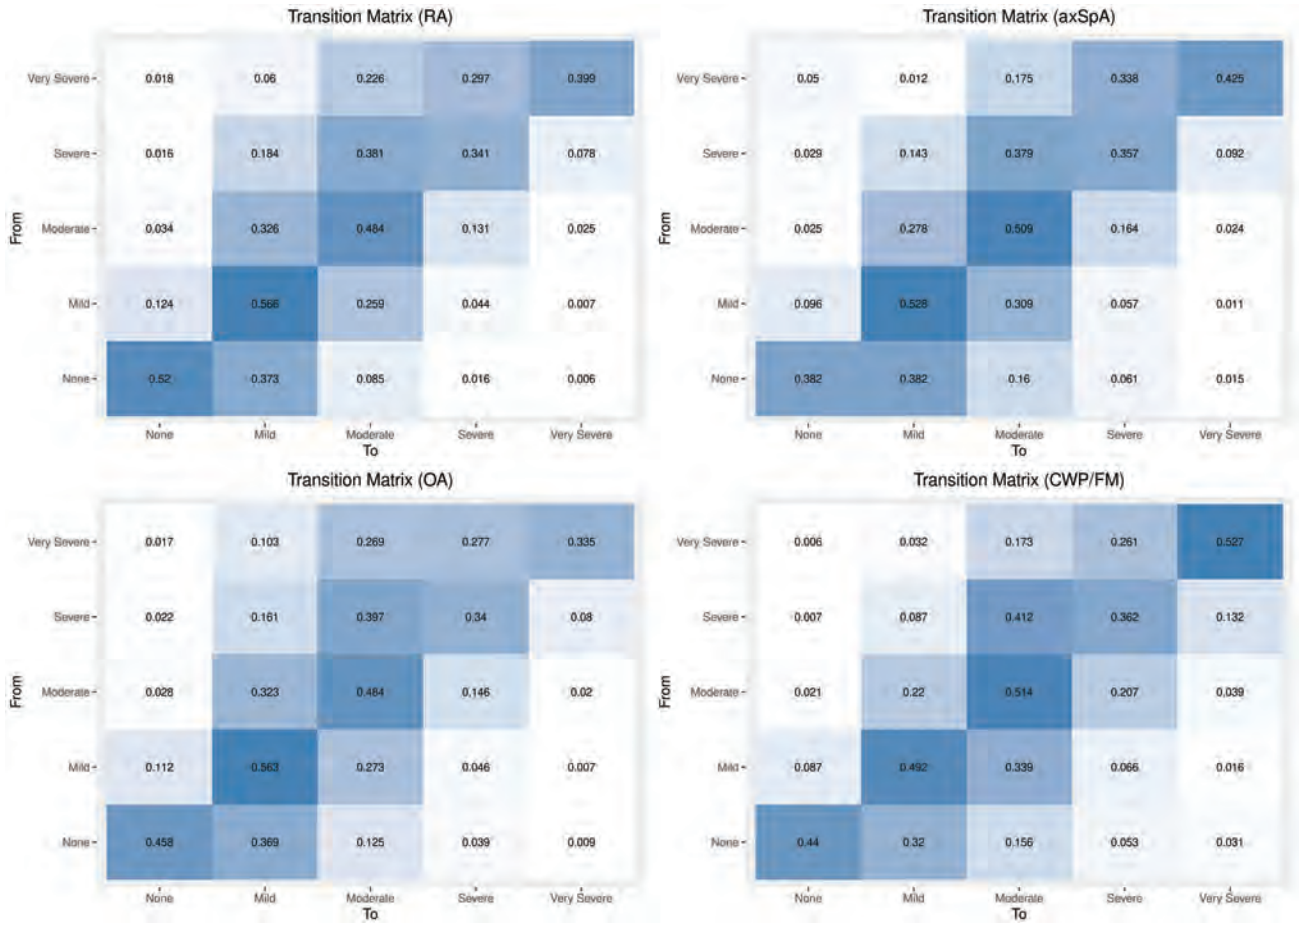

Figure 2. Heat map plots for the Markov transition model stratified by rheumatic and musculoskeletal diseases

level (71.1% reported moderate-very severe pain), followed by participants with axSpA, OA, and RA (57.8%, 52.0%, and 47.9% reported moderate-very severe pain respectively). The long-term change in pain was significantly different between participants, with steeper time-based improvements in pain for participants with higher initial pain scores across all diseases. The day-to-day pain state transitions were unchanged in 50% of days across diseases, although the event of any increase in pain state was noted in 25% of days (e.g., ≥2-point increase was noted in 4% of days). 53% of those with CWP/FM remained in the 'very severe' pain state with minimal variation.

Conclusion: Participants with CWP/FM had the highest overall pain level followed by participants with axSpA, OA, and RA. These daily pain scores allow the assessment of gradual day-to-day changes through time. Patterns of improvement in those with higher initial pain scores were seen across diseases, perhaps representing regression to the mean. The volatility of changing pain states was comparable across diseases, suggesting no difference in flares. Our future work in identifying patterns of day-to-day pain will focus on analyzing the magnitude of day-to-day change in pain and the constructs of pain volatility.

Exercise Among Older Adults Living with Rheumatic Disease: Physical Activity Habits and Patient Reported Outcomes

Alexis Ogdie[1], Sofia Pedro[2], Joshua Baker[3], Kaleb Michaud[4] and Patricia Katz[5], [1]University of Pennsylvania, Philadelphia, PA, [2]FORWARD-The National Data Bank for Rheumatic Diseases, Wichita, [3]Perelman School of Medicine at the University of Pennsylvania, Philadelphia, PA, [4]FORWARD-The National Data Bank for Rheumatic Diseases; University of Nebraska Medical Center, Wichita, [5]University of California, San Francisco, Novato, CA

SESSION INFORMATION

Session Date: Saturday, November 7, 2020

Session Title: Epidemiology & Public Health Poster II: OA, Osteoporosis, & Other Rheumatic Disease

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: Among patients with rheumatic disease, physical activity is important for maintaining health and improving outcomes. EULAR recommendations suggest at least 30 min of vigorous exercise three times weekly. This may be particularly important for older adults in whom it is important to maintain strength and physical function. The objective of this study was to describe patient-reported level of physical activity across different diagnoses as well as the association between activity level and patient reported outcomes (PROs) among adults age 65 and older with rheumatic disease.

Methods: We performed a cross-sectional analysis among adults age 65 and older using data from Forward, The National Databank for Rheumatic Diseases, a patient registry based in the U.S. As a part of the registry, participants (pts) complete a survey every 6 months. Three questions about physical activity were added to the survey in 2019: level of physical activity, number of days per week during the month the participant exercised for 30 min or more, and perceived activity level compared to others their age. Pts also complete several other PROs including the PROMIS29 assessment, medication use, side effects, and interactions with the health care system. Proportion of pts with each disease reporting levels of disease activity and mean PRO scores by level of disease activity were descriptively reported.

Results: Among 5,335 pts completing the first questionnaire, 3,343 were age 65 or older and among these, 2,278 pts had rheumatoid arthritis (RA), 681 osteoarthritis (OA), 111 spondyloarthritis (SpA, including both axial SpA and psoriatic arthritis), 161 systemic lupus erythematosus (SLE) and 137 fibromyalgia syndrome (FMS, diagnosed by physician) (diagnoses were not mutually exclusive). The mean age overall was 74.4 (SD 6.6). Most pts were female

	RA	OA	SpA	SLE	FMS
Age (mean, SD)	74.4 (6.6)	75.4 (6.9)	72.6 (6.1)	72.8 (5.4)	72.2 (5.9)

Comorbidity index (mean, SD)	2.3 (1.7)	2.6 (1.8)	2.6 (1.9)	2.8 (1.9)	2.6 (1.6)
Obese	32%	40%	39%	32%	45%
College education	43%	51%	54%	44%	48%
Depression	12%	14%	14%	16%	26%

Abbreviations: RA = rheumatoid arthritis, OA = osteoarthritis, SpA = spondyloarthritis, SLE = systemic lupus erythematosus, FMS = fibromyalgia syndrome, SD = standard deviation

Table 1. Patient Demographics

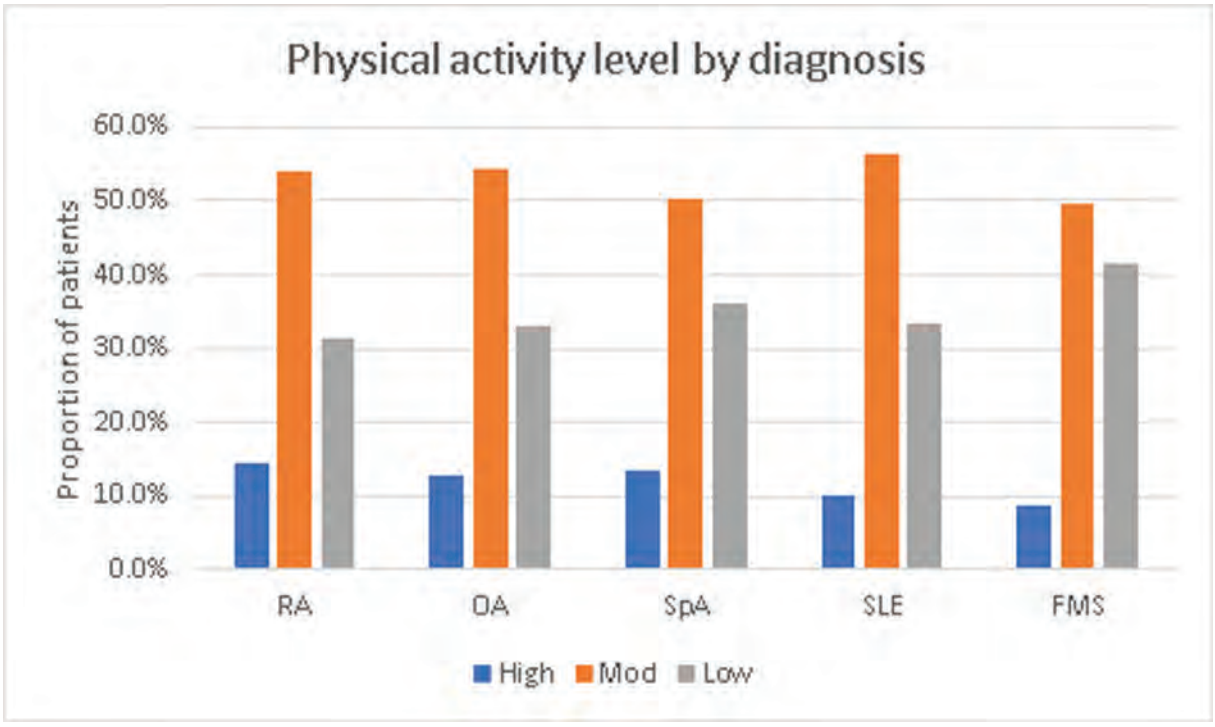

Figure 1. Physical activity level by diagnosis. Physical activity level was categorized as high (vigorously active for at least 30 min, 3 times per week), moderate (moderately active for at least three times per week) or low (seldom active).

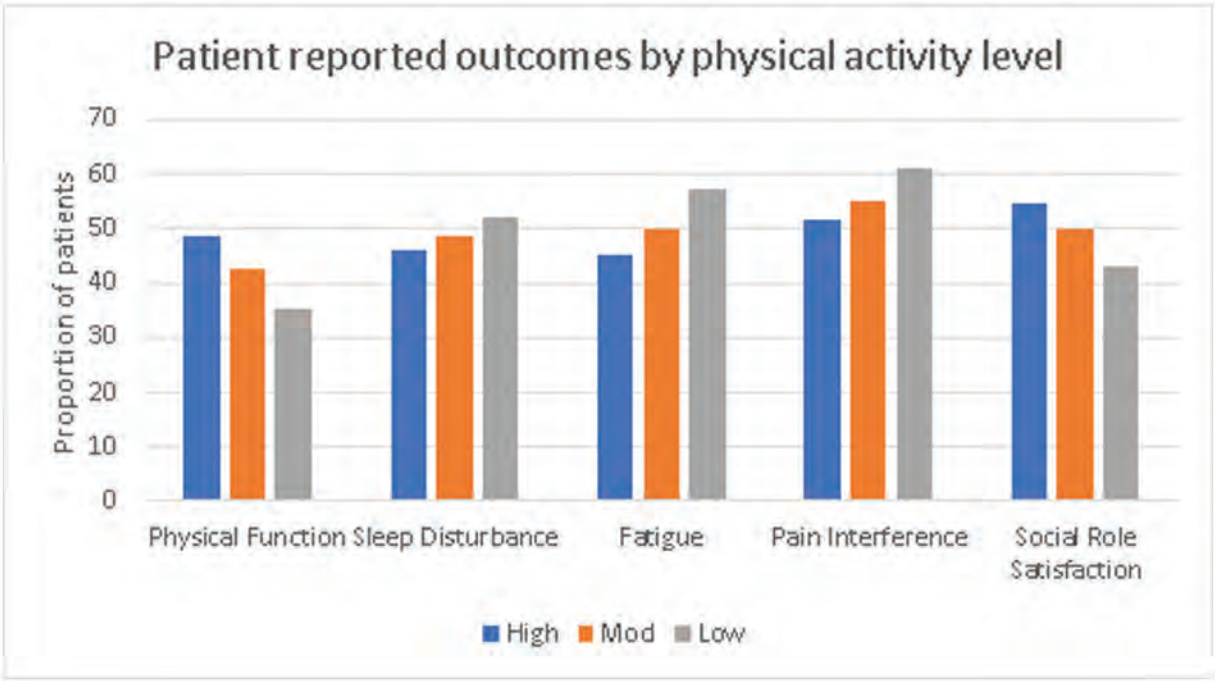

Figure 2. Patient reported outcomes by level of physical activity. Physical activity level was categorized as high (vigorously active for at least 30 min, 3 times per week), moderate (moderately active for at least three times per week) or low (seldom active). PROMIS scores increase for a patient having 'more' of the construct (i.e., higher physical function scores are good, higher pain scores are bad).

(83%). Overall, 468 (14%) pts reported vigorous physical activity for at least 30 minutes 3 or more days were week, 1,799 (54%) reported moderate activity 3 or more days per week, and 1,076 (32%) reported seldom being active. This was similar across diseases. (**Figure 1**) Overall, participants reported a median of 7 days of physical activity

per month (IQR 0-15). Obese participants were significantly more likely to report low levels of activity (44% of obese compared to 25% of non-obese individuals). Similarly, among patients with depression, 48% reported a low level of activity compared to 30% of those without depression. Finally, diminishing levels of physical activity were associated with poorer sleep, fatigue, physical function, pain, and pt global assessment of disease (**Figure 2**).

Conclusion: Levels of physical activity were relatively low among older pts with RA, OA, SpA, SLE and fibromyalgia. Because people tend to over-report their amount of exercise, the actual proportion exercising is likely even lower. Participants with the lowest level of physical activity were more likely to have depression, poor sleep, and fatigue and more likely to be obese. As these factors can improve with activity, these patients may be ideal targets for physical activity engagement strategies.

Abstract Number: 0544

Risk Factors for Lumbar Vertebral Osteoporosis Do Not Reflect Factors Traditionally Associated with Osteoporosis at the Hip

Marwan Bukhari[1] and **Mrinalini Dey**[2], [1]Rheumatology Department, University Hospitals of Morecambe Bay NHS Trust, Lancaster, United Kingdom, [2]Institute of Life Course and Medical Sciences, University of Liverpool, Liverpool, United Kingdom

SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: Epidemiology & Public Health Poster II: OA, Osteoporosis, & Other Rheumatic Disease
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: The most common site of osteoporotic fragility fractures is the thoracic spine. However, bone mineral density (BMD) measurements at the hip are used to predict fracture risk using tools like FRX™, while spinal measurements only assess response to treatment. Dual energy X-ray absorptiometry (DEXA) measures BMD at lumbar vertebrae L1-3 and L1-4, user-dependant. It is not known if predictors of hip osteoporosis and fracture mimic those for vertebral osteoporosis.

Aim:

1. Evaluate factors associated with osteoporosis in the lumbar spine in female patients presenting for BMD estimation.

Methods: Female patients presenting for BMD estimation at a district general hospital in North West England, 2004-2016, were studied. In addition to BMD in L1-4, demographics, fracture history, and risk factors were recorded. Logistic regression models at each lumbar vertebral level were used to identify predictors of osteoporosis (T-score≤-2.5).

Results: 26119 unique patients underwent BMD estimation during our study period, mean age of 65.0 years (SD 12.4). Other characteristics are shown in Table 1. Fragility fractures were significantly associated with increased osteoporosis risk at all lumbar levels. Current aromatase inhibitor-use and hormone replacement therapy (HRT) were associated with significantly decreased likelihood of osteoporosis at all lumbar levels. All other demographics, co-morbidities, and medications investigated were associated with osteoporosis at varying lumbar levels.

Table 1. Odds ratios for risk of osteoporosis, associated with co-morbidities and medication-use, in the lumbar vertebral spine

Conclusion: Our results show a clear difference in co-morbidities and medication-use associated with osteoporosis at different lumbar levels. Traditional risk factors for osteoporosis are not associated with decreased BMD in the lumbar spine. Patients with vertebral osteoporosis were more likely to sustain fragility fractures as expected. HRT is bone-protective and was therefore associated with decreased likelihood of osteoporosis. Current aromatase inhibitor use was associated with decreased likelihood of osteoporosis at all lumbar levels, while current corticosteroid use was associated with decreased likelihood of osteoporosis in the lower lumbar region. Both medications are known to reduce BMD- these results are confounded by concurrent use of calcium, vitamin D, and bisphosphonate treatment.

SLE was associated with reduced likelihood of osteoporosis at the superior and inferior lumbar spine, also likely confounded by treatment. Current hyperthyroidism was associated with significantly increased risk of osteoporosis averaged throughout the lumbar spine, consistent with previous studies. Current alcohol intake was associated with decreased risk of osteoporosis at L3, consistent with previous work demonstrating a protective effect of low-moderate alcohol intake on bone health.

In conclusion, we demonstrate risk factors for low BMD are not equal throughout the lumbar spine, and differ from traditional osteoporotic risk factors, including those commonly used in predictive scores for fracture. Our results suggest a need to consider risk factors specific to lumbar spine osteoporosis when planning prevention and management of vertebral fragility fractures.

The Use of Tocilizumab and Tofacitinib in Patients with Resolved Hepatitis B Infection: A Case Series

Naomi Serling-Boyd[1], Amir Mohareb[2], Arthur Kim[2], Emily Hyle[2] and Zachary Wallace[3], [1]Massachusetts General Hospital, Boston, MA, [2]Massachusetts General Hospital, Boston, [3]Massachusetts General Hospital, Newton, MA

SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: Epidemiology & Public Health Poster II: OA, Osteoporosis, & Other Rheumatic Disease
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: The use of immunosuppressive medications in patients with a history of hepatitis B virus (HBV) infection is associated with an increased risk of HBV reactivation which can lead to liver failure and death. Rates of HBV reactivation have been reported in up to 24% of people with resolved HBV (positive core antibody [HBcAb], negative surface antigen [HBsAg], and positive or negative surface antibody [HBsAb]) and 34% of people with chronic HBV (positive HBsAg) in patients who are treated with tumor necrosis factor inhibitors, rituximab, and other biologics. Outside of Asia, there are limited data regarding the risk of reactivation in patients taking tocilizumab or tofacitinib, both of which have emerged as potential treatments for the systemic inflammatory manifestations of coronavirus disease 2019.

Methods: In this retrospective study, we identified patients in the Mass General Brigham (MGB) healthcare system who had ≥ 1 prescription for either tocilizumab or tofacitinib and resolved or chronic HBV between 1995 and 2018. Details regarding demographics, medical history, and laboratory results were extracted from the electronic health record. HBV reactivation was defined as a greater than 10-fold increase in HBV deoxyribonucleic acid (DNA) levels from baseline, an absolute increase > 10^5 copies/mL, or a positive HBsAg when previously negative.

Results: Twenty patients, all with resolved HBV, were included (**Table 1**). Four patients received tofacitinib and tocilizumab sequentially such that there were 24 medication exposures. The median age at treatment initiation was 59 years (tofacitinib) and 66 years (tocilizumab) and the majority were female. The majority of patients treated with tocilizumab (16, 100%) and tofacitinib (7, 88%) were HBsAb positive at baseline. Concurrent immunosuppression was used in 12 (75%) tocilizumab-treated patients and 6 (75%) tofacitinib-treated patients. Anti-viral treatment was prescribed in 25% of cases in both groups. Median follow-up time after treatment initiation was 4.0 years in the tocilizumab group and 3.1 years in the tofacitinib group. During follow-up, all patients had aminotransferases measured at least once, and no patients had transaminitis attributed to HBV reactivation. Among the patients who had ≥ 1 HBV polymerase chain reaction or HBsAg assessed after treatment initiation (13 [81%] in the tocilizumab group and 4 [50%] in the tofacitinib group), none were positive.

Conclusion: We found no instances of HBV reactivation in patients with resolved HBV exposed to tocilizumab or tofacitinib. A quarter of people in our study were prescribed antivirals and many had no follow up serologic studies to evaluate for reactivation, reflecting the uncertainty regarding best practices for patients with resolved HBV. Our findings suggest that tocilizumab or tofacitinib may be safely used in patients with resolved HBV infection.Table 1. Demographics, clinical characteristics, and follow up of study population

Stepping up for Inflammatory Arthritis (SUFIA): A Pilot Trial to Test Behavioral Economics Strategy to Increase Physical Activity in Inflammatory Arthritis

Alexis Ogdie[1], Kathleen Bush[1], Michael George[1], Mitesh Patel[1], William Nowell[2], Kelly Gavigan[3], Jeffrey Curtis[4] and Joshua Baker[5], [1]University of Pennsylvania, Philadelphia, PA, [2]Global Healthy Living Foundation, New York City, NY, [3]Global Healthy Living Foundation, Upper Nyack, NY, [4]Division of Clinical Immunology and Rheumatology, University of Alabama at Birmingham, Birmingham, AL, [5]Perelman School of Medicine at the University of Pennsylvania, Philadelphia, PA

SESSION INFORMATION

Session Date: Saturday, November 7, 2020

Session Title: Epidemiology & Public Health Poster II: OA, Osteoporosis, & Other Rheumatic Disease

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: Regular physical activity may have benefits for patients with rheumatoid arthritis (RA) and psoriatic arthritis (PsA), but patients with active disease are often reluctant to increase activity. Principles from behavioral economics (BE), a field combining psychology and economics, have been applied to motivate increased physical activity in non-arthritis patients. The objective of this study was to assess the feasibility and efficacy of a loss aversion financial incentive for increasing step counts and improving disease symptoms in RA and PsA patients with active disease.

Methods: A double-blind randomized controlled pilot trial was performed among patients with RA and PsA. Participants were required to have active disease defined by having at least one swollen joint and a Routine Assessment of Patient Index Data-3 (RAPID3) score >3 (range 0-30 with < 3 indicating remission). The primary goal of this study was to establish feasibility of the platform and study conduct. The primary outcome was change in RAPID3 between the two arms. The trial included two visits (Figure 1) and weekly check-ins via virtual trial platforms, Way to Health and the ArthritisPower app. Patients were given a Fitbit Alta at baseline and completed a two-week run-in period to assess average step count. Patients were then prompted to select a step count goal (30, 40, or 50% above baseline daily step count) and complete a commitment contract. After selection of a goal, participants randomized to the

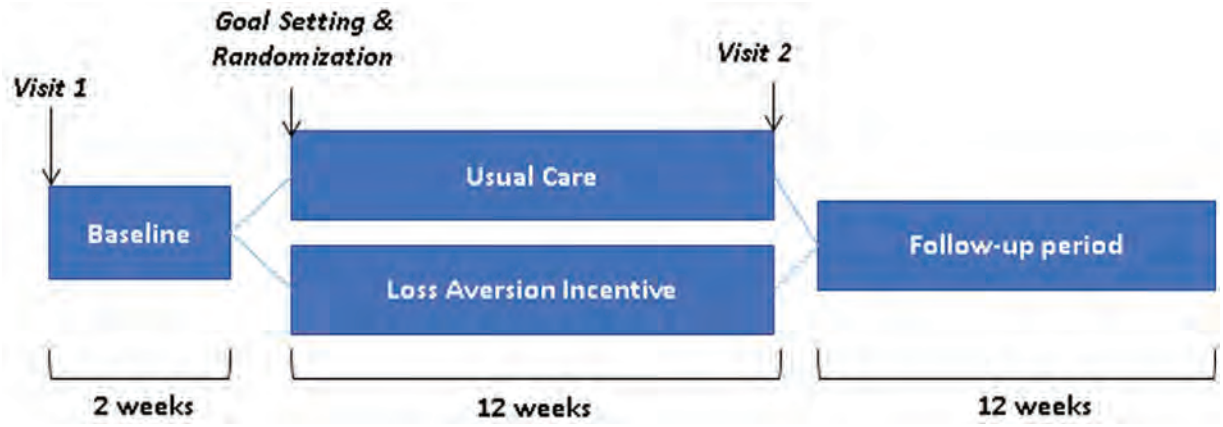

Figure 1. Study diagram. There were two study visits (weeks 0 and 14). The first two weeks served as a baseline period to establish a baseline step count. Patients then selected a step count goal which was either 30%, 40%, or 50% above the baseline step count and signed a commitment contract. Patients were then randomized to a financial incentive or no incentive. The primary outcome (change in RAPID3) occurred at week 14.

Table 1. Baseline Characteristics of Patients Enrolled in Pilot SUFIA Study

N	27
Age	50 (13)

Ankle	56%
Midfoot	37%
Toes	19%
	37%
RAPID3	10.4 (4.6)
PROMIS Fatigue	53.4 (7.8)
PROMIS Sleep Disturbance	49.7 (3.3)

All patients are on therapy for IA. *We used the 66/68 joint count for assessment of all patients to capture lower extremity involvement. **Lower extremity involvement could be swelling or tenderness.

Table 1. Baseline Characteristics of Patients Enrolled in Pilot SUFIA Study

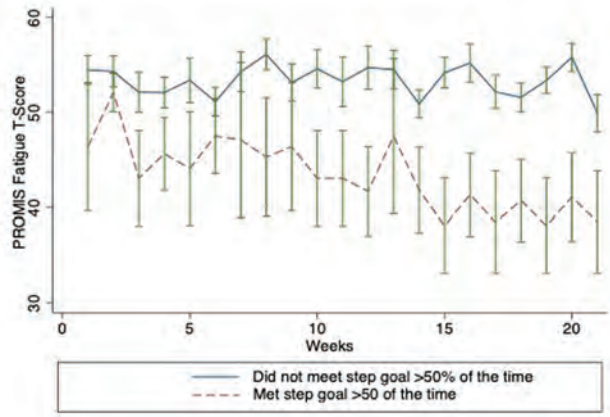

Figure 2. Change in fatigue severity among those with greater adherence to step count goals. The PROMIS fatigue score increases with worse fatigue and decreases with improving fatigue.

intervention arm received a financial loss aversion incentive (each month, patients started with $75 in their account and lost $2.50 for each day they did not reach their goal). All patients received weekly text message prompts providing feedback about their performance over the past week and completed weekly PROs. After 12 weeks of the intervention (at week 14), the incentive was removed and patients were followed to 26 weeks to determine how long the effect persisted.

Results: In the pilot trial, 71 patients were verbally consented for screening, 34 underwent screening (of these, two were ineligible), 27 were randomized, and 22 patients completed the 14-week study visit. The mean step count at baseline was 5,962. By 28 days, 65% of patients increased their step count. Participants receiving the incentive had an average of 714 more steps per day over the first 14 weeks and a greater probability of reaching 10,000 steps per day during follow-up (30% v. 21%, p=0.41). Among patients who achieved their step count goals more than 50% of days, we observed more improvement in sleep quality, fatigue, and overall well-being ($p< 0.05$) (Figure 2). After adjusting for baseline RAPID3, the 14-week RAPID3 scores were lower in the group that achieved their step goals 50% of the time [B: -3.91 (-11.8, 3.99); a difference that approximates the minimal clinically important difference (MCID) for the RAPID3 (3.6).

Conclusion: While financial incentives have worked well in patients without arthritis, the estimated effect of the financial incentive in this small study was more modest in patients with RA and PsA. Those that were able to increase their physical activity and meet their step goals had greater improvements in symptoms over the course of the study.

Abstract Number: 0547

Transgender Patients in the Rheumatology Setting

Chantelle Carneiro[1], Jessica Chee[2], Karen Beattie[2] and Kimberly Legault[2], [1]McMaster University, Toronto, ON, Canada, [2]McMaster University, Hamilton, ON, Canada

SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: Epidemiology & Public Health Poster II: OA, Osteoporosis, & Other Rheumatic Disease
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Minimal medical research exists regarding transgender patients, particularly within the field of rheumatology. A few case reports note that male to female transitions may precede presentation of autoimmune disease, with a possible link to exogenous estrogen, while exogenous testosterone was noted to improve a case of subacute cutaneous lupus. There is currently no research assessing transgender demographics and disease presentation in the rheumatologic setting.

Methods: We conducted a retrospective chart review of transgender patients who presented to our academic and community clinics or inpatient rheumatology service. We collected information on patients' medical history and rheumatologic diagnoses, transition (legal, social and medical), presenting symptoms and treatment.

Results: From 25 rheumatologists contacted, 12 transgender patients were identified. Patients' ages ranged from 22-66 years old and had the following diagnoses: PsA, seronegative SpA, PM with SSc overlap, SSc, PMR, FM, leucocytoclastic vasculitis, periodic fever syndrome and osteopenia. Five (42%) patients had uncontrolled disease or relapse of their disease requiring adjustment of their treatment regimens. The most common co-morbidity was depression and anxiety (n=7, 58% patients). A family history of autoimmune disease was documented in 5 (42%) patients. Nine (75%) of patients were transgender males, 8 of whom were using intramuscular testosterone and 2 of whom had hysterectomies with bilateral salpingoopherectomies. Only 3/9 transgender male patients had a docu-

mented start time of testosterone therapy. However, 7 patients had either been on testosterone at diagnosis or were on it for at least 1 year before being diagnosed with their rheumatologic conditions. Of 3 transgender females, 2 were exposed to estrogen therapy prior to presentation. One patient had only a one-time use of exogenous estrogen and significant silica exposure for >20 years that was her major risk factor for developing systemic sclerosis.

Conclusion: The majority of patients presenting in our rheumatology clinics and inpatient service were transgender males undergoing transition. These data correlate with prior research that most rheumatologic diseases have a higher prevalence for biologic females. However, of the diseases with female prevalence in our study (PM, PMR, SSc, osteopenia and FM), almost half the patients diagnosed were biologically male (3/7). We believe larger studies need to be done to assess whether hormone transitions, either via gonadectomy and/or with exogenous hormones, can affect the prevalence of these diseases in transgender patients. In addition, we recommend rheumatologists carefully document when medical transitions occur relative to their rheumatologic condition in order to track timing of new diagnoses or changes in their disease. Additionally, given the high prevalence of depression seen in our study, we recommend that physicians pay particular attention to the mental health of their transgender patients at each follow-up and direct them to supports as needed.

SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: Epidemiology & Public Health Poster II: OA, Osteoporosis, & Other Rheumatic Disease
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: To determine the incidence and risk factors implicated in the development of first cardiovascular (CV) event (CVE) in patients with chronic inflammatory rheumatic diseases (CIRD) attending Spanish rheumatology clinics after 5 years of follow-up.

Methods: Analysis of data of patients included in an observational prospective study [CARdiovascular in rheuMAtology (CARMA) project] after 5 years of follow-up. The study includes a cohort of patients with CIRD [rheumatoid arthritis (RA, n=775, ankylosing spondylitis (AS, n=738), and psoriatic arthritis (PsA, n=721)], and another cohort of matched individuals (n=677) without CIRD attending outpatient rheumatology clinics from 67 public hospitals in Spain. Cumulative incidence per 1000 patients of CVE was estimated in both cohorts at 5 years from the start of the project. Weibull proportional hazard model was used to calculate the Hazard Ratio (HR) and 95% confidence intervals (95% CI) of the risk factors involved in the development of CV events. Losses to follow-up and their causes were also analyzed.

Results: The total number patient who completed the follow-up visit at 5 years was 2.382 (81.9% of those who started the study). Fifteen patients died due to CVE and sixty due to non-CVE. Cardiovascular cumulative incidence of CVE in patients with CIRD was higher in PsA patients (48.9; 95% CI: 40.7-57.1). The higher risk of developing a first CVE during the 5 years of follow-up was seen in patients with AS (HR: 4.60 ; 95% CI: 1.32-15.99; p=0.02), those with older age (HR:1.09; 95% CI: 1.05-1.13; p< 0.001), higher systolic blood pressure (HR: 2.64; 95% CI: 1.32-5.25; p=0.006), and those with longer duration of the rheumatic disease (HR: 1.07; 95% CI: 1.03-1.12; p=0.002). In contrast, woman gender was a protective factor (HR: 0.45; 95% CI: 0.21-0.99; p=0.047).

Conclusion: Patients with AS prospectively followed-up at rheumatology outpatient clinics showed higher risk of developing a CVE than those with RA or PsA. Besides traditional CV disease risk factors, a longer time course of the disease is a risk factor for the development of CV disease in patients with CIRD.

Abstract Number: 0549

Developing an Algorithm for Identifying Mortality in MarketScan Claims Data Using Machine Learning

Fenglong Xie[1], Hong Zhao[1], Huifeng Yun[2], Sasha Bernatsky[3] and **Jeffrey R Curtis**[2], [1]University of Alabama at Birmingham, Birmingham, AL, [2]Division of Clinical Immunology and Rheumatology, University of Alabama at Birmingham, Birmingham, AL, [3]The Research Institute of the McGill University Health Centre, Montreal, ON, Canada

SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: Epidemiology & Public Health Poster II: OA, Osteoporosis, & Other Rheumatic Disease
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: In 2016, MarketScan data no longer included information about inpatient mortality, compromising the ability to study fatal hospitalization events. Using data through 2015 when mortality remained available, we developed an algorithm to accurately identify in-hospital mortality using coverage patterns, proximate healthcare claims diagnoses, and corresponding information for family members.

Methods: We selected the latest hospital claim in 2011-2015 MarketScan data for each individual. Hospitalizations with discharge status of (20, 40, 41) were defined as death, and (21, 87, missing) as alive. Predictors included age, sex, coverage disenrollment post hospitalization, diagnosis codes and timing of last submitted claim, and corresponding information from family members linked by family ID (to confirm family members remained enrolled). Individual predictors were optimized using the c (concordance) index. Datasets were split into Training (80% random sample of hospitalizations, 2011-2013); Test1 (80% in 2014-2015) and Test2 (remaining 20%, 2011-2015). Machine learning (ML) methods included decision tree (DT), random forest (RF), elastic-net regularization (ER) and XGBoost methods. Hyper-parameters were tuned using a random search method with 10-fold cross validation across a preset range. was used to assess model performance. Each model was validated in Test1 and Test2 datasets separately. Sensitivity, specificity, positive predicted value (PPV) and accuracy were calculated in all datasets.

Results: 1,307,532 hospitalizations were selected among patients; mean age was 47.4 (standard deviation 25.9) years and 43.6% were male. Training data included 727,887 hospitalizations, 23.1% ending in death. Disenrollment

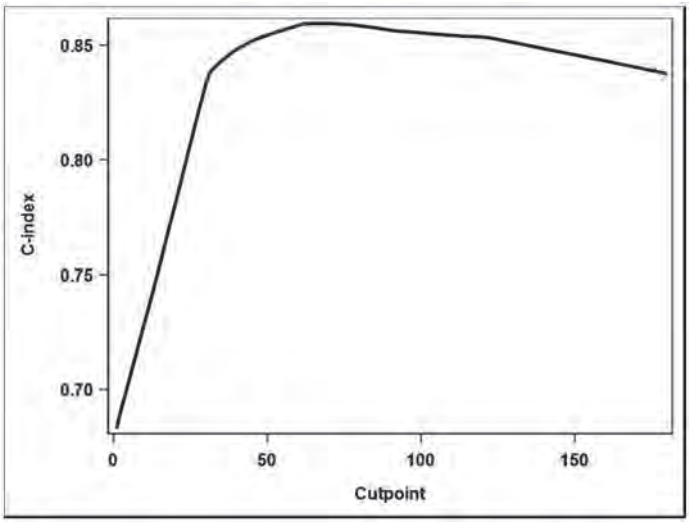

Figure 1. Optimization of cut-point for disenrollment

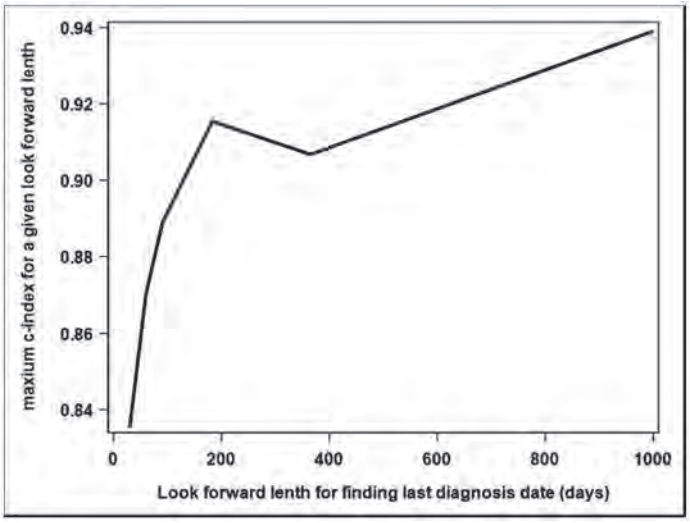

Figure 2. Optimization of interval from hospital discharge date to last claim

Dataset	Train				Test1				Test2			
ML Method	SN	SP	PPV	ACC	SN	SP	PPV	ACC	SN	SP	PPV	ACC
Decision Tree	0.83	0.95	0.82	0.92	0.88	0.96	0.87	0.94	0.84	0.95	0.84	0.93
Random Forest	0.93	0.96	0.88	0.96	0.93	0.96	0.88	0.95	0.93	0.96	0.88	0.95
Elastic Net	0.86	0.97	0.89	0.94	0.89	0.97	0.91	0.95	0.87	0.97	0.89	0.94
XG Boost	0.94	0.96	0.87	0.95	0.94	0.96	0.88	0.95	0.94	0.96	0.87	0.95

ACC: Accuracy; DT: Decision tree; ER: elastic-net regularization; ML: Machine Learning;
PPV: Positive predicted value; RF: random forest; SN: sensitivity; SP: Specificity; XGB: XGBoost.

Table Model performance to classify in hospital mortality in Training and Test datasets

ending within 30 days (Figure 1), and last claim within 90 days were optimized as single predictors (Figure 2). Models using different ML methods performed well in all datasets, albeit with a trend for less optimal parameters with decision tree methods. In test datasets, PPV and accuracy was as high as 0.91 and 0.95 respectively.

Conclusion: We derived and validated an algorithm for identifying in-hospital mortality in Marketscan claims data which performed well with >90% accuracy. This represents filling of a key gap for health outcomes research with Marketscan data.

Mapping Multimorbidity Using Drug Concept Unique Identifiers (RxCUIs) via the Rx-Risk Comorbidity Index

Jared Vanderbleek[1], Justin Owensby[1], Alex Mccannaly[1], Lang Chen[1], Bryant England[2], **Jeffrey R Curtis**[3] and Huifeng Yun[3], [1]University of Alabama at Birmingham, Birmingham, AL, [2]University of Nebraska Medical Center, Omaha, NE, [3]Division of Clinical Immunology and Rheumatology, University of Alabama at Birmingham, Birmingham, AL

SESSION INFORMATION

Session Date: Saturday, November 7, 2020

Session Title: Epidemiology & Public Health Poster II: OA, Osteoporosis, & Other Rheumatic Disease

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: Identifying and accurately classifying comorbid conditions in large, real-world data sources is crucial for cohort establishment and confounder adjustment. However, the ability to conduct proper confounding control may be challenging when data for diagnosis codes and lab tests are incomplete, such as in a single-specialty EHR system where comorbidities are incompletely recorded by specialists. Thus, we updated a method to allow researchers to identify comorbid conditions using only medication information in circumstances where diagnosis codes are under-captured.

Using the RxNorm application program interface (API) and its web-based clients, RxMix and RxClass, we mapped Drug Concept Unique Identifiers (RxCUIs) to the Rx-Risk. In an established RA cohort in the ACR RISE registry, we compared Rxrisk with other comorbidity indices. These included the Charlson comorbidity index, Rheumatic Disease Comorbidity Index (RDCI) and Elixhauser.

Methods: For each of the 46 Rx-Risk categories, we identified corresponding RxNorm ingredients via RxClass and expanded them to all RxCUI term types (TTYs) using RxMix (RxNorm May 2020 release) based on FDA indications. Glucocorticoid products were confined to the comorbidity categories: Allergies, Chronic airway disease, and steroid-responsive disease by administration route. After finalizing the Rxrisk categories, we conducted descriptive analyses and compared the distribution of Rxrisk with more traditional diagnosis-based comorbidity scores among RA patients who were 18 years of age with $^{3}2$ consecutive visits with ICD-10 codes for RA using ACR RISE data, a rheumatologist-based RA registry. Medications and comorbidity diagnoses were assessed using all available data prior to the 2nd RA diagnosis code.

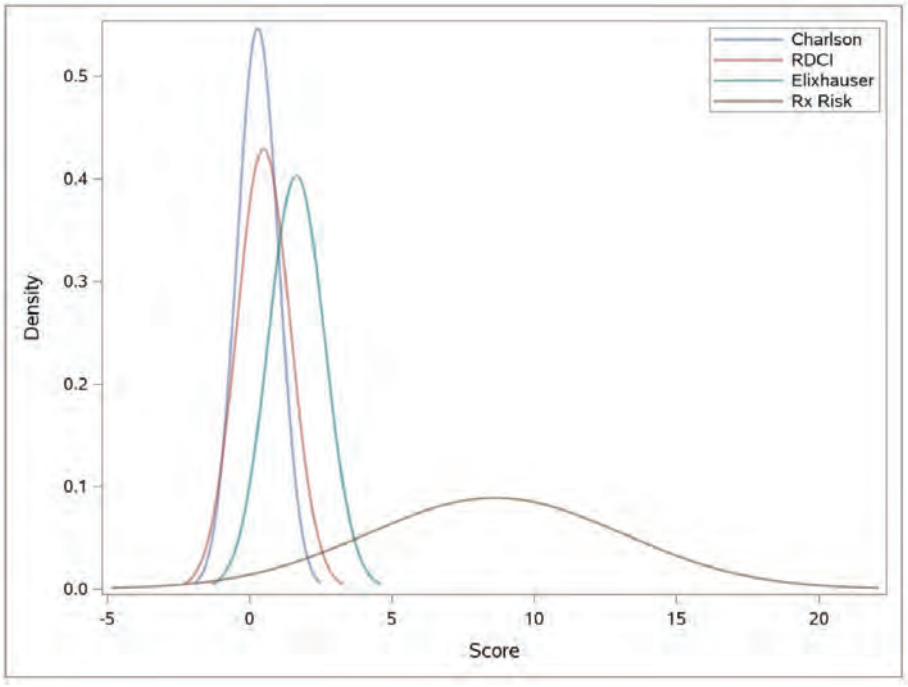

Figure Distribution of Rx Risk, Charlson, RDCI and Elixhauser among RA patients identified from ACR RISE registry.

Results: We identified 913 ingredient RxCUIs representing the 46 Rx-Risk comorbidity categories. 65,895 RxCUIs for all TTYs were returned from our initial query. After excluding Dosage Form related RxCUIs, a total of 56,217 RxCUIs were included in our analysis. The most common TTYs were Semantic Clinical Drug (19.8%), Demantic Brand Drug (13.0%), and Semantic Branded Drug Component (11.9%), while pain (17.7%), allergy (11.7%), and malignancy (6.2%) products were most frequent among the 46 comorbidity categories. The median score (25^{th}/75^{th} percentile) for Rxrisk was much greater: 8 (5,12) than for charlson index: 0 (0,0); Elixhauser: 1 (1,2); RDCI: 0 (0,1). For patients with Charlson score of 0 (85% of total), both the RDCI and Elixhauser were close to 1, but the Rxrisk score ranges from 0 to 20 (Figure).

Conclusion: The misclassification and under ascertainment of comorbidities in a single specialty EHR can largely be overcome by using a medication-focused comorbidity index that we have recently updated.

Physical Performance as a Mediator of the Association Between Depression and Pain in Knee Osteoarthritis

Alan Rathbun[1], Elizabeth Stuart[2], Michelle Shardell[1], Trang Nguyen[2], Alice Ryan[1], Joseph Gallo[2], Michelle Yau[3], Megan Schuler[4] and Marc Hochberg[1], [1]University of Maryland School of Medicine, Baltimore, MD, [2]Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, [3]Hinda and Arthur Marcus Institute for Aging Research, Boston, MA, [4]RAND Corporation, Boston, MA

SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: Epidemiology & Public Health Poster II: OA, Osteoporosis, & Other Rheumatic Disease
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Depression is common in knee osteoarthritis (OA), and leads to reduced physical function, which may mediate the effect of depression on pain. However, research has used self-reported functional measures and assumed that depression is additively related to pain both directly (unmediated) and indirectly (mediated) by physical function. The aim was to assess the direct effect of depression on pain and indirect effect mediated, possibly synergistically, through physical function using an objective physical performance measure among individuals with radiographic knee OA.

Methods: Participants were from the Osteoarthritis Initiative (n=2,484) who had radiographic disease (Kellgren-Lawrence [K-L] grade ≥ 2) and complete data on variables measured at baseline (time *t)*. Depression was measured on a severity continuum using the Center for Epidemiologic Studies Depression (CES-D) Scale as a continuous score (range=0-60) from baseline to third annual follow-up visit (time *t*+3). Physical performance was assessed via 20-meter gait speed (meters per second [m/s]) from the first (time *t*+1) through fourth (time *t*+4) annual follow-up visit. Pain was measured with the Western Ontario and McMaster Universities Osteoarthritis Index (WOMAC) pain subscale (rescaled range=0-100) from the second (time *t*+2) to fifth (time *t*+5) annual follow-up visit. Time-invariant confounders were age, sex, race, marital status, education, smoking, alcohol consumption, employment status, health insurance, Charlson comorbidity index, and presence of frequent knee symptoms. Time-varying confounders measured concurrent to depression were knee injections, analgesic medication use, body mass index, K-L grade, gait speed,

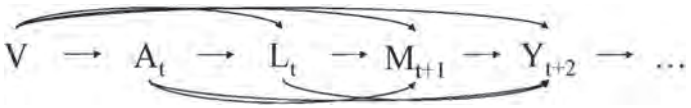

Figure 1. Directed acyclic graph illustrating the repeated measures study design with time-invariant confounders (V), and time-varying depression exposure (A), confounders (L), and physical performance mediator (M), as well as pain outcome (Y), where the subscript t corresponds to time point.

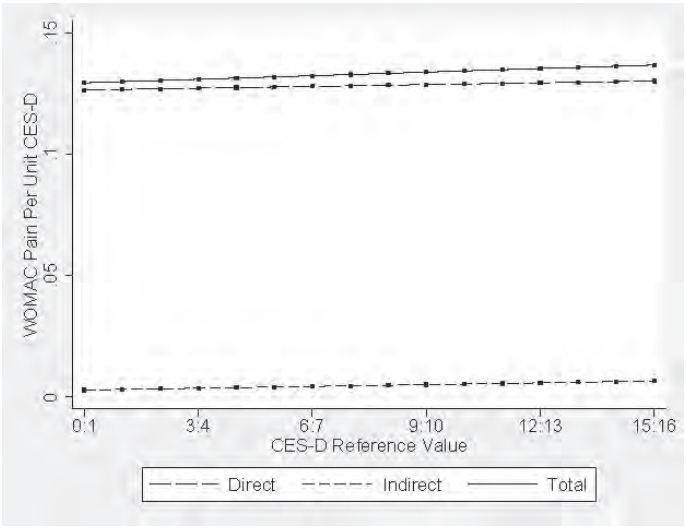

Figure 2. Incremental direct, indirect, and total effects.

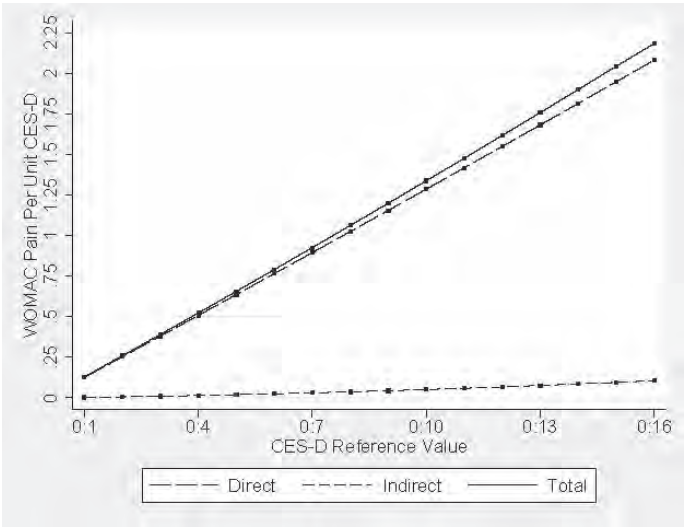

Figure 3. Cumulative direct, indirect, and total effects.

and WOMAC pain. A two-stage marginal structural model approach for effect decomposition in scenarios with exposure-mediator interaction estimated direct, indirect, and total effects between depression, physical performance, and pain (Figure 1).

Results: Incremental effects for one-unit differences in CES-D score indicated that associations (Figure 2) increased with higher depression severity. Direct effects of depression on pain were 0.126 (95% CI: 0.124, 0.128) and 0.130 (95%: 0.128, 0.132) WOMAC units for a CES-D score difference of 1 vs. 0 compared to 16 vs. 15, respectively. Indi-

rect effects of depression on pain mediated by physical performance were smaller in magnitude but showed larger proportional increases: CES-D score 1 vs. 0 = 0.003 (95% CI: 0.002, 0.004) WOMAC units; and CES-D score 16 vs. 15 = 0.066 (95% CI: 0.003, 0.009) WOMAC units. Cumulative effects (Figure 3) implied a 16-unit CES-D score difference (16 vs. 0) yielded a direct effect of 2.082 (95% CI: 2.052, 2.112) WOMAC units and indirect effect mediated by physical performance of 0.105 (95% CI: 0.054, 0.157) WOMAC units.

Conclusion: Effects of depression on pain increase with higher depressive symptom severity, but the proportion of the association mediated by physical performance is small. Findings suggest that exercise interventions for depression may reduce pain by acting directly on depressive symptoms or by increasing physical activity rather than function.

Fast Food Habits and Serum Urate Change in Young Adults: 15-Year Prospective Cohort Analysis

Chio Yokose[1], Na Lu[2], Natalie McCormick[1], John Choi[3], Yuqing Zhang[4] and Hyon Choi[5], [1]Massachusetts General Hospital, Boston, MA, [2]Arthritis Research Canada, Vancouver, BC, Canada, [3]Massachusetts General Hospital, Boston, [4]Massachusetts General Hospital, Quincy, MA, [5]Massachusetts General Hospital, Department of Medicine, Division of Rheumatology, Lexington, MA

SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: Epidemiology & Public Health Poster II: OA, Osteoporosis, & Other Rheumatic Disease
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Fast food consumption has strong positive associations with weight gain and insulin resistance. Obesity and insulin resistance are, in turn, strongly associated with elevated serum urate (SU) levels. This is largely mediated by the anti-uricosuric ability of insulin. The objective of this study was to investigate the relationship between fast food consumption and changes in SU over a 15-year period among young black and white adults in the United States.

Methods: Coronary Artery Risk Development in Young Adults (CARDIA) is a longitudinal study of cardiovascular disease risk factors and development among black and white adults in the United States who were 18-30 years of age in 1985-86 who underwent repeated dietary questionnaires and clinical and laboratory examinations. Our analysis included data from participants who had SU data available both at baseline and Year 15. Frequency of fast food consumption (fast food frequency, FFF) was quantified on a semicontinuous scale and classified as < 1, 1-2, or >2 times per week. Multivariable linear regression models were used to investigate the association of FFF at baseline as well as change in FFF with 15-year changes in SU. Difference in baseline FFF was defined as a difference in FFF

Table 1. Participant Characteristics

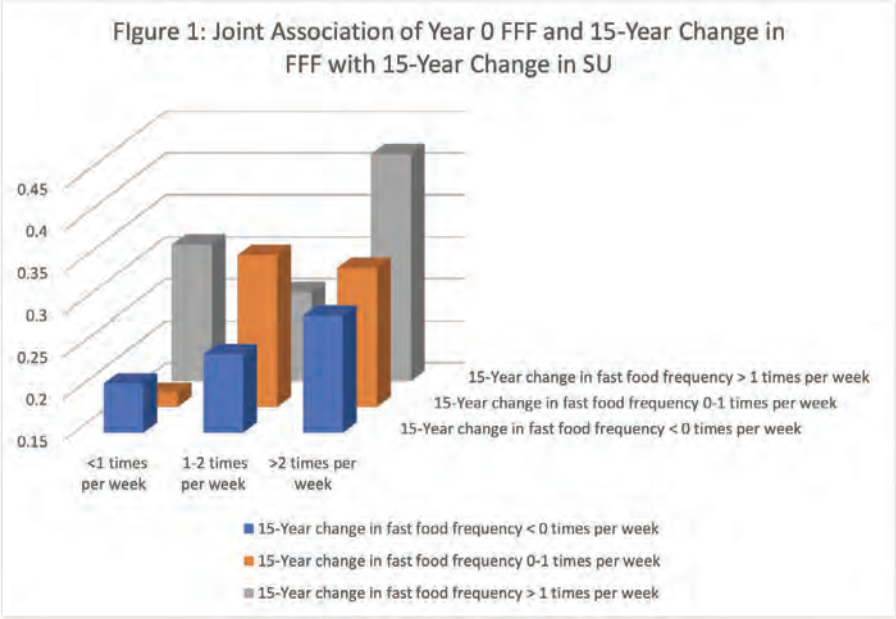
Characteristic	Blacks (n=1468)	Whites (n=1654)
Age, years (Year 0)	24.4 (3.8)	25.6 (3.3)
Male (%)	44	48
Weight, kg (Year 0)	72.8 (16.7)	70.0 (14.0)
Weight, kg (Year 15)	87.9 (20.9)	80.7 (18.6)
Serum urate, mg/dL (Year 0)	5.1 (1.4)	5.4 (1.4)
Serum urate, mg/dL (Year 15)	5.6 (1.4)	5.5 (1.4)

All values reported as mean (SD) unless otherwise noted.

Table 2. Mean Adjusted Change in Serum Urate by Baseline and Change in Fast Food Frequency

	Fast Food Variable	Blacks		Whites	
		Beta (SE)	p	Beta (SE)	p
Model 1	Baseline	0.11 (0.04)	0.01	0.11 (0.04)	0.01
	Change	0.003 (0.033)	0.93	0.09 (0.04)	0.01
Model 2	Baseline	0.12 (0.04)	0.01	0.09 (0.04)	0.02
	Change	0.004 (0.03)	0.88	0.08 (0.04)	0.03

Model 1: age, sex, education, baseline height and weight, baseline SU
Model 2: model 1 + alcohol, physical activity, and smoking (both baseline and year 15 change



consumption of 3 times a week (approximately the mean difference between individuals with low vs. high FFF) between participants. Change in FFF was defined as 3 times a week (approximately the mean range in change over time between individuals with low vs. high FFF) 15-year change within participants.

Results: Our analysis included data from 3,122 participants (**Table 1**). After adjustment for age, sex, education, baseline height and weight, and baseline SU, Year 15 SU increased by 0.11 mg/dL per 3 times a week difference in Year 0 FFF among both black and white participants (p=0.01 for both) (**Table 2**). SU increased by 0.09 mg/dL per 3 times a week increase in FFF from Year 0 to Year 15 among white participants (p=0.01) but not black participants (beta =0.003, p=0.93) (**Table 2**). There was a significant correlation between weight change and SU change (correlation coefficient 0.34, p< 0.001). **Figure 1** depicts the joint associations of Year 0 FFF and 15-year changes in FFF with change in weight. Compared to the average 15-year SU change among participants with baseline FFF < 1 time per week and 15-year FFF change < 0 time per week, those with high FFF at both baseline and follow-up had an extra

0.21 mg/dL increase (i.e., 75% of overall population SU increase over 15 years [0.28 mg/dL]) in SU during that time. After adjusting for covariates in model 2, change in weight (beta=0.03, p< 0.001) and homeostasis model for insulin resistance (HOMA) (beta=0.05, p< 0.001) remained significantly associated with SU change.

Conclusion: Fast food consumption has strong positive associations with SU, suggesting that fast food increases the risk of hyperuricemia and gout. The observed association is likely mediated by weight gain and resultant changes in insulin resistance.

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: An association between ulcerative colitis (UC) and peripheral arthritis has been known since the 1930's and more recently has been described as a part of the spectrum of peripheral Spondyloarthritis (p-SpA).

Table 1. UC Questionnaire Peripheral Joint Arthralgia Distributions in US Adults: NHANES II.

	All UC (n=131)		No UC (n=10,273)		
Peripheral Arthralgias:	n	% (95%CI)	n	% (95%CI)	*p-value*
Arthralgias Any Joint	55	34.4 (23.8-45.0)	2163	20.7 (19.1-22.3)	0.01

*Insufficient sample size for reliable statistical estimation

Prevalence rates of p-SpA in UC have been reported with varying estimates from clinical and cohort studies. To our knowledge there are no US population-based studies to estimate the prevalence of UC-associated peripheral arthritis or arthralgia. We describe herein population-based rates of peripheral arthritis and arthralgia among those with and without UC using previously unreported data from NHANES II (1976-80), a nationally-representative survey of the US population.

Methods: NHANES II participants ages 20-69 were interviewed and examined by physicians at mobile examination centers and defined as having UC if they reported having been diagnosed with UC by a physician. Previous analysis of NHANES II and NHANES 2009-10 data showed these self-reports to be consistent with true UC given corresponding high rates of colonoscopy, surgery, UC-related comorbidities, and UC-related symptoms.

Interview data was collected for a present or past history of peripheral arthralgias for ≥6 weeks (Table 1) and of arthritis signs and symptoms (arthralgias plus joint swelling and tenderness for ≥1 month) (Table 2). A physician joint exam was also performed (Table 3). Statistical analysis used SASTM 9.4 using survey design variables and sample weights to produce nationally representative estimates.

Results: 10,404 participants were interviewed and examined, 131 with a history of UC. 34% of those with UC reported present or past peripheral arthralgias (an estimated 400,000 persons nationwide) compared to 21% of those without ($p=0.01$). Rates of overall present or past polyarticular arthralgias, and of arthralgias at the hand and wrist, elbow, shoulder, hip, knee, and foot and ankle were all elevated among those with UC (all $p< 0.05$) (Table 1). 20% of participants with UC reported present or past peripheral arthritis compared to 11% without ($p=0.02$; Table 2). Rates of arthritis at the hand and wrist and knee were significantly elevated in UC ($p< 0.05$ for both). Rates of arthritis at the elbow, shoulder, hip, and foot and ankle were all elevated, but sample size precluded statistical evaluation (Table 2).

Overall, those with UC had significantly increased exam findings (28% vs. 12% without; $p=0.03$), notably increased pain on passive joint motion (12% with UC vs. 7% without; $p=0.03$). The rates of joint swelling on exam were similarly low in both groups (Table 3). On exam, Heberden's Node prevalences were similar between both groups.

Conclusion: Rates of self-reported peripheral arthralgia and arthritis were elevated in NHANES II participants who reported a history of UC compared to the general population. However, while rates of joint pain with motion on exam were elevated in UC, rates of examination-based swelling were not. This may suggest that much of much of UC patients' joint pain is due to peri-articular structure involvement, including possible tenosynovitis and enthesitis, and that point-prevalence of true arthritis is low consistent with p-SpA patients.

Increased Burden of Painful Arthritis and Rheumatism Following the Chikungunya Epidemic 2006: India Rural Population Survey 2018

Arvind Chopra[1], Ravi Ghorpade[2], Anuradha Venugopalan[1], Manjit Saluja[1] and Kiran Adam[1], [1]Center for Rheumatic Diseases, Pune, India, [2]Center for Rheumatic Diseases, Pune

SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: Epidemiology & Public Health Poster II: OA, Osteoporosis, & Other Rheumatic Disease
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: A spectrum of post Chikungunya (Chik) arthritis , often RA like, were referred to an urban rheumatology centre (Pune India)during the 2006 epidemic (Arthritis & Rheumatism 2008). We examined 449 (51.3%) adult cases of acute Chik in a nearby rural survey (Bavi, Solapur) in 2006 ; 35% cases persisted with arthritis which reduced substantially by 6 months. Only 5% cases suffered non-specific arthralgias (mostly knees, elevated IL-6) by 24 months (Epidemiol Infect 2012. In a prior rural survey (Ralegaon Sidhi) in 2003, we reported 27% painful MSK (0.8% undifferentiated IA, 0.3% clinical RA, 0.3% SpA (Ind J Rheumatol 2015). Sporadic cases of Chik related arthritis continue. In the current study, we demonstrate the impact of the earlier Chik epidemic 2006 on the current MSK arthritis landscape.

Methods: The WHO Community oriented program for control of rheumatic diseases Bhigwan model (J Rheumatol 2009) was used to identify MSK disorders arthritis (> 16 years age) using standard questionnaire in a house to house survey in Bavi; May-Aug 2018. We verified residency from village records (including electoral) and interviews. 2131 population (70% response, 49% women, 15% aged 65 years +) was screened and classified: 784 residents also surveyed in 2006 (BRS), 1120 residents not included in the 2006 survey (BRNS), 227 post 2006 migrants (BM); 127 had died. Most of the BRNS lived in the outskirts of Bavi. Clinical diagnosis was based on standard rheumatology approach. Blood samples (26% population) were assayed in the urban centre. Standard statistics included crude point prevalence; significant $p< 0.05$.

Results: 549 (25.7%) subjects suffered from painful MSK disorders, predominantly (¬80%) mild moderate and with mild HAQ disability. 206 cases (39.9%) recalled past acute Chik illness. 422 (61.7%) healthy subjects and 362 (80.6%) cases from the 2006 survey cohort were available; correspondingly 17.5% healthy and 44.8% cases reported painful MSK (2018 survey).10 patients were diagnosed clinical RA (50% seropositive RF). 13 (2.5%) cases (1 RA) in 2006 survey were seropositive (cut off 40 IU/ml) for RF; correspondingly 22 (4%) cases (5 RA, 440-1170 IU/ml) in 2018 survey. 6/22 seropositive RF cases (5 RA) tested seropositive for anti CCP. Table 1 & Table 2 show the classification break up (proportion) in the 2018 survey, and compares MSK per se with and without onset following CHIK; Abbreviations in text

2018 Survey subjects	BRS	BRNS	Total
Number Screened	784	1120	2131
MSK	30.1	25.0	25.8
WOMEN Cases	59.3	54.6	58.8
Post Chik MSK	20.7	4.3	10.2
RA	0.6	0.2	0.5
IA-Undifferentiated	2.8	1.3	1.9
SpA	0.0	0.4	0.2
OA	11.7	11.8	10.9

2018 Survey subjects	BRS	BRNS	Total
Non Specific Arthralgia	14.8	10.3	11.5
Soft Tissue Rheumatism	0.1	1.1	0.8

	POST CHIK MSK	NON CHIK MSK	'p'
Number of Cases	217	332	
RA	1.8	1.8	0.77
IA-Undifferentiated	10.6	5.1	0.02
SPA	0.0	1.5	0.17
OA	42.4	42.2	0.96
Non Specific Arthralgia	44.2	45.2	0.83
Soft Tisuue Rheumatism	0.9	4.2	0.02

Conclusion: A substantial burden and spectrum of painful MSK disorders, in particular related to Chik was demonstrated in this rural survey. There seemed to be an increase in inflammatory arthritis (not necessarily RA) following the Chik 2006 epidemic in this otherwise robust population.

Utilization and Adherence Among Infliximab Biosimilar Initiators in a U.S. National Commercial Insurance Database

Sujith Sarvesh[1], Joseph Alanaeme[1], Jeffrey R Curtis[2] and **Huifeng Yun**[2], [1]University of Alabama at Birmingham, BIrmingham, AL, [2]Division of Clinical Immunology and Rheumatology, University of Alabama at Birmingham, Birmingham, AL

SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: Epidemiology & Public Health Poster II: OA, Osteoporosis, & Other Rheumatic Disease
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Infliximab Biosimilar, the first biosimilar to infliximab, was approved for multiple indications in the U.S. in 2016. Since the utilization of biosimilar in the U.S. has not been studied, it is unclear if patients on Infliximab Biosimilar are adherent to their treatment. Therefore, we evaluated the characteristics of Infliximab Biosimilar initiators and their adherence using national commercial administrative data.

Methods: We identified Infliximab Biosimilar initiators based on procedure and pharmacy codes in 2016-2017 IBM Marketscan data. Using all available data, we classified Infliximab Biosimilar initiators as naïve Infliximab Biosimilar users (never used infliximab), infliximab early switchers with < 2yr of infliximab use, and late switchers with long-term (>2yr) use of infliximab. Eligible patients were ≥18 years of age and continuously enrolled with medical and pharmacy coverage in 2014-2017. The date of the first prescription for infliximab biosimilar was considered as "Index date". Baseline was defined as 365 days prior to the index date. Follow up period started from the index date and ended at the earliest date of death, loss of coverage, and 12/31/2018.We evaluated baseline characteristics in all patients and calculated the proportion of days covered (PDC) at the 12 months of follow up among patients who had >=12m of coverage during follow-up. The PDC adherence level was further categorized as < 50%, 50 to 80%, and > 80%.

Adherence among individuals with at least 12 Months of follow up period.

Cohort	N	Follow up adherence N (%)		
		<50%	50%-80%	80%
Naïve Inflectra cohort.	69	21(30.4%)	11(15.9%)	37(53.6%)
Inflectra (with one to 2 years of infliximab exposure).	88	41(46.6%)	8(9.1%)	39(44.32%)
Inflectra (with prevalent use of infliximab).	66	18(27.3%)	11(16.7%)	37 (56.1%)

Results: We identified 98 Naïve Infliximab Biosimilar users, 114 early switchers, and 113 late switchers. Compared to (early or late) switchers, naive users were younger and more likely to be female. The highest proportion of auto-immune disease was inflammatory bowel disease (40.9-45.4%), followed by rheumatoid arthritis (15.4-29.6%) and psoriasis (9.7-13.9%). Among patients who had >=12m of follow-up, 53.6% naive users, 44.3% early switchers, and 56.1% late switchers continued to be adherent (>80%) at 12 months (Table).

Conclusion: Approximately half of the Infliximab Biosimilar initiators were highly adherent at 12 months. Further studies are needed to evaluate the long-term adherence among Infliximab Biosimilar users.

Session Title: Epidemiology & Public Health Poster II: OA, Osteoporosis, & Other Rheumatic Disease
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Biosimilar infliximab offers a potentially lower-cost treatment option compared to its bio-originator. However, uptake of biosimilars in general in North America has been slow. To describe new users of infliximab in the US, comparing biosimilar and bio-originator, in terms of missed doses and discontinuation.

Methods: We used from data Marketscan® Commercial Claims and Encounters and the Medicare Supplemental and Coordination of Benefits databases (January 1st, 2017 to December 31st, 2018). We studied adult individuals (age≥18 years), who were infliximab-naïve (new users). The date of first infliximab claim was defined as the index date. We assessed i) first missed dose and, ii) occurrence of complete discontinuation. Missed dose was defined as any gap between infusions beyond recommended intervals (0, 2, and 6 weeks during the induction phase and 8 weeks in the

[1]Based on the date of diagnosis closest to the start of treatment with infliximab.

[2]Includes rheumatoid arthritis, ankylosing spondylitis, and psoriatic arthritis

[3]Includes Crohn's disease and ulcerative colitis.

[4]Including abatacept, golimumab, certolizumab, tocilizumab, and rituximab.

Table 1. Baseline characteristics of new users of infliximab biosimilar and infliximab originator, Marketscan, 2017-2018.

maintenance phase). If there was no record of an infliximab infusion at the expected date of the next injection (plus a grace period of 7 days), a discontinuation event was assigned.

Results: In the new-user cohort there were 5,596 new users of infliximab, including 301 biosimilar users. Baseline characteristics of individuals included in the analysis are shown in Table 1. Among patients initiating treatment with infliximab biosimilar, 30.9% missed at least one scheduled infusion during the induction phase, similar to the percent (28.6%) among the originator infliximab users. After multivariable adjustment for age, sex, date of treatment initiation, medication use (other biologic medications, synthetic DMARDs, and corticosteroids), and underlying diseases, we were unable to detect if first missing dose in the induction phase differed between the two groups (adjusted hazard ratio, aHR = 1.14; 95% CI = 0.92-1.41). For patients completing the induction phase (n=3,282), 33.1% of biosimilar users missed at least one infusion within one year during the maintenance phase, which was not statistically different from the originator users (40.1%). The adjusted analysis showed no clear difference for first missed dose between groups (aHR = 0.94, 95% CI =0.71;1.24). Complete discontinuation in the maintenance phase (a gap more than 90 days beyond the expected infusion date without restarting therapy), was similar in the biosimilar group (13.1%) and originator group (15.5%). In adjusted analysis, we were unable to show significant difference among groups for complete discontinuation (aHR = 1.00, 95% CI =0.63;1.59)

Conclusion: Biosimilar infliximab use in the United Sates continues to be low over 2017-2018. In new users, we were unable to detect differences between biosimilar and bio-originator, in terms of missed doses and discontinuation.

SESSION INFORMATION

Session Date: Saturday, November 7, 2020

Session Title: Epidemiology & Public Health Poster II: OA, Osteoporosis, & Other Rheumatic Disease

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: Knee cartilage requires loading, e.g., walking, to remain healthy. When cartilage is deprived of loading, i.e., during bouts of sedentary time, it becomes vulnerable to damage. Thus, achieving more steps/day, and distributing steps throughout the day, may be important for cartilage health. However, the joint effects of walking and sedentary bouts on cartilage health are not known.

We conducted an exploratory analysis to examine the joint association of walking and sedentary bouts with worsening cartilage damage in the medial tibiofemoral joint (TFJ), a common site for knee osteoarthritis (OA), in adults with or at risk for knee OA. We also stratified our analysis by obesity status, as it may modify the above relationship.

Methods: We used data from the Multicenter Osteoarthritis (MOST) Study, a NIH-funded cohort study of adults with or at risk of knee OA. Participants had minute-by-minute accelerometry data collected via the StepWatch Activity Monitor (Orthocare Innovations) at baseline. We included participants with ≥4 days of ≥10 hours/day of wear. For each participant, we estimated **average steps/day** and **typical sedentary bout length (SED, minutes)**; the latter was estimated using an established weighted median approach (Chastin, 2010). We dichotomized steps/day by the sample median: **Active** (≥9,300 steps/day) and **Not Active** (< 9,300 steps/day). We dichotomized typical sedentary bout length by the median: **Short SED** (< 30 min) or **Long SED** (≥30 min). This yielded four groups: 1) Active/Short SED (REF); 2) Not Active/Short SED; 3) Active/Long SED; 4) Not Active/Long SED.

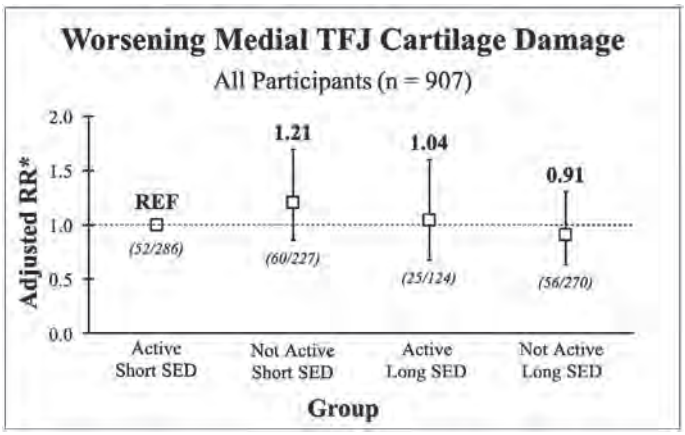

Figure 1. RR and 95%CI (represented by error bars) for worsening medial TFJ cartilage damage in all participants. *Analyses were adjusted for age, sex, and BMI.

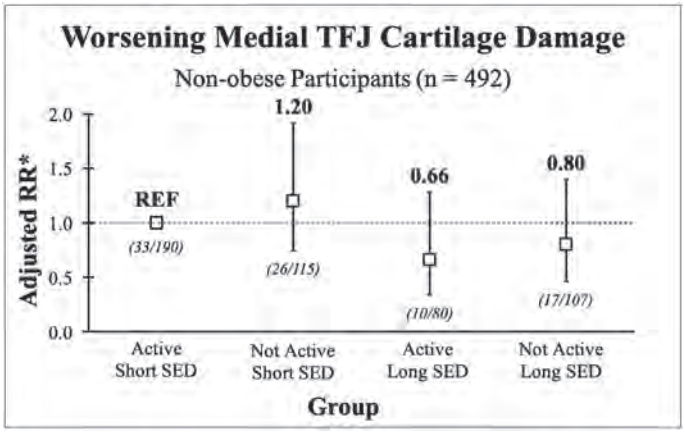

Figure 2. RR and 95%CI (represented by error bars) for worsening medial TFJ cartilage damage in participants who are non-obese. *Analyses were adjusted for age, sex, and BMI.

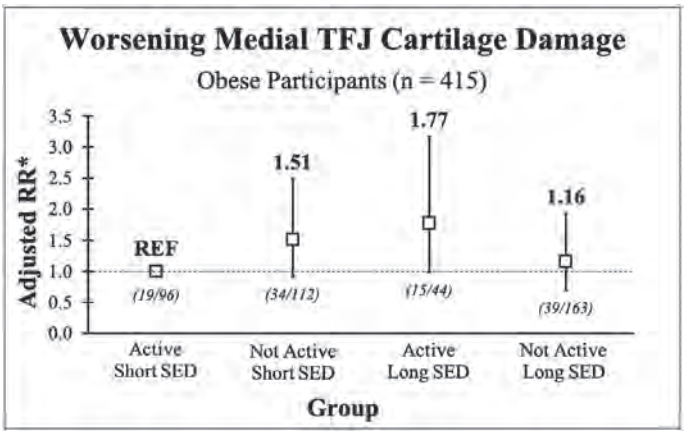

Figure 3. RR and 95%CI (represented by error bars) for worsening medial TFJ cartilage damage in participants who are obese. *Analyses were adjusted for age, sex, and BMI.

Participants had knee MRIs (1.0T, OrthOne) at baseline and two years. Cartilage morphology was scored from 0-6 in 5 subregions of the medial TFJ using the Whole Organ Magnetic Resonance Imaging Score by two musculoskeletal radiologists. Our outcome, worsening medial TFJ cartilage damage over 2 years, was defined as an increased score

in any medial TFJ subregion, including within-grade changes. We used binomial regression with robust variance estimation to calculate risk ratios (RR) and 95% confidence intervals (95% CI) for worsening damage in each group. Analyses were adjusted for age, sex, and body mass index (BMI). We also separately analyzed those who were non-obese (BMI < 30 kg/m^2) vs. obese (BMI ≥ 30 kg/m^2).

Results: We included 907 participants (66.7 years, 62% female, BMI: 29.7 kg/m^2). Risk for worsening medial TFJ cartilage damage was not different between groups in the full sample or in non-obese participants (n=492). However, among obese participants (n=415), those in the Not Active/Short SED and Active/Long SED groups had 1.51 [0.92-2.48] and 1.77 [0.99-3.17] times the risk for worsening damage, respectively, compared with those in the Active/Short SED (REF) group, though neither reached statistical significance. Participants in the Not Active/Long SED group did not have greater risk (1.16 [0.70-1.93]) for worsening damage compared with the REF group.

Conclusion: For adults with or at risk for knee OA who are obese, either lower steps/day or longer typical sedentary bout length may be related to worsening medial TFJ cartilage damage; however, the combination of fewer steps/day and longer sedentary time was not related to worsening damage.

Statin Use Pattern in Patients with Inflammatory Joint Disease in a Single Site VA Medical Center

Lenche Kostadinova[1], Sofi Damjanovska[2], Angela Gupta[3], Ibtissam Gad[4], Sameena Syed[4], Alyssa Lange[5], Corinne Kowal[6], Carey Shive[7], Christopher Burant[4], Brigid Wilson[4], David Canaday[4], David Zidar[8], Donald Anthony[9] and Maya Mattar[10], [1](1) Department of Medicine, VA Medical Center and VA GRECC, Case Western Reserve University, Cleveland OH, Highland Heights, OH, [2](1) Department of Medicine, VA Medical Center and VA GRECC, Case Western Reserve University, Cleveland OH, Cleveland, OH, [3](1) Department of Medicine, VA Medical Center and VA GRECC, Case Western Reserve University, Cleveland OH, Cleveland, [4](1) Department of Medicine, VA Medical Center and VA GRECC, Case Western Reserve University, Cleveland OH, ohio, [5]Case Western Reserve University, Cleveland, [6]Case western reserve university/Cleveland VA Medical Center, ohio, [7](2) Department of Pathology, Case Western Reserve University, ohio, [8]Case Western Reserve University/Cleveland VA Medical Center, Cleveland, [9]Case Western Reserve University/Cleveland VA Medical Center/MetroHealth Medical Center, Cleveland, OH, [10]Department of Medicine, VA Medical Center and VA GRECC, Case Western Reserve University, Cleveland OH, Cleveland, OH

SESSION INFORMATION

Session Date: Saturday, November 7, 2020

Session Title: Epidemiology & Public Health Poster II: OA, Osteoporosis, & Other Rheumatic Disease

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: Patients with inflammatory joint disease, including rheumatoid arthritis (RA), psoriatic arthritis (PsA) and ankylosing spondylitis (AS) carry increased risk of cardiovascular disease (CVD). Mechanisms underlying this increased risk are thought to be attributable to a combination of traditional and novel CVD risk factors (engaged pathogenic inflammatory pathways). Lipid lowering statin therapy is one of the most commonly used CVD preventive

	RA	AS	PsA	Control	P value[1]
Number	200	41	94	19	
ASCVD-10 year score median (IQR)	21.8 (13.8; 32.7)*	13 (4.2; 17.4)	14.15(7.1; 31.6)	8.5 (3.4; 11.7)	<0.001
Subset with ASCVD ≥ 7.5[2] Number (% of parent population)	176 (88%)	27 (65.8%)	69 (73.4%)	11(57.8%)	
ASCVD-10 year score median (IQR)	23.8 (16.9; 34.8)	15 (13.0; 25.2)	26 (11.2;35.0)	9.6 (9.0;16.5)	0.005
Age,median(IQR)(years)	70(65;73)	63 (56; 70)	65 (56;70)	61 (54; 72)	<0.001
Gender (male)(%)	174 (98.8%)	27 (100%)	66 (96.6%)	11 (100%)	0.4
Diabetes Mellitus (%)	60 (34.4%)	8 (29.6%)	40 (57.9%)*	3 (27.3%)	0.003
Hypertension (%)	126 (71.5%)*	12(44.5%)	47 (68.1%)	6(54.5%)	0.03
On Statin (%)	92 (51.8%)	10 (37%)	47 (68.1%)	9 (81.8%)	0.06

medications. We explored statin use patterns in patients with inflammatory joint disease (RA, PsA and AS) accounting for traditional CVD risk factors.

Methods: This was a retrospective chart review study conducted at the Cleveland VA Medical Center. ICD 10 diagnoses for RA, AS and PsA identified local populations of these patients. Medical charts of 200 RA (all seropositive for either RF or CCP in this sample set), 41 AS, 94 PsA and 19 patients with no inflammatory joint disease (general medical clinic patients) were reviewed. Diagnoses were verified using rheumatology clinic visit information and ACR, ASAS, or CASPAR criteria. Records were reviewed for ASCVD risk score components (age, gender, race, presence of hypertension or diabetes, lipid profile, and smoking status). We examined patient race, body mass index (BMI), and treatment history. When calculating ASCVD Risk Score, if age or lipid levels were above or below the limitations of the calculator, either the upper or lower limit values were used, respectively.

Results: Clinical characteristics are shown in **Table 1**. Most of the patients were male, consistent with the VA patient population. Patients with RA had higher ASCVD scores compared to patients with AS and PsA. In the subgroups with ASCVD score above or equal to 7.5, RA and PsA patients more commonly had diabetes mellitus, while RA patients were older and more commonly had hypertension. Only 51.8% of RA, 37% of AS and 68% or PsA patients with ASCVD score at or above 7.5 were prescribed statin compared to 81.8% of patients with no inflammatory joint disease (p=0.06). Chart review for reasons patients were not on statin included: 1) undergoing a trial of dietary change and weight loss; 2) patient declining recommended medication; and 3) other.

Conclusion: Patients with inflammatory joint disease and traditional CVD risk factor with indication for statin may benefit of provider education and improvement of CVD risk assessment and initiation of proper preventive measures in these high risk inflammatory joint disease patient populations.

SESSION INFORMATION

Session Date: Saturday, November 7, 2020

Session Title: Epidemiology & Public Health Poster II: OA, Osteoporosis, & Other Rheumatic Disease

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: Autoimmune systemic rheumatic disease (SARD) diagnostic approach is complex and recently there are some diagnostic tools to rule-out autoimmune disease diagnoses. ANAS/DFS70 antibodies have attracted interest as a positive result in patients without clinical evidence of SARD, but we are scarce on data validation

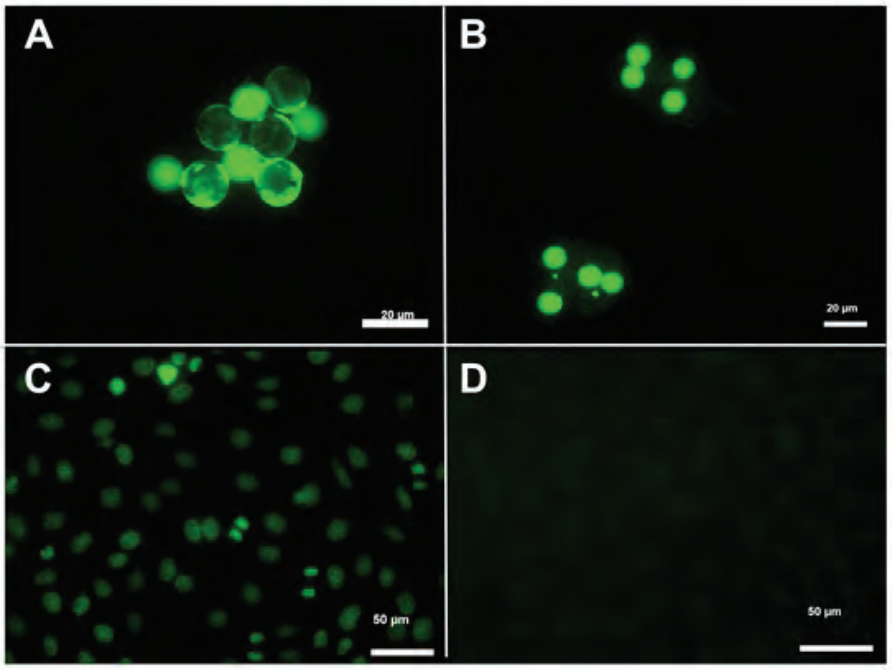

Figure 1. Indirect immunofluorescence for ANA: A: Postive Cytobeads ANA for DFS70, B: positives control beads for cytobeads, C: ANA: AC-2 - Nuclear dense fine speckled (Speckled pattern distributed throughout the interphase nucleus with characteristic heterogeneity in the size and D: ANA: AC-0 – Negative.

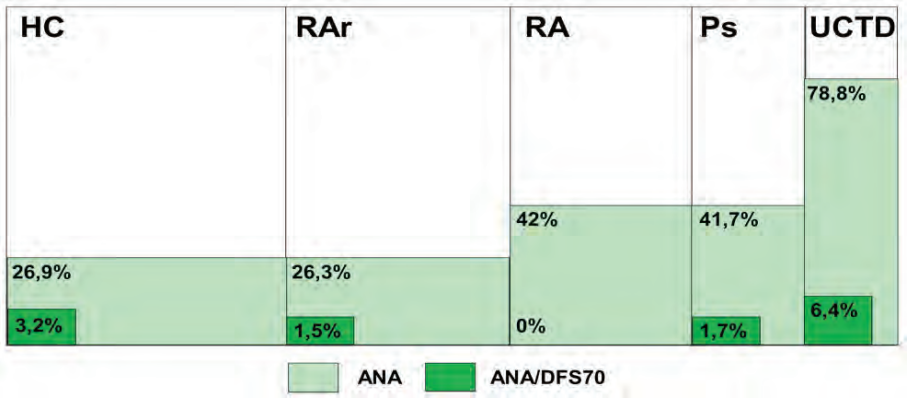

Figure 2. Participants were RA 19%, 25,8% RA first degree relatives, Ps 11,3%, UCTD 8,9%, and 35% healthy controls. ANA/DFS70 was positive in a 6,4% in UCTD, 3,2% in healthy controls, 1,7% in Ps, 1,5% in relatives of RA, no RA had positive results.

in Latin American countries population. The objective of this study was to assess ANA/DFS70 performance in a large population with SARD compared with first degree relatives and healthy controls.

Methods: A cross-sectional study was conducted. We analyzed 531 individuals between 18-65 years old, 101 early rheumatoid arthritis (eRA) patients (ACR/EULAR 2010 classification criteria), 137 first degree relatives (FDR) from RA, 60 psoriasis (Ps) patients (Colombian classification consensus), 47 Undifferentiated connective tissue diseases (UCTD) patients and 186 healthy controls matched by age and sex. The healthy control group were individuals who lived and work similarly like those patients those criteria of exclusion criteria were to present autoimmune or auto-inflammatory disease, infectious, neoplasms, diabetes, antibiotic treatment, pregnancy or lactation, consanguinity with autoimmune entities.

The determination of ANA-HEp2 antibodies (ANA-Hep-2 AESKU.Dignostic®, Autoantiboy test SYSTEM IMCO DIAGNOSTICS REF 1103® and ANA-Hep-2 AESKU.Dignostic®) was carried out. The positive results (standard AC-2) are used as a confirmatory test the determination of ANAS / DFS70: AUTOANTIBOY TEST SYSTEM IMMCO DIAGNOSTICS (Knocked out, for the psip gene) REF 1108® and CytoBead ANA Generic Assays ref 8065 ® by indirect immunofluorescence-IFI technique (Figure 1). In addition, serum levels of C-reactive protein (CRP), erythrocyte sedimentation rate (ESR), IgG/IgA antibodies against citrullinated peptide (ACPA), and rheumatoid factor (RF). Absolute and relative frequencies were established.

Results: 531 participants were included: eRA 19%, 25,8% RA FDR, Ps 11,3%, UCTD 8,9%, and 35% healthy controls. eRA mean age was 41,8±12,2 years, female 82,2%, with ANA test(+) result 42%. In Ps mean age 49,1±15,7 years, female 53,3%, ANA test(+) 41,7%. UCTD mean age 41,3±15,2 years, female 85,1%, and ANA test(+) 78,7%. RA FDR mean age 38,7±12,2 years, female 73%, ANA test(+) 26,3%. And healthy controls mean age 41,3±12,2 years, female 74,7%, and ANA test(+) 26,9%. ANA/DFS70 was positive in a 6,4% in UCTD, 3,2% in healthy controls, 1,7% in Ps, 1,5% in RA FDR, no eRA had positive results (Figure 2). These 12 participants were negative for acute phase reactants (ESR[-] 83,3% and CRP[-] 66,6%), as well as they were all negative for RF and two were positive for APCA from UCTD.

Conclusion: ANAS/DFS70 autoantibodies were present in very low frequency in patients with SARD, specially no eRA patient had a positive test result. Thus, patients with a positive result tend to have a mild or non-progressing phenotype of SARD, as UTCD. This is the first time ANA/DFS70 are tested in a large population cohort in Latin American countries which coincide with previous results in RA and RA relatives.

Abstract Number: 0560

Mortality Burden of Immune-Mediated Inflammatory Diseases (IMID): Race/Ethnicity, Sex, and Geographic Variation in the United States

Ram Singh[1], Eric Yen[2] and Meifang Wu[2], [1]UCLA David Geffen School of Medicine, Los Angeles, CA, [2]UCLA, Los Angeles, CA

SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: Epidemiology & Public Health Poster II: OA, Osteoporosis, & Other Rheumatic Disease
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Almost every organ system can be affected by immune-mediated inflammatory diseases (IMID) characterized by inflammation and therapeutic response to immune-suppressive or anti-inflammatory drugs. Since IMID are purported to have shared pathogenic mechanisms, it would be important to understand their burden of disease together. Our goal is to determine 1) the burden of IMID deaths relative to the leading causes of death published by the Centers for Disease Control and Prevention (CDC) and 2) the mortality associations of IMID with major demographic/geographic variables.

Methods: This is a nationwide population-based study using a U.S. national mortality database and census data from 2013 to 2017. A list of forty-four IMID was compiled based on their relative high prevalence. Crude death rates for each IMID were calculated by dividing death counts of each IMID by the U.S. population between 2013 and 2017 and ranked. Pooled death counts of the fifteen IMID with highest crude death rates were further ranked among CDC's official leading-causes-of-death ranklist for eleven age groups and charted. Mortality associations with four demographic/geographic variables were analyzed with multinomial logistic regression.

Results: 362,150 deaths were attributed to the top fifteen IMID from 2013 to 2017. Of these deaths, IMID were recorded as the underlying cause in 202,430 deaths and as the contributing cause in 159,720 deaths. These IMID deaths (underlying + contributing) ranked 6th to 9th for all age groups in relation to the CDC's official leading causes of death. The ranking was even higher in Black persons, particularly in young females. IMID deaths ranked number 4 in Black females at 35-54 age groups. Multinomial logistic regression analysis revealed that young (< 45 years) and middle (45-64 years) ages, female sex, race/ethnicity of non-Hispanic Black or American Indian/Alaska Native, and census region of West or Midwest were independently associated with higher IMID mortality. IMID caused premature mortality in several race/ethnic groups, especially in Blacks and American Indians/Alaska Natives. American Indians/Alaska Natives living in the Midwest or West had the highest risk for IMID mortality.

Conclusion: IMID is an unrecognized leading cause of death. IMID caused premature mortality, especially in Black females, and in American Indians/Alaska Natives living in the Midwest and West. These data highlight that IMID is a major public health problem. Similar to various forms of cancer, various IMIDs should be considered as a collective disease entity. The recognition of IMID as a leading cause of death may influence healthcare prioritization and research funding, which may help to reduce their disease burden. Our data have implications for developing precision public health strategies to target IMID high-risk vulnerable populations including Black females and American Indians/Alaska Natives living in the Midwest and West.

Risk Factors for Falls Among Individuals with Knee OA: A Longitudinal Community-based Study

Jessica Wilfong[1], Anthony Perruccio[2] and Elizabeth Badley[2], [1]Krembil Research Institute, University Helath Network, Toronto, ON, Canada, [2]Krembil Research Institute, UHN; University of Toronto, Toronto, ON, Canada

SESSION INFORMATION

Session Date: Saturday, November 7, 2020

Session Title: Epidemiology & Public Health Poster II: OA, Osteoporosis, & Other Rheumatic Disease

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: Knee osteoarthritis (OA) is a known risk factor for falling, but little is known about what factors contribute to the risk of falling among people with knee OA. Our purpose was to identify factors that contributed to an individual with knee OA experiencing one or multiple (≥2) falls within an 18-month follow-up period.

Methods: Data from the baseline and 18-month follow-up of the Canadian Longitudinal Study on Aging (CLSA) of individuals aged 45-85 who reported doctor diagnosed knee OA at baseline were analyzed. At the follow-up, individuals reported if they experienced 0, 1, ≥2 falls in the past year where they were hurt enough to limit some of their normal activities. A multinomial logistic regression model was used to assess predictors of reporting falls at follow-up (≥2, 1, 0 (referent group)). Self-reported and performance-based predictors were considered: age, sex, body mass index, alcohol use, sleeping problems, vision problems, previous fall, neurological condition, respiratory condition, incontinence, depression, other types of arthritis, other chronic conditions, and the timed up and go, chair rise, 4-metre walk, and standing balance tests.

Results: 4,495 individuals reporting knee OA at baseline were included (15% of the CLSA sample). Fourteen percent reported a fall(s) at follow-up: 10% reported 1 fall, 4% reported ≥2 falls. Reporting a past fall, taking depression medication, and having a worse standing balance time was associated with an increased risk of any number of future falls. Being female and having troubles sleeping were associated with an increased risk of having 1 fall, while specific comorbidities (e.g. diabetes, depression) were associated with an increased risk of ≥2 falls. Older individuals were not more likely than younger individuals to experience multiple falls.

Conclusion: There are differences between the predictors of one versus multiple falls among individuals with knee OA. Some of these are potentially modifiable with opportunities for clinical intervention and fall prevention strategies. Relationships between risk factors and falling among individuals with knee OA can be complex. There is a need for better understanding these relationships in OA.

The Relationship Between Heart Disease Risk Profile and Osteoarthritis, Overall and by Multi-/Single-Joint Involvement

Anthony Perruccio[1], Shatabdy Zahid[2], Calvin Yip[3], J Denise Power[2], Mayilee Canizares[2], George Heckman[4] and Elizabeth Badley[1], [1]Krembil Research Institute, UHN; University of Toronto, Toronto, ON, Canada, [2]Krembil Research Institute, University Health Network, Toronto, ON, Canada, [3]University of Toronto, Toronto, ON, Canada, [4]University of Waterloo, Waterloo, ON, Canada

SESSION INFORMATION

Session Date: Saturday, November 7, 2020

Session Title: Epidemiology & Public Health Poster II: OA, Osteoporosis, & Other Rheumatic Disease

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: Osteoarthritis (OA) and heart disease (HD) are among the most common chronic conditions. Several studies have shown that OA increases the risk of HD later in life, even after adjusting for socioeconomic factors, functional limitations and obesity. Much of the literature considers OA of a specific joint, but there is increasing realization that OA is a multi-joint disease for many, with a greater potential for systemic inflammatory load, a risk factor for HD. Our objective was to compare the burden of HD risk factors between those with and without OA, and consider differences between those with single- and multi-joint OA.

Methods: Data are from cycle 1 of the Canadian Longitudinal Study on Aging, a national study of a representative sample of individuals aged 45-85. Respondents indicated a doctor diagnosis of OA in the knees, hips or hands. Those reporting arthritis other than OA, any form of HD, or use of HD medications were excluded. A 1:1 age and sex

Table 1: Distribution of heart disease (HD) risk score by OA status.

		No OA (%)	OA (%)	Single-joint OA (%)	Multi-joint OA (%)
HD Risk Score	0 – 6	30.1	22.1	23.8	16.7
	7 – 9	28.6	26.7	27.6	23.9
	10 – 11	17.1	19.4	19.0	20.6
	12+	24.2	31.9	29.6	38.8

Table 2: Multinomial logistic regressions* investigating relationship between HD risk score (0-6 (ref), 7-9, 10-11, 12+) and a) OA overall and b) single- and multi-joint OA.

Predictor	Outcome: HD risk score (ref: 0-6)		
	Risk score 7-9	Risk score 10-11	Risk score 12+
	Odds Ratio (95% Confidence Interval)		
OA overall vs. no OA	**1.21 (1.05 - 1.39)**	**1.43 (1.22 - 1.68)**	**1.59 (1.38 - 1.83)**
Single-joint OA vs. no OA	**1.18 (1.02 - 1.37)**	**1.35 (1.14 - 1.59)**	**1.45 (1.24 - 1.68)**
Multi-joint OA vs. no OA	**1.33 (1.04 - 1.71)**	**1.82 (1.39 - 2.37)**	**2.21 (1.75 - 2.80)**

*Models are age-sex matched and adjusted for education, income, physical activity score, timed up and go test, and chronic conditions.

non-OA match was randomly selected for every individual with OA. OA was characterized as single or multi-joint OA. HD risk factors: high sensitivity C-reactive protein (hsCRP), high density lipoprotein (HDL), triglycerides, cholesterol, body fat %, body mass index, blood pressure, waist size, Hemoglobin A1c, and smoking history. Each risk factor was scored 0, 1, or 2 using established cut-offs for low/medium/high HD risk, then summed to give an HD risk score and categorized as 0-6, 7-9, 10-11 and 12+ based on quartiles. Covariates: age, sex, education, income, physical activity score, timed up and go functional test and comorbidity count. The association between HD risk score category and a) OA overall and b) single- and multi-joint OA was quantified using multinomial logistic regressions, adjusting for covariates.

Results: The matched sample consisted of 6098 respondents (3049 with OA). The median age was 63 years, 55.8% were female. Several HD risk factors were elevated among those with OA vs. without, including hsCRP, a systemic inflammation marker. Individuals with OA were in the 'high' risk category more frequently than non-OA individuals for all but 3 (HDL, cholesterol, and smoking) risk factors. This was reflected in the overall HD risk score: the proportion of OA respondents in the higher score categories was also more frequent for multi- vs. single-joint OA (Table 1). The age-sex matched and covariate adjusted regressions showed that those with OA had significantly greater odds of higher HD risk score than those without OA, with a significant trend of increasing odds for increasing quartile of HD risk score (Table 2). The trend of increasing odds was greater for those with multi-joint than single-joint OA.

Conclusion: Individuals with OA and without HD, and more so those with multi-joint OA, had a worse HD risk profile than individuals without OA. Greater joint involvement and systemic features may be an additional link between OA and HD. Improving overall HD risk-stratification for people with OA is important for enhanced approaches to prevention/intervention. Furthermore, the findings suggest that an exclusive focus on individual joints in OA care and research may limit our ability to effectively manage, treat and understand OA.

Abstract Number: 0563

Relation of Pain Sensitization to Isokinetic Knee Extension Torque: The MOST Study

Patrick Corrigan[1], Tuhina Neogi[2], Laura Frey Law[3], Neil Segal[4], Michael Nevitt[5], Beth Lewis[6] and Joshua Stefanik[1], [1]Northeastern University, Boston, MA, [2]Boston University School of Medicine, Boston, MA, [3]University of Iowa, Iowa City, IA, [4]University of Kansas Medical Center, Iowa City, IA, [5]Department of Epidemiology and Biostatistics, University of California San Francisco, Orinda, CA, [6]University of Alabama at Birmingham, Birmingham

SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: Epidemiology & Public Health Poster II: OA, Osteoporosis, & Other Rheumatic Disease
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Central and local alterations in nociception are related to heightened pain severity and can be present in people who have knee osteoarthritis (OA). Yet, it is unknown if pain sensitization independently contributes to alterations in muscle function beyond the effect of pain severity. Thus, we aimed to examine the relation of pain sensitization to knee extension torque in adults with or at risk for knee OA.

Methods: Data from the 60-month visit of the MOST Study were used for this cross-sectional analysis. MOST is a cohort study of persons with or at risk for knee OA. Pain pressure threshold (PPT) and temporal summation (TS) were assessed at the right wrist and patella. PPT was measured with mechanical algometry (tip size=1 cm^2; rate=0.5 kg/s), and defined as the minimum pressure that caused slight pain. Three trials were performed at each site and averaged. For analysis, PPTs were divided into sex-specific tertiles. TS was assessed by repeatedly touching the skin (rate=1 Hz) with a 60 g monofilament for 30 s, and the presence of TS was defined as new or increased pain. Isokinetic knee extension torque was measured for the right leg at 60°/s with a computerized dynamometer. Maximum concentric knee extension torque was extracted from 4 maximal-effort trials, and normalized to body mass. Separate general linear regression models determined the relation of PPT and TS at the right wrist and patella to maximal knee extension torque of the right leg. Models were adjusted for age, sex, body mass index (BMI), clinic site, depressive symptoms, pain catastrophizing, average knee pain severity in the past month (Visual Analog Scale; VAS), and the presence of radiographic OA (ROA). Additionally, analyses were repeated after stratifying by sex and the presence of pain (VAS > 0) separately.

Results: 1702 participants (60% female) were included, with a mean (SD) age of 67.3 (7.7) years, BMI of 30.3 (5.6) kg/m^2, VAS of 15.3 (19.6) mm, and maximum knee extension torque of 1.03 (0.41) Nm/kg. Mean PPTs at the right wrist and patella were 3.4 (1.5) and 5.2 (2.2) kg/cm^2, respectively. Knee extension torque was significantly less in those with lower PPTs (i.e., higher pain sensitivity) compared to those with high PPTs (Table 1). Notably, those with the lowest PPTs at the patella were 14.3% weaker than those with the highest PPTs. For TS, the prevalence was 40.8% at the right wrist and 39.7% at the patella. Knee extension torque was significantly less in those with TS compared to those without TS, but the difference was small (i.e., < 5% weaker) (Table 1). In sex-specific analyses, lower PPTs were significantly associated with lower knee extension torques for both sexes, but the presence of TS was only associated with lower knee extension torques for females (Table 2). Lastly, low PPTs were associated with lower knee extension torques regardless of the presence of pain, but the presence of TS was only associated with lower knee extension torques for those with pain (Table 3).

Table 1. Relation of pain sensitization to maximum normalized knee extension torque (Nm/kg).

	Adjusted Mean Torque (95% CI)*	Adjusted Mean Torque (95% CI) **
Wrist PPT:		
Lowest Tertile	0.98 (0.95-1.01) †	1.01 (0.98-1.03) †

Conclusion: Increased pain sensitivity, centrally and locally, is related to lower knee extension torque in adults with or at risk for knee OA. This relation is independent of knee pain severity and provides support that nervous system alterations may not only affect pain severity, but also muscle function.

SESSION INFORMATION

Session Date: Saturday, November 7, 2020

Session Title: Epidemiology & Public Health Poster II: OA, Osteoporosis, & Other Rheumatic Disease

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: Foot osteoarthritis (OA) is a common cause of disability in older adults yet remains an understudied area. The purpose of this study was to examine the incidence and progression of foot osteoarthritis (OA), as well as potential risk factors, in a large population-based cohort.

Methods: Data were from the Johnston County Osteoarthritis Project (JoCoOA), a prospective population-based cohort of African American and White adults. Participants completed foot radiographs at baseline (2013-2015) and follow-up (2016-2018), which were scored using the La Trobe Foot Atlas to examine osteophytes (OP, score 0-3) and joint space narrowing (JSN, score 0-3) in the first metatarsophalangeal (1st MTP), first cuneometatarsal (1st CMT), second cuneometatarsal (2nd CMT), naviculocuneiform (NC), and talonavicular (TN) joints. Incident foot radiographic OA (rOA) was defined as baseline score < 2 OP and JSN in all 5 joints with ≥2 OP or JSN at follow-up in any of the 5 joints. Progression was defined as worsening score of OP or JSN in a joint with baseline foot rOA. At baseline and follow-up,

Table 1. Characteristics of the study sample by foot radiographic osteoarthritis (rOA) status at baseline and frequency of outcomes.

Characteristics	All participants (n=541)	No Foot rOA at baseline	Foot rOA at baseline
Age, mean (years)	69.4	69.2	70.2
Men	29.4%	31.1%	23.3%
African-American	35.1%	33%	42.5%
BMI, mean (kg/m^2)	31.2	30.6	33.2
Current smoker	7.9%	8.8%	5.0%
NSAID use in past two weeks	60.1%	58.9%	64.2%
Work disability	22.0%	21.1%	25.0%
Gout	6.2%	6.4%	5.2%
Foot injury	2.4%	2.2%	3.9%
Joints involved:			
1st MTP	5.9%	n/a	41.6%
1st CMT	1.2%	n/a	8.4%
2nd CMT	3.1%	n/a	22.1%
NC	3.5%	n/a	24.7%
TN	4.4%	n/a	31.2%

BMI=body mass index. Current smoker=smoking any amount of cigarettes during time of questionnaire. NSAID=non-steroidal anti-inflammatory and does exclude use of low-dose aspirin (81 mg daily).

Table 2. Association (adjusted odds ratio [95% confidence interval]) between covariates, foot radiographic osteoarthritis (rOA) incidence and progression, and worsening pain, aching or stiffness (PAS) in sample size of n=1082

Risk Factors	Incidence or progression	Incidence or progression and PAS present	PAS worsening
Women vs men	n/a	2.35 (0.77, 7.22)	1.58 (0.93, 2.71)
• No rOA at baseline	**4.10 (1.22, 13.8)**	n/a	n/a
• rOA at baseline	0.46 (0.19, 1.08)	n/a	n/a
BMI: 5 kg/m^2 increase	n/a	n/a	1.16 (0.97, 1.38)
• No rOA at baseline	**1.60 (1.31, 1.97)**	**1.81 (1.39, 2.36)**	n/a
• rOA at baseline	1.11 (0.90, 1.36)	1.07 (0.78, 1.47)	n/a
Age: 5 years older	1.14 (0.97, 1.34)	1.101 (0.76, 1.35)	n/a
• No rOA at baseline	n/a	n/a	1.02 (0.85, 1.23)
• rOA at baseline	n/a	n/a	**0.70 (0.50, 0.99)**
Work disability	0.74 (0.39, 1.42)	1.24 (0.43, 3.63)	**1.81 (1.07, 3.04)**
Gout	**2.75 (1.25, 6.07)**	2.01 (0.68, 5.92)	1.42 (0.81, 2.49)
Foot injury	2.75 (0.73, 10.4)	**4.99 (1.57, 15.9)**	1.59 (0.61, 4.13)

Bolded text indicates statistical significance.

BMI=body mass index, NSAID=nonsteroidal anti-inflammatory drug. Work disability was patient reported and included individuals that received work disability payments from either government or disability insurance. Gout was defined as self-report of being told by a physician of having gout at the feet. Foot injury was defined as injury that limited an individual's ability to walk for at least two days. Models adjusted for race, work disability, NSAID use, any foot PAS at baseline

For PAS worsening, a sample size of n=1080 was used.

Table 3. Association (adjusted odds ratio [95% confidence interval]) between covariates and worsening by Foot and Ankle Outcome Score (FAOS) subscale scores.

Risk Factors	Worsening FAOS Symptoms (n=1080)	Worsening FAOS Pain (n=1080)	Worsening FAOS-Activities of Daily Living (n=1080)	Worsening FAOS Sports & Recreation (n=1080)	Worsening FAOS Quality of Life (n=1080)
Women vs men	n/a	1.41 (0.93, 2.13)	**1.58 (1.04, 2.42)**	**1.57 (1.01, 2.43)**	1.31 (0.89, 1.94)
No rOA at baseline	**1.47 (0.95, 2.27)**	n/a	n/a	n/a	n/a
rOA at baseline	0.60 (0.26, 1.37)	n/a	n/a	n/a	n/a
BMI: 5 kg/m^2 increase	**1.40 (1.19, 1.66)**	**1.22 (1.05, 1.41)**	**1.21 (1.04, 1.41)**	**1.31 (1.11, 1.54)**	**1.24 (1.06, 1.44)**
Age: 5 years older	1.13 (0.99, 1.31)	n/a	n/a	n/a	1.01 (0.89, 1.15)
No rOA at baseline	n/a	1.01 (0.88, 1.16)	1.09 (0.94, 1.26)	1.12 (0.97, 1.29)	n/a
rOA at baseline	n/a	**0.74 (0.58, 0.96)**	**0.77 (0.60, 0.98)**	0.89 (0.71, 1.13)	n/a
Work disability	1.39 (0.85, 2.27)	**2.08 (1.26, 3.43)**	**2.09 (1.33, 3.27)**	**2.19 (1.35, 3.55)**	**1.60 (1.02, 2.50)**
Gout	0.98 (0.65, 1.47)	0.87 (0.54, 1.40)	**1.59 (1.09, 2.31)**	**1.47 (1.10, 1.96)**	1.56 (0.93, 2.62)
Foot injury	n/a	1.52 (0.56, 4.13)	**2.57 (1.18, 5.61)**	1.17 (0.43, 3.19)	1.21 (0.55, 2.68)

Bolded text indicates statistical significance.

BMI=body mass index. Work disability was self-reported and included participants that received work disability payments from either government or disability insurance. Gout was defined as self-report of being told by a physician of having gout and included his/her feet. Foot injury was defined as injury that limited the participant's ability to walk for at least two days. Models adjusted for race, work disability, NSAID use, any foot PAS at baseline.

participants were asked to rate their pain, aching, or stiffness [PAS] in each foot as 0-10 (none to extreme) on most days of any month in the past 12 months. PAS worsening was defined as an increase in the PAS from baseline to follow-up. The Foot and Ankle Outcome Score (FAOS) (pain, other symptoms, activities of daily living [ADL], sport and recreation function [Sports & Rec], foot and ankle-related quality of life [QOL]) was also obtained at both time points. Joint-based logistic regression models with generalized estimating equations were used to examine associations of foot rOA incidence and progression and covariates of interest (Table 1). Two-way interactions between risk factors and foot rOA status at baseline were assessed at a 0.10 alpha level and adjusted odds ratios and 95% confidence intervals (aOR [95% CI]) were shown by baseline status if significant; otherwise overall associations were reported.

Results: A total of 541 participants (1082 feet) were included (71% women, mean age 69 years; 35% African American, 53% obese; Table 1). Among 928 feet without baseline rOA, 4% developed incident foot rOA and roughly 2% of those had PAS of the same foot at follow-up (Table 1). Among 154 feet with baseline foot rOA, 55% had radiographic progression and 16% of those had PAS of the same foot at follow-up. Female sex and higher BMI were associated with incident foot rOA, while history of gout was associated with both incidence and progression of foot rOA (Table 2). History of foot injury was associated with foot OA with PAS present. Work disability was associated with PAS and FAOS worsening particularly for pain, ADL, and Sports & Rec subscales (Table 3). BMI was associated with worsening of all FAOS subscales, and history of gout was associated with worsening for FAOS ADL and Sports & Rec subscales.

Conclusion: Progression of foot rOA is relatively common, although it is not necessarily related to worsening symptoms. Given the increased risk of foot OA outcomes with higher BMI, foot injury, and history of gout, further studies could examine interventions (e.g., weight loss, injury prevention, intensive gout control) to reduce or manage foot OA.

In Those with Unilateral Frequent Knee Pain, Between-Limb Differences in Stance Time During Walking Increase the Risk of Frequent Pain in the Other Knee: The MOST Study

Patrick Corrigan[1], David Felson[2], Cara Lewis[3], K. Douglas Gross[4], Michael Nevitt[5], Beth Lewis[6], James Torner[7] and Joshua Stefanik[1], [1]Northeastern University, Boston, MA, [2]Boston University School of Medicine, Boston, MA, [3]Boston University, Brookline, MA, [4]MGH Institute of Health Professionals, Boston, MA, [5]Department of Epidemiology and Biostatistics, University of California San Francisco, Orinda, CA, [6]University of Alabama at Birmingham, Birmingham, [7]University of Iowa, Iowa City, IA

SESSION INFORMATION

Session Date: Saturday, November 7, 2020

Session Title: Epidemiology & Public Health Poster II: OA, Osteoporosis, & Other Rheumatic Disease

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: Knee osteoarthritis (OA) commonly begins as a unilateral disease, with pain in only one knee. Yet 88% of persons with unilateral knee OA develop bilateral disease within 10 years. Between-limb differences in stance time while walking may be a modifiable risk factor that plays a role in the progression from unilateral to bilateral disease. Therefore, the purpose of this study was to determine if stance time asymmetry while walking is a risk factor for incident frequent pain in the contralateral knee for older adults with unilateral frequent knee pain (FKP).

Methods: Participants with unilateral FKP (i.e., pain on most days of the past month) at the 60-month visit of the MOST study were included in this analysis. MOST is a NIH-funded cohort study of persons with or at risk for knee OA. Participants performed 4 walking trials at their usual walking speed over a 4.9 m instrumented walkway. Average stance time was calculated for each leg with all steps taken during the walking trials. A stance time limb symmetry index (LSI) was calculated as (Stance Time without FKP / Stance Time with FKP) x100, with values >100% indicating longer stance time on the leg without FKP, values < 100% indicating longer stance time on the leg with FKP, and 100% indicating equal stance times. Incident FKP was defined by the presence of FKP at the 84-month visit for the knee without FKP at the 60-month visit. Logistic regression models determined the relation of stance time LSI to incident FKP. Covariates included age, sex, BMI, race, gait speed, previous surgery or injury to the knee without FKP, and knee pain severity of the knee without FKP. Analyses were repeated for females and males independently.

Results: 300 participants in the MOST cohort had unilateral FKP at the 60-month visit. 63% were female, 86% were white, mean (SD; min-max) age was 66.9 (8.1; 55.5-84.9) years, and BMI was 31.2 (6.8; 20.4-62.4) kg/m^2. For the gait evaluation, mean stance time was 708 (69; 529-986) ms on the leg with FKP and 712 (72; 514-970) ms on the leg without FKP, with a mean LSI of 100.6 (2.8; 83.9-111.3) %. Of the 300 participants, 97 (32%) developed FKP by the 84-month visit in the knee without FKP originally. Stance time LSI was significantly associated with incident FKP, with a five-unit increase in LSI (i.e., 5% longer time spent on the leg without FKP) associated with a 67% increased odds of incident FKP (OR 1.67, 95%CI 1.03-2.69, p=0.04). For females, a five-unit increase in stance time LSI was associated with a 86% increased odds in incident FKP (OR 1.86, 95%CI 1.01-3.43, p=0.048), while for males a five-unit increase was associated with a 65% increased odds in incident FKP (OR 1.65, 95%CI 0.71-3.83, p=0.24).

Conclusion: A high proportion (32%) of individuals with unilateral FKP have frequent pain in their contralateral knee at 2-year follow-up. A longer stance time on the leg without FKP compared to the leg with FKP appears to be a risk factor for developing frequent pain in the knee without FKP originally. The effect was similar for females and males independently. Future research is needed to determine how to best intervene.

Healthcare Utilization and Costs Prior to Diagnosis of ANCA Vasculitis in Medicare Beneficiaries

Shirley Huang[1], Xintong Li[2], Joehl Nguyen[2], Jacob Robinson[2], Susan Hogan[3], Vimal Derebail[3] and Carolyn Thorpe[2], [1]University of North Carolina at Chapel Hill, Chapel Hill, [2]University of North Carolina Eshelman School of Pharmacy, Chapel Hill, [3]University of North Carolina Kidney Center, Chapel Hill

SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: Epidemiology & Public Health Poster II: OA, Osteoporosis, & Other Rheumatic Disease
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Antineutrophil cytoplasmic antibody (ANCA) vasculitis (AV) is a complex group of autoimmune disorders affecting blood vessels in multiple organ systems. Delays in diagnosis are common because AV symptoms can be non-specific and present heterogeneously. This may result in increased healthcare utilization in the months preceding diagnosis. We examined whether Medicare beneficiaries with AV experience increased healthcare utilization and costs in the year before the first diagnosis was recorded in claims, relative to Medicare beneficiaries without AV.

Methods: This retrospective cohort study used 2015-16 Medicare Part A/B medical claims and Part D prescription drug data. Beneficiaries with newly diagnosed AV were identified by having ≥1 inpatient claim or ≥2 non-inpatient claims at least 7 days apart in 2016 with an ICD-10 code for granulomatosis with polyangiitis, microscopic polyangiitis, or eosinophilic granulomatosis with polyangiitis, with no AV claims in the year prior. Beneficiaries with AV were matched 1:1 on age and sex to beneficiaries without any diagnosis codes for any type of systemic vasculitis in 2016. The study index date for AV beneficiaries was the first AV claim in 2016, which also served as the index date for the matched control. Beneficiaries were required to have continuous enrollment in Parts A, B, and D in the year prior to index. Outcomes included annual Medicare and beneficiary expenditures for Part A/B medical services, Part B and D medications, and annual counts of events in 12 categories of medical services (e.g., inpatient stays, outpatient visits, tests), for the year prior to the index date. Linear regression was used to test for differences, controlling for race/ethnicity, dual Medicaid enrollment or the Part D low-income subsidy, entitlement due to disability, and US region. Bias-corrected bootstrapped standard errors were used to calculate 95% confidence intervals (CI), accounting for non-normal distributions of dependent variables.

Results: A total of 1,626 AV beneficiaries and 1,626 matched controls met study criteria (mean age = 70.4 years, 62% female). The mean (SD) unadjusted Medicare and beneficiary Part A/B payments in the year prior to diagnosis were $23,445.23 (33,646.70) and $4,380.64 (5,064.45) for AV beneficiaries, respectively, and $10,136.05 (19,944.70) and $1,907.44 (3,292.49) for matched controls (Table 1). Adjusted regression analyses revealed that AV beneficiaries had significantly higher Medicare and beneficiary payments for all cost categories, and higher number of all types of utilization events, compared to matched controls ($p< 0.001$). Of note, AV beneficiaries on average incurred an additional $13,726 (95% CI: $11,946-$15,845) in Medicare Part A/B expenditures and had 21.2 (95% CI: 18.3-24.5) more hospital outpatient visits vs. matched controls.

	Descriptive Statistics				Adjusted Regression Model*	
	Beneficiaries without AV N=1,626		Beneficiaries with AV N=1,626

*p<0.001 for all comparisons of AV vs. non-AV beneficiaries
AV: ANCA vasculitis, SD: standard deviation, Q1: quartile 1, Q3: quartile 3, CI: confidence interval

Table 1. Total one-year utilization and costs prior to diagnosis for AV beneficiaries and matched controls

Conclusion: In the year prior to AV diagnosis, Medicare beneficiaries have significantly higher healthcare utilization and costs when compared to age- and sex-matched beneficiaries without AV. This study highlights that pre-diagnosis manifestations in AV can be costly and further improvement may be needed to allow for timely diagnosis.

Rheumatologist's Perception of the Efficacy, Safety and Willingness to Prescribe Infliximab and Use Alternate Drug Supply Programs to Lower Cost of Rheumatoid Arthritis Care

Cesar Galan[1], Alan Puric[2], Guy Cozzi[2], **Michele Hamburger**[3], Elisea Avalos-Reyes[4] and Kjel Johnson[1], [1]CVS Health, Lincoln, RI, [2]CVS Health, Northbrook, IL, [3]Frances Hamburger Institute, Hauppauge, NY, [4]CVS Health, Irving, TX

SESSION INFORMATION

Session Date: Saturday, November 7, 2020
Session Title: Health Services Research Poster
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: There is interest in employing biosimilar therapies for patients with rheumatoid arthritis (RA), which have been shown comparable to originator biologics in safety and efficacy but lower in cost; another strategy is “white bagging” where rheumatologist administered drugs are sent by a specialty pharmacy to the rheumatologist’s office.To date, four infliximab biosimilars are available and various payors have implemented white bagging programs. We assessed what drives rheumatologists to prescribe an infliximab biosimilar and participate in white bagging drug programs.

Methods: We conducted an online cross-sectional survey of hospital and community-based rheumatologists in July 2019 and June 2020. Questions assessed willingness to prescribe biosimilars, the quality, safety and effectiveness of biosimilars compared to originator biologics, what influences a rheumatologist’s decision to prescribe a biosimilar and reasons rheumatologists would not switch from buy-and-bill to white-bagging. We used a Likert scale rating of “Never,” “Seldom,” “Sometimes,” “Often” and “Always.” Descriptive statistics and percentages are reported (n=43).

Results: Rheumatologists reported prescribing an originator biologic drug often or always 58% of the time. When asked to what degree a biosimilar matches the originator biologic in terms of safety, effectiveness and quality, rheumatologists reported the biosimilar as being the same 77%, 74% and 72% of the time, respectively. In spite of this, when asked to report their expected likelihood of prescribing a biosimilar in the future, only 35% of rheumatologists believed they would often or always prescribe a biosimilar. Provided financial equivalence, rheumatologists reported being more likely to prescribe a biosimilar 65% of the time to new patients and 47% of the time to existing patients. The top 3 reasons for prescribing a biosimilar are the patient’s out of pocket cost, cost to the practice and the value of reimbursement, 72%, 67% and 56%, respectively in fee-for-service reimbursement arrangements and 72%, 63% and 51%, respectively, in value-based reimbursement arrangements. When asked why rheumatologists would not switch from buy-and-bill to white-bagging, financial benefit to the rheumatologists’ practice (63%) and control of the drug (58%) were the top 2 reasons.

Conclusion: The majority of rheumatologists in this study reported currently prescribing originator biologics most of the time at their practice. The rheumatologists also perceived biosimilars to be as safe and effective as the originator biologic. Additionally, the surveyed rheumatologists expressed a willingness to prescribe biosimilars in the future, provided income would not be reduced. RA is associated with considerable economic burden; lower-cost biosimilars may provide an opportunity to reduce overall patient and health system costs; white bagging programs are not supported by rheumatologists due to revenue loss and chain of control concerns. Supporting provider income in any cost reduction program is key to program success.

Abstract Number: 0568

Clinical Timelines and Management Delays in Suspected Giant Cell Arteritis

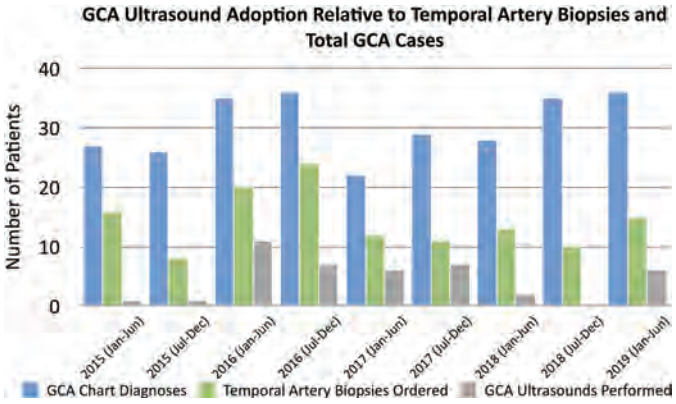
Stephen Slade[1], Cindy Chiu[1], Erin Bauer[1] and Amish Dave[1], [1]Virginia Mason Medical Center, Seattle, WA

SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: Health Services Research Poster
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

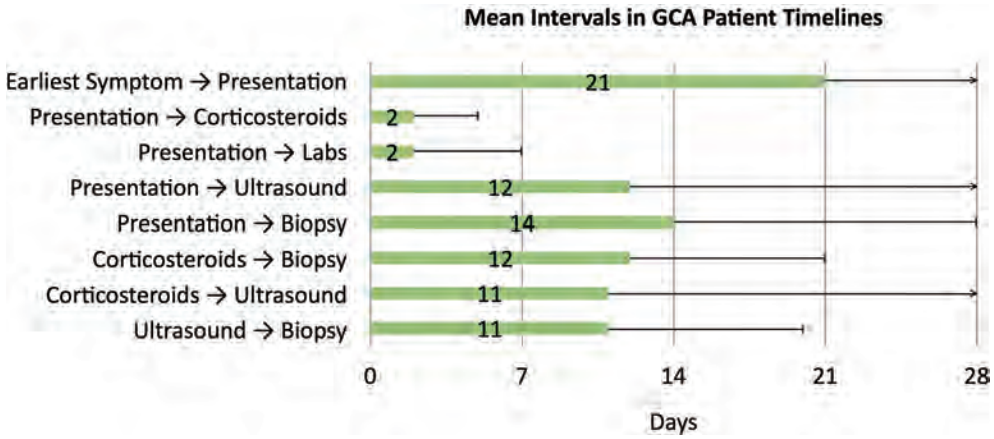
Background/Purpose: Giant cell arteritis (GCA), the most common systemic vasculitis, may have diagnostic and treatment delays that can increase risk of vascular complications. Diagnostic color doppler ultrasound (US) has potential to decrease time to diagnosis, limit corticosteroid exposure, and avoid need for a surgical procedure, all at lower cost than temporal artery biopsy (TAB).

Identification of bottlenecks in patient workup and delays in treatment can guide targeted quality improvement interventions. Our goal was twofold: to determine institutional use of US and TAB and to construct a timeline of key clinical events for patients with suspected GCA.

Methods: All data was obtained from the integrated electronic health record at our community-based multi-site health system from a 4.5-year timeframe starting in 2015 with GCA by International Classification of Diseases-9 or 10 diagnostic codes, and TAB order dates were determined by current procedural terminology codes. Because our outcomes were agnostic to final diagnosis, we did not designate GCA classification criteria for all patients. Using retrospective chart review, we identified dates of milestone events for patients who underwent GCA US: earliest of common GCA symptoms from a predefined list, medical presentation, corticosteroid initiation, inflammatory marker evaluation, US, and TAB.



Comparing US and TAB among 274 patients with new GCA diagnoses, 100 (36%) had TAB only ordered, 29 (11%) had both TAB ordered and had US, and 12 (4%) had US only.



Timeline mean intervals with standard deviation. Symptom onset to presentation 21 ± 43, presentation to corticosteroids 2 ± 3, presentation to labs 2 ± 5, presentation to US 12 ± 23, presentation to TAB 14 ± 14, corticosteroids to TAB 12 ± 9, corticosteroids to US 11 ± 27, and US to TAB 11 ± 9. Time from presentation to US versus TAB was not significantly different (p=0.77).

Where available, we calculated intervals by subtraction of event dates, and where unavailable, approximated based on clinical documentation. Mean durations were rounded to the nearest whole day and excluded negative integers (e.g. patient excluded if prescribed corticosteroids for different indication days prior to presentation with suspected GCA and new, high-dose corticosteroid indication).

Results: Comparing US and TAB among 274 patients with new GCA diagnoses, 100 (36%) had TAB only ordered, 29 (11%) had both TAB ordered and had US, and 12 (4%) had US only. Timeline values were as follows (mean ± standard deviation, in days): symptom onset to presentation 21 ± 43, presentation to corticosteroids 2 ± 3, presentation to labs 2 ± 5, presentation to US 12 ± 23, presentation to TAB 14 ± 14, corticosteroids to TAB 12 ± 9, corticosteroids to US 11 ± 27, and US to TAB 11 ± 9. Time from presentation to US versus TAB was not significantly different (p=0.77). Ten of 37 patients (27%) with calculable corticosteroid dates were not prescribed high-dose empiric corticosteroids within two days of presentation.

Conclusion: Patients with suspected GCA had widely variable times to key events in their clinical courses, including initial presentation. US was used in only a minority of suspected GCA cases. Future work could target interventions to reduce variability in diagnostic access and empiric therapy initiation, such as through a fast-track clinic model.

Abstract Number: 0569

Ability and Willingness to Utilize Telemedicine Among Rheumatology Patients – a Cross Sectional Survey

Steve Kong[1], **Lilian Otalora Rojas**[2], Amnie Ashour[3], Mathew Robinson[1] and Neha Bhanusali[1], [1]University of Central Florida College of Medicine, Orlando, [2]University of Central Florida HCA Healthcare GME, Orlando, [3]Stony Brook University School of Medicine, New York

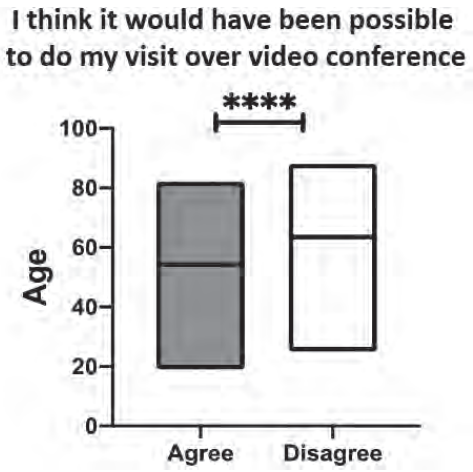
SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: Health Services Research Poster
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Telemedicine (TM) is the delivery of health care services using information and communication technologies. TM presents unique opportunities and benefits specifically in rheumatology as most rheumatic illnesses are chronic requiring frequent disease monitoring, outpatient therapies, and a strong patient-physician relationship. This study aims to assess the patients' ability and willingness to utilize telemedicine along with some of the barriers to a more widespread adoption of TM in rheumatology.

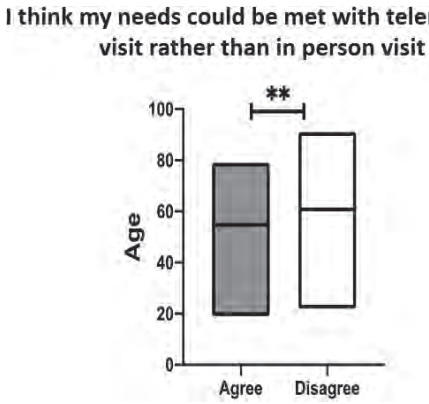
Methods: A cross sectional survey of patients visiting a rheumatology clinic in Florida from March-August 2018 was conducted. We used a Tele-Rheumatology Questionnaire to assess patients' attitude on the effectiveness of TM versus in-person visits, patients' access to technology (telephone, front facing camera, and high-speed internet), distance traveled by the patient to attend the clinic visit, and demographic parameters (age, sex, race, new patient vs follow-up, and diagnosis). Data was analyzed using Statistical Package for Social Sciences and descriptive statistics were calculated.

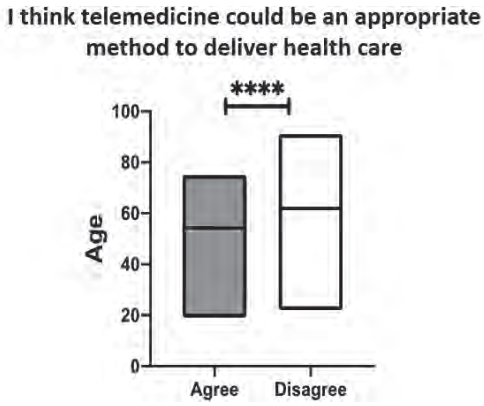
Results: 214 rheumatology patients participated in this study. 82.7% were women and 17.3% were men with an average age of 58.3 ±13.5. We found statistically significant associations between age and the following responses: access to—front facing camera (mean difference -12.8), —telephone (mean difference -14.4), and —stable internet connection (mean difference -15.1); conflict in appointments and work hours (mean difference -11.73); willingness to—utilize telephone consultation (mean difference -3.97) or —live video consultation (mean difference -8.09); —try TM with a new rheumatologists (mean difference -7.82); —try TM with an established rheumatologist (mean difference -11.19); —try TM for other specialties (mean difference -8.16); —try TM to reduce time between appointments (mean difference -10.79).

Follow-up patients were more likely to feel that their visit could have been possible over the phone (mean difference -1.13) or video conferencing (mean difference -1.13) compared to new patients.

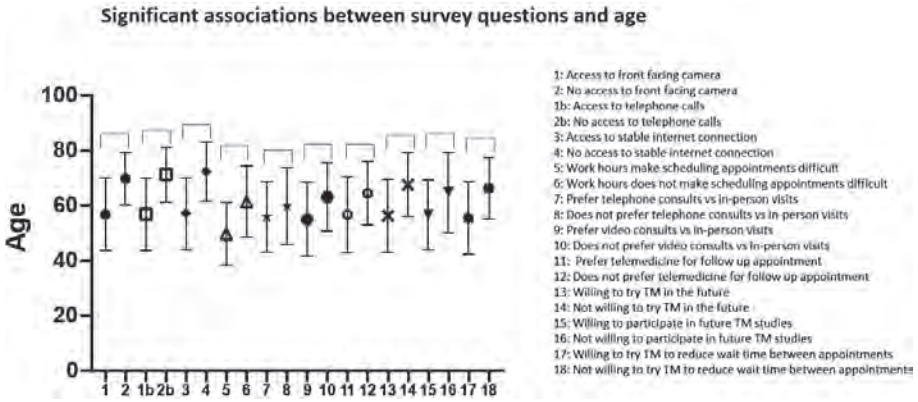


Left: Statistically significant correlation between age and patients who responded that the purpose of the clinic visit could have been possible over telephone, in which a negative correlation of -0.207 ($p=0.003$) was seen. Right: statistically significant correlation between age and patients who responded that the purpose of the clinic visit could have been possible over video conference, in which a negative correlation of -0.333 ($p<0.001$) was seen.





Left: Statistically significant correlation between age and patients who responded that their needs could have been met with telemedicine, in which a negative correlation of -0.224 ($p<0.001$) was seen. Right: Statistically significant correlation between age and patients who responded that telemedicine could be an appropriate method of healthcare, in which a negative correlation of -0.298 ($p<0.001$) was seen.



Statistically Significant correlation between age and "yes and no" questions on the TRQ. The mean difference in age between 1 and 2 = -12.837 ($p<0.001$), between 1b and 2b = -14.417 ($p<0.001$), between 3 and 4 = -15.107 ($p<0.001$), between 5 and 6 = -11.733 ($p<0.001$), between 7 and 8 = -3.973 ($p<0.040$), between 9 and 10 = -8.099 ($p<0.001$), between 11 and 12 = -7.826 ($p<0.001$), between 13 and 14 = -11.193 ($p<0.001$), between 15 and 16 = -8.167 ($p<0.001$), between 17 and 18 = -10.797 ($p<0.001$).

Older patients were less likely to think that the purpose of their rheumatology visits could be achieved over the phone (r-.207, p=0.003) or video conferencing (r -.331, p=0.001). Negative correlations were found between increase in age and believing that their needs could be met through TM (r -.224, p< 0.001) and thinking that TM could be an appropriate alternative method of healthcare (r -.298, P< 0.001).

The further the distance traveled, the more the patients were willing to utilize telephone consultation compared to in-person visits (r 0.167,p=0.019).

Conclusion: With the COVID-19 pandemic, rheumatology clinics are increasingly turning to TM as the main, and sometimes only, method of seeing patients. The results of this study suggest that technology may still be limited in certain demographics, particularly the elderly. This study helps to understand some of the limitations of TM that can be crucial in the development of solutions to make it a better option for all rheumatological patients. Futures studies are needed to evaluate if this sample population felt the same once telehealth was actually utilized.

Abstract Number: 0570

The Patient Perspective on Using Digital Resources to Address Unmet Needs in Systemic Lupus Erythematosus

Jennifer Ra[1], Jerik Leung[2], Elizabeth Baker[2] and Alfred Kim[1], [1]Washington University School of Medicine, St. Louis, MO, [2]Saint Louis University, College for Public Health and Social Justice, St. Louis

SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: Health Services Research Poster
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: The clinical variability of systemic lupus erythematosus (SLE) caused by the unpredictability of flares contributes to patients experiencing a diminished sense of social support. Digital health interventions (DHI) – interventions accessible through digital technologies (i.e. apps, internet) on devices such as mobile phones, tablets, and computers – have the potential to improve this eroded social support. Digital resources have shown to improve disease self-management and health-related quality of life in other chronic diseases like rheumatoid arthritis and chronic pain. However, DHIs for SLE have yet to be studied extensively. Our objective was to assess: 1) general and SLE-specific internet usage and 2) specific suggestions for SLE-related digital resources and tools among SLE patients at the Washington University Lupus Clinic.

Methods: Fifty-six patients with American College of Rheumatology or Systemic Lupus International Collaborating Clinics classified SLE were recruited from the Washington University Lupus Clinic. Because SLE affects mostly women, only female patients were considered. No other specific characteristics were sought.

Ten-minute structured interviews were conducted. Multiple choice questions assessed internet access, types of devices used to access the internet, how patients currently use the internet for their SLE, what topics they would be interested to see in the future, and demographics. Open-ended questions assessed what other SLE-related information or support they would like to use the internet for and what would make them more likely to use it for their SLE needs. Descriptive statistical analysis was conducted with the quantitative data, while the qualitative data was analyzed using an open coding approach, where similar or recurring responses were categorized into themes and subthemes.

Results: Nearly all respondents indicated having access to the internet (98.2%, n=55). Currently, 80.0% (n=44) use the internet to locate SLE-related information, all of whom were interested in continuing or increasing this use. Participants indicated that they were interested in most topics presented (i.e. connecting with other SLE patients, nutrition and SLE, new/alternative treatments). The qualitative data indicated that SLE patients: 1) used the internet for understanding flares, changes in their symptoms, and/or lab results; 2) wanted a greater variety of SLE information; 3) wanted to exchange personal experiences and knowledge of SLE with others; and 4) desired increased diversity in the methods of delivering digital SLE information.

Conclusion: Our findings indicate that patients were not only already using the internet for their SLE, but also eager to provide suggestions to improve current digital resources. A primary suggestion from patients was a desire for dynamic, interactive resources that would enable patients to access content according to the symptomatology they are experiencing. Other considerations include developing interventions that are customizable to the patient and provide SLE information that is consistent with that received from their healthcare providers. We believe that our findings will aid future development of DHIs for SLE patients.

Abstract Number: 0571

Improving Care for Patients with Inflammatory Arthritis by Enabling Physical Therapists to Directly Refer to Rheumatologists: A Qualitative Study

Debbie Ehrmann Feldman[1], Tatiana Orozco[1], Sasha Bernatsky[2], François Desmeules[1], Jean Légaré[3], Kadija Perreault[3], Andrews Kwabena Tawiah[4], Linda Woodhouse[5], Michel Zummer[6] and Anne Hudon[7], [1]Université de Montréal, Montreal, QC, Canada, [2]The Research Institute of the McGill University Health Centre, Montreal, ON, Canada, [3]Université Laval, Québec, QC, Canada, [4]University of Alberta, Edmonton, AB, Canada, [5]Curtin University, Perth, Australia, [6]CH Maisonneuve-Rosemont, Montreal, Canada, [7]Université de Montréal, Montreal, Canada

SESSION INFORMATION

Session Date: Saturday, November 7, 2020

Session Title: Health Services Research Poster

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: Early referral to rheumatology of persons with suspected inflammatory arthritis is associated with better outcomes. Typically, patients are first seen by a family physician who assesses the need for referral to a rheumatologist. However, many people who do not have a regular family physician may consult a physical therapist where no physician referral is required. Enabling direct referral from a physical therapist to a rheumatologist could enhance early access to a rheumatologist; recent evidence indicates that physical therapists can appropriately identify patients with inflammatory arthritis. Our objective was to explore perceptions of professionals and patients regarding enabling physical therapists to refer patients with inflammatory arthritis directly to rheumatologists.

Methods: We conducted 5 focus groups with a total of 29 participants. There were 4 homogeneous groups with: 1) 5 rheumatologists, 2) 7 family physicians, 3) 6 physical therapists and 4) 6 patients. The fifth group was mixed and included 3 physical therapists and 2 patients. We used purposive and snowball sampling to recruit participants. All 8 patients with inflammatory arthritis were recruited via the Canadian Arthritis Society. Meetings were audio-taped and transcripts were analyzed using thematic analysis.

Results: Two common core themes were identified from all focus groups: 1) difficulties accessing care, and 2) interprofessional relationships. The first theme included aspects such as waiting times to consult rheumatologists and physical therapists in the public sector, as well as financial barriers related to consulting physical therapists in the private sector. The second theme included perceptions of physical therapists' roles and abilities, appropriateness of referrals, multidisciplinary vs. solo practitioners, communication pathways and traditionalist vs. contemporary style of practice by family physicians. Besides these two main themes, several groups discussed other issues. The health care groups (rheumatologists, family physicians and physical therapists) talked about lack of awareness of the new agreement that physical therapists can directly refer to rheumatologists. In the physician groups, 2 other issues were discussed: professional responsibilities (e.g. scope of practice, gatekeeping and coordination of care) and the consult fee for rheumatologists. In the physical therapist focus group, self-confidence in identifying inflammatory vs. non-inflammatory conditions was also raised.

Conclusion: Regarding difficulties accessing care, waiting time to see a rheumatologist remains the biggest barrier for patients with new-onset inflammatory arthritis followed by the lack of access to physical therapists and family physicians. Further developing the relationship among the health professionals involved with these patients could optimize patient care. This could be done through education about everyone's role, building efficient communication pathways and creating opportunities for interprofessional connections. In addition, professional regulatory bodies

should increase awareness about the new agreement regarding direct referral by physical therapists to rheumatologists.

Abstract Number: 0572

Two-year Cost-effectiveness Between Two Gradual Tapering Strategies in Rheumatoid Arthritis: Cost-utility Analysis of the TARA Trial

Elise van Mulligen[1], Angelique Weel[2], Mieke Hazes[3], Annette van der Helm - van Mil[4] and Pascal de Jong[1], [1]Erasmus MC, Rotterdam, Netherlands, [2]Erasmus School of Health Policy & Management, Maasstad hospital, Erasmus MC, Rotterdam, Netherlands, [3]Erasmus Medical Center, Rotterdam, Netherlands, [4]Leiden University Medical Center, Erasmus Medical Center, Leiden, Netherlands

SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: Health Services Research Poster
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: The benefits of tapering are a decreased risk of long-term adverse events and a reduction of health care costs, especially when bDMARDs are tapered. However, tapering treatment may lead to more transient or persistent disease flares, which have a direct impact on patients' lives and societal costs. We aimed to evaluate the two year cost-utility ratio between tapering the csDMARD first followed by the TNF-inhibitor, and tapering the TNF-inhibitor first followed by the csDMARD.

Methods: The TARA trial is a multicenter single-blinded randomized controlled trial. RA patients that used a csDMARD(s) plus a TNF-inhibitor and who had a well-controlled disease for at least 3 months, defined as a DAS≤2.4 and a swollen joint count (SJC) ≤1, were included. Patients were randomized into gradual tapering their csDMARD in the first year followed by the TNF-inhibitor in the second year, or vice versa. Medication was tapered in three steps over the course of 6 months. Gradual tapering was done by cutting the dosage into half, a quarter and thereafter it was stopped. Data on quality adjusted life years (QALYs, measured with the Dutch EuroQol [EQ5D]), health care costs and productivity costs were used to calculate the Incremental Cost Effectiveness Ratio (ICER). The ICER, the cost-effectiveness acceptability curve (CEAC), and the incremental net monetary benefit (iNMB) were used to assess cost-effectiveness between both tapering strategies.

Results: Of the 189 included patients, 94 started tapering their TNF-inhibitor first, while the other 95 tapered their csDMARD first. QALYs (sd) were, respectively, 1.64 (0.22) and 1.65 (0.22). Medication costs were significantly lower in the patients who tapered the TNF-inhibitor first, while indirect cost were higher due to more productivity loss (p=0.10). Therefore, total costs (sd) were €38,833 (€39,616) for tapering csDMARDs first, and €39,442 (€47,271) for tapering the TNF-inhibitor first (p=0.88). The ICER (95% CI) between tapering csDMARDs first minus the TNF-inhibitor first was €60,919 per QALY (95% CI, -€90,638 per QALY to €212,475 per QALY)(figure 1). The iNMB was €1134 (95% CI €761 to €1507) in favor of tapering TNF-inhibitor first for a willingness-to-pay (WTP) level of €50,000, which is the current level of WTP in the Netherlands for treatment of RA (figure 1). According to the CEAC, for WTP levels < €53,800 tapering the csDMARD first has the highest probability of being cost-effective, while for WTP levels >€83,800 tapering the TNF-inhibitor first has the highest probability (figure 2).

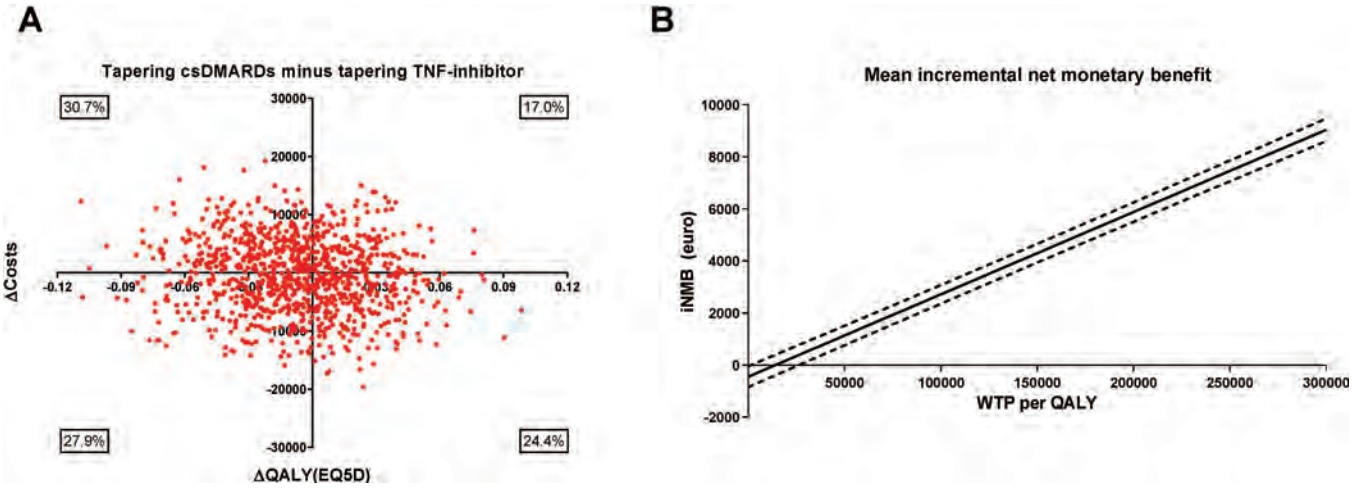

Figure 1. Summary of economic evaluation of tapering csDMARDs first minus tapering TNF-inhibitor first. (A) Results of 1000 bootstrapped replications, presented in a cost-effectiveness plane which represents uncertainty of the cost-effectiveness ratio. (B) Mean incremental net monetary benefit (iNMB) for tapering csDMARDs minus tapering TNF-inhibitors with 95% confidence intervals plotted against different levels of willingness to pay (WTP) per quality adjusted life year (QALY). The iNMB was calculated as the incremental benefit times different levels of WTP, minus the incremental costs. csDMARDs: conventional synthetic DMARDs; iNMB: incremental net monetary benefit; QALY: quality adjusted life year; WTP: willingness to pay.

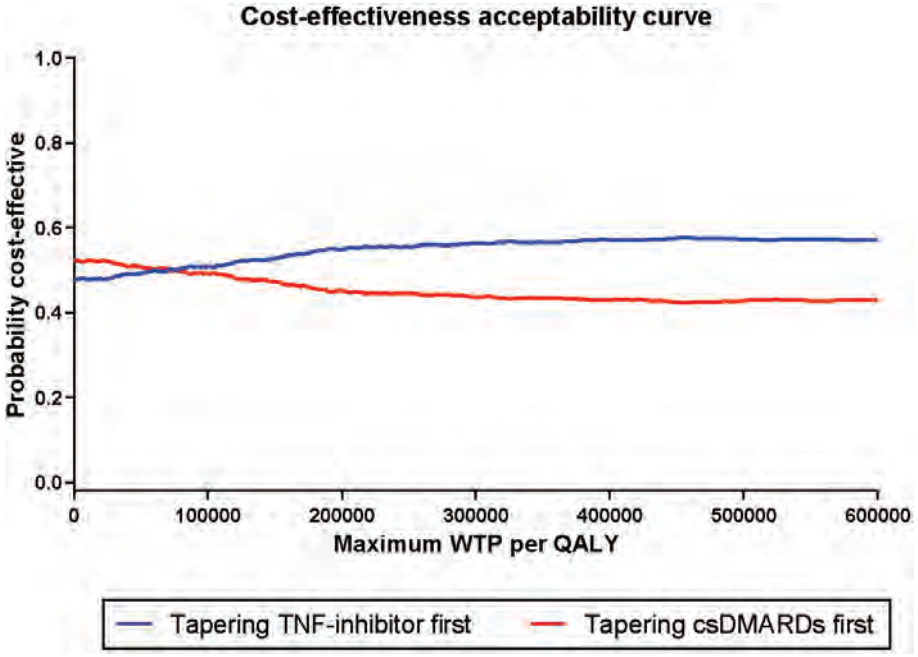

Figure 2. Cost effectiveness acceptability curve for tapering csDMARDs first versus tapering TNF-inhibitor first. Results of 1000 bootstrapped replication, presented for several levels of willingness to pay, indicated per quality adjusted life year (QALY). csDMARDs: conventional synthetic DMARDs; QALY: quality adjusted life year; WTP: willingness to pay.

Conclusion: Our economic evaluation shows that costs are similar for both tapering strategies. Depending on the WTP threshold, either tapering the TNF-inhibitor first or csDMARD first has the highest probability of being cost-effective.

Abstract Number: 0573

Effects of Successive Switches of Two Different Biosimilars of Etanercept on Outcomes in Inflammatory Rheumatic Diseases in Daily Practice

Uta Kiltz[1], Styliani Tsiami[2], Xenofon Baraliakos[1] and Juergen Braun[1], [1]Rheumazentrum Ruhrgebiet, Ruhr-University Bochum, Herne, Germany, [2]Rheumazentrum Ruhrgebiet Herne, Ruhr-University Bochum, Herne, Germany

SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: Health Services Research Poster
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: A single *switch* from an originator to a *biosimilar* product has been shown to be safe and effective in the treatment of rheumatic musculoskeletal diseases (RMDs). The availability of biosimilars has created a financial incentive to encourage switching to cheaper products ("non-medical switch"). This is naturally associated with multiple switches. However, the effect of multiple switching between biosimilars of the same reference product has not been thoroughly investigated to date. To assess the effectiveness and safety of systematic non-medical switching from innovator etanercept (ETN) to biosimilar ETN (SB4) and successive to another biosimilar ETN (GP2015) in adult patients with rheumatoid arthritis (RA), psoriatic arthritis (PsA) or axial spondyloarthritis (axSpA) in a real-life setting.

Methods: This retrospective study was performed in a tertiary center in adult patients with RA, PsA or axSpA who had been treated with the innovator ETN and who had been switched to two ETN biosimilars for economic reasons thereafter. The first switch from innovator ETN to the first biosimilar ETN occurred between February-May 2017 and the second switch from the first to the second biosimilar ETN occurred between September-December 2017. The end of the observation period was October 2019. Disease activity, function and adverse events (AE) were regularly assessed, and any changes in outcome were recorded during the follow-up period. The scores documented at week 12 week after the second switch were taken as primary outcome.

Results: A total of 100 patients (54 RA, 27 axSpA, 19 PsA, mean age 54.3±15.1, 46% male) who switched twice to those ETN biosimilars over a follow-up period of 21.1±7.4 months were included. The retention rate after the second ETN biosimilar switch was 89% about 6 months after the second switch. While 2 patients were lost to follow-up and 1 patient died (cardiac arrest), 7 patients discontinued due to inefficacy or AE, including one pancreatic cancer.

	Assessment	Baseline (n=100)	SB4 Follow-up 12 weeks (n=100)	SB 4 Follow-up 24 weeks (n=100)	Second switch to GP2015 (n=100)	GP2015 Follow-up 12 weeks (n=97)	GP2015 Follow-up 24 weeks (n=89)
RA	DAS28	3,0 (1,2)	2,9 (1,4)	3,1 (1,2)	2,8 (1,4)	3,4 (2,5)	3,0 (1,4)
	HAQ	1,4 (0,8)	1,6 (0,9)	1,0 (0,9)	1,5 (0,8)	1,5 (0,8)	1,6 (0,9)
PsA	DAS28	3,8 (1,4)	1,9 (1,4)	2,8 (1,5)	3,1 (1,1)	4,5 (2,6)	3,6 (2,6)
	HAQ	1,2 (0,9)	1,0 (0,9)	0,9 (0,9)	1,0 (0,8)	1,0 (0,9)	1,2 (0,8)
axSpA	BASDAI	5,1 (2,7)	4,5 (2,6)	5,1 (3,8)	4,1 (2,2)	4,6 (2,5)	4,3 (2,4)
	ASDAS	3,4 (0,8)	2,5 (0,8)	2,7 (0,8)	3,2 (1,8)	2,7 (1,2)	2,5 (0,9)
	BASFI	4,4 (2,7)	4,3 (2,7)	4,3 (3,2)	4,6 (2,6)	4,5 (2,7)	4,8 (3,0)

*Values are mean ± standard deviation

One patient was withdrawn due to pregnancy. Overall, 14 AEs were reported in 8 patients. Among them, 4 patients switched back to originator etanercept in month 6, 1 patient re-administered GP2015 successfully in month 3 after suffering from mucosal erosions and in 3 patients another mode of action was prescribed. The scores at week 12 of both, disease activity and function, remained unchanged (Table 1).

Conclusion: The retention rate after multiple switches from innovator ETN to two ETN biosimilars was close to 90%. No major changes in disease activity and function were observed in all three indications.Table 1: Patient characteristics

Abstract Number: 0574

Is Hydroxychloroquine Use a Proxy for Health Care Access? Predictors of First Dispensing Among Medicaid Beneficiaries with Incident Lupus

Katherine Pryor[1], Chang Xu[1], Jamie Collins[1], Karen Costenbader[2] and Candace Feldman[1], [1]Brigham and Women's Hospital, Boston, [2]Brigham and Women's Hospital and Harvard Medical School, Boston, MA

SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: Health Services Research Poster
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Hydroxychloroquine/chloroquine (HCQ/CQ) is considered to be the backbone of systemic lupus erythematosus (SLE) care. Differences in receipt of HCQ/CQ may exacerbate disparities in adverse events, as well as bias observational studies examining the association between HCQ/CQ use and outcomes. We investigated factors associated with first dispensing of HCQ/CQ among individuals with incident SLE. We hypothesized that individuals receiving HCQ/CQ may have better health care access, as measured by outpatient visits and preventive care (e.g., cancer screening and vaccinations), and fewer comorbidities.

Methods: Using Medicaid claims from 2000-2006 (47 states) and 2007-2010 (29 states), we identified individuals age 18-65 years with incident SLE (≥3 SLE ICD-9 codes separated by ≥30 days within 24 months. We required 24 months of continuous enrollment without SLE codes and without HCQ/CQ use prior to the first SLE code (index date). The primary outcome was the first dispensing of HCQ/CQ on or within 24 months of the index date. We used Cox proportional hazards regression models to examine the association (HR, 95% CI) between baseline sociodemographic factors, comorbidities, health care utilization, preventive care and medication use and time to first HCQ/CQ dispensing in the first 24 months following SLE diagnosis.

Results: We identified 9560 Medicaid beneficiaries with incident SLE; 41% received HCQ (N=3949) or CQ (N=14) within 24 months of diagnosis. The mean age was 35.7 (SD 11.7) years for HCQ/CQ users and 39.9 (SD 12.2) years for non-users. Seventy-two percent received any glucocorticoids within 24 months of diagnosis; of these, 51% also received HCQ/CQ. Cox models demonstrated that younger patients (age 18-25) were 2.3 times more likely to receive HCQ/CQ compared with 51-65 year-olds (**Table 1**). All racial/ethnic groups were more likely to receive HCQ/CQ than whites. Alcohol use disorder, opioid use, diabetes, end-stage renal disease and smoking were associated with a lower rate of dispensing. Receiving 1-2 preventive care services was associated with 29% higher rate of receipt; ≥2

Heath Care Utilization (ref=none)	
• 1-5 Outpatient visits	1.08 (0.99-1.18)
• >5 Outpatient visits	**1.10 (1.00-1.21)**

with a 46% higher rate. Individuals with more outpatient visits were more likely to receive HCQ/CQ while those with more hospitalizations were less likely.

Conclusion: HCQ/CQ use is central to SLE treatment however only 41% of Medicaid beneficiaries with SLE received HCQ/CQ within 2 years of diagnosis. Preventive care and outpatient visits, markers of access to health care, were associated with higher rates of initial HCQ/CQ dispensing, whereas frequent hospitalizations, high-risk lifestyles and complex comorbidities were associated with lower rates. All non-white races had higher rates of first dispensing

compared to whites suggesting that in this Medicaid population, initial HCQ/CQ dispensing differences likely do not explain racial/ethnic disparities in adverse outcomes. Overall these findings suggest that we must cautiously interpret potential physiologic effects of HCQ/CQ on outcomes in observational studies comparing users to non-users as they may be biased by differences in access to care and measured and unmeasured confounders.

Abstract Number: 0575

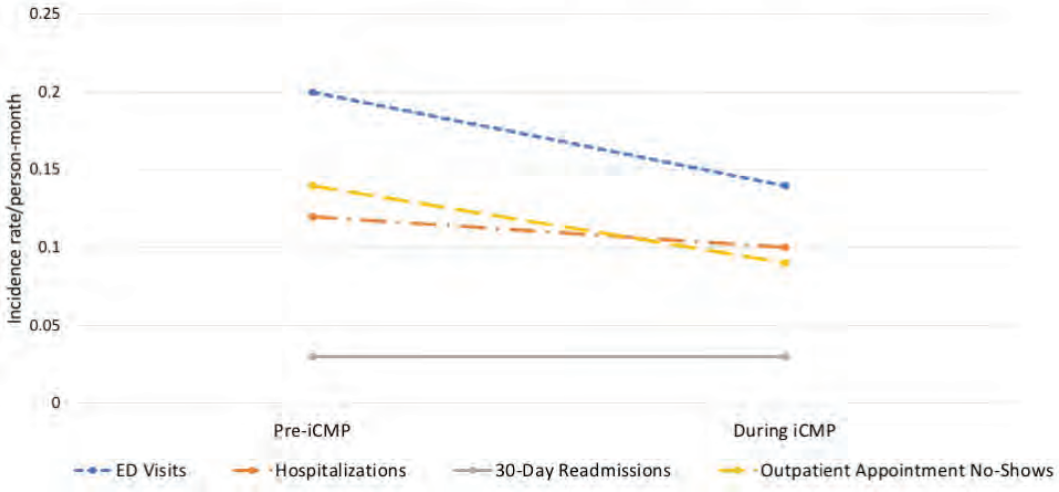
The Impact of an Integrated Care Management Program on Acute Care Utilization and Outpatient Appointment Attendance Among High-Risk Patients with Lupus

Jessica Williams[1], Weixing Huang[2], Jamie Collins[3], Kreager Taber1, Katherine McLaughlin[1], Rebecca Cunningham[1], Christine Vogeli[4], Lisa Wichmann[1] and Candace Feldman[3], [1]Brigham and Women's Hospital, Boston, MA, [2]Division of Rheumatology, Inflammation, and Immunity; Brigham and Women's Hospital and Harvard Medical School, Boston, [3]Brigham and Women's Hospital, Boston, [4]Massachusetts General Hospital, Boston, MA

SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: Health Services Research Poster
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Patients with systemic lupus erythematosus (SLE) are often members of disadvantaged groups and some struggle with high acute care utilization and missed outpatient appointments. An integrated care management program (iCMP) was established at our multihospital system whereby nurses lead care coordination efforts for patients considered high risk for frequent emergency department (ED) visits and hospitalizations. We aimed to determine whether this program was effective at decreasing acute medical care use and outpatient no-show rates among patients with SLE.

Figure. Rates of Medical Care Utilization and Outpatient Appointment No-Shows Among High-Risk Patients with SLE Before and During iCMP



Methods: The top two percent of medically and psychosocially complex patients within our multihospital system are enrolled in iCMP – a longitudinal primary care-embedded care management program. We used a validated electronic health record (EHR) machine learning algorithm (PPV 90%) to identify adults ≥18 with SLE enrolled in iCMP from January 2012-February 2019 and verified the diagnosis with EHR review. We used EHR data linked to insurance claims to compare the incidence rates of ED visits, hospitalizations, 30-day readmissions, and outpatient appointment no-shows during iCMP enrollment to the 12-months prior. We used Poisson regression to examine the incidence rate ratios (IRR) during versus pre-iCMP enrollment for each of these utilization measures, adjusting for age, sex, race/ethnicity, number of comorbidities and calendar year of entry, accounting for within-patient clustering.

Results: We identified 67 iCMP enrollees with SLE and linked EHR-claims data. Fifty-five met 1997 ACR criteria for SLE, 9 met 2012 SLICC criteria, and 3 did not meet criteria but were diagnosed and treated by a rheumatologist. The mean duration of iCMP enrollment was 46 (SD 29) months. The mean age was 60 (SD 17) years and 93% were female. Enrollees were 55% white, 25% black, 16% other race and 3% Asian, and 21% were Hispanic. Twenty patients had commercial insurance, 59 had Medicare, 4 had Medicaid and 16 had ≥1 one insurance. The rate of ED visits averaged 0.14/person-month during iCMP enrollment compared to 0.20/person-month pre-iCMP (IRR 0.66, 95% CI 0.48-0.92, p=0.01), the rate of hospitalizations averaged 0.10/person-month during iCMP compared to 0.12/person-month pre (IRR 0.89, 95% CI 0.64-1.24, p=0.5), and the rate of outpatient appointment no-shows was 0.09/person-month during iCMP compared to 0.14/person-month pre (IRR 0.74, 95% CI 0.57-0.97, p=0.03); see **Figure**. After adjusting for demographics, enrollment year, comorbidities, and repeated measures, there was a 37% reduction in the rate of ED visits during iCMP compared to the year prior (p=0.003) and trends towards reduced hospitalizations (IRR 0.88, 95% CI 0.65-1.19, p=0.39) and fewer missed appointments (IRR 0.80, 95% CI 0.62-1.04, p=0.097).

Conclusion: In a single arm, pre-post observational study, we found that a nurse-led, primary care-based integrated care management program appeared effective at decreasing the rate of ED visits for high-risk SLE patients and likely also reduced rates of missed appointments. Further studies are needed to determine the root causes of high utilization patterns for vulnerable patients and to develop strategies to comprehensively address these issues.

Medical Savings of Timely Rheumatoid Arthritis Diagnoses

Kathryn Johnson[1], Christine Sawicki[1], Cristina Sotelo[2], Tanvi Kalevar[3], Sylvie Lardeux[4], Fabio Casadio[3], David Baghdadi[5], **Michele Hamburger**[6], Elisea Avalos-Reyes[7] and Kjel Johnson[1], [1]CVS Health, Lincoln, RI, [2]CVS Health, Austin, TX, [3]CVS Health, New York, NY, [4]CVS Health, Wellesley, MA, [5]CVS Health, Woonsocket, RI, [6]Frances Hamburger Institute, Hauppauge, NY, [7]CVS Health, Irving, TX

SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: Health Services Research Poster
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Previous studies suggest that early rheumatoid arthritis (RA) recognition and treatment provides greater clinical benefits than treatment started later in the disease course. However, the impact of early treatment initiation on the total cost of care in RA patients has not been well studied. Additional data on the clinical and economic impact of RA in the US are required to provide better information for healthcare and health policy deci-

Table 1. Demographic Characteristics of Newly Diagnosed RA Patients in 2019.

sion-making. The purpose of this study was to determine the medical cost savings of a timely RA diagnosis 6 months pre-and post-diagnosis.

Methods: This retrospective cohort study evaluates newly diagnosed RA patients insured by a large commercial and Medicare health plan in the United States between January 1, 2019 and December 31, 2019. We defined a "late" RA diagnosis as a patient diagnosed for the first time as part of an emergency department (ED)/inpatient (IP) setting as these patients likely had symptoms of RA prior to this visit but were not properly diagnosed. We defined a "timely" RA diagnosis as a patient diagnosed for the first time in an in-office setting. We defined newly diagnosed as a patient who had medical insurance but no paid claim for RA for at least six months before the initial claim with an RA diagnosis. We defined diagnosis in the ED/IP setting as patients with their first RA claim in an ED/IP setting. A Targeted Likelihood Estimation Model (TMLE) was used to assess relationships between patient characteristics and the total cost of care per member (PM) 6 months before and 6 months after diagnosis.

Results: The study included 42,350 patients with a new RA diagnosis in 2019, the majority were female (69.3%) and the mean age was 59.4 years (SD = 16.8). Ten percent of the new RA cases were diagnosed in an ED/IP setting (late diagnosis). The total cost of care 6 months pre-diagnosis was driven by an increase in ED costs (a $418 PM over 6 months increase for commercial patients (p< 0.001) and a $547 PM over 6 months increase for Medicare patients (p<

	Commercial	Medicare
Total Spend (6 months pre-diagnosis)	**$2,676**	**$2,512**
Inpatient	$2,712	$1,341
Emergency Room	$418	$547
Pharmacy	$271	-$34
Office visits	$34	$151
Lab	-$24	$47
Other	-$734	$460
Total Spend (12 months 6 pre and 6 post-diagnosis)	**$4,055**	**$1,670**
Inpatient	$2,220	$1,074
Emergency Room	$1,261	$353
Pharmacy	$13	-$52
Office visits	$102	$33
Lab	-$41	-$43
Other	$443	$306

Total spend calculated as total cost of newly diagnosed in an ED/IP setting – newly diagnosed in other settings.
Targeted Likelihood Estimation Model (TMLE) was used to assess total spend and adjusted for risk score and demographic characteristics.

Table 2. Total Spend Differences Between Patients Diagnosed in an ED/IP Setting and Patients Diagnosed in Other Settings by Type of Insurance

0.001)) and IP costs (a $2,712 PM over 6 months increase for commercial patients (p< 0.001) and a $1,341 PM over 6 months increase for Medicare patients (p< 0.001)). After adjusting for risk score and demographic characteristics, the adjusted total cost of care PMPY for new RA patients diagnosed in an ED/IP setting was higher than new RA patients diagnosed in other settings by a $4,055 PM over 12 months increase (p< 0.01) in commercial patients and a $1,670 PM over 12 months increase (p< 0.01) in Medicare patients. Most of the increase in cost occurred during the 6 month period pre-diagnosis, there was no significant difference in total cost of care in the 6 month post-diagnosis period.

Conclusion: In this study, a late RA diagnosis was associated with a significantly higher total cost of care, compared to a timely RA diagnosis; a trend that was observed for both commercial and Medicare patients. Newly diagnosed RA patients in an ED/IP setting spent significantly more on IP and ED costs prior to their RA diagnosis. Future studies are needed to identify and predict patients at risk of developing RA to reduce unnecessary healthcare costs of a delayed diagnosis.

Abstract Number: 0577

Qualitative Review of Unsuccessful Pilot Study of Super-Utilizer Systemic Lupus Erythematosus (SLE) Patients Enrollment into Team Based Program to Improve Patient Outcomes

Sarah Min[1], Devy Setyono[2], Sunghye Kim[3], Feben Girma[1], Melanie Martin[1] and Rachel Wolfe[1], [1]Wake Forest Baptist Medical Center, Winston-Salem, NC, [2]Emkey Arthritis and Osteoporosis Clinic, Wyomissing, PA, [3]W.G. Hefner VA Medical Center, Salisbury, NC

SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: Health Services Research Poster
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: SLE is a chronic multi-system autoimmune disease, affecting mostly women of child-bearing age and more racial minorities, with a wide spectrum of outcomes: from long-standing remission to frequent flares and mortality. Although survival rate of SLE has improved, healthcare utilization among SLE patients is still high, including hospitalizations. Our internal data indicate that 30-day readmission rate among SLE patients is 28%. CarePlus is a team-based primary care for healthcare super-utilizers at Wake Forest Baptist Medical Center (WFBMC). The objective of the initial pilot study was to test if team-based care through CarePlus with comprehensive services (i.e. mental health care, medication education, social assistance and patient hotline) would help reduce healthcare utilization of those SLE patients with the highest utilization (>3 admissions/ED visits in 18 months). Their primary rheumatologists contacted each patient to determine interest in enrollment in the CarePlus program. Only those interested at that time were included in the pilot study. The initial study was prematurely discontinued due to difficulty of contacting patients, scheduling, and no showing to appointments. The aim of this study was to characterize patient factors in declining CarePlus and barriers to attending the initial CarePlus appointment.

Methods: In the initial pilot study, a cohort of patients with SLE were identified as healthcare super-utilizers and 12 agreed to be scheduled with CarePlus. For those 12 patients, demographics were obtained via chart review.

Study-eligible SLE patients were interviewed over the phone about reasons for declining CarePlus and barriers to attending the initial appointment.

Results: Median age was 44 years (range 27-64) with 92% female. Thirty-three percent were Caucasian, 50% African-American, and 17% Hispanic. Two-thirds had previously no-showed to rheumatology appointments. Three patients were successfully enrolled in CarePlus (only 1 during the 5 month study enrollment period). All 3 enrolled patients live in the county in which the clinic is located or adjacent county; the 8 patients who did not enroll lived further out of these counties. Of the 9 patients who did not enroll, eight patients could be contacted and interviewed. Factors in declining CarePlus and barriers to attending appointments included: personal health issues (3), did not want to switch primary care physician (2), transportation (2), and forgetfulness (2). Subsequent to the interview, two patients still wanted to enroll in CarePlus.

Conclusion: The qualitative review of the factors that led patients to fail to establish in the CarePlus program provides new insights into how to better structure a patient-centered home for our SLE healthcare super-utilizers. Specific factors such as the established relationship with their current primary care doctors and proximity to the clinic were limitations to our study's enrollment. The recent increased implementation of telemedicine may be a unique and helpful tool in developing a more effective team-based approach for the care of SLE super-utilizers in the future especially to address the barriers noted in this particular study.

Going Digital Due to COVID 19 Crisis: A Rapid Reorganisation of Medication Clinics

Rian Penford[1], Angela Reith[1], Elaine Wren[1] and **Kirsten Mackay**[1], [1]Torbay and South Devon NHS Foundation Trust, Torquay, United Kingdom

SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: Health Services Research Poster
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Until the COVID 19 crisis we initiated DMARD(s) and Biologic therapies using shared medical clinics. More than 30 patients could seen per week, with a maximum of 6 per group, for each different medication to be started, (see fig 1). This allowed us to manage the increase in workload, and start patients efficiently on their medications, both safely, and within 10 working days. This took 3-4 hours per week of Rheumatology nurse time.

However, with the onset of the pandemic, we had to stop these clinics immediately, but, we did not have capacity to start everyone on their medications in a timely manner by telephone. Telephoning each individual took > 9 hours per week.

Methods: We scripted and organised the filming of 10 short healthcare videos very rapidly (www.torbayandsouthdevon.nhs.uk), to give patients all the information they required to start a range of DMARDs and biologics.

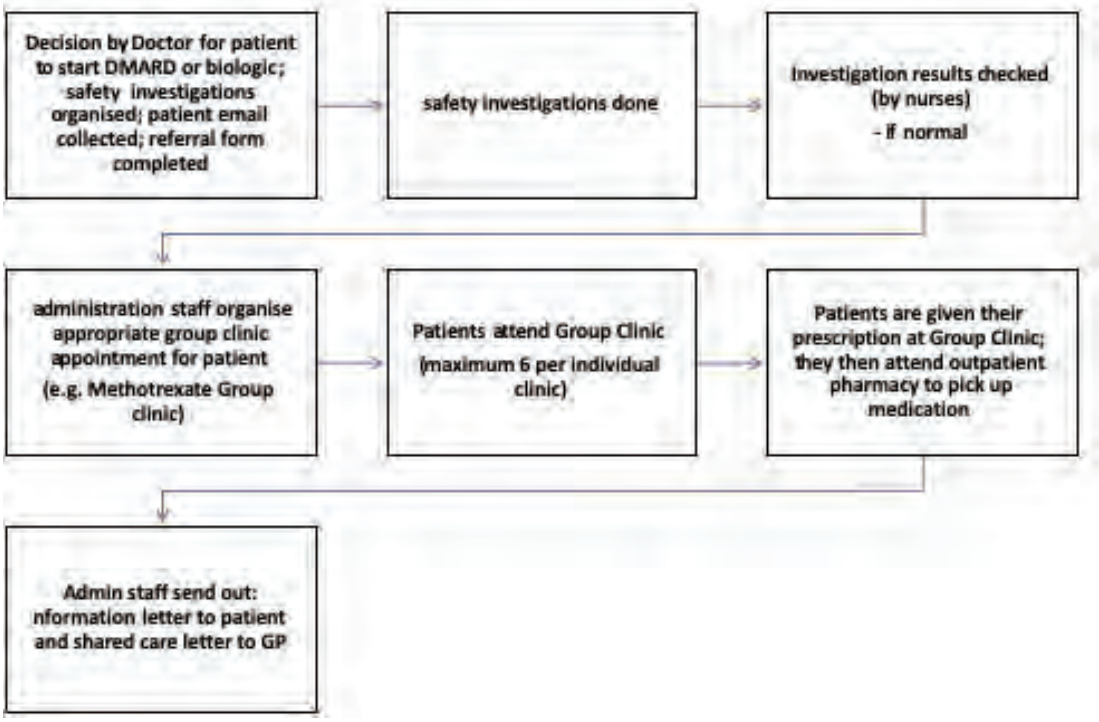

Figure 1. Our original Shared Medical Appointment Approach to start DMARDs and Biologics

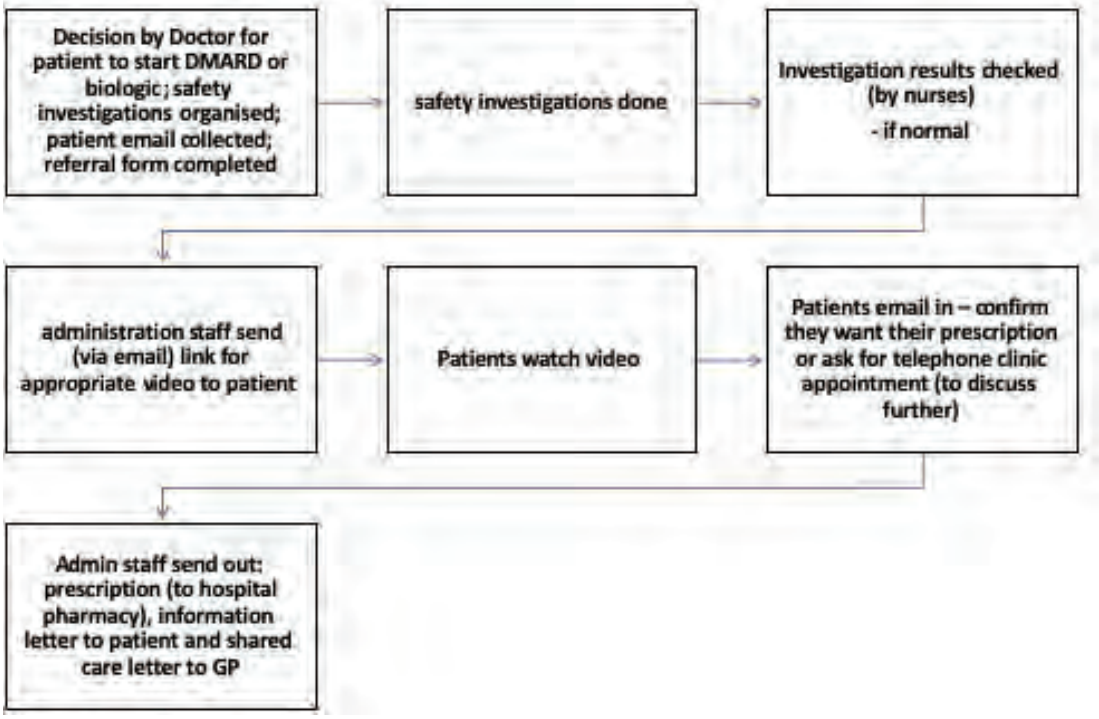

Figure 2. Our digital solution for medication clinics

We developed a new algorithm (Fig 2) and now patients are asked to view the relevant video, contact our department to confirm they understand the safety monitoring, risks, potential side effects, dose increases etc. As soon as they confirm by email they are happy to start treatment, a prescription is generated and emailed to the hospital outpatient pharmacy, where it is dispensed and delivered to the patient's home (usually within 3 working days). We also send

them a follow up reminder letter about blood test monitoring etc (with copy to their GP) and a 'shared care agreement' to their GP. Alternatively, if they are uncertain about anything, we organise for them to have a telephone clinic appointment with a specialist nurse.

Results: Of those requiring DMARDs, 55% reviewed the video, completed the checklist and confirmed by email they were happy to start treatment, within 24-hours. A further 26% completed the process within 3 days.

Almost half the patients (48%) were starting DMARDs for the first time, of those 8% requested a telephone consultation to discuss treatment further with the Rheumatology nurses. None of the patients already taking a DMARD and due to start a second medication required a telephone clinic appointment.

As this is a new service, we asked for feedback, receiving replies from 26%, all scoring between 9/10 and 10/10.

Conclusion: This has altered the way we work and we will continue with this approach over the long term. It has reduced the necessity for face-to-face appointments, enabled us to start patients on their rheumatology medications more quickly and efficiently than previously, allowed the nursing staff time to spend more time working in our telephone clinic and we have had excellent feedback. Although, we are aware, this is at a cost of no peer-to-peer interaction, which has been of value in the past.

Risk Factors of Nonadherence in New Rheumatoid Arthritis Patients

Guy Cozzi[1], Pavlo Kyrychenko[2], **Michele Hamburger**[3] and Elisea Avalos-Reyes[4], [1]CVS Health, Northbrook, IL, [2]CVS Health, Norhtbrook, IL, [3]Frances Hamburger Institute, Hauppauge, NY, [4]CVS Health, Irving, TX

SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: Health Services Research Poster
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Biologic disease-modifying antirheumatic drug (bDMARD) therapies are commonly prescribed for rheumatoid arthritis (RA) treatment. However, their high out-of-pocket (OOP) cost may limit patient access to therapy. While insurance typically covers bDMARDS, they often require cost-sharing. Prior studies have shown that cost-sharing can have negative consequences, such as nonadherence and increased use of medical services. However, no study has examined adherence changes by drug class across OOP cost ranges in the commercial population. The purpose of this study is to assess the impact of patient OOP cost range, drug class and referral source on adherence in patients with RA.

Methods: This is a retrospective cohort study of RA patients insured by a large commercial health plan in the United States who reported a first RA drug fill for (medical or pharmacy benefit) from March 1, 2018, to February 28, 2019 (index fill), from a single specialty pharmacy. Demographic characteristics, OOP cost, drug class and referral source were obtained from the specialty pharmacy's dispense data. We defined a direct referral as any incoming referral from a prescriber, another specialty pharmacy, a payor or a patient. We defined a hub referral as a referral from the manufacturer. All other referrals were included in the "other" category. Medication adherence was calculated using the medication possession ratio (MPR). MPR was defined as the sum of the days' supply for all fills of RA drugs

Variables	
Age, years (mean, SD)	50.8 (12.0)
Race, n(%)	
White	13,842 (85.4%)
Black	1,662 (10.3%)
Asian	696 (4.3%)
Gender, n(%)	
Female	12,096(74.7%)
Male	4,104 (25.3%)
Annual Income, (mean, SD)	$61,705 ($23,949)
Co-pay per day, (mean, SD)	$0.89 ($5.79)
Used a drug coupon, n(%)	
Yes	13,193 (81.4%)
No	3,007 (18.6%)
Used a 90-day supply, n(%)	
Yes	1,724 (10.6%)
No	14,476 (89.4%)
Drug Class	
TNF-alpha inhibitors	12,375 (76.4%)
Janus kinase inhibitors	1,844 (11.4%)
T-cell blockers	1,118 (6.9%)
IL-6 inhibitors	863 (5.3%)
Referral Source, n(%)	
Direct	12,761 (78.8%)
Other	3,266 (20.2%)
Hub	173 (1.1%)

§Due to rounding percent's may not add up to 100%
TNF-alpha inhibitors include: etanercept, certolizumab, adalimumab, infliximab-dyyb, infliximab, infliximab-abda, and golimumab
IL-6 inhibitors include: tocilizumab and sarilumab
T-cell blockers include abatacept
Janus kinase inhibitors include: tofacitinib, baricitinib and upadacitinib

Table 1. Demographic Characteristics (N=16,200)

during a year after the index fill, divided by 365. A generalized linear model (GLM) was used to estimate predictors of adherence.

Results: The study included 16,200 patients, the majority were female (74.7%) and the mean age was 50.8 years (SD = 12.0). The average copay per day supply was $0.89 (SD = $5.79). Most (81.4%) patients used a coupon at least once to pay for their medication. Patients in the lowest copay category, compared to the other copay categories, were more likely to use a coupon (83.2%) to pay for their medication ($p < 0.001$). After adjusting for the variables in the model, MPR decreased as OOP cost increased. Above an OOP cost of $181 per month, MPR decreased significantly ($p = 0.0004$). MPR was significantly different by drug class ($p < 0.01$), IL6 = 59.9%, TCB = 64.2%, TNF = 66.8% and JAK = 66.8%. Patients who received a direct referral had a significantly higher MPR (66.5%) compared to patients who received a referral from an "other" source (61.1%) ($p < 0.0001$).

Conclusion: This study suggests that as member OOP costs increase adherence decreases and adherence differs by drug class and referral source. Source of referral and an appropriate formulary and patient copayment structure must be considered when assessing adherence.

Characteristics	MPR	p-value
Therapy		
IL-6 inhibitors	59.9%	Reference
T-cell blockers	64.2%	**0.0029**
TNF-alpha inhibitors	66.8%	**<0.0001**
Janus kinase inhibitors	66.8%	**<0.0001**
Co-pay category (OOP cost per month)		
$0-$60	67.3%	Reference

Risk of Severe Acute Localized Reactions for Different Intra-Articular Hyaluronic Acid Knee Injections in a Real World Setting

Kevin Ong[1], Jack Farr[2], Louis McIntyre[3], Andrew Gudeman[2], Iain Murray[4], Charles Hummer[5], Wilson Ngai[6], Heather Good[7], Edmund Lau[8] and **Roy Altman**[9], [1]Exponent, Philadelphia, [2]Indiana University Department of Orthopaedic Surgery, Indianapolis, [3]US Orthopedics, Tarrytown, [4]Department of Orthopaedics, The University of Edinburgh, Edinburgh, United Kingdom, [5]Premier Orthopaedics and Sports Medicine, Glen Mills, [6]Sanofi US, Bridgewater, [7]Sanofi US, Bridgewater, FL, [8]Exponent, Menlo Park, [9]David Geffen School of Medicine, University of California, Agua Dulce, CA

SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: Health Services Research Poster
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Case reports of severe acute localized reactions (SALR) following intra-articular (IA) hyaluronic acid (HA) injections for knee osteoarthritis (OA) have been described. These have been speculated to be related to the crosslink of hylan or an allergic reaction to avian-derived hyaluronan, but reactions have also been reported for non-crosslinked, non-animal, and/or naturally derived HA. We compared surrogate SALR measures between patients using hylan G-F 20 and specific non-hylan G-F 20 HA products.

Methods: Knee OA patients were identified from the Optum Clinformatics dataset (Jan 2006-June 2016), stratified into hylan G-F 20 and non-hylan G-F 20 HA users, matched by single or multiple injection products. Occurrences of surrogate SALR measures including inflammation/infection, intra-articular corticosteroid (CS) injections, arthrocentesis/aspiration, arthrotomy/incision and drainage, arthroscopy, and office visits were evaluated (with ICD/CPT codes)

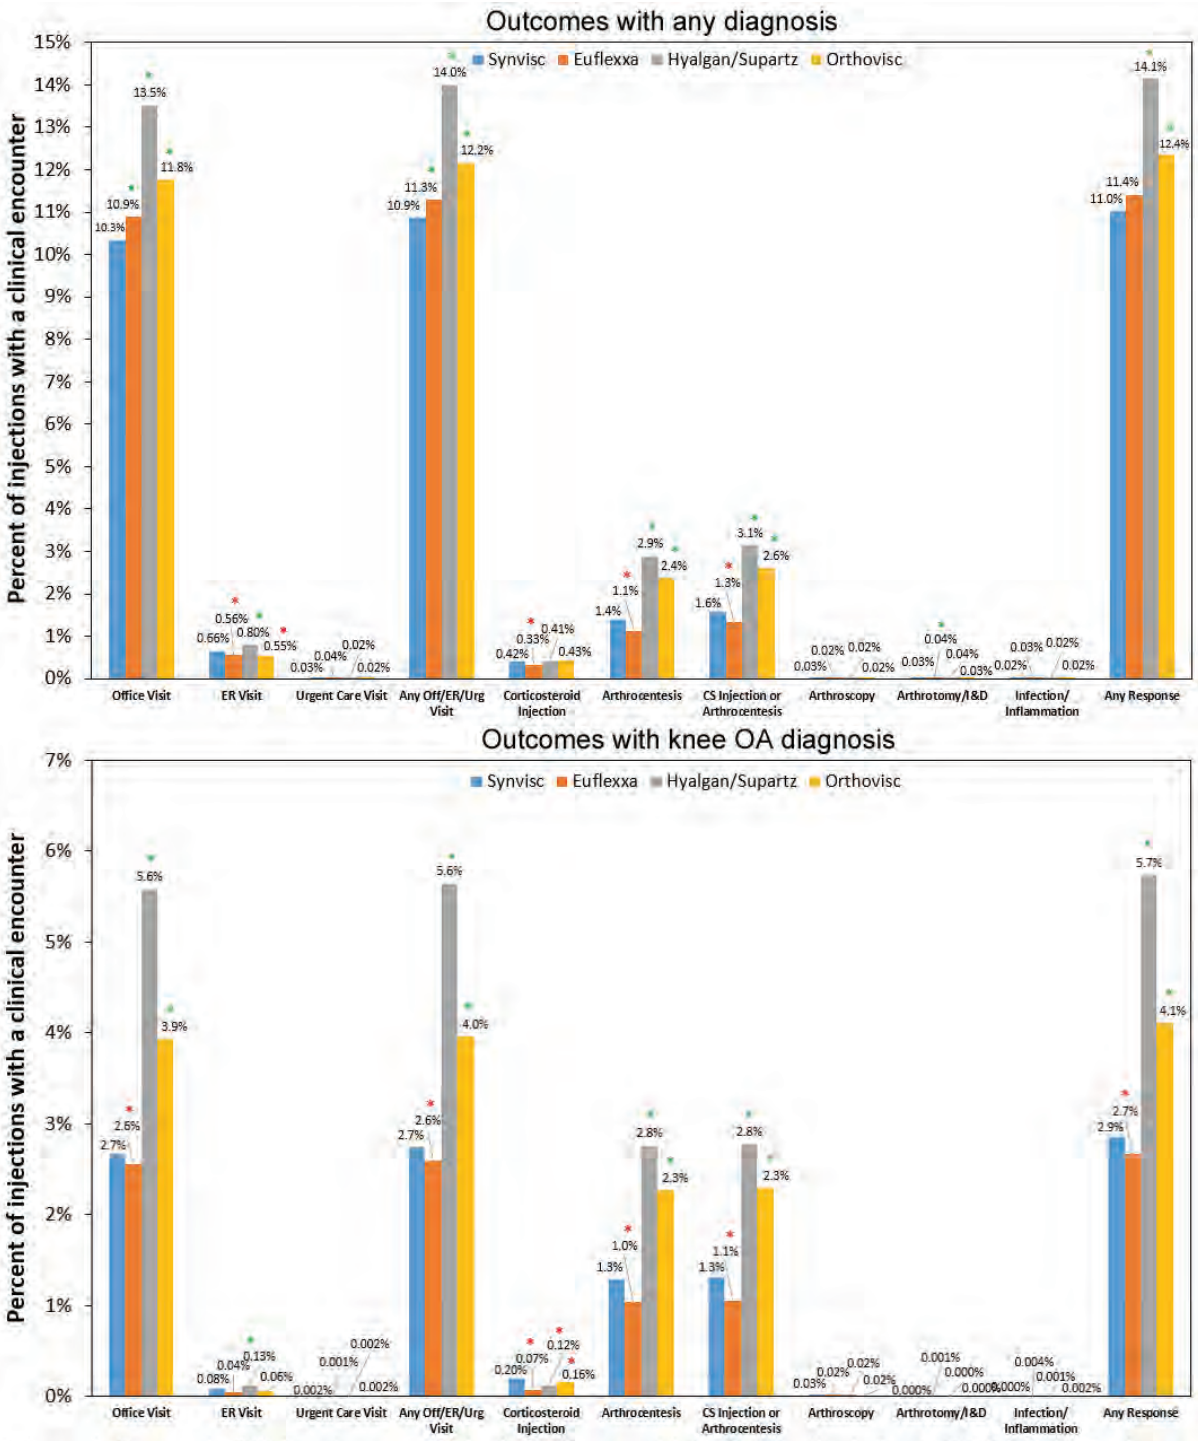

Figure 1. Surrogate SALR outcomes within three days post-injection for the hylan G-F 20 (3-injection), Euflexxa, Hyalgan/Supartz, and Orthovisc patient groups (top: outcomes with any diagnosis on the claims; bottom: outcomes with knee OA diagnosis on the claims). Statistically significant differences are indicated with an asterisk (* p<0.05; green and red for lower and greater adjusted risks in the hylan G-F 20 (3-injection) group, respectively).

Figure 1. Surrogate SALR outcomes within three days post-injection for hylan G-F 20 (3-injection), Euflexxa, Hyalgan/Supartz, and Orthovisc patient groups (top: outcomes with any diagnosis on the claims; bottom: outcomes with knee OA diagnosis on the claims). Statistically significant differences are indicated with an asterisk (* p<0.05; green and red for lower and greater adjusted risks in the hylan G-F 20 (3-injection) group, respectively).

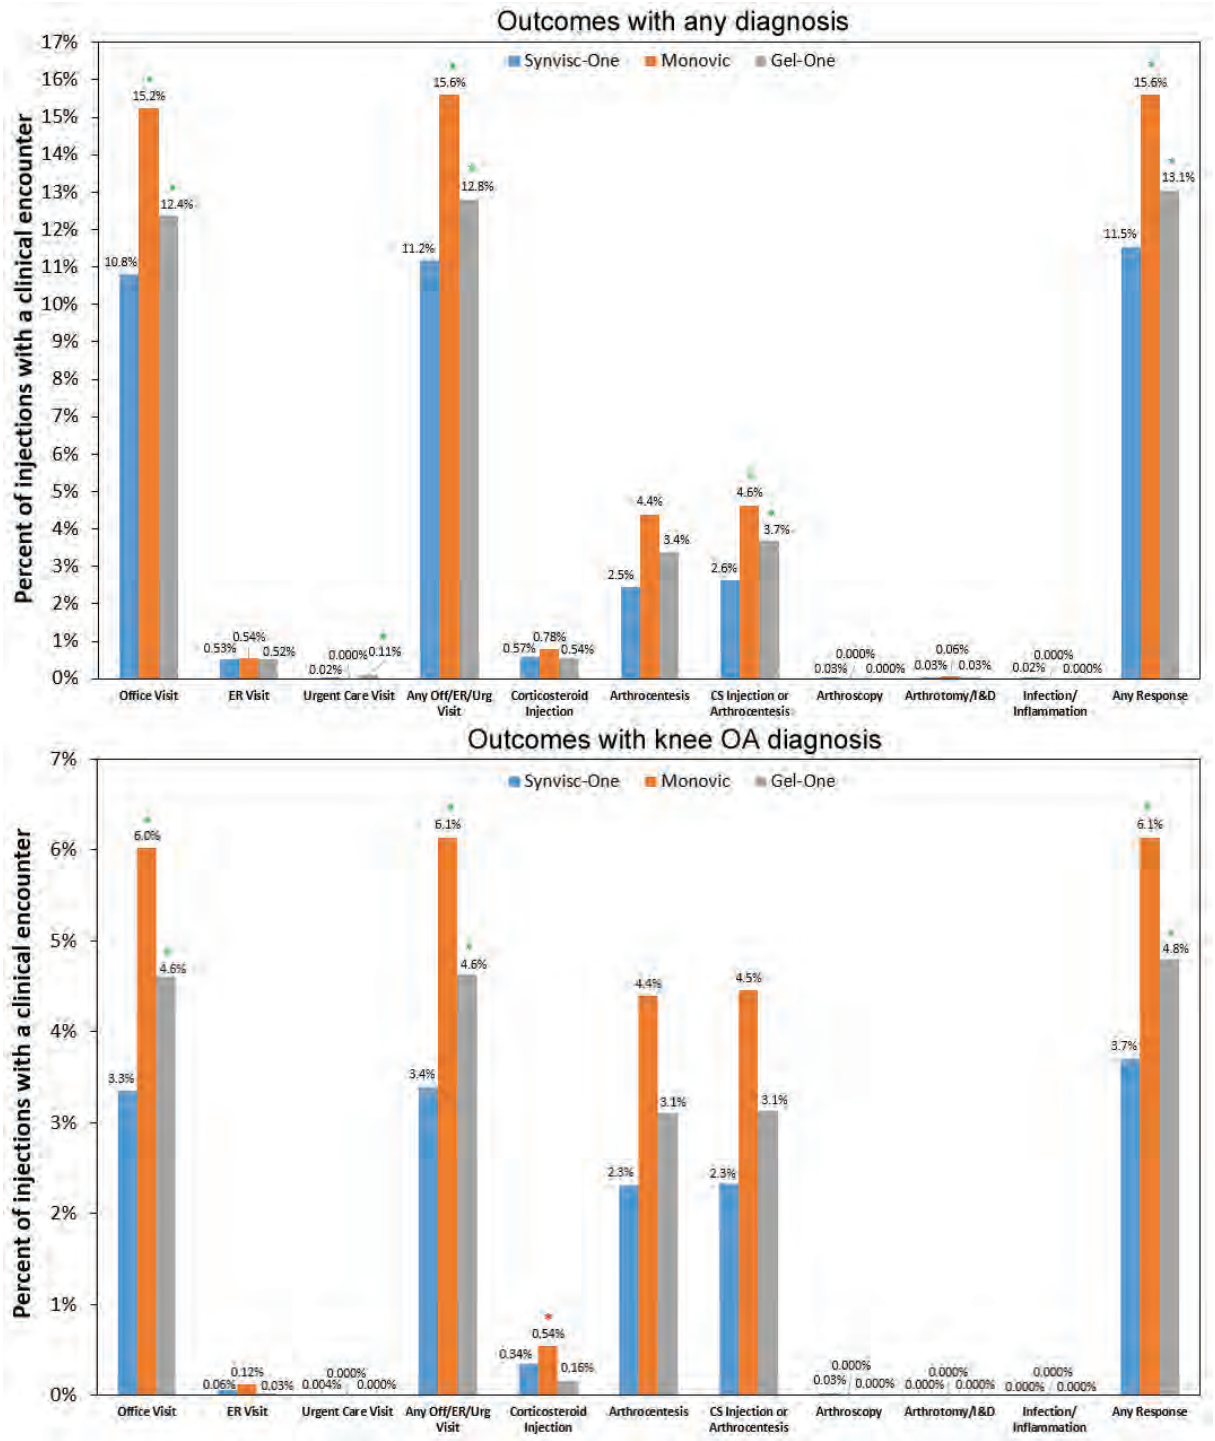

Figure 2. Surrogate SALR outcomes within three days post-injection for the hylan G-F 20 (1-injection), Monovisc, and Gel-One patient groups (top: outcomes with any diagnosis on the claims; bottom: outcomes with knee OA diagnosis on the claims). Statistically significant differences are indicated with an asterisk (* p<0.05; green and red for lower and greater adjusted risks in the hylan G-F 20 (1-injection) group, respectively).

Figure 2. Surrogate SALR outcomes within three days post-injection for hylan G-F 20 (1-injection), Monovisc, and Gel-One patient groups (top: outcomes with any diagnosis on the claims; bottom: outcomes with knee OA diagnosis on the claims). Statistically significant differences are indicated with an asterisk (* p<0.05; green and red for lower and greater adjusted risks in the hylan G-F 20 (1-injection) group, respectively).

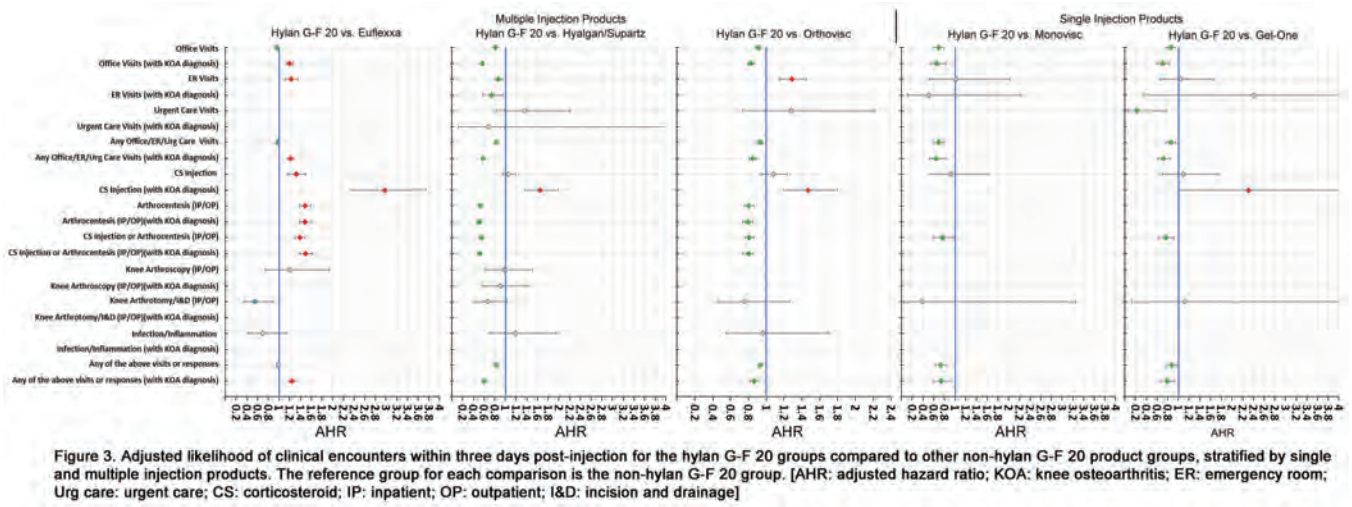

Figure 3. Adjusted likelihood of clinical encounters within three days post-injection for the hylan G-F 20 groups compared to other non-hylan G-F 20 product groups, stratified by single and multiple injection products. The reference group for each comparison is the non-hylan G-F 20 group. [AHR: adjusted hazard ratio; KOA: knee osteoarthritis; ER: emergency room; Urg care: urgent care; CS: corticosteroid; IP: inpatient; OP: outpatient; I&D: incision and drainage]

within three days of HA use, adjusting for demographics and clinical factors. These were stratified by single/multiple injection products and evaluated for claims that had a corresponding knee OA diagnosis (knee OA related), as well as those that did not (any diagnosis).

Results: A total of 694,404 HA injections were included in the study. Inflammation/infection rate (with any diagnosis) was rare within three days of HA use (hylan G-F 20 (3-injection): 0.02%; Euflexxa: 0.03%; Hyalgan/Supartz: 0.02%; Orthovisc: 0.02%; hylan G-F 20 (1-injection): 0.02%; Monovisc: none; Gel-One: none) (Figs. 1 and 2); no statistical differences between hylan G-F 20 and non-hylan G-F 20 groups were observed (Table 1). The risk of arthrocentesis was greater for hylan G-F 20 (3-injection; 1.4%) than Euflexxa patients (1.1%) (adjusted hazard ratio (AHR) 1.48; $p< 0.001$), but lower than Hyalgan/Supartz (2.9%) (AHR 0.53; $p< 0.001$) and Orthovisc (2.4%) (AHR 0.80; $p< 0.001$) patients. When considering the collective occurrence of any of the surrogate SALR outcomes, the risk was found to be similar between hylan G-F 20 (3-injection) and Euflexxa cohorts ($p=0.062$), except when limited to those with corresponding knee OA diagnoses (AHR 1.24 for hylan G-F 20; $p< 0.001$). The overall risks were lower for hylan G-F 20 (3-injection) than Hyalgan/Supartz ($p< 0.001$) or Orthovisc ($p< 0.001$) patients and lower for hylan G-F 20 (1-injection) than Monovisc ($p< =0.007$) or Gel-One patients ($p< =0.012$).

Conclusion: The present study examined potential SALR risk in a real-world setting of almost 700,000 HA injections. Diagnoses of inflammation or infection diagnoses were extremely rare (0 to 0.03%) within three days of HA injections. While our arthrocentesis results are consistent with a randomized controlled trial (Kirchner 2006), which reported a greater rate of local reactions in terms of effusions, in hylan G-F 20 (3-injection) than Euflexxa patients, the collective risk of any of the surrogate SALR outcomes was not found to be significantly different between hylan G-F 20 and non-hylan G-F 20 products (single or multiple injection products).

Table 1. Identified outcomes in PsA disease and the GRAPPA treatment guidelines specifying which disease domains are treated using specific treatments.

Background/Purpose: Psoriatic arthritis (PsA) manifests heterogeneous signs and symptoms (e.g., dactylitis, enthesitis, axial involvement, skin- and nail disease), which may respond to treatments differently. While a wide variety of treatments are available for psoriatic arthritis (PsA), variability in treatment response across different patient types is not well-documented. Understanding patient heterogeneity and its consequences on outcomes is critical to making appropriate treatment decisions. Our objective is to characterize the heterogeneity of PsA and develop a conceptual framework to explore the therapeutic and financial impacts of specific treatments on these five PsA manifestations.

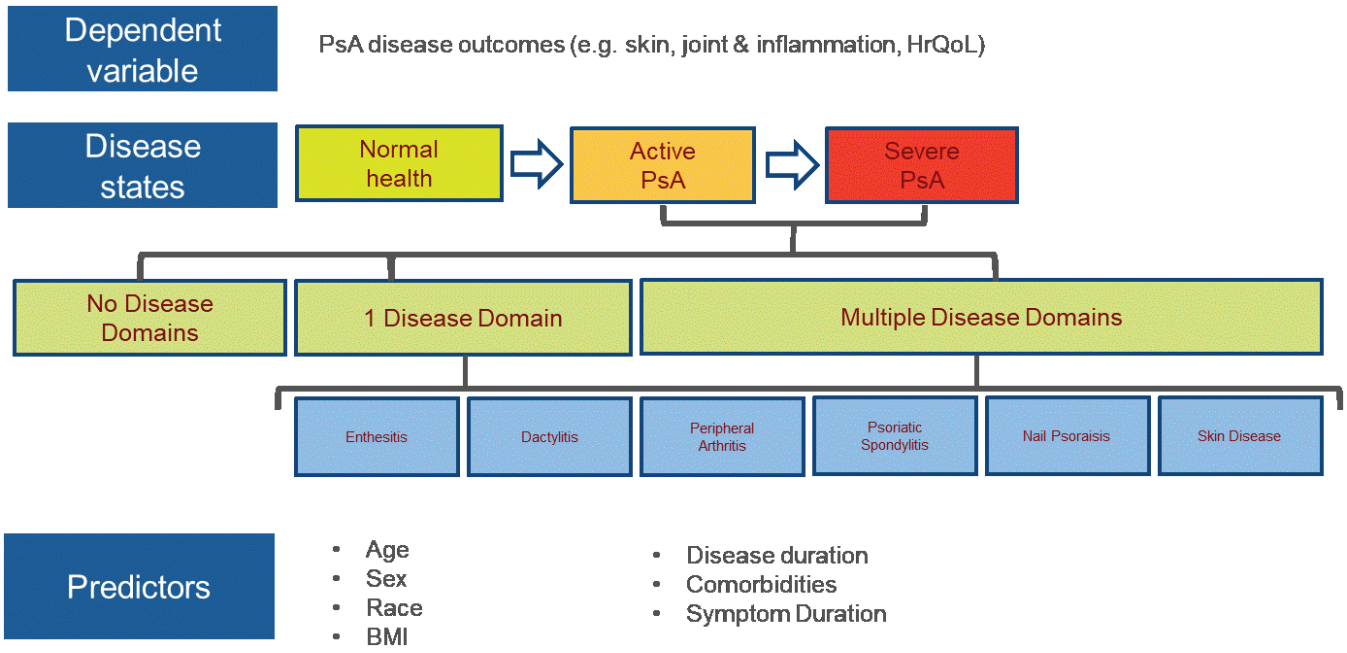

Figure 1. PsA Outcome Risk Model Components

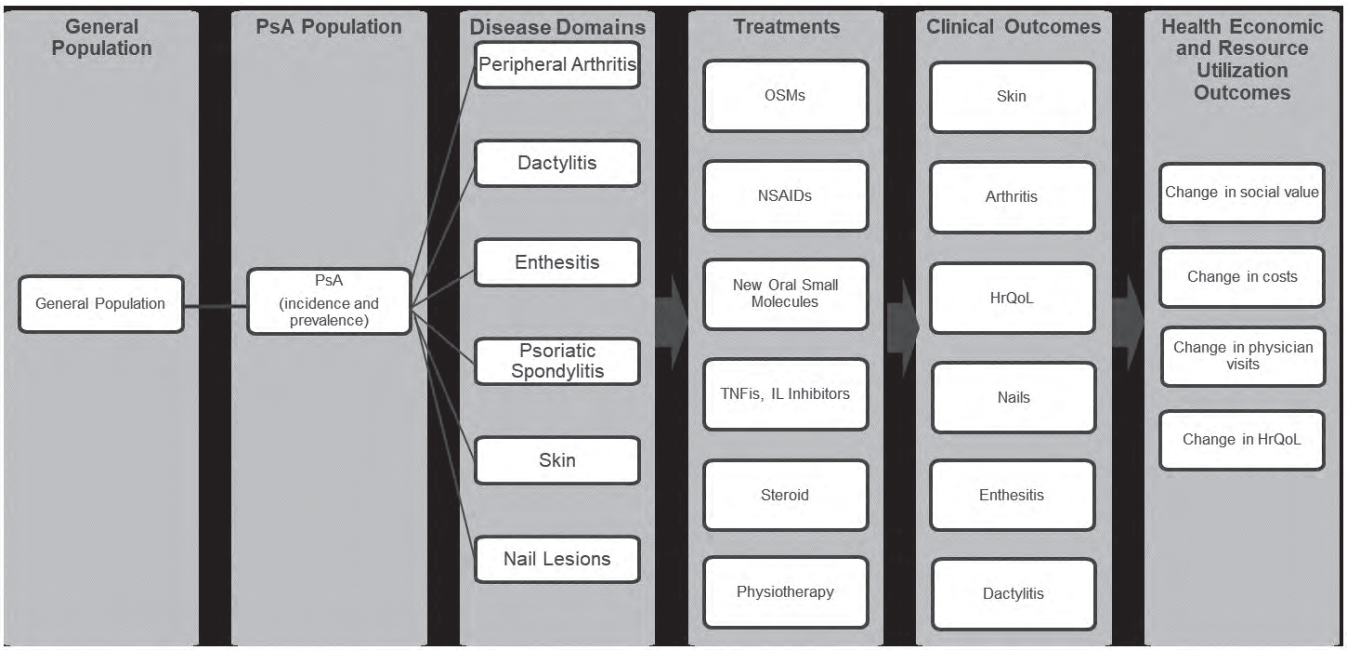

Figure 2. Treatments and clinical outcomes can be grouped by type to simplify the conceptualization of PsA disease manifestation and treatment.

Methods: We conducted a narrative literature review to determine the key prevalent PsA disease domains. We present the existing evidence base to measure the treatment effects of existing PsA treatments on the various disease domains. Finally, we propose an economic modeling framework that could estimate the economic value of treatments for addressing specific PsA disease domains.

Results: The key prevalent disease domains in PsA include peripheral arthritis, dactylitis, enthesitis, psoriatic spondylitis, skin, and nail lesions. However, the evidence base for the effect of a specific treatment on a given domain was less robust, as was the comparative evidence base of how existing market PsA treatments perform on one or more disease domains relative to each other (Table 1). Our review of clinical trials and the literature of the relevant outcomes also found no comparative effectiveness analysis of PsA domains. Our economic modeling framework to estimate the economic value of treatments for addressing specific PsA disease domains requires further clinical and real-world evidence to be generated on the relative efficacy or effectiveness on each disease domain. Given the evidence challenges, we would suggest a cohort-level model, with potential parallel modeling for the different disease domains, to estimate total social value calculated as quality-adjusted life-years as well as the cost per grouped outcome and changes in cost per symptom avoided. An individual/patient-level simulation would be the ideal design to represent patient heterogeneity but may not be feasible due to limited available data. As PsA is a chronic lifelong disease, we propose that this model use a lifetime horizon. We believe that a model as outlined in Figure 1-2 would provide valuable economic input to help inform treatment decision making.

Conclusion: Psoriatic arthritis is a heterogeneous disease, with patients presenting a variety of disease manifestations. A more granular understanding of the interaction between disease domains and treatments, such as the one proposed in Figure 3, would benefit both providers and patients in making value-based, personalized treatment decisions.

Abstract Number: 0582

Mortality and Cost of Hospitalization: Do Hospitals Caring for More SLE Patients Perform Better?

Christine Anastasiou[1], Laura Trupin[1], Patricia Katz[2], Zara Izadi[3], Milena Gianfrancesco[1], Gabriela Schmajuk[4] and Jinoos Yazdany[5], [1]University of California, San Francisco, San Francisco, CA, [2]University of California, San Francisco, Novato, CA, [3]University of California San Francisco, San Francisco, CA, [4]University of California, San Francisco, Atherton, CA, [5]UCSF, San Francisco, CA

SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: Health Services Research Poster
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Individuals with systemic lupus erythematosus (SLE) have an increased risk of hospitalization throughout their lifetime, potentially leading to higher patient mortality and healthcare costs. Establishing minimum volume thresholds for other medical and surgical conditions has been proposed as a way to improve outcomes. We evaluated the relationship between a hospital's yearly SLE volume and two outcomes: mortality and cost of hospitalization.

Methods: We used the National Inpatient Sample (NIS), which after weighting provides annual estimates for more than 35 million community hospitalizations in the US. Analysis was limited to adults without missing relevant variables hospitalized in 2017. Admissions with SLE were captured in ICD-10-CM codes (M32.1x, M32.8, M32.9). Hospital specific costs were obtained using NIS cost-to-charge ratio files. We used linear regression to model average cost for admissions with a diagnosis of SLE based on the number of yearly SLE discharges at the treating hospital (analysis conducted with continuous variable of SLE volume per year, and repeated with a categorical variable establishing 50 or more SLE discharges yearly), controlling for the Ward systemic lupus-specific risk adjustment index[1] modified for ICD-10, demographics (age, sex, race/ethnicity), health insurance, income quartile in the ZIP Code of residence, and hospital characteristics (bed size, rural/urban/teaching status). In addition, we used Poisson regression to model mortality risk based on hospital SLE volume and the covariates listed above. All analyses accounted for the complex sampling design of the NIS.

Results: Adults with SLE included in the analysis accounted for a nationally estimated 172,135 discharges in 2017 (0.48% of all hospital discharges). Mean cost per SLE discharge was $14,420 (SE $207); 2% of hospitalizations resulted in death. In adjusted analysis, cost per SLE discharge was higher for hospitals caring for more SLE patients per year. Approximately 18.6% of included hospitals had a yearly SLE volume greater than 50. Hospitals with a yearly SLE volume greater than 50 had a higher average cost per SLE discharge compared to those with an SLE volume less than 50 (cost difference $3,399; 95% CI $1,803 to $4,996). Risk of inpatient mortality did not significantly vary based on SLE hospital volume.

Conclusion: Higher yearly SLE hospital volume was associated with greater cost per discharge, without significant differences in mortality rates compared to hospitals with lower SLE volumes. If the lupus-specific risk adjustment index we used does not fully capture patient disease severity or if there were coding differences between hospitals, this could have potentially affected the results. Our findings do not suggest a minimum volume threshold for SLE care that can be used to improve inpatient outcomes.

SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: Health Services Research Poster
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Psoriasis (Ps) and psoriatic arthritis (PsA) have a major impact on patients' health-related quality of life. Cost of illness of patients with Ps, PsA and both diseases (PsA+Ps) is an important subject as they are associated with a substantial economic impact, with implications from a health management perspective.

The objective of our work was to describe the economic burden of direct non-healthcare and indirect resources of patients with Ps, PsA and PsA+Ps in Spain.

Methods: COEPSO ("Evaluation of Costs in patients with Psoriatic Disease") was an observational, retrospective, cross-sectional study performed in 22 Spanish centers (17 Dermatology and 14 Rheumatology Services), from February 2017 to February 2018, including moderate to severe Ps and PsA patients (with or without Ps), naive to biologics. Direct non-healthcare (social services, home care, physical adaptations, private health and non-health professionals, non-reimbursed and non-pharmaceutical therapies), indirect (loss of productivity) and total costs (direct non-healthcare and indirect costs) related to the disease during the previous year to the study were obtained. Unitary costs (€, 2018) were calculated: out-of-pocket costs were specified directly by patients and loss of productivity costs by means of average salaries based on occupation specified by patients. The information was collected through a case report form filled out by the investigators and a telephone survey administered to the patients.

Results: A total of 318 patients were included (196 Ps; 43 PsA and 79 PsA+Ps), mean age 48.7 years and 51.3% males. Metabolic syndrome was the most frequent comorbidity in all groups. The average annual total cost per patient was 1,042.71€ (SD 3,817.55), 1,137.84€ (SD 3,070.39) and 1,830.26€ (SD 5,835.81) for Ps, PsA and PsA+Ps, respectively. The average annual direct non-healthcare cost per patient was 749.57€ (SD 2,393.77), 750.50€ (SD 1,641.82) and 1,247.56€ (SD 4,467.19) for Ps, PsA and PsA+Ps, respectively. The average annual indirect cost per patient was 293.14€ (SD 2,855.27), 387.35€ (SD 2,409.63) and 582.71€ (SD 3,842.12) for Ps, PsA and PsA+Ps, respectively. Patients with combined PsA+Ps had higher annual total cost (direct non-healthcare and indirect costs) than patients with only one of these manifestations separately (75.5% and 60.9% above patients with Ps and PsA, respectively). Total costs in patients with Ps and PsA were similar. Direct non-healthcare costs represent between 66.0% (patients with PsA) to 71.9% (patients with Ps) of total cost. Indirect costs represent between 28.1% (patients with Ps) to 34.0% (patients with PsA) of total cost.

Conclusion: PsA and Ps have proved to be diseases with a high economic burden, and the total costs were mainly driven by direct non-healthcare costs. Moreover, although annual total costs in patients with PsA were similar to those of Ps patients, the combination of both manifestations yielded the highest costs suggesting the importance of the increased disease load.

Abstract Number: 0584

Total Cost of Care for Patients with Rheumatoid Arthritis

Kjel Johnson[1], Rebecca Karos[2], Elisea Avalos-Reyes[3], Fabio Casadio[4], **Michele Hamburger**[5] and Chiara Leprai[4], [1]CVS Health, Lincoln, RI, [2]CVS Health, Wellesley, MA, [3]CVS Health, Irving, TX, [4]CVS Health, New York, NY, [5]Frances Hamburger Institute, Hauppauge, NY

SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: Health Services Research Poster
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: The range of medical costs associated with rheumatoid arthritis (RA) is, in part, related to the various treatment options. Treatment for RA focuses on the control and management of inflammation. Patients with new RA diagnoses or less severe disease are usually prescribed less expensive non-biologic disease-modifying anti-rheumatic drugs (DMARDs). In contrast, patients who do not respond to DMARD treatment or exhibit more advanced disease are treated with biologics. It is estimated that treating RA with biologic therapies is three times more expensive than nonbiologic DMARDs. However, the initial cost of biologic therapy may be offset through reduced disease progression, health care utilization, and health care expenditures throughout the disease. The purpose of this study was to estimate the total cost of care among RA patients with commercial health insurance.

Methods: We identified patients with RA using medical claims data from January 1, 2019, to December 31, 2019. We defined total cost of care as the sum of allowed costs paid for medical and pharmacy claims per year. We compared the allowed costs of fully-insured and self-insured commercial patients with health insurance through a large national insurer.

Results: From January 2019 to December 2019, we identified 7,489 fully-insured RA patients and 11,824 self-insured RA patients. The average annual total cost of care for fully-insured and self-insured patients was $31,561 and $33,753, respectively. Pharmacy costs (both medical and pharmacy benefits) accounted for 70% of total costs for fully-insured and self-insured patients. Inpatient facility, specialist physician and ambulatory facility costs accounted for 9%, 7% and 5%, respectively, of total costs for fully-insured and self-insured patients. In 2019, 622 patients were

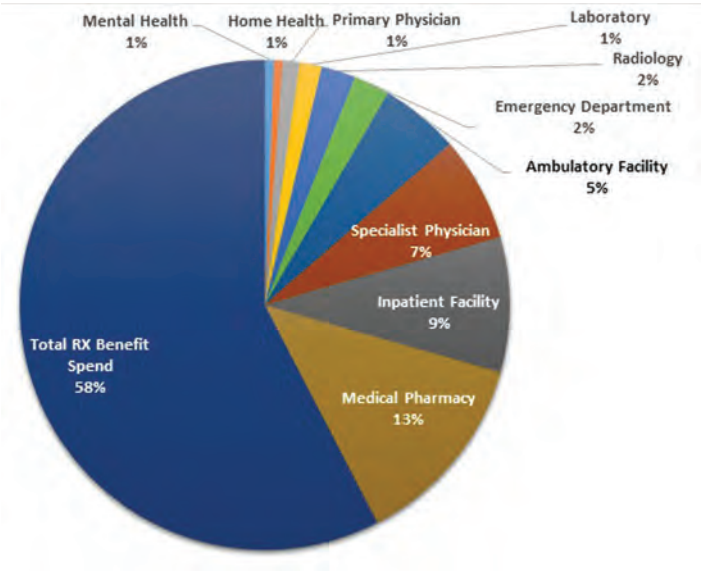

Figure 1. Total Cost of Care Distribution for Members with Rheumatoid Arthritis, 2019

prescribed infliximab for the treatment of RA, the majority of these patients (72%) received infusions in their doctor's office. The annual total cost of care for patients on infliximab ranged from $57,612 for those receiving infusions in their doctor's office to $131,616 for those receiving infusions in a hospital.

Conclusion: Direct medical costs for patients with RA are significant. In this study, pharmacy costs comprised a substantial portion of RA total cost of care. While pharmacy costs comprise a significant portion, the actual amount spent varies significantly by type of therapy and site of care, which presents an opportunity of future study and potential optimization of cost outcomes.

Abstract Number: 0585

Cost-effectiveness of Motivational Counselling and SMS-reminders on Daily Sitting Time in Patients with Rheumatoid Arthritis

Jan Sorensen[1], Mette Aadahl[2], Merete Hetland[3], Bente Appel Esbensen[4] and Tanja Thomsen[2], [1]Healthcare Outcomes Research Centre, Dublin, Dublin, Ireland, [2]Centre for Clinical Research and Prevention, Frederiksberg, Denmark, [3]Copenhagen Center for Arthritis Research (COPECARE), Glostrup, Denmark, [4]University of Copenhagen, Glostrup, Hovedstaden, Denmark

SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: Health Services Research Poster
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: The "Joint Resources – Sedentary Behaviour" randomised controlled trial (RCT) (1,2,3) aimed to reduce sedentary behaviour in patients with rheumatoid arthritis (RA) by means of a 16-week intervention consisting of motivational counselling and text message reminders. The results showed significant between-group differences on behavioral, patient-reported and cardio-metabolic outcomes, both after 4 and 22 months. This secondary, protocolised cost-effectiveness analysis compared the intervention costs and improvement in HAQ and EQ-5D health utility between the intervention and control group.

Methods: Eligible RA patients (meeting the ACR classification criteria for RA) were randomised to the intervention (IG) or control group (CG). The healthcare perspective was applied for the cost analysis and outcomes were reported in terms of objectively measured daily sitting time, HAQ and EQ-5D scores during the 22-month observation period. Cost-effectiveness was reported as incremental cost-effectiveness ratios (ICER) and cost-effectiveness acceptability curve.

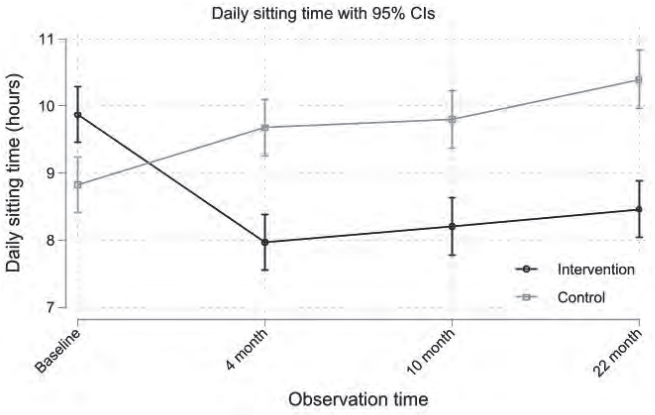
Outcomes were assed at baseline, at 4 months (after completed intervention), 10 and 22 months after baseline. Intervention mean cost included fixed planning costs and variable running cost. The incremental time weighted outcomes were related to the intervention cost. The ratio of intervention cost and gain in QALYs were illustrated in a scatterplot and cost-effectiveness acceptability curve.

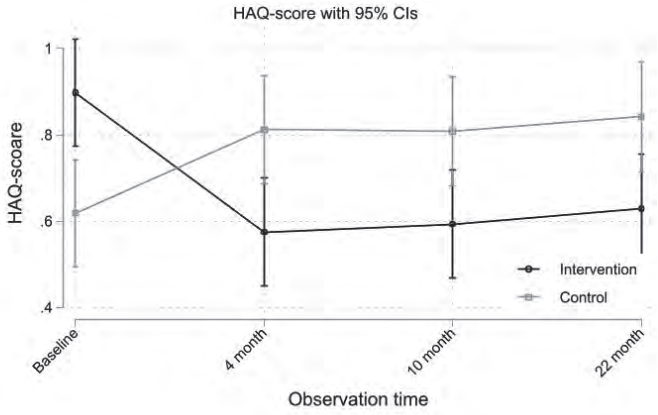
Results: The intervention cost was estimated at €145 per participant. The difference in mean outcomes are shown in Figure 1. At follow-up the intervention group had shorter daily sitting time, better HAQ and EQ-5D scores. The time weighted outcomes and ICERs are shown in Table 1. Figure 2 shows A) the relation between bootstrapped intervention cost and incremental quality-adjusted life years (QALY) based on EQ-5D outcomes and B) the cost-effectiveness acceptability curve. These figures suggest that the intervention is cost-effective at a threshold value of €3800 per QALY.

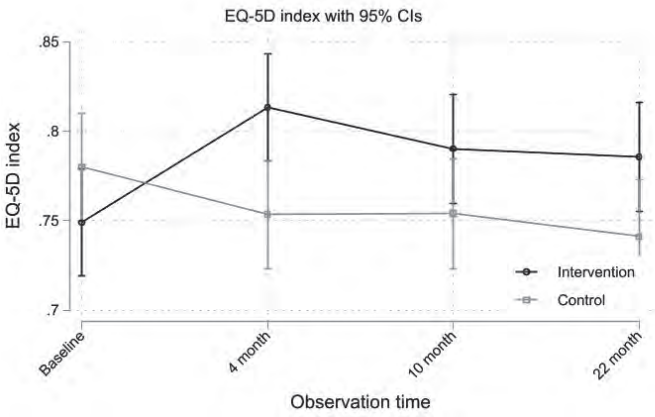
Table 1. Time-weighted outcomes (mean and 95% confidence interval)

	Intervention group (n=75)	Control group (n=75)	Incremental difference
Outcomes			
Daily sitting time (hours)	8.4 (8.1-8.8)	9.8 (9.5-10.2)	-1.4 (-1.9 - -0.9) p<0.001
HAQ score (low value better)	0.62 (0.52-0.73)	0.80 (0.67-0.92)	-0.17 (-0.33 - -0.01) p=0.035
EQ-5D utility (high value better)	0.79 (0.77-0.81)	0.75 (0.73-0.78)	0.04 (0.02 - 0.074) p=0.037
Incremental Cost-Effectiveness ratio			ICER (2019-€)
Cost per reduced daily sitting hour			101
Cost per reduced HAQ score			844
Cost per gain in QALY			3800

Missing observations replaced with last observation carried forward. Mean intervention cost per participant: €1







Conclusion: This secondary, protocolised cost-effectiveness analysis was based on data from an RCT with high participation rates and good completion of return outcome measurements. The results suggest that the ICER of the individually tailored, behavioural intervention is €3800 per QALY which is well below traditional threshold values. These results suggest that the intervention is cost effective to implement in routine care.

Abstract Number: 0586

Performance Characteristics of ANA by Elisa and Immunofluorescence

Gitanjali Lobo[1], Michael Luggen[2] and Chris Crutchfield[3], [1]TriHealth Good Samaritan Hospital, Cincinnati, OH, [2]University Hospital/University of Cincinnati College of Medicine, Cincinnati Rheumatic Disease Study Group, Inc, Cincinnati, OH, [3]University Hospital/University of Cincinnati College of Medicine, Cincinnati, OH

SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: Health Services Research Poster
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: The ANA is a critical test in the evaluation of patients with suspected lupus and other connective tissue diseases. Clinical laboratories have relied increasingly on automated solid phase methods for its detection and, more recently, on automated pattern recognition systems for the indirect immunofluorescence (IFA) technique.

Table 1. ANA by Elisa and IFA

	N	+ ANA by Elisa (%)	+ ANA by IFA (%)	Concordant Results (%)	Discordant Results (%)
Total pts	312				
Positive N (%)		165 (52.9)	204 (65.4)		
				207 (66.3)	105 (33.7)
Final Dx					
RA	20	8 (40.0)	13 (65.0)	13 (65.0)	7 (35.0)
SLE	37	27 (73.0)	24 (64.9)	22 (59.5)	15 (40.5)
IPA[1]	28	12 (42.9)	18 (64.3)	22 (85.7)	6 (21.4)
UCTD	52	40 (76.9)	38 (73.1)	38 (73.1)	14(26.9)
SSC	8	7 (87.5)	8 (100)	7 (87.5)	1 (12.5)
SS	13	9 (69.2)	10 (76.9)	10 (76.9)	3 (23.1)
DM	3	-	-	-	-
PM	1	-	-	-	-
CTD	62	46 (74.2)	45 (72.6)	41 (66.1)	21 (33.9)
EUCTD[2]	142	98 (69.0)	101 (71.3)	101 (71.1)	41 (28.9)
IRD[3]	162	106 (65.4)	114 (70.4)	114 (70.4)	48 (29.6)

1: inflammatory polyarthritis; 2: early undifferentiated connective tissue disease; 3: inflammatory rheumatic disease

The performance characteristics of both methods have not been rigorously evaluated and have not been studied prospectively.

Methods: Patients who were seen by an academic rheumatologist, who had ANA's obtained within 30 days by both Elisa (Zeus Elisa™) and IFA (Euroimmune ANA Diagnostics ™), and whose diagnosis had yet to be established, were evaluated. Patients were followed to establish a diagnosis. Patients were classified at their last office visit by clinical diagnosis, confirmed by independent review, and were further grouped into those with: 1) Connective tissue disease (CTD) including pts with definite and probable CTD who were also receiving DMARD/ immunomodulating therapy; 2) Early undifferentiated connective tissue disease (EUCTD) which included CTD, possible CTD, as well as undiagnosed inflammatory polyarthritis (IPA); and, 3) inflammatory rheumatic diseases (IRD) which included all with EUCTD as well as patients with RA.

Sensitivity, specificity, predictive values, likelihood and diagnostic odds ratios and their confidence intervals were calculated and compared.

Results: 312 patients were identified and followed for a median of 9.96 months (IQR: 1.9, 18.5). At their last visit the following diagnoses were established: CTD- 62 (SLE-37, SS-13, SSC-8, DM-3, PM-1), EUCTD-142, IRD-162. Percent positive ANAs by Elisa and IFA were 52.9% and 65.4% respectively. Concordance of results was found in 66.3% The performance characteristics of the two ANA techniques are shown in Table 1 and Table 2.

Table 2. Performance Characteristics of ANAs by Elisa and by IFA

	RD (95% CI)	EUCTD (95% CI)	CTD (95% CI)
Elisa Sensitivity	0.654 (0.581, 0.728)	0.690 (0.614, 0.766)	0.742 (0.633, 0.851)
IFA Sensitivity	**0.704 (0.633,0.774)**	**0.711 (0.637, 0.786)**	**0.726 (0.615, 0.837)**
Elisa Specificity	0.607 (0.529, 0.685)	0.601 (0.532, 0.679)	0.524 (0.462, 0.586)
IFA Specificity	**0.400 (0.322, 0.478)**	**0.394 (0.321, 0.468)**	**0.364 (0.304,0.424)**
Elisa PPV[1]	0.642 (0.569, 0.716)	0.594 (0.519, 0.669)	0.278 (0.210, 0.347)
IFA PPV	**0.559 (0.491, 0.627)**	**0.495 (0.4265, 0.564)**	**0.221 (0.164, 0.278)**
Elisa NPV[2]	0.619 (0.541, 0.698)	0.701 (0.627, 0.775)	0.891 (0.841, 0.942)
IFA NPV	**0.556 (0.462, 0.649)**	**0.620 (0.529, 0.712)**	**0.842 (0.774, 0.911)**
Elisa Accuracy	0.631 (0.575, 0.685)	0.644 (0.588, 0.697)	0.567 (0.510, 0.623)
IFA Accuracy	**0.558 (0.501, 0.614)**	**0.541 (0.485, 0.598)**	**0.496 (0.380, 0.458)**
Elisa LR+[3]	1.66 (1.32, 2.09)	1.75 (1.41, 2.17)	1.56 (1.28, 1.90)
IFA LR+	**1.17 (0.99, 1.38)**	**1.19 (1.01, 1.40)**	**1.14 (0.95, 1.37)**
Elisa LR-[4]	0.57 (0.44, 0.73)	0.51 (0.39, 0.67)	0.49 (0.32, 0.76)
IFA LR-	**0.74 (0.54, 1.01)**	**0.72 (0.52, 0.99)**	**0.75 (0.49,1.17)**
DOR[5] Elisa	2.91 (1.84, 4.63)	3.42 (2.14, 5.48)	3.16 (1.70, 5.89)
DOR IFA	**1.52 (0.99, 2.53)**	**1.60 (1.00, 2.58)**	**1.52 (0.82, 2.80)**

1: Positive Predictive Value; 2: Negative Predictive Value; 3: Positive Likelihood Ratio; 4: Negative Likelihood Ratio; 5: Diagnostic Odds Ratio

In general, the test methodologies provided comparable results. IFA was somewhat more sensitive (NS) while Elisa was more specific ($p < 0.05$). Diagnostic accuracy was higher with Elisa than with IFA for definite CTD (0.567 vs 0.436, $p < 0.05$). Diagnostic odds ratios where higher with Elisa (2.91-3.42) than with IFA (1.52-1.60) although the differences did not achieve statistical significance.

Conclusion: ANA by Elisa and ANA by IFA performed similarly in this short-term, prospective study. Elisa appears to be more specific and possibly more accurate in patients who had developed a definite CTD. Further observation will be necessary to definitively determine any meaningful differences in testing approaches.

Abstract Number: 0587

Barriers to Rheumatologic Care and Antimalarial Refills Among a Cohort of Patients with Systemic Lupus Erythematosus During the COVID-19 Pandemic

Alfredo Aguirre[1], Laura Trupin[1], Sarah Patterson[2], Kimberly DeQuattro[2], Patricia Katz[3], Cristina Lanata[2], Stephanie Rush[1], Lindsey Criswell[4], Maria Dall'Era[5] and Jinoos Yazdany[1], [1]University of California, San Francisco, San Francisco, CA, [2]UCSF, San Francisco, CA, [3]University of California, San Francisco, Novato, CA, [4]Rosalind Russell/Ephraim P. Engleman Rheumatology Research Center, University of California San Francisco, San Francisco, CA, [5]Division of Rheumatology, University of California, San Francisco, CA

SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: Health Services Research Poster
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: The pandemic of coronavirus disease 19 (COVID-19) has led to widespread disruptions across the spectrum of healthcare. We sought to investigate barriers to medical care, including access to ambulatory rheumatology appointments and routine medications such as antimalarials among patients with systemic lupus erythematosus (SLE) in the San Francisco Bay Area using a diverse, population-based cohort.

Methods: Subjects with SLE in the longitudinal California Lupus Epidemiology Study (CLUES) were administered a structured telephone interview during the COVID-19 pandemic. Participants were asked about SLE disease activity, COVID-19 exposures and infection, demographic factors and patient-reported outcomes. We collected data on access to ambulatory rheumatology appointments. Participants were also asked about difficulties in obtaining timely antimalarial refills since March 2020, encompassing partially filled, delayed or denied refills. Using a multivariable logistic regression model, we investigated demographic (age, female sex, nonwhite race) and disease-related factors (Systemic Lupus Activity Questionnaire, or SLAQ) associated with barriers to timely antimalarial refills.

Results: 202 CLUES cohort members participated in this interview. The mean age was 50 (±13 SD), 91% were female, and 64% reported a nonwhite race/ethnicity. 89 of 99 (90%) participants who tried to access ambulatory rheumatologic care were able to obtain an appointment; 79% of this care was delivered via telephone or video visits. Of the 111 participants who attempted to refill their antimalarial since March 2020, 39 (35%) reported partially filled, delayed or denied refills. Barriers to timely antimalarial refills were not associated with age, female sex, nonwhite race or SLAQ score.

Conclusion: These data suggest that in the San Francisco Bay Area, there were minimal disruptions in access to rheumatologic care for people with SLE, which parallels the high rate of virtual care provided during the first months of the pandemic. However, participants with SLE did report considerable difficulties in obtaining antimalarial refills. This highlights the importance of ensuring an adequate supply and appropriate stewardship of a critical medication for patients with chronic diseases during the COVID-19 pandemic.

Feast or Famine? An Institutional Assessment of Hydroxychloroquine Screening Practices

Alanna James[1], Kelli Kam[1], Vaneet Sandhu[2] and Christina Downey[3], [1]Loma Linda University Health, Loma Linda, CA, [2]Loma Linda University, Loma Linda, CA, [3]Loma Linda University Medical Center, Redlands, CA

SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: Health Services Research Poster
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Hydroxychloroquine (HCQ) is a generally safe and widely used rheumatologic drug. Maculopathy is an adverse effect in < 1% in the first 5 years of use; risk rises with exposure and presence of comorbidities. The American Academy of Ophthalmology (AAO) screening guidelines for HCQ maculopathy recommend a baseline within the 1st year and, if normal, annual screening after 5 years. Patients are screened at baseline with a fundus examination at minimum and per the provider's discretion may also undergo additional testing.

We evaluated our institutional screening practices and determined the cost of excess services provided and whether this practice led to an increase in detection of toxic maculopathy. We hypothesize that patients in our system are over screened, leading to waste.

Table 1
Demographics of Participants

Gender	
Female	132
Male	25
Weight Based Dosing (mg/kg/day)	
Average	4.5
Range	1.5-8.8
Patients on <5 mg/kg/day	97
Patients on >5 mg/kg/day	46
Unknown dose	13
Age	
Average	52.8
Range	4-99
Time on Hydroxychloroquine	
Less than 1 yr	41
1-5 yrs	59
> 5 yrs	57
CKD Status	
Present	28
Absent	129
Tamoxifen use	
Yes	2
No	155

Table 1. Demographics of included patients on hydroxychloroquine. CKD = Chronic Kidney Disease

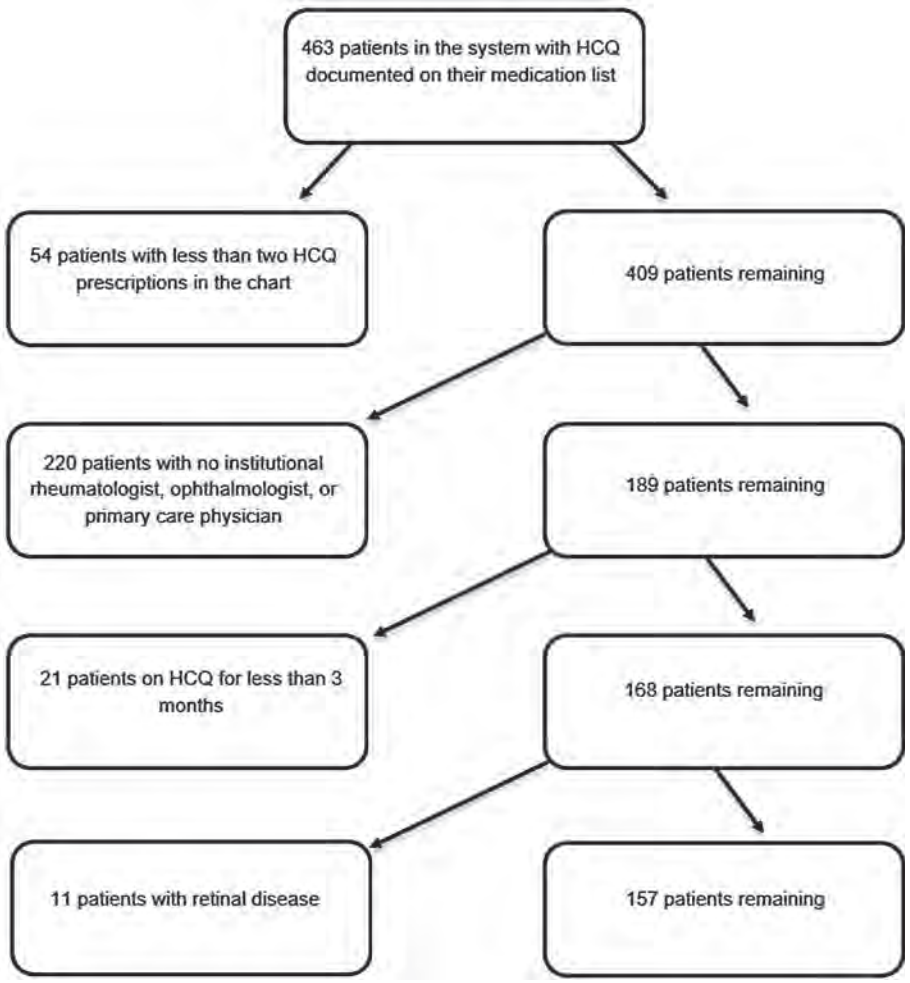

Figure 1. Diagram of method of patient exclusion from study

Methods: All patients with an HCQ prescription in their medication list were included. Exclusions were: macular disease, single prior prescription, never-users or those with adverse effect with < 3 months of use, and those without appointments with rheumatology, ophthalmology or primary care within the institution. Electronic chart-based data collection included: weight-based dose of HCQ, duration of treatment (< 1, 1-5, or >5 years), tamoxifen use, history of kidney disease, and presence of toxic maculopathy. Screening recommendations were evaluated in compliance with the AAO recommendations for baseline and follow-up screening.

Results: 463 patients were prescribed HCQ between January 2010 and April 2020; 157 were included. HCQ use duration was distributed into 3 groups: < 1 year (n= 41), 1-5 years (n= 59), and >5 years (n= 57).

Of the 157 included patients, 38.7% underwent baseline ophthalmologic exam within one year of starting HCQ, 27.7% did not, and 33.6% had no documentation of a retinal exam. 33.6% of patients were inappropriately recommended to be screened again after baseline exam within 1 year. Only 2% of patients were advised to rescreen following baseline exam after 5 years exposure per AAO guidelines. 9% of patients on HCQ for more than 5 years were appropriately receiving annual screening; 12.2% were not. All 3 cases of HCQ maculopathy in our system were diagnosed in appropriately screened patients. Over screening resulted in an additional $1853 per patient.

Length of Time on HCQ	<1 year		1-5 years		>5 years		Cumulative Data	
	n	%	*n*	%	*n*	%	*n*	%
Baseline Screen								
Appropriate	17	42.5	28	48.3	15	26.3	60	38.7
Not Done	0	0	25	43.1	14	24.6	39	25.1
Not Applicable	19	10	0	0	0	0	19	12.2
Unknown	4	47.5	5	8.6	28	49.1	37	23.9
Recommended Follow-Up from Baseline Screen								
Within 1 year	11	30.6	23	41.8	15	27.3	49	33.6
At 5 years of treatment	0	0	1	1.8	2	3.6	3	2.0
Not Applicable	21	58.3	16	29.1	16	29.1	53	36.3
Unknown	4	11.1	15	27.3	22	40	41	28.1
5 Year Screen								
Appropriate	0	0	4	6.9	24	42.1	28	18
Not Done	0	0	0	0	10	17.5	10	6.4
Not Applicable	41	100	50	86.2	7	12.2	98	62.8
Unknown	0	0	4	6.9	16	28	20	12.8
Annual Screening after 5 years								
Yes	0	0	0	0	14	24.6	14	9
No	0	0	0	0	19	33.3	19	12.2
Not Applicable	41	100	58	100	19	33.3	118	75.6
Unknown	0	0	0	0	5	8.8	5	3.2

Table 2. Screening practices and follow up recommendations for patients divided into length of time on hydroxychloroquine (HCQ)

Conclusion: Our analysis of institutional screening practices for HCQ reveal that only 41% of patients are being appropriately screened. Contrary to our hypothesis, of the inappropriately screened patients, 29% were over screened and 71% were under screened. Of patients who had recorded follow-up recommendations after baseline exam, 94% were inappropriately recommended to follow up in 1 year, while only 6% were recommended to follow up after 5 years of HCQ use per AAO guidelines. Insurance demands regarding specialty care may be a cause of over screening as follow up visits greater than one year out require more administrative burden. Limitations to this study include inadequate available data and reliance on clinical documentation to establish screening methods. In those over screened, utilization costs were high, an additional $1853/patient. For those under screened, the health and financial consequences remain unknown.

Abstract Number: 0589

The Ideal Mhealth Application for Rheumatoid Arthritis: Qualitative Findings from Stakeholder Focus Groups

Diederik De Cock[1], Maryline Vandeputte[2], Rani Van Melder[2], Michael Doumen[2], Delphine Bertrand[1], Veerle Stouten[1], Sofia Pazmino[1], Rene Westhovens[3] and Patrick Verschueren[4], [1]KU Leuven, Leuven, Belgium, [2]KU Leuven, Leuven, [3]University Hospitals Leuven, Belgium, Leuven, Belgium, [4]University Hospital Leuven, Leuven, Belgium

SESSION INFORMATION

Session Date: Saturday, November 7, 2020

Session Title: Health Services Research Poster

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: Early access to specialized rheumatological care is under increasing pressure. Many countries are currently confronted with a relative shortage of practicing rheumatologists, while recent shifts in the management strategies of rheumatoid arthritis (RA) have made ambulatory care more labor intensive. These developments have prompted the exploration of innovative care models for RA, including the use of mobile health (mhealth) applications, such as mobile apps and wearables. Mhealth applications could facilitate the monitoring of disease activity in between clinic visits and thus offer opportunities to provide personalized care for RA patients at the right time. This could potentially result in a significant reduction in the number of unnecessary clinic visits and reduce waiting times for an appointment. In Belgium, mhealth applications have only sparsely been integrated in routine care for RA patients. Little is known about their applicability in Belgian rheumatology care. The aim of this study was to gain more insight in possible barriers and facilitators of mhealth applications for the ambulatory care for RA patients, according to different stakeholders.

Methods: We performed a qualitative study with focus group interviews. Focus groups were organized with the following stakeholders: nurses specialized in the care of patients with RA, patients with RA and rheumatologists. The qualitative analysis guide of Leuven (QUAGOL) was used to analyze the data obtained during the focus groups by 3 researchers (MVDP, RVM, DDC).

Results: In total, 2 focus groups with nurses (n=16), 2 with patients (n=17) and 2 with rheumatologists (n=19) took place. Due to the Covid-19 pandemic, 1 focus group with patients was cancelled, and 1 with rheumatologists was performed online.

Most stakeholders expressed some form of familiarity with mhealth applications. However, reluctance of seeing these applications as a care innovation was observed. Especially rheumatologists underlined such applications were suitable for only a subgroup of patients. Some stakeholders feared the complexity of mhealth applications and doubted the added benefit versus a face-to-face visit. However, the evolution towards mhealth applications was expressed as inevitable in modern society. Mhealth tools were viewed as complementary to routine care. Especially rheumatologists underlined their role as experts of RA care, fearing to be replaced by mhealth techniques. Expectations of such an application were high. An ideal tool was said to aggregate as much practical, clinical and educational aspects for a patient as possible and to incorporate easy access for all stakeholders to stimulate application use while ensuring privacy.

Conclusion: Although stakeholders expressed doubts towards mhealth applications in daily practice, many saw this evolution as inevitable. Therefore, it would be wise to develop an app integrating the viewpoints of all parties involved in the care of patients with RA to ensure implementation in practice.

A Web-Based Data Capture System Can Successfully Collect Detailed and Quantifiable Physical Therapy Intervention Data Post Total Knee Replacement

Carol Oatis[1], Jeremie Laraque-Two Elk[2], Joseph Rizk[2], Ellen Benbow[2], Hua Zheng[3], Wenjun Li[3] and Patricia Franklin[4], [1]Arcadia University, Philadelphia, PA, [2]Arcadia University, Glenside, PA, [3]University of Massachusetts Medical School, Worcester, MA, [4]Northwestern University, Chicago

SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: Health Services Research Poster
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Variation in clinical care of patients post total knee replacement (TKR) is well-known. Experts suggest that electronic health records (EHR) can be used to decrease unwarranted practice variation and to provide real world evidence for comparative effectiveness research (CER). However close examination of EHRs shows that they rarely include adequate intervention detail to replicate or replace randomized controlled trials. Using content recommendations from PT experts we designed a web-based data capture system to collect detailed, quantifiable intervention data from physical therapists (PTs) treating patients following TKR. PTs were instructed to enter every intervention provided at every visit using drop-down menus. If unable to describe their intervention using the menus, PTs provided explanations of the interventions in a Clinical Notes text box. We deployed the system to 8 outpatient physical therapy practices and 33 sites in 3 different US states. The purpose of this study was to evaluate the system's ability to capture detailed quantifiable intervention data from multiple clinical sites and practitioners by describing the use of the Clinical Notes text box to identify interventions.

Methods: 81 PTs entered intervention data for 153 patients over a total of 2442 visits. All clinical notes were reviewed by at least two trained physical therapy reviewers to determine if the interventions in the clinical notes were: 1) additional information about interventions already identified by the PT in the menus; 2) additional interventions that were available but not identified in the menu by the PT; or 3) additional interventions not represented in the menus. We identified the frequency of visits when interventions were entered into the clinical texts but not entered using the menus. We determined the number of PTs who included interventions in the clinical notes but not in the menus. We also determined what interventions listed in the text box were unavailable in the menus.

Results: 46 PTs (57 %) used the Clinical Notes text box to include interventions they had not chosen from the menus. Clinical Notes from 424 visits (17%) included interventions which had not been identified in the menus. The most common reason (148 visits) for including interventions in the text box but not in the menu was because the therapist exceeded the maximum allowable number (10) of strengthening exercises. In 257 visits (11%) the PT listed interventions in the text box that had been available in the menus. 19 visits (0.008%) included interventions in the text box that could not have been identified in the menus. PTs reported documentation was quick and easy.

Conclusion: It is possible to use a structured, menu-driven data capture system to collect detailed and quantifiable intervention data across multiple practice sites and among multiple PTs in patients post TKR. While many PTs used text to describe their interventions, better training of the PTs and minor changes to the capture system will minimize the need for text in data capture, making detailed and quantifiable descriptions of interventions and dosages straight forward across treatment sites and practitioners. This will allow large pragmatic CER and may lead to decreased practice variation.

Abstract Number: 0591

Intervention to Improve SLE Medication Adherence Using Surescripts Pharmacy Refill Data

Kai Sun[1], Jennifer Rogers[2], Rebecca Sadun[3], Amanda Eudy[3], Jayanth Doss[3], Lisa Criscione-Schreiber[4], Ann Cameron Barr[5], Lena Eder[6], Mithu Maheswaranathan[3], Amy Corneli[7], Hayden Bosworth[1] and Megan Clowse[8], [1]Duke University Hospital, Durham, [2]Duke University Hospital, Durham, DE, [3]Duke University, Durham, NC, [4]Division of Rheumatology and Clinical Immunology, Department of Medicine, Duke University Medical Center, Durham, NC, [5]Duke University Hospital, Durham, NC, [6]Duke University Hospital, Chapel Hill, NC, [7]Duke University, Durham, [8]Duke University, Chapel Hill, NC

SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: Health Services Research Poster
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Medication nonadherence is as high as 80% among SLE patients and leads to higher morbidity, mortality, and healthcare costs. Few studies have tested interventions to improve adherence in SLE patients, and none was effective among adults with SLE in the US. We developed an intervention based on prior study results and data from Surescripts, the largest health information network in the US, in collaboration with lupus clinic stakeholders, including patients, providers, and staff. The intervention uses Surescripts pharmacy refill data which draws from nearly all pharmacies and electronic health record systems, to monitor nonadherence and prompt tailored discussions surrounding medication use during the clinic encounter. We pilot-tested this intervention to assess feasibility, acceptability, appropriateness, and to explore its effect on adherence.

Methods: We conducted a 12-week pilot intervention at an university lupus clinic among consecutive follow-up patients on SLE medications, including HCQ, MTX, AZA, MMF, LEF, and belimumab. Adherence was assessed by medication possession ratio (MPR) based on Surescripts refill data, using MPR ≥80% as a cutoff for being adherent. During an encounter, the clinic note template prompted the provider to share the screen with the patient and review pharmacy refill data together (Figure 1). Patients with MPR ≥80% received encouraging statements. For those with MPR < 80%, providers asked open-ended questions to elicit and address adherence barriers. Discussions were documented in the note. We measured feasibility, acceptability, and appropriateness using patient and provider surveys. Feasibility was also assessed by medical record documentation. We explored change in adherence by comparing MPR in the 3-month periods before and after the intervention visit.

Results: All 6 lupus clinic rheumatologists participated, and 134 follow-up SLE patients were seen during the pilot period (mean age 43, 96% female, and 53% black). Provider surveys showed high scores for acceptability (4.4/5), appropriateness (4.6/5), and feasibility (4.7/5) of the intervention. Among 48 patients who completed surveys, the most common reactions to the intervention visit were feeling determined (24%), empowered (21%), and proud (12%). No patient reported being angry, upset, or embarrassed. Ninety percent of clinic notes contained documentation of reviewing Surescripts data with the patient. Adherence rates comparing 3 months before and after the intervention visit increased for HCQ (n=121) from 60% to 71% (p=0.02), for DMARDs (n=85) from 49% to 61% (p=0.06), and for MMF (n=37) from 50% to 59% (p=0.1).

Conclusion: We developed an intervention based on formative results in collaboration with lupus clinic stakeholders that showed excellent acceptability, appropriateness, and feasibility among patients and providers. The intervention led to a statistically significant improvement in HCQ adherence and a trend for improvement in DMARD and MMF

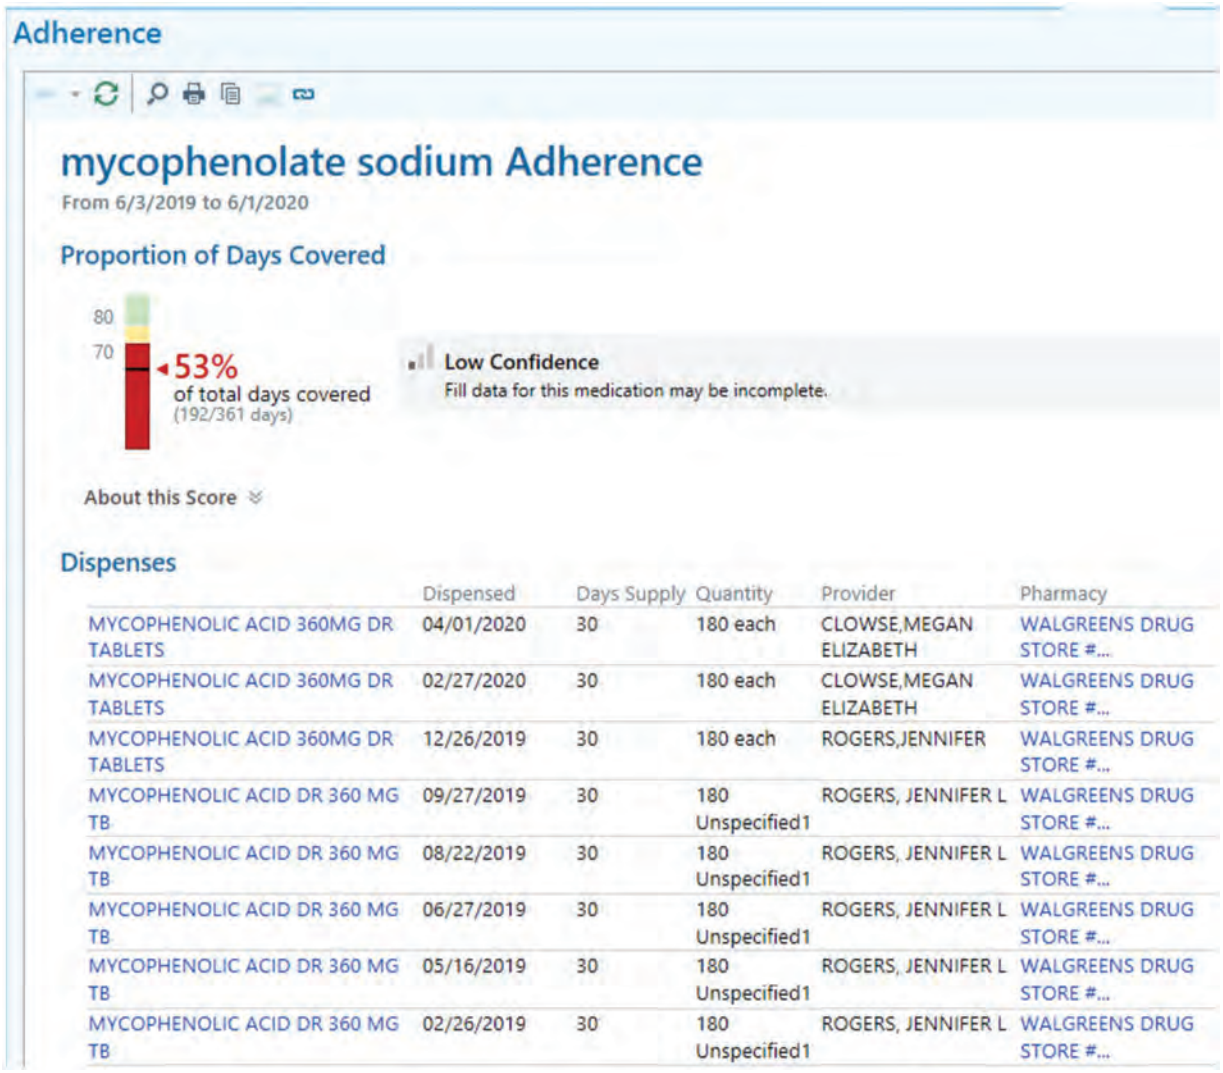

Figure 1. Screen shot of Surescripts pharmacy refill information providers review with patients during the clinical encounter.

adherence. Future work should elucidate the mechanisms by which this intervention works, assess its efficacy in a controlled setting, and adapt its use among other chronic rheumatic conditions.

A Rheumatology-Driven Protocol and Treatment Algorithm of SARS-CoV-2 Cytokine Release Syndrome and Its Associated Outcomes

Sandy Lee[1], Neha Chiruvolu[2], Muntarin Karim[3], Patil Injean[4], Loomee Doo[5], Donna Jose[6], Deepa Panikkath[1], Micah Yu[5], Anna Lafian[5], Wendy De La Pena[7], Albert Chow[8], Karina Torralba[9], Vaneet Sandhu[10], Mehrnaz Hojjati[5], Marven Cabling[5] and Christina Downey[1], [1]Loma Linda University Medical Center, Redlands, CA, [2]UC Riverside School of Medicine, Riverside, CA, [3]Loma Linda University Health System, Loma Linda, CA, [4]LOMA LINDA UNIVERSITY MEDICAL CENTER - RHEUMATOLOGY, Redlands, CA, [5]Loma Linda University Medical Center, LOMA LINDA, CA, [6]Loma Linda University Medical Center, Ontario, CA, [7]PRCSG, Cincinnati Children's Hospital Medical Center, Cincinnati, OH, [8]Loma Linda University, San Bernardino, CA, [9]Loma Linda University School of Medicine, Redlands, CA, [10]Loma Linda University, Loma Linda, CA

SESSION INFORMATION

Session Date: Saturday, November 7, 2020

Session Title: Health Services Research Poster

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: The newly identified SARS-CoV-2 has brought Cytokine Release Syndrome (CRS) to a level of prominence not often seen in adult medicine. Mortality rates of CRS in JIA, Kawasaki disease and SLE are between 30-60%. There is no published mortality rate due to SARS-CoV-2-CRS. A rheumatology division handling inpatient consultation services at an academic medical center and a county hospital developed institutionally mandated treatment algorithms with the goal to identify and treat patients with CRS. We are unaware of any other rheumatology division in the USA that has taken an institution-level role in managing SARS-CoV-2-CRS. The objective of this study is to determine if this algorithm was effective in preventing mortality rates of more than 30%.

Methods: Representatives from the Divisions of Rheumatology, Infectious Disease, Pulmonary and Critical Care Medicine, and the head of Pharmacy and the Pharmacy and Therapeutics (P&T) Committee were involved in institutional protocol development at each hospital. With the acknowledgement that CRS is a rheumatologic condition, four rheumatologists and five fellows reviewed rheumatologic and hematologic medical literature on CRS in JIA, SLE, Kawasaki Disease and hemophagocytic lymphohistiocytosis to define clinical features that would guide diagnosis and treatment of CRS. Consensus was reached for laboratory tests and result thresholds for early CRS monitoring and diagnosis, and for first and second-line agents including contraindications and precautions for each (Figure 1, Table 1). Final approval was done by the protocol development committee. During implementation, further revisions

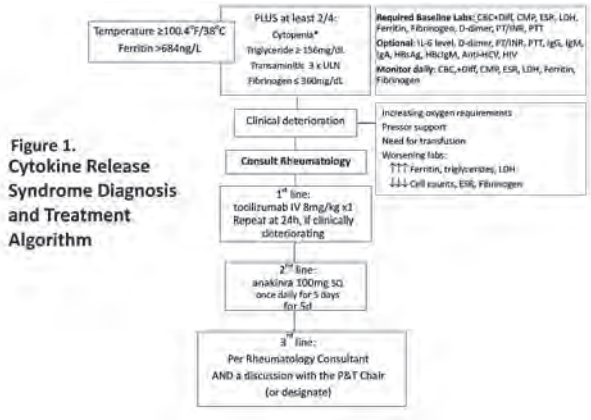

Figure 1. Cytokine Release Syndrome Diagnosis and Treatment Algorithm

Figure 1. Cytokine Release Syndrome Diagnosis and Treatment Algorithm

Table 1. Treatment Considerations for Cytokine Release Syndrome due to SARS-CoV-2 for patients referred to a Rheumatology Consultation Service

	Therapy	Dose	Comments
1st Line	tocilizumab (anti-IL6)	8mg/kg IV x 1 (800mg maximum dose); repeat if no clinical improvement within 24-48 hours For dosing, consider rounding to the nearest available vial size: 80mg, 200mg, 400mg	• Pertinent Drug Interaction: CYP3A4 Substrates (High risk with Inducers) • No renal adjustment; • Contraindications: Known hypersensitivity to Tocilizumab or any component • Caution: Monitor liver enzymes, platelet counts, neutrophils • Risks: GI perforation risk; thrombocytopenia, neutropenia; liver enzyme elevation; Herpes zoster reactivation
2nd Line	anakinra (anti-IL1)	100 mg SQ once daily x 5 days	• Not to be combined with other biologic DMARDs; clozapine; live vaccines • Contraindications: Hypersensitivity to E.coli derived proteins, anakinra or any component of the formulation; use with caution: CrCl<30mL/minute or ESRD
3rd Line	Per Rheumatology Consultant AND after discussion with the P&T Committee Chair (or designate)		
	Any use of the above immunomodulatory drugs intended as treatment of COVID-19 complications which deviates from this table, including administration route &/or dosing, requires a discussion with the P&T Committee Chair (or designate) before the drug is verified by the Pharmacist, or administered by Nursing.		

Table 1. Treatment Considerations for Cytokine Release Syndrome due to SARS-CoV-2 for patients referred to a Rheumatology Consultation Service

Table 2. Outcomes of SARS-CoV-2-CRS patients managed using a Rheumatology-Driven Treatment Algorithm at a University Medical Center and County Hospital

Patients diagnosed with SARS-CoV-2 referred to rheumatology for CRS evaluation	Total N = 150	University Hospital, N= 64	County Hospital N=86
Patients diagnosed with CRS and received a biologic agent	71 (47.3%)	21 (32.8%)	50 (58.1%)
Deaths	31 (20.7%)	16 (25%)	15 (17.4%)
Deaths attributed to MAS/CRS or its complication	20 (28.2%)	9 (42.9%)	11 (22%)
Patients requiring ICU admission	65 (43.3%)	31 (48.4%)	34 (39.5%)
Patients with CRS requiring ICU admission	43 (60.6%)	16 (76.2%)	27 (54%)
Patients with CRS not needing ICU level of care	29 (40.8%)	5 (23.8%)	24 (48%)
Patients with CRS discharged from the ICU	19 (26.8%)	7 (33.3%)	12 (24%)
Patients with CRS still hospitalized in the ICU	5 (7%)	1 (4.8%)	4 (8%)
Patients with worsening labs but did not meet criteria to make the diagnosis of CRS, treated with corticosteroids	27 (18%)	14 (21.9%)	13 (15.1%)

Table 2. Outcomes of SARS-CoV-2-CRS patients managed using a Rheumatology-Driven Treatment Algorithm at a University Medical Center and County Hospital

to biologic contraindications and third-line agent options were made. Regular updates to biologic supplies were coordinated between rheumatology and pharmacy. Outcome assessments included tracking 1) mortality rates among the general SARS-CoV-2 population vs those with CRS, 2) number of CRS patients requiring admission to the intensive care unit (ICU), 3) number of CRS patients who received biologics vs those who received corticosteroids.

Results: Rheumatology was consulted on 150 patients diagnosed with SARS-CoV-2 infection for evaluation for possible CRS between March 15, 2020 through May 30, 2020. Protocol criteria for CRS was met by 71 patients (Table 2) with 43 of those patients requiring ICU admission. There were 19 patients stable for transfer back to non-COVID medicine service. There were 27 patients who did not formally meet CRS criteria who were given corticosteroids for a suspicion for impending CRS. With overall hospital mortality rate of 20.7%, 31 deaths from the referral cohort were noted, with 20 attributed to CRS, rendering a mortality rate 28.2%.

Conclusion: Using our protocols, we met our goal to minimize mortality rates below 30%. Advantages to having a rheumatology protocol include regulation of hospital pharmacy supplies of biologics, gaining experience in handling medication side effects in consideration of past and current medical issues, and improving interdisciplinary care across pharmacy and various medical services.

Abstract Number: 0593

Patient Characteristics and Factors Affecting Decision-Making Regarding Total Knee Replacement by Different Types of Physicians Treating Patients with Knee OA

Angela Bedenbaugh[1], Vinson Lee[1], Gary Oderda[2], Sarah Kennedy[1], Jeyanesh Tambiah[1], Diana Brixner[2] and **Timothy McAlindon**[3], [1]Samumed, LLC, San Diego, CA, [2]University of Utah, Salt Lake City, UT, [3]Tufts Medical Center, Boston, MA

SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: Health Services Research Poster
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Total knee replacement (TKR) is considered an effective knee OA treatment and is a commonly performed orthopedic procedure that relieves pain and improves function and quality of life.[1] However, up to 20% of patients may not achieve good clinical outcomes.[2] Also, comorbidities and patient factors may limit the ability to safely perform the TKR. The objective of this was to identify the percentage and distribution of TKR surgical candidates across specialties (rheumatologists [RH], orthopedic surgeons [OS], sports medicine [SM] physicians, and pain specialists [PS]) to gain insight into patient characteristics influencing TKR candidacy.

Methods: Board-certified physicians with >2 years in practice and >10 knee OA patients per week participated in an interview about their two most recent knee OA patients. Interviews were conducted from March to April 2019 and assessed demographics, referral patterns, comorbidities, time to treatment, imaging use, candidacy for TKR, and reasons for noncandidacy. Multiple reasons for TKR noncandidacy per patients were allowed. Since no patient-iden-

Smoking status	5%	

tifying information was included, this project was exempt from IRB review and HIPAA consent. As this study was designed to assess multiple characteristics and associated effect modifications, a confidence level of 90% was used.[3]

Results: Overall, the mean age of knee OA patients was 65 years (range: 63 years for SM patients to 66 years for PS patients) (Table 1). Primary care physicians were the most common referrers to RH (83%) and the reported mean time from symptom onset to diagnosis was 3.4 years (longest in RH patients; 4.5 years). Overall, the mean number of comorbidities was 2.6, with the most common being hypertension and obesity (Table 2). The mean pain score was 5.5 (0–10 NRS) and 58% of RH patients had moderate pain. RH saw predominantly KL grade 3 (55.6%) patients whereas OS saw more KL grade 4 (45.3%) patients. TKR candidacy was assessed for 779 patients; approximately half of these were identified as future surgical candidates, with 38% projected to undergo TKR within the next 12 months. Overall, of 286 (37%) identified as TKR noncandidates, 65% had mild disease or well-controlled symptoms. Among RH noncandidates (42%, n=105), additional reasons for TKR exclusion included patient preference (30%), age (11%), overall health (10%), weight (5%), and smoking habits (5%) (Table 2). Limitations to this study included potential

Table 2: Comorbidities and reasons for TKR noncandidacy

Weight	10% (n=29)	14% (n=11)[B]	5% (n=5)	13% (n=9)[B]	13% (n=4)
Smoking status	5% (n=14)	6% (n=5)	5% (n=5)	---	13% (n=4)

Key: Statistical significance, $P<0.1$; A: versus orthopedist, B: versus rheumatologist, C: versus sports medicine physician, D: versus pain specialist

selection bias, confounding by risk factors, inability to show causation, small n's, missing data, and pre-COVID-19 proposed timeline for TKR.

Conclusion: In this observational chart review, of the 42% of TKR noncandidates who were RH patients, several patient factors were identified as reasons for exclusion (patient preference, age, overall health, and lifestyle choices [such as smoking]). Patient preference contributed the largest impact (30%) and other influences were well characterized, suggesting further investigation of patient-focused factors that impact decision-making regarding TKR is warranted.

Mechanical and Temperature Stress During Biologic Shipments to Rheumatology Patients

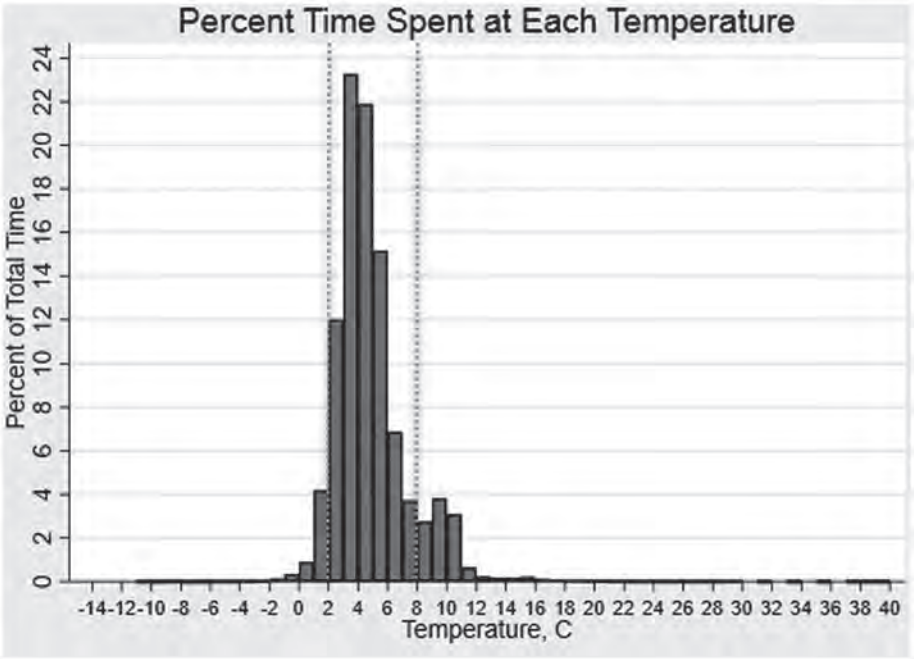
Sarah Dill[1], Elizabeth Cheng[2], Kyle Brees[2], John Carpenter[3] and Liron Caplan[2], [1]University of Colorado, Denver, CO, [2]Rocky Mountain Regional Veterans Affairs Medical Center, Aurora, CO, [3]University of Colorado Skaggs School of Pharmacy, Aurora, CO

SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: Health Services Research Poster
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

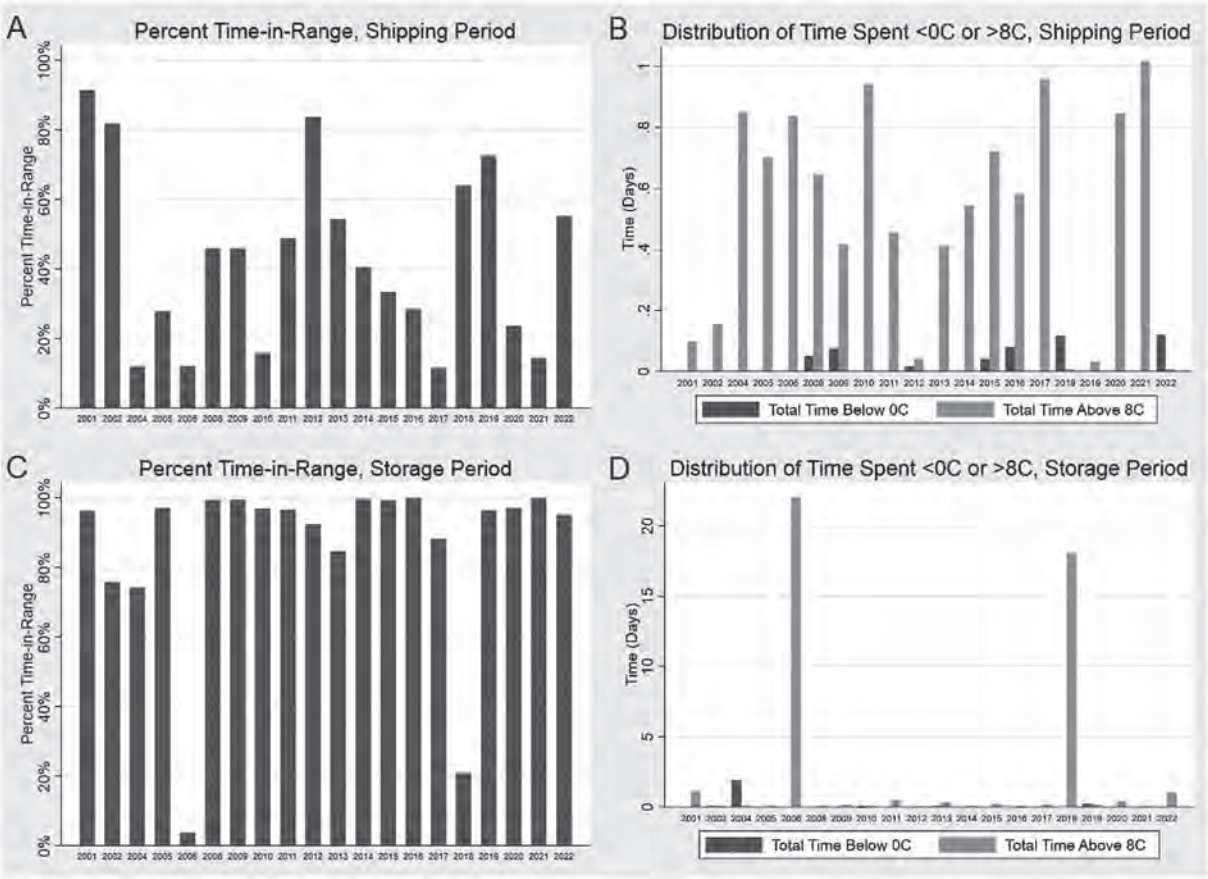
Background/Purpose: Biologic medications are expensive, and unfortunately their immunogenicity contributes to loss of efficacy over time. Protein particles may form as a result of medication mishandling and are known to enhance the immunologic response to biologics. In order to identify factors contributing to mishandling, we evaluated the temperature excursions and mechanical shock exposures during shipment of biologic medications to patients and described the storage practices of these medications by patients.

Methods: Colorimetric shock indicators registered the highest forces sustained during shipments. During both shipment and patient storage, thermocouple data loggers recorded temperatures every 2 minutes. After medication administration, patients completed and returned a questionnaire along with the data logger. The questionnaire evaluated factors like patient storage habits, refrigerator age, and frequency of adverse medication events. Temperature differences were compared between transit and storage intervals using the Wilcoxon rank-sum test. We also determined if refrigerator location was associated with temperature percent time-in-range and number of excursions out of range under controlled conditions.

Results: Twenty shipments were analyzed. Shock sensor results showed that 95%, 25%, and 5% of sensors experienced an impact of 25*g*, 50*g* and 75*g*, respectively. Medications were in-range (2-8^{0}C) temperatures only 84% of the total time (Fig. 1). The shipping period had an overall percent time-in-range of 43%, compared to 86% during the storage period (Fig 2A,C). In both shipping and storage periods, time spent over 8^{0}C was more common than time spent below 0^{0}C (Fig. 2B,D). Under controlled experimental conditions for biologic packaging, we identified a relationship between refrigerator location and both percent time in range (p=0.05) and number of excursions (p=0.004) (Fig. 3A,C). The interior rear of the refrigerator near the cold output accounted for this difference with only 68%



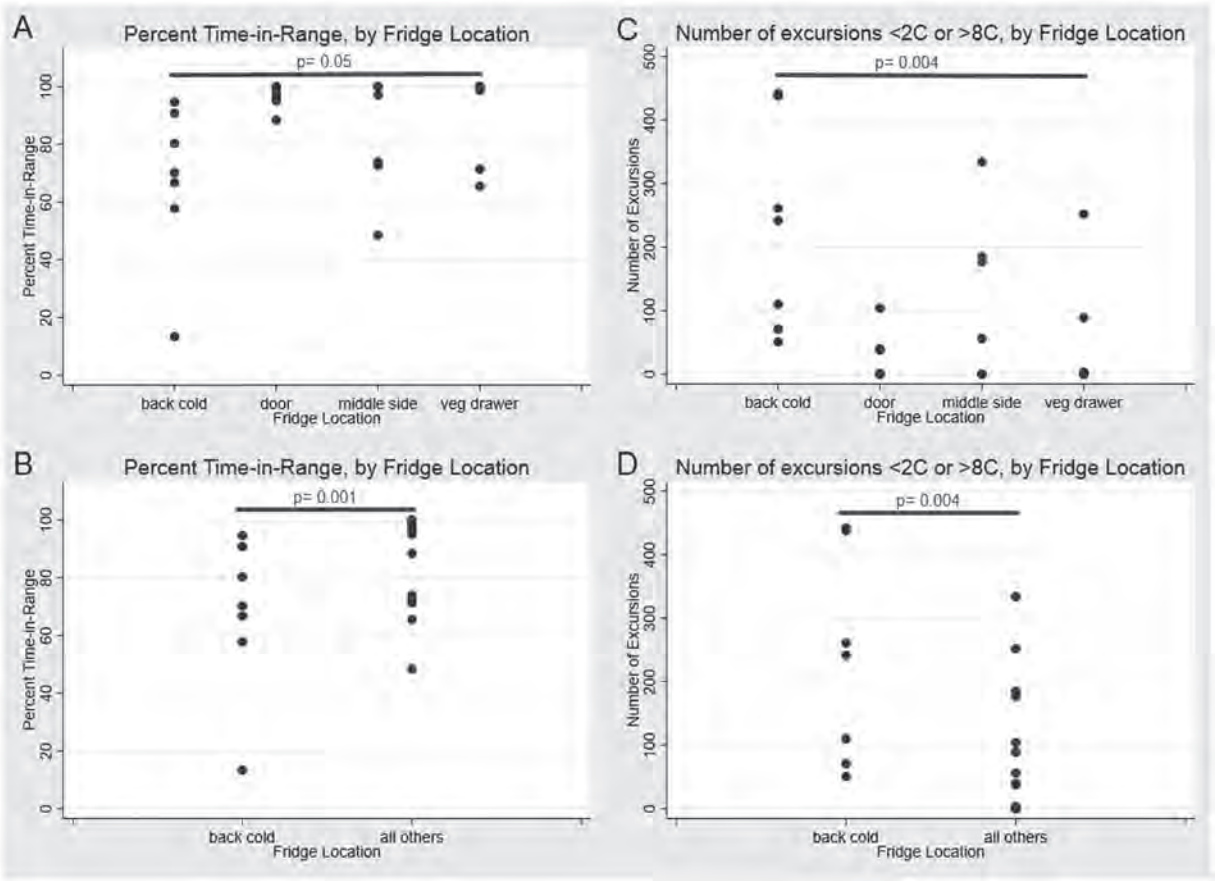
Percent time at each temperature for all trips in aggregate. Dashed lines indicate recommended temperature range.



Depicts the percent time in range and the distribution of time spent "hot" (>8^{0}C) or "cold" (<0^{0}C), for shipping (3A, 3B) and storage (3C, 3D) periods.

percent time-in-range and 231 average excursions, (p=0.01 and p=0.004 vs. other locations, Wilcoxon rank sum) (Fig. 3B,D). Dermatologic reactions were the most common adverse event, but there was no association between frequency of adverse events and mishandling (temperature excursions and mechanical shock).

Conclusion: Our current packaging strategy is insufficient both to maintain recommended temperatures during shipping and to mitigate mechanical shocks. Patients maintained biologics at more appropriate storage temperatures compared to temperature control during shipping, but additional patient education may lead to further improvements.



Scatter plots comparing each location overall for percent time-in-range (4A) and number of excursions (4B). Also comparing the back cold (near cold output) to all other areas, percent time-in-range (4C) and number of excursions (4D).

High Satisfaction with Tele-medicine in a New York City Clinic

Tommy Chen[1], Cathy Guo[1], Wei Tang[1], Leila Khalili[1] and Anca Askanase[2], [1]Columbia University Medical Center, New York, NY, [2]Columbia University College of Physicians & Surgeons, New York, NY

SESSION INFORMATION

Session Date: Saturday, November 7, 2020
Session Title: Health Services Research Poster
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: The face of medicine is changing with the time. A twenty-first century technological revolution in medicine happened in March 2020 as the COVID-19 pandemic reached the US. As it quickly became clear that face-to-face clinical medicine could not continue, at least not for some time, medical practices across the country were forced to offer virtual medicine encounters to the vast majority of patients. This change, while protecting patients, also had a cost that we are still trying to ameliorate. In Rheumatology, and other cognitive specialties, the physical exam is a critical component of the evaluation of patients with rheumatic diseases and the ability of current

technology to allow for accurate evaluations are limited. As we are struggling to understand the correct balance between face-to-face and telemedicine over the next several months, we sought to evaluate patients' satisfaction with telemedicine in a New York City rheumatology practice.

Methods: Questionnaires asking about the level of satisfaction with their telemedicine experience were offered to patients that had had a recent telemedicine encounter. The questionnaires asked about their experience and satisfaction with telemedicine and communication with the provider. The abstract reports these responses.

Results: Of the 100 patients, 91% were women, mean age 44.3, 25% black, 26% Hispanic, all insured, and over 90% had a diagnosis of SLE or other types of inflammatory arthritis (RA, UCTD, SS, PsA, SpA). Patients were asked how satisfied they were with telemedicine, and the results were unexpected: 84% reported high levels of satisfaction

Table 1. Telemedicine Evaluation Survey

Respondents ($n = 100$)	*n= 100*
How satisfied were you with your previous telemedicine visit?	
Highly satisfied	50 (50%)
Satisfied	34 (34%)
Neither satisfied not unsatisfied	11(11%)
Not Satisfied	5 (5%)
Highly Unsatisfied	0 (0%)
Reasons for satisfaction	73 (73%)
Avoid coming into the office	77 (77%)
Call went smoothly	75 (75%)
Decrease their concerns over condition, medications and risks of COVID	
Reasons for dissatisfaction	4 (4%)
Technical difficulties.	2 (2%)
Visit was too short.	4 (2%)
Visit was too basic for their needs.	
How comfortable were you with your previous telemedicine visits?	
Very comfortable	62 (62%)
Comfortable	24 (24%)
Neither comfortable nor uncomfortable	11 (11%)
Uncomfortable	3 (3%)
Highly uncomfortable	0 (0%)
The physician was able to address what was bothering me through the telemedicine visit	
Strongly agree	54 (54%)
Agree	37 (37%)
Don't Know	5 (5%)
Disagree	4 (4%)
Strongly disagree	0 (0%)
Overall, compared to an in-person visit, the telemedicine visit was?	
Much better	10 (10%)
Better	6 (6%)
Same	57 (57%)
Worse	25 (25%)
Much worse	2 (2%)
I would have a telemedicine appointment in the future, if given the option.	
Yes	77 (77%)
Unsure	14 (14%)
No	9 (9%)

Table 2. Demographic of patients

(highly satisfied or satisfied) with only 5% reporting that they were not satisfied. 86% of patients reported that they were comfortable with the new format. In 92% of patient reports, physicians were able to satisfactorily address the issues and concerns that prompted the visit. 57% of patients reported that the experiences were very similar to the in person experiences. Finally, when asked whether they would use telemedicine in the future, 77% of patients responded "yes". See further details in the table below. None of the demographic variables correlated with satisfaction or comfort with telemedicine visits.

Conclusion: These data support a high level of patient satisfaction and comfort with telemedicine, suggesting that the transition from in person medicine to telemedicine has been successful. The balance for each subspecialty between face-to-face, when signs and symptoms need to be elicited, and telemedicine remains to be determined. Further data that comprise wider demographics, socio-economics, disease manifestations, and insurance are needed to fully understand the impact of telemedicine on patient care in Rheumatology practices.

Clinical Academic Rheumatology: A Boon for Health Systems

Kathleena D'Anna[1], Karina Torralba[2], Christina Downey[3] and Carlos Silva Lynch[4], [1]Loma Linda University Medical Center, Moreno Valley, CA, [2]Loma Linda University School of Medicine, Redlands, CA, [3]Loma Linda University Medical Center, Redlands, CA, [4]Loma Linda University Medical Center, Loma Linda

SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: Health Services Research Poster
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Finding a balance between clinical and scholarly productivity is a challenge for many academic clinician-educator (CE) rheumatologists. An examination of workload and practice-generated downstream revenue serves to determine if the financial value generated by services rendered by rheumatologists are proportionate to the financial value created for a health system. A 2005 study found that academic rheumatologists generate $10.02 for every $1.00 they receive for an office visit.[1] 15 years later, this study aims to determine the financial gains an academic health system can expect from CE rheumatologists.

Methods: A retrospective analysis of ordering practices from August 2017 - February 2019 was done.

Individual workload as averaged full-time equivalents (FTEs) based on time spent on inpatient consultation, outpatient faculty practice income-generating activities, academic and administrative duties. Revenue-generating activities were classified as those that benefited the hospital directly (downstream revenue) and the rheumatology division directly through the faculty practice (Table 1). CPT codes for all charges were assigned based on Medicare Allowable Charges for 2019.

Table 1. Academic productivity by 5 academic rheumatologists over an 18-month period

Academic marker	Outcome
Promotion/Rank	1 full professor (achieved within 5 years of start of employment), 1 associate professor (within 4 years), 3 assistant professors
Teaching time	2 half-days of trainee supervision on average per week, 1 monthly lecture for trainees
Peer Reviewed publications	In total, 12 publications in high quality rheumatology journals
ACR abstracts	12 accepted and presented
Book Chapters	1 book chapter each by 2 faculty
Ongoing research projects including clinical trial	1 NIH funded research, 1 investigator initiated pharmaceutical company sponsored research, 4 industry sponsored trials, 7 non-funded investigator initiated research
Centers development	7 virtual centers approved and under development (Lupus, Inflammatory arthritis, Bone Health and Osteoporosis, Vasculitis, Scleroderma, Myositis, Sjogren's Disease)

Table 2. Revenues generated per clinical activity by rheumatologists August 2017 - February 2019

Activity	Average Revenue
Direct Rheumatology In-Office Clinical Revenue (Non-Hospital Based Clinic)	
Procedures (I,e, Arthrocentesis)	$5,903
Point-of-care ultrasounds	$5242
Infusions*	$48,372
Downstream Revenue to Hospital from Rheumatology Clinics	
Referred procedures to other specialties	$60,310
Inpatient consultations	$300,189
Laboratory tests	$347,542
Radiology (i.e. MRI, CT, xrays, DXA)	$123,900
Hospital Infusion Center** Single Drug revenue based on	$35,748,000 Reference drug: Rituximab 100mg vial cost: $9818.09 Estimated 340b pricing: 60% below WAC 100 infusions, $10,000 base charge
Contracted Services***	

Legend: MRI, magnetic resonance imaging; CT, computed tomography, DXA, dual energy absorptiometry; US, ultrasound, WAC, wholesale acquisition price *In-office infusion revenues were based solely on procedure codes for infusions. We currently do not engage in drug buy & bill or other reimbursement programs. **Estimates of revenue as numbers of patients on various medications referred, 340b pricing and hospital charges for each drug, and each infusion procedure (J) code, for were not made available by administrators. Notes. Faculty also provide services at a county hospital, and 2 FQHCs. Average faculty salary $225,000 based on 80% private practice area salary and 20% academic salary

One limitation encountered was the unavailability of hospital-based infusion center revenue. We extrapolated data based on infusion drug costs and reimbursement values of the most commonly prescribed drug prescribed (Rituximab 1000mg). We also reviewed academic productivity of faculty in the said period (Table 1).

Average FTE allocation is 0.2 FTE academic time, and 0.8 clinical duties with 0.4 FTE allocated for clinic care with trainees, and 0.4 FTE faculty practice clinic care. Faculty practice care was reduced for on-call hospital consultations (0.5 FTE). Additional FTEs allowances were given for clinical directorships (0.1 FTE), division chief (0.1 FTE) and fellowship program directorship (0.3 FTE). Academic productivity was notable (Table 1).

Results: An average of $229,041 between the five physicians for office visits was generated in evaluation and management services. The total downstream revenue generated from these visits averaged $36,579,941 per physician (Table 2). To calculate hospital infusion revenues, Rituximab 1000mg x 2 doses was used as a reference point dosed

every six months (3 doses during the study time frame). 100 vials totaling 1,000mg at $9,818.09 per vial with 340b pricing considered gross revenue was $35,748,000 per physician.

Conclusion: For every $1 generated though office visits by the five practicing Academic Rheumatologists at our institution $159.70 dollars were generated through downstream revenue, nearly 16 times the 2005 study. Most likely this is an underestimation as this study is unable to account for eleven other infusion products. Consideration must be made to consider hospital-based support for by academic rheumatologists, and for additional compensation mechanisms that consider academic productivity.

Telemedicine in Pediatric Rheumatology During COVID-19: The PR-COIN Experience

Y. Ingrid Goh[1], Nancy Pan[2], Julia Harris[3], Andrew Warmin[4], Janalee Taylor[4], Sheetal Vora[5], Fatima Barbar-Smiley[6], Jon Burnham[7], Tzielan Lee[8], Cagri Yildirim-Toruner[9], Kendra Wiegand[10] and Esi Morgan[11], [1]The Hospital for Sick Children, Toronto, ON, Canada, [2]Hospital for Special Surgery, New York, NY, [3]Children's Mercy Kansas City, Overland Park, KS, [4]Cincinnati Children's Hospital, Cincinnati, OH, [5]Atrium Health Levine Children's Hospital, Charlotte, NC, [6]Nationwide Children's Hospital/The Ohio State University, Columbus, OH, [7]Children's Hospital of Philadelphia, Philadelphia, PA, [8]Stanford University School of Medicine, Palo Alto, CA, [9]Nationwide Children's Hospital, Houston, TX, [10]Cincinnati Children's Hospital, Cincinnati, [11]Cincinnati Children's Hospital Medical Center, Cincinnati, OH

SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: Health Services Research Poster
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Healthcare teams were forced to rethink the way they practiced medicine during the COVID-19 pandemic. Many teams transitioned from conducting in-person visits to virtual telemedicine visits with limited knowledge, experience with, or infrastructure for telemedicine. PR-COIN, a quality improvement collaborative of 20 North American pediatric rheumatology centers, set out to capture the experience of the rapid adoption of telemedicine, understand its usage and acceptability, and gather opinions on its continued use.

Methods: A REDCap® survey was sent to a representative from each PR-COIN site to collect data about their experience with telemedicine and its use during COVID-19. Quantitative data were analyzed using descriptive statistics and qualitative data were thematically analyzed.

Results: 19/20 of the PR-COIN sites responded to the survey. All sites transitioned from in-person to virtual telemedicine visits during the COVID-19 state of emergency (Figure 1). Most centers reported using both videoconferencing system and telephone to conduct their telemedicine visits (Table 1). All centers reported seeing both new consultations and follow up patients over telemedicine.

13/19 (68%) reported at least 50% of their providers consistently used pediatric Gait Arms Legs and Spine (PGALS) to document musculoskeletal exams in patients with juvenile idiopathic arthritis (JIA). Items that were not well-doc-

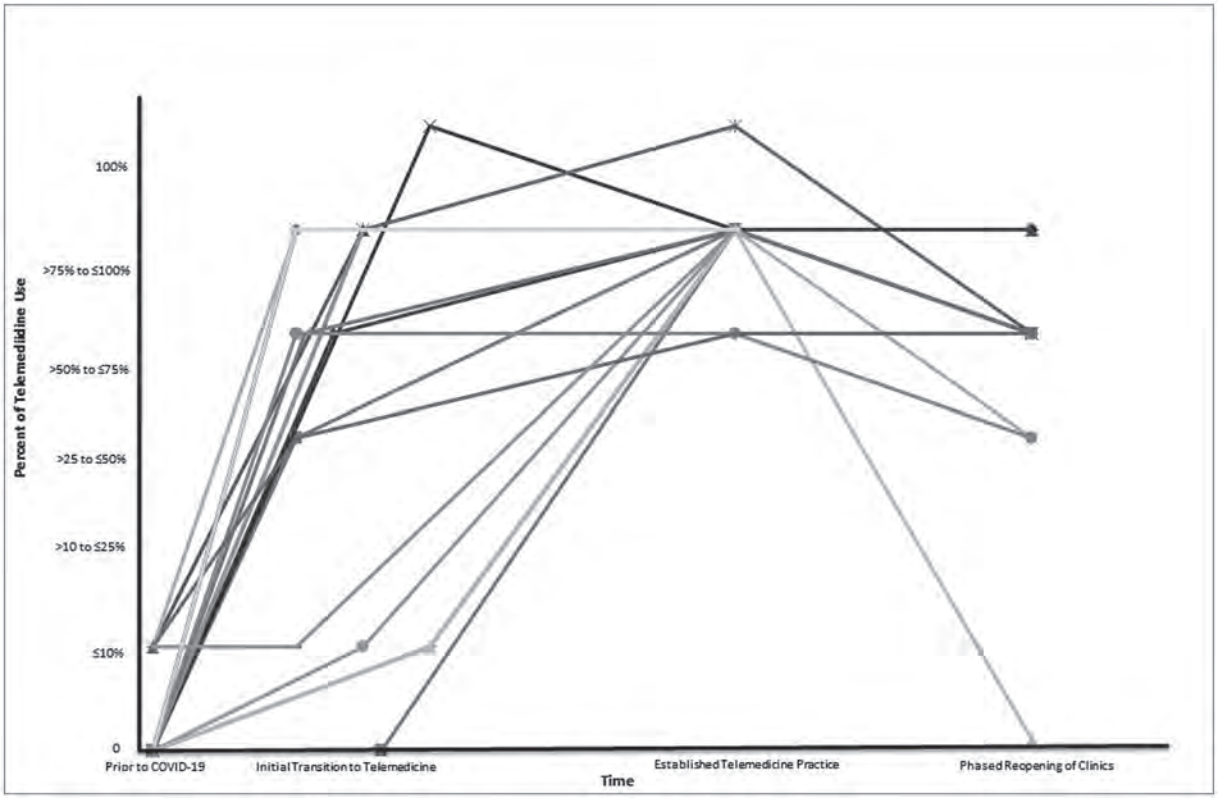

Figure 1. Use of Telemedicine Over Time

Videoconferencing system, telephone, electronic health record patient portal, telemedicine center	1

Table 1. Mediums Used to Conduct Virtual Telemedicine Visits

umented during telemedicine visits included: weight, height, disease activity, and treatment targets. 11/19 (58%) centers reported collecting patient global assessment, pain intensity and morning stiffness during the telemedicine visits. Two sites indicated they did not collect any patient reported outcome measures (PROMs), while three indicated they collected more complex PROMs.

7/19 (37%) centers reported performing research-related activity during telemedicine visits. 2/7 (29%) reported the ability to consent patients over telemedicine and 6/7 (86%) reported performing follow-up visits for observational studies.

All responding PR-COIN centers agreed that telemedicine visits were able to meet provider needs and the providers from all but one center believed that telemedicine visits were able to meet patient needs. Reasons to justify an in-person visit included presence of active disease, worsening of condition, and parent request/desire.

Identified benefits of telemedicine visits included convenience, no travel, and continuity of care for families who were hesitant to have an in-person visit. Identified challenges with telemedicine visits included limited ability to perform physical exams, difficulty assessing disease activity, and access to technology.

All centers supported the continued use of telemedicine after the pandemic. Centers indicated that they would be willing to see both new [15/19 (79%)] and follow up [14/19 (74%)] patients over telemedicine.

Conclusion: Healthcare providers have recognized the potential of incorporating telemedicine into their routine practice to serve a portion of their patients. PR-COIN plans on identifying best practices and creating tools to address existing barriers.

Abstract Number: 0598

Impact of a Dedicated Lupus Nephritis Clinic to Improve Time to Biopsy and Care Quality

Shivani Garg[1], Callie Plafkin[2], Tripti Singh[1], Sarah Panzer[3] and Christie Bartels[4], [1]UW Madison, Madison, WI, [2]UW Madison, Madison, [3]UW-Madison, Madison, [4]University of Wisconsin School of Medicine and Public Health, Department of Medicine, Division of Rheumatology, Madison, WI

SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: Health Services Research Poster
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Lupus nephritis (LN) contributes to a 10-fold higher risk to develop kidney failure and 26-fold higher mortality compared to peers. Kidney biopsy remains a gold-standard to diagnose LN and start therapy. Yet, our prior study highlighted that the average wait time to see a specialist and undergo a kidney biopsy was >50 days, with no change over 20 years (1997-2017). Further, studies report that high-impact quality process measures, such as ACE inhibitors use and addressing social needs, are often missed during routine SLE visits, contributing to poor LN outcomes. Therefore, we implemented a multidisciplinary LN clinic to provide targeted strategies to overcome such barriers to improve care and LN outcomes. We aimed to examine time to biopsy and quality measures provided to LN patients before and after the implementation of LN clinic.

Methods: All validated adult LN patients with diagnostic kidney biopsy preformed between 2011-2020 were identified from our comprehensive native kidney biopsy database at an academic center. Data on sociodemographic, disease characteristics and biopsy date were abstracted from this database. We manually abstracted data on medications, date of abnormal labs or LN specialist referral, vaccinations and social needs to examine quality process measures. Time to biopsy was defined as time from abnormal labs or LN specialist referral until biopsy. Pre- and post-LN clinic period included patients who underwent biopsies between 2011-2017 and 2018-2020, respectively. We used KM analysis to compare time to biopsy during the two periods, and Cox Proportional hazards models to examine predictors of time to biopsy. We used Fisher and two-sample t-tests to compare socio-demographics and quality measures during these two periods.

Table 1. Demographics of Adult LN Patients During Pre- and Post-LN Clinic Periods

	Pre-LN Clinic n = 53	Post-LN Clinic n = 21	OR (95% CI)*	p value**
Socio-Demographics

Social Needs & Referral, n(%)	**4 (8%)**	**11 (52%)**	**15 (4-81)**	**<0.0001**

**OR and **p calculated using Fisher test for qualitative data & t-test for quantitative data; AZA Azathioprine; CKD Chronic Kidney Disease; CYC Cyclophosphamide; DM Diabetes Mellitus; Dx Diagnosis; IQR Inter-Quartile Range; HCQ Hydroxychloroquine; RTX Rituximab*

Table 1. Demographics of Adult LN Patients During Pre- and Post-LN Clinic Periods

Results: The pre-LN clinic period included 53 LN patients, the mean age was 36 years, 75% were female and 74% were white (Table 1). During the post-LN clinic period, 21 LN patients underwent diagnostic biopsy. The mean age was 35.6 years, 62% were female and 51% were white.

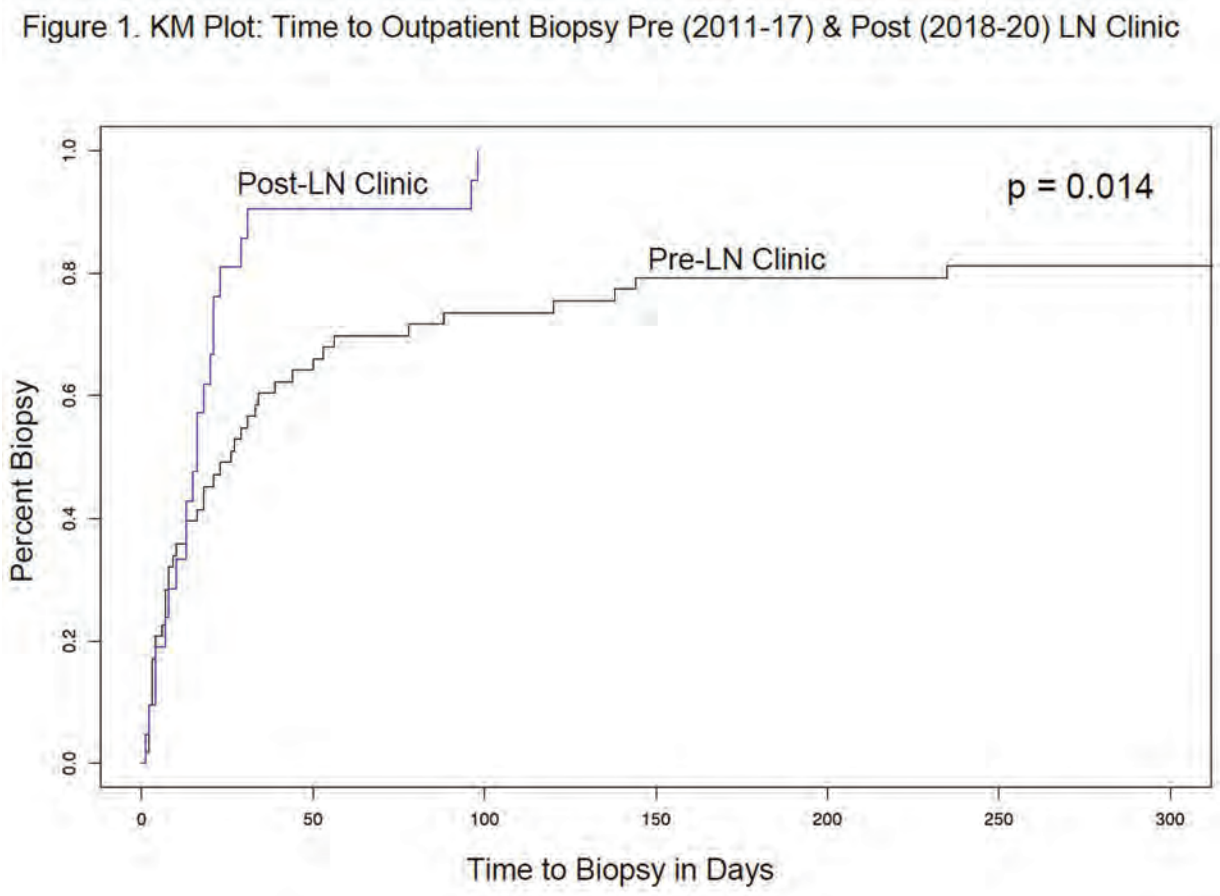

Figure 1. KM Plot: Time to Outpatient Biopsy Pre (2011-17) & Post (2018-20) LN Clinic

Table 2. Cox Proportional Hazards Model to Examine Predictors of Time to Biopsy

Variable	HR (95% CI)	p value
Age at LN Biopsy	0.98 (0.9-1.0)	0.6
Non-White Race	1.3 (0.5-3.2)	0.6
Female	1.3 (0.5-4.0)	0.5
Social Needs Identified	**4.1 (1.2-12)**	**0.007**
Urine Protein Creatinine Ratio, Time of Biopsy	1.1 (0.95-1.3)	0.2
CKD Stage 3 or above	2.2 (0.7-6.0)	0.2

Model includes all variables with p < 0.1 on univariate analysis; CKD Chronic Kidney Disease; LN Lupus Nephritis

Table 2. Cox Proportional Hazards Model to Examine Predictors of Time to Biopsy

The mean and median time to biopsy in the pre-LN clinic period were 202 and 26 (IQR 7-120) days, and during the post-LN clinic period were 22 and 16 (IQR 8-21) days. The median time to biopsy decreased by 10 days after starting the LN clinic (*p 0.014*; Figure 1). We found social barriers as the strongest predictor of longer wait times (*HR 4.1, 95% CI 1.2-12, p 0.007;* Table 2).

We found 13-fold higher odds of ACE inhibitors use in LN, 10-fold higher odds to complete pneumococcal vaccination, and 15-fold higher odds to address social needs during the post-LN clinic period compared to the previous period (Table 1). We noted a trend of increased hydroxychloroquine use in the post-LN clinic period.

Conclusion: This is one of the first studies to report significant improvement in wait times to diagnose LN after establishing a multidisciplinary LN clinic. Our study highlights that system and social barriers predict a delay in diagnosis, which can be addressed by including a social worker in specialized clinics. Finally, our study supports previous reports on higher quality measure performance in SLE subspecialty clinics.

Abstract Number: 0599

Evaluation of Telephone Consultations in Germany as an Additional Tool in Outpatient Rheumatology Clinics During the COVID-19 Pandemic

Ulrich Drott[1], Axel Braner[1], Thomas Kollewe[2], Harald Burkhardt[3] and **Florian Meier**[1], [1]Department of Rheumatology, University Hospital Frankfurt, Goethe University, Frankfurt, Germany, Frankfurt, Germany, [2]J. W. Goethe-Universität Frankfurt, FB Medizin, Frankfurter Arbeitsstelle für Medizindidaktik, Frankfurt, Germany, Frankfurt, Germany, [3]Department of Rheumatology, University Hospital Frankfurt, Goethe University, Frankfurt, Germany, Frankfurt am Main, Germany

SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: Health Services Research Poster
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: The Covid-19 pandemic holds multiple challenges for the healthcare system. Quick adoptions and adjustments are the mainstays during these times. Hygiene management and plans in a primary care center for Covid-19, especially for prone patients such as patients with inflammatory rheumatic diseases receiving immunosuppressive or immunomodulatory therapies, are difficult. Nonetheless, monitoring of these treatments must be ensured. As a result, implementation of telephone visits was sought and rapidly achieved for most of the outpatient consultations.

The aim of this retrospective analysis was to evaluate the opinion of the patients regarding telephone consultations as a substitute for regular outpatient visits during the COVID-19 pandemic.

Methods: Patients were pre-screened for applicability and availability of a telephone consultation. After four weeks of mixed outpatient clinics (physical visits and majorly telephone visits), we performed a survey to inform our current concept during the outbreak. Patients (n=104) were randomly selected assuring to pick visits throughout the consulting hours. A 14-item questionnaire was developed and applied (graduation from 1 [do not agree at all]) to 5 [fully agree]). Additionally, we noted changes in therapy.

Results: On average, patients were 54 years old and for the most part female (69.2%). In general, patients reported an high agreement for the telephone visit (median 5 for the first six items: questions were equally answered as in regular visits; symptoms were reported sufficiently, and readily; telephone visit adequate if no acute problems were

present; time saving; nonetheless well looked after). The quality of the connection did not influence the consultation and many (median 4) would participate in future telephone visits. Patients highly agreed to implement telephone visits as an additional tool for outpatient clinics despite the pandemic (median 5), however patients were divided as to favour physical visits or telephone or video consultations. Dosage adjustments were made in 14.4%, change of therapy at least in 5.7% of cases.

Conclusion: The participation in a pre-screened telephone consultation as an additive tool in the outpatient care of patients with rheumatic disease showed a high level of acceptance. It remains a matter of ongoing health services research as to which extent telephone and/or video consultations should steadily be implemented in outpatient rheumatology clinics, even after the Covid-19 outbreak, with regard to the current deficits in rheumatologic care, especially in Germany.

Abstract Number: 0600

Gout Increases Length of Stay in Patients Hospitalized for Heart Failure Exacerbation

Daniel DeMizio[1], Guojing Wu[2], Ying Wei[2], Joan Bathon[3] and Runsheng Wang[4], [1]Columbia University Irving Medical Center, Division of Rheumatology, Staten Island, NY, [2]Columbia University Mailman School of Public Health, Department of Biostatistics, New York, NY, [3]Division of Rheumatology, Columbia University Vagelos College of Physicians and Surgeons, New York, NY, [4]Columbia University Irving Medical Center, Division of Rheumatology, New York, NY

SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: Health Services Research Poster
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: There is growing evidence that both the prevalence of gout and its burden on healthcare costs has increased over recent decades. It has been shown that hospitalization increases the risk of acute gout flare, which may prolong hospital stay compared to those without gout flare. It is unclear whether patients with history of gout would have longer hospital stays in general, or only when they have a flare. The objective of this study is to examine the effect of gout diagnosis and flare on the length of stay in patients admitted for heart failure exacerbation in a health care system.

Methods: We conducted a case control study using electronic medical record data from Columbia University Irving Medical Center. We searched for patients ≥18 years, with an inpatient hospitalization for a primary discharge diagnosis of heart failure exacerbation from 7/1/2012 to 6/30/2017 using ICD-9 and ICD-10. Cases were defined as those with two or more gout diagnoses prior to their heart failure admission. Controls were defined as patients without any diagnosis of gout prior to their admission. Cases were matched 1:2 to controls on the basis of age, sex, and total number of heart failure admissions during the study period. Gout flare was defined as any clinician documentation of gout flare during a hospitalization, and was ascertained by manual review. Primary outcome was length of stay (LoS). We used two-sample t-test to compare the log LoS between cases and controls. We used linear mixed effect model

Table 1.

	Controls (n= 492)	Cases (n = 246)
Age, *years*	71.67 (±13.95)	71.67 (± 13.95)
Sex, *no. (%)*		
Male	304(61.7%)	152(61.7%)

Insurance, *no.(%)*		
Commercial	243 (49.4%)	111 (45.1%)
Medicare	217 (44.1%)	126 (51.2%)
Self-Pay	7 (1.4%)	2 (0.8%)
Medicaid	25 (5.1%)	7 (2.9%)
Number of Admissions , *days*	1.325 (± 0.61)	1.325 (± 0.61)
Ejection Fraction, %	36.97 (± 18.97)	38.96 (± 18.55)
BMI	28.28 (± 11.55)	29.04(±8.00)
Elevated Troponin, *no.(%)*	111(22.6%)	39 (15.9%)
Baseline Na, *mEq/L*	137.78 (± 4.78)	138.51 (± 4.43)
Baseline BNP, *mEq/L*	5539.3 (± 11574.2)	5145.41 (± 8596.18)
Baseline Cr, *mEq/L*	1.76 (±1.48)	2.22 (± 1.60)

Baseline characteristics of patients with prior gout diagnosis (cases) and patients without prior gout diagnosis (controls). Except where indicated otherwise, values are mean ± SD. BMI: body mass index; Na: sodium; BNP: brain natriuretic peptide; Cr: creatinine, SD: standard deviation.

with random intercept to adjust for potential confounders and compared the adjusted LoS of gout patients with flare, gout patients without flare, and controls.

Results: We identified 545 admissions for heart failure exacerbation in 293 patients with a history of gout, and 5461 admissions for heart failure exacerbation in 3798 patients without a history of gout. A total of 978 admissions, consisting of 246 cases and 492 matched controls, were included in our analysis. Baseline data for cases and controls are summarized in *Table 1*. The log LoS was significantly longer in cases (1.86 ± 0.95) compared with controls (1.72 ± 0.94; $p = 0.0278$). Out of 326 case admissions, a gout flare was confirmed to have occurred in 42 (13%) admissions. The median LoS for those gout patients who flared was 10 days (interquartile range (IQR) = 10), compared to 6 days in those without flare (IQR = 8), and 6 days in patients without a history of gout (IQR = 9). The log LoS was significantly longer in those with gout who flared (2.41 ± 0.96) compared to those without gout (1.77 ± 0.90, $p < 0.0001$). The log LoS in those with gout who did not flare was not different from controls (1.82 ± 0.83; $p = 0.2465$). After adjusting for age, baseline electrolytes, body mass index, cardiac function, and socioeconomic status, the log LoS of patients that flared ($p < 0.0001$) remained significantly longer than controls, but not those who did not flare ($p = 0.042$).

Conclusion: Heart failure patients with gout had significantly longer hospitalizations than those without gout, an effect driven primarily by those gout patients who flare during hospitalization. Future work will focus on identifying risk factors for gout flares and its prevention in hospitalized patients.

Abstract Number: 0601

The "Why" of Drug Discontinuation; Clinical Review of EMR Notes for 2,545 Patients with Rheumatic Diseases

Kent Kwas Huston[1], Simon Helfgott[2], Scott Milligan[3], Jasvinder Singh[4], Nehad Soloman[5], Brandon Weil[3] and Colin Edgerton[6], [1]Kansas City Physician Partners, Kansas City, MO, [2]BWH- HMS, Boston, MA, [3]Trio Health, Louisville, CO, [4]University of Alabama at Birmingham, Birmingham, AL, [5]Arizona Arthritis & Rheumatology Associates, P.C., Peoria, AZ, [6]Articularis Healthcare, Summerville, SC

SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: Health Services Research Poster
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Persistence on therapy is an important consideration in rheumatic diseases. There are multiple treatment options that influence long term disease management and a better understanding of the causes for medication discontinuation are needed. Possible reasons for discontinuation may be inferred from fielded data, when present, in EMR, claims, or specialty pharmacy records; however, actual reasons may be different. We reviewed open text notes within the EMR to understand why drugs were discontinued for patients with rheumatic diseases.

Methods: The ARN-TRIO Rheumatology registry contains EMR (fielded and open text), lab, procedure, infusion, medical claims, and specialty pharmacy data generated in care of >75,000 patients by ARN, a network of independent practices with >200 rheumatologists across the US. Data present in open text notes are extracted by clinically trained scribes who review the full patient histories for each patient and collect supplemental information into customized data forms. The collected data undergo a two-level audit process. Open text notes assessed were those specific to patients who discontinued csDMARD and/or targeted immune modulating drugs (TIM) between 2015 to 2019. Only the last discontinuation event per patient drug was considered for this study. Comparisons were made using chi-square with column proportions compared by z-test.

Results: Open text notes were reviewed for 2545 patients receiving 3616 regimens for which 4027 drugs were discontinued. Study population characteristics: 75% (1918) female, 77% (1325/1712) white, mean (range) age 57 (18-89), 67% (1706) with rheumatoid arthritis (RA). Reasons for discontinuation differed by drug type. [FIGURE 1] Perceived association or complication with one or more medical conditions was most commonly indicated for csDMARDs (44% [725/1644]) with 49% (350/715) indicated as gastrointestinal. [FIGURE 2] Lack or loss of efficacy was listed as the predominant reason for TIM discontinuation (53% [1260/2382]). To assess alignment of fielded data with recorded discontinuation reasons within the notes, we examined disease activity scores (RAPID3 or CDAI [DAS]) closest but preceding drug discontinuation for the subset of patients with RA. Of 2780 drug discontinuations, DAS were recorded for 73% (2042); 68% (1891) within 6 months prior to discontinuation. For TIM (but not for csDMARD discontinuations), DAS scores were significantly different for those indicated as "lack or loss of efficacy" v. not. [FIGURE 3] Approximately 15% (TIM) and 16% (csDMARD) of discontinuations indicated as "lack or loss of efficacy" had near remission or low DAS.

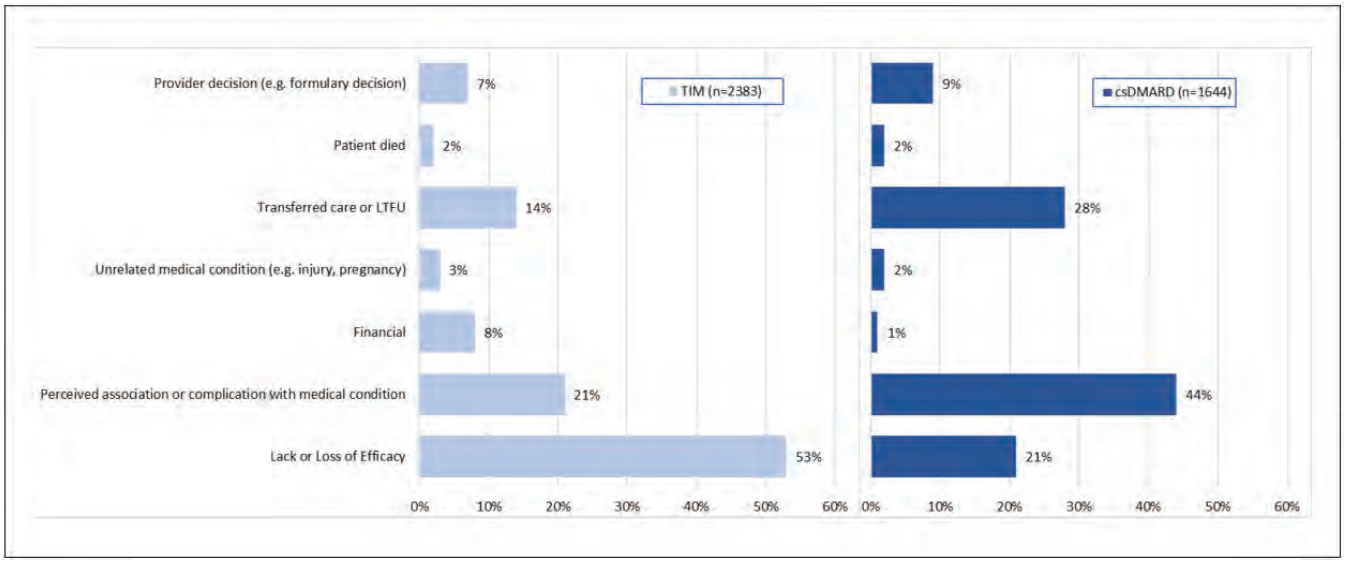

Figure 1. Reasons for discontinuation by type of discontinued drug. An individual patient may have >1 discontinuation reason

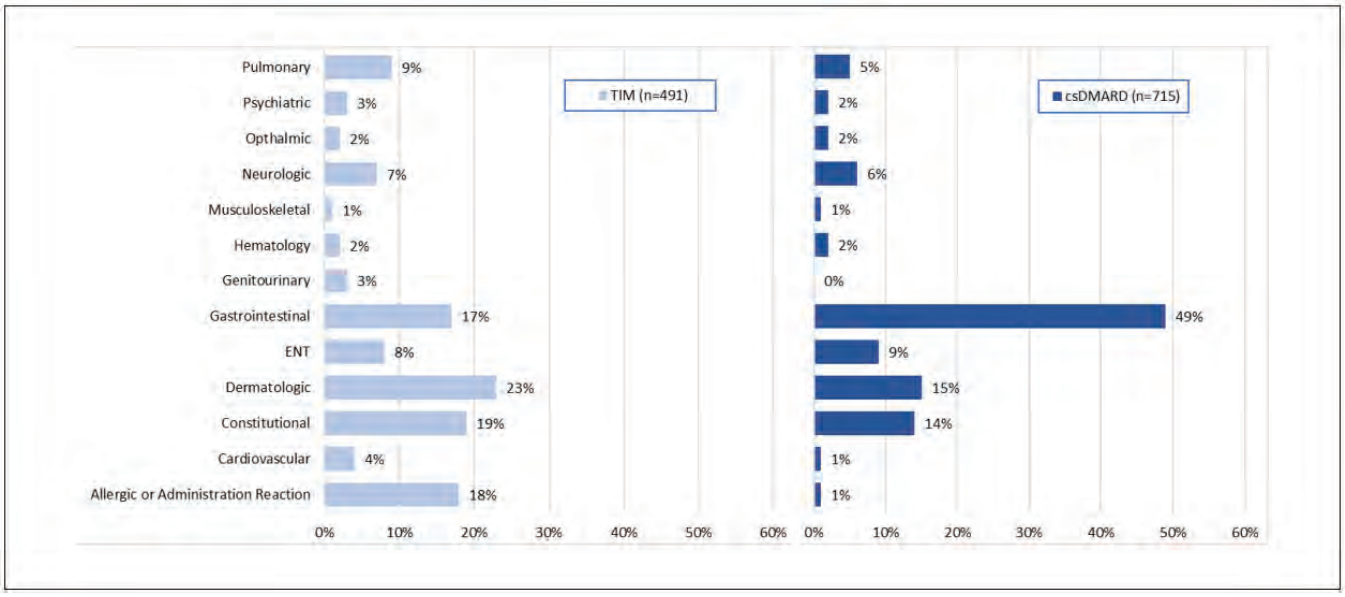

Figure 2. Systems indicated when discontinuation associated with 1 or more medical condition

Conclusion: Actual reasons for discontinuation may be directionally aligned with recorded data in the EMR, though the lack of fielded data for ~30% of evaluated discontinued drugs limits full understanding of what drives drug discontinuation. In addition, reported data that would appear to be at odds with the discontinuation reason suggest that other measures or inputs may contribute to how physicians or patients define successful treatment. To fully understand care, ongoing chart review along with full data extraction are necessary.

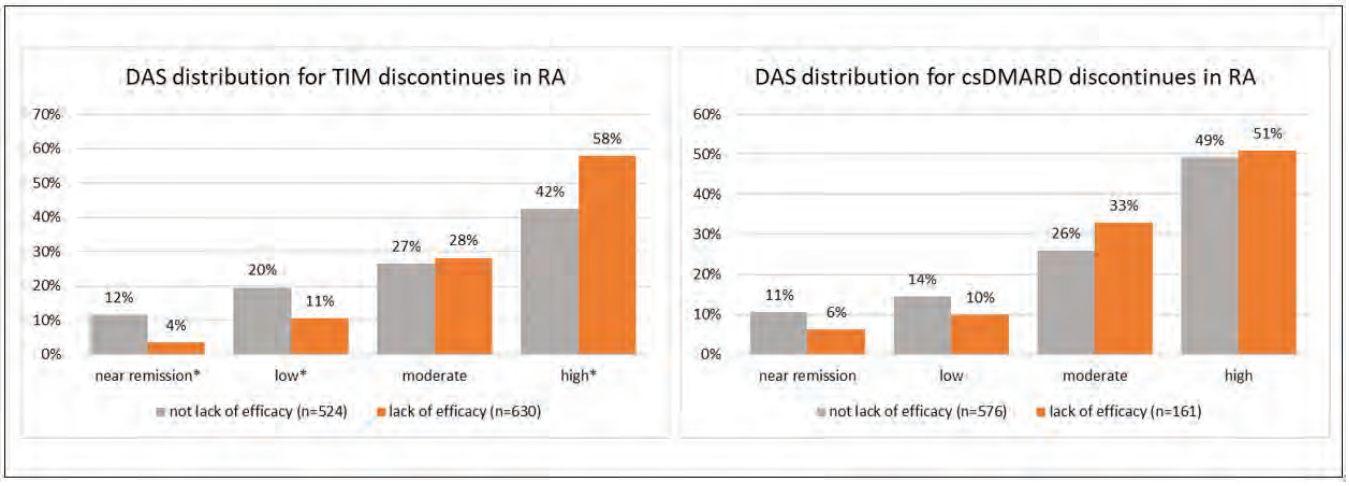

Figure 3. Distribution of DAS scores by discontinued drug type and reason of loss/lack of efficacy v. not in patients with RA. * indicates proportions that are significantly different ($p<0.05$)

Abstract Number: 0602

Labor Impact of SARS-COV-2 Pandemic in Argentine Rheumatologists

Scarafia Santiago[1], Emilio Buschiazzo[2], María Victoria Martire[3], César Graf[4] and Rodrigo Garcia Salinas[5], [1]Hospital Municipal "San Cayetano", Buenos Aires, Ciudad Autonoma de Buenos Aires, Argentina, [2]Hospital Señor del Milagro, Salta., Salta, Salta, Argentina, [3]Instituto Médico Platense, La Plata, La Plata, Buenos Aires, Argentina, [4]Sociedad Argentina de Reumatología, Paraná, Entre Rios, Argentina, [5]Hospital Italiano La Plata, La Plata, Argentina

SESSION INFORMATION

Session Date: Saturday, November 7, 2020
Session Title: Health Services Research Poster
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: The novel coronavirus SARS2-COV-2 has precipitated the present outbreak of COVID-19, the worldwide spread has strong impact on general population and on healthcare workers. The objective of the present study was to describe the impact of the COVID-19 outbreak on Argentinian rheumatologists. Also to describe the current employment situation of the specialty.

Methods: A voluntary survey was carried out by e-mail to Argentine Society of Rheumatology (SAR) associates, during the mandatory preventive isolation (quarantine) ordered in Argentina by the national state (March 18th, 2020). After a brief explanation, the physicians were invited to join a fully anonymous online closed survey and the access link was sent. A 27-items survey was designed and developed by the authors. Transferred to STATA 14 for analysis:

descriptive statistics, Mann-Whitney or T-test for continuous variables and Fisher's exact test or Chi2 for categorical ones, p 0.05 was considered significant.

Results: More than one thousand physicians registered in SAR were invited. Responses were collected from April 22nd to May 22nd, 2020, (days: 34-64 the of quarantine). For the final analysis, 272 were included.

Women 65.59%, median age 44 years (ICR 38-52). Most (85.03%) lives in big cities (more than 100,000 h). 9.68% were in trainee. Only 17 rheumatologist (6.09%) works exclusively at public sector.

In total, 96.06% of the physicians has been in virtual contact with patients, the most frequent via was WhatsApp (78.8%). The most frequent reason was: request medical prescription (81.8%), 90% (RIC 70-100) were able to obtain medications in digital format, although 52.7% contacted again for same reason. Of the large number of non-face-to-face consultations, only in 5% (RIC 0-40) have received payment. On average, reported a 65% drop (RIC 50-80) in their monthly income.

The 34% reported having had some change in their job functions, 30% were assigned to COVID-19 patient care. A similar proportion has had, unilaterally by their employer, decrease in their workload, and even nine have lost a job in this period. Only 57.66% reported having the proper personal protective equipment (PPE).

About 40% of the population of the country lives in the metropolitan area of Buenos Aires (AMBA), being this one´s that concentrates the largest number of cases of patients with SARS2-COV-2 infection (at the time of conducting the survey and of making this report). Sub-analysis: 43.7% of the physicians were from AMBA and 56.3% from others regions. Before the quarantine, outside AMBA have a greater number of weekly outpatient clinic (average) [60 (RIC 40-80) vs 50 (RIC 30-70), p: 0.009] and currently the residents in AMBA have consultations [5 (RIC 2-10) vs 10 (RIC 3-15) p: 0.03]. Outside AMBA report a greater drop in their monthly income [70% (RIC 50-90) vs. 50% (RIC 30-80) p: 0.004].

Conclusion: The lack of safe and effective systems to virtual consultations make rheumatology patients unable to continue with the adequate follow-up. The deteriorated quality of work and poor payment of doctors in Argentina is deepened at the moment, sharing with much of the rest of the world's doctors the lack of PPE to perform tasks related to the pandemic.

Abstract Number: 0603

Multisite Study of the Impact of COVID-19 Era Telemedicine Expansion on Reduction in No-Show Rates

Christie Bartels[1], David Gazeley[2], Ann Rosenthal[3], Sancia Ferguson[4], Edmond Ramly[5], Monica Messina[6] and Douglas White[7], [1]University of Wisconsin School of Medicine and Public Health, Department of Medicine, Division of Rheumatology, Madison, WI, [2]Medical College of Wisconsin, Wauwatosa, WI, [3]Medical College of Wisconsin, Milwaukee, WI, [4]University of Wisconsin-Madison School of Medicine and Public Health, Department of Medicine, Division of Rheumatology, Oakland, CA, [5]University of Wisconsin School of Medicine and Public Health, Department of Family Medicine and Community Health;, Madison, [6]University of Wisconsin School of Medicine and Public Health, Department of Medicine, Rheumatology Division, Madison, WI, [7]Gundersen Health System, Onalaska, WI

SESSION INFORMATION

Session Date: Saturday, November 7, 2020
Session Title: Health Services Research Poster
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: The COVID-19 pandemic led to rapid expansion of telemedicine in all fields, including rheumatology. We hypothesized that increased use of telemedicine would reduce no-show visits, given greater convenience and reduced barriers such as travel or transportation, which could also potentially reduce disparities in visit attendance.

Table 1. Comparison of Gundersen, MCW, and UW Health system population characteristics

Group	Primary County	Academic/ Community	Rural %	Population Density/ sq. mi	White non-Hispanic	Black	Hispanic/ Latino	Asian	Other Race
Gundersen	La Crosse	Community	17%	254	90%	2%	2%	5%	2%
MCW	Milwaukee	Academic	<1%	3,926	53%	27%	14%	4%	4%

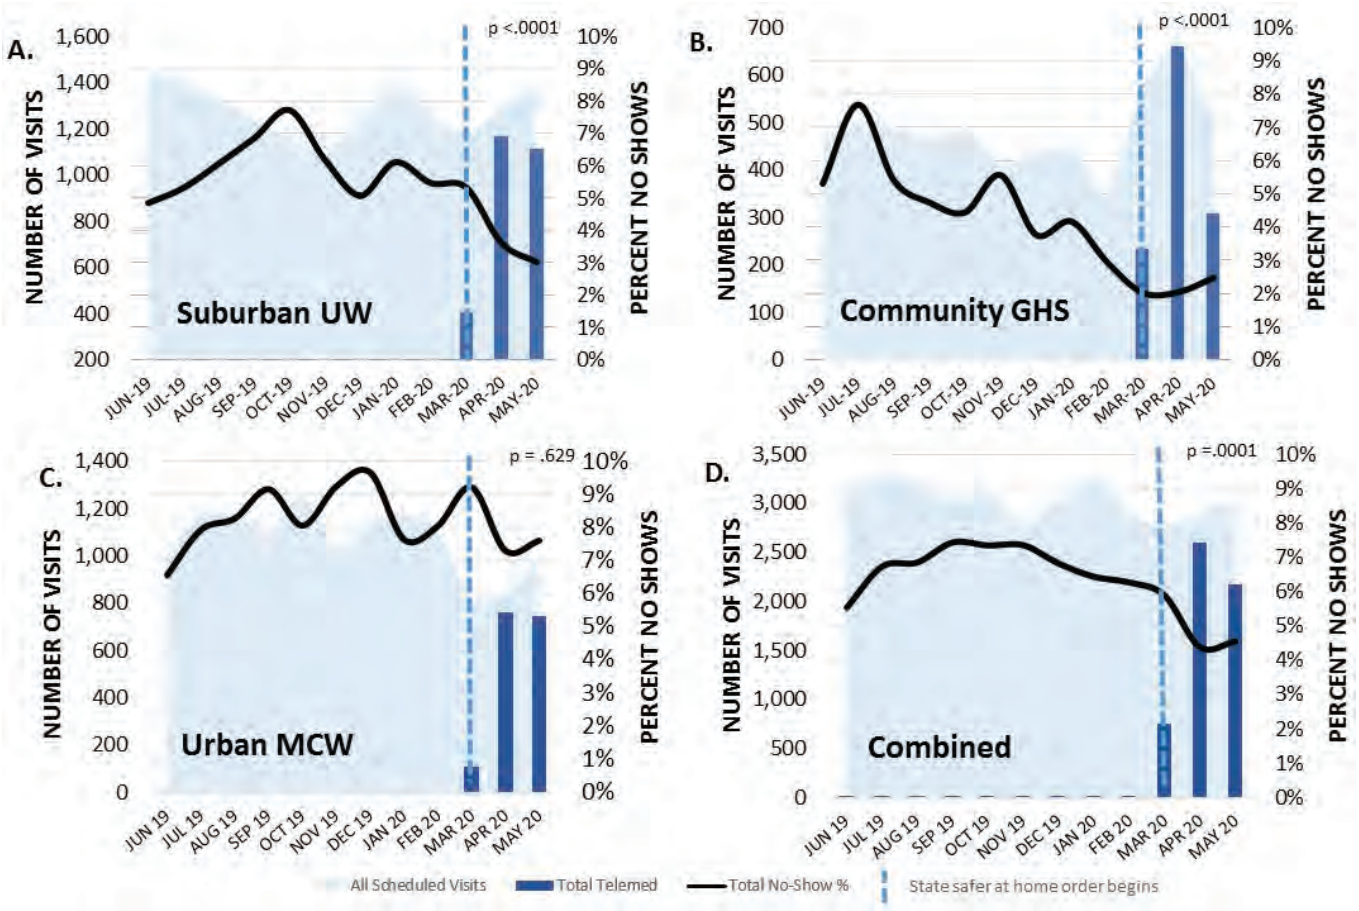

Figure 1. Total visits, telemedicine visits & no-show encounters by month at three centers and overall combined

Methods: We conducted an observational study with three rheumatology groups in one state (Table 1) serving diverse academic urban (Medical College of Wisconsin-MCW in Milwaukee), suburban (University of Wisconsin-UW in Madison), and community populations (Gundersen Health System-GHS in Lacrosse). To compare rates of no-shows before and after a statewide safer at home order 3/26-5/26/2020, electronic health record (EHR) data were queried for monthly rates of in-clinic visits, telemedicine visits, and no-show counts across one year, 6/1/2019-5/31/2020. Telemedicine included scheduled telephone or video encounters versus in-person clinic visits; most were via telephone. No-show rates were defined as the proportion of visits that did not successfully reach a patient divided by the total number of scheduled clinic or telemedicine visits. Chi square calculations compared no-shows and completed visits before and after March 2020 at each site and combined. The project was exempted by local IRBs.

Results: At baseline, only one center used telemedicine with a mean of five visits per month. In March 2020, telemedicine visits increased at all centers. By April, telemedicine outnumbered clinic visits 13-fold, while total volumes remained high (Table 2). Two sites saw no-show rates decline from 4.2-8.4% before to 2.0-5.8% after March 2020. As hypothesized, rates declined in months with higher telemedicine volumes at two centers (Fig 1A & B black lines $p< 0.0001$). However, declines were not statistically significant at the urban center (Fig 1C). Combined data (Fig 1D) showed declines in no-show rates at the time of telemedicine expansion (p.0001).

Limitations include limited information regarding telemedicine implementation across sites (e.g., live pre-visit reminder calls with telemedicine vs. automated reminders), possible missed no-show visits, and the lack of adjustment in our observational study. Personal interaction via reminder calls from office staff, or the novelty of telemedicine might have also reduced no-show rates and merits further study.

Conclusion: Our findings suggest that in the period of increased telemedicine visits after March 2020, no-show rates decreased while overall total visit volumes remained high. Two centers serving more rural populations showed particular gains in reducing no shows. The urban center did not see reduced no-show rates, potentially predicting ongoing healthcare delivery disparities with telemedicine or a need for more implementation support in urban populations. Future studies should follow longitudinal trends and compare multivariable predictors (e.g., race, age group, travel distance) of no-shows for in-clinic versus telemedicine. Likewise, further work should examine how to optimize telemedicine implementation overall and with vulnerable populations, and how policy can support optimal telemedicine use.

Abstract Number: 0604

Increasing the Rate of Pneumococcal Vaccination in an Academic Rheumatology Outpatient Clinic

Maria Bacalao[1], Swathi Reddy[2] and Nilofar Syed[3], [1]UT Southwestern, Dallas, TX, [2]Veterans Affairs North Texas Healthcare System / UT Southwestern Medical Center, Dallas, TX, [3]UT Southwestern Medical Center, RICHARDSON, TX

SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: Health Services Research Poster
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Many patients with rheumatic diseases are at increased risk of infection, including invasive pneumococcal infection, due to both disease-related abnormalities of the immune system as well as the use of immunomodulatory medications. The Centers for Disease Control and Prevention recommends that people with immunocompromising conditions receive vaccination with both a pneumococcal conjugate vaccine (PCV-13), and pneumococcal polysaccharide vaccine (PPSV-23). However, significant confusion persists in rheumatology clinics regarding

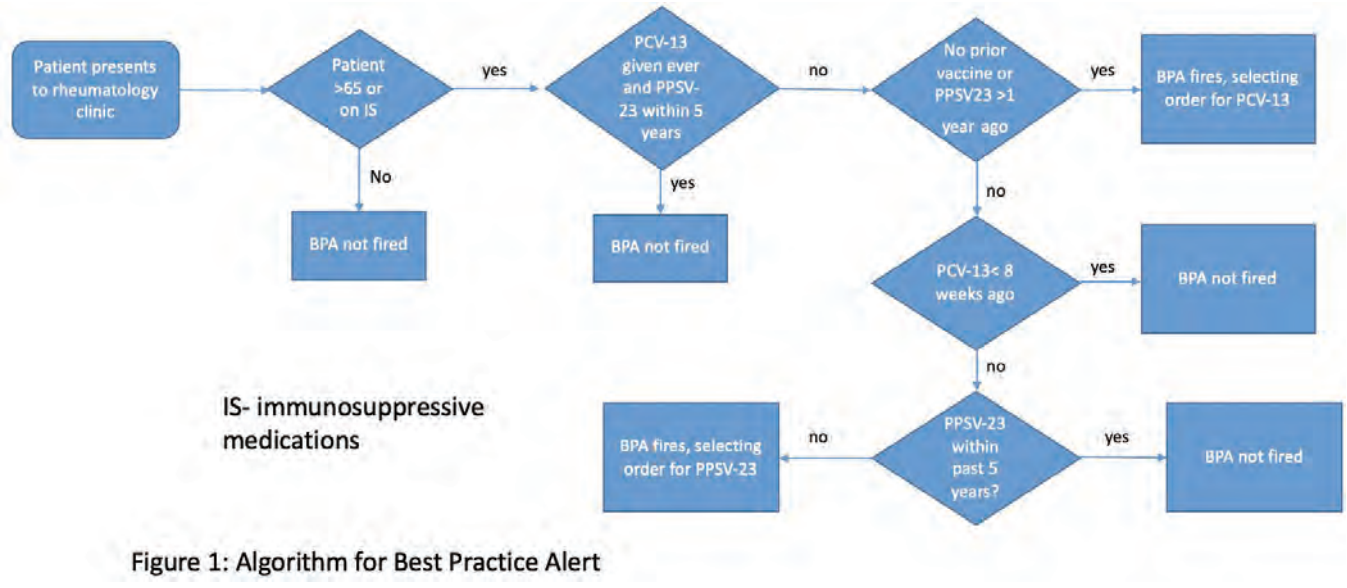

Figure 10. Vaccine Algorithm

Table 1: Data from Intervention

Pre-intervention Data

	Up to date	Not up to date	Not due yet	percent up to date
Pneumovax	23	26	1	49.0%
PCV13	10	34	6	31.4%

Post-intervention Data

	Up to date	Not up to date	Not due yet	percent up to date
Pneumovax	32	11	7	78.0%
PCV13	28	20	2	60.0%

Table 1. Intervention Data

Table 2: Patient Characteristics

Patients	Pre-intervention N=50	Post-intervention N=50
Age, ≥65	22%	24%
Gender, male	24%	18%

Rituximab	9.2%	12.0%
Sulfasalazine	15.1%	16.0%
Tofacitinib	34.5%	2.0%

Table 2. Patient characteristics

pneumococcal vaccine indications and algorithms for administering the vaccine. Furthermore, multiple competing demands in clinic often leave inadequate time to discuss indicated vaccinations with patients. The aim of our quality improvement initiative was to improve the percentage of patients who are up to date on pneumococcal vaccines in an academic county hospital rheumatology clinic from 33% to 53% for PCV-13 and from 49% to 70% for PPSV-23 from January 2019 to January 2020.

Methods: We created a Best Practice Alert (BPA) in our electronic medical record that would alert the provider when a patient is due for either a PCV-13 or PPSV-23 vaccine (Figure 1). The BPA opens an order set with the appropriate vaccine preselected. The provider then has to sign the vaccine order and a nurse will administer it as part of the checkout process. A comprehensive list of immunosuppressive medications was given to the hospital information technology department to incorporate into the BPA algorithm. The BPA went live in December 2019. In order to have consistent results, we reviewed 50 patient charts from the first week of January 2019 and 50 patient charts from the first week of January 2020. Patients seen by the authors, who refused vaccination, or who did not have an indication for pneumococcal vaccination were excluded. Patients who had received one vaccination but were not yet due for the other were counted as up to date on vaccination status.

Results: Of 50 patient charts reviewed pre-intervention from January 2019, 31% were up to date on PCV-13 and 49% were up to date on PPSV-23 vaccination. In January 2020, post-intervention, 60% were up to date on PCV-13 and 78% of patients were up to date on PPSV-23, exceeding our goal. The vast majority of patients were on at least one immunosuppressive medication (Tables 1 and 2).

Conclusion: Patients with rheumatic conditions have an indication for pneumococcal vaccination, but are not always vaccinated. This quality improvement project utilizes the medical record to remind providers to discuss appropriate pneumococcal vaccination based on an algorithm and rapidly order the vaccine if the patient agrees. We have shown in our clinic that BPAs are effective at increasing pneumococcal vaccination rates in our outpatient rheumatology clinic. Further data will be needed to assess sustainability of the intervention.

SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: Health Services Research Poster
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Since December 2019, a novel coronavirus (SARS-CoV-2) pandemic was declared. Social isolation became a mainstay for the prevention of disease expansion. Outpatient follow-up of patients with rheumatic diseases was restricted. Thus, a revolution in rheumatology practice has been observed. Attitudes, behaviors, and practice studies are used to investigate patterns of community reactions to a disease. The aim of this study was to explore the influence of COVID-19 pandemic in the practice of rheumatologists in Latin America.

Methods: We performed a cross-sectional observational study by means of a digital anonymous survey (RedCap®). We included rheumatologists from PANLAR non-English-speaking countries. We retrieved demographics, COVID-19 diagnosis and perceived risk of being infected, information on practice prior and during the pandemic, the quantitative impact on wage and employment, practices concerning communication with patients and adjustment of immunomodulators, attitudes and behaviors regarding telehealth, the rheumatologist's role on the pandemic, and the perceived discrimination as a health worker. We calculated median and interquartile range (IQR) for quantitative variables and frequencies and percentages for qualitative variables.

Results: Our interim results include 476 rheumatologists from 18 countries. The median age is 48 (39-58) years, most of them are women (55%). The most frequent practice scenarios are private practice (73.9%) and institutional

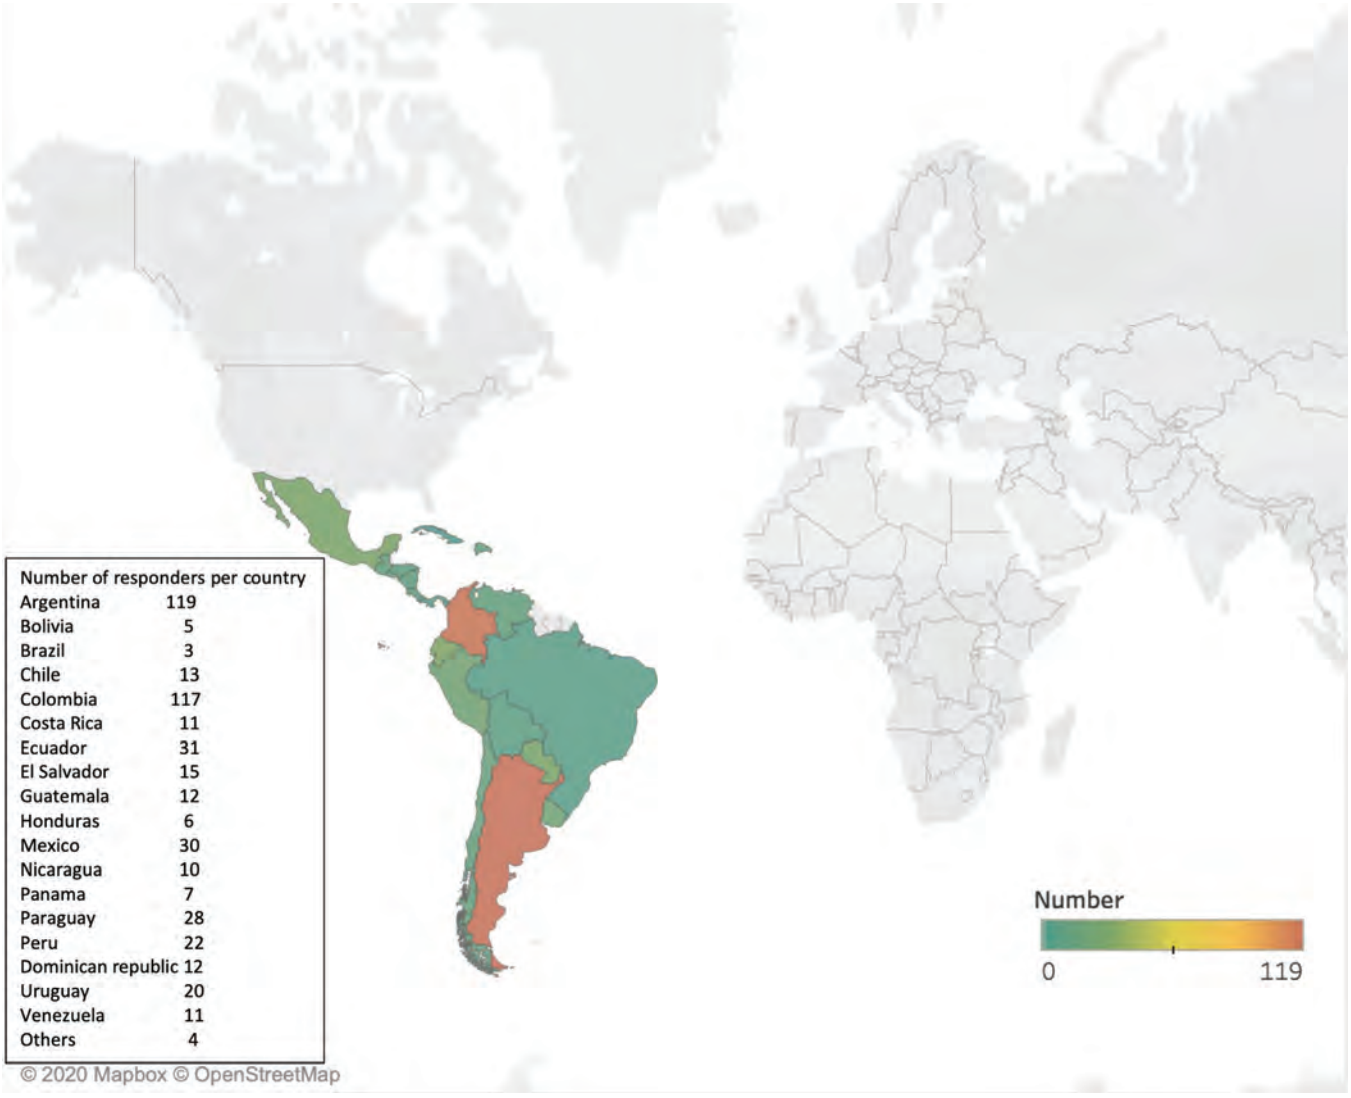

Figure 1. Number of rheumatologists filling the survey per country

Consider they should participate	365 (76.7)
Did actually participate	155 (32.6)
At least one episode of discrimination as a health worker during the pandemic	49 (10.3)
Median percentage of perceived risk of being infected with SARS-CoV-2/COVID19 during the pandemic (IQR)	50 (30-60)

Table 1. Demographics, attitudes and practices prior and during COVID-19 pandemic of rheumatologists in non-English-speaking PANLAR countries.

outpatient clinics (58.8%). Fifteen (3.2%) responders were diagnosed with COVID-19. A reduction of in-person practice hours was observed prior and during the pandemic; the median proportion of cancelled appointments was 80% (50-100). Forty-five percent perceived a reduction in patient's adherence during the pandemic. Most rheumatologists continued DMARDs at the same doses. Most of the responders have performed telehealth, with a median of 8 (3-16) hours/week. Forty-seven percent of responders have reduced their consult fee, with a median reduction of 50% (30-60) from baseline. Most of the responders (88%) reported a reduction of monthly wage, with a median reduction of 50% (40-70). Although 89.7% consider telehealth as a valid strategy during the pandemic, this reduces to 55.7% as a hypothetical alternative after the pandemic. More than two-thirds of responders believe that rheumatologists should take part of the development of local COVID-19 guidelines, however, only a third actually got involved in in-

stitutional panels. Ten percent reported an episode of perceived discrimination during the pandemic. Nine percent of rheumatologists have lost their jobs and 14.5% have being required to care for internal medicine patients, including COVID-19 cases.

Conclusion: SARS-CoV2/COVID-19 pandemic has reshaped rheumatology practice in Latin America and has had a profound impact on rheumatologists' behaviors. Telehealth is perceived as a valid alternative to in-person consults during the pandemic. A larger effort to participate in the elaboration of disease management strategies should be pursued. Our study is still ongoing and we present interim results; it is planned to collect data until July 31th, 2020.

Abstract Number: 0606

A Systematic Review Exploring Pre-COVID-19 Telehealthcare Models Used in the Management of Patients with Rheumatological Disease

Alexandra Nelson[1] and Marina Anderson[2], [1]University of Liverpool, Liverpool, United Kingdom, [2]Lancaster University, Lancaster, United Kingdom

SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: Health Services Research Poster
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Recent advancements in the delivery and utilization of information and communication technologies (ICTs) have led to an increased application of telehealthcare services. Global coronavirus disease (COVID-19) has further accelerated pressure on healthcare systems. Patients with rheumatological disease, particularly those on immunosuppressant therapy, are potentially at increased risk of COVID-19 and developing the severe consequences of the disease. Furthermore, this group have been advised to shield during the COVID-19 pandemic. This review aims to assess the baseline use of telehealthcare in rheumatology before COVID-19, to which future comparisons of newer interventions adapted during the crisis can be made.

Methods: A registered systematic literature search (CRD42020180695) was performed using MEDLINE, EMBASE, CENTRAL and PubMed databases. All full-length articles comparing telehealthcare delivery models to standard care in the management of patients with rheumatic conditions were assessed for inclusion. This systematic review was conducted in accordance with The Cochrane Collaboration principles of Systematic Reviews and reported following the Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) guidelines.

Results: 4809 studies were identified. 108 studies were suitable for review by full text of which 13 studies met full criteria for this review. Five studies (38%) included patients with rheumatoid arthritis, four studies (31%) included patients with mixed disease cohorts, two studies (15%) included patients with osteoarthritis, one study (8%) included patients with juvenile idiopathic arthritis and one study (8%) included patients with fibromyalgia. The majority of

patients were female representing 38-100% of patients and the average age of patients ranged from 13.1-64.4 years. Six studies (46%) used telephone, three studies (23%) used mixed method communication, three studies (23%) used videoconferencing and one study (8%) used website delivered telecommunication as their method of telehealthcare delivery. Modality of telehealthcare intervention ranged throughout studies with six studies (46%) delivering virtual consultation, three studies (23%) delivering a self-management program, two studies (15%) delivering a health education program, one study (8%) delivering cognitive behaviour therapy and one study (8%) delivering a self-efficacy program. Seven studies (54%) identified the telehealthcare intervention to be effective and superior to standard care and six studies (46%) identified the telehealthcare intervention as non-inferior to standard care.

Conclusion: Current evidence for telehealthcare in rheumatology is lacking and the evidence for superiority or non-inferiority is limited by methodological bias and clinical heterogeneity of telehealthcare interventions. With a paradigm shift in the nature of patient consultation, fit for purposeful assessment is essential in rheumatology following the COVID-19 crisis. Scrutinous assessment of the current telehealthcare interventions used during COVID-19 is required to accommodate recommendations directed from international working groups.

Abstract Number: 0607

The Evolution of Rheumatologist's Practice in Response to the COVID19 Pandemic

Maria Bacalao[1], Kathryn Dao[2] and John Cush[2], [1]UT Southwestern, Dallas, TX, [2]University of Texas Southwestern Medical School, Dallas, TX

SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: Health Services Research Poster
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: The COVID19 pandemic was a turning point for Rheumatology. This survey of rheumatologists (rheums) assessed its impact on care delivery, patient counseling and drug use in the first 3 months of the pandemic.

Methods: 2406 rheums were surveyed by email in June 2020. The 26 questions assessed respondent demographics, geography, practice type, care delivery, counseling, risks and prevalence of COVID in rheumatic disease (RMD) patients (pts).

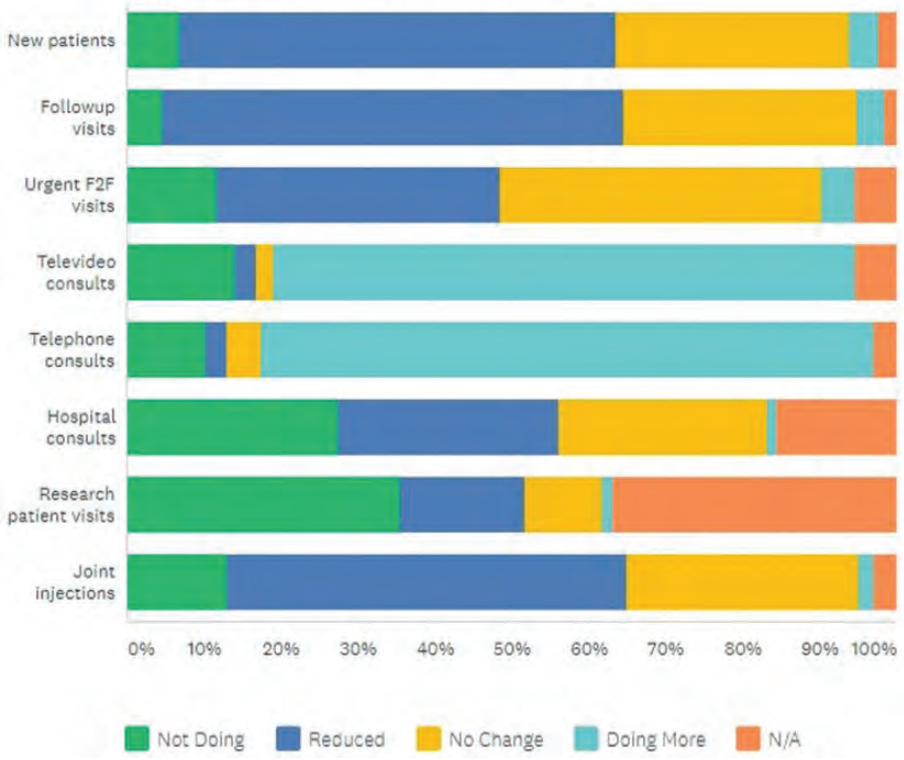
Results: 400 responses (16.7%) were received. Average respondent age was 54 yrs, 61% male, in practice for 21 years, avg 67 pts seen per week; most were in private practice (group 27%, solo 27%, multispecialty 22%) or academics (24%). 5% of respondents practiced outside the US.

Care Delivery: Figure 1 shows substantial reductions in number of new pt visits (64%), hospital consults (56%), follow-ups visits (55%), joint injections (55%), urgent (49%) and research visits (42%). Major service increases were seen in telehealth (>75%) visits. Many noted < 20% patients had no telemedicine access. Rheums temporarily closed their clinics, for either 4 weeks (32%), 6-8wks (28%) or 12 wks (14%); 19% have still not reopened. A major

Table. 1 COVID Infection Rates by US Region

	COVID infections	COVID deaths	#infections per Rheum	#Deaths per Rheum
Northeast	235	16	5.3	0.36
Atlantic	23	6	2.3	0.6
Southeast	182	8	2.6	0.11
Midwest	82	1	1.9	0.02
Southwest	34	2	1.2	0.07
Northwest	16	0	1.6	0
Western	40	3	1.7	0.13
Rest of world	54	2	4.5	0.15
Overall	875	52	2.5	0.15

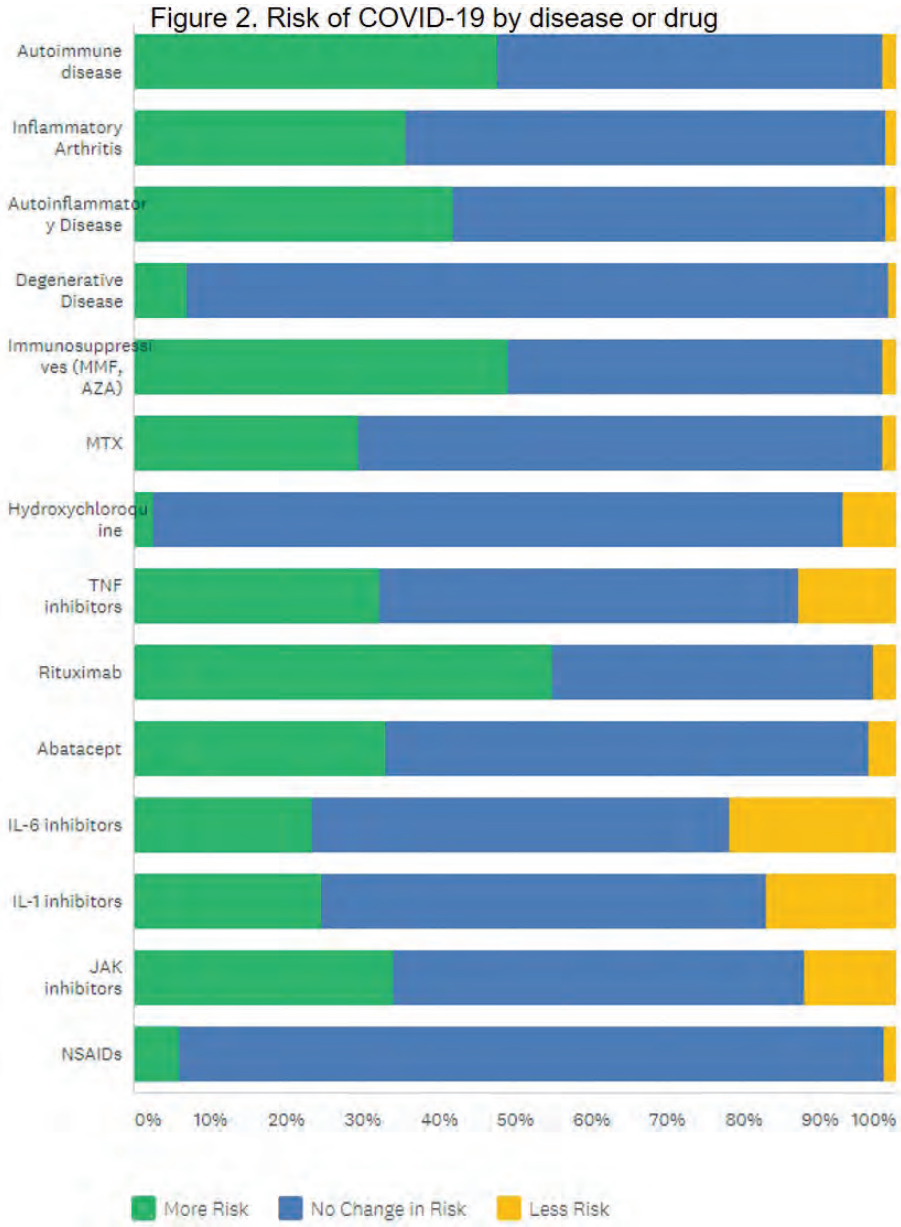
Fig 1. Practice Changes Since COVID-19



disruption to practice was noted by 46% rheums; 4% had no change. A major income loss was claimed by 31%, and 17% had no income loss.

Patient Counseling: 40% rheums noted ongoing patient confusion about COVID. Two-thirds informed pts their disease does NOT increase COVID risk. RA & SLE pts were told risk is not higher if they are well controlled on stable meds (27%) or that risk was due to comorbidities & age (21%); rather than meds (9%). Majority noted no COVID risk imposed by NSAIDs (93%), OA (92%), HCQ (91%), MTX (69%), abatacept (64%) or inflammatory arthritis (63%). Rheums suggested an increased risk with rituximab (55%), immunosuppressives (49%) or active autoimmune disease (47%). Rheums perceptions of COVID risk are shown in Figure 2.

Prescribing Habits: Overall, rheums did not change their use of NSAIDs, MTX, HCQ, TNF inhibitors abatacept, IL-6 inhibitors, or MMF. Prednisone use decreased 41%, as did rituximab 26%, cyclophosphamide 19% and denosumab 18%; antidepressants (9%) and hydroxychloroquine (7%) increased. Nearly all rheums (94%) said ≤25% of patients



reduced or discontinued meds without seeking advice. 10% prescribed antimalarials as COVID prophylaxis, and 82% of rheums reported patients had difficulty getting antimalarials (shortages/cost issues).

Rheums Role: Most (61%) have not been involved in COVID-19 care, while 30% were consulted about DMARD/biologics; only 6% have managed cytokine storm (CSS). The preferred agent for CSS was IL-6 inhibitor (66%), and 14% did not know what to use. A total of 348 rheums reported 875 cases of COVID, (2.51 patients/Rheum). With an average Rheum patient panel of 1350 patients, the COVID infection rate was 0.18% in RMD pts. Total of 52 deaths were reported, with a COVID death rate of 0.01% in RMD patients.

Conclusion: Rheums substantially changed their practices, counseling and health care delivery during the pandemic. COVID infection and death rates among RMD patients appears to be lower than the general US population. Maintenance of drug therapy and patient compliance appears potentially protective to SARS-CoV-2.

Patient and Parent Perspectives in a Academic Pediatric Rheumatology Transition Clinic

Rebecca Overbury[1], Tracy Frech[2], John Bohnsack[3], CJ Inman[1], Sara Stern[1], Karen James[1], Erin Treemarcki[4] and Aimee Hersh[4], [1]University of Utah and Primary Children's Hospital, Salt Lake City, UT, [2]University of Utah and Salt Lake Veterans Affair Medical Center, Salt Lake City, UT, [3]University of Utah and Primary Children's Hospital, Cincinnati, OH, [4]University of Utah and Primary Children's Hospital, Salt Lake City

SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: Health Services Research Poster
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: In November 2018 we initiated a transition clinic called ACCORD (Adult Center for Childhood Onset Rheumatic Disease). Our unique structure integrates an adult rheumatologist in a pediatric rheumatology clinic setting to initiate clinical transition of our patients. Patients are seen when they are ≥ 16 years old. All patients and parents receive education on transition planning and provide feedback on their experience.

Methods: Metrics collected in the ACCORD clinic include the 'Transition Readiness Assessment' (Got Transition$_{TM}$) and the 'Mind the Gap' scale, a validated metric using 7-point Likert scales to assess satisfaction with transitional health care among adolescents and young adults (AYA) with chronic illness and their parents. The preliminary data from these metrics were analyzed to evaluate the perspectives and satisfaction of our AYA as well as their parents.

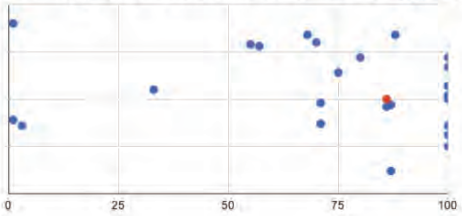
Table 1. Demographics of Transition Clinic *

	Sex		Mean Age (years)		Race					
	Male n (%)	*Female n (%)*	*Male/ Female*	*White n (%)*	*Black n (%)*	*Asian n (%)*	*American Indian or Alaskan Native n (%)*	*Native Hawaiian or Pacific Islander n (%)*	*Unknown/Not Reported/Other n (%)*	*Total*
Juvenile Idiopathic Arthritis or Rheumatoid Arthritis	4 (11.4)	19 (54.3)	22.1	19.7	17 (48.6)	1 (2.9)	1 (2.9)	0	1 (2.9)	3 (8.6)	23
SLE (or other CTD)	1 (2.9)	8 (22.9)	18.5	19.9	5 (14.3)	0	2 (5.7)	1 (2.9)	0	1 (2.9)	9
Other	0	3 (8.6)	N/A	18.4	3 (8.6)	0	0	0	0	0	3
Total											35

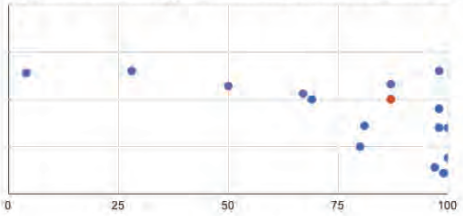
*All percentages are of entire cohort (n = 35)

Figure 1. Transition Readiness Assessment

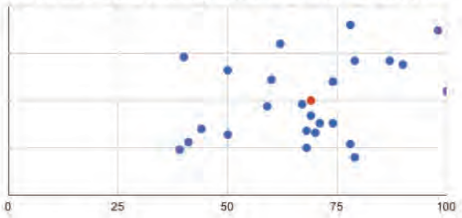
AYA: "How Important is it to you to prepare for/change to an adult doctor before age 22?"



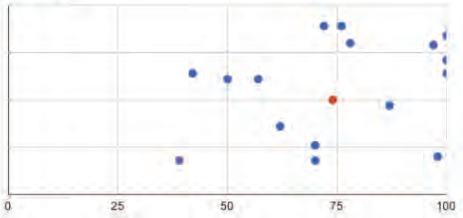
Parents: "How important is it for your child to prepare for/change to an adult doctor before age 22?"



AYA: "How confident do you feel about your ability to prepare for/change to an adult doctor?"



Parents: "How confident do you feel about your child's ability to prepare for/change to an adult doctor?"



Discrete variables are reported as percentages. Linear variables are reported as means and compared using independent one-tailed t-test ($p < .05$).

Results: 35 families have participated in our transition clinic (Table 1). 25 AYA and 16 parents completed a 'Transition Readiness Assessment'. On an importance scale from 0 (not) – 100 (very), AYA rated "the importance of preparing for/changing to an adult doctor before the age of 22" as 73.3 (M = 73.3, SD = 32.2). For parents, "how important is it for your child to prepare for/change to an adult doctor before age 22" was rated 77.1 (M = 77.1, SD = 29.3). When asked "how confident do you feel about your ability to prepare for/change to an adult doctor" 0 (not) – 100 (very), AYA responded 67.8 (M = 67.8, SD = 17.2). When asked "how confident do you feel about your child's ability to prepare for/change to an adult doctor" parents responded 74.9 (M = 74.9, SD = 21.0) (Figure 1). Parents were more confident than AYA, but this change did not reach statistical significance ($t(39) = -1.1808$, $p = .12$). AYA and 6 parents completed a 'Mind the Gap' scale. For AYA, those variables felt "extremely important" by the majority of respondents included: "does not waste my time at clinic," and "has staff who are very knowledgeable about my disease and latest treatments" (n = 8, 61.5% for each). For parents, those variables felt "extremely important" by the majority of respondents included: "provides me with honest explanations of my child's condition and treatment options (including side-effects)," "provides my child with honest explanations of their condition and treatment options (including side-effects)," and "helps me and my child prepare for their move to adult services," (n = 6, 100.0% for each).

Conclusion: This research shows that AYA and their parents believe transition planning and successful clinical transition to an adult sub-specialist is important. Although the difference is not statically significant in this small sample, parents are more confident than AYA in their child's/own ability to successfully make this transition. Of most value to both AYA and their parents are efficient clinic processes, which include deliberate transition preparation, and are led by knowledgeable staff. Parents especially value honest explanations of their child's condition and treatment that target both the parent and the AYA.

Abstract Number: 0609

Impact of Depressive Symptoms, Anti-depression Treatment on Direct Medical Costs Among Medicare Beneficiaries with Knee Osteoarthritis (KOA)

Shuang Song[1], Jeffrey Katz[2] and Elena Losina[2], [1]Brigham and Women's Hospital, Brighton, MA, [2]Harvard Medical School / The Orthopaedic and Arthritis Center for Outcomes Research (OrACORe) at Brigham and Women's Hospital, Boston, MA

SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: Health Services Research Poster
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Depressive symptoms are prevalent among knee OA (KOA) patients and likely lead to additional medical costs. We sought to quantify the prevalence of depressive symptoms among Medicare Beneficiaries with KOA and patterns of depression treatment in this population. We compared annual direct medical costs in KOA Medicare beneficiaries with and without depressive symptoms.

Methods: We identified a Knee Osteoarthritis (KOA) cohort using Medicare Current Beneficiary Survey (MCBS) Cost and Use files (2009-2015) among community-dwelling Medicare survey responders who had at least one outpatient visit resulting in Medicare Part A or Part B claims. We used ICD-9/10 diagnostic codes in both Part A and Part B claims to identify KOA cohort. We determined the prevalence of depressive symptoms using self-reported data on sadness or anhedonia during the past year, consistent with DSM-IV criteria. We divided KOA patients into three groups: 1. No reported depressive symptoms; 2. Reported depressive symptoms, no depression-related treatments costs; 3. Reported depressive symptoms and depression-related treatment costs. We ascertained claim payments to physician/suppliers, hospitals, outpatients, skilled nursing facilities, hospice, durable medical equipment, and home health agency. We used these payment data to estimate direct medical costs for each of three groups. We used a generalized linear model to compare mean annual total direct medical cost across three groups, adjusting for general health, comorbid conditions, year of MCBS, and interaction of MCBS year with depressive symptoms/treatment.

Table. Annual direct medical costs stratified by depressive symptoms and depression treatment status

	Mean Annual Medical Cost (SD)	Adjusted Mean Annual Medical Cost (SD)	Adjusted Mean Annual Medical Cost Difference (95%CL)	
			Comparing to no depressive symptoms	Comparing treated and non-treated groups among those with depressive symptoms
Treated Depression Symptoms	$21,627 (2,008)	$17,504 (2,003)	$6,390 ($1,387, $11,393)	$5,290 ($16, $10564)
Untreated Depression Symptoms	$13,563 (1,022)	$12,214 (1,048)	$1,100 (-$1,748, $3,948)	(REF)
No depressive Symptoms	$9,499 (573)	$11,114 (711)	(REF)	

Results: We identified 1,918 individuals with KOA. 28% self-reported depressive symptoms and 5% received depression-related billable medical services. The mean adjusted annual direct medical cost ranged from $11,114 for Medicare beneficiaries with KOA without depressive symptoms, to $12,214 among those with KOA and depressive symptoms who did not accrue depression treatment related costs to $17,504 among those with KOA and depressive symptoms who received depression-related treatment (Table). Subjects with depressive symptoms who were treated had $5,290 (43%) higher direct medical cost compared to those with depressive symptoms who were not treated and $6,390 (57%) higher direct medical costs compared to those without depressive symptoms.

Conclusion: Over one quarter of Medicare beneficiaries with KOA self-reported depressive symptoms but just 5% of the population received treatment for depression. The presence of depressive symptoms leads to higher direct medical costs that are somewhat attenuated after accounting for other medical comorbidities.

Abstract Number: 0610

Change in Utilization of Outpatient Services at US Community Rheumatology Practices During COVID-19 Outbreak

Kent Kwas Huston[1], Nehad Soloman[2], Janna Radtchenko[3], Simon Helfgott[4], Jasvinder Singh[5] and Colin Edgerton[6], [1]Kansas City Physician Partners, Kansas City, MO, [2]Arizona Arthritis & Rheumatology Associates, P.C., Peoria, AZ, [3]Trio Health, Louisville, CO, [4]BWH- HMS, Boston, MA, [5]University of Alabama at Birmingham, Birmingham, AL, [6]Articularis Healthcare, Summerville, SC

SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: Health Services Research Poster
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Patients (pts) with autoimmune diseases managed by rheumatologists represent vulnerable population with risk of serious complications if exposed to novel coronavirus SARS-CoV2. The first case of COVID-19, disease caused by SARS-CoV2, was diagnosed in the US on January 20, 2020. By the beginning of April, 42 states implemented stay-at-home advisories limiting non-essential activity including non-emergency healthcare services leading to the majority of routine healthcare visits being conducted via telehealth method using audio and/or video technology. In May states began lifting stay-at-home orders and gradually renewing economic activity. We evaluated impact of these policies on volume and type of care provided by US community rheumatology practices.

Methods: EMR records from the American Rheumatology Network (ARN) - Trio Health Rheumatology registry were used for the study. The ARN is a physician led and owned organization that supports some of the largest independent practices with over 200 practicing rheumatologists across the US. Pts with rheumatic diseases in care in Jan'19-May'20 were selected for analysis. Trends were evaluated for in-office drug administrations, new starts on targeted immune modulating therapy (TIM) both in-office and self-administered, drug administration, new and existing patient visits, telehealth visits, telephonic services, labs, x-rays, minor surgical procedures, and other diagnostic and treatment procedures.

Results: Of 120,780 pts treated in the study period, 19,449 (16%) were treated in central region, 44,055 (36%) in western, and 57,276 (48%) in southern; there were no practices representing northeast hardest hit by COVID-19.

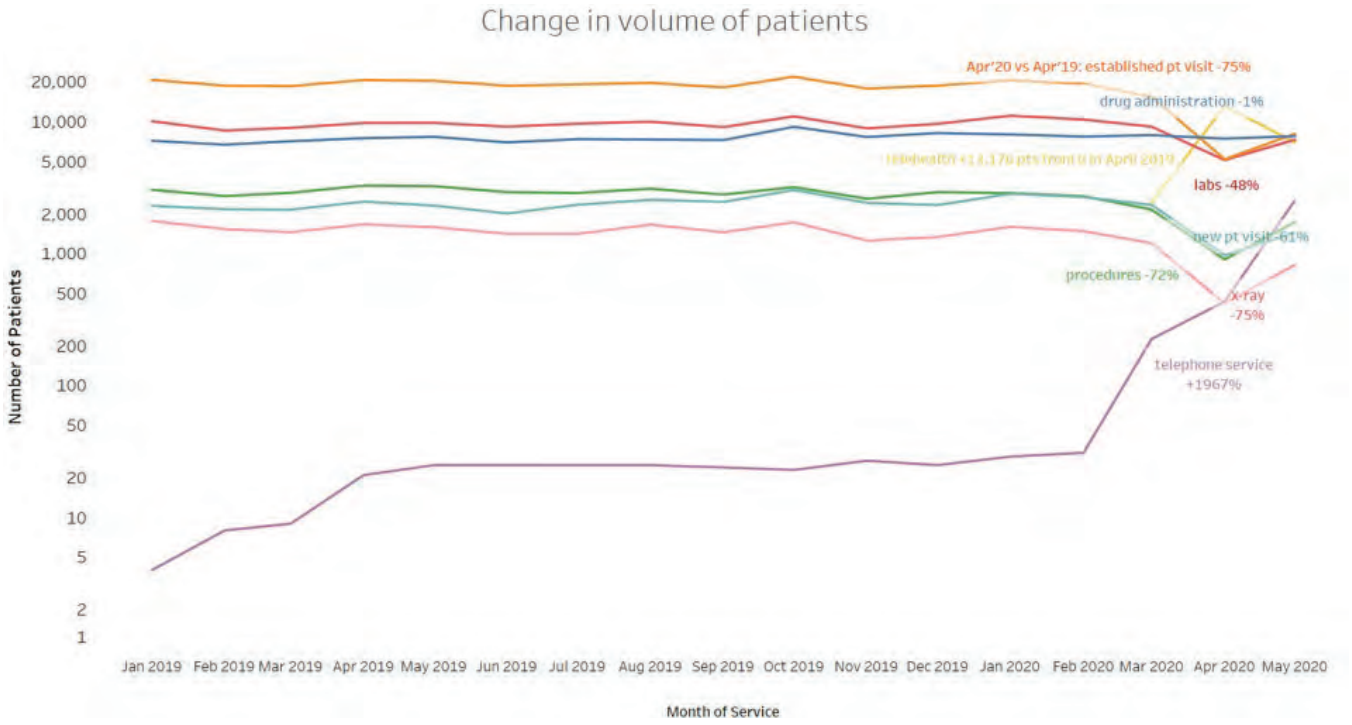

Figure 1. Change in patient volume

In Mar'20, treated pt number declined 6% vs Feb'20 and 0.4% vs Mar'19; in Apr'20 pt number declined 4% vs Mar'20 and 13% vs Apr'19, while in May'20 pt number was flat vs Apr'20 and down 12% vs May'19. Considering all services delivered by the practices, there was 12% decline in service volume in Mar'20 vs Feb, 28% decline in Apr'20 vs Mar, and 22% increase in May'20 vs Apr; there was 2% decline in Mar, 36% in Apr, and 23% in May'20 vs corresponding months of 2019.

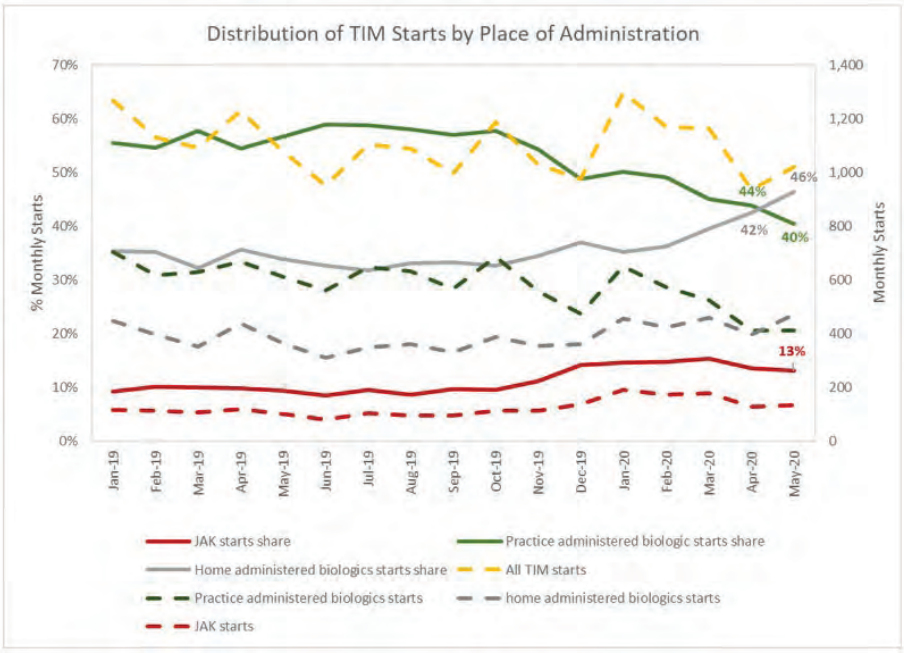

Figure 2. Distribution of starts on targeted immune modulating therapy (TIM)

Most affected services in Mar-Apr were procedures, new and established pt visits, x-rays, and labs [Figure 1]. Telehealth was implemented in Mar'20 with 2,449 pts seen via telehealth visits. Telehealth grew 438% in Apr from Mar reaching 13,176 pts and declined 47% in May over Apr. Telephone services were provided to 226 pts in Mar'20 vs 9 pts in Mar'19, telephone services were up 92% in Apr'20 vs Mar and 487% in May vs Apr. Drug administrations were + 3% in Mar'20 vs Feb, -6% in Apr vs Mar, and +7% in May vs Apr.

Growing pre-COVID trend towards home administration of biologics continued during stay-at-home advisory: in May pt starts on home administered biologics overtook starts on practice administered biologics [Figure 2].

Conclusion: During COVID-19 outbreak in the US stay-at-home advisory period significantly influenced care patterns of pts with rheumatic diseases with sharp growth of telehealth and decline in in-person visits, drug administrations, and diagnostic testing. Further research is needed to evaluate these trends as the pandemic continues.

Disease Activity and Disability Are Not Associated with Rehabilitation Utilization in African Americans with Rheumatoid Arthritis

Louise Thoma[1], Rebecca Cleveland[2], S. Louis Bridges[3], Beth Jonas[1] and Leigh Callahan[4], [1]University of North Carolina at Chapel Hill, Chapel Hill, NC, [2]University of North Carolina, Chapel Hill, NC, [3]University of Alabama at Birmingham, Mountain Brk, AL, [4]University of North Carolina Thurston Arthritis Research Center, Chapel Hill, NC

SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: Health Services Research Poster
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Considerable advances in pharmacological care for adults with rheumatoid arthritis (RA) over the last 25 years have reduced disease activity in individual patients, but disability has not improved to the same extent. Rehabilitation, including physical therapy (PT) and occupational therapy (OT), is recommended to address disability and functional limitations, yet utilization of rehabilitation for adults with RA in the United States is low. Reductions in RA disease activity and disability are associated with utilization of rehabilitation services in Caucasian adults with RA, but it is unclear if associations are similar in African Americans. Thus, we examined the association of disease activity and disability with rehabilitation utilization in African Americans with RA.

Methods: We analyzed baseline data from the Consortium for the Longitudinal Evaluation of African Americans with RA (CLEAR) I Registry (disease duration < 24 months) and the CLEAR II Registry (any disease duration). Data were collected in a single visit for each participant at one of four southeastern US institutions. The clinical variables of

Table 2. Association of disease activity and disability with rehabilitation utilization

interest were disease activity, defined by the Disease Activity Score 28 with C-Reactive Protein (DAS28-CRP), and disability, measured with the Health Assessment Questionnaire (HAQ). Rehabilitation utilization variables were self-reported recall of PT or OT in the prior 6 months (yes/no) and any prior PT or OT utilization (yes/no). We examined the association of disease activity and disability with rehabilitation utilization using separate binary logistic regression models to estimate odds ratios and 95% confidence intervals. We adjusted for age (years), sex, body mass index (BMI, kg/m^2), disease duration (months), use of disease modifying anti-rheumatic drugs (DMARD; yes/no), comorbidities (number), household income (>$30k vs. ≤$30k), and education (more than high school vs. high school grad or less). We repeated the analyses with the sample stratified by disease duration: early RA and established RA.

Results: Of 1067 participants, 14% reported utilizing rehabilitation in the prior 6 months, and 41% reported ever utilizing rehabilitation (Table 1). Rehabilitation utilization in the prior 6 months was similar among those with early and established RA (13% vs. 15%), but a greater proportion of those with established RA reported any past rehabilitation utilization (31% vs. 48%). Disease activity and disability at the time of baseline visit were not associated with rehabilitation utilization in the past 6 months or ever, in unadjusted and adjusted models (Table 2).

Conclusion: Among African Americans with RA, rehabilitation utilization was low (14%) in the 6 months prior to enrollment into CLEAR, and was not associated with disease activity or disability level. Factors driving rehabilitation

utilization in African Americans with RA, as well as success in reducing disease activity and disability, are unclear, and should be a focus of future research to facilitate delivery of appropriate and effective rehabilitation services.

Abstract Number: 0612

Differences in 30-Day Rehospitalization Risk and Predictors by Age Group Among Patients with Lupus in Medicare

Maria Schletzbaum[1], Yi Chen[2], Ann Sheehy[3], Farah Kaiksow[3], Ryan Powell[4], Andrea Gilmore-Bykovskyi[5], Amy Kind[6] and Christie Bartels[7], [1]University of Wisconsin-Madison School of Medicine and Public Health, Department of Population Health Sciences, Madison, WI, [2]University of Wisconsin School of Medicine and Public Health, Department of Biostatistics and Medical Informatics, Madison, WI, [3]University of Wisconsin School of Medicine and Public Health, Department of Medicine, Hospital Medicine Division, Madison, WI, [4]University of Wisconsin School of Medicine and Public Health, Department of Medicine, Geriatrics Division, Madison, WI, [5]University of Wisconsin - Madison, School of Nursing, Madison, WI, [6]University of Wisconsin-Madison School of Medicine and Public Health, Department of Medicine, Health Services and Care Research Program, Geriatrics Division, Madison, WI, [7]University of Wisconsin School of Medicine and Public Health, Department of Medicine, Division of Rheumatology, Madison, WI

SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: Health Services Research Poster
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Although our recent research demonstrates that young adult Medicare beneficiaries (age 18-35) with lupus (SLE) have higher risk of 30-day rehospitalization, predictors specific to young SLE patients have not been evaluated. The objectives of this study are to assess the risk of and predictors for 30-day rehospitalization in young adults with SLE on Medicare compared to non-SLE and older SLE Medicare beneficiaries to inform targeted efforts for readmission reduction.

Table 1. Patient Characteristics of Hospitalizations of Medicare Beneficiaries

Patient Characteristic n (%)		Non-SLE n= 1,378,654	SLE Age 18-35 n= 1,133	SLE Age 36-64 n= 4,855	SLE Age 65+ n= 4,880

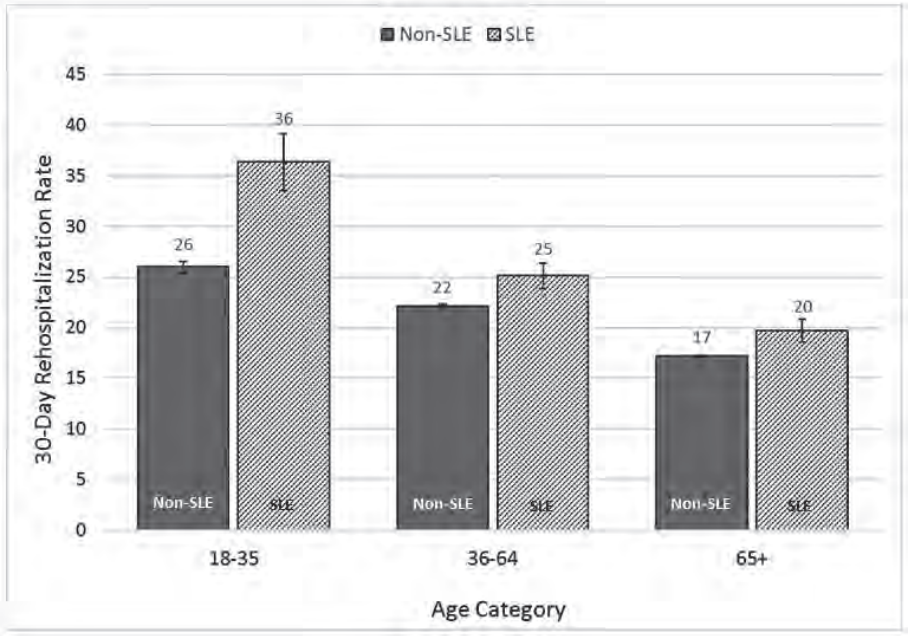

Figure 1. 30-Day Rehospitalization Rates by Age Group for Medicare Beneficiaries with and without SLE. Percentage of hospitalizations resulting in re-hospitalization within 30 days from discharge by age group among Medicare beneficiaries with (hatched bar) and without (solid bar) SLE. Error bars represent 95% confidence intervals.

Methods: This retrospective cohort study utilized a 20% random sample of all adult hospitalizations in Medicare from 2013-2014. Inclusion required at least 1 year of continuous Medicare AB coverage before hospitalization; hospitalizations with a SLE diagnosis code were included in the SLE sub-cohort. Observations from HMO or Railroad beneficiaries or specialty care hospitals were excluded.

Table 2. Multivariable Models for Rehospitalization within 30-Days in Patients with SLE by Age Group

		SLE Age 18-35 N= 1,133	p	SLE Age 36-64 N= 4,855	p	SLE Age 65+ N= 4,880	p

Hypertension with Complications		1.15 (0.71, 1.86)	0.58	0.93 (0.75, 1.15)	0.50	1.04 (0.85, 1.27)	0.72
Electrolyte Disorder		**2.29 (1.48, 3.53)**	**<0.001**	**1.27 (1.05, 1.53)**	**0.01**	1.15 (0.96, 1.39)	0.13
Renal Failure		1.03 (0.70, 1.53)	0.87	1.12 (0.90, 1.39)	0.98	1.01 (0.82, 1.24)	0.95

Thirty-day rehospitalization rates were calculated by age group among SLE and non-SLE patients. Initial generalized logistic regression clustered by individual estimated the odds of rehospitalization by age group, presence of SLE, and interactions between age group and SLE. Multivariable regressions were then performed within each SLE age group strata based on *a priori* and LASSO selected predictors of rehospitalization in young adults including socioeconomic, hospitalization, and comorbidity factors.

Results: Among 1,378,654 non-SLE and 10,868 SLE Medicare hospitalizations (Table 1), the observed 30-day rehospitalization rate in young adults without SLE was 26% (Figure 1). For young adults with SLE, the rehospitalization rate was 36%, decreasing to 20% in those over 65. Both young adult age (aOR 1.69, CI 1.60-1.78) and having SLE (aOR 1.18, CI 1.08-1.28) significantly increased odds of rehospitalization compared to patients of older age or without SLE; young adults with SLE had further increased odds (interaction term aOR 1.38, CI 1.11-1.71).

In multivariable models within age strata of SLE patients, each added day of index hospitalization length was associated with increased odds of rehospitalization in all age groups (Table 2). Among 18-64 year olds, increasing age was protective against rehospitalization. Medicare's hierarchical condition category (HCC) score (designed to predict expenditures and mortality) was significantly associated with greater odds of rehospitalization in each age group, although the magnitude of effect was lower in young adults who had additional predictive factors such as heart failure, drug use, and coagulopathy.

Conclusion: Hospitalized young adults with SLE in the Medicare population are more racial diverse, from more disadvantaged areas, and have more comorbid conditions, and more than 1 in 3 are rehospitalized within 30 days of discharge. Comorbidities such as coagulopathy, drug use disorder, and heart failure conferred a greater increase in odds of 30-day rehospitalization in young adults with SLE than in older adults with SLE. Together these findings suggest a critical need to develop targeted interventions with young adults to support these high-risk patients and reduce rehospitalizations.

Abstract Number: 0613

Modeling the Effects of Covid-19 Protective Behaviors and Healthcare Delivery on the Health of Patients with Rheumatic Disease

Kevin Kennedy[1], Emily Sirotich[2], Salman Surangiwala[3], Maggie Larche[2], Mitchell Levine[1] and Jonathan Hausmann[4], [1]McMaster University, Hamilton, Canada, [2]McMaster University, Hamilton, ON, Canada, [3]Queen's School of Medicine, Kingston, Canada, [4]Boston Children's Hospital / Beth Israel Deaconess Medical Center, Cambridge, MA

SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: Health Services Research Poster
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: COVID-19 has caused global disruptions in the management of chronic illnesses. The extent to which patients with rheumatic disease have been affected by COVID-19 and the related changes to methods of health service delivery is unknown. We present a model capturing the effects of the pandemic on the physical and mental health of a sample of adult patients with rheumatic disease.

Disclaimer: The views expressed here are those of the authors and participating members of the COVID-19 Global Rheumatology Alliance and do not necessarily represent the views of the American College of Rheumatology, the European League Against Rheumatism (EULAR), or any other organization.

Methods: The COVID-19 Global Rheumatology Alliance Patient Experience Survey was disseminated online to patients with rheumatic disease. Patients reported age, gender, WHO region, employment status, ethnicity, change in employment status, smoking status, current rheumatic disease control, methods of communicating with rheumatologist, medications, possible exposure to COVID-19, COVID-19 diagnosis, hospitalization due to COVID-19, mental/physical health, and methods taken to protect from COVID-19, were entered in two multivariable regression models. The two models assessed the associations with the entered variables with PROMIS Global Health Mental and Global Health Physical scales.

Results: Out of 9,393 patients, 1,544 were removed due to missingness. PROMIS Global Health Physical was associated with the additive independent predictors entered into the model with a large effect size ($R2adj = 0.41$, $F = 123.744, 7804$, $p < 0.001$). After adjusting for employment status, region, ethnicity, age, disease activity, smoking status, medications, and gender, patients unable to communicate with their rheumatologist reported a decreased physical health (-0.25, $p < 0.001$). Patients who quarantined, or those with COVID-19 diagnosis, experienced worse physical health (-0.18, $p < 0.001$; -0.21, $p < 0.001$). PROMIS Global Health Mental was associated with the independent predictors with a moderate effect size ($R2adj = 0.27$, $F = 67.9444, 7804$, $p < 0.001$). Patients who have not needed to communicate with their rheumatologist, were hospitalized with COVID-19, and had COVID-19 expressed better mental health (0.14, $p = 0.022$; 0.67, $p < 0.01$; 0.31, $p < 0.01$). Patients who identified possible contact with COVID-19 expressed a lower mental health state (0.15, $p < 0.001$).

Conclusion: By modeling the effects of COVID-19 behaviors and health care service delivery, we demonstrated that patients unable to communicate with their rheumatologist, quarantined, and/or with COVID-19, experienced decreased physical health. In contrast, patients experienced better mental health if they reported no need to communicate with their rheumatologist, had COVID-19, and/or were hospitalized due to COVID-19.

It is evident that COVID-19 caused worse physical health, however, having or surviving COVID-19 paradoxically led to improved mental health. It is possible that these patients perceived a reduced mortality risk, despite the consequences to their physical health.

In contrast, patients who reported potential COVID-19 exposures endorsed poorer mental health, perhaps due to a greater perceived risk of mortality. Further exploration of patient characteristics and behaviors in a principal component analysis may provide additional insight into the experience of patients with rheumatic disease amidst a global pandemic.

Abstract Number: 0614

Impact of COVID-19 Pandemic on the Rheumatology Practice in Mexico: Mexican College of Rheumatology Survey

Natllely Ruiz[1], José Enrique Ruiz Guizar[2], Erick A Zamora Tehozol[3], Iris Jazmín Colunga Pedraza[4], Cristina Hernández-Díaz[5], Vijaya Rivera-Terán[6], Cesar Pacheco Tena[7] and **Deshire Alpizar-Rodriguez**[6], [1]Instituto Nacional de Enfermedades Respiratorias, Mexico City, Distrito Federal, Mexico, [2]Independent, Mexico City, Distrito Federal, Mexico, [3]Centro Médico Pensiones, Merida, Yucatan, Mexico, [4]Rheumatology service, Hospital Universitario "Dr. José Eleuterio González", Universidad Autónoma Nuevo León, Monterrey, Mexico, [5]Instituto Nacional de Rehabilitación, Mexico City, Distrito Federal, Mexico, [6]Colegio Mexicano de Reumatología, Mexico City, Distrito Federal, Mexico, [7]Universidad Autonoma de Chihuahua, Chihuahua, Chihuahua, Mexico

SESSION INFORMATION

Session Date: Saturday, November 7, 2020

Session Title: Health Services Research Poster

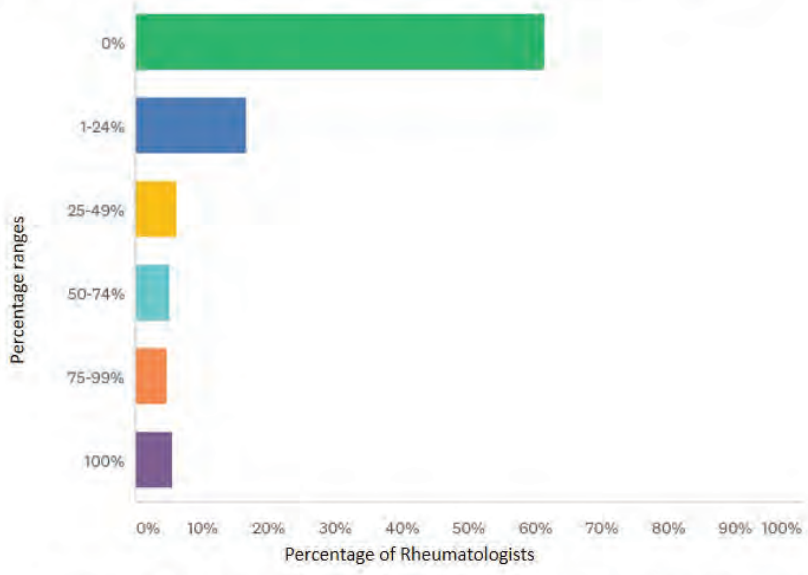
Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: COVID-19 pandemic is an evident challenge for healthcare systems and daily clinical practice in developing countries. Particularly, chronic diseases attention has faced difficulties. The Mexican College of Rheumatology (MCR) is a professional membership organization committed to helping the development, communication of knowledge, and the improvement for the care of patients with rheumatic diseases, with 619 active members from the 32 regions in Mexico. We aimed to explore the impact of COVID-19 pandemic on the rheumatology practice among MCR members.

Methods: An anonymous web-based survey was developed and distributed via social media groups and e-mail to all members of the MCR from May 14th to June 12th, 2020. The survey included 27 questions exploring sociodemo-

Fig 1. Percentage of Mexican rheumatologists attending COVID-19 patients.



*Responses to the question ¿Which percentage of your activities are aimed to give attention to COVID-19 patients? Answer options: 0%, 1-24%, 25-49%, 50-74%, 75-99% and 100%.

graphic aspects, the impact of the pandemic in rheumatology practice and, the economic impact for the Mexican rheumatologists. Descriptive statistics were used.

Results: A total of 239 respondents from 24 regions of Mexico completed the survey. By gender, 130 (54.4%) were women and 109 (45.6%) men. The median (IQR) age was 46 years (36-56). Rheumatologist practice was private only in 82 (34.3%) of cases, public only in 8 (4.4%), and both in 144 (60.3%); 5 rheumatologists (2.1%) did not have clinical practice. Among those with private practice, 147 (84.0%) reported a reduction of more than 50% in the number of patient visits and 27 (12.4%) closed their practice. The main protective measures used in private practice were increasing hygienic measures (83.2%) and reducing the number of patients by hour/day (63.1%). Rheumatologist reported expenses in more than 25% of their total income to implement protective measures in their practices in 34.4% of the cases. Different online platforms were used by 76.3% rheumatology specialists, 80% reported they have reduced their fees and 14.1% did not charge when giving online consultation. Those having public practice, 118 (82.9%) reported a reduction of more than 50% in the number of patient visits and 43 (29.9%) did not give rheumatology consultations anymore. The reduction of more than 50% of consultations number was not associated with age neither in private, nor in public practice (p=0.25 and p=0.53, respectively) and no association with gender was found (p=0.52 and p=0.30, respectively). Most of the rheumatologists working in public practice (83.3%) have bought themselves the protective equipment needed. Of all rheumatologists who answered the survey, 15.7% reported more than 50% of their activities were aimed to see patients with COVID-19, and 11 (5.1%) had been diagnosed with the disease.

Conclusion: The survey shows the negative impact in the Mexican rheumatology clinical practice of COVID-19 outbreak with the reduction of overall public and private consultations and supports the need to establish appropriate measures to keep the attention of patients with rheumatic diseases during COVID-19 pandemic.

Abstract Number: 0615

Rheumatology Going Digital: Developing a Rheumatology App for Use by All Patients Attending Our Department to Aid Remote Working and Self-management

Kirsten Mackay[1], Mark Clemence[1] and Rian Penford[1], [1]Torbay and South Devon NHS Foundation Trust, Torquay, United Kingdom

SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: Health Services Research Poster
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Patients with a rheumatological condition require information regarding the disease itself and treatments regimes. This is particularly important for new patients.

Our local patient focus group asked for reliable information, produced by their rheumatology team with the aim to help self-management. They wanted readily accessible information in one place, that they could review, replay and access, as required.

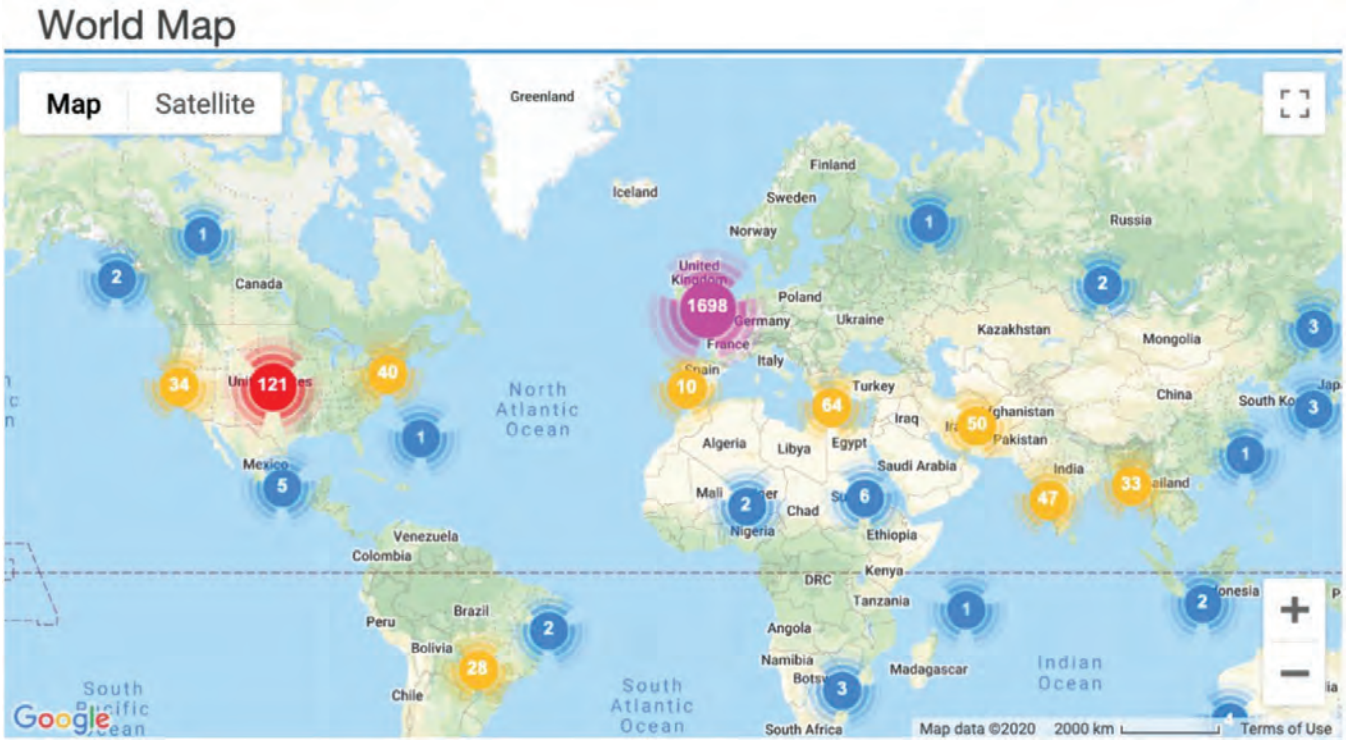

Figure 1. Downloads and where the App is being used

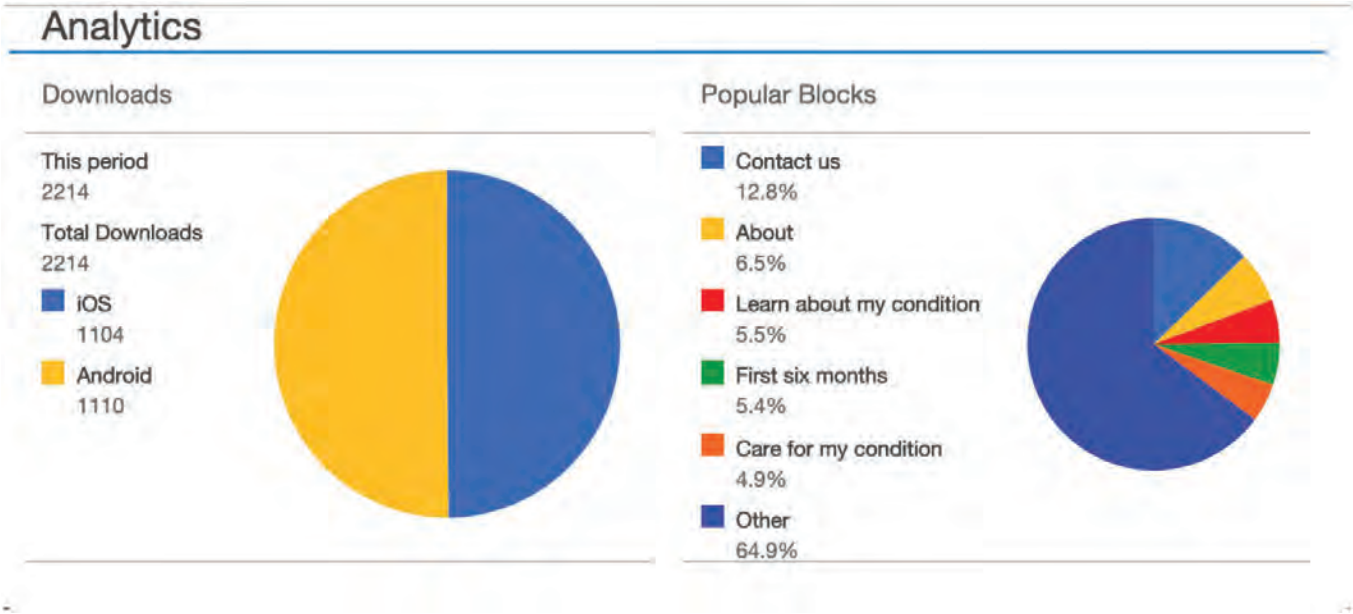

Figure 2. Most frequently viewed sections of the App

Methods: We decided the way forward was to produce a Rheumatology App, thus we gathered together a number of patients with a rheumatological condition, of various ages, the Rheumatology multi-disciplinary team (MDT) and identified an industry partner, hci.digital, who was able to advise on the development of an appropriate Application. We called this App 'Rheumatology Connect'.

A picture is worth a thousand words, hence we developed over 40 short videos. Then, we provided links to other relevant patient websites e.g. NASS, Versus Arthritis, NRAS etc. We produced written information about various dis-

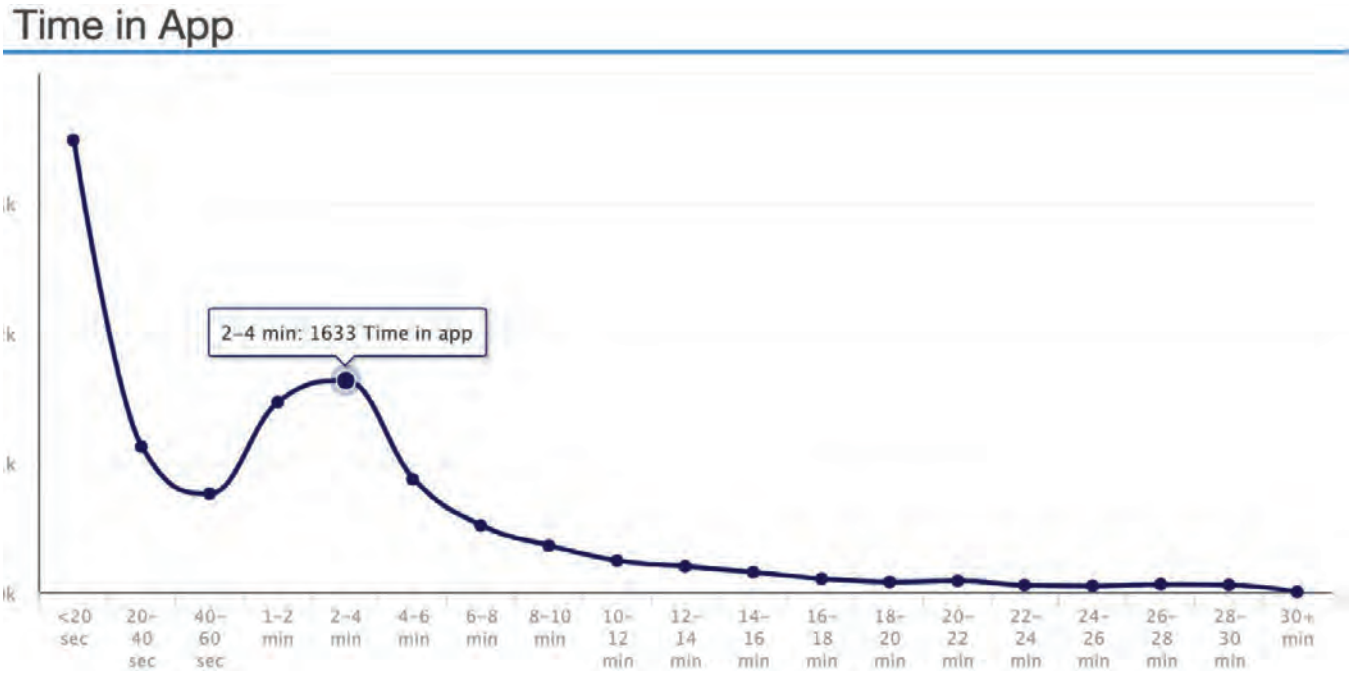

Figure 3. Time spent in App

eases and treatments e.g. Methotrexate. We also provided direct contact details, information about the local hospital and where to park. The written content, including video scripts, was provided by the authors and filmed by hci.digital.

Naturally, our patients were involved at all times and helped considerably in ensuring the App is easily navigable by all.

The results were presented to our patients in June 2018, who gave us their candid opinion of our efforts and how they would like us to develop the App further.

Results: Our App has been downloaded 2214 times, with over 10,000 visits and 35,000 page views, with peaks around the time of our monthly education sessions when we advertise the App to new patients.

Over 73% spent between 2-4 minutes in the App on each occasion with most of the videos being between 2-3 minutes long. Common hits include: videos on medications, contact details, different conditions, services available and clinic locations.

Patients have made spontaneous contact saying how valuable they find the information we have given them.

Emails and telephone calls can be made directly from the App, helping patients and aiding an efficient service by allowing direct phone calls or emails to the correct member of the MDT e.g. rheumatology physio, rather than going through the secretaries. Emailing rather than telephoning helps the department by making our services more efficient, as it frees up secreatarial time for other work.

Conclusion: Our patients have continued to download and use the App and it has become an important part of our patient education efforts, in particular, for those with a new diagnosis.

We can respond to patient queries more quickly now patients are contacting us by email rather than telephone and avoiding difficult to hear ansa-phone messages.

Our patient steering committee has asked us to develop interactive PROMS, a calendar reminder function and medicines management function and this is in process, having raised funds to develop this. The update of the App should be available by the end of the Summer 2020.

Download free from App store (search '*Rheumatology Connect'*) or go to www.rheumatologyconnect.info.

Correlation Between Disease Activity and Perceived Economic Barriers to Care in a Population of African American Women with Systemic Lupus Erythematosus

Ashley White[1], Trevor Faith[1], Aissatou Ba[1], Viswanathan Ramakrishnan[2], Hetlena Johnson[3], Jillian Rose[4], Clara Dismuke-Greer[5], Jim Oates[6], Leonard Egede[7] and Edith Williams[1], [1]Medical University of South Carolina, Charleston, SC, [2]medical university of south carolina, south carolina, [3]LupusCSC, Columbia, SC, [4]Hospital for Special Surgery, New York, [5]Palo Alto VA, Palo Alto, CA, [6]Medical University of South Carolina, Charleston, SC, Charleston, SC, [7]Medical College of Wisconsin, Milwaukee, WI

SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: Health Services Research Poster
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Systemic Lupus Erythematosus (SLE) is a complex, multifactorial disease with heterogeneous presentation. Disease activity – the number and severity of symptoms – can be influenced by a multitude of patient level and environmental factors. This examination seeks to explore the relationship between economic barriers to care and self-reported disease activity among a cohort of patients diagnosed with the disease.

Methods: Data for this study were aggregated from the baseline (pre-intervention) visits of the Peer Approaches to Lupus Self-Management (PALS) and Care Coordination Approaches to Learning Lupus Self-Management (CALLS) studies. Disease activity was assessed using the Systemic Lupus Activity Questionnaire. We used a Pearson Correlation to evaluate the correlation between disease activity and economic hardship in this using the "Systemic Lupus Activity Questionnaire" as an indicator of disease activity and questions from financial/travel surveys as indicators of economic hardship. The PALS study enrolled African American women with SLE at the Medical University of South Carolina while the CALLS study enrolled recently hospitalized SLE patients at the same institution. The CALLS study was not limited to African American women; however, the cohort was disproportionately made up of this population.

Results: There was no correlation between the indicator of disease activity during the past four weeks from and the indicators of economic barriers and financial barriers to care outside the MUSC hospital setting. As well as no correlation between disease activity and healthcare utilization outside of MUSC. There was no correlation between our indicator of disease activity during the past three months from the Systemic Lupus Activity Questionnaire and our indicators of economic barriers and financial barriers to care outside the MUSC hospital setting. As well as no

correlation between our indicator of disease activity during activity during the past three months and health utilization outside of MUSC.

Conclusion: These results indicate that economic and financial barriers to care and healthcare utilization outside the MUSC hospital setting are not statistically significant to estimate short term disease activity among this cohort of lupus patients. However, the majority of Lupus Quality of Life scores were high, indicating less interference of health and emotional issues on work and daily routine. These findings suggest that long-term studies are needed to further elucidate the impact of economic barriers on disease activity among lupus patients. Impaired access to care has profound implications for chronic and progressive disease care. With limited access to appropriate primary and specialty care, SLE patients are likely to seek care in emergency departments which increases the cost of care and diverts resources from acute care needs. Moreover, patients who forgo standard care are more likely to experience disease flares and develop organ damage which can be life threatening.

Support Methodologies for African American Women with Lupus – Comparing Two Study's Effects on Patient Activation

Ashley White[1], Trevor Faith[1], Aissatou Ba[1], Viswanathan Ramakrishnan[2], Hetlena Johnson[3], Jillian Rose[4], Clara Dismuke-Greer[5], Jim Oates[6], Leonard Egede[7] and Edith Williams[1], [1]Medical University of South Carolina, Charleston, SC, [2]medical university of south carolina, south carolina, [3]LupusCSC, Columbia, SC, [4]Hospital for Special Surgery, New York, [5]Palo Alto VA, Palo Alto, CA, [6]Medical University of South Carolina, Charleston, SC, Charleston, SC, [7]Medical College of Wisconsin, Milwaukee, WI

SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: Health Services Research Poster
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Systemic Lupus Erythematosus (SLE) is a chronic inflammatory disease in which the immune system of affected individuals attacks their own healthy tissues. While pharmaceutical therapies are an important part of disease management, many behavioral interventions have been implemented to increase patients' disease self-management skills, provide social support, and encourage patients to take a more active role in their care. This study seeks to compare two studies providing support to SLE patients and their subsequent effect on patient activation.

Methods: Within these two studies three interventions are considered. A peer-to-peer methodology and patient support group were evaluated in the Peer Approaches to Lupus Self Management (PALS) and a patient navigator mediated program was evaluated in the Care-Coordination Approach to Lupus Self-Management (CALLS). Both studies were implemented for patients with SLE at the Medical University of South Carolina (MUSC). The outcomes of interest for this examination are the Patient Activation Measure and Lupus Self Efficacy Score. We used a Least Squares Means model to analyze change in the total Patient Activity Measure and Lupus Self Efficacy scores independently in each cohort. We adjusted for demographics such as age, education, income, employment, and insurance. Participants in this study were largely African American women with SLE. Participants in the peer-to-peer arm and support group arms (PALS) were entirely African American women and recruited at the MUSC. The patient navigator arm

(CALLS) was not exclusively made up of African American women, but was disproportionately so. These subjects were identified due to recent hospitalizations at MUSC.

Results: Within the PALS study, the model that adjusted for demographic covariates described the data better but there was not a statistically significant difference between patient activation measures and lupus self-efficacy measures from baseline to post intervention measures. Within the CALLS study, the model that adjusted for demographic covariates described the data better but there was not a statistically significant difference between patient activation measures and lupus self-efficacy measures from baseline to post intervention measures. Comparing PALS to CALLS, the difference between baseline and postintervention measures seems to greater for the PALS study, thus warranting further investigation of the differing methodologies of the two studies.

Conclusion: These findings suggest that there is a difference between the two studies and their effects on patient activation and lupus self-efficacy.

Tailored interventions are a critical pathway towards improving disease self-management among SLE patients. Ideal interventions may look to include the peer mentoring approach.

Abstract Number: 0618

The Effect of Travel Burden on Depression and Anxiety in African American Women Living with Systemic Lupus

Trevor Faith[1], Ashley White[1], Aissatou Ba[1], Viswanathan Ramakrishnan[2], Hetlena Johnson[3], Jillian Rose[4], Clara Dismuke-Greer[5], Jim Oates[6], Leonard Egede[7] and Edith Williams[1], [1]Medical University of South Carolina, Charleston, SC, [2]medical university of south carolina, south carolina, [3]LupusCSC, Columbia, SC, [4]Hospital for Special Surgery, New York, [5]Palo Alto VA, Palo Alto, CA, [6]Medical University of South Carolina, Charleston, SC, Charleston, SC, [7]Medical College of Wisconsin, Milwaukee, WI

SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: Health Services Research Poster
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: The United States has a deficit of rheumatology specialists. This leads to an increased burden accessing care for patients with autoimmune and connective tissue disorders requiring specialized care. Given that most rheumatologists are located in urban centers at large hospitals, many Systemic Lupus Erythematosus (SLE) patients must travel long distances for routine appointments. The present work aims to determine whether travel burden is associated with increased levels of depression and anxiety among these patients.

Methods: Data for this study were collected from the baseline visits of patients participating in two SLE studies at MUSC. At the baseline time point a travel/economic burden survey was assessed as well as the Patient Health Questionnaire 8 and the Generalized Anxiety Disorder 8 survey as measures of depression and anxiety respectively. A linear regression model was used to determine if travel burden contributes to depression/anxiety. Travel burden was determined using the “Travel Burden” questionnaire while depression/anxiety were measured using the total “Personal Health Depression Questionnaire (PHQ) 8” or total Generalized Anxiety Disorder Screener (GAD) 8” scores.

Both models adjusted for the systemic lupus activity questionnaire. Participants in these studies were largely African American women, all of whom were diagnosed with SLE.

Results: Indicators of travel burden did not have a statistically significant association with indicators of depression and anxiety during the time frame of two weeks measured by the total Personal Health Questionnaire assessment scores. However, specifically, 'transportation issues for medical care increasing stress' was a statistically significantly associated with Personal Health. After adjusting for disease activity during the past three months, travel burden did have a statistically significant association with indicators of depression and anxiety. Additionally, indicators of travel burden did have a statistically significant association with indicators of depression and anxiety during the time frame of two weeks measured by the total Generalized Anxiety Disorder assessment score. However, after adjusting for disease activity during the past three months the association was no longer statistically significant.

Conclusion: Previous studies have identified patient travel costs as being problematic. Our findings support the impact of travel burden on depression and anxiety among lupus patients. The difference in the impact of disease activity with associations of travel burden indicators, the Personal Health Questionnaire and the Generalized Anxiety Disorder assessment suggest a potentially larger role with disease activity during the past three months. Our findings suggest investigating long term disease activity to further examine the influence of travel burden. Travel burden remains a significant barrier to care for many SLE patients. Not only does inadequate access to care lead to greater direct healthcare costs but it can also result in the development or worsening of comorbid conditions. Compounding chronic conditions further complicates the treatment process for these patients and impedes appropriate resource delivery.

Abstract Number: 0619

Pharmacist Intervention: Reducing Insurance Denials of Specialty Medications

Nisha Sharma[1], Nicole Girardi[1] and Karen Wong[1], [1]Beth Israel Deaconess Medical Center, Boston, MA

SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: Health Services Research Poster
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Insurance companies have inconsistent formularies that do not align with Rheumatology clinical treatment guidelines. We are faced with the ongoing challenge of insurance companies denying access to specialty medications for patients with very individualized needs. This abstract will examine the common reasons for insurance denials of specialty medications and how pharmacist intervention can impact these denials.

Methods: A retrospective analysis of pharmacist interventions pertaining to insurance denials of prescribed specialty medications was conducted. The interventions consisted of pharmacist written appeal letters for 41 denials (98%) and providing supporting literature for 1 denial (2%). Another data point considered was the number of medication claims for off-label use versus FDA-approved use. The data was compiled from pharmacy intervention records which occurred from July 2019 through May 2020.

The denials involved the following specialty medications for reference: abatacept, adalimumab, anakinra, apremilast, canakinumab, certolizumab, etanercept, infliximab, ixekizumab, pirfenidone, rituximab, secukinumab, sildenafil, tadalafil, tocilizumab, and tofacitinib.

The denials involved the following diagnoses for reference: Adult-Onset Still's Disease, AS, Autoimmune Inner Ear Disease, Behcet's Disease, Checkpoint Inhibitor-induced Arthritis, Chronic Recurrent Multifocal Osteomyelitis, Familial Mediterranean Fever, IgG4-Related Disease, Myhre Syndrome, Psoriatic Arthritis, Raynaud Phenomenon, Recurrent Pericarditis, Relapsing Polychondritis, Rheumatoid Arthritis, SAPHO Syndrome, Schnitzler's Syndrome, and SLE.

Results: Of the 42 insurance denials that required pharmacist intervention, 32 (76%) were medication claims for off-label use and 10 (24%) were for FDA-approved use.

Of the 42 challenged insurance denials, 30 denials were overturned (71%) and 12 denials were upheld (29%). Of the 30 overturned denials, 24 (80%) of the approvals were for medication claims for off-label use and 6 (20%) were for FDA-approved use.

Of all appeal approvals, the average time from date of denial to date of approval was 9 days.

The reasons for initial insurance denials were as follows: non-FDA approved use (27; 64%), step therapy requirements (12; 29%), and quantity limits (3; 7%).

Conclusion: Rheumatologic conditions are progressive and debilitating. In consequence, it is necessary to tailor treatments to the individual patient and not allow medication access to be at the discretion of the insurance company. Based on the data presented, a significant percentage of insurance denials were due to non-FDA approved use or step therapy requirements. Greater than two-thirds of the analyzed insurance denials were overturned, with a remarkable average turnaround time of 9 days. Pharmacists have advanced clinical training and skills to conduct literature review, making them very effective in overturning insurance medication denials, and increasing patient access to medications as a result. It is indicated that pharmacists are a valuable asset to increase the focus on unchallenged insurance denials and reduce existing burden on providers to improve patient care in a timely manner.

Do Physical Therapists Follow Evidence-Based Practice Recommendations for Treatment of Inflammatory Arthritides?

Debbie Ehrmann Feldman[1], Tatiana Orozco[1], Sasha Bernatsky[2], François Desmeules[1], Maude Laliberté[3], Kadija Perreault[4], Jonathan El-Khoury[5], Jean Légaré[4] and Linda Woodhouse[6], [1]Université de Montréal, Montreal, QC, Canada, [2]The Research Institute of the McGill University Health Centre, Montreal, ON, Canada, [3]Integrated Health and Social Services University Network for West-Central Montreal, Montreal, Canada, [4]Université Laval, Québec, QC, Canada, [5]Université de Sherbrooke, Montreal, QC, Canada, [6]Curtin University, Perth, Australia

SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: Health Services Research Poster
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Physical therapy plays an important role in the global management of rheumatoid arthritis (RA) and ankylosing spondylitis (AS). Therapeutic exercises (mobility, strength and aerobic) and patient education are recommended whereas passive modalities, such as electrotherapy, are more controversial. Our purpose was to document the type of interventions used by physical therapists for patients with RA and AS, to assess whether intervention choices follow current evidence-based practice recommendations, and to explore factors associated with such choices.

Methods: We sent an online survey to physical therapists in the province of Quebec, Canada. Participants were asked about what kind of treatment they would provide for 2 patients showing typical signs and symptoms of RA and AS. Descriptive statistics were used to illustrate the proportions for each treatment chosen by physical therapists. We explored associations between choice of treatments with physical therapists' demographic and practice related factors, using inferential statistics and regression analyses.

Results: A total of 298 physical therapists responded to the online survey. For both RA and AS respectively, the most common interventions were mobility exercises (91.0%; 98.3%) and patient education (90.1%; 92.8%). For both cases, just over 60% selected strength exercises. Passive manual forms of therapy were chosen by 36% of PTs for RA and 58% for AS, and electrotherapy was chosen by 30% for RA and 40.9% for AS. Aerobic exercise was rarely selected as a mode of treatment (less than 3% of the PTs for both RA and AS). For RA, choosing electrotherapy ($p= 0.006$) and passive manual forms of therapy ($p< 0.001$) were highly associated with working in the private sector. For AS, selecting passive manual forms of therapy were highly associated with working in the private sector ($p< 0.001$) and having taken post-graduate related courses ($p< 0.001$).

Conclusion: Most physical therapists chose mobility exercises and patient education, which both represent evidence-based treatment approaches for RA and AS. Despite evidence recommending strength and aerobic exercise for these clienteles, physical therapists underutilize these interventions, especially aerobic exercise. There is a need for better knowledge translation to physical therapists regarding the importance of strength and aerobic exercise for patients with RA and AS.

Abstract Number: 0621

Effectiveness of Screening in Patients with Rheumatic Disease Before Commencing Biologic Therapy and Risk of Active Tuberculosis

Sultana Abdulaziz[1], Suzan Attar[2], Wael Bajhammoh[3], Eman Alsindi[3], Eman Bakhashwain[4] and Doaa Ayish[5], [1]King Fahd Hospital, Jeddah, Saudi Arabia, [2]King Abdulaziz University, Jeddah, Saudi Arabia, [3]King Fahad Hospital, Jeddah, Saudi Arabia, [4]East Jeddah Hospital, Jeddah, Saudi Arabia, [5]Prince Mohammed Bin Nasser Hospital, Gizan, Saudi Arabia

SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: Infection-related Rheumatic Disease Poster
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Treatment with biologic therapy has been associated with a high risk of reactivation of latent tuberculosis (TB). Preventive strategies for tuberculosis remain a crucial step before initiating biologics in rheumatic disease.

The study aimed to access the effectiveness of TB screening recommendations before the initiation of biological therapy and identify the incidence of active TB among these patients.

Methods: We performed a hospital-based retrospective cohort study among rheumatic disease patients on biological therapy in two centers in Jeddah between January 2005 to December 2019. Medical files were retrospectively reviewed for demographics data, baseline screening for TB, use of prophylaxis, information on DMARDs and biological therapies, and outcomes results were collected.

Results: A total of 365 patients were included over a period of 14 years. Two hundred ninety-two (80%) had Rheumatoid arthritis (RA),13% psoriatic arthritis (PSA), 9% spondyloarthritis (SPA), 2% SLE, and 4% others. The mean age was 47.54 (±14.2), 311 (85%) were females with a mean duration of disease 8.45 years (± 6.58). Hundred forty-nine (42.3%) were on steroids. Anti TNFs were prescribed in 213 (58.4%) patients, Non Anti-TNFs 124 (36.6%) patients, and Jak inhibitors 18 (5%) patients.TB screening was done to all patients except 3 patients (data missing) before commencing biologics. Forty-four (12.1%) patients had latent TB at baseline and all received chemoprophylaxis with isoniazid before starting biologics. There was no significant difference in patients with latent TB and those without regarding the demographics, comorbid illnesses, old TB, inflammatory markers, BMI, or steroid use.

Four patients with active TB were identified (one with Behcet's disease and three with RA). One patient had a reactivation of latent TB and 3 patients developed de novo TB. Three out of four had an infection in the first 6 months of treatment (one on infliximab and two on rituximab) and one case after 1 year of stopping adalimumab. Two cases had pulmonary TB and two others with extrapulmonary TB (pericarditis and brain abscess each). All four patients with active TB were treated with standard anti TB medications. Three had complete resolution of their TB and one died.

Conclusion: Baseline screening has been effectively carried out in our cohort as per recommendations. Physicians should be vigilant for symptoms and signs of active TB as not only reactivation of latent TB can occur with patients on biologics but also de novo TB can occur.

Nickerson et al (2012)	47 M, fever, decreased urine output, abdominal pain, hypotension and petechial rash. PMH of 2-month history of lymphadenopathy.	No	2 months	*R. rickettsii*	AAV	Broad spectrum antibiotics including doxycycline	Hydrocortisone 1200 mg/dayfor 7 days and then tapered to prednisone 40 mg daily.	Remission of vasculitis
Oumerzouk et al. (2013)	40 M, muscle weakness evolving to flaccid tetraparesis, diffuse myalgia, arthralgia, 10 kg weight loss for 2 months before admission.	No	Does not clarify	CMV	AAV	No	IVIG (0.4 g/kg/day) 5 days followed by methylprednisolone 500 mg/d. Switched to oral prednisolone 1 mg/kg/d, without improvement. Administration of Cyclophosphamide led to partial recovery.	Remission of vasculitis

Mirsaeidi et al. (2013)	25 M, 2-day history of cough, hemoptysis, fevers and 1day hematuria. Nausea, vomiting, abdominal pain and reduced urine output over the last 2 weeks.	Yes	Does not clarify	EBV in the setting of HIV/AIDS	AAV	No	Prednisone and cyclophosphamide	Remission of vasculitis
Xu et al. (2014)	16 F, fever for 3 weeks. Microscopic hematuria and nephrotic range proteinuria. Diagnosed with acute EBV and given ganciclovir plus NSAIDS. Within a week severe anemia and acute kidney injury ensued.	Yes	4 weeks	EBV	AAV	Gancyclovir	IV methylprednisolone 1 mg/kg/d	Remission of vasculitis
Yamaguchi et al. (2014)	80 F, PMH of MAC infection 2 years prior, p/w 2-month history of hearing loss and 1-month history of fever. Workup demonstrated necrotizing GN.	Yes	2 months	EBV	MPA	No	Methylprednisolone pulse therapy, followed by mizoribine and low-dose prednisolone	Remission of vasculitis
Lizarraga et al. (2015)	66 F, fever, fatigue, puffy eyes, frothy urine, hypertention and rapidly progressive GN	Yes	4 weeks	Dengue virus	AAG	No	Methylprednisolone pulses, prednisone, plasma exchange, IV cyclophosphamide	Remission of vasculitis
Asano et al. (2016)	73 F, untreated pulmonary MAC infection for 1 year, fever, polyarthritis, livedo reticularis, purpura, crescentic GN	Yes	11 months	MAC	AAV	Anti-mycobacterial regimen	Prednisolone 1 mg/kg/d	Remission of vasculitis
Addy et al. (2018)	70 F, recurrent chest infections, middle lobe bronchiectasis, purpuric rash, small joint arthralgia, peripheral neuropathy.	No	10 years and 3 months	*M. abscessus*	MPA	Anti-mycobacterial regimen	High dose prednisolone and cyclophosphamide	Relapse of infection and vasculitis
Alnaser et al. (2018)	27 M, lung cavitation, miliary nodules, and necrotizing glomerulonephritis	Yes	2 months	*M. kansasii*	MPA	Anti-mycobacterial regimen	Prednisone 60mg/d.	Died from infection and vasculitis, following treatment discontinuation
Azar et al. (2020)	64 M, fevers, malaise, mild cough, and pain in the left flank. Diagnosed with persistent focal pneumonia and GN	Yes	4,5 months	*Coccidioides* spp.	AAG	Amphoteracin B, after the dissemination of infection from immunosuppressive Tx	IV methylprednisolone, followed by oral cyclophosphamide, therapeutic plasma exchange and rituximab	Died from infection
Hashimoto et al. (2020)	11 F, PMH: chronic back pain for 1 year and proteinuria/hematuria for 3 months history with positive MPO-ANCA. Workup revealed MSSE osteomyelitis of T11.	Yes	9 months	*S.epidermidis*	AAG	2 weeks of IV cefazolin followed by a 3-month course of oral cefaclor	Prednisolone 1 mg/kg per alternate day	Remission of GN

*Possible glomerulonephritis due to the presence of acute kidney injury or proteinuria or hematuria. Patient did not consent to biopsy. CMV, Cytomegalovirus; EBV, Epstein-Barr Virus; MPO-ANCA, Myeloperoxidase specific antineutrophil cytoplasmic antibody; AAV, ANCA associated vasculitis; AAG, ANCA associated glomerulonephritis; GN, glomerulonephritis; M, male; F, female; AV, atrial valve; MV, mitral valve; MPA, Microscopic polyangiitis; MAC, *Mycobacterium avium complex*; MAI, *Mycobacterium avium intracellulare*; MSSE, Methicillin sensitive *Staphylococcus epidermidis*; IV, intravenous; PMH, Past medical history; IVIG, intravenous immunoglobulin.

to identify and describe all infections that induce MPO-ANCA AAV and describe the patients' clinical characteristics and outcomes.

Methods: PubMed/Medline and Scopus databases were searched without any restrictions, from inception to March 2020, in accordance with PRISMA guidelines. Published articles were included, describing the development of

MPO-ANCA AAV during or after infection. The data retrieved were including the causative pathogen, patients' clinical features, the reported diagnosis, the therapeutic regimen used, and the patient outcomes. Two authors independently selected the studies, extracted data and assessed risk of bias.

Results: Among the 595 abstracts identified, 17 case reports articles were included, each describing a single patient (Table 1 and 2). The mean age was 53.8 (range 11-80 years), and the majority were female (58.8%). Seven patients (41.2%) were diagnosed with MPA, 7 (41.2%) with MPO-ANCA AAV, and 3 (17.6%) with MPO-ANCA associated glomerulonephritis. The median time between infection and development of vasculitis was 3 months (range: 3 weeks - 10 years).

The most common pathogens associated with the preceding infections were viruses (35.2%), followed by mycobacterial (29.4%) and bacterial infections (29.4%). The viral infections were caused by EBV, CMV, and 1 case by Dengue virus infection. Mycobacterium avium complex was the most frequent mycobacterial species pathogen, and infective endocarditis due to staphylococcus aureus was the common bacterial infection.

Renal involvement was the most frequent clinical manifestation (70.5%) with renal biopsy-proven glomerulonephritis in 53% of cases, followed by respiratory, musculoskeletal, cutaneous, and nerve involvement. Glucocorticoids and anti-infective agents were administered in the vast majority of patients, and cyclophosphamide in 47%. Three (17.6%) patients expired during follow-up. Vasculitis regressed after the resolution of infection in 10/17 (58.8%). MPO-ANCA titers decreased significantly on follow-up in all 10 cases where they were estimated.

Conclusion: Several infectious agents can lead to the development of MPO-ANCA and the clinical manifestations of MPO-ANCA AAV, which appear to regress with the resolution of infection. Clinicians should be alert for the presence of an underlying infection in patients presenting with MPO-ANCA associated vasculitis, as early detection will enable prompt treatment with the combination of anti-infective and immunosuppressive regimens.

Cytokine Storm: Outcomes in SARS-CoV-2 Patients Treated with Biologics in a Rheumatology Cohort

Neha Chiruvolu[1], Muntarin Karim[2], Patil Injean[3], Sandy Lee[3], Karina Torralba[4], Christina Downey[3], Mehrnaz Hojjati[5], Loomee Doo[5], Donna Jose[6], Deepa Panikkath[3], Micah Yu[5], Anna Lafian[5], Marven Cabling[5] and Vaneet Sandhu[7], [1]UC Riverside School of Medicine, Riverside, CA, [2]Loma Linda University Health System, Loma Linda, CA, [3]Loma Linda University Medical Center, Redlands, CA, [4]Loma Linda University School of Medicine, Redlands, CA, [5]Loma Linda University Medical Center, Loma Linda, CA, [6]Loma Linda University Medical Center, Ontario, CA, [7]Loma Linda University, Loma Linda, CA

SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: Infection-related Rheumatic Disease Poster
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Cytokine Release Syndrome (CRS) or Macrophage Activation Syndrome (MAS) is a life threating hyperinflammatory condition that can complicate rheumatic disease as well as infections like SARS-CoV-2 (SARS-CoV-2-CRS). Immunomodulators are traditionally used to treat MAS in SLE, Kawasaki disease, and systemic

JIA, but have the potential to treat SARS-CoV-2-CRS. An institution-mandated rheumatology SARS-CoV-2-CRS management algorithm was developed for 2 health systems with use of tocilizumab (TOC) and anakinra (ANA) as first and second-line agents. The objective of this study is to determine characteristics of patients from a SARS-CoV-2-CRS cohort with the overall goal to understand the clinical disease course of these patients and the impact of biologic management.

Methods: A retrospective chart review was completed on SARS-CoV-2 patients at an academic medical center and a county hospital for whom rheumatology consultations were completed for CRS evaluation from March 15-May 30, 2020. Both institutions shared the same electronic medical record system. Patients meeting CRS diagnostic criteria who were treated with biologic therapy were compared to those without CRS not given biologic therapy for the following outcomes: survival, deaths, infections, intensive care unit (ICU) admissions and duration, length of hospitalization, thrombosis and trends in laboratory markers including blood cell counts, liver enzymes, and acute phase reactants.

Results: Out of 150 patients with SARS-CoV-2 referred for rheumatology consultation, 71 (47%) were diagnosed with CRS and were treated with the following biologics: TOC only in 63 (89%), ANA only in 1 (1%), abatacept only in 1 (1%), and 6 (8%) patients who received both TOC and ANA separately. Steroids were given in 64 (90%) CRS patients. Comparing baseline characteristics of all 150 patients (Table 1), CRS patients required more ICU admissions (61%), but had similar need for ventilator support (23%). Biologic treatment resulted in improved ferritin, platelets, and ESR; yet, other laboratory tests remained similar or worse 3-5 days after the first dose (Table 2). Death occurred in 20 (28%) while 36 (51%) were discharged from the hospital (Table 3). Bacterial co-infection at time of diagnosis was noted in 10 (14%); 10 (14%) patients developed a second co-infection after biologic treatment.

Table 1. Characteristics of SARS-CoV-2 patients evaluated for Cytokine Release Syndrome

Characteristic	**SARS-CoV-2-CRS (n= 71)**	**SARS-CoV-2 without CRS (n= 79)**
Age (average years (range))	60 (20-88)	63 (33-102)
Steroid treatment[a]		
Average initial steroid dose	226 mg[b]	129 mg
Average daily steroid dose	162 mg[b]	67 mg
ICU admissions, n (%)	43 (61)	30 (38)
Ventilator support, n (%)	16 (23)	18 (23)
Hypoxia at admission, n (%)	56 (79)	51 (66)
Requiring oxygen during hospitalization, n (%)[d]	69 (97)	70 (89)

Outcomes in SARS-CoV-2-CRS treated with biologic and Non-SARS-CoV-2-CRS not treated with biologic

Conclusion: SARS-CoV-2-CRS patients had similar baseline comorbidities to patients without CRS except for co-infections at time of diagnosis that were more common in the latter group. Within the time frame laboratory tests were reviewed, only the ferritin, platelets, and ESR improved after biologic treatment, but overall, patients with CRS had more critical laboratory test results compared to those without CRS. Death was noted to be two-fold higher in CRS patients. All deceased were in the ICU at the time, suggesting a sicker population at greater risk for death. Additional studies are needed including a longitudinal evaluation of trends in laboratory tests post-biologic use in consideration of drug pharmacokinetics and more robust cytokine profiling. Furthermore, outcomes in CRS patients that received biologics should be compared to a control arm that did not receive biologics.

Association of Regional Body Composition and Physical Function Using the Short Physical Performance Battery Among Peruvian Women with HIV

Diego Cabrera[1], Mijahil Pavel Cornejo Ortega[2], Yvett Pinedo[3], Patricia Garcia[4] and Evelyn Hsieh[5], [1]Yale University, Universidad Peruana Cayetano Heredia, Lima, Peru, [2]Hospital Nacional Arzobispo Loayza, Lima, Peru, [3]Hospital Nacional Arzobispo Loayza, Lima, [4]Universidad Peruana Cayetano Heredia, Lima, Peru, [5]Yale University School of Medicine; West Haven VA, New Haven, CT

SESSION INFORMATION

Session Date: Saturday, November 7, 2020

Session Title: Infection-related Rheumatic Disease Poster

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: The musculoskeletal (MSK) system is significantly affected by HIV and its treatment. Changes in body composition can reflect important changes in bone and MSK health, particularly among populations at risk for developing fat redistribution syndromes, like HIV-positive women (HpW). Although more than half of HIV-infected population worldwide are women, there are limited data about characteristics of women aging with HIV in Latin American and the Caribbean (LAC). No studies from LAC have focused on the relationship between body composition changes and physical function among these individuals. We aimed to explore the scope of this problem among Peruvian women aging with HIV.

Methods: We enrolled HpW and HIV-negative women (HnW) ≥40 years of age receiving care at a large HIV clinic in Lima, Peru. Dual X-ray absorptiometry (DXA) was used to measure trunk and limb lean mass (LM) and fat mass (FM). Physical performance was assessed with the well-established Short Physical Performance Battery (SPPB) and physical strength with the grip strength test (GST) using a hand hydraulic dynamometer. We used linear regression to model associations between HIV status, body composition and physical test scores.

Results: 104 HpW and 212 HnW were enrolled with a mean age of 52.4±8.2 and 56.4±8.8 years (p< 0.001) and BMI of 26.4±5.1 and 27.6±4.1 kg/m^2 (p=0.03), respectively. Among HpW, the mean years since HIV diagnosis was 11.8±6

Characteristics	HIV-positive women N= 104	HIV-negative women N = 212	P-value
SPPB			
Overall score, mean (SD)	9.99 (1.4)	10.81 (1.12)	**<0.001**

*SPPB, short physical performance battery; FM, fat mass; LM, lean mass; BMC, bone mineral content; BMI, body mass index; %fat, percentage of FM; *p ≤ 0.05; ‡p ≤ 0.01; ¥p ≤ 0.001*

Table 2. Unadjusted and Adjusted Linear Regression for SPPB and Grip Strength

and everyone was on antiretroviral treatment (9.9±5.3 years). Fat mass index (FMI) was 9.6±3 vs 10.9±2.7 kg/m^2 (p< 0.001) between HpW and HnW, respectively. Overall mean SPPB score was 9.9 vs 10.8 between HpW and HnW, respectively (p< 0.001). Mean grip strength was 19.9±5.9 vs 19.8±5.4 kg (p=0.83) between HpW and HnW, respectively. In multivariate models adjusted by age and HIV status, increased trunk FM was independently associated with decreased SPPB score (p< 0.001), increased arm LM was independently associated with increased GST(p< 0.001) and increased arm %fat was independently associated with decreased GST (p< 0.001).

Conclusion: In this study, trunk FM and arm LM were independent predictors for the physical performance and function tests described, and HIV status was independently associated with SPPB score. Larger prospective studies are needed among PWH in LAC to help identify individuals at high risk for declines in physical function, and to inform prevention guidelines.

Machine Learning Model to Predict Culture Positivity in Suspected Septic Arthritis

Vinit Gilvaz[1], Elinor Mody[2], Alwyn Rapose[2], Shree Radhakrishnan[3], Saud Abaalkhail[1] and Sri Vibhavari Guntupalli[1], [1]Saint Vincent Hospital, Worcester, MA, [2]Reliant medical group, Worcester, MA, [3]Innovation Incubator Inc, San Jose, CA

SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: Infection-related Rheumatic Disease Poster
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Arthrocentesis is typically performed on patients with an acutely inflamed joint of unclear etiology. This is most often done to rule out septic arthritis, especially in patients with a red, swollen, and painful joint.

In the absence of a positive gram stain, an elevated synovial fluid (SF) white count of >25,000 is usually suggestive of an infected joint. However, there does not appear to be a reliable cut off to make a diagnosis of septic arthritis. Missing a diagnosis or a delay in the treatment can lead to extensive damage to the articular cartilage. Hence making an early diagnosis is especially important.

Baseline characteristics (Mean ± SD)

Figure 2

Artificial intelligence (AI) applications in healthcare have seen a steady rise over the past decade. Machine learning and deep learning models have been extensively used to discover patterns and predict patient outcomes. AI applications have shown promise in a number of fields, from radio diagnostics to infectious diseases. Our study was aimed at developing and accessing a machine learning model to predict the likelihood of septic arthritis before synovial fluid culture results are available.

Methods:

- We retrospectively collected data on 98 patients that had synovial fluid aspirations done at our community hospital over a 4-year period. A diagnosis of septic arthritis was confirmed based on the results of the synovial cultures on day 5.
- Medical history, presenting clinical features, and corresponding laboratory values were recorded (Fig 1).
- Prior to building the model, the data was preprocessed and normalized. Boolean values were converted to binary representations and categorical features were converted to numerical values.
- The dataset was then split into a training and test set, with an 80:20 randomly sampled split.
- A Random Forest Classifier algorithm was used to build the model, which was then evaluated using the test set.
- Feature importance was plotted, and a confusion matrix generated to view the false positives/negative count (Fig 2).
- Finally, column correlations were generated using a heatmap (Fig. 3) to explore the data and validate the features that the model had selected.

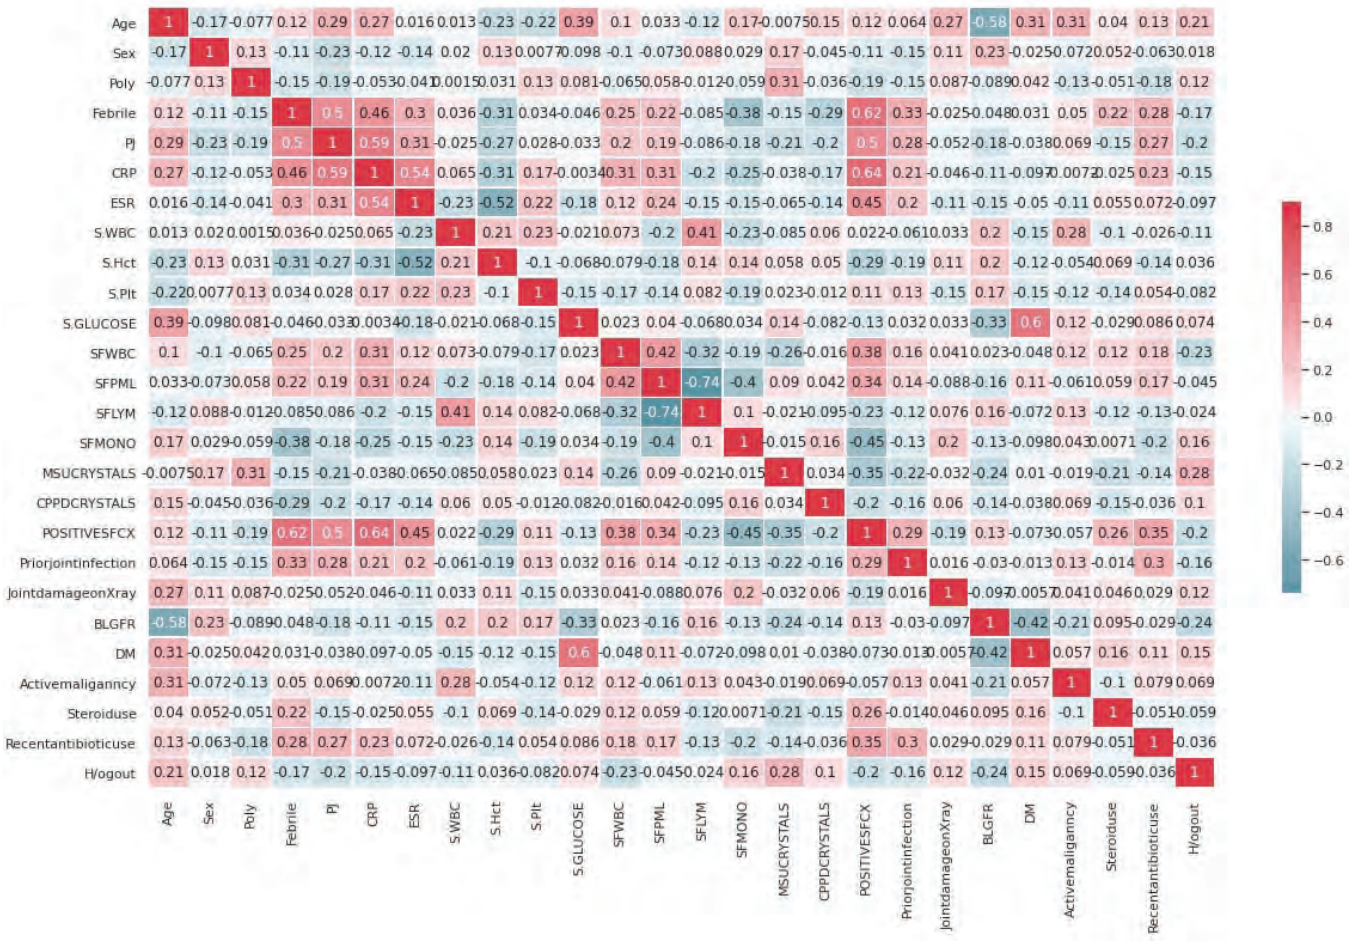

Figure 3

Results:

- In total, 33 of the 98 (33.6%) SF cultures came back positive.
- The most common organism identified was methicillin-sensitive staphylococcus aureus (42% of positive cultures).
- 22 of the 65 patients (33.8%) with ultimately negative cultures were empirically started on antibiotics at presentation, while, 3 of the 33 patients (9%) with positive cultures had not been initiated on antibiotics.
- Our feature importance plot indicated that CRP and SF monocytes were the strongest positive and negative predictors of SA, respectively.
- When evaluated with the test set, our prediction model proved to be quite accurate with a sensitivity of 87% and a specificity of 100% (accuracy of 95%).

Conclusion: Our proof of concept indicated that it is possible to build a well-performing model to predict septic arthritis cases using machine learning. With a larger sample size, more robust methods can be leveraged for predictive modeling and higher performance and accuracy. Ultimately, the output can be used to generate a risk score to determine a patient's likelihood of septic arthritis.

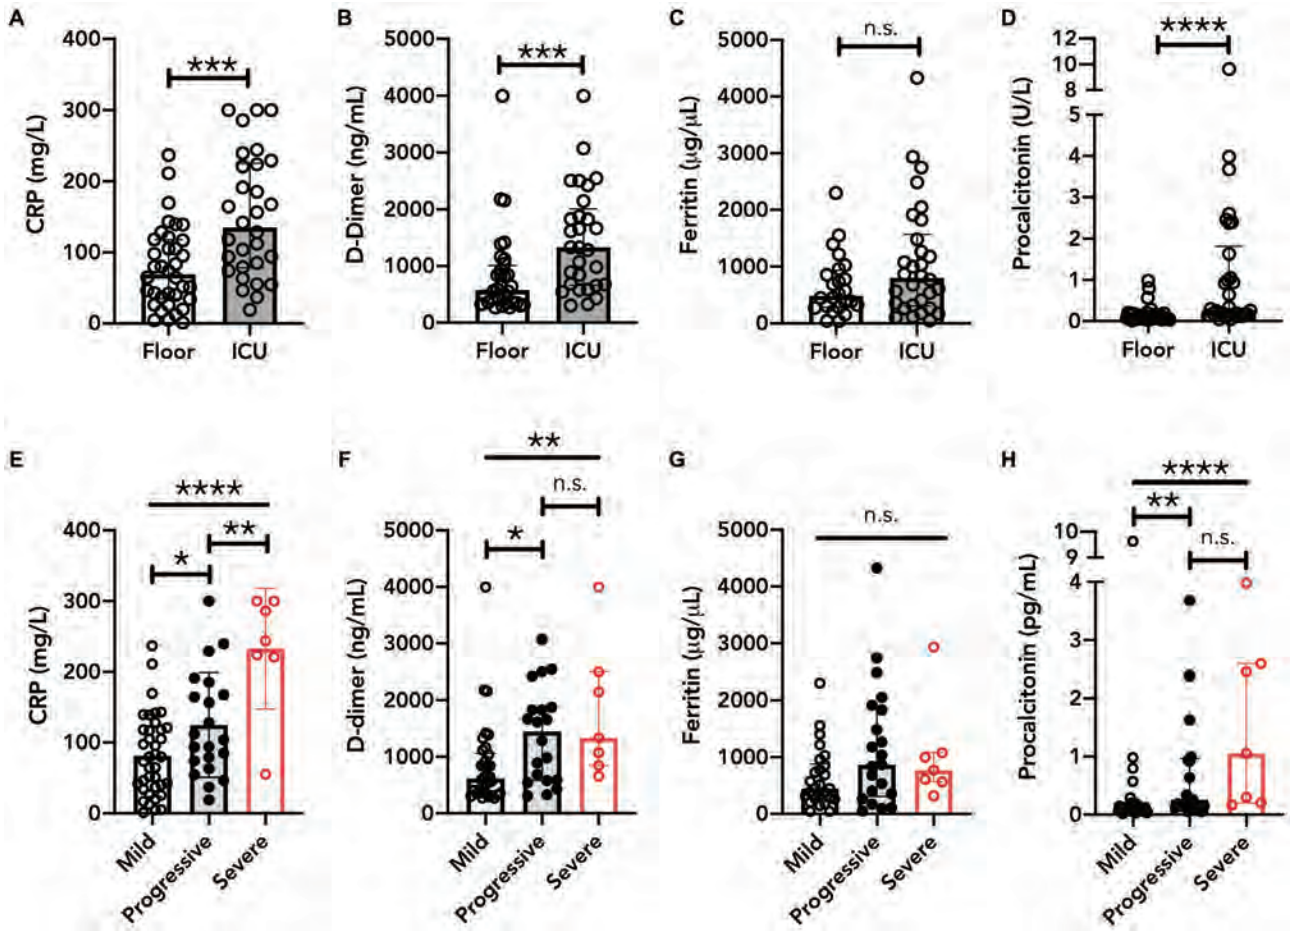
Early Rise in CRP Is Associated with Progression to Respiratory Failure and Intubation in COVID-19 Patients

Alisa Mueller[1], Tomoyoshi Tamura[2], Julia Jezmir[3], Erin Penn[1], Gregory Keras[4], Anthony Massaro[5] and Edy Kim[5], [1]Brigham and Women's Hospital, Division of Rheumatology, Inflammation, and Immunity, Boston, MA, [2]Brigham and Women's Hospital, Division of Pulmonary and Critical Care Medicine, Boston, MA, [3]Brigham and Women's Hospital, Department of Medicine, Boston, MA, [4]Brigham and Women's Hospital, Division of Rheumatology, Inflammation, and Immunity, Boston, MA, [5]Brigham and Women's Hospital, Division of Pulmonary and Critical Care Medicine, Boston, MA

SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: Infection-related Rheumatic Disease Poster
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: During the course of hospitalization, it is often unclear which COVID-19 patients will progress from non-critical to critical illness. Timely identification of these patients is crucial to guiding triage and early immunomodulatory intervention. Biomarkers linked with inflammation, such as CRP, D-dimer, ferritin, and procalcitonin are associated with critical illness or mortality in COVID-19 infection. These laboratory values are of particular interest due to their correlation with pathologic mechanisms related to IL-1 and IL-6 signaling as well as coagulopathy. We sought to determine whether these markers could be predictive in assessing whether a patient with non-critical illness would progress to critical disease.

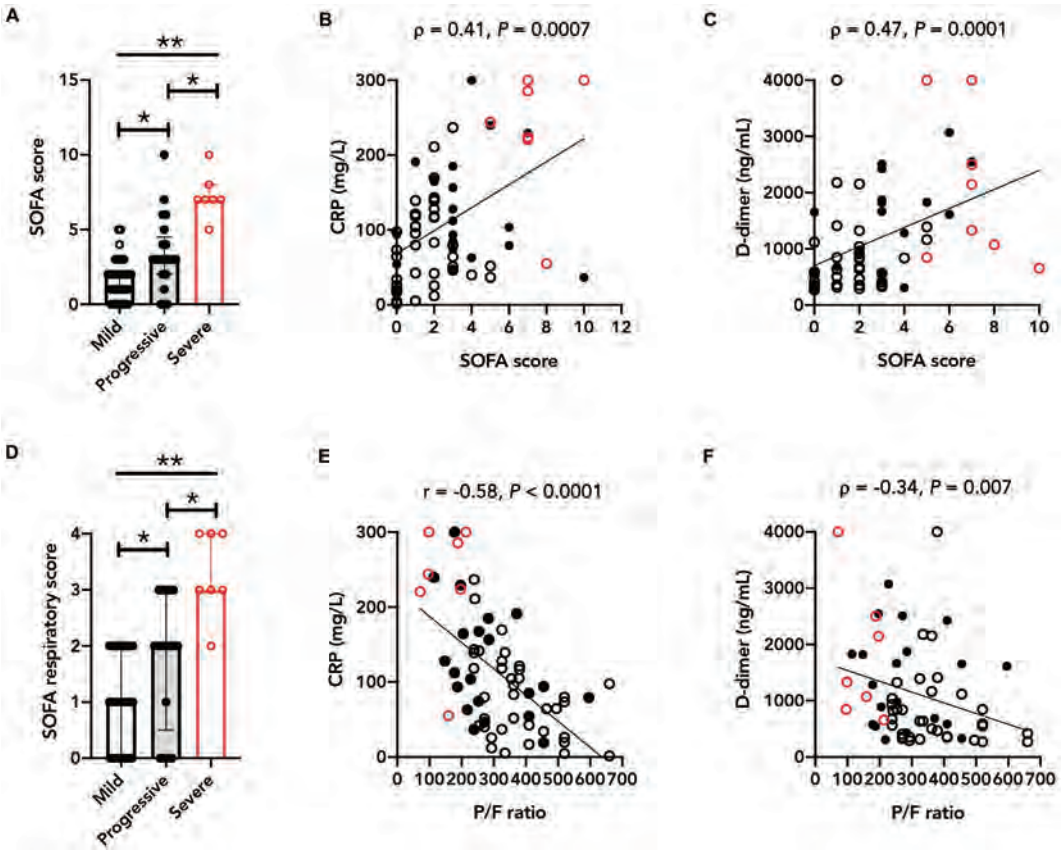
Methods: In our single-center retrospective cohort analysis of the first 66 patients admitted for COVID-19 infection, we examined inflammation biomarkers to distinguish non-critically ill inpatients who remained stable from those that had progressive respiratory failure requiring intubation and ICU transfer. Unlike the typical approach where patients are grouped into the two categories of non-critical and critical illness, COVID-19 patients in our study were classified



into three cohorts by severity and stability of respiratory failure: stable non-critical illness ("mild", 38 [58%]); non-critical illness at admission that progressed to critical illness ("progressive", 21 [32%]); and critical illness at admission ("severe", 7 [11%]). This approach allowed us independently profile patients with progressive disease from those who were already critically ill on admission.

Results: We found that while admission CRP level was weakly associated with future progressive respiratory failure, it had limited clinical utility as the progressive cohort showed modestly increased levels of CRP compared to the mild cohort, with significant overlap (125.0 ± 74 vs. 81.3 ± 57 mg/L, $P = 0.05$) (Figure 1). Despite the limited predictive value of admission CRP levels, these measurements were indeed clinically relevant as they correlated with SOFA score ($\rho = 0.41$, $P < 0.001$) and hypoxemic respiratory failure (P_aO_2/F_iO_2, $r = -0.58$, $P < 0.001$) (Figure 2). A closer examination of CRP trend showed that dynamic trend of CRP levels within the first 72 hours of admission rather than the static CRP level at admission showed a much stronger association with respiratory deterioration. Specifically, rise in CRP levels most clearly distinguished mild and progressive cohorts (24-48h post-admission: 170.6 ± 95 vs. 91.0 ± 67 mg/L, $P = 0.03$; 48-72h post-admission: 185.0 ± 92 vs. 81.6 ± 63 mg/L, $P = 0.002$) (Figure 3).

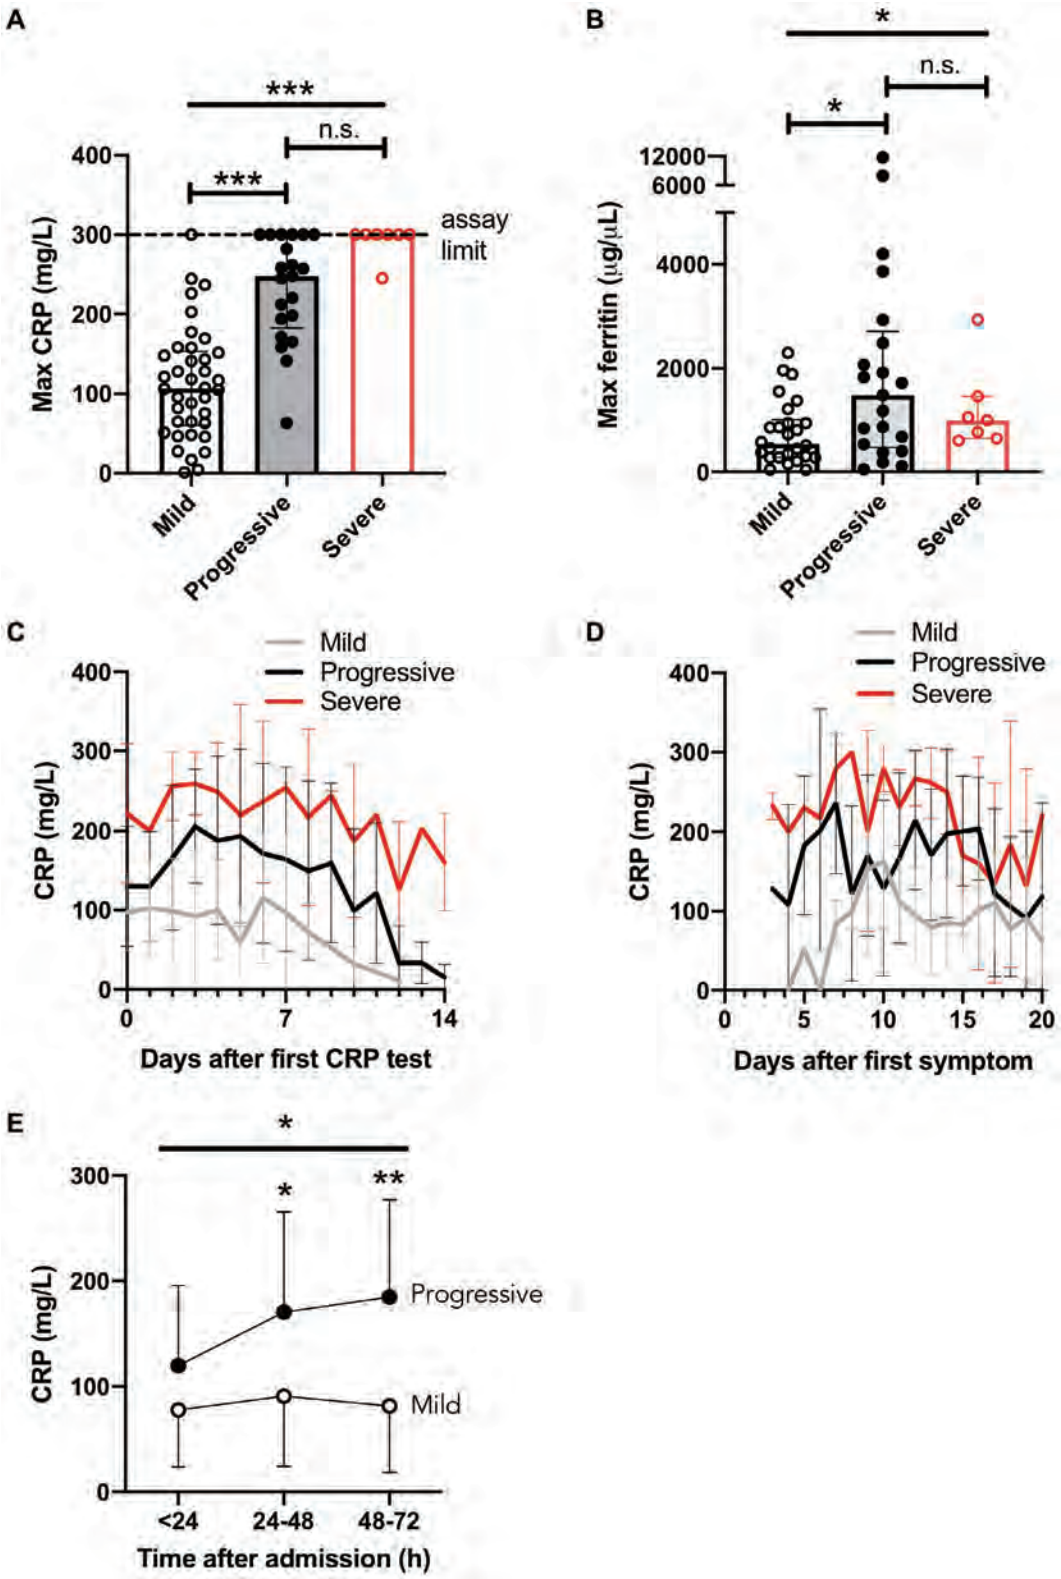
Conclusion: Closely tracking the CRP levels in the hyper-acute phase of admission for COVID-19 patients was predictive of progression to critical illness, suggesting that trends of inflammatory biomarkers, rather than absolute admission values, may have most utility for clinical triage and targeting therapeutic immunomodulation. Moreover, separating out patients with progressive disease identified a unique biomarker phenotype, indicating that clinical trials of anti-IL6 receptor monoclonal antibodies should pay parti



Admission CRP and D-dimer values associate with mild, progressive and severe respiratory failure. A-D: Initial levels of A) CRP; B) D-dimer; C) Ferritin; D) Procalcitonin are shown for patients with non-critical illness ("Floor"; n = 36) or with critical illness ("ICU"; n = 30). E-H: Patients grouped into "mild" (stable, non-critical respiratory failure; n = 38), "progressive" (initial non-critical respiratory failure that progressed to intubation during admission; n = 21), and "severe" (intubation on day of admission; n = 7) cohorts. Initial levels of E) CRP, F) D-dimer, G) Ferritin, and H) Procalcitonin are shown. Mann-Whitney U test performed for A-G. ANOVA and Tukey's multiple comparison performed for H. *P < 0.05, **P < 0.01, ***P < 0.001, ****P < 0.0001. Kruskal-Wallis test with Dunn's multiple comparison used for E-H. CRP, C-reactive protein; n.s., non-significant.

Admission CRP values associate with SOFA score and PaO2/FiO2 (P/F) ratio. COVID-19 inpatients are grouped into mild, progressive or severe cohorts defined by respiratory failure. A) SOFA scores on admission. B-C: Correlation of SOFA scores to initial B) CRP; C) D-dimer. D) SOFA respiratory scores on admission. E-F: Correlation of P/F ratios to initial E) CRP; F) D-dimer. Open black circles, mild; filled black circles, progressive; open red circles, severe. Kruskal-Wallis test and Dunn's multiple test were performed for A and D; Spearman rank correlation for B, C, and F; Pearson correlation for E. *P < 0.05, **P < 0.01. CRP, C-reactive protein; P/F, PaO2/FiO2; SOFA, Sequential Organ Failure Assessment.

Hyper-acute CRP trend distinguishes stable and progressive respiratory failure. COVID-19 inpatients are grouped into mild, progressive or severe cohorts defined by respiratory failure. A-B: Maximum values during hospital course are shown for A) CRP; B) ferritin. C-D: Mean CRP values are shown as a function of C) days after first recorded CRP level; D) days after onset of first symptom. E) CRP values for patients with mild or progressive disease taken 0-24, 24-48, and 48-72 hours after admission. A-B, median and interquartile range are plotted; C-E, mean and standard deviation are plotted. Open black circles, mild; filled black circles, progressive; open red circles, severe. Kruskal-Wal-



lis test and Dunn's multiple test were performed for A and B; a mixed effect model was used for E. *P < 0.05, **P < 0.01, ***P < 0.001. CRP, C-reactive protein; Max, maximum; n.s., non-significant.

Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: People with rheumatic diseases may be at high risk for poor outcomes related to COVID-19; on the other hand, immunomodulatory medications are used as therapy for severe COVID-19. Here, we report a case series of 26 patients with known rheumatic disease who were confirmed as having COVID-19 and compared medication use and other characteristics of hospitalized patients with those who were not hospitalized.

Methods: Established patients being followed at Temple Rheumatology Associates as well as patients admitted to Temple University Hospital in Philadelphia who tested positive for SARS-CoV2 were identified. We analyzed the demographic and clinical characteristics of patients with rheumatic disease and COVID-19 as well as associated outcomes.

Results: Of the patients in our case series, most common rheumatic conditions seen in both hospitalized and non-hospitalized groups were RA and SLE (35%, 23%) (Table 1). The majority of patients in both the hospitalized and non-hospitalized groups were in remission or low disease states (58%).

23% were receiving biologic medications and 20% were on no therapy. The most common therapy among both hospitalized and non-hospitalized patients was HCQ (40%, 50%), with 25% and 33% on HCQ monotherapy, respectively.

The most prevalent comorbidities were obesity (35%), hypertension (46%), COPD/asthma (27%), and diabetes (27%).

Conclusion: We report a case series of 26 patients with rheumatic disease and COVID-19 followed at an academic medical center in a geographic "hot spot." High numbers of patients who are Black or of Latinx ethnicity in this case series are in line with prior published reports. Our rate of hospitalization (77%) is also relatively high; however, this calculation as well as assessment of frequency of complications is likely confounded by low testing rates in our area for asymptomatic or minimally symptomatic patients, and our baseline number of COVID-19 patients may be much larger.

The most frequent complication in hospitalized patients was hyperinflammatory syndrome (65%), a complication of severe COVID-19 (Table 2); in our center, this was treated aggressively with further immunosuppression such as IL-1 and IL-6 inhibitors and systemic steroids. There was only one death among all included patients. The cause of this discrepancy between severity of illness and death is not clear and may be related to the local rate of infection as well as treatment practices at our center.

In terms of treatment, the most common therapy among our patients was HCQ (42%). Interestingly, no patients were on IL-1, IL-6, IL-17, IL-12/23, CTLA4-Ig, or tsDMARDs. However, absence of evidence is not evidence of absence, and this finding may reflect the social distancing measures being practiced by our patients.

Table 1. Baseline characteristics of patients with rheumatic disease and COVID-19

Characteristic	All patients (N=26)	Hospitalized patients (N=20)	Non-hospitalized (N=6)
Mean age – years (range)	56 (25-84)	59 (25-84)	45 (32-54)

Factors Associated with Knee Osteoarthritis in an Outpatient HIV-1 Clinic over a 26 Year Interval

Benjamin Naovarat[1], Francis Williams[1], Jonathan Dau[2], Marka Lyons[3], Binh Nguyen[4], Gloria Salazar[3] and John Reveille[5], [1]The University of Texas McGovern Medical School, Houston, TX, [2]Massachusetts General Hospital, Harvard Medical School, Boston, MA, [3]University of Texas Houston, McGovern Medical School, Division of Rheumatology and Clinical Immunogenetics, Houston, TX, [4]The University of Texas-McGovern Medical School, Houston, TX, [5]Department of Internal Medicine, University of Texas, Houston, TX

SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: Infection-related Rheumatic Disease Poster
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: With the advent of combined antiretroviral therapy (cART), patients with HIV-1 began living longer and started to develop diseases associated with aging such as osteoarthritis (OA). This study examined the epidemiologic, clinical, and immunological data in patients with concomitant HIV-1 and knee OA.

Methods: We examined with knee OA treated at a HIV-1 outpatient clinic seen between 1994 and 2020. At baseline visit, demographic parameters, lymphocyte subsets, HIV-1 viral load, knee OA date of diagnosis, pertinent lab findings, knee radiographs, and relevant clinical information were collected. All patients met the American College of Rheumatology Classification Criteria for knee OA. Antiretroviral medications were categorized into protease inhibitors, nucleoside reverse transcriptase inhibitors (NRTIs), non-nucleoside reverse transcriptase inhibitors (NNRTIs), and integrase inhibitors. Univariate and multivariate analyses were conducted that looked at age, BMI, ethnicity, gender, CD4 count, HIV viral load, antiretroviral medication use, and time of knee OA diagnosis on the risks of developing knee OA.

Results: Comparing the pre-HAART (1994-1997) to the era after the introduction of HAART (1998-2020), the frequency of DILS and reactive arthritis fell whereas the osteoarthritis, particularly of the knee, and carpal tunnel syndrome

+ univariate analysis *compared to whites ** compared to no therapy

Table 2. Demographic and Clinical Parameters in HIV Rheumatology Patients with and without Knee OA

rose dramatically (Table 1). A total of 217 patients with HIV-1 infection and knee OA were identified out of the 1671 patients referred to the HIV Rheumatology Clinic. Patients with knee OA were more likely to be female and to be black or Latino than white (Table 2). The knee OA patients were older (average age of 51.1 [±9.1] years compared to 46.7 [±9.8] years in the non-knee OA group). In addition, knee OA patients had a greater body mass index (BMI-average of

32.8 [±7.9] compared to 28.5 [±6.6] in the non-knee OA group). Patients with knee OA were more likely to have CD4 >200 cells/μL at baseline than those with other diagnoses. Medication use with NRTI and integrase inhibitors respectively, were significantly associated with knee OA. However, on multivariable analysis, independent associations of CD4 count, HIV viral load, NRTI and integrase inhibitor usage were not observed. When stratifying antiretroviral usage into the categories of no therapy, mono-drug therapy, and multi-drug therapy, those on multidrug-therapy had higher odds of having knee OA that those on no therapy. However, in the multivariable analysis, this association was not independently observed. Moreover, between the period of 1994 and 2020, we noted an increase in the frequency of knee OA over time on both the univariable ($p< 0.001$) and multivariable analyses ($p< 0.001$).

Conclusion: To date, this is the largest cohort of concomitant HIV-1 and knee OA patients followed longitudinally to date. Our cohort confirmed the risk factors of BMI, age, ethnicity, and female gender as well as demonstrating that there is a relationship with CD4 >200 cells/μL and an increase in the frequency of knee OA diagnoses over the period 1994-2006, probably reflecting the longer survival of patients with HIV with effective treatment and factors associated with HIV treatment itself.

SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: Infection-related Rheumatic Disease Poster
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Patients with immune-mediated inflammatory diseases (IMID) have a higher risk of infections related to their disease, comorbidities or immunosuppressive treatments, but recent studies addressing severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2) infection (COVID-19) didn´t support more frequent or severe disease in these patients. Our objective is to describe our cohort of patients with IMID who had a probable or confirmed SARS-CoV-2 infection.

Methods: Patients with IMID currently followed in the Rheumatology Department of Ramón y Cajal University Hospital with probable or confirmed SARS-CoV-2 infection diagnosed between 01-02-2020 and 22-05-2020 were selected. Confirmed infection was defined if the patient had a positive nasopharyngeal swab for SARS-CoV-2 or characteristic bilateral infiltrates on chest radiograph/computerized tomography (CT); probable infection was defined by 2 or more symptoms related to COVID-19 (fever, dry cough, dyspnoea, myalgia, anosmia or ageusia) if other causes were excluded. We analysed the demographic and clinical data on patients who had IMID with symptomatic COVID-19.

female. Thirty-one patients were treated as outpatients, 49 were admitted in our hospital, out of them 11 died. Their characteristics are described and compared in table 1.

All patients that were hospitalised (n=49) suspended their conventional and biologic DMARDs at the time of admission. Their outcome and treatment prescribed during hospitalization is represented in table 2.

Conclusion:

- We found that patients with IMID share risk factors for hospitalization/death described for the general population.
- Patients with systemic vasculitis, polymyalgia rheumatica (PMR) and IMID-associated interstitial lung disease had a worse prognosis (more frequent hospitalization and/or higher mortality). Patients treated with moderate/high GC doses for their IMID had a worse outcome, while patients treated with anti-TNF or tocilizumab had a better prognosis.
- Among the patients that were hospitalised, those who developed ARDS or heart failure and those who required non-invasive mechanical ventilation (NIMV) had higher mortality.
- Nevertheless, these results must be interpreted with caution, given the relatively low number of patients, interaction between variables associated with mortality couldn´t be analysed.

SESSION INFORMATION

Session Date: Saturday, November 7, 2020

Session Title: Infection-related Rheumatic Disease Poster

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: Vertebral osteomyelitis (VO) can be associated with neurological complications. We showed in a previous study that they occurred in 40% of patients with VO. Spine immobilization is recommended to prevent those complications but with poor evidence from the literature.

The aim of our study was to describe the practice of spine immobilization in a large multicentered cohort of patients with VO, and to evaluate the association between immobilization and neurological complications.

Methods: We prospectively recruited patients with VO from 2016 and 2019 in 11 centers. We included adults patients with VO confirmed by imaging and identification of causative agent or a good response to antibiotic therapy if all samples were sterile. We collected clinical, microbiologic, imaging and therapeutic characteristics at admission and during follow up, at 3 and 6 months. Characteristics of the type and duration of immobilization were especially recorded.

Results: 250 patients were included. Mean age was 66.7 +/- 15 years old, mostly men (67.2%, n=168). Median duration of pain before diagnosis was 25 (0-427) days. Lumbo-sacral level was the most frequently involved (54.4%), cervical level was involved in 12.8% of cases. Staphylococcus aureus was the most frequent pathogen (33.6%).

At diagnosis, 25.6% patients (n=64) had minor neurological symptoms (radicular pain, reflex abolition, sensitive loss) and 9.2% (n=23) major neurological complications (motor weakness or sphincter dysfunction). During follow up, new minor neurological complications occurred in 9.2% (n=23) of patients, and major ones in 6.8% of patients (n=17) medianly 11 (1 to 45) days.

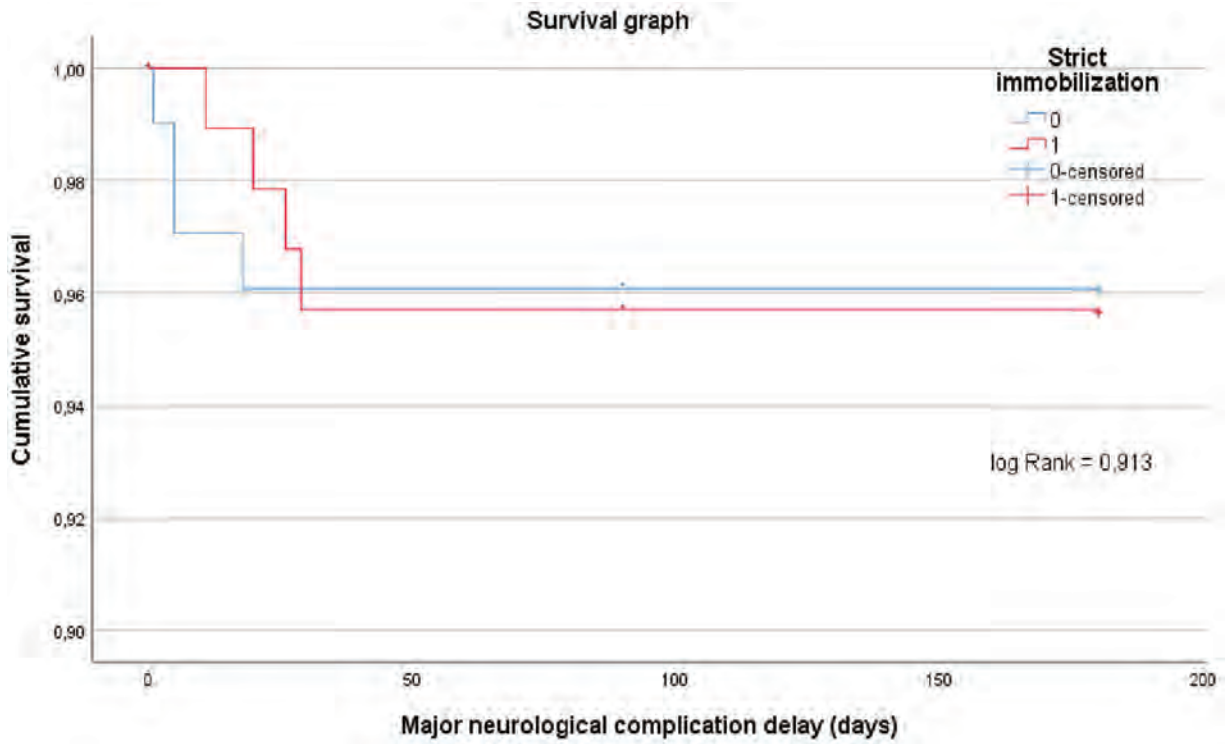
Table 1 : Population characteristics	Total 250 (100%)	Strict Immobilization 110 (44%)	No strict immobilization 119 (47.9%)	p
Male	67.2% (168/250)	71.8% (79/110)	61.3% (73/119)	0.094
Age : mean (standard deviation)	66.7 (15.0)	63.45 (15.2)	69.37 (13.9)	**0.002**
Diagnosis delay : median (min-max)	25 (0-427)	24 (0-207)	26.5 (0-427)	0.861
Anterior back surgery	5.6% (14/250)	7.3% (8/110)	4.2% (5/119)	0.316
Frailty (0 "very fit" to 5 "severely frail") : mean (standard deviation)	1.3 (1.031)	0.9 (0.901)	1.41 (1.039)	**0.005**
Level involved:				
Cervical	12.8% (32/241)	18.7% (20/107)	7.7% (9/117)	**0.014**
Cervico-thoracic	1.6% (4/241)	0.9% (1/107)	1.7% (2/117)	0.61
Thoracic	22.4% (56/241)	25.2% (27/107)	23.9% (28/117)	0.82
Thoraco-lumbar	5.2% (13/241)	3.7% (4/107)	6.8% (8/117)	0.30
Lumbar	54.4% (136/241)	51.4% (55/107)	59.8% (70/117)	0.20
Endocarditis	22.4% (56/249)	17.3% (19/110)	28.8% (34/118)	**0.039**
MRI	87.2% (218)			
Multifocal	24.4% (61/239)	25% (27/108)	23.7% (27/114)	0.819
Vertebral destruction > 50%	9.2% (23/234)	10.3% (11/107)	9.1% (10/110)	0.767
Destruction of posterior arc	7.6% (19/226)	10.8% (11/102)	5.6% (6/107)	0.171
Sagittal angulation	18.8% (47/224)	25.5% (26/102)	17.1% (18/105)	0.142
Epidural inflammation	54% (135/221)	70.6% (72/102)	51.5% (53/103)	**0.005**
Epidural abscess	17.6% (44/224)	24.5% (25/102)	15.1% (16/106)	0.088
Spinal cord hypersignal	7.6% (19/218)	14.1% (14/99)	2.9% (3/103)	**0.004**
Subarachnoid space effacement	17.6% (44/221)	28.7% (29/101)	12.5% (13/104)	**0.004**
Dural sac compression	20% (50/222)	32.7% (33/101)	13.3% (14/105)	**0.001**
Duration of antibiotherapy : median (min-max)	45 (5-417)	46 (5-417)	45 (9-377)	0.153
Surgery	11.2% (28/250)	17.3% (19/110)	5.1% (6/118)	**0.03**
Initial pain evaluation: mean (standard deviation)	53.6 (28,65)	54.7 (27,17)	51.8 (30,42)	0.595
Minor neurological symptom	25.6% (64/250)	28.2% (31/110)	22.7% (27/119)	0.34
Major neurological symptom	9.2% (23/250)	14.5% (16/110)	5% (6/119)	**0.015**

Median duration of antibiotherapy was 45 (5-417) days, 11.2% of patients (n=28) underwent surgery.

Immobilization was prescribed in 69.2% (n=173) of cases, 94.2% (n=162) were rigid bracing. However a strict immobilization (defined by a rigid brace for at least 6 weeks) was prescribed for only 44% of the patients (n=110). In multivariate analysis, factors significantly associated with strict immobilization were: Centre (p=0.035), younger age (p=0.005), dural sac compression (p=0.005) and major neurological signs at diagnosis (p=0.036). Vertebral destruction or epidural abscesses were not associated with strict immobilization. Lumbar localization was not less strictly immobilized.

There was no significant difference in the apparition of new minor neurological complications between strictly immobilized patients and others (10.9% (n=12) and 5.9% (n=7) respectively; log Rank = 0.315). Same results were found for new major complications (4.5% (n=5) and 6.7% (n=8) respectively; log Rank = 0.913).

Duration of immobilization prescription was not associated with apparition of severe complications.



In patients without prescription of any rigid bracing, subarachnoid space effacement was significantly associated with apparition of major neurological complications in multivariate analysis (p=0.016).

Conclusion: Only 44% of the patients were strictly immobilized in our cohort. We did not observe significant differences in terms of neurological complications between strictly immobilized patients and others.

Clinical Manifestations and Outcomes in DMARD-Naïve Patients with Chronic Chikungunya Arthritis

Nicolle Medina-Cintrón[1], Idali Martínez[1], Naydi Pérez-Ríos[2], Yaritza Berríos-López[2] and Luis Vilá[3], [1]University of Puerto Rico Medical Science Campus, San Juan, Puerto Rico, [2]University of Puerto Rico Medical Sciences Campus, San Juan, Puerto Rico, [3]University of Puerto Rico Medical Sciences Campus, San Juan

SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: Infection-related Rheumatic Disease Poster
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Chikungunya virus (CHIKV) is characterized by fever, maculopapular rash, and severe polyarthralgia and polyarthritis. Up to 80% of affected individuals may develop chronic CHIKV arthralgias and arthritis. Most studies on chronic CHIKV arthritis include patients treated with disease-modifying anti-rheumatic drugs (DMARDs),

Table 1. Demographic features, lifestyle behaviors, comorbidities, and clinical manifestations in patients with and without chronic CHIKV arthritis.

Features	Chronic CHIKV Arthritis (n=33)	Resolved CHIKV arthritis (n=28)	p value
Gender, %women	69.7	64.3	0.786
Age, mean years (SD)	52.5 (10.5)	48.3 (13.7)	0.205
Time period, mean months (SD)	25.3 (10.8)	21.1 (7.0)	0.651
Educational level, mean years (SD)	16.3 (3.9)	17.0 (3.9)	0.631
Lifestyle behaviors, %			
Smoking	12.1	14.3	>0.999
Exercise	21.2	57.1	0.004
Comorbidities, %			
Overweight/obese (BMI ≥ 25)	87.9	78.6	0.490
Arterial hypertension	24.2	28.6	0.775
Diabetes mellitus (type 1 or type 2)	18.2	0.0	0.027
Dyslipidemia	18.2	25.0	0.517
Chronic back pain	24.2	0.0	0.006
Osteoarthritis	15.2	14.3	>0.999
Clinical manifestations on acute infection, %			
Arthralgia	100	96.4	0.459

most likely altering the expression of clinical manifestations during the chronic phase. Therefore, we sought to evaluate the clinical features and correlates in patients with chronic CHIKV arthritis who did not receive therapy with DMARDs.

Methods: We conducted a cross-sectional study in adult (≥21 years) patients with serologically-confirmed CHIKV infection in Puerto Rico. All patients had inflammatory polyarthritis in the acute phase of infection. None received treatment with corticosteroids one year before study visit and, none receive DMARDs at any time. Demographic features, lifestyle behaviors, clinical manifestations, comorbidities, disease activity (per Clinical Disease Activity Index [CDAI]), functional status (per Health Assessment Questionnaire [HAQ]), and pharmacologic treatment were ascertained. Patients with and without chronic CHIKV arthritis were compared. Furthermore, a sub-analysis was performed among patients with chronic CHIKV who presented with low disease activity (CDAI < 10) versus moderate-high disease activity (CDAI ≥ 10) at study visit. Statistical analyses were performed using Fisher's exact test, Pearson Chi-squared test, and Wilcoxon rank-sum test, as appropriate.

Table 2. Demographic features, lifestyle behaviors, comorbidities, and clinical manifestations on acute infection and at study visit in patients with chronic CHIKV presenting with mild and moderate/high activity.

Features	All chronic CHIKV arthritis (n=33)	Low disease activity (n=14)	Moderate-High disease activity (n=19)	p value

Morning stiffness	90.9	78.6	100	0.067
HAQ mean score (SD)	0.95 (0.56)	0.63 (0.50)	1.19 (0.47)	0.006
HAQ categories, mean score (SD)				
Dressing & grooming	0.8 (0.7)	0.4 (0.5)	1.2 (0.6)	<0.001
Arising	1.2 (0.7)	0.8 (0.7)	1.4 (0.5)	0.009
Eating	0.6 (0.7)	0.4 (0.6)	0.8 (0.8)	0.070
Walking	1.1 (0.7)	0.9 (0.7)	1.3 (0.7)	0.083
Hygiene	0.7 (0.6)	0.5 (0.7)	0.9 (0.5)	0.034
Reaching	1.2 (0.9)	0.9 (0.9)	1.5 (0.8)	0.025
Grip	0.8 (0.8)	0.6 (0.6)	1.0 (0.8)	0.121
Activities	1.1 (0.8)	0.7 (0.8)	1.4 (0.7)	0.006

Results: In total, 61 patients were studied; 41 (67.2%) were women and the mean (standard deviation [SD]) period between onset of CHIKV infection and study visit was 23.4 (9.4) months. Thirty-three patients had chronic arthritis and 28 had resolved arthritis. Patients with chronic arthritis were more likely to have diabetes mellitus, chronic back pain, other symptoms on the acute phase (fever, tiredness, and myalgia), and to receive treatment with NSAIDs on the acute phase (Table 1). Among patients with chronic CHIKV arthritis, joint tenderness was most common in MCP joints (54.6%), shoulders (51.5%), PIP joints (45.5%), and knees (39.4%) at study visit. Swelling was observed in PIP joints (15.2%), MCP joints (12.1%), shoulders (9.1%), wrists (6.1%), ankles (6.1%), and MTP joints (3.0%). The mean (SD) HAQ score was 0.95 (0.56) and 57.6% had moderate-high disease activity per CDAI. Patients with moderate-high disease activity were more likely to have higher scores in overall HAQ and HAQ categories (dressing & grooming, arising, hygiene, reaching, and activities) when compared to those with mild activity (Table2).

Conclusion: In this group of DMARD-naïve patients with chronic CHIKV arthritis, nearly 58% had moderate to severe disease activity. Those patients had major functional disability, including significant dysfunction in several HAQ categories. Diabetes mellitus, chronic low back pain, and some manifestations on acute infection (fever, tiredness, and myalgias) were associated with chronic CHIKV arthritis.

Abstract Number: 0632

Systems Approach to Understanding Reasons for Influenza Vaccine Hesitancy in Rheumatic Diseases

Valeria Valerio[1], Mariana Useche[1], Erin Field[2], Mianbo Wang[3], Elizabeth M. Hazel[4], Brian Ward[5] and **Ines Colmegna**[1], [1]The Research Institute of the McGill University Health Centre, Montreal, Canada, [2]The Research Institute of the MUHC, Montreal, Canada, [3]Lady Davis institute for Medical Research, Montreal, QC, Canada, [4]McGill University Health Centre, Montreal, Canada, [5]The Research Institute of the McGill University Health Centre, Monreal, QC, Canada

SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: Infection-related Rheumatic Disease Poster
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: A vaccination coverage goal of 80% with the seasonal influenza vaccine was established to protect people at high-risk for influenza-related complications or hospitalizations (e.g. rheumatic diseases - RD). Inactivated influenza vaccine (IIV) coverage in RD patients remains below target. Vaccine hesitancy (i.e. delay in acceptance or refusal of vaccination despite availability of vaccination services) is a complex issue that threatens vaccine uptake. Understanding the reasons for influenza vaccine hesitancy among RD patients is fundamental to enhance vaccination coverage.

Methods: Between November and March 2020, we conducted a cross-sectional study of consecutive RD patients presenting to a rheumatology clinic at a Canadian university hospital. Patients indicated in a 10-point scale how likely they were to get the IIV. Three groups were defined: (a) refuse IIV (values 0-1-2), (b) accept IIV (values 8-9-10), and (c) uncertain (values 3-7). Demographic data, education, employment, RD diagnosis, treatment, and smoking status were compared between groups. Patients completed the WHO-Strategic Advisory Group of Experts (SAGE) questions on vaccine hesitancy (i.e. vaccine hesitancy determinants matrix). Multivariate logistical regression analyses were performed to evaluate predictors of vaccine hesitancy.

Table 1 (*Accept IIV as reference group*)	Refuse vs Accept		Uncertain vs Accept	
	OR (95% CI)	P values	OR (95% CI)	P values
Sex

Yes	Ref		Ref	

Results: 294 patients (101 rheumatoid arthritis-RA, 107 SLE/vasculitis-SARD, 55 spondyloarthropathies-SpA, 31 osteoarthritis-OA) were included in the analysis. Over a third them did not receive IIV in the previous year (RA 38.4%, SARD 39.1%, SpA 48.2%, OA 38.7%). According to how likely they were to get the IIV, three groups were defined: refused (n=67), accepted (n=165) and uncertain (n=40). Demographics, education, and smoking status did not differ between the three groups. Retired patients were more frequent among those who refused IIV (35% vs 12% in the uncertain group). The use of biologics was higher in the group that 'accepted IIV' (27% vs 13.4% in those who refused IIV). Reported reasons for hesitancy according to the WHO-SAGE matrix was similar across diseases. Table 1 summarizes the predictors of vaccine hesitancy.

Conclusion: Forty percent of RD patients, irrespective of their education, either refuse or express uncertainty about getting IIV. Concerns about adverse events and doubts that pharmaceutical companies are providers of safe and effective vaccines are key determinants of IIV hesitancy.

Vitamin D Serum Status in a Cohort of COVID-19 Patients

Alberto Sulli[1], Emanuele Gotelli[1], Sabrina Paolino[1], Andrea Casabella[1], Carmen Pizzorni[1], Elisa Alessandri[1], Vanessa Smith[2] and Maurizio Cutolo[1], [1]Research Laboratory and Academic Division of Clinical Rheumatology, Department of Internal Medicine, University of Genova, IRCCS San Martino Polyclinic, Genoa, Italy, [2]Department of Rheumatology, Ghent University Hospital, Department of Internal Medicine, VIB Inflammation Research Centre Ghent University, Ghent, Belgium

SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: Infection-related Rheumatic Disease Poster
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Vitamin D serum levels have been inversely associated with risk of pulmonary infections and autoimmune inflammatory disease activity and severity [1,2]. A possible role of vitamin D in patients with SARS-Cov-2 infection was also recently reported [3].

The aim of the study was to evaluate 25OH-vitamin D serum levels in a cohort of patients hospitalized for SARS-Cov-2 infection, looking in particular for correlations with parameters of lung involvement.

Methods: Sixty consecutive COVID-19 patients (mean age 76±8 years, mean disease duration 13±13 days, 26 males and 34 females) and sixty sex- and age-matched healthy subjects (CNT) were evaluated. Pulmonary involvement (radiological findings), respiratory parameters (PaO_2/F_IO_2, pO_2, sO_2), clinical parameters, duration of hospitalization and global disease duration were recorded.

Results: Vitamin D serum levels were found significantly lower in COVID-19 patients than in CNT (median 7.8 vs 16.0 ng/ml, p=0.0003). Among COVID-19, vitamin D sufficiency (>30 ng/ml), insufficiency (between 20 and 30 ng/ml) deficiency (between 10 and 20 ng/ml) and severe deficiency (< 10 ng/ml) were observed respectively in 11, 12, 20 and 57 % of patients. In CNT, the same vitamin D distribution occurred in 21, 22, 34 and 23 % of subjects respectively.

A statistically significant positive correlation was observed between vitamin D serum levels and PaO_2/F_IO_2 (p=0.02), pO_2 (p=0.04), sO_2 (p=0.05), while a statistically significant negative correlation was found between vitamin D serum levels and percentage of O_2 in Venturi Mask (p=0.04). Vitamin D serum levels negatively correlated also with C-reactive protein (p=0.04), D-dimer (p=0.04), and parathyroid hormone (p=0.05).

A negative correlation was also found between vitamin D levels and severity of radiographic pulmonary involvement, but this did not reach the statistical significance (median vitamin D levels in patients with Mild, Moderate and Severe lung involvement were respectively 10.9, 7.7 and 5.5 ng/dl; p=0.11). However, vitamin D serum levels were found significantly lower in COVID-19 patients with either multiple lung consolidations or severe interstitial lung involvement than in those with either normal or mild interstitial lung involvement (p=0.02).

Finally, lower vitamin D serum levels were found associated with longer global disease duration (p=0.05).

Conclusion: Deficiency of 25OH-vitamin D serum levels seem associated with more severe lung involvement and longer disease duration in COVID-19 patients.

Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Many pediatric rheumatology patients are at increased risk of influenza due to immunosuppressive medication use. Annual influenza vaccination is recommended for all children by the Centers for Disease Control and Prevention. Our division has tracked influenza vaccination rates since 2015 and have done quality improvement efforts to increase our vaccination rate. The vaccination rate plateaued at 71%, which prompted a survey to assess patient-reported vaccination rate, knowledge of influenza, and barriers to influenza vaccination.

	Parent (n=21)	Patient (n=14)	Total (n=35)
1. I think the flu shot can cause the flu	19%	35.7%	25.7%
2. The flu shot makes you sick	19%	14.3%	17.1%
3. The injection is painful	4.8%	7.1%	5.7%
4. I worry the vaccine will flare/worsen my child's/my rheumatic disease	42.9%	7.1%	28.6%
5. I do not think the vaccine will work	23.8%	14.3%	20%
6. My child does/I do not get the flu, so it is not worth getting the vaccine	9.5%	7.1%	8.6%
7. The flu is not that serious	4.8%	0%	2.9%
8. I would have given my child/gotten the vaccine but forgot to get it	9.5%	28.6%	17.1%
9. I would have given/gotten the flu vaccine, but the doctor's office did not have it available	0%	0%	0%
10. I do not give any vaccinations to my child	14.3%	N/A	N/A
11. My parent does not believe in any vaccinations	N/A	0%	N/A
12. I choose not to receive any vaccinations	N/A	0%	N/A
13. I would have gotten the flu shot but my parent refused	N/A	0%	N/A

*Respondents were able to select more than one answer

Table 1. Reasons why influenza vaccine not received*

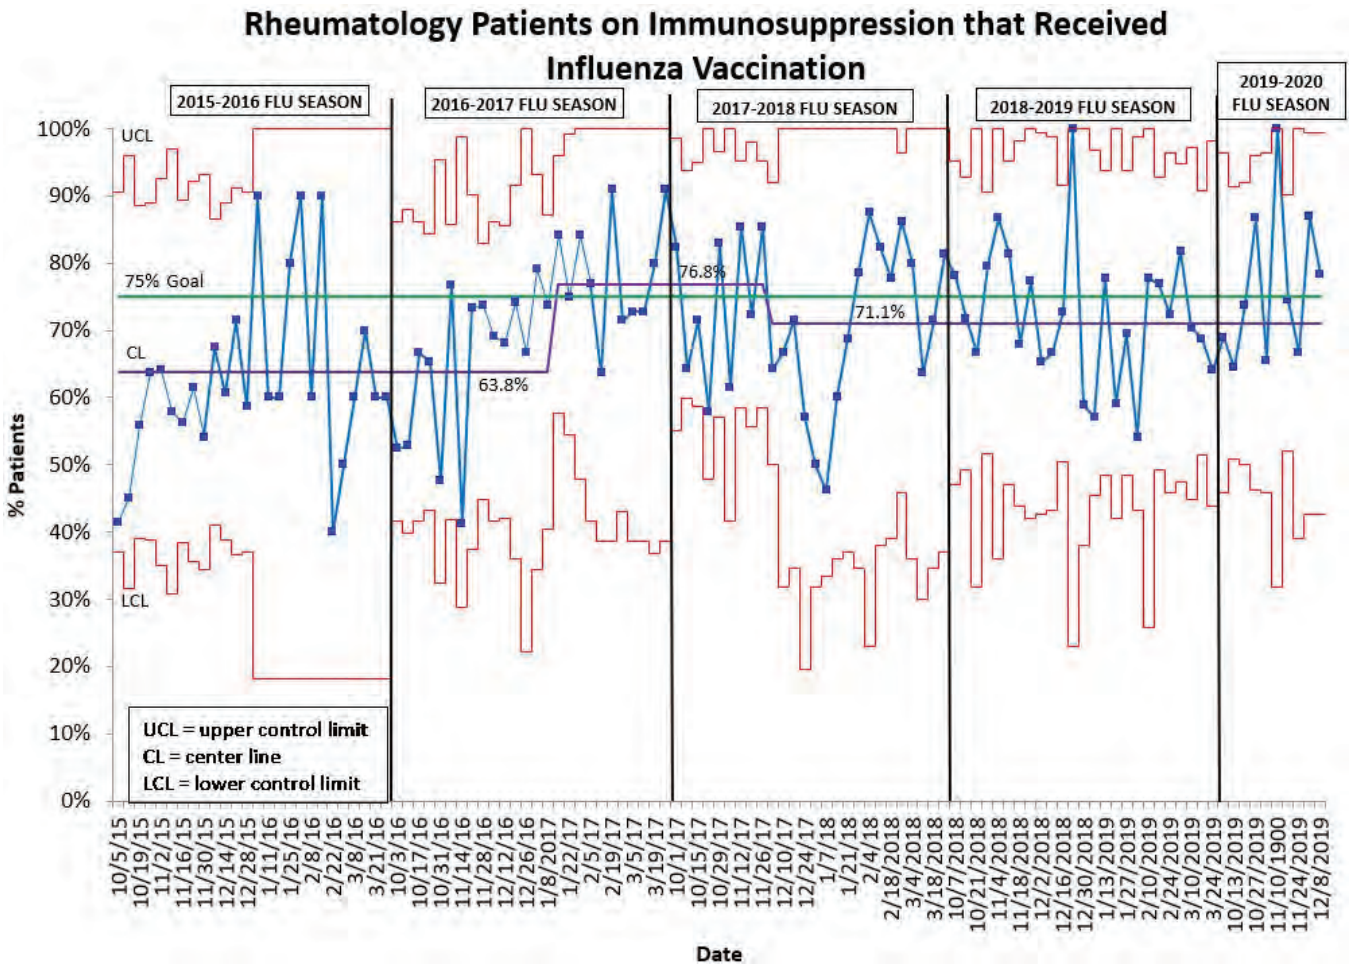

Figure 1. Control chart demonstrating influenza vaccination rates in immunosuppressed rheumatology patients

Methods: In the Rheumatology Clinic, a parent or patient (15 years and older) on immunosuppressive medication was eligible to complete a REDCap survey. Survey questions assessed demographics, rheumatology diagnosis, immunosuppressive medication type, medical providers recommendation of the influenza vaccination, influenza knowledge, and barriers to influenza vaccination. Self-reported vaccination rate referred to the 2018-2019 influenza season; if no vaccine received, a follow-up question asked for reasons why. The survey began in July 2019, and this project is ongoing. Influenza vaccination rates of immunosuppressed patients are acquired each flu season via chart review and tracked on a control chart that our division has maintained since 2016.

Results: Of 212 surveys, 139 (65.6%) were completed by parents and 73 (34.4%) by patients. The patients had an average age of 11.4 years for those under 17 years of age, and 13.2% of respondents were 18 years or older. The majority (61.3%) were diagnosed with juvenile idiopathic arthritis, while 8.5% had juvenile dermatomyositis and 8% had systemic lupus erythematosus. Methotrexate was the most common (52.4%) immunosuppressive medication followed by a tumor necrosis factor inhibitor (41%). The majority (84.9%) of parents reported their child received an influenza vaccine while patient report was 80.8%. The most common reasons for not receiving the influenza vaccine included: worry about disease flare (28.6%), concern the vaccine will cause influenza (25.7%), and presumed lack of vaccine effectiveness (20%) (**Table 1**). When asked for the two most common symptoms of influenza, 82.5% correctly answered fever and 73.5% correctly answered cough and/or congestion; however, 23.1% answered gastrointestinal symptoms and 9.6% joint swelling. Almost all the respondents (95.3%) were aware that influenza could cause death and that the prescribed medication increased risk of infection. The average weekly influenza vaccination rate

from October to December 2019 was 76.6%, which was higher than the 72.1% vaccination rate from the 2018-2019 season (**Figure 1**).

Conclusion: The influenza survey of immunosuppressed patients indicates that patients and parents understand the potential severity of influenza and the increased risk of infection due to medication use, however, many respondents inaccurately identified the most common symptoms of influenza. Additionally, self-reported vaccination rate was higher than expected. The barriers identified in this survey will help drive further improvement efforts to increase influenza vaccination rates in this high-risk population.

Abstract Number: 0635

Hydroxychloroquine Is Not Associated with Reduced Influenza Admissions in Rheumatoid Arthritis Patients

Bonnia Liu[1], Victor Yang[2], Christopher McMaster[3], Russell Buchanan[4], Albert Frauman[5] and David Liew[6], [1]Austin Health, Heidelberg, Victoria, Australia, Macleod, Victoria, Australia, [2]Austin Health, Heidelberg, Victoria, Australia, Glen Waverley, Victoria, Australia, [3]Austin Health, Melbourne, Victoria, Australia, Pascoe Vale South, Victoria, Australia, [4]Austin Health, Melbourne, Victoria, Australia, Heidelberg, Melbourne, Victoria, Australia, [5]Austin Health, Melbourne, Victoria, Australia, Melbourne, Victoria, Australia, [6]Austin Health, Melbourne, Victoria, Australia, Heidelberg, Victoria, Australia

SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: Infection-related Rheumatic Disease Poster
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Hydroxychloroquine (HCQ) is commonly used as a disease-modifying anti-rheumatic drug (DMARD) for patients with rheumatoid arthritis (RA). HCQ has previously been the subject of interest for its in-vitro antiviral activity against influenza A strains, although in-vivo studies have yielded conflicting results. There has recently been renewed interest in the use of HCQ as prophylaxis and treatment for respiratory viral infections. Patients with RA are known to have increased risk of influenza infections and influenza-associated hospitalizations. They thus potentially provide the opportunity to explore the antiviral effects of HCQ. Our study aims to examine the association of HCQ use among RA patients with hospital inpatient admissions for influenza.

Methods: We examined general medical inpatient admissions for patients with a diagnosis of RA in a large tertiary hospital between January 2014 and December 2018. Natural language processing, ICD-10 codes, and medical record review were utilized to determine patient demographic data (age, gender, and smoking history), medical diagnosis, and medication use. Major confounders (smoking status, chronic obstructive pulmonary disease (COPD), age, gender, and other DMARD use) were selected. DMARD use was defined as medical record documentation of use at time of admission. Multivariate logistic regression models were used to assess the association of HCQ use and inpatient admission for influenza. The strength of association was assessed using adjusted odds ratios (OR) and associated 95% confidence intervals (CI).

Results: From 909 inpatient admissions during the study period, 23 admissions were primarily for influenza. There were no statistical differences in patient demographics or DMARD medication between the two groups (Table 1). A

Variable	No Influenza Diagnosis	Influenza Diagnosis	p-value
Admissions	886	23	
Age (years)	77.0	77.2	0.9037
Length of stay (hours)	382	218	0.0723
Smoking	47 (9%)	3 (13%)	0.8122
COPD	97 (19%)	4 (17%)	1.000
Proportion of admissions on DMARDs			
Hydroxychloroquine	265 (30%)	9 (39%)	0.4707
Methotrexate	301 (34%)	8 (35%)	1.000
Corticosteroid	483 (55%)	14 (61%)	0.6948

Table 1. Characteristics of rheumatoid arthritis patients admitted for influenza compared to those admitted for other indications.

total of 265 (30%) non-influenza admissions and 9 (39%) influenza admissions used HCQ at time of admission. In our multivariate regression model, HCQ use among patients with RA was not associated with a statistically significant difference in inpatient admission for influenza when adjusted for confounders (OR 1.45, CI 0.58 – 3.59). Likewise, the lack of association was persistent when adjusted for methotrexate (OR 1.42, CI 0.58 – 3.50) and corticosteroid use (OR 1.40, CI 0.56 – 3.54).

Conclusion: There was no association in our cohort to support the contention that HCQ use prevents inpatient admission for influenza among RA patients, and in fact may even favour the possibility of increased risk. This study contributes to the growing evidence that HCQ does not confer a protective effect for respiratory viral infections.

Abstract Number: 0636

Rheumatology Patient Experience and Trends During the SARS-COV-2 Pandemic

Cuoghi Edens[1], Kichul Ko[1] and Kimberly Trotter[1], [1]University of Chicago, Chicago, IL

SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: Infection-related Rheumatic Disease Poster
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Rheumatic disease patients are counseled on the immunosuppressive aspect of their rheumatic disease treatment and their increased risk of infection. Little is known about the experience of rheumatic disease patients during a pandemic, their medication trends, or resource utilization.

Methods: Rheumatologist-created 32 question electronic questionnaire was shared through social media platforms including Facebook, Reddit, and Twitter on disease-specific pages from April-June 2020 with goal of being by patients with any rheumatic disease.

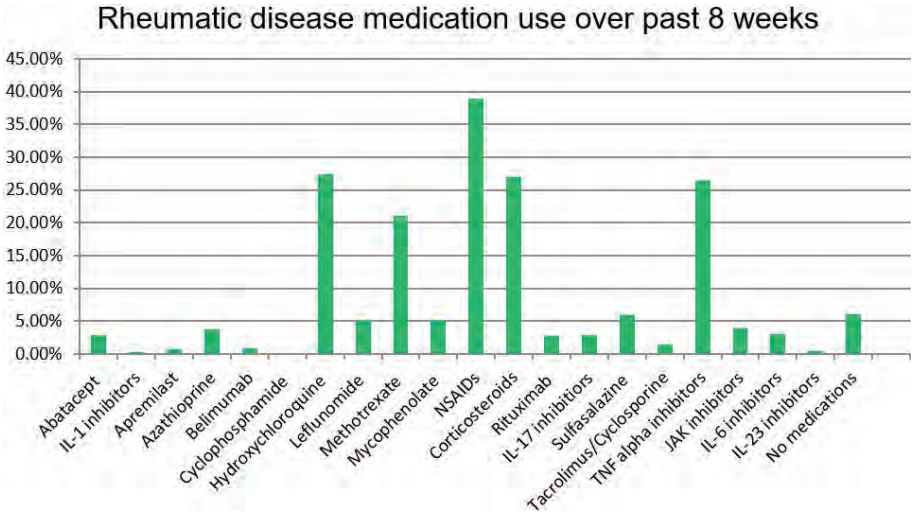

Figure 1.

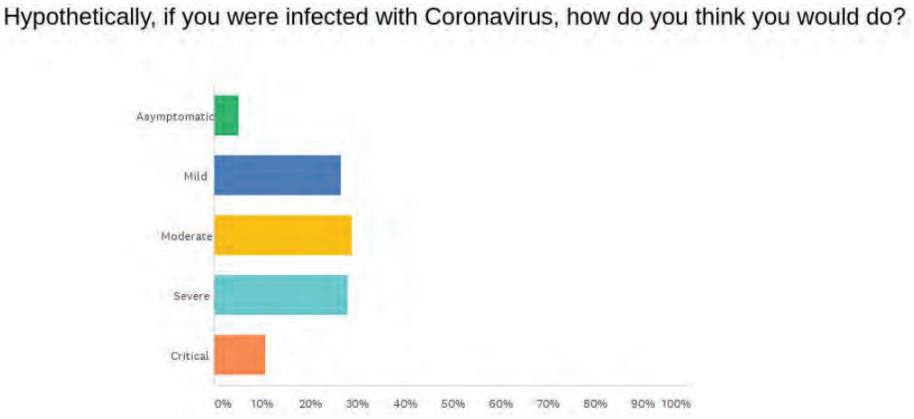

Figure 2.

Results: 2244 questionnaires were completed, the majority by Caucasian women (88%) ages 35-64 from across the United States (85%) who had obtained higher education. Multiple self-declared diagnoses could be chosen, the majority had any form of inflammatory arthritis (59%) with systemic lupus, mixed connective tissue disease, and Sjogren's syndrome noted by 23%. All categories of rheumatic diseases were represented. Most commonly used medications were: Corticosteroids, TNF inhibitors, NSAIDs, and Methotrexate, 5% were on no medications (Figure 1). One quarter of subjects had a pulmonary, renal, and/or cardiac condition. Eighty percent of those surveyed considered themselves immunocompromised, with 4% of these on no immunosuppressive medications. When typically ill almost half of patients reported they continue all of their medications.

Across all diseases, almost 50% had contacted their rheumatologist or another medical provider with questions regarding the novel coronavirus in the past 8 weeks prior to the survey completion, with those on no medications more likely to reach out. In this time period, 20% held at least one of their medications. Of those, 15% held their rheumatic medication as directed by their rheumatologist due to the SARS-Cov-2 pandemic (not infected) and 30% held medication without medical consultation. Specifically 10% stopped taking NSAIDs due to concern of SARS-CoV-2. Patients felt they would do poorly if infected with SARS-CoV-2 (Figure 2) this correlated with underlying pulmonary, renal, or cardiac conditions but also correlated with the patient reported taking no medications. Medications popularized at time of survey with potential to treat SARS-CoV-2 were not correlated with presumption of less severe outcomes.

Very few had been diagnosed with SARS-CoV-2 (0.7% tested, 3% presumed), nor had their household contacts. Only about 40% were working from home, 12% of those surveyed were unemployed or furloughed. Traditional news sources was the most often consulted resource as knowledge in regard to how coronavirus affects those with rheumatic diseases, followed by disease-specific foundations and the CDC.

Conclusion: In the initial months of the SARS- CoV-2 pandemic, patients were either told to stop or self-stopped their rheumatic disease medications. Patients overall felt they would do worse than those without a rheumatic disease, however did not correlate to specific medication or disease but with organ involvement. Disease specific foundations were seen as a resource for reliable information pertaining to their disease.

Clinical and Treatment Features of Rheumatoid Arthritis in HIV-Infected Individuals Followed Longitudinally over Time

Benjamin Naovarat[1], Francis Williams[1] and John Reveille[2], [1]The University of Texas McGovern Medical School, Houston, TX, [2]Department of Internal Medicine, University of Texas, Houston, TX

SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: Infection-related Rheumatic Disease Poster
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: With the successful treatment of HIV-1 infection with combination anti-retroviral treatment, immune-mediated diseases that were rarely encountered in HIV positive individuals in the pre-treatment era have emerged, including rheumatoid arthritis. The management of RA poses a particular challenge since the use of immunomodulatory medications could increase immunosuppression. The purpose of this study was to examine the clinical features and treatment outcomes of HIV-infected individuals with rheumatoid arthritis (RA) in a large outpatient HIV rheumatology clinic.

Methods: A retrospective chart review of patients with concomitant RA and HIV-1 were evaluated at the Harris County HIV Rheumatology Clinic from 1994-2020. All patients met the American College of Rheumatology criteria for RA and were seen by the same investigators (FMW, JDR). At baseline visit the following were collected: demographic data, disease features, laboratory data, medications, and follow up visit data. Antiretroviral medications were stratified into protease inhibitors, nucleoside reverse transcriptase inhibitors (NRTIs), non-nucleoside reverse transcriptase inhibitors (NNRTIs), and integrase inhibitors.

Results: From 1994-2020, we saw 27 patients with concomitant RA and HIV-1 infection from a total cohort of 1671 HIV-1 rheumatology patients (Table 1). The first case of RA noted in our clinic was 2003 with an average of 7.3 (±4.9) years of follow up. Mean age at presentation was 51.9 (±9.6) years, 14 were female and 13 patients male. Ethnically, the RA patients included three white, 14 black, and 10 Latino patients. Average BMI on presentation was 29.13 (±6.57) compared to 27.98(±8.25) on follow up. Average CD4 count at presentation was 629.3 (±432.2) cells/μL with five patients having a CD4< 200 cells/μL compared to 634.7 (±422.2) cells/μL at their most recent visit. Only one patient had a CD4< 200 at follow up. Four patients had a detectable viral load at presentation; however, at subsequent follow up only one of these still had a detectable viral load. Twelve patients were seropositive by either positive

rheumatoid factor (RF) or anti-cyclic citrullinated peptides (anti-CCP). In regards to RA medications we have used methotrexate since 1994 (on non RA patients). Fourteen patients were on DMARDs, 10 on prednisone (at doses of < 10 mg/day) , 15 were taking NSAIDs and four were treated with TNF blockers (with no adverse effects). As far as antiretroviral medications are concerned, seven took protease inhibitors, 22 on NRTI, eight on NNRTI, and six integrase inhibitors. Two patients were on no HIV therapy and only one patient was on mono-drug therapy with the rest of the patients being on two or more anti-retroviral medications. With follow up, 18 patients had clinical remission on treatment, seven patients were treatment noncompliant, and two patients had no improvement on methotrexate.

Conclusion: Patients treated for rheumatoid arthritis in the setting of HIV-1 with anti-rheumatic and antiretroviral medications had improvement in laboratory values in regard to CD4 and viral loads. Additionally, our cohort demonstrated a high prevalence of seronegative rheumatoid arthritis cases compared to what has been reported in the literature.

SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: Infection-related Rheumatic Disease Poster
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: In mid-March 2020, state of alarm was declared in Spain due to the novel coronavirus disease 2019 (COVID-19) pandemic. Patients with rheumatic diseases (RD) under immunosuppressive drugs are considered at high risk of severe outcome. Some commonly used treatments in RD such as corticosteroids, hydroxychloroquine or anti-IL6 drugs are also hypothesized to help treat COVID-19. We set out to determine the prevalence of SARS-CoV-2 infection among patients who reported respiratory symptoms during COVID-19 pandemic from March up to June 2020 in a group of patients treated with biological agents such as anti-TNF, anti-IL6, abatacept and JAK inhibitors like baricitinib or tofacitinib.

Methods: A registry of all patients under treatment with adalimumab, anti-IL6, abatacept, baricitinib and tofacitinib in our Rheumatology Service was obtained. All the patients were called and asked to participate in a telephone survey screening for infectious respiratory symptoms in the past 4 months (phone calls were made from mid-April to early-June)**.** Other epidemiological data (previous contact with a suspected case, number of household members and confinement measures) were collected. Reported symptoms were evaluated by a clinician to assess whether or not these were suggestive of acute respiratory disease. Those who presented new onset acute respiratory symptoms were tested for SARS-Cov-2 serology (IgM/IgG).

Results: A total of 355 patients participated in the survey, 66.5% were females. Mean age (S.D.) was 54.7 years (16.5). Rheumatoid arthritis was the most common diagnosis (56%), followed by spondyloarthritis (16.3%), psoriasic arthritis (11.3%), idiopathic juvenile arthritis (6.8%) and others (9.6%). Adalimumab (46%) and tocilizumab (20.9%) were the most common treatment groups, followed by abatacept (12.4%), tofacitinib (12.1%), baricitinib (6.5%) and sarilumab (2.3%). Mean time under current treatment was 59.8 months.

Patients were asked for the presence of respiratory symptoms out of a list with 20 items. Follow-up questions were asked when necessary to determine the acute or chronic nature of the symptoms. The most common reported symptoms were cough (8.2%), odynophagia (6.8%), fatigue (5.4%), shortness of breath (4.8%), joint or muscular pain (3.7%) and diarrhea (3.4%). 87.24% complied with the confinement measures. 4.94% reported contact with people with symptoms suspicious of COVID-19. No patient required hospital care.

A total of 25 were selected for serological testing based on reported symptoms compatible with COVID-19 disease. The remaining 330 patients reported no symptoms or had symptoms not attributable to infection. Peak incidence of reported symptoms occurred in March (n = 10). All patients tested negative for IgM and only one patient was positive for IgG.

Conclusion: Patients with RD showed a high level of compliance to confinement measures. COVID-19 was extremely low among patients with RD treated with biological agents or JAK inhibitors. Confinement measures are key to prevent SARS-Cov-2 transmission.

Immunological Abnormalities in a SARS-CoV-2-Cytokine Release Syndrome Rheumatology Cohort

Patil Injean[1], Sandy Lee[1], Neha Chiruvolu[2], Muntarin Karim[3], Loomee Doo[4], Deepa Ragesh Panikkath[5], Donna Jose[4], Micah Yu[4], Anna Lafian[4], Vaneet Sandhu[6], Karina Torralba[7], Christina Downey[1], Marven Cabling[8] and Mehrnaz Hojjati[9], [1]Loma Linda University Medical Center, Redlands, CA, [2]UC Riverside School of Medicine, Riverside, CA, [3]Loma Linda University Health System, Loma Linda, CA, [4]Loma Linda University Medical Center, Loma Linda, CA, [5]Loma Linda University Health, Department of Rheumatology, Loma Linda, CA, [6]Loma Linda University, Loma Linda, CA, [7]Loma Linda University School of Medicine, Redlands, CA, [8]Loma Linda University Medical Center, Loma Linda, [9]Loma Linda University, Loma Linda

SESSION INFORMATION

Session Date: Saturday, November 7, 2020

Session Title: Infection-related Rheumatic Disease Poster

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: Cytokine release syndrome (CRS) is a condition characterized by a sepsis-like condition and laboratory abnormalities such as high ferritin, low ESR, and low fibrinogen which has a mortality rate of up to 60%. Patients with SARS-CoV-2 can develop CRS (SARS-CoV-2-CRS). There have been reports of features of antiphos-

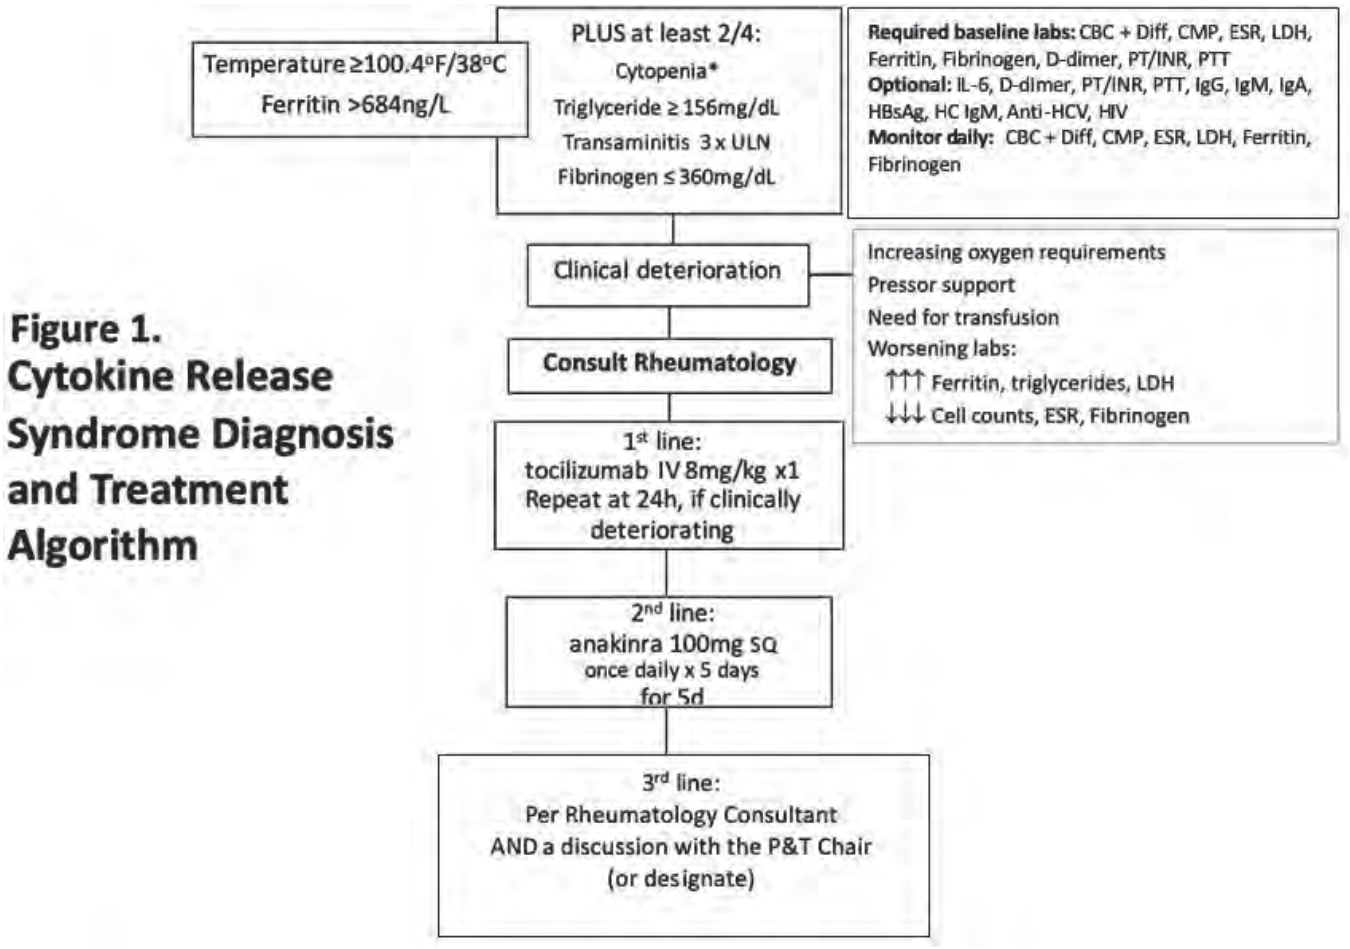

Figure 1. Cytokine Release Syndrome Diagnosis and Treatment Algorithm

Table 1. Treatment Considerations for Cytokine Release Syndrome due to SARS-CoV-2 for patients referred to a Rheumatology Consultation Service

	Therapy	Dose	Comments
1st Line	tocilizumab (anti-IL6)	8mg/kg IV x 1 (800mg maximum dose); repeat if no clinical improvement within 24-48 hours For dosing, consider rounding to the nearest available vial size: 80mg, 200mg, 400mg	• Pertinent Drug Interaction: CYP3A4 Substrates (High risk with Inducers) • No renal adjustment; • Contraindications: Known hypersensitivity to Tocilizumab or any component • Caution: Monitor liver enzymes, platelet counts, neutrophils • Risks: GI perforation risk; thrombocytopenia, neutropenia; liver enzyme elevation; Herpes zoster reactivation
2nd Line	anakinra (anti-IL1)	100 mg SQ once daily x 5 days	• Not to be combined with other biologic DMARDs; clozapine; live vaccines • Contraindications: Hypersensitivity to E.coli derived proteins, anakinra or any component of the formulation; use with caution: CrCl<30mL/minute or ESRD
3rd Line	Per Rheumatology Consultant AND after discussion with the P&T Committee Chair (or designate)		
	Any use of the above immunomodulatory drugs intended as treatment of COVID-19 complications which deviates from this table, including administration route &/or dosing, requires a discussion with the P&T Committee Chair (or designate) before the drug is verified by the Pharmacist, or administered by Nursing.		

Table 1. Treatment Considerations for Cytokine Release Syndrome due to SARS-CoV-2 for patients referred to a Rheumatology Consultation Service

pholipid antibody syndrome, lupus and Kawasaki disease occurring in SARS-CoV-2 patients, but no other study has looked at these features in patients with CRS. Studies are needed to determine if immunological laboratory abnormalities occur in SARS-CoV-2-CRS patients, and can help predict poor outcomes. Institution-mandated rheumatology treatment protocols for SARS-CoV-2-CRS were developed at a university medical center and county Hospital (Figure 1, Table 1). This study aims to establish if immunological abnormalities and poorer outcomes are present in SARS-CoV-2-CRS patients when compared to those without CRS.

Methods: SARS-CoV-2 patients referred to Rheumatology SARS-CoV-2-CRS for CRS evaluation (March 15-May 30, 2020) were included in this retrospective chart review. Demographics (age, sex, and ethnicity) and histories of diabetes, autoimmune disease, and medications were noted. Laboratory data reviewed included white blood cell count, hemoglobin, platelets, ferritin, fibrinogen, liver enzymes, complement, immunoglobulin levels, antinuclear antibody and antiphospholipid antibody panels and interleukin 6. Clinical outcomes tracked included oxygen and ventilation requirements, development of infections, and mortality. Descriptive statistics were used.

Results: 150 patients were included in this chart review. Majority were 109 (73%) males, with a mean age of 61.6. 28 (19%) were health facility residents, 11 (7%) health care workers, and 34 (23%) inmates. Ethnicities included 44 (30%) white non-Hispanic, 64 (43%) Hispanic, 24 (16%) Asian, 14 (9%) Black, and 2 (1%) other. 71 (47%) of patients were diagnosed with SARS-CoV-2-CRS. Compared to patients without CRS, greater proportions of patients with CRS were noted to have lower Ig, complement and platelet levels, higher liver enzyme, triglyceride, ferritin, IL6 and IL2 receptor levels, positive antiphospholipid antibody tests, (Table 2). Bacterial co-infections were actually higher among non-CRS patients. CRS patients had a higher rate of death and thrombosis compared to those without CRS.

Conclusion: A larger proportion of SARS-CoV-2-patients who developed CRS had certain immunological laboratory abnormalities when compared to those without CRS. This data serves as preliminary analysis of an ongoing study. More detailed analysis of categorized deviations of laboratory abnormalities relative to the timed occurrence of adverse outcomes (i.e. death) and to the use of therapies, and how these correlate with other features such as physical

Table 2. Laboratory features and clinical outcomes in a patient population referred to Rheumatology for SARS-CoV-2-CRS diagnosis and management

	Met diagnostic criteria for SARS-CoV-2-CRS, N = 71	Did not meet Diagnostic criteria for SARS-CoV-2-CRS, N = 79
Specific Immunology Laboratory tests (Cut offs for abnormal and units where applicable)	N (%)	N (%)
Positive ANA	7 (10)	5 (6)
low C3 (<70 mg/dL)	7 (8)	1 (1)
low C4 (<11 mg/dL)	5 (7)	1 (1)
High Immunoglobulin M (>230mg/dL)	1 (1)	1(1)
High Immunoglobulin G (680-1490mg/dL)	7 (10)	4(5)
Low Immunoglobulin G (<680 mg/dL)	3 (4)	1 (1)
Low Immunoglobulin M (<54 mg/dL)	7 (10)	0 (0)
High Interleukin 6 (>1.8 pg/mL)	29 (41)	24 (30)
High Interleukin 2 Receptor (>1,033 pg/mL)	12 (17)	2 (3)
Positive Anticardiolipin IgG or IgM or IgA (U/mL)	8 (11)	2 (3)
Positive Beta2 Glycoprotein IgG or IgM or IgA(U/mL)	4 (6)	0 (0)
Positive Lupus Anticoagulant	10 (14)	5 (6)
High D-Dimer (>0.4 ug/mL)	65 (92)	70 (89)
Laboratory tests for diagnosis of CRS (cut offs for abnormal)		
Hyperferritinemia(>350 ng/mL)	64 (90)	65 (82)
Leukopenia (<4.0 bil/L)	13 (15)	15 (19)
Thrombocytopenia (<150 bil/L)	17 (24)	12 (15)
Transaminitis (AST > 35 U/L, ALT >45 U/L)	62 (87)	60 (76)
Elevated ESR (>30mm/hr)	65 (92)	71 (90)
Inappropriately low ESR*	4 (6)	2 (3)
Hypertriglyceridemia (>150mg/dL)	47 (66)	44 (56)
Clinical Outcomes		
Need for increased Oxygen requirement Mechanical ventilation	69 (97) 16 (23)	70 (89) 18 (23)
New thrombosis	8 (11)	2 (3)
Bacterial co-infection	10 (14)	25 (32)
Deceased	20 (28)	11 (14)

*An inappropriately low ESR was defined as a an ESR that was normal or low or only mildly elevated despite a critical clinical course defined by increasing oxygenation requirements, need for mechanical ventilation or having a sepsis-like picture

Table 2. Laboratory features and clinical outcomes in a patient population referred to Rheumatology for SARS-CoV-2-CRS diagnosis and management

exam findings and imaging results are needed. Autopsy data also need to be included. Follow up of survivors are being done to determine if these abnormalities persist, and if other clinical features suggestive of autoimmune diseases and immunodeficiency disorders develop.

Covid-19 and Rheumatic and Musculoskeletal Disease Patients: Infection Rates, Attitudes and Medication Adherence

Kieran Murray[1], Sean Quinn[2], Matthew Turk[2], Anna O'Rourke[3], Eamonn Molloy[1], Lorraine O'Neill[4], Anne Mongey[5], Ursula Fearon[6] and Douglas Veale[7], [1]Saint Vincent's University Hospital, Dublin 4, Dublin, Ireland, [2]Saint Vincent's University Hospital, Dublin 4, Ireland, [3]Saint James' University Hospital, Dublin 6, Ireland, [4]Saint Vincent's University Hospital, Dublin, Ireland, [5]Saint Vincent's University Hospital, Co Dublin, Ireland, [6]Molecular Rheumatology, Trinity College Dublin, Dublin, Dublin, Ireland, [7]EULAR Centre for Arthritis and Rheumatic Diseases, St Vincents University Hospital, UCD, Dublin, Dublin, Ireland

SESSION INFORMATION

Session Date: Saturday, November 7, 2020

Session Title: Infection-related Rheumatic Disease Poster

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: Covid-19 has caused >400,000 deaths. The relationship between RMDs, immunosuppressive medications and Covid-19 is unclear. This study explores Covid-19 prevalence, DMARD adherence, information sources and attitudes to virtual clinics amongst RMD patients during the current pandemic.

Methods: An anonymous online survey to assess Covid-19 status, RMD diagnoses, adherence and information sources was performed. The respondents' primary information source was assessed for quality and readability using validated scoring systems. Binary logistic regression was used to calculate odds ratios for symptoms of Covid-19.

Gender	
Female	1207 (87.8%)
Male	168 (12.2%)
Age	
<40	331 (24.1%)
41-60	814 (59.2%)
>60	230 (16.7%)
RMD*	
Rheumatoid Arthritis	726 (52.9%)
Spondyloarthropathy	451 (32.9%)
CTD/Vasculitis	77 (5.6%)
Other RMD	193(14.1%)
None	118(8.6%)
Covid-19 status	
Asymptomatic, without infected contact risk	1176 (91.8%)
Asymptomatic, with infected contact risk	58 (4.5%)
Symptomatic, without infected contact risk	39 (3.0%)
Symptomatic, with infected contact risk	8 (0.6%)
Covid-19 test status	
Not tested	1203 (92.7%)
Negative	89 (6.9%)
Positive	6 (0.5%)
RMD medications	
Biologic/JAKi	664 (51.8%)
csDMARD (excluding HCQ/chloroquine)	526 (40.8%)
Glucocorticoid	116 (12.9%)
HCQ/chloroquine	118 (9.2%)
None of the above	290 (22.5%)

*Some respondents had more than one RMD

None	17 (5.8%)	2.17 (1.15-4.10)	0.017

*excludes HCQ/chloroquine

Table 3. Odds ratio of COVID-19 symptoms by medications and information source

Odds ratios for Covid-19 symptoms were higher amongst those with a SpA and other RMDs and lower in those on immunosuppression, csDMARDs, multiple immunosuppressives and those compliant with health authority guidance (Tables 2 and 3). Adherence to RMD medications was high at 84.1%. The most common reason for non-adherence was concern of an increased risk of infection (58.8%). 57.1% report using health authority guidelines for information on medication use. Importantly, adherence rates were higher amongst those who cited guidelines ($p< 0.001$), and conversely lower in those with Covid-19 symptoms ($p=0.004$). Moreover, we found the health authority guidance good quality and highly readable.

68.9% were unsure about potential Covid-19 therapies. Hydroxychloroquine was the most commonly selected potential agent (10.6%). Those with Covid-19 symptoms were more likely to think NSAIDs had a role in treating Covid-19 (20.9% versus 8.4%, $p=0.010$) amongst those with Covid-19 symptoms.

Finally, the use of virtual clinics was supported by 70.4% of respondents.

Conclusion: The rate of Covid-19 positivity in RMD patients was similar to the general population. Covid-19 symptoms were lower amongst respondents on immunosuppressive medication and those adherent to medication guidelines. Adherence rates were higher than previous studies. Interestingly, a higher proportion of respondents adherent with medications cited health authority guidelines. This study suggests provision of high quality, readable information may significantly influence behaviour with better awareness of social distancing and cocooning guidance and increase adherence and decrease the spread of Covid-19. Respondents were supportive of health authority advice and virtual clinics.

Abstract Number: 0641

Cohort of Rheumatic Patients Treated with Rituximab and COVID-19: Does Rituximab Treatment Increases the Severity of SARS-COV2 Infection?

Antía García-Fernández[1], Fernando López-Gutiérrez[1], Jesús Loarce-Martos[1], Ivan Del Bosque-Granero[2], Laura Calvo-Sanz[1], Boris Blanco-Cáceres[1], Cristina Pijoan-Moratalla[1], Lourdes Villalobos-Sánchez[3], Javier Bachiller-Corral[1] and Mónica Vázquez[1], [1]Rheumatology, Hospital Universitario Ramón y Cajal, Madrid, Spain, [2]Rheumatology, Hospital Universitario Ramón y Cajal, Madrid, Madrid, Spain, [3]Rheumatology, Hospital Universitario Ramón y Cajal, Madrid

SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: Infection-related Rheumatic Disease Poster
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: There are very few studies reporting COVID-19 in patients with rheumatic diseases, without clear evidence supporting more frequent or severe disease in these patients. Nevertheless, to our knowledge, there are no studies analysing Rituximab effect within autoimmune diseases. The aim is t o describe the impact and outcome of SARS-CoV-2 infection in our cohort of patients with rheumatic diseases treated with Rituximab.

Methods: A retrospective, descriptive study was conducted on patients treated with Rituximab followed in the rheumatology unit of a referral hospital. Patients were screened by telephone interview and a comprehensive review of health records from 01/02/2020 to 22/05/2020. Patients were classified in 4 groups: Non suspected infection (asymptomatic), suspected infection (compatible symptoms not confirmed), inpatients with confirmed infection, deceased patients with confirmed infection. The clinical characteristics and outcome of these 4 groups were described.

Results: Seventy-six patients treated with Rituximab were reviewed. Among the 76 patients, 63 (82,8%) were classified as non suspected SARS-COV 2 infection, 5 (6,6%) had a suspected non confirmed infection, 5 (6,6%) were admitted to hospital with confirmed infection and 3 (4%) were admitted to hospital and died during hospitalization. Their baseline characteristics according to infection severity are described in table 1. At the beginning of COVID19 outbreak, 76,9% of patients were on remission of their rheumatic disease, 15,4% had low disease activity and 7,7% had active disease despite treatment.

Chest x-ray, n %			
Normal	NA	0 (0)	0 (0)
Unilateral/unilobar pneumonia	NA	1 (20)	0 (0)
Bilateral Pneumonia	NA	4 (80)	3 (100)
PAFI <300, n %	NA	2 (40)	3 (100)

Table 2: SARS-COV-2 Treatment. AZT= Azithromycin, HCQ= Hydroxychloroquine, L/R= Lopinavir/Ritonavir, NIMV= non-invasive mechanical ventilation.

Severe SARS-COV2 infection was developed in 61,5% of patients (8/13), requiring hospitalization. Patients were hospitalized a median of 10 days [range (4-29)] and 62,5% (5/8) of patients experienced a clinical worsening after >10 days from symptoms onset. Inpatients had a higher rate of comorbidities: mainly HTA, COPD and CV disease. Up to 75% of inpatients had pulmonary involvement, being ILD the most frequent (4/6 66,7%). Respiratory insufficiency was present in 87,5% of hospitalized patients, 3/7 (42,9%) required non-invasive mechanical ventilation and 5/8 (62.5%) fulfilled ARDS criteria (PAFI< 300 and bilateral pneumonia).

Three out of eight (37,5%) patients died during hospitalization, all having 3 or more comorbidities. One longstanding RA patient with ILD complicated with a pulmonary embolism despite prophylactic heparin, a SLE patient with Evans Syndrome and COPD with chronic supplementary oxygen and an ANCA-vasculitis with renal and pulmonary involvement.

Conclusion: In our cohort of patients treated with Rituximab we found a high rate of hospitalization and death. Rituximab treatment might be taken into consideration as a risk factor for severe SARS-COV-2 infection in rheumatic pati ents.

SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: Infection-related Rheumatic Disease Poster
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: SARS COV 2 pandemic has been an issue which has challenged the health care systems around the world. Rheumatology has been involved in two ways: in the one hand, due to the use, in its treatment, of specific agents usually indicated in rheumatologic conditions and, on the other hand, the fear that our patients could be at higher risk due to the use of immunosuppressive agents.

The main objective of our study was to analyze the incidence of COVID infection in rheumatologic patients on treatment with targeted therapies (TT) (b and stDMARD) and to compare the incidence of such infection in the general population.

Methods: All patients with rheumatologic inflammatory conditions and COVID infection (confirmed by PCR of nasopharyngeal swab or serology) followed at three university referral centers from Basque Country (Spain) were identified. Patients on treatment with TT were selected. Characteristics of rheumatologic condition, type of TT and outcome of the infection were registered. Infection rates with the different TT were calculated and compared with the general population.

Results: Among 97 rheumatologic patients with COVID-19 infection 19 (12 with TNFi, 2 with anti-IL6 and 1 with abatacept, rituximab, ustekinumab, anakinra and baricitinib) were on treatment with TT at the COVID-19 infection diagnosis. Although, no significant differences were observed with those not taking TT with regards to severe disease outcome (hospital admission or death), the admission rate was 31.8% (greater than that commonly reported in general population ≈ 20%) and the mortality rate 13.8%, higher than that observed in our region (7.8%). In comparison with the general population of our region, the total infection rate for patients on TT was 4% vs 0.9%.

Specifically, in those taking TNFi the infection rate was of 3.5% and in those taking anti-IL6 of 3.1%.

Conclusion: Rheumatologic patients taking TT present higher rates of COVID infection than those seem in the general population (under the same criteria for infection definition). The admission rates observed in these patients suggest also a more severe course of the infection.

SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: Infection-related Rheumatic Disease Poster
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: To analyze the risk of admission for COVID19 infection and outcome of patients treated with b/tsDMARD from our center, to compare with all patients admitted for COVID-19 infection.

Methods: Records of the b/tsDMARD patients admitted for COVID-19 infection between March 8 and June 8, 2020 were analyzed retrospectively. Age, gender, and outcome of all patients admitted to our hospital for COVID19 infection on the same dates were collected. Chi-square, Student's t and Man-Whitney U tests were used when appropriate.

Results: 1,668 patients with IMID treated with b/tsDMARD were included. Median age 53.0 years (range 17-91), 52.4% women. Diagnoses and DMARD distribution are shown in tables 1 and 2. 21/1668 (1.3%; 4.2/100 patient-years) were admitted for severe COVID19 infection. Mortality ratio: 4/21 (19.0%). Median age of the admitted patients was higher: 61.0y (SD 14.7) vs 53.0y (SD 15.0); $p < 0.006$. Median age of deceased patients was also higher 69.5y (SD 20.3) vs 53.0y (SD 15.0); p: NS. Female gender had a worse prognosis trend: 52.4% of all group, 61.9% of those hospitalized, 75.0% of those who died. Females had a higher median age than men: 55.0y (SD 14.9) vs. 50.0y (SD 14.9); $p < 0.001$.

When comparing patients treated with DMARD admitted for COVID19 infection with all patients hospitalized for the same reason (2,684 patients), no differences were found neither in age (61.0y [SD 14.7] vs 60.0y [SD 19.0]; NS) nor gender (female: 61.9% vs 50.2%; NS). Mortality rate was not different: 4/21 (21.0%) vs 551/2684 (20.5%); p: NS, but patients treated with b/tsDMARD died at a younger age: 69.5y (SD 20.3) vs 81.5 (SD 11.3); p: NS.

Rheumatoid arthritis patients were admitted more frequently: (9/392 (2.3%) vs 12/1276 (0.9%); $p < 0.035$. And were older: median 62y (SD 13.5) vs 50.0y (SD 14.4); $p < 0.001$.

Patients treated with anti-TNF suffered less admissions: 6/1055 (0.6%) vs 15/613 (2.4%); p< 0.001 and were younger: median 51.0y (SD 15.0) vs 55.0y (SD 14.7); p < 0.001. Anti-TNF were less used in patients with rheumatoid arthritis 188/392 (48.0%) vs 867/1276 (67.9%); p< 0.001.

Table 1:

Disease	N (%)	Admitted	deaths
Rheumatoid arthritis	392 (23.5%)	9/392 (2.3%)	1
Spondylarthritis	277 (16.6%)	3/277 (1.1%)	1
Psoriatic arthritis	124 (7.4%)	1/124 (0.8%)	0
JIA	30 (1.8%)	0/30 (0.0%)	0
CTD	31 (1.9%)	1/31 (3.2%)	1
Vasculitis	20 (1.2%)	0/20 (0.0%)	0
IBD	582 (34.9%)	4/578 (0.7%)	1
Psoriasis	202 (12.1%)	3/202 (1.5%)	0
others	10 (0.6%)	0/10 (0.0%)	0
TOTAL	1,668 (100%)	21/1668 (1.3%)	4/21 (19.0%)

Table 2:

Treatment	N (%)	Admitted	deaths
Anti-TNF	1055 (63.2%)	6/1055 (0.6%)	2
Anti-CD20	79 (4.7%)	3/79 (3.8%)	1
Anti-IL6	96 (5.8%)	3/96 (3.1%)	0
CTLA4-Ig	44 (2.6%)	3/44 (6.8%)	1
Anti-IL17	92 (5.5%)	3/92 (3.3%)	0
Anti-IL12/23	143 (8.6%)	1/143 (0.7%)	0
Anti-integrin	79 (4.7%)	0/79 (0.0%)	0
JAK inhibitor	34 (2.0%)	1/34 (2.9%)	0
PDE4 inhibitor	32 (1.9%)	1/32 (3.1%)	0
Anti-IL23	14 (0.8%)	0/14 (0.0%)	0
TOTAL	1,668 (100%)	21/1668 (1.3%)	4/21 (19.0%)

Conclusion: It is reasonable that patients with inflammatory diseases treated with b/tsDMARD continue their treatment during the COVID19 epidemic. The different rates of hospitalization based on the diagnosis or DMARD may be due to comorbidity, confounding by indication and other bias. The study is not powerful enough to study these confounders.

Abstract Number: 0644

Characterizations of Cytokine Storm Associated with COVID19

Ofer Perzon[1], Avi Abutbul[1], Sigal Sviri[1] and **Dror Mevorach**[1], [1]Hadassah-University Hospital, Jerusalem, Yerushalayim, Israel

SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: Infection-related Rheumatic Disease Poster
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: COVID-19, the name given to the clinical syndrome associated with the newly recognized virus SARS-CoV-2 has become pandemic with mortality estimated based on reports from China between 1-3% and complications among hospitalized patients leading to up to 15-25% admissions to the ICU. The clinical presentation includes both upper and lower respiratory tract infection, but patients may also be asymptomatic. The term "cytokine storm" calls up vivid images of an immune system gone awry and an inflammatory response flaring out of control. The term has captured the attention of the public and the scientific community alike and is increasingly being used in both the popular media and the scientific literature. Indeed, a few publications have indicated an important part of the complications in COVID19 are related to a cytokine storm.

Methods: Over 100 patients were hospitalized at Hadassah-Hebrew University Hospital, Jerusalem, in the recent 3 months with the diagnosis of COVID19. We summarized the clinical outcomes and their correlation (using NEWS2) to a cytokine storm at Hadassah. 30 different cytokines/chemokines/ hematopoietic growth factors were analyzed and compared to clinical manifestations. Serum cytokine/chemokine measurement was performed using the Luminex MAGPIX system (Luminex Corp, Texas, USA) and analyzed with Milliplex analysis software (Millipore MA, USA). The following cytokine/ chemokines were measured by sandwich ELISA kits: IL-18 (R&D), MCP-3 (R&D), TNFR1 (R&D), TREM-1 (R&D), procalcitonin (PCT) (IBL-America, MN, USA).

Results: We were able identify a correlation between disease severity (NEWS2), and 16 immunological biomarkers including IL6, TNF-alpha, IL18, IFN-a, IFN-b, IFN-g, IL-2R, IL-8, IL-10, TNF-R1, IL-1Ra, MCP-1, MIP-1 alpha, IP-10, IL8 and GM-CSF that have been associated with disease severity. IL-1 was not markedly elevated. The NEWS2 severity was strongly supported by a correlation to CRP, ferritin, d-dimer, and lymphopenia.

Conclusion: In this cohort of patients with COVID19, cytokine storm surprisingly did not include IL-1b and is typically characterized by both pro-inflammatory and anti-inflammatory cytokines/ chemokines / hematopoeitic growth factors. Typ1 1 IFN were not decreased upon development of the storm.

Prevalence and Clinical Features of COVID-19 in a Large Cohort of 199 Patients with Sarcoidosis

Anne-Claire Desbois[1], **Cindy Marques**[1], Leila Lefèvre[1], Serge Barmo[1], Camille Lorenzo[1], Mathilde Leclercq[1], Gaëlle Leroux[1], Chloé Comarmond[1], Catherine Chapelon-Abric[1], Fanny Domont[1], David Saadoun[1] and Patrice Cacoub[1], [1]AP-HP, Groupe Hospitalier Pitié-Salpêtrière, Department of Internal Medicine and Clinical Immunology, F-75013, Paris, France, Centre national de références Maladies Autoimmunes et systémiques rares et Maladies Autoinflammatoires rares, Paris, France

SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: Infection-related Rheumatic Disease Poster
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: To investigate the prevalence, clinical features and outcomes of coronavirus disease 2019 (COVID-19) among sarcoidosis patients.

Methods: We retrospectively collected clinical features, treatments and outcomes of COVID-19 in a cohort of patients with sarcoidosis followed in a single tertiary university hospital.

Results: Among 199 sarcoidosis patients [mean age 58.8 (±14) years, 86 (43.2%) men], 26 (13%) were diagnosed with COVID-19 [definite (n=7), probable (n=12) and possible (n=7)]. Twenty-four out of 26 patients (92%) had at least one comorbidity, and 11/26 (42%) had two or more comorbidities. Demographic and clinical features of patients COVID-19 positive were similar to those of sarcoidosis patients COVID-19 negative. The administration of hydroxychloroquine or immunosuppressant was not associated with the occurrence or the severity of COVID-19. Four out of 26 (15.4%) COVID-19 positive patients required admission to hospital and two of them died. Hospitalized patients [mean age of 61 (±11.5) years] were receiving higher doses of long-term treatment with corticosteroids than non-hospitalized patients; 4/4 had pulmonary and 2/4 cardiac involvement of sarcoidosis, and all one or more comorbidity.

Conclusion: The prevalence of COVID-19 in sarcoidosis is slightly higher to that of the general population. Almost half of the COVID-19 positive patients have two or more comorbidities and about 15% present a severe course.

Abstract Number: 0646

"An Apple Pie a Day Does Not Keep the Doctor Away". Fictional Depictions of Gout in Contemporary Film and Television

Rachel Murdoch[1], Christina Derksen[2], Keith Petrie[1] and Nicola Dalbeth[1], [1]University of Auckland, Auckland, New Zealand, [2]Jacobs University, Bremen, Germany

SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: Metabolic & Crystal Arthropathies Poster
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Views about gout as a self-inflicted condition of dietary excess can contribute to stigma and lead to ineffective management strategies. Fictional portrayals of illness and medical management in film and television may perpetuate cultural stereotypes about illness. The aim of this study is to analyse fictional depictions of gout in contemporary film and television.

Methods: We conducted a search for English language depictions of gout in film and television since 1990 using the Internet Movie Database (IMDb), other internet media databases, a google search and member contributions from the Gout, Hyperuricemia and Crystal-Associated Disease Network (G-CAN). Film and television shows depicting gout were analysed (n=44).

Results: Gout was used as a plot device to represent nobility or to explain the absence of characters from important events. Characters with gout were most often male and frequently portrayed as overweight and ageing. The most

Table 1. Fictional depictions of dietary associations with gout

Food/drink portrayed as triggers or causes of gout	Food/drink portrayed as protective or recommended for gout
Alcohol	Drink plenty of water
Apple pie	Fish
Bacon	Fruit and vegetables
Blood gravy	Omelette
Champagne	Salad
Chopped chicken liver	
Deli foods	
Drinkable cheese	
Garlic	
Lard cakes	
Liver balls	
Lung loaf	
Mackerel	
New York style food	
Organ meats: kidney, hearts, liver	
Pancakes	
Preserved fish like anchovies or herrings	
Red wine	
Rich food	
Skillet dripping	
Smothered chicken fried bacon	
Smothered chicken fried bananas	
Smothered pork chops	
Wine	

commonly depicted causes of gout were overindulgence of food and alcohol (61%), and numerous dietary causes of gout were portrayed (Table). Depictions of biological causes were infrequent (12%). Common management strategies described were change in diet (36%) and pain relief (32%), with only one mention of urate-lowering therapy (5%). The majority of films and television episodes depicted gout as humorous (59%) and embarrassing (50%).

Conclusion: In contemporary film and television, gout is portrayed as a humorous and embarrassing condition, caused by dietary indulgence. These negative depictions may reinforce inaccurate beliefs about the causes of gout and its management.

Abstract Number: 0647

Dual-energy CT versus Ultrasound, Alone or in Combination, for the Diagnosis of Gout: A Diagnostic Performance Study

Jasvinder Singh[1], Fabio Becce[2], Jean--Francois Budzik[3] and Tristan Pascart[4], [1]University of Alabama at Birmingham, Birmingham, AL, [2]Lausanne University, Lausanne, Switzerland, [3]University of Lille, Lille, France, [4]Ghicl, Hôpital Saint-Philibert, department of rheumatology, Lomme, France

SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: Metabolic & Crystal Arthropathies Poster
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: To examine the diagnostic accuracy of dual-energy computed tomography (DECT) vs. ultrasound or their combination for the diagnosis of gout.

Methods: Using data from an outpatient rheumatology clinic, we examined the sensitivity, specificity, positive and negative predictive value (PPV, NPV) and area under the receiver operating characteristic (ROC) curve (AUC) of either modality or their combination for gout diagnosis. We used two standards: (1) demonstration of monosodium urate (MSU) crystals in synovial fluid (gold); and (2) 2015 American College of Rheumatology and European League Against Rheumatism (ACR-EULAR) classification criteria for gout, modified to exclude points based on DECT and ultrasound findings (silver), since these were test standards.

Results: Of the 147 patients who provided data, 48 had synovial fluid analysis performed (38 had MSU crystals and 10 were MSU-crystal negative). The mean age of 64.7 years (standard deviation, 14.3) and a mean symptom duration of 9.2 years. 113 (77%) met the silver standard, i.e. modified ACR-EULAR classification criteria for gout, and 34 (23%) did not.

Compared to the gold standard of synovial fluid MSU crystal positivity, the accuracy statistics for feet DECT, knee DECT, feet ultrasound double contour (DC) sign, combined feet DECT and feet ultrasound diagnosis (DC sign or tophus), and combined knee and feet DECT and ultrasound were: (1) sensitivity, 87%, 91%, 76%, 95%, 97%; (2) specificity, 100%, 87%, 60%, 60%, 50%; (3) PPV, 100%, 97%, 88%, 90%, 88%; (4) NPV, 67%, 75%, 40%, 70%, 83%; (5) AUC, 0.93, 0.89, 0.68, 0.77, and 0.74 (**Table 1**). These findings were replicated compared to the modified ACR-EULAR gout classification criteria, but with lower numbers (**Table 2**). Feet DECT, followed by knee DECT had the highest accuracy for the diagnosis of gout (**Figure 2**); ultrasound DC sign or the combination of DECT and ultrasound or across joints had lower accuracy.

Conclusion: In a single-center rheumatology clinic study, feet or knee DECT had the best overall accuracy statistics for the diagnosis of gout. DECT/ultrasound combination or multiple joint imaging may offer no additional increase in overall diagnostic accuracy.

Table 1. Diagnostic accuracy of DECT and ultrasound modalities for gout with MSU positivity as the gold standard (n=48)

Anatomical region	Imaging technique	Sensitivity (95% CI)	Specificity (95% CI)	PPV (95% CI)	NPV (95% CI)	AUC (95% CI)

Abstract Number: 0648

Dual Energy CT Has Additional Prognostic Value over Clinical Measures in Gout Including Tophi: Best Evidence Synthesis

Sally Stauder[1] and Paul Peloso[2], [1]Tulane University, Ponte Vedra Beach, FL, [2]Horizon Therapeutics plc, Gurnee, IL

SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: Metabolic & Crystal Arthropathies Poster
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Dual Energy CT Scan (DECT) can detect monosodium urate crystals in joints and periarticular tissues. EULAR gout guidelines (Richette, 2020) recognized DECT's value in making a clinical diagnosis, when joint aspiration is difficult. DECT demonstrates crystal depositions in 50% of gout patients without tophi (Dalbeth 2017).

Since clinical tophi predict excess all-cause and cardiovascular mortality (Vincent 2017 & Perez-Ruiz 2013) it's possible that subclinical urate depositions on DECT could provide more prognostic information. To have prognostic value, DECT should be reliable and valid. Validity should be evident on measures of death, disability and distress (pain, gout flares). We used a best evidence synthesis framework to and summarize the evidence for DECT as a prognostic gout tool.

Methods: PUBMED and EMBASE were searched from initiation to December 2019, keywords (DECT, gout, tophaceous gout, chronic gout, monosodium urate crystals OR monosodium urate burden OR tophi OR monosodium urate volume OR flares OR pain OR distress OR death OR disability OR function). Titles, abstracts and full articles were identified and supplemented with a manual search of secondary sources. Data extraction was conducted by both authors; final data inclusion represents consensus.

Results: Of 344 eligible articles, 76 titles/abstracts met screening inclusion criteria (22%); a full manuscript was pulled. Thirty-nine articles informed this analysis (11.3%). Four systematic reviews showed high DECT reliability; intra-class correlations, 0.78-0.99. DECT has content validity. Dalbeth (2015) showed DECT and X-Rays correlate

Table 1. Construct Validity for DECT in Gout Patients

Stage of Gout / Consequence	Hyperuricemia	Clinical Gout: DECT positive, No tophi	Clinical Gout: DECT positive and Palpable tophi	Clinical Gout: DECT not measured, Palpable Tophi

with feet erosion scores in tophaceous gout patients, r=0.70, p< 0.001. Vincent (2017) and Perez-Ruiz (2013) showed clinical tophi associated with increased mortality; no study has examined mortality against DECT volume. Dalbeth (2007) showed hand function, (Sollerman Hand Disability Score), correlated with tophi burden (r^2=0.59, p=0.024); no study has examined DECT volume with foot or knee function. Higher DECT volumes associate with gout flares. Dalbeth (2017) showed DECT associated with greater flare recall over 3 and 12 months (p< 0.01) in 152 patients. Pascart (2018) showed an odds ratio of 2.03 (95% CI: 1.15-4.38) for flares in 36 patients over 1 year; flared subjects had near doubled DECT knee volumes vs. non-flaring subjects (0.6 cm^3 vs 1.1 cm^3). Dalbeth (2019) correlated DECT volume and flares at 2 years, r=0.36, p< 0.001. Dalbeth (2017) showed DECT is abnormal in controlled and uncontrolled gout. DECT scans of hands/wrists, feet/ankles/Achilles, knees were abnormal in 47% of those with uric acid < 6.0 mg/dL and no palpable tophi; DECT was abnormal in 90% with uric acid >6.0 mg/dL and palpable tophi. DECT is sensitive to change with therapy. Araujo (2015) showed a 95% change in DECT volume in 152 patients receiving pegloticase. DECT volume decreased from 9.15 to 1.89 cm^3 over 12 months.

Conclusion: DECT imaging is highly reliable and has content validity in gout. There is evidence of added prognostic value with DECT, especially for future gout flares. DECT is sensitive to change with urate lowering therapy. Future studies should evaluate DECT's ability to predict mortality and disability in gout.

A Multicenter, Open-Label, Efficacy and Safety Study of Pegloticase in Patients with Uncontrolled Gout Who Have Undergone Kidney Transplantation: Early Data Report

Abdul Abdellatif[1], Lin Zhao[2], Paul Peloso[3], Katya Cherny[2], Brad Marder[2], John Scandling[4] and **Kenneth Saag**[5], [1]Baylor College of Medicine, Division of Nephrology, Houston, TX, [2]Horizon Therapeutics plc, Lake Forest, IL, [3]Horizon Therapeutics plc, Gurnee, IL, [4]Stanford Medicine, Department of Nephrology, Stanford, CA, [5]University of Alabama at Birmingham, Division of Clinical Immunology and Rheumatology, Birmingham, AL

SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: Metabolic & Crystal Arthropathies Poster
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Gout's high prevalence in kidney transplant (KT) recipients has been associated with heavy residual urate burden, decreased urate excretion related to reduced renal function, and high calcineurin inhibitor use in this population. The management of gout can be particularly challenging in KT patients due to decreased urate lowering therapy (ULT) renal clearance and drug-drug interactions. Pegloticase (pegylated recombinant uricase) is a treatment indicated for uncontrolled gout and tophi burden that rapidly metabolizes uric acid to allantoin which is readily cleared from the circulation. The use of pegloticase with immunomodulation therapy has been rising in order to reduce anti-drug antibody generation that decreases treatment efficacy and can increase risk of infusion reactions (IRs). Immunomodulator/pegloticase co-therapy markedly improves treatment responder rates[1-3]. However, only a few case reports[4,5] of pegloticase use in solid organ transplant patients have been published and phase 3 pegloticase

Table. Serum uric acid and kidney function parameters in kidney transplant recipients undergoing pegloticase treatment for uncontrolled gout

Patient	sUA (mg/dL)			eGFR (mL/min/1.73m^2)			UACR	
	Last Visit Prior to Data Cut	Baseline	Last Value	Last Visit with eGFR and UACR values	Baseline	Last Value	Baseline	Last Value

*ongoing pegloticase therapy. †experienced an SAE (Patient 1, SAE of stomach ulcer deemed unrelated to pegloticase; Patient 4, SAE of cellulitis deemed unrelated to pegloticase).

trials excluded organ transplant recipients. We conducted the PROTECT trial (NCT04087720) to examine pegloticase use in KT recipients with uncontrolled gout.

Methods: We are examining pegloticase treatment (12 biweekly 8 mg infusions over 24 weeks) in adult KT recipients (KT >1 year ago, eGFR ≥15 mL/min/1.73m^2) with uncontrolled gout (serum uric acid [sUA] ≥7 mg/dL, ULT contraindication/inefficacy, and either tophi, chronic gouty arthritis, or ≥2 flares in past year). The primary endpoint is the proportion of pegloticase responders (sUA < 6 mg/dL for ≥80% of time during Month 6). We are also examining sUA levels, eGFR, urine albumin-to-creatinine ratio (UACR), and health assessment questionnaire (HAQ) pain scores.

Results: At the time of this analysis (April 30, 2020), 7 patients who had undergone KT 15.3 ± 5.0 years earlier had enrolled (age: 52.0 ± 11.2 years, sUA: 10.0 ± 1.4 mg/dL, gout duration: 5.9 ± 4.3 years; COVID-19 reduced enrollment). All patients were on stable doses of ≥2 immunosuppressants. 1 patient had completed the 24-week treatment, 5 were in treatment, and 1 had discontinued early due to COVID-19 (non-infection) reasons (Table); the number of infusions received ranged from 2 to 12. In the 5 ongoing patients, all post Day 1 central lab sUA levels were < 1 mg/dL, indicative of treatment response. No notable changes in eGFR were observed; 2 patients with baseline albuminuria >300 mg/g showed >35% reduction in UACR by week 14. HAQ pain (0 to 100 VAS) decreased by 33.8 ± 2.7 (n=3) from baseline at week 20. 2 patients experienced flares; no IRs occurred. 2 SAEs (stomach ulcer, cellulitis), deemed unrelated to pegloticase, were reported.

Conclusion: Early findings of the ongoing PROTECT clinical trial suggest that pegloticase can safely and effectively be used in KT recipients to treat uncontrolled/refractory gout. Further efficacy and safety data in the KT population are pending.

Risk of Vertebral Fractures at Lateral Chest Radiographies in Patients with Gout

Marco Ferrández-Jiménez[1], **Irene Calabuig**[2], Maria Luisa Peral[2], Miguel Gómez-Garberí[1] and Mariano Andrés[2], [1]Universidad Miguel Hernández de Elche, Alicante, Spain, [2]Hospital General Universitario de Alicante-ISABIAL and Universidad Miguel Hernández de Elche, Alicante, Spain

SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: Metabolic & Crystal Arthropathies Poster
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Osteoporosis causes significant morbidity and mortality through the development of fragility fractures, including vertebral fractures (VF). Patients with gout may show an increased risk of osteoporotic fractures, as the urate crystals-led inflammatory state has been associated with an accelerated bone resorption, though data to date is conflicting. This field study aims to evaluate the risk of osteoporotic VF associated with gout.

Methods: Patients admitted for cardiovascular events were screened for gout by face-to-face interview following 2015 ACR/EULAR criteria; 40 gout patients, out of the 266 assessed (15%), were identified. Participants with available lateral view of chest radiography (at admission or in the previous six months) were selected for the present analysis (n=126). Two observers, blinded to clinical data and trained by web-based program on VF assessment by the International Osteoporosis Foundation, simultaneously reviewed the radiographies. Presence of VF (defined as height loss ≥20%), number and severity (by Genant semi-quantitative scale), were registered. Chi-squared and Mann-Whitney's U tests were used for group comparisons. To analyze the relation between gout and presence of VF, odds ratios (OR) with 95% confidence interval (95%CI) were calculated, adjusting for age, female gender and chronic kidney disease by multiple logistic regression.

Results: Chest radiographies from 126 participants were analyzed, 21 of them (16.67%) identified as gout patients. Prevalence of VF in the whole sample was 14.3% (n=18). Results are shown in Table 1. Presence of VF was more frequent in gout patients, while there were no differences in number and severity. Across subgroups, VF numerically predominated in gout at lower age tertile (≤64.0 years: 50.0% vs 5.5%; p=0.184) and in males (23.5% vs 4.1%; p=0.022), compared to controls.

The OR for the presence of VF in gout was 3.10 (95%CI 1.01-9.52), persisting the association after multivariate adjustment (adjusted OR 5.21, 95%CI 1.32-20.61).

Table 1. Vertebral fractures and comparison across subgroups (#).

Conclusion: An independent association between gout and vertebral fractures at lateral chest radiographies was confirmed in patients with a cardiovascular event. Further studies should confirm this finding in other settings.

Readmission Risk and Quality of Care in Patients Presenting to the Emergency Department with Gout Flares

Luigi Brunetti[1], Janaki Vekaria[1], Peter Lipsky[2] and Naomi Schlesinger[3], [1]Rutgers Ernest Mario School of Pharmacy, piscataway, NJ, [2]AMPEL BioSolutions LLC., Charlottesville, VA, [3]Rutgers Robert Wood Johnson Medical School, New Brunswick, NJ

SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: Metabolic & Crystal Arthropathies Poster
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Gout is the most common inflammatory arthritis and its economic burden is substantial, with estimates for the overall cost exceeding $20 billion (US) annually. Contributing to the economic burden are hospital admissions and iatrogenic events associated with pharmacotherapy. Identification of modifiable risk factors would be an important contribution to clinical practice.

The purpose of this study was to identify opportunities for enhancing gout care in patients presenting to the Emergency Department (ED) with gout flares.

Methods: This retrospective cohort study used data from electronic medical records (EMR) at a large community hospital. All consecutive patients visiting the medical center ED with a primary diagnosis of gout from 1/1/2016 to 7/1/2019 were included. Patients were then followed for 90 days to determine whether they were readmitted to the ED for any reason. A chart review identified whether they were on appropriate medications in terms of gout flare management. All data were summarized using descriptive statistics. A multiple logistic regression was constructed to identify risk factors for ED utilization within 90 days of the index visit.

Results: A total of 214 patients were included in the analysis. Most patients were male (79%), mean age was 59.4 ± 15.6 years, and mean Charlson comorbidity index was 0.5 ± 1.14. The most common medications prescribed during the ED visit included NSAIDs (41.6%), opioids (28%), corticosteroids (26.6%), and colchicine (21%). Allopurinol and febuxostat were initiated in the ED in 4.7% and 0.9%, respectively. Discharge medications for the management of gout included NSAIDs (37%), corticosteroids (34.6%), opioids (23.8%), colchicine (14%), febuxostat (7%), and allopurinol (6.5%). Of the patients sent home with an opioid, 40% were newly prescribed. An anti-inflammatory medication was not prescribed in 29.6% of patients discharged from the ED. Readmission within 90 days was recorded in 16.8% of patients. Of these readmissions, 33.3% were gout-related and 11.1% were cardiac related.

After adjusting for age and comorbidity index, patients receiving colchicine were 2.8 times more likely (OR, 2.81; 95% CI, 1.12 to 7.02; p=0.027) to return to the ED within 90 days. The most common cause of readmission in this subset was gout-related (54.5%).

Conclusion: Approximately 30% of patients were discharged from the ED without an anti-inflammatory medication, whereas initiation of urate lowering therapy was rare. Opiates were used frequently, but the indication was uncertain. Only 5.6% of subjects revisited the ED for gout-related diagnoses in the subsequent 3 months. Colchicine prescription was associated with an increased risk of gout-related ED utilization within 90 days. Treatment of gout in the ED is sub-optimal and often does not follow established guidelines.

Changes in Serum Urate, in the First 6-months of Initiation or Change of Urate-Lowering Therapy, Associate with Immediate Health-Related Quality of Life Outcomes in People with Gout

Ruth Topless[1], Tony Merriman[1], Siamak Noorbaloochi[2] and **Jasvinder Singh**[3], [1]University of Otago, Dunedin, New Zealand, [2]University of Minnesota, Minneapolis, [3]University of Alabama at Birmingham, Birmingham, AL

SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: Metabolic & Crystal Arthropathies Poster
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Few studies, if any, have found association of the biochemical cause of gout (high serum urate) with functional limitation and health-related quality of life (HRQoL) and productivity decrements in gout. We examined the associations of changes in serum urate in the immediate term with HRQoL using data from five intervention clinical trials of urate-lowering therapies (ULT).

Methods: Data were obtained from the following trials: Combining Lesinurad With Allopurinol in Inadequate Responders (CLEAR1 and CLEAR2; 1217 participants, 12 months); Long-term Allopurinol Safety Study Evaluating Outcomes in Gout (LASSO;1735 participants, 6 months); Lesinurad Monotherapy in Gout Subjects Intolerant to Xanthine Oxidase Inhibitors (LIGHT; 214 participants, 6 months; Combination Treatment Study in Subjects With Tophaceous Gout With Lesinurad and Febuxostat (CRYSTAL; 330 participants, 12 months). We excluded participants in LASSO who had also taken part in CLEAR or LIGHT (n=154). HRQoL measures were assessed at baseline and at 3 monthly intervals (LASSO only at baseline and 6 months), serum urate was measured monthly in each trial.

Primary outcome measures were physical (PCS) and mental (MCS) health functioning taken using the respective component summary scores from Short-form 36 (SF-36) data, Health Assessment Questionnaire Disability Index

Table1: Associations of absolute change in urate in preceding month with patient reported outcomes in first six months with initiation or change of urate-lowering therapy

	Urate (mg/dL)		Absolute urate change (mg/dL)		
HRQoL	Beta	95% CI	Beta	95% CI	N subjects (N observations)
PCS	-0.334	-0.45 - -0.22	-0.120	-0.26 - -0.08	3295 (7231)
MCS	-0.240	-0.35 - -0.13	-0.345	-0.49 - -0.20	3295 (7231)
HAQ-DI Score	-0.003	-0.008 - 0.002	0.013	0.007 - 0.019	3295 (7251)
SDS Score	0.335	0.23 - 0.44	0.175	0.04 - 0.31	3199 (6484)
PGA	0.792	0.49 - 1.10	0.500	0.10 - 0.90	3302 (8488)
Pain	0.828	0.38 - 1.28	0.666	0.17 - 1.17	1731 (4604)

PHYS and MENT negative scores indicate increased disability. HAQ-DI, SDS, PGA and pain positive scores indicate increased disability. HRQoL, health-related quality of life measure; CI, confidence interval.

Table 2: Associations of absolute change in urate in preceding month with patient reported outcomes, stratified into increasing and decreasing observations, in first six months with initiation or change of urate-lowering therapy

	Decreasing urate (mg/dL)			Increasing urate (mg/dL)		
HRQoL	Beta	95% CI	N observations	Beta	95% CI	N observations
PCS	-0.266	-0.47 - -0.07	4013	0.291	-0.09 - 0.68	2902
MCS	-0.375	-0.57 - -0.18	4013	-0.186	-0.56 - 0.19	2902
HAQ-DI Score	0.019	0.01 - 0.029	4023	0.000	-0.08 - 0.02	2910
SDS Score	0.323	0.14 - 0.51	3589	-0.113	-0.46 - 0.23	2623
PGA	0.954	0.41 - 1.50	4679	-0.714	-1.67 - 0.24	3433
Pain	1.226	0.56 - 1.89	2681	-0.419	-1.72 - 0.88	1722

PHYS and MENT negative scores indicate increased disability. HAQ-DI, SDS, PGA and pain positive scores indicate increased disability. HRQoL, health-related quality of life measure; CI, confidence interval.

Score (HAQ-DI), Sheehan Disability Scale (SDS) score, Patient Global Assessment (PGA), and pain in the last week. For each outcome, we investigated the underlying distribution and then a series of corresponding random intercept and slope (month) generalized linear mixed models were used to test the adjusted effect of the fixed predictors on the outcome across all timepoints over the first six month. Serum urate, change in urate in the last month, number of flare-affected days in the last month, baseline BMI, age, number of comorbidities, sex, ethnicity, trial and treatment, and tophi status were modelled as fixed effects. Subject, and the month of trial were modelled as random effects.

Results: Higher current serum urate correlated with reduced physical and mental health functioning, and increased disability and pain but not with HAQ-DI Score (Table 1). However absolute change in serum urate levels associated with poorer outcomes on the HAQ-DI scale (β (95% CI) = 0.013 (0.007 - 0.019)) and the five other measures. Observations were stratified into those which followed a month of serum urate reduction (n = 4023) or increase (n = 2910) (Table 2). Reduction of serum urate levels was associated with poorer outcomes in all six measures. Timepoints with increasing serum urate levels showed no significant associations with the outcomes.

Conclusion: High serum urate levels associate with poorer HRQoL outcomes. Importantly, very recent fluctuations in serum urate levels associate with reduced HRQoL, primarily driven by effects of reduction in serum urate. Clinical emphasis on maintaining stable and reduced concentrations of serum urate may improve patient reported functional outcomes. This study provides further support for serum urate as central to disease pathophysiology and its impact on an individual's health.

Nutrient Content of Gout Flare Trigger Foods

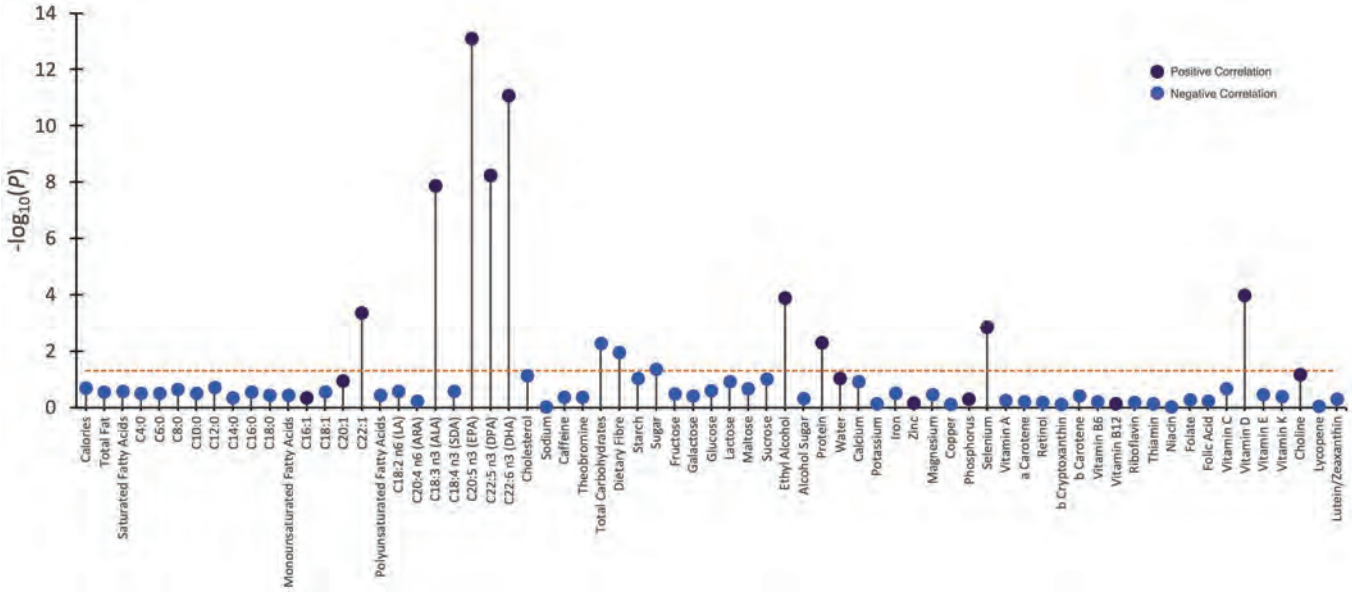
Tanya Major[1], Ruth Topless[1], Elsa Sanchez-Lopez[2], Jennie Harré Hindmarsh[3], Lisa Stamp[4], Nicola Dalbeth[5], Monica Guma[6], Robert Terkeltaub[7] and **Tony Merriman**[1], [1]University of Otago, Dunedin, New Zealand, [2]University of California San Diego, San Diego, CA, [3]Ngāti Porou Hauora, Te Puia Springs, New Zealand, [4]University of Otago Christchurch, Christchurch, New Zealand, [5]University of Auckland, Auckland, New Zealand, [6]University of California San Diego, La Jolla, CA, [7]VA/UCSD, San Diego, CA

SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: Metabolic & Crystal Arthropathies Poster
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: A wide variety of foods are reported by patients to be triggers of gout flares. Some of these foods have been associated with serum urate levels and onset of gout, and their possible mechanism for involvement in gout explained through their high purine content and subsequent influence on the purine metabolism pathway (e.g. red meat and seafood). However, not all reported gout flare trigger foods have a high purine content and acute increases in serum urate are not thought to be the primary mechanism leading to inflammation. This study aimed to assess which nutrients are commonly found within gout flare trigger foods.

Methods: Participants with gout recruited across Aotearoa/New Zealand (n = 2,106) were asked to list their dietary gout flare triggers in an open-text format. Their answers were aligned with a list of 115 foods commonly included in food frequency questionnaire forms. The nutrient content (per 100 g) of these 115 foods was estimated using the USDA Food Central database and the Cronometer website (https://cronometer.com; 70 different nutrients, vitamins, and minerals). The proportion of participants who included each food as a gout flare trigger was calculated and this proportion was associated with the estimated nutrient content of these foods using a linear regression.

Results: Nine of the food nutrients analysed were more likely to be present within foods listed as gout flare triggers; protein (β = 4.28 g, P = 0.005), vitamin D (β = 45.70 ug, P = 1.1x10-4), ethyl alcohol (β = 12.60 g, P = 1.34x10-4), selenium (β = 2.43 ug, P = 0.001), the monounsaturated fatty acid C22:1 (β = 1.40 mg, P = 4.5x10-4), and four omega 3 polyunsaturated fatty acids C18:4 (β = 7.97 mg, P = 1.4x10-8), C20:5 (β = 2.50 mg, P = 8.0x10-14), C22:5 (β = 8.84 mg, P = 5.7x10-9), and C22:6 (β = 1.30 mg, P = 8.4x10-12). Three of the food nutrients analysed were less likely to be



present within foods listed as gout flare triggers by participants with gout. These three nutrients were; carbohydrates (β = -1.39 g, *P* = 0.005), dietary fibre (β = -10.08 g, *P* = 0.011), and sugars (all types combined; β = -1.48 g, *P* = 0.044).

Conclusion: This study identified nine nutrients commonly found in foods reported by people with gout to trigger their flares. Another three nutrients were less likely to be found in gout flare trigger foods. The link between increased vitamin D and selenium content of foods listed as gout flare triggers is a novel finding; as is the reduced carbohydrate, dietary fibre, and sugar content of these foods. The association of ethyl alcohol, several fatty acids, and protein (a proxy for purine-content) aligns with current knowledge of pathways involved in gout flare onset and reinforce the robustness of our analysis methodology. This work provides greater insight into the mechanisms involved in the triggering of a gout flare.

Correlations between 70 different nutrients, vitamins and minerals and frequency of food items being listed as gout flare triggers by participants. Purple points indicate positive correlations, blue points indicate negative correlations. Points above the orange dashed line are significant at P<0.05.

Session Title: Metabolic & Crystal Arthropathies Poster

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: Diet is a significant determinant of hyperuricemia and risk for gout. Dietary recommendations to prevent gout emphasize reducing purine intake; however, low-purine diets are often ineffective in preventing gout and have unknown effects on cardiovascular disease risk factors, such as hypertension and hyperlipidemia, which often accompany gout. Meanwhile, studies suggest that the DASH diet reduces serum urate while also lowering blood

Table 1. Baseline Change in Serum Urate, mg/dL (N=163)

	Mean, 95% CI	Mean Change from Baseline, 95% CI	*P*
Baseline	5.1 (4.9, 5.3)	-	-
Carbohydrate Diet			
4-week	5.1 (4.9, 5.3)	0.02 (-0.09, 0.12)	0.72
6-week	5.0 (4.9, 5.2)	-0.03 (-0.15, 0.09)	0.63
Combined 4-week and 6-week measures	5.1 (4.9, 5.2)	-0.00 (-0.11, 0.10)	0.93
Protein Diet			
4-week	5.0 (4.8, 5.2)	-0.08 (-0.19, 0.03)	0.16
6-week	4.9 (4.7, 5.1)	**-0.16 (-0.28, -0.05)**	**0.006**
Combined 4-week and 6-week measures	4.9 (4.8, 5.1)	**-0.12 (-0.23, -0.02)**	**0.02**
Unsaturated Fat Diet			
4-week	5.1 (4.9, 5.3)	0.01 (-0.10, 0.12)	0.85
6-week	5.1 (4.9, 5.2)	-0.01 (-0.11, 0.09)	0.81
Combined 4-week and 6-week measures	5.1 (4.9, 5.2)	-0.00 (-0.10, 0.10)	0.98

Table 2. Mean difference between diets (combined 4-week and 6-week measures), overall and stratified by baseline serum urate

	Mean Difference (95% CI)	*P*		Mean Difference (95% CI)	*P*		Mean Difference (95% CI)	*P*	*P*-interaction
Overall			**Baseline SUA < 6 mg/dL, N=134**			**Baseline SUA ≥ 6 mg/dL, N=29**			
CARB vs baseline	0.00 (-0.11, 0.10)	0.93	**CARB vs baseline**	0.08 (-0.02, 0.18)	0.126	**CARB vs baseline**	**-0.39 (-0.68, -0.10)**	**0.01**	**0.003**
PROT vs baseline	**-0.12 (-0.23, -0.02)**	**0.02**	**PROT vs baseline**	-0.04 (-0.15, 0.07)	0.508	**PROT vs baseline**	**-0.52 (-0.79, -0.24)**	**< 0.001**	**0.001**
UNSAT vs baseline	0.00 (-0.10, 0.10)	0.98	**UNSAT vs baseline**	0.08 (-0.02, 0.18)	0.106	**UNSAT vs baseline**	**-0.39 (-0.62, -0.16)**	**0.001**	**< 0.001**

Abbreviations: CARB represents carbohydrate diet; PROT represents protein diet; UNSAT represents unsaturated fat diet; SUA represents serum urate

pressure and lipids. Whether DASH-pattern diets that emphasize different macronutrient proportions might enhance serum urate reduction is not known.

Methods: We conducted a secondary analysis of the Optimal Macronutrient Intake Trial to Prevent Heart Disease (OmniHeart) feeding study, a 3-arm, crossover design, randomized trial of 191 adults with prehypertension or stage I hypertension (defined at the time of the trial as systolic blood pressure 120-159 mm Hg or diastolic blood pressure 80-99 mm Hg) who were not on antihypertensive medications. Participants were randomized to one of three DASH-pattern diets that emphasized either carbohydrates (CARB), protein (PROT), or unsaturated fat (UNSAT). Calories were adjusted as needed to maintain body weight throughout the study. We compared the effects of these diets on serum urate at weeks 4 and 6 of each feeding period.

Results: A total of 163 participants were included in the final analysis (mean age 53.5 yrs, 45% women, 55% black). The mean BMI was 30.2 kg/m^2 and 56.7% had hypertension. The PROT diet reduced serum urate from baseline at the end of the 6-week feeding period (-0.16 mg/dL; 95% CI: -0.28, -0.05; P = 0.006) (**Table 1**). In contrast, neither the CARB diet (-0.03 mg/dL; 95% CI: -0.15, 0.09; P = 0.63) or the UNSAT diet (-0.01 mg/dL; 95% CI: -0.11, 0.09; P = 0.81) reduced serum urate. Compared with the CARB and UNSAT diets, the PROT diet lowered serum urate by 0.12 mg/dL (95% CI: -0.20, -0.04; P = 0.005) and 0.12 mg/dL (95% CI: -0.20, -0.05; P = 0.001), respectively (**Table 2**). When stratified by baseline serum urate ≥ 6 mg/dL (n = 29), all diets significantly reduced serum urate from baseline (-0.39 to -0.52 mg/dL) and there was no significant difference between diets.

Conclusion: A DASH-pattern diet emphasizing plant-based protein lowered serum urate compared with those emphasizing carbohydrates or unsaturated fat. These findings suggest that a DASH-pattern diet emphasizing plant-based protein may enhance serum urate reduction. Overall, a DASH-pattern diet emphasizing plant-based protein has the potential to lower serum urate while also improving hypertension and hyperlipidemia. A definitive trial to test the ability of a DASH-pattern diet emphasizing plant-based protein to lower the incidence of gout is warranted.

SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: Metabolic & Crystal Arthropathies Poster
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Despite scarce evidence regarding the effects of weight loss in gout[1], international guidelines recommend dietary advice and weight loss as a core management strategy in people with gout and concomitant obesity. We explored whether there are potential clinical benefits associated with intensive weight loss in obese individuals with gout.

Objectives: To compare in a proof-of-concept randomized trial the effect of an intensive, 16-weeks weight loss program (full meal replacement with hypocaloric products and weekly visits to a dietician), relative to a dietary advised control group (ordinary food and visits to a dietician only at baseline and at week 8), on primarily changes in body weight and secondarily serum urate, fatigue and pain in people with gout and concomitant obesity.

Methods: Participants were randomized using permuted blocks and stratification (i.e. sex (male vs. female), obesity (BMI< 40kg/m^2 vs BMI≥40kg/m^2), serum urate (< 6mg/dL vs ≥6mg/dL)). he primary outcome was change in body weight at 16 weeks, analyzed using repeated measures mixed models. According to the Statistical Analysis Plan, the key secondary outcomes were changes in serum urate, VAS gout pain, and VAS fatigue after 16 weeks. ClinicalTrials.gov (NCT03664167).

Results: Overall, 61 participants were enrolled and randomized, of whom 29 were assigned to intensive weight loss and 32 to dietary control. The participants had an average age of 60.3 (SD, 9.9) years, average BMI of 35.6 (SD, 5.0) kg/m^2 and 59 (97%) were men. There was a statistically and clinically significant difference in the change in body weight from baseline to 16 weeks between the dietary and control groups (least squares means: -15.4 kg and -7.7 kg, respectively; difference: -7.7 kg (95%CI -10.9 to -4.7, p< 0.001). Mean changes in serum urate levels at the 16 weeks visit were -0.6 mg/dL and -0.3 mg/dL, respectively, with a difference between groups of -0.3 mg/dL (95%CI -0.9 to 0.3, p=0.744). The corresponding mean change in VAS fatigue was -17.4 mm compared to -8.6 mm, with a group difference of -8.8 mm (95%CI -25.5 to 7.9). Mean change in VAS pain corresponded to -2.5 mm compared to -12.5 mm, with a group difference of 9.9 mm (95% CI -11.1 to 31.0).

Conclusion: An intensive dietary intervention can effectively lower body weight in people with gout and concomitant obesity. Although absolute differences were present, we were not able to reject the null hypotheses for serum urate, fatigue, and pain in this proof-of-concept study with a small sample size

Abstract Number: 0656

A Sugar Tax Results in Reduced Incident Gout, Quality Adjusted Life Years Lost and Economic Cost from Gout: A Health Economic Analysis

Philip Robinson[1], Nicola Dalbeth[2], Chris Frampton[3], Tony Merriman[3], Amanda Phipps-Green[3] and Peter Donovan[4], [1]University of Queensland, Herston, Queensland, Australia, [2]University of Auckland, Auckland, New Zealand, [3]University of Otago, Dunedin, New Zealand, [4]Royal Brisbane & Women's Hospital, HERSTON, Queensland, Australia

SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: Metabolic & Crystal Arthropathies Poster
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Intake of sugar is associated with increased incident gout. Sugar taxes have been effective at reducing the intake of sugar in several jurisdictions. We aimed to model the impact of a sugar tax on incident gout (assuming causality through increased serum urate levels and a consequent increase in incident gout), quality adjusted life years (QALY) lost and the excess economic cost of new incident gout.

Methods: We modelled the effect of a sugar tax on incident gout in the US population (n=330M) on the study by Choi and colleagues (Arthritis Care & Research 2008;59:109-116). Our model assumptions were a 20% *ad velorum* (value of the item) taxation level, a price elasticity of -0.95 (defined as the percentage change in the quantity demanded over the percentage chance in price). A passthrough rate of 100% (the amount of tax passed through from the manufacturer to the consumer), a 2.5% per annum discount rate, healthcare inflation rate of 6.5% per annum, and a marginal disutility rate of 0.05 (this is the impact on QALY of a diagnosis of gout). We modelled incident gout rates using the Atherosclerosis Risk in Communities Study (ARIC), Coronary Artery Risk Development in Young Adults Study (CARDIA), and both the Original and Offspring cohorts of the Framingham Heart Studies (FHS). We modelled 3, 5, 10 and 15 year incident gout from < 3.0mg/dL up to 6mg/dL in 0.1mg/dl increments. Our outcomes were incident gout, increases in QALY and economic savings from the reduced gout. In modelling all time points we simulated death using US life tables. We assumed a societal perspective for costs (i.e. costs of treatment were considered regardless to whom they accrue), and a marginal cost of gout over non-gout of US$6,560 per annum. We undertook sensitivity analyses of key input parameters. We did not model the revenue to the government of the sugar tax.

Results: We fitted linear models to the raw incident gout rates from < 3mg/dL to 6mg/dL from the combined cohorts. This enabled fine scale prediction of the effect of sugar tax on reducing SU and consequent incident gout.

	3 years	5 years	10 years	15 years
Reduction in incident gout (n)	1,485	7,915	49,233	84,830
QALY saved	1,602	3,876	13,108	26,398
Economic savings (US$)	203.2M	482.5M	1.56B	3.00B

Table 1: Main model Results

We found a reduction in incident gout was achievable (n=84,830) with a 20% *ad velorum* sugar tax over 15 years (Table 1). Based on this reduction in incident gout we were also able to model a saving of 26,398 QALY over 15 years. This led to a saving of 3.15B in net present value.

Sensitivity analyses demonstrated the model was robust to changes in key inut variables.

Conclusion: Assuming a causal relationship, based purely on the reduction in incident gout, QALY savings and economic savings, we provide evidence supporting a sugar tax to be an effective public health measure to address the growing incidence of gout. The reduction in gout and the consequent savings of QALY and costs should be included when considering the implementation of a sugar tax.Table 1: Main model Results

Abstract Number: 0657

Gout and Heart Failure in the US

Gurkipal Singh[1], Maanek Sehgal[2] and Alka Mithal[3], [1]Stanford University, Stanford, CA, [2]UCLA, Los Angeles, CA, [3]ICORE, Woodside, CA

SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: Metabolic & Crystal Arthropathies Poster
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Heart failure (HF) is the eighth leading cause of death in the US, with a 38% increase in the number of deaths due to HF from 2011 to 2017 (1). Gout and hyperuricemia have previously been recognized as significant risk factors for heart failure (2), but there is little nationwide data on the clinical and economic consequences of these comorbidities. The objective was to study heart failure hospitalizations in patients with gout in the United States (US) and estimate their clinical and economic impact.

Methods: The Nationwide Inpatient Sample (NIS) is a stratified random sample of all US community hospitals. It is the only US national hospital database with information on all patients, regardless of payer, including persons covered by Medicare, Medicaid, private insurance, and the uninsured. We examined all inpatient hospitalizations in the NIS in 2017, the most recent year of available data, with a primary or secondary diagnosis of gout and heart failure. Over 69,800 ICD 10 diagnoses were collapsed into a smaller number of clinically meaningful categories, consistent with the CDC Clinical Classification Software.

Results: There were 35.8 million all-cause hospitalizations in patients in the US in 2017. Of these, 351,735 hospitalizations occurred for acute and/or chronic heart failure in patients with gout. These patients had a mean age of 73.3

years (95% confidence intervals 73.1 – 73.5 years) and were more likely to be male (63.4%). The average length of hospitalization was 6.1 days (95% confidence intervals 6.0 to 6.2 days) with a case fatality rate of 3.5% (95% confidence intervals 3.4% – 3.7%). The average cost of each hospitalization was $63,992 (95% confidence intervals $61,908 - $66,075), with a total annual national cost estimate of $22.8 billion (95% confidence intervals $21.7 billion - $24.0 billion).

Conclusion: While gout and hyperuricemia have long been recognized as potential risk factors for heart failure, the aging of the US population is projected to significantly increase the burden of illness and costs of care of these co-morbidities (1). This calls for an increased awareness and management of serious co-morbid conditions in patients with gout.

Identification of Two Novel Dysfunctional Variants in a Physiologically Important Urate Transporter *ABCG2* in Paediatric-onset Familial Hyperuricemia and Gout Patients in Three Generations

Blanka Stiburkova[1], Yu Toyoda[2], Katerina Pavelcova[1], Jana Bohata[1], Pavel Ješina[3], Yu Kubota[2], Tappei Takada[2] and Hiroshi Suzuki[2], [1]Institute of Rheumatology, Prague, Czech Republic, [2]Department of Pharmacy, The University of Tokyo Hospital, Tokyo, Japan, Tokyo, Japan, [3]Department of Pediatrics and Adolescent Medicine, First Faculty of Medicine, Charles University and General University Hospital in Prague, Prague, Czech Republic

SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: Metabolic & Crystal Arthropathies Poster
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: *ABCG2* is a high-capacity urate transporter gene. Common dysfunctional variants of *ABCG2* that result in decreased urate excretion in humans are major causes of hyperuricemia and gout, especially in pediatric-onset patients [1]. In the present study, we identified and functionally characterized a novel *ABCG2* variants in a family with three generations of early-onset hyperuricemia and gout.

Methods: A 12-year-old girl was examined for chronic asymptomatic hyperuricemia (397–405 µmol/L) with decreased fractional excretion of uric acid (2.2–3.5%). From positive family history of early hyperuricemia and gout < 35 year (her mother, maternal uncle and maternal grandfather), we performed a metabolic investigation. The results suggested that their hyperuricemia were mainly due to a defect in the urate excretion system and did not result from an excess production of urate. Since this type of hyperuricemia is reportedly related to ABCG2 dysfunction, we analyzed *ABCG2* coding regions of our patients using their genomic DNA. We carried out a series of biochemical analyses for

the functional validation of the identified ABCG2 variants using ABCG2-expressing plasma membrane vesicles as we report previously [2]. This study was approved by the Ethics Committee of the Institute of Rheumatology in Prague (no. 6181/2015).

Results: We identified two novel heterozygous variants: c.393G >T (p.M131I) and c.706C >T (p.R236X) in *ABCG2* gene in the proband. The segregation analysis showed existence of those variants in her mother, maternal brother and maternal grandfather. Immunoblotting for *N*-glycosidase treated whole cell lysates of 293A cells transiently-expressing each ABCG2 variant demonstrated that p.M131I had minimal effect on the protein level and *N*-linked glycosylation status, while the p.R236X variant was detected as truncated forms with weaker band intensity compared with that of ABCG2 wild-type. Confocal microscopy showed that similar to ABCG2 wild-type, p.M131I variant localized on the plasma membrane; the p.R236X variant exhibited little plasma membrane localization. Functional assay revealed that contrary to the wild-type, p.M131 had limited ATP-dependent urate transport activity; ABCG2-mediated urate transport activity of this variant was calculated as 14 ± 2% of wild-type control. Moreover, p.R236X variant was functionally null.

Conclusion: We found a representative case of paediatric hyperuricemia with familial gout that harboured two dysfunctional variants of a physiologically important urate transporter *ABCG2*. Biochemical analyses revealed that ABCG2 p.M131I and p.R236X were functionally deficient and null, respectively. Our identification of novel dysfunctional ABCG2 variants confirmed a key role of ABCG2 transporter and its link with early-onset hyperuricemia and gout.

Polynesian-Specific Gout-Associated Frameshift Variant in *PRPSAP1*

Megan Leask[1], Nicola Dalbeth[2], Lisa Stamp[3], Tony Merriman[4], Amanda Phipps-Green[4], Ruth Topless[4], James Boocock[5], Hyon Choi[6], Keresoma Leaupepe[1] and Eli Stahl[7], [1]University of Otago, Dunedin, Otago, New Zealand, [2]University of Auckland, Auckland, New Zealand, [3]University of Otago Christchurch, Christchurch, New Zealand, [4]University of Otago, Dunedin, New Zealand, [5]David Geffen School of Medicine at UCLA, Los Angeles, CA, [6]Massachusetts General Hospital, Department of Medicine, Division of Rheumatology, Lexington, MA, [7]Mt Sinai School of Medicine, New York, NY

SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: Metabolic & Crystal Arthropathies Poster
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Polynesian (NZ Māori and Pacific) populations have increased prevalence of gout. Hyperuricaemia is contributed to by increased urate production in the liver via the purine pathway. PRPSAP1 (phosphoribosyl

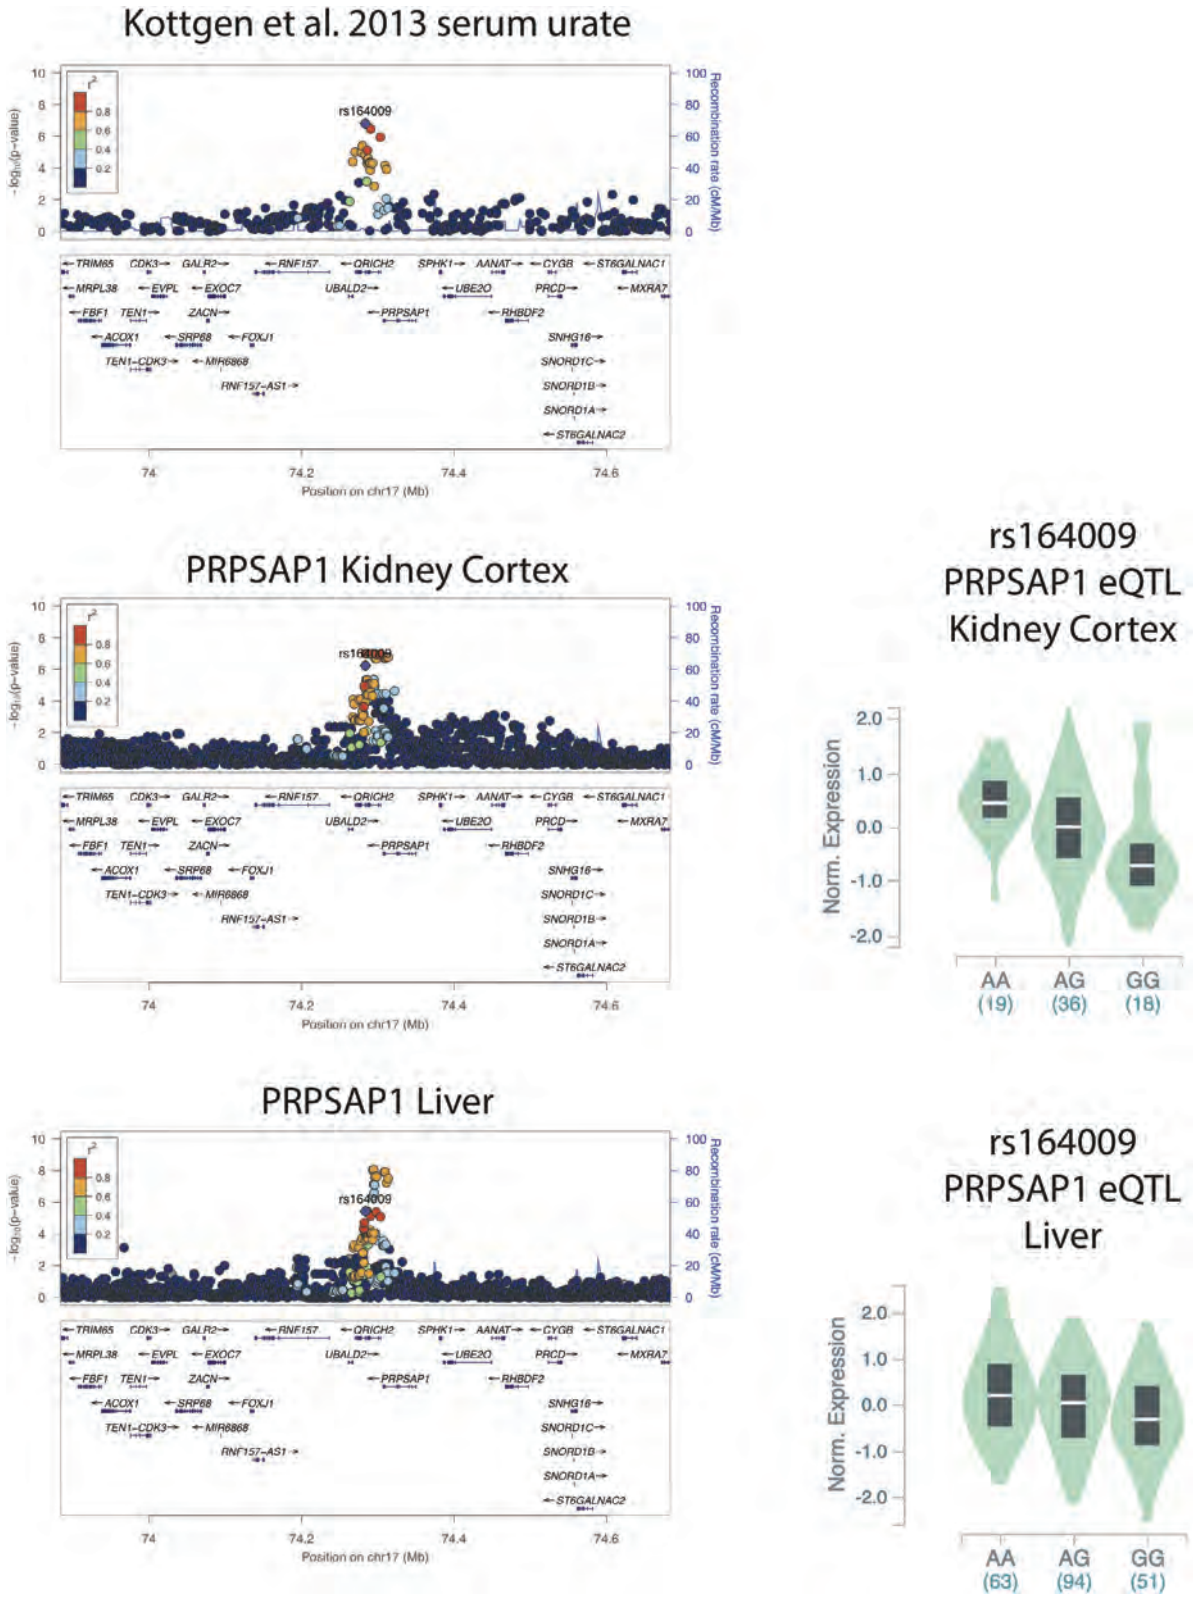

Figure 1. Regional association plots for serum urate (Köttgen et al. 2013) and gene expression of PRPSAP1 in Kidney Cortex and Liver tissue. eQTL violin plots for directionality of expression for the lead Köttgen SNP at PRPSAP1.

pyrophosphate (PRPP) synthetase-associated protein 1) binds PRPP synthetase and negatively regulates the production of PRPP and urate. Genetic variants in close proximity to *PRPSAP1* have been associated with serum urate and colocalize with an expression quantitative trait locus (eQTL) for *PRPSAP1* (Boocock et al. 2020 PMID 31985003), implicating *PRPSAP1* as a causal gene for hyperuricemia. We hypothesize that functional variants within genes that function in the purine pathway (*PRPS1* and *PRPSAP1*) could contribute to the risk of gout.

Methods: *PRPS1* and *PRPSAP1* were sequenced from 811 individuals of Polynesian or European ancestry in order to identify protein-altering variants. A second cohort of 3203 individuals of Polynesian ancestry of gout cases and controls was used to test association with gout using TaqMan®. eQTL data from the latest Genotype Tissue Expression Project release (GTEx v8), that now includes kidney, was used to test for a kidney eQTL.

Results: Two variants within *PRPSAP1* predicted to be protein altering and splice site acceptor variants (rs749392722 and rs201995246, respectively) were identified. No protein-altering variants were identified in *PRPS1*. rs749392722 is a frameshift variant, found only in 19 Polynesian participants, predicted to abolish almost the entirety of exon 3 of *PRPSAP1*. rs201995246 was identified in one hyperuricaemic male (8.1 mg/dL) of European ancestry. In the larger cohort of Māori and Pacific cases and controls (n = 3203) rs74939722 had a minor allele frequency of 0.025. rs749392722 significantly associates with increased risk of gout in Eastern Polynesian people (OR = 2.074, $p = 9.0 \times 10^{-3}$) and this association was confirmed in a meta-analysis (OR = 2.19, $P_{overall} = 4.0 \times 10^{-3}$) carried out on all Polynesian groups.

The maximal urate-associated SNP at the *PRPSAP1* locus, identified previously by genome-wide association study (rs164009; Boocock et al.), is tightly correlated with the maximally associated SNPs for the *PRPSAP1* eQTL in Kidney Cortex (Figure 1). rs164009_A raises serum urate and increases *PRPSAP1* expression in the Kidney Cortex. In contrast rs164009 is not amongst the maximally associated SNPs at the *PRPSAP1* eQTL in Liver, where there is an eQTL with a different genetic pattern of genetic control.

Conclusion: A *PRPSAP1* frameshift Polynesian genetic variant increases risk to gout perhaps by increased production of urate in the liver. The GTEx expression data indicate that the common serum urate association at *PRPSAP1* overlaps a kidney eQTL for *PRPSAP1*, where the urate-raising allele increases *PRPSAP1* expression, which would be expected to decrease production of urate via the purine pathway. *PRPSAP1* expression in the kidney may be important in serum urate control and this could be independent of any role of PRPSAP1 in regulating PRPP synthetase activity in the liver.

*Chronic kidney disease (CKD) defined as CKD stage 4, CKD stage 5, or renal replacement therapy (dialysis or transplant). BMI: body mass index; GFR: glomerular filtration rate; HbA1c: glycated hemoglobin; NSAID: non-steroidal anti-inflammatory drug; SD: standard deviation.

Table 2. Hazard of developing gout among SGLT2-i users

	Canagliflozin (n=3,287)	Dapagliflozin (n=12,504)	Empagliflozin (n=6,258)
New cases of gout (n)	63	195	51
Total follow-up time (person-years)	5,497	28,247	8,057
Mean follow-up time (years)	1.7	2.3	1.3
Incidence Rate (per 1,000 person-years)	11.5	6.9	6.3
Unadjusted Hazard Ratio (95% CI)	1.59 (1.19 – 2.11)	1.0	0.84 (0.61 – 1.15)
Adjusted* Hazard Ratio (95% CI)	1.57 (1.18 – 2.09)	1.0	0.81 (0.59 – 1.11)

* Potential confounders (assessed at baseline) included in the adjusted hazards ratio model: 1) general (age, gender, body mass index); 2) duration of type 2 diabetes mellitus; 3) complications of type 2 diabetes mellitus (diabetic nephropathy, diabetic neuropathy, diabetic retinopathy); 4) comorbidities (chronic kidney disease, coronary artery disease, heart failure, hypertension, peripheral vascular disease) 5) medication use (diuretics, insulin, losartan, non-steroidal anti-inflammatory drug). CI: confidence interval; SGLT2-i: sodium-glucose co-transporter 2 inhibitors.

tor agonists. In a post-hoc analysis of a randomized controlled trial (RCT), canagliflozin, a SGLT2-i, decreased risk of gout that seemed to be more than may be expected by serum urate reduction, suggesting potential anti-inflammatory effects beyond urate reduction. *In-vitro*, canagliflozin, but not dapagliflozin or empagliflozin, activated AMPK and suppressed IL-1β stimulated secretion of IL-6 and monocyte chemoattractant protein-1 (MCP-1). However, dapagliflozin and empagliflozin activated AMPK in other studies. Whether there may be differences in gout risk between SGLT2-i's is not known.

Methods: We performed a cohort study using data from The Health Improvement Network (THIN), a UK general practitioner (GP) electronic health records (EHR) database. We included subjects aged 18–89 with type 2 diabetes mellitus and incident use of a SGLT2-i (canagliflozin, dapagliflozin, empagliflozin) between 01/01/2013 and 12/ 31/2018 who had been enrolled in the GP practice for 6 months prior to study entry. We excluded individuals with gout diagnosis (Read code), use of gout medications (allopurinol, febuxostat, probenecid, sulfinpyrazone, or colchicine) or without body mass index assessment prior to SGLT2-i initiation. Follow-up started from the index date (date of first SGLT2-i prescription) and continued until incident gout diagnosis (diagnostic Read code or prescription of gout medications), switch to another SGLT2-i, death, or end of study. We compared the risk of developing gout across the 3 SGLT2-i's using multivariable Cox proportional hazards regression, adjusting for potential confounders.

Results: Of 22,049 subjects with type 2 diabetes mellitus, there were 3,287 incident users of canagliflozin, 12,504 incident users of dapagliflozin and 6,258 incident users of empagliflozin. Baseline characteristics are shown in Table 1. After adjusting for potential confounders, canagliflozin had 1.57 (95% confidence interval (CI) of 1.18 to 2.09) times the risk of developing gout, while empagliflozin had 0.81 (95% CI 0.59–1.11) times the risk compared with dapagliflozin, although the latter the effect estimate was not statistically significant (Table 2).

Conclusion: While SGLT2-i agents as a class and canagliflozin in particular have been shown to reduce the risk of gout in prior studies, in this cohort study from a UK EHR database, the beneficial effects appeared to be strongest for dapagliflozin and empagliflozin, with no significant differences noted between the two of them. Although canagliflozin reduced risk of gout compared with placebo in a RCT, in these data, it had a less favorable effect than dapagliflozin. The clinical relevance of the *in vitro* data on the potential anti-inflammatory effects of the various agents in this drug class is not clear.

Genomic Regions Jointly Associated with eGFR and Serum Urate: Implications for Shared Genetic Etiology of Hyperuricemia and Chronic Kidney Disease

Nick Sumpter[1], Alexa Lupi[2], Megan Leask[3], Tony Merriman[4], Ana Vazquez[2] and Richard Reynolds[1], [1]University of Alabama at Birmingham, Birmingham, AL, [2]Michigan State University, East Lansing, MI, [3]University of Otago, Dunedin, Otago, New Zealand, [4]University of Otago, Dunedin, New Zealand

SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: Metabolic & Crystal Arthropathies Poster
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Gout and hyperuricemia (HU), serum urate (SU) > 6.8 mg/dL, often present in the context of chronic kidney disease. It has long been known that estimated glomerular filtration rate (eGFR) and SU levels are correlated. Recent GWAS studies of SU and eGFR indicate nine overlapping large effect variants including *GCKR, A1CF,* and *VEGFA*, which suggests that the traits are also correlated genetically. Here we estimate the local genetic covariance of eGFR/SU across the genome and test whether expression quantitative trait loci (eQTL) are a potential source of the shared genetic effects on eGFR/SU.

Methods: We computed eGFR/SU genetic covariance estimates from the UK Biobank, consisting of SNP genotypes and clinical data measured on a total of 333,542 unrelated individuals, all of European ancestry. Estimates were generated from sets of SNPs comprising 511,828 genomic windows distributed across the genome. SNPs were included in the same window if they had pairwise linkage disequilibrium (LD) greater than 0.1. Genetic covariance was computed using estimates of variance explained by sets of SNPs on the outcomes from three separate models: 1) eGFR alone 2) SU alone 3) eGFR + SU. Variances were estimated using Bayesian inference, and bootstrap 95% confidence intervals of selected covariance estimates were generated. The Gene and Tissue Expression (GTEx) database (version 8) was used to test *cis*-eQTLs for variants comprising windows with significant covariance estimates on eGFR/SU. Colocalization of eQTL and GWAS signals was assessed using COLOC.

Results: The cohort was 53.7% female with an average age of 56.9 ± 8.0 years old. The average (SD) for eGFR was 112.8 ± 39.4 ml/min/1.73 m2, and the average (SD) for SU was 4.1 ± 1.1 mg/dL. Out of 511,828 genomic windows, 268 produced genetic covariance estimates between eGFR/ SU with 95% confidence intervals which did not overlap zero (Figure 1). Seven of the 15 largest magnitude covariance estimates validate shared loci from the marginal GWAS of eGFR/SU with the remainder representing novel shared eGFR/SU loci (Table 1). Sixteen shared eGFR/SU loci also colocalized with gene expression (posterior probability of colocalization (PPC) > 0.8). At the *A1CF* locus the eGFR/SU associations colocalize (PPC = 0.99) with an eQTL for *A1CF* (Figure 2). Furthermore, eQTL for *FGF5* in kidney cortex, *CD86* in whole blood and two transporter genes *SLC15A2* and *SLC7A9* were also identified.

Conclusion: Using our novel approach allowing direct estimates of the genetic covariance of eGFR/SU in specific windows of the genome, we demonstrate a set of loci contributing to the association between SU and eGFR. Many shared genomic regions also associate with gene expression thereby highlighting their potential functional signifi-

Chr	Locus	Window size	Genetic covariance [95% CI]	Novel

Table 1. List of 15 genomic windows with largest magnitude significant genetic covariance estimates. Chr column defines chromosome. Window size column contains # SNP markers/ window followed by its width [starting base pair position - ending base pair position]. Novel is defined as a locus that has not previously been implicated as a shared locus for eGFR/SU.

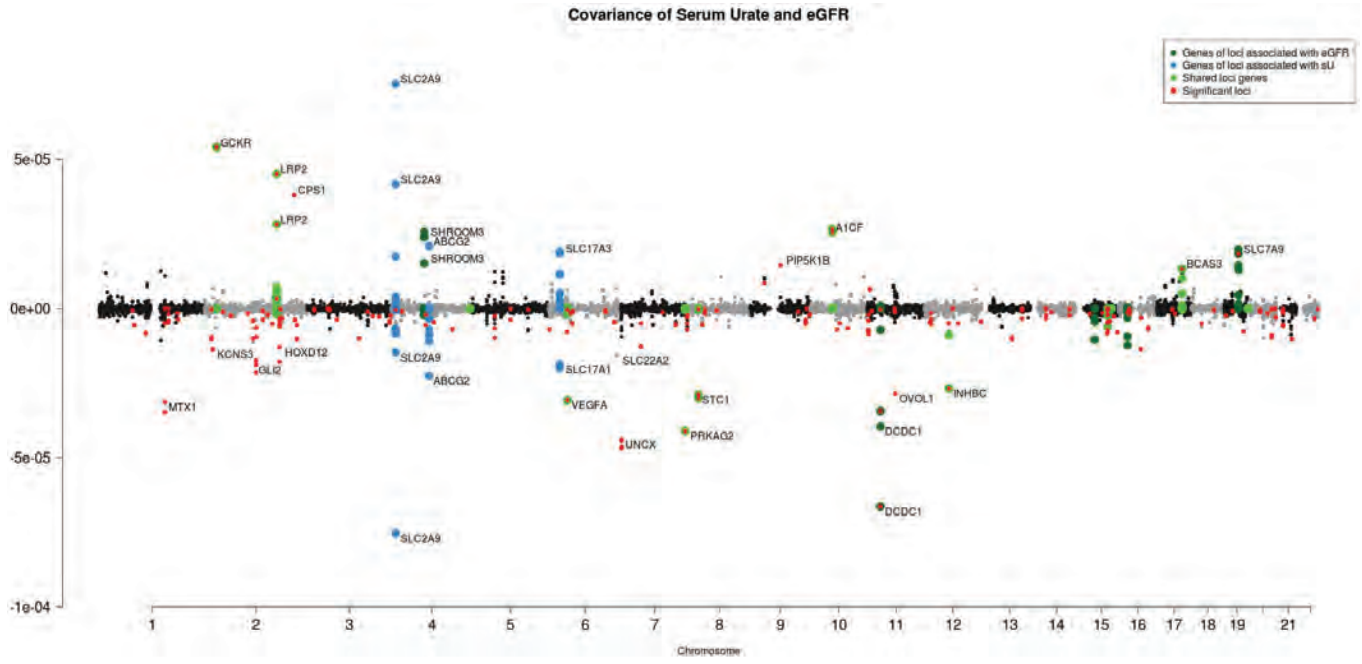

Figure 1. Covariance estimates of LD windows in the UK Biobank. Windows that contained SNPs in genes associated with known eGFR genes are highlighted in dark green, windows that contained SNPs in genes associated with serum urate are highlighted in blue, and windows that contained SNPs in genes associated with both serum urate and eGFR (from comparing separate GWAS, Johnson et al.5) are highlighted in lime green. Windows with confidence limits not overlapping zero are highlighted in red.

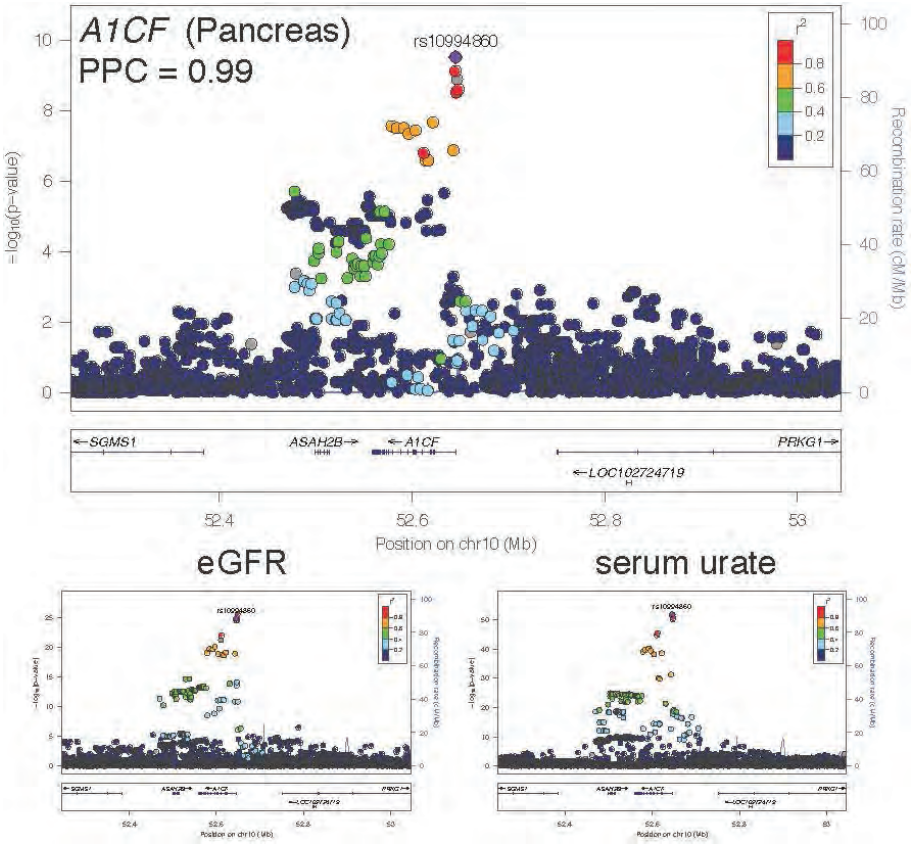

Figure 2. Regional association plots at the A1CF locus for an A1CF eQTL in pancreas (above) and corresponding urate and eGFR associations (below). The color of the surrounding SNPs indicates the strength of LD with the lead A1CF eQTL SNP (in purple) according to the key in the left top hand corner, measured as r2 found in the European HapMap data (hg19/1000 genomes Nov 2014). The plots were generated using LocusZoom.

cance. The extensive genetic signal shared between eGFR/SU suggests that pleiotropy, acting through gene expression differences, contributes to the genetic basis of the association between gout/HU and CKD.

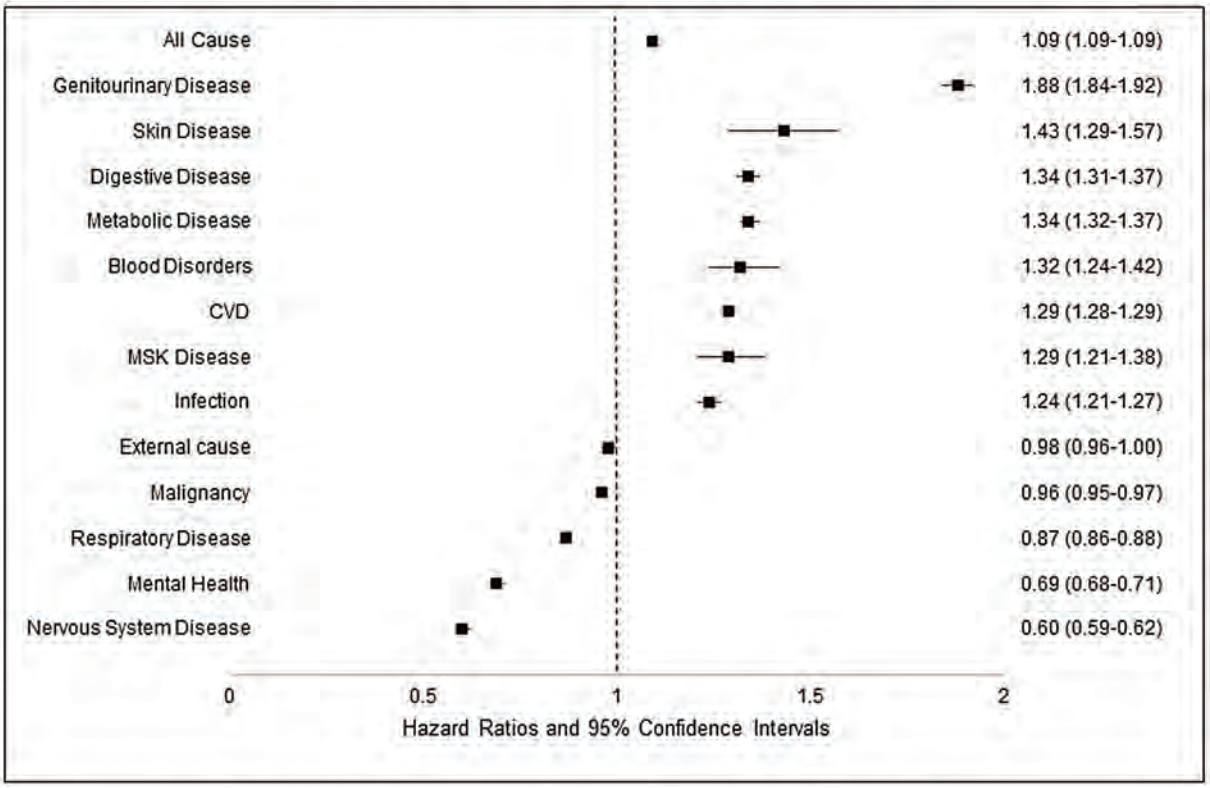
*Gout and non-gout cases matched on age and sex; all other factors shown differed ($p < 0.05$) between groups

Background/Purpose: Gout is the most common type of inflammatory arthritis, with a prevalence in the Veteran's Health Administration (VHA) of nearly 6%. While gout flares prompt patients to seek medical attention, the longer-term consequences of gout are important considerations for patients, clinicians, and health systems. Associated with increased all-cause mortality, an understanding of the cause-specific mortality risk in gout remains incomplete. The purpose of this study was to compare all-cause and cause-specific mortality risk between gout and non-gout patients in the VHA.

Methods: We performed a retrospective, matched cohort study, identifying patients with gout using the VHA administrative data from 1/1999-9/2015 based on the presence of ≥2 ICD-9 codes for gout (274.X). The index date was defined as the date of the 2nd diagnostic code. Gout patients were matched up to 1:10 on birth year, sex, and year of VHA enrollment with non-gout patients (no prior diagnostic codes or urate lowering therapy). Patients were followed from the index date until death, censoring due to end of study period or subsequently fulfilling the gout algorithm (non-gout patients could cross-over and contribute to gout "at risk" observation). Vital status and cause of death (20

Figure 1. Associations of Gout with All-Cause and Cause-Specific Mortality in the Veteran's Health Administration



*Top causes by category: Malignancy (lung, prostate, and colon); Respiratory (COPD and pneumonia); Metabolic disease (diabetes mellitus and hyperlipidemia); Genitourinary disease (CKD, acute renal failure, and urinary tract infections); Digestive disease (cirrhosis and GI bleed); Nervous system disease (Alzheimer's disease and Parkinson's disease); Mental Health (dementia and vascular dementia); MSK disease (osteomyelitis and rheumatoid arthritis); Skin disease (cellulitis and decubitus ulcer); Blood disease (anemia and coagulation defect).

unique ICD-10 chapters) were obtained from the National Death Index (through 12/2017). Associations of gout with all-cause and cause-specific mortality were examined using Cox regression.

Results: Gout patients (n = 559,253) were matched to 5,431,582 non-gout controls. Gout patients had a higher BMI and greater comorbidity (**Table 1**). There were 246,291 deaths over 4,250,477 patient-years in gout patients and 1,995,863 deaths over 40,469,354 patient-years of follow-up in controls. Associations of gout with all-cause and cause-specific mortality are shown in **Figure 1**. The strongest associations of gout with cause-specific mortality were observed with genitourinary conditions. Kidney failure was the most common specific cause of death in this category. Of the 20 unique ICD-10 chapters examined, mortality was increased among gout patients for 8 specific causes. In contrast, gout patients were at lower risk from death related to neurologic (e.g., Alzheimer's, Parkinson's, and other neurodegenerative disorders), mental health, respiratory, and malignancy related conditions.

Conclusion: Using data from the largest integrated health system in the U.S, we found that gout patients in the VHA have an ~10% higher rate of all-cause mortality. Although patients with gout are well recognized to have higher all-cause and cardiovascular mortality, these results suggest that survival is negatively impacted by a number of other health conditions with genitourinary causes acting as the most over-represented cause of death in gout. Likewise, these data suggest that gout patients exhibit a survival advantage for both neurologic and mental health causes. Additional research examining factors associated with cause-specific survival in this Veteran population are needed as this could inform future strategies aimed at improving long-term outcomes in gout.

Analysis of Common Gout Comorbidities in the UK Biobank Cohort Reveals Sex-Specific Effects and Genetic Differentiation

Nicholas Sumpter[1], Murray Cadzow[2], Alexander So[3], Richard Reynolds[1] and Tony Merriman[2], [1]University of Alabama at Birmingham, Birmingham, AL, [2]University of Otago, Dunedin, New Zealand, [3]University of Lausanne, Lausanne, Switzerland

SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: Metabolic & Crystal Arthropathies Poster
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: This study aimed to estimate the extent to which gout associated genetic variants are associated with the presence/absence of common comorbidities in gout patients of the UK Biobank cohort. Previous studies have shown that the odds-ratios of comorbidities tend to be higher among women in comparison to men (Dirken-Heukensfeldt et al., 2010; Zhu et al., 2012).

Methods: The total cohort size for this study was 332,360 (mean [SD] age was 57.1 [7.9] years old; 48% male). Common gout comorbidities (hypertension, type 2 diabetes, obesity, dyslipidemia, chronic kidney disease (CKD), liver disease, coronary heart disease, heart failure, cerebrovascular disease and sleep apnea) were defined using self-report data, ICD-10 codes, medications and measured biomarkers/metrics.

Trait	Number (whole cohort)	Percentage (whole cohort)	Number (gout only)	Percentage (gout only)
Gout	7,131	2.15	7,131	100.00
Hypertension	117,129	35.24	4,949	69.40
Dyslipidemia	77,061	23.19	3,581	50.22
Type 2 diabetes	20,352	6.12	1,278	17.92
Renal failure	163	0.05	28	0.39
CKD stage 3	13,255	3.99	894	12.54
CKD stage 4	664	0.20	148	2.08
CKD stage 5	431	0.13	100	1.40
Obesity	76,625	23.05	3,428	48.07
Coronary heart disease	31,685	9.53	1,549	21.72
Heart failure	5,938	1.79	465	6.52
Cerebrovascular disease	11,078	3.33	490	6.87
Sleep apnea	4,503	1.35	312	4.38

Table 1. Prevalence of comorbidities.

rs738409 (*PNPLA3*)	1.11 [0.98; 1.26]	0.085

Table 3. Genetic analysis of the presence of any comorbidity among gout patients.

Each comorbidity was tested for association with gout using generalized linear models, adjusted for age and sex, and in sex-specific models, adjusted for age.

Variant genotypes from 12 genome-wide significant gout loci (from the UK Biobank) were used to calculate an effect size weighted gout genetic risk score (GRS). The GRS was tested for association, using a generalized linear model, with the presence of any comorbidity within the gout cohort (N = 7,131), adjusting for age and sex. Each variant was also tested separately.

Results: The prevalence of comorbidities in the whole cohort ranged from 1.8% (heart failure) to 35.2% (hypertension) (Table 1). All comorbidities were roughly 2-3x as common in gout patients alone relative to the entire cohort,

ranging from 6.5% (heart failure) to 69.4% (hypertension) (Table 2). Additionally, we showed that these comorbidities are more prevalent in female gout cases, with all odds ratios showing higher, non-overlapping confidence intervals in females compared to males.

The GRS was confirmed to associate with gout in the entire cohort (OR = 1.73 [95%-CI: 1.69; 1.77], $P < 10^{-300}$). The GRS associated with a reduced likelihood of having any comorbidity among gout patients (Table 3). This was largely driven by variants at the *ABCG2* locus and the *ADH1B* locus, which associated significantly on their own.

Conclusion: This study showed evidence for a stronger likelihood of comorbidities among female gout cases in comparison to males. We also established that there is a significant contribution of gout genetic risk variants to the presence or absence of any comorbidity in gout patients. Variants at the *ABCG2* and *ADH1B* loci contributed the most to this association, showing significance when modeled alone with presence of any comorbidity. This likely represents the concept of primary versus secondary gout, with a higher genetic risk amongst individuals without comorbidities (primary gout) and a second group of individuals with lower genetic risk but prevalent comorbidities (secondary gout).

Uric Acid Level Is Associated with Severity of Heart Failure with Preserved Ejection Fraction

Ana B. Arevalo[1], Alba Munoz[2], Faris Haddadin[2], Karan Sud[2], Gustavo Contreras[2], Shane Murray[2], Yousaf Ali[2] and Edgar Argulian[2], [1]Mount Sinai St. Luke's-West/ Icahn School of Medicine, New York, NY, [2]Mount Sinai St. Luke's-West/ Icahn School of Medicine, New York

SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: Metabolic & Crystal Arthropathies Poster
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Hyperuricemia (HUC) has been shown to have an impact in the left atrium and left ventricle remodeling leading to the development of heart failure (HF).

Experimental studies have shown that the increase of HUC results in cardiomyocyte hypertrophy, myocardial oxidative stress, interstitial fibrosis, and impaired diastolic relaxation. Ultimately, patients with HUC may also develop heart failure with preserved ejection fraction (HFpEF).

Methods: We conducted a cross-sectional study to determine the correlation between serum uric acid levels and the severity of HFpEF, after receiving the Institutional Review Board (IRB) approval (IF2467628). HUC was defined as a mean serum uric acid level equal to or more than 7.0 mg/dL. 161 patients with a diagnosis of HUC were screened by chart review between January 2016 to December 2018 following these inclusion criteria: 1) reported HUC at least one year before the echocardiogram (TTE) was performed, 2) echocardiographic parameters to classify the severity of diastolic dysfunction.

Fisher's exact test was used for qualitative variables and Pearson chi-square test for quantitative variables. Multiple regression analysis, including potential confounders factors (age, gender, race, use of uric acid lowering agents, use of Losartan, low-dose Aspirin, diuretic agent, use of more than 3 blood pressure-lowering agents, history of comorbid

Table 1. Baseline Characteristics

conditions related to diastolic dysfunction (HTN, resistant HTN, Afib, DM, obesity, CKD), presence of Gout and mean ejection fraction) was performed. Calculation of coefficient ratios and their 95% confidence interval for the association between mean uric acid level and grade of severity of diastolic dysfunction was performed. P-value < 0.05 was considered statistically significant. STATA (IC-15.1; Stata Corp) was used for the statistical analysis.

Diastolic dysfunction grade	Mean uric acid level (+/- SD)	P value
Normal Grade I Grade II Grade III	7.54 +/- 1.64 8.67 +/- 1.91 8.71 +/- 3.44 12.54 +/- 3.10	< 0.001

	Normal	Grade I	Grade II
Grade I	1.12 P=0.752		
Grade II	1.16 P=0.999	0.04 P=0.999	
Grade III	4.99 P < 0.001	3.86 P=0.009	3.83 P=0.020

Table 2. Mean uric acid level across diastolic dysfunction grades

	Mean uric acid level in normal and impaired relaxation vs higher grade diastolic dysfunction	Coef. (95% CI)	P value
Unadjusted risk of higher-grade diastolic dysfunction with mean uric acid level	8.06 ±0.29 vs 9.36 ±1.09	0.034 (-0.009 to 0.077)	0.119
Adjusted* risk of higher-grade diastolic dysfunction with mean uric acid level		**0.053 (0.001 to 0.106)**	**0.047**
***Adjusted** to age, gender, race, use of uric acid lowering agents, use of Losartan, use of low-dose Aspirin, use of a diuretic agent, use of more than 3 BP lowering agent, history of comorbid conditions related to diastolic dysfunction (HTN, resistant HTN, Afib, DM, obesity, CKD), presence of gout and mean ejection fraction.			

Table 3. Correlation between mean uric acid level and the severity of HFpEF

Results: Out of the 161 patients, 56 patients met our inclusion criteria of which 78.6 % had a mean uric acid level above 7 mg/dL. For normal left ventricle function and Grade I diastolic dysfunction group, the mean age was 65.8 (±13.6) years and mean uric acid level was 8.06 (±0.29) mg/dL, as compared to 60.1 (±20.8) years and mean uric acid of 9.36 (±1.09) mg/dL for Grade II and III diastolic dysfunction group. 47.5% of patients with normal and impaired relaxation were on a uric acid lowering agent versus 62.5% of patients in the group with higher grade diastolic dysfunction. 85% of the low-grade diastolic dysfunction group had a co-existing diagnosis of Gout versus 93.7% of the group with grade II and III diastolic dysfunction. The difference of mean uric acid level between Grade III diastolic dysfunction and normal diastolic function was of 4.99 mg/dL ($p< 0.001$), 3.86 mg/dL ($p= 0.009$) for Grade I and 3.83 mg/dL ($p= 0.020$) for Grade II diastolic dysfunction. Our results (Table 4) showed that the risk of severe diastolic dysfunction increases by 0.053 (95%-CI 0.001-0.106; $p= 0.047$) for every unit of increase in mean of uric acid level.

Conclusion: There is a directly proportional correlation between the level of uric acid and the severity of diastolic dysfunction. The group with higher diastolic dysfunction had a higher prevalence of Gout independent of confounding variables.

Abstract Number: 0665

Trends in Immunomodulation/pegloticase Co-therapy from 2015-2019: A Claims Database Study

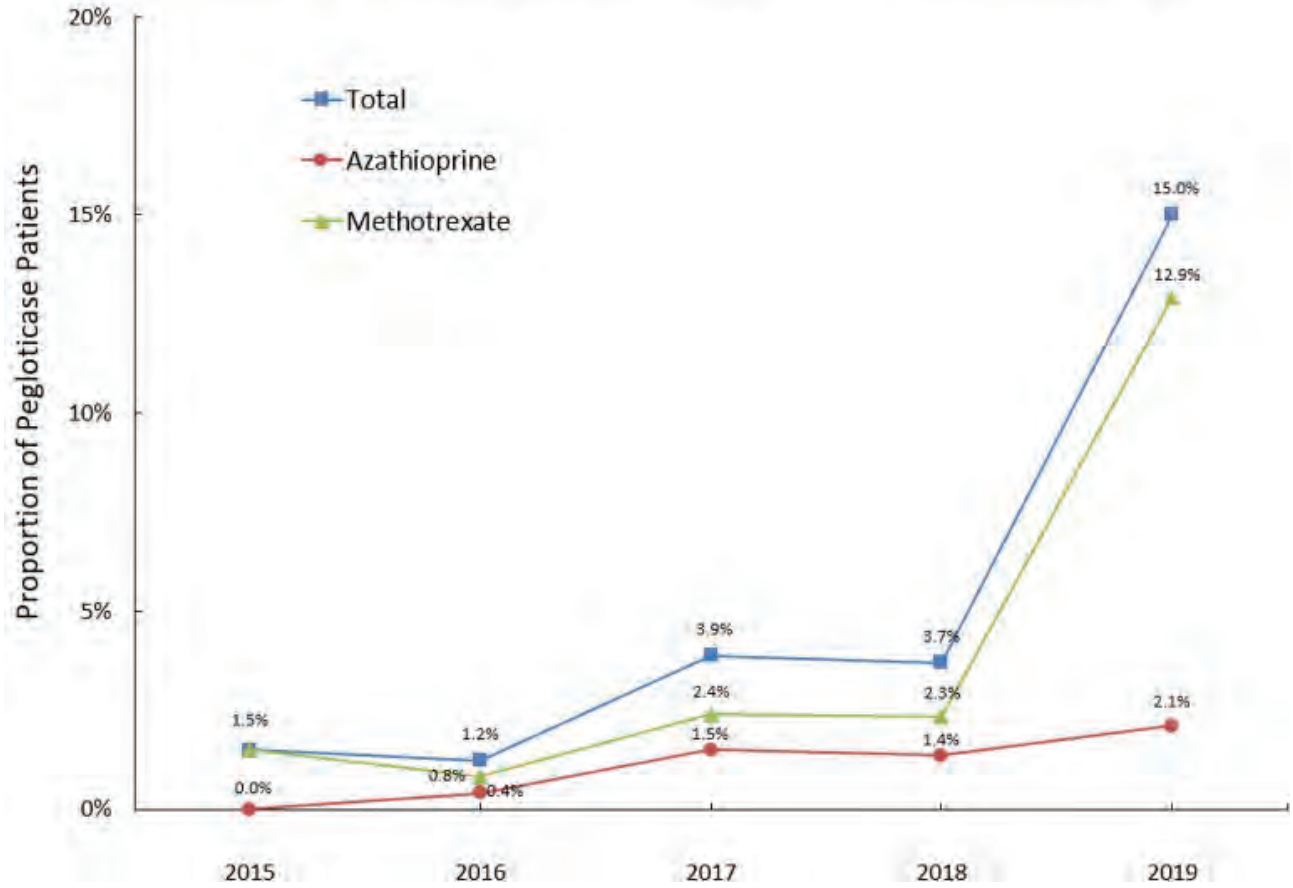
Brian LaMoreaux[1], **John Botson**[2], Megan Francis-Sedlak[1], Karl Svensson[1] and Robert Holt[1], [1]Horizon Therapeutics plc, Lake Forest, IL, [2]Orthopedic Physicians Alaska, Anchorage, AK

SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: Metabolic & Crystal Arthropathies Poster
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Pegloticase, a recombinant, PEGylated uricase enzyme, is used to treat uncontrolled gout in patients who do not improve on or are intolerant of oral urate-lowering therapies. As with other biologics, anti-drug antibodies (ADAs) against pegloticase can develop and cause infusion reactions and loss of treatment efficacy.[1] As a result of ADA formation, the pegloticase response rate in clinical trials was 42%.[2] DMARDs (e.g., azathioprine, methotrexate) are frequently used when treating autoimmune diseases with biologics to attenuate ADA development, often resulting in a more successful response to biologic therapy, and lower adverse event rates.[3] Starting with a case-series presentation in late 2018, growing evidence in the literature supports using pegloticase with immunomodulation co-therapy, consistently showing a marked increase in treatment responder rates.[4-8] However, little is known about whether this practice is being implemented in clinical practice and, if so, how treatment patterns have changed over time. This study examined a large medical claims database to better understand immunomodulator use with pegloticase in the United States.

Methods: The IQVIA database contains 1.3 billion claims (made from November 2014 thru December 2019) of 30 million patients diagnosed with gout or chronic kidney disease. Patients who had received pegloticase were identified and classified based on immunomodulator use. Patients who were prescribed methotrexate or azathioprine within 60 days (before or after) of receiving the first pegloticase infusion were considered to have received co-administration of pegloticase/immunomodulator.

Figure 1: Proportion of pegloticase patients receiving immunomodulation therapy by year



Note – Immunomodulation/pegloticase co-therapy usage defined as any patient starting either methotrexate or azathioprine within 60 days before or after their first pegloticase infusion, excluding immunotherapy usage one year before starting pegloticase.

Results: Pegloticase/immunomodulation co-therapy rates were consistently low (1.2%-3.9%) from 2015 through 2018 (Figure 1). However, this rate markedly increased to 15.0% in 2019. The majority of patients (86%) who started an immunomodulator did so within 30 days of their first pegloticase infusion. Methotrexate was more commonly used as the immunomodulator compared to azathioprine.

Conclusion: A dramatic increase in the use of immunomodulators with pegloticase was observed in 2019, most likely sparked by a case series presented in November 2018 that showed a marked improvement in treatment response rate with methotrexate/pegloticase co-therapy[4,5] compared to pegloticase alone.[2] Therefore, physicians appear to be using DMARDs with increasing frequency in patients with uncontrolled gout who are treated with pegloticase to potentially maximize treatment response rates. Controlled trials are currently ongoing to further validate this therapeutic approach.

Identification of Intracellular Vacuoles in Synovial Fluid with Calcium Pyrophosphate and Monosodium Urate Crystals

Maria Luisa Peral[1], Irene Calabuig[1], Ana Martín-Carratalá[2], Mariano Andrés[1] and Eliseo Pascual[1], [1]Hospital General Universitario de Alicante-ISABIAL and Universidad Miguel Hernández de Elche, Alicante, Spain, [2]Universidad Miguel Hernández de Elche, Alicante

SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: Metabolic & Crystal Arthropathies Poster
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Synovial fluid analysis using polarized microscopy is the gold standard for the diagnosis of crystal-related arthritis. In our experience, we have noted that, when calcium pyrophosphate(CPP) crystals are observed, they sometimes appear within intracellular vacuoles. However, this phenomenon is not seen in those samples containing monosodium urate (MSU) crystals.This finding has been scantly reported in the literature, but may be useful in clinical practice to ensure accurate crystal identification.

Objectives: our study aims to assess hether the presence of vacuoles contributes to identifying the type of crystal, and also to gauge the frequency of their presentation.

Methods: We conducted an observational study in a rheumatology unit between February and June of 2019. Synovial fluids containing CPP or MSU crystals, obtained in daily clinical practice, were consecutively included for analysis. Two observers simultaneously analyzed the presence of vacuoles by ordinary light and phase contrast microscopy in less than 24 hours after their extraction, using a microscope equipped with two viewing stations. The primary study variable was to determine whether CPP and MSU crystals are seen inside intracellular vacuoles, and to calculate the frequency of this finding for each type of crystal, stimating their 95% confidence interval (95% CI) and comparing rates using Fisher's exact test.

Results: Twenty-one samples were obtained. Data is given in the Table. MSU crystals were present in 7 (33.3%) and CPP crystals in 14 (66.6%). Interestingly, none of the MSU samples showed crystal-containing vacuoles (95% CI 0-35.4%). On the contrary, cytoplasmic vacuoles containing crystals were present in all of the CPP samples (95% CI 78.5-100%). The findings were confirmed by phase-contrast microscopy. Differences were statistically significant ($p< 0.001$).

SAMPLES ACCORDING TO TYPE OF MICROCRYSTAL (n=21)	SAMPLES WITH VACUOLES (UNDER ORDINARY LIGHT)	SAMPLES WITH VACUOLES (UNDER PHASE CONTRAST)
CPP (14; 66.6%)	14 (100%) *(95%CI 78.5-100%)*	14 (100%) *(95%CI 78.5-100%)*
MSU (7; 33.3%)	0 (0%) *(95%CI 0-35.4%)*	0 (0%) *(95%CI 0-35.4%)*

Table 1. Results

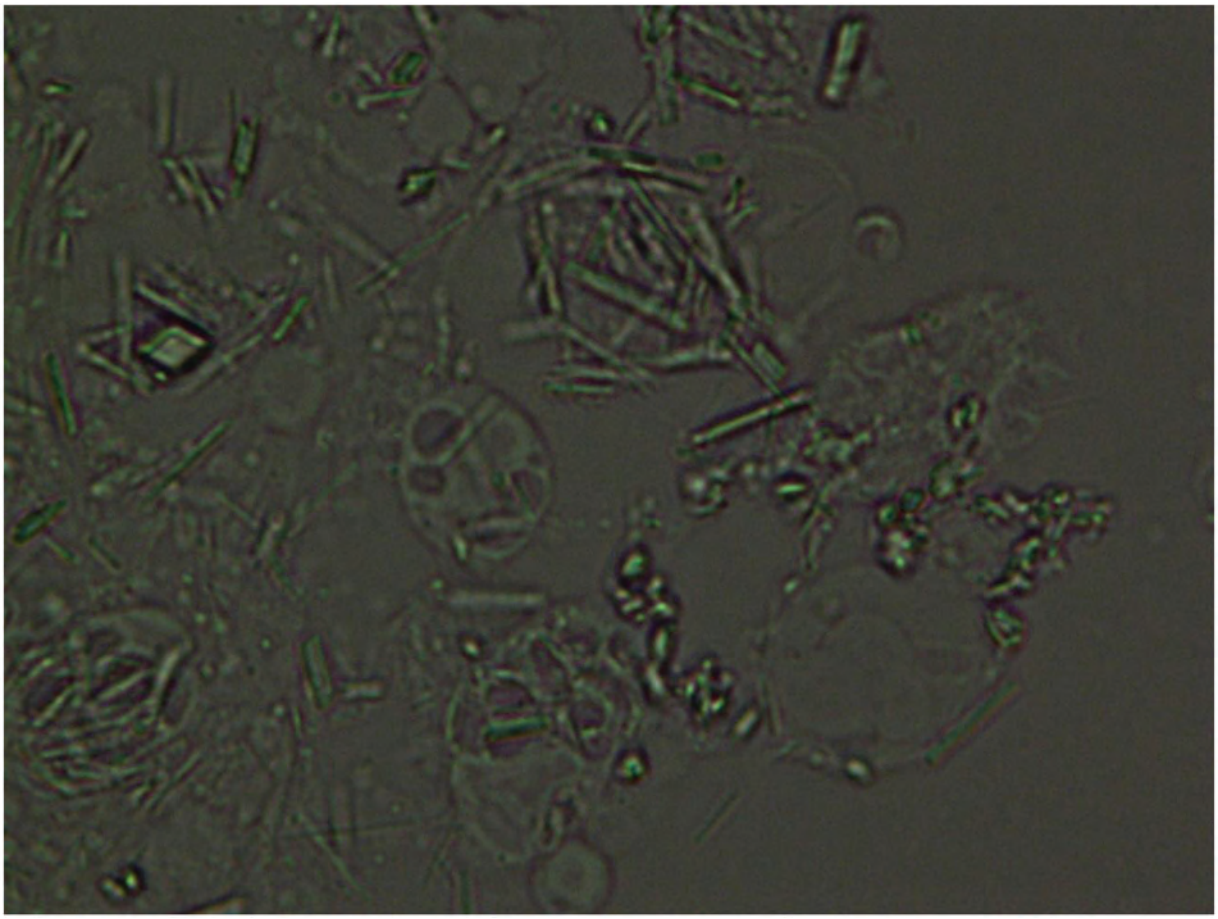

Image 1. Microscopy with ordinary light. Cells with cytoplasmic vacuoles are observed, as well as abundant intra and extracellular CPP crystals.

Conclusion: The presence of vacuoles may be a useful and easy way to differentiate MSU and CPP crystals when performing synovial fluid microscopy in clinical practice, since it appears to be a distinctive feature in CPP crystal fluids.

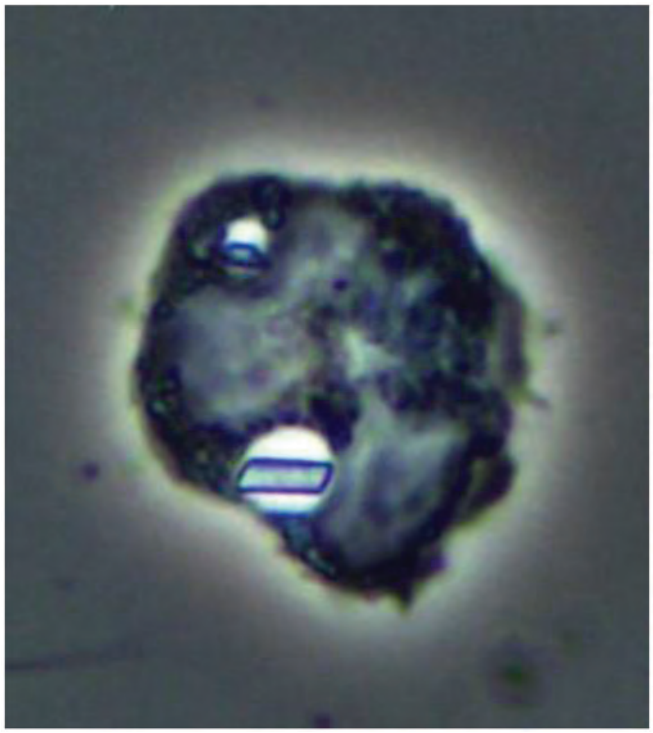

Image 2. Microscopy with phase contrast technique. Cells with intracellular vacuoles are observed inside which have microcrystals with parallelepiped morphology, compatible with CPP.

Gout Management Beyond Prescription Writing: The Role of the Pharmacist

Emma Dorris[1], Paul Ryan[2], Mariosa Kieran[3], Nicola Dalbeth[4] and Geraldine McCarthy[5], [1]School of Medicine, Dublin, Dublin, Ireland, [2]Mayfield Family Practice, Cork, Cork, Ireland, [3]Pharmacy Department, Dublin, Dublin, Ireland, [4]University of Auckland, Auckland, New Zealand, [5]University College Dublin, Dublin, Dublin, Ireland

SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: Metabolic & Crystal Arthropathies Poster
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Urate lowering therapy (ULT) is recommended for long-term gout management. However, gout flares are common at the time of starting ULT, and these flares can impact on adherence to ULT. Co-prescription of low dose colchicine as anti-inflammatory prophylaxis is recommended for the first 6 months of ULT. Pharmacists play a key role in community gout education. We investigated pharmacist knowledge of gout treatment. In response to the findings, an educational intervention was developed and assessed in a cohort of Irish pharmacists.

Methods: A ten-question questionnaire about gout management was developed as per Kelley (2003 (1)). Non-random sampling was used. The survey was disseminated through the Pharmaceutical Society of Ireland, PharmaBuddy

Knowledge of Gout Management Survey	Answer Options	Frequency
Where is your primary area of practice?	Community	155 (89.6%)
	Hospital	14 (8.1%)
	Academia	1 (0.6%)
	Industry	1 (0.6%)
	Other	2 (1.2%)
Urate-lowering therapy (ULT) is targeted to serum urate level	True	126 (72.8%)
	False	17 (9.8%)
	Don't Know	28 (16.2%)
First-line therapy for gout involves a combination of a xanthine oxidase inhibitor (e.g. allopurinol) combined with a prophylactic agent (e.g. colchicine)	True	61 (35.3%)
	False	109 (63.0%)
	Don't Know	3 (1.7%)
Colchicine at a dose of 0.5mg twice daily should be given in combination with urate lowering therapy (ULT) for at least 6 months after initiation of ULT, as a prophylaxis for gout flares	True	50 (28.9%)
	False	109 (63.0%)
	Don't Know	14 (8.1%)
It is common for gout to flare when. . .	Starting ULT	66 (38.2%)
	Stopping ULT	28 (16.2%)
	Increasing ULT	3 (1.7%)
	All of the Above	64 (37.0%)
	None of the above	12 (6.9%)
Patients should stop ULT during a gout attack	True	42 (24.3%)
	False	116 (67.1%)
	Don't Know	15 (8.7%)
Patients are advised to take colchicine continuously for six months or longer after initiation of ULT	True	39 (22.5%)
	False	117 (67.6%)
	Don't Know	17 (9.8%)
Patients should dose-reduce rather than stop colchicine if they experience side-effects (e.g. diarrhoea)	True	77 (44.5%)
	False	72 (41.6%)
	Don't Know	24 (13.9%)
Which information sources for colchicine do you find helpful?	BNF	148 (85.5%)
	SPC	100 (57.8%)
	Guidelines (e.g. EULAR or ACR)	15 (8.7%)
Cost of gout medication is a factor in patient non-adherence	Agree	40 (23.1%)
	Disagree	87 (50.3%)
	Neither Agree nor Disagree	46 (26.6%)

Knowledge Of Gout Management Survey

(a pharmacist-only closed forum) and word-of-mouth. Survey analysis employed factor analysis with varimax principal component analysis (PCA) and frequency analysis. An educational intervention was co-developed between a consultant rheumatologist and a general practitioner who also works as a community pharmacist in the form of a 13-minute video tutorial on pharmaceutical gout management. The effectiveness of this intervention was assessed via the same questionnaire in a cohort of n=53 (n=25 intervention group; n=28 control group of pharmacists who had not watched the video). Data was analysed via frequency analysis using Pearson's Chi-Square test for association between groups.

Results: There was n=173 pharmacist respondents to the initial survey. 63% did not know that first-line therapy for gout involves a combination of a xanthine oxidase inhibitor combined with a prophylactic agent. 22.5% of respondents knew patients were advised to take colchicine continuously for six months or longer after initiation of ULT. 28.9% selected 'true' to the statement that colchicine twice daily in combination with ULT acted as a prophylaxis for gout flares. Regarding side-effects, 45% believed patients should dose-reduce rather than stop colchicine if they experience side-effects such as diarrhoea, with 42% selecting false and 14% unsure. (Table 1).

Following educational intervention, pharmacists where more likely to know patients are advised to take colchicine continuously for six months after initiation of ULT (84% intervention group compared to 36% control, p=*0.002*). Furthermore, they understood colchicine was given up to twice daily in combination with ULT as a prophylaxis for gout flares (84% intervention, 32% control, *p=0.001*) and that the goal of ULT is to reduce serum urate level (96% intervention, 68% control, *p= 0.029*). There was no difference in community: hospital practice between intervention and control groups (*p=0.74*).

Conclusion: Gout management recommendations can be impeded if translation into pharmacy practice is neglected. Pharmacists are a valuable information resource for patients. Low-cost educational interventions can greatly improve their knowledge of gout management and in turn empower patients to assume self-management of gout.

Abstract Number: 0668

Outcomes and Resource Utilization After Total Knee Arthroplasty in Calcium Pyrophosphate Crystal Deposition Disease Patients: Insights from the National Inpatient Sample Database

Konstantinos Parperis[1], **Mohanad Hadi**[2] and Bikash Bhattarai[3], [1]University of Arizona College of Medicine Phoenix and University of Cyprus Medical School, Phoenix, [2]Creighton University - Maricopa Medical Center/ Valleywise Health Medical Center, Phoenix, AZ, [3]Valleywise Health, University of Arizona College of Medicine, Phoenix, AZ

SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: Metabolic & Crystal Arthropathies Poster
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Total knee arthroplasty (TKA) is one of the most frequently performed orthopedic procedures in patients with joint cartilage destruction. Calcium pyrophosphate crystal deposition (CPPD) disease is a crystal-induced arthropathy characterized by the deposition of calcium pyrophosphate crystals in the articular and periarticular tissues that might lead to inflammatory arthritis, joint damage and the need for TKA. No prior studies exist evaluating the outcomes of CPPD patients after TKA. We aim to determine the in-hospital complications, mortality, and resource utilization following TKA in patients with and without CPPD.

Methods: We queried the US National Inpatient Sample (NIS) Database from 2009-2014 in order to identify patients who had TKA. The ICD-9 code was used to identify the patients who underwent primary TKA (81.54, V43.65), and of those, we classified the patients into two groups: (i) with ICD-9 codes defining CPPD (275.49 and 712.1–712.39) and (ii) those without any CPPD code. Data collection included patient demographics and co-morbidities. Outcomes after-TKA were in-hospital mortality, length of hospitalization, hospital charges, in-hospital complications such as surgical site infections, blood loss and need for transfusion, re-operation, thromboembolism, popliteal artery injury, peroneal nerve palsy. Associations between CPPD and specific morbidity were evaluated with chi-square tests. Wilcoxon rank-sum tests were used for continuous variables.

Results: Among the 4,180,274 (adjusted for sampling weight) patients who have undergone TKA during the 7-year period (2009-2014), 7660 (0.18%) had CPPD, with a median age of 73 years and 57.9% were females (Table). Compared with patients without CPPD, patients with CPPD patients were more likely to be older (median age78 vs 73 years; $p< 0.0001$). Co-morbidities that were more frequent among CPPD patients included chronic kidney disease, gout and knee fracture. Regarding postoperative complications, the need for re-operation was significantly more common in CPPD patients ($p < 0.0001$). Further, TKA in CPPD patients was associated with prolonged median length of stay than those without CPPD (4 vs 3 days; $p < 0.0001$), although the median total charges were higher in the CPPD

Table. Demographics, clinical characteristics, outcomes and resource utilization of patients with and without CPPD who undergone total knee arthroplasty.

	No CPDD, n (%)	CPPD, n (%)	P-value*
Age in years at admission, median (mean ± SD)	71 (72.0 ± 26.2)	78 (75.7 ± 24.2)	<0.001†
Female	2623105 (62.8)	4439 (57.9)	<0.001

Resource utilization			
Length of stay, median (mean ± SD)	3 (4.67 ± 10.23)	4 (5.54 ± 12.21)	<0.001†
Total hospital charges, median (mean ± SD)	$30,272 (43753 ± 111227)	$30, 718 (45092 ± 123920)	0.440†
Death during hospitalization	51354 (1.2)	50 (0.65)	<0.001

*Chi-square P except †Wilcoxon rank-sum

group, this finding was not statistically significant ($30,718 vs $30,272; p=0.44). The in-hospital mortality was lower in the CPPD patients (0.65 vs 1.2; p< 0.001).

Conclusion: To our knowledge, this the first study demonstrating that patients with CPPD patients who had undergone TKA were more likely to be older than those without CPPD, had increased length of stay; however, the in-hospital mortality was lower. These findings merit further study.

Calcium Pyrophosphate Crystal Deposition in Gouty Tophi

Hang-Korng Ea[1], Alan Gauffenic[2], Quand Nguyen[3], Nhu Pham[3], Oceane Olivier[2], Vincent Frochot[4], Dominique Bazin[5], Nghia Le[3], Caroline Marty[2], Agnès Ostertag[2], Martine Cohen-Solal[1], Jean-Denis Laredo[6], Pascal Richette[7] and Thomas Bardin[8], [1]Université de Paris, INSERM UMR 1132, BIOSCAR, AP-HP, DMU Locomoteur, Paris, France, [2]Université de Paris, INSERM UMR 1132, BIOSCAR, Paris, France, [3]Vien Gut Medical Center and French-Vietnamese research center on gout and chronic diseases, Ho Chi Ming, Vietnam, [4]Hôpital Tenon, Service des explorations fonctionnelles multidisciplinaires, Sorbonne université, UMR_S1155, Paris, France, [5]Institut de Chimie Physique, Université Paris-Saclay et CNRS - UMR8000, Orsay, France, [6]AP-HP Université de Paris, Paris, [7]Department of Rheumatology, Lariboisière Hospital, AP-HP Université de Paris, INSERM U1132, Paris, [8]Université de Paris, INSERM U1132 and Hôpital Lariboisièe, Paris, France, Paris, France

SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: Metabolic & Crystal Arthropathies Poster
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: The coexistence of calcium pyrophosphate (CPP) and monosodium urate crystals is rarely reported in gouty tophi. We investigated CPP crystal deposits in a series of gouty tophi removed by surgery and associated factors.

Methods: 25 tophi from 22 patients were analyzed by light microscopy, field-emission-scanning electron microscopy (FE-SEM) and μ Fourier transform infrared (FTIR) spectroscopy

Results: Tophi consisted of multiple lobules separated by fibrous septa and surrounded by a foreign-body giant cell reaction. CPP crystal aggregates were identified in 8 of 25 tophi from 5 patients. CPP crystals were dispersed or highly compacted, localized at the edge or inside the tophus lobules or filled some of them. Both monoclinic and triclinic CPP crystal phases were identified by FE-SEM and μ FTIR. As compared with patients without CPP, those with CPP-containing tophi were older (mean 61.2 vs 47.8 years, p=0.009), and had long-term gout (mean 19.0 vs 9.0 years, p=0.007) and tophus (mean 11.4 vs 4.7 years, p< 0.0001). None had radiological chondrocalcinosis of the knee or wrist

Conclusion: CPP crystal formation seems to be a late and frequent event of tophus maturation and could contribute to the apparent persistence of tophus sometimes observed even after long-lasting and efficient urate-lowering therapy.

Risk Factors for Pseudogout: An Electronic Medical Record Case-Control Study

Sara Tedeschi[1], Kazuki Yoshida[1], Weixing Huang[2] and Daniel H. Solomon[1], [1]Brigham & Women's Hospital and Harvard Medical School, Boston, MA, [2]Division of Rheumatology, Inflammation, and Immunity; Brigham and Women's Hospital and Harvard Medical School, Boston

SESSION INFORMATION

Session Date: Saturday, November 7, 2020

Session Title: Metabolic & Crystal Arthropathies Poster

Session Type: Poster Session B

Session Time: 9:00AM–11:00AM

Background/Purpose: Prior studies of calcium pyrophosphate crystal deposition disease (CPPD) epidemiology either focused on the entire spectrum of CPPD or identified patients with its acute manifestation, pseudogout, using single non-validated diagnosis codes. We investigated previously identified risk factors for CPPD or pseudogout—including bisphosphonates, diuretics, osteoarthritis, and hyperparathyroidism—among well-defined pseudogout patients.

Methods: We performed a case-control study by applying a validated algorithm to identify pseudogout cases using electronic medical record (EMR) data (PPV 81%) at an academic medical center. Case index date was the earlier of 1st positive synovial fluid calcium pyrophosphate crystal analysis or 1st natural language processing concept "pseudogout" in narrative notes. Cases were matched to up to 4 general EMR controls not classified as pseudogout by the algorithm. Matching occurred on year of 1st EMR encounter and index date (encounter ±30d of case index date). We required age ≥50 at index date and ≥2 encounters in the 365 days before index date for cases and controls. We pre-specified covariates of interest: (1) comorbidities previously associated with CPPD in the literature, identified by ≥1 billing code from 1st EMR encounter through index date and (2) prescriptions for medications previously associated with CPPD in the literature, recorded in the 90 days prior to and including index date. A multimorbidity score was calculated for each patient using a validated method based on billing codes for 40 conditions. A multivariable logistic regression model estimated the odds ratio (OR) and 95% CI for each pre-specified covariate adjusted for age, total number of encounters from 1st EMR encounter through index date, multimorbidity score, and all pre-specified covariates.

Table. Characteristics and odds ratios (95% CI) for pseudogout

	Acute CPP crystal arthritis cases n=1856	General patient controls n=7180	Multivariable-adjusted odds ratio (95% CI)*
Male	47.7	43.0	1.42 (1.25, 1.61)
Race			
White	82.3	80.2	1.00 (Ref)
Black	7.4	10.9	0.53 (0.42, 0.67)
Other or unknown	10.2	9.0	1.03 (0.84, 1.26)
Comorbidities*			
Osteoarthritis	66.4	30.2	3.92 (3.43, 4.48)
Hyperparathyroidism	4.4	1.2	2.36 (1.54, 3.64)
Hypomagnesemia	2.9	0.6	2.07 (1.18, 3.62)
Hypophosphatasia	0.8	0.2	1.20 (0.50, 2.85)
Hemochromatosis	0.7	0.1	6.43 (2.02, 20.43)
Medications**			
Proton pump inhibitor	26.3	9.6	2.00 (1.69, 2.37)
Loop diuretic	15.7	5.8	1.75 (1.42, 2.15)
Thiazide diuretic	10.7	6.4	1.38 (1.11, 1.72)
Bisphosphonate	3.9	2.4	1.06 (0.75, 1.49)

Values are percentages or odds ratio (95% CI)

*Multivariable model includes all covariates listed in the table, age at index date, total number of encounters from 1st EMR encounter through index date, and multimorbidity score based on ICD-9 billing codes for 40 chronic conditions (Radner H, et al. Seminars Arthritis Rheum 2015;45:167-73)

*Defined by ≥ 1 ICD-9 or ICD-10 from 1st EMR encounter through index date

**Prescribed at any time from 90 days before index date through index date (oral or intravenous)

Results: We identified 1856 cases matched to 7180 controls. Mean age was 73 years, 56.0% were female, 80.6% white, 10.2% black, and 9.2% other/unknown race. Among pseudogout patients, 12.8% were age 50-59, 25.9% age 60-69, 31.7% age 70-79, and 29.6% age ≥80. Each of the pre-specified covariates were more common in pseudogout cases than controls (Table). Risk for pseudogout was significantly higher for patients with osteoarthritis (OR 3.92), male sex (OR 1.42), proton pump inhibitors (OR 2.00), loop diuretics (OR 1.75), thiazides (OR 1.38), and rare metabolic disorders including hyperparathyroidism, hypomagnesemia, and hemochromatosis. Bisphosphonates were not significantly associated with pseudogout. Black race was associated with significantly lower risk for pseudogout compared to white race (OR 0.53).

Conclusion: Using a validated algorithm to identify >1800 pseudogout cases, we identified important metabolic correlates of this acute manifestation of CPPD. This is the first study to report higher risk for pseudogout among men and lower risk among black compared to white patients. We confirmed several previously published risk factors, but in contrast to prior studies we did not identify an association between bisphosphonates and pseudogout.

Structured Cardiovascular Assessment in Gout Incorporating Carotid Ultrasound: Analysis of Subsequent Events in the Follow-Up

Mar Monzó[1], Neus Quilis[2], Laura Ranieri[2], Alejandro San-Martín[3] and **Mariano Andrés**[4], [1]Universidad Miguel Hernández, Alicante, Spain, [2]Hospital Universitario del Vinalopó, Alicante, Spain, [3]Clínica HLA Vistahermosa, Alicante, Spain, [4]Hospital General Universitario de Alicante-ISABIAL and Universidad Miguel Hernández de Elche, Alicante, Spain

SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: Metabolic & Crystal Arthropathies Poster
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Gout is an independent cardiovascular (CV) risk factor. This excess of morbidity and mortality requires optimal management, especially in high-risk individuals. Therefore, the inclusion of subclinical atherosclerosis screening by carotid ultrasound in the initial evaluation may help to accurately stratify the CV risk. However, longitudinal outcomes using this approach are not available in gout. This study aimed to analyze the new CV events occurred in patients with gout after structured CV assessment incorporating carotid ultrasound.

Methods: Retrospective analysis of an inception cohort of patients with crystal-proven gout. At baseline, a structured CV assessment was performed considering age, gender, traditional risk factors, CV and renal disease, laboratory data, SCORE and Framingham risk tools, and carotid ultrasound; according to 2013 ESC guidelines, CV risk was stratified as low, moderate, high or very high. The cohort includes 356 patients, mean (SD) aged 64 years (14.0), mostly males (86.0%), 21.8% with tophaceous gout and mean serum urate at diagnosis of 8.2mg/dL (1.8). The CV risk stratification at baseline was low in 20 patients (5.6%), moderate in 47 (13.2%), high in 34 (9.6%), and very high in 242 (68.0%). Major CV events (coronary heart disease (CHD), heart failure (HF), stroke, peripheral artery disease (PAD) and CV death) were recorded during the follow-up by electronic case reports review. A binary composite endpoint of *new major CV events* was used. The incidence after inclusion in the cohort was estimated. To evaluate potential baseline predictors (clinical and gout-related) of CV events, a Cox regression model was built.

	Simple Cox regression		Multiple Cox regression	
	Hazard ratio (95%CI)	*P*	Hazard ratio (95%CI)	*P*
Very high CV risk at baseline	9.54 (2.30-39.64)	**0.002**	4.11 (0.89-19.02)	0.070
Age	1.07 (1.04-1.11)	**<0.001**	1.04 (1.00-1.08)	**0.031**
Female gender	3.27 (1.68-6.33)	**<0.001**	1.24 (0.55-2.81)	0.605
Body mass index	1.00 (0.94-1.06)	0.863	-	-
Glomerular filtration rate	0.98 (0.97-0.99)	**<0.001**	1.00 (0.99-1.01)	0.766
Serum urate at diagnosis	1.19 (1.00-1.42)	0.052	1.12 (0.94-1.33)	0.227
ULT at diagnosis	0.81 (0.29-2.27)	0.688	-	-
Tophi	1.33 (0.66-2.66)	0.422	-	-
Years since first flare	1.00 (0.97-1.03)	0.772	-	-
Number of flares suffered	0.99 (0.97-1.00)	0.255	-	-
Number of involved joints	1.00 (0.89-1.12)	0.976	-	-
Joint pattern at presentation				
- *Monoarticular*	1.00 (ref)	-	1.00 (ref)	-
- *Oligoarticular*	1.86 (0.91-3.80)	0.089	1.35 (0.65-2.82)	0.421
- *Polyarticular*	2.75 (1.05-7.22)	**0.039**	1.34 (0.48-3.76)	0.579

Table. Analysis of baseline predictors of new cardiovascular events in the follow-up.

Results: Mean (SD) follow-up in the cohort was 41.5 months (16.8). Forty new major CV events have been identified (incidence 3.25 /100patient-year), distributed as follows: HF 1.46 (n=18), CV death 0.65 (n=8), CHD 0.49 (n=6), stroke 0.33 (n=4), and PAD 0.33 /100patient-year (n=4). Per risk stratification, the incidence of a new event was 0.16/100patient-year in the high-risk group and 3.01 /100patient-year in the very high-risk, while no events occurred in low and moderate groups. Noteworthy, five events occurring in the moderate (three) and high-risk (two) groups formed without considering carotid findings, were captured in the very-high risk group after the complete assessment.

The table shows the univariate and multivariate analysis of baseline predictors. An independent association and a trend towards significance were noted for age and to be classified at a very-high CV risk at baseline, respectively.

Conclusion: First longitudinal study assessing the use of subclinical atherosclerosis screening as part of CV risk assessment in new patients with gout. Those classified at the very high-risk group presented the majority of events, being HF the most frequent. Age, and likely being classified as very-high risk, independently predicted a new CV event during follow-up, data that may be of interest for the management of patients with gout at the time of diagnosis.

Prospective Study of the Patterns of Joint Involvement for Sequential Gout Flares

Natalie McCormick[1], Chio Yokose[1], Clara Chen[2], Tuhina Neogi[3], David Hunter[4], Hyon Choi[5] and Yuqing Zhang[6], [1]Massachusetts General Hospital, Boston, MA, [2]Boston University School of Public Health, Boston, MA, [3]Boston University School of Medicine, Boston, MA, [4]Institute of Bone and Joint Research, University of Sydney, St Leonards, New South Wales, Australia, [5]Massachusetts General Hospital, Department of Medicine, Division of Rheumatology, Lexington, MA, [6]Massachusetts General Hospital, Harvard Medical School, Boston

SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: Metabolic & Crystal Arthropathies Poster
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Cross-sectional radiologic evidence suggests monosodium urate crystal deposition among gout patients is a symmetrical phenomenon,[1] but no study has examined the longitudinal patterns in the locations of clinically symptomatic gout flares. We used data from a longitudinal follow-up study of individuals with gout to evaluate patterns in joint involvement for sequential gout flares.

Methods: We used data from the Boston Online Gout Study, a longitudinal internet-based case-crossover study conducted between 2003 and 2012. Gout patients who had at least one gout flare in the past year and lived in US were recruited online. Diagnosis was confirmed by medical record review. Participants were followed prospectively online. When a participant experienced a gout flare, s/he logged into the study website and answered a series of questions, indicating (on a homunculus) the joint(s) where the gout flare occurred. Possible joints included were the big toe, other toes, instep (mid-foot), heel, ankles, knees, elbows, wrists, and fingers.

Among subjects who reported at least two gout attacks during the follow-up period, we calculated the risk of the second gout flare occurring at the ipsilateral same location, according to the first gout flare in a given joint during the study, using Generalized Estimating Equations with log-binomial distribution model. We repeated the same analyses for the risk of having gout flare at the contralateral same location.

Results: We included 374 participants (mean age 55±12 years, 78% male, 37% overweight, 55% obese, mean gout duration 8.6±9.3 years) who experienced at least two gout attacks. Overall, the risk of flare was highest at the big toe, followed by the instep and ankle (**Table 1**).

For all nine sites evaluated, the magnitude of association between the first gout flare at a specific joint, and the risk of subsequent flare at the ipsilateral same location (e.g., left 1st MTP à left 1st MTP), was much stronger than the risk for the contralateral same joint (e.g., left 1st MTP à right 1st MTP) (**Table 2**). For example, participants affected in the left big toe during the first flare were 2.52-times more likely to experience their second flare in the left big toe (95%

Site	First Flare	Subsequent Flare	
	N Affected (% of all Joints)	Risk of Occurrence at Ipsilateral Same Location (vs. other sites)	Risk of Occurrence at Contralateral Same Location (vs. other sites)
Big Toe	233	0.39	0.16
Instep	159	0.36	0.13
Ankle	138	0.36	0.11
Knee	78	0.29	0.06
Heel	58	0.24	0.06
Other Toe	57	0.19	0.07
Finger	54	0.39	0.05
Wrist	40	0.43	0.04
Elbow	28	0.43	0.03

Table 1. Prevalence of Sites Affected During the First Flare, and Risk of Occurrence in Same Site During the Second Flare

Site	RR (95% CI) for Ipsilateral Same Location*	RR (95% CI) for Contralateral Same Location **	Ratio of RR: Ipsilateral/Contralateral
Big Toe	2.52 (1.93 to 3.29)	1.21 (0.90 to 1.62)	2.08
Instep	2.79 (2.07 to 3.77)	1.41 (1.03 to 1.94)	1.98
Ankle	3.07 (2.18 to 4.33)	1.64 (1.14 to 2.34)	1.87
Knees	4.17 (2.62 to 6.63)	1.82 (1.07 to 3.10)	2.29
Heel	4.06 (2.15 to 7.65)	1.35 (0.57 to 3.21)	3.01
Other Toe	3.09 (1.65 to 5.75)	0.60 (0.21 to 1.73)	5.15
Fingers	5.30 (2.70 to 10.40)	2.11 (1.02 to 4.35)	2.51
Wrist	9.25 (5.01 to 17.06)	1.59 (0.81 to 3.10)	5.82
Elbow	9.53 (4.84 to 18.79)	1.67 (0.78 to 3.55)	5.71

*mutually adjusted for the same joint on the contralateral side
**mutually adjusted for the same joint on the ipsilateral side

Table 2. Relative Risk (RR) of a Second Flare Occurring in the Same Site as the First Flare, on the Ipsilateral and Contralateral Sides

CI 1.93 to 3.29), versus a different site, and 1.21-times more likely to experience their next flare in the right big toe (95% CI 0.90 to 1.62), versus a different site. Ratio of relative risk ranged from 1.87 at the ankle to 5.82 at the wrist.

Conclusion: Among this community-based cohort of gout patients, the risk of recurrent gout flare was highest at big toe joint, and at all sites, subsequent flares were more likely to occur at the ipsilateral same joint than the contralateral same joint. These flare patterns facilitate diagnosis of gout flares during subsequent episodes and may also have pathogenetic implications such as sufficient composition of causal factors repeated in the same location.

Abstract Number: 0673

Gout Is an Independent Risk Factor for Undergoing an Amputation Procedure

Brian LaMoreaux[1], Megan Francis-Sedlak[1], **Scott Neville**[2] and Robert Holt[1], [1]Horizon Therapeutics plc, Lake Forest, IL, [2]Foot and Ankle Center, Mooresville, IN

SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: Metabolic & Crystal Arthropathies Poster
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Gout can cause uric acid deposition in joints, soft tissues, and organs (1) and is associated with heart disease, kidney disease, hypertension, hyperlipidemia, diabetes, and metabolic syndrome (2). Infected tophi, osteomyelitis, and diabetic ulcers can appear clinically similar which can cause clinical challenges in diagnosis and treatment (3). Uncontrolled gout can lead to amputation, but amputations in patients with gout are rarely described in the literature. It is well known that patients with diabetes are at increased risk for requiring amputation procedures, along with subsequent adverse health sequelae and mortality (4,5). The current population-based study assessed and compared amputation risk in populations with gout, diabetes, and concomitant gout and diabetes to investigate a potential association between gout and increased risk of amputation. Patients without gout or diabetes were examined as a control group.

Methods: The TriNetX "Diamond" network is a large U.S. claims database that contains data from 190 million patients. Data were used to examine the occurrence of amputation procedural codes (foot, toes, hand, fingers) in adult patients with gout and in those with diabetes. Groups were further stratified into patients with diabetes only, gout only, both diabetes and gout, and neither diabetes nor gout (control).

Results: A total of 4,467,721 patients with gout and 25,972,726 patients with diabetes were identified. Amputation rate in patients with diabetes (regardless of gout comorbidity) and gout (regardless of diabetes comorbidity) was comparable at 0.484% and 0.434%, respectively. However, non-overlapping gout and diabetes cohorts had different amputation rates (gout only: 0.162%, n=2,471,430; diabetes only: 0.461%, n=23,976,435), but both were higher than in the control population (no gout or diabetes: 0.035%, n=144,705,645; 4.6- and 13.2-fold higher, respectively). Patients with both gout and diabetes (n=1,996,291) had the highest amputation rate of 0.770%, which was 1.7-fold higher than the diabetes only population and 22.0-fold higher than the control population. The amputation rate in all groups differed significantly from the control ($p< 10^{-16}$).

Conclusion: This large population-based study demonstrated that patients with gout only, diabetes only, and comorbid gout and diabetes had amputation rates 4.6, 13.2, and 22.0 times higher than patients without gout or diabetes, respectively. These findings indicate that increased risks of amputation incurred by patients with diabetes and gout are independent and synergistic. Given that both conditions are associated with cardiovascular, renal, and metabolic complications, independent risk was expected, but additive risk was not. More research is needed to understand prognostic patient features underlying this amputation rate increase.

Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Japanese guidelines for managing gout and hyperuricemia recommend the initiation of urate-lowering therapy (ULT) to prevent gouty arthritis in subjects having asymptomatic hyperuricemia with serum uric acid (sUA) ≥8.0 mg/dL under certain conditions [Yamanaka H. Japan Med Assoc J. 2012;55:324-9.]. This is a distinctive difference from policies in Europe and the US. However, we lack clear documentation of the extent of clinical treatment for asymptomatic hyperuricemic subjects and of correlations between such treatment and the prevention of gouty arthritis. This study evaluated the association between disease control, defined as the relationship among prescription of ULT, occurrence of gouty arthritis, and level of sUA after 1 year, and gouty arthritis in subjects with asymptomatic hyperuricemia newly detected at medical check-up.

Methods: This research is based on Japanese health insurance claims and medical check-up data from April 2012 through June 2019. We identified subjects who had sUA ≥8.0 mg/dL in one or more medical check-ups from April 1, 2013 to March 31, 2016. The earliest available measurement date during that period was considered the index date. Subjects of analysis were health insurance subscribers whose records did not show the disease name of “gout” or “asymptomatic hyperuricemia” and for whom ULT had not been prescribed during the 1-year period prior to the index date. From the index date to the medical check-up 1 year later (follow-up date) was considered Period 1, and from the day after the follow-up date was considered Period 2. Disease control was investigated during Period 1, and disease burden (incidence rate of gouty arthritis) was assessed in relation to disease control during Period 2 (Figure 1).

Results: The analysis population consisted of 19,261 health insurance subscribers who met the eligibility criteria. During Period 1, ULT was initiated in 8.4% of that group (1,625 /19,261). Gouty arthritis was experienced by 3.1% (597/19,261), of whom 32.3% (193/597) were not under treatment with ULT. For 90.6% (17,443/19,261), no ULT was prescribed and no gouty arthritis was experienced during Period 1. Within that group, 40.4% (7,049/17,443) showed sUA ≥8.0 mg/dL on the follow-up date. Only 2.3% (438/19,261) had been prescribed ULT and had achieved sUA ≤6.0 mg/dL by the follow-up date (Figure 2). During Period 2, the incidence rate of gouty arthritis was calculated for each

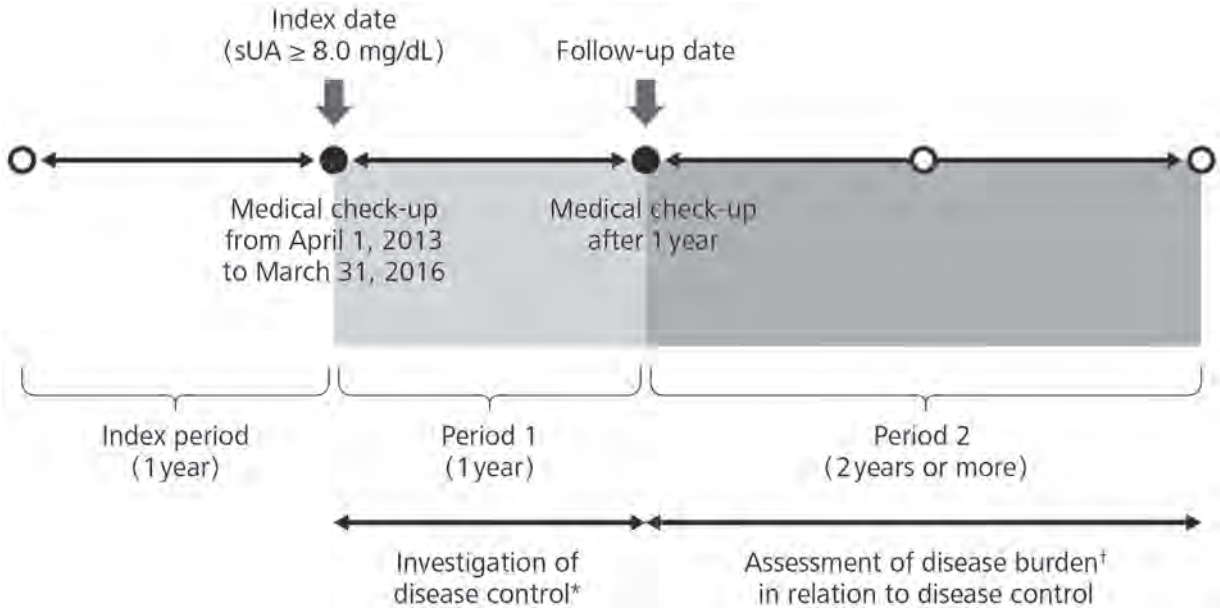

Figure 1 Study design * Disease control: Relationships among prescription of ULT, occurrence of gouty arthritis, and level of sUA after 1 year † Incidence rate of gouty arthritis sUA, serum uric acid; ULT, urate-lowering therapy

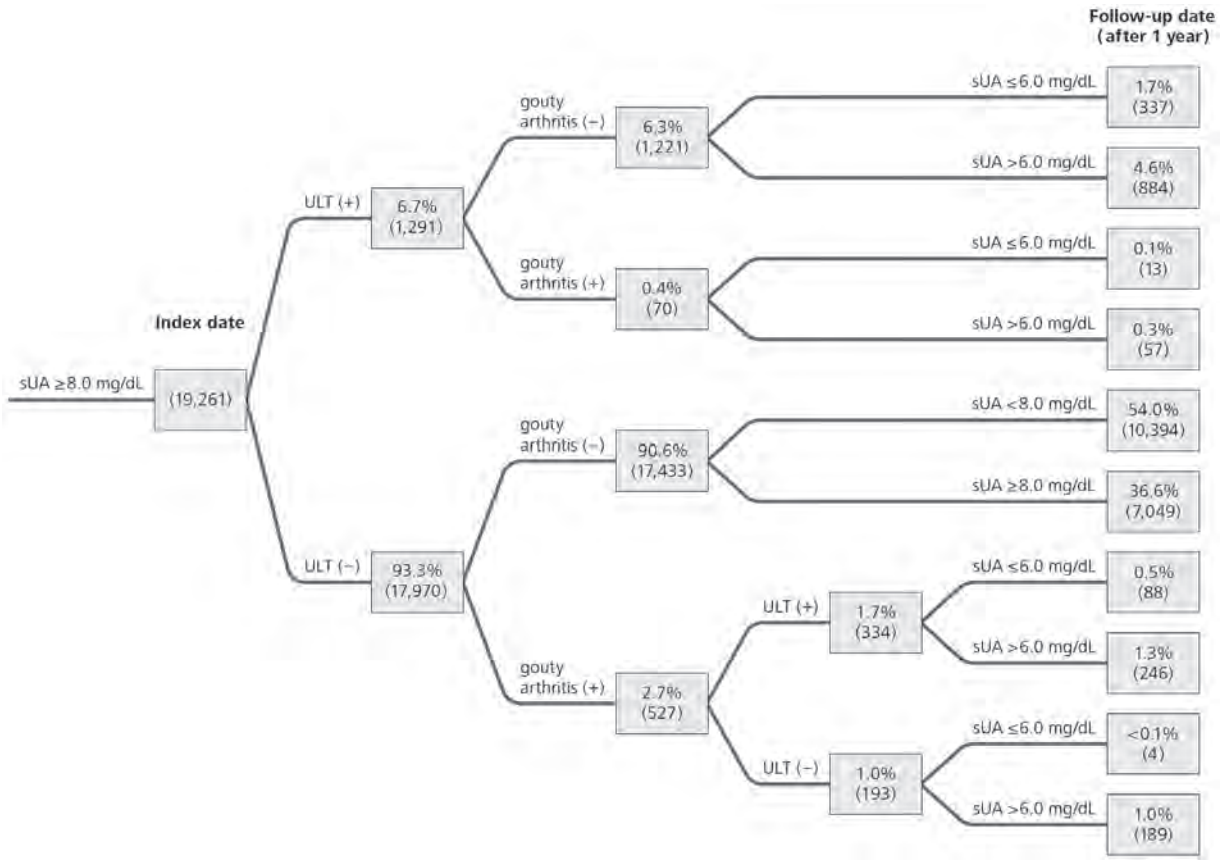

Figure 2 Event tree analysis of disease control from index date to follow-up date (Period 1) Parentheses indicate the number of subjects. For percentages, the denominator was 19,261 subscribers. sUA, serum uric acid; ULT, urate-lowering therapy

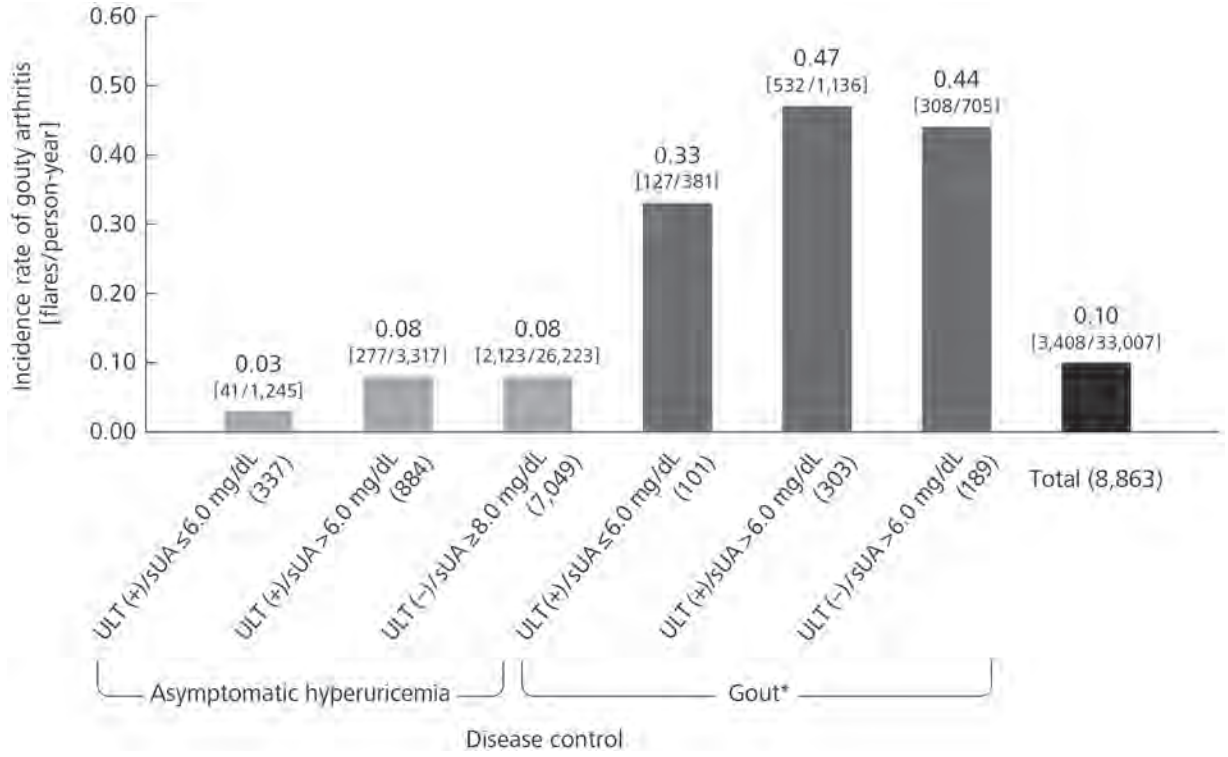

Figure 3 Incidence rate of gouty arthritis during Period 2 Parentheses indicate the number of subjects. Brackets indicate the number of flares/person-years. * Subjects who had experienced at least one incident of gouty arthritis during Period 1. sUA, serum uric acid; ULT, urate-lowering therapy

type of disease control assessed during Period 1. Both for asymptomatic hyperuricemia and for gout in subjects who had experienced at least one incident of gouty arthritis during Period 1, the incidence rate of gouty arthritis during Period 2 was lower in subjects who had sUA ≤6.0 mg/dL than in those whose sUA was >6.0 mg/dL, with or without ULT (Figure 3).

Conclusion: Of those subscribers with newly detected hyperuricemia according to medical check-up records, only 2.3% had been prescribed ULT and had achieved sUA ≤6.0 mg/dL for the 1-year period. Both for asymptomatic hyperuricemia and for gout, the incidence rate of gouty arthritis was lower in subjects whose sUA was ≤6.0 mg/dL than those whose sUA was >6.0 mg/dL, with or without ULT. Further analysis by adjusting for confounding will be required to discuss causality.

AR882, a Potent and Selective Uricosuric Agent, Significantly Reduced Serum Urate Levels Following Multiple Ascending Once-Daily Doses in Healthy Subject Volunteers

Zancong Shen[1], Elizabeth Polvent[2], Vijay Hingorani[2], Andrea Clouser-Roche[2], Chris Mikelatis[2], Rongzi Yan[2], Shunqi Yan[2] and **Li-Tain Yeh**[2], [1]Arthrosi therapeutics, Laguna Hills, CA, [2]Arthrosi Therapeutics Inc, Laguna Hills, CA

SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: Metabolic & Crystal Arthropathies Poster
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: AR882 is a potent and selective uric acid transporter 1 (URAT1) inhibitor under development for the treatment of hyperuricemia or gout. AR882 exhibited linear pharmacokinetic (PK) properties, dose-dependent serum urate (sUA) lowering effect and was well tolerated in a single ascending dose (SAD) study in humans. A multiple ascending dose (MAD) study was therefore conducted in healthy subjects to evaluate the PK, pharmacodynamic (PD) and safety profiles of AR882 following once-daily (QD) doses for 10 days.

Methods: In this randomized, double-blind, placebo-controlled MAD study, 30 healthy male volunteers received AR882 oral capsules under fasted conditions at 25, 50, or 75 mg (ten subjects per group [8 active and 2 placebo]). On Day -1, Day 1 and Day 10, serial blood samples were collected for measurement of AR882 plasma concentrations and sUA levels for PK/PD assessments. Urine samples were collected at 6- to 12-hour intervals for assessment of uric acid excretion. Adverse events, laboratory safety tests, vital signs, and electrocardiograms were collected throughout the study.

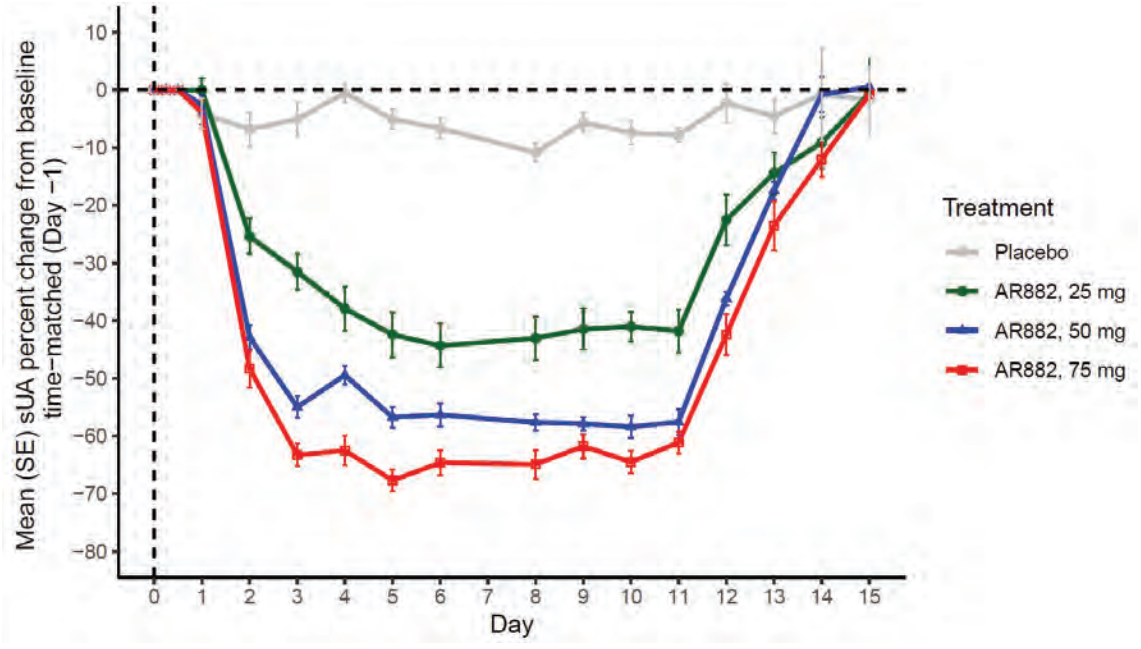

Figure Mean Serum Urate Concentrations: Percent Change from Baseline Following Once-Daily Oral Doses of AR882

Results: Following QD administration, AR882 plasma levels exhibited dose proportional increases between 25 and 75 mg. AR882 exposures were well below those observed at the no-observed-adverse-effect level (NOAEL) in preclinical studies. The median T_{max} ranged between 1.5 and 3.5 hours postdose, and accumulation in C_{max} and AUC was between 30-50%. On Day 10 predose, AR882 showed significant PD effects by reducing sUA concentrations by 41%, 58%, and 65%, respectively, following 25, 50, and 75 mg doses. Steady-state sUA lowering effect was achieved after approximately 5 days. Higher amounts of uric acid were eliminated through urine on Day 1 at all collection intervals. On subsequent days, daily urine uric acid gradually decreased. Fractional excretion of uric acid (FEUA) showed dose-dependent increases on Day 1 and Day 10, consistent with reduction in serum urate levels. AR882 was well tolerated at all doses tested. All AEs were mild, there were no discontinuations due to AEs, and no serious adverse events (SAEs) were reported. There were no clinically significant laboratory or ECG abnormalities noted.

Conclusion: Following once-daily doses over a 10-day treatment period, AR882 exhibited significant sUA lowering effects at all doses tested (58% at Day 10 predose and up to 67% maximum intraday reduction at 50 mg). These results support the potential utility of AR882 when given once-daily to treat hyperuricemia or gout. Studies in patients are underway.

Abstract Number: 0676

Surveying Practicing Rheumatologists Regarding Gout Management and Barriers in Gout Care

Joshua Gavin[1], Yashswee KC[2], Evan Dombrosky[3], Nehal Shah[4] and Youssef Roman[4], [1]Virginia Commonwealth University School of Medicine, Richmond, [2]Virginia Commonwealth University School of Medicine, Henrico, VA, [3]Virginia Commonwealth University School of Medicine, Glen Allen, VA, [4]Virginia Commonwealth University School of Medicine, Richmond, VA

SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: Metabolic & Crystal Arthropathies Poster
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: The management of gout is heterogeneous across specialties and clinical settings. Gout has been demonstrated to be one of the most poorly managed conditions in healthcare. Identifying the gaps in gout management can help in focusing research to identify novel interventions or models of care that may enhance gout management and improve clinical outcomes. The purpose of this study was to assess current practices and perspectives in gout management regarding the etiology of substandard gout management amongst rheumatologists internationally.

Methods: A cross-section non-compensated survey of rheumatologists across the world was distributed to practicing rheumatologist members of the ACR and Gout, Hyperuricemia and Crystal-Associated Disease Network (G-CAN) using a 28-item questionnaire designed to evaluate current clinical practice of gout management and to assess barriers to optimal gout management. This was an anonymous internet survey open from 05/1/2020 to 05/14/2020.

Results: The survey had a response rate of 8.5% (161/1900) with 60.2% being male. The age groups of respondents was evenly distributed from under 35 to great than 66 years. Majority of respondents had greater than 10 years of

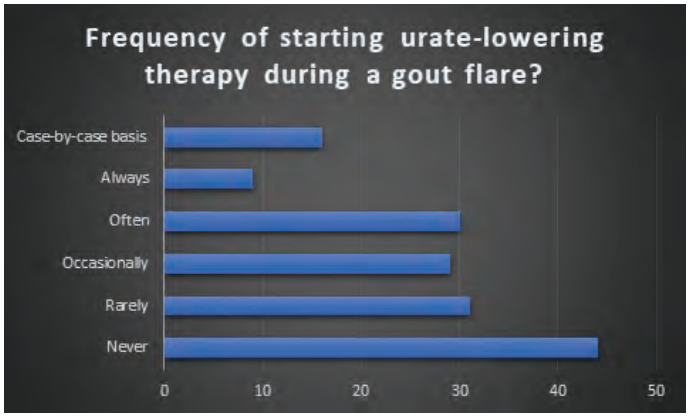

Figure 1

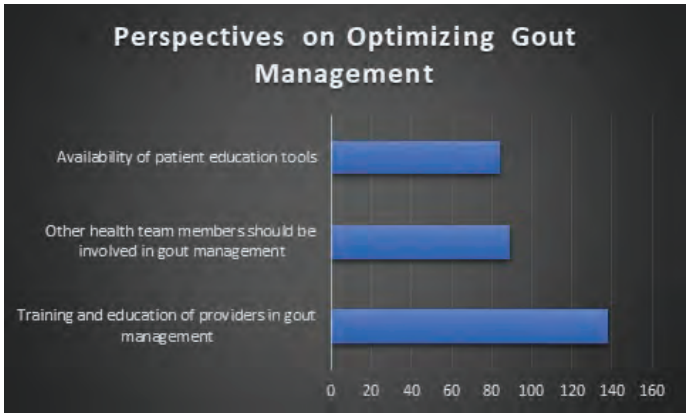

Figure 2

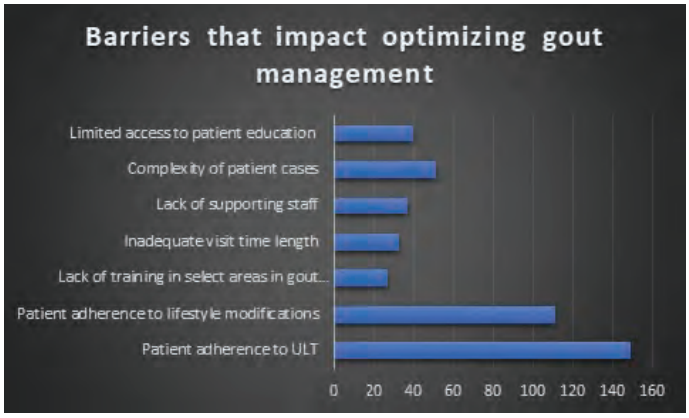

Figure 3

clinical practice (65.6%). 70.2% were academic rheumatologists. 71.4% practiced in the United States. 31.3% of respondents were G-CAN members. The mean number of gout cases seen per month by respondents was 21.3 with a median of 10. The overall survey results were concordant with the 2020 ACR guidelines. Two areas of discordance with these guidelines were identified. 1) 64.6% of respondents preferred not to start ULT during an acute flare. (Figure 1) 2) 59.6% of respondents reported “never” or “rarely considered” HLA-B*58:01 genetic testing.

Regarding improving gout management, respondents identified patient compliance with ULT (94.3%) and lifestyle changes (70.3%) as the predominant factors(Figure 2). From the perspective of healthcare improvement of gout care,

physician education, involvement of other members of the healthcare team, and better access to patient education tools, were all identified as areas of potential improvement(Figure 3).

Conclusion: Despite the modest response rate, our study highlights a variety of targets to improve care of patients with gout. Education for physicians regarding the potential benefits of initiation of ULT during an acute flare appears to be a straightforward concept to address. The polled rheumatologist's current gout management practices per our survey results are consistent with the 2020 ACR gout management guidelines. This consistency in guideline directed care of gout patients provides evidence for a rheumatologist directed gout care team.

We identified two main areas of focus for future studies based on our results: 1) Methods of assisting patients with adherence to ULT and lifestyle changes 2) Enhanced inclusivity of the entire healthcare team in treatment of gout patients. Programs targeting these gaps may lead to better management of gout by the healthcare system and aid in reducing the prevalence of this burdensome disease.

A Multicenter, Efficacy and Safety Study of Methotrexate to Increase Response Rates in Patients with Uncontrolled GOut Receiving Pegloticase (MIRROR): 12-Month Results of an Open-Label Study

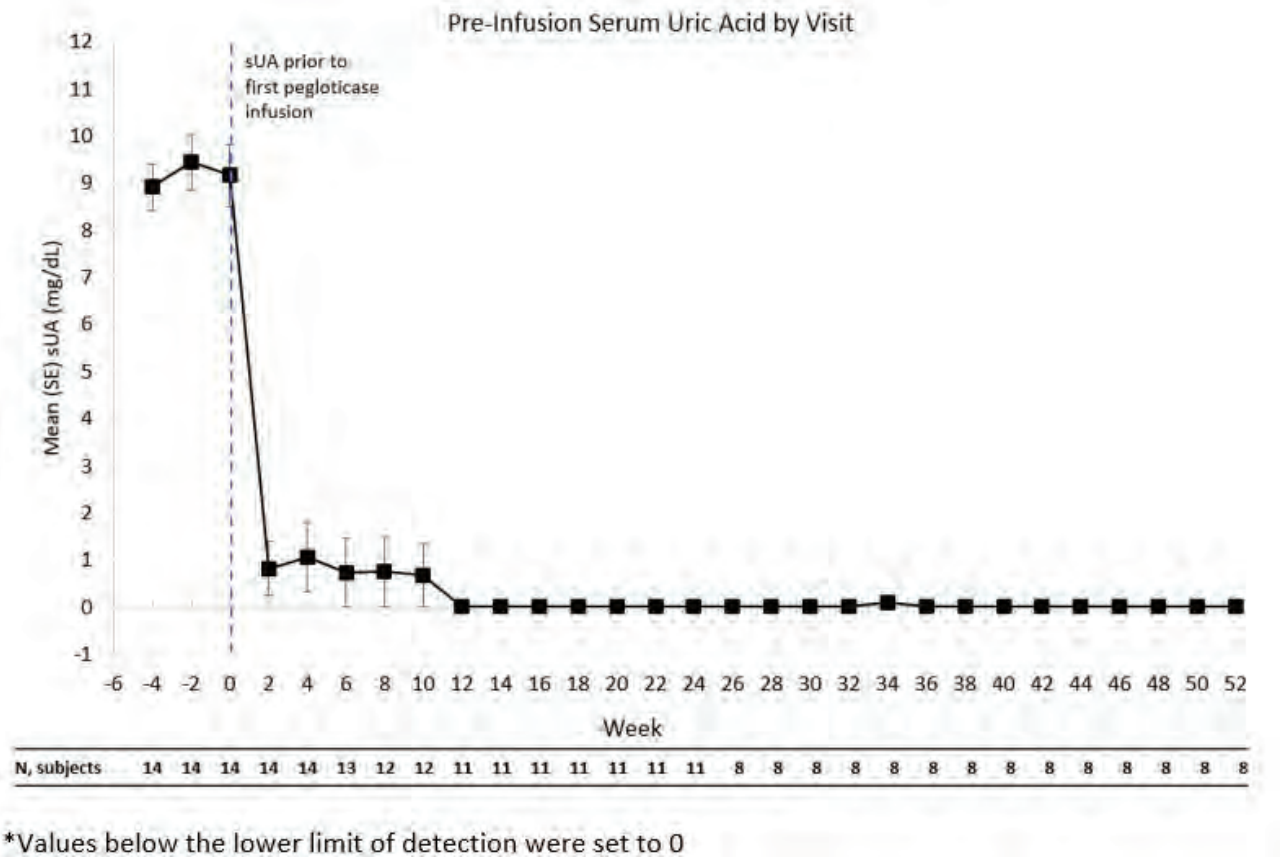
John Botson[1], Paul Peloso[2], Katie Obermeyer[3], Brian LaMoreaux[3], Lin Zhao[3], Michael Weinblatt[4] and Jeff Peterson[5], [1]Orthopedic Physicians Alaska, Anchorage, AK, [2]Horizon Therapeutics plc, Gurnee, IL, [3]Horizon Therapeutics plc, Lake Forest, IL, [4]Brigham and Women's Hospital, Boston, MA, [5]Western Washington Medical Group Arthritis Clinic, Bothell, WA

SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: Metabolic & Crystal Arthropathies Poster
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Consistent, though limited, published data suggests that methotrexate (MTX) improves treatment response in patients treated with pegloticase for uncontrolled (refractory) gout. Recent case series[1-3] (25 patients total) showed an 80%-100% response rate in patients co-treated with MTX and pegloticase, versus the 42% response rate reported in clinical trials with pegloticase monotherapy. The current clinical trial prospectively examined efficacy and safety of pegloticase in patients with uncontrolled gout who were co-treated with oral MTX.

Methods: This study included adult patients from 6 sites. Uncontrolled gout was defined as serum uric acid (sUA) ≥6 mg/dL with ≥1 of the following: sUA ≥6 mg/dL despite oral urate lowering therapy (ULT), intolerance to ULT, or functionally limiting tophaceous deposits. Key exclusion criteria included immunocompromised status, G6PD deficiency, severe renal impairment, and MTX contraindication. Oral MTX (15 mg/wk) and folic acid (1 mg/day) were initiated 4 wks prior to the first pegloticase infusion and were continued during pegloticase therapy (8 mg every 2 wks). The protocol originally consisted of 24 wks of co-therapy, but was amended to extend to 52 wks. Primary outcome was the proportion of responders during Month 6 (sUA < 6 mg/dL for ≥80% of time). Analyses were performed on the modified intent-to-treat (mITT) population (patients who received ≥1 pegloticase infusion).

Figure. Pre-infusion serum uric acid levels (sUA) during the MTX Run-in and Pegloticase + MTX treatment period.



*Values below the lower limit of detection were set to 0

Results: 14 patients made up the mITT population. All patients were male with a mean age 49.3 ± 8.7 yrs. The time since diagnosis of gout was 13.8 ± 7.4 yrs. Mean sUA was 9.2 ± 2.5 mg/dL before the first pegloticase infusion. 12 patients had visible tophi. Eleven patients (78.6%, 95%CI: 49.2-95.3%) were considered 6-month pegloticase responders and 3 non-responders discontinued pegloticase after 2 consecutive sUA levels >6 mg/dL. Of the 11 patients who were responders in month 6, 1 did not extend (pre-protocol amendment), 2 discontinued pegloticase due to meeting their treatment goals (continued on allopurinol; 1 met responder definition during month 12), and 8 continued pegloticase/MTX co-therapy and remained responders at Month 12. Mean sUA over time is displayed in Figure. Gout flares occurred in 13/14 patients (92.9%) in the first 12 weeks and in 2/8 (25%) patients in weeks 36-52. A serious adverse event (AE) of sepsis occurred in 1 patient in the first 6 months; AEs that occurred in >1 patient during co-treatment were diarrhea, nasopharyngitis, sinusitis, upper respiratory tract infection, muscle strain, arthralgia, and hypertension. No new safety issues were observed.

Conclusion: The 6-month response rate of MTX/pegloticase co-therapy was 78.6%. Responders at month 6 who remained on treatment continued to be responders at month 12 with sUA remaining below 1 mg/dL. The MTX/pegloticase co-therapy was well tolerated over this 12 month period with a reduced incidence of gout flares over time.

Patient Characteristics and Patterns of Urate-lowering Treatments in Older Patients with Incident Gout

Kazuki Yoshida[1], Jun Liu[2], Daniel H Solomon[3] and Seoyoung Kim[3], [1]Brigham & Women's Hospital and Harvard Medical School, Boston, MA, [2]Brigham and Women's Hospital, Boston, [3]Brigham and Women's Hospital, Boston, MA

SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: Metabolic & Crystal Arthropathies Poster
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Gout is a common inflammatory arthritis caused by monosodium urate crystal deposition in the joints. Despite this well-understood pathophysiologic mechanism of disease and ACR and EULAR recommendations for a treat-to-target strategy with urate-lowering therapy (ULT), management of gout is generally suboptimal. ULT initiation in older patients with gout can be challenging as many of them have substantial comorbidities. We aimed to examine characteristics of older patients newly diagnosed with gout and their patterns of ULT initiation.

Methods: Using Medicare claims data (2007–2016 Parts A/B/D) linked to EHR from 2 health care provider networks, we identified patients newly diagnosed with gout based on the first gout diagnostic code (ICD9 274.00–03, 81, 82, 39, 9; ICD10 M10) after the baseline period of at least 365 days. All patients were required to be continuously enrolled during the baseline period. Patients with age < 65 or use of any gout-related medications (allopurinol, febuxostat, probenecid, colchicine, lesinurad, and pegloticase) in this period were excluded. We described these incident gout patients for their baseline characteristics, subsequent ULT initiation, and treatment patterns at the initiation.

Results: We identified a total of 20,193 patients who we regarded as incident gout patients by our definition. The mean (SD) age was 77.3 (7.7) years and 48.4% were male. Many patients had comorbidities prior to the gout diagnosis (**Table 1**). Hypertension was the most common comorbidity (86%) followed by hyperlipidemia (75%), diabetes (36.7%), malignancy (30%), and heart failure (25%). Use of cardiovascular medication was also common (e.g., ACE/ARB 53%, diuretics 55%, and statin 60%). 34% experienced hospitalization during the baseline 365-day period. On average, they visited physician offices 14 times (median 12), emergency department 1.6 times, and took 10.8 discrete medications during the baseline period. During the entire follow-up (median 656 days [25th 168, 75th 1454]), only 24.3% had a ULT initiation. Cumulative incidence of ULT initiation was 17.8% at 1 year 21.2% and at 2 years after the diagnosis, handling disenrollment (55%) as censoring and death (21%) as a competing event. Most ULT initiators (95%) started allopurinol. Febuxostat was used in 3% and probenecid in 2%. The median starting doses were low consistent with ACR guidelines (**Table 2**). However, concomitant use of colchicine for flare prophylaxis was low (allopurinol 26%; febuxostat 31%), except probenecid (80%), which included a combination formulation.

Conclusion: Older patients with incident gout had a substantial comorbidity and medication burden. The overall rate of ULT initiation was low (< 25%) and suboptimal, particularly in the first year after the diagnosis (18%). While the initial ULT doses were appropriately low as recommended; less than a third used gout flare prophylactic treatments at the time of ULT initiation. As the treat-to-target strategy for gout is contingent upon ULT initiation, better understanding of patient and physician barriers to ULT is essential to improving the quality of care in older patients with gout.

Epidemiology of Intra-Articular Mineralization on Knee Dual-Energy Computed Tomography: The Multicenter Osteoarthritis Study

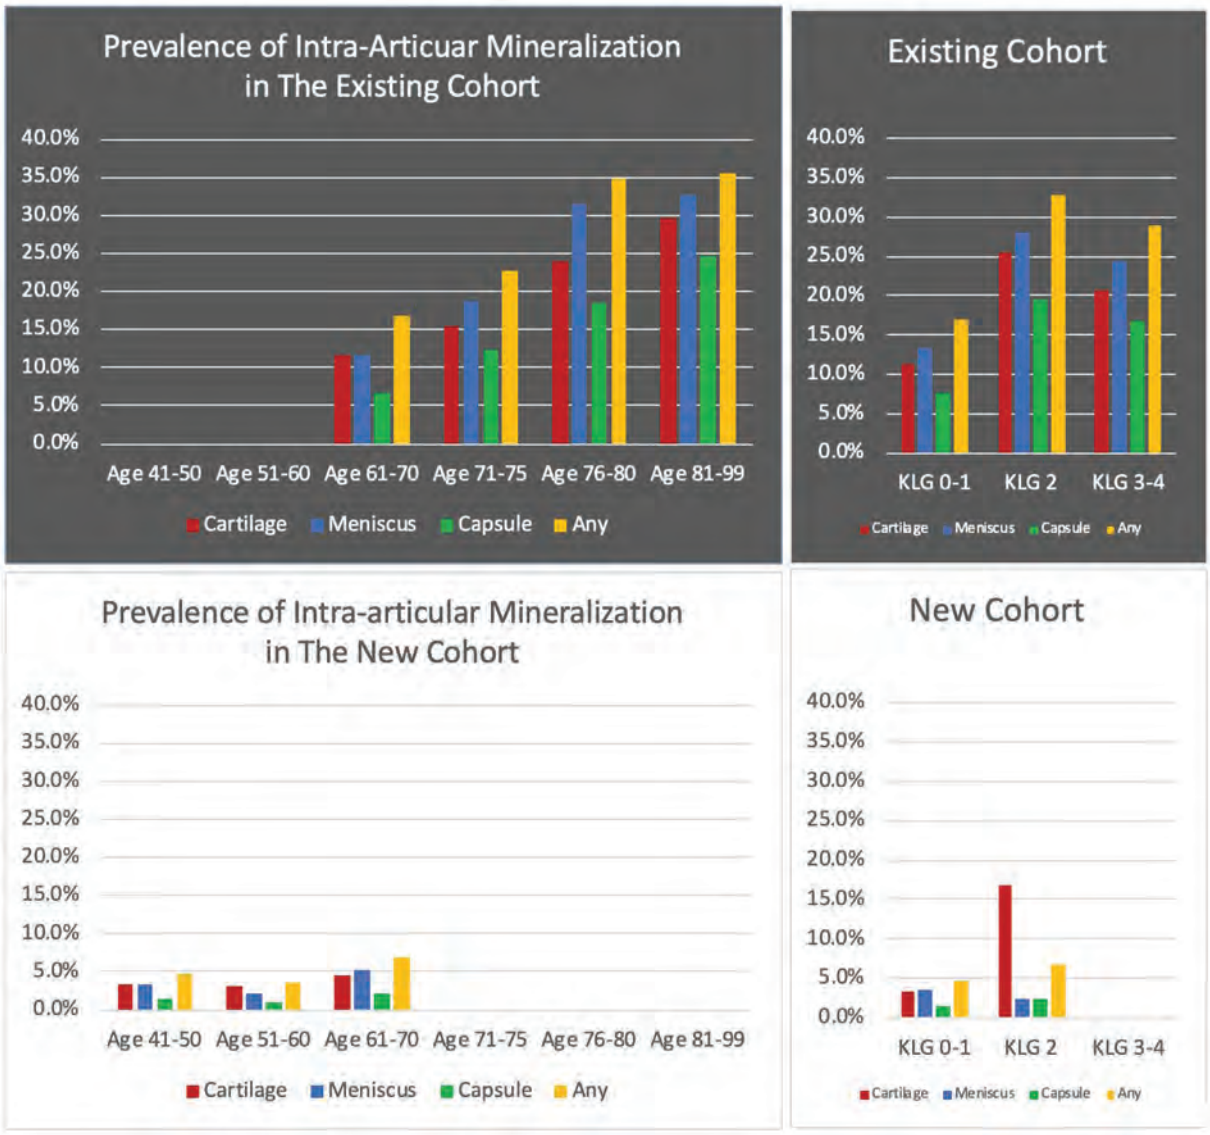
Mohamed Jarraya[1], **Tuhina Neogi**[2], John Lynch[3], David Felson[2], Piran Aliabadi[4], Michael Nevitt[3], Cora Lewis[5], James Torner[6] and Ali Guermazi[2], [1]Boston University School of Medicine, Boston, [2]Boston University School of Medicine, Boston, MA, [3]University of California at San Francisco, San Francisco, [4]Brigham and Womens Hospital, Boston, [5]University of Alabama Birmingham, Birmingham, AL, [6]University of Iowa, Iowa City, IA

SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: Metabolic & Crystal Arthropathies Poster
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Computed tomography (CT) has a higher sensitivity for the detection of intraarticular mineralization in comparison with commonly used imaging techniques in knee osteoarthritis (OA) including radiographs and MRI. The role of intra-articular mineralization in knee OA has been unclear, contributed to by inadequate imaging assessment of this phenomenon. The aim of this study is to report the prevalence of CT-detected intra-articular mineralization in older adults with or at risk of knee OA.

Methods: We used data from the Multicenter Osteoarthritis (MOST) Study, a NIH-funded cohort of people with or at risk of knee OA. The existing cohort was recruited in 2003-2005 (age 50-79), with the current analysis focusing on the 12th-year visit as the baseline for this analysis as this was the first study visit at which bilateral dual energy knee CTs were obtained. In addition coinciding with the 12th year study visit in 2016-2017, a new cohort was recruited (age 45-69) who had Kellgren Lawrence (KL) grade < =2 in both knees, and either no knee pain or if they had knee pain, it could not be severe or constant. Participants also had bilateral PA knee radiographs obtained, scored for KL grade by a musculoskeletal radiologist blinded to the CTs. A separate musculoskeletal radiologist scored multiplanar CT images using an ordinal score (0-3) for degree of mineralization in each of the MOAKS subregions of cartilage and menisci, as well as ligaments, capsule, and vasculature. Prevalence of intra-articular mineralization was computed for the total sample, and stratified by age and KL grade.

Results: The existing cohort included 635 subjects (1270 knees) (57.3 % female, mean age 71.8, mean BMI 29.9). The new cohort included 1473 subjects (2946 knees) (56 % female, mean age 56.6, mean BMI 28.4). CT-detected intra-articular mineralization (of either cartilage, meniscus, and/or capsule) was 23.3% in the existing cohort and 4.9% in the new cohort. For the existing cohort, the prevalence in specific locations was: 16.7% articular cartilage (vs. 3.6% in the new cohort), 19.5% meniscus (vs. 3.5% in the new cohort), and 12% capsule (vs. 1.5% in the new cohort). Articular and meniscal mineralization increased with age and was most prevalent in KL grade 2, both for the existing and new cohorts (**Figure**). The prevalence of intra-articular mineralization among KL grade 3 and 4 was lower



Prevalence of Intra-Articular Mineralization in the Existing and New Cohorts of the MOST Study

in comparison with KL grade 2 in the existing cohort, though this was unadjusted for age and could reflect less cartilage present at higher KL grades to allow for mineralization to be detected. Overall, the prevalence of vascular calcifications was 52.9% in the existing cohort (vs. 19.9% for the new cohort), which increased with age in both cohorts.

Conclusion: CT provides good visualization of intra-articular mineralization within the hyaline articular cartilage, meniscus, and soft tissue, which will provide novel opportunities to evaluate the longitudinal relation of intra-articular mineralization to adjacent articular tissue pathology and overall OA progression.

Sustained Treat to Target Uric Acid Lowering Therapy Markedly Lowers Fatty Acids Levels in Gout Patients

Monica Guma[1], Roxana Coras[2], Ru Liu-Bryan[3] and Robert Terkeltaub[4], [1]Division of Rheumatology, University of California San Diego, Department of Medicine, Autonomous University of Barcelona, La Jolla, CA, [2]University of California San Diego, La Jolla, CA, [3]Department of Medicine, VAMC/University of California San Diego, San Diego, [4]VA Medical Center/UC San Diego, San Diego, CA

SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: Metabolic & Crystal Arthropathies Poster
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Though hyperuricemia is implicated in cardiovascular disease, the metabolic syndrome, and type 2 diabetes in both gout and in asymptomatic patients, the core metabolism pathways involved in these associations are unknown. Metabolomics provides valuable information about disease status. We conducted a prospective study, in which we characterized gout patient metabolic profiles at baseline and 12 and 24 weeks of treat to target uric acid (UA)-lowering therapy (ULT), to gain new mechanistic insight into association of metabolic and cardiovascular comorbidities with gout and hyperuricemia.

Methods: Recruited patients meeting the 2015 ACR/EULAR gout classification criteria (n=20) had hyperuricemia (serum UA 7-11.3 mg/dL at baseline, and 45% patients (9 out of 20) had flare rate ≥5/year at baseline. Six patients were already on ULT but hyperuricemic (at serum UA 6.8 mg/dL or higher), and 14 patients started xanthine oxidase inhibitor with allopurinol or febuxosat at recruitment. Blood was collected at time zero (baseline), and 12 and 24 weeks as all patients underwent ULT titration to attempt to achieve serum UA target < 6 mg/dL. Serum MS spectra were aquired with Ultrahigh Performance Liquid Chromatography-Tandem Mass Spectroscopy (UPLC-MS/MS). Raw data was extracted, peak-identified and processed using Metabolon hardware and software. Principal component analysis (PCA) with hierarchical clustering analysis (HCA) as well as random forest (RF) analysis was performed. Metabolites altered by ULT were identified using 2-way repeated measures ANOVA.

Results: Serum UA levels at week 12 (mean 5.9651.734SD) and week 24 (mean 5.6551.763SD) were significantly lower compared to baseline (mean 8.211.139SD), and 80% and 90% patients achieved reduced serum UA to < 7 mg/dL at week 12 and week 24, respectively. PCA along with HCA with all the samples demonstrated overlap between samples collected at time zero, as well as 12 and 24 weeks following treatment clustered based on the subject but not treatment itself. Yet, RF analysis resulted in predictive accuracy of 52%. RF analysis also identified several metabolites contributing most to the separation between baseline and 24 weeks. Top metabolites generated by RF analysis pointed heavily towards changes in selected metabolic pathways (Figure 1), including nucleotide *(urate, xanthine, adenosine and cytosine)* and lipid metabolism. Two-way repeated measures ANOVA identified 115 metabolites (89 downregulated and 26 upregulated) significantly differing between baseline and 24 weeks. Other than purine metabolites, short, medium and long chain fatty acids, and biliary acids were significantly decreased at 24 weeks, suggesting an association between urate levels and fatty acid synthesis in both the liver and adipose tissue (Figure 2).

Conclusion: The metabolomic blood profiles linked with patient response to xanthine oxidase inhibitor ULT, indicated a reduction of fatty acid synthesis. Although further studies are required to investigate how urate modulates lipid metabolism in liver and adipose, our findings point fatty acid synthesis reduction in response to ULT therapy in gout as being highly pertinent to comorbid metabolic and cardiovascular disease in gout.

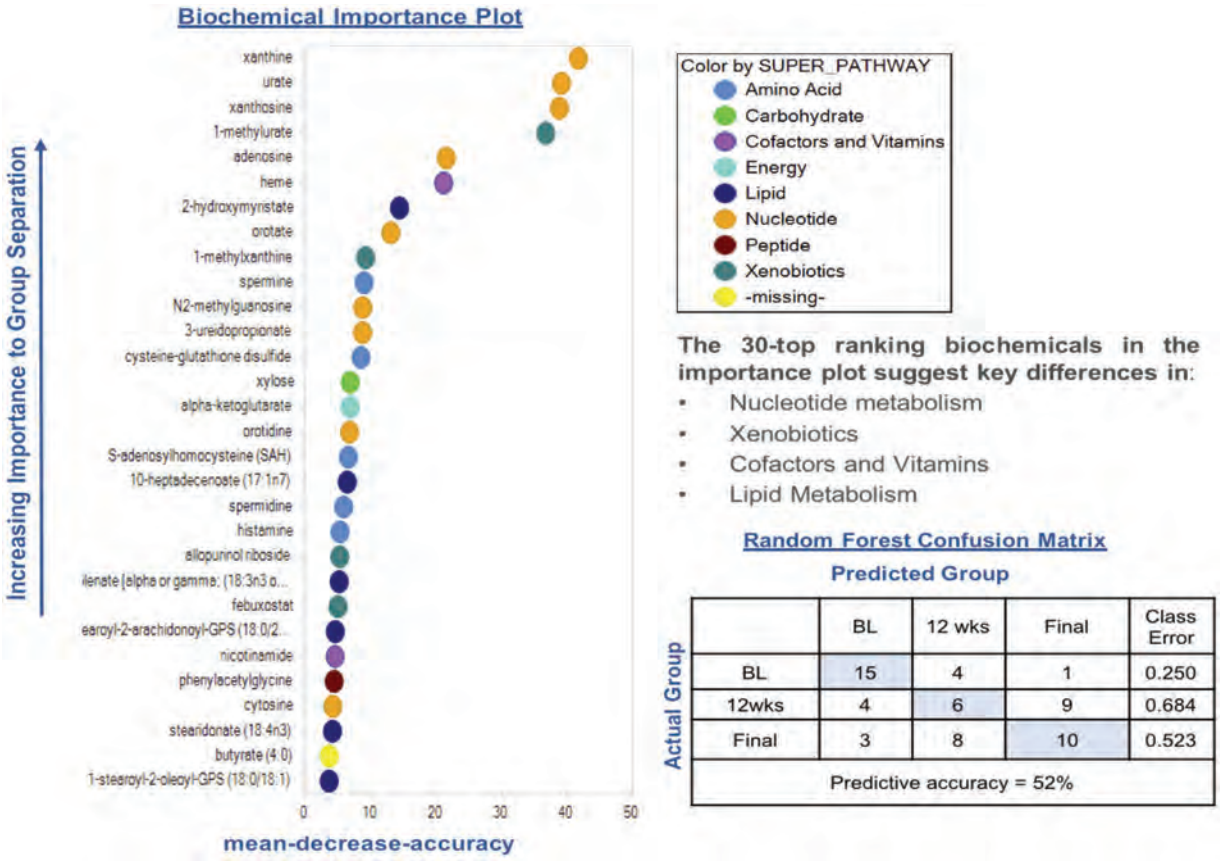

Figure 1. Random Forest classification using named metabolites detected in human serum collected from gout patients undergoing a treatment identified several metabolites contributing most to the separation of the groups. BL: baseline (time zero); wks: weeks. Final (24 weeks of ULT titrated to target).

SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: Metabolic & Crystal Arthropathies Poster
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Spinal gout is reported as a rare event, presenting as acute back pain, neuropathy, and spinal compression. Diagnosis is commonly based on identification of a mass, followed by tissue confirmation of monosodium urate (MSU) deposition. It is likely that many more cases of gout involve the spine asymptomatically or with non-specific or under-recognized symptoms.

Methods: Using dual-energy CT (DECT), we are determining the prevalence/extent of MSU deposition in the lumbosacral spines of patients with gout vs without gout, and with tophaceous vs non-tophaceous gout. We are recruiting 25 controls, 25 non-tophaceous and 25 tophaceous gout patients, 50-80 years old. Exclusion criteria include known CPPD disease, RA, spondyloarthropathy or active spinal malignancy. All gout subjects meet ACR classification criteria and have entry serum urate (sU) of >6.8 mg/dL, or sU >6.0 mg/dL on ULT for < 6 months. Demographics, gout history, Aberdeen back pain scale, sU, ESR, and CRP are collected. Subjects undergo DECT of the lumbosacral spine to assess for MSU deposition and osteoarthritic changes.

Results: 61 subjects are enrolled to date (25 control, 24 non-tophaceous and 12 tophaceous gout). Control and gout (all pooled) subjects have similar mean age in years (controls, 61.8±3.8 vs gout, 64.1±7.32, p=0.15), but differ in BMI (controls, 28.3±6.5 kg/m^2 vs gout, 32.35±6.9 kg/m^2, p=0.02) and creatinine (controls, 1.0±0.2 mg/dL vs gout, 1.5±0.7 mg/dL, p< 0.05). Mean sU and ESR are higher in gout subjects (sU-controls, 5.3±1 mg/dL vs gout, 8.7±1.7 mg/dL, p< 0.05; ESR-controls, 13.7±13.8 mm/h vs gout, 25.3±18.3 mm/h, p< 0.05). Using default threshold settings for MSU visualization, greater MSU deposition is observed in the spine of gout patients (controls, 2.2±1.2 cm^3 vs gout, 10.8±32.2 cm^3, p=0.18; Fig 1). When a single gout outlier with excessively high sU and spinal MSU is excluded, spinal MSU deposition between controls and gout patients becomes significant (controls, 2.2±1.2 cm^3 vs gout, 5.6±7.8 cm^3, p=0.04). Reanalysis of several scans using narrower threshold settings to limit possible artifact confirms increased MSU signal among gout patients. Although many subjects in each group do not have excessive MSU deposition, deposition is more common in both gout groups (Fig 2). Thus far, MSU deposition is not different between non-tophaceous and tophaceous gout patients (non-tophaceous, 12.3±2.92 cm^3 vs tophaceous, 7.9±3.2 cm^3, p = 0.7). No subject demonstrated a frank spinal tophus. Gout patients report higher back pain scores (controls, 5.7±8.3, vs gout, 11.8±14.3, p=0.06). Across all groups deposition is greater in patients with higher sU.

Conclusion: Based on preliminary results, gout patients have higher inflammatory markers, more spinal MSU deposition, and increased back pain versus controls. Preliminary results with more stringent DECT threshold settings suggests these differences are not artifact, but analysis is ongoing. These data suggest that non-tophaceous MSU

Role of Inflammatory and Oxidative Stress Pathway Biomarkers in Renal Disease in Gout

Fatima Alduraibi[1], Karina Ricart[1], Rakesh Patel[1], Alexander Szalai[1], Joshua Melnick[2] and Jasvinder Singh[1], [1]University of Alabama at Birmingham, Birmingham, AL, [2]University of Alabama at Birmingham (UAB), Vestavia Hills, AL

SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: Metabolic & Crystal Arthropathies Poster
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: To understand the role of inflammatory cytokines and oxidative stress biomarkers in the renal disease in people with gout. We hypothesized that higher gout severity, the lack of urate-lowering treatment (ULT) use and elevated inflammatory cytokines and oxidative stress markers will be associated with the presence of advanced renal disease in people with gout.

Methods: We prospectively enrolled patients with clinically diagnosed gout in the UAB Rheumatology Arthritis Database and Repository (RADAR) from January 2018 to December 2019. All except one patient (score of 7; the threshold of >=8) met ACR-EULAR gout classification criteria. Demographic and clinical data including gout severity and allopurinol use were collected. Serum and plasma were assayed for key inflammatory markers and oxidative stress pathway metabolites, and renal function tests and other clinical end points were assessed. Gout severity was assessed on the basis of: (1) High disease activity defined as treating physician's impression or ≥ one gout flare in the last 3-6 month, or serum urate level above target (6 mg/dl) necessitating escalation of ULT; (2) presence of tophi (yes/no); and (3) the current serum urate. We used analysis of variance (continuous) and chi-square (categorical) to examine association of gout severity, ULT use and cytokines and oxidative stress markers with advanced renal disease, defined as glomerular filtration rate (GFR) ≤ 60 ml/min.

Results: Our study included a total of 90 patients with gout, 73% males, 48% African American, 48% Caucasian and 11% active smokers. Of these, 54% (N=49) hadat least one gout attack in this period, 89% had non-tophaceous gout and 74% had hypertension (**Table 1**). The mean serum urate level, serum creatinine and glomerular filtration rate (GFR) were 6.48 mg/dl (2.21), 1.83 mg/dl (3.34), 38.6 ml/min (16.4) respectively. Four inflammatory markers were increased in patients with advanced renal disease (GFR ≤60 ml/min) versus non-renal disease (GFR >60 ml/min); IL-1beta, PDGF-AA, A PDGF-BB and TNF- alpha, which statistically significant (P=0.03, 0,02, 0,03, 0.02; **Table 2**). 8-Isoprostane levels were low in people with advanced renal disease with no significant differences in other oxidative stress pathway markers including nitrotyrosine, carbonyl content, oxyHb, MetHb, nitrite or nitrates. Severity of gout disease, the presence of tophi, current allopurinol use and serum urate < 6 mg/dl were not associated with the presence of advanced renal disease (**Table 3**).

Conclusion: High level of oxidative stress and inflammatory cytokine markers were associated with the presence of advanced renal disease in patients with gout. These associations need further study in larger samples.

Pharmacokinetics of Pegloticase and Methotrexate Polyglutamate(s) in Patients with Uncontrolled Gout Receiving Pegloticase and Co-treatment of Methotrexate

Yang Song[1], Yan Xin[1], **Michael Weinblatt**[2], Jason Chamberlain[1], Katie Obermeyer[3], Lin Zhao[3], Colleen Canavan[3], Paul Peloso[4] and Srini Ramanathan[1], [1]Horizon Therapeutics plc, South San Francisco, CA, [2]Brigham and Women's Hospital, Boston, MA, [3]Horizon Therapeutics plc, Lake Forest, IL, [4]Horizon Therapeutics plc, Gurnee, IL

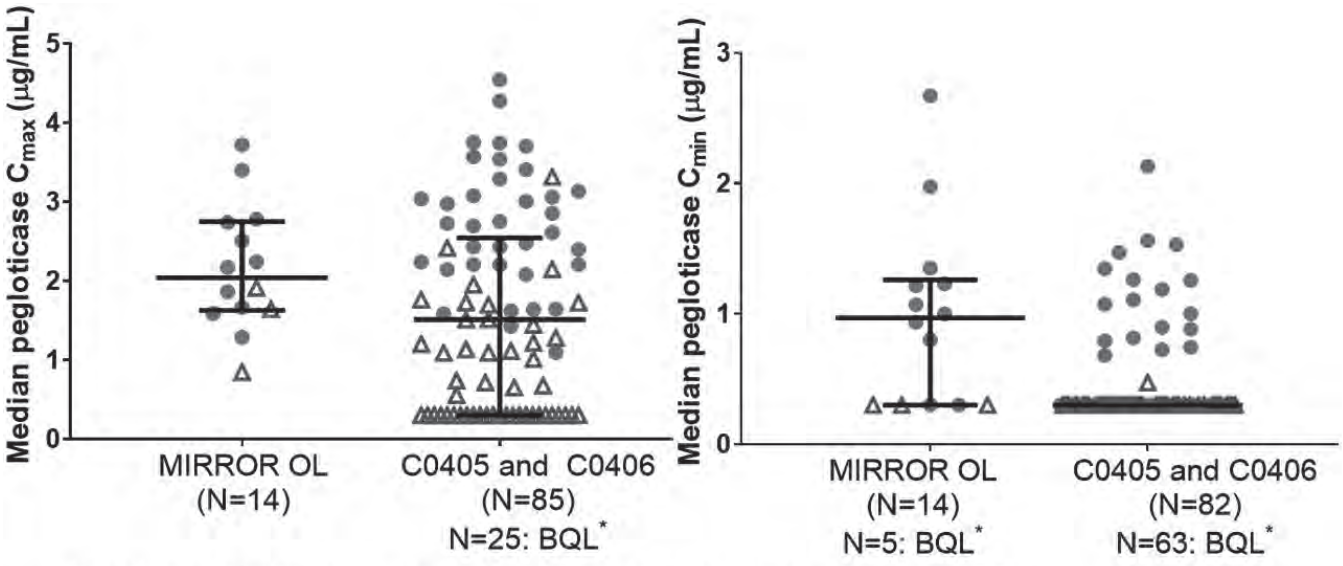
SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: Metabolic & Crystal Arthropathies Poster
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: In an open-label trial in adult patients with uncontrolled gout (MIRROR open-label [OL] trial) evaluating pegloticase co-treatment with methotrexate (MTX), 78.6% patients maintained serum uric acid < 6 mg/dL for at least 80% of the time during month 6 [weeks 20, 22, and 24] versus 42% in pegloticase historical monotherapy trials (C0405 and C0406)[1]. MTX co-treatment can affect the pharmacokinetics (PK) of biologics by attenuating the formation of anti-drug antibodies[2]. The aim of this analysis was to determine the systemic exposures of pegloticase and methotrexate polyglutamate(s) (MTX-PGs) in uncontrolled gout patients receiving pegloticase and MTX and to evaluate the effect of MTX on the PK and immunogenicity of pegloticase in comparison to historical pegloticase monotherapy trials (C0405 and C0406)[3,4].

Methods: In the MIRROR OL trial, MTX (15 mg/week) was given orally 4 weeks prior to the 1st pegloticase dose and continued weekly, in combination with pegloticase 8 mg given intravenously every 2 weeks, for a treatment duration of 52 weeks. Pre-infusion samples were collected to measure MTX-PGs in red blood cells. Pre- and post-infusion blood samples were obtained to measure the peak (C_{max}) and trough (C_{min}) concentrations of pegloticase at multiple visits. Anti-drug antibody blood samples were collected at multiple visits. The impact of MTX on pegloticase PK was evaluated by comparing pegloticase exposures with MTX from this trial to historical monotherapy data (C0405 and C0406)[3,4]. The observed pegloticase concentrations with MTX were also overlaid with the 90% prediction interval based on the population PK model from C0405 and C0406[5].

Results: Pegloticase and MTX-PG levels were determined in fourteen patients. Responders (11/14) were generally associated with higher pegloticase exposures, especially C_{min} (**Figure 1**). Concomitant treatment of MTX resulted in fewer patients with C_{min} below quantitation limit (BQL) (5/14 [36%] with MTX vs 63/82 [77%] without MTX), and higher overall C_{min} (median: 0.97 µg/ml with MTX vs BQL without MTX); C_{max} was slightly higher (median [Q1, Q3]: 2.04 [1.65, 2.68] µg/mL with MTX vs 1.51 [BQL, 2.48] µg/mL without MTX). Pegloticase co-treatment with MTX resulted in more concentrations above the predicted median value of pegloticase, compared to monotherapy (**Figure 1,2**). This may be due to the effect of MTX in reducing the immunogenicity of pegloticase. Concentrations of MTX-PGs were maintained during the treatment course, suggesting compliance of MTX administration. There was no apparent relationship between response and MTX-PGs exposures.

Conclusion: Pegloticase 8 mg IV every 2 weeks co-treatment with MTX 15 mg weekly resulted in fewer patients with pegloticase C_{min} BQL, and higher overall C_{min} compared to pegloticase monotherapy and was associated with an improved response rate for pegloticase in patients with uncontrolled gout.



*Data that are BQL (Below quantitation limit of 0.6 µg/mL) were imputed as 0.3 µg/mL (LLOQ/2).
Closed circles: Responders (11/14 in MIRROR OL; 36/85 in C0405 and C0406);
Open triangles: Non-responders (3/14 in MIRROR OL; 49/85 in C0405 and C0406).
Lower, middle and upper lines represent Q1, median and Q3 of data range.
Median pegloticase Cmin and Cmax were calculated based on observed values across visits.

The Shrinking Toe: A Sign of Crystal Dissolution During Urate Lowering Treatment of Severe Gouty Arthropathy

Thomas Bardin[1], Nguyen Dinh Quang[2], Hieu Le Nghia[2], Tran Minh Khoi[2], Hang Korng EA[3], Valérie Bousson[4] and Pascal Richette[5], [1]Université de Paris, INSERM U1132 and Hôpital Lariboisièe, Paris, France, Paris, France, [2]Vien Gut Medical Center, Ho Chi Minh City, Vietnam, [3]Universite de Paris, AP-HP, INSERM, paris, France, [4]Lariboisière Hospital, Paris, France, [5]Department of Rheumatology, Lariboisière Hospital, Paris, France

SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: Metabolic & Crystal Arthropathies Poster
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Serum urate (SU) lowering has been reported to improve gout erosions. We observed that it may also lead to compaction of toe MTP or IP joints involved by severe gouty arthropathy.

Methods: We performed a retrospective analysis of 10 patients with severe tophaceous gout and destructive arthropathy, who did not receive urate-lowering drugs (ULDs) before inclusion and developed toe shortening (a sign we called the shrinking toe sign) during urate lowering treatment (ULT) at the Vien Gut Medical Center (Ho Chi Minh City, Vietnam). Data were retrieved from anonymized electronic files, including sequential foot radiographs and photographs. Antero-posterior non-weight bearing digital radiographs of the feet taken before ULT start, and during follow-up, were analyzed by using the COREL DRAW software (Corel Corporation, CANADA), which allowed standardization of the size and orientation of patients' radiographs, and measurement of toe shortenings.

Results: The 10 patients were men with a mean age of 39 +/- 6.6 years at gout onset. At inclusion, their mean age was 51.4 (SD 9.6) years, mean gout duration 12.4 (3.8) years, mean uricemia 528.2 (51.9) micromoles/l, mean BMI 22.5 (3.8) kg/m^2. Patients were treated by progressively increased doses of allopurinol (n=6; mean maintenance dose: 650 mg/d; range 450-900), or febuxostat (n=4; mean maintenance dose 130 mg/d; range 80-160). All patients achieved the < 300 micromoles/l serum urate (SU) target after a mean of 7.4 months (range 1-15).

Example of the shrinking toe sign

During a mean total radiological follow-up of 27 (15) months (range 6-48), the 10 patients had a mean of 1.8 radiographs each (range 1-4). The shrinking toe sign involved 12 toes: 7 first MTPs (Fig.) (mean shortening 8.7 mm; range: 3-13.8), 3 second MTPs (mean 12.4 mm; range: 9.5-17.9), and 2 second toe DIPs (9.5 and 4.4 mm). Toe shortening was also observed clinically, as confirmed by sequential photographs (Fig.).

In one patient, subchondral lytic bone collapse of P1 basis was observed 9 months before the SU target was reached, leading to shortening of a big toe, with no sign of tophus decrease, suggesting that the shrinking toe sign can occur in poorly treated gout. In the other 9 patients, shrinking toes were observed after the target had been reached at a mean follow-up of 22.9 months (range 2-47). Dissolution of MSU deposits within the joint space and/or subchondral bone lytic areas, leading to their collapse, despite the frequent observation of bone reconstruction, appeared to be the main explanation for toe shortening, associated with subluxation of the involved joint in 3 patients. 5 patients

underwent multiple follow-up radiographs; in 4, toes shortened progressively with time in parallel with decrease of tophus opacities, whereas the 5th, who had 3 follow-up radiographs up to 27 months, exhibited maximum shortening at the first follow-up radiograph (month 11), when tophus opacities had already vanished.

Conclusion: The shrinking toe sign that we described in this study involved the 1st and 2d toes, where constraints are maximized. It may be a feature of severe gouty arthropathy, but was mainly observed during MSU dissolution under ULT, which appeared to fragilize the involved joints.

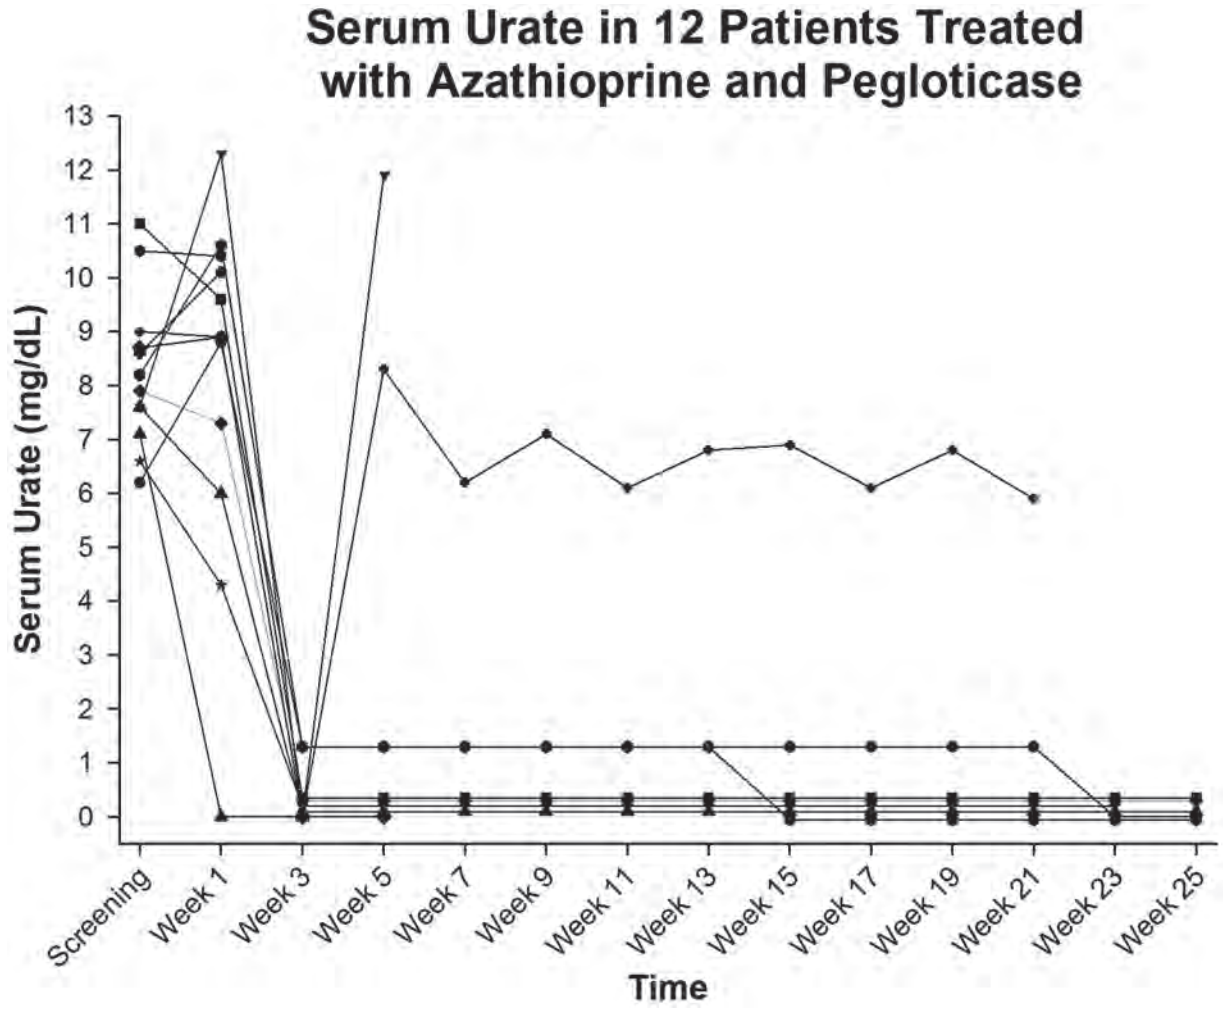
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Pegloticase is a mammalian recombinant uricase coupled to monomethoxy polyethylene glycol that is approved in the US for treatment of patients with chronic refractory gout and causes profound reductions in serum urate. However, treatment with pegloticase is limited by the induction of anti-drug antibodies and loss of responsiveness in nearly half of treated patients.

The goal of this study was to determine whether co-therapy with azathioprine (AZA) would increase the frequency of chronic refractory gout patients who had persistent urate lowering from pegloticase therapy.

Methods: This open label multicenter study enrolled subjects with chronic gout who failed to lower serum urate to < 6 mg/dL despite medically indicated doses of urate lowering therapy (NCT02598596). Patients were screened for adequate levels of the AZA metabolizing enzyme thiopurine methyl transferase and then started on daily oral AZA 1.25 mg/kg for 1 week and then 2.5 mg/kg for the remainder of the trial. Blood levels of AZA metabolites 6-thioguanine and 6-methylmercaptopurine were measured biweekly. After receiving 2 weeks of AZA, patients were started on pegloticase (8 mg IV) and were treated biweekly for 24 weeks. The primary endpoint was the persistent lowering of serum urate to < 6 mg/dL at the last three consecutive study visits. Patients who had an increase in serum urate to >6 mg/dL while on therapy did not receive additional pegloticase. All patients received infusion prophylaxis with hydrocortisone as well as gout flare prophylaxis.

Results: To date, 12 patients have been enrolled. All patients were male, 75% white and 25% African American. Mean age was 62.4 ± 14.7 years, the mean BMI was 31.1 ± 4.5 and the mean duration of gout was 13.8 ± 9.2 years. At baseline, all patients had visible tophi; 58.3% suffered from gout flares; 81.8% had hypertension; 45.5% had dyslipidemia and 9.0% had coronary artery disease. Of the 12 patients, 6 have completed the full course of treatment



with persistent urate lowering and 2 remain on treatment also with persistent urate lowering (figure). 2 patients lost the urate lowering effect, both after 2 doses of pegloticase, and did not receive additional therapy. 1 patient experienced an infusion reaction during the first dose (1 infusion reaction in 90 infusions [1.1%] in the entire trial to date) and 1 subject had subjective symptoms of AZA intolerance with no laboratory abnormalities; these subjects discontinued the study and were not evaluable for the endpoint. No adverse events related to AZA were reported and gout flares were noted in 6 subjects (mean 1.5 flares/patient with flares).

Conclusion: AZA can be used safely in subjects with chronic refractory gout and appears to increase the frequency of subjects experiencing long term lowering of serum urate.

Abstract Number: 0686

Renal Evolution During the First Year of Urate-lowering Therapy According to Sonographic Joint Deposition: Data from the Lille-Alicante Inception Cohort

Irene Calabuig[1], Anne Marty-Ané[2], Laurène Norberciak[3], Jean--Francois Budzik[4], Agustín Martínez-Sanchis[5], Mariano Andrés[1] and Tristan Pascart[3], [1]Hospital General Universitario de Alicante-ISABIAL and Universidad Miguel Hernández de Elche, Alicante, Spain, [2]GHICL, Lille, France, [3]GHICL, Lomme, France, [4]University of Lille, Lille, France, [5]Hospital General Universitario de Alicante-ISABIAL, Alicante, Spain

SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: Metabolic & Crystal Arthropathies Poster
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Gout is associated with chronic kidney disease, but how the kidney function evolves when gout is treated with urate lowering therapy (ULT) is still a matter of debate. Gouty nephropathy is led by crystal deposition in renal medulla, so we hypothesized that patients with a high monosodium urate (MSU) crystal burden could have the highest potential of benefiting from effective crystal depletion in the kidneys. Joint ultrasound provides an assessment of the extent of MSU crystal deposition within joints (the double contour (DC) sign) and within tissues (tophi). The objective of this study was to determine if the burden of MSU crystals as assessed by ultrasound could predict kidney response to ULT in gout patients.

Methods: Gout patients from two referral centers in Spain (Alicante) and France (Lille) requiring ULT initiation were recruited to undergo baseline ultrasound scans and a 1-year follow-up. Ultrasound scans assessed 6 joints for the presence of the DC sign and tophi. Demographic data, comorbidities, treatments, gout history, biological data including the estimated glomerular filtration rate (eGFR) and serum urate levels, were collected at the baseline visit and at the month 12 visit. A 5-point change in the eGFR at month 12 was considered significant. The number of joints affected with the DC sign and presence of tophi were compared between patients improving, preserving and degrading their eGFR using the Khi-2 and Mann-Whitney-Wilcoxon tests respectively.

Results: A total of 165 patients were recruited (n=81 from Alicante and n=84 from Lille) aged 63 years old (±14.5), predominantly male (86.1%) and with 7.5 years (±9.8) of gout duration. Baseline eGFR was 75.2 ml/min/1.73m^2 (±23.9) and serum urate levels were 8.4 mg/dL (±1.8). Overall, 81.0% of patients had ultrasound tophi and the number of joints with the DC sign was 1.4 (±1.3).

At month 12, 37 patients were lost to follow-up. A target serum urate level below 6.0mg/dL was reached for 88 patients (70.4%) and eGFR was 72.6 ml/min/1.73m^2 (±23.4). Overall, 16.4% of patients had significantly improved their eGFR, while 31.2% degraded. Patients improving their eGFR numerically achieved more frequently the serum urate target below 6.0mg/dL (83.3%) than those degrading their eGFR (64.9%) (p=0.27). Neither the presence of ultrasound tophus (p=0.53 and 0.75) nor the number of joints with the DC sign (p=0.23 and 0.18) were associated to the improvement or degradation of the renal function. In the subgroup of patients achieving serum urate levels below 6.0mg/dL at month 12, all (100%) patients improving their eGFR had an ultrasound tophus versus 87% in those not improving (p=0.35), and the number of joints with the DC sign was 1 [1 ; 2] versus 1 [0 ; 2] (p=0.83).

Conclusion: The MSU crystal burden assessed by ultrasound does not help predict the evolution of renal function during the first year of ULT, likely because ultrasound signs of depositions (especially tophi) are quite constant in pa-

tients with gout. The study was not sufficiently powered to establish a clear link between reaching the target serum urate level and preserving/improving the renal function.

Musculoskeletal Manifestations in Patients with CD73 Deficiency

Cornelia Cudrici[1], Kam Newman[2], Deepak Lakshmipathy[1], Elisa Ferrante[1], Rebecca Huffstutler[1], Katherine Carney[1], Blas Betancourt[2], Markku Miettinen[3], James Katz[4], Leon Nesti[5], Han Wen[1], Manfred Boehm[6] and Alessandra Brofferio[1], [1]National Heart, Lung, and Blood Institute, National Institutes of Health, Bethesda, MD, [2]National Institute of Arthritis and Musculoskeletal and Skin Diseases, National Institutes of Health, Bethesda, MD, [3]National Cancer Institute, National Institutes of Health, Bethesda, MD, [4]NIH NIAMS, Bethesda, MD, [5]Clinical and Experimental Orthopaedics, Walter Reed National Military Medical Center, Bethesda, MD, [6]Center for Molecular Medicine, National Heart, Lung, and Blood Institute, National Institutes of Health, Bethesda, MD

SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: Metabolic & Crystal Arthropathies Poster
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Arterial calcification due to deficiency of CD73 (ACDC) is a hereditary autosomal recessive ectopic mineralization syndrome caused by loss-of-function mutations in the 5'-nucleotidase Ecto (*NT5E*) gene that encodes for CD73also known as ecto-5′-nucleotidase. In ACDC patients, arterial calcification predominantly involves the lower extremities causing early onset of intermittent claudication. Periarticular calcification has been reported in the first reports of ACDC, but the clinical characterization of arthritis has not been systematically investigated. Here, we describe the musculoskeletal manifestations in eight ACDC patients and characterize the microstructure and chemical composition of periarticular calcifications and synovial fluid crystals.

Methods: Eight ACDC patients with either homozygous or compound heterozygous mutations in the *NT5E* gene were included in this study and underwent extensive rheumatological and radiological evaluation over a period of 11 years. Periarticular and synovial biopsies were obtained from four ACDC patients with pathological evaluation of synovial tissue and synovial fluid, as well as characterization of crystal composition by compensated polarized light microscopy and Alizarin red staining for synovial fluid along with x-ray diffraction and x-ray micro tomosynthesis for periarticular calcification.

Results: Arthritis in ACDC patients has a distinctive presentation with episodic inflammatory manifestations of small joints along with mixed erosive-degenerative joint changes, as shown by x-ray, CT and MRI with a median age of onset of arthritis symptoms at 17. Over several decades, arthritis in these patients frequently leads to the development of fixed deformities and functional limitations. Large joints also become involved later in life with bulky periarticular calcifications and presence of enthesophytes. X-rays of cervical and thoracic spine vertebrae show osteoarthritis, osteophytes, intervertebral disk calcification, and arthritis of the facet joints. Further, we have identified calcium pyrophosphate and hydroxyapatite crystals in synovial fluid collected in four ACDC patients. With these samples, we identified by x-ray diffraction that periarticular calcifications are mostly composed of *hydroxyapatite* crystals. Some patients have multiple spherical calcifications with fibrosis showing histology similar to calcific tendinitis or tumoral calcinosis-like lesions.

Conclusion: This is the largest study to describe the musculoskeletal manifestations of ACDC patients over a period of 11 years and is the first study to report the crystal composition of periarticular calcifications and the presence of synovial fluid crystals in these patients. Based on the findings in this study, the joint involvement is best defined as an erosive arthropathy that includes peripheral and axial enthesopathic calcifications along with periarticular calcifications. Joint biopsy samples analysis reveals that calcium hydroxyapatite crystals are the main component of periarticular calcifications and synovial fluid, although pyrophosphate crystals were also found in the synovial fluid.

The Discontinuation of Allopurinol in the Inpatient Setting and the Risk of Gout Flare: A Community-Hospital Experience

Artem Minalyan[1], Waqas Ullah[2], Shristi Khanal[3], Bikash Basyal[4] and Qian Zhang[3], [1]Department of Medicine/Abington Hospital - Jefferson Health, Jenkintown, PA, [2]Department of Medicine/Abington Hospital - Jefferson Health, Horsham, [3]Department of Medicine/Abington Hospital - Jefferson Health, Jenkintown, [4]Department of Medicine/Abington Hospital - Jefferson Health, Abington

SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: Metabolic & Crystal Arthropathies Poster
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: The discontinuation of urate-lowering therapy (ULT) in the outpatient setting increases the risk of gout flare. It was reported that in hospitalized patients with gout flare in almost a quarter of admissions allopurinol was discontinued or decreased on day of admission. We have reviewed the hospitalizations of patients with a history of gout presenting to our hospital for conditions other than gout. The aim of the study was to determine if there was an association between the discontinuation of allopurinol upon admission to the hospital and the risk of developing a gout flare during hospitalization.

Methods: This was a retrospective chart review of patients with a history of gout, on chronic ULT with allopurinol, who were admitted to our hospital for conditions other than gout from 03/01/2017 - 03/31/2019. We only included patients hospitalized for at least 2 days. Charts were reviewed for patient demographics, length of stay, allopurinol discontinuation, gout flare, and corresponding risk factors. Data were summarized using descriptive statistics for baseline characteristics and outcomes. Inferential statistics were performed where appropriate to compare patients with and without continued allopurinol treatment during hospitalization. All p-values were two-tailed and a level of < 0.05 was considered significant.

Results: A total of 401 patients with a history of gout and allopurinol listed as an outpatient medication on the day of admission were included in the study. The mean age of the included population was 75+/- 13 years old (ranging between 40 and 99 years old). The majority of included patients were males (296 subjects comprising 74% of the population). The mean length of stay (LOS) was 6.29 days (ranging between 2 and 57 days). Most of the patients were obese with the mean body mass index (BMI) of 30 kg/m2 (17-61 kg/m2). The baseline characteristics (age, gender, BMI, use of loop and thiazide diuretics, history of renal failure, smoking status) of no-allopurinol (allopurinol discontinued on admission) and yes-allopurinol (allopurinol continued on admission) groups were not significantly different be-

tween the two groups. 23.3% (7/30) of patients who had allopurinol discontinued on admission (no-allopurinol group) developed gout flare during hospitalization. In contrast, only 2.2% (8/371) of patients in the yes-allopurinol group developed gout flare during hospitalization. The odds of having gout flare in the no-allopurinol group were significantly higher than in the yes-allopurinol group (Fisher exact probability test OR 13.8, CI 4.6 - 41.4, p=< 0.0001). In our study, the LOS was not affected by the development of gout flare during hospitalization (6.2 vs 6.3 days, respectively).

Conclusion: Hospitalized patients who have allopurinol discontinued upon admission are almost 14 times more likely to develop gout flare than those patients in whom allopurinol is continued during their hospital stay. Medication reconciliation remains an important step in providing care to hospitalized patients. Understanding the role of continuation of ULT in the inpatient setting is of paramount importance in decreasing the risk of gout flare in hospitalized patients.

Abstract Number: 0689

The Changing Epidemiology of Inpatient Gout and Associated Mortality: A 17-year National Study

Jasvinder Singh[1] and John Cleveland[1], [1]University of Alabama at Birmingham, Birmingham, AL

SESSION INFORMATION
Session Date: Saturday, November 7, 2020
Session Title: Metabolic & Crystal Arthropathies Poster
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: Knowledge gaps exist regarding time-trends for the main causes (Cardiac/renal disease vs. infections) hospitalizations in gout. Therefore, we examined whether specific causes (cardiovascular, renal, musculoskeletal, pulmonary, infection) of non-gout hospitalizations and mortality, have changed over time in people with gout.

Methods: We used the U.S. National Inpatient Sample (NIS) data from 1998 to 2014, the last calendar year with International Classification of Diseases, ninth revision, clinical modification (ICD-9-CM) in the U.S. NIS represents a 20% stratified sample of discharges for the U.S., a part of the Agency for Healthcare Research and Quality's (AHRQ) healthcare cost and utilization project (HCUP).

Our study cohort included people hospitalized with a secondary diagnosis of gout based on an ICD-9-CM code, 274.xx, a valid approach with high sensitivity (90%), specificity (100%) and positive predictive value (80%). We assessed whether the rank (and % hospitalizations) of specific diseases in the top 25 Clinical Classifications Software (CCS; and top 5) categories associated with hospitalizations in gout changed between the first (1998-99) and the last study periods (2013-14). CCS is a tool for clustering patient diagnoses and procedures (primary or secondary) into manageable clinically meaningful categories [5]. We chose 2014 as the last study year, due to switching from ICD-9-CM to ICD-10-CM in 2015.

Results: Non-gout Hospitalizations in people with gout: There were 501,847 non-gout hospitalizations in 1998-99 and 1,665,355 in 2013-14. The top four CCS categories did not change rank from 1998-99 to 2013-14, but both top 2-ranked categories, circulatory system and heart diseases, decreased by 9-10%. Infection categories increased from three in the top 25 CCS categories in 1998-99 (rank # 11, 15 and 20) to five in 2013-14 (rank #10, 11, 12, 18 and

21; **Figure 1A**), and included pneumonia, respiratory infections, infections/parasitic diseases and sepsis. Musculoskeletal diseases were rank #5 for hospitalization in 2013-14 and osteoarthritis was also newly added to the top 25 ranks for non-gout hospitalizations.

In-hospital mortality: Circulatory system disease was rank #1 in both in 1998-99 and 2013-14, but the attributed proportion decreased from 40% to 29%. Two infection categories were in the top ten in 1998-99 (respiratory infection, rank #7; pneumonia, rank #8) versus four infection categories in the top five CCS categories in 2013-14 (rank #2, #3, #4 and #5; **Figure 1B**). Most cardiac diseases and neoplasms were less frequent, while infection, respiratory failure, renal disease were more frequent in 2013-14 (**Figure 1B**).

Conclusion: Non-gout hospitalizations in people with gout increased over 2-decades. In-hospital mortality in patients with gout showed a replacement of cardiac/respiratory causes in ranks #2-5 in 1998-99 by infectious disease/sepsis in 2013-14. Cardiovascular diseases were the main reasons for non-gout hospitalizations in people with gout in both periods; but more importantly, their relative contribution decreased over 2-decades, while relative contributions of infectious and musculoskeletal diseases (including osteoarthritis) increased.

SESSION INFORMATION

Session Date: Saturday, November 7, 2020
Session Title: Metabolic & Crystal Arthropathies Poster
Session Type: Poster Session B
Session Time: 9:00AM–11:00AM

Background/Purpose: AR882 is a potent and selective uric acid transporter 1 (URAT1) inhibitor under development for the treatment of hyperuricemia or gout. Phase 1 single ascending dose and multiple ascending dose clinical studies in healthy adult male subjects demonstrated linear pharmacokinetics and dose-dependent serum uric acid (sUA) lowering effect. A phase 2a study in patients with gout is ongoing to evaluate efficacy following a three-week treatment regimen comparing AR882 with 40 mg febuxostat.

Methods: In a phase 2a, single-center, two-sequence, cross-over study, adults with gout (sUA > 7 mg/dL) were randomized to receive a once-daily, three-week treatment with AR882 50 mg alone or in combination with febuxostat 40 mg. Eleven patients have been enrolled in this ongoing study. Serial blood samples were collected for measurement of sUA, AR882 or febuxostat pharmacokinetics and pharmacodynamics at the end of each treatment week (Day 7, Day 14 and Day 21). Urine samples were collected for assessment of uric acid excretion. Laboratory safety tests, vital signs, and electrocardiograms were collected throughout the study.

Results: Following treatment of AR882, 100% of patients had sUA levels below 6 mg/dL, with 63% of patients below 5 mg/dL. AR882 reduced sUA from baseline (9.0 ± 1.3 mg/dL) to 4.7 ± 0.7 mg/dL at 24 hours postdose following multiple doses, corresponding to 47.1 ± 9.4% reduction. In comparison, febuxostat 40 mg reduced sUA levels to 6.1 ± 1.3 mg/dL (33.7 ± 6.7% reduction), with 50% and 13% patients below 6 and 5 mg/dL, respectively. The combination of AR882 and febuxostat further reduced sUA levels to 3.5 ± 1.1 mg/dL (61.0 ± 10.0% reduction) at 24 hours postdose with percentage of patients < 6, 5, 4 mg/dL at 100%, 78%, 67%, respectively. Fractional excretion of uric acid following AR882 treatment was higher than baseline. Exposure of AR882 in gout patients was slightly lower than in healthy subjects presumably due to higher BMI and body weight. AR882 showed similar exposure between patients with normal renal function and mild renal impairment. In mildly renal impaired patients, AR882 reduced sUA from 8.6 ± 1.1 mg/dL mg/dL to 4.5 ± 0.8 mg/dL. AR882 was well tolerated. There were no clinically significant laboratory or ECG abnormalities noted. All adverse events were mild or moderate in severity. One subject with viral bronchitis was discontinued due to concern of COVID-19.
