Arthritis & Rheumatology

AN OFFICIAL JOURNAL OF THE AMERICAN COLLEGE OF RHEUMATOLOGY

ABSTRACT SUPPLEMENT

ACR Convergence 2021

November 5–9, 2021

Virtual

American College of Rheumatology
Empowering Rheumatology Professionals

WILEY

Table of Contents

10:30 AM – 12:00 PM
Plenary Session III
(#1424-1429)

10:30 AM – 11:30 AM
Oral Abstract Sessions
(1430–1433) Innate Immunity
(1434–1437) Systemic Sclerosis & Related Disorders – Basic Science

2:00 PM – 3:00 PM; 2:00 PM – 3:30 PM
Oral Abstract Sessions
(1438–1441) Cytokines & Cell Trafficking
(1442–1445) RA – Treatments II: New Findings in Established Therapies
(1446–1451) Clinical Epidemiology

3:30 PM – 5:00 PM
Oral Abstract Sessions
(1452–1457) Miscellaneous Rheumatic & Inflammatory Diseases: New Insights into Therapies & Mechanisms of Disease
(1458–1463) SLE – Treatment: New Agents, Old Agents

Tuesday, November 9

8:30 AM – 10:30 AM
Poster Session D
(#1464-1888)

9:00 AM – 10:00 AM
Oral Abstract Sessions
(1889–1892) RA – Animal Models

10:30 AM – 11:30 AM
Oral Abstract Sessions
(1893–1896) Measures & Measurement of Healthcare Quality
(1897–1900) Metabolic & Crystal Arthropathies – Basic & Clinical Science
(1901–1904) Orthopedics, Low Back Pain, & Rehabilitation

2:00 PM – 3:00 PM; 2:00 PM – 3:30 PM
Oral Abstract Sessions
(1905–1908) B Cell Biology & Targets in Autoimmune & Inflammatory Disease
(1909–1914) Patient Outcomes, Preferences, & Attitudes
(1915–1918) RA – Diagnosis, Manifestations, & Outcomes II: Heart & Lung
(1919–1922) Spondyloarthritis Including PsA – Diagnosis, Manifestations, & Outcomes II

3:30 PM – 4:30 PM
Oral Abstract Sessions
(1923–1926) Epidemiology & Public Health II: Inflammatory Arthritis
(1927–1930) Pediatric Rheumatology – Basic Science
(1931–1934) SLE – Diagnosis, Manifestations, & Outcomes II: Predictors & Longitudinal Outcomes

4:00 PM – 5:00 PM
Oral Abstract Sessions
(1935–1938) Genetics, Genomics & Proteomics
(1939–1942) RA – Treatments I: Safety & Harms
(1943–1946) Spondyloarthritis Including PsA – Treatment II: Biologic Therapies

Patient Perspectives

Sunday, November 7

8:30 AM – 10:30 AM
Poster Session B
(#PP01–PP09) Patient Perspectives Poster

3:30 PM – 4:30 PM
Oral Session
(PP10–PP13) Patient Perspectives

Abstract Embargo Policy

Accepted abstracts are made available to the public online in advance of the meeting and are published in a special online supplement of our scientific journal, *Arthritis & Rheumatology*. Information contained in those abstracts may not be released until the abstracts appear online.

Academic institutions, private organizations, and companies with products whose value may be influenced by information contained in an abstract may issue a press release to coincide with the availability of an ACR abstract on the ACR Abstract website. However, the ACR continues to require that information that goes beyond that contained in the abstract (e.g., discussion of the abstract done as part a scientific presentation or presentation of additional new information that will be available at the time of the meeting) is under embargo until **November 1 at 10:00 AM ET.** Journalists with access to embargoed information also cannot release articles before this time.

Violation of this policy may result in the abstract being withdrawn from the meeting and other measures deemed appropriate. Authors are responsible for notifying colleagues, institutions, communications firms, and all other stakeholders related to the development or promotion of the abstract about this policy. If you have questions about the ACR abstract embargo policy, please contact ACR abstracts staff at abstracts@rheumatology.org.

Abstract Reprint (Reproduction) Policy

Copyright law covers all ACR Convergence abstracts published by the American College of Rheumatology. All rights reserved. No abstracts may be reproduced in any form or by any means without the prior permission of the publisher, except as permitted under section 107 and 108 of the 1976 United States Copyright Act.

For the purposes of this statement, the term **ACR Abstracts** refers to all ACR Convergence abstracts as published in *Arthritis & Rheumatology* and posted online, including the abstracts accepted for presentation during ARP sessions and the late-breaking category.

For the purposes of this statement, the term **ACR Posters** refers to the accepted abstract **POSTER PRESENTATIONS** as presented in the poster hall during ACR Convergence. **This does not include abstract text published in the online supplement of *Arthritis & Rheumatology*.** All **ACR Posters** are the property of the ACR and the presenting author and cannot be reproduced or distributed without written permission from the ACR and the presenting author.

- For the purposes of this statement, the term "reproduce" includes all forms of reproduction, including, but not limited to, print, electronic and photographed formats.
- For the purposes of this statement, the term "presenting author" refers to the author who is designated as the individual who will present the work during ACR Convergence, as identified through the abstract submission process.

Approval Process for ACR Abstracts

- Excerpts or the entirety of ACR Abstracts may not be reproduced without the prior written permission of the publisher.
- Permission requests for abstract content and other permission inquiries should be addressed to:

Permissions Department
c/o John Wiley & Sons, Inc.
111 River Street
Hoboken, NJ 07030
Fax: 201-748-6008
wiley.com/go/permissions

- Commercial entities seeking permission to reprint must obtain all materials from the author and/or publisher John Wiley & Sons, Inc. The ACR cannot provide any materials.

Approval Process for ACR Posters

- Reprint requests for the actual poster abstract text published in the Arthritis & Rheumatology supplement are considered ACR Abstracts and must submitted to Wiley (see approval process above).
- Requests to reproduce individual ACR posters, figures from ACR posters, or booklets of poster presentations (e.g., two or more) must be submitted via e-mail to abstractreprints@rheumatology.org.
- Poster reproduction requests must include the following:
  – Abstract ID Number
  – Abstract Title
  – Presenting Author's Name
  – A copy of Presenting Author's written approval (Please Note: An e-mail approval from Presenting Author is acceptable)

Reproducing ACR Abstracts and Posters for Dissemination Prior to ACR Convergence

- Requests to reproduce abstracts for dissemination prior to ACR Convergence *will not be approved*.
- Per the ACR Embargo Policy (see above), academic institutions, private organizations, and companies with products whose value may be influenced by information contained in an abstract may issue a press release to coincide with the availability of an abstract online.
- Permission to issue a press release does not require ACR approval. However, it must comply with the ACR Embargo Policy; violation of this policy may result in the abstract being withdrawn from the meeting or other measures deemed appropriate.
- For more information regarding press releases, please contact the ACR public relations department at pr@rheumatology.org.

Reproducing ACR Abstracts and Posters for Dissemination During ACR Convergence

Following approval (see approval process above), an exhibiting organization may:

- Following approval (see approval process above), an exhibiting organization may disseminate copies of individual ACR Abstracts from its exhibit space. Booklets of abstracts (e.g., two or more) may not be produced.
- Following approval, an exhibiting organization may disseminate information summaries (title/date/time/poster number) of ACR Abstracts from its exhibit space. Summaries may not reference company or product names. Requests for approval must be submitted in writing to abstractreprints@rheumatology.org.
- Presenting authors may disseminate individual copies of their ACR Poster during their assigned poster presentation time. Dissemination must be limited to the area directly in front of their assigned poster space and may not interfere with other poster presentations.
- An electronic copy of the poster may be provided via a QR code generated by the presenter and included on the poster.

Reproducing ACR Abstracts and ACR Posters for Dissemination After ACR Convergence

ACR Abstracts

Following approval from Wiley (see approval process above), the ACR permits ACR Abstracts (i.e., all abstract content published in the online supplement) to be reprinted and disseminated following ACR Convergence.

- Abstracts and booklets of abstracts (e.g., two or more) must include the following statement on the front of the abstract/booklet:
  Abstract(s) reprinted from ACR Convergence held [insert meeting dates]. The American College of Rheumatology does not guarantee, warrant, or endorse any commercial products or services. Reprinted by [insert name of supporting company].
- Booklets cannot contain corporate or product logos or any advertisements. No exceptions.

ACR Posters

Following approval from the presenting author and the ACR (see approval process above), copies of actual ACR poster presentations (i.e., images from the poster presentation hung in the poster hall) may be reproduced.

1. Reprint requests for the actual poster abstract text published in the Arthritis & Rheumatology supplement are considered ACR Abstracts and must submitted to Wiley (see approval process above).

- **IMPORTANT: The ACR does not retain and cannot provide poster presentation images.**
- The following statement must be listed under each Poster reprint:
  Reprinted from ACR Convergence held [insert meeting dates]. The American College of Rheumatology does not guarantee, warrant, or endorse any commercial products or services. Reprinted by [insert name of supporting company].

Use of the ACR Name

The names, insignias, logos and acronyms of the ACR, the ARP, and the Rheumatology Research Foundation are proprietary marks. Use of the names in any fashion, by any entity, for any purpose, is prohibited without the express written permission of the American College of Rheumatology.

Use of the ACR Scientific Program Content

- Information displayed or presented at all sessions during ACR Convergence is the property of the ACR or the presenter. Information may not be recorded, photographed, copied, photocopied, transferred to electronic format, reproduced or distributed without the prior written permission of the ACR and the presenter.
- Any use of the program content, which includes but is not limited to oral presentations, audiovisual materials used by speakers and program handouts, without the written consent of the ACR is prohibited.
- This policy applies before, during and after the meeting.
- The ACR will enforce its intellectual property rights and penalize those who infringe upon it.

Use of the ACR Disclosure Key

It is suggested when referencing disclosures in the reprints, that the ACR's disclosure key be added to provide adequate context for abstracts:

None: Has no relevant financial relationship to disclose.

1. Advisor or Review Panel member
2. Consultant
3. Employee
4. Officer or Board Member
5. Grant/Research Support
6. Speaker/Honoraria includes speakers bureau, symposia, and expert witness
7. Independent Contractor
8. Ownership Interest
9. Royalties
10. Intellectual Property / Patents
11. Stock options or bond holdings in a for-profit corporation or self-directed pension plan
12. Other Financial or Material Support

Autoantigenic Properties Indicated for the Entire Aminoacyl tRNA Synthetase Family in Idiopathic Inflammatory Myopathies

Charlotta Preger[1], Antonella Notarnicola[1], Cecilia Hellström[2], Edvard Wigren[1], Catia Cerqueira[3], Peter Nilsson[2], Ingrid E Lundberg[1], Helena Persson[4], Susanne Gräslund[1] and Per-Johan Jakobsson[5], [1]Karolinska Institutet, Karolinska University Hospital, Division of Rheumatology, Department of Medicine Solna, Stockholm, Sweden, Stockholm, Sweden, [2]Division of Affinity Proteomics, Department of Protein Science, KTH Royal Institute of Technology & SciLifeLab, Stockholm, Sweden, [3]4Dcell, Montreuil, France, [4]Drug Discovery and Development Platform, SciLifeLab & School of Engineering Sciences in Chemistry, Biotechnology and Health, Royal Institute of Technology (KTH), Solna, Sweden, [5]Karolinska Institutet, Stockholm, Sweden

SESSION INFORMATION
Session Date: Saturday, November 6, 2021
Session Title: B Cell Biology & Targets in Autoimmune & Inflammatory Disease Poster (0001–0010)
Session Type: Poster Session A
Session Time: 8:30AM–10:30AM

Background/Purpose: Autoantibodies are thought to play a key role in the pathogenesis of idiopathic inflammatory myopathies (IIM). However, 40% of IIM patients, even those with clinical manifestations of anti-synthetase syndrome (ASS), test seronegative to all known myositis specific autoantibodies (MSAs). Therefore, we hypothesized the existence of new potential autoantigens and we included all human cytoplasmic aminoacyl tRNA synthetases (aaRS) in an autoantibody screening of patients with IIM.

Methods: Plasma samples and clinical data from 217 IIM patients were collected from the Karolinska University Hospital myositis cohort. Fulfillment of the 2017 classification criteria (1) for IIM and Connor's criteria (2) for ASS was verified for all patients. Patients were divided into two groups based on the ASS status (not available for 2/217 patients) and clinical manifestations were compared. Autoantibodies (MSAs and myositis associated autoantibodies (MAAs)) were tested in the clinic by standardized immunoassays (ELISA, line lot or immunoprecipitation). The 217 plasma samples were screened, using a multiplex bead array assay, for the presence of autoantibodies against a panel of 118 recombinant protein variants, representing 33 myositis-related proteins, including all 20 cytoplasmic aaRS.

Results: Fifty patients with and 165 without ASS were identified. In the non-ASS group, 69% were seronegative for MSAs. Frequency of muscle and skin involvement did not statistically differ between the two groups, while Raynaud's phenomenon, arthritis, ILD and cardiac disease were statistically more frequent in the ASS group. On the contrary, dysphagia was statistically more prevalent among the non-ASS patients. By performing the multiplex assay, we could confirm reactivity to Jo1, PL-12, PL-7, and EJ in 44/49 patients with ASS, but not to OJ (1 patient) in the ASS group. We identified patients positive for anti-Zo (n=5), -KS (n=2) and -HA (n=3), 9/10 from the non-ASS group. In addition, we identified 12 patients positive for autoantibodies targeting other aaRS (3 from the ASS group, and 9 from the non-ASS group). These novel reactivities could be confirmed by ELISA. Ten of 22 reactivities were identified in patients previously known as seronegative.

Conclusion: Our results suggest that all aaRS may become autoantigenic. Autoantibodies against new aaRS might be found in plasma of patients previously classified as seronegative with potential high clinical relevance.

Salivary Sodium Levels in the Parotid Salivary Gland of SS Patients Suggest B-cell Mediated Epithelial Sodium Channel Disruption

Sarah Pringle[1], Bas Berkhof[1], Martha S. van Ginkel[2], Silvia Liefers[1], Bert van der vegt[2], Fred Spijkervet[2], Hendrika Bootsma[1], Arjan Vissink[1] and Frans Kroese[1], [1]University Medical Center Groningen, Groningen, Netherlands, [2]University of Groningen, University Medical Center Groningen, Groningen, Netherlands

SESSION INFORMATION
Session Date: Saturday, November 6, 2021
Session Title: B Cell Biology & Targets in Autoimmune & Inflammatory Disease Poster (0001–0010)
Session Type: Poster Session A
Session Time: 8:30AM–10:30AM

Background/Purpose: Patients with Sjögren's syndrome (SS) suffer from significantly reduced saliva production. Saliva is important for oral health. A careful of sodium, chloride, potassium and phosphate ions in saliva is essential for this. Studies have suggested that salivary levels of sodium are increased in SS patients but no mechanism for the increased sodium has been suggested. We aimed to perform an extensive characterization of sialochemical parameters in SS patient saliva compared to non-SS sicca patients, correlate this with SS histopathology, and investigate potential mechanisms underpinning any differences observed.

Methods: Unstimulated and stimulated submandibular/sublingual (SmSl), and stimulated parotid (Par) saliva was collected from 32 SS patients diagnosed according to the 2016 ACR-EULAR criteria. For comparison, 62 non-SS sicca control patients were analysed. Sodium, chloride, phosphate and potassium ion concentration, α-amylase activity and total protein content were measured as sialochemical parameters. CD45, CD20 and CD3 percentage positive cell area in parotid biopsies were quantified, and determination of lymphoepithelial lesion (LEL) severity was carried out as published (1,2). Epithelial sodium channel (ENaC) immunostaining was performed according to standard protocols.

Results: Sodium concentrations were significantly higher in unstimulated SmSl ($p< 0.0001$), stimulated SmSl ($p=0.002$), and stimulated Par saliva ($p< 0.0001$) of pSS patients, compared to non-SS controls (Fig1A). No other sialochemical readout was so significantly different between in saliva from pSS and controls. Stimulated Par saliva sodium levels positively correlated with the percentage of $CD45^+$ infiltration ($r=0.69$, $p< 0.001$; Fig1B) and $CD20^+$ B cells in pSS patient parotid glands ($r=0.73$, $p< 0.0001$; Fig1C) and maximum LEL severity score ($r=0.46$, $p=0.02$; Fig1D) in patient parotid glands. Percentage area of $CD3^+$ T cells were only fairly correlated with salivary sodium ($r=0.23$, $p=0.015$). No significant correlation between other sialochemical parameters and infiltration was observed.

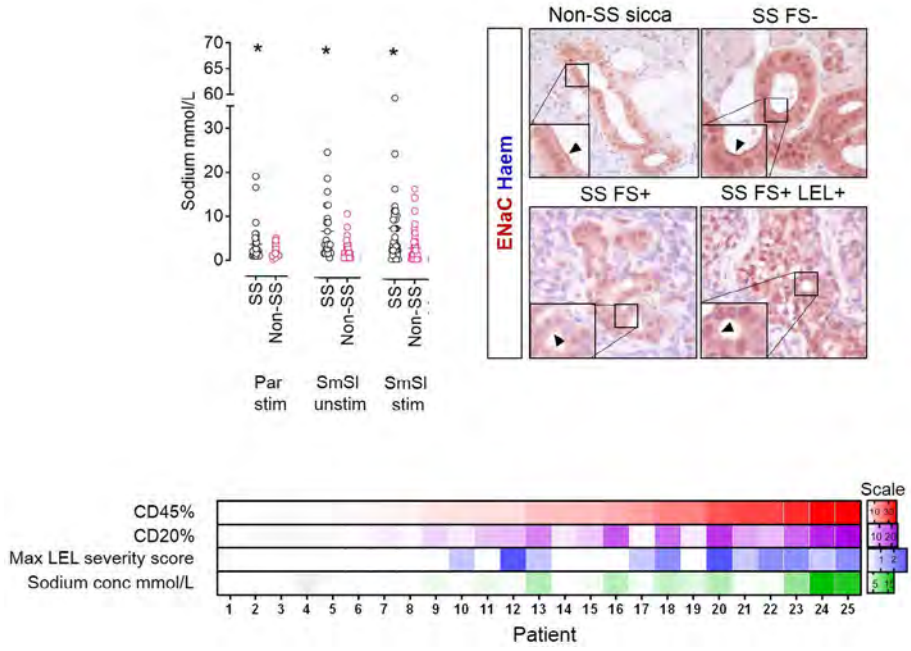

Figure 1. *Salivary sodium levels in pSS patients suggest a role for B cells in dysregulation of epithelial sodium channels.* A) Sodium concentration in stimulated parotid saliva, unstimulated submandibular/sublingual saliva and stimulated submandibular/sublingual saliva, in SS and non-SS patients B-D) Heatmaps of CD45 percentage area (B), CD20+ cell percentage area (C) and maximum lymphoepithelial lesions (LEL) score (D), matched with patient salivary sodium concentration. Scales for each parameters are given to the right of each parameter. E-H) Immunohistochemical staining for the epithelial sodium transporter channel ENaC, in E) non-SS parotid gland tissue, F) SS tissue with a negative focus score (FS) G) SS tissue with a positive FS and H) SS tissue with a positive FS and presence of a LEL.

In non-SS control parotid tissue, ENaC, responsible for transport of sodium out of saliva, into ductal cells, was clearly localized at the apical membrane of the luminal striated duct cells (Fig1E,F). In tissue from SS patients with a positive FS, and SS patients with positive FS and presence of LELs, ENaC appeared to be absent from the apical membrane of the ductal cells (Fig1G,H).

Conclusion: We confirm that salivary sodium levels are increased in patients with SS and extend this observation by correlating these levels with the percentage of $CD45^+$ and $CD20^+$ infiltration. In SG tissue of SS patients with inflammatory foci (with and without LELs), the ENaC protein does not appear to be present at the apical membrane of the ductal cells. We hypothesize that B cell-related cytokines in SS are directly responsible for the dysregulation of sodium transport channels in SS and may represent a larger driving force behind decreased oral health in SS patients than previously appreciated.

Abstract Number: 0003

Clinically Identifiable Autoreactivity Is Common in Severe SARS-CoV-2 Infection

Richard Ramonell[1], Matthew Woodruff[2], Mark Rudolph[3], F. Eun-Hyung Lee[1] and Iñaki Sanz[4], [1]Emory University, Atlanta, GA, [2]Emory University, Decatur, GA, [3]Exagen Inc., Vista, CA, [4]Emory University School of Medicine, Atlanta, GA

SESSION INFORMATION

Session Date: Saturday, November 6, 2021
Session Title: B Cell Biology & Targets in Autoimmune & Inflammatory Disease Poster (0001–0010)
Session Type: Poster Session A
Session Time: 8:30AM–10:30AM

Background/Purpose: A massive expanson of plasmablasts or antibody secreting cells (ASC) have been shown in severe patients with SARS-CoV-2 infection and in patients with autoimmune disease i.e. Systemic Lupus Erythematosus (SLE). The ASC responses in severe SARS-CoV-2 infections are associated with an intense extrafollicular (EF) B cell response reminiscent of flares in SLE patients. Additionally, autoantibodies against phospholipids, type-I interferons, and other targets have been reported in SARS-CoV-2 infection. These observations raise the possibility that severe SARS-CoV-2 infection results in breaks of self-tolerance to autoantigens.

Methods: Peripheral blood was prospectively collected from two groups of patients with COVID-19: 26 critically ill and 18 outpatients together with 15 healthy adults. Plasma from these samples was tested for a variety of autoimmune serologies. Additionally, we retrospectively collected data from 31 critically ill patients with COVID-19 who had autoimmune serologies ordered by their treatment team in the course of their ICU care in two academic ICUs in Atlanta, Georgia, USA.

Results: In the prospective cohort, autoantibodies were found more frequently in the plasma of critically ill subjects compared to healthy donors. Although there was no significant difference between dsDNA levels or ANA titers between groups, there were significantly higher levels of anti-carbamylated antibodies in the critically ill group. Notably, these levels were similar to levels in donors with SLE. In the retrospective cohort, 44% of patients had positive levels of ANA at ≥ 1:80 in a predominantly speckled pattern (50%). Of positive tests, 81% displayed titers of ≥1:160, with the higher titers ranging from 1:320-1:640. Anti-RNP and anti-centromere IgG titers were detected in 2 of 22 ANA+ patients. Reactivity against rheumatoid factor (10/52), phospholipids (3/52), prothrombin (2/52), and c-ANCA (2/52), with or without ANA reactivity, suggests broad autoimmune targeting. 59% of ANA+ patients displayed at least one other positive auto-reactive antibody test. Longitudinal data in seven patients showed that two subjects had increased ANA titers, one remained at 1:360, and one became negative.

Conclusion: Our findings invite two interpretations. Either patients with undocumented and pre-existing autoimmunity comprise the majority of the critical illness within our cohort or, more likely, the immunological environment of serious COVID-19 infection is sufficient to drive de novo autoreactivity against a variety of self-antigens. Longitudinal study of recovered patients will be critical in understanding the persistence of this autoreactive state, its role in the increasingly documented cases of 'lingering' COVID-19, and its propensity for conversion into self-sustaining autoimmunity.

SESSION INFORMATION

Session Date: Saturday, November 6, 2021

Session Title: B Cell Biology & Targets in Autoimmune & Inflammatory Disease Poster (0001–0010)

Session Type: Poster Session A

Session Time: 8:30AM–10:30AM

Background/Purpose: The impact of immune mediators on weight homeostasis and systemic metabolism remains underdefined. Interrogation of resistance to diet-induced obesity in mice lacking a negative regulator of Toll-like receptor signaling serendipitously uncovered a role for B cell activating factor (BAFF). Here, we sought to define noncanonical roles for role BAFF and the BAFF homolog, A proliferation-inducing ligand (APRIL), as regulators of systemic metabolism and weight homeostasis.

Methods: Multiple murine genetic models with variable levels of BAFF and APRIL sufficiency/overexpression were examined in the context of an *in vivo* model of obesogenic diet-induced obesity. Direct effects of BAFF on murine white adipose tissue and brown adipose tissue adipocytes were examined *in vitro* and *in vivo*. Whether these effects on murine metabolism were relevant to humans was assessed by examining plasma BAFF and APRIL levels with BMI change in response to bariatric surgery in obese individuals. Similarly, the direct effects on human white adipose tissue were assessed by examining the expression of orthologous human genes on white adipose tissue adipocytes in response to treatment with recombinant human BAFF and APRIL.

Results: Overexpression of BAFF in multiple mouse models associates with protection from weight gain, approximating a log-linear dose response relation to BAFF concentrations. Gene expression analysis of BAFF-stimulated adipocytes unveils upregulation of lipid metabolism pathways, with BAFF inducing white adipose tissue (WAT) lipolysis. Brown adipose tissue (BAT) from BAFF-overexpressing mice exhibits increased Ucp1 expression and BAFF promotes brown adipocyte respiration and energy expenditure. A proliferation-inducing ligand (APRIL), a BAFF homolog, similarly modulates WAT and BAT lipid handling. Genetic deletion of both BAFF and APRIL augments diet-induced

obesity. Importantly, BAFF/APRIL effects are conserved in human adipocytes and higher BAFF/APRIL levels correlate with BMI decrease after bariatric surgery. Finally, preliminary results suggest that the critical source BAFF in these models is intestinal epithelial cells.

Conclusion: Together, our results define the BAFF/APRIL axis as a multifaceted immune regulator of weight gain and adipose tissue function. The percentage change in BAFF sufficient to modify obesity in murine models is comparable to levels that increase risk of Lupus and Multiple Sclerosis in humans. Thus, these findings will inform our understanding of the unexpected potential metabolic effects of B-cell targeted therapies in humans.

Maturation and Dysfunction of Autoreactive B Cell Clones in Tissues of Patients with Sjögren's Syndrome

Mathijs Broeren[1], Giulia Balzaretti[2], Jing Wang[3], Patricia Groenen[1], Barbera van Schaik[4], Tim Chataway[3], Charlotte Kaffa[1], Sander Bervoets[1], Konnie Hebeda[1], Gergana Bounova[5], Ger Pruijn[1], Tom Gordon[3], Niek De Vries[6] and **Rogier Thurlings**[7], [1]Radboud University Medical Center, Nijmegen, Netherlands, [2]Amsterdam, Netherlands, [3]Flinders University, Adelaide, Australia, [4]Amsterdam University Medical Centers, Amsterdam, Netherlands, [5]Enpicom BV, Den Bosch, Netherlands, [6]Amsterdam UMC, Amsterdam, Netherlands, [7]Radboud University Medical Centre, Nijmegen, Netherlands

SESSION INFORMATION
Session Date: Saturday, November 6, 2021
Session Title: B Cell Biology & Targets in Autoimmune & Inflammatory Disease Poster (0001–0010)
Session Type: Poster Session A
Session Time: 8:30AM–10:30AM

Background/Purpose: Sjögren's syndrome (SjS) involves chronic inflammation of exocrine glands that can be complicated by extranodal marginal zone lymphoma of mucosa-associated lymphoid tissue (MALT). We analyze the generation of the antinuclear (ANA) and rheumatoid factor (RF)-specific B cell repertoires, and their interaction in patient tissues before and at disease relapse after rituximab treatment.

Methods: We analyzed blood and tissues of 6 SjS patients with anti-Ro60, anti-Ro52, anti-La and RF autoantibodies. We analyzed the tissues of 2 patients that had been diagnosed with MALT lymphoma and were subsequently treated with rituximab monotherapy. We analyzed anti-Ro60, anti-Ro52, anti-La and RF clones using a combination of new, partly self-developed tools to analyze autoreactive B cell receptors at DNA, RNA, protein and single cell level.

Results: In affected tissues anti-Ro52, anti-La and anti-Ro60 clones outnumbered RF clones. Compared to ANA clones affinity maturation of RF clones was IgM directed and depended on the structural integrity of the frame work regions of preferred variable immunoglobulin segments. In MALT lymphoma tissues lymphomatous clones were

solitary large RF clones using shared sequence motifs and displaying high intra-clonal diversification. These co-occurred with a high number of ANA clones. At clinical relapse after rituximab treatment dominant persistent MALT or other RF clones proliferated in a memory, intra-clonal diversification directed recall response. In the same tissues many small ANA clones displayed a plasma cell directed recall response.

Conclusion: We find divergent affinity maturation of RF compared to ANA clones, that exacerbates in RF-clone derived MALT lymphomas and at regeneration of disease manifestations after rituximab.

Metabolic Characteristics of Age-related B Cells in Lupus-prone Mice and Effects on Follicular Helper T Cells

Ivan Ramirez[1], Betty Diamond[2] and Sun Jung Kim[3], [1]Northwell, Little Neck, NY, [2]Northwell Health, Manhasset, NY, [3]Feinstein Institutes for Medical Research, Manhasset, NY

SESSION INFORMATION

Session Date: Saturday, November 6, 2021
Session Title: B Cell Biology & Targets in Autoimmune & Inflammatory Disease Poster (0001–0010)
Session Type: Poster Session A
Session Time: 8:30AM–10:30AM

Background/Purpose: Since the description of age-associated B cells (ABC), there has been a growing interest in the role of these cells in autoimmunity. Evidence suggests that ABC are involved in antigen presentation, autoantibody production and demonstrates a particular response to Toll-like receptor stimulation[1,2]. The study of lymphocyte metabolism in SLE has revealed that metabolic pathways are hyperactivated in lupus-prone mice compare to controls and that the treatment with metabolic inhibitors reverses these changes[3,4]. In this study, we test the hypothesis that ABC cells show increased metabolic activity and the altered metabolism in ABCs is responsible for the promotion of Tfh cell differentiation.

Methods: ABC cells were identified by the definition of CD11c+/ CD11b+ in CD19+ B cells by flow cytometry analysis. For the metabolism study, ABCs were isolated from spleens of 10–12-month old lupus-prone mice, triple congenital *sle1,2,3* (TC) and B6.lpr, and age-matched C57BL/6 controls, and metabolism (oxygen consumption (OCR) and extracellular acidification rate (ECAR)) was analyzed by the seahorse assay with XFp cell mito stress kit. Tfh differentiation was conducted by co-culture of naïve CD4+ T cells and isolated ABCs or follicular B cells (FO B) for 3 days. After the co-culture, Tfh cells were identified by CXCR5+/PD1+ CD4+, and activation of T cells were measured by the expression of CD44 on T cells by flow cytometry analysis. Under similar co-culture condition of ABC and Naïve CD4+ T cells, the effects of various agents, Metformin, Etomoxir and N-Acetyl cysteine on differentiation was assessed.

Results: We observed that ABCs have increased mitochondrial metabolism (but not glycolysis measured by ECAR) in lupus-prone mice compared to ABC from age-matched controls. No difference in metabolism was found in FO B cells between lupus mice and controls. After 72 hours of coculture condition naïve CD4 T cells with B cells, both FO B and ABCs induced T cell activation and proliferation equally, but there was a higher percentage of activated T cells differentiated into CXCR5+ PD1+ Tfh cells by ABCs compared to T cells with FO B. The differentiation and activation of T cells were suppressed by metformin treatment.

Conclusion: ABC cells show an increase in mitochondrial metabolism measured by OCR compared to controls. Coculture of ABCs with naïve CD4 T cells induced differentiation to T cells with makers of Tfh cells. Blocking of mitochondrial activation by metformin could suppress Tfh differentiation. This data suggests that this increase in metabolic activity might correspond with the inflammatory profile of ABCs.

Divergent Reactivities of Rheumatoid Factors and Anti-Modified Protein Antibodies Converge on IgG Epitopes

Aisha Mergaert[1], Zihao Zheng[1], Michael Denny[1], Maya Amjadi[1], Janna Bashar[1], Michael Newton[1], Vivianne Malmström[2], Caroline Grönwall[2], Sara McCoy[1] and **Miriam Shelef**[1], [1]University of Wisconsin, Madison, WI, [2]Karolinska Institutet and Karolinska University Hospital, Stockholm, Sweden

SESSION INFORMATION
Session Date: Saturday, November 6, 2021
Session Title: B Cell Biology & Targets in Autoimmune & Inflammatory Disease Poster (0001–0010)
Session Type: Poster Session A
Session Time: 8:30AM–10:30AM

Background/Purpose: Rheumatoid arthritis (RA) patients often develop rheumatoid factors (RFs), antibodies that bind IgG Fc, and anti-modified protein antibodies (AMPAs), multi-reactive autoantibodies that commonly bind citrullinated, homocitrullinated, and acetylated antigens. Recently, antibodies that bind citrulline-containing IgG epitopes were discovered in RA, suggesting that additional undiscovered IgG epitopes could exist and that IgG could be a shared antigen for RFs and AMPAs. The objective of this study was to reveal new IgG epitopes in rheumatic disease and to determine if cross-reactive AMPAs bind IgG.

Methods: Using RA, lupus, Sjögren's syndrome, and spondyloarthropathy sera, IgG binding to native, citrulline-containing, and homocitrulline-containing linear epitopes of the IgG constant region were evaluated by peptide array with novel epitopes further evaluated by ELISA. Monoclonal AMPA binding to IgG-derived peptides and IgG Fc was evaluated by ELISA.

Results: Seropositive RA sera had high IgG binding to multiple citrulline- and homocitrulline-containing IgG-derived peptides, whereas only anti-SSA+ Sjögren's Syndrome had consistent binding to a single linear native epitope of IgG. AMPAs bound citrulline- and homocitrulline-containing IgG peptides and modified IgG Fc.

Conclusion: The repertoire of epitopes bound by AMPAs includes modified IgG epitopes, positioning IgG as a common antigen that connects the divergent reactivities of RFs and AMPAs.

Jo-1-Binding and Clonally-Expanded Memory B Cells Express Germline and Somatically-Mutated B Cell Receptors in Anti-tRNA Synthetase Syndrome Patients

Erin Wilfong, Alberto Cisneros, **Jennifer Young-Glazer**, Scott Smith, Leslie Crofford and Rachel Bonami, Vanderbilt University Medical Center, Nashville, TN

SESSION INFORMATION
Session Date: Saturday, November 6, 2021
Session Title: B Cell Biology & Targets in Autoimmune & Inflammatory Disease Poster (0001–0010)
Session Type: Poster Session A
Session Time: 8:30AM–10:30AM

Background/Purpose: Anti-tRNA synthetase syndrome (ARS) is a severe systemic autoimmune disease associated with myositis, interstitial lung disease, rash, and arthritis. ARS is associated with autoantibodies towards the tRNA synthetases, the most common being anti-histidyl tRNA synthetase (Jo-1). We previously showed Jo-1-binding B cells (JoBCs) isolated from Jo-1 autoantibody+ (Jo-1 ARS) patients are skewed towards a non-class-switched B cell subset that has phenotypic features of autoreactive-prone memory B cells. Mutated JoBC B cell receptors (BCRs), which dictate antigen specificity, would imply a requirement for T cell selection, whereas germline BCRs would point to T cell-independent mechanisms of JoBC expansion. Our objective was to define BCR V gene usage and mutation among BCRs expressed by JoBCs and determine phenotypic and BCR repertoire features of highly expanded B cell clones in ARS patients.

Methods: We applied human hybridoma technology to identify Jo-1 autoantigen-binding B cells. Additionally, single-cell, tandem RNAseq/BCRseq and a modified Seurat and IMGT/HighVQUEST-based pipeline was used to identify and analyze expanded B cell clones isolated from Jo-1 ARS, non-Jo-1 ARS, and healthy control peripheral blood (n=5 donors per group). BCR gene structure and phenotypic attributes were determined.

Results: JoBC hybridoma clones expressed germline and mutated BCRs. VH4-34 and VH3-21 were identified among JoBC hybridomas as well as clonally expanded B cells in our single-cell dataset isolated from distinct donors. Clonally-expanded B cells were biased towards memory and plasmablast subsets in both Jo-1 ARS and non-Jo-1 ARS patients. The majority of Jo-1 ARS expanded clones were not class-switched, whereas IgG and IgA class-switched clones were more predominant in non-Jo-1 ARS.

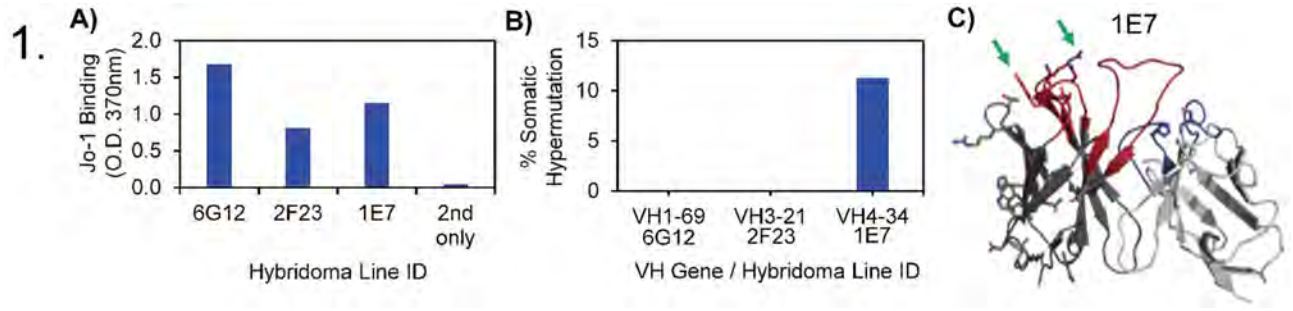

Figure 1. Somatically-mutated as well as germline BCRs confer Jo-1 autoantigen recognition. A) Jo-1 reactivity of representative JoBC monoclonal hybridoma lines is shown by ELISA. B) % Somatic hypermutation (y-axis) and VH gene identity (x-axis) is shown. C) BCR structural model of JoBC hybridoma line 1E7 depicts amino acid mutations as sticks (e.g., arrows). VH CDR loops (red), VL CDR loops (blue).

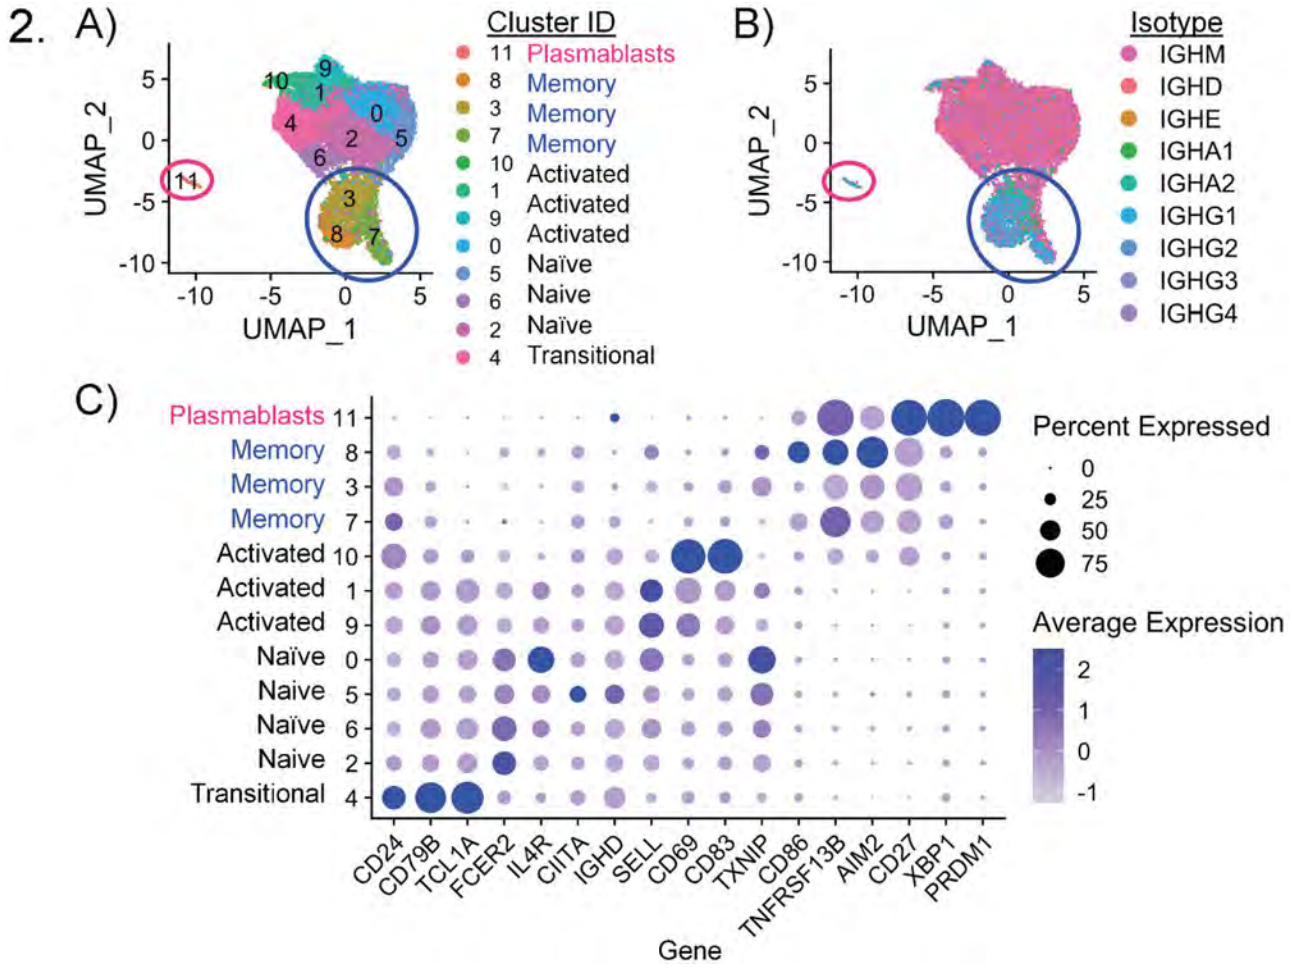

Figure 2. Single-cell transcriptomics identifies distinct B cell subsets in peripheral blood. Single-cell RNAseq and BCRseq technology was used to profile purified B cells isolated from ~5x106 cryopreserved PBMCs per donor from Jo-1 ARS patients, Non-Jo-1 ARS patients, and healthy controls (n=5 donors per group). Seurat was used to determine A) RNAseq-based B cell clusters, B) BCR isotype, and C) specific gene expression profiles to define B cell cluster identities (expression of selected genes is shown). Memory B cell (blue circles) and plasmablast subsets (pink circles) are highlighted in panels A-B.

Conclusion: These data suggest B cell clones can expand, enter memory, and differentiate into plasmablasts prior to class-switching, particularly in Jo-1 ARS patients. Our approaches to identify autoantigen-specific and clonally-expanded B cells could be used to track B cell perturbations as correlates of conventional or experimental immune therapy responsiveness. Improved monitoring of deleterious expansion of autoantigen-specific B cells could improve disease management in ARS patients and other rheumatic diseases. Germline VH4-34 cross-reacts with commensal bacteria, providing a potential mechanism for JoBC immune tolerance breach prior to somatic hypermutation and T cell selection.

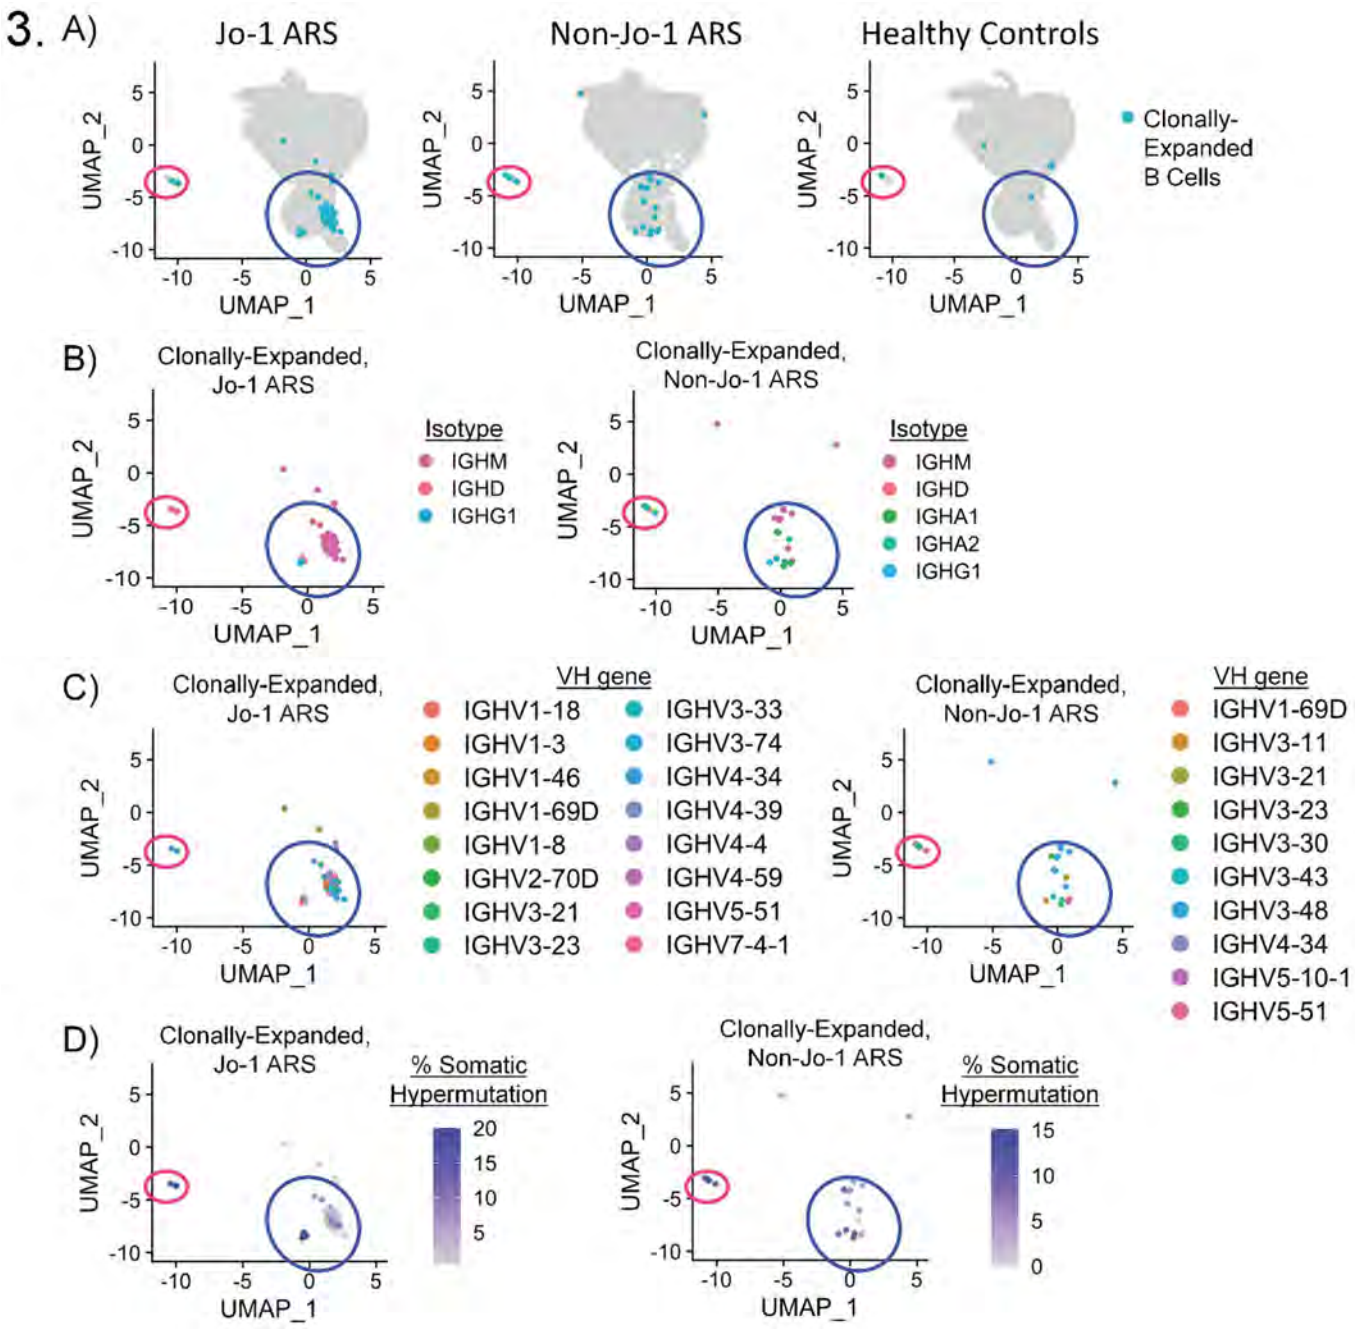

Figure 3. Clonally expanded, memory B cells isolated from Jo-1 ARS and non-Jo-1 ARS patients express both minimally and highly mutated BCRs, which are skewed towards non-class-switched isotypes in Jo-1 ARS patients. B cell subsets were identified as in Fig. 2; memory B cell (blue circles) and plasmablast subsets (pink circles) are highlighted. A) Integrated Seurat and IMGT/HighV-QUEST BCR gene analysis identified clonally expanded B cells (n≥3 clones per clonotype, teal) among Jo-1 ARS (left), non-Jo-1 ARS (middle), or healthy controls (right), n=5 participants per group. B-D) Data filtered on clonally-expanded B cells from Jo-1 ARS or Non-Jo-1 ARS patients show: B) BCR isotypes, C) BCR V gene usage, and D) BCR somatic hypermutation (depicted by heat scale).

SESSION INFORMATION

Session Date: Saturday, November 6, 2021

Session Title: B Cell Biology & Targets in Autoimmune & Inflammatory Disease Poster (0001–0010)

Session Type: Poster Session A

Session Time: 8:30AM–10:30AM

Background/Purpose: We compared humoral immune responses against SARS-CoV-2 to responses against spike-antigen after vaccination.

Methods: 800 health-care workers from University Medical Center Freiburg, Germany, were pursued for 9 months; 120/800 had COVID-19 infections. IgM, IgG and IgA responses against spike, nucleocapsid, ORF3A, ORF8 were determined by ELISA. Spike-specific and neutralizing antibody concentrations were quantified by functional assays. IgM, IgA, IgG and neutralizing antibody titers against Wuhan, B1.17 and B1.351 spike variants were measured after BNT162b2-vaccination.

Results: While acute infection induced robust and strong IgM, IgG and IgA response against viral spike and nucleocapsid proteins, antibody titers and neutralizing antibody concentrations decreased over time in ~50% of samples. IgM, IgG, IgA antibodies against ORF3A/ORF8 were also found in non-infected individuals. Furthermore, SARS-CoV2 infections induced strong humoral response against endemic coronaviruses HCoV-229E, -OC43, -NL63 and -HKU1. Spike-specific IgG+ memory B-cells were detected in ≤ 1/1000 B-cells also in convalescents with low virus-specific antibody titers indicating that SARS-CoV-2-directed memory B-cell formation may differ from humoral anti-viral responses. BNT162b2 prompted strong primary immune response against the Wuhan, B1.17 and B1.351 variants starting 1.5 weeks post vaccination. Inhibition of ACE2-binding and virus neutralization assays revealed higher neutralizing activity against Wuhan and B1.17 than against B1.351.

Conclusion: Humoral response against SARS-CoV-2 often subsides within nine months, whereas memory B-cells apparently uphold immune response. Cross-reactivity of anti-SARS-CoV-2 IgG with endemic coronaviruses could bias interpretation of POC tests. ORF3A and ORF8-antibodies are detectable in non-infected individuals and therefore not indicative of SARS-CoV-2 infections. Vaccination with BNT162b2 elicits higher anti-spike antibody titers than infection with SARS-CoV-2.

Relaxed Peripheral Tolerance Drives Broad *de Novo* Autoreactivity in Severe COVID-19

Matthew Woodruff[1], Richard Ramonell[2], Ankur Singh Saini[2], Mark Rudolph[3], F. Eun-Hyung Lee[2] and Iñaki Sanz[4], [1]Emory University, Decatur, GA, [2]Emory University, Atlanta, GA, [3]Exagen Inc., Vista, CA, [4]Emory University School of Medicine, Atlanta, GA

SESSION INFORMATION
Session Date: Saturday, November 6, 2021
Session Title: B Cell Biology & Targets in Autoimmune & Inflammatory Disease Poster (0001–0010)
Session Type: Poster Session A
Session Time: 8:30AM–10:30AM

Background/Purpose: An emerging feature of COVID-19 is the identification of autoreactivity in patients with severe disease that may contribute to disease pathology, however the origins of these responses remain unclear. Previously, we identified extrafollicular B cell activation as a shared immune feature between severe COVID-19 and active rheumatic disease. In autoimmune settings, this pathway is associated with relaxed peripheral tolerance in the antibody secreting cell compartment and the generation of *de novo* autoreactive responses.

Methods: To further investigate these responses in COVID-19, we performed single-cell B-cell repertoire analysis on 7 patients with severe disease to understand the nature of the antibody secreting cell compartment. We paired these data with cytometry-based and serological assays to detail the nature of these cells, and their contribution to antiviral, and autoreactive responses.

Results: In these patients, we identify a unique low-mutation IgG1 fraction of the antibody secreting cell compartment that lacks surface-expressed B cell receptor, and thus cannot be studied through traditional antigen-labeling studies. These cells are not memory derived, display very low levels of selective pressure, and are enriched for autoreactivity-prone V gene *IGHV4-34*. Within this compartment, we identify B cell lineages that display specificity to both SARS-CoV-2 and autoantigens, and describe progressive, broad, clinically relevant autoreactivity within these patients including emerging reactivity against the glomerular basement membrane. While progressive early in acute infection, we identify the contraction of this pathway 6 months post-recovery, and a re-establishment of tolerance standards coupled with a concomitant loss of acute-derived responders irrespective of antigen specificity.

Conclusion: In total, this study reveals the origins, breadth, and resolution of emerging autoreactivity in severe COVID-19, with significant implications in both acute-phase rheumatologic interventions and potential treatment of patients with post-COVID sequelae.

Differential Inflammation-mediated Function of Prokineticin 2 in the Synovial Fibroblasts of Patients with Rheumatoid Arthritis Compared to Osteoarthritis

Kentaro Noda, Bianca Dufner and Rainer Straub, Laboratory of Experimental Rheumatology and Neuroendocrine Immunology, Department of Internal Medicine I, University Hospital Regensburg, Regensburg, Germany

SESSION INFORMATION
Session Date: Saturday, November 6, 2021
Session Title: RA – Etiology & Pathogenesis Poster (0011–0045)
Session Type: Poster Session A
Session Time: 8:30AM–10:30AM

Background/Purpose: Prokineticin 2 (PK2) is a secreted protein involved in several pathological and physiological processes, including the regulation of inflammation, sickness behaviors, and the circadian rhythm. Recently, it was reported that PK2 is associated with the pathogenesis of collagen-induced arthritis in mice. However, whether PK2 influences the pathogenesis of rheumatoid arthritis (RA) or osteoarthritis (OA) remains unknown.

Methods: We collected synovial tissue, plasma, and synovial fluid from RA and OA patients. Fibroblast-like synoviocytes (FLS) were induced from synovial tissue. We examined the expressions of PK2 and its receptors prokineticin receptor (PKR) 1 and 2 in RA and OA synovial tissues and FLS using immunohistochemistry and measured the concentration of PK2 in plasma and synovial fluid using ELISA. To study the cellular expression of PK2, PKR1, and PKR2

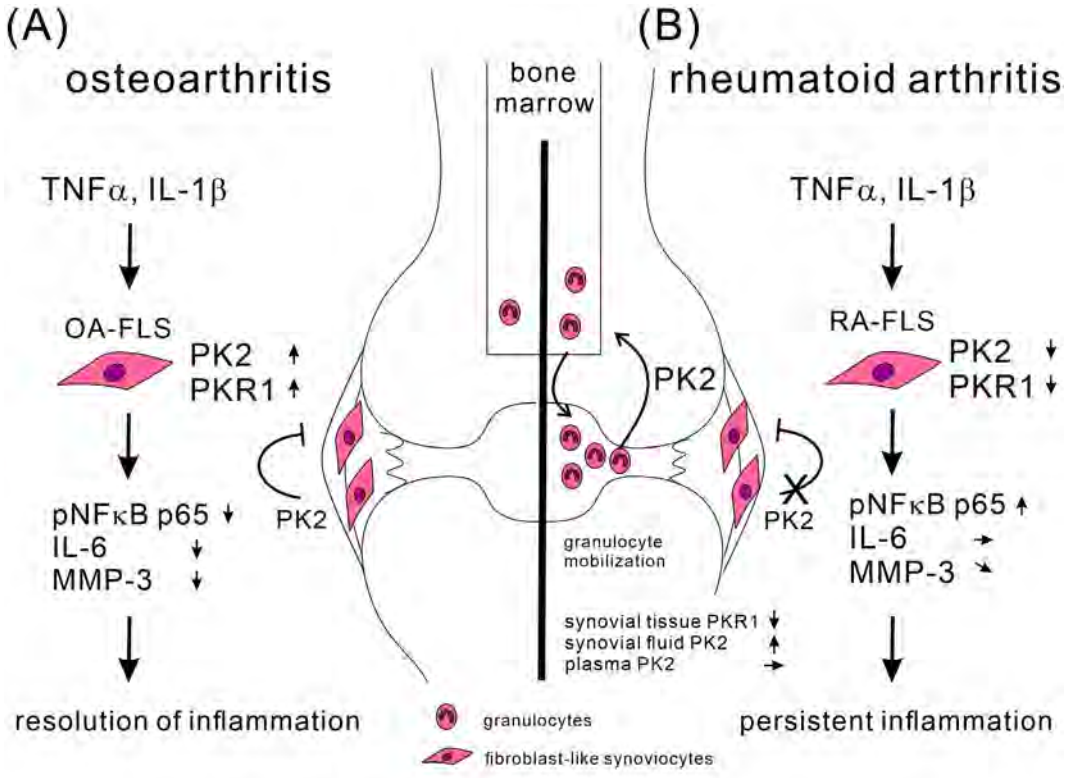

Figure Model describing the dysregulation of endogenous inflammation by PK2 in RA.

under proinflammatory conditions, we stimulated FLS with TNFa (10 ng/ml), IL-1b (200 pg/ml), and TGFb (10 ng/ml) for 24 and 48 h and examined the expression of PK2, PKR1, and PKR2 using cell-based ELISA. Finally, we analyzed the effect of PK2 on TNFa-pretreated FLS using IL-6 and MMP-3 ELISAs.

Results: PK2, PKR1, and PKR2 were expressed in RA and OA synovial tissues. PKR1 expression in RA synovial tissue was downregulated compared with OA synovial tissue. PK2 and PKR1 were expressed in RA and OA-FLS. However, PKR2 was not expressed in FLS. PK2 expression in RA-FLS was downregulated at 24 h after stimulation with TNFa, IL-1b, and TGFb. PKR1 expression was upregulated at 48 h after stimulation with TNFa and TGFb in OA-FLS and downregulated at 48 h after stimulation with IL-1b in RA-FLS. PKR2 expression in OA- and RA-FLS was upregulated at 24 and 48 h after stimulation with TGFb and at 48 h after stimulation with TNFa in RA-FLS. The PK2 concentration was higher in RA synovial fluid than in OA synovial fluid but similar between RA and OA plasma. PK2 suppressed the production of IL-6 and MMP-3 from TNFa-prestimulated OA-FLS, and this effect was attenuated in TNFa-prestimulated RA-FLS.

Conclusion: We demonstrated that PK2, PKR1, and PKR2 were expressed in synovial tissue. This indicates that PK2 acts locally. Indeed, PK2 had an anti-inflammatory effect on OA-FLS that was likely mediated through the PKR1 pathway, whereas this anti-inflammatory effect was attenuated in RA-FLS because of PKR1 downregulation. This study provides a new model to explain some aspects regarding the chronicity of inflammation in RA.

In OA, exposure to proinflammatory cytokines upregulates the expression of PKR1. PK2 secreted from OA-FLS acts on PKR1 in an autocrine or paracrine manner and reduces the secretion of IL-6 and MMP-3 from OA-FLS (A). In contrast, in RA-FLS, exposure to proinflammatory cytokines downregulates the expression of PK2 and PKR1 (B). Therefore, PK2 does not exhibit a similarly strong anti-inflammatory effect in RA-FLS compared with OA-FLS. Indeed, the expression of PKR1 in RA synovial tissue was decreased compared with OA synovial tissue. This dysregulation in the endogenous inflammation-mediated modulation of PK2 in RA-FLS may be associated with the chronicity of inflammation in the pathogenesis of RA.

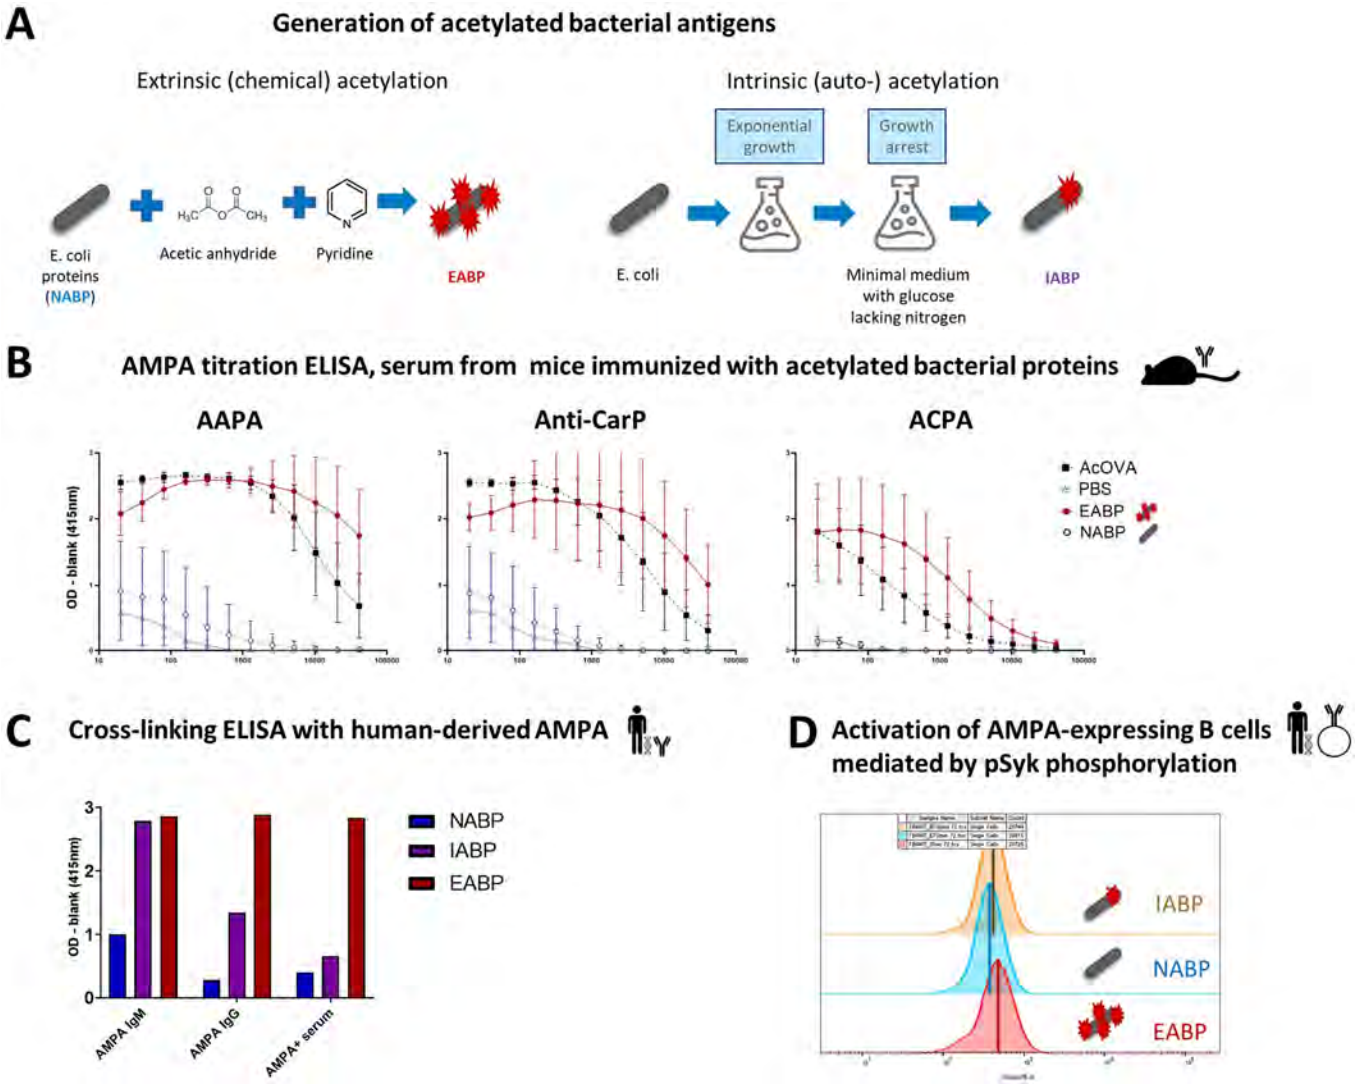
A Novel Mechanism Linking Mucosal Bacteria with Autoantibody Responses in RA: Acetylated Bacterial Lysate as a Model Antigen

Mikhail Volkov, Arieke Kampstra, Karin van Schie, Joanneke Kwekkeboom, Tom WJ Huizinga, René Toes and Diane van der Woude, Leiden University Medical Center, Leiden, Netherlands

SESSION INFORMATION
Session Date: Saturday, November 6, 2021
Session Title: RA – Etiology & Pathogenesis Poster (0011–0045)
Session Type: Poster Session A
Session Time: 8:30AM–10:30AM

Background/Purpose: Rheumatoid arthritis (RA) is characterized by autoantibodies against post-translationally modified proteins (AMPA) such as citrullinated, carbamylated and acetylated proteins. Importantly, these antibodies are highly multireactive, as they often recognize more than one of these post-translational modifications. Despite extensive research, the antigens inducing the breach of tolerance remain unknown, although microbial antigens are often suspected. Various bacteria are known to be capable of acetylation, therefore, it is intriguing to know which



A: Methods of E. coli proteins acetylation. B: AMPA reactivities in mice immunized with extrinsically (chemically) acetylated bacterial proteins and control antigens. Delta OD values measured with titrated mice serum on modified fibrinogen ELISA are depicted. C: Recognition of bacterial protein samples by AMPA derived from RA patients. Delta OD obtained with cross-linking ELISA are depicted. D: Activation of AMPA IgG expressing B cells as measured by Syk phosphorylation assay using flow cytometry. Histograms visualizing mean fluorescence intensity values of stimulated cells stimulated with different bacterial protein samples are depicted.

mechanisms underlie the breach of tolerance towards acetylated proteins and development of AMPA. The aim of this project was to investigate whether acetylated proteins of bacterial origin (1) are recognized by human derived AMPA and AMPA-expressing B cells; and (2) can induce AMPA development when used to immunize mice.

Methods: Acetylated E. coli proteins were acquired with two separate methods (Figure A): by culturing E. coli in a condition promoting auto-acetylation (intrinsically acetylated bacterial proteins, IABP), or by directly acetylating lysate-derived proteins via a chemical reaction (extrinsically acetylated BP, EABP). Acetylated ovalbumin (AcOVA) served as positive control for AMPA induction in mice, while non-acetylated BP (NABP) and phosphate buffer saline (PBS) served as negative control. Mice were immunized with these proteins and the resulting antibody response was studied by ELISA. Furthermore, EABP/IABP/NABP were investigated for recognition by human-derived AMPA with ELISA and AMPA-expressing B cells with spleen tyrosine kinase (Syk) phosphorylation assay; acetylated human fibrinogen and native fibrinogen served as positive and negative control.

Results: Intrinsic acetylation resulted in partial, while extrinsic/chemical acetylation resulted in complete acetylation of E. coli proteins. Repetitive immunization of mice with EABP resulted in an AMPA response recognizing acetylated, carbamylated and citrullinated proteins, which was not observed in mice immunized with NABP or IABP (Figure B). Human-derived AMPA recognized EABP and IABP (Figure C). B cell activation (measured by Syk phosphorylation) assay indicated that AMPA-expressing B cells recognized EABP and (to a lesser extent) IABP, but not NABP (Figure D).

Conclusion: Acetylated bacterial proteins are potent antigens that can induce cross-reactive AMPA responses in mice, and can be recognized by human AMPA and AMPA-expressing B cells. This suggests that acetylated bacterial proteins could potentially be involved in the breach of tolerance in RA.

Cyclin Dependent Kinase 4 and 6 Determine the Cytokine Responsiveness by Stabilizing JUN in Rheumatoid Arthritis Synovial Fibroblasts

Tadashi Hosoya[1], Tetsuya Saito[2], Hiroyuki Baba[2], Nao Tanaka[2], Seiji Noda[2], Yoji Komiya[2], Yasuhiro tagawa[2], Akio Yamamoto[2] and Shinsuke Yasuda[2], [1]Tokyo Medical and Dental University(TMDU), Tokyo, Japan, [2]Tokyo Medical and Dental University (TMDU), Tokyo, Japan

SESSION INFORMATION
Session Date: Saturday, November 6, 2021
Session Title: RA – Etiology & Pathogenesis Poster (0011–0045)
Session Type: Poster Session A
Session Time: 8:30AM–10:30AM

Background/Purpose: Although current inflammation-targeted therapy improved the outcome of patients with rheumatoid arthritis (RA), the achievement of complete disease remission was still challenging. Since synovial fibroblasts (SFs) in RA are epigenetically altered, acquiring invasiveness, and excessive cytokine-producing and proliferating capacity, SFs-targeted therapy was expected to be alternative or complementally therapeutic strategy. This study was designed for discerning the underlying mechanisms involved in cyclin-dependent kinase (CDK) 4/6-mediated regulation of inflammatory mediators, including matrix metalloproteinases.

Methods: CDK4/6 activity in RASFs was inhibited or enhanced using a small-molecule CDK4/6 inhibitor (CDKI) or gene transduction. The gene and protein expressions were evaluated with quantitative PCR and ELISA under the combination treatment with IL-1β and TNFα (0.2 ng/ml, respectively) as a stimulation in the presence (10%) or absence (0.5%) of fetal bovine serum (FBS). The nuclear protein binding to the DNA sequence was assessed with an electrophoresis mobility shift assay. Protein expression and ubiquitination were assessed with Western blotting using specific antibodies. Gene knockdown was performed using RNA interfering. RNA-Seq was performed to identify genes affected by CDKI treatment in cytokine stimulation using RASFs from 5 individuals.

Results: In RASFs, cytokine productions induced with the combination of IL-1β and TNFα were enhanced in the presence of FBS. Among them, CDKI suppressed the production of MMP-1 and MMP-3, but not MMP-2, CXCL8 and IL-6. MMP-1 and MMP-3 shared AP-1 binding motif in their promoter region. CDKI impaired the binding of AP-1 components to DNA. CDK4/6 protected JUN, one of the AP-1 components, from proteasome-dependent degradation by inhibiting ubiquitination, indicating that CDK4/6 inhibition would result in the repression of a set of genes regulated by AP-1. The RNA-Seq analysis confirmed the hypothesis, namely, the AP-1 motif was enriched in a set of genes

suppressed by CDKI treatment. Interestingly, according to the KEGG pathway classification, these CDKI-repressing inflammatory genes were also enriched in RA associated genes (Q value 0.03), Cytokine-cytokine receptor interaction (Q value 0.07), and IL-17 signaling (Q value 0.07).

Conclusion: The active CDK4/6 enhanced transcriptional activity of AP-1 via JUN stabilization, indicating that CDK4/6 would determine the cytokine hyper-responsiveness of RASFs. We have revealed that inhibition of CDK 4/6 prevented joint destruction in animal models of arthritis by inhibiting synovial cell proliferation and by synergizing with TNF inhibition or IL-6 inhibition. Since the pharmacologic inhibition of CDK4/6 was established as tolerable in the cancer treatment, it would exert anti-arthritic effects to attenuate pathogenic characteristics of RASFs in addition to suppressing synovial hyperplasia.

Low Baseline Expression of Pyruvate Kinase and Succinate Dehydrogenase Genes in the Peripheral Blood of Rheumatoid Arthritis Patients Treated with Tofacitinib Is Associated with Clinical Remission at the End of Follow-up

Elena Tchetina[1], Azamat Satybaldyev[2], Galina Markova[1] and Alexander Lila[2], [1]Nasonova Research Institute of Rheumatology, Moscow, Russia, [2]V.A. Nasonova Reseach Institute of Rheumatology, Moscow, Russia

SESSION INFORMATION
Session Date: Saturday, November 6, 2021
Session Title: RA – Etiology & Pathogenesis Poster (0011–0045)
Session Type: Poster Session A
Session Time: 8:30AM–10:30AM

Background/Purpose: Rheumatoid arthritis (RA) is an autoimmune disease of unknown etiology, which is characterized by erosive arthritis and systemic inflammation. Tofacitinib (TFCN) is a Janus kinase (JAK) inhibitor that targets JAK1/JAK3. Presently it is not possible to predict TFCN efficacy in every patient while some patients are non-responsive to the drug that may produce adverse effects. However, identification of patients sensitive to TFCN before treatment could significantly improve therapy outcome. TFCN function in RA patients has been recently associated with alterations in bioenergetics, mitochondrial function, and ATP production [McGarry et al. Arthritis Rheumatol, 2018; 70:1959.]. Therefore, we hypothesized that baseline metabolic status of RA patients prior to drug administration can predict the therapeutic outcome. We aimed to investigate the importance of baseline expression of genes involved in energy generation in RA patients, which could serve prognostic biomarkers for treatment response to tofacitinib.

Methods: Peripheral blood of 28 RA patients aged 52.2±15.6 years old, average disease duration 3.5 years (range 0.6-19) treated with TFCN (5-10 mg twice a day) during three months and 26 healthy age-matched control subjects were examined. Clinical response was assessed by serum levels of ACPA antibodies, rheumatoid factor (RF), C-reactive protein (CRP), erythrocyte sedimentation rate (ESR), and disease activity score (DAS28-ESR). Clinical remis-

sion was assessed according to ACR criteria and DAS28 (DAS28 < 2.6). Protein concentrations were measured using ELISA. Total RNA was isolated and used in gene expression studies performed with quantitative real-time RT-PCR.

Results: All of the patients were Steinbrocker's radiographic stage II-III at baseline. The majority of patients demonstrated erosive arthritis (23 out of 28), they were ACPA- (25 out of 28) and RF- (24 out of 28) positive. TFCN treatment significantly decreased the disease activity according to DAS28. At the end of the study, the majority of patients demonstrated moderate disease activity (3.2< DAS28 < 5.1), four patients retained high disease activity while 8, attained remission (DAS28 < 2.6). This was accompanied by significant decrease in CRP and the number of swollen and tender joints. ESR values were not changed significantly. Gene and protein expression analysis revealed that RA patients, which attained clinical remission after TFCN treatment demonstrated significantly lower baseline expression of genes associated with glycolysis (pyruvate kinase) and oxidative phosphorylation (succinate dehydrogenase) compared to other examined RA patients. Moreover, in RA patients who attained clinical remission these gene expressions were tending to increase while in other examined patients, to downregulate in the course of follow-up.

Conclusion: Our preliminary study demonstrated that clinical remission attainment in RA patients treated with tofacitinib was associated with lower baseline expression of genes related to energy generation pathways (pyruvate kinase and succinate dehydrogenase) compared to other examined subjects.

Rheumatoid Factor Recognizes Specific Domains of IgG Heavy Chain Complexed with HLA Class II Molecules

Shanshan Zhang[1], Hideaki Tsuji[1], Hui Jin[2], Koji Kitagori[1], Shuji Akizuki[3], Kosaku Murakami[1], Ran Nakashima[1], Hajime Yoshifuji[1], Masao Tanaka[1], Hisashi Arase[2], Koichiro Ohmura[4] and Akio Morinobu[1], [1]Kyoto University, Kyoto, Japan, [2]Osaka University, Osaka, Japan, [3]Kyoto Universtiy, Kyoto City, Japan, [4]Kobe City Medical Center General Hospital, Kobe, Japan

SESSION INFORMATION
Session Date: Saturday, November 6, 2021
Session Title: RA – Etiology & Pathogenesis Poster (0011–0045)
Session Type: Poster Session A
Session Time: 8:30AM–10:30AM

Background/Purpose: Rheumatoid factor (RF) is an autoantibody that binds to IgG Fc region (C_H2 and C_H3 domains) and is detectable in patients with rheumatoid arthritis (RA). We previously reported that IgG heavy chain (IgGH) was transported to the cell surface by HLA class II molecule via association with the peptide binding groove and that IgGH / HLA class II complex could be specifically recognized by RF. However, its mechanisms have not been fully understood. Here we tried to identify the binding sites of IgGH to HLA class II and recognition sites of IgGH by RF.

Methods: The heavy chain of IgG contains a variable region (V_H) and 3 constant regions (C_H). Each single domain (V_H, C_H1, C_H2, and C_H3) or 2~3 contiguous domains of human IgGH were sub-cloned and transfected with HLA-DR4 into HEK293T cells. The Flag-tagged IgGH domains presented by the HLA-DR molecules on the cell surface were detected by anti-Flag antibody using flow cytometry (FCM). Next, RF recognition to IgGH domains / HLA-DR complex was evaluated by FCM after RA patients' sera and anti-human IgM antibody staining. We also made constructs of IgGH single domains linked to Cw3 peptide which binds strongly to HLA-DR4 peptide binding groove. We co-transfected

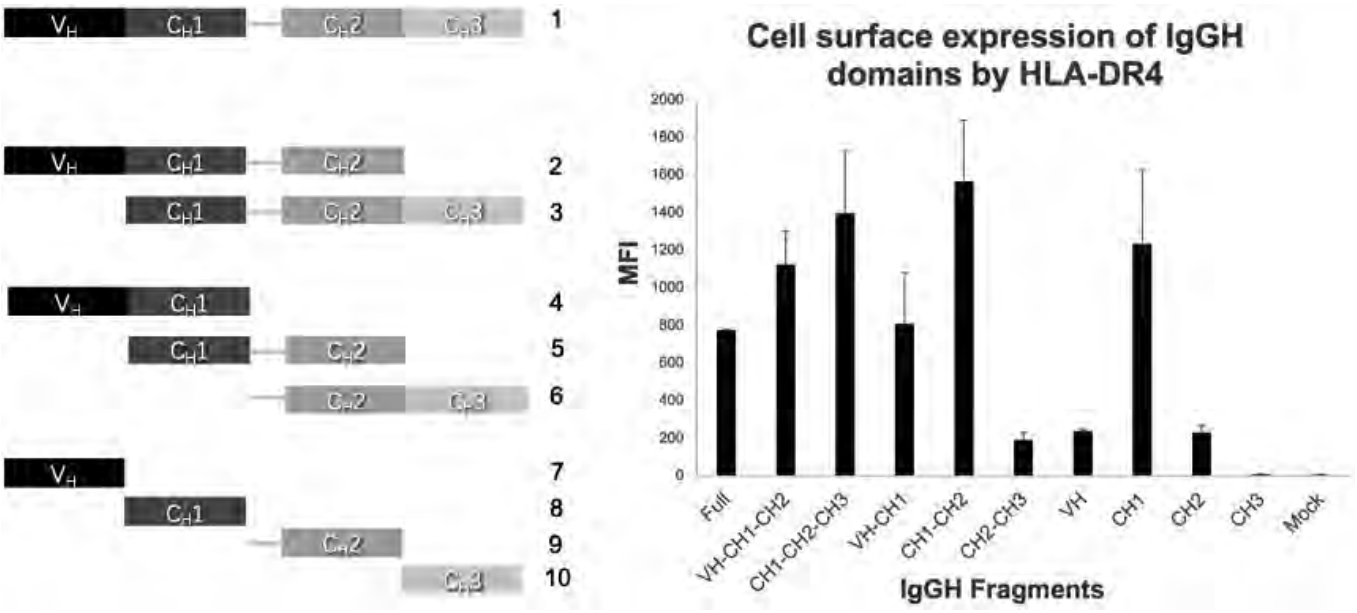

Figure 1. Each fragment of human IgGH was transfected with HLA-DR4 into HEK293T cells. The Flag-tagged IgGH domains presented by the HLA-DR molecules on the cell surface were detected by anti-Flag antibody using flow cytometry.

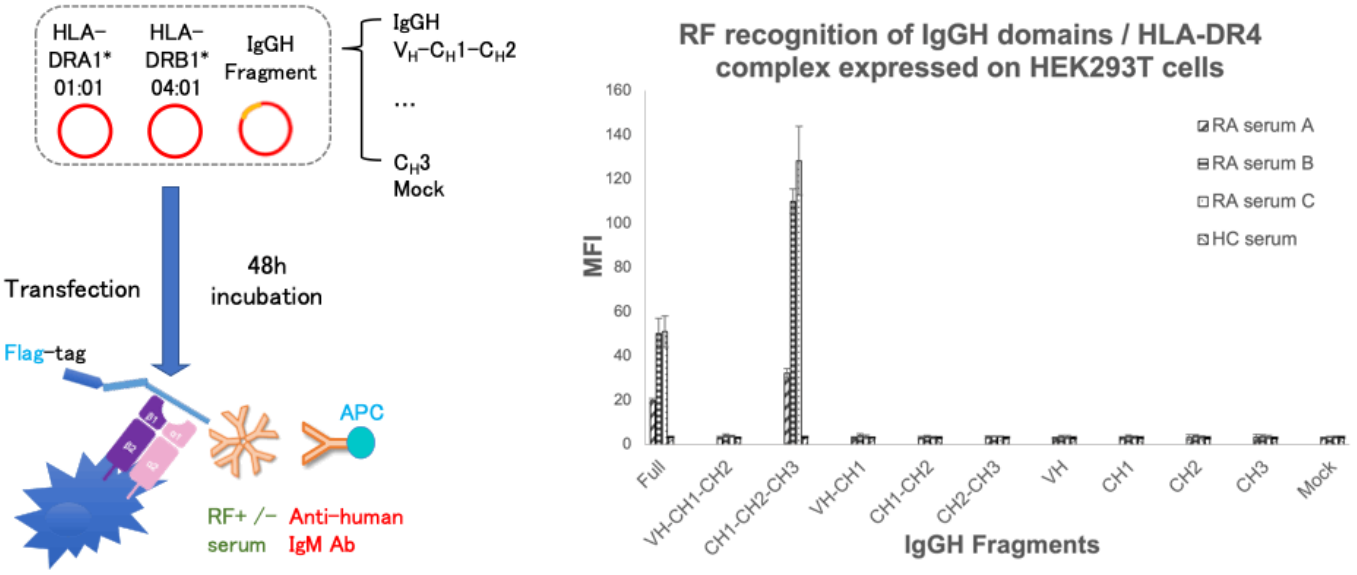

Figure 2. IgGH fragments and HLA-DR4 were co-transfected into HEK293T cells and binding of RF to IgGH domains / HLA-DR4 complex was evaluated by RA patients' sera using flow cytometry.

the HLA-DR4 and IgGH single domains with or without Cw3 peptide then compared the IgGH fragment expression and RF reactivity.

The RF positive sera were obtained from the patients diagnosed with RA based on the ACR / EULAR criteria for RA in 2010.

Results: The expression of fragments containing C_H1 on the cell surface by HLA-DR4 were equal to or rather higher than the full IgGH's expression, while fragments without C_H1 (C_H2-C_H3, V_H, C_H2 and C_H3) were presented at a far lower level compared with full IgGH, especially the C_H3 domain (Figure 1).

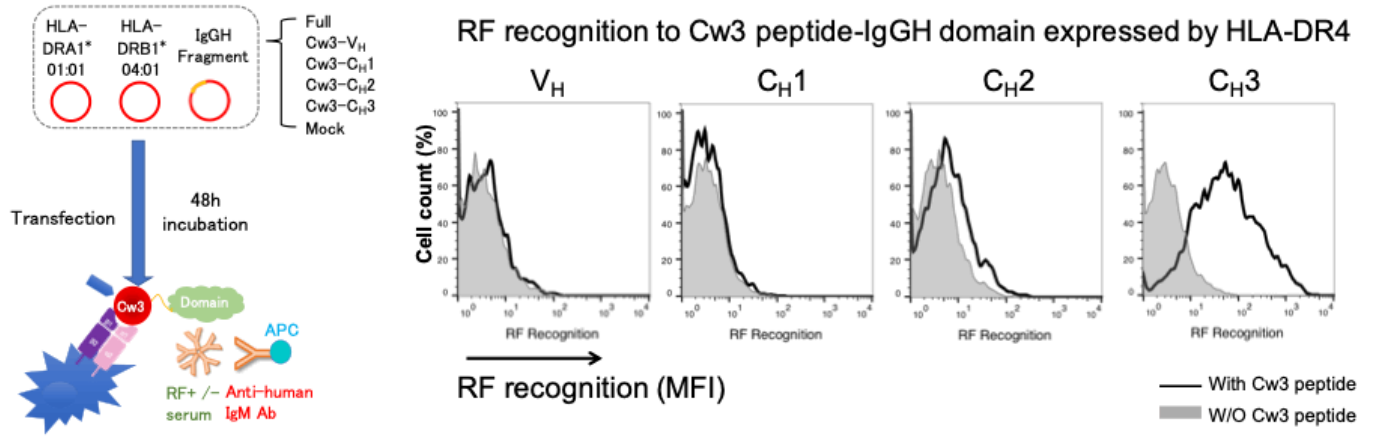

Figure 3. IgGH fragments with or without Cw3 peptide were transfected with HLA-DR4 into HEK293T cells and RF reactivity to the complex with HLA-DR4 complex were compared by RA patients' sera using flow cytometry.

Next, among all the fragments, RF only recognized C_H1-C_H2-C_H3 fragment besides full IgGH chain (Figure 2). On the other hand, Cw3 peptide-linked IgGH domain study revealed that RF recognized C_H3 single domain linked to Cw3 peptide presented by HLA-DR4 but none of other Cw3-linked single domains were recognized (Figure 3). All of the sera from 43 RF-positive RA patients showed the same results.

Conclusion: Our data suggest that HLA-DR presents IgG heavy chain mainly by binding to C_H1 domain, while RFs recognize the epitope on C_H3 domain.

Session Title: RA – Etiology & Pathogenesis Poster (0011–0045)

Session Type: Poster Session A

Session Time: 8:30AM–10:30AM

Background/Purpose: Juvenile Idiopathic Arthritis (JIA) is a common childhood illness, characterized by inflammation of the joint, chronic pain and decreased physical functioning. To date, the underlying neurobiological mechanisms that drive pain and sensorimotor dysfunction are unclear and understudied. Thus, in this pilot study, we explored the morphology and functionality of salience and sensorimotor structures in JIA patients.

Methods: Nine JIA patients (12.4 ± 2.8 years of age) and 13 control subjects matched by age, gender and handedness were enrolled. All JIA patients were on active treatment and had prior or ongoing symptoms in hand-wrist joints. High-resolution structural magnetic resonance imaging (MRI), diffusion tensor imaging (DTI), functional MRI (fMRI), and Pseudo-continuous arterial spin labelling (ASL) were performed. In addition, clinical lab tests and the 9-hole peg test for hand-motor function were administered.

Results: Morphology: Morphological analysis (Freesurfer v7.1.1) of the structural neuroimaging data revealed a significant decrease ($P < 0.05$) of cortical thickness in the left hemisphere insular cortex in JIA patients (**Figure 1**). Furthermore, cortical volume of the caudate nucleus (CN) was negatively correlated with patient-reported pain severity (Left CN: $P = 0.04$, $R = -0.70$; Right CN: $P = 0.03$, $R = -0.71$). Functional connectivity: In JIA patients, seed-based functional connectivity analysis (CONN-fMRI v18.b and SPM 12) showed altered connectivity from anterior insula (AI) subregions, as defined by Deen et al., to key hubs of the salience (e.g., anterior cingulate cortex (ACC)) and sensorimotor (e.g., pre- and postcentral gyri) networks. The most robust finding was that of decreased functional connectivity from the dorsal AI (dAI) to angular/ supramarginal gyrus regions in JIA patients (**Figure 1)**. Structural connectivity: Probabilistic tractography (FMRIB's Software Library v6.0.4) revealed higher connectivity from the left and right AI to several ipsilateral and contralateral regions of the salience network in JIA patients. Connectivity from the left ventral AI (vAI) to the left ACC, which is associated with affective processes, was increased in JIA patients ($P = 0.015$), and left vAI to right ACC was correlated to erythrocyte sedimentation rate (ESR) and pain (ESR: $P = 0.03$, Pain: $P = 0.01$) (**Figure 1**). Cerebral blood flow (CBF): CBF analysis (BASIL toolbox) did not reveal significant group differences for the insular cortex or other regions of the salience network (**Figure 1**). However, assessment of regional CBF in JIA patients and controls revealed significantly higher CBF values in multiple subcortical areas within the sensorimotor network for the JIA group (**Figure 2**). These values were positively correlated with left to right hand ratio motor performance, calculated from subjects' time score on the 9-hole peg test (**Figure 3**).

Conclusion: This pilot study points toward several structural and functional alterations in salience and sensorimotor networks, which could be at the core of pain and sensorimotor deficits in JIA. Future studies may focus on whether

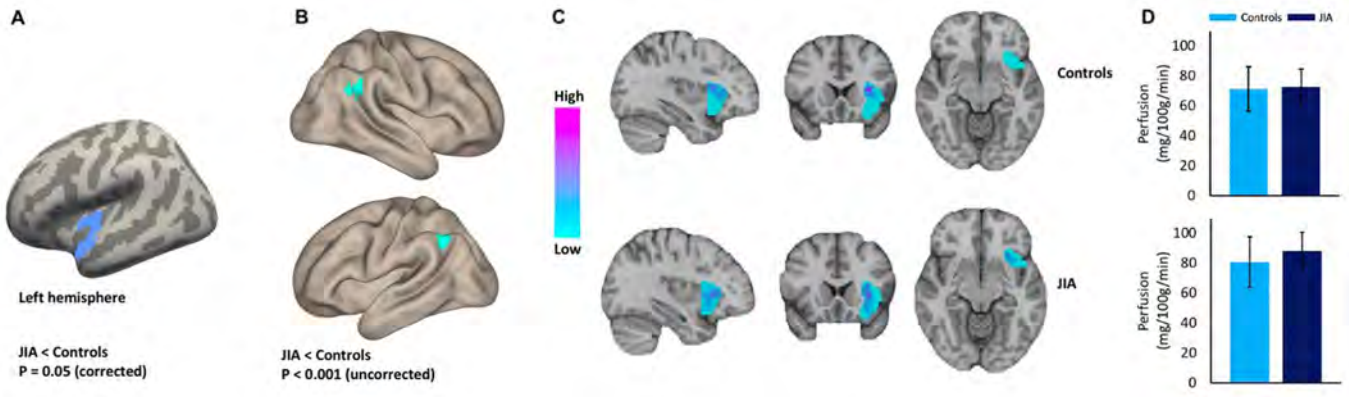

Figure 1. Anterior Insula Alterations in JIA patients. A. Insular cortex regions (blue cluster) showing a significant decrease in cortical thickness in JIA patients vs. healthy controls. Only the left-hemisphere insular cluster remained significant after correction for multiple comparisons. B. Significantly decreased seed-based functional connectivity from the left dAI to bilateral angular gyrus/ supramarginal gyrus regions (blue clusters) in JIA patients vs. healthy controls. C. Increased structural connectivity of AI to the left anterior cingulum: AI connectivity map for controls and JIA patients. D. rCBF in the AI in the left (top) and right (bottom) hemisphere.

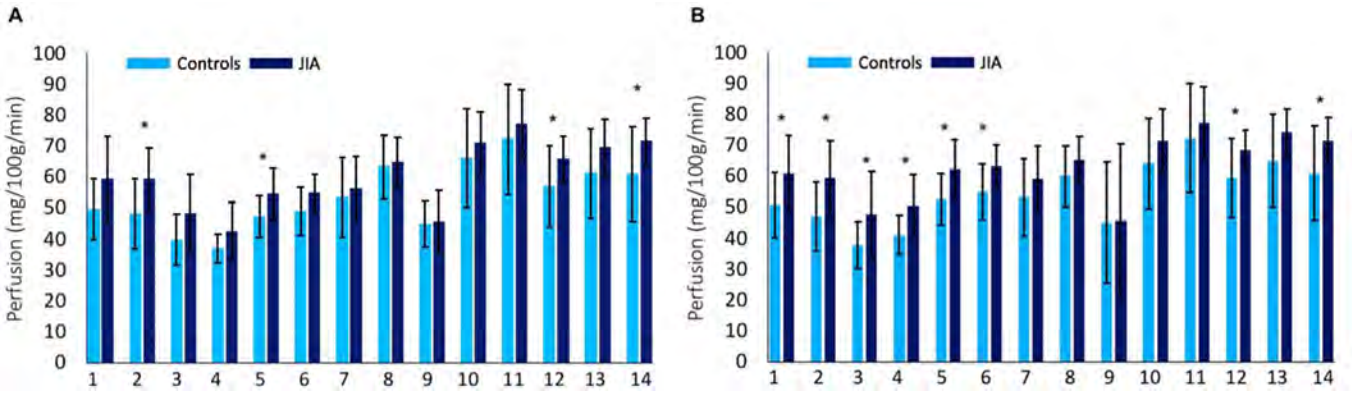

Figure 2. rCBF Differences in Sensorimotor Areas. rCBF values (mg/100g/min) for (A) left and (B) right hemisphere. (1) Red Nucleus, (2) SNpc, (3) SNpr, (4) Thalamus VA, (5) Thalamus VL, (6) Thalamus VPL, (7) Caudate, (8) Putamen, (9) Pallidum, (10) Postcentral Gyrus, (11) Precentral Gyrus, (12) Cerebellum lobule V, (13) Cerebellum lobule VI, (14) Vermis. Asterisk (*) indicates significant ($P < 0.05$) group differences. Error bars represent standard deviations.

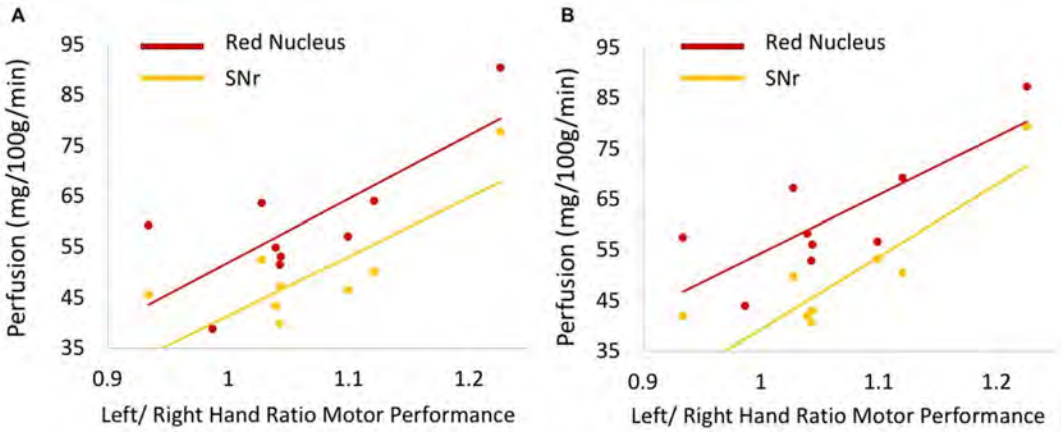

Figure 3. Left to Right Hand Ratio Correlations to rCBF in Sensorimotor Areas. Significant correlations are shown for (A) left hemisphere Red Nucleus ($P = 0.0094$, $R = 0.7547$) and SNpr ($P = 0.0064$, $R = 0.7821$), and for the (B) right hemisphere Red Nucleus ($P = 0.0063$, $R = 0.7829$) and SNpr ($P = 0.0014$, $R = 0.8610$). Ratio was calculated with time (s) to complete the 9-hole Peg Test with each hand.

central changes are maladaptive or adaptive in nature, and how CNS properties are impacted by standard of care and novel therapies.

Lessons Learnt from Associations Between Anti-modified Protein Antibodies and Risk Factors: Human Leukocyte Antigen - Shared Epitope Alleles Solely Associate with Anti-citrullinated Protein Antibodies

Tineke J van wesemael, Annemarie L. Dorjee, Tom WJ Huizinga, Annette H.M van der Helm-van Mil, René Toes and Diane van der Woude, Leiden University Medical Center, Leiden, Netherlands

SESSION INFORMATION

Session Date: Saturday, November 6, 2021
Session Title: RA – Etiology & Pathogenesis Poster (0011–0045)
Session Type: Poster Session A
Session Time: 8:30AM–10:30AM

Background/Purpose: Rheumatoid arthritis (RA) is characterized by the presence of auto-antibodies to post translationally modified proteins (anti-modified protein antibodies (AMPA)): anti-citrullinated protein antibodies (ACPA), anti-carbamylated protein antibodies (anti-CarP) and anti-acetylated protein antibodies (AAPA). ACPA is unique since an association with the risk factors smoking and the human leukocyte antigen (HLA) - shared epitope (SE) is found only in the ACPA positive patients. However the association of SE and smoking with all three AMPA has remained unstudied. Nonetheless, this association is of great interest, since it would increase our understanding if the pathological mechanisms underlying the development of these auto-antibodies are unique of shared.

Objective: To investigate the association of SE and smoking with the different kinds of AMPA.

Methods: 648 RA patients fulfilling the 1987 RA criteria from the Leiden Early Arthritis Cohort, of whom data were available on the presence of ACPA, AAPA and anti-CarP, smoking and SE status were included. SE positivity was defined as having ≥1 of the following HLA alleles: DRB1*01:01, *01:02, *04:01, *04:04, *04:05, *04:08 and*10:01. Healthy controls (n=1211) for SE analysis were randomly selected from the collection of the section of Immunogenetics and Transplantation Immunology from the Leiden University Medical Center. The association between auto-antibodies and SE and smoking was assessed by logistic regression analysis.

Results: When investigating the association of smoking with the presence of the various combinations of AMPA, a significant association was only found in the triple positive patients (OR 1.67 (1.08 – 2.60), p0.02), table 1. There was no association with smoking for patients positive for one or two auto-antibodies.

SE was solely associated with ACPA positive patients, whereas the association with SE was similar among patients who were single-positive for ACPA compared to patients harboring 1 or 2 additional auto-antibodies (AAPA and/or anti-CarP), indicating that SE is only associated with ACPA.

Table 1 Association of smoking with anti-modified protein antibodies

Autoantibody status	Smoking neg n (%)	Smoking pos n (%)	OR (95% CI)	p-value
ACPA-AAPA-CarP-	198 (78.3)	55 (23.7)	1 (ref)	-
ACPA+AAPA-CarP-	32 (69.6)	14 (30.4)	1.58 (0.79 – 3.16)	0.20
ACPA-**AAPA+**CarP-	3 (75.00)	1 (25.0)	0.84 (0.35 – 2.02)	0.69
ACPA-AAPA-**CarP+**	30 (81.01)	7 (18.9)	1.20 (0.12 – 11.76)	0.89
ACPA+AAPA-**CarP+**	49 (74.2)	17 (25.8)	1.25 (0.67 – 2.34)	0.70
ACPA+AAPA+CarP+	30 (81.1)	7 (18.9)	0.84 (0.35 – 2.02)	0.70
ACPA-**AAPA+CarP+**	0 (0.0)	0 (0.0)	-	-
ACPA+AAPA+CarP+	114 (68.3)	53 (31.7)	**1.67 (1.08 – 2.60)**	**0.02**

Table 2 Association of SE with anti-modified protein antibodies

			Reference = healthy controls		Reference = single ACPA pos patients	
Autoantibody status	**SE neg n(%)**	**SE pos n(%)**	**OR (95% CI)**	**p-value**	**OR (95% CI)**	**p-value**
Healthy controls	674 (55.7)	537 (44.3)	1 (ref)	-		
ACPA-AAPA-CarP-	132 (51.8)	123 (48.2)	1.17 (0.89 – 1.53)	0.26		
ACPA+AAPA-CarP-	10 (21.7)	36 (78.3)	**4.52 (2.22 – 9.19)**	**0.000**	1 (ref)	-
ACPA-**AAPA+**CarP-	1 (25.0)	3 (75.0)	3.77 (0.39 – 36.30)	0.25		
ACPA-AAPA-**CarP+**	21 (56.8)	16 (43.3)	0.96 (0.49 – 1.85)	0.89		
ACPA+AAPA+CarP-	9 (24.3)	28 (75.7)	**3.90 (1.83 – 8.35)**	**0.000**	0.86 (0.31 – 2.41)	0.78
ACPA+AAPA-**CarP+**	15 (22.7)	51 (77.3)	**4.27 (2.37 – 7.67)**	**0.000**	0.94 (0.38 – 2.34)	0.90
ACPA-AAPA+**CarP+**	0 (0.0)	0 (0.0)	-	-	-	-
ACPA+AAPA+CarP+	32 (19.2)	171 (80.3)	**5.30 (3.52 – 7.91**	**0.000**	1.17 (0.53 – 2.61)	0.70

Conclusion: This in-depth analysis of the exact association between risk factors and AMPA presence revealed striking differences regarding the associations for smoking versus SE. Since smoking is associated with the concurrent presence of multiple AMPA, this implies that smoking is involved in a general process of auto-antibody development. However SE is solely associated with the presence of ACPA, and not with anti-CarP or AAPA. This suggests that, despite the similarity in antigenic targets and partial cross reactivity between AMPA responses, the pathophysiological mechanisms underlying their development differ for the various AMPA.

Caspase-8 Variant G Regulates Rheumatoid Arthritis Fibroblast-Like Synoviocyte Aggressive Behavior

Cecilia Ansalone[1], Gyrid Nygaard[1], Richard Ainsworth[1], Rizi Ai[1], Deepa Hammaker[1], Narayanan Perumal[2], Ken Weichert[2], Frances Tung[2], Lalitha Kodandapani[2], Michael Sauder[2], Elisabeth Mertsching[2], Robert Benschop[3], Wei Wang[1], David Boyle[1] and Gary Firestein[1], [1]University of California San Diego, San Diego, CA, [2]Eli Lilly and Company, San Diego, CA, [3]Eli Lilly and Company, Indianapolis, IN

SESSION INFORMATION
Session Date: Saturday, November 6, 2021
Session Title: RA – Etiology & Pathogenesis Poster (0011–0045)
Session Type: Poster Session A
Session Time: 8:30AM–10:30AM

Background/Purpose: Rheumatoid arthritis (RA) fibroblast-like synoviocytes (FLS) display an aggressive phenotype, including abnormal migration and invasion. Using data from our previous studies defining the epigenetic landscape of RA FLS, *CASP8* (encoding caspase-8) was identified as a gene of interest in RA that might be implicated in this behavior due to abnormal epigenetic marks. Caspase-8 has proteolytic functions that regulate apoptosis and non-proteolytic functions that affect cell movement. However, the specific isoforms responsible for the latter are unknown. In this study, we identified the mechanisms of caspase-8 function in RA FLS and identified the specific isoform responsible.

Methods: RA FLS lines were obtained from synovial tissues at arthroplasty and used at passage 5-8 (n=20). *CASP8* deficiency was induced with siRNA to deplete either all isoforms or individual isoforms; non-targeting siRNA was used as control. RT-qPCR and western blot were used to assess gene and protein expression, respectively. PDGF-induced migration (scratch assay), invasion (through Matrigel membrane), and adhesion to fibronectin and collagen type II in CASP8-deficient and control cells were assessed. Talin cleavage was measured by western blot and calpain cleavage activity assessed via fluorescent assay. Analysis of *CASP8* epigenetic marks and transcript isoforms in RA and osteoarthritis (OA) FLS was evaluated using public databases (ChIPseq and RNAseq). Crystal structures of variant B and G were determined.

Results: Silencing total *CASP8* reduced RA FLS migration (36.7%±7.2, n=6, P=0.008) and invasion (41.6±6.3%, n=4, P=0.01) after PDGF stimulation, and lower adhesion to fibronectin and collagen type II (n=4; P=0.002 and P=0.005 respectively). Decreased migration after PDGF stimulation was associated with decreased talin cleavage and calpain activity. The caspase enzymatic inhibitor Z-IETD-FM did not affect FLS migration nor invasion. Of the 20 known alternatively spliced variants of caspase-8, only variant C and G are expressed in FLS, with G > >C. Epigenetic analysis found enhanced H3K4me1 and H3K27ac peaks in the promoter region of variant G and C in RA FLS compared

with OA. Expression of caspase-8 variant G, but not other variants, was induced by PDGF (1.5±0.1 fold increase at 6h, n=6, *P*=0.003). Selective silencing of variant G showed that this isoform is solely responsible for the effect of caspase-8 on FLS invasion and calpain activity (n=6, $P \leq 0.01$). The crystal structures of caspase-8 isoform G and B were identical aside for a unique unstructured 59aa N-terminal domain in variant G.

Conclusion: Non-enzymatic functions of caspase-8 regulate key activities associated with aggressive RA FLS behavior. RA FLS have a restricted pattern of *CAPS8* alternative splicing, and variant G is solely responsible for this function. Because caspase-8 variant G has a unique amino acid tail, selective targeting could potentially inhibit FLS invasion without the deleterious effects of blocking caspase-8-mediated apoptosis.

Increased Circulating CD39+FoxP3+CD4+ Treg Cells in Early Rheumatoid Arthritis Facilitate the Antiinflammatory Action of Methotrexate

Laura Nuño[1], Alejandro Villalba[1], Marta Novella-Navarro[2], Irene Monjo[1], Diana Peitado[1], Sara Garcia-Carazo[1], Alejandro Balsa[2] and **Maria-Eugenia Miranda-Carus**[1], [1]Hospital La Paz - IdiPAZ, Madrid, Spain, [2]Immuno-Rheumatology Research Group, Hospital La Paz Institute for Health Research-IdiPAZ, Rheumatology, La Paz University Hospital, Madrid, Spain

SESSION INFORMATION
Session Date: Saturday, November 6, 2021
Session Title: RA – Etiology & Pathogenesis Poster (0011–0045)
Session Type: Poster Session A
Session Time: 8:30AM–10:30AM

Background/Purpose: Inhibition of AICAR transformylase by MTX results in augmented release of adenine nucleotides to the extracellular space; these are rapidly hydrolysed by ectonucleotidases CD39 and CD79 rendering the antiinflammatory agent adenosine. CD39, the rate-limiting enzyme in this cascade, is highly expressed by a subset of human FoxP3+CD4+ regulatory T cells (Treg39+)[2-4] and MTX may act synergistically with Tregs in the control of inflammation. Our objective was to study the expression of CD39 on circulating Treg cells of untreated early RA (ERA) patients and its relation with the ex vivo effect of MTX.

Methods: Peripheral blood was drawn from 30 DMARD- and steroid- naïve ERA (disease duration < 24 weeks), 15 longstanding RA patients (LRA, duration > 2 years) and 45 healthy controls (HC). LRA patients were naïve for biologicals and received low-dose weekly MTX. 10 ERA patients who achieved remission 12 months after initiating MTX were re-evaluated (ERA-R). The frequency of Treg cell subsets was determined by flow cytometry. CD4+CD25+CD127- (total T reg), CD4+CD27+CD127-CD39+ Treg (Treg39+) and CD4+CD25-CD39- responder T (Tresp39-) cells were isolated by sorting. The suppressor potency of Tregs was assessed in cocultures with Tresp, at different Treg/Tresp ratios. Proliferation was determined by CFSE dilution and cytokine secretion by ELISA of culture supernatants.

Results: ERA but not LRA patients demonstrated a superior frequency of circulating Treg (CD4+CD25+CD127-FoxP3+) cells. In addition, the proportion of Tregs that expressed CD39 (Treg39+) was increased in ERA but not LRA. Total ERA Tregs were more potent suppressors of proliferation, TNFα and IFNγ secretion when compared with HC

or LRA, and this difference was downmodulated in the presence of adenosine deaminase (ADA), or the adenosine A2A receptor (A2AR) antagonists DMPX (3,7-dimethyl-1-propargylxanthine) or ZM 241385, but not of the adenosine A1 receptor antagonist DPCPX (8-cyclopentyl-dipropylxanthine). When adding MTX, the suppressor potency of total Tregs was further enhanced in all 3 groups of patients, and this enhancement was significantly higher in ERA total Treg/Tresp39- cocultures as compared with HC or LRA. This effect of MTX was significantly abrogated by ADA, DMPX or ZM 241385 but not DPCPX. We then tested the suppressor potency of isolated Treg39+ together with the enhancer effect of MTX on this potency, and observed that there were no longer differences among ERA, LRA and HC; this further suggests that the differences observed in assays using total Tregs can be attributable to the increased Treg39+ proportions present in ERA. The frequency and function of ERA-R Treg cells were not different from HC or LRA Tregs.

Conclusion: The suppressor action of CD39+Tregs is mediated at least in part by adenosine trough A2AR ligation, and the superior suppressive potency of total ERA Tregs is associated with their higher proportion of TregCD39+ cells. The augmented suppressor effect observed in the presence of MTX is partly mediated by an increased adenosine production acting on A2AR and is more marked in ERA patients reflecting again their higher proportion of Treg39+ cells. This indicates that MTX cooperates with Treg39+ cells in the control of inflammation.

Citrullination Drives the Expression of Pro-fibrotic Genes in Rheumatoid Arthritis Fibroblast-like Cells

Peter Maloley, Evan Ryan, Nozima Aripova, Michael Duryee, Bryant England, Ted Mikuls and Geoffrey Thiele, University of Nebraska Medical Center, Omaha, NE

SESSION INFORMATION
Session Date: Saturday, November 6, 2021
Session Title: RA – Etiology & Pathogenesis Poster (0011–0045)
Session Type: Poster Session A
Session Time: 8:30AM–10:30AM

Background/Purpose: The pathophysiology of rheumatoid arthritis (RA) is hallmarked by joint inflammation, thickening of the pannus, and resultant joint destruction. Within the synovial tissue, citrullinated antigens and malondialdehyde-acetaldehyde (MAA)-modified proteins co-localize, implicating a potential synergistic role in the induction of immune and pro-fibrotic responses. To further elucidate the mechanisms by which these modifications contribute to RA pathogenesis, we studied fibrotic gene expression by human fibroblast-like synoviocytes from RA patients (HFLS-RA) in response to stimulation with citrullinated and/or MAA-modified fibrinogen.

Methods: HFLS-RA cells were treated with native fibrinogen versus citrullinated and/or MAA-modified fibrinogen for 8 hours with sham treated HFLS-RA cells as reference, and mRNA was isolated. Expression of 763 genes was quantified using the NanoString® nCounter® Human Fibrosis Panel. Comparisons of gene expression across treatment groups were performed using differential expression analysis. Only genes with increased or decreased expression

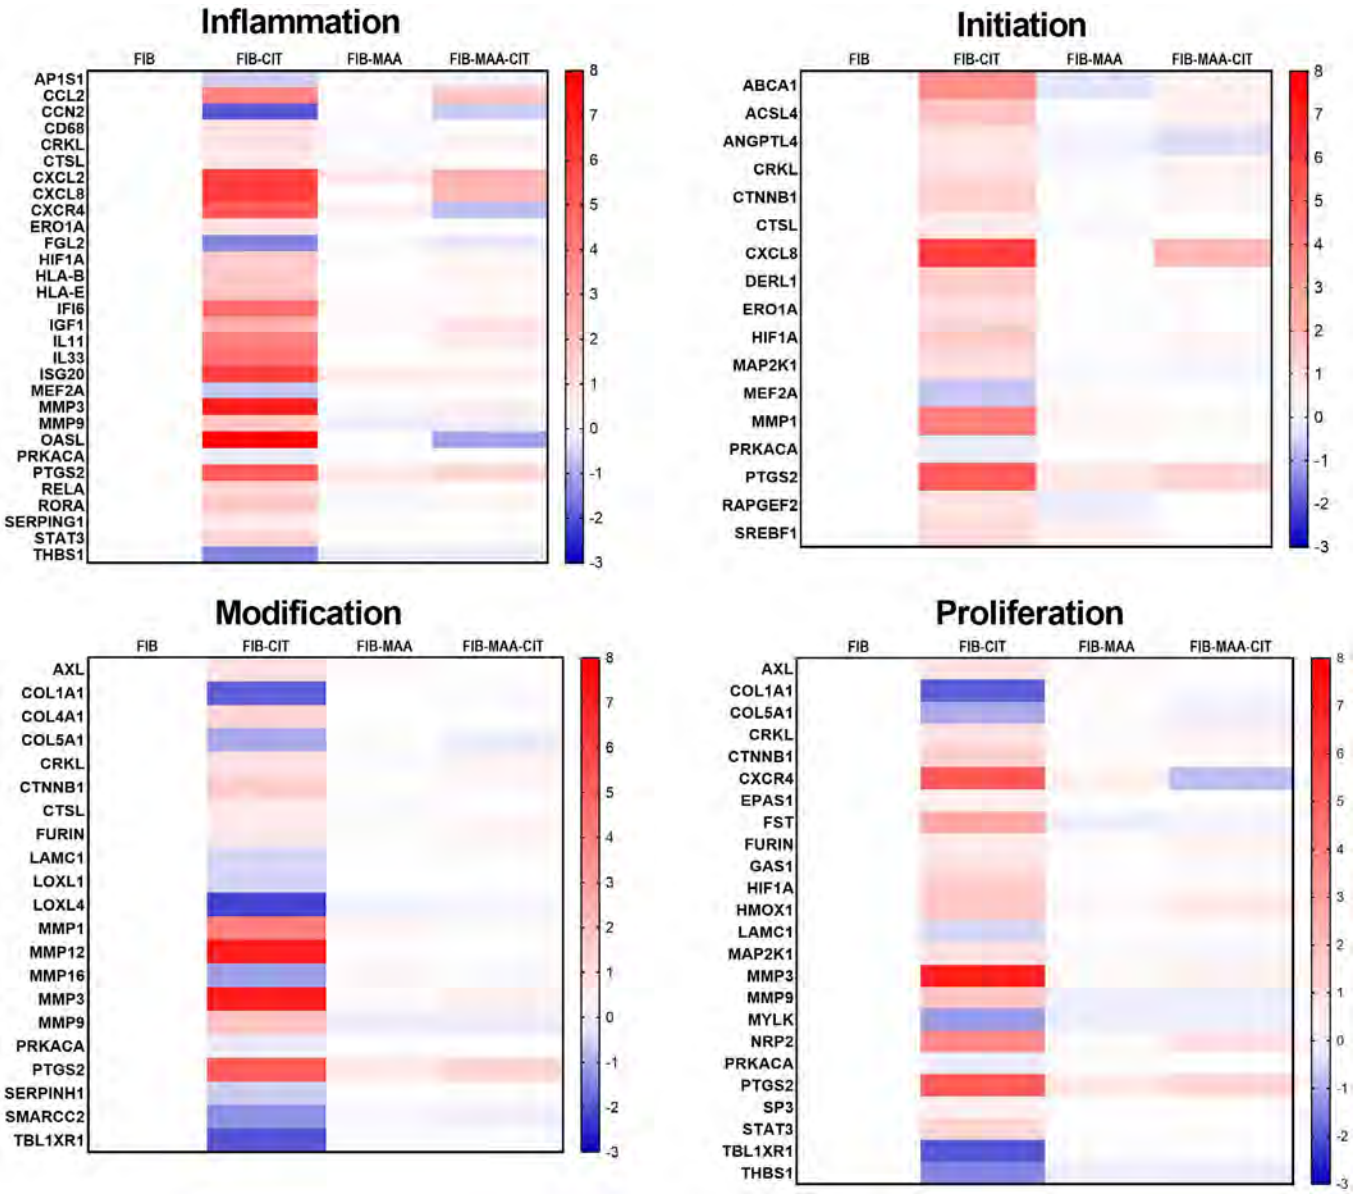

Figure 1. Heat map (red = increased; blue = decreased) of significant genes expressed following 8-hour treatment of HFLS-RA cells with native fibrinogen (control), citrullinated fibrinogen, MAA-modified fibrinogen, or MAA-modified and citrullinated fibrinogen. Gene profiles were categorized into inflammation, initiation, modification, and proliferation. The heat map bar on the right is expressed as fold-change compared to control.

compared to untreated HFLS-RA cells were reported in the final results. Data was reported using $\log_2$ of normalized ratio with the sham group as reference.

Results: The gene responses of treated HFLS-RA cells were categorized based on their role in the fibrotic pathway (inflammation, initiation, modification, and proliferation) with many genes having influence on multiple pathways. Of the 763 genes analyzed, 58 demonstrated differential expression when exposed to modified antigen (Figure 1). Forty genes exhibited significantly increased expression when treated with citrullinated-fibrinogen alone compared to native unmodified fibrinogen (Figure 2). Of these 40 genes, four also demonstrated increased expression after treatment with fibrinogen co-modified with citrulline and MAA (Figure 3). One gene, CCL2 (inflammation), yielded increased gene expression in response to co-modified fibrinogen but not to citrullinated antigen alone (Figure 3). Treatment with MAA-modified fibrinogen alone did not generate any significant differential expression.

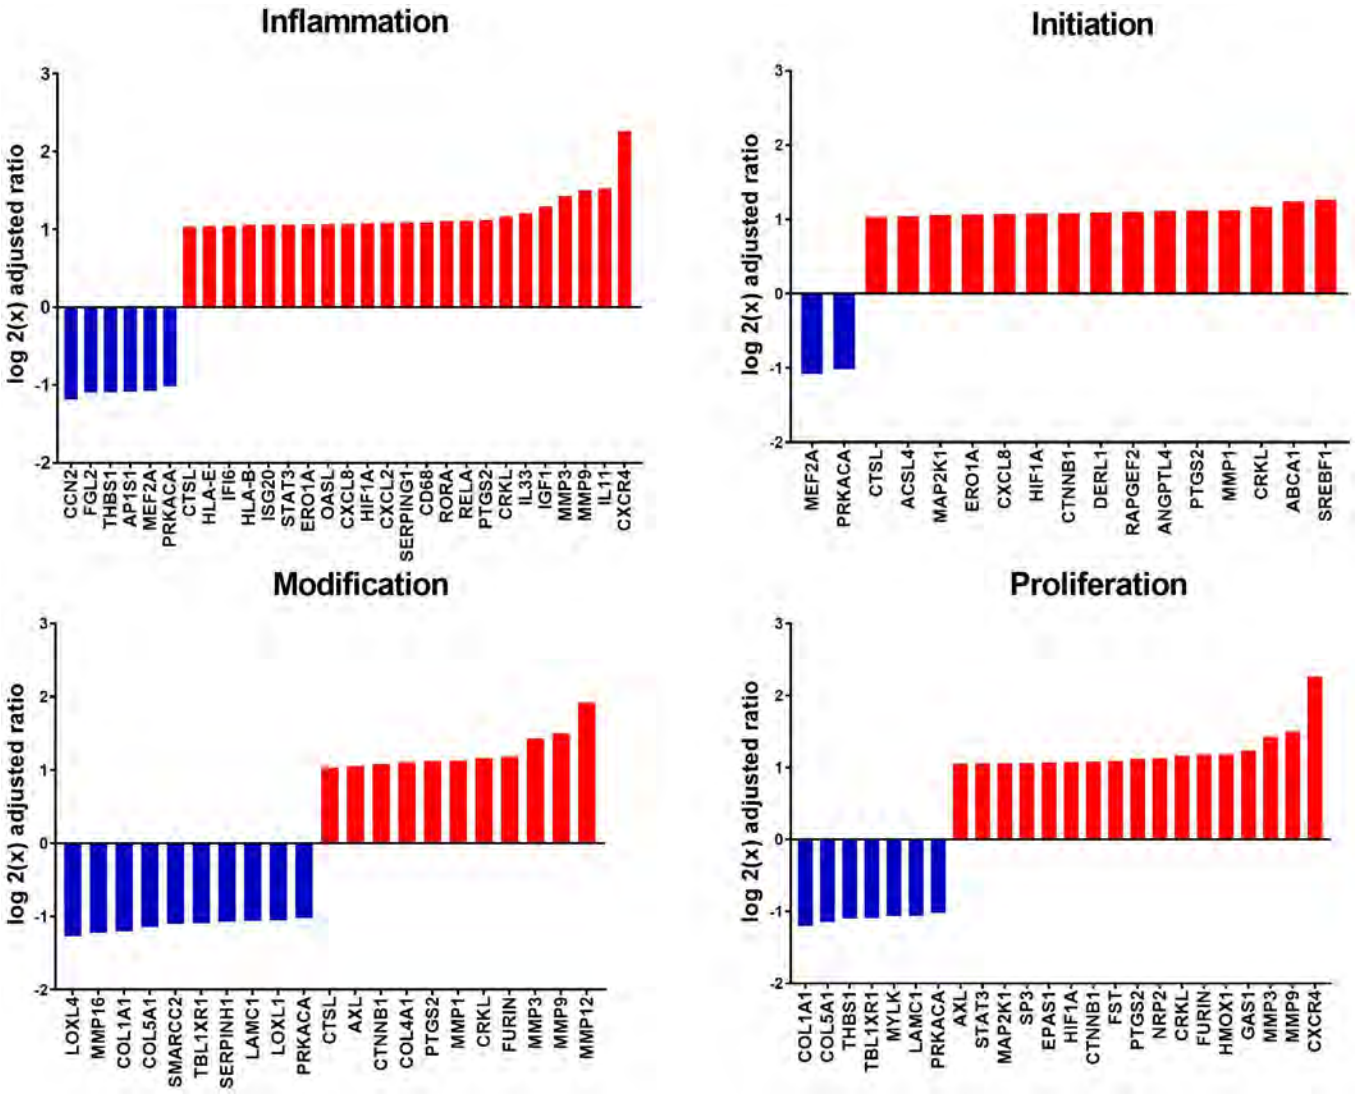

Figure 2. Genes that were significantly increased (red) or decreased (blue) by citrullinated fibrinogen were extracted from the heat maps and expressed as the log2 ratio compared to native fibrinogen (control). Gene profiles were categorized into inflammation, initiation, modification, and proliferation. Data is expressed as fold-change compared to control.

Conclusion: In this study, citrullinated fibrinogen augmented gene expression most conspicuously, whereas MAA-modification alone did not. Interestingly, co-modification did demonstrate a synergistic pro-fibrotic synovial response in one gene (CCL2) that was not seen with either single modification alone. Many of the genes identified have previously been shown to correlate with anti-citrullinated antibodies and RA disease activity, and thus, these post-translationally modified proteins may play a role in the development of fibrosis that contributes to joint pathology in RA. We would benefit from further elucidation of the synergistic role MAA and citrulline play and if that could be a target of diagnostic and/or therapeutic clinical practice.

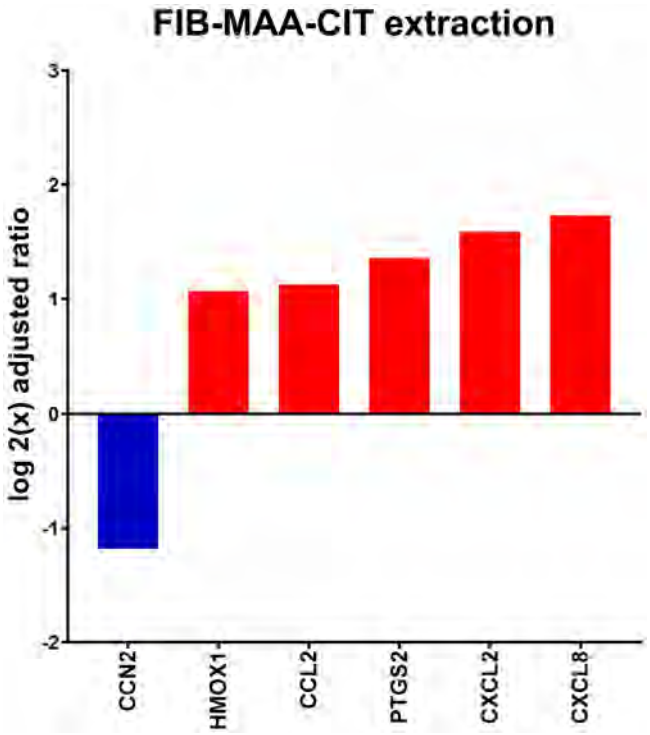

Figure 3. Genes that were significantly increased (red) or decreased (blue) by co-modification of fibrinogen with MAA and citrulline (Fib-MAA-CIT) were extracted from the heat maps and expressed as the log2 ratio compared to native fibrinogen (control). Data is expressed as fold-change compared to control.

help and both are increased in the peripheral blood in patients with seropositive RA. However, it is unknown whether these cell populations are expanded and/or altered in the peripheral blood prior to the onset of clinically apparent RA. Moreover, the contribution of these cells to the pathogenesis of RA may differ according to genetic and environmental backgrounds. Herein, we explored circulating Tph (cTph) cells and circulating Tfh (cTfh) cells from anti-citrullinated protein antibodies (ACPA)+ individuals both before and after development of RA in two ethnically distinct populations.

Methods: We recruited 14 and 10 ACPA+ individuals without arthritis but at-risk of future RA (ARI), 15 and 10 ACPA+ patients with early RA (2010 criteria and < 1 year from diagnosis), and 14 and 15 healthy controls (HC) from the Studies of the Etiologies of RA (SERA) population at University of Colorado (CU) and the rheumatology outpatient clinic at Tokyo Women's Medical University (TWMU) in Japan, respectively (Table 1). Cryopreserved peripheral blood mononuclear cells were analyzed by flow cytometry to quantify cTph cells (PD-1^{hi}CXCR5^{-}CD4^{+} memory T cells) and cTfh cells (PD-1^{hi}CXCR5^{+}CD4^{+} memory T cells). We also assessed the expression of activation markers, HLA-DR and ICOS, on these cells.

Results: In both ethnic populations, cTph cells were significantly increased in RA but not in ARI compared to HC (Figure 1A and 2A). In the CU population, the frequency of cTph cells was moderately correlated with serum IgM-RF levels in both ARI (Spearman's ρ=0.56, p=0.04) and RA (Spearman's ρ=0.68, p=0.005) (Figure 1B), while no correlation was observed between the frequencies of cTph cells and serum ACPA levels in either ARI or RA. There were no significant differences in the expressions of HLA-DR and ICOS on cTph cells or cTfh cells between CU study groups (Figure 1C). Unlike the CU population, the TWMU population did not show positive correlation between the frequency of cTph cells and serum IgM-RF levels in either ARI or RA (Figure 2B). In that population, however, the expression of HLA-DR on cTph cells was increased in both ARI and RA (Figure 2C).

Conclusion: cTph cells were expanded in RA but not in ARI in both ethnic populations, suggesting a relationship of these cells with clinically-apparent inflammatory arthritis. In addition, unique alterations in cTph cells among ACPA+ individuals with different ethnic backgrounds and in relationship to IgM-RF suggest their shared importance but potentially different roles in the future transition of ACPA+ ARI to early RA.

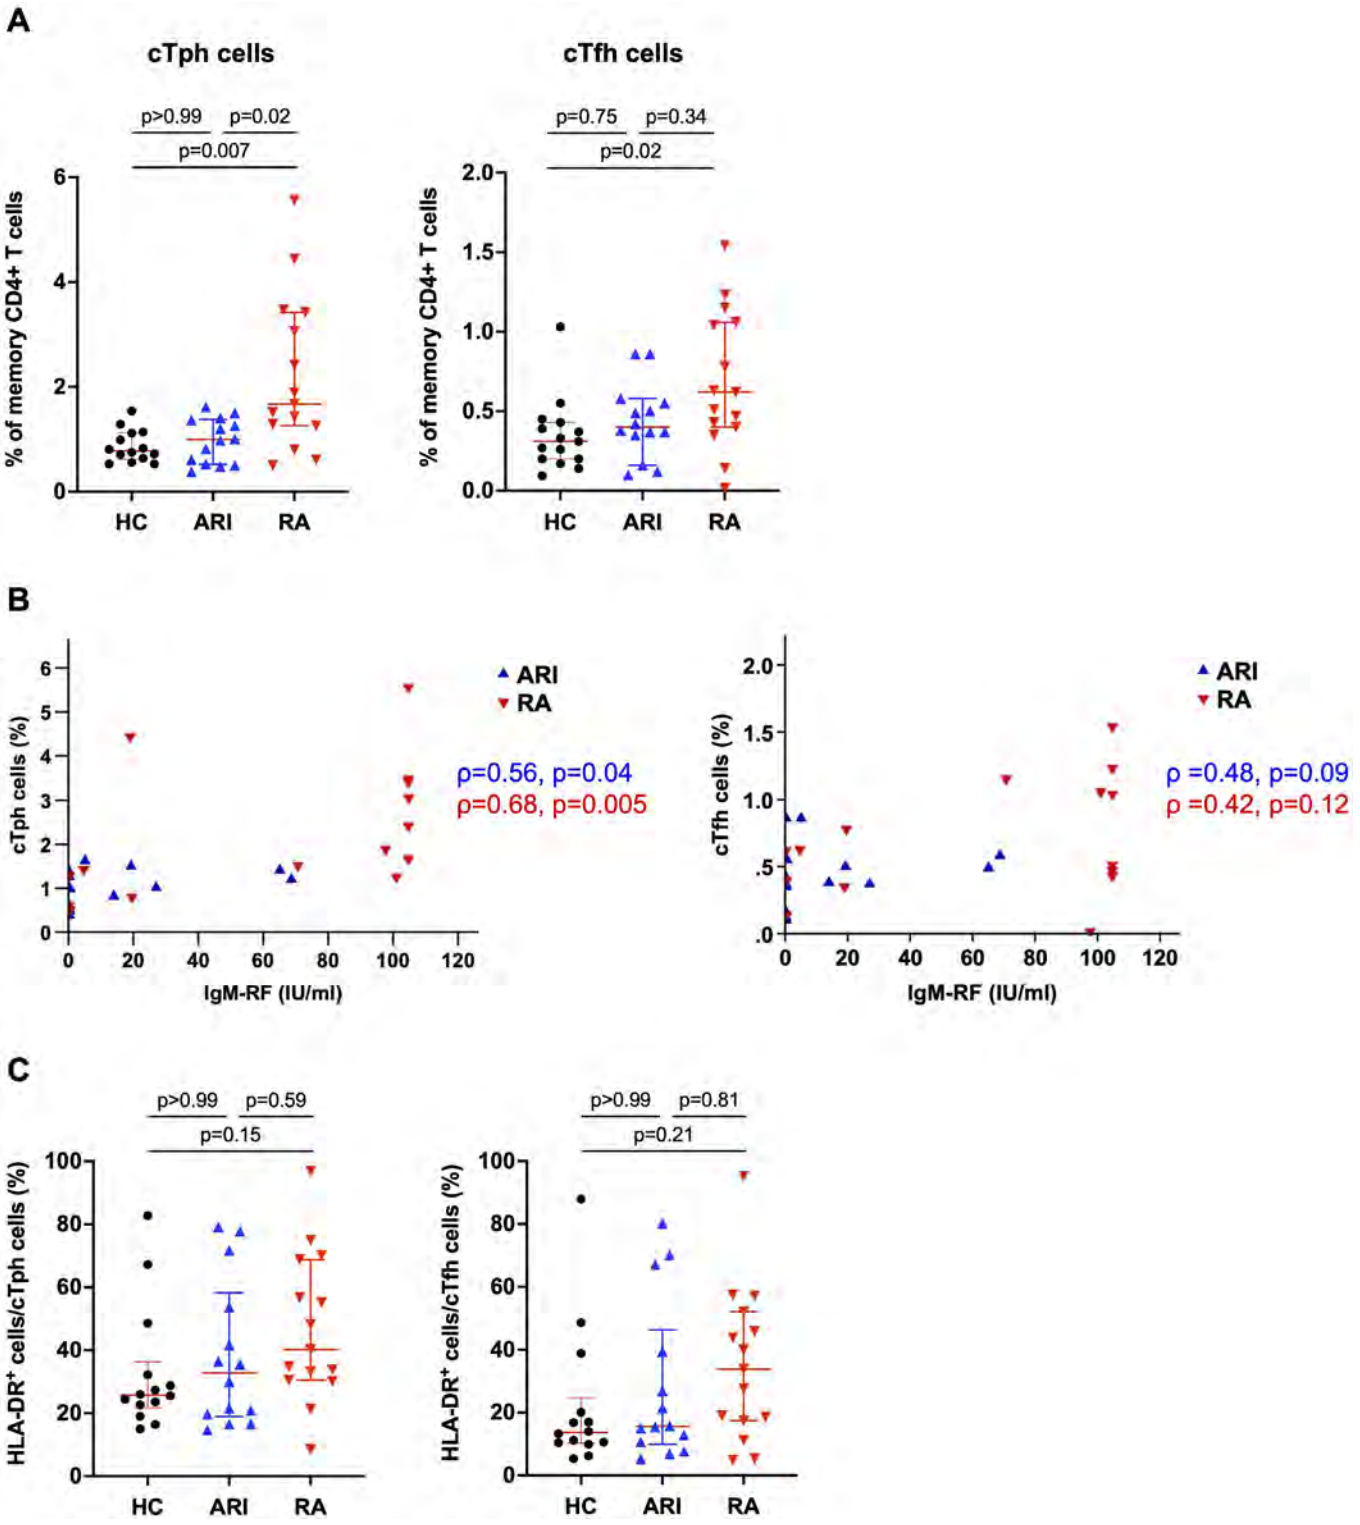

Figure 1. Flow cytometry analysis of cTph and cTfh cells in ACPA+ individuals at-risk of future RA (ARI) and ACPA+ early RA patients, and healthy controls (HC) at University of Colorado. A) Frequencies of cTph and cTfh cells in each study group. B) Correlation between frequencies of cTph or cTfh cells and serum IgM-RF levels in ARI and RA. C) Expression of HLA-DR on cTph or cTfh cells in each study group. P-values were calculated using Kruskal-Wallis one-way analysis of variance followed by Dunn's multiple comparisons test (Panel A and C) and Spearman's rank correlation (Panel B).

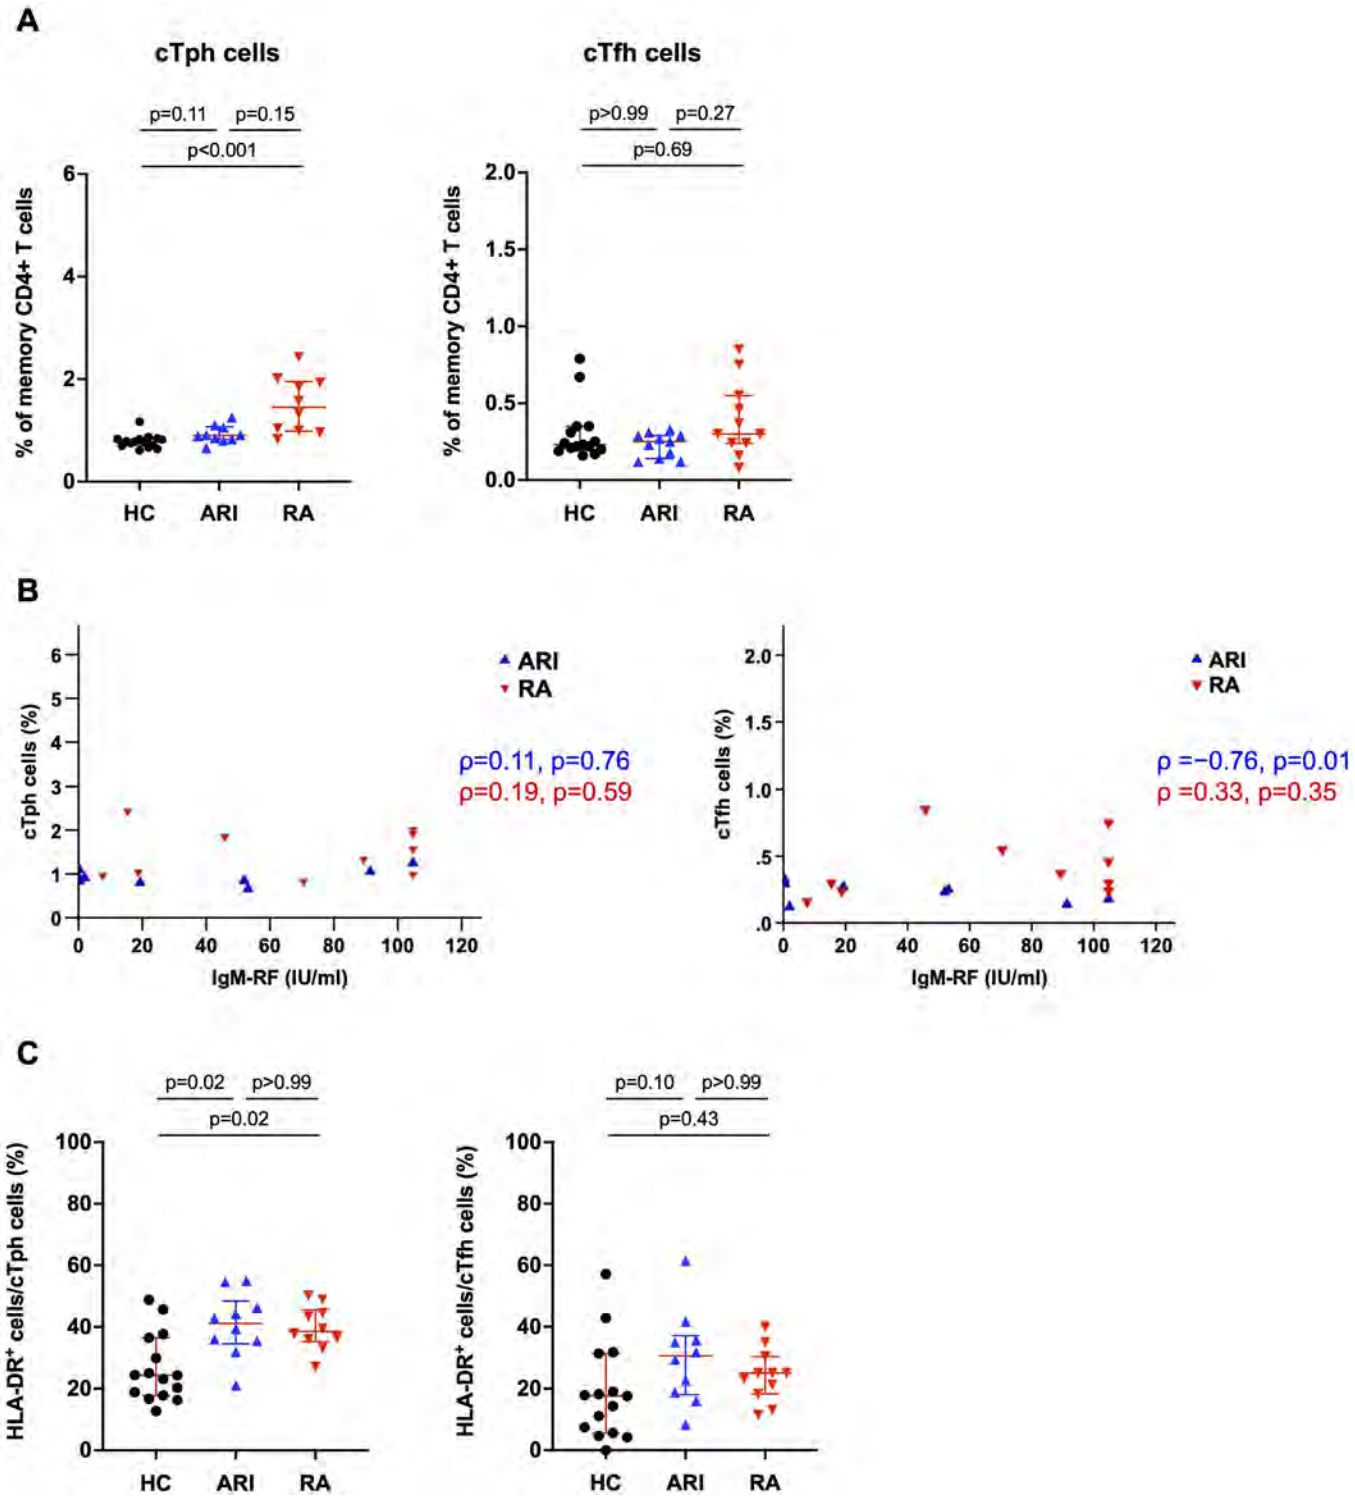

Figure 2. Flow cytometry analysis of cTph and cTfh cells in ACPA+ individuals at-risk of future RA (ARI) and ACPA+ early RA patients, and healthy controls (HC) at Tokyo Women's Medical University. Abstract Number: 0022

The Effects of MAA-Modified and/or Citrullinated Proteins on Calcium Influx and Peptidyl Arginine Deiminase (PAD) Expression in Macrophage

Andrew Gerber, Michael Duryee, Nozima Aripova, Bryant England, James O'Dell, Ted Mikuls and Geoffrey Thiele, University of Nebraska Medical Center, Omaha, NE

SESSION INFORMATION
Session Date: Saturday, November 6, 2021
Session Title: RA – Etiology & Pathogenesis Poster (0011–0045)
Session Type: Poster Session A
Session Time: 8:30AM–10:30AM

Background/Purpose: Expressed in synovial fluid mononuclear and other inflammatory cells, peptidyl arginine deiminase (PAD) catalyzes post-translational citrullination of synovial proteins in a calcium (Ca2+)-dependent manner. Prior reports have demonstrated that post-translational modification of proteins with malondialdehyde-acetaldehyde (MAA) are also common in the RA synovium where they co-localize with citrullinated antigen. However, little is known about the effects of MAA modified proteins on PAD expression or intracellular Ca2+ concentrations. The purpose of this study was to examine the intracellular Ca2+ levels, and the PAD-4 mRNA and protein levels in macrophages following treatment with a MAA-modified antigen.

Methods: THP-1 human macrophage cells were treated with unmodified fibrinogen (Fib) as a negative control or MAA-modified fibrinogen (Fib-MAA) for 24 hours. Cells were washed and incubated with a Fluo-4 AM calcium-binding protein for 30 minutes and subjected to live cell imaging on a 710 Ziess confocal microscope. Images were

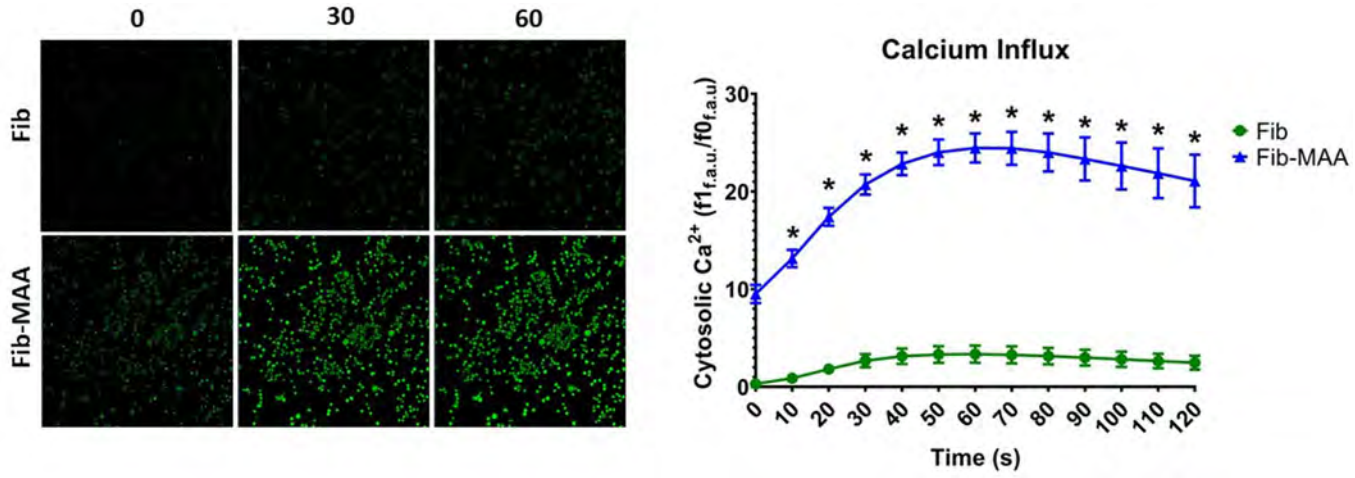

Figure 1. Intracellular calcium increase following 24 hour treatment of THP-1 macrophage with native fibrinogen or MAA modified fibrinogen. Data is expressed as fluorescence of cells with no treatment divided by time 0 fluorescence. *p<0.001 significantly increased compared to Fib. N=5.

acquired in 10-second intervals for 120 seconds and analyzed using Image J. RTPCR was performed on the cells to determine the expression of PAD-4 as well as the calcium binding proteins Inositol 1,4,5-triphosphate receptor-3 (ITPR3) and calcium/calmodulin-dependent protein kinase (CAMKK)-2. THP-1 cells were subjected to Western Blot for protein expression of PAD-4 using an anti-PAD antibody. Group differences were examined using ANOVA with a post-hoc test to account for multiple comparisons.

Results: Human macrophages incubated with Fib-MAA significantly increased ($p < 0.001$) the Ca2+ influx compared to unmodified Fib (**Figure 1**). Exposure to Fib-MAA had no meaningful impact on ITPR3 expression ($p > 0.05$) (**Figure 2**). In contrast, CAMKK2 expression was significantly ($p < 0.001$) increased in macrophages stimulated with Fib-MAA compared to cells stimulated with unmodified Fib. Likewise, PAD-4 mRNA expression was significantly ($p < 0.01$) increased in only the Fib-MAA vs. native Fib. In contrast to the mRNA expression, Western Blot revealed a decrease in PAD-4 protein expression for Fib-MAA vs. unmodified Fib, suggesting protein depletion (**Figure 3**).

Conclusion: The increase in Ca2+ influx following treatment with a MAA-modified antigen provides a critical element needed for PAD-mediated protein citrullination in human macrophages, while the observed increase in PAD-4 expression provides the requisite catalyst. The lack of effect seen on ITPR3 (which promotes intracellular movement from the endoplasmic reticulum) suggests that the overall increase likely stems from extracellular sources. The increased expression of CAMKK2 following Fib-MAA exposure could account for changes in cellular activity such as cell differentiation, changes in cell cycle and/or cytoskeletal architecture even though the source of calcium is different. Taken together, these data for the first time implicate MAA-modified proteins as promoters of macrophage-mediated citrul-

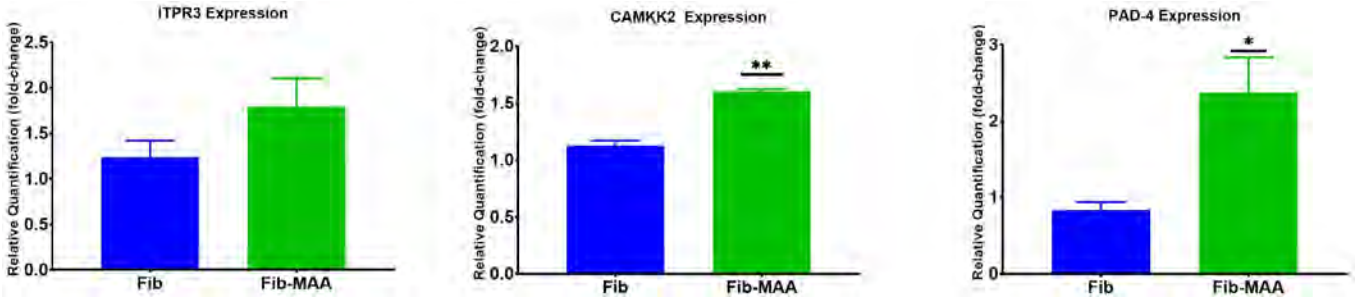

Figure 2. Expression of mRNA by RTPCR following 24 hour treatment of THP-1 macrophage with native fibrinogen or MAA modified fibrinogen. ITPR3 expression was not significant compared to Fib. CAMKK2 expression **p<0.01 significantly increased compared to Fib treatment. PAD-4 expression *p<0.01 significantly increased compared to Fib treatment. N=5.

lination, a process that is critical in RA pathogenesis and that appears to be dependent on increases in both Ca2+ influx and increased PAD expression.

Investigating Temporal Changes in Pregnancy Among Women with Rheumatoid Arthritis and Healthy Women Using Co-expression Network Analysis

Matthew Wright[1], Dana Goin[2], Mette Smed[3], J Lee Nelson[4], Nicholas Jewell[5], Jorn Olsen[6], Merete Hetland[7], Vibeke Zoffmann[3] and **Damini Jawaheer**[8], [1]UCSF Benioff Children's Hospital Oakland, Oakland, CA, [2]University of California San Francisco, San Francisco, CA, [3]Juliane Marie Center, Rigshospitalet, Copenhagen, Denmark, [4]Fred Hutchinson Cancer Research Center, University of Washington, Seattle, WA, [5]University of California Berkeley, Berkeley, CA, [6]Aarhus University Hospital, Aarhus, Denmark, [7]DANBIO and COPECARE, Centre for Rheumatology and Spine Diseases, Rigshospitalet, Glostrup, Denmark, [8]UCSF Benioff Children's Hospital Oakland / University of California San Francisco, Oakland, CA

SESSION INFORMATION
Session Date: Saturday, November 6, 2021
Session Title: RA – Etiology & Pathogenesis Poster (0011–0045)
Session Type: Poster Session A
Session Time: 8:30AM–10:30AM

Background/Purpose: Rheumatoid arthritis (RA), while still an incurable disease, can often improve naturally during pregnancy. The specific mechanism(s) underlying this pregnancy-induced improvement, however, are not known. Our goal was to use our prospective pregnancy cohort (a) to identify genes whose expression are modulated during pregnancy in healthy women and in RA, as the disease improves, and (b) to investigate their functional enrichment using co-expression network analysis.

Methods: Data and samples were collected at pre-pregnancy (T0) and each trimester (T1, T2, T3) from women with RA who improved during pregnancy (n=14) and healthy women (n=15) enrolled in our prospective pregnancy cohort. Total RNA samples from whole blood were sequenced (RNA-seq). Following alignment (HISAT2) and transcript assembly (StringTie), gene-level expression was quantified (featureCounts) and normalized (edgeR). Cell type proportions were inferred through deconvolution (CIBERSORTx). Generalized Estimating Equation (GEE) models were used to assess modulation of gene expression across pregnancy in each group of women, adjusting for changes in cell type proportions across time points. Thresholds of FDR< 0.05 and fold-change >=2 (vs T0) were used to determine significance. Functional enrichment analysis (Webgestalt, Enrichr) and co-expression network analysis (WGCNA) were also performed.

Results: Temporal changes were observed in the proportions of neutrophils, resting NK cells, and resting CD4 memory T cells among healthy women only, and of monocytes among the women with RA. Numerous genes (334 protein-coding and 115 non-coding) were significantly up- or down-regulated during pregnancy among the women with RA, some demonstrating significant changes starting from early pregnancy (T1: n=26) or mid-pregnancy (T2: n=262) or during late-pregnancy (T3: n=161). Of those, 116 demonstrated similar temporal expression patterns among healthy women; another 112 genes were modulated during pregnancy only in the healthy group. The genes whose expres-

sion were modulated during pregnancy as RA improved were enriched in specific co-expression network modules related to neutrophil activation (upregulated in early pregnancy), binding of erythroid transcription factors (upregulated in mid-pregnancy), immunoglobulin constant and variable chain genes (downregulated in mid-pregnancy), and translation (mostly ribosomal genes, upregulated in late pregnancy). Similar enrichment in co-expression modules were observed in healthy pregnancy, except for the module related to binding of erythroid transcription factors which seemed to be specific to the RA group. Additionally, a module related to interferon signaling was enriched in genes modulated only in healthy pregnancy.

Conclusion: In our pregnancy cohort, multiple co-expression modules overlapped between the RA and healthy pregnancies. However, there were also differences including a specific module related to binding of erythroid transcription factors that was unique to RA, and a module related to interferon signaling that was unique to healthy pregnancy. It remains to be investigated how those differences may influence improvement of the disease during pregnancy.

Heterogeneity of Inflammatory HLA-DR$^+$ Synovial Fibroblasts in Rheumatoid Arthritis Is Driven by Responses to Leukocyte-Derived Cytokines

Melanie Smith[1], Alejandro Kochen[1], Vianne Gao[2], Michail Schizas[2], Edward DiCarlo[1], Susan Goodman[1], Christina Leslie[3], Laura Donlin[1] and Alexander Rudensky[4], [1]Hospital for Special Surgery, New York, NY, [2]Memorial Sloan Kettering Cancer Center, New York, NY, [3]Computational and Systems Biology Program Memorial Sloan Kettering Cancer Center, New York, NY, [4]Memorial Sloan Kettering Cancer Center / Howard Hughes Medical Institute, New York, NY

SESSION INFORMATION
Session Date: Saturday, November 6, 2021
Session Title: RA – Etiology & Pathogenesis Poster (0011–0045)
Session Type: Poster Session A
Session Time: 8:30AM–10:30AM

Background/Purpose: Treatment-refractory rheumatoid arthritis (RA) represents a major unmet need with substantial societal burden. Targeting RA-associated fibroblast-like synoviocytes (FLS) may provide a less-immunosuppressive therapeutic option. Recent single cell RNA-sequencing (scRNA-seq) studies of RA synovial tissue have identified distinct fibroblast subsets, including a population of HLA-DR$^+$ FLS that are expanded in RA and express pro-inflammatory cytokines as well as interferon gamma (IFNg) and tumor necrosis factor alpha (TNFa) response signatures (1). Donors with an expansion of HLA-DR$^+$ FLS have an expansion of inflammatory monocytes, which express interleukin 1 beta (IL-1b), and CD8$^+$ T cells, which express both TNFa and IFNg (1). TNFa stimulated macrophages that produce IL-1b induce key genes expressed by HLA-DR$^+$ FLS, including IL6 (2). Here we explored the ability of distinct combinations of cytokines predominant in RA to impart gene expression features observed in HLA-DR$^+$ FLS and localize these FLS within the inflamed synovium.

Methods: Synovial tissue was obtained from a prospective cohort of RA patients undergoing arthroplasty or synovectomy who are screened for active RA at the time of surgery (HSS IRB no. 2014-233). For cultured FLS, synovial

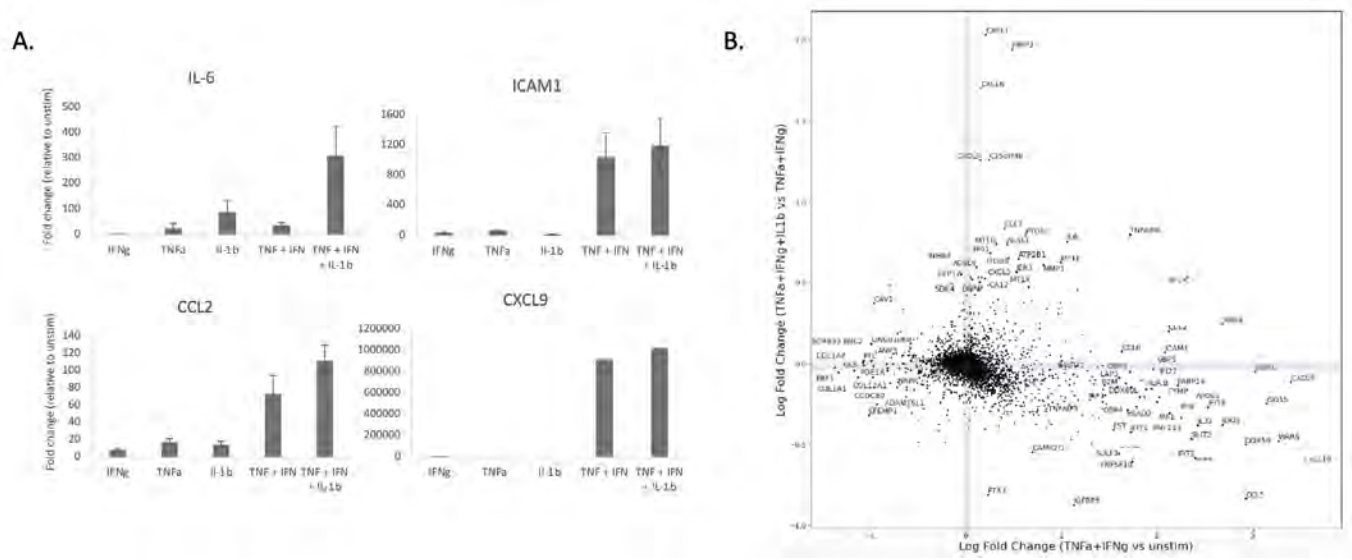

Figure 1. Stimulation of cultured FLS with combinations of dominant RA cytokines reveals marked synergy and distinct gene signatures driven by either TNFa + IFNg ± IL-1b. A. qPCR on cultured, cytokine-stimulated FLS. n = 3 donors. Mean ± SD. B. Differential expression analysis from scRNA-seq of cultured, cytokine-stimulated FLS derived from single RF+/CCP+ patient on methotrexate monotherapy with active disease.

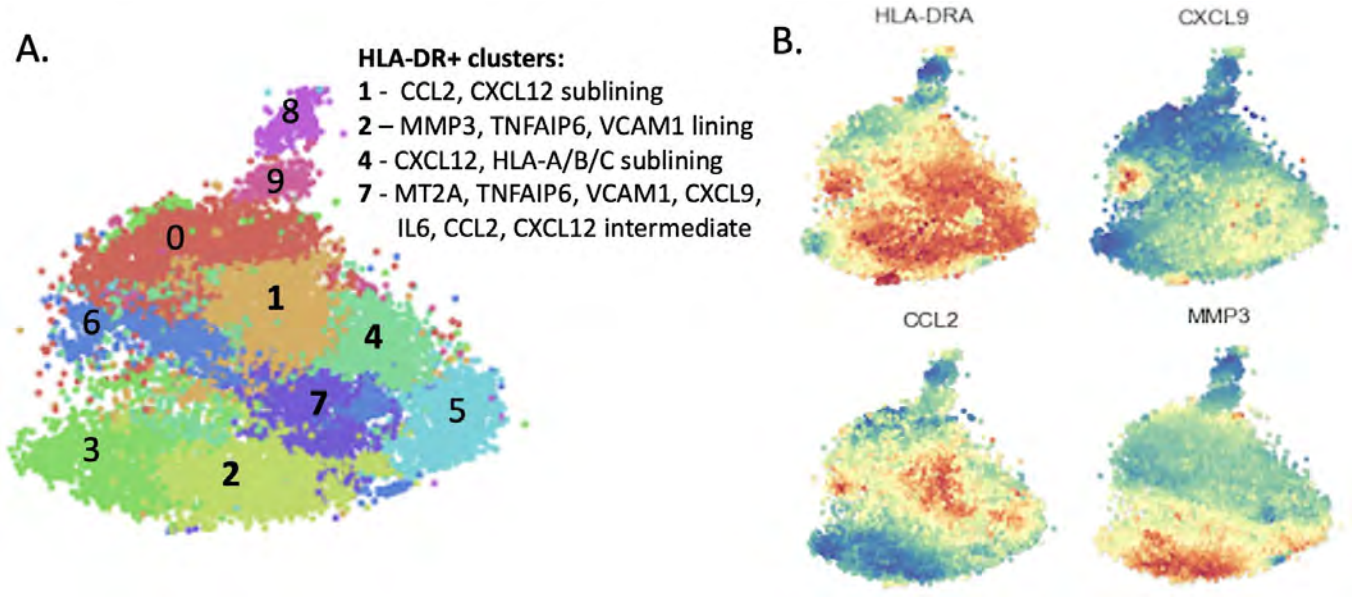

Figure 2. Heterogeneity of HLA-DR+ FLS including clusters with expression of genes induced cytokine combinations. ScRNA-seq of freshly dissociated, sorted FLS from same patient as in Fig 1. A. t-SNE showing clusters of transcriptionally similar FLS in which clusters 2 and 3 are lining, 5 and 7 are intermediate sublining/lining and 0, 1, 4, 6, 8, and 9 are sublining. B. Expression of HLA-DRA as well as genes induced by IFNg + TNFa (CXCL9), IL-1b (MMP3) or IFNg + TNFa + IL-1b (CCL2).

tissue was dissociated and cultured as in (2). FLS were cultured with cytokines for 24 hours. ScRNA-seq was performed on sorted FLS ($CD45^-$, $CD31^-$, $PDPN^+$) from dissociated synovial tissue. Multiparameter immunofluorescence (IF) was carried out using Iterative Bleaching Extends Multiplexity (IBEX) (3).

Results: The combination of IFNg, TNFa +/- IL-1b induced FLS expression of genes characteristic of HLA-DR^+ FLS such as IL6, CCL2, CXCL9 and ICAM1 (Fig 1A). Differential gene expression analysis of cytokine-stimulated FLS revealed distinct transcriptional features elicited by IFNg + TNFa vs IL-1b (Fig 1B). When used in combination, the cytokines were able to exert a synergistic effect on FLS gene expression with a small set of genes induced by the

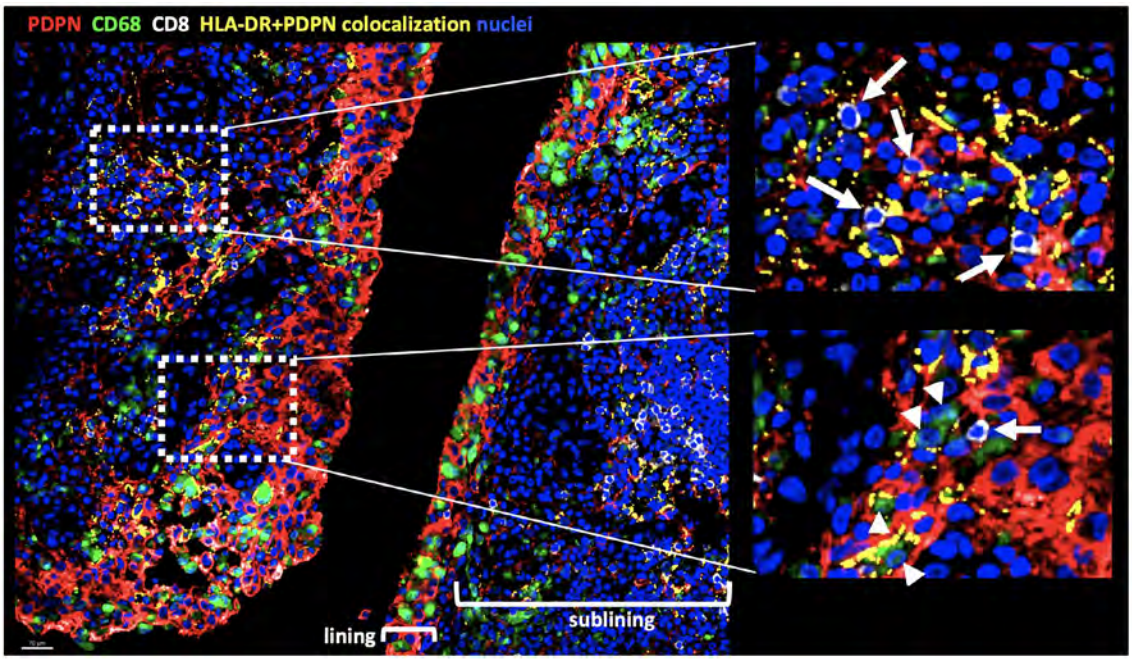

Figure 3. HLA-DR+ FLS are found within both synovial sublining and lining. IF of RA synovial tissue from same patient as in Fig 1 and 2 where HLA-DR+ FLS can be found near both CD68+ macrophages (arrow heads) and CD8+ T cells (arrows). Black space in full sized image represents synovial fluid space between two hypertrophied villi of the inflamed synovium.

combination of all three cytokines (IL6, TNFAIP6, MT2A, CCL2, MT1E). Unsupervised clustering analysis of gene expression of freshly dissociated FLS shows heterogeneity of HLA-DR$^+$ FLS with expression in both lining and sublining clusters as well as in clusters with an intermediate lining/sublining phenotype (Fig 2A). Clusters have differential expression of genes driven by TNFa + IFNg (CXCL9), IL-1b (MMP3) or all three cytokines (CCL2) (Fig 2B). IF analysis of inflamed synovium revealed localization of HLA-DR$^+$ FLS to both the lining and sublining areas in proximity to CD68$^+$ macrophages and CD8$^+$ T cells, respectively, (Fig 3).

Conclusion: Pro-inflammatory cytokine exposure of FLS accounts in part for the HLA-DR$^+$ FLS heterogeneity observed in the arthritic synovium *in situ*. Our analyses suggest that gene expression patterns observed in HLA-DR$^+$ FLS, which we were able to reconstruct with combinatorial cytokine stimulation *in vitro,* may originate from interacting CD8$^+$ T cells and inflammatory macrophages in the synovium.

The Modulatory Capacity of Galectin-3 on the Programmed Death-1 Signaling Axis in Rheumatoid Arthritis

Kathrine Pedersen[1], Morten Aagaard Nielsen[2], Malene Hvid[1], Bent Deleuran[1] and Stinne Greisen[1], [1]Aarhus University, Aarhus, Denmark, [2]Aarhus University / Aarhus University Hopital, Aarhus, Denmark

SESSION INFORMATION
Session Date: Saturday, November 6, 2021
Session Title: RA – Etiology & Pathogenesis Poster (0011–0045)
Session Type: Poster Session A
Session Time: 8:30AM–10:30AM

Background/Purpose: Rheumatoid arthritis (RA) is a chronic autoimmune disease characterized by inflammation of the synovium. Despite a variety of treatments, 30-40% of RA patients fail to respond to any of the approved treatment options. Thus, improving the understanding of the molecular background and complex disease mechanisms in RA is of utmost importance.

Programmed death 1 (PD-1) is an inhibitory glycosylated immune checkpoint receptor that dampens immune responses, and high PD-1 expression is considered desirable in RA. However, the exact effects of the PD-1 signaling axis in RA remains to be elucidated.

Extracellular Galectin-3 (Gal-3) is suggested to be associated with RA disease severity and inflammation. In contrast, Gal-3 has immune suppressing capabilities in cancer. Thus, effects of Gal-3 are complex, but could potentially be explained by Gal-3s diverse effect on immune checkpoint receptors.

Here, we aimed to investigate whether Gal-3 is a binding partner to PD-1, and how this interaction affects PD-1 signaling as well as inflammatory markers.

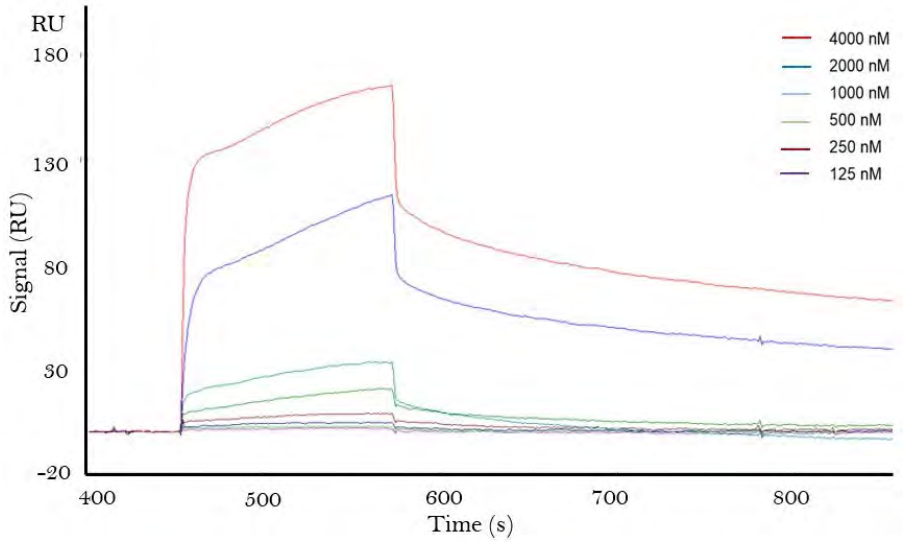

Figure 1. Surface plasmon resonance data. Recombinant human PD-1 coupled to Protein G and immobilized onto a sensor chip, while recombinant human Gal-3 is added to the buffer and run over the sensor chip. PD-1 and Gal-3 interaction will give rise to increased signal (Response Units (RU)). Here increasing concentrations of rhGal-3 is run over the sensor chip and demonstrating how rhGal-3 can interact with rhPD-1.

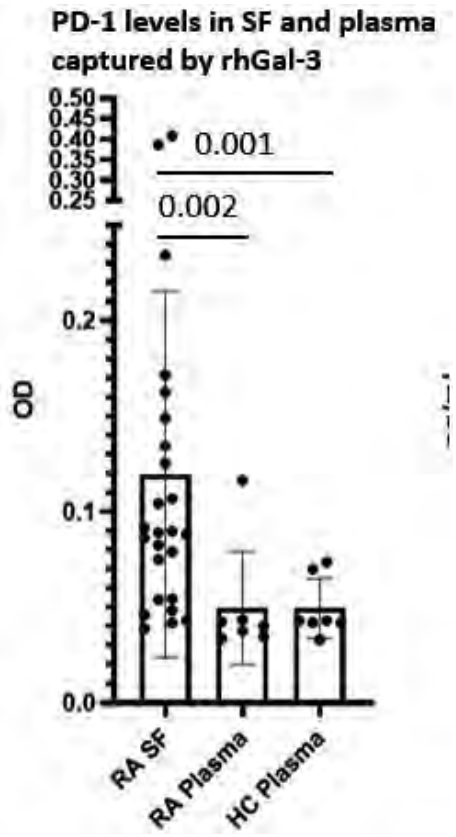

Figure 2. ELISA data. Visualizing levels of soluble PD-1 captured by rhGal-3 in synovial fluid and plasma samples from RA patients as well as plasma samples from healthy controls (HC). Significantly higher levels of PD-1 was detected in synovial fluid compaired to both RA plasma ($p<0.01$) and HC plasma ($p<0.01$).

Methods: Patient material consisted of synovial fluid (SF, n=25), plasma, peripheral blood mononuclear cells (PBMCs) and synovial fluid mononuclear cells (SFMCs) from chronic (c) RA patients. Patients presented with a disease flare when samples were obtained. Surface Plasmon Resonance (SPR) was performed using recombinant human (rh) Gal-3 and PD-1 to investigate potential binding. PD-1 and Gal-3 interaction in patient samples was measured by ELISA. Surface expression of Gal-3 and PD-1 on PBMCs and SFMCs, as well as intracellular IL-2 levels upon stimulation were assessed by flow cytometry. Statistical analysis and graphs were performed using GraphPad Prism 9.0.2 Software.

Results: Using SPR, we demonstrated that Gal-3 binds PD-1 as well as PD-L1 with an estimated K_D of 10^{-6} and 10^{-5}, respectively (Fig. 1). This binding was confirmed in SF and plasma samples from RA patients, where rhGal-3 could capture soluble PD-1 (Fig. 2). Significantly higher levels of PD-1 were detected by rhGal-3 in SF (n=25) compared to plasma samples from both RA (n=7, p=0.002) and healthy controls (n=7, p=0.001).

RA PBMCs (n=6) and SFMCs (n=6) were stimulated using anti-CD3/anti-CD28 stimulation. Significantly higher levels of cells expressing either PD-1 (p=0.007), as well cells positive for both PD-1 and Gal-3 (p=0.04), were observed in SFMCs compared to PBMCs, supporting the effects of Gal-3 in the local inflamed microenvironment. Treating stimulated CD4+ cells with rhPD-L1, caused IL-2 levels to decrease (p=0.059). When rhGal-3 was administered alone it also resulted in decreased IL-2 levels (p=0.02), however, treating stimulated CD4+ cells with both rhPD-L1 and rhGal-3 the effect of each treatment was repelled (p=0.03), which could be explained by Gal-3s capability to interact directly with PD-1 and its ligands (Fig. 3).

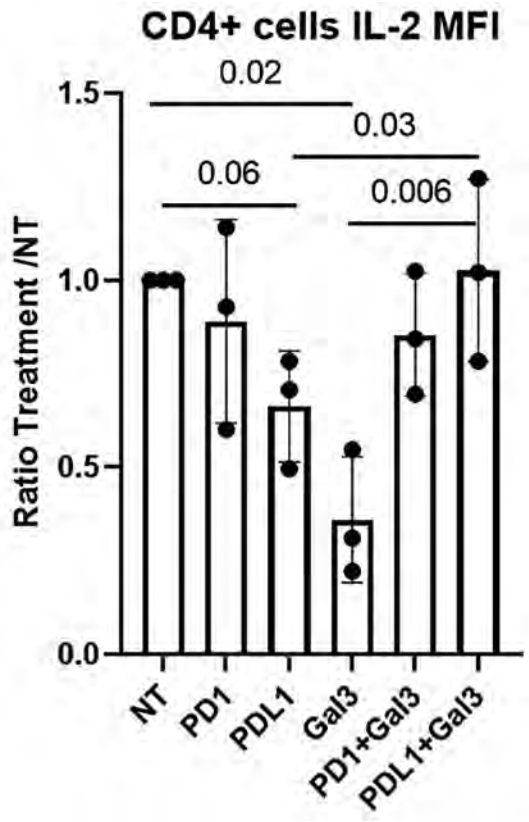

Figure 3. Flow cytometry and intracellular staining for IL-2. The ratio between IL-2 mean fluorescence intensity (MFI) on CD4+ T cells in cells stimulated with anti-CD3 and anti-CD28 and given various treatments. Treating cells with rhPD-L1 resulted in decreased IL-2 MFI (p=0.0591). IL-2 MFI is also decreased when treating cells with rhGal-3 (p=0.02). However, when cells are treated with rhPDL1 and rhGal-3, the effect is repelled (PD-L1 vs PD-L1+Gal-3, p=0.03; NT+s vs PD-L1+Gal-3, p=0.9).

Conclusion: Here we showed how Gal-3 binds PD-1. Data support that the effect of Gal-3 on PD-1 signaling are more pronounced in a local inflammatory milieu in the synovium. Finally, when both Gal-3 and PDL1 were present, the anti-inflammatory effect of PD-1 signaling in decreasing IL-2 was repelled by high levels of local Gal-3.

Synovial Fibroblasts Acquire a Proinflammatory and Destructive Phenotype After Exposure to αS1-Casein (CSN1S1)

Nadine Honke[1], Tim Appel[1], Matthias Schneider[2] and Georg Pongratz[3], [1]Department of Rheumatology, Hiller Research Center Rheumatology, University Hospital Düsseldorf, Germany (* contributed equally), Düsseldorf, Germany, [2]Policlinic & Hiller Research Unit Rheumatology, UKD, Heinrich-Heine University, Düsseldorf, Germany, [3]Polyclinic and Functional Area for Rheumatology & Hiller Research Center Rheumatology, University Hospital Düsseldorf, Düsseldorf, Germany

SESSION INFORMATION

Session Date: Saturday, November 6, 2021

Session Title: RA – Etiology & Pathogenesis Poster (0011–0045)

Session Type: Poster Session A

Session Time: 8:30AM–10:30AM

Background/Purpose: The milk protein αS1-Casein (CSN1S1) was described to be overexpressed in synovial tissue of patients with rheumatoid arthritis (RA) and osteoarthritis (OA). Recently we were able to show that αS1-Casein is capable of inducing the secretion of proinflammatory cytokines in human monocytic cells. Since synovial fibroblasts are known to regulate propagation of inflammation and contribute to cartilage and bone destruction in RA, our aim was to investigate whether αS1-Casein increases the pathogenic potential of RA and OA synovial fibroblasts (RASF and OASF).

Methods: Fibroblasts were isolated from synovial tissues obtained from patients diagnosed with RA and OA who underwent synovectomy due to total joint replacement. RASF and OASF were cultivated in the presence or absence of procaryotic recombinant human αS1-Casein and LPS. Polymyxin B (5µg/ml, Px5) was added to cultured cells to rule out any LPS-effects. After 24 hours fibroblast-derived IL-6, IL-8 and MMP-3 were measured in the supernatant by ELISA.

Results: ELISA analysis showed that synovial fibroblasts from RA and OA patients acquire a proinflammatory and destructive phenotype after treatment with αS1-Casein. This proinflammatory phenotype was induced by αS1- Casein in a concentration-dependent manner with elevated secretion of IL-6 (Ctrl. vs. αS1-Casein (500ng/ml); n=5-6, RA: p***=0.0001; OA: p**=0.0048), IL-8 (Ctrl. vs. αS1-Casein (500ng/ml); n=5, RA: p****< 0.0001; OA: p*=0.0179) and MMP3 (Ctrl. vs. αS1-Casein (500ng/ml); n=5-6, RA: p***=0.0007; OA: n.s.). LPS treatment alone increased the levels of IL-6 (Ctrl. vs. LPS 1ng/ml; n=5-6, RA: p*=0.0455, OA: n.s.; Ctrl. vs. LPS 10ng/ml; n=5-6, RA: p**=0.0039; OA: p**=0.0014), IL-8 (Ctrl. vs. LPS 1ng/ml; n=4-5, RA: p**=0.0037, OA: p**=0,0094; Ctrl. vs. LPS 10ng/ml; n=4-5, RA: p***=0.0005; OA: p***=0.0002) and MMP3 (Ctrl. vs. LPS 1ng/ml; n=5-6, RA: n.s; OA: p*=0.0433; Ctrl. vs. LPS 10ng/ml; n=5-6, RA: p*=0,0287; OA: p**=0.002). Addition of polymyxin B to αS1-Casein-treated fibroblasts did not significantly influence the secretion of the investigated factors (IL-6, IL-8, MMP3: αS1-Casein vs. αS1-Casein+Px5, n=4-6) while polymyxin B completely blunted the LPS-induced secretion (IL-6: LPS 10ng/ml vs. LPS 10ng/ml +Px5, n=5, RA: p*=0.0326; OA: p*=0.014; IL-8: LPS 10ng/ml vs. LPS 10ng/ml +Px5, n=5-6, RA: p**=0.0038; OA: p****< 0.0001; MMP3: LPS 10ng/ml vs. LPS 10ng/ml +Px5, n=6, RA: p*=0.0287; OA: n.s.). Furthermore, by using immunofluorescence histology of synovial tissue from RA and OA patients, we demonstrated that infiltration of casein-positive cells occurs mainly in RA and not OA patients.

Conclusion: In conclusion, our results suggest that casein-positive infiltrating cells are responsible for inducing a proinflammatory phenotype in RASF and augment their destructive capability. αS1-Casein might therefore be part of the pathomechanism of RA.

Metabolomic Study of Rheumatoid Arthritis Using ^{1}H Nuclear Magnetic Resonance (^{1}H NMR)

Konstantina Tsezou, Dimitra Benaki, Katerina iliou, Emmanuel Mikros and Panayiotis Vlachoyiannopoulos, National and Kapodistrian University of Athens, Athens, Greece

SESSION INFORMATION
Session Date: Saturday, November 6, 2021
Session Title: RA – Etiology & Pathogenesis Poster (0011–0045)
Session Type: Poster Session A

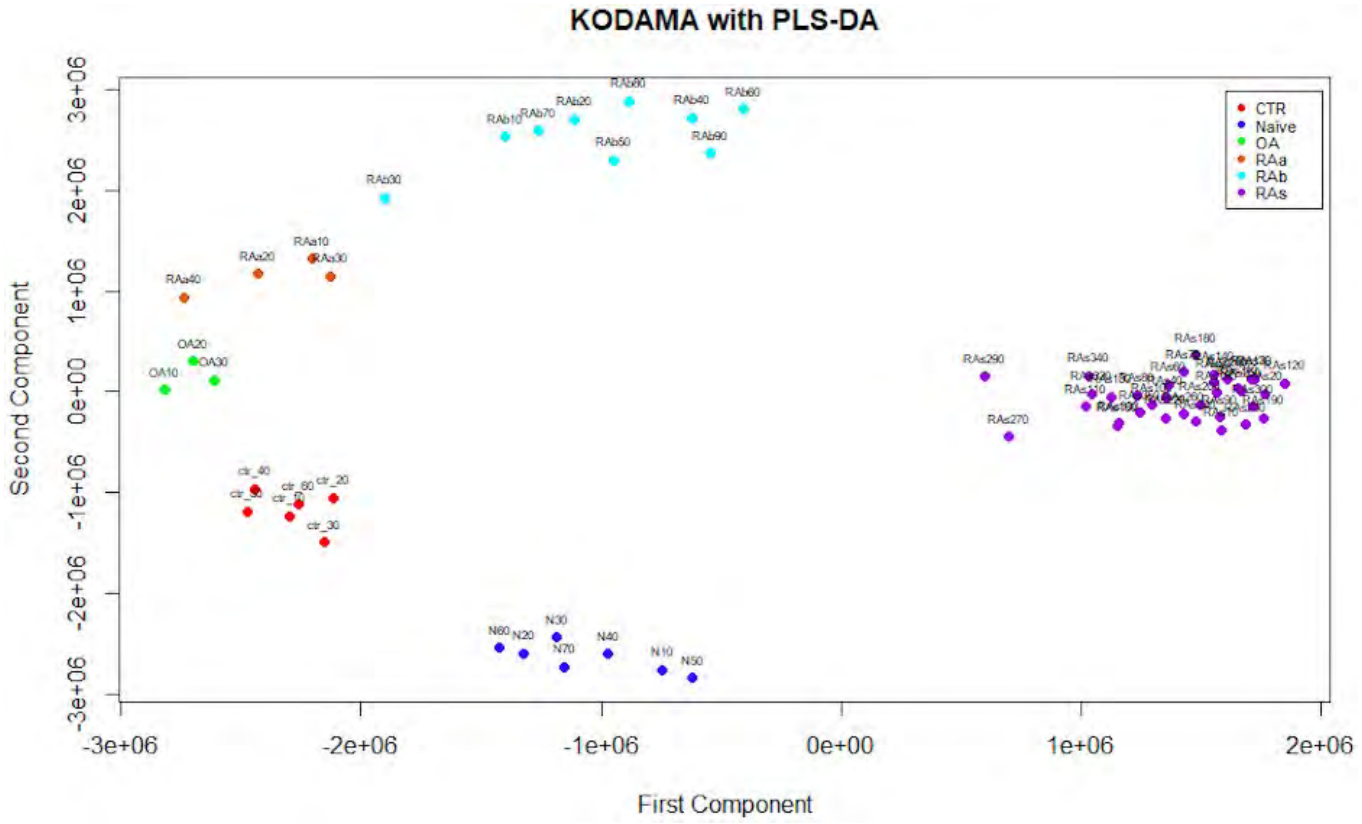

Figure 1. KODAMA is a supervised multivariate statistical analysis. This graph shows that the 6 experimental groups show a characteristic clustering, hence suggesting that each group has a unique metabolic fingerprint.

Session Time: 8:30AM–10:30AM

Background/Purpose: Rheumatoid arthritis (RA) remains a disease with high morbidity. Biologic agents revolutionized the therapy of RA, but they are withdrawn in 50% of patients in 5 years due to loss of efficacy or side-effects. Predictive biomarkers for drug efficacy or side effects are missing while a personalized approach in RA therapy is imperative. Several reports support the notion that specific metabolomics profiles are good predictors for response to TNF blockers. However, the results of many studies are inconclusive due to the small sample size, lack of sequential samples and synchronization of sample collection with initiation or change of therapy.

The aim is to create a metabolic profile for RA patients at different time-points of therapy (DMARDs/bDMARDs), identify biomarkers related to therapy-response, monitor the disease progression, and predict the optimal disease management.

Methods: Plasma was collected from fasted RA patients according to their therapy timepoint: newly diagnosed Naïve (N, n=5) without therapy, before (RAb, n=9) and after (RAa, n=4) therapy (follow up of Naïve and RAb), and patients on standard therapy (RAs, n=35) either DMARD/bDMARD being in a stable condition. Osteoarthritis (OA, n=3) patients and healthy controls (ctr, n=6) were also included in the study. Metabolomic profiling was carried out with 1H NMR spectroscopy. Uni- and multivariate statistical analyses were done to investigate clustering of the experimental groups and define the responsible metabolites. Knowledge Discovery by Accuracy Maximization (KODAMA) was applied for feature extraction in an unsupervised and semi-supervised approach, using principal component analysis-canonical analysis with k-Nearest Neighbor (PCA-CA-kNN) and Partial least squares discriminant analysis (PLS-DA) as classifiers.

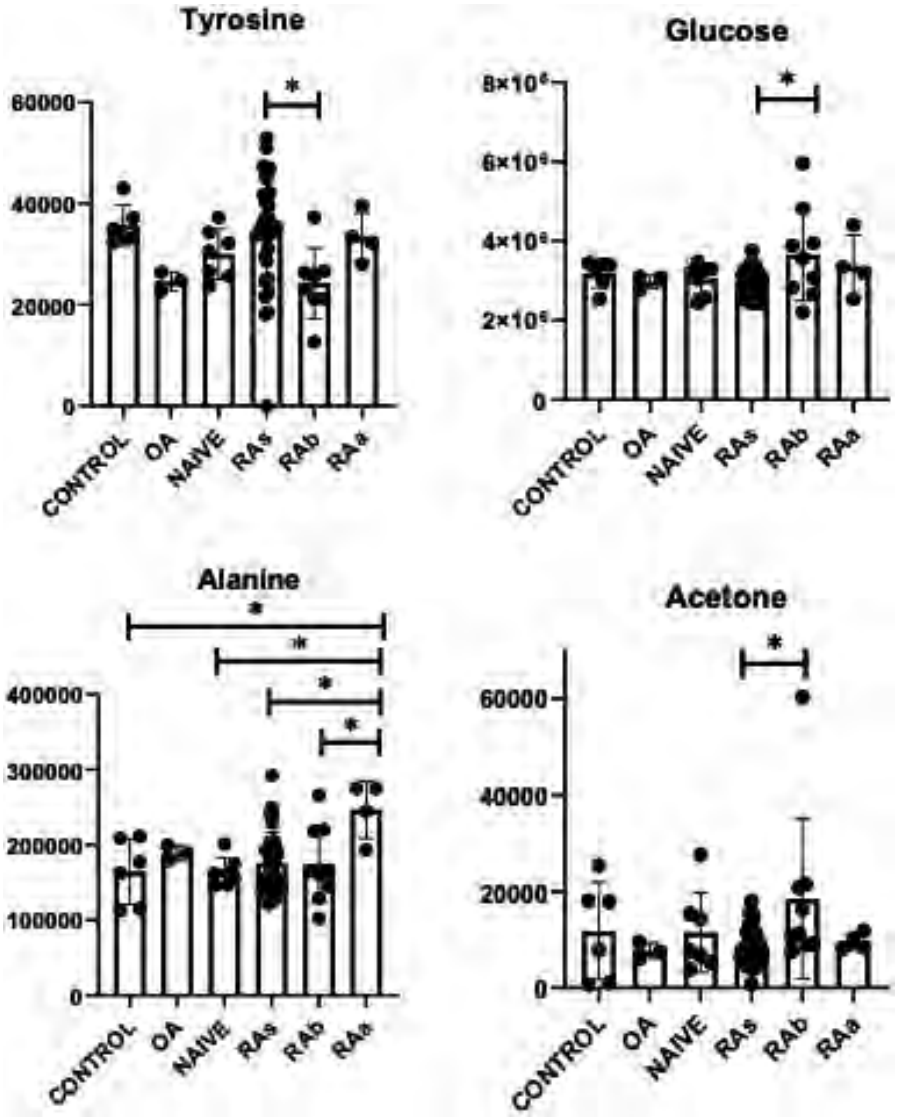

Figure 2. Univariate analysis showed statistical significance (p>0.05) of the metabolites Tyrosine, Alanine, Glucose, and Acetone.

Results: Multivariate analysis using KODAMA revealed distinct metabotypes for the six groups, with acetone, tyrosine and alanine, posing the highest importance for discriminating RA patients. Pairwise comparisons using Orthogonal PLS-DA could also differentiate Naïve patients from ctr and RAa patients, as well as RAb from RAa patients. Univariate study showed that RAa patients are characterized by elevated alanine levels compared to the other groups (mean ± SD, 103) 246.8±38.5 in RAa, 174.1±51.2 in RAb, 175.6±40.4 in RAs, 163.9±19.3 in Naïve; p< 0.01. Tyrosine was significantly increased in RAs compared to RAb, 35.5±8.8 vs 24.3±6.9 respectively; p=0.005, while glucose (2943.5±316.0, 3659.8±1166.8; p=0.01) and acetone were decreased (2943.5±316.0, 3659.8±1166.8; p=0.01). Significant alterations were also observed in macromolecule signals attributed to VLDL and LDL, indicating a putative role of these lipoproteins in differentiating Naïve from RAa and RAs patients.

Conclusion: These data confirm that the metabolic profile of RA patients from Greek populations shows differences related to therapeutic treatment. Biomarkers like alanine and tyrosine can help evaluate the response to therapy. Lastly, the lipoprotein profile is expected to provide additional biomarkers to improve patient classification helping the treatment planning.

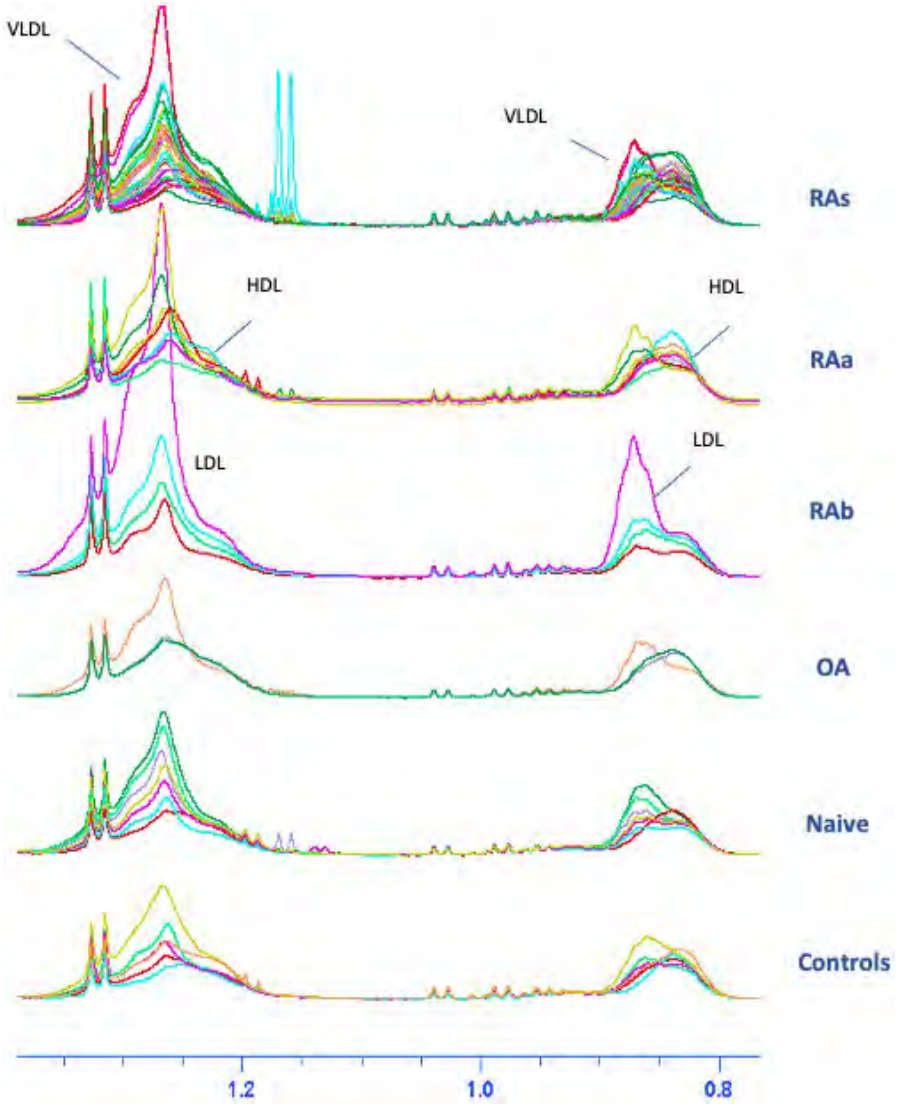

Figure 3. Changes in the lipoprotein signal on the NMR spectra between the experimental groups.

Abstract Number: 0028

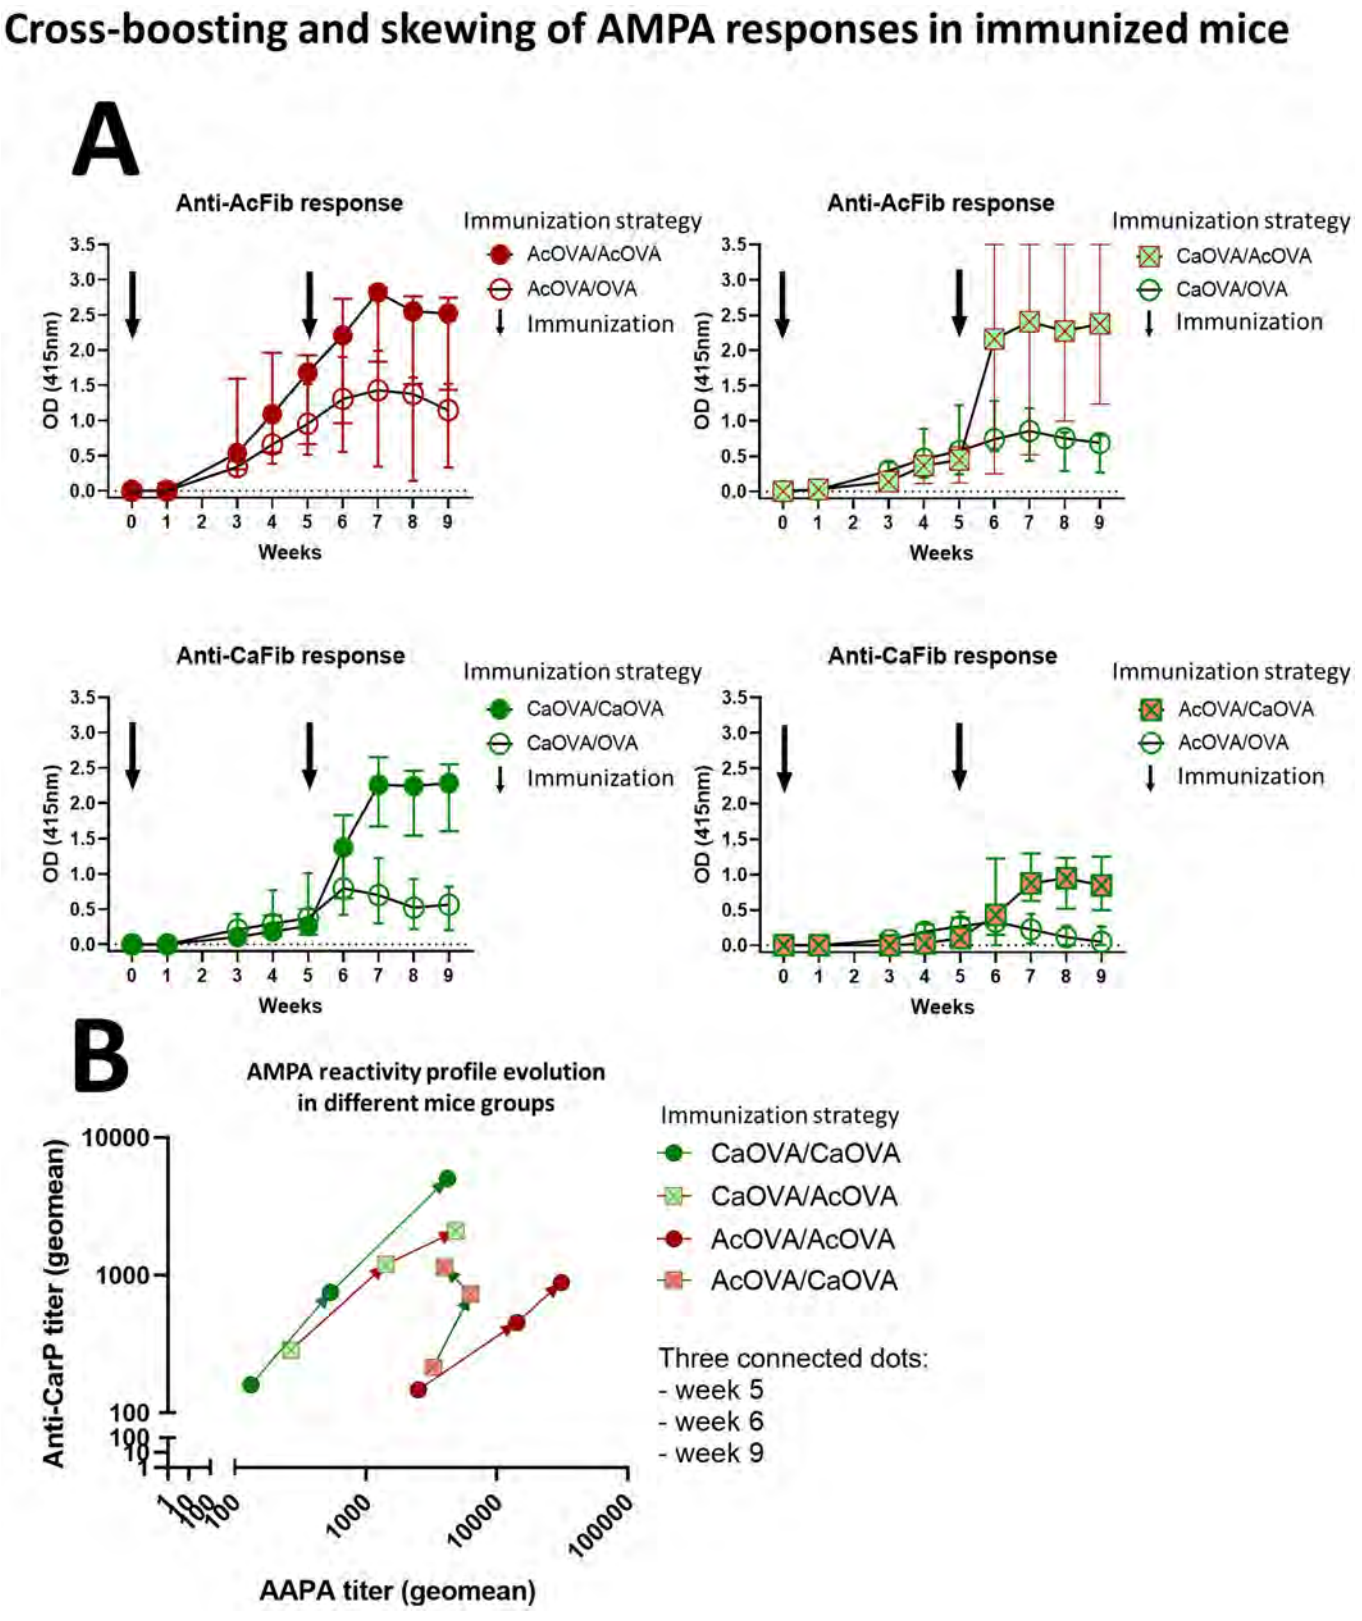
Evolution of Anti-modified Protein Antibody Responses Can Be Driven by Consecutive Exposure to Different Post-translational Modifications

Mikhail Volkov, Arieke Kampstra, Karin van Schie, Tom WJ Huizinga, René Toes and Diane van der Woude, Leiden University Medical Center, Leiden, Netherlands

SESSION INFORMATION

Session Date: Saturday, November 6, 2021
Session Title: RA – Etiology & Pathogenesis Poster (0011–0045)
Session Type: Poster Session A
Session Time: 8:30AM–10:30AM

Background/Purpose: Besides anti-citrullinated protein antibodies (ACPA), rheumatoid arthritis patients (RA) often display autoantibody reactivities against other post-translationally modified (PTM) proteins, more specifically carbamylated and acetylated proteins. Immunizing mice with one particular PTM results in an anti-modified protein antibody (AMPA) response recognizing multiple PTMs. Furthermore, human AMPA, isolated based on their reactivity



to one PTM, cross-react with other PTMs at the monoclonal and polyclonal level. However, it is unclear whether the AMPA reactivity profile is "fixed" in time, or whether consecutive exposure to different PTMs can shape the evolving AMPA-response. In this work, we aimed to investigate the evolution of the AMPA response in mice with controlled exposure to PTMs as well as in humans at risk of RA and with early RA.

Methods: Mice were immunized with acetylated (or carbamylated) protein (ovalbumin) twice or cross-immunized with an acetylated and then a carbamylated protein (or vice versa) and their serum was analyzed for AMPA responses using a different backbone protein (fibrinogen) bearing the same modifications. Longitudinally collected serum samples of human individuals at risk of RA and with early RA were tested to investigate the evolution of the AMPA responses over time.

Results: Mice immunized twice with either solely acetylated or solely carbamylated ovalbumin (AcOVA or CaOVA) developed reactivity against both acetylated and carbamylated antigens. Irrespective of the PTM used for the first immunization, a booster immunization with the other PTM resulted in increased titers to the second/booster PTM (Figure A), indicating that immunization with a defined PTM-antigen leads to the generation of anti-PTM memory B cells able to cross-recognize other PTMs. Furthermore, immunizing with CaOVA and boosting with AcOVA (or vice versa) skewed the overall AMPA-response profile towards a relatively higher reactivity against the "booster" PTM (Figure B). Human data also illustrated dynamic changes in AMPA reactivity profiles in both individuals at risk of RA and in early RA patients (not shown).

Conclusion: The relationship between different reactivities within the AMPA response is dynamic. The initial exposure to a PTM antigen induces cross-reactive response that can be boosted by this or other PTMs. The overall reactivity pattern can be shaped by subsequent exposure to other PTMs. These data might explain temporal differences in the AMPA-response profile and point to the possibility that the PTM responsible for the initiation of the AMPA response may differ from the PTM predominantly recognized later in time.

JAK1 Regulates Autophagy and Reinforces the Inflammatory and Autoimmune Potentials in Rheumatoid Arthritis Synovial Fibroblasts

Keita Ninagawa[1], Masaru Kato[1], Yuki Kudo[2], Masaru Yoshimura[2], Michihito Kono[2], Yuichiro Fujieda[1], Kenji Oku[2] and Tatsuya Atsumi[3], [1]Department of Rheumatology, Endocrinology and Nephrology, Faculty of Medicine and Graduate School of Medicine, Hokkaido University, Sapporo, Japan, [2]1. SESSION INFORMATION
Session Date: Saturday, November 6, 2021
Session Title: RA – Etiology & Pathogenesis Poster (0011–0045)
Session Type: Poster Session A
Session Time: 8:30AM–10:30AM

Background/Purpose: Rheumatoid arthritis (RA) is pathologically characterized by autoimmunity against citrullinated proteins, proliferative synovitis, and ultimately joint destruction. Synovial fibroblasts (SFs) are, when activated, capable of hyperproliferating and producing large amounts of proinflammatory mediators including IL-6, thus considered to be

the key effector cells in RA pathogenesis. SFs obtained from RA patients have high autophagy activity, probably contributing their active phenotype [1]. Besides, our recent study suggests SFs' autoimmune potential by demonstrating the increase of citrullinated vimentin and its interaction with MHC class II when treated with IFN-γ and autophagy inducers [2]. JAK1 is an emerging therapeutic target in RA, but its roles in the active phenotype of SFs remain to be elucidated. To clarify the role of JAK1 in the regulation of autophagy and in the inflammatory and autoimmune potentials in SFs.

Methods: SFs were derived from synovial tissue specimens obtained from RA patients during joint replacement surgery and used between passages 4-8 for all experiments. To inhibit JAK1, SFs were treated with its selective inhibitor upadacitinib for 6-24 h with the optimal concentration determined by BrdU assay. To induce autophagy, SFs were starved using serum-free medium for 2h or treated with 10μM of the proteasome inhibitor MG132 for 24h in the presence or absence of 5mM of the autophagy inhibitor 3-methyladenin. The expression of autophagy-related proteins/genes, including LC3-II, *BECN1*, *ATG5* and *ATG7*, were analyzed by Western blotting or real-time PCR. The expression of IL-6 was measured in cell culture supernatants by ELISA. The interaction between citrullinated vimentin and MHC class II (HLA-DR) were analyzed by *in situ* proximity ligation assays. P values were calculated by ratio paired t-test and considered significant when less than 0.05.

Results: JAK1 inhibition with upadacitinib resulted in the significantly decreased expression of LC-3II ($p = 0.016$ triplicated, $n = 3$), *BECN1* ($p = 0.01$, $n = 5$), *ATG5* ($p = 0.03$, $n = 5$) and *ATG7* ($p = 0.02$, $n = 5$) in starved SFs. Similar results were obtained in SFs treated with IFN-γ. The treatment of SFs with 100 ng/mL of IFN-γ for 24 h increased the expression of IL-6 in cell culture supernatants ($p = 0.017$, $n = 3$), which was inhibited by upadacitinib ($p = 0.02$, $n = 5$). The interaction between citrullinated vimentin and MHC class II was increased in SFs following treatment with starvation and IFN-γ (100ng/mL, 24h) ($p = 0.003$, $n = 6$). The effect was cancelled by the addition of upadacitinib ($p = 0.009$, $n = 6$) or 3-methyladenin ($p = 0.02$, $n = 6$).

Conclusion: Our current results indicate that JAK1 positively regulates autophagy and reinforces the inflammatory and autoimmune potentials in SFs. The mode of action of JAK inhibitors would include the mitigation of SFs' active phenotype.

Interleukin-9 Enhances the Osteoclastogenesis in Rheumatoid Arthritis

Santanu Kar[1], Dipendra Mitra[2], Vijay Kumar D[1] and **Sushmita Chakraborty**[1], [1]AIIMS, New Delhi, India, [2]ALL INDIAN INSTITUTE OF MEDICAL SCIENCES, New Delhi, India

SESSION INFORMATION
Session Date: Saturday, November 6, 2021
Session Title: RA – Etiology & Pathogenesis Poster (0011–0045)
Session Type: Poster Session A
Session Time: 8:30AM–10:30AM

Background/Purpose: Rheumatoid Arthritis (RA) is a chronic inflammatory disease characterized by synovial inflammation leading to bone destruction. Bone erosion in RA results from excessive resorption of bone by osteoclasts and inadequate formation of bone by osteoblasts. Osteoclasts are specialized multinucleated cells that are derived from cells of monocyte-macrophage lineage. The pro-inflammatory cytokines exert their influence on the biology of osteoclast and thereby enhances the joint destruction in RA. Recently, our group and others have observed increased levels of interleukin-9 (IL-9) in the synovial fluid of patients with RA. Therefore, we investigated the impact of IL-9 on *in vitro* osteoclastogenesis in RA.

Methods: The study was conducted in active RA patients, diagnosed based on American College of Rheumatology (ACR), 1987 criteria. Peripheral blood (PB) was collected in heparinized vial. For TRAP assay, Mononuclear cells were stimulated with 50 ng/ml recombinant(r) human sRANKL, 50 ng/ml M-CSF and 100ng/ml of rIL-9 for 21 days. Cells were then fixed and stained using Acid Phosphatase, Leukocyte Kit. Tartrate resistant acid phosphatase (TRAP)-positive cells with three or more nuclei were scored as osteoclasts. Quantitative RT-PCR of osteoclast specific gene was performed after 3 days of stimulation as indicated using the QuantStudio® 5 Real-Time PCR System. Whole transcriptome analysis was performed using Illumina HiSeq X10 sequencing platform. Bone samples were obtained under sterile conditions from patients undergoing orthopedic surgery for non-pathological fractures and immediately placed in phosphate buffer saline (PBS) containing antibiotics. Samples were broken into tiny pieces and cultured in complete αMEM medium. Bone explant cultures were performed in six well plates with one piece of bone in a final volume of 6 ml, and in the presence or absence of 100ng/ml IL-9.

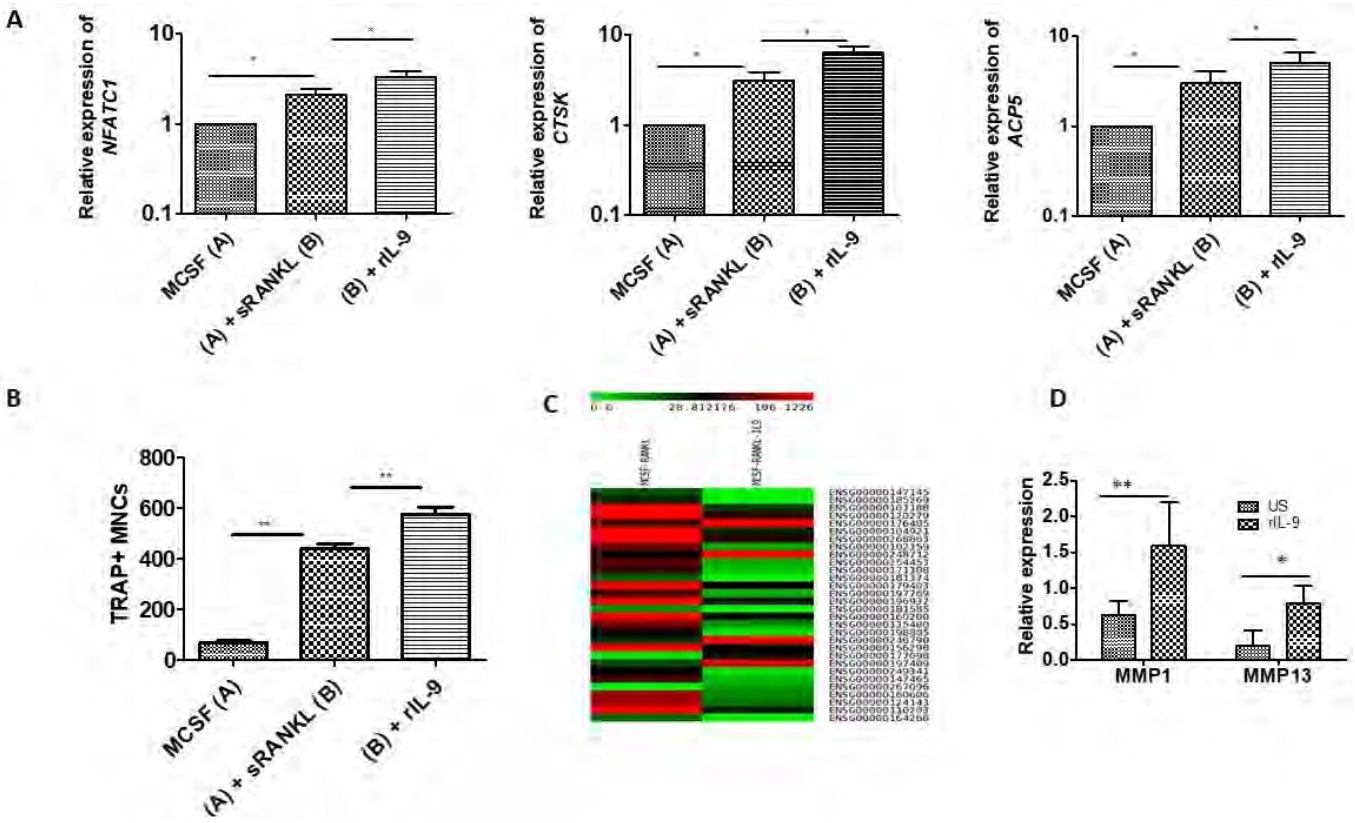

Figure 1. Impact of IL-9 on Osteoclast formation and Matrix metalloproteinases (A) Quantitative Real-Time PCR (RT-PCR) of osteoclast specific genes, nuclear factor of activated T-cells, cytoplasmic 1 (NFATc1), cathepsin K (CTSK) and acid phosphatase 5, tartrate-resistant (ACP5) was performed after 3 days of stimulation as indicated (* $p<0.05$). (B)Tartrate resistant acid phosphatase (TRAP) positive multinucleated cells (MNCs) were scored as osteoclasts (** $p<0.005$). (C) Heat map of RNA-Seq transcriptome analysis for top 30 genes at 2 foldchange and p value 0.05 of samples treated with MCSF+RANKL in presence or absence of IL-9. Differential expression analysis was done using DESEQ software. (D) Quantitative RT-PCR of MMP-1 and MMP13 was performed after 5 days of stimulation with or without rIL-9 (** $p<0.005$* $p<0.05$).

Results: We observed that rIL-9 stimulation along with M-CSF/sRANKL significantly enhanced the expression of nuclear factor of activated T-cells, cytoplasmic 1 (*NFATc1*), acid phosphatase 5, tartrate-resistant (*ACP5*) and cathepsin K (*CTSK*) as compared to M-CSF/sRANKL stimulation. Furthermore, we observed significant increase in the number of osteoclasts with rIL-9 stimulation along with M-CSF/sRANKL. Next, we performed transcriptome analysis between IL-9/M-CSF/sRANKL treated samples and M-CSF/sRANKL treated samples. Transcriptome analysis revealed differential gene expression with rIL-9 stimulation along with M-CSF/sRANKL as compared to stimulation with M-CSF/sRANKL. Using trabecular bone explant, we checked the effect of rIL-9 on matrix metalloproteinases (MMPs), which are critical regulators of extracellular matrix (ECM) proteolysis. We observed that IL-9 modulates the expression of collagenases *MMP1* and *MMP13,* which plays critical role in bone and cartilage degradation.

Conclusion: Our observations indicate towards the IL-9 mediated structural damage in the RA by the enhancing the differentiation of osteoclasts and modulating the expression of MMPs. Thus, blocking IL 9 pathway might be an attractive immunotherapeutic target for RA.

A New Pharmacostatistical Model to Assess MTX-adherence in RA Patients

Marion Geoffroy[1], Claire Gozalo[2], Loic Pauvele[2], Elise Abboud[2], Zoubir Djerada[3] and Jean hugues Salmon[4], [1]CHU Reims, France, REIMS, France, [2]CHU Reims, Reims, France, [3]CHU Riems, Reims, France, [4]Rheumatology, CHU Maison blanche, Reims, Reims, France

SESSION INFORMATION
Session Date: Saturday, November 6, 2021
Session Title: RA – Etiology & Pathogenesis Poster (0011–0045)
Session Type: Poster Session A
Session Time: 8:30AM–10:30AM

Background/Purpose: Methotrexate (MTX) is the first-line therapy for rheumatoid arthritis (RA). While therapeutic adherence is essential to the successful management of the patient, an estimated 40% of patients are thought to be non-adherent. Adherence to MTX is challenging to monitor as no objective MTX assay is currently available.

Our objective was to describe the urinary kinetics of MTX and its major 7-OH-MTX metabolite in treated patients and to evaluate the possibility to use one or both of these markers as an objective MTX-adherence assay.

Methods: Fifty-nine patients with RA (2010 ACR/EULAR criteria) treated with subcutaneous MTX were recruited.

Patients underwent urinary MTX pharmacokinetic assessment using high-performance liquid chromatography-mass spectrometry (HPLC-MS/MS) analysis. The urine sample was analyzed before and after subcutaneous injection (from 2 hours to 10 days after injection). Confirmed administration at hospital therapy was the reference of MTX-adherence.

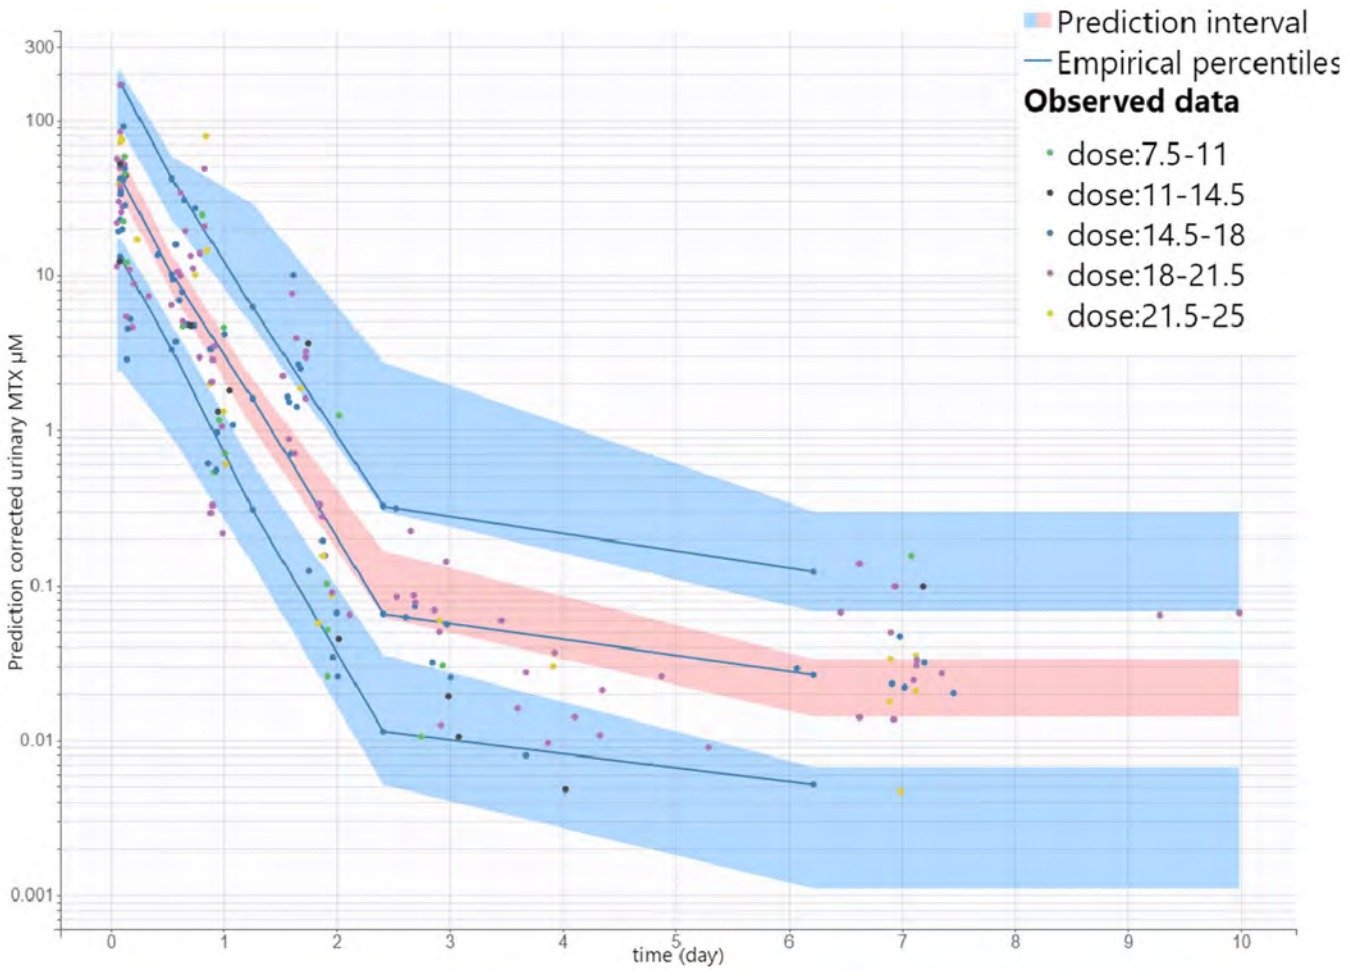
MTX and 7-OH-MTX concentrations were analyzed, and a population pharmacokinetic model was developed to describe the kinetics of MTX as a function of time and weekly dose.

From this model, the urinary MTX concentrations in treated patients were compared with the urinary concentrations of controls (n = 18 referent patient adherent and 10 patient with undifferentiated inflammatory arthritis without mtx treatment).

Results: A total of 363 urine samples (range 2-6 per patient) were obtained from patients treated with subcutaneous MTX. The average weekly dose of MTX was 17.2 mg/week (7.5-25mg)

A 2-compartment model with nonlinear renal elimination kinetic best described the urine MTX concentration versus time curves. This model allowed us to characterize the standard kinetic profiles of the observant patients as a function of different associated factors. Thus, 95% of MTX urine concentration values were above 0.9 nM regardless of the delay between MTX injection and urine sampling and independently associated MTX-adherence. A discriminatory cut-off value of 0.9 nM (v.s control group 0.22, CI95% [0.19-0.25] µM) made it possible to have an assay sensitivity and specificity of more than 93% and an AUC-ROC above 96 %, regardless of the MTX doses.

Conclusion: Using urine MTX concentration, we developed a pharmacostatistical model to monitor subcutaneous MTX adherence of RA patients. This allowed us to propose a new and objective MTX-adherence assay, which could help in current practice to differentiate patients who do not respond to methotrexate from non-adherent patients. After further validation, this test could therefore improve patient management by avoiding unnecessary intensification in non-adherent patients.



Visual predictive check of urinary MTX model with observed data (dot). Prediction intervals (95 %) for each percentile are estimated across all simulated data and displayed as colored areas (pink for the 50th percentile, blue for the 10th and 90th percentiles).

IL-40: A New B-cell Associated Cytokine Up-regulated in Rheumatoid Arthritis Decreases Following the Rituximab Therapy and Correlates with Disease Activity, Autoantibodies and NETosis

Adela Navratilova[1], Lucie Andrés Cerezo[1], Hana Hulejová[2], Viktor Bečvář[2], Michal Tomcik[3], Dana Tegzova[2], Martina Olejárová[1], David Veigl[4], Karel Pavelka[3], Jiri Vencovsky[2] and Ladislav Senolt[3], [1]Institute of Rheumatology and Department of Rheumatology, First Faculty of Medicine, Charles University, Prague, Czech Republic, [2]Institute of Rheumatology, Prague, Czech Republic, [3]Institute of Rheumatology, Department of Rheumatology, 1st Faculty of Medicine, Charles University, Prague, Czech Republic, [4]First Orthopaedic Clinic, 1st Faculty of Medicine, Charles University, Prague, Czech Republic, Prague, Czech Republic

SESSION INFORMATION
Session Date: Saturday, November 6, 2021
Session Title: RA – Etiology & Pathogenesis Poster (0011–0045)
Session Type: Poster Session A
Session Time: 8:30AM–10:30AM

Background/Purpose: Interleukin 40 (IL-40) is recently identified B cell - associated cytokine implicated in humoral immune responses and in B cell development and homeostasis. As B cells play a pivotal role in autoimmunity, we aimed to investigate the function of IL-40 in rheumatoid arthritis (RA).

Methods: IL-40 expression was determined in the synovial tissue from RA and osteoarthritis (OA) patients. IL-40 was analysed in the serum and synovial fluid of patients with RA (n=50), systemic lupus erythematosus (SLE, n=69), OA (n=44), and in healthy controls (HC, n=50). All patients met the ACR-EULAR criteria of the particular disease (1,2,3). We also assessed the changes of IL-40 levels in RA patients following the B-cell depletion therapy by rituximab (n=33) or after the TNF inhibition by adalimumab (n=25). We examined the relationship between IL-40, disease activity, autoantibodies, cytokines and markers of NETosis. The effect of IL-40 on synovial fibroblasts was determined.

Results: We observed increased expression of IL-40 in the RA synovial tissue compared to OA, particularly in synovial lining cells and infiltrating immune cells. The levels of IL-40 were up-regulated in the synovial fluid of RA compared to OA patients ($p< 0.0001$). Similarly, IL-40 was increased in the serum of RA patients compared to HC, OA or SLE patients ($p< 0.0001$ for all) and decreased after 16 and 24 weeks ($p< 0.01$ and $p< 0.01$) following rituximab treatment. No significant effect of adalimumab on serum IL-40 was observed. IL-40 levels in RA patients correlated with rheumatoid factor-IgM and anti-*cyclic* citrullinated peptides (anti-CCP) in the serum ($p< 0.0001$ and $p< 0.01$), as well as in the synovial fluid ($p< 0.0001$ and $p< 0.001$). Synovial fluid IL-40 was also associated with DAS28 ($p< 0.05$), synovial fluid leukocyte count ($p< 0.01$), neutrophil attractants IL-8 ($p< 0.01$), MIP-1α ($p< 0.01$), and markers of NETosis such as proteinase 3 ($p< 0.0001$) and neutrophil elastase ($p< 0.0001$). RA synovial fibroblasts exposed to recombinant IL-40 increased the secretion of IL-8 ($p< 0.01$), MCP-1 ($p< 0.05$) and MMP-13 ($p< 0.01$) compared to the unstimulated cells.

Conclusion: We show the up-regulation of IL-40 in RA and its decrease following B-cell depletion therapy. The association of IL-40 with autoantibodies, chemokines and markers of NETosis may imply its potential involvement in RA development. Moreover, IL-40 up-regulates the secretion of chemokines and MMP-13 in synovial fibroblasts, indicating its role in the regulation of inflammation and tissue destruction in RA.

SESSION INFORMATION
Session Date: Saturday, November 6, 2021
Session Title: RA – Etiology & Pathogenesis Poster (0011–0045)
Session Type: Poster Session A
Session Time: 8:30AM–10:30AM

Background/Purpose: 1) to evaluate the relationship among adipose tissue dysfunction, autoimmunity and disease activity in rheumatoid arthritis (RA) patients; 2) to analyze the direct effect of antibodies to citrullinated protein antigens (ACPAs) on the adipose tissue (AT) function and 3) to evaluate the role of insulin resistance (IR) and adipocytokines in the therapeutic response with biological treatments.

Methods: 1) Design: cross-sectional study (150 RA patients and 50 healthy donors (HDs)) and longitudinal study (122 RA patients treated with anti-TNF-a (45), anti-IL6R (22) and anti-CD20 (55) therapies after 6 months of treatment). Patients were classified in responders or non-responders based on EULAR criteria. Disease activity (DAS-28), autoimmunity, acute phase reactants (CRP and ESR) and cardiovascular disease (CVD) risk factors were evaluated. The serum levels of adipocytokines (TNF-a, IL-1b, IL-6, leptin, adiponectin, resistin, visfatin, omentin and vaspin) were measured by ELISA. Next, in vitro experiments with human AT and adipocyte and macrophage cell lines treated with G immunoglobulins isolated from HDs and RA patients were performed. The expression of genes related to inflammation, lipid accumulation and adipogenesis was analyzed in all experiments; 3) a collagen induced arthritis (CIA) mice was developed. Plasma and AT were analyzed.

Results: The levels of adipocytokines were significantly altered in RA serum and associated with disease activity. Likewise, homeostatic model assessment of insulin resistance (HOMA-IR) correlated to DAS28. On the other hand, ACPAs levels correlated with adipocytokine profile suggesting a role of ACPAs in the dysregulation of AT. AT of lean CIA mice showed higher gene expression of specific markers of B and plasmatic cells and M1 macrophages as disease activity increased. Furthermore, the *in vitro* treatment of human AT with ACPAs could promote the adipose tissue dysfunction promoting an inflammatory state through the M1 polarization of macrophages and the blockage of adipocyte differentiation. Next, RA patients with higher levels of HOMA-IR presented a worse response to biological treatments. Besides, levels of vaspin and visfatin were significantly increased before the treatment in the non-responders group. Although, all treatments significantly reduced disease activity after 6 months of treatment, the effect of each one was different being the anti-CD20 treatment which modified a higher number of adipocytokines.

Conclusion: 1) IR and the altered adipocytokine profile in RA patients is associated with disease activity, the presence of autoimmunity and a worse response to therapy; 2) adipose tissue in the context of RA is altered in parallel with the disease progression, characterized by an inflammatory state due to the infiltration of macrophages and B and plasmatic cells; 3) ACPAs could be at least partially the responsible of adipose tissue dysfunction inducing inflammation and IR in macrophages and promoting a defective adipocyte differentiation.

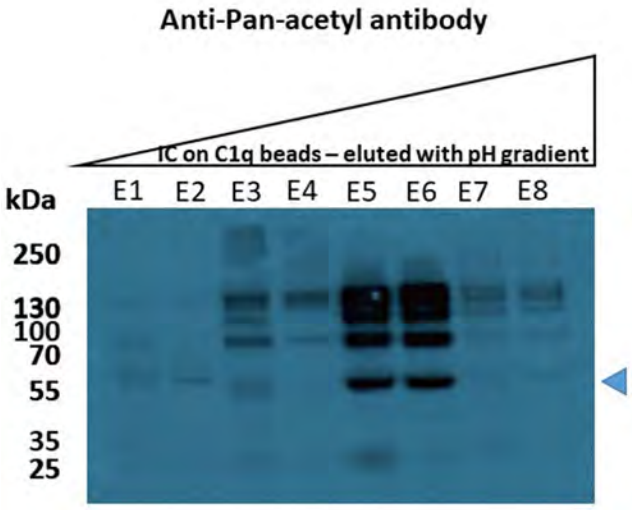
SESSION INFORMATION
Session Date: Saturday, November 6, 2021
Session Title: RA – Etiology & Pathogenesis Poster (0011–0045)
Session Type: Poster Session A
Session Time: 8:30AM–10:30AM

Background/Purpose: Rheumatoid arthritis (RA) is an autoimmune disease characterized by genetic predisposition and associated immunological features including the production of autoantibodies against various epitopes. Several pathways have been implicated in the induction of autoantibodies against novel epitopes through post-translational modifications such as citrullination, carbamylation and acetylation. However, the spectrum of these antibodies and their contributions in the pathogenesis e.g. by the formation of immune complexes in the synovial fluid has not been fully uncovered.

Methods: Synovial fluids (SF) were collected from 17 RA patients and 40 individuals from a disease control (CG) including reactive arthritis and psoriasis arthritis. Paired serum and SF samples were used from 16 RA and 19 CG compared to serum from 70 healthy donors (HD). ELISA kits for anti CCP-IgG, anti-mutated citrullinated vimentin



(MCV)-IgG, anti-acetylated Lysine Antibody (anti-HC55)-IgG and anti-carbamylated vimentin (carbVim)-IgG were used to test reactivity against modified proteins. Immune complexes (IC) were purified from sera and SF by applying a technique using purified human C1q, which was immobilised on magnetic tosylactivated microparticles (Dynabeads M-280) according to the manufacturer's recommendations for activation of amine groups. C1q beads were washed and incubated with 20 µL serum or SF in an Eppendorf microliter tube for 1.5 hours on shaker (600 rpm) at 37°C. Antibodies from the C1q-bound IC were recovered in a two-step procedure- first with 0.1 M glycine–HCl, pH 2.5, followed by 25% methanol, pH 11.5. Fractions were neutralized immediately. Extracted antigens from the IC were investigated with Western blot for specific modifications or individual antigens with the corresponding antibodies. Citrullinated and acetylated vimentin was identified as part of IC via mass spectroscopy. Purified anti modified protein antibodies (AMPAs) from serum or SF (isolated from IC or as soluble antibodies) were investigated on a custom-made LineBlot array containing 24 different antigens either citrullinated, carbamylated, acetylated or unmodified/native counterparts.

Results: Titers of anti-CCP and anti-acetylated (anti-HC55) reactivity were higher in SF of RA patients compared to CG. In contrast, no significant differences were detected in the titers of anti-carbVim and anti-MCV in SF of both groups. AMPAs were detected in SF in immune complexes as well as free antibodies. Surprisingly, in addition to citrullinated vimentin, the acetelylated form was also detected in the eluted fractions. Like carbamylated proteins, haptoglobin and fibrinogen fragments were identified in small concentrations. The spectrum of identified acetylated proteins included human proteins such as histones as well as fragments of bacterial filament proteins.

Conclusion: AMPAs recognize different modified antigens and form immune complexes in the SF of RA patients. The higher titers of anti-acetylated protein antibodies and immune complexes in the synovium point to their contribution in the pathogenesis of RA.

The identification of acetylated antigens in the synovium of RA patients is especially intriguing, as infections (bacteria) are known to not only acetylate their own proteins, but also modify host proteins. Acetylated vimentin (MW 57 kDa) was detected in eluted fractions (arrow). IC: immune complexes.

Session Title: RA – Etiology & Pathogenesis Poster (0011–0045)

Session Type: Poster Session A

Session Time: 8:30AM–10:30AM

Background/Purpose: Hypoxia and subsequent oxidative stress are early events in the RA joint and contribute to the activation of synovial fibroblasts (SF). Small molecule inhibitors targeting the members of the bromodomain and extra-terminal (BET) protein family (BRD2, BRD3, BRD4) have anti-inflammatory properties in RA. Here we analyzed the potential of BET inhibitors in regulating stress response pathways in RA SF.

Methods: SF were obtained from shoulder and hand joints of RA patients undergoing joint replacement surgery. We mimicked hypoxic conditions by treatment of SF with dimethyloxalylglycine (DMOG; 0.5 mM, 24 h). Stabilization of HIF1α and GLUT1 protein expression were assessed by Western blotting. Oxidative stress was induced by treatment of SF with 4-hydroxynonenal (4-HNE; 5 μM, 48h), a lipid peroxidation product present in synovial fluids, and TNF (10 ng/ml, 48h). Experiments were performed in absence and presence of the pan-BET inhibitor I-BET151 (1 μM). The expression of hypoxic response (*VEGFA, PDK1, GLUT1, HK2*) and oxidative stress response genes (*CAT, GPX1, SOD2, HMOX1*) was measured by Real-time PCR (n=7-10). Autophagy was assessed by Western blotting using LC3B-II as an autophagy marker (n=7).

Results: Treatment of SF with DMOG stabilized HIF1α protein. I-BET treatment suppressed the DMOG-induced expression of the hypoxic response genes *VEGFA, PDK1, GLUT1* and *HK2* (Figure 1A). Hypoxic conditions induced the GLUT1 protein expression by 101.8-fold (± 108.2-fold), which was suppressed by 62.2% (± 32.1%) in presence of I-BET ($p< 0.05$). TNF treatment induced the expression of all measured stress response genes. Oxidative stress further induced the TNF-induced expression of *VEGFA, PDK1, GLUT1, HK2* and *CAT* (Figure 1B). In contrast to results obtained under hypoxic conditions, I-BET treatment further increased the expression of hypoxia response genes under oxidative stress conditions. We have detected similarities and differences regarding the BET-meditated regulation of oxidative stress response genes under different stress conditions. I-BET increased basal *HMOX1* and *CAT* expression in all conditions, and suppressed *GPX1* expression under hypoxia and oxidative stress. In contrast, BET inhibition decreased the expression of *SOD2* only during oxidative stress but not under hypoxia. I-BET further increased the expression of *HMOX1* during oxidative stress, but suppressed the expression of *HMOX1* during hypoxia. I-BET induced the accumulation of LC3B-II protein by 2.7 (± 1.4)-fold, which was further increased to 4.5 (± 2.9)-fold in presence of DMOG ($p< 0.05$). Oxidative stress conditions did not further induce the I-BET-induced expression of LC3B-II.

Conclusion: BET protein inhibition affects stress-response target genes in a stimulus-dependent manner. Our data suggest that hypoxia and oxidative stress conditions regulate individual stress response genes via distinct enhancers. Furthermore, we have identified BET proteins as regulators of autophagy.

The NAD$^+$ Metabolism Is Altered in Rheumatoid Arthritis and Its Modulation with NAD$^+$ Boosters Exhibits Key Anti-Inflammatory and Anti-Oxidant Effects

Carlos Pérez-Sánchez[1], Luz Marina Sanchez-Mendoza[2], Nuria Barbarroja[3], M.Carmen Abalos-Aguilera[4], Maria Luque-Tevar[5], Alejandra Patiño-Trives[5], Iván Arias de la Rosa[3], Cristobal Román-Rodriguez[6], Juan Antonio Moreno[2], Maria Isabel Buron[2], Jose Antonio Gonzalez-Reyes[2], Marta Rojas-Gimenez[4], Eduardo Collantes-Estevez[6], alejandro Escudero[6], Jose Manuel Villalba[2] and Chary lopez-pedrera[6], [1]IMIBIC, Córdoba, Spain, [2]Department of Cell Biology, Physiology and Immunology, University of Córdoba, Campus de Excelencia Internacional Agroalimentario, ceiA3, Cordoba, Spain, [3]University of Cordoba/IMIBIC/Reina Sofia Hospital, Cordoba, Spain, [4]Rheumatology service, IMIBIC/Reina Sofia Hospital/University of Córdoba, Cordoba, Spain, [5]Rheumatology Department, Reina Sofia University Hospital/ Maimonides Institute for Research in Biomedicine of Cordoba (IMIBIC)/ University of Cordoba, Cordoba, Spain, [6]IMIBIC/Reina Sofia Hospital/University of Córdoba, Córdoba, Spain

SESSION INFORMATION

Session Date: Saturday, November 6, 2021

Session Title: RA – Etiology & Pathogenesis Poster (0011–0045)

Session Type: Poster Session A

Session Time: 8:30AM–10:30AM

Background/Purpose: NAD$^+$ is a key cofactor and second messenger for multiple cellular processes that exhibits antioxidant, anti-apoptotic, and anti-inflammatory properties. Numerous publications and clinical trials have shown the beneficial effects of NAD$^+$ boosters in different diseases. However, to date no studies have evaluated the NAD$^+$ metabolism and the therapeutic effects of NAD$^+$ boosters in RA patients.

Aims: 1- To study the NAD^+ metabolism in RA patients and its association with key clinical features; 2-To evaluate the effect of anti-TNF therapy in the NAD^+ metabolism; 3- To analyze the beneficial effects of NAD^+ boosters in leukocytes from active RA patients.

Methods: Plasma and PBMCs were purified from 100 RA patients and 50 healthy donors (HDs). NAD^+ levels were determined by using the NAD/NADH-Glo Assay. Gene expression analysis of markers related to the synthesis (NAMPT, NMNAT2, NRK1), transport (Cx43) and consumption of NAD^+ (PARP-1, Sirtuin-1, CD157, CD38 y CD73) were performed in PBMCs by RT-PCR.

Moreover, in a second cohort of 50 RA patients treated with anti-TNF therapy, changes in the levels of NAD^+ were analyzed before and after 6 months of treatment.

In parallel, PBMCs from a third cohort of 10 active RA patients were treated *ex vivo* with 1 mM of NAD^+ boosters including nicotinamide (NAM), nicotinamide riboside (NR), and nicotinamide mononucleotide (NMN). After 24 hours, intracellular reactive oxygen species (ROS) levels and the % of apoptotic PBMCs were assessed by flow cytometry. Finally, a panel of key pro-inflammatory genes was evaluated by RT-PCR.

Results: NAD^+ levels were significantly reduced in plasma of RA patients compared with HDs, and directly related to disease activity. Accordingly, the expression levels of genes involved in the consumption of NAD^+ such as SIRT-1, CD38 and PARP-1 were found up-regulated in PBMCs from RA patients. The levels of NAMPT and Cx43 were found increased suggesting a compensatory response of the organism against the depletion of NAD^+ levels. The altered metabolism of NAD^+ was associated with the increased expression of several cytokines such as TNF, IL6, IL1, IL8 and CCL2 highlighting the role of inflammation in the altered NAD^+ metabolism.

Anti-TNF therapy restored the altered NAD^+ levels towards those showed by HDs. Furthermore, the clinical response promoted by anti-TNF therapy correlated with changes in NAD^+ levels.

In vitro treatments of PBMCs isolated from active RA patients with NAD^+ boosters significantly increased the NAD^+ levels and promoted a deep reduction of intracellular ROS levels, the percentage of apoptotic cells and the expression levels of key inflammatory mediators, such as IL-6, IL-8, IL-1b, TNF-α, CCL2, IL-23, and STAT-3.

Conclusion: 1. NAD^+ metabolism is altered and associated with the disease activity and the pro-inflammatory status of RA patients. 2. Anti-TNF therapy restored NAD^+ levels, which was directly linked to the clinical effectiveness. 3. NAD^+ boosters reduced the oxidative, apoptotic, and inflammatory profile of RA leukocytes through the parallel increase of intracellular NAD^+ levels. Thus, NAD^+ boosters might be considered novel therapeutic tools for RA patients.

SESSION INFORMATION

Session Date: Saturday, November 6, 2021

Session Title: RA – Etiology & Pathogenesis Poster (0011–0045)

Session Type: Poster Session A

Session Time: 8:30AM–10:30AM

Background/Purpose: The presence of anti-citrullinated protein antibodies (ACPAs) is a highly specific hallmark of rheumatoid arthritis (RA), that is present also in early disease. However, 20% of RA subjects test negative for ACPA and thus their early diagnosis and treatment may be delayed. Furthermore, despite the high specificity of the cyclic citrullinated tests, their low sensitivity indicates that a negative result does not rule out the disease. Therefore, an increased knowledge about the presence of other circulating biomarkers related with early RA is needed to improve its diagnosis and to better understand the pathogenic mechanisms underlying the different RA subsets. In this study, we aimed to search for plasma autoantibodies associated with ACPA status that could be useful to assist the early diagnosis of RA.

Methods: We firstly profiled the plasma IgG and IgA repertoire of 80 ACPA positive and 80 ACPA negative subjects entering the Epidemiological Investigation of Rheumatoid Arthritis (EIRA) early RA cohort. To this end, we employed an antigen suspension bead array built with 260 protein fragments within Human Protein Atlas and selected from an initial untargeted screening on planar arrays. A validation phase using a suspension bead array including 27 antigens was carried out on another set of samples from EIRA which included 386 ACPA positive, 358 ACPA negative and 372 age and sex-matched control subjects. A sample-specific threshold was selected to determine the reactivity of all the samples. The Wilcoxon rank sum test and Fisher's test were applied for the comparison of autoantibody levels and reactivity frequencies between the sample groups.

Results: Reactivities towards four different antigens were significantly associated to ACPA status (Figure 1 and Figure 2). IgG autoantibody levels towards Testis-specific Y-encoded-like protein 4 (TSPYL4) were higher in ACPA negative subjects compared to controls (Figure 1A). The prevalence of IgG autoantibodies towards TSPYL4 was also higher in ACPA negative compared to ACPA positive (8% *vs*. 3%) (Figure 1B). Higher IgG autoantibody levels towards dual specificity mitogen-activated protein kinase kinase 6 (MAP2K6), were also observed in ACPA negative subjects

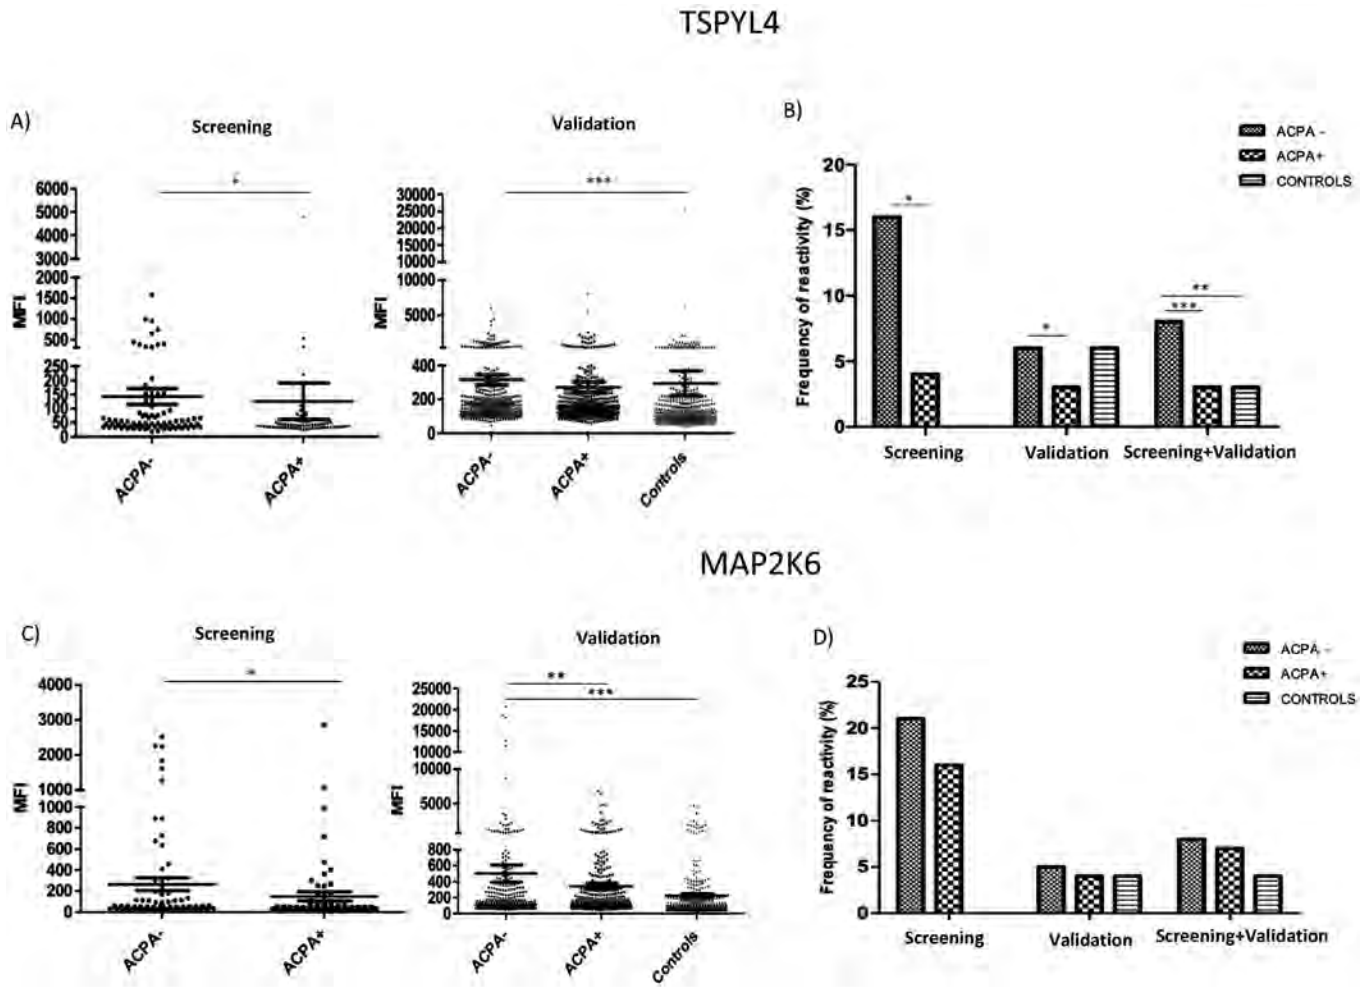

Figure 1. IgG autoantibodies associated with ACPA negative status. MFI: median fluorescence intensity.*P<0.05;**P<0.01;***P<0.001.

compared to ACPA positive and controls, but no differences were observed on their prevalence (Figure 1C,1D). In contrast, higher IgG autoantibody levels towards muscle related coiled-coil protein (MURC) and Anosmin-1 (ANOS-1) were observed in ACPA positive individuals compared to ACPA negative and controls (Figure 2A, 2C). The prevalence of IgG autoantibodies towards ANOS-1 was also higher in ACPA positive subjects compared with ACPA negative and controls (22%, 9% and 6% respectively) (Figure 2D). Interestingly, three out of the four antigens discovered are highly expressed in lungs and heart, two of the extraarticular sites affected in RA. No significant differences were validated at IgA reactivity levels for any of the antigens analyzed.

Conclusion: Although further validation in other early RA sample cohorts is needed, our data suggest the measurement of these four autoantibodies might be useful to assist the early diagnosis of RA and give insight into its pathogenesis.

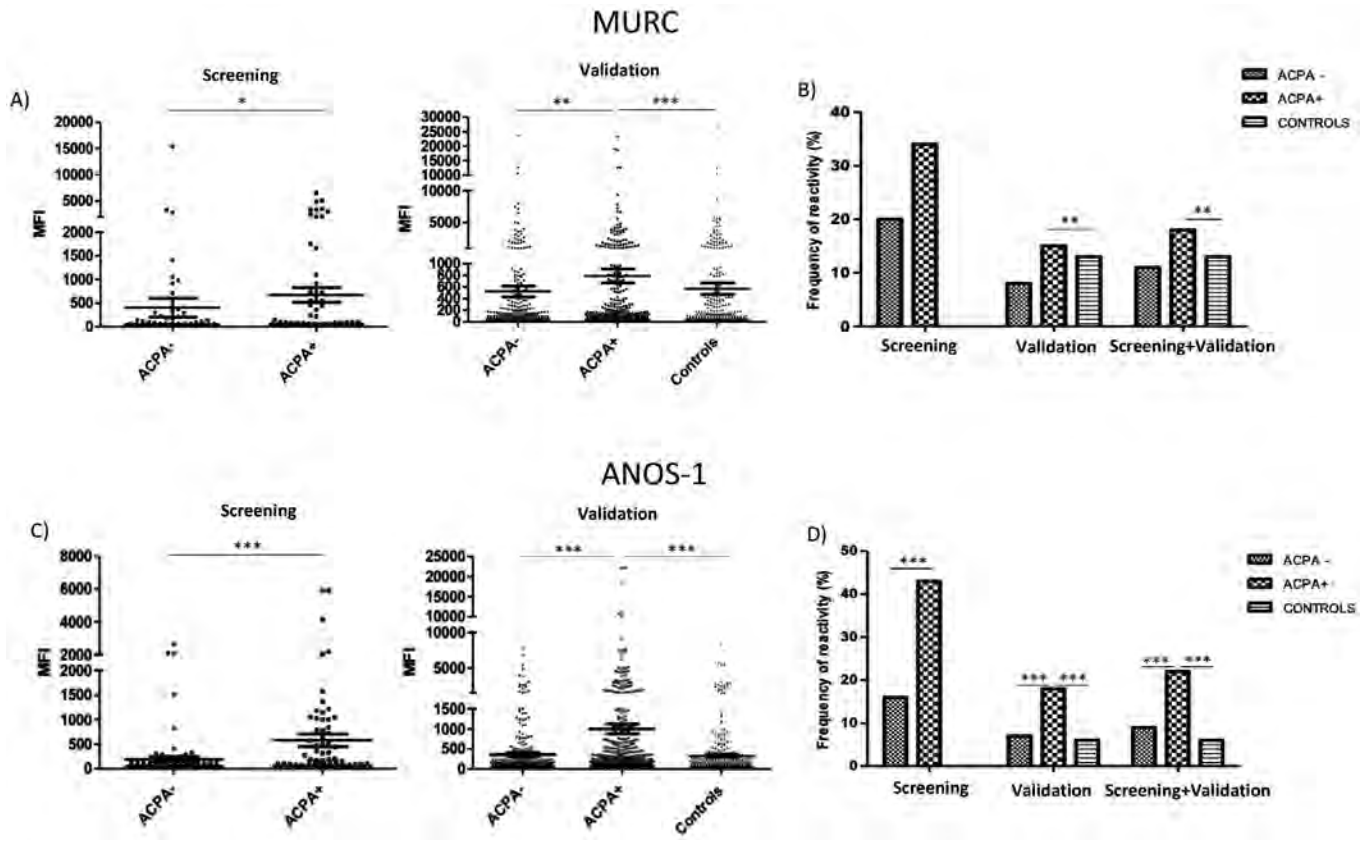

Figure 2. IgG autoantibodies associated with ACPA positive status. MFI: median fluorescence intensity.*P<0.05;**P<0.01;***P<0.001.

comparable to that of already diagnosed patients [1] We aimed to investigate the autoimmunity to other autoantibodies, beside ACPA, and study its importance in relation to clinical variables and inflammatory proteins, in risk stratification of predisposed individuals.

Methods: ACPA-positive individuals with musculoskeletal complaints referred from primary care (93%) and other specialist (7%), to a rheumatology clinic were recruited in the Risk-RA Karolinska research program and followed-up for up to 3 years or until arthritis diagnosis (April 2014 and February 2020). In order to investigate early disease mechanisms all individuals lacked both clinical arthritis and subclinical arthritis (measured by ultrasound according to EULAR-OMERACT definitions) in hands, feet and any other symptomatic joints. Blood samples collected at inclusion were analyzed for 14 ACPA specificities along with their arginine counterparts as well as 5 anti-modified protein antibodies (AMPA) against homocitrulline-, acetyl- and lysine- modified filaggrin 307-324 along with acetylated- histone 2B and histone 4 peptides, using custom made peptide array. We further screened for 92 inflammation-associated protein biomarkers (by multiplex immunoassay with Olink extension technology) and HLA-SE (DR low resolution kit). Statistical analysis used univariate and multivariate models with backwards selection and cox regression.

Results: 267 individuals (median age 48 CI: 36-58) were recruited, out of which 210 (78%) were females and with mean presence of 5 ACPA and 1 AMPA reactivities. 79 (30%) developed arthritis within 11 (4-21) months of follow-up compared to 21 (14-28) months median follow-up in those remaining arthritis free. In univariate models, specific ACPAs and AMPAs were associated with progression towards arthritis (Table 1.) Rheumatoid factor positivity (p 0.0003), presence of HLA-SE (p 0.005) and levels of certain inflammatory proteins (CCL20, CXCL6, CXCL9, IL6, IL15, IL17, DNER and TWEAK) associated with arthritis development. In multivariate (backwards selection) cox regression analysis the presence of anti-cit-filaggrin 307-324 (HR 2.1, 95% CI 1.2-3.7, p 0.005), IL6 levels (HR 1.4, 95% CI 1.2-1.7, p< 0.001) and tenosynovitis (HR 2.9, 95% CI 1.7-5.0, p < 0.001) remained significant predictors for arthritis onset. All other types of AMPA for filaggrin lost significance.

Conclusion: Risk-RA phase is characterized by several types of ACPAs and AMPAs, however anti-cit-filaggrin and ACPA reactivities show the strongest risk for progression to arthritis along with inflammatory proteins and ultrasound-detected tenosynovitis. The biological mechanisms need to be further explored in detail.

Elevated IgA Subclass Levels in Rheumatoid Arthritis Patients: Indications of a Mucosal Origin?

Veerle Derksen, Cornelia F. Allaart, Annette H.M van der Helm-van Mil, Tom WJ Huizinga, René Toes and Diane van der Woude, Leiden University Medical Center, Leiden, Netherlands

SESSION INFORMATION
Session Date: Saturday, November 6, 2021
Session Title: RA – Etiology & Pathogenesis Poster (0011–0045)
Session Type: Poster Session A
Session Time: 8:30AM–10:30AM

Background/Purpose: Mucosal surfaces may be involved in the pathophysiology of rheumatoid arthritis (RA) (1). IgA is the most abundant class of immunoglobulin at mucosal sites and has an important function in intestinal homeostasis. Therefore, it is worthwhile to study this isotype in more detail in the context of RA. Humans have two IgA subclasses, IgA1 and IgA2, which are not evenly distributed. IgA1 is dominant in serum, whereas IgA1 and IgA2 are more balanced at mucosal surfaces (2). Besides these differences in location, IgA2 has also been ascribed pro-inflammatory properties (3). As IgA subclasses might provide insights into mucosal involvement and potential pro-inflammatory mechanisms in RA, we measured total and autoantibody specific IgA subclasses in sera of rheumatoid arthritis patients.

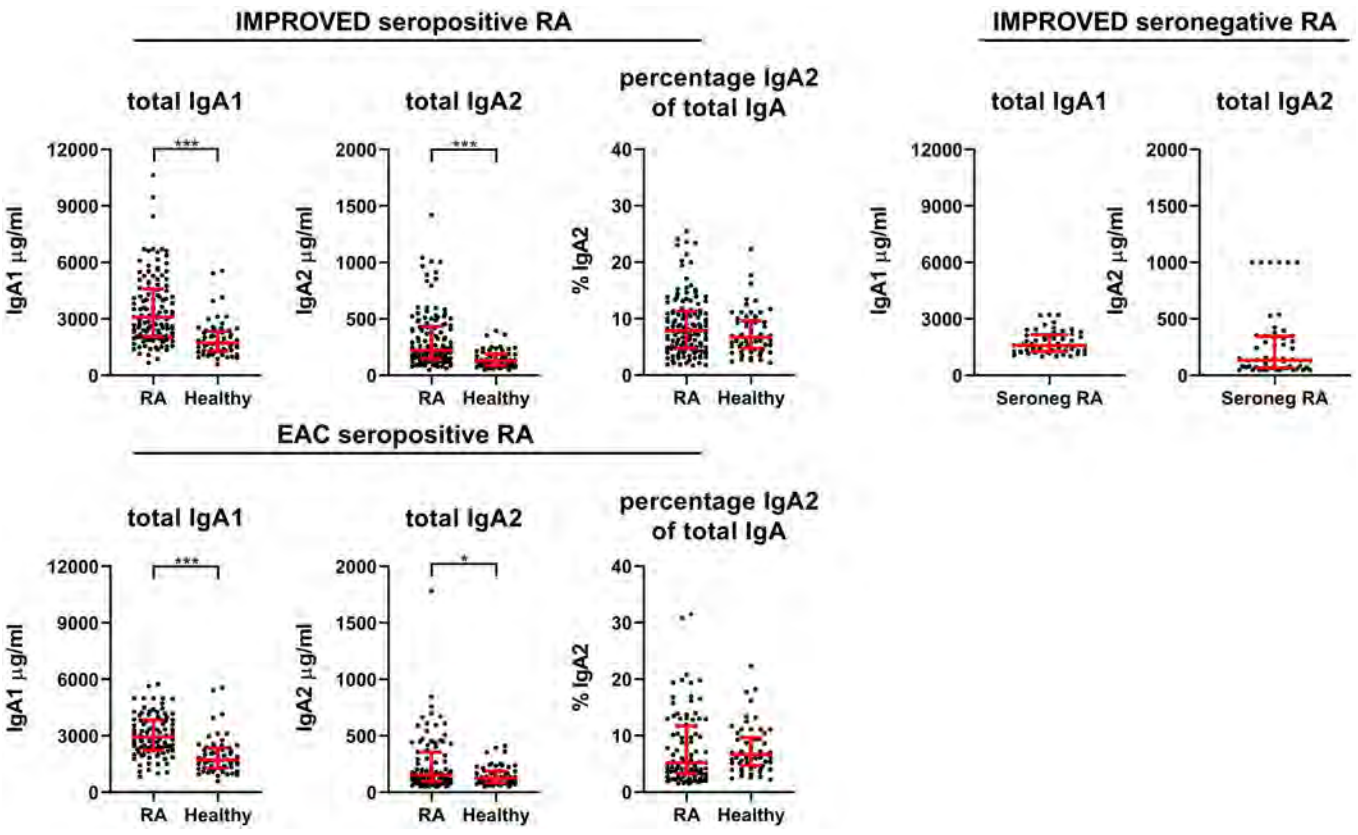

Figure 1. Total IgA1 and IgA2 levels in seropositive and seronegative RA patients.

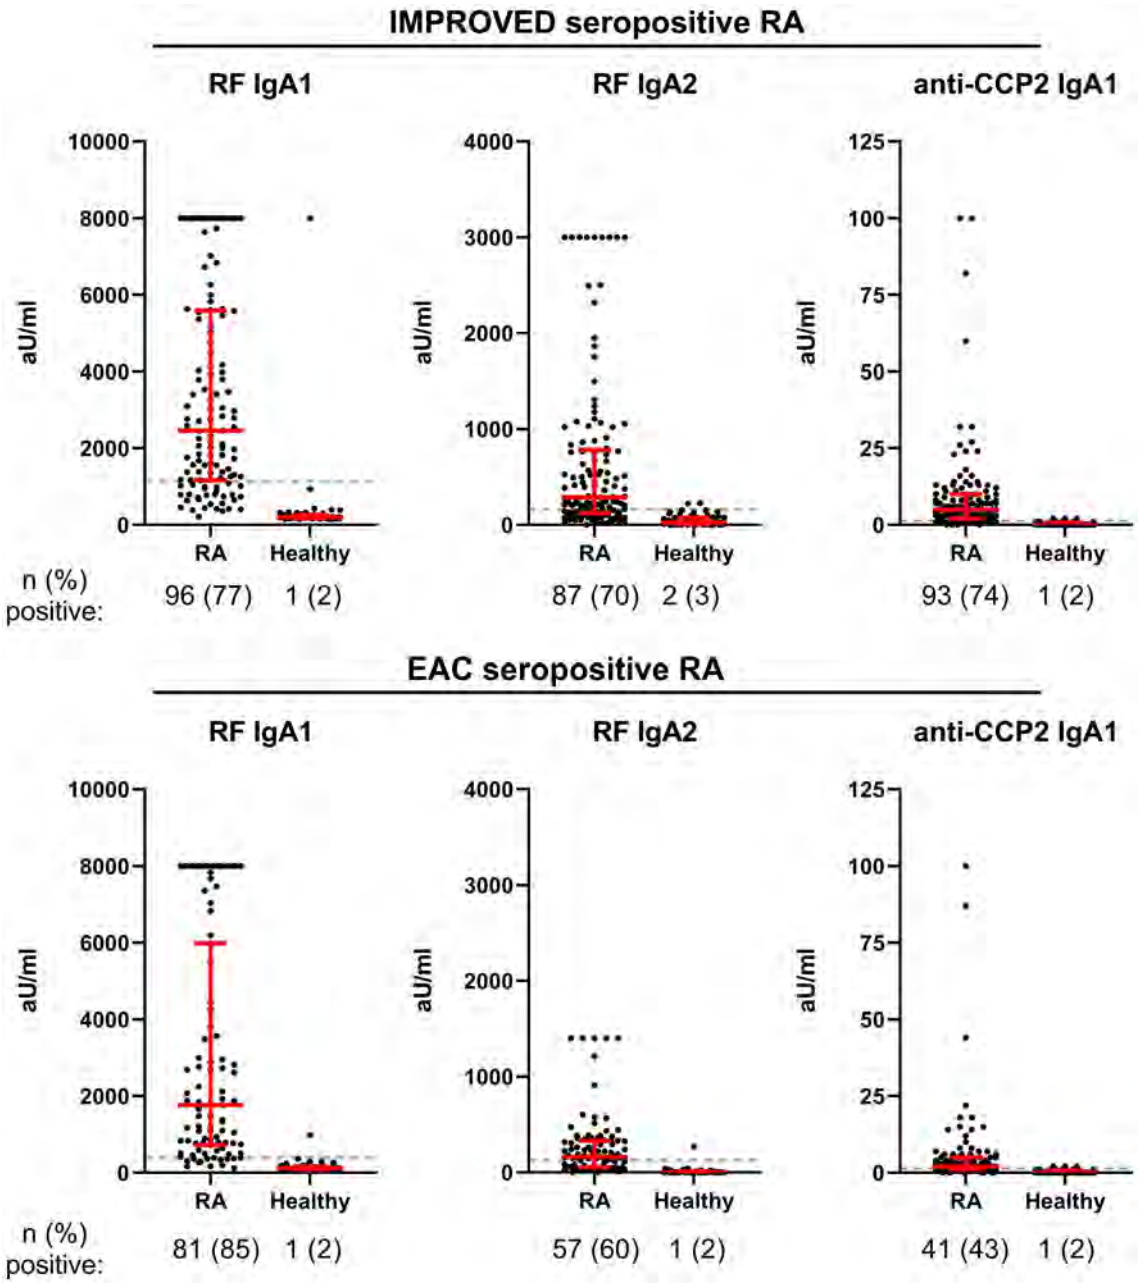

Figure 2. RF IgA1 & IgA2 levels and anti-CCP2 IgA1 levels in RA patients.

Methods: RA patients from two cohorts, the IMPROVED and the EAC, were selected based on previous autoantibody measurements. Samples were collected at baseline in the IMPROVED study and at the 1-year visit in the EAC. All patients fulfilled the 1987 (EAC) or 2010 (IMPROVED) ACR criteria for RA. Rheumatoid factor (RF), anti-citrullinated protein antibodies (ACPA) and total IgA subclasses were measured in these sera using in-house ELISA's, and compared to healthy donors. The association of IgA subclass levels with CRP, disease activity score (DAS) and smoking was investigated using Spearman's rank correlation and Mann–Whitney U tests.

Results: Both total IgA1 and IgA2 were increased in seropositive RA, but not in seronegative RA patients in the IMPROVED (Figure 1). In seropositive RA, both IgA subclasses were raised to the same extent. RF and ACPA IgA1 and IgA2 were also detected in seropositive RA patients (Figure 2), but measurements of ACPA IgA2 levels proved challenging due to interference of RF IgA and are therefore not depicted. Although IgA2 has been postulated to be

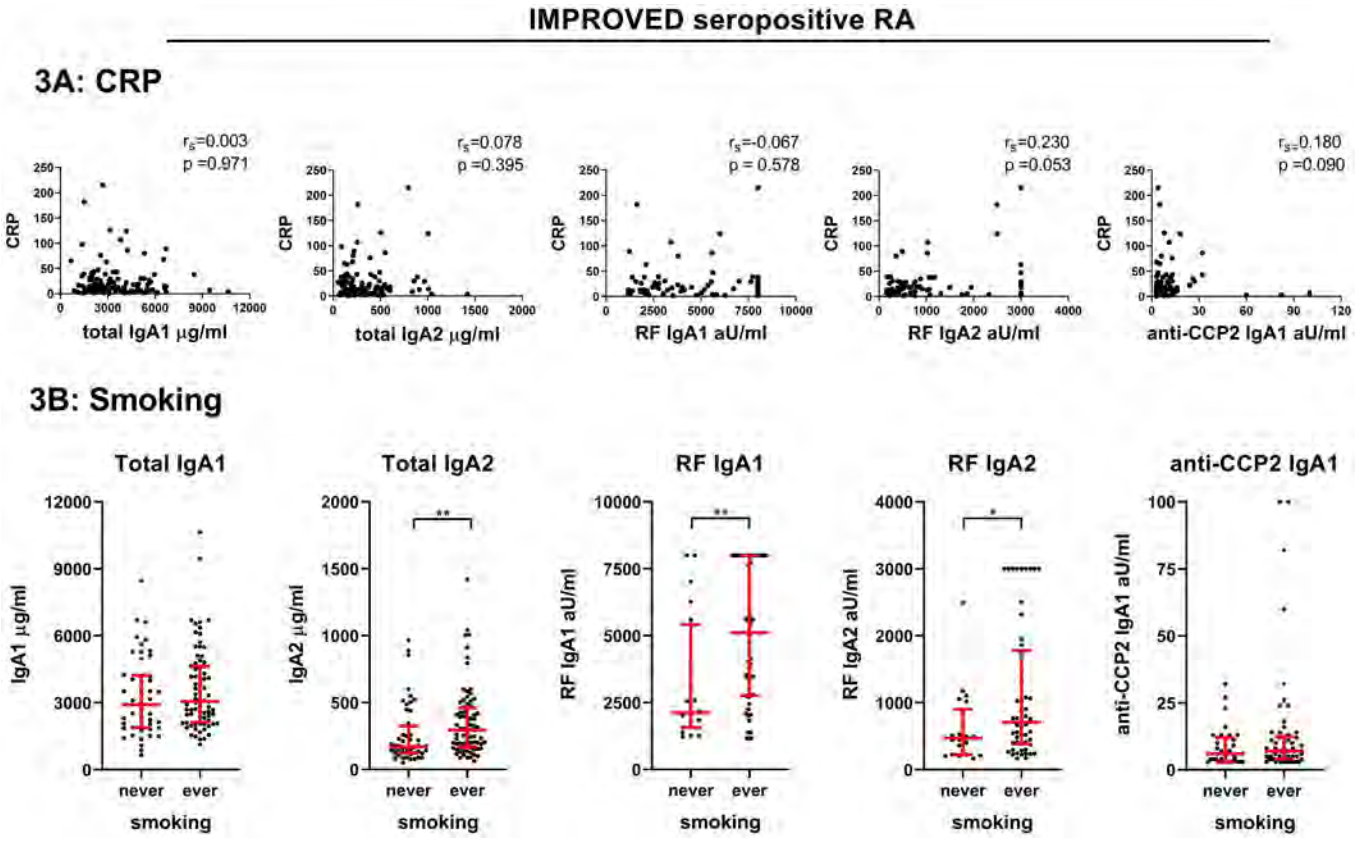

Figure 3. A) Association of total and autoantibody IgA subclasses with CRP in IMRPOVED B) Association of total and autoantibody IgA subclasses with smoking in IMPROVED.

more proinflammatory, no relevant associations were found between total, RF and ACPA IgA subclass levels and CRP (Figure 3A, IMPROVED only) or DAS. In smoking seropositive RA patients, a selective minor increase in total IgA2, RF IgA1 and RF IgA2 was seen in both cohorts (Figure 3B, IMPROVED only), although all were non-significant in the EAC.

Conclusion: Seropositive RA patients have equally raised IgA1 and IgA2 levels and can also harbor RF and ACPA IgA subclasses. No indications of a mucosal source, such as a predominance of total IgA2, were found, although smokers might have slightly increased total IgA2. However, these results do consolidate the concept that seropositive versus seronegative RA have different pathophysiological traits, with seropositive patients perhaps displaying more aspecific B cell hyperreactivity.

SESSION INFORMATION
Session Date: Saturday, November 6, 2021
Session Title: RA – Etiology & Pathogenesis Poster (0011–0045)
Session Type: Poster Session A
Session Time: 8:30AM–10:30AM

Background/Purpose: Rheumatoid Arthritis (RA) is a chronic autoimmune disorder affecting 1% of the population worldwide [1]. Monocytes/macrophages are known to play a crucial role in modulating the immune inflammatory response through their possible polarization into “pro-inflammatory” (M1) or “anti-inflammatory” (M2) phenotypes [2]. In RA, CTLA4-Ig fusion protein (abatacept) has been found to reduce the proinflammatory activity of macrophages, by interacting with the costimulatory molecule CD86 [3,4].

This study aimed to investigate the *in vitro* capability of CTLA4-Ig to induce the M2 phenotype in cultured monocyte-derived macrophages (MDMs) obtained from RA patients and in M1-polarized MDMs obtained from healthy subjects (HSs).

Methods: Five RA patients (mean age 54±13 years), who fulfilled the 2010 ACR/EULAR Classification Criteria for RA, and ten age-matched HSs were enrolled for the study after signed informed consent and local EC approval. Cultured MDMs were obtained from circulating blood mononuclear cells and stimulated with phorbol myristate acetate (PMA, 5ng/ml) for 24 hours (hrs). HS MDMs were then stimulated with lipopolysaccharide (LPS, 1mg/mL) for 4 hrs to induce a pro-inflammatory M1-MDM phenotype. Therefore, both RA-MDMs and M1-MDMs were treated with CTLA4-Ig (100μg/mL or 500μg/mL) for 3, 12, 24 and 48 hrs. Gene expression of CD80, CD86 and TLR4 (M1 markers), CD163, CD204 and CD206 (M2 markers) were evaluated by qRT-PCR. Moreover, protein synthesis of M2 markers was investigated by Western blotting. The statistical analysis was performed by non-parametric Wilcoxon t-test.

Results: In LPS induced M1-MDMs (HS), CTLA4-Ig (100μg/mL and 500μg/mL) significantly downregulated the gene expression of all M1 phenotype markers (CD80, CD86, TLR4: 3 hrs $p< 0.01$; 12 hrs $p< 0.05$ for all) and significantly upregulated all M2 markers after 12 hrs of treatment (CD163: $p< 0.01$ and $p< 0.05$; CD206: $p< 0.05$ and $p< 0.01$; CD204: $p< 0.05$ by CTLA4-Ig 100μg/mL). Accordingly, CTLA4-Ig (500μg/mL) increased the protein synthesis of M2 markers, significantly after 48 hrs of treatment ($p< 0.05$).

On the other hands, in RA-MDMs, CTLA4-Ig generally downregulated the gene expression of M1 markers at both concentrations and all timing, but in a significant manner only that of TLR4 and CD80 and only by the highest dose (500μg/mL, 12 hrs, $p< 0.05$). Of note, CTLA4-Ig (100μg/mL) upregulated significantly the gene expression of CD163 (M2 phenotype marker; $p< 0.05$). However, gene expression and protein synthesis of all the investigated M2 markers at both concentrations increased in a non-significant manner compared to untreated cells.

Conclusion: CTLA4-Ig seems to induce the *in vitro* polarization, from M1 to M2, of cultured MDMs obtained from RA patients and of M1-MDMs from HSs, therefore proving a new aspect for the anti-inflammatory activity exerted by abatacept in RA pts.

Vascularized 'Synovium-on-a-Chip' - A Novel and Adaptable Model for Dissecting Inflammatory Biology Underlying Rheumatoid Arthritis

Theresa Wampler Muskardin[1], Chao Ma[2], Benteng Ma[2], Kayla Van Buren[3], Timothy Niewold[4] and Weiqiang Chen[2], [1]Colton Center for Autoimmunity, NYU School of Medicine, New York, NY, [2]New York University, New York, NY, [3]Mnemo Therapeutics, New York, NY, [4]Colton Center for Autoimmunity NYU School of Medicine, New York, NY

SESSION INFORMATION
Session Date: Saturday, November 6, 2021
Session Title: RA – Etiology & Pathogenesis Poster (0011–0045)
Session Type: Poster Session A
Session Time: 8:30AM–10:30AM

Background/Purpose: Rheumatoid arthritis (RA) is a common multisystem inflammatory condition, affecting approximately 1% of the world population. The mechanisms underlying RA are still incompletely defined and current therapies, such as TNF-alpha inhibition, are mainly applied to mitigate the abnormal inflammation with limited success. RA fibroblast-like synoviocytes (FLS) in the synovium release cytokines that drive inflammation and attract immune cells, particularly monocytes, to the synovium microenvironment. These monocytes can further polarize to inflammatory macrophages, exacerbate the tissue inflammation and contribute to joint destruction. Herein, we engineered an organotypic, perfusable 'Synovium-on-a-Chip' to recapitulate the *in vivo* pathophysiology of RA synovial microenvironments and to dissect the RA FLS and monocyte associated inflammatory mechanisms that contribute to RA.

Methods: The microfluidic Synovium-on-a-Chip was constructed using a polydimethylsiloxane (PDMS)-based soft lithography technique. The chip contains two areas (**Fig. 1A**). The inner ring was infused with endothelial cells to form a 3D vascularized sublining layer. The outer ring was inoculated with RA FLS which aligned to form a synovial lining layer in a fibrin hydrogel (**Fig. 1B-D**). Monocytes were isolated from peripheral blood mononuclear cells and then loaded into the 3D vasculature (**Fig. 1C**). We analyzed cellular architecture and motility, gene expression, and cytokine secretion. Flow cytometry was used to assess cells after culture.

Results: We found that RA FLS released several cytokines, such as IL-6, CCL5, and CCL8, which facilitate the monocyte recruitment and drive inflammation in the RA niche (**Fig. 1D**). We confirmed that TNF-α (a major pathogenic

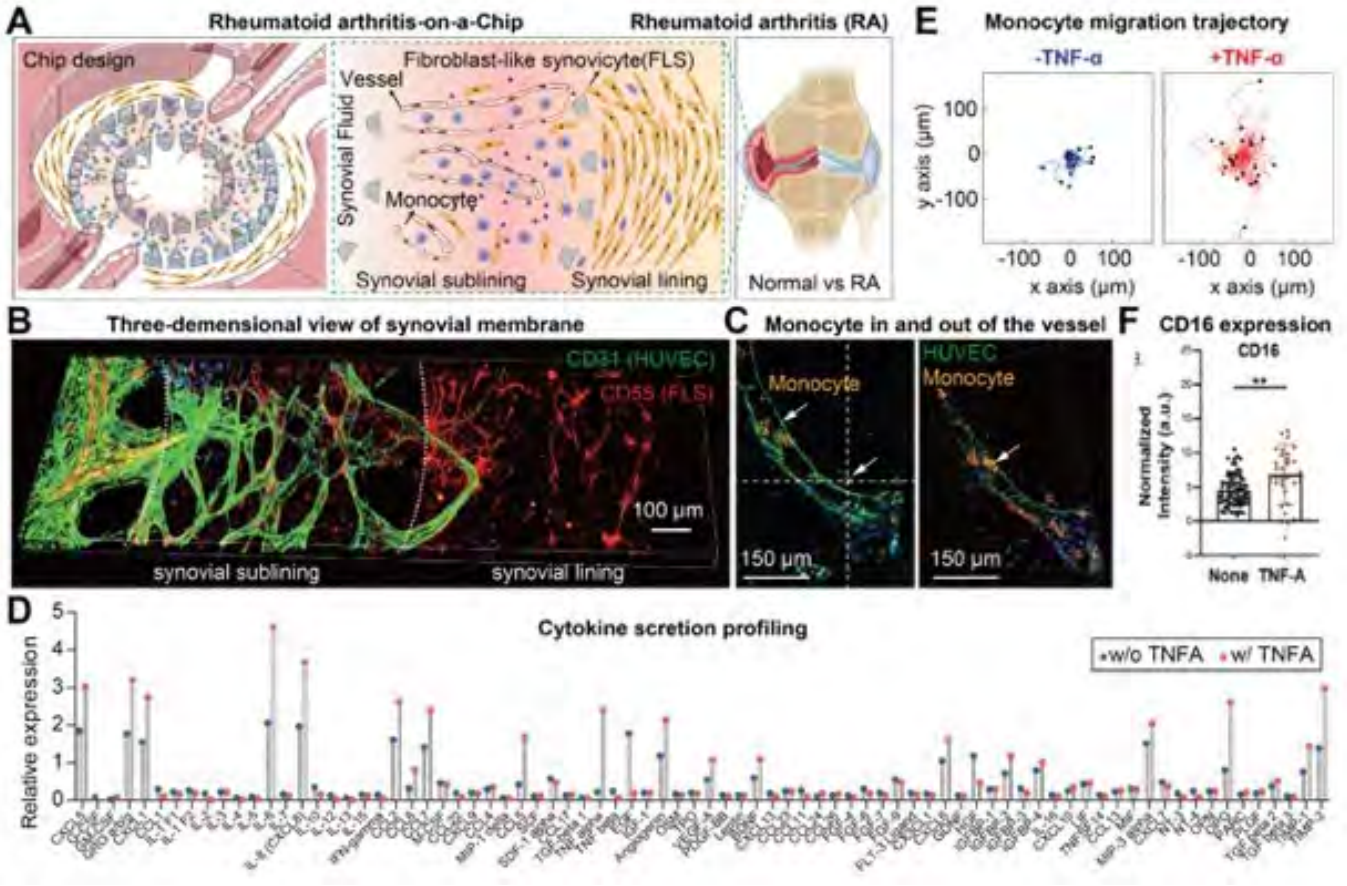

Figure 1. An organotypic Synovium-on-a-Chip. (A) Schematic of the RA niche and microfluidic design and (B) the resultant RA chip. (C) 3D view of monocytes loaded into the vascular network. (D) Cytokine profile of the RA niche identified inflammatory cytokines. (E) Migration trajectory of monocyte into RA niche treated with or without TNF-α. (F) TNF-α promoted non-classical monocyte emergence. **p < 0.01.

cytokine in RA) induced inflammatory cytokine production and enhanced monocyte migration in the inflammatory environment (**Fig. 1E**). We also observed RA FLS and TNF-α treatment enhanced intermediate/non-classical CD16+ monocyte emergence (**Fig. 1F**).

Conclusion: We engineered a biomimetic 'Synovium-on-a-Chip' system that reconstitutes *in vivo* RA pathophysiology and dissected interactions between RA FLS and peripheral blood monocytes and their associated inflammatory milieu involved in RA. To our knowledge, ours is the first vascularized device used in biomimetic synovial culture and testing.

High-throughput Testing for Modified-protein Antibodies in Patients Diagnosed with "Seronegative" Rheumatoid Arthritis

Michael Richter[1], Hari Krishnamurthy[2], Sylvia Posso[3], Jeffrey Carlin[4] and Jane Buckner[3], [1]University of Washington, Mercer Island, WA, [2]Vibrant Sciences, San Carlos, CA, [3]Benaroya Research Institute at Virginia Mason, Seattle, WA, [4]Virginia Mason Medical Center, Seattle, WA

SESSION INFORMATION
Session Date: Saturday, November 6, 2021
Session Title: RA – Etiology & Pathogenesis Poster (0011–0045)
Session Type: Poster Session A
Session Time: 8:30AM–10:30AM

Background/Purpose: Antibodies to citrullinated and other modified proteins play a critical role in the pathogenesis of rheumatoid arthritis (RA). The prevalence and degree of multi-site peptide reactivity of these antibodies in patients classified as "seronegative" is unclear.

Methods: An ultra-dense peptide array consisting of two million sequences was manufactured using photolithography. The peptide library was random but biased to include the sequences of filaggrin, fibrinogen, vimentin, collagen II, enolase, histones, and 14-3-3 eta with native, citrullinated, and carbamylated epitopes. A machine-learning algorithm identified 314 RA-specific peptides from a testing cohort of 140 RA patients, 480 healthy controls, and 136 disease controls based on signal-to-noise ratio. A validation cohort of 249 patients with RA (Table 1) was then analyzed on the basis of anti-cyclic citrullinated peptide (CCP) and rheumatoid factor (RF) positivity.

Results: The validation cohort included 106 patients (43%) who were negative for both CCP and RF ("seronegative"). Within this group, 25% had antibody binding to at least one site in the library of 314 peptides, compared with 98% of patients in the CCP and RF positive group ($p < 0.0001$). Only one control patient (1%) had any positive result. A heat-map of peptide reactivity is shown in Figure 1. Multi-site reactivity was more limited among the "seronegative" patients, with only 4% having antibody binding to at least 50 sites, compared to 80% in the CCP and RF positive group ($p < 0.0001$) (Figure 2). There was no significant difference in the ratio of antibodies to carbamylated vs. citrullinated proteins between "seronegative" and CCP positive patients. The presence of any HLA shared epitope allele was associated with positivity in this assay, with odds ratios of 3.56 (95%CI 1.99-6.37) for any binding and 4.22 (95%CI 2.22-6.37) for binding to greater than 50 sites.

Conclusion: This high-throughput assay demonstrated the presence of modified protein antibodies in a subset of "seronegative" patients, though multi-site reactivity was rare relative to CCP positive patients. This suggests that the mechanisms driving polyreactivity are features of seropositive RA and "seronegative" disease may have unique pathogenic features even when autoantibodies are present.

Table 1. Demographics of the validation cohort

	CCP+ RF+ (N=69)	CCP+ RF- (N=30)	CCP- RF+ (N=44)	"Seronegative" (N=106)	Controls (N=89)

Takinib Inhibits IL-1β-Induced Activation of Signal Transducer and Activator of Transcription 3 (STAT3) in Human Rheumatoid Arthritis Synovial Fibroblasts

Anil singh[1], Paul Panipinto[1], Ruby Siegel[1], Farheen Shaikh[1], Mukesh Chourasia[2] and Salah-uddin Ahmed[1], [1]Washington State University, Spokane, WA, [2]Amity University, Noida, India

SESSION INFORMATION
Session Date: Saturday, November 6, 2021
Session Title: RA – Etiology & Pathogenesis Poster (0011–0045)
Session Type: Poster Session A
Session Time: 8:30AM–10:30AM

Background/Purpose: Interleukin-1 (IL-1) is a crucial mediator of inflammatory cartilage and bone destruction in rheumatoid arthritis (RA). IL-1β signaling relies on the activation of TGF-beta activated kinase 1 (TAK1), a serine/threonine kinase that centrally regulates the mitogen activated protein kinase (MAPK) and nuclear factor kappa B (NF-κB) pathways, which makes it an attractive therapeutic target. Takinib is a small molecule inhibitor proposed to inhibit TNF-α-induced inflammation by targeting TAK1, however, its efficacy against IL-1β-driven inflammation and the underlying mechanism of its action remains to be tested. In the present study, we evaluated the effect of takinib on IL-1β-activated RA synovial fibroblasts (RASFs).

Methods: Human RASFs isolated from RA synovial tissue were serum starved overnight followed by two-hour pre-treatment with takinib at various concentrations (0.1-10 μM) before treatment with IL-1β (10 ng/mL) for 24 hours to determine the cell viability and the production of soluble proteins by ELISA, or for 30 minutes to evaluate the effect on IL-1β-activated signaling pathways. Irreversible type I (5z-7-oxozeaenol; 5Z-7o; 1 μM) and reversible type II (NG-25; 1 μM) inhibitors of TAK1 served as experimental controls. Effect of takinib on the kinome was determined using a human proteome profiler phospho-kinase array. Conditioned media was used for ELISA, whole cell lysates and nuclear/cytoplasmic extract were used for Western blot analysis. Effect on the cell viability was determined using an MTT-based assay. Molecular docking of Takinib as a ligand was performed on human STAT3 protein.

Results: Human phospho-kinase array results from RASFs identified phosphorylation of STAT3 at Ser^{727} and Tyr^{705} as a primary target of takinib (10 μM) in response to IL-1β stimulation. Pretreatment of RASFs with takinib (0.1-10 μM) showed a dose-dependent reduction in ENA-78/CXCL5, IL-6, IL-8 and MCP-1/CCL2 production, which were completely abrogated by 5Z-7o and NG-25 at 1 μM ($n=3$; $p< 0.05$). We also observed a significant reduction in cell viability by takinib at 10 μM ($n=4$; $p< 0.05$). Evaluation of the signaling pathways in RASFs further confirmed that takinib abrogates the non-canonical activation of STAT3 in response to IL-1β stimulation by suppressing Ser^{727} and Tyr^{705} activation. Surprisingly, takinib showed a dose-dependent increase in IL-1β-induced phospho-TAK1 at its kinase domain ($Thr^{184/187}$) in human RASFs. In corroboration of the kinome results, Western blot analysis showed that takinib inhibited the nuclear translocation of IL-1β-induced STAT3, but not of NF-κBp65, in human RASFs ($n=3$; $p< 0.05$). Molecular docking of takinib with STAT3 protein suggests binding of takinib at Gln^{644} and Tyr^{657} residues in the DNA binding domain. These may be essential for STAT3 activation and translocation to the nuclear compartment.

Conclusion: Our findings suggest STAT3 is an important target of takinib in the IL-1β signaling pathway, which may further be utilized for therapeutic purposes.

Autoantibodies Against Malondialdehyde-modifications Promote Osteoclast Development by Reprogramming Cellular Metabolism

Koji Sakuraba[1], Akilan Krishnamurthy[1], Alexandra Circiumaru[2], Jitong Sun[1], Vijay Joshua[1], Heidi Wähämaa[1], Marianne Engström[1], Meng Sun[1], Xiaowei Zheng[1], Cheng Xu[1], khaled amara[1], Vivianne Malmström[1], Sergiu Catrina[1], Caroline Grönwall[1], Anca Catrina[1] and **Bence Réthi**[1], [1]Karolinska Institutet and Karolinska University Hospital, Stockholm, Sweden, [2]Division for Rheumatology, Karolinska Institutet; Center for Rheumatology, Academic Specialist Center, Stockholm Region, Stockholm, Sweden

SESSION INFORMATION
Session Date: Saturday, November 6, 2021
Session Title: RA – Etiology & Pathogenesis Poster (0011–0045)
Session Type: Poster Session A
Session Time: 8:30AM–10:30AM

Background/Purpose: Malondialdehyde (MDA) is a highly reactive compound generated during lipid-peroxidation in conditions associated with oxidative stress. MDA can irreversibly modify proteins (e.g. lysine, arginine and histidine residues). In addition, acetaldehyde can further react with the MDA adducts to form malondialdehyde-acetaldehyde (MAA) modification. Such protein modifications can lead to immunogenic neo-epitopes that are recognized by autoantibodies. In fact, anti-MDA/MAA IgG levels are increased in the serum of patients with autoimmune diseases, such as rheumatoid arthritis (RA).

Very little is known about the pathogenic pathways induced by different types of autoantibodies in RA. Interestingly, anti-MDA/MAA antibodies have been shown to promote osteoclast (OC) differentiation in cell culture, suggesting a potential role for these antibodies in bone damage associated with RA. Here we elucidated the pathways specifically triggered by anti-MDA/MAA autoantibodies in developing osteoclasts.

Methods: Recombinant human monoclonal anti-MDA/MAA antibodies, which were previously cloned from single synovial B cells of RA patients, or control antibodies were added to different OC assays. OCs were generated from monocyte-derived macrophages in the presence of RANK-L and M-CSF. OC development was monitored by light microscopy following tartrate-resistant acid phosphatase (TRAP) staining and in erosion assays using calcium phosphate-coated plates. Bone morphometrics were analyzed in anti-MDA/MAA-injected mice using X-ray microscopy. Cellular metabolism was analyzed by mass spectrometry, Seahorse XF Analyzer and a colorimetric L-Lactate assay.

Results: Anti-MDA/MAA antibodies induced a robust OC differentiation *in vitro* and bone *loss in vivo*. The anti-MDA/MAA antibodies acted on developing OCs by increasing glycolysis through an Fcγ receptor I-mediated pathway and the upregulation of the transcription factors HIF-1α and Myc. Such regulation of cellular metabolism was exclusively observed in the presence of the osteoclastogenic anti-MDA/MAA antibodies, but not in the presence of other autoantibodies (e.g. ACPA or other anti-MDA/MAA). The anti-MDA/MAA treatment induced a shift in the tricarboxylic acid (TCA) cycle activity in developing OCs, increasing citrate production. Interestingly, osteoclast differentiation was in general associated with the accumulation of citrate/aconitate in the cells, which suggested intense lipid biosynthesis. Indeed, we detected a profound shift in cellular lipid compositions in developing OCs and we showed that phosphoglyceride/triacylglyceride biosynthesis was essential for osteoclast development.

Conclusion: We described a novel type of autoantibody-induced pathway in RA, which could contribute to increased OC activation and a consequent bone loss. Our results showed that anti-MDA/MAA antibodies promoted osteoclast development by increasing glycolysis and modulating the TCA cycle through a signaling pathway that included Fcγ receptor I and transcription factors acting on glycolysis. A TCA cycle bias towards citrate production suggested that anti-MDA/MAA antibodies might stimulate osteoclastogenesis via increasing lipid biosynthesis.

Session Title: RA – Etiology & Pathogenesis Poster (0011–0045)
Session Type: Poster Session A
Session Time: 8:30AM–10:30AM

Background/Purpose: Inflammatory arthritides (IA) including rheumatoid arthritis are associated with increased cardiovascular disease (CVD) mortality. Although inflammation-driven endothelial dysfunction is considered a major factor, the mechanisms driving this risk are incompletely understood. Endothelial colony forming cells (ECFC) are endothelial cells derived from peripheral blood. Due to their implied role in vessel repair, ECFC frequency in the circulation has been proposed as a marker of vascular dysfunction. Furthermore, these patient-derived EC provide an opportunity to study endothelial functions relevant to vascular injury in IA. In this ongoing study, we assessed inflammation-driven endothelial dysfunction in IA by measuring ECFC frequency and phenotype in patients before and after initiation of DMARD therapy.

Methods: ECFC were isolated from healthy controls (HC) (n=30) and patients with clinically active, IA naïve to DMARDs (n=37) (Table 1). In patients who commenced DMARDs (MTX+HCQ n=12, MTX, n=6), ECFC were isolated 4 months post initiation (n=16). ECFC frequency was evaluated by colony count normalised to number of PBMC seeded. After confirmation of endothelial purity by flow cytometry ($CD31^+/CD144^+/CD146^+/CD45^-/CD14^-$), ECFC phenotype was interrogated at passage 5 using proliferation and pro-inflammatory activation assays, and by transcriptional analysis of 85 key endothelial genes (Qiagen qPCR arrays). Data is presented as median [IQR]. Non-parametric statistical comparisons were made.

Results: ECFC frequency did not differ between treatment-naïve IA patients and controls (0.59 [0.27-0.75] and 0.75 [0.28-1.35] colonies/10^7 PBMC respectively) and no correlation was observed between frequency and DAS28, ESR or CRP. DMARD initiation led to a non-significant increase in ECFC frequency (1.49 [0.95-4.89] fold, p=0.083), but was unrelated to treatment response (DAS28, ESR, CRP).

Table 1. Basic Characteristics.

	Inflammatory Arthritis	Healthy Controls
N	37	30
Age (yr)	53.3 (48.4-61.4)	47.7 [36.8-58.5]
Female (%)	28 (76%)	20 (51.3%)
Caucasian (%)	20 (54%)	22 (56.4%)
Disease Duration		
≤6 months	21 (57%)	
<12 months	4 (11%)	
>12 months	12 (32%)	
Diagnosis		
Rheumatoid Arthritis	28 (76%)	
Other	9 (24%)	
Rheum. Factor+	18 (49%)	
CCP+	33 (62%)	
Elevated CRP (>5mg/L)	22 (59%)	
Elevated ESR (>23mm/h)	24 (65%)	
Disease Activity (DAS28-ESR)		
Low (≤3.2)	4 (10.8%)	
Moderate (>3.2 and ≤5.1)	9 (24.3%)	
High (>5.1)	22 (56.7%)	

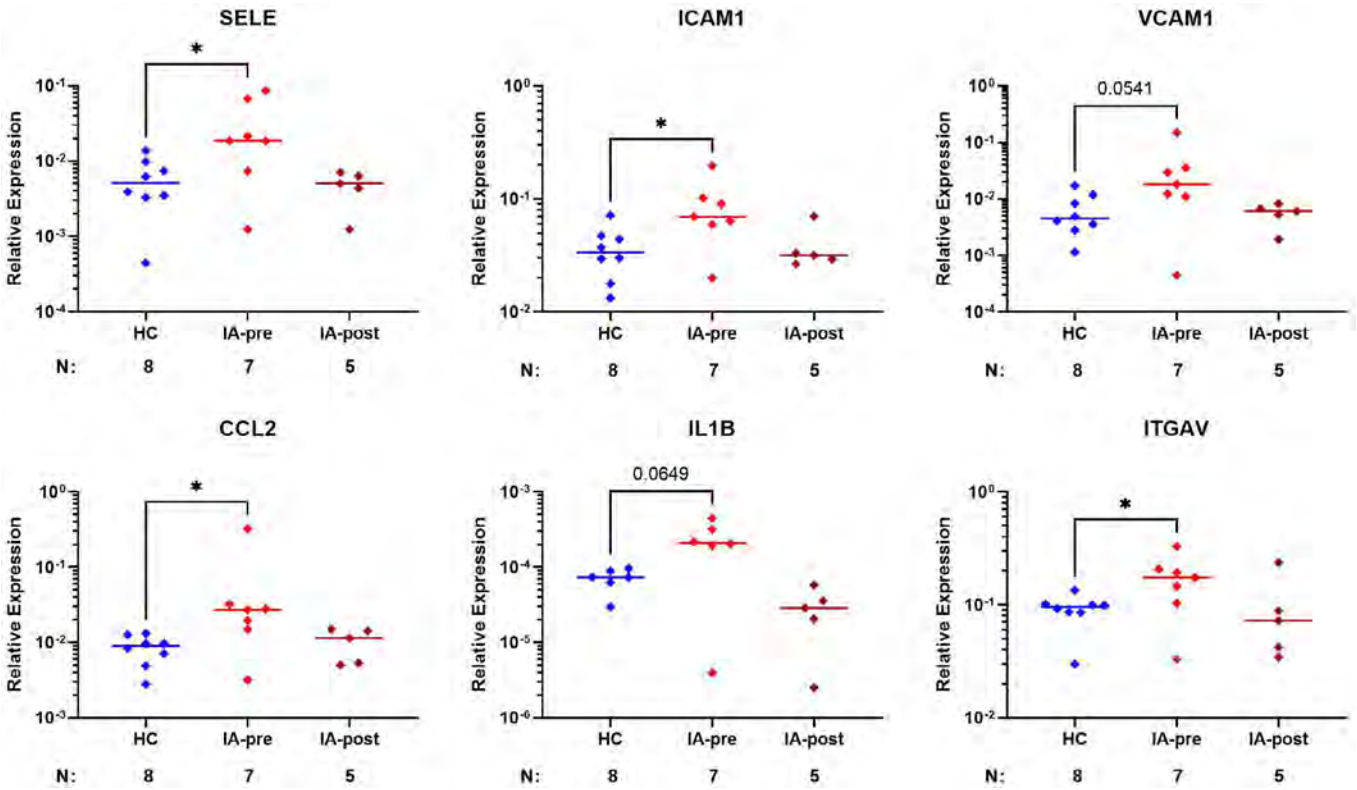

Figure 1. Gene expression Results. *P<0.05.

In comparison to HC, ECFC from treatment-naïve IA patients tended to be less proliferative and had significantly increased expression of CCL2, ICAM1, SELE, ITGAV and a non-significant increase in VCAM1 and IL1B suggesting a primed pro-inflammatory state (Fig. 1). Treatment-naïve ECFC were also more sensitive to pro-inflammatory activation (TNFα), expressing 3.7-13-fold higher mRNA levels of VCAM1 (p=0.0012), ICAM1 (*p*=0.0006) and E-selectin

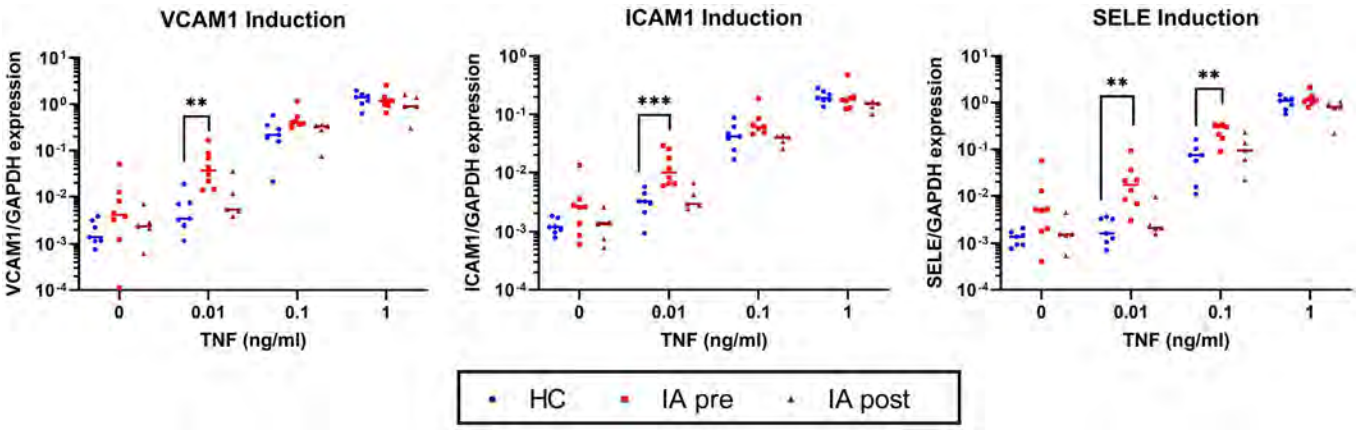

Figure 2. TNF stimulation. *P<0.05, **P<0.01, ***P<0.005.

(p=0.0041) with low dose TNFα stimulation. Of note, ECFC isolated after DMARD initiation demonstrated a reversal in this primed state, as exhibited by a reduction in pro-inflammatory gene expression (Fig. 1) and normalisation of TNFα sensitivity (Fig. 2).

Conclusion: Our data do not support an association between ECFC frequency and severity of inflammation or disease activity in IA. Increased ECFC frequency following DMARD initiation proved to be unrelated to inflammatory changes and may reflect a direct action of the medications. Evaluation of ECFC phenotype demonstrated a pro-inflammatory state that persisted despite *ex vivo* culture and which was reversed following DMARD initiation. These findings have mechanistic implications for inflammatory-driven vascular dysfunction and further analysis may highlight avenues for therapeutic targeting.

Psoriatic Arthritis Skin Is Transcriptionally Different to Psoriasis Skin and Enriched in Immunoglobulin Transcripts

Hanna Johnsson[1], John Cole[1], Stefan Siebert[1], Iain McInnes[2] and Gerard Graham[1], [1]University of Glasgow, Glasgow, United Kingdom, [2]University of Glasgow, School of Medicine, Glasgow, Scotland, United Kingdom

SESSION INFORMATION

Session Date: Saturday, November 6, 2021
Session Title: Spondyloarthritis Including PsA – Basic Science Poster (0046–0068)
Session Type: Poster Session A
Session Time: 8:30AM–10:30AM

Background/Purpose: Up to 30% of patients with psoriasis develop psoriatic arthritis (PsA). The traditional assumption is that the skin disease is the same in both conditions, although a previous proteomic analysis found differences[1]. The aim of this project was to investigate and compare the skin transcriptome in PsA and psoriasis.

Methods: Full thickness skin biopsies were obtained from healthy controls (HC) and paired lesional and uninvolved skin from patients with PsA. Libraries for bulk RNA sequencing were prepared from polyA selected RNA and

sequenced on NovaSeq 6000. Sequencing data were analysed using Searchlight2. Read counts of HC, lesional and uninvolved skin from patients with psoriasis without PsA obtained by Tsoi et al 2019 [2](GEO accession GSE121212) were analysed using Searchlight2. Results from the two analyses were compared. Read counts of patients with PsA from the Tsoi cohort were used for validation.

Results: The PsA cohort had 9 participants and the psoriasis cohort 16 participants in each group. The Tsoi PsA cohort had 4 participants. Both PsA skin lesions (PsA L) and psoriasis skin lesions (PsO L) formed distinct populations in the respective principal component analysis plot. While the HC and PsA uninvolved skin (PsA U) populations were mixed, the psoriasis uninvolved skin (PsO U) population was skewed from the HC population toward the PsO L population. Consistent with this, there were 15 differentially expressed genes between the PsA U and HC groups, and 124 differentially expressed genes between the PsO U and HC groups. All but one overlapped with genes differentially expressed in PsO L versus HC and pathway analysis showed enrichment of pathways also enriched in PsO L.

In lesional skin, most enriched pathways were shared between PsA L and PsO L. However, PsA L skin was enriched in immunoglobulin genes while PsO L skin was not. Increased expression of immunoglobulin genes was also seen in PsA L skin in the Tsoi cohort.

Conclusion: This study found differences in the transcriptomes of psoriasis and PsA skin. PsA U skin is closer to healthy skin than PsO U skin, which shares some transcriptomic changes with PsO L skin. Although PsA L and PsO L skin share many inflammatory pathways, transcriptomic changes suggest differences in immunoglobulin pathways.

A Role for Neutrophils in Disease Onset and Severity of Spondyloarthritis

Holly Rosenzweig[1], Emily Vance[2], Rouhin sen[3], Liron Caplan[4] and **Ruth Napier**[1], [1]Oregon Health & Science University, Portland, OR, [2]VA Portland Health Care System, Portland, OR, [3]Colorado University Anschutz Medical Campus, Denver, CO, [4]Rocky Mountain Regional Veterans Affairs Medical Center (VAMC)/University of Colorado School of Medicine, Aurora, CO

SESSION INFORMATION
Session Date: Saturday, November 6, 2021
Session Title: Spondyloarthritis Including PsA – Basic Science Poster (0046–0068)
Session Type: Poster Session A
Session Time: 8:30AM–10:30AM

Background/Purpose: Spondyloarthritis (SpA) is a group of inflammatory diseases that includes axial spondyloarthritis (axSpA) and psoriatic arthritis (PsA). AxSpA patients have irregular neutrophil responses, as indicated clinically by neutrophilia, increased neutrophil to lymphocyte ratios, and aberrant neutrophil activation. However, the role of

neutrophils in disease pathogenesis remains unknown. Here we employed an experimental model of SpA (SKG mice) in tandem with SpA patient data to determine the role of neutrophils in SpA.

Methods: Arthritis was induced in SKG mice by intraperitoneal injection of 1.5mg β-glucan (zymosan). Splenic CD4+ T cells were stimulated *in vitro* with PMA/ionomycin and the Th17 response was quantified by flow cytometry. Neutrophils were depleted in SKG mice with anti-Ly6G (1A8) or isotype control (2A3) beginning 24h prior to zymosan and every 2d for 5d. For mouse studies, three independent experiments were performed (n=5-6 mice/genotype), and data analyzed using non-parametric statistics. SpA patients with axSpA or PsA from the Program to Understand the Long term Outcomes in Spondyloarthritis Registry (Pulsar) were included. Regression was used to assess for associations of absolute neutrophil count (ANC) and neutrophil percentage, with measures of functional capacity determined using the Bath Ankylosing Spondylitis Functional Index (BASFI) Test.

Results: We induced disease in neutrophil-sufficient or -deficient SKG mice. Five days post-zymosan (disease induction), neutrophil-sufficient SKG mice developed autoreactive Th17 responses and arthritis; however, neutrophil-deficient SKG mice had decreased Th17 responses and no signs of arthritis, indicating a role for neutrophils in induction of arthritis. Conversely, 8 weeks post-zymosan neutrophil depletion resulted in worsened disease indicating neutrophils play a protective role during established/chronic disease. In human subjects, both absolute neutrophil count (ANC) ($p=0.002$) and neutrophil percentage ($p=0.008$) were associated with increased disease severity, as indicated by BASFI scores. On average, for every increasing increment of 5,000 neutrophils/mm^3, disability status worsened by approximately 15% (ΔBASFI of 1.5). These associations were also present in treatment-naïve SpA subjects, further supporting a role for neutrophils in SpA pathogenesis rather than an artifact of treatment. In corroboration with SKG mice, treatment-naïve SpA subjects within 5 years of diagnosis (earlier disease) had greater ANC than controls ($p < 0.001$), whereas subjects with more established disease demonstrated lower ANCs.

Conclusion: Our data suggest neutrophils may play a role in initiation of pathogenic Th17 responses and disease in Spa patients. Future studies aimed at understanding how dysregulation of neutrophil numbers and function contributes to SpA will inform development of novel therapeutics.

A Novel Technology to Study the Role of Intestinal Biology in Spondyloarthritis Pathogenesis: Human Colonic Organoids and Epithelial Monolayers

Manuel Rodriguez[1], Alec Furst[1], James T. Rosenbaum[2] and **Tejpal Gill**[1], [1]Oregon Health & Science University, Portland, OR, [2]Departments of Ophthalmology, Medicine, and Cell Biology, Oregon Health & Sciences University and Chair Emeritus, Legacy Devers Eye Institute, Portland, OR

SESSION INFORMATION
Session Date: Saturday, November 6, 2021
Session Title: Spondyloarthritis Including PsA – Basic Science Poster (0046–0068)
Session Type: Poster Session A
Session Time: 8:30AM–10:30AM

Background/Purpose: Ankylosing spondylitis (AS) is a complex genetic disease with strong association to the human leukocyte antigen (HLA)-B27. Several observations including frequent, occult histologic evidence for inflamma-

tion, clinical overlap with Crohn's disease, and microbial dysbiosis point to the gut as a potential primary cause of spondyloarthritis. However, the role of HLA-B27 associated gut epithelial biology or host-microbe interaction is not clear in spondyloarthritis pathogenesis. While immortalized cell-lines transfected with HLA-B27 can be studied, they cannot mimic the complexity of the epithelial tissue. In addition, animal and cell line models cannot recapitulate the interindividual variability of the human population. To counter these issues, we have developed human colonic organoids and epithelial monolayers from colon biopsies of HLA-B27 positive and negative healthy individuals to study the effect of HLA-B27 on host-microbe interactions and epithelial cell biology.

Methods: To generate colonic organoids, frozen biopsies from healthy individuals undergoing elective colonoscopies were used. These biopsies were minced and the tissue digested on a shaker to release the crypts. The crypts were washed and resuspended in undiluted Cultrex reduced-growth-factor basement membrane extract. The organoids were expanded after ~1 week by mechanical disruption and splitting. After 2-5 passages, these organoids were frozen during exponential growth phase for optimal recovery. To generate epithelial monolayers, organoids were washed and mechanically disrupted and cells were plated over Matrigel matrix coated transwells to form monolayers.

Results: We have developed colonic organoids and epithelial monolayers from multiple HLA-B27 positive and negative individuals and are in the process of generating colonic organoids from AS patients. We have shown that organoids maintain their stemness after being frozen, as confirmed by the presence of spheroids (early-stage organoids), and their ability to differentiate into mature (lobular) organoids and epithelial monolayers. These organoids have been characterized for the presence of goblet cells, and experiments using various proliferation markers to confirm recapitulation of key aspects of *in vivo* sample are underway. Monolayers will be used to study HLA-B27 associated alteration of epithelial cell biology. In addition, organoids/monolayers will be cultured with either microbial products (e.g., lipopolysaccharide) or HLA-B27 associated microbes as determined in our previous studies, and the loss of barrier function will be analyzed by global gene expression, tight-junction proteins, and production of antimicrobial peptides.

Conclusion: To our knowledge, we are amongst the first groups to use human colonic organoids to study the role of intestinal epithelial cells in barrier function and host-microbe interaction in any rheumatic disease. Using organoids developed from HLA-B27 positive AS patients and healthy individuals and HLA-B27 negative controls, we will be able to functionally assay whether HLA-B27 is associated with altered barrier function and host-microbe interactions.

Session Title: Spondyloarthritis Including PsA – Basic Science Poster (0046–0068)

Session Type: Poster Session A

Session Time: 8:30AM–10:30AM

Background/Purpose: Mitogen-activated protein kinase-activated protein kinase-2 (MK2), a direct downstream target of p38, has been identified as a promising candidate for treatment of inflammatory diseases. Activation of the p38 pathway leads to increased production of pro-inflammatory cytokines via MK2-mediated increases in the stability and translation of their mRNA (eg, TNF, IL-17, IL-6). Previously, p38 inhibitors were investigated for the treatment of autoimmune diseases, but tachyphylaxis was observed with the lack of sustained inhibition of inflammation despite continuous treatment.[1,2] MK2 inhibition is hypothesized to avoid the negative feedback network that may have limited p38 inhibitors. CC-99677 is a novel covalent MK2 inhibitor being developed for the treatment of inflammatory diseases.

Methods: In the *in vitro* model of tachyphylaxis, CC-99677 and p38 inhibitors similarly decreased TNF production at early time points. However, on day 9, loss of TNF inhibition was noted for all p38 inhibitors tested. In contrast, the MK2 inhibitor, CC-99677, sustainably suppressed TNF production throughout the treatment period. MK2 inhibition with CC-99677 resulted in reduced TNF and IL-17A/F production in *in vitro*-stimulated PBMCs from patients with PsA. In the animal model of psoriasis and PsA, a new cumulative score based on paw swelling, ear thickness, skin flaking, and joint severity score was devised: Psoriatic Arthritis Severity Index (PsASI). CC-99677 reduced the PsASI score in a dose-dependent manner.

Results: In the *in vitro* model of tachyphylaxis, CC-99677 and p38 inhibitors similarly decreased TNF production at early time points. However, on day 9, loss of TNF inhibition was noted for all p38 inhibitors tested. In contrast, the MK2 inhibitor, CC-99677, sustainably suppressed TNF production throughout the treatment period. MK2 inhibition with CC-99677 resulted in reduced TNF and IL-17A/F production in *in vitro*-stimulated PBMCs from patients with PsA. In the animal model of psoriasis and PsA, a new cumulative score based on paw swelling, ear thickness, skin flaking, and joint severity score was devised: Psoriatic Arthritis Severity Index (PsASI). CC-99677 reduced the PsASI score in a dose-dependent manner.

Conclusion: CC-99677 is an MK2 inhibitor that exhibits sustained inhibition of TNF *in vitro* and effectively reduces TNF production in stimulated immune cells from patients with PsA. In the *in vivo* MIP model of psoriasis and PsA, MK2 inhibition was efficacious in reducing skin and joint inflammation, reflected in a dose-dependent reduction in PsASI score. These data extend previous results demonstrating reduction in cytokine production in stimulated PBMCs from patients with AS and efficacy in the rat HLA-B27 transgenic model of AS.[5] Thus, our *in vitro* and *in vivo* data support investigating CC-99677 in clinical studies planned in patients with spondyloarthritis.

Session Title: Spondyloarthritis Including PsA – Basic Science Poster (0046–0068)

Session Type: Poster Session A

Session Time: 8:30AM–10:30AM

Background/Purpose: Gender has been shown to impact disease expression in ankylosing spondylitis. Men with AS are more likely to develop radiographic joint damage, while women have latter onset of disease, higher symptomatic burden but slow progression of structural damage and impaired response to treatment. An important observation was made in a recent study which showed that male patients with AS had a distinctive up-regulation of the Th17 signature,

Table1. Disease Activity and Function Outcome Measures in Patients

Figure 1. Dysregulated differential genes in AS male vs AS female.

while female patients with AS had Th17 cell profiles comparable with those of the healthy control subjects (1). We propose that mRNAs are differentially expressed in IL-17 producing cells between males and females with AS and disparately regulate the genes in males and females and subsequently contribute to the difference in disease phenotype.

Methods: 10 female and 10 male subjects ≥18 years of age with AS based on NYCS, were enrolled. Patients were recruited as per approved IRB protocol. Peripheral blood samples (30 ml) were obtained in the Clinical Research Unit of MetroHealth Medical Center. The PBMCs obtained were stimulated with CytoStim for 4 h (Miltenyi Biotec GmbH, Bergisch Gladbach, Germany). After stimulation, the cells were processed through the interleukin (IL)-17-phycoerythrin (PE) cytokine secretion assay enrichment kit (Miltenyi Biotec). The IL-17 positive cells were counted and total RNA was extracted as per Takara kit (Takara Biotech, Japan). Changes in mRNA expression were identified using next

generation RNA-sequencing (RNA-seq). To proceed 500 ng of RNA from each sample was sent to Novogene for sequencing. Analysis of the data was done using Ipathway guide by Advaita Bioinformatics (ipathwayguide.advaitabio.com). Genes were identified using a threshold of 0.05 for statistical significance (p-value) and a log fold change of expression with absolute value of at least 0.6. These data were analyzed in the context of pathways obtained from the KEGG database, miRNAs from the miRBase and TARGETSCAN databases, network of regulatory relations from BioGRID, and diseases from the KEGG database.

Results: Patient demographics and disease activity and functional outcomes are reported in table 1. In this experiment, 2,373 differentially expressed (DE) genes B were identified out of a total of 15,294 genes with measured expression as in Fig 1. 613Gene Ontology (GO) terms, 40 miRNAs, 201 upstream regulators, and 14 diseases were found to be significantly enriched before the correction for multiple comparisons. In summary, 15 pathways were found to be significantly impacted.

Conclusion: The study revealed multiple cytokine genes were found to be dysregulated between men and women with AS. The IL23R, IL12R, IL6R, JAK, STAT and TYK2 genes were downregulated in men compared to women while S100A2, S100A4, S100A6, S100B, chemokine CCL-17 and PGE2 related genes were upregulated. These data need to be confirmed by RTPCR and may provide clues for understanding the pathogenesis and phenotypic differences.

Identification of Biomarkers and Deregulated Pathways in Psoriatic Arthritis Through Proteomic Analysis of Synovial Fluid

Jacqueline Lai[1], Sara Rahmati[2], Raam Sivakumar[2], Katerina Oikonomopoulou[3], Fatima Abji[4] and Vinod Chandran[5], [1]McMaster University, Hamilton, ON, Canada, [2]University Health Network, Toronto, ON, Canada, [3]Krembil Research Institute, Toronto, ON, Canada, [4]University of Toronto, University Health Network, Toronto, ON, Canada, [5]Schroeder Arthritis Institute, Krembil Research Institute, Toronto Western Hospital, Toronto, ON, Canada

SESSION INFORMATION

Session Date: Saturday, November 6, 2021
Session Title: Spondyloarthritis Including PsA – Basic Science Poster (0046–0068)
Session Type: Poster Session A
Session Time: 8:30AM–10:30AM

Background/Purpose: Psoriatic arthritis (PsA) is an inflammatory arthritis that currently lacks diagnostic biomarkers. We hypothesized that there are differences in the protein intensities in the synovial fluid (SF) of patients with osteoarthritis (OA), rheumatoid arthritis (RA) and PsA. We aimed to identify markers for PsA by proteomic analysis of knee joint SF. Our objectives were to identify proteins and pathways differentially expressed between:

1. OA and the inflammatory arthritides (PsA and RA).
2. PsA and RA.

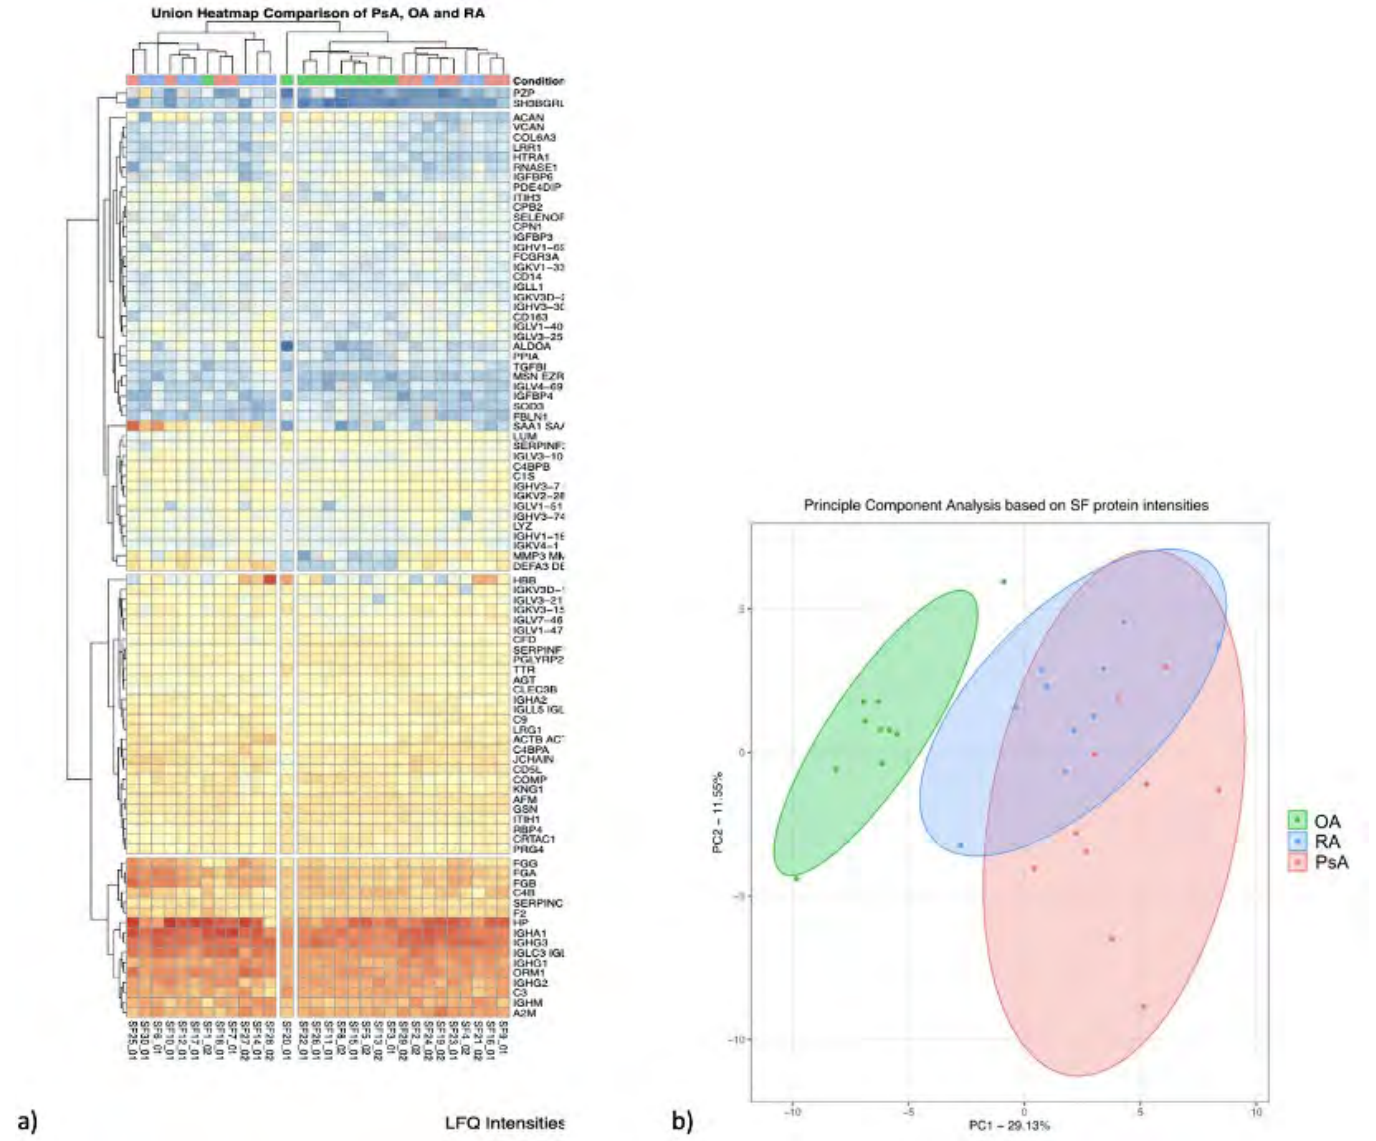

Figure 1. Hierarchical clustering (a) and principal component analysis (b) distinguish OA from the inflammatory arthritides based on mass spectrometry data of proteins with significant differential intensities in at least one of the three comparisons.

Methods: Mass spectrometry was used to identify the SF proteome from 10 OA, 10 PsA, and 10 RA patients. All patients satisfied the classification criteria for their disease. First, we used student's t-test for differential intensity analysis (p-value < 0.05; fold change > 1.5) to identify potential protein biomarkers of each disease. Next, we performed protein-protein interaction (PPI) network and pathway enrichment analysis to obtain biological insights on systems biology of these diseases.

Results: Aim 1: 4 proteins were present and 45 were absent in OA SF compared to PsA and RA. Among those present in all conditions, we detected 56 and 66 proteins with differential intensities in OA compared to PsA and RA, respectively. Hierarchical clustering and principal component analysis confirmed the power of these proteins in distinguishing OA from the inflammatory arthritides (Fig 1). In both comparisons, enriched pathways were involved in inflammation and immune response. Additionally, PPI network analysis of both lists revealed connected subnetworks of proteins with high fold change enriched in immune-system and extracellular matrix (Fig 2a,b). In both comparisons, VIM showed the highest fold change and was central in connecting other high fold change proteins.

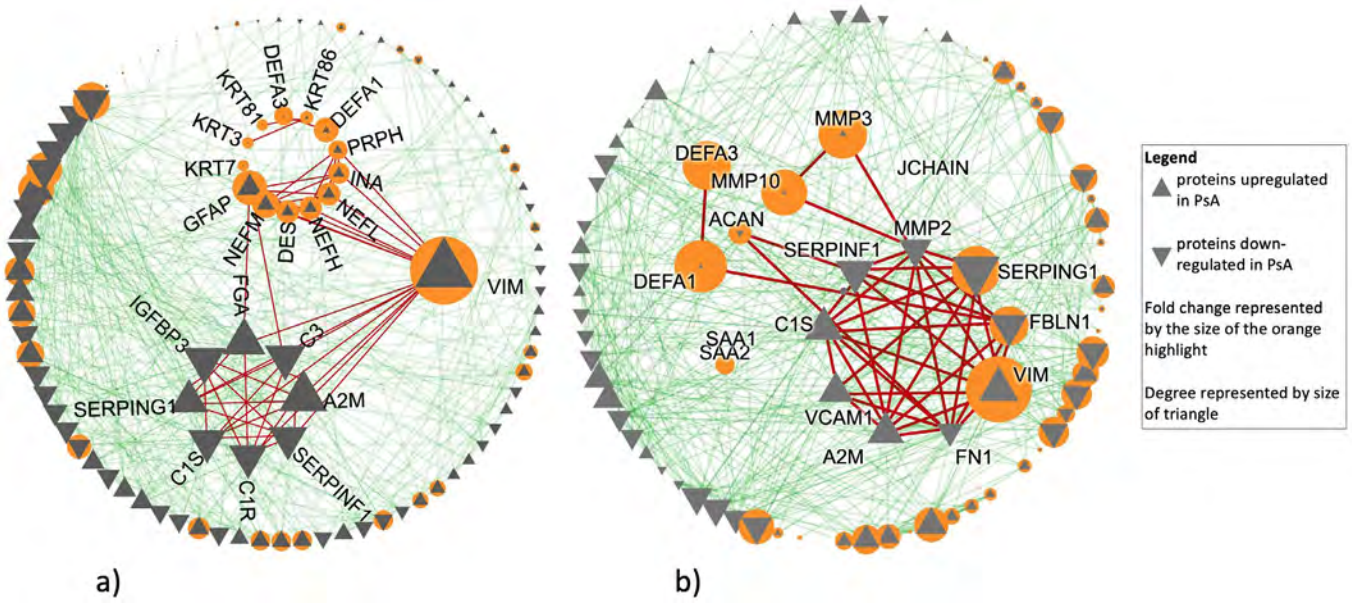

Figure 2. Comparison between OA and the inflammatory arthritides a) OA vs RA b) OA vs PsA. To build the network, we first annotated the physical PPI network (obtained from http://iid.ophid.utoronto.ca) with differential intensities. We expanded the list of differential proteins by relaxing the thresholds for fold change and p-value. Instead, they must interact with at least another differential protein. Next, we selected proteins whose PPI count (degree) and/or fold change was within the top 10th percentile of protein degrees and/or fold changes in each network. Finally, we arranged all other proteins in a big circular layout around these selected proteins. Selected proteins with a high degree form a densely connected network module in both comparisons. In addition, they maintain physical connectivity among proteins with high fold change. PPIs within the proteins inside the large circular layout are shown in red. Networks are visualized in http://navigator.ophid.utoronto.ca/navigatorwp.

Aim 2: 22 proteins with differential intensities between PsA and RA were identified. In addition to immune system pathways, these proteins were enriched in cell metabolism pathways, such as glycolysis which has been previously suggested to distinguish PsA and RA. PPI analysis identified three densely connected network modules (Fig 3a). All upregulated proteins in PsA formed one dense module enriched in complement and clotting pathways (Fig 3b). We identified one highly densely connected subnetwork enriched in transcription-related pathways (Fig 3c) which has four interactions with one upregulated protein (VCAM1). All other proteins were downregulated and have many interactions with the upregulated module. These proteins were highly enriched in glycolysis and glycogenesis, followed by immune pathways (Fig 3d). Previous research has shown interplay between glycolysis and complement pathways. Unlike in Aim 1, VIM shows small but statistically significant differences.

Conclusion: We have identified differential proteins and pathways between PsA, OA, and RA. VIM was a central protein in connecting proteins with differential intensities between OA and the inflammatory arthritides. Additionally, we identified three large network modules enriched in complement, transcription, and glycolysis pathways that may distinguish PsA from RA. Our results suggest disrupted interplay between complement and glycolysis pathways in PsA vs RA.

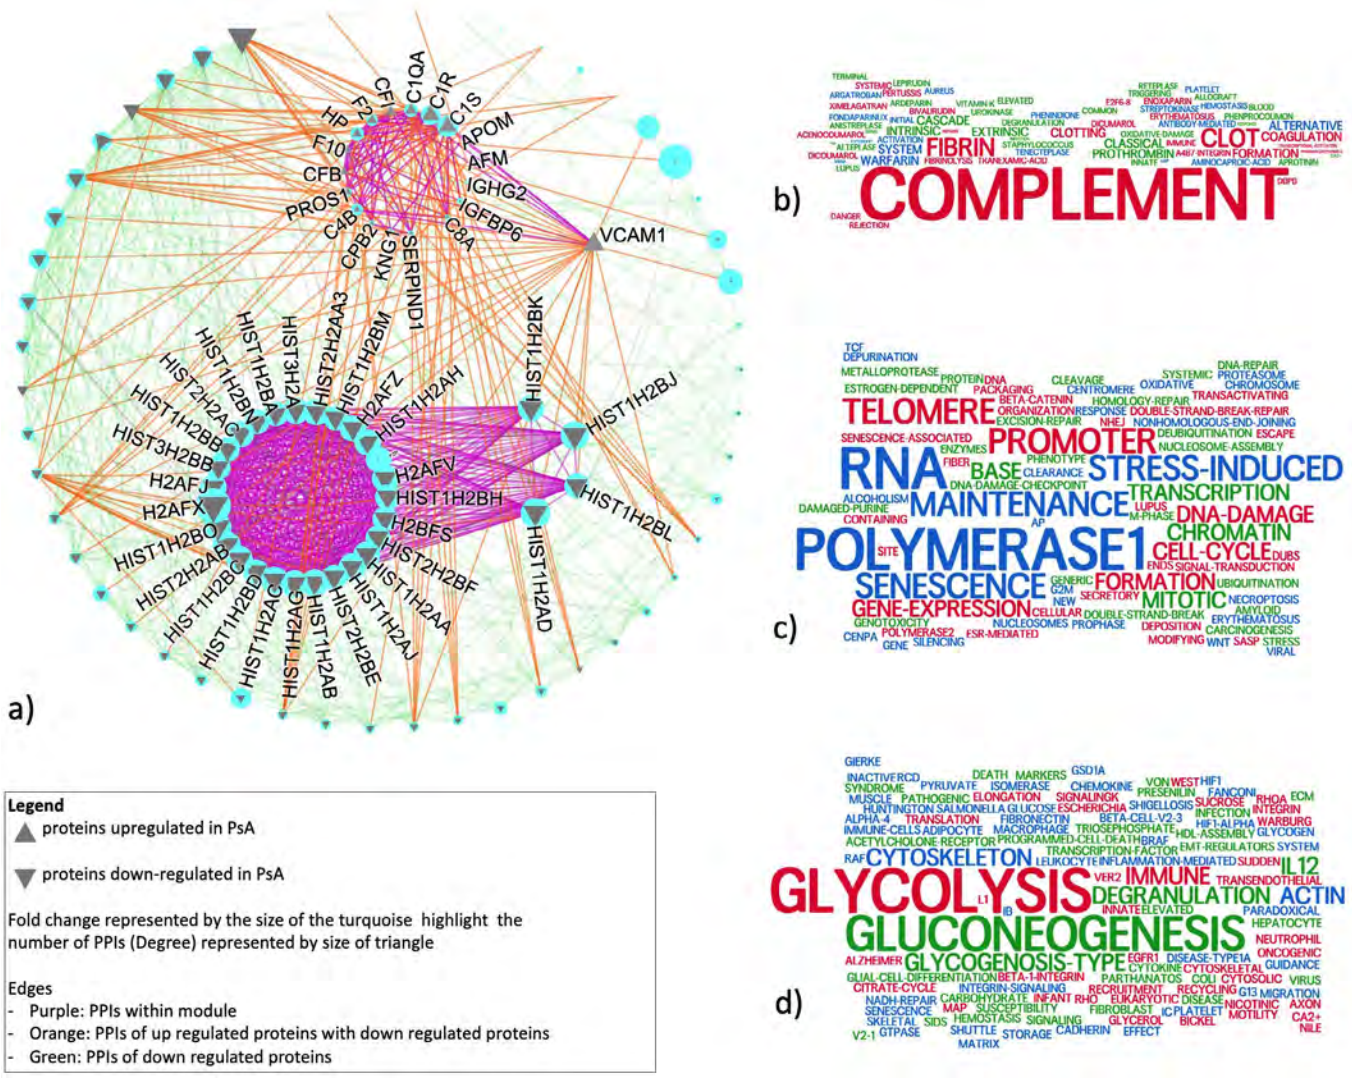

Figure 3. Network and pathway analysis of differential proteins between SF of PsA vs RA. a) To build the network, we first annotated the physical PPI network with differential intensities. We expanded the list of differential proteins by relaxing the thresholds for fold change and p-value. Instead, they must interact with at least another differential protein. Analysis of this network revealed three densely connected modules involved in different pathway groups. Module 1: covers all of the upregulated proteins in PsA compared to RA (arranged in the smallest circular subnetwork); module 2: consists of downregulated proteins with high intra-module connectivity (formed mainly by histone proteins); and module 3: includes all downregulated proteins not in module 2 (arranged on the large network circle). Most of these proteins have interactions with at least one upregulated protein (module 1). b) Key-terms in titles of pathways enriched in proteins of module 1 shows strong enrichment in complement pathways. c) Module 2 is enriched in pathways related to transcription. Polymerase, RNA, and Promoter are three major keywords in the titles of these pathways. This module was also connected to only one upregulated protein in the whole network - VCAM1. d) Proteins in module 3 are enriched in glycolysis and gluconeogenesis. Most proteins in module 3 have PPIs with proteins in module 1 that suggest differential interplay between complement and glycolysis pathways in PsA vs RA. Pathway and key-term analysis are done by http://ophid.utoronto.ca/pathDIP/ and word-clouds are made by http://www.edwordle.net.

Session Title: Spondyloarthritis Including PsA – Basic Science Poster (0046–0068)

Session Type: Poster Session A

Session Time: 8:30AM–10:30AM

Background/Purpose: Axial spondyloarthritis (AxSpA) is immune-mediated inflammatory arthritis, which affects the sacroiliac and spinal joints, and is associated with gut inflammation. Disease pathogenesis is associated with host genetics (HLA-B27), environmental factors, and gut microbial dysbiosis. Previous studies have shown HLA-B27-associated microbial dysbiosis in ankylosing spondylitis patients as well in experimental models of spondyloarthritis. However, not all microbial changes might drive the chronic inflammatory response or elicit host IgA responses. Here, we report the presence of specific IgA-coated microbes that may be disease contributors in AxSpA patients.

Methods: Microbial community structure and IgA coating from feces and saliva samples from AxSpA patients (n=17) and healthy controls (n=12-14) were determined by 16S rRNA sequencing (16S sequencing) and IgA sequencing (IgA-SEQ) respectively. IgA-SEQ involves sorting IgA-coated microbes using flow cytometry and performing 16S sequencing on the IgA positive and negative fractions. Correlation analyses were performed to determine the disease association between IgA-coated microbes in AxSpA patients and the disease activity score. Furthermore, metagenomic contribution of IgA positive and negative microbes was estimated by using the bioinformatic tool PICRUSt2

Results: 16S sequencing of oral and fecal microbiota showed distinct microbial community composition in AxSpA patients as compared with the healthy controls. AxSpA patients showed a significant decrease in oral microbial diversity, whereas the decrease in fecal microbial diversity was not significant. However, the lack of microbial differences in diversity in fecal samples did not suggest a lack of immunological impact of the gut microbes. AxSpA patients had many microbes at a genus level with increased IgA coating (e.g., *Akkermansia*, *Klebsiella*, *Ruminococcus*, *Lachnospira*, *Pseudomonas*) in comparison with the healthy controls. Despite significant changes in microbial diversity in the saliva of AxSpA patients, only a few microbes such as Prevotellaceae*,* NK3831 group, and *Alloprevotella* were enriched in IgA coating. We also found a positive correlation between IgA-coated *Clostridium Family XIII* and the disease activity. Predictive metagenomic analysis of IgA coated microbes showed perturbation of pathways belonging to propanoate and glutathione metabolism, biosynthesis of secondary metabolites, and bacterial secretion system in AxSpA patients. Analysis of individual genes showed the alterations of the genes belonging to the tryptophan and butanoate pathways, further emphasizing the importance of IgA coating in targeting immune responsive bacteria.

Conclusion: We show that the immune response to oral and fecal microbes is altered in AxSpA patients, with IgA coated *Clostridium* positively correlating with disease activity. Predictive metagenome analysis revealed perturbations of metabolic and oxidative stress-related pathways in AxSpA patients. Taken together, our results suggest that

HLA-B27-associated increase in IgA coated microbes may indicate an aberrant immune response to gut commensal microbes, which may contribute to the development of AxSpA.

Susceptibility Factors for Psoriatic Arthritis Single-cell RNA-Sequencing of Patients with Psoriatic Disease

Ameth Garrido[1], Rohan Machhar[2], Omar Cruz Correa[3], Darshini Ganatra[3], Sarah Crome[4], Joan Wither[3], Igor Jurisica[5] and Dafna Gladman[6], [1]Institute of Medical Sciences, University of Toronto, Toronto, ON, Canada, [2]Krembil Research Institute, University Health Network, Toronto, ON, Canada, [3]University Health Network, Toronto, ON, Canada, [4]Ajmera Transplant Centre, Toronto General Hospital Research Institute, University Health Network, Toronto, ON, Canada, [5]Schroeder Arthritis Institute, Krembil Research Institute, Toronto, ON, Canada, [6]Schroeder Arthritis Institute, Krembil Research Institute, Toronto Western Hospital, Toronto, ON, Canada

SESSION INFORMATION
Session Date: Saturday, November 6, 2021
Session Title: Spondyloarthritis Including PsA – Basic Science Poster (0046–0068)
Session Type: Poster Session A
Session Time: 8:30AM–10:30AM

Background/Purpose: Psoriatic arthritis (PsA) is an inflammatory musculoskeletal disease that affects 30% of patients with psoriasis. Thus, early diagnosis of this subgroup is crucial to reduce disease progression and prevent joint destruction. GWAS and epigenome studies have identified major susceptibility genes albeit having low odds ratios. Single cell RNA-seq provides increased resolution to identify novel cell types and cell-specific differential gene expression. We aim to identify a set of genes that can lead to an earlier diagnosis of PsA.

Methods: Three PsA patients, three cutaneous psoriasis (PsC) patients and two healthy control samples were profiled with 10X genomics single cell RNA-seq. The patients recruited were recently diagnosed with PsA and were not treated with biologics. The gene profiles of peripheral blood mononuclear cells (PBMC) were selected for sequencing. The raw data were processed using the CELLRANGER pipeline. R version 4.0.1 was used for secondary analysis using the following packages: SingleCellExperiment, scran, scater and Seurat. These packages were used to cluster the cells and perform differential gene expression analysis. Cell clusters were manually annotated based on canonical markers generated from the 'findallmarkers' function in Seurat and differentially expressed genes were selected in each cluster. A ranking was assigned to genes in each cluster to identify suitable targets for validation by considering the results of the differential gene expression analysis, network analysis using the Integrated Interactions Database version 2018-11, GO and pathway over-representation analysis which was conducted using Pathdip 4.0. A score was assigned to every gene based on their log fold change difference, adjusted p-value in the differential gene expression analysis, closeness centrality and connectivity in the protein interaction network.

Results: The aggregated data revealed the presence of 18 clusters with 15 unique cell types. In the T-Cell and Classical Monocyte populations pathways related to inflammation, cell migration and apoptosis were enriched. Genes belonging to the AP-1 transcription factor JUN, JUNB, and FOS were ranked highly across both T-Cell and Monocyte clusters. Interestingly, the classical monocyte population included several highly ranked genes that are responsive

to interferon-alpha: MNDA and IFI6. The genes that are listed above were found to be consistently differentially expressed across healthy controls and either PSA or PsC.

Conclusion: Several genes were identified in specific cell types; these will be validated using multiple gene and protein assays.

TCR Immune Profiling of Patients with Psoriatic Disease

Ameth Garrido[1], Rohan Machhar[2], Omar Cruz Correa[3], Sarah Crome[4], Joan Wither[3], Igor Jurisica[5] and Dafna Gladman[6], [1]Institute of Medical Sciences, University of Toronto, Toronto, ON, Canada, [2]Krembil Research Institute, University Health Network, Toronto, ON, Canada, [3]University Health Network, Toronto, ON, Canada, [4]Ajmera Transplant Centre, Toronto General Hospital Research Institute, University Health Network, Toronto, ON, Canada, [5]Schroeder Arthritis Institute, Krembil Research Institute, Toronto, ON, Canada, [6]Schroeder Arthritis Institute, Krembil Research Institute, Toronto Western Hospital, Toronto, ON, Canada

SESSION INFORMATION
Session Date: Saturday, November 6, 2021
Session Title: Spondyloarthritis Including PsA – Basic Science Poster (0046–0068)
Session Type: Poster Session A
Session Time: 8:30AM–10:30AM

Background/Purpose: $CD8^+$ and $CD4^+$ T cell subsets have been implicated in the pathogenesis of psoriatic disease. Here, we explore the T-cell repertoire in psoriatic disease using single-cell RNA sequencing to identify novel susceptibility markers of disease by focusing on T cells with clonal expansion.

Methods: We profiled frozen peripheral blood mononuclear cells derived from 3 psoriasis, 3 psoriatic arthritis (biologic naïve, matched for age, gender and disease duration) and 2 healthy control samples using 10X genomics 5' single cell gene expression technology. TCR immune cell profiling was employed, and sequencing data was processed using the CELLRANGER pipeline. We identified 4579 TCRs in psoriasis, 3323 in psoriatic arthritis, and 1843 in healthy control samples. Secondary analysis of TCR beta and alpha chains was conducted in R version 4.0.1 using scran, scater, SingleCellExperiment, Seurat, scREPERTOIRE and Immunarch. The online tool GLIPH2.0 was used to cluster the TCR beta CDR3 amino acid sequences based on motif similarity and VDJdb was used to predict antigen specificity. VDJ gene differential expression analysis was conducted across multiple groups using the Dunn.test function in R.

Results: The shared motifs from the clustering results from GLIPH2.0 comprising only psoriatic arthritis and/or psoriasis patients had a predicted antigen specificity for Cytomegalovirus (CMV) proteins Immediate-Early1 (IE1) or pp65. The variable beta chain genes TRBV2 (FC= 0.14, p-value= 0.033), TRBV7-2(FC=1.49, p-value= 0.0098), TRBV7-7(FC=1.00, p-value= 0.018) and TRBV6-3 (FC= 1.17, p-value=0.033) were elevated and significantly differentially expressed in psoriatic arthritis patients when compared to psoriasis patients. A clonal expansion of $CD8^+$ cytotoxic T-cells was observed in a psoriatic arthritis patient. It accounted for approximately 7% of all clonotypes for that individual. The predicted antigen was IE1 from CMV.

Conclusion: Antigen selection may be occurring in psoriatic arthritis patients. Further investigation is required to determine if the predicted antigens pp65 and IE1 are relevant in the pathogenesis of psoriatic arthritis.

SESSION INFORMATION

Session Date: Saturday, November 6, 2021

Session Title: Spondyloarthritis Including PsA – Basic Science Poster (0046–0068)

Session Type: Poster Session A

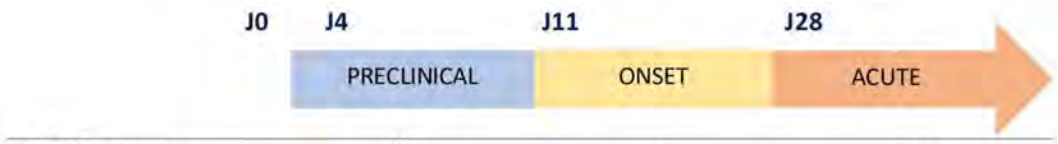
Session Time: 8:30AM–10:30AM

Background/Purpose: Intestinal inflammation (I-Inf) and increased intestinal permeability (IP) and intestinal damage (ID) have been observed in patients with spondyloarthritis (SpA). However, whether these changes might be causal or are the consequence of SpA is unknown. To answer this question, the present study investigated the time-course of I-Inf and IP in a rat model of reactive arthritis, a subgroup of SpA, the adjuvant-induced arthritis model.

Methods: Adjuvant-induced arthritis (AIA) was induced in 6-week-old male Lewis rats by injection at the base of the tail of *Mycobacterium butyricum* in incomplete Freund's adjuvant (Day 0). Control rats received saline. I-Inf and IP were studied at 3 phases of arthritis: pre-arthritic phase (Day 4, AIA-preclinical), onset of arthritis (Day 11, AIA-onset) and acute inflammatory phase (Day 28, AIA-acute). IP was assessed by measuring plasma levels of zonulin (ELISA) and ileal mRNA expression of zonulin and occludin (RT-qPCR). Ileal inflammation was assessed by TCD4+ and TCD8+ lymphocyte count from rat ileum (immunohistochemistry) and by measuring ileal mRNA expression of IL-8, IL-33, IL-17, IL-23p19 and TNF-α (RT-qPCR). The integrity of the intestinal barrier was evaluated by measuring plasma levels of intestinal fatty acid binding protein (iFABP) by ELISA. Joint damage was assessed by determination of an arthritis score (Sa) and of a radiographic score (Sr) of hind paws.

Results: AIA induced arthritis symptoms beginning at day 11, leading to a severe clinical and radiographic arthritic disease at day 28 (Sa=3.9±1.0; Sr=23.8±8.1). Compared to control rats, plasma levels of zonulin increased at pre-clinical phase, at onset but not at the acute phase. While ileal zonulin mRNA expression was enhanced at the onset phase, no change in occludin mRNA expression was observed. Plasma levels of iFABP levels were increased in AIA rats at all stages of arthritis course. Regarding inflammation, preclinical phase was characterized by increased mRNA expression of IL-8, IL-33 and IL-17. At the onset phase, TNF-α, IL-23p19 and IL-8 mRNA expression were increased. No changes in cytokines mRNA expression were observed at the acute phase. Consistent with these findings, increased TCD4+ and TCD8+ number was measured in AIA ileum as compared to controls at Day 4 and Day D11. No correlation was found between clinical and radiographic arthritis scores and zonulin levels. A negative correlation was observed between intestinal IL-8 mRNA expression and Sa. A positive correlation was observed between Sa and the CD4 lymphocyte count.

Conclusion: Intestinal changes associated to reactive arthritis occurred prior the development of articular symptoms. These data are in favour of the "causative" hypothesis of intestinal changes in SpA.



Arthritis score	0	+	++
Radiographic score	0	+	++
Intestinal inflammation	++	++	0
Intestinal permeability	+	++	0
Alteration of intestinal integrity	+	++	++

Peripheral Blood Immune Cell Profiling in Psoriatic Arthritis: Comparison of Patients with Healthy Controls

Lihi Eder[1], Darshini Ganatra[2] and Vinod Chandran[3], [1]University of Toronto, Toronto, ON, Canada, [2]University Health Network, Toronto, ON, Canada, [3]Schroeder Arthritis Institute, Krembil Research Institute, Toronto Western Hospital, Toronto, ON, Canada

SESSION INFORMATION
Session Date: Saturday, November 6, 2021
Session Title: Spondyloarthritis Including PsA – Basic Science Poster (0046–0068)
Session Type: Poster Session A
Session Time: 8:30AM–10:30AM

Background/Purpose: Heterogeneity in immune cell populations among patients with psoriatic arthritis (PsA) may determine disease expression and treatment response. The objective of this study was to compare peripheral blood immune cell profiles in patients with PsA (before- and after- advanced therapy) and healthy controls using mass cytometry.

Methods: Patients with PsA who were initiating treatment with advanced therapies for active peripheral musculoskeletal disease were recruited along with healthy controls. We performed mass cytometry (CyTOF) using a panel of 30 metal-tagged antibodies (Maxpar Direct, Fluidigm) to characterize over 37 immune cell populations in whole blood from patients (before- and 3 months after therapy) and controls. The frequencies of the different immune cells populations were automatically quantified for each sample based on combinations of their associated canonical cellular markers using Probability State Modelling algorithms in a commercially available automated analysis system (MaxparPathsetter, Fluidigm). The levels (counts per 100 cells) of the different cell populations were compared between PsA patients vs. controls and among patients with PsA (before- and after- therapy) using Mann-Whitney U test and cluster analysis was performed using differential cell population levels.

Results: A total of 37 samples from 12 patients with PsA (14 treatment periods) and 9 controls were analyzed. In general, large variability was found in the different cell populations across patients with PsA, while the levels were more homogenous across the controls (Figure 1). Most variability was found in the lymphocytic cells populations, in

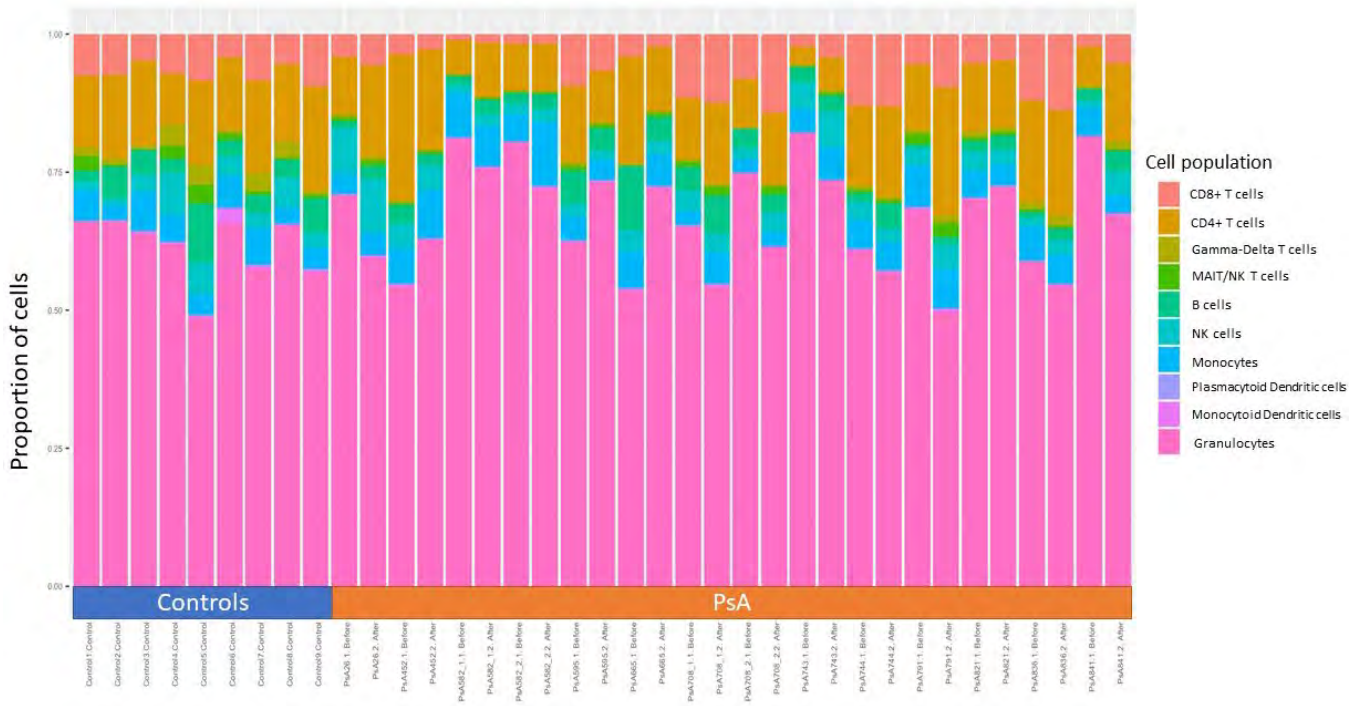

Figure 1. Distribution of the different immune cell populations in PsA and controls.

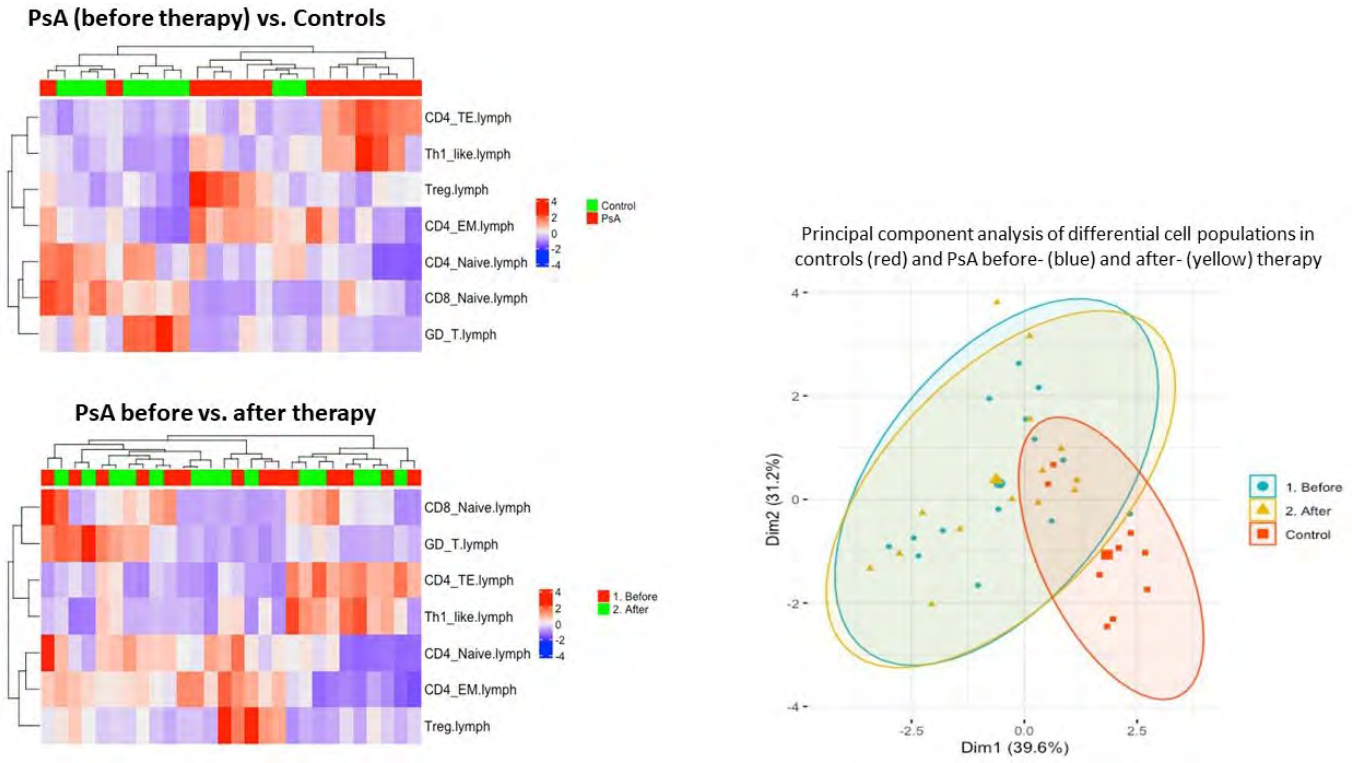

Figure 2. Clustering of PsA (before and after therapy) and controls of differential cell population levels.

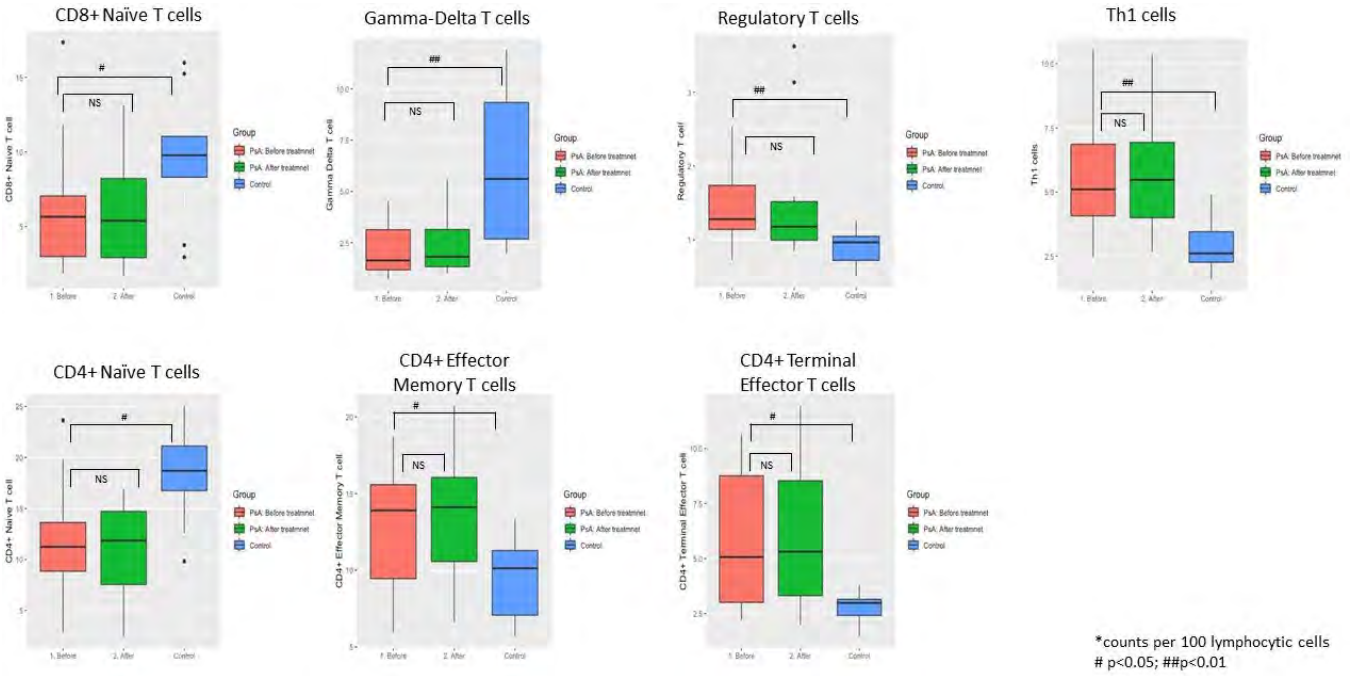

Figure 3. Differences in T cell sub-populations between PsA (before and after therapy) and controls*.

particular among the T cell sub-populations, thus the analysis was restricted to lymphocytic cells. We found significant differences in T cell sub-populations between PsA and controls (Figures 2). Patients with PsA had higher levels of CD4+ Terminal effector and CD4+ Effector memory T cells, CD4+ Th1 cells and CD4+ regulatory T cells, while higher levels of CD8+ and CD4+ Naïve T cells and gamma-delta T cells were found in controls (Figure 3). No significant differences were found in lymphocytic cell populations before and after advanced therapy. In addition, no significant differences were found in the levels of the following cell types and their sub populations between PsA vs. controls and among PsA patients before and after treatment: B cells, NK cells, granulocytes, monocytes and dendritic cells.

Conclusion: Considerable variability was found in T cell sub-populations among patients with PsA. Differences in the levels of specific T cell populations with a shift towards terminal and memory T cells as well as Th1 axis was seen in patients with PsA compared to control. Whether immune cell profile predict response to advanced therapy in PsA remains to be examined.

Session Title: Spondyloarthritis Including PsA – Basic Science Poster (0046–0068)

Session Type: Poster Session A

Session Time: 8:30AM–10:30AM

Background/Purpose: The response to treatment in spondylarthropaties is heterogeneous, due to factors yet to be better described. For that reason, it is important to find tools that might help clinicians to decide what is the best available therapeutic option for each patient.

The goal of this study is to use comprehensive molecular profiling to characterize clinical response to therapy in a real-world setting. Specifically, to identify molecular biomarkers differentiating good responders and non-responders to TNF inhibitors (TNFi) treatment, using adalimumab, in radiographic axial spondyloarthritis | ankylosing spondylitis (r-axSpA|AS) patients context.

Methods: Whole-blood mRNA and plasma proteins were measured in a cohort of biologic naïve r-axSpA|AS patients (n = 35) from the Bioefficacy study (Biomarkers identification of anti-TNF alpha agent efficacy in AS patients using RNA sequencing and mass spectrometry), pre and post (14 weeks) TNFi treatment using adalimumab. Response to treatment was categorized according to ASAS20. Results of differential expression analysis were used to identify the most enriched pathways and in predictive models to distinguish responses to TNFi.

Results: A treatment-related signature, independent of the type of response, suggests a reduction in inflammatory disease activity. We found genes and proteins robustly differentially expressed between baseline and week 14 in responders, including the GWAS AS-associated genes *TNFRSF1A, FCGR2A, TYK2, TBKBP1, IL1R1, IL6R, ICOSLG, IL7R, HHAT and LTBR*. Moreover, CRP and HP proteins showed strong and early decrease in the plasma of AS patients, while a cluster of apolipoproteins (APO1, APO2, APO3) showed an increased expression at week 14. Good responders to TNFi treatment tend to have higher expression of innate immunity genes at baseline, and lower expression of markers associated with adaptive immunity, particularly B-cells. A logistic regression model incorporating

ASDAS-CRP, gender and *Gene x*, the top differentially expressed gene at baseline between responders and non-responders, enabled an accurate prediction of response to adalimumab in our cohort (AUC=0.97).

Conclusion: Differences in disease activity and/or innate/adaptive immune cell type composition at baseline may be a major contributor to response to adalimumab in r-axSpA|AS. Alternatively, a model including clinical and gene expression variables could be considered, particularly in patients with mild disease activity.

Effect of Anti-inflammatory Drugs on Intestinal Epithelial Damage and Bacterial Translocation in the Adjuvant-induced Arthritis Model

Sophie Hecquet[1], Perle Totoson[2], Maude Tournier[2], Clement Prati[1], Daniel Wendling[1], Céline Demougeot[2] and Frank Verhoeven[1], [1]Service de rhumatologie, CHU de Besançon, Besançon, France, [2]PEPITE EA4267, FHU INCREASE, Bourgogne Franche-Comté University, Besançon, France

SESSION INFORMATION
Session Date: Saturday, November 6, 2021
Session Title: Spondyloarthritis Including PsA – Basic Science Poster (0046–0068)
Session Type: Poster Session A
Session Time: 8:30AM–10:30AM

Background/Purpose: The intestine is no longer considered as an organ targeted by spondyloarthritis (SpA) but also an actor of the disease alongside environmental and immunological phenomena. In patients with SpA, increased intestinal permeability (IP) and bacterial translocation (BT) has been described. Whereas anti-inflammatory drugs (non- steroidal anti-inflammatory drugs, NSAIDs, or glucocorticoids, GCs) are known to induce deleterious intestinal changes in the general population, their effects in case of arthritis have been poorly studied. This aim of this study was to determine the effect of NSAIDs and GC on bacterial translocation and intestinal integrity in rats with adjuvant-induced arthritis (AIA).

Methods: AIA was induced in 6-week-old male Lewis rats by injection at the base of the tail of *Mycobacterium butyricum* in incomplete Freund's adjuvant. At first signs of arthritis, rats were treated daily with naproxen (10 mg/kg/day, i.p.), diclofenac (5mg/kg twice daily, i.p.), celecoxib (3 mg/kg/day, i.p.), prednisolone (10 mg/kg/day, i.p.) or vehicle (saline). After 21 days of treatment, intestinal damage was assessed by measure of plasma levels of intestinal Fatty Acid Binding Protein (iFABP, ELISA) and bacterial translocation by measure of serum levels of soluble CD14 (sCD14, ELISA). Joint damage was assessed by the determination of an arthritis score (Sa).

Results: Compared to vehicle, all treatments reduced arthritis score in AIA rats ($p< 0.05$). Compared to AIA-vehicle, treatment with prednisolone and naproxen significantly decreased both circulating iFABP and sCD14 levels. Celecoxib decreased sCD14 but had no effect on iFABP levels. Diclofenac changed neither sCD14 nor iFABP levels.

Conclusion: This study demonstrated that NSAIDs and GC induced changes in intestinal damage and bacterial translocation in arthritis. Contrary to what is observed in healthy population, none anti-inflammatory drug enhanced intestinal damage or bacterial translocation but on the contrary, prednisolone and naproxen decreased these two

parameters. Of interest, our data showed that the effect of NSAIDs is not a class-effect but depends on the balance of cyclooxygenase 1/2 inhibition.

Session Title: Spondyloarthritis Including PsA – Basic Science Poster (0046–0068)
Session Type: Poster Session A
Session Time: 8:30AM–10:30AM

Background/Purpose: Cross talk between different cell types, such as T cell subsets and other immune cell populations, is important in psoriatic disease. Imaging Mass Cytometry (IMC) is a novel technology that enables comprehensive analysis of cellular phenotypes and their interrelationships at the tissue level. We performed a multi-parameter

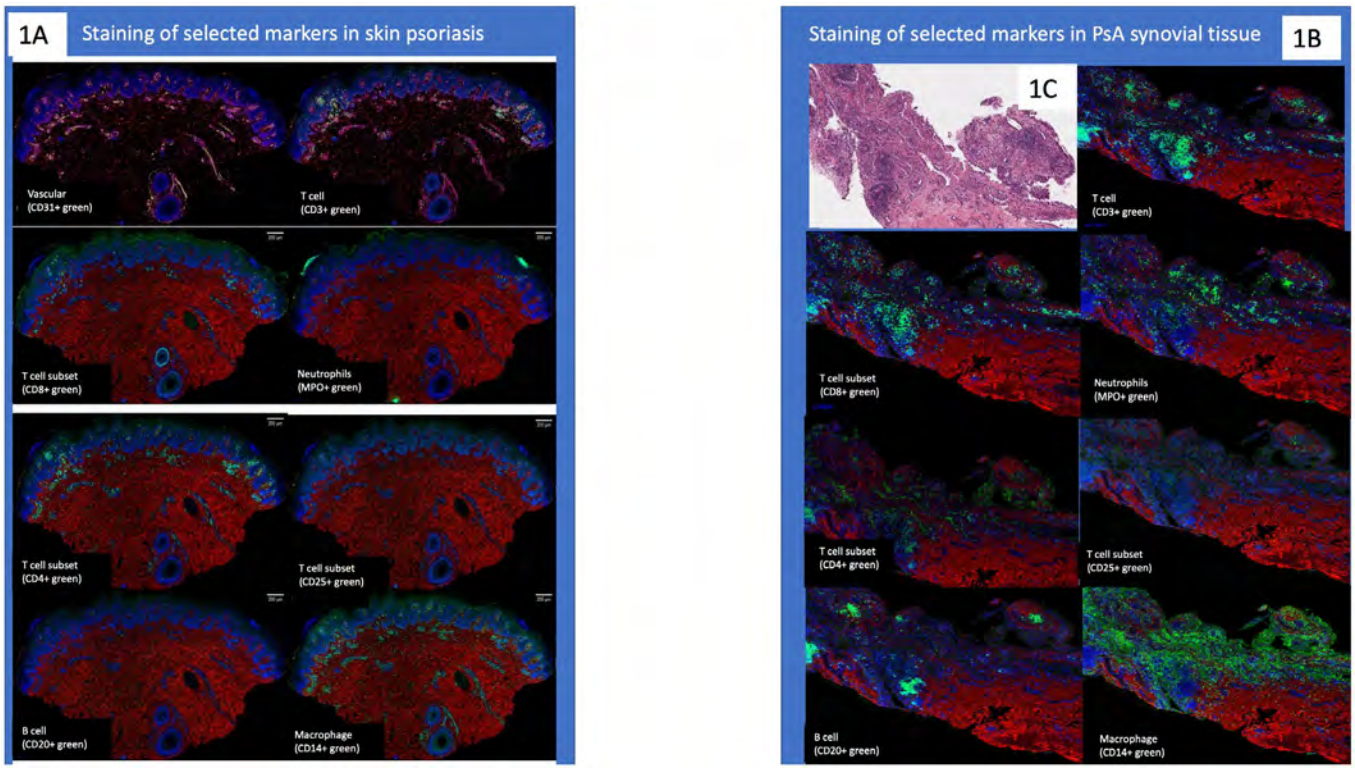

Figure 1. Staining of selected cellular markers using imaging mass cytometry in skin psoriasis (1A) and PsA synovial tissue (1B). Red=Collagen, blue=DNA and green=selected marker. (1C). H&E staining of the same synovial section.

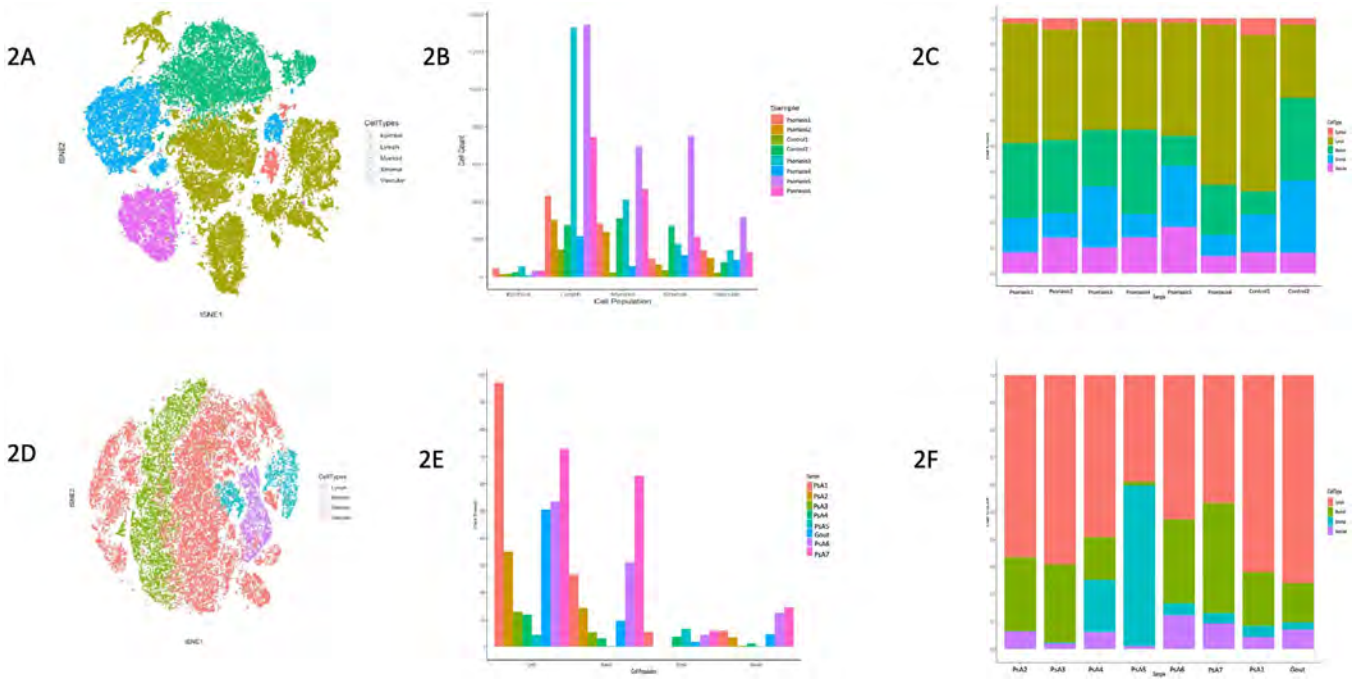

Figure 2. Immune and non-immune cells in skin and synovial tissue in patients with psoriasis and PsA. 2A t-SNE plot of all cell types in psoriasis skin; 2B Distribution of cell population counts in psoriasis skin samples; 2C Proportion of the various cell population types in psoriasis skin samples; 2D t-SNE plot of all cell types in PsA synovium; 2E Distribution of cell population counts in PsA synovium samples; 2F Proportion of the various cell population types in PsA synovial samples.

characterization of various immune cell populations and assessed their spatial interactions in skin and synovial tissue samples from patients with psoriatic disease.

Methods: A total of 6 skin and 7 synovial formalin-fixed, paraffin embedded samples from patients with plaque psoriasis and psoriatic arthritis (PsA), respectively, were analyzed. Additionally, 1 synovial sample from a gout patients and a skin sample from a control patient were analyzed. We used a panel of 36 of metal-tagged antibodies to stain different cell populations. IMC was performed using the Hyperion Imaging System (Fluidigm). Tissue of 5-μm thickness was ablated with Nd:YAG 213 mm laser and analyzed in a Fluidigm CyTOF mass cytometer. Images were analyzed using MCD Viewer. Data were converted to TIFF format and segmented into single cells using previously developed methods. Individual cells were segmented using a combination of in-house program and CellProfiler to classify pixels on the basis of a combination of antibody stains to identify membranes and nuclei. The maps were then segmented into single-cell object masks using CellProfiler. Cell were classified into cell categories based on pre-specified markers (epithelial, vascular, stromal, myeloid and lymphoid) and further classified into immune cells types (T cell, macrophage, B cell, neutrophils, plasma cells). Single-cell marker expressions were summarized by mean pixel values for each channel. To visualize the number of cells per image the cell counts were normalized by the image area (total number of pixels) and displayed as cell density.

Results: Markers identifying stromal and immune cell types performed well and correlated with the expected location and morphological features of the various cell types (Figure 1). Among all cell types in the skin and synovium, lymphoid cells accounted for the most prevalent cell type followed by myeloid cells (Figure 2A-2B). Large degree of inter-patient heterogeneity was found in the prevalence of the various immune cell population across the different skin and synovial samples (Figure 3A-3B). T cells accounted for the largest immune cell type in both skin and synovial samples followed by macrophages and lower counts of neutrophils, B cells and plasma cells. Neighborhood analysis

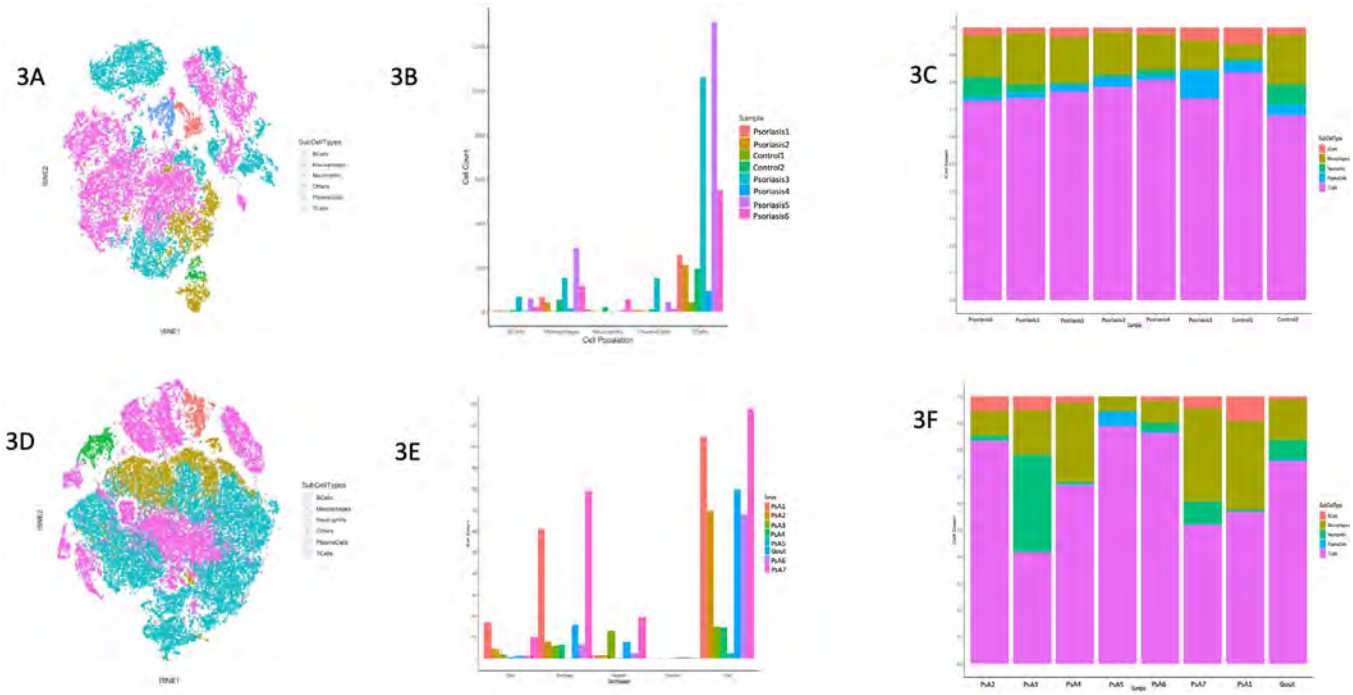

Figure 3. Immune cells in skin and synovial tissue in patients with psoriasis and PsA. 3A t-SNE plot of immune types in psoriasis skin; 3B Distribution of immune cell population counts in psoriasis skin samples; 3C Proportion of various immune cell population types in psoriasis skin samples; 3D t-SNE plot of all cell types in PsA synovium; 3E Distribution of cell population counts in PsA synovium samples; 3F Proportion of the various cell population types in PsA synovial samples.

showed high correlation between CD20+, CD3+, CD4+ and CD8+ in the synovial tissue, which suggest close physical proximity and cross-talk between these T cell subsets and B cells in the synovium.

Conclusion: Innate and adaptive immune cells can be reliably identified using IMC in skin and synovial tissue. Cross talk between T cell subsets and innate immune cells in the skin and synovial tissue plays a role in psoriatic disease. IMC technology provides opportunities for exploring the underlying mechanisms driving psoriasis and PsA.

Lipidomic Profiling Identifies Different Expression of Oxylipins Between Synovial Tissue and Plasma of Patients with Rheumatoid and Psoriatic Arthritis

Abha Singh[1], Jessica Murillo Saich[2], **Roxana Coras**[3], Julio Ramirez[4], Eric Chang[2], Raquel Celis[5], Aaron Armando[2], Oswald Quehenberger[2], Arthur Kavanaugh[2], Juan D Cañete[6] and Monica Guma[7], [1]University of California San Diego, San Diego, CA, [2]University of California San Diego, La Jolla, CA, [3]University of California San Diego/Department of Medicine, Autonomous University of Barcelona, San Diego, CA, [4]Arthritis Unit, Rheumatology Department, Hospital Clinic and IDIBAPS, Barcelona, Spain, [5]Hospital Clinic and IDIBAPS, Barcelona, Spain, [6]Rheumatology Department, Hospital Clinic, Barcelona, Spain, [7]University of California San Diego/San Diego VA Healthcare Service/Department of Medicine, Autonomous University of Barcelona, La Jolla, CA

SESSION INFORMATION

Session Date: Saturday, November 6, 2021
Session Title: Spondyloarthritis Including PsA – Basic Science Poster (0046–0068)
Session Type: Poster Session A
Session Time: 8:30AM–10:30AM

Background/Purpose: Oxylipins are bioactive lipids derived from polyunsaturated fatty acids (PUFAs) that modulate inflammation. Oxylipins derived from n-6 PUFA precursors, such as arachidonic acid (AA), linoleic acid (LA), and dihomo-ylinolinic acid (DGLA), are known for their proinflammatory effects. Oxylipins, derived from the n-3 PUFA precursors such as decosahexanoic acid (DHA), eicosapentanoic acid (EPA), and α-linoleic acid (ALA), have inflammation resolving properties. Several studies have suggested that these mediators in plasma might be biomarkers of synovial pathology. The goal of this study is to evaluate the expression of oxylipins in synovial biopsies obtained from patients with rheumatoid arthritis (RA) and psoriatic arthritis (PsA), and correlate oxylipin levels between synovial tissue and plasma.

Methods: Thirteen patients with established RA and 11 patients with established PsA with active disease in at least one knee or one wrist were recruited, and synovial tissue (ST) was collected by either arthroscopy or ultrasound-guided synovial biopsy. 9 patients with RA and 8 patients with PsA had blood collected at the time of the procedure. Oxylipins in plasma and ST were determined by liquid chromatography with tandem mass spectrometry (LC-MS-MS) and were classified into groups according to their precursor: AA, LA, ALA, DHA, EPA and DGLA. The levels of oxylipins are expressed in pmoles/ml. Data were analyzed using SPSS v27.0 Results were considered significant if the 2-sided P value was less than 0.05.

Results: We included a total of 24 ST and 17 plasma samples. A total of seventy-five oxylipins where identified in ST but only 39 were identified in plasma (Figure 1). While most of the proinflammatory AA-derived oxylipins were detected in both synovial tissue and plasma, several of the anti-inflammatory EPA- DHA- and LA-derived oxylipins

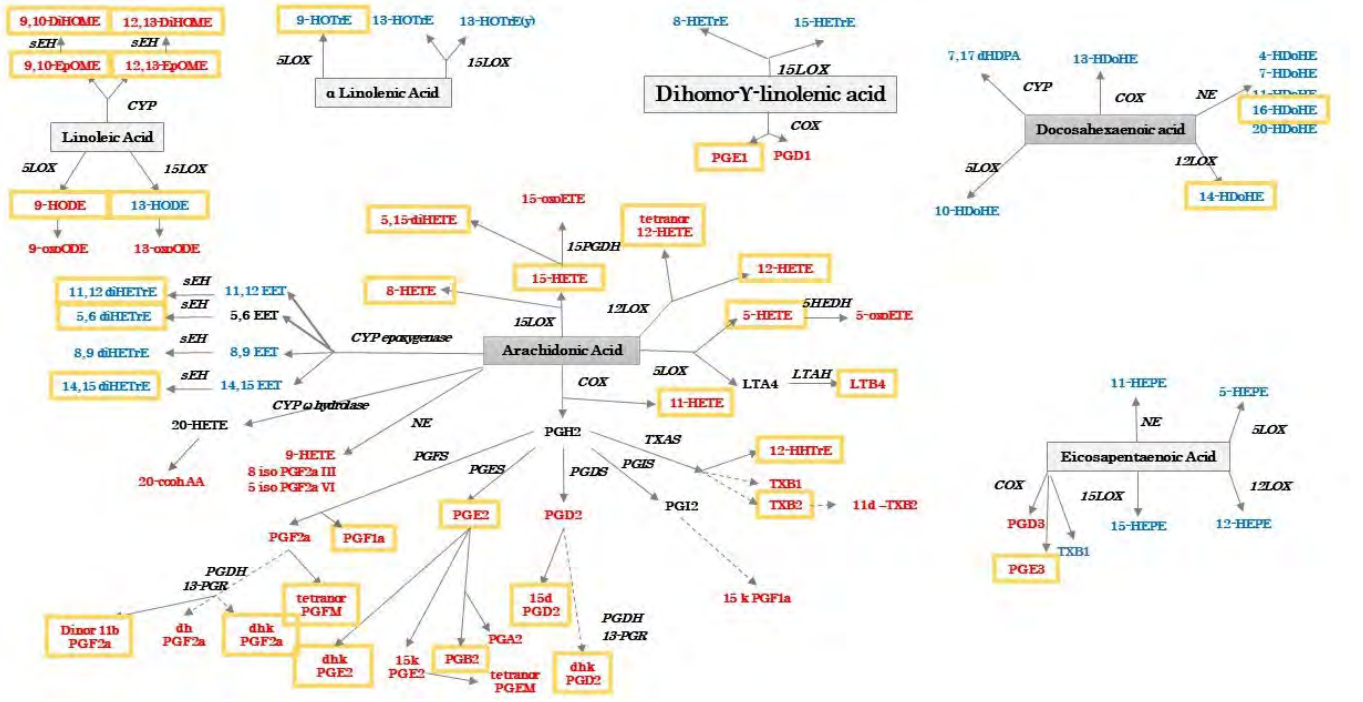

Figure 1. Oxylipins expressed in synovial tissue (n=24). Proinflammatory oxylipins are marked in red and oxylipins associated with resolution of inflammation are marked in blue. In italic, key enzymes involved in oxylipin metabolism. Only 39 oxylipins (in yellow box) were also found in plasma (n=17).

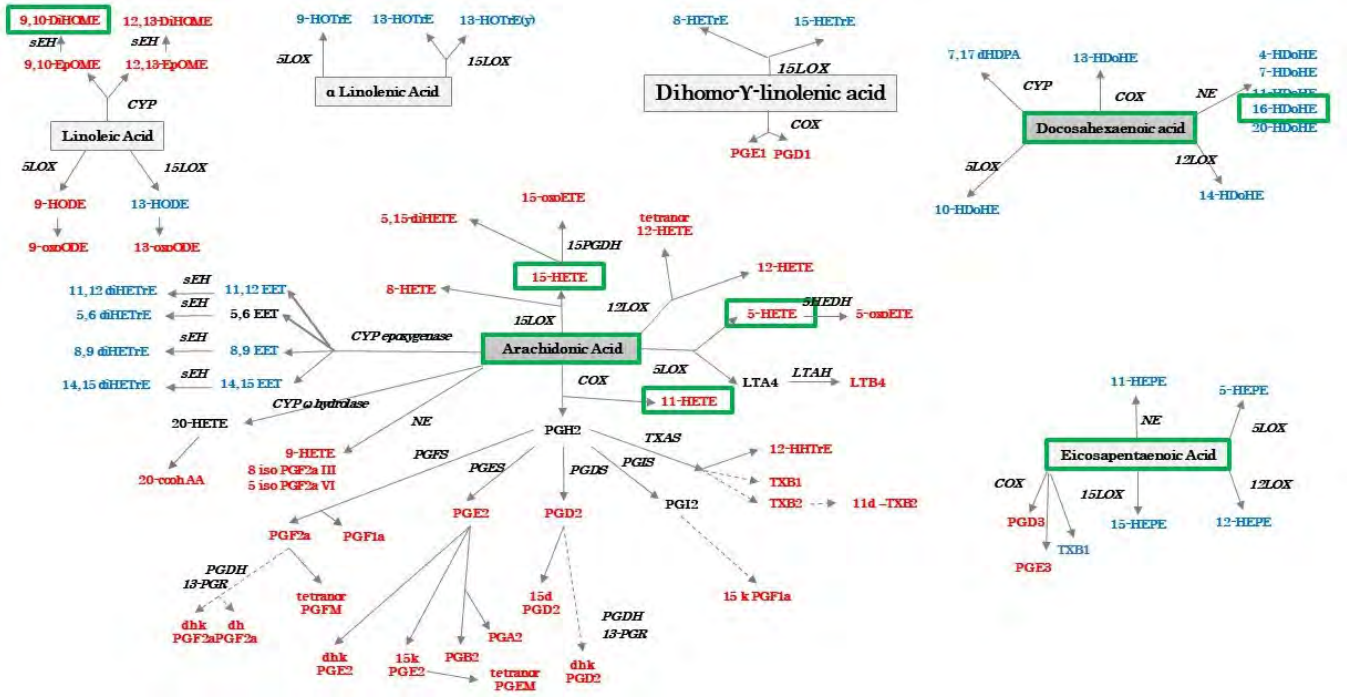

Figure 2. Pearson correlation of oxylipins between synovial tissue and plasma (n=17). Proinflammatory oxylipins are marked in red and oxylipins associated with resolution of inflammation are marked in blue. In italic, key enzymes involved in oxylipin metabolism. Oxylipins with a statistically significant Pearson correlation between ST and plasma are highlighted with a green box.

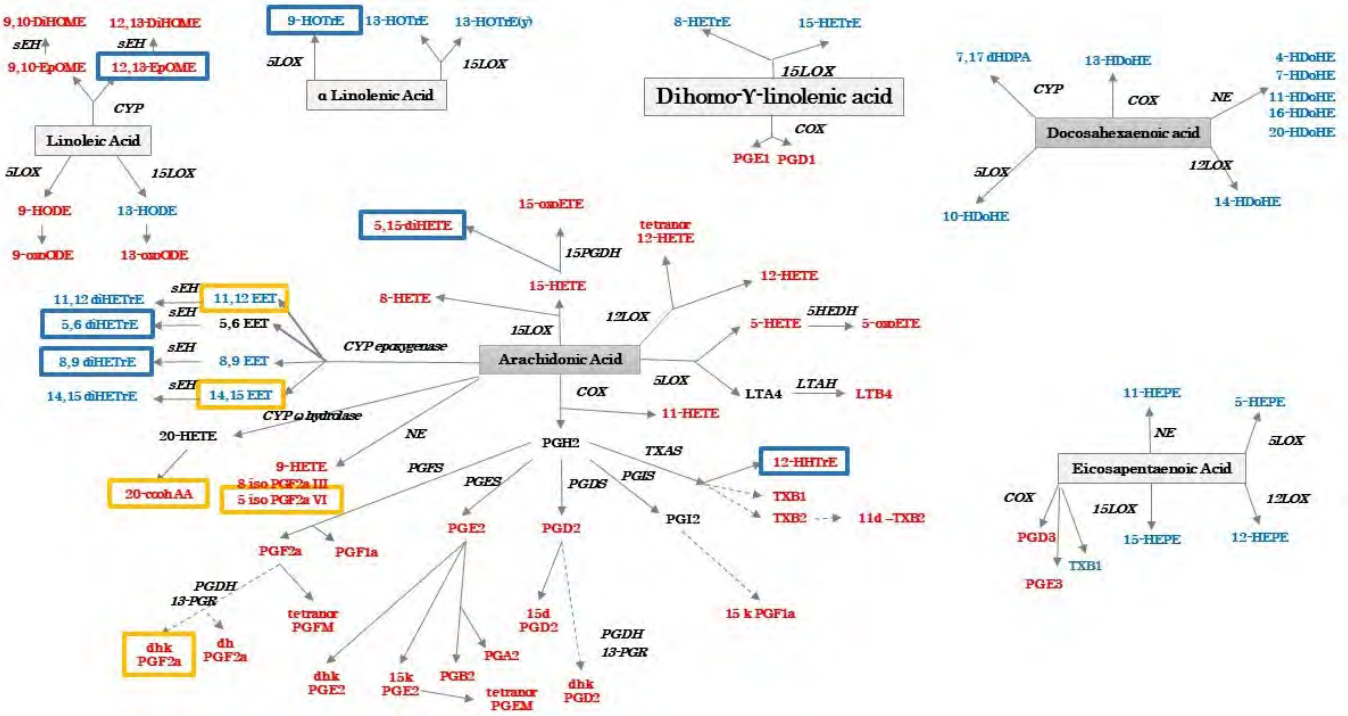

Figure 3. Oxylipin profile in ST from RA and PsA patients. Proinflammatory oxylipins are marked in red and oxylipins associated with resolution of inflammation are marked in blue. In italic, key enzymes involved in oxylipin metabolism. Oxylipins, whose level were higher in RA than PsA are highlighted with a yellow box, whereas the ones whose levels are higher in PsA than RA are highlighted with a blue box.

were only detected in ST (Figure 1). Only levels of 11-HETE, 5-HETE, 15-HETE, 9,10-DiHOME and 16-HDoHE had a statistically significant positive correlation between plasma and ST (Figure 2). In addition, while several oxylipins were different in ST between RA and PsA patients (Figure 3) only the levels of 9-HOTrE and 5,15-diHETE were different between both diseases in plasma.

Conclusion: Lipidomic profiling detected almost twice the number of oxylipin species in synovial tissue as compared with plasma. More importantly, levels of only a few oxylipins correlated between plasma and synovial tissue. This work suggests that lipidomic profiling in synovial tissue can more accurately identify biomarkers than in plasma. Further studies with early, non-treated arthritis patients are needed to determine whether lipidomic profiling of synovial tissue can identify new therapeutic targets in inflammatory arthritis.

Harnessing Spatially-Resolved Gene Expression to Characterize the Transcriptional Landscape of Psoriatic Skin

Rochelle Castillo[1], Ikjot Sidhu[1], Di Yan[1], Piotr Konieczny[1], Rebecca Haberman[1], Brandon Hsieh[1], Andrea Neimann[1], Shruti Naik[1] and Jose Scher[2], [1]NYU Langone Health, New York, NY, [2]New York University School of Medicine, New York, NY

SESSION INFORMATION
Session Date: Saturday, November 6, 2021
Session Title: Spondyloarthritis Including PsA – Basic Science Poster (0046–0068)
Session Type: Poster Session A
Session Time: 8:30AM–10:30AM

Background/Purpose: The skin is recognized as a window into the immunopathogenic mechanisms in the psoriatic arthritis (PsA) joint. This is evidenced by the fact that skin disease precedes joint involvement in ~90% of PsA patients and by the greater degree of overlap between gene expression in the synovial tissue of PsA and lesional skin in psoriasis (PsO) compared to synovium in other forms of inflammatory arthritis.[1] Thus, the study of the psoriatic skin transcriptome has the potential to yield revolutionary insights into the immunopathogenesis of PsA. Spatial transcriptomics (ST) is a ground-breaking technology that allows for mRNA sequencing from histologically-intact tissue sections, facilitating precise localization of the site of gene expression (Fig. 1). A platform for ST (Visium Spatial Gene Expression Solution by 10X Genomics) has been made available; however, it remains to be optimized for human skin tissue, which is inherently challenging to use in transcriptomic studies due in part to its preponderance of RNAses.[2,3] To date, there are no published studies on ST in either healthy or psoriatic human skin. Through a multidisciplinary collaboration, we have successfully optimized both healthy and psoriatic human skin tissue for use with ST.

Methods: Workflow

1. Skin biopsy
2. Cryopreservation

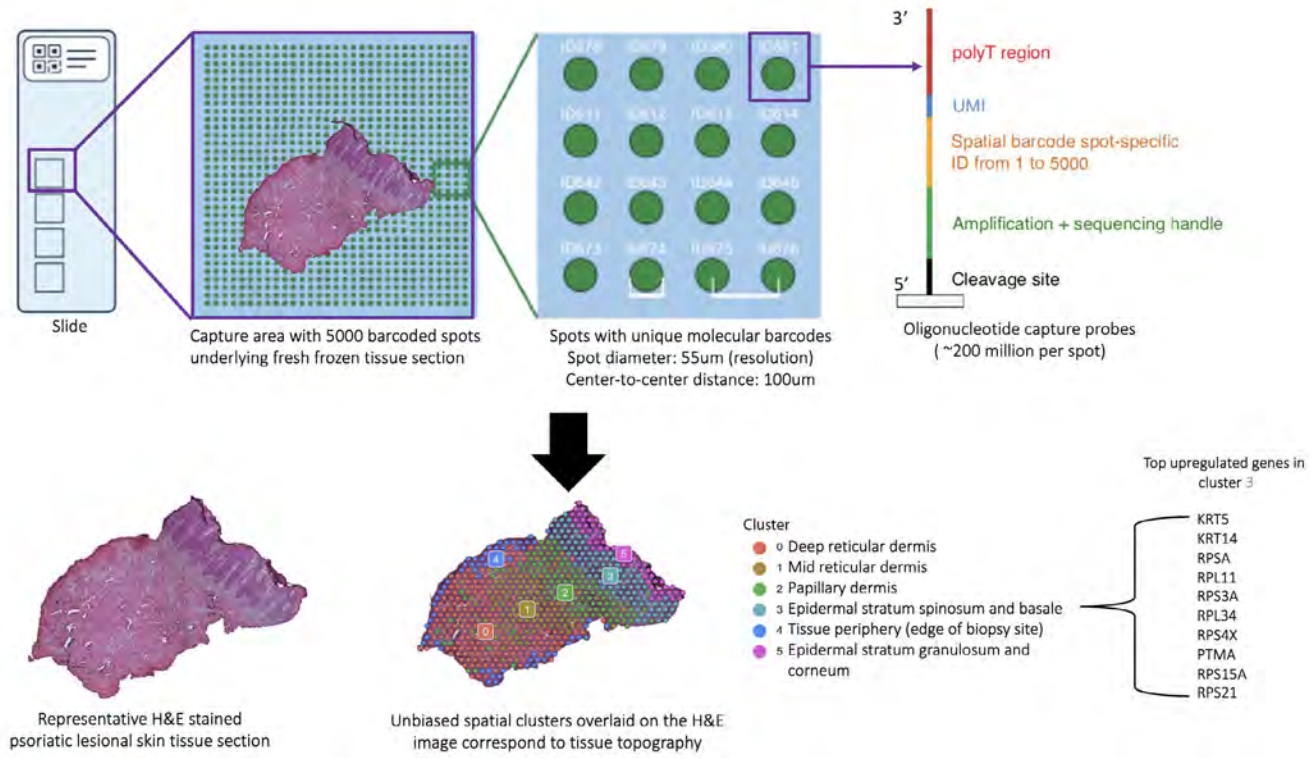

Figure 1. Overview of spatial transcriptomics. The spatial transcriptomics platform utilizes a slide containing four capture areas, each with 5000 molecularly barcoded, spatially encoded spots over which an intact fresh frozen tissue section is placed, stained, imaged, and permeabilized. Permeabilization results in the release of mRNA transcripts from the tissue that are then captured by ~200 million oligonucleotide capture probes. The unique spatial barcode allows the transcripts to be mapped to their exact location in the tissue section. Imaging and RNA sequencing data are processed together, resulting in whole transcriptome gene expression mapped to the tissue image. Each generated spatial cluster represents unbiased grouping based on gene expression and should ideally correlate with tissue topography. Gene expression in each cluster can then be explored.

3. Sectioning and staining
4. Confirmation of RNA integrity
5. Optimization of permeabilization
6. Sequencing
7. Data analysis

Results: To date, we have accrued samples from 3 controls, 4 PsA patients, and 6 PsO patients. All samples met the platform's quality control (QC) metrics for spots and mapping, with reads in spots under tissue >50% (range: 63.1 to 87.1) and reads mapped confidently to exonic regions >30% (range: 80.1 to 91.5). The expected biological variation in transcriptional activity as evidenced by molecular counts (which correlate strongly with unique genes)[4] across disease states and tissue regions was observed, with gene expression strikingly greater in the cell-dense epidermis and in appendageal structures than in the dermis and in psoriatic lesional skin compared to non-lesional and control skin (Fig. 2A). To detect technical variation, two contiguous sections from the same control sample were run on separate slides (Fig. 2B). Clustering and the Uniform Manifold Approximation and Projection (UMAP) plot architecture were consistent between the two replicates. Importantly, accuracy of spatial localization of gene expression and biological consistency of unbiased clustering was observed, with concordance of histopathologically annotated regions with gene-expression based clustering (Fig. 3).

Conclusion: Successful optimization of both healthy and psoriatic human skin tissue for ST was achieved, with all samples meeting the platform's QC metrics. The expected biological variance in transcriptional activity across tissue

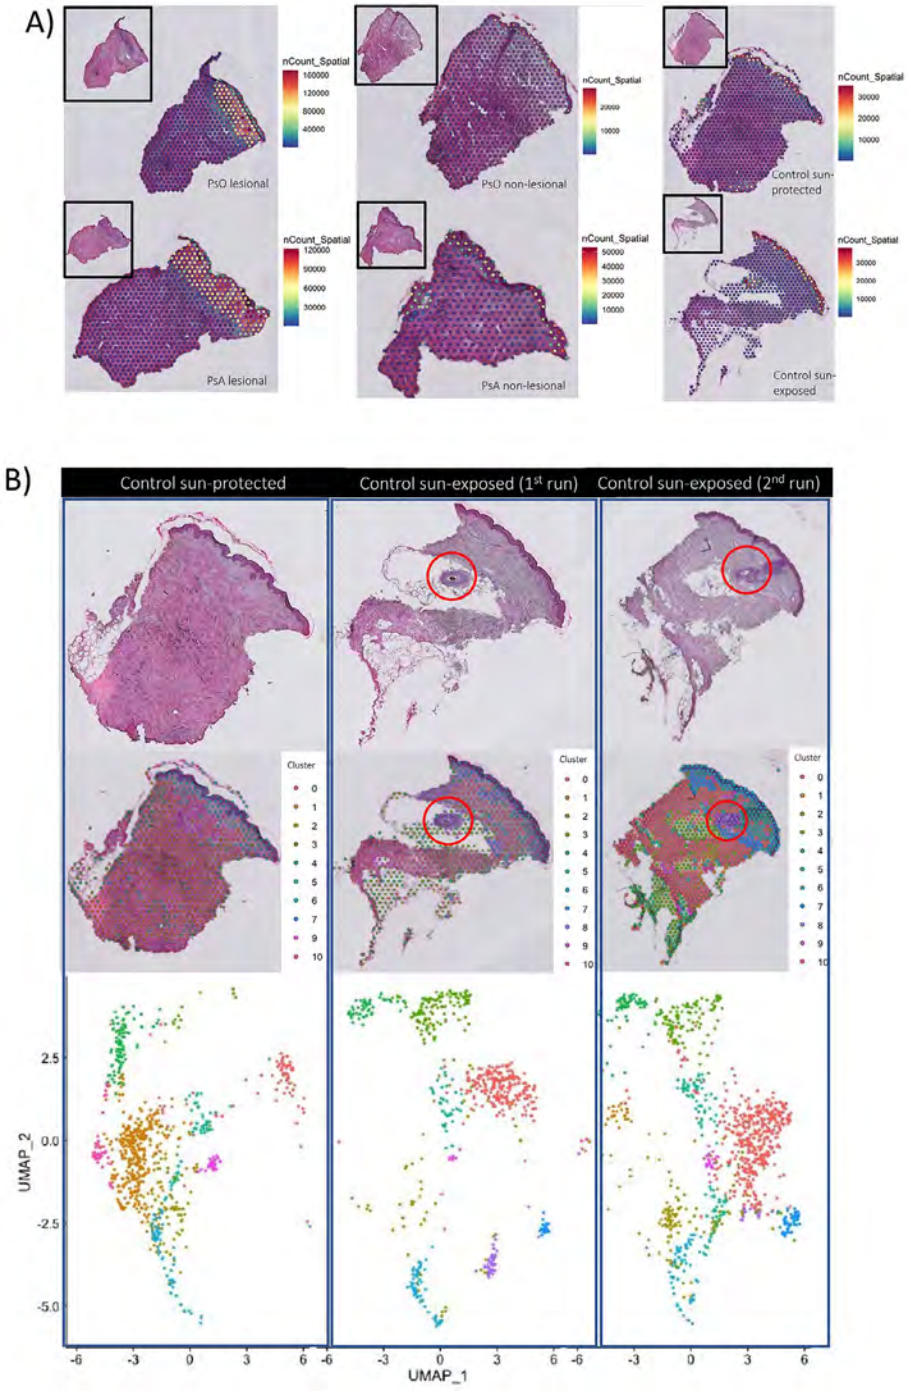

Figure 2. Transcriptional activity and reproducibility of spatial transcriptomics in control (non-psoriatic) and psoriatic skin. A.) Molecular counts mapped to each spot across disease states (psoriatic lesional, non-lesional, control) and tissue regions. Across all disease states, the epidermis and appendageal structures (hair follicles, sebaceous glands) were found to be more transcriptionally active than the dermis, consistent with the much higher cell density in these regions compared to the dermis, which consists mostly of collagen and elastic fibers and ground substance. Lesional skin from PsO and PsA patients was strikingly more transcriptionally active than non-lesional skin and control skin, which is consistent with epidermal hyperproliferation characteristic of psoriatic disease. B.) Determining reproducibility across runs. To detect technical variation, two contiguous sections from the same control sun-exposed skin sample (center and right panel) were run on the ST platform on separate slides. For comparison, results from a separate control sample are also shown (left panel). All three sections were computationally merged to render the clusters comparable. Identical clusters (middle row) and largely similar overall UMAP plot architecture (bottom row) was noted, save for an increase in the density of spots in the second run, which can be attributed to an increase in the volume of tissue overlying the spots. Of note, cluster 8, which contains the hair follicle (encircled in red), does not appear in the control sun-protected sample, which is devoid of hair follicles, and supports accuracy of spatial localization of gene expression.

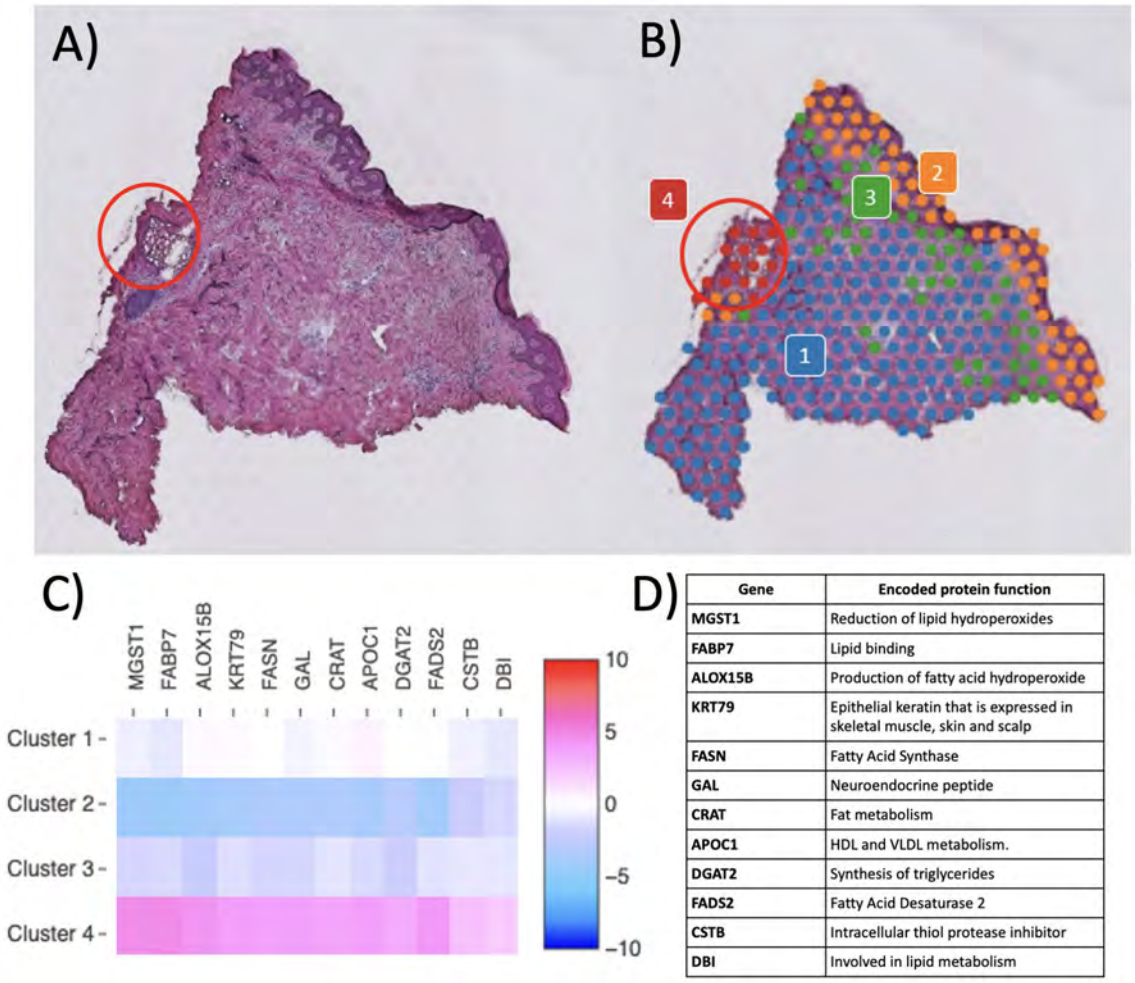

Gene	Encoded protein function
MGST1	Reduction of lipid hydroperoxides
FABP7	Lipid binding
ALOX15B	Production of fatty acid hydroperoxide
KRT79	Epithelial keratin that is expressed in skeletal muscle, skin and scalp
FASN	Fatty Acid Synthase
GAL	Neuroendocrine peptide
CRAT	Fat metabolism
APOC1	HDL and VLDL metabolism.
DGAT2	Synthesis of triglycerides
FADS2	Fatty Acid Desaturase 2
CSTB	Intracellular thiol protease inhibitor
DBI	Involved in lipid metabolism

Figure 3. Concordance of histopathologic annotation with unbiased gene expression-based clustering. A.) H&E stained non-lesional skin section with sebaceous gland manually annotated (encircled in red). B.) Unbiased clustering of spots by gene expression results in unique segregation of sebaceous gland region (Cluster 4) (k means=4). C.) Heatmap of top globally differentially expressed genes (DEG) in the cluster containing the sebaceous glands (Cluster 4). D.) Description of DEG in cluster containing the sebaceous glands. The vast majority are involved in the metabolism of various lipids such as cholesterol, fatty acids, triglycerides which make up sebum, the production and secretion of which is the primary function of sebaceous glands.

regions and disease states was noted, the quantity, quality, and location of reads was biologically consistent, and there was no technical variation between samples. Thus, spatial profiling of gene expression in psoriatic skin through spatial transcriptomics can be performed and has the potential to offer invaluable insights into the immunopathogenesis of psoriatic disease.

SESSION INFORMATION
Session Date: Saturday, November 6, 2021
Session Title: Spondyloarthritis Including PsA – Basic Science Poster (0046–0068)
Session Type: Poster Session A
Session Time: 8:30AM–10:30AM

Background/Purpose: Deep profiling of gut microbiota may reveal new pathways of how SpA and its related diseases such as Crohn's disease (CD) and acute anterior uveitis (AAU) are initiated and perpetuated. The aim of our study was to characterize a shared gut microbiota signature for SpA and its related diseases, as well as for each individual disease, compared with individual controls.

Methods: Patients were recruited with a definite diagnosis of axial SpA, AAU or CD, and were compared with controls (patients with back pain and previously ruled out SpA/CD/AAU diagnosis). Fecal samples were collected, and microbiota composition was determined by 16S rRNA gene sequencing, followed by computational analysis using the LotuS pipeline (v1.62) and referencing the taxonomic classification by the SILVA (v138), Greengenes (v13.5) and HITdb (v1.0.0) databases. Nonparametric Wilcoxon tests were used to calculate differential abundances between binary groups, and the Spearman correlation was used with continuous covariates. Nested linear models and likelihood ratio tests were used to assess confounding with respect to patient characteristics, HLA-B27 expression, inflammatory markers, and the presence of other immune-mediated diseases.

Results: A total of 300 patients were recruited for the study: 111 axial SpA, 110 AAU, and 79 CD patients and were compared with 63 control individuals. The average age was 39.1±12.3 years (mean±SD) and 53% were males. The prevalence of HLA-B27 was 63.0% by all patients (87.4% in axial SpA, 77.3% in AAU and 8.9% in CD patients) compared to 7.9% by control individuals.

At the phylum level, patients with axial SpA, AAU and CD were dominated by Firmicutes, followed by Bacteroidetes and Actinobacteria, except for CD patients who were richer in Proteobacteria than Actinobacteria. At the genus level, patients displayed a shared gut microbiome signature differing from that of control individuals including enrichments in *Veillonella* and *Lactobacillus* (that correlated with increased CRP) and a strong depletion of *Blautia* and other Firmicutes such as *Fusicatenibacter*, *Lachnospiraceae FCS020* and *Roseburia*. By looking at each separate disease phenotype, CD patients differed significantly from the control individuals with respect to many genera. These primarily consisted of depletions in Clostridiales (*Roseburia*, *Coprococcus*, *Ruminococcaceae*), and enrichments of pathogen-harboring genera such as *Escherichia-Shigella* and *Fusobacterium*. Axial SpA patients were uniquely enriched in *Collinsella* and depleted in *Cupriavidus*. HLA-B27+ individuals were enriched in several Firmicutes, most

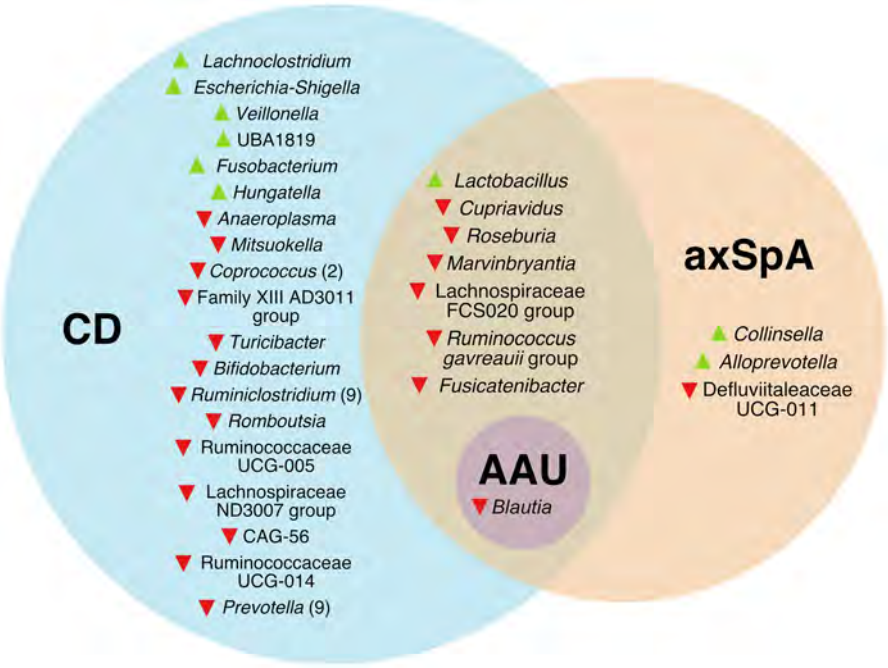

Figure 1. Taxa associations within and between the groups resulting from comparing each with the control group and accounting for disease concomitance and patient characteristics (FDR ≤ 0.05). AAU, anterior acute uveitis; CD, Crohn's disease; SpA, spondyloarthritis.

notably *Faecalibacterium, but also Rominococcaceae* and *Lachnospiraceae NK4A136*. AAU patients shared many of the same enrichments, including a significant increase in *Coprococcus*.

Conclusion: There is a robust shared taxonomic signature among related immune-mediated diseases, in addition to individual disease phenotype signatures. Patients shared a strong depletion in *Blautia* and enrichment in *Veillonella* and *Lactobacillus*. SpA patients were uniquely enriched in *Collinsella*.

SESSION INFORMATION

Session Date: Saturday, November 6, 2021

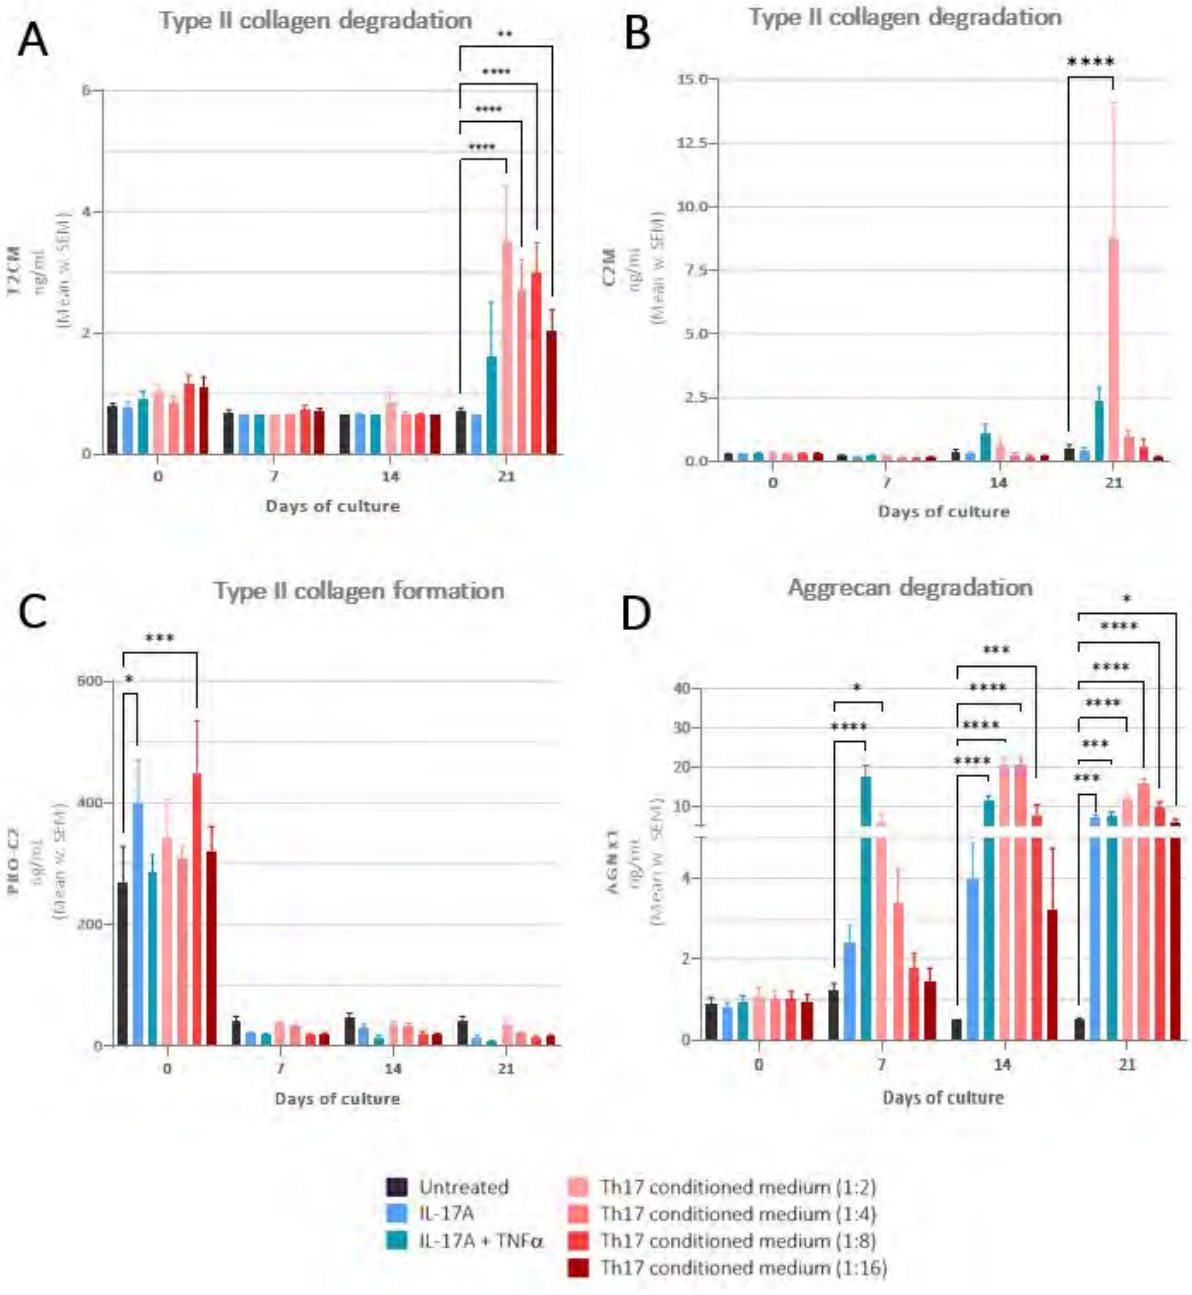
Session Title: Spondyloarthritis Including PsA – Basic Science Poster (0046–0068)

Session Type: Poster Session A

Session Time: 8:30AM–10:30AM

Background/Purpose: In spondyloarthritis (SpA) Th17 cells play a critical role in activating the pathogenic chain leading to manifestations related to skin, joints and entheses. Elevated levels of both Th17 cells and IL-17A have been detected in skin lesions, blood, and synovial fluid from patients with psoriatic arthritis (PsA) and ankylosing

Fig. 1



Extracellular matrix biomarkers quantified in supernatant from bovine cartilage explant model.

spondylitis (AS). The important role of IL-17A in SpA manifestations is reflected by the suppression of disease activity seen with IL-17A inhibitors in psoriasis, PsA and AS. However, it is still not well understood how IL-17A affects the extracellular matrix (ECM) of the joint. The aim of this study is to establish a cartilage model co-cultured with conditioned medium from Th17 cells to explore the effect of IL-17A on joint tissue remodeling.

Methods: $CD4^+$ T cells were isolated from healthy human buffy coat and differentiated into Th17 cells. After 5 days of incubation conditioned medium from Th17 cells was harvested. The Th17 differentiation was confirmed by flow cytometry. Cytokine concentrations were quantified in conditioned medium by ELISA. Bovine cartilage explants (BEX) were cultured for 21 days with 7 different treatments; 1) Culture medium, 2) IL-17A [9.25 ng/mL], 3) IL-17A + TNF-α [9.25 + 20 ng/mL], 4-10) 2-fold titration of Th17 supernatant from 1:2 to 1:16 [9.25 to 0.58 ng/mL]. Each group comprised of 6 replicates. The BEX supernatant-harvest and addition of new treatment were repeated 3 times a week. Metabolic activity was measured by AlamarBlue. Neo-epitope biomarkers of type II collagen formation (PRO-C2) and degradation (T2CM, C2M), together with aggrecan degradation (AGNx1) were quantified in BEX supernatant by ELISA. Differences between groups were compared by two-way RM ANOVA with Dunnett's multiple comparisons test.

Results: The cytokine concentrations of IL-17A/F/AF, IL-22 and TNF-α were quantified to 18.57, 0.05, 2.82, 1.58 and 12.8 ng/mL. In the BEX model, the metabolic activity was stable throughout study. T2CM and C2M were significantly upregulated in groups treated with Th17 conditioned medium at day 21 (Fig.1A-B), while PRO-C2 was downregulated in all groups compared to untreated (Fig.1C). Furthermore, on day 21 the AGNx1 release was significantly increased in all groups compared to untreated (Fig.1D).

Conclusion: The conditioned medium from Th17 cells showed to significantly increase the degradation of type II collagen and aggrecan, while type II collagen formation was decreased. Translational ECM biomarkers combined with *ex vivo* models can have great potential as output for describing joint disease mechanisms and predicting structural effect of treatment on bone and cartilage. Thus, this model may provide early indications of structural treatment efficacy in a clinical setting.

UV: uveitis, AS: ankilosing spondyitis. CRP: c-reactive protein, ESR: Erythrosedimentation rate

spondyloarthritis. These conditions share a number of extra musculoskeletal manifestations, the most common being acute anterior uveitis.

To determine the frequency and characteristics of SpA associated uveitis, to elucidate associated clinical features of SpA in patients with uveitis, and to identify SpA features that can predict flares of uveitis (UV).

Uveitis occurs more commonly in axial SpA (axSpA) than in PsA

Methods: Patients followed in the axSpA and PsA clinics at a single centre from January 2004 to December 2020 at 6–12-month intervals, according to a standard protocol including demographic and clinical variables, treatment and acute phase reactants.

T and chi-squared tests were performed at baseline visits on demographic and clinical factors on both the SpA and PsA populations, to compare patients with and without UV. Cox proportional-hazard models with time-dependent covariates were performed on patients with UV, with their first instance of a UV flare as the outcome event. Univariate analysis was done for each clinical and demographic factor, controlling for age, sex, and disease duration. Factors significant (< 0.1) in the univariate analysis were included in a multivariate analysis, controlling for age, sex and disease duration.

Results: A total of 3306 patients were included, 1724 patients with axSpA and 1582 patients with PsA. 30.2% of the axSpA cohort having uveitis (UV), vs 7.6% in the PsA. The rate of flares per person years at risk was 12.12% in the axSpA cohort, vs 1.71% in the PsA.

Demographic and clinical features are depicted in Table 1. There were more men in the total cohort (axSpA 65% and PsA 56%). More men with UV in the axSpA cohort (65% compared to 47% in the PsA). Most patients were Caucasian (axSpA 67%, 94% PsA)

Among axSpA patients 1169 (68%) were HLA*B27+, and 435 had UV. Among PsA patients 201 (16%) patients were HLA*B27+, and 32 had UV.

The multivariate analysis of the axSpA cohort showed that higher CRP (HR 1.009 p=0.004) increased the risk of a flare, while biologic agents decrease risk of flare (HR 0.702 p=0.040) in patients with UV. In the PsA cohort, being HLA*B27+ (HR 3.084 p=0.007) increased the risk of a UV flare, while being on a DMARD decreased the risk of a flare in patients with UV (HR 0.262 p=0.0088)

Conclusion: The results confirm the hypothesis that uveitis is more common in the axSpA than in the PsA population. New onset of UVs was also more commonly seen in the axSpA cohort. Factors that increase the risk of new uveitis flare were elevated ESR and CRP in the axSpA cohort and being a male or HLA-B27+ in the PsA population.

SESSION INFORMATION

Session Date: Saturday, November 6, 2021

Session Title: Spondyloarthritis Including PsA – Basic Science Poster (0046–0068)

Session Type: Poster Session A

Session Time: 8:30AM–10:30AM

Background/Purpose: Recent studies have shown that microRNAs (miRNAs) play a role in various disorders, including immune mediated inflammatory diseases. Therefore, we studied relationship between miRNA profiles, disease activity and selected clinical manifestations of axial spondyloarthritis (axSpA).

Methods: We studied the whole miRNome in peripheral blood mononuclear cells (PBMC) of patients with non-radiographic (n=38) and radiographic (n=38) axSpA. The miRNA expression was profiled by massive parallel sequencing. The expression of particular miRNAs was correlated with disease activity (ASDAS, BASDAI and CRP) and selected clinical manifestations (e.g. uveitis). Sequencing data were analysed using DESeq2 algorithm, which additionally assessed the relationship of miRNA expression with BASDAI or the presence of uveitis, and the relationship with ASDAS and CRP were analysed using generalized linear modelling with negative binomial assumption (GLM-NB).

Results: Although DESeq2 did not reveal associations between miRNA expression, BASDAI or uveitis; the expression of several miRNAs correlated with the levels of CRP ($p < 0.05$). The pairwise comparison of ASDAS levels by Dunnett`s test revealed that 14 miRNAs were significantly different in axSpA patients with high and very high disease activity compared to patients with inactive disease. The pathway enrichment analysis by MIENTURNET revealed a list of pathways, with emphasis on interleukin (e.g., IL-4, IL-6, IL-10), JAK-STAT and NOTCH signalling pathways, in which dysregulated miRNAs are potentially involved. Additionally, the screening revealed that miR-1246 was differently expressed between radiographic and non-radiographic axSpA patients.

Conclusion: Our results revealed altered expression of several miRNAs in patients with high disease activity of axSpA, which may affect their target genes associated with pathogenesis of the disease.

Characterization of αβTCR of HLA-B*27-Restricted CD8 T-Cell Clones Associated with Spondyloarthropathies

Jose Garrido-Mesa[1], Nicholas Harvey[2], Aimee Hanson[3], Tony Kenna[4], Chi Wong[5], Charles Bridgewood[5], Dennis McGonagle[5] and Matthew Brown[1], [1]King's College London, London, United Kingdom, [2]Molecular Genetics, London, United Kingdom, [3]University of Queensland, Brisbane, Australia, [4]Queensland University of Technology, School of Biomedical Sciences, Brisbane, Australia, [5]University of Leeds, Leeds, United Kingdom

SESSION INFORMATION

Session Date: Saturday, November 6, 2021

Session Title: Spondyloarthritis Including PsA – Basic Science Poster (0046–0068)

Session Type: Poster Session A

Session Time: 8:30AM–10:30AM

Background/Purpose: The mechanism by which HLA-B27 induces Ankylosing Spondylitis (AS) and related disease is unknown, but a leading hypothesis is that it presents 'arthritogenic epitopes' to CD8 T-lymphocytes. Supporting this hypothesis, we have previously demonstrated clonal expansions of CD8 TRB clones adhering to the CASSVG(V/I/L)(Y/F)STDTQYF CDR3 motif in AS patients (PMID: 32162785), which have also been reported by 2 recent independent studies in AS, as well as in samples from patients with bacterial-induced reactive arthritis (PMID: 10201900; 12472659; 28002888). The presence of those clones exclusively in *HLA-B*27*+ve disease points to a common antigen engaged by receptors of similar structure. The aim of our study was to obtain the paired αβTCR carried by these cells, characterize their phenotype, and, furthermore, to determine whether such clones reside at the normal enthesis.

Methods: We used PBMCs of 2 AS donors screened in our previous study and flow-sorted memory CD8 T-lymphocytes carrying the relevant TRBV genes (TRBV9 and TRBV27) to enrich for our low-frequency target population. Using single-cell RNA sequencing, the whole transcriptome and targeted VDJ sequences were obtained. Healthy enthesal tissue (n=3) was obtained from patients undergoing elective spinal surgery and the peri-enthesal bone (PEB) and the enthesis soft tissue (EST) were disaggregated by mechanical and enzymatic digestion. PEB and EST single-cell suspensions were analyzed by flow cytometry.

Results: The analysis of the enriched memory CD8 T cells from AS patients captured 8 different clonal expansions containing the same TRB consensus CDR3 sequence CASSVGL(Y/F)STDTQYF, and all carried the TRBV9 TCRB. These clones all paired with the same TRAV gene and presented similar TRA-CDR3 sequences. These cells were characterized by the expression of KLRB1, LGALS3, DUSP1, GNLY, ID2, FOS, and JUN whilst lacking HLA-II expression, a marker of activation. Higher expression of inflammatory genes was also observed, including the upregulation of CD69, NFKBIA, TNFAIP3, and PDE4D, an AS-relevant therapeutic target. The analysis of the healthy enthesal tissue confirmed the presence of TRBV9 carriers amongst the memory CD8 and CD4 T cell populations in both the PEB and the EST.

Conclusion: This study confirms the identification of expanded CD8 clonotypes in AS patients, carrying highly conserved TCRB CDR3 sequences, and also demonstrates restriction of the clonotypic TCRA carriage to a single TRAV gene in patients studied thus far. This is consistent with AS being driven by exposure to a common antigen presented by HLA-B27 ie the 'arthritogenic peptide' theory of causation of AS. On-going analysis will determine whether the AS-associated clonal expansions resemble the T cell clones that populate the healthy spinal enthesis PEB and EST.

Session Title: Spondyloarthritis Including PsA – Basic Science Poster (0046–0068)

Session Type: Poster Session A

Session Time: 8:30AM–10:30AM

Background/Purpose: Susceptibility to ankylosing spondylitis (AS) is known to be highly influenced by genetic factors, with heritability assessed in twins of >90%, with >115 genetic variants having been demonstrated to be associated with the disease. Assignment of causality from association studies remains challenging, and for many AS-associated loci the key gene and associated protein involved remain unclear. Using large-scale proteomic data-sets and Mendelian randomisation approaches, potential disease-causative associations, where disease-associated

Figure 1. Summary of results obtained from pQTL MR analysis. The direction of regulation was determined from association beta estimates.

genes operate through effects on protein levels to cause the disease concerned, can be investigated. We aimed to identify possible plasma protein level and pathway level changes that may influence the development of AS.

Methods: For the selection of protein exposures, we used an established pipeline (Zheng J et al, 2020). Briefly, this pipeline consisted of five plasma-based pQTL studies of European individuals, in which pQTLs of 1,064 proteins were pooled and used as exposure instruments for MR analysis. We also included a sixth study from a subset of the TwinsUK dataset (n=184, 33 pQTLs) to increase the number of available pQTL exposure instruments in our analysis. To determine AS outcome data for the MR analysis, we used a large-scale GWAS of Caucasian AS cases (n=11,352) vs controls (n=35,446). We performed Mendelian randomisation (MR) using the '*TwoSampleMR*' package in R v4.0.2 to estimate the putative causal effect of the 1,097 plasma proteins on AS incidence. To ascertain the biological effect of the protein changes, we conducted over-representation analysis (ORA) using the GOBP function of the '*clusterProfiler*' package in R to determine pathway changes resulting from likely pQTLs.

Results: We identified 37 plasma proteins showed putative causal link with AS using MR (FDR< 0.05).

Of these, n=19 (45%) SNPs were likely to increase the effector protein, whereas n=23 (55%) were predicted to have a limiting effect on protein expression. Upregulated proteins included ERAP1 (rs27033, rs17482078, rs469735), IL-23R (rs11581607), IL-12B (rs4921484), and IL-1RL1 (rs10179654). Downregulated proteins included IL-27 (rs181209), GSTM3 (rs115929572), IL-5RA (rs77400868), IL-6R (rs4129267), and ERAP2 (rs17408150). The pQTLs corresponded to immune based gene ontology terms such as 'GO:0032693 - negative regulation of IL-10 production', 'GO:0002697 - regulation of immune effector processes', and 'GO:0051707 - response to other organism'.

Conclusion: The results obtained strengthen the hypothesis that immune proteins, particularly cytokines in the IL-23 pathway (including IL-12, IL-23 and IL-27) and their receptor (IL-23R), as well as novel pathways such as the IL-33 pathway, are inherently dysregulated in AS patients. In addition, the 'response to other organism' processes may indicate a possible mechanism for gut dysbiosis in AS. These findings point to novel potential therapeutic targets in AS, and support further research targeting proteins upstream of IL-23R for therapy or prevention of AS.

Gut Bacteria Causing Ankylosing Spondylitis Identified Through Mendelian Randomization Studies

Nicholas Harvey[1], Jose Garrido-Mesa[2], Zhixiu Li[3], David Evans[4], Peter Sternes[5] and Matthew Brown[2], [1]Molecular Genetics, London, United Kingdom, [2]King's College London, London, United Kingdom, [3]Queensland University of Technology, Brisbane, Australia, [4]University of Queensland, Brisbane, Australia, [5]Queensland University of Technology, Bisbane, Australia

SESSION INFORMATION
Session Date: Saturday, November 6, 2021
Session Title: Spondyloarthritis Including PsA – Basic Science Poster (0046–0068)
Session Type: Poster Session A
Session Time: 8:30AM–10:30AM

Background/Purpose: There is strong evidence from animal models, human microbiome profiling studies, genetic analyses, and from the model of reactive arthritis, that AS is caused by interaction of the gut mucosal immune system with the gut microbiome. We and others have recently confirmed expansion of CD8 T-lymphocyte clonotypes, in AS patients but not HLA-B27 matched healthy controls, that are also known to be expanded in bacterial-induced reactive arthritis. As disturbance of the gut microbiome can potentially result from either effects of the microbiome on disease or the converse, we sought to examine the causal impact of the gut microbiome on AS using Mendelian randomisation (MR) methodology.

Methods: We utilised MR analysis to investigate potential causal associations between AS genetics and gut microbiome composition. To determine outcome instruments for MR analysis, we used a large-scale GWAS of Caucasian AS cases (n=11,352) vs controls n=35,446). For the exposure instruments, we obtained publicly available data for genomewide significant microbe QTLs as identified by *Kurilshikov A et al*, 2021 (PMID 33462485). Briefly, the study performed GWAS on a meta-analysed population of European host gut microbiomes as determined by 16S ribosomal sequencing.

Results: We identified a significant protective (β=-0.96, FDR=0.011) causal relationship between presence of *Ruminococcus torques* and AS through the rs35866622 variant, which tags the *FUT2* gene determining secretor status, the ability to secrete ABO blood group antigens and other fucosylated mucus glycans in the gastrointestinal mucosa.

Conclusion: Using MR analysis, we demonstrate that the bacterium *Ruminococcus torques* is associated with the gene *FUT2* to influence the risk of developing AS. The observed negative correlation is consistent with previous findings demonstrating reduced carriage of this taxon in the stool microbiome of AS cases (PMID 31377126; 31662318), and with similar Mendelian randomization study findings in inflammatory bowel disease (PMID 33462485). These results support the hypothesis that AS is a gut microbiome driven disease and encourage the evaluation of novel therapeutic approaches targeting the gut microbiome. Correcting the underlying dysbiosis as part of AS clinical management could result in direct improvement for patients, and we hypothesize could be used as a preventative treatment in individuals at high risk of the disease.

Session Date: Saturday, November 6, 2021

Session Title: Antiphospholipid Syndrome Poster (0069–0083)

Session Type: Poster Session A

Session Time: 8:30AM–10:30AM

Background/Purpose: APS ACTION "Registry" was created to study the natural course of disease over 10 years in persistently antiphospholipid antibody (aPL)-positive patients with/without other systemic autoimmune diseases (SAIDx). The objective of this study was to update the incident first and recurrent thrombosis risk in persistently aPL-positive registry patients, previously reported in 2018 as 1.53% and 2.75%, respectively (*Arthritis Rheumatol*.2018;70[suppl 10]).

Methods: A web-based data capturing system is used to store patient demographics, history, and medications. The inclusion criteria are positive aPL according to Updated Sapporo Classification Criteria tested within one year prior to the enrollment. Patients are followed every 12±3m with clinical data and blood collection; they also receive counseling on cardiovascular disease (CVD) and venous thromboembolism (VTE) prevention at each visit. In this prospective analysis, based on patients who completed 1-8-year follow-up visits, we report the incident thrombosis risk in persistently aPL-positive patients without and with a history of thrombosis. We also compare the demographic and clinical characteristics of patients with and without new thrombosis.

Results: As of March 2021, 886 patients were included: aPL/APS without SAIDx: 546 (aPL without APS classification: 101; thrombotic APS [TAPS]: 320; obstetric APS [OAPS]: 59; and TAPS+OAPS: 66]; and aPL/APS associated with SAIDx: 340 [aPL without APS: 91; TAPS: 178; OAPS: 21; and TAPS+OAPS: 50]). Of 886 patients, 705, 605, 527, 456, 401, 328, 200 and 49 completed 1, 2, 3, 4, 5, 6, 7, and 8-year follow-up, respectively. Mean follow-up was 4.67 years (1270 patient-years [pt-y]) and 4.19 years (2572 pt-y) for those without and with a history of thrombosis, respectively. Based on *13 initial events in 13 patients,* and *67 recurrent events in 54 patients* (Tables 1 and 2), the incident throm-

Table 1: Clinical and Laboratory Characteristics of Patients (Baseline) with Initial and Recurrent Thrombosis Since the Inception of APS ACTION Registry

N (%)	aPL-positive Patients with Initial Events n: 13*	APS Patients with Recurrent Events n: 54**
Mean age ± SD (registry entry)	42.92 ± 13.2	44.63 ± 14.6
Female	11 (85%)	38 (70%)
Systemic Autoimmune Disease	8 (61%)	21 (39%)
aPL Profile		
· Triple aPL-positive	2 (15%)	27 (50%)
· Double aPL-positive	3 (23%)	10 (18%)
· Single aPL positive (aCL or $a\beta_2GPI$)	2 (15%)	3 (5%)
· Single aPL positive (LA)	6 (46%)	14 (26%)
· LA-positive with/without aCL/$a\beta_2GPI$	11 (85%)	46 (85 %)

*3, 2, 5, 2, and 1 initial events reported in 13 patients during the 1st, 2nd, 3rd, 4th and 5th year follow-up periods, respectively. ** 18, 13, 10, 10, 8, 3 , 4, and 1 recurrent events (total: 67) reported in 54 patients during the 1st, 2nd, 3rd, 4th, 5th, 6th, 7th and 8th year follow-up periods, respectively

The APS ACTION registry was created using REDCAP provided by the Clinical and Translational Science Center at Weill Cornell Medical College (CTSC grant UL1 TR000457).

bosis risk was 1.02 and 2.09 per 100 pt-y in patients without and with a history of thrombosis, respectively. Demographics, concomitant lupus, aPL-profile, medications, and non-aPL thrombosis risk factors were not different between aPL-positive patients with (n=13) or without (n=259) first thrombosis, and between APS patients with (n=54) or without (n=560) recurrent thrombosis except APS patients with recurrence were younger and more likely to have triple aPL positivity compared to those without recurrence (42.1 ± 14.1 vs 46.6 ± 13.3, p 0.02, and 31% vs 50%, p 0.006).

Conclusion: Based on approximately 4000 patient-years of follow-up, the incident thrombosis risk in persistently aPL-positive patients remains relatively low (1.02 and 2.09 per 100 pt-y in patients without and with a history of thrombosis, respectively). Lupus anticoagulant and/or triple aPL-positivity, sub-therapeutic international normalized ratios, and additional CVD and VTE risk factors were relatively common at the time of the new events. Future Cox proportional hazards analysis will help us better define the risk and protective factors for thrombosis in persistently aPL-positive patients.

SESSION INFORMATION
Session Date: Saturday, November 6, 2021
Session Title: Antiphospholipid Syndrome Poster (0069–0083)
Session Type: Poster Session A
Session Time: 8:30AM–10:30AM

Background/Purpose: APS ACTION Registry was created to study the natural course of disease over 10 years in persistently antiphospholipid antibody (aPL) positive patients with or without systemic autoimmune diseases. The objective of this analysis was to describe the new pregnancy outcomes of the aPL-positive patients since the inception of the registry.

Methods: A web-based data capture system is used to store patient demographics, history, and medications. The inclusion criteria are positive aPL according to Updated Sapporo Classification Criteria tested within one year prior to enrollment. Patients are followed every 12±3 months with clinical data and blood collection. We identified patients recorded as "pregnant" during prospective follow-up; new "*aPL-related composite pregnancy morbidity*" was defined as: a) preterm live birth (PTLB) at or before 37th week due to (pre)eclampsia (PEC) and/or small-for-gestational age (SGA); and b) fetal death (FD) after the 10th week. In addition to descriptive characteristics, we analyzed pregnancy outcomes based on different aPL-related histories.

Results: Since the inception of the registry in 2012, 77 completed pregnancies were recorded in 55 patients (mean maternal age: 33.4 ± 5.2y; primary aPL/APS: 41 [75%]; and SLE: 14 [25%]) (Table 1). Of 55 patients, 15 (27%) did not

Session Title: Antiphospholipid Syndrome Poster (0069–0083)

Session Type: Poster Session A

Session Time: 8:30AM–10:30AM

Background/Purpose: Damage Index in APS (DIAPS) is a scoring system developed to assess long-term damage in thrombotic primary antiphospholipid syndrome (PAPS), which also correlates with impaired quality of life (EuroQoL) in Latin Americans. DIAPS is not validated in aPL-positive patients without thrombosis. Our primary objective was to quantify damage accrual measured by DIAPS in aPL-positive patients with or without a history of thrombosis in an international cohort. Secondly, we aimed to identify clinical and laboratory characteristics associated with damage in aPL-positive patients.

Methods: In this cross-sectional study, we analyzed the baseline damage, measured by DIAPS, in APS ACTION Registry patients. The inclusion criteria were positive aPL according to Updated Sapporo Classification Criteria tested within one year prior to enrollment. We excluded patients with other autoimmune diseases. We analyzed the demographic, clinical, and laboratory characteristics of patients based on two subgroups: (1) thrombotic APS patients with high (DIAPS ≥3) *versus* low damage (DIAPS < 3); and (2) non-thrombotic aPL-positive patients with damage (DIAPS >0) *versus* without damage (DIAPS=0). Chi-square, Fisher's exact test, Mann-Whitney U and Student t test were used when applicable. In the multivariate analysis, our model included age, gender, race and variables with $p < 0.10$ in the univariate analysis.

Results: Of the 826 aPL-positive patients included in the registry as of April 2020, 576 with no other systemic autoimmune diseases were included in the analysis (412 thrombotic and 164 non-thrombotic [108 aPL only and 56 obstetric]). Baseline demographic, clinical and laboratory characteristics are summarized in Table 1. *For the thrombotic group*, the most frequent domains contributing to damage were peripheral vascular (n=260, 63% - mainly deep vein

Table 1. Demographic, clinical and laboratory characteristics of aPL-positive patients. For thrombotic PAPS, patients were compared regarding the presence of high (DIAPS ≥3) and low damage (DIAPS <3). For the non-thrombotic group, patients were compared based on the presence (DIAPS >0) or absence (DIAPS=0) of damage.

Autoimmune hemolytic anemia	3 (2.7%)	8 (2.6%)	.965	0	4 (3.1%)	.300
Skin ulcer*	20 (18.2%)	3 (1.0%)	**<.001**	3 (8.8%)	0	NA
MS-like disease	1 (0.9%)	1 (0.3%)	.455	1 (2.9%)	0	NA

*Biopsy-proven microthrombosis: 6 (26.1%).
CAPS: catastrophic APS; MS: multiple sclerosis.
The APS ACTION registry was created using REDCAP provided by the Clinical and Translational Science Center at Weill Cornell Medical College (CTSC grant UL1 TR000457).

thrombosis), neuropsychiatric (n=107, 30% - mainly ischemic stroke with sequelae) and cardiovascular (n=57, 14% - mainly heart valve disease). Older age, male gender, hypertension, hyperlipidemia and obesity were associated with high damage (Table 1). In the multivariate analysis, male gender (OR 1.73, 95%CI 1.10-2.71, p=.018) and hypertension (OR 1.90, 95%CI 1.21-2.99, p=.006) were independently correlated with high damage. *For the non-thrombotic group*, the most frequent domains contributing to damage were neuropsychiatric (n=25, 15% - mainly cognitive impairment) and cardiovascular (n=13, 8% - mainly heart valve disease). Hypertension and hyperlipidemia were independently associated with damage in the multivariate analysis (OR 2.72, 95%CI 1.09-6.80, p=.032 and OR 4.48, 95%CI 1.62-12.29, p=.004, respectively). There was no correlation between aPL profile (triple vs double vs single aPL) and damage in either group.

Conclusion: DIAPS was able to discriminate damage in a large multicenter cohort of aPL-positive patients. Traditional cardiovascular risk factors, namely older age, male gender, hypertension, hyperlipidemia and obesity, correlate with higher damage in thrombotic primary APS patients. Hypertension and hyperlipidemia also correlate with damage in aPL-positive patients without a history of thrombosis.

Session Date: Saturday, November 6, 2021

Session Title: Antiphospholipid Syndrome Poster (0069–0083)

Session Type: Poster Session A

Session Time: 8:30AM–10:30AM

Background/Purpose: The APS ACTION Registry was created to study the natural course of antiphospholipid syndrome (APS) over 10 years in persistently antiphospholipid antibody (aPL) positive patients with or without systemic autoimmune diseases (SAIDx). Given data to support the role of immunosuppression (IS) in the management of APS patients with certain clinical phenotypes, e.g, diffuse alveolar hemorrhage (DAH), our primary objective was to characterize IS use in aPL-positive patients without other SAIDx.

Table: Immunosuppressive Medications Recorded (ever) in 50 Primary Antiphospholipid Antibody-positive Patients (Pts) with Selected Non-criteria Manifestations (NCM)[1] (*some patients had more than one NCM simultaneously or at different time points; thus, medications reported were not necessarily used only for the individual NCM*)

Medications (# of Pts)	DAH	aPL-N*	LV**	TP***	HA	VD
Only NCM (# of Pts)	**3**	**3**	**15**	**58**	**6**	**17**
Total NCM (# of Pts)	**5**	**15**	**26**	**85**	**12**	**35**
IVIG (n:26 pts)	3	0	2	19	5	4
RTX (n: 17 pts)	4	4	4	11	2	1
MMF (n: 8 pts)	2	3	4	3	0	0
AZT (n:9 pts)	0	0	1	5	2	3
PE (n:4 pts)	1	0	0	5	0	2
Other (n:6 pts)****	0	0	3	2	0	2
Hydroxychloroquine	2	6	17	38	7	13
Anticoagulation	4	9	23	65	7	31
-Thrombosis Hx (+)	(4)	(9)	(22)	(54)	(5)	(23)
-Thrombosis Hx (-)	(0)	(0)	(1)	(11)	(2)	(8)
Antiplatelet Agent alone	0	5	3	15	5	3
No Antiplatelet Agent + No Anticoagulation	1	0	0	5	0	1

DAH: diffuse alveolar hemorrhage; **aPL-N**: aPL- nephropathy; **LV**: livedoid vasculopathy; **TP**: persistent thrombocytopenia < 100 x 10^9/l; **HA**: hemolytic anemia; and **VD**: cardiac valve disease. **IVIG:** intravenous immunoglobulin; **RTX**: rituximab; **MMF:** mycophenolate mofetil; **AZT**: azathioprine; **PE**: plasma exchange; and **Hx**: history. * Biopsy proven aPL-N=15/15; ** Biopsy proven LV-related skin ulcer=6/26. ***: "Current" (N=27) and "Not Current" (N: 57) at baseline; mean platelet count at baseline: 85 x 10^9/L; ****: Cyclophosphamide (CYC), Cyclosporine, Methotrexate (MTX), Belimumab.

[1]**Potential additional indications in the remaining 20/70 (29%)** patients: lupus- like disease with musculoskeletal, renal, and/or neurologic involvement (n: 6, IVIG, MMF, AZT, CYC, MTX); infertility (n=1, IVIG); anticoagulation-resistant thrombosis (n=2, PE, RTX, AZT); arthralgia (n=2, MTX); autoimmune hepatitis (n=1, AZT); Crohn's disease (n=1, AZT), and unknown (n=7).

Acknowledgment: The APS ACTION registry was created using REDCAP provided by the Clinical and Translational Science Center at Weill Cornell Medical College (CTSC grant UL1 TR000457)

Methods: A central online database was used to collect detailed clinical data. The inclusion criteria were positive aPL based on the laboratory section of the current APS Classification Criteria, tested at least twice within one year prior to enrollment. For this descriptive analysis, we only included aPL-positive patients without other SAIDx and excluded those with catastrophic APS (CAPS). We retrieved data on demographics, aPL/APS-related history including selected non-criteria manifestations (DAH, antiphospholipid-nephropathy [aPL-N], livedoid vasculopathy-related skin ulcers [LV], thrombocytopenia [TP], hemolytic anemia [HA], and cardiac valve disease [VD]); and IS use (ever) (Table).

Results: As of 1/2021, 866 patients were included in the registry; 325 (38%) were excluded due to another SAIDx and an additional five due to CAPS. Of the remaining 536 patients (mean age at entry: 45±13y; 70% female; 70%

white; 432 [81%] meeting the APS Classification; and 143 [27%] with at least one selected non-criteria manifestations), 70 (13%) used IS (ever) excluding corticosteroids (CS) and hydroxychloroquine (HCQ). *Of 70 IS users* (non-CS/HCQ), 50 (71%) had at least one of the selected non-criteria manifestations. *Of 143 patients with at least one of the selected non-criteria manifestations*, 38 (27%) had no history of thrombosis; 19/38 (50%) received anticoagulation with/without antiplatelets, 15/38 (39%) antiplatelets alone, and 4/38 (11%) no antithrombotic agents. Four of 5 (80%) DAH patients, 6/15 (40%) aPL-N, 10/26 (39%) LV, 32/85 (38%) TP, 7/12 (58%) HA, and 9/35 (26%) VD patients were reported to receive non-CS/HCQ immunosuppression (Table).

Conclusion: In our multi-center international cohort, 13% of aPL-positive patients without other systemic autoimmune diseases, mostly those with selected non-criteria manifestations, were reported to use immunosuppressives other than corticosteroids and hydroxychloroquine. Given the inconsistent reporting of immunosuppression use in aPL-positive patients with non-criteria manifestations, systematic studies are urgently needed to better define the role of immunosuppression for different aPL-related non-criteria manifestations.

SESSION INFORMATION

Session Date: Saturday, November 6, 2021

Session Title: Antiphospholipid Syndrome Poster (0069–0083)

Session Type: Poster Session A

Session Time: 8:30AM–10:30AM

Background/Purpose: Data on fluctuation of antibodies against domain 1 (anti-D1) of β_2-glycoprotein I (β_2GPI) are scarce. Patients with antiphospholipid syndrome (APS) and all three criteria tests for antiphospholipid antibodies (aPL) display higher titers of anti-D1, which correlate with aβ_2GPI levels. This project aims at evaluating anti-D1 titers over time in a large international cohort of persistently aPL positive patients.

Methods: AntiPhospholipid Syndrome Alliance For Clinical Trials and InternatiOnal Networking (APS ACTION) Registry was created to study the course of persistently aPL-positive patients with or without autoimmune disorders over at least 10 years. Inclusion criteria are positive aPL by Updated Sapporo Criteria tested within one year prior to enrolment. Patients are followed up every 12±3 months with clinical data and blood collection. Patients with available blood samples from at least three time points were included in this analysis. Anti- β_2GPI and anti-D1 IgG were tested by chemiluminescence (BioFlash, INOVA Diagnostics) at APS ACTION core laboratories. Positive results were defined as >20 CU. Clinical data were retrieved from APS ACTION online database. Anti-D1 titers within the same subject were compared by Friedman's test. The association between categorical and continuous variables was assessed by chi-squared and Spearman's tests.

Results: In this longitudinal study, 1942 samples from 515 patients were tested for anti-D1 and aβ2GPI IgG; 230 patients with anti-D1 tested at ≥3 time points were included (Table). Patients with thrombotic APS had anti-D1 titers significantly higher than those without thrombosis (p=0.022). Among 135 patients with at least one anti-D1 positive result, anti-D1 titers varied significantly over time (Friedman statistics: 508.5, p< 0.0001; anti-D1 geometric mean [95%CI] at baseline 189.0 [115.9-308.3]; T1 132.3 [81.1-215.8]; T2 113.8 [69.8-185.5]; T3 109.2 [66.9-178.1]. Anti-D1 titers were significantly higher at baseline compared to T3 (p=0.029). Over time, anti-D1 titers significantly decreased in 107 patients, and increased in 28 (p< 0.0001). In 11.3% of patients, anti-D1 results changed from positive to neg-

Table: Demongrahic and Clinical Characteristics of 230 APS ACTION Registry Patients with anti-D1 tested ≥3 time points during the follow-up

Demographics	N (%)
Age in years, mean (SD)	12.7 (45.0)
Gender, %F (n)	159 (69.1)
Caucasian	179 (77.8)
APS Classification	
Thrombotic APS	124 (53.9)
Obstetric APS	21 (9.1)
Thrombotic and obstetric APS	26 (11.3)
Primary APS	105 (45.6)
APS with associated autoimmune disease	66 (28.7)
Positive aPL without APS	59 (25.7)
Positive aPL without associated autoimmune disease	30 (13.0)
Positive aPL with associated autoimmune disease	29 (12.6)
Positive criteria aPL (baseline)	
aCL IgG	143/227 (63.0)
aCL IgM	74/227 (32.6)
aβ$_2$GPI IgG	161/227 (70)
aβ$_2$GPI IgM	66/227 (29.1)
Lupus anticoagulant	126/173 (72.8)

ative (n: 20), or negative to positive (n: 6). (Mc Nemar's $\chi 2=6.5$; p=0.011). Anti- β2GPI titers correlated with anti-D1 titers and significantly reduced at T3 compared to baseline (aβ2GPI at baseline 187.1 [14.5-1586.5]; T1 150.8 [11.1-1379.2]; T2 124.9 [12.2-1304]; T3 117.6 [8.7-1136.6]; Friedman statistics=11.32, p=0.010).

Conclusion: Anti-D1 antibodies vary significantly overtime and approximately 10% may become negative during follow up. Our future analysis of the registry will demonstrate the clinical relevance of this variation, and the impact of treatment.

Abstract Number: 0074

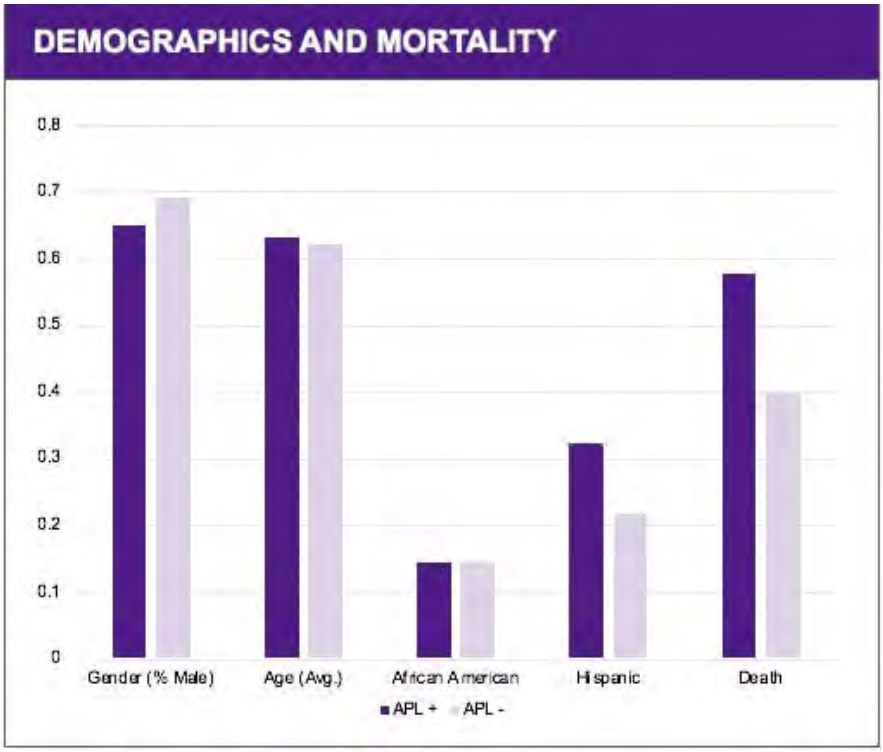
Association of Anti-phospholipid Antibodies (aPL) with Poor Clinical Outcomes in Hospitalized Patients with COVID-19

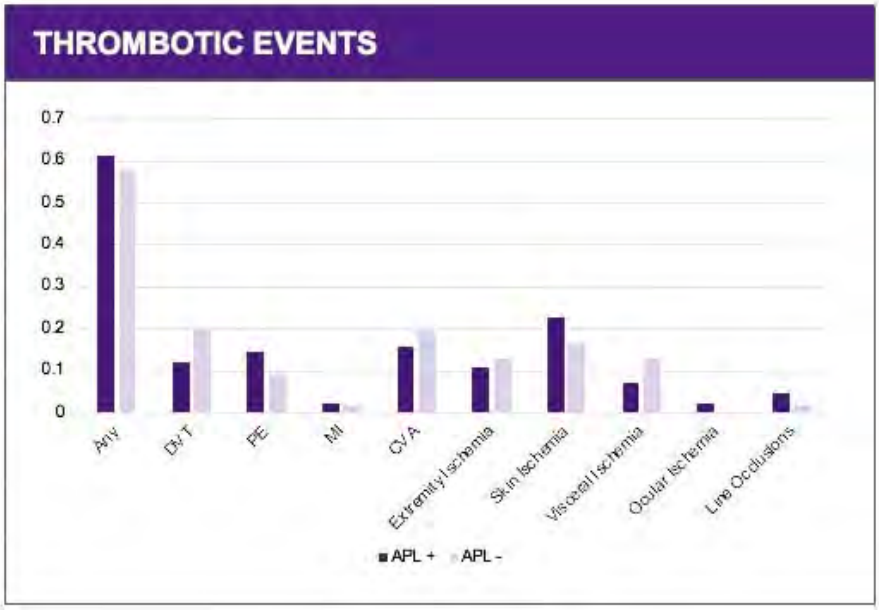
David Yaich[1], Brandon Ptak[1], Emma Roellke[1], Erin Miller[1], Juliet Kim[1], Juan Gaztanaga[1], Wendy Drewes[1], James Ciancarelli[2], Jasmin Divers[1], Megan Winner[1], Amy Rapkiewicz[1] and Steven Carsons[3], [1]NYU Langone Hospital - Long Island, Mineola, NY, [2]NYU Hospital Hospital- Long Island, Mineola, NY, [3]NYU Long Island School of Medicine, Mineola, NY

SESSION INFORMATION
Session Date: Saturday, November 6, 2021
Session Title: Antiphospholipid Syndrome Poster (0069–0083)
Session Type: Poster Session A
Session Time: 8:30AM–10:30AM

Background/Purpose: Critically ill patients with COVID-19 infection have a profound hypercoagulable state and can often develop thromboses in many different vascular beds. Given the presence of anti-phospholipid antibodies among COVID-19 patients reported previously, we hypothesized that poor outcomes and thrombosis could also be promoted by autoimmunity. In this retrospective case control analysis, we aimed to evaluate associations between aPL titers, clinical outcomes and mortality in hospitalized patients admitted with COVID-19 infection.

Methods: We analyzed 138 electronic medical records of patients who were admitted to NYU Langone Hospital - Long Island between the months of March-April 2020 with findings of COVID-19 positivity via PCR and who had aPL titers determined. Patients with elevated titers of beta-2-Glycoprotein IgG, IgM, IgA and/or cardiolipin IgG, IgM, IgA were compared to those who were not elevated. Patients with positive lupus anticoagulant titers only were excluded due to prevalent use of anti-coagulation during this time.





KEY LABORATORY PARAMETERS

Parameter	APLA +	APLA -	P
C-Reactive protein (CRP) mg/L	283.1 (231.3, 358.6)	214.6 (153.7, 321.0)	**0.0007**
D-dimer (ng/ml)	10,805 (4764.5, 30,376.0)	7073 (2144.0, 12,316.0)	**0.04**
Ferritin (ng/ml)	2904.0 (1513.0, 6442.0)	2356.0 (1364.0, 4094.0)	0.31
Interleukin-6 (IL-6) (pg/ml)	227.0 (79.0, 478.0)	89.0 (30.0, 377.0)	**0.04**
Lactic dehydrogenase (LDH) (U/L)	895.0 (692.5, 1306.5)	747.0 (565.2, 1084.2)	**0.01**
Procalcitonin (ng/ml)	4.1 (1.0, 13.6)	3.1 (0.6, 13.6)	0.42
Troponin (ng/ml)	0.3 (0.1, 1.0)	0.2 (0.1, 0.8)	0.12

COVID-19 positive patients with aPL titers were assessed for clinical events (including DVT, PE, MI, CVA, extremity ischemia, skin ulcerations, visceral thrombosis and ocular and line occlusions) and mortality. The control group included patients that were negative for aPL antibody titers. Associations between Anti-Phospholipid (aPL) titer positivity and clinical events was assessed by Chi-square analysis using Fisher's exact test.

Results: The predominant aPL species that was noted in COVID-19 patients was anti-cardiolipin IgM. Of those patients with elevated antibody titers, cardiolipin IgM, IgG, IgA, and β2GPI antibodies were prevalent at rates of 98.9%, 26.7%, 19.2%, and 16.5%, respectively. Multiple aPL isotypes were detected in several patients.

There was a positive association between aPL positivity and elevations in IL-6, CRP, D-dimer, and LDH ($P < 0.05$). There was an increased incidence of clinical events in patients with COVID-19 and positive aPL titers (52/83 or 62%) compared to those who were aPL negative (32/55 or 58%), however this association was not statistically significant.

No significant association was detected between positive aPL titers and gender, age, or self-identified ethnicity. An increased incidence of ARDS and a rising serum creatinine was noted in the aPL positive group (P = 0.03 and P= 0.05 respectively). A significant increase in mortality was identified for the aPL positive group (P=0.01).

Conclusion: These findings suggest that aPL titers may provide insight into disease prognosis and outcome in hospitalized patients with COVID-19. Despite lack of significant association with discrete thrombotic events, association of aPL positivity with rising serum creatinine and ARDS suggest that aPL may contribute to end organ dysfunction through enhanced microthrombosis, resulting in increased mortality.

SESSION INFORMATION
Session Date: Saturday, November 6, 2021
Session Title: Antiphospholipid Syndrome Poster (0069–0083)
Session Type: Poster Session A
Session Time: 8:30AM–10:30AM

Background/Purpose: Patients with COVID-19 are at high risk for occlusion of vascular beds of all sizes. Considering endothelial cell activation has regularly been described as part of the COVID-19 thrombo-inflammatory storm, we aimed to characterize potential upstream mediators of this activation including neutrophil extracellular traps (NETs) and antiphospholipid antibodies (aPL).

Methods: Cultured human umbilical vein endothelial cells (HUVECs) were exposed to sera from 118 patients hospitalized with COVID-19. Plasma samples from 100 non-COVID sepsis patients were also characterized alongside 72 COVID samples. Upregulation of surface cell adhesion molecules E-selectin, ICAM-1, and VCAM-1 was determined by in-cell ELISA. Soluble E-selectin was measured in serum. HUVECs were also stimulated with IgG purified from three COVID patients positive for anticardiolipin IgG and separately five positive for anti-PS/PT IgG.

Results: As compared with sera from 38 healthy controls, COVID sera triggered an activated HUVEC phenotype as evidenced by markedly increased surface expression of the cell adhesion molecules E-selectin (mean 1.67-fold increase, $p< 0.0001$), VCAM-1 (mean 1.89-fold increase, $p< 0.0001$), and ICAM-1 (mean 1.66-fold increase, $p< 0.0001$). While non-COVID sepsis plasma elicited higher expression of surface ICAM-1 than did control plasma, the effect was even more robust with COVID-19 plasma ($p< 0.05$ comparing COVID-19 to sepsis). Beyond the in-cell ELISA platform, we also found significantly higher levels of soluble E-selectin in COVID serum as compared with healthy controls ($p< 0.0001$), where it correlated with clinical parameters that track with COVID-19 severity including C-reactive protein ($r=0.31$, $p=0.005$), D-dimer ($r=0.31$, $p=0.008$), calprotectin ($r=0.29$, $p=0.003$), and oxygenation efficiency ($r=-0.31$, $p=0.002$). One marker of NET remnants, myeloperoxidase-DNA complexes, modestly correlated with the ability of serum to increase expression of both VCAM-1 ($r=0.26$, $p< 0.01$) and ICAM-1 ($r=0.28$, $p< 0.01$) on

Table 1: Correlation of HUVEC cell adhesion molecules with antiphospholipid antibodies in COVID patients

	E-selectin		ICAM-1		VCAM-1	
Spearman	r	p	r	p	r	p
Antiphospholipid antibodies						
IgG anticardiolipin	0.450	****	0.346	***	0.421	****
IgM anticardiolipin	0.365	****	0.357	****	0.252	**
IgG anti-β_2GPI	0.145	ns	0.076	ns	0.213	*
IgM anti-β_2GPI	0.017	ns	0.150	ns	0.047	ns
IgG anti-PS/PT	0.439	****	0.299	***	0.252	**
IgM anti-PS/PT	0.249	**	0.276	**	0.115	ns
Other biomarkers						
C-reactive protein	-0.008	ns	0.003	ns	0.173	ns

Calprotectin	0.187	*	0.197	*	0.203	*
ns=not significant; *p<0.05, **p<0.01, ***p<0.001, and ****p<0.0001						

HUVECs, while cell-free DNA and citrullinated histone H3 (additional markers of NETs) correlated with VCAM-1 only (r=0.24, p< 0.05 and r=0.22, p< 0.05, respectively). Interestingly, we detected robust correlations between various aPL in serum, especially anticardiolipin IgG/M and anti-phosphatidlyserine/prothrombin (anti-PS/PT) IgG/M, and the three markers of HUVEC activation (E-selectin, VCAM-1, and ICAM-1) (Table 1). As compared with mock depletion, IgG depletion strongly abrogated the ability of pooled COVID sera (anticardiolipin-positive and anti-PS/PT-positive) to upregulate HUVEC E-selectin (p< 0.01 and p< 0.05, respectively), VCAM-1 (p< 0.05 and p< 0.01) and ICAM-1 (p< 0.01 for both). Furthermore, IgG (100 µg/ml) purified from the anticardiolipin-positive and anti-PS/PT-positive COVID serum increased expression of ICAM-1 (p< 0.01 for both) when spiked into control serum.

Conclusion: These data are the first to suggest that patient antibodies are a driver of endothelial cell activation in COVID-19 and add important context regarding thrombo-inflammatory effects of aPL-like autoantibodies in severe COVID-19.

Predicting the Transitions Between Lupus Anticoagulant Status and Thrombosis in SLE Using a Multi-state Markov Model

Selcan Demir[1], Jessica Li[2], Laurence Magder[3] and **Michelle Petri**[4], [1]Hacettepe University Faculty of Medicine, Ankara, Turkey, [2]Johns Hopkins University, Baltimore, MD, [3]University of Maryland, Baltimore, Baltimore, MD, [4]Johns Hopkins University School of Medicine, Baltimore, MD

SESSION INFORMATION

Session Date: Saturday, November 6, 2021
Session Title: Antiphospholipid Syndrome Poster (0069–0083)
Session Type: Poster Session A
Session Time: 8:30AM–10:30AM

Background/Purpose: Antiphospholipid syndrome (APS) is a significant cause of morbidity and mortality in patients with SLE and lupus anticoagulant (LAC) positivity is the best predictor of thrombosis. However, in SLE LAC positivity can fluctuate over time. We determined the probabilities of transitions between the lupus anticoagulant states and thrombosis, and identify predictors of these transitions.

Methods: SLE patients in a longitudinal cohort had LAC determined using ISTH guidelines at every visit. A dRVVT of 45 or more seconds and a positive confirm ratio of more than 1.4 were defined as positive for LAC. Missing values were handled using multiple imputation based largely on the degree of elevation of dRVVT. At each visit, patients were classified into state 1 (a negative LAC), state 2 (a positive LAC), or state 3 (thrombosis). Multistate Markov models were used to provide estimates of relative transitions rates and to identify predictors in these transitions. The multiply imputed datasets were analyzed for complete data by imputation. Then, the results were pooled from the multiple analyses.

Table 1. The observed transitions in states between visits for patients in the Hopkins Cohort

From \ To	LAC-	LAC+	Thrombosis
LAC-	32888 (97.6%)	626 (1.9%)	200 (0.6%)
LAC+	640 (35.5%)	1135(63%)	26 (1.5%)

Table 2. Transition probability between states after SLE diagnosis and expected time in each state. The table presents the estimated probability from state 1 (LAC-), state 2 (LAC+) to the LAC states and to first thrombotic event

	Estimated probabilities of being in the RVVT state			Estimated time spent in the RVVT state (in years)		
	LAC-	***LAC+***	***Thrombosis***	***LAC-***	***LAC+***	***Thrombosis***

Anti-hypertensive medications: yes	1.03 (0.84, 1.27)	1.8 (1.28, 2.52)	0.92 (0.74, 1.14)	1.79 (0.57, 5.67)
Cholesterol>=200	1.18 (0.96, 1.45)	1.69 (1.23, 2.32)	1.09 (0.89, 1.34)	0.4 (0.08, 1.93)
age at visit >=50	0.99 (0.79, 1.23)	1.47 (1.04, 2.07)	1.45 (1.16, 1.8)	1.05 (0.28, 3.94)
Low C3	0.97 (0.75, 1.25)	1.63 (1.13, 2.35)	0.62 (0.48, 0.81)	7.26 (2.07, 25.43)
SLEDAI (per 1 unit increase)	1.05 (1.01, 1.08)	1.09 (1.05, 1.13)	1 (0.96, 1.03)	0.82 (0.67, 1.02)

Results: 1781 patients (37296 clinic visits) were eligible to be included for this analysis. 93% were female, 41% were African American, 50% were Caucasian. The mean age at SLE diagnosis was 32 years (SD=13 years). Patients had the higher probability of improving (LAC+ to LAC-) than deteriorating (LAC- to LAC+), regardless of years after SLE diagnosis (Table 1, 2). In 5 years, the probability of remaining in the same state was 87.6% for state 1, and 4.6% for state 2. 7.7% of the patients initially in state 1 and 9.7% of the patients initially in state 2 transitioned to developing a thrombosis (Table 2). Multivariable regression results showed that African American ethnicity, normal C3, and being on hydroxychloroquine treatment were at higher rates of transitioning from positive LAC to negative LAC while male sex, SLEDAI, and obesity predicted higher rates of transition from LAC negative to positive states. For patients transitioning from positive LAC, obesity and low C3 levels were risk factors for thrombosis and being on hydroxychloroquine was protective against thrombosis (Table 3).

Conclusion: In SLE, transitions between LAC status could be estimated by multistate Markov model. We can estimate the risk of future thrombosis based on the baseline RVVT status, C3, ethnicity, gender, disease activity and obesity.

Abstract Number: 0077

Association of Lupus Nephritis and Other Clinical Features with Antiphospholipid Antibody Positivity Among Patients with Systemic Lupus Erythematosus

Prarthana Jain, Jim Oates, Dulaney Wilson and Diane Kamen, Medical University of South Carolina, Charleston, SC

SESSION INFORMATION
Session Date: Saturday, November 6, 2021
Session Title: Antiphospholipid Syndrome Poster (0069–0083)
Session Type: Poster Session A
Session Time: 8:30AM–10:30AM

Background/Purpose: Antiphospholipid antibody (aPL) positivity is associated with elevated risk of thrombosis among patients with SLE, but other clinical associations are less well-known. The goal of our study was to determine clinical correlations with aPL seropositivity among patients with SLE to help inform risk factor prediction models and provide insights to improve management strategies.

Methods: We used data from a longitudinal research registry of patients with SLE seen at our institution between 2003-2020. Patients were selected using a case-control design based on having known aPL and/or lupus anticoagulant (LAC) status (normal or elevated). aPL status included IgM and IgG anticardiolipin and anti-b2glycoprotein, categorized by Ig level (any positive >20 GLP/MLP, or high positive >40 GLP/MLP). Demographic information, American College of Rheumatology (ACR) and SLICC classification criteria for SLE, SLICC Damage Index (SDI), and renal biopsies were evaluated. Statistical analysis was performed using Fisher's exact or Pearson's chi-squared testing.

Results: A total of 400 patients with SLE were evaluated, the majority black (69.9%) and female (93.9%). Table 1 compares aPL status by race, gender, and age of SLE diagnosis. Table 2 compares aPL and LAC status by presence of clinical characteristics. Lupus nephritis was more prevalent among black compared to non-black patients (59.3% vs. 26.4%, p< 0.01), childhood-onset SLE compared to those diagnosed in adulthood (67.1% vs. 45.8%, p< 0.01), and men compared to women (64.7% vs. 48.9%, p=0.07). Table 2 shows associations between clinical characteristics and any positive aPL, high positive aPL, and positive LAC. Positive aPL was associated with lupus nephritis in 58.6% of patients compared to 45.1% of those negative for aPL (p=0.03). After evaluating renal biopsy data, we found no significant difference in nephritis biopsy classes between those positive or negative for aPL or LAC. In addition to nephritis, discoid rash and neurologic disorder were significantly associated with positive aPL status. Serositis, thrombocytopenia and neurologic disorder were significantly associated with high positive aPL and neurologic disorder with positive LAC. High positive aPL was associated with disease damage, as measured by SDI,

Table 1. Demographic Characteristics for Patients with SLE by aPL Positivity (N=400)

		Any Positive aPL

SLICC Damage Index									
Any damage (>0)	153 (60.0)	95 (65.5)	0.29	173 (59.2)	75 (69.4)	**0.05**	88 (56.1)	15 (65.2)	0.54
High Damage (>1)	96 (37.6)	59 (40.7)	0.55	107 (36.6)	48 (44.4)	0.16	57 (36.3)	10 (43.5)	0.51

but no significant difference was seen with lower titer positive aPL or LAC positivity. Although no significant difference was seen in prevalence of thrombosis and aPL status, the use of low dose aspirin (45.5%) and warfarin (18.6%) were significantly higher among patients with any positive aPL compared to those negative for aPL ($p< 0.01$).

Conclusion: We found that within this predominately African American cohort of patients with SLE, elevated levels of aPL antibodies are associated with lupus nephritis, discoid rashes, and neurologic disorder. At high titers, aPL status was associated with serositis, neurologic disorder and thrombocytopenia. The strongest association of LAC was with neurologic disorder. Further studies will determine the timing of aPL status to these clinical manifestations and potential benefit of antiplatelet and/or anticoagulation on nonthrombotic manifestations such as lupus nephritis, when aPL antibodies are elevated.

Session Date: Saturday, November 6, 2021
Session Title: Antiphospholipid Syndrome Poster (0069–0083)
Session Type: Poster Session A
Session Time: 8:30AM–10:30AM

Background/Purpose: Although APS was originally described in those with SLE, the epidemiology and clinical characteristics of secondary APS (2APS) has not been well described in SLE populations with large numbers of Blacks.

Methods: The Georgia Lupus Registry is a Centers for Disease Control and Prevention-funded population-based registry of validated SLE patients in Atlanta and was designed to determine SLE prevalence in 2002 and incidence in 2002–04. Diagnoses were validated through medical record and database review without the requirement of patient consent. Case definitions included those with ≥4 ACR criteria or 3 ACR criteria with a final diagnosis of SLE by a board-certified rheumatologist. Case finding efforts included searching for APS-related elements from medical records and labs. Validated prevalent and incident SLE cases were matched with the state Hospital Discharge Database from 2002–13, which captured all hospital admissions along with associated diagnoses and procedure codes. 2APS was defined by 1) the treating rheumatologist diagnosis and/or 2) ≥1 clinical and ≥1 laboratory criteria after SLE diagnosis using a modified Sydney classification criteria. Clinical criteria included vascular thromboses and pregnancy morbidity captured by medical record review and/or hospital diagnosis codes. Laboratory criteria for an-

[1] as of December 31, 2004; [2] Immunologic Disorder without antiphospholipid antibodies; SD=standard deviation; Unk=unknown

ticardiolipin (aCL), lupus anticoagulant (LA), and/or anti-b2 glycoprotein-I IgG or IgM (ab2) were captured by medical record and laboratory review. Frequency of clinical and laboratory characteristics were reported for prevalent and incident SLE cases overall and compared between SLE cases with (+APS) and without 2APS (-APS) and between Black and non-Black SLE cases +APS.

Results: In prevalent SLE, 14.3% (194/1353) had 2APS with no differences in age, SLE duration, or sex between APS status [Table 1]. In +APS, there were 67% aCL, 51.5% LA, and 7.7% ab2 (-APS: 11.2, 5.6, and 1.1%, respectively) with 61.9% vascular thromboses and 22.2% pregnancy morbidity. Anti-dsDNA and/or Sm, livedo reticularis, serositis, renal, neurologic, and hematologic disorder were also more frequent. In incident SLE, 11.9% (40/336) had 2APS with no differences in age, SLE duration, or sex between APS status. In +APS, there were 65% aCL, 52.5% LA, and 12.5% ab2 (-APS: 12.2, 4.4, and 1.7%, respectively) with 65% vascular thromboses and 27.5% pregnancy morbidity. There was also more smoking, arthritis, serositis, and ANA positivity. Blacks with prevalent SLE had 2APS less frequently than non-Blacks (143/1024 or 14.0% vs 51/329 or 15.5%) and were younger and had more vascular thromboses, discoid, serositis, and renal disorder but less livedo, ab2, and photosensitivity compared to non-Blacks [Table 2]. Blacks with incident SLE had 2APS less frequently than non-Blacks (28/247 or 11.3% vs. 12/89 or 13.5%) and had less photosensitivity.

Conclusion: The burden of 2APS in SLE in this population-based study ranged from 11.9 to 14.3%. There were notable differences in prevalent and incident SLE by APS status and by race, which may provide insight into the pathophysiology of 2APS. Further research is needed into this important subgroup.

SESSION INFORMATION

Session Date: Saturday, November 6, 2021

Session Title: Antiphospholipid Syndrome Poster (0069–0083)

Session Type: Poster Session A

Session Time: 8:30AM–10:30AM

Background/Purpose: APS is a rare autoimmune disease characterized by thrombotic events and/or pregnancy morbidities in the presence of confirmed positivity for aPL. Complement was demonstrated to be involved in aPL-related pregnancy loss in animal models and human disease. According to some authors, Hydroxychloroquine (HCQ) can control the activation of the complement system. HCQ has been shown to improve pregnancy outcome and to reduce aPL title. In murine model of obstetrical APS, HCQ was able to prevent placental and fetal abnormalities and to lower serum C5a levels. This study was conducted to verify the effect of HCQ in a multicenter cohort of Primary APS (PAPS) and aPL carriers pregnant women and possible correlation with preconception serum C3/C4 levels.

Methods: Medical records of pregnant women with confirmed positivity for aPL antibodies attending 12 referral centers from January 2010 to December 2020 were retrospectively evaluated. We considered as aPL-related adverse pregnancy outcome (APO): spontaneous abortions (< 10 weeks of gestation), fetal loss (≥10 weeks of gestation), neonatal death (death of a formed fetus alive at birth in the first 28 days of life), preterm delivery before 37 weeks of

gestation, preeclampsia, eclampsia or HELLP syndrome. The presence of one or more of them were considered for the definition of gestational outcome. No patients with SLE or other autoimmune disease were included.

Results: We have analyzed 164 singleton pregnancies (22 aPL carriers - 13%) in 128 patients: all the patients were treated with combination therapy (low dose aspirin, LDA + low molecular weight heparin, LMWH), and in 30 HCQ was added. 58 pregnancies (43%) had low levels of preconception C3 and/or C4. A triple aPL positivity was observed in 54 pregnancies (40%), 14 (26%) of them were treated with combination therapy + HCQ. When considering the whole cohort, the addition of HCQ did not significantly improved the gestational outcome (14/30, 47% vs 72/134, 54%, p=0.317, ns). Further stratification was performed on the basis of complement consumption. In the group of patients with preconception low C3 and/or C4 the addition of HCQ did not significantly improve pregnancy outcome (7/11, 64% vs 15/47, 32%, p=0.264, ns). We have lastly evaluated 40 pregnancies that were characterized by a high-risk profile (triple aPL positivity and complement consumption) to assess whether the administration of HCQ on the top of combination therapy during pregnancy could influence gestational outcome. HCQ significantly improved gestational outcome (7/10, 70% vs 7/30, 23%, p=0.018). This observation could not be confirmed in patients with single or double aPL positivity (p=1, ns).

Conclusion: The study shows that administering HCQ in addition to combination therapy can improve gestational outcome in aPL/APS high-risk patients defined as triple aPL positive, with decreased C3 and /or C4 levels. This observation confirms that HCQ exerts a beneficial effect on aPL pregnancies by complement inhibition as it was shown in animal models. In addition, our results provide the clinicians a useful tool to implement conventional treatment in patients at high risk of pregnancy complication or loss.

Abstract Number: 0080

One Point Increase in the Initial Damage as Measured by the Damage Index for Antiphospholipid Syndrome Predicts Mortality in a Multi-Ethnic Group of Thrombotic Antiphospholipid Syndrome Patients

Pedro Gaspar[1], Filipa Farinha[2], Zara Sayar[3], Maria Efthymiou,[4], Hannah Cohen[3] and David Isenberg[2], [1]Department of Internal Medicine 2, University Hospital of Santa Maria, Lisbon, Portugal, [2]Centre for Rheumatology, University College London, London, United Kingdom, [3]Department of Haematology, University College London Hospitals NHS Foundation Trust, London, United Kingdom, [4]Haemostasis Research Unit, Department of Haematology, University College London, London, United Kingdom

SESSION INFORMATION
Session Date: Saturday, November 6, 2021
Session Title: Antiphospholipid Syndrome Poster (0069–0083)
Session Type: Poster Session A
Session Time: 8:30AM–10:30AM

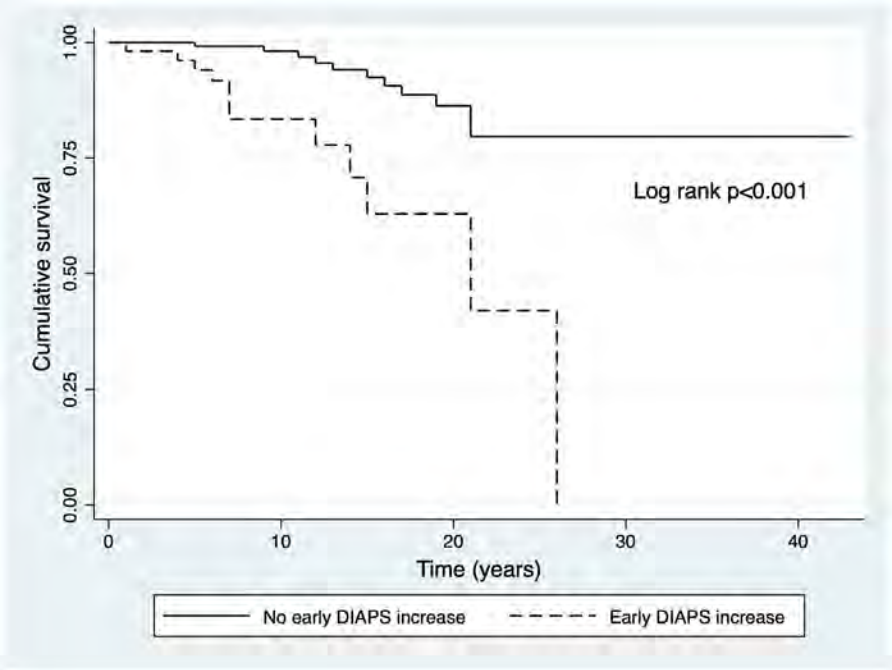

Figure 1. Kaplan–Meier curve showing cumulative survival according to the presence of early DIAPS increase.

Background/Purpose: The chronic and recurrent nature of antiphospholipid syndrome (APS) leads to damage accrual that impairs long-term functional status and survival. The Damage Index for Antiphospholipid Syndrome (DIAPS) is a validated instrument designed to capture the damage accrual in thrombotic APS, but it is not known whether it correlates with mortality. We aim to determine whether early damage, as measured by the DIAPS, predicts long-term mortality in thrombotic APS.

Methods: We carried out a retrospective analysis of all medical records to calculate the yearly DIAPS score of 197 thrombotic APS patients attending the Rheumatology and/or Haematology clinics at a tertiary hospital for up to 43 (median 10) years. Patients fulfilled the 2006 Sydney classification criteria. The disease onset was the time the first thrombotic event related to APS was diagnosed. Early damage refers to damage present at six months after the disease onset. Early DIAPS increase refers to the increase of at least one point from the initial DIAPS score within the first five years after the disease onset. DIAPS score is shown as median (interquartile range, IQR). We used logistic, and uni and multivariable Cox regression models to analyse risk factors affecting mortality. Survival was analysed through the Kaplan-Meier method.

Results: The median age at APS onset was 40 (IQR 51-28) years, with a female (71%) and primary APS (66%) preponderance. Caucasian ethnicity was the most prevalent (72%), followed by Asian (10%), Afro-Caribbean (9%) and other (9%). Damage developed in 143 (73%) patients with a median DIAPS score of 1 (IQR 2-0) at the last visit. Early damage was present in 69 (35%) patients. Early DIAPS scored low values in the whole group (0, IQR 1-0). We identified 23 fatalities (12%). Patients who died had higher last DIAPS (2, IQR 3-1 vs. 1, IQR 2-0, p=0.012) but similar early DIAPS score (0, IQR 1-0 vs. 0, IQR 1-0, p=0.318) compared to those who survived. Secondary APS (HR 3.07, 95% CI 1.32-7.12, p=0.009), male gender (HR 3.14, 95% CI 1.35-7.33, p=0.008) and age at APS onset ≥40 years (HR 5.34, 95% CI 1.96-14.53, p=0.001) were risk factors for death. Early damage was not associated with death (HR 1.65, 95% CI 0.73-3.78, p=0.231). Conversely, early DIAPS increase, present in 29% (53/181) of patients, was associated with death (HR 5.40, 95% CI 2.33-12.52, p< 0.001), even after adjusting individually for APS category (secondary, HR 5.05, 95% CI 2.18-11.72, p< 0.001), gender (male, HR 5.40, 95% CI 2.29-12.73, p< 0.001) and age at APS onset (≥40 years, HR 3.41, 95% CI 1.43-8.20, p=0.006). Figure 1 shows the survival analysis. Having a first arterial thrombotic

event was associated with early damage (OR 7.24, 95% CI 3.74-14.03, $p< 0.001$), but not with early DIAPS increase (OR 1.22, 95% CI 0.64-2.33, $p=0.539$) nor with the risk of death (HR 1.85, 95% CI 0.79-4.27, $p=0.151$).

Conclusion: These findings suggest that damage accrual accessed by DIAPS is associated with increased mortality in a large multi-ethnic group of APS patients. In particular, an increase of at least one point on DIAPS in the first five years after disease onset, but not early damage, is an important predictor of mortality regardless of the nature of the first thrombotic event, gender, APS category and age.

Thrombin Generation Assay and Lupus Anticoagulant Identify Different Populations of Patients with Antiphospholipid Antibodies

Massimo Radin[1], **Alice Barinotti**[1], Irene Cecchi[2], Silvia Grazietta Foddai[1], Elena Rubini[1], Dario Roccatello[1], Elisa Menegatti[1] and Savino Sciascia[1], [1]University of Turin, Turin, Italy, [2]University of Turin, Torino, Italy

SESSION INFORMATION
Session Date: Saturday, November 6, 2021
Session Title: Antiphospholipid Syndrome Poster (0069–0083)
Session Type: Poster Session A
Session Time: 8:30AM–10:30AM

Background/Purpose: Risk stratification in patients with antiphospholipid antibodies (aPL) remains a clinical challenge. We aim to evaluate the role of Thrombin Generation Assay (TGA) in distinguishing various populations of aPL positive patients (with and without lupus anticoagulant - LA) and its association with β2GPI-dependent and anti-phosphatidyl-serine/prothrombin (aPS/PT) antibodies.

Methods: One-hundred-and-eight patients were tested with TGA and divided as follows: 21 patients with aPS/PT IgG/IgM, 29 with aβ2GPI IgG/IgM, 31 with aPS/PT and aβ2GPI IgG/IgM, 27 with aPS/PT and/or aβ2GPI IgM low-titers. Table 1 resumes the clinical characteristics of the APS patients (excluding aPL asymptomatic). Thirty-one healthy donors (HDs) and 24 controls treated with VKA were also included.

Results: The most deranged TGA and LA profile was observed in patients with both aPS/PT and aβ2GPI when compared to those with an isolated positivity for aPS/PT or aβ2GPI and patients with aPS/PT and/or aβ2GPI IgM at low titres (Figure 1). Similarly, patients with aPS/PT and/or aβ2GPI at medium/high titres presented with the higher rate of clinical manifestations.

When comparing the TGA curves of APS patients, asymptomatic aPL positive (aPL+) subjects, HDs and controls treated with VKA, we observed that aPL+ patients (particularly those with a confirmed diagnosis of APS) showed a characteristic profile (Figure 2). Moreover, both in aPL+ subjects and in the control groups we observed a correlation between TGA and LA parameters.

	Group 1: isolated aPS/PT+ IgG/IgM (16)	Group 2: isolated aβ2GPI+ IgG/IgM (20)	Group 3: aPS/PT+ and aβ2GPI+ IgG/IgM (24)	Group 4: aPS/PT+ and/or aβ2GPI+ IgM low titres (15)
APS clinical manifestations				
Thrombosis (Y/N), n (%)	14 (87,5%)	16 (80%)	21 (87,5%)	13 (86,6%)
N of thrombotic events	21	23	36	15
Arterial thrombosis (Y/N), n (%)	10 (62,5%)	9 (45%)	14 (58,3%)	11 (73,3%)
Arterial events, n	13	10	21	12
Venous thrombosis (Y/N), n (%)	6 (37,5%)	10 (50%)	11 (45,8%)	3 (20%)
Venousevents, n	9	13	15	3
Pregnancy morbidity, n (%)	3 (18,8%)	4 (20%)	3 (12,5%)	2 (13,3%)
Stroke, n (%)	4 (25%)	4 (20%)	9 (37,5%)	7 (46,6%)
TIA, n (%)	1 (6,2%)	3 (15%)	4 (16,6%)	0
DVT, n (%)	4 (25%)	8 (40%)	11 (45,8%)	2 (13,3%)
PE, n (%)	2 (12,5%)	3 (15%)	2 (8,3%)	1 (6,6%)
Recurrent thrombosis (Y/N), n (%)	3 (18,8%)	3 (15%)	7 (29,1%)	0
Livedo reticularis, n (%)	1 (6,2%)	1 (5%)	4 (16,6%)	0
Thrombocytopenia, n (%)	4 (25%)	4 (20%)	6 (25%)	2 (13,3%)
Valvular, n (%)	1 (6,2%)	0	2 (8,3%)	0
Peripheral artery disease, n (%)	0	3 (15%)	4 (16,6%)	0
Diffuse alveolar hemorrhage, n (%)	0	0	1 (4,1%)	0

Conclusion: TGA seems a valuable approach to stratify aPL+ patients according to their risk profile. The differences among groups and different populations of autoantibodies specificities obtained from this test can be considered a translational validation of the increased thrombotic risk of patients with triple or tetra aPL positivity.

“Classical” and “Extra-criteria” APS clinical manifestations of each group (considering solely patients with a confirmed diagnosis of APS).

Graphical representation of the differences between TGA and LA profiles between groups. The differences between groups that reached statistical significance ($p<0,05$) are indicated in the graph. Abstract Number: 0082

Association of Current Cigarette Smoking and Obesity with Antiphospholipid Antibodies and Thrombosis in 1216 International Patients Evaluated for Suspected Antiphospholipid Syndrome (APS)

Medha Barbhaiya[1], Deanna Jannat-Khah[1], Doruk Erkan[1], Karen Costenbader[2] and On Behalf of New APS Classification Criteria Development Case Collectors[1], [1]Hospital for Special Surgery, New York, NY, [2]Brigham and Women's Hospital, Belmont, MA

SESSION INFORMATION
Session Date: Saturday, November 6, 2021
Session Title: Antiphospholipid Syndrome Poster (0069–0083)
Session Type: Poster Session A
Session Time: 8:30AM–10:30AM

Background/Purpose: Few studies have evaluated the role of environmental factors in APS. While antiphospholipid antibodies (aPL) may be induced by environmental stiumuli, e.g., viruses, cardiovascular disease and venous thromboembolism (VTE) risk factors may contribute to thrombosis in aPL-positive patients. In particular, we hypothesized that cigarette smoking and obesity might be risk factors for aPL positivity and thrombosis development based on previous literature. Using international multi-center data on patients referred for "suspected APS", we tested the association of smoking and obesity with aPL positivity and thrombosis.

Methods: We collected 1216 cases of patients referred to 32 major centers in North America, South America, Europe, and Asia for suspected APS (aPL-positive/negative cases with/without history of thrombosis were collected as part of the new APS classification criteria development efforts, with additional questions specific for this project). Demographic, exposure, and clinical data were collected in a standardized format using an online secure REDCap database. For the current analysis, for each case, we also collected information related to current/past/never smoking history and most recent body mass index (BMI) at the office visit. We used t-tests or chi-square tests to evaluate associations of smoking (current versus former/never) and obesity (BMI≥ 30 versus < 30) with ever positive and most recent positive aPL (lupus anticoagulant [LA], anticardiolipin antibody [aCL] IgG, or anti-βeta-2-glycoprotein-I antibody [aβ2GPI] IgG) and with history of any thrombosis (including venous thromboembolism [VTE] or arterial thrombosis [AT]). aPL positivity was defined as test result above the laboratory normal range.

Results: Median age of 1216 cases was 42 years (IQR: 35, 55.5); 78.5% were female, 82.1% White, 10.4% Hispanic/Latinx, and 52.6% were European, and 37.7% North American. 64.2% of patients had positive LA tests, 42.9% had positive aβ2GPI IgG, and 53.6% had positive aCL IgG. 8.6% of patients were current smokers, while 22.8% had BMI≥ 30 kg/m2 at office visit (Table 1). We found no association of current smoking with history of ever or most recent positive LA, aCL IgG, aβ2GPI IgG as well as history of thrombosis overall, VTE, or AT (Table 2). However, obesity was associated with ever (but not most recent) positive LA (p=0.04) and history of thrombosis (p < 0.01), but not ever or most recent positive aCL or aB2GPI IgG positivity (Table 2). Obesity was specifically associated with VTE (p=0.01), but not AT.

Conclusion: Within a cohort of international cases referred for suspected APS, obesity was associated with a history of ever positive LA and with VTE. No clear association of current smoking was demonstrated, possibly due to

Cardiac Valve Surgery Outcomes in the Antiphospholipid Syndrome

Tali Eviatar[1], Stanley Niznik[2], Nancy Agmon-Levin[2] and Daphna Paran[3], [1]Tel Aviv Sourasky Medical Center, Givataim, Israel, [2]Sheba Medical Center, Ramat Gan, Israel, [3]Tel Aviv Sourasky Medical Center-Ichilov Hospital, Even Yehuda, Israel

SESSION INFORMATION
Session Date: Saturday, November 6, 2021
Session Title: Antiphospholipid Syndrome Poster (0069–0083)
Session Type: Poster Session A
Session Time: 8:30AM–10:30AM

Background/Purpose: Cardiac valve involvement in the APS is prevalent, necessitating valve surgery in about 5% of the patients. Data regarding valve surgery outcomes in APS relies on small case series and case reports with a mortality rate ranging from 12.5% to 40%. We aimed to describe the outcome and prognosis of cardiac valve surgery in patients with primary and secondary APS, and to determine factors associated with outcome.

Methods: All patients with APS, (primary or secondary to SLE), who underwent valve surgery at the Sheba-Tel-Hashomer or Tel Aviv Sourasky medical centers in Israel in the last 3 decades were included in this retrospective analysis. Data regarding clinical characteristics, valve involvement, treatment before surgery, type of valve used and early and late complications were collected and analyzed.

Results: We identified 23 patients who underwent cardiac valve surgery from 1992-2021. Of whom, 17 (73.9%) were female, median age at surgery was 45 years (range 18-71). Ten patients (43.5%) had APS secondary to SLE. The median time from APS diagnosis to valve surgery was 17 years (range 0-40). Triple positive aPL were noted in 16 of 21 patients (76.2%), and 19 of 21 (90.5%) had a positive lupus anticoagulant (LA).

The mitral valve (MV) was the most common valve affected (n=15, 65.22%), followed by the aortic valve (n=7, 30.43%). Findings compatible with Libman-Sacks endocarditis (LSE) were noted in 13 (56.52%) of the patients. Moderate-severe pulmonary hypertension was evident in 50% of the patients before surgery, and the mean New-York Heart Association score was 2.09.

A mechanical valve was used in 14 of 23 (60.87%) patients, one patient underwent MV repair and one tricuspid valve repair. One patient required concomitant coronary bypass surgery (CABG).

Mean follow up following surgery was 66.59±80.12 months.

Thirteen patients (56.52%) had an early (30 day post-surgery) complication, including 8 severe complications - 2 deaths, 2 post-pericardiotomy syndrome, valve infection, valve thrombosis, stroke and major bleeding (one of each). Eight of 20 patients (40%) had a late complication - one death (4 years after MV replacement); valve thrombosis; stroke and major bleeding; newly developed LSE; major bleeding; stroke; E. coli bacteremia and chronic pericarditis (one of each). All mortality cases occurred in patients with mechanical valves.

In a univariate analysis pre-surgical warfarin treatment (p=0.02) and valve repair (p=0.03) were associated with a better outcome (no complications or death). Whereas a past history of DVT (p=0.02), pre-surgical heparin treatment (p=0.009), and CABG (p=0.008) were linked with mortality.

Conclusion: In this cohort of APS patients from two tertiary centers in Israel the mortality rate was 13.04%, which was lower than some previous case series. The total complication rate was 73.91%.

We have identified possible predictors of outcome, however valve surgery in APS patients continues to carry a guarded prognosis. Larger studies and registries are needed to define risk factors for severe valvular involvement, the best surgical approach and medical treatment post-surgery.

COVID-19 Pneumonia in Two Hospitals: Similar Outcomes Despite Differential Use of Tocilizumab

Leanna Wise[1], Lauren Mathias[2], Wendy Mack[2], Aarya Kafi[3], Yash Kothari[2], Omkar Rao[3] and William Stohl[4], [1]LAC+USC/Keck Medicine of USC, Pasadena, CA, [2]University of Southern California, Los Angeles, CA, [3]University of California San Diego, San Diego, CA, [4]University of Southern California Keck School of Medicine, Los Angeles, CA

SESSION INFORMATION
Session Date: Saturday, November 6, 2021
Session Title: Epidemiology & Public Health Poster I: COVID-19 & Vaccination (0084–0117)
Session Type: Poster Session A
Session Time: 8:30AM–10:30AM

Background/Purpose: A substantial number of patients with COVID-19 pneumonia develop a hyperinflammatory state. The anti-IL-6 receptor (IL-6R) mAb tocilizumab (TCZ) has been used in such setting. However, studies to date have had mixed results.

Our institution is unique in that nearly all services to two independent hospitals, Keck Medical Center (KMC, a private non-profit hospital owned and managed by USC) and the Los Angeles County + University of Southern California Medical Center (LAC+USC MC, a public hospital owned and managed by the County of Los Angeles), are provided by the same pool of physicians who follow similar protocols for management of COVID-19, with one crucial exception – patients admitted to LAC+USC MC do not receive TCZ, while those admitted to KMC are eligible to receive TCZ. This difference in access to TCZ results in two arms of “real-world” patients that are “quasi-randomized”, resulting in a setting that combines components of a randomized trial with real-world practice.

Methods: The records of patients with COVID-19 admitted to KMC or LAC+USC MC between March 1, 2020, and August 31, 2020 (COVID surge 1), and between February 20, 2021, and April 20, 2021 (COVID surge 2), were reviewed. Forty patients with severe COVID-19 pneumonia at KMC received at least a single TCZ dose (400 mg IV).

Remdesivir (n=173)	9 (22.5%)	24 (18.0%)	0.50

Numbers are mean (SD) for continuous variables and frequency (percent) for categorical variables. Group comparisons by Wilcoxon rank sum test for continuous variables and Fisher's exact test for categorical variables.
BMI: body mass index. SOFA: sequential organ failure assessment. HCQ: hydroxychloroquine

These patients were matched to 133 LAC+USC MC controls on gender, age, and BMI, and, when feasible, the presence or absence of diabetes. Day 0 for KMC patients was the day of in-patient TCZ administration, and the matching day 0 for LAC+USC MC patients was the day of emergency room presentation + the number of days for which their matched KMC counterpart had been admitted prior to receiving TCZ. This numbering scheme ensured that disease timelines were similar. Outcomes were assessed at 72 hrs, day 14, and day 28. Primary outcome was ≥2-point improvement on the ordinal scale for clinical improvement (a 7-point scale based on hospitalization status, oxygen requirements, and presence of other organ support). Secondary outcome was survival at days 14 and 28.

Results: Demographics are shown in Table 1. The two populations were balanced in most baseline demographics and characteristics, although they differed in proportions of individuals of Hispanic ethnicity, presence of diabetes,

Table 2: Clinical Improvement: Improvement of at least 2 grades on COVID Ordinal Scale

and use of hydroxychloroquine for treatment of COVID-19. Our findings failed to demonstrate improved clinical outcomes among patients receiving vs not receiving TCZ at any of the time points (Table 2). Moreover, there was also no difference between these cohorts in survival at days 14 and 28 (Table 3).

Conclusion: While our two hospitals are separate, the same physicians and similar treatment protocols (other than TCZ use) resulted in a natural experimental setting. In our study, use of TCZ for COVID-19 pneumonia did not lead to a significant benefit in this quasi-randomized, real-world environment. Moreover, clinical outcomes of patients in our public hospital were no worse than those in our private hospital. The hyperinflammatory state of severe COVID-19 is unlikely to be driven by a single inflammatory cytokine, and the risks of using any and all types of immunosuppression must be carefully weighed against the perceived benefits.

SESSION INFORMATION
Session Date: Saturday, November 6, 2021
Session Title: Epidemiology & Public Health Poster I: COVID-19 & Vaccination (0084–0117)
Session Type: Poster Session A
Session Time: 8:30AM–10:30AM

Background/Purpose: Patients with immune-mediated diseases have similar risk of severe COVID-19 versus the general population but CD20 inhibitor users may be at increased risk of COVID-19-related death. We examined whether CD20 inhibitor users have worse COVID-19 outcomes than general population comparators.

Methods: We performed a comparative cohort study of CD20 inhibitor users in immune-mediated diseases and general population comparators for COVID-19 outcomes. We identified cases who used CD20 inhibitors for immune-mediated diseases (non-oncologic/non-transplant indication) within one year prior to index date of PCR-confirmed COVID-19 between January 31, 2020, and January 31, 2021, in a large healthcare system. Details regarding demographics, medical history, CD20 inhibitor treatment, and COVID-19 were extracted from the electronic health record. Comparators with COVID-19 were matched up to 5:1 by age, sex, and index date of PCR positivity. We estimated hazard ratios (HRs) and 95% confidence intervals (CIs) for hospitalization, mechanical ventilation, and death in CD20 inhibitor users versus comparators using Cox regression. We also assessed these associations among cases with rheumatic conditions and shorter (< 1 year) or longer (>1 year) CD20 inhibitor duration versus comparators.

Table 1. Clinical characteristics of immune-mediated cases on CD20 inhibitors with COVID-19 and age, sex, and COVID-19 diagnosis date-matched comparators.

COVID-19, Coronavirus Disease 2019; SD, standard deviation; IQR, interquartile range.

Results: We identified 114 cases with COVID-19 who used CD20 inhibitors for immune-mediated diseases and 559 matched comparators with COVID-19 (Table 1). Rheumatic disease (59 [52%]) and neurologic conditions (48 [42%]) were the most common indications for CD20 inhibition (Table 2). The total duration of CD20 inhibitor use was < 1 year in 33 (29%), 1-3 years in 51 (45%), and >3 years in 30 (26%). Forty-eight (42%) patients received a CD20 inhibitor dose within 3 months before COVID-19 onset. CD20 inhibitor-treated cases had higher mortality (aHR 2.16; 95% CI: 1.03 to 4.54) than matched comparators. Risks of hospitalization (aHR 0.88; 95% CI: 0.62 to 1.26) and mechanical ventilation (aHR 0.82; 95% CI: 0.36 to 1.87) were similar (Table 3). Approximately half of deceased patients in each group were not mechanically ventilated due to “Do Not Intubate” status. Deaths were numerically higher in patients on CD20 inhibitors for rheumatic diseases (7 [13%] vs. 15 [5%]), unadjusted HR 2.52; 95% CI: 1.07 to 5.90), which was attenuated in the adjusted model (aHR 1.76, 95% CI: 0.50 to 6.15). Short-term CD20 inhibitor users (< 1 year) had higher risk of death (7 [9%] vs. 11 [3%], unadjusted HR 2.82, 95% CI: 1.34 to 5.96) than comparators, which was attenuated in the adjusted model (aHR 2.33, 95% CI: 0.92 to 5.91). Lastly, those with long-term CD20 inhibitor use had numerically higher risk of death (5 [15%] vs. 10 [6%]) than comparators, and a similar trend in unadjusted (HR 2.92, 95% CI: 0.95 to 8.99) and adjusted (aHR 2.41, 95% CI: 0.66 to 8.87) models.

Conclusion: Patients who used CD20 inhibitors for immune-mediated diseases prior to COVID-19 infection had higher mortality than matched comparators. These results highlight the urgent need to mitigate excess risks in CD20 inhibitor users during the ongoing COVID-19 pandemic. Additional studies are needed to better stratify these risks and guide decision-making.

Table 2. Disease characteristics of immune-mediated cases with CD20 inhibitor use prior to COVID-19.

Characteristic	CD20 Inhibitor-Treated Cases (n=114)
Type of CD20 inhibitor, n (%)*	
Rituximab or biosimilar	90 (79)

SESSION INFORMATION

Session Date: Saturday, November 6, 2021

Session Title: Epidemiology & Public Health Poster I: COVID-19 & Vaccination (0084–0117)

Session Type: Poster Session A

Session Time: 8:30AM–10:30AM

Background/Purpose: The relative risk of COVID-19 among patients with rheumatic and musculoskeletal disease (RMD) and the comparative severity of COVID-19 infection in RMD remain uncertain. This systematic review seeks to quantify the risk for SARS-CoV-2 infection and to describe the clinical course and outcomes of COVID-19 in people with RMD.

Methods: A systematic literature search was conducted across 14 databases from inception to February 13th 2021. We included observational studies and experimental trials in RMD patients reporting the following outcomes: 1) comparative rates of SARS-CoV-2 infection, 2) hospitalization, 3) oxygen supplementation/ICU admission/mechanical ventilation, and 4) mortality. Studies were screened, data extracted, and quality assessment performed by two independent reviewers with a third reviewer to resolve conflicts. The methodological quality of all included studies was evaluated using the Newcastle-Ottawa scale or JBI Critical Appraisal Tools.

Table 1. Studies reporting comparative rates of COVID-19 infection (n=47)

Results: Of 5799 abstracts screened, 528 articles underwent full text review, and 100 studies met criteria for inclusion. Most studies (54%) had low risk of bias. br>

47 studies reported comparative rates of SARS-CoV-2 infection in people with RMD, 15 showed increased rates, 28 no difference, and 4 decreased rates (Table 1). Adjusted comparative risk measures were reported in 8 studies; 4 reported increased risk, 4 showed no difference in risk.

70 studies reported hospitalization rates among RMD patients. Of the 11 studies providing comparative data (Table 2) 3 showed increased risk among patients with RMD, and 7 showed no significant effect. No studies found decreased risk for hospitalization. In 5 studies reporting adjusted analyses, 2 reported increased risk, whereas 3 found no significant differences.

In terms of oxygen supplementation (n=28 studies), 3 studies reported comparative findings: 1 showed increased risk among patients with RMD, while 2 found no significant difference. Regarding ICU admission (n=52 studies), 11 comparative studies were identified, 2 showed increased risk among RMD patients and the remainder showed no differences. For mechanical ventilation (n=42 studies), among 8 comparative studies, 7 showed no effect of RMD status and 1 showed a positive correlation. Only 2 studies reported adjusted risk estimates for ICU admission/mechanical ventilation, with 1 reporting a positive correlation, and the other, no effect.

Table 3. Studies reporting comparative mortality rates in RMD patients (n=16)

Authors	Design	N	Mortality and Inference	Bias assessment	Direction of effect

Aries	Cross-sectional	11771 RMD (on DMARD) 1814000 non-RMD	0/30 (0%) DMARD-treated RMD vs 226/5120 (4.4%) in General population	High risk	-

71 studies reported mortality;16 reported comparative mortality rates (Table 3). Of these, 5 reported increased risk, 9 no difference, and 2 decreased risk in the RMD group; notably the 3 largest studies showed increased risk. 7 studies reported adjusted risk estimates. Compared to the general population, 2 studies reported increased mortality and 1 found no difference. Compared to non-RMD comparators 4 studies reported no difference in mortality.

Conclusion: This is the largest systematic review to date on COVID-19 in RMD. Although distillation of the overall results was limited by study heterogeneity, a similar number of studies reported increased risk or equal risk for RMD patients with few reporting decreased risk.

SESSION INFORMATION

Session Date: Saturday, November 6, 2021

Session Title: Epidemiology & Public Health Poster I: COVID-19 & Vaccination (0084–0117)

Session Type: Poster Session A

Session Time: 8:30AM–10:30AM

Background/Purpose: While tumor necrosis factor inhibitors (TNFi) are widely prescribed globally due to their high efficacy across immune-mediated inflammatory diseases (IMIDs), the impact of COVID-19 on individuals with IMIDs receiving TNFi remains poorly understood. The objective of this study was to assess the association between TNFi monotherapy and COVID-19-related hospitalization or death among individuals with IMIDs, compared to other commonly prescribed immunomodulatory regimens.

Table: Patient and clinical characteristics of the study population and COVID-19 outcomes.

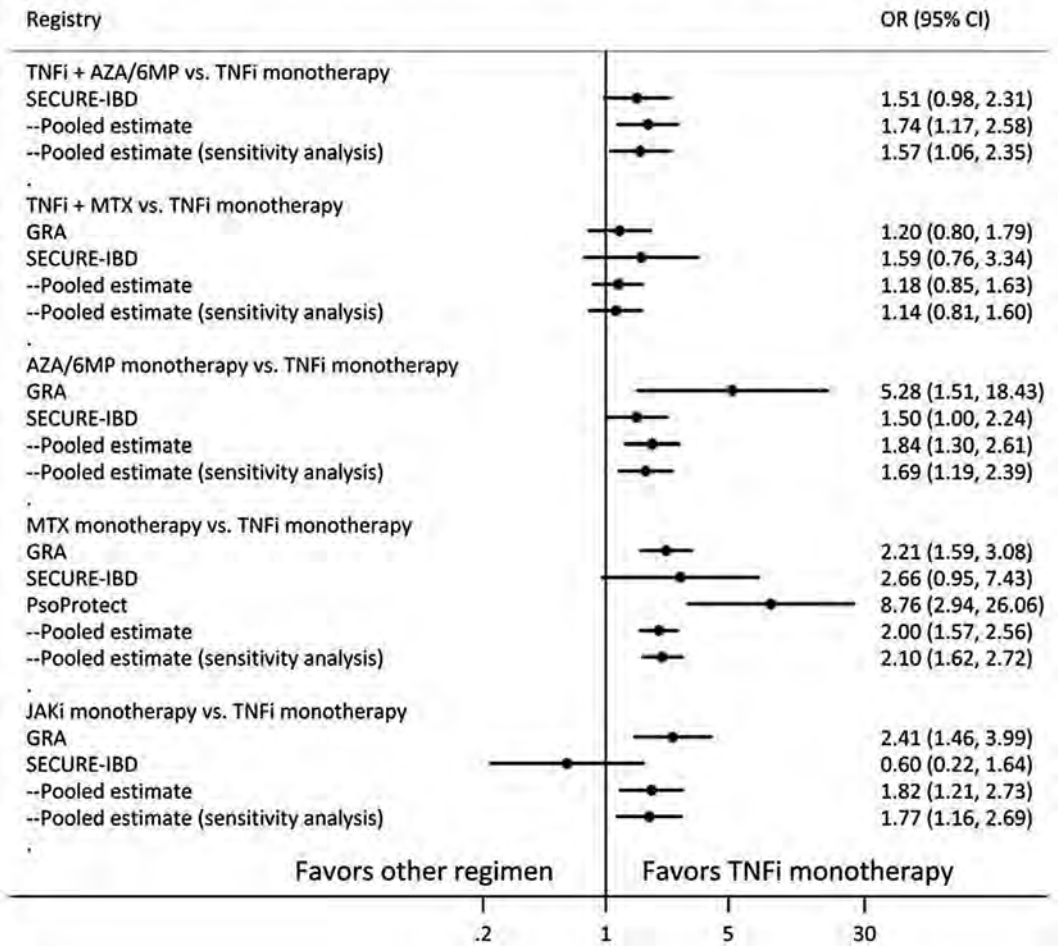
Presumptive COVID-19 case**	752 (21.9)	0 (0)	112 (37.3)	864 (14.2)

Methods: We used data from three global COVID-19 registries of individuals with rheumatic diseases, IBD, and psoriasis. Healthcare providers reported COVID-19 outcomes and demographic and clinical characteristics of individuals with IMIDs with confirmed or suspected COVID-19. We included resolved adult COVID-19 cases with a diagnosis of inflammatory arthritis (IA), IBD, or psoriasis reported on or before February 1st, 2021. Medication exposure was defined as a categorical variable with the following categories: TNFi monotherapy (reference), TNFi in combination with MTX, TNFi in combination with AZA/6-mercaptopurine (AZA/6MP), MTX monotherapy, AZA/6MP monotherapy, and janus kinase inhibitor (JAKi) monotherapy. The outcome was COVID-19-related hospitalization or death. Registry-level analyses and a pooled analysis of data across the three registries were conducted using multilevel multivariable mixed-effects logistic regression, adjusting for demographics, clinical characteristics, comorbidities, concomitant immunomodulatory medications, and accounting for country, calendar-month, and registry-level correlations. In a sensitivity analysis we excluded patients whose COVID-19 diagnosis was based on symptoms alone.

Results: A total of 6,077 cases from 74 countries were included. Mean (SD) age was 48.8 (16.5) years and 58.6% were female (Table). The most common diagnoses were rheumatoid arthritis (35.3%) and Crohn's disease (25.3%).

Figure: Adjusted odds of COVID-19 related hospitalization or death for immunomodulatory treatment regimens compared with tumor necrosis factor inhibitor monotherapy in registry-specific and pooled analyses.



*Categories are mutually exclusive. **Presumptive diagnosis was based on symptoms alone. Abbreviations: GRA: Global Rheumatology Alliance; SECURE-IBD: Secure Epidemiology of Coronavirus Under Research Exclusion for Inflammatory Bowel Disease; PsoProtect: Psoriasis Patient Registry for Outcomes, Therapy and Epidemiology of COVID-19 Infection. JAKi: janus kinase inhibitor; 6MP: 6-mercaptopurine; TNFi: tumor necrosis factor inhibitor; HCQ: hydroxychloroquine; GC: glucocorticoid; IA: inflammatory arthritis; IBD: inflammatory bowel disease.

Over one-fifth (21.3%) of cases were hospitalized for COVID-19 and 3.1% died. In the pooled analysis, compared with TNFi monotherapy, higher odds of hospitalization or death were observed with TNFi in combination with AZA/6MP (odds ratio: 1.7, 95% CI: 1.2-2.6), AZA/6MP monotherapy (1.8, 1.3-2.6), MTX monotherapy (2.0, 1.6-2.6), and JAKi monotherapy (1.8, 1.2-2.7). ORs obtained from registry-specific analyses were generally in the same direction and of similar magnitude as those obtained from the pooled analysis (Figure). Similar findings were obtained after excluding patients whose COVID-19 diagnosis was based on symptoms alone.

Conclusion: Among individuals with IMIDs, TNFi monotherapy is associated with a lower risk of adverse COVID-19 outcomes compared with other commonly prescribed immunomodulatory regimens. These data can help inform treatment decisions for individuals with IMIDs during the pandemic.

TNFi monotherapy is the reference category. Pooled sensitivity analysis excludes COVID-19 diagnoses based on symptoms alone. Odds ratios derived using multilevel multivariable mixed-effects logistic regression. Registry-level

analyses adjusted for demographics, clinical characteristics, comorbidities, concomitant medications, and accounted for country and calendar-month correlations. Pooled analyses additionally accounted for registry-level correlations. Abbreviations: MTX: methotrexate; TNFi: tumor necrosis factor inhibitor; AZA/6MP: azathioprine/6-mercaptopurine; JAKi: janus kinase inhibitor. N = 3,523 (GRA); 2,336 (SECURE-IBD); 300 (PsoProtect); 6,159 (Pooled); 5,223 (Pooled, sensitivity analysis).

Abstract Number: 0088

Evaluation of Patient Characteristics and Clinical Outcomes Among SARS-CoV-2-Diagnosed Patients with and Without RA or PsA Treated with Systemic Therapies: A Retrospective Cohort Study Using US Optum® COVID-19 Electronic Health Record Data

Jeffrey Curtis[1], Xiaofeng Zhou[2], Jinoos Yazdany[3], Philip Robinson[4], Yan Chen[2], Ann Madsen[2], Jamie Geier[2] and Birgitta Benda[2], [1]Division of Clinical Immunology and Rheumatology, Department of Medicine, Department of Epidemiology, University of Alabama at Birmingham, Birmingham, AL, [2]Pfizer Inc, New York, NY, [3]University of California San Francisco, San Francisco, CA, [4]Faculty of Medicine, The University of Queensland, Herston, Australia

SESSION INFORMATION

Session Date: Saturday, November 6, 2021

Session Title: Epidemiology & Public Health Poster I: COVID-19 & Vaccination (0084–0117)

Session Type: Poster Session A

Session Time: 8:30AM–10:30AM

Background/Purpose: Patients with chronic rheumatic diseases are considered to be at increased risk for some infections, with prescribed immunomodulatory (IM) therapies increasing this risk further. It is unclear if patients with RA or PsA receiving IM therapies are at increased risk for SARS-CoV-2 infection, and if they experience more severe COVID-19 clinical outcomes compared with the general population. We describe the characteristics and COVID-19 clinical outcomes in this patient population.

Table. Baseline characteristics and IPs of clinical manifestations/outcomes in the RA, PsA, and comparator cohorts[a]

	RA cohort[b] (N=2,306)	PsA cohort[b] (N=421)	Comparator cohort[c] (N=311,563)
Baseline demographics[d]			
Age (yrs), median (range)	61 (19–89)	55 (22–89)	49 (18–89)
Female, n (%)	1,795 (77.8)	226 (53.7)	177,732 (57.1)
White, n (%)	1,634 (70.9)	367 (87.2)	218,293 (70.1)
Baseline IM therapy, n (%)[d]			
Tofacitinib	69 (3.0)	13 (3.1)	0 (0.0)

[a]Patients who did not have complete data, including encounter data, were excluded

[b]At least 1 diagnosis of RA or PsA and treatment with IM therapy (JAK inhibitor, TNFi, non-TNFi biologic, or csDMARD) within 2 yrs prior to SARS-CoV-2 diagnosis date

[c]Absence of a diagnosis of RA, PsA, or UC, and no IM therapy within 2 yrs prior to SARS-CoV-2 diagnosis date

[d]Baseline was defined as within 6 months prior to SARS-CoV-2 diagnosis date

[e]csDMARDs included aursnofin, aurothioglucose, azathioprine, chloroquine hydrochloride, chloroquine phosphate, cyclophosphamide, cyclosporine, gold sodium thiomalate, hydroxychloroquine sulfate, leflunomide, mercaptopurine, mesalamine, methotrexate, minocycline hydrochloride, n-acetylpenicillamine, penicillamine, primaquine, sulfasalazine, tacrolimus, and thalidomide

[f]Within 90 days prior to SARS-CoV-2 diagnosis date

[g]Denominator is the number of patients hospitalized within 30 days of SARS-CoV-2 diagnosis; defined as death during hospitalization

[h]Within 90 days of SARS-CoV-2 diagnosis date

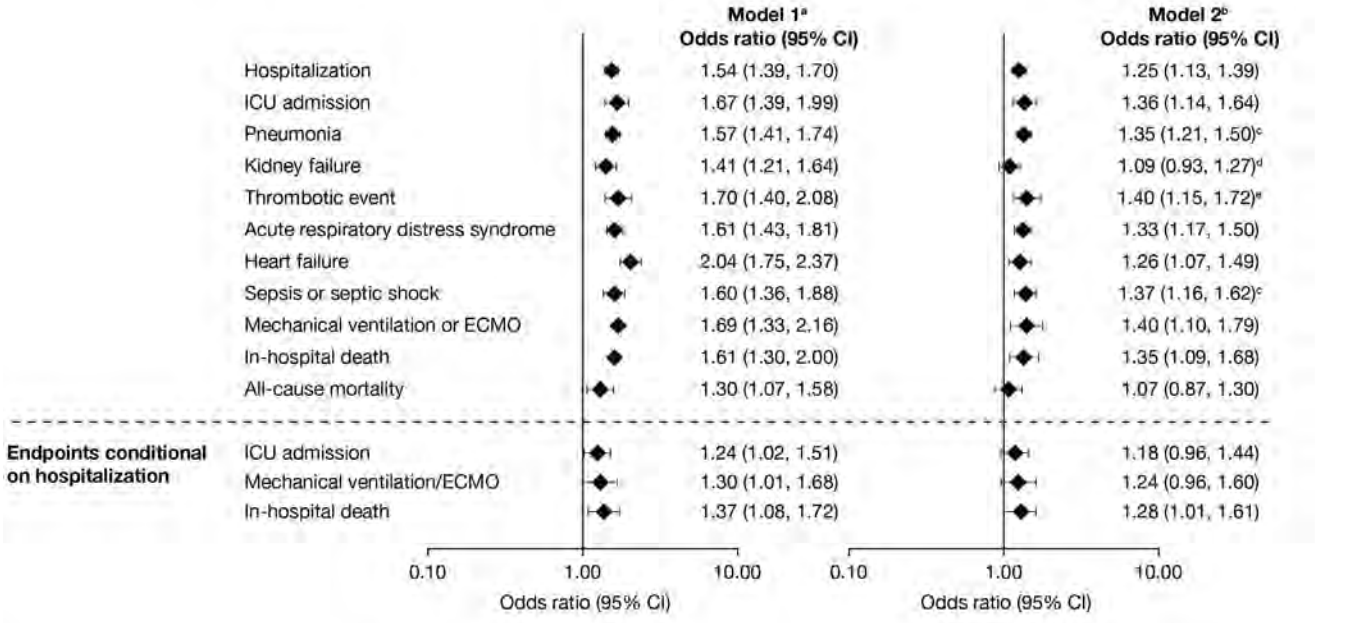
[i]Within 30 days of SARS-CoV-2 diagnosis date

CI, confidence interval; CKD, chronic kidney disease; COPD, chronic obstructive pulmonary disease; csDMARD, conventional synthetic DMARD; ECMO, extracorporeal membrane oxygenation; ICU, intensive care unit; IM, immunomodulatory; IP, incidence proportion; IV, intravenous; JAK, Janus kinase; N, number of patients in the cohort; n, number of patients in the specified category; TNFi, TNF inhibitor; UC, ulcerative colitis; VTE, venous thromboembolism

Methods: This descriptive retrospective cohort study (a post-approval safety study of tofacitinib [approved for RA, PsA, and ulcerative colitis (UC) at the time of the study] in the context of the COVID-19 pandemic) used data from the US Optum® deidentified COVID-19 electronic health record dataset (2007–2020). Adults with a COVID-19 diagnosis (≥ 1 diagnosis code or positive SARS-CoV-2 laboratory test [including PCR, antibody, or antigen]) were stratified into 3 cohorts: patients with RA or PsA and evidence of treatment with IM therapy in the 2 yrs prior to COVID-19 diagnosis (RA and PsA cohorts); and patients without a diagnosis of RA, PsA, or UC and no record of IM therapy in the 2 yrs prior to COVID-19 diagnosis (comparator cohort). Baseline (SARS-CoV-2 diagnosis date) demographics, comorbidities, and IM therapy class were evaluated. The incidence proportions (IPs; with 95% confidence intervals) of primary endpoints (hospitalization and intensive care unit [ICU] admission) and COVID-19 clinical manifestations/outcomes of interest were calculated. Logistic regression was used in exploratory analyses to estimate the risk of endpoints, adjusting for demographics (age, sex, race, region), and demographics plus comorbidities.

Results: As of December 09, 2020, there were 2,306 patients in the RA cohort, 421 patients in the PsA cohort, and 311,563 patients in the comparator cohort. Compared with the comparator cohort, patients with RA and PsA were older and had a higher prevalence of baseline comorbidities (Table). Crude IP of hospitalization due to COVID-19 was higher in the RA cohort compared with the PsA and comparator cohorts (Table). ICU admission (conditional on hospitalization) was similar in the RA and comparator cohorts. Adjusting for demographics, COVID-19 patients with RA had an increased risk of hospitalization and in-hospital death, compared with the comparator cohort (Figure 1). The increased risk was also observed when adjusted for demographics plus comorbidities. Risk of hospitalization was lower in COVID-19 patients with RA receiving TNF inhibitors (TNFi) vs non-TNFi biologics and the comparator cohort

Figure 1. Adjusted odds ratios of each endpoint in the RA cohort



[a]Covariates included in logistic regression models were age, sex, race, and region

[b]Covariates included in logistic regression models were age, sex, race, region, lung disease (interstitial lung disease, asthma, and COPD), VTE, hypertension, coronary artery disease, serious infections (hospitalized), cancer, diabetes, CKD/dialysis, and liver disease

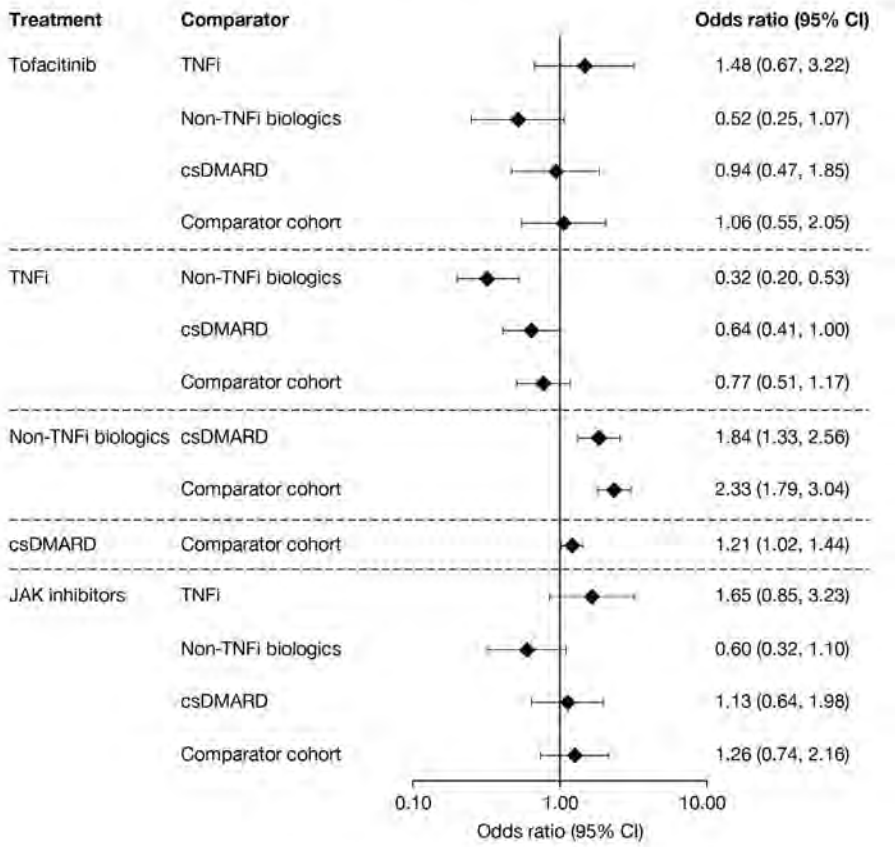
[c]Serious infections (hospitalized) was not included as a covariate

[d]CKD/dialysis was not included as a covariate

[e]VTE was not included as a covariate

CI, confidence interval; CKD, chronic kidney disease; COPD, chronic obstructive pulmonary disease; ECMO, extracorporeal membrane oxygenation; ICU, intensive care unit; VTE, venous thromboembolism

Figure 2. Adjusted odds ratios of hospitalization according to baseline systemic IM therapy in the RA cohort



Covariates included in logistic regression models were age, sex, race, region, hypertension, diabetes, and CKD/dialysis

CI, confidence interval; CKD, chronic kidney disease; csDMARD, conventional synthetic DMARD; IM, immunomodulatory; JAK, Janus kinase; TNFi, TNF inhibitor

(Figure 2). In the RA cohort, risk of hospitalization due to COVID-19 was similar between patients receiving tofacitinib and the comparator cohort (Figure 2).

Conclusion: Compared with the comparator cohort, patients with RA were at higher risk of more severe or critical COVID-19; except for non-TNFi biologics, immunosuppressive therapies such as TNFi did not further increase the risk.

SARS-CoV-2 Seroprevalence and Seroconversion in a Systemic Lupus Erythematosus Cohort and Comparison to General Population Controls

Hannah Mathew[1], May Choi[2], Katherine Buhler[1], Ann Clarke[1], Xenia Gukova[1], Francesca Cardwell[3] and Marvin Fritzler[1], [1]University of Calgary, Calgary, AB, Canada, [2]Brigham and Women's Hospital | University of Calgary, Calgary, AB, Canada, [3]University of Waterloo, Waterloo, ON, Canada

SESSION INFORMATION
Session Date: Saturday, November 6, 2021
Session Title: Epidemiology & Public Health Poster I: COVID-19 & Vaccination (0084–0117)
Session Type: Poster Session A
Session Time: 8:30AM–10:30AM

Background/Purpose: At the outset of the SARS-CoV-2 pandemic, it was speculated that SLE patients may be at significant risk of developing COVID-19 due to underlying immune dysregulation and use of immunomodulatory therapies. Our aims were to:

1. Compare SARS-CoV-2 seroprevalence pre- and intra-pandemic in a local SLE cohort to (a) ambulatory individuals tested for autoantibodies, and (b) a geographically similar general population.
2. Assess rates of RT-PCR testing and positivity.
3. Evaluate relationships between SARS-CoV-2 exposure and demographic and clinical features in the SLE cohort.

Methods: Sera from 173 SLE patients were included, with pre-pandemic samples biobanked prior to 01/01/2020 and intra-pandemic samples collected from 03/15/2020 to 01/31/2021. One hundred pre-pandemic and 148 intra-pandemic sequential, unselected sera from ambulatory individuals served as controls. All sera were tested for SARS-CoV-2 antibodies using two FDA early use authorized assays: an ELISA measuring IgA and IgG anti-spike 1 (S1) (Euroimmun AG, Lübeck, Germany) and an xMAP® assay detecting IgG antibodies to nucleocapsid (N), S1, and receptor-binding domain (RBD) of S1 (Luminex Corp., Austin, TX). The seroprevalence rate of a geographically similar general population was obtained from online published jurisdiction rates. RT-PCR testing was performed in the SLE cohort by a government-sanctioned laboratory. Differences in seropositivity between cohort and controls, and differences in demographic and clinical features between SLE patients with and without SARS-CoV-2 exposure (defined as positive RT-PCR and/or antibodies to SARS-CoV-2) were assessed using 95% confidence intervals (CI).

Table 1. Pre-pandemic demographic and clinical and features in the SLE cohort. Clinical features were measured at the time of the pre-pandemic serum sample date

Age (mean years (SD))	48.5 (14.7)
Sex (% Female)	94.8
Race/Ethnicity (% White)	57.2
Disease Duration (mean years (SD))	11.7 (11.3)

[1] between cohort and controls.

Table 3. Comparison of pre-pandemic demographic and clinical features among those with and without SARS-CoV-2 exposure (defined as positive serology and/or positive RT-PCR) in the intra-pandemic SLE cohort

	Exposed (n = 9)	Non-exposed (n = 164)	Difference[1] (95% CI)
Age (mean years (SD))	46.7 (11.9)	48.6 (14.9)	-1.9 (-10.0, 6.2)
Sex (% Female)	88.9	95.1	-6.2 (-27.0, 14.6)
Ethnicity (% White)	55.6	57.3	-1.7 (-35.0, 31.6)
Disease Duration (mean years (SD))	10.3 (9.1)	11.8 (11.4)	-1.5 (-7.7, 4.7)
SLEDAI-2K Score (mean (SD))	4.2 (3.1)	2.9 (3.7)	1.3 (-0.8, 3.4)
Anti-malarials (% use)	77.8	84.8	-7.0 (-34.7, 20.7)
CS (% use)	33.3	28.7	4.6 (-27.0, 36.2)
Other Immunomodulators[2] (% use)	55.6	43.9	11.7 (-21.6, 45.0)
Other Biologics (% use)	0.0	7.3	-7.3 (-11.3, -3.3)

Abbreviations: SLEDAI-2K, Systemic Lupus Erythematosus Disease Activity Index 2000; CS, corticosteroids.

[1] between exposed and non-exposed patients to SARS-CoV-2.

[2] Azathioprine, Methotrexate, Cyclophosphamide IV, Cyclophosphamide PO, Mycophenolate Mofetil, Tacrolimus, or Mycophenolic Acid.

Results: The SLE cohort was 95% female with a mean age of 48.5 years (SD 14.7) and mean disease duration of 11.7 years (SD 11.3) (Table 1). Eighty-six percent were using anti-malarials, 29% corticosteroids, and 45% other immunomodulators.

In the pre-pandemic samples, none of the SLE cohort vs. 5 (5%) of the ambulatory controls had at least one antibody to any SARS-CoV-2 antigens (difference (dif) -5.0%, 95% CI -9.3, -0.7%; Table 2). In the intra-pandemic samples, 6 (3.5%) SLE patients vs. 5 (3.4%) of the ambulatory controls (dif 0.1%, 95% CI -3.9%, 4.1%) and 2.9% of the geo-

graphically similar general population (dif 0.6%, 95% CI -2.2%, 3.4%) had at least one SARS-CoV-2 antibody. Eighty-one (47%) SLE patients received an RT-PCR test, of which 6/81 (7%) were positive.

Within the SLE cohort, the only significant difference in pre-pandemic characteristics between those with and without SARS-CoV-2 exposure was biologic use (0.0% vs. 7.3%; dif -7.3, 95% CI -11.3, -3.3) (Table 3).

Conclusion: Despite underlying immune dysregulation and frequent use of immunomodulatory therapies, our SLE patients did not appear to have higher exposure to SARS-CoV-2 or greater risk of developing COVID-19 compared to the general population. Further, none of the SLE patients had pre-pandemic (i.e., cross-reactive) antibodies to SARS-CoV-2 N, S1, or RBD proteins. More effective use of infection control principles may contribute to reducing SARS-CoV-2 infections in SLE.

SESSION INFORMATION
Session Date: Saturday, November 6, 2021
Session Title: Epidemiology & Public Health Poster I: COVID-19 & Vaccination (0084–0117)
Session Type: Poster Session A
Session Time: 8:30AM–10:30AM

Background/Purpose: Many uncertainties remain for IL-6 blockers on the management of COVID-19 such as the optimal time of intervention, the schedule of administration and predictors of response. To date, data on the use of subcutaneous sarilumab (SAR) is scarce and no randomized controlled trial (RCT) results are available. Therefore, we aimed at evaluating the effect of subcutaneous SAR vs standard of care (SOC) in hospitalized patients with moderate to severe COVID-19.

Methods: Single center open-label RCT. We included admitted adult patients with documented COVID-19 infection with pneumonia confirmed by chest imaging, laboratory evidence of inflammatory phenotype and no need for invasive ventilation. Patients were randomized from March 14th to October 30th 2020, to receive SAR or SOC in a 2:1 proportion. The experimental arm received a single 400 mg dose of SAR in two 200 mg subcutaneous injections added to SOC. The control arm received usual supportive care as per local protocols.

The primary endpoints included 30-day mortality, mean change in clinical status at day 7 on an ordinal scale ranging from death (category1) to discharged (category 7), and duration of hospitalization. The primary efficacy analysis was conducted on the intention to-treat population. Secondary outcomes included time to became afebrile for 48 hours

Table 1. Baseline clinical characteristics of the study population AST: Aspartate amino-transferase; ALT: Alanine amino- transferase; COPD: Chronic obstructive pulmonary disease; CRP: C-reactive protein; GGT: Gamma-glutamyl transferase; IL-6: Interleukin-6; LDH: Lactate Dehydrogenase; NIV: noninvasive ventilation; PaO2/Fi02: partial pressure of arterial oxygen/fraction of inspired oxygen; PCT: Procalcitonin. a) O2 flow ≤ 15l/min e.g. by face mask, nasal cannula (NC); b) O2 flow >15l/min, e.g. by face mask, 'High Flow' devices (e.g. HFNC), CPAP or NIV including BiPAP and other devices; c) Corticosteroids: ≥ 30 mg Prednisone/d or equivalent; intravenous bolus of 6-Metilprednisolone 120-125 mg/d, except 1 patient 80 mg/d; d) All radiologic exams were assessed and reported by radiologists with pneumological expertise

Secondary Outcomes					
Median change on the ordinal scale, day 14	3 (3-3)	4 (2-4)			0.36
Time to became afebrile for at least 48 h, days[b]	3 (3-6)	4 (4-8)	1.60 (0.97)		0.39
Progression to NIMV, n (%)	4 (20)	0 (0)		15.09 (22.52)	0.27
Progression to IMV, n (%)	3 (15)	0 (0)		15.10 (22.52)	0.5
Time to suppl oxygen withdrawal, days from randomization	5.5 (3 -13)	4.5 (2-12)	0.83 (0.37)	-	0.83

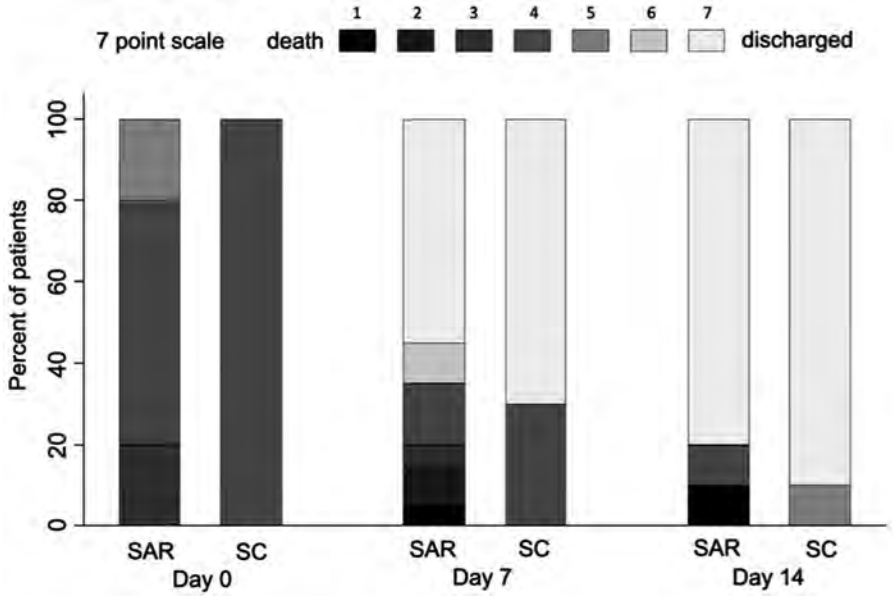

Figure 1. Evolution of clinical status in COVID-19 patients from baseline to day 14 according to the 7-category ordinal scale. Data are shown as the percentage of patients at each ordinal point.

Results: Thirty out of sixty-five screened patients underwent randomization: 20 to SAR and 10 to SOC. Most patients were male (20/30, 67%) with a median (interquartile range, IQR) age of 61.5 (56-72) **(Table 1)**.

At day 30, 2/20 patients died in the SAR and none in the SOC arm (Log HR 15.11, SD 22.64, p 0.54). At day 7, no significant differences were seen in the median change on a 7-category ordinal scale (2 [0-3] vs 3 [0-3], p 0.32) **(Figure 1)**. The median days to discharge were similar (7 [6-11] vs 6 [4-12]; HR 0.65, SD 0.26; p 0.27). No significant differences were seen for any of the secondary outcomes. In the SAR arm, 4/20 (20%) and 3/20 (15%) patients required NIMV and IMV respectively vs none in the SOC **(Table 2)**. Regarding safety, the rate of AE of special interest were similar in the SAR (50%) and SOC (40%) arms.

Conclusion: In our study, subcutaneous SAR added to SOC showed no additional benefit in 30-day mortality, clinical status at day 7, or hospital stay.

Abstract Number: 0091

Vaccination of Patients with Chronic Inflammatory Rheumatic Diseases: An Analysis of Barriers and Facilitators in a Prospective Cohort

Ioana Andreica, Iulia Roman, Xenofon Baraliakos, Juergen Braun and **Uta Kiltz**, Rheumazentrum Ruhrgebiet Herne, Ruhr-Universität Bochum, Herne, Germany

SESSION INFORMATION
Session Date: Saturday, November 6, 2021
Session Title: Epidemiology & Public Health Poster I: COVID-19 & Vaccination (0084–0117)
Session Type: Poster Session A
Session Time: 8:30AM–10:30AM

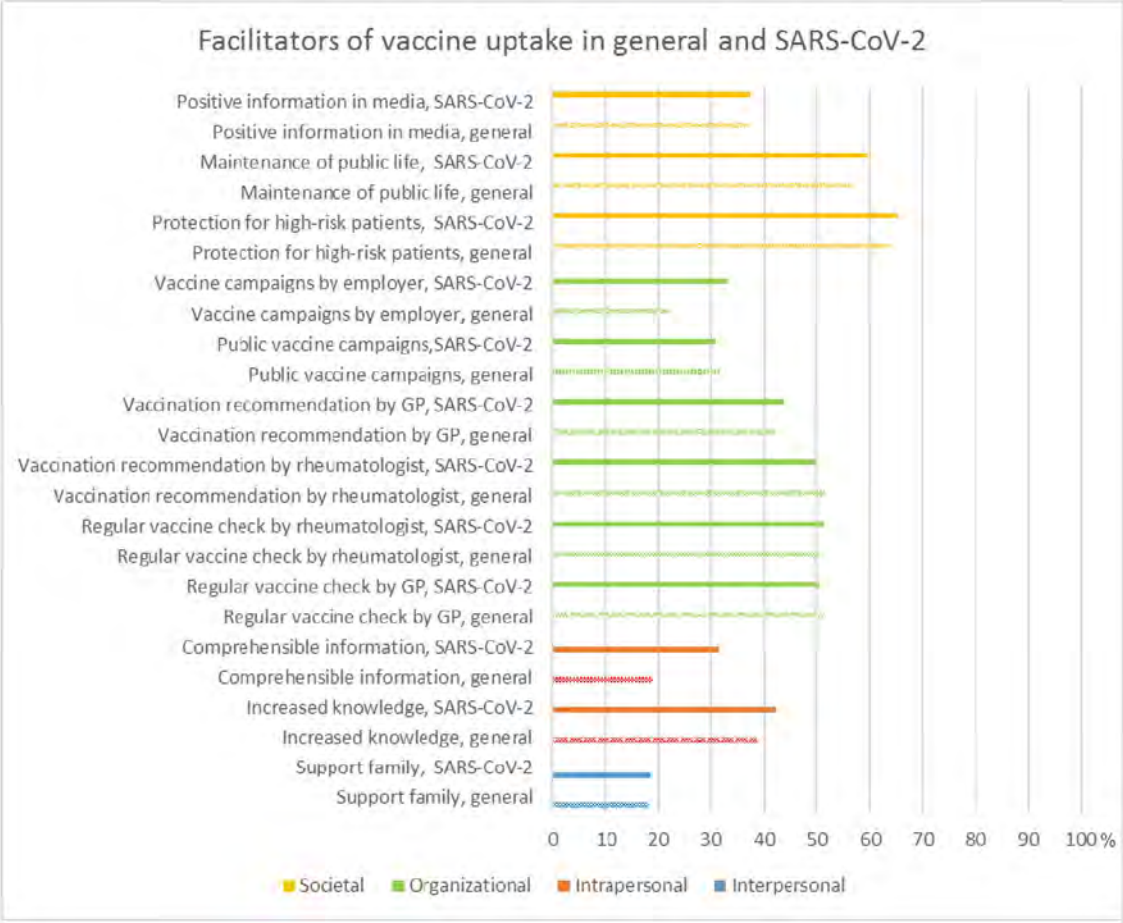

Figure 1. Facilitators of vaccine uptake in general and for SARS-CoV-2.

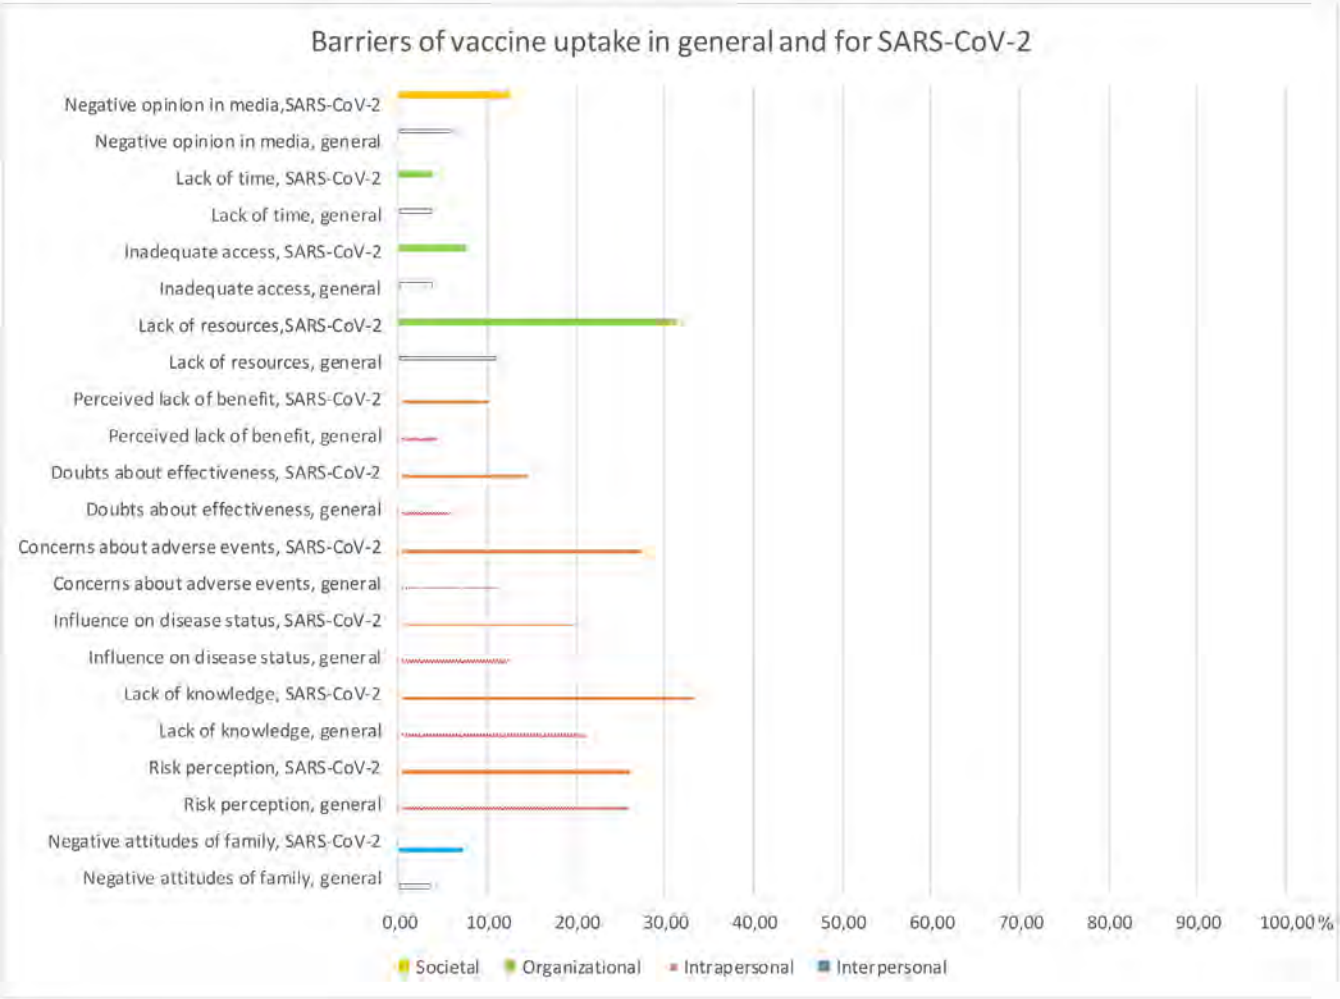

Figure 2. Barriers of vaccine uptake in general and for SARS-CoV-2.

Background/Purpose: Patients (pts.) with chronic inflammatory rheumatic diseases (CIRD) are often not adequately protected against infectious diseases. As shown in an earlier study, less than 50% of CIRD pts. were vaccinated against pneumococci and influenza before the SARS-CoV-2 pandemic started [1]. High vaccination rates are critical to achieve herd immunity. Knowledge on barriers and facilitators of vaccine uptake in CIRD pts. is limited. The aim of this study was to characterize barriers and facilitators towards vaccines in general and specifically against pneumococci, influenza and SARS-CoV-2 in adult CIRD pts..

Methods: In early 2021, consecutive CIRD pts. completed a structured questionnaire including knowledge on vaccination, attitudes, and perceived barriers and facilitators towards vaccination. A total of 12 facilitators and 11 barriers towards vaccination was assessed in general, and specifically for vaccination against pneumococci, influenza and SARS-CoV2. The Likert scales had 4 response options, ranging from 1 (completely disagree) to 4 (completely agree). Patient and disease characteristics, their vaccination history and attitudes towards vaccination against SARS-CoV-2 were assessed.

Results: Of 514 prospectively recruited pts., 441 responded (85.8%) to the questionnaire (table 1). Self-reported vaccine uptake was 48.8% against pneumococci and 66.2% against seasonal influenza. The majority (82.2%) was willing to be vaccinated against SARS-CoV-2. The majority (≥70%) had decent knowledge about vaccination, and

variables as mean (SD)

only < 10% doubted its effectiveness. The level of knowledge did not differ between the studied 3 vaccinations. Pts. were more likely to rate statements about facilitators favorably compared to statements about barriers. Facilitators for SARS-CoV-2 vaccination did not differ from vaccination in general (figure 1). Societal and organizational facilitators such as public vaccine campaigns or protection for high risk pts. were more commonly named compared to inter- or intrapersonal facilitators. Protection of high-risk pts. was by far the most frequently cited facilitator. Most pts. indicated that they were likely to receive a vaccine if their health care professional would recommend it – without preference for GP or rheumatologist. The frequency of barriers was much lower compared to facilitators and more barriers towards SARS-CoV-2 vaccination were reported in comparison to vaccination in general or pneumococci and influenza, respectively. However, pts. frequently cited intrapersonal issues as barriers against vaccination. Importantly, the major barrier was an inadequate risk perception between the severity of COVID-19 and the potential adverse events of the vaccine.

Conclusion: A relatively high number of pts. was vaccinated against pneumococci and influenza, actually more than in our last study – a probable campaign success. Importantly, more than 80% of pts. were willing to be vaccinated against SARS-CoV-2. Facilitators were of greater significance than barriers. The high number of societal and organizational facilitators enables the implementation of effective strategies to increase future vaccination rates.

Clinical Outcomes of Patients with Systemic Rheumatic Diseases Hospitalized for COVID-19 at a Large Academic Center in New York City

Caroline Siegel[1], Jacky Choi[2], Debra D'Angelo[2], Paul Christos[2], Lindsay Lally[1], Parag Goyal[2], Lisa Mandl[1] and Medha Barbhaiya[1], [1]Hospital for Special Surgery, New York, NY, [2]Weill Cornell Medicine, New York, NY

SESSION INFORMATION
Session Date: Saturday, November 6, 2021
Session Title: Epidemiology & Public Health Poster I: COVID-19 & Vaccination (0084–0117)
Session Type: Poster Session A
Session Time: 8:30AM–10:30AM

Background/Purpose: While patients with systemic rheumatic diseases (SRDs) are in general more vulnerable to infections due to their underlying immune dysregulation and immunomodulatory therapies, data related to COVID-19 is conflicting. Early case series suggest that patients with SRD do not have more severe outcomes from COVID-19. This contrasts with data from retrospective cohort studies which suggest that patients with SRD have higher risk of mechanical ventilation or intensive care unit (ICU) admission than age- and sex- matched patients without SRD. Prior studies have been limited by sample size, lack of comparator groups, and/or appropriate statistical analysis. We used a large, multicenter cohort of patients hospitalized with COVID-19 in New York City during the first wave of the pandemic to determine whether patients with SRD hospitalized with COVID-19 were at increased risk of severe outcomes.

Methods: This retrospective observational cohort study included patients aged ≥18 years with confirmed SARS-CoV-2 infection hospitalized at any of three NewYork-Presbyterian hospital sites from March 3-May 15, 2020. We used chi-square tests and t-tests, as appropriate, to compare baseline characteristics, COVID-19-related symptoms, and outcomes between patients with and without SRD. Inverse probability of treatment weighting based on propensity scores (PS) was applied to a logistic regression model to assess the multivariable (MV) association between SRD status and the primary composite outcome of mechanical ventilation, admission to the ICU, or in-hospital death. Covariates with an absolute standardized mean (or proportion) difference (SMD) ≥0.10 in the PS model were adjusted for in the MV logistic regression outcome model (Figure 1).

Results: Out of 3,680 patients hospitalized with COVID-19, 92 (2.5%) had SRD. Mean age of the cohort was 63.7 [16.9] years, and 41% were female, 29% White, and 34% Hispanic/Latinx. Compared to patients without SRD, patients with SRD had similar age and BMI, but were more likely to be female, ever smokers, White or Black, and less likely to be Hispanic/Latinx (Table 1). Patients with SRD had a higher proportion of coronary artery disease, hypertension, and pulmonary disease, as well as use of hydroxychloroquine, corticosteroids, and immunosuppressive medications than patients without SRD (Table 1). Although presenting symptoms were similar, patients with SRD were more likely than those without SRD to be treated with steroids during hospitalization (51% vs. 17%, $p< 0.001$) (Table 2). In the weighted MV analysis, patients with SRD had an OR of 1.27 [95% CI 1.12-1.44, $p< 0.001$] for the composite

outcome of mechanical ventilation, ICU admission, or death compared to patients without SRD after adjustment for the remaining covariates with an absolute SMD ≥0.10.

Conclusion: During the initial peak of the pandemic in New York City, patients with SRD hospitalized with COVID-19 were 1.27 times more likely to experience mechanical ventilation, ICU admission, or death than patients without SRD. Our findings, which used inverse weighting to balance covariates in a large observational inpatient cohort in a COVID-19 "hotspot", warrant confirmation in population-based cohorts.

The Association of General and Covid-19-Specific Stress with Changes in Patient-Reported Outcomes and Comorbidities

Patricia Katz[1], Kristin Wipfler[2], Sofia Pedro[3] and Kaleb Michaud[4], [1]University of California San Francisco, San Francisco, CA, [2]FORWARD, The National Databank for Rheumatic Diseases, Omaha, NE, [3]Forward, The National Databank for Rheumatic Diseases, Wichita, KS, [4]University of Nebraska Medical Center, Omaha, NE

SESSION INFORMATION

Session Date: Saturday, November 6, 2021

Session Title: Epidemiology & Public Health Poster I: COVID-19 & Vaccination (0084–0117)

Session Type: Poster Session A

Session Time: 8:30AM–10:30AM

Background/Purpose: We previously showed that perceived stress during the COVID-19 pandemic was associated with concomitant increases in symptoms of depression and anxiety. In lupus alone, perceived stress during the pandemic was associated with concomitant increases in patient-reported disease activity, pain, fatigue, and cognitive functioning. We examined the role of both general and COVID-specific stress during the early stages of the pandemic with subsequent changes in patient-reported outcomes and comorbidities among individuals with rheumatic disease

Methods: Data are from FORWARD, The National Databank for Rheumatic Diseases, a longitudinal registry of individuals with rheumatic diseases. Data are regularly collected via semi-annual questionnaires. Participants with active emails were asked to respond to 5 COVID-19-specific questionnaires from March 25 through June 2, 2020. The COV-

Table 1. Characteristics of Participants	
	Total (n = 1135)
Age	66.4 ± 10.6
Female	84.9 (963)
Education (yrs)	15.4 ± 2.0
Rural residence	21.2 (240)
Disease duration (yrs)	23.4 ± 12.4
Pre-COVID Global severity rating	3.1 ± 2.4
Stress	
COVID-19-specific	6.0 ± 1.9
General (PSS)	2.4 ± 1.8
Patient-reported outcomes	
PAS2	2.9 ± 2.0
HAQ2	0.77 ± 0.59
Pain rating	3.2 ± 2.5
Fatigue rating	3.5 ± 2.8
Sleep problem rating	3.4 ± 2.9
Rheumatic Disease Comorbidity Index	2.4 ± 1.8
Global severity rating range 0 – 10 Both stress measures re-scaled for range 0 – 10.	

ID-19 questionnaire included an item about COVID-19-specific stress and the 4-item Perceived Stress Scale (PSS), which assesses general stress. Both stress scale scores were transformed to 0 – 10 scores to facilitate comparison. PROs examined were Patient Activity Score (PAS)-II, Health Assessment Questionnaire (HAQ)-II, and numeric rating scales for pain, fatigue, and sleep disturbance (0=no problem, 10=severe). Comorbidity burden was measured with the Rheumatic Disease Comorbidity Index (RDCI). Participant characteristics and baseline PRO scores were taken from the most recent pre-COVID-19 semi-annual questionnaire. Follow-up PRO scores were from the semi-annual questionnaire collected between July-December 2020. Predictors of PRO/RDCI worsening among respondents with rheumatoid arthritis (RA), osteoarthritis (OA), and lupus (SLE) were identified using multiple logistic regression, focusing on the role of COVID-19-specific stress and PSS, and controlling for age, sex, race, education, rural residence, disease duration, pre-COVID-19 global disease severity rating, and the pre-COVID PRO/RDCI outcome value.

Results: 7217 participants were invited for the COVID-19 questionnaire; 2000 (28%) responded. Of these, 1135 also responded to the July 2020 questionnaire and are included in analyses (Table 1). The frequency worsening of PROs ranged from 12.2% for the HAQ2 to 32.4% for sleep disturbance (Table 2). 16.5% had an increase in RDCI. General stress during the pandemic was associated with significantly greater odds of subsequent worsening of all PROs and an increase in RDCI (Table 2). COVID-specific stress was associated with significantly greater odds of subsequent worsening of PAS2, HAQ2, and fatigue.

Conclusion: Substantial portions of these individuals with rheumatic diseases experienced worsening in patient-reported outcomes and comorbid conditions. General stress levels early in the pandemic were significantly associated with those subsequent changes. Results suggest an important role for stress levels in patient outcomes and highlight the importance of the assessment of stress in clinical settings and identification of effective stress management techniques.

Table 2. Association of Stress with Worsening of Disease Activity and Symptoms and Comorbid Conditions

			Odds (95% CI) of worsening	
	Definition of worsening (increase in score)	% (n) with worsening	COVID-specific stress	General stress
PAS-II	≥0.50	27. (317)	1.15 (1.07, 1.25)	1.16 (1.06, 1.26)
HAQ-II	≥0.25	12.2 (146)	1.11 (1.01, 1.23)	1.12 (1.01, 1.25)
Pain (0-10 rating)	≥1	28.1 (352)	1.04 (0.96, 1.12)	1.09 (1.01, 1.19)
Fatigue (0-10 rating	≥1	30.6% (384)	1.11 (1.01, 1.23)	1.12 (1.01, 1.25)
Sleep problems (0-10 rating)	≥1	32.4% (362)	1.08 (0.996, 1.17)	1.09 (1.003, 1.19)
RDCI	≥1	16.5 (219)	1.05 (0.97, 1.15)	1.14 (1.03, 1.25)

Values are odds ratio (95% confidence interval) from multiple logistic regression analyses adjusting for age, sex, education, race, rural residence, and pre-COVID global severity rating, hydroxychloroquine use, and PHQ4 depression or anxiety score.

Characteristics Associated with Severe Outcomes in Patients with Systemic Rheumatic Diseases Hospitalized for COVID-19 in New York City

Caroline Siegel[1], Jacky Choi[2], Debra D'Angelo[2], Paul Christos[2], Lindsay Lally[1], Parag Goyal[2], Lisa Mandl[1] and Medha Barbhaiya[1], [1]Hospital for Special Surgery, New York, NY, [2]Weill Cornell Medicine, New York, NY

SESSION INFORMATION

Session Date: Saturday, November 6, 2021

Session Title: Epidemiology & Public Health Poster I: COVID-19 & Vaccination (0084–0117)

Session Type: Poster Session A

Session Time: 8:30AM–10:30AM

Background/Purpose: Patients with systemic rheumatic diseases (SRD) are potentially at increased risk of severe outcomes from SARS-CoV-2 infection due to their underlying immune dysregulation and chronic use of immunosuppressive therapies. Older age, medical comorbidities, and steroid use have been identified as potential risk factors for COVID-19-related hospitalization in SRD patients, but still need to be confirmed. Our study aims to identify characteristics associated with severe COVID-19, characterized by mechanical ventilation, admission to an intensive care unit (ICU), or death, in patients with SRD hospitalized for COVID-19 in a U.S. "hotspot" during the initial wave of the pandemic.

Methods: This retrospective observational cohort study included patients aged ≥18 years with SRD hospitalized for COVID-19 at one of three NewYork-Presbyterian (NYP) hospital sites between March 3-May 15, 2020. Data were manually abstracted from the medical chart. We used chi-square tests and t-tests, as appropriate, to compare baseline demographics, comorbidities, outpatient medications, presenting symptoms, COVID-19 treatment, and laboratory values in patients hospitalized for COVID-19 with underlying SRD, stratified on the composite outcome of mechanical ventilation, ICU admission, or in-hospital death. We also examined the prevalence of secondary clinical outcomes in SRD patients.

[2]Composite Outcome of Intensive Care Unit Admission (N=19) or Mechanical Ventilation (N=20) or Death (N=24)
[3]Mean (SD); n (%)
[4]Wilcoxon rank sum test; Pearson's Chi-squared test; Fisher's exact test

Results: Among 3,680 patients included in the NYP COVID-19 registry, 92 had an SRD (mean age 66.3 [16.5] years; 82% female, 40% White, and 26% Hispanic/Latinx; mean BMI 28.2 [6.7]). Patients with SRD and severe COVID-19 (N=35) were more likely to be older (73.5 [12.8] versus 61.8 [17.1] years), male, White or Asian, and have history of pulmonary disease or stroke compared to patients without severe COVID-19 (Table 1). No difference in baseline medications was noted. Both groups predominantly presented with fever and dyspnea, although the frequency of these symptoms was higher in the non-severe group (Table 2). Patients with SRD and severe COVID-19 had higher peak white blood cell count, creatinine, aspartate aminotransferase, and alanine aminotransferase levels; they also had higher peak inflammatory markers, including erythrocyte sedimentation rate, C-reactive protein, ferritin, D-dimer, lactate dehydrogenase, and fibrinogen (Table 2). There were no differences in in-hospital treatments. Thromboses, respiratory coinfections, septic shock, cardiac complications, and renal dysfunction were more common in patients with severe COVID-19 (Table 2).

Conclusion: Among SRD patients who were hospitalized for COVID-19 during the peak of the pandemic in New York City, demographic factors and medical comorbidities, but not baseline immunosuppressive medication use, were associated with severe COVID-19 leading to mechanical ventilation, ICU admission, or death. We were underpowered to perform subgroup analyses by SRD type. Future analyses are needed to evaluate the role of social determinants of health, access to care, and geocoding.

Risk Factors for "Long Haul" COVID-19 in Rheumatology Outpatients in New York City

Medha Barbhaiya[1], Deanna Jannat-Khah[1], Jonah Levine[1], Huong Do[1], Jessica Gordon[1], Vivian Bykerk[2] and Lisa Mandl[1], [1]Hospital for Special Surgery, New York, NY, [2]Division of Rheumatology, Hospital for Special Surgery, New York City, NY

SESSION INFORMATION
Session Date: Saturday, November 6, 2021
Session Title: Epidemiology & Public Health Poster I: COVID-19 & Vaccination (0084–0117)
Session Type: Poster Session A
Session Time: 8:30AM–10:30AM

Background/Purpose: COVID-19 'long-haulers' are individuals who experience persistent symptoms after COVID-19 diagnosis. Whether this is of particular concern for rheumatic disease patients, due to their underlying immune dysregulation and use of immunosuppressive medications, is poorly studied. We evaluated the prevalence of "long haul" COVID-19 symptoms as well as its potential risk factors in Rheumatology outpatients in New York City.

Methods: We emailed a secure web-based survey on March 5, 2021 to 7,505 patients aged ≥18 years evaluated at least once by a rheumatologist between 2018-2020 at a large Rheumatology center in New York City and who previously agreed to participate in surveys on COVID-19. We included patients who completed a questionnaire on COVID-19 history, and also collected data on sociodemographics, medical comorbidities, medication use, and health related quality of life using PROMIS-29. ICD-10 algorithms identified patients with SRD. COVID-19 status was confirmed (self-report of a positive nasopharyngeal PCR or antigen test) or suspected (told by a healthcare provider of a COVID-19 diagnosis); the latter was included as testing was not readily available early in the pandemic in New York. We defined COVID "long haul" as symptoms persistent for ≥3 months and used descriptive statistics to compare factors associated with this group compared to patients with COVID-19 symptoms < 1 month.

Results: Among 2572 patients (34.3%) who completed our COVID-19 questionnaire, 254 patients indicated a history of suspected/confirmed COVID-19. 142 (55.9%) patients indicated ≥3 months of COVID-19 symptoms and 112 (44.09%) had < 1 month. No differences in demographics were noted between the ≥3 months versus < 1 month groups (Mean age 55.1 [14.6] vs. 56.9 [14.3] years; 83.1% vs. 75% female; 93.7% vs. 86.6% White, and 9.9% vs. 5.4% Hispanic/Latinx) (Table 1). COVID-19 long-haulers were more likely to have ≥1 or more medical comorbidities (Table 1) and to be a current or former smoker. No difference in SRD or non-SRD status was observed; only 2 patients with long haul symptoms had Fibromyalgia. Patients with long-haul COVID-19 were more likely to have used corticosteroids for ≥3 months at time of COVID-19 diagnosis (p=0.002). The long-haul group had significantly higher frequency of most COVID-19 symptoms at presentation, most commonly chills, cough, fatigue/malaise, headache/migraine, loss of smell or taste, muscle aches, memory/concentration problems, joint pain, and shortness of breath (Table 2). PROMIS-29 T-scores demonstrated significantly and clinically worse anxiety, depression, fatigue and pain in the long hauler group (Table 2).

Conclusion: Over half of rheumatology outpatients with COVID-19 reported persistent symptoms for ≥3 months; these "long hauler" patients were more likely to have more medical comorbidities, a smoking history, and use chronic corticosteroids at time of COVID-19 diagnosis. COVID-19 symptoms at presentation were more common in long-haulers, who also reported worse quality of life. Future prospective analyses accounting for additional potential covariates are underway to identify risk factors in this vulnerable group.

SESSION INFORMATION

Session Date: Saturday, November 6, 2021

Session Title: Epidemiology & Public Health Poster I: COVID-19 & Vaccination (0084–0117)

Session Type: Poster Session A

Session Time: 8:30AM–10:30AM

Background/Purpose: Observational data have shown that rheumatic patients seem not to be more susceptible to SARS-CoV-2 infection neither to worse outcomes. However, the true prevalence of COVID-19 is still unknown due to the high proportion of subclinical infection. In this scenario, measuring the seroprevalence of SARS-CoV-2 may be crucial to improve the knowledge about the impact of COVID-19 in rheumatic patients.

The aim of this study is to estimate the prevalence of anti-SARS-CoV-2 antibodies in a large cohort of patients with rheumatoid arthritis or spondyloarthritis treated with biologic (b-) or targeted synthetic (ts-) DMARDs, living in a COVID-19 high-endemic area (Lombardy, Italy).

Methods: A seroprevalence cross-sectional study was conducted in the period between 4th May and 16th June 2020, including consecutive patients with confirmed RA or SpA treated with b- or tsDMARDs. Enrolled patients were tested

Table 1. Prevalence of anti-SARS-CoV-2 antibodies

Antibodies	Posivite(n)	Seroprevalence (%)	(95% CI)
IgG	27	9%	(6.2 – 12.7)
IgG anti-N	26	8.6%	(5.9 – 12.3)
IgG anti-RBD	18	6%	(4.3 – 10)
IgM	41	13.6%	(10.2 – 18)
IgM anti-N	35	11.6%	(8.5 – 15.7)
IgM anti-RBD	25	8.3%	(5.7 – 12)
IgA	40	13.3%	(9.9 – 17.6)
IgA anti-N	37	12.3%	(9.0 – 16.5)
IgA anti-RBD	25	8.3%	(5.7 – 12)
IgG+IgM	23	7.6%	(5.1 – 11.2)
IgG+IgM+IgA	22	7.3%	(4.9 – 10.5)
IgG+IgA	24	8%	(5.4 – 11.6)
IgG/IgM/IgA	56	18.6%	(14.6 – 23.4)

RA rheumatoid arthritis, SpA spondyloarthritis, PDN prednisone, csDMARDs conventional synthetic disease-modifying anti-rheumatic drugs, b/tsDMARDs biological/targeted synthetic disease-modifying anti-rheumatic drugs, MTX methotrexate, CVD coronary heart disease, DM II diabetes mellitus type II.

for anti-SARS-CoV-2 IgG, IgM, and IgA antibodies against main viral antigens (nucleoprotein [N], receptor-binding domain [RBD]) using ELISA. Demographical and clinical data were also collected and patients were questioned about history of COVID-19 symptoms in order to identify potential factors that correlate with anti-SARS-CoV-2 positivity. Results were compared with those observed in the healthy population in the same period and region [1].

Results: The study population included 300 patients (62% females, mean age 53 years), diagnosed with RA (56%), psoriatic arthritis (23%), or ankylosing spondylitis (21%). Most patients were being treated with anti-TNF (57%), and the remainder were receiving abatacept (20%), anti-IL6 (11%), or JAK inhibitors (5%). Four patients (1.3%) referred a prior diagnosis of COVID-19 defined by nasopharyngeal swab. Immunoglobulin titers were evaluated resulting in 9%, 13.6%, and 13.3% positive patients for IgG, IgM, and IgA, respectively, with no significant difference to the healthy population. Among seropositive patients, 55.3% were asymptomatic, 16% had minor and 19.6% major symptoms, 7.1% were hospitalized. No deaths or admission to intensive care units occurred. No differences were found between seronegative and seropositive patients in relation to age, sex, rheumatic diagnosis, and treatments with b- or tsDMARDs. Conversely, corticosteroids therapy was associated with an increased risk of seropositivity in a dose-dependent manner with a significantly high OR for doses above 10 mg (OR 11.6, p 0.009). Relative increased risk was associated with the presence of at least one comorbidity (OR 5.25; 95%CI 1.95 – 14.08, p 0.001), especially hypertension (OR 5, p 0.001) and obesity (OR 5.4, p 0.01).

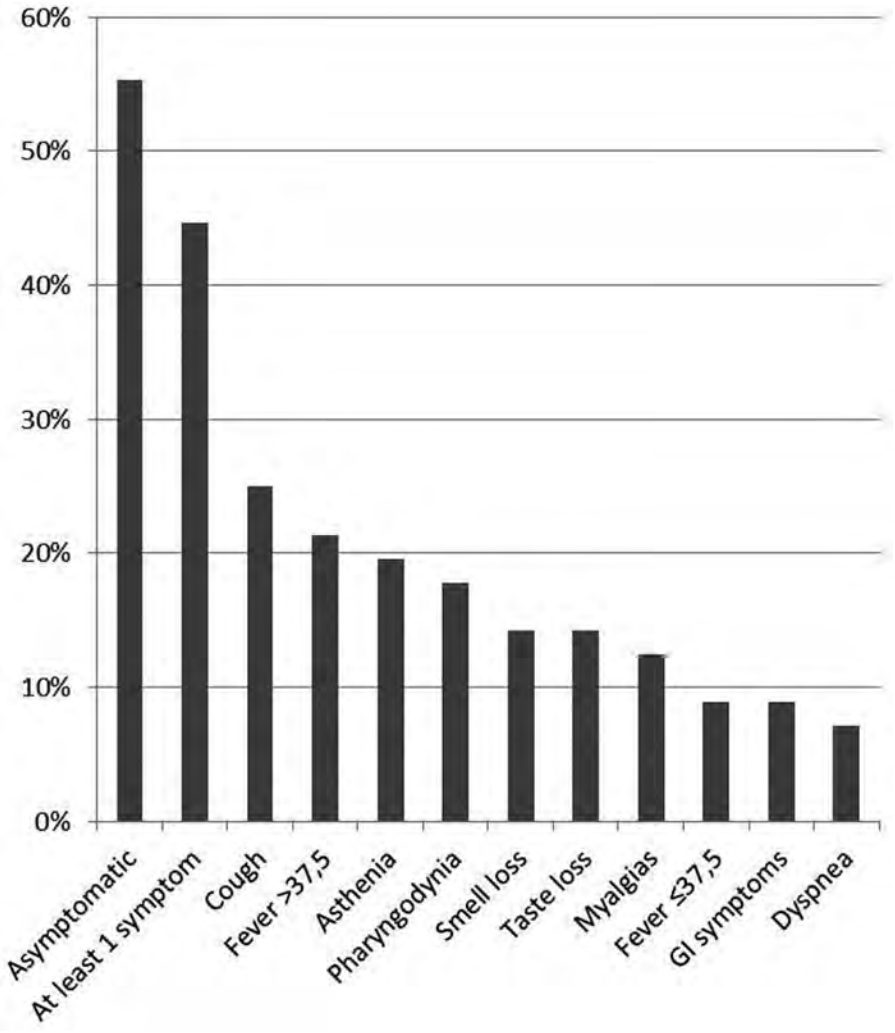

Figure 1. Clinical manifestations of seropositive patients.

Conclusion: This study confirms that, even in a cohort of rheumatic patients, the spread of SARS-CoV-2 infection is much greater than that observed by capturing only swab-diagnosed COVID-19 cases, but consistent with healthy population. The underlying rheumatic disease and ongoing therapy with b/tsDMARD do not seem to impact SARS-CoV-2 antibody positivity, which conversely seems to be associated with the presence of comorbidities and with CS therapy. The project was co-financed by Lombardy Region 2014-2020 Regional Operational Programme under the European Regional Development Fund.

SESSION INFORMATION

Session Date: Saturday, November 6, 2021

Session Title: Epidemiology & Public Health Poster I: COVID-19 & Vaccination (0084–0117)

Session Type: Poster Session A

Session Time: 8:30AM–10:30AM

Background/Purpose: Janus kinase inhibitors (JAK-i) offer a potent mode of action to treat rheumatic diseases. Little is known on the course and outcome of SARS-CoV-2 infections in RA patients treated with JAK-i. The aim of this study is to describe the outcome of SARS-CoV-2 infection in RA patients treated with JAK-i in comparison to patients treated with TNF-inhibitors (TNF-i).

Methods: In the German COVID-19 registry for inflammatory rheumatic diseases, the course and outcome of proven SARS-CoV-2 infections are documented by treating rheumatologists. From March 30th, 2020 until April 5th, 2021 a total of 2253 cases was collected. 982 were reported with RA, of which 128 were treated with JAK-i and 190 with TNF-i. Patient characteristics and outcome of the SARS-CoV-2 infection were analysed descriptively. Differences in characteristics were tested by the Pearson Chi-Square-Test.

Results: Median age in both treatment groups was comparable (tab.1). Concomitant glucocorticoids (GC) were used in 50% of the JAK-i and 31% of the TNF-i patients ($p < 0.001$). Additional conventional synthetic (cs) disease-modifying anti-rheumatic drugs (DMARD) were used in 29% of the JAK-i and in 49% of the TNF-i patients ($p < 0.001$). Moderate and high disease activity before acquisition of the infection was more frequently reported in JAK-i patients than under TNF-i treatment ($p=0.042$). Comorbidities that were recently found to be associated with a higher risk of hospitalisation and death, namely cardiovascular disease and hypertension were also more frequent in patients with JAK-i. Hospitalisation due to COVID-19 was necessary for 33% of patients treated with JAK-i and 13% of patients treated with TNF-i , and oxygen treatment was required in 25% and 7% of the patients, respectively ($p < 0.001$). Eight versus none ($p < 0.001$) fatal cases were reported in the JAK-i versus the TNF-i group.

Conclusion: The higher rate of hospitalisation and death among RA patients treated with JAK-i compared to TNF-i is remarkable. However, this has to be interpreted with caution, since RA patients under JAK-i harboured some differences in potentially confounding *RA-related and unrelated* factors like disease activity, concomitant use of GCs, and certain comorbidities. To address this, further analyses with adjustments for baseline differences should follow.

Table 1. Characteristics of JAK-i and TNF-i treated patients with SARS-CoV-2 infections

	JAK-i (n=128)	TNF-i (n=190)
Baseline characteristics		
Female	85% (109)	74% (141)
Age (median) in years	58 (24-86)	57 (23-91)

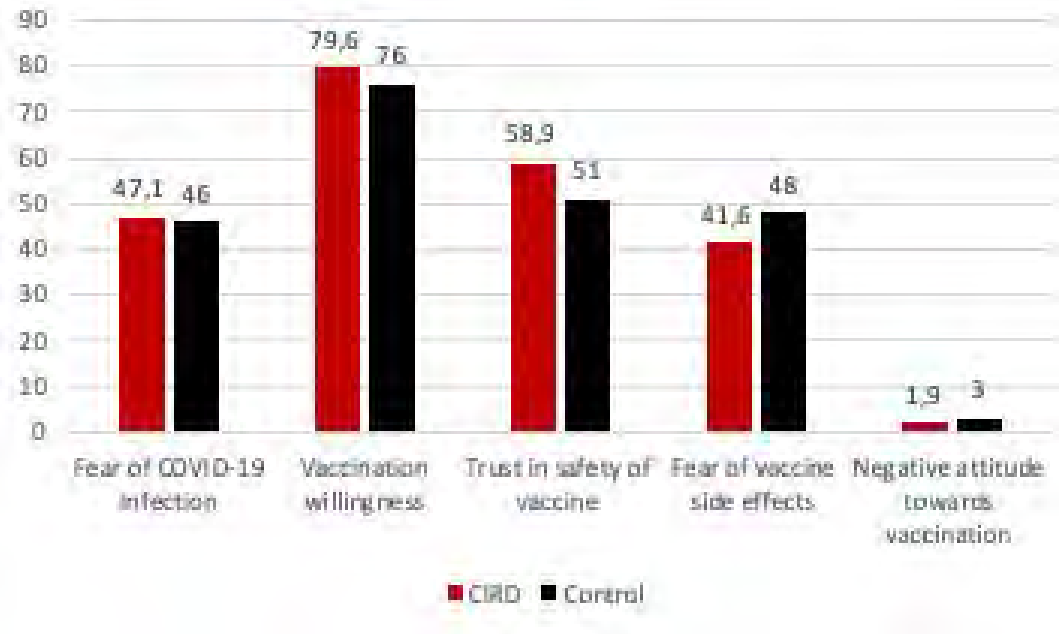

Figure 1. Vaccination willingness and its predictors as percentage.

Background/Purpose: The SARS-CoV-2 pandemic has affected life in most countries around the world for more than a year now. It is not entirely clear if patients with chronic inflammatory rheumatic diseases (CIRD) are at increased risk for COVID19, but some drugs seem to be associated with worse outcomes. Vaccination has now started but knowledge about patients' attitudes and acceptance to be vaccinated is limited.

To study the attitudes of patients with CIRD towards the pandemic and their acceptance to be vaccinated against SARS-CoV-2.

Methods: In preparation of this prospective cross-sectional study, a detailed questionnaire was developed. After approval by the ethical committee, patients of our tertiary rheumatology hospital were consecutively included to answer questions regarding the upcoming vaccination against SARS-CoV-2. A numerical rating scale (NRS) ranging from 0 (fully disagree) to 10 (fully agree) was used. A definite positive answer was assumed if ratings were ³ 7. Sociodemographic and comorbidity data, a detailed history of infections, disease characteristics, medication and compliance with hygiene rules were recorded. The data were compared with a control group consisting of patients without CIRD.

Results: A total of 514 CIRD and 100 controls were included (table 1). No significant differences were found in the history of infections or their severity between groups. Recurrent and/or severe infections were reported by 10.5% and 4.5% of CIRD patients vs. 16% and 13% in controls, respectively. A positive PCR test for SARS-CoV-2 was found in 4%-5% of both groups. A larger percentage of CIRD patients felt that they are at increased risk of COVID 19: 60.4% vs. 48.5% in controls (p=0.02), while 47.2% vs. 46.5%, respectively, stated to be afraid of COVID19. Only 63.7% of CIRD patients thought that their medication is 'immunosuppressive'. About 20% of patients in both groups reported to have experienced COVID 19 associated deaths in their acquaintance. The compliance with hygiene rules was similar with over 90% reporting strict adherence. More CIRD patients reported financial losses due to pandemic: 34% vs. 19%, respectively. Slightly more CIRD patients (79.6%) than controls (76%) were willing to be vaccinated against SARS-CoV-2. About 60% of CIRD patients thought that the vaccines are safe, while 42% were afraid of side effects (figure 1). A generally negative attitude towards vaccination was more often found in controls.

Conclusion: These data indicate that CIRD patients have less severe and recurrent infections than controls but most CIRD patients think that they are at increased risk of a COVID19 infection, but they are less often afraid of being infected. However, CIRD patients have adhered very well to hygiene protection measures, even though their knowledge about their medication seems to be limited. This study also confirms that 80% of CIRD patients are ready to be vaccinated against SARS-CoV-2 even though many admitted fear of side effects. Less than 5% of CIRD patients have been infected with SARS-CoV-2, not much different from the control group. More controls were general opponents of vaccination.

SESSION INFORMATION
Session Date: Saturday, November 6, 2021
Session Title: Epidemiology & Public Health Poster I: COVID-19 & Vaccination (0084–0117)
Session Type: Poster Session A
Session Time: 8:30AM–10:30AM

Background/Purpose: It has been suggested that 100% of SARS-CoV2 infections leads to development of specific IgG antibodies that remain detectable for a long period of time. Targeted Immune-Modulating Therapies (TIMT) such as anti-TNF, anti-interleukins and Janus Kinase inhibitors (JAKi) for treatment of Immune Mediated Inflammatory diseases (IMID) could theoretically interfere with cytokine storm and humoral immune response against COVID19. We investigate the seroprevalence of SARS-CoV2 IgG in relation to previous exposure to COVID19 and ongoing IMID treatment in a Belgian, real-life population of IMID patients in the prevaccine era.

Methods: A cross-disciplinary, prospective, observational cohort study was set up at two university hospitals. Between 17/12/2020 and 28/02/2021, all patients with IMIDs of the joints (rheumatoid arthritis, psoriatic arthritis, spondyloarthritis, the gut (Crohn's disease (CD), ulcerative colitis (UC)), and skin (psoriasis, hidradenitis suppurativa, atopic dermatitis) visiting the respective clinics were asked to participate. Both patients under conventional treatment and/or TIMT were included. Patients were asked to fill out an electronic survey (REDCap®, based on WHO-ISARIC) and blood samples were drawn for serology testing (SARS-CoV-2 IgG Abbott – Architect kit®). Statistical analyses were performed with SPSS26.

Results: In total 2166 IMID patients consented to take part. Of these, 1913 responded to the survey, including 415 rheumatology patients, 1217 IBD patients (64.7% CD, 34.3% UC, 1% undifferentiated colitis) and 218 dermatology patients. There were 372 patients (19.5%) who reported having experienced symptoms suggestive of COVID19 (Fig.

1). Fatigue (61.3%), headache (48.1%), sore throat (46.9%) and dry cough (38.7%) were most frequent symptoms. Gastrointestinal symptoms such as diarrhoea or abdominal pain were present in less than 20.0% (Fig. 2). Ninety-six IMID patients (5.04%) had a positive SARS-CoV2 PCR test on nasal or throat swab. In 44/96 (45.8%) anti-SARS-CoV2 IgG seroconversion was confirmed. There was no significant difference in seroconversion rate between patients treated with TIMT compared to conventional therapy (P=0.192). Of the seroconverted group, 75.0% were treated with TIMT. The interval between reported positive PCR date and serology test date ranged from 3 to 24 weeks with a mean of 10 weeks. Of all survey responders, 25 were hospitalized for respiratory symptoms since 01/02/2020, six of these had positive SARS-CoV2 PCR.

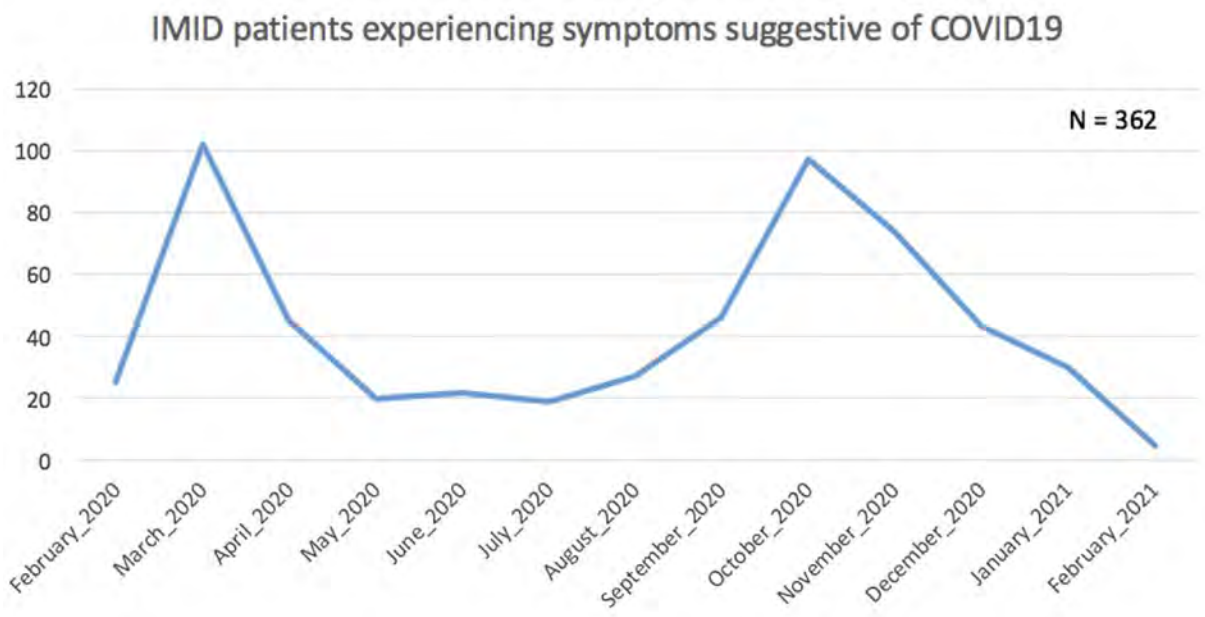

Figure 1. Number of IMID patients experiencing symptoms suggestive of COVID19 per month.

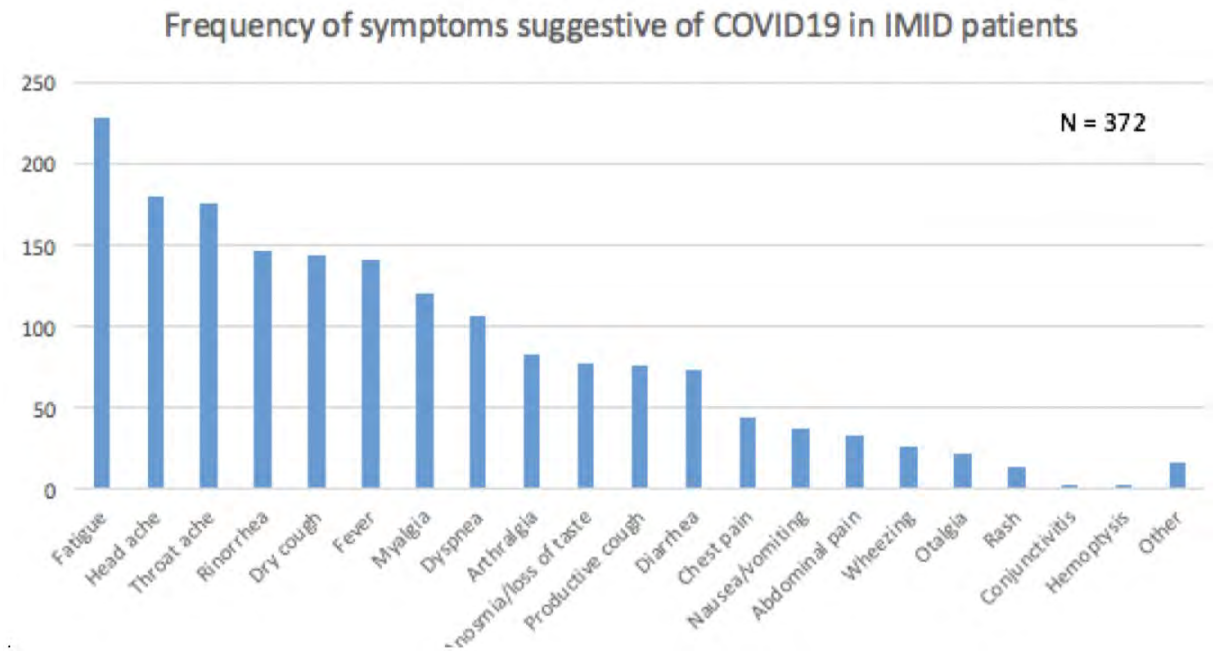

Figure 2. Frequency of experienced symptoms suggestive of COVID19 in IMID patients.

Conclusion: Prevalence of COVID19 symptoms and number of confirmed COVID19 cases by PCR in this cohort of IMID patients remain low regardless of treatment modality. There was no significant difference in SARS-CoV2 IgG seroconversion rate between TIMT or conventional treatment in patients with positive PCR.

SESSION INFORMATION

Session Date: Saturday, November 6, 2021

Session Title: Epidemiology & Public Health Poster I: COVID-19 & Vaccination (0084–0117)

Session Type: Poster Session A

Session Time: 8:30AM–10:30AM

Background/Purpose: Among patients with rheumatic and musculoskeletal diseases (RMDs) and their treating physicians, concerns prevail about the effectiveness and safety of vaccination against COVID-19, especially with respect to triggering RMD flares. The aim of our study was to collect safety data among RMD patients receiving COVID-19 vaccines.

Methods: The German COVID-19 vaccination registry is an observational longitudinal study launched February 8th, 2021. Data are entered voluntarily by RMD patients who have received at least 1 vaccination against SARS-CoV-2. The characteristics of all patients registered until May 29th, 2021 is presented here.

Table 1. Characteristics of COVID-19 vaccinated RMD patients.

Total, n	866	
Age (years, median)	54	Range: 18-86
Female	702	81%
Inflammatory rheumatic diseases (multiple selections possible)		
Rheumatoid Arthritis	432	50%
Spondyloarthritides	272	31%
Connective tissue disease	250	29%
ANCA-associated vasculitides	18	2%
Polymyalgia/ Giant cell arteritis	27	3%
Other inflammatory rheumatic diseases	45	5%
Osteoarthritis	182	21%
Fibromyalgia	77	9%
Small Fiber-Neuropathy	13	2%
Days with diseases flares within 12 months prior to COVID-19 vaccination	1 (Median)	Range: 0-365
Immunomodulation (multiple selections possible)		
Glucocorticoids	286	33%
Methotrexate	278	32%
Azathioprine	36	4%
Cyclosporine	2	0%
Leflunomide	39	5%
Hydroxychloroquine	109	13%
Sulfasalazine	39	5%
Janus kinase inhibitors	73	8%
TNF-inhibitors	186	22%
Interleukin 17-inhibitors	42	5%
Interleukin 6-inhibitors	23	3%
Interleukin 1-inhibitors	3	0%
Abatacept	18	2%
Rituximab	26	3%

Change of immunomodulation due to disease flare	**(n=115)**	
No change of treatment	61	53%
Addition of low dose prednisolone (≤ 5 mg/day) or use of NSAIDs	26	23%
Addition of > 5 mg prednisolone/day	21	18%
Change of immunomodulating treatment	2	0%
Addition of another DMARD	5	1%

Results: So far, 866 patients reported their experience after the first COVID-19 vaccination. Median age was 54 years (range 18-86) and 81% of the participants were female (table 1). Most of the patients (50%) were diagnosed with rheumatoid arthritis, followed by spondyloarthritides (31%). At the time of vaccination, 33% were treated with glucocorticoids, 59% with conventional synthetic DMARDs, 23% with TNF-inhibitors, 9% with JAK-inhibitors, and 5% with IL17-inhibitors. No immunomodulatory therapy was reported from 9% of the patients. Within the last 12 months, 42% of the patients reported no disease activity and 40% did not state further comorbidities. The most common comorbidity was arterial hypertension (33%). Prior to COVID-19 vaccination, 77% of the patients had received ever influenza and 57% pneumococcal vaccinations. The majority of the patients were vaccinated with Pfizer-BioNTech vaccine (67%), followed by AstraZeneca vaccine (28%). Most of the participants reported no or low concerns regarding COVID-19 vaccination (80%) and 70% did not change their immunomodulation around the vaccination period. The most common side effect was pain at the injection site (71%), followed by fatigue (41%), headache (33%), and arthralgia (24%). Only 1% of the patients reported allergic reactions. Side effects lasted in median for two days (range 0-99 days) and 15% reported no relevant side effects. Disease flares after first COVID-19 vaccination as reported by patients on a 1-10 scale was indicated in 13% of the patients. In these patients, 6% needed a change of their immunomodulation treatment. In 41% of the cases with disease flares, increasing the GC dose was sufficient to cope with the flares.

Conclusion: The first COVID-19 vaccination was well tolerated by the majority of RMD patients. Adverse events were similar to those observed in the general population. Only in 13% of the patients, self-reported disease flare was indicated and in these patients, only 6% needed changes in their immunomodulatory therapy. These preliminary results support the recommendation for COVID-19 vaccination in RMD patients.

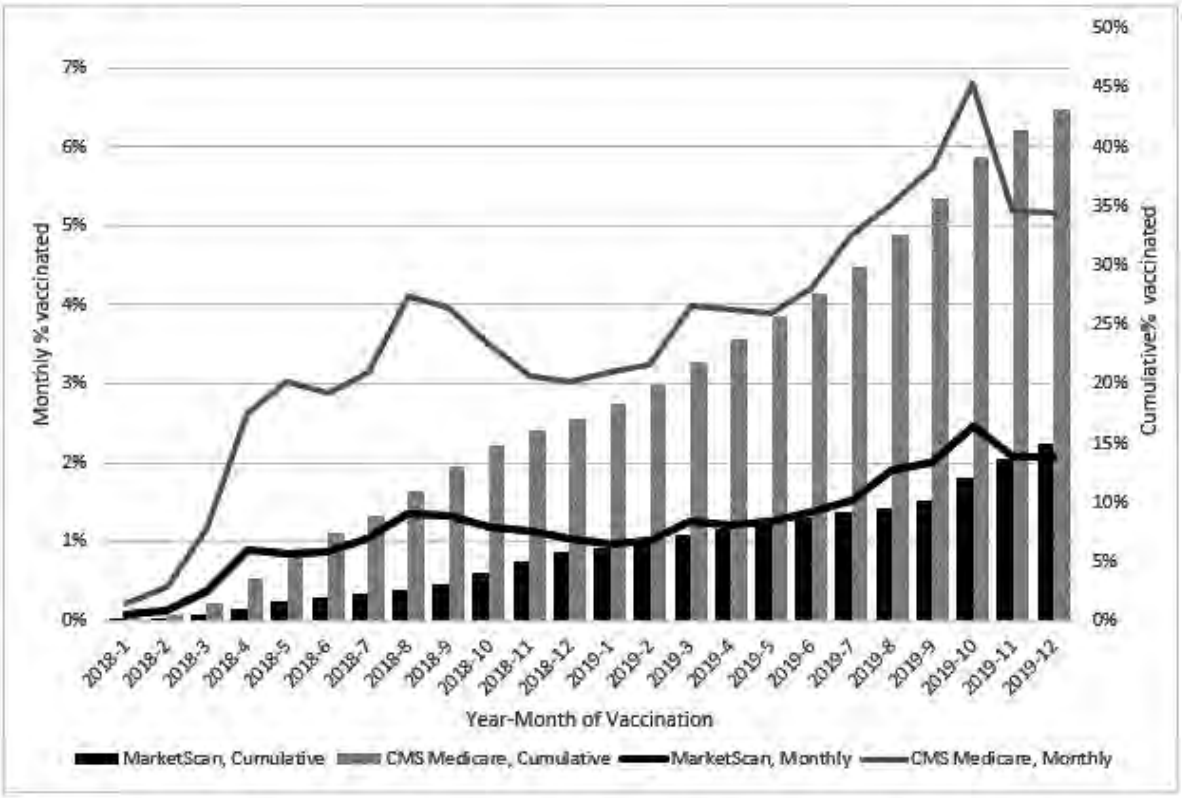
[a]2-dose RZV vaccination completion within 6 months of receipt of their first dose of RZV among persons who received their first dose before July 1, 2019 to allow for a 6-month follow-up period.

Background/Purpose: Persons with immune mediated Inflammatory diseases (IMIDs) are at increased risk of developing herpes zoster (HZ) and postherpetic neuralgia. In 2018, CDC recommended a highly efficacious (>90% efficacy) adjuvanted recombinant zoster vaccine (RZV, Shingrix) that was licensed as a two-dose series for prevention of HZ for immunocompetent persons age ≥50 years. In a 2018 national survey, ~2.4% of adults age ≥50 years self-reported receipt of RVZ, but RZV coverage in persons with IMIDs is unknown. We estimated the proportion of adults with selected IMIDs who received RZV vaccination between 2018–2019.

Methods: We used medical claims data from the 2017–2019 IBM® MarketScan® (persons age 50–64 years) and 2017–2019 Centers for Medicare and Medicaid Services Medicare (persons age ≥65 years) databases to examine RZV vaccination in persons with IMIDs (Rheumatoid Arthritis, RA; Ankylosing Spondylitis, AS; Axial Spondyloarthritis, SpA; Psoriatic Arthritis, PsA; Psoriasis, PsO; Inflammatory Bowel Disease, IBD; Crohn's Disease, CD; Ulcerative Colitis, UD; Systemic lupus erythematosus, SLE). Vaccine coverage was defined as receipt of ≥1 RZV dose. IMIDs were defined using all 3 of the following criteria: (a) ≥2 outpatient visits for their respective conditions, and (b) ≥1 claim for disease-specific medications, and (c) ≥1 visit to a relevant specialist (rheumatologist for RA, AS, SpA, PsA, SLE; gastroenterologist for IBD, CD, UC; dermatologist for PsO). RZV vaccination was defined using NDC and CPT codes.

Results: Among the 54,270 MarketScan enrollees with IMIDs, 14.8% received ≥1 dose of RZV, ranging from 11.6–21.5% depending on condition [Table 1]. There were 160,521 Medicare enrollees with IMIDs, among whom 43.2% had received ≥1 dose of RZV, ranging from 25.1–56.8% depending on the condition. Persons with RA, AS, and SPA

Figure 1. Monthly (Line graph) and Cumulative (Bar graph) Recombinant Zoster Vaccine (RZV) Coverage in Persons with Immune Mediated Inflammatory Diseases (IMIDs), MarketScan, 50–64-year-olds, and CMS Medicare, ≥65-year-olds, 2018–2019



Disclaimer: *The findings and conclusions in this report are those of the authors and do not necessarily represent the official position of the Centers for Disease Control and Prevention, US Department of Health and Human Services.*

Financial Disclosures: None

had the highest proportion vaccinated and persons with PsO had the lowest proportion. Among persons who initiated RZV vaccination, two-dose series completion within 6 months was 76.6% in MarketScan enrollees as compared to 85.5% in Medicare enrollees. Cumulative RZV vaccination and frequency of persons vaccinated monthly steadily increased during 2018–2019 [Figure 1]. When provider specialty prescribing vaccination was known among ≥65 year-olds (90% of vaccine doses), it was most frequently prescribed by physicians in family practice or internal medicine (52.9%) and pharmacists, (14.3%), and uncommonly by rheumatologists, dermatologists, or gastroenterologists (< 1% each).

Conclusion: A substantial proportion of adults age ≥50 years with IMIDs have received RZV vaccination; approximately 15–25% who received the first dose of RZV did not complete the 2-dose series within 6 months. RZV vaccination with at least one dose and 2-dose series completion was higher in ≥65 year-olds than 50–64 year-olds. Coverage in persons with IMIDs and in older ages may be higher than the general or younger populations because of physician recommendation for RZV or patient perception of increased risk for HZ. Additional data on efficacy and safety of RZV vaccination in this population, and vaccine policy recommendations may help to further increase RZV coverage.

SESSION INFORMATION

Session Date: Saturday, November 6, 2021

Session Title: Epidemiology & Public Health Poster I: COVID-19 & Vaccination (0084–0117)

Session Type: Poster Session A

Session Time: 8:30AM–10:30AM

Background/Purpose: Due to the impressive efforts of the global scientific rheumatology community, increasing evidence about inflammatory rheumatic and musculoskeletal diseases (RMD) specific risk factors in the pandemic has been achieved. In this analysis from the German COVID19-Rheuma registry, we analysed the risk factors for the outcome of SARS-CoV-2 infection in patients with RMD, specifically focusing on the impact of the RMD treatment.

Methods: Data from the German physician-reported COVID-19 registry for RMD from March 30th, 2020 until April 9th, 2021 were analysed. Ordinal outcome of SARS-CoV-2 infection severity was defined in three groups: neither hospitalized, ventilated nor deceased; hospitalized with or without non-invasive ventilation, but neither invasively ventilated

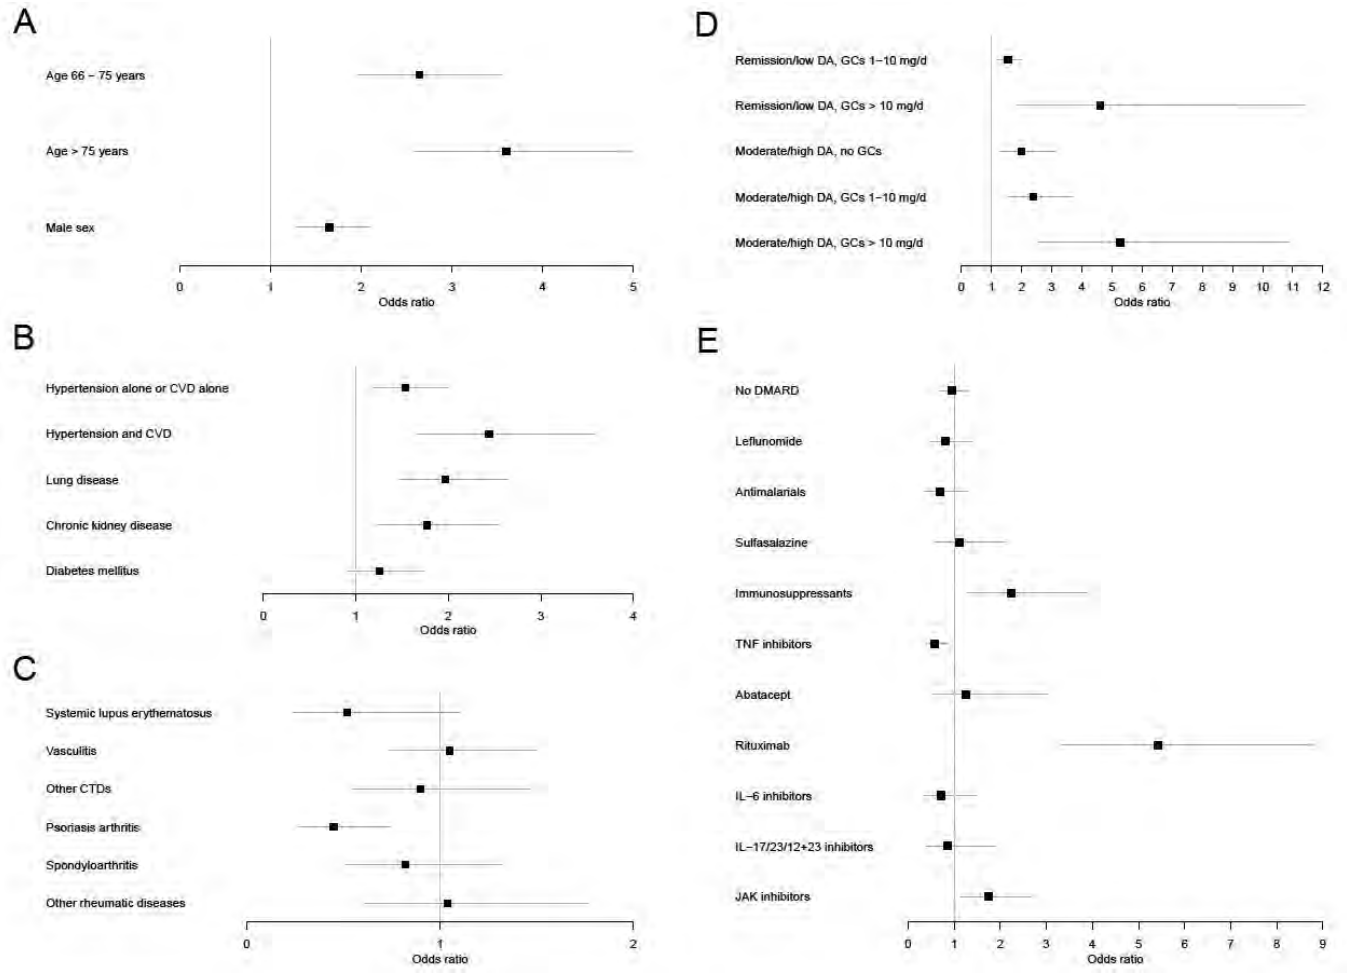

Figure 1A-E. Results of the ordinal regression analysis. Shown are multivariable-adjusted ORs for the outcome SARS-CoV-2 infection severity with 95% CIs, assessing the association with (A) general patient characteristics, (B) comorbidities, (C) rheumatic disease diagnoses (RMD), (D) disease activity and glucocorticoids, and (E) rheumatic disease medications.

nor deceased; invasively ventilated or deceased. Independent associations between demographic and disease features and SARS-CoV-2 infection-related severity were estimated by multivariable ordinal logistic regression using the proportional odds model and reported as odds ratio (OR) and 95% confidence interval (CI).

Results: 2,274 patients were included. Baseline characteristics are shown in table 1. 83 patients died, resulting in a case fatality rate of 3.6%.

In the ordinal regression analysis, age, male sex, cardiovascular disease, hypertension, chronic lung diseases, and chronic kidney disease were independently associated with a worse outcome of SARS-CoV-2 infection (fig. 1 a, b). Compared to RA, patients with PsA showed a lower OR (fig. 1c). Disease activity and glucocorticoids (GC) were associated with severity of SARS-CoV-2 infection as shown in figure 1d.

For the analysis of the impact of RMD treatment, MTX monotherapy was used as reference. TNFi showed a significant association with a better outcome of SARS-CoV-2 infection. In contrast, immunosuppressants (mycophenolate mofetil, azathioprine, cyclophosphamid, ciclosporin), JAKis and rituximab were independently associated with a worse outcome of SARS-CoV-2 infection (figure 1e).

Table 1. Baseline characteristics stratified by SARS-CoV-2 infection severity

Cyclosporin monotherapy	0	1 (0.3)	0	1 (0)
Cyclosporin combination therapy	5 (0.3)	1 (0.3)	0	6 (0.3)
bDMARDs monotherapy	440 (24.8)	57 (15.2)	29 (22.5)	526 (23.1)

Conclusion: Known general risk factors for severity of SARS-CoV-2 infection such as age, male sex, and certain comorbidities play a similar role in RMD patients. PsA patients have a better outcome of SARS-CoV-2 infection compared to RA. The influence of disease activity is of great importance as patients in high disease activity - even without GCs - have a worse outcome. Regarding RMD treatment, patients on TNFi show a better outcome of SARS-CoV-2 infection than MTX patients. The negative impact of sulfasalazin shown in the global rheumatology alliance analysis

Data are N (column %) for categorical variables or mean (SD) for continuous variables. Table includes all patients with a non-missing outcome and non-missing values for age, sex and disease-modifying anti-rheumatic drugs (DMARDs) (4 patients excluded). Data refers to patients with non-missing values for the respective variable; total N for patients with non-missing values is given in parentheses for variables with missing values; the total number of missing values is also given in parenthesis, for the applicable variables. (#) Includes patients with a missing glucocorticoid dosage.

bDMARD, biological disease-modifying anti-rheumatic drugs; BMI, body mass index; csDMARD, conventional synthetic disease-modifying anti-rheumatic drugs; CTD, connective tissue diseases; DMARD, disease-modifying anti-rheumatic drugs; IL, interleukin; JAK, Janus kinase; JIA, juvenile idiopathic arthritis; N, number; NSAID, non-steroidal anti-inflammatory drugs; SLE, Systemic lupus erythematosus; TNF; tumour necrosis factor; tsDMARD, targeted synthetic disease-modifying anti-rheumatic drugs.

[1] was not reproduced in this analysis. This might be due to the larger homogeneity in our data deriving from one country, resulting in less bias. The signals showing a less favorable outcome of SARS-CoV-2 infection for immunosuppressants, rituximab, and JAKi could be reproduced. These associations with a worse outcome of SARS-CoV-2 infection may be attributed to residual and unmeasured confounding due to higher burden of comorbidity or cumulative effect of therapies. However, the data show that the individual risk/benefit ratios for the different RMD treatments should be carefully considered and further evaluated.

SESSION INFORMATION

Session Date: Saturday, November 6, 2021

Session Title: Epidemiology & Public Health Poster I: COVID-19 & Vaccination (0084–0117)

Session Type: Poster Session A

Session Time: 8:30AM–10:30AM

Background/Purpose: Retrospective studies have suggested that patients with rheumatic diseases may be at increased risk of severe COVID-19 related disease, and that this risk may partly be related to specific antirheumatic therapies. We investigated this in a large prospective controlled cohort study. The primary objective of the study was to investigate whether patients with rheumatic diseases are at increased risk of developing severe COVID-19 manifestations, defined as hospitalizations, compared to the general population. Secondary objectives were to analyze associations between anti-rheumatic treatment and disease severity of COVID-19, and to monitor the sustainability of SARS-CoV-2 specific IgG antibody titers over time.

Methods: All adult patients with inflammatory rheumatic diseases from the Amsterdam Rheumatology & Immunology Center, Amsterdam and Amsterdam UMC were invited to participate in the study (Netherlands Trial Register, trial ID NL8513). Patients were asked to register their own healthy control subject who were of the same sex and comparable age. During follow-up, participants received three digital questionnaires assessing patient and COVID-19 related characteristics. Serum samples were collected at two different time points, and analyzed for the presence of SARS-CoV-2 specific antibodies using a highly sensitive RBD-Ab bridging ELISA. COVID-19 cases were defined as participants with at least one positive PCR or a positive antibody test result.

Results: Between April, 2020, and March, 2021, 3279 rheumatic patients and 1110 healthy controls were included in the study. The mean age of patients and controls was 58 ± 13 and 56 ± 13 years respectively, and 1647 (63%) patients and 626 (69%) controls were female. Diagnosis of COVID-19 was confirmed in 307 (9%) patients and 128 (12%) healthy controls. The COVID-19 related hospitalization rate was significantly higher in patients compared to controls; 18 (6%) patients and 1 (1%) healthy control were hospitalized (*P* 0.02). Table 1 compares characteristics of non-hospitalized and hospitalized rheumatic patients with a confirmed COVID-19 diagnosis. It can be seen that patients with older age, male sex, a history of chronic pulmonary disease or diabetes, and patients who were treated with prednisone or rituximab were more frequently hospitalized. In contrast, patients treated with hydroxychloroquine or TNF-inhibitors were less frequently hospitalized.

Table 1. Characteristics of rheumatic patients: non-hospitalized vs. hospitalized COVID-19 cases.		
Patient characteristics	**Non-hospitalized patients (n=307)**	**Hospitalized patients (n=18)**
Age (years) – mean ± SD	54 ± 13	60 ± 12
Female sex – no. (%)	216 (67)	7 (39)
BMI – mean ± SD	26 ± 5	27 ± 5
Coexisting conditions – no. (%)		
Cardiovascular disease	18 (6)	1 (6)
Chronic pulmonary disease	23 (6)	2 (11)
Diabetes	11 (4)	4 (22)
Immunosuppressive medication – no. (%)		
Methotrexate	119 (38)	6 (33)
Hydroxychloroquine	43 (14)	1 (6)
TNF inhibitor	97 (32)	3 (17)
Tocilizumab	5 (2)	0 (0)
Abatacept	6 (2)	0 (0)
Rituximab	4 (1)	2 (12)
Oral glucocorticoids	32 (10)	3 (17)

Values are displayed as mean ± standard deviation (SD) or frequencies with corresponding percentages (%). BMI = Body mass index.

Conclusion: Our data suggest, albeit based on a limited number of patients in the hospitalization group, that patients with rheumatic diseases are at increased risk of COVID-19 related hospitalization. In addition, treatment with rituximab or prednisone seems to increase the risk of COVID-19 related hospitalization, while treatment TNF-inhibitors and hydroxychloroquine may have protective effects.

SESSION INFORMATION

Session Date: Saturday, November 6, 2021
Session Title: Epidemiology & Public Health Poster I: COVID-19 & Vaccination (0084–0117)
Session Type: Poster Session A
Session Time: 8:30AM–10:30AM

Background/Purpose: Clinical trials on efficacy and safety of SARS-CoV-2 vaccines did not include patients with autoimmune diseases. We previously demonstrated that concerns of adverse events and disease exacerbations due to SARS-CoV-2 vaccinations are important reasons for vaccine hesitancy in this patient group. Consequently, data on effects of SARS-CoV-2 vaccinations on patients with autoimmune diseases are urgently needed. The primary objective was to compare the frequency and severity of adverse events following SARS-CoV-2 vaccinations between patients with autoimmune diseases and healthy controls. Secondary objectives were to assess whether autoimmune disease activity was influenced by SARS-CoV-2 vaccinations, and whether any vaccine (AstraZeneca, Pfizer/BionN-Tech or Moderna) would be preferable for patients with autoimmune diseases.

Methods: On April 14th, 2021, a digital questionnaire evaluating consequences of SARS-CoV-2 vaccinations was sent to patients with systemic autoimmune diseases and healthy controls, who were enrolled in two ongoing prospective cohort studies of the Amsterdam Rheumatology & Immunology Center, Amsterdam and Amsterdam UMC (Netherlands Trial Register, trial ID NL8513 and NCT04498286). Mild adverse events were defined as annoying but not limiting daily activities, moderate adverse events as limiting daily activities, and severe adverse events as necessity of a visit to a medical expert. Multivariable logistic regression analyses were used to compare the occurrence of any adverse event, and the occurrence of moderate/severe adverse events following SARS-CoV-2 vaccinations between patients and controls. Effect modification was investigated for gender and vaccine type.

Results: On April 25th, 2021, 501 patients (420 patients with rheumatic diseases and 81 patients with multiple sclerosis) and 184 healthy controls were vaccinated against SARS-CoV-2 and included for analyses. The mean age of patients and controls was 63 (SD 11) and 64 (SD 11) years respectively, and 329 (66 %) patients and 119 (65%) controls were female. AstraZeneca and Pfizer/BioNTech were the most commonly applied vaccines in both patients and controls. The majority of patients and controls experienced at least one mild adverse event (56% vs. 58%), a minority at least one moderate adverse event (23% vs. 21%), and severe adverse events were rare (1% vs. 0%). A small proportion of patients (5%) reported to experience a deterioration of their autoimmune disease following SARS-CoV-2 vaccination. Results of the regression analyses are shown in table 1. After adjusting for age, gender and vaccine type, the odds for patients and healthy controls to experience any, systemic or moderate/severe adverse event(s) following the first SARS-CoV-2 vaccination were comparable. No effect modification by gender or vaccine type was demonstrated.

Conclusion: Our data demonstrate that patients with autoimmune diseases are not at an increased risk of experiencing adverse events from vaccination with AstraZeneca, Moderna or Pfizer/BioNTech compared to the general population, and that the impact of these vaccines on autoimmune disease activity is minimal.

Table 1. The risk of adverse events following the first SARS-CoV-2 vaccination in patients with autoimmune diseases compared to healthy controls.

	Any adverse event			Systemic adverse event			Moderate/severe adverse event		
First vaccination									
All patients	1.1	(0.7 – 1.6)	P = 0.73	1.1	(0.8 – 1.6)	P = 0.60	1.1	(0.8 – 1.8)	P = 0.48
RA patients	0.9	(0.6 – 1.4)	P = 0.54	1.0	(0.6 – 1.6)	P = 0.94	1.0	(0.6 – 1.7)	P = 0.96
MS patients	1.2	(0.6 – 2.4)	P = 0.55	1.5	(0.8 – 2.9)	P = 0.18	1.4	(0.7 – 2.8)	P = 0.32

Values are displayed as odds ratios with corresponding 95% confidence intervals and P-values. Odds ratios are adjusted for age, gender and vaccine type. RA = rheumatoid arthritis, MS = multiple sclerosis.

SESSION INFORMATION

Session Date: Saturday, November 6, 2021

Session Title: Epidemiology & Public Health Poster I: COVID-19 & Vaccination (0084–0117)

Session Type: Poster Session A

Session Time: 8:30AM–10:30AM

Background/Purpose: Patients with rheumatic and musculoskeletal diseases (RMDs) remain at an increased risk of morbidity and mortality from vaccine preventable infections, often as a result of disease activity, comorbidities, and immunosuppressive medication.[1] Despite increased risk, vaccine uncertainty and hesitancy remain ongoing

Table 1. Impact of COVID-19 vaccination on SpA symptoms

Do you believe taking the COVID-19 vaccine affected your SpA symptoms? (N=1292)	
Response:	**Count (n [%])**
Receiving the vaccine has not affected my SpA symptoms	997 (77.2)
My disease activity changed but I believe this was the result of something other than the vaccine, such as holding medication	116 (9.0)
The 2nd shot made my disease significantly worse	71 (5.5)
The 1st shot made my disease significantly worse	63 (4.9)
Both shots made the disease significantly worse	33 (2.6)
The 1st shot made my disease significantly better	<10 (<0.8)
Both shots made the disease significantly better	<10 (<0.8)
The 2nd shot made my disease significantly better	<10 (<0.8)

Table 2. Medication modifications due to COVID-19 vaccination

Did you modify your medications due to vaccination? And if so, which medicines were reduced or stopped temporarily?* (N=1539)	
Response:	**Count (n [%])**
No, I did not modify medication	1020 (66.3)
Yes, I modified biologics	222 (14.4)
Yes, I modified NSAIDs	129 (8.4)
Yes, I modified MTX	92 (6.0)
Yes, I modified another medication	40 (2.6)
Yes, I modified prednisone	17 (1.1)
Yes, I modified SSZ	<10 (<0.6)
Yes, I modified a JAK inhibitor	<10 (<0.6)
Yes, I modified HCQ	<10 (<0.6)
*Participants may select multiple responses	

challenges among this population and continue to be observed during the COVID-19 pandemic.[2] Even as COVID-19 vaccinations become more accessible, relatively low acceptance of the vaccine among the general population may negatively impact RMD populations, who would benefit from increased protection against COVID-19 illness.[3]

Methods: We conducted a web-based follow-up survey of spondyloarthritis (SpA) patients in the U.S. and Canada who had previously participated in a Spondylitis Association of America-sponsored COVID-19 survey. Fifteen multiple-choice questions were designed to capture information related to COVID-19 vaccine acceptance, attitudes, medication modification, perceived impact of vaccination on disease activity, past and present vaccine hesitancy or refusal, and COVID-19 vaccine information sources among SpA patients. Beginning April 1st 2021, participants were prompted to complete the follow-up questions via an email blast and social media posts.

Results: Between April 1st and April 27th, 1745 self-reported SpA participants responded to the survey. Overall, 1430 (81.9%) indicated they had received at least one dose of a COVID-19 vaccine and 10.1% planned to be vaccinated in the future. Fifty-one (2.9%) were undecided about receiving a COVID-19 vaccination and only 88 (5%) did not intend to receive the vaccine in the future. Among the 1539 responses from vaccinated participants (multiple selections possible), 1020 (66.3%) did not modify their SpA treatment due to vaccination, 222 (14.4%) modified a biologic, 129 (8.4%) modified an NSAID, 92 (6%) modified MTX, and 73 (4.9%) modified another medication. Among 1292 vaccinated participants, 997 (77.2%) indicated the COVID-19 vaccine had no effect on their SpA symptoms, 167 (12.9%) reported worsening symptoms after the first, second, or both vaccines, and 116 (9%) indicated a change in disease activity that they attributed to another factor, such as modified medication. Among 194 unvaccinated participant responses (multiple selections possible), 61 (31.4%) indicated fear of potential vaccine side effects as their main reason to decline, 39 (20.1%) indicated that the vaccine wasn't mandated and it was their right to decline, and 36 (18.6%) indicated fear of worsened disease symptoms.

Conclusion: Willingness to receive the COVID-19 vaccine was high and uncertainty and hesitancy were low among survey participants; over half of respondents were eager to be vaccinated. Nearly 80% of vaccinated participants indicated that the vaccine had no effect on their SpA symptoms, and only 1/3 modified their SpA treatment due to vaccination. These findings highlight the lower impact of vaccination on SpA disease activity, and may encourage other hesitant or unsure SpA patients concerned about increased disease activity to get vaccinated against SARS-CoV-2.

Abstract Number: 0106

COVID-19 Mortality and Hospitalization Risk in Patients with Rheumatic Diseases: A Single Center Retrospective Cohort Study

Mousa Albalwi, Ben Brintz, Srinivasan Beddhu, Guo Wei and Julie Thomas, University of Utah, Salt Lake City, UT

SESSION INFORMATION
Session Date: Saturday, November 6, 2021
Session Title: Epidemiology & Public Health Poster I: COVID-19 & Vaccination (0084–0117)
Session Type: Poster Session A
Session Time: 8:30AM–10:30AM

Background/Purpose: Following SARS-CoV-2 infection, patients with rheumatic diseases seem to have similar or slightly poorer outcomes compared with those without rheumatic disease. However, robust data is lacking to inform our understanding of mortality and morbidity following COVID-19 infection in patients with rheumatic diseases.

Methods: The University of Utah COVID-19 database identifies all adult patients that tested positive with Covid-19 at a University of Utah facility throughout the state of Utah. This database was used to identify and glean data from all Covid-19 positive patients retrospectively from January 1, 2020 to March 26, 2021. Patients with rheumatic diseases testing positive for Covid-19 were identified from this database using ICD-10 codes of the most common rheumatic diseases, including rheumatoid arthritis, lupus, inflammatory myositis, vasculitis, spondyloarthritis, sarcoidosis, and gout. Outcomes of interest included mortality, hospitalization, and length of stay. For each outcome, we conducted univariable analysis and used weighted (propensity scores) and unweighted multivariable logistic regression to estimate odds ratio (ORs) and 95% confidence interval (CI) based on the presence of rheumatic diseases. Age, sex, Charleson Comorbidity Index (CCI) and BMI were included as covariates in multivariable logistic regression models. Subgroup analysis was performed for glucocorticoids, conventional synthetic disease modifying agents (cDMARDs) and biological disease modifying agents (bDMARDs) medications.

Results: The University of Utah COVID-19 database identified 39,114 patients with confirmed COVID-19 infection with 195 deaths (0.5 %) from January 1, 2020 to March 26, 2021. 979 patients were identified with rheumatic diseases (2.5%) (see Table 1). In weighted and unweighted multivariable logistic regression, rheumatic disease was associated with higher odds of death (OR 1.5, 95% CI 1.01 to 2.22) and (OR 1.57, 95% CI 1.02 to 2.39), respectively. Rheumatic disease was also associated with higher odds of hospitalization (OR 1.77, 95% CI 1.48 to 2.13). Independent factors associated with COVID-19-related death were age (OR 1.08, 95% CI 1.07 to 1.1), male sex (2.52, 1.83 to 3.47) and CCI (1.27, 1.21 to 1.32). In the immunosuppressants subgroup analysis, there was no evidence for a difference in odds of death in glucocorticoids (OR 0.65, 95% CI 0.23 to 1.84), conventional synthetic DMARDs (OR 0.39, 95% CI 0.13 to 1.22) and biological DMARDs (OR 1.13, 95% CI 0.12 to 10.43).

Table 1. Summary of Group Characteristics in a Univariate Analysis

Variable		No Rheumatic Diseases (N=38135)	Rheumatic Diseases (N=979)	P-value
Gender :	Female	19494 (51.1%)	531 (54.2%)	0.16[f]
	Male	18618 (48.8%)	448 (45.8%)	-
Race :	White	18278 (47.9%)	336 (34.3%)	<0.001[c]
	Non-white	19857 (52.1%)	643 (65.7%)	-
Age :	Mean (SD)	38.9 (15.1)	52.5 (16.5)	<0.001[t]
BMI :	Mean (SD)	29.7 (8.8)	31.7 (8.2)	<0.001[t]
Charleson Comorbidity Score :	Mean (SD)	0.4 (1.3)	3.0 (3.1)	-
Death from COVID :	No	37976 (99.6%)	943 (96.3%)	<0.001[f]
	Yes	159 (0.4%)	36 (3.7%)	-
Hospitalization :	No	36181 (94.9%)	759 (77.5%)	<0.001[c]
	Yes	1954 (5.1%)	220 (22.5%)	-
Length of Stay in Days *:	- Mean (SD)	5.77 (8.8)	8.57 (9.9)	-

[f] Fisher's exact test, [c] Chi-squared test, [t] T-test, [w] Wilcoxon rank sum test.
**Based on only patients who have at least an overnight stay in the hospital*

Conclusion: Among patients with COVID-19 infection, persons with rheumatic diseases have an increased odds of death and hospitalization compared to persons without rheumatic diseases.

SESSION INFORMATION

Session Date: Saturday, November 6, 2021
Session Title: Epidemiology & Public Health Poster I: COVID-19 & Vaccination (0084–0117)
Session Type: Poster Session A
Session Time: 8:30AM–10:30AM

Background/Purpose: The first COVID-19 vaccines were authorized in December 2020. However, their acceptability remains debated and has never been evaluated in patients with chronic rheumatic disease and health care professionals (HCPs) in the Arab countries. The primary objective of this study was to assess the acceptability of COVID-19 vaccines in patients with chronic rheumatic disease and HCPs in the Arab countries and to evaluate the factors associated with acceptability.

Table 1. Characteristics of the Participants in the Arab COVID-19 Perceptions (ARCOVAX) study and Vaccination status

	Patients	Health Care Professionals	All Participants

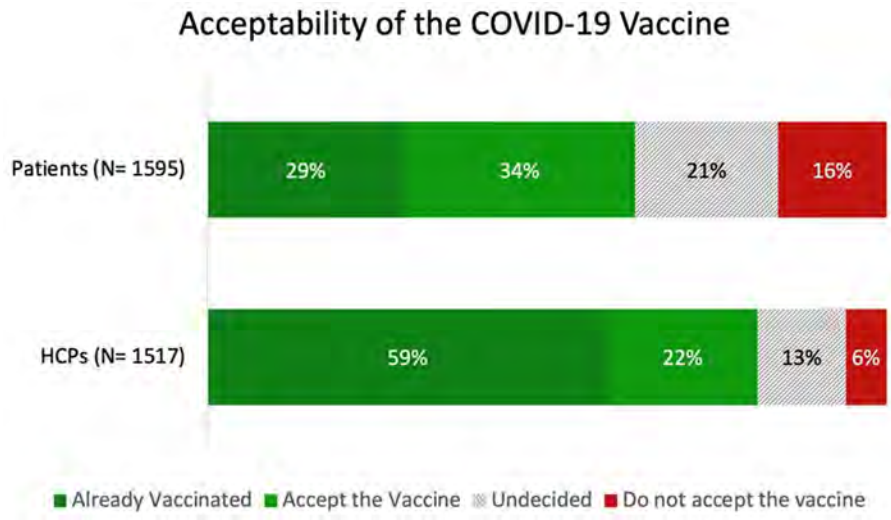

Figure 1. Acceptability of the COVID-19 Vaccination in Patients and in Health Care Professionals (HCPs).

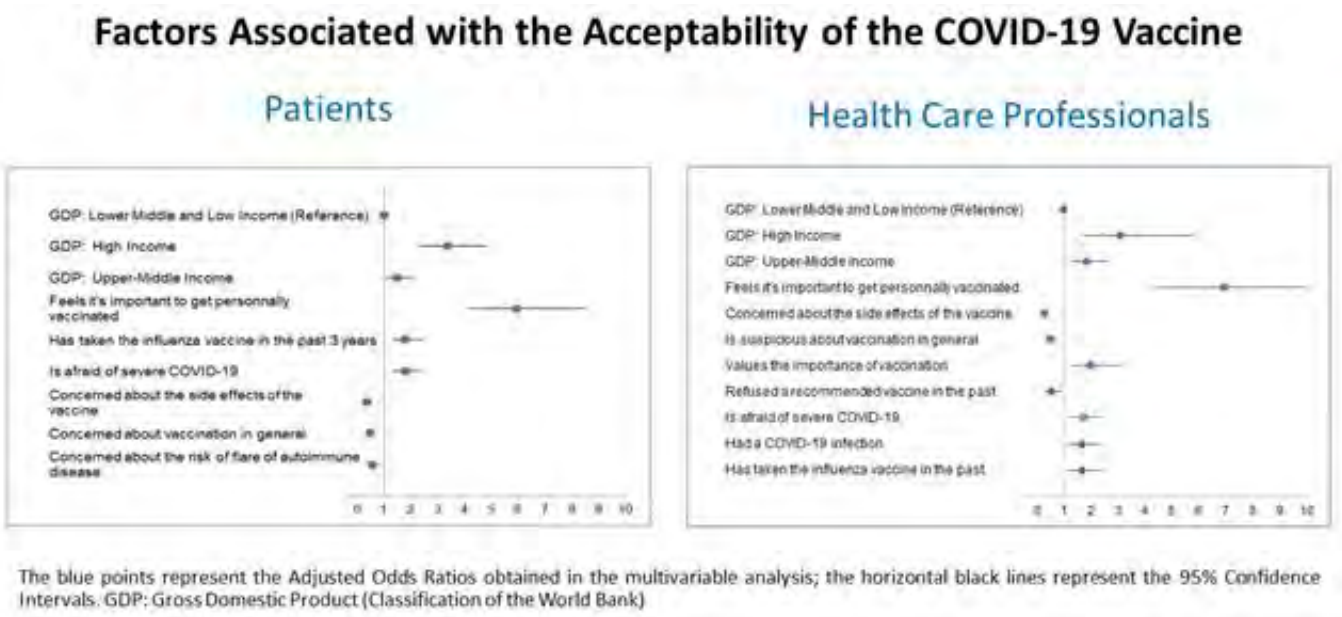

Figure 2. Factors associated with the acceptability of the COVID-19 vaccine in patients and health care professionals in the multivariable analysis.

Methods: The ARCOVAX (Arab League of Associations for Rheumatology (ArLAR) COVID Vaccination study) utilized an anonymous web-based survey that was adapted from the VAXICOV study (1), translated to Arabic by the authors, and validated by the scientific committee of the ArLAR. The survey was disseminated online in three languages: Arabic, English, and French between April 13th and May 11th, 2021, through multiple social media platforms (Facebook, Twitter, Instagram, Snapchat), patients' associations, mass emails from ArLAR and AAAA (Arab Adult Arthritis Awareness) group, WhatsApp messages to rheumatologists and patients, and direct invitation to patients while in the waiting room. Acceptability was defined by participants who were already vaccinated or willing to get vaccinated; non-acceptability was defined by participants who were undecided or refused to get vaccinated. Demographic and disease data, perceptions about COVID-19 vaccines were presented in numbers and percentages for categorical variables and means and standard deviations or medians and interquartile ranges for continuous variables, as appropriate. The factors associated with acceptability were evaluated using two separate binary logistic regression models for patients and HCPs, respectively.

Results: A total of 3,176 participants from 19 Arab countries completed the survey (1,594 patients and 1,517 HCPs). The mean age of the patients was 39 years, 73% were female and 18% had a university degree (Table 1). Twenty-nine percent of the patients were already vaccinated, versus 59% of the HCPs. Acceptability was significantly lower in patients (63%) compared to HCPs (81%), p< 0.001 (Figure 1), and remained significantly lower when considering the non-vaccinated participants only (p=0.006). Among the patients who were not vaccinated, 57% of the undecided and 40% of those who refused the vaccine would be willing to get vaccinated if it were recommended by their physician. In both patients and HCPs, acceptability was associated with a higher country gross domestic product, the feeling that it is important to be personally vaccinated, previous Influenza vaccination, fear of COVID-19 and lower levels of concerns regarding the vaccines side effects (Figure 2).

Conclusion: Acceptability of the COVID-19 by patients (63%) was significantly lower than HCPs (81%) but may be substantially improved if the vaccine was recommended by the doctor. Addressing the main determinants of acceptability, i.e., perceptions regarding vaccination and concerns regarding the side effects of the COVID-19 vaccines may facilitate the uptake of the vaccine in patients and in HCPs.

Abstract Number: 0108

Efficacy of *SARS-CoV-2* Vaccine in Patients with Rheumatic Diseases: A Systematic Review and Meta-Analysis

Akhil Sood[1], Vijaya Murthy[1] and Emilio Gonzalez[2], [1]University of Texas Medical Branch, League City, TX, [2]University of Texas Medical Branch (utmb Health), Galveston, TX

SESSION INFORMATION
Session Date: Saturday, November 6, 2021
Session Title: Epidemiology & Public Health Poster I: COVID-19 & Vaccination (0084–0117)
Session Type: Poster Session A
Session Time: 8:30AM–10:30AM

Background/Purpose: The mRNA-based *SARS-CoV-2* vaccine has shown efficacy in large vaccine trials. However, patients on immunosuppressive therapies including those with rheumatic disease (RD) were excluded. Recent studies have examined the immunogenicity of *SARS-CoV-2* vaccination in immunocompromised patients. We thus conducted a systematic review and meta-analysis on the humoral immune response of *SARS-CoV-2* vaccination in patients with rheumatic disease.

Methods: We systematically searched Pubmed/Medline, Scopus, and MedRxiv from January 1, 2021- May 30, 2021 to identify eligible studies that examined the immunogenicity of *SARS-CoV-2* vaccination in RD patients. Included studies provided information on proportion of RD patients who developed an immune response following the second dose of the vaccine. Immune response was defined as development of IgG antibodies to *SARS-CoV-2* S anti-receptor binding domain (RBD) or neutralizing antibodies with cutoffs established by manufacturer. Information on RD type and immunosuppressant use was also obtained from each study. Meta-Analysis was performed using Comprehensive Meta-Analysis.

Results: Our meta-analysis included eight studies (3 observational studies, 5 case-control studies) which was comprised of 1482 RD patients. The pooled response rate following vaccination against *SARS-CoV-2* was 0.88 (95% CI 0.75-0.94). Compared to non-RD patients, RD patients had significantly decreased response to *SARS-CoV-2* vaccination (RR 0.88, 95% 0.84-0.93). Patients on rituximab (37%), mycophenolate (70.8%), prednisone (86.6%), and methotrexate (91.9%) showed lower vaccine response. On the other hand, patients on TNF (100%), JAK (96.3%), and IL-17 inhibitors (92.9%) showed higher vaccine response.

Conclusion: In this systematic review and meta-analysis, majority of RD patients developed an immune response following second dose of *SARS-CoV-2* vaccine. However, the vaccine response rate was significantly lower in RD patients compared to controls. This is likely driven by certain immunosuppressants particularly B-cell depleting therapy which can hamper the humoral immune response. Future studies need to examine the use and timing of these immunosuppressants prior to *SARS-CoV-2* vaccination.

COVID-19 Infection and Outcomes in Patients with Rheumatic Diseases: A Systematic Review and Meta-Analysis

Akhil Sood[1], Ronak Gandhi[2], Vijaya Murthy[1], Emilio Gonzalez[3] and Mukaila Raji[2], [1]University of Texas Medical Branch, League City, TX, [2]University of Texas Medical Branch, Galveston, TX, [3]University of Texas Medical Branch (utmb Health), Galveston, TX

SESSION INFORMATION
Session Date: Saturday, November 6, 2021
Session Title: Epidemiology & Public Health Poster I: COVID-19 & Vaccination (0084–0117)
Session Type: Poster Session A
Session Time: 8:30AM–10:30AM

Background/Purpose: Early studies published at the beginning of COVID-19 pandemic suggested lower risk of COVID-19 and less severe disease course in patients with rheumatic diseases (RD). Subsequent studies have been published worldwide since the onset of the COVID-19 pandemic with studies showing mixed results. We thus conducted a systematic review and meta-analysis on the prevalence and outcomes of COVID-19 in patients with rheumatic diseases.

Methods: PubMed/Medline and Scopus were systematically searched from January 1, 2020 to April 31, 2021 to identify observational and case-control studies that reported prevalence and outcomes of confirmed *SARS-CoV-2* infection (by polymerase chain reaction or serologies) among patients with inflammatory and autoimmune rheumatic diseases (RD). The secondary outcomes measured were hospitalization, admission to Intensive Care Unit (ICU), use of mechanical ventilation, and death. Additional information including demographics and medication use were obtained from each of the studies. Medications were classified by conventional synthetic disease-modifying antirheumatic drugs (csDMARD), biologic/targeted synthetic DMARD (b/tsDMARD), and glucocorticoids (GC).

Results: Our meta-analysis included 35 observational studies composed of 68,537 patients with rheumatic disease. The pooled prevalence of COVID-19 was 0.016 (95% CI 0.008-0.031). The hospitalization rate was 0.54 (95% CI 0.46-0.62); admission to ICU was 0.12 (95% CI 0.09-0.17); death was 0.12 (95% CI 0.10-0.15). Both csDMARDs (OR 2.21 (95% CI 1.55-3.14) and glucocorticoids (OR 2.55 (95% CI 1.13-3.61) were associated with increased risk for hospitalization. Patients on biologic/targeted synthetic DMARDs had decreased risk for hospitalization (OR 0.56,

95% CI 0.40-0.78). Meta-analysis of 16 case control studies showed that RD patients were at increased risk for COVID-19 infection compared to general population (OR 1.57, 95% CI 1.35-1.82). The risk for hospitalization was not increased compared to controls (OR 1.01, 95% CI 0.62-1.63). However, among those hospitalized, patients with RD—compared to non-RD controls—were at increased risk for admission to intensive care unit (OR 1.05, 95% CI 0.75-1.48), use of mechanical ventilation (OR 1.20, 95% CI 0.80-1.80) and death (OR 1.17, 95% CI 1.01-1.36).

Conclusion: In this systematic review and meta-analysis, patients with rheumatic diseases had similar rate of COVID-related hospitalization as non-RD controls. However, hospitalized RD patients had poorer in-hospital outcomes and higher mortality. The poor in-hospital outcomes in RD population with COVID-19 may—at least in part—reflect the use of immunomodulating medications such as glucocorticoids and csDMARDs. A counterintuitive finding from our meta-analysis is the association of b/tsDMARDs with lower risk for hospitalization due to COVID-19. Future studies are necessary to closely examine the risk and protective factors for severe outcomes in RD patients with COVID-19.

Mortality in 2020 Due to COVID-19 in U.S. Adults with Rheumatic Diseases: Data from a Large, National, Multi-Rheumatic Disease Registry

Kaleb Michaud[1], Sofia Pedro[2], Rebecca Schumacher[3], Mukund Kumar[1], Bryant England[1] and Alison Freifeld[1], [1]University of Nebraska Medical Center, Omaha, NE, [2]Forward, The National Databank for Rheumatic Diseases, Wichita, KS, [3]Forward Databank, Wichita

SESSION INFORMATION
Session Date: Saturday, November 6, 2021
Session Title: Epidemiology & Public Health Poster I: COVID-19 & Vaccination (0084–0117)
Session Type: Poster Session A
Session Time: 8:30AM–10:30AM

Background/Purpose: Recent studies have detailed the excess death due to COVID-19 during the pandemic, yet few have examined these rates within a rheumatic disease population predisposed to COVID-19 and with extensive disease characterization. We sought to investigate the risk of mortality among patients with rheumatic diseases during 2020, and further examine aspects of those who died of COVID-19.

Methods: We studied non-deceased participants in FORWARD, The National Databank for Rheumatic Diseases, a longitudinal observational study following patients through biannual questionnaires as of January 1, 2020. Primary rheumatic disease diagnosis was confirmed through physicians and categorized as either inflammatory (Inflam) or non-inflammatory (Non-Inflam) and, in a large subset, RA vs Non-Inflammatory Rheumatic Disease (NIRD) that excludes primary fibromyalgia. Mortality was confirmed through US National Death Index-matched death records from 1/1999 through recently released 12/2020. Death records were classified by conditions that appeared concomitantly with COVID-19 to better identify possible misclassification of non-COVID-19 cases earlier in the pandemic (1). Patients were characterized at baseline or study enrollment in Forward. Cox regressions with baseline covariables were used to investigate the risk of mortality by diagnoses. Secondary analyses examined respiratory specific causes and those who died of COVID-19 during 2020. Finally, deaths that occurred in 2020 were compared to a similar cohort of deaths that occurred in 2019.

Results: Among 37,853 participants, 1100 died during 2020 (2.9%) and are characterized in Table 1. Those who died were older, more frequently had a diagnosis of RA, had worse socioeconomic status and disease measures,

and completed fewer questionnaires. By cause of death, those with inflammatory disease or RA had increased respiratory-specific cause of death, while those with NIRD had increased deaths related to heart failure, dementia, and renal failure (Table 2). Deaths from COVID-19 were found in 81 patients, most frequently together with respiratory-specific and diabetes diagnoses. Predictors of mortality were studied among Inflam vs Non-Inflam and also RA vs NIRD. Adjusting for baseline confounders such as sex, age age^2, disease severity, comorbidities, smoking and socioeconomic status, HRs were 1.31 (1.09 – 1.58) for Inflam vs Non-Inflam and 1.28 (1.02-1.60) for RA vs NIRD. For respiratory-specific deaths, the same HR were 1.72 (1.07 – 2.80) and 1.66 (0.92 – 3.00), respectively. There were 1074 deaths in 2019 and the causes of death were similar between 2019 and 2020 with the exceptions of COVID-19 and reduced other causes of death not associated with COVID-19 in 2020.

Conclusion: Using a large, multi-rheumatic disease registry and expedited NDI data, we found COVID-19 to be recorded in 8% of all 2020 deaths and was associated with respiratory failure, diabetes, renal failure, and disassoci-

SESSION INFORMATION
Session Date: Saturday, November 6, 2021
Session Title: Epidemiology & Public Health Poster I: COVID-19 & Vaccination (0084–0117)
Session Type: Poster Session A
Session Time: 8:30AM–10:30AM

Background/Purpose: New cases of the novel coronavirus disease (COVID-19) continue to occur even one year since the declaration of a global pandemic. Although most people will experience mild-to-moderate symptoms, some patients will experience severe and potentially fatal outcomes. Patients with rheumatic diseases may be at higher risk of experiencing severe outcomes compared to the general population. The purpose of this study was to compare the risk of hospitalization, admission to intensive care and mortality due to COVID-19 in patients with rheumatic diseases compared to the general population.

Methods: We used administrative health data from British Columbia (BC), Canada (population 5.1M) to conduct a population-based matched cohort study. Among all COVID-19 cases in BC between February 6, 2020 and April 15, 2021, we used ICD codes to identify all individuals with a rheumatic disease including: rheumatoid arthritis (RA), psoriasis/psoriatic arthritis (PsO/PsA), ankylosing spondylitis (AS), gout, systemic lupus erythematosus (SLE), and other systemic autoimmune rheumatic diseases (SARDs, including systemic sclerosis, Sjogren's syndrome, myopathy, undifferentiated connective disease, and adult systemic vasculitides). All cases of COVID-19 were confirmed by a positive SARS-CoV-2 PCR test from the provincial Centre for Disease Control. Each individual with a rheumatic disease was matched with up to 5 individuals without rheumatic disease of similar age (± 5 years), sex, month and year of COVID-19 diagnosis and health authority. The risk of COVID-19 related hospitalization, intensive care unit (ICU) admission, mortality after COVID-19 diagnosis, and mortality with COVID-19 listed as primary cause were compared using multivariate logistic regression adjusting for age and Charlson Comorbidity Index score.

Results: Among the 104,508 cases of COVID-19 in BC up to April 15th, 2021, we matched 1581 individuals with RA, 1950 PsO/PsA, 378 AS, 1773 gout, 179 SLE, and 660 other SARDs to individuals without rheumatic disease. There was a statistically significant increase in the adjusted risk of hospitalization due to COVID-19 for individulas with RA (OR: 1.58),PsO/PsA (OR: 1.39), AS (OR: 2.16), gout (OR: 1.43), and other SARDs excluding SLE (OR: 1.71). While the risk of ICU admissions was significantly increased only for individuals with RA (OR: 1.43), AS (OR: 2.29) and other

Table 1. Baseline characteristics of rheumatic disease and general population cohorts

	Mean age (SD)	% Female	Mean Charlson Commorbidity Index score (SD)
RA (n=1581)	61.1 (18.4)	69.5	0.75 (1.50)
Non-RA (n=7807)	60.2 (18.2)	69.4	0.64 (1.40)
PsO/PsA (n=1950)	51.7 (18.7)	47.3	0.57 (1.40)
Non-PsO/PsA (n=9699)	51.3 (18.6)	47.2	0.44 (1.22)
AS (n=378)	50.5 (16.2)	50.3	0.52 (1.32)
Non-AS (n=1184)	50.1 (16.1)	50.3	0.34 (1.01)
Gout (n=1773)	62.8 (15.9)	18.3	1.00 (1.83)
Non-gout (n=8787)	62.1 (15.9)	18.3	0.71 (1.49)
SLE (n=179)	51.9 (15.6)	85.5	0.93 (1.68)
Non-SLE (n=887)	51.5 (15.6)	85.3	0.42 (1.20)
Other SARD (n=660)	58.0 (18.1)	70.9	0.84 (1.47)
Non-SARD (n=3267)	57.4(18.0)	71.1	0.58 (1.39)

SARDs excluding SLE (OR: 1.90). Lastly, the risk of mortality was not significantly increased for individuals with rheumatic diseases compared to the general population.

Conclusion: Compared to individuals without a rheumatic disease, individuals with RA, PsO/PsA, AS, gout and SARDs excluding SLE were more likely to experience severe outcomes of COVID-19 including admissions to hospital and ICU. Furthermore, SLE was not associated with an increased risk of severe outcomes of COVID-19 when compared to the general population. Our findings have important implications for patients with certain rheumatic diseases and could inform targeted preventive measures, such as differential isolation measures, priority testing and optimization of vaccination schedules.

Table 2. Association between rheumatic disease status and COVID-19 outcomes

Background/Purpose: The COVID-19 pandemic has led to a significant shift to home-based telemedicine including video and phone-only visits in many medical specialties. However, patients may be agnostic about the relative value and satisfaction with one form of telemedicine compared to another. Thus, the goal of our study was to determine if patient satisfaction with phone-only visits was noninferior to video visits in rheumatology and two other medical clinics at a large tertiary referral center in the Deep South, a region which is home to many socioeconomically disadvantaged older individuals.

Methods: We conducted a parallel group, randomized (1:1), single-blind, noninferiority trial comparing satisfaction rates for two telemedicine delivery methods: phone-only (intervention group) and video visits (standard group). Adults, age >= 60 years or with public insurance (Medicare/Medicaid) were recruited from rheumatology, family medicine,

Table 2. Patient experience with telemedicine phone or video, modified intent-to-treat (mITT) and per protocol analyses; No (%) represented unless otherwise stated.

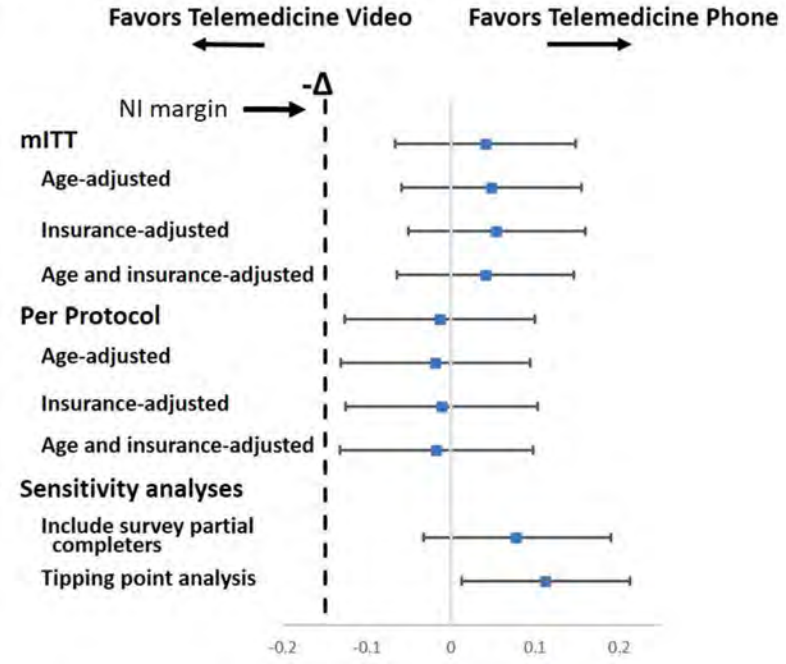
All	80 (83.3)	94 (90.4)		53 (80.3)	71 (89.9)	
Most	12 (12.5)	9 (8.7)		10 (15.2)	8 (10.1)	
Some	4 (4.2)	1 (1.0)		3 (4.5)	0 (0.0)	

Figure 1. Satisfaction (scores of 9 or 10) rates (95% confidence intervals) from modified intent-to-treat (mITT), per protocol, and sensitivity analyses; NI, noninferiority margin.



cardiology clinics. The primary outcome was visit satisfaction rate (9 or 10 on a 0-10 satisfaction scale). Noninferiority was determined if satisfaction with phone-only (intervention) versus video visits (comparator) was no worse by a -15% noninferiority margin. We performed modified intent-to-treat (mITT) and per protocol analysis. We also examined preference for the next visit type, whether patient concerns were addressed during the visit, and whether patients recommended telemedicine.

Results: A total of 200 participants (87.3%), including 96 assigned to video group and 104 assigned to phone-only group, completed surveys on average 2.7 (3.4) days post-visit. A third of the participants were recruited from the rheumatology clinic. This population defines the modified intent-to-treat (mITT) analysis. Overall, participants who completed the surveys were predominately women (N=136, 68%), 86 (43%) were Black with a mean age in the early sixties consistent with the inclusion criteria, and the majority had at least some college education (N=148, 74%) (Table 1).The satisfaction rates were higher than anticipated in both groups (78.1% for video vs 84.6% for phone-only) and not significantly different, (p = 0.32) (Table 2). In the mITT analysis, phone-only visits were noninferior by an adjusted difference of 3.2% (95% CI, -7.6% to 14%). In the per protocol analysis, phone-only were noninferior by an adjusted difference of -4.1% (95% CI, -14.8% to 6.6%) (Figure 1). The proportion of participants who indicated they preferred the same type of telemedicine visit as their next clinic visit were similar (30.2% versus 27.9% video versus phone-only group, p = 0.78) and a majority said their medical concerns were addressed and would recommend a telemedicine visit.

Conclusion: Among a group of diverse, medically at-risk patients seen in rheumatology and two other medical clinics the satisfaction rate for phone-only was noninferior to video visits. Our findings provide added data on patients' acceptance and satisfaction with different types of telemedicine in populations of concern, which can inform clinical, regulatory, and administrative context of telemedicine and related reimbursement policies for medical care of patients with chronic diseases during and beyond the COVID-19 era.

SESSION INFORMATION

Session Date: Saturday, November 6, 2021

Session Title: Epidemiology & Public Health Poster I: COVID-19 & Vaccination (0084–0117)

Session Type: Poster Session A

Session Time: 8:30AM–10:30AM

Background/Purpose: Little is known about the reactogenicity and related SARS-CoV-2 vaccine response in patients with chronic inflammatory disease (CID). While researchers have hypothesized increased symptomatology following vaccine would indicate a more robust vaccine response, this has not been demonstrated in the general population. Our objective was to characterize the adverse event (AE) profile in patients with CID receiving the SARS-CoV-2 vaccines and to better understand the relationship between reactogenicity and immunogenicity of the SARS-CoV-2 vaccines in patients with CID.

Methods: This study was part of a larger prospective study examining the immunogenicity and safety profile of the SARS-CoV-2 vaccines in patients with CID. Adults with CID and healthy controls eligible to receive the SARS-CoV-2 vaccine were enrolled. Subjects participated in 3 study visits (pre-vaccine, after dose 1, after dose 2) where blood and clinical data were collected. Assessment of AEs including local and systemic symptoms were solicited within 7 days

Table 1. Demographic and Clinical Characteristics of Participants

Demographic Data	CID (n=134)	Control (n=44)	P-value
Age [years], mean (SD)	46.1 ± 16.3	37.5 ± 18.3	0.003
<65 (%)	85.7	91.1	0.38

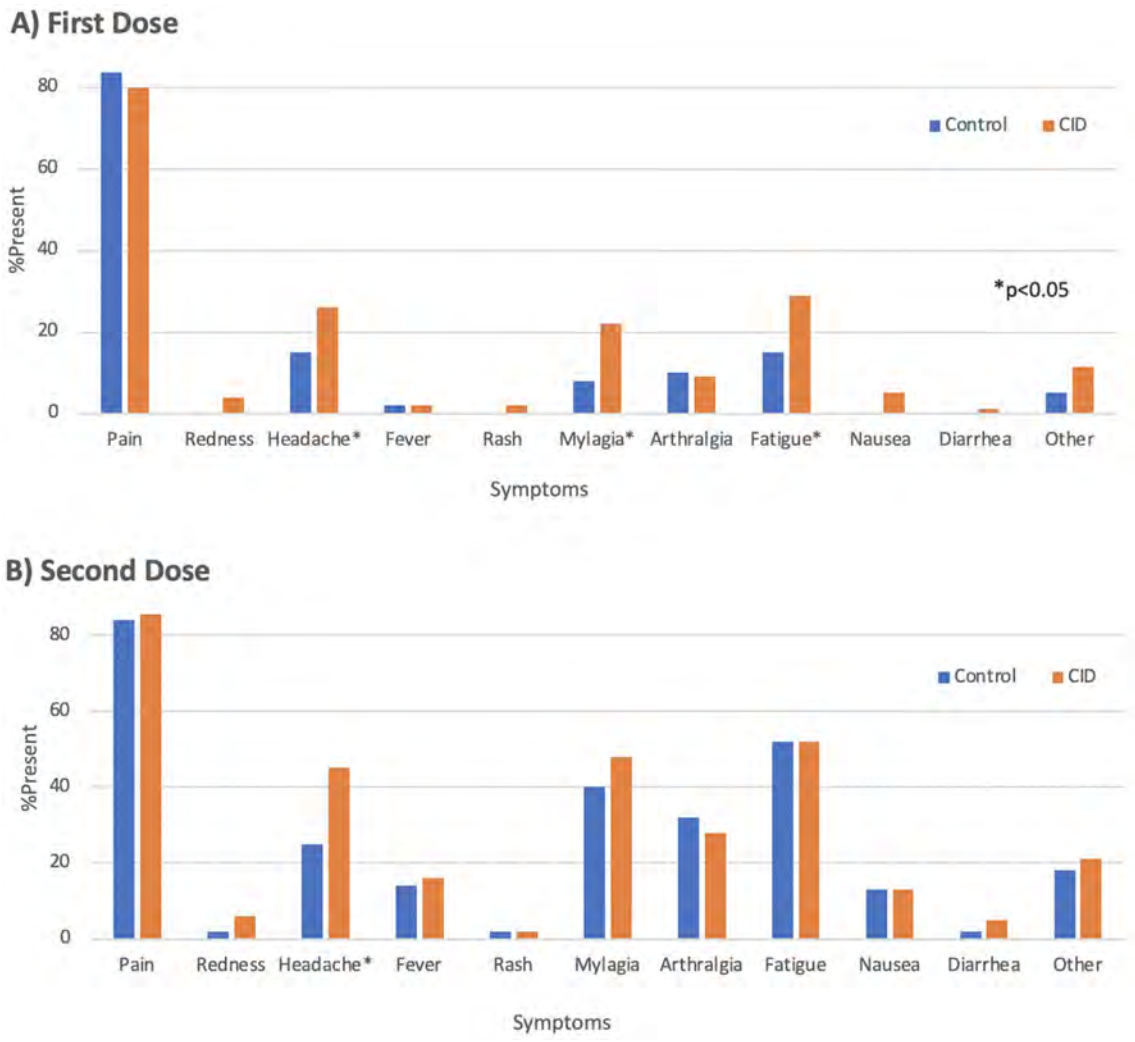

Figure 1. Solicited Symptoms among Control vs. CID Patients.

of receiving each vaccine dose. Serum anti-SARS-CoV-2 spike (S) IgG$^{\pm}$ antibody titerswere quantified to assess the magnitude of the humoral response following vaccination. Statistical analysis of solicited symptoms was performed utilizing two sample t-test and z-test. To study reactogenicity impact on vaccine antibody response, tobit regressions adjusting for patient status, age, gender, and vaccine type were utilized to account for left-censoring below the response detect limit.

Results: 178 participants were included in this study including 134 patients with CID and 44 healthy controls. Demographic and clinical characteristics are shown in Table 1. Solicited symptoms among controls and CID patients are shown in Figure 1. CID patients experienced significantly more symptoms after the 1st dose of vaccine compared to controls (p=0.04), including more headache, myalgia and fatigue (p< 0.05). For immunogenicity, after adjustment for covariates, a higher number of reported symptoms after the second dose was associated with higher antibody titers (p=0.028). Each increase of one endorsed symptom was associated with 15.9% increase in antibody titer. Among all individual symptoms (Table 2), the most strongly associated at each dose included site pain after 1st dose (p=0.04) with 118% increase in antibody titer when present and fatigue after 2nd dose (p=0.02) with 91.6% change in antibody titer when present.

Table 2. Symptom measures associated with increased SARs-CoV-2 antibody titers

Symptom (Dose)	CID Antibody Titer (x10³)	Control Antibody Titer(x10³)	%Change§	P value
Site Pain (1)			118.0%	0.037
Present	6.0 ± 12.0	8.6 ± 6.8		
Absent	2.6 ± 3.2	7.5 ± 4.9		
Fatigue (2)			91.6%	0.023
Present	6.8 ± 14.4	9.8 ± 6.9		
Absent	3.9 ± 4.6	6.6 ± 5.6		
Nausea (2)			130.4%	0.043
Present	12.5 ± 27.1	9.7 ± 3.9		
Absent	4.4 ± 5.0	8.0 ± 6.9		
Myalgia (2)			67.4%	0.074
Present	6.9 ± 14.9	10.2 ± 6.8		
Absent	4.0 ± 4.8	6.3 ± 5.6		

SARS-CoV-2 Antibody Titer reported as 10^3. §Percent change in SARS-CoV-2 antibody titer if the symptom is present vs absent after adjusting for patient status, age, gender and vaccine type.

Conclusion: This study is one of the first to examine reactogenicity of the novel SARS-CoV-2 vaccines among patients with CID and the relationship between reactogenicity and vaccine response. We demonstrated that patients with CID have a distinct reactogenicity profile from their healthy control counterparts with CID patients having more numerous symptoms following 1st dose of vaccine. Furthermore, we demonstrated an association between reactogenicity and immunogenicity in CID patients. This finding, thus far not seen in the general population, may speak to the more variable immunogenicity in patients with CID and could be an important indicator of vaccine response to the novel SARS-CoV-2 vaccines.

Background/Purpose: The best strategy for the prevention of SARS-CoV-2 infection is vaccination. Both mRNA and vector vaccines have demonstrated a satisfactory safety profile in general population but information about their utility in patients with immune-mediated rheumatic diseases (IMRD) is scarce. Both mRNA and viral vector vaccines have demonstrated a satisfactory safety profile in general population but information about their utility in patients with immune-mediated rheumatic diseases (IMRD) is scarce.

Methods: Observational prospective study conducted in a tertiary University center in Catalonia, Spain in patients with IMRD vaccinated between January to May 2021. Patient's information was obtained during clinical visits and follow-up was made by telephonic interviews. Vaccination was confirmed using the electronic clinical records of the local health system. We considered as fully vaccinated those patients with 2 doses of mRNA vaccines and 1 for vector or patients with previous SARS-CoV-2 infection who received 1 dose. Descriptive analysis was done. This study was approved by our hospital's Ethical Committee.

Results: At the end of May, 285 patients with IMRD were registered. Most of the patients were female 193 (67%) with a mean age of 53.2 ± 14.5 years (range 18-92). Main IMRD were rheumatoid arthritis in 126 (42%), followed by spondyloarthropathies in 61 (21%), psoriatic arthritis in 46 (16%) and systemic lupus erythematosus in 21 (7.4%) among others (See Table).

Eight percent of patients had previous SARS-CoV-2 infection before vaccination. At the moment of the first dose, 73% of patients were in remission, 17% with low disease activity, 3% with moderate activity and only 2% with high disease activity.

A total of 160 (57%) patients were under DMARD treatment and 65 (22%) with glucocorticoids (mean dose 6.0 ± 4.4 mg/d), 218 (76%) were under targeted therapies (207 bDMARD and 11 with JAK inhibitors). The main bDMARD used are described in detail in Table.

A total of 128 (45%) of patients were fully vaccinated. Vaccines received included: Moderna in 73%, Pfizer/BioNTech in 17.5%, Astra Zeneca in 9 % and Janssen in 0.4%. Eighteen and 8% of patients stop or delayed DMARD and bDMARD, respectively after vaccination.

Underlying IMRD flare was reported in 16 (5.6%) of patients all of them mild or moderate. Main symptoms included arthralgias (9), arthritis (4), inflammatory back pain (2), and psoriasis (1). Only 1 patient had COVID-19 infection 1 week after first vaccine dose. A total of 153 (53%) patients reported any symptom related to vaccination, basically injection site pain (48%), myalgias (11%), and fever (8%). One patient had oral herpes after vaccination.

Conclusion: Among patients with IMRD, the safety profile of vaccines for SARS-CoV-2 was satisfactory. Disease flares were uncommon (5%) and mostly mild. Vaccination side effects were similar to expected for the general population reassuring the importance of SARS-CoV2 vaccination in patients with IMRD.

Rheumatic Disease Management by Resilient Rheumatology Providers in COVID-19 Pandemic: A National Veterans Affairs Follow-up Survey Assessing Provider Practice and Views Since June 2020

Jasvinder Singh[1], John Richards[2], Elizabeth Chang[3], Amy Joseph[4] and Bernard Ng[5], [1]University of Alabama at Birmingham, Birmingham, AL, [2]Veterans Affairs Pittsburgh Healthcare System, Pittsburgh, PA, [3]Phoenix Veterans Affairs Medical Center (VAMC), Phoenix, AZ, [4]Washington University / St. Louis VA, St Louis, MO, [5]VA Puget Sound HCS, Seattle, WA

SESSION INFORMATION
Session Date: Saturday, November 6, 2021
Session Title: Epidemiology & Public Health Poster I: COVID-19 & Vaccination (0084–0117)
Session Type: Poster Session A
Session Time: 8:30AM–10:30AM

Background/Purpose: To assess the experience, current practices, views and opinions of rheumatology providers at Veterans Affairs (VA) facilities for the care of the patients with rheumatic disease during the COVID-19 pandemic in 2020-21

Methods: We performed an anonymized cross-sectional survey to assess VA rheumatology provider perspective on COVID-19 healthcare issues and resilience, from November 2020 to January 2021, and compare practices to the baseline survey from April-May 2020 (Singh JA, ACR 2020).

Results: Of the 153 eligible VA rheumatologists, 114 (75%) completed the survey. The mean CD-RISC2 score was 6.8 (SD, 1.11; range 0-8; higher=more resilient), higher than the original survey score of 6.35 (SD, 1.26; p=0.004 and p=0.008, respectively). The proportion of rheumatology providers who chose telephone or VVC as the best modality for follow-up of established patients varied widely across rheumatic diseases as follows (Figure 1): (1) gout, osteoporosis, polymyalgia rheumatica, or osteoarthritis (OA), 90-100%; (2) stable rheumatoid arthritis (RA), stable spondyloarthritis (SpA) or stable lupus, scleroderma or vasculitis, 73-88%; (3) local musculoskeletal conditions or tendinitis, 45-46%; (4) lupus, scleroderma, vasculitis, RA or SpA with immunosuppressive, glucocorticoid or disease-modifying antirheumatic disease drug (DMARD)/biologic) changes, 9-20% (Figure 1).

Compared to the original survey, the use of telephone visits was lower by 10-20%, while VVC and in-person were higher by about 10%.

Comfort with Technology: Established Patients. Provider comfort with technology was essentially unchanged compared to the original survey: (1) telephone visits, 82%; (2) VVC visits, 63%. 33% were comfortable with CVT visits, with no previous comparator question (Figure 2). *New patients*. Provider comfort with technology increased compared to the original survey: telephone visits, 40% vs. 25% (p=0.019); VVC visits, 47% vs. 34% (p=0.051; Figure 2).

Comfort with the Quality of Outpatient Visits and Improvement in Comfort Since June 2020 (no previous data/comparator): Providers comfort with the quality of clinical encounter for *established vs. new patients* was as follows (Figure 3): (1) telephone, 63% vs. 27%; (2) VVC, 63% vs. 47%; and (3) CVT 32% vs. 27%. Improvement in comfort with the quality of the clinical encounter since June 2020 for *established vs. new patients* was as follows: telephone, 66% vs. 46%; VVC, 67% vs. 58%; and CVT, 31% vs. 27%.

Adjusted for age, sex, and ethnicity, high provider resilience was significantly associated with a higher odds ratio (OR) of comfort with technology and comfort with the quality of the VVC visit: (1) established patient, 1.71 (95% CI, 0.67-4.40) and 4.13 (95% CI, 1.49-11.44); (2) new patient, 2.79 (95% CI, 1.11-7.05); and 2.69 (95% CI, 1.06-6.82), respectively.

Conclusion: Utilization of and comfort with video visits during the COVID-19 pandemic increased over time among VA rheumatology providers, also associated with provider resilience

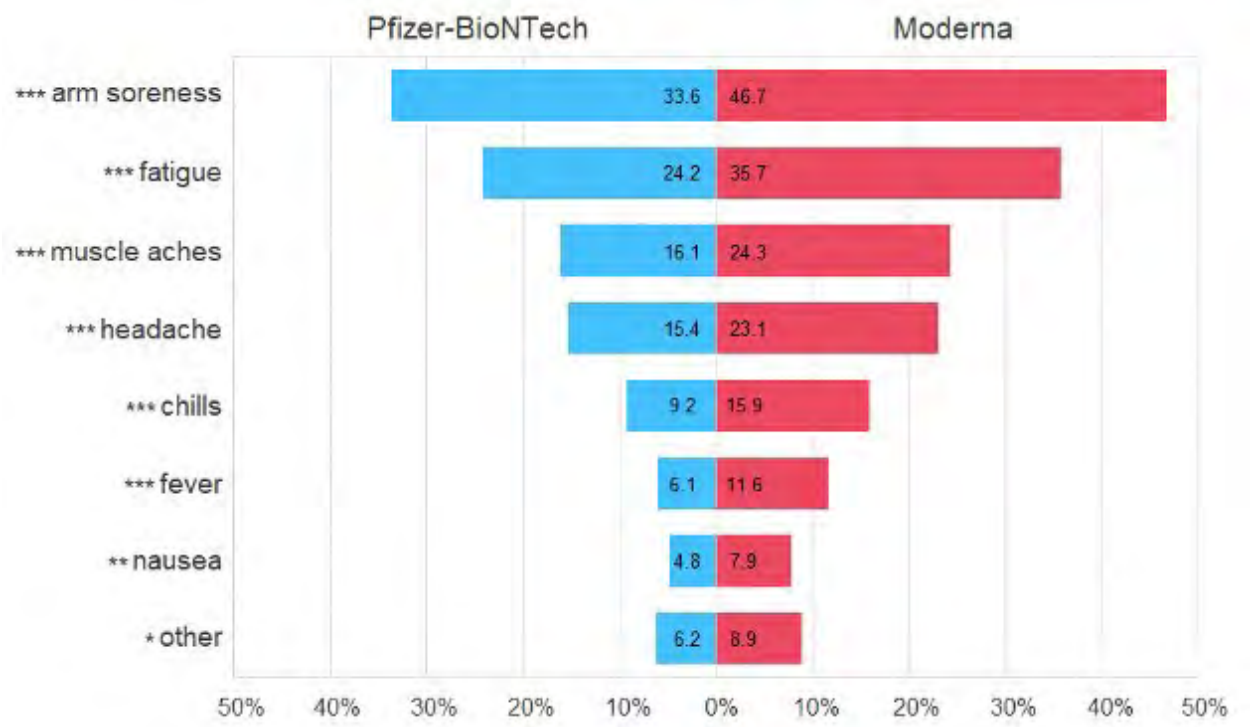

Figure 1. Frequency of side effects by vaccine type. Asterisks indicate statistical significance (*p<0.05, **p<0.01, ***p<0.001).

Background/Purpose: Over 135 million Americans were fully vaccinated to COVID-19 by June 2021, yet there was a paucity of data on side effects for those with autoimmune conditions commonly seen in rheumatology. Side effects can prevent recipients from receiving a second vaccination and can be related to the immunogenicity of the vaccine and/or recipient. The purpose of our study was to characterize the rates and types of COVID-19 vaccine side effects in adults with rheumatic diseases and assess if there were associations with disease treatment, severity, or vaccine type.

Methods: Data were provided by adults enrolled in FORWARD, The National Databank for Rheumatic Diseases. Participants complete comprehensive semiannual questionnaires and were invited to answer supplemental questionnaires focused on COVID-19 vaccination in March and April 2021. Only individuals who received Pfizer-BioNTech or Moderna vaccines were included in this study due to insufficient sample sizes for other vaccines. Vaccinated respondents were compared by whether they reported experiencing side effects following vaccination and by vaccine type, with significance ($p < 0.05$) assessed by Student's t-tests and chi-squared tests, as appropriate. Factors associated with side effects were identified with logistic regression models for the full cohort and for each vaccine type adjusted for age, sex, race, education, rural residency, BMI, physical function (HAQ-II), COVID-19-specific stress (Likert scale), corticosteroid use, hierarchical DMARD group (reference: no DMARD), and diagnosis (reference: OA).

Results: Among 1825 vaccinated respondents, 876 (48%) reported experiencing side effects (Table 1). The most reported side effects included arm soreness (40%), fatigue (30%), muscle aches (20%), and headache (19%). The ranked frequency of each side effect did not differ by vaccine type, though incidence of each side effect was significantly higher among those who received the Moderna vaccine than in those who received the Pfizer-BioNTech vaccine (Figure 1). In the full cohort, younger age, female sex, higher education, full vaccination, and higher COVID-19-related stress were all associated with higher risk of experiencing side effects (Figure 2). Differences by age held true in both the Pfizer-BioNTech (OR 0.96 [0.94, 0.98]) and Moderna (0.97 [0.95, 0.99]) models. Differences by sex (OR 1.83 [1.04, 3.24]) and by COVID-19-related stress (1.5 [1.13, 2.00]) were specific to Moderna vaccine recipients, while differences by education (1.16 [1.04, 1.30]) were specific to Pfizer-BioNTech vaccine recipients.

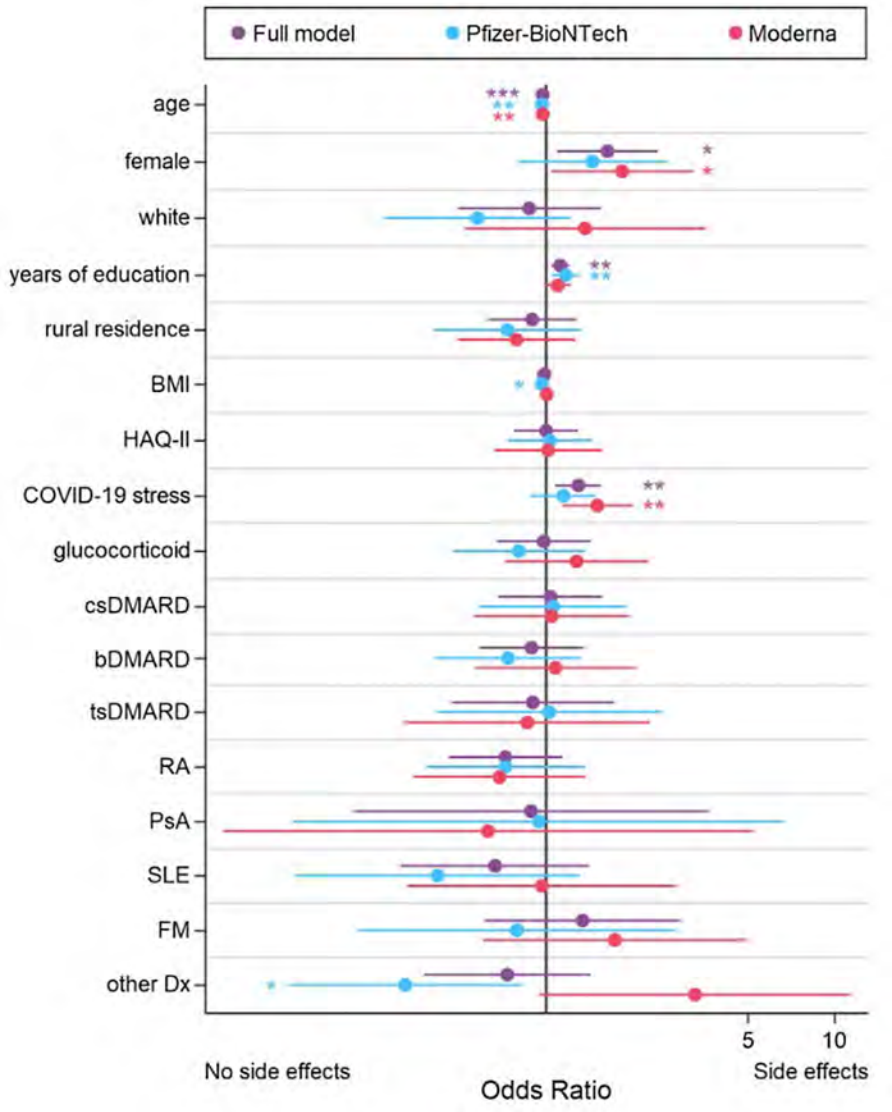

Figure 2. Odds ratios and 95% confidence intervals for factors associated with side effects to COVID-19 vaccine for the full cohort (purple), Pfizer-BioNTech vaccine recipients (blue), and Moderna vaccine recipients (red). Asterisks indicate statistical significance (*$p<0.05$, **$p<0.01$, ***$p<0.001$).

Conclusion: Our findings of increased side effects to Moderna vaccines was consistent with the larger US population, though our side effect rates were comparatively lower and more similar to CDC surveillance[1] after only the first mRNA vaccine even after accounting for our cohorts' older age. A lack of reactogenicity with rheumatic disease, severity, and treatments may be reassuring for the vaccine hesitant, but additional investigation is needed to understand if these lower rates are due to a potentially reduced immune response.

Abstract Number: 0117

Flares Following Herpes Zoster Recombinant Zoster Vaccination Among Adults Age ≥50 Years with Immune Mediated Inflammatory Diseases in the United States

Jeffrey Curtis[1], yujie Su[2], Fenglong Xie[2] and cassie Clinton[2], [1]Division of Clinical Immunology and Rheumatology, Department of Medicine, Department of Epidemiology, University of Alabama at Birmingham, Birmingham, AL, [2]University of Alabama at Birmingham, Birmingham, AL

SESSION INFORMATION
Session Date: Saturday, November 6, 2021
Session Title: Epidemiology & Public Health Poster I: COVID-19 & Vaccination (0084–0117)
Session Type: Poster Session A
Session Time: 8:30AM–10:30AM

Background/Purpose: Although persons with immune mediated inflammatory diseases (IMIDs) are at increased risk of herpes zoster (HZ), there are limited data published on the safety of recombinant zoster vaccine (RZV, Shingrix), or novel vaccine adjuvants, in these populations. We conducted a self-controlled case series analysis (SCCS) to evaluate the risk of possible vaccine-related flares following RZV vaccination in adults with IMIDs.

Methods: We used medical claims data from the 2017–2019 IBM® MarketScan® (persons age 50–64 years) and 2017–2020 Centers for Medicare and Medicaid Services Medicare (persons age ≥65 years) databases to examine flares after RZV vaccination in persons with IMIDs (Rheumatoid Arthritis, RA; Ankylosing Spondylitis, AS; Axial Spondyloarthritis, SpA; Psoriatic Arthritis, PsA; Psoriasis, PsO; Inflammatory Bowel Disease, IBD; Crohn's Disease, CD; Ulcerative Colitis, UD; Systemic lupus erythematosus, SLE). IMIDs were defined using all 3 of the following criteria: (a) ≥2 outpatient visits for their respective conditions, and (b) ≥1 claim for disease-specific medications, and (c) ≥1 visit to a relevant specialist (rheumatologist for RA, AS, SpA, PsA, SLE; gastroenterologist for IBD, CD, UC; dermatologist for PsO). RZV vaccination was defined using NDC and CPT codes. Presumed flares were defined as hospitalization or ER visit for their condition, or treatment with a Medrol Dosepak or steroid injection. We used SCCS methods to compare the rates of flares 1–42 days after (risk window) as compared to 98–140 days prior to RZV vaccination (control window) within individuals.

Results: There were 7,069 50–64-year-olds and 72,434 ≥65-year-olds with both an IMID and ≥1 dose of RZV [Table 1]. Among 50–64-year-olds, 10% developed flares during the control window, and 9% developed flares in the risk window following 1 or 2 doses of RZV. Among ≥65-year-olds, 13% developed flares during the control window, and 11–12% developed flares in the risk window following 1 or 2 doses of RZV. We did not find a statistically significant increase in flares following RZV vaccination for any IMID condition in either age group following either 1 or 2-doses of RZV [Table 2].

Conclusion: This observational study provides new data on the safety of RZV vaccination in adults age ≥50 years with selected IMIDs. Within the limitations of administrative data and our presumed flare definition, we did not find a significant increase in presumed flares for any IMID condition evaluated or by RZV vaccine dose. There were a number of limitations with this study related to distinguishing vaccine-induced flares from reactogenicity and disease worsening. Additional work is ongoing to refine and validate IMID case and flare definitions. Further evaluation of the safety of RZV vaccination in this population is needed to inform vaccine policy recommendations and clinical guidance.

Multidimensional Phenotypes of Sleep Quality Using the Pittsburg Quality Sleep Index and Associations Among Sleep Dimensions and Symptoms in Women Diagnosed with Fibromyalgia

Victoria Menzies, Debra Lynch Kelly and Miichael Weaver, University of Florida, Gainesville, FL

SESSION INFORMATION
Session Date: Saturday, November 6, 2021
Session Title: Fibromyalgia & Other Clinical Pain Syndromes Poster (0118–0127)
Session Type: Poster Session A
Session Time: 8:30AM–10:30AM

Background/Purpose: There are over 10 million people in the United States suffering with fibromyalgia syndrome (FMS). Individuals with FMS typically report multiple concurrent symptoms including chronic pain, fatigue, distressed mood and sleep disturbances. Evidence demonstrates that 70%-80% of FMS patients suffer from non-restorative sleep; however, dimensions of sleep disturbance in patients with FMS and associations with symptoms are relatively unexamined in this population but necessary to develop personalized strategies to mitigate symptoms and improve functionality and quality of life for this patient population.

Methods: The objective of this analysis was to phenotype dimensions of sleep in a cohort of 50 women at least 18 years old with a confirmed diagnosis of FMS using previously collected data and to examine associations among sleep dimensions and symptoms (pain, fatigue, depression and anxiety). Sleep dimensions were evaluated using the 19-item self-report Pittsburgh Quality Sleep Index (PQSI) that provides information about multiple dimensions of sleep (quality and patterns). Total PQSI scores over 5 indicate severe sleep disturbance. Well-validated measures were used to assess pain, fatigue, depression and anxiety. R version 4.05 was used for statistical analyses. Descriptive statistics report demographic and clinical characteristics. Distributions for robust correlation coefficients among sleep and symptoms were estimated using a Bayesian approach. Bayes factors (BF) were used as measure of strength of evidence for presence of an association.

Results: The mean age of the sample was 48 (SD=11.8). The majority were white (n=26) and non-Hispanic (n=49). Mean global sleep quality was 11.7 (SD=4.7). Mean pain severity reported was 6.0 (SD=1.7) and pain interference was 6.0 (SD=2.3). Severe fatigue was reported by 50% of the participants. At least moderate depressive symptoms were reported by 56% of study participants, and the mean trait and state anxiety were 48.9 (SD=12.8) and 44.1 (SD=13.5) respectively. Forty-eight (48) bivariate correlations were examined: 19 demonstrated at least moderate evidence supporting an association, with coefficients ranging from .30 to .54: 4 had BF 3-10 (moderate), 7 had BF 10-30 (strong), 1 had a BF 30-100 (very strong), and 7 had a BF >100 (extreme evidence). Associations between sleep dimensions and symptoms with a BF > 100 were noted between depression and sleep quality, sleep meds, days dysfunction, and global sleep quality, and between anxiety trait with sleep quality and sleep medications.

Conclusion: This research provides an in-depth examination of multidimensional sleep phenotypes in a cohort of patients with FMS and punctuates associations among multiple sleep dimensions and symptoms of FMS. Given the severity of sleep disturbance reported in this population, strategies to combat this problem are needed to reduce symptom burden in this vulnerable population. This study provides evidence to prompt the development and testing of personalized interventions to mitigate sleep disturbance and improve functionality and quality of life for individuals with FMS.

Note: CESD=Center for Epidemiological Studies-Depression; Trait_Anx=Trait Anxiety; State_Anx=State Anxiety; BPI-S=Brief Pain Inventory-Severity; BPI-I=Brief Pain Inventory-Interference; BFI=Brief Fatigue Inventory; PSQI= Pittsburgh Sleep Quality Index; SubjSlpQual=Subjective Sleep Quality; SlpLatency=Sleep Latency; SlpDuration=Sleep Duration; SlpEfficiency=Sleep Efficiency; SlpDisturb=Sleep Disturbance; SlpMeds=Use of sleeping medications; DayDysfunct=Daytime Dysfunction

*Note: Correlation coefficient: This is the estimated robust bivariate correlation coefficient; Credibility Interval: Provides the values encompassing 95% of the Highest Posterior Density (HPD); ROPE: This is Region of Practical Equivalence, a range of values considered to indicate practically no effect (or, in this case, practically no correlation). For the correlation coefficient, this is the range -0.05, 0.05, which is half the value of a negligible correlation as suggested by Cohen's (1988) rules of thumb. What is provided in the table is the % of estimated correlation values that are contained within that range; Bayes Factor: The Bayes Factor can be thought of as providing a measure of support for the alternate hypothesis (H1) compared to the null hypothesis (H0): >100=Extreme evidence for H1; 30-100=Very strong evidence for H1; 10-30=Strong evidence for H1; 3-10=Moderate evidence for H1; 1-3= Anecdotal evidence for H1; 1= No evidence.

Worsened Depression but Improved Fatigue Were the Main Impacts of Severe Lockdown in Non- COVID Infected Australian Fibromyalgia Patients

Benjamin Worcester[1], Emma Guymer[2] and Geoffrey Littlejohn[2], [1]Monash Health, Melbourne, Australia, [2]Monash University, Melbourne, Australia

SESSION INFORMATION
Session Date: Saturday, November 6, 2021
Session Title: Fibromyalgia & Other Clinical Pain Syndromes Poster (0118–0127)
Session Type: Poster Session A
Session Time: 8:30AM–10:30AM

Background/Purpose: To gauge the impact of severe COVID-19 related lockdown restrictions on the mental and physical wellbeing of Australian fibromyalgia patients and their recovery following the conclusion of the lockdown.

Methods: Telephone or online surveys were conducted with sequential patients from a single Australian tertiary centre specialist fibromyalgia clinic during an enforced 100-day stage 4 lockdown in Melbourne in October 2020. Patients were invited to participate if they had been seen in the 12 months prior to lockdown and had recorded illness impact data from that visit. The patients were reassessed 6 months following the end of the lockdown. There was a 73% response rate. Demographic and clinical information was collected. The Fibromyalgia Impact Questionnaire (Revised Version) (FIQR) was used to assess current fibromyalgia illness impact. The Patient Health Questionnaire 9 (PHQ-9) was used to assess depression symptoms.

Table 1. Mean scores (SD) of FIQR, PHQ-9 and selected sub-component scores (n=50/35) (*=p<0.05)

	Pre-lockdown (n=50)	Lockdown (n=50)	t-Test p-value	Post-lockdown (n=35)	t-Test p-value
Mean FIQR Score (SD)	69.61 (16.86)	66.59 (16.13)	0.126	66.41 (15.50)	0.500
Mean PHQ-9 Score (SD)	12.77 (6.74)	14.48 (5.03)	0.01*	13.40 (4.20)	0.041*
Pain (SD)	6.95 (2.16)	6.79 (2.02)	0.598	6.60 (1.50)	0.524
Sleep (SD)	8.33 (1.90)	8.44 (1.59)	0.636	8.06 (0.94)	0.731
Anxiety (SD)	6.53 (3.04)	6.3 (2.71)	0.574	4.43 (2.05)	<0.001*
Depression (SD)	5.28 (3.22)	5.98 (2.63)	0.048*	6.60 (2.14)	0.002*
Fatigue (SD)	8.25 (2.98)	7.29 (2.13)	0.009*	8.29 (1.02)	0.002*

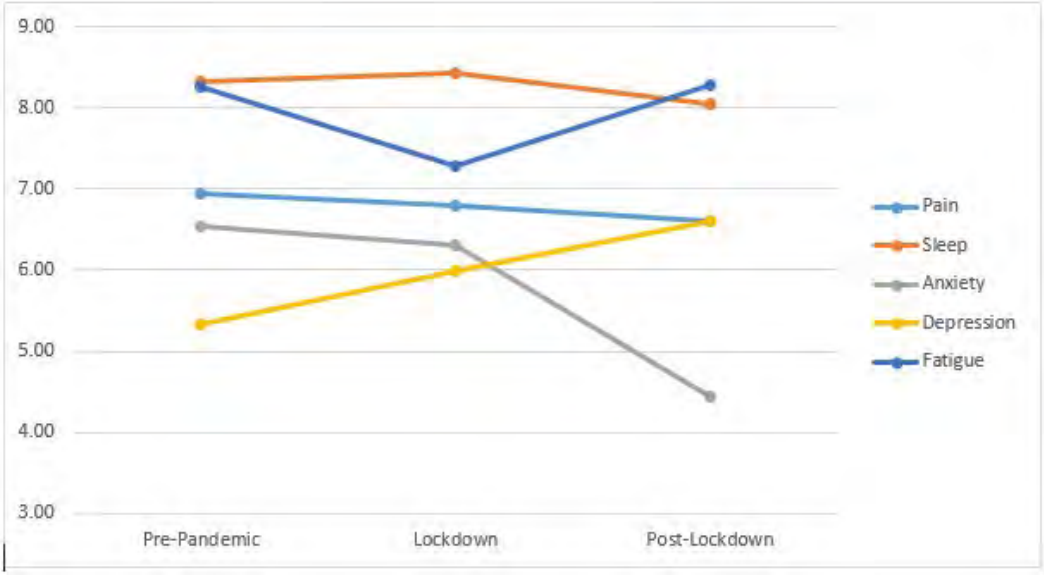

Figure 1. Changes in mean FIQR subdomain scores over time.

Results: Sixty-nine patients were invited to participate, 50 responses were received during the lockdown and 35 responded following the conclusion of the lockdown. No subjects had been diagnosed with COVID infection at any time. Most patients reported increased isolation, decreased exercise, worse sleep and increased use of fibromyalgia-related medications. Twenty-five (50%) of patients had a PHQ-9 score ≥ 15, with 20 patients (40%) reporting moderately-severe and 5 patients (10%) reporting severe depression with an overall mean PHQ9 score of 14.48, this is significantly different to previously collected data from the same cohort where a mean PHQ9 of 12.77 was found (p=0.01). No significant difference was found between pre-lockdown and during lockdown FIQR total score. There was a significant worsening in depression scores and a significant improvement in fatigue subdomain scores. Additionally, there were trends for worse pain, and sleep (table 1).

Six months after the conclusion of the lockdown, surveyed patients self-reported depression had continued to worsen. This seems to contrast with the PHQ-9 scores which show an overall improvement in depression severity compared to the lockdown, resulting in scores not significantly worse than before the lockdown began (Figure 1).

The percentage of patients with mod-severe depression had improved to twelve (34%) patients but this remains higher than previously published data (25%). The observed improvement in fatigue was not sustained with scores returning to pre-pandemic levels. There was a significant improvement in anxiety following the end of the lockdown.

Conclusion: Severe COVID related lockdown restrictions in Melbourne in 2020 resulted in significantly worse reported features of depression and significantly improved fatigue. Other clinical aspects of fibromyalgia were not found to be significantly different from previously reported levels. These changes, other than a continued sense of depression, were not sustained following the conclusion of the lockdown. Whilst the overall mean PHQ-9 score did improve, this remained non-significantly higher than prior to the pandemic. The improvement in fatigue may relate to increased opportunity to rest through the lockdown.

Fibromyalgianess and Glucocorticoid Persistence Among Patients with Rheumatoid Arthritis

Beth Wallace[1], Meriah Moore[2], Andrew Heisler[3], Lutfiyya Muhammad[4], Jing Song[5], Daniel Clauw[2], Clifton Bingham[6], Marcy Bolster[7], Wendy Marder[2], Tuhina Neogi[8], Alyssa Wohlfahrt[9], Dorothy Dunlop[10] and Yvonne Lee[10], [1]Michigan Medicine, VA Ann Arbor Healthcare System, Ann Arbor, MI, [2]University of Michigan, Ann Arbor, MI, [3]Bronson Rheumatology Specialists, Kalamazoo, MI, [4]Northwestern University Feinberg School of Medicine, Chicago, IL, [5]Northwestern University, Worthington, IL, [6]Johns Hopkins University, Baltimore, MD, [7]Massachusetts General Hospital, Boston, MA, [8]Boston University School of Medicine, Boston, MA, [9]Tufts University School of Medicine, Boston, MA, [10]Northwestern University, Chicago, IL

SESSION INFORMATION
Session Date: Saturday, November 6, 2021
Session Title: Fibromyalgia & Other Clinical Pain Syndromes Poster (0118–0127)
Session Type: Poster Session A
Session Time: 8:30AM–10:30AM

Background/Purpose: Over one-third of patients with rheumatoid arthritis (RA) exhibit evidence of fibromyalgianess, a cluster of somatic symptoms associated with increased sensitivity to painful stimuli. Fibromyalgianess is associated with higher rates of disability among RA patients and inadequate responsiveness to disease-modifying antirheumatic drugs (DMARDs). Up to half of patients with RA often remain on oral glucocorticoids (GCs) for prolonged periods, despite the well-described risk of dose-dependent morbidity and mortality. We know little about how fibromyalgianess might influence GC use in RA. In this study, we examined the longitudinal association between fibromyalgianess and oral GC persistence among RA patients.

Methods: We used data from the Central Pain in Rheumatoid Arthritis (CPIRA) cohort to follow participants with active RA on oral prednisone after they initiated a new DMARD. Fibromyalgianess was measured using the Fibromyalgia Survey Questionnaire (FSQ), previously shown to correlate with key fibromyalgia features often superimposed upon RA. Severity of fibromyalgianess was stratified as follows: FSQ< 8 low, 8-10 moderate, and >10 high/very high. GC persistence was defined as GC use at three-month follow-up visit. The association between baseline fibromyalgianess (exposure) and GC persistence at 3-month follow-up (outcome) was assessed using multiple logistic regression. The analysis was adjusted for baseline demographics, RA duration, serologic status, and inflammatory activity as measured by swollen joint count and C-reactive protein.

Table 1. Baseline characteristics of patients taking glucocorticoids at enrollment (N = 97), stratified by baseline fibromyalgianess severity group

Mean (SD) or %	Fibromyalgianess severity group			
	Low FSQ: 0-7 n = 28	Moderate FSQ: 8-10 n = 26	High FSQ: 11-15 n = 28	Very High FSQ: >15 n = 15
FSQ score (range 0-31)	4.68 (2.04)	9.04 (0.87)	13.21 (1.37)	17.93 (2.49)
WPI score (0-19)	1.86 (1.21)	4.77 (1.61)	6.75 (2.32)	10.60 (1.99)
SSS score (0-12)	2.82 (1.68)	4.27 (1.71)	6.46 (2.40)	7.33 (1.72)
Age (years)	59.85 (14.29)	56.95 (12.08)	52.57 (15.34)	59.75 (12.20)
Female, %	64.3	80.8	82.1	100.0
Caucasian, %	71.4	68.0	74.1	80.0
BMI (kg/m^2)	28.4 (7.67)	28.04 (7.62)	29.31 (8.27)	33.11 (6.05)
Disease duration (years)	9.25 (13.15)	8.99 (11.95)	12.21 (13.68)	10.82 (11.45)
Seropositive, %	92.9	84.0	67.9	73.3
CDAI (range 0-76)	18.98 (11.92)	21.79 (13.89)	22.12 (12.47)	40.95 (15.66)
Patient global (0-10)	2.80 (1.85)	4.07 (2.71)	4.08 (2.02)	4.93 (1.60)
Physician global (0-10)	2.62 (1.39)	3.56 (2.13)	3.31 (2.01)	5.22 (2.39)
Swollen joint count (0-28)	7.96 (8.18)	9.96 (8.97)	10.50 (7.94)	20.20 (8.27)
Tender joint count (0-28)	5.25 (4.99)	5.81 (5.02)	3.64 (3.51)	10.60 (6.93)
CRP (mg/L)	6.29 (6.08)	9.78 (10.18)	7.97 (16.19)	12.16 (12.71)

FSQ: fibromyalgia survey questionnaire; WPI: widespread pain index; SSS: symptom severity score, CDAI: clinical disease activity index

Results: Of 97 participants on prednisone at baseline, 65% were taking prednisone at follow-up. Fifty-seven percent of participants with low baseline fibromyalgianess had persistent GC use, compared to 84% with high or very high fibromyalgianess. After adjustment as outlined above, participants with high/very high baseline fibromyalgianess remained more likely to be on prednisone at follow-up, relative to those with low fibromyalgianess (OR 4.99 [95% CI 1.20 – 20.73]).

Conclusion: In this cohort of patients with active RA, high fibromyalgianess is associated with persistent GC use, independent of inflammatory activity. This finding suggests that non-inflammatory pain related to fibromyalgianess may be misclassified by patients or providers as inflammatory pain related to RA disease activity. Greater insights into clinician and patient perspectives on GC tapering in RA patients with high fibromyalgianess are required to help clinicians distinguish active RA symptoms from manifestations of other chronic pain conditions.

Table 2. Association between A) baseline fibromyalgianess severity group, B) baseline WPI severity group, C) baseline SSS severity group, and persistent use of glucocorticoids at 3 month follow-up (N = 97)

A.	FSQ score category*

Abstract Number: 0121

The Efficacy of Group Behavioral Activation versus Usual Treatment in Patients with Fibromyalgia and Major Depression

Josefina Duran, Alvaro Verges, Ana Rocío Vázquez-Taboada, Matias Gonzalez and Lydia Gomez-Pérez, Pontificia Universidad Católica de Chile, Santiago, Chile

SESSION INFORMATION

Session Date: Saturday, November 6, 2021
Session Title: Fibromyalgia & Other Clinical Pain Syndromes Poster (0118–0127)
Session Type: Poster Session A
Session Time: 8:30AM–10:30AM

Background/Purpose: Fibromyalgia (FM) and major depression frequently coexist. Patients with both conditions have a worse prognosis and higher disability, and their treatment options are scarce. Behavioral activation (BA) is

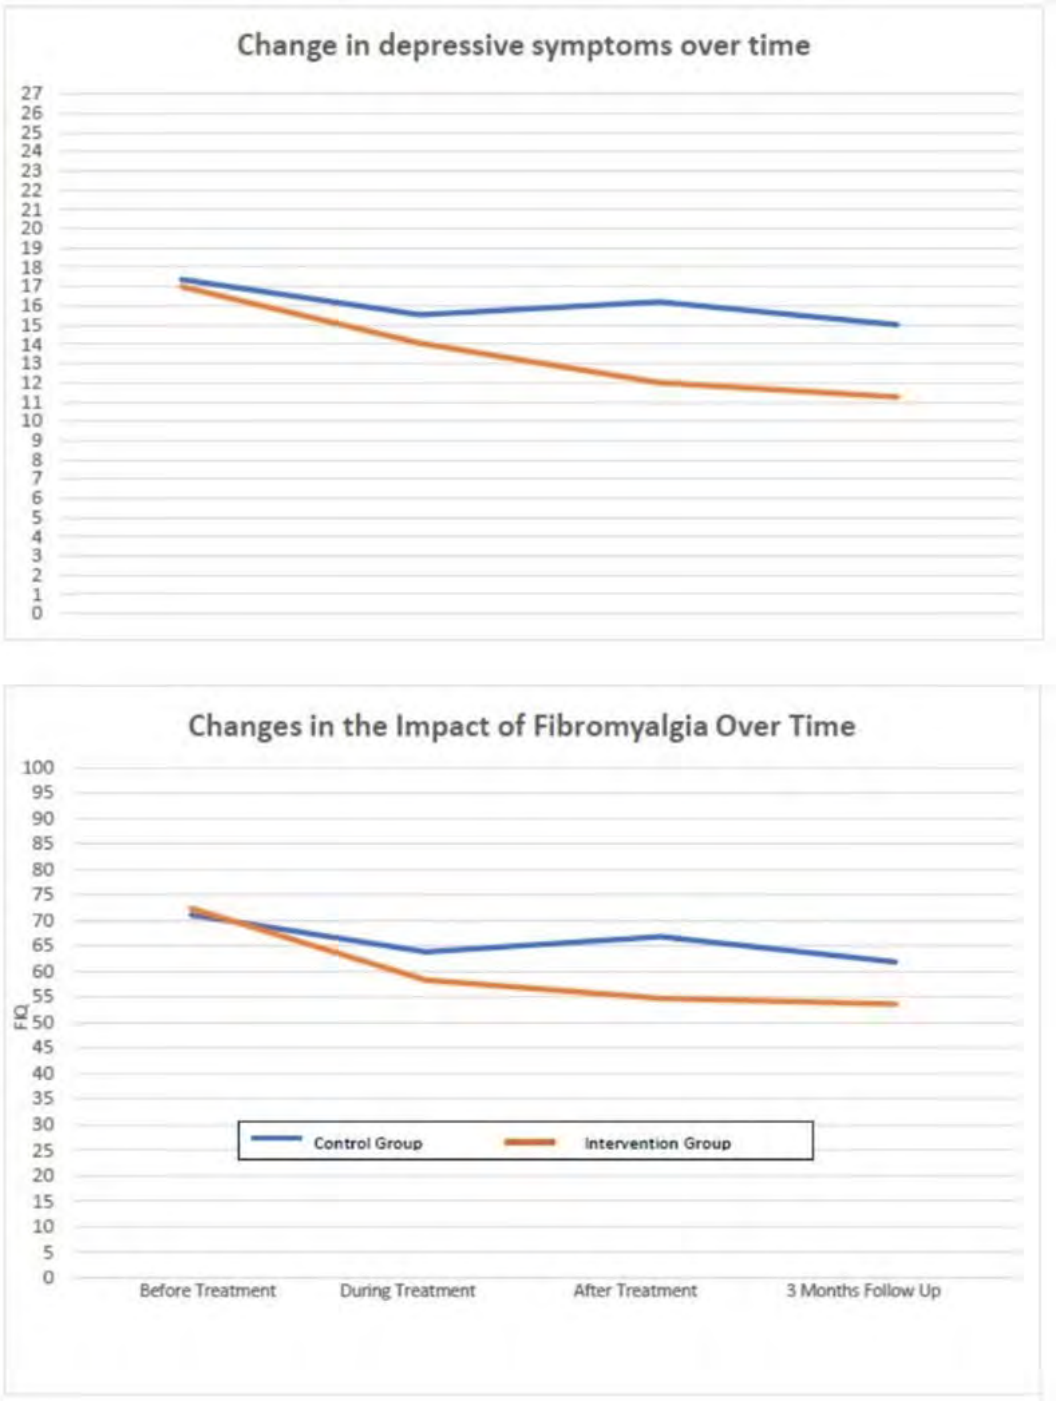

Figure 1. Change in depressive symptoms and in fibromialgia impact (FIQ) at baseline, during the intervention and after follow up.

an evidence-based therapy for depression that is easy to implement and can be implemented as group therapy. Case studies indicate BA may be useful in the management of pain in Fibromyalgia (FM). In this study we aimed to determine the efficacy of group BA for decreasing depressive symptoms and pain intensity in subjects with FM and concomitant depression. This study was funded by a grant from CONICYT (FONIS SA16I0305)

Methods: A randomized controlled trial was performed in which BA in addition to usual care was compared to usual care in women with FM and depression. All subjects included received a stable dose of duloxetine and no other antidepressants. Outcomes were assessed before, during, and after the intervention, as well as at a three months

follow-up using the following instruments: Chilean version of the Patients Health Questionnaire-9 (PHQ-9), Composed Pain Intensity Index, Fibromyalgia Impact Questionnaire Revised (FIQ-R), Pain Catastrophizing Scale (PCS), Pain Vigilance and Awareness Questionnaire (PVAQ), Patients Health Questionnaire (PHQ-15), and Activation subscale of the Behavioral Activation for Depression Scale (BADS). Intent to treat analysis was performed. A Hierarchical Linear Model for repeated measures was performed to determine change in all outcomes described and a Cochran-Mantel-Haenszel test was performed to compare the percentage of subjects that had a reduction in 50% of depressive symptoms. This study was approved by the Medicine Scientific Ethics Committee of the Pontificia Universidad Católica de Chile, Santiago, Chile (N 15-221).

Results: There was a significant improvement in depressive symptoms in the regression model (F 4.71 p=0.03). In addition, the outcome greater than 50% decrease in symptoms also showed a significant improvement both at the end of treatment (χ^2 (1) = 9,43; p = .001) and at the end of follow-up (χ^2 (1) = 3,83; p= .025). Regarding the impact of FM, FIQ showed significant improvement in multiple regression(F 4.22, p=0.006). Finally, catastrophizing decreased (p 0.035) and behavioral activation increased (p =0.003). Pain (p=0.14) and physical symptoms measured by PHQ-15 did not improve (p=0.059).

Conclusion: BA was effective in improving depression, catastrophizing and decreasing FIQ in subjects with depression and FM, making it a potential therapeutic strategy. However no significant change in pain intensity was seen.

Abstract Number: 0122

Clinical Impact of a Digital Behavioral Therapy for Fibromyalgia Management: A Randomized Controlled Trial

Stephanie Catella[1], Michael Gendreau[2], Nicolette Vega[1], Allison Kraus[1], Michael Rosenbluth[1], Sherry Soefje[3], Shishuka Malhotra[4] and Lesley Arnold[5], [1]Swing Therapeutics, San Francisco, CA, [2]Gendreau Consulting, LLC, Poway, CA, [3]Excell Research, Oceanside, CA, [4]Neuro-Behavioral Clinical Research, North Canton, OH, [5]University of Cincinnati, Cincinnati, OH

SESSION INFORMATION
Session Date: Saturday, November 6, 2021
Session Title: Fibromyalgia & Other Clinical Pain Syndromes Poster (0118–0127)
Session Type: Poster Session A
Session Time: 8:30AM–10:30AM

Background/Purpose: Recommendations for fibromyalgia management include both pharmacologic and nonpharmacologic treatments. Cognitive behavioral therapy (CBT) has demonstrated level 1A evidence for fibromyalgia management, though access is limited due to few trained clinicians and cost. An at home digital behavioral therapy could significantly increase access.

A smartphone-based Acceptance and Commitment Therapy (ACT) program was developed for fibromyalgia management. ACT is a modern type of CBT increasingly used to manage chronic pain that focuses on acceptance of uncontrollable and untreatable symptoms. A multi-site study is underway to understand the feasibility of a largely virtual study and determine the impact of smartphone-delivered ACT compared to a digital active control.

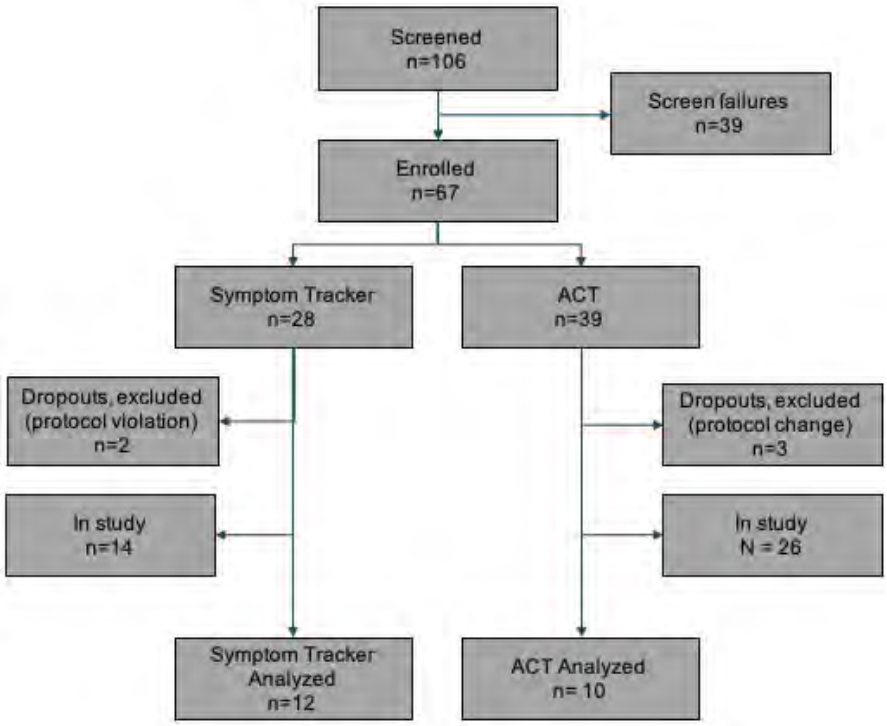

Figure 1. Flow of participants in the SMART-FM study (Consort diagram).

Methods: Participants diagnosed with fibromyalgia using 2016 criteria were randomized to digital ACT or an active control. Participants remained stable on other ongoing fibromyalgia treatment. The digital ACT intervention consists of 41 daily sessions of structured ACT lessons, mindfulness practices, and activities to encourage paced exercise and behavior change. An active control was implemented to account for study engagement and expectation biases. Components of the active control (Symptom Tracker, or ST) include daily symptom tracking and monitoring and access to patient education. During the 12 week study, participants were expected to use the smartphone applications at least 5 days a week.

FIQ-R, the primary outcome, was administered weekly. Secondary outcomes include PGIC, weekly recall pain intensity and interference, and sleep quality (NRS), BDI-II, PROMIS-29, Five Facets of Mindfulness, and Psychological Inflexibility in Pain Scale.

The study has enrolled 67 participants. Twenty-seven participants have completed the study to date and 22 are included in the current analysis set (Figure 1).

Results: The characteristics of the participants are summarized in Table 1. Engagement in both arms is high throughout the study (an average completion of 5 sessions per week in each arm).

Improvement of 20% or greater in total FIQR score was observed in 50% of the ACT group compared to 25% in the ST group. Participants in ACT improved on average 10.5 points (20%) in total FIQR score compared to 4.8 points (9%) in ST. Forty percent of ACT participants reported “much improved” or greater on the PGIC compared to 0% in ST. More improvement was seen in ACT over ST in most other outcome measures. No treatment related adverse events have been observed. This study is ongoing and full results are expected this summer.

Conclusion: A mostly virtual digital therapy study is feasible with high engagement in both ACT and the active control. Participants in the ACT arm achieved greater reductions on FIQ-R and showed greater improvement on PGIC

Table 1. Background characteristics of study participants

Characteristics	Total (N = 67)
Female	66 (99%)
Average age (SD)	52.8 (10.3)

compared to ST. Participants in the ACT arm showed greater improvement relative to the ST arm on ACT process measures, suggesting digital ACT is effectively targeting therapeutic processes of change.

The findings suggest that digital ACT may improve fibromyalgia management and appears to be well tolerated.

Vestibulocortical Stimulation with Caloric Irrigation Reduces Pain and Improves Subjective Well-Being in Fibromyalgia: An Open-Label Pilot Trial

Michael Kaplan[1], Celine Zhou[1], Emily Carroll[1], Alan Weinberg[2], Daniel Clauw[3], Trung Thanh Ngo[4] and Ioannis Tassiulas[5], [1]The Mount Sinai Hospital, Manhattan, NY, [2]The Mount Sinai Hospital, New York, NY, [3]University of Michigan, Ann Arbor, MI, [4]University of Queensland & Translational Research Institute, Woolloongabba, Australia, [5]Icahn School of Medicine at Mount Sinai, New York, NY

SESSION INFORMATION

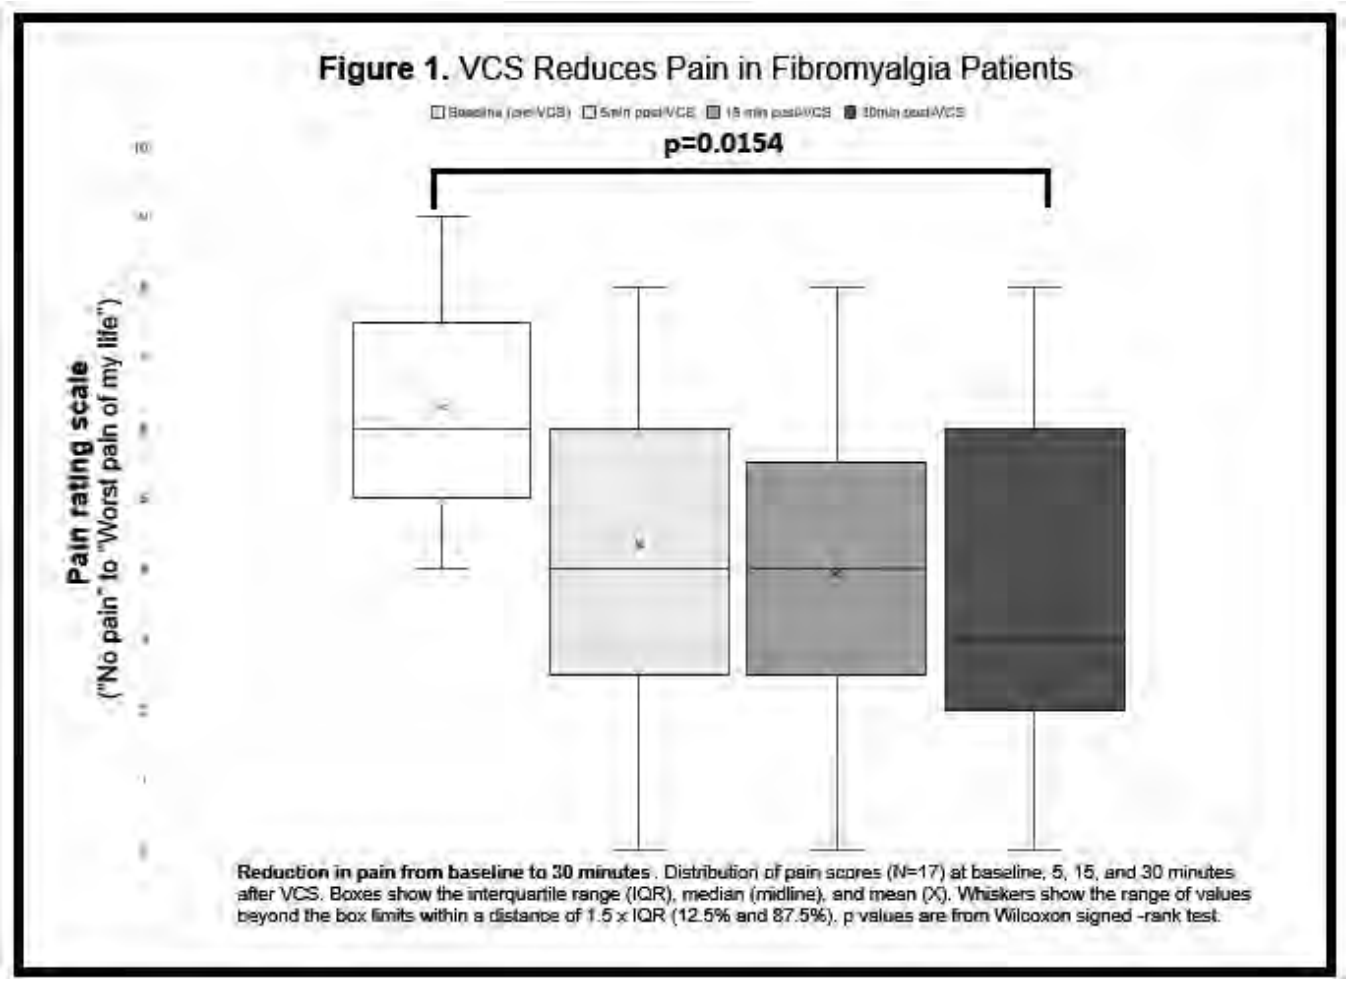
Session Date: Saturday, November 6, 2021

Session Title: Fibromyalgia & Other Clinical Pain Syndromes Poster (0118–0127)

Session Type: Poster Session A

Session Time: 8:30AM–10:30AM

Background/Purpose: Safe and effective therapies for fibromyalgia (FM) remain a major unmet clinical need. Vestibulocortical stimulation (VCS) via caloric irrigation is a safe, inexpensive, non-invasive and non-pharmacologic method of brain stimulation with demonstrated analgesic effects in persistent pain syndromes. VCS has also improved mood

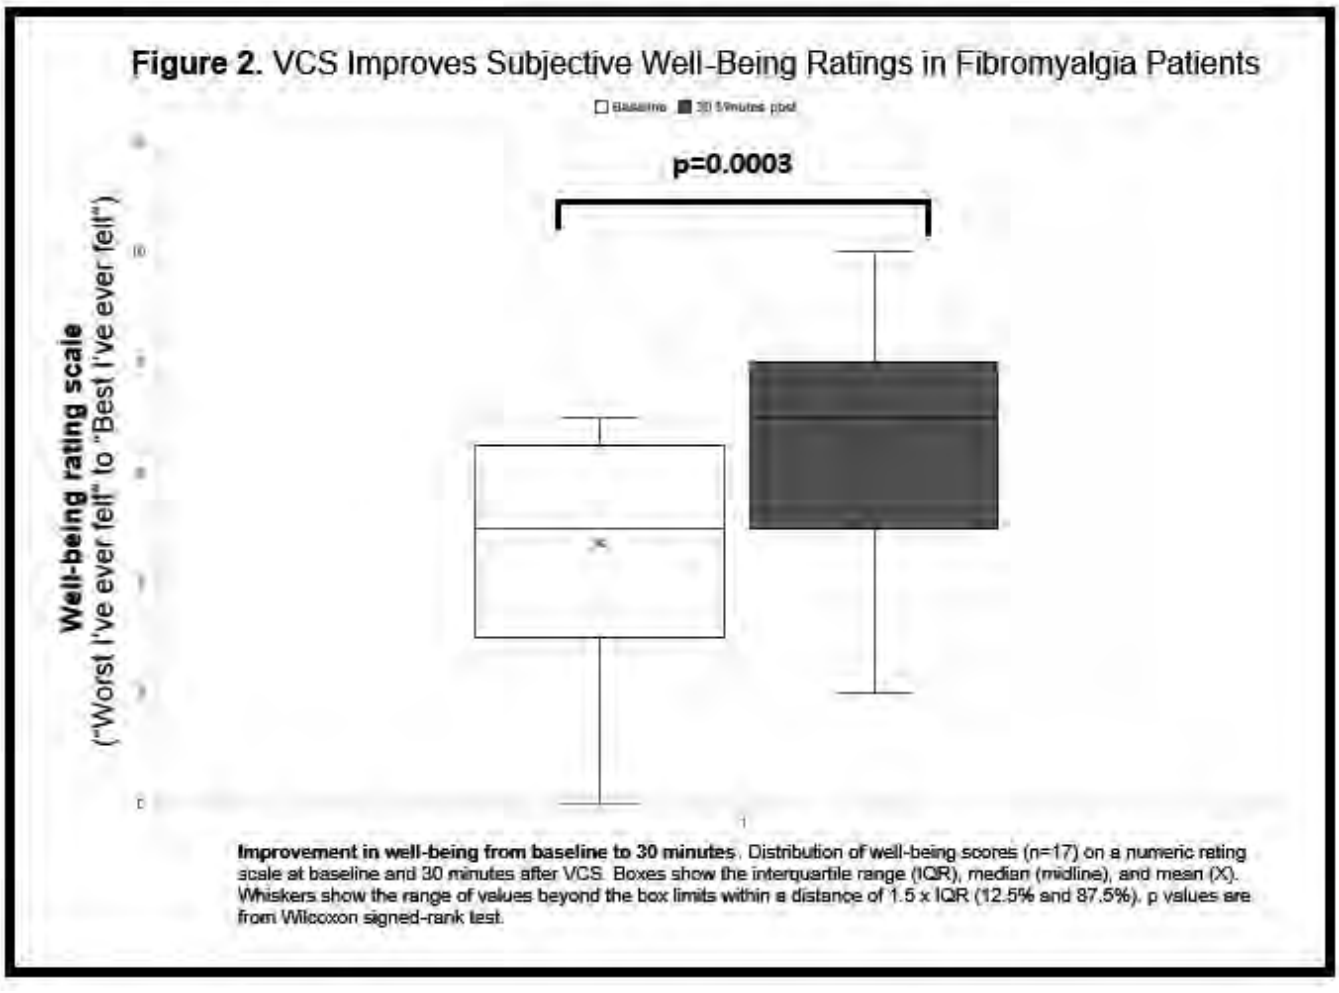


VCS Reduces Pain in Fibromyalgia Patients.

in psychiatric & healthy participants. Here we investigated whether VCS can similarly reduce pain & improve subjective well-being in FM patients.

Methods: We conducted a convenience-based non-randomized open-label pilot trial in 16 FM patients (mean age = 47.1 years; 15 female) recruited from a single rheumatology department. All patients met criteria for FM — defined as ≥7 widespread pain index (WPI) with ≥5 symptom severity score (SSS) or ≥4 WPI with ≥9 SSS. Half of the patient sample had primary FM, while underlying inflammatory disorders were present in 50%. Each participant underwent VCS with 50 cc of cold-water irrigation (4°C) into the right ear at 1–2 cc/second (which induces predominantly left-hemisphere activation). Vestibular stimulation was confirmed by post-procedural nystagmus & subjective vertigo. Pain scores (0–10) were recorded at baseline (before VCS) and at 5min, 15min & 30min after VCS; overall subjective well-being (0–10) was also assessed at baseline & 30min post-procedure. The primary outcome measure was change in mean pain scores collected each day/week following the VCS procedure. There were several secondary outcome measures, including immediate change in pain & subjective well-being after VCS.

Results: Of the outcome measures examined to date, the immediate effects of VCS are most evident. Overall there was a rapid pain reduction at 5 min post-VCS and, at 30 min, pain had decreased in 14/17 (82.4%) participants, increased in 1/17 (6%) and unchanged in 2/17 (12%) (Figure 1; p = .0003—Wilcoxon signed-rank test). In those with pain reductions, half (7/14) showed an improvement of at least 50% from baseline, 1/14 (7%) improved at least 30% and 6/14 (43%) improved < 30%. Subjective well-being ratings had also improved at 30 min post-VCS in 9/17 (53%)



VCS Improves Subjective Well-Being Ratings in Fibromyalgia Patients.

participants, worsened in 3/17 (18%) and were unchanged in 4/17 (24%) (Figure 2; p = .0154—Wilcoxon signed-rank test). While a proportion of participants (8/12 or 67%) reported the procedure was uncomfortable, it was otherwise generally well-tolerated with the large majority (11/12 or 92%) indicating they would have VCS again if it reduced their pain by ≥50% for at least one week — in keeping with recently published VCS tolerability results in a persistent pain cohort (Ngo et al., 2020 *Brain Stimul* 13: 1446–8). There were also no major adverse events in the current trial. Longer-term VCS effects will be reported when primary outcome data collection is completed, however three patients to date have reported sustained & meaningful pain relief for one week after a single VCS administration.

Conclusion: These preliminary results suggest VCS is a safe & well-tolerated procedure with positive effects on pain & subjective well-being in FM. Further investigation is required with repeated VCS (rVCS) in a placebo-controlled randomized trial.

BPI global pain severity (range 0-10)	4.5 (4.3, 5.5)	5.5 (4.6, 6.4)	0.041	5.0 (4.3, 6.1)
Pain Catastrophizing Score total (range 0-52)	15 (8, 24)	16 (9, 25)	0.763	15 (8, 25)

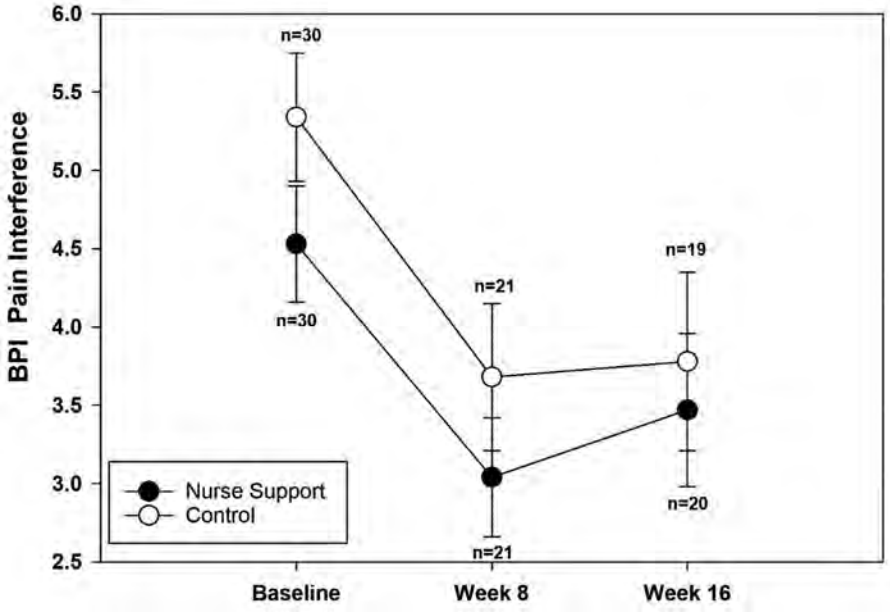

Figure 1. Plot of BPI interference by treatment group over time.

Table 2. Results of primary outcome analysis showing statistically significant improvements from baseline in BPI pain intensity, BPI pain interference, and BPI global pain severity scores between weeks 8 and 16 respectively. Results are given as mean (95% confidence interval) for change from baseline, with * indicating a significant non-zero change

PRIMARY OUTCOMES (Δ from baseline)	Nurse support group (n=30)	Control group (n=30)	P values
BPI global pain severity	3.8 (0.2) -1.2 (-1.7, -0.8)*	3.8 (0.2) -1.5 (-1.9, -1.0)*	0.770
BPI pain intensity	4.0 (0.2) -1.2 (-1.7, -0.6)*	4.2 (0.2) -1.3 (-1.8, -0.8)*	0.542
BPI pain interference	3.5 (0.3) -1.3 (-2.0, -0.7)*	3.5 (0.3) -1.7 (-2.3, -1.0)*	0.924
PROMIS physical function	40.6 (0.7) 3.3 (1.8, 4.7)*	40.1 (0.7) 2.9 (1.4, 4.4)*	0.641

Background/Purpose: Pain accounts for greater than 40% of all symptom-related outpatient visits totaling over 100 million outpatient encounters worth hundreds of billions of dollars annually in the U.S alone. Face-to-face and internet-delivered web-based cognitive behavioral therapy (CBT) have proven safe and effective in managing chronic musculoskeletal pain (CMP), demonstrating clinically significant improvements in pain-related disability and severity. Nonetheless, the effect size for CBT in CMP has been small partly due to low compliance or engagement by study participants. The purpose of this pilot study was to evaluate the effectiveness of nurse-supported web-based CBT in the outpatient setting for management of CMP.

Methods: Sixty subjects with CMP were recruited from the internal medicine and rheumatology clinics at Wake Forest Baptist Medical Center. Subjects were randomized to web-based self-guided CBT with six phone-based nurse support calls (nurse support group, n=30) vs. web-based self-guided CBT alone (control group, n=30). The purpose of the phone calls was to encourage completion of the eight learning modules within the web-based CBT program.

The nurse support calls were made from baseline to week 8. All participants had access to the CBT program from baseline to week 16. Outcome measures were collected at baseline, week 8, and week 16.

Results: Using analysis of covariance (ANCOVA) of week 8 and 16 outcome measures, both nurse support and control groups showed statistically significant improvements from baseline in BPI pain intensity (-1.2 [-1.7, -0.6], P< 0.05; -1.3 [-1.8, -0.8], P< 0.05), BPI pain interference (-1.3 [-2.0, -0.7], P< 0.05; -1.7 [-2.3, -1.0], P< 0.05), and BPI global pain severity (-1.2 [-1.7, -0.8], P< 0.05; -1.5 [-1.9, -1.0], P< 0.05) scores respectively. Amongst all secondary outcome measures, only the PROMIS sleep disturbance showed significant differences between the two groups and favored the nurse support group over the control group (50.5 [1.3] vs. 54.3 [1.3]; P=0.039). All subjects had comparable baseline characteristics including duration of pain ≥ 1 year, number of painful body sites (≥3 vs. < 3), Brief Pain Inventory (BPI) pain intensity, interference, and global pain severity scores (range 0-10), Patient-Reported Outcomes Measurement Information System (PROMIS) measures, Patient Health Questionnaire (PHQ-8) depression scale scores (≥ 10), and pain catastrophizing scores. Twenty (66.7%) of patients in the nurse support group vs. 19 (63.3%) of patients in the control group completed the study. The proportion of subjects who completed ≥ 6 learning modules were 17 (56.7%) in the treatment group vs. 18 (62.1%) in the control group. From baseline to week 8, the median number of completed phone calls made by the nurses were 3.5 calls (Interquartile Range [IQR]: 2, 5) and the median duration of each phone call was about 7 minutes (IQR: 5, 10).

Conclusion: Web-based CBT alone showed similar benefits in pain relief and pain-related disability in comparison to web-based CBT with phone-based nurse support over the short term. If confirmed in a larger study, web-based CBT without phone-based nurse support should be routinely included in any treatment algorithm for CMP.

SESSION INFORMATION

Session Date: Saturday, November 6, 2021

Session Title: Fibromyalgia & Other Clinical Pain Syndromes Poster (0118–0127)

Session Type: Poster Session A

Session Time: 8:30AM–10:30AM

Background/Purpose: Fibromyalgia (FM) is characterized by chronic musculoskeletal widespread pain, fatigue, sleep disturbances and functional symptoms. The primary endpoint of our study aimed to determine whether FM

could affect body composition of post-menopausal women. The secondary objectives investigated potential correlations between disease severity, measured subjectively by patient-compiled questionnaires, with body mass variables.

Methods: Thirty post-menopausal FM female patients (median age 58 years, BMI = 25.8) were diagnosed according to either ACR 1990 fibromyalgia classification criteria or ACR 2010 preliminary diagnostic criteria. They underwent Dual-energy X-ray absorptiometry (DEXA) for clinical purposes (i.e. screening for osteoporosis). The parameters analyzed by a dedicated software (GE Lunar, USA) were the spine and femoral bone mineral density (BMD), the total lean mass and the total body fat (TBF), quantitative variables of bone, muscle and fat composition. Additionally, qualitative analysis of the bone was indexed by the trabecular bone score (TBS). All the variables were compared with the parameters of 30 healthy controls (median age 59 years, BMI = 24.4) matched for sex and age. For each patient, data on disease duration, comorbidities, current treatment and disease severity self-reported scores were collected. The last ones derived from the Italian Fibromyalgia Impact Questionnaire Revised version that each patient independently compiled before the medical visit: widespread pain index (WPI), symptom severity scale (SSS), polysymptomatic distress scale (PDS), modified fibromyalgia assessment status (modFAS) and FIQR total score (FIQ-R).

Results: The clinical features of the patients included in our cohort are reported in table 1. No statistically significant differences were observed between femoral/spine BMD, TBS and muscle mass between patients and controls (p = 0.3, p = 0.06, p = 0.16, p = 0.8 respectively). Conversely, both total and central body fat were significantly higher in patients compared with healthy controls (29.4 kg vs 25.2 kg, 15.7 kg vs 13.2 kg, p = 0.006 and p = 0.01 respectively).

	Patients, N = 30
Age	58.0 [53.8, 69.2]
BMI	25.8 [23.0, 28.4]
Disease duration (years), Median [IQR]	4.5 [2.2, 9.2]
ModFAS, Median [IQR]	24.5 [20.0, 29.2]
PDS, Median [IQR]	17.5 [16.0, 23.2]
SSS, Median [IQR]	8.0 [6.0, 9.0]
WPI, Median [IQR]	12.0 [7.8, 15.0]
FIQ-R, Median [IQR]	57.9 [32.4, 68.8]
Current pharmacological treatment	
Cyclobenzaprine N (%)	24 (80)
Fluoxetine N (%)	5 (16.6)
Duloxetine N (%)	4 (13.3)
Gabapentinoids N (%)	2 (6.6)
Tizanidine N (%)	2 (6.6)
Benzodiazepines N (%)	2 (6.6)
Cannabinoids N (%)	3 (10)
Non-pharmacological treatment	
Aerobic physical activity N (%)	5 (16)
Comorbidities	
Hypertension N (%)	10 (33.3)
Diabetes N (%)	3 (10)
Osteoarthritis N (%)	10 (33.3)
Anxiety/depression N (%)	3 (10)
Psoriasis N (%)	3 (10)

Table 1. Clinical features of FM patients included in our cohort

No significant correlations were observed between body mass composition indexes with scores of disease severity. Body mass composition variables did not statistically differ when patients were sub-analyzed according to pharmacological treatment and comorbidities.

Conclusion: Our preliminary results suggest that FM does not significantly impair bone mass and quality in postmenopausal women, a conclusion in line with the majority of literature evidences [1]. Interestingly, total and central adipose tissue mass resulted higher in our cohort of patients compared with controls despite these findings did not correlate with disease severity. This might be due to a disease-induced sedentary lifestyle and reinforces the concept that physical activity not only should be the mainstay of treatment but also represents the best preventive method of overweight and obesity, one of most reported comorbidities of FM patients.

Abstract Number: 0126

Prevalence of Dyslipidemia in Fibromyalgia: A Single Center Case Control Study from South India

Mithun CB[1], Sandeep Surendran[2], **Sumanth Madan**[2], Arun Tiwari[3], Spoorthy Raj[2], Sekhar Easwar[2] and Greeshma Ravindran[2], [1]Amrita Institute of Medical Sciences, Muvattupuzha, India, [2]Amrita Institute of Medical Sciences, Kochi, India, [3]Amrita Institute of Medical Sciences, Ernakulam, India

SESSION INFORMATION
Session Date: Saturday, November 6, 2021
Session Title: Fibromyalgia & Other Clinical Pain Syndromes Poster (0118–0127)
Session Type: Poster Session A
Session Time: 8:30AM–10:30AM

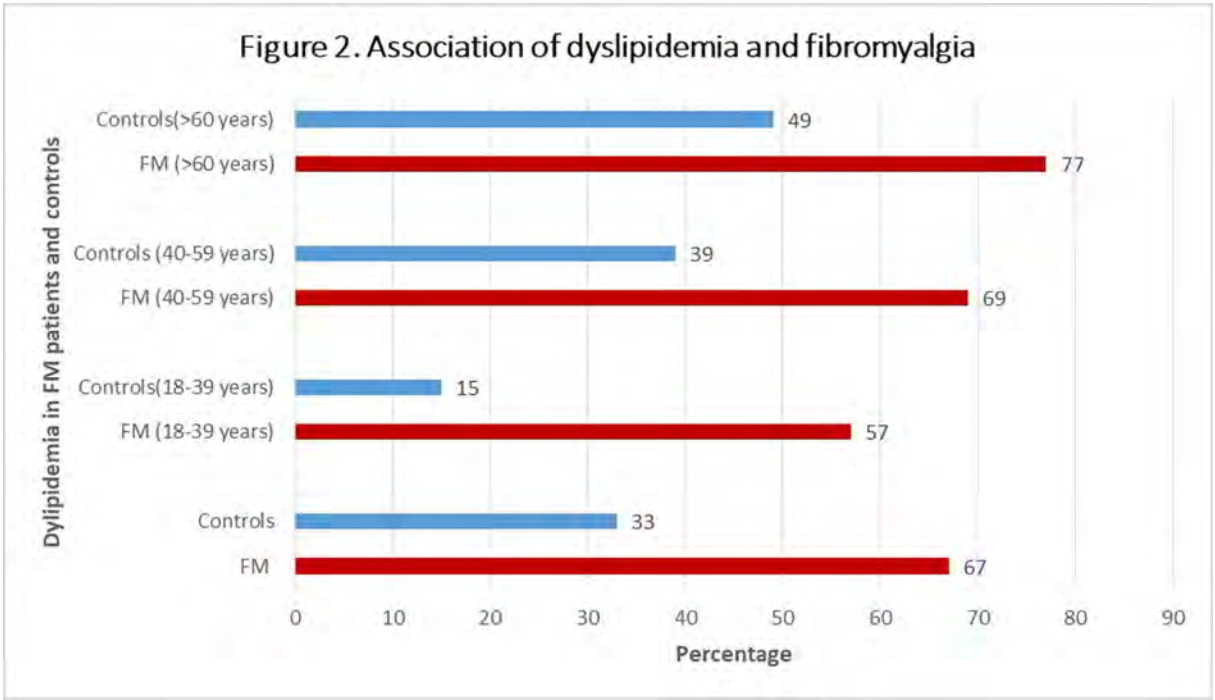
Background/Purpose: Fibromyalgia (FM), a condition characterized by chronic widespread pain, has implications beyond functional disability. FM has been associated with an increased risk of cardiovascular disease in multiple studies, however, there is a paucity of studies looking for dyslipidemia in diagnosed cases of FM. This study sought to explore the association between FM and dyslipidemia.

Methods: This was a case-control study conducted at a tertiary care center in South India from March 2018 to December 2020. FM patients and healthy controls were enrolled in a 1:3 ratio. FM was diagnosed as per the 2016 modified ACR 2010/2011 criteria. Healthy controls who were age, gender, ethnicity and body mass index (BMI) matched were recruited in the study. Fasting lipid profile was obtained from study participants and dyslipidemia was defined by the "Adult treatment panel III criteria". [(1)]The revised fibromyalgia impact questionnaire (FIQR) was used as a tool to ascertain disease severity in FM at diagnosis. The prevalence of dyslipidemia in FM was compared with that of healthy controls and odds ratio was calculated. We also studied the correlation of FIQR with fasting lipid profile. Chi- square test and Pearson correlation coefficient was computed and linear regression t test were applied to test statistical significance. A p value < 0.05 was considered significant.

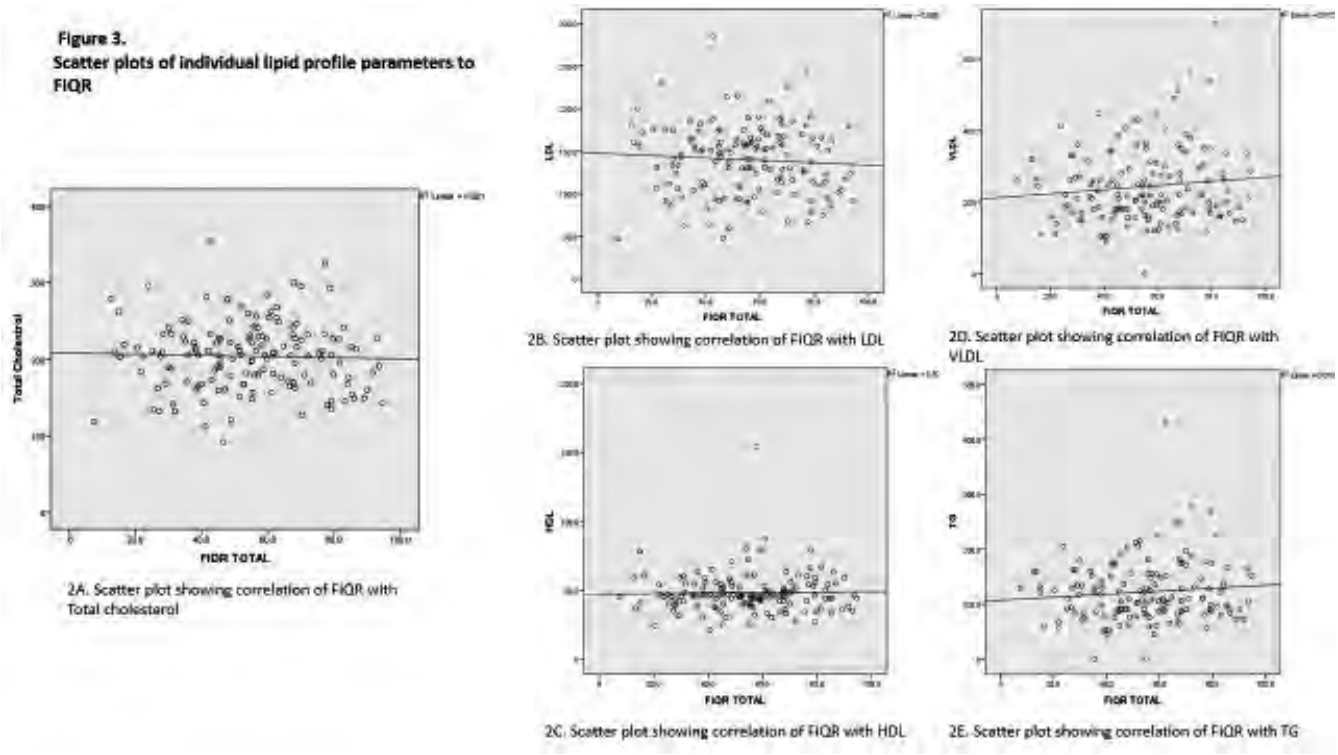
Figure 1: Comparison of presence of dyslipidemia in FM and controls*

	Dyslipidaemia present -no(%)	Dyslipidaemia absent -no (%)	p-value	Odds ratio (95% CI)
FM (n= 149)	100 (67.1%)	49 (32.9%)	<0.001	4.193 (2.826-6.221)
Controls(n=449)	147 (32.7%)	302 (67.3%)		
Age group 18-39 years				
FM (n= 30)	17 (56.7%)	13 (43.3%)	<0.001	7.701 (3.200-18.531)
Controls(n=124)	18 (14.5%)	106 (85.5%)		
Age group 40-59 years				
FM (n= 106)	73 (68.9%)	33 (31.1%)	<0.001	3.539 (2.201-5.692)
Controls(n=286)	110 (38.5%)	176 (61.5%)		
Age group >60 years				
FM (n=13)	10 (76.9%)	3 (23.1%)	0.076	NA
Controls (n=39)	19 (48.7%)	20 (51.3%)		

* FM denotes- fibromyalgia, CI- Confidence interval.



Results: A total of 149 (females- 147) FM cases and 449 healthy controls were enrolled in the study. We noted that dyslipidemia was present in 100 (67%) FM cases and 147 (33%) controls, their difference was statistically significant (p< 0.001; OR 4.193). Subgroup analysis amongst individual age groups showed an increased prevalence of dyslipidemia in the 18-39 years with 17 (57%) amongst FM cases as compared to 18 (15%) in control group (p< 0.001;



OR 7.701). In the 40-59 years age group, 73 (68%) FM patients were dyslipidemic as compared to 110 (39%) of the controls (p< 0.001, OR: 3.539). There was no statistically significant difference in prevalence of dyslipidemia between cases and controls of age greater than 60 years. (Figure 1, Figure 2). There was also no statistically significant correlation between FIQR and individual components of lipid profile (p >0.05). (Figure 3)

Conclusion: In this study, dyslipidemia was more prevalent in FM patients as compared to general population. The findings were consistent in subgroup analysis of age groups 18-39 and 40-59 years. However, FM disease severity did not correlate with individual components of fasting lipid profile in our study. These findings emphasize the need for evaluation of dyslipidemia in fibromyalgia patients.

Abstract Number: 0127

Interleukin 1 Receptor Antagonist (IL-1Ra) Variable Number of Tandem Repeat (VNTR) Polymorphism in Fibromyalgia Patients in South India

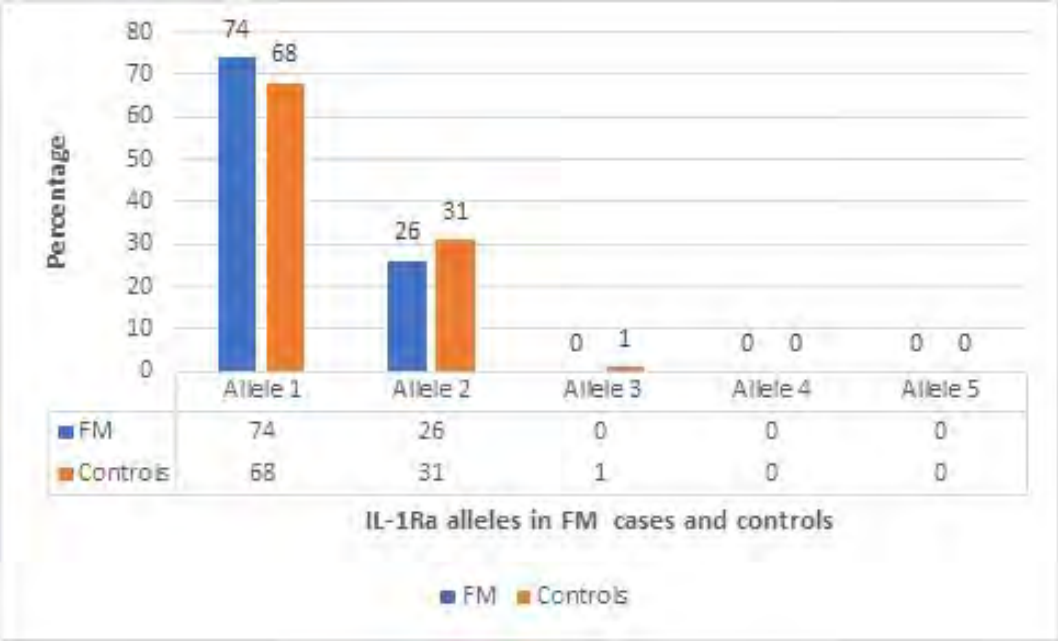
Arun Tiwari[1], Mithun CB[2], Lalitha Biswas[3], Sandeep Surendran[3], Vishal Marwaha[3], Pranav Chickermane[3] and Amisha Shahul[3], [1]Amrita Institute of Medical Sciences, Ernakulam, India, [2]Amrita Institute of Medical Sciences, Muvattupuzha, India, [3]Amrita Institute of Medical Sciences, Kochi, India

SESSION INFORMATION
Session Date: Saturday, November 6, 2021
Session Title: Fibromyalgia & Other Clinical Pain Syndromes Poster (0118–0127)
Session Type: Poster Session A
Session Time: 8:30AM–10:30AM

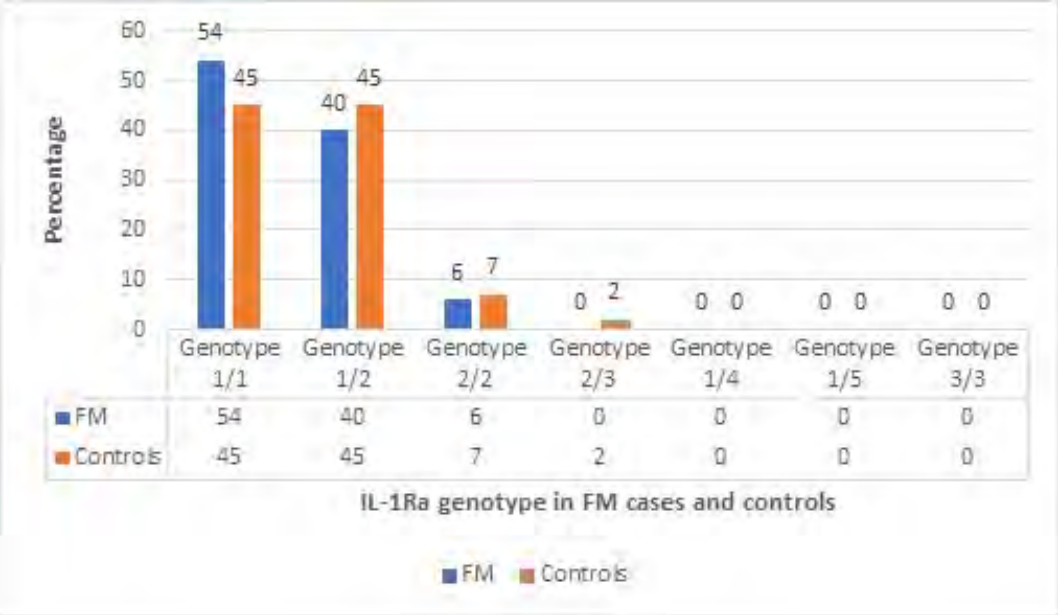
Background/Purpose: Interleukin-1 receptor antagonist (IL-1Ra) variable number of tandem repeats (VNTR) polymorphism is a known to influence the production of IL-1Ra and has been considered as a susceptibility marker for various autoimmune diseases.[1] Serum IL-1Ra levels were found to be low in fibromyalgia (FM) patients in our previous study.[2] Here, we have studied the role of IL-1Ra VNTR polymorphism in influencing disease susceptibility in FM.

Methods: This case-control study was performed at a tertiary care centre in South India from March 2020 to March 2021. FM patients diagnosed as per 2016 modified ACR 2010/2011 criteria and age, gender, and BMI matched healthy controls were included in the study. FM patients with other co-existing rheumatological disease or psychiatric illness were excluded. Genomic DNA was isolated from the peripheral blood of all the enrolled participants and was subjected to polymerase chain reaction to study the frequency of alleles and genotypes of the IL-1Ra gene (IL-1RN) in FM cases and controls. Chi-square and Fisher's exact test were applied to test statistical significance.

Results: A total 79 participants (35 FM cases and 44 matched controls, all females) were enrolled; of the 5 known alleles of IL-1Ra only 3 alleles and out of 8 known genotypes of IL-1Ra only 4 genotypes were detected in our study



Frequency of IL-1 Ra alleles in FM cases and controls.



Frequency of IL-1Ra genotype in FM cases and controls.

Baseline clinical characteristics and disease severity assessment parameters feature of FM patients across the genotypes*

	Genotype 1/1 (n = 19)	Genotype 1/2 (n = 14)	Genotype 2/2 (n = 2)	p-value¶
Age at diagnosis of FM (years)	40.89 ± 10.05	45.71 ± 6.68	46.00 ± 8.48	0.129
BMI (kg/m^2)	24.52 ± 2.75	28.00 ± 3.80	23.00 ± 1.41	**0.012**
WPI	11.26 ± 3.19	10.42 ± 2.73	15.50 ± 2.12	0.437

FIQR	48.05 ± 20.67	48.21 ± 19.08	59.50 ± 4.95	0.982
BPI pain	683.94 ± 181.95	637.14 ± 254.52	883.00 ± 165.46	0.542
BPI function	613.52 ± 206	535.42 ± 202.75	450.00 ± 306.88	0.288

* Percentages may not total 100 because of rounding. All the variables are represented in Mean ± Standard deviation. BMI denotes - Body mass index, WPI- Widespread pain index, SSS- Symptom severity score, FIQR- Revised Fibromyalgia Impact Questionnaire, and BPI- Brief pain inventory.

¶ There were only two patients with genotype 2/2 hence it was excluded from this part of statistical analysis and the p-value mentioned here is on comparing various parameters in genotype1/1 and genotype 1/2.

Baseline clinical characteristics and disease severity assessment parameters feature of FM patients across the genotypes.

population. IL-1Ra allele 1 frequency in FM patients was 52 (74%) and 60 (68%) in controls; IL-1Ra allele 2 frequency in FM patients was 18 (36%) and 27 (31%) in controls; IL-1Ra allele 3 was present in only one control; these differences were not significant statistically (p = 0.512) (Figure-1).

IL-1Ra genotype1/1 was present in 19 (54%) FM patients and 20 (45%) controls, genotype 1/2 was present in 14 (40%) FM patients and 20 (45%) controls, genotype 2/2 was present in 2 (6%) of FM patients and 3 (7%) controls, and genotype 2/3 was noted only in one participant of the control group; these differences were not significant statistically (p = 0.753) (Figure-2).

On comparison of baseline characteristics of FM patients with IL-1Ra genotype 1/2 had higher mean BMI- (28.0, SD-3.8 kg/m^2) compared IL-1Ra genotype 1/1 FM patients mean BMI (24.52, SD- 2.75 kg/m^2) and this difference was statistically significant ($p = 0.012$).There was no association of baseline disease severity of FM (assessed by wide spread pain index, symptom severity score, revised fibromyalgia impact questionnaire, brief pain inventory pain and function score) with IL-1Ra genotype and allelic frequency ($p > 0.05$) (Figure-3).

Conclusion: IL-1Ra VNTR polymorphism was not a susceptibility marker for FM in our study population and it did not show any association with FM disease severity parameters. Obesity in FM patients was associated with IL-1Ra genotype 1/2.

Increased Risk of Major Adverse Cardiac Events in Patients with Systemic Lupus Erythematosus After Non-Cardiac Surgery

Sebastian Bruera[1], Xiudong Lei[2], Brandon Blau[1], Hui Zhao[2], Anita Deswal[2], Jinoos Yazdany[3], Sharon Giordano[2] and Maria Suarez-Almazor[2], [1]Baylor College of Medicine, Houston, TX, [2]University of Texas MD Anderson Cancer Center, Houston, TX, [3]University of California San Francisco, San Francisco, CA

SESSION INFORMATION
Session Date: Saturday, November 6, 2021
Session Title: Health Services Research Poster I: Lupus, Inflammatory Arthritis, & More (0128–0148)
Session Type: Poster Session A
Session Time: 8:30AM–10:30AM

Background/Purpose: The association between systemic lupus erythematosus (SLE) and cardiovascular disease has been well-studied. Cardiovascular disease is a risk factor for major adverse cardiac events (MACE) after surgery. The objective of this study was to estimate the risk of MACE in patients with SLE undergoing moderate to high-risk non-cardiac surgeries compared to control patients with and without diabetes.

Methods: This retrospective, observational study used deidentified administrative data from the Optum Clinformatics Data Mart to identify adult patients who underwent non-cardiac surgery in 2007-2020 via Current Procedural Terminology (CPT) codes. Two independent providers (SB, BB) omitted low risk procedures such as simple skin procedures, endoscopies, ocular surgeries, or orthopedic surgeries that were distal to the elbow or knee joints. From this pool, we defined a SLE cohort (patients who had two or more international classification of diseases (ICD) 9 or 10 codes of 710.0 or M32.xx but not M32.0 within one year before surgery), a diabetic cohort, and a non-diabetic cohort. We matched SLE cases with the diabetic and non-diabetic cohorts by age and gender. Our primary outcome was MACE (including death, myocardial infarction, ischemic stroke, or pulmonary embolism defined by ICD or CPT

Table 1. Multivariable conditional logistic regression model for MACE including death in one month after surgery based on matched cohorts aged 18+.

		Model 1		Model 2		Model 3	
		Odds Ratio (95% CI)	P	Odds Ratio (95% CI)	P	Odds Ratio (95% CI)	P
Cohorts							
	Non-DM Control	1		1		1	
	DM control	1.92 (1.72 to 2.14)	<0.001	1.26 (1.12 to 1.41)	<0.001	1.26 (1.12 to 1.41)	<0.001
	SLE	1.51 (1.09 to 2.08)	0.013	0.97 (0.7 to 1.36)	0.88	0.96 (0.69 to 1.34)	0.82
RCRI							
	0			1		1	
	1			2.92 (2.57 to 3.32)	<0.001	2.92 (2.57 to 3.32)	<0.001
	2			8.4 (7.21 to 9.79)	<0.001	8.35 (7.16 to 9.73)	<0.001
	3+			12.72 (10.39 to 15.59)	<0.001	12.68 (10.35 to 15.54)	<0.001
Race							
	White					1	
	Black					1.26 (1.07 to 1.48)	0.005
	Hispanic					0.65 (0.5 to 0.85)	0.002
	Asian					1.3 (0.88 to 1.92)	0.18

codes) within one month post-surgery. We performed a multivariable conditional logistic regression to estimate the odds of MACE within one month of surgery for the three cohorts after adjusting for pre-operative Revised Cardiac Risk Index (RCRI) scores and race (white, black, Hispanic, Asian, and unknown). The RCRI scores include congestive heart failure, coronary artery disease, insulin-dependent diabetes, cerebrovascular disease, and chronic kidney disease (all these variables were defined by claims). Scores greater than one are considered moderate to high risk. We also performed multivariable logistic regression models for MACE amongst SLE patients only that included RCRI scores, age, gender, race, and SLE disease activity (Garris index).

Results: We included 4,750 SLE patients, 484,986 non-diabetes controls, 496,381 diabetes controls and After matching, no significant differences were observed between SLE and diabetic patients in MACE rates. Without adjustment, SLE patients had an increased risk of MACE compared to non-diabetic controls (Table 1, OR 1.51, 95% CI 1.09-2.08); however, the association became nonsignificant after adjusting for RCRI scores (OR 0.97, 95% CI 0.70 – 1.36. Amongst SLE patients, higher RCRI scores, older age, and non-white race were associated with increased risks of MACE, but not gender, pre-operative cardiac testing, or SLE disease activity.

Conclusion: Patients with SLE have an increased risk of MACE within one month after surgery similar to diabetes controls but higher than non-diabetes controls. This risk normalizes after adjusting for pre-operative RCRI scores, suggesting that SLE patients are at an increased risk of MACE because of underlying comorbidities including cardiovascular disease. Our results indicate that SLE confers an increased risk for MACE, independently of disease severity, mediated by pre-existing cardiovascular disease.

Abstract Number: 0129

Real-World Flare Rates and Progression by Treatment Settings Among the Commercially-Insured Systemic Lupus Erythematosus Population in the U.S

Sandra Sze-jung Wu[1], Allison Perry[2], Helen Varker[2], Richard Bizier[2], Joseph Tkacz[2] and Robert Ortmann[3], [1]AstraZeneca, Wilmington, DE, [2]IBM Watson Health, Bethesda, MD, [3]AstraZeneca, Greenwood, IN

SESSION INFORMATION
Session Date: Saturday, November 6, 2021
Session Title: Health Services Research Poster I: Lupus, Inflammatory Arthritis, & More (0128–0148)
Session Type: Poster Session A
Session Time: 8:30AM–10:30AM

Background/Purpose: The clinical presentation of systemic lupus erythematosus (SLE) is complicated, as patients cycle through periods of active disease (flares) and remission. To establish the burden of SLE, the heterogenous nature of the population must also be taken into consideration, particularly as it relates to the frequency and nature of flare treatment. The purpose of this study was to assess and characterize the annual rate of SLE flares by the site of care where treated (inpatient hospital [IP], emergency room [ER], and outpatient [OP]), and to observe the progression of specific flare rates and types in a subsequent year.

Methods: SLE patients were selected from IBM MarketScan commercial claims and encounters databases between 1/1/2013–3/31/2019. Inclusion criteria: 1) ≥1 inpatient claim with a diagnosis for SLE, or ≥2 non-diagnostic SLE outpatient claims with at least one rheumatologist or nephrologist specialty designation (index date set to a random SLE service date with ≥12 months of SLE disease history preceding it to create a prevalence cohort), 2) continuous enrollment with medical and pharmacy benefits for 12 months pre- and post-index, and 3) valid steroid Rx claims. SLE flares were defined using a published claims-based algorithm based on presence of SLE-related treatment and diagnosis[1]; results were presented during the 12-month period preceding (year 1) and following index (year 2). Flare

Table 1. Flare Frequency and Severity in Year 2 as a Function of Year 1 Flare Status

	All Patients N = 22,385	
Flare Characteristics in Year 1

Patients with ≥1 flare treated at ER setting (N, %)	41	3.9%	290	24.9%	565	27.3%	1,303	7.2%
Patients with ≥1 flare treated at OP setting (N, %)	664	63.8%	1,113	95.7%	1,969	95.0%	17,200	95.0%
Among patients with flares by treatment settings (Mean, SD)								
Number of flares treated at IP (Mean, SD)	1.2	0.4	1.4	0.9	1.2	0.5	1.1	0.4
Average length of stay (in days) per flare treated at IP (Mean, SD)	4.8	5.3	6.3	6.9	5.0	5.0	4.5	5.2
Number of flares treated at ER (Mean, SD)	1.1	0.3	1.7	1.2	1.6	1.0	1.2	0.5
Number of flares treated at OUT (Mean, SD)	2.0	1.2	4.1	1.8	3.9	1.8	4.0	1.9

progression from year 1 to year 2 were observed among four mutually exclusive cohorts of patients who had ≥1 flare treated in IP, ≥1 flare in ER but no IP, ≥1 flare in OP but no IP/ER, and no flares in year 1.

Results: 22,385 SLE patients qualified for the study; 95.4% (N=21,345) presented ≥1 flare in year 1; 5.4% (n=1,163) were treated in the IP, 9.7% (n=2,072) in the ER, and 84.8% (n=18,110) in an OP setting. Nearly 2/3 of patients without a flare in year 1 presented a flare in year 2, with 19.0% presenting ≥3 flares (Table 1). Among patients with a flare in year 1, 75.3% presented ≥3 flares in year 2. Compared to patients without a year 1 flare, those with a prior-year flare were more likely to present year 2 flares in the IP (4.2% vs. 1.0%), ER (10.1% vs. 3.9%), and OP (71.2% vs. 34.6%). Analyses segmented by baseline flare site of care revealed that, among patients with a flare treated in the IP setting, 19.3% presented an IP flare in year 2, and 24.9% presented an ER flare, substantially higher than patients without prior-year flares treated in the IP (Table 2). Compared to patients with baseline flares in the ER or OP settings, those with baseline flares in the IP setting were more likely to present ≥3 flares in that same year (84.7% vs. 80.1% and 74.1%; Figure 1).

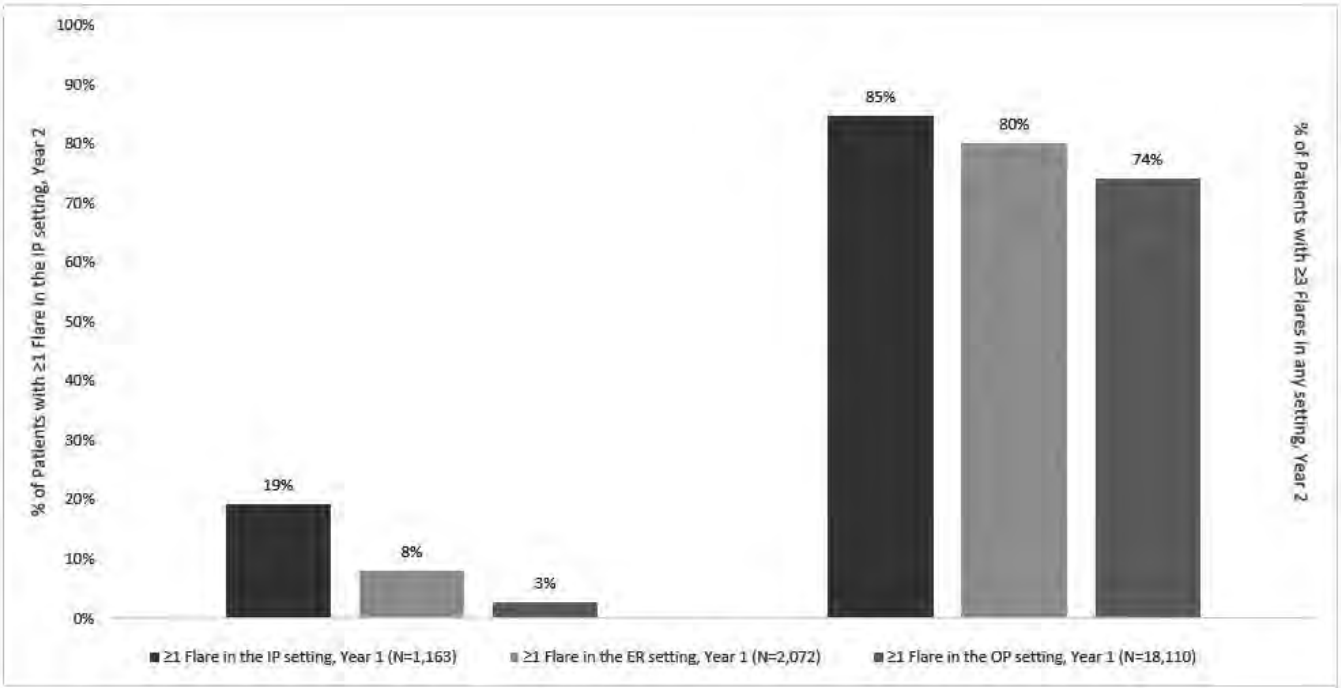

Figure 1. SLE Flare Outcomes in Year 2 as a Function of Prior Year Category.

Conclusion: Rates of SLE flares vary by patient subgroups over time and by flare history. SLE patients with more resource-intensive flares may be more likely to experience additional flares of similar or worse intensity in the future. An accurate assessment of disease flares is critical to quantifying the burden of SLE, and can inform the development of treatment options to control disease and minimize healthcare burden at the population level. Results highlight a potential unmet need in the current treatment landscape.

that may vary both within and across sub-populations. The objective of this study was to characterize a prevalence population of SLE and to assess outcomes related to comorbidities, healthcare resource utilization, and flares across disease severity levels and payer channels.

Methods: SLE patients were selected from IBM MarketScan Commercial Claims (COM), Medicare Supplemental (MDCR), and Medicaid (MDCD) Databases from 1/1/2013-3/31/2019. Inclusion criteria were 1) ≥1 inpatient claim with an SLE diagnosis or ≥2 non-diagnostic outpatient SLE claims with ≥1 rheumatologist or nephrologist specialty designation (index date set to random SLE claim with ≥12 months of SLE disease history preceding it), 2) continuous enrollment for 12 months pre-index, and 3) valid steroid Rx claims. SLE disease flares and severity were assessed using a published claims-based algorithm[1]; patient characteristics, healthcare service use/costs, and flare outcomes were assessed during the year prior to index. All results were presented by disease severity and payer channel.

Results: 22,385 COM (23% mild; 44% moderate; 33% severe), 2,035 MDCR (20% mild; 39% moderate; 41% severe), and 8,191 MDCD (15% mild; 34% moderate; 51% severe) patients were included. Mean overall age was 46.5[11.5], 71.3[7.4], 40.9[12.2] years for COM, MDCR, and MDCD, respectively; older age was associated with an increase in disease severity for MDCD patients (p< 0.001). The majority of patients across all subgroups were female (88.2-93.3%) (**Table 1**). The mean Elixhauser Comorbidity Index was 0.5-2.0[3.9-0.6], which increased as SLE disease severity increased (p< 0.001). Common comorbidities included cardiovascular disease (20.7-63.1%), osteoarthritis (13.6-51.1%), and fatigue (10.7-23.0%). Across all payer channels, all-cause inpatient admissions increased significantly with disease severity (4.5%-9.2% mild; 9.9%-17.3% moderate; 24.2%-37.5% severe), with similar trends for emergency room utili-

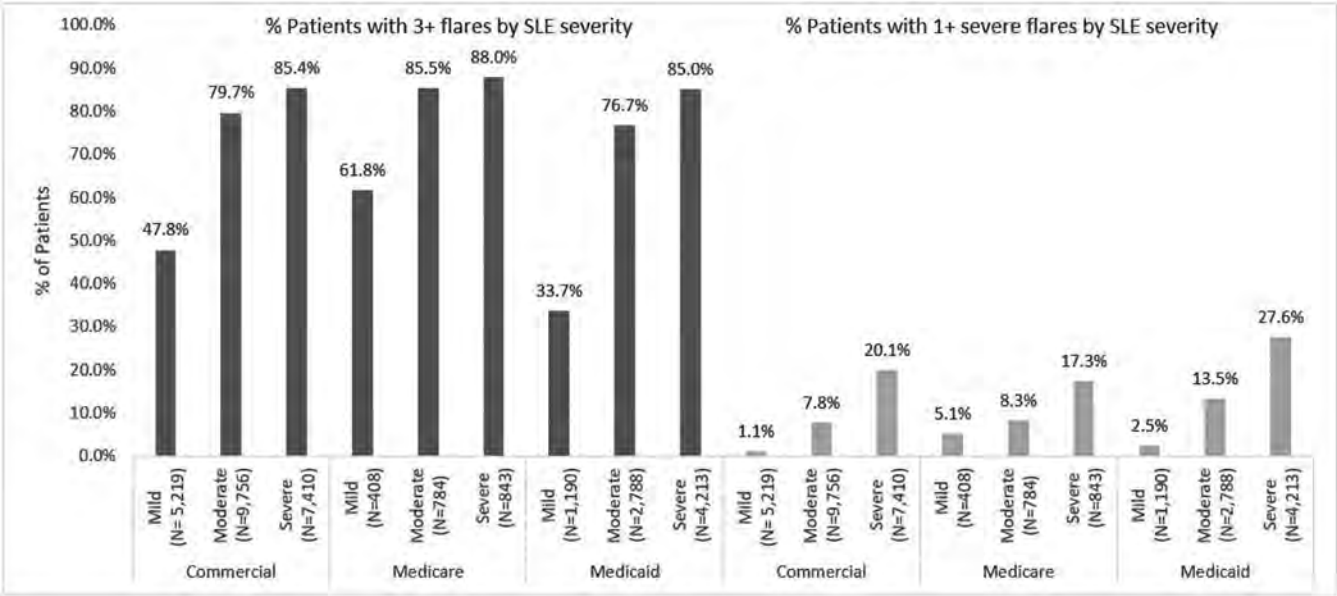

Figure 1. SLE Flare Outcomes by Disease Severity for Each Payer Channel.

zation (17.6%-52.3% mild; 28.6%-66.6% moderate; 44.4%-77.7% severe; all p< 0.001) (**Table 2**). Total healthcare costs were 4-to-6-fold higher among patients with severe vs. mild disease ($29,354-68,253 among severe vs. $5,133-16,273 among mild; p< 0.001). Across all payer groups, the proportion of patients with a severe SLE flare, as well as the proportion of patients with 3+ flares, increased as disease severity also increased (**Figure 1**).

Conclusion: SLE-related comorbidities, disease flares, and healthcare expenditure vary by both disease severity and payer status. SLE patients with more severe SLE disease experience higher rates of comorbidities and SLE flares, which are associated with more intensive resource utilization and costs; Medicaid beneficiaries presented the highest use of ER and IP services. Overall, results demonstrate a potential unmet need in the SLE treatment landscape, especially among patients with more severe disease.

Session Title: Health Services Research Poster I: Lupus, Inflammatory Arthritis, & More (0128–0148)

Session Type: Poster Session A

Session Time: 8:30AM–10:30AM

Background/Purpose: Over 33% of U.S. adults have limited health literacy or numeracy. Limited health literacy and numeracy have been associated with higher disease activity and worse patient-reported outcomes in systemic lupus erythematosus (SLE). Health literacy involves ability to understand and use health information. A component of health literacy is numeracy, which involves quantitative math skills and is important for understanding and managing complex medication regimens. The objective of this study was to assess the relationship between health numeracy and medication adherence in SLE; we hypothesized that patients with limited numeracy would have higher rates of medication non-adherence.

Methods: SLE patients meeting ACR or SLICC criteria were recruited from a university clinic from March 2019 through January 2021. Numeracy was assessed with the Subjective Numeracy Scale (SNS-3); limited numeracy was defined as SNS-3 $\leq$ 12. Self-reported adherence for SLE medications was obtained using the visual analog scale component of the MASRI (Medication Adherence Self-Report Inventory), a patient-reported percentage of taking medications in the past 1 month (0-100%). In a subset of patients (n=146), objective medication adherence to SLE medications was also determined by Medication Possession Ratio (MPR), the proportion of days with medication supply over a 3-month period, using pharmacy refill data from the electronic health record. Non-adherence was defined as MASRI < 90% and MPR < 80%. We evaluated relationships between numeracy and adherence using descriptive statistics. Logistic regression models estimated the associations of numeracy with non-adherence, adjusting for education level.

Results: The cohort included 218 patients with SLE. The average age was 43, with 94% female and 59% Black race. Mean disease duration was 13 years, with average SLEDAI 3.0 and PGA 0.5; 45% had a history of lupus nephritis.

Compared to patients with adequate numeracy, those with limited numeracy had lower self-reported adherence (54% vs 73%) but paradoxically higher objective adherence (56% vs 44%). In a multivariable logistic regression adjusted for education, patients with low numeracy were twice as likely to self-report non-adherence by MASRI (OR 1.94; 95% CI: 1.07, 3.51) (Table 1).

Conclusion: In our cohort, limited numeracy and non-adherence are common. Although patients with low numeracy filled SLE medications at similar rates to those with adequate numeracy, we found paradoxically they were more likely to report non-adherence. This may reflect true non-adherence but could also be due to difficulty interpreting the adherence question or estimating the percentage they have taken medications. Future studies are needed to further elucidate this relationship.

Adjusted for education, patients with low numeracy were twice as likely to self-report non-adherence by MASRI (OR 1.94; 95% CI: 1.07, 3.51).

Table 1: Logistic Regression of the Associations of Health Numeracy with Adherence

	Adequate Numeracy	Limited Numeracy	p-value	Adjusted OR (95% CI)	p-value
	n=135	n=83			
% Adherent by **Self-Report** (MASRI ≥ 90%)	98 (73%)	45 (54%)	0.008	1.94 (1.07, 3.51)	0.03
	n=89	n=57			
% Adherent by **Objective Adherence** (MPR ≥ 80%)	39 (44%)	32 (56%)	0.2	0.58 (0.29, 1.14)	0.1

Abstract Number: 0132

Hospitalization Rates Among Patients with Systemic Lupus Erythematosus: A Population Based Study

Jesse Dabit[1], Mehmet Hocaoglu[2], Maria Valenzuela-Almada[3], Shirley-Ann Osei-Onomah[1], Sebastian Vallejo-Ramos[1], Rachel Giblon[1], Kurt Greenlund[4], Kamil Barbour[4], Cynthia Crowson[5] and Ali Duarte-Garcia[1], [1]Mayo Clinic, Rochester, MN, [2]University of Maryland Medical Center, Midtown Campus, Baltimore, MD, [3]Division of Rheumatology, Mayo Clinic, Rochester, MN, [4]Centers for Disease Control, Atlanta, GA, [5]Mayo Clinic, Eyota, MN

SESSION INFORMATION

Session Date: Saturday, November 6, 2021

Session Title: Health Services Research Poster I: Lupus, Inflammatory Arthritis, & More (0128–0148)

Session Type: Poster Session A

Session Time: 8:30AM–10:30AM

Background/Purpose: Systemic lupus erythematosus (SLE) is a chronic autoimmune multiorgan disease associated with significant morbidity and mortality. Although the survival rate for SLE patients has improved, hospitalization rates and healthcare utilization among SLE patients remain higher than the general population. By using a population-based cohort, we describe hospitalization rates, causes and risk factors among SLE patients compared to non-SLE patients between 2015 and 2020.

Methods: Using an established population-based research infrastructure that links the medical records of all individuals in a geographically well-defined 27-county US population, we identified SLE cases meeting the 2019 ACR/EULAR classification criteria. SLE patients who were residents in the 27-county region on January 1, 2015 were in-

Table 1. Demographic and hospitalization characteristics among SLE patients and comparators

Characteristic	SLE N=479	Comparators N= 479	P-Value
Age, years, Mean (SD)	53.2 (16.2)	53.2 (16.2)	0.99
Female Sex, N (%)	394 (82)	394 (82)	1.00
Race/Ethnicity, N (%)			
White	404 (85%)	412 (86%)	0.93
Asian	15 (3%)	17 (4%)	
other/mixed	8 (2%)	5 (1%)	
Black	18 (4%)	19 (4%)	
American Indian	2 (0%)	2 (0%)	
Hispanic Ethnicity	29 (6%)	24 (5%)	
Length of Stay (days) Median (Range)	4 (0-112)	3 (0-42)	0.001

Table 2. Rate of hospitalization by primary discharge diagnosis using the Clinical Classifications Software among SLE patients and comparators

Grouped primary discharge diagnosis	SLE hospitalization rate/100 person-years	Non-SLE hospitalization rate/100 person-years	Rate Ratio (95% CI)
Overall	26.24	9.27	2.83 (2.43-3.31)
Cardiovascular	4.23	1.57	2.67 (1.86-3.96)
Respiratory	3.40	0.68	4.88 (3.00-8.75)
Musculoskeletal	2.90	0.77	3.72 (2.30-6.50)
Injury/poisoning	2.16	0.47	4.45 (2.48-9.13)
Gastrointestinal	1.99	0.85	2.31 (1.41-4.00)
Infectious	1.70	0.51	3.24 (1.80-6.52)
Genitourinary System	1.29	0.26	4.73 (2.23-12.84)
Mental Illness	0.95	0.77	1.24 (0.68-2.33)
Neoplasm/Oncology	0.91	0.47	1.91 (0.97-4.12)
Pregnancy Morbidity	0.71	0.60	1.18 (0.59-2.43)
Hematologic	0.71	0.04	11.38 (3.24-159.95)
Endocrine/Metabolic	0.66	0.26	2.48 (1.07-6.98)
Dermatological	0.54	0.17	2.93 (1.11-10.50)
Neurological	0.46	0.17	2.49 (0.91-9.03)
Multiorgan/ill defined	0.29	0.13	2.09 (0.63-9.55)

cluded. Patients with SLE were matched by age, sex, race/ethnicity and county of residence to non-SLE patients and were followed until 12/2020. Variables included were age, sex, race/ethnicity, number of hospitalizations, length of stay (LOS) and primary discharge diagnosis. Chi-square and Kruskal-Wallis rank sum tests were used to assess difference in characteristics between cases and controls. Hospitalization data were analyzed using person-year methods and rate ratios were obtained from Poisson models.

Results: We identified 479 SLE patients and 479 comparators. Mean age of SLE patients was 53.2 (SD 16.2) years, 82% were females and 85% were white (Table 1). Between 2015 and 2020, the hospitalization rate of SLE patients was 26.2/100 person-years compared to 9.3/100 person-years among comparators (rate ratio (RR) 2.83; 95% confidence interval (CI) 2.43-3.31; Table 2). LOS was higher among SLE patients (median 4 vs. 3 days; p=0.001). SLE patients were hospitalized at a significantly higher rate than subjects without SLE in 10 of 15 diagnosis categories (Table 2). The highest RR was observed for hematologic diseases (RR 11.38; 95% CI 3.24-159.95) followed by respiratory diseases (RR 4.88; 95% CI 3.00-8.75) and genitourinary diseases (RR 4.73; 95% CI 2.23-12.84). SLE hospitalization rates compared to non-SLE comparators were highest among males (RR 3.18; 95% CI 2.31-4.5), those with SLE duration < 5 years since diagnosis (RR 3.05; 95% CI 2.59-3.62) and age 50-64 years (RR 4.5; 95% CI 3.37-6.2) (Table 3).

Conclusion: SLE patients had nearly 3-fold more hospitalizations than comparators with an increased risk of hospitalization for most diagnosis categories.

Table 3. Rate of hospitalizations among SLE patients and comparators by sex, age and disease duration

Characteristic	SLE hospitalization rate/100 person-years	Non-SLE hospitalization rate/100 person-years	Rate Ratio (95% CI)
Age			
20-49	17.91	5.22	3.4 (2.46-4.86)
50-64	29.54	6.51	4.5 (3.37-6.2)
65+	32.84	16.2	2.02 (1.63-2.52)
Sex			
Female	24.42	8.89	2.74 (2.31-3.27)
Male	35.21	11.01	3.18 (2.31-4.5)
Disease Duration			
<5 years	26.83	8.77	3.05 (2.59-3.62)
5-10 years	22.49	12.82	1.74 (1.19-2.62)

Abstract Number: 0133

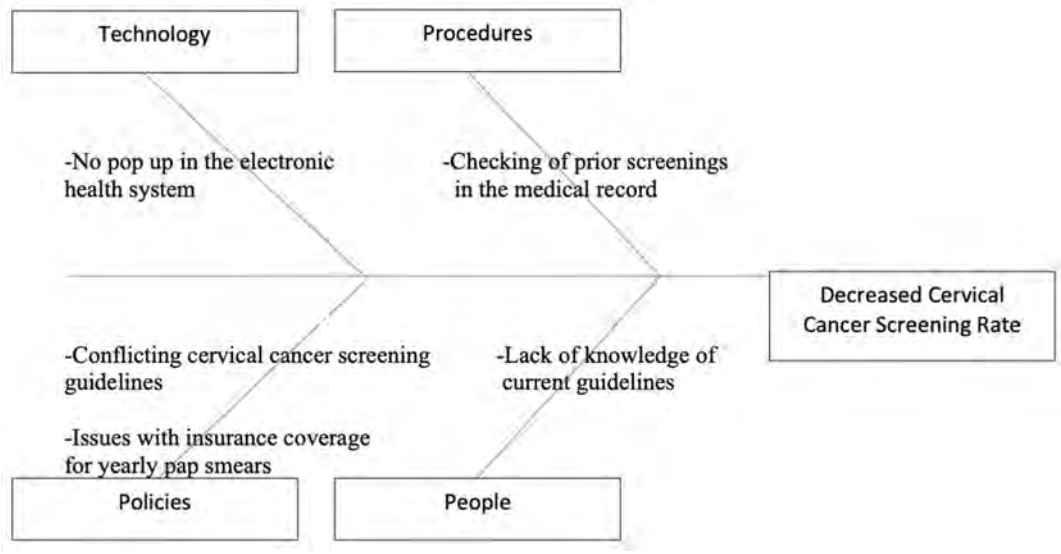
Cervical Cancer Screening Rate in Women with Systemic Lupus Erythematosus

Erica Rosen[1] and Megan Krause[2], [1]University of Kansas, Kansas City, MO, [2]University of Kansas, Kansas City, KS

SESSION INFORMATION

Session Date: Saturday, November 6, 2021
Session Title: Health Services Research Poster I: Lupus, Inflammatory Arthritis, & More (0128–0148)
Session Type: Poster Session A
Session Time: 8:30AM–10:30AM

Background/Purpose: Females with systemic lupus erythematosus have increased rates of cervical cancer especially if on immunosuppressive therapy. The American Cancer Society reports the incidence of cervical cancer in the general public to be 7.5/100,000. The incidence has been reported to be significantly higher in females with SLE. Prior studies suggested that women with SLE have lower rates of undergoing timely cervical cancer screenings compared to the general population. The American Cancer Society recommends screening women with SLE at age 21 or 1 year after sexual activity, whichever comes first, with annual pap testing for patients age < 30 and a yearly pap with HPV co-testing if >30. For the general population of women ages 21-65 pap testing every 3 years is recommended for patients < 30 and if >30 cytology is recommended every 3 years or cytology with HPV co-testing every 5 years. This study aimed to determine the rate of cervical cancer screening and incidence of cervical cancer in women with SLE at our single academic institution.



Cause and Effect Diagram.

Methods: A retrospective chart review was conducted at a single tertiary center. Females were included who had the diagnosis of SLE by ICD9/10 codes, had three or more rheumatology visits, and two or more visits with family medicine, internal medicine or OBGYN between the years of 2004-2020. Eligible patients were between 21-65 years of age. The search also included the number of pap smear procedure codes per patient. The rate of cervical cancer screening was estimated for each patient by finding the time difference between the first office visit and last office visit divided by the number of pap smears. A search was also conducted to identify patients who had hysterectomy and only time prior to hysterectomy was included when determining the screening rate. A search was also conducted to identify the incidence of cervical cancer.

Results: 145 patients were identified. 21 patients were found to have had a hysterectomy at some point during the time period and only the time prior to hysterectomy was included. The average time between cervical cancer screenings was found to be 55 months or 4.5 years. Furthermore, increasing age directly correlated with a decrease in screening. The average time between cervical cancer screening for women ages 21-29 was 27 months, women ages 30-39 was 53 months, women ages 40-49 was 50 months, women ages 50-59 was 63 months and women ages >60 was 80 months. Additionally, 4 patients had developed cervical cancer resulting in an incidence of 2.7%. A root cause analysis was preformed to identify causes for decreased cervical cancer screenings.

Conclusion: This chart review identified inadequate cervical cancer screening in women with SLE at this tertiary center. The time between screenings decreased with increasing age. Further research is needed to determine an appropriate screening interval for these patients to avoid unnecessary invasive procedures and increased costs. Future steps are to collaborate with the OBGYN department to provide an interdisciplinary approach in determining appropriate screening intervals and an intervention to improve the overall cervical cancer screening rate in this patient population.

Systemic Lupus Erythematosus Is a Risk Factor for Mortality in Older Patients with Early-Stage Breast Cancer

Sebastian Bruera[1], Xiudong Lei[2], Xerxes Pundole[2], Hui Zhao[2], Sharon Giordano[2], Surabhi Vinod[1] and Maria Suarez-Almazor[2], [1]Baylor College of Medicine, Houston, TX, [2]University of Texas MD Anderson Cancer Center, Houston, TX

SESSION INFORMATION
Session Date: Saturday, November 6, 2021
Session Title: Health Services Research Poster I: Lupus, Inflammatory Arthritis, & More (0128–0148)
Session Type: Poster Session A
Session Time: 8:30AM–10:30AM

Background/Purpose: Women with systemic lupus erythematosus (SLE) who develop breast cancer (BC), may receive different therapies (e.g. radiation) than women with BC who do not have SLE. They also have more comorbidities that may affect survival. Our objective was to evaluate survival in women with both SLE and BC, compared with women with BC alone or SLE without cancer.

Methods: We conducted a retrospective observational study using the Surveillance, Epidemiology, and End Results (SEER) and the Texas Cancer Registry (TCR) dataset linked to Medicare claims. We included women aged ≥66 years diagnosed with BC from 2005-2015, and a 5% Medicare non-cancer random sample who resided in the SEER/TCR region. Based on BC and SLE status, we included three groups: 1) BC SLE, 2) BC non-SLE, 3) non-cancer SLE. For women with BC, we collected cancer characteristics (age and year at diagnosis, stage, hormone receptor status) and treatment (chemotherapy, radiation therapy, and surgery type). We matched BC SLE and BC non-SLE with cancer characteristics. We matched non-cancer SLE women with BC SLE with birth year and race and used the matched date of diagnosis as the index date for non-cancer women. SLE was defined with ≥2 international classification of diseases (ICD) 9 or 10 diagnosis codes within 1 year before BC diagnosis (or index date). Overall survival (OS) and breast cancer specific survival (BCSS, only for BC women) were measured from date of diagnosis (or index date). Kaplan-Meier methods and multivariable Cox proportional hazards models were implemented to evaluate the association of survival outcomes with groups adjusting for cancer characteristics and treatment (for BC), comorbidities and the Garris index of SLE disease severity (for SLE only).

Results: We identified 494 BC SLE cases, 145,517 BC non-SLE, and matched 268 non-cancer SLE. The 5-year overall survival for women with early breast cancer (stages 0-II) with and without SLE was 74% (95% confidence interval [CI] 68%-78%) and 86% (95% CI 85%-86%) ($p < 0.001$) respectively. In multivariable models adjusting for cancer characteristics, treatment and comorbidities, BC SLE had increased risks of death (HR 1.65; 95% CI 1.38 to 1.98) compared to the BC non-SLE group but no significant association with BCSS. Comparisons between the SLE groups showed that BC SLE had increased risks of death compared non-cancer SLE after adjusting for SLE disease severity (HR 1.42; 95% CI 1.05 to 1.92).

Conclusion: Our data shows that patients with BC and SLE are at risk of earlier mortality compared to patients with BC alone, even after adjusting for SLE disease activity and comorbidities. Further research is needed to investigate the determinants of these findings and improve survival in this population.

Comparing Rheumatoid Arthritis (RA), Psoriatic Arthritis (PA) and Systemic Lupus Erythematosus (SLE) Total Cost of Care (TCC) in Those with Optimally Managed Depression to Those with Sub-optimally Managed Depression

Joseph Couto[1], Elisea Avalos-Reyes[2], Amanda McCarthy[3], Olga Matlin[4], Michele Hamburger[5], Gerard Maher[6] and Kjel Johnson[1], [1]CVS Health, Lincoln, RI, [2]CVS Health, Irving, TX, [3]CVS Health, Greensboro, GA, [4]CVS Health, Northbrook, IL, [5]Frances Hamburger Institute, Hauppauge, NY, [6]Frances Hamburger Institute, Hauppaugue, NY

SESSION INFORMATION
Session Date: Saturday, November 6, 2021
Session Title: Health Services Research Poster I: Lupus, Inflammatory Arthritis, & More (0128–0148)
Session Type: Poster Session A
Session Time: 8:30AM–10:30AM

Background/Purpose: Rheumatic diseases (RD) are characterized by systemic signs and symptoms, including articular and extra-articular manifestations. Three common forms of RDs are RA, PsA and SLE. RDs are associated with a high risk for psychiatric comorbidities, particularly depression. The impact of comorbid depression on RD patients could substantially impact clinical and economic outcomes. The purpose of this study is to compare the total cost of care (TCC) and medication adherence in RD patients with and without optimally managed depression (OMD).

Methods: This retrospective cohort study identified RD patients with and without depression and patients with depression only, insured by a large Commercial health plan in the United States between January 1, 2017, and December 31, 2017, who were followed up until December 31, 2019. We defined "sub-optimally-managed depression" (SOMD) as having one or more of the following: suboptimal antidepressant adherence (< 80% portion of days covered (PDC)), at least one inpatient admission or emergency room visit with a primary diagnosis of depression or exceeding $5,000 in claims for place of service (POS) 51-58. We defined "OMD" as patients not meeting any of the previously mentioned criteria. Multiple linear regression was used to model the difference between baseline and follow-up for the different cohorts, adjusting for confounders.

Comparing RD Adherence by Cohort Adjusted with Multiple Linear Regression.

Results: This study included 56,156 patients; the majority were female (68.4%); the mean age was 51.7 years (SD = 17.6). After adjustment, the annualized TCC of patients with OMD+RD was $6,884 ($p< 0.001$) more than those with RD alone, a difference that was largely driven by medical benefit spend ($p< 0.001$). Patients with SOMD+RD spent $2,980 ($p=0.254$) less than those with RD alone. When examining RD-related medical cost differences in patients, those with OMD spent $1,218 ($p< 0.001$) more than those with RD alone. During the follow-up period, TCC within patients was largely represented by drug costs, as medical benefit costs excluding RD-medication costs represented, on average, 5% of TCC in the RD alone cohort, 5.5% in the RD cohort and 3.5% in the SOMD+RD cohort. There were no significant differences in RD-medication adherence between groups.

Conclusion: In this study, OMD+RD patients spent significantly more in TCC than SOMD+RD patients. Previous research has shown patients with RDs and comorbid depression have poorer clinical outcomes than patients without comorbid depression. Defining suboptimal treatment of disease through administrative claims has inherent limitations, thus further research is required to understand how closely this definition correlates with clinical outcomes. However, given the dominating expense of targeted immunomodulators in treating RD patients, poorer outcomes in

patients with comorbid depression do not appear to be readily observed when evaluating patient financial outcomes. It is imperative that as alternative payment models are developed for treating RD patients, provider incentives to manage comorbidities effectively are developed beyond TCC related incentives, as these alone could inadvertently disincentivize effective management of depression and other mental health conditions.

Abstract Number: 0136

Underutilization of Mental Health Services in a Busy Tertiary Care Rheumatology Facility

David Lim[1], Manushi Aggarwal[1] and Vaneet Sandhu[2], [1]Loma Linda University Health, Redlands, CA, [2]Loma Linda University Health, Loma Linda, CA

SESSION INFORMATION
Session Date: Saturday, November 6, 2021
Session Title: Health Services Research Poster I: Lupus, Inflammatory Arthritis, & More (0128–0148)
Session Type: Poster Session A
Session Time: 8:30AM–10:30AM

Background/Purpose: Mental health disorders are prevalent in patients with rheumatic diseases, particularly since many of these diseases present early, have a chronic course, and significantly impact one's daily function. The prevalence of depression and anxiety in SLE is 71-80%.[2] Depression in RA is up to 50%.[1] Some medications (i.e. steroids) also bear potential mental health effects. Rheumatology patients with psychiatric comorbidities use healthcare resources more than their counterparts. While rheumatologists demonstrate awareness of mental health disorders in their patients, utilization of formal screening tools and mental health services is lacking.

Table 1. Patient Demographics, Comorbidities, and Pre-existing Mental Health Disorders, n=63

Age in years (mean)	20-83 (mean=50)
Gender, % (n)	
Male	16% (10)
Female	84% (53)
Comorbidities, % (n)	
Hypertension	40% (25)
Thyroid Disease	24% (15)
Chronic Kidney Disease	16% (10)
Diabetes	14% (9)
Migraine	14% (9)
Hyperlipidemia	13% (8)
Obesity	3% (2)
Pre-existing Mental Health Disorders, % (n)	
General Anxiety Disorder	41% (26)
Major Depressive Disorder	38% (24)
Attention Deficit Hyperactivity Disorder	6% (4)
Bulimia Nervosa	2% (1)

Percentages may not add to one-hundred due to overlap in comorbidities and pre-existing mental health disorders.

Table 2. Underlying Rheumatic Diseases and Reasons for Referral

Reason for Referral to Neuropsychology, n=30, % (n)	
Cognitive Dysfunction	97% (29)
Hallucinations	3% (1)
Reason for Referral to Psychiatry/Psychology, n=33, % (n)	
Pain	37% (12)
Anxiety	30% (10)
Mood Disorder	24% (8)
Schizophrenia	3% (1)
Pseudo-seizures	3% (1)
Cognitive Dysfunction	3% (1)
Underlying Rheumatic Disease(s), % (n)	
Systemic Lupus Erythematosus	40% (25)
Fibromyalgia	32% (20)
Rheumatoid arthritis	14% (9)
Sjogren's Syndrome	10% (6)
Psoriatic Arthritis	8% (5)
Vasculitis	6% (4)
Neuropathy	6% (4)
Raynaud's Syndrome/Phenomenon	5% (3)
Antiphospholipid syndrome	5% (3)
Undifferentiated Connective Tissue Disease	5% (3)
Systemic Sclerosis	3% (2)
Spondyloarthropathy	2% (1)
Gout	2% (1)
Pseudogout	2% (1)
Osteoporosis	2% (1)
Ehlers Danlos Syndrome	2% (1)
Chronic Fatigue Syndrome	2% (1)

Percentages may not add to one-hundred due to overlap in underlying rheumatic disease(s).

Methods: We evaluated all patients referred from the rheumatology clinic at a tertiary care center to mental health providers (psychiatry/psychology/neuropsychology) over a 2-year period (2/2019 – 2/2021). Data collected included age, sex, underlying rheumatic disease, additional medical and psychiatric comorbidities, and reason(s) for referral to mental health services. Subsequent appointments with a mental health provider were noted.

Results: Of 6154 patients seen in the rheumatology clinic over 2 years, only 63 (1%) were referred to mental health providers. Patient demographics and underlying comorbidities are noted in Table 1. The age range of patients was 20-83 years, of whom 84% were female. Reasons for referral are noted in Table 2. 48% of referrals were for neuropsy-

chology, most commonly for evaluation of cognitive dysfunction. 52% of referrals were for psychiatry/psychology, most commonly for evaluation of chronic pain, anxiety, and mood disorders. While most patients had multiple rheumatic diagnoses, SLE was the most common underlying rheumatic disease diagnosis in patients who were referred to mental health (40%), followed by fibromyalgia (32%) and RA (14%). Only 1/3rd of patients originally referred for mental health services were seen by a mental health provider.

Conclusion: Our findings demonstrate a significant underutilization of mental health services by rheumatologists. This is particularly worrisome since our institutional behavioral health and neuropsychology departments offer comprehensive treatment for a variety of mental and behavioral health issues. Although we recognize that the COVID-19 pandemic and limitations of telehealth visits may have contributed to the lower referrals to mental health services, there was, in fact, a greater need for mental health optimization during this time, with anxiety and depression being more prevalent in patients with rheumatic disease during the COVID-19 pandemic. Our study serves as a call for action to appropriately assess and timely refer patients to mental health providers. Further studies on reasons for lack of follow up may provide additional insight for improvement in the care of these patients

Abstract Number: 0137

Antiviral Use and Healthcare Resource Utilization Among Patients with Rheumatoid Arthritis and Influenza in Three Influenza Seasons, 2016–2019

Edward Neuberger[1], Tu My To[1], Arpamas Seetasith[1], Stella Arndorfer[2] and Christopher Wallick[1], [1]Genentech, Inc., South San Francisco, CA, [2]Genesis Research, South San Francisco, CA

SESSION INFORMATION
Session Date: Saturday, November 6, 2021
Session Title: Health Services Research Poster I: Lupus, Inflammatory Arthritis, & More (0128–0148)
Session Type: Poster Session A
Session Time: 8:30AM–10:30AM

Background/Purpose: Seasonal influenza poses a large burden on the healthcare system. Patients with certain chronic diseases, such as rheumatoid arthritis (RA), are especially vulnerable to developing severe complications due to influenza.

Methods: A retrospective claims analysis to assess whether influenza patients with RA who received antiviral therapy incur lower Healthcare Resource Use (HRU) and costs compared with propensity score matched untreated influenza RA patients by influenza season (October to April of the following year) for three consecutive years (2016–2019). Data from the IBM MarketScan® Commercial US Database for patients diagnosed with RA [1 hospitalization or 2 outpatient claims for RA on separate dates at least 30 days apart] were selected if they contracted influenza (first

instance of an influenza diagnosis), in the outpatient or emergency department (ED) setting each season. HRU (hospitalizations, outpatient visits, or pharmacy fills) and costs were assessed at 14 days & 28 days post-fill date. For the matched untreated group, proxy fill date was determined based on the number of days from index flu diagnosis to first antiviral treatment of matched cases.

Results: From a total of 568,228 patients with a diagnosis of RA, 7743 (1.4%) were diagnosed with influenza during 1 of 3 influenza seasons (2016–2017, 2017–2018, or 2018–2019). Among the 4946 patients with RA meeting the study inclusion criteria (≥18 years old, continuous enrollment) who were diagnosed with influenza from 2016–2019, 3371 (68.2%) received antiviral influenza therapy, 3331 of these were not hospitalized before filling the treatment prescription, and 2638 remained in the sample after propensity score matching. Of 1442 (29.2%) patients with RA and influenza who did not receive antiviral influenza treatment within 30 days after diagnosis, 1348 were not hospitalized and 1319 remained in the sample after matching. At 14 days of follow-up after initiation of antiviral treatment fill, most (>76%) treated and untreated patients had all-cause HRU, and >90% had all-cause HRU after 28 days of follow-up. Outpatient visits were the most common type of HRU and occurred among >70% of treated and untreated patients after 28 days of follow-up. The mean (SD) number of all-cause outpatient visits was 1.21 (1.84) versus 0.96 (1.20) after 14 days ($p < 0.001$) and 2.24 (2.91) versus 1.94 (2.10) after 28 days ($p = 0.0010$), for untreated vs treated, respectively. After 28 days, all-cause ED visits were more common among untreated (8.8%) than treated patients (6.5%) across all influenza seasons; ($p = 0.0118$). Inpatient visits occurred among ~2% of treated and untreated patients during 28 days of follow-up. Mean all-cause HRU-related costs after 28 days of follow-up were >$500 for treated vs $723 for untreated for inpatient stays and >$150 for outpatient visits across both treatment cohorts.

Conclusion: In a large real-world sample of patients with RA and influenza, antiviral treatment was associated with lower healthcare burden compared with no treatment in various categories evaluated.

ASDAS	2.2 (1.1)	2.0 (1.0)	3.0 (1.2)	2.7 (0.9)	2.3 (0.2)
BASFI	3.5 (2.6)	3.0 (2.5)	5.4 (2.4)	3.4 (1.6)	5.4 (1.6)

+values are given as mean (SD)

Background/Purpose: Adalimumab (ADA) retention rates are impaired in patients (pts.) with chronic inflammatory rheumatic diseases (CIRD) due to loss of efficacy and adverse events, causing ADA discontinuation by 50% of pts. within 5 years (Neovius et al., 2015, Ann Rheum Dis). The introduction of ADA biosimilars has increased non-medical switching from originator to ADA biosimilars in rheumatologic care. This study aims at analysing treatment trajectories over two years in CIRD pts. receiving originator ADA.

Methods: CIRD pts. on originator ADA who switched to ADA biosimilar from 10/2018 onwards were identified and followed until 2020. Disease activity (ASDAS), physical function (HAQ, BASFI), and treatment changes were documented every 3 months. The four predefined treatment trajectories “continued ADA biosimilar therapy”, “back-switch to originator ADA therapy”, “switch to another biological (b) disease modifying anti-rheumatic drug (DMARD) therapy”, and “stopped bDMARD therapy /death /drop out” were used to compare pts. characteristics with different trajectories.

Results: 111 CIRD pts. treated with originator ADA were switched to ADA biosimilar (Table). The majority of pts. (67,6%) continued biosimilar therapy (Figure) while 16% switched back to originator ADA, 7% switched to a different bDMARD, and 9% either stopped treatment (n=9) or died (n=1). Pts. continuing ADA biosimilar were mostly male, older and/or with a longer disease duration than the back switchers to originator ADA and thoseswitching to a different bDMARD (Table). No functional impairment (HAQ, BASFI) and higher disease activity (ASDAS) were observed in switching pts. compared to pts. continuing ADA biosimilar therapy (Table). CsDMARD and glucocorticoid treatment were increased in pts. continuing ADA biosimilar therapy, while pts. switching therapy had more previous bDMARD therapies (Table).

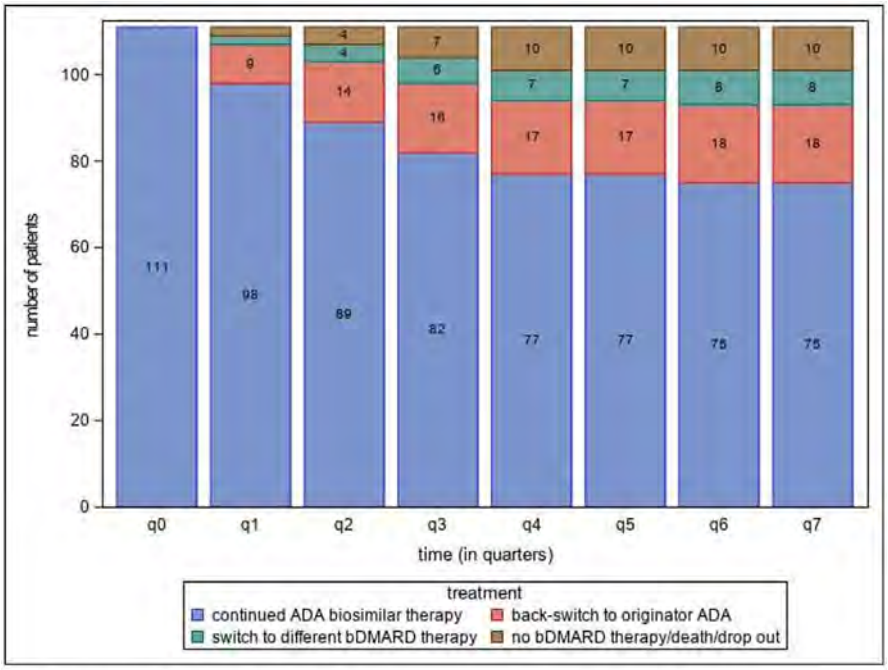

Figure. Treatment trajectories of ADA therapy in patients with CIRD during two years; ADA: adalimumab; bDMARD: biological disease modifying anti-rheumatic drug.

Conclusion: Two thirds of pts. who switched to ADA biosimilar remained on this therapy for 2 years. However, as many as 16% of pts. switched back to ADA originator. Whether or to what degree nocebo effects influenced this needs further study.

Treatment of Ankylosing Spondylitis by Primary Care Physicians and Rheumatologists in an Academic Health System: A Retrospective Study

Alexis Ogdie-Beatty[1], Marina Magrey[2], Robert Fitzsimmons[1], Shahrzad Abdollahi[1], Ana Biljan[3], Christopher Saffore[4] and Jessica Walsh[5], [1]University of Pennsylvania, Philadelphia, PA, [2]Case Western Reserve University, MetroHealth Medical Center, Cleveland, OH, USA, Richfield, OH, [3]Abbvie Inc., Chicago, IL, [4]AbbVie, North Chicago, IL, [5]Salt Lake City Veteran Affairs Medical Center (VAMC)/University of Utah Hospital, Salt Lake City, UT

SESSION INFORMATION

Session Date: Saturday, November 6, 2021

Session Title: Health Services Research Poster I: Lupus, Inflammatory Arthritis, & More (0128–0148)

Session Type: Poster Session A

Session Time: 8:30AM–10:30AM

Background/Purpose: While recommendations for the treatment of ankylosing spondylitis (AS) are largely aligned across various guidelines,[1,2] there remains variability in the treatment. Patients with inflammatory lower back pain, a key symptom of AS, often first visit and receive treatment from their primary care provider (PCP) as opposed to a specialist such as a rheumatologist, which may contribute to this treatment variability. The objective of this analysis was to examine prescribing habits of rheumatologists and PCPs treating AS patients in an academic medical center.

Methods: A retrospective cohort study was performed using the University of Pennsylvania Health System electronic medical record. Patients with a diagnosis of AS (ICD10 M45.X code or M08.1) between January 2017 and September 2020 were included. Baseline characteristics at the time of first diagnosis, visits to rheumatologists and PCPs, and prescribed therapies all within the health system are descriptively reported.

Results: A total of 1,271 patients with a diagnosis code of AS during the study period were identified. The mean age was 51 years, 55% were male, and common comorbidities included hyperlipidemia, hypertension, anemia, and depression (**Table 1**). Nearly 10% of patients had a diagnosis of uveitis prior to or on the date of the AS diagnosis. Within the healthcare system, 49% of patients were seen by both a rheumatologist and PCP on or after their AS diagnosis; 42% saw only a PCP (**Figure 1**). Over a third (36%) of patients followed by a rheumatologist were prescribed a biologic disease-modifying antirheumatic drug (bDMARD) during their follow-up, while only 9% of patients followed

Table 1. Baseline Characteristics in Patients With a Diagnosis of AS

Baseline Characteristics[a]	Patients N = 1,271
Year of first observed diagnosis	
2017	487 (38.3)
2018	302 (23.8)
2019	300 (23.6)
2020	182 (14.3)
Number of diagnosis codes during study, mean (SD)[b]	4.53 (6.74)
1 diagnosis code	528 (41.5)
2 diagnosis codes	227 (17.9)
≥3 diagnosis codes	516 (40.6)
Age at first observed AS diagnostic code, mean (SD)	51.16 (16.88)
Male	698 (54.9)
Relevant Medical History/Comorbidities	
Anemia	263 (20.7)
Anxiety	208 (16.4)
Cancer	119 (9.4)
Chronic pain	175 (13.8)
Depression	211 (16.6)
Diabetes	158 (12.4)
Fatty liver disease	36 (2.8)
Fibromyalgia (ICD-10 codes only)	54 (4.3)
Fibromyalgia (ICD-9 and ICD-10 codes)	126 (9.9)
Hyperlipidemia	391 (30.8)
Hypertension	417 (32.8)
Inflammatory bowel disease	170 (13.4)
Psoriasis	63 (5.0)
Psoriatic arthritis	65 (5.1)
Uveitis	122 (9.6)
Venous thromboembolism	45 (3.5)

[a]n (%) unless otherwise noted. Assessed prior to or on date of diagnosis, and based on a single code
[b]Includes first AS code date

Figure 1. Types of Clinicians Seen Within Healthcare System On or After AS Diagnosis

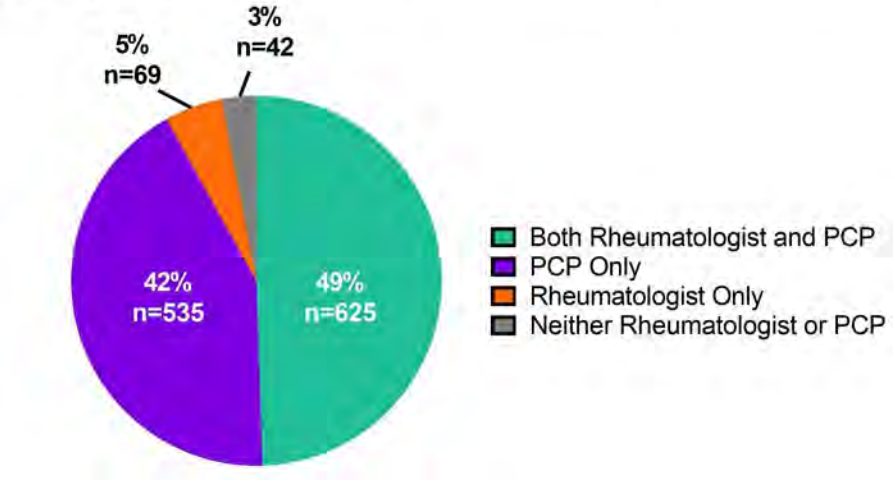

Figure 2. Proportion of Patients Receiving a Prescription for Select Therapies Over the Course of Follow-up by Type of Clinician Seen

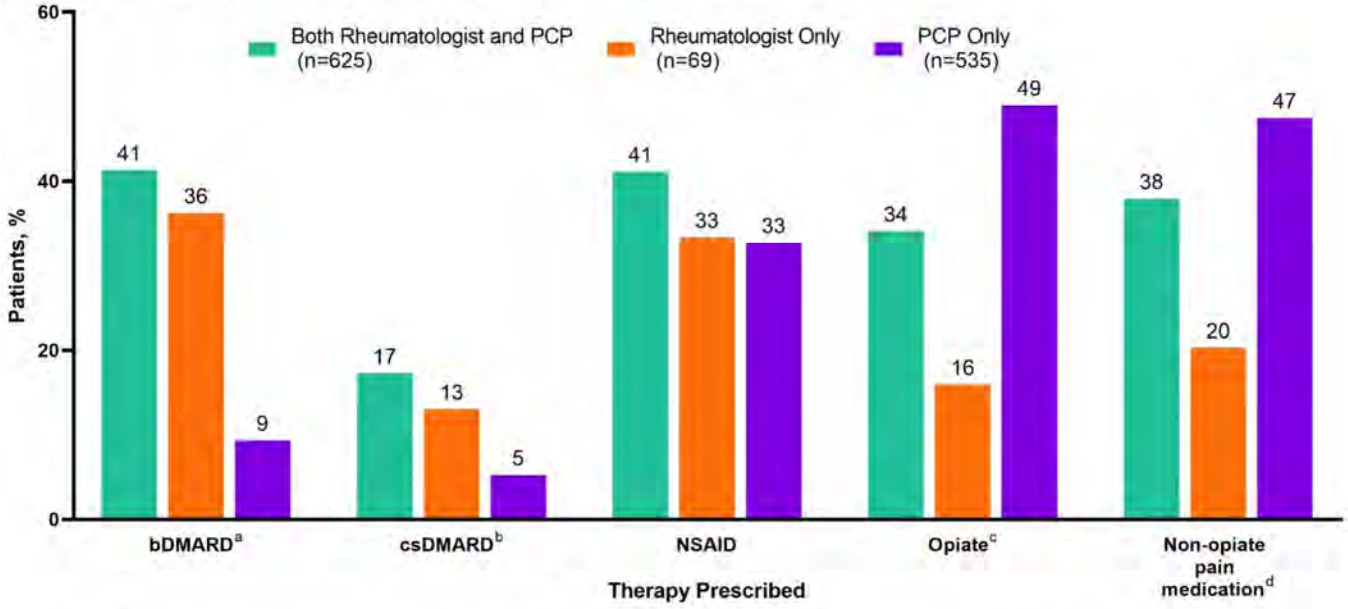

bDMARD, biologic disease-modifying antirheumatic drug; csDMARD, conventional synthetic disease-modifying antirhumatic drug; JAKi, Janus kinase inhibitor; NSAID, non-steroidal anti-inflammatory drug; PCP, primary care physician; TIM, targeted immunomodulator.
No patients received a prescription for leflunomide during the course of follow-up.
[a]bDMARD includes tumor necrosis factor (TNF) inhibitor or interleukin-17 (iL-17) inhibitor.
[b]csDMARD includes methotrexate, sulfasalazine, and hydroxychloroquine.
[c]Opiates includes codeine, hydrocodone, morphine, fentanyl, oxycodone, and tramadol.
[d]Non-opiate pain medications includes acetaminophen, duloxetine, aspirin, gabapentin, pregabalin, nortriptyline, and amitriptyline.

by a PCP were prescribed a bDMARD (**Figure 2**). Nearly half of patients followed by only a PCP were prescribed an opiate (49%) or non-opiate (47%) pain medication, while these therapies were prescribed to 16% and 20%, respectively, of patients followed by a rheumatologist without PCP care. Conventional synthetic DMARDs were prescribed to 13% and 5% of patients seen by a rheumatologist only and PCP only, respectively. Among patients followed only by a PCP, opiates (43%), non-opiate pain medication (41%), and NSAIDs (28%) were the most commonly prescribed therapies during the first year after their AS diagnosis. When a patient was followed by both a rheumatologist and

PCP, bDMARDs (31%), NSAIDs (27%), and non-opiate pain medications (27%) were most commonly prescribed in the first year.

Conclusion: In this population of patients with AS followed at an academic medical center, bDMARDs and csDMARDs were more frequently prescribed to patients seen by rheumatologists, while opiate and non-opiate pain medications were more frequently prescribed to patients who saw only a PCP. These findings demonstrate the variability in prescribing patterns between PCPs and rheumatologists and highlight areas for targeted education among non-specialists.

Therapeutic Management and Clinical Remission in a Specialized Dermatological-Rheumatological Center for Patients with Psoriasis and Psoriatic Arthritis

Jana Ziob[1], Charlotte Behning[1], Peter Brossart[2], Thomas Bieber[1], Dagmar Wilsmann-Theis[3] and **Valentin Schäfer**[4], [1]University Hospital Bonn, Bonn, Germany, [2]Department of Internal Medicine III, Oncology, Hematology and Rheumatology, University Hospital Bonn, Bonn, Germany, [3]Department for Dermatology and Allery, University Hospital Bonn, Bonn, Germany, [4]Clinic of Internal Medicine III, Oncology, Haematology, Rheumatology and Clinical Immunology, University Hospital Bonn, Bonn, Germany

SESSION INFORMATION
Session Date: Saturday, November 6, 2021
Session Title: Health Services Research Poster I: Lupus, Inflammatory Arthritis, & More (0128–0148)
Session Type: Poster Session A
Session Time: 8:30AM–10:30AM

Background/Purpose: An interdisciplinary approach involving dermatologists and rheumatologists is required for the management of patients with psoriatic arthritis (PsA). The purpose of our study was to examine dermatological-rheumatological therapeutic management of patients with psoriasis and PsA.

Methods: A retrospective cohort analysis was performed of all dermatology-rheumatology consultations from April 1st, 2016 to January 31st, 2020. From March 1st, 2018 a specialized interdisciplinary PsA center was established. Clinical data including baseline characteristics, treatment status and treatment outcome were collected and analyzed. A follow-up was performed until January 27th, 2021.

Results: A total of 404 consultations were studied, including 218 psoriasis patients and 103 PsA patients. 34.4 percent of psoriasis patients and 69.9 percent of PsA patients switched systemic medication following consultation.

Most of them began systemic medication, this was twice as common in PsA patients compared to psoriasis patients (Psoriasis: 32.11 %, PsA: 65.05 %). In this context, methotrexate (40.78%), oral glucocorticosteroids (19.42 %), and IL-17 inhibitors (9.71 %) were the most commonly prescribed medications in PsA (Figure 1 and 2). This close collaboration lead to a long-lasting remission time of musculoskeletal complaints (at least 22.5 (IQR:3.0-53.0) median months) and skin lesions (at least 22.0 (IQR:3.0-53.0) median months) in over 60 % of PsA patients (Figure 3).

Conclusion: We were able to demonstrate that close collaboration between dermatology and rheumatology can result in improved therapeutic management of psoriasis and PsA patients with a high degree of achieved clinical remission.

Sankey Chart of psoriasis patients illustrating therapeutic management over time in a specialized dermatological-rheumatological center Therapeutic profile of psoriasis patients at time of consultation and initiated systemic therapy divided into conventional therapy, conventional synthetic disease-modifying anti-rheumatic drugs (csDMARDs), targeted synthetic DMARDs (tsDMARDs), and biologic DMARDs (bDMARDs)

SESSION INFORMATION

Session Date: Saturday, November 6, 2021
Session Title: Health Services Research Poster I: Lupus, Inflammatory Arthritis, & More (0128–0148)
Session Type: Poster Session A
Session Time: 8:30AM–10:30AM

Background/Purpose: Annual influenza vaccination is recommended for adults with RA, but remains low in established RA. We examined influenza vaccination coverage in the year prior to and following RA diagnosis, and individual characteristics including RA medication beliefs associated with vaccination among newly diagnosed participants in the Canadian Early Arthritis Cohort (CATCH).

Methods: The sample included adults enrolled in CATCH between Dec 2017 and Mar 2021 who met 2010 ACR/EULAR criteria, had 1+ year of follow-up, and had completed the Beliefs about Medicines Questionnaire. Vaccinated and non-vaccinated groups were compared using t-tests and chi-square and multivariable logistic regression was used to identify characteristics associated with vaccination in the year prior to (pre-dx) vaccination and the first year of RA (post-dx).

Results: At enrollment, participants (N=405) were mostly white (80%) women (67%) with a mean (SD) age of 56 years and symptom duration of 5 months. Pre-dx, 37% reported being vaccinated, increasing to 42% post-dx. Among 233 patients with vaccination info available post-dx, most (68%) of those vaccinated post-dx reported having been vaccinated pre-dx.

In adjusted analyses, pre-dx influenza vaccination was associated with age ≥65 and having more comorbidities, but not sex, racial background, education, smoking, CDAI, or RA medication beliefs at baseline. Post-dx vaccination was

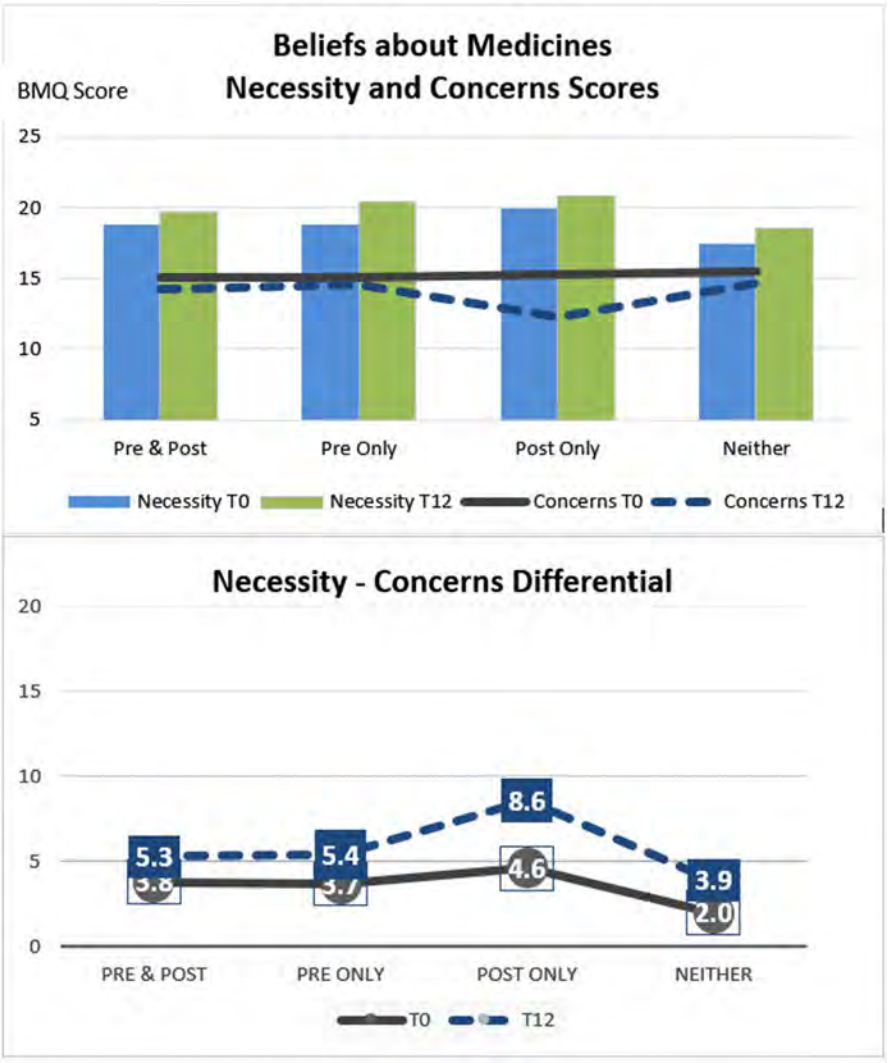
CDAI: Clinical Disease Activity Index; DMARDs: Disease Modifying Antirheumatic Drugs; MTX: Methotrexate; RA: Rheumatoid Arthritis; RDCI: Rheumatic Disease Comorbidity Index. Note: Akaike Information Criterion for Model 1: 218.4; Model 2: 167.6; Model 3: 166.5 *Advanced therapy: Use of biologics or JAKs in the first 12 months.

Multivariable logistic regression models predicting influenza vaccination in the first year after rheumatoid arthritis diagnosis.



RA medication necessity beliefs, concerns and difference score in relation to influenza vaccination in the year prior to (T0) and post (T12) RA diagnosis.

associated with male sex, white racial background, not smoking, biologics/JAK inhibitor use, higher mean Necessity-Concerns differential scores, and pre-dx vaccination (Table). Individuals who were not vaccinated pre-dx but vaccinated post-dx had lower mean Concerns and higher mean Necessity-Concerns differential scores compared to those vaccinated at both timepoints, only pre-diagnosis, or neither timepoints (Figure).

Conclusion: In Canadians with early RA, influenza vaccination coverage remains suboptimal. Certain individual (male sex, non-white race, smoking, medication beliefs/concerns) and treatment characteristics (advanced therapeutics, prior vaccination) were associated with a greater likelihood of vaccination. Higher concerns about RA medications and low necessity beliefs may also predict vaccine hesitancy. Conversations about beliefs and attitudes about RA medications and vaccination history as part of the diagnostic workup may help increase influenza vaccine coverage.

Description of a Scleroderma Cohort and Management of Lung Disease Risk at a Rural Academic Medical Center

Jenna Marinock[1], P. Daniel Nicholas[2], Kirsten Koons[3], Rakesh Kriplani[4], Andrea Berger[4] and David Bulbin[5], [1]Geisinger Commonwealth School of Medicine, Philadelphia, PA, [2]Geisinger Medical Center, Danville, PA, [3]Geisinger Medical Center, Lewisburg, PA, [4]Department of Population Health Sciences, Geisinger Medical Center, Danville, PA, [5]Geisinger Health System, Danville, PA

SESSION INFORMATION
Session Date: Saturday, November 6, 2021
Session Title: Health Services Research Poster I: Lupus, Inflammatory Arthritis, & More (0128–0148)
Session Type: Poster Session A
Session Time: 8:30AM–10:30AM

Background/Purpose: Systemic sclerosis interstitial lung disease (SSc-ILD) and pulmonary hypertension (SSc-PH) are leading causes of morbidity and mortality in patients with SSc. Few screening guidelines exist to identify patients early in their disease course. The aim of this study is to characterize a cohort of patients diagnosed with SSc, compare their lung disease risk to that of a subset of the EUSTAR cohort, and better understand screening practices for SSc by rheumatologists in our medical center.

Methods: We conducted a retrospective analysis of patients with SSc at a rural academic medical center. We identified patients 18 years and older with a SSc diagnosis (via ICD-9 and -10 codes) and seen by a rheumatologist between 01/01/2018 and 12/31/2020. We reviewed pulmonary function tests (PFTs) and transthoracic echocardiogram (TTE) orders between 01/01/2017 and 12/31/2020 for monitoring, focusing on diffusion capacity (DLCO) and pulmonary artery systolic pressure (PASP). Patients were defined as having PH if their PASP was >36.0 or if the TTE report stated evidence of PH. We compared the mean DLCO and PASP values to the EUSTAR subset using a two-sample t-test with unequal variance, age using a two-sample t-test with equal variances, and percent female patients using a Pearson's chi-square test. Statistical significance was defined as $p< 0.05$. Rheumatologists were invited to participate in an online, self-administered survey of 15 questions about PFT and TTE ordering practices and physician behaviors regarding abnormal results.

Table 1. Demographics and clinical characteristics of patients with SSc seen between 1/1/2018 and 12/31/2020

Characteristic	N = 244 Patients
Age, mean (SD)	60.3 (13.4)
Female, n (%)	202 (82.8%)
White, n (%)	240 (98.4%)
Year of Most Recent Rheumatology Visit	
2018	22 (8.6%)
2019	36 (14.8%)
2020	187 (76.6%)
Survival Status	
Living	227 (93.0%)
2018 Mortality	2 (0.8%)
2019 Mortality	8 (3.3%)
2020 Mortality	6 (2.5%)
2021 Mortality	1 (0.4%)
DLCO Completed Between 1/1/2017 and 12/31/2020	181 (74.2%)
DLCO, mean (SD)	63.6 (22.0)
DLCO, minimum/maximum	13, 116
Most Recent DLCO Result	
Less than 50	49 (20.1%)
50 or Greater	132 (54.1%)
No PFT Between 1/1/17 and 12/31/20	63 (25.8%)
TTE Order Between 1/1/2017 and 12/31/2020	189 (77.5%)
TTE Completed Between 1/1/2017 and 12/31/2020	186 (76.2%)
PASP, mean (SD) *n = 99*	34.6 (13.7)
PASP, minimum/maximum *n = 99*	12, 112
TTE Interpretation	
Positive for PH	35 (18.8%)
Negative for PH	89 (47.8%)
Inadequate Doppler Signal	48 (25.8%)
No Comment on PH	14 (7.5%)

SSc: systemic sclerosis; SD: standard deviation; DLCO: diffusion capacity; PFT: pulmonary function test; TTE: transthoracic echocardiogram; PASP: pulmonary artery systolic pressure; PH: pulmonary hypertension

Results: A total of 244 patients with a SSc diagnosis were seen in a 3-year period, with 187 (over 75%) patients having a visit in the last year. Please see Table 1 for demographic data. 181 patients (74.2%) had PFTs completed. Of those completed, the average DLCO was 63.6% and 20% of patients had a DLCO less than 50%. For TTEs, 189 patients (77.5%) had TTEs ordered with 3 incomplete tests. Of interest, only 99 (53%) had a reported PASP value, and mean PASP was 34.6mmHg (Table 1). Compared to EUSTAR, patients were older (60.3 vs. 56.3 years; $p< 0.0001$) and mean DLCO values were lower (63.6% vs. 68.7%; $p=0.0031$). Mean PASP comparatively was 34.6 mmHg vs. 29.8 mmHg ($p=0.0009$) (Table 2). The self-administered survey had a completion rate of 84.6% with 11 of 13 physicians electing to participate. Please see Figure 1 for survey results.

Conclusion: We identified an opportunity for early detection of SSc-ILD and SSc-PH in scleroderma patients within our academic health system. This would be achieved by improving ordering practices of PFTs and TTE for scleroderma monitoring. Additionally, we identified our population as, statistically, having potentially more severe disease compared to the EUSTAR cohort. We intend to investigate these findings further and explore clinical and social factors possibly playing a role in disease progression. We are hoping to institute improvements in best practice and develop EHR toolkits to improve monitoring of our SSc patients in the future.

Table 2. Demographics and lung disease risk of rural SSc cohort vs. EUSTAR subset

	EUSTAR n=1476	**Rural cohort n=244**	**p-value**	**Difference in means (95% CI)**
Age, mean (SD)	56.3 (13.5)	60.3 (13.4)	**<0.0001**	4.02 (2.19, 5.85)
Female, n (%)	1280 (86.7%)	202 (82.8%)	0.0992	-
	EUSTAR n=1340	**Rural cohort n=180**	**p-value**	**Difference in means (95% CI)**
DLCO, mean (SD)	68.7 (19.5)	63.6 (22.0)	**0.0031**	-5.15 (-8.55, -1.75)
	EUSTAR n=1476	**Rural cohort n=99**	**p-value**	**Difference in means (95% CI)**
PASP, mean (SD)	29.8 (9.5)	34.6 (13.7)	**0.0009**	4.8 (2.0, 7.6)

SD: standard deviation; CI: confidence interval; DLCO: diffusion capacity; PASP: pulmonary artery systolic pressure. Statistically significant findings are in bold.

Abstract Number: 0143

Economic and Healthcare Resource Use Burden of Systemic Sclerosis

Dinesh Khanna[1], Dan Furst[2], Justin Li[3], Qian Meng[4], Tamara Lesperance[5], Kenyatta Peoples[6], Farah Ali[5], Brian LaMoreaux[5] and Stephanie Taylor[7], [1]University of Michigan, Ann Arbor, MI, [2]University of California Los Angeles, Los Angeles, CA, [3]Trinity Partners, Waltham, MA, [4]Trinity Life Sciences, Waltham, MA, [5]Horizon Therapeutics plc, Deerfield, IL, [6]Horizon Therapeutics plc, Lake Forest, IL, [7]Horizon Therapeutics plc, Whitehouse Station, NJ

SESSION INFORMATION
Session Date: Saturday, November 6, 2021
Session Title: Health Services Research Poster I: Lupus, Inflammatory Arthritis, & More (0128–0148)
Session Type: Poster Session A
Session Time: 8:30AM–10:30AM

Background/Purpose: The clinical burden of systemic sclerosis (SSc) is substantial and typically characterized by progressive skin, gastrointestinal, pulmonary, and cardiovascular complications and premature death. The objective of this analysis was to describe the healthcare resource use (HCRU) and costs of SSc patients prior to and immediately after diagnosis.

Methods: A retrospective cohort comparison was performed using a claims dataset (IBM® MarketScan® Commercial Database) capturing beneficiary-level claims between 2015-19. SSc patients were identified using diagnosis codes for SSc. Eligible subjects had ≥ 24 months of enrollment without a SSc diagnosis before their first SSc claim ('index date') and ≥ 12 months of enrollment thereafter. Total HCRU and costs, as well as mean cost by care setting for inpatient, outpatient, physician office (PO), and prescription drugs were reported in 2019 USD as mean per member per year (PMPY) amounts for 3 time intervals: 2- and 1-year before and 1-year after index diagnosis. To show the relative cost of SSc, patients with rheumatoid arthritis (RA) but not SSc and a general population ('unaffected') cohort without SSc or RA were matched 1:1 to SSc patients on age and gender.

Results: 902 SSc patients were eligible. Mean age at index SSc diagnosis was 54.3 years old and 84.7% were female. Total mean PMPY cost increased each year from $22,383 to $29,708 to $47,095, 2 years before, 1-year before, and 1-year after index diagnosis, respectively. These costs were higher than the RA (by 17, 27, and 28%) and unaffected (by 119, 208, and 278%) cohorts. Among SSc patients, the outpatient setting represented the largest proportion of cost 1-year after index ($16,392), followed by prescription drugs ($10,692), PO ($10,523), and inpatient ($9,448) settings. PMPY cost for diagnostic imaging services increased each year from $807 to $1,383 to $1,779. 1-year after SSc diagnosis, mean PMPY costs for immunosuppressant, corticosteroid, endothelin receptor antagonist, and proton-pump inhibitor drugs were $4,183, $1,746, $814, and $783, respectively. Among SSc patients, mean

Table. Cost and healthcare resource use among SSc patients by time-interval

Cohort	2 years before Index	1 year before Index	1 year after Index
Systemic sclerosis (N =902)			
Total mean cost (2019, USD)	$22,383	$29,708	$47,095
Inpatient	$3,735	$5,810	$9,488
Outpatient	$7,754	$10,503	$16,392
Physician office	$6,151	$7,456	$10,523
Prescription drug	$4,743	$5,939	$10,692
Mean services per patient	21.9	27.3	36.8

healthcare services per patient increased each year from 22 to 27 to 37 services and were higher as compared to the RA (21, 26, and 32) and unaffected (13, 14, and 15) cohorts.

Conclusion: SSc patients appear to accrue markedly greater healthcare costs and require more services than a matched unaffected general population. Elevated expenditures and HCRU are observed from at least 2 years before a confirmed SSc diagnosis with both increasing over time, a dynamic that likely reflects both the progressive, multisystem nature of SSc and the potential challenges and delays in diagnosis. Additionally, despite no proven disease modifying therapy, SSc patients still accrued substantial drug costs for therapies likely used to suppress emerging sequalae of the underlying disease. Together these findings suggest that SSc patients pose a substantial burden on the US healthcare system and highlights the need for early diagnosis and effective therapies.

Healthcare Utilization and Costs Following Kawasaki Disease in Ontario, Canada

Cal Robinson[1], Rahul Chanchlani[2], Anastasia Gayowsky[3], Elizabeth Darling[2], Hsien Seow[2] and **Michelle Batthish**[2], [1]The Hospital for Sick Children, Hamilton, ON, Canada, [2]McMaster University, Hamilton, ON, Canada, [3]ICES, Hamilton, ON, Canada

SESSION INFORMATION
Session Date: Saturday, November 6, 2021
Session Title: Health Services Research Poster I: Lupus, Inflammatory Arthritis, & More (0128–0148)
Session Type: Poster Session A
Session Time: 8:30AM–10:30AM

Background/Purpose: The incidence of Kawasaki Disease (KD) has increased by nearly 50% in Ontario, Canada over the past two decades. Little is known about the long-term burden of illness and healthcare utilization among KD survivors, particularly in a universal healthcare system. The aim of our study was to describe patterns of healthcare utilization and associated costs among KD survivors *vs*. matched controls in Ontario, Canada.

Methods: We used population-based health administrative databases to identify all children (0-18yr) hospitalized for KD in Ontario between 1995-2018. We excluded non-Ontario residents. Each case was matched to 100 non-exposed comparators by age, sex, and index year and follow-up continued until death or March 2019. Our primary outcomes were hospitalization, emergency department and outpatient visits. We evaluated healthcare costs (in Canadian Dollars [CAD], adjusted for inflation to the 2018 year) associated with each event type, as well as composite healthcare costs, including hospitalizations, ED visits and outpatient costs (i.e., lab services, physician billings and capitation payments).

Table 1. Healthcare utilization following Kawasaki disease diagnosis

Type of healthcare utilization		0-1 year following diagnosis		1-5 years following diagnosis		5+ years following diagnosis

Mean cost difference	+ 3113.89	Ref	+ 1416.95	Ref	+ 965.37	Ref	+ 8281.16	Ref
Median cost per patient (IQR)	2,466 (1,888-3,420)	234 (78-521)	1,395 (700-2,523)	689 (239-1,464)	1,566 (519-3,705)	951 (189-2,580)	9,174 (5,100-16,070)	3,148 (1,464-6,115)
Median cost difference	+ 2232	Ref	+ 706	Ref	+ 615	Ref	+ 6026	Ref

Results: We compared 4,597 KD survivors to 459,700 matched comparators. Median follow-up duration was 11.1 years (IQR 5.5-17.0) for KD cases and 10.0 years (IQR 4.5-16.0) for non-exposed children. KD survivors had higher rates of hospitalization (adjusted rate ratio 2.07, 95%CI 2.00-2.15), outpatient visits (1.30, 95%CI 1.28-1.33) and ED visits (1.22, 95%CI 1.18-1.26) throughout follow-up (Table 1). Within 1yr post-discharge, 717 (15.6%) of KD cases were re-hospitalized, 4587 (99.8%) had ≥1 outpatient physician visit and 1695 (45.5%) had ≥1 ED visit. KD survivors had higher composite healthcare costs throughout follow-up (median $9,174 *vs*. $3,148 CAD) (Table 2). Total healthcare costs for KD cases in Ontario were $13.9 million (within one year post-discharge) and $54.8 million (throughout follow-up). Outpatient care was the largest cost driver for both KD (50% of total healthcare costs) and non-exposed cohorts (55%) (Figure 1). However, the proportion of costs attributable to hospitalizations was higher among KD cases (43% *vs*. 36% non-exposed), due to higher hospitalization costs within the first year post-discharge.

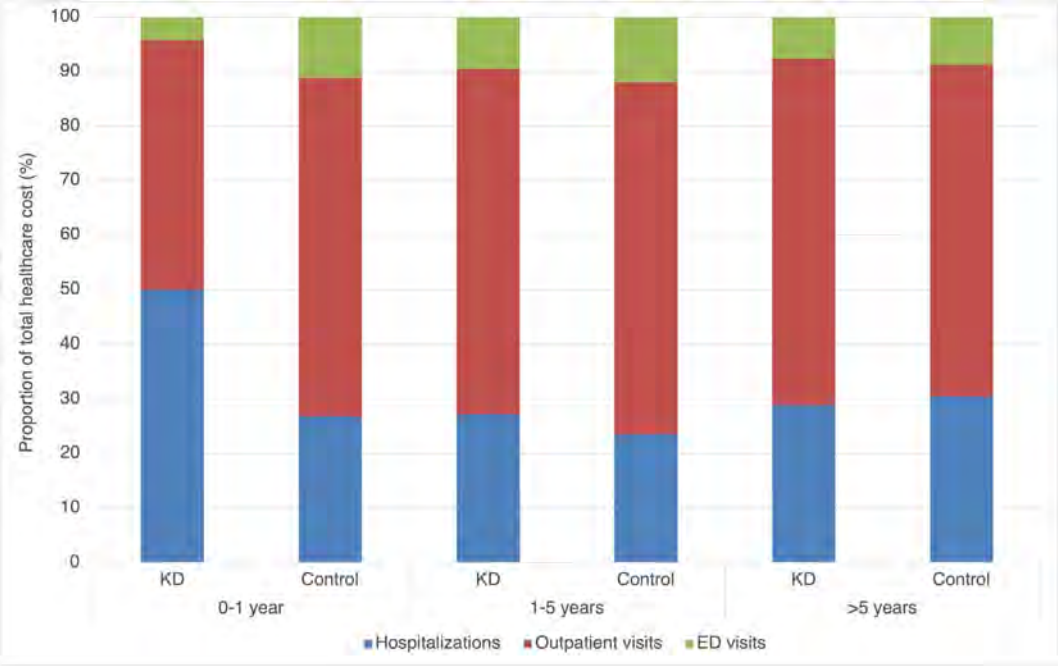

Figure 1. Distribution of healthcare costs following Kawasaki disease diagnosis.

Conclusion: Compared to non-exposed children, KD survivors had significantly higher long-term rates of healthcare utilization and cost. Nearly all KD cases were seen by a pediatrician or primary care physician within one year post-discharge, while less than half were seen by a cardiologist. The rising incidence and attributable costs associated with KD place a significant burden on Ontario's healthcare system.

Abstract Number: 0145

Rheumatology Provider Perspectives on Using Patient-Reported Outcomes in Clinical Care

Yomei Shaw[1], Neda Kortam[2], Adam Chalak[2], Yujia Li[2], Faith Reger[2], Vivek Nagaraja[2] and Dinesh Khanna[2], [1]University of Michigan, East Lansing, MI, [2]University of Michigan, Ann Arbor, MI

SESSION INFORMATION

Session Date: Saturday, November 6, 2021

Session Title: Health Services Research Poster I: Lupus, Inflammatory Arthritis, & More (0128–0148)

Session Type: Poster Session A

Session Time: 8:30AM–10:30AM

Background/Purpose: Patient-reported outcomes (PROs) are surveys completed by patients to provide measurements of health, quality of life, symptoms, and functional status. PROs are useful for documenting changes in patient's health status over time as well as facilitating patient-provider communication about symptoms. Despite the potential benefits for the management of rheumatic diseases, uptake of PROs among rheumatology health care providers has been limited. The authors have been developing methods to promote the integration of specific PROs

(PROMIS® measures for pain intensity, physical function, and sleep disturbance) into rheumatology care at our institution. To inform our future efforts, we conducted a qualitative study to describe rheumatology provider attitudes towards the feasibility and acceptability of reviewing and discussing PROMIS or other PROs in rheumatology practice.

Table 1. Interview participant characteristics (n=8)

Characteristic	Attribute values among interviewees
Type of health care provider	7 physicians, 1 advanced nurse practitioner
Year of health professional degree	Ranged from 1975-2014
% time seeing patients	Ranged from 25-100%
Patient population	Mixed (5), SLE and mixed (1), vasculitis and mixed (1), SLE (1)
Used PROMIS as part of previous study	2 out of 8
Currently uses PROMIS in clinical care	4 out of 8
Currently uses PROMIS/other PROs in clinical care	6 out of 8

Table 2. Perceived benefits/disadvantages of use of patient-reported outcomes in rheumatology care

Perceived benefits	
Theme	**Quote**
Facilitation of patient-provider communication about symptoms	Their numbers [PRO results] don't necessarily match the exam[ination] or my conversation with them, so sometimes, it helps me to clarify what their real pain is and how it's impacting.
Improvement of the patient-provider relationship	Patients like them [PROs], let me tell you one thing, as long as you don't make them fill a million papers. Particularly patients with chronic pain or fatigue, they like it because it's a way for them to express themselves and to perhaps voice those symptoms that are not visible […] If you have swelling, you see it, but the fatigue or the pain, it's not visible.
Informing clinical decisions	I show [the patient their scores], "Your physical function has gone down like this, and your pain score continues to rise. This is all pointing towards somebody who's not in remission. We need to escalate your therapy." The patient gets it.
Documentation/tracking of patient symptoms over time	I think that the greatest benefit [of using PROs] is to understand the current situation. The secondary benefit is to understand the trend.
Supplementing/ complementing physical exam and objective findings	They [PROs] definitely won't replace the physical exam. […] Because actually, I cannot interpret them without the physical exam, right? […] No, they don't replace. They complement if you want something.
Perceived disadvantages	
Theme	**Quote**
Perceived lack of direct positive impact on health outcomes	It's [PROs] helped to explain [things to patients], but I don't know if it necessarily helps with improved outcomes.
PRO information is not always actionable	They're [PROs are] valuable, but they don't allow me to make decisions.
Doubts about the validity of results	[…] patients sometimes use them [PROs] to vent, right, whatever is going on in their life. They will answer bad if they are depressed or if they fight with their husband, so sometimes it's hard to interpret that data objectively for us.
Lack of applicability for certain patients	I think you need to understand which ones [PROs] work for your patient population or for the disease that you are following because they're [PROs are] too broad.

Table 3. Perceived barriers/facilitators for use of patient-reported outcomes in rheumatology care

Barriers	
Theme	**Quote**
Perceived time burden of reviewing and documenting PROs	I would say my initial reaction to it was, this is yet another thing I have to do in a [short clinic visit], and it causes more documentation issues.
Patients not completing PRO questions before the consultation	[…] if you're running 15 minutes behind because you're waiting for someone to finish filling this out, that just doesn't—it's very frustrating at times.
Perception that discussing the scores with patients would be time-consuming/ burdensome	Trying to explain to someone that their PROMIS score going up by one point, 0.1 point—I don't know what the scale is—matters or doesn't matter, especially if it doesn't matter, is disruptive.
Lack of confidence in accessing/ documenting/ interpreting PRO results	I think that a large barrier to feasibility is the provider having to figure out what the result means and then convey it to the patient.
Facilitators	
Theme	**Quote**
Simplicity and ease of reviewing/ documenting/ discussing PRO results with patients	It [reviewing and discussing PROs] is feasible. I think it's very important for the providers to be aware that this is something that doesn't take that much time because we always think of anything else outside of what we need to do with our patients, in terms of clinical matters, is less relevant.
Receipt of training	I think the things that would help me the most would be training so that I can quickly and clearly explain the measure to the patient […] visually, in a way the patient isn't terribly confused and I'm not terribly confused […]
Recommendation by trusted colleagues	When I heard that <Name>, someone who I really respect, who you probably know very well, I bet, has done a lot of work on PROs and the PROMIS scores, I had all intention of—if <Name> doing that and he's spearheading this, then maybe my attitudes on this should change, and I should incorporate these into my note and using the dot phrase he showed me.

Methods: In-depth semi-structured interviews were conducted with health care providers at our institution, who were asked to discuss their experiences and attitudes towards the use of PROs in rheumatology care. We recruited providers who had received training on the use of PROMIS as part of a previous study led by 2 of the authors, as well as providers who had not participated in the previous study. The interviews were conducted via phone or video call and lasted between 30-120 minutes. Written informed consent was obtained from participants before the interviews. The interviews were audio recorded and transcribed for analysis.

Qualitative analysis of the transcripts was conducted using NVivo software. Five of the authors carried out the analysis. We used a combination of inductive and deductive coding. Each transcript was coded independently by at least 2 team members, who met to discuss and reconcile any discrepancies in coding that were >=20% for individual codes. The resulting coded data was reviewed and summarized as themes to describe current uptake, perceived benefits and disadvantages, and perceived barriers and facilitators of using PROMIS/PROs.

Results: The 8 health care providers interviewed included 7 physicians and 1 advanced nurse practitioner; 6 of these currently used PROMIS or other PROs in clinical care (Table 1). Two of the providers were trained in the use of PROMIS as part of our previous study—these providers still used PROMIS in clinical care for their patients. Un-

expectedly, two other providers (1 physician and 1 advanced nurse practitioner) reported routinely using PROMIS in clinical care, although they had not participated in the previous study.

The perceived benefits/disadvantages and barriers/facilitators of using PROs in rheumatology care identified by interviewees are summarized in Tables 2-3.

Conclusion: Rheumatology health care providers had a range of attitudes towards the use of PROMIS/PROs in clinical practice and addressing their concerns will be important for promoting the use of PROMIS and other PROs. Demonstrating the value and ease of using PROs in clinical care is essential for gaining support from health care providers.

Improving Medication Toxicity Lab Monitoring During the COVID-19 Pandemic

Akrithi Udupa[1], Catherine Sims[2], Poorva Apte[2], Megan Milne[2], Isaac Smith[1], D Ryan Anderson[1], Mithu Maheswaranathan[2], Jayanth Doss[2] and David Leverenz[2], [1]Duke University Hospital, Durham, NC, [2]Duke University, Durham, NC

SESSION INFORMATION
Session Date: Saturday, November 6, 2021
Session Title: Health Services Research Poster I: Lupus, Inflammatory Arthritis, & More (0128–0148)
Session Type: Poster Session A
Session Time: 8:30AM–10:30AM

Background/Purpose: The COVID-19 pandemic led to the rapid implementation of telehealth in rheumatology with unknown implications for medication toxicity lab monitoring. The purpose of this quality improvement (QI) project is to evaluate and improve lab monitoring in patients with rheumatoid arthritis (RA) seen by telehealth. This project was led by adult Rheumatology fellows at a single academic institution as part of our QI curriculum.

Methods: We targeted patients with RA (ICD10 M05/M06), taking methotrexate, sulfasalazine, leflunomide, or azathioprine, seen in a telehealth visit, and no aspartate aminotransferase (AST) in the 2 months before the visit. Our primary aim was to increase the proportion of targeted patients with an AST at our institution in the 2 months after the visit from less than 35% to greater than 50%. A secondary aim was to increase scanned external lab results in the two months after the visit from 7% to greater than 15%. Data were obtained with SlicerDicer, an analytic data tool within our electronic health record and validated by manual review of encounters seen by fellows leading the QI initiative from 7/1/2020 - 10/31/2020. Data were monitored throughout the study period. Providers continuously shared

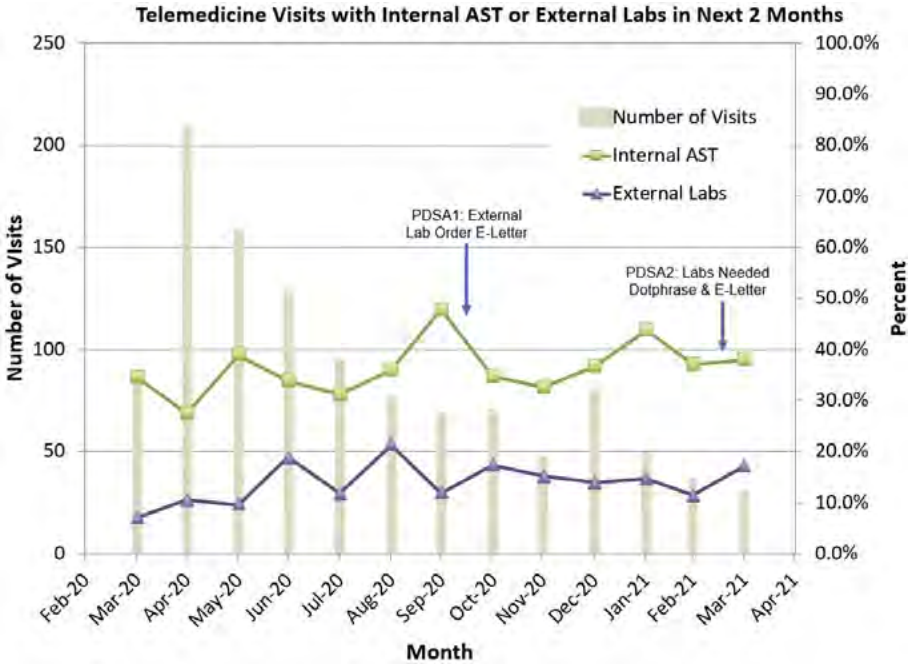

Figure 1. Divisional chart run via SlicerDicer of telemedicine visits with AST at our institution (Internal AST) or External Labs in next 2 months.

resources and best practices. In addition, the following interventions occurred using Plan-Do-Study-Act (PDSA) methodology: (1) standardized process for sending external lab orders to patients electronically (9/15/2020) and (2) letter for patients with detailed instructions on obtaining labs (3/2/2021). Providers in our division were surveyed via Redcap on 2/19/2021 to gather more input on lab monitoring.

Results: There were 1,116 telehealth visits with RA patients targeted by our project from 3/1/2020 – 3/31/2021 (Figure 1). The number of visits declined from a peak of 207 in 4/2020 to 29 in 3/2021. At baseline, patients with an AST performed at our institution in the 2 months after the telehealth visit was 34.5% in 3/2020 and 27.5% in 4/2020. We did not reach our aim of 50% during the study period; the highest proportion was 47.8% in 9/2020. External labs scanned over 2 months at baseline were 7.1% in 3/2020 and 10.6% in 4/2020. Our goal of 15% was reached in half of the months from 6/2020 – 3/2021. PDSA interventions did not substantially impact lab monitoring. The manual chart review included 31 patients; 20 (64.5%) had labs ordered to be done at our institution, 9 (29.0)% externally, and 2 (6.5%) did not have labs ordered. There were 21 (67.7%) without an AST in the preceding two months. Of these, 6/21 (71.4%) had an AST done in the next two months at our institution or externally. The provider survey was sent to 34 providers in our practice; 27 (79.4%) responded. Results are shown in Table 1. Although 23 (85.2%) agreed or strongly agreed that they knew what an “overdue results” in-basket message meant, only 6 (22.2%) “usually” or “always” reacted to these messages. Free text responses on reasons for this discordance are shown in Table 2.

Conclusion: Our study revealed gaps in medication toxicity lab monitoring among RA patients seen via telehealth. Monitoring improved throughout the study period but we have not yet reached our primary aim. An important next step is to develop a standardized process for acting on overdue lab messages.

Table 1. Divisional provider survey responses via RedCap.

I know/understand:	Strongly Disagree n (%)	Disagree n (%)	Agree n (%)	Strongly Agree n (%)
How to instruct patients on obtaining labs at a "lab and leave" location.	1 (3.7%)	4 (14.8%)	14 (51.9%)	8 (29.6%)
How to instruct patients on scheduling a lab appointment at [our clinic] locations.	1 (7.4%)	8 (29.6%)	15 (55.6%)	2 (7.4%)
How to send patients external lab orders electronically through MyChart.	1 (3.7%)	11 (40.7%)	4 (14.8%)	11 (40.7%)
How to mail a letter with external lab orders to a patient's home.	0 (0%)	4 (14.8%)	10 (37%)	13 (48.1%)
What an "overdue results" in-basket message means.	1 (3.7%)	3 (11.1%)	18 (66.7%)	5 (18.5%)
For your telemedicine patients who need lab monitoring for rheumatologic medications, how often do you:	**Never n (%)**	**Sometimes n (%)**	**Usually n (%)**	**Always n (%)**
List an "expected by" date on future lab orders.	4 (14.8%)	2 (11.1%)	5 (18.5%)	15 (55.6%)
Order "standing" labs instead of "future" (one-time) labs.	1 (18.5%)	17 (63%)	2 (7.4%)	3 (11.1%)
React to "overdue results" in-basket messages by reminding the patient they need to get the labs done (or have staff remind them).	11 (40.7%)	10 (37%)	5 (18.5%)	1 (3.7%)

Table 2. Selection of divisional provider survey free responses via RedCap

When you react to "overdue results" in-basket messages by reminding the patient about the labs, what specific actions do you usually take? Please describe.	"Message if needed." "Ask staff/nurse/MA to contact patient." "MyChart message to patient or ask staff assistant to call depending on the urgency." "None. I delete them." "Ask [RNs] to contact patient, find out [if] labs have been drawn, and track down results if they have." "Call patient." "I have a prepped mychart message that I send, but I have not figured out how to do this as a quick action." "I do not have time to address this at all … I am sure that would be helpful, however. I need someone to look through the orders, read my last note and take care of this - not send something else to my in basket." "Scan through them and delete most of them. For some labs, if I recall it as being more important, I will call patient to remind." "Hit 'Done'." "Briefly glance at chart to make sure labs are not up-to-date elsewhere (such as care everywhere or external) … if they have my chart, send a my chart message using a dot phrase … if no my chart, I asked staff to call patient to remind them." "[Forward] to MA." "I do not get these alerts." "Telephone call to staff to call patient to have done."
What major issues have you encountered in ordering and obtaining disease and medication toxicity monitoring labs for telemedicine patients? Please list as many issues as necessary.	"Overdue results coming in incorrectly for external labs." "I don't have time to go through the over due labs. I just won't refill their meds when they ask for refills." "Patients refused to get labs because too scared to go to lab." "The faxed in labs are often lost." "No easy reminder system for people to get standing labs done." "Labs not in system, difficult to find prior outside labs without wasted time searching documents and attachments." "Wasted time going back and forth asking nurses to remind patients to get labs, trying to get results. All the extra time adds up in your day, making it difficult to do other tasks or see more patients." "Lab results getting sent to email without any patient information so impossible to find later." "Even if the lab results get scanned into the [medical record] they are in the [medical record] as a PDF and aren't trendable or meaningfully useful down the road." "Need for [lab] appointment." "Patients don't want to have [labs] done." "Takes months for external labs to get scanned in." "Very cumbersome to order compared to in person lab ordering. Takes multiple extra clicks. Also I have to spend additional time to instruct patient on where to go, perhaps even needing to look up Google Maps on where they live compared to lab facility and verbally tell them phone number. Can take additional 5 minutes." "Patient forgets, disregards instructions to get them done, wants them done externally but for various reasons they are not done or results not received."

Abstract Number: 0147

A Qualitative Analysis of Methotrexate Self-Injection Education Videos on YouTube: An Update

Amy Semaka, Hillary Wilson and Steven Katz, University of Alberta, Edmonton, AB, Canada

SESSION INFORMATION
Session Date: Saturday, November 6, 2021
Session Title: Health Services Research Poster I: Lupus, Inflammatory Arthritis, & More (0128–0148)
Session Type: Poster Session A
Session Time: 8:30AM–10:30AM

Background/Purpose: Patients are turning to the Internet for guidance and information at an increasing rate, requiring clinicians to be aware of the constantly changing resources and quality of information that is available. A previous study demonstrated a minority of YouTube videos were useful for teaching methotrexate self injection.

Methods: Using the search term "Methotrexate injection", two reviewers analyzed the first 75 videos in the YouTube search results. Videos were classified as useful, misleading or a personal patient view. Videos were rated for reliability, comprehensiveness and quality. Discrepancies in ratings were resolved by discussion between the two reviewers.

Results: Out of the 75 videos reviewed, 12 were classified as useful (16%), 47 misleading (63%), and 16 personal patient view (21%). Although this represents a substantial increase from the 2014 study in the proportion of videos that were deemed misleading (63% vs 28%), many of these videos were on methotrexate in general. Mean reliability rating was 4/5 (±0.5) for useful videos, 4/5 (±0.8) for misleading videos, and 3/5 (±0.3) for patient videos ($p < 0.0001$). Mean comprehensiveness was 4/4 (±0.0) for useful videos, 0/4 (±0.0) for misleading videos, and 2/4 (±2) for patient videos ($p < 0.0001$). Mean global quality score was 5/5 (±0.3) for useful videos, 4/5 (±0.7) for misleading videos, and 4/5 (±0.8) for patient videos ($p=0.0002$). Compared to the 2014 study, videos classified as misleading or personal patient view scored significantly higher in the categories of reliability and global quality score ($p < 0.0001$).

Conclusion: While the majority of the videos from the YouTube search were deemed misleading for teaching subcutaneous methotrexate injection, the useful videos were of good quality and had the highest ratings for comprehensiveness. In general, reliability and global quality scores were increased from the previous study, suggesting improvement in overall videos over time. Logistics of the YouTube algorithm may still impede access to the 'best' videos for patient teaching; therefore, clinicians should be prepared to recommend strategies for patients to find high quality videos.

Abstract Number: 0148

Implementation of an Interprofessional Safety Check to Screen for Latent Tuberculosis at an Academic Tertiary Referral Rheumatology Clinic Increased Screening Rates Compared to Historical Levels

Meera Subash, Hailyn Nielsen, Neda Noori Nassr, Diana Ung and Andrew Gross, University of California San Francisco, San Francisco, CA

SESSION INFORMATION
Session Date: Saturday, November 6, 2021
Session Title: Health Services Research Poster I: Lupus, Inflammatory Arthritis, & More (0128–0148)
Session Type: Poster Session A
Session Time: 8:30AM–10:30AM

Background/Purpose: Certain disease-modifying anti-rheumatic drugs (DMARDs) increase the risk of reactivation of latent tuberculosis (TB). While screening for latent TB prior to initiation of these DMARDs is recommended for a most patients, low rates of screening have been reported in national rheumatology registry data[3]. A prior study conducted in our rheumatology clinic at an academic tertiary referral center suggested that only 63% of eligible patients from 2013-2017 were screened for latent TB prior to DMARD initiation. We highlight our approach of implementing a pharmacy-integrated safety check to capture this key safety measure.

Methods: Analysis 1: In October of 2019, we implemented a new pharmacy-integrated workflow in which clinicians prescribe new oral or injectable DMARDs to the university specialty pharmacy which reviews cases for adequate TB screening. DMARD prescriptions were filled or routed to patients' contracted specialty pharmacies only once adequate TB screening was completed unless the clinician specified otherwise. Analysis 2: Using SQL to extract data from the electronic health record (EHR) for the calendar year 2020, we generated a list of patients eligible for TB screening which served as the denominator in calculating our TB screening rate. First, all qualifying DMARD prescriptions were identified. We excluded refills, patients switching between DMARDs, and patients with a history of TB using historic prescription data and information from the past medical history of problem list. Adequately screened cases (numerator) had a result for an interferon gamma release assay or purified protein derivative test within 365 days prior to or 60 days after the DMARD prescription start date We validated all inadequately screened cases by manual chart review.

Results: Analysis 1: In 2020, 97 new qualifying DMARD prescriptions were routed through our workflow. In three cases, the medication was not started due to patient or clinician preference or lack of insurance coverage. These were excluded from the denominator. In two instances, the clinician overrode the requirement for TB screening within 365 days as it had been performed with the prior 18 months. Analysis 2: EHR data extraction identified 159 cases in 2020 eligible for TB screening, and 130 were screened adequately for a TB screening rate of 82%. Differences in numbers of eligible patients in EHR data versus through the workflow were analyzed via manual chart review. Chart review also suggested reasons for inadequate screening including prior TB screening outside of the defined timeframe, treatment hiatus, and prescription of an infusion.

Conclusion: Our intervention was associated with a significant improvement of 19% in our clinic's TB screening rate compared to historic rates. Reviewing EHR data identified additional reasons for missed screening. These reasons for missed screening may inform future process improvement cycles related to capturing this key safety measure.

Abstract Number: 0149

Development of Joint Effusion, Hyperperfusion and Enthesitis After One Hour of Age-and Gender Adjusted Weight Training

Julia Schreiner[1], Dennis Scheicht[2], Pantelis Karakostas[3], Jana Ziob[1], Charlotte Behning[1], Peter Preuss[4], Peter Brossart[5] and **Valentin Schäfer**[1], [1]University Hospital Bonn, Bonn, Germany, [2]Porz am Rhein Hospital, Cologne, Germany, [3]Clinic of Internal Medicine III, Oncology, Haematology, Rheumatology and Clinical Immunology, University Hospital Bonn, Bonn, Germany, [4]University of Bonn, Bonn, Germany, [5]Department of Internal Medicine III, Oncology, Hematology and Rheumatology, University Hospital Bonn, Bonn, Germany

SESSION INFORMATION

Session Date: Saturday, November 6, 2021

Session Title: Imaging of Rheumatic Diseases Poster (0149–0182)

Session Type: Poster Session A

Session Time: 8:30AM–10:30AM

Background/Purpose: Ultrasound is an established tool to detect changes of joints, tendons and entheses in rheumatology. However, several studies detected structural and vascular changes in tendons and entheses as well as joint effusion in athletes and physical active individuals (1–3). This evidence may raise the question, whether a patient's ultrasound findings are related to a rheumatic disease or associated with sports activities. The purpose of this study was to evaluate the development of joint effusion, hyperperfusion and enthesitis in large and medium joints of young healthy individuals after one hour of supervised weight training.

Methods: We applied ultrasound to examine the shoulder, elbow, wrist, hip, knee, and ankle joints, as well as associated entheseal sites such as the Achilles tendon and the plantar aponeurosis, in healthy individuals under the age of 30. The ultrasound examination was carried out before, 24h after and 48h after the participants conducted one hour of supervised weight training. Friedman test was applied to determine significant changes of the prevalence of joint effusion and enthesitis within 48h after the physical activity. Bonferroni-corrected p-values are shown for post-hoc tests.

Results: Fifty-one healthy individuals with a mean age of 23.7 years (19;30 ± 2.46) were included, 52.9% were female with a mean BMI of 22.5 kg/m2 (18.6;36.6 ± 3.07). The percentage of individuals with joint effusion in at least one joint increased from 72.55% (n=37) at baseline to 88.24% (n=45) after 24h and to 94.12% (n=48) 48h after the training. The mean number of joints affected by effusion were 1.49 at baseline, 2.82 after 24h and 4.16 after 48h.

Fourteen participants (27.45%) presented with entheseal pathology in at least one enthesis at baseline, 47.06% (n=24) showed pathologies after 24h and in 56.86% (n=29) entheseal pathology was observed 48h after the weight training. The only entheseal pathology observed 24h and 48h after the training was hyperperfusion.

The Friedman test and post-hoc tests revealed a significant increase in joints with effusion within 48 hours of weight training ($Q=-1.255$, $p< 0.0001$). Results also showed a significant increase of detected entheseal pathology from baseline to 48h after the weight training ($Q= -0.588$, $p=0.009$).

Conclusion: Prevalence of joint effusion in large and medium joints as well as the prevalence of entheseal pathology increase significantly within 48h after weight training. Therefore, the patient's sports activities should be taken into account when performing a musculoskeletal ultrasound examination.

Session Title: Imaging of Rheumatic Diseases Poster (0149–0182)
Session Type: Poster Session A
Session Time: 8:30AM–10:30AM

Background/Purpose: Precapillary Pulmonary Hypertension (PPH) is a known complication of connective tissue disease-associated interstitial lung disease (CTD-ILD) but at present requires right heart catheterization (RHC) for definitive diagnosis. Computed tomography (CT) imaging measures of vascular pruning have been associated with pulmonary vascular disease, but it is unknown whether these CT measures associate with PPH in patients with CTD-ILD. The aims of this study were to 1) compare clinical characteristics of patients with CTD-ILD with and without PPH,

Table 1. Underlying Rheumatic Disease Diagnosis in CTD-ILD Number of patients that met inclusion criteria for each underlying rheumatic disease diagnosis

Rheumatic Disease Diagnosis in CTD-ILD	n
ANCA-associated Vasculitis 2/2 Microscopic Polyangiitis	6
Anti-synthetase Syndrome	13
Diffuse Systemic Sclerosis	9
Limited Systemic Sclerosis	12
Systemic Sclerosis sine Scleroderma	2
Rheumatoid Arthritis	10
Polymyositis	3
Sjogren's Syndrome	1
Systemic Lupus Erythematosus	5
Interstitial Pneumonia with Autoimmune Features (IPAF)	9
Mixed Connective Tissue Disease	11
Total	81

Arterial Blood Vessel Volume of all vessels > 10mm2 [IQR]	18.5 [13.1, 24.1]	13.6 [10.1, 19.4]	0.01
Total Arterial Blood Vessel Volume [IQR]	38.1 [30.2, 46.4]	33.6 [27.3, 38.5]	0.01
Total Venous Blood Vessel Volume [IQR]	22.8 [17.6, 30.4]	23.1 [18.7, 30.4]	0.99

2) assess if there are quantitative CT vascular measures that associate with the presence of PPH, and 3) determine if these comparisons differed across various rheumatic diseases.

Methods: We performed a retrospective review of adult patients (>18 years old) with ICD-code diagnoses of ILD and connective tissue disease (CTD) with both a CT chest and RHC within two years of each other in the electronic medical record. Medical charts were reviewed for confirmation of ILD by a pulmonologist, CTD by a rheumatologist, and presence of PPH or absence of pulmonary hypertension by a pulmonologist. CT chest images underwent automated 3D vasculature reconstruction using the Chest Imaging Platform (www.chestimagingplatform.org) with vessel size estimation for calculation of blood vessel volume in arterial, venous, and total blood vessels of size greater than or less than 5 mm^2 and 10 mm^2; these values were divided by CT_{LV} (total lung volume in Liters) to measure blood vessel volume normalized to total lung volume. Descriptive and comparative analyses using Chi-square (categorical variables) and Wilcoxon-ranked sum (continuous variables) tests were performed using R version 4.0.2.

Results: 81 patients met our inclusion criteria (41 without PPH and 40 with PPH; 6 microscopic polyangiitis, 13 antisynthetase syndrome, 9 diffuse systemic sclerosis (SSc), 12 limited SSc, 2 SSc sine scleroderma, 10 rheumatoid arthritis, 3 polymyositis, 1 Sjögren's, 5 systemic lupus erythematosus (SLE), 9 interstitial pneumonia with autoimmune features (IPAF), and 11 mixed CTD). There were no statistical differences in age, sex, race, ethnicity, positive ANA, other autoimmune serologies, spirometry, and TLC measures in patients with PPH and patients without pulmonary hypertension. Predicted carbon monoxide diffusion capacity (DLCO) was significantly reduced in PPH (p=0.002). On quantitative CT compared to patients without pulmonary hypertension, patients with PPH had significantly greater blood vessel volume in arterial vessels (p=0.014), and in arterial vessels greater than 5 mm^2 (p=0.016) and 10 mm^2 (p=0.014), respectively.

Conclusion: Patients with CTD-ILD and precapillary pulmonary hypertension were found on quantitative CT to have greater arterial lung blood volume in vessels of size greater than 5 mm^2 and 10 mm^2. This suggests that distal increases in pulmonary vascular resistance lead to proximal arterial vascular dilation and an increased arterial blood volume on CT scan. Quantitative analysis of CT chest imaging in CTD-ILD may be a useful diagnostic tool for precapillary pulmonary hypertension; however, prospective studies are needed.

Usefulness of Ultrasound and (FDG) PET/CT to Detect Cranial and Extracranial Artery Involvement in Patients with Suspected Large Vessel Vasculitis

Juan Molina[1], Isabel Castrejón[2], Javier Rivera[2], Julia Martínez Barrio[2], Juan Carlos Nieto[2], Katerine López[2], Fernando Montero[2], Laura Trives Folguera[2], Carlos González[3] and Jose Maria Alvaro-Gracia[2], [1]Hospital General Universitario Gregorio Maran, Madrid, Spain, [2]Hospital General Universitario Gregorio Marañón, Madrid, Spain, [3]CEIMI, Hospital General Universitario Gregorio Marañón, Madrid, Spain

SESSION INFORMATION
Session Date: Saturday, November 6, 2021
Session Title: Imaging of Rheumatic Diseases Poster (0149–0182)
Session Type: Poster Session A
Session Time: 8:30AM–10:30AM

Background/Purpose: Ultrasound (US) is recommended as the first imaging modality to assess patients presenting with predominantly cranial symptoms of giant cell arteritis (GCA). However, its value in assessing extra-cranial involvement remains unclear, being the ^{8}F-fluorodeoxyglucose (FDG) PET/CT the ancillary study recommended. We aim to compare US versus FDG PET/CT to detect cranial and extra-cranial artery involvement in patients with suspected large vessel vasculitis (LVV).

Methods: Retrospective observational study including patients referred to a GCA fast track pathway (FTP) over a 2-years period. All patients underwent US exam of temporal (TA) and large vessel (LV) (carotid, subclavian and axillary) arteries within 24 hours of referral per protocol. Positive US findings were defined as a halo and/or compression sign in TA and a halo and/or intima media thickness >1mm in LV arteries. FDG PET/CT was performed per clinician criteria and was defined as positive if an artery FDG uptake was higher than liver uptake. The qualitative FDG uptake in the aorta, its aortic branches (carotid, axillary and subclavian), iliac and cranial arteries was also registered. All US

Table 1. Clinical, laboratory and imaging findings of patients included in the fast track pathway with and without LVV. LVV: large vessel vasculitis; PMR: polymyalgia rheumatica; CRP: C-reactive protein; ESR: erythrocyte sedimentation rate; US: ultrasound; SD: standard deviation

exams were made before the FDG PET/CT evaluation. The external criterion for US and FDG PET/CT comparison was LVV clinical confirmation after 6 months follow-up.

Results: A total of 113 patients were included, 74.3% female with mean age 74 (11) years. After 6 months of follow-up, 37 (32.7%) patients had LVV clinical confirmation (34 GCA and 3 Takayasu). Only 3 (3.9%) patients without LVV versus 32 (86.5%) with LVV had positive US findings (Table 1). Among patients with LVV, 24 (64.9%) had TA involvement and 16 (43.2%) had extra-cranial LVV according to US examination (37.8% axillary, 29.7% subclavian and 32.4% carotid artery involvement). We found a mixed pattern with involvement of both TA and LV arteries in 8 (21.6%) patients. Overall, sensitivity and specificity of US for LVV was 86.5% and 96.1%, respectively, and for exclusively LV involvement was 94.1% and 80.2 %, respectively. A total of 28 patients underwent a FDG-PET/CT, of whom 12 (42.9%) showed positive findings. Taking FDG-PET/CT as the reference, US showed positive extracranial findings in 10 (83.3%) of those 12 patients and was able to detect 2 (12.5%) additional cases of large vessel involvement with negative FDG-PET/CT examination (Table 2). On the other hand, FDG-PET/CT showed LV artery involvement in 2 patients with negative US findings (1 patient with isolated aortitis and 1 patient with aorta and iliac artery involvement) (Table 3). FDG-PET/CT showed cranial arteries uptake in none of patients.

Table 2. Ultrasound findings of patients included in the fast-track pathway taking FDG-PET/CT as the reference for large vessel vasculitis. LVV: large vessel vasculitis; US: ultrasound

	Total n= 28	Patients with positive FDG-PET/CT findings for LLV n=12 (%)	Patients without positive FDG-PET/CT findings for LLV n=16 (%)	p
Positive US findings, no. of patients	16 (57.1%)	10 (83.3%)	6 (37.5%)	0.015
Temporal artery positive, no. of patients	9 (32.1%)	5 (41.7%)	4 (25%)	0.432
Large vessel arteries positive, no. of patients	12 (42.9%)	10 (83.3%)	2 (12.5%)	<0.001
Axillary positive, no. of patients	11 (39.3%)	9 (75%)	2 (12.5%)	0.001
Subclavian positive, no. of patients	9 (32.1%)	8 (66.7%)	1 (6.3%)	0.001
Carotid positive, no. of patients	9(32.1%)	8 (66.7%)	1 (6.3%)	0.001

Table 3. Comparison between US and PET/CT findings in patients with PET/TC proven LVV. TA: temporal artery; CA: carotid artery; AA: axillary artery; SA: subclavian artery, IA: iliac artery

	Ultrasound				FDG-PET/CT					
Patient	TA	CA	SA	AA	TA	CA	SA	AA	Aorta	IA
1	+	+	-	-	-	+	-	-	-	-
2	-	-	-	-	-	-	-	-	+	+
3	+	-	+	+	-	+	+	-	+	+
4	+	-	+	+	-	+	+	+	+	-
5	-	+	+	+	-	-	-	-	+	+
6	+	+	+	+	-	-	+	-	+	+
7	-	+	+	+	-	+	+	+	+	+
8	-	+	+	+	-	+	+	+	+	+
9	-	-	-	-	-	-	-	-	+	-
10	-	+	+	+	-	-	+	-	+	-
11	+	+	+	+	-	+	+	+	+	-
12	+	+	+	+	-	-	+	-	+	-

Conclusion: US is comparable to FDG-PET/CT for LVV diagnosis. Although presence of US extra-cranial artery inflammation is consistent with FDG-PET/CT examination, a negative US scan does not rule out extracranial involvement. FDG-PET/CT is of limited value for assessing cranial arteries. Thus, US may be used as the first line investigation not only in suspected cranial, but also extracranial LVV.

50th percentile PXS score	3.17	3.13	0.13
85th percentile PXS score	9.54	8.02	0.02
PXS score >9, n (%)*	14 (20)	49 (11)	0.02

PXS, pulmonary x-ray severity score.
*Based on the highest PXS score within ±2 weeks of COVID-19 diagnosis.

patients and general population comparators using a deep learning algorithm that extracts a quantitative measure of radiographic lung disease severity.

Methods: We performed a comparative cohort study of patients with rheumatic disease who had confirmed COVID-19 and at least one chest radiograph within ±2 weeks of COVID-19 diagnosis between January 31, 2020 and January 31, 2021 in a large healthcare system and comparators (matched up to 10:1 by age, sex, date of diagnosis, and chest radiograph location). Covariates and COVID-19 outcomes (mechanical ventilation and death) were ex-

tracted from a centralized data warehouse. A previously validated convolutional Siamese neural network algorithm was used to calculate the Pulmonary X-Ray Severity (PXS) score, a quantitative measure of COVID-19 lung severity. Higher scores indicate more severe pulmonary disease (Figure 1). We compared the PXS scores between rheumatic diseases cases and comparators using quantile regression at the 50th and 85th percentiles. We then evaluated the association of severe PXS score (>9) with risk of mechanical ventilation and death among patients with rheumatic diseases using logistic regression.

Results: We identified 70 rheumatic disease patients and 463 general population comparators. Rheumatic disease patients had more comorbidities such as hypertension (54% vs. 32%, p< 0.001), diabetes (31% vs. 15%, p< 0.001), and interstitial lung disease (6% vs. 1%, p< 0.01) (Table 1). The most common rheumatic diseases were rheumatoid arthritis (37%), other inflammatory arthritis (17%), and systemic lupus erythematosus (14%). The maximum PXS score within 2 weeks of COVID-19 diagnosis was similar in the rheumatic disease patients and comparators at the 50th percentile (3.17 vs. 3.13, respectively, p=0.10) but significantly higher among rheumatic disease patients at the 85th percentile (9.54 vs. 8.02, p=0.03) (Table 2). Rheumatic disease patients were more likely to have a maximum PXS score >9 (20% vs. 11%, p=0.02), indicating severe pulmonary disease. Among rheumatic disease patients, those with maximum PXS score >9 more frequently required mechanical ventilation (85% vs. 5%, p< 0.0001) and died (14% vs. 2%, p=0.08) compared to those with PXS score ≤9.

Conclusion: Using a previously validated deep learning algorithm, patients with rheumatic disease and COVID-19 had more severe radiographic lung disease than matched comparators. Among rheumatic disease patients, more severe radiographic disease was associated with higher risk of mechanical ventilation. Future studies are needed to determine if PXS scores may help to risk-stratify patients with rheumatic disease and COVID-19.

Synovitis Phenotype (number)	
Type A	61
Type B	31
Type C	6

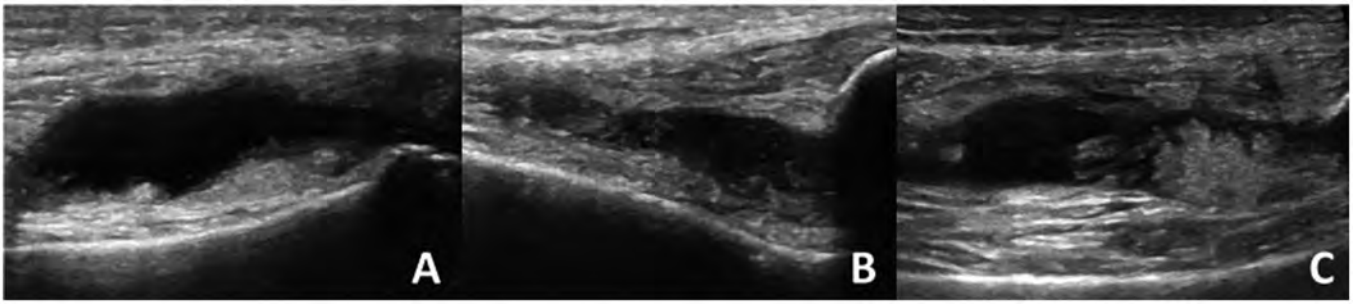

Figure 1. A: Type A synovitis is characterized by a synovial volume predominantly composed of anechoic material (synovial fluid). Little to no circumferential synovial thickening is seen. B: Type B synovitis includes a significant intra-articular abnormal solid component of inflamed synovium which is primarily characterized by low-level echoes. C: In Type C synovitis, inflammation is accompanied by a significant intra-articular solid component of synovium characterized by high level echoes with or without nodular appearance (fronding).

have failed to find any features of inflammation measured by ultrasound (US) that are associated with pain/function response. Our objective is to test whether nuanced features of sonographically-detected inflammation including synovial tissue quality and synovial vascularity are associated with response after IACS.

Methods: KOA patients presenting to a rheumatology center for regular follow up and steroid injection were administered a standardized US and completed patient surveys prior to injection. Using random-effects linear and logistic models, baseline US features were tested for association with improvement in pain, function, patient-reported global assessment (PGA) of disease activity, and OARSI-OMERACT-defined responder status 18-28 days after IACS injection.

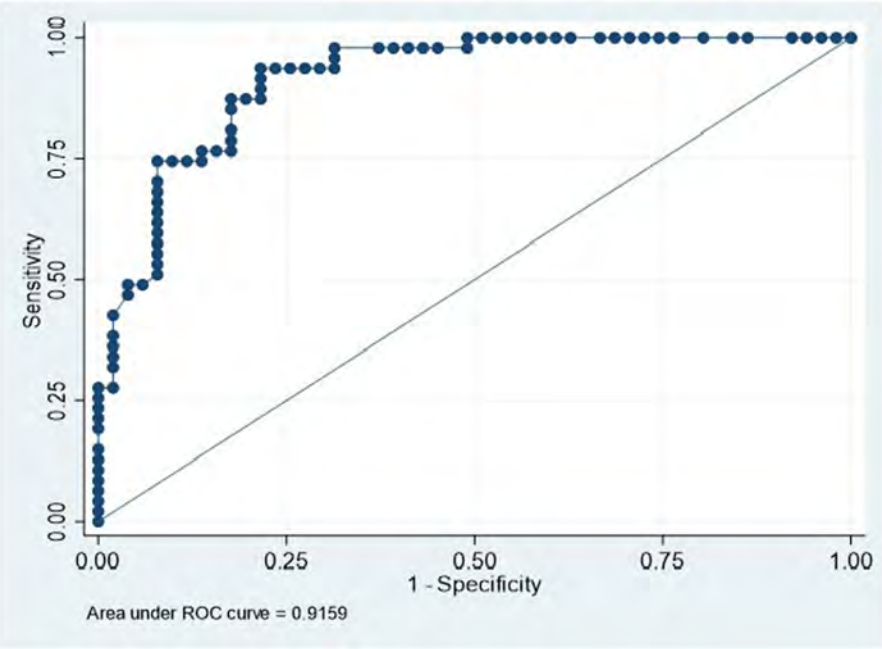

Figure 3. Baseline WOMAC pain and radiographic severity defined as KL grade 3 or 4 (model 1) discriminate between OARSI-OMERACT response with an AUC of 0.9159. With a cut-off probability of P(y)=0.5964, 83.67% of patients are correctly classified into responders or non-responders (sensitivity 74.47% specificity 92.16%).

Results: Individuals with echogenic synovium and positive Power Doppler (PD) signal have an improved response to pain (β= 14.500 & 7.655, respectively) and function (β= 11.677 & β= 7.650, respectively) after IACS. Patients with metabolic syndrome have as much as a 30% reduced response to IACS as measured by PGA of disease activity. Only baseline pain (OR= 1.042) and radiographic severity (OR= 5.282) were associated with OARSI-OMERACT-defined response.

Conclusion: Inflammation is not homogeneous across KOA patients, and response to IACS injections depends on baseline symptoms, the phenotype of synovitis, the presence of blood flow within synovium, and baseline radiographic severity.

Utilization of Magnetic Resonance Imaging in Early Rheumatoid Arthritis: Results from a Population-based Cohort (1999-2014)

Caitrin Coffey[1], Cynthia Crowson[2], Cassondra Hulshizer[1], Gavin McKenzie[1], Nicholas Rhodes[1], John Davis[1] and Kerry Wright[1], [1]Mayo Clinic, Rochester, MN, [2]Mayo Clinic, Eyota, MN

SESSION INFORMATION
Session Date: Saturday, November 6, 2021
Session Title: Imaging of Rheumatic Diseases Poster (0149–0182)
Session Type: Poster Session A
Session Time: 8:30AM–10:30AM

Background/Purpose: Early diagnosis and treatment initiation improve outcomes for patients with rheumatoid arthritis (RA). Delays to diagnosis and treatment affect patients with seronegative vs seropositive RA disproportionately. Magnetic resonance imaging (MRI) is superior to clinical examination for detecting synovitis in patients with RA and can predict progression to clinical RA from undifferentiated arthritis. We hypothesized that MRI utilization is higher in seronegative vs seropositive patients with early RA, and is increasing over time in recent years.

Methods: A retrospective study was performed of a population-based cohort of patients with incident RA between 1999-2014 who fulfilled either the 1987 or 2010 ACR/EULAR classification criteria. Patients who underwent MRI within (+/-) 1 year of fulfillment of the earlier of either classification criteria for RA were identified using Current Procedural Terminology codes corresponding to MRI studies of the extremities (hand, wrist, elbow, shoulder, foot, ankle, knee, hip). Studies were confirmed via manual chart review. MRIs performed for indications unrelated to arthritis were excluded. MRI utilization was compared between seropositive (RF+ and/or CCP+) and seronegative (RF-, CCP-) patients. Factors associated with undergoing MRI within one year of meeting criteria were analyzed. Comparisons between groups were made using Kruskal-Wallis and Chi-square tests. Utilization of MRI over time was evaluated with a test for trend.

Results: 789 patients with incident RA who fulfilled 1987 and/or 2010 ACR/EULAR classification criteria for RA were included. Of these, 554 (70%) were female, 709 (90%) Caucasian, 534 (68%) RF and/or CCP positive, mean age 55.9 (SD 15.2) at time of meeting criteria. At least one MRI was performed within one year of fulfilling criteria in 165 (21%) of patients over the study interval. Age, sex, race/ethnicity, and smoking status did not differ between groups who did and did not undergo MRI.

RF and CCP autoantibodies were negative in 77 (47%) of those who underwent MRI, versus 178 (29%) who did not ($p< 0.001$). At time of meeting classification criteria, presence of morning stiffness rheumatoid nodules, erosive disease, and abnormal sedimentation rate or C-reactive protein were similar among patients who did and did not undergo MRI. Patients with symptom duration ≥ 6 weeks (64% vs. 46%, $p< 0.001$) and involvement of 4-10 (22% vs. 13%) small joints or >10 (39% vs. 30%) joints ($p< 0.001$) were more likely to have an MRI performed. Prevalence of obesity (BMI ≥ 30 kg/m^2) was similar between MRI (45%) and no MRI (39%) ($p=0.18$) groups.

The median year of fulfilling RA criteria was later in the MRI (2010; IQR 2005-2013) vs no MRI (2008; IQR 2003-2011) ($p< 0.001$) groups. MRI utilization overall increased over time by 9% per calendar year (OR:1.09; 95% CI: 1.05-1.14; $p< 0.001$).

Conclusion: In this population-based cohort of patients with incident RA, MRI was used for evaluation of arthritis within one year of fulfilling classification criteria in 21% of patients. MRI was more commonly used in seronegative than seropositive patients, which may reflect diagnostic uncertainty in the seronegative group. MRI utilization increased over time during the 15-year study interval.

The Additional Value of MRI in Diagnosis of Rheumatoid Arthritis in Undifferentiated Arthritis Patients

Nikolet den Hollander[1], Marloes Verstappen[1], Navkiran Sidhu[1], Elise van Mulligen[2], Monique Reijnierse[1] and Annette H.M van der Helm-van Mil[1], [1]Leiden University Medical Center, Leiden, Netherlands, [2]Erasmus Medical Center, Rotterdam, Netherlands

SESSION INFORMATION
Session Date: Saturday, November 6, 2021
Session Title: Imaging of Rheumatic Diseases Poster (0149–0182)
Session Type: Poster Session A
Session Time: 8:30AM–10:30AM

Background/Purpose: Identifying patients that will develop rheumatoid arthritis (RA) among those presenting with undifferentiated arthritis (UA) remains a clinical dilemma. According to EULAR recommendations magnetic resonance imaging (MRI) is helpful. An important limitation is that UA is not uniformly characterized. UA is formally defined as not fulfilling RA classification criteria (1987- or 2010-criteria). In clinical practice, rheumatologists identify UA based on clinical expertise. The diagnostic value of MRI has only been determined in UA-patients not fulfilling the 1987-criteria. The data on the value of MRI in UA according to the two common and current definitions is lacking. Therefore, we performed a large study to determine this.

Methods: In total 1234 patients, consecutively included in the Leiden early-arthritis cohort (EAC) between august-2010 and march-2020 underwent MRI-scans of hand and foot, that were scored for erosions, bone marrow edema (BME), synovitis (SYN) and tenosynovitis (TS). Two UA-populations were studied: not fulfilling 1987/2010-criteria and having no other diagnosis (criteria-based UA-population, n=405), and expert-opinion of UA (n=564). Patients were followed up for RA-development (fulfilling 1987/2010-criteria) after 1-year. Logistic regression was used, test characteristics and predictive values were determined, also in clinically-relevant subgroups.

Results: Within criteria-based UA-patients, 21% developed RA. Except for BME, all MRI-features were prognostic for RA-development. Only MRI-TS was independently associated with RA-development (OR 2.79, 95% CI: 1.40-5.58), especially within ACPA-negative UA-patients (OR 2.91; 1.42-5.96). Particularly within the oligoarthritis-subgroup, MRI-TS was predictive for RA-development (NPV 93%; PPV 28%; sensitivity 85%; specificity 45%). Compared with oligo-/polyarthritis alone, MRI-TS improved prediction of RA-development within the oligoarthritis-subgroup (Net Reclassification Index 0.28). Similar results were found in the expert opinion UA-population.

Conclusion: This large cohort study showed MRI has additional prognostic value for early identification of RA. The value was highest within ACPA-negative UA-patients with oligoarthritis. Although cost-effectiveness remains to be determined, this shows MRI is useful for early recognition of RA in subgroups of UA-patients.

Session Title: Imaging of Rheumatic Diseases Poster (0149–0182)
Session Type: Poster Session A
Session Time: 8:30AM–10:30AM

Background/Purpose: It is known that seronegative rheumatoid arthritis has different characteristics from seropositive RA. Objectives: To estimate the frequency of rheumatoid arthritis (RA) in a cohort of patients who consulted for polyarthralgia, including arthralgia of the hands, and to identify differential features, at diagnosis, between patients with seropositive RA and seronegative RA.

Methods: Prospective cohort study, which included patients over 18 years of age who were admitted for polyarthralgia, including hand arthralgias, to the ¨Reuma-check¨® program from August 2017 to March 2020. In this program, in the first visit (baseline) was performed: laboratory studies (including acute phase reactants, RF and anti-CCP), X-rays of hands and feet, ultrasound of hands with power Doppler technique (22 joints: wrists, MCFs and IFPs bilaterally and 20 tendons: 6 carpal extensor compartments and flexor tendons of 2nd to 5th fingers bilaterally) and interview where sociodemographic data (age, sex), clinical data (time of evolution of arthralgias, comorbidities) and clinimetry

Table 1. Characteristics of patients with a final diagnosis of RA.

	Rheumatoid arthritis, n: 128
Age (years), mean (SD)	56.6 (14.2)
Female, n (%)	90 (70.3)
Smoking, n (%)	54 (42.1)

Tender joints (28), mean (SD)	5.3 (3.2)
Swollen joints (28), mean (SD)	1.9 (2.7)
CDAI, mean (SD)	17.7 (8)
DAS28-ERS, mean (SD)	4.2 (1.1)
HAQ, mean (SD)	0.8 (0.4)
RF, n (%)	83 (64.8)
Anti-CCP, n (%)	51 (39.8)
ESR, mean (SD)	29.8 (24.7)
CRP, mean (SD)	9.7 (19.8)
X-ray bone erosions, n (%)	23 (17.9)
Ultrasound tenosynovitis with positive power Doppler signal, n (%)	21 (16.4)
Ultrasound synovitis with positive power Doppler signal, n (%)	37 (28.9)
Median months from symptom onset to diagnosis (IQR)	12 (4,7-36)

Table 2. Comparison of the different features between patients with seropositive RA and seronegative RA.

	Seropositive RA, n: 87	Seronegative RA, n: 41	p value
Age (years), mean (SD)	56.4 (13.7)	57 (15.5)	0.84
Female, n (%)	70.1	70.7	0.94
Smoking, n (%)	54.4	44	0.36
Patient global VAS (0-100), mean (SD)	54.9 (17.4)	58.7 (21.2)	0.54
Tender joints (28), mean (SD)	5 (3.3)	6.3 (2.9)	0.08
Swollen joints (28), mean (SD)	1.9 (2.9)	2.2 (2.1)	0.65
CDAI, mean (SD)	17.1 (8.3)	19.7 (6.8)	0.16
DAS28-ERS, mean (SD)	4.1 (1.1)	4.5 (1.1)	0.16
HAQ, mean (SD)	0.8 (0.4)	0.9 (0.4)	0.23
ESR, mean (SD)	30.8 (25)	26.3 (23.6)	0.41
CRP, mean SD)	9.9 (21)	8.9 (15.5)	0.81
X-ray bone erosions, n (%)	22.7	20	0.77
Ultrasound tenosynovitis with positive power Doppler signal, n (%)	13.7	41.6	0.0028
Ultrasound synovitis with positive power Doppler signal, n (%)	34.9	32	0.78

(Global VAS of the patient, joint count, HAQ); each evaluator (laboratory, imaging and clinical) did not know the data of the other studies carried out. In subsequent visits (only patients who completed at least 2 visits were included), the results were evaluated, and the definitive diagnosis of RA was established or not according to the ACR / EULAR 2010 classification criteria. It was considered as seronegative RA when the patients were negative for both RF and anti-CCP.

Statistical analysis: descriptive statistics, Chi2 test, Fisher's exact test, Student's T-test and Mann Whitney were performed.

Results: A total of 746 (74.4% female and mean age 53.6 years, SD: 14.5) patients with polyarthralgia, including hand arthralgias, were included, of which 128 (17.1%, 95% CI: 14.6- 20) ended with a final diagnosis of RA (Table 1). Of these 128 patients, 87 (67.9%) were seropositive (RF and/or anti-CCP positive), while 41 (32%) were seronegative (RF and anti-CCP negative).

Table 2 shows a comparison of the different features between patients with seropositive RA and seronegative RA. The only feature that showed significant differences was the presence of tenosynovitis detected by ultrasound with a positive power Doppler signal, 13.7% of the patients with seropositive RA vs 41.6% of the patients with seronegative RA ($p = 0.0028$).

Conclusion: The frequency of RA in our cohort of patients with polyarthralgia, including hand arthralgias, was 17.1% and the only differential feature of patients with seronegative RA was the higher proportion of tenosynovitis detected by ultrasound with a positive power Doppler signal in comparison with patients with seropositive RA.

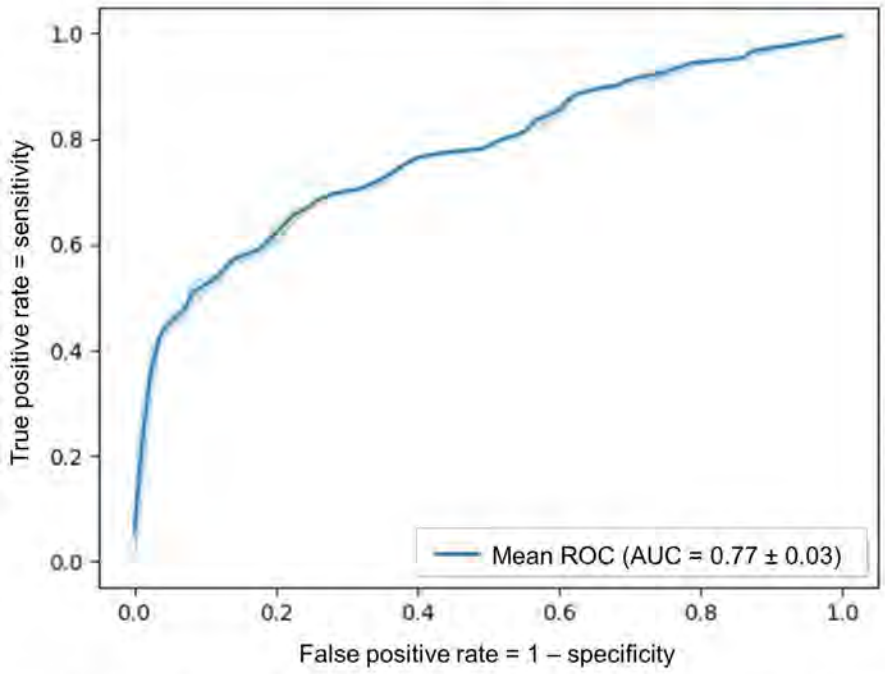
Session Title: Imaging of Rheumatic Diseases Poster (0149–0182)

Session Type: Poster Session A

Session Time: 8:30AM–10:30AM

Figure 1. Case-level BME lesion detection ROC curve for the 7-fold cross-validation experiment: bootstrapped (n=1000) ROC curve of our method



Mean is shown in dark blue, with ± 1SD shaded in lighter blue. AUC: area under curve; BME: bone marrow edema; ROC: receiver operating characteristic; SD: standard deviation.

Background/Purpose: Magnetic resonance imaging (MRI) plays a critical role in assisting the diagnosis of axial spondyloarthritis (axSpA). There are many characteristic MRI lesions that can be present in patients with axSpA; these have been well characterized in the literature,[1] and, alongside clinical presentation and laboratory features, can be used to assist diagnosis. However, in-depth knowledge of these lesions and their definitions, as well as reliability of identification and scoring, varies amongst general radiologists and rheumatologists.[2] The use of artificial intelligence to develop automated recognition of MRI lesions associated with axSpA has the potential to vastly improve diagnosis of this condition. We present a data-driven approach to automatically detect sacroiliitis on MRI.

Methods: We built a training database of de-identified sacroiliac joint (SIJ) MRI scans containing short tau inversion recovery (STIR) and T1 sequences acquired on 12 scanner models from three vendors (50% Siemens, 46% GE and 4% Philips). This dataset contains baseline MRI images from 202 patients (mean age: 38 years [range: 18–74]; 52% male) scanned at 34 clinical sites in 7 countries (97% from Europe) from interventional studies in patients with axSpA (C-axSpAnd [NCT02552212], BE MOBILE 1 [NCT03928704] and BE MOBILE 2 [NCT03928743]). 85% of the images were from patients with non-radiographic axSpA. Informed consent was collected from all patients for these studies. Three expert readers independently and manually delineated bone marrow edema (BME) lesions in a subset of cases. A positive case was defined as a patient with one or more BME lesions. We developed a two-stage lesion detection pipeline: firstly, a deep learning model binary classified each voxel present in the 3D image as either a normal or BME lesion (mimicking the reader's delineations); secondly, this voxel-level information was aggregated to a binary case-level prediction (positive if one or more BME lesions were predicted). The time to read one patient was < 0.5 min. We then performed a stratified 7-fold cross-validation experiment comparing the automated predictions with ground truth read-outs from the readers.

Results: A total of 280 lesions in 116 BME-positive patients were identified. The presented method achieved case-level BME lesion detection results of 77% area under the receiver operating characteristic (ROC) curve (95% confidence interval [CI]: 71% to 83%; Figure 1), 74% specificity (95% CI: 64% to 83%), 70% sensitivity (95% CI: 62% to 78%) and 79% precision (95% CI: 71% to 86%).

Conclusion: Using MRI images from 202 patients, our automated method achieved robust case-level BME lesion detection results. This methodology has the potential to support radiologists and rheumatologists in detecting BME lesions on MRI scans to aid early and accurate diagnosis of axSpA. Further investigations, including confirmatory analyses and methodological improvements and validation, are warranted.

Abstract Number: 0158

The Influence of Age on the Prevalence of Inflammatory and Post-inflammatory MRI Lesions in the Sacroiliac Joints of Patients with and Without Axial Spondyloarthritis

Xenofon Baraliakos, Styliani Tsiami, Anna Kühn, Martin Fruth and Jürgen Braun, Rheumazentrum Ruhrgebiet Herne, Ruhr-Universität Bochum, Herne, Germany

SESSION INFORMATION
Session Date: Saturday, November 6, 2021
Session Title: Imaging of Rheumatic Diseases Poster (0149–0182)
Session Type: Poster Session A
Session Time: 8:30AM–10:30AM

Background/Purpose: Axial spondyloarthritis (axSpA) is clinically characterized by chronic inflammatory back pain and by inflammatory and structural changes in the sacroiliac joint (SIJ) as assessed by magnetic resonance imaging (MRI). Several studies have reported high rates of bone marrow edema (BME) suggestive of inflammatory SIJ changes in up to 20% of individuals in the general population < 45 years. An update of the definition of a positive MRI of the SIJ in axSpA for classification purposes, based on the number of slices or quadrants showing BME or structural changes such as erosions or fat lesions (FL), was recently published by ASAS. The aim of this study is to compare the influence of age on the prevalence of inflammatory and structural MRI changes in the SIJ of patients with chronic low back pain diagnosed with axSpA or non-SpA.

Methods: MRIs of the SIJ of patients referred for differential diagnosis of back pain who were finally diagnosed with axSpA or not by experienced rheumatologists, were evaluated using semi-coronal STIR and T1-weighted MRI sequences. All images were scored blinded to, age, sex and diagnosis for the occurrence of BME, FL, erosions and

Table. Comparison of MRI findings between axSpA and non-SpA patients at different age groups

Age subgroup	Diagnosis	Mean number of SIJ quadrants			Proportion of patients with...		
		BME	FL	Erosion	BME	FL	Erosion
until 29 years	axSpA (n=46)	6.0±3.7	6.8±5.7	4.4±3.8	95.7%	80.4%	89.1%
	non-SpA (n=25)	1.4±1.5	5.4±4.4	0.8±1.5	64,0%	76,0%	48,0%
	p-value	*<0.001*	*0.311*	*<0.001*	*<0.001*	*0.664*	*<0.001*
30-39 years	axSpA (n=50)	5.0±4.1	8.7±5.9	4.6±3.7	92,0%	98,0%	82,0%
	non-SpA (n=26)	1.0±1.3	9.5±6.0	1.1±1.3	46.2%	92.3%	53.8%
	p-value	*<0.001*	*0.485*	*<0.001*	*<0.001*	*0.23*	*0.01*
40-49 years	axSpA (n=47)	4.2±3.7	11.3±6.0	4.6±3.7	85.1%	97.9%	87.2%
	non-SpA (n=35)	1.4±2.9	10.3±5.8	1.6±2.4	34.3%	97.1%	62.9%
	p-value	*<0.001*	*0.413*	*<0.001*	*<0.001*	*0.833*	*0.010*
≥50 years	axSpA (n=32)	5.2±4.9	16.4±5.4	5.5±4.1	87.5%	100,0%	87.5%
	non-SpA (n=48)	1.9±2.1	13.4±4.5	2.0±2.0	66.7%	100%	72.9%
	p-value	*0.001*	*0.006*	*<0.001*	*0.036*	*1,000*	*0.121*

ankylosis on the level of SIJ-quadrants (SIJ-Q). Patient groups were built based on decade of age (until 29, 30-39, 40-49 and ≥50 years).

Results: A total of 309 patients (175 axSpA and 134 non-SpA) with complete MRI sets were included in the analysis. The mean age was 38.5±11.4 and 43.4±13.8, 66.9% and 35.8% were male, the mean CRP was 1.6±2.4 and 1.1±2.1mg/dl and the median back pain symptom duration was 48 and 60 months, respectively. The number of SIJ-Q with BME and erosions was significantly higher in axSpA vs. non-SpA independent of the age group (Table). In comparison, with exception of the patients in the oldest population (≥50 years), the number of SIJ-Q with FL and the number of patients with at least one FL was not different between subgroups, while the number of erosions and FL but not BME was higher in both groups with increasing age. In the univariate analysis, only female sex was significantly associated with higher occurrence of FL.

Conclusion: Despite a relatively high prevalence in non-SpA patients, BME and erosions were significantly more frequent in axSpA independent of age, while the presence of FL was not different between groups. FL and erosions are increasingly found in older age groups independent of diagnosis. These data are relevant for the interpretation of MRI findings in the SIJ of patients suspicious of axSpA.

SESSION INFORMATION
Session Date: Saturday, November 6, 2021
Session Title: Imaging of Rheumatic Diseases Poster (0149–0182)
Session Type: Poster Session A
Session Time: 8:30AM–10:30AM

Background/Purpose: The aim of this study is to investigate the performance of the modified Stokes Ankylosing Spondylitis Scoring System (mSASSS) in assessing spinal radiographic damage and progression in axial spondyloarthritis (axSpA) using different approaches of radiographs (CR) evaluations.

Methods: Complete sets of cervical and lumbar CRs of patients with axSpA from the German SpA Inception Cohort (GESPIC) at baseline and after 2 years were first blinded to all clinical and demographic characteristics and then

scored using the mSASSS by 5 different experienced readers, 2 blinded and 3 unblinded to the timepoint of CR performance. The final mSASSS score was calculated as a mean of 2 (blinded) or 3 (unblinded exercise) readers. Descriptive statistics, cumulative probability plots and shift analyses *(agreement of 2/2 readers in the blinded group and 2/3 readers in the unblinded group on the level of single vertebral edges)* were performed for each reader group.

Results: A total of 210 patients (mean age 37.3 years, 51% male, 79% HLA-B27 positive) with axSpA (115 radiographic and 95 non-radiographic at baseline) were included. The mean mSASSS score at baseline was 4.3±8.3 vs. 3.4±7.9, while the mean radiographic progression was 0.7±2.3 vs.1.0±1.9 mSASSS units for the blinded vs. the unblinded group, respectively (Figure). On the patient level, progression of ≥2 mSASSS units was found in 30 (14.3%) vs. 37 (17.6%) patients in the blinded vs. the unblinded group, while agreement between both groups was seen in 179 (85.2%) patients, 18 (8.9%) patients for progression and 161 (76.7%) for no progression.

In a more specific analysis of 'definite' CR findings (only scores of 2 for syndesmophytes or 3 for ankylosis), the mean mSASSS score at baseline was 3.3±8.0 vs. 2.6±7.2 and the mean radiographic progression was 0.6±2.4 vs. 0.8±2.1 mSASSS units for the blinded vs. the unblinded group, respectively. On the patient level, progression was found in 37 (17.6%) vs. 33 (15.7%) patients in the blinded vs. the unblinded group, while agreement between groups was seen in 188 (89.5%) patients, 24 (11.3%) for progression and in 164 (78.1%) patients for no progression.

In the shift analysis, mSASSS worsening was found in 35 (0.8%) and mSASSS 'improvement' in only 4 (0.1%) out of the total of 4.373 vertebral edges analyzed in the blinded group and in 109 (2.2%) and 2 (0.04%), respectively, out of the total of 4.914 vertebral edges analyzed in the unblinded group (Table). The majority of progression was found for the development of 'definite' signs of progression (development of syndesmophytes or ankylosis) in both the blinded (25/35, 71.4%) and the unblinded (61/109, 56%) group, while more vertebral edges showing 'minor' signs of progression (no syndesmophytes or ankylosis) were found in the unblinded (48/109, 44%) as compared to the blinded (10/25, 28.6%) group.

Blinded reading						
mSASS Scores		2-year follow-up				Total
		0	1	2	3	
Baseline	0	4.166	10	8	9	4.193
	1	0	29	4	0	33
	2	3	1	48	4	56
	3	0	0	0	92	92
Total		4.169	40	60	105	4.374

Unblinded reading						
mSASS Scores		2-year follow-up				Total
		0	1	2	3	
Baseline	0	4.575	48	14	3	4.640
	1	1	75	16	8	100
	2	0	0	69	20	89
	3	0	1	0	84	85
Total		4.576	124	99	115	4.914

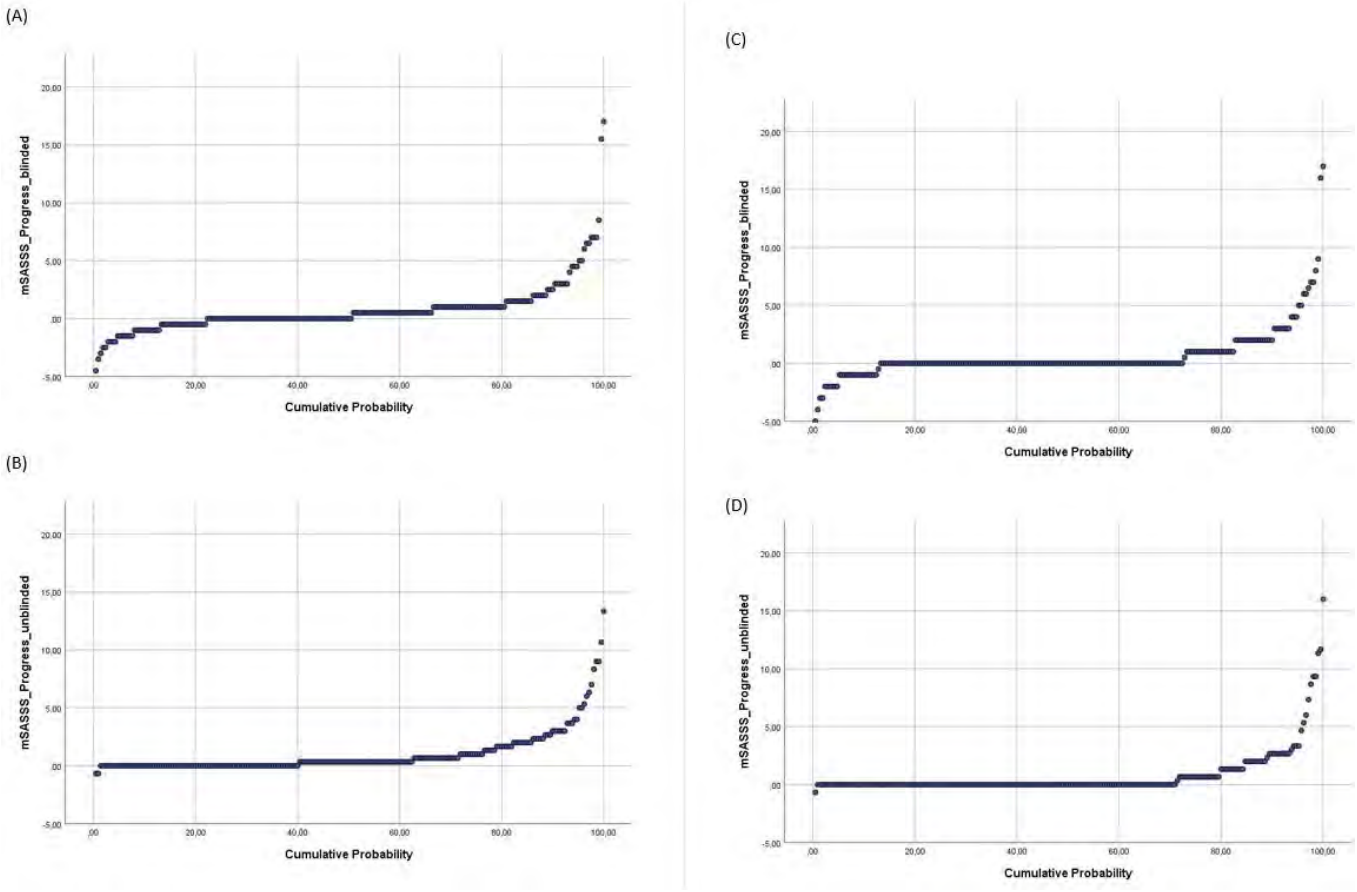

Figure. Cumulative probability plot for mean mSASSS scores for all scores in a blinded (A) and unblinded (B) scoring approach and for 'definite' scores in a blinded (C) and unblinded (D) scoring approach

Conclusion: Despite lower mean mSASSS baseline values, higher mean mSASSS progression was found with the unblinded approach, while in the shift analysis this approach was more specific, confirming the absence of 'improvement' over time.

Abstract Number: 0160

Identifying Erosive Disease from Radiology Reports of Veterans with Inflammatory Arthritis with Natural Language Processing

Gopi Penmetsa[1], Jessica Walsh[2], Shaobo Pei[3], Brian Sauer[4], Kevin Douglas[5], Jodi Walker[5], Jerry Clewell[6] and Bingjian Feng[1], [1]Salt Lake City Veteran Affairs and University of Utah Medical Centers, Salt Lake City, UT, [2]Salt Lake City Veteran Affairs Medical Center (VAMC)/University of Utah Hospital, Salt Lake City, UT, [3]VAMC, Salt Lake City, SLC, [4]Veterans Affairs Medical Center, Salt Lake City, UT, [5]AbbVie Inc., North Chicago, IL, [6]Abbvie Inc, North Chicago, IL

SESSION INFORMATION

Session Date: Saturday, November 6, 2021

Session Title: Imaging of Rheumatic Diseases Poster (0149–0182)

Session Type: Poster Session A

Session Time: 8:30AM–10:30AM

Background/Purpose: The presence of erosive disease influences diagnosis, management, & prognosis in inflammatory arthritis (IA). Inflammatory arthritis research in large datasets is limited by a lack of methods for identifying erosions.

The aim of our project was to develop methods for identifying articular erosions in radiology reports from veterans with IA.

Methods: Included veterans had ≥2 ICD codes for ankylosing spondylitis (AS), psoriatic arthritis (PsA), or rheumatoid arthritis (RA) between 2005- 2019, in Veterans Affairs Corporate Data Warehouse. Chart review & annotation of radiology notes produced the reference standard, & identified erosion terms that informed classification rule development. A rule-based natural language processing (NLP) model was created & revised in training snippets. The NLP method was validated in an independent reference sample of IA patients at the snippet & patient levels.

Results: In 168,667 veterans with inflammatory arthritis, the mean age was 63.1 & 90.3% were male. Method development involved radiology note & erosion term selection, rule development, NLP model building, & method validation. The NLP model accuracy was more than 95% at the snippet level & 90.0% at the patient level, for all IA patients.

Conclusion: The methods accurately identify erosions from radiology reports of veterans with inflammatory arthritis. They may facilitate a broad range of research involving cohort identification & disease severity stratification.

Step	Description	Number & example
1 Radiology notes	a. Select note titles potentially relevant to IA b. Extract notes with titles potentially related to IA	a. 35,141 notes titles b. 2,926,113 radiology notes
2 Possible meaningful terms	a. Compile list of root terms that may indicate erosion b. Query radiology notes for root term variations c. Select possible meaningful terms	a. 11 root terms (i.e. ero*, pencil*cup, irreg*) b. 1178 variations (i.e. erosion, erotic, erode) c. 179 possible terms (i.e. erosion, erode)
3 Annotation	a. Extract snippets^ containing possible meaningful terms b. Classify snippets according to: 1) Meaningful term, 2) Relevance to joint, 3) Attribution to IA, 4) Affirmation	a. 5000 snippets from radiology notes b. 4068 classifications with 1017 snippets (in rounds of 50-417 snippets for NLP training & testing)
4 Rule development	a. Identify meaningful terms representing erosion b. Exclude erosive processes irrelevant to joint(s) c. Exclude articular erosive processes not attributed to IA d. Classify as affirmed/negated (erosion present/absent)	a. 6 terms (pencil * cup, erosion, erosive, etc.) b. 28 irrelevant processes (i.e. gastric erosion) c. 5 non-IA processes IA (i.e. infection) d. 83 affirmation/negation rules
5 NLP training	Design & revise NLP model until accuracy ≥90%	6 rounds, 817 snippets (AS 417, RA 200, PsA 200)
6 NLP testing	Test NLP model	200 snippets (AS 100, RA 50, PsA 50)
7 Pt classification	a. Develop rules for classifying pts with discordant snippets b. Build reference sample (pts classified as erosive or non-erosive via chart review)	a. 5 rules developed in 368 pts b. 30 IA pts (10 AS, 10 RA, 10 PsA)
8 NLP validation	Validate NLP model in reference sample at snippet level	149 snippets (29 AS, 76 RA, 44 PsA)
9 Method validation	Validate methods (NLP+pt classification) at pt level	30 IA pts (reference sample)

pt= patient. ^Snippets include text containing 30 words before & after meaningful terms

	Training & testing (n=1017 patients)		****Validation in independent population (n=60 patients)**	
	NLP model training (n=817 snippets)	NLP model testing (n=200 snippets)	NLP model validation (n=254 snippets)	Method validation (n=60 patients)
All Inflammatory arthritis	92.9	95.0	94.5	91.7
Ankylosing spondylitis	90.6	95.0	96.2	95.0
Rheumatoid arthritis	93.0	92.0	96.7	90.0
Psoriatic arthritis	97.5	98.0	89.9	90.0

Patient level classifications involve assigning rules for classifying patients with conflicting snippet classifications (in subset of patients with >1 snippet) **Included 20 RA patients, 20 PsA patients, 20 AS patients.

	NLP model training (n=817 snippets)	NLP model testing (n=200 snippets)	NLP model validation (n=254 snippets)	Method validation (n=60 patients)
All Inflammatory arthritis	92.9	95.0	94.5	91.7
Ankylosing spondylitis	90.6	95.0	96.2	95.0
Rheumatoid arthritis	93.0	92.0	96.7	90.0
Psoriatic arthritis	97.5	98.0	89.9	90.0

Accuracy of the NLP methods

Does ^{18}F-FDG-PET/MRI Add Metabolic Information to Anatomic Image in Childhood-onset Takayasu's Arteritis Patients? A Multicenter Case Series

Gleice Clemente[1], Alexandre Souza[2], Hilton Leão Filho[3], Fernando Coelho[3], Carlos Buchpiguel[4], Marcos Lima[4], Daniela Petry Pioto[5], Melissa Fraga[1], Ana Paula Sakamoto[6], Camila Carneiro[4], Rosa Pereira[7], Nadia Aikawa[7], Clovis Artur Silva[7], Lucia Campos[8], Camilla Astley[9], Bruno Gualano[10] and Maria Terreri[11], [1]Universidade Federal de São Paulo, São Paulo, Brazil, [2]UNIFESP-EPM, São Paulo, Brazil, [3]Universidade de Sao Paulo/Radiology Institute, São Paulo, Brazil, [4]Universidade de São Paulo/Department of Radiology and Oncology, São Paulo, Brazil, [5]Pediatric Rheumatology Unit, Universidade Federal de São Paulo, São Paulo, SP, Brazil, [6]Federal University of So Paulo (UNIFESP), São Paulo, Brazil, [7]Hospital das Clinicas da Faculdade de Medicina da Universidade de São Paulo, São Paulo, Brazil, [8]children's institute, Sao Paulo, Brazil, [9]University of Sao Paulo, Sao Paulo, Brazil, [10]Universidade de Sao Paulo/Rheumatology Division, São Paulo, Brazil, [11]UNIFESP, São Paulo, Brazil

SESSION INFORMATION
Session Date: Saturday, November 6, 2021
Session Title: Imaging of Rheumatic Diseases Poster (0149–0182)
Session Type: Poster Session A
Session Time: 8:30AM–10:30AM

Background/Purpose: The disease activity assessment in c-TA is a challenge in clinical practice, especially in patients who are under immunosuppression. Our aim was to perform comparison between positron emission tomography (PET) and magnetic resonance angiography (MRA) findings in childhood-onset Takayasu's arteritis (c-TA) patients.

Methods: A three-center cross-sectional study with 17 children and adolescents who fulfilled the EULAR/PRINTO/PReS criteria for c-TA was conducted. The patients underwent ^{18}F-FDG-PET/MRI imaging (SIGMA^{TM} PET/MR, GE Healthcare, Milwakee-MI, USA). Positive MRA consisted of arterial wall thickening with contrast-enhancement, whereas positive PET was defined as arterial wall uptake higher than the normal liver degree of FDG uptake. Patients were divided in three groups according to the different combinations of imaging findings as following: group 1 (PET+MRA+), group 2 (PET+MRA-) and group 3 (PET-MRA+).

Results: Seventeen c-TA patients (65% female) were included. Mean disease duration was nine ±3.6 years. PET identified high-grade ^{18}F-FDG arterial wall uptake in 15 (88.2%) patients and MRA detected thickening with contrast-enhancement in 10 (58.8%). Nine patients were classified as group 1, six as group 2 and 1 as group 3. One patient had no vessel-wall changes in both images. Median of metabolic inflammatory volume (MIV) value was significantly higher in group 1 compared to group 2 (2346 vs. 1177 cm^3; p=0.036) (Table 1). Fifty-four (19%) from 284 available arterial segments presented vessel-wall changes in one or both imaging. Positive PET was found in 35 (12.3%) and positive MRA in 26 (9.2%) vessels (Table 2). Positive findings in vessel-wall were concordant between PET and MRA exams in seven (2.5%) and were not concordant in 47 (16.5%) arterial segments.

Conclusion: Our study demonstrated that ^{18}F-FDG-PET/MRI is a new exam that adds metabolic information to anatomic image in c-TA patients, and may help therapeutic decision, especially for those during immunosuppressive withdrawal.

Table 1. Clinical, laboratorial, treatment data and PET findings in group 1 and 2 in c-TA patients. c-TA: childhood-onset Takayasu's arteritis; ESR: erythrocyte sedimentation rate; CRP: C reactive protein; PET: positron emission tomography; MRA: magnetic resonance angiography; SUVmax: maximum standardized uptake value; MIV: metabolic inflammatory volume. Numerical values are presented in median (IQR). *1 patient had no vessel wall changes in MRA or PET imaging and 1 patient had vessel-wall changes in MRA but no vessel-wall changes in PET

	Group 1: n=9 (PET + MRA +)	Group 2: n=6 (PET + MRA -)	*P value*
Disease duration, years	11.0 (7.1-12.1)	8.1 (3.8-13.5)	0.906
Diagnosis delay, months	11.0 (3.0-27)	20.5 (1.6-41.3)	0.595

SESSION INFORMATION

Session Date: Saturday, November 6, 2021

Session Title: Imaging of Rheumatic Diseases Poster (0149–0182)

Session Type: Poster Session A

Session Time: 8:30AM–10:30AM

Background/Purpose: The magnitude of pericardial delayed hyperenhancement (DHE) by cardiac magnetic resonance imaging (CMR) illustrates the severity of inflammation in pericarditis. We hypothesized that patients with more severe DHE at baseline may experience earlier recurrence of pericardial disease after interruption of pharmacotherapy that had led to clinical response.

Methods: RHAPSODY is a phase 3 randomized withdrawal (RW) trial of rilonacept, an Interleukin-1α and 1β trap, in patients with recurrent pericarditis (RP) presenting with acute symptoms despite standard of care. Following a run-in period of 12 weeks of rilonacept treatment, clinical responders on rilonacept monotherapy were randomized 1:1 to placebo or continued rilonacept in a double-blind RW period. CMR was collected at baseline prior to rilonacept initiation in 25/86 patients, of whom 14 were later randomized to placebo in the RW period. CMRs were graded (none, trace, mild, moderate, severe, or not measurable) by a central imaging laboratory. We analyzed the baseline CMR data in the context of time to recurrence after randomization.

Results: 25 patients had CMR at baseline: 8% trace, 28% mild, 20% moderate, and 44% severe DHE. In patients randomized to placebo with moderate or severe DHE at baseline, 71.4% experienced a recurrence, with a median time to recurrence of 4.2 weeks. In patients randomized to placebo with trace or mild DHE at baseline, 71.4% experienced a recurrence, but with a longer median time to recurrence of 10.7 weeks after randomization. In patients with CMR at baseline randomized to receive continued rilonacept, none experienced a recurrence during the RW period; 82% had moderate or severe DHE at baseline.

Conclusion: These data support the hypothesis that more severe pericardial DHE at baseline may be associated with shorter time to pericarditis recurrence after interruption of rilonacept therapy. There is growing evidence that the assessment of DHE in the broader context of the evaluation of patients with recurrent pericarditis could be a helpful adjunct for determining treatment duration in affected patients.

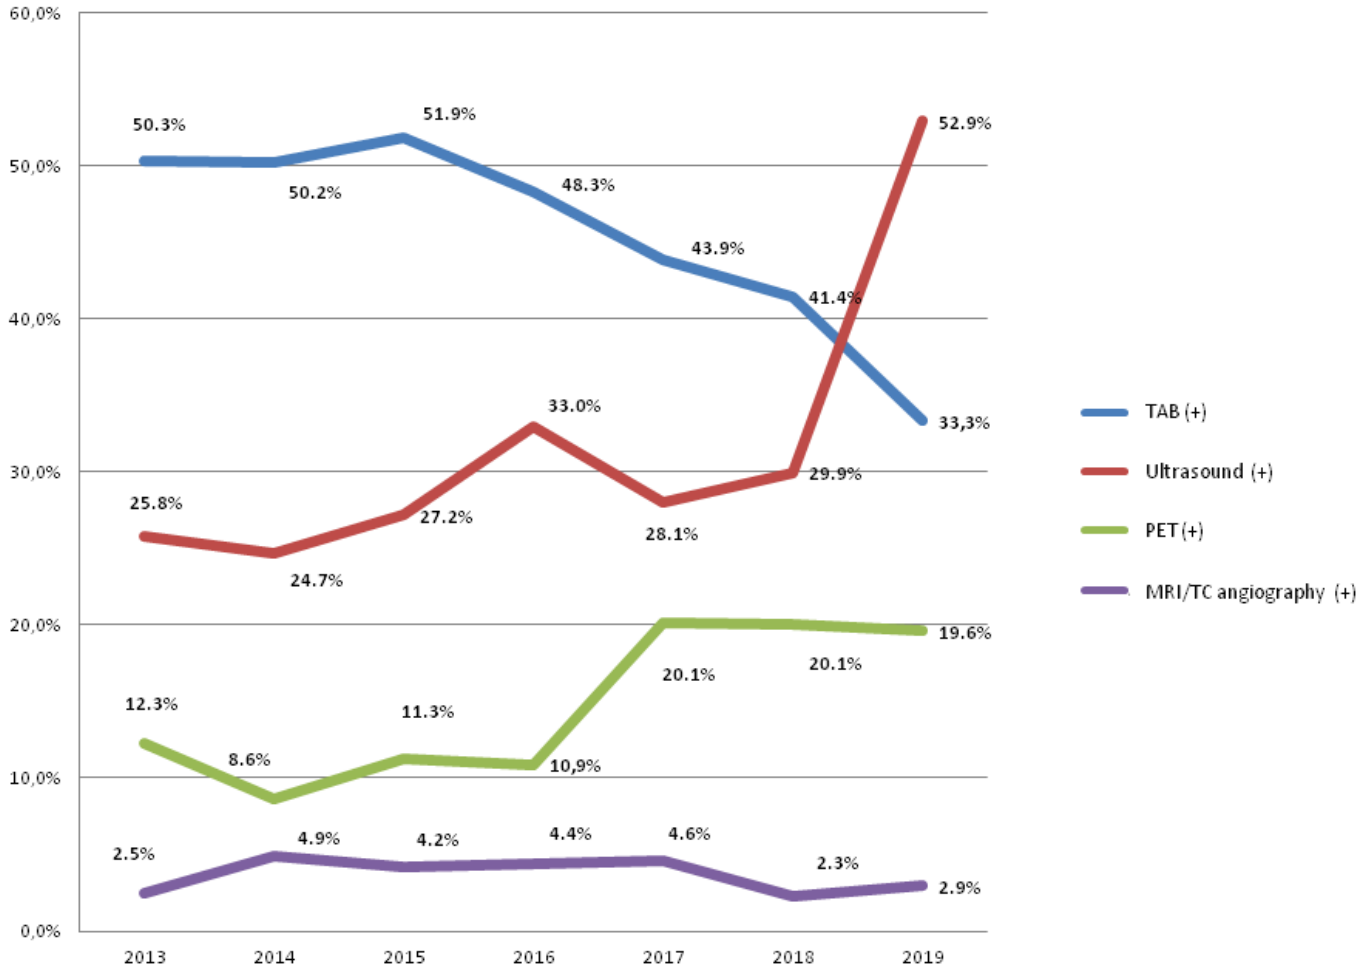
Session Title: Imaging of Rheumatic Diseases Poster (0149–0182)

Session Type: Poster Session A

Session Time: 8:30AM–10:30AM

Background/Purpose: To standardize research studies different classification systems are used. Currently, the ACR Giant Cell Arteritis (GCA) 1990[1] classification criteria is probably the most widely used, but the positive predictive value of these criteria is based on the high specificity of temporal artery biopsy (TAB), but a low sensitivity of TAB has been reported. Therefore, in the last EULAR recommendations for the use of imaging in GCA[2], imaging techniques



were accepted as useful in the diagnosis of GCA. This means that the GCA classification criteria are currently under discussion and evolution. Meanwhile, the diagnosis is based on the experience and judgment of the clinician. Our main objective was to know, how the diagnosis of GCA was made in our country and if the publication of the EULAR recommendations has influenced in the diagnosis of GCA in our clinical practice.

Methods: ARTESER is a multicenter observational retrospective study promoted by the Spanish Society of Rheumatology with 26 participating centers and in which all patients diagnosed with GCA between June 1 2013 and March 29 2019 were included. The gold standard for the diagnosis of the disease was the opinion of the responsible physician according to the clinical, analytical, imaging and TAB data available. This analysis includes the data collected from TAB and imaging (ultrasound, PET, and MRI/CT-angiography).

Results: 1675 patients with GCA were included, mean age ± SD (76.9 ± 8.1) years, 1178 women (70.3%). 776 patients had a positive TAB (46.3%), 503 (30.0%) positive ultrasound, 245 positive PET (14.6%) and 64 positive MRI/CT-angiography (3.8%). Figure 1 shows the temporal evolution of TAB and imaging techniques in the diagnosis of GCA throught the study time.

When the patients who had several of these positive tests were analyzed as support of clinical diagnosis, it was found that TAB was the only specific test performed in 531 patients (31.7%), ultrasound in 257 (15.3%), PET in 135 patients (8.1%) and MRI/CT-angiography in 14 patients (0.8%). Likewise, the data collected showed that the diagnosis based on clinical criteria or physician's opinion without TAB or imaging tests had been made in 417 patients (24.9%).

Conclusion: TAB is the most widely used diagnostic test to confirm GCA. Following the publication of the 2018 EULAR recommendations, ultrasound has displaced TAB as the first diagnostic test. PET is performed in 20% of patients in recent years. There is a wide margin of improvement in the diagnosis of GCA since the clinical diagnosis, without TAB or additional imaging tests, still supports 25% of the diagnoses.

Disrupted Executive Control Network Structural-Functional Integration Is Associated with Inferior Performance of Cognitive Switching Tasks in Patients with Systemic Lupus Erythematosus (SLE)

Xing Qian[1], Danielle S Bassett[2], Kwun Kei Ng[1], Beatrice RY Loo[1], Amelia J Koh[1], Juan Helen Zhou[1] and **Anselm Mak**[3], [1]Center for Sleep and Cognition, Department of Medicine, Yong Loo Lin School of Medicine, National University of Singapore, Singapore, Singapore, [2]Departments of Physics & Astronomy, Bioengineering, Electrical & Systems Engineering, Neurology, and Psychiatry, University of Pennsylvania, Philadelphia, PA, [3]National University of Singapore, Singapore, Singapore

SESSION INFORMATION
Session Date: Saturday, November 6, 2021
Session Title: Imaging of Rheumatic Diseases Poster (0149–0182)
Session Type: Poster Session A
Session Time: 8:30AM–10:30AM

Background/Purpose: Cognitive flexibility, a process that enables goal-oriented cognitive switching between mental function modes, is central to executive function which is impaired in SLE patients. Multimodal integration of brain network anatomy and functional signals has recently been shown to mediate the cognitive switching process. Specifically, alignment between blood-oxygenation-level-dependent (BOLD) signals and the architecture of the underlying white matter (WM) network is associated with higher cognitive flexibility. In SLE patients, whether WM networks that constrain brain dynamics during cognitive switching is altered remains unknown. Here, brain structural-functional alignment and liberality between SLE patients and healthy controls (HC) were studied by performing the Modified Wisconsin Card Sorting Test (MCST) that probed cognitive flexibility. We hypothesized that the structural-functional integration of the executive control network (ECN) would be disrupted, with behavioral implications in SLE patients.

Methods: We studied 17 SLE patients without neuropsychiatric manifestation (aged 33.3±7.9 years) and 44 HC (aged 28.3±8.2 years). Functional brain magnetic resonance imaging (MRI) during MCST, T1-weighted structural and diffusion MRI were conducted. Region-of-interest (ROI) time series were extracted using a 144-ROI brain functional parcellation scheme. We constructed the anatomical brain network by defining the connectivity between each pair of ROIs as the normalized connection probability derived from probabilistic diffusion tractography. BOLD signals were decomposed into a proportion that aligned with the anatomical network and a proportion that indicated liberality (Fig. 1).

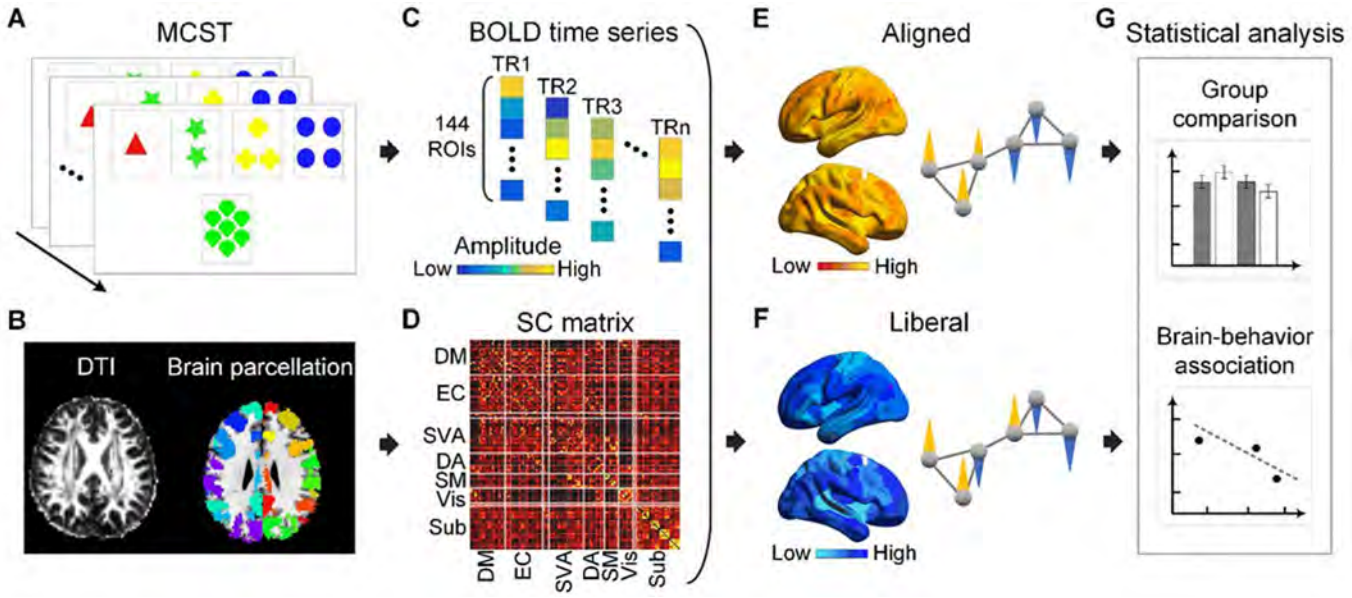

Figure 1. Study design schematic diagram. Subjects performed the Modified Wisconsin Card Sorting Test (MCST) in which they were asked to match the stimulus card at the bottom of the screen to one of the four index cards displayed at top of the screen while undergoing functional MRI scan (A). Structural connectivity (SC) network was constructed using diffusion tensor imaging (DTI) for each individual based on a predefined set of 144 regions of interest (ROIs), which included 114 cortical ROIs and 30 subcortical regions (B & D). ROI blood oxygen level-dependent (BOLD) time series were extracted from fMRI data and decomposed into a proportion which was aligned well with the structural network and a proportion which was liberal from the network (C, D, E & F). We conducted group comparison on functional alignment and liberality between SLE and healthy controls and examined the association of alignment and liberality with task performance (G). Abbreviations: DM: default mode, EC: executive control, SVA: salience/ventral attention, DA: dorsal attention, SM: somatomotor, Vis: visual, Sub: subcortical.

We performed group comparison on alignment and liberality at the global and network levels using two-sample t-tests (a=0.05) and evaluated their relationships with MCST performance.

Results: The two groups did not differ in overall MCST performance. SLE patients showed higher global functional liberality and lower global functional alignment with the structural networks during MCST (p=0.014 and 0.045, respectively) compared to HC. At the network level, SLE patients showed higher liberality in the ECN compared to HC (FDR-corrected, p=0.026). Focusing on the 3 ECN sub-networks (Fig. 2H), the abnormality of functional organization atop the ECN anatomy was driven by the lower alignment in ECN-A and higher liberality in ECN-A and ECN-B in SLE patients (FDR-corrected p=0.007, 0.008 and 0.026, respectively). ECN-A and ECN-B are the typical lateral fronto-parietal executive control regions while ECN-C is near to the default mode network. Higher liberality and lower alignment were correlated with reduced task accuracy ($p< 0.05$). The correlation between ECN liberality and task accuracy remained significant (p=0.023) after controlling for global liberality and alignment.

Conclusion: Our study demonstrated reduced functional-structural alignment of the ECN in SLE patients using a novel graph signal processing method that constrained BOLD signal magnitude to the anatomical network architecture. Reduced functional-structural alignment was associated with poorer cognitive switching performance.

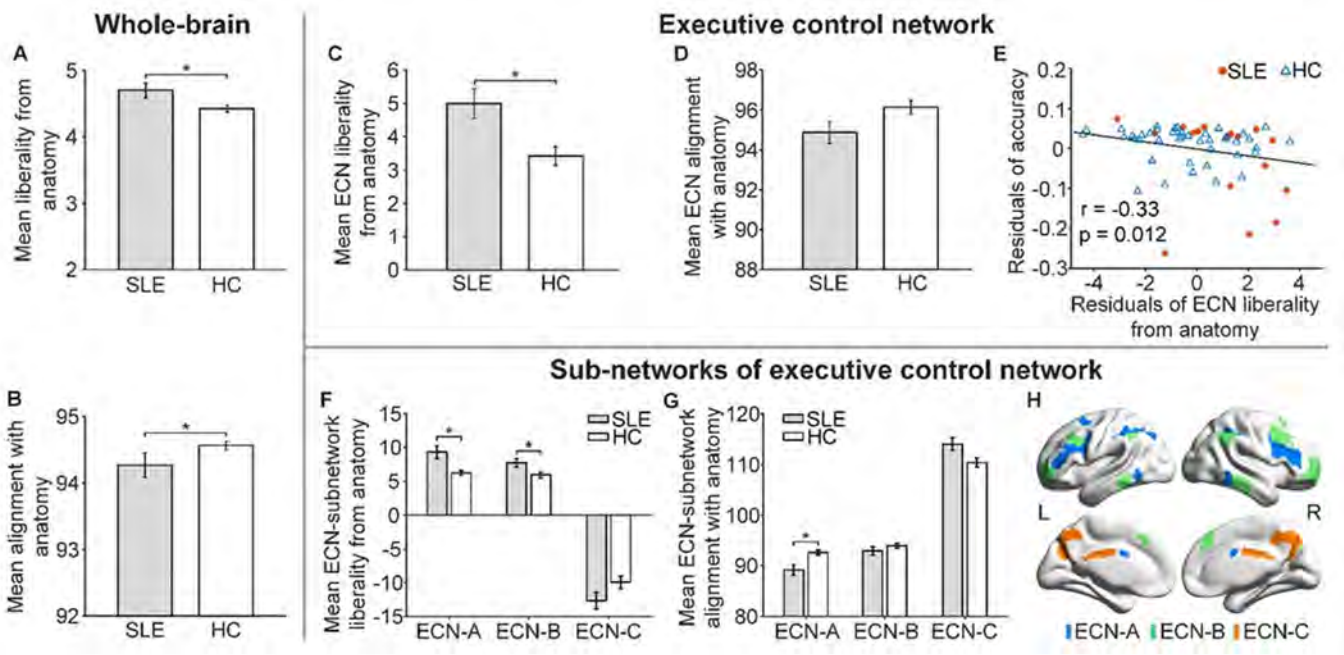

Figure 2. Patients with SLE had higher liberality from anatomy and lower alignment with anatomy related to MCST performance. Patients with SLE showed higher mean liberality from anatomy and lower mean alignment with anatomy during MCST than HC ($p<0.05$, A&B). SLE patients showed higher mean liberality from anatomy in ECN (FDR corrected $p<0.05$) and a trend towards lower mean alignment in ECN during MCST than HC (C&D). Increased mean liberality in ECN was correlated with reduced task accuracy across SLE and HC groups (E). Amongst ECN sub-networks highlighted in the brain surfaces (H), ECN-A and ECN-B showed higher mean liberality from anatomy during MCST in SLE patients than HC, and ECN-A showed lower mean alignment with anatomy during MCST in SLE patients than HC (FDR corrected $p<0.05$, F&G). Error bars represent standard errors. Abbreviations: SLE: systemic lupus erythematosus, HC: healthy control, ECN: executive control network, MCST: Modified Wisconsin Card Sorting Test.

SESSION INFORMATION

Session Date: Saturday, November 6, 2021

Session Title: Imaging of Rheumatic Diseases Poster (0149–0182)

Session Type: Poster Session A

Session Time: 8:30AM–10:30AM

Background/Purpose: Salivary-gland ultrasound has recently shown to help in the diagnosis and monitoring of primary Sjögren's syndrome (pSS)[1]. Shear-wave elastography (SWE) is a promising tool for the quantitative assessment of tissue stiffness[2]. However, studies evaluating its role in ultrasound evaluation of pSS are still limited. This study aimed to investigate the diagnostic performance of SWE in pSS and its correlation with B-mode findings.

Methods: Cross-sectional study including consecutive patients fulfilling the ACR/EULAR 2016 classification criteria for pSS, followed at our Rheumatology clinic, and age and gender-matched healthy controls. A protocolized clinical and ultrasound evaluation was performed for each patient. The four major salivary glands (parotid and submandibular glands, bilaterally) were assessed by SWE and B-mode modalities by 2 and 3 independent operators, respectively, blinded to the diagnosis. B-mode scans were rated using the Hocevar score[3], and mean shear-wave velocity (SWV) values were obtained from 6 different measures for each gland. Student's t-test, chi-square test and Pearson's

Table 1. Patient's clinical characteristics at protocolized evaluation (N=50). SD- standard deviation; ESSDAI – EULAR Sjögren's Syndrome Disease Activity Index; NSAIDs- Nonsteroidal Anti-inflammatory Drugs

Table 2. Shear-wave elastography and B-mode findings for the four major salivary glands at protocolized evaluation. pSS- Primary Sjögren's syndrome

	pSS (N=50)	Controls (N=25)	*p* value
Shear-wave velocity (m/s)			
Total, mean (SD)	2.09 (0.32)	1.74 (0.24)	<0.001
Left parotid gland, mean (SD)	2.25 (0.40)	1.83 (0.30)	<0.001
Right parotid gland, mean (SD)	2.25 (0.53)	1.83 (0.31)	<0.001
Left submandibular gland, mean (SD)	1.94 (0.45)	1.70 (0.32)	0.020
Right submandibular gland, mean (SD)	1.90 (0.45)	1.61 (0.32)	0.005
***Hocevar et al.* (range 0-48)**			
Total, mean (SD)	22.2 (8.76)	3.72 (3.46)	<0.001
Left parotid gland, mean (SD)	5.14 (2.45)	0.92 (1.26	<0.001
Right parotid gland, mean (SD)	5.68 (2.43)	0.68 (0.85)	<0.001
Left submandibular gland, mean (SD)	5.68 (2.27)	1.28 (1.31)	<0.001
Right submandibular gland, mean (SD)	5.76 (2.29)	0.84 (1.11)	<0.001

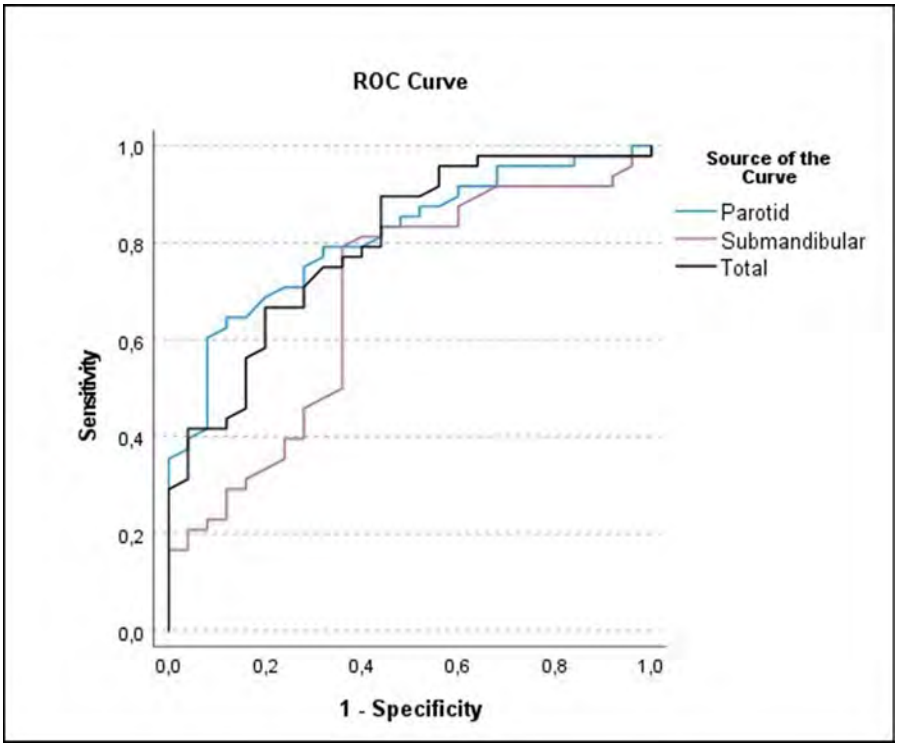

Figure 1. Receiver Operating Characteristics (ROC) analysis for parotid, submandibular and total mean shear wave velocity.

correlation were performed to compare data, as appropriate. Inter and intra-rater reliability were calculated using intraclass-correlation coefficient (ICC). Cut-off values for differentiating pSS patients from controls were calculated using Receiver-Operating Characteristics (ROC) curves.

Results: We included 50 pSS patients (mean (SD) age 56.2 (13.7); 98.0% females) and 25 controls (mean (SD) age 53.5 (9.2); 96.0% females) (Table 1). For SWE and B-mode modalities, inter-rater reliability was moderate to good (ICC: 0.64 and ICC:0.78-0.95, respectively), while intra-rater reliability was good to excellent (ICC:0.74-0.83 and IC-C:0.95-0.98, respectively). Hocevar scores were higher in pSS patients than in controls ($p< 0.001$) in all four glands examined (Table 2). The mean total SWV (2.09 m/s (0.32); $p< 0.001$), mean parotid SWV (2.25 m/s (0.53)) and mean

submandibular SWV values (1.86 m/s (0.36)) were significantly higher in patients than in controls. No significant correlation between Hocevar scores and SWV values was observed. The cut-offs of 1.95 m/s, 1.96 m/s and 1.60 m/s for total, parotid and submandibular SWV values differentiated pSS patients from controls with sensitivity of 65.3%, 77.6% and 79.2% and specificity of 80.0%, 68.0% and 64.0%, respectively. The area under the ROC curve (AUROC) was not significantly different between total SWV (AUROC=0.78) and parotid SWV (AUROC=0.81), p=0.696. Both were significantly greater than AUROC for submandibular SWV (AUROC=0.68), p< 0.05 (Figure 1).

Conclusion: SWE may represent a relevant additional tool for the diagnosis of pSS. SWV values did not correlate with B-mode, probably due to the difficulty in scoring severely fibrotic glands using Hocevar score. Larger studies including patients with pSS and patients with sicca syndrome, as well as standardization of SWE protocols, are warranted to assess the role of SWE in the diagnostic algorithm of pSS.

Abstract Number: 0166

Digital Extensor Paratenonitis Is Frequent in Early Rheumatoid Arthritis

Mihaela Maruseac[1], Adrien NZEUSSEU TOUKAP[2] and **Maria S. Stoenoiu**[3], [1]Rheumatology department, Cliniques Universitaires Saint-Luc, Brussel, Belgium, [2]Rheumatology department, Cliniques Universitaires Saint-Luc, Institut de Recherche Expérimentale et Clinique (IREC), Université catholique de Louvain, Brussels, Belgium, [3]Rheumatology department, Cliniques Universitaires Saint-Luc, Institut de Recherche Expérimentale et Clinique (IREC), Brussels, Belgium

SESSION INFORMATION
Session Date: Saturday, November 6, 2021
Session Title: Imaging of Rheumatic Diseases Poster (0149–0182)
Session Type: Poster Session A
Session Time: 8:30AM–10:30AM

Background/Purpose: Finger extensor tendon involvement (FEP) or paratenonitis has previously been described by ultrasound (US) in patients suffering from early psoriatic arthritis. Contradictory results were published in patients suffering from rheumatoid arthritis.

We aimed to assess the involvement of FEP in early rheumatoid arthritis (ERA) patients and in asymptomatic subjects.

Methods: Inclusion criteria for ERA patients were: symptom duration < 6 months prior to ERA diagnosis; age >18 years; no DMARD treatment at time of US examination. Inclusion criteria for asymptomatic subjects group were: age >18 years; no other known rheumatic disease (connective tissue diseases, rheumatoid, psoriatic arthritis, spondyloarthritis, hand osteoarthritis, gout, chondrocalcinosis); no psoriasis, no inflammatory bowel diseases. Patients were evaluated clinically (44-tender and 44-swollen joint count), and answered health assessment questionnaires (HAQ). Hand, wrist, feet X-ray and laboratory tests including anti-citrullinated protein antibodies (ACPA), rheumatoid factor (RF) and C-reactive protein (CRP) were performed in all patients. US assessments were performed blinded to clinical and laboratory data. FEP was assessed in longitudinal and in transverse view at all metacarpophalangeal (MCP) joints

and proximal phalangeal joints, both in grey-scale and Doppler mode. FEP was defined as abnormal anechoic and/or hypoechoic (relative to tendon fibers) paratenon widening seen in two perpendiculars planes and was scored as present/absent.

Results: One hundred and four consecutive ERA patients and 44 asymptomatic subjects were included in this study. Mean age and comparable gender distribution were observed between the groups (50.1±1.3 y, ERA *vs*. 45.8±2.0 y, asymptomatic subjects). ACPA were present in 63.5%, RF in 62.5%, tobacco use in 22.1% and x-ray bone erosions in 33.7% of ERA patients. Age, gender, delay between the first symptom and diagnosis, SDAI, CDAI, CRP level, HAQ did not differ significantly between patients with FEP involvement and those without. FEP was present in two-third of ERA patients and absent in asymptomatic subjects (60.6% vs. 0%, p< 0.001). In univariate analysis, the presence of FEP was significantly associated with the presence of MCP erosion (p=0.02), ACPA positivity (p=0.017), rheumatoid factor (p=0.009) and tobacco use (p=0.015). In multivariate analysis, the presence of FEP was significantly associated with the presence of MCP erosions, ACPA positivity and tobacco use (p< 0.01).

Conclusion: FEP is relatively frequent in ERA patients and it is not present in asymptomatic subjects. Our results show that FEP is associated with ACPA positivity and bone erosions, thus identifying patients early with a possibly more aggressive or severe disease.

SESSION INFORMATION

Session Date: Saturday, November 6, 2021

Session Title: Imaging of Rheumatic Diseases Poster (0149–0182)

Session Type: Poster Session A

Session Time: 8:30AM–10:30AM

Background/Purpose: The clinical decision-making process in pediatric arthritis lacks an objective, reliable bedside imaging tool. Musculoskeletal ultrasound (MSUS) is increasingly being utilized in children. In order to provide objective assessments of arthritis, reliable scoring systems are needed. Recently, a joint-specific scoring system for the assessment of arthritis of the pediatric elbow, wrist and finger joints were proposed[1]. These scoring systems have excellent reliability when used by experienced ultrasonographers (>7 years of experience). This study aims to assess

Table 1. Inter-rater Reliability Exercise for the Pediatric Elbow, Wrist and Finger Joints

		B-Mode ICC (95% CI)	Power Doppler ICC (95% CI)
Elbow	Anterior recess	0.97 (0.96-0.98)	0.89 (0.84-0.92)
	Posterior Recess	0.96 (0.94-0.97)	0.90 (0.86-0.92)
Wrist	Distal Radioulnar Joint	0.94 (0.92-0.96)	0.96 (0.94-0.97)
	Dorsal Midline Recess	0.93 (0.91-0.94)	0.97 (0.96-0.98)
	Dorsal Ulnar Recess	0.87 (0.81-0.93)	0.83 (0.61-0.91)
	Tendon	0.89 (0.83-0.92)	0.78 (0.66-0.86)
Finger	MCP Dorsal	0.93 (0.91-0.97)	0.97 (0.96-0.98)
	MCP Volar	0.93 (0.91-0.94)	0.85 (0.81-0.88)
	PIP Volar Long	0.96 (0.95-0.97)	0.87 (0.84-0.90)
	PIP Dorsal Long	0.96 (0.94-0.97)	0.95 (0.93-0.97)

Intraclass correlation coefficient (ICC) was based on a two-way random effects model for a single measure. Excellent ICC was defined to be between 0.75-1.00, good 0.60-0.74, fair 0.40-0.59 and poor <0.4. CI: confidence interval. MCP: metacarpophalangeal joint, PIP: proximal interphalangeal joint.

the reliability of a B-Mode and Power Doppler (PD) scoring system for arthritis in the pediatric elbow, wrist and finger when used by sonographers with different levels of expertise.

Methods: As part of the Childhood Arthritis and Rheumatology Research Alliance (CARRA) MSUS workgroup, a 2-hour training session and calibration exercise for each target joint was completed. Subsequently, B-mode and PD scoring exercises of still-images for each targeted joint were performed. Agreement between raters was determined using two-way single score intra-class correlation coefficients (ICC).

Results: 17 pediatric rheumatologists with different levels of ultrasound expertise (1 – 15 years) completed a 2-hour training session and calibration exercise for each targeted joint. Table 1 shows the inter-rater reliability obtained after the scoring exercise was completed for each joint. In general, there was excellent agreement for all B-mode views of the elbow, wrist, and finger joints. The reliability for PD views was excellent for the elbow and finger but was good for the dorsal ulnar recess and tendon views.

Conclusion: This effort identified the need for further training in PD settings and its scoring system(s). A training exercise and calibration exercise addressing the identified needs is ongoing. A novel BM and PD scoring systems for assessing arthritis of the pediatric elbow, wrist and finger joints were shown to have excellent reliability among pediatric MSUS sonographers with different levels of expertise. This reliable joint-specific scoring system for pediatric arthritis could serve as a clinical tool and outcome measure for scientific purposes with further refinement and validation.

SESSION INFORMATION

Session Date: Saturday, November 6, 2021

Session Title: Imaging of Rheumatic Diseases Poster (0149–0182)

Session Type: Poster Session A

Session Time: 8:30AM–10:30AM

Background/Purpose: Rheumatoid arthritis (RA) is a common chronic autoimmune disease characterized by inflammation of the synovium, leading to joint space narrowing and osseous erosions. The most widely used method for quantifying joint damage is the visual inspection of radiographic images by highly trained readers. This subjective, time-consuming, non-scalable method is an impediment to research on factors associated with RA joint damage and lack of quantitative information on progression of damage may delay appropriate treatment decisions by clinicians. To develop a rapid, automated scoring method and perform a rigorous and unbiased evaluation of method performance, we designed the RA2-DREAM Challenge, a crowdsourced competition to engage the international community of problem solvers (http://www.synapse.org/ra2).

Methods: We provided Challenge participants with 674 sets of radiographic images (hands/wrists and feet) and expert-curated modified Sharp/van der Heijde (SvH) scores on 562 unique patients from two completed NIH supported clinical studies, CLEAR and TETRAD. The data for participants were divided into three subsets: training (367 sets of images and corresponding scores), leaderboard (119 sets of images, no scores), and test datasets (188 sets of images, no scores). Challenge participants submitted containerized methods to automatically score overall RA-related damage (Sub-challenge 1), joint space narrowing (Sub-challenge 2), and erosions (Sub-challenge 3). Participants were allowed multiple submissions during the training phase, up to three submissions during the leaderboard phase, and one final submission. Submitted models were evaluated using a model-to-data framework against the manually curated scores using the weighted root mean square error (RMSE). To determine the overall performance, we ranked each team according to their RMSE, determined the robustness of the ranking by bootstrapping the predictions, and evaluated using the Bayes factor.

Results: We received 189 valid submissions from 26 teams in this open science competition. From the 16 final submissions, four teams were named top performers across the three Sub-challenges. Winning algorithms used various approaches, including joint segmentation annotation, deep learning neural networks (e.g. YOLO, RCNN, ResNet, XGBoost), regression modeling, and ensembled methods. In addition, the submitted models were validated using a set of 50 additional patient images from an independent study, the TEAR Trial. These validation analyses revealed results similar to those of the original Challenge. All submitted models were containerized to aid in the goal of producing a rigorous and reproducible scoring methodology.

Conclusion: After further validation, algorithms from this Challenge may provide feasible, accurate, and quick methods to quantify joint damage in RA. These and other artificial intelligence approaches may be applied to radiographic images from electronic health records to quantitate radiographic damage in RA, providing many datasets for research on factors influencing damage. Automated scoring of damage in RA may also help rheumatology health professionals to make prompt treatment decisions to improve patient outcomes.

Ultrasonography of Auricular Cartilage Is a Useful Tool for Diagnosing and Monitoring Disease Activity in Relapsing Polychondritis

Yoshinori Taniguchi[1], Hirofumi Nishikawa[2], Takeshi Yoshida[3], Satoshi Inotani[4] and Yoshio Terada[2], [1]Department of Endocrinology, Metabolism and Nephrology, Kochi Medical School, Nankoku, Japan, [2]Kochi Medical School Hospital, Nankoku, Japan, [3]Chikamori Hospital, Kochi, Japan, [4]Kochi Medical School Hospital, Kochi-city, Japan

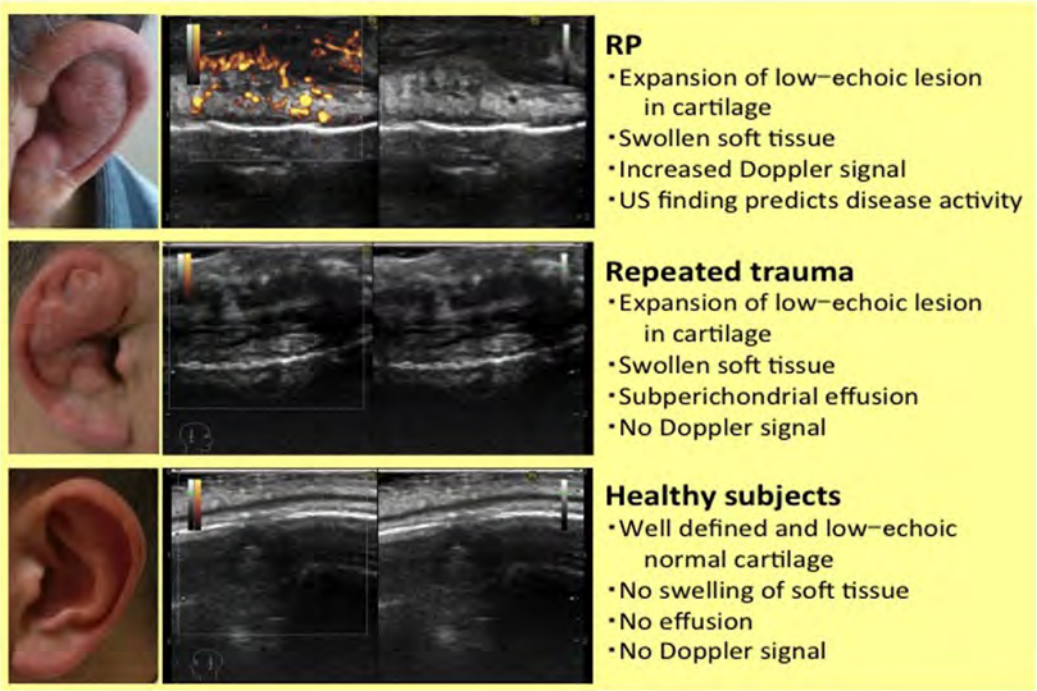
SESSION INFORMATION
Session Date: Saturday, November 6, 2021
Session Title: Imaging of Rheumatic Diseases Poster (0149–0182)
Session Type: Poster Session A
Session Time: 8:30AM–10:30AM

Background/Purpose: In patients with atypical clinical symptoms or imaging findings, because there are no specific and easily measurable markers for RP serologically, it is often difficult to diagnose RP and detect RP flare earlier. Although previous studies have reported the usefulness of imaging tests such as contrast-enhanced CT, MRI, FDG-PET/CT and bone scintigraphy for diagnosis and assessment of disease activity, performing these imaging tests frequently is not realistic without careful consideration of cost, convenience, invasiveness and radiation exposure. Therefore, it is necessary to establish a more convenient and less invasive imaging modality that can be repeatedly used for diagnosis and evaluation of disease activity.

Objective: To assess the clinical utility of ultrasonography (US) in the diagnosis and monitoring of disease activity in relapsing polychondritis (RP).

Methods: Auricular and nasal chondritis of patients with RP (n = 6) were assessed by US before treatment initiation. Changes in the US findings as well as clinical findings and serum inflammatory markers were longitudinally assessed. We also performed US in patients with repeated ear trauma (n = 6), auricular cellulitis (n = 2), and healthy subjects (n = 6) and compared among groups.

Results: In all cases of RP, US finding before treatment showed low-echoic swollen auricular and nasal cartilage with increased Power Doppler signals (PDS), corresponding to biopsy findings. After treatment with prednisolone (PSL) combined with methotrexate, the clinical and serum inflammatory markers were completely resolved. Although perichondrial swelling and PDS on auricular US were also significantly improved, PDS remained in 2 of 6 cases, and these cases showed flare early after tapering PSL. Finally, US findings of RP were substantially differentiated from patients



with repeated trauma and cellulitis and healthy subjects due to the thickness of soft tissue around the cartilage, PDS and subperichondrial serous effusion.

Conclusion: Assessment of RP lesions by US was useful for the evaluation of cartilaginous lesions and monitoring of disease activity, especially when considering the treatment response and the timing of drug tapering.

Direct and Conditional Effects of Epicardial Adipose Tissue Volume on Coronary Plaque Progression in Rheumatoid Arthritis

George Karpouzas[1], sarah ormseth[2], Elizabeth Hernandez[2] and Matthew Budoff[3], [1]Harbor-UCLA Medical Center, Torrance, CA, [2]The Lundquist Institute, Harbor-UCLA Medical Center, Torrance, CA, [3]Division of Cardiology, and the Lundquist Institute ay Harbor-UCLA Medical Center, Torrance, CA

SESSION INFORMATION

Session Date: Saturday, November 6, 2021

Session Title: Imaging of Rheumatic Diseases Poster (0149–0182)

Session Type: Poster Session A

Session Time: 8:30AM–10:30AM

Background/Purpose: Epicardial adipose tissue volume (EATv) predicts coronary atherosclerosis presence, progression and cardiovascular events in general patients. We recently reported that EATv associated with greater subclinical coronary plaque burden, noncalcified plaque presence and vulnerable plaque characteristics in patients with rheumatoid arthritis (RA). The relationship was stronger in patients without traditional cardiac risk factors, who were not obese and had lower disease duration. We here evaluate the role of EATv on long-term coronary plaque progression and moderators of the association between EATv and plaque formation.

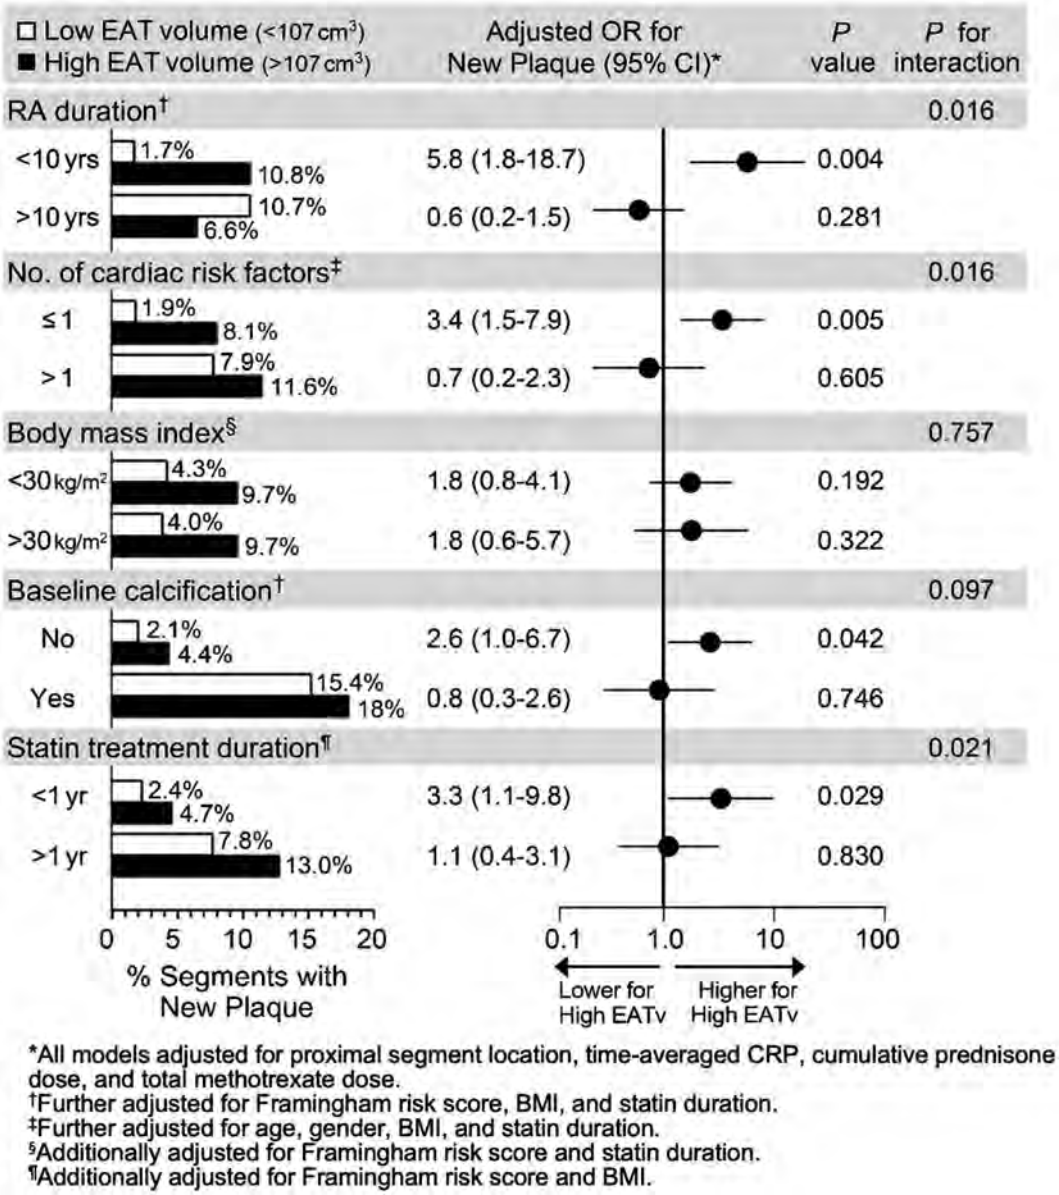

Figure 1. Moderators of influence of EATv on new coronary plaque formation at follow-up.

Methods: This single center observational cohort study included 100 patients without cardiovascular disease who underwent computed tomography angiography for evaluation of EATv and coronary atherosclerosis at baseline and 6.9±0.3 years later, to evaluate plaque progression. New plaque formation in segments without plaque at baseline was the main outcome. Robust multivariable logistic regression evaluated the effect of high versus low EATv (based on median) on likelihood of new plaque formation, accounting for clustering of segments within patients. Potential moderator effects of prespecified predictors were also assessed.

Results: High EATv (>107 cm^3) predicted new plaque formation in segments without baseline plaque (OR 2.77 [95% CI 1.43-5.37], p= 0.003); however, significance was lost in the multivariable model. Importantly, high EATv associated with formation of higher-risk noncalcified and partially calcified plaque after adjusting for Framingham D'Agostino risk score, obesity, segment location, time-averaged CRP, duration of bDMARD and statin treatment and cumulative prednisone dose (adjusted OR 2.57 [95% CI 1.02-6.48], p= 0.045). RA duration (< 10 versus >10 years), cardiac risk factor burden (1 versus >1), presence of partially/ fully calcified plaque in other coronary segments at baseline, and statin exposure (1 versus >1 year, based on median) moderated the effect of EATv on all new plaque formation (all p

for interaction 0.021). Specifically, high EATv predicted new plaque formation in patients with RA duration < 10 years (adjusted OR 5.75 [95% CI 1.77-18.67]), those with 1 cardiac risk factors (adjusted OR 3.40 [95% CI 1.46-7.90]), those without calcification at baseline (adjusted OR 2.65 [95% CI 1.11-6.31]) and those with statin treatment < 1 year (adjusted OR 3.33 [95% CI 1.13-9.77]). This was not the case for patients with RA >10 years, 1 cardiac risk factors, calcification at baseline and statin treatment >1 year (figure 1).

Conclusion: High baseline EATv independently predicted future higher-risk non- and partially calcified coronary plaque in RA. Moreover, it conditionally promoted new plaque formation overall in patients with earlier disease, low cardiac risk factor burden, who had little or no atherosclerosis at baseline and who had limited exposure to statins. These findings indicate the need for a larger prospective evaluation of the role of EATv as a biomarker of coronary atherosclerosis development in RA.

Bone Erosions and Osteophytes in Premenopausal Women with Long-standing Rheumatoid Arthritis: Association with Systemic Bone Involvement Using HR-pQCT

Mariana Perez[1], Camille Figueiredo[1], Lucas Sales[1], ANA MEDEIROS-RIBEIRO[1], Liliam Takayama[1], Diogo Domiciano[1], Karina Bonfiglioli[1], Valeria Caparbo[1] and Rosa Pereira[2], [1]Rheumatology Division, University of São Paulo, São Paulo, SP, Brazil, [2]Rheumatology Division, University of São Paulo, São Paulo, Brazil

SESSION INFORMATION
Session Date: Saturday, November 6, 2021
Session Title: Imaging of Rheumatic Diseases Poster (0149–0182)
Session Type: Poster Session A
Session Time: 8:30AM–10:30AM

Background/Purpose: Two patterns of bone involvement are described in rheumatoid arthritis (RA), systemic and localized. Systemic bone involvement is characterized by loss of generalized bone mass, osteoporosis and risk of fractures, and the localized by periarticular osteopenia, cysts and bone erosions. High-resolution peripheral quantitative computed tomography (HR-pQCT) is an imaging methodology capable of assessing volumetric bone mineral density (vBMD) and bone microarchitecture at the distal tibia and radius, as periarticular bone lesion, catabolic (erosion) and anabolic (osteophytes) in arthropathies inflammatory. The purpose of this study is to evaluate premenopausal women with long-standing RA and to explore the relationship between parameters of systemic and localized bone involvement.

Methods: Eighty consecutive RA premenopausal women were evaluated. Volumetric bone mineral density, microarchitecture and finite element analysis were performed using HR-pQCT at the distal radius and tibia and compared with parameters from 160 female healthy controls matched by age and body mass index. Localized bone involvement was also analyzed using HR-pQCT in the metacarpophalangeal and proximal interphalangeal joints to identify erosions and osteophytes.

Results: The mean age of RA patients was 39.4 ± 6.7 years and disease duration 9.8 ± 5.3 years. RA patients had impaired trabecular, cortical and bone strength parameters, at the distal radius and tibia, compared with healthy controls ($p < 0.05$). Bone erosions and osteophytes were found in 75% and 41.3% of patients, respectively. Comparing patients with and without erosions, at the distal radius and tibia, a lower cortical vBMD (radius: 980 ± 72 versus 1021

± 47mgHA/cm^3, p=0.03; tibia: 979 ± 47 versus 1003 ± 34 mgHA/cm^3, p=0.04) and higher cortical porosity (radius: 2.8 ± 2.5 versus 1.8 ± 1.6%, p=0.04; and tibia: 3.7 ± 1.6 versus 2.7 ± 1.6%, p=0.01) were observed in patients with erosions. At the distal radius, osteophyte volume was positively correlated with trabecular vBMD (0.392, p=0.02), trabecular number (0.381, p=0.03) and stiffness (0.411, p=0.02), and negatively with trabecular separation (-0.364, p=0.04).

Conclusion: This study showed that premenopausal women with long-standing RA had systemic bone fragility at peripheral sites. Moreover, erosions were associated mainly with cortical bone fragility at the distal radius and tibia, and osteophytes correlated with repair of trabecular bone at the radius.

Session Title: Imaging of Rheumatic Diseases Poster (0149–0182)

Session Type: Poster Session A

Session Time: 8:30AM–10:30AM

Background/Purpose: Imaging has been extensively used for the diagnosis of Calcium Pyrophosphate Deposition Disease (CPPD) but the exact prevalence of joint calcifications at imaging in patients with CPPD has not been thoroughly assessed.

This systematic literature review (SLR) is aimed to estimate the prevalence of calcium crystal deposition in peripheral joints by imaging in suspected or definite CPPD patients to establish relevant joints for CPPD monitoring.

Methods: After defining PICOs, Pubmed and Embase were searched from inception to October 2020 for identifying studies that evaluated the application of Conventional Radiography (CR), Ultrasound (US), Computed Tomography (CT) and Dual Energy Computed Tomography (DECT) in detecting calcifications at peripheral joints in patients with defined or probable CPPD diagnosis. Search strategies based on Mesh terms and free text were applied. Six reviewers independently screened the articles. In a first step, the evaluation was based only on titles and abstracts and

then, the eligible articles were evaluated in full text for inclusion and data extraction. Prespecified criteria were used for including or excluding the articles.

Results: The SLR identified 1826 manuscripts. 543 papers entered in the full text evaluation and 162 articles were finally included. Regarding the first phase, were excluded 954 abstracts, 352 as duplicate, 156 for the language, 47 for the study type, 171 for the population, 171 for the intervention and 57 for the outcome. During the full text evaluation, were excluded 49 for the unavailability of the full text, 18 as duplicate, 8 for the language, 113 for the study type, 48 for the population, 19 for the intervention and 126 for the outcome. Among included, 36 papers considered patients with definite CPPD with a total population of 1530 patients, 977 cases and 533 controls and 126 papers referred to patients with suspected CPPD with a total population of 30569 patients, 3125 affected by CPPD and 27444 controls.

The results about each joint included are summarized in the table attached (since the low number of studies that evaluated CT and DECT, respectively 7 and 1, the data are not shown). In patients with definite diagnosis, knee and wrist are the joints with the higher prevalence of calcifications at both XR and US, followed by the hip, while in patients with suspected CPPD, the knee is the most prevalent followed by the wrist, hip and shoulder (only sites with more than 50 patients assessed considered). The hand joints have the lowest prevalence of CPPD at imaging. The presence of bilateral imaging findings varies depending on the technique used, the site and the type of patient.

Confirmed CPPD Diagnosis

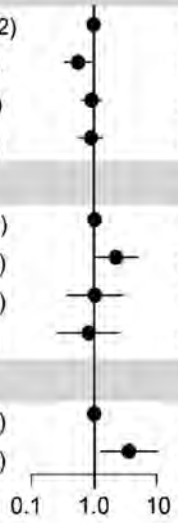
Session Title: Imaging of Rheumatic Diseases Poster (0149–0182)
Session Type: Poster Session A
Session Time: 8:30AM–10:30AM

Background/Purpose: The relationship between serum lipoproteins and cardiovascular (CV) disease risk in rheumatoid arthritis (RA) is complex. Their levels and function may vary based on disease activity and medication use. Treatment benefits on high-density lipoprotein (HDL) levels, structure and behavior, in response to treatment have been described. Yet, the impact of HDL-C levels over time on coronary atherosclerosis progression in RA is unknown. We here evaluated the influence of HDL-C levels over time on long-term coronary plaque formation and progression in RA.

Methods: One hundred one patients without CV disease who underwent computed tomography angiography study of coronary atherosclerosis had repeat assessments after 6.9±0.3 years to evaluate plaque progression. Clinical, laboratory and medication data were captured at baseline and throughout follow-up. Robust logistic regression assessed associations between time-averaged HDL-C and likelihood of new plaque formation in segments without plaque at baseline, and transition of partially calcified to fully calcified plaque. Robust multinomial logistic regression evaluated effects of time-averaged HDL-C on likelihood of new noncalcified, partially or fully calcified plaque in segments without plaque (compared to remaining without plaque), and noncalcified plaque regression or transition to partially or fully calcified plaque (compared to remaining noncalcified). Models accounted for clustering of segments within patients and adjusted for Framingham CV risk score, segment location, time-averaged CRP, prednisone dose, bDMARD and statin duration, obesity, and time-averaged triglycerides.

Outcome	No. of coronary segments (%)	Adjusted OR (95% CI) per 1-SD increment in time-averaged HDL*	*P* value
New plaque formation			
None to none	1331 (93.2)	1.00 (reference)	—
None to non-calcified	20 (1.4)	0.56 (0.35-0.92)	0.021
None to mixed	21 (1.5)	0.93 (0.65-1.33)	0.678
None to calcified	56 (3.9)	0.91 (0.59-1.41)	0.673
Non-calcified plaque transition			
Non-calcified to non-calcified	42 (42.9)	1.00 (reference)	—
Non-calcified to none	32 (32.7)	2.21 (1.02-4.83)	0.045
Non-calcified to mixed	16 (16.3)	1.02 (0.37-2.87)	0.961
Non-calcified to calcified	8 (8.2)	0.81 (0.26-2.51)	0.712
Mixed plaque progression			
Mixed to mixed	36 (69.2)	1.00 (reference)	—
Mixed to calcified	16 (30.8)	3.56 (1.25-10.17)	0.018



*Adjusted for Framingham D'Agostino cardiac risk score, proximal segment location, time-averaged CRP, biologic DMARD treatment duration, statin treatment duration, cumulative prednisone dose, waist-to-height ratio, and time-averaged triglycerides.

Figure 1. Impact of HDL-C over time on coronary plaque progression in RA.

Results: Participants were mostly female (n=87, 86.1%), 51.5±10.3 years old and time-averaged HDL-C was 51.7±13.9. Ninety-seven new plaques formed in segments without baseline plaque; 20 were noncalcified, 21 partially, and 56 were fully calcified. Time-averaged HDL-C had no effect on new total plaque formation (adjusted OR 0.88 [95% CI 0.64-1.21]). However, each SD increase in time-averaged HDL-C associated with a 44% lower chance of new noncalcified plaque (adjusted OR 0.56 [95% CI 0.35-0.92], Figure 1); no effect on incident partially or fully calcified plaque was observed. Of 98 noncalcified plaques at baseline, 42 remained unchanged, 32 regressed, 16 transitioned to partially and 8 to fully calcified plaques. Each SD increase in time-averaged HDL-C yielded a 2.2-fold greater chance of noncalcified plaque regression (adjusted OR 2.21 [95% CI 1.02-4.83]). Sixteen of 52 partially calcified plaques transitioned to fully calcified lesions; each SD increment in time-averaged HDL-C) predicted 3.5-fold greater odds of transition of partially to fully calcified plaque (adjusted OR 3.56 [95% CI 1.25-10.17]).

Conclusion: Higher HDL-C over time predicted regression of existing and decreased formation of new higher-risk noncalcified plaque. It also associated with transition of partially calcified to more stable fully calcified plaque. All effects were independent of RA treatment duration, prednisone dose and statin exposure.

Abstract Number: 0174

Imaging Neoangiogenesis in Rheumatoid Arthritis II (INIRA II): Whole-body Synovial Uptake of ^{99m}Tc-Maraciclatide Correlates with Power Doppler Ultrasound and Serum Neoangiogenic Biomarkers

Laura Attipoe[1], Sujith Subesinghe[2], Cristina Blanco Gil[2], Maria Opena[2], Kathryn Steel[3], Sarah Ryan[3], Sam Norton[3], Mark Rosser[4], Gary Cook[3], Andrew P Cope[3] and Toby Garrood[2], [1]Guy's and St Thomas' NHS Foundation Trust, London, United Kingdom, [2]Guy's and St Thomas' NHS Foundation Trust, London, [3]King's College London, London, United Kingdom, [4]Serac Healthcare, London, United Kingdom

SESSION INFORMATION

Session Date: Saturday, November 6, 2021

Session Title: Imaging of Rheumatic Diseases Poster (0149–0182)

Session Type: Poster Session A

Session Time: 8:30AM–10:30AM

Background/Purpose: ^{99m}Tc-maraciclatide (^{99m}Tc-M) (Serac Healthcare) is a radio-labelled tracer which binds with high affinity to integrin $\alpha_v\beta_3$, a cell-adhesion molecule up-regulated on neoangiogenic blood vessels. It therefore has the potential to image synovial inflammation at the whole-body level.

Our group has previously published interim results showing that ^{99m}Tc-M uptake correlated with power Doppler ultrasound (PDUS) in 25 patients with rheumatoid arthritis (RA)[1]. This study now explores correlation with PDUS and serum biomarkers in a larger group of patients.

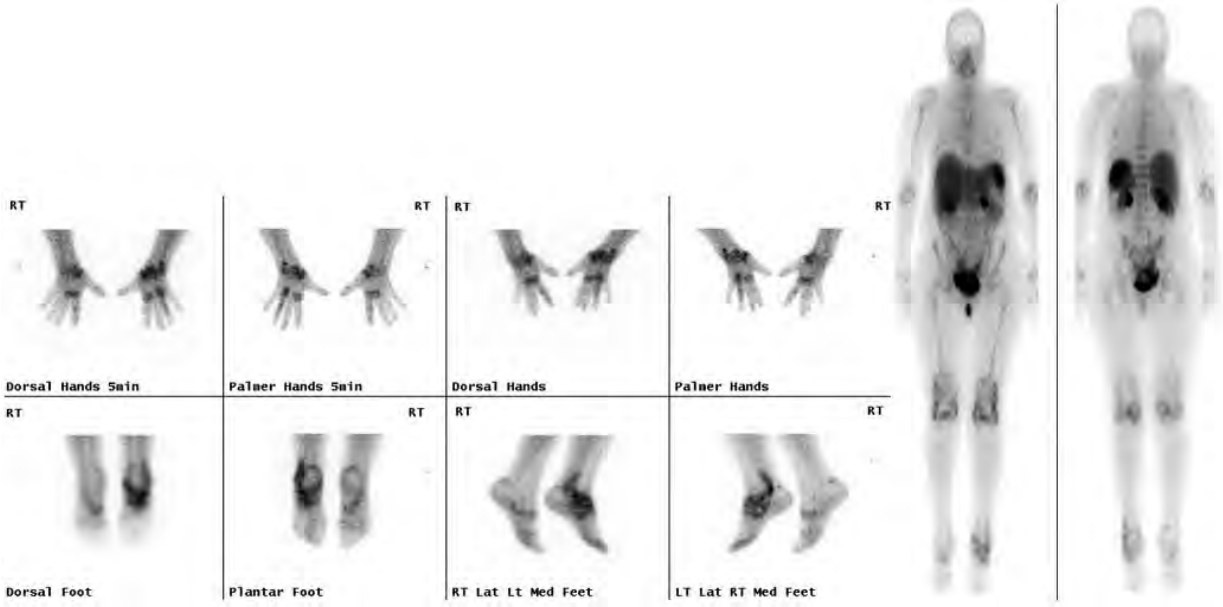

Figure 1: 99mTc-maraciclatide whole body anterior and posterior images; dorsal, palmer, and oblique hand images; and dorsal, plantar, and medial/lateral foot images
Images of a patient with DAS28-CRP of 7.09 showing uptake to the left ring finger flexor and left peroneal tendons, and left PIP4, left MCP2/3, right PIP2, right MCP2/4, bilateral wrist, bilateral elbow, bilateral knee, left ankle, and right mid foot joints

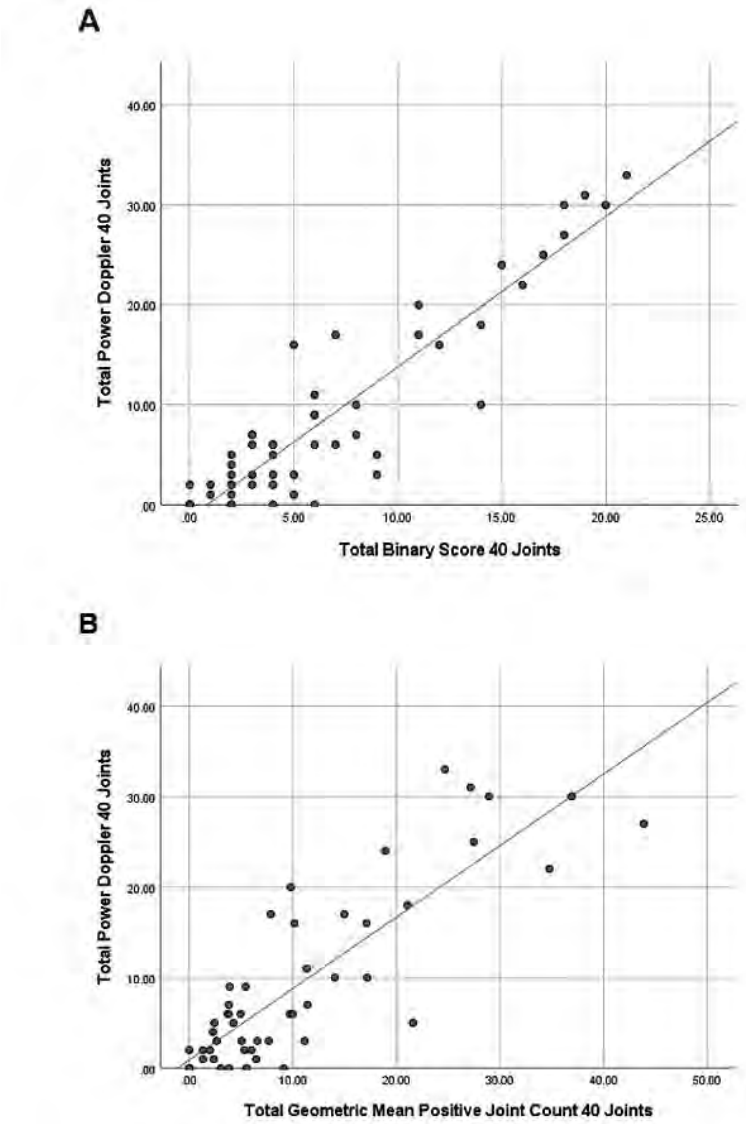

Figure 2 Correlation between Power Doppler Ultrasound and ^{99m}Tc-maraciclatide uptake
A – Total Power Doppler Ultrasound vs Total Binary Score of 40 Joints, r = 0.90, r^2 = 0.82
B – Total Power Doppler Ultrasound vs Total Geometric Mean of 40 Joints, r = 0.85, r^2 = 0.72

Methods: 50 patients with RA (mean disease duration 12.8 (SD 8.2, 1-35 range) years, mean DAS28-CRP 4.8 (1.2, 1.9-7.1)) fulfilling ACR 2010 classification criteria were recruited. Patients had an ultrasound scan of 40 joints. Each joint was scored on a scale of 0-3 for greyscale and PD with a total score calculated per patient.

Within 3 hours patients were injected with 740 MBq of ^{99m}Tc-M. Whole body planar views, and static hand and foot views were taken 2 hours after injection. Acquisition time was 20 minutes for whole body and 20 minutes for hand and foot views. ^{99m}Tc-M images were scored as positive or negative uptake for each joint (binary score). A quantitative (geometric mean, GM) score was calculated for each joint where there was uptake with this corrected for background uptake. Total binary and GM scores per patient were calculated.

Sera was taken from each patient on the day of imaging with analysis of 24 biomarkers via multiplex bead assay.

Total PDUS and ^{99m}Tc-M scores were tested for correlation using Pearson's coefficient of determination (r^2). Spearman's rank correlation (r_s) was used to evaluate correlation between serum biomarkers and imaging modalities. Significance was set at $p< 0.05$.

Results: ^{99m}Tc-M uptake was clear on visual assessment of small and large joints (Figure 1). Strong correlation was observed when total PDUS was compared to total binary ($r^2 = 0.82$, Figure 2) as compared to total GM ^{99m}Tc-M scores ($r^2 = 0.72$). Total GSUS scores also correlated with total binary ($r^2 = 0.74$) and total GM ^{99m}Tc-M scores ($r^2 = 0.60$). p was < 0.001 for all values.

There was substantial inter-assessor agreement with a kappa of 0.79 for PDUS, and 0.82 for ^{99m}Tc-M scan binary scoring respectively. Concordance correlation coefficient was strong at 0.82 for GM scoring.

^{99m}Tc-M uptake at a single joint level had a sensitivity of 78% (95% CI 73-83), specificity of 91% (89-92), positive predictive value (PPV) of 57% (53-61), and negative predictive value (NPV) of 96% (95-97). When assessing small joints alone, sensitivity was 78% (95% CI 72-83), specificity was 94% (93-96), PPV was 72% (67-77), and NPV was 96% (95-97).

There was moderate correlation between MMP3 and total binary ($r_s = 0.44$, $p = 0.002$), and GM ($r_s = 0.52$, $p = 0.001$) scores. There was statistically significant weak correlation between VEGF, IL6, YKL40, IL8 and both imaging modalities (Table 1).

Conclusion: ^{99m}Tc-M uptake is highly correlated with PDUS, and weakly to moderately correlated with serum biomarkers highlighting its potential as an alternative imaging modality that captures total synovial inflammatory load. Recruitment is underway to expand the data to a larger group of patients.

Table 1: Spearman's rank correlation (r_s, p value)

	Power Doppler	Binary Score	Geometric Mean	VEGF	IL-6	MMP-3	YKL-40	IL-8
Power Doppler	X							
Binary Score	0.825 p = 0.001	X						
Geometric Mean	0.734 p = 0.001	0.880 p = 0.001	X					
VEGF	0.368 p = 0.009	0.258 p = 0.074	0.267 p = 0.063	X				
IL-6	0.275 p = 0.05	0.362 p = 0.010	0.390 p = 0.005	0.035 p = 0.809	X

Abstract Number: 0175

Correlation of Subclinical Synovitis with Juvenile Idiopathic Arthritis Outcome Measurements

Patricia Vega-Fernandez[1], Edward Oberle[2], Michael Henrickson[1], Jennifer Huggins[1], Mekibib Altaye[3], Amy Cassedy[4], Johannes Roth[5] and Tracy Ting[1], [1]Cincinnati Children's Hospital Medical Center, Cincinnati, OH, [2]Nationwide Children's Hospital, Columbus, OH, [3]Cincinnati Children's Hospital, Cincinnati, OH, [4]Cincinnati Children's Hospital and Medical Center, Cincinnati, OH, [5]University of Ottawa, Ottawa, ON, Canada

SESSION INFORMATION
Session Date: Saturday, November 6, 2021
Session Title: Imaging of Rheumatic Diseases Poster (0149–0182)
Session Type: Poster Session A
Session Time: 8:30AM–10:30AM

Background/Purpose: Juvenile Idiopathic Arthritis (JIA) is the most common rheumatologic disease of childhood. Active joint count (AJC) is one of the key JIA Core Set variables. However, AJC is a subjective measurement with poor-to-moderate inter-rater agreement. Musculoskeletal Ultrasound (MSUS) is a radiation-free, objective imaging tool currently being used to assess joint inflammation. A novel joint-specific MSUS scoring system for JIA was recently proposed[1]. The aims of this study are: 1. Determine the frequency of subclinical synovitis as per MSUS in all peripheral joints in JIA, 2. Correlate AJC as determined by expert clinician physical examination with moderate to severe MSUS synovitis, 3. Examine the correlation between MSUS synovitis and Juvenile Arthritis Disease Activity Score (JADAS) and patient-reported outcomes

Methods: Data obtained from a previously described study looking to determine the key joints to perform a MSUS examination in JIA[1] was used for the current analysis. Briefly, JIA patients presenting with an AJC >4 and able to perform MSUS within 1 week of starting a Disease-modifying Antirheumatic Drug were eligible for this study. Clinical data including physician global assessment (PhGA), patient global assessment (PGA), patient pain visual analogue scale (VAS) and the Child Health Assessment Questionnaire (CHAQ) were obtained. A comprehensive AJC examination and a 42 joint MSUS examination by an American College of Rheumatology MSUS certified pediatric rheumatologist were performed at baseline and at 3 months. Gray-scale B mode and Power Doppler (PD) images were obtained for each view. Images were scored following a semiquantitative scoring system ranging from 0-normal to 3-severe. Subclinical synovitis was defined as grade 2 and 3 synovitis appreciated by MSUS only. Clinical-JADAS 10 (cJADAS-10) was calculated by the addition of PhGA, PGA, and AJC up to 10 joints. Pearson correlation was used to assess the correlation between AJC and subclinical synovitis. Spearman's correlation coefficients were calculated to determine the association between MSUS synovitis, cJADAS-10 and patient-reported outcomes

Results: A total of 30 patients were enrolled. Table 1 shows the frequency of subclinical synovitis per joint. In general, MSUS detects moderate to severe synovitis in about 25% of the joints determined as normal by physical exam.

Table 1. Frequency of Subclinical Synovitis in Peripheral Joints

Baseline visit *				
	Joint with arthritis by PE *only* (%)	**Joint with arthritis by MSUS *only* (%)**	**Joint with arthritis *on both* PE and MSUS (%)**	**Joint with arthritis by PE *and/or* MSUS (%)**
PIP (n=300)	19 (6.3)	104 (34.7)	75 (25)	198 (66)
MCP (n=300)	20 (6.7)	117 (39)	64 (21.3)	201 (67)
Wrist (n=60)	7 (11.7)	11 (18.3)	32 (53.3)	50 (83.3)
Elbow (n=60)	9 (15)	18 (30)	12 (20)	39 (65)
Shoulder (n=60)	5 (8.3)	13 (21.7)	3 (5)	21 (35)
Hip (n=60)	7 (11.7)	9 (15)	1 (1.7)	17 (28.3)
Knee (n=60)	2 (3.3)	15 (25)	27 (45)	44 (73.3)
Ankle (n=60)	10 (16.7)	16 (26.7)	25 (41.7)	51 (85)
Toes (n=300)	21 (7)	97 (32.3)	10 (3.3)	128 (42.7)
Follow-up visit**				
	Joint with arthritis by PE *only* (%)	**Joint with arthritis by MSUS *only* (%)**	**Joint with arthritis on *both* PE and MSUS (%)**	**Joint with arthritis by PE *and/or* MSUS (%)**
PIP (n=290)	35 (12.1)	67 (23.1)	69 (23.8)	171 (59)
MCP (n=290)	25 (8.6)	73 (25.2)	54 (18.6)	152 (52.4)
Wrist (n=58)	9 (15.5)	13 (22.4)	22 (37.9)	44 (75.9)
Elbow (n=58)	5 (8.6)	20 (34.5)	10 (17.2)	35 (60.3)
Shoulder (n=58)	3 (5.2)	13 (22.4)	2 (3.5)	18 (31)
Hip (n=58)	4 (6.9)	4 (6.9)	0 (0)	8 (13.8)
Knee (n=58)	2 (3.5)	17 (29.3)	12 (20.7)	31 (53.5)
Ankle (n=58)	11 (19)	13 (22.4)	17 (29.3)	41 (70.7)
Toes (n=290)	21 (7.2)	77 (26.6)	11 (3.8)	109 (37.6)

*n = 30 participants ** n= 29 participants. PIP: proximal interphalangeal joint, MCP: metacarpal phalangeal joint. PE: physical examination, MSUS: musculoskeletal ultrasound

Except for the knee where the correlation between MSUS synovitis and AJC was moderate, the correlation between MSUS and AJC for all other peripheral joints was slight to fair (Table 2). MSUS synovitis and patient reported outcomes including CHAQ, patient pain VAS and PGA had slight to fair correlation for B-Mode and moderate correlation for PD. Correlation between MSUS and cJADAS-10 was moderate for both B Mode and PD images. (Table 3)

Conclusion: Subclinical synovitis is commonly observed in a cohort of newly diagnosed JIA patients with greatest differences in digits. The fair to moderate correlation of MSUS synovitis with cJADAS-10 and patient-reported outcomes, suggest that MSUS assesses a different, possibly more objective, domain not determined by traditional JIA outcome measurements. MSUS has the potential to support the diagnosis and assessment of JIA

Table 2. Correlation between MSUS and Physical Exam for each Joint Area

	Baseline		Follow up Visit	
	Pearson Correlation[a]	p Value	Pearson Correlation[a]	p Value
PIPs	0.28	<0.001	0.29	<0.001
MCPs	0.2	0.001	0.3	<0.001
Wrist	0.31	0.015	0.23	0.076
Elbow	0.1	0.417	0.18	0.178

Legend: Domain 1 (Total Parenchymal Score); Domain 2 (Total Pulmonary Nodules/Cavitations/Cysts/Masses Score); Domain 3 (Total Pleural and Pericardial Effusions/Pleural Thickness Score); Domain 4 (Pulmonary Hypertension Score); S1 (Radiologist 1); S2(Radiologist 2); S3 (Radiologist 3); IQR (Interquartile Range from 25th to 75th percentile)

Diffuse Lung Disease Score [PRDLDS], Table 1) to assess the prevalence of diffuse lung disease (DLD) assessed by SCT in pediatric rheumatologic patients.

Methods: Three radiologists with varying DLD imaging experience independently scored 1-2 mm inspiratory chest CT scans (96 non-contrast/24 contrast) in 120 pediatric subjects (DG: N=42 PR patients with DLD; DCG: N=34 PR patients without DLD; and NCG: N=44 pediatric normal control subjects with chest CT scans) from 3 medical centers (Children's Hospital of LA, Stanford Children's Health, Mayo Clinic). The SCT scoring system was developed as a modification of the Goldin scoring system[1] for systemic sclerosis adults to account for the full spectrum of DLD findings in PR patients (Table 2). It quantifies the extent of disease for 6 lung zones based on 4 domains: 1) parenchymal domain score (PDS); 2) pulmonary nodule/cavitary/cyst/mass DS; 3) total effusion/pleural thickening DS; and 4) pulmonary hypertension domain score (PHDS).

Results: The overall prevalence of DLD in the disease group based on a cutoff score of ≥ 8 for all lung zones was 68% by the most experienced scorer (S1) in comparison to 41% (S2, S3); the prevalence of total disease was primarily driven by the PDS (74% [S1], 38% [S2, S3] with significant contributions from pure ground glass opacities (GGO) and pure fibrosis (PF) subscores (SS). There was lower disease prevalence noted in domains 2 (7 - 19%), 3 (2 - 5%), and 4 (4 - 23%). Prior DLD scoring experience impacted both the PDS and GGO & PF subscores; radiologist (S1) identified more disease and had greater specificity to discriminate between groups than the more naïve DLD scorers; for S1 scorer: DG - PDS (median 7.0 [IQR:11.5]), GGO SS (median 2.5 [IQR: 5.5]), PF SS (median 4.0 [IQR: 5.00] vs. DCG and NCG both having (median 0.0 [IQR:0.0]). Refer to Table 3.

Conclusion: Semi-quantitative scoring using the PRDLDS is a feasible tool to assess DLD in PR patients. Preliminary data revealed that our PR patients had mild DLD which is primarily contributed by parenchymal disease. Our data demonstrated high inter-rater variability for parenchymal scoring, and problems with PHDS which supports that 1) further training with DLD imaging experts is necessary to improve the reliability and validity of the PRDLDS in quantifying milder lung disease ; 2) non-contrast CTs make it more difficult to evaluate PH accurately; 3) quantitative CT assessment tools are needed to reliably evaluate pulmonary interstitial lung disease in pediatric rheumatologic patients. We are currently evaluating our study cohort with CALIPER (Computer Aided Lung Informatics for Pathology Evaluation and Rating), a quantitative chest CT analyzer that is validated in adults with DLD.

Dual-Energy Computed Tomography Three Material Decomposition Improves the Sensitivity of Gout Detection

Justin Tse[1], Douglas Kondro[2], Yves Pauchard[3], Andrea Veljkovic[4], Viviane Frasson[5], David Holdsworth[6], Sarah Manske[7], Paul MacMullan[8] and Peter Salat[7], [1]UNIVERSITY OF CALGARY, Calgary, AB, Canada, [2]STEMCELL Technologies, Cambridge, United Kingdom, [3]Department of Electrical and Software Engineering, Schulich School of Engineering, Calgary, AB, Canada, [4]University of British Columbia, Department of Orthopaedics, Vancouver, BC, Canada, [5]University of Calgary, Human Performance Lab, Calgary, AB, Canada, [6]University of Western Ontario, Department of Surgery, London, ON, Canada, [7]University of Calgary, Department of Radiology, Calgary, AB, Canada, [8]University of Calgary, Department of Rheumatology, Calgary, AB, Canada

SESSION INFORMATION

Session Date: Saturday, November 6, 2021
Session Title: Imaging of Rheumatic Diseases Poster (0149–0182)
Session Type: Poster Session A
Session Time: 8:30AM–10:30AM

Background/Purpose: Gout, a curable musculoskeletal disease, is characterized by the deposition and accumulation of monosodium urate (MSU) crystals within affected joints. Dual-energy computed tomography (DECT), an x-ray-based imaging technique, can non-destructively and non-invasively detect and localize large MSU depositions (*i.e*. tophi). Two recent advancements have made significant contributions to improve DECT's MSU specificity and sensitivity: (1) software generated virtual pseudo-monochromatic images (VMI); and (2) three-material decomposition (3MD) post-processing algorithms. To our knowledge, no studies have examined the effects of combining these two techniques when applied to MSU. Thus, we propose combining VMI and 3MD to improve DECT's sensitivity to MSU.

Methods: A bone (HA) quality phantom (Quality Assurance in Radiology in Medicine) and in-house MSU phantom were scanned together with a fast-kVp switching (80 and 140 kVp) DECT scan (GE Revolution GSI, GE Healthcare). The HA phantom contained rods of 100, 400, and 800 mgHA. The MSU phantom was created by mixing varying concentrations of MSU with 3% agarose to achieve 0, 0.0344, 0.133, 0.283, and 0.652 g/mL. VMIs at 50 and 65 keV were generated (GE Gemstone Spectral Imaging) and decomposed *via* 3MD (Tse *et al*., 2017) into three tissue volumes: soft tissue, bone, and MSU. Results of 3MD + VMI were compared with manufacturer (GE)-based material decomposition (GEMD) and commonly used dual-thresholding.

Additionally, a participant with gout was scanned with above-mentioned DECT protocol, with their foot resting atop both HA and MSU phantoms. Resulting images were decomposed into tissue-specific images *via* 3MD + VMI and GEMD.

Statistical analysis was performed on mean values acquired from 10 × 10 × 10 voxels placed within identical soft tissue (100% agar), bone (HA phantom), and MSU (MSU phantom) regions-of-interest within each decomposed tissue volume. A statistical significance was noted if $p < 0.05$.

Results: The combination of 3MD + VMI performed equally to the manufacturer's in-house material decomposition (GEMD), and both techniques appeared to perform better than common dual-thresholding at all HA and MSU concentrations (Table 1). The only exception between 3MD + VMI and GEMD was the highest MSU concentration (0.652 g/mL), in which 3MD + VMI was slightly significantly different from the standard (p = 0.0479).

Table 1. Mean reported results, and their p-value when compared to the known concentration, of 10 × 10 × 10 voxels placed within ROIs of the HA and MSU phantom under varying decomposition techniques (i.e. 3MD + VMI, GEMD, and Dual-Threshold). * = significant difference (p < 0.05) from standard

Phantom	Concentration	3MD + VMI (*p*-value)	GEMD (*p*-value)	Dual-Threshold (*p*-value)
HA	100 mgHA	89.7 mgHA (0.945)	129.2 mgHA (0.105)	N/A
	400 mgHA	393 mgHA (0.546)	460.1 mgHA (0.475)	N/A
	800 mgHA	796 mgHA (0.196)	904.6 mgHA (0.426)	N/A
MSU	0.0 g/mL	0.0 g/mL (0.223)	0.0 g/mL (>0.999)	N/A
	0.0344 g/mL	0.038 g/mL (0.762)	0.03 g/mL (0.0823)	0.0 g/mL (<0.0001*)
	0.133 g/mL	0.156 g/mL (0.432)	0.09 g/mL (0.345)	0.015 g/mL (<0.0001*)
	0.283 g/mL	0.248 g/mL (0.256)	0.139 g/mL (0.389)	0.390 g/mL (0.252)
	0.652 g/mL	0.650 g/mL (0.0479*)	0.652 g/mL (>0.999)	0.644 g/mL (0.760)

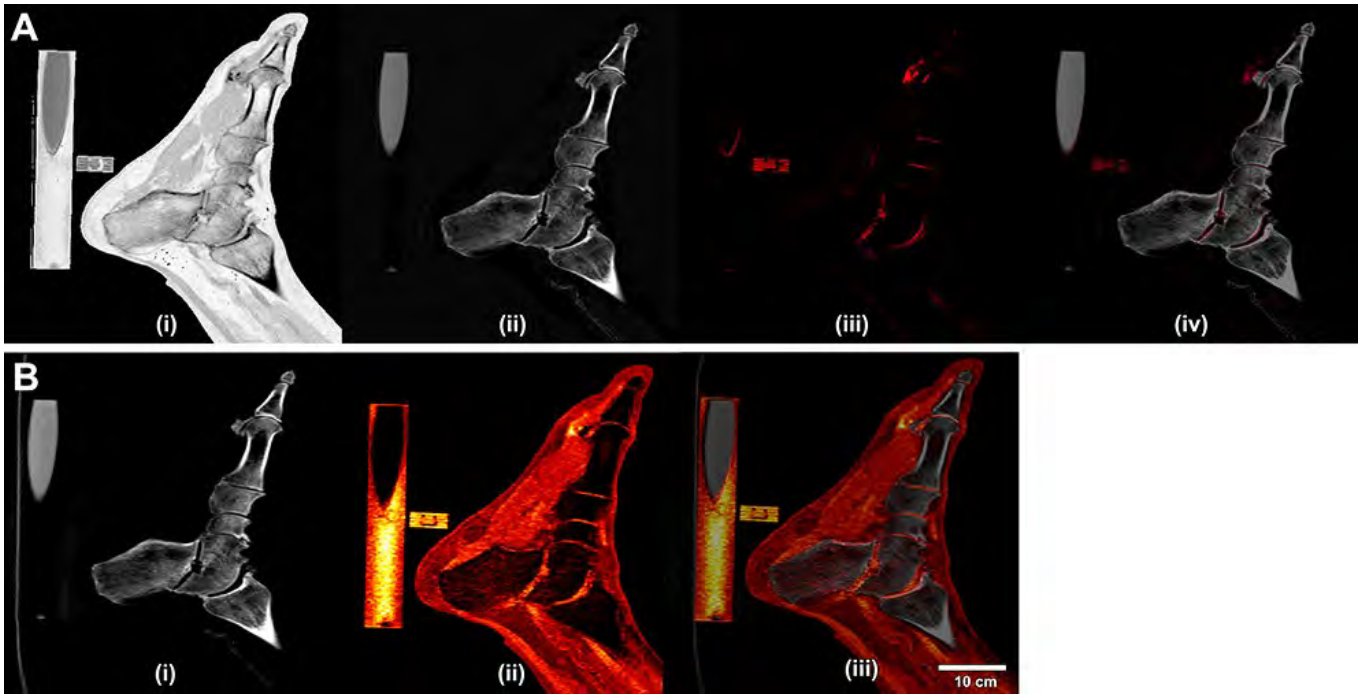

Figure 1. Results of DECT decomposition. (A) The combination of 3MD and VMI results in the distinct and separate visualization of (i) soft tissue, (ii) bone, (iii) MSU, and (iv) an overlay of bone and MSU. (B) GEMD results in the distinct visualization of (i) bone, (ii) MSU deposits, and (iii) an overlay of bone and MSU.

The combination of 3MD + VMI produced clearer depictions MSU deposition (Fig. 1Aiii), when compared to images generated *via* GEMD (Fig. 1Bii), due to the decomposition of a third tissue (*e.g*. soft tissue).

Conclusion: No significant differences between 3MD + VMI *vs* GEMD were observed when measuring HA and MSU concentrations of phantoms being the only objects within the field-of-view (FOV). A preliminary demonstration of 3MD + VMI's enhanced visualization of soft tissue, bone, and MSU was performed (Fig. 1A). Further analysis is required to determine whether the addition of human anatomy may cause artefacts (*e.g*. beam hardening) that will affect measurements of lower MSU concentrations. Additionally, further work can determine whether a better pair of VMIs could further improve the available detection limit by maximizing the DECT decomposition ratio.

Abdominal Obesity May Confound Accuracy of Cardiovascular Risk Prediction in Rheumatoid Arthritis; Can Coronary Atherosclerosis Imaging and Biomarkers Help?

George Karpouzas[1], sarah ormseth[2], Elizabeth Hernandez[2] and Matthew Budoff[3], [1]Harbor-UCLA Medical Center, Torrance, CA, [2]The Lundquist Institute, Harbor-UCLA Medical Center, Torrance, CA, [3]Division of Cardiology, and the Lundquist Institute ay Harbor-UCLA Medical Center, Torrance, CA

SESSION INFORMATION

Session Date: Saturday, November 6, 2021
Session Title: Imaging of Rheumatic Diseases Poster (0149–0182)
Session Type: Poster Session A
Session Time: 8:30AM–10:30AM

Background/Purpose: Accurate cardiovascular risk stratification is essential in rheumatoid arthritis (RA) care. Previous studies evaluated the impact of obesity (defined as body mass index) on all cause and cardiovascular disease (CVD) mortality in RA patients. However, the effect of obesity and particularly abdominal (central) obesity on the predictive ability of cardiovascular risk score models in RA is unclear. We explored the obesity-related predictive value of the Framingham Cardiovascular Risk Score (FRS-CVD) in RA patients without known CVD and interrogated the potential utility of cardiovascular imaging and serum biomarkers to improve risk prediction.

Methods: We evaluated 150 RA patients with coronary CT angiography for atherosclerosis assessment and prospective follow-up for cardiovascular events over 6.0±2.4 years. The 10-year FRS-CVD score was computed at baseline. Abdominal obesity was defined as waist circumference >88 cm in females and >102 cm in males. Extensive plaque was defined as having >5 coronary segments with atherosclerosis. Serum highly-sensitive cardiac troponin I (hscTnI) was measured with Erenna immunoassay. Serum leptin, which is closely related to obesity, was measured with radioimmunoassay. Differences in the predictive value of the FRS-CVD in non-obese versus obese and patients and those with high (>22.1 ng/mL) versus low (< 22.1 ng/mL) leptin were evaluated using area under the curve (AUC) comparisons. The incremental predictive value of extensive plaque and elevated hscTnI (>2.1, highest tertile) beyond the FRS-CVD was explored using change in AUC, continuous net reclassification index (NRI) and integrated discrimination improvement (IDI).

Results: The predictive accuracy of the FRS-CVD was lower in obese patients (AUC 0.660, [95% CI 0.487-0.832] versus non-obese: AUC 0.95 [95% CI 0.897-1.007], *P* for difference = 0.002, Figure 1A) and those with higher leptin (AUC 0.618 [95% CI 0.393-0.842]; versus lower leptin: AUC 0.874 [95% CI 0.772-0.976], *P* for difference = 0.042,

*p<0.05

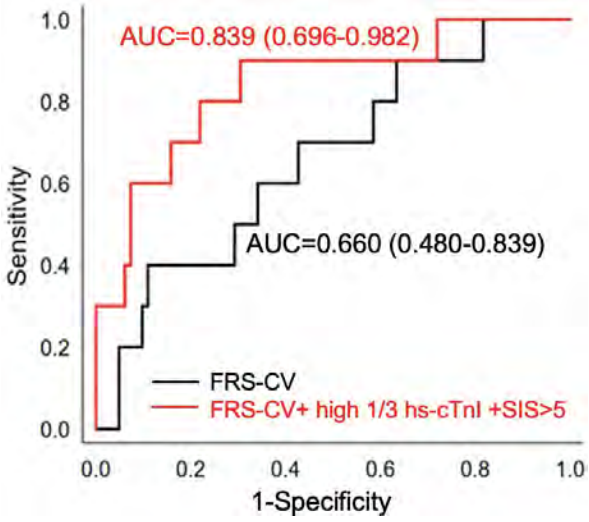

Figure 2. Added predictive accuracy of hscTnI and extensive plaque presence versus Framingham-CVD score alone in obese RA patients.

Figure 1B). The added predictive ability of hscTnI and extensive plaque was evaluated for obese patients given the observed limitations of the FRS-CVD for this subgroup. Sequential addition of elevated hscTnI and extensive plaque presence to the FRS-CVD base model significantly improved risk prediction estimates based on changes in all AUC, NRI and IDI (Table 1). The final model including hscTnI and extensive plaque accurately predicted 83.9% of CVD events in the obese subgroup (Figure 2).

Conclusion: Cardiovascular risk estimate accuracy was significantly lower in RA patients who were obese. The optimization of cardiac risk stratification with the help of non-invasive assessment of coronary atherosclerosis burden and related cardiac damage biomarkers in the serum may warrant further study.

Impaired Myocardial Flow Reserve on ^{82}Rubidium Positron Emission Tomography Imaging Predicts Adverse Events in Patients with Autoimmune Rheumatic Disease

Attila Feher[1], Nabil Boutagy[1], Evangelos Oikonomou[1], Yi-Hwa Liu[1], Edward Miller[1], Albert Sinusas[1] and Monique Hinchcliff[2], [1]Yale School of Medicine, New Haven, CT, [2]Yale School of Medicine, Westport, CT

SESSION INFORMATION
Session Date: Saturday, November 6, 2021
Session Title: Imaging of Rheumatic Diseases Poster (0149–0182)
Session Type: Poster Session A
Session Time: 8:30AM–10:30AM

Background/Purpose: Coronary microvascular dysfunction (CMVD) has been described in patients with autoimmune rheumatic disease (ARD). By noninvasive evaluation of myocardial blood flow (MBF) and myocardial flow reserve (MFR) quantification, positron emission tomography (PET) imaging has emerged as the noninvasive gold standard CMVD assessment. However, to date, no large studies have evaluated PET-derived MFR in ARD patients. It is also unknown whether MFR can predict adverse events in this population.

Methods: Patients with ARD without coronary artery disease who underwent dynamic rest-stress ^{82}Rubidium PET from 05/2012-05/2019 for a clinical indication were retrospectively studied and compared to patients without ARD matched for age, gender and comorbidities. The association between MFR and a composite endpoint of mortality or myocardial infarction (MI) or heart failure (HF) admission was evaluated with time to event and Cox-regression analyses.

Results: In 101 patients with ARD (88% female, age: 62±10 years), stress MBF did not significantly differ between patients with ARD (median with interquartile range [IQR], 1.68 [IQR: 1.39 – 2.07]) compared to those without ARD (1.49 [IQR: 1.26 – 1.93]) (Figure 1A). Conversely, rest MBF was significantly higher in ARD patients (1.00 [IQR: 0.84 – 1.21]) compared to those without an ARD diagnosis (0.80 [IQR: 0.68 – 0.99]) (Figure 1B). Consequently, MFR was significantly reduced in ARD patients compared to patients without ARD (1.68 [IQR: 1.34 – 2.05] vs. 1.86 [IQR: 1.58 – 2.28]) (Figure 1C). MFR did not differ among subtypes of ARDs. During the median follow-up of 3.8 years, there were twelve deaths, two MIs and 18 HF admissions in ARD patients. In survival analysis, patients with ARD and low MFR (MFR< 1.5) had decreased event-free survival for the combined endpoint, when compared to patients with and without ARD and normal MFR (MFR >1.5) and when compared to patients without ARD and low MFR, after adjustment

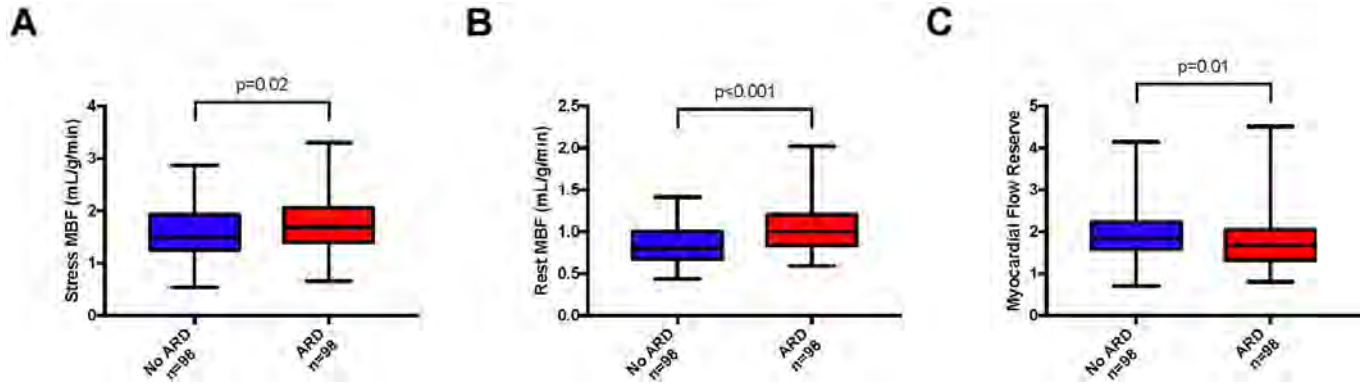

Figure 1. Stress (Panel A) and rest (Panel B) myocardial blood flow (MBF) and myocardial flow reserve values (Panel C) in patients with or without autoimmune rheumatic disease (ARD).

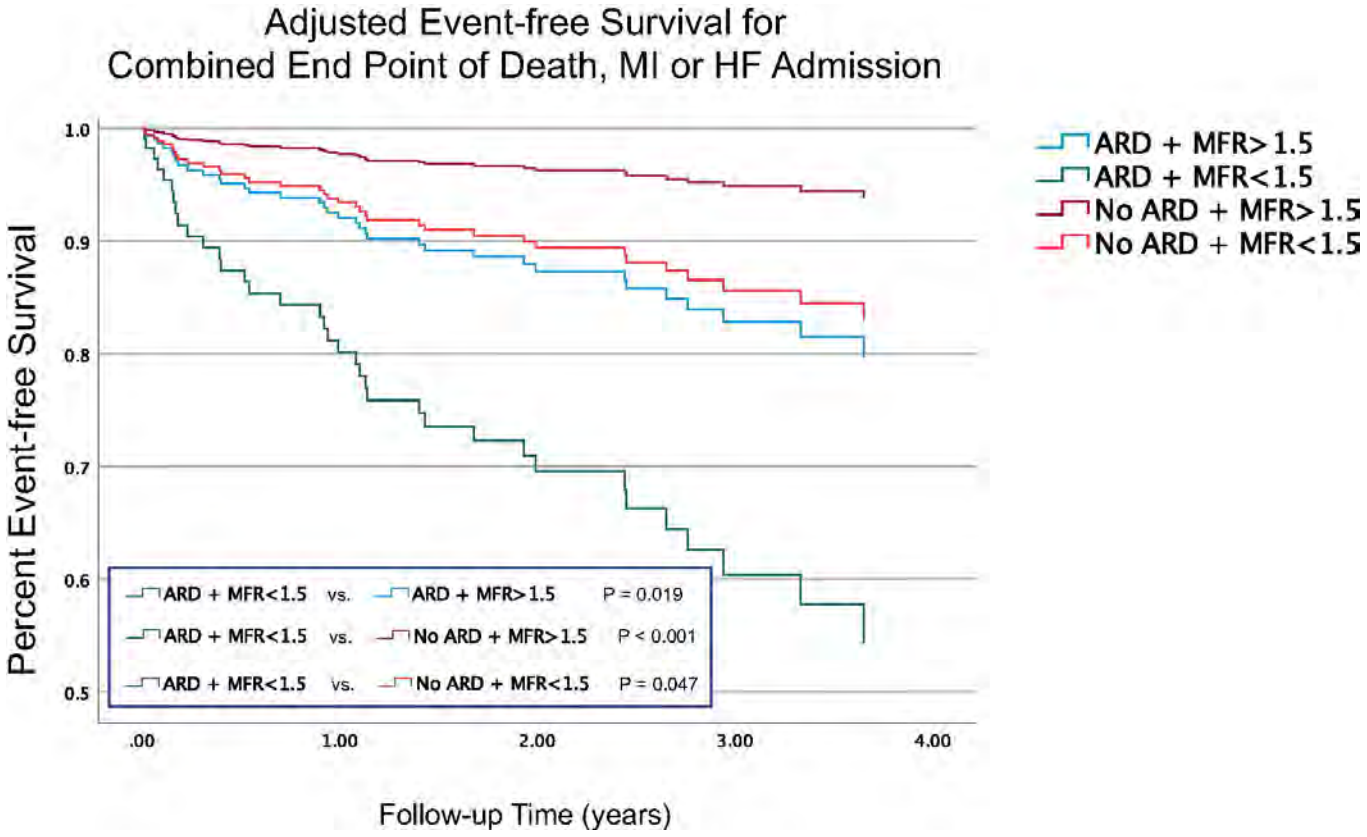

Figure 2. Kaplan Meier plots for event-free survival for the combined end point of death, myocardial infarction (MI) or heart failure (HF) admission in patients with autoimmune rheumatic disease (ARD) based on myocardial flow reserve (MFR).

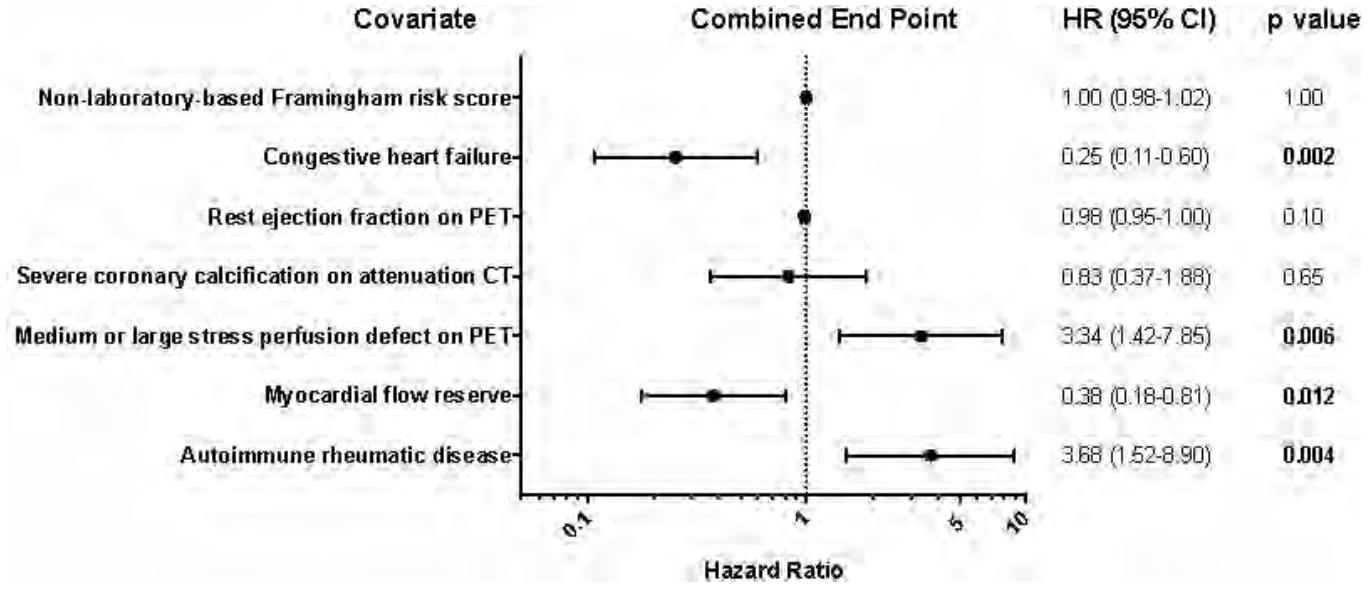

Figure 3. Forest plot of hazard ratios (HR) for the combined end point of death, myocardial infarction or heart failure admission in multivariate Cox proportional hazards regression models in patients with autoimmune rheumatic disease. CT: computed tomography, PET: positron emission tomography.

for the non-laboratory-based Framingham risk score, rest left ventricular ejection fraction, severe coronary calcification, and the presence of medium/large perfusion defects (Figure 2). In Cox-regression analysis, ARD diagnosis and MFR were both independent predictors of adverse events in ARD patients along with congestive HF diagnosis and presence of medium/large stress perfusion defects on PET (Figure 3).

Conclusion: Patients with ARD have significantly reduced PET MFR compared to age-, gender- and comorbidity-matched patients without ARD. Reduced PET MFR and ARD diagnosis are both independent predictors of adverse outcomes.

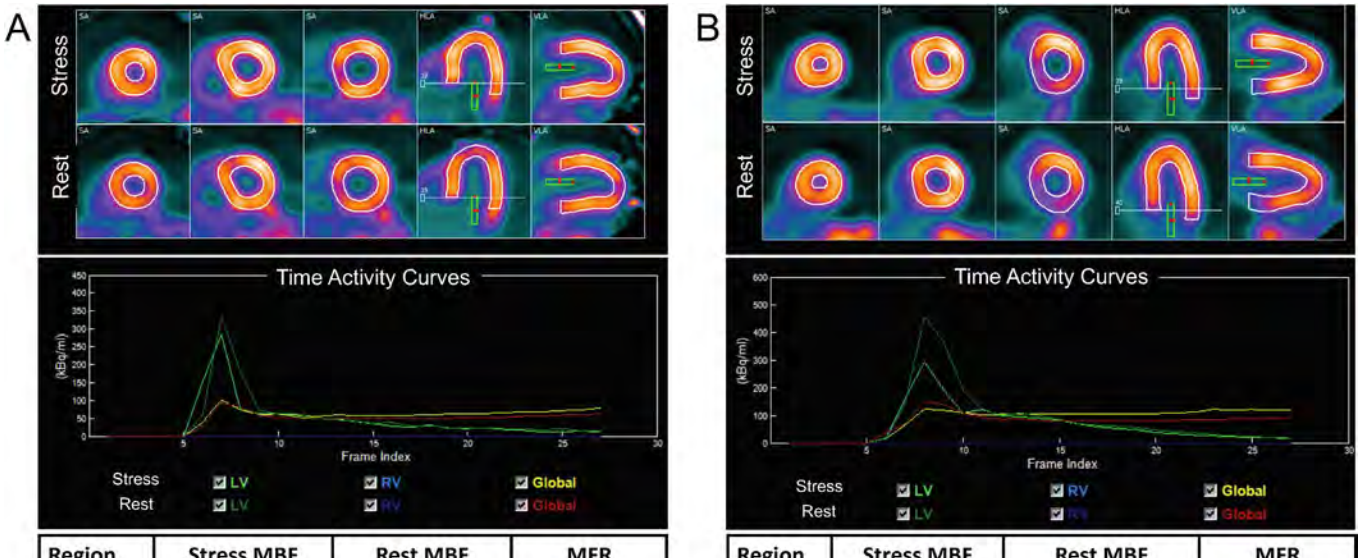
Session Date: Saturday, November 6, 2021
Session Title: Imaging of Rheumatic Diseases Poster (0149–0182)
Session Type: Poster Session A
Session Time: 8:30AM–10:30AM



Region	Stress MBF (mL/min/g)	Rest MBF (mL/min/g)	MFR
LAD	1.37	1.06	1.28
LCx	1.37	1.24	1.10
RCA	1.22	1.02	1.19
Global	1.32	1.08	1.22

Region	Stress MBF (mL/min/g)	Rest MBF (mL/min/g)	MFR
LAD	2.77	1.11	2.50
LCx	2.58	1.15	2.24
RCA	2.78	0.87	3.20
Global	2.71	1.04	2.60

Figure 1. Representative relative perfusion images, time activity curves and myocardial blood flow (MBF) values obtained at stress (Str) and rest (Rst) for a patient with systemic sclerosis (A) and for a healthy control subject (B). Perfusion imaging showed no perfusion defects, however for the systemic sclerosis patient blood flow quantification revealed global reduction in stress myocardial blood flow and myocardial flow reserve (<2.0) whereas the healthy control subject had normal myocardial blood flow values. SA: short axis, HLA: horizontal long axis, VLA: vertical long axis, LV: left ventricle, RV: right ventricle, LAD: left anterior descending artery, LCX: left circumflex artery, RCA: right coronary artery.

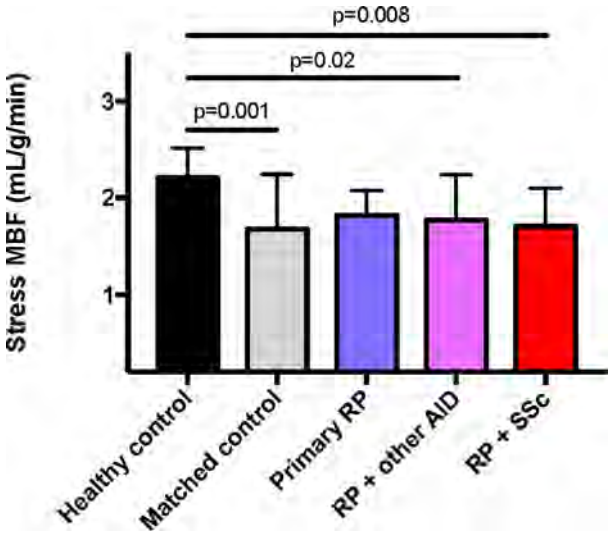


Figure 2. Stress myocardial blood flow (MBF) in healthy controls, matched control patients without Raynaud phenomenon (RP) and in patients with primary RP, secondary RP with autoimmune disease (AID) other than systemic sclerosis (SSc) and in patients with SSc.

Background/Purpose: To investigate the association between Raynaud phenomenon (RP) and coronary microvascular dysfunction, we measured myocardial flow reserve (MFR) using positron emission tomography/computed tomography (PET/CT) in patients with primary and secondary RP and controls.

Methods: Patients with RP and matched controls who underwent dynamic rest-stress 82-Rubidium PET/CT from 09/2012-09/2019 for evaluation of chest pain or dyspnea were studied. Differences in heart rate-blood pressure product corrected MFR and clinical predictors of reduced MFR (< 2.0) were determined (Figure 1.).

Results: 49 patients (80% female, 65 ± 11 years) with RP (11 with primary RP, 18 with systemic sclerosis (SSc) and 20 with other autoimmune diagnoses (AID, n=6 systemic lupus erythematosus, n=6 rheumatoid arthritis, n=4 overlap syndrome, n=2 Sjogren's syndrome, n=2 inflammatory arthritis), 49 patients without RP matched for age, gender and cardiovascular co-morbidities (78% female, 64 ± 13 years) and 14 healthy controls (50% female, 35 ± 5 years) were studied. Primary RP patients, healthy participants and matched control patients had comparable MFR (Figure 2.). In secondary RP patients, only those with underlying SSc had significantly reduced MFR (1.62 ± 0.32) compared to healthy participants (p=0.01, 2.22 ± 0.44) and to matched controls (p=0.03, 2.06 ± 0.61). In univariate (Fig 3A) and multivariable logistic regression (Figure 3B), only SSc was a significant predictor of reduced MFR. We have also identified a correlation between time since autoimmune disease diagnosis and MFR (r= -0.37; 95% CI: -0.61 to -0.09; p=0.01).

Conclusion: Our findings suggest that only secondary, not primary, RP is associated with reduced MFR, and that SSc-RP patients have reduced MFR compared to primary RP and other autoimmune disease patients. Larger prospective studies are warranted to fully elucidate the prognostic value of MFR in patients with secondary RP.

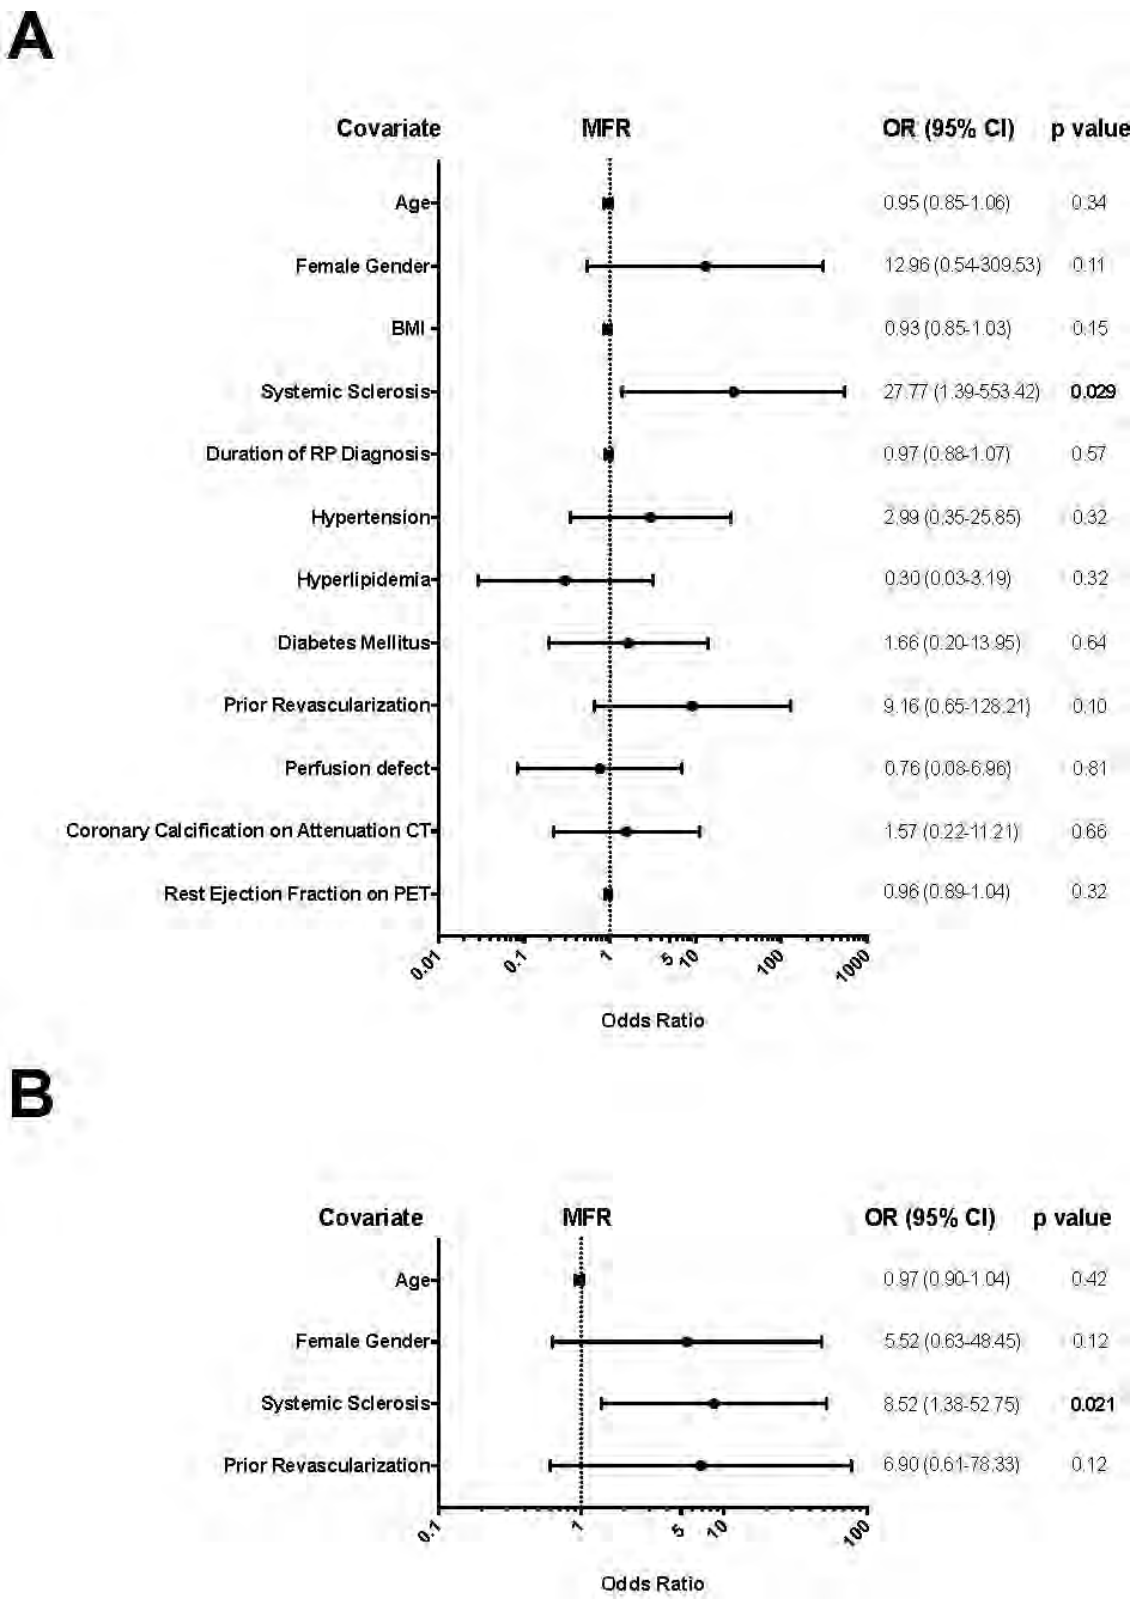

Figure 3. Forest plot of odds ratios (OR) of clinical predictors of reduced myocardial flow reserve (MFR <2.0) in univariate (A) and multivariate (B) regression models. BMI: body mass index, RP: Raynaud phenomenon, CT: computed tomography, PET: positron emission tomography, CI: confidence interval.

Magnetic Resonance Imaging Findings in Early Rheumatoid Arthritis: Are There Differences Based on Autoantibody Status?

Caitrin Coffey[1], Gavin McKenzie[1], Nicholas Rhodes[1], Cassondra Hulshizer[1], Cynthia Crowson[2], John Davis[1] and Kerry Wright[1], [1]Mayo Clinic, Rochester, MN, [2]Mayo Clinic, Eyota, MN

SESSION INFORMATION
Session Date: Saturday, November 6, 2021
Session Title: Imaging of Rheumatic Diseases Poster (0149–0182)
Session Type: Poster Session A
Session Time: 8:30AM–10:30AM

Background/Purpose: Magnetic resonance imaging (MRI) is increasingly used as an adjunct to the physical examination in early rheumatoid arthritis (RA). Characteristic differences in MRI findings between patients with early seropositive and seronegative RA have not previously been described. We aimed to determine whether hand and/or wrist MRI findings differed between patients with incident RA based on autoantibody status.

Methods: Patients with incident RA from a population-based cohort between 1999-2014 who fulfilled either the 1987 or 2010 ACR/EULAR classification criteria for RA were retrospectively reviewed. Patients who underwent MRI of the hand and/or wrist within ± 1 year of fulfillment of the earlier of 1987 or 2010 classification criteria as part of their routine clinical care were identified using Current Procedural Terminology (CPT) codes. Studies were confirmed via manual chart review. MRI images were reviewed and scored according to the Outcome Measures in Rheumatology Clinical Trials (OMERACT) RA MRI scoring system (RAMRIS), by an experienced musculoskeletal radiologist blinded to patients' clinical data. Studies with incomplete images or artifact precluding scoring were excluded at the radiologist's discretion. Serial studies of the ipsilateral hand or wrist were excluded for each patient. RAMRIS scores were compared between seronegative (RF-, CCP-) and seropositive (RF+ and/or CCP+) patients using generalized linear models, with random intercepts to account for multiple studies per patient.

Results: 86 patients with a total of 137 MRI studies of the hand and/or wrist were included for RAMRIS scoring. RF and/or CCP were negative in 53 (62%) of patients. Patients were 71% female, mean age 54.7 (SD 12.5) years, 95% white, 19% current smokers with no significant differences between groups.

57 total hand studies were scored. Mean total hand RAMRIS score was 7.4 (SD 5.1) for seropositive and 8.9 (SD 6.3) for seronegative patients. Mean synovitis, bone erosions, and bone marrow edema scores were comparable between groups (Table).

55 total wrist studies were scored. Mean total wrist RAMRIS score was 9.8 (SD 13.9) for seropositive and 7.8 (SD 6.1) for seronegative patients. Mean total wrist bone marrow edema score was 7.3 (SD 11.3) for seropositive and 2.4 (SD 3.2) for seronegative patients. Mean synovitis and bone erosions scores were comparable between groups (Table).

Estimates using generalized linear models showed that wrist bone marrow edema scores were on average 4.9 RAMRIS units higher in seropositive vs seronegative patients (p=0.014). There was a trend toward higher hand bone marrow edema scores in seronegative vs seropositive patients by 1.07 RAMRIS units that did not reach significance (p=0.067). Other mean RAMRIS scores did not differ significantly between groups.

MRI Site (N)	RF and/or CCP (+)		RF and CCP (-)	
	Mean (SD*)	Median (IQR**)	Mean (SD)	Median (IQR)
Hand				
Total RAMRIS (57)	7.4 (5.1)	6.0 (3.2-10.8)	8.9 (6.3)	8.0 (4.5-11.0)
Synovitis (57)	5.0 (2.4)	4.5 (3.2-6.8)	5.5 (2.7)	5.0 (4.0-8.0)
Erosions (62)	1.5 (2.3)	0 (0-2.5)	1.9 (2.5)	1.0 (0-3.0)

Total RAMRIS (55)	9.8 (13.9)	4.0 (3.0-9.0)	7.8 (6.1)	5.5 (4.0-10.8)
Synovitis (56)	3.9 (1.8)	3.0 (3.0-5.0)	4.1 (2.1)	4.0 (3.0-6.0)
Erosions (75)	2.5 (3.3)	1.0 (0.0-4.5)	1.5 (2.4)	0.0 (0.0-2.2)
Edema (75)	7.3 (11.3)	1.0 (0.0-7.0)	2.4 (3.2)	1.0 (0.0-4.0)

*SD = standard deviation; **IQR = interquartile range

Conclusion: RAMRIS scores for MRIs of the hands and wrists performed as part of routine clinical care for patients with early, incident RA varied widely. Mean wrist bone marrow edema score was significantly higher in seropositive vs seronegative patients, though mean total RAMRIS scores, synovitis scores, and bone erosions scores did not differ significantly based upon autoantibody status.

Abstract Number: 0182

Tenderness and Radiographic Progression in Rheumatoid Arthritis and Psoriatic Arthritis

Irina Gessl[1], Mihaela Popescu[2], Gabriela Supp[1], Martina Durechova[1], Michael Zauner[1], Josef Smolen[1], Daniel Aletaha[3] and Peter Mandl[1], [1]Medical University of Vienna, Vienna, Austria, [2]Maisonneuve Rosemont Hospital, Longueuil, QC, Canada, [3]Medical University Vienna, Vienna, Austria

SESSION INFORMATION
Session Date: Saturday, November 6, 2021
Session Title: Imaging of Rheumatic Diseases Poster (0149–0182)
Session Type: Poster Session A
Session Time: 8:30AM–10:30AM

Background/Purpose: In rheumatoid arthritis (RA) and psoriatic arthritis (PsA), swelling is regarded as a sign of synovitis and is associated with radiographic progression. However, recent studies show that tenderness might only be a sign of inflammation in early, but not in long-standing disease. Furthermore, the association of tenderness with radiographic progression is not clear. The aim of this study was to assess the predictive value of tenderness in RA and in PsA generally as well as in early and long- standing disease.

Methods: Patients with RA and PsA with at least one tender joint were included. Sonographic (Power Doppler (PD) and gray-scale (GS)) and clinical examination (tenderness and swelling) of 22 joints of the hands as well as x-ray of the hands were performed. Radiographs were scored for erosions and joint space narrowing (JSN) and progression

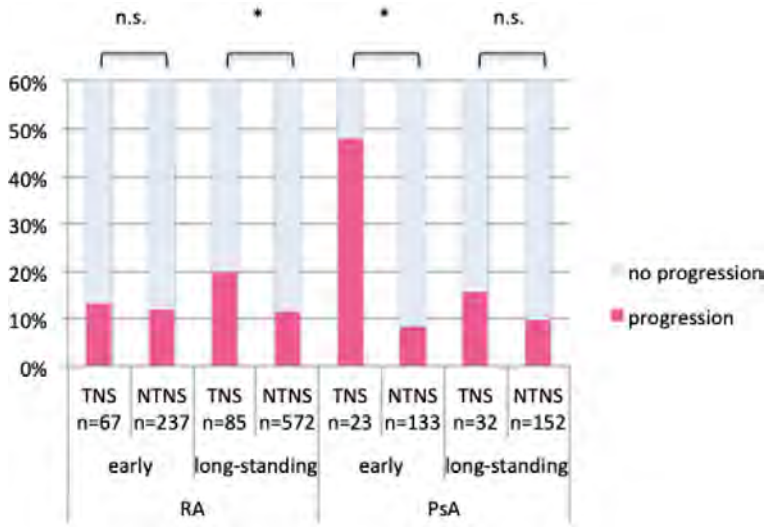

Figure 1. The proportion of joints with progression in tender non-swollen joints (TNS) and non-tender non-swollen joints (NTNS) in patients with early and long-standing rheumatoid arthritis (RA) and psoriatic arthritis (PsA).

in each joint was assessed on a follow-up x-ray after 2 years. Patients were divided into early (≤3 years) and long-standing (≥5 years) disease groups. Logistic regression analyses (forward stepwise conditional approach) including tenderness, GS and PD (model 1) as well as additional factors erosion and JSN at baseline (model 2) in non-swollen joints were calculated for each group.

Results: We included 2.288 joints in RA and 484 joints in PsA. In early RA, only PD remained in model 1 (OR 3.58 95%CI 1.50-8.57, p< 0.01) and only JSN remained in model 2 (OR 1.83, 95%CI 1.26-2.65, p< 0.01). In long-standing RA only PD (OR 2.78, 95%CI 1.53-5.08, p< 0.01) and tenderness (OR 2.00, 95%CI 1.09-3.64, p=0.02) remained in model 1, while only JSN (OR 1.27, 95%CI 1.12-1.44, p< 0.01) and PD (OR 2.19, 95%CI 1.15-4.17, p=0.02) remained in model 2.

In early PsA, only tenderness (OR 6.60, 95%2.04-21.31, p=0< 0.01) remained significant in model 1, while in model 2, only erosions (OR 30.37, 95%CI 5.26-175.37, p< 0.01) remained significant. In model 1 in long-standing PsA, only PD (OR 10.36, 95%CI 3.25-33.03, p< 0.01) remained in the model. In model 2 in long-standing PsA only JSN (OR 2.59, 95%CI 1.59-4.22, p< 0.01) remained significant.

Conclusion: The results of this study show that tenderness in non-swollen joints is not a major risk factor for subsequent radiographic progression in RA and PsA. In all observed groups, tenderness did not remain in the model after adding JSN and erosions suggesting that tenderness might be rather an indicator of structural damage than of current inflammation. Over all groups, PD showed a higher association with radiographic progression than tenderness except for early PsA, where tenderness seems to be a risk factor for subsequent damage.

SESSION INFORMATION
Session Date: Saturday, November 6, 2021
Session Title: Miscellaneous Rheumatic & Inflammatory Diseases Poster I (0183–0209)
Session Type: Poster Session A
Session Time: 8:30AM–10:30AM

Background/Purpose: Risankizumab (RZB) is a humanized immunoglobulin G1 monoclonal antibody that specifically inhibits interleukin 23 by binding to its p19 subunit. RZB is being investigated as a treatment for adults with psoriatic arthritis (PsA).

Methods: KEEPsAKE 2, a double-blind, phase 3 trial, evaluated the safety and efficacy of RZB vs. placebo (PBO) for the treatment of active PsA in patients that had previous inadequate response or intolerance to conventional synthetic disease modifying antirheumatic drug (csDMARD-IR) or 1 or 2 biologic therapies (Bio-IR). The KEEPsAKE 2 trial enrolled adults with a diagnosis of active PsA, active plaque psoriasis or nail psoriasis, ≥ 5 swollen joints, and ≥ 5 tender joints.

Patients were randomized (1:1) to receive blinded subcutaneous RZB 150 mg or PBO at weeks 0, 4, and 16. The primary endpoint was the proportion of patients achieving 20% improvement in the American College of Rheumatology score (ACR20) at week 24. Table 1 shows primary and secondary endpoints by prior biologic therapy utilization (0 or ≥ 1). Efficacy was assessed using non-responder imputation incorporating multiple imputations to handle missing data due to COVID-19 (NRI-C) for categorical data and Mixed-Effect Model Repeated Measurement (MMRM) analysis for continuous data. Safety was assessed throughout the study. Results reported here are from the 24-week double-blind period; the open-label period with all patients receiving RZB is ongoing.

Results: A total of 443 patients completed the KEEPsAKE 2 analysis at 24 weeks. Overall, demographics and baseline disease characteristics were similar between the patients receiving RZB and patients receiving PBO; 237 patients were csDMARD-IR (119 RZB and 118 PBO) and 206 patients were Bio-IR (105 RZB and 101 PBO). A numerically higher proportion of patients receiving RZB achieved improvement in disease severity measures compared to those receiving PBO, regardless of prior biologic experience (Table 1). Patients receiving RZB reported numerically greater improvements in patient-reported outcomes compared to those receiving PBO, regardless of prior biologic experience (Table 1). RZB was well tolerated in patients compared to PBO, and no new safety signals were observed.

Conclusion: RZB treatment resulted in improvements in signs and symptoms of PsA compared with PBO in both csDMARD-IR and Bio-IR patients and was well tolerated with no new safety signals.

Table 1. 24 Week Efficacy Results by Prior Biologic Experience

	No Prior Biologic (csDMARD-IR)		Prior Biologic (Bio-IR)	
	RZB 150mg N = 119	PBO N=118	RZB 150 mg N=105	PBO N=101

SESSION INFORMATION

Session Date: Saturday, November 6, 2021

Session Title: Miscellaneous Rheumatic & Inflammatory Diseases Poster I (0183–0209)

Session Type: Poster Session A

Session Time: 8:30AM–10:30AM

Background/Purpose: BI 695501 is a FDA-approved biosimilar to adalimumab RP (AbbVie), and is approved in seven indications, including rheumatoid arthritis, psoriatic arthritis, juvenile idiopathic arthritis, and ankylosing spondylitis. The objectives of our study were to assess pharmacokinetic similarity, as well as efficacy, immunogenicity, and safety in patients with moderate-to-severe chronic plaque psoriasis receiving adalimumab RP continuously versus those who switched several times between BI 695501 and adalimumab RP.

Methods: Patients with moderate-to-severe chronic plaque psoriasis received adalimumab RP (80 mg Day 1; 40 mg/0.8 mL every other week [EOW] from Weeks 2–12) and were then randomized to 'switching' (BI 695501 40 mg/0.8 mL Weeks 14 and 16; adalimumab RP Weeks 18 and 20; BI 695501 EOW Weeks 22–48) or 'continuous' (adalimumab RP EOW Weeks 14–48) treatment. Primary endpoints were $C_{max,30–32}$ and $AUC_{\tau,30–32}$ (bioequivalence acceptance limits: 80–125%). Secondary endpoints included: PASI75 response, anti-drug antibodies (ADA) and neutralizing ADAs (nAb) at Week 32, and drug-related treatment-emergent adverse events (TEAEs) post-randomization (NCT03210259).

Results: Baseline characteristics were generally balanced between groups (switching, n=118; continuous, n=120). In the analyzable switching (n=104) and continuous groups (n=99), adjusted mean $C_{max,30–32}$ was 7.08 and 7.00 µg/mL, respectively (point estimate for the ratio: 101.14%; 90.2% CI: 93.26, 109.70); adjusted mean $AUC_{\tau,30–32}$ was 2025.83 and 1925.90 µg·h/mL, respectively (105.19%; 90.2% CI: 96.58, 114.64). At Week 32, in the analyzable switching and continuous groups, respectively: 100/118 (85%) and 94/119 (79%) patients had PASI75 response (difference: 5.75%; 90% CI: -2.45, 13.96); 101/112 (90%) and 104/110 (95%) patients were ADA positive; 46/112 (41%) and 46/110 (42%) patients were nAb positive. Post-randomization, 67/118 (57%; switching) and 75/120 (63%; continuous) patients had ≥1 drug-related TEAE.

Conclusion: These data support BI 695501's designation as an interchangeable biosimilar to adalimumab RP, based on similar outcomes between the switching and continuous treatment groups, in terms of pharmacokinetics efficacy, immunogenicity and safety. The results of this study are highly applicable to patients with rheumatoid disease, for which BI 695501 is approved.

Phase 1 Study Results of GS-5718, an Oral IRAK4-Inhibitor: Pharmacodynamics of Single and Multiple Doses of GS-5718 in Healthy Subjects

Silke Roedder[1], Emily Wendt[2], Chad Burris[2], Jonathan Nazareon[2], Grace Park[3], Phil Pangilinan[2], Gianna Huang[2], Anubhav Mathur[2], James Taylor[2], Andrew Billin[2] and Franziska Matzkies[4], [1]Gilead Sciences, Menlo Park, CA, [2]Gilead Sciences, Foster City, CA, [3]Gilead Sciences, Seattle, WA, [4]Gilead Sciences, Inc., Foster City, CA

SESSION INFORMATION
Session Date: Saturday, November 6, 2021
Session Title: Miscellaneous Rheumatic & Inflammatory Diseases Poster I (0183–0209)
Session Type: Poster Session A
Session Time: 8:30AM–10:30AM

Background/Purpose: Adaptive and innate immune pathways are involved in inflammation and pathogenesis of autoimmune diseases including Rheumatoid Arthritis (RA) and Lupus Erythematosus (LE). Immune complexes found in RA and LE can stimulate production of (pro-) inflammatory cytokines via Toll-like receptor (TLR) activation. Interleukin (IL) receptor-associated kinase 4 (IRAK4) is a key signal transducer downstream of the myddosome-associated TLRs and IL-1 receptors. IRAK4 inhibition blocks (pro-) inflammatory cytokine production and is a potential therapeutic target for RA and LE. This Phase 1 first in human healthy volunteer study evaluated the pharmacodynamics (PD) of GS-5718, a potent and selective IRAK4 inhibitor in clinical development for treatment of RA and LE.

Methods: In this blinded, randomized, placebo-controlled, single and multiple (once daily for 10 days) oral dose Phase 1 study, healthy male and female subjects were enrolled in ascending dose cohorts to receive GS-5718 (15, 50 or 150 mg) or placebo under fasted (single dose cohorts) and fed conditions (multiple dose cohorts). For PD, serial whole blood samples were collected pre-dose and over up to 72 hours after single (Day 1) and multiple dose (Day 1 and 10) administration. A whole blood assay was developed to measure GS-5718 inhibition of ex-vivo (TLR7/8, R848) stimulated secretion of (pro-) inflammatory cytokines. Several (pro-) inflammatory cytokines were evaluated. TNF-α was chosen for the primary PD analysis as it showed the least variability and highest probability to see dose-dependent responses in healthy volunteers in pre-clinical in-vitro studies. The primary PD parameter was percent change of cytokine secretion from baseline (%Δ).

Results: A total of 74 subjects (n = 62 GS-5718; n = 12 placebo) enrolled, completed study drug treatments in this study and were evaluated for PD.

GS-5718 doses ≥ 15 mg significantly decreased ex-vivo stimulated TNF-α compared to placebo in a dose-dependent manner 1 hour until up to 72 hours post single and multiple doses. GS-5718 resulted in sustained >90% inhibition of TNF-α 24 hours after single and multiple doses of 50 mg and 150 mg GS-5718 on day 1 (SAD, MAD) and day 10 after the last dose (MAD), respectively. Administration of 50 mg GS-5718 with food did not result in significantly prolonged time to reach maximal % Δ compared to administration of GS-5718 50 mg under fasting conditions. Percent inhibition of all cytokines measured were highly correlated with each other in all dose cohorts.

Conclusion: GS-5718, administered once daily, resulted in significant and sustained inhibition of ex-vivo stimulated secretion of TNF-α, the main PD biomarker. The PD profile of GS-5718 supports once daily dosing and further development in patients with RA and LE.

SESSION INFORMATION
Session Date: Saturday, November 6, 2021
Session Title: Miscellaneous Rheumatic & Inflammatory Diseases Poster I (0183–0209)
Session Type: Poster Session A
Session Time: 8:30AM–10:30AM

Background/Purpose: In the INBUILD trial in patients with progressive fibrosing ILDs other than idiopathic pulmonary fibrosis (IPF), nintedanib reduced the rate of decline in forced vital capacity (FVC) over 52 weeks compared with placebo, with adverse events that were manageable for most patients. The safety and efficacy of nintedanib over longer-term use are being assessed in an open-label extension trial, INBUILD-ON. Here we present the safety and efficacy of nintedanib in patients with autoimmune disease-related ILDs in INBUILD-ON.

Methods: Patients in the INBUILD trial had diffuse fibrosing ILD (reticular abnormality with traction bronchiectasis, with or without honeycombing) of >10% extent on HRCT, FVC ≥45% predicted, DLco ≥30%–< 80% predicted, and met criteria for progression of ILD within the 24 months before screening, despite management deemed appropriate in clinical practice. Patients who completed the INBUILD trial on treatment (nintedanib or placebo) were eligible to enter INBUILD-ON. We analyzed adverse events and the change in FVC from baseline to week 60 of INBUILD-ON in the subgroup of patients with autoimmune disease-related ILDs based on a data snapshot taken on 15 October 2020. Analyses were descriptive.

Results: Of the 434 patients treated in INBUILD-ON, 113 had autoimmune disease-related ILDs (52 RA-ILD, 29 SSc-ILD, 13 MCTD-ILD, 19 other autoimmune disease-related ILDs). Of these, 61.9% took ≥1 disease-modifying antirheumatic drug or high-dose glucocorticoid during the trial. Diarrhea was the most frequent adverse event (Table 1). Adverse events led to discontinuation of nintedanib in 11.5% of patients who continued nintedanib in INBUILD-ON (having taken nintedanib in INBUILD) and 29.5% of patients who initiated nintedanib in INBUILD-ON (having taken placebo in INBUILD). The adverse event that most frequently led to discontinuation of nintedanib was diarrhea (Table 2). Mean (SE) changes in FVC from baseline to week 60 of INBUILD-ON were –77.6 (41.1) mL in patients who continued nintedanib (n=32), –32.8 (29.3) mL in patients who initiated nintedanib (n=32) and –55.2 (25.2) mL in all patients (n=64), similar to the change from baseline to week 52 of the INBUILD trial in patients with autoimmune disease-related ILDs who received nintedanib (–78.8 [29.5] mL).

Table 1. Most frequent adverse events in patients with autoimmune disease-related ILDs in INBUILD-ON

	Continued nintedanib (n=52)	Initiated nintedanib (n=61)
Diarrhea	21 (40.4)	33 (54.1)
Nausea	4 (7.7)	10 (16.4)
Aspartate aminotransferase increased	2 (3.8)	11 (18.0)
Alanine aminotransferase increased	1 (1.9)	11 (18.0)
Dyspnea	4 (7.7)	7 (11.5)
Vomiting	3 (5.8)	8 (13.1)
Cough	3 (5.8)	7 (11.5)
Gamma-glutamyltransferase increased	1 (1.9)	8 (13.1)

Data are n (%) of patients with ≥1 such adverse event with onset date between first nintedanib intake and last intake plus 28 days. Adverse events were coded based on preferred terms in the Medical Dictionary for Regulatory Activities. Adverse events that were reported in >10% of patients in either the "continued nintedanib" or "initiated nintedanib" group are shown.

Table 2. Most frequent adverse events that led to discontinuation of nintedanib in patients with autoimmune disease-related ILDs in INBUILD-ON

	Continued nintedanib (n=52)	Initiated nintedanib (n=61)
Diarrhea	2 (3.8)	2 (3.3)
Decreased appetite	0	2 (3.3)
Alanine aminotransferase increased	0	2 (3.3)
Aspartate aminotransferase increased	0	2 (3.3)

Data are n (%) of patients with ≥1 such adverse event with onset date between first nintedanib intake and last intake plus 28 days. Adverse events were coded based on preferred terms in the Medical Dictionary for Regulatory Activities. Adverse events that led to discontinuation in >2% of patients in either the continued nintedanib or initiated nintedanib group are shown

Conclusion: The adverse event profile of nintedanib in patients with autoimmune disease-related ILDs participating in INBUILD-ON was characterized mainly by gastrointestinal events and was consistent with that reported over 52 weeks in INBUILD. These data support the manageable safety profile of nintedanib over continued use in patients with autoimmune disease-related ILDs.

Abstract Number: 0187

Safety and Tolerability of Nintedanib in Patients with Autoimmune Disease-Related Interstitial Lung Diseases: Pooled Data from the SENSCIS and INBUILD Trials

Vanessa Smith[1], Shervin Assassi[2], Yannick Allanore[3], Lazaro Loaiza[4], Inga Tschoepe[5], Madhu Kanakapura[4] and Elizabeth Volkmann[6], [1]Department of Rheumatology and Internal Medicine, Ghent University Hospital, Ghent, Belgium, [2]University of Texas McGovern Medical School at Houston, Houston, TX, [3]Department of Rheumatology A, Descartes University, APHP, Cochin Hospital, Paris, France, [4]Boehringer Ingelheim International GmbH, Ingelheim am Rhein, Germany, Ingelheim, Germany, [5]Elderbrook Solutions, Bietigheim-Bissingen, Germany, Bietigheim-Bissingen, Germany, [6]Department of Medicine, Division of Rheumatology, University of California, David Geffen School of Medicine, Los Angeles, CA

SESSION INFORMATION

Session Date: Saturday, November 6, 2021

Session Title: Miscellaneous Rheumatic & Inflammatory Diseases Poster I (0183–0209)

Session Type: Poster Session A

Session Time: 8:30AM–10:30AM

Background/Purpose: The efficacy and safety of nintedanib have been investigated in patients with systemic sclerosis-associated ILD (SSc-ILD) in the SENSCIS trial and in patients with progressive fibrosing ILDs other than idiopathic pulmonary fibrosis in the INBUILD trial. We used data from these trials to characterize the safety and tolerability of nintedanib in patients with autoimmune disease-related ILDs.

Methods: In both the SENSCIS and INBUILD trials, patients were randomized to receive nintedanib 150 mg bid or placebo. Dose reductions to 100 mg bid and treatment interruptions were permitted to manage adverse events. For this post-hoc analysis, data were pooled from all patients in the SENSCIS trial and patients with autoimmune disease-related ILDs in the INBUILD trial. Adverse events reported by investigators, irrespective of causality, over 52 weeks were analyzed. Analyses were descriptive.

Table. Most frequent adverse events (reported irrespective of causality) in patients with autoimmune disease-related ILDs

	Nintedanib (n=370)	Placebo (n=376)
Diarrhea	271 (73.2)	115 (30.6)
Nausea	113 (30.5)	49 (13.0)
Vomiting	85 (23.0)	36 (9.6)
Skin ulcer	54 (14.6)	50 (13.3)
Nasopharyngitis	46 (12.4)	62 (16.5)
Weight decreased	44 (11.9)	14 (3.7)
Decreased appetite	42 (11.4)	13 (3.5)
Abdominal pain	40 (10.8)	23 (6.1)
Upper respiratory tract infection	39 (10.5)	39 (10.4)
Cough	36 (9.7)	58 (15.4)

Data are n (%) of patients with ≥1 such adverse event over 52 weeks. Adverse events were coded based on preferred terms in the Medical Dictionary for Regulatory Activities (MedDRA). Adverse events that were reported in >10% of patients in either group based on single MedDRA preferred terms are shown.

Results: The pooled data set comprised 746 patients with autoimmune disease-related ILDs (615 SSc-ILD, 89 RA-ILD, 19 MCTD-ILD, 23 other ILDs), of whom 370 received nintedanib and 376 received placebo. Mean (SD) exposure to trial medication was 10.4 (3.6) months in the nintedanib group and 11.3 (2.6) months in the placebo group. In the nintedanib and placebo groups, respectively, serious adverse events were reported in 26.2% and 23.9% of patients and fatal adverse events in 2.2% and 2.1% of patients. Adverse events led to dose reduction in 32.2% of patients treated with nintedanib and 3.2% of patients in the placebo group. Adverse events led to permanent treatment discontinuation in 16.5% of patients treated with nintedanib and 9.0% of patients in the placebo group. The most frequent adverse event was diarrhea, which was reported in 73.2% of patients treated with nintedanib and 30.6% of patients in the placebo group (Table). Diarrhea led to permanent treatment discontinuation in 6.8% and 0.5% of patients in the nintedanib and placebo groups, respectively. Based on a standardized MedDRA query, liver-related investigations, signs and symptoms were reported in 16.8% of patients in the nintedanib group and 4.5% of patients in the placebo group. In the nintedanib and placebo groups, respectively, major adverse cardiovascular events were reported in 2.7% and 1.9%, myocardial infarction in 0.3% and 0.8%, bleeding in 11.6% and 8.2%, and gastrointestinal perforation in 0% and 0.3% of patients.

Conclusion: In patients with autoimmune-disease related ILDs, the adverse events associated with nintedanib were characterized predominantly by gastrointestinal events and were managed without treatment discontinuation in most patients. The adverse event profile of nintedanib in patients with autoimmune disease-related ILDs was consistent with that observed in patients with other ILDs.

SESSION INFORMATION

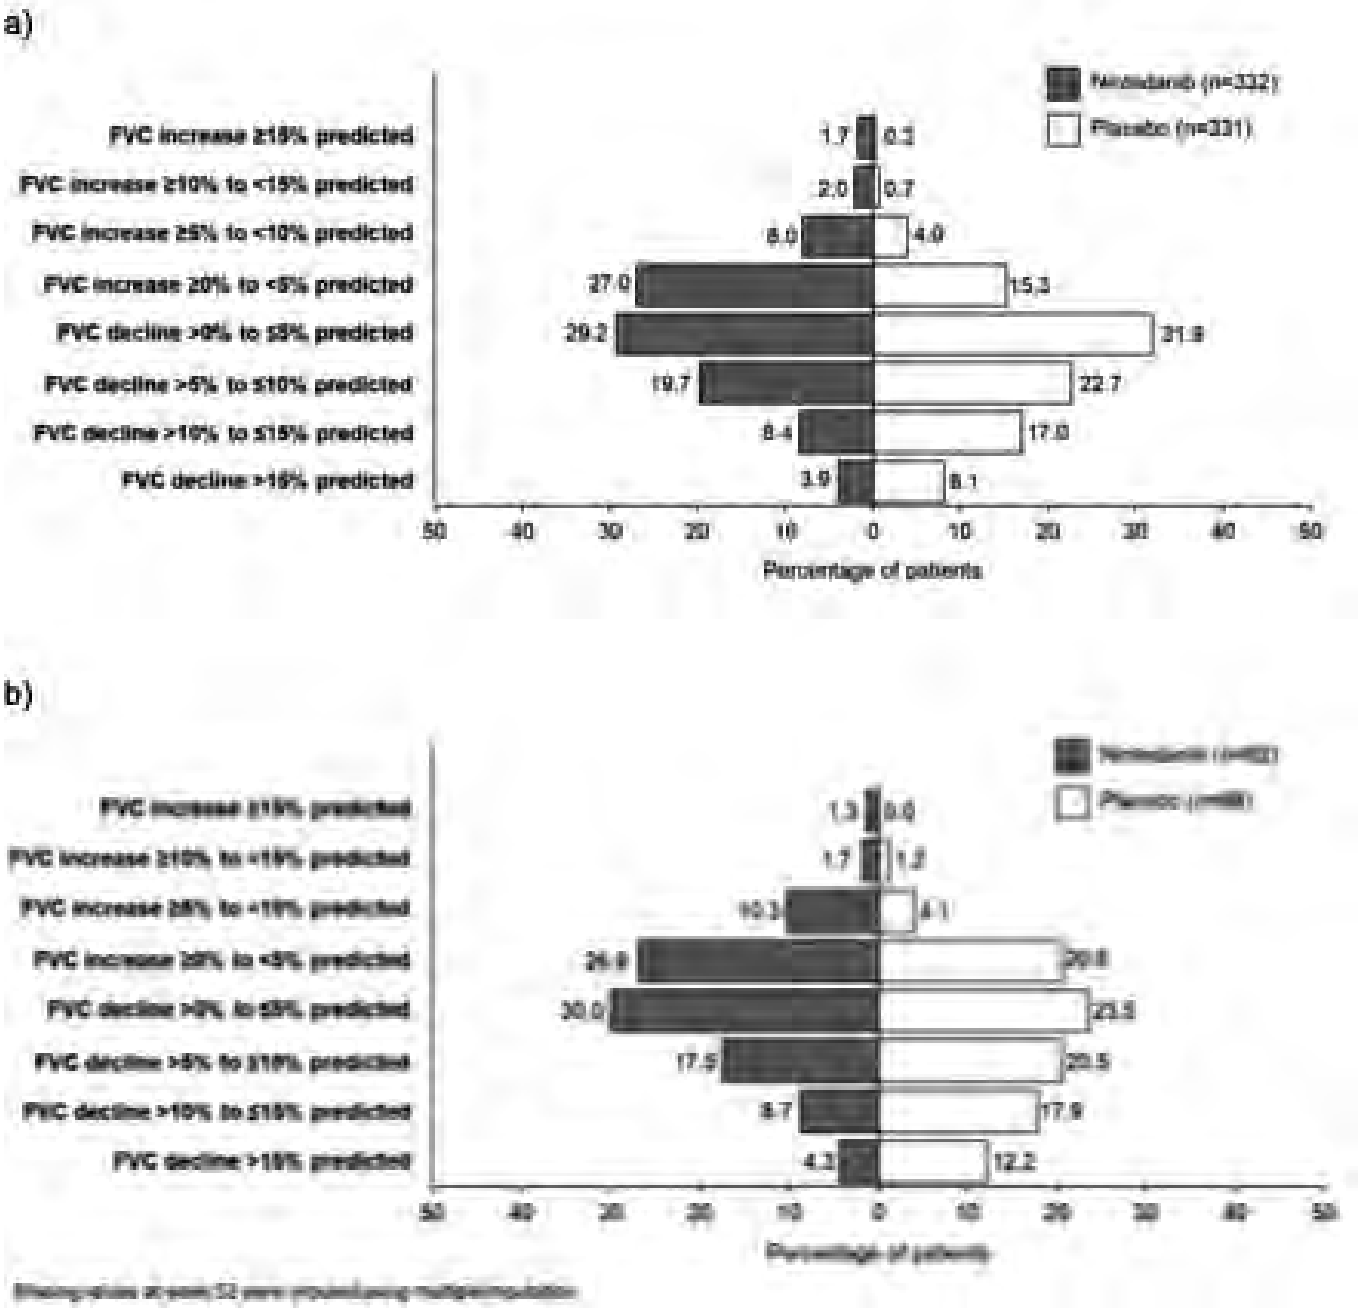
Session Date: Saturday, November 6, 2021

Session Title: Miscellaneous Rheumatic & Inflammatory Diseases Poster I (0183–0209)

Session Type: Poster Session A

Session Time: 8:30AM–10:30AM

Figure. Proportions of subjects with absolute increases and declines in FVC % predicted at week 52 in a) the overall population, and b) subjects with autoimmune disease-related ILDs.



Background/Purpose: In the INBUILD trial in subjects with progressive fibrosing interstitial lung diseases (ILDs) other than idiopathic pulmonary fibrosis (IPF), nintedanib reduced the rate of decline in FVC (mL/year) over 52 weeks by 57% versus placebo. We assessed the effect of nintedanib on categorical changes in FVC % predicted over 52 weeks.

Methods: Subjects in the INBUILD trial had diffuse fibrosing ILD (reticular abnormality with traction bronchiectasis, with or without honeycombing) of >10% extent on HRCT, FVC ≥45% predicted, DLco ≥30%–< 80% predicted, and

met criteria for progression of ILD within the 24 months before screening, despite management deemed appropriate in clinical practice. In *post-hoc* analyses, we assessed the proportions of subjects with categorical absolute increases or declines in FVC % predicted at week 52. Missing values at week 52 were imputed using multiple imputation. Analyses were descriptive.

Results: Overall, 332 subjects were treated with nintedanib and 331 received placebo. At baseline, mean (SD) FVC was 68.7 (16.0) % predicted in the nintedanib group and 69.3 (15.2) % predicted in the placebo group. In the nintedanib and placebo groups, respectively, 19.7% and 22.7% of subjects had absolute declines in FVC of >5% to ≤10% predicted and 12.3% and 25.1% had absolute declines in FVC >10% predicted, while 11.7% and 5.0% of subjects had absolute increases in FVC of ≥5% predicted (Figure). Similar findings were observed in the subgroup of 170 patients with autoimmune disease related ILDs (Figure).

Conclusion: In the overall population of the INBUILD trial and in the subgroup of subjects with autoimmune disease-related ILDs, the proportions of subjects with clinically relevant declines in FVC over 52 weeks were lower in the nintedanib group than in the placebo group. These results provide further support for the benefit of nintedanib on slowing the progression of ILD in subjects with progressive fibrosing ILD other than IPF.

SESSION INFORMATION

Session Date: Saturday, November 6, 2021
Session Title: Miscellaneous Rheumatic & Inflammatory Diseases Poster I (0183–0209)
Session Type: Poster Session A
Session Time: 8:30AM–10:30AM

Background/Purpose: Post-episode tapering of Standard of Care (SoC) medication in patients with recurrent pericarditis (RP) varies considerably. Gradual tapering of corticosteroids (CS) is recommended in ESC guidelines (e.g., decreasing by 1-2.5 mg/day every 2-6 weeks over 1-2 years) to prevent recurrence. We describe successful faster tapering of SoC treatment onto rilonacept monotherapy during RHAPSODY, a Phase 3, placebo-controlled, randomized-withdrawal (RW) trial in RP.

Methods: Patients with acute symptomatic RP despite stable doses of NSAIDs, colchicine, and/or CS in any combination enrolled in a 12-week run-in period in which weekly rilonacept was initiated. After 1-week of stabilization, tapering of CS began at a rate dependent on baseline dose, to be completed by Week 10 for randomization at Week 12 when clinical response was confirmed by reduced pain and normalized CRP levels. Colchicine tapering/discontinuation was initiated no earlier than Week 4. This analysis evaluates time to rilonacept monotherapy in subgroups receiving different combinations of background therapies.

Results: 79 of 86 patients were receiving pharmacotherapy at run-in baseline. Median (95% CI) time to monotherapy (n=79) was 7.9 (7.0-8.1) weeks. Of the patients receiving CS at baseline (41/86 [48%]), 39 (95%) tapered to rilonacept monotherapy, and median time to monotherapy was 7.9 (7.1-8.1) weeks. Of the patients receiving colchicine at baseline (65/86 [76%]), 61 (94%) patients achieved rilonacept monotherapy, and median time to monotherapy was 8.0 (7.1-8.3) weeks. Patients receiving only one SoC therapy achieved rilonacept monotherapy faster (6.1 [0.4-8.1] weeks) than those receiving 2 (8.0 [6.7-9.9] weeks) or 3 (7.7 [7.0-8.3] weeks) therapies. All patients who did not achieve monotherapy had withdrawn from the study for reasons unrelated to pericarditis.

Conclusion: All patients randomized in the RHAPSODY trial discontinued SoC and transitioned to rilonacept monotherapy (median time 7.9 weeks) without a recurrent pericarditis episode during run-in. In patients treated with rilonacept, time to successful discontinuation of SoC, including CS, was substantially shorter than that described in ESC guidelines for pericardial disease (Adler et al. Eur Heart J. 2015;36(42)2921-2964).

SESSION INFORMATION

Session Date: Saturday, November 6, 2021

Session Title: Miscellaneous Rheumatic & Inflammatory Diseases Poster I (0183–0209)

Session Type: Poster Session A

Session Time: 8:30AM–10:30AM

Background/Purpose: Autoinflammatory periodic fever syndromes (PFS) are characterized by severe systemic and organ inflammation. In clinical trials, successful treatment was achieved with the interleukin-1β inhibitor canakinumab (CAN).

The present study explores the long-term efficacy and safety of CAN in routine clinical practice conditions in pediatric (age ≥2 years) and adult patients with CAPS (cryopyrin-associated periodic syndromes), FMF (familial Mediterranean fever), TRAPS (tumor necrosis factor receptor-associated periodic syndrome) and HIDS/MKD (hyperimmunoglobulinemia D syndrome/mevalonate kinase deficiency).

Methods: RELIANCE is a prospective, non-interventional, observational study based in Germany. Patients with clinically confirmed diagnoses of PFS routinely receiving CAN are enrolled. Besides efficacy parameters regarding disease activity and remission, safety parameters were recorded at baseline and assessed at 6-monthly intervals.

Results: Here we present the interim analysis of 168 patients with PFS enrolled in the RELIANCE Registry between October 2017 and December 2020. Mean age in this cohort was 24.7 years (2-79 years) and the proportion of female patients was 51 %. At baseline, median duration of prior CAN treatment was 3 years (0-12 years).

Table. Overview of the CAN safety data of the RELIANCE study across all study indications (N=168 patients). ‡IR, incidence rate per 100 patient years; AE, adverse event; SAE, severe adverse event, SADR, severe adverse drug reaction

Type of event	Number of events	IR‡
AE total	489	173.33
AE non-serious	436	154.33
AE, non-serious, not related	221	78.34
AE, ARI	13	4.61
AE, non-serious adverse drug reaction	215	76.21
SAE, total	53	18.79
SAE, not related	32	11.34
SADR#, total	21	7.44

#Alport's syndrome, appendicitis, blister, cardiovascular disorder, chest pain, circulatory collapse, erythema, febrile convulsion, glomerulonephritis, Hemophilus test positive, pneumonia, premature delivery, skin discoloration, tonsillitis bacterial, tonsillitis streptococcal (each n=1 event, IR 0.35‡), tonsillectomy (2 events, IR 0.71‡), pyrexia (3 events, IR 1.06‡), not yet coded (hospital admission due to exsiccosis upon gastroenteritis, 1 event, IR 0.35‡)

A total of 101 patients (60%) experienced any adverse event (AE) and 22 patients (13%) were affected by severe adverse events (SAE). In 9 patients (5%) SAE were classified as drug related. Of 489 AE, 53 were severe and a total of 21 SAE were classified as treatment-related (table). Overall, 13 AE comprised upper respiratory tract infections (ARI).

Conclusion: The interim data from the RELIANCE study, the longest running real-life canakinumab registry for autoinflammatory periodic fever syndromes, confirm safety of long-term canakinumab treatment across the entire study population.

SESSION INFORMATION

Session Date: Saturday, November 6, 2021

Session Title: Miscellaneous Rheumatic & Inflammatory Diseases Poster I (0183–0209)

Session Type: Poster Session A

Session Time: 8:30AM–10:30AM

Background/Purpose: The IL-1 inhibitor canakinumab (CAN) induces rapid remission of symptoms of CAPS (Cryopyrin-associated periodic syndromes), a monogenic autoinflammatory disease with severe systemic inflammation, both in clinical trials and in routine practice.The aim of the present study is to investigate the long-term efficacy and safety of CAN in pediatric (≥ 2 years) and adult patients with CAPS (incl. Muckle-Wells syndrome [MWS], familial cold-induced autoinflammatory syndrome [FCAS], and neonatal onset inflammatory systemic disease [NOMID]/chronic infantile neurologic-cutaneous-articular syndrome [CINCA]) in relation to weight-dependent CAN dosing under routine clinical practice conditions.

Methods: The prospective, non-interventional, observational RELIANCE study with 3-year follow-up includes patients with clinically confirmed CAPS diagnosis who routinely receive CAN. Clinical data, physician assessment, and patient-reported outcomes are evaluated at 6-month visits from baseline.

Results: The interim analysis included data from 91 CAPS patients (50% females; 14 [15%] NOMID/CINCA subtypes) enrolled by December 2020. At baseline, median age was 20.5 years and median duration of prior CAN treatment was 6 years. According to physician assessment, 66% of patients achieved disease remission with increasing absence of disease activity according to PGA (physician global assessment, 50-60%). Patients reported stable, low levels of disease activity, fatigue, and Auto-Inflammatory Diseases Activity Index (AIDAI) scores. CAPS affected the social life of 50% of patients and 50% reported days of absence from school/work. At baseline, 2% of patients received less than the standard dose* CAN (SD; < 87.5% of SD), 49% received standard dose CAN (SD CAN; 150 mg and 2mg/kg respectively per 8 weeks) and another 49% received higher than SD CAN (>112.5% of SD). At 30 months, 82% of patients received higher than SD CAN. The laboratory parameters as well as physicians´ and patients´ rating of disease activity remained stable over time, showing sustained remission and disease control in all dosing groups (Table 1).

Table 1. Stratification of efficacy parameters for CAN dosing and weight (N=91)#. *Body weight >40kg: Standard dose is 150 mg per 8 weeks; Body weight ≤40 kg: Standard dose is 2mg per kg per 8 weeks; #Numbers and percentages do not sum up to N=91 or 100%, respectively, due to the number of patients with unknown weight.

		Baseline	12 months	24 months	30 months
% of patients on low/**standard**/high dose CAN, *number of patients analyzed (N)*		2/**49**/49, *N=80*	10/**19**/71, *N=59*	7/**25**/68, *N=28*	0/**18**/82, *N=22*
		PGA absent/mild-moderate/severe			
Physician Global Assessment (PGA), %# of patients	less than CAN SD*	71/14/7	36/64/0	25/63/0	100/0/0
	CAN SD*	19/81/0	22/78/0	50/50/0	0/100/0
	more than CAN SD*	35/57/2	34/54/3	56/39/0	62/38/0
		VAS 0–10, (min; max)			
Patients' assessment of current disease activity (median)	less than CAN SD*	0 (0; 7)	1 (0; 7)	1 (0; 7)	0 (0; 0)
	CAN SD*	2 (0; 6)	2 (0; 4)	3 (2; 4)	2 (1; 3)
	more than CAN SD*	2 (0; 10)	3 (0; 10)	1 (0; 10)	0 (0; 7)

Treatment-related severe adverse events (SAE) occurred in 8 patients, none of them under standard dosing (in 1 patient: less than SD, in 7 patients more than SD).

Conclusion: The 30-month interim analysis of the RELIANCE study shows that long-term treatment with CAN is safe and effective in patients with CAPS. A clear trend towards updosing to more than SD CAN could be observed.

SESSION INFORMATION

Session Date: Saturday, November 6, 2021

Session Title: Miscellaneous Rheumatic & Inflammatory Diseases Poster I (0183–0209)

Session Type: Poster Session A

Session Time: 8:30AM–10:30AM

Background/Purpose: Familial Mediterranean Fever (FMF) is characterized by severe systemic and organ inflammation. Successful treatment with rapid remission of symptoms and normalization of laboratory parameters was achieved in most patients with the interleukin-1β inhibitor canakinumab (CAN) in clinical trials. The aim of the present analysis was the evaluation of long-term efficacy and safety of CAN in pediatric (age ≥2 years) and adult patients with FMF with respect to weight-dependent CAN dosing in routine clinical practice.

Methods: RELIANCE is a prospective, non-interventional, observational study based in Germany. Patients with clinically confirmed diagnoses of autoinflammatory periodic fever syndromes routinely receiving CAN are enrolled. Efficacy and safety parameters, CAN dosing as well as weight were recorded at baseline and assessed at 6-monthly intervals within the 3-year observation period of the study.

Results: The interim analysis of the RELIANCE Registry comprises data of 54 FMF patients enrolled by December 2020. Of these, the % of patients reported to receive standard dose CAN (SD CAN; 150 mg or 2mg/kg respectively per 4 weeks) halved from 77% at baseline to 36% at month 18 in favor of less than SD CAN (< 87.5% of SD) and higher than SD CAN (>112.5% of SD). Patients´ and physicians´ rating of disease activity was higher in patients receiving SD CAN and higher (table 1), even though CRP was equally well controlled in all three dosing groups. A total of 11 serious adverse events was reported, of which 1 case of tonsillectomy was classified as drug-related.

Conclusion: The present interim data from the RELIANCE study confirm efficacy and safety of long-term CAN treatment in clinical routine. CRP levels were well controlled in all dosing groups. Remaining disease activity was mainly observed in patients under SD CAN and especially higher than SD CAN.

Table 1. Stratification of efficacy parameters by CAN dose category and weight (N=54)#. *Body weight >40 kg: SD is 150 mg per 4 weeks; Body weight ≤40 kg: SD is 2 mg/kg per 4 weeks #Numbers/percentage do not sum up to N=54/100%, due to unknown weight of some patients

SESSION INFORMATION

Session Date: Saturday, November 6, 2021

Session Title: Miscellaneous Rheumatic & Inflammatory Diseases Poster I (0183–0209)

Session Type: Poster Session A

Session Time: 8:30AM–10:30AM

Background/Purpose: Familial Mediterranean Fever (FMF) is the most common auto-inflammatory disease characterized by chronic inflammation, recurrent episodes of fever, abdominal and thoracic pain due to serositis, skin irritations and arthralgia. FMF patients are at risk for severe organ failure due to amyloidosis. Colchicine and IL-1 antagonists are approved therapeutic options but alternative treatment options are still warrant. Tocilizumab (TCZ) is a monoclonal antibody directed against the IL-6 receptor and approved for several other autoimmune diseases that go along with high inflammation markers.

Methods: This was a randomized, blinded, placebo-controlled trial conducted at 5 German centres. Adult patients with FMF, who had at least one known mutation of the MEFV gene and active disease with inadequate response or intolerance to colchicine were included. The physician's global assessment of disease activity (PGA) based on a 5 point-scale was used as a clinical score and had to be >2 at screening. Patients were randomized 1:1 to either receive

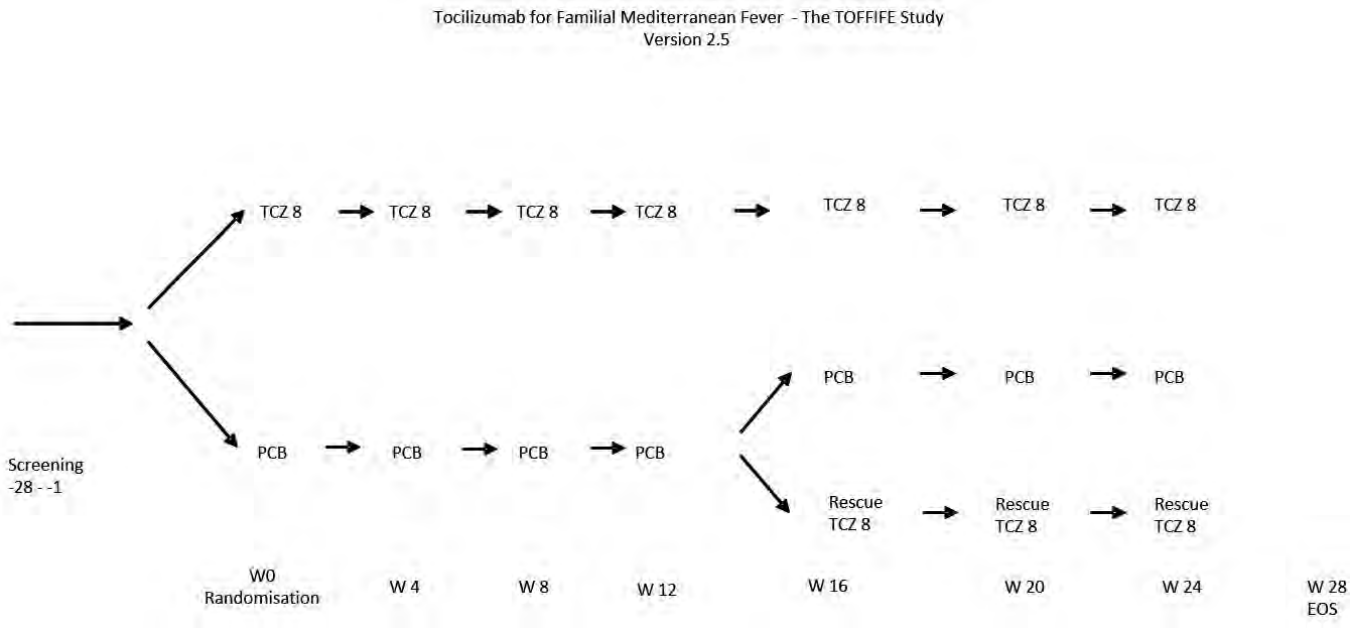

Figure 1. Trial scheme with 1:1 randomization and rescue arm, at week 16.

TCZ intravenously with 8 mg/kg bodyweight or placebo over a period of 24 weeks. Patients with inadequate response after week 12 had the opportunity to receive open label TCZ at week 16. The primary endpoint was the number of patients achieving an adequate response to treatment at week 16, defined as a PGA ≤ 2 + normalized ESR or CRP + normalized SAA. Patients filled out a patient's diary to help the investigators to judge the PGA

Results: Of the 31 included patients, only 25 were randomized, 6 patients dropped out before randomization due to missing data, withdrawal or incompliance. For further evaluation the intention to treat population consisted of 25 patients with a median age of 31 years (range 18 - 53y), of which 14 (56%) were female. In their medical history all were treated with colchicine with inadequate response, whereas in 3 patients anakinra and in 1 patient canakinumab were ineffective. At week 16, the primary endpoint was met by only 2 patients in the TCZ, but none of the patients in the placebo arm (P-value of 0.089). The difference was primarily due to the failed normalization of the laboratory parameters in the placebo group, whereas the difference in PGA was not significant. No new safety aspects occurred.

Conclusion: This is the first randomized, placebo-controlled study on the efficacy of TCZ in patients with active FMF. Our results demonstrate the superiority with regard to our primary endpoint: more patients in the TCZ arm experienced an adequate response to treatment in comparison to placebo. SAA levels only normalized in TCZ treated patients. As TCZ normalizes CRP levels in almost all patients this effectiveness has to be confirmed in a larger trial.

Session Title: Miscellaneous Rheumatic & Inflammatory Diseases Poster I (0183–0209)
Session Type: Poster Session A
Session Time: 8:30AM–10:30AM

Background/Purpose: There is a lack of robust guidance and consistently effective treatment modalities in non-paraneoplastic autoimmune retinopathy (npAIR) with cystoid macula edema (CME), which is often jointly treated by the Rheumatology provider. This retrospective case series was generated as further evidence is needed to understand options for treatment to include the effect of anti-interleukin-6 (IL-6) receptor monoclonal antibodies Tocilizumab (humanized monoclonal antibody) and Sarilumab (fully humanized monoclonal antibody) in eyes with npAIR with CME.

Table 2. Clinical characteristics of patients who were treated with anti-IL-6 therapy for npAIR with CME

Anti-IL-6 = anti-interleukin-6, CST = central subfield thickness (microns), TMV = total macular volume (cubic millimeter)
Statistical analysis could not be performed on subgroups in which n = 1, these P-values are marked with the placeholder "-"

Methods: This retrospective case series included Fourteen eyes from 8 patients with npAIR and CME, all were seropositive for anti-retinal antibodies, treated with anti-IL-6 therapy and had a negative workup for paraneoplastic etiologies. Visual acuity (VA) and central subfield thickness (CST), total macular volume (TMV), and ellipsoid zone integrity change in central 6mm on foveal scan as measured by optical coherence tomography were extracted from charts prior to and at 3, 6, 12, 18, and 24 months after anti-IL-6 therapy was initiated. Eyes that had a >20% reduction in CST were defined as treatment responders, >20% increase in CST as failures, and ≤20% change in CST as stable. The main outcome measures were VA CST, TMV, and ellipsoid zone integrity change.

Results: Eleven eyes of six patients had failed multiple prior immunosuppressive therapies (Table 2). There was a significant reduction (P< .05) in CST at baseline (473.1 mm) after initiation of anti-IL-6 therapy that began at 3 months (389.2 mm) and continued through 24 months (348.7 mm). Similarly, there was a significant reduction (P< .05) in TMV baseline (10.15 mm^3) after initiation of anti-IL-6 therapy that began at 3 months (8.91 mm^3) and continued through 24 months (7.67 mm^3). VA improved from 0.84 to 0.52 at 24-month follow-up but did not reach statistical significance (P=.157). Nine of 14 eyes (64.3%) were treatment responders, 4 eyes (28.6%) were stable, and 1 eye (7.1%) was a treatment failure. After initiation of IL-6 therapy, there was a significant decrease in velocity of EZ change, experiencing an average restoration of 22.7 mm per month (P=.008). At least one eye of all patients responded to anti-IL-6 treatment. No patient experienced adverse effects or required discontinuation of therapy while on anti-IL-6 medication.

Conclusion: In this cohort of patients with npAIR and CME, treatment with anti-IL-6 medications tocilizumab and sarilumab, was associated with reduced CME, partial restoration of the ellipsoid zone, and a trend towards improved VA, while reducing burden of prior immunosuppressive therapies (Table 3). The treatment was well tolerated and

these largely positive and sustained results are important given the limited number of viable treatment options in the management of npAIR.

JAK Inhibitors in Refractory Adult and Childhood-Onset Still's Disease

Louise GILLARD[1], Stéphane Mitrovic[2], Jacques Pouchot[3], Fleur Cohen[1], Martin Michaud[4], Heloise Reumaux[5], Isabelle Kone-Paut[6] and Bruno Fautrel[7], [1]Pitié Salpêtrière Hospital, Paris, France, [2]Pitié Salpêtrière Hospital - Institut Mutaliste Montsouris, Paris, France, [3]AP-HP, RUEIL-MALMAISON, France, [4]Joseph Ducuing Hospital, Toulouse, France, [5]Jeanne de Flandre Hospital, Lille, France, [6]APHP, Bicetre hospital, Le Kremlin bictre, France, [7]Pitié Salpêtrière Hospital, APHP, Sorbonne Université, Paris, France

SESSION INFORMATION
Session Date: Saturday, November 6, 2021
Session Title: Miscellaneous Rheumatic & Inflammatory Diseases Poster I (0183–0209)
Session Type: Poster Session A
Session Time: 8:30AM–10:30AM

Background/Purpose: Excessive and inappropriate production of pro-inflammatory cytokines such as interleukin IL-1, IL-6 or IL-18, is a pathogenic cornerstone in adult and childhood onset Still's disease. Beyond therapies targeting IL-1 or IL-6, Janus kinases (JAK) inhibitors have been proposed for AOSD patients refractory to or intolerant of treatment with biologicals. Recently, it has been suggested that JAK inhibitors might be efficient in refractory AOSD patients.

Methods: This retrospective study was based on a national survey of the departments of rheumatology, paediatric rheumatology and internal medicine in all French hospitals from an online call of the "Club Rhumatismes et Inflammation" (www.cri-net.com). The data were collected using a standardized questionnaire, and analyzed at different time points (treatment initiation, M1, M3, M6 and end of the follow-up). The response to JAK inhibitors was categorized as: complete remission (resolution of all clinical and biologic signs), partial remission (clinical improvement with persistence of a few symptoms) or failure (lack of clinical or biological improvement).

Results: 7 patients (5 adults and 2 children) were recruited (Table). Mean age at treatment start was 39.6 +/- 9.6 years for the AOSD patient and 11.0 +/- 7.07 years for the sJIA patients, and mean disease duration was years. The clinical expression was predominantly systemic in 6 patients and chronic articular in one. Response to corticosteroids, conventional synthetic or biological Disease Modifying Anti-Rheumatic Drugs had been considered inadequate in all patients. Baricitinib was used in 4 patients (of whom one was later switched to upadacitinib), ruxolitinib in 2, and tofacitinib in 1. Steroids were concurrently used in all patients, anakinra in one, methotrexate and anakinra in one who was then switched to colchicine and anakinra. At a mean follow-up of 11.3 +/- 9.3 months, partial response was observed in 4 cases (57%) (patients with ruxolitinib, baricitinib or tofacitinib) and failure in 3 (43%) (patients with baricitinib or ruxolitinib). No patient achieved complete remission. At the last visit, steroids could be decreased but not stopped in all patients. Patients with partial response had an average decrease of 63% (40% for tofacitinib and 80% for ruxolitinib between the start and the follow-up end date) and patients with no response were able to reduce steroids by 65% (Table). JAK inhibitors tolerance was excellent in all but one patient who developed organized pneumonia which led to discontinuation of the treatment.

Table. Characteristics of the AOSD patients

No.	Sex	Age (years)	Main symptoms	Treatments before JAKi onset	JAK inhibitors	Steroids at onset (mg/day)	Concomitant treatment	Response at last follow-up	Steroids at the end of follow-up (mg/day)	Follow-up (months)
1	F	6	Fever, polyarthritis, rash	AINS, MTX, ANAKI, TOCI, CANAKI, ADA, THALI	RUXOLITINIB 5mg x 2/day (majoration at 15 mg x 2/day)	3	INDOCID (stop)	Partial Response	1	25
2	F	16	Fever, polyarthritis	ANAKI, MTX, INFLIX, ETANERCEPT, CANAKI, TOCI	BARICITINIB 4 mg/day (majoration at 8 mg/day)	40	APRANAX	Partial Response	14	9
3	M	28	Fever, polyarthritis, rash	ANAKI	BARICITINIB 4mg/day	80	0	**No Response**	10	1
4	M	32	Fever, polyarthritis, rash	TOCI+MTX, ANAKI+MTX, CANAKI+MTX, ADA, CICLO, IgIV	BARICITINIB 4mg/day (stop at M17) UPADACITINIB 15 mg/day	16	MTX 20 mg/week (stop) ANAKINRA 100mg/day COLCHICINE 1.5 mg/day	Partial Response	13	22
5	F	40	Fever, polyarthritis, rash	MTX, IMUREL, CICLO, ETANERCEPT, ANAKI+MTX, TOCI+MTX, IgIV	RUXOLITINIB 15mg x 2/day	60	ANAKI 200mg/day	**No Response**	15	9
6	F	48	Fever, polyarthritis, rash	TOCI, ANAKI, CICLO, CANAKI, IMUREL	TOFACITINIB 5mg x 2/day	50	0	Partial Response	30	12
7	F	50	Fever, polyarthralgia, rash	ANAKI	BARICITINIB 4mg/day	60	0	**No Response**	40	1

Conclusion: JAK inhibitors therapy may be helpful for some patients with refractory Still's disease, but not in monotherapy. However, no complete response was observed in this short series of cases. There might be a difference of response between the molecules, although the number of patients is too low to draw conclusions. Additional information is thus needed to evaluate more precisely the risk-benefit ratio of this treatment, and a possible difference in efficacy among the different groups of JAK inhibitors.

Session Title: Miscellaneous Rheumatic & Inflammatory Diseases Poster I (0183–0209)

Session Type: Poster Session A

Session Time: 8:30AM–10:30AM

Table 1. Outcomes with anakinra verses placebo, modified intent to treat analysis; N (%) unless otherwise stated. * P values < 0.05

	Anakinra Arm (N = 15)	Placebo Arm (N = 15)	p-value
Primary Outcomes			
Survival Day 10	14 (93.3)	13 (86.7)	1.0
Survived hospitalization	11 (73.3)	11 (73.3)	1.0
Did not require mechanical ventilation	10 (66.7)	10 (66.7)	1.0
Secondary Outcomes			
75% improvement from Day 0 ferritin and CRP elevations by Day 10, N=26	6 (46.2)	7 (53.9)	1.0
75% improvement from Day 0 LDH and D-dimer elevations by Day 10, N=26	0 (0.0)	7 (53.9)	0.005*
Able to maintain oxygen saturation >92% on RA by Day 10, N=27	4 (28.6)	9 (69.2)	0.06

Table 2. Estimation of anakinra effect on the composite of death from any cause or need for invasive mechanical ventilation, after adjustment for potential confounding factors, using a multivariable Cox proportional hazards model.

	Hazard ratio	95% CI	p value
Anakinra group vs Placebo group	1.688	0.354 – 8.048	0.51
Female *vs* Male	0	NA	1
Age ≥65 *vs* <65	2.438	0.0.438 – 13.562	0.31
Number of comorbidities ≥2 *vs* 0-1	0.771	0.054 – 10.93	0.85
Increase in oxygen requirement or oxygen delivery measures to maintain oxygen saturation >90% at Day 2 *vs* no increase in oxygen requirement or oxygen delivery measures to maintain oxygen saturation >90% at Day 2	3.0879E8	NA	1

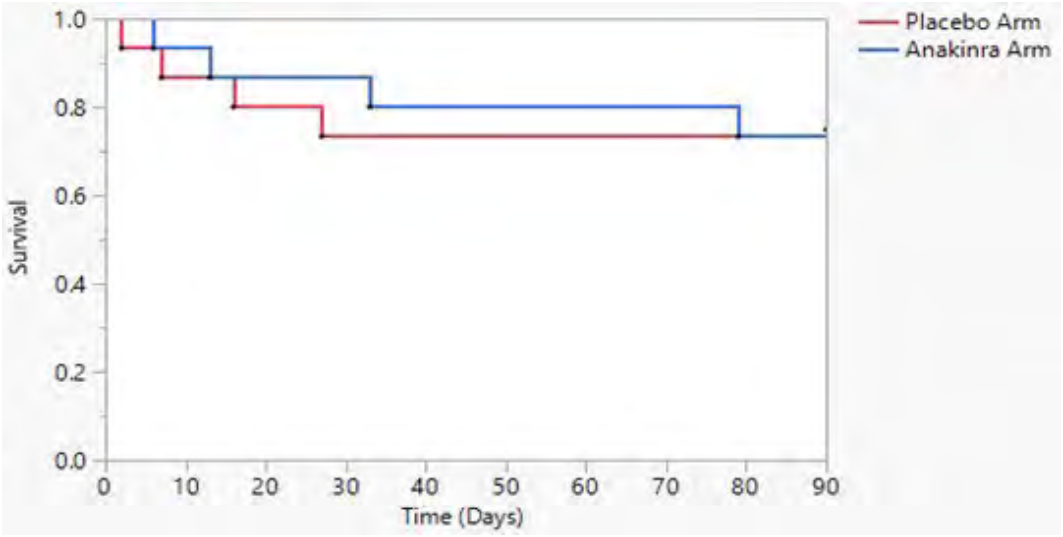

Figure 1. Kaplan Meier Curve demonstrating survival according to treatment with anakinra and placebo groups.

Background/Purpose: Some patients with COVID-19 develop respiratory distress and cytokine storm syndrome (CSS) which is characterized by hyperinflammation and may progress to multi-organ failure. Anakinra is a recombinant interleukin-1 receptor antagonist used to treat some inflammatory disorders and has previously demonstrated mortality benefit in sepsis patients with CSS. Anakinra may play a role in certain patients with COVID-19 to reduce hyperinflammation and improve outcomes. The aim of this study was to assess the efficacy and safety of anakinra when added to standard of care in patients with COVID-19 infection and features of cytokine storm syndrome.

Methods: In this single center, randomized, double-blind, placebo-controlled trial (ClinicalTrials.gov, NCT04362111), adult inpatients were recruited with molecular PCR RNA confirmed SARS-CoV-2 infection, radiographic evidence of COVID-19 pneumonia based on imaging, new or increasing oxygen requirement, ferritin ≥700 ng/ml, and any three of the following: D-dimer ≥500 ng/ml, platelet count < 130,000/mm^3, white blood cell count < 3500/mm^3 or lymphocyte count < 1000/mm^3, AST or ALT >2X the upper limit of normal (ULN), LDH >2X the ULN, C-reactive protein >100 mg/L. Eligible patients were randomly assigned (1:1) to standard of care (SoC) plus anakinra (100 mg subcutaneous every 6 hours for 10 days) or SoC plus placebo. All received dexamethasone. Primary outcome was survival and discharge from the hospital without the need for intubation/mechanical ventilation at day 10. All analyses were done on a modified intention-to-treat basis.

Results: Between August 5, 2020 and January 2, 2021, 32 patients (235 screened) were recruited: 15 assigned to the anakinra group and 17 to placebo group. Two patients in the placebo group withdrew in the initial 48 hours and were excluded from analysis. Mean age was 63 (SD 10.3), 20 (66.7%) participants were men, and 20 (66.7%) were Caucasian. At day 10, 1 (6.7%) patient in the anakinra group had died and 2 (13.3%) patients in the placebo group had died (p=1.0). At hospital discharge, 4 (26.7%) patients in the anakinra group and 4 (26.7%) patients in the usual care group had died. Confirmed microbial infections occurred in 4 patients in the anakinra group and 2 in the placebo group (p=0.7).

Conclusion: Anakinra added to dexamethasone did not significantly impact outcomes in this study of patients with clinical laboratory features of early CSS and mild-to-moderate COVID-19 pneumonia. Additional studies are needed to assess the efficacy and optimal dosing duration of anakinra in patients with more severe COVID-19.

Successful Treatment of Severe COVID-19 Pneumonia with Simultaneous Tocilizumab and Anakinra - A Case Series

Hildrun Haibel[1], Stefan Angermair[2], Michael Schumann[2], Janis Vahldiek[3], Denis Poddubnyy[4] and Thomas Schneider[2], [1]Department of Gastroenterology, Infectiology and Rheumatology (including Nutrition Medicine), Charité – Universitätsmedizin Berlin, corporate member of Freie Universität Berlin and Humboldt-Universität zu Berlin, Berlin, Germany, [2]Charité University Medicine Berlin Campus Benjamin Franklin, Berlin, Germany, [3]Charité University Medicine Berlin, Berlin, Germany, [4]Department of Rheumatology, Charité – Universitätsmedizin, Berlin, Germany

SESSION INFORMATION
Session Date: Saturday, November 6, 2021
Session Title: Miscellaneous Rheumatic & Inflammatory Diseases Poster I (0183–0209)
Session Type: Poster Session A
Session Time: 8:30AM–10:30AM

Background/Purpose: Severe and life threating COVID-19 pneumonia is often characterized by local and systemic immune-mediated hyperinflammation At the early disease stage activated monocytes are migrating to the lung and cause the typical opac infiltrates, which lead to an reduction of oxygen uptake. This was the rationale use this combination anti-inflammatory drugs in severe Covid-19 disease. Interleukin (IL)-6 and IL-1 blockade alone, respectively showed contradictory results in severe COVID-19 pneumonia that might be related to the differences is patient populations (early vs. late stage) and to the fact that blockade of just one cytokine might be not sufficient against the cytokine storm. Here we report results of an open-label treatment with a combination of an IL-6 receptor blocker to-

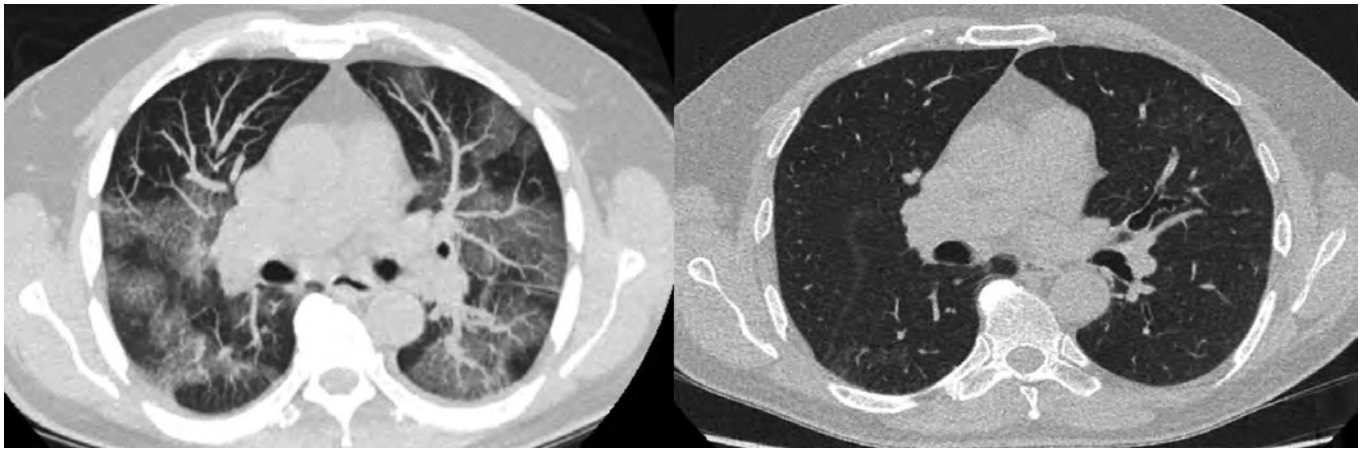

Image 1. CT-Scan of a patient with active COVID-19 infection before and one month after treatment with a combination of tocilizumab and anakinra.

cilizumab and an IL-1 receptor antagonist anakinra in patients with early (up to 10 days since symptom onset) severe COVID-19 pneumonia with evidence of cytokine release.

Methods: Adult patients with, according to WHO criteria, severe to critical COVID-19 infection associated pneumonia and cytokine release, requiring oxygen supplementation and evidence of rapid deterioration and decrease of oxygen saturation to ≤ 95% hospitalized between May 2020 and April 2021 were treated with tocilizumab 8 mg/kg up to 800 mg intravenously and anakinra 100 to 300 mg for 3 to 5 days, starting at the same day. We excluded patients with a symptom duration of > 10 days, patients with evidence of bacterial infection, indicated by an elevated procalcitonin serum level, patients with severe pre-existing lung disease such as severe COPD or heart failure of > II according to the NYHA classification and patients > 80 years. Laboratory parameters and chest CT were performed before and one month after treatment. A semi-quantitative CT score was calculated based on the extent of lobar pneumonia involvement (0:0%; 1, < 5%; 2:5-25%; 3:26-50%; 4:51-75%; 5, > 75%; range 0-5; global score 0-25) for each time point. All patients were informed about the off label use in reference to the statement of the German Robert Koch Institute regarding therapies in “off label use” in COVID-19 patients after carefull consideration of the individual risk-benefit ratio and written individual consents were obtained.

Results: Thirty-one adult patients with severe COVID-19 pneumonia and signs of cytokine release, mean age 54 (30-79) years, 5 female, 26 male, mean symptom duration 6 (3-10) days, were treated. Patients with more than > 10 days of symptoms, evidence of bacterial infection/ elevated procalcitonin and other severe lung diseases were excluded. Computed tomography (CT) scans of the lung were performed initially and after one month; inflammatory activity was assessed on a scale 0 to 25. Twenty-five patients survived without intubation and mechanical lung ventilation, two patients died. C-reactive protein decreased in 19/31 patients to normal ranges. The mean activity CT score decreased from 14 (8-20) to 6 (0-16, n=16).

Conclusion: In conclusion, most of our patients recovered fast and sustained, indicating that early interruption of cytokine release might be very effective in preventing patients from mechanical ventilation, death and long-term damage.

SESSION INFORMATION

Session Date: Saturday, November 6, 2021

Session Title: Miscellaneous Rheumatic & Inflammatory Diseases Poster I (0183–0209)

Session Type: Poster Session A

Session Time: 8:30AM–10:30AM

Background/Purpose: Rapid and effective remission-inducing therapy is mandatory in uveitis to avoid irreversible structural and functional damage. In some severe cases biological agents might be required (1-6). High-dose intravenous methylprednisolone (IVMP) may achieve prompt control of inflammation in most immune mediated inflammatory diseases (IMID), including non-infectious uveitis (NIU). The objective is to evaluate the efficacy and safety of IVMP pulse therapy in NIU of different IMID.

Methods: Multicentre study of 71 patients with severe uveitis who received IVMP. The underlying diseases were: Vogt-Koyanagi-Harada disease (VKHD) (n=24), Behçet disease (BD) (19), Sarcoidosis (5) and idiopathic NIU (23). The main outcome variable was Best-Corrected Visual Acuity (BCVA) estimated using the Snellen chart. BCVA that was assessed at 0 (basal), 2-5, 7, 15 and 30 days after IVMP. The results are expressed as mean ±SD in normally distributed variables, or as median [IQR] when are not. Comparison of continuous variables was performed using the Wilcoxon test.

Results: We studied 46♀/ 25♂ patients. The main features are shown in TABLE. IVMP dose ranged from 250 to 1000 mg/day administered for 3-5 consecutive days, the dose was established according to the presence or not of other systemic manifestations apart from uveitis. All of them had active intraocular inflammation at the moment of the study. BCVA values improved considerably after 1 month (FIGURE). No major side effects were observed.

Conclusion: High-dose IVMP pulse therapy is useful and safe for a prompt control of BCVA regardless of the underlying IMID.

Session Title: Miscellaneous Rheumatic & Inflammatory Diseases Poster I (0183–0209)

Session Type: Poster Session A

Session Time: 8:30AM–10:30AM

Background/Purpose: Cystoid Macular Edema (CME) is the most important cause of blindness in non-infectious uveitis (NIU) (1). Corticosteroids and conventional and/or biological immunosuppressant may be required (1-6). High-dose intravenous methylprednisolone (IVMP) pulse therapy may induce a rapid improvement.

Table. Main features of 66 patients with cystoid macular edema

	VKH (n=24)	Idiophatic (n=23)	Behcet's disease (n=19)	Overall (n=66)
Men/Women, n	5/19	9/14	9/10	66
Mean age (years)	42 ± 11	47 ± 15	33 ± 10	-
Unilateral/Bilateral, n (%)	2 (8.3) /22 (91.7)	10 (43.5) /13 (56.5)	4 (21) /15 (79)	16/50
Inflammatory ocular patterns, n (%)

HLA B51	0 (0)	5 (21.7)	8 (42)	13

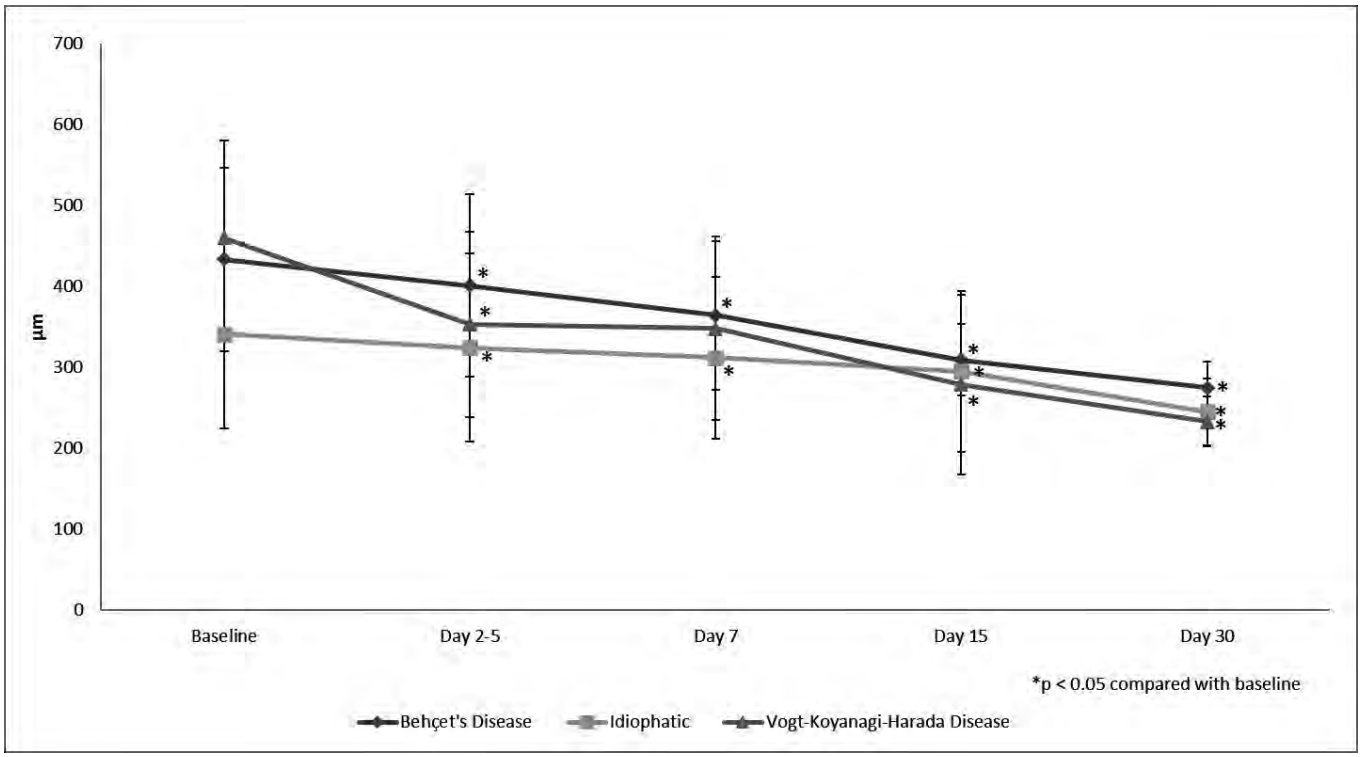

Figure. Improvement of OCT in 66 patients with cystoid macular edema.

The objective is to evaluate the efficacy and safety of IVMP pulse therapy in CME of different immune mediated inflammatory diseases (IMID).

Methods: Multicentre study of 66 patients with severe ocular inflammation who received IVMP. The underlying diseases were: Vogt-Koyanagi-Harada disease (VKHD)(n=24), Behçet's disease (BD) (19) and idiopathic NIU (23). The main outcome variable was macular thickness and macular edema (Optical coherence tomography [OCT] >300 µm); that was assessed at 0 (basal), 2-5, 7, 15 and 30 days after IVMP. The results are expressed as mean ±SD for normally distributed variables, or as median [IQR] when are not. Comparison of continuous variables was performed using the Wilcoxon test.

Results: We studied 43♀/ 23♂ patients. The main features are shown in TABLE. IVMP dose ranged from 250 to 1000 mg/day administered for 3-5 consecutive days, the dose was established according to the presence or not of

other systemic manifestations apart from uveitis. All of them had active intraocular inflammation at the moment of the study. A rapid and maintained statistically improvement was observed in OCT values in all underlying diseases (FIGURE). No major side effects were observed.

Conclusion: High-dose IVMP pulse therapy is useful and safe in the prompt control of CME, regardless of the underlying IMID.

Abstract Number: 0200

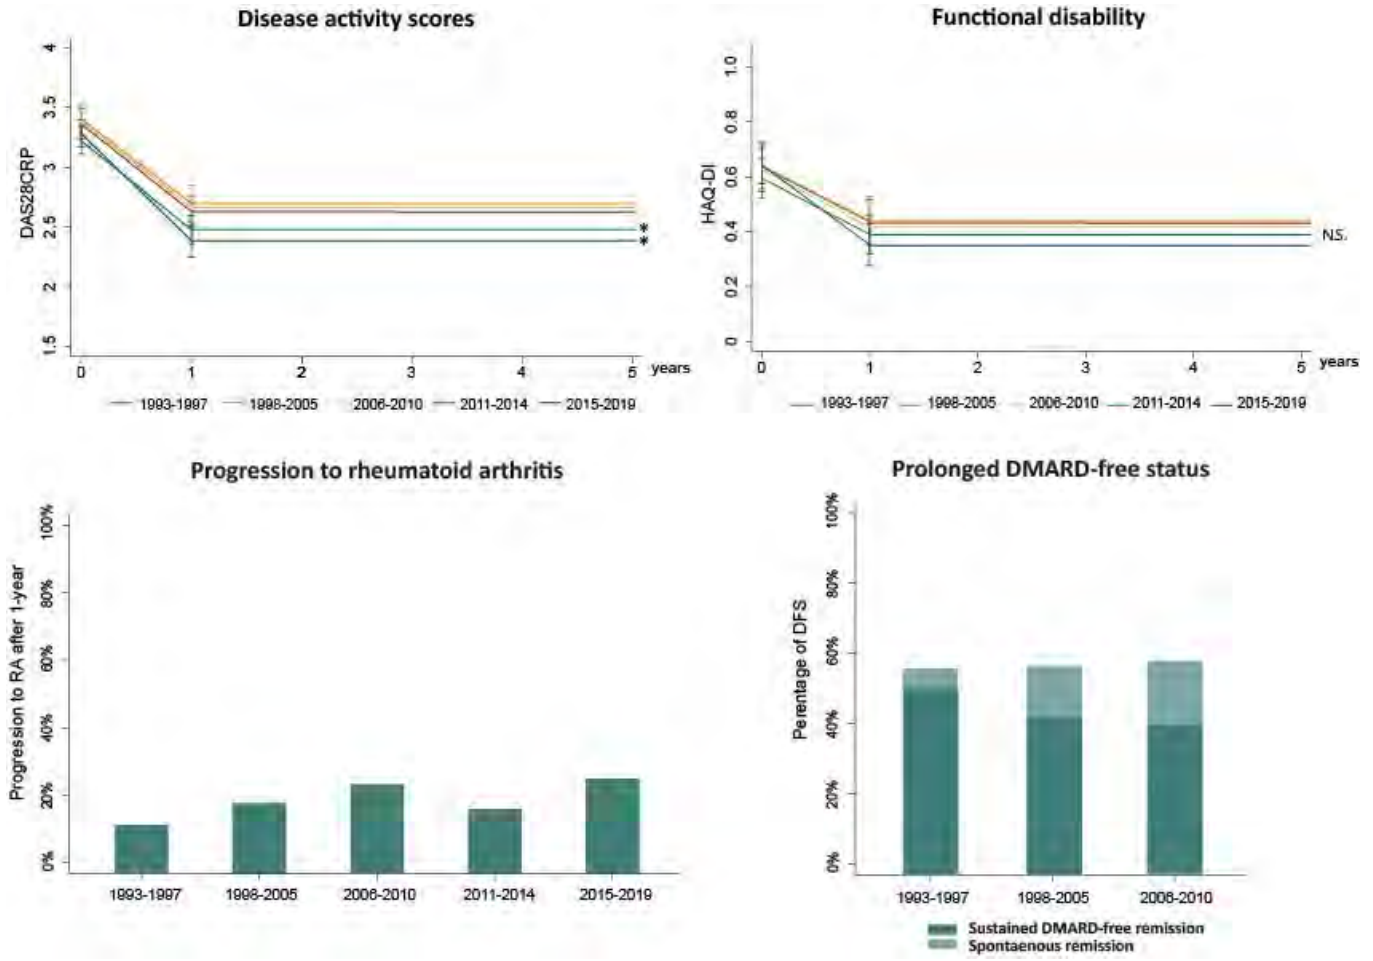
In Undifferentiated Arthritis, DMARD-treatment Intensified During the Last Decennia but Did Not Result in Improved Outcomes

Marloes Verstappen, Xanthe Matthijssen and Annette H.M van der Helm-van Mil, Leiden University Medical Center, Leiden, Netherlands

SESSION INFORMATION
Session Date: Saturday, November 6, 2021
Session Title: Miscellaneous Rheumatic & Inflammatory Diseases Poster I (0183–0209)
Session Type: Poster Session A
Session Time: 8:30AM–10:30AM

Background/Purpose: International guidelines stress timely DMARD-initiation in early arthritis, also when classification-criteria are not yet fulfilled. Consequently, undifferentiated arthritis (UA)-patients are increasingly treated despite placebo-controlled evidence for DMARD-effectivity in UA. Furthermore, since the introduction of the 2010 classification-criteria, the UA-population changed and trials including UA-patients not fulfilling the 1987- *and* 2010-criteria are absent. With 25-years of observational data, using inclusion-period as instrumental variable for DMARD-treatment, we studied whether enhanced treatment-strategies improved (long-term) outcome in UA.

Methods: UA was defined, in retrospect, as clinical arthritis neither fulfilling the 1987 nor the 2010 criteria for RA, nor any other distinct diagnosis. In total, 1132 UA-patients, consecutively included in the Leiden Early Arthritis Clinic between 1993-2019, were studied, divided into 5 inclusion-periods; 1993-1997, 1998-2005, 2006-2010, 2011-2014, 2015-2019. Frequency of DMARD-initiation was compared between the inclusion-periods as were the following



Legend: Baseline disease activity scores and the decline in the first year did not differ between the inclusion periods. Disease activity after 1-year of follow-up improved from 2011 onwards. HAQ-DI scores at baseline and during follow-up remained similar in all inclusion periods, as did prevalence of DFS (spontaneous remission and sustained remission after DMARD-discontinuation). Also, percentage of patients who progressed to RA after 1-year did not improve. DAS: disease activity score, CRP: C-reactive protein, HAQ-DI: Health Assessment Questionnaire Disability Index, DFS: DMARD-free status, RA: rheumatoid arthritis.

outcomes: DAS28CRP and HAQ-DI during follow-up, prevalence of DMARD-free status (DFS; spontaneous remission or sustained remission after DMARD-stop) and progression to RA (according to the 1987 and/or 2010-criteria).

Results: The current UA-population has relatively mild disease; median SJC 1, TJC 2 and median HAQ 0.6. DMARD-treatment increased from 17% (1993-1997) up-to 52% (2015-2019), in which methotrexate became more common in the last decade. DAS28CRP during follow-up improved from 2011 onwards (range;-0.18,-0.25/p< 0.05). HAQ-scores remained similar (range;-0.00,-0.09/p >0.05), as did DFS-prevalence: 57%, 58%, 59% (1993-1997/1998-2005/2006-2010;p=0.59). Also, the percentage of patients that developed RA did not decrease (14%/21%/26%/18%/27% in the respective inclusion-periods).

Conclusion: Although intensified DMARD-treatment in UA might have led to lower disease activity scores, functionality and long-term outcomes did not improve, indicating potential overtreatment. Stratification methods for the up-to-date UA-population, to identify patients that will develop RA, are warranted.

	Total N = 1132	1993-1997 N = 222	1998-2005 N = 216	2006-2010 N = 214	2011-2015 N = 247	2016-2019 N = 233	*p-value*

Australian Psoriatic Arthritis (PsA) Biologic Disease-modifying Antirheumatic Drug (bDMARD) Treatment Pathways Using Sankey Diagrams and Predictive Analysis: A Combined Australian Rheumatology Association Database (ARAD) and Pharmaceutical Benefits Scheme (PBS) Analysis

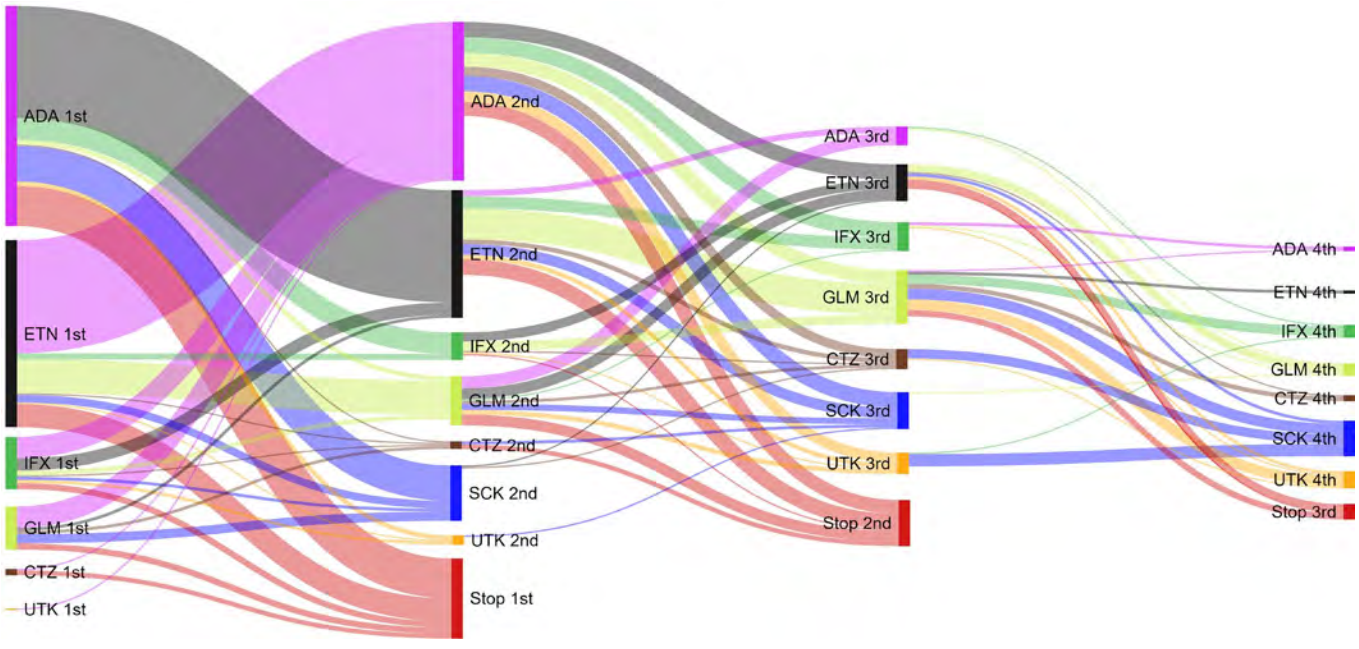
Ashley Fletcher[1], Lyn March[2], Marissa Lassere[3], Catherine Hill[4], Claire Barrett[5], Graeme Carroll[6], Premarani Sinnathurai[7] and Rachelle Buchbinder[8], [1]Cabrini Health, Malvern, Australia, [2]Institute of Bone and Joint Research, Kolling Institute, University of Sydney; Department of Rheumatology, Royal North Shore Hospital, Northern Sydney Local Health District, St Leonards, Sydney, Australia, [3]St George Hospital; School of Population Health, University of New South Wales, Carlton, Australia, [4]Queen Elizabeth Hospital, Woodville, Australia, [5]Redcliffe Hospital, University of Queensland, Margate Beach, Australia, [6]Fiona Stanley Hospital, Perth, Australia, [7]Institute of Bone and Joint Research, Kolling Institute, University of Sydney; Department of Rheumatology, Royal North Shore Hospital, Northern Sydney Local Health District, Sydney, Australia, [8]Cabrini Health/Monash University, Malvern, Australia

SESSION INFORMATION
Session Date: Saturday, November 6, 2021
Session Title: Miscellaneous Rheumatic & Inflammatory Diseases Poster I (0183–0209)
Session Type: Poster Session A
Session Time: 8:30AM–10:30AM

Background/Purpose: To describe current bDMARD treatment patterns for ARAD participants with PsA, after combining with linked government PBS data.

Methods: ARAD, a voluntary longitudinal observational database established in 2001, collects long-term outcome data for people with inflammatory arthritis in Australia. Participants complete semi-annual, then annual questionnaires. Demographic, clinical, drugs, patient-reported outcome (PRO) measures and reasons for stopping bDMARD therapy, such as inefficacy or side-effects, were extracted from Sept. 2001 to June 2020 for all PsA participants. Socioeconomic status (SES) was derived from the participants address and assigned an Australian Bureau of Statistics (ABS) Socio-Economic Indexes for Areas (SEIFA) score of the Index of Relative Socio-economic Advantage and Disadvantage (IRSAD). PBS is the Australian Government program that subsidises medicines, ARAD participants were linked to PBS data from 2011 to 2018. Logistic regression was used to evaluate baseline characteristics of participants who switched compared to those who did not. Switching patterns determined for each bDMARD and time on first, second and third-line bDMARDs were analysed and reasons for switching in the ARAD data were assessed.

Results: 673 PsA participants were included, 5.4% were excluded as ARAD did not match PBS and 31.3% extended medication records beyond the last ARAD questionnaire. First-line bDMARDs were adalimumab (n=283), etanercept (n=178), golimumab (n=44), infliximab (n=32), secukinumab (n=9), certolizumab (n=6) and ustekinumab (n=4). At 1 year 26.9% starting first-line bDMARD therapy switched to another bDMARD, 37.0% switched from second-line therapies and 31.3% switched from third-line therapies. For First-line bDMARDs, females (OR 1.78; 95%CI: 1.18-2.66), higher SES (lowest vs highest OR 2.47; 95%CI: 1.25-4.87), opioid users (OR 1.64; 95%CI: 1.02-2.63) and worse PRO measures (i.e. EuroQol (EQ-5D) OR 0.28; 95%CI: 0.11-0.69) were more likely to switch. Inefficacy (first-line 50.5%, second-line 65.4%, third-line 62.0%) or side effects (first-line 19.0%, second-line 12.0%, third-line 14.0%) were the most commonly cited reasons for stopping therapy irrespective of line of treatment.



Flow of bDMARD use - switching and stopping from first-line therapy to fourth-line therapy.

Conclusion: Patient self-report medication data in ARAD has a high degree of accuracy when compared with the PBS government database. The treatment pathways for bDMARD use by PsA patients in Australia is complex with 30% switching to another bDMARD therapy after 1 year. Common reasons for switching or stopping were inefficacy and side effects.

Variables Associated with Response to Therapy in Patients with Interstitial Pneumonia with Autoimmune Features

Elena Joerns[1], Traci Adams[1], Chad Newton[1], Lesley Davila[2], Kiran Batra[1], Jose Torrealba[1], Craig Glazer[1], Joan Reisch[1], Bonnie Bermas[3], David Karp[2] and Una Makris[4], [1]UT Southwestern, Dallas, TX, [2]UT Southwestern Medical Center, Dallas, TX, [3]UTSouthwestern Medical Center, Dallas, TX, [4]UT Southwestern Medical Center, Dallas Veterans Administration, Dallas, TX

SESSION INFORMATION
Session Date: Saturday, November 6, 2021
Session Title: Miscellaneous Rheumatic & Inflammatory Diseases Poster I (0183–0209)
Session Type: Poster Session A
Session Time: 8:30AM–10:30AM

Background/Purpose: We have limited knowledge of the characteristics of patients with interstitial pneumonia with autoimmune features (IPAF) that are associated with response to immunosuppression. Thus, we currently have no data to guide optimal IPAF patient selection for therapy or the optimal immunosuppressive regimen in IPAF. In this study, we use a rigorously phenotyped cohort (based on published IPAF criteria) to characterize features associated with response to immunosuppressive treatment.

Methods: We conducted a retrospective cohort study of 65 IPAF patients to evaluate for serologic, clinical, and radiographic characteristics associated with response to immunosuppression, defined as % relative functional vital capacity (FVC) decline of less than 10%, and absence of death or lung transplant within the first year of continuous immunosuppressive therapy. We used Fisher's exact test, chi-squared test, and Mann Whitney U test, as appropriate, to evaluate for significant differences in characteristics between patients with significant progression and those who did not progress. Multivariate logistic regression was used to further evaluate significant variables while controlling for confounders.

Table 1. Baseline characteristics of the IPAF cohort

	Total (n=65)	Non-progressor (n=51*)	Progressor (n=14*)	p-value
Mean age at diagnosis, years (SD)	58.71 (10.68)	58.15 (10.73)	60.73 (10.60)	0.413
Mean age at continuous immunosuppression initiation, yrs (SD)	60.60 (10.90)	60.01 (10.94)	62.73(10.87)	0.425
Mean duration from diagnosis to start of continuous IS for at least one year, years (SD)	2.05 (2.48)	2.06 (2.55)	2.01 (2.31)	0.786
Gender				0.276
Male	16 (24.62%)	11 (21.57%)	5 (35.71%)	
Female	49 (75.38%)	40 (78.43%)	9 (64.29%)	
Race/Ethnicity				0.188

MMF/prednisone	45 (69.23%)	39 (76.47%)	6 (42.86%)	**0.016**
AZA/prednisone	15 (23.08%)	9 (17.65%)	6 (42.86%)	0.072
*Monotherapy***	10 (15.38%)	6 (11.76%)	4 (28.57%)	0.203
*Combination therapy****	55 (84.62%)	45 (88.24%)	10 (71.43%)	0.203

**Unless otherwise indicated*
***Treatment with a single agent during the treatment period*
****Treatment with two or more agents during the treatment period*
Abbreviations: SD – standard deviation; PFT – pulmonary function test, FVC – forced vital capacity; DLCO – diffusing lung capacity for carbon monoxide; MMF – mycophenolate mofetil; AZA – azathioprine.

Results: No baseline features predicted IPAF progression while on treatment, There was a trend of greater progression amongst men, ever smokers, and those with UIP radiographic pattern, although the differences were not statistically significant (Table 1). There was a statistically significant difference in the proportion of patients who were treated with combination therapy of mycophenolate mofetil (MMF) and prednisone whose disease did not progress.

Conclusion: Our study suggests that a combination therapy with MMF and prednisone may be associated with lack of progression in IPAF, including IPAF-UIP, although causality cannot be established. In the future studies, knowledge of cytokine profiles in different IPAF phenotypes may inform management in the early stages of the disease.

SESSION INFORMATION

Session Date: Saturday, November 6, 2021

Session Title: Miscellaneous Rheumatic & Inflammatory Diseases Poster I (0183–0209)

Session Type: Poster Session A

Session Time: 8:30AM–10:30AM

Background/Purpose: Tuberculosis (TB) may be increased with biologic therapy (BT). Diagnosis and treatment of latent TB infection (LTBI) is the best strategy to prevent TB. In Rheumatic Immune-Mediated Diseases (R-IMID) and LTBI, chemoprophylaxis must be used before BT. The drugs more frequently used are Isoniazid (INH), Rifampicin (RIF) and Fluoroquinolones (FQ). These drugs may be associated with side-effects, especially hepatotoxicity.

Our aim was to assess, in a single University Hospital, a) used chemoprophylactic drugs and, b) adverse events with these drugs.

Methods: We included all consecutive patients in the last five years (2016-2020) with a diagnosis of R-IMID and a positive LTBI test (positive tuberculin skin test and/or interferon-γ–release assay), who received chemoprophylaxis prior to BT.

Table. Adverse events with isoniazid at months 1 and 3 and after month 3

	Month 1 (n=232)			Month 3 (n=222)			After month 3 (n=214)		
Adverse events, n (%)	Total	Requiring switching	Requiring suspension	Total	Requiring switching	Requiring suspension	Total	Requiring switching	Requiring suspension
Hepatotoxicity	38 (16.4)	6 (2.6)	0	33 (14.9)	5(2.3)	2 (0.9)	16 (7.5)	2 (0.9)	0
Gastrointestinal side effects	4 (1.3)	3 (1.3)	1 (0.4)	3 (1.5)	0	3 (1.5)	2 (0.9)	0	1 (0.5)
Cutaneous toxicity	2 (0.9)	1 (0.4)	0	0	0	0	0	0	0
Dizziness	1 (0.4)	1 (0.4)	0	0	0	0	0	0	0
Total	44 (19)	11 (4.7)	1 (0.4)	36 (16.2)	5 (2.3)	5(2.2)	18 (8.4)	2 (0.9)	1 (0.5)

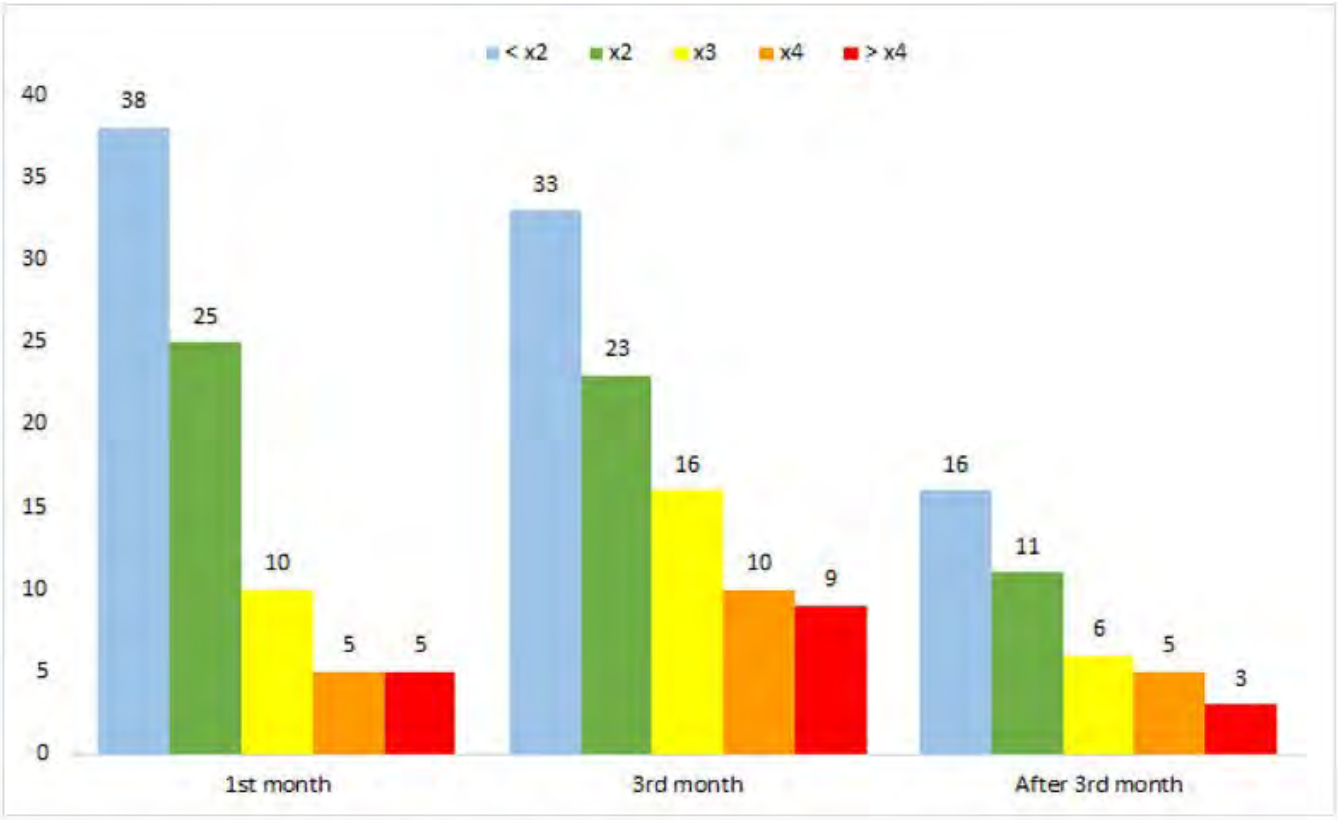

Figure. Liver enzyme elevation over baseline in patients in treatment with isoniazid.

Dose of chemoprophylactic drugs were a) INH (5 mg/kg/d, maximum, 300 mg; for 9 months with vitamin B6), b) RIF (10 mg/kg/d, maximum, 600 mg for 4 months) and c) FQ levofloxacin (500 mg/day for 9 months).

In all patients analytic controls that included liver enzymes were performed at the 1st and 3rd month and then at a variable time.

Results: 240 patients were analyzed (165 women/ 75 men), mean age of 56±11 years. The underlying R-IMID of patients receiving chemoprophylaxis were rheumatoid arthritis (n=74, 30.8%), axial spondyloarthritis (n=59, 24.6%), psoriatic arthritis (n=62, 25.8%), conectivopathies (n=17, 7.1%), vasculitis (n=12, 5%), sarcoidosis (n=2, 0.8%), Behçet's disease (n=1, 0.4%), inflammatory myopathies (n=1, 0.4%) and other (n=12, 5%).

At the onset of chemoprophylaxis they were taking: Prednisone in 61 patients (24 of them above 10 mg/day) and the following conventional DMARD, methotrexate (n=109, 45.4%), hydroxychloroquine (n=20, 8.3%), sulfasalazine (n=11, 4.6%), leflunomide (n=4, 1.7%) and azathioprine (n=2, 0.8%).

The first-line chemoprophylactic drug was INH in 232 (96.7%) patients and RIF in the remaining 8 (3.3%). Due to adverse events, second-line therapy was used in 18 (RIF, n=17 and Levofloxacin, n=1) patients previously treated with INH.

Adverse events were more frequent with INH, being observed in 55 patients (23.7%) out of 232. (TABLE, FIGURE). By contrast, only 1 out of 25 (4%) receiving RIF presented an adverse event, which was hepatotoxicity, requiring suspension of RIF. No adverse events were described in the only patient receiving levofloxacin.

Conclusion: INH is the most used first-line treatment for LTBI. RIF was mainly used as second-line therapy if an adverse event with INH was observed. Treatment was generally well tolerated and most adverse events did not require the withdrawal of the treatment. Hepatotoxicity was the most frequent adverse event with INH and the most frequent cause of treatment withdrawal.

IMIDs, n (%)				0.030
Rheumatoid arthritis	23 (38.3)	9 (39.1)	14 (37.8)	
Ankylosing spondylitis	7 (11.7)	5 (21.7)	2 (5.4)	
Crohn's disease	20 (33.3)	9 (39.1)	11 (29.7)	
Ulcerative colitis	8 (13.3)	0	8 (21.6)	
Others	2 (3.3)	0	2 (5.4)	
Biologics, n (%)				0.593
Anti-TNF-α agents	55 (91.7)	22 (95.7)	33 (89.2)	
Other biologics	5 (8.3)	1 (4.3)	4 (10.8)	
Baseline HBV DNA, IU/ml, median (IQR)	2.1×10^2 (0*–4.6×10^3)	5.4×10^2 (2.0×10^2 –5.6×10^5)	3.7×10^1 (0*–4.3×10^2)	0.001
Anti-viral agents, n (%)				0.222
Entecavir	25 (41.7)	9 (39.1)	16 (43.2)	
Tenofovir	25 (41.7)	8 (34.8)	17 (45.9)	
Lamivudine	9 (15.0)	6 (26.1)	3 (8.1)	
Telbivudine	1 (1.7)	0	1 (2.7)	
Development of HBV reactivation, n (%)	3 (5.0)	1 (4.3)	2 (5.4)	1.000

Background/Purpose: Prophylactic anti-viral therapy is required in patients with hepatitis B virus (HBV) infection receiving biologics because of the high risk of HBV reactivation. However, it is unclear when to start biologics after anti-viral prophylaxis. We investigated the risk of HBV reactivation according to the timing of biologics initiation after anti-HBV prophylaxis in IMID patients with HBV infection.

Methods: We retrospectively evaluated the incidence of HBV reactivation in IMID patients who received biologics between July 2005 and April 2020. The patients were divided into two groups ("within 1-week " vs. "after 1-week") according to the timing of biologics initiation after anti-HBV prophylaxis. The cumulative probabilities and factors associated with HBV reactivation were evaluated.

Results: A total of 60 hepatitis B surface antigen-positive patients with IMID received biologics (within 1-week group, *n* = 23 [38%]; after 1-week group, *n* = 37 [62%]). During a median follow-up of 34 months (interquartile range, 20–74), three (5%) patients developed HBV reactivation. In the univariate analysis, the timing of biologics after HBV prophylaxis was not significantly associated with the risk of HBV reactivation (hazard ratio, 0.657; 95% confidence interval, 0.059–7.327; p = 0.733). The cumulative probabilities of HBV reactivation did not significantly differ according to the timing of biologics as well (p = 0.731).

Conclusion: The risk of HBV reactivation was not significantly associated with the timing of biologics administration after anti-HBV prophylaxis. Thus, biologics may be initiated early in patients with IMID under prophylactic treatment for HBV.

SESSION INFORMATION

Session Date: Saturday, November 6, 2021

Session Title: Miscellaneous Rheumatic & Inflammatory Diseases Poster I (0183–0209)

Session Type: Poster Session A

Session Time: 8:30AM–10:30AM

Background/Purpose: Available evidence suggests that timely and effective management of patients with psoriatic arthritis (PsA) can improve long-term outcomes. Current information on the factors which influence the management decisions for PsA is limited in Turkey. The purpose of this study was to evaluate the impact of clinical rheumatology setting on management steps of patients with a confirmed PsA diagnosis from inflammatory musculoskeletal symptom onset to PsA diagnosis.

Methods: All patients were assessed by both rheumatologists and dermatologists across 30 centers in Turkey, and patients with confirmed diagnosis of PsA according to CASPAR criteria were included in the study. Primary outcome of this study was the timeframe from symptom onset to PsA diagnosis; secondary outcomes were time taken from PsA diagnosis to first conventional synthetic disease-modifying antirheumatic drug (csDMARD) and to first biologic DMARD (bDMARD) including switch data for csDMARD and bDMARD.

Results: Of 287 patients enrolled in the study, 243 patients with confirmed diagnosis of PsA were included in this analysis. It was observed that majority of patients were women (n=147, 60.5%). Of 134 patients in rheumatology setting, mean clinical disease activity PsA score (cDAPSA) was 13.42±14.11, demographic and clinical characteristics of patients included in the rheumatology setting are presented in Table 1. In the rheumatology setting the mean time from symptom onset to diagnosis of PsA was 11.12 ± 52.68 months. The mean time from PsA diagnosis to first csDMARD and bDMARD was 2.62 ± 43.10 and 54.61 ± 76.52 months, respectively. Mean time from first csDMARD to first bDMARD was 37.34 ± 46.68 months. In the rheumatology setting patients showed a significantly shorter mean time from symptom onset to diagnosis (11.12 vs. 17.69 months, as compared to dermatologists). The proportion of patients receiving any treatment for PsA was greater in the rheumatology setting (99.3% vs. 82.5%). A higher proportion of patients with PsA in rheumatology setting were treated with csDMARDs (86.5% vs. 62.2%). The first

Table 1. Demographic and clinical characteristics of PsA patients from Rheumatology Setting of the LOOP study

Characteristic	Rheumatology setting (n = 134)	%
Age (years, mean; ±SD)	45.8 (±12.2)	-
Gender (%)		
Female	83	61.9
Male	51	38.1
BMI (kg/m^2, mean; ±SD)	28.3 (±5.9)	-
Skin Symptoms	131	97.8
Dactylitis	78	58.2
Swollen Joints	107	79.9
Family history of psoriasis	50	37.3
Comorbidities		
Any	80	59.7
Depression and/or anxiety	40	29.9
Hypertension	37	27.6
Obesity	32	23.9
Lipid disorder	25	18.7
Diabetes (Type II)	17	12.7
Cardiovascular disease	14	10.4
Osteoporosis	8	6.0

csDMARD in this setting was methotrexate (79.1%) and first bDMARD was a TNF inhibitor (42.5%). Disease activity of 243 patients determined by cDAPSA scores showed 54 (22.2%) of the patients had remission, 73 (30.0%) had low disease activity, 47 (19.3%) had moderate disease activity, 26 (10.7%) had high disease activity and 43 (17.7 %) patients had missing data.

Conclusion: Our study conducted in several regions in Turkey results and obtained from patients with a confirmed PsA diagnosis who were diagnosed and treated by rheumatologists were similar with the globally published data. These results support again significant collaboration of rheumatology and dermatology specialists recommended by well-accepted treatment guidelines and approaches.

Session Title: Miscellaneous Rheumatic & Inflammatory Diseases Poster I (0183–0209)

Session Type: Poster Session A

Session Time: 8:30AM–10:30AM

Background/Purpose: Hydroxychloroquine (HCQ) is an extensively used drug in immune-mediated diseases (IMID). Despite its general safety, HCQ can cause serious toxicity such as heart conduction disorders. Atrioventricular block (AVB) is an underrecognized adverse effect that can potentially cause significant morbidity and mortality.

Table. Comparative study between patients with and without AVB

	with AVB *n*= 19	without AVB *n* = 274	*p*

# Use of other cardiotoxic drugs, n (%)	2 (10.5)	11 (4.0)	0.723
HCQ cumulative dose, mg mean±SD	813.2±206.0	996.3±266.9	0.527

(beta blockers, calcium channel blockers, tricyclic drugs, other AVB inducers)

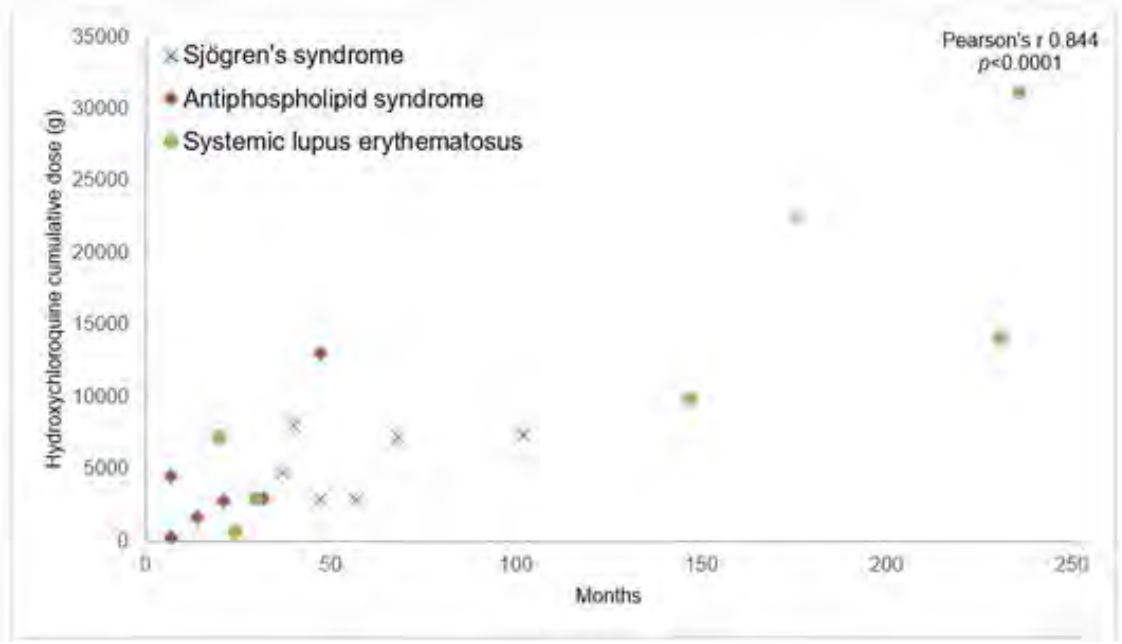

Figure. Presentation of atrioventricular block according to hydroxychloroquine cumulative dose and treatment duration.

The aim of this study was to analyze incidence, presentation, and characteristics of HCQ-induced AVB in IMID.

Methods: Open-label single center study of 293 patients with IMID treated with HCQ for at least 3 months. Electrocardiograms were analyzed at baseline and during HCQ treatment. In addition, a comparative study between patients with and without AVB was conducted.

Results: We studied 293 patients (270 women/23 men; mean age 59.7±14.7 years). Underlying IMID were systemic lupus erythematosus (n=109, 40.6%); undifferentiated connective-tissue disease (n=70, 23.9%), Sjögren's syndrome (n=70, 23.9%), antiphospholipid syndrome (n=31,10.6%) and other IMID (n=13, 4.4%). HCQ was used for 4.1±3.5 years.

After 11.8±8.9 years of follow-up (HCQ mean cumulative dose: 979.7±272.1 g). AVB was observed in 19 out of 293 (6.5%) patients: 16 (84.2%) were first-degree AVB and 3 (15.8%) complete AVB. 4 patients with AVB were treated with a permanent pacemaker.

A comparative study between patients with and without AVB was performed (TABLE). Patients with AVB were older (p=0.014) and had a higher incidence of diabetes mellitus (p=0.033). HCQ cumulative dose and duration of IMID were similar in both groups (p >0.05).

Presentation of atrioventricular block according to hydroxychloroquine cumulative dose and treatment duration is shown in FIGURE. Most of AVB happened in the first 40 months, regardless of HCQ cumulative dose.

Other adverse effects of HCQ were retinopathy (n=16, 5.4%), gastrointestinal alterations (n=14, 4.8%), cutaneous alterations (n=14, 4.8%), allergic reactions (n=4, 1.4%) and myopathy (n=1, 0.3%).

Conclusion: AVB was observed in 6.5% of patients with IMID treated with HCQ. Most AVB were first-degree AVB. HCQ increased the risk of developing an AVB in patients with IMID regardless of HCQ cumulative dose or underlying disease duration. Older patients with diabetes mellitus had a higher risk of developing an AVB.

SESSION INFORMATION

Session Date: Saturday, November 6, 2021
Session Title: Miscellaneous Rheumatic & Inflammatory Diseases Poster I (0183–0209)
Session Type: Poster Session A
Session Time: 8:30AM–10:30AM

Background/Purpose: Ocular involvement is a relatively frequent and potentially severe complication of sarcoidosis. Oral corticosteroids (OCS) are the first-line treatment. Conventional immunosuppressive agents (cIS) and biological therapy (BT) can be used in refractory cases.

The aim of this study was to evaluate the treatment and visual outcomes of a cohort of patients diagnosed with ocular sarcoidosis.

Methods: Study of a large cohort (n=384) of all consecutive patients diagnosed with sarcoidosis from January 1, 1999 to December 31, 2019 at a single University Hospital. Finally, 344 patients were included according the ATS/ERS/WASOG criteria / Different ocular manifestations and the following systemic treatments were assessed: **a)** OCS, **b)** cIS), **c)** monoclonal TNF inhibitors, **d)** Etanercept (ETN), **e)** Tocilizumab (TCZ). Best Corrected Visual Acuity (BCVA) according to different systemic treatments was compared at diagnosis and after one year of follow-up (Kruskall Wallis test).

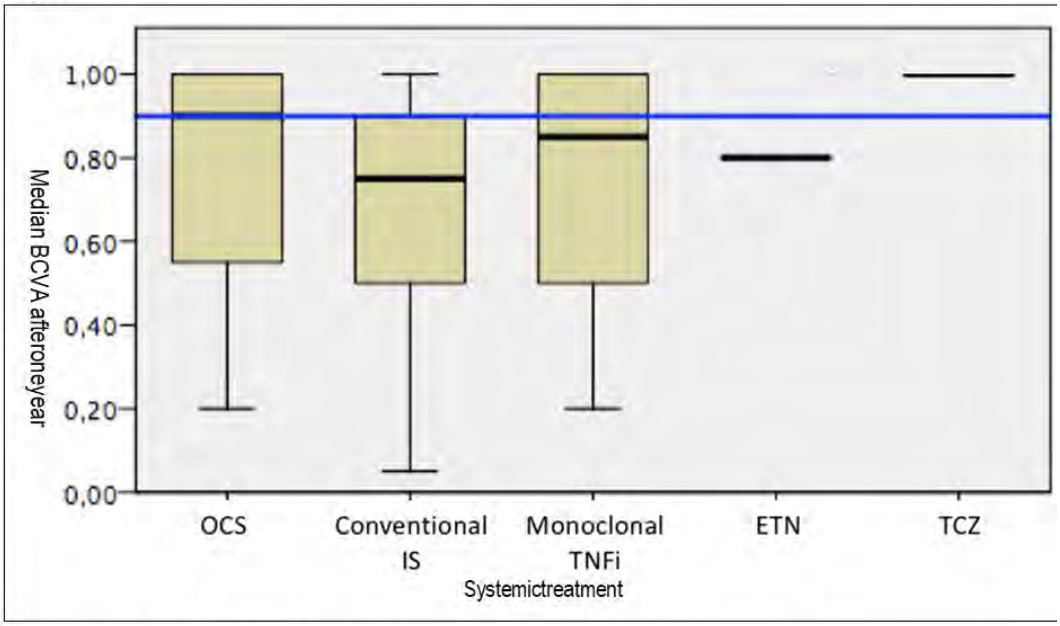
Results: 344 patients were reviewed. From these, 65 (18.9%) presented ocular manifestations as uveitis (83.1%), orbital lesions (7.7%), retinal vasculitis (6.2%), dry eye (6.2%) and scleritis (1.5%). All of them received systemic treatment. BT was particularly used in patients with retinal vasculitis (100%), panuveitis (75%) and orbital lesions (40%). Systemic treatment and BCVA outcome according to ocular manifestations are shown in table. Median BCVA

Table. Median BCVA at onset and after one year according to ocular manifestations and type of systemic therapy.

Type of ocular affectation	*n (%)*	*Median BCVA at onset [IQR]*	*Median BCVA after 1 year [IQR]*	*OCS n (%)*	*cIS n (%)*	*monoclonal TNFi n (%)*	*ETN n (%)*	*TCZ n (%)*
Uveitis	54 (83.1)	0.6 [0.3-0.8]	0.9 [0.6-1]	44 (81.5)	29 (53.7)	16 (29.6)	3 (5.5)	3 (5.5)
- **Anterior**	31 (47.7)	0.7 [0.3-0.8]	0.8 [0.5-1]	22 (70.9)	12 (38.7)	2 (6.5)	2 (6.5)	0
- **Intermediate**	2 (3.1)	0.5	0.7	2 (100)	1 (50)	1 (50)	1 (50)	1 (50)
- **Posterior**	5 (5.2)	0.5 [0.1-0.9]	0.9 [0.9-1]	4 (80)	4 (80)	3 (60)	0	0
- **Panuveitis**	16 (24.6)	0.4 [0.2-0.7]	0.9 [0.5-1]	16 (100)	12 (75)	10 (62.5)	0	2 (12.5)
Orbital lesions	5 (7.7)	0.5 [0.1-0.6]	1 [0.1-1]	4 (80)	2 (40)	2 (40)	0	1 (20)
Retinal vasculitis	4 (6.2)	0.6 [0.5-0.8]	1 [0.6-1]	4 (100)	4 (100)	1 (25)	0	1 (25)
Dry eye	4 (6.2)	1	0.9	2 (50)	1 (25)	0	0	0
Scleritis	1 (1.5)	1	1	1 (100)	0	0	0	0

Abbreviations: BCVA: Best Corrected Visual Acuity; IQR: Interquartile Range; OCS: Oral Corticosteroid; cIS: Conventional Immunosuppressants; Monoclonal TNFi: monoclonal tumour necrosis factor inhibitors; ETN: Etanercept; TCZ: Tocilizumab.

Figure. Median [25,75 IQR] BVCA after one year follow up according to type of systemic treatment in sarcoid uveitis.



Abbreviations: BCVA: BestCorrected Visual Acuity; OCS: Oral Corticosteroid; Conventional IS: Conventional immunosupressants (methotrexate, azathioprine, mycophenolate, cyclophosphamide); Monoclonal TNFi: monoclonal tumour necrosis factor inhibitors (infliximab, adalimumab, golimumab); ETN: Etanercept; TCZ: Tocilizumab.

at onset and after one year was 0.6 [interquartile range (IQR) 0.3-0.8] and 0.9 [0.6-1], respectively. No statistically significant differences were observed between systemic treatments in BCVA of patients with uveitis after 1 year of follow-up **(Figure)**.

Conclusion: Panuveitis, intermediate uveitis and orbital lesions, require a more aggressive treatment than other manifestations of ocular sarcoidosis. In uveitis, an important improvement in BCVA after 1 year of follow-up was observed regardless of the type of treatment used.

Abstract Number: 0208

Musculoskeletal Immune-Related Adverse Effects of Immune Checkpoint Inhibitors at a Single Site in a Hispanic Population in Puerto Rico

Adianez Santiago[1], Salvador Vila[1] and Fernando Cabanillas[2], [1]Department of Medicine, Division of Rheumatology, Allergy and Immunology; University of Puerto Rico-School of Medicine, San Juan, PR, [2]Auxilio Cancer Center at Hospital Auxilio Mutuo, San Juan, PR/ University of Puerto Rico-School of Medicine, San Juan, PR

SESSION INFORMATION
Session Date: Saturday, November 6, 2021
Session Title: Miscellaneous Rheumatic & Inflammatory Diseases Poster I (0183–0209)
Session Type: Poster Session A
Session Time: 8:30AM–10:30AM

Background/Purpose: Immune checkpoint inhibitors (ICI) belong to a novel group of biologic agents used to treat cancer. ICI increase the immune response to tumor cells by blocking cancer induced immune inhibitory pathways. Immune-related adverse effects (irAE) are a recognized complication of these drugs. Musculoskeletal (MSK) irAE have been described. We studied irAE of ICI in Hispanics at a single site in Puerto Rico, their management and outcome. We report the MSK irAE identified in the population studied.

Methods: A retrospective medical record analysis of 193 patients treated with an ICI was conducted at the Cancer Center of Hospital Auxilio Mutuo in Puerto Rico, beginning from the first therapy with ICI to August 31, 2020. Data abstracted included demographic information, type of cancer, ICI used alone, in combination or sequentially, dose and cycles of ICI, treatment prescribed prior to and during ICI use, comorbidities, development and type of irAE, time to development of irAE from start of ICI, management and outcome of irAE, and autoimmune diseases diagnosed prior to ICI use.

Results: A total of 16 MSK irAE were identified among 14 (7.25%) patients. MSK adverse effects were the third most common irAE identified (8%), following skin (17%) and gastrointestinal involvement (9%). Nine patients were female, and 5 patients were male with a mean age of 63 years (range 34-90).

MSK irAE were observed in 9 of 97 (9.3%) patients that were treated with nivolumab monotherapy and in 3 of 75 (4%) treated with pembrolizumab monotherapy. One in five (20%) patients treated with pembrolizumab followed by nivolumab had a MSK irAE and 1 of 20 (5%) treated with combination ipilimumab and nivolumab experienced a MSK irAE. The most common MSK irAE was arthralgia in 10 patients (71%), polyarticular arthritis in 2 patients (14%), followed by eosinophilic fasciitis, inflammatory myopathy, sicca syndrome, and xerostomia in 7% respectively. The mean time from starting ICI therapy to the development of a MSK irAE was 17 weeks (range 1-111).

***Table 1**: Patient characteristics and musculoskeletal immune-related adverse effects associated to immune checkpoint inhibitors*

Age (years)	Sex	Cancer diagnosis	ICI prescribed	Time in weeks of treatment with ICI	MSK irAE	Time in weeks of irAE after ICI	Other irAE	Time in weeks of irAE after ICI	Other irAE	Time in weeks of irAE after ICI	Treatment	Resolution
63	F	Kidney	Nivolumab	27	Arthralgias	17	Primary Hypothyroidism	14	Bullous rash	35	Analgesics, Synthroid	Partial
68	M	Liver	Nivolumab	104	Arthralgias	12	None	None	None	None	Narcotics	Full
34	F	Hodgkin's	Nivolumab	14	Arthralgias	2	Inflammatory myopathy	2	None	None	Low dose prednisone	Full
36	F	Hodgkin's	Nivolumab	139	Arthralgias	40	New onset pneumonitis	96	None	None	Moderate dose prednisone/ IV steroids	Partial
75	F	NSCLC	Nivolumab	62	Arthralgias	20	None	None	None	None	Low dose prednisone	Partial
75	M	Kidney	Nivolumab	53	Arthralgias	1	Diarrhea	1	None	None	Low dose prednisone	Partial
59	M	Urothelial	Nivolumab	264	Arthralgias	45	Glomerulonephritis	65	Maculopapular rash	29	Moderate dose prednisone/ Topical steroids	Partial
52	F	Non-Hodgkin's lymphoma	Pembrolizumab	72	Arthralgias	5	Polyarticular arthritis	15	None	None	Interval delay of ICI	Partial
90	F	Colorectal	Pembrolizumab	91	Arthralgias	26	None	None	None	None	NSAIDS	Full
57	M	Kidney	Ipilimumab and Nivolumab	9	Arthralgias	2	None	None	None	None	None	Full
72	M	Head/Neck	Pembrolizumab x 6 weeks, Nivolumab x 168 weeks	174	Polyarticular arthritis	111	Nonspecific colitis	140	None	None	Moderate dose prednisone/ Azulfidine	Partial
78	F	NSCLC	Nivolumab	117	Sicca symptoms	20	None	None	None	None	Local oral lubricant	Partial
40	F	Hodgkin's	Pembrolizumab	20	Xerostomia	32	None	None	None	None	Local oral lubricant	Partial
65	M	Head/Neck	Nivolumab	53	Eosinophilic fasciitis	62	None	None	None	None	Moderate dose prednisone/ ICI discontinued	Partial

*Low dose prednisone <20mg/day, †Moderated dose prednisone >20-40mg/day, MSK, musculoskeletal, irAE, immune-related adverse effect, ICI, Immune checkpoint inhibitor

Management of the irAE included prescription of corticosteroids, NSAIDs, sulfasalazine and delay or discontinuation of ICI therapy. Full resolution of the MSK irAE was achieved in 4 patients, while partial resolution was achieved in 10.

Conclusion: ICI MSK irAE were observed in 7.25% of the Hispanic population studied. The most frequent MSK irAE was arthralgias (71%), which was associated with the use of nivolumab as monotherapy in 7 of 10 patients. Two patients (12.5%) experienced more than 1 MSK irAE. However, 5 of 14 patients (35.7%) had an MSK irAE that concurred with a non-MSK irAE. Treatment of the irAE achieved full resolution in 29% of patients. ICI discontinuation or delay in prescription was required in 2 patients and 1 patient required hospitalization. No patients with a prior MSK autoimmune disease had a relapse of their disease on ICI therapy.

IgG4 Related Disease: Response to Immunosuppressive Therapy - A Single Centre Retrospective Study in the United Kingdom

Shirish Sangle[1], Neil Morton[2], Alina Casian[2], Louise Nel[2], Jennifer Hannah[3] and David D'Cruz[4], [1]Guy's and St Thomas' Hospital NHS Trust, London, United Kingdom, [2]Guys and St Thomas' NHS Trust, London, United Kingdom, [3]Kings College Hospital, London, United Kingdom, [4]Guy's and St Thomas' NHS Foundation Trust, London, United Kingdom

SESSION INFORMATION
Session Date: Saturday, November 6, 2021
Session Title: Miscellaneous Rheumatic & Inflammatory Diseases Poster I (0183–0209)
Session Type: Poster Session A
Session Time: 8:30AM–10:30AM

Background/Purpose: IgG4 related disease (IgG4-RD) is a rare immune-mediated condition, increasingly being recognised as a multi-organ disorder. It is a relatively new entity and the precise prevalence is not known. It is a chronic fibro-inflammatory condition with raised levels of immunoglobulin G4 and accumulation of plasma cells and fibrosis in the affected tissue. A recent 3-step classification criteria has been developed jointly by ACR/EULAR to help to diagnose IgG4-RD. It includes a variety of exclusion criteria as well as weighted inclusion criteria.

Methods: We present a retrospective observational study of patients seen at Guy's and St Thomas' NHS Foundation Trust Hospitals, London, UK. The data conducted was analysed for clinical presentation, laboratory markers of inflammation, immunoglobulin subsets, autoantibody profiles, imaging and histopathology and compared to the 2019 ACR/EULAR criteria to determine confirmed diagnosis of IgG4-RD. Data was also collected post standard-of-care treatment, including patient clinical outcomes and possible improvement. IgG4 Responder Index was also calculated for each patient before and after treatment.

Results: The study included a multi-ethnic cohort of 83 patients with multi-organ involvement.

Fifty-nine out of eighty-three analysed were classed as confirmed IgG4-RD rather than possible (71%). Seventy-one patients had biopsies of which 49 (91% of confirmed IgG4-RD) were consistent with IgG4-RD. Fifty patients had PET-CT scanning of which uptake was seen in 76% of those with confirmed IgG4-RD (26/34). Immunoglobulin IgG subclass analysis showed significantly higher IgG4 levels in the confirmed IgG4-RD group. Treatments were with corticosteroids and immunosuppressants such as azathioprine, methotrexate, mycophenolate, cyclophosphamide and rituximab.

Post treatment, IgG4-RI was significantly improved. Post-treatment IgG4 levels, as well as inflammatory markers, were significantly reduced in the patients with IgG4-RD disease who had had an initially high IgG4 level (31/43). This was correlated with clinical improvement in twenty-four (77%) of those patients. Fifty-three patients in total showed clinical improvement after treatment (79%). Of the biologics patients (n=15), eleven showed improvement (73%).

Conclusion: IgG4-RD is a fibro-inflammatory disorder involving multiple organs. If not treated adequately patients may develop severe organ damage. It often responds to corticosteroids but may require other immunosuppressive therapy as we have shown, with IgG4 levels and IgG4-RI providing good markers of disease activity. Treatment with biologics such as B cell depletion therapy results are encouraging. It will be interesting to see the outcomes of future biologics controlled trials in IgG4-RD.

Using Machine Learning to Predict Medial Knee Cartilage Worsening over 2 Years Using Gait and Physical Activity: The MOST Study

Kerry Costello[1], David Felson[1], S. Reza Jafarzadeh[2], Neil Segal[3], Cora Lewis[4], Michael Nevitt[5], Cara Lewis[6], Vijay Kolachalama[2] and Deepak Kumar[1], [1]Boston University, Boston, MA, [2]Boston University School of Medicine, Boston, MA, [3]University of Kansas Medical Center, Iowa City, IA, [4]University of Alabama Birmingham, Birmingham, AL, [5]University of California San Francisco, Orinda, CA, [6]Boston University, Brookline, MA

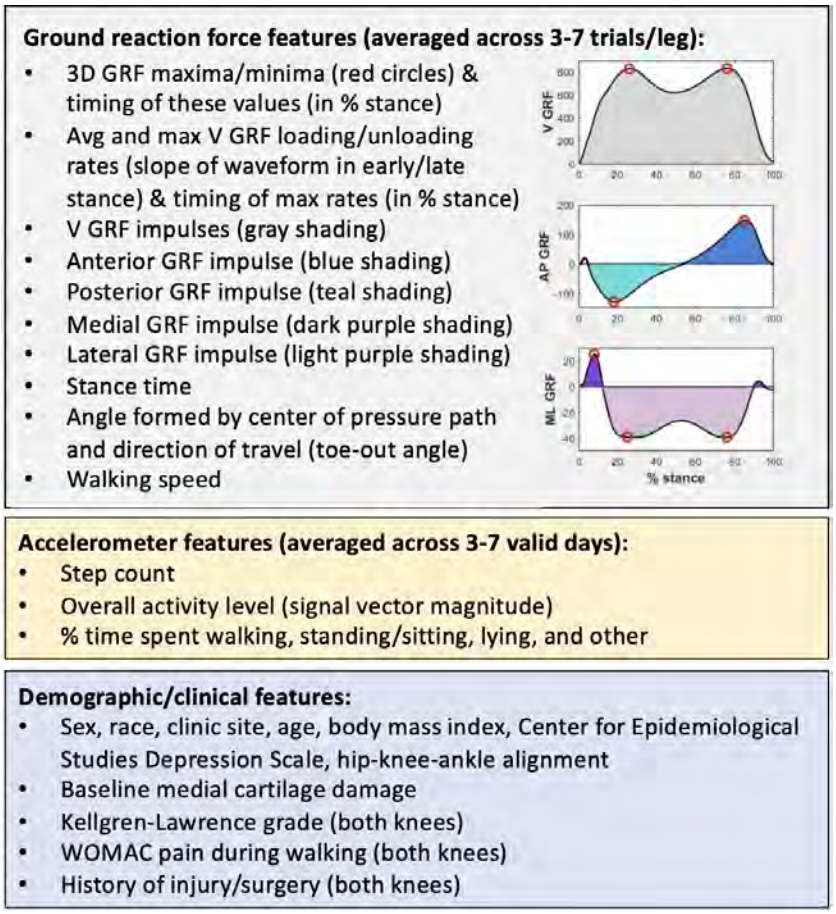

Figure 1. Inputs for Super learning.

SESSION INFORMATION
Session Date: Saturday, November 6, 2021
Session Title: Osteoarthritis – Clinical Poster I (0210–0224)
Session Type: Poster Session A
Session Time: 8:30AM–10:30AM

Background/Purpose: Identifying knees at risk of worsening osteoarthritis (OA) could help to identify individuals in need of interventions. While gait and physical activity are considered important for knee OA pathogenesis, the interrelations between these factors are complex and challenging to specify using traditional statistical models. Machine learning approaches remove the need to pre-specify these underlying relationships among factors when predicting an outcome. Our objective was to investigate the ability of gait and physical activity measures to predict medial tibiofemoral cartilage worsening over 2-years in the Multicenter Osteoarthritis Study (MOST) using machine learning.

Methods: Demographic and clinical data, ground reaction force (GRF) data during self-selected speed walking, and physical activity data from 7 days of accelerometer wear were collected from participants with and without knee pain or radiographic OA at baseline. Cartilage damage was assessed using the MRI Osteoarthritis Knee Score (MOAKS) in one knee per person by two musculoskeletal radiologists in 5 medial tibiofemoral subregions at the baseline and 2-year visits. Progression was defined as worsening cartilage size or depth MOAKS score in any subregion. Knees with Kellgren-Lawrence grades > 2 were excluded to focus on an earlier disease stage. "Super learning" (an ensemble machine learning approach) was used to predict cartilage worsening over 100 random splits into 70% training:30% test data from standardized GRF, accelerometer, and demographic/clinical features (Figure 1). Performance was evaluated using AUC. Important predictors were identified as the 10 features most frequently appearing in the top 10 contributors to prediction (via a variable importance measure statistic) across the 100 data splits. Marginal effects plots were used to determine direction of associations.

Table 1. Baseline sample characteristics

Sample characteristic	n = 1323 participants
Female Sex, n (%)	784 (59.3%)
Race, n participants (%):	
Black or African American	154 (11.6%)
White or Caucasian	1126 (85.1%)
Clinic Site University of Iowa, n (%)	845 (63.9%)
Mean Age in years (s.d.)	58.5 (7.9)
Mean Body Mass Index in kg/m^2 (s.d.)	27.7 (4.9)
Mean Center for Epidemiologic Studies Depression score (s.d.)	5.6 (6.3)
Hip-knee-ankle alignment in degrees (s.d.), negative values indicate varus	-1.3 (2.7)
Baseline medial cartilage damage, n knees (%)	523 (39.5%)
Kellgren-Lawrence Grade, n knees (%):	
KLG = 0	791 (60.1%)
KLG = 1	314 (23.9%)
KLG = 2N (definite osteophyte, no joint space narrowing)	60 (4.6%)
KLG = 2 (definite osteophyte and joint space narrowing)	151 (11.5%)
Previous injury/surgery, n knees (%)	256 (19.3%)
WOMAC pain during walking, n knees (%):	
None	1043 (78.8%)
Mild	241 (18.2%)
Moderate	34 (2.6%)
Severe	4 (0.3%)
Extreme	1 (0.1%)

WOMAC = Western Ontario and McMaster Universities Osteoarthritis Index

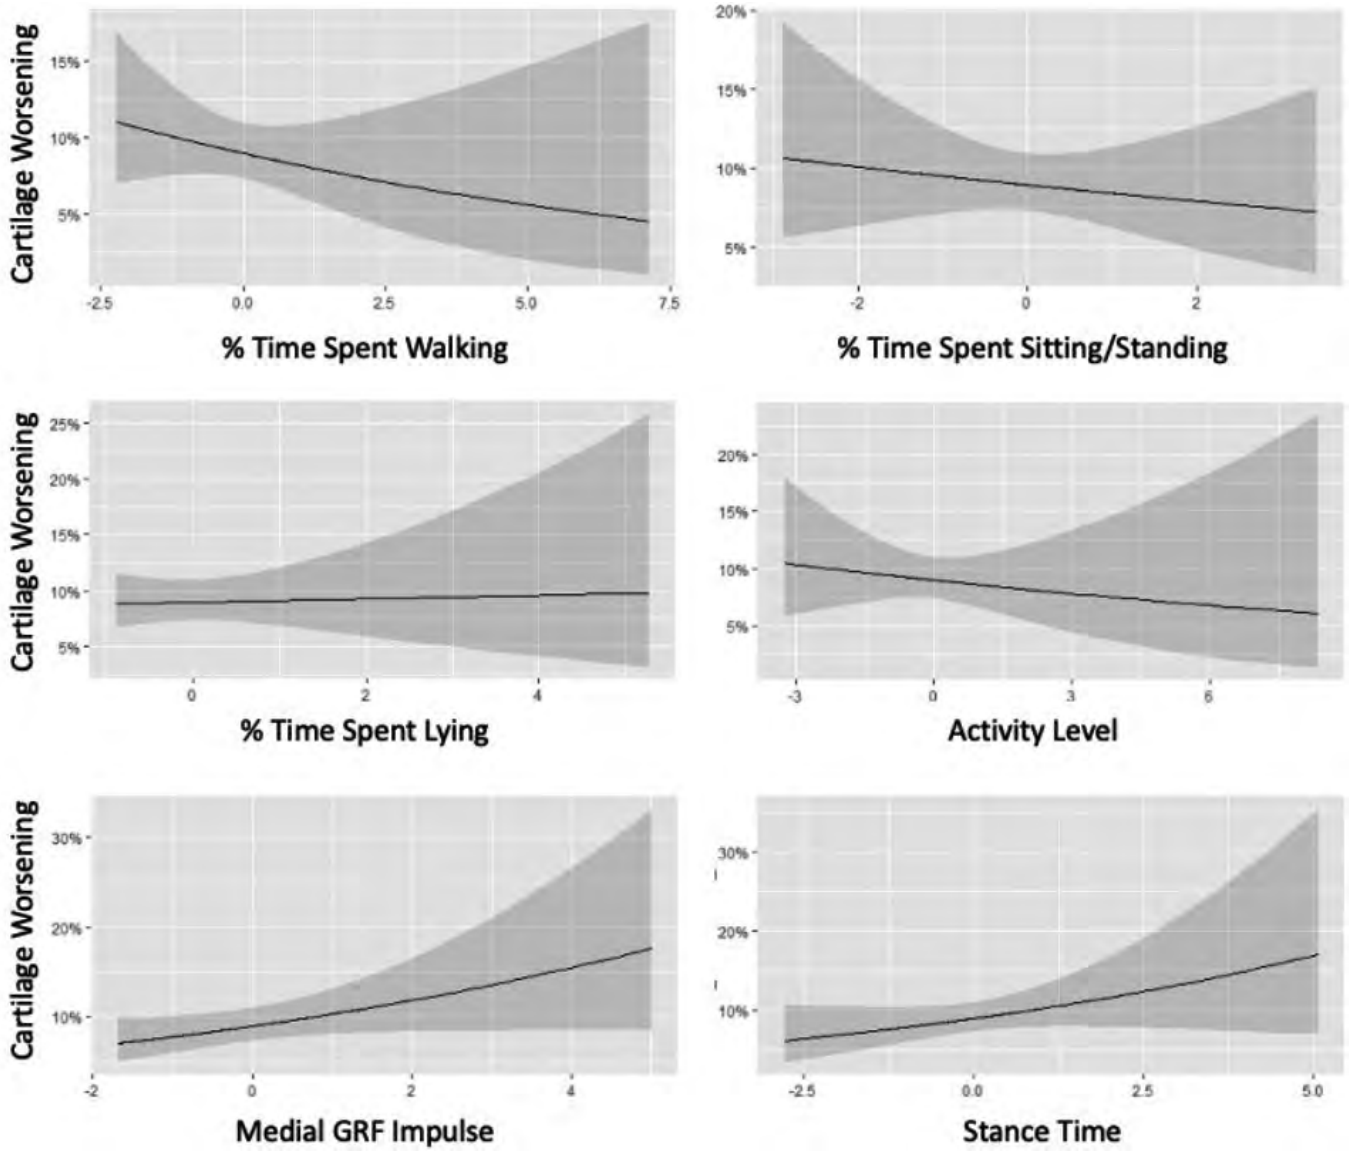

Figure 2. Marginal effects of important physical activity and gait predictors.

Results: Of 1323 legs included in the analysis (Table 1), 14% experienced medial cartilage worsening over 2-years. Across 100 model runs, the median AUC (2.5- and 97.5-th percentiles) on the held-out test sets was 0.78 (0.73-0.85). Important predictors (frequency of appearance in top 10 contributors) included: baseline medial cartilage damage (100), Kellgren-Lawrence grade (83), % time walking (80), % time sitting/standing (65), age (65), % time lying (62), % time in other activities (61), activity level (54), medial GRF impulse (37), and stance time (31). Cartilage worsening was associated with lower % time walking, % time sitting/standing, and activity level, higher % time lying and medial GRF impulse, and longer stance time (Figure 2).

Conclusion: An ensemble machine learning approach incorporating gait, physical activity, and clinical/demographic features showed good performance for predicting cartilage worsening over two years. While determining the relationships among predictors and cartilage loss outcome in the model is not straightforward, this analysis suggests that addressing low time spent walking and overall activity level and/or high medial GRF impulse, among others, may be potential targets to reduce medial tibiofemoral cartilage worsening.

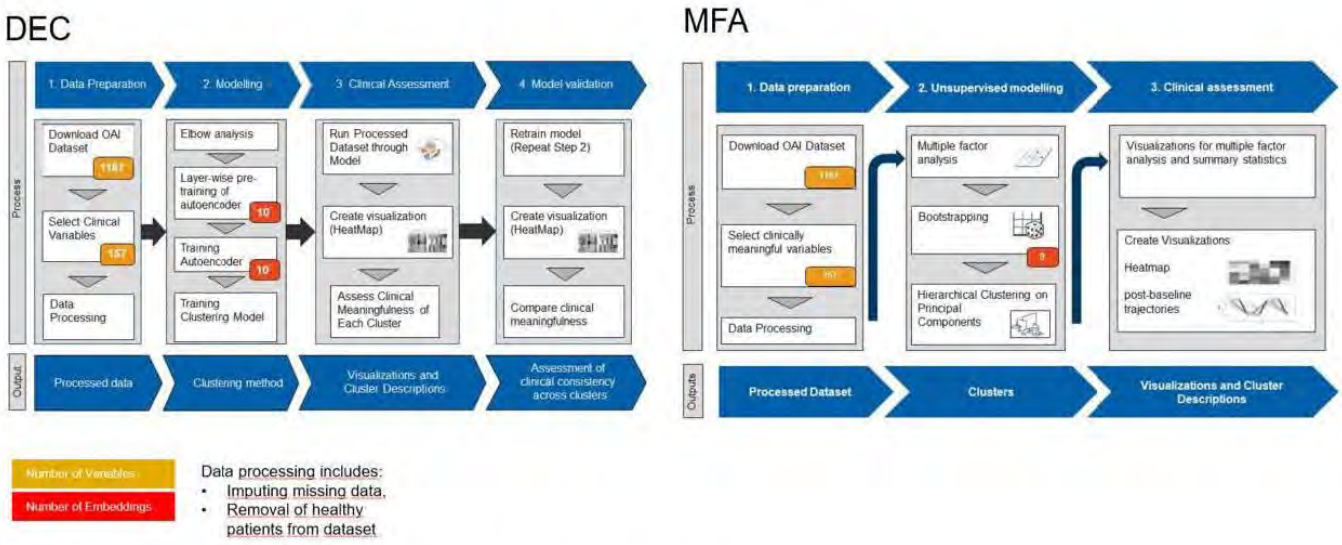
SESSION INFORMATION
Session Date: Saturday, November 6, 2021
Session Title: Osteoarthritis – Clinical Poster I (0210–0224)
Session Type: Poster Session A
Session Time: 8:30AM–10:30AM

Background/Purpose: Osteoarthritis (OA) is a chronic disabling disease, for which there are only limited treatment options. One major challenge in the development of effective treatment strategies for knee OA is the complexity of the underlying pathogenesis. Segmenting patient populations using readily available clinical, radiographic and biological features to define different phenotypes is a prerequisite for personalized patient management. The present study aimed to identify clinical OA phenotypes and their progression based on readily available characteristics using two fundamentally different machine learning algorithms.

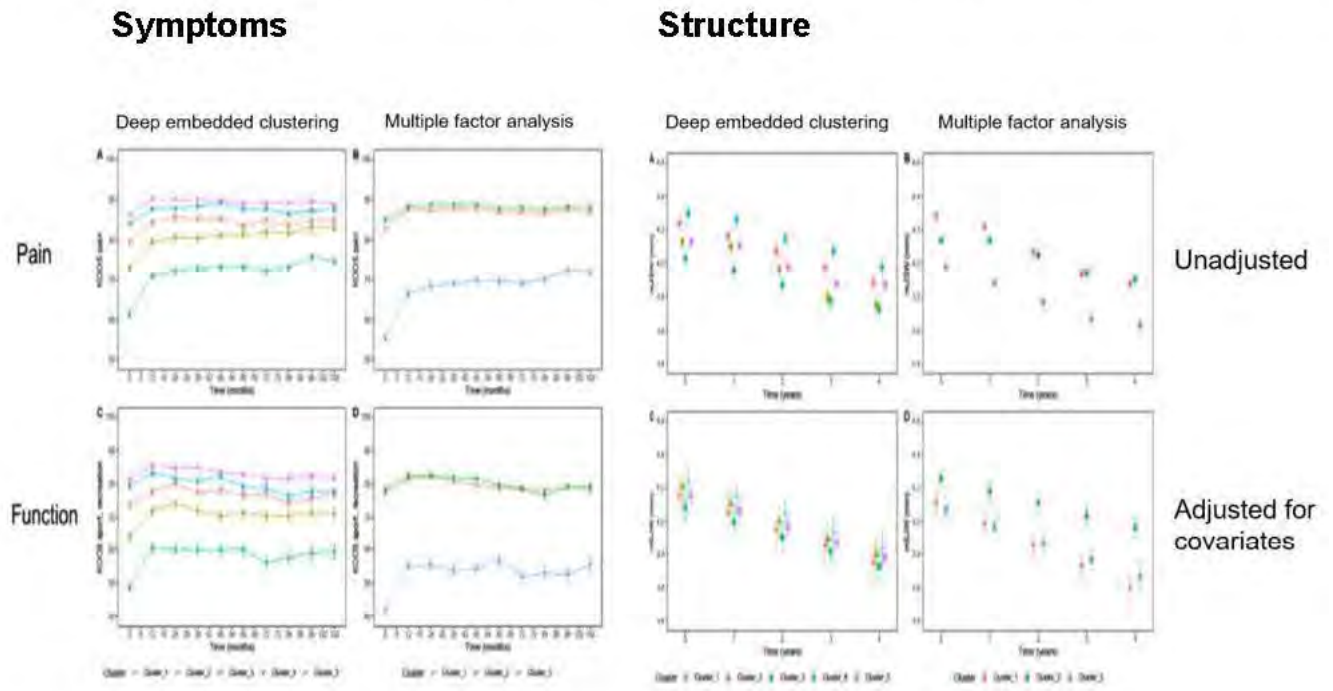
Methods: Clusters were based on 157 easily accessible clinical variables collected from the Osteoarthritis Initiative (OAI) baseline dataset, which included 4,674 participants covering the entire spectrum of knee OA severity. After

Figure 1. Data management from download to analysis



DEC, deep embedded clustering; MFA, multiple factor analysis

Figure 2. Clinical, structural and radiographic progression in the different clusters



KOOS, Knee Injury and Osteoarthritis Outcome Score; mJSW, medial minimum joint space width

reduction of data-dimensionality (i.e., reduction of the complexity without loss of information), the analysis relied on deep embedded clustering (DEC) and multiple factor analysis (MFA), respectively, for the identification of homogenous groups (Figure 1). In addition, radiographic progression of OA was analyzed in the different clusters both clinically (using the Knee Injury and Osteoarthritis Outcome Score, KOOS) over 9 years and structurally (via minimal medial joint space width) over 4 years using a linear mixed effects model.

Results: The analysis yielded 5 clusters in DEC and 3 clusters in MFA with overlap between the two techniques: Both the approaches identified a comorbid cluster which comprised predominantly females with high body mass index (BMI), peri-articular pain, a high burden of comorbidities and depression, low activity levels, pain (KOOS) and functional limitations (cluster 3 in both analyses, Figure 2). Moreover, both approaches identified a cluster of more active participants with low levels of pain measured with the Physical Activity Scale for the Elderly (PASE) and KOOS (cluster 1, Figure 2). This cluster was characterized by a dominance of male patients in MFA analysis. The 3rd MFA cluster was slightly older, relatively lean, with low pain but functional limitations (cluster 2). The three remaining clusters after DEC differed in their levels of pain, waist circumference, activity and/or age. After an initial improvement in all clusters, the intensity of symptoms was stable on cluster-specific level (Figure 2).

Radiographic progression profiles differed only for MFA clusters (Figure 2): the more active (cluster 1), as well as the comorbid cluster (cluster 3) showed faster progression than the older, less active patients (cluster 2). Age, gender, BMI, abdominal obesity, presence of knee pain and malalignment were independent risk factors for structural progression.

Conclusion: We identified differentiated, clinically relevant subpopulations within the OAI data set by using two different machine learning approaches. The cluster-specific baseline characteristics will allow for refinement of inclusion criteria for future interventional clinical trials in specific knee OA phenotypes.

SESSION INFORMATION

Session Date: Saturday, November 6, 2021

Session Title: Osteoarthritis – Clinical Poster I (0210–0224)

Session Type: Poster Session A

Session Time: 8:30AM–10:30AM

Background/Purpose: Osteoarthritis (OA) is a prevalent degenerative joint disease and a major cause of pain and disability worldwide. Inflammation of the synovium and surrounding tissues likely contributes to the symptoms and structural progression of OA. The heterogenous nature has posed challenges to the development of disease modifying therapies likely due to different pathogenic mechanisms underlying distinct subtypes of OA. Efforts to subtype the disease have been limited, and integrative approaches are lacking. Here, we applied unsupervised clustering analysis of histology and ultrasound data to identify clinically-relevant knee OA subtypes in patients undergoing total knee arthroplasty (TKA).

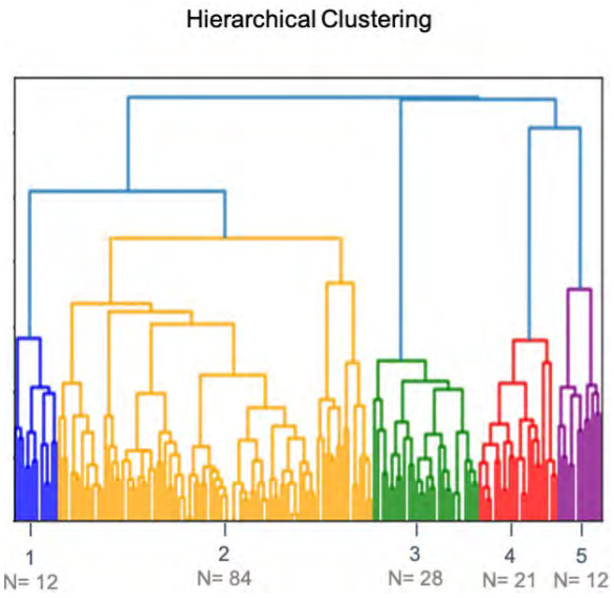

Figure 1. Knee OA subtypes identified by hierarchical clustering. Euclidean Hierarchical clustering revealed 5 knee OA clusters. The number of patients included in each cluster is indicated.

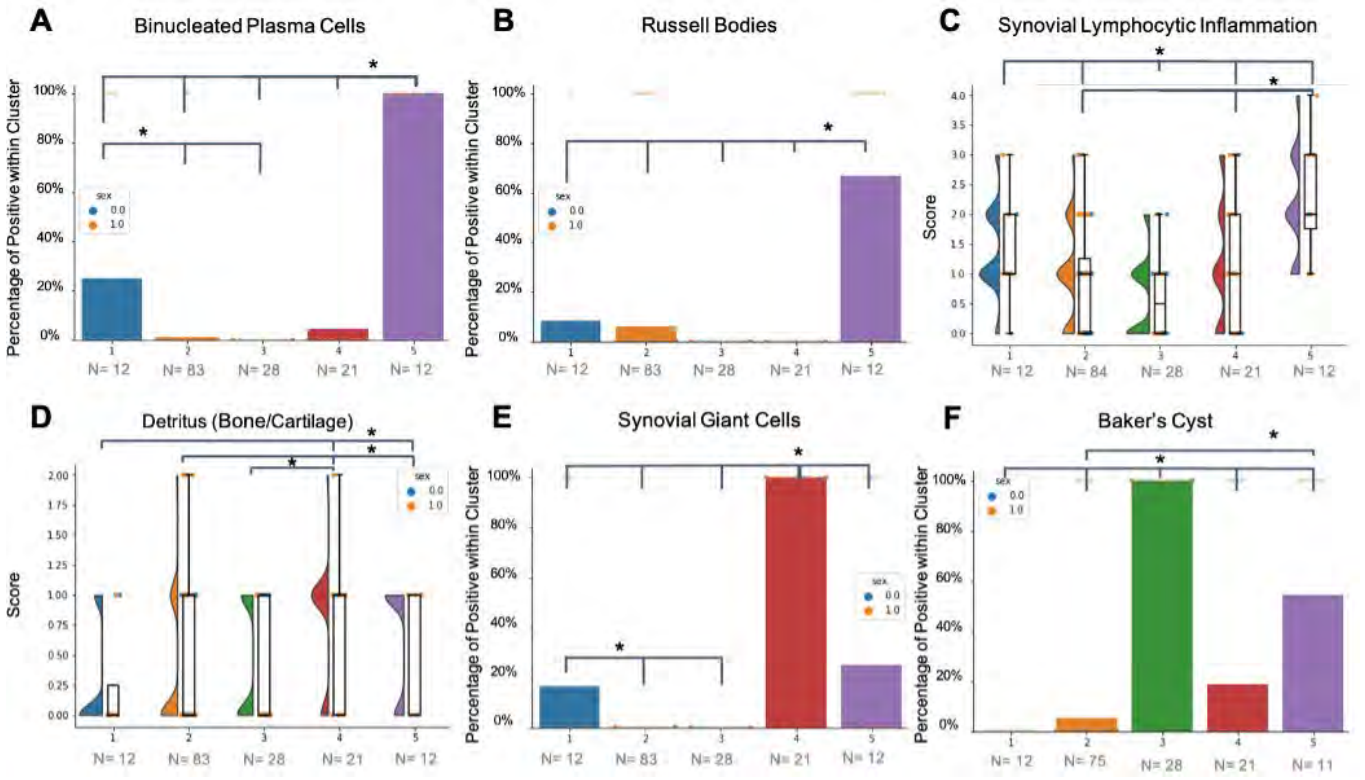

Figure 2. Selected features. Pathology features (A) Binucleated Plasma Cells, (B) Russell Bodies, (C) Synovial Lymphocytic Inflammation, (D) Detritus, and (E) Synovial Giant Cells, and one ultrasound feature (F) Baker's Cyst Presence were important features that determined our cluster separation. Graphs depict a bar plot representing the percentage of patients that had a presence of the indicated variable: Binucleated Plasma Cells, Russell Bodies, Baker's Cyst, and Synovial Giant Cells or a vertical rainbow plot (half violin plot, left, box plot overlaying individual data points, right) representing ordinal variables (Synovial Lymphocytic Inflammation and Detritus) with an increase in score representing worsening pathology. Box plot represents median and interquartile range. Wilcoxon Rank Sum Test was performed, and significance is represented as $P<0.05$ *.

Methods: We prospectively enrolled 160 patients (age 45-75) with end-stage knee OA scheduled for TKA. We collected clinical data, patient-reported data and ultrasounds (43 features, recorded using B-Mode and doppler and evaluated by two radiologists) preoperatively. 21 histologic features were scored by two trained pathologists on hematoxylin and eosin (H&E)-stained synovial biopsies. Histology and ultrasound features with ≥ 5% of variance (n=17) from 157 subjects (with ≤65% missing data) were used for analyses. Min-max scaling was applied, and unsupervised clustering using Euclidean distance and agglomerative hierarchical clustering was conducted. Wilcoxon Rank Sum tests (continuous variables) and Chi squared tests (categorical variables) were performed for statistical comparisons between clusters.

Results: Hierarchical clustering of 12 synovial histology features and 5 ultrasound features revealed 5 OA subtypes (**Figure 1A, B**). These subtypes were defined by the differences in features between subjects and were named accordingly: a *High Inflammatory Subtype* (N=12) with high levels of inflammatory cell infiltrates including plasma cells and lymphocytes, a *Moderate Inflammatory Subtype* (N=12) with moderate levels of the same synovial features, a *Detritic and Synovial Giant Cell Infiltration Subtype* (N=21), *a Minimal Pathology Subtype* (N=28) with presence of Baker's cyst on ultrasound and low levels of synovial inflammation histologic features, and a *Heterogeneous Subtype* (N=84) with little to no findings of inflammation or differences in ultrasound features (**Figure 2A-F**). Both the high and moderate inflammatory subtypes were associated with increased BMI (p=0.048), African American (AA) race (p=0.015), increased levels of ESR (p=0.043) and HS-CRP (p=0.023). The high inflammatory subtype was associated with patient reported major trauma to the affected joint (p=0.025) (**Table 1**).

Table 1. Patient subtypes and demographics. Baseline demographics, clinical features, and blood biomarkers of systemic inflammation were collected at the time of enrollment. Alcohol use is defined as an ordinal variable that represents five categories: 0: No alcohol use, 1: <3 servings per day, 2: 3-5 servings per day, 3: 5-7 servings per day, 4: >7 servings per day. Morning knee stiffness within the week before their pre-surgical screening visit and presence of major trauma to the affected knee are represented as the percentage of patient-reported incidents. Blood Biomarkers were categorized based on subjects that had the presence of levels above normal ranges. Normal ranges for ESR levels differed based on sex and age (females < age 50: 0.0 – 20.0 mm/hr, males < age 50: 0.0 – 15.0 mm/hr, females > age 50: 0.0 – 30.0 mm/hr, males > age 50: 0.0 – 20.0 mm/hr. High sensitivity CRP (HS-CRP) is represented as an ordinal variable that represents patients within normal levels of HS-CRP as 0 and patients outside normal ranges as the deviation from normal ranges. 1 < HS-CRP value < 2 = 1, 2 < HS-CRP value < 3 = 2, 3 < HS-CRP value < 4 = 3, 4 < HS-CRP value < 5 = 4, 5 < HS-CRP value = 5. Data is represented as mean ± SD. Wilcoxon Rank Sum tests were performed for statistical comparisons of continuous variables and Chi Squared tests were performed to compare categorical variables between clusters. Significance is indicated in bold as P<0.05

Cluster Demographics

	All (N = 157)	Cluster 1 (N = 12)	Cluster 2 (N = 84)	Cluster 3 (N = 28)	Cluster 4 (N = 21)	Cluster 5 (N = 12)	P value

Alcohol use (0-4)	1.2 ± 1.3	0.6 ± 1.0	1.5 ± 1.3	1.2 ± 1.4	1.3 ± 1.2	0.5 ± 0.7	0.137
Morning Knee Stiffness Presence	79.0%	67.0%	80.0%	86.0%	76.0%	75.0%	0.730
Major Trauma to Affected Knee	12%	8%	6%	22%	10%	33%	**0.025**
Blood Biomarkers							
Binarized ESR (mm/hr) (0/1)	30.0%	45.0%	21.0%	46.0%	25.0%	50.0%	**0.043**
Ordinal HS-CRP (mg/dL) (0.0 – 1.0 mg/dL) (0-5)	1.7 ± 1.7	2.6 ± 1.9	1.4 ± 1.5	2.2 ± 1.8	1.7 ± 1.7	2.3 ± 2.3	**0.023**

Conclusion: Clustering analysis of synovial histology and ultrasound scoring features identified 5 OA patient subtypes. Two subtypes were associated with AA race, increased BMI, and synovial inflammation, which suggests that demographical factors may play a role in the mechanisms underlying knee OA and warrants further investigation. Our findings suggest that the clinical features and patient reported outcomes represent predictive variables with the potential to be built into algorithms that could be used in the future to guide targeted personalized treatment of these OA subtypes.

Quantitative Assessment of Volumetric Change in Hip Effusion Using Artificial Intelligence in Patients with Osteoarthritis of the Hip

Jacob Jaremko[1], Banafshe Felfeliyan[2], Abhilash Hareendranathan[1], Bashiar Thejeel[1], Vanessa Quinn-Laurin[1], Mikkel Ostergaard[3], Philip Conaghan[4], Robert Lambert[1], Janet Ronsky[2] and Walter Maksymowych[1], [1]University of Alberta, Edmonton, AB, Canada, [2]University of Calgary, Calgary, AB, Canada, [3]Copenhagen Center for Arthritis Research, Center for Rheumatology and Spine Diseases, Rigshospitalet, Glostrup, and Department of Clinical Medicine, University of Copenhagen, Glostrup, Denmark, [4]Leeds Institute of Rheumatic and Musculoskeletal Medicine, University of Leeds, Leeds, United Kingdom

SESSION INFORMATION
Session Date: Saturday, November 6, 2021
Session Title: Osteoarthritis – Clinical Poster I (0210–0224)
Session Type: Poster Session A
Session Time: 8:30AM–10:30AM

Background/Purpose: Accurate quantification of hip effusion volume may aid effective OA management as synovitis of the hip has been associated with pain and structural damage progression. Previous work has shown that volume quantification measures more closely correlate to clinical parameters than conventional measures like femoral neck fluid thickness (FTM). Recently, Artificial Intelligence (AI) based approaches have shown promise in measuring hip effusion volume from MRI sequences. This study examined the feasibility of using AI to quantify the change in effusion volume post intra-articular steroid injection (IASI) using Short-τ Inversion Recovery (STIR) MRI sequences.

Methods: We prospectively collected MRI images from 97 patients who met the ACR clinical classification criteria for hip OA at baseline (before IASI) and at 8 weeks follow-up (after receiving IASI). Two human readers measured the difference in effusion volumes in each image using an interactive tool developed inhouse.

Manually segmented masks of effusion regions from 72 patients were used to train a Mask R-CNN [8] AI model. Changes in effusion volume between baseline and follow-up measured from the remaining 25 patients was used to compare and validate AI measurements vs 2 human readers. The agreement was assessed using the difference in volume (DV), Coefficients of Variation (CoV), and intra-class correlation coefficient (ICC).

Results: The AI model automatically detected effusion regions successfully (Fig 1). Regions of effusion identified by the model both at baseline and follow-up correlated well with human assessment (Fig 2). Agreement in change of effusion volume (DV) measured between human readers was good (ICC=0.80 [0.53, 0.92]). Similarly, ICC between each human reader vs AI predicted ranged between moderate to good (ICC = 0.71-0.76) as summarized in Table 1.

Conclusion: Initial results of automatic quantification of change in effusion volume post -IASI shows moderate to high agreement between AI and human experts. This approach could potentially save expert time in OA MRI assessment resulting in overall improvement in OA care.

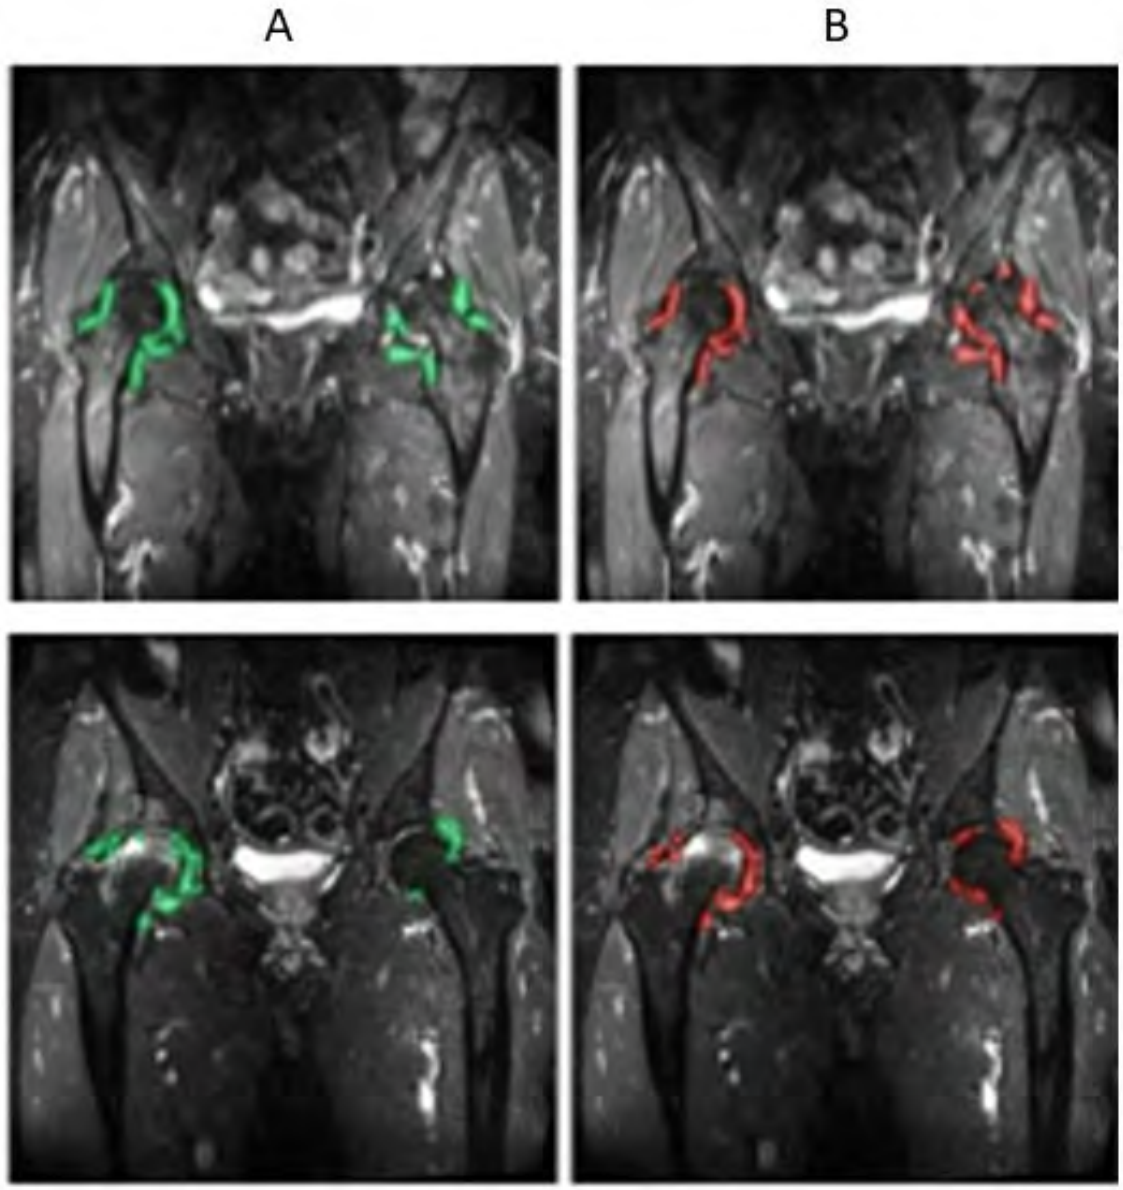

Figure 1. Regions of joint fluid detected by human readers (green, column A) and AI (red, column B) overlain on the original STIR MRI slice from 2 different patients with OA.

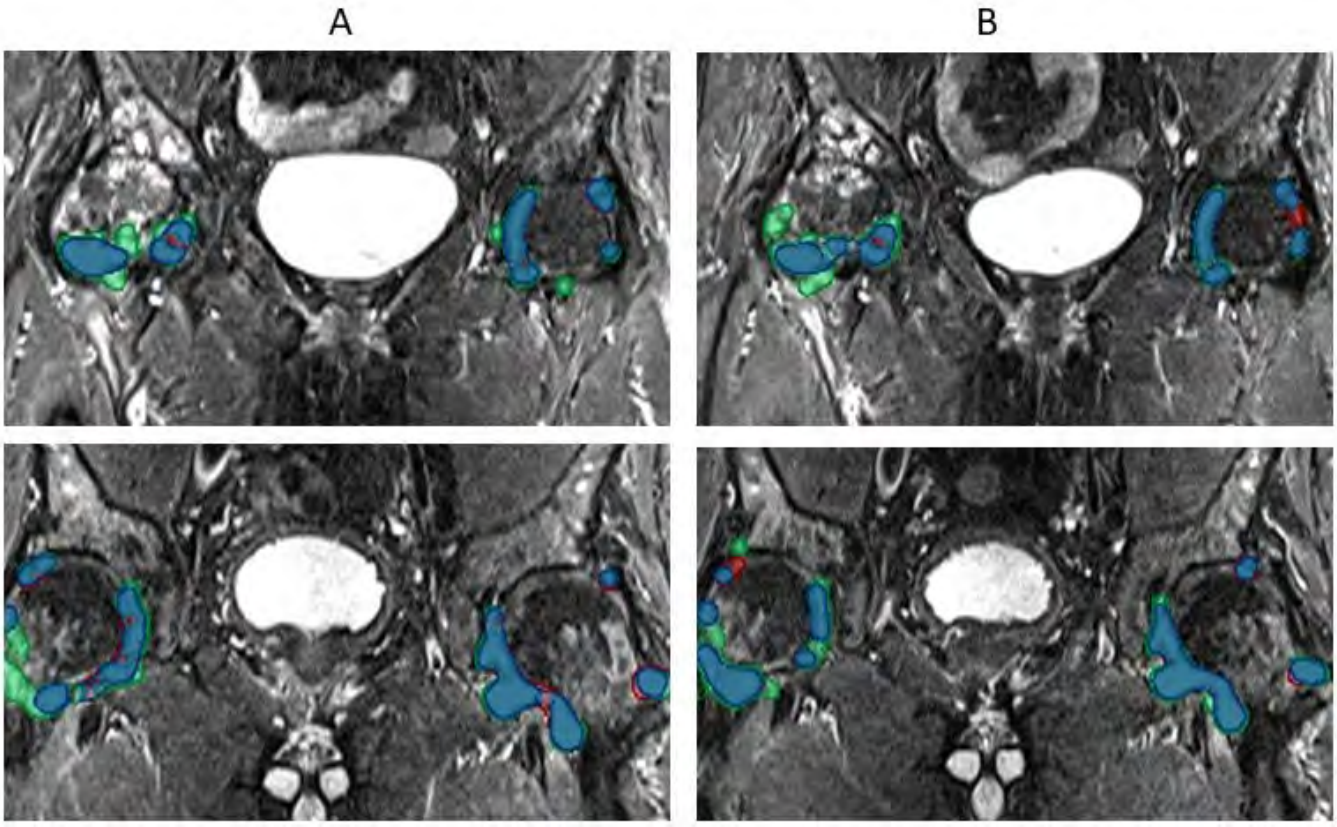

Figure 2. Regions of joint fluid detected by AI on images at baseline (column A) and follow-up (column B) in 2 different patients. Regions of perfect overlap between AI and human readers are shown in blue, segmentation by human readers in green and AI segmentations in red.

Table 1. Agreement in change in effusion volume after IASI measured by human readers and AI assessed using the difference in volume, CoV and ICC

Agreement between reader pairs			
Reader Pair	Difference in Volume Mean ± Standard Deviation	CoV	ICC
Reader 1-2	1130 ± 900	0.21	0.80 [0.53, 0.92]
Reader 1-AI	3060 ±1770	0.33	0.71[0.49,0.87]
Reader 2-AI	2260 ± 1310	0.22	0.76[0.51,0.89]

Baseline Cam or Pincer Morphology Is Associated with Loss of Quantitative Joint Space Width at the Hip: The Johnston County Osteoarthritis Project

Amanda Nelson[1], Carolina Alvarez[1], Yvonne Golightly[1], Jamie Stiller[2], Jordan Renner[1], Nigel Arden[3], Charles Ratzlaff[4] and Jeffrey Duryea[5], [1]University of North Carolina at Chapel Hill, Chapel Hill, NC, [2]Alamance Regional Medical Center, Durham, NC, [3]University of Oxford, Oxford, United Kingdom, [4]University of British Columbia, Vancouver, BC, Canada, [5]Brigham and Women's Hospital, Boston, MA

SESSION INFORMATION
Session Date: Saturday, November 6, 2021
Session Title: Osteoarthritis – Clinical Poster I (0210–0224)
Session Type: Poster Session A
Session Time: 8:30AM–10:30AM

Background/Purpose: To determine the association between radiographic cam and pincer morphology and loss of hip quantitative joint space width (qJSW) in a community-based cohort.

Methods: Data were from Johnston County OA Project (JoCoOA) participants (>45 years of age) with anteroposterior (AP) pelvis radiographs from baseline and up to 2 follow-up timepoints. A musculoskeletal radiologist assigned all hips a Kellgren-Lawrence grade (KLG). Hip morphology measures were defined on baseline radiographs using OxMorf software (Oxford, UK) by two readers. An independent reader measured qJSW at all timepoints (at 3 locations, Fig 1) using a validated method. All readers were blinded to all other data. Participants self-reported age and race; their height was measured, and body mass index (BMI) calculated at clinic visits. Change in qJSW from baseline to final available follow-up divided by time was modeled by location (10, 30, and 50°) and stratified by sex. Population-averaged linear regression was used to model qJSW change in mm/10 years (mm/10y), accounting for correlation among hips and adjusting for baseline age, race, height, BMI, and qJSW to produce β and 95% confidence intervals [CI]. A sensitivity analysis considered only those hips without baseline rHOA (KLG < 2).

Results: Data from 821 individuals (38% men, 26% Black) with 1619 hips, baseline mean ± SD age 62 ± 9 years, BMI 29 ± 6 kg/m^2 and follow-up (at T1 and/or T2; 9 ± 3 years) were included. At baseline, 9% of women and 26% of men had an AP alpha angle >60° consistent with cam morphology. Acetabular under-coverage (i.e., lateral center edge

Multivariable regression modeling change in qJSW (mm/10y) adjusting for baseline: age, race, height, body mass index, and qJSW; Population-averaged linear models accounting for correlation among hips; Models are stratified by sex to provide adjusted β and 95% confidence intervals and are **bold** when significant at alpha=0.05; na=not applicable; for 3 FAI continuous variables, unit change is chosen to correspond approximately to 1SD

angle [LCEA] £ 25°) was present in about ¼ of the sample and more common in men (31% vs. 22%), while acetabular over-coverage (i.e., LCEA >40° or protrusio) was more common in women (9% vs 5% and 6% vs 0%, respectively). Baseline mean qJSW was around 5mm and decreased by an average of 0.1mm/10y (Table 1).

Among women, AP alpha angle and mixed cam/pincer morphology were significantly associated with loss of qJSW at the 50-degree location (up to 0.31mm/10y). In men, indicators of cam morphology (AP alpha angle and triangular index) were associated with loss of qJSW at all 3 locations (up to 0.33mm/10y). Acetabular under- or over-coverage were not significantly associated with change in qJSW in men or women (Table 2).

When considering only 1303 hips without baseline rHOA (data not shown), AP alpha angle was no longer significantly associated with loss of qJSW in women at the 50-degree location, but acetabular overcoverage became significant (-0.22 [-.40, -0.04]mm/10y), and mixed cam/pincer morphology was strongly associated with qJSW loss (-1.20 [-1.67, -0.73]mm/10y). In men, greater triangular index height remained associated with loss of qJSW at most locations (around 0.1mm/10y) but associations with other cam morphologies were not significant.

Conclusion: These data support a role for cam and pincer morphologies in progression of hip joint space loss. Some of these morphologies increased loss of joint space by more than 3 times (e.g., 0.3mm vs 0.1mm/10y) over the baseline average, suggesting that such measures could be used for risk stratification in clinical studies to identify hips at higher risk for progression.

Abstract Number: 0215

Ultrasonographic Assessment of Knee Osteoarthritis and Its Agreement with Radiography

Khoa Nguyen[1] and Duc Tran[2], [1]Deparment of Rheumatology, Cho Ray Hospital, Ho Chi Minh City, Vietnam, [2]Department of Rheumatology, Cho Ray Hospital, Ho Chi Minh, Vietnam

SESSION INFORMATION
Session Date: Saturday, November 6, 2021
Session Title: Osteoarthritis – Clinical Poster I (0210–0224)
Session Type: Poster Session A
Session Time: 8:30AM–10:30AM

Background/Purpose: Ultrasonography (US) has been increasingly utilized for the assessment of various musculoskeletal conditions. However, the value of this tool in diagnosis of osteoarthritis (OA) in clinical practice remains unclear. This study was to 1) to characterize ultrasonographic features of knee OA and their relationship with pain and functional levels and 2) to determine the degree of correlation and agreement between the US and conventional radiography in the assessment of knee OA.

Methods: A cross sectional study was carried out on 145 patients (83.4 % female), aged 40 years or older, with mean age of 61.7 years, and clinically diagnosed with primary knee OA, at the outpatient Rheumatology Clinic, Cho Ray Hospital in the period between August 2018 and August 2019. Patients with concomitant inflammatory joint diseases were excluded. All subjects were clinically assessed for pain using a visual analog scale (VAS) and functional status using the Western Ontario and McMaster Universities Arthritis Index (WOMAC), and underwent knee radiography and US examination. Correlation between ultrasonographic findings and clinical and radiographic features was investigated.

Results: A total of 290 knee joints were evaluated. The most common findings on the US were reduced cartilage thickness (74.5%), osteophytes (66.9%), effusion (55.9%), medial meniscal extrusion (78.6%), lateral meniscal extrusion (39.3%), thickened synovial membrane (17.2%) and Baker's cyst (15.2%). The VAS and WOMAC pain scores correlated positively with the level of effusion and the osteophyte size, and negatively with the medial femoral cartilage thickness measured on the US. There was a positive correlation between the sonographic medial cartilage thickness and the radiographic medial joint space width ($r_s = 0.3$, $p < 0.01$), and between sonographic and radiographic osteophyte grades ($r_s = 0.69$, $p < 0.01$ and $r_s = 0.47$, $p < 0.01$ for medial and lateral joint space, respectively). Osteophytes were found on both US and radiography in 129 (44.5%) knees, only the US in 44 (34.1%) knees, and only radiography in 17 (13.2%) knees (Kappa = 0.58; $p < 0.01$).

Conclusion: These results support the validity of US in the assessment of knee OA lesions in comparison to conventional radiography. Moreover, US appears to be more sensitive than radiophraphy in detecting early changes of knee OA such as cartilage damage and mild osteophytes

Distribution of Medial Femur and Tibia Cartilage Volume Change over 48 Months on MRI: Comparison Among Kellgren-Lawrence Grades

Rebecca Amesbury[1], Hedieh Ragati Haghi[1], Todd Laffaye[1], Rebekah Stein[1], Erin Ashbeck[2], C. Kent Kwoh[3], Alexander Mathiessen[1] and Jeffrey Duryea[1], [1]Brigham and Women's Hospital, Boston, MA, [2]University of Arizona Arthritis Center, Tucson, AZ, [3]University of Arizona College of Medicine, Tuscon, AZ

SESSION INFORMATION
Session Date: Saturday, November 6, 2021
Session Title: Osteoarthritis – Clinical Poster I (0210–0224)
Session Type: Poster Session A
Session Time: 8:30AM–10:30AM

Background/Purpose: Semi-automated Local Area Cartilage Segmentation (LACS) software uses two robust coordinate systems to measure cartilage change in focused regions in the femur and tibia. (Figure 1) LACS also offers a topological method to assess change in cartilage volume through the use of responsiveness heat-maps. The purpose of this study was to provide a descriptive assessment of cartilage volume change in the medial femur (MF) and medial tibia (MT) for different (Kellgren-Lawrence) KL grades with the hypothesis that there will be evidence for different patterns of changes in cartilage volume across KL grades 1, 2 and 3.

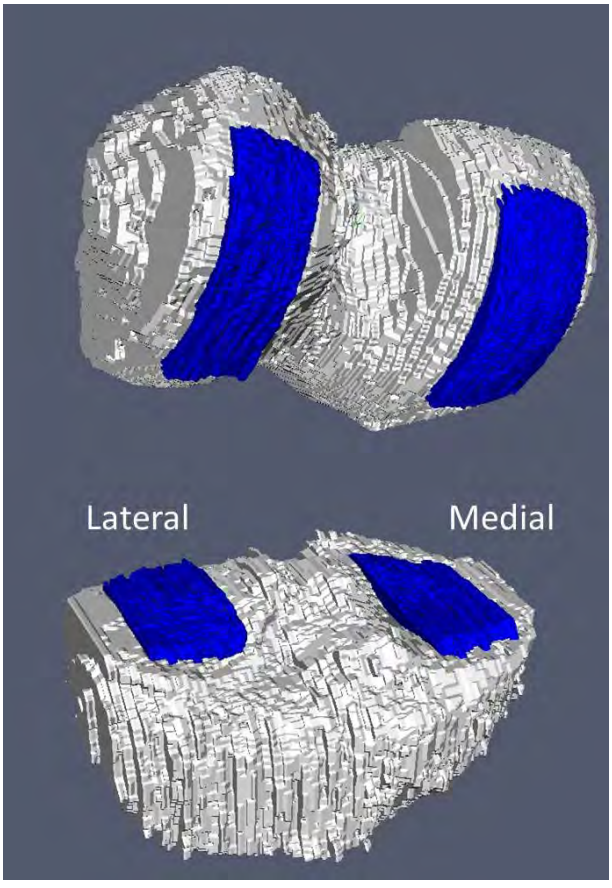

Figure 1. Examples of LACS subregions defined by cylindrical (femur) and Cartesian (tibia) coordinate systems.

Table 1. SRM values for different KL grades

	KL1 (N=160)	KL2 (N=316)	KL3 (N=194)	All (N=670)
MF	-0.32	-0.36	-0.73	-0.46
MT	-0.44	-0.42	-0.61	-0.48

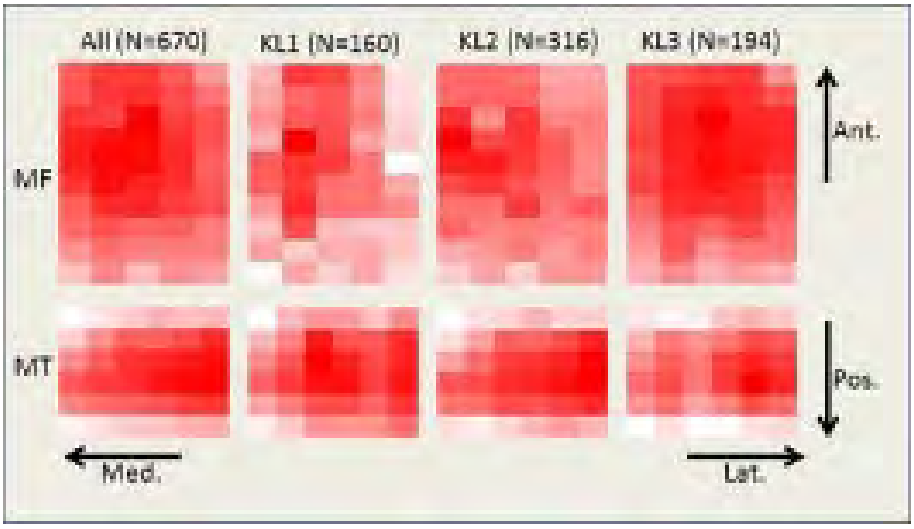

Figure 2. Responsiveness heat-maps for the MF and MT based on the SRM values. Each shaded rectangle represents the sub-regions of cartilage shown in Figure 1. Note, the range of intensities has been renormalized for each condition. Overall magnitude of the change for each category can be appreciated by the values in Table 1.

Methods: Cartilage volume was measured in a central weight-bearing portion of the MF and MT using the LACS method at the baseline (BL) and 48 month visits of 670 participants from the Osteoarthritis Initiative (OAI), a longitudinal observational cohort study. Participants with at least one knee KL 1, 2, or 3 on centrally read baseline posterior-anterior weight-bearing knee radiographs were selected. Participants with a prosthetic knee or KL4 knee at baseline were excluded. One knee per participant was selected, based on maximum KL grade or randomly, if both knees had the same KL grade. Cartilage volume change was calculated as standardized response mean (SRM) for both plates separately. LACS SRM was estimated over grids in the sample and displayed in the form of responsiveness heat-maps, showing topographical change as SRM values over each cartilage plate region. (i.e., blue sub-regions in Figure 1) The mathematical nature of the LACS method permits any grid location to be determined consistently.

Results: At baseline, the participants had a mean age of 61.3 years, a mean BMI of 28.9, and were 41.5% male. The baseline distribution of KL grades was: KL1: 23.9% (N=160), KL2: 47.1% (N=316), KL3: 29.0% (N= 194). SRM values are shown in Table 1. These data indicate that the cartilage volume change is similar between KL1 and KL2 with a substantial increase for KL3. The responsiveness heat-maps are shown in Figure 2. We observed different patterns of change across the heat-maps. With increasing KL grade from 1 to 3, there appeared to be greater amount of change in the lateral portion of both the MF and MT compartments with the MT and MF having similar patterns of change.

Conclusion: As expected, loss of cartilage volume is increased in KL3 knees. But the heat-maps suggest there is more cartilage loss in the inner (lateral) portion of the knee in patients with more advanced OA as seen by a modestly higher intensity in the right-hand side of each heatmap with increasing KL grade. The variation in patterns of change in cartilage volume by KL grade demonstrate that the heat-map approach may offer a way to characterize different disease-related patterns of knee osteoarthritis progression. Additional studies will be necessary to better understand the role of responsiveness heat-maps. In the future, this work will be extended to the lateral compartment, and differences by gender, BMI, age, knee alignment, and other clinical variables will be assessed.

and degree of synovitis for the treatment of OA. We have developed the OMERACT Knee Inflammation MRI Scoring System (KIMRISS) and have recently refined it to maximize reliability and sensitivity to change. Innovations include custom-designed electronic overlays suitable for a touch-screen interface for assessment of BML in 500 subregions on consecutive sagittal slices, a web-based interface with direct online scoring, and real-time iterative calibration (RETIC) prior to formal reading exercises. We aimed to test the feasibility, reliability, and responsiveness of KIMRISS versus an established method, MOAKS, in a multi-reader exercise.

Methods: KIMRISS incorporates web-based graphic overlays for each of femur, tibia, and patella to score BML in 500 subregions on consecutive sagittal slices. S-E is recorded as the largest diameter of the fluid signal on all *consecutive* sagittal slices (scoring range 0-100). All scores are pro-rated for a standardized number of MRI slices. In a pre-reading exercise for KIMRISS, readers scored a RETIC module to attain scoring proficiency, pre-specified as an ICC of ≥0.80 and ≥0.70 for status and change scores of BML and S-E when compared to developer reads. A new web-based scoring platform with overlays designating subregions for scoring BML was developed for MOAKS. We compared reliability for status and change scores of BML and S-E in 2 international multi-reader exercises of baseline and 1-year MRI scans from the Osteoarthritis Initiative: A. 4 expert readers and an OMERACT fellow scored 38 cases selected for MOAKS BML score ≥1. B. 8 expert readers and an OMERACT fellow scored 60 cases selected for MOAKS BML ≥3 and Kellgren-Lawrence (K-L) grade < 3. Reliability was assessed by intra-class correlation coefficient (ICC) and Smallest Detectable Change (SDC), responsiveness by the standardized response mean (SRM), and feasibility using the System Usability Scale (SUS scoring range 0-100).

Results: For exercises A/B, subjects were 55.3%/ 26.7% male, mean(±SD) age 61.7(±9.1)/61.9(8.8) years, and radiographic K-L grade ≤2 in 39.4%/100%. Change was small in both exercises (< 5% of scoring range for KIMRISS and MOAKS BML and S-E) with comparable responsiveness (Table 1). Despite this, ICC for change was consistently good to very good for both BML and S-E and consistently better for KIMRISS with lower SDC as % of scoring range (Table 2). Significant correlations between WOMAC baseline pain scores and KIMRISS and MOAKS baseline BML and S-E scores were observed; significant correlations between WOMAC change and KIMRISS and MOAKS BML change were also noted (Table 3). Mean SUS scores were 88.2 for KIMRISS and 54.3 for MOAKS.

Conclusion: The KIMRISS method for scoring BML and Synovitis-Effusion scores highly for feasibility and demonstrates consistently high reliability when compared to MOAKS. Correlations with WOMAC pain are demonstrable with both methods for both BML and S-E. Further validation for responsiveness is necessary in cases with greater change in MRI features than in the OAI dataset.

Synovitis Does Not Mediate the Relationship Between Body Mass Index and Progression of Radiographic Knee Osteoarthritis: Data from the Osteoarthritis Initiative

Marina Bañuls[1], Alecio Lombardi[1], Eric Chang[1], Aladdin H Shadyab[1], Nancy Lane[2] and Monica Guma[3], [1]University of California San Diego, San Diego, CA, [2]University of California Davis, Hillsborough, CA, [3]University of California San Diego, La Jolla, CA

SESSION INFORMATION
Session Date: Saturday, November 6, 2021
Session Title: Osteoarthritis – Clinical Poster I (0210–0224)
Session Type: Poster Session A
Session Time: 8:30AM–10:30AM

Background/Purpose: Synovial inflammation is associated with knee osteoarthritis (KOA) progression. Body mass index (BMI) has also been associated with KOA progression. Yet, it is unclear whether synovial inflammation mediates the association of BMI with KOA progression. Here, we examined the mediating effect of synovitis in the association between BMI and progression of radiographic KOA in the Osteoarthritis Initiative (OAI) cohort.

Methods: We conducted a case-control study within the OAI. Cases (n = 315) were right knees with an increase of ≥ 1 Kellgren-Lawrence (K-L) from baseline to 48 months of follow-up. Controls (n = 315) were right knees that had no K-L change over 48 months. Cases and controls were matched by age, gender, race and baseline K-L. MRI Osteoarthritis

Presence (%)	51.9	61.9	42.0
Score (mean +- SD)	0.61 +- 0.66	0.78 +- 0.73	0.44 +- 0.54

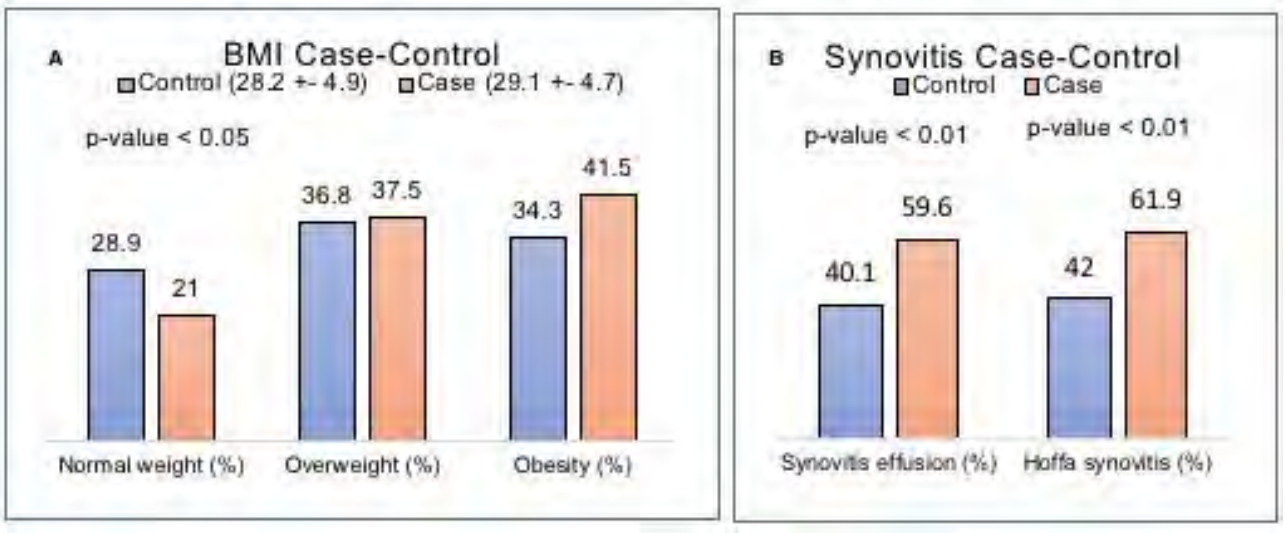

Figure 2. A: Percentage of cases and controls by BMI. P value is overall test of significant for chi square test. B: Percentage of cases and controls with synovitis effusion or Hoffa synovitis. P value is overall test of significant for chi square test.

Knee Score (MOAKS) was used for a semi-quantitative evaluation (0-3) of effusion synovitis and Hoffa-synovitis at baseline. The SPSS PROCESS macro was used to test the mediating effects.

Results: The mean age of participants was 61 years, 70.8% were women, and 87% were white. Baseline knee KL was as follows: 36.8% grade 0, 30.2% grade 1, 25.1% grade 2 and 7.9% grade 3. 24.9% were normal weight (BMI < 24.9 kg/m2), 37.1% were overweight (BMI 25-29.9 kg/m2) and 37.0% were obese (BMI ≥ 30 kg/m2). Average BMI was 28.63 ± 4.8. 49.8% had synovitis effusion with a score of 0.56 ± 0.6, and 51.9% had Hoffa synovitis with a score or 0.61 ± 0.66. Compared with controls, cases had higher BMI (29.1 ± 4.7 vs 28.2 ± 4.9,p< 0.05), and were more likely to be obese (41.5% vs. 34.3%) than controls (p < 0.05). At baseline, cases had higher prevalence of both synovitis

effusion and Hoffa-synovitis than controls (59.6% vs 40.1%, p< 0.01 for synovitis-effusion and 61.9% vs 42%, p< 0.01, for Hoffa synovitis respectively). Yet, in the mediation analysis, neither synovitis effusion nor Hoffa synovitis mediated the relationship between BMI and KOA progression.

Conclusion: Preliminary findings from mediation analysis showed that neither synovitis effusion nor Hoffa synovitis mediated the relationship between BMI and progression of radiographic KOA over a 4-year period. A longer duration of follow-up may be required to determine if synovitis mediates the association between BMI and progression of KOA.

Intra-Articular Mineralization on Knee CT and Risk of Cartilage Loss: The Multicenter Osteoarthritis Study

Jean Liew[1], John Lynch[2], Ali Guermazi[1], Mohamed Jarraya[3], David Felson[1], Na Wang[1], Cora Lewis[4], James Torner[5], Michael Nevitt[6] and Tuhina Neogi[7], [1]Boston University, Boston, MA, [2]University of California San Francisco, San Francisco, CA, [3]Massachusetts General Hospital, Boston, MA, [4]University of Alabama Birmingham, Birmingham, AL, [5]University of Iowa, Iowa City, IA, [6]University of California San Francisco, Orinda, CA, [7]Boston University School of Medicine, Boston, MA

SESSION INFORMATION
Session Date: Saturday, November 6, 2021
Session Title: Osteoarthritis – Clinical Poster I (0210–0224)
Session Type: Poster Session A
Session Time: 8:30AM–10:30AM

Background/Purpose: Intra-articular (IA) mineralization due to crystal deposition may contribute to OA pathology through inflammation, release of pro-catabolic factors, or altered cartilage biomechanical properties. Prior conflicting studies regarding whether chondrocalcinosis (from IA mineralization) is associated with OA structural progression were limited by the use of insensitive radiographs for visualizing IA mineralization. We studied the relation of IA mineralization on CT (a more sensitive modality) to cartilage loss on knee MRI in older adults, with particular attention to potential joint location- and tissue-specific effects of mineralization on cartilage pathology.

Table. Relationship of IA mineralization to cartilage loss, on knee-level and compartment-specific analyses

	Knee-level	Compartment-specific
IA mineralization	**Risk ratio (95% CI)**	**Risk ratio (95% CI)**
Any mineralization	1.05 (0.90, 1.24)	1.16 (0.88, 1.53)
Any cartilage	1.05 (0.87, 1.27)	**1.40 (1.04, 1.88)**
Any meniscus	1.03 (0.86, 1.24)	1.07 (0.81, 1.42)
Any joint capsule	1.16 (0.95, 1.42)	—

Adjusted for age, sex, race/site, BMI.
Any IA mineralization includes cartilage, meniscus, and joint capsule for knee-level analyses; and cartilage and meniscus for compartment-specific analyses.

Methods: Participants from the Multicenter Osteoarthritis (MOST) study, a longitudinal prospective cohort of older adults, who had knee CTs and MRIs, were included in this longitudinal analysis. IA mineralization was assessed on CT using the Boston University Calcium Knee Score (BUCKS), with semi-quantitative scoring of extent of crystal mineralization 0-3 in WORMS subregions. We categorized presence of mineralization as a BUCKS score >0 in the following tissues: 1) anywhere in the knee; 2) cartilage; 3) meniscus; 4) joint capsule. For cartilage and meniscus, we further classified mineralization as occurring in the medial and/or lateral tibiofemoral compartment. Cartilage worsening on MRI was defined as any increase in the semi-quantitative MOAKS score between baseline and two-year follow-up in a compartment-specific manner and for the whole knee. We evaluated the relation of IA mineralization (defined above) to the presence of MRI cartilage worsening using binomial regression, and with generalized estimating equations for compartment-specific analyses to account for correlations between compartments within a knee. Analyses were performed in a compartment-specific manner for cartilage and meniscus mineralization (i.e., relation of presence of medial mineralization to risk of medial cartilage worsening), and at the whole knee level for capsular mineralization. Analyses were adjusted for age, sex, and body mass index (BMI).

Results: We included 1673 participants (mean age 60.1±9.1, 56% female, mean BMI 28.6±5.0 kg/m^2). Overall, 9.0% had any IA mineralization in the knee; mineralization in the cartilage, meniscus, and joint capsule was present in 6.3%, 7.1%, and 4.0%, respectively. 46.5% had cartilage loss on follow-up anywhere in the knee. In compartment-specific analyses, presence of cartilage mineralization was associated with a 1.40 higher risk of cartilage loss in the same compartment (95% CI, 1.04-1.88); no association was noted for mineralization of the meniscus (Table). Mineralization of any tissue in the knee, regardless of location or tissue type was not associated with cartilage worsening at any location in the knee.

Conclusion: IA mineralization in the cartilage, but not in the meniscus, was associated with higher risk of cartilage loss in the same compartment over two years. Mineralization of the joint capsule was also not associated with cartilage loss anywhere in the knee. These findings suggest potential tissue-specific and localized effects of IA mineralization on cartilage pathology in knee OA.

Relation of Knee Extensor Power to Worsening Cartilage Damage in the Knee: The MOST Study

Joshua Stefanik[1], David Felson[2], Cara Lewis[3], Gabriela Rabasa[2], Ali Guermazi[2], Frank Roemer[4], Michael Nevitt[5], Cora Lewis[6] and Neil Segal[7], [1]Northeastern University, Boston, MA, [2]Boston University, Boston, MA, [3]Boston University, Brookline, MA, [4]Friedrich-Alexander University Erlangen-Nurnberg, Erlangen, Germany, [5]University of California San Francisco, Orinda, CA, [6]University of Alabama Birmingham, Birmingham, AL, [7]University of Kansas Medical Center, Iowa City, IA

SESSION INFORMATION
Session Date: Saturday, November 6, 2021
Session Title: Osteoarthritis – Clinical Poster I (0210–0224)
Session Type: Poster Session A
Session Time: 8:30AM–10:30AM

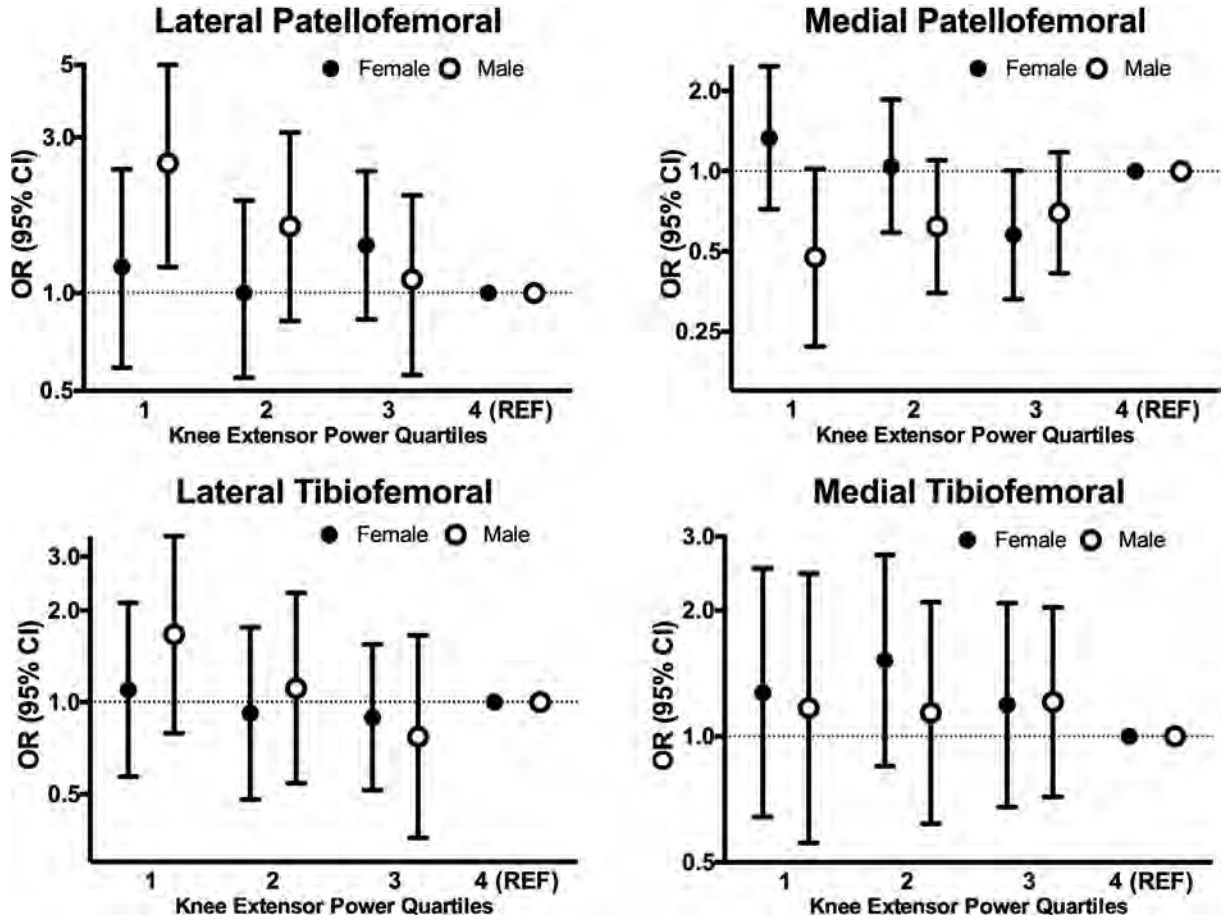

Figure. Relation of quadriceps power quartiles to worsening knee joint cartilage damage in men and women.

Background/Purpose: The relation between knee extensor muscle weakness and osteoarthritis (OA) outcomes has been well-studied. Muscle power, another measure of knee extensor function, however, has been less studied in the context of knee OA. Power is the rate at which a load is moved. Velocity of muscle contraction declines with aging, leading to a more precipitous drop in muscular power than in strength and increases vulnerability to joint injury with minor perturbations. Greater knowledge of the extent to which knee extensor power is a risk factor for worsening structure is clinically important, as muscle power is a potentially modifiable risk factor. Identifying relationships between power and structural change may affect current rehabilitation approaches to manage knee OA by shifting the focus from increasing strength to increasing velocity. Thus, our objective was to determine the relation of knee extensor power to worsening cartilage damage in the knee.

Methods: Knee extensor power was assessed using a HUMAC Norm dynamometer. An isotonic knee extension one repetition maximum (1RM) was first determined. Then participants extended each knee as fast and as hard as they could while moving 40% of the 1RM load. Three trials were performed, and the maximum value in Watts was used in the analyses. Knee extensor power was divided into quartiles. Cartilage damage was assessed using the MRI Osteoarthritis Knee Score (MOAKS) by two musculoskeletal radiologists in 14 subregions of the knee at the 144- and 168-month study visits. Worsening cartilage damage was defined as any increase in score, either in size or depth, over 2 years. Analyses were performed separately for the medial/lateral patellofemoral joints (PFJ) and medial/lateral tibiofemoral joints (TFJ). Our unit of analysis was the subregion (e.g., the lateral patellofemoral joint analyses included the lateral patella and lateral anterior femur subregions). Logistic regression with GEE was used to determine the relation of knee extensor power quartiles to any worsening of cartilage damage adjusting for age, BMI, race, and previous knee injury/surgery. Analyses were performed in women and men separately.

Results: 1547 participants were included in the current analysis; mean age and BMI were 61.0 (9.2) years and 28.6 (4.9) kg/m^2, respectively; 56% were female and 84% white. The mean knee extensor power was 2.8 (1.0) and 3.9 (1.3) Watts in women and men, respectively. Cartilage worsening was present in 7.3, 6.9, 4.9, and 4.6% of subregions in the lateral PFJ, medial PFJ, medial TFJ, and lateral TFJ in women, respectively. In men, cartilage worsening was present in 8.2, 8.5, 7.0, and 2.6% of subregions in the lateral PFJ, medial PFJ, medial TFJ, and lateral TFJ, respectively. There was no relation between knee extensor power and cartilage worsening in any knee compartment in women. In men, compared to those in the highest knee extensor power quartile, those in the lowest quartile had 2.5 (1.2, 5.0) and 0.48 (0.22, 1.0) times the odds (95% CI) of cartilage worsening in the lateral and medial PFJ, respectively.

Conclusion: In men, lower knee extensor power was associated with increased odds of cartilage worsening in the lateral PFJ and decreased the odds of medial PFJ cartilage worsening.

Trunk Movement Compensation Is Associated with Physical Performance Measures and Fatigue Deficits in Hip Osteoarthritis

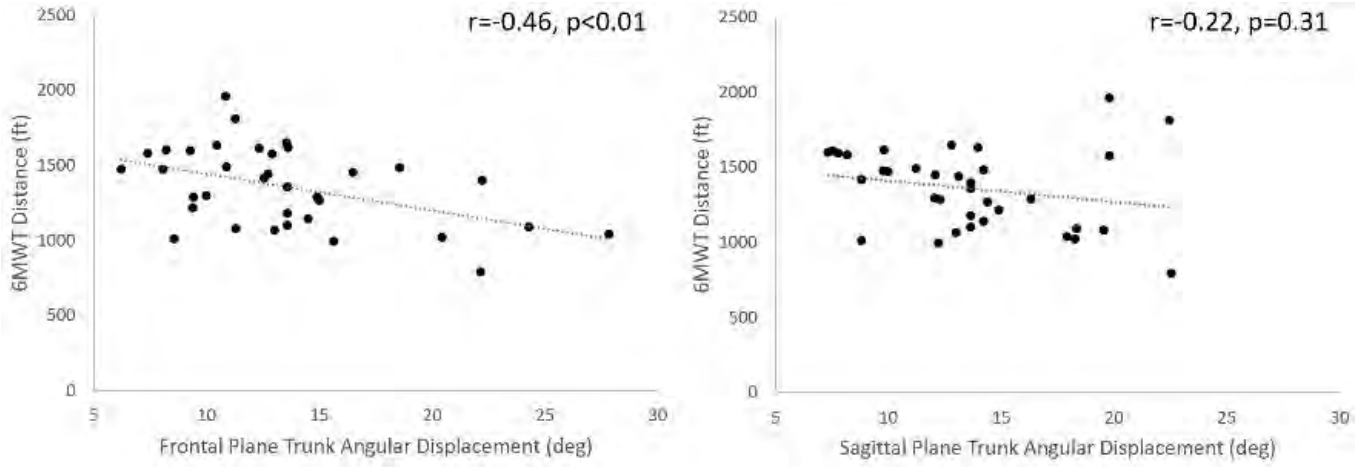
Jesse Christensen[1], **David Quammen**[2], Justin Rigby[2], Cory Christiansen[3] and Jennifer Stevens-Lapsley[3], [1]VA Salt Lake City Health Care System, Salt Lake City, UT, [2]University of Utah, Salt Lake City, UT, [3]Department of Physical Medicine and Rehabilitation, University of Colorado Anschutz Medical Campus, Aurora, CO

SESSION INFORMATION
Session Date: Saturday, November 6, 2021
Session Title: Osteoarthritis – Clinical Poster I (0210–0224)
Session Type: Poster Session A
Session Time: 8:30AM–10:30AM

Background/Purpose: Movement compensation is common in people with hip osteoarthritis (HOA) and a biomarker of physical performance and muscle strength deficits in older adults. Inertial measurement units (IMUs) offer novel methods for identifying movement compensation during functional activities. However, the relationship between deficits in physical performance, muscle strength and fatigue on movement compensation is unknown in people with HOA. Therefore, the purpose of this study was to compare the relationship between trunk movement compensation identified by IMUs and physical function assessed by validated physical performance and muscle strength measures.

Methods: Thirty-five participants (63.3±7.4 years, 57% male, 28.6±4.5 kg/m^2) with end-stage HOA who were scheduled to undergo a total hip arthroplasty were enrolled in the study. A cross-sectional study design was used. Two inertial measurement units were used to assess trunk onto pelvis movement compensation during the six-minute walk test (6MWT). Hip abduction, knee extension and knee flexion strength were measured using hand-held dynamometer. General linear regression models were used to regress trunk movement compensation onto 6MWT performance and muscle strength measures. Pairwise t-tests were used to evaluate the influence fatigue has on trunk movement compensation by comparing the first and last minute of the 6MWT.

Results: Greater trunk movement compensation was related to poorer 6MWT ($p< 0.01$; $r=-0.46$). Greater hip abduction weakness was related to increased trunk movement compensation in both the sagittal ($p=0.01$; $r=-0.44$) and



Relationship between trunk angular displacement on six-minute walk test performance.

Table 2. Peak trunk movement compensation during six-minute walk test

Variable	6MWT First Minute			6MWT Last Minute					
	Max	Min	Sum^	Max	Min	Sum^	Mean Diff[d]	SE	p-value[f]
Frontal Plane[a]	0.36 (8.75)	12.24 (9.30)	12.61 (3.70)	0.72 (10.8)	13.95 (12.03)	14.68 (5.32)	2.06	0.66	0.005*
Sagittal Plane[b]	11.70 (6.07)	1.19 (6.41)	13.21 (4.48)	13.80 (6.72)	0.08 (7.15)	13.88 (5.86)	0.67	0.55	0.312

Note: Angular displacement of the trunk during sagittal and frontal plane movement during six-minute walk test. 6MWT, six-minute walk test; Max, maximum; Min, minimum; Diff, difference score between the maximum and minimum peak mean values.

[a] *Values are peak means (standard deviations) from raw data (degrees), positive values indicate angular displacement over the involved limb. Negative values indicate angular displacement over non-involved limb.*

[b] *Values are peak means (standard deviations) from raw data (degrees), positive values indicate angular displacement anteriorly. Negative values indicate angular displacement posteriorly.*

^ *Values are the summation of the magnitude of the maximum and minimum angular displacement.*

[f] *Values are peak mean differences (standard error) from linear regression model*

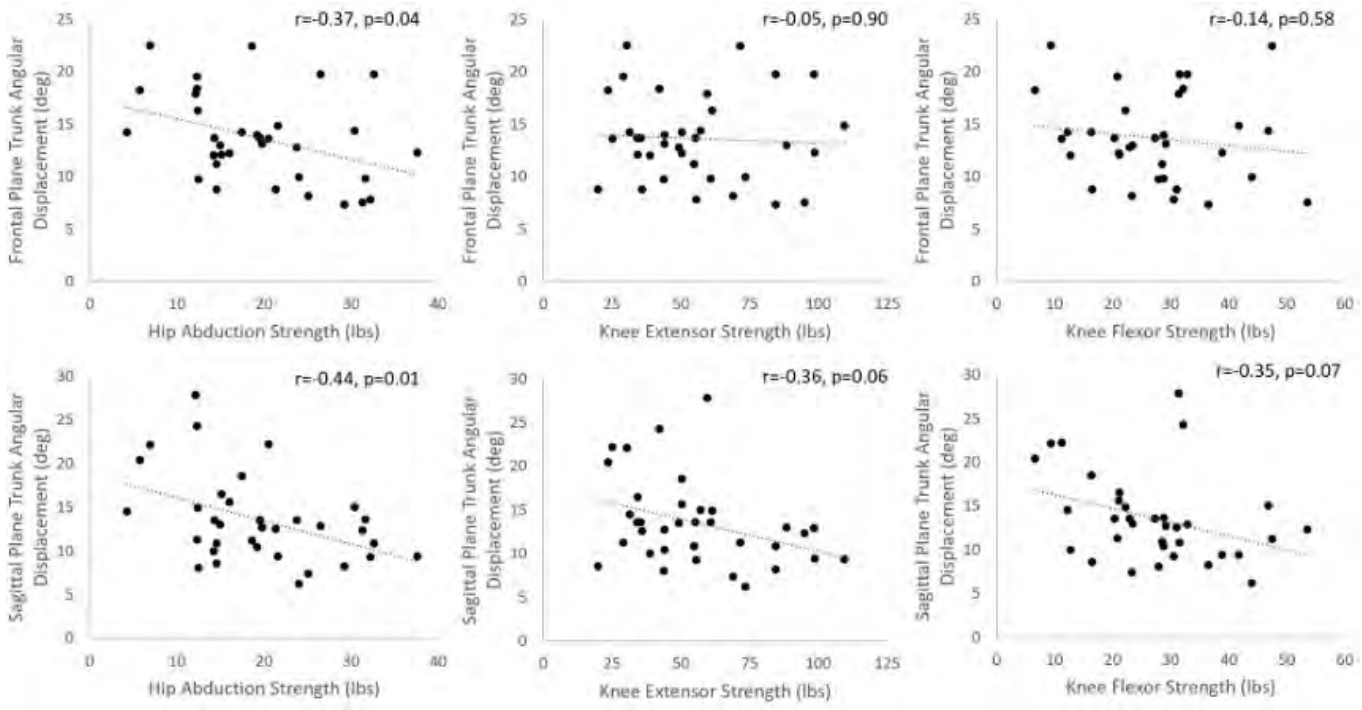
[‡] *p-values adjusted based upon Tukey-Ciminera-Heyse multiple comparison procedure*

* *significant at p<0.05*

Peak trunk movement compensation during the six-minute walk test.

frontal (p=0.04; r=-0.37) planes. Participants demonstrated greater trunk movement compensation during the last minute compared to the first minute (p< 0.01) of 6MWT.

Conclusion: Trunk movement compensation has a negative influence on physical function in people with HOA. Greater trunk movement compensation relates to poorer performance on the six-minute walk test and greater hip



Relationship between muscle weakness on trunk angular displacement during six-minute walk test.

abduction weakness. Prolonged walking leads to a greater increase in trunk movement compensation, which could have future ramifications of accelerated arthritic changes in secondary joints.

Effects of Multi-Joint Osteoarthritis Phenotypes on Self-Reported Physical Function over 3.5 Years: The Johnston County Osteoarthritis Project

Amanda Nelson[1], Carolina Alvarez[1], Liubov Arbeeva[1], Jordan Renner[1], Virginia Kraus[2], Duncan Lascelles[3] and Yvonne Golightly[1], [1]University of North Carolina at Chapel Hill, Chapel Hill, NC, [2]Duke University, Durham, NC, [3]North Carolina State University, Raleigh, NC

SESSION INFORMATION

Session Date: Saturday, November 6, 2021
Session Title: Osteoarthritis – Clinical Poster I (0210–0224)
Session Type: Poster Session A
Session Time: 8:30AM–10:30AM

Background/Purpose: To determine the differential effects of several literature-based definitions of multi-joint osteoarthritis (MJOA) on change in self-reported physical function in a community-based cohort.

Methods: We previously defined 10 forms of MJOA (Table) based on results from a systematic review of MJOA definitions (PMID 30390991). Here, we focus on the influence of symptomatic MJOA (sxMJOA, i.e., meeting a given MJOA definition with at least one site being symptomatic, see Table) on change in physical function 3.5 years later. The outcome of interest was the change in scores on the Patient Reported Outcomes Measurement Information System

Table. Symptomatic MJOA associations with PROMIS-PF change from baseline (T3) to follow-up (T4)

		Overall	Women	Men	White	Black
MJOA definition (at least one sx joint)	*N*	*β (95% CI)*	*β (95% CI)*	*β (95% CI)*	*β (95% CI)*	*β (95% CI)*
1. ≥1 IP node and ≥2 other sites (hip, knee, spine, ankle, or foot)	582	-0.8 (-1.8, 0.2)	-0.6 (-1.8, 0.6)	-1.3 (-3.1, 0.5)	-1.2 (-2.4, 0.1)	-0.1 (-1.7, 1.6)

*Multivariable regression modeling difference in PROMIS-PF from baseline (T3) to follow-up (T4) adjusting for baseline: cohort, age, sex, race, education, BMI, Charlson Comorbidity Index, PROMIS-PF score, and follow-up time; An interaction term was used to provide adjusted β by sex or race, respectively; *=interaction significant at p-value<0.1; **BOLD**=statistically significant.*

Physical Function Scale, Short Form 10a version 1.0 (PROMIS-PF, PMID 21914216). Data were from participants in the Johnston County OA Project (JoCoOA) who completed the baseline (T3; 2013-15) and follow-up (T4; 2017-18) visits and had data for both baseline sxMJOA and PROMIS-PF scores at baseline and follow-up.

Multivariable linear regression models were performed to assess the association of sxMJOA definitions with PROMIS-PF change from baseline to follow-up, adjusting for baseline: cohort, age, sex, race, education, body mass index (BMI), Charlson Comorbidity Index, PROMIS-PF score, and follow-up time. β and 95% confidence intervals for sx-MJOA are reported, with negative values representing greater reduction in PF in those with sxMJOA. An interaction term was included in the model to provide estimates by sex or race, respectively; as these stratified results were of particular interest, they are reported regardless of statistical significance of this term.

Results: Included individuals (n=586, 71% women, 36% Black) had a mean age of 70 ± 7 years and mean body mass index (BMI) of 32 ± 7 kg/m^2 at baseline. Depending on the definition, the prevalence of sxMJOA ranged from 1 to 51%. Overall PROMIS-PF scores declined (worsened) by about 1 point (mean -1.2 [SD 6.4]) over the 3.5 ± 1 year follow-up, with 53% of individuals experiencing a worsening in score.

Statistically significant decreases in PROMIS-PF scores were seen overall for those with sxMJOA-2, -4, and -7 (Table). The effects of sxMJOA-1, -2, -4 and -5 were similar across sex and race. The largest effect on PROMIS-PF (4–5-point reduction) was from the relatively infrequent sxMJOA-7 (involvement of the bilateral knees and spine), an effect that was strongest in women and Blacks. Men with sxMJOA-8 had reductions in PF not seen in women or by race. sxMJOA-10 (interphalangeal hand OA) was associated with significantly poorer PF scores only in Black participants (3.5-point reduction, p< 0.1 for interaction). sxMJOA-3, -6, and -9 were not associated with PF changes, nor were sums of affected joint sites (data not shown).

Conclusion: Specific subtypes of sxMJOA in which at least one joint site is symptomatic are associated with varying decrements in self-reported physical function, beyond simple summing of affected numbers of joints. In some cases,

important differences by sex and race are observed. These findings suggest the importance of MJOA phenotypes, future work will include other physical function measures, both self-reported and performance-based, and longer follow-up times.

Abstract Number: 0223

The Association of Clinical and Structural Knee Osteoarthritis with Physical Activity in the Middle-aged Population: The Netherlands Epidemiology of Obesity Study

Sietse Terpstra[1], Jeroen van der Velde[1], Renée de Mutsert[1], Dieuwke Schiphof[2], Monique Reijnierse[1], Frits Rosendaal[1], Lotte van de Stadt[1], Margreet Kloppenburg[1] and Marieke Loef[1], [1]Leiden University Medical Center, Leiden, Netherlands, [2]Erasmus Medical Center, Rotterdam, Netherlands

SESSION INFORMATION
Session Date: Saturday, November 6, 2021
Session Title: Osteoarthritis – Clinical Poster I (0210–0224)
Session Type: Poster Session A
Session Time: 8:30AM–10:30AM

Background/Purpose: Physical activity is a potential target for interventions in knee OA. However, most of the available studies concerning physical activity in individuals with knee OA were performed in relatively old populations with an inactive lifestyle. It is unclear how previous results can be generalized to other populations with different lifestyle and physical activity habits.

Therefore, we investigated if knee OA is associated with lower physical activity in a general middle-aged Dutch population. Furthermore, we investigated the association of physical activity with patient reported outcomes such as knee pain and function, and health-related quality of life in individuals with knee OA.

Methods: We used cross-sectional data from the Netherlands Epidemiology of Obesity (NEO) study, in which participants aged 45-65 years were included. Clinical knee OA was defined using the criteria by Altman et al. Structural knee OA was defined on MRI using the modified criteria by Hunter et al. in a random subset of 1,285 individuals of our study population.

We assessed knee pain and function with the Knee injury and Osteoarthritis Score (KOOS), and health-related quality of life (HRQoL) with the Short Form (SF)-36. Physical activity (in Metabolic Equivalent of Task (MET) hours per week) was assessed using the Short Questionnaire to Assess Health-enhancing physical activity (SQUASH).

We used linear regression analyses to investigate 1) the association of knee OA with physical activity, and 2) of physical activity with knee pain, function, and HRQoL in participants with clinical knee OA. All analyses were adjusted for age, sex, body mass index (BMI), ethnicity, educational level and comorbidities. To account for possible information bias, we performed a sensitivity analysis to assess the association between clinical knee OA and physical activity measured by an accelerometer in a random subset of 15% of the study population.

Table 1. Characteristics of the NEO study population. Numbers represent mean (SD) or percentages. ^median (25th, 75th percentiles). Abbreviations: OA = osteoarthritis. BMI = Body Mass Index. MET = Metabolic Equivalent of Task.

	All	No clinical knee OA	Clinical knee OA
	n = 6,214	86%	14%
General population characteristics			
Age (year)	55.7 (6.0)	55.4 (6.1)	57.5 (5.0)
Sex (% women)	55	54	67
BMI (kg/m^2)	26.3 (4.4)	26.1 (4.3)	27.6 (5.1)
Comorbidities (% present)	24	23	32
Physical activity			
Total^ (MET-hours per week)	118.8 (76.8;155.0)	118.4 (76.6;154.4)	123.5 (77.8;157.2)

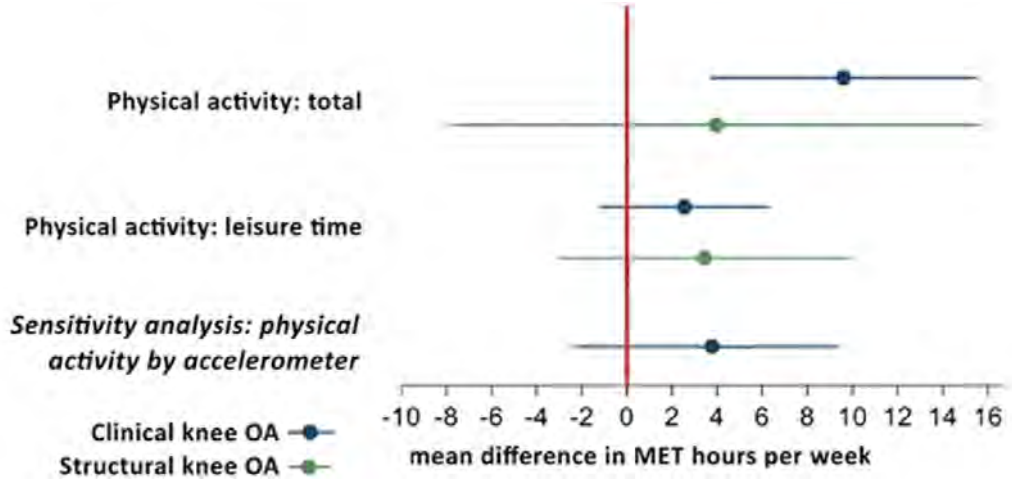

Figure 1. The association of clinical and structural knee osteoarthritis with physical activity adjusted for age, sex, body mass index, ethnicity, educational level and comorbidities. Reference: participants without knee osteoarthritis. MET = Metabolic Equivalent of Task.

Results: Of 6,212 participants, we observed clinical knee OA in 14%, and structural knee OA in 12%. The general population characteristics and median physical activity of our study population are presented in **table 1**. In comparison to participants without knee OA, participants with clinical knee OA had on average 9.60 (95% CI 3.70;15.50) MET hours per week more total physical activity (**figure 1**). Structural knee OA was associated with 3.97 (-7.82; 15.76) MET hours per week more physical activity, compared with no structural knee OA.

Sensitivity analysis showed a weak positive association of clinical knee OA with physical activity measured by an accelerometer: 2.37 (-6.05; 10.80) MET hours per week more physical activity was found in participants with clinical knee OA, compared with participants without clinical knee OA. In the subpopulation of participants with clinical knee OA, physical activity was not associated with knee pain, function or HRQoL.

Conclusion: Knee OA was not associated with lower physical activity in this middle-aged Dutch population. Future research should indicate the optimal treatment advice regarding physical activity for individual knee OA patients.

Session Title: Osteoarthritis – Clinical Poster I (0210–0224)
Session Type: Poster Session A
Session Time: 8:30AM–10:30AM

Background/Purpose: Only a small proportion of people with knee osteoarthritis (OA) meet the recommended guidelines for physical activity and it is still unclear why. Lacking regular participation in physical activity is a risk factor for functional limitations in people with knee OA. Psychological factors, such as kinesiophobia (fear of movement), have been linked to activity avoidance behaviors in this population. The purpose of our study was (i) to investigate the effects of selected physical function measures in explaining physical activity, and (ii) to determine whether kinesiophobia may contribute to activity level beyond what is explained by physical function measures.

Methods: Thirty participants (16F | 14M; age, 40-75 y) with doctor diagnosed uni- or bilateral knee OA consented to participate in this cross-sectional study. Physical activity was assessed by self-report using the UCLA activity rating scale (1-10, inactive to regular participation in impact sports). Physical function was assessed using the four square step test (FSST), 30-sec chair stand (CST), timed up and go (TUG), and 40-m fast paced walk (FPWT). These performance-based measures were selected because they assess different domains of physical performance and functional ability. The Tampa Scale for Kinesiophobia (TSK; scale 17-68, no fear to extreme fear of movement) was used to assess the degree of kinesiophobia. We used Spearman correlations and multiple regression analysis to examine the relationships between UCLA activity scores and the predictors. Separate regression models were calculated for each physical function measure, in which TSK score and the covariate sex were the other independent variables, and UCLA score was the dependent variable in all models. Alpha was set at $p < 0.05$ for all analyses. Prior to parametric analysis, data were transformed when necessary, using logarithmic transformations.

Results: Better performance on all physical function measures and lower TSK scores (less fear) were associated with higher self-reported activity levels (Table 1). Regression models significantly accounted for 66.4% to 78.7% of the variance in UCLA scores (Table 2). Better performance on all functional measures predicted higher UCLA scores after controlling for sex and TSK. Lower TSK score (less fear) was a significant predictor of higher UCLA scores in all models after accounting for physical function and sex. Physical function measures were the most important predictors

Table 1. Correlations between UCLA score and predictor variables

	TUG	FPWT	FSST	CST	TSK
Spearman's Rho	-.802*	.758*	-.676*	.663*	-.702*
Mean	9.9	1.4	12.3	9.7	40.2
SD	3.9	0.34	6.4	4.5	7.7

Note: TUG, timed up and go (sec); FPWT, 40-m fast paced walk test (m/sec); FSST, four square step test (sec); CST, 30-sec chair stand test (count); TSK, Tampa Scale for Kinesiophobia. *$p < .01$. Mean UCLA score = 5.13 ± 2.1.

Table 2. Regression parameters from each model predicting UCLA score[a]

	β	t	*p*	R^2	sr^2
Model 1					
Sex	.269	2.85	.008		.067
TUG[a]	-.634	-5.78	<.001	.787	.275
TSK	-.236	-2.09	.047		.036
Model 2					
Sex	.202	1.93	.065		.037
FPWT	.542	4.78	<.001	.740	.228
TSK	-.363	-3.17	.004		.100
Model 3					
Sex	.207	1.88	.071		.039
FSST[a]	-.505	-4.26	<.001	.713	.201
TSK	-.384	-3.21	.004		.114
Model 4					
Sex	.285	2.40	.024		.075
CST	.457	3.42	.002	.664	.151
TSK	-.349	-2.52	.018		.082

Note. [a]Log transformed. β = standardized beta coefficient. sr^2 = the squared semi-partial correlation indicates unique effect of each independent variable. Sex, male = 1. TUG, timed up and go. FPWT, 40-m fast paced walk test. FSST, four square step test. CST, 30-sec chair stand test. TSK, Tampa Scale for Kinesiophobia. All models statistically significant ($p < .001$).

of UCLA scores in each model, uniquely explaining 15.1% to 27.5% of the variation in UCLA scores. However, TSK score uniquely explained 3.6% to 11.4% of the variation seen in UCLA scores.

Conclusion: Physical function measures were associated with UCLA scores, however kinesiophobia also contributed to explaining physical activity level even after accounting for physical function and sex. Assessing both kinesiophobia and physical function could help clinicians better identify knee OA patients that may be prone to avoiding certain activities or exercises.

Prevalence of Sexual Dysfunction and Depression in German Patients with Psoriasis and Psoriatic Arthritis – Results of the PIPPA Study

Sebastian Saur[1], Alexandra Schloegl[2], Caroline Höppner[3], Anastasia Gubar[2], Katharina Meier[4], Matthias Hahn[2] and Jorg Henes[2], [1]Universtiy Hostpiatl Tübingen, Tuebingen, Germany, [2]University Hospital Tuebingen, Tuebingen, Germany, [3]Charite Berlin, Berlin, Germany, [4]Department of Dermatology, Venereology and Allergology – Universitätsmedizin Berlin, corporate member of Freie Universität Berlin and Humboldt-Universität zu Berlin, Berlin, Germany, Berlin, Germany

SESSION INFORMATION

Session Date: Saturday, November 6, 2021

Session Title: Patient Outcomes, Preferences, & Attitudes Poster I: Impact (0225–0240)

Session Type: Poster Session A

Session Time: 8:30AM–10:30AM

Background/Purpose: As known chronic inflammatory diseases have an impact on sexuality. To date, there are only a few studies from North and Latin America which investigated the influence of inflammatory diseases on sexual life

and practically none on patients with psoriasis (Pso) and psoriatic arthritis (PsA) (1-3). Reliable data on the prevalence of sexual dysfunction, quality of life and depression in this population compared to the general population are lacking.

Methods: Patients with psoriasis and psoriatic arthritis in two German tertiary university hospitals were evaluated with a self-designed questionnaire on various sexual and disease specific aspects, a 19-item version of the validated Female Sexual Function Index (FSFI), 15-item version of International Index of Erectile Function (IIEF), Dermatology Life Quality Index (DLQI), the 9-item questionnaire Qualisex, and the Beck's depression inventory (BDI) in a prospective study. The study was approved by our ethics committee and all patients gave written informed consent.

This work was supported by an unrestricted grant by Novartis.

Results: 416 patients were included into the study. Among them 219 suffered from Pso, 94 being females (mean age 45 years) and 125 males (mean age 43 years), as well as 197 PsA patients, 80 being females (mean age 47.5 years) and 117 males (mean age 45 years). The Healthy Control Group (HCG) is composed of 87 women with a median age of 34 years (ranging from 18-64) and 119 men with a median age of 52 years (ranging from 20-69).

The prevalence of sexual dysfunction (SDF) was similarly high in patients with Pso and PsA (82.6 vs. 75.6%) and significantly lower in the HCG (44.8%, p= < 0.0001). Erectile Dysfunction did only differ significantly in younger patients (18-35 years) with moderate-severe manifestation and Pso or PsA (11.8 vs. 9.4%) and no affected men in the HCG (0%, p=0.05).

The prevalence of depression in this cohort was highest in female patients with psoriatic arthritis, with no significant increase compared to female patients with psoriasis (50.1 vs. 34.0%). In comparison, only 3.5% of the women in the healthy control group had depression, which was a highly significant difference (p=0.0001). A similar picture was seen in the male patients with Pso and PsA, with a lower prevalence of depression, especially the severe forms, compared to the female patients (23.2 vs. 29.9%). Here, too, there was a highly significant difference compared to the male control group with a prevalence of 8.5% (p=0.0001).

Conclusion: In this work, for the first time Pso and PsA were studied separately and together with regard to their influence on sexuality and possible depression in men and women and compared with a healthy control group. Our work shows the impact of chronic diseases, such as Pso and PsA, on the sexuality and mood of our patients in a large collective. In patients who suffer from additional articular disease in combination with skin disease, the proportion of erectile dysfunction and depression is particularly high. Physicians should pay more attention to these common comorbidities and consciously address during the medical consultations.

High Efficacy, Safety, and Tolerability of Secukinumab Injection with 2 mL Auto-injector (300 Mg) in Adult Patients with Moderate to Severe Plaque Psoriasis: 52-week Results from MATURE, a Randomised, Placebo-controlled Trial

Bardur Sigurgeirsson[1], John Browning[2], Stephen Tyring[3], **Jacek Szepietowski**[4], Raquel Rivera-Díaz[5], Isaak Effendy[6], Deborah Keefe[7], Gerard Bruin[8], Bertrand Paguet[9], Rong Fu[10], Isabelle Hampele[9] and Maximilian Reinhardt[9], [1]University of Iceland, Reykjavík, Iceland, [2]Texas Dermatology and Laser Specialists, Texas, TX, [3]Center for Clinical Studies, Texas, [4]Department of Dermatology, Venereology and Allergology, Wroclaw Medical University, Wroclaw, Poland, [5]Hospital Universitario 12 de Octubre, Madrid, Spain, [6]Departrment of Dermatology and Allergology, University Hospital of Bielefeld, Bielefeld, Germany, [7]Novartis Pharmaceuticals Corporation, East Hanover, NJ, [8]Novartis Institutes for Biomedical Research, Basel, Switzerland, [9]Novartis Pharma AG, Basel, Switzerland, [10]Novartis Institutes of for Biomedical Research, Shanghai, China (People's Republic)

SESSION INFORMATION

Session Date: Saturday, November 6, 2021

Session Title: Patient Outcomes, Preferences, & Attitudes Poster I: Impact (0225–0240)

Session Type: Poster Session A

Session Time: 8:30AM–10:30AM

Background/Purpose: The MATURE study investigated administration of 300 mg secukinumab (SEC) using a 2 mL autoinjector (AI) device. The objective of this study was to assess efficacy, safety, tolerability, and pharmacokinetics (PK) of the 2 mL AI for SEC 300 mg in patients with moderate to severe plaque psoriasis (PsO).

Methods: MATURE was a multicentre, randomised, double-blind, placebo (PBO)-controlled, parallel-group Phase III trial (NCT03589885) conducted at 22 sites worldwide. The study consisted of 3 periods: screening (screening to baseline [BL]), treatment period 1 (BL to Week 12; pre-dose), and treatment period 2 (Week 12 dose to Week 52). Eligible patients were randomised to receive SEC 300 mg in a 2 mL AI or 2x 1 mL pre-filled syringe (PFS) or PBO. The

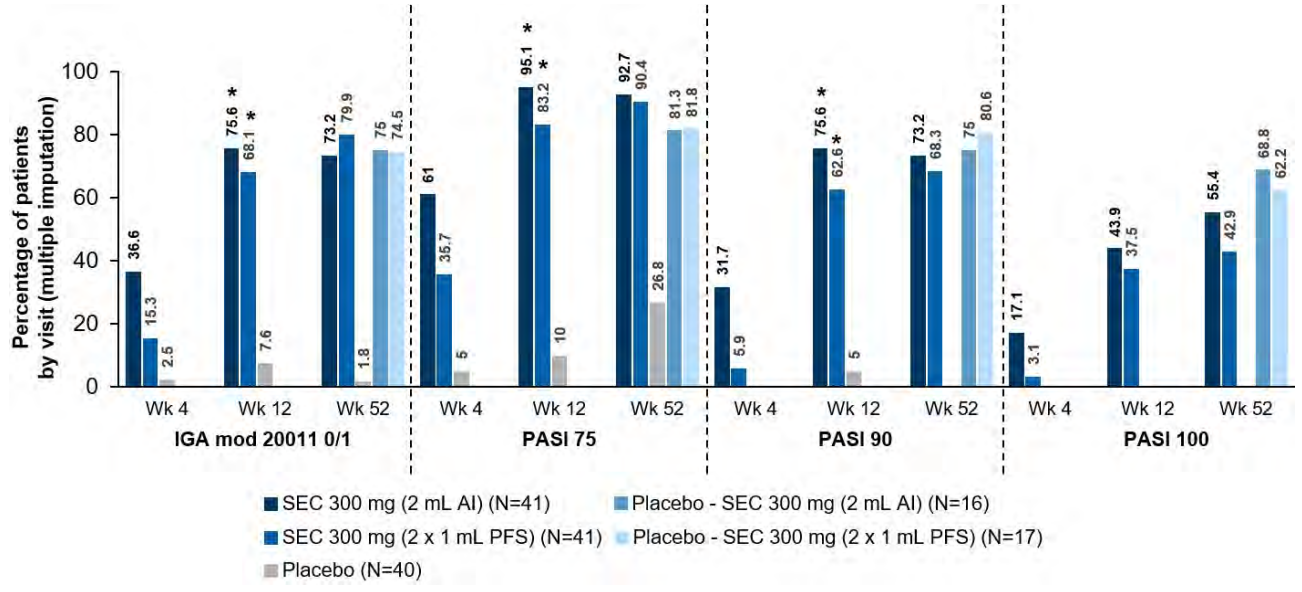

Figure 1. Clinical response rates over time for IGA mod 2011 0/1; PASI 75; PASI 90 and PASI 100. *P<0.0001 vs. placebo at Week 12. AI, autoinjector; IGA mod 2011, investigator's global assessment 2011 modified version; N, number of patients; PASI, Psoriasis Area and Severity Index; PFS, pre-filled syringe.

co-primary endpoints were Psoriasis Area and Severity Index (PASI) 75 and Investigator's Global Assessment (IGA) modified 2011 0/1 responses at Week 12. The key secondary endpoint was PASI 90 response at Week 12. Other secondary endpoints were PK assessments, PASI 75/90/100 responses, DLQI score of 0/1, usability of 2 mL AI (rated through a Self-Injection Assessment Questionnaire [SIAQ]), and safety over a period of 52 weeks.

Results: In total, 122 patients were randomised as follows: SEC 300 mg 2 mL AI (N=41), SEC 300 mg 2x 1 mL PFS (N=41), or PBO (N=40). The study met both co-primary and key secondary endpoints ($p< 0.0001$). At Week 12, SEC 300 mg 2 mL AI and 2x 1 mL PFS showed superior PASI 75 response rates (95.1% and 83.2%, respectively), and IGA mod 2011 0/1 response rates (75.6% and 68.1%, respectively), compared with PBO (10.0% for PASI 75; 7.6% for IGA mod 2011 0/1) (Fig. 1). At Week 12, the PASI 90 response was significantly higher with both SEC groups (2 mL AI [75.6%] and 2x 1 mL PFS [62.6%]) than with PBO (5.0%; $p< 0.0001$ for both) (Fig. 1). Both SEC treatment groups (2 mL AI and 2x 1 mL PFS) showed a similar trend of efficacy to Week 52 (Fig. 1). Similarly, higher DLQI 0/1 response rates were observed in both SEC groups (2 mL AI [71.1%] and 2x 1 mL PFS [72.5%] at Week 12) compared with PBO (8.1%); the trend of high DLQI 0/1 response was sustained up to Week 52 in both SEC groups. The higher mean SEC concentration observed with the 2 ml AI, may explain the slightly faster and numerically higher PASI 90 response. This difference did not affect the incidence of adverse events in either group. SIAQ results showed high usability of self-injection with the 2 mL AI device. In the secukinumab 300 mg (2 mL AI) group, the proportion of "very satisfied" and "satisfied" patients increased substantially from 31.6% before the injection (pre-SIAQ at baseline) to 78.3% (post-SIAQ at baseline) after the first injection and remained above 85% at later visits, reaching 100% at Week 28. Throughout the entire treatment period, only two patients (1.7%) reported one "injection-site reaction" each; both events were attributed to the AI administration (one of them with active drug, the other one with placebo). No new safety signals were observed with the use of the AI over the 52-week period.

Conclusion: SEC 300 mg administered with the 2 mL AI demonstrated superior efficacy over PBO, good tolerability, and convenience of administration in patients with moderate to severe plaque PsO.

Abstract Number: 0227

Work Participation Is Impaired Months Before Clinical Arthritis Is Apparent

Cleo Rogier[1], Pascal de Jong[2], Annette H.M van der Helm-van Mil[3] and Elise van Mulligen[4], [1]Erasmus MC, Rotterdam, [2]Erasmus MC, Hendrik Ido Ambacht, Netherlands, [3]Leiden University Medical Center, Leiden, Netherlands, [4]Erasmus Medical Center, Rotterdam, Netherlands

SESSION INFORMATION
Session Date: Saturday, November 6, 2021
Session Title: Patient Outcomes, Preferences, & Attitudes Poster I: Impact (0225–0240)
Session Type: Poster Session A
Session Time: 8:30AM–10:30AM

Background/Purpose: Work participation is still a major issue for patients with rheumatoid arthritis (RA) despite improved management and outcomes. Work loss can be divided into presenteeism (i.e. impaired productivity while at work) and absenteeism (i.e. absence due to illness). Both constitute limitations for the patient as well as an economic burden for society. It is known that in the phase preceding clinical arthritis patients already experience pain and functional limitations. We therefore aimed to investigate how work participation is affected in patients with arthralgia in the 'pre-RA phase' during transition to RA or symptom resolution, and to compare this to the course of the work participation in early RA-patients.

Methods: Three groups of patients were studied; 143 arthralgia-patients converting to clinical arthritis within two years (the Leiden CSA cohort, the SONAR cohort), 617 early RA-patients during 4 years of follow-up (the Leiden EAC) and 57 arthralgia-patients not converting to clinical arthritis with spontaneous resolution of symptoms (Leiden CSA cohort). WPAI and IPCQ were used to measure work-related outcomes. Both presenteeism (impaired productivity at work; scale 0-10 where 0=complete impairment and 10=no impairment) and absenteeism (sick leave and decrease in working hours) were taken into account. Linear Mixed Models and Mixed effect logistic regression models were used to investigate whether the work-related outcomes changed over time. Outcomes were also stratified for ACPA status.

Results: A total of n=103 (72%), n=291 (47%) and n=50 (88%) had paid work at baseline (i.e. the working population). One year prior to the development of clinical arthritis, productivity decreased with 36% (95% CI 24% to 48%), following a downward trend towards the level of RA-patients at diagnosis which was decreased with 50% (95% CI 47% to 53%). Sick leave was reported by 28% (95% CI 20% to 36%) one year prior to the development of clinical arthritis and followed an upward trend towards the level of RA-patients at diagnosis (36% 95% CI 30% to 41%) (Figure1). After treatment start in RA, productivity improved ($p< 0.0001$), and sick leave decreased significantly ($p< 0.0001$. Despite an improvement in productivity and sick leave, working hours significantly decreased over time after being diagnosed with RA($p< 0.0001$). Within the arthralgia-patients with spontaneous symptom relief (n=50), a significant improvement in productivity was observed over time ($p=0.0016$). Stratifying for ACPA showed no difference in work-related outcomes.

Conclusion: Before clinical arthritis is apparent, the productivity level of arthralgia-patients is decreased towards a similarly reduced productivity level in early RA-patients. This underlines the importance of recognizing patients in the pre-arthritis phase, as intervention in this phase could potentially prevent loss in work participation.

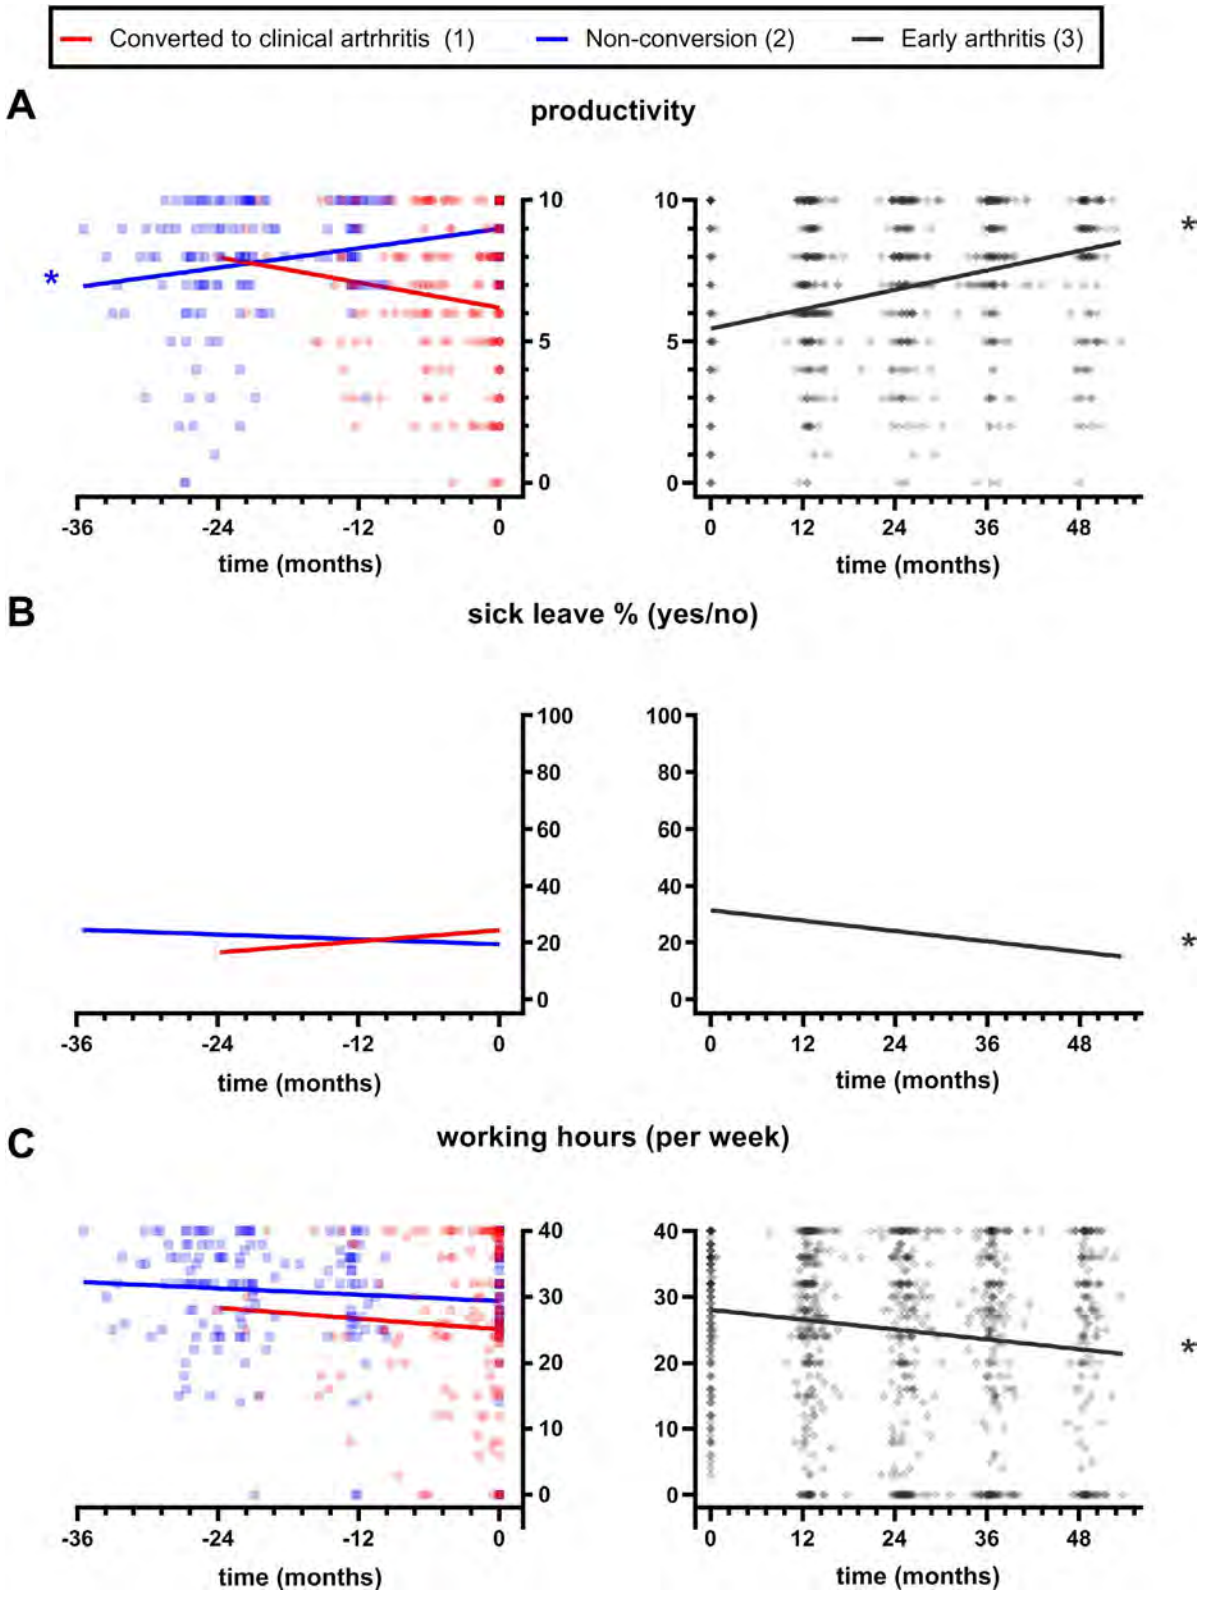

Figure 1. The course of presenteeism and absenteeism over time in; (1) arthralgia-patients converting to clinical arthritis (2) non-converting arthralgia-patients with spontaneous symptom relief and (3) RA-patients. Legend: (1) arthralgia-patients converting to clinical arthritis; 0 at x-axis marks the moment arthritis is diagnosed (2) non-converting arthralgia-patients with spontaneous symptom relief; 0 at x-axis marks the moment patients were symptom free (3) RA-patients; 0 at x-axis marks the moment of diagnosis. Productivity where 0=minimal workplace productivity, 10=maximal workplace productivity. *marks a significant change over time.

Optimizing Social Media as a Recruitment Tool for Hard-to-Reach Populations in Rheumatology Clinical Research

Vladislav Tsaltskan[1], Katherine Nguyen[1], Christina Eaglin[1], Kevin Deane[2], V. Michael Holers[3] and Gary Firestein[1], [1]University of California San Diego, San Diego, CA, [2]University of Colorado Denver, Denver, CO, [3]University of Colorado, Denver, CO

SESSION INFORMATION
Session Date: Saturday, November 6, 2021
Session Title: Patient Outcomes, Preferences, & Attitudes Poster I: Impact (0225–0240)
Session Type: Poster Session A
Session Time: 8:30AM–10:30AM

Background/Purpose: Standard methods of recruitment for clinical research, such as traditional media advertisements, can be inefficient and expensive, especially for underserved communities and asymptomatic individuals. To address this need, we explored the use of online recruitment tools that might improve access to these populations. We evaluated the effectiveness of two online approaches to recruit subjects for an observational study of asymptomatic individuals at risk for developing rheumatoid arthritis (RA): 1) Web-based methods; and 2) Facebook-based advertisements. This strategy focused on asymptomatic first-degree relatives of individuals with RA who self-identify for an observational longitudinal study on transitions to clinical RA.

Methods: A county-wide web-based recruitment campaign was conducted from October through December 2020 consisting of image and text-based ads displayed on various websites and mobile applications. The goal was to identify individuals to participate in screening visit for a study evaluating the evolution of RA with the inclusion of individuals who were CCP3 >2x ULN and no inflammatory arthritis. Ads were targeted to potential subjects using a combination of geofencing (eg, visits to medical centers or rheumatologists), keyword retargeting (eg, “rheumatoid arthritis”), and website remarketing techniques. A Facebook-based recruitment campaign was then conducted from February through April 2021. Facebook users were targeted based on demographics, group membership, and user association. An individual that clicked on an ad was directed to a website containing information about the study, where they could fill out a contact form to provide their information to study staff. Both advertising campaigns were administered by a third-party vendor.

Results: A total of 413,289 ads were displayed during the web campaign and 392,408 ads were displayed during the Facebook campaign. Throughout the duration of the web campaign, there were 428 individual clicks on an ad (0.10% of ads). Only one person contacted the study staff and was screened but did not enroll. Throughout the duration of the Facebook campaign, there were 3649 individual clicks on an ad (0.93% of ads) and 43 people contacted the study staff for screening ($p< 0.0001$ for web-based vs Facebook for clicks). 34 individuals were successfully screened and two were enrolled, with mean age of 52.3±11.3 yrs. In terms of characteristics, 94% of screened individuals were female and 24% were Hispanic. The cost per click for the web campaign was $2.80 and for the Facebook campaign it was $0.71, which corresponded to a cost per self-identifying subject of $1600 for the Web campaign and $60 for the Facebook campaign.

Conclusion: The Facebook recruitment campaign resulted in more screened subjects and was more cost-effective than the web recruitment campaign. A preponderance of women responded to the campaign, and there was excellent representation among the Hispanic population. Facebook ad targeting improved access to individuals who were

closely linked to rheumatoid arthritis patients in their social network and more likely to respond to the ad. The data suggest that social media campaigns can improve outreach to hard-to-reach populations.

The Effects of Self-efficacy on Fatigue and Pain Interference in Black Women with Systemic Lupus Erythematosus: The Role of Depression, Age, and Education

Cristina Drenkard[1], Kirk Easley[1], Gaobin Bao[1], Charmayne Dunlop-Thomas[1], Teresa Brady[2] and S Sam Lim[3], [1]Emory University, Atlanta, GA, [2]Clarity Consulting and Communications, Atlanta, GA, [3]Department of Medicine, Division of Rheumatology, Emory University School of Medicine, Atlanta, GA

SESSION INFORMATION
Session Date: Saturday, November 6, 2021
Session Title: Patient Outcomes, Preferences, & Attitudes Poster I: Impact (0225–0240)
Session Type: Poster Session A
Session Time: 8:30AM–10:30AM

Background/Purpose: Fatigue and pain are pervasive symptoms that cause escalating distress in patients with SLE, particularly among Black women and other high-risk groups. While these are reportedly amongst the most challenging symptoms to self-manage by SLE patients, self-efficacy can mitigate their negative impact on daily activities. However, older and depressed patients and those with low education may have low self-efficacy. We examined whether self-efficacy affects fatigue and pain interference in Black women with SLE, and whether depression, age, and education alter those relationships.

Methods: Transversal analysis of Black women with a validated diagnosis of SLE, who were enrolled in a population-based cohort called the Georgians Organized Against Lupus (GOAL). PROMIS short forms were used to measure Fatigue, Pain interference, Self-efficacy to manage symptoms (SEMS), Self-efficacy to manage medications and treatment (SEMMT), and Depression. Linear regression analyses were performed to examine the relationship between each outcome (Fatigue and Pain interference) and self-efficacy (SEMS and SEMMT) and the interactions of age, education, and depression with self-efficacy, after adjusting for confounders.

Results: Of 699 participants, 143 (21%) were 18-34, 329 (47%) 35-54, and 227 (33%) ≥55 years old; 261 (37%) attained ≤high school, 226 (32%) some college, and 211 (30 %) ≥bachelor's degree. Table 1 shows an inverse association between Fatigue and SEMS, Fatigue and SEMMT, Pain interference and SEMS, Pain interference and

Table 1: Univariate Linear Regression of Fatigue and Pain interference on Self-efficacy Measures

Factor	Fatigue			Pain interference		
	Slope* (±SE)	P value	MSE	Slope* (±SE)	P value	MSE
SEMS (per 1 point ↑)	-0.556 ± 0.044	<0.001	97.4	-0.394 ± 0.042	<0.001	87.4
SEMMT (per 1 point ↑)	-0.282 ± 0.044	<0.001	113.4	-0.152 ± 0.041	<0.001	96.7

Abbreviations: SE=standard error; MSE=mean squared error; SEMS=self-efficacy to manage symptoms; SEMMT= self-efficacy to manage medications and treatment; *Indicates b regression coefficient.

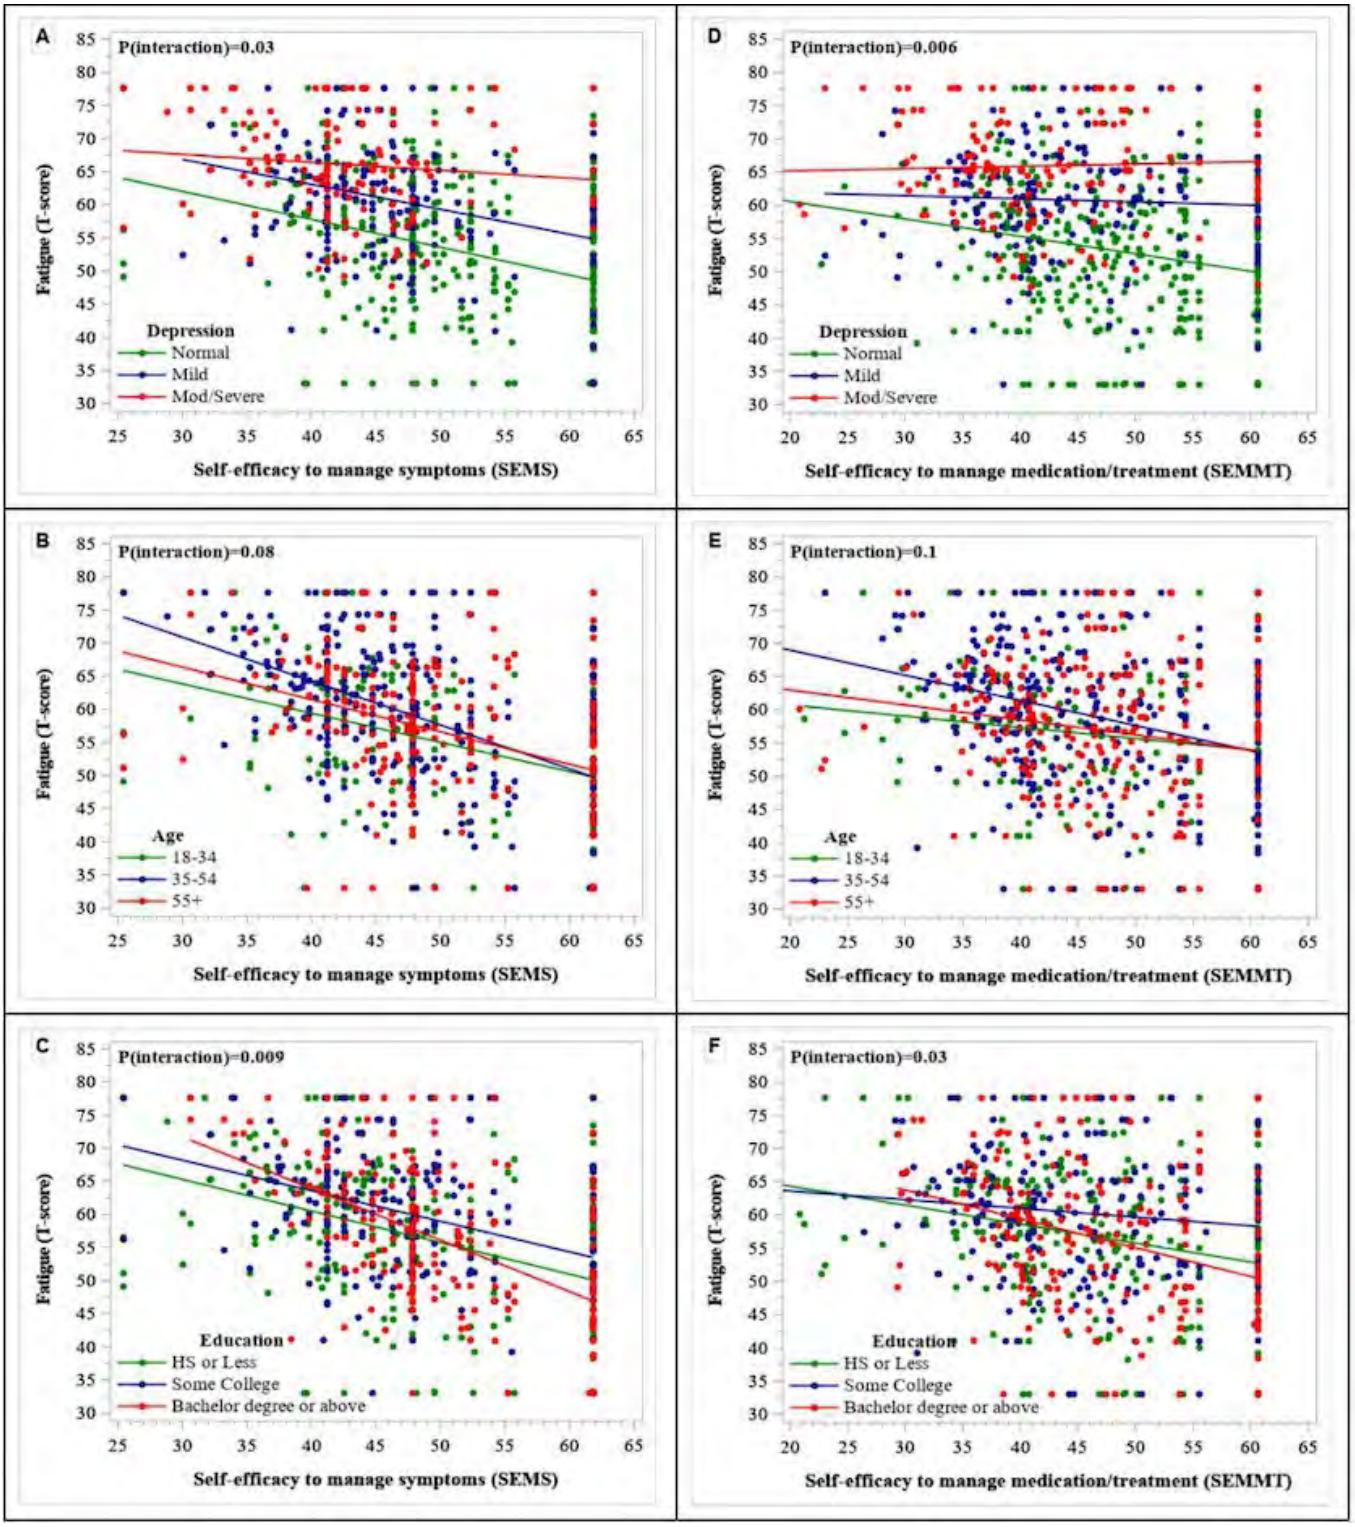

Figure 1. Regression of Fatigue on Self-efficacy to manage symptoms (SEMS) and Self-efficacy to manage medications and treatments (SEMMT) by Depression, Age, and Educational Attainment Categories.

SEMMT. Figure 1 depicts significant interactions between SEMS*Depression (p=0.03), SEMMT*Depression (p=0.006), SEMS*Education (p=0.03) and SEMMT*Education (p=0.009) on Fatigue. Figure 2 shows significant interactions between SEMMT*Depression (p=0.03), SEMS*Age (p=0.03), and SEMS*Education (p=0.0009) on Pain Interference. After adjusting for confounders, SEMS*Depression (p=0.04) and SEMMT*Depression (p=0.009) remained signifi-

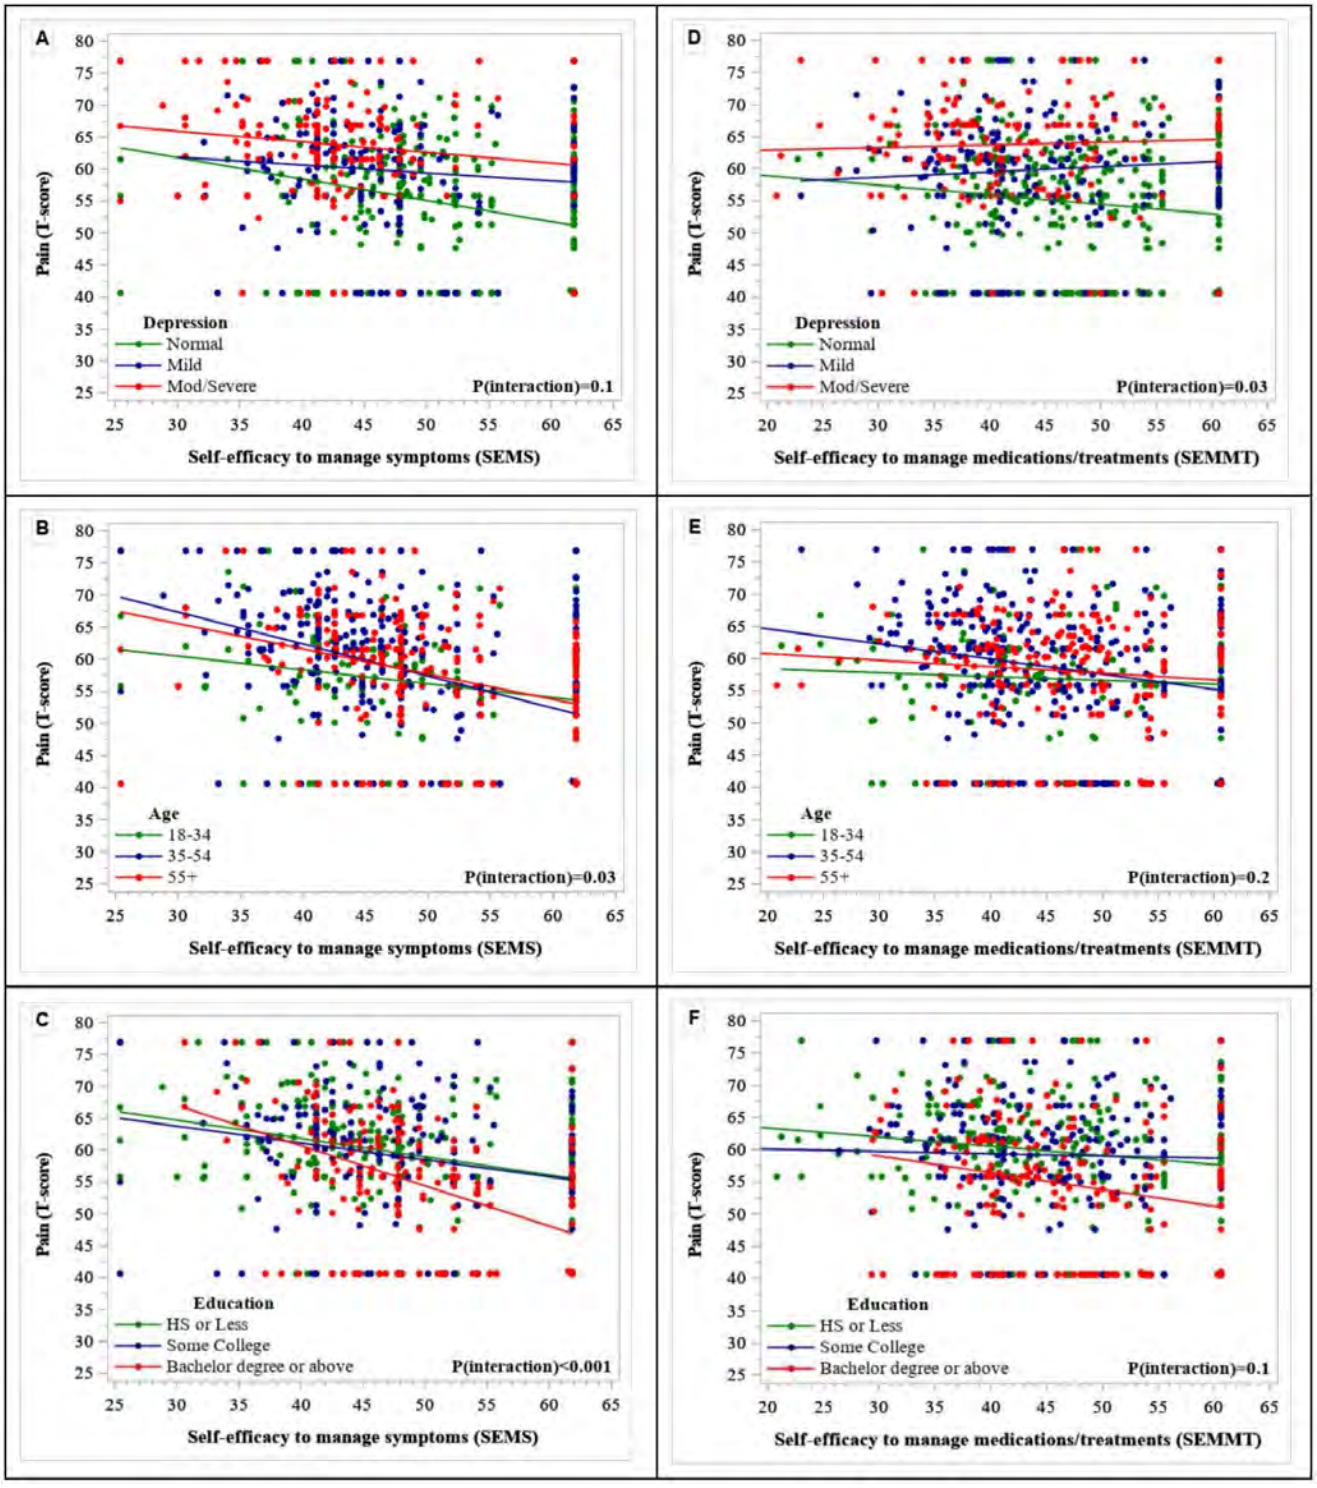

Figure 2. Regression of Pain interference on Self-efficacy to manage symptoms (SEMS) and Self-efficacy to manage medications and treatments (SEMMT) by Depression, Age, and Educational Attainment Categories.

cantly associated with Fatigue, and SEMS*Depression with Pain Interference (p=0.05), with greater adjusted means of each outcome in those with higher depression. SEMS*Education remained significantly associated with Fatigue (p=0.05) and with Pain interference (p=0.04), with lower adjusted means in those with higher education. SEMS*Age was associated with Pain interference (p=0.02), with higher adjusted means of each outcome in older women.

Conclusion: Self-efficacy (to manage symptoms and to manage medications and treatment) were inversely related to both fatigue and pain interference. Depression, age, and education altered those relationships in different ways. These finding may help predict who might benefit most from to efficacy-enhancing interventions.

Abstract Number: 0230

Fatigue and Inflammation in Rheumatoid Arthritis Are Already Disconnected Before Clinical Arthritis Develops

Sarah J.H. Khidir[1], Annette H.M van der Helm-van Mil[1] and Elise van Mulligen[2], [1]Leiden University Medical Center, Leiden, Netherlands, [2]Erasmus Medical Center, Rotterdam, Netherlands

SESSION INFORMATION

Session Date: Saturday, November 6, 2021
Session Title: Patient Outcomes, Preferences, & Attitudes Poster I: Impact (0225–0240)
Session Type: Poster Session A
Session Time: 8:30AM–10:30AM

Background/Purpose: Fatigue is disabling and common in Rheumatoid Arthritis (RA); the causation of fatigue in RA is multidimensional and only partially explained by inflammation. The question arises how fatigue develops in the preclinical phases of RA, and how inflammation is related to fatigue in the pre-arthritis phase. We hypothesized that inflammation explains fatigue to a greater extent at the beginning of developing RA, when processes are not yet chronified. Our aims are therefore (1) to describe the course of fatigue in patients with clinically suspect arthralgia (CSA) towards progression to RA, and (2) to assess the correlation between fatigue and inflammation in CSA patients and compare this to RA at the time of diagnosis.

Methods: 595 CSA patients were included between April 2012 and May 2020 in the Leiden CSA cohort and were followed for the development of RA. Additionally, baseline data of 710 consecutive early RA patients who were included in the Leiden Early Arthritis Cohort between August 2010 and March 2020, were studied. Inflammation was defined by MRI detected inflammation on contrast-enhanced 1.5T-MRI of hand and forefoot (scored according to the RAMRIS-method) and by C reactive protein (CRP) levels, representing local and systemic inflammation, respectively. Fatigue severity was measured on a numerical rating scale (NRS) from 0 (no fatigue) to 10 (extreme fatigue). A linear mixed model was used to analyze whether fatigue increased over time towards the development of RA. Correlations between fatigue and inflammation were studied using Spearman's rank correlation coefficient.

Results: At first presentation, baseline fatigue (mean (SD)) was 4.5 (3) for patients who developed RA. Over time, fatigue severity increased gradually towards 4.7 ± 3.0 at the time of RA development; (β= -0.08 per month away from arthritis development, p=0.07, Figure 1). Assessing the correlation of fatigue with inflammation at CSA onset in patients who later on developed RA, revealed weak correlations with MRI-detected inflammation (*ρ=-0.147,* p=0.25) and with CRP-levels (*ρ=0.165,* p=0.17). For comparison at RA diagnosis, correlations between fatigue severity and

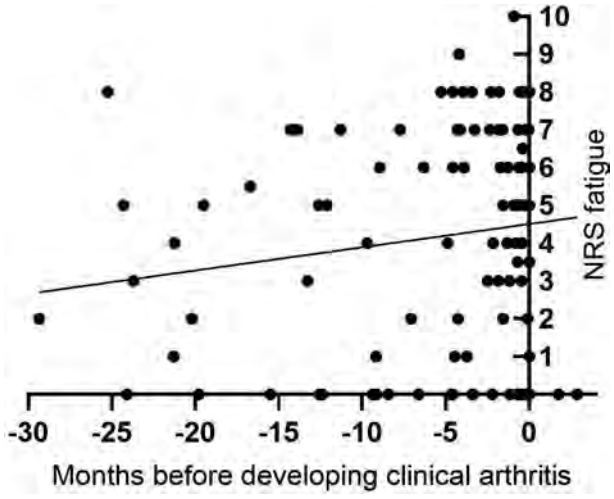

Figure 1. Fatigue in the months preceding development of Rheumatoid Arthritis.

inflammation were *ρ=-0.074*, p=0.09 for MRI-detected inflammation and ρ=*0.023*, p=0.34 for CRP-levels. Hence, although the correlation coefficients were slightly higher at CSA onset than at RA development, the correlations of fatigue with inflammation were weak at both disease phases.

Conclusion: Fatigue increased gradually during progression from arthralgia to RA. The correlation between fatigue with inflammatory measures in pre-RA patients were slightly higher than in early RA patients, but were still weak. This suggests that fatigue symptoms are largely disentangled from inflammation, even in the pre-arthritis phase of RA.

Reducing the Number of Outpatient Clinic Visits by Using the Routine Assessment of Patient Index Data 3 as a Screening Tool

Jimmy Wiegel[1], Bart Seppen[1], Marieke ter wee[2], Maarten Boers[3], Michael Nurmohamed[4] and wouter Bos[5], [1]Reade, Amsterdam, Netherlands, [2]Amsterdam UMC, location VUmc, Amsterdam, Netherlands, [3]Amsterdam UMC, Vrije Universiteit, Amsterdam, Netherlands, [4]Reade and Amsterdam University Medical Center, location VUmc, Amsterdam, Netherlands, [5]Reade Amsterdam, Amsterdam, Netherlands

SESSION INFORMATION
Session Date: Saturday, November 6, 2021
Session Title: Patient Outcomes, Preferences, & Attitudes Poster I: Impact (0225–0240)
Session Type: Poster Session A
Session Time: 8:30AM–10:30AM

Background/Purpose: The long-term and frequent evaluation of disease activity in patients with rheumatoid arthritis (RA) leads to a large burden of planned consultations at outpatient clinics. It might be possible to reduce that burden by prescreening for patients in remission or low disease activity with the electronic Routine Assessment of Patient Index Data 3 (RAPID3). For this purpose, accurate classification of patients in the low or remission category with the RAPID3 is a necessity. The objective is to evaluate the test characteristics and agreement in the low disease activity categories between the Disease Activity Score 28 (DAS28) and the RAPID3 in patients with RA.

Total measurements	4921
Total patients	1630
Female (%)	1234 (76)
Age, mean (SD)	60 (5)
Disease duration, median (IQR)	4,0 (0-7)
Type of RA (%)	
Seropositive	320 (19,6)
Seronegative	132 (8,1)
Unspecified	1178 (72,3)
DAS28, median (IQR)	2,62 (1,78-3,61)
DAS28 per category. (%)	
Remission	2429 (49,4)
Low	819 (16,6)
Medium	1336 (27,1)
High	337 (6,8)
RAPID3, median (IQR)	3,8 (1,8-5,6)
RAPID per category (%)	
Remission	719 (14,6)
Low	669 (13,6)
Medium	1261 (25,6)
High	2272 (46,2)
CRP, median (IQR)	2,5 (0,9-8,0)
BSE, median (IQR)	9 (5,0-24,0)

Table 1: baseline characteristics

Baseline characteristics.

		DAS28		Total
		Low (<3.2)	High (≥3.2)	
RAPID3	Low (≤2.0)	1275 (92,4%)	105 (7,6%)	1380 (28,0%)
	High (>2.0)	1973 (55,7%)	1568 (44,3%)	3533 (72,0%)
Total		3248 (66,0%)	1673 (34,0%)	4921 (100%)
Percentage agreement: 57,8%. Kappa: 0,26				

Table 3: agreement and Cohen's kappa between DAS28 and RAPID3

Agreement and Cohen's kappa between DAS28 and RAPID3.

Methods: We performed a retrospective database study with available clinical data collected as part of usual care from the electronic medical record at Reade Amsterdam. The dataset comprised each completed RAPID3 between June 2014 and March 2021, followed by a DAS28 within 2 weeks in patients with RA. The disease activity categories for both the RAPID3 and DAS28 were dichotomized in low (remission and low disease activity) and high (moderate and high disease activity). Cutoff values were 2.0 for RAPID3 and 3.2 for DAS28. Test characteristics and agreement (Cohen's kappa) were calculated.

Results: A total of 4921 combined RAPID3 and DAS28 measurements were done at Reade in 1630 unique RA patients. The mean age was 60 years and 76% were female with a median disease duration of 4 years. The agreement was considered fair (k=0,260). In total, 1630 (28%) of the RAPID3 measurements were classified as low. The sensitivity to detect low disease activity was 0.39, specificity was 0.94 and the positive predicted value was 0.92.

Conclusion: We showed that when the RAPID3 classifies a patient into the remission or low disease activity state, it is for 92% accurate. Of all consultations, 28% could possibly be postponed following screening with RAPID3. We propose a system where the RAPID3 is one of a few conditions that need to be met before consultations are postponed. Other conditions could include patient-, and physician approval and within-range lab results. Future research needs to focus on the feasibility of this system and finding the proper conditions for it to safely and effectively reduce the number of consultations.

The Impact of Deucravacitinib on Health-Related Quality of Life Measured by the Short Form Health Survey 36-Item Questionnaire: Analysis of a Phase 2 Trial in Patients with Active PsA

Vibeke Strand[1], Philip Mease[2], Atul Deodhar[3], June Ye[4], Miroslawa Nowak[4], Jiyoon Choi[4] and Brandon Becker[4], [1]Stanford University School of Medicine, Portola Valley, CA, [2]Swedish Medical Center/Providence St. Joseph Health and University of Washington, Seattle, WA, [3]Oregon Health & Science University, Portland, OR, [4]Bristol Myers Squibb, Princeton, NJ

SESSION INFORMATION
Session Date: Saturday, November 6, 2021
Session Title: Patient Outcomes, Preferences, & Attitudes Poster I: Impact (0225–0240)
Session Type: Poster Session A
Session Time: 8:30AM–10:30AM

Background/Purpose: Patients (pts) with PsA experience pain, loss of physical function, joint damage, and significant impairments in social and emotional well-being. The Short Form Health Survey 36-item questionnaire (SF-36v2), a generic measure of pt-reported health-related quality of life (HRQOL), includes 36 items and measures 8 domains—physical functioning (PF), role-physical (RP), bodily pain (BP), general health (GH), vitality (VT), social functioning (SF), role-emotional (RE), and mental health (MH)—that contribute to both physical component summary (PCS) and mental component summary (MCS) scores. Deucravacitinib is a novel, oral selective inhibitor of tyrosine kinase 2 (TYK2), an intracellular kinase that mediates cytokine signaling pathways implicated in the pathogenesis of PsA. In a Phase 2 trial in pts with active PsA, the primary endpoint, ACR 20 response at Week (Wk) 16, was met and deucravacitinib was well tolerated versus placebo (PBO).[1] This analysis further evaluated the effect of deucravacitinib treatment on SF-36 scores.

Methods: This 1-year, randomized, double-blind, placebo-controlled, multicenter Phase 2 trial (NCT03881059) enrolled pts with a PsA diagnosis ≥6 months who fulfilled Classification Criteria for Psoriatic Arthritis at screening and had active joint disease (≥3 tender and ≥3 swollen joints), high-sensitivity CRP ≥3 mg/L, and ≥1 plaque psoriasis lesion (≥2 cm). Pts failed or were intolerant to ≥1 NSAID, conventional synthetic DMARD, and/or 1 TNF inhibitor (TNFi; ≤30%). Pts were randomized 1:1:1 to receive deucravacitinib 6 mg once daily (QD) or 12 mg QD, or PBO. Changes from baseline (BL) in SF-36 PCS and MCS scores at Wk 16 were prespecified key secondary and additional endpoints, respectively. Analyses evaluated the 8 SF-36 domain scores at Wk 16. The proportion of patients who reported improvements ≥2.5 and ≥5-points (the minimum clinically important difference [MCID]) in SF-36 summary and domain scores, respectively, were evaluated.

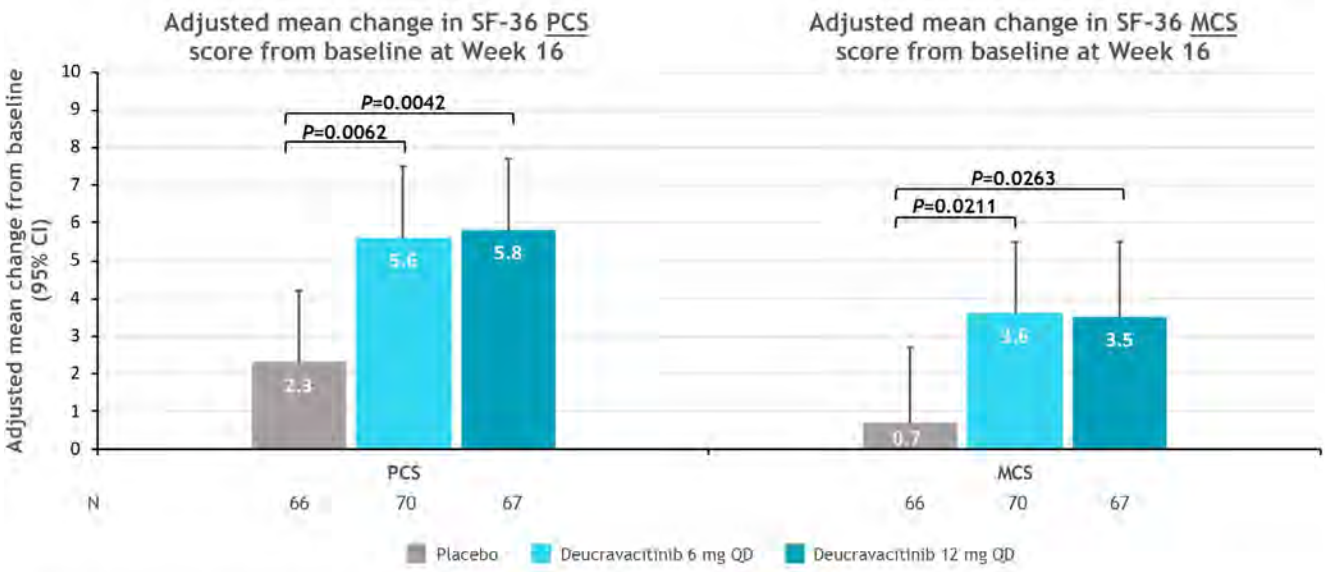
Table. Demographic and Baseline Disease Characteristics

	Placebo n=66	Deucravacitinib 6 mg QD n=70	Deucravacitinib 12 mg QD n=67
Age, years, mean	48.5	50.5	50.5
Gender, female, n (%)	40 (60.6)	30 (42.9)	34 (50.7)
Baseline BMI, kg/m^2, mean	31.2	29.6	30.3
Disease duration since diagnosis, years, median (range)	4.5 (0.6-22.9)	5.3 (0.1-42.8)	3.8 (0.6-27.7)
Tender joint count, mean (SD)	16.9 (9.79)	18.1 (10.33)	19.4 (11.84)
Swollen joint count, mean (SD)	10.5 (7.74)	11.9 (6.99)	11.3 (8.96)
HAQ-DI, mean (SD)	1.3 (0.56)	1.3 (0.59)	1.3 (0.59)
Patients with SPARCC enthesitis score ≥1 at baseline, n (%)	34 (51.5)	43 (61.4)	34 (50.7)
Psoriasis body surface area ≥3% at baseline, n (%)	54 (81.8)	59 (84.3)	52 (77.6)
PASI score at baseline in subjects with ≥3% BSA at baseline, mean (range)	9.09 (1.2-31.4)	8.47 (1.6-33.8)	7.92 (1.4-31.8)
SF-36 PCS score, mean (SD)	33.4 (7.5)	34.0 (8.0)	34.5 (7.0)
SF-36 MCS score, mean (SD)	47.5 (10.9)	45.4 (10.3)	46.9 (10.7)
Oral steroid use at baseline, n (%)	12 (18.2)	7 (10.0)	6 (9.0)
Mean daily dose, mg	4.40	3.71	3.54
Use of csDMARDs at baseline, n (%)	44 (66.7)	45 (64.3)	43 (64.2)
Use of MTX at baseline, n (%)	39 (59.1)	35 (50.0)	37 (55.2)
Mean weekly dose, mg	16.7	16.4	16.5
Prior TNF-inhibitor use, n (%)	11 (16.7)	12 (17.1)	9 (13.4)

BMI, body mass index; BSA, body surface area; csDMARD, conventional synthetic disease-modifying antirheumatic drug; HAQ-DI, Health Assessment Questionnaire-Disability Index; MCS, mental component summary; MTX, methotrexate; PASI, Psoriasis Area and Severity Index; PCS, physical component summary; QD, once daily; SF-36, Short Form Health Survey 36-item questionnaire; SPARCC, Spondyloarthritis Research Consortium of Canada; TNF, tumor necrosis factor.

Results: Of 203 pts randomized, 180 (89%) completed 16 wks of treatment (deucravacitinib 6 mg QD, 63/70 [90%]; deucravacitinib 12 mg QD, 59/67 [88%]; PBO, 58/66 [88%]). Demographic and BL disease characteristics were similar across groups. Mean age was 49.8 years and median PsA duration since diagnosis was 4.5 years. BL mean SF-36 PCS and MCS scores were similar among deucravacitinib 6 mg QD, 12 mg QD, and PBO groups (PCS: 34.0,

Figure 1. Adjusted mean change from baseline in SF-36 scores at Week 16[1]



Nominal *P*-values for pairwise comparison vs placebo.
CI, confidence interval; MCS, mental component summary; PCS, physical component summary; QD, once daily; SF-36, Short Form-36.

34,5, and 33.4; MCS: 45.4, 46.9, and 47.5, respectively; **Table**). At Wk 16, adjusted mean changes from BL in SF-36 PCS and MCS scores were significantly improved ($P< 0.05$) with deucravacitinib 6 and 12 mg QD treatment vs PBO (**Figure 1**). Reported improvements in domain scores with both doses exceeded MCID and were significant in 5 of 8 domains with deucravacitinib 6 mg QD (PF, RP, BP, VT, and SF) and 6 of 8 domains with deucravacitinib 12 mg QD (RE in addition; **Figure 2**).

Conclusion: Pts with PsA receiving deucravacitinib treatment reported clinically meaningful and significant improvements in HRQOL, including fatigue and social functioning in addition to physical functioning and pain, at Wk 16.

SESSION INFORMATION

Session Date: Saturday, November 6, 2021

Session Title: Patient Outcomes, Preferences, & Attitudes Poster I: Impact (0225–0240)

Session Type: Poster Session A

Session Time: 8:30AM–10:30AM

Background/Purpose: The Lupus Foundation of America (LFA) has completed a 5-year cooperative agreement with the CDC to develop and evaluate an online lupus self-management (SM) program based on the Transtheoretical Model of Change. The program, *Strategies to Embrace Living with Lupus Fearlessly* (SELF), is designed to help users adopt 4 key lupus SM behaviors shown to have the highest impact on health and functional status: 1) managing symptoms, 2) managing stress, 3) managing medications, and 4) working with your healthcare team. The pilot was conducted using mixed methods to assess the feasibility and acceptability of SELF.

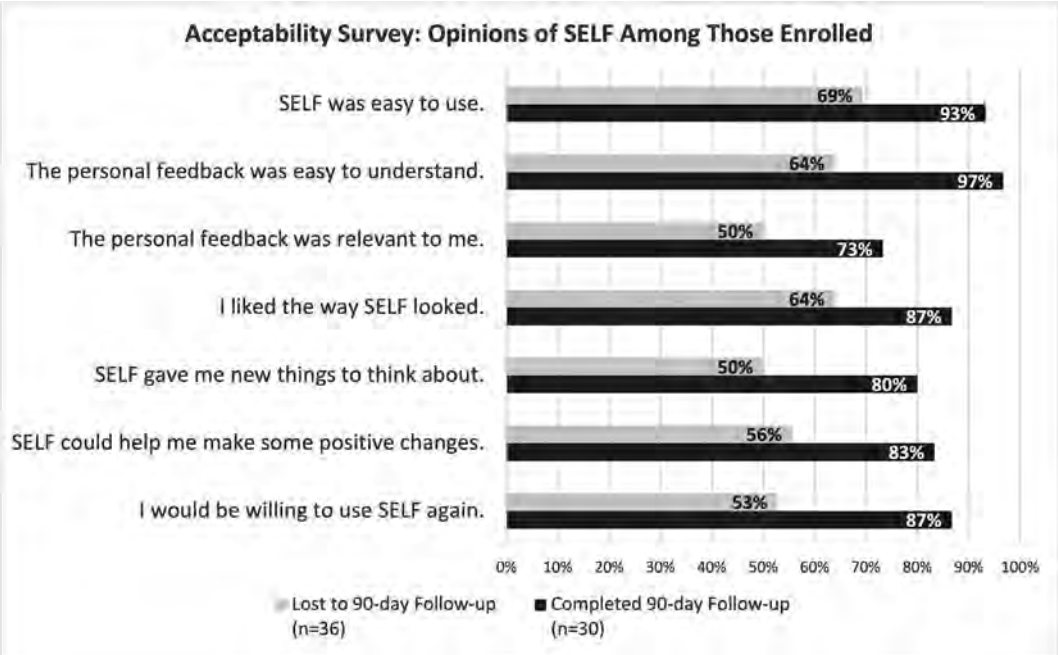

Figure 1. Acceptability surveys were sent to both users who completed 90-day follow-up in SELF and users who disengaged/ were lost to 90-day follow-up in SELF. Most users provided favorable opinions of SELF. Users who completed 90-day follow-up held more favorable opinions than users who were lost to 90-day follow-up.

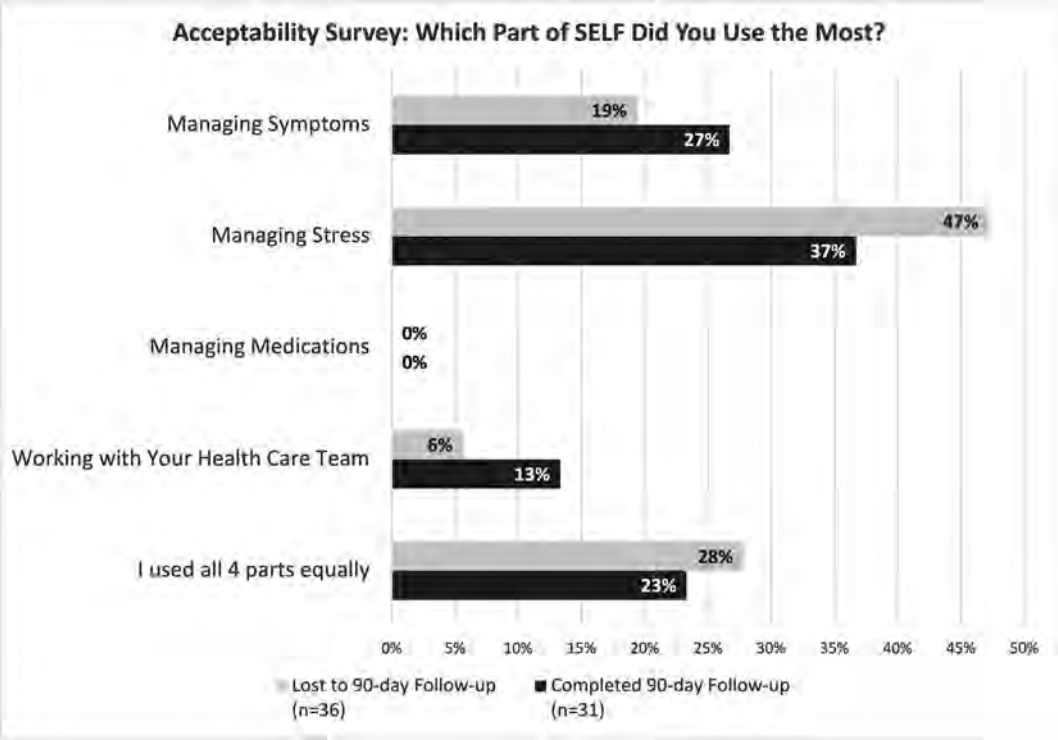

Figure 2. Acceptability surveys were sent to both users who completed 90-day follow-up in SELF and users who disengaged/ were lost to 90-day follow-up in SELF. Managing symptoms and managing stress were the most popular modules.

Methods: SELF consists of an intake assessment, user-tailored SM behavior change guidance/education, and a follow-up assessment every 90 days. At intake, users report their readiness to engage in the 4 SM behaviors consisting of 3-5 skills each. Users select one SM behavior as a focus for a 2-week period and begin the program via a customized web portal. In addition to tailored digital coaching, SELF offers: symptom and medication trackers; a journal; tailored text/email tips; and links to the LFA National Resource Center on Lupus, Health Educators, and LupusConnect™, an online community for peer-to-peer support.

Participants with a lupus diagnosis were recruited from three academic medical centers and the LFA constituency to take part in the 90-day pilot. Program evaluation included intake and follow-up assessments, a follow-up email survey and in-depth interviews. At intake, users were evaluated for their stage of change for each SM skill. They were defined as having a 'skill gap' when staged at one of the building stages. They 'mastered a skill' if they improved from a building stage of change at baseline to a mastery stage at follow-up. Feasibility and acceptability were assessed using enrollment/retention, utilization, readiness for and improvement to SM behaviors, and user feedback.

Results: Of those who registered, 62% (n=150 of 241) completed the intake assessment and 28% (n=42) remained engaged through the 90-day follow-up. Self-reported barriers to engagement included the impact of the COVID-19 pandemic, busy lives, length of intake, and belief that SELF's target audience was newly diagnosed people with lupus (PWL).

Users showed substantial need; 80% had moderate/ high skill gaps in key SM skills. Users who completed the program were successful in building new skills; 57% mastered 1 or more SM skills. Most users provided favorable opinions of SELF (Figure 1) with managing stress and managing symptoms being the most popular modules (Figure 2).

Conclusion: Although the COVID-19 pandemic and other factors impacted participants' time and ability to engage with SELF, this pilot provided valuable insights for optimizing SELF to improve enrollment and retention (e.g., adding

social login and text/email reminders, reducing length of intake). SELF is designed to provide a cohesive, tailored experience to help PWL manage their condition. The pilot showed promising results in meeting user needs and building skills to impact behavior change.

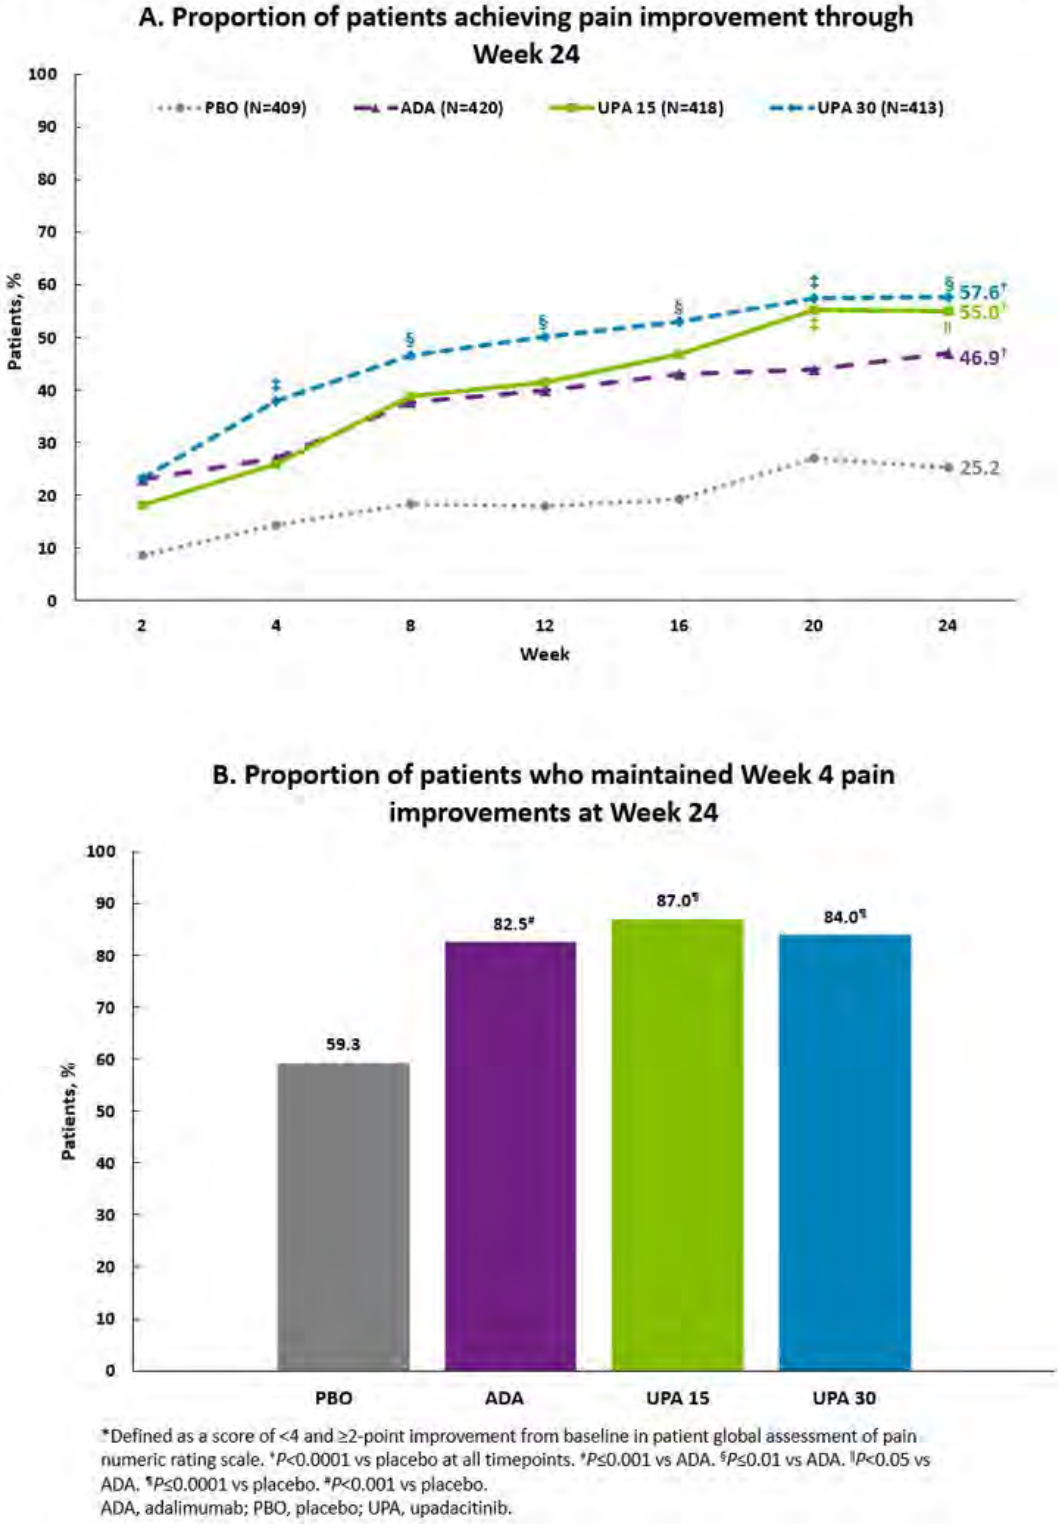
SESSION INFORMATION
Session Date: Saturday, November 6, 2021
Session Title: Patient Outcomes, Preferences, & Attitudes Poster I: Impact (0225–0240)
Session Type: Poster Session A
Session Time: 8:30AM–10:30AM

Background/Purpose: Pain is a dominant feature of PsA and has been identified by the GRAPPA-OMERACT working group as a core disease domain. Its control is a largely unmet need, especially in patients failing non-biologic DMARDs. The purpose of this study was to evaluate if clinically meaningful improvement in pain, particularly at earlier timepoints after treatment initiation, is associated with greater improvements in other patient reported outcomes (PROs).

Methods: The phase 3 SELECT-PsA1 trial randomized patients with inadequate responses to ≥1 non-biologic DMARDs to receive upadacitinib (UPA) 15 mg once daily (QD), UPA 30 mg QD, adalimumab (ADA) 40 mg every other week, or placebo (PBO) for 24 weeks. Patients with baseline patient global assessment (PGA) of pain numeric rating scale (NRS) score >2 were evaluated. Outcomes assessed included the proportion of patients achieving meaningful pain improvement (defined as achievement of a score of < 4 and ≥2-point decrease from baseline in PGA of pain NRS) through Week 24 and, for those achieving meaningful pain improvement at Weeks 4 (UPA/ADA arms only) or 24, the percentage of patients achieving minimum clinically important differences (MCID) at Week 24 on Health Assessment Questionnaire-Disability Index (HAQ-DI), Functional Assessment of Chronic Illness Therapy-Fatigue (FACIT-F), 36-Item Short-Form Health Survey (SF-36), EuroQoL-5 Dimension, 5 level (EQ-5D-5L), and Work Productivity and Activity Impairment (WPAI). Analyses were performed using the Cochran-Mantel-Haenszel test, adjusting for DMARD use, with non-responder imputation for comparison between treatments, and Chi Square test, with as observed analysis for comparison between responders/nonresponders. *P*-values < 0.05 were nominal.

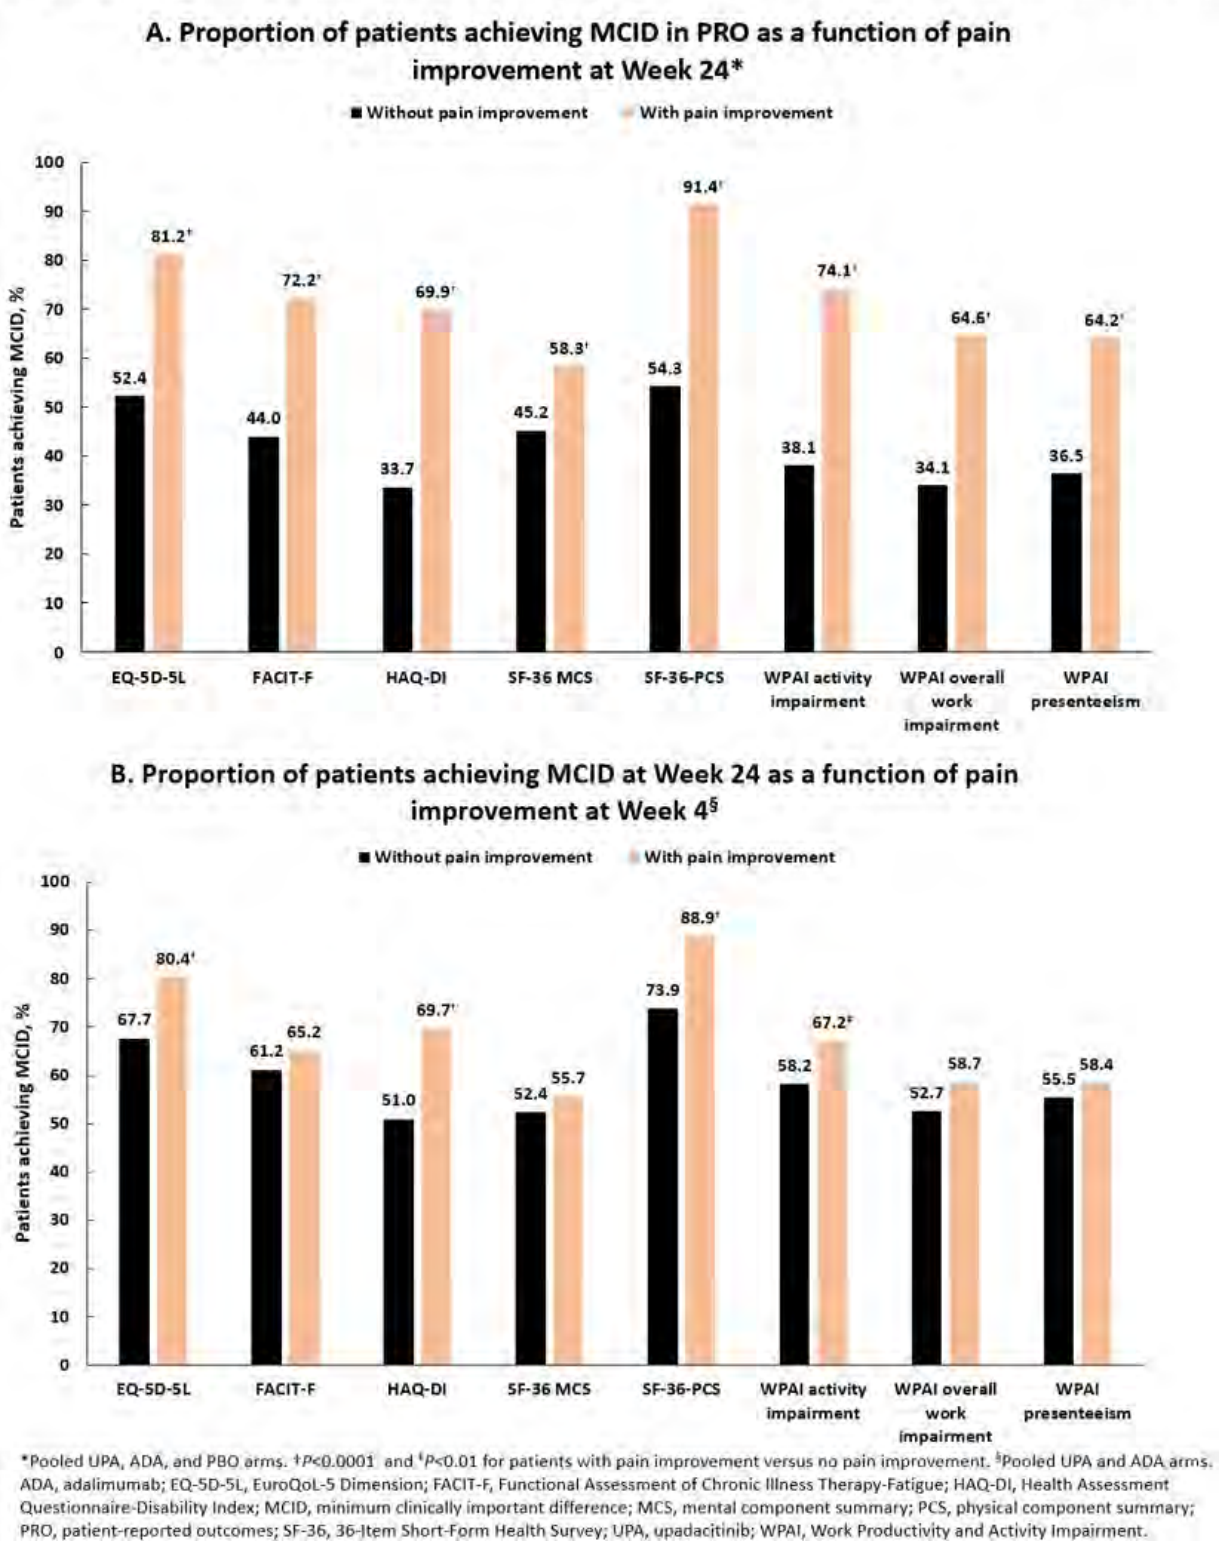
Figure 1. Proportion of patients achieving meaningful pain improvements* with treatment



*Defined as a score of <4 and ≥2-point improvement from baseline in patient global assessment of pain numeric rating scale. †P<0.0001 vs placebo at all timepoints. ‡P≤0.001 vs ADA. §P≤0.01 vs ADA. ‖P<0.05 vs ADA. ¶P≤0.0001 vs placebo. #P<0.001 vs placebo.
ADA, adalimumab; PBO, placebo; UPA, upadacitinib.

Results: A significantly greater proportion of patients with PsA had meaningful pain improvement with UPA 15 mg (N=418), UPA 30 mg (N=413), and ADA (N=420) compared with PBO (N=409) starting as early as Week 2 (P< 0.0001, Figure 1A). Compared with ADA, a significantly greater proportion of patients achieved meaningful pain improvement with UPA 15 mg starting at Week 20 (P< 0.05), and UPA 30 mg starting at Week 4 (P≤0.01). Meaningful pain improve-

Figure 2. Proportion of patients achieving MCID in PRO as a function of pain improvement



*Pooled UPA, ADA, and PBO arms. †$P<0.0001$ and ‡$P<0.01$ for patients with pain improvement versus no pain improvement. §Pooled UPA and ADA arms. ADA, adalimumab; EQ-5D-5L, EuroQoL-5 Dimension; FACIT-F, Functional Assessment of Chronic Illness Therapy-Fatigue; HAQ-DI, Health Assessment Questionnaire-Disability Index; MCID, minimum clinically important difference; MCS, mental component summary; PCS, physical component summary; PRO, patient-reported outcomes; SF-36, 36-Item Short-Form Health Survey; UPA, upadacitinib; WPAI, Work Productivity and Activity Impairment.

ment was maintained at Week 24 by over 80% of patients on UPA and ADA who had achieved improvement at Week 4 (Figure 1B). For patients who attained meaningful pain improvement at Week 24 vs those who did not, a significantly greater proportion reported values ≥ MCID in all PROs ($P< 0.0001$, Figure 2A). Similarly, for all UPA/ADA patients who

did vs did not attain meaningful pain improvement at Week 4, a significantly greater proportion achieved MCID in EQ-5D-5L, HAQ-DI, SF-36 physical component summary, and WPAI activity impairment at Week 24 ($P < 0.01$, Figure 2B).

Conclusion: A greater proportion of patients achieved meaningful pain improvement with UPA and ADA vs PBO throughout the 24-week treatment period, and with UPA 15 mg vs ADA by Week 20. Meaningful pain improvement by Week 4 was associated with more patients reporting improvements ≥ MCID in several PROs at Week 24. Overall, meaningful pain improvement is closely linked with meaningful improvements in other important outcomes for PsA patients.

SESSION INFORMATION
Session Date: Saturday, November 6, 2021
Session Title: Patient Outcomes, Preferences, & Attitudes Poster I: Impact (0225–0240)
Session Type: Poster Session A
Session Time: 8:30AM–10:30AM

Background/Purpose: The availability of biosimilars has created a financial incentive to encourage non-medical switching if cheaper products are on the market. In patients with chronic inflammatory rheumatic diseases (CIRD), we have previously reported a relatively high retention rate after switching from originator etanercept to its biosimilar. However, this has been different in other studies and the reasons for non-adherence are poorly understood. Comorbidity has recently gained much attention in patients with CIRD and might be a reason for non-adherence.

The aim of this study was to analyse the effectiveness and safety of systematic non-medical switching from originator adalimumab (ADA) to ADA ABP501 biosimilar (ABP) over 6 months in patients with CIRD and to investigate the influence of comorbidities on retention rates.

Methods: Patients with CIRD on originator ADA who switched to ABP subsequently from October 2018 onwards were identified from a large routine database and then followed for 6 months. The presence of comorbidities and

Table 1. Patients and disease characteristics

	Total N=111	RA N=23	axSpA N=68	PsA N=15	Other N=5
Age (years), mean (SD)	51.2 (14.5)	65.1 (12.0)	47.3 (13.1)	51.1 (11.2)	41.8 (14.2)

Values are shown as % (N) if not stated otherwise.
b/cs/tsDMARD: biological / conventional synthetic / targeted synthetic disease-modifying anti-rheumatic drug; IQR: interquartile range; NSAIDs: non-steroidal anti-inflammatory drugs; SD: standard deviation.

disease characteristics as well as measures of disease activity, physical function and changes in treatment were documented at baseline (the time of switching from originator ADA to ABP), and at months 3 and 6. Longitudinal data including information on the clinical efficacy and safety of ABP, and the reasons for discontinuation were documented.

Results: A total of 111 CIRD patients on treatment with originator ADA were switched to the biosimilar ABP. This comprised 23 patients with rheumatoid arthritis (RA), 68 with axial spondyloarthritis (axSpA), and 15 with psoriatic arthritis (PsA). More than half of the patients (62%) had a Charlson comorbidity score of zero, though there were differences between disease subtypes. RA patients were comparatively older (mean age 65 years) and had the highest mean Charlson score (1.8), see Table 1.

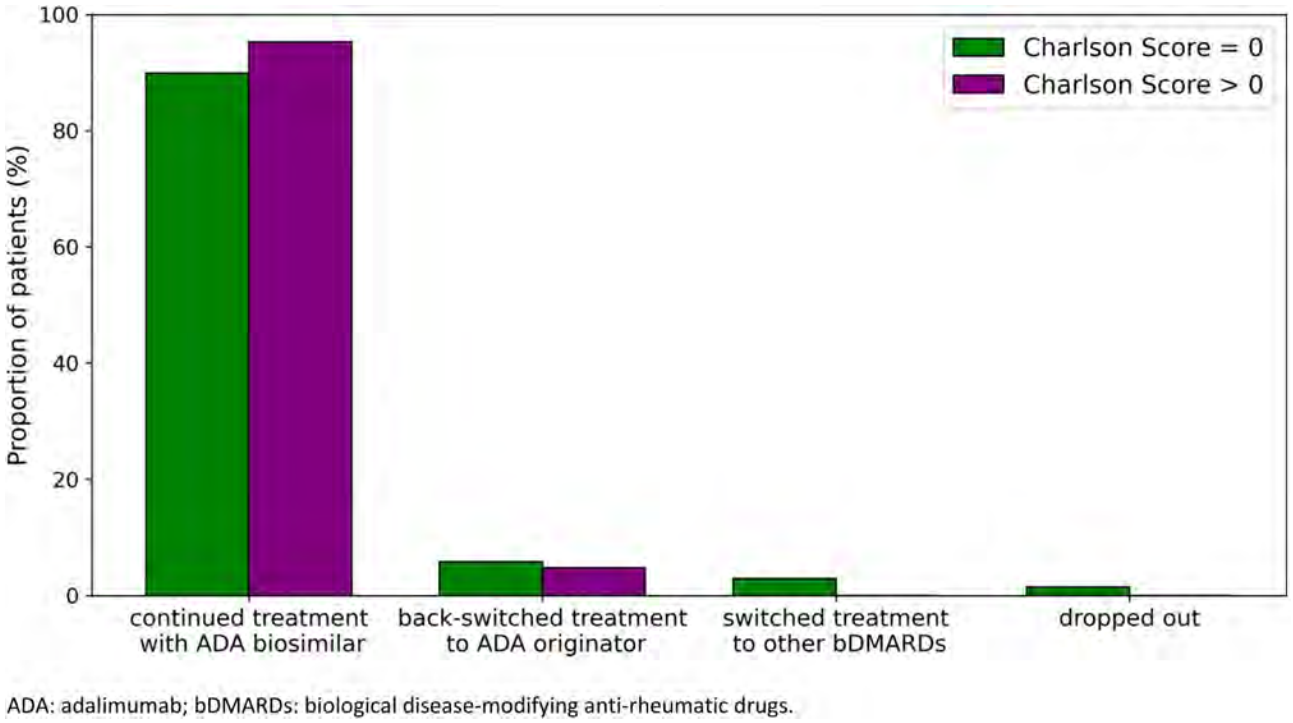

Figure 1. Treatment retention after 6 months stratified by the Charlson comorbidity score.

Treatment retention varied only slightly between patients with a Charlson score of zero and those with a higher score (Figure 1). In both groups, the majority of patients (90% vs 95%) continued therapy with ABP, while only a small proportion either switched back to originator ADA (6% vs 5%), switched to a different biologic (3% vs 0%), or dropped out (1% vs 0%). The main reason for back switch was the occurrence of adverse events, mostly subjective complaints, most frequently pain. Spaghetti plots show the trajectories of scores for disease activity and physical function stratified by disease subtype (Figure 2). Patients with a Charlson comorbidity score > 0 tended to have poorer scores in this regard.

Conclusion: Comorbidity had no influence on the biosimilar retention rate after 6 months in this study but the majority of patients did not have Charlson scores > 0. However, disease activity and physical function tended to be worse among CIRD patients with comorbidity. Cardiovascular disease and osteoporosis were more often present in RA patients than in axSpA or PsA patients, while neurological and psychological comorbidities were more often observed in the latter.

Gonzalez", Monterrey, Mexico, [3]Hospital Universitario Dr. José Eleuterio González, Monterrey, Mexico

SESSION INFORMATION

Session Date: Saturday, November 6, 2021

Session Title: Patient Outcomes, Preferences, & Attitudes Poster I: Impact (0225–0240)

Session Type: Poster Session A

Session Time: 8:30AM–10:30AM

Background/Purpose: Untreated perinatal anxiety symptomatology can be related to symptoms of anxiety and depression during the postpartum. The psychological bond created by the mother between mother and fetus helps to mitigate physical and emotional problems on this stage and in the postpartum. Prenatal maternal attachment acquires special importance because it has been shown that can be a predictor for healthier behavior during pregnancy and better birth outcomes. The aim of this study to correlate the scores between State Trait Anxiety Inventory (STAI), Maternal Antenatal Attachment Scale (MAAS) and Edinburgh Postnatal Depression Scale (EPDS).

Table 1. Demographic characteristics and total scores

	n= 23
Age, mean, years, SD	27.60 (±7.76)
Rheumatic diagnosis, n (%)	
Rheumatoid arthritis	10 (43.47)
Antiphospholipid syndrome	5 (21.73)
Systemic lupus erythematosus	4 (17.39)
Fibromyalgia	2 (8.69)
Dermatomyositis	1 (4.34)
Sjogren's syndrome	1 (4.34)
Questionnaires total score, mean, SD	
State Trait Anxiety Inventory (STAI)	133.82 (±8.46)
Maternal Antenatal Attachment Scale (MAAS)	43.82 (±5.08)
Edinburgh Postnatal Depression Scale (EPDS)	7.65 (±6.0)

SD: standard deviation

Methods: A cross-sectional and descriptive study was conducted from January 2019 to May 2021 at the Pregnancy and Rheumatic Diseases Clinic from the University Hospital "Dr. Jose E. Gonzalez" in Monterrey, Mexico. Pregnant women with ARDs were invited to participate. The STAI is a questionnaire used in clinical settings to diagnose anxiety and to distinguish it from depressive syndromes. It has 20 items for assessing trait anxiety and 20 for state anxiety. All items are rated on a 4-point scale. Higher scores indicate greater anxiety. The MAAS is a 19-item self-report questionnaire which calculates a total attachment score and two subscale scores; one score estimating the quality of the affective attachment and the other that estimates the intensity of concern about the fetus. The EPDS is a set of 10 screening items that can indicate whether a parent has symptoms that are common in women with depression and anxiety during pregnancy and in the year following the birth of a child. The total score is calculated by adding the numbers selected for each of the 10 items, with a cut-off score of 10 points. The validated Spanish version of those instruments were applied during the third trimester. The statistical analysis was performed using the Pearson´s correlation test. Data included descriptive statistics. A p-value < 0.05 was statistically significant. The data were evaluated using the IBM SPSS v24 statistical package (IBM, Armonk, USA).

Results: A total of 23 pregnant women were recruited. A mean age of 27.6 years. The most common diagnosis was rheumatoid arthritis with 10(43.47), followed by antiphospholipid syndrome 5(21.73) and systemic lupus erythematosus 4(17.3), and other diagnosis (fibromyalgia (2), dermatomyositis (1) and Sjogren's syndrome (1)). The STAI mean score was 133.82 points, the MAAS mean score was 43.82 points, and the EPDS mean score was 7.65 points. A negative moderate correlation was found between MAAS and EPDS (-.605, p=0.002) and also a positive moderate correlation between STAI and EPDS (0.442, p=0.034).

Conclusion: The maternal antenatal attachment had a moderate negative correlation with postnatal depression, meaning the less attachment equals a higher frequency of depressive symptoms. Moreover, a positive correlation between anxiety symptoms and depressive symptoms were found. Strategies to enhance the maternal bond must be addressed during all pregnancy stages. Postpartum women should receive psychological support and be screened for depression and anxiety, especially women with preexisting conditions such as ARDs and other chronic diseases.

DAS28-ESR (at the baseline)	0.72 (0.63; 0.82)	< 0.001	0.89 (0.76; 1.05)	0.165

Background/Purpose: SF-36 and its components, as well as other PROs have been shown to predict various disease outcomes. We hypothesized that positive responses to questions (Q) 11A "I seem to get sick a little easier than other people", and 11C "I expect my health to get worse" from the general health (GH) domain of the SF-36 v1 questionnaire may correspond to a more fragile self-perceived GH status, and thus serve as possible predictors of future disease outcomes in patients with rheumatoid arthritis (RA). We aimed to investigate whether these 2 questions could predict therapeutic response in patients with RA starting their first anti-TNF therapy.

Table 3. Patients' responses and occurrence of remission after 12 months - univariable logistic regression models after PS matching

	D1		D2	
Parameters	OR (95% CI)	p	OR (95% CI)	p
Expectation of disease worsening:	N=845		N=333	
definitely yes / mostly yes (vs. definitely no / mostly no)	1.33 (1.00; 1.77)	0.050	1.51 (0.97; 2.34)	0.066
It seems I become ill more easily than other people:	N=965		N=365	
definitely yes / mostly yes (vs. definitely no / mostly no)	1.56 (1.19; 2.05)	0.001	1.70 (1.12; 2.59)	0.013

Methods: We have used two separate datasets from the Czech biologics registry ATTRA to validate our hypothesis. Dataset D1 included RA patients with at least 1 year follow-up and all relevant data available starting their first-line anti-TNF treatment within period 01/01/2012-31/12/2017 (N=1808), and dataset D2 pts starting in in 01/01/2018–01/01/2020 (N=734). Our primary outcome was DAS28-ESR remission (REM) at 12 months. REM was defined as DAS28< 2.6. Patients were grouped according their response (definitely/mostly yes vs. definitely/mostly no) to Q11A and Q11C at baseline. REM rates after 12 months of 1st-line anti-TNF treatment were compared across patients' groups with Pearson chi-squared test. Firstly, odds ratios (ORs) using logistic regression (univariate, and then adjusted to baseline DAS28 and HAQ) were calculated to predict REM at 12M. Secondly, ORs were calculated after matching pts with positive or negative responses by a propensity score (PS) using sex, age, disease duration, baseline DAS28, calendar year and co-medication to balance baseline differences.

Results: At baseline, 79% and 80% pts were female, mean (SD) age was 52(12) and 54(13) years, DAS28 6.3 (0.9) and 6.2 (1.1), HAQ 1.5(0.6) and 1.5(0.6), 74% and 68% were RF+, 70% and 69% ACPA+ in D1 and D2 resp. In D1 34% and 31% pts, and in D2 32% and 30% responded positively to Q11A and 11C resp. Patients with positive responses to Q11A and 11C tended to have slightly (but statistically significantly) higher DAS28, HAQ, CRP or ESR, and patient- and physician global activity assessment at baseline. At 12 months, 40% (49%), 31% (37%), and 30% (40%) patients with positive, negative and neutral response to Q 11A reached REM; p< 0.001 (p=0.018) in D1 (D2) resp. At 12 months, 42% (51%), 31% (37%), and 30% (40%) patients with positive, negative and neutral response to Q 11C reached REM; p< 0.001 (p=0.04) in D1 (D2) resp. Crude and adjusted ORs for reaching REM according to responses to Q11A and Q11C are shown in tables 1-3.

Conclusion: We provide a robust evidence that self-perceived general health at start of anti-TNF therapy predicts reaching remission at 12 months in pts with RA.

Maternal characteristics of patients with autoimmune disease and comorbid preeclampsia compared to patients with autoimmune disease without preeclampsia.

Background/Purpose: Rheumatic diseases, such as SLE, are associated with serious maternal, pregnancy, and infant complications. The role that preeclampsia plays in these outcomes in women with SLE and other rheumatic disease remains unclear. We compared pregnancy and infant outcomes among women with SLE and other rheumatic diseases with and without preeclampsia in a single academic center.

Methods: Deliveries in women with rheumatic disease were identified from both a prospective cohort of women with rheumatic disease who received care within a university rheumatology clinic and a chart-reviewed list of deliveries to women with an ICD-9/10 code for SLE. Mothers with rheumatic disease were matched with their infants through the electronic medical record (EMR) to allow data extraction. Preeclampsia was determined by the obstetric team at the time of delivery and collected through chart review. Pregnancy and infant outcomes were compared between those with and without preeclampsia.

Results: 263 singleton deliveries were included in the study of whom 14% had preeclampsia. Preeclampsia was significantly more common among women with SLE than with other rheumatic diseases (SLE 27% vs other rheumatic diagnoses 8%, p< 0.001); this pattern persisted among both Black and White women and women with private health insurance. Among women with SLE, however, the rate of preeclampsia was similar between Black and White women

**Non-SLE rheumatic disease included Mixed Connective Tissue Disease, Undifferentiated Connective Tissue Disease, Sjogren's syndrome, Antiphospholipid Syndrome, Adult Onset Still's Disease, seronegative spondyloarthropathies, juvenile inflammatory arthritis, rheumatoid arthritis, Behcet's disease, Familial Mediterranean Fever, inflammatory eye disease, inflammatory myopathy, sarcoidosis, systemic sclerosis, cutaneous lupus, systemic vaculitides.*

Infant Outcomes of children born to patients with autoimmune disease and comorbid preeclampsia compared to patients with rheumatic disease without preeclampsia.

and those with and without private insurance. Having preeclampsia increased the mother's hospital stay for delivery by an average of 2 days for women with SLE and 1 day for women with other rheumatic diseases.

Infants born to preeclamptic mothers were delivered an average of 3.3-weeks earlier than those without preeclampsia; they were 4-times more likely to be born preterm (55.3% vs 14.5%, p< 0.001), a difference that persisted in mothers with SLE and other rheumatic diagnoses. More than twice as many infants born to preeclamptic mothers were admitted to the neonatal intensive care unit (NICU; 36.8% vs 15.1%, p< 0.0001). While infants born to women with SLE without preeclampsia had modestly higher rates of preterm birth and NICU admission compared to women with other rheumatic diseases, preeclampsia drove these rates significantly higher in all women.

Conclusion: Preeclampsia has important health consequences on mothers with rheumatic disease, including increasing hospitalization at delivery by 1-2 days, and on the infant, increasing the frequency of preterm delivery and NICU admission. Preeclampsia was particularly common among women with SLE in this cohort. These data suggest that preventing preeclampsia could have a dramatic impact on the short- and long-term health of women with rheumatic disease and their children.

Work Disability Associated with Fatigue in Patients with Psoriatic Arthritis – a Retrospective Study Using Claims Data, 2009-2019

Elaine Husni[1], Steven Peterson[2], Natalie Dennis[3], Feifei Yang[4], Iris Lin[4], Yiting Wang[5], Soumya Chakravarty[6], Claire Fischer[3], May Shawi[7], Arthur Quenéchdu[3] and Joseph Merola[8], [1]Cleveland Clinic, Cleveland, OH, [2]Janssen Immunology Global Commercial Strategy Organization, Raritan, NJ, [3]Amaris, Health Economics and Market Access, Paris, France, [4]Janssen Immunology Global Commercial Strategy Organization, Horsham, PA, [5]Janssen R&D, LLC, Titusville, NJ, [6]Janssen Scientific Affairs, LLC and Drexel University College of Medicine, Horsham, PA, [7]Janssen Immunology Global Commercial Strategy Organization, Toronto, ON, Canada, [8]Brigham and Women's Hospital, Harvard Medical School, Boston, MA

SESSION INFORMATION
Session Date: Saturday, November 6, 2021
Session Title: Patient Outcomes, Preferences, & Attitudes Poster I: Impact (0225–0240)
Session Type: Poster Session A
Session Time: 8:30AM–10:30AM

Background/Purpose: Fatigue is a complex symptom affecting physiological, psychological, and social factors and is commonly seen in psoriatic arthritis (PsA). Fatigue has been shown to be associated with both short-term and long-term work absences. The objective of this study was to evaluate the impact of fatigue on short-term disability among patients with PsA in the United States.

Methods: Adults eligible for short-term disability benefits between 2009 and 2019 were screened in the IBM® MarketScan® Commercial and Health and Productivity Management Databases. Patients with ≥ 2 diagnoses for PsA ≥ 30 days apart were included. Patients with fatigue (i.e., cases) had ≥ 1 fatigue diagnosis after their initial PsA diagnosis, and the first fatigue diagnosis was defined as the index date. Controls were PsA patients who had no fatigue diagnoses during the study period; their index date was defined using the cases' median time from initial PsA to the first fatigue diagnosis. Patients had continuous enrollment from ≥ 6 months before their initial PsA diagnosis (baseline period) to ≥ 12 months after the index date (follow-up period) and had to be eligible for short-term disability benefits

Vitamin D deficiency	211 (6.2%)	108 (8.5%)	112 (9.0%)	103 (8.3%)
Acute upper respiratory infection	370 (10.9%)	195 (15.4%)	183 (14.7%)	188 (15.1%)

Table 2. Short-term disability outcomes during follow-up.

	Control group	PsA with fatigue	P-value
Number of patients	1,244	1,244	
Patients with short-term disability leave – N (%)	82 (6.6%)	127 (10.2%)	0.0014
Number of short-term disability days – Mean (SD)	3.41 (20.70)	6.92 (32.20)	0.0013
Costs associated with short-term disability – Mean (SD)	$438.09 (2645.63)	$896.54 (4180.10)	0.0011

during the entire follow-up period. Patients with rheumatoid arthritis, ankylosing spondylitis, Crohn's disease, or ulcerative colitis during the study period were excluded from the analyses. Controls were matched 1:1 to cases based on propensity scores that balanced age, gender, year of initial PsA diagnosis, PsA treatment, related conditions, the Charlson Comorbidity Index, variables associated with PsA disease severity, vitamin D deficiency, and common infections (Table 1). Change in short-term disability and associated costs (in 2019 USD) were calculated from baseline through follow-up.

Results: 1,244 patients with fatigue were matched to the control group (Table 1). The average age at baseline was 46.3 years and 43.0% were female. Patients with PsA and fatigue missed an average of 6.9 days due to short-term disability, whereas controls missed an average of 3.4 days (p=0.0013, Table 2). Average costs associated with short-term disability were $438 and $897 for controls and PsA patients with fatigue, respectively (p=0.0011). During follow-up, 6.6% of patients in the control group had at least one short-term disability leave compared to 10.2% of patients with fatigue (p=0.0014).

Conclusion: Higher rates of annual short-term disability were observed among patients with PsA and fatigue than without fatigue. These results highlight the substantial indirect costs and economic burden of fatigue in patients with PsA.

SESSION INFORMATION

Session Date: Saturday, November 6, 2021

Session Title: Patient Outcomes, Preferences, & Attitudes Poster I: Impact (0225–0240)

Session Type: Poster Session A

Session Time: 8:30AM–10:30AM

Background/Purpose: Fatigue is a complex symptom affecting physiological, psychological, and social factors and is commonly seen in psoriatic arthritis (PsA). The objectives of this study were to evaluate healthcare resource utilization and costs associated with fatigue among patients with PsA in the United States.

Methods: The IBM® MarketScan® Commercial Database was used to identify adult patients with PsA between 2009 and 2019. Patients with ≥ 2 diagnoses for PsA ≥ 30 days apart were included. Patients with fatigue (i.e., cases) had ≥ 1 fatigue diagnosis after their initial PsA diagnosis, and the first fatigue diagnosis was defined as the index date. Controls were PsA patients who had no fatigue diagnoses during the study period; their index date was defined using the case's median time from initial PsA to the first fatigue diagnosis. Patients had continuous enrollment from ≥ 6 months before their initial PsA diagnosis (baseline period) to ≥ 12 months after the index date (follow-up period). Patients with comorbid rheumatoid arthritis, ankylosing spondylitis, Crohn's disease, or ulcerative colitis during the study period were excluded from the analyses. Controls were matched 1:1 to patients with PsA and fatigue based on propensity scores that balanced age, gender, year of initial PsA diagnosis, PsA treatment, related conditions, the Charlson Comorbidity Index, variables associated with PsA disease severity, vitamin D deficiency, and respiratory infection (Table 1). Healthcare resource utilization and costs (in 2019 USD) were evaluated during follow-up.

Results: Fatigue was present among 30% of included patients with PsA. 7,350 patients with fatigue were matched to the control group (Table 1). The average age at baseline was 48 years and 59% were female. Average annual all-cause healthcare costs per patient were $26,102 and $34,344 for the control group and patients with fatigue,

Table 1. Baseline characteristics before and after matching (1) (1) Variables were evaluated during the 6-month baseline period (2) Variables in italic were not included in the matching

≥ 2 - N (%)	*1281 (7.4%)*	*768 (10.1%)*	*692 (9.4%)*	*695 (9.5%)*
Disease severity				
Number of rheumatology visits - Mean (SD)	2.71 (5.32)	3.40 (6.24)	3.30 (6.26)	3.32 (6.13)
Inflammation marker test ordered - N (%)	8751 (50.3%)	4425 (58.4%)	4193 (57.0%)	4234 (57.6%)
Joint pain diagnosis - N (%)	5392 (31.0%)	3082 (40.6%)	2901 (39.5%)	2905 (39.5%)
Number of imaging procedures - Mean (SD)	0.64 (1.00)	0.84 (1.15)	0.79 (1.13)	0.80 (1.11)
Difficulty walking – N (%)	*73 (0.4%)*	*48 (0.6%)*	*44 (0.6%)*	*43 (0.6%)*
Other confounding factors – N (%)				
Vitamin D deficiency	1259 (7.2%)	861 (11.4%)	783 (10.7%)	774 (10.5%)
Acute upper respiratory infection	2139 (12.3%)	1395 (18.4%)	1286 (17.5%)	1279 (17.4%)

respectively ($p< 0.0001$). The costs were greater among patients with fatigue due to greater inpatient costs (controls: $2,046, fatigue: $3,959), outpatient medical costs (controls: $7,058, fatigue: $11,182), and outpatient pharmacy costs (controls: $16,998, fatigue: $19,203) (Figure 1). Across all categories of healthcare resources, utilization was greater among patients with PsA and fatigue than the control group (Table 2). Patients with PsA and fatigue had significantly more physician office visits than controls during follow-up (average of 11.4 and 8.0, respectively, $p< 0.0001$).

Conclusion: PsA patients with fatigue incurred significantly greater healthcare costs and resource utilization than patients without fatigue. Effective treatments that help reduce fatigue among patients with PsA may improve patient outcomes including decreased healthcare costs. Further research is warranted to better understand what is driving these greater costs.

Abstract Number: 0241

Psoriasis Rate Is Increased by the Exposure to TNF Inhibition in Children with JIA

yongdong Zhao[1], Erin Sullivan[2], Mary Beth Son[3] and Timothy Beukelman[4], [1]University of Washington, Redmond, WA, [2]Seattle Children's Research Institute, Seattle, WA, [3]Boston Children's Hospital, Brookline, MA, [4]University of Alabama at Birmingham, Birmingham, AL

SESSION INFORMATION
Session Date: Saturday, November 6, 2021
Session Title: Pediatric Rheumatology – Clinical Poster I: JIA (0241–0265)
Session Type: Poster Session A
Session Time: 8:30AM–10:30AM

Background/Purpose: Paradoxical psoriasis has been increasingly reported in adults after exposure to tumor necrosis factor inhibitors (TNFi). Systematic studies in the pediatric population are lacking. We aimed to investigate the relationship between TNFi therapy and the onset of new psoriasis in children with juvenile idiopathic arthritis (JIA) using Childhood Arthritis and Rheumatology Research Alliance (CARRA) Registry data.

Table 1. Baseline Demographics and Summary of Psoriasis Incidence

	Total Population N=8225
Gender (%Male)	2371 (28.8%)
Mean (Std) Age in Years at JIA Diagnosis	7.5 (4.8)
Initial ILAR Category	
Enthesitis related	854 (10.4%)
Oligoarthritis	2937 (35.7%)
Polyarthritis	3177 (38.6%)
Psoriatic	338 (4.1%)
Systemic	711 (8.6%)
Undifferentiaed	208 (2.5%)
Race	
White	6253 (76.0%)
Black	341 (4.2%)
Hispanic	896 (10.9%)
Asian	223 (2.7%)
Other	512 (6.2%)
TNFi Exposure	
Any Use	4437 (53.9%)
Etanercept	2818 (34.3%)
Adalimumab	2516 (30.6%)
Infliximab	590 (7.2%)
First TNFi Prescribed for Use	
Etanercept	2675 (60.3%)
Adalimumab	1527 (34.4%)
Infliximab	207 (4.7%)

Table 2. Association of TNFi Exposure* with New Onset of Psoriasis Among Patients with Juvenile Idiopathic Arthritis

	Unadjusted Hazard Ratio (95% CI)	p-value	Adjusted** Hazard Ratio (95% CI)	p-value
TNFi Ever Exposure				
Never Exposed	ref	-	ref	-
Ever Exposed	3.02 (2.26 to 4.02)	< 0.01	2.93 (2.15 to 3.98)	< 0.01

*TNFi exposure defined as any time observed after initial TNFi prescription, followed until psoriasis or censor

**Adjusted for methotrexate exposure (ever vs. never), gender, race, family hx of psoriasis, and initial ILAR category

Table 3. Summary of Psoriasis Incidence

	Incidence Rate Cases/1,000 Person-years (95%CI)	Median follow-up time (months)	Raw totals
Overall (All Follow-up time)	5.33 (4.67 to 6.07)	46.9	223 cases/41,831 person years
Never exposed to TNFi	3.27 (2.62 to 4.03)	20.4	84 cases/25,700 person years
Ever exposed to TNFi	8.62 (7.27 to 10.14)	33.3	139 cases/16,132 person years
First Exposure to TNFi	8.65 (6.67 to 11.03)	13.5	61 cases/7,056 person years
TNFi Specific exposure			
First Exposure Only			
Etanercept	6.78 (4.69 to 9.50)	15.1	31 cases/4,573 person years
Adalimumab	12.32 (8.22 to 17.8)	11.1	26 cases/2,110 person years
Infliximab	9.04 (2.30 to 24.59)	12.2	3 cases/ 332 person years
Ever Exposure*			
Etanercept	6.97 (4.88 to 9.68)	14.5	33 cases/4,731 person years
Adalimumab	11.98 (8.60 to 16.27)	9.4	38 cases/3,173 person years
Infliximab	6.44 (2.36 to 14.28)	10.4	5 cases/ 776 person years
Total Exposure			
Etanercept	5.46 (3.96 to 7.36)	22.5	40 cases/7,324 person years
Adalimumab	13.41 (10.30 to 17.18)	12.2	59 cases/4,400 person years
Infliximab	8.77 (4.88 to 14.61)	21.8	13 cases/1,483 person years

*With or without other prior TNFi Exposure

Methods: De-identified data were obtained from CARRA registry for patients enrolled in CARRA Registry with a diagnosis of JIA from June 30, 2015 to January 1, 2020 with follow up data available. Patients with Inflammatory Bowel Disease or psoriasis documented on or prior to JIA diagnosis date were excluded, as were patients with incomplete data regarding medication start/stop dates. New onset psoriasis was defined by first recorded instance of psoriasis following JIA diagnosis. Exposure time to TNFi was defined as: 1. Ever Exposure: any time observed after the patient's first exposure to a TNFi until censoring (psoriasis developed, or most recent visit date if continuing TNFi, or 60 days after the discontinuation of the TNFi, whichever was sooner); or 2. Total Exposure: any time observed while actively on TNFi, until censoring; or 3. First Exposure Only: any time observed while actively on the first TNFi, until censoring. Baseline characteristics were analyzed with descriptive statistics. Hazard ratios were calculated between exposed and unexposed groups adjusted for methotrexate exposure, sex, race, family history of psoriasis and initial JIA category.

Results: A total of 8,222 patients were included with a median follow up of 5.3 years. Over half of the patients were prescribed TNFi (n=4,435, 54%; Table 1). The hazard ratio of new onset of psoriasis after Ever Exposure to TNFi was 3.02 (CI 2.26 to 4.02, unadjusted) and 2.93 (2.15 to 3.98, adjusted) ($p< 0.01$) (Table 2). The incidence rate of psoriasis was the highest in children who received adalimumab in Ever Exposure, Total Exposure and First Exposure Only calculations (Table 3). A subanalysis of patients with psoriatic arthritis showed that the risk of new onset TNFi-associated

psoriasis was increased but the increased risk was lower than observed in the other categories combined. The adjusted hazard ratios (95% CI) of psoriasis after TNFi exposure was 1.68 (1.11 to 2.54, adjusted, p=0.01) in psoriatic JIA and 5.60 (3.47 to 9.05, adjusted, p< 0.01) in non-psoriatic JIA.

Conclusion: In a large prospective JIA patient registry, we observed a nearly 3 fold increased risk of psoriasis after TNFi exposure. Increasing awareness of this unwanted side effect in pediatric community is important to ensure timely diagnosis and treatment. Authors include the CARRA Registry Investigators

Abstract Number: 0242

FiRst Line Options for Systemic JIA Treatment (FROST): Results from a Childhood Arthritis and Rheumatology Research Alliance (CARRA) Registry Consensus Treatment Plan Observational Study

Timothy Beukelman[1], George Tomlinson[2], Peter Nigrovic[3], Anne Dennos[4], Vincent Del Gaizo[5], Mary Ellen Riordan[6], Laura Schanberg[7], Shalini Mohan[8], Erin Pfeifer[9] and Yukiko Kimura[10], [1]University of Alabama at Birmingham, Birmingham, AL, [2]University of Toronto, Toronto, ON, Canada, [3]Boston Children's Hospital, Brookline, MA, [4]Duke University, Durham, NC, [5]Childhood Arthritis & Rheumatology Research Alliance (CARRA), Whitehouse Station, NJ, [6]Hackensack University Medical Center, Westwood, NJ, [7]Duke University Medical Center, Durham, NC, [8]Genentech, Inc., South San Francisco, CA, [9]Genentech, Inc., Englewood, CO, [10]Hackensack University Medical Center, New York, NY

SESSION INFORMATION
Session Date: Saturday, November 6, 2021
Session Title: Pediatric Rheumatology – Clinical Poster I: JIA (0241–0265)
Session Type: Poster Session A
Session Time: 8:30AM–10:30AM

Background/Purpose: The optimal initial treatment for systemic juvenile idiopathic arthritis (sJIA) is unclear. To further study the initial treatment of sJIA, the Childhood Arthritis and Rheumatology Research Alliance (CARRA) developed Consensus Treatment Plans (CTPs) to formalize and standardize current treatment practices into 4 CTPs: initial systemic glucocorticoid (GC) only; initial methotrexate (MTX) +/- GC; initial IL-1 inhibition (IL-1i) +/- GC; and initial IL-6 inhibition (IL-6i) +/- GC. FiRst Line Options for sJIA Treatment (FROST) was a prospective observational study designed to assess the effectiveness and safety of each of the 4 CTPs.

Methods: Patients with recent onset sJIA who were initiating therapy were considered for enrollment in FROST. Key inclusion criteria were fever for ≥2 weeks, arthritis for ≥ 10 days, and at least 1 of the following: evanescent rash, generalized lymphadenopathy, hepatomegaly, splenomegaly, or serositis. Treatment assignment was at the discretion of the treating physician and family. Actual medication usage was captured. The primary study outcome was clinical inactive disease (CID; Wallace ACR provisional criteria) and no current use of GC at 9 months. Selected secondary outcomes included CID irrespective of current GC use and cJADAS-10 without current fever. Because few patients were treated with the GC, MTX, and IL-6i arms, only results for biologic therapy (IL-1i/IL-6i) and non-biologic therapy (GC/MTX) are presented. Results were attributed to the intended CTP, irrespective of treatment actually received (intention to treat). No statistical comparisons were made between treatment arms. Imputation of missing data was not performed.

Table 1. Characteristics of Participants in FROST at study enrollment (N=73)

Characteristic	Overall (N=73)	IL-1i/IL-6i (N=63)	GC/MTX (N=10)
Age (median (IQR))	6.8 (4.1, 11.0)	7.0 (4.0, 11.3)	6.2 (5.6, 7.8)
Male (%)	60%	64%	40%
White Race (%)	63%	67%	40%
Days Since Symptom Onset (mean (sd))	46 (64)	49 (68)	28 (18)
Days Since Diagnosis (median (IQR))	2 (0, 8)	1 (0, 8)	5.5 (0.5, 7)
Physician Global Assessment (mean (sd))	6.0 (2.2)	6.3 (2.1)	4.7 (2.8)
Parent Global Assessment (mean (sd))	5.6 (3.3)	5.7 (3.3)	5.4 (3.6)
Number of Active Joints (mean (sd))	6.6 (7.6)	7.0 (8.0)	4.1 (4.4)
ESR (median (IQR))	73 (57, 97)	71 (54, 97)	88 (76, 90)
C-RP (median (IQR))	15.4 (7.5, 58.1)	16.4 (7.5, 58.1)	13.5 (7.3, 51.4)
Ferritin (median (IQR))	829 (249, 2603)	884 (290, 2652)	363 (81, 779)
Hemoglobin (median (IQR))	10.2 (9.1, 11.4)	10.7 (9.1, 11.5)	9.4 (9.0, 10.2)
CHAQ (mean (sd))	1.3 (1.0)	1.4 (1.0)	1.2 (0.9)
cJADAS-10 (median (IQR))	17.0 (10.5, 21.5)	17.5 (12.0, 21.0)	14.0 (8.0, 23.0)

Table 2. Clinical outcomes at 9 months following enrollment in FROST (N=57)

Outcome	Overall	IL-1i/IL-6i	GC/MTX
CID without current GC use (N (%))	30/53 (57%)	27/47 (57%)	3/6 (50%)
CID irrespective of current GC use (N (%))	32/53 (60%)	29/47 (62%)	3/6 (50%)
cJADAS-10 ≤ 1 + no fever without current GC use (N (%))	32/48 (67%)	29/43 (67%)	3/5 (60%)
cJADAS-10 ≤ 1 + no fever irrespective of current GC use (N (%))	34/48 (71%)	31/43 (72%)	3/5 (60%)
cJADAS-10 ≤ 2.5 + no fever without current GC use (N (%))	36/48 (75%)	33/43 (77%)	3/5 (60%)
cJADAS-10 ≤ 2.5 + no fever irrespective of current GC use (N (%))	38/48 (79%)	35/43 (81%)	3/5 (60%)
cJADAS-10 (mean (SD))	1.5 (3.3)	1.3 (3.0)	3.4 (5.6)
cJADAS-10 (median (IQR))	0 (0, 1.0)	0 (0, 1.0)	0 (0, 4.0)

Results: Overall, 73 patients (characteristics in Table 1) were enrolled in FROST (63 IL-1i/IL-6i and 10 GC/MTX). As intended, all patients in the IL-1i/IL-6i arm started biologic therapy. Initiation of biologic therapy ranged from 7 days prior to enrollment to 61 days after with 75% initiating within 1 day after enrollment. 8/59 (14%) patients who initiated IL-1i subsequently switched to IL-6i, and 0/4 (0%) patients switched from IL-6i to IL-1i. Among patients in the GC/MTX arm, 5 (50%) eventually initiated biologic therapy during the study period (time to initiation 10 to 101 days). The 9-month outcomes are shown in Table 2. 16 patients did not have a 9-month visit recorded. Overall, 57% of patients met the primary outcome of CID without current GC use, and 75% had cJADAS-10 score ≤ 2.5 with no fever and no current GC use. Overall, there were 16 CTCAE grade 3 or higher safety events observed (all in IL1i/IL-6i arm), including 6 episodes of MAS. One patient died of acute liver failure.

Conclusion: Treatment practices have changed tremendously since the CARRA sJIA CTPs were initially developed. Initial biologic therapy is now the most common treatment approach among sJIA patients enrolled in the CARRA Registry. A substantial proportion of patients not initially started on biologics subsequently started a biologic within

the first few months following diagnosis. Excellent treatment outcomes were observed in 57% to 75% of FROST patients overall, depending on the outcome definition.

SESSION INFORMATION

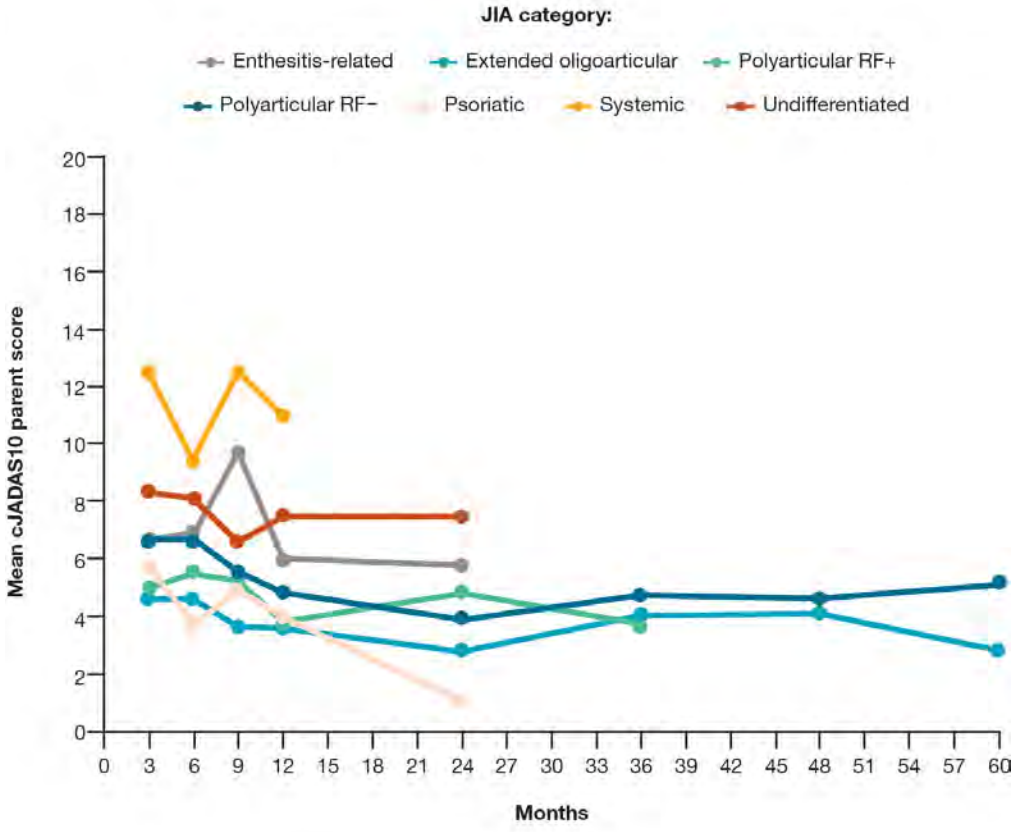
Session Date: Saturday, November 6, 2021
Session Title: Pediatric Rheumatology – Clinical Poster I: JIA (0241–0265)
Session Type: Poster Session A
Session Time: 8:30AM–10:30AM

Background/Purpose: Long-term treatment with abatacept, a selective T-cell co-stimulation modulator, is effective and well tolerated in patients with JIA.[1–4] The objective of this analysis was to provide real-world data on the longitudinal effectiveness of intravenous (IV) and subcutaneous (SC) abatacept in patients with JIA, classified by category, enrolled in the Pediatric Rheumatology Collaborative Study Group (PRCSG)/Paediatric Rheumatology INternational Trials Organisation (PRINTO) registry.

Methods: Following a standardized protocol and data collection process, clinical sites across 23 countries enrolled patients with JIA receiving/initiating IV or SC abatacept with a planned 10-year duration of follow-up. Treatment response was assessed at 3, 6, 9, 12, 24, 36, 48, and 60 months, and was evaluated in this analysis by clinical 10-joint Juvenile Arthritis Disease Activity Score (cJADAS10). The cJADAS10 used validated cut-offs for low disease activity (LDA; ≤3.8), inactive disease (ID; ≤ 1.0)[5], and remission (ID for ≥ 6 months). An as-observed analysis is presented.

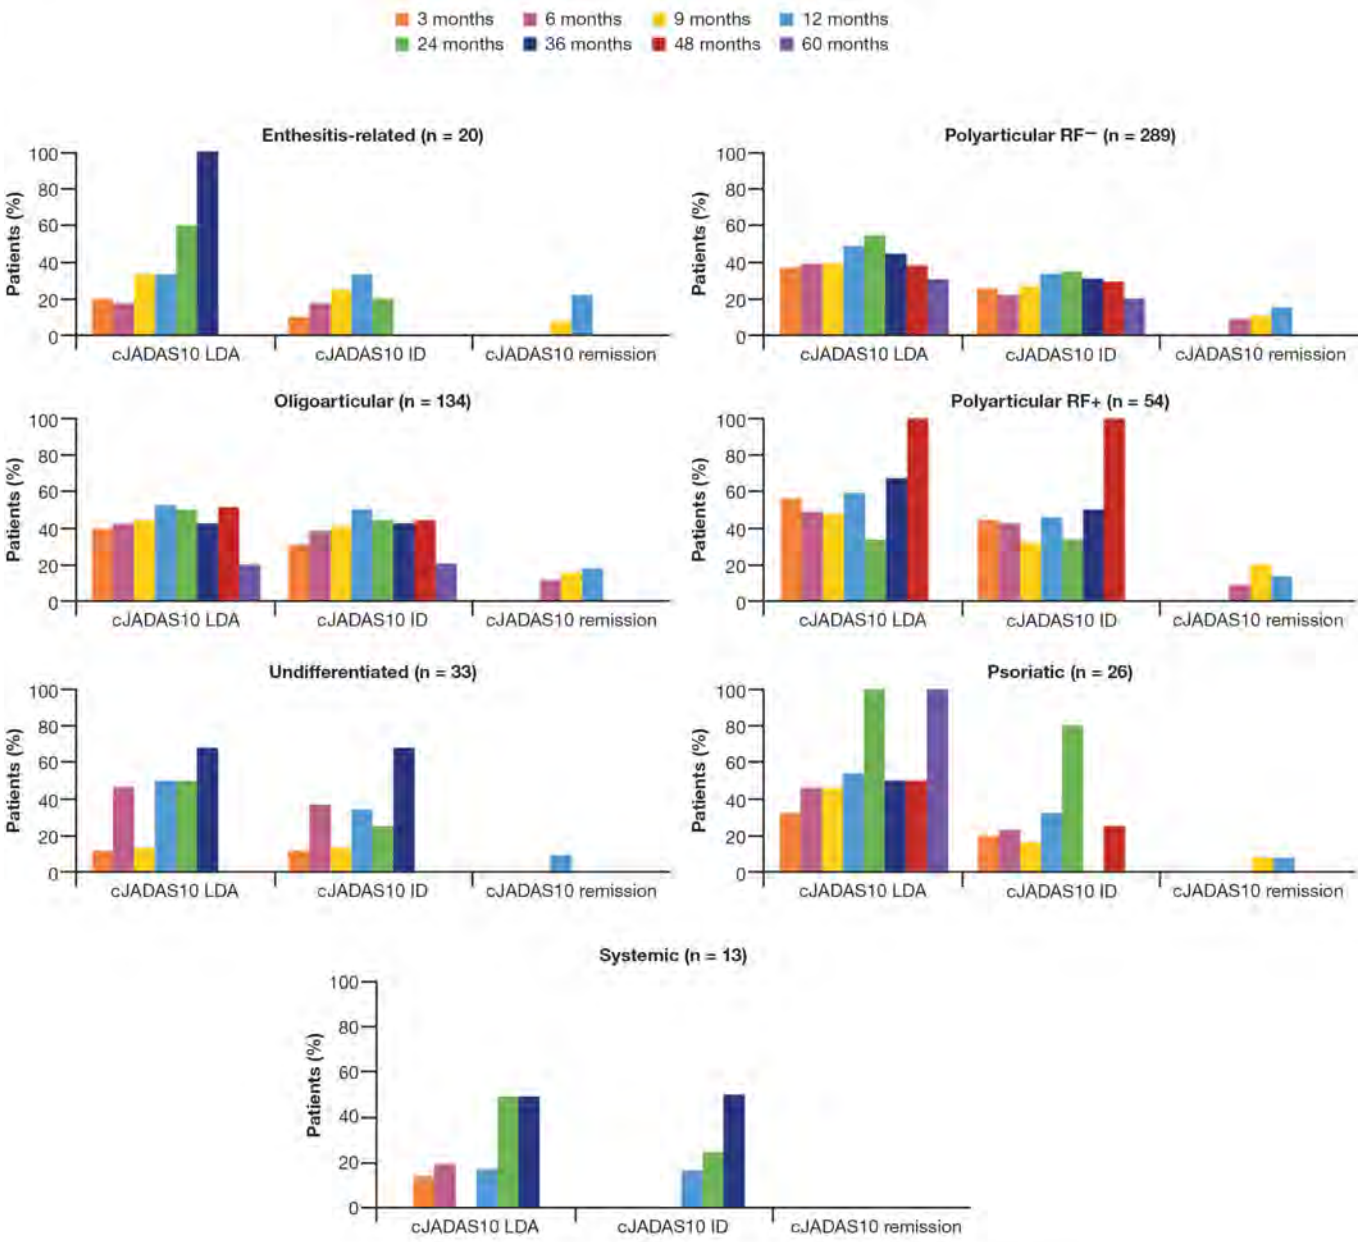
Results: As of March 31, 2020, 569 patients were enrolled in the PRCSG/PRINTO registry; 454 (79.8%) were female. Mean age at enrollment was 13.1 years, mean time since JIA diagnosis was 66.1 months, and mean abatacept treat-

Figure 1. Mean cJADAS10 score (parent) over time by JIA category (as-observed analysis; data for n ≥ 5 shown)



cJADAS10, clinical 10-joint Juvenile Arthritis Disease Activity Score.

Figure 2. Proportions of patients who achieved cJADAS10 (parent) LDA, cJADAS10 (parent) ID, and cJADAS10 (parent) remission over 60 months by JIA category (as-observed analysis)



Validated cJADAS cut-off scores for polyarticular JIA were used: LDA (≤ 3.8), ID (≤ 1.0), and remission (defined as ID for ≥ 6 months).
cJADAS10, clinical 10-joint Juvenile Arthritis Disease Activity Score; ID, inactive disease; LDA, low disease activity.

ment duration was 13.1 months. Half of the patients (n = 289; 50.8%) had polyarticular RF– JIA and a quarter (n = 134; 23.6%) had extended oligoarticular JIA; other enrolled patients had polyarticular RF+ (n = 54; 9.5%), psoriatic (n = 26; 4.6%), enthesitis-related (n = 20; 3.5%), undifferentiated (n = 33; 5.8%), and systemic (n = 13; 2.3%) JIA. The treatment response (patient and parent cJADAS10 score) by JIA category from baseline to month 60 is shown in Table 1. The change in mean cJADAS10 score over time by JIA category (Figure 1) demonstrates a general trend towards reduced score over time. The proportions of patients achieving cJADAS10 LDA and ID by JIA category were generally improved or sustained over time (Figure 2). The low patient numbers in some JIA categories at later time

points were mainly due to patients being lost to follow-up or not having reached those time points due to ongoing enrollment. At 60 months, 30% and 20% of patients with polyarticular RF– JIA (most prevalent category) had achieved and maintained cJADAS10 LDA and ID, respectively. Overall, 14.7% of patients achieved cJADAS10 remission by month 12; similar trends (7–22%) were seen in most JIA categories.

Conclusion: A proportion of patients in each JIA category achieved cJADAS10 LDA and ID. As sample size decreased over time in some JIA categories, these data should be interpreted with caution. Clinically important and sustained responses with abatacept, generally up to 36 and 48 months, were seen in all JIA categories.

SESSION INFORMATION

Session Date: Saturday, November 6, 2021

Session Title: Pediatric Rheumatology – Clinical Poster I: JIA (0241–0265)

Session Type: Poster Session A

Session Time: 8:30AM–10:30AM

Central experts' MRI findings
Inflammation
Inflammation in subchondral bone marrow?
Inflammation at site of an erosion cavity?
Inflammation in SIJ capsule?
Joint space enhancement on a contrast enhanced sequence?
Joint fluid?
Enthesitis outside the SI joint?
Structural lesions
Sclerosis?
Erosion?
Fat lesion?
Fat metaplasia in an erosion cavity?
Ankylosis?

Figure 1. Lesions reported by majority of central imaging team as present or absent during the juvenile spondyloarthritis experts' case review that included clinical factors plus central imaging team assessment.

Background/Purpose: As part of a larger study developing classification criteria for axial disease in children with spondyloarthritis (SpA), the objective of this project phase was to identify the strength of association of clinical and imaging features with expert classification.

Methods: We identified key clinical and imaging features to classify children with axial disease through an iterative process that included international Delphi exercise for item generation, systematic literature review, and an item reduction exercise. Case report forms and pelvic imaging (MRI and, if available, radiograph) of children with SpA and suspected axial disease were collected from 14 international centers. All imaging was rated by ≥2 of 7 radiologists from a central imaging team. The central imaging assessment consisted of presence or absence of the lesions shown in Figure 1. Fourteen juvenile SpA experts completed two global assessments using: (1) clinical features and local radiograph report (if available) and (2) clinical factors plus central imaging team assessment (MRI ± radiograph). Each SpA expert rated their confidence that the case was "juvenile SpA with axial disease" on a scale with anchors -3 (very unlikely) to +3 (very likely). High confidence in expert assessment was defined as ≤-2 or ≥+2. Each case was reviewed by 3 experts and consensus was defined as ≥2/3. Strength of association was measured using odds ratios.

Results: Eight domains were chosen for inclusion in the preliminary classification criteria (Table 1). 304 cases were assessed by the experts, of which 208 (68.4%) had findings typical of axial juvenile SpA by the central imaging team. Expert consensus was achieved on 132 (43%) and 202 (66%) of cases with clinical factors (± radiograph) or clinical factors plus central imaging assessment. With central imaging data, the presence of HLA-B27, pain most days, and morning stiffness in the hip/groin were most highly associated with rater confidence in presence of axial disease (Table 1). After the addition of central imaging data, several factors lost their significant association with rater confidence in presence of axial disease, including patient-reported lumbar spinal pain, sacroiliac pain on examination, and nighttime pain. Adding central imaging data affected the consensus assessment of high confidence in the presence/absence of axial disease for 55% (168/304) of cases. The addition of central imaging data facilitated achievement of a majority consensus on an additional 113 cases but lost consensus on 37; of the 113 cases gaining consensus, 43 and 70 reached consensus with high confidence that the case was or was not likely axial disease, respectively. For 18 (5.9%) cases, it changed the directionality of high confidence; 5 cases from axial disease present to axial disease absent and 13 cases from not axial disease to axial disease present.

Conclusion: Imaging significantly impacts the assessment of the presence/absence of axial disease in juvenile SpA and the association of several clinical domains with axial disease. In addition to imaging, HLA-B27 presence, pain

experienced most days, and stiffness in the hip and groin are significantly associated with high rater confidence in axial disease.

Table 1. Features associated with high rater confidence in axial disease with and without central imaging data. Cohort limited to cases where majority raters had high confidence the case was not likely to be axial disease or high confidence the case was likely to be axial disease.

		Clinical data +/- radiograph (N=132)	Clinical plus central imaging data (N=202)
	DOMAIN and Levels	OR (95%CI)	
1	PAIN LOCATION (in groin/hip/buttocks/sacrum/lumbar spine)		
	Lumbar spine pain (patient-reported)	8.82 (4.01-19.43)	1.09 (0.62-1.90)
	Sacroiliac pain with deep palpation/FABER/Mennell/Gaenslen maneuvers	3.19 (1.56-6.51)	1.71 (0.97-2.99)
	Groin/Hip pain (patient-reported)	2.8 (1.38-5.68)	2.83 (1.59-5.03)
	Sacral/Buttock pain (patient-reported)	7.95 (2.81-22.50)	3.49 (1.79-6.82)
2	PAIN CHRONICITY (in groin/hip/ buttocks/sacrum/lumbar spine)		
	Duration		
	≥6 but <12 weeks	0.95 (0.33-2.73)	1.81 (0.52-6.25)
	≥12 weeks	1.2 (0.46-3.13)	2.07 (0.67-6.40)
	Frequency		
	Most days (≥4 days per week)	3.71 (1.19-11.50)	5.5 (1.30-23.32)
	Present every day	2.55 (0.91-7.11)	4.08 (1.07-15.59)
3	PAIN PATTERN (in groin/hip/ buttocks/sacrum/lumbar spine)		
	Nighttime pain	3.17 (1.09-9.17)	1.42 (0.66-3.04)
	Insidious onset	4.71 (1.35-16.50)	3.11 (1.06-9.13)
	Moderate to total relief with nonsteroidal anti-inflammatory medications	4.95 (1.33-18.41)	3.07 (1.12-8.40)
	Improves with activity	13.87 (5.00-38.42)	3.57 (1.83-6.95)
4	STIFFNESS DURATION (in groin/hip/buttocks/sacrum/lumbar spine)		
	≥15 min to <30mins	5.75 (1.00-32.95)	1.36 (0.41-4.47)
	≥30 mins	2.63 (0.53-13.10)	2.07 (0.66-6.54)
5	STIFFNESS PATTERN (in groin/hip/buttocks/sacrum/lumbar spine)		
	Improves with rest	0.47 (0.16-1.41)	1.65 (1.02-2.69)
	Nighttime stiffness	4.71 (0.51-43.36)	2 (0.48-8.41)
	Improves with activity	8.44 (1.50-47.48)	5.09 (1.39-18.60)
	Morning stiffness in buttocks/sacrum/lumbar spine	40.44 (14.52-112.66)	2.46 (1.36-4.46)
	Morning stiffness in hip/groin	6.41 (2.74-14.99)	4.51 (2.24-9.09)

SESSION INFORMATION

Session Date: Saturday, November 6, 2021

Session Title: Pediatric Rheumatology – Clinical Poster I: JIA (0241–0265)

Session Type: Poster Session A

Session Time: 8:30AM–10:30AM

Table 1. Baseline characteristics for the overall JIA population

Characteristic	Patients, N	Value
Age at enrollment, years	569	13.6 (2.9–20.1)
Sex, n (%)		
Female	569	454 (79.8)
Male		115 (20.2)
Months since JIA diagnosis	569	53.7 (0.8–198.5)
Time on abatacept treatment at baseline, months, mean (median)	569	13.1 (6.5)
Physician global disease activity, VAS (0–100)	569	1.0 (0.0–9.5)
JAMAR functionality scale		
Patient	457	3.0 (0.0–36.0)
Parent	482	3.0 (0.0–40.0)
Number of active joints	569	1.0 (0.0–42.0)
Number of joints with LOM	569	1.0 (0.0–65.0)

Data are median (1st–3rd quartiles) unless otherwise stated.

JAMAR, Juvenile Arthritis Multidimensional Assessment Report; LOM, limited range of motion; VAS, visual analog scale.

Table 2. Safety summary for the overall JIA registry population for the total 5-year follow-up period

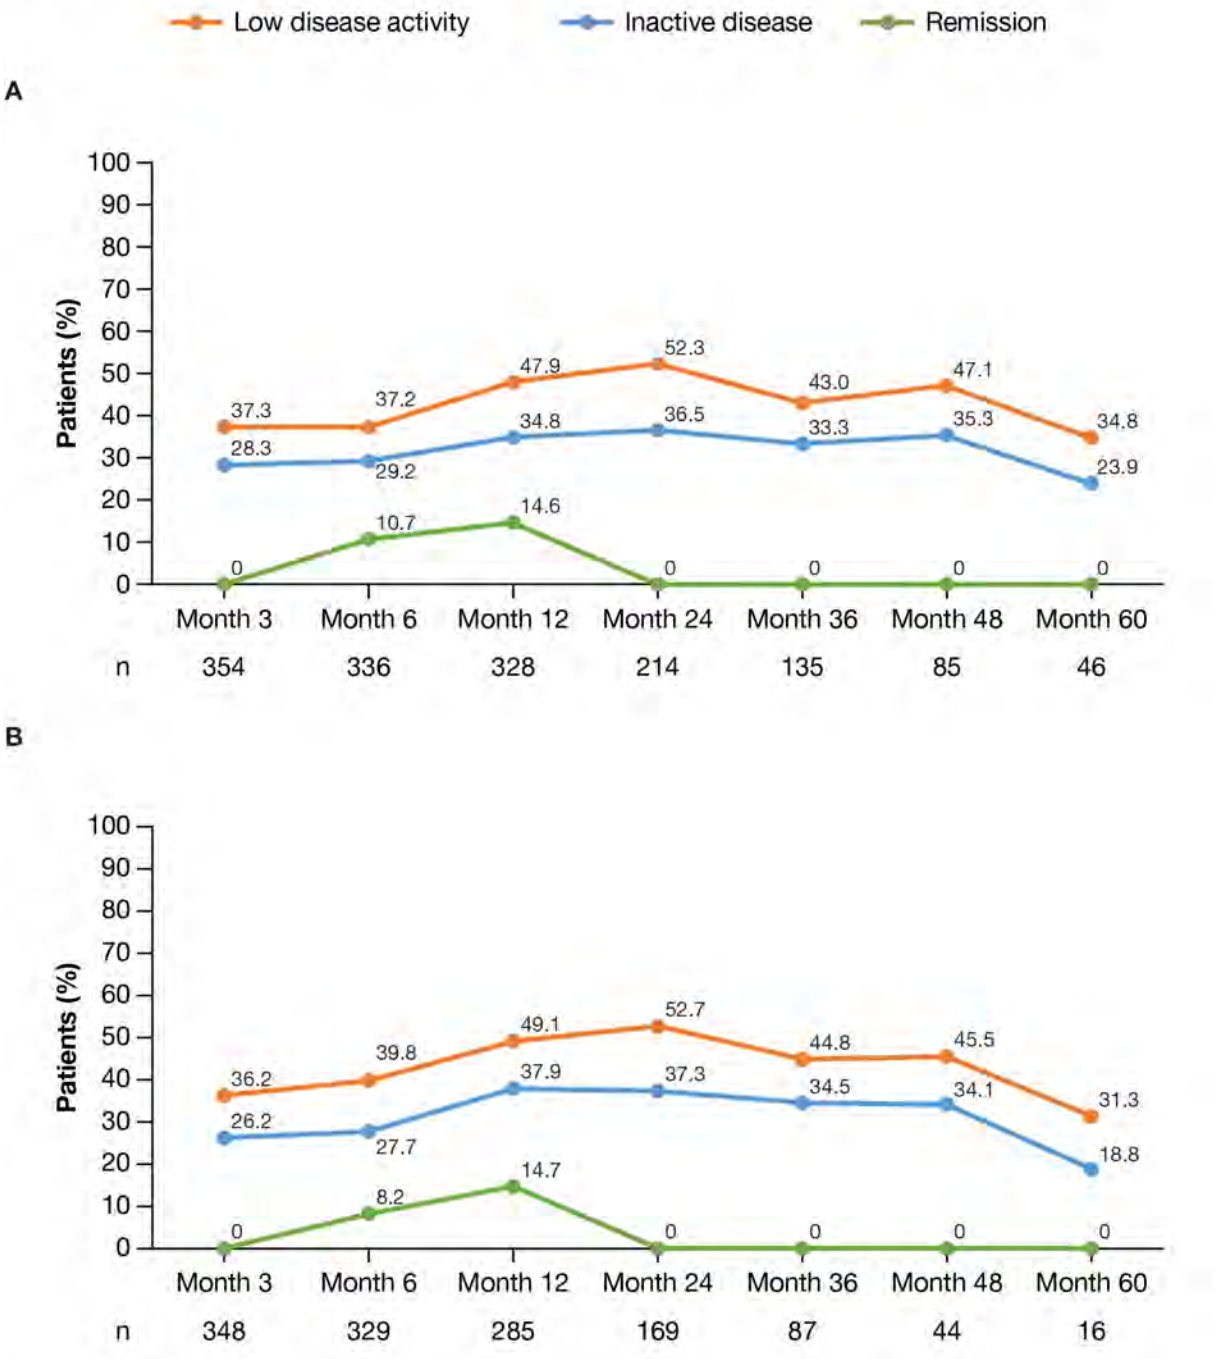
Outcome	Patients, n (%) (N = 569)	Incidence rate[a] (95% CI)
Patients with ≥ 1 AE	95 (16.7)	7.82 (6.33–9.56)
Patients with ≥ 1 SAE	67 (11.8)	5.52 (4.27–7.01)
Patients with ≥ 1 treatment-related SAE	16 (2.8)	1.32 (0.75–2.14)
Patients with ≥ 1 AE causing permanent discontinuation	9 (1.6)	0.74 (0.34–1.41)
Patients with any AE resulting in death[b]	1 (0.2)	0.08 (0.00–0.46)
Patients with ≥ 1 event of special interest	44 (7.7)	3.62 (2.63–4.86)
Serious/targeted infections	18 (3.2)	1.48 (0.88–2.34)
Other autoimmune diseases	8 (1.4)	0.66 (0.28–1.30)
Skin and subcutaneous tissue disorders	8 (1.4)	0.66 (0.28–1.30)
Malignancy	1 (0.2)	0.08 (0.00–0.46)
Antibody testing	**Tests, n (%) (N = 202)**	
Anti-abatacept antibody positive[c]	12 (5.9)	N/A

[a]Incidence rate per 100 patient-years per 569 subjects with 1214.61 person-years of follow up; [b]Due to a cardiovascular event related to pre-existing disease and assessed as unrelated to abatacept treatment; [c]n = 11 specifically for CTLA-4 and possibly for immunoglobulin, and n = 1 specifically for immunoglobulin and/or junction region.

AE, adverse event; CTLA-4, cytotoxic T-lymphocyte associated antigen 4; N/A, not available; SAE, serious AE.

Background/Purpose: Abatacept (ABA) is well tolerated and effective in patients with JIA.[1] The Pediatric Rheumatology Collaborative Study Group (PRCSG)/ Paediatric Rheumatology INternational Trials Organisation (PRINTO) registry monitors long-term safety and efficacy of ABA for JIA treatment.[2] The objective of this analysis was to assess

Figure 1. Proportions of patients achieving cJADAS10 low disease activity, inactive disease, and remission as reported by (A) patients and (B) parents



Remission was defined as inactive disease for ≥ 6 months. Decreasing n over time is due to ongoing enrollment (patients may not have reached later time points at data cut) and loss to follow-up.
cJADAS10, clinical 10-joint Juvenile Arthritis Disease Activity Score.

long-term (5-year) safety and efficacy of ABA in patients with JIA in a real-world setting using data from the PRCSG/PRINTO registry.

Methods: All patients with JIA receiving IV/SC ABA enrolled in the PRCSG/PRINTO registry with ≥ 5 years follow-up were included. Safety and efficacy were assessed at 3, 6, 12, 24, 36, 48, and 60 months. Safety was evaluated by recording serious adverse events (SAEs), events of special interest (ESI; incidence rate [IR]/100 patient-years (py) [95% CI]) and anti-ABA antibody levels. Efficacy outcomes: physician global assessment of disease activity, physician assessment of JIA severity, Juvenile Arthritis Multidimensional Assessment Report (JAMAR) functionality score, overall well-being score, number of active joints, joints with limited range of motion (LOM), clinical 10-joint Juvenile Arthritis Disease Activity Score (cJADAS10), and JIA-ACR30, 50, 70, and 90. cJADAS10 used validated cut-offs for low disease activity (LDA), inactive disease (ID), and remission (ID for ≥ 6 months). As-observed analysis is presented.

Results: Data for 569 patients (1214.61 py of follow-up) were available up to Mar 31, 2020. Baseline characteristics are summarized in Table 1. Over 60 months, IRs/100 py (95% CIs) of patients with ≥ 1 SAE, treatment-related SAE, or ESI were 5.5 (4.3–7.0), 1.3 (0.8–2.1), and 3.6 (2.6–4.9), respectively (Table 2). Overall, 5.9% (12/202) anti-ABA antibody tests were positive. From months 3–60, median physician global disease activity, number of active joints, and joints with LOM were unchanged. The proportion of patients with physician-assessed mild JIA increased from 86% to 96%; corresponding proportions of patients with moderate or severe JIA decreased from 11% to 4% and from 3% to 0%, respectively. Median JAMAR functional scores were 2.0 (patient) and 3.0 (parent) at month 3, and 1.0 each at month 60; a similar pattern was observed for overall well-being scores. Median cJADAS10 scores were 4.0 (patient) and 4.5 (parent) at baseline, and 4.3 (patient) and 3.3 (parent) at month 60. As early as month 3, cJADAS10 LDA and ID were achieved by 37% and 28% of patients, respectively, and sustained over time (Figure 1).

Conclusion: Overall, in patients with JIA, abatacept was well tolerated with no new safety signals. Treatment with abatacept resulted in well-controlled disease activity, with approximately 30% of patients achieving cJADAS10 ID by month 3, which was sustained over 2 years. For the majority of patients, initial improvement on abatacept occurred prior to registry enrollment; therefore the ability to maintain response with ongoing treatment is reflected. These real-world data support the safety and efficacy profile of abatacept as seen in clinical trials.

SESSION INFORMATION

Session Date: Saturday, November 6, 2021

Session Title: Pediatric Rheumatology – Clinical Poster I: JIA (0241–0265)

Session Type: Poster Session A

Session Time: 8:30AM–10:30AM

Background/Purpose: Systemic Juvenile Idiopathic Arthritis (SJIA) is the most acute and severe form of JIA. Despite the substantial evidence supporting the effectiveness of biologic drugs in the treatment of SJIA, the clinical response has not been largely investigated in Turkey. Macrophage activation syndrome (MAS) is a complication that often occurs during SJIA and associated with mortality.

TURSIS, the 24-month, multi-center, retrospective, non-interventional study aimed to assess the clinical response to biological treatments for SJIA and provide real life data to improve disease outcomes.

Methods: This was a retrospective, multi-center study in patients with SJIA for whom a biological treatment had been initiated. This real-life study is based on secondary data collection from medical records of patients evaluated at the 8 Pediatric Rheumathology Clinics in Turkey (Mar 2013-Dec 2018). Patients' characteristics, clinical inactivity, safety related variables, and ACR70 response were assessed.

Results: The study population (147 patients) consisted of 76 females (51.7%).

During the 2-year study period, 51.0% of patients (n=75) remained on the same biologic. 62 patients (42.2%) had experienced 1 switch in biological drug, and 10 patients (6.8%) switched twice.

32 patients (22.4%) had experienced a MAS attack between the diagnosis of SJIA and baseline (median 5 months). Most of the patients (81.3%) had experienced a single MAS attack; the highest number of MAS attacks per patient was 4. The frequent clinical signs of MAS were persistent fever (93.8%) and rash (81.3%). The frequencies of other clinical findings such as lung and CNS involvement, seizures and encephalopathy were lower during MAS attacks. Available data about the laboratory findings associated with MAS (n=32) revealed that hyperferritinemia was the most observed finding (96.9%) followed by a decrease in Hb level (84.4%) and an increase in LDH level (71.9%). Increased liver function tests (65.6%), hypofibrinogenemia (56.3%), hypoalbuminemia (62.5%), decrease in ESR (59.4%) and hemophagocytosis (53.1%) were the other laboratory findings observed in more than half of the patients with MAS.

Nine patients experienced MAS after baseline during study period. MAS attack was not observed in any patient 12 months after the initiation of biological therapy.

At Month 3, 73.5% of patients were clinically inactive. ACR30, 50 and 70 responses could be achieved in 95.5%, 50% and 45.5% of patients, respectively.

Conclusion: This study described the patient characteristics and the impact of biological drugs on disease activity in a real-life study of patients with SJIA in Turkey. Overall biological therapies resulted in improvement in clinical activity early after initiation. There was a decrease in the frequency of MAS after initiation of biological drugs compared with time to initiation of biologic therapy. Biological drugs were generally well tolerated. Further studies can reveal the differences between the biological drugs on disease outcomes and guide treatment decisions, thereby improving patient management.

SESSION INFORMATION
Session Date: Saturday, November 6, 2021
Session Title: Pediatric Rheumatology – Clinical Poster I: JIA (0241–0265)
Session Type: Poster Session A
Session Time: 8:30AM–10:30AM

Background/Purpose: The ongoing phase 4 Pediatric Rheumatology Collaborative Study Group (PRCSG)/Paediatric Rheumatology INternational Trials Organisation (PRINTO) registry was designed to assess the long-term (up to 10 years) safety and efficacy of abatacept in pediatric patients with all JIA subtypes in a real-world setting.[1] The objective of this analysis was to assess the real-world effectiveness of intravenous and subcutaneous abatacept over 3 years in patients with JIA who initiated treatment with abatacept within 1 month of enrollment in the PRCSG/PRINTO registry.

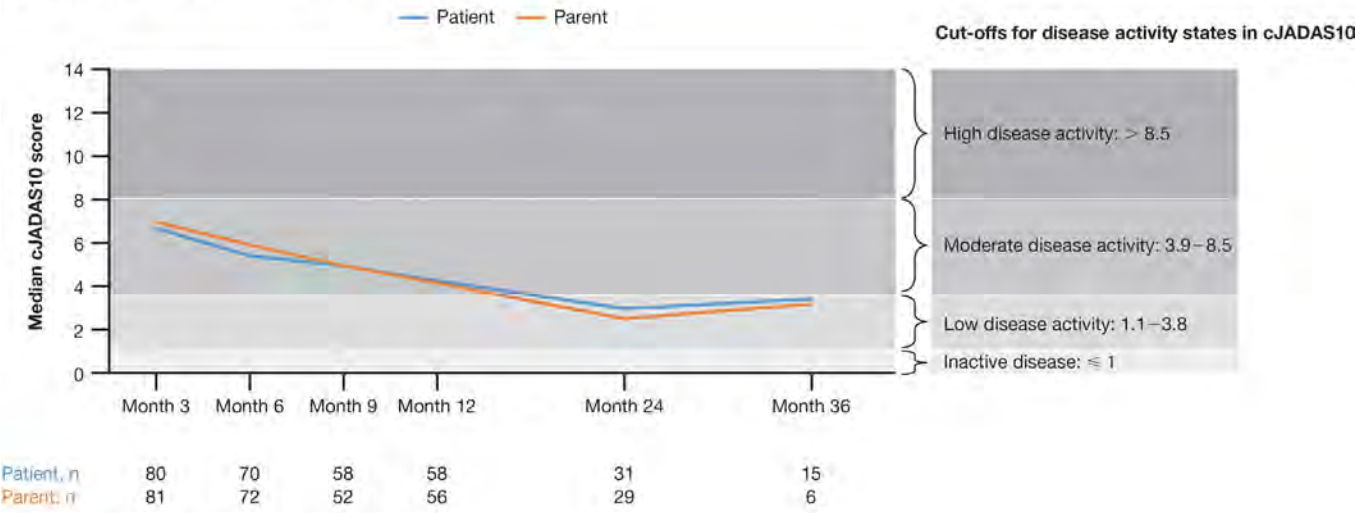
Table 1. Effectiveness outcomes over time in patients with JIA who initiated abatacept within 1 month of enrollment in the PRCSG/PRINTO registry

Outcome	Baseline (N = 134)	Month 3 (N = 134)	Month 6 (N = 134)	Month 9 (N = 134)	Month 12 (N = 134)	Month 24 (N = 134)	Month 36 (N = 134)
Physician global disease activity	3.8 (3.8)	n = 104 2.4 (2.0)	n = 98 2.4 (2.0)	n = 74 1.8 (1.0)	n = 74 1.8 (1.0)	n = 44 1.2 (0.3)	n = 18 1.6 (0.8)
Overall well-being score	4.5 (5.0)	n = 81 3.3 (3.0)	n = 72 3.2 (2.5)	n = 52 2.8 (2.0)	n = 56 2.6 (2.0)	n = 29 2.3 (2.0)	n = 6 1.7 (1.5)
Number of active joints	6.1 (3.0)	n = 104 3.3 (1.0)	n = 98 2.9 (1.0)	n = 74 1.8 (0.0)	n = 74 1.5 (0.0)	n = 44 1.8 (0.0)	n = 18 1.8 (0.0)
Number of joints with limitation in range of motion	6.3 (2.0)	n = 104 3.2 (1.0)	n = 98 2.9 (1.0)	n = 74 2.7 (1.0)	n = 74 1.9 (1.0)	n = 44 3.0 (0.0)	n = 18 3.5 (1.0)
JIA-ACR30, n (%)	N/A	n = 128 39 (30.5)	n = 120 44 (36.7)	n = 110 40 (36.4)	n = 105 45 (42.9)	n = 85 26 (30.6)	n = 71 8 (11.3)
JIA-ACR50, n (%)	N/A	n = 128 32 (25.0)	n = 120 36 (30.0)	n = 110 31 (28.2)	n = 105 42 (40.0)	n = 85 23 (27.1)	n = 71 8 (11.3)
JIA-ACR70, n (%)	N/A	n = 128 18 (14.1)	n = 120 24 (20.0)	n = 110 20 (18.2)	n = 105 28 (26.7)	n = 85 17 (20.0)	n = 71 7 (9.9)
JIA-ACR90, n (%)	N/A	n = 128 8 (6.3)	n = 120 15 (12.5)	n = 110 9 (8.2)	n = 105 15 (14.3)	n = 85 15 (17.6)	n = 71 5 (7.0)

Data are mean (median), unless otherwise stated. As-observed analysis. Outcomes reported by parents.

JIA-ACR30/50/70/90, 30/50/70/90% improvement in JIA-ACR criteria; N/A, not applicable; PRCSG, Pediatric Rheumatology Collaborative Study Group; PRINTO, Paediatric Rheumatology INternational Trials Organisation.

Figure 1. Median cJADAS10 endpoints over time



cJADAS10, clinical 10-joint Juvenile Arthritis Disease Activity Score.

Methods: Using a standardized protocol and data collection process, clinical sites enrolled patients with JIA receiving/starting abatacept. For the current analysis, all patients with JIA who initiated abatacept within 1 month of enrollment in the PRCSG/PRINTO registry were included. Effectiveness was assessed at baseline and at 3, 6, 9, 12, 24, and 36 months. Outcomes include physician global assessment of disease activity, overall well-being score, number of active joints and joints with limited range of motion, the clinical 10-joint Juvenile Arthritis Disease Activity Score (cJADAS10), and JIA-ACR30, 50, 70, and 90. The cJADAS10 used validated cut-offs for low disease activity (LDA; ≤ 3.8), inactive disease (ID; ≤ 1.0), and remission (ID for ≥ 6 months). An as-observed analysis is presented.

Results: As of March 31, 2020, 134 patients who initiated abatacept within 1 month of enrollment in the PRCSG/PRINTO registry were included in this analysis. Of these, 110 (82.1%) were female, the baseline mean (median) age

at enrollment was 12.8 (13.1) years, the time since JIA diagnosis was 60.2 (45.6) months, and the time on abatacept treatment at baseline was 0.28 (0.03) months. Median cJADAS10 scores decreased from month 3 to month 36 and the proportions of patients achieving cJADAS10 LDA and cJADAS10 ID increased over time (**Figure 1**). JIA-ACR 30, 50, 70, and 90 responses were seen as early as month 3 and were sustained over time to month 24; the percentage of patients achieving these responses at month 36 was influenced by the relatively low number of patients (due to ongoing enrollment and loss to follow-up) available for the analysis (**Table 1**). In addition, physician global assessment of disease activity and number of active joints decreased over time (**Table 1**).

Conclusion: In patients with JIA who initiated abatacept within 1 month of joining the PRCSG/PRINTO registry, there were rapid, clinically relevant responses, such as improvement in cJADAS10 scores, number of active joints, number of joints with a limited range of motion and overall well-being. These improvements were sustained over 24 months.

SESSION INFORMATION

Session Date: Saturday, November 6, 2021

Session Title: Pediatric Rheumatology – Clinical Poster I: JIA (0241–0265)

Session Type: Poster Session A

Session Time: 8:30AM–10:30AM

Background/Purpose: Systemic-onset juvenile idiopathic arthritis (sJIA) is a pediatric autoinflammatory condition, known for significant variability between patients in its severity and long-term outcomes. The classification of disease course into monophasic, polyphasic (intermittent) and persistent disease has been commonly used, with polyphasic

disease usually recognized in a small portion of patients[1,2] . However, this proportion was established according to data mostly collected before the biologic IL-1 and IL-6 inhibitors were available. It has been recently suggested [3,4] that these medications, now the mainstay of treatment in sJIA, can potentially alter the long-term course of the disease, especially with earlier use.

Methods: A multi-center, retrospective chart review was conducted from 3 hospitals in Israel and 2 in the US, involving patients diagnosed with sJIA between 1998-2019, with a minimum follow-up of 1 year. Disease course classification was done according to previously released definitions.[1] Remission was defined as inactive disease (no active signs or symptoms and no elevation of inflammatory markers) while not receiving any medications for a period of at least 3 months. Polyphasic disease was defined as at least one disease relapse after a period of drug-free remission. Persistent disease was defined as at least 2 years of disease (either active or in remission on immunosuppressive medication) with no drug-free remissions. Monophasic disease was defined as a single episode lasting less than 2 years.

Results: 85 patients met the inclusion criteria (mean follow up 3.6 years, SD ± 2.8). 54 of the patients (63.5%) were female; median age at diagnosis was 5.8 years (IQR = 5.9). 67 (78.9%) were diagnosed in 2012 or later, when IL-1 and IL-6 inhibitors became widely used. 56 (65.9%) were treated with a biologic drug during their disease course. The rates of monophasic, polyphasic and persistent disease were 43.5%, 43.5% and 12.9%, respectively, with a higher-than-expected rate of polyphasic disease and a lower rate of persistent disease than previously published. [1,2,5]

Conclusion: In the age of IL-1 and IL-6 inhibitors, polyphasic sJIA disease course may be more common than previously described, suggesting that cytokine blockers may potentially alter the natural history of this disease.

Session Title: Pediatric Rheumatology – Clinical Poster I: JIA (0241–0265)

Session Type: Poster Session A

Session Time: 8:30AM–10:30AM

Background/Purpose: CLIPPER2 was an 8-year, open-label extension of the phase 3b, multicenter, 2-year CLIPPER study of the safety and efficacy of etanercept (ETN) in the treatment of patients (pts) with juvenile idiopathic arthritis (JIA) categorized as extended oligoarticular arthritis (eoJIA), enthesitis-related arthritis (ERA), or psoriatic arthritis (PsA). The objective of this analysis was to describe the safety of ETN in this population after 10-years of follow up.

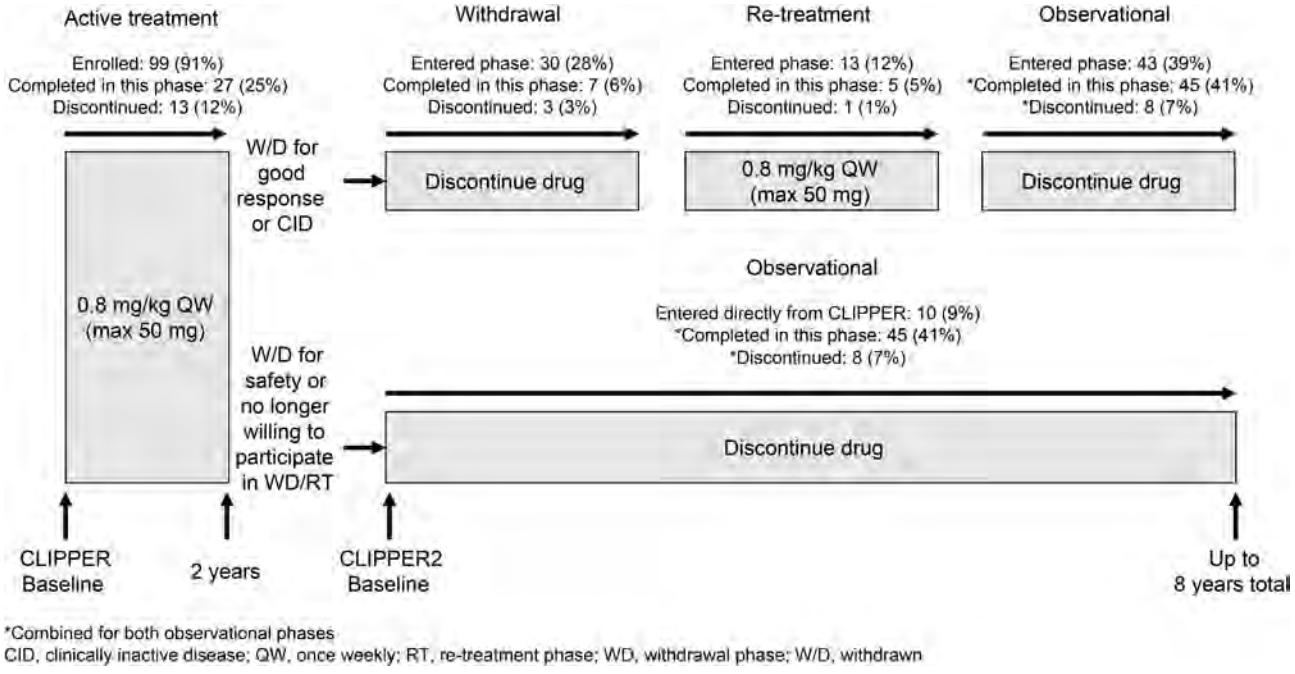

Figure 1. Study Design and Subject Disposition.

Table. ETN Safety Summary (from CLIPPER BL to m120), N (EP100PY) (FAS)*

	eoJIA (EXP = 313.667 PY)	ERA (EXP = 206.971 PY)	PsA (EXP = 162.576 PY)	Total (EXP = 683.214 PY)
TEAEs†	269 (85.76)	176 (85.04)	114 (70.12)	559 (81.82)
Serious TEAEs†	16 (5.10)	17 (8.21)	7 (4.31)	40 (5.85)
TE ISRs	23 (7.33)	29 (14.01)	12 (7.38)	64 (9.37)
TE infections	418 (133.26)	99 (47.83)	155 (95.34)	672 (98.36)
Serious TE infections‡	5 (1.59)	4 (1.93)	5 (3.08)	14 (2.05)
Opportunistic infections§	0	1 (0.48)	1 (0.62)	2 (0.29)
TEAEs causing withdrawal†	7 (2.23)	9 (4.35)	2 (1.23)	18 (2.63)
TE infections causing withdrawal	2 (0.64)	0	1 (0.62)	3 (0.44)

*While on active ETN treatment or within 30 days of last dose

†Excluding infections/ISRs

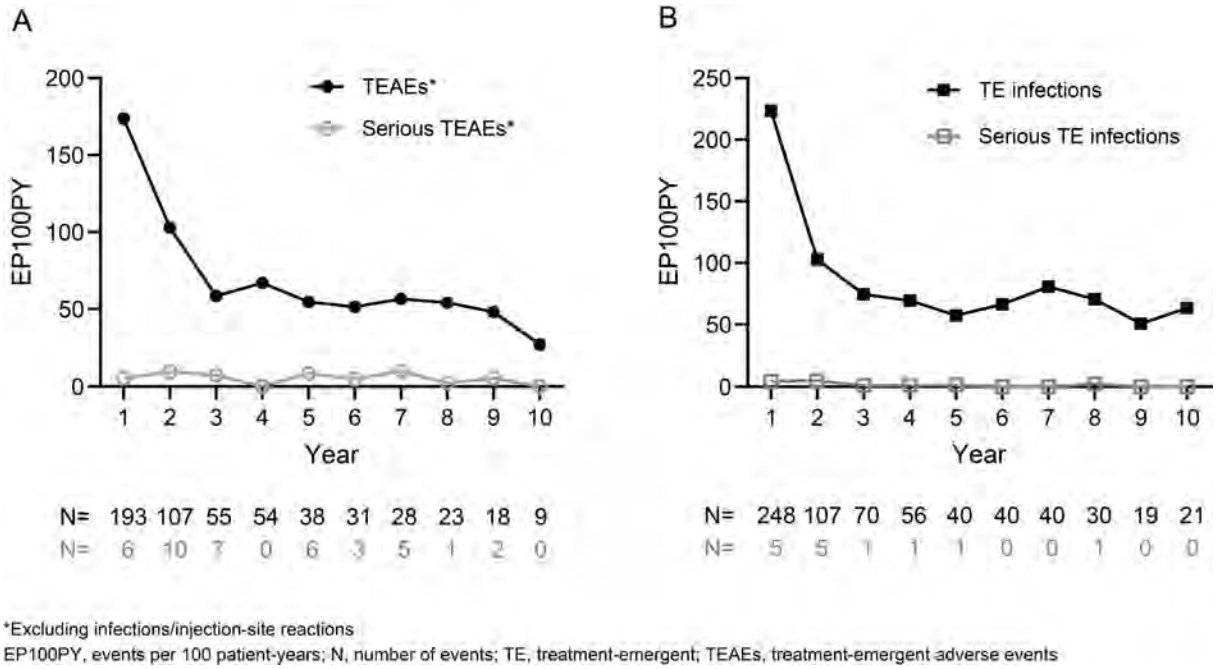
‡Gastroenteritis, 2 (0.29); acute tonsillitis, anal abscess, bronchopneumonia, gastrointestinal infection, helicobacter gastritis, influenza, peritonitis, pharyngitis, pyelocystitis, sepsis, urinary tract infection, viral infection, all 1 (0.15)

§Both herpes zoster

BL, baseline; eoJIA, extended oligoarticular juvenile idiopathic arthritis; EP100PY, events per 100 patient-years; ERA, enthesitis-related arthritis; ETN, etanercept; EXP, exposure to ETN; FAS, full analysis set; ISR, injection-site reaction; m, month; N, number of events; PsA, psoriatic arthritis; PY, patient years; TE, treatment-emergent

Methods: Pts (n=127) with eoJIA (2-17 years), ERA, or PsA (each 12-17 years) who received ≥1 ETN dose (0.8 mg/kg once weekly [max, 50 mg]) in CLIPPER were eligible to enter CLIPPER2. The primary outcome measure was the occurrence of malignancy. Long-term safety was assessed as the total incidence of events from CLIPPER baseline (BL) to month (m) 120, frequency of events per 100 patient-years (EP100PY), and frequency of events in each study year.

Results: A total of 109/127 (86%) pts entered CLIPPER2; 99 (91%) continued in the active treatment period. At m120, 84/109 (77%) pts had completed the study; 27 (25%) while actively taking ETN, 7 (6%) had withdrawn from treatment due to low/inactive disease; 5 (5%) had re-started ETN following an earlier withdrawal from treatment; and 45 (41%) had stopped ETN (but remained under observation) (Figure 1); 25/109 (23%) pts permanently discontinued from the CLIPPER2 study.



*Excluding infections/injection-site reactions
EP100PY, events per 100 patient-years; N, number of events; TE, treatment-emergent; TEAEs, treatment-emergent adverse events

Figure 2. Incidence of TEAEs (A) and TE Infections (B) in CLIPPER/CLIPPER2 by Study Year, N (EP100PY).

In CLIPPER/CLIPPER2, 1 case of malignancy (Hodgkin's disease) was reported (1 pt with eoJIA in year 3). There was 1 case of uveitis (1 pt with eoJIA in year 8) and 3 of Crohn's disease (2 pts with ERA, year 1/year 6; 1 pt with eoJIA, year 5). There were 2 cases of opportunistic infections (both herpes zoster), and no deaths. Overall, there were 559 (81.82 EP100PY) treatment-emergent adverse events (TEAEs) excluding infections and injection-site reactions (ISRs). The overall rate of TE serious infections was low (N=14; 2.05 EP100PY) (Table), with the most common TE serious infection being gastroenteritis (N=2; 0.29 EP100PY). The most frequently reported TEAEs (N [EP100PY]) were headache (28 [4.10]), arthralgia (24 [3.51]), pyrexia (21 [3.07]), diarrhea (14 [2.05]), and leukopenia (12 [1.76]). Overall, 39 patients reported serious TEAEs (excluding infections/ISRs).

The number and frequency (N [EP100PY]) of TEAEs (excluding infections/ISRs) decreased over the 10-year study period from 193 [173.81] in year 1 to 9 [27.15] in year 10. The number and frequency of TE infections and serious TE infections also decreased over the 10-year study period. There was no clear trend of a decrease over time for the incidence of serious TEAEs (Figure 2).

Conclusion: ETN treatment to m120 was well tolerated in this patient population and consistent with the known safety profile. Frequency of TEAEs and TE infections decreased over time. Over 10 years there was I reported event of malignancy and the overall rate of TE serious infections was low.

Trial Registration: NCT00962741/NCT01421069

Abstract Number: 0250

Is There a Need for a New Classification Criteria in Juvenile Spondyloarthritis?

Maria Martha Katsicas[1], Maria Cecilia Bertinotti[2] and Maria Giselle Villarreal[2], [1]Hospital de Pediatria J.P Garrahan, Buenos Aires, Argentina, [2]Garrahan, Buenos Aires, Argentina

SESSION INFORMATION
Session Date: Saturday, November 6, 2021
Session Title: Pediatric Rheumatology – Clinical Poster I: JIA (0241–0265)
Session Type: Poster Session A
Session Time: 8:30AM–10:30AM

Background/Purpose: Juvenile SpA (JSpA) involve enthesitis related arthritis (ERA), juvenile psoriatic arthritis and undifferentiated arthritis (UA) according to the ILAR criteria. Two different patterns have been found: axial and peripheral. The pediatric form differs from that in adults by a predominant peripheral involvement. The evolution to ankylosis has been reported in one third of all cases after several years. The proposed PRINTO classification criteria for JIA introduced a new approach changing ERA to enthesitis/spondylitis-related JIA (ESRA) resulting in a definition harmonized with that for adults. The purposes were to assess the sensibility and specificity of the provisional new PRINTO JIA classification criteria for ESRA and to compare its performance to others adult´s classification criteria. To identify predictive variables for ankylosis progression.

Methods: Consecutive patients with JSpA (defined as ERA or UA according to ILAR) followed in our center were included. Randomly selected patients with oligoarthritis (23), polyarthritis RF negative (22) and systemic (20) served as controls. Variables recorded included: arthritis, enthesitis, tarsitis, inflammatory back pain (IBP), SI- joint tenderness, presence of HLA-B27 antigen, acute anterior uveitis, history of SpA in a first-degree relative. Imaging on SI-joints (SI joints) on X-ray and/or MRI. Classification criteria for adults were ASAS and Modified New York (NY). Patients with ankylosing progression fulfilled NY criteria. Summary statistics: sensitivity, specificity, positive predictive value (PPV), negative predictive value (NVP), positive Likelihood ratio (+LR) and negative Likelihood ratio (-LR). Univariate and multivariate logistic regression for predictors variables.

Results: 112 patients with JSpA (89 ERA, 23 UA) were included (M: 94), median age at onset: 10 (1-15) years, disease duration at time of first visit 8.5 (1-48) months, follow-up 7 (1-15) years. Controls: 65 JIA (M: 27). At first visit showed: 107 (95%) arthritis, 69 (62%) elevated CRP, 54 (48%) limitation of lumbar spine motion, 56 (50%) HLA-B27, 48(43%) enthesitis, 44 (40%) tarsitis, 42 (37%) IBP, 31 (30%) SI- joint tenderness, 30 (27%) good response to NSAIDS, 26 (23%) positive family history, 12 (10%) dactylitis, 7(6%) uveitis,7(6%) diarrhea, 5(5 %) infectious previous, 2(2%) urethritis, 2(2%) IBD, 2 (2%) buttock pain. Imaging for sacroiliitis: 30 (27%) on X-Ray (23 grade 2 bilateral and 7 grade 3), 26 (23%) on MRI. At first visit (112 patients): 95 (87%) fulfilled ESRA criteria. Disease course (102 patients): 97 (95%). Patients who meet NY criteria: 64 (63%). Table 1 shows the accuracy for classification criteria. The unique predictor variable for ankylosing progression was lumbar limitation (p=0.02). Table 2 shows the accuracy of the selected variables at onset of the disease for predicting the risk of developing JAS.

Conclusion: The new proposed PRINTO criteria was a more sensitive classification criteria than adults' criteria. Lumbar limitation was a predictor variable for ankylosing. The accuracy of each selected variable at onset suggests the probability of a higher suspected index for JSpA.

First Visit	Sensitivity	Specificity	PPV	NPV	+LR	-LR
PRINTO (ESRA)	85%	86%	91%	76%	6.12	0.17
Global ASAS	72%	86%	90%	64%	5.22	0.32
Peripheral ASAS	70%	86%	90%	63%	5.09	0.34
Axial ASAS	23%	96%	92%	42%	7.54	0.79
NY	21%	100%	100%	42%	Infinity	0.78
Disease Course						
PRINTO (ESRA)	95%	86%	91%	92%	6.87	0.05

Abstract Number: 0251

A Comparative Study of the Validity of the DAS28-ESR and JADAS-27 Disease Activity Assessment Indexes for Juvenile Idiopathic Arthritis in Transition and Adults

Takako Miyamae[1], Eiichi Tanaka[1], Eisuke Inoue[2], Katsunori Ikari[1] and Masayoshi Harigai[3], [1]Tokyo Women's Medical University, Tokyo, Japan, [2]Showa University, Tokyo, Japan, [3]Tokyo Women's Medical University School of Medicine, Tokyo, Japan

SESSION INFORMATION
Session Date: Saturday, November 6, 2021
Session Title: Pediatric Rheumatology – Clinical Poster I: JIA (0241–0265)
Session Type: Poster Session A
Session Time: 8:30AM–10:30AM

Background/Purpose: The 2020 Rheumatoid Arthritis Clinical Practice Guidelines by the Ministry of Health, Labour, and Welfare Research Group recommends the JADAS27 as a measure of disease activity in transitional and adult JIA, reflecting the characteristics of JIA-affected joint localization, and citing the possibility of underestimation by the DAS28. We compared the validity of DAS28-ESR and JADAS27 in transitional and adult JIA.

Methods: Patients aged 18 years or older at the time of the study with an onset of younger than 18 years were selected from the prospective observational studies of IORRA conducted by the Institute of Rheumatology, Tokyo Women's Medical University.

Results: A total of 3,528 cases (age 39.1(SD 15.1) years at the survey, 13.5 (SD 3.8) years of onset, 25.6 (SD 16.0) years of disease duration) were included in the study. Activity according to both disease activity indices in order of high, medium, low disease activity and remission were DAS28-ESR (mean 2.9, SD 1.3):5.5%, 31.7%, 19.5%, 43.3%, JADAS27 (mean 7.6, SD 6.3): 65.2%, 16.3%, 7.8%, 10.7%, and JADAS 27 and JADAS 27 presented a higher disease activity configuration than DAS28-ESR. The high frequency of active joints was 23.0% in the hands and 12.4% in the elbows. JADAS27-specific joints were active in the ankle (11.3%), neck (2.6%), and hips (1.2%), and in 686 cases (19.4%) with these joints, the DAS28-ESR mean of 2.8 (SD 1.3) and the JADAS27 mean of 7.3 (SD 6.5) was not underestimated by the DAS28-ESR compared to the whole subject.

Conclusion: JADAS27 has been applied to the severity classification of articular JIA as the designated incurable disease in Japan and is socially important in transitional and adult JIA, but it is necessary to recognize the difference between the JADAS27 and the DAS28-ESR in its application.

Abstract Number: 0252

Role of Clinical and Laboratory Parameters in Differentiating Infection from Disease Flare in Febrile Patients of Systemic Juvenile Idiopathic Arthritis

Rajesh Kanumuri[1], Suma Balan[2], Vishal Marwaha[2], Sajitha Krishnan[2] and Pranav Chickermane[2], [1]Amrita Institute of Medical Sciences, Guntur, India, [2]Amrita Institute of Medical Sciences, Kochi, India

SESSION INFORMATION
Session Date: Saturday, November 6, 2021
Session Title: Pediatric Rheumatology – Clinical Poster I: JIA (0241–0265)
Session Type: Poster Session A
Session Time: 8:30AM–10:30AM

Background/Purpose: Fever is the most common presentation of systemic juvenile idiopathic arthritis (SJIA) and it is difficult to predict whether the fever is due to infection or underlying disease flare. This study has been undertaken to determine the role of clinical and laboratory parameters in differentiating infection and disease flare in febrile patients of SJIA, with particular reference to serum procalcitonin levels.

Methods: In this cross-sectional study, patients diagnosed with SJIA (as per ILAR classification criteria) who presented with fever (temperature ≥38°C) for more than ≥48 hours under the age of 16years between March 2018 to October 2019 were included. Blood samples for hemogram, acute phase reactants (ESR, C- Reactive protein and ferritin) procalcitonin levels were collected along with cultures of the respective body fluids at the time of presentation for the evaluation of fever. Patients were stratified into infection group and disease flare (with or without MAS) group.

Clinical parameter	Yes/No (n)	Infection n (%)	Disease flare n (%)	p value
Quotidian Fever	Yes (23)	2 (8.7)	21 (91.3)	0.046
	No (29)	10 (34.5)	19 (65.5)	
Evanescent Maculopapular rash	Yes (24)	1 (4.2)	23 (95.8)	0.003
	No (28)	11 (39.3)	17 (60.7)	
Joint pains	Yes (19)	0 (0)	19 (100)	0.002
	No (33)	12 (36.4)	21 (63.6)	
Joint swellings	Yes (12)	0 (0)	12 (100)	0.027
	No (40)	12 (30)	28 (70)	

Figure 1. Comparison of clinical manifestations with respect to infection and disease flare groups.

Lab parameter	Group (n)	Mean (SD)	Median (IQR)	p value
Total WBC (count x10^3/μL)	Infection	14.91(6.78)	14.81(8.47)	0.152
	Disease flare	20.67(10.46)	21.02(14.55)	
Hemoglobin (g/dL)	Infection	9.55 (1.77)	10 (2.4)	0.441
	Disease flare	9.85(1.58)	9.8(2.4)	
Platelet (x10^3/μL)	Infection	368.10(202.91)	393 (345)	0.339
	Disease flare	431.97 (214.61)	456 (258)	
ESR (mm/hr)	Infection	41.5 (30.32)	27 (37)	0.253
	Disease flare	55.38 (31.99)	55 (56)	
CRP (mg/dL)	Infection	97.63 (92.55)	72.55 (90.1)	0.15
	Disease flare	135.21 (101.22)	103.51 (119.26)	
Ferritin (ng/ml)	Infection	3650.78 (4237.17)	875.65 (8381)	0.34
	Disease flare	8385.51 (12152.98)	2623 (11376)	
Procalcitonin (ng/ml)	Infection	14.35 (30.42)	1.86 (6.27)	0.38
	Disease flare	5.44 (16.56)	0.38 (2.76)	

Figure 2. Comparison of lab parameters with respect to infection and disease flare groups.

Febrile episodes were categorized as “Infection” based on their clinical profile along with body fluid evaluation & culture or tissue culture or serological assays or any imaging study suggestive of infection and their prompt response to antibiotics without hiking the immunosuppression. “Disease flare” group was defined as those patients with daily fever ≥38°C for ≥2 days in a diagnosed case of SJIA, without any laboratory evidence of infection and the prompt response to hike in immunosuppression. MAS was defined as per the EULAR/ACR 2016 classification criteria. The receiver operating characteristic (ROC) curve analysis was used to find out the respective cut-off values.

Results: A total of 52 visits of 25 patients were included. Twelve (23.1%) were in the infection group and 40 (76.9%) were in the disease flare group (27 were disease flare without MAS and 13 were disease flare with MAS). The mean (SD) & median (IQR) values of laboratory parameters including serum procalcitonin levels did not show any statistical significance in differentiating infection and disease flare groups, whereas clinical parameters like quotidian pattern of fever, evanescent maculopapular rash and joint symptoms showed statistical significance (p value: < 0.05). In patients with disease flare, cut-off values of procalcitonin ≥0.95ng/ml, CRP ≥103mg/L and ferritin ≥ 3842.5 ng/ml predicted MAS with good sensitivity and specificity (p value: < 0.05).

Laboratory parameter	Cut-off value (n)	Disease flare Group		Sensitivity (%)	Specificity (%)	p value	PPV (%)	NPV (%)	Accuracy (%)	PLR	NLR
		With MAS	Without MAS								
Procalcitonin (ng/ml)	≥0.95 (16)	10	6	76.9	77.8	0.002	62.5	87.5	77.5	3.46	0.29
	<0.95 (24)	3	21								
CRP (mg/L)	≥103 (21)	10	11	69.2	63	0.046	47.4	81	65	1.87	0.49
	<103 (19)	3	16								
Ferritin (ng/ml)	≥ 3842.5 (15)	12	3	92.3	88.9	<0.001	80%	96%	90	8.30	0.09
	< 3842.5 (25)	1	24								

MAS: Macrophage activation syndrome, PPV: Positive predictive value, NPV: Negative predictive value, PLR: Positive likelihood ratio, NLR: Negative likelihood ratio.

Figure 3. Cut-off values of Procalcitonin, CRP and Ferritin in differentiating patients of disease flare with MAS and without MAS.

Conclusion: In our study none of the laboratory parameters including serum procalcitonin levels, were useful in differentiating infectious cause of fever from disease flare in febrile patients with SJIA. Serum procalcitonin levels were elevated even in the absence of infection in SJIA disease flare with MAS and a value of ≥0.95ng/ml was found to be a reliable predictor in identifying the MAS complicating SJIA. Presence of classical clinical features of SJIA are helpful in differentiating the disease flare from infection with high accuracy.

Rheumatoid Factor Status as a Predictor of Disease Activity and Disability: An Analysis of the New CARRA Registry Polyarticular Juvenile Idiopathic Arthritis Cohort

Nayimisha Balmuri[1], William Soulsby[2], Victoria Cooley[3], Linda Gerber[4], Erica Lawson[2] and Karen Onel[1], [1]Hospital for Special Surgery, New York, NY, [2]University of California San Francisco, San Francisco, CA, [3]Weil Cornell Medicine, New York, NY, [4]Weill Cornell Medicine, New York, NY

SESSION INFORMATION
Session Date: Saturday, November 6, 2021
Session Title: Pediatric Rheumatology – Clinical Poster I: JIA (0241–0265)
Session Type: Poster Session A
Session Time: 8:30AM–10:30AM

Background/Purpose: Children with rheumatoid factor (RF) positive polyarticular JIA (pJIA) are less likely to go into remission and more likely to develop erosive disease than those with RF negative pJIA. Differences in disease activity and disability over the first year of diagnosis between RF+ versus RF- pJIA have not been described in the new Childhood Arthritis and Rheumatology Research Alliance (CARRA) Registry. In this study, we investigate the differences in disease activity and disability by RF status at time of diagnosis and at 12 months among pJIA patients enrolled in the new CARRA Registry.

Methods: We analyzed data from the CARRA Registry collected from July 2015 through February 2020. Inclusion criteria were USA residency and pJIA diagnosis with recorded >4 joints involved in first 6 months of disease, and exclusion criteria was additional diagnosis of other autoimmune disease. Groups were categorized by RF status (positive, negative, or unknown). Duration of morning stiffness was collected and categorized as none, ≤15 minutes, 15-60 minutes, ≥60 minutes, or unknown. Disease activity was assessed with the Clinical Juvenile Arthritis Disease Activity (cJADAS). The Child Health Assessment Questionnaire (CHAQ) scores were collected to assess functional

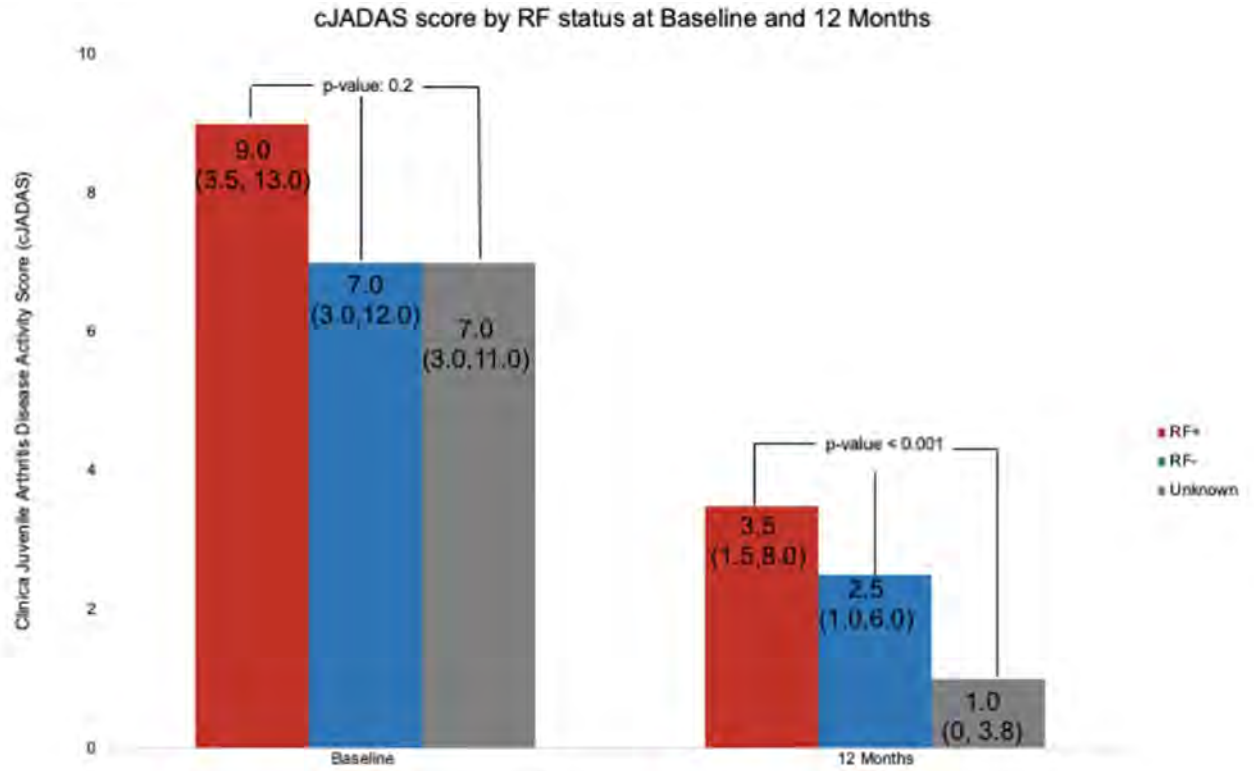
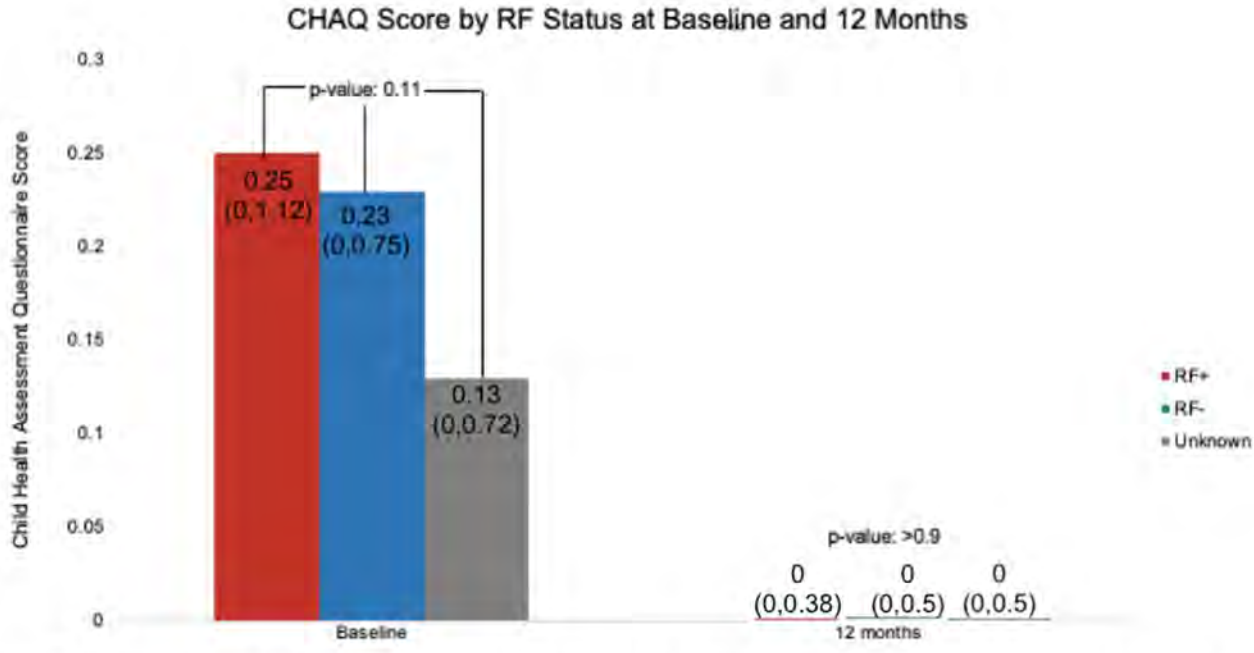
[2] Pearson's Chi-squared test

disability. Pearson's chi-squared test used to analyze differences in morning stiffness by RF status at baseline and 12 months. Kruskal- Wallis testing was used to assess differences in disease activity and disability by RF status at baseline and 12 months.

Results: 1684 patients were included in the study. The majority of patients (71%) were RF negative, 18% were RF positive (Table 1). At diagnosis and 12-month visits, RF+ patients had a longer duration of morning stiffness (Table 2,p=< .001, and p< .047, respectively). RF+ pJIA patients had high disease activity (median cJADAS=9, 3.5-13) while RF negative and RF unknown patients had moderate disease activity (Figure 1). There was no statistical difference in cJADAS (p=.2) or CHAQ (p=.11) by RF status at diagnosis. By 12 months, all groups' cJADAS improved, but RF positive patients had a statistically significant higher activity score compared to RF negative or RF unknown patients (p< .001). Despite these clear differences in disease activity, all RF status groups had a CHAQ median score of 0 or no reported disability (p=0.9) at the 12-month visit.

Conclusion: In our unadjusted model, all pJIA patients demonstrated improvement of disease activity as measured by cJADAS and disability as measured by CHAQ during the first year of enrollment in the CARRA registry. However, at the 12-month visit, RF positive patients reported longer duration of morning stiffness duration and a statistically significant higher cJADAS score as compared to other RF groups. Additional studies are needed to assess modifiable factors contributing to this difference in long term disease activity.





cJADAS: Inactive disease ≤1; low disease activity 1.1-2.5; moderate disease activity 2.51-8.5; high disease activity >8.5
CHAQ: No disability = 0; mild disability 0.1 - ≤0.25; mild/moderate disability 0.26 - ≤ 1.25, moderate disability 1.26 - ≤ 2.00; severe disability 2.00 - ≤3.00

Patient and Disease-Level Factors Associated with Sustained Cessation of Medication for Disease Remission in Systemic Juvenile Idiopathic Arthritis

Elaine Flanagan[1], Rosemary Peterson[2], Susan Shenoi[3], Helena Chang[4], Kelly Wang[4], Rebecca Trachtman[4] and Karen Onel[5], [1]Emory/CHOA, Atlanta, GA, [2]Dell Children's Medical Center, Austin, TX, [3]Seattle Children's Hospital, Seattle, WA, [4]Icahn School of Medicine at Mount Sinai, New York, NY, [5]Hospital for Special Surgery, New York, NY

SESSION INFORMATION
Session Date: Saturday, November 6, 2021
Session Title: Pediatric Rheumatology – Clinical Poster I: JIA (0241–0265)
Session Type: Poster Session A
Session Time: 8:30AM–10:30AM

Background/Purpose: The emergence of IL-1 and IL-6 inhibitors (biologics) for the treatment of systemic juvenile idiopathic arthritis (SJIA) has dramatically improved patient outcomes. With higher proportions of patients achieving clinically inactive disease (CID), knowledge gaps exist regarding frequency and predictors of remission off of medications. We leveraged data within the Childhood Arthritis and Rheumatology Research Alliance (CARRA) registry to identify demographic, clinical, and laboratory factors associated with sustained cessation (≥6 months) of glucocorticoid, biologic, and non-biologic disease modifying anti-rheumatic drugs (DMARDs) for disease remission in patients with SJIA.

Methods: 766 patients with a diagnosis of SJIA enrolled in the CARRA registry database between August 2015 - July 2020 were evaluated. Patients were excluded if they were diagnosed after enrolment, had missing diagnosis date, had change in diagnosis or unclear diagnosis, was a screen failure, if medication already discontinued prior to enrolment or administered too late after enrolment, if the diagnosis date was after medication start date, or if no exposure to pre-selected medications of interest (glucocorticoids, IL-1 inhibitor, IL-6 inhibitor, methotrexate, and/or tofacitinib). The primary outcome was medication cessation for disease remission for at least 6 month-period. Time-to-event models incorporating left truncation and right censoring with Firth correction were used to assess the association of patient demographics, SJIA disease features, baseline laboratory results, timing of medication start, and macrophage activation syndrome (MAS) with the primary outcome. Variable selection proceeded in two stages. In the first stage, univariable models were constructed. Variables that were significant at the 0.20 significance level in the univariable analysis were candidates for the multivariable model in the second stage. A backward selection approach was used to identify significant factors at the 0.05 level.

Results: A total of 493 SJIA patients met criteria for inclusion in the analysis (Table 1). Eighteen percent (90/493) of SJIA were able to wean off medications for ≥6 months. Table 2 presents the univariate relationships. In the multivariable model, younger age (HR 0.95; 95% CI 0.90-0.99; p=0.02), normal CRP levels defined as < 10 mg/L (>=10 mg/L vs < 10 mg/L HR 0.45; 95% CI 0.26-0.78; p=0.005), and shorter time between diagnosis and start of medications (HR 0.90; 95% CI 0.82-0.995; p=0.04) were associated with successful discontinuation of medications for ≥6 months. A total of 19 (3.9%) patients developed MAS, none of whom were able to discontinue medications for ≥6 months.

Conclusion: In the CARRA SJIA cohort, being younger at enrolment, having a shorter time to start medications after diagnosis, and having a normal CRP were associated with successful medication cessation for disease remission for ≥6 month-period. This study reinforces the existing understanding of a window of opportunity in which earlier initiation of treatment for SJIA patients may lead to better outcomes.

Identification of Tolerated Disease Activity Level for Individuals with Juvenile Idiopathic Arthritis in the Childhood Arthritis and Rheumatology Research Alliance Registry

Melissa Mannion[1], Fenglong Xie[1], Timothy Beukelman[1], Jeffrey Curtis[2] and , for the CARRA Registry Investigators[3], [1]University of Alabama at Birmingham, Birmingham, AL, [2]Division of Clinical Immunology and Rheumatology, Department of Medicine, Department of Epidemiology, University of Alabama at Birmingham, Birmingham, AL, [3]CARRA, Durham, NC

SESSION INFORMATION
Session Date: Saturday, November 6, 2021
Session Title: Pediatric Rheumatology – Clinical Poster I: JIA (0241–0265)
Session Type: Poster Session A
Session Time: 8:30AM–10:30AM

Background/Purpose: Recent treat to target recommendations for the treatment of juvenile idiopathic arthritis (JIA) recommend frequent evaluation and treatment intensification until the disease activity target (low or inactive disease) is reached. Our objective was to identify the range of disease activity states that was accepted by patients and physicians, using a lack of medication change as a proxy for a sufficiently tolerable disease activity state that did not require JIA treatment change.

Methods: We included all subjects with non-systemic JIA enrolled in the Childhood Arthritis and Rheumatology Research Alliance (CARRA) Registry, a clinical registry of >70 North American sites. Tolerated disease activity was determined at the registry visit following no medication change for >180 days prior to the registry visit and 60 days after the visit. Disease activity was assessed by physician global assessment (PGA) (0-10 visual analog scale (VAS), parent/patient global assessment (PtGE) (0-10 VAS), active joint count (AJC), duration of morning stiffness, clinical Juvenile Arthritis Disease Activity Score (cJADAS), American College of Rheumatology (ACR) preliminary criteria for

Table 1. Percentiles for visit disease activity scores at the time of tolerated disease activity (no medication change for >6 months)

	50th percentile	75th percentile	90th percentile	95th percentile	range
PGA (n=14466)	0	1	3	4	0-10
PtGE (n=13167)	0	2	5	6	0-10

cJADAS LDA – clinical Juvenile Arthritis Disease Activity Score Low Disease Activity, OR – odds ratio, CI – confidence interval, ref – reference, JIA – juvenile idiopathic arthritis, RF – rheumatoid factor, ERA – enthesitis related arthritis, DMARDs – disease modifying anti-rheumatic drug, PGA – physician global assessment, AJC – active joint count, PtGE – patient/parent global assessment of wellbeing, cJADAS – clinical Juvenile Arthritis Disease Activity Score , provCID – ACR provisional criteria for clinical inactive disease, preCID – ACR preliminary criteria for clinical inactive disease

clinical inactive disease (preCID), and the ACR provisional criteria for clinical inactive disease (provCID). Subjects could contribute more than one observation. The association of tolerated inactive or active disease and clinical characteristics were assessed by logistic regression.

Results: There were 8,244 subjects with non-systemic JIA enrolled in the CARRA Registry. No medication change for >180+60 days occurred 16,214 times in 6,235 subjects. Among eligible participants with measurement at the time of the first eligible visit, mean age was 11.7 years, most had oligoarthritis (36%) or rheumatoid factor negative (RF-) polyarthritis (35%), were female (72%), and were white (82%). A physician global score >0 occurred at 45% of tolerated disease activity visits, ≥1 active joints were documented at 29% of visits (Table 1), and 10% patients reported >15 minutes of morning stiffness.

Only 33% (n=6445) of visits met preCID, 29% (n=5753) met provCID, and 25% (n=4815) met cJADAS inactive disease (ID). Black race was associated with decreased likelihood of cJADAS low disease activity (LDA), preCID, and provCID, but not cJADAS ID at the time of tolerated disease activity (Table 2). Polyarticular disease and preCID at the prior visit were associated with increased likelihood of preCID and provCID at tolerated disease activity visit. Enthesitis-related arthritis and time since diagnosis were associated with decreased likelihood of cJADAS LDA and Hispanic ethnicity and PtGE were associated with decreased likelihood of both cJADAS LDA or ID at the tolerated disease activity visit.

Conclusion: In a large North American registry, patients with JIA frequently had episodes of no medication changes for >6 months. At the time of presumed tolerated disease activity, many patients with JIA had active disease by simple and composite measures. Additional studies are needed to investigate the patient characteristics associated with disease activity and to assess the outcomes following maximally tolerated disease activity states.

SESSION INFORMATION

Session Date: Saturday, November 6, 2021

Session Title: Pediatric Rheumatology – Clinical Poster I: JIA (0241–0265)

Session Type: Poster Session A

Session Time: 8:30AM–10:30AM

Table 1. Top ranked answers from second voting rounds for question 1 about key elements in target setting

Table 1 **Question 1: What are the most important elements to consider when setting an individual's target, that considers both the patient/family point of view as well as the point of view of the health care team (i.e., shared decision making)?**
Round 2 results: 140 responses, 20 voters (number of votes received, percent of voters selecting the item)
1. Patient goals (21, 100%) 2. Disease activity score (cJADAS) (18, 80%) 3. Pain domain (16, 70%) 4. Quality of life (12, 60%) 5. Medication domain (12, 60%) 6. Presence of risk factors for poor outcomes (8, 40%) 7. Joint count (7, 25%) 8. Functional ability (6, 30%) 9. Pain interference (6, 25%) 10. Social participation (5, 25%)

Background/Purpose: Treat to target (T2T) is a strategy of adjusting treatment until a therapeutic target is reached. There is growing evidence supporting the use and efficacy of T2T in chronic rheumatic conditions. In 2018, an international task force that did not include parents or patients recommended T2T for juvenile idiopathic arthritis (JIA) treatment. After a successful pilot study, the Pediatric Rheumatology Care and Outcomes Improvement Network (PR-COIN), a collaborative learning health network of 21 pediatric rheumatology centers across the United States and Canada, has been working together in partnership with patients and families to implement a T2T strategy. For successful implementation in a standard and reliable way in clinical practice, agreement is needed on the following areas: key elements of both (1) target setting and (2) T2T strategy, (3) identifying barriers to implementation and (4) determining eligible patients. In response, a consensus conference was held amongst PR-COIN stakeholders centered around four questions related to the listed areas in order to understand community priorities, to include patient/parent representation, as well as to gain agreement on a statement of understanding regarding the PR-COIN approach.

Table 2. Top ranked answers from second voting rounds for question 2 about key elements in Treat to Target

Table 2 **Question 2: What are the most important elements of a treat to target strategy?**
Round 2 results: 126 responses, 18 voters (number of votes received, percent of voters selecting the item)
1. Shared decision making (19 votes, 100%) 2. Clearly measurable outcomes (17, 89%) 3. Adjustment of treatment to meet goals (12, 83%) 4. Incorporate T2T into clinic workflow (12, 67%) 5. Training of providers and patients on the T2T process (10, 56%) 6. Patient's individual target (9, 50%) 7. Frequent assessment of activity and target status (9, 39%) 8. Provider, patient, and family buy-in (7, 39%) 9. Data collection into registry/EMR and display progress to patients (6, 28%) 10. Use of clinical decision support (5, 28%)

Table 3. Top ranked answers from second voting rounds for question 3 and 4 about important barriers in implementation of Treat to Target and eligible patients

Table 3 **Question 3: What are the most important barriers to implementation of a treat to target strategy?**	**Question 4: Who are the most important patients/patient groups to enroll in a treat to target strategy?**
Round 2: 20 voters, 140 responses (number of votes received, percent of voters selecting the item)	**Round 2: 19 voters, 133 responses** (number of votes received, percent of voters selecting the item)
1. Lack of incorporation of T2T into workflow (21, 90%) 2. Lack of buy-in domain (17, 85%) 3. Lack of resource domain (15, 75%) 4. Clinician time constraints (14, 55%) 5. Virtual care: inability to capture information needed (10, 50%) 6. Patient non-adherence (9, 45%) 7. Change management in providers and staff (9, 45%) 8. Resistance to change by providers and families (6, 30%) 9. Different perceptions and expectations of patients and clinicians (5, 25%) 10. Technical barriers (EMR -PRO measurements) (4, 20%)	1. All JIA patients (27, 58%) 2. Patients with poor prognostic factors (15, 68%) 3. Patient with a high disease burden (13, 63%) 4. Newly diagnosed JIA patients (12, 63%) 5. Diversity (10, 42%) 6. Any condition where disease activity is linked with damage (9, 32%) 7. JIA patient with active disease (8, 42%) 8. JIA patients with a flare (7, 37%) 9. Where targets are defined (6, 37%) 10. Patient seen by multiple providers (6, 26%)

Methods: PR-COIN stakeholders, including health care providers (n=16) and parents (n=4), were invited to form a voting panel. Using nominal group technique, two rounds of voting were held to address the above four areas to select the top 10 responses in rank order. Answers were recorded into an electronic polling software simultaneously by the pollsters and were viewable to the voting members. Each participant placed 7 total votes on answers they thought were of highest significance. Members were allowed to place multiple of their 7 votes on a single answer if desired. Once all votes were recorded, the pollsters revealed the top 10 items for the respective round.

Results: On October 22, 2020, a PR-COIN Consensus Conference was held. (1) Incorporation of patient goals ranked most important when setting a treatment target in both voting rounds. (2) Use of shared decision making (SDM), tracking measurable outcomes, and adjusting treatment to achieve goals were voted as top elements of T2T strategy. (3) Lack of incorporation of T2T into clinic workflow and provider participation in T2T strategy were identified as key barriers to T2T implementation. (4) Patients with JIA with poor prognostic factors and at risk for high disease burden were leading candidates for a T2T approach. Results of the second round of panel voting on the four questions are shown in Tables 1-3.

Conclusion: Thisconsensus conference identified the importance of incorporating patient goals as part of target setting and the influence of patient-stakeholder involvement in drafting treatment recommendations. The PR-COIN approach to T2T will be modified to address the above findings including solicitation of patient goals, optimizing SDM, and better workflow integration. Additional efforts will be required to optimally solicit patient goals and conduct longitudinal monitoring of progress.

SESSION INFORMATION

Session Date: Saturday, November 6, 2021

Session Title: Pediatric Rheumatology – Clinical Poster I: JIA (0241–0265)

Session Type: Poster Session A

Session Time: 8:30AM–10:30AM

Table 1: Performance measures and (95% CI) for three ways of combining the two questions in a FAST index

Measure	HARD+HELP/8	Linear Regression	LASSO
Custom Kappa	0.43 (0.36, 0.51)	0.46 (0.39, 0.54)	0.52 (0.44, 0.60)
Quadratic Kappa	0.62 (0.54, 0.70)	0.65 (0.56, 0.74)	0.69 (0.61, 0.78)
MSPE*	0.31 (0.24, 0.38)	0.16 (0.12, 0.21)	0.14 (0.10, 0.18)
CLOSE**	40% (33, 47)	50% (43, 57)	51% (42, 59)

* MSPE is the mean squared prediction error, the smaller the number the smaller the squared differences between the estimated CHAQ and the measured CHAQ.

** CLOSE is the percent of estimated CHAQ scores that fall within 0.125 units of the measured CHAQ

Background/Purpose: To assess if a combination of two questions (Functional Arthritis Screening with Two Questions - FAST index) can detect and roughly estimate the degree of disability in children with juvenile idiopathic arthritis (JIA) when compared to the 30-item Childhood Health Assessment Questionnaire Disability Index (CHAQ).

Methods: Children newly diagnosed with JIA enrolled in the Canadian Alliance of Pediatric Rheumatology Investigators (CAPRI) Registry from February 2017 to December 2018 formed a development cohort, while children diagnosed from January 2019 to February 2020 formed a validation cohort. At enrolment and at 1y parents completed the CHAQ. At every clinic visit they answered two questions: 1) Is it hard for your child to run and play because of arthritis? (HARD), 2) Does your child usually need help from you or another person because of arthritis? (HELP). Responses were scored on 21-point horizontal numerical rating scales from 0 to 10 at 0.5 intervals. We explored >20 different models for combining the two questions to estimate CHAQ scores, using cross-validation to measure performance in subjects not used in model development. Model performance was assessed by concordance with measured CHAQ scores (Kappa using quadratic weights or custom weights selected a priori), mean squared prediction error (MSPE), and the proportion of estimated scores within 0.125 units of the measured CHAQ (CLOSE). The selected model will be validated in the validation cohort.

Results: The development cohort included 216 children at enrolment and 159 at 1y. Both questions correlated with the CHAQ at enrolment (Spearman correlation 0.65 for HARD and 0.64 for HELP) and their scores (0 to 10) were stable in patients deemed unchanged by their parents; mean change -0.16 (95%CI -0.5, 0.1) for HARD, -0.3 (-0.5, -0.03) for HELP. Relative to simply adding the two question scores and dividing by 8, a linear regression model including only

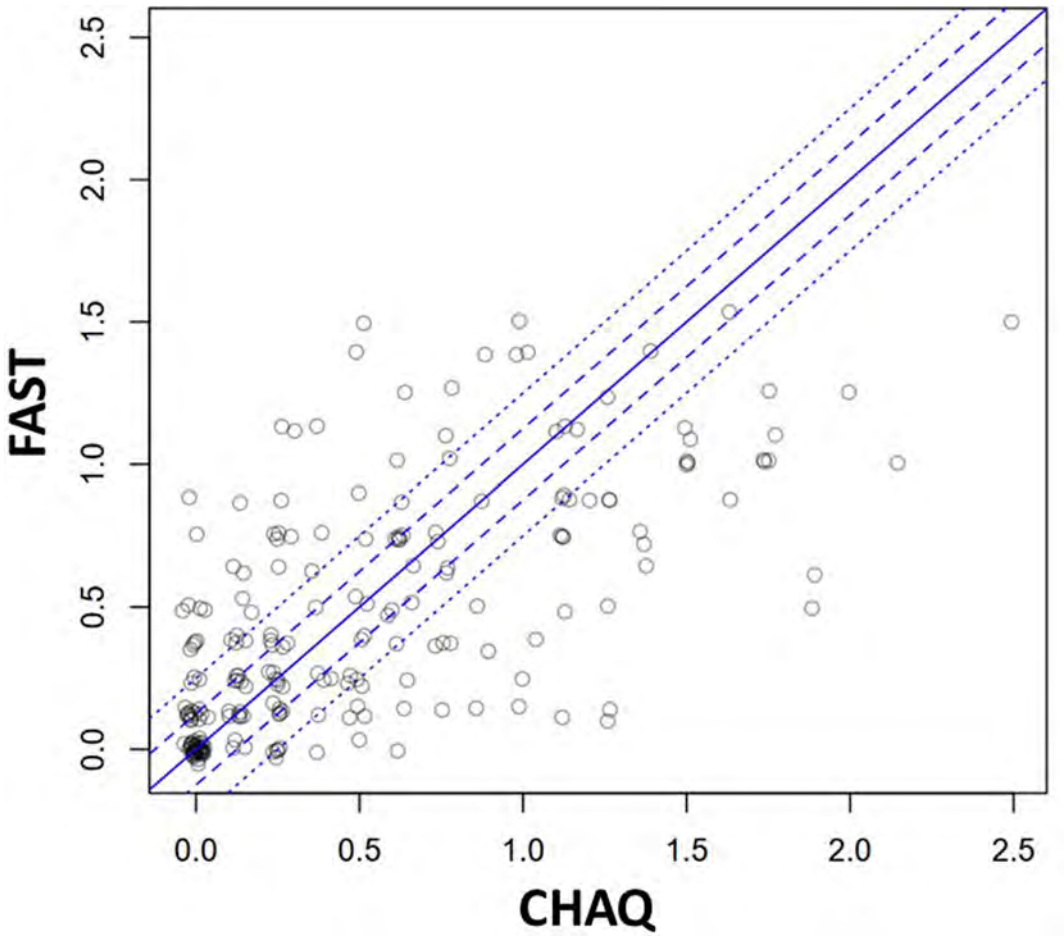

Figure 1. Two-way scatter plot of CHAQ scores estimated with the FAST index and measured CHAQ scores.

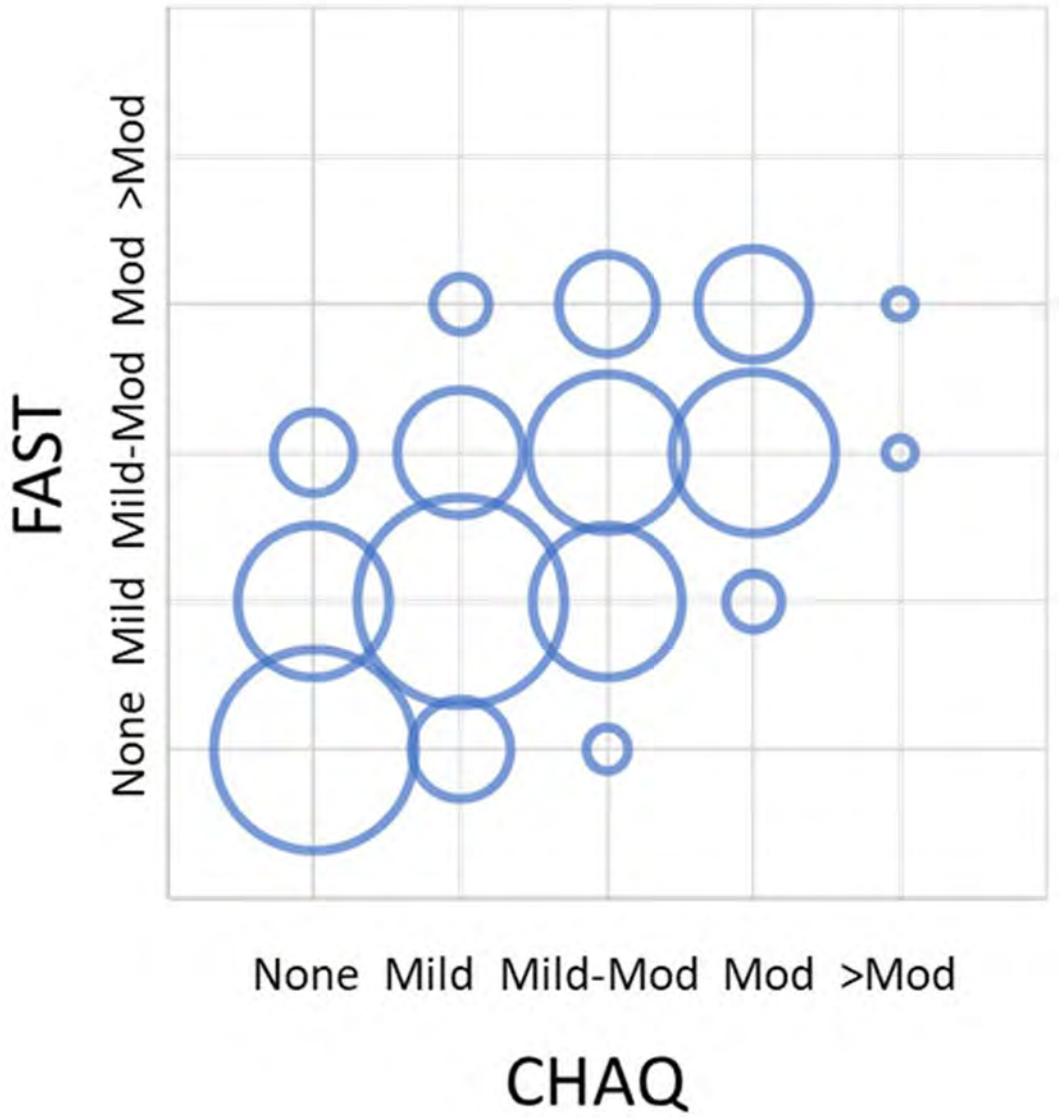

Figure 2. Ability of FAST to detect degrees of disability according to published CHAQ cut-offs (Dempster et al 2001).

HARD and HELP decreased the MSPE by half (Table 1). Using a Least Absolute Shrinkage and Selection Operator (LASSO) to add other patient characteristics led to further improvements. The best LASSO model combined HARD and HELP with age, JIA category, number of active joints and pain intensity to estimate CHAQ scores. We selected the FAST linear regression model for its balance of simplicity and performance. Figure 1 shows the concordance of this model with the measured CHAQ. Sensitivity to detect any disability (CHAQ >0) was 0.94 with a specificity of 0.56. FAST detected some disability in 27/61 (44%) of patients with a CHAQ of zero and often reported higher levels of disability than the CHAQ at lower CHAQ scores (Figure 2). Responsiveness (SRM, mean change from enrolment to 1y divided by the standard deviation) was 0.52 for FAST and 0.40 for CHAQ. Validation cohort analyses are underway.

Conclusion: This FAST index seems highly sensitive to detect disability in children with JIA and often detects unmeasured disability in patients with a CHAQ of zero. It had moderate concordance with levels of disability assessed by CHAQ, but greater sensitivity to change. It could be used as a quick and simple screen for disability at every clinic visit.

Abstract Number: 0258

Developing Electronic Health Record Algorithms That Accurately Identify Patients with Juvenile Idiopathic Arthritis

Hannah Peterson[1], April Barnado[2] and Anna Patrick[2], [1]Lipscomb University College of Pharmacy, Nashville, TN, [2]Vanderbilt University Medical Center, Nashville, TN

SESSION INFORMATION
Session Date: Saturday, November 6, 2021
Session Title: Pediatric Rheumatology – Clinical Poster I: JIA (0241–0265)
Session Type: Poster Session A
Session Time: 8:30AM–10:30AM

Background/Purpose: Electronic Health Records (EHRs) store nearly all clinical data in one central location providing increased accessibility, accuracy, and security. At our institution, the Synthetic Derivative (SD) is a de-identified EHR containing over 3.2 million records that links to a DNA biorepository, BioVU. The objective of this study is to develop an algorithm to detect a highly sensitive and specific cohort of juvenile idiopathic arthritis (JIA) patients in the EHR. Within this cohort, we determine characteristics of the identified JIA patients.

Methods: We developed our cohort by searching International Classification of Diseases, Ninth (ICD-9) and Tenth (ICD-10-CM) Revisions and keywords in the SD. *A priori*, ICD-9 and ICD-10-CM codes and keywords clinically rele-

Table 1. ICD codes and keywords used in JIA algorithms

ICD-9		ICD-10	
714	Disorders of the Musculoskeletal System	M08	Disorders of the Musculoskeletal System
714.3	Juvenile chronic polyarthritis	M08.0	Unspecified juvenile rheumatoid arthritis
714.30	Polyarticular juvenile rheumatoid arthritis, chronic or unspecified	M08.1	Juvenile ankylosing spondylitis
714.31	Polyarticular juvenile rheumatoid arthritis, acute	M08.2	Juvenile rheumatoid arthritis with systemic onset
714.32	Pauciarticular juvenile rheumatoid arthritis	M08.3	Juvenile rheumatoid polyarthritis (seronegative)
714.33	Monoarticular juvenile rheumatoid arthritis	M08.4	Pauciarticular juvenile rheumatoid arthritis
		M08.8	Other juvenile arthritis
		M08.9	Juvenile arthritis, unspecified
		L40	Psoriasis
		L40.54	Psoriatic juvenile arthropathy
Keywords			
"juvenile rheumatoid arthritis" "uveitis"		"juvenile idiopathic arthritis" "enthesitis"	

Table 2. Algorithms with the highest F-scores

Algorithm		PPV	Sensitivity	F-Score
Code Search	Keyword Search			
≥4 counts of any ICD-9 or ICD-10-CM JIA code	juvenile idiopathic arthritis ***OR*** juvenile rheumatoid arthritis ***OR*** uveitis ***OR*** enthesitis	0.865	0.874	0.869
≥3 counts of any ICD-9 or ICD-10-CM JIA code	juvenile idiopathic arthritis ***OR*** juvenile rheumatoid arthritis ***OR*** uveitis ***OR*** enthesitis	0.833	0.895	0.863
≥4 counts of any ICD-9 or ICD-10-CM JIA code	juvenile idiopathic arthritis ***OR*** juvenile rheumatoid arthritis **plus** uveitis ***OR*** enthesitis	0.961	0.768	0.854
≥4 counts of any ICD-9 or ICD-10-CM JIA code	-	0.83	0.874	0.851

vant to juvenile arthritis were selected (Table 1). Keywords were identified by a survey of pediatric rheumatologists at a single site. Keywords selected were included in at least 75% of survey responses and returned less than 3000 cases in individual searches of the SD. Uveitis returned >3000 cases in the SD but was retained due to recurring appearances in confirmed JIA charts. We then combined the ICD codes with the keywords for possible algorithms. Algorithms used varying ICD code counts and searched keywords by "and" or "or" functions. A training set of 200 random charts was identified from a search of ≥1 count of the ICD-9 and ICD-10-CM JIA codes. Case status was determined by a pediatric rheumatologist who required a rheumatology clinic note documenting a JIA diagnosis before age 20. Positive predictive values, sensitivities, and F-scores were calculated for each algorithm. The F-score is the harmonic mean of the PPV and sensitivity and is frequently used in bioinformatics, as it accounts for both PPV and sensitivity.

Results: We analyzed 21 algorithms and ranked them by F-score. Our highest performing algorithm required ≥4 ICD-9 or ICD-10-CM code counts and any of the selected keywords to be present. It identified 1,514 patients and produced an F-score of 0.87. Other high performing algorithms used similar search methods (Table 2). Demographic data and age at first diagnosis in the EHR were analyzed for the cohort with the highest performing algorithm. Our JIA population was 72% female and 81% Caucasian. Approximately 20% of the JIA population had EHR diagnosis in the first 3 years of life, and 84% had EHR diagnosis appearing before 16 years of life. The ICD code that appeared most frequently in our cohort was the ICD-9 code, "Polyarticular juvenile rheumatoid arthritis, chronic or unspecified" (714.30).

Conclusion: We have developed algorithms for accurately identifying JIA patients in the EHR. Combining ICD-9 codes, ICD-10-CM codes and keywords produced a more sensitive and specific cohort than using ICD-9 or ICD-10-CM codes alone. Requiring multiple instances of the ICD-9 or ICD-10-CM codes also improved algorithm performance. Our identified cohort reveals demographic and diagnosis patterns among the JIA patients in our region. Assembling an EHR-based JIA cohort will enable longitudinal, de-identified chart review and linkage to the BioVu DNA repository for future studies.

JIA Diagnoses and Trends from 2006-2019: Has the U.S. ICD-9-to-ICD-10 Transition Created Coding Artifacts?

Daniel Horton[1], Lauren Parlett[2], Cecilia Huang[3], Stephen Crystal[4], Amy Davidow[5], Tobias Gerhard[6], Carlos Rose[7], Kevin Haynes[2] and Brian Strom[8], [1]Rutgers Robert Wood Johnson Medical School, New Brunswick, NJ, [2]HealthCore, Wilmington, DE, [3]Rutgers Institute for Health, New Brunswick, NJ, [4]Rutgers School of Social Work, New Brunswick, NJ, [5]Rutgers School of Public Health, New Brunswick, NJ, [6]Ernst Mario School of Pharmacy, New Brunswick, NJ, [7]Thomas Jefferson University, Wilmington, DE, [8]Rutgers Biomedical and Health Sciences, Newark, NJ

SESSION INFORMATION

Session Date: Saturday, November 6, 2021

Session Title: Pediatric Rheumatology – Clinical Poster I: JIA (0241–0265)

Session Type: Poster Session A

Session Time: 8:30AM–10:30AM

Background/Purpose: JIA is the most common rheumatic disease of childhood, but recent data on diagnostic trends in the US are lacking. Furthermore, the impact of the ICD-9/ICD-10 transition on the rates of JIA diagnoses is unclear. We sought to characterize recent trends in JIA claims, including changes related to the US International ICD-9/ICD-10 transition in late 2015.

Methods: We studied JIA diagnoses within administrative claims data on commercially insured children under age 18 from 14 geographically diverse US states in the HealthCore Integrated Research Database (2006-2019). JIA diagnoses were defined by claims with diagnostic codes (ICD-9 696.0, 714, or 720; ICD-10 L40.5, M05, M06, M08, or M45), requiring at least 1 inpatient claim or 2 outpatient claims between 8 and 52 weeks apart. Incident diagnoses were defined as having at least 6 months of baseline data without previous JIA claim; prevalent diagnoses could have occurred at any time. Incidence and prevalence of JIA were calculated quarterly 2006-2019, excluding 6 months before and 6 months after the ICD-9/10 transition to limit transitional coding errors. Trends and changes in level around the

Table. Characteristics of children diagnosed with JIA in commercial administrative claims data, 2006-2019

	Incident JIA Outpatient		Prevalent JIA Outpatient		Incident JIA Inpatient		Prevalent JIA Inpatient	
Characteristics	ICD-9 (n=10,390)	ICD-10 (n=3,830)	ICD-9 (n=14,458)	ICD-10 (n=5,745)	ICD-9 (n=1,118)	ICD-10 (n=511)	ICD-9 (n=1,355)	ICD-10 (n=600)
Age group, %								
0 - 5 years	11.9%	12.7%	15.7%	14.8%	17.5%	14.7%	18.9%	15.1%
6 - 11 years	24.5%	27.6%	29.6%	31.6%	25.1%	25.0%	24.2%	25.4%
12 - 17 years	63.6%	59.7%	54.7%	53.6%	57.3%	60.3%	56.9%	59.4%
Age								
Mean (standard deviation)	12.6 (4.5)	12.2 (4.5)	11.7 (4.6)	11.7 (4.5)	11.7 (4.9)	12.2 (4.8)	11.6 (5.1)	12.2 (4.8)
Sex, %								
Female	63.3%	67.6%	64.5%	69.4%	59.7%	62.0%	59.6%	63.3%
Male	36.7%	32.4%	35.5%	30.6%	40.3%	38.0%	40.4%	36.7%
DMARD dispensed within 6 months after JIA diagnosis, %								
Conventional DMARD	14.7%	27.5%	26.5%	38.8%	18.2%	23.3%	21.2%	25.5%
Biologic DMARD	6.0%	20.6%	17.1%	40.7%	10.9%	30.5%	15.3%	33.5%
Number of medications dispensed within 6 months after JIA diagnosis, mean (standard deviation)								
Number of medication classes	1.9 (2.8)	2.7 (3.0)	2.3 (3.2)	3.4 (3.8)	3.3 (4.1)	4.1 (4.4)	3.8 (4.6)	4.6 (5.0)
Number of medications dispensed	4.6 (7.7)	6.7 (8.9)	6.0 (9.4)	9.0 (11.6)	8.0 (12.0)	10.7 (13.6)	9.5 (13.7)	12.3 (15.4)

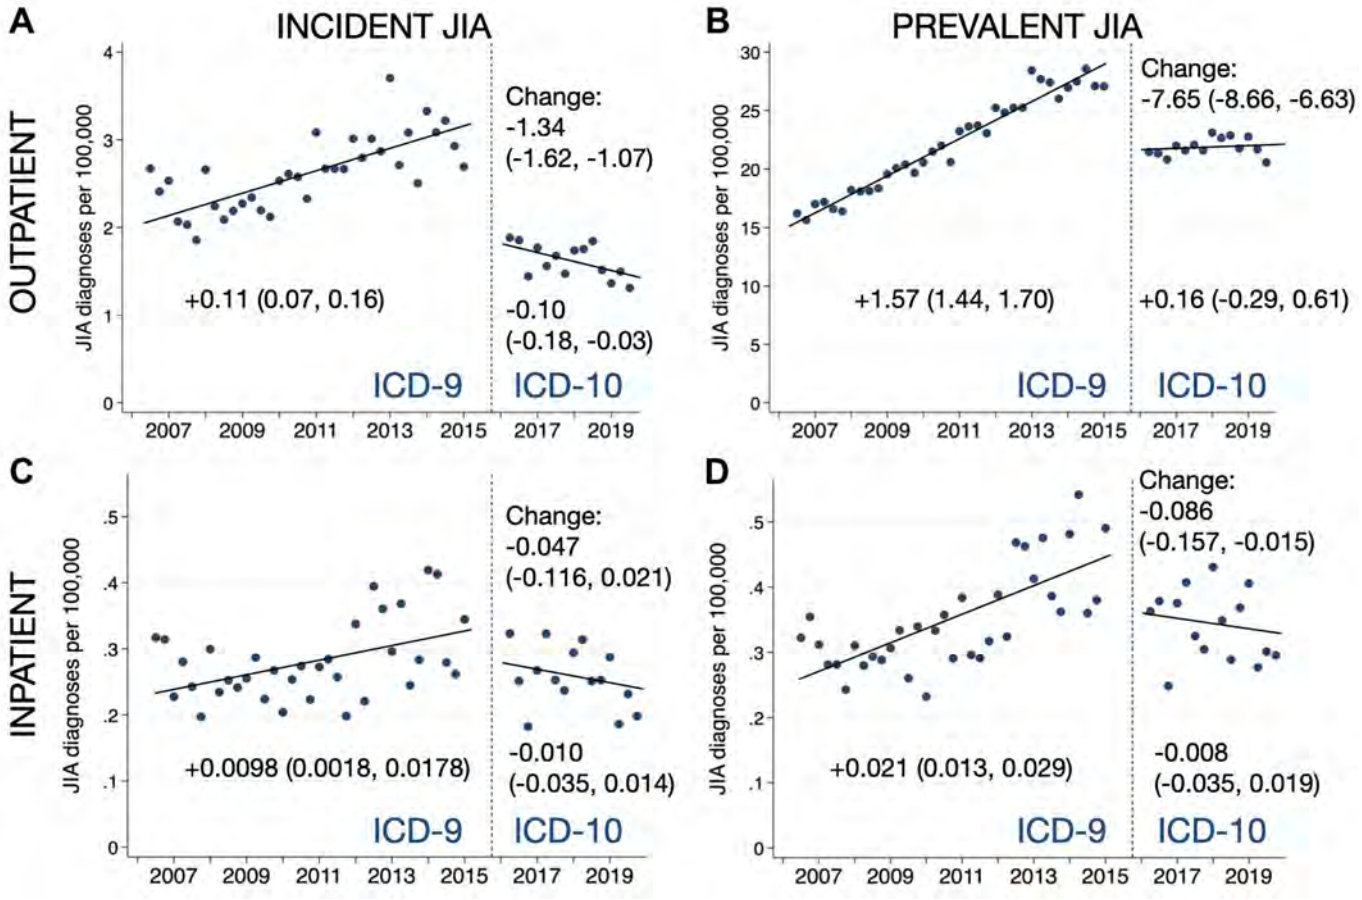

Figure. Trends and changes in ICD-9 and ICD-10 claims for JIA in commercial administrative claims data, 2006-2019. Graphs show yearly rates of JIA diagnoses per 100,000 children in commercial claims data based on ICD-9 codes (2006-2015) or ICD-10 codes (2016-2019). Diagnoses reflected ≥2 outpatient claims 8-52 weeks apart (A and B) or ≥1 inpatient claim (C and D). Incident JIA diagnoses (A and C) required ≥6 months of JIA-free baseline time; prevalent JIA diagnoses (B and D) could have occurred at any time. Trends and changes in level before and after the ICD-9/10 transition were estimated using segmented regression from interrupted time-series.

ICD-9/10 transition were analyzed by single-group interrupted time-series using ordinary least-squares segmented regression.

Results: Of 26.5 million children identified, 22,158 had claims for JIA by ICD-9 or ICD-10 code in any setting (0.084%). Over half of children diagnosed with JIA were 12-17 years old, and approximately 2/3 were female (Table). ICD-9-based incident and prevalent diagnoses of JIA steadily increased in both outpatient and inpatient settings (Figure). Rates of JIA, both incident and prevalent, dropped abruptly in both outpatient and inpatient settings at the time of the ICD-9/10 transition (Figure). In outpatient settings, ICD-10-based incident JIA diagnoses have declined since then, whereas prevalent JIA diagnoses have remained stable (Figure). There have been modest, but not statistically significant, declines in ICD-10-based diagnoses from inpatient settings (Figure). Rates of recorded conventional and biologic DMARD use were higher among children diagnosed by ICD-10 code than children diagnosed by ICD-9 code (Table).

Conclusion: Among commercially insured children, apparent incident and prevalent rates of claims for JIA declined abruptly with the US transition from ICD-9 to ICD-10, likely reflecting an artifact of changes in the sensitivity and specificity of coding practices. The higher prevalence of DMARD use by children diagnosed with JIA in the ICD-10 era could suggest greater diagnostic specificity, but the uncertain validity of both ICD-9 and ICD-10 claims warrants

further research. New JIA diagnoses appeared to rise until 2015 and fall since 2016; more work is needed to establish to what extent these trends reflect temporal changes in coding practices versus true changes in JIA epidemiology.

Impact on Caregivers of Patients with Juvenile Idiopathic Arthritis: A Hospital-based Study from India

Nikhil Gowda[1], Abhishek Samuel[1], Akash Yadav[1], Amita Aggarwal[2] and **Anu Balakrishnan**[1], [1]Sanjay Gandhi Postgraduate Institute of Medical Sciences, Lucknow, India, [2]Sanjay Gandhi Post Graduate Institute of Medical Sciences, Lucknow, India

SESSION INFORMATION
Session Date: Saturday, November 6, 2021
Session Title: Pediatric Rheumatology – Clinical Poster I: JIA (0241–0265)
Session Type: Poster Session A
Session Time: 8:30AM–10:30AM

Background/Purpose: Juvenile idiopathic arthritis is a chronic disease that impacts patient's physical and mental health. Caregivers act as a bridge between physicians and patients, by ensuring good adherence to treatment and they also help in assessing the day-to-day life of the patient. The extra burden of caring for a child with JIA and seeing a child with disease can have a significant impact on the caregiver-child or caregiver-family member relations. Data on the impact of JIA on caregivers from South Asia is limited thus, we used a recently described questionnaire.

Methods: Caregivers of patients with JIA who visited the outpatient clinic of the Department of Clinical Immunology and Rheumatology of a tertiary care hospital in North India and consented to participate in the study were included. They were asked to fill out a questionnaire of 28 questions (CAREGIVERS questionnaire described by Torres-Made et al) regarding the emotional, social, financial, labor, family, and relations impact. Information about educational level and relationship to the patient was also collected. Data on disease activity, damage, and medications were collected from patient's hospital records.

Results: Caregivers of 99 patients with JIA were enrolled. 60 of them were fathers and 15 of them mothers, the rest included other relatives Among these 99 patients 59 had enthesitis-related arthritis, 26 had polyarticular JIA, 10 had systemic JIA and 4 had oligoarticular JIA. 40 patients had active disease while the rest were in remission. 12 children had joint damage (JADI score 1-10) and none had any extraarticular damage. 67 patients were on DMARDs, 11 were on NSAIDs alone and 9 were on no treatment. Only 5 patients were on biologicals or tofacitinib.

All of the caregivers had a significant impact on the emotional, social, economic, and labour domains, but spirituality and relations were less affected.

54% of caretakers expressed sadness at the time of diagnosis and 29% expressed denial. This changed to 36 percent showed concern, 24 percent showed sadness and 22 percent of them expressed relief. They were worried about the pain of the patient (34%), the restrictions on mobility (47%) and 10% concerned about the expenses of treatment, and 4%

concerned about the medical appointments. They worried about the future of the child, 39% worried they will have major problems, and 25% worried that child will have some problems in the future. 85% had anxiety and 55 % were sad about sharing the news of child's disease, and 15% didn't want to share it with anyone. Their social life changed a lot for 24% and a little for 31% whereas for 43% it has not changed much. 32% of caretakers neglected their health and 14% became sick. The financial condition worsened for 61% and didn't change for 31%. 54% had to borrow money from others and 6% had to stop buying medicines for their child because of poverty. 28% received financial aids for the treatment.

This impact was equal across all the subtypes of JIA. There was no relationship with the disease activity, damage, or type of medications.

Conclusion: JIA has a significant emotional, social, labor and economic impact on caregivers. Strategies to cope with this impact need to be addressed in the clinic by social workers.

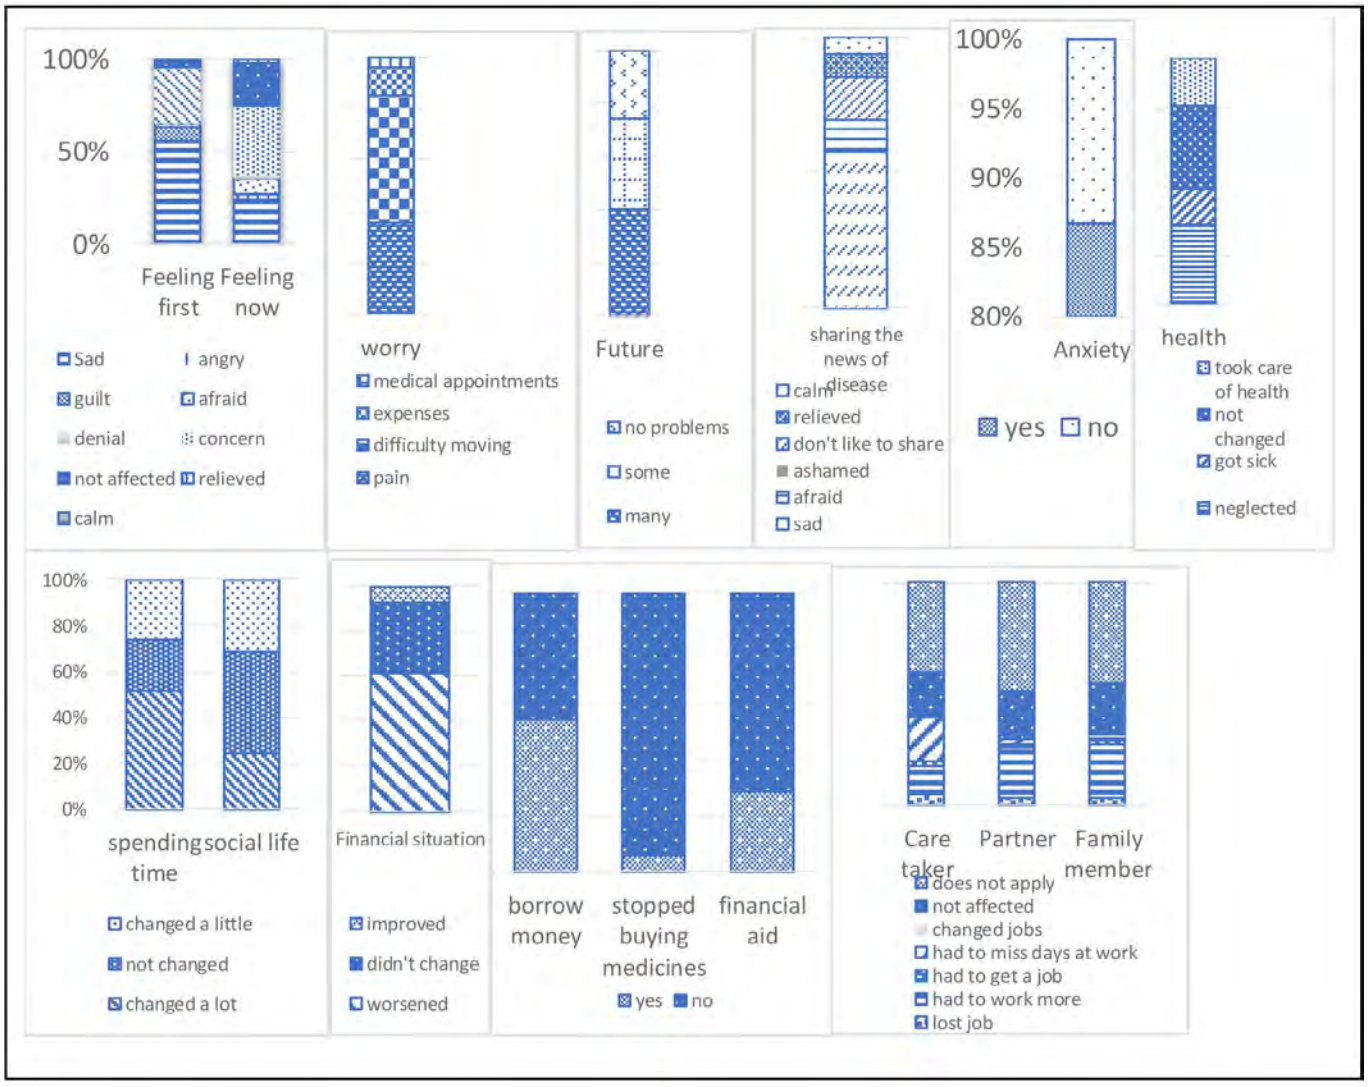

Figure 1. Emotional, social, economic, and labor impact on caregivers of JIA

Domains	Total Score (Min-Max)	Mean	Median (IQR)	Correlation with the total score (r)
Emotional Impact	4-18	13.46±3.89	14(12-15)	0.56(p<0.001)
Social Impact	2-9	5.45±3.82	6(4-7)	0.58(p<0.001)
Economic Impact	0-5	2.33±2.25	2(1-3)	0.38(p<0.001)
Labour Impact	0-15	4.16±8.32	3(0.25-6.75)	0.67(p<0.001)
Family Impact	4-16	6.52±3.26	6(5-8)	0.47(p=0.56)
Relationship Impact	0-8	1.51±2.04	2(1-2)	0.06(p=0.56)
Impact on spirituality	0-5	0.75±1.78	1(0-1)	0.07(p=0.53)
Impact of social networks	0-8	1.48±4.41	0(0-4)	0.34(p=0.01)
Total Score	10-84	35.75±16.68	34(31-40)	1

Methotrexate Withdrawal and Outcomes in Participants with Well-controlled Non-systemic JIA Within the CARRA Registry

Marinka Twilt[1], Kevin Baszis[2], Sarah Ringold[3], Timothy Beukelman[4], Anne Dennos[5], Peter Shrader[6] and Daniel Horton[7], [1]Alberta Children's Hospital, Calgary, AB, Canada, [2]Washington University School of Medicine, St Louis, MO, [3]Seattle Children's Hospital, Seattle, WA, [4]University of Alabama at Birmingham, Birmingham, AL, [5]Duke University, Durham, NC, [6]Duke Clinical Research Institute, Durham, NC, [7]Rutgers Robert Wood Johnson Medical School, New Brunswick, NJ

SESSION INFORMATION
Session Date: Saturday, November 6, 2021
Session Title: Pediatric Rheumatology – Clinical Poster I: JIA (0241–0265)
Session Type: Poster Session A
Session Time: 8:30AM–10:30AM

Background/Purpose: Methotrexate (MTX) is currently the recommended first-line conventional DMARD for the treatment of JIA with oligo- or polyarthritis. There are limited data on how or when to stop MTX monotherapy for well-controlled JIA. The aims of this study were to 1) describe the MTX withdrawal strategies used for well-controlled JIA in the Childhood Arthritis and Rheumatology Research Alliance (CARRA) registry, 2) compare time to flare among different MTX withdrawal strategies, and 3) evaluate the duration of disease remission after MTX withdrawal.

Methods: The study population consisted of patients enrolled in the CARRA Registry with a diagnosis of non-systemic JIA on MTX monotherapy for at least 12 months and with 2 consecutive registry visits with no reported disease activity (based on joint count = 0 and no changes in medication). Subjects with systemic JIA, non-JIA rheumatic diseases or inflammatory bowel disease were excluded. Subjects were divided into 3 cohorts: 1) MTX continuation,

Table 1. Selected subject characteristics in the three MTX withdrawal cohorts

Characteristic	Continuing use (N=233)	Tapering (N=90)	Discontinue without taper (N=54)	P-value[1]
DEMOGRAPHICS				
Age in years at diagnosis, median (IQR)	4.04 (2.26, 9.05)	5.12 (2.73, 10.01)	5.75 (2.78, 8.71)	0.21
Female sex	174 (74.68%)	69 (76.67%)	41 (75.93%)	0.93
JIA CHARACTERISTICS				
Years of JIA at baseline, median (IQR)	2.85 (1.52, 6.15)	3.01 (1.80, 5.81)	2.79 (1.80, 5.38)	0.90
JIA Category				0.59
Oligoarthritis	106 (45.69%)	44 (48.89%)	26 (48.15%)	
Polyarthritis (RF -)	90 (38.79%)	37 (41.11%)	19 (35.19%)	
Polyarthritis (RF +)	9 (3.88%)	0 (0.00%)	3 (5.56%)	
Psoriatic arthritis	12 (5.17%)	5 (5.56%)	5 (9.26%)	
Enthesitis related arthritis	8 (3.45%)	2 (2.22%)	1 (1.85%)	
Undifferentiated arthritis	7 (3.02%)	2 (2.22%)	0 (0.00%)	
Prior disease flare	25 (10.73%)	10 (11.11%)	3 (5.56%)	0.49
TREATMENT CHARACTERISTICS				
Months of methotrexate, Median (IQR)	21.70 (17.97, 29.38)	22.03 (18.56, 28.33)	23.20 (16.98, 30.13)	0.97
Any prior TNF inhibitor use	28 (12.02%)	6 (6.67%)	6 (11.11%)	0.37

IQR interquartile range

[1] P-value by Chi-square test, Fisher exact test, or Wilcoxon rank sum test, as appropriate

2) MTX tapering, or 3) MTX discontinuation without taper. Rates of flare (new or increased JIA medication, > 0 joint count) were compared among groups using Kaplan-Meier curves and multivariable Cox regression, adjusted for demographic, disease, and medication history covariates. Rates of remission were also compared between subjects who stopped MTX without taper and subjects who tapered MTX, using descriptive statistics.

Results: Of 9835 persons in the CARRA Registry, 377 fulfilled the study criteria. MTX monotherapy was continued in 233 (61.8%), tapered in 90 (23.9%) and stopped in 54 (14.3%). Of MTX continuers, 25 (10.7%) were subsequently observed to withdraw MTX (2 tapered, 23 stopped). Subject characteristics (Table 1) did not differ significantly among the groups. Most subjects (85%) had oligoarthritis or RF – polyarthritis, consistent with overall JIA enrollment distribution. Prior TNF inhibitor use was less common among those who tapered, while prior flares were less commonly recorded among those who stopped MTX without taper. No association was found between flare of JIA and MTX withdrawal strategy in unadjusted analyses (Figure) or adjusted models (taper vs. continuation: 0.89, 95% CI

Table 2. JIA remission rates after MTX withdrawal

Disease remission	Discontinue without taper[1] (N=58)	All tapers, time from start of taper[1] (N=81)	P-value	Subjects who stopped MTX after taper (N=31)	
				Time from start of taper (N=31)	Time from end of taper (N=24)
@6 months	36 (62.1%)	60 (74.1%)	0.13[2]	28 (90.3%)	15 (62.50%)
@12 months	17 (41.5%)	34 (51.5%)	0.31[2]	14 (60.9%)	7 (43.75%)
Median months in remission (IQR)	6.8 (4.9, 12.9)	10.8 (6.7, 15.6)	0.01[3]	11.9 (7.8, 15.6)	7.4 (4.2, 11.8)

IQR interquartile range; SD standard deviation

[1] Includes some subjects who initially continued MTX before withdrawal

[2] P-value by Chi-square test

[3] P-value by Wilcoxon rank sum test

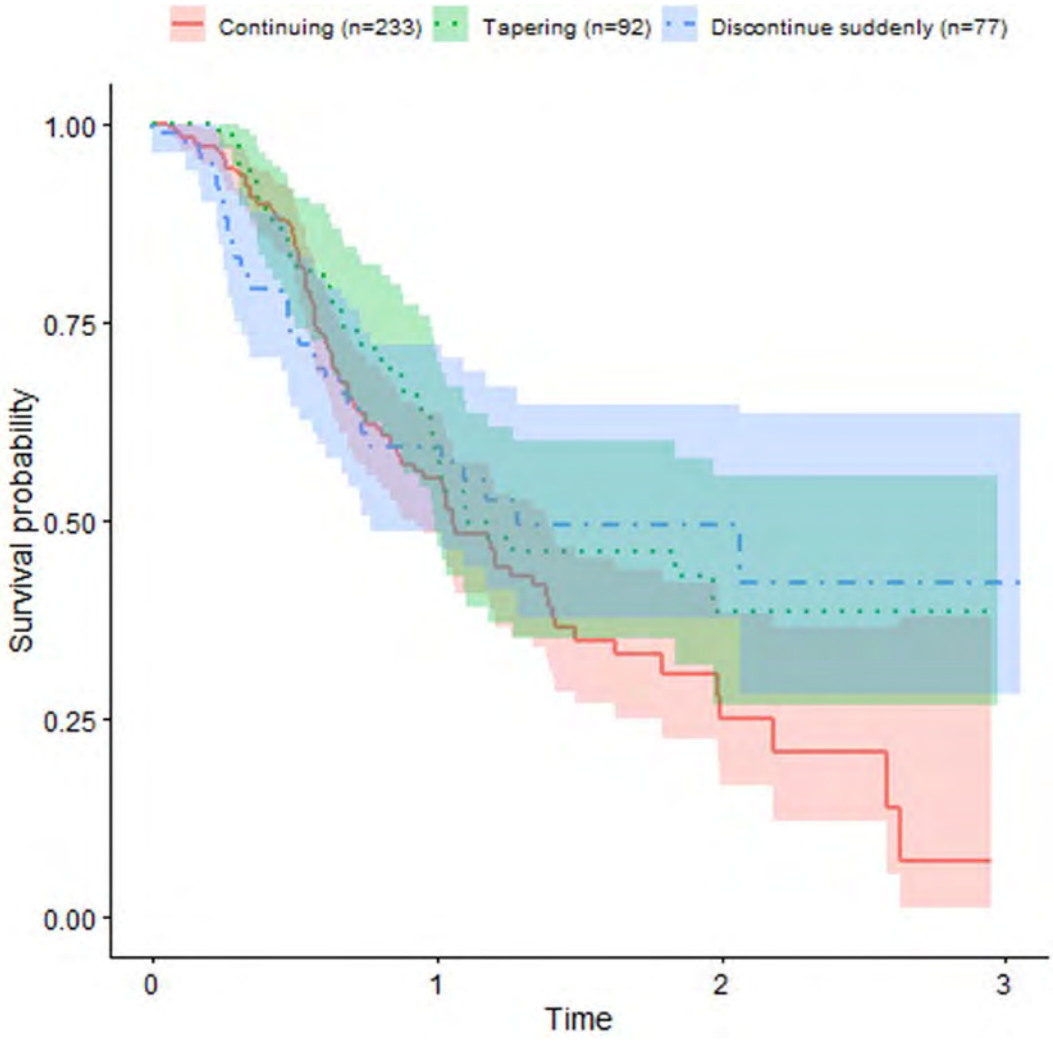

Figure. Kaplan-Meier survival curves comparing risk of flare based on MTX withdrawal strategy.

0.59-1.34; discontinuation vs. continuation: 0.90, 95% CI 0.54-1.48). Rates of sustained remission and median time in remission were modestly higher among those who tapered MTX compared to those who stopped MTX (Table 2). Among those who were in sustained remission after tapering MTX, rates of remission were higher before tapering than afterwards (Table 2).

Conclusion: Within the CARRA Registry, we did not observe significant differences in time to flare between subjects with non-systemic JIA who continued MTX and those who tapered or stopped MTX. This may reflect bias from residual confounding. Rates of sustained remission were modestly higher during times of MTX tapering compared to times after discontinuation.

SESSION INFORMATION
Session Date: Saturday, November 6, 2021
Session Title: Pediatric Rheumatology – Clinical Poster I: JIA (0241–0265)
Session Type: Poster Session A
Session Time: 8:30AM–10:30AM

Background/Purpose: Increasing evidence indicates that synovial tissue analysis can deliver pathophysiological insights but also individual clinically-relevant information in adult-onset inflammatory arthritides. Little is known about synovial pathology in juvenile idiopathic arthritis, especially regarding inter-patient variability of histopathological features.

To assess the heterogeneity of main synovial features (synoviocyte hyperplasia and immune cells infiltration) in juvenile idiopathic arthritis (JIA) patients and a cohort of young adults (< 30 years old) with early rheumatoid arthritis (RA).

Methods: Synovial biopsies were sampled using needle arthroscopy or ultra-sound (US) guided biopsy during intra-articular joint injection. Tissue was embedded in paraffin then sections were stained with hematoxylin and eosin. Synoviocyte hyperplasia (SH) and immune cells infiltration (ICI) was assessed by an experienced pathologist on a 0 – 3 scale where 0 represents the absence of the feature and 3 the highest level.

Results: 34 JIA patients (age (median ±SD): 15.5±6.47 years, oligo-articular JIA n=28/34, polyarticular JIA n=6/34, ANA-RF-ACPA positivity=56%-10%-3%) and 22 RA (age (median ±SD): 24.3±2.6 years, ANA-RF-ACPA positivity=10%-36%-32%) patients were included. Synovial tissue was obtained from knee (n=49/56), wrist (n=4/56) or metacarpophalangeal/intercarpophalangeal joints (n=3/56), using US guided biopsy in 27% of patients and needle arthroscopy in 73%.

Individual scores of SH and ICI were correlated in both JIA (Spearman's *r*=0.503, p value=0.0024) and RA (Spearman's *r*=0.636, p value=0.0015). There was no significant difference in SH and ICI scores between the 2 groups (SH score (Q25-Q50-Q75) in JIA= 0.5-1.125-2 and in RA = 0.75-2-2 ; ICI score (Q25-Q50-Q75) in JIA= 1-2-2 and in RA = 0.75-2-2.25). Intra-group variability of the two assessed features was comparable between the 2 groups (SH coefficient of variation: 72.2% for JIA and 68.2% for RA ; ICI coefficient of variation: 52.2% for JIA and 71.2% for RA). Within JIA patients, there was no significant difference in SH/ICI scores between groups based on ANA positivity, oligo or polyarticular involvement nor ongoing treatment.

Conclusion: Studying main histological features of synovitis, we found no difference between JIA and young RA patients. Furthermore, we report a similar degree of inter-patient heterogeneity in synovial pathological features of JIA and RA patients. These variations were not explained by common clinical characteristics. Whether they relate to different molecular signatures as suggested in adult RA will be further investigated using bulk tissue RNA sequencing.

Patterns of Medication Switching in Juvenile Idiopathic Arthritis: A Retrospective Analysis of a National Administrative Claims Database

Mei-Sing Ong[1], Sarah Ringold[2], Melissa Mannion[3], Marc Natter[4], Laura Schanberg[5] and Yukiko Kimura[6], [1]Harvard Medical School & Harvard Pilgrim Healthcare Institute, Boston, MA, [2]Seattle Children's Hospital, Seattle, WA, [3]University of Alabama at Birmingham, Birmingham, AL, [4]Boston Children's Hospital, Boston, MA, [5]Duke University Medical Center, Durham, NC, [6]Hackensack University Medical Center, New York, NY

SESSION INFORMATION
Session Date: Saturday, November 6, 2021
Session Title: Pediatric Rheumatology – Clinical Poster I: JIA (0241–0265)
Session Type: Poster Session A
Session Time: 8:30AM–10:30AM

Background/Purpose: Although the increasing availability of biologic disease-modifying antirheumatic drugs (bDMARDs) and targeted synthetic DMARDs (tsDMARDs) has significantly improved outcomes for patients with Juvenile Idiopathic Arthritis (JIA), a substantial proportion of patients do not respond to an initial therapy, requiring switching to a second bDMARD/tsDMARD. Subsequent treatment decisions for children with continuing disease activity are haphazard, following a "trial and error approach". The objective of this study is to characterize patterns of bDMARD/tsDMARDswitching among patients with JIA in real-world clinical settings following the initial bDMARD/tsDMARD therapy.

Table 1. Study subjects (n=2,076)

Attribute	
Gender, n (%)	
Female	1346 (64.8)
Male	730 (35.2)
Age, median (IQR)	14 (10 – 18)
Number of switches during the study period, n (%)	
1	644 (31.0)
2	203 (9.8)
3	72 (3.5)
4	19 (0.9)
5	9 (0.4)
6	2 (0.1)
% of early switchers (switching within 180 days of initial therapy)	
Years 2008 to 2010	12.1
Years 2011 to 2013	13.3
Years 2014 to 2016	11.5
Years 2017 to 2020	13.1
First biologic, n (% of total cohort)	
TNFi	1893 (91.2)
Abatacept	45 (2.2)
Tocilizumab	30 (1.4)
Others*	108 (5.2)
Second biologic, n (% of those who received second biologic)	
TNFi	489 (75.9)
Abatacept	32 (5.0)
Tocilizumab	43 (6.7)
Others*	80 (12.4)
Third biologic, n (% of those who received third biologic)	
TNFi	97 (47.8)
Abatacept	23 (11.3)
Tocilizumab	45 (22.2)
Others*	38 (18.7)

*Others include anakinra, canakinumab, rituximab, tofacitinib, ustekinumab, secukinumab

Methods: We conducted a retrospective study of a national administrative claims database in the US (January 2008 to March 2020). Study subjects included children (age < 19 years) who initiated a new bDMARD/tsDMARD therapy, had a medical claim associated with JIA diagnosis, and had been enrolled in the health plans for at least 6 months prior to starting initial bDMARD/tsDMARD therapy. Medications of interest comprised tumor necrosis factor inhibitors (TNFis), abatacept, tocilizumab, anakinra, canakinumab, tofacitinib, ustekinumab, rituximab, and secukinumab.

Results: 2,076 eligible children with JIA were prescribed bDMARD/tsDMARD therapy, most of whom started with TNFis (91%) (Table 1). Median follow-up was 699 days following first reported bDMARD/tsDMARD prescription (IQR

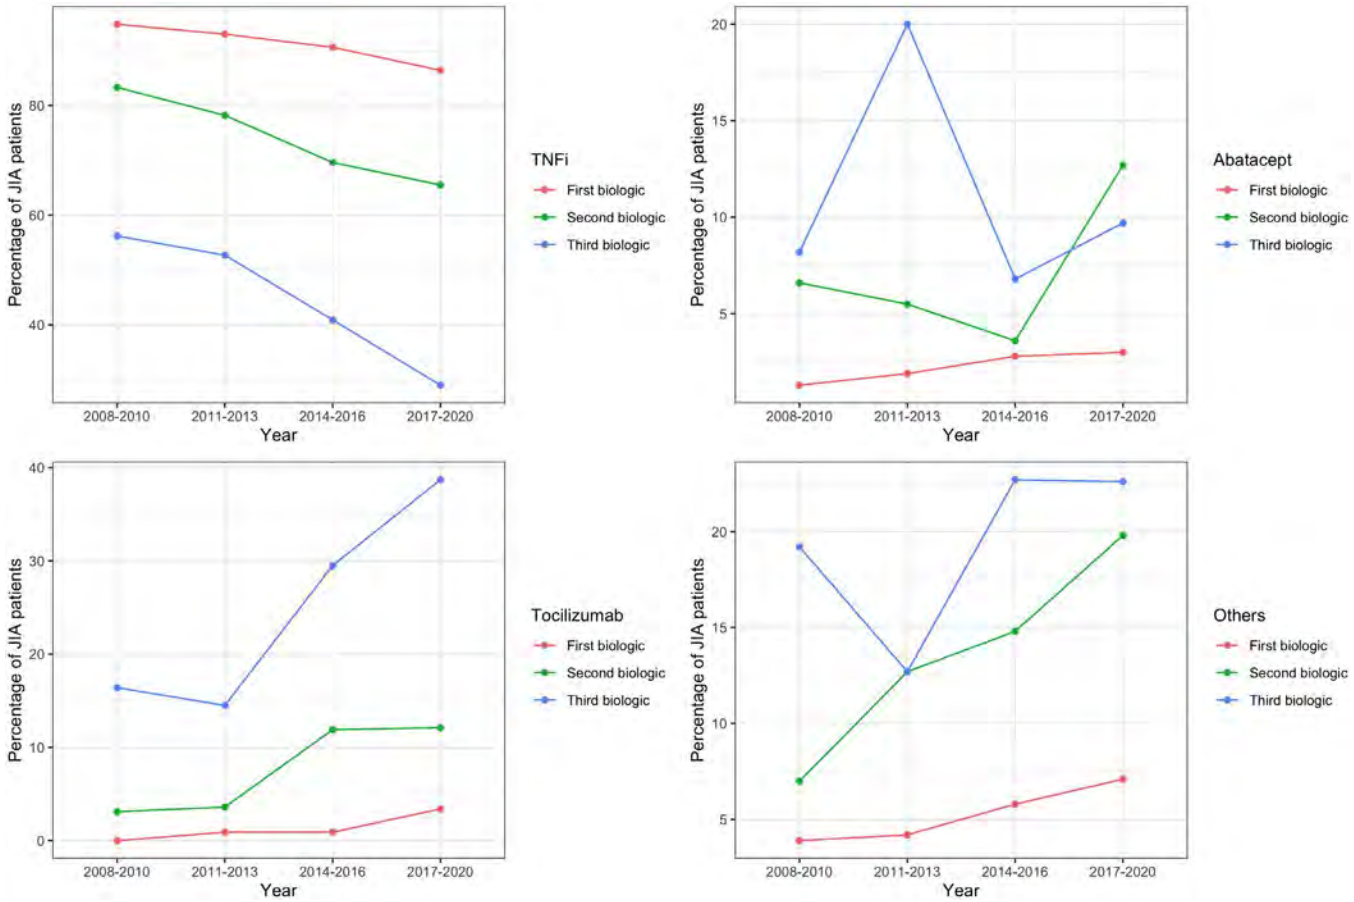

Figure 1. Trends in the use of bDMARD/tsDMARD as initial, second, and third therapy. Others include biologic therapies anakinra, canakinumab, rituximab, ustekinumab, and secukinumab, and the non-biologic therapy tofacitinib. Tocilizumab was FDA approved for use in systemic-onset JIA in 2011.

289-1503). During follow-up, 644 (31%) switched to a second bDMARD/tsDMARD, most commonly to a second TNFi (76%). A further 203 (9.8%) switched to a third bDMARD/tsDMARD and 30 (1.4%) patients received 4 or more bDMARD/tsDMARD therapies. The median time to initiating a second and third bDMARD/tsDMARD were 345 days (IQR 160-835) and 770 days (IQR 395-1435), respectively.

1,745 patients were followed-up for at least 180 days following start of the initial bDMARD/tsDMARD therapy, or switched to a second bDMARD/tsDMARD within 180 days. Among these patients, 193 (11%) started a second bDMARD/tsDMARD within 180 days of the initial therapy (i.e. early switchers). 88% of these patients received TNFi as the initial therapy and 76% switched to another TNFi. Children older than 12 years were more likely to be early switchers, compared with younger children (OR 1.05; 95% CI 1.02-1.08; p< 0.001).

The proportion of early switchers did not vary significantly over the study period. However, changes in the types of bDMARD/tsDMARD used were observed. Notably, there was a significant reduction in the use of TNFi as initial (from 95% in 2008-2010 to 86% in 2017-2020; p< 0.001), second (from 83% in 2008-2010 to 66% in 2017-2020; p< 0.001), and third therapy (from 56% in 2008-2010 to 29% in 2017-2020; p=0.010). There was also a significant trend towards increased use of tocilizumab and other bDMARD/tsDMARD as initial and subsequent therapies (Fig 1).

Conclusion: For many children with JIA, sequential use of bDMARD/tsDMARD is common. One-third of patients in our cohort received a second therapy and one in ten patients switched within 6 months of the initial therapy. More research is needed to evaluate the outcomes and optimal sequence of therapies in this population.

Joint Acoustic Emissions as a Biomarker to Differentiate Between Active and Inactive Juvenile Idiopathic Arthritis via 2-stage Machine Learning Classifier

Luis Rosa[1], Sevda Gharehbaghi[1], Omer Inan[1], Daniel Whittingslow[2], Lori Ponder[3] and Sampath Prahalad[4], [1]Georgia Institute of Technology, Atlanta, GA, [2]Emory University School of Medicine, Atlanta, GA, [3]Children's Healthcare of Atlanta, Atlanta, GA, [4]Emory + Children's Pediatric Institute, Atlanta, GA

SESSION INFORMATION
Session Date: Saturday, November 6, 2021
Session Title: Pediatric Rheumatology – Clinical Poster I: JIA (0241–0265)
Session Type: Poster Session A
Session Time: 8:30AM–10:30AM

Background/Purpose: Juvenile Idiopathic Arthritis (JIA) is the most prevalent chronic rheumatic disease and can result in disability in children. JIA most commonly affects the knee. Despite the widespread occurrence of JIA, its heterogeneous presentation and lack of reliable biomarkers make diagnosis and quantifying treatment response challenging. If untreated, the synovitis in JIA can lead to cartilage degeneration and even bone erosion. To evaluate knee health status non-invasively, we can use contact accelerometers that capture the vibrations generated by internal friction of articulating surfaces during movement, also known as joint acoustic emissions (JAE). In this study, we used JAEs to evaluate children's knees and distinguish between healthy, inactive JIA, and active JIA.

Methods: We collected knee JAEs from 51 participants while performing flexion/extensions, including 34 subjects with JIA (23 active/11 inactive) and 17 healthy controls. To these JAE signals, we applied filtering and denoising techniques to extract 15 time-frequency audio features to be used as training data for our Logistic Regression machine learning (ML) classification model. This classifier was implemented in two stages, where at each we obtained a knee health score that indicates the predicted class. The first stage distinguished between healthy and JIA subjects with active and inactive JIA grouped together. The second stage then took only the subjects identified as JIA and classified them as either active or inactive. Hence, our 2-stage classifier was used to evaluate not only presence of, but also severity of JIA.

Results: We validated our 2-stage classifier through leave-one-subject-out cross-validation and obtained an overall 3-class accuracy of 76% when differentiating between healthy, inactive JIA, and active JIA subjects. We obtained a Stage 1 accuracy of 78% and a Stage 2 accuracy of 81%. The least accurate class was inactive JIA, which had both the lower number of sample subjects for training (11) and has the most uncertain label since designation of knee arthritis as "inactive" is primarily clinical and thus is subject to variability. Notice error compounding from both stages results in a lower overall accuracy since second stage depends on first stage predictions, hence, with further ML optimization, we see potential for improved diagnostic accuracy.

Conclusion: These results support the use of JAEs as a novel non-invasive digital biomarker for knee joint health assessment. More accurate characterization of synovitis by magnetic resonance imaging can facilitate improved accuracy of our training dataset which in turn could allow us to differentiate between different levels of synovial inflammation. We have shown that close collaboration between clinicians and bioengineers can result in personalized assessment and thereby improving management of arthritis in children.

Development and Preliminary Acceptability of JIActiv, a Social Media-Based Program Promoting Engagement in Physical Activity Among Young People Living with Juvenile Idiopathic Arthritis

Sabrina Cavallo[1], Karine Toupin April[2], Ciaran Duffy[2], Karina Cristea[1], Jihene Tlili[1], Imane Brahmi[1], Zeinab Ahmadian[1], Michele Gibbon[3], Alexandra Sirois[4], Laurie Proulx[5], Sara Ahmed[6], Claudine Auger[1] and Jennifer Stinson[7], [1]Université de Montréal, Montréal, QC, Canada, [2]University of Ottawa, Ottawa, ON, Canada, [3]Children's Hospital of Eastern Ontario, Ottawa, ON, Canada, [4]Canadian Arthritis patient Alliance, Montréal, QC, Canada, [5]Canadian Arthritis Patient Alliance, Ottawa, ON, Canada, [6]Children's Hospital of Eastern Ontario, Montréal, QC, Canada, [7]The Hospital for Sick Children, Toronto, ON, Canada

SESSION INFORMATION
Session Date: Saturday, November 6, 2021
Session Title: Pediatric Rheumatology – Clinical Poster I: JIA (0241–0265)
Session Type: Poster Session A
Session Time: 8:30AM–10:30AM

Background/Purpose: Young people with juvenile idiopathic arthritis (JIA) are at greater risk for adopting chronic sedentary behaviours and not meeting national physical activity guidelines compared to healthy peers, which can have an important impact on their health, daily function and quality of life. Despite the benefits of engaging in an active lifestyle, to our knowledge few appealing, educational and interactive options exist to promote physical activity among young people living with JIA. Our study aimed to develop and explore the preliminary acceptability (i.e. how well the program is received by users, and how it meets their needs) of JIActiv, a 12-week educational and interactive social media-based program promoting physical activity from the perspectives of adolescents and young adults with JIA and parents, and to refine program format and content.

Methods: The JIActiv prototype was developed based on our earlier work which included three systematic reviews, as well as results from our qualitative needs assessment with key stakeholders (young people with JIA, parents, health care professionals and researchers). JIActiv is an educational and interactive program aimed at promoting physical activity in young people with JIA through the delivery of evidence-based information and use of behavior-change strategies via social media. A descriptive qualitative study design was used to assess the acceptability of the JIActiv prototype. Two adolescents 13 to 17 years of age, 13 young adults 18 to 26 years with JIA, and 2 parents were recruited from arthritis patient groups and a Canadian rehabilitation center. Individual audiotaped interviews lasting 60 to 90 minutes were conducted with each participant over Zoom (Enterprise version 5.0.2). Audiotaped findings were transcribed verbatim, sorted, organized and coded using the QDAMiner software. Data was categorised into emerging themes using simple content analysis. Qualitative findings reported on the format, content and potential usefulness of the program.

Results: The vast majority of participants preferred Instagram as the platform for the program and appreciated the presented functionalities. All participants felt that the proposed length of the program and the number of activities per week were appropriate. The informational videos, individual educational and interactive group activities were thought to be pertinent and helpful to motivate young people to engage in physical activity. Participants found that the esthetics of the program could be improved by choosing one color scheme for all postings. None of the participants reported any concerns regarding cyber-bullying. Most participants thought that having a mentor and access to a health care professional would be very helpful to help answer their questions and offer social support. The group format (size and age range of participants) was well accepted by participants.

Conclusion: The JIActiv social media-based program has good preliminary acceptability and is potentially useful for promoting engagement in physical activity among young people with JIA. Participants proposed ideas on how the program could be improved. Additional interview cycles will help to further refine the program.

Abstract Number: 0266

The Psychosocial Impact of the COVID-19 Pandemic on the Rheumatology Patient Experience

Melissa Flores, Priscilla Toral, Roberta Horton, Adena Batterman, Mavis Seehaus, Juliette Kleinman and Jillian Rose, Hospital for Special Surgery, New York, NY

SESSION INFORMATION
Session Date: Saturday, November 6, 2021
Session Title: Psychology/Social Sciences Poster (0266–0267)
Session Type: Poster Session A
Session Time: 8:30AM–10:30AM

Background/Purpose: Research shows people with rheumatic conditions may be more susceptible to severe illness from COVID-19 due to their immunocompromised state. The COVID-19 pandemic has been associated with negative impacts on mental health (MH) & there is higher prevalence of depression & anxiety in patients with rheumatic illness. Most studies have focused on the medical impact of COVID-19; however, less is known about the MH impacts in this population. This needs assessment explores the psychosocial impact & needs of rheumatic disease patients during the pandemic.

Methods: A 95-item online survey in English & Spanish with Likert scale & open-ended questions was disseminated nationally from July-Oct. 2020 to rheumatic disease patients age 18+, promoted in NYC hospitals, local/national support programs & social media. The survey assessed physical & mental health, illness management, access to care, social environment & resources. The Patient Health Questionnaire-4 (PHQ-4) & the Hospital Anxiety & Depression Scale (HADS) assessed MH. A comparative analysis was conducted for those who reported a change in emotional health (ECs) vs. those who did not (NECs). Independent samples t-tests & chi-square tests were used to examine differences.

Results: Of the 382 responses received, most were age 35+ (79%), female (91%) & Non-Hispanic (77%). Almost half (46%) were White, 9% Asian, 8% African American & 6% Other. Almost all (96%) had health insurance; 50% were employed.

Most participants had SLE (67%), RA (19%), & Sjogren's syndrome (8%) with a mean of 13 years since diagnosis. Over half (63%) reported a flare since the pandemic & 16% had COVID-19. Only 19% reported no changes to their care during the pandemic; 33% indicated their care switched to telehealth visits or appointments were postponed (19%).

Most (76%) reported a change in their mood and/or emotional health, with 81% indicating that this change was due to the pandemic. The mean PHQ-4 score for all respondents was 4.3 (SD: 3.5) with 31% scoring moderate/severe for psychological distress. The mean HADS Anxiety & HADS Depression scores were 8.2 (SD: 4.9) & 7 (SD: 4.3) with 54% & 43% scoring borderline/abnormal. Most (82%) shared they "feel isolated from others."

Patients who experienced a negative emotional change (ECs) had significantly higher PHQ-4 & HADS scores ($P< 0.001$) than those who did not (NECs). Significant differences were found across these areas: ↑ % switching to telehealth (45% v 23%, $P=0.001$), receiving MH services (31% v 7%, $P< 0.001$), taking medication for their MH (29% v 5%, $P< 0.001$) & starting counseling (14% v 0%, $P=0.001$).

Almost half ECs desired support programs to cope with their condition (49% v 21%, $P< 0.001$), indicating virtual programs on coping with illness, MH resources & virtual support groups would be most helpful.

Conclusion: Despite limitations due to a convenience sample, results contribute to research on the psychosocial impact of the pandemic on rheumatic disease patients—the toll on emotional health & increased isolation. The significant differences found in those who reported an emotional change vs. those who did not support the need for the care team to assess & address MH issues during the pandemic. Further study is needed to assess long-term impacts.

Session Date: Saturday, November 6, 2021
Session Title: Psychology/Social Sciences Poster (0266–0267)
Session Type: Poster Session A
Session Time: 8:30AM–10:30AM

Background/Purpose: Disruptions of routines or livelihood and worry during the COVID-19 pandemic may have impacted systemic lupus erythematosus (SLE) patients in multiple ways. We explored pre- and during pandemic changes of SLE disease activity, general health, and psychosocial factors in a large and diverse cohort.

Methods: We examined longitudinal data from Georgians Organized Against Lupus (GOAL), a population-based cohort of adults from Atlanta, Georgia, with a validated diagnosis of SLE. All participants fulfilled 3 or more ACR classification criteria and had a final diagnosis of SLE by a board-certified rheumatologist. Participants responded to validated self-administered instruments on health outcomes at least annually. This study included participants who

Table 1: Characteristics in the GOAL Cohort – Pre-Pandemic and During Pandemic (n=852)

	Pre-Pandemic	During pandemic	P-value (paired)
Health Insurance			
Insurance Type 1) No Insurance	109 (12.8)	86 (10.2)	
2) Private	313 (36.8)	306 (36.2)

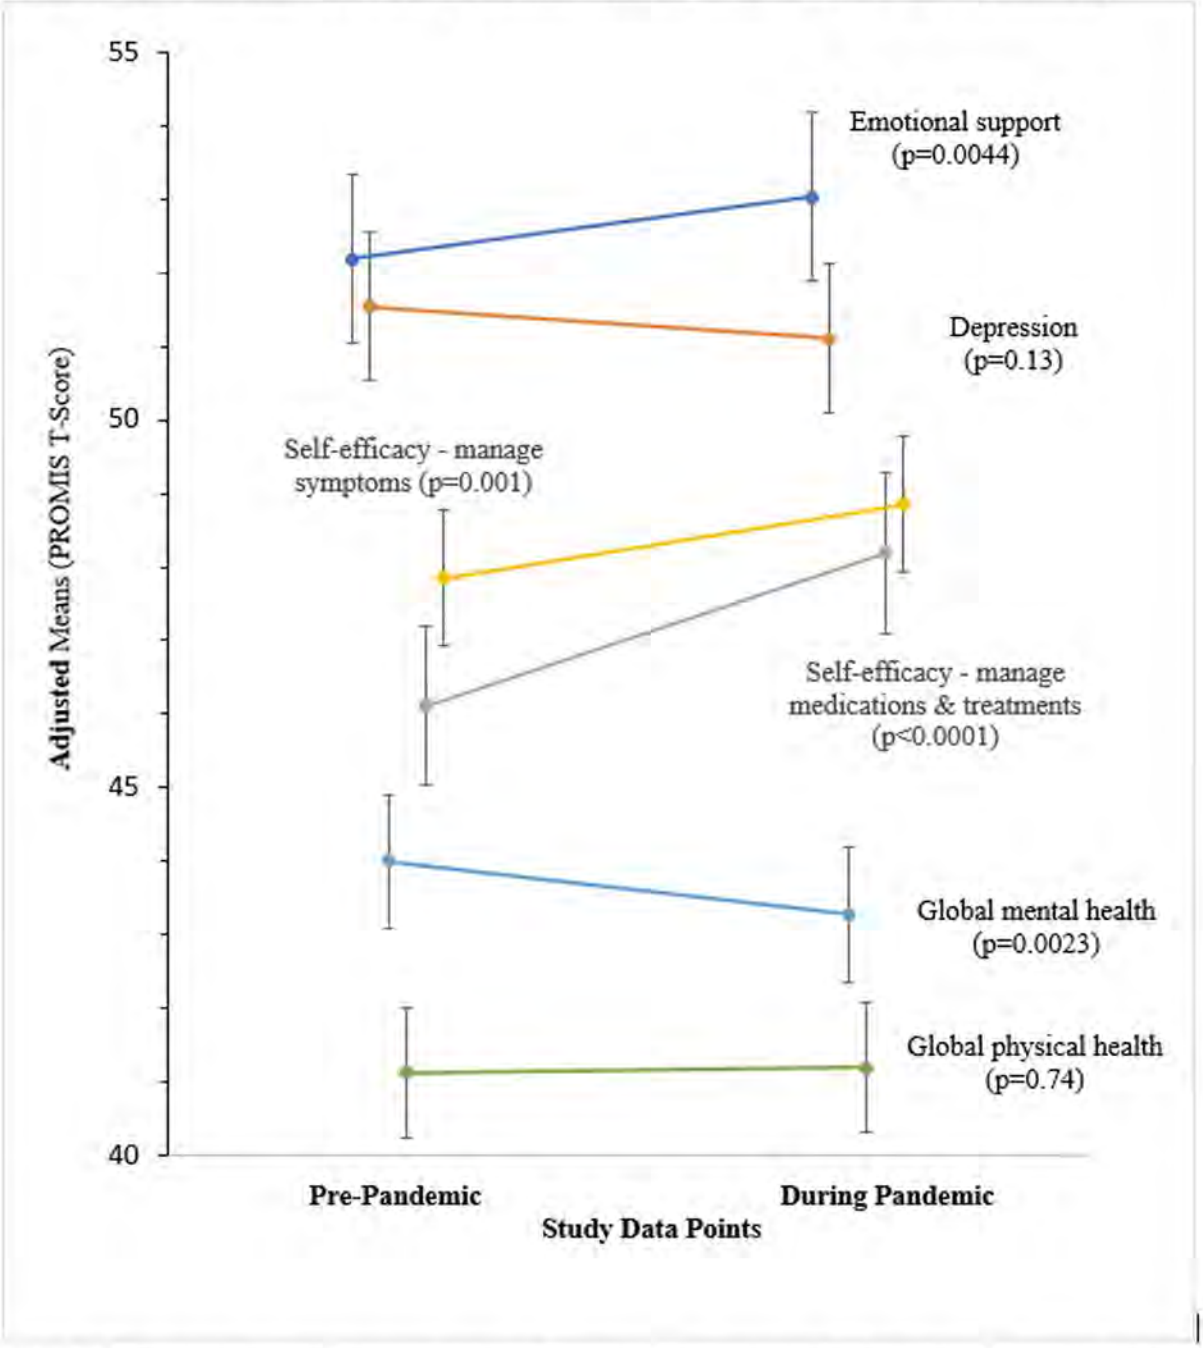
SLAQ - SLE Activity Questionnaire (range 0-47), Everyday Discrimination (range 1-4), PSS10- Cohen's Perceived Stress Scale 10 (range 0-40)
*PROMIS T-score rescales the raw score into a standardized score with a mean of 50 and a standard deviation of 10. Higher scores represent more of the concept being measured.
** Symmetry Test.

completed one survey before (2017-2019) and another survey during the pandemic (2020-2021). We explored changes in SLE disease activity, health, and psychosocial elements with the following measures: Systemic Lupus Activity Questionnaire (SLAQ), PROMIS short forms (Global physical and mental health, Depression, Emotional Support, Self-efficacy for managing symptoms, Self-efficacy for managing medications and treatments), Everyday Discrimination Scale, and Cohen's Perceived Stress Scale. Changes in mean scores were assessed using a paired test (univariate analysis). Multivariate regression analysis was performed to further exam differences, with the adjustments for socio-demographics (age, gender, race, education), insurance status, disease damage, stress, and discrimination.

Results: We evaluated 852 participants (94% women, 81% Black, mean age 48). SLE-related characteristics included an average age of diagnosis of 32.2 years (SD ± 11.8), average disease duration of 15.5 years (SD ± 10.2), and

Figure 1: Pre-Pandemic and During Pandemic: Health, Social Support, and Self-Efficacy



PROMIS T-score rescales the raw score into a standardized score with a mean of 50 and a standard deviation of 10. Higher scores indicate more of the domain measured. T-scores adjustments: socio-demographics (age, race, education), insurance, disease severity (SLAQ, SA-BILD), stress, and discrimination.

over 50% with severe disease damage based on the Self-administered Brief Index of Lupus Damage (score ≥ 3). Overall, insurance categories remained without significant changes during the pandemic (Table 1). Except for global mental health, all measures showed significantly better mean scores during the pandemic than pre-pandemic. After adjustments for confounders, mean scores for emotional support and self-efficacy remained markedly better during the pandemic than before the pandemic (Figure 1). The original paired test showed no difference for global mental health; however, mental health was associated with significant worsened change after adjustments.

Conclusion: Our results in a diverse cohort with large numbers of socially vulnerable people show that participants reported improved confidence to manage symptoms, medications, and other treatments in challenging times. Additionally, they received more emotional support during the pandemic. However, global mental health deteriorated. We hypothesize that the stay-at-home pandemic recommendations allowed patients to seek out supportive resources and focus on self-management. Further observations post-pandemic will offer more insight regarding the mental health impact on SLE.

Abstract Number: 0268

Effect of Biologic Agents on Lipids and Cardiovascular Risk in Rheumatoid Arthritis Patients

Dimitrios Pappas[1], George Reed[2], Kevin Kane[2], Jeffrey Curtis[3] and Joel Kremer[4], [1]Columbia University, New York, NY, [2]University of Massachusetts, Worcester, MA, [3]Division of Clinical Immunology and Rheumatology, Department of Medicine, Department of Epidemiology, University of Alabama at Birmingham, Birmingham, AL, [4]Albany Medical College, Latham, NY

SESSION INFORMATION
Session Date: Saturday, November 6, 2021
Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster I: Cardiovascular Pulmonary Disease (0268–0295)
Session Type: Poster Session A
Session Time: 8:30AM–10:30AM

Background/Purpose: Cardiovascular disease (CVD) risk scores incorporating measures of inflammation such as the Reynolds risk score (RRS) may be appropriate to predict CVD risk in patients (pts) with rheumatoid arthritis (RA), even though not yet validated for RA pts. The purpose of this analysis was to investigate the effect of biologic DMARDs on lipids and the RRS.

Methods: Pts with at least moderate disease activity (CDAI >10) initiating a biologic DMARD participated in a comparative effectiveness trial (CERTAIN) nested within CorEvitas (formerly known as Corrona) RA registry. Characteristics, including lipid values, hsCRP and RRS in pts initiating a TNF-α inhibitor (TNFi) or non-TNFi (rituximab [RTX], abatacept [ABT] or tocilizumab [TCZ]), were measured at baseline, 3- and 6- months later. Longitudinal mixed models examined the association of individual biologics with changes in lipid levels, hsCRP and RRS after 3- and 6-months of therapy. Log transformations used for skewed distributions (TG, hsCRP, RRS). Generalized structural equation models were estimated to model mediation of CRP, CDAI or swollen joint count on lipid changes when comparing TCZ vs other biologics. TCZ was selected for this comparison given the known - and observed in this analysis (see below) - effects on lipid levels. Patients who interrupted therapy prior to follow up visits or without complete lipid data at all time points were excluded.

Results: 1698 initiations of a biologic were analyzed. Baseline characteristics: 78.7% women, 89.2% Caucasian, 72.3% seropositive. Mean ± SD age was 56.9 ± 12.8, RA disease duration 8.9 ± 9.2 years; CDAI 29.0 ± 12.7. 36.8% of pts were biologic naïve and 24.5% on anti-hyperlipidemic therapy. CVD history (7.9% of patients) did not exclude patients from the analysis. Diabetes mellitus was present in 9.4% of patients and 42.0% were obese (BMI >30). Table 1 shows lipid levels, hsCRP and RRS adjusted changes after 3- and 6-months of therapy. Pts initiating TCZ had a significant increase in total cholesterol, LDL, triglycerides (TG) and a significant decrease in hsCRP compared with patients initiating TNFi. Pts initiating ABT had a significant increase in hsCRP compared with patients initiating TNFi.

Table 1. Baseline lipid levels, log hsCRP and Reynolds Risk Score and adjusted effect of individual biologics at 3 and 6 months after initiating biologic therapya

Change in Lipid Levels, Mean (SE)	TNFi (Ref) N=941	Rituximab N=114	Abatacept N=349	Tocilizumab N=294	P-value[b]

Change (6 mon-base)	-0.28 (0.05)	0.44 (0.12)**	0.19 (0.07)**	-1.43 (0.08)**	<0.001
Log Reynolds Risk Score					
Change (3 mon-base)	-0.03 (0.02)	0.13 (0.05)*	0.01 (0.03)	-0.14 (0.03)**	<0.001
Change (6 mon-base)	0.01 (0.02)	0.12 (0.05)	0.07 (0.03)	-0.14 (0.03)**	<0.001

* Indicates change from baseline $p < 0.05$
** Indicates change from baseline $p < 0.01$

[a] Mixed Models were fit at 3 and 6 months adjusted for baseline levels and compared among the four drug groups using TNF inhibitors as the reference group. Linear mixed effect regression models are estimated with patient as a random effect. Model adjusted for patient demographics (age, gender, race), behaviors (smoking, drinking), BMI and change in BMI, disease measures including RF+, CCP+,CDAI and HAQ at baseline and change in CDAI and HAQ, prior history of CVD, malignancies, hospitalized infections, and diabetes; use of cholesterol lowering medications, fish oil and flax seed use and any change in cholesterol lowering meds or fish oil. Adjustment was made for patient demographics (age, gender, race), behaviors (smoking, drinking), BMI and change in BMI, disease measures including RF+, CCP+,CDAI and HAQ at baseline and change in CDAI and HAQ, prior history of CVD, malignancies, hospitalized infections, and diabetes; use of cholesterol lowering medications, fish oil and flax seed use and any change in cholesterol lowering meds or fish oil.

[b] *P*-value comparing within row differences between all drug groups (null hypothesis of all means equal)

ABT had significant decreases in log RRS at 3- and 6-month compared to other biologics. Mediator analyses estimated significant effect of hsCRP but not CDAI or swollen joints on lipid changes. Table 2 presents direct, indirect effects, and total effects of TCZ vs other biologics on lipid changes.

Conclusion: The impact of lipid changes on CVD risk must be considered in the context of the burden of inflammation in pts with RA. Lipid increases may not be atherogenic and may occur in the context of the "lipid paradox". In this analysis moderate increases in lipid levels were associated with the therapy initiated and with changes in CRP. Lipid increase did not translate to an increased CVD risk as captured by RRS.

Table 2. Mediator analysis - CRP association with lipid changes for TCZ vs other biologics after 3 and 6 months of therapy[a]

	Lipid change[b]	95% CI	p-value[c]
Combined Effects on LDL at 3 and 6 Months			
Direct Effect of TCZ	7.104	4.527, 9.681	<0.001
Indirect Effect via CRP	1.837	0.853, 2.820	<0.001
Total Effect	8.941	6.554, 11.327	<0.001
Combined Effects on Total Cholesterol at 3 and 6 Months			
Direct Effect of TCZ	7.431	4.498, 10.365	<0.001
Indirect Effect via CRP	4.115	2.911, 5.317	<0.001
Total Effect	11.456	8.818, 14.273	<0.001
Combined effect on log TG at 3 and 6 Months			
Direct Effect of TCZ	0.004	-0.040, 0.047	0.869
Indirect Effect of CRP	0.039	0.022, 0.056	<0.001
Total Effect	0.043	0.004, 0.082	0.033

[a] Generalized structural equations models were used to model the effects of TCZ on lipid levels with CRP as a mediator. Adjustment was made for patient demographics (age, gender, race), behaviors (smoking, drinking), BMI and change in BMI, disease measures including RF+, CCP+,CDAI and HAQ at baseline and change in CDAI and HAQ, prior history of CVD, malignancies, hospitalized infections, and diabetes; use of cholesterol lowering medications, fish oil and flax seed use and any change in cholesterol lowering meds or fish oil.

[b]Difference in change in lipids (LDL, total cholesterol, log triglycerides) between TCZ and other biologics

[c]P-value is the comparison to the null hypothesis that the effect equals zero

Abstract Number: 0269

Autoantibodies and the Risk of Incident Cardiovascular Disease in US Veterans with Rheumatoid Arthritis

Tate Johnson[1], Michael Duryee[2], Carlos Hunter[2], Punyasha Roul[2], Yangyuna Yang[2], Jeremy Sokolove[3], William Robinson[4], Joshua Baker[5], Geoffrey Thiele[2], Ted Mikuls[2] and Bryant England[2], [1]University of Nebraska Medical Center, Elkhorn, NE, [2]University of Nebraska Medical Center, Omaha, NE, [3]Stanford University School of Medicine, Berwyn, PA, [4]Stanford University, Stanford, CA, [5]University of Pennsylvania, Philadelphia, PA

Table 1. Associations of RF, anti-CCP, and anti-MAA antibodies with incident cardiovascular disease in US Veterans with rheumatoid arthritis

Autoantibody	MACE aHR (95% CI)	CVD Death aHR (95% CI)
Rheumatoid Factor		
Seropositive (>15 U/mL)	1.28 (0.92-1.78)	**1.72 (1.04-2.86)**
Concentration	**1.15 (1.04-1.27)**	1.16 (0.99-1.34)
Anti-CCP		
Seropositive (>5 U/mL)	0.91 (0.61-1.35)	1.29 (0.78-2.13)
Concentration	1.11 (0.98-1.25)	**1.27 (1.11-1.45)**
Anti-MAA, IgG		
Seropositive*	1.02 (0.83-1.27)	1.38 (0.98-1.95)
Concentration	1.16 (0.99-1.35)	**1.24 (1.06-1.43)**
Anti-MAA, IgM		
Seropositive*	1.20 (0.82-1.75)	1.54 (0.97-2.44)
Concentration	**1.20 (1.03-1.39)**	**1.22 (1.05-1.42)**
Anti-MAA, IgA		
Seropositive*	1.05 (0.67-1.66)	1.20 (0.79-1.82)
Concentration	1.16 (0.93-1.44)	1.14 (0.98-1.33)

Antibodies each assessed in separate models adjusting for age, sex, BMI, current smoking, hypertension, diabetes, lung disease, prior MACE, medications (methotrexate, TNF biologic, prednisone), and DAS28. Values are adjusted hazard ratios per 1 SD change in antibody concentration. Bold values indicate $p<0.05$.

*Anti-MAA antibody status was considered positive if concentrations fell in the top two tertiles among study participants

Abbreviations: CCP = cyclic citrullinated peptide, CI=confidence interval, CVD = cardiovascular disease, aHR=adjusted hazard ratio, MAA = malondialdehyde acetaldehyde, MACE=major adverse cardiovascular event, RF = rheumatoid factor

SESSION INFORMATION

Session Date: Saturday, November 6, 2021
Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster I: Cardiovascular Pulmonary Disease (0268–0295)
Session Type: Poster Session A
Session Time: 8:30AM–10:30AM

Background/Purpose: Autoantibodies are hypothesized as one of the RA specific factors contributing to a heightened risk of cardiovascular disease (CVD) in this population. However, prior epidemiologic studies of RF and ACPAs with CVD risk in RA are conflicting, and the role of antibodies to other post-translationally modified peptides/proteins

Table 2. Associations of ACPA subtypes with incident cardiovascular disease in US Veterans with rheumatoid arthritis

Autoantibody Antigen	MACE aHR (95% CI)	CVD Death aHR (95% CI)

Histone 2B (62-81) cit cyclic	1.09 (0.93-1.27)	1.11 (0.90-1.37)
Vimentin cit	1.04 (0.88-1.23)	1.06 (0.90-1.25)
Vimentin (58-77) cit3 cyclic	1.02 (0.90-1.17)	1.03 (0.87-1.23)

Antibodies each assessed in separate models adjusting for age, sex, BMI, current smoking, hypertension, diabetes, lung disease, prior MACE, medications (methotrexate, TNF biologic, prednisone), and DAS28. Values are adjusted hazard ratios per 1 SD change in antibody concentration. Bold values indicate $p<0.05$.

Abbreviations: CCP = cyclic citrullinated peptide, CI=confidence interval, cit=citrullinated, CVD = cardiovascular disease, aHR=adjusted hazard ratio, MACE=major adverse cardiovascular event, RF = rheumatoid factor

including malondialdehyde acetaldehyde (anti-MAA) are not well understood. We evaluated the associations of RF, ACPAs, and anti-MAA antibodies with major adverse cardiovascular events (MACE) in RA.

Methods: We studied patients in a multicenter prospective cohort of U.S. veterans with RA. We measured RF by nephelometry, anti-CCP antibody by 2nd generation ELISA, and anti-MAA antibody (IgG, IgM, and IgA) by ELISA on

banked serum from enrollment. In a subset of patients (n=1,422), 19 ACPA subspecificities were measured with a multiplex bead-based assay. Autoantibody concentrations were log-transformed and standardized (per 1 SD). RF and anti-CCP positivity were defined per assay cut-offs while anti-MAA was considered positive if in the upper two tertiles, yielding a similar frequency of positivity. MACE was defined as a composite of myocardial infarction, coronary revascularization, stroke, or CVD-related death identified from VA databases and the National Death Index using a previously validated administrative algorithm. Baseline covariates were obtained from registry and administrative data and included demographics, smoking status, BMI, LDL cholesterol, comorbidities (hypertension, diabetes, lung disease, prior MACE), medications (MTX, TNFi biologics, prednisone), and DAS28. We used multivariable Cox regression to examine the associations of autoantibodies with incident MACE and CVD death.

Results: Among 2,362 RA patients (90% male, mean age 72 years), there were 388 MACE outcomes over 19,868 person-years (PY) of follow-up and 220 CVD deaths. Higher concentrations of RF (aHR per 1 SD 1.15 [1.04-1.27]) and IgM anti-MAA (aHR 1.20 [1.03-1.39]) were associated with risk of MACE (Table 1). Effect sizes were similar for other autoantibodies, though not statistically significant. Similarly, higher concentrations of anti-CCP (aHR 1.27 [1.11-1.45]) and IgG (aHR 1.24 [1.06-1.43]) and IgM (aHR 1.22 [1.05-1.42]) anti-MAA were significantly associated with CVD-death, and non-significant associations were observed for other autoantibodies. When evaluated as seropositivity, estimates were less precise with only RF significantly associated with CVD-death (aHR 1.72 [95% CI 1.04-2.86]). Analyses of ACPA subtypes revealed associations between higher concentrations of anti-cit fibrinogen with MACE (aHR 1.12 [1.03-1.23]) and CVD death (aHR 1.20 [1.08-1.33]) as well as anti-cit apolipoprotein E, biglycan, and filaggrin with CVD death (aHR 1.12 [1.02-1.23], 1.16 [1.07-1.25], and 1.13 [1.00-1.26]).

Conclusion: Higher concentrations of several RA-related autoantibodies were associated with MACE and/or CVD-mortality, providing support to the hypothesis that autoantibodies may directly contribute to excess CVD risk in RA. Additional study is needed to elucidate pathophysiological mechanisms underpinning these epidemiologic associati ons.

SESSION INFORMATION

Session Date: Saturday, November 6, 2021

Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster I: Cardiovascular Pulmonary Disease (0268–0295)

Session Type: Poster Session A

Session Time: 8:30AM–10:30AM

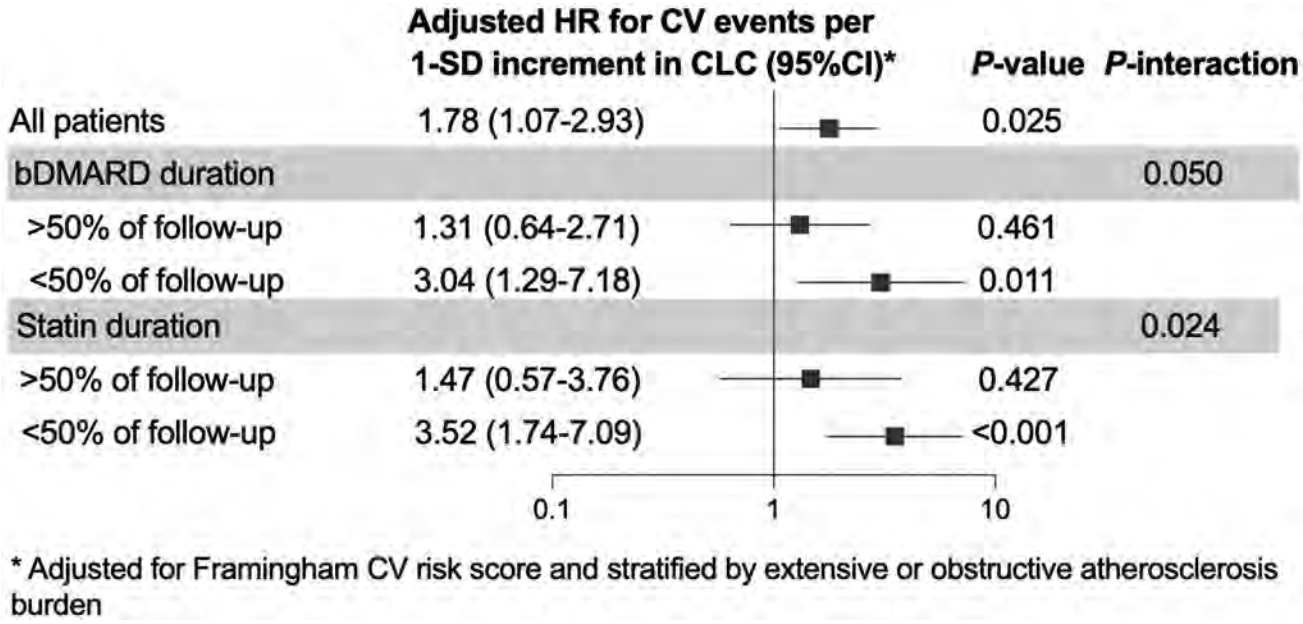

Figure 1. bDMARD and statin therapy condition the impact of CLC on cardiovascular risk in RA.

Background/Purpose: Statins and bDMARDs may decrease cardiovascular risk in RA by lowering coronary plaque formation, promoting regression and altering the composition of atherosclerotic lesions. Macrophage cholesterol loading capacity (CLC) of serum is a functional parameter reflecting both quality and quantity of lipoproteins and is potentially related to foam cell formation. We evaluated the associations between CLC, coronary plaque burden and cardiovascular (CVD) risk in patients with RA. We further explored the moderating effects of RA treatments on these relationships.

Methods: 107 patients with baseline coronary CT angiography for atherosclerosis evaluation and prospective follow-up for cardiovascular events over 6.0±2.4 years were studied. Coronary artery calcium score (CAC), number of segments with plaque and plaque composition were assessed. CLC was the macrophage cholesterol content, measured by fluorometric assay, after a 24 hour incubation with whole serum. Adjusted robust Cox regression evaluated main

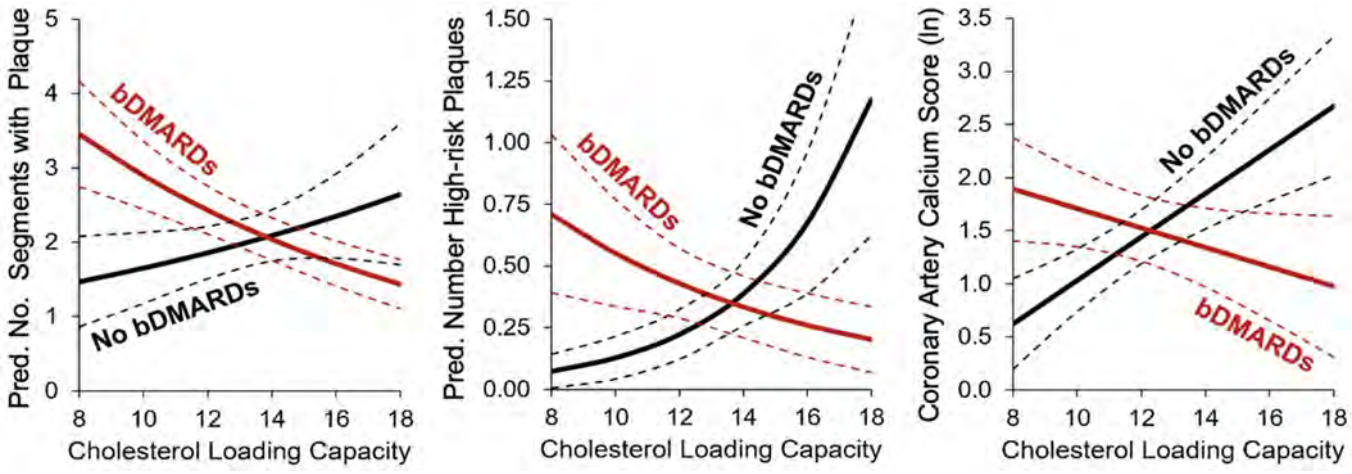

Figure 2. bDMARD therapy conditions the impact of CLC on coronary atherosclerosis burden.

effects and interactions of CLC with bDMARD and statin treatment duration on event risk. Robust linear regression examined the interaction between CLC and bDMARD therapy on CAC burden. Robust negative binomial regressions evaluated interactions between CLC and bDMARD exposure on total and high-risk low-attenuation plaque (LAP) burden.

Results: CLC associated with incident CVD risk (per SD increment; adjusted hazard ratio [aHR] 1.78 [95% CI 1.07-2.93], *P*=0.025), after accounting for Framingham CVD score and baseline atherosclerosis burden. The effect was stronger in patients with less exposure to bDMARDs (< 50% of follow-up: aHR 3.04 [95% CI 1.29-7.18]; versus >50% of follow-up: aHR 1.31 [95% CI 0.64-2.71], Fig. 1) and statins (< 50% of follow-up: aHR 3.52 [95% CI 1.74-7.09]; versus >50% of follow-up: aHR 1.47 [95% CI 0.57-3.76], Fig. 1). In cross-sectional analyses adjusting for Framingham CVD score and DAS28-CRP, CLC (per 1-SD unit) was not related to number of segments with plaque (adjusted rate ratio [aRR] 0.91 [95% CI 0.74-1.13]), number of vulnerable plaques (aRR 1.03 [95% CI 0.64-1.66]) or ln-transformed CAC (β -0.01 [95% CI -0.15-0.14]). However, in analyses stratified by baseline bDMARD use, CLC (per 1-SD unit) was positively related to number of vulnerable plaques (aRR 2.30 [95% CI 1.16-4.57]) and ln-transformed CAC (β 0.27 [95% CI 0.03-0.50]) among bDMARD naïve individuals (Fig. 2). In addition, CLC inversely associated with number of segments with plaque (per SD increment; aRR 0.76 [95% CI 0.61-0.94]) only in bDMARD exposed patients (Fig. 2).Baseline statin use did not significantly modify the effect of CLC on baseline coronary plaque (data not shown).

Conclusion: We showed for the first time that enhanced cholesterol loading onto macrophages (CLC) in RA associated with greater cardiovascular risk; this risk was modified by statin and bDMARD use. CLC further associated with greater CAC score and LAP burden in bDMARD-naïve but not bDMARD-treated patients. The negative association of CLC with total plaque burden in bDMARD-treated patients may reflect lower plaque formation and reduction in atherogenic lipoprotein disposal through vessels.

Higher Prevalence of Subclinical Atherosclerosis in the First Five Years of Rheumatoid Arthritis Diagnosis

Natalia Guajardo-Jauregui, **Dionicio Galarza-Delgado**, Iris Colunga-Pedraza, Jose Azpiri-Lopez, Alejandra Rodriguez-Romero, Julieta Loya-Acosta, Alejandro Meza-Garza, Jesus Cardenas-de La Garza, Salvador Lugo-Perez and Jessica Castillo-Treviño, Hospital Universitario "Dr Jose E. Gonzalez", Monterrey, Mexico

SESSION INFORMATION
Session Date: Saturday, November 6, 2021
Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster I: Cardiovascular Pulmonary Disease (0268–0295)
Session Type: Poster Session A
Session Time: 8:30AM–10:30AM

Background/Purpose: Patients with rheumatoid arthritis (RA) have a higher risk of developing a cardiovascular (CV) event than the general population, due to an accelerated process of atherosclerosis, which has been documented to begin in early stages of the disease and is directly associated with systemic inflammation.

The aim of this study was to compare the prevalence of subclinical atherosclerosis detected by carotid ultrasound (US) in patients with RA in the first five years of diagnosis and healthy controls.

Table 1. Demographic and clinical characteristics.

	RA patients (n=53)	Controls (n=53)	*p-value*
Age years, mean ± SD	54.48 ± 9.09	54.86 ± 6.83	NS
Women, n (%)	49 (92.5)	49 (92.5)	NS
T2DM, n (%)	8 (15.1)	7 (13.2)	NS
HTN, n (%)	17 (32.1)	17 (32.1)	NS
Dyslipidemia, n (%)	19 (35.8)	19 (35.8)	NS
Obesity, n (%)	21 (39.6)	20 (37.7)	NS
Active smoking, n (%)	3 (5.7)	4 (7.5)	NS
BMI kg/m^2, median (IQR)	28.78 (25.92-33.21)	27.59 (24.55-33.34)	NS
Disease duration, mean ± SD	2.48 ± 1.31	-	-
DAS28-CRP, median (IQR)	3.21 (1.89-4.12)	-	-
MTX, n (%)	39 (73.6)	-	-
Glucocorticoids, n (%)	29 (54.7)	-	-

NS, not significant; T2DM, type 2 diabetes mellitus; HTN, hypertension; BMI, body mass index; DAS28, disease activity score using 28 joints; CPR, C-reactive protein; MTX, methotrexate.

Methods: This was a cross-sectional, observational, and comparative study. A total of 53 patients aged 40-75 years old, with RA diagnosis, in the previous five years, according to the 2010 ACR/EULAR classification criteria, and 53 controls matched by age (±5 years), gender and comorbidities were included in this study. Subjects with a previous CV event were excluded. A carotid US was performed in all study subjects. Subclinical atherosclerosis was evaluated as the presence of carotid plaque (CP) or an increased carotid intima media thickness (cIMT). CP was defined as a cIMT ≥1.2mm or a focal narrowing ≥0.5mm of the surrounding lumen, and an increased cIMT was defined as a value ≥0.8mm. Distribution was evaluated with the Kolmogorov-Smirnov test. Comparisons were done with χ^2 test and Fisher's exact test for qualitative variables, and Student's T test and Mann-Whitney's U test for quantitative variables. A p-value < 0.05 was considered statistically significant.

Results: Comparisons of demographic characteristics showed no difference between the RA group and the control group (Table 1). When comparing carotid US findings there was a difference in the presence of CP, being more prevalent in RA patients (26.4% vs 11.3%, p=0.047), in the presence of an increased cIMT, being more prevalent in RA patients (32.1% vs 3.8%, p=< 0.001), in the cIMT as a quantitative variable, being higher in RA patients (0.75mm vs 0.60mm, p=0.001), and in the presence of subclinical atherosclerosis overall, being more prevalent in RA patients (52.8% vs 15.1%, p=< 0.001) (Table 2).

Conclusion: Patients with RA in the first five years of diagnosis have a higher prevalence of subclinical atherosclerosis than the general population. CV evaluation including a carotid US should be done at the time of diagnosis of RA

Table 2. Carotid ultrasound findings.

	RA patients (n=53)	Controls (n=53)	*p-value*
Carotid plaque, n (%)	14 (26.4)	6 (11.3)	**0.047**
Unilateral carotid plaque, n (%)	6 (11.3)	4 (7.5)	NS

RA Disease Activity Is an Independent Predictor of Left Ventricular Mass Changes in an RA Cohort Without Cardiovascular Disease

Elizabeth Park[1], Kazato Ito[1], Christopher Depender[1], Jon Giles[1] and Joan Bathon[2], [1]Columbia University Irving Medical Center, Division of Rheumatology, New York, NY, [2]Columbia University, New York, NY

SESSION INFORMATION
Session Date: Saturday, November 6, 2021
Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster I: Cardiovascular Pulmonary Disease (0268–0295)
Session Type: Poster Session A
Session Time: 8:30AM–10:30AM

Background/Purpose: Rheumatoid arthritis (RA) patients have 50% increased risk of heart failure (HF) vs non-RA patients with a distinct phenotype, preserved ejection fraction on transthoracic echocardiography (TTE) and attenuation of classic HF symptoms. Left ventricular (LV) remodeling (abnormal mass and wall thickness) is hypothesized to be an important precursor to clinical HF in the general population. Accordingly, LV structural abnormalities are prevalent in RA patients *without* clinical HF. Specifically, RA patients demonstrate higher mean LV mass index (LVMI) vs non-RA patients in cross-sectional TTE studies, with few correlates to RA associated inflammatory measures. However, pro-

Table 1. Baseline and Follow-up Changes in LV Remodeling Categories

Prob>F	0.20	
R-Squared	0.32	
Adjusted R-Squared	0.099	

spective changes in LVMI and their significant clinical predictors remain poorly characterized in RA patients without clinical HF. Here we report on the evolution of LVMI in a prospective RA cohort without clinical cardiovascular disease (CVD), as well as its significant RA associated predictors, while adjusting for CV risk factors.

Methods: RA patients (n=164) without CVD underwent RA and CV clinical assessment and TTE at baseline. A subset (n=64) returned for follow-up TTE 3-6 years later. Real-time 3-dimensional (3D) echocardiography was utilized to calculate LV mass (indexed to height ($m^{2.7}$)). LV remodeling categories [concentric remodeling (CRM), concentric hypertrophy (CH), and eccentric hypertrophy (EH)], utilizing the conventional cut-off for relative wall thickness (RWT) >0.42 and LVMI cut-off of >90% tile, were identified in the cohort (Table 1). Multivariable regression models (with LVMI as outcome) were utilized to adjust for biologically plausible confounders identified from univariable regressions.

Results: At baseline, up to 35% demonstrated abnormal LV geometry (CRM, CH, EH) and on follow-up this increased to 55% (Table 1). Specifically, the prevalence of CRM increased significantly from baseline to follow-up (p=0.01) (Table 1). The use of TNF inhibitors (TNFi) was associated (p=0.053) with higher baseline LVMI in multivariable models adjusted for RA and CV factors (no TNFi use vs TNFi use: 28.9 g/$m^{2.7}$ vs 30.5 g/$m^{2.7}$). On follow-up, mean LVMI increased 0.69 g/$m^{2.7}$ per year but this was not statistically significant (p=0.82). The highest tertile of averaged CDAI was associated with the lowest increase in LVMI over time (from 0.86 g/$m^{2.7}$ per year to 0.43 g/$m^{2.7}$ per year) (Figure 1). Averaged CDAI also significantly predicted annualized rate of change in LVMI (p=0.046) (Table 2).

Conclusion: LV remodeling, particularly concentric remodeling, increased over time in RA patients without known CVD. At baseline, the use of TNF inhibitors was significantly associated with higher adjusted LVMI. On follow-up, higher averaged CDAI was associated with the lowest increase in LVMI. Further study is needed to clarify how lowering of RA disease activity through DMARD escalation impacts LVMI, and ultimately the development of clinical HF.

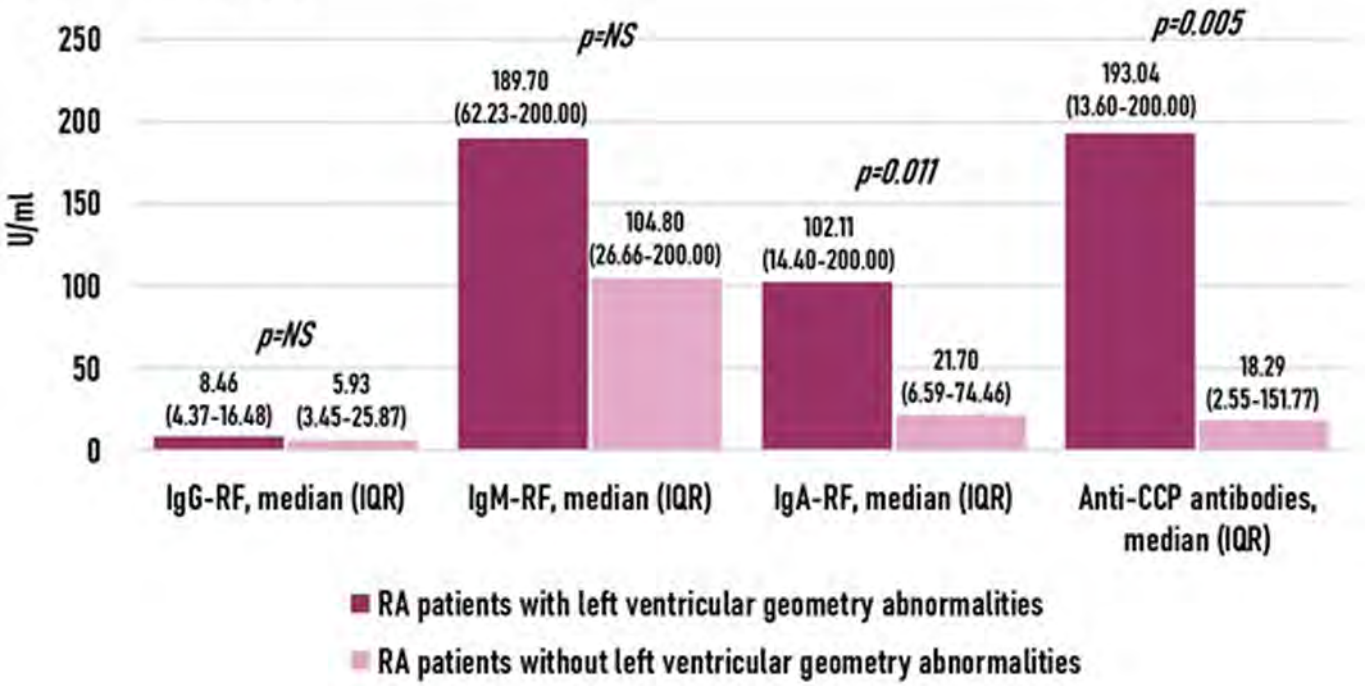
RA, rheumatoid arthritis; LV, left ventricular; NS, not significant; T2DM, type 2 diabetes mellitus; HTN, hypertension; BMI, body mass index; CDAI, clinical disease activity index; DAS28, disease activity score using 28 joints; CPR, C-reactive protein; MTX, methotrexate.

Figure 1. Antibody titers.



Background/Purpose: Rheumatoid arthritis (RA) patients have a higher risk of developing left ventricular (LV) geometry abnormalities which can result in cardiac death. High titers of rheumatoid factor (RF) and anti-cyclic citrullinated peptide (anti-CCP) antibodies are associated with a worse cardiovascular (CV) prognosis in RA patients.

The aim of this study was to assess the association between RF and anti-CCP antibody titers and LV geometry abnormalities detected by a transthoracic echocardiogram.

Methods: This was a cross-sectional, observational, and comparative study. Patients aged 40-75 years who fulfilled the 2010 ACR/EULAR classification criteria underwent a transthoracic echocardiogram. Patients with RA and LV geometry abnormalities were matched to RA-patients without LV geometry abnormalities, by age, gender, comorbidities, and disease characteristics. LV geometry was evaluated with LV mass index and relative wall thickness. A blood sample was taken to measure RF and anti-CCP antibody titers. Comparisons were done with χ^2 test for qualitative variables and Student's t test and Mann-Whitney's U test for quantitative variables. A p-value < 0.05 was considered statistically significant.

Results: A total of 82 RA-patients were included in this study, 41 patients with LV geometry abnormalities and 41 patients without LV geometry abnormalities. Of the 41 patients with LV geometry abnormalities, 37 (90.2%) presented LV concentric remodeling and 4 (9.8%) presented LV concentric hypertrophy. There were no differences in the demographic and clinical characteristics between both groups (Table 1). Patients with altered LV geometry showed higher titers of IgA-RF (102.11 U/mL vs 21.70 U/mL, p=0.011) and anti-CCP antibodies (193.04 U/mL vs 18.29 U/mL, p=0.005). IgG-RF and IgM-RF showed no significant differences between groups (Figure 1).

Conclusion: RA patients with LV geometry abnormalities had higher titers of IgA-RF and anti-CCP antibodies. This suggests an association between antibody titers and CV prognosis in RA patients. Rheumatologists should take these data into account when evaluating CV risk in RA patients, assessing the possibility of performing an echocardiogram for early detection of CV abnormalities and an opportune treatment in this group of patients.

Angiopoietin-Like Protein 4, Apolipoprotein C3 and Lipoprotein Lipase Axis in the Abnormal Lipid Profile of Patients with Rheumatoid Arthritis: Relation to Subclinical Atheromatosis

juan Carlos Quevedo[1], Laura de Armás-Rillo[2], Antonia de Vera-González[3], Laura Cáceres[1], Cristina Almeida[1], Alejandra González-Delgado[3] and **Iván Ferraz-Amaro**[3], [1]Hospital Universitario Dr. Negrín, Las Palmas de Gran Canaria, Spain, [2]Universidad Europea de Canarias, Santa Cruz De Tenerife, Spain, [3]Hospital Universitario de Canarias, Santa Cruz de Tenerife, Spain

SESSION INFORMATION

Session Date: Saturday, November 6, 2021

Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster I: Cardiovascular Pulmonary Disease (0268–0295)

Session Type: Poster Session A

Session Time: 8:30AM–10:30AM

Background/Purpose: Rheumatoid arthritis (RA) is associated with an increase in cardiovascular (CV) risk, attributed, among other factors, to the existence of an abnormal lipid profile. The axis made up of angiopoietin-like protein 4 (ANGPTL4), apolipoprotein C3 (ApoC3) and lipoprotein lipase (LPL) has been associated with cardiovascular mortality in healthy population. However, this axis has not been yet characterized in patients with RA. The objective of this study was to evaluate whether there are differences between RA patients and controls in the serum levels of the molecules of this axis, and to analyze their relationship with the activity of the disease or the markers of systemic inflammation as well as with the subclinical atheromatosis that is present in the disease.

Table 1. Multivariable analysis of the differences in lipid profile and angiopoyetin like protein 4, apolipoprotein C3 and lipoprotein lipase serum levels between RA patients and controls

	Controls (n=246)	RA patients (n=323)	Univariable model	Model #1 beta coef (95% CI), p	Model #2 beta coef (95% CI), p

Data represent means ± standard deviation or median (interquartile range) when data were not normally distributed.

HDL: high-density lipoprotein; LDL: low-density lipoprotein.

Model #1: Adjusted for sex, body mass index, abdominal circumference, hypertension, diabetes and statins (variables with a p value < 20 difference between patients and controls).

Model #2: Adjusted for model #1 + rest of lipid molecules (with a p value < 0.20 in the univariate analysis) other than the one that is compared Because collinearity LDL cholesterol, LDL:HDL ratio, non-HDL cholesterol, apoB:apoA, and atherogenic index were excluded of the multivariable analyses in model 2.

Methods: We performed a cross-sectional study that encompassed 569 individuals; 323 patients with RA and 246 controls. Full lipid profile was assessed including serum levels of ANGPTL4, apoC3 and LPL. Carotid intima-media thickness (cIMT) and carotid plaques were assessed in patients. A multivariable analysis, adjusted for standard CV risk factors, was performed to evaluate if there were differences in this axis between patients and controls, and to study the relationship of this axis with data associated with the disease and the presence of subclinical atheromatosis.

Results: After multivariable analysis, adjusted for CV risk factors and for the changes that the disease produces itself over other lipid profile molecules, patients with RA showed higher levels of ANGPTL4 (beta coef. 295 [95% CI 214-376] ng/ml, p=0.000) and ApoC3 (beta coef. 30 [CI95% 18-41] mg / dl, p=0.000), but lower circulating LPL (beta coef. -172 [CI95% -211-133] ng/ml, p=0.000).

Regarding the data related to the disease, an association was found between ESR and ANGPTL4 (beta coef. -3 [CI95% -6--1] ng/ml, p = 0.02), and C-reactive protein and apoC3 (beta coeff. 0.53 [IC95% 0.12-0.95] mg/dl, p=0.01). Likewise, ESR was positively associated with LPL levels (beta coef. 1 [95% CI 0-3] ng/ml, p=0.03). An association was also found between the use of certain treatments and higher serum levels of LPL (hydroxychloroquine, beta coef. 116 [95% CI 30-202] ng/ml, p=0.008; salazopyrin, beta coef. 143 [95% CI 41 -245] ng/ml, p=0.006 and anti-TNF therapy, beta coefficient 101 [95% CI 33-169] ng / ml, p=0.004).

The ANGPTL4-Apoc3-LPL axis did not show a relationship with the presence of carotid plaque in patients with RA. However, while ApoC3 and LPL levels were not associated with cIMT, ANGPTL4 serum levels showed a positive association with it after multivariate analysis (beta coef. 0.06 [95% CI 0.02-0.09] microns, p=0.000).

Conclusion: RA patients have an abnormal ANGPTL4-Apoc3-LPL axis compared to controls. Certain characteristics of the disease related to inflammation justify this alteration. ANGPTL4 serum levels show an independent and significant positive relationship with IMT in patients with RA.

Gonzalez", Monterrey, Mexico

SESSION INFORMATION
Session Date: Saturday, November 6, 2021
Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster I: Cardiovascular Pulmonary Disease (0268–0295)
Session Type: Poster Session A
Session Time: 8:30AM–10:30AM

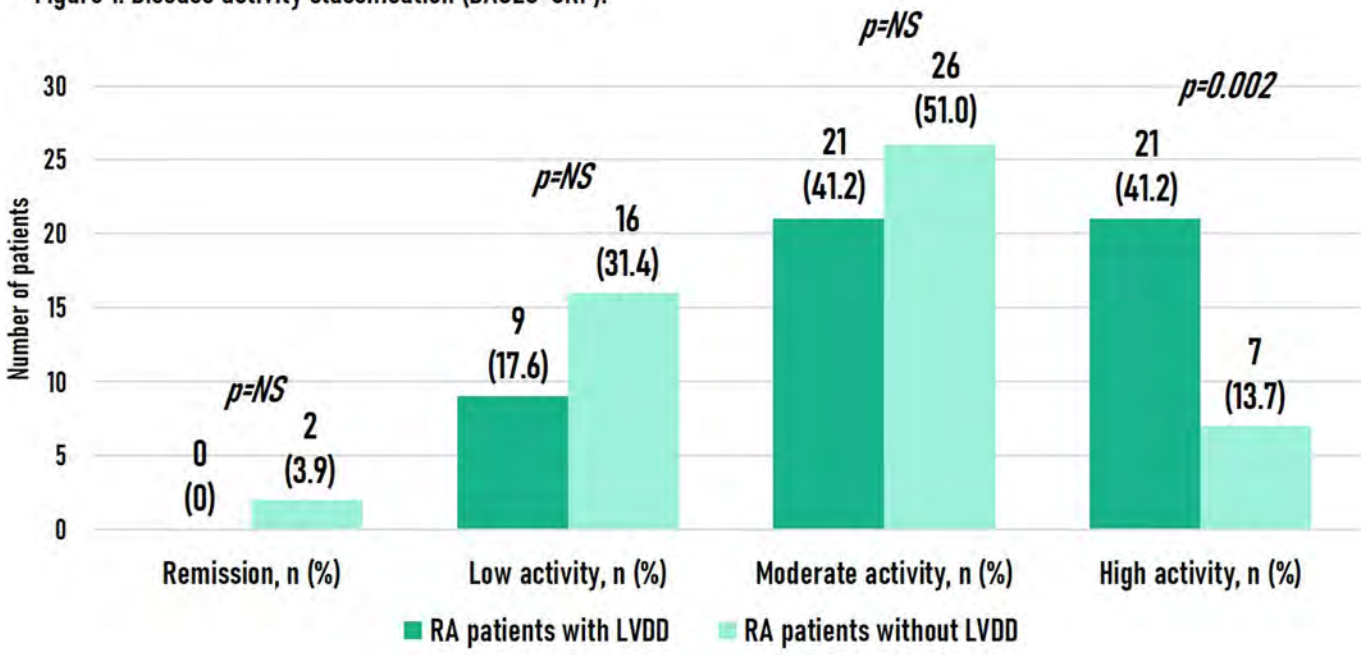
Background/Purpose: Cardiovascular disease (CVD) is the main cause of mortality in patients with rheumatoid arthritis (RA) reflected by a higher prevalence of cardiovascular risk factors (CVRFs), a chronic systemic inflammatory state and heart failure compared to the general population. Left ventricular diastolic dysfunction (LVDD) is attributable to structural abnormalities such as hypertrophy or interstitial fibrosis and impaired myocyte relaxation resulting from ischemia and is frequently asymptomatic. The presence of LVDD could be considered as the first step to development of heart failure.

Table 1. Demographic and disease characteristics

	RA patients with LVDD (n=51)	RA patients without LVDD (n=51)	*p-value*
Women, n (%)	50 (98)	47 (92.2)	NS
Age, years ± SD	56.12 ± 8.76	53.91 ± 5.61	NS
HTN, n (%)	17 (33.3)	13 (25.5)	NS
T2DM, n (%)	6 (11.8)	10 (19.6)	NS
Dyslipidemia, n (%)	17 (33.3)	11 (21.6)	NS
Active smoking, n (%)	5 (9.8)	5 (9.8)	NS
BMI, kg/m² ± SD	28.20 ± 4.89	29.40 ± 5.13	NS
Disease duration, years (IQR)	10.70 (5.16-17.87)	5.66 (2.67-15.64)	**0.033**
DAS28-CRP, median (IQR)	4.88 (3.53-5.45)	3.56 (3.00-4.69)	**0.004**

NS, not significant; HTN, hypertension; T2DM, type 2 diabetes mellitus; BMI, body mass index; DAS28, disease activity score using 28 joints; CPR, C reactive protein.

Figure 1. Disease activity classification (DAS28-CRP).



The aim of the study was to identify the association of disease activity and the presence of LVDD in RA patients.

Methods: This was a cross-sectional, observational, and comparative study of RA subjects that fulfilled the 2010 ACR/EULAR classification criteria, aged 40-75 years. A transthoracic echocardiogram was performed and reviewed by two certified echocardiographers, in all study subjects. A total of fifty-one RA patients diagnosed with LVDD according to the 2016 American Society of Echocardiography (ASE) criteria, and 51 RA patients without LVDD, matched by age, gender, and comorbidities, were included in this study. Disease activity was evaluated with the disease activity score using 28 joints-C reactive protein (DAS28-CRP). Distribution was evaluated with the Kolmogorov-Smirnov test. Chi-square test, Student's t test and Mann-Whitney U test were used for comparations between groups. A p-value < 0.05 was considered statistically significant.

Results: There were no differences between groups regarding age, gender, and comorbidities. Patients with LVDD demonstrated a higher disease activity evaluated by DAS28-CRP (4.88 vs 3.56, $p=0.004$) (Table 1). It was observed that patients with LVDD had a higher prevalence of being classified in the high disease activity category compared to patients without LVDD (41.2% vs. 13.7%, $p=0.002$) (Figure 1). When performing a binary logistic regression, including traditional CVRFs and disease activity, it was found that a high disease activity was the only independent predictor for the presence of LVDD, with an OR 4.70, (95% CI 1.63-13.50, p=0.004).

Conclusion: Patients with RA and LVDD have higher disease activity, so emphasis should be placed on strict antirheumatic treatment to achieve disease control and therefore avoid the risk of developing a CVD and the progression to heart failure.

SESSION INFORMATION
Session Date: Saturday, November 6, 2021
Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster I: Cardiovascular Pulmonary Disease (0268–0295)
Session Type: Poster Session A
Session Time: 8:30AM–10:30AM

Background/Purpose: Pulse pressure (PP) is defined as the difference between systolic and diastolic blood pressure and represents arterial compliance and reflective properties of blood flow. It is well known that gender, age, and ethnicity are intrinsic factors of the patient that influence PP. Brachial PP has recently been associated with subclinical cardiovascular disease after adjustment with traditional cardiovascular risk factors in the general population. However, this relationship has not been studied in patients with rheumatoid arthritis (RA) and its identification would allow earlier adjustments of cardiovascular therapies in this high-risk group.

Table 1. Demographic characteristics.

	RA (n=92)	Controls (n=92)	*p-value*
Women, n (%)	85 (92.4)	85 (92.4)	NS
Age years, mean ± SD	58.0 (55.0-63.0)	56.5 (54.0-61.0)	NS
T2DM, n (%)	17 (18.5)	15 (16.3)	NS
Hypertension, n (%)	33 (35.9)	33 (35.9)	NS
Dyslipidemia, n (%)	30 (32.6)	29 (31.5)	NS
Obesity, n (%)	30 (32.6)	31 (33.7)	NS
Active smoking, n (%)	11 (12.0)	20 (21.7)	NS
	RA patients with CP (n=39)	**RA patients without CP (n=53)**	***p-value***
Women, n (%)	36 (92.3)	49 (92.5)	NS
Age years, mean ± SD	60.13 ± 5.98	58.08 ± 7.00	NS
T2DM, n (%)	9 (23.1)	8 (15.1)	NS
Hypertension, n (%)	16 (41.0)	17 (32.1)	NS
Dyslipidemia, n (%)	13 (33.3)	17 (32.1)	NS
Obesity, n (%)	15 (38.5)	15 (28.3)	NS
Active smoking, n (%)	6 (15.4)	5 (9.4)	NS
Disease duration years median (IQR)	8.44 (3.00-15.50)	12.86 (4.66-19.66)	NS

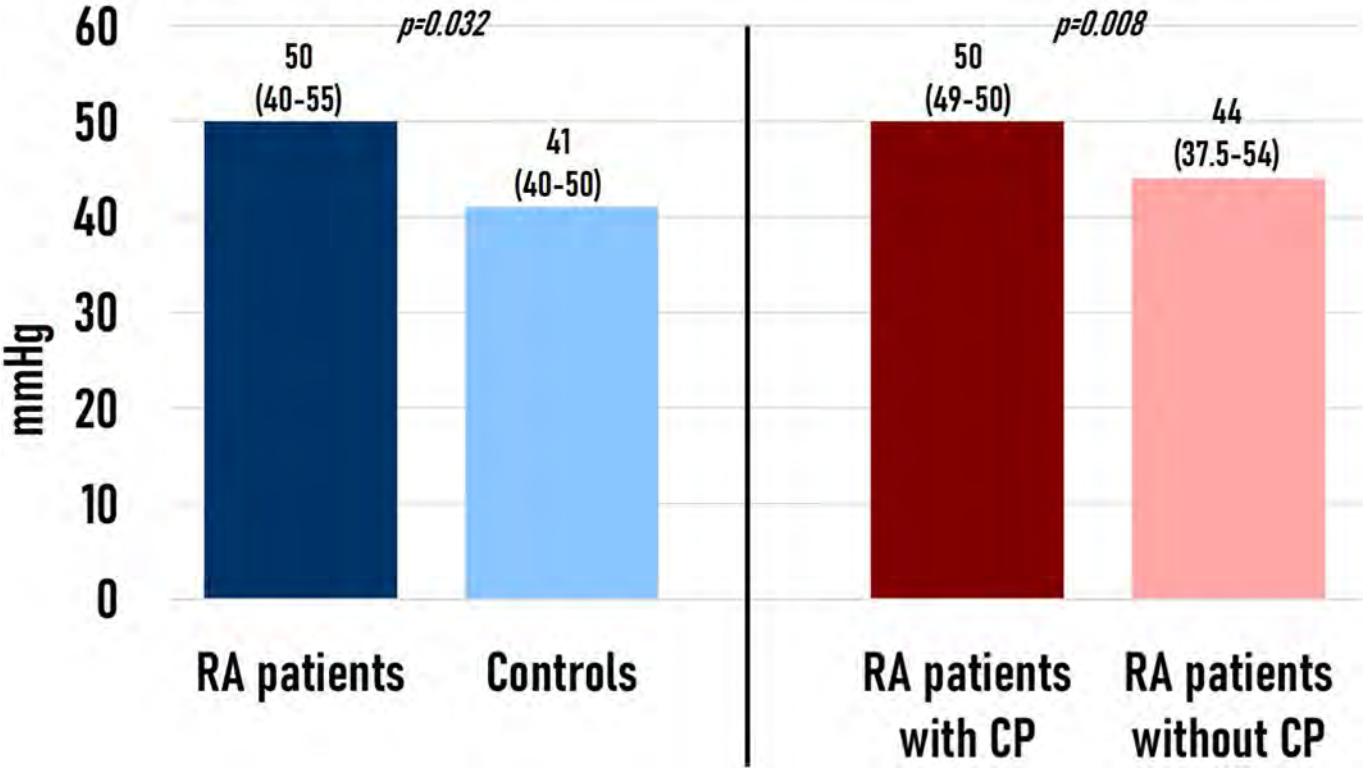
NS, not significant; T2DM, type 2 diabetes mellitus; CP, carotid plaque.

The aim of the study is to analyze the difference of PP between patients with RA and healthy controls. Additionally, to analyze the difference between RA patients with carotid plaque (CP) and without CP.

Methods: This was a cross-sectional, observational, and comparative study of 92 patients with RA aged 40-75 years and who fulfilled the 2010 ACR/EULAR classification criteria. Also, we included 92 controls without RA, matched by gender, age and comorbidities. A carotid ultrasound was performed in RA patients and they were divided into two subgroups, patients with CP and without CP. Blood pressure measurement was taken after 15 minutes of rest on the left arm of all study subjects. Distribution was evaluated with the Kolmogorov-Smirnov test. Descriptive analysis was done using measures of central tendency. Chi-square, Student's t test and Mann-Whitney U test were used for comparations between groups.

Results: We found no differences between groups regarding age, gender, and comorbidities (type 2 diabetes mellitus, hypertension, dyslipidemia, and active smoking) (Table 1). There was a significant difference in PP between patients with RA and controls (50 mmHg vs 41 mmHg respectively, *p=0.032*). When comparing RA patients there was a significant difference in PP of patients with CP and without CP (50 mmHg vs 44 mmHg respectively, *p=0.008*)

Figure 1. Pulse pressure.



(Figure 1). When performing a binary logistic regression, it was found that PP was the only independent risk factor for the presence of CP in patients with RA, OR 1.054 (95% CI 1.008-1.101, *p=0.020*).

Conclusion: Patients with RA had a higher PP than controls. Binary logistic regression showed PP as the only independent risk factor for the presence of subclinical atherosclerosis in RA patients. PP is a parameter that all rheumatologists should consider when evaluating cardiovascular risk in patients with RA.

Session Time: 8:30AM–10:30AM

Table 1. Discriminatory capacity of the different cardiovascular risk calculators.

Calculators (cut-off point)	AUC	CI 95%		p	Sensitivity	Specificity
		Inferior	Superior			
QRISK3 (≥4.60)	0.646	0.537	0.754	**0.012**	73.8%	54.5%
SCORE	0.591	0.475	0.706	NS	-	-
OMNIBUS (≥3.80)	0.621	0.509	0.734	**0.038**	57.1%	68.2%
FRSL	0.594	0.480	0.707	NS	-	-
FRS-BMI (≥11.02)	0.642	0.530	0.754	**0.015**	61.9%	57.6%
RRS (≥2.25)	0.627	0.514	0.741	**0.029**	47.6%	78.8%

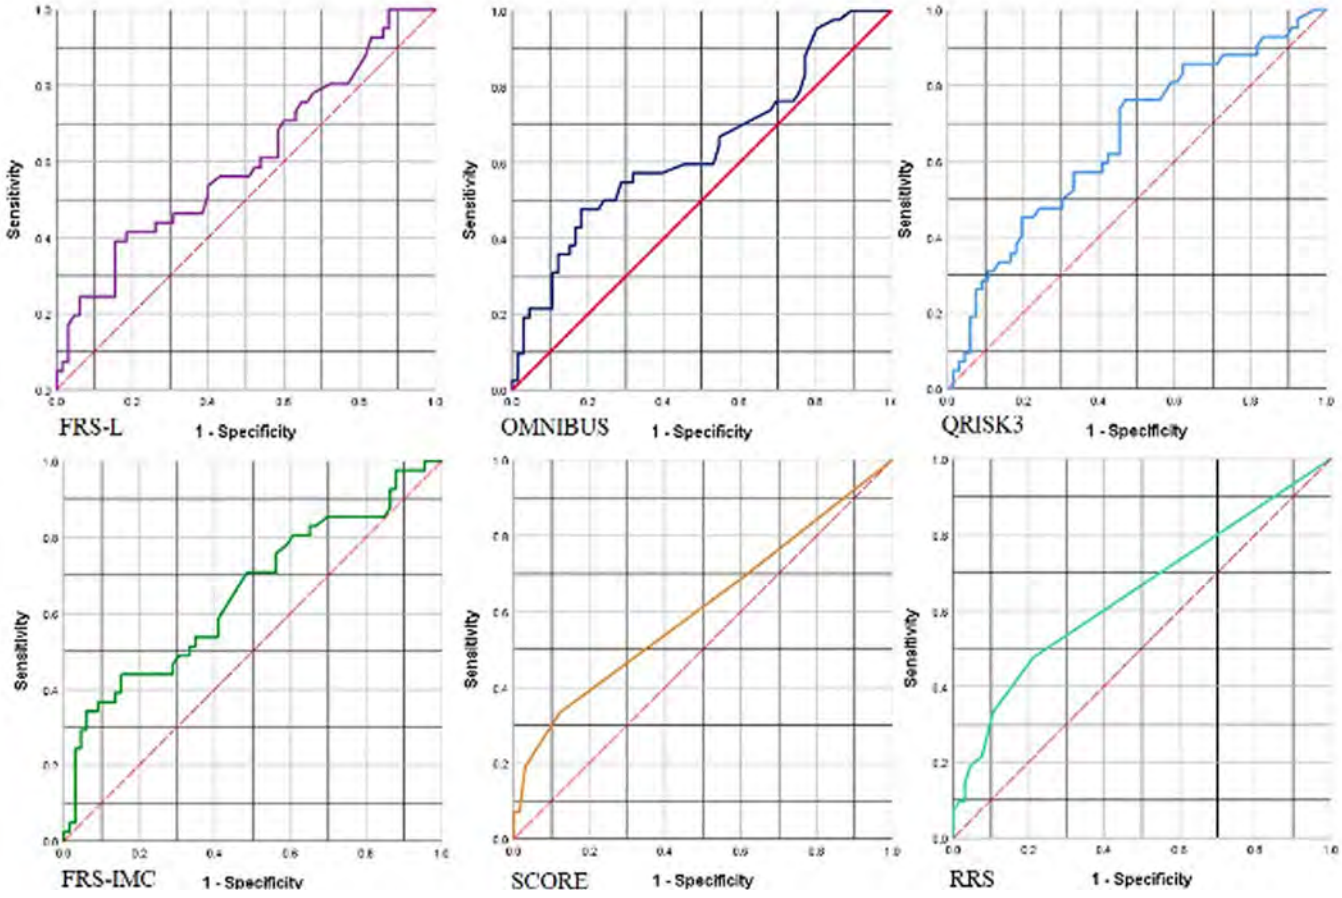
Area Under the Curve, AUC; Framingham Risk Score-Lipids, FRSL; Framingham Risk Score-Body Mass Index, FRS-BMI; Reynolds Risk Score, RRS.

Background/Purpose: A relationship between rheumatoid arthritis (RA) and the presence of abnormalities in left ventricular (LV) geometry such as eccentric remodeling has recently been determined, even in the absence of cardiovascular risk factors and before clinical manifestations. The 2016 EULAR recommendations that cardiovascular (CV) risk prediction models should be adapted by a 1.5 multiplication factor in RA patients. Risk prediction algorithms based on the CV risk factors have been an important tool for adopting preventive measures and intensifying therapies based on the estimated risk but their application in predicting cardiac structural abnormalities has never been studied. The aim of the study is to determine the CV risk calculator that best predicts alterations in ventricular geometry in RA.

Methods: A cross-sectional, observational study of 108 RA patients between 40-75 years, who fulfilled ACR/EULAR 2010 classification criteria. The QRISK3, OMNIBUS, Framingham Risk Score-Lipids, Framingham Risk Score-Body Mass Index (FRS-BMI) and Reynolds Risk Score (RRS) calculators were compared. The diagnostic performance was determined by ROC curves, and the discriminative capacity by the Area Under the Curve (AUC) 95% CI. The echocardiogram was the diagnostic gold standard.

Results: The prevalence of abnormalities in LV geometry was 38.9%. QRISK3 reported AUC of 0.656, 95% CI (0.537-0.754, *p = 0.012*), cut-off point ≥4.6, sensitivity of 73.8% and specificity of 54.5%, and likelihood ratio of +1.62. FRS-BMI showed AUC of 0.642, 95% CI (0.543-0.762, *p = 0.008*), cut-off point ≥11.02, sensitivity and specificity of 61.9% and 57.6% respectively, and likelihood ratio of +1.46. OMNIBUS showed AUC of 0.635, CI 95% (0.525-0.746,

Figure 1. ROC curves of the different cardiovascular risk calculators.



p = 0.018), cut-off point ≥3.8, sensitivity and specificity of 57.1% and 68.2%. While RRS had AUC 0.644, 95% CI (0.534-0.755, *p = 0.012*), cut-off point of 2.25, sensitivity of 47.6% and specificity 78.8%, and likelihood ratio of +2.24 (Figure 1 and Table 1).

Conclusion: The QRISK3 calculator showed the highest discriminative ability and sensitivity to predict abnormalities in LV geometry. However, all calculators demonstrated the need for a lower cut-off point to predict alterations in ventricular geometry. Our findings require adequate reproducibility in other population groups to determine the applicability of CV risk algorithms as predictors of structural alteration of LV.

SESSION INFORMATION

Session Date: Saturday, November 6, 2021

Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster I: Cardiovascular Pulmonary Disease (0268–0295)

Session Type: Poster Session A

Session Time: 8:30AM–10:30AM

Background/Purpose: Patients with Rheumatoid Arthritis (RA) have a higher prevalence of cardiovascular diseases and a strong association with abnormalities in the left ventricular (LV) geometry. Both concentric and eccentric remodeling have been determined as an independent factor for sudden cardiac arrest in the general population with normal or slightly decreased ventricular function but there is still controversy about the factors involved and the pathophysiology in patients with RA. Therefore, the aim of the study is to determine the characteristics of LV geometry and the impact of RA diagnosis.

Methods: A case-control study with 52 RA patients that fulfilled ACR/EULAR 2010 classification criteria, aged 40-75 years, and a control group of 50 healthy subjects matched by age, gender, and comorbidities were included for this study. Subjects were evaluated using a transthoracic echocardiogram performed and reviewed by two certified echocardiographers. Ventricular geometry was evaluated with indexed left ventricular mass and relative wall thickness. Descriptive analysis was done using measures of central tendency. Chi-square, Students' T test and Mann-Whitney

Table 1. Demographic characteristics and echocardiographic findings between groups.

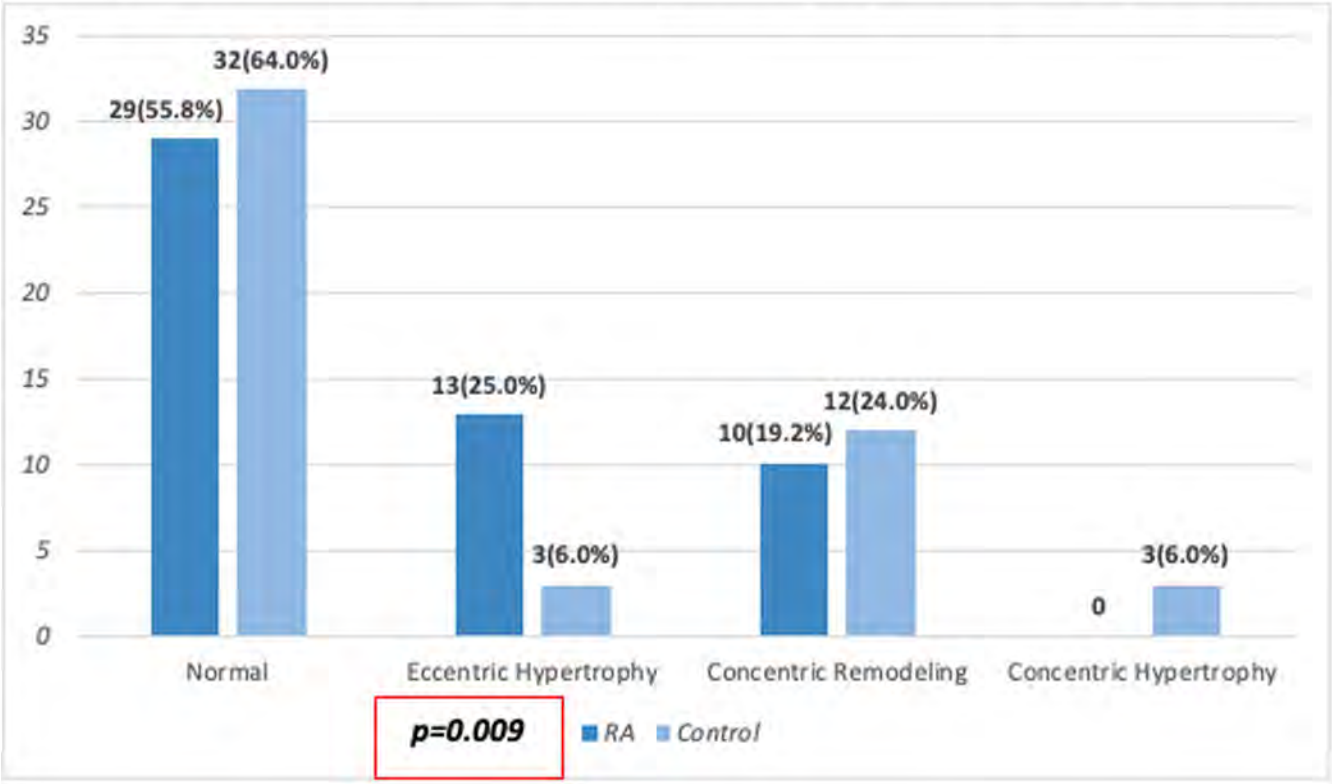
NS, no significant; BMI, body mass index; BSA, body surface area; LVPWTd, left ventricular posterior wall thickness at end-diastole; LVIDd, left ventricular internal dimension at end-diastole; RWT, relative wall thickness.

Figure 1. Abnormalities in left ventricular geometry in patients with RA and controls.



U test were used for comparations between groups. A logistic binary regression was performed with the traditional cardiovascular risk factors (CVRF), age and RA diagnosis.

Results: No significant differences were found in the traditional CVRF (diabetes mellitus, dyslipidemia, active smoking, and hypertension) (Table 1). Most of the subjects reported normal geometry in both groups (55.8% for RA group vs 64.0% for controls). A higher prevalence of eccentric hypertrophy was found in the RA group, 13 (25%) subjects versus 3 (6%) in the control group, *p = 0.009*. The binary regression showed that the diagnosis of RA was the only independent risk factor for the presence of eccentric hypertrophy, OR 7.22 95% CI (1.68-31.02, *p = 0.008*).

Conclusion: There is a higher prevalence of eccentric remodeling in patients with RA independently of traditional CVRF. The diagnosis of RA is an independent risk factor for the presence of eccentric hypertrophy that is associated with higher mortality. Treatment of cardiovascular comorbidities should be intensified in those patients with abnormalities in LV geometry in order to prevent cardiovascular diseases such as heart failure.

***p<0.001, **p<0.01, *p<0.05, †p<0.10

essential step in foam cell formation, the establishment and progression of atherosclerosis. RA therapies may modify atherosclerosis trajectory by intercepting several of those processes. We evaluated the relationship of inflammation, LDL particle structure, oxidation and immune system recognition of oxidized epitopes with CLC. We next evaluated interactions between RA treatments and these processes on macrophage cholesterol loading.

Methods: 107 RA patients from our previously described PROTECT-RA cohort with coronary atherosclerosis evaluation were studied. Lipoprotein classes and subclasses and their cholesterol content were directly measured using single vertical spin density gradient ultracentrifugation. Oxidized LDL (oxLDL) was measured with monoclonal antibody E06. IgM and IgG antibodies to oxLDL (anti-oxLDL) were assessed with chemiluminescence Elisa. Proinflammatory cytokines were measured with microparticle immunoassay and singe molecule counting (Erenna, Singulex). CLC was measured by fluorometric assay- as macrophage cholesterol content- after a 24-hour incubation with whole serum. Robust, multivariable generalized linear models evaluated associations between inflammation, LDL particle content, LDL oxidation and antibodies against oxLDL with CLC. Similar models explored interactions between RA treatments and markers of inflammation on CLC.

Results: Patients were middle aged (53.9 10.7), mostly female (86%) with seropositive (92%), erosive (66.4%) and well controlled disease (DAS28= 2.49 0.96). Smaller-sized LDL3 and LDL4 levels, oxLDL and anti-oxLDL IgG levels positively associated with CLC (all $p < 0.032$, Table 1); in contrast, anti-oxLDL IgM levels negatively associated with CLC (adjusted β= -0.28 [95% CI -0.44,-0.12], p=0.001). Inflammation modified the effect of LDL oxidation on CLC (p for interaction= 0.001); oxLDL significantly associated with CLC (adjusted β= 0.45 [95% CI 0.23-0.67], p< 0.001) in patients with CRP > 4mg/L (median split), but not those with CRP < 4mg/L. Significant interactions between bDMARD use and Interleukin-6 levels (p= 0.031) and between bDMARD and statin use (p= 0.038) on CLC were also observed. In bDMARD-naïve patients, interleukin-6 positively associated with CLC (adjusted β= 0.31 [95% CI 0.06-0.57], p=0.017) whereas statin use negatively associated with CLC (adjusted β= -0.78 [95% CI -1.28, -0.27], p= 0.003). Neither interleukin-6 nor statin use related to CLC in bDMARD-exposed patients.

Conclusion: Higher content of smaller-sized, readily oxidizable LDL subclasses, greater oxLDL levels -especially in the context of higher inflammation- and greater anti-oxLDL IgG serum concentration associated with greater cholesterol macrophage loading in RA. bDMARD therapies modified the impact of inflammation, lipid particle structure and statin use on CLC.

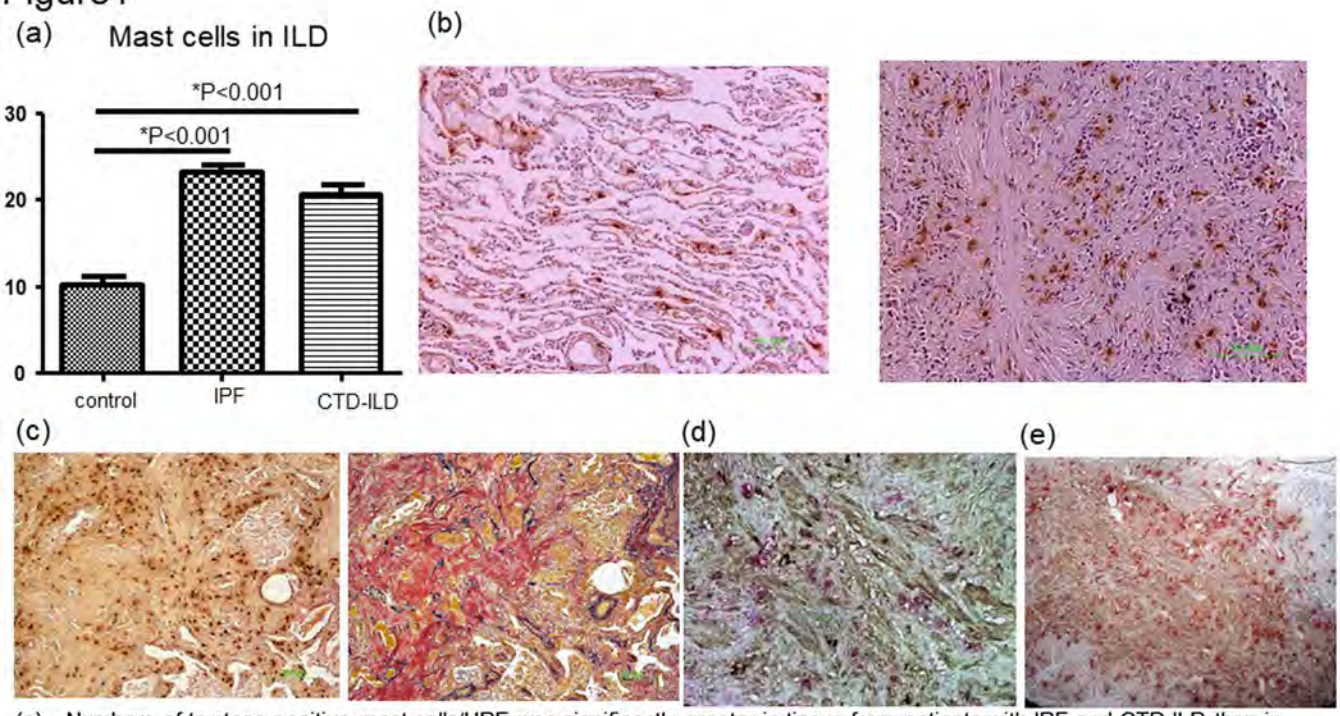
Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster I: Cardiovascular Pulmonary Disease (0268–0295)
Session Type: Poster Session A
Session Time: 8:30AM–10:30AM

Figure1



(a) Numbers of tryptase-positive mast cells/HPF was significantly greater in tissue from patients with IPF and CTD-ILD than in tissue from control individuals.

(b) Immunohistochemistry with an anti-tryptase antibody revealed upregulation of mast cells in the lung tissues from patients with IPF(right) compared to that from control individuals(left).

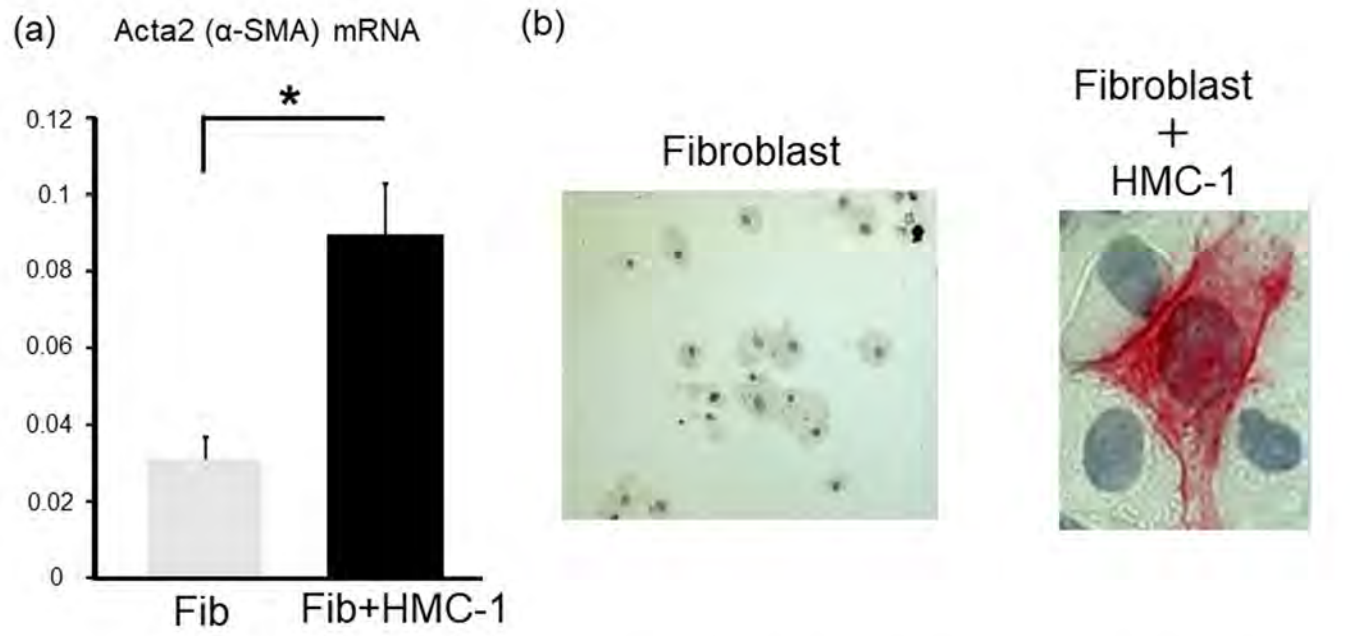
(c) Representative results of tryptase(left) and Verhoeff–Van Gieson staining (right) in serial sections of lung tissue from patients with IPF. Tryptase-positive mast cells (brown cells in the right panel) are frequently in close proximity to Verhoeff–Van Gieson-stained fibroblastic lesions. (left panel).

(d,e) Representative results of double immunohistochemical staining for tryptase and vimentin(d) and tryptase and α-SMA(e) in the lung tissue obtained from patients with IPF. Tryptase-positive mast cells (red cells) were close proximity to vimentin-positive fibroblasts(brown cells) or α-SMA-positive myofibroblasts (brown cells).

Background/Purpose: Idiopathic pulmonary fibrosis is an interstitial lung disease of unknown etiology. The most critical event in the evolution of fibrosis is the appearance of activated myofibroblasts. Mast cells (MC) are reportedly involved in various inflammatory and fibrotic conditions, although little is known about their roles in interstitial lung disease (ILD). Since the pathogenic role of MC in ILD remains unclear, we examined whether MCs play a critical role in the development of pulmonary fibrosis.

Methods: Lung tissue was examined using histology and immunohistochemistry. The samples for biopsy were obtained from the involved lung tissue of 13 patients with idiopathic pulmonary fibrosis (IPF) and 13 patients with connective tissue disease (CTD)-associated-ILD (RA 7 systemic sclerosis 6). As a control, we used noncancerous lung sections of 10 patients who had undergone surgery for lung cancer. We used immunohistochemistry to identify and quantify tryptase-, prolyl-4-hydroxylase β-, and alpha-smooth muscle actin (α-SMA)-positive cells as MCs, fibroblasts, and myofibroblasts, respectively. The co-culture of the human mast cell line (HMC-1) with pulmonary fibroblasts was performed in a Transwell system. Fibroblasts cultured with or without HMC-1 cells were cytospun and the expression of α-SMA, a marker of myofibroblast differentiation, was examined by immunohistochemistry after 7 days of culture. The ACTA2 mRNA synthesis in the fibroblasts was evaluated by RT-qPCR. The conditioned medium for the fibroblast culture was obtained from HMC-1 cells stimulated with recombinant human IL-33 and stem cell factor for 24 hours. Fibroblasts were treated with HMC-1-conditioned medium for 24 hours and the ACTA2 mRNA synthesis in

Figure2



Human pulmonary fibroblasts were cultured with or without human mast cell, HMC-1 for 1 wk in the lower and upper chambers, respectively, of a transwell apparatus. After 1wk co-culture, total RNA was isolated from fibroblasts, followed by qPCR employing primers specific for α-SMA and β-actin.

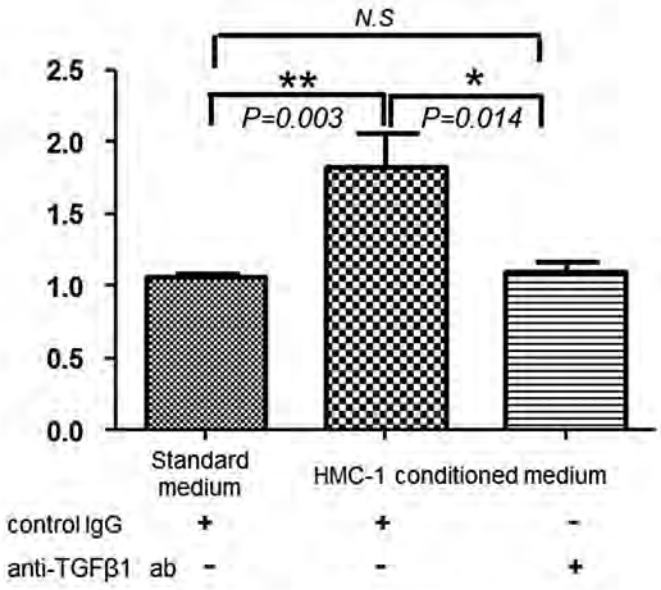
(a) Mast cells promote α- SMA mRNA expression in fibroblasts.
(b) Fibroblasts were detached and placed on glass slides using a standard cytospin approach. Immunocytochemical staining rdetected the positive signal for α-SMA in fibroblasts after coculture with HMC-1.

the fibroblasts was evaluated by RT-qPCR. Neutralization antibodies for human TGF-β1, 2, and 3 were used during the fibroblast culture with HMC-1-conditioned or standard culture media.

Results: MCs were significantly more numerous in the lung samples with IPF and CTD-ILD than in the control (Fig. 1a and b). MCs were proximal to the Elastica van Gieson (EVG)-stained fibrous tissue and pulmonary fibroblasts and myofibroblasts (Fig 1c, d, and e). We examined whether MCs induced pulmonary fibroblasts to differentiate into myofibroblasts. In the co-culture experiment, the ACTA2 mRNA level significantly increased compared to that in the control fibroblast monoculture (Fig. 2a). Consistently with this result, the upregulation of α-SMA in the fibroblasts during the co-culture was confirmed by immunohistochemistry. Furthermore, the ACTA2 mRNA was significantly upregulated in fibroblasts conditioned with the HMC-1 medium compared to that in fibroblasts cultured in a standard medium (Fig. 3). In addition, the neutralization of TGF-β abolished the ACTA2 mRNA upregulation in fibroblasts conditioned in the HMC-1 medium, thereby suggesting that HMC-1-derived TGF-β contributes to myofibroblast differentiation (Fig. 3).

Conclusion: The findings suggest a novel role for MCs in the development of lung fibrosis via TGF-β production-induced myofibroblast differentiation.

Figure3 Mast cell-derived TGFβ induces α-SMA mRNA expression in fibroblast



Fibroblasts cultured in HMC-1 conditioned medium exhibited significant upregulation of α-SMA mRNA. Treatment with neutralizing antibodies specific for TGFβ led to abrogation of this upregulation effect.

Unsupervised Machine Learning of Expanded Autoantibodies, Cytokines, and Chemokines Improves the Identification of Interstitial Lung Disease in Rheumatoid Arthritis

Bryant England[1], Dana Ascherman[2], Michael Duryee[1], Carlos Hunter[1], Yangyuna Yang[1], Punyasha Roul[1], Harlan Sayles[1], Fang Yu[1], Jill Poole[1], Joshua Baker[3], Geoffrey Thiele[1] and Ted Mikuls[1], [1]University of Nebraska Medical Center, Omaha, NE, [2]University of Pittsburgh, Pittsburgh, PA, [3]University of Pennsylvania, Philadelphia, PA

SESSION INFORMATION
Session Date: Saturday, November 6, 2021
Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster I: Cardiovascular Pulmonary Disease (0268–0295)
Session Type: Poster Session A
Session Time: 8:30AM–10:30AM

Background/Purpose: Interstitial lung disease (ILD) frequently complicates the rheumatoid arthritis (RA) disease course, leading to significant morbidity and premature mortality. RA-ILD may be underdiagnosed or detected later in the disease course because of inadequate screening methods. Several peripheral blood biomarkers have been investigated in RA-ILD, but the performance of composite biomarker profiles for identifying RA-ILD in larger RA cohorts is unknown.

Methods: We studied participants in a prospective cohort of U.S. Veterans with RA fulfilling ACR criteria. Demographics, RA history, smoking status, and ACR core measures are collected regularly, complementing a biorepository

Table 1. Association of peripheral biomarkers with prevalent interstitial lung disease in a rheumatoid arthritis cohort

Component (Eigenvalue)	Loading Biomarkers [a]	Adjusted OR (95% CI) for ILD [b]	P value
1 (12.4)	**MCP-4/CCL13, TARC/CCL17, IL-27, MDC/CCL22, IL-6, MCP-1/CCL2**	**0.92 (0.86, 0.98)**	**0.01**
2 (5.1)	IL-4, IL-12p70, IL-1β, IL-2	1.01 (0.93, 1.09)	0.84
3 (2.6)	**IgA anti-MAA-albumin, IgM anti-MAA-albumin, IgG anti-MAA-albumin**	**1.19 (1.03, 1.38)**	**0.02**
4 (2.0)	VEGF, IL-1ra, IL-8	1.16 (0.99, 1.37)	0.07
5 (1.6)	IL-12/23p40, IL-17a	0.91 (0.79, 1.05)	0.18
6 (1.5)	**RF, Anti-CCP, IL-5**	**1.42 (1.21, 1.67)**	**<0.001**
7 (1.2)	IL-15, IL23, IL-3, IL-5	1.00 (0.86, 1.17)	0.97
8 (1.1)	IgA anti-MAA-collagen, IgM anti-MAA-collagen, IgG anti-MAA-collagen	1.11 (0.95, 1.29)	0.20

a. Biomarkers listed are those with principal component loadings >0.3 (in descending order).
b. Model adjusted for age, sex, race, and cigarette smoking history.

of peripheral blood samples obtained at enrollment. We measured 33 cytokines and chemokines (via the MesoScale platform), RF concentration (by nephelometry), anti-CCP concentration (by 2nd generation ELISA), and anti-malondialdehyde acetaldehyde (MAA) antibody concentration (IgA, IgM, and IgG anti-MAA-albumin and anti-MAA-collagen, all by ELISA) from banked serum. Prevalent ILD was determined through validated methods that included detailed, systematic review of medical records for clinical diagnoses, imaging findings, and biopsy reports. The aforementioned biomarkers were log-transformed and standardized. Subsequently, principal component analysis (PCA) was performed, retaining components with eigenvalues >1. The ability of the resultant principal component (PC) scores to improve ILD identification was assessed in multivariable logistic regression models. Receiver operating characteristic curves were generated for clinical (age, sex, race, and cigarette smoking history) and clinical + PC score models.

Results: Among 2,044 RA patients (86% male, mean age 64 years, 79% smoking history), 121 had prevalent ILD. PCA of 33 cytokines/chemokines and 8 RA autoantibodies identified 8 unique biomarker PCs. Biomarkers loading onto each PC after orthogonal rotation are shown in **Table 1**. Kaiser-Meyer-Olkin (KMO) testing showed high adequacy for PCA (KMO=0.93). PC 1 scores (characterized by inflammatory monocyte/macrophage mediators) were negatively associated with the presence of ILD while PC 3 scores (anti-MAA-albumin) and PC 6 scores (RF & anti-CCP) were positively associated with the presence of ILD (**Table 1**). Adding PC scores to a clinical only model improved the discrimination of ILD in the RA cohort, evidenced by an increase in the area under the curve (AUC) from 0.62 to 0.70 (p=0.002; **Figure 1**).

Conclusion: In a large RA cohort with validated ILD diagnoses, we found that unsupervised machine learning of 33 cytokines and chemokines and 8 autoantibodies improved the identification of RA-ILD. RA-related autoantibodies (anti-MAA-albumin, RF, and anti-CCP) were the peripheral biomarkers most closely associated with the presence of RA-ILD, suggesting that serologic antibody responses may have the greatest potential for identifying ILD or at-risk patients. Cohort-wide screening for RA-ILD using peripheral blood biomarkers shows promise as an ILD screening modality and should be further validated in other cohorts.

Background/Purpose: Rheumatoid arthritis (RA) is associated with higher cardiovascular disease (CVD) risk due to the underlying inflammation.It is uncertain if the excess CV risk could be reduced by effective suppression of inflammation using the treat-to-target (T2T) approach in patients with early RA (ERA).

Methods: This study compared the 5-year cardiovascular event (CVE) rate among ERA patients managed by a T2T strategy with a CV risk factor-matched non-RA population.

This was an observational study using the Hong Kong Hospital Authority population-based hospital database known as the Clinical Data Analysis and Reporting System (CDARS) and the Clinical Rheumatology Systematic Treat-to-target in Asia Leadership (CRYSTAL) registry. ERA subjects from the registry with baseline disease duration less than 2 years were recruited between 2012-2016. All patients received a tight control, T2T treatment strategy aiming at remission and had been followed for at least 5 years. Each ERA subject was matched to 3 non-RA controls according

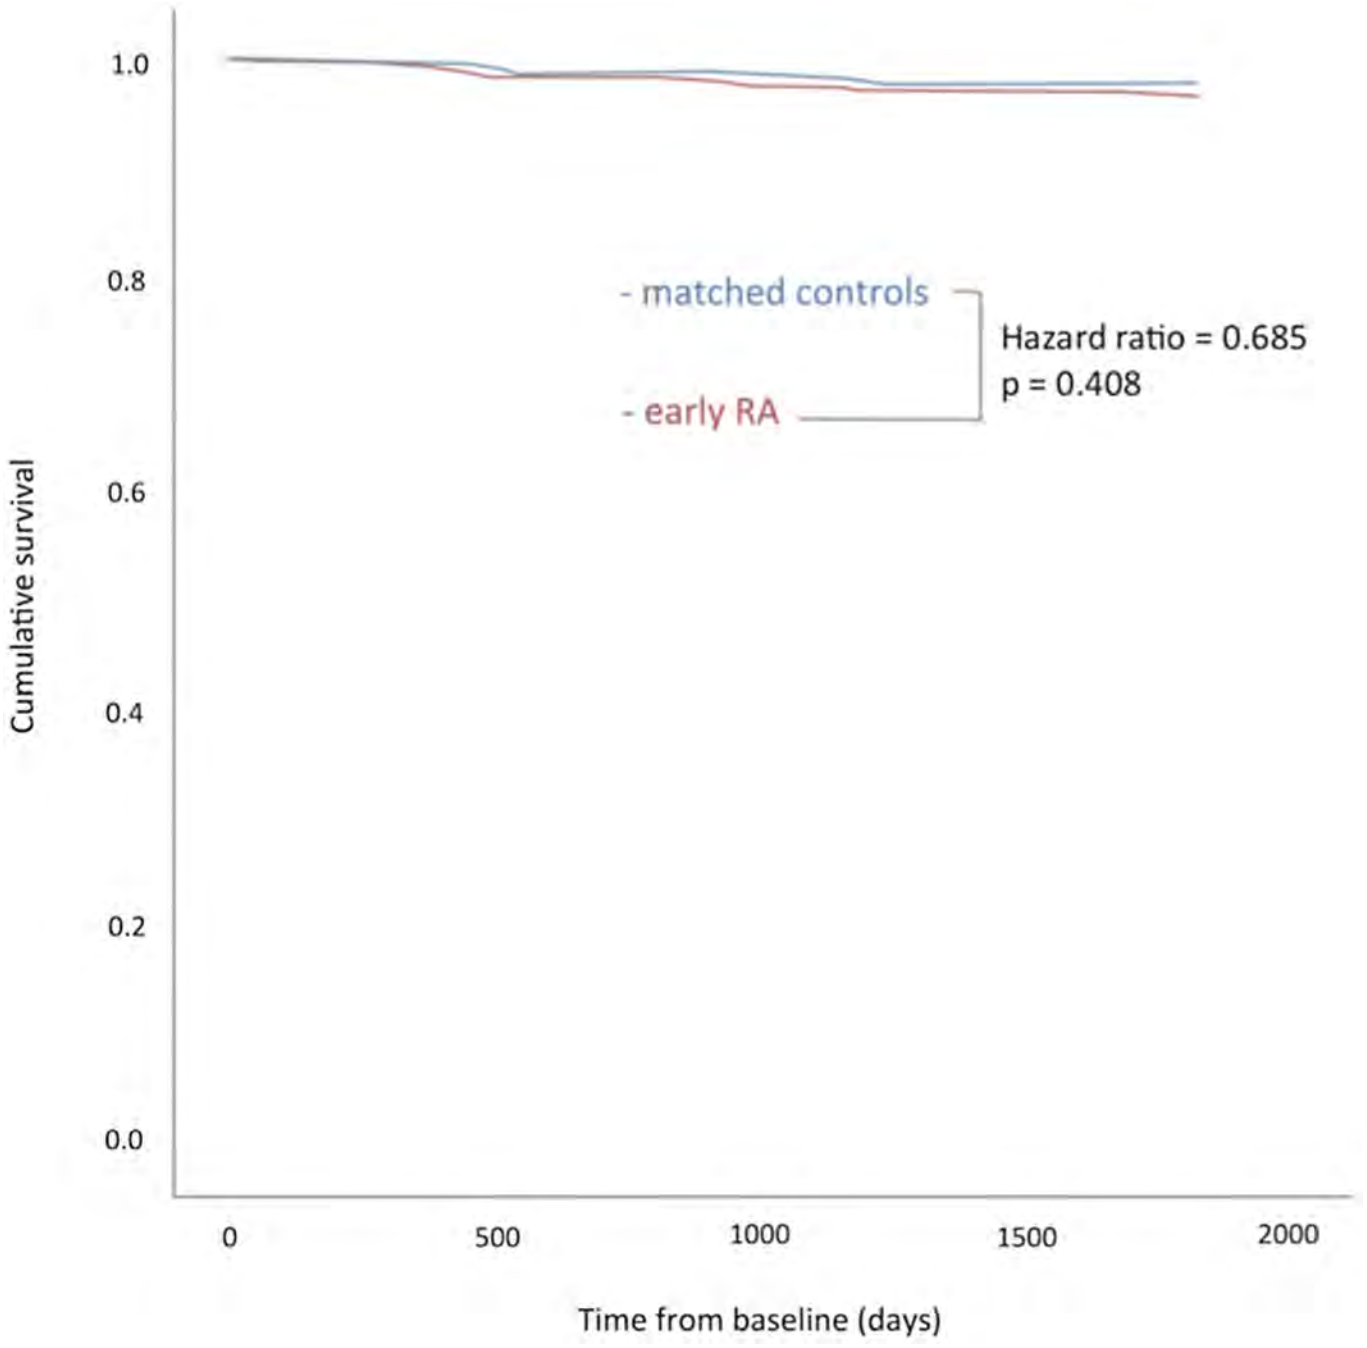

Figure 1. CVE-free survival curves of ERA subjects & matched controls.

to age, gender, smoking status, and the presence of diabetes mellitus (DM), hypertension (HT) and hyperlipidaemia (HL). All subjects on antiplatelet agents, with pre-existing CVD or chronic kidney disease were excluded. All subjects were analysed up to 5 years from baseline. The primary end point was the first occurence of a CVE, namely ischaemic cerebrovascular disease, ischaemic heart disease and heart failure.

Results: The study identified 261 ERA subjects and 783 matched controls. Their characteristics were shown on Table 1. The mean age was 60+/-12 years, 78% were female, 18% were smokers, 8%, 25% and 22% had DM, HT and HL respectively.

CVEs occurred in 2.3% ERA subjects and in 3.3% controls.. The difference was statistically insignificant. The CVE-free survival was shown in Figure 1.

In the ERA cohort, after adjusting for baseline age and atherogenic index, cox-regression analysis showed that i) a longer DAS28 remission duration was protective for CVE with an adjusted hazard ratio (AHR) of 0.46 (95% CI 0.23-0.93), while ii) poor baseline function as reflected by a higher health assessment questionnaire (HAQ) score was predictive of CVE with an AHR of 5.2 (95% CI 1.2-23).

Conclusion: ERA patients treated by a T2T strategy did not develop excess CVE compared to CV risk factor-matched controls over 5 years. A longer disease remission duration was protective while a higher baseline HAQ was associated with a higher CVE risk.

Cardiovascular Risk Management in Patients with Rheumatoid Arthritis: A Single-centered Cross-sectional Study

SAMAR ABOULENAIN[1], Khaled Deeb[2], Mohamed Abdul Qader[1] and Can Jones[1], [1]University of Miami Miller School, West Palm Beach, FL, [2]West Palm Beach VA Medical Center, West Palm Beach, FL

SESSION INFORMATION
Session Date: Saturday, November 6, 2021
Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster I: Cardiovascular Pulmonary Disease (0268–0295)
Session Type: Poster Session A
Session Time: 8:30AM–10:30AM

Background/Purpose: Cardiovascular (CV) disease is the leading cause of death in patients with rheumatoid arthritis (RA) and is estimated to be responsible for 29%-32% of all-cause mortality. Meta-analyses of previous cohort studies showed that patients with RA were found to be at 50-60% increased risk of cardiovascular death compared to the general population. Most current American Heart Association (AHA) guidelines place patients with RA as a special population requiring special attention considering it is one of the risk enhancers that prompt physicians to have a lower threshold to initiate statin therapy. The main objective of this study is to evaluate and identify any clinical gaps in the primary prevention of CV risk in patients with RA.

Methods: Data from West Palm Beach VA Medical Center was used to undergo this analysis. All patients from ages 40-79 who had received a diagnosis of RA using the specific ICD09/ICD-10 codes were identified, excluding those with coronary artery disease, cerebrovascular disease or peripheral vascular disease. Data was manually extracted from the Computerized Patient Record System (CPRS), including demographic information (e.g., age, gender and ethnicity), smoking status, vital signs, medical history, active medications, and lipid panel. Patients with an estimated 10-year CV risk of 7.5% or more are determined to be candidates for lipid-lowering therapy.

Results: A total of 317 patients were identified with a mean ± standard deviation (SD) age of 68 ± 8 years, and the majority (77%) were white males. (See Table 1). Three hundred and one (95%) patients had their lipid profile screening

Table 1. Demographic characteristics of the study population and groups based on statin therapy.

Demographic characteristics		Total (n=317)	On statin (n=154)	Not on statin (n=163)	p-value
Age		69 (7)	70 (6)	66 (9)	<0.001*
Male gender		283 (89%)	143 (93%)	140 (86%)	0.04*
Race					0.78
	White	263(83%)	130 (84%)	133 (82%)	
	African American	39 (12%)	16 (10%)	23 (14%)	
	Other	7 (2%)	4 (2.5%)	3 (2%)	
Smoking status					0.33
	Current	64 (20%)	27 (18.5%)	37 (23%)	
	Former	91 (29%)	49 (34%)	42 (27%)	
	Never	149 (47%)	70 (48%)	79 (50%)	
Comorbidities					
	Diabetes mellites	70 (22%)	52 (34%)	18 (11%)	<0.001*
	Hypertension	183 (58%)	109 (71%)	74 (45.5%)	<0.001*
	Coronary artery disease	58 (18%)	43 (28%)	15 (9%)	<0.001*
	Peripheral artery disease	8 (2.5%)	4 (2.5%)	4 (2.5%)	0.93
	Cerebrovascular accident	11 (3.5%)	6 (4%)	5 (3%)	0.68
Antiplatelet use		118 (37%)	84 (45.5%)	34 (20%)	<0.001*
ASCVD risk		23 (14)	28 (14)	19 (13)	<0.001*

Variables are reported as frequency and percentages (%) or median (standard deviation).
ASCVD risk: atherosclerosis and cardiovascular disease risk estimated in 10 years.
*P values < 0.05

test collected in the past 5 years. Out of 165 patients who met the criteria for CVD primary prevention, 68 were on statin therapy (41%). Of which, 48 patients were on a low-intensity statin (71%) despite being candidates for high-intensity statin therapy. Patients on statins were more likely to be older males with diabetes mellites, hypertension, coronary artery disease, or peripheral artery disease, on antiplatelet therapy, and have a higher ASCVD risk score (p-value < 0.05).

Conclusion: Efforts for primary prevention of CV risk in patients with RA are not fully optimized, despite the appropriate screening process for the possible modifiable risk factors. In addition, our study suggests a potential health disparity with regards to prescribing statin in younger and female patients with RA. There is a compelling need for initiating quality improvement projects aimed to improve CV risk control in this particularly vulnerable patient population to improve survival and quality of life.

Risk Factors for Dementia in Patients with Incident Rheumatoid Arthritis: A Population-based Cohort Study

Elena Myasoedova[1], Michelle Mielke[1], Cassondra Hulshizer[1], John Davis[1], Vijay Ramanan[1], Maria Vassilaki[1] and Cynthia Crowson[2], [1]Mayo Clinic, Rochester, MN, [2]Mayo Clinic, Eyota, MN

SESSION INFORMATION

Session Date: Saturday, November 6, 2021

Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster I: Cardiovascular Pulmonary Disease (0268–0295)

Session Type: Poster Session A

Session Time: 8:30AM–10:30AM

Background/Purpose: Growing evidence from observational studies suggests that patients with rheumatoid arthritis (RA) are at increased risk for cognitive impairment and dementia. Longitudinal population-based studies assessing risk factors for Alzheimer's Disease and related dementias (AD/ADRD) in RA are lacking. We aimed to assess risk factors for incident AD/ADRD in a population-based cohort of patients with incident RA.

Methods: This retrospective population-based cohort study included residents of a geographical area who were at least 18 years of age and met 1987 ACR criteria for RA between 1980 and 2014. All individuals were followed until death, migration, or 12/31/2019. Incident dementia was defined as two ICD-9/10 codes for AD/ADRD at least 30 days apart. Patients with AD/ADRD before RA incidence were excluded (n=12). Information on socio-demographics, RA disease characteristics, ever use of antirheumatic medications (i.e. conventional and/or biologic disease-modifying drugs; glucocorticoids), cardiovascular/cerebrovascular disease (CVD) risk factors, and comorbidities was available from medical records. The definition of any CVD included coronary heart disease (i.e., angina pectoris, coronary artery disease, myocardial infarction [MI], and coronary revascularization procedures), cerebral stroke and chronic heart failure. Cox proportional hazards models were used to examine the association between each of these risk factors and incident ADRD, adjusting for age, sex, and calendar year of RA incidence. Time-dependent covariates were used to represent factors that developed during follow-up.

Results: A total of 1,366 patients with RA (mean age 56 years, 69% females, 64% positive for rheumatoid factor and/or cyclic citrullinated peptide antibody) were included. During the median follow-up of 9.4 years, 107 patients (8%) developed AD/ADRD. Older age (hazard ratio [HR] per one year increase 1.15, 95% confidence interval [CI] 1.13-1.17), ever presence of large joint swelling (HR 2.2, 95%CI 1.2-3.9), diabetes mellitus (HR 1.6, 95%CI 1.02-2.5), any CVD (HR 2.4, 95%CI 1.5-4.0), and particularly stroke (HR 3.2, 95%CI 1.9-5.5) and heart failure (HR 1.8, 95%CI 1.1-3.0) were associated with increased risk of AD/ADRD. Use of low-dose aspirin (HR 2.3, 95%CI 1.4-3.8) was associated with increased risk for AD/ADRD, likely due to confounding by indication for CVD. Sex, race, education, smoking, obesity, extraarticular features of RA, antirheumatic medications, hypertension, dyslipidemia, or MI were not associated with risk of AD/ADRD among RA patients.

Conclusion: Apart from age, a universally recognized risk factor for AD/ADRD, clinically active RA manifesting with large joint swelling and the presence of CVD and diabetes mellitus were associated with elevated risk of AD/ADRD among RA patients. Among CVD conditions, cerebral stroke and chronic heart failure were associated with the risk of ADRD. These findings suggest that in addition to aging, the risk of AD/ADRD in RA may be driven by RA disease-related factors while CVD may be partially mediating these associations. Studies are ongoing to further evaluate the role of systemic inflammation and CVD in AD/ADRD overall and by dementia subtype in patients with RA.

Abstract Number: 0285

Risk of Cardiovascular Disease in Newly Diagnosed Rheumatoid Arthritis: A Current Risk Assessment

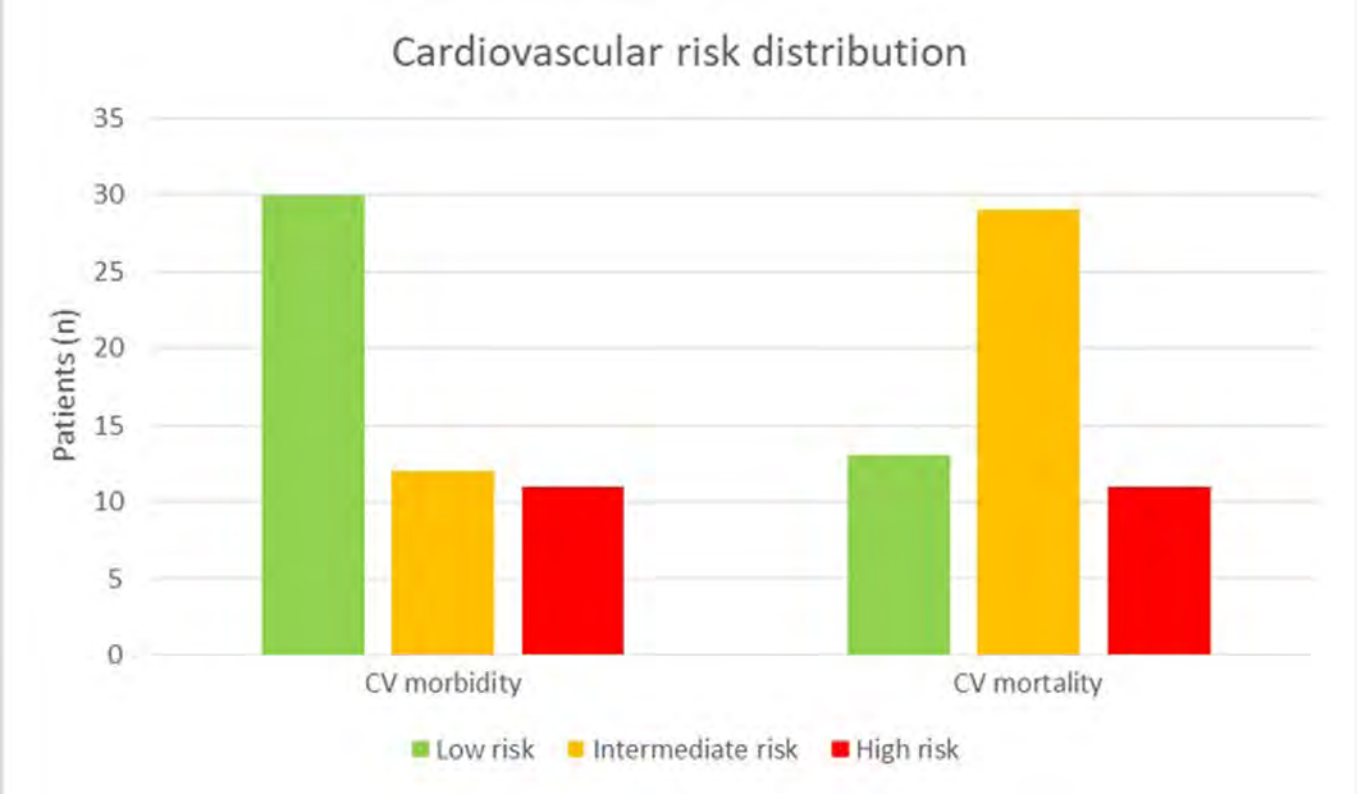
Reinder Raadsen[1], Romy Hansildaar[1], Maaike Heslinga[2], Arno van Kuijk[1] and Michael Nurmohamed[3], [1]Reade, Amsterdam, Netherlands, [2]Amsterdam University Medical Center, location VUmc, Amsterdam, Netherlands, [3]Reade and Amsterdam University Medical Center, location VUmc, Amsterdam, Netherlands

SESSION INFORMATION
Session Date: Saturday, November 6, 2021
Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster I: Cardiovascular Pulmonary Disease (0268–0295)
Session Type: Poster Session A
Session Time: 8:30AM–10:30AM

Background/Purpose: Patients with rheumatoid arthritis (RA) are known to have an increased risk of developing, mainly ischemic cardiovascular diseases (CVD). This is partly explained by a higher incidence of traditional CV risk factors as hypertension and/or hypercholesterolemia but also due to the systemic inflammation characteristic to RA. RA is considered an independent CV risk by National and International CVD risk management guidelines, and therefore CVD risk screening is recommended. However, the implementation of CV risk management is often poorly performed in daily clinical practice.

The aim of the current study was to investigate the cardiovascular disease risk of newly diagnosed RA patients, and review if and to what extent implementation of CVD risk management had previously taken place.

Methods: Every newly diagnosed RA patient in a large Dutch outpatient rheumatology clinic had CV screening within their first year post-diagnosis during a regularly scheduled visit, where among others smoking habits, blood pressure and lipid profile were measured. A 10-year cardiovascular risk was calculated using a modified SCORE calculator from www.u-prevent.com, which predicts the risk of myocardial infarction, stroke, heart failure, peripheral arterial disease and CV death based on several CV risk factors. To account for RA as a risk factor, the calculator multiplies the risk by 1.5, in accordance with the Dutch CV risk management guideline. The calculated 10-year cardiovascular morbidity risk was categorized in low (< 10%), intermediate (10-19%) and high (≥20%), and the 10-year mortality risk was also categorized in low (< 1%), intermediate (1-4%) and high (≥5%).



Distribution of 10-year cardiovascular risk in rheumatoid arthritis patients. CV = cardiovascular.

Results: A total of 53 patients were included up to this point. Of these, the average age was 57 (±8.5), and 39 (74%) were women. Mean systolic blood pressure was 129 (±17.7) mmHg, with 38 (72%) patients having hypertension. Mean total cholesterol, LDL and HDL were respectively 5.5 (±1.0) mmol, 3.43 (±0.82) mmol and 1.78 (±0.54) mmol, with 30 patients having hypercholesterolemia. The average calculated 10-year morbidity risk of all patients was 13%, and the mortality risk was 3%. Distribution of the 10-year risk in low, intermediate and high is presented in figure 1. Only one patient reported having previous used medication for hypercholesterolemia, but not at the time of enrollment in this study.

Conclusion: 43% of newly diagnosed RA patients had an intermediate or high calculated 10-year CV morbidity risk, and 76% had an intermediate or high mortality risk. Patients with early RA still often have underdiagnosed and severely undertreated risk factors of CVD, such as hypertension and hypercholesterolemia. Early CV risk assessment and management in patients with RA is critical and needs to be implemented as standard care.

SESSION INFORMATION
Session Date: Saturday, November 6, 2021
Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster I: Cardiovascular Pulmonary Disease (0268–0295)
Session Type: Poster Session A
Session Time: 8:30AM–10:30AM

Background/Purpose: Patients with inflammatory rheumatic diseases such as rheumatoid arthritis (RA), psoriatic arthritis (PsA) and ankylosing spondylitis (AS) are at a higher risk for developing cardiovascular diseases (CVD) than the general population. This increased risk is partly due to a higher incidence of traditional cardiovascular (CV) risk factors, such as hypertension and dyslipidemia, and partly due to the underlying systemic inflammation. During the past two decades, the burden of the systemic inflammation has been reduced by more efficacious anti-inflammatory treatment, which somewhat attenuated the increased CV risk of rheumatic patients. However, it remains important to monitor the effects of these new treatment strategies on the prevalence of CVD in patients with a rheumatic disease in systematically controlled cohorts.

The aim of the current report was to evaluate whether the CV risk of patients with inflammatory rheumatic diseases still differs from the general population, despite advances In anti-rheumatic treatment strategies.

Methods: In March 2020, all adult patients with an inflammatory rheumatic disease from the Amsterdam Rheumatology and Immunology Center, location "Reade" were systematically asked to participate in a prospective cohort study. The primary aim of this study was to monitor the impact of the COVID-19 pandemic on patients with inflammatory rheumatic diseases compared to age and sex matched healthy controls. Between April 26, 2020 and May 27, 2020,

Table 1. Values are displayed as mean ± standard deviation (SD), median with interquartile range (IQR) or frequencies with percentages (%). RA = rheumatoid arthritis, PsA = psoriatic arthritis, AS = ankylosing spondylitis, BMI = body mass index, TNF = anti-tumor necrosis factor, IL = interleukin

Table 1. Baseline characteristics

Patient characteristics	All patients (n=1455)	RA (n=979)	PsA (N=261)	AS (n=215)	Controls (n=414)
Mean age - yr	55 ± 13	58 ± 12	55 ± 13	48 ± 13	53 ± 13
Female sex - no (%)	934 (64)	728 (74)	119 (46)	87 (41)	298 (72)
BMI (IQR)	25 (23-28)	25 (22-28)	26 (24-30)	25 (22-28)	24 (22-27)
Smoking - no (%)	178 (12)	126 (13)	17 (7)	35 (16)	34 (8)
Cardiovascular disease – no (%)	157 (11)	107 (11)	28 (11)	22 (10)	30 (7)
Rheumatic medication - no (%)					
csDMARDs	877 (60)	712 (73)	148 (57)	17 (8)	N.A.
Oral glucocorticoids	161 (11)	139 (14)	17 (7)	5 (2)	2 (0.4)
TNF inhibitor	563 (39)	336 (34)	121 (46)	106 (49)	N.A.
IL-6 inhibitor	19 (1)	19 (2)	0	0	N.A.
IL-17 inhibitor	17 (1)	2 (0.2)	7 (3)	8 (4)	N.A.

participants completed the first online questionnaire of the study. Amongst others, information on demographic data, including CV comorbidities and risk factors, and medication use was collected. The baseline characteristics and prevalence of CVD were compared between RA, PsA or AS and healthy controls.

Results: In total, 1455 consecutive patients with an inflammatory rheumatic disease (979 RA patients, 261 PsA patients and 215 AS patients), and 414 healthy controls completed the first questionnaire, as shown in table 1. CV comorbidities were more frequently reported in RA, PsA and AS patients compared to healthy controls; 107 (11%), 28 (11%) and 22 (10%) compared to 30 (7%), respectively. Unadjusted odds ratios with corresponding 95%-confidence intervals for patients with RA, PsA and AS compared to controls were 1.57 (1.03-2.40), 1.54 (0.90-2.64) and 1.46 (0.82-2.60).

Conclusion: We demonstrated that the prevalence of CVD is approximately 1.5 times higher in patients with rheumatic diseases compared to healthy controls (11% vs. 7%, respectively). This corresponds with previous research, although the reported prevalence of CVD in PsA and AS patients is even higher compared to prior studies. This suggests that the CVD risk of patients with rheumatic diseases is still elevated in 2020 compared to the general population, despite the improved management of rheumatic disease activity. Therefore, adequate and timely treatment of CV risk factors remains relevant, not only in patients with RA, but in patients other rheumatic diseases as well.

20 Years Follow-up of Cardiovascular Event Risk in Rheumatoid Arthritis Compared to Diabetes

Reinder Raadsen[1], Rabia Agca[2], Alexandre Voskuyl[3], Maarten Boers[4], Willem Lems[5], Arno van Kuijk[1] and Michael Nurmohamed[2], [1]Reade, Amsterdam, Netherlands, [2]Reade and Amsterdam University Medical Center, location VUmc, Amsterdam, Netherlands, [3]Amsterdam University Medical Center, location VUmc, Amsterdam, Netherlands, [4]Amsterdam UMC, Vrije Universiteit, Amsterdam, Netherlands, [5]VUmc, Amsterdam, Netherlands

SESSION INFORMATION

Session Date: Saturday, November 6, 2021

Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster I: Cardiovascular Pulmonary Disease (0268–0295)

Session Type: Poster Session A

Session Time: 8:30AM–10:30AM

Background/Purpose: Patients with rheumatoid arthritis have an increased risk for developing cardiovascular diseases (CVD) compared to the general population, similar to the CVD risk in patients with diabetes mellitus (DM). However, there are no controlled studies investigating the incidence of cardiovascular (CV) events in RA patients with follow up of more than 20 years.

The objectives of the current study were to investigate the incidence rates of CV events in a long-term follow up cohort of RA patients, and to compare these to a similar cohort representing the general population, ie. The Hoorn study.

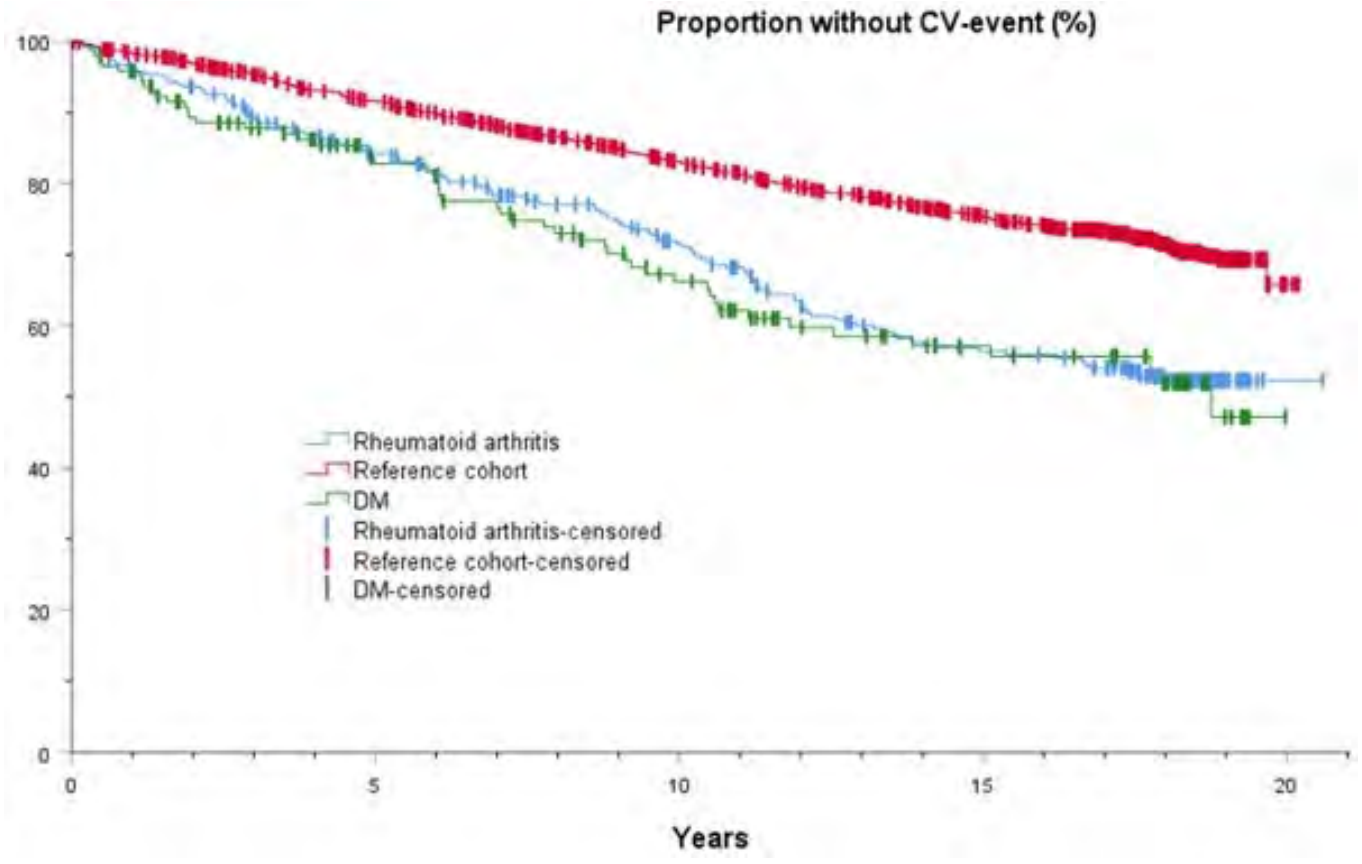

Figure 1. Cardiovascular event-free survival.

Methods: The CARRÉ study is an ongoing prospective cohort study, which started in 2001, investigating CV mortality and morbidity in 353 randomly selected patients with RA. Primary endpoints, i.e. verified medical history of coronary, cerebral or peripheral arterial disease, were determined at baseline, and after three, ten, fifteen and twenty years of follow up. Patients were censored at the date of an experienced CV event or their death. Incidence density rates per 100 patient years were calculated. Data were compared to results from the Hoorn study, a Dutch cohort study of glucose metabolism and other CV risk factors that began in 1989. All participants were subject to an extensive and repeated CV screening program similar to that used in the CARRÉ study. 1.356 nondiabetic controls and 144 patients with DM were used in the comparison.

Results: During follow up, 122 (35%) of RA patients developed a CV event, compared to 353 (26%) of the general population and 53 (37%) of the DM patients. The incidence rate of CV events in RA patients was 3.1 per 100 patient years, with 3.915 years at risk, compared to 1.9 per 100 patient years in the general population and 3.9 per 100 patient years in the DM patients, with 18.791 and 1.374 years at risk, respectively. CV event-free survival is shown in figure 1.

Conclusion: The incidence rate of CV events in RA patients has during 20 years remained consistently higher compared to the general population. The rate of CV events in RA patients has remained the same, despite better control of inflammation, suggesting under-treatment of "traditional" CV risk factors. This again emphasizes the need for timely CVD-risk screening and management

SESSION INFORMATION

Session Date: Saturday, November 6, 2021

Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster I: Cardiovascular Pulmonary Disease (0268–0295)

Session Type: Poster Session A

Session Time: 8:30AM–10:30AM

Background/Purpose: Bronchiectasis is a known extra-articular manifestation of rheumatoid arthritis (RA) characterized by bronchial damage and excessive mucus production that predispose patients to risk of serious infection and increased mortality. Traction bronchiectasis is a consequence of architectural distortion from RA-associated interstitial lung disease (RA-ILD), but little is known about risk factors for isolated RA-associated bronchiectasis (RA-BR) that occurs independently of RA-ILD. We investigated factors associated with isolated RA-BR among RA patients.

Table 1: Characteristics of RA bronchiectasis cases and controls

Characteristic	Isolated RA-bronchiectasis cases (n=52)	RA controls without lung disease (n=311)	p-value
Demographics			
Female sex (n, %)	45 (86.5%)	236 (75.9%)	0.09

RF negative	1.00	Ref
RF positive (>1x ULN)	**4.32 (2.01-9.28)**	**0.0002**
RF negative	1.00	Ref
RF low-positive (>1-3x ULN)	2.02 (0.67-6.06)	0.21
RF high-positive (>3x ULN)	**5.71 (2.59-12.60)**	**<0.0001**
CCP negative	1.00	Ref
CCP positive (>1x ULN)	**3.17 (1.49-6.72)**	**0.003**
CCP negative	1.00	Ref
CCP low-positive (>1-3x ULN)	2.24 (0.52-9.61)	0.28
CCP high-positive (>3x ULN)	**3.21 (1.50-6.88)**	**0.003**

*Adjusted for age, sex, race, RA duration, smoking status, pack-years, and body mass index
BR = bronchiectasis; CCP = cyclic citrullinated peptide; CI = confidence interval; OR = odds ratio; RA = rheumatoid arthritis; RF = rheumatoid factor; ULN = upper limit of normal

Methods: We performed a case-control study using a large institutional biobank and research data repository that recruited patients from clinical sites throughout a multi-hospital healthcare system in New England. Patients with RA were identified using a previously described algorithm and confirmed by medical record review. All patients with RA who had chest computed tomography (CT) imaging, lung biopsy, or autopsy data were reviewed for RA-related lung disease. For each patient, the CT chest imaging performed closest to enrollment was independently reviewed by two expert radiologists and scored for the presence of RA-ILD and interstitial lung abnormalities. Cases of RA-BR were confirmed by review of clinical records and CT scan report, and isolated RA-BR was defined as clinical evidence of bronchiectasis with no evidence of RA-ILD or interstitial lung abnormalities on expert radiology review. Controls had RA but no RA-related lung disease on expert review of CT chest imaging. Covariate data were obtained through survey enrollment and medical record review. The associations between demographic, lifestyle, and clinical factors and RA-BR were examined using multivariable logistic regression.

Results: We identified 52 isolated RA-BR cases and 311 RA controls without RA-related lung disease. There was no significant difference in age between RA-BR cases and controls (median 53.5 vs. 52.0 years, p=0.26); 86.5% of RA-BR cases and 75.9% of controls were female (p=0.09). The median body mass index (BMI) was lower (25.2 kg/m^2, IQR 22.6, 28.4) in RA-BR cases than controls (28.1 kg/m^2, IQR 24.1-33.1; p=0.001). There was a greater proportion of seropositive patients among RA-BR cases (86.5%) than in the control group (57.2%) (p< 0.0001). Seropositive RA had multivariable OR for RA-BR of 4.40 (95%CI 1.87-10.35) compared to seronegative RA. Older age and longer RA duration were each associated with RA-BR (OR 1.46 per decade [95%CI 1.07-1.98], and OR 1.04 per year [95%CI 1.00-1.08], respectively). There was no association of smoking with RA-BR. Patients with high-positive RF had OR for RA-BR of 5.71 (95%CI 2.59-12.60). High-positive CCP was also associated with RA-BR (OR 3.21, 95%CI 1.50-6.88).

Conclusion: We identified seropositivity, older age at RA onset, longer RA duration, and lower BMI as potential novel risk factors for isolated bronchiectasis in RA not due to RA-ILD. High-positive RF and CCP were each strongly associated with RA-BR, suggesting a pathogenic link between RA-related autoantibodies and airway damage in bronchiectasis.

SESSION INFORMATION

Session Date: Saturday, November 6, 2021

Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster I: Cardiovascular Pulmonary Disease (0268–0295)

Session Type: Poster Session A

Session Time: 8:30AM–10:30AM

Background/Purpose: Interstitial lung disease (ILD) can be detected in 20% to 60% of patients with rheumatoid arthritis (RA) on high-resolution computed-tomography (HRCT) chest scan and is clinically significant in near 10%. Despite a high morbi-mortality rate, there are no definite strategy for preclinical ILD screening in patients with RA.

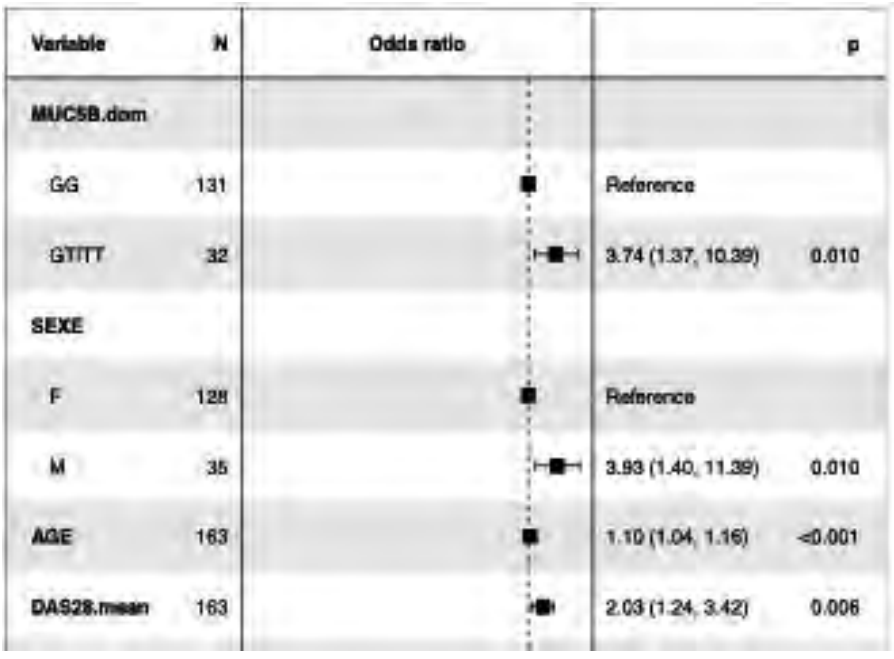

Figure 1. Predictors of ILD occurrence after at least 10 years-follow-up.

To date, several factors have been reported to increase the risk of RA-ILD occurrence (*i.e.* older age at RA onset, ACPA positivity, male sex, RA disease activity, the *MUC5B* rs35705950 promoter variant...). However, none of these risk factors has been validated in a prospective cohort. The ESPOIR prospective cohort includes patients with recent arthritis (less than 6 months) and a definite or probable diagnosis of RA. The objective of our study was to develop and replicate a predictive score that could identify patients with preclinical RA-ILD.

Methods: An ILD detection by chest HRCT scan was systematically offered to every patient with definite RA after at least 10 years-follow-up. Potential predictors of ILD were prospectively collected from baseline to the date of the HRCT scan, and all included patients were genotyped for *MUC5B* rs35705950. A logistic model was used to identify independent predictors for the occurrence of ILD on HRCT scans. A predictive score for preclinical ILD occurrence was developed based on the identified predictors. The score was replicated in an independent population of patients with RA without pulmonary symptoms investigated with chest HRCT.

Results: 163 RA patients according to 2010 ACR/EULAR classification criteria, none of whom had pulmonary symptoms, were investigated with a chest HRCT scan in the ESPOIR cohort (128 women (78.5%), mean RA duration 13.7 ± 1.1 years, age at inclusion 47.6 y/o ± 10.4, mean disease activity score [DAS]-28 during follow up was 3.1 ± 1.0). ILD was detected in 31 patients (19.0%). After logistic regression, independent predictors for preclinical RA-ILD were male sex (OR=3.9 CI $_{95\%}$ [1.4-11.4]), older age at RA onset (OR=1.1 per year CI $_{95\%}$ [1.0-1.2]), mean DAS-28 score during the follow-up (OR=2.0 CI $_{95\%}$ [1.2-3.4]) and *MUC5B* rs35705950 T risk allele (OR=3.7 CI $_{95\%}$ [1.4-10.4]) (Figure 1). The logistic model could predict preclinical ILD occurrence with an AUC=0.82 CI $_{95\%}$ (0.72-0.91). A predictive score for preclinical RA-ILD based on the 4 identified predictive risk factors was developed (Sensitivity [Se] 80%, Specificity [Sp] 56%). The score was replicated in an independent population of 89 RA patients investigated with chest HRCT scan. 15 patients (16.9%) had preclinical RA-ILD. The score could predict RA-ILD in 13 patients (Se 86.7%, Sp 40.5%, negative predictive value 93.8%, positive predictive value 22.3%).

Conclusion: In this study, we developed and replicated a predictive score for preclinical RA-ILD that could help physicians identifying patients with RA in whom a HRCT scan should be performed.

Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster I: Cardiovascular Pulmonary Disease (0268–0295)

Session Type: Poster Session A

Session Time: 8:30AM–10:30AM

Background/Purpose: Rheumatoid arthritis-related lung disease (RA-LD) is a common manifestation of rheumatoid arthritis (RA) and associated with excess mortality. Many studies to date were focused on RA-associated interstitial lung disease (RA-ILD). There are few studies reporting the whole lung manifestations of RA. In this study, we aimed to determine the prevalence of RA-LD and to assess the predictors of mortality in RA-LD patients.

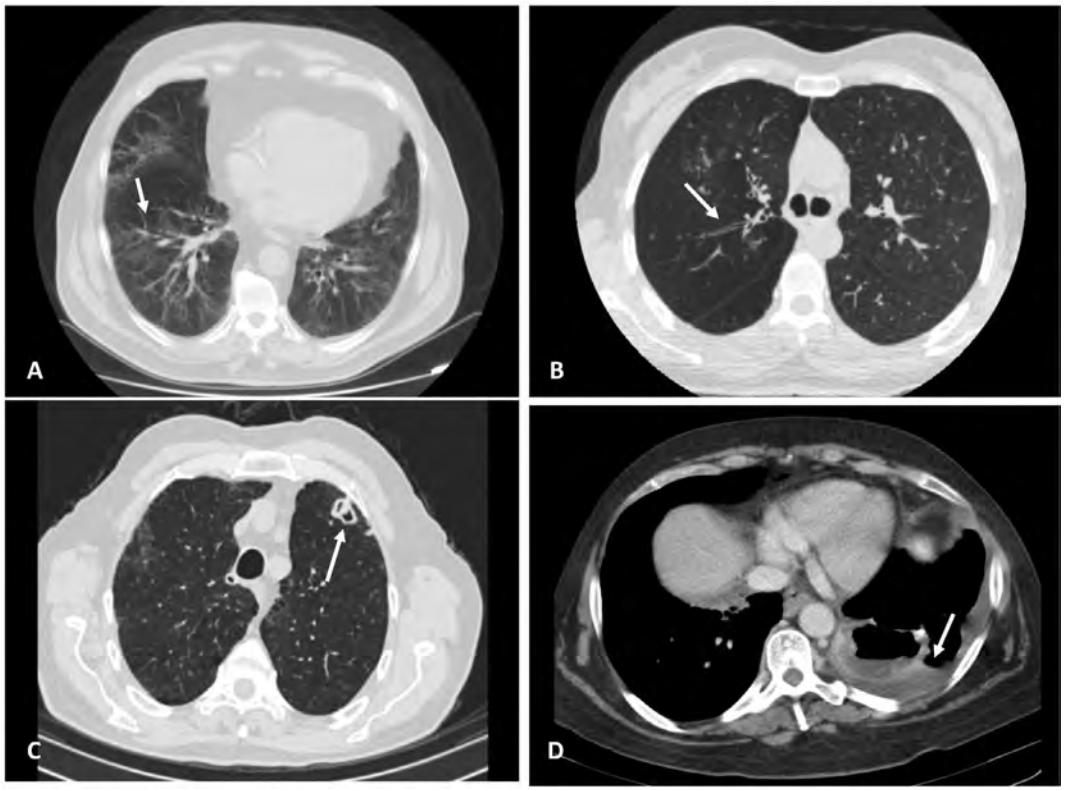

Figure 1. Images of different RA-LD subtypes. Interstitial lung disease with a pattern of nonspecific interstitial pneumonia (A), airway disease presenting with tubular bronchiectasis (B), necrobiotic cavitary rheumatoid nodule (C), pleural effusion (D).

Table 1. Characteristics of patients with different RA-LD subtypes

	RA-ILD (n= 107)	AD (n=119)	RA-PN (n= 70)	RA-PE (n= 31)
Age at RA diagnosis, mean (SD)	54.2 (13.0)	51.9 (12.9)	51.5 (11.4)	49.2 (11.8)
Age at RA-LD diagnosis, mean (SD)	61.6 (10.4)	61.1 (9.7)	59.1 (9.2)	57.0 (10.8)
Male sex, n(%)	54 (50.5)	28 (23.5)	36 (51.4)	20 (64.5)
Smoking, n (%)	52/96 (54.2)	35/96 (36.5)	43/67 (64.2)	21/29 (72.4)
Seropositivity, n (%)	95 (88.8)	103 (86.6)	66 (94.3)	30 (96.8)
CRP (mg/L), median (Q1-Q3)	50.8 (66.5)	41.9 (59.8)	45.3 (52.7)	85.2 (96.3)
High CRP (>5 mg/L), n (%)	99 (92.5)	105 (88.2)	62 (88.6)	29 (93.5)
ESR (mm/h), median (Q1-Q3)	41.9 (26.9)	40.2 (27.5)	42.6 (29.2)	54.3 (37.4)
High ESR (>20 mm/hour), n (%)	84 (78.5)	85 (71.4)	51 (72.9)	25 (80.6)
Antinuclear antibody, n (%)	46/95 (48.4)	57/111(51.4)	26/63 (41.3)	13/30 (43.3)
Erosions on X-ray, n (%)	61 (57.0)	65 (54.6)	37 (52.9)	15 (48.4)
Subcutaneous rheumatoid nodules, n (%)	18 (16.8)	4 (3.4)	10 (14.3)	4 (12.9)
Secondary Sjögren's syndrome, n (%)	8 (7.5)	11 (9.2)	4 (5.7)	1 (3.2)
RA-ILD, n (%)	-	20 (16.8)	28 (40.0)	9 (29.0)
AD, n (%)	20 (18.7)	-	13 (18.6)	5 (16.1)
PN, n (%)	28 (26.2)	13 (10.9)	-	12 (38.7)
RA-PE, n (%)	9 (8.4)	5 (4.2)	12 (17.1)	-
All cause pleural effusion, n (%)	14 (13.1)	16 (13.4)	15 (21.4)	-
2+ subtypes, n (%)	45 (42.1)	28 (23.5)	43 (61.4)	19 (61.3)
Emphysema, n (%)	50 (46.7)	23 (19.3)	30 (42.9)	18 (58.1)
CVD, n (%)	25 (23.4)	21 (17.6)	12 (17.1)	6 (19.4)
Malignancy, n (%)	11 (10.3)	5 (4.2)	4 (5.7)	3 (9.7)
Need for long-term oxygen therapy, n (%)	12 (11.2)	5 (4.2)	2 (2.9)	3 (9.7)
Death, n (%)	30 (28.0)	22 (18.5)	12 (17.1)	8 (25.8)

RA-LD= rheumatoid arthritis-related lung disease, RA-ILD= rheumatoid arthritis-related interstitial lung disease, AD= airway disease, RA-PN= rheumatoid arthritis-related pulmonary nodules, RA-PE= rheumatoid arthritis-related pleural effusion, RA= rheumatoid arthritis, CRP= C reactive protein, ESR= erythrocyte sedimentation rate, CVD= cardiovascular disease

Methods: Patients who attended our rheumatology clinic between January 2010-December 2020 and fulfilled 2010 ACR/EULAR classification criteria for RA were retrospectively evaluated. Among them, patients with abnormal computed tomography of the chest (chest-CT) were scrutinized. RA-LD was defined as the existence of RA-ILD, airway disease (AD), rheumatoid pulmonary nodules (RA-PN) or RA-related pleural effusion (RA-PE). Thoracentesis or lung biopsy results were also used to confirm the existence of RA-LD. The patient data was recorded for each subtype of RA-LD. The date of RA-LD diagnosis was considered the date of the first chest-CT detecting the pathology. To assess the predictors associated with all-cause mortality, logistic regression analysis was performed.

Table 2. Predictors of mortality in RA-LD patients

	Univariate OR (95% CI)	p	Multivariable OR (95% CI)	p
Age at RA-LD diagnosis	1.07 (1.03-1.11)	**<0.001**	1.04 (1.01-1.09)	**0.020**
Male sex	0.92 (0.49-1.71)	0.784	0.72 (0.34-1.52)	0.393
Smoking	0.72 (0.37-1.41)	0.342		
Seropositivity	1.86 (0.62-5.58)	0.267		
RA-ILD (yes vs no)	2.20 (1.18-4.08)	**0.013**	2.28 (1.12-4.64)	**0.023**
All cause pleural effusion	2.22 (1.09-4.53)	**0.028**	3.30 (1.43-7.62)	**0.005**
bDMARDS or tsDMARDs usage	0.42 (0.21-0.84)	**0.015**	0.55 (0.26-1.19)	0.131
Methotrexate usage	0.33 (0.17-0.64)	**0.001**	0.40 (0.19-0.84)	**0.016**
CVD (yes vs no)	2.19 (1.06-4.53)	**0.035**	1.41 (0.61-3.26)	0.420

RA-LD= rheumatoid arthritis-related lung disease, RA-ILD= rheumatoid arthritis-related interstitial lung disease, bDMARDS= biologic disease-modifying anti-rheumatic drugs, tsDMARDs= targeted synthetic disease-modifying anti-rheumatic drugs, CVD= cardiovascular disease

Results: Among 9756 RA patients, 253 (2.6%) patients (38.7% male; mean age at RA and RA-LD diagnoses 52.1 ± 12.4 and 59.9 ± 9.8 years, respectively) had RA-LD. AD was the most common subtype of RA-LD and detected in 119 (47.0%) patients followed by 107 (42.3%) patients with RA-ILD, 70 (27.7%) patients with RA-PN and 31 (12.3%) patients with RA-PE (Figure 1). The characteristics of patients with each subtype are shown in Table 1. Sixty-one (24.1%) patients had 2 or more RA-LD subtypes during their follow-up. After a median of 3.9 years (IQR 5.1), 52 (20.6%) patients died and the 5-year survival rate was 81.8%. In multivariable logistic regression analysis, the existence of RA-ILD, pleural effusion and older age at RA-LD diagnosis were positively associated with higher mortality (odds ratios (OR) were 2.28, 3.30 and 1.04, respectively), whereas methotrexate usage was protective (OR 0.40) (Table 2).

Conclusion: In this single center retrospective study, we showed that the prevalence and mortality of RA-LD was approximately 3% and 20%, respectively. As well as RA-ILD and older age, which are known risk factors, having pleural effusion was also related to mortality. Patients, who received methotrexate, had low mortality rates.

IgA Anti-Cyclic Citrullinated Peptide Antibodies in Bronchoalveolar Lavage Fluid from Patients with Idiopathic Pulmonary Fibrosis Are Associated with Reduced Mortality

Scott Matson[1], Candace Cephers[2], Timothy Wilson[3], Valerie Minarchick[3], Kevin Brown[4], Joshua Solomon[4] and Kristen Demoruelle[5], [1]University of Kansas, Kansas City, MO, [2]St Joseph Hospital, Internal Medicine, Denver, CO, [3]University of Colorado, Denver, CO, [4]National Jewish Health, Denver, CO, [5]University of Colorado Anschutz Medical Campus, Aurora, CO

SESSION INFORMATION
Session Date: Saturday, November 6, 2021
Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster I: Cardiovascular Pulmonary Disease (0268–0295)
Session Type: Poster Session A
Session Time: 8:30AM–10:30AM

Background/Purpose: Idiopathic pulmonary fibrosis (IPF) is a form of interstitial lung disease (ILD) that shares many clinical features with rheumatoid arthritis (RA) associated ILD. Our published data found that serum RA-related antibodies, particularly IgA antibodies to CCP, were significantly more prevalent in IPF patients (23%) compared to population controls (6%). However, the mechanisms that lead to anti-CCP generation in IPF are unknown. Of interest, neutrophil extracellular trap (NET) formation externalizes citrullinated proteins and has been implicated in the generation of anti-CCP in RA, including in the lung. The goal of this study was to explore relationships between anti-CCP, markers of NET formation in the lung and outcomes in IPF.

Methods: We included 176 IPF patients from National Jewish Health who had stored bronchoalveolar lavage fluid (BALF). BALF was analyzed for anti-CCP-IgA (in house ELISA), total protein (ELISA) and markers of NETs (neutro-

phil elastase (NE), ELISA, and double stranded (ds)DNA, fluorometric assay). All CCP, NE and dsDNA values were adjusted for total protein level. Date of death was determined by the CDC's National Death Index and mortality was analyzed by Spearman's correlation using days from BALF collection to death within 5 years of BALF collection and cox proportional hazards model. The majority of patients (n=169) also had pulmonary function testing (PFTs), including % predicted forced vital capacity (% FVC) and % predicted diffusion capacity of carbon monoxide (% DLCO), performed within 3 months of BALF collection.

Results: Clinical characteristics of the cohort are listed in Table 1. Overall, we found a significant association between higher levels of BAL anti-CCP and lower 5-year mortality (Figure 1A). In contrast, we found a significant association between higher levels of dsDNA and NE and higher 5-year mortality (Figure 1B-C). Of interest, when IPF patients were stratified by BALF anti-CCP level, the 'Low BALF anti-CCP' group had a significant correlation between markers of NETosis and clinical variables including: 5-year mortality, %FVC and %DLCO while the 'High BALF anti-CCP' group had no association between NETosis markers and these outcomes (Table 2). There was also a significant positive correlation between BALF levels of anti-CCP and markers of NETs (for NE, r=0.20, p=0.010; for dsDNA, r=0.27, p< 0.001).

Conclusion: This is the first study to report anti-CCP-IgA levels in the lung of IPF patients and identify an association with improved mortality. We also found a strong association between anti-CCP and markers of NETs in the lung, suggesting that NETs may lead to anti-CCP generation in the lung in IPF, similar to reports in RA. Based on published studies in IPF that associate BALF neutrophilia with increased mortality, it was not surprising that NET markers in BALF were associated with mortality in our study. However, it was of interest that this association was markedly blunted in IPF patients with the highest BALF anti-CCP levels, suggesting that anti-CCP-IgA may be protective against the detrimental effects of neutrophils in the lung in IPF. Future studies are needed to understand the mechanisms by which such a protective effect in the lung could occur.

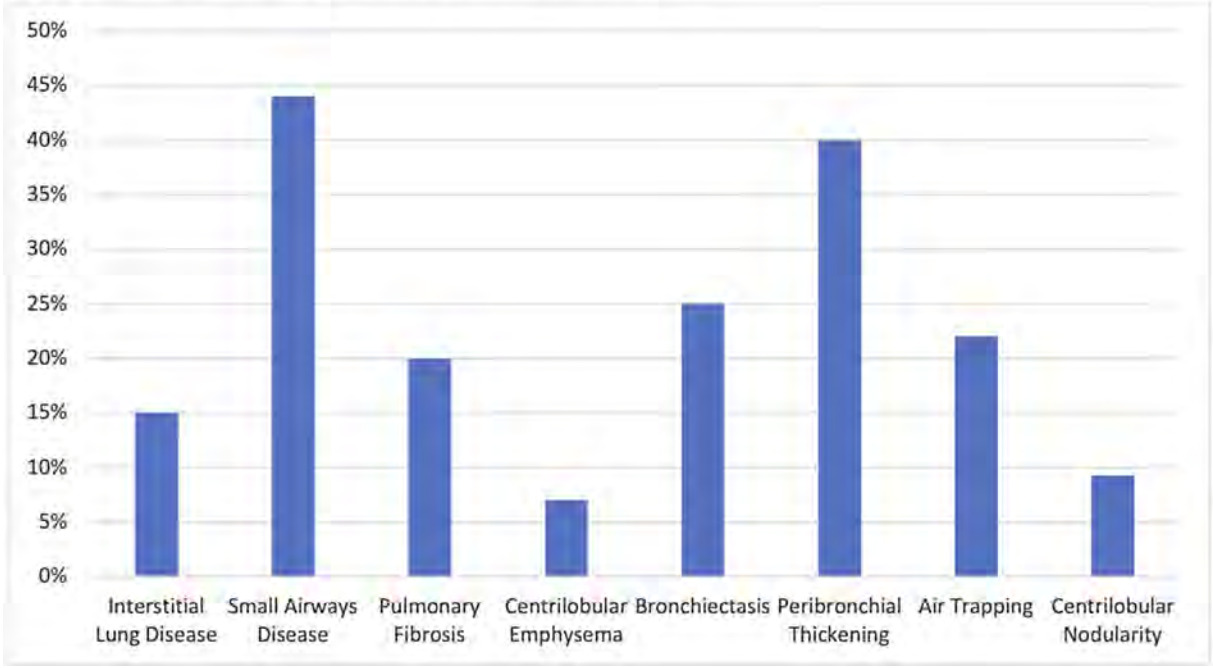
Suppressed Paraoxonase-1 Activity and Elevated Oxylipins Associate with the Presence of Small Airways Disease in Patients with Rheumatoid Arthritis

Amir Razmjou[1], Jennifer Wang[2], Ani Shahbazian[2], Srinivasa Reddy[3] and Christina Charles-Schoeman[2], [1]University of California Los Angeles Medical Center, Los Angeles, CA, [2]Department of Medicine, University of California, Los Angeles, Los Angeles, CA, [3]David Geffen School of Meicine, UCLA, Los Angeles, CA

SESSION INFORMATION
Session Date: Saturday, November 6, 2021
Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster I: Cardiovascular Pulmonary Disease (0268–0295)
Session Type: Poster Session A
Session Time: 8:30AM–10:30AM

Background/Purpose: Lung disease in patients with rheumatoid arthritis (RA) is common and associates with significantly increased morbidity and mortality. Oxidative stress plays an important role in the inflammatory responses in airway diseases such as asthma and COPD, but has not been fully investigated in RA-associated lung disease (RA-LD). In the current work, we evaluated associations of the biochemical and genetic determinants of the anti-oxidant

Figure 1: Radiographic Lung Disease in an RA Patient Cohort



HDL-associated protein, paraoxonase 1 (PON-1), and measures of systemic oxidative stress with the presence of RA-LD in a longitudinal RA cohort.

Methods: This study was conducted as a retrospective chart review of a longitudinal single-center cohort of 250 RA patients. All RA patients with an available computed tomographic (CT) scan of the chest were included in the analysis. Scans were reviewed by the interpreting radiologist for the presence of interstitial lung disease (ILD), bronchiectasis, pulmonary fibrosis, centrilobular emphysema, and small airways disease (SAD). SAD was defined by the presence of peribronchial thickening, air trapping, or centrilobular nodularity. PON-1 activity was measured by its lactonase, arylesterase, and paraoxonase activities, the PON-1 Q192R polymorphism, and total plasma oxylipins were measured as described previously (Sci Rep2020 Oct 8;10(1):16848, A&R 2013Nov:65(11):2765-72).

Results: Out of 250 RA patients, 108 (43.2%) had CT scans of the chest available for review. The distribution of lung disease involvement in the cohort (figure 1) included 48 patients (44.4%) with SAD and demonstrated peribronchial thickening in 43 (39.8%), air trapping in 24 (22.2%), and centrilobular nodules in 10 (9.3%). Patients with SAD demonstrated significantly lower PON-1 activity as measured by both arylesterase and lactonase activities and higher levels of several oxylipins compared to patients without SAD (Table 2). Lower PON-1 activities correlated with higher levels of 12-HETE, 15-HETE, and 20-OH LTB4 ($r = -0.2$- -0.3, $p < 0.05$). In multivariate logistic regression analyses controlling for known SAD risk factors (RA disease duration, age, sex, smoking, and obesity), lower lactonase and arylesterase activities of PON-1, and higher levels of 12-HETE and 15-HETE remained independently associated with the presence of SAD in RA patients. Such associations were not noted with other types of RA-LD (data not shown).

Conclusion: RA patients with radiographic evidence of SAD demonstrate significantly lower arylesterase and lactonase activities of PON-1 and higher levels of systemic oxidative stress measured by circulating oxylipins, including higher 12-HETE and 15-HETE, which correlated with reduced PON-1 activity. Future studies are warranted to evaluate the relationship of PON-1 and pro-inflammatory oxylipins to the pathogenesis of RA lung disease.

Table 1: Clinical and Laboratory Characteristics of RA Patients with and without Small Airways Disease

	Small Airways Disease Present (n=48, 44.4%)	Small Airways Disease Absent (n=60, 55.6%)

Abstract Number: 0293

Increased Prevalence of Scleroderma Specific Autoantibodies in Sero-positive Rheumatoid Arthritis with Lung Involvement

Vasiliki Koulouri[1], Kyriaki Tavernaraki[2], Mayra Giannelou[3] and **Clio Mavragani**[1], [1]National and Kapodistrian University of Athens, Athens, Greece, [2]Imaging and Interventional Radiology, Sotiria General and Chest Diseases Hospital, Athens, Greece, [3]Department of Rheumatology, General Hospital of Athens "G. Gennimatas", Athens, Greece

SESSION INFORMATION
Session Date: Saturday, November 6, 2021
Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster I: Cardiovascular Pulmonary Disease (0268–0295)
Session Type: Poster Session A
Session Time: 8:30AM–10:30AM

Background/Purpose: To evaluate the prevalence of scleroderma (SSc) specific and anti-Ro52 autoantibodies in seropositive rheumatoid arthritis (RA) patients with lung involvement.

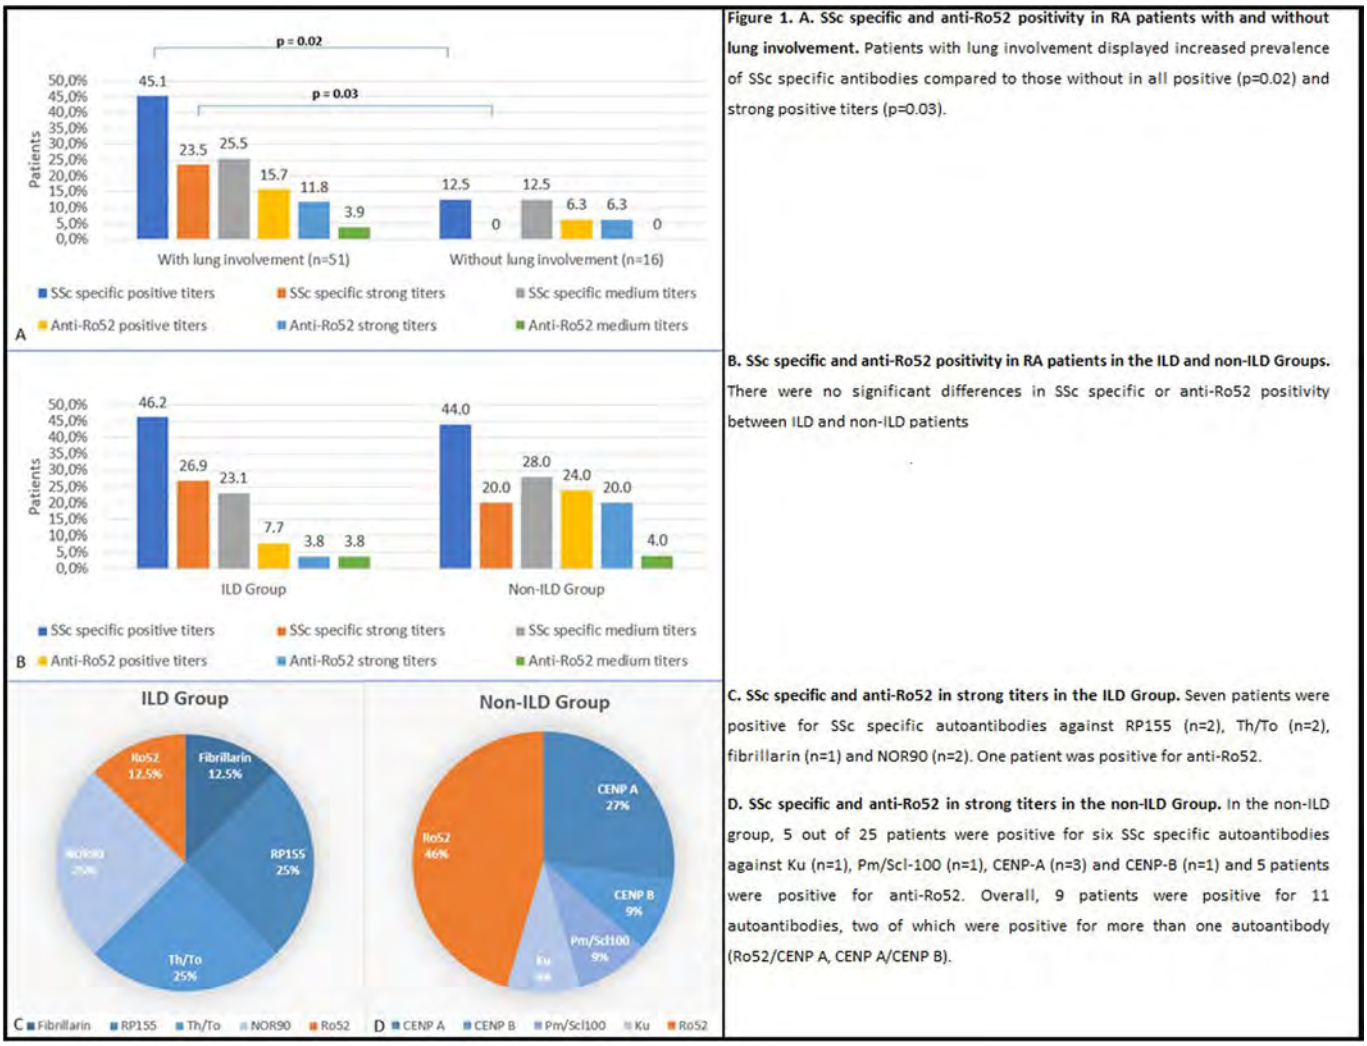

Figure 1. A. SSc specific and anti-Ro52 positivity in RA patients with and without lung involvement. Patients with lung involvement displayed increased prevalence of SSc specific antibodies compared to those without in all positive (p=0.02) and strong positive titers (p=0.03).

B. SSc specific and anti-Ro52 positivity in RA patients in the ILD and non-ILD Groups. There were no significant differences in SSc specific or anti-Ro52 positivity between ILD and non-ILD patients

C. SSc specific and anti-Ro52 in strong titers in the ILD Group. Seven patients were positive for SSc specific autoantibodies against RP155 (n=2), Th/To (n=2), fibrillarin (n=1) and NOR90 (n=2). One patient was positive for anti-Ro52.

D. SSc specific and anti-Ro52 in strong titers in the non-ILD Group. In the non-ILD group, 5 out of 25 patients were positive for six SSc specific autoantibodies against Ku (n=1), Pm/Scl-100 (n=1), CENP-A (n=3) and CENP-B (n=1) and 5 patients were positive for anti-Ro52. Overall, 9 patients were positive for 11 autoantibodies, two of which were positive for more than one autoantibody (Ro52/CENP A, CENP A/CENP B).

Figure 1. SSc-specific and anti-Ro52 antibodies in seropositive RA patients with different types of lung involvement.

Methods: Sera from 67 seropositive RA patients with available high-resolution computed tomography scans (HRCTs) were tested for the presence of SSc-specific and anti-Ro52 antibodies. According to the band intensity, samples were classified in those with medium and strong positive titers. Demographic, clinical, laboratory, imaging and pulmonary function data were recorded. 26 patients suffered from interstitial lung disease (ILD group), 25 had some other type of lung involvement (non-ILD group) and 16 had normal HRCTs (no-lung group).

Results: Autoantibody testing revealed a significantly higher prevalence of positive SSc-specific antibodies in patients with lung involvement compared to the no-lung group (45.1% vs 12.5%, p=0.02) (Figure 1A). Lung involvement was also associated with older age, male sex, heavier smoking, and increased white blood cell counts, CRP and RF values (Table 1). Prevalence of anti-Ro52 positivity was also higher in these patients, but no statistical significance was reached. ILD and non-ILD groups displayed a similar frequency (Figure 1B) but a distinct non-overlapping pattern of SSc-specific antibodies (in strong titers) against RP155, Th/To, fibrillarin and NOR90 autoantigens in the ILD group (Figure 1C) and towards Ku, Pm/Scl100, CENP-A/B in the non-ILD group (Figure 1D)

Table 1. Demographic, clinical, serological and laboratory features of seropositive RA patients with and without lung involvement

	Lung involvement Group (n=51)	No lung Group (n=16)	p value
Demographic Data			
Age of RA diagnosis (years) mean ± SD	52.5 ± 14.7	45.9 ± 14.8	0.16

ANA positivity %	61.7	69.2	0.62
Anti-Ro positivity %	11.8	10	0.88
Anti-La positivity %	2.9	0	0.58
ANCA positivity %	5.9	0	0.80
Laboratory values			
WBC (cells/μL) ± SD	8819 ± 2962	7183 ± 1741	**0.04**
CPK (IU/L) ± SD	67 ± 40	84 ± 75	0.82
LDH (IU/L) ± SD	225 ± 74	250 ± 125	0.57
CRP (mg/dL) ± SD	2.0 ± 2.7	0.7 ± 0.7	**0.02**

Conclusion: Seropositive RA patients with lung involvement display several demographic, clinical and laboratory characteristics along with increased rates of SSc-specific autoantibodies. These data imply that seropositive RA patients with lung involvement probably represent a distinct overlap entity, requiring tailored diagnostic and therapeutic approaches.

Comparison of Factors Associated with CT-Scan Progression of Interstitial Lung Disease in Rheumatoid Arthritis and Idiopathic Pulmonary Fibrosis. Retrospective Multicenter Study of 144 Patients

Charlotte Lucas[1], Aurore Tremblay[1], Thibaut Lapotre[2], Stéphane Jouneau[3], Mathieu Lederlin[2] and Aleth Perdriger[1], [1]Rheumatology department, University Hospital, Rennes, France, [2]Radiology Department, University Hospital, Rennes, France, [3]Department of Respiratory Medicine, Competences Centre for Rare Pulmonary Diseases, Univ Rennes, CHU Rennes, Inserm, EHESP, Irset (Institut de recherche en santé, environnement et travail) - UMR_S 1085, F-35000 Rennes, France, Rennes, France

SESSION INFORMATION

Session Date: Saturday, November 6, 2021

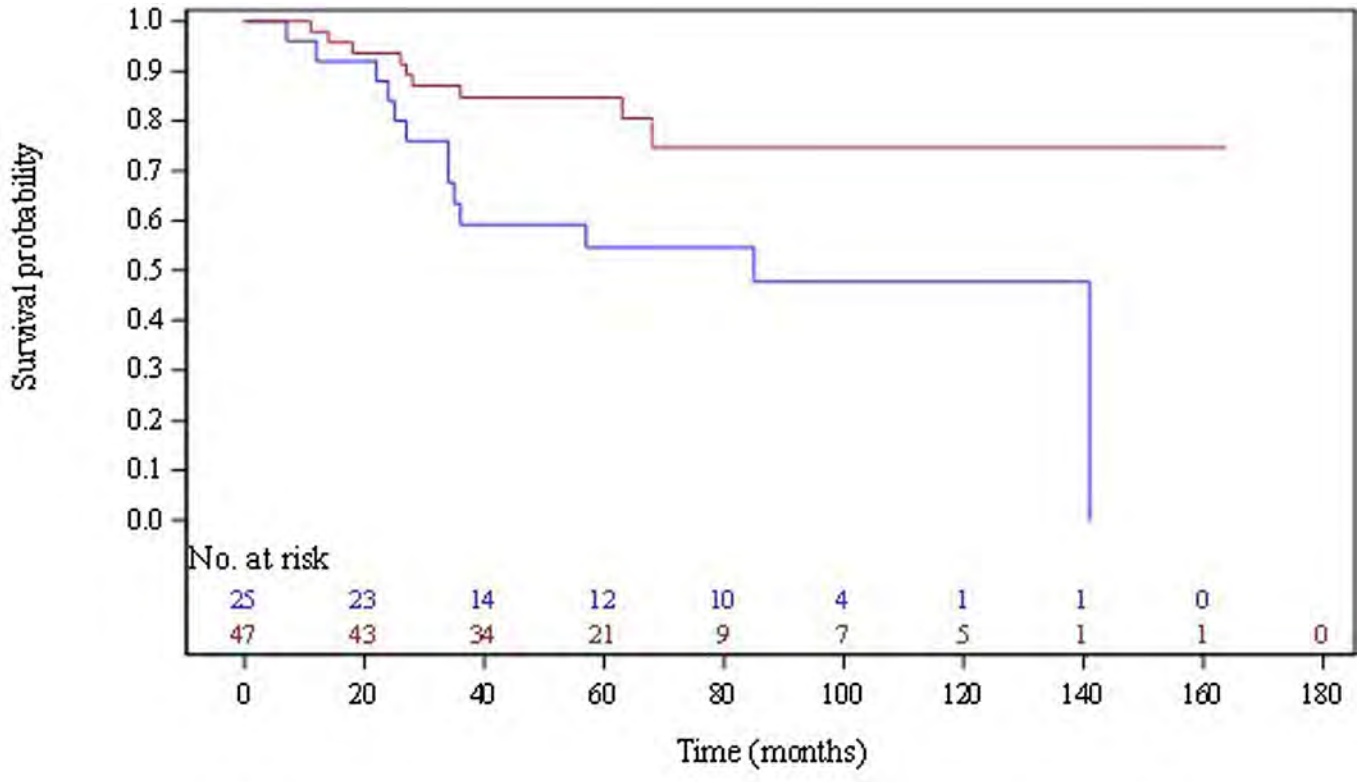
Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster I: Cardiovascular Pulmonary Disease (0268–0295)

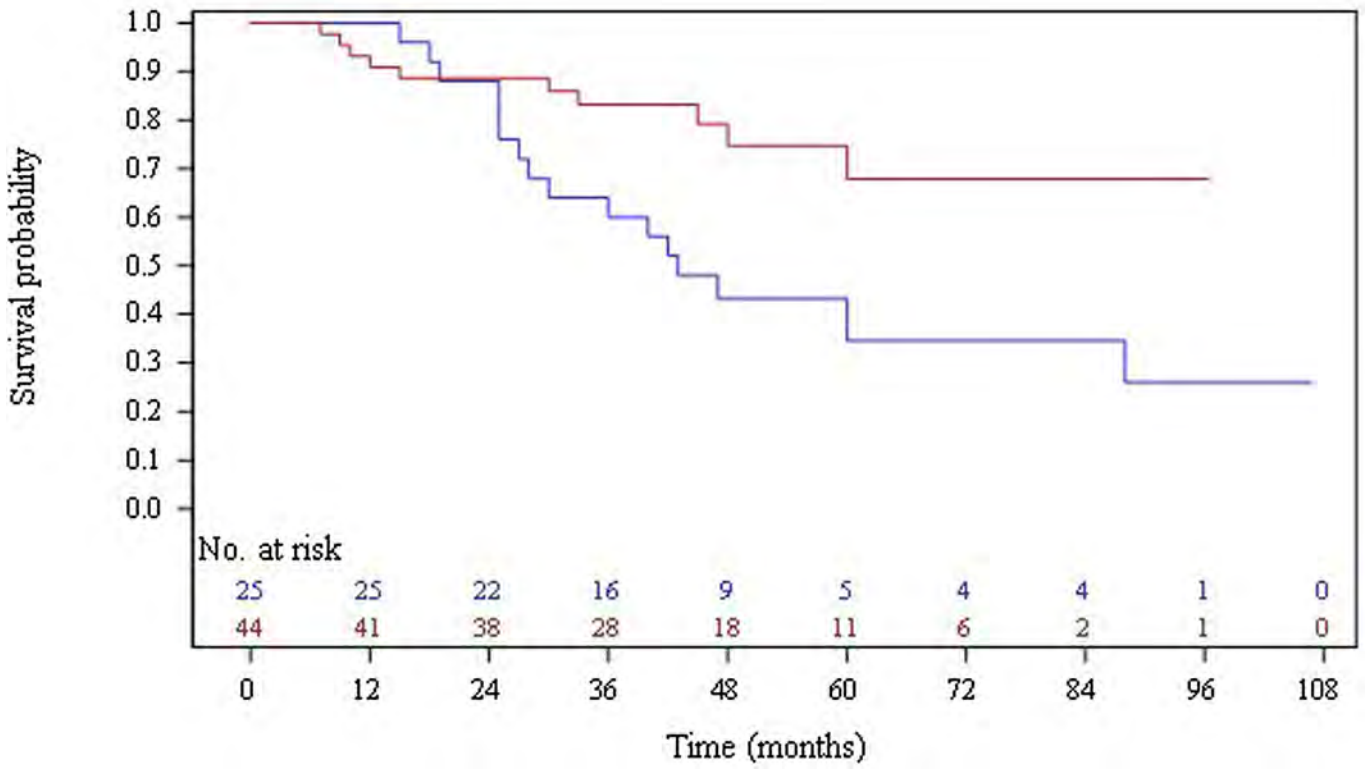
Session Type: Poster Session A

Session Time: 8:30AM–10:30AM

Background/Purpose: Compare factors associated with interstitial lung disease (ILD) progression determined on CT-scan analysis and survival in two distinct populations, patients with rheumatoid arthritis associated interstitial lung disease (RA-ILD) and patients with idiopathic pulmonary fibrosis (IPF).

Methods: RA and IPF patients with ILD confirmed by 2 CT-scans spaced from 6 or more months apart (T0: first CT chest scan describing ILD; Tx: last CT chest scan available) were consecutively included in this retrospective multicenter study from 2010 to 2020. CT-scans were blindly analyzed for each patient at T0 and Tx by 2 independent radiologists to determinate ILD pattern (definite usual interstitial pneumonia (UIP), probable UIP, indeterminate UIP, non-UIP) and progression during the follow-up (progressive or stable ILD) defined by the variation of the fibrosis





score. Characteristics of patients (demographic-clinical-biological findings, pulmonary function tests, and treatments exposure) at T0 and during the follow-up (T0-Tx) were analyzed as potential determinants of ILD progression through multivariable logistic regression analysis. Overall survival was analyzed using Kaplan-Meier method.

Results: 74 RA-ILD patients and 70 IPF patients were included. During a T0-Tx follow-up of 2.8 ± 2 years, ILD progression was identical in the two populations, of 36%. RA-ILD patients and IPF patients were comparable in terms of age, sex, BMI, smoking history, and severity of initial pulmonary function tests, but T0 CRP rate was higher in RA-ILD patients (29 ± 36mg/L vs 9 ± 35mg/L; p< 0.0001) and T0 CT damage was slightly more pronounced in RA-ILD patients (T0 fibrosis score=27% vs 21%; p=0.05). Multivariate analysis identified different risk factors for ILD progression in the 2 populations. A treatment by Methotrexate at ILD diagnosis was associated negatively with ILD progression in RA-ILD patients (OR=0.14 [0.04-0.52]; p=0.0031) while UIP pattern was positively associated with ILD progression (OR=12 [4.38; 39.85], p=0.0001). In IPF patients, pulmonary comorbidities (OR=8.4 [1.4; 51.4], p=0.02) and the need to oxygen therapy during T0-Tx (OR=5.2 [1.2-22.3], p=0.03) were poor prognosis factors. The follow-up to death or end of collection (July 2020) was longer in RA-ILD patients (5.1 years vs 3.8; p=0.001) but survival rate was not significantly different (31% in RA-ILD patients vs 38 % in IFP patients; HR=1.59 [0.89; 2.84], p=0.1) and better for stable ILD than for progressive ILD in both RA-ILD and IPF populations.

Conclusion: We did not identify any common risk factors for ILD progression in RA-ILD and IPF patients, but in both populations, about one third of patients had ILD progression and died.

Survival of RA-ILD population according to ILD progression. Red line represents patients without ILD progression (stable ILD). Blue line represents patients with ILD progression (progressive ILD). HR = 2.73 [1.16;6.42], p = 0.0239.

Survival of IPF population according to ILD progression. Red line represents patients without ILD progression (stable ILD). Blue line represents patients with ILD progression (progressive ILD). HR = 2.73 [1.23;6.06], p = 0.0136.

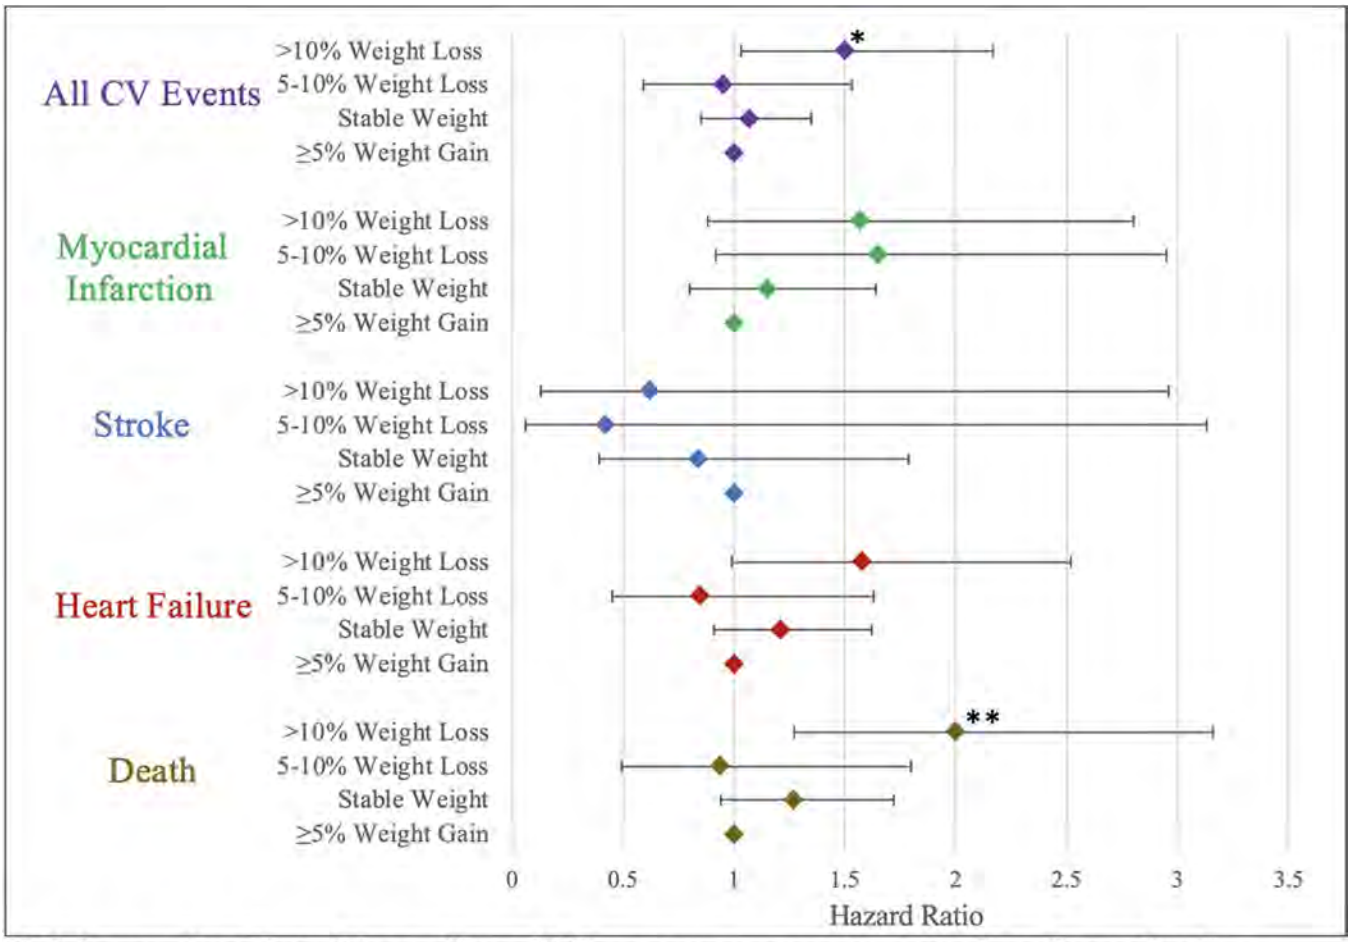
Models 1 and 2 were also adjusted for age, sex, race, start date, disease duration, smoking history, prednisone use, methotrexate use, and biologic therapy use.
Model 2 was further adjusted for NSAID use, RDCI, HAQ, pain score, severity score, history of diabetes, history of hypertension, and history of lung disease.
PY: person-years; BMI: Body Mass Index. *p<0.05, **p<0.01, ***p<0.001.

mass index (BMI) are not always observed to have higher long-term risks of obesity-related complications, perhaps as the result of long-term pathologic weight loss. Self-report of weight loss may thus serve as a helpful tool in risk-stratification by identifying individuals with adverse metabolic health. In this study, we evaluated the relationship between weight loss since age 30 and CVD along with factors associated with weight loss in patients with RA.

Methods: We studied RA patients (>40 years old, without prior heart disease) enrolled in the FORWARD registry from 1998 to 2021. Weight change from reported weight at age 30 to enrollment was categorized as >10% weight loss, 5-10% weight loss, stable weight, and ≥5% weight gain (reference, due to being the expected change in lifespan). The primary outcome was a composite of nonfatal and fatal CVD since enrollment identified using ICD-9/10 codes (myocardial infarction [MI], stroke, and heart failure [HF]) and validated using hospital/death records. Secondary outcomes were individual CVD events. Multivariable Cox proportional hazards models were used to evaluate associations for weight changes adjusting for confounding variables (age, sex, race, enrollment BMI, year, RA duration, smoking, methotrexate, prednisone, biologic DMARD use). Models were further adjusted for factors that might be influenced by metabolic disturbance and contribute to CVD including the Rheumatic Disease Comorbidity Index (RDCI), Health Assessment Questionnaire Disability Index (HAQ) score, pain score, severity score, diabetes, hypertension, and lung disease.

Results: Among 15,843 participants, 6% had >10% weight loss, 4% had 5-10% weight loss, 17% had a stable weight, and 74% had ≥5% weight gain since age 30. Participant characteristics differed substantially by weight change category (Table 1). There were 579 CVD incidents over 109,211 person-years of follow-up. Weight loss of >10% since age 30 was associated with 50% greater CVD risk independent of baseline BMI category and other baseline characteristics (HR 1.50, 95% CI 1.03-2.17). Weight loss (>10%) was also associated with a 2-fold increase in fatal CVD risk (HR 2.0, 95% CI 1.27-3.16) (Figure 1) and increased MI (HR 1.57, 95% CI 0.88-2.80) and HF risks (HR 1.58, 95% CI 0.99-2.52), although the latter two did not reach statistical significance. Fully adjusted models that



Models were also adjusted for enrollment BMI category, age, sex, race, start date, disease duration, smoking history, prednisone use, methotrexate use, and biologic therapy use.
*p<0.05, **p<0.01 compared to weight gain category.

Figure 1. Associations between weight change category and CVD events by event type in Cox proportional hazards models.

considered metabolic diseases, total comorbidity, disability, and symptoms demonstrated no significant association between weight loss and CVD events (HR: 1.23, 95% CI 0.83-1.82) (Table 2).

Conclusion: Long-term weight loss of >10% body weight is associated with increased CVD risk in RA independent of baseline BMI. The effect is largely explained by a higher prevalence of metabolic risk factors, comorbidity, and disability at enrollment, suggesting that the risk of weight loss in patients with RA is likely explained by worse metabolic health. Historical weight loss may serve as a marker of adverse metabolic health and aid in CVD risk stratification in RA.

Abstract Number: 0296

The Impact of Delayed Primary Sjögren's Syndrome Diagnosis on Patient Outcomes: A Real-World Survey in the US

Briana Ndife[1], Sophie Barlow[2], Megan Hughes[2] and Nicola Booth[2], [1]Novartis, East Hanover, NJ, [2]Adelphi Real World, Bollington, United Kingdom

SESSION INFORMATION

Session Date: Saturday, November 6, 2021
Session Title: Sjögren's Syndrome – Basic & Clinical Science Poster (0296–0322)
Session Type: Poster Session A
Session Time: 8:30AM–10:30AM

Background/Purpose: Diagnosis of primary Sjögren's syndrome (pSS) is challenging due to the disease's phenotypic heterogeneity. pSS patients frequently experience a prolonged period between symptomatic onset and diagnosis, hypothesised to prove detrimental to patient outcomes. The objective of this study was to describe the impact of delayed diagnosis on disease severity and patient outcomes in patients with pSS.

Methods: Data were drawn from the Adelphi Primary Sjögren's Syndrome (pSS) Disease Specific Programme™, a real-world point-in-time survey of rheumatologists and their consulting pSS patients in the United States. Physicians provided data on patient demographics and clinical characteristics. Patients self-completed patient-reported outcome (PRO) tools; including the EuroQol 5-dimension 5-level utility score (EQ-5D), EuroQol visual analogue scale (EQ VAS), Work Productivity and Activity Impairment Index questionnaire (WPAI), and the Functional Assessment of Chronic Illness Therapy – Fatigue (FACIT-F). EULAR Sjögren's Syndrome Disease Activity Index (ESSDAI) and EULAR Sjögren's Syndrome Patient Reported Index (ESSPRI) proxy scores were calculated by assigning scores to physician-perceived severity in each of the associated domains. Patients were compared according to the time between onset of pSS symptoms and diagnosis (< 3 months, 3-6 months, 6-12 months, and >12 months). Analysis of variance and

Moderate	105 (38.0)	26 (32.1)	11 (19.6)	25 (51.0)	43 (47.8)	
Severe	7 (2.5)	0 (0.0)	1 (1.8)	2 (4.1)	4 (4.4)	

Kruskall-Wallis tests were used to examine the impact of delayed diagnosis on ESSDAI, ESSPRI and PRO measures, and Mann-Whitney U-test for physician-perceived current severity using < 3 months as the reference group.

Results: 71 rheumatologists provided information for 276 pSS patients: mean age 52.3 years, 89.1% female and average time since diagnosis 51.6 months (Table 1). Of these patients, 29.3% were diagnosed within 3 months of the onset of pSS symptoms, 20.3% 3-6 months, 17.8% 6-12 months and 32.6% >12 months, with a mean (SD) of 27.5 (68.2) months from the onset of symptoms to diagnosis. Comparative analyses showed that there were significant differences (< 0.05) in EQ-5D utility score, EQ-5D VAS, FACIT-F, proxy ESSPRI scores and physician reported severity between patients with differing time to diagnosis (Table 2), assessed at the time of consultation. Relationships between diagnosis duration and WPAI scores were not statistically significant.

Conclusion: Delayed diagnosis of pSS is associated with poorer patient outcomes; including worsening PRO scores, and ESSPRI scores. pSS diagnosis periods could likely be attenuated by increasing disease awareness amongst physicians; thus improving patient outcomes in pSS.

Describing the Disease Burden of Primary Sjögren's Syndrome Patients: Results from a Real-World Survey in the US

Briana Ndife[1], Ben Hoskin[2], Megan Hughes[2] and Nicola Booth[2], [1]Novartis, East Hanover, NJ, [2]Adelphi Real World, Bollington, United Kingdom

SESSION INFORMATION
Session Date: Saturday, November 6, 2021
Session Title: Sjögren's Syndrome – Basic & Clinical Science Poster (0296–0322)
Session Type: Poster Session A
Session Time: 8:30AM–10:30AM

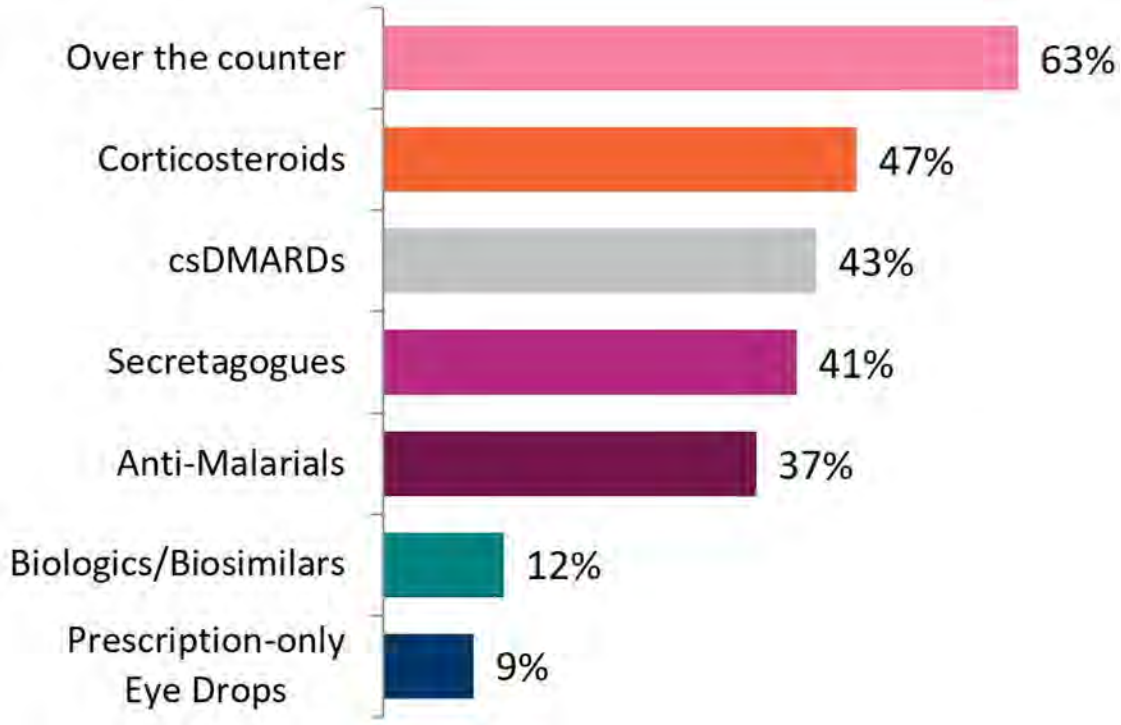

Figure 1. Treatment classes currently received (n=511).

Background/Purpose: Primary Sjogren's syndrome is a highly heterogeneous condition, with limited understanding of the burden of disease. The objective of this study was to describe the patient profile and disease burden of patients with primary Sjogren's syndrome (pSS).

Methods: Data were drawn from the Adelphi primary Sjögren's syndrome Disease Specific Programme™, a real-world point-in-time survey of rheumatologists and their consulting pSS patients in the United States. Rheumatologists provided data about patient demographics and clinical characteristics. Derived EULAR Sjogren's Syndrome Disease Activity Index (ESSDAI) scores were calculated for each patient by assigning a score to the rheumatologists' perception of "not present", "mild", "moderate" or "severe" for each of the twelve domains of the ESSDAI. Patients self-completed patient reported outcome (PRO) tools including the EuroQol 5-Dimension utility score (EQ-5D), Work Productivity and Activity Impairment questionnaire (WPAI) and The Functional Assessment of Chronic Illness Therapy – Fatigue (FACIT-F). Derived EULAR Sjogren's Syndrome Patient-Reported Index (ESSPRI) scores were calculated using the patients' rating of dryness, fatigue, and pain.

Results: Rheumatologists (n=84) provided data for 511 pSS patients, mean age 53.3 years, 88.5% female, 79.8% white/Caucasian and mean time since diagnosis 4.6 years. Classes of treatment patients were receiving at the time of data collection are shown in Figure 1. Dry eyes and dry mouth were the most prevalent symptoms, present in 86.3% and 62.6% of patients respectively. Almost three quarters of patients (74.8%) experienced physical fatigue and over a third of patients (35.8%) experienced muscle pain at the time of data collection. Most patients experienced articular involvement, with 4.1% of patients experiencing no organ involvement, Table 1. Over half (55.8%) of patients were considered moderate-severe in terms of their derived ESSDAI score at the time of data collection, Table 1. At diagnosis of pSS, 14.9% of patients were considered severe by their physician, 59.7% moderate and 25.4% mild. At the time of consultation 3.9% of patients were severe, 39.9% moderate and 56.2% mild. Scores from PRO tools indicate

Derived ESSPRI score, mean (SD) [n]	4.0 (2.1) [297]	3.2 (1.9) [146]	4.6 (2.0) [139]	5.9 (2.1) [12]

the impairment that patients experience in everyday life and whilst at work, which worsens with physician-perceived current severity of pSS, Table 2.

Conclusion: Patients experience sicca symptoms and organ involvement, with physical fatigue affecting the majority of patients. Over half of patients are classified moderate-severe in terms of derived ESSDAI scores, despite many patients receiving off-label systemic therapies. PRO scores show patients experience a burden of disease impacting their daily life and work.

SESSION INFORMATION
Session Date: Saturday, November 6, 2021
Session Title: Sjögren's Syndrome – Basic & Clinical Science Poster (0296–0322)
Session Type: Poster Session A
Session Time: 8:30AM–10:30AM

Background/Purpose: Dry mouth and eyes are the main clinical features of Sjögren's syndrome (SS), although a minority of patients present without sicca manifestations and isolated cases of oral or ocular dryness are rare. The purpose of this study is to investigate whether isolated mouth or eye dryness constitute distinct clinical phenotypes of SS.

Methods: From a total population of 1765 consecutive patients fulfilling the 2016 ACR-EULAR criteria for SS, who were followed-up in 4 centers from Greece and Italy (Universities of Athens, Pisa, Harokopio and Ioannina) (PAHI group), those with isolated mouth or eye dryness, were identified and matched according to age at SS diagnosis, gender and disease duration from SS diagnosis to last follow up in a 1:2 ratio, with SS patients exhibiting both oral and ocular dryness. The 2 study groups of isolated dryness were defined as follows: a) patients with ocular dryness without oral dryness and b) patients with oral dryness without ocular dryness as documented by the AECG validated questionnaires. Cumulative data regarding glandular (dry mouth, dry eyes, parotid gland enlargement) and extra-glandular manifestations (Raynaud's phenomenon, lymphadenopathy, arthralgias/arthritis, palpable purpura, liver involvement, kidney involvement, lymphoma), serology (anti Ro/SSA, anti La/SSB, rheumatoid factor, cryoglobulinemia, low C4 complement levels) and histologic features (focus score) were recorded and compared between each study group with their matched SS controls and between the 2 study groups as well. Statistical analysis for categorical data was performed by Fisher exact test or χ^2 square test accordingly and numerical data with Man Whitney test.

Table 1. Comparison of clinical and laboratory features between SS patients with isolated ocular dryness and SS controls with both mouth and eye dryness

years old (range: 21-68) and 53,5 (range: 16-79) respectively. SS patients with isolated eye dryness had statistically significant lower frequency of salivary gland enlargement (35,4% vs 28,7%, p=0,05) and lymphoma (0% vs 11,3%, p=0,001) (Table 1) while in SS patients with isolated oral dryness arthralgias (39,1% vs 65,5%, p= 0,0003) and arthritis (8,6% vs 20,3%, p= 0,05) appeared less frequently, compared to their SS controls, respectively. After comparing the 2 study groups, it was found that SS patients with isolated oral dryness were diagnosed at older age (median: 53,5

vs 46 years old, p=0,005) and were more prone to develop lymphoma (9,4% vs 0%, p=0,01) compared to patients with isolated ocular dryness, without any difference in classical lymphoma predictors, including focus score (Table 2).

Conclusion: Patients with isolated ocular or oral mucosa dryness constitute 8% of total SS population and those with isolated dry eyes display lower frequency of lymphoma.

Reported as N (%) or RR (95% CI). *Adjusted for age, race/ethnicity, and health insurance type.

Background/Purpose: Sjögren's syndrome (SS) is the most female predominant systemic autoimmune disease, with peak onset around perimenopause. Estrogen appears to protect against SS, but prior studies lack details on surgical interventions and timing or type of exogenous hormone exposure. The purpose of this study was to determine how specific endogenous and exogenous hormone exposures contribute to SS Risk.

Methods: We performed a retrospective case-control study of adult women, nested within a defined population of Marshfield Clinic Health System (MCHS) patients in north-central Wisconsin. SS cases included patients with one SS diagnosis by a rheumatology provider or two SS diagnoses > 4 weeks apart from a non-rheumatology provider. Those with overlapping autoimmune diseases were excluded. Three controls were included for each SS case and were matched on age. We calculated a composite estrogen score (CES) for each patient, with one point for: 1) body mass index (BMI) ≥30 kg/m^2, 2) menopause ≥55 years, 3) hormone replacement therapy >90 days, and 4) hysterectomy, which was considered a marker of high estrogen because hysterectomy is most often performed for fibroids and

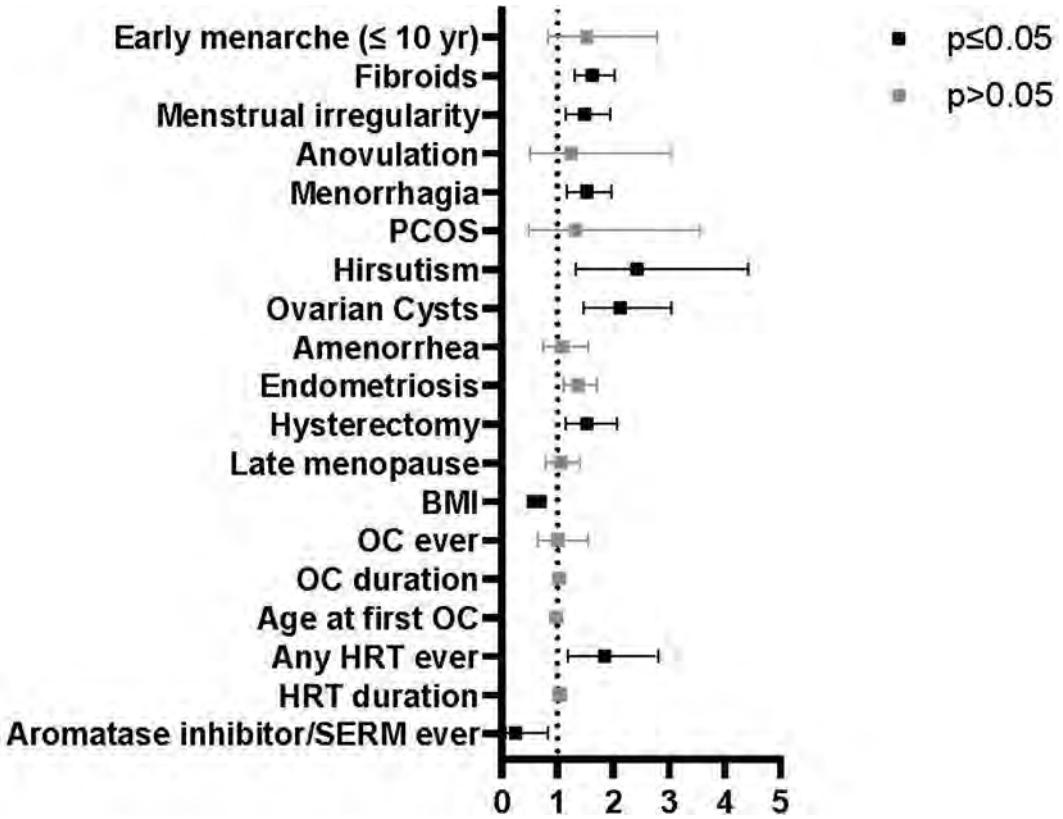

Figure 1. Risk ratios and 95% confidence intervals of individual sex hormone exposure variables controlled for age at index, Caucasian, Ethnicity, and insurance type. Abbreviations: PCOS=polycystic ovarian syndrome; BMI=body mass index; OC=oral contraceptive; HRT=hormone replacement therapy; SERM=selective estrogen receptor modulator.

post-surgical management often includes exogenous hormones. Risk ratios for SS were reported, adjusted for age, race/ethnicity, and health insurance.

Results: There were 546 SS cases and 1,637 age-matched controls. The distribution of CES was 0 (n= 698 (32%)), 1 (n= 918 (42%)), 2 (n= 449 (21%)), and >= 3 (n=118 (5%)) (Table 1). Age, race, and ethnicity were similar between CES groups but health insurance differed. CES was not significantly associated with SS in adjusted models (Table 2). As outlined in Figure 1, the top three individual hormone exposures that were independently associated with SS included hirsutism (RR 2.42 [95% CI 1.32-4.43]), ovarian cysts, (2.12 [1.48-3.04]) and exogenous hormone replacement therapy (1.84 [1.20-2.81]). High BMI (0.62 [0.50-0.77]) and aromatase inhibitor use (0.25 [0.07-0.83]) appeared to be protective against SS.

Conclusion: Higher CES did not result in greater SS risk in this study, but several novel individual SS risk factors were observed, most notably hirsutism and ovarian cysts, which are associated with high androgen and lower estrogen excess. In contrast, high BMI, which is associated with higher levels of peripherally produced estrogen and lower androgen, was associated with lower SS risk. Aromatase inhibitor or SERM use also appeared protective, potentially representing confounding by indication because higher levels of estrogen are associated with breast cancer. These data suggest that the influence of sex hormones on SS pathogenesis may be more complex than prior studies have indicated; SS risk is potentially dependent on androgen-to-estrogen ratios. Further prospective studies are needed to confirm these findings.

Salivary Gland Epithelial Cells Transcriptomic Analysis Highlight Their Potential Involvement in Extracellular Matrix Modification in Sjögren's Syndrome

Elodie Rivière[1], Juliette Pascaud[1], Franck Letourneur[2], Gaetane Nocturne[1] and Xavier Mariette[3], [1]Immunology of viral Infections and Autoimmune Diseases, IDMIT, CEA - Université Paris Sud - INSERM U1184 ; Rheumatology, APHP, Université Paris Saclay, Le Kremlin Bicêtre, France, [2]Plateforme Génomique : GENOM'IC — Institut Cochin, Paris, France, [3]Université Paris- Saclay, Rheumatology, Paris, France

SESSION INFORMATION
Session Date: Saturday, November 6, 2021
Session Title: Sjögren's Syndrome – Basic & Clinical Science Poster (0296–0322)
Session Type: Poster Session A
Session Time: 8:30AM–10:30AM

Background/Purpose: Salivary gland epithelial cells (SGECs) participate to the hyper activation of the immune system in primary Sjögren's syndrome (pSS). This study aimed to analyze the transcriptomic characteristics of primary cultured SGECs from pSS patients compared to controls, in order to identify pathways involved in pSS pathogenesis.

Methods: Minor salivary gland (MSG) biopsies were obtained from patients referred for suspicion of pSS. pSS was defined according to the 2016 ACR/EULAR criteria. Controls had sicca symptoms without anti-SSA/SSB and with normal MSG. Primary cultures of SGECs were established from MSGs. After 2 to 3 weeks of culture, cells were dissociated and incubated at 37°C for 24h. Total RNA was extracted and reverse-transcribed. Libraries were sequenced

Table 1. Characteristics of the patients included in the study

	RNA-seq experiments on primary cultured SGECs	
	pSS (n=5)	control (n=5)
Median age (min-max)	31 (23-53)	52 (34-56)
Female sex, n (%)	5 (100)	5 (100)
Pathologic Schirmer	2 (50)	2 (50)
Pathologic salivary flow	0 (0)	0 (0)
Focus score ≥ 1, n (%)	5 (100)	0 (0)
SSA, n (%)	5 (100)	0 (0)
Mean ESSDAI (min-max)	4 (2-10)	

on Illumina Nextseq 500. Statistical analyses of the RNA-Seq used DESeq2 package. Absolute FC value >1.5 and p-value< 0.05 was applied to identify up and down-regulated genes.

Results: Patient's characteristics are presented in Table 1. The comparison of gene expression in primary cultured SGECs of pSS compared to controls showed 511 differentially expressed genes: 251 upregulated and 260 down-regulated. Functional enrichment pathway analysis highlighted an over-representation of the Inhibition of Matrix Metalloproteases signaling pathway (Table 2). Among the most upregulated genes, we identified genes involved in extracellular matrix formation, including several collagen genes: *COL3A1* and *COL1A2* with the higher fold-change (FC) (log2FC = 2.40, log2FC = 2.12, respectively). There were also several ADAMDTS genes (A Disintegrin and Metalloproteinases with a Thrombospondin motif) related genes such as *ADAMTS2, ADAMTS16, ADAMTS12* (log2FC = 2.09, log2FC = 1.57, log2FC =1.31, respectively). Other genes that might have a role in saliva secretion such as *CFTR* and *AQP6* were differentially expressed. *CFTR,* which codes for a channel that conducts chloride ions across epithelial membranes, was upregulated (log2FC=1.67), whereas *AQP6* was downregulated (log2FC=-1.44). There was an upregulation of *HLA-C* (log2FC=0.63), as well as *CCR7* (log2FC=1.26). Lastly, we identified an upregulation of the *androgen receptor* (*AR*) gene (log2FC=1.71). A schematic representation of these results is presented in Figure 1.

Conclusion: Differentially expressed genes between pSS and controls SGECs included genes involved in the extracellular matrix formation. This result suggests a role for SGECs in salivary gland fibrosis development. We also

Table 2. Enrichment pathway analysis of primary cultured SGECs from pSS compared to controls in different conditions of stimulation. Selection of the 10 most significant pathways

Ingenuity Canonical Pathways	-log(p-value)

γ-linolenate Biosynthesis II (Animals)	2.34
Mitochondrial L-carnitine Shuttle Pathway	2.34
Folate Transformations I	2.3
Glycine Betaine Degradation	2.16
GP6 Signaling Pathway	2.06
Acyl-CoA Hydrolysis	2.03

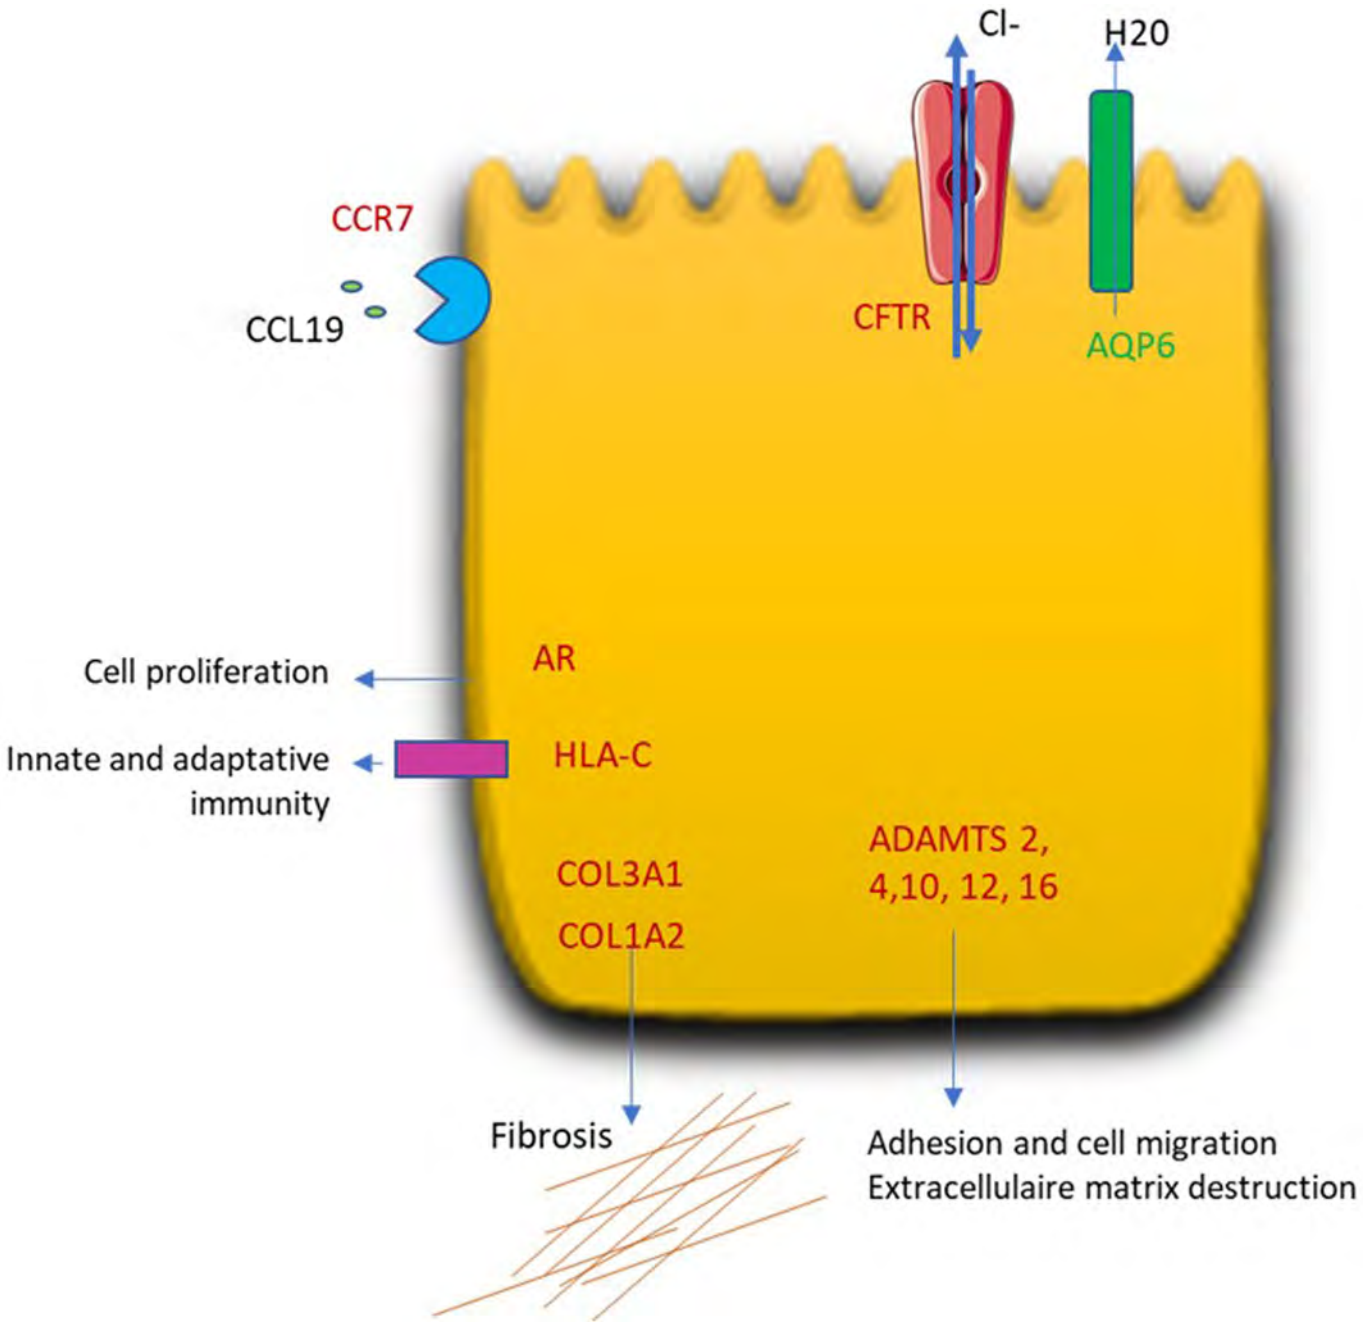

Figure 1. Schematic representation of the differentially expressed genes between pSS and controls in primary cultured SGECs.

observed a downregulation of *AQP6*. A potential role of AQP5 abnormal localization on saliva secretion in pSS has already been described, however, *AQP6* potential involvement in pSS pathophysiology has, to our knowledge, never been described. *CFTR* upregulation in SGECs from pSS compared to controls could be reactive to the salivary gland damage and dysfunction. The differentially expressed genes identified in this RNA-seq analysis need to be confirmed by qPCR.

These results open the perspective of new potential pathogenic pathways involved in pSS, suggesting the involvement of SGECs in extracellular matrix and fibrosis constitution.

SESSION INFORMATION
Session Date: Saturday, November 6, 2021
Session Title: Sjögren's Syndrome – Basic & Clinical Science Poster (0296–0322)
Session Type: Poster Session A
Session Time: 8:30AM–10:30AM

Background/Purpose: Akt is a phosphoinositide-dependent serine/threonine kinase with diverse regulatory functions that has been implicated in numerous pathological processes, including oncogenesis and autoimmune diseases. Indirect lines of evidence suggest that this pathway may be implicated in pathogenesis of primary Sjögren's syndrome (pSS). The purpose of this study is to investigate the expression and activation of Akt kinase pathway in different clinical phenotypes of pSS and related lymphomagenesis.

Methods: The expression of the entire protein, the threonine 308-phosphorylated Akt kinase and serine 473-phosphorylated Akt kinase, as well as substrates PRAS40 and FoxO1 (total and phosphorylated forms), which are phosphorylated by Akt, were evaluated by immunohistochemistry in minor salivary glands (MSG) of pSS patients (n=29), non-SS sicca-complaining individuals with negative biopsy (sicca-controls; n=10) and gastric biopsies from patients with MALT lymphoma associated with *Helicobacter pylori* infection (n=5). Sicca-controls and gastric MALT lymphomas served as control goups. The pSS patients group included 10 at low risk for lymphoma development, 10 at high-risk [four of whom, namely pre-lymphoma, developed lymphoma 7.46 years (median time to lymphoma diagnosis, range 2.0-15.5 years) after the MSG biopsy], and 9 with pSS-associated lymphoma.

Results: The phosphorylated forms of Akt, PRAS40 and FoxO1 were strongly detected in the epithelia and all infiltrating mononuclear cells at the MSGs of 27 pSS patients and stomachs of all patients with gastric lymphoma. Low staining was detected in two pSS patients and two sicca-controls. The rest sicca-controls were negative for all molecules. The activation of Akt pathway was not associated with a higher risk for lymphoma development, lymphoma or other disease features.

Conclusion: Our findings disclosed a strong activation of the Akt/mammalian target of rapamycin (mTOR) pathway in MSGs of pSS patients, independently of their clinical phenotype suggesting a role in disease pathogenesis.

Abstract Number: 0302

Loss of TAM Receptor Mer Contributes to Sjögren's Syndrome–like Disease in Mice

Richard Witas and Cuong Nguyen, University of Florida, Gainesville, FL

SESSION INFORMATION
Session Date: Saturday, November 6, 2021
Session Title: Sjögren's Syndrome – Basic & Clinical Science Poster (0296–0322)
Session Type: Poster Session A
Session Time: 8:30AM–10:30AM

Background/Purpose: Sjögren's syndrome (SjS) is a chronic autoimmune disease primarily involving the exocrine glands where the involvement of the innate immune system is largely uncharacterized. Mer signaling has been found to be protective in several autoimmune diseases but remains unstudied in SjS. Here, we sought to investigate the protective capacity of Mer signaling in SjS.

Methods: SjS patient sera was evaluated for levels of soluble, inactivated Mer (sMer) via ELISA and sMer levels were correlated to disease manifestations. C57BL/6.NOD-*Aec1Aec2* (SjS^S) mice were assessed for sMer levels, TACE activity, and Mer signaling outcomes. SjS diagnostic criteria were examined in MerKO mice.

Results: sMer levels were elevated in SjS patient sera and positively correlated with focus score, ocular staining scores, rheumatoid factor, and Ro60 autoantibody levels. Increased sMer was also detected in SjS^S mouse sera, coinciding with higher TACE activity, the enzyme responsible for cleavage of Mer, and inactivation of such. Mer signaling outcomes were observed to be diminished in SjS^S mice as evidenced by impaired efferocytosis in SjS^S mouse macrophages and decreased *Socs1* and *Socs3* expression in SjS^S salivary gland (SG). MerKO mice developed SG infiltrates of B and T lymphocytes, SG apoptotic cells, antinuclear antibodies, and reduced saliva flow.

Conclusion: Our data indicate that Mer plays a protective role in SjS, similar to other autoimmune diseases. Furthermore, we suggest a series of events where enhanced ADAM17 activity increases Mer inactivation, depresses Mer signaling, and removes a protection against the loss of self-tolerance and onset of autoimmune disease in SjS^S mice.

Extraglandular Manifestations as Initial Presentation in a Cohort of Patients with Primary Sjögren's Syndrome

Lucia Alascio[1], Silvia Papasidero[1], María Alejandra Medina[1], Juan Manuel Bande[1], Silvana Perez[1], Eliana Serrano[1], Diana Klajn[1], Jose Caracciolo[1], Rosella Tralice[2], Erick Rodríguez[2], Felix Romanini[2], Anastasia Secco[2], Sinda Zalles[3], Carolina Segura Escobar[3], Julia Demarchi[3], Geofredo Guillermo Earsman[4], Laura Raiti[5], Sofia Velez[6] and Alejandro Martinez[7], [1]Hospital General de Agudos Dr. Enrique Tornú, Buenos Aires, Argentina, [2]Hospital Rivadavia, Buenos Aires, Buenos Aires, Argentina, [3]Hospital Británico, Buenos Aires, Buenos Aires, Argentina, [4]Hospital Británico, Buenos Aires, La Lucila, Argentina, [5]Clínica Bessone, Buenos Aires, Buenos Aires, Argentina, [6]Consultorio privado de reumatología, Buenos Aires, Argentina, [7]Fundación respirar, Buenos Aires, Mexico City, Mexico

SESSION INFORMATION
Session Date: Saturday, November 6, 2021
Session Title: Sjögren's Syndrome – Basic & Clinical Science Poster (0296–0322)
Session Type: Poster Session A
Session Time: 8:30AM–10:30AM

Background/Purpose: Primary Sjögren's Syndrome (pSS) is a systemic autoimmune disease which is mostly characterized by the presence of xerophthalmia and xerostomia, caused by the lymphoplasmacytic cell infiltration of the lacrimal and salivary glands. This pathological change can also affect other organs and produce various extraglandular manifestations (EGM), which may precede the typical sicca symptoms. The diversity of clinical presentations may partially explain the delay in diagnosis and determine the prognosis of the disease.

The purpose of this study was to describe the frequency of EGM as initial presentation in a cohort of patients with pSS and to evaluate the delay in diagnosis among patients with EGM versus sicca as initial symptoms. A secondary objective was to correlate disease onset form with age, sex, disease activity, accumulated damage, and other concomitant EGM.

Methods: Multicenter, observational, analytical, cross-sectional study. Consecutive patients ≥ 18 years of age with a diagnosis of pSS were included. Demographic and disease characteristics and clinimetric indices were recorded. EGM were defined by the EULAR-SS disease activity index (ESSDAI). The delay time from the EGM presentation to the diagnosis of the disease, and the time since the pSS diagnosis to the EGM presentation were considered.

Results: One-hundred eleven patients were included, 93% women, mean age 48.7 years (SD 13.2). 97.3% of the patients presented sicca symptoms (being the initial manifestation of the disease in 47% of them) and 90.9% had at least one EGM (being the initial symptom in 53% of the cases). The most frequent initial EGM was joint involvement (70.3%), followed by biological (32.6%) and pulmonary involvement (23.7%). No significant difference was observed in the time from the first manifestation and the diagnosis between the group that started with sicca (92 months [CI95 39.3-134.9] and that with EGM at onset (44.2 months [CI 95 29.2-59.2]); p = 0.063. Patients with EGM as initial symptom were younger at diagnosis compared to those who started with sicca symptoms (46.3 vs 51.4 years, p = 0.042). Mean ESSDAI score was higher in the group with EGM as initial symptom (1.2 vs 0.9; p = 0.002), while mean Sjögren's Syndrome Disease Activity Index (SSDI) score was higher those with initial sicca symptoms (1.3 vs 0.9; p = 0.023). No significant differences were observed in other disease characteristics, or in the distribution of different EGM between the groups with sicca or EGM onset.

Conclusion: More than half of the patients with pSS presented an extraglandular involvement at disease onset. There were no differences in the time from the first manifestation to the diagnosis between the groups with sicca or extranglandular onset.

Background/Purpose: Renal disease in primary Sjogren's syndrome (pSS) can occur in form of tubulointerstitial nephritis (TIN) or glomerulonephritis (GN). Data from India on pSS is sparse and that on nephritis is even less. Thus, we studied the prevalence and impact of renal disease on patient outcomes.

Methods: Retrospective review of 179 (F:M 12.7:1, age 41.7±12.9 years) patients of pSS (ACR 2016 criteria) was carried out from electronic health records at a single centre from 2000 to 2020. Data on nephritis and other clinical and laboratory variables was collected from baseline visit. Outcomes studied were chronic kidney disease (CKD) and death. Multivariate logistic regression was used to identify predictors. Linear mixed effects models were used to predict rise in creatinine on follow up. Kapan Meier survival analysis was undertaken for a composite outcome of death or CKD.

Results: Among 179 patients with pSS 54 (30.17%) patients had nephritis. Their mean age was 40.19 (13.28) years and they had 157.3 person years follow up. 26 of these 54 patients presented with hypokalemic paralysis (Table 1). Of the 10 renal biopsies, TIN was present in 8 and mesangioproliferative GN in 2.

Vasculitis (OR 2.33), fatigue (OR 3.29), ANA positivity (OR 7.79), anti-Ro52 (OR 2.74), anti-La (OR 2.13), both Ro and La (OR 2.4) and lymphopenia (OR 2.27) were associated with nephritis on univariate analysis. On multivariate analysis, only fatigue (OR 2.83) and an interaction between polyarthritis and vasculitis (OR 9.17) was associated with nephritis.

Creatinine at 1 year (1.6±1.17 vs 0.8±0.2) and 2 years (1.62±1.19 vs 0.8±0.2) follow-up was higher in the nephritis group than those without nephritis (Figure 1a). Adjusted for immunosuppression used, baseline hematuria, leucocyturia, 24 hour urinary protein and thrombocytopenia were independent predictors of rise in creatinine on follow up. Six patients died and 10 patients developed CKD. Event (death or CKD) free survival was 89.1% at 5 years (Figure 1b). Patients with nephritis had worse event free survival as compared to those without nephritis (Figure 1c).

Conclusion: In our cohort almost 1/3rd had nephritis and its presence lead to higher probability of death or CKD.

Artificial Neural Networks Approaches to Predict Myocardial Fibrosis in Primary Sjögren Syndrome Patients Without Cardiac Symptoms

Hitomi Kobayashi[1], Yasuyuki Kobayashi[2], Atsuma Nishiwaki[1], Isamu Yokoe[1], Haraoka Masaki[3], Eichi Takaya[3], Yousuke Nagasawa[1], Noboru Kitamura[1], Masami Takei[1] and Hideki Nakamura[1], [1]Nihon University School of Medicine, Itabashi, Japan, [2]St. Marianna University School of Medicine, kowasaki, Japan, [3]St. Marianna University School of Medicine, Kawaski, Japan

SESSION INFORMATION
Session Date: Saturday, November 6, 2021
Session Title: Sjögren's Syndrome – Basic & Clinical Science Poster (0296–0322)
Session Type: Poster Session A
Session Time: 8:30AM–10:30AM

Background/Purpose: A recent meta-analysis of cardiovascular diseases demonstrated that the odds of heart failure (HF) was more than 2.54-fold higher in primary Sjögren syndrome (pSS) patients than controls. Cardiac magnetic resonance imaging (CMR) is useful for the early assessment of myocardial abnormalities that precede the development of overt HF. Myocardial dysfunction may arise from a number of distinct processes, including myocardial fibrosis. Global longitudinal strain (GLS), using non-contrast feature tracking cardiac magnetic resonance (FT-CMR), has been reported to be significantly associated with the extent of myocardial fibrosis. Late gadolinium enhancement (LGE) is correspond to myocardial fibrosis. In the last years, artificial neural networks (ANNs) approaches have been shown to be an established method for analyzing large datasets. ANNs could be a useful prediction tool in medical scenarios. This study aimed to predict myocardial fibrosis in pSS assessed by FT-CMR and LGE, by using ANNs models.

Methods: This was a cross-sectional study of patients with pSS registered in our hospital between January 2014 and April 2018. Healthy volunteers were recruited as a control group to be frequency-matched to the age and sex distribution of the pSS patients. pSS patients and controls with no known heart disease or risk factors who underwent CMR. We used a random forest classifier to predict myocardial abnormality in two indices (LGE, GLS). This is an algorithm that uses multiple decision trees for classification. The number of trees in the forest were set as 100. The criteria used to measure the quality of a split was Gini impurity. The classification threshold was set to 0.5. Inputs for the classifier included many valuables including attributes and observed values. The number of variables was finally reduced to 10 (e.g., age, duration, Raynaud phenomenon, body mass index, Framingham score, ESR, rheumatoid factor, IgG, hemoglobin A1c, and N-terminal pro b-type natriuretic peptide) by feature selection based on the trained model.

Results: We evaluated 52 patients with pSS (100% women; mean age, 59.5 ± 9. 0 years) and 20 healthy controls (100% women; mean age, 55.7 ± 4.5 years). All 72 subjects underwent FT-CMR and 52 patients underwent LGE. The pSS patients had significantly lower GLS (p = 0.015) than controls. Abnormal LGE was seen in 10/52 subjects (19%). We created a mathematical model to be able to predict abnormal GLS and LGE with an area under the curve value of 0.72 and 0.79, respectively. The accuracy, sensitivity, specificity, positive predictive value, and negative predictive value for prediction of GLS and abnormal LGE value were 88%, 40%, 100%, 100%, 86%, and 67%, 30%, 88%, 56%, 70%, respectively.

Conclusion: We applied ANNs to identify a prediction model for myocardial fibrosis in pSS patients without cardiac symptoms assessed by CMR. The use of laboratory and clinical items enabled to construct a mathematical model,

potentially identifying pSS patients with myocardial fibrosis. This prediction tool could be used in a clinical practice setting to stratify pSS patients according to myocardial fibrosis.

Session Title: Sjögren's Syndrome – Basic & Clinical Science Poster (0296–0322)

Session Type: Poster Session A

Session Time: 8:30AM–10:30AM

Background/Purpose: Allergic disorders are occasionally seen in patients with primary Sjögren's syndrome (pSS) [1]. Risk factors are unclear for allergic disorders.

We aimed to compare the prevalence of allergic disorders in pSS and rheumatoid arthritis (RA) ,and to compare the clinical features at diagnosis of pSS with and without drug allergies.

Methods: We retrospectively examined consecutive patients diagnosed with pSS or RA in our hospital from 2010 to 2020. The patients with SS met the criteria of the 1999 revised Japanese Ministry of Health criteria [2]. We included patients with pSS without RA or other rheumatic diseases. The patients with RA met the EULAR/ACR 2010 criteria. We included patients with RA without other rheumatic diseases.

Table 1. Allergic Disorders and Drug Allergies in pSS and RA

	pSS (n = 292)	RA(n= 413)	P
at least one type of allergy, n (%)	160 (54.8)	144 (34.9)	<0.01
food allergy, n (%)	35 (12.0)	27 (6.7)	0.02
drug allergy, n (%)	76 (26.1)	69 (16.7)	<0.01
allergic contact dermatitis, n (%)	10 (3.4)	19 (4.6)	0.6
allergic rhinitis and/or conjunctivitis, n (%)	99 (33.9)	35 (8.5)	<0.01
asthma, n (%)	29 (9.9)	25 (6.1)	0.06

Table 2. Characteristics of patients and prevalence of drug allergy in patients with pSS

	With drug allergy (n = 77)	Without drug allergy (n = 215)	P
Female, n (%)	74 (96.1%)	201 (93.5%)	0.57
Age, year	56.0±15.8	57.8±15.8	0.40

Patients with anti-SSA antibody, n (%)	69 (89.6%)	169 (79.2%)	0.06
Patients with anti-SSB antibody, n (%)	37 (48.7%)	80 (40.0%)	0.22

The first analysis was performed on five types of allergic reactions: (1) food allergy (exanthema, angioedema and anaphylaxis after foods exposure), (2) drug allergy (exanthema, angioedema and anaphylaxis after drug exposure), (3) allergic contact dermatitis such as metals, alcohol swab, and other cosmetics, (4) seasonal allergic rhinitis and/or allergic conjunctivitis, and allergic rhinitis and/or allergic conjunctivitis associated with house dust, and (5) asthma.

The secondary analysis was performed on patient baseline laboratory data at diagnosis of pSS and RA patients with or without drug allergies.

Results: In the first analysis, 292 patients with pSS and 413 patients with RA were enrolled (Table 1). The mean ages (pSS, RA) were 57.3±15.8, 66.0±14.6 years old. Females were 94.2% , 78.2%. The mean observation period was 82.7±70.8, 65.6±37.0 months. 54.8% of pSS patients and 34.9% of RA patients presented at least one type of allergic disorders or drug allergies. These included food allergy, drug allergy, allergic rhinitis/conjunctivitis, and asthma. Allergic disorders and drug allergies were more frequent in patients with pSS.

In the second analysis, 77 patients with drug allergies and 215 patients without drug allergies were enrolled (Table 2). The mean ages with drug allergies and without drug allergies were 56.0±15.8 and 57.8±15.8 years old, respectively; females were 96.1% and 93.5%; the mean observation period was 90.9±72.4 and 79.8±70.2 months (Table 2). The pSS patients with drug allergies had higher levels of Immunoglobulin G (IgG) ($p = 0.01$), higher levels of eosinophils ($p< 0.019$), and higher positivity rate of anti–Sjögren's-syndrome-related antigen A autoantibody (anti-SSA antibody) than those without drug allergies ($p = 0.06$) (Table 2).

Conclusion: Patients with pSS had a higher prevalence of allergic disorders and drug allergies than patients with RA. Among patients with pSS, patients with drug allergies had higher levels of IgG, higher levels of eosinophils, and higher positivity rate of anti-SSA antibody than those without drug allergies.

Cerebellar Ataxia in Primary Sjogren's Syndrome, Is Gluten Sensitivity the Answer?

Fu Chuen Kon[1], Mohammed Akil[2], Rachael Kilding[2], Kar-Ping Kuet[2], Priya Shanmugarajah[3], Nigel Hoggard[4] and Marios Hadjivassiliou[3], [1]Department of Rheumatology, Sheffield Teaching Hospitals NHS Trust, Sheffield, [2]Department of Rheumatology, Sheffield Teaching Hospitals NHS Trust, Sheffield, United Kingdom, [3]Academic Department of Neurosciences, Sheffield Teaching Hospitals NHS Trust and University of Sheffield, Royal Hallamshire Hospital, Sheffield United Kingdom, Sheffield, United Kingdom, [4]Academic Unit of Radiology, Royal Hallamshire Hospital, Sheffield, United Kingdom

SESSION INFORMATION
Session Date: Saturday, November 6, 2021
Session Title: Sjögren's Syndrome – Basic & Clinical Science Poster (0296–0322)
Session Type: Poster Session A
Session Time: 8:30AM–10:30AM

Background/Purpose: Cerebellar ataxia is an uncommon neurological complication of Primary Sjogren's Syndrome (PSS), with case reports being the highest level of evidence available. The underlying disease pathogenesis is unknown, although an immunologically mediated mechanism seems plausible. Gluten sensitivity is common amongst patients with PSS and is a known cause of immune mediated ataxia (gluten ataxia). We aimed to investigate the presence of ataxia in patients with PSS seen in the joint rheumatology-neurology clinics at our institution, and determine if gluten sensitivity is responsible for cerebellar ataxia in some of these patients.

Methods: A retrospective review of all patients who attend the rheumatology and joint rheumatology-neurology clinics was conducted. Patient data including patient demographics, the presence of gluten sensitivity-related antibodies (anti-tissue transglutaminase 2, anti-gliadin IgG and IgA, endomysial antibodies, anti-transglutaminase 6 IgG and IgA), were collected. Patients attending the rheumatology clinics with PSS were asked about the presence of any symptoms of unsteadiness. Such patients underwent MR spectroscopy of the cerebellum looking for any evidence of abnormal cerebellar metabolites (N-acetylaspartate–to-creatine (NAA/Cr) ratio < 1). Electrophysiology results in the form of nerve conduction studies (NCS) or electromyography (EMG) were also collected.

Results: We identified 45 patients with symptoms of impaired balance. Not all of the 236 patients with PSS who regularly attend the rheumatology clinics were assessed for any evidence of loss of balance. Nonetheless, at least 45 out of 236 patients (19.1%) complained of balance problems. The majority of these patients were female (41/45, 91.1%) with a mean age of 64.3 years. Thirty-three out of 45 patients with ataxia (73.3%) tested positive for one or more of gluten sensitivity-related antibodies, with IgA TG6 being the most common (17/33 patients, 51.5%). Out of the 33 gluten sensitive patients, 25 had MR spectroscopy of the cerebellum and 17/25 (68%) had an abnormal NAA/Cr ratio. Twenty-two patients had NCS/EMG studies performed, of which 13 (59.1%) had either a sensory-motor neuropathy or sensory ganglionopathy.

Conclusion: The high prevalence of gluten sensitivity-related autoantibodies, combined with objective evidence of ataxia, suggest that gluten sensitivity may be responsible for the majority of cases of ataxia in PSS. The presence of a neuropathy in some of these patients suggests that sensory ataxia may also be contributing to the impaired balance in some of these patients. There is, however a cohort of patients with ataxia and PSS who are not gluten sensitive. These patients may well have primary autoimmune cerebellar ataxia (PACA). Whilst a therapeutic response to a gluten free diet in patients with gluten ataxia has already been established, it remains to be seen if those patients with PSS and ataxia who have no evidence of gluten sensitivity may benefit from immunosuppression.

Sleep Disorders and Serum Brain-derived Neurotrophic Factor Levels in Patients with Primary Sjögren's Syndrome

Yaxin Han[1], Li Long[2], Xixi Chen[2], Qing Peng[2], GUO TANG[3], Jiajun Liu[2] and Yan Liu[2], [1]The People's Hospital of Wenjiang,China; Sichuan Provincial People's Hospital, University of Electronic Science and Technology of China, Chengdu, China;Chinese Academy of Sciences Sichuan Translational Medicine Research Hospital, Chengdu, China (People's Republic), [2]Department of Rheumatology, Sichuan Provincial People's Hospital, University of Electronic Science and Technology of China; Chinese Academy of Sciences Sichuan Translational Medicine Research Hospital, Chengdu, China (People's Republic), [3]Chongqing Bishan People's Hospital, Chongqing, China (People's Republic)

SESSION INFORMATION
Session Date: Saturday, November 6, 2021
Session Title: Sjögren's Syndrome – Basic & Clinical Science Poster (0296–0322)
Session Type: Poster Session A
Session Time: 8:30AM–10:30AM

Background/Purpose: This study aimed to evaluate the sleep quality and its influenced factors in patients with primary Sjögren's syndrome (pSS), and another purpose is to initially explore the clinical significance of serum brain-derived neurotrophic factor (BDNF) in pSS patients.

Methods: A total of 111 pSS patients and 40 age- and sex-matched healthy controls were enrolled in a comparative study of sleep quality using the Pittsburgh Sleep Quality Index(PSQI). Participants completed the following questionnaires including demographic, clinical and laboratory data, assessment of psychological conditions. Serum samples of 63 patients and 25 healthy controls among the all subjects were be collected and serum BDNF levels of them were be detected with ELISA kits.

Results: The frequency of sleep disorder was higher in the pSS patients(68.5%) than in the control subjects(25%). There were positive correlations among age, disease duration, pain, fatigue, anxiety/depression, Xerostomia, and sleep quality in pSS patients. Meanwhile, logistic regression models identified depression, EULAR SS Patient Reported Index (ESSPRI), sweating symptoms were independent risk factors for sleep disorders.

Mean serum levels of BDNF in pSS patients with sleep disorder were significantly higher than in healthy controls and negatively correlated directly with sleep quality in patients with pSS.

Conclusion: The majority of Chinese pSS patients suffered from poor sleep, which significantly impairs their quality of life. The data suggested the need for holistic assessment and management of pSS patients and the importance of objective interventions to improve their sleep quality and finally to lead a better life. BDNF is reduced in pSS patients with sleep disorders, and it may be a biomarker for predicting sleep disorders.

SEROLOGY			
Rheumatoid Factor	63.4% (52/82)	58.6% (95/162)	0.56
Anti-Ro	86.9% (80/92)	65.7% (117/178)	**0.0003**
Anti-La	54.9% (50/91)	33.1% (58/175)	**0.0009**
LOW C4	69.4% (58/85)	34.7% (59/167)	**<0.0001**
Monoclonality	14.1% (11/78)	8.8% (15/169)	0.30
Cryoglobulinemia	25.3% (11/63)	13%(16/84)	0.09
ANA antibodies	94.1% (80/85)	84.5% (149/176)	**0.03**
LYMPHOMA	22.8% (21/92)	10% (19/182)	**0.01**

Background/Purpose: Peripheral lymphopenia and leukopenia in Sjögren's syndrome (SS) may suggest systemic disease activity and have been proposed as lymphoma predictors. However, the clinical phenotype of these subsets of SS patients is poorly defined. The objective of the present study is to investigate whether leukopenia and lymphopenia at SS diagnosis interferes with clinical manifestations, serology, disease course and lymphoma development.

Table 2. Comparison of clinical and laboratory features between SS lymphopenic patients and non lymphopenic SS controls

DEMOGRAPHICS	LYMPHOPENIA n= 68	CONTROLS n= 136	P VALUE
Median age at disease diagnosis, years (range)	57, (26-77)	56, (23-77)	0.66
Median disease duration from SS diagnosis to last follow up, years (range)	6, (0-25)	4.5, (0-23)	0.39
GLANDULAR AND NON SPECIFIC MANIFESTATIONS			
Dry mouth	95.5% (65/68)	89.7% (122/136)	**0.04**
Dry eyes	94.1% (64/68)	88.8% (120/135)	0.30
Salivary gland enlargement	45,4% (30/66)	22.3% (30/134)	**0.001**
Raynaud's phenomenon	30.8% (21/68)	28.5% (38/133)	0.85
Arthralgias	58.8% (40/68)	72.7% (99/136)	0.06

Autoimmune hepatitis	1.4% (1/68)	1.9% (2/104)	1
Peripheral nervous disease	4.4% (3/68)	2.2% (3/136)	0.40
Palpable purpura	29.4% (20/68)	8.8% (12/136)	**0.0003**
Persistent lymphadenopathy	22% (15/68)	12.5% (17/136)	0.11
Periepithelial manifestations			
Tubulointerstitial nephritis	0% (0/68)	2.2% (3/136)	0.55
Small Airway disease	4.4% (3/68)	2.2% (3/135)	0.40
Primary biliary cholangitis	0% (0/68)	2.9% (4/136)	0.30
Autoimmune thyroiditis	25% (10/40)	35.4% (22/62)	0.37
SEROLOGY			
Rheumatoid Factor	58.4% (38/65)	57.8% (74/128)	0.94
Anti-Ro	74.2% (49/66)	65.4% (87/133)	0.27
Anti-La	45.4% (30/66)	36.1% (47/130)	0.26
LOW C4	67.1% (43/64)	33% (40/121)	**<0.0001**
Monoclonality	16.3% (10/61)	5.5% (7/127)	**0.03**
Cryoglobulinemia	29.4% (15/51)	11.1%(7/63)	**0.02**
ANA antibodies	95.2% (60/63)	84.6% (110/130)	**0.03**
LYMPHOMA	39.7% (27/68)	13.2% (18/136)	**<0.0001**

Methods: From a total population of 1017 consecutive patients fulfilling the 2016 ACR-EULAR criteria for SS, who were followed-up in 3 centers from Greece (Universities of Athens, Harokopio and Ioannina), those with persistent lymphopenia or leukopenia were identified and matched with non-lymphopenic and non-leukopenic SS controls respectively, according to age at SS diagnosis, gender and disease duration from SS diagnosis to last follow up in a 1:2 ratio. Persistent lymphopenia and leukopenia were defined as an absolute lymphocyte and white blood cell count

< 1000/mm^3 and 4000/mm^3, respectively, detected in at least 3 consecutive visits within 1 year after SS diagnosis. Cumulative data regarding glandular (dry mouth, dry eyes, parotid gland enlargement) and extra-glandular manifestations (Raynaud's phenomenon, lymphadenopathy, arthralgias/arthritis, palpable purpura, liver involvement, kidney involvement, lymphoma), serology (anti Ro/SSA, anti La/SSB, rheumatoid factor, cryoglobulinemia, low C4 complement levels) and histologic features (focus score, presence) were recorded and compared between each study group and their matched SS controls. Statistical analysis for categorical data was performed by Fisher exact test or χ^2 square test accordingly and numerical data with Man Whitney test.

Results: Ninety-two SS patients with leukopenia and 68 with lymphopenia were identified and compared with 184 and 136 non-lymphopenic and non-leukopenic SS controls, respectively. Twenty-four SS patients had both leukopenia and lymphopenia and participated in both study groups. The median disease duration of leukopenic and lymphopenic SS patients was 5 (range: 0 -22) and 6 years (range: 0-25) respectively whereas the median age of SS diagnosis was 53 (range: 20-79) and 57 (range:26-77) years old respectively. SS patients with leukopenia had statistically significant higher frequency of salivary gland enlargement (38,4% vs 18,8%, p=0,0007), palpable purpura (16,3% vs 7,6%, p=0,04), persistent lymphadenopathy (20,6% vs 10%, p=0,04), ANA antibodies (94,1% vs 79,9%, p=0.03), anti SSA/Ro antibodies (86,9% vs 65,7%, p=0,0003), anti SSB/La antibodies (54,9% vs 33,1%, p=0,0007), low C4 serum levels (69,4% vs 34,7%, p=0,007) and lymphoma (22,8% vs 10,4%, p= 0.01) (Table 1). SS patients with lymphopenia had more frequently salivary gland enlargement (45,4% vs 22,3%, p=0.001), palpable purpura (29,4% vs 8,8%, p=0.0003), ANA antibodies (95,2% vs 79,9%, p=0.003)), low C4 serum levels (67,1% vs 33%, p< 0.0001), cryoglobulinemia (29,4% vs 11,1%, p=0.02) and lymphoma (39.7% vs 13.2%, p= < 0.001) (Table 2).

Conclusion: SS patients with leukopenia and lymphopenia constitute specific disease subgroups with distinct clinical phenotypes associated with increased lymphoma prevalence.

SESSION INFORMATION

Session Date: Saturday, November 6, 2021

Session Title: Sjögren's Syndrome – Basic & Clinical Science Poster (0296–0322)

Session Type: Poster Session A

Session Time: 8:30AM–10:30AM

Background/Purpose: Primary Sjögren's syndrome is a systemic autoimmune disease characterized by dryness of the mouth and eyes. The impact of the disease on salivary glands can be assessed in three different ways: by salivary gland histopathology, measuring salivary flow and salivary gland ultrasonography. To understand the relative value of these different approaches for disease evaluation, it is crucial to understand the relationship between them. As we are in the unique position to explore this relationship in the parotid gland, we aimed to assess construct validity between the three different modalities in the same parotid gland.

Methods: Consecutive patients underwent a diagnostic work-up including a parotid gland biopsy, collection of stimulated parotid gland saliva and parotid ultrasonography. Patients who were classified as primary Sjögren's syndrome according to the ACR-EULAR criteria were included. Construct validity was assessed using Spearman's correlation coefficients.

Results: A total of 41 patients with primary Sjögren's syndrome were included. All patients completed a full work-up within a mean time interval of 2.6 months. Correlations between histopathological items and stimulated parotid salivary flow were poor to fair (ρ=-0.123 for focus score and ρ=-0.259 for percentage of $CD45^+$ infiltrate). Likewise, poor correlations were observed between stimulated parotid salivary flow and parotid ultrasonography (ρ=-0.196). Moderate to good associations were found between histopathological items and parotid ultrasound scores (total ultrasound score: ρ=0.510 for focus score and ρ=0.560 for percentage of $CD45^+$ infiltrate; homogeneity: ρ=0.574 for focus score and ρ=0.633 for percentage of $CD45^+$ infiltrate).

Conclusion: Parotid gland salivary flow was not related to parotid gland histology, nor to parotid gland ultrasonography. Although pSS associated ultrasonographic findings correlated to some extent with the amount of inflammatory infiltrate in the parotid gland biopsy, we conclude that the three modalities that evaluate salivary gland involvement assess different (or at best partly related) constructs. Therefore, histopathology, salivary flow and ultrasonography are complementary measurements and cannot directly replace each other in the work-up of pSS.

Ultra High-frequency Ultrasound (UHFUS) of Labial Glands in Primary Sjögren's Syndrome: Serological and Histological Correlations

Giovanni Fulvio[1], Francesco Ferro[1], Rossana Izzetti[2], Gianmaria Governato[1], Silvia Fonzetti[1], Gaetano La Rocca[1], Valentina Donati[3], Davide Caramella[4], Marta Mosca[5] and Chiara Baldini[6], [1]University of Pisa, Rheumatology Unit, Pisa, Italy, [2]University of Pisa, Unit of Dentistry and Oral Surgery, Department of Surgical, Medical and Molecular Pathology and Critical Care Medicine, Pisa, Italy, [3]AOUP, Unit of Pathological Anatomy, Pisa, Italy, [4]University of Pisa, 3Diagnostic and Interventional Radiology, Department of Translational Research and of New Technologies in Medicine and Surgery, Pisa, Italy, [5]Rheumatology Unit, Department of Clinical and Experimental Medicine, University of Pisa, Pisa, Italy, [6]University of Pisa, Pisa, Italy

SESSION INFORMATION
Session Date: Saturday, November 6, 2021
Session Title: Sjögren's Syndrome – Basic & Clinical Science Poster (0296–0322)
Session Type: Poster Session A
Session Time: 8:30AM–10:30AM

Background/Purpose: Last-generation ultra high-frequency ultrasound (UHFUS) transducers are highly sensitive tools potentially able to open new avenues for the identification of imaging biomarkers. Recently UHFUS has been applied to the study of labial salivary glands (LSG) in patients with suspected primary Sjögren's syndrome (pSS) showing a good diagnostic accuracy in identifying pSS from no-SS sicca. Objective**:**1. to assess the association between UHFUS scoring and LSG histology in patients with established pSS; 2. to explore the association between LSG-UHFUS scoring and anti-Ro antibody specificity (i.e. both anti-Ro60 and Ro52 or isolated anti-Ro52 and anti-Ro60 antibodies).

Methods: Out of a cohort of 207 patients who underwent a UHFUS guided LSG biopsy for suspected pSS (Jan 2018-Apr 2021), we identified 92 patients with an established newly diagnosed pSS (ACR/EULAR 2016 criteria). Patients' clinical, biological and histological features were collected. The anti-Ro antibody specificity and titer were determined by immunoblotting. UHFUS of LSG was performed by using VEVO MD, equipped with a 70 MHz probe, evaluating parenchymal inhomogeneity (score 0-3). For each of the LSG specimens number of foci, focus score (FS) and ectopic lymphoid structures (ELS) were assessed.

Results: We included a total of 92 pSS patients: 41 (44.6%) with anti-Ro60 and anti-Ro52, 6 (6.5%) with anti-Ro60 alone, 25 (27.2%) with anti-Ro52 alone, and 20 (21.7%) with neither antibody. A UHFUS score 1 was observed in 32 (34.8%), a UHFUS score 2 in 47 (51.1%) and a UHFUS score 3 in 13 (14.1%) pSS patients. The UHFUS scoring was equally distributed within the four serotype subgroups; however, we observed a moderate correlation (r=0.300, p=0.01) between the UHFUS scoring and the anti-Ro60 titer. UHFUS score correlated also with IgG levels and with parotid and submandibular US (p< 0.05). No correlation was observed between UHFUS and ESSPRI, salivary flow and ocular tests. Regarding LSG histology, the higher was the UHFUS grading, the higher were: the number of foci (foci, mean (S.D) : 2.6 (2.8) in UHFUS-score 1 vs 5.9 (3.3) in UHFUS-score 3, p=0.001), the FS (FS, mean (S.D): 1.3 (1.2) in UHFUS-score 1 vs 2.1 (0.9) in UHFUS-score 3, p=0.01) and the number of ELS (ELS, mean (S.D): 0.9 (1.1) in UHFUS-score 1 vs 2.5 (1.9) in UHFUS-score 3, p=0.01). Noteworthy, out of the 13 patients with a UHFUS-score 3, 12/13 presented at least one ELS in their biopsies (p=0.01). UHFUS score-3 showed a specificity of 97.1% and a positive predictive value of 92.3% in the evaluation of ELS in LSGs.

Conclusion: UHFUS of LSG appeared significantly associated with serological and histological findings in pSS and may have a role in patients' stratification.

Prognostic Value of Salivary Gland Ultrasonography in Primary Sjögren's Syndrome

Francesco Ferro[1], Gianmaria Governato[1], Giovanni Fulvio[1], Gaetano La Rocca[1], Silvia Fonzetti[1], Giacomo Aringhieri[2], Valentina Donati[3], Marta Mosca[4] and Chiara Baldini[5], [1]University of Pisa, Rheumatology Unit, Pisa, Italy, [2]University of Pisa, 3Diagnostic and Interventional Radiology, Department of Translational Research and of New Technologies in Medicine and Surgery, Pisa, Italy, [3]AOUP, Unit of Pathological Anatomy, Pisa, Italy, [4]Rheumatology Unit, Department of Clinical and Experimental Medicine, University of Pisa, Pisa, Italy, [5]University of Pisa, Pisa, Italy

SESSION INFORMATION

Session Date: Saturday, November 6, 2021

Session Title: Sjögren's Syndrome – Basic & Clinical Science Poster (0296–0322)

Session Type: Poster Session A

Session Time: 8:30AM–10:30AM

Background/Purpose: In the last decade, salivary gland ultrasonography (SGUS) has appeared as a useful tool for the diagnosis of primary Sjögren's syndrome (pSS) and for the identification of different disease phenotypes. Purpose: To evaluate the usefulness and prognostic value of SGUS in identifying pSS patients at risk of lymphoma

Methods: Sonographic data from a monocentric cohort of pSS patients were collected from 2012 to 2021. Salivary glands were scored using the latest 2019 OMERACT semiquantitative SGUS scoring systems (0-3) based on parenchyma inhomogeneity; SGUS≥2 indicates moderate or severe glandular alterations. For both the parotid glands (PG) and the submandibular glands (SMG), the worse finding of the two sides was used in the analyses. Patients demographics, clinical and histological data were recorded.

Results: We included 137 pSS patients (2 M:135 F, mean age 57±14 yrs) followed for a median follow-up of 43 (22) months. At baseline, 59/137 (43.1%) patients presented a PG-SGUS≥2 and 50/137 (36.5%) a SMG-SGUS≥2. Patients with a SGUS≥2 (either in their PGs or SMGs) presented more frequently hypergammaglobulinemia, Rheumatoid Factor, anti-Ro/SSA positivity and a higher focus score ($p< 0.01$). Patients with a PG-SGUS≥2 presented significantly more often markers of lymphoma development, such as salivary gland swelling, lymphopenia and low complement levels ($p< 0.01$). Over the follow-up, 4/137 patients developed a MALT lymphoma in their PGs. At baseline, all of them had a SGUS grade 3 in their PGs, and two had also a SGUS grade 3 in their SMGs. A significant association emerged between MALT lymphoma and both PG-SGUS≥2 and SMG- SGUS≥2 at baseline ($p< 0.05$). Particularly, PG-SGUS grade 3 was significantly associated with MALT lymphoma development ($p=0.01$).

Conclusion: SGUS may help to identify pSS patients at risk of lymphoma. Patients presenting a PG-SGUS grade 3 deserve a careful assessment to recognize possible lymphoproliferative complications in severely damaged salivary glands.

Session Title: Sjögren's Syndrome – Basic & Clinical Science Poster (0296–0322)
Session Type: Poster Session A
Session Time: 8:30AM–10:30AM

Background/Purpose: Ultrasonographically depicted morphological changes of major salivary glands (SG) have been recently correlated with the disease activity in primary Sjögren's (pSS)[1]. The aim of our prospective, cross-sectional study was to determine whether pSS patients with normal SG ultrasound indeed have less active disease at baseline.

Methods: We included 129 consecutive adult pSS patients, diagnosed at our secondary - tertiary center between 2017-2019. All patients fulfilled the 2016 ACR/EULAR classification criteria[2] and underwent a routine diagnostic procedure including major SG ultrasound[3] and minor SG biopsy. Disease activity was assessed with ESSDAI[4]. Multivariate logistic regression was used to evaluate factors predicting baseline ESSDAI.

Results: Our pSS cohort consisted of 120 females and 9 males, with a median (IQR) age 62 (51-69) years, and median (IQR) symptom duration of 24 (10-41) months. Among them 95 (73.6 %) had antinuclear antibodies, 98 (76.0%) anti-SSA, 21 (16.3%) had anti-SSB, and 37 (28.6%) had rheumatoid factor (RF), respectively. Four patients had anticentromere antibodies. Twenty-nine (22.5%) patients had 3 or more different autoantibodies. Minor salivary gland biopsy was positive in 83 (64%) patients. Forty-nine patients (38.0%) had a positive major SG ultrasound. Median (IQR) ESSDAI was 2 (0-6), range 0-34 at baseline. Among the ESSDAI components articular and biological component predominated (Figure 1). Using multivariate analysis, we found no association between baseline ESSDAI, and SG US changes, histological focus score, the number of antibodies, patients' age, sex, symptom duration time, inflammatory parameters (ESR and CRP). The single parameter that predicted baseline ESSDAI was the presence of RF ($P < 0.001$). Only anti-SSB ($p=0.004$)) and antinuclear antibodies ($p=0.003$) emerged as predictors of positive SG ultrasound.

Figure 1. ESSDAI by components in our pSS cohort.

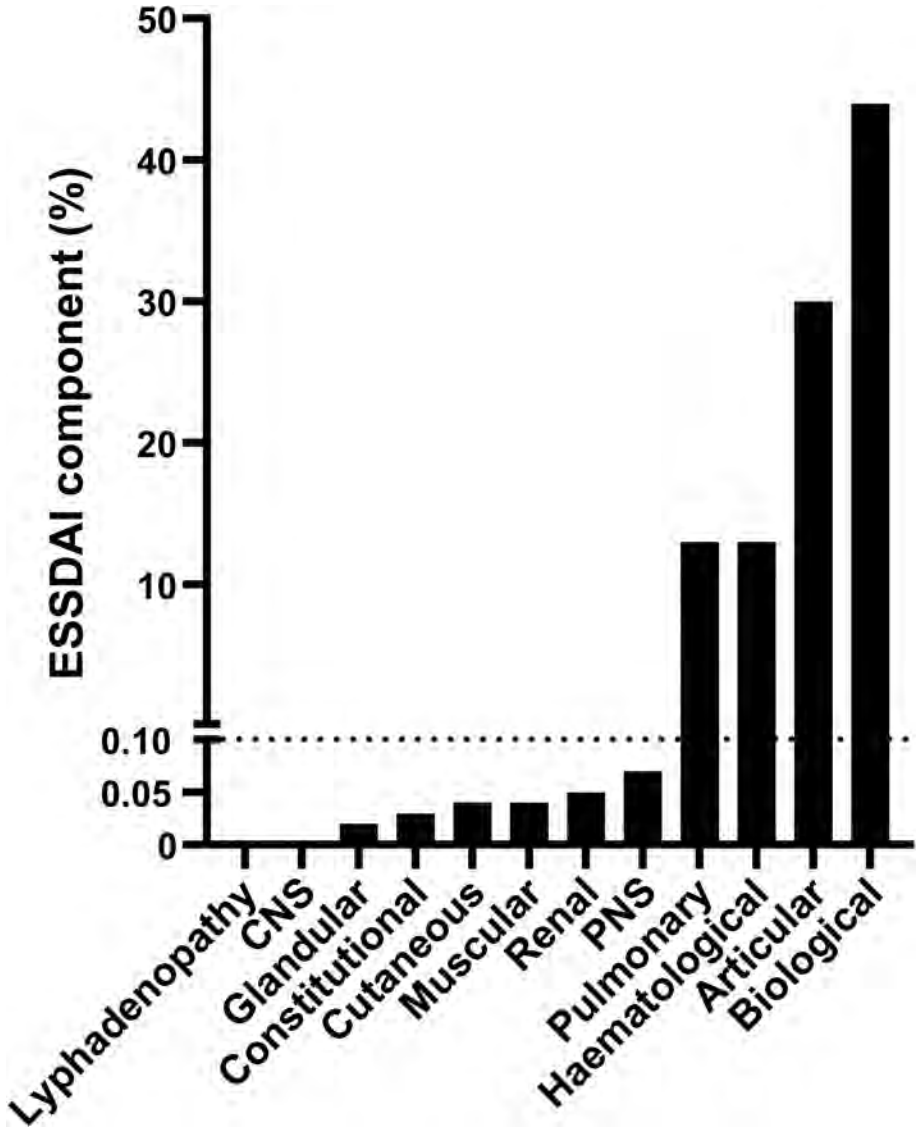

Table 1. Baseline demographic and clinical characteristics of patients who met 2016 ACR/EULAR Classification Criteria for Sjogren's Syndrome compared to those with sicca not otherwise specified (NOS)

Demographic/Clinical Characteristic	Primary Sjogren's Syndrome (n=227)	Sicca NOS (n=85)	*p* value
Age, mean (SD)	57 (14)	54 (12)	**0.030**
Gender, (n, % female)	211 (92%)	78 (92%)	0.92
Race (n, % white)	187 (82%)	69 (81%)	0.94
Ethnicity (n, % non-Hispanic)	220 (97%)	82 (99%)	0.28
Symptom Duration (SD), months	13.4 (9.3)	10.5 (7.9)	**0.013**
Lip Biopsy (n, % positive) *	59/84 (70%)	3/80 (3%)	**<0.001**
Anti-SSA antibodies (n, % positive)	206 (90%)	2 (2.4%)	**<0.001**
Schirmer's test (n, % <5 mm/5 min)	156 (68%)	25 (29%)	**<0.001**
Salivary Flow (n, % <0.1 ml/min)	93 (41%)	18 (21%)	**<0.001**
Current Medication Use:			
Hydroxychloroquine	139 (61%)	32 (38%)	**<0.001**
Methotrexate	25 (11%)	8 (9%)	0.69
Leflunomide	5 (2%)	3 (4%)	0.51
Azathioprine	6 (3%)	1 (1%)	0.44
Rituximab	15 (7%)	2 (2%)	0.14
Anxiolytic	47 (21%)	24 (28%)	0.15
Anti-depressant	54 (24%)	24 (28%)	0.41
ESSPRI (SD)			
Total (0-10)	5.4 (2.2)	5.5 (2.2)	0.73
Pain (0-10)	4.7 (2.9)	5.1 (2.7)	0.36
Dryness (0-10)	6.0 (2.6)	5.7 (2.5)	0.48
Fatigue (0-10)	5.6 (2.7)	5.8 (2.9)	0.59
PROMIS Global Profile Mean T-Score (SD)			
Pain Interference	56.9 (11.0)	60.3 (12.0)	**0.016**
Physical Function	44.2 (9.8)	41.6 (9.0)	0.360
Fatigue	57.2 (10.6)	59.7 (13.2)	0.080
Social Participation	46.9 (10.8)	43.5 (11.7)	**0.015**
Sleep Disturbance	52.2 (10.2)	55.3 (10.6)	**0.020**
Anxiety	52.7 (12.0)	54.7 (12.2)	0.18
Depression	49.1 (11.1)	50.8 (13.3)	0.24

ESSPRI= EULAR's Sjogren's Syndrome Patient Reported Index. *Positive lip biopsy defined as focal lymphocytic sialadenitis; of note, 63% of SS and 11% of sicca NOS patients did not have a completed lip biopsy.

Conclusion: Our results imply that SG US does not predict baseline pSS disease activity, determined by ESSDAI.

PROMIS Provides a Broad Overview of Health-Related Quality of Life in the Evaluation of Sjogren's Syndrome

Dana DiRenzo[1], Susan Robinson[2], Clifton Bingham[1], Alan Baer[3] and Thomas Grader-Beck[1], [1]Johns Hopkins University, Baltimore, MD, [2]Johns Hopkins, Baltimore, MD, [3]Johns Hopkins University School of Medicine, Baltimore, MD

SESSION INFORMATION
Session Date: Saturday, November 6, 2021
Session Title: Sjögren's Syndrome – Basic & Clinical Science Poster (0296–0322)
Session Type: Poster Session A
Session Time: 8:30AM–10:30AM

Background/Purpose: Sjogren's Syndrome (SS) is a systemic autoimmune disease that has considerable impact on health-related quality of life (HRQL). The European League Against Rheumatism (EULAR) Sjogren's Syndrome Patient Reported Index (ESSPRI) is the most widely used questionnaire to evaluate severity of patient-reported symptoms but is limited in scope. We sought to evaluate predictors of pain, fatigue, and social participation in SS using the Patient Reported Outcome Measurement Information System (PROMIS®) HRQL instruments to supplement ESSPRI findings.

Methods: A cross-sectional evaluation was performed on completed questionnaires of consecutive adult patients during visits to a multidisciplinary Sjogren's clinic between March 2018-February 2020. Questionnaires included PROMIS short-forms (depression 4a.v1, anxiety 4a.v1, fatigue 8a.v1, physical function 4a.v2, pain interference 8a.v1

(PI), sleep disturbance 4a.v1, participation in social roles and activities 8a.v1) and the ESSPRI. Patients were either classified as SS by 2016 ACR/EULAR criteria or labeled as "sicca not otherwise specified" (NOS) and used as a comparison group. Descriptive statistics were calculated for disease-related and sociodemographic variables and Pearson correlation was used to evaluate the relationship between subdomains of the ESSPRI and PROMIS. Uni- and multivariable linear regression (MVR) models were used to evaluate predictors of PROMIS PI, fatigue, and social participation after controlling for age, gender, race, ethnicity, and symptom duration.

Results: 227 SS patients and 85 patients with sicca NOS were included. Patients with SS were slightly older (mean (SD) years 57 (14) vs 54 (12), p=0.030) and were mostly female and white (Table 1). Mean (SD) PROMIS T-scores for PI (56.9 (11.0)), fatigue (57.2 (10.6)), and physical function (44.2 (9.8)) were at least ½ SD worse than US population normative values. Among SS patients PROMIS PI (r=0.72) and fatigue (r=0.80) highly correlated with respective ESSPRI pain and fatigue sub-domains. PI, sleep disturbance, poor physical function, and impaired social participation predicted fatigue and similarly fatigue, sleep disturbance, poor physical function, and impaired social participation predicted PI (all p's< 0.01) (Table 2). Fatigue and PI, but not dryness or mood disturbance, were the strongest predictors of social participation in MVR in this SS cohort. Patients with sicca NOS had greater mean T-Scores (SD) for PI (60.3 (12.0)) than the SS cohort in addition to worse social participation (43.5 (11.7)) and SD (55.4 (10.6)) (p's < 0.05). There were no significant differences in ESSPRI domains between patients with SS and sicca NOS.

Conclusion: In our SS cohort, PROMIS PI and fatigue scores correlated highly with respective ESSPRI domains. Fatigue and PI, but not dryness, were found to be the strongest negative predictors of social participation. Given the ability of PROMIS instruments to identify HRQL domains of high impact on SS patients beyond those ascertained through ESSPRI, these questionnaires should be considered as a supplement when evaluating SS patients in clinical care and trials.

SESSION INFORMATION

Session Date: Saturday, November 6, 2021

Session Title: Sjögren's Syndrome – Basic & Clinical Science Poster (0296–0322)

Session Type: Poster Session A

Session Time: 8:30AM–10:30AM

Background/Purpose: The aim of this study was to gain qualitative patient feedback on the appropriateness of two Patient Reported Outcome (PRO) measures as assessments of symptoms of Sjögren's. The Sjögren's Syndrome Symptom Diary (SSSD) is a novel daily diary assessing the severity of six core symptoms: eye dryness, mouth dryness, skin dryness, genital dryness (females only), fatigue, and muscle/joint pain. Recently, the SSSD fatigue item wording has been updated to 'tiredness' and two supplementary items have been drafted to capture the most bothersome and most important to improve symptoms from a patient perspective. The Functional Assessment of Chronic Illness Therapy-Fatigue (FACIT-F) is a well-established, 13-item measure of an individual's fatigue and tiredness over the past week, however the content validity of the FACIT-F items has not been confirmed in Sjögren's. In this study the 13-item FACIT-F and new and updated SSSD items were tested with patients with Sjögren's. Patient perceptions of meaningful change on the SSSD were also explored.

Methods: Twelve semi-structured, cognitive telephone interviews were conducted with US adult patients with Sjögren's to cognitively debrief the new SSSD items ('most bothersome' and 'most important to improve'), and the updated SSSD 'tiredness' item. Cognitive debriefing involves actively testing a measure with patients to determine whether each instruction/item is understood as intended and relevant to patient experiences of the condition. In qualitative research a sample of 12 patients is typically considered sufficient to provide a comprehensive assessment of the PRO measure. Meaningful change was explored in relation to the six core SSSD items and for SSSD total average scores. Understanding and relevance of the 13 FACIT-F items were also explored.

Results: The new and updated SSSD items were well-understood by all patients (n=12/12) and all patients selected the same symptom as their most bothersome and the most important to improve from their perspective. The symptom most frequently reported as the most bothersome and important to improve was eye dryness (n=7/12). Meaningful improvement on individual SSSD items varied depending on patients' current Sjögren's severity, and meaningful improvement in relation to the SSSD total score varied from 1-point to 7-points (mean: 2.3 points; mode: 2 points). Such changes were described in relation to improvements in patients' feeling and functioning. FACIT-F items were generally well-understood, although there were some instances of patients not understanding the term 'listless' (n=4/12) in the item 'I feel listless (washed out)'. FACIT-F items were generally relevant; however, there was some variation in patient experiences of fatigue and tiredness related to Sjögren's. The FACIT-F item 'I am too tired to eat' was not relevant to any patients.

Conclusion: These results suggest that the new and updated SSSD items, and FACIT-F items, have good content validity as PRO measures of Sjögren's symptoms. Patient perceptions of meaningful change on the SSSD will be valuable for aiding interpretation of psychometrically-derived responder definitions and informing clinical trial endpoints.

SESSION INFORMATION
Session Date: Saturday, November 6, 2021
Session Title: Sjögren's Syndrome – Basic & Clinical Science Poster (0296–0322)
Session Type: Poster Session A
Session Time: 8:30AM–10:30AM

Background/Purpose: Sjögren's is a chronic autoimmune disease symptomatically characterized by dryness, pain and fatigue, which are typically assessed in clinical trials using EULAR Sjögren's Syndrome Patient Reported Index (ESSPRI). However high placebo response rates are observed when responder definition guidelines (ESSPRI score ≤5 and improvement of ≥1-point or ≥15%) are implemented. The aim of this study was to explore possible options for alternative responder definitions that indicate the optimal balance of sensitivity (the ability to correctly identify improved patients) and specificity (the ability to correctly identify stable patients) to reduce possible misclassification of patients in Sjögren's clinical trial analyses.

Methods: Thresholds for alternative responder definitions were derived using blinded data from a Phase 2b randomized, double-blind, placebo-controlled, multicenter, parallel-group trial (NCT02962895) in primary Sjögren's (n=190 at Week 24) and were validated using blinded pooled data from three Phase 2 randomized, double-blind, placebo-controlled, parallel studies (NCT02775916; NCT02291029; NCT02149420) in primary Sjögren's (n=116 at Week 12; n=68 at Week 24).

Anchor- and distribution-based methods were conducted and triangulated to derive thresholds for an alternative responder definition based on a minimal symptom severity threshold and a more conservative minimal meaningful improvement threshold. A range of anchors were included in the anchor-based analyses based on suitable correlations with ESSPRI (>0.30), including Patient Global Assessment (PaGA), Physician Global Assessment (PhGA), Short Form-36 (SF-36) physical component score (PCS) and mental component score (MCS; validation analyses only), Functional Assessment of Chronic Illness Therapy - Fatigue (FACIT-F; derivation analyses only), and Multidimensional Fatigue Inventory (MFI; validation analyses only).

Results: Both analysis populations were predominantly female (>90%), white (90%), and with a mean age of 50 years (range: 20-75). A realistic meaningful change threshold range between 1- and 2-points was identified through derivation analysis; ROC estimates and correlation weighted minimal important mean change supported a minimal threshold of 1.5-1.6 for ESSPRI total score. Correlation weighted mean change estimates and upper 95% confidence intervals supported a more conservative value of 2 or more. The minimal symptom severity threshold range was between 3.0 and 5.3, however 3 or less showed the greatest sensitivity and specificity. Validation analyses generally supported the threshold ranges suggested by the derivation analyses, with a meaningful change threshold range of 1.46-2.11 and a minimal symptom severity range of 2.7 to 4.0 based on the most suitable anchors (PaGA and PhGA).

Conclusion: The results of these analyses suggest that an alternative, more conservative composite ESSPRI responder definition could be used in future trials: an ESSPRI score of ≤3 and an improvement in ESSPRI score of 1.5-points or more. Further analysis in unblinded data is warranted to further test the utility of this new endpoint.

Patient and Physician Perspectives on EULAR Sjögren's Syndrome Patient Reported Index (ESSPRI) and EULAR Sjögren's Syndrome Disease Activity Index (ESSDAI): A Qualitative Interview Study

Samantha Wratten[1], Carl Cooper[2], Jessica Flynn[2], Natasha Griffiths[2], Rebecca Hall[3], Linda Abetz-Webb[2], Simon J Bowman[4], Wolfgang Hueber[5], Briana Ndife[6] and Pushpendra Goswami[5], [1]Adelphi Values, Macclesfield, United Kingdom, [2]Adelphi Values, Bollington, United Kingdom, [3]Adelphi Values Ltd, Bollington, United Kingdom, [4]Department of Rheumatology, University Hospitals Birmingham NHS Foundation Trust, Birmingham, United Kingdom, [5]Novartis Pharma AG, Basel, Switzerland, [6]Novartis, East Hanover, NJ

SESSION INFORMATION
Session Date: Saturday, November 6, 2021
Session Title: Sjögren's Syndrome – Basic & Clinical Science Poster (0296–0322)
Session Type: Poster Session A
Session Time: 8:30AM–10:30AM

Background/Purpose: The aim of this research was to gain qualitative patient and physician feedback on the EULAR Sjögren's syndrome patient reported index (ESSPRI) and the EULAR Sjögren's syndrome disease activity index (ESSDAI). ESSPRI is a 3-item Patient-Reported Outcome measure of Sjögren's symptom severity (dryness, fatigue, joint/muscle pain). ESSDAI is a 12-domain Clinician-Reported Outcome measure of Sjögren's disease activity. Each domain is rated using pre-defined descriptions for each disease activity level (No/Low/Moderate/High). ESSPRI and ESSDAI have been psychometrically validated using data from over 700 patients and with input from over 50 experts (Seror *et al.,* 2016), however qualitative confirmation of the content validity has not been documented.

Methods: Qualitative, semi-structured, cognitive, telephone interviews were conducted with US adult patients with Sjögren's (N=12) and expert Sjögren's physicians in the US, UK and Germany (N=10). These samples are typical of qualitative research and are supplementary to the numerous patients and expert physicians previously involved in the validation of these measures. ESSPRI was tested with patients to explore understanding, relevance, and appropriateness of the 2-week recall period, and obtain patient perspectives of meaningful change in relation to their ESSPRI total score. ESSDAI was tested with physicians to explore the appropriateness of ESSDAI domain weightings, domain-level clinically meaningful improvement, and meaningful change in ESSDAI total scores. Physicians were also asked about the clinical relevance of the ESSPRI 2-week recall period.

Results: ESSPRI items were generally relevant to and well-understood by patients; however, there was some variation in interpretation of the locations of dryness considered when answering the dryness item (most frequent: eye dryness, n=9/12). Most patients (n=11/12) reported that it was easy to remember their symptoms over the past two weeks, as specified by the ESSPRI recall period. Patient-reported meaningful improvement in relation to ESSPRI total scores varied from 1-point to 6-points (mean: 2.4 points; mode: 2 points).

Physicians generally reported that the ESSDAI domain weightings were appropriate. Some physicians suggested that some weightings could be adjusted, with Articular (n=6/10), Haematological (n=5/10), and Biological domains (n=5/10) reported as under-weighted, and Muscular reported as over-weighted by most physicians (n=7/10). Most physicians considered a 1-level change in domain-level disease activity (e.g. from 'High' to 'Moderate') as clinically meaningful for most domains, and improvements of between 2-6 points in total ESSDAI scores were also considered meaningful. Most physicians (n=7/10) reported that the ESSPRI 2-week recall period was appropriate.

Conclusion: These results support the use of ESSPRI and ESSDAI as fit-for-purpose in their current formats, with some suggestions for optimization if desired. Perceptions of meaningful changes on these measures can be useful in interpreting psychometrically-derived responder definitions and informing clinical trial endpoints.

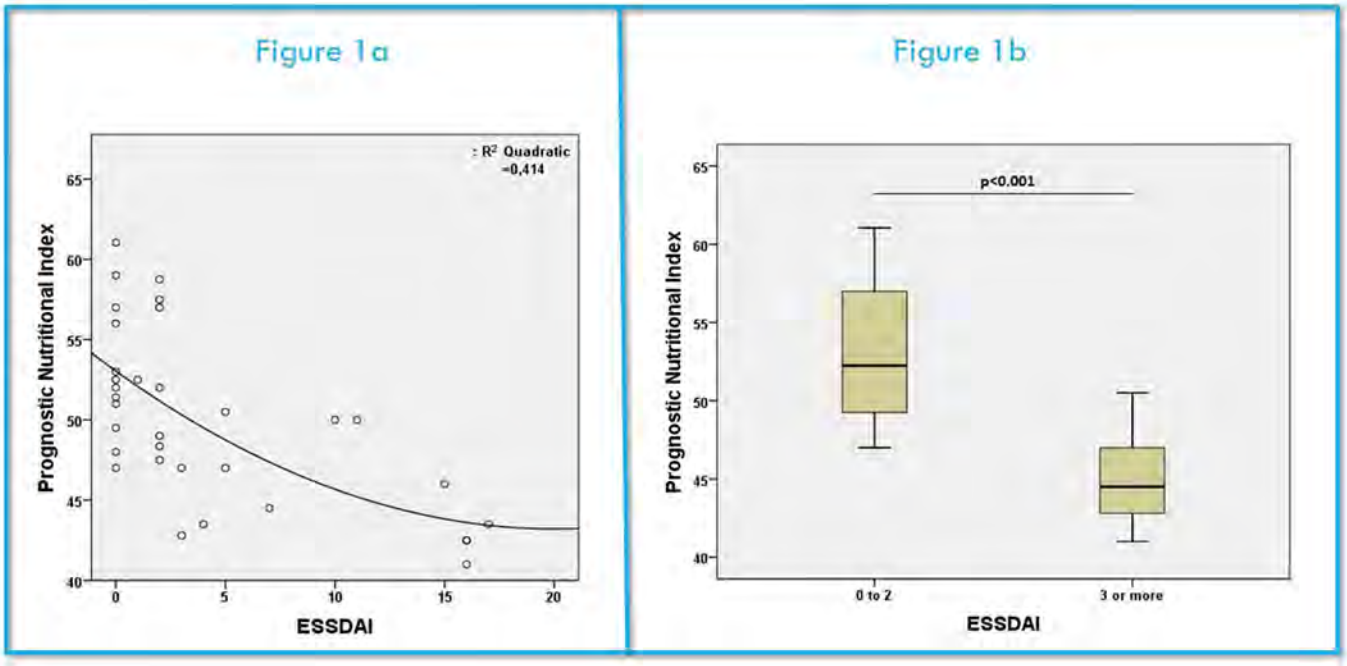
PNI=Prognostic Nutritional Index, WBC=white blood cell, PLT=platelet, ESR=erythrocyte sedimentation rate, CRP=C-reactive protein



Background/Purpose: Since primary Sjögren's Syndrome (pSS) is a very heterogeneous disease with systemic manifestations, factors influencing the outcome of patients with pSS need to be investigated. Considering previous evidence suggests that markers of serum albumin level and lymphocyte count might be able to predict inflamatory burden, we hypothesised that PNI, calculated from the serum albumin level and total lymphocyte count, could represent convenient and cost-effective biomarker for predicting disease activity in pSS. Therefore, we aimed to investigate the association of PNI with Sjögren disease activity measured by validated EULAR Sjögren's Syndrome Disease Activity Index (ESSDAI).

Methods: In this this cross-sectional study, we included a total of 36 women adult patients with pSS met the 2016 ACR-EULAR Classification Criteria for primary Sjögren's Syndrome which was evaluated in rheumatology clinic from January 2020 to January 2021. We collected laboratory data including erythrocyte sedimentation rate (ESR), C-reactive protein (CRP) level, lymphocyte, and serum albumin levels at diagnosis and last visit. PNI at diagnosis was calculated as (10 × serum albumin [g/dL] + 0.005 × lymphocyte count [/mm^3]). Disease activity was assessed with ESSDAI scores, visual analogue scales (VASs) (global disease, pain, and fatigue) was determinated and compared with PNI.

Results: Median age and disease duration were 57 (IQR: 10) years and 36 (IQR: 45) months, respectively. Demographic, clinical and laboratory features of the patients were provided in Table 1. PNI at the time of diagnosis was 49.9±5.5 and found to be slightly lower in patients with positive anti-Ro antibodies (48.4±5.8 and 52.3±3.7, p=0.023). Baseline PNI also correlated with white blood cell and platelet counts and serum complement levels but not with ESR and CRP (Table 2). Current PNI was 50.1±4.9 and not statistically different from the baseline PNI (p=0.773). It had a moderate negative correlation with ESSDAI (rho=-0.518, p=0.002) but not with the patient global (r=-0.118, p=0.512), physician global (r=-0.134, p=0.456), pain (r=-0.114, p=0.526), and fatigue (r=-0.091, p=0.615) VAS scores. There was a quadratic relationship between the PNI and ESSDAI (Figure 1a). Patients with an ESSDAI of 3 or more had significantly lower PNI compared to those with an ESSDAI of 0 to 2 (45.4±3.2 and 53±4.3, p< 0.001) (Figure 1b).

Conclusion: Our study demonstrates that pSS patients with higher ESSDAI scores had lower values of baseline PNI calculated at the disease diagnosis. In the present study, to the best of our knowledge, we have first evaluated the clinical significance of PNI in patients with pSS. We hypothesize that a lower PNI at diagnosis could indicate a higher inflammatory burden and PNI might be a prognostic tool in pSS however future studies with larger numbers of patients may provide additional information regarding the role of PNI in pSS patients.

Assessment of EULAR Sjögren's Syndrome Disease Activity Index (ESSDAI) Domains in Routine Clinical Practice in an Integrated Delivery Network in the United States

Briana Ndife[1], Irina Pivneva[2], Carmine Rossi[2] and James Signorovitch[3], [1]Novartis, East Hanover, NJ, [2]Analysis Group, Inc., Montréal, QC, Canada, [3]Analysis Group, Inc., Boston, MA

SESSION INFORMATION
Session Date: Saturday, November 6, 2021
Session Title: Sjögren's Syndrome – Basic & Clinical Science Poster (0296–0322)
Session Type: Poster Session A
Session Time: 8:30AM–10:30AM

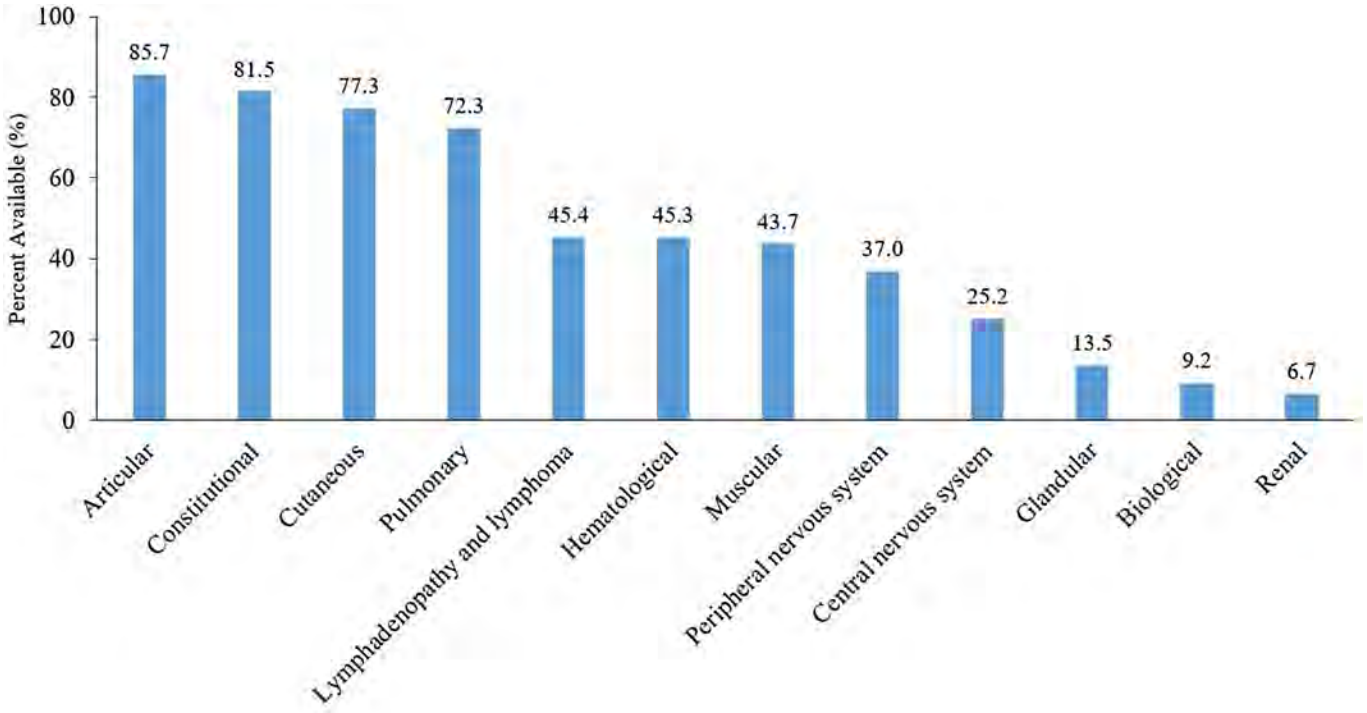

Figure 1. ESSDAI Domains Available for Assessment in Patient Charts.

Background/Purpose: Sjögren's syndrome (SS) is a chronic autoimmune disease associated with diverse phenotypes, which may include systemic disease activity. In real-world practice, the clinical presentation of SS is not well-documented. The purpose of this study was to first assess systemic domain-specific activity using the EULAR Sjögren's Syndrome Disease Activity Index (ESSDAI), a validated composite measure of SS severity, and then to describe clinical characteristics and medication use among patients with moderate-to-severe SS and lower severity SS receiving clinical care in the United States (US).

Methods: A retrospective patient chart review was used to identify adult patients with SS receiving care at a major integrated delivery network in Massachusetts. Clinical information needed to assess ESSDAI specific-domain activity was abstracted by research nurses following a review of past rheumatologist visits among patients with SS as part of routine care. Based on the abstracted data from different domains, ESSDAI scores were computed. Patients with ESSDAI scores ≥5 were considered to have moderate-to-severe SS; while those with ESSDAI < 5 would have lower severity SS. Clinical characteristics including comorbidities, medication use, and frequency of specialist visits, were assessed using linked electronic medical records (EMR) and insurance claims 12 months prior to the rheumatologist visit.

Results: As data collection is still ongoing, data from a total of 119 patients with SS collected to date with linked EMR and claims were analyzed. The mean age of patients was 63.6 years, 92.4% were female, and 52.9% experienced SS symptoms for ≥10 years. The three ESSDAI domains with the information available most commonly were articular (85.7%), constitutional (81.5 %), and cutaneous (77.3 %), whereas the least commonly were glandular (13.5%), biological (9.2%), and renal (6.7%, Figure 1). Overall, the most commonly observed comorbidities were rheumatic disease (77.3%), pulmonary disease (28.6%), pain (21.9%), and depression (20.2%, Table 1). Polypharmacy was observed, with DMARDs (37.0%), dermatological (36.1%), and ulcer drugs (36.1%) most frequently reported (Table 2). Specialist visits for internal medicine and rheumatology were most frequently observed, with a mean of 13.1 visits and 4.4 visits per year, respectively (Table 2). Although based on the available information in patient charts, only 3.4% of patients would be classified as having moderate-to-severe SS. Among those potentially classified as having lower severity SS (i.e., ESSDAI < 5), an elevated CCI score and polypharmacy were still observed.

Table 1. Comorbidities

	Overall (N = 119)	Moderate-to-severe SS (N = 4)	Low SS Severity (N = 115)
Medication use, n (%)			
Antianxiety agents	23 (19.3%)	3 (75.0%)	20 (17.4%)
Antiasthmatic	31 (26.1%)	2 (50.0%)	29 (25.2%)
Antidepressants	35 (29.4%)	2 (50.0%)	33 (28.7%)
Anti-infective agents	20 (16.8%)	1 (25.0%)	19 (16.5%)
Anti-inflammatory analgesics	36 (30.3%)	0 (0.0%)	36 (31.3%)
Antimalarials	22 (18.5%)	1 (25.0%)	21 (18.3%)
Corticosteroids	33 (27.7%)	2 (50.0%)	31 (27.0%)
Dermatologicals	43 (36.1%)	3 (75.0%)	40 (34.8%)
DMARDs	44 (37.0%)	3 (75.0%)	41 (35.7%)
Fluoroquinolones	14 (11.8%)	0 (0.0%)	14 (12.2%)
Macrolides	15 (12.6%)	1 (25.0%)	14 (12.2%)
Minerals electrolytes	18 (15.1%)	2 (50.0%)	16 (13.9%)
Multivitamins	12 (10.1%)	1 (25.0%)	11 (9.6%)
Nasal agents	25 (21.0%)	1 (25.0%)	24 (20.9%)
Non-narcotic analgesics	11 (9.2%)	0 (0.0%)	11 (9.6%)
Nonsteroidal anti-inflammatory agents	32 (26.9%)	0 (0.0%)	32 (27.8%)
Ophthalmic agents	37 (31.1%)	3 (75.0%)	34 (29.6%)
Opioid analgesics	36 (30.3%)	2 (50.0%)	34 (29.6%)
Penicillins	20 (16.8%)	1 (25.0%)	19 (16.5%)
Tetracyclines	15 (12.6%)	0 (0.0%)	15 (13.0%)
Ulcer drugs	43 (36.1%)	1 (25.0%)	42 (36.5%)
Vitamins	24 (20.2%)	2 (50.0%)	22 (19.1%)
Specialist visits (PPPY), mean ± SD			
Cardiology	1.2 ± 3.3	4.5 ± 5.8	1.1 ± 3.1
Dermatology	0.7 ± 3.7	0.5 ± 1.0	0.7 ± 3.7
Family practice	1.7 ± 5.1	3.5 ± 7.0	1.7 ± 5.0
Internal medicine	13.1 ± 15.3	22.5 ± 12.1	12.8 ± 15.3
Neurology	0.7 ± 2.1	2.5 ± 5.0	0.6 ± 1.9
Obstetrics and gynecology	0.9 ± 2.7	0.0 ± 0.0	1.0 ± 2.8
Ophthalmology	1.4 ± 2.5	6.0 ± 3.6	1.2 ± 2.3
Psychiatry	1.6 ± 6.5	7.3 ± 13.8	1.4 ± 6.2
Pulmonology	1.4 ± 4.5	3.8 ± 7.5	1.3 ± 4.4
Radiology	1.8 ± 2.3	2.3 ± 1.7	1.7 ± 2.3
Rheumatology	4.4 ± 7.2	2.8 ± 3.4	4.5 ± 7.3

DMARD: Disease-modifying antirheumatic drugs; PPPY: per-patient-per-year

Conclusion: Information needed to fully and reliably assess clinical activity in ESSDAI domains was observed to be frequently incomplete in routine clinical practice, likely underestimating the true number patients with moderate-to-severe SS. A high comorbidity burden and polypharmacy were still observed among these patients, who were mostly classified with lower severity SS, suggesting possible misclassification based on incomplete information in specific ESSDAI domains.

Table 2. Medication use and specialist visits

	Overall (N = 119)	Moderate-to-severe SS (N = 4)	Low SS Severity (N = 115)

Performance of the Clinical Trials ESSDAI (ClinTrialsESSDAI), an Adjusted ESSDAI Score, in Two Randomised Clinical Trials in Patients with Primary Sjögren's Syndrome

Liseth de Wolff[1], Suzanne Arends[2], Elena Pontarini[3], Michele Bombardieri[3], Simon J Bowman[4] and Hendrika Bootsma[2], [1]University Medical Centre Groningen, Groningen, Netherlands, [2]University Medical Center Groningen, Groningen, Netherlands, [3]Queen Mary University of London, William Harvey Research Institute, London, United Kingdom, [4]Department of Rheumatology, University Hospitals Birmingham NHS Foundation Trust, Birmingham, United Kingdom

SESSION INFORMATION
Session Date: Saturday, November 6, 2021
Session Title: Sjögren's Syndrome – Basic & Clinical Science Poster (0296–0322)
Session Type: Poster Session A
Session Time: 8:30AM–10:30AM

Background/Purpose: Recent randomised controlled trials (RCTs) in primary Sjögren's syndrome (pSS) failed to show clinical efficacy.[1-3] Several RCTs used the EULAR Sjögren's Syndrome Disease Activity Index (ESSDAI) as primary endpoint, showing large response rates in active treatment and placebo groups.[1,3] The ESSDAI consists of some domains which are more sensitive to change and easy to score compared to other domains.[4] The objective of this study was to develop the Clinical Trials ESSDAI (ClinTrialsESSDAI), an adjusted ESSDAI score consisting of frequently active and sensitive to change domains, and to compare the performance of the ClinTrialsESSDAI to the Clinical (Clin)ESSDAI and ESSDAI in two RCTs.

Methods: The ASAP-III trial in abatacept (80 pSS patients)[1] and TRACTISS trial in rituximab (133 pSS patients)[2] were used for development and analyses of the ClinTrialsESSDAI. These trials were selected since ASAP-III included only patients with moderate to high disease activity according to ESSDAI, whereas TRACTISS did not apply this inclusion criterion, leading to higher baseline ESSDAI scores in ASAP-III than in TRACTISS (median 13 vs. 4). Activity of ESSDAI domains at baseline was analysed. The six most frequently active domains were selected for the ClinTrialsESSDAI, with exclusion of the biological domain. This is in line with the ClinESSDAI, which does not include the biological domain, to measure a 'true' clinical effect. The ClinTrialsESSDAI score was calculated using existing weights of the ClinESSDAI. Responsiveness of the ClinTrialsESSDAI, ClinESSDAI and ESSDAI was calculated using the standardised response mean (SRM) at the primary endpoint visits: week 24 for ASAP-III, week 48 for TRACTISS. Percentage of patients who reached the minimal clinically important improvement (MCII, decrease of ≥3 points) and low disease activity (LDA, score < 5) was analysed for all three scores.

Results: Besides the biological domain, the six most frequently active domains at baseline in the ASAP-III and TRACTISS trial were the glandular (any activity: 91% and 21%, respectively), articular (58% and 44%), haematological (43% and 24%), constitutional (46% and 15%), lymphadenopathy (29% and 9%) and cutaneous (23% and 11%) domain (Figure 1). These domains were selected for the ClinTrialsESSDAI. Responsiveness was similar using any of the three scores at primary endpoint visits of the ASAP-III and TRACTISS trials (Table 1). Discrimination between active treatment and placebo groups based on MCII and LDA responders was also similar using any of the three scores (Figure 2).

Conclusion: The ClinTrialsESSDAI, consisting of six frequently active and sensitive to change domains of the ESSDAI, shows similar responsiveness and discrimination between treatment groups compared to the ClinESSDAI and ESSDAI in the ASAP-III and TRACTISS RCT. Therefore, this ClinTrialsESSDAI will not solve the problem of discrimination and a composite endpoint combining response at multiple clinically relevant items seems more suitable as primary study endpoint.

SESSION INFORMATION
Session Date: Saturday, November 6, 2021
Session Title: Sjögren's Syndrome – Basic & Clinical Science Poster (0296–0322)
Session Type: Poster Session A
Session Time: 8:30AM–10:30AM

Background/Purpose: Primary Sjögren's syndrome (pSS) is characterized by B-cell hyperactivity and elevated serum and saliva B-lymphocyte stimulator (BLyS) levels.[1] Sequential administration of belimumab (BEL; anti-BLyS) and rituximab (RTX; anti-CD20) is a promising strategy to target B cells through distinct but complementary mechanisms.[2] This analysis assesses the changes in minor salivary gland (MSG) and peripheral blood B cells following sequential administration of subcutaneous (SC) BEL and intravenous (IV) RTX (BEL/RTX) in patients with pSS.

Methods: This Phase 2, double-blind study (GSK Study 201842; NCT02631538) randomized 86 adults with active pSS to placebo (PBO; N=13), BEL/RTX (N=24; BEL 200 mg SC weekly to Week [Wk] 24 followed by PBO SC weekly

Table. Key biomarker levels following treatment (completer population)

to Wk 52 plus RTX 1000 mg IV, Wk 8 + 10), BEL monotherapy (N=24; BEL 200 mg SC weekly to Wk 52), or RTX monotherapy (N=25; RTX 1000 mg IV, Wk 8 + 10). Primary and secondary endpoints were safety and efficacy.[3] Reported here are the exploratory biomarker endpoints, performed on the completer population (N=60; patients who completed the treatment phase and follow-up). The analyses include CD20+ B-cell, plasma cell and memory B-cell quantification within MSG biopsies (baseline + Wk 24), and changes in peripheral blood B-cell numbers over time to Wk 68.

Results: MSG histology demonstrated that the numbers of infiltrating CD20+ B cells at Wk 24 were lowest in the BEL/RTX arm, with incomplete depletion observed in the monotherapy and PBO arms (Table). Although the levels of MSG memory B cells (CD20+, CD27+) were also lowest in the BEL/RTX and RTX arms, plasma cell numbers were maintained irrespective of treatment. Total peripheral blood CD19+ B cells in circulation were almost completely depleted in the BEL/RTX and RTX arms (Table). In the BEL/RTX arm, after BEL discontinuation at Wk 24, a trend of delayed repopulation of total B cells in circulation was evident relative to RTX. In the BEL/RTX and BEL arms, circulating memory B cells increased initially (baseline [BL]/Wk 1 median [interquartile range, IQR] number of cells/mm^3: BEL/RTX: 28.0 [13.0, 36.0]/47.0 [30.0, 72.5], BEL: 18.0 [14.0, 30.0]/45.0 [19.0, 63.0]), and then returned toward baseline levels over time. However, in the BEL/RTX arm, following the BEL-induced increase, circulating memory B cells reached near complete depletion (Wk 24 median [IQR]: BEL/RTX: 0.2 [0.1, 0.4] cells/mm^3) and remained supressed until Wk 68 (median [IQR]: 3.5 [1.5, 5.0] cells/mm^3).

Conclusion: Relative to BEL or RTX monotherapy, BEL/RTX showed trends for near complete depletion of B cells in MSG, greater depletion of circulating memory B cells, and a longer period of sustained B-cell depletion. Overall, these data support the hypothesis that combined anti-BLyS and anti-CD20 act in a mechanistically complementary manner in pSS. This sequential therapy represents a novel treatment option for patients with pSS with moderate-to-severe disease activity.

Abstract Number: 0322

Histopathological Changes in Parotid and Labial Salivary Gland Tissue in Primary Sjögren's Syndrome Patients After Abatacept Treatment

Uzma Nakshbandi[1], Liseth de Wolff[2], Frans Kroese[1], Silvia Liefers[3], Neelanjana Ray[4], Gwenny Verstappen[1], Fred Spijkervet[3], Marleen Nys[5], Arjan Vissink[6], Robert Wong[7], Bert van der vegt[3] and Hendrika Bootsma[1], [1]University Medical Center Groningen, Groningen, Netherlands, [2]University Medical Centre Groningen, Groningen, Netherlands, [3]University of Groningen, University Medical Center Groningen, Groningen, Netherlands, [4]Bristol-Myers Squibb Company, Lawrenceville, GA, [5]Bristol Myers Squibb, Braine-l'Alleud, Belgium, [6]University of Groningen, University Medical Center Groningen, Leek, Netherlands, [7]Bristol Myers Squibb, Basking Ridge, NJ

SESSION INFORMATION

Session Date: Saturday, November 6, 2021

Session Title: Sjögren's Syndrome – Basic & Clinical Science Poster (0296–0322)

Session Type: Poster Session A

Session Time: 8:30AM–10:30AM

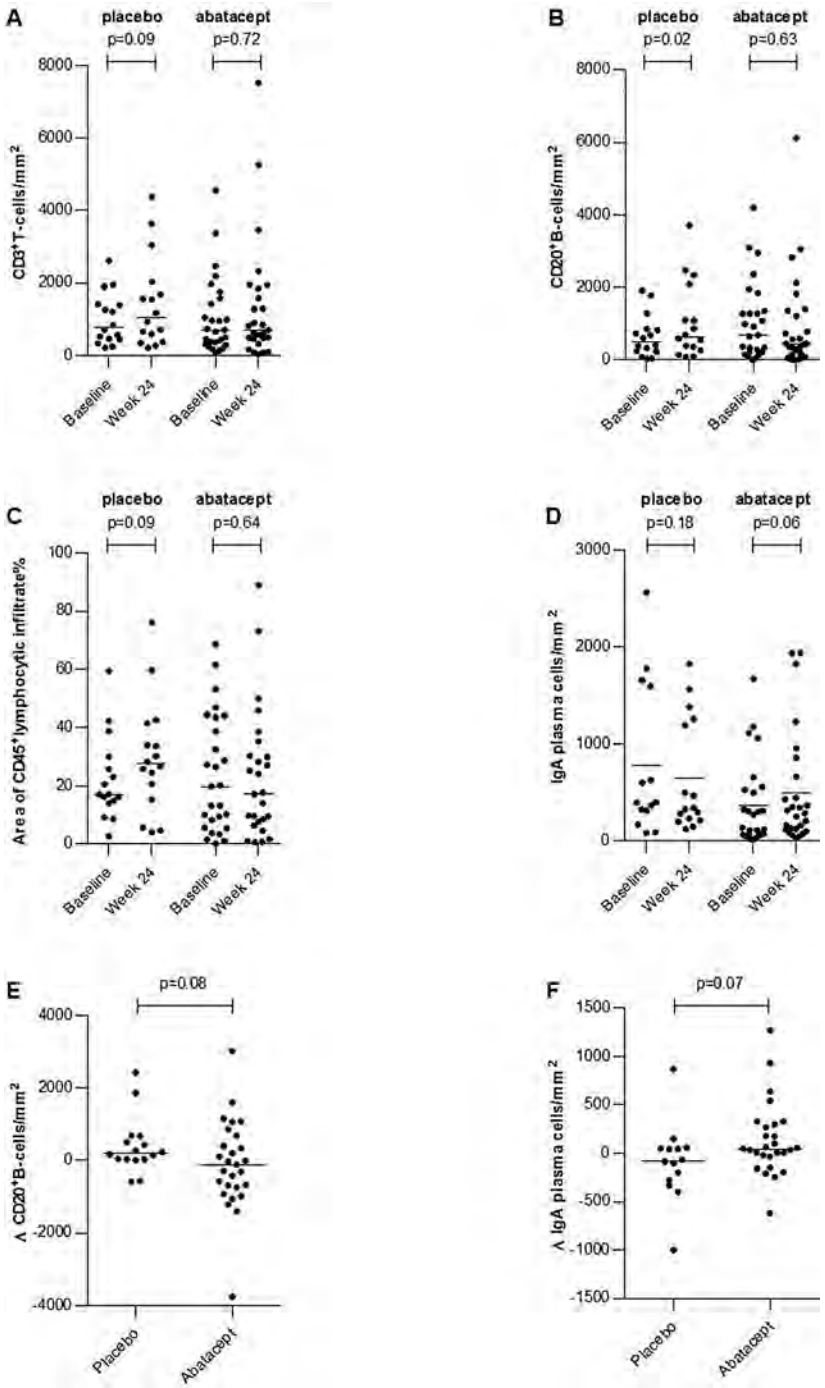

Figure 1. Histological analysis of parotid and labial salivary gland tissue of primary Sjögren's syndrome patients treated with placebo or abatacept. The number of CD3+T-cells (A), CD20+B-cells (B, E) and the relative area of CD45+infiltrates (C) increased in placebo treated patients, while numbers remained stable after treatment with abatacept. In contrast to patients treated with placebo, the number of IgA plasma cells/mm2 in salivary glandular tissue increased after 24 weeks abatacept treatment (D, F). Wilcoxon signed-rank test and McNemar's test were used to compare differences over time within groups. Mann-Whitney U test and Fisher's Exact test were used to compare differences between the abatacept and placebo groups. P-values <0.05 were considered statistically significant.

Table 1. Differences in histopathological characteristics in labial and parotid salivary glandular tissue on baseline in CRESS responders and non-responders

	CRESS responders (n=19)	CRESS non-responders (n=10)	P-value
Area of salivary gland section in mm²	5.00 (2.97-13.38)	4.79 (2.73-7.41)	0.60
Focus score	2.21 (1.44-7.35)	2.56 (1.49-4.94)	1.00
LELs/mm²	0 (0-0.32)	0.19 (0-0.51)	0.46
FDC-networks/mm²	0.35 (0-0.55)	0.20 (0-0.55)	0.80
GCs/mm²	0 (0-0.27)	0 (0-0)	0.29
CD3⁺cells/mm²	500 (296-1432)	745 (420-746)	0.48
CD20⁺cells/mm²	360 (130-1845)	956 (227-1277)	0.80
CD3/CD20 segregation, n(%)	12 (63.0)	5 (50.0)	0.39
CD45⁺cells (%)	13.2 (8.3-44.1)	20.0 (5.2-34.2)	0.95
IgA/IgG plasma cell shift, n(%)	12 (63.0)	9 (90.0)	0.14
IgA plasma cells/mm²	135 (66-661)	306 (64-451)	0.98
IgG plasma cells/mm²	278 (38-723)	156 (81-292)	0.60
IgM plasma cells/mm²	134 (6-155)	117 (3-593)	0.57

Abbreviations: LEL, lymphoepithelial lesion; FDC, follicular dendritic cell; GC, germinal center. Data are presented as median (IQR) or n(%). Mann-Whitney U test and Fisher's Exact test were used to compare differences between CRESS responders and non-responders. P-values <0.05 were considered statistically significant.

Background/Purpose: In a previous open-label phase II study, we showed that abatacept treatment might inhibit local formation of autoreactive memory B cells in parotid glands of primary Sjögren's syndrome (pSS) patients by affecting germinal center (GC) formation, a process dependent on co-stimulation by activated follicular-helper-T-cells[1]. However, limitations of that study were small number of patients, restriction to parotid gland tissue and lack of a placebo group. Therefore the aim of this study was 1) assess the effect of abatacept in pSS patients based on analysis of parotid and labial gland biopsies, and 2) assess the prognostic value of histological characteristics of salivary glandular tissue with regard to responsiveness to abatacept treatment using the newly developed Composite of Relevant Endpoints for Sjogren's Syndrome (CRESS)[2].

Methods: Patients from the Active Sjögren Abatacept Pilot (ASAP II, and ASAP III) and the international (IM101603) trial[3,4] were combined in whom a labial (n=13) or parotid (n=30) salivary gland biopsy was obtained at baseline and after 24 weeks of treatment. Patients received either abatacept (n=27) or placebo (n=16) treatment. After salivary gland biopsies were processed, sections were stained with H&E and immunohistochemically for CD3, CD20, CD45, CD21, Bcl6, IgA/IgG, IgA, IgG and IgM. All sections were evaluated for focus score (FS), GCs, number of lymphoepithelial lesions (LELs) per mm² and their maximal severity, presence of B/T-cell segregation within a focus, follicular dendritic cell (FDC) networks and presence of an IgA/IgG shift. Digital image analysis was used to assess the relative amount of CD45⁺lymphocytic infiltrates and the numbers of CD3⁺T cells, CD20⁺B cells and plasma cell density per mm². Histopathological data at baseline were compared between CRESS responders (n=19) (response to ≥3 of the 5 items) and non-responders (n=10) to abatacept treatment[2].

Results: In parotid and labial glandular sections, the number of $CD20^+$B cells/mm^2 increased significantly in placebo-treated patients (p=0.02), while counts remained stable in patients treated with abatacept. A similar trend was observed in the placebo group for $CD3^+$T cells (p=0.09) and the relative area of $CD45^+$infiltrate (p=0.09). The number of IgA plasma cells/mm^2 increased after 24 weeks of abatacept treatment (p=0.06) (figure 1). No significant decrease in GCs/mm^2 was observed in abatacept-treated pSS patients. Abatacept did not reduce FS, LELs/mm^2, presence of B/T-cell segregation, presence of IgA/IgG shift, nor number of IgG and IgM plasma cells/mm^2. No significant differences in histopathological parameters were found between CRESS responders and non-responders (table 1).

Conclusion: Abatacept potentially inhibits further progression of salivary gland inflammation by preventing further increase in T cell dependent B cell hyperactivity. Salivary gland histopathology could not predict responsiveness to abatacept in pSS patients.

SESSION INFORMATION
Session Date: Saturday, November 6, 2021
Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster I: Diagnosis (0323–0356)
Session Type: Poster Session A
Session Time: 8:30AM–10:30AM

Background/Purpose: Antibodies to Ro60 (SSA) or Ro52 (SSB) have been described as one of the defining autoantibodies in Sjogren syndrome but they are also commonly observed in patients with systemic lupus erythematosus (SLE). Sjogren syndrome and SLE frequently coexist and share common pathogenesis and clinical features. We aim to examine the clinical significance of Ro positivity in an Australian SLE cohort.

Methods: Patients from the Australian Lupus Registry and Biobank, all fulfilling SLE classification criteria, were studied according to their baseline anti-Ro positivity status (either Ro60 or Ro52 or both). Comparison between Ro+ve and Ro-ve patients was made using descriptive statistics. Clinical associations of Ro positivity with patient and disease characteristics were studied using logistic regression.

Table 1. Association of anti-Ro positivity with common SLE complications

SLE Complications	Anti-Ro Positivity			Evidence of Association^ OR (95% CI; p-value)
	Total Sample (n = 393)	Ro Negative (n=208)	Ro Positive (n=185)	
Outcomes				
Adjusted mean SLEDAI > 4	113 (28.8%)	46 (22.1%)	67 (36.2%)	**1.95 (1.25 - 3.06; 0.003)**
Annual mild/moderate Flare Rate ≥ 1	86 (21.9%)	40 (19.2%)	46 (24.9%)	1.36 (0.84 - 2.20; 0.216)

^Reference category is the group of patients not experiencing the SLE complication

[P]Includes exposure to proteinuria, lupus nephritis, urinary casts, haematuria or pyruria convention to use symbols rather than numbers for footnotes

[~]Includes exposure to seizure, psychosis, delirium, peripheral neuropathy, CNS, cranial nerve disorder, lupus headache or stroke

[&]Includes exposure to Azathioprine, Ciclosporin, Cyclophosphamide, Leflunomide, Methotrexate, Mycophenolate, Tacrolimus, Chloroquine, Mercaptopurine, Sulfasalazine, Rituximad or Belimumab

[†]Includes exposure to Citalopram , Desvenlafaxine, Duloxetine, Escitalopram, Fluoxetine, Mirtazapine, Sertraline or Venlafaxine

* Includes exposure to Buprenorphine, Codeine, Fentanyl Patch, Oxycodone, Oxycodone, Naloxone, Paracetamol or Tramadol

Results: 393 patients were studied; 47.1% have positive anti-Ro status. Ro+ patients were more likely to be non-Caucasians (Asian OR 2.92, 95% CI 1.88-4.54, p< 0.001), and have significant association with positive serology other than the well-recognised association with anti-La (SSB) and rheumatoid factor, including positivity to anti-dsDNA and hypocomplementemia. There were no association with positive antiphospholipid antibodies. Ro positive SLE patients were more likely to have High Disease Activity Status (HDAS) (OR 1.68, 95% CI 1.12-2.52, p=0.012) and increased likelihood of high adjusted mean SLEDAI (greater than 4) (OR 1.95, 1.25-3.06, p=0.003). Interestingly there was no difference in damage accrual between the two groups.

25.8% of the Ro positive cohort have associated sicca symptoms that may qualify them for diagnosis of Sjogren syndrome. Consistent with the observation that their overall disease activity is higher, Ro+ SLE patients are more likely to have to have malar or discoid rash (OR 1.68, 95%CI 1- 2.82, p=0.048), haematological manifestation (OR 1.79, 95% CI 1.16-2.76, p=0.009), renal disease (OR for proteinuria was 1.98, 95% CI 1.33-2.97, p=0.0010) (See table 1). Maximum urine proteinuria creatinine ratio was higher in Ro+ve SLE patients (p< 0.001). The minimum lymphocyte and neutrophil counts were also significantly lower in Ro+ve SLE patients (p=0.004 and p=0.001 respectively). Sjogren features such as parotitis, leucocytoclastic vasculitis, interstitial lung disease, and interstitial cystitis were seen in this lupus cohort but did not occur frequently enough to show a difference between Ro+ve and Ro-ve groups. Hypergammaglobulinemia occurred significantly more frequently (OR 1.77, 1.00 -3.16, p-0.05).

Ro+ patients were more likely to be treated with prednisolone (OR 1.94, 1.19-3.15, p=0.007) and immunosuppressants (OR 1.94, 1.22-3.08, p=0.005).

Table 2. Association of patient characteristics with anti-Ro positivity

Patient Characteristics	Anti-Ro Positivity			Evidence of Association^ OR (95% CI; p- value)
	Total Sample (n = 395)	Ro Negative (n=209)	Ro Positive (n=186)	
Female sex	341 (86.8%)	175 (84.1%)	166 (89.7%)	1.65 (0.90 - 3.01; 0.105)
Ethnicity

Anti-Jo1+	4 (1.0%)	0 (0.0%)	4 (2.2%)	0.14 (0.54 - 189.64; 0.121)

^Where reference category not specified, the reference category is the absence of the patient characteristic listed in the Table above.

Table 3. Association of anti-Ro positivity with Sjogren syndrome complications

Sjogren Complications	Anti-Ro Positivity			Evidence of Association^ (p- value)
	Total Sample (n = 393)	Ro Negative (n=208)	Ro Positive (n=185)	
Fatigue	119 (30.3%)	61 (29.3%)	58 (31.4%)	0.69
Reflux	90 (22.9%)	46 (22.1%)	44 (23.8%)	0.69
Hypergammaglobulinemia	74 (18.8%)	29 (13.9%)	45 (24.3%)	**0.05**
16 - 20	39 (9.9%)	15 (7.2%)	24 (13.0%)	0.13
> 20	33 (8.4%)	13 (6.3%)	20 (10.8%)	0.22
Fibromyalgia	53 (13.5%)	32 (15.4%)	21 (11.4%)	0.24
Lymphadenopathy	48 (12.2%)	25 (12.0%)	23 (12.4%)	0.90
Autoimmune haemolysis	37 (9.4%)	20 (9.6%)	17 (9.2%)	0.89
Leucocytoclastic vasculitis	27 (6.9%)	13 (6.3%)	14 (7.6%)	0.61
Interstitial lung disease	20 (5.1%)	10 (4.8%)	10 (5.4%)	0.79
Myositis	14 (3.6%)	9 (4.3%)	5 (2.7%)	0.43
Gastrointestinal dysmotility (excluding reflux)	7 (1.8%)	5 (2.4%)	2 (1.1%)	0.45
Parotitis	6 (1.5%)	1 (0.5%)	5 (2.7%)	0.10
B cell lymphoma	5 (1.3%)	3 (1.4%)	2 (1.1%)	1
Renal tubular acidosis	2 (0.5%)	0 (0.0%)	2 (1.1%)	0.22
Interstitial cystitis	1 (0.3%)	0 (0.0%)	1 (0.5%)	0.47

^Where reference category not specified, the reference category is the absence of the patient characteristic listed in the Table above.

Conclusion: Ro positivity is seen frequently in SLE patients. Overlapping lupus and Sjogren features are seen in many patients, and Ro positivity can be used as a biomarker to denote a more severe disease phenotype.

Abstract Number: 0324

Machine Learning: Identifying Lupus Nephritis Within Systemic Lupus Erythematosus in the Real World

Bruno Teixeira, David Bell, Tim Holbrook and Ben Hoskin, Adelphi Real World, Bollington, United Kingdom

SESSION INFORMATION
Session Date: Saturday, November 6, 2021
Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster I: Diagnosis (0323–0356)
Session Type: Poster Session A
Session Time: 8:30AM–10:30AM

Background/Purpose: Around 40-70% of patients with systemic lupus erythematosus (SLE) develop lupus nephritis (LN). LN is often underdiagnosed and early diagnosis is crucial for reducing kidney damage. Various tests can diagnose LN including kidney biopsy, but LN symptoms can vary greatly between patients making diagnosis challenging especially in the early stages. We aimed to develop a machine learning (ML)-based approach to classify SLE patients at high risk of LN to assist rheumatologists in their diagnosis.

Methods: Data were drawn from the Adelphi Lupus Disease Specific programme™, a point-in-time survey of rheumatologists and nephrologists and their SLE/LN patients conducted in France, Germany, Italy, Spain, the United Kingdom and the United States of America from Aug–Oct 2015. Rheumatologists and nephrologists each completed record forms for their next 5 consecutive adult SLE and LN patients, respectively, capturing demographic and clinical characteristics. Patients were categorized as LN or non-LN based on physicians' assessment.

We subset data for training and testing the ML model, selecting 354 variables (from a total of 30 record form questions) based on specialist knowledge of LN pathophysiology. To ensure maximum discriminative power, the training set comprised all nephrologist-diagnosed patient and 70% rheumatologist-diagnosed patient data; the testing set comprised the remaining 30% rheumatologist-diagnosed patient data. Training and hyperparameter tuning were done using 10-fold cross-validation with R and Tidymodels Package. Model predictive performance was assessed by receiver operating characteristic area under the curve (AUC) metric.

Results: The model used data collected by 304 physicians on 1,209 SLE patients including both LN (n=483) and non-LN (n=726) patients (Fig. 1). After testing 2,520 models using the 6 most commonly used classification algorithms we found that the penalized logistic regression (PLR) with elastic net regularization predicted which SLE patients were at highest risk of LN (AUC: 0.91, with negative/positive predictive values of 0.96 and 0.68, respectively) in the testing set. The 3 variables that best predicted LN risk were disease progression, skin problems (both contributing negatively to risk) and musculoskeletal organs affected at diagnosis (with a positive contribution to risk, Fig. 2).

Conclusion: PLR successfully predicted SLE patients' LN risk using real-world data. Although linear discriminant analysis had a slightly better AUC (0.92), PLR results are easier to interpret, making it a suitable model to support rheumatologists identifying LN patients within the SLE population to guide further testing and treatment.

The PLR model had better discriminative power in non-LN vs LN patients. This may have resulted from undiagnosed LN patients remaining within the non-LN patient pool and thus generating false positives, since these high LN risk non-LN patients shared a number of characteristics with LN patients (Fig. 3).

Predictive analysis has shown promising results for LN risk assessment in SLE patients using real-world data, we recommend further prospective validation is required prior to use in a clinical setting.

Abstract Number: 0325

A Multianalyte Assay Panel with Cell-bound Complement Activation Products Demonstrates Clinical Utility for the Diagnosis and Treatment of Systemic Lupus Erythematosus

Roberta Alexander[1], Scott Rey[1], John Conklin[1], Vinicius Domingues[2], Mansoor Ahmed[3], Jazibeh Qureshi[4] and Arthur Weinstein[5], [1]Exagen Inc., Vista, CA, [2]Florida State university, Daytona beach, FL, [3]Arthritis Osteo Ctr of KY, Richmond, KY, [4]Rheumatology Express, Catonsville, MD, [5]Loma Linda University (Voluntary Position), Claremont, CA

SESSION INFORMATION

Session Date: Saturday, November 6, 2021
Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster I: Diagnosis (0323–0356)
Session Type: Poster Session A
Session Time: 8:30AM–10:30AM

Background/Purpose: The multianalyte assay panel (MAP) consists of cell-bound complement activation products (CB-CAPs) with lupus and non-lupus autoantibodies combined in an algorithm (Dervieux et al., *J Immunol Methods* 2017). The test is intended for patients suspected of systemic lupus erythematosus (SLE) to aid the diagnosis. We demonstrated previously that *t*he MAP has clinical utility, as it facilitates SLE diagnosis and treatment decisions (Wallace *et al., Lupus Sci & Med 2019)*. As the number of patients with a positive MAP in that study was small, the present study was conducted to enrich the population of the MAP positive patients and to generate additional data on the clinical utility of MAP.

Methods: Systematic multicenter retrospective review of medical charts was conducted at 12 rheumatology practices in the United States. Adult patients for chart review were selected by Exagen based on the MAP score. To decrease the risk of bias, sets of 5 possible eligible patients were identified for each site. Each set included 2 negative (< -0.1) and 3 positive (> 0.1): tier-1 positive [MAP(Tier1+)]; tier-2 score > 1 [MAP(High+)]; tier-2 > 0.1 and ≤ 1 [MAP(Low+)]). The cutoff of 1 was based on the likelihood ratio positive of the test. Charts were reviewed at T0 (when the MAP was ordered), T1 (when the results were reviewed) and, if available, T2 (latest visit ≥8 months after T1). Statistical analysis (R) consisted of Kaplan-Meier survival analysis with Cox proportional hazard model and ordered logistic regression, as appropriate.

Results: T0 and T1 were performed for 161 patients. All sites but one reviewed charts as multiples of 5 (5 - 25 patients per site). Charts were reviewed also at T2 for a subset of 90 patients (56%). At T0, physician confidence in SLE diagnosis was low for 93 (58%), moderate for 49 (30%), and high for 19 (12%) patients. Odds of higher confidence in SLE diagnosis increased during the study by 1.74-fold for every unit of increase of the MAP score (p< 0.001). The lupus ICD-10 section (M32) was used as a proxy for diagnosis. Positive MAP led to increased assignment of an SLE code by Cox proportional hazard model (Figure 1). In particular, M32 was assigned to 22 of 65 (34%) MAP positive patients who were anti-dsDNA negative. In addition, MAP negative was superior to anti-dsDNA negative at excluding of an SLE code, as more anti-dsDNA negative than MAP negative patients were at risk of M32 assignment (63% vs 52%) (Figure 1B). Only 3 of the 63 MAP negative patients (5%) were assigned a lupus ICD-10 code during the study, indicating a 95% probability of excluding the SLE diagnosis in MAP negative patients. We also evaluated the use of hydroxychloroquine (HCQ) during the study in the 126 patients who were prescribed HCQ after T0. Kaplan-Meier

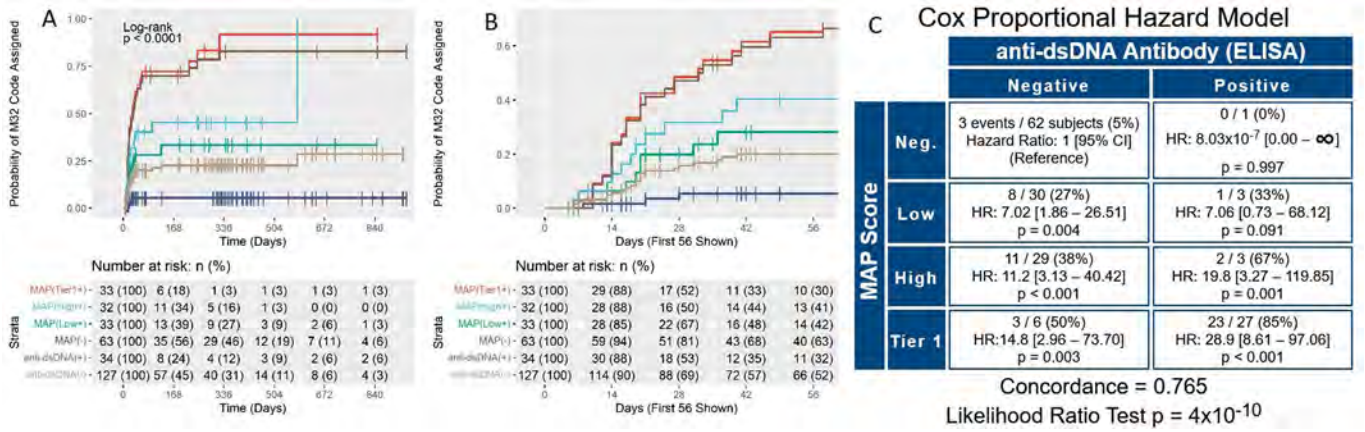

Figure 1. Panels A and B. Kaplan-Meier time-to-event curves for assignment of the M32 ICD-10 section over time. Curves show the percent probability of being assigned the M32 section after T0 for the 4 study groups : tier-1 (MAP(Tier1+)), high tier-2 (MAP(High+)), low tier-2 (MAP(Low+)) negative (MAP(-)), in addition to anti-dsDNA positive (anti-dsDNA(+)) and negative (anti-dsDNA(-)) patients throughout the study. The X-axis reports the number of days since T0. Panels A and B report the same data analysis, with panel B allowing better visualization of the initial portion of the survival curves. Panel C. Cox proportional hazard model comparing the MAP test score (Neg.: negative; Low: low tier-2; High: high tier-2, Tier 1: tier-1 positive) vs. anti-dsDNA antibodies for assignment of the M32 section. In each quadrant, the numerators represent the number of subjects that developed an M32 section after T0 (events, n=51 in total) while the denominators represent all subjects in that quadrant. Concordance and p value of the likelihood ratio test are also reported. For data analysis, we used the date of the visit when the M32 section was recorded in the ICD-10 list.

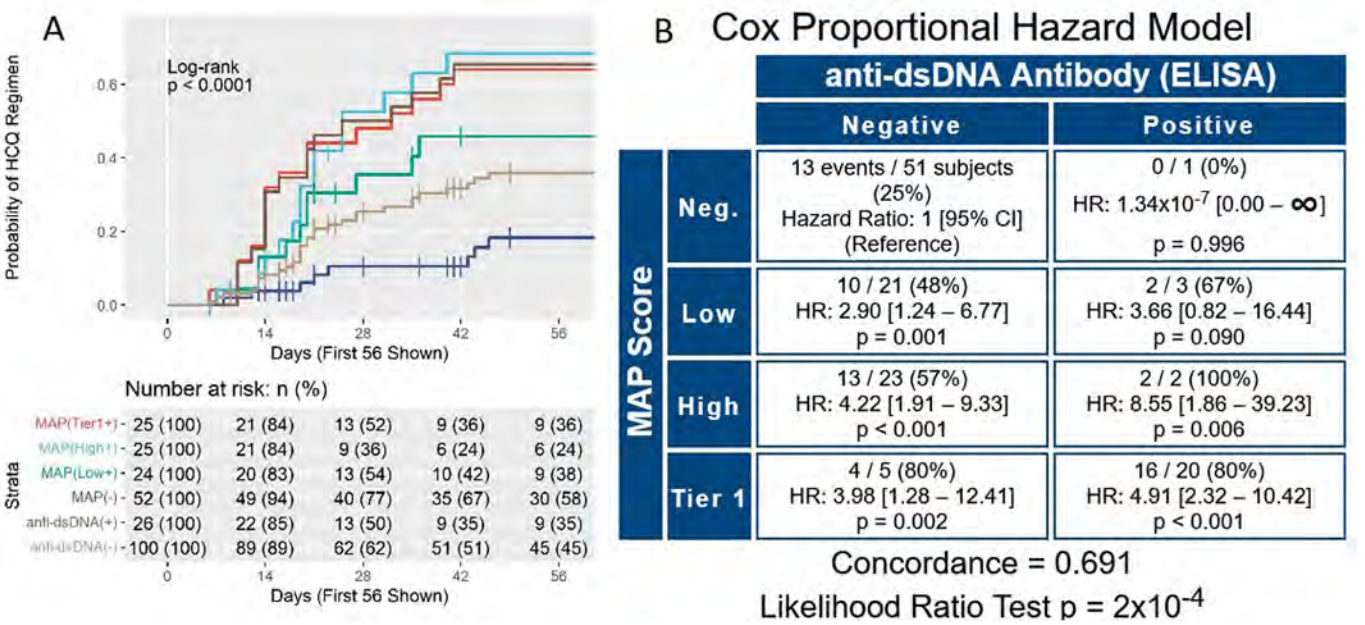

Figure 2. Panel A. Kaplan-Meier time-to-event curves for use of HCQ over time. Curves show the percent probability of using HCQ after T0 for the 4 study groups: tier-1 (MAP(Tier1+)), high tier-2 (MAP(High+)), low tier-2 (MAP(Low+)) negative (MAP(-)), in addition to anti-dsDNA positive (anti-dsDNA(+)) and negative (anti-dsDNA(-)) patients throughout the study. The X-axis reports the number of days since T0 and was truncated at 56 days to allow better visualization of the initial portion of the survival curves. Panel B. Cox proportional hazard model comparing the MAP score (Neg.: negative; Low: low tier-2; High: high tier-2, Tier 1: tier-1 positive) vs. anti-dsDNA antibodies for use of HCQ. In each quadrant, the numerators represent the number of subjects on HCQ after T0 (events, n=60 in total) while the denominators represent all subjects in that quadrant. Concordance and p value of the likelihood ratio test are also reported. For data analysis, we used the date of the visit when HCQ use was recorded in the medication list.

curves and hazard ratios for initiation of HCQ show that MAP positivity led to HCQ treatment, and that MAP negative was superior to anti-dsDNA negative in avoiding HCQ prescription (58% vs. 45%) (Figure 2).

Conclusion: This study demonstrates that the MAP helps to both diagnose and exclude SLE in patients suspected of the disease and, importantly, informs appropriate treatment decisions in this patient population.

Apolipoprotein L1 (APOL1) in African-American SLE: Frequency and Clinical Associations

Michelle Petri[1], Romy Kallas[2], Jessica Li[3], Laurence Magder[4] and Daniel Goldman[1], [1]Johns Hopkins University School of Medicine, Baltimore, MD, [2]Lankenau Medical Center, Lankenau, PA, [3]Johns Hopkins University, Baltimore, MD, [4]University of Maryland, Baltimore, Baltimore, MD

SESSION INFORMATION

Session Date: Saturday, November 6, 2021
Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster I: Diagnosis (0323–0356)
Session Type: Poster Session A
Session Time: 8:30AM–10:30AM

Background/Purpose: The APOL1 gene is implicated in induction of TLR3 agonists and interferons as well as in autophagy. Two genetic variants, G1 (2 single nucleotide polymorphisms) and G2 (6 base pair deletion) have been selected evolutionarily as protective against Trypanosoma. These APOL1 high risk allelles are associated with progression to end stage renal disease (ESRD), including lupus nephritis, and in one study with avascular necrosis in SLE. We examined the association of APOL1 in ESRD, avascular necrosis, atherosclerotic events and pulmonary fibrosis in African-American SLE.

Methods: APOL1 G1 (rs73885319 and rs60910145) and G2 (rs71785313) genetic variants were genotyped in 294 SLE African American patients in the Hopkins Cohort using TaqMan assays (Thermofisher Scientific, Waltham MA). APOL1 variants were classified as G1/G1 homozygous (in our dataset, G/G), G2/G2 homozygous (-/-), compound heterozygous G1/G2 (G/T or A/G AND TTATAA/-), G0/G1 heterozygous (G/T or A/G), or G0/G2 heterozygous (TTATAA/-). Based on the variants, patients were stratified into groups with 0, 1, or 2 risk alleles. To address the association between APOL1 group and the three outcomes, we used Kaplan Meier approach to estimate the distribution of time to outcomes from date of birth and log-rank test to compute the p-value. Cox regression was used to estimate the hazard ratio and adjust the relationships. The follow up for each patient ended at the patient's last cohort visit, or at the time of their first event.

Results: 294 African American patients were included in the analysis. 275 (93.5%) were female. The frequency of two copies of the APOL1 risk allele was 12.2% (Table 1). There was a higher proportion of patients with smoking history in the group with 2 risk alleles compared to the low risk groups (Table 2). There was an association with ESRD, but not with AVN, pulmonary fibrosis or cardiovascular events (Table 3).

Conclusion: Our study showed a significantly higher risk of progression to renal failure/ESRD among those with at least one risk allele, with a hazard ratio of 3.50 (p=0.0234 after adjusting for sex, ever smoking and hypertension).

Table 1. Frequency of the alleles and genotypes of APOL1

		Distribution of events	
	n (%)	AVN	Renal failure/ESRD
APOL1 alleles			
0 risk alleles	120 (40.8%)	23 (19.2%)	4 (3.3%)
1 risk allele	138 (46.9%)	25 (18.1%)	17 (12.3%)
2 risk alleles	36 (12.2%)	7 (19.4%)	3 (8.3%)
Genotype			
G0/G0	120 (40.8%)	23 (19.2%)	4 (3.3%)
G0/G1	89 (30.3%)	16 (18.0%)	8 (9.0%)
G0/G2	49 (16.7%)	9 (18.4%)	9 18.4%)
G1/G1	15 (5.1%)	4 (26.7%)	1 (6.7%)
G1/G2	16 (5.4%)	3 (18.8%)	2 (12.5%)
G2/G2	5 (1.7%)	0	0

Table 2. Patient characteristics based on APOL1 genotype

Characteristics	*0 APOL1 risk alleles n=120*	*1 APOL1 risk allele n=138*	*2 APOL1 risk alleles n=36*	*p-value*
Female sex	113 (94.2%)	128 (92.8%)	34 (94.4%)	0.8747
Age at diagnosis	31.6 (10.9)	31.0 (12.6)	28.1 (12.2)	0.3067
Duration of SLE at last follow up	19.8 (8.4)	18.9 (11.8)	21.9 (12.1)	0.3355
Less than or equivalent of high school graduate (<=12yrs)	46 (38.3%)	48 (35%)	15 (41.7%)	0.7233
Family income				
<$30,000	52 (44.8%)	53 (39%)	18 (51.4%)	0.5300
$30,000-<$65,000	32 (27.6%)	42 (30.9%)	11 (31.4%)	
>=$65,000	32 (27.6%)	41 (30.2%)	6 (17.1%)	
Smoking history, ever	39 (32.8%)	38 (27.7%)	18 (51.4%)	0.0285
History of hypertension	76 (63.3%)	93 (67.4%)	24 (66.7%)	0.7836
History of diabetes	16 (13.3%)	10 (7.3%)	4 (11.1%)	0.2682

Table 3. Relationships between events and APOL1 risk alleles (>=1 vs. 0)

	Unadjusted		Adjusted	
	HR (95% CI)	p-value	HR (95% CI)	p-value
Renal insufficiency	1.35 (0.93, 1.96)	0.1166	1.27 (0.87, 1.85)[2]	0.2087[2]
Renal failure/ESRD	3.65 (1.25, 1.069)	0.0181	3.50 (1.19, 10.32)[2]	0.0234[2]
AVN	0.98 (0.57, 1.68)	0.9423	0.80 (0.46, 1.39)[3]	0.4252[3]
Atherosclerotic events	1.17 (0.65, 2.10)	0.6117	1.20 (0.65, 2.20)[4]	0.5598[4]
Pulmonary fibrosis	1.01 (0.56, 1.82)	0.9679	1.05 (0.58, 1.90)[2]	0.8646[2]
[2]adjusted for sex, smoking history and hypertension [3]adjusted for sex, smoking history and highest prednisone dose [4]adjusted for sex, smoking history, hypertension, high cholesterol, obesity				

We did not find an association between APOL1 risk alleles and avascular necrosis/ atherosclerotic events/pulmonary fibrosis. Our analysis included adjustment for smoking, as it is a risk factor for all the outcomes, and included larger numbers of African-American patients and outcomes than previous studies.

Session Date: Saturday, November 6, 2021
Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster I: Diagnosis (0323–0356)
Session Type: Poster Session A
Session Time: 8:30AM–10:30AM

Background/Purpose: Lipoprotein(a) [Lp(a)] is a well-recognized, independent risk factor for atherosclerotic cardiovascular disease. Cardiovascular disease is one of the leading causes of death in patients with systemic lupus erythematosus (SLE). Indeed, women with lupus have 2.66 times increased risk compared to controls, with both

SLE-specific and traditional cardiovascular risk factors playing a role. In this cross-sectional study, we evaluated Lp(a) levels in patients with SLE and evaluated for an association between atherosclerotic events, thrombotic events, renal disease, and disease activity.

Methods: SLE patients fulfilling the revised American College of Rheumatology (ACR) or SLICC classification criteria with a measurement of Lp(a) were included in the analysis. A cutoff of 125 nmol/L was chosen based on expert

Table 2. Associations between events and Lp(a). Lp(a) levels were grouped into <125 and >=125nmol/L

Outcomes	<125 (n=279)	>=125 (n=96)	adjusted estimate (95% CI)[1]	adjusted p-value[1]
Events (ever)				
Any atherosclerotic events	52(18.6%)	13(13.5%)	0.74 (0.37, 1.49)	0.3997
Any cardiovascular events	47(16.8%)	13(13.5%)	0.82 (0.4, 1.66)	0.584
MI	11(3.9%)	3(3.1%)	0.82 (0.21, 3.22)	0.7781
CVA	26(9.3%)	5(5.2%)	0.61 (0.22, 1.7)	0.3462
Angina or Coronary artery bypass grafting	13(4.7%)	6(6.4%)	1.95 (0.65, 5.87)	0.2354
Cardiomyopathy	6(2.2%)	3(3.2%)	1.09 (0.25, 4.68)	0.9072
PAD (claudication, tissue loss)	7(2.5%)	1(1.1%)	0.55 (0.06, 4.8)	0.5856
Any thrombosis (venous or arterial)	73(26.2%)	22(22.9%)	0.75 (0.42, 1.33)	0.3231
Any venous thrombosis	46(16.5%)	16(16.7%)	0.78 (0.4, 1.53)	0.4684
DVT	42(15.1%)	14(14.6%)	0.66 (0.33, 1.36)	0.2619
Proteinuria (history)	126(45.2%)	61(63.5%)	1.78 (1.07, 2.97)	0.0267
Avascular necrosis	21(7.5%)	9(9.4%)	0.84 (0.35, 2.01)	0.6947
Clinical measures at the visit				
PGA, mean (SD)	0.61 (0.62)	0.87 (0.71)	0.19 (0.03, 0.35)[2]	0.0224[2]
UPCR>=500	30 (11.1%)	19 (21.1%)	1.69 (0.84, 3.37)	0.1392
EGFR<60	50 (18.1%)	27 (28.1%)	1.92 (1.05, 3.54)	0.0349

[1]OR (95% CI)/mean estimate (95% CI) and p-values were adjusted for age, sex, and race
[2]mean estimate calculated from linear regression, others are odds ratios
Abbreviations: PGA=physician's global assessment, UPCR=Urine protein to creatinine ratio

opinion. Chi-square test was used to compare the differences between patient characteristics, including traditional and disease specific cardiovascular risk factors, and Lp(a) levels. Logistic regression or linear regression were used, where appropriate, to assess the association between Lp(a) values and the measured outcomes.

Results: 389 measurements of Lp(a), contributed from 375 patients were analyzed; 12 patients had 2 measurements and 1 had 3 measurements. Of these patients, 90% were female, 42% African American, and 47% Caucasian. The distribution of Lp(a) was heavily right skewed; values ranged from 8 to 671 nmol/L with a mean of 94 and median of 47nmol/L. Men, African American patients, patients with history of hypertension and hypercholesterolemia were more likely to have Lp(a) levels >=125 nmol/L. Patients with a history of diabetes were less likely to have levels >=125 nmol/L (Table 1).

In this study, we did not observe an association between Lp(a) and atherosclerotic or thrombotic events. There was an association between elevated Lp(a) level and a history of proteinuria (OR 1.78, p-value=0.026). This association remained significant following adjustment for age, sex, race, low C3, and elevated anti-dsDNA (OR=1.74, p-value=0.0498). There was also an association with eGFR< 60 (p=0.03). Patients with higher Lp(a) levels also had higher physician global activity (p=0.02).

Conclusion: Consistent with the general population, Lp(a) levels skewed toward lower values in patients with SLE. There was not an association between Lp(a) and atherosclerotic or thrombotic events, but this may have been limited due to small sample size. Elevated levels of Lp(a) were associated with proteinuria, reduced eGFR and physician global activity, with an inverse association observed with type 2 diabetes mellitus. An increase in Lp(a) concentrations has previously reported in non-SLE renal disease even prior to reduction in eGFR. The role of Lp(a) as a potential biomarker for early renal disease and poor renal outcomes in SLE warrants further evaluation with consideration for more granular subphenotyping.

Natural Language Processing to Identify Lupus Nephritis Phenotype in Electronic Health Records

Yu Deng[1], Jennifer Pacheco[1], Anh Chung[1], Chengsheng Mao[1], Joshua Smith[2], juan zhao[1], Wei-Qi Wei[2], April Barnado[3], Chunhua Weng[4], Cong Liu[4], Adam Gordon[1], Jingzhi Yu[1], Yacob Tedla[1], Abel Kho[1], Rosalind Ramsey-Goldman[1], Theresa Walunas[1] and Yuan Luo[1], [1]Northwestern University, Chicago, IL, [2]Vanderbilt Universty Medical Center, Nashville, TN, [3]Vanderbilt University Medical Center, Nashville, TN, [4]Columbia University, New York, NY

SESSION INFORMATION
Session Date: Saturday, November 6, 2021
Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster I: Diagnosis (0323–0356)
Session Type: Poster Session A
Session Time: 8:30AM–10:30AM

Background/Purpose: Lupus nephritis (LN) is a major disease manifestation of Systemic lupus erythematosus (SLE) leading to organ damage and increased mortality. Accurately identifying lupus nephritis in electronic health records (EHRs), a key component of SLE classification criteria domain, would add value to observational studies and clinical trials. However, information related to LN, e.g., kidney biopsy findings are usually present in clinical notes, not as structured data. In this study, we developed algorithms to identify LN with and without natural language processing (NLP) using EHR data from the Northwestern Medicine Enterprise Data Warehouse (NMEDW). We hypothesize that NLP algorithms including information from the clinical notes will outperform the baseline algorithm using structured data only.

Methods: We identified 472 patients with SLE from the Chicago Lupus Database who also had at least four encounters in the NMEDW. We developed four algorithms: a rule-based algorithm using only structured data and three different NLP algorithms based on L2-regularized logistic regression. In the first NLP algorithm (Full-MetaMap-binary), we used the presence or absence of all the MetaMap extracted concept unique identifiers (CUIs) as features. In the second NLP algorithm (Full-MetaMap-count), we used the same CUIs as features but their number of occurrences as the feature value. In the third NLP algorithm (MetaMap-mixed), we used a mixture of features from structured data, regular expression (regex) concepts, and a curated list of CUIs related to LN. We evaluated all four algorithms in an

internal validation dataset based on F-measure, sensitivity, specificity, positive predictive value (PPV), and negative predictive value (NPV). We further validated the baseline algorithm and the best performed NLP algorithm on an external dataset from Vanderbilt University Medical Center (VUMC).

Results: In the NMEDW internal validation dataset, the Full-MetaMap-binary, Full-MetaMap-count, and MetaMap mixed model achieved F measures of 0.72, 0.71, 0.79, respectively, compared to the baseline model (F measure, 0.41) (see Table). In the external validation dataset, our best performing NLP model (MetaMap mixed model) improved F measure (0.62 vs 0.96) compared to the structured data only algorithm.

Table 1. Algorithm performance

Dataset	Algorithm	Sensitivity	Specificity	PPV	NPV	F Measure
NMEDW (internal validation)	Baseline	0.43	0.6	0.39	0.64	0.41
NMEDW (internal validation)	Full-MetaMap-binary	0.63	0.93	0.85	0.81	0.72
NMEDW (internal validation)	Full-MetaMap-count	0.6	0.95	0.88	0.8	0.71
NMEDW (internal validation)	MetaMap-mixed	0.74	0.92	0.84	0.86	0.79
VUMC	Baseline	0.92	0.61	0.46	0.96	0.62
VUMC	MetaMap-mixed	1	0.97	0.93	1	0.96

Conclusion: We developed three NLP models and compared them to a structured data only algorithm to identify LN from EHR. The best performing NLP algorithm incorporating structured data, CUIs, and regex concepts improved the F-measure in both internal and external validation datasets. NLP algorithms can serve as powerful tools to accurately identify LN in EHR for clinical research.

Abstract Number: 0329

Racial and Ethnic Disparities in Risk of End-Organ Disease Following SLE Diagnosis in a Multi-Ethnic Cohort

ALFREDO AGUIRRE[1], Andrea Seet[1], Laura Trupin[2], Patricia Katz[1], Kamil Barbour[3], Cristina Lanata[4], Maria Dall'Era[5] and Jinoos Yazdany[1], [1]University of California San Francisco, San Francisco, CA, [2]UC San Francisco, San Francisco, CA, [3]Centers for Disease Control, Atlanta, GA, [4]University of California San Francisco, Moss Beach, CA, [5]University of California San Francisco, Corte Madera, CA

SESSION INFORMATION
Session Date: Saturday, November 6, 2021
Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster I: Diagnosis (0323–0356)
Session Type: Poster Session A
Session Time: 8:30AM–10:30AM

Background/Purpose: Racial and ethnic minorities experience a disproportionate burden of systemic lupus erythematosus (SLE) as well as earlier development of lupus manifestations as compared to White individuals. Data on onset of lupus symptoms across multiple organ domains and in Asian patients in the US is lacking. We analyzed racial/

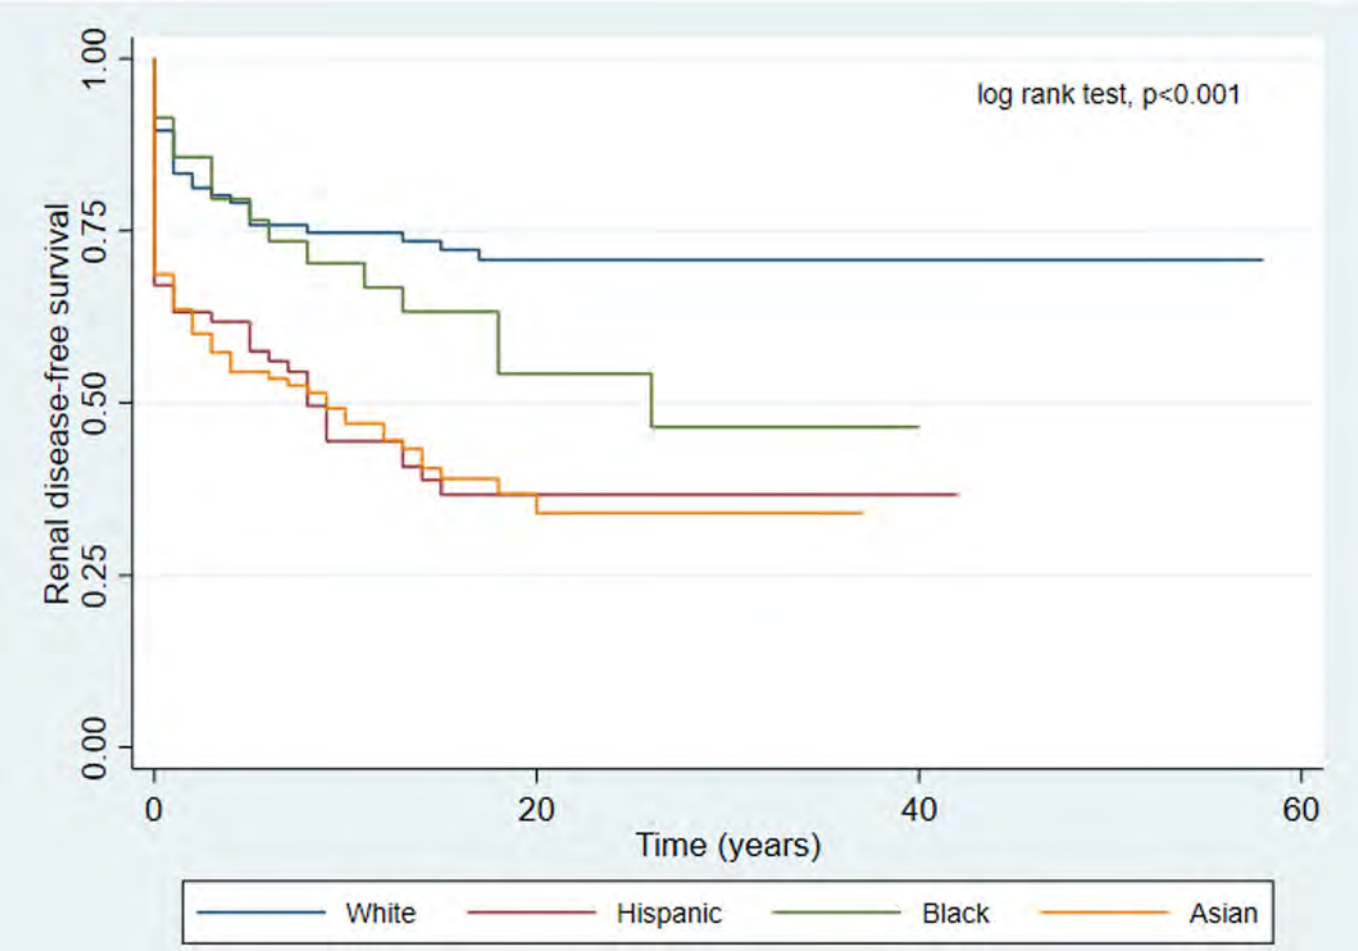

Figure 1. Kaplan-Meier curve depicting time to onset of renal disease by race/ethnicity.

ethnic differences in time to onset of renal, neuropsychiatric, hematologic, cardiovascular, and multiorgan disease following SLE diagnosis in a multi-ethnic cohort of patients.

Methods: The California Lupus Epidemiology Study (CLUES) is a longitudinal cohort of 431 individuals with SLE, of whom 332 participated in a baseline in-person study visit. Data on major end-organ manifestations including dates of onset were collected and confirmed by study rheumatologists. Manifestations of end-organ disease were categorized by organ system: renal (lupus nephritis), neuropsychiatric (seizure, stroke, mononeuritis multiplex, peripheral/cranial neuropathy, myelitis), hematologic (immune thrombocytopenic purpura, autoimmune hemolytic anemia, thrombotic thrombocytopenic purpura), and cardiovascular (heart failure, myocardial ischemia, cardiac arrythmia, Libman-Sacks endocarditis). Multiorgan disease was defined as manifestations in ≥2 of the above organ systems. Self-reported race/ethnicity was categorized as White, Hispanic, Black, and Asian. Kaplan-Meier methods and log-rank tests compared organ system-free survival following SLE diagnosis by race/ethnicity; participants who did not develop outcome of interest were censored at their CLUES study visit. Cox proportional hazard models assessed the risks of end-organ disease by race/ethnicity, with age at diagnosis and female sex as covariates.

Results: CLUES participants are 89% female and have a mean age and age at diagnosis of 45 and 29 years, respectively. The distribution of self-reported race/ethnicity was as follows: 29% White, 23% Hispanic, 11% Black, and 36% Asian. Renal, neuropsychiatric, hematologic, cardiovascular, and multiorgan disease was confirmed in 154 (46%), 53 (16%), 62 (19%), 30 (9%), and 79 (24%) subjects, respectively. The median time to development of multiorgan disease was 9.5, 5, 8, and 3.5 years for White, Hispanic, Black and Asian subjects, respectively. Race/ethnicity

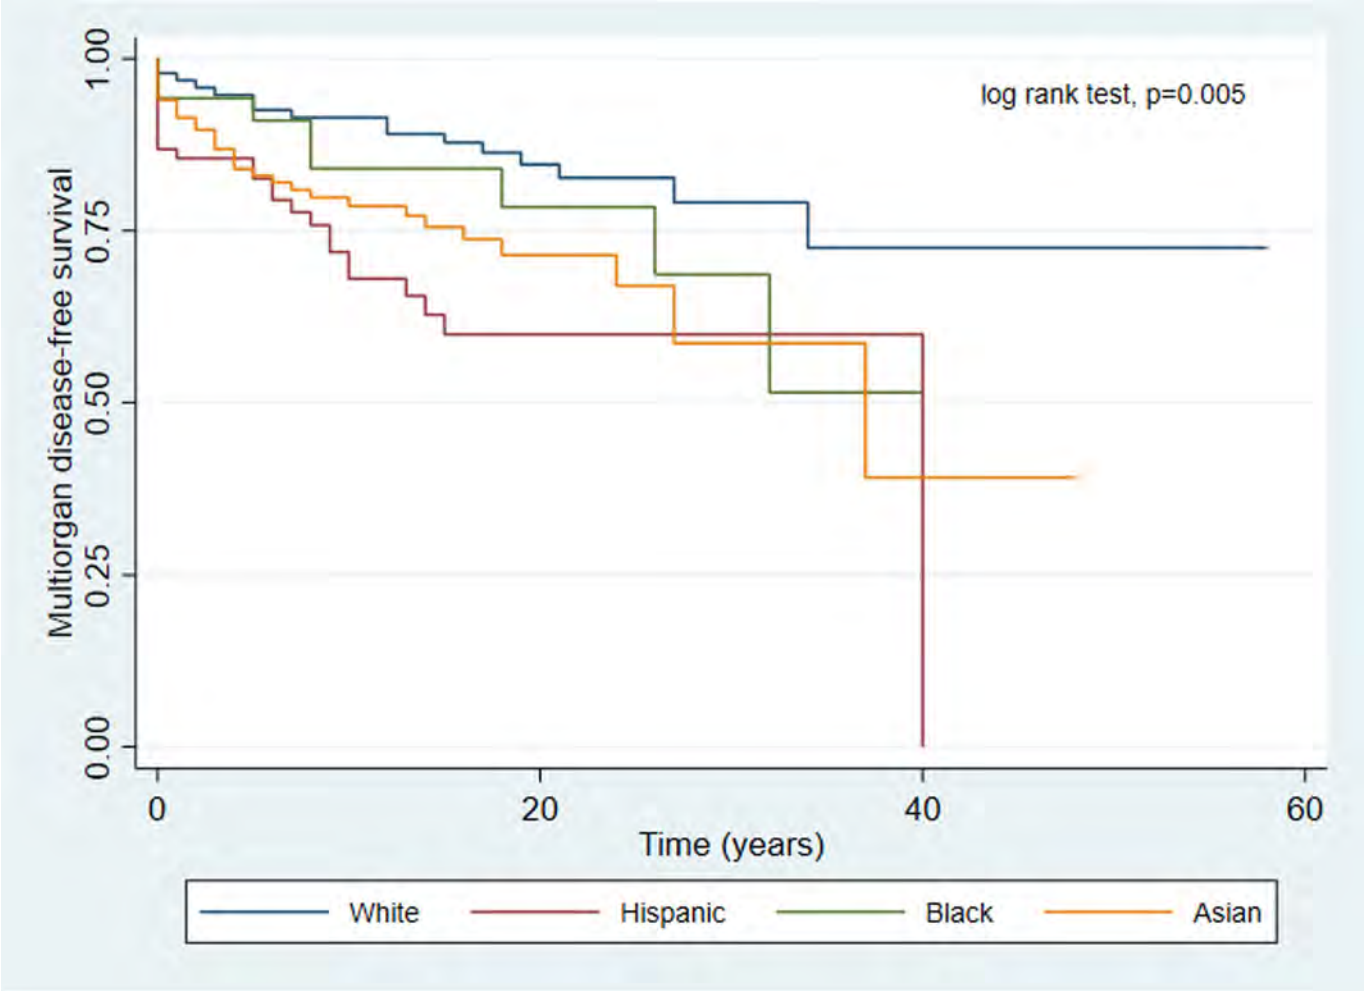

Figure 2. Kaplan-Meier curve depicting time to onset of multiorgan disease by race/ethnicity.

was associated with significant differences in time to onset of renal and multiorgan disease (Figures 1 and 2). Cox regression models showed that non-White racial/ethnic groups experienced greater risks of renal, hematologic, and multiorgan disease as compared to White participants (Table 1).

Table 1. Factors associated with renal, neuropsychiatric, hematologic, cardiovascular, and multiorgan disease following SLE diagnosis in CLUES cohort participants

Variable	Renal*	Neuropsychiatric	Hematologic	Cardiovascular	Multiorgan
Age at diagnosis	0.99 (0.97 - 1.00)	1.02 (1.00 - 1.04)	0.96 (0.94 - 0.99)	1.02 (0.99 - 1.06)	1.01 (0.99 - 1.03)
Female sex	0.40 (0.26 - 0.62)	0.72 (0.32 - 1.62)	0.80 (0.38 - 1.70)	0.62 (0.21 - 1.82)	0.53 (0.28 - 0.99)
Race/ethnicity					
White	*Ref*	*Ref*	*Ref*	*Ref*	*Ref*
Hispanic	2.70 (1.66 - 4.38)	1.23 (0.60 - 2.53)	2.39 (1.16 - 4.92)	1.40 (0.53 - 3.71)	3.02 (1.60 - 5.69)
Black	1.95 (1.03 - 3.71)	1.39 (0.59 - 3.25)	2.11 (0.82 - 5.41)	1.67 (0.56 - 5.02)	1.71 (0.72 - 4.06)
Asian	2.87 (1.82 - 4.51)	0.79 (0.39 - 1.60)	1.70 (0.84 - 3.43)	1.10 (0.43 - 2.82)	2.28 (1.23 - 4.21)

*Hazard ratio (95% confidence interval), estimated using Cox regression models including age at SLE diagnosis and female sex as covariates. Ref, reference category.

Conclusion: Racial/ethnic minorities with lupus are at higher risk for developing end-organ disease as compared to White patients. Black patients experience higher hazards of lupus nephritis compared to White patients, although conclusions in other domains are limited by sample size. Our data highlight the risk of lupus nephritis and multiorgan disease among Hispanic and Asian patients, and hematologic manifestations among Hispanics, who experience these manifestations earlier in their lupus disease course as compared to White patients.

* only one low-positive

Background/Purpose: To determine if a serologic phenotype can be identified in SLE patients with myositis and/or ILD.

Methods: Adult SLE patients (without myositis or ILD at baseline) had annual assessments and provided bio-samples between 2000-2017. Potential new-onset myositis was identified using the SLICC Damage Index (SDI) muscle atrophy/weakness item, the SLEDAI-2K item for myositis, and annual serum creatinine kinase testing. Potential new-onset ILD was identified using the SDI pulmonary fibrosis item. Chart review confirmed cases. Randomly sampled patients from baseline visit (from 2000 onward) became a sub-cohort (N=72). Cases and sub-cohort were compared regarding baseline characteristics. Patients' myositis-related biomarkers were assessed at baseline and one randomly selected follow-up between baseline and end of observation (date of myositis/ILD diagnosis or Dec. 31, 2017).

Table 3. Hazard Ratio for baseline characteristics of SLE patients with myositis and/or ILD (univariate and adjusted models)

Variables	Hazard Ratio for characteristics at baseline	
	Unadjusted HR (95% CI)	Adjusted HR (95% CI)[a]
Female sex	1.43 (0.32, 6.46)	3.43 (0.36, 32.5)
Caucasian race/ethnicity	0.54 (0.18, 1.62)	0.43 (0.13, 1.48)
Age at SLE diagnosis, years	0.98 (0.93, 1.02)	0.98 (0.93, 1.03)
KL-6/MUC-1 >500 U/ml	**2.87 (1.00, 8.26)**	**4.94 (1.27, 19.2)**
Anti TERF1 > 500 U/ml	1.96 (0.24, 15.7)	1.07 (0.12, 9.80)
Anti Ku ≥31 (Med or High positive)	**4.01 (1.07, 15.1)**	**6.30 (1.01, 39.5)**
Anti Ro52/TRIM21 ≥31 (Med or High positive)	1.74 (0.60, 5.10)	1.16 (0.31, 4.31)
Anti NT5c1A/Mup4 ≥31 (Med or High positive)	1.58 (0.20, 12.3)	2.10 (0.22, 20.0)
Anti CENPA ≥31 (Med or High positive)	1.04 (0.13, 8.00)	0.05 (0.00, 3.15)
Anti CENPB ≥31 (Med or High positive)	3.88 (0.84, 17.8)	**9.36 (1.00, 87.5)**

[a] Adjusted for all variables shown

Line immunoassay (Euroimmun AG, Luebeck, Germany) detected autoantibodies to Mi2-α, Mi2-β, MDA5, NXP2, TIF1γ, PM/Scl75, PM/Scl100, Ku, SRP, Jo-1, EJ, OJ, PL7, PL12, Ro52, HMGCR, NT5c1A/Mup44, CENP-A, -B, Scl70, NOR90, RNAP, and Th/To (hPOP1). An addressable laser bead immunoassay was used to detect antibodies to TERF-1. KL-6 levels were determined by ELISA (R&D Systems). Descriptive analyses and hazards ratios (HRs) were generated for myositis and/or ILD incidence, focusing on baseline serology and adjusting for demographic variables (sex, ethnicity, and age at SLE diagnosis) and positive biomarkers.

Results: The median (IQR) SLE duration at baseline was 1.8 (0.41, 5.6) years. Between 2000-2017, 14 SLE patients (12, 85.7% female) developed myositis and/or ILD over an average follow up of 9.2 years (incidence 17.6 cases per 1000 patient-years). Thirteen of these (92.9%) had at least one medium/high positive biomarker at baseline, versus 47 (65.3%) SLE patients who never developed myositis and/or ILD. The most common baseline biomarkers in patients with myositis and/or ILD were KL-6, anti-Ku, anti-Ro52. In multivariate Cox regression analyses, SLE patients were more likely to develop myositis and/or ILD if they had elevated baseline KL-6, anti-Ku positivity, or anti-CENP-B positivity. Potential limitations include the relatively low number of events.

Conclusion: In this SLE sample, KL-6, anti-Ku, and anti-CENP-B at baseline were highly associated with myositis and/or ILD risk. Ours is the first study of this serologic phenotype, identifying SLE patients most at risk of myositis/ILD.

Urinary MicroRNAs as Systemic Lupus Erythematosus Biomarkers and Its Potential for Accurate Assessment of Disease Severity

Hiroki Yamaguchi[1], Yoriko Ando[1], Mika Mizunuma[1], Masamichi Inami[2], Kenichi Suzumura[2] and Yuki Ichikawa[1], [1]Craif Inc., Nagoya, Japan, [2]Analysis & Pharmacokinetics Research Labs., Astellas Pharma Inc., Tsukuba, Japan

SESSION INFORMATION
Session Date: Saturday, November 6, 2021
Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster I: Diagnosis (0323–0356)
Session Type: Poster Session A
Session Time: 8:30AM–10:30AM

Background/Purpose: Systemic lupus erythematosus (SLE) is a systemic autoimmune disease characterized by autoantibody production, immune complex deposition, and heterogeneous clinical manifestations affecting many organs, including the skin, joints, the central nervous system, and the kidneys. Once clinical symptoms have developed, prompt diagnosis and proper management of SLE remain great challenges to physicians. Due to the heterogeneity of immune dysregulation, the severity and progression of the disease largely varies among patients, while no single biomarker has emerged as a surrogate for disease activity or severity of SLE.

Recently, evidence indicates that exosomes play important roles in immune modulation and are associated with the immune pathogenesis of autoimmune diseases, including systemic lupus erythematosus. Exosomes are 20-150 nm-sized vesicles that function as a vital medium for cellular communication. It encapsulates microRNAs (miRNAs), a non-coding RNA, which are known as gene expression modulators, and strongly relates to physiological conditions like disease status. Here, we have developed a mass-producible and sterilizable nanowire-based device (nanowire device) that can extract urinary exosomal microRNAs efficiently. Our objective of the research is to extract urinal exosomes and detect microRNAs using nanowire devices, and identify biomarkers which could support SLE diagnosis and identify its status and severity.

Methods: Exosomes were extracted by nanowire device and miRNA expression was measured from urine samples of 30 SLE patients and 30 non-SLE donors using a microarray to yield comprehensive microRNA expression profiles.

Results: Differential expression analysis revealed 242 biomarker miRNAs candidates,160 up-regulated and 82 down-regulated in SLE patients compared with healthy individuals. Down-regulation patterns were related to the severity of the disease, revealing severity-specific miRNAs.Pathway analyses revealed the candidate miRNAs showed relation with genes strongly related to SLE including JAK-STAT and BCL pathways. Moreover, we adopted a support vector machine model and successfully developed a classifier to detect SLE based on these miRNA expression patterns, which showed remarkably high sensitivity (0.89) and specificity (0.82).

Conclusion: These findings show that urinary miRNAs may provide insights into SLE pathogenesis, and could be a potential biomarker of disease activity, paving the way to a liquid biopsy for individualized SLE treatment.

Background/Purpose: Systemic lupus erythematosus (SLE) is a chronic, multi-organ, autoimmune disease whose prevalence in the US has not been recently updated in real-world studies. Prevalence estimates range from 50-150 per 100,000 adults in the US, but these estimates are due to be refreshed. In addition, the heterogeneity of the clinical manifestations of SLE and lack of a diagnostic test make SLE prevalence challenging to quantify. Therefore, our study sought to utilize recent nationally representative population data to estimate prevalence estimates of SLE in the US.

Methods: We analyzed data from the 2016 - 2018 Medical Expenditure Panel Surveys (MEPS), an annual survey using a complex sampling strategy to represent the US civilian non-institutionalized population. Prevalence was defined as self-reported SLE diagnosis with additional SLE-related medication use and/or any rheumatologist visit during the calendar year. Two other SLE diagnostic criteria were used as a sensitivity analysis (sensitive: SLE diagnosis only; restrictive: SLE diagnosed and currently treated). Self-reported SLE was linked to a specific visit to a healthcare professional (outpatient or inpatient). The annual prevalence was reported per 100,000 US adults and 95 % confidence interval (CI) stratified by key demographic characteristics.

Results: From 2016-2018, 96,996 adults reported annual data in MEPS, of which 199 (0.20%) reported SLE diagnosis, 154 (0.16%) respondents report SLE with either SLE-related medication and/or rheumatologist visit, and 139 (0.14%) respondents reported SLE with SLE-related medication. The pooled weighted annual prevalence of SLE using each respective SLE-definition was 261 (95% CI: 203, 319); 195 (95% CI: 149, 242) and 168 (95% CI: 130, 206) per 100,000 adults. From 2016 to 2018, the prevalence of SLE appeared to increase slightly. The prevalence of SLE was about 9 times higher in females compared to males (343 vs. 37 per 100,000 adults). Individuals who reported Black or multiple races and Mexican Hispanic ethnicity appeared to have a higher prevalence of SLE compared to white or non-Hispanic adults, respectively. Respondents with public insurance (Medicare or Medicaid) were twice as likely to report SLE than those privately insured (311 vs. 168 per 100,000 adults). Respondents in the Southern region of the US had a slightly higher prevalence of SLE compared to other regions (North, West, or East). The 95% confidence intervals were relatively wide across most stratified analyses, limiting the ability to detect population differences.

Conclusion: The self-reported SLE prevalence in the US was higher across all three disease definitions in MEPS than the currently accepted estimate of 50 to 150 per 100,000 adults. Similar to other studies, females, Black, and Hispanic respondents were found to have a higher prevalence of SLE compared to males and white or non-Hispanic individuals. While many real-world studies include only single-payer populations, we demonstrate a more diverse payer patient-population and a higher burden of SLE. SLE prevalence is challenging to quantify; however, this study suggests that the actual US of SLE prevalence may be higher than reported.

Session Time: 8:30AM–10:30AM

Table 1

Classification criteria	Sensitivity	Specificity	AUC of ROC curve
1997 ACR	85.9%	94.3%	0.948
2012 SLICC	97.7%	86.3%	0.980
2019 EULAR/ACR with 10 points as cut-off	96.1%	85.8%	0.979
2019 EULAR/ACR with 9 points as cut-off	97.5%	65.8%	
2019 EULAR/ACR with 11 points as cut-off	95.0%	88.0%	
2019 EULAR/ACR with 10 points as cut-off (men)	94.4%	93.1%	
2019 EULAR/ACR with 10 points as cut-off (women)	96.2%	84.5%	
a2019 EULAR/ACR with 10 points as cut-off (age >50 years)	93.4%	91.1%	
2019 EULAR/ACR with 10 points as cut-off (age ≤50 years)	96.7%	79.2%	

Background/Purpose: To validate the 2019 EULAR/ACR classification criteria for SLE in Hong Kong Chinese patients and compare its performance with the 2012 Systemic Lupus International Collaborating Clinics (SLICC) and 1997 American college of rheumatology (ACR) criteria

Methods: We retrospectively reviewed the medical records of consecutive patients who attended the Rheumatology clinics in Tuen Mun and Pok Oi hospitals between May and September 2019. Patients with anti-nuclear antibody (ANA) ≥1:80 were included and patients with ANA < 1:80 or no ANA results were excluded. Patients were evaluated and cross-checked for the fulfilment of the 1997 ACR, 2012 SLICC and 2019 EULAR/ACR criteria by two investigators (YKC,CL). Medical records were then reviewed by an expert panel consisting of 3 senior rheumatologists, who were blinded for the results of the criteria evaluation, for a diagnosis of SLE based on the clinical judgement and therapeutic decisions. Teleconferences were arranged by the panel to discuss the discrepancies of the final diagnosis and agreement was made by voting. The three SLE criteria were evaluated against the clinical diagnosis of SLE as judged by the expert panel on the sensitivity and specificity, which was calculated by 2x2 contingency tables ("condition positive" = clinical diagnosis of SLE; "test positive" = criteria positive for SLE) with standard formulas (sensitivity = true positive/[true positive + false negative]; specificity = true negative / [true negative + false positive]). Receiver operating characteristic (ROC) curve was used to study the optimal cut-off points from the EULAR/ACR criteria for the highest summation of specificity and sensitivity.

Results: 3967 patients were screened; 1533 patients who were positive for ANA (≥1:80) were included (88.2% women). The mean age of these patients at first rheumatology clinic attendance was 45.6±15.6 years and the duration of follow-up was 8.3±6.4 years. A total of 562 patients were judged to have SLE by the expert panel (discrepancy of clinical diagnosis in 135 patients resolved with voting). The sensitivity and specificity of the three SLE classification criteria in our patients are listed in Table 1. ROC analysis showed that the best cut-off for a clinical diagnosis of SLE using the EULAR/ACR criteria was 10 points (area under the curve [AUC] 0.979; sensitivity 96.1% and specificity 85.8%). Similar figures were obtained for subgroups of patients stratified by gender and different age ranges.

Conclusion: In our cohort of Hong Kong Chinese patients, the 2019 EULAR/ACR criteria is more sensitive but less specific when compared with 1997 ACR criteria for classifying SLE. On the other hand, the EULAR/ACR criteria is less sensitive but more specific than the 2012 SLICC criteria. The specificity of the EULAR/ACR criteria for SLE is higher in male than female patients. In our patients older than 50 years, the EULAR/ACR criteria is less sensitive but more specific for a classification of SLE. Overall, the performance of the EULAR/ACR criteria for a diagnosis of SLE in our study is similar to that reported in recent Asian studies although the sensitivity is lower, which may be related to the inclusion of ANA+ patients only.

Abstract Number: 0334

Association Between Systemic Lupus Erythematosus and Myasthenia Gravis: A Population-Based National Study

Sali Merjanah[1], Ann Igoe[2], David Kaelber[3] and Robert Hal Scofield[4], [1]Boston University, Boston, MA, [2]OhioHealth Hospital, Mansfield, OH, [3]The MetroHealth System Campus of Case Western Reserve University, Cleveland, OH, [4]Oklahoma Medical Research Foundation, Oklahoma City, OK

SESSION INFORMATION
Session Date: Saturday, November 6, 2021
Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster I: Diagnosis (0323–0356)
Session Type: Poster Session A
Session Time: 8:30AM–10:30AM

Background/Purpose: Systemic lupus erythematosus (SLE) and myasthenia gravis (MG) are two autoimmune disorders that have a young female preponderance, relapsing-remitting course, and positive antinuclear antibodies. The coexistence of SLE and MG has been reported in the literature with the majority of cases MG preceding SLE diagnosis[1]. There has been no controlled epidemiological study to prove a real association between these two diseases.

This study aims to estimate the prevalence of SLE among MG patients compared to non-MG patients and to study the demographics of the MG patients who developed SLE preceding or following MG diagnosis.

Methods: This is a retrospective observational study using the IBM Explorys database, a pooled de-identified clinical database of > 60 million unique patients in the US with patient-level data. The Explorys collects aggregated, standardized, and normalized clinical data from different electronic health records automatically updated in near real-time. International Classification of Diseases – 9 (ICD-9) diagnosis codes were used to define SLE and MG patients. For SLE patients, the ICD code was used along with at least two rheumatologist visits for patients ≥ 18 years of age. The control group included adults ≥ 18 years of age with the exclusion of MG diagnosis. We further stratified the cohorts by adding the following variables to the search tool: age, race, gender, smoking status, thymectomy, autoimmune

Table 1. Demographics and clinical characteristics of MG patients and controls with SLE

Variables	MG with SLE n=370 n (%)	Controls with SLE n=65,000 n (%)
Age		
> 65 years	130 (35.14)	19,740 (30.37)

Autoimmune comorbidities			
Autoimmune thyroiditis	40 (10.81)	530 (2.09)	<0.0001
Pernicious anemia	20 (5.4)	310 (1.22)	<0.0001
Psoriasis	30 (8.11)	470 (1.85)	<0.0001
Systemic vasculitis	10 (2.7)	60 (0.24)	<0.0001
Rheumatoid arthritis	110 (29.73)	1,040 (4.1)	<0.0001
Miscellaneous comorbidities			
Diabetes Mellites			
Type 1	30 (8.11)	810 (3.19)	<0.0001
Type2	100 (27.03)	7,090 (27.93)	0.7
Kidney Disease			
Chronic kidney disease	90 (24.32)	3,230 (12.73)	<0.0001
End stage renal disease	10 (2.7)	380 (1.5)	0.06
Thyroid Disease			
Hypothyroidism	160 (43.34)	6,100 (24.03)	<0.0001
Hyperthyroidism	50 (13.51)	1,340 (5.28)	<0.0001
Essential hypertension	220 (59.46)	14,890 (58.69)	0.76
Metabolic syndrome	10 (2.7)	330 (1.3)	0.02
Coronary artery disease	80 (21.62)	5,070 (19.98)	0.43
Cerebral infarction	60 (16.22)	2,080 (8.19)	<0.0001
Chronic obstructive lung disease	90 (24.32)	3,580 (14.1)	<0.0001

and miscellaneous comorbidities. The index date was defined as the date of the SLE diagnosis occurring in the MG patients. A chi-square test of association was performed along with the odds ratio (OR), its standard error, and the 95% confidence interval (CI).

Results: Prevalence rates of SLE and MG among total active patients of 59,896,040 were found to match the reported rates in the literature (0.1% and 0.04% subsequently)[2,3].

Of the 26,110 patients with MG, 370 had a diagnosis of SLE (1.42%) compared to 65,000 of 59,869,730 controls (0.11%). MG patients found to have increased odds of SLE compared to control group (OR 13.38, 95% CI: 2.08 to 14.84, P < 0.0001).

Demographics and clinical characteristics of MG patients and controls with SLE are shown in table 1. Risk factors for increased SLE risk among MG patients are shown in table 2. Female sex, African American race, thymectomy, autoimmune diseases, and miscellaneous comorbidities such as thyroid disease were significantly more common in MG patients who developed lupus.

The MG cohort who underwent thymectomy (n = 730) had an increased risk of SLE (30 out of 730) compared to MG patients who didn't undergo thymectomy (340 out of 25,380), (OR 3.11, 95% CI: 2.12 to 4.55, P < 0.0001).

Conclusion: Our study strongly supports the higher prevalence of SLE in MG patients and highlights the risk factors of the development of lupus in MG patients. MG patients should be evaluated for the coexistence of SLE especially in post-thymectomy patients and the young African American women with a history of other autoimmune diseases. Additionally, assessment for MG is suggested in lupus patients with unexplained muscular weakness.

Abstract Number: 0335

Performances of Different Classification Criteria for Systemic Lupus Erythematosus in a Single Center Cohort from Turkey

Ege Sinan Torun[1], Erdem Bektaş[1], Fatih Kemik[2], Murat Bektaş[3], Cigdem Cetin[4], Yasemin Yalcinkaya[4], Bahar Esen[4], Ahmet Gül[5] and Murat Inanc[6], [1]Istanbul University Istanbul Faculty of Medicine, İstanbul, Turkey, [2]Istanbul Faculty of Medicine, Istanbul University, Department of Internal Medicine, İstanbul, Turkey, [3]Istanbul Faculty of Medicine, Istanbul, Turkey, [4]Division of Rheumatology, Department of Internal Medicine, Istanbul Faculty of Medicine, Istanbul University, Istanbul, Turkey, [5]Division of Rheumatology, Istanbul University Istanbul School of Medicine, Istanbul, Turkey, [6]Istanbul University Faculty of Medicine, Istanbul, Turkey

SESSION INFORMATION
Session Date: Saturday, November 6, 2021
Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster I: Diagnosis (0323–0356)
Session Type: Poster Session A
Session Time: 8:30AM–10:30AM

Background/Purpose: Recently developed EULAR/ACR classification criteria for systemic lupus erythematosus (SLE) has important differences compared to the 2012 Systemic Lupus International Collaborating Clinics (SLICC) SLE classification criteria and the revised 1997 American College of Rheumatology (ACR) crite-

Table 1- Sensitivity, positive predictive value, specificity and negative predictive value of 1997 ACR, 2012 SLICC and 2019 EULAR/ACR classification criteria

	SLE (+)	SLE (-)	Sensitivity (%)	Positive Predictive Value (%)	Specificity (%)	Negative Predictive Value (%)
1997 ACR	(+) 306 (-) 86	15 279	78.1	95.3	94.9	76.4
2012 SLICC	(+) 356 (-) 36	26 268	90.8	93.2	91.2	88.1
2019 EULAR/ACR	(+) 368 (-) 24	28 266	93.8	92.9	90.5	91.7

ria:The obligatory entry criterion of antinuclear antibody (ANA) positivity is introduced and a "weighted" approach is used.Sensitivity and specificity of these three criteria have been debated and may vary in different populations and clinical settings. We aim to compare the performances of three criteria sets/rules in a large cohort of patients and relevant diseased controls from a reference center with dedicated clinics for SLE and other autoimmune/inflammatory connective tissue diseases from Turkey.

Methods: We reviewed the medical records of SLE patients and diseased controls for clinical and laboratory features relevant to all sets of criteria. Criteria sets/rules were analysed based on sensitivity, positive predictive value, specificity and negative predictive value, using clinical diagnosis with at least 6 months of follow-up as the gold standard. A subgroup analysis was performed in ANA positive patients for both SLE group and control group. SLE patients that did not fulfil 2012 SLICC criteria and 2019 EULAR/ACR criteria and diseased controls that fulfilled these criteria were evaluated.

Results: A total of 392 SLE patients and 294 non-SLE diseased controls (48 undifferentiated connective tissue disease, 51 Sjögren's syndrome, 43 idiopathic inflammatory myopathy, 50 systemic sclerosis, 52 primary antiphospholipid syndrome (APS), 15 rheumatoid arthritis, 15 psoriatic arthritis and 20 ANCA associated vasculitis) were included in the study. Hundred and fourteen patients (16.6%) were ANA negative.

Sensitivity was more than 90% for both 2012 SLICC criteria and 2019 EULAR/ACR criteria and positive predictive value was more than 90% for all three criteria (Table 1). Specificity was the highest for 1997 ACR criteria. Negative predictive value was 76.4% for ACR criteria, 88.1% for SLICC criteria and 91.7% for EULAR/ACR criteria.

In ANA positive patients, sensitivity was 79.1% for 1997 ACR criteria, 91.9% for 2012 SLICC criteria and 96.1% for 2019 EULAR/ACR criteria. Specificity was 92.6% for ACR criteria, 87.8% for SLICC criteria and 85.1% for EULAR/ACR criteria.

Eleven clinically diagnosed SLE patients had insufficient number of items for both 2012 SLICC and 2019 EULAR/ACR criteria. Both criteria were fulfilled by 16 diseased controls: 9 with Sjögren's syndrome, 5 with APS, one with dermatomyositis and one with systemic sclerosis.

Conclusion: In this cohort, although all three criteria have sufficient specificity, the sensitivity and negative predictive value of 1997 ACR criteria are the lowest. Overall, 2019 EULAR/ACR and 2012 SLICC criteria have a comparable performance, but if only ANA positive cases and controls are analysed, the specificity of both criteria decrease to less than 90%. Some SLE patients with a clinical diagnosis lacked sufficient number of criteria. Mostly, patients with Sjögren's syndrome or antiphospholipid syndrome are prone to misclassification by both recent criteria.

The Incremental Clinical Utility of a Multianalyte Assay Panel with Cell-Bound Complement Activation Products versus a Traditional ANA Testing Strategy for the Diagnosis and Treatment of SLE

Tyler O'Malley[1], Fenglong Xie[2], yujie Su[2], cassie Clinton[2], Debra J. Zack[1], Jeffrey Curtis[3] and John Wegener[1], [1]Exagen Inc., Vista, CA, [2]University of Alabama at Birmingham, Birmingham, AL, [3]Division of Clinical Immunology and Rheumatology, Department of Medicine, Department of Epidemiology, University of Alabama at Birmingham, Birmingham, AL

SESSION INFORMATION

Session Date: Saturday, November 6, 2021

Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster I: Diagnosis (0323–0356)

Session Type: Poster Session A

Session Time: 8:30AM–10:30AM

Background/Purpose: The comparative clinical utility of various diagnostic tests to aid the differential diagnosis of SLE is unclear. We compare the outcomes of testing with a multianalyte assay panel (MAP) with cell-bound complement activation products vs. standard of care lab testing in patients suspected of having SLE.

Methods: We used data from the electronic health record (EHR)-based Columbus registry from 1/2016 to 12/2020 for analysis and linked Healthcore medical, pharmacy, and claims data. We established two cohorts for comparison, the MAP testing strategy cohort and the traditional ANA testing strategy cohort (tANA), with or without anti-dsDNA or anti-Smith. All lab results from the MAP cohort were obtained directly from the lab vendor. Results from the tANA cohort were available from within the EHR. Baseline data was collected for both cohorts at 12 months (or more) before first testing. Using this data, we characterized the demographics, comorbidities, other autoimmune diagnoses, and medications (including SLE treatments and glucocorticoids). Except for SLE (which might have been only a working diagnosis), patients with pre-existing rheumatology conditions already identified at time of testing were excluded. Descriptive statistics compared the characteristics of MAP and tANA testing episodes. Logistic regression was used to estimate odds ratios (OR) comparing the likelihood of SLE medication initiation and SLE diagnosis between the MAP and tANA cohorts. Multivariable adjustment was performed and included all imbalanced covariates described in table 1 with standardized mean difference (SMD) >0.10. A subgroup analysis was conducted in patients new to the practice in the preceding 12 months

Results: The MAP and tANA cohorts consisted of 21,827 and 22,778 testing episodes, respectively. Patients in both cohorts were of similar age, mean 51 and 54 years, respectively for MAP and tANA, predominantly female (85 and 81%), and majority white (57 and 64%). Approximately 4-5% of MAP and tANA patients already had a SLE diagnosis ICD-10 code prior to testing. A total of 2,437 (11.17%) patients tested positive by MAP compared to 5,364 (23.55%) of patients who tested positive by tANA.

Among patients with no baseline prescription for a SLE medication, MAP positive patients were more likely to initiate SLE medications compared to tANA positive patients (43% vs. 32%, adjusted OR = 2.13, 95% CI 1.85-2.44). Effects were stronger in the subgroup of patients new to the practice, 55% vs. 33% (adjusted OR = 2.77, 95% CI 2.31-3.32). MAP positive patients were approximately fivefold more likely to be diagnosed with SLE as compared to the tANA positive patients, 31 vs. 8% (adjusted OR = 4.78, 95% CI 4.04-5.65); similar results were observed in the subgroup

of new patients (adjusted OR = 6.34, 95% CI 5.12-7.86). Among MAP algorithm negative patients, 96% were not diagnosed with SLE compared to 99% of tANA negative patients.

Table 1: Baseline* Characteristics of patients undergoing AVISE and tANA (tANA) tests without pre-existing (non-SLE) autoimmune diagnoses

	AVISE	tANA	SMD

Gap from new patient/consultation 99XXX*** visit			
Days, mean (SD),	38.3 (155.4)	28.6 (120.8)	0.07
Missing, %	12,842 (58.8)	4,641 (20.4)	0.86

*baseline refers to all available data before the AVISE and tANA test result was reported †For AVISE group is the tANA, for tANA is the AVISE ‡New patient ambulatory codes: 99201-5; new consultation codes: 99241-5 tANA – traditional antinuclear antibody; SLE – systemic lupus erythematosus; UCTD – undifferentiated connective tissue disease; HCQ – hydroxychloroquine; MMF – mycophenolate; MTX – methotrexate; AZA – Azathioprine; LEF – leflunomide; RTX – rituximab; BEL – Belimumab; NSAID – non-steroidal anti-inflammatory; SNRI – serotonin-norephinephrine reuptake inhibitors; SSRI - selective serotonin reuptake inhibitor; SMD = standardized mean difference (SMDs > 0.10 are considered potentially clinically important).

Table 2. Diagnostic and SLE treatment outcomes among all patients testing MAP positive as described previously (Dervieux et al., *J Immunol Methods* 2017) vs. tANA positive patients (defined as an ANA ≥ 1:160 and/or positive anti-dsDNA and/or positive anti-Smith based on laboratory cutoffs). SLE medication initiation was defined as a new (post-test) prescription for hydroxychloroquine, methotrexate, mycophenolate, azathioprine, leflunomide, rituximab, or belimumab.

Outcome	Adjusted* Odds Ratio (95% CI)
SLE Medication initiation MAP vs. tANA (referent)	2.13 (1.85-2.44)
Diagnosis (M32 ICD 10 code) MAP vs. tANA (referent)	4.78 (4.04-5.65)

*adjusted for imbalanced covariates described in table 1 with SMD >0.10

Table 3. Subgroup analysis of diagnostic and SLE treatment outcomes among newly referred (<12 months) patients testing MAP positive vs. tANA positive.

Outcome	Adjusted* Odds Ratio (95% CI)
SLE Medication initiation MAP vs. tANA (referent)	2.77 (2.31-3.32)
Diagnosis (M32 ICD 10 code) MAP vs. tANA (referent)	6.34 (5.12-7.86)

*adjusted for imbalanced covariates described in table 1 with SMD >0.10

Conclusion: Positive MAP results associated with a greater likelihood to initiate SLE medications and to receive a SLE diagnosis compared to tANA while maintaining comparable negative predictive value. The findings highlight the superior actionability of MAP results vs. tANA.

Abstract Number: 0337

Rarity of Pneumocystis Jirovecii Pneumonia in Patients with Systemic Lupus Erythematosus Using a Real-world, Electronic Health Record

Ben Boone and April Barnado, Vanderbilt University Medical Center, Nashville, TN

SESSION INFORMATION

Session Date: Saturday, November 6, 2021
Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster I: Diagnosis (0323–0356)
Session Type: Poster Session A
Session Time: 8:30AM–10:30AM

Background/Purpose: Infection is the leading cause of mortality and one of the most common causes of hospitalization in patients with systemic lupus erythematosus (SLE). *Pneumocystis jirovecii* pneumonia (PJP) is a highly morbid but preventable opportunistic infection in SLE patients. Prior studies have not investigated patient factors associated

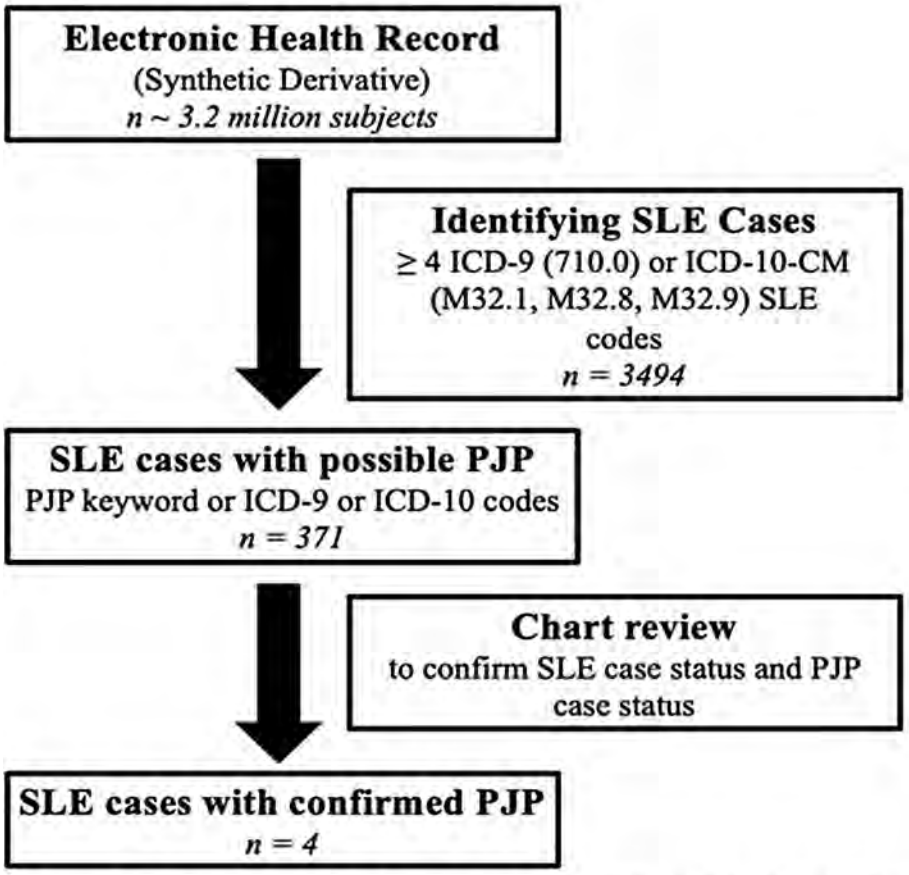

Figure 1. Flow chart of cohort selection. Potential SLE patients with PJP were selected from a de-identified EHR by first applying ≥ 4 SLE ICD-9 or ICD-10-CM codes and then applying PJP keywords and ICD-9 and ICD-10-CM codes. These patients were then all chart reviewed to determine if a PJP case.

with PJP infection in SLE using an electronic health record (EHR) cohort. Using a real-world, EHR cohort, we assessed the frequency of PJP infection in SLE patients and patient factors associated with infection.

Methods: We identified potential SLE cases from a de-identified EHR called the Synthetic Derivative with over 3.2 million subjects with over 30 years of follow-up using a previously validated algorithm of 4 or more SLE ICD-9 or ICD-10 CM codes with a positive predictive value of 90%. Within this set, we then required either a PJP ICD-9 or ICD-10 CM code or PJP keywords. PJP keywords included "PJP", "*Pneumocystis jirovecii*", "Pneumocystis", "PJP pneumonia", or "pneumocystis pneumonia". The cohort selection is summarized in Figure 1. Confirmed PJP infection was defined by positive immunofluorescence, polymerase chain reaction, or Gömöri methenamine silver staining on sputum or bronchoalveolar lavage specimen. We reviewed charts to collect data on demographics, SLE disease manifestations, medication exposure, laboratory values, and PJP prophylaxis use. We assessed for current and preceding 90-day cumulative dosing of corticosteroids at time of diagnosis from notes, inpatient and outpatient electronic prescribing systems, and phone messages. The current and recent use of non-steroid immunosuppressants over 90 days was recorded, as well as any co-morbid immunodeficiency.

Results: We conducted chart review on 371 SLE patients with any mention of PJP from 1989 to 2020. A total of 119 patients underwent bronchoscopy for PJP testing, 16 underwent sputum sampling, and 10 underwent testing from

Table 1. Characteristics of Patients with SLE Diagnosed with PJP.

Age	Sex	Race	*Pneumocystis jirovecii* testing Modality	Current daily prednisone dose (mg)[1]	Cumulative prednisone dose in previous 90 days (mg)[1]	Non-steroid immuno-suppressants in previous 90 days[1]	HIV/ AIDS[1]	WBC[1] (cells/μL)	Lymphocytes[1] (cells/μL)	CD4 count[1] (cells/μL)
28	F	African-American	PCR[2]	15	1,120	Azathioprine	No	6300	310	N/A[4]

other sites. We confirmed PJP infection in 4 of these patients. The characteristics of these patients, including relevant therapies and laboratory evaluation, are summarized in Table 1. Two of the 4 patients were infected with human immunodeficiency virus (HIV) and acquired immunodeficiency syndrome (AIDS) with CD4 lymphocyte counts less than 200 cells/mL. Neither of these patients had been exposed to any steroids or non-steroid immunosuppressive therapy in the 90 days preceding PJP diagnosis. Of the 2 SLE patients without HIV/AIDS, both had significant lymphopenia in addition to significant recent steroid exposure. None of the 4 patients were on PJP prophylaxis.

Conclusion: Using a large EHR cohort, 2 SLE patients without co-morbid HIV/AIDS were identified as having PJP. Both patients were on moderate doses of corticosteroids, with one on a non-steroid immunosuppressant, and neither on PJP antimicrobial prophylaxis. With 2 confirmed cases of PJP in non-HIV/AIDS SLE patients in over 30 years at a large academic institution, PJP seems to be a rare complication in SLE. This rarity may contribute to lack of well-defined risk factors for PJP infection or formal recommendations for PJP prophylaxis in SLE patients.

Session Date: Saturday, November 6, 2021

Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster I: Diagnosis (0323–0356)

Session Type: Poster Session A

Session Time: 8:30AM–10:30AM

Background/Purpose: Galectin-9, interferon-inducible protein-10 (IP-10) and sialoadhesin (SIGLEC-1) are proteins associated with interferon signature, and considered as potential biomarkers reflecting disease activity in patients with systemic lupus erythematosus (SLE). In this study, we aimed to investigate the association of serum and urine levels of galectin-9, IP-10 and SIGLEC-1 with disease activity in patients with SLE.

Table 1. Serum and urine levels of biomarkers across study groups.

Biomarker	Active SLE (n=63)	Inactive SLE (n=30)	Healthy Control (n=32)
sGalectin-9 (ng/ml)	11.73 (7.52-14.15)	8.66 (7.51-10.02)	5.61 (4.56-6.6)
sIP-10 (pg/ml)	279.4 (147.5-430.3)	173.4 (142.2-247.9)	74.3 (58.8-103)
sSIGLEC-1 (pg/ml)	181.2 (157.8-213.9)	182.5 (169.9-203.1)	258.3 (179-602)
uGalectin-9 (ng/ml)	8.83 (4.07-18.11)	11.54 (7.03-15.07)	10.63 (5.55-17.4)
uIP-10 (pg/ml)	34.4 (15.9-73,9)	20.8 (9.9-53.3)	12.2 (1.8-25.7)
uSIGLEC-1 (pg/ml)	321 (236.3-370.9)	297.6 (247.7-371)	290 (205.1-323.5)
uGalectin-9 (ng/mgCre)	15.50 (9.60-32.05)	11.41 (8.78-19.54)	13.57 (11.27-22.08)
uIP-10 (pg/mgCre)	73.4 (40.9-136.9)	26.1 (18.1-55.1)	16.4 (5-32.5)
uSIGLEC-1 (pg/mgCre)	619.6 (389.4-1056.5)	393.2 (248.6-715.8)	425.6 (264.7-925.9)

Methods: Sixty-three patients with active SLE (31 renal and 32 extrarenal) were included in the study. Thirty inactive patients with SLE (15 renal and 15 extrarenal) and 32 healthy volunteers were selected as control groups. Serum (s) and urine (u) levels of galectin-9, IP-10 and SIGLEC-1 were tested using ELISA. Urine levels of biomarkers were normalized by urine creatinine.

Results: Groups were comparable with regard to sex and age distribution. Of 125 participants, 102 (81.6%) were female and median age was 33 (28-44.5) years. Proliferative lupus nephritis (LN) (class III/III+V and IV/IV+V) were found

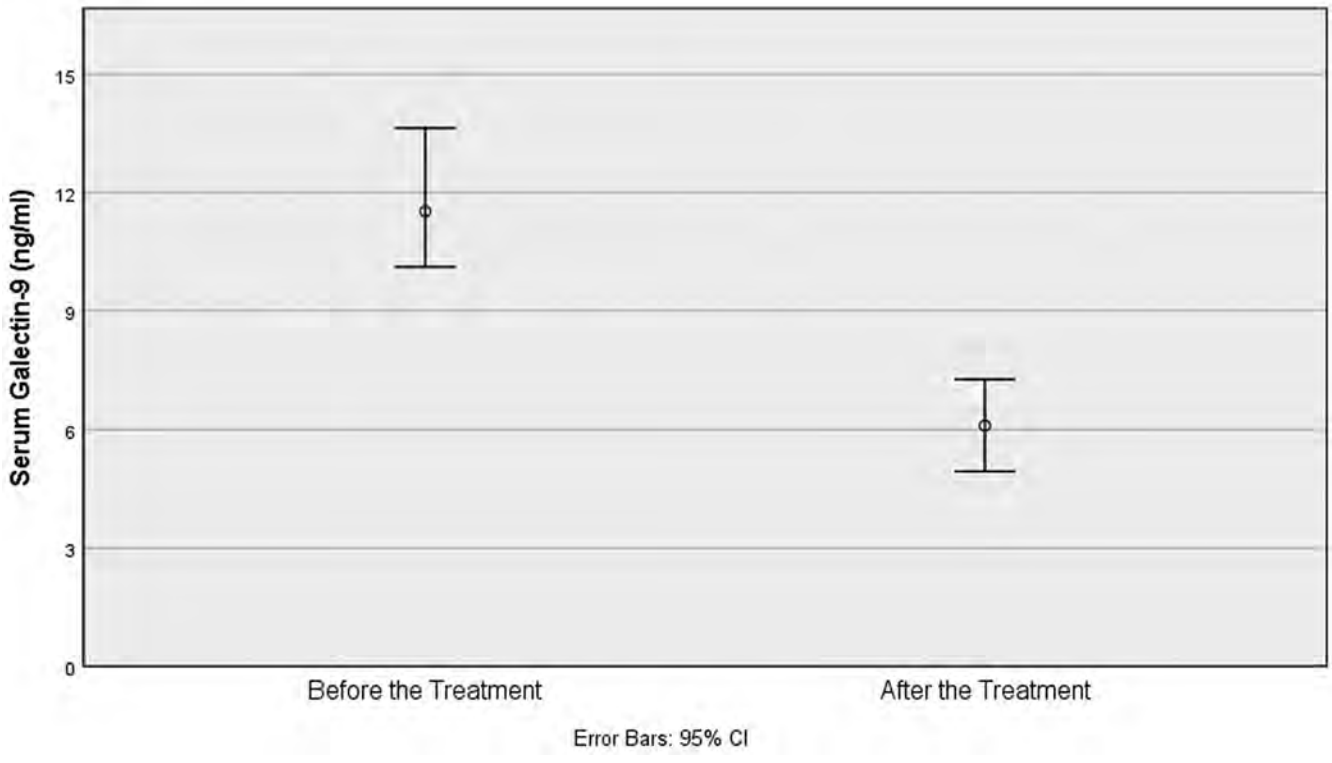

Figure 1. Serum levels of galectin-9 before and after the treatment in 41 patients with active SLE.

in 22 patients with active renal SLE (70.9%), while 6 patients (19.3%) had pure class V and 3 (9.7%) had class II LN. Levels of sIP-10, uIP-10, sGalectin-9 and uSIGLEC-1 were significantly higher in the active SLE group compared to the inactive SLE group (sIP-10 p=0.046, uIP-10 p< 0.001, sGalectin-9 p=0.031 and uSIGLEC-1 p=0.006); however, no differences were detected in the comparison of uGalectin-9 and sSIGLEC-1 between the groups (uGalectin-9 p=0.180 and sSIGLEC-1 p=0.699) (Table 1). Serum and urine levels of galectin-9, IP-10 and SIGLEC-1 did not differ between patients with active renal and extrarenal SLE. Levels of sIP-10, uIP-10 and uSIGLEC-1 were correlated with SLE Disease Activity Index (SLEDAI). Serum and urine levels of all biomarkers were re-tested in 41 of 63 patients (65%) with active SLE after a median treatment of 8 (5-22.5) months. At the time of the second tests, there was a significant decrease in disease activity as measured by SLEDAI [2 (0-4)] compared to the time of the first tests [10 (6-15.5)]. Comparison of sGalectin-9 levels between the serum at the time of active disease and remission showed a very significant decline (p< 0.001) as shown in Figure 1. uGalectin-9, sIP-10 and uSIGLEC-1 also decreased after treatment; however, the difference was not statistically significant.

Conclusion: sIP-10, uIP-10, sGalectin-9 and uSIGLEC-1 are associated with disease activity in SLE. None is able to discriminate active renal from active extrarenal disease. sGalectin-9 may be a valuable biomarker to monitor response after treatment for active disease (Funded by Scientific Research Projects Coordination Unit of Istanbul University. Project number: TSA-2019-34218).

Abstract Number: 0339

Trends in Disparity by Age, Sex and Race for Systemic Lupus Erythematosus Patients

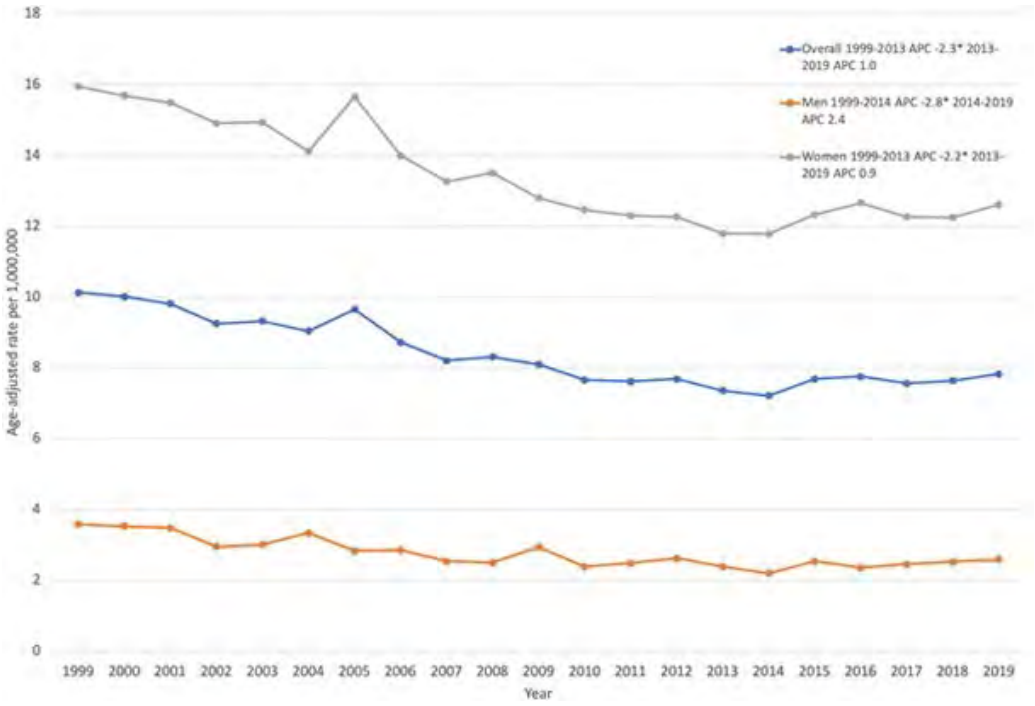
Anum Akhlaq[1] and Abdul Mannan Khan Minhas[2], [1]Orange Park Medical Center, Orange Park, FL, [2]Forrest General Hospital, Hattiesburg

SESSION INFORMATION

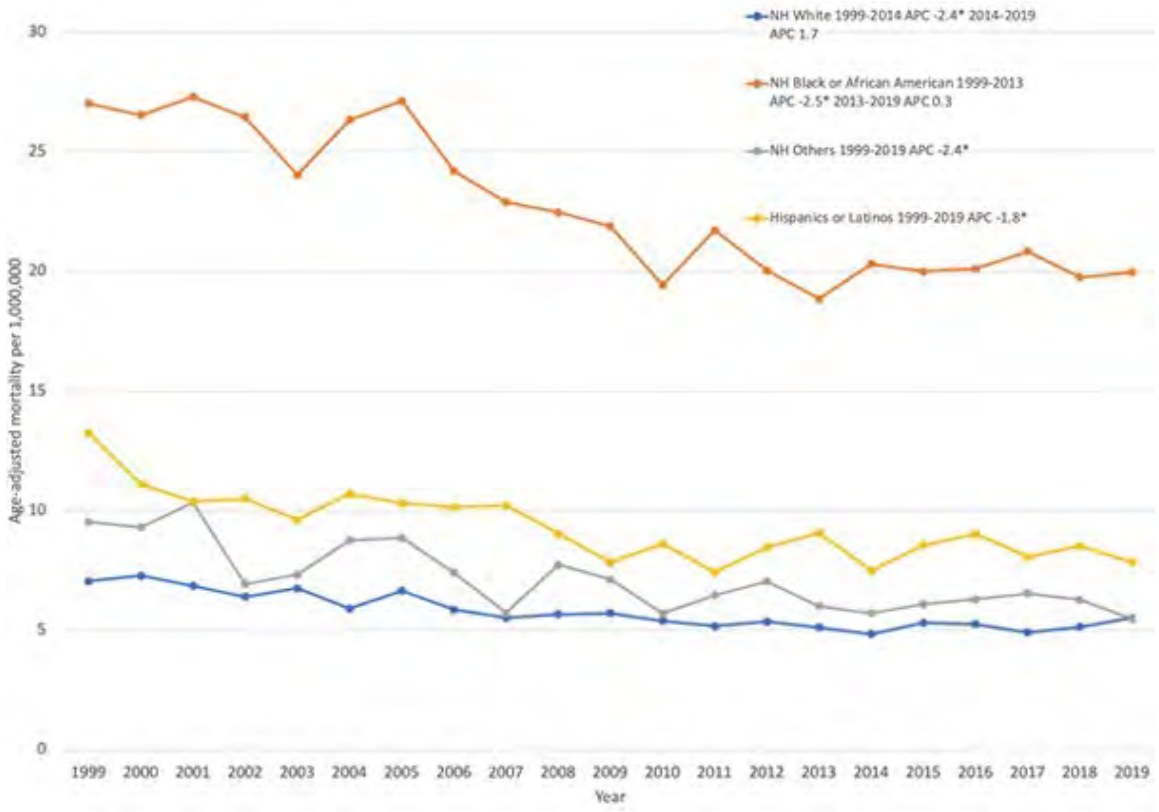
Session Date: Saturday, November 6, 2021
Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster I: Diagnosis (0323–0356)
Session Type: Poster Session A
Session Time: 8:30AM–10:30AM

Background/Purpose: Important disparities in SLE patients persist based on their sex and racial/ethnic status. The aim of this study is to examine the trends in SLE-related deaths stratified on age, sex, and race/ethnicity in the United States from 1999 to 2019.

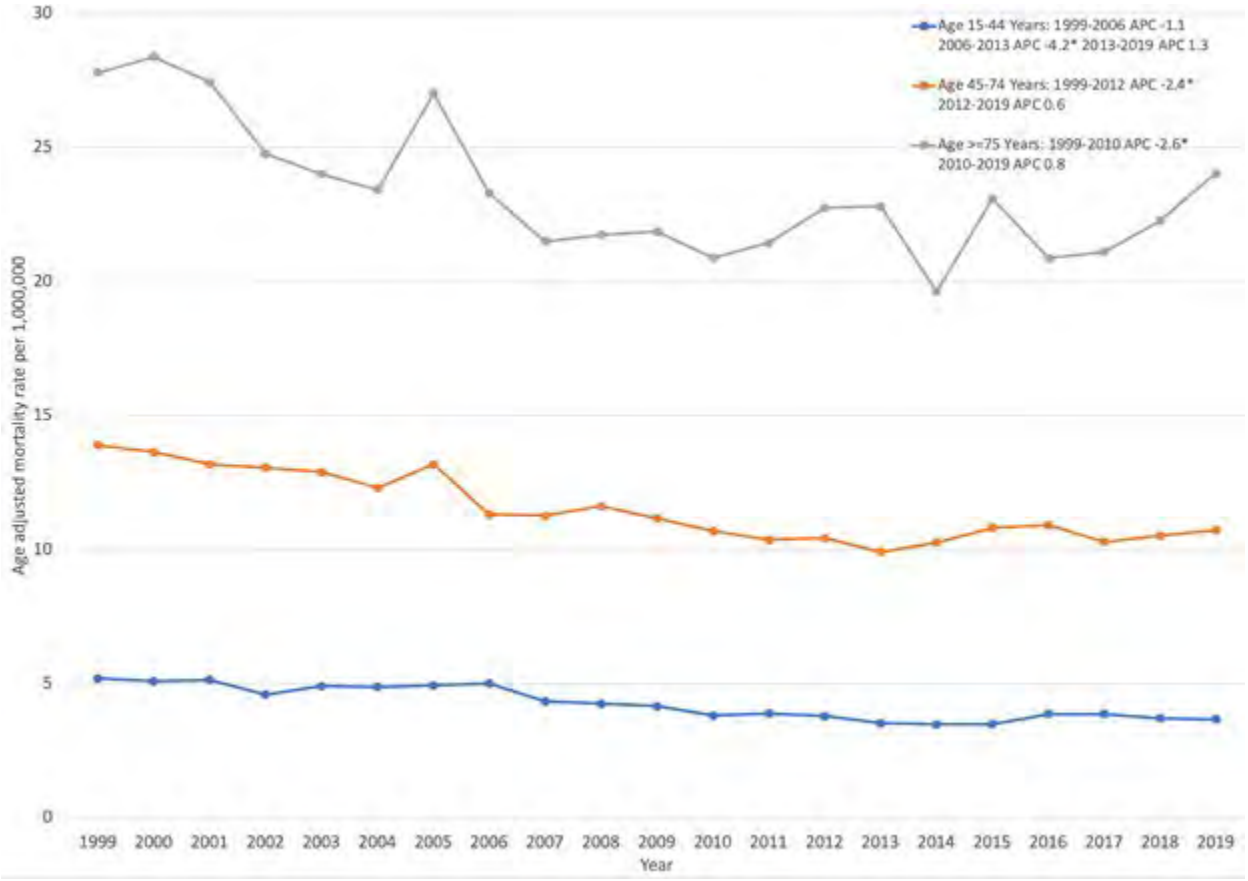
Methods: We used CDC Wide-ranging Online Data for Epidemiologic Research (CDC WONDER) to access National Vital Statistics System data from 1999 to 2019. SLE-related deaths (age >/= 15 years) were identified using the International Classification of Diseases, Tenth Revision, codes M32.x from multiple causes of death and were represented as age-adjusted mortality rates (AAMR) per 1,000,000 population. Joinpoint regression was used to examine changes in trend and annual percentage change (APC) in SLE related deaths overall and stratified by age groups (15-44 years [young], 45-74 years [midlife], and >/=75 years [old]), sex, racial/ethnic groups (non-Hispanic whites [NHWs], non-Hispanic blacks [NHBs], Hispanics, non-Hispanic Others [NH Others] (includes Asian or Pacific Islanders, and American Indian or Alaska Natives)).



Overall and sex-stratified SLE–related mortality rates in the United States, 1999 to 2019. *Indicates that the APC is significantly different from zero at α=0.05.



SLE–related mortality rates stratified by race/ethnicity in the United States, 1999 to 2019. *Indicates that the APC is significantly different from zero at α=0.05.



SLE–related mortality rates stratified by age groups in the United States, 1999 to 2019. *Indicates that the APC is significantly different from zero at α=0.05.

Results: AAMR related to SLE decreased from 10.13 to 7.36 in 2013 (APC -2.3[95% CI, –2.7 to –1.9]) and then remained stable (7.83) after that till 2019 (APC 1.0[95% CI, 1.1 to [95% CI, –0.5 to –2.5]). AAMR was higher in women (13.41) than men (2.73) in all years. Among the racial/ethnic groups, AAMR was highest in NHBs (22.51), followed by Hispanics (9.07), NH-Others (6.93), and lastly, NHWs (5.76) in all years. AAMR was highest in old (23.24) followed by midlife (11.46) and young (4.28). APC in AAMR decreased in men (-2.8) till 2014 and women (-2.2) till 2013 and remained stable after that. APC in AAMR decreased in NHWs (-2.4) until 2014 and NHBs (-2.5) until 2013 and remained stable after that. APC in AAMR decreased throughout the study period in NH Others (-2.4) and Hispanics (-1.8). APC in AAMR decreased from 2006-2013 in young (-4.2) and remained stable after that. APC in AAMR decreased in midlife (-2.4) until 2012 and old (-2.6) until 2010 and remained stable after that.

Conclusion: After the initial decline, SLE-related mortality has remained stable since 2013. Stratification by racial/ethnic status reveals significant disparities, which calls for further research to understand the underlying factors to help develop preventative strategies.

Urinary L-selectin Predicts Disease Activity and Histological Changes in Lupus Nephritis

Huihua Ding[1], Yiwei Shen[1], Min Dai[1], Chandra Mohan[2] and Nan Shen[3], [1]Shanghai JiaoTong University School of Medicine, Shanghai, China (People's Republic), [2]University of Houston, Houston, TX, [3]Shanghai Jiang Tong University School of Medicine, Shanghai, China (People's Republic)

SESSION INFORMATION

Session Date: Saturday, November 6, 2021

Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster I: Diagnosis (0323–0356)

Session Type: Poster Session A

Session Time: 8:30AM–10:30AM

Background/Purpose: There remains unmet needs of non-invasive markers of disease activity, damage, prognosis, and treatment response in lupus nephritis patients. Here, we aim to validate urinary L-selectin (CD62L) as a novel biomarker of disease activity and histological changes of LN in a Chinese SLE cohort.
