Methods: Within the prospective cohorts of female nurses, Nurses' Health Study (NHS) (1976-2016) and NHSII (1989-2018), lifestyle, environmental, and medical data were collected at baseline and on subsequent biennial questionnaires. Incident physician diagnosed SLE was self-reported on biennial questionnaires and confirmed by medical record review to meet 1997 ACR classification criteria. Genotyping was performed on blood samples collected in 1989 (NHS) and 1997 (NHSII) from ~25% of participants. We conducted a nested case-control study in which women who had donated a blood sample and developed incident SLE were matched on age (± 4 years) and race to women who had donated a blood sample but did not develop SLE. Our previously derived and published SLE weighted genetic risk score, (wGRS, Cui J et al, *Arthritis Rheum*, 2019) includes 86 single nucleotide polymorphisms (SNPs) and 10 classical *HLA* alleles associated with SLE risk. Lifestyle/environmental variables, including smoking, alcohol use, socioeconomic status, U.S. region, menarchal age, oral contraceptive use, menopausal status/postmenopausal hormone use, body mass index, were assessed on the questionnaire prior to SLE diagnosis (or matched index date). We used multivariable logistic regression to develop sequential models of SLE risk prediction, calculating the area under the receiver operating characteristic curve (AUC). Three models were generated: 1) SLE wGRS, 2) age, race, cohort, lifestyle and environmental factors and 3) model 2 + SLE wGRS. Models were internally validated using a bootstrapped estimate of optimism of the AUC. This measure of overfitting is based on average difference between predictive ability of model using original sample, and that of models using each bootstrap sample.

Results: 138 incident cases of SLE were matched to 1136 women who did not develop SLE. Characteristics of the SLE cases and their matched controls are shown in Table. The results of our three successive prediction models are shown in Figure. The expanded model 3, including both lifestyle and genetic factors, had the best discrimination, with an AUC of 0.721 and optimism corrected AUC of 0.691.

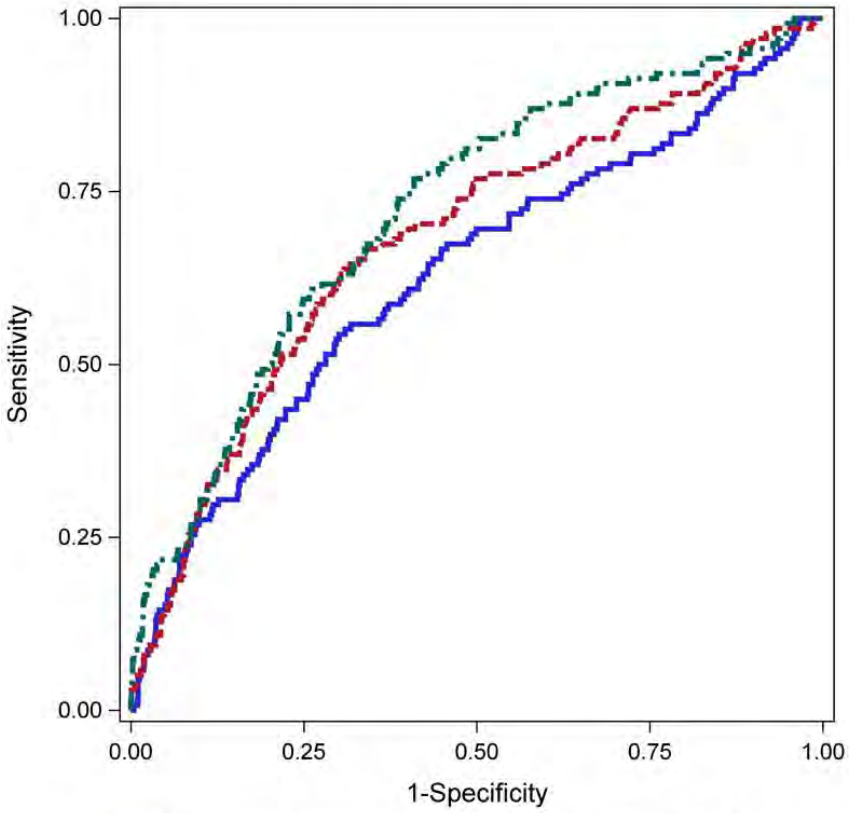
Conclusion: A combination of lifestyle and environmental factors and weighted genetic risk score accurately classified future SLE risk with good AUC of 0.721. To our knowledge, this is the first SLE prediction model using environmental and genetic factors and might be feasibly employed in at-risk populations. The NHS cohorts include few non-White women with blood samples, and mean age at incident SLE was in early 50s given enrollment age, limiting generalizability and calling for further research in more diverse cohorts.

Table. Demographic and Clinical Characteristics of the Female Nurses' Health Study SLE Cases and their Matched Controls at Index Date of SLE Diagnosis

	NHS SLE Cases (138)	NHS Controls (1136)
Mean age in years (SD)	51.8 (10.9)	53.5 (10.3)
Non-European ancestry %	1.5	1.4
Never/Distant Smoker %	82.6	85.1
Current/Recent* Smoker %	17.4	14.9
Mean number of 1997 American College of Rheumatology Criteria for SLE Classification (SD)	4.7 (1.2)	--
ANA+ %	94.9	--
Arthritis %	76.1	--
Hematologic involvement %	53.6	--
Renal involvement %	14.5	--
dsDNA+ %	39.1	--

* quit within 4 years

Figure. Receiver Operating Characteristic (ROC) Curves for SLE Risk Prediction in Nested Case-Control Study within Nurses' Health Study Cohorts (1976-2018)



------ **Model 1**: SLE weighted genetic risk score (wGRS, 86 SNPs and 10 HLA) **(0.6288)**
------ **Model 2**: Age, race, cohort and lifestyle/environmental factors (smoking (current/recent vs. past/never), alcohol use (≤ vs. >5 gms/day), socioeconomic status (zip-code level median household income), U.S. region, menarchal age (< vs ≥ age 10), oral contraceptive use (current/past/never), menopausal status/ postmenopausal hormone use, body mass index (non-obese vs. obese > 35 kg/m^2) **(0.6820)**

SESSION INFORMATION

Session Date: Sunday, November 7, 2021

Session Title: Abstracts: Epidemiology & Public Health I: Risk in Rheumatic Diseases (0988–0991)

Session Type: Abstract Session

Session Time: 4:00PM–5:00PM

Background/Purpose: Hydroxychloroquine (HCQ) is a key treatment for patients with lupus and other rheumatic diseases; however, the known risk factors for HCQ retinopathy (its major toxicity), are mostly derived from prevalent case analyses. We determined the risk factors for incident HCQ retinopathy within a large-scale, longitudinal incident user cohort.

Methods: We conducted a nested case-control study within a large cohort of incident HCQ users identified from a US integrated health network who continued HCQ for ≥5 years during the study period, 1997-2020. We assessed the outcome of retinopathy by prospective assessment of spectral domain-optical coherence tomography (SD-OCT) scans. All scans were reviewed by an expert ophthalmologist (RM), and a second expert ophthalmologist (MM) reviewed all abnormal scans and a random subset of normal scans. Discrepant cases were adjudicated by consensus between the two readers. We identified the dates of earliest abnormal scans. Each SD-OCT scan was graded as

ABW, actual body weight; IBW, ideal body weight; CKD, chronic kidney disease
*For all models, patients were matched by age, sex, and HCQ initiation year. For race/ethnicity, models adjusted for CKD and number of prescription days covered. For CKD, model adjusted for race/ethnicity and number of prescription days covered. For duration of use, models adjusted for race/ethnicity, CKD, and average daily dose per 100mg. All other models adjusted for race/ethnicity, CKD, and number of prescription days covered.

mild, moderate, or severe retinopathy, no retinopathy, or non-HCQ retinopathy (such as macular degeneration), and retinopathy cases were subclassed as parafoveal or pericentral pattern. Cases with incident HCQ retinopathy were matched with up to 5 controls by age, sex, and HCQ initiation year using risk set sampling. Using pharmacy dispensing records, we assessed HCQ duration of use, cumulative dose, average daily dose, and dose per actual body weight (ABW) and ideal body weight (IBW). Candidate risk factors also included race/ethnicity and chronic kidney disease (CKD). We used conditional logistic regression to assess the association between potential risk factors and the risk of HCQ retinopathy overall, by severity, and by pattern.

Results: Of 4,899 long-term HCQ users, we identified 164 patients with incident HCQ retinopathy (100 mild, 38 moderate, and 26 severe cases), with a parafoveal pattern in 131 and pericentral pattern in 33 patients. We matched 159 cases with 755 controls. The mean age at HCQ initiation was 56 years; over 90% were female (**Table 1**). The risk of HCQ retinopathy doubled for every additional 5 years of use (**Table 2**). Cumulative dose was associated with an

Average HCQ daily dose, per IBW		
Less than 5.2 mg/kg	1.0 (reference)	1.0 (reference)
Between 5.2-<6.5 mg/kg	2.49 (1.13-5.50)	2.23 (0.97-5.14)
Between 6.5-<7.8 mg/kg	7.63 (3.20-18.24)	6.61 (2.59-16.86)
Greater than or equal to 7.8 mg/kg	9.26 (2.83-30.36)	10.06 (2.69-37.57)

ABW, actual body weight; IBW, ideal body weight; CKD, chronic kidney disease
*For all models, patients were matched by age, sex, and HCQ initiation year. For race/ethnicity, models adjusted for CKD and number of prescription days covered. For CKD, model adjusted for race/ethnicity and number of prescription days covered. For duration of use, models adjusted for race/ethnicity, CKD, and average daily dose per 100mg. All other models adjusted for race/ethnicity, CKD, and number of prescription days covered.

adjusted risk ratio of 4.28 (95% CI 2.69-6.81) per additional 500g, and dosing category per mg/kg of ABW or IBW strongly correlated with the risk of retinopathy. Asian patients had an increased risk of HCQ retinopathy overall, moderate/severe grade, and the pericentral pattern. CKD was associated with 2x higher risk of overall retinopathy and a 3x higher risk of moderate/severe retinopathy (**Table 3**).

Conclusion: The risk of incident HCQ retinopathy increases with higher dosing per ABW and per IBW in a dose-response manner. We found cumulative HCQ dose, duration of use, CKD, and Asian race to be independent risk factors for incident HCQ retinopathy including moderate/severe cases. Patients with these risk factors may warrant closer monitoring.

Abstract Number: 0990

Lower Incidence of COVID-19 but Higher Mortality in Patients with Inflammatory Arthritis Compared to Controls in Wales, United Kingdom: A Population Epidemiological Study

Roxanne Cooksey[1], Mark Atkinson[2] and **Ernest Choy**[3], [1]Cardiff University, Cardiff, Wales, United Kingdom, [2]Swansea University, Swansea, Wales, United Kingdom, [3]CREATE Centre, Cardiff University, Cardiff, Wales, United Kingdom

SESSION INFORMATION
Session Date: Sunday, November 7, 2021
Session Title: Abstracts: Epidemiology & Public Health I: Risk in Rheumatic Diseases (0988–0991)
Session Type: Abstract Session
Session Time: 4:00PM–5:00PM

Background/Purpose: The COVID-19 pandemic has caused over 3 million deaths. Having inflammatory arthritis (IA) and anti-rheumatic medications increase the risk of infections. Comorbidities, common in IA, have been associated with increased mortality with COVID-19. In the U.K, including Wales, governments advised vulnerable individuals including many patients with IA to self-isolate at home (shielding) by letters.

A small primary care cohort and the global rheumatology registry found an increased risk of severe disease and mortality in patients with rheumatic diseases (4-5). Comorbidities and a moderate to a high dose of glucocorticoids were associated with a higher risk of being hospitalised.

Using the complete COVID-19 test data for the entire nation of Wales, U.K, we compared the incidence and mortality of COVID-19 in patients with IA with controls for an entire nation with a 3 million population

Methods: All individuals who tested positive for COVID-19 from 1/3/20 to 12/05/21 formed the population. Primary care and hospital healthcare records were linked anonymously using a multiple encryption system by NHS Wales Informatics Service (6). Individuals with diagnosis codes for Rheumatoid Arthritis, Psoriatic Arthritis and Ankylosing Spondylitis comprised the IA patients, while those without these codes were the control population. Individuals who were under 18 years of age when tested for COVID-19 were excluded from the analysis.

The incidence rate of COVID-19 was assessed by Chi-square statistics. COX proportional hazard models were used to generate hazard ratios (HR) of death following COVID-19 for IA patients compared to controls. Univariable analysis informed the significant candidate variables (at $p< 0.05$ level of significance) to be added to the final model in a stepwise model. Analyses were conducted for 1st (Mar-Jun 20) and 2nd (Sep 20-May 21) waves as well as in between these periods.

Results: Over 3 million COVID-19 tests were conducted. The incidence rate of COVID-19 for patients with IA was 2,031/100,000, compared to 22,755/100,000 for those without IA (Chi-Square p=0.0001). Patients with IA were statistically significantly older and had more comorbidities.

The proportion of patients with IA admitted to hospital post-COVID test was statistically significantly higher compared to those without IA (1st wave: difference 24.5%, 95% CI: 18.4-30.7). The proportion of patients deceased following COVID-19 was statistically significantly higher in IA patients during the first wave (difference 21.4, 95% CI: 15.7 to 27.4) and second wave (difference 10.9, 95% CI: 8.6 to 13.6) (Table 1).

Table 1: Hazard ratio of risk of death of IA patients compared to controls across the pandemic

	Wave 1:		Period between waves		Wave 2

Glucocorticoids	2.36 (2.16 to 2.57)*	-	2.81 (2.13 to 3.69)*	-	2.71 (2.52 to 2.9)*	1.10 (1.01 to 1.19)*

** Significant at p<0.05*

Adjusted COX hazard models showed that being a shielded individual, advanced age, ever smoker, diabetes, previous history of serious infection requiring hospitalisation and glucocorticoids were associated with increased risk of death in IA patients compared to controls (Table 1). Being female was associated with a reduced risk of death.

Conclusion: Patients with IA have a lower risk of contracting COVID perhaps due to shielding. Mortality was significantly higher in IA patients compared to controls which was due to older age and had more comorbidities. The only IA related risk factor associated with higher mortality was corticosteroids.

Does Diet Affect Gout Risk Differently Among Genetically Predisposed Women?: Prospective Female Cohort Study Findings over 34 Years

Chio Yokose[1], Natalie McCormick[2], Na Lu[3], Amit Joshi[2] and Hyon K. Choi[4], [1]Massachusetts General Hospital, Waltham, MA, [2]Massachusetts General Hospital, Boston, MA, [3]Arthritis Research Canada, Vancouver, BC, Canada, [4]Massachusetts General Hospital, Lexington, MA

SESSION INFORMATION

Session Date: Sunday, November 7, 2021

Session Title: Abstracts: Epidemiology & Public Health I: Risk in Rheumatic Diseases (0988–0991)

Session Type: Abstract Session

Session Time: 4:00PM–5:00PM

Background/Purpose: Gout has long been considered a male disease. However, several recent analyses of the Global Burden of Disease (GBD) Study report a disproportionate worsening of gout burden among women (Xia Rheumatology 2020), suggesting intensive dietary measures for gout prevention are indicated, especially in women. The Dietary Approaches to Stop Hypertension (DASH) diet lowers serum urate and is associated with a lower risk of incident gout while the Western diet is associated with an increased risk (Rai BMJ 2017). However, whether the dietary impact is affected by genetic risk remains unknown. We investigated the potential interaction between genetic predisposition and diet on the risk of incident gout among women.

Methods: We examined the role of genes on the association between two dietary patterns (DASH and Western) on the risk of incident gout in 18,247 women from the Nurses' Health Study (NHS) over 34 years. Using validated food frequency questionnaires, for each participant we derived: 1) DASH score emphasizing fruits, vegetables, nuts and legumes, whole grains, low-fat dairy, and reduced intake of saturated fat and sugar-sweetened beverages (SSBs) and 2) Western diet score characterized by high intake of red and processed meats, SSBs, desserts, French fries, and refined grains. The DASH and Western diet scores were categorized into quintiles, with higher quintiles indicating higher adherence to these dietary patterns. We derived a genetic risk score (GRS) using 114 serum urate single nucleotide polymorphisms from the latest GWAS (Tin Nat Genet 2019), with a higher GRS indicating a higher genetic predisposition for hyperuricemia.

Table 1. Baseline Gout Risk Factors by Genetic Risk Score

	NHS	
	Genetic Score of 114 SNPs	
	Below Mean (n = 9165)	Above Mean (n = 9082)
Age, years, mean (SD)	47.1 (6.9)	47.0 (6.9)
Systolic blood pressure, mm Hg, mean (SD)	123.9 (14.4)	124.2 (14.6)
Diastolic blood pressure, mm Hg, mean (SD)	78.8 (7.6)	79.1 (7.7)
Reported hypertension, %	15	17
BMI, kg/m^2, mean (SD)	24.5 (4.5)	24.5 (4.4)
Estrogen use, %		
Physical activity, MET-hours/week, mean (SD)	14.6 (20.8)	14.0 (19.3)
Alcohol, g/d, mean (SD)	6.5 (10.2)	6.6 (10.5)
Sweetened soft drink intake, servings/d, mean (SD)	0.3 (0.6)	0.3 (0.6)
Meat intake, servings/d, mean (SD)	1.1 (0.8)	1.1 (0.8)
Seafood intake, servings/d, mean (SD)	0.2 (0.2)	0.2 (0.2)
Low-fat dairy foods intake, servings/d, mean (SD)	0.9 (1.0)	0.9 (1.0)
High-fat dairy foods intake, servings/d, mean (SD)	1.4 (1.3)	1.4 (1.3)
Diuretic use, %	9.6	10.1

Values are age-adjusted (except for age).

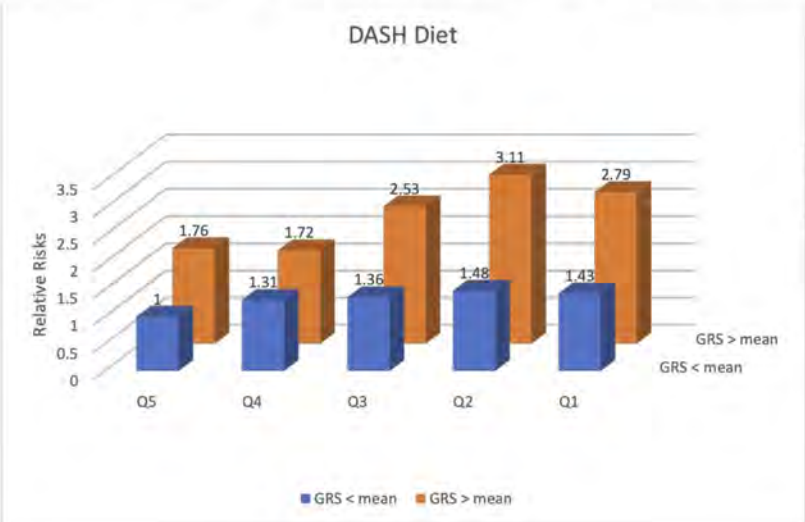
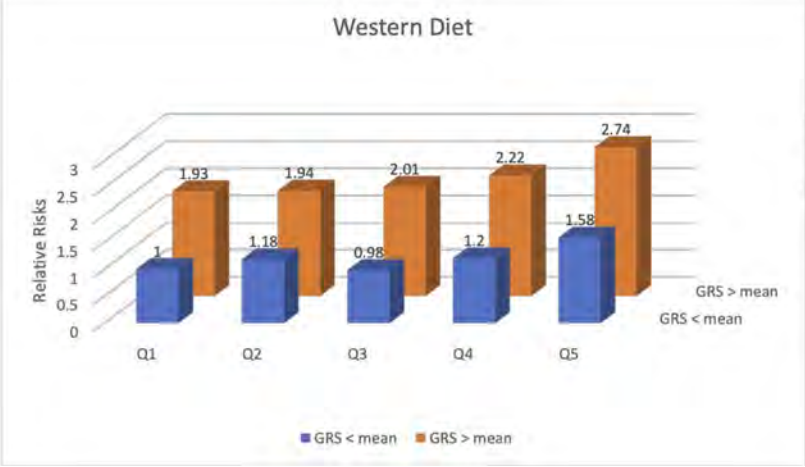
*Adjusted for age (continuous), menopause, use of hormone therapy (never, past or current), history of hypertension, systolic and diastolic blood pressure (continuous), alcohol (continuous), total energy intake (continuous), and intake of meat, seafood, and dairy foods (continuous).

Figure 1. Joint Association of GRS and Diet on Relative Risk of Incident Gout



RERI (additive interaction): 0.57 (p=0.06)
Multiplicative interaction: 1.12 (p=0.56)



RERI (additive interaction): 0.20 (p=0.52)
Multiplicative interaction: 0.90 (p=0.57)

Results: We ascertained 481 incident cases of self-reported gout among women without a genetic predisposition and 859 incident cases among women with a genetic predisposition in NHS. The baseline clinical gout risk factors were similarly distributed among women with and without a genetic predisposition (Table 1). For the DASH diet, the multivariable relative risks (RR) of gout for quintiles 5 through 1 were 1.0, 1.31, 1.36, 1.48, 1.43 (95% CI, 1.06 to 1.92) among those without a genetic predisposition and 1.76, 1.72, 2.53, 3.11, 2.79 (95% CI, 2.15 to 3.61) among those with a genetic predisposition, respectively (Figure 1 and Table 2). Comparing quintiles 5 vs. 1, this yielded a relative excess risk due to interaction (RERI) of 0.57 (95% CI, -0.02 to 1.17) which approached statistical significance (p=0.06). For the Western diet, the RR of gout for quintiles 1 through 5 were 1.0, 1.18, 0.98, 1.20, 1.58 (95% CI, 1.17 to 2.14) among those without a genetic predisposition and 1.93, 1.94, 2.01, 2.22, 2.74 (95% CI, 2.07 to 3.62) among those with a genetic predisposition, respectively (Figure 1 and Table 2). This yielded RERI of 0.20 (95% CI, -0.40 to 0.81, p=0.52).

Conclusion: In this large prospective female cohort with 34 years of follow-up, regardless of genetic predisposition, DASH diet was associated with lower risk of incident gout while Western diet was associated with higher risk. The impact of DASH diet appeared stronger among those with a genetic predisposition to gout. These data support the recent GBD study's recommendation for intensive dietary measures for gout prevention, especially in females.

Inflammatory Arthritis in HIV-Infected Humanized Mice

Can Sungur[1], Ayse Ozanturk[1], Hongbo Gao[1], Li-ping Yang[1], Liang Shan[1] and Wayne Yokoyama[2], [1]Washington University, St Louis, MO, [2]Washington University School of Medicine, St. Louis, MO

SESSION INFORMATION
Session Date: Monday, November 8, 2021
Session Title: Innate Immunity Poster (0992–1006)
Session Type: Poster Session C
Session Time: 8:30AM–10:30AM

Background/Purpose: Human immunodeficiency virus (HIV) remains a significant life-threatening agent and burden on public health. Lesser studied and understood aspects of HIV include HIV-associated inflammatory arthritis. By utilizing humanized mice with human cytokine knock-ins that better support a human immune system than other models, we studied HIV-associated arthritis and enthesitis to understand their development and progression.

Methods: MISTRG-IL15 mice (human M-CSF/GM-CSF, IL-3, SIRPα, TPO, RAG2 -/-, IL2rg-/-, and IL-15 knocked into the respective endogenous mouse loci) were reconstituted with CD34+ hematopoietic stem cells obtained from human fetal cord blood. After checking for engraftment after 6-8 weeks, we infected reconstituted mice with HIV. Synovial tissues were obtained from the knee joints of the hind limbs at different time points and processed into single cell suspensions. Intercellular staining was performed on cells incubated with PMA/Ionomycin for 4 hours and then permeabilized and fixed for flow cytometry. NK cells were defined as CD3-CD56+. Histochemistry was also performed on hind paws that were fixed in 4% paraformaldehyde. Samples were then sectioned and stained with H&E for histologic analysis. Different chemokine receptor-tropic HIV viruses were also utilized to determine importance of specific infected cells on development of inflammation.

Results: Humanized MISTRG-IL15 mice developed inflammatory arthritis as well as enthesitis after HIV infection. Significant increases in total inflammatory cells and NK cells were seen in the synovial tissue throughout the course

of infection. GM-CSF producing NK cells also increased throughout the course of HIV infection. Late in the course of infection, IFNγ- and granzyme B-producing NK cells increased, along with a pro-inflammatory environment in the synovial tissue. Histologic analysis showed increased cellular infiltrate in the synovium and tendons of mice infected by HIV infection with erosive changes that worsened during course of infection. Antiretroviral therapy (ART) eliminated cellular infiltration while cessation of therapy resulted in return of cellular infiltration in synovial tissue. Use of a chemokine receptor-tropic HIV virus that does not infect macrophages (X4-tropic) showed reduced pro-inflammatory cytokine production by NK cells, strongly suggesting HIV-infected macrophages induced the NK cell changes.

Conclusion: We have developed a unique humanized mouse model of HIV infection which allows opportunities to study HIV-associated arthritis and enthesitis in depth. In addition to providing a model to study arthritis induced by other human pathogens, findings from such studies will provide mechanistic understanding of inflammatory arthritis and enthesitis.

The Mechanistic Basis of anti-CD6 as a Novel Form for the Treatment of Autoimmune Diseases and Cancer

Mikel Gurrea-Rubio[1], Jeffrey Ruth[1], Qi Wu[1], Eliza Pei-Suen Tsou[1], Phillip Campbell[1], Peggy Randon[1], M.Asif Amin[1], Nora Singer[2], Feng Lin[3] and David Fox[1], [1]University of Michigan, Ann Arbor, MI, [2]The MetroHealth System, Cleveland, OH, [3]Cleveland Clinic, Cleveland, OH

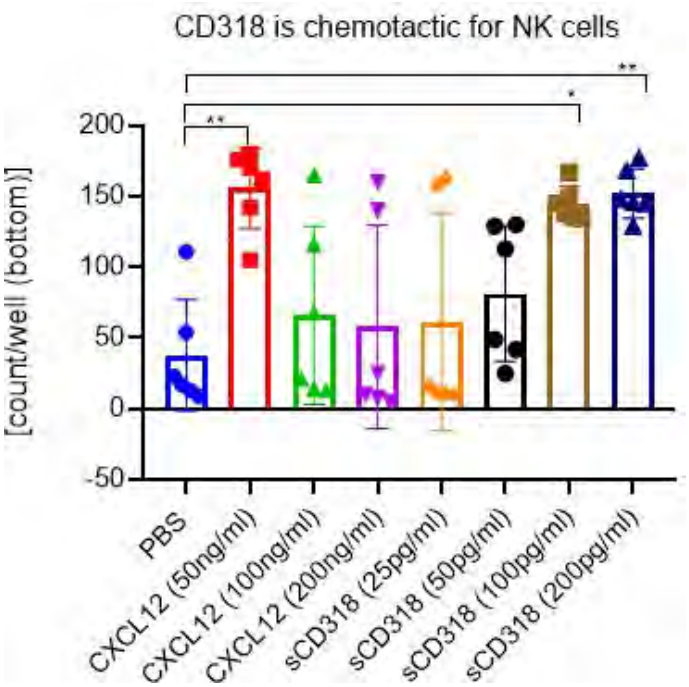
SESSION INFORMATION
Session Date: Monday, November 8, 2021
Session Title: Innate Immunity Poster (0992–1006)
Session Type: Poster Session C
Session Time: 8:30AM–10:30AM

Background/Purpose: The use of Immune Checkpoint Inhibitors (ICIs) is limited by the induction of immune-related adverse events. CD6 is expressed by most T lymphocytes and a subset of natural killer (NK) cells, and engages the ligands *CD166/ALCAM* and *CD318*. Interrupting CD6 interaction with its ligands using UMCD6 (anti-CD6) reverses autoimmunity in mouse models of rheumatoid arthritis, multiple sclerosis and uveitis, due to suppression of differentiation of effector Th1 and Th17 cells. Recently, we have demonstrated that UMCD6 directly activates CD8+T and NK cells, enhancing these cells to kill breast, lung, and prostate cancer lines, even more robustly than ICIs directed to the PD-1/PD-1L pathway. We now explore the mechanisms by which UMCD6 activates NK cells while controlling the differentiation of CD4 cells.

Methods: RNAseq was used to study the molecular changes occurring during NK activation by CD6 blockade. Data analysis was conducted using DESeq2 software, and genes showing a Padjusted ≤0.05 were considered significantly differentially expressed.

Chemotaxis of NK cells was assessed by the number of isolated human NK cells using an IncuCyte® Chemotaxis System assay. One-way ANOVA was used to compare groups. Significance was defined as $p < 0.05$.

To identify NK structures that are involved with the functional pathway that is triggered by UMCD6, we generated monoclonal antibodies from Balb/C mice immunized with NK-92 cells.



Results: Our RNAseq data from UMCD6-treated NK cells demonstrate extensive changes in gene expression induced by UMCD6. Expression of 180 genes was altered significantly. These genes included: i) activating NK receptors (e.g., Hcst [DAP10], and CD244 [2B4]), and ii) genes whose protein products are important in the immunoregulatory signaling pathways PI3K, AKT, and mTOR.

NK cells migrate in response to sCD318 with a peak response at 200 pg/ml ($p < 0.01$). This concentration of sCD318 is detectable in supernatants of cancer cell lines that we have used as targets for UMCD6-stimulated lymphocytes. NK cells also migrate toward stromal cell-derived factor (SDF)-1α (CXCL12) at a concentration of 25 ng/ml ($p < 0.01$), consistent with studies of NK chemotaxis to CXCL12 into sites of inflammatory responses or malignancies.

Hybridoma supernatants from Balb/C mice immunized with NK-92 cells have been screened to select antibodies whose corresponding surface structures are up-or down-regulated by UMCD6, co-internalize with UMCD6, and/or inhibit or augment target cell killing by NK cells. Thus far, 10 hybridomas have been selected based on informative positive results from this screening process.

Conclusion: The profound changes in gene expression induced by UMCD6 (anti-CD6) are consistent with our previous studies showing UMCD6 to concurrently control autoimmunity through effects on CD4+ lymphocyte differentiation while enhancing killing of cancer cells through activation of CD8+ and NK cells. The chemotactic properties of sCD318, a ligand of CD6, toward NK cells also demonstrates the importance of CD6 in migration of cytolytic lymphocytes into the tumor microenvironment. Altogether, these data point to a potential new approach to cancer immunotherapy that would suppress rather than instigate autoimmunity.

CD318 is chemotactic for NK cells. Chemotaxis of NK cells was assessed by the number of isolated human NK cells using an IncuCyte® Chemotaxis System assay. NK cells migrate in response to sCD318 with a peak response at 200 pg/ml ($p<0.01$). NK cells also migrate toward stromal cell-derived factor (SDF)-1α (CXCL12) at a concentration of 25 ng/ml ($p<0.01$). PBS was used as negative control.

Abstract Number: 0994

Role of SLE Associated Cytokines in Generation of Mature Neutrophils

Neelakshi R. Jog, Julia Nguyen and Judith James, Oklahoma Medical Research Foundation, Oklahoma City, OK

SESSION INFORMATION
Session Date: Monday, November 8, 2021
Session Title: Innate Immunity Poster (0992–1006)
Session Type: Poster Session C
Session Time: 8:30AM–10:30AM

Background/Purpose: Systemic lupus erythematosus (SLE) is a systemic autoimmune disease characterized by autoantibody production and periods of elevated disease activity. Recent studies indicate that along with dysfunctional adaptive immune responses, neutrophils are also important in disease pathogenesis. SLE patients have higher numbers of low-density granulocytes (LDGs) in peripheral blood that express neutrophil markers and are hyperresponsive to external stimuli. LDGs are suggested to be pathogenic in lupus. However, the mechanisms leading to increased LDGs in SLE patients are unclear.

Methods: Peripheral blood mononuclear cells from 19 SLE patients with varying disease activity and 11 controls were enriched by density gradient centrifugation. LDG numbers were determined by flow cytometry. Plasma cytokines were measured by xMAP assays. Induced pluripotent stem cells (iPSC) derived from adult peripheral blood CD34+ cells were differentiated into neutrophils using feeder-culture conditions. Cultures were supplemented with IL-13 at different stages of differentiation: day 7 (hemangioblasts-like cells to CD34+ hematopoietic stem cells (HSC)), day 12 (HSC into CD45+ hematopoietic cells), day 18 (CD45+ cells into neutrophil precursors), day 23 (maturation to segmented neutrophils).

Results: SLE patients with elevated disease activity had significantly higher frequency of immature LDGs as determined by surface marker expression (p=0.005). IL-13 levels were higher in SLE patients with elevated disease activity compared to low disease activity patients (p=0.01) and controls (p=0.006), and the levels correlated negatively with absolute neutrophil numbers (r = -0.4404, p= 0.0354). Our goal was to test whether abnormal timing and excessive IL-13 exposure of hematopoietic stem cells (HSC) leads to generation of immature neutrophils in SLE patients due to defective differentiation. The iPSC cultures were induced into neutrophilic differentiation. By day 23 of differenti-

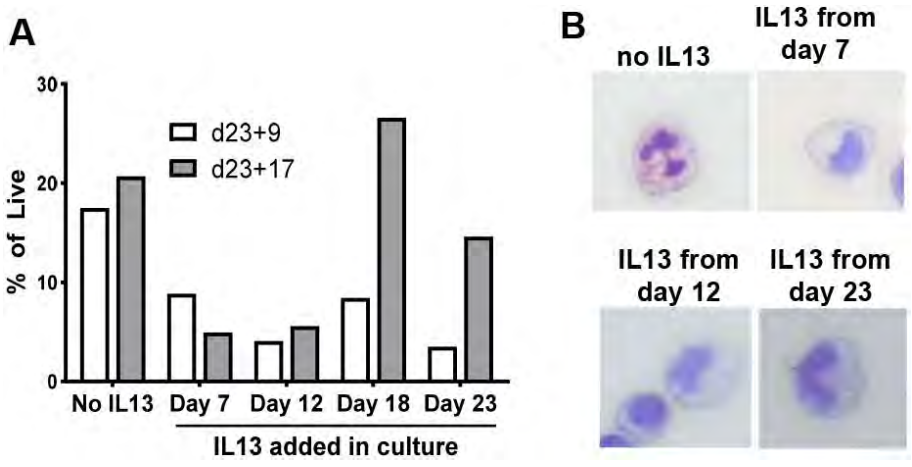

Figure 1. Early IL-13 exposure inhibits neutrophil differentiation. CD45+cells from day 23 of iPSC differentiation were allowed to mature into neutrophils additional 17 days. A. Flow cytometry was performed on day 9 (Day 23+9) and 17 (Day 23+17). Percent of mature neutrophils are shown. B. Giemsa staining on cytospins of differentiating cells. Days are the day of differentiation IL-13 supplementation was started.

ation, presence of IL-13 reduced frequencies of neutrophilic cells. The presence of IL-13 did not inhibit early stages of neutrophil differentiation. However, the frequencies of more mature band and segmented cells was significantly reduced when exposed to IL-13 at day 7. In the cultures where IL-13 supplementation was started at day 18 and day 23, neutrophils were generated when allowed to differentiate for a longer duration (Fig 1). Thus, although delayed, maturation was restored with late IL-13 exposure. Although IL-13 inhibited neutrophilic differentiation, it did not affect the generation of CD34+ HSC or CD45+ cells.

Conclusion: Our data suggest that SLE patients may have dysregulated development of myeloid cells in the bone marrow due to the cytokine milieu during elevated disease activity. Abnormal timing and exposure to IL-13 may increase immature neutrophils in SLE patients, possibly by altering the differentiation potential of CD34+ HSC. The functional responses of these newly generated neutrophils may differ due to differences in the bone marrow transit time. The dysregulation of granulopoiesis therefore may generate neutrophils that further exacerbate autoimmune response.

Innate Immune Tolerance Attenuates Zymosan-Induced Arthritis, Inflammatory Gene Expression and Synovial Neutrophil Infiltration

Richard Bell, Chao Yang, Caroline Brauner, Upneet Sohki, Rouxi Yuan, Bikash Mishra, Mahesh Bachu and Lionel Ivashkiv, Hospital for Special Surgery, New York, NY

SESSION INFORMATION
Session Date: Monday, November 8, 2021
Session Title: Innate Immunity Poster (0992–1006)
Session Type: Poster Session C
Session Time: 8:30AM–10:30AM

Background/Purpose: Zymosan (Zym) induces arthritis through TLR2- and Dectin-1-activated NK-κB signaling and inflammatory myeloid cell infiltration into the synovium of the injected joint. Innate immune tolerance after an initial TLR challenge dampens inflammatory responses induced by a second challenge. It is currently unknown if this innate immune tolerance affects Zym responses and can attenuate the effector phase of inflammatory arthritis. We hypothesize that LPS preconditioning dampens zymosan-induced innate inflammatory response and arthritis.

Methods: C57BL6 mice were administrated 10ul/g PBS or 0.5mg/kg lipopolysaccharide (LPS) intraperitoneally for 24 h and then given intraarticular (IA) injections of 180μg Zym in the right knees (n=5-12/group). H&E histology on D7 after IA Zym was performed to measure synovitis. Serum cytokine analysis at 3 h after IA Zym (n=3-4/group) and flow cytometry (FC) for myeloid cell subsets in the periarticular tissue at D2 and D7 after IA Zym (n=6-8/group) were conducted. $CD14^+$ cells from healthy human whole blood donors were isolated, cultured with M-CSF overnight, and either allowed to “rest” (R), treated with 10 ng/ml LPS for 24 h (L), stimulated with 16 μg/ml Zym for 3 h (Z), or LPS-24 h + Zym-3 h (L+Z). Cells were then harvested for mRNA expression (n=7) or stained for intracellular cytokine (n=3) analysis via FC. Western blot of TBK1, NF-κB and MAPK p38 signaling activation at 5, 15, 30, and 60 min after Zym treatment was performed (n=3).

Results: IA injection of Zym significantly induced synovitis, periarticular inflammation and immune cell infiltration while LPS pretreatment significantly attenuated synovitis (Fig 1). Serum neutrophil chemoattractant proteins CXCL1

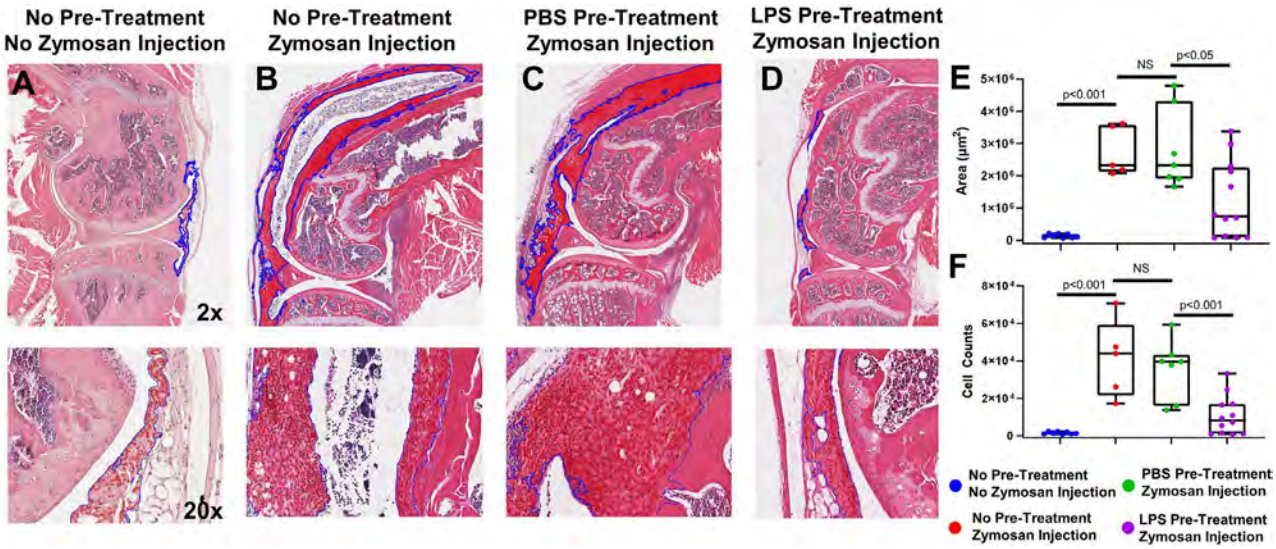

Figure 1. LPS pre-treatment attenuates zymosan induced arthritis. Compared to the un-injected knee (A), zymosan intraarticular injection induces synovitis (B) with no change in the PBS pre-treatment. However, LPS pretreatment reduces the amount of synovitis that occurs 7 days after Zym injections. Quantification of the synovial area by semi-automated segmentation (Blue outline in A-D) showed a significant expansion of area with zymosan injections with a decrease with LPS pretreatment (E). Nuclei counting via a watershed nuclei identification algorithm (Red Outline in A-D) within the segmented area showed a similar result (F). Statistical analysis performed with an ANOVA and Tukey's post-hoc test (NS = Not Significant, Data are the average of 1-3 histologic levels per knee).

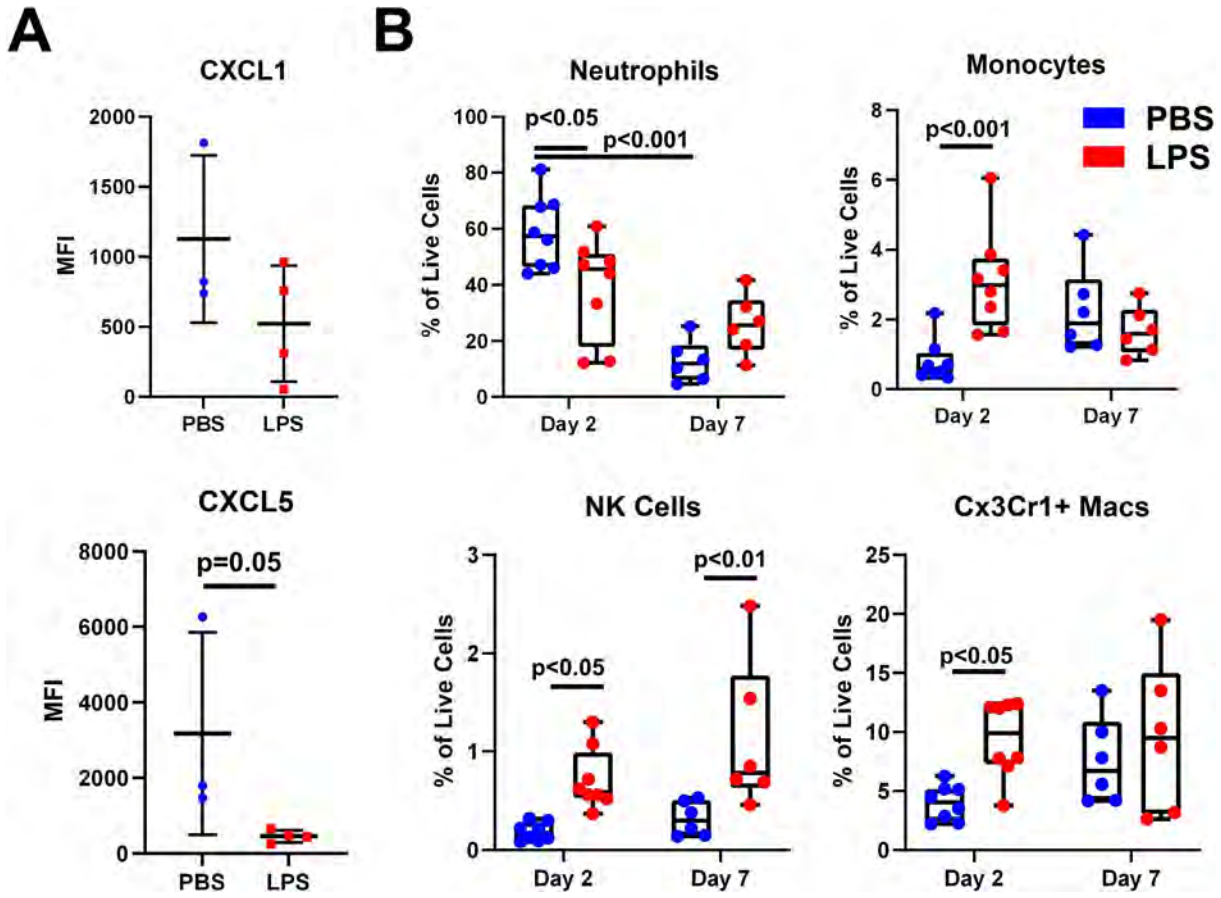

Figure 2. Neutrophil infiltration into the synovium is suppressed at day 2 after zymosan injection. Serum collected at 3 hours after zymosan IA injection in PBS and LPS treated mice suggest that the neutrophil chemokines Cxcl1 and Cxcl5 are lower in LPS treated mice (A). Flow cytometry analysis demonstrates that neutrophile infiltration in to the synovial tissue is decreased at day 2 while monocytes, NK cells and Cx3Cr1 macrophages are all increased at day 2. Statistical analysis was performed with either a Mann-Whitney test or 2-way ANOVA with Tukey's post-hoc test.

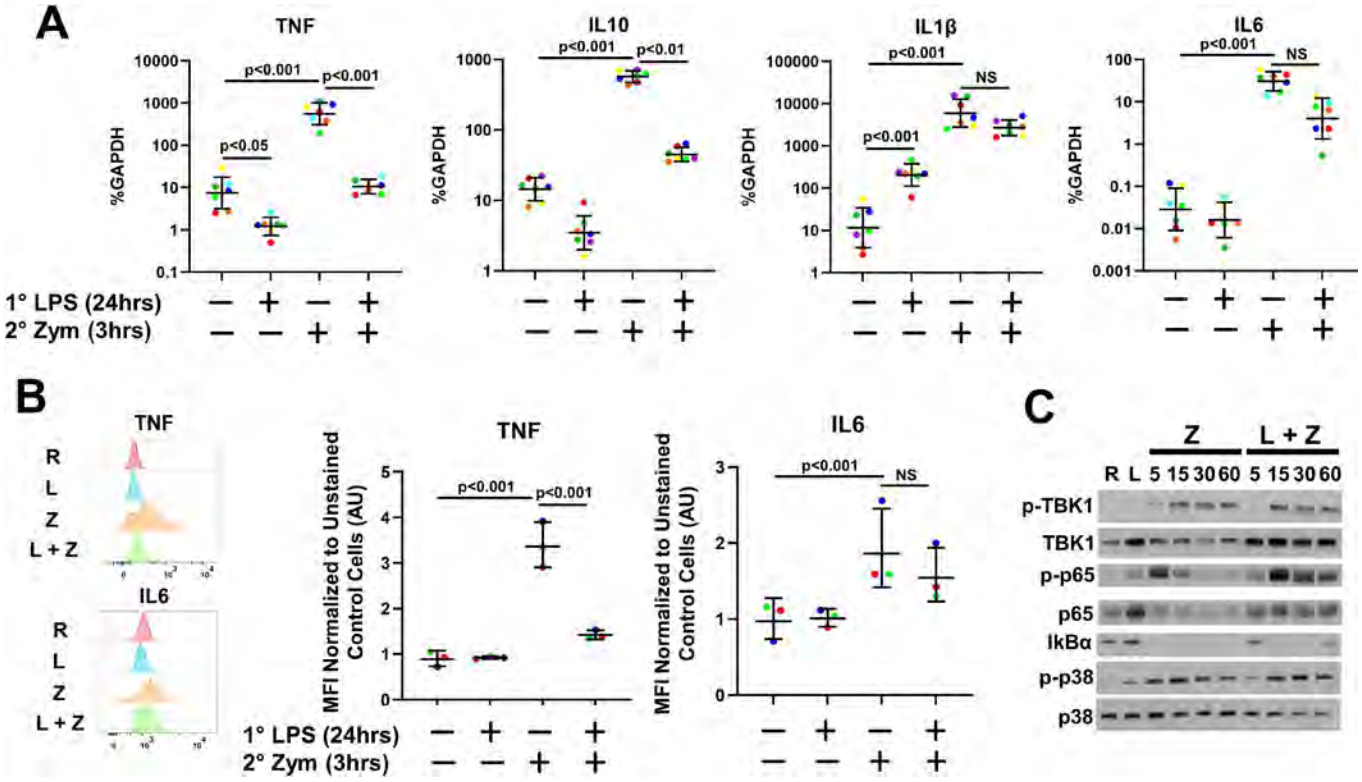

Figure 3. Gene specific tolerization by LPS of the Zymosan inflammatory response in human CD14+ cells. CD14+ cells stimulated with Zym for 3h have increased gene expression and intracellular cytokine staining of TNF, IL10, IL1β and IL6 compared to the resting condition (A, B). However, when these cells are pretreated with LPS for 24h only TNF and IL10 displayed reduced expression. Western blot analysis demonstrates zymosan induced phosphorylation of TBK1, p65, p38 and degradation of IκBα is largely unaffected by LPS pre-treatment (C). Statistical analysis was performed by log transformation of gene expression values with 2-way Repeated Measures ANOVAs and a Tukey's post-hoc test (Each colored dot indicates an individual donor).

and CXCL5 were reduced at 3 h after IA Zym in the LPS pretreated group compared to PBS group (Fig 2A). FC analysis revealed a significant reduction of synovial neutrophils at D2, while Ly6C+/Cd11c- monocytes, NK cells and CX3CR1+/CD11b+/F4-80+ macrophages were increased at D2 after arthritis induction (Fig 2B). RNA and intracellular cytokine expression of CD14+ cells challenged with Zym showed gene-specific tolerization of *Tnf* and *Il10* expression by LPS pretreatment, while *Il1b* and *Il6* induction remained intact (Fig 3 A, B). Western blots of NF-kB, TBk1 and MAPK p38 signaling suggested that LPS pretreatment minimally affects Zym-induced signaling (Fig 3C). Zym-induced expression of *CXCL2* and *CXCL8* in the human monocytes was also suppressed by LPS.

Conclusion: LPS attenuated production of neutrophil chemokines in vivo and in vitro and reduced neutrophil abundance in the synovium, thereby decreasing Zym induced synovitis. LPS pretreatment displayed gene-specific tolerization of Zym-induced gene expression in human monocytes in vitro. Monocyte, macrophage and NK cell infiltration were increased in vivo, however, our in vitro data suggests these populations could be partially tolerized. Interestingly, gene-specific tolerance occurred in the context of intact signaling, suggesting epigenetic mechanisms of gene silencing. Overall, these results suggest that LPS significantly disrupts the inflammatory response to Zym and that innate immune memory could play a role in the effector phase of inflammatory arthritis.

The Stimulator of Interferon Genes (STING) Protects from Bone Loss Through Regulation of Tonic and Induced Type I Interferon Pathways

Susan MacLauchlan[1], Priyanka Kushwaha[1], Albert Tai[2], Jia (Sijia) Chen[3], Catherine Manning[1], Katherine Fitzgerald[4], Shruti Sharma[2] and Ellen Gravallese[5], [1]Brigham and Women's Hospital, Boston, MA, [2]Tufts University School of Medicine, Boston, MA, [3]Brigham and Women's Hospital, Cambridge, MA, [4]University of Massachusetts Medical School, Worcester, MA, [5]Brigham and Women's Hospital, Harvard Medical School, Chestnut Hill, MA

SESSION INFORMATION
Session Date: Monday, November 8, 2021
Session Title: Innate Immunity Poster (0992–1006)
Session Type: Poster Session C
Session Time: 8:30AM–10:30AM

Background/Purpose: The intracellular DNA sensing Stimulator of Interferon Genes (STING) pathway is critical for detection of viral and bacterial pathogen DNA. Hyperactivating mutations in this innate immune pathway are associated with autoinflammatory and autoimmune diseases, including gain of function mutations in STING that lead to STING-Associated Vasculopathy with onset in Infancy (SAVI). Type I interferons (IFN-I) are downstream of STING and regulate many cellular processes. An often under-appreciated aspect of IFN-I signaling, tonic (constitutive) IFN-I signaling, has been proposed as a critical element of cellular homeostasis. Vital for maintaining a balanced threshold of immune genes, tonic interferon-stimulated genes (ISGs) serve to regulate immune responses. We have focused on the role of the STING pathway in both tonic and inducible type I interferon (IFN-I) signaling and its impact on bone homeostasis.

Methods: STING deficient, myeloid specific STING-deficient ($STING^{flox/flox}$LysM $cre^{+/}$), and SAVI mice (activating murine point mutants STING V154M) were studied. Osteoclastogenesis assays were performed *in vitro*, osteoclasts were enumerated *in vivo*, and serum C terminal pyridinoline cross-linked peptide (CTX), a marker of bone resorption, was determined by ELISA. RNA sequencing was performed on osteoclast precursors before and during differentiation with M-CSF and RANKL. In SAVI osteoclastogenesis assays, differentiation was tested in the absence and presence of an IFN-I blocking antibody.

Results: We previously reported that STING-deficient and $STING^{LysM}$-deficient osteoclast precursors form greater numbers of osteoclasts *in vitro* and that STING-deficient mice lose trabecular bone faster than littermate controls, an effect consistent with increased osteoclast activity. Myeloid STING is sufficient for this effect, as ovariectomized $STING^{LysM}$-deficient mice exhibit a significantly greater loss of bone compared to controls. We extend these findings by showing that both STING-deficient and $STING^{LysM}$-deficient mice have increased osteoclast numbers *in vivo,* with evidence of increased bone resorption by serum CTX assays. To address mechanism, bulk RNAseq was performed and showed that STING-deficient osteoclast precursors exhibit a marked reduction in both tonic ISG expression prior to and following RANKL stimulation (Figure 1). To further test whether STING-mediated IFN-I limits osteoclast differentiation, osteoclastogenesis assays were performed using precursor cells from STING gain of function (SAVI) mice. SAVI osteoclast precursor cells showed significantly inhibited osteoclastogenic potential, associated with a decreased expression of differentiation factors. Importantly, blockade of IFNAR1 restored the ability of SAVI precursor cells to form osteoclasts, indicating that STING-regulated IFN-I limits osteoclastogenesis (Figure 2).

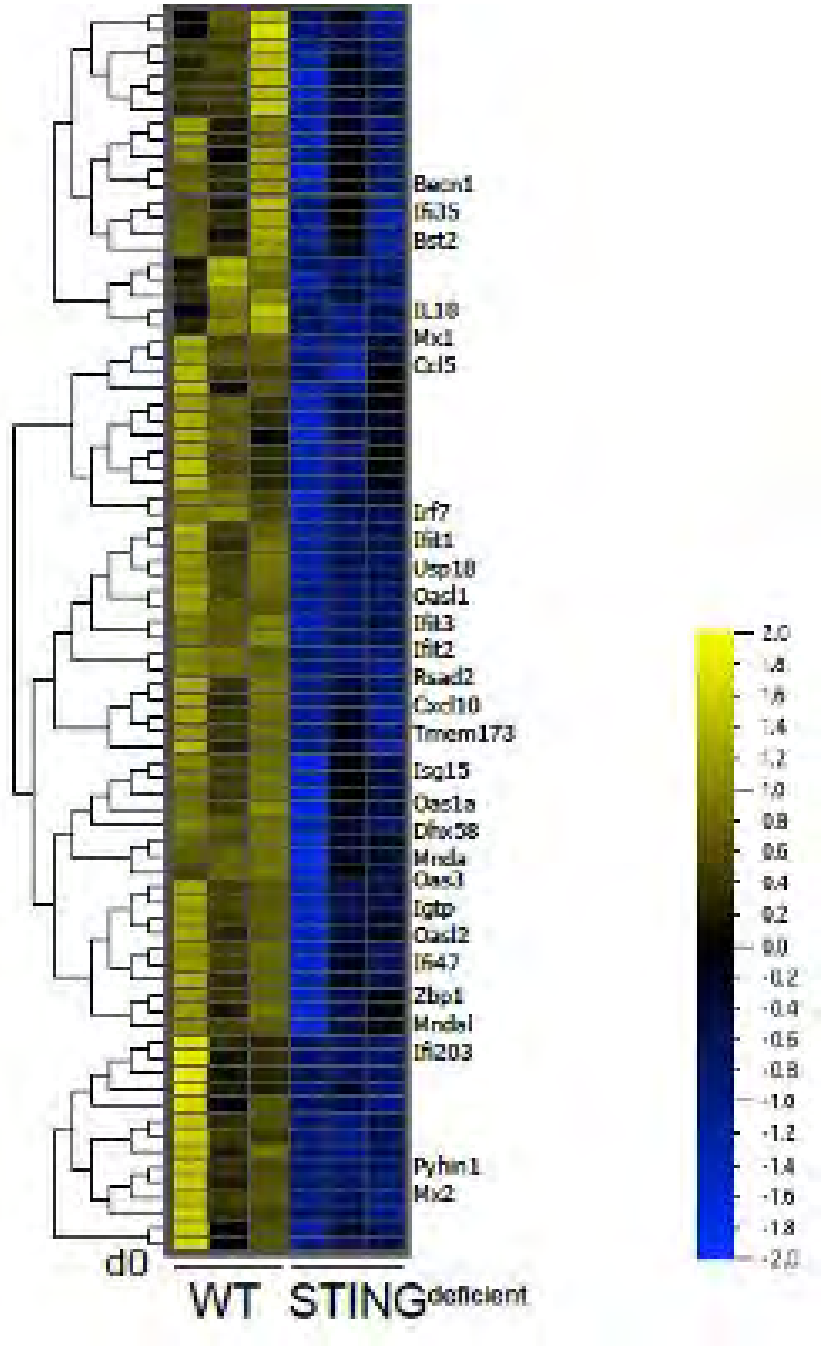

Figure 1. Analysis of the osteoclast precursor transcriptome reveals a STING-dependent tonic IFN-I signature. Heatmap representation shows multiple downregulated ISGs at d0 in STING-deficient osteoclast precursors compared to WT.

Conclusion: STING is an upstream mediator of both tonic and RANKL-induced IFN-I signaling, providing a break on osteoclast formation and protection from bone loss. These data also demonstrate that in settings in which the STING pathway is abnormal or is therapeutically altered, there may be important effects on bone.

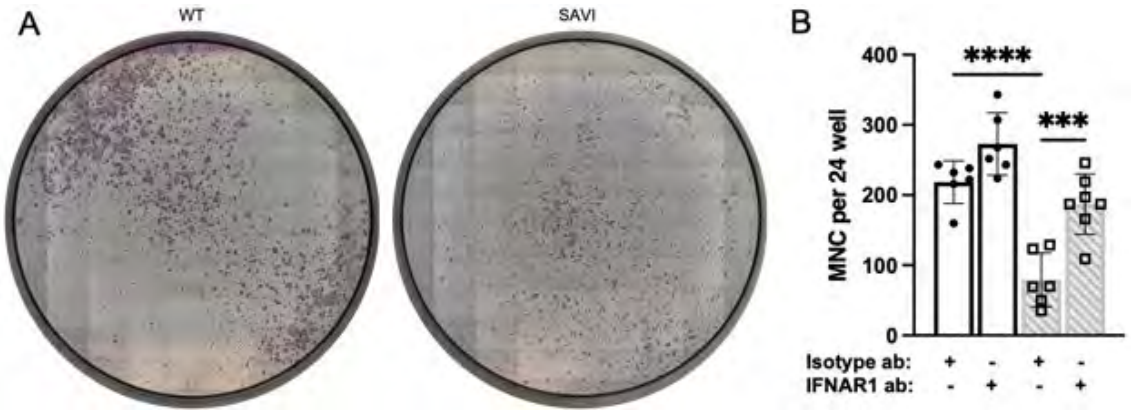

Figure 2. STING activation by SAVI point mutation limits osteoclast formation in an IFNAR1-dependent fashion. A) Representative low magnification images of TRAP stained (purple) WT and SAVI osteoclastogenesis assays at d5. B) More multinuclear cells (MNCs) form in WT (white bars) than SAVI (grey bars), which is reversed in the presence of IFN-blocking antibody (IFNAR1 ab) compared to isotype treated controls.

Citrullinated Vimentin Induces Epigenetic Memory of the Innate Immune System

Katerina Laskari[1], Shweta Sabu[2], Oliver Distler[3], Emmanuel Karouzakis[2] and Michel Neidhart[2], [1]Center of Experimental Rheumatology, Department of Rheumatology, University Hospital Zurich, University of Zurich, Zürich, Switzerland, [2]Center of Experimental Rheumatology, Department of Rheumatology, University Hospital Zurich, University of Zurich, Zurich, Switzerland, [3]Center of Experimental Rheumatology, Department of Rheumatology, University Hospital Zurich/University of Zurich, Zurich, Switzerland

SESSION INFORMATION
Session Date: Monday, November 8, 2021
Session Title: Innate Immunity Poster (0992–1006)
Session Type: Poster Session C
Session Time: 8:30AM–10:30AM

Background/Purpose: During trained immunity, monocytes and macrophages undergo a functional and transcriptional reprogramming toward activation, which is induced by a priming stimulus and results in enhanced responsiveness to subsequent triggers. We aimed to investigate if citrullinated vimentin (c-vimentin), a damage-associated pattern in rheumatoid arthritis (RA), induces trained immunity in vitro in healthy individuals.

Methods: Monocytes isolated from the peripheral blood (EDTA blood, n=22; buffy coats, n=6) of healthy donors by Ficoll-paque centrifugation and negative selection, were stimulated with c-vimentin (0.1 μg/ml) for 24h and re-stimulated 5 days later with the lipopolysaccharide of E.coli (LPS) (10 ng/ml). Protein release (ELISA, Western blot) and gene expression levels (RNA sequencing) were measured. Chromatin accessibility changes were assessed by ATAC sequencing. The methylation of histone H3 at lysine 4 (H3K4) was examined by chromatin immunoprecipitation. The ligand-receptor glycocapture technology was used to identify candidate cell surface targets of c-vimentin.

Results: Priming with c-vimentin induced training in human monocytes, as suggested by the significantly increased levels of secreted interleukin-6 (IL-6), the chemokine CXCL1 and CCL20/Macrophage Inflammatory Protein 3a, upon

restimulation with LPS (1.29-2.32-fold increase, n=22, all p< 0.001). A significant increase in proinflammatory cytokine and chemokine expression was also shown in RNA sequencing (n=4), beside up-regulation of genes related to glucose and lipid metabolism as well as epigenetic effectors. Exposition to c-vimentin induced chromatin rearrangement (n=4), with increased proportion of accessible promoters (14.4% on day 6 vs. 2.4% on day 1), and a positive correlation to gene expression (r=0.35). Besides, c-vimentin induced H3K4 methylation with increased levels of this mark in the promoter of the IL-6 gene (n=6, p=0.020). Interestingly, we observed an upregulation in the expression of histone methyltransferase PRDM8 (37-fold, SD +/-10.8). At the same time, by inhibiting histone methyltransferases with methylthioadenosine (1 mM), trained immunity was reversed (8.43-fold decrease in IL-6 release, n=6, p=0.031). A shift in metabolism was supported by high lactate production measured by ELISA in the trained cells (n=9, p=0.004), while by inhibiting the metabolic pathway of glycolysis with 2-deoxyglucose (11 mM), the induction of trained immunity could be counteracted (5.32-fold decrease in IL-6 release, n=6, p=0.030). Finally, STING was identified as cell surface receptor for the ligand c-vimentin. Indeed, c-vimentin induced activation of TBK1, which is implicated in the STING signaling pathway, by phosphorylation, while STING inhibition with the covalent small molecule H151 (2 μM) abolished this effect, and decreased IL-6 release (1.61-fold decrease, n=5, p=0.051).

Conclusion: C-vimentin induces epigenetic and metabolic changes in monocytes, probably through a STING and TBK1-dependent activation, resulting in enhanced cytokine and chemokine production upon restimulation. Inhibition of the STING signaling pathway may be a novel therapeutic target against myeloid activation in RA.

Increasing Age Impairs the Metabolic Adaptation of Human Neutrophils to Glucose Deprivation

Moritz Pfeiffenberger[1], Pierre-Louis Krau[2], Yuling Chen[3], Thomas Buttgereit[4], Alexandra Damerau[1], Timo Gaber[1] and Frank Buttgereit[4], [1]Charité – Universitätsmedizin Berlin, corporate member of Freie Universität Berlin and Humboldt-Universität zu Berlin, Berlin, Germany, [2]Charit Universittsmedizin Berlin, corporate member of Freie Universitt Berlin, Humboldt-Universitt zu Berlin, and Berlin Institute of Health, Department of Rheumatology and Clinical Immunology, Berlin, Germany, [3]Charité University Medicine Berlin, Berlin, Germany, [4]Charité – Universitätsmedizin Berlin, Berlin, Germany

SESSION INFORMATION
Session Date: Monday, November 8, 2021
Session Title: Innate Immunity Poster (0992–1006)
Session Type: Poster Session C
Session Time: 8:30AM–10:30AM

Background/Purpose: Age-related impairment of characteristic neutrophil functions is well described (Fortin, McDonald et al. 2008). However, experimental evidence for age-related alterations of neutrophil metabolic adaptation towards nutrient deprivation -a feature of neutrophil battlefields- remains elusive. Moreover, differences in neutrophil metabolic adaptation may contribute to age-related pathologies such as autoimmune diseases including rheumatoid arthritis or other pathologies as atherosclerosis or cancer.

Therefore, we hypothesized that metabolic adaptation of human neutrophils to glucose deprivation is impaired with increasing age.

Methods: In order to test the hypothesis, we compared isolated human peripheral CD15+ neutrophils from four healthy young donors (mean age: 23.4 ± 2.7) with four healthy elderly donors (mean age of 58.7 ± 2.4). First, we analyzed the survival of neutrophils either stimulated with PMA or left untreated and subsequently incubated for 0 h and 6 h under various glucose concentrations (0, 1, 5, and 10 mM). To address this, we performed 7-AAD staining by flow cytometry, while basal respiration, ATP-bound respiration, maximal respiration, and spare capacity were determined using Seahorse™ technology.

Results: We observed that neutrophils (purity > 97%) survived for 6 hours *in vitro*, independent of treatment with PMA or glucose concentrations in the culture medium. With minor differences between the various concentrations of glucose used, the percentage of living cells after 6 h was 95% ± 2.5 without PMA and 75% ± 4.7 with PMA stimulation. No differences were uncovered between the two age groups. However, Seahorse™ technology revealed significant differences in basal, maximal, and spare respiratory capacity. Briefly, oxygen consumption rate (OCR; pmol/min/cell count) with respect to basal, maximal and reserve respiratory capacity was lower in the elderly donors compared to the young donors. For instance, with a concentration of 5 mM glucose, the OCR was 17 ± 0.7 in elderly donors compared to 22.5 ± 1 in young donors, while the maximal respiration was 25 ± 0.8 in elderly and 41 ± 0.6 in the young donor group. Interestingly, these differences were independent of glucose concentrations in the medium.

Conclusion: Our initial experiments show that basal metabolic parameters differ between neutrophils from young and older donors. Further experiments are needed to understand in detail the mechanisms and effects of age-related differences in metabolism on neutrophil functions.

Crescenz VAMC, Department of Dermatology, U Penn, Philadelphia, PA, [2]FIU Wertheim College of Medicine, Virginia Beach, VA, [3]Philadelphia College of Medicine, Philadelphia, PA, [4]University of Pennsylvania, Philadelphia, PA

SESSION INFORMATION
Session Date: Monday, November 8, 2021
Session Title: Innate Immunity Poster (0992–1006)
Session Type: Poster Session C
Session Time: 8:30AM–10:30AM

Background/Purpose: Ultraviolet B irradiation (UVB) contributes to skin inflammation. As UVB mostly affects the epidermis, with just 10% getting into the dermis, the crosstalk between epidermis and dermis in the response to UVB warrants investigation. Extracellular vesicles (EVs), lipid bilayer membrane vesicles secreted by many cells, can carry lipids, proteins and nucleic acids to mediate signal transduction. As a critical sensor and adaptor for the host immune response to cytosolic DNA and cyclic dinucleotides, stimulator of interferon genes (STING) plays critical roles in immunity and inflammation. Initiated by cytosolic pattern recognition receptors, inflammasome activation-mediated pyroptosis is a highly inflammatory form of programmed cell death. Thus, we hypothesized that EVs derived from UVB-irradiated keratinocytes might trigger STING and inflammasome-mediated proinflammatory responses in dermal cells; The goal here was to evaluate the crosstalk between STING and the inflammasome during EVs-mediated proinflammatory responses in dermal cells.

Methods: Human keratinocytes (HaCaT) cells were irradiated with UVB light. After irradiation, cells were cultured for 24 hours and the supernatant was harvested for EV collection. EVs were isolated by ultracentrifugation and used to stimulate fibroblasts or macrophages with/without STING or inflammasome signaling inhibitors. The supernatant was harvested for ELISA and the lysed cells were collected for Western blot. C57BL/6J (Stock No.: 000664) and C57BL/6J-Sting1gt/J (Stock No.: 017537) mice purchased from Jackson Laboratory were treated with or 100 mJ/cm^2 UVB for five consecutive days. Dorsal skin samples were collected for histological analysis.

Results: UVB irradiated HaCaT cells released more extracellular vesicles than unirradiated cells (1.78x10^9/mL vs. 3.31x10^8/mL), with a similar mean size (74.7nm *vs* 73.5nm). UVB-irradiated-keratinocyte-derived EVs (KEV-UVB) expressed more small extracellular vesicle surface markers (CD81, CD9, CD63) than non-irradiated-KEVs. KEV-UVB triggered more interferonb (IFNb) release from macrophages than fibroblasts (111.1±21.45 vs. 4.85±0.72 pg/mL $P<$ 0.05 n=3). STING antagonist H-151 attenuated KEV-UVB triggered IFNb production in macrophages (13.18±6.38 vs. 111.1±21.45 pg/mL $P<$ 0.05). TBK1 inhibitor MRT67307 also showed a similar effect (12.6±0.71 vs. 304.6±94.4 pg/mL $P<$ 0.05). Inhibition of the STING signaling pathway also suppressed KEV-UVB triggered interleukin 1b (IL1b) production in macrophages (60.52±11.41 vs. 325.2±62.68 pg/mL $P<$ 0.05), while suppression of the inflammasome pathway by VX765 and Ac-YVAD-cmk only attenuated KEV-UVB triggered IL1b (22.00±5.01 vs. 34.67±5.85 pg/mL $P<$ 0.05) but not IFNb production in macrophages (636.9±165.1 vs. 680.8±147.1 pg/mL $P>$0.05). Furthermore, UVB irradiation triggered more skin inflammation in STING knockout mice than WT mice *in vivo*.

Conclusion: KEV-UVB were mediators of inflammation, and triggered both STING and inflammasome-mediated cytokine release. Targeting the STING signaling pathway may provide insight into a potential therapeutic approach for UVB-induced skin inflammation.

Molecular Mechanism of Inhibition of CD38 in Attenuation of Monosodium Urate Crystal-induced Inflammatory Responses in Macrophages

Huaping Qin[1], Patricia Oliveira[1], Tiffany Yan[1], Robert Terkeltaub[2] and **Ru Liu Bryan**[3], [1]University of California San Diego, La Jolla, CA, [2]VA/UCSD, San Diego, CA, [3]University of California San Diego and VASDHS, San Diego, CA

SESSION INFORMATION
Session Date: Monday, November 8, 2021
Session Title: Innate Immunity Poster (0992–1006)
Session Type: Poster Session C
Session Time: 8:30AM–10:30AM

Background/Purpose: CD38 can function as a degrading enzyme of nicotinamide adenine dinucleotide (NAD), a critical metabolic intermediate serving as enzyme cofactor in redox reactions and as a co-substrate by many enzymes such as sirtuins (SIRTs). We have recently observed that expression of CD38 is increased in PBMCs of gout patients compared to health controls, and inhibition of CD38 attenuated monosodium urate (MSU) crystal-induced acute inflammatory responses in mice *in vivo*. In this study, we investigated the molecular mechanism mediating beneficial effect of inhibition of CD38 in macrophages in response to MSU crystals *in vitro*.

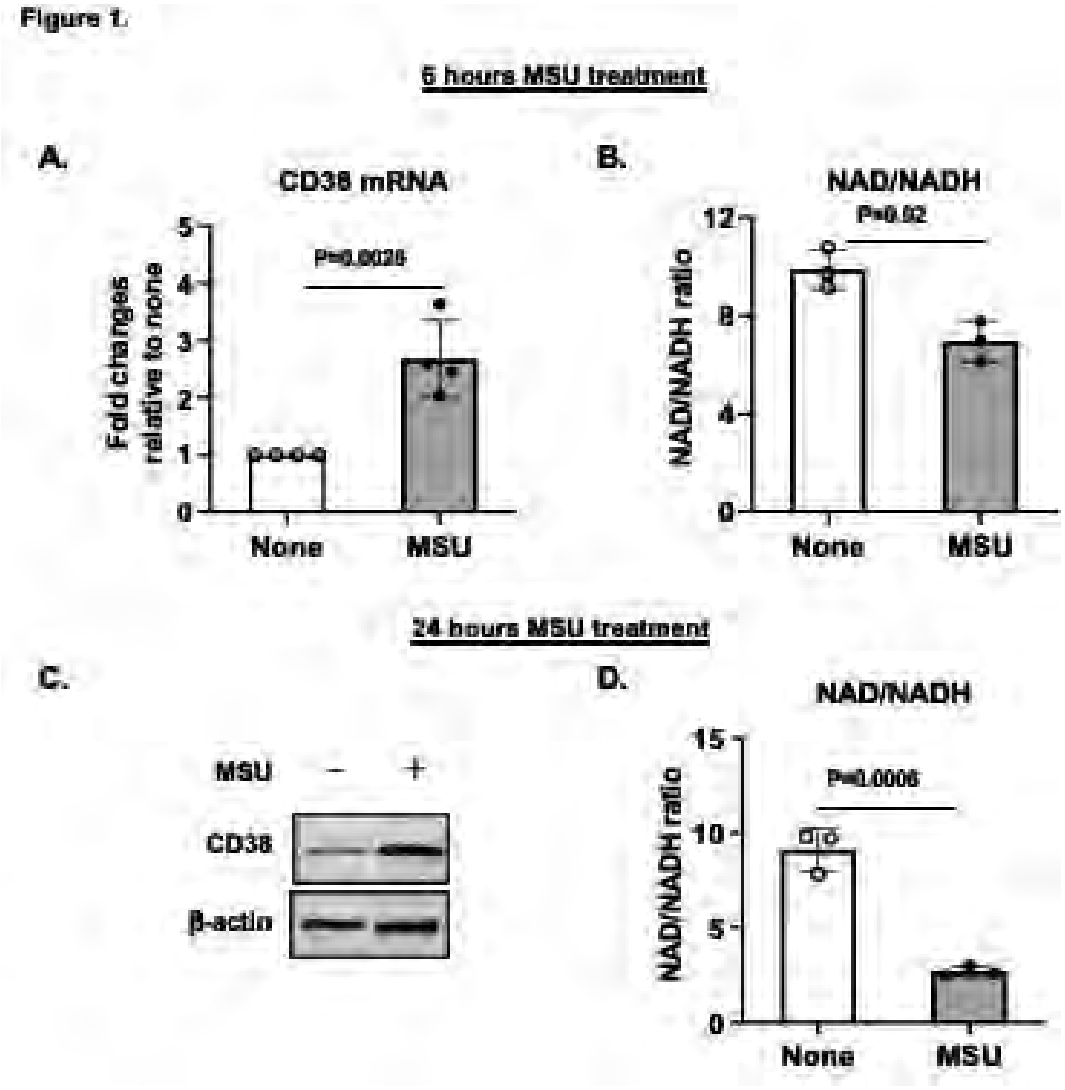

Figure 1. Induction of CD38 expression by MSU crystals correlated with decreased NAD/NADH ratio in mouse BMDMs.

Methods: Bone marrow derived macrophages (BMDMs) prepared from CD38 knockout (KO) and wild type (WT) were treated with MSU crystals (0.2 mg/ml) in the presence or absence of apigenin (25 μM), a flavonoid that selectively inhibits CD38 for 6 and 24 hours. Expression of CD38 was examined at both mRNA and protein levels by qRT-PCR and Western blot analysis. The NADH/NAD Quantification Kit (BioVision) was used to measure the intracellular NAD, NADH and their ratio. Western blot analysis was carried out to examine expression of NAD-dependent SIRT3 and acetylated SOD2, expression of NLRP3 and cleaved caspase-1. ELISA was performed to determine the release of IL-1β from the conditioned media. RNA sequencing analysis was also carried out to profile differentially expressed genes.

Results: The NAD/NADH ratio was significantly reduced in BMDMs treated with MSU crystals at both 6 and 24 hours, correlated with increased CD38 expression at both mRNA and protein levels, respectively. Apigenin inhibited CD38 expression, prevented a decrease in NAD/NADH ratio, prohibited a decrease in expression of SIRT3 and an increase in expression of acetylated SOD2, an antioxidant enzyme in the mitochondria, in BMDMs treated with MSU crystals. Apigenin also suppressed NLRP3 expression at both mRNA and protein levels, inhibited expression of cleaved casepase-1, and attenuated IL-1ß release in response to MSU crystals. RNA-seq analysis showed that 163 genes upregulated in WT+MSU BMDMs ($log_2FC \geq 1$)were downregulated in both WT+MSU+apigenin and CD38KO BMDMs

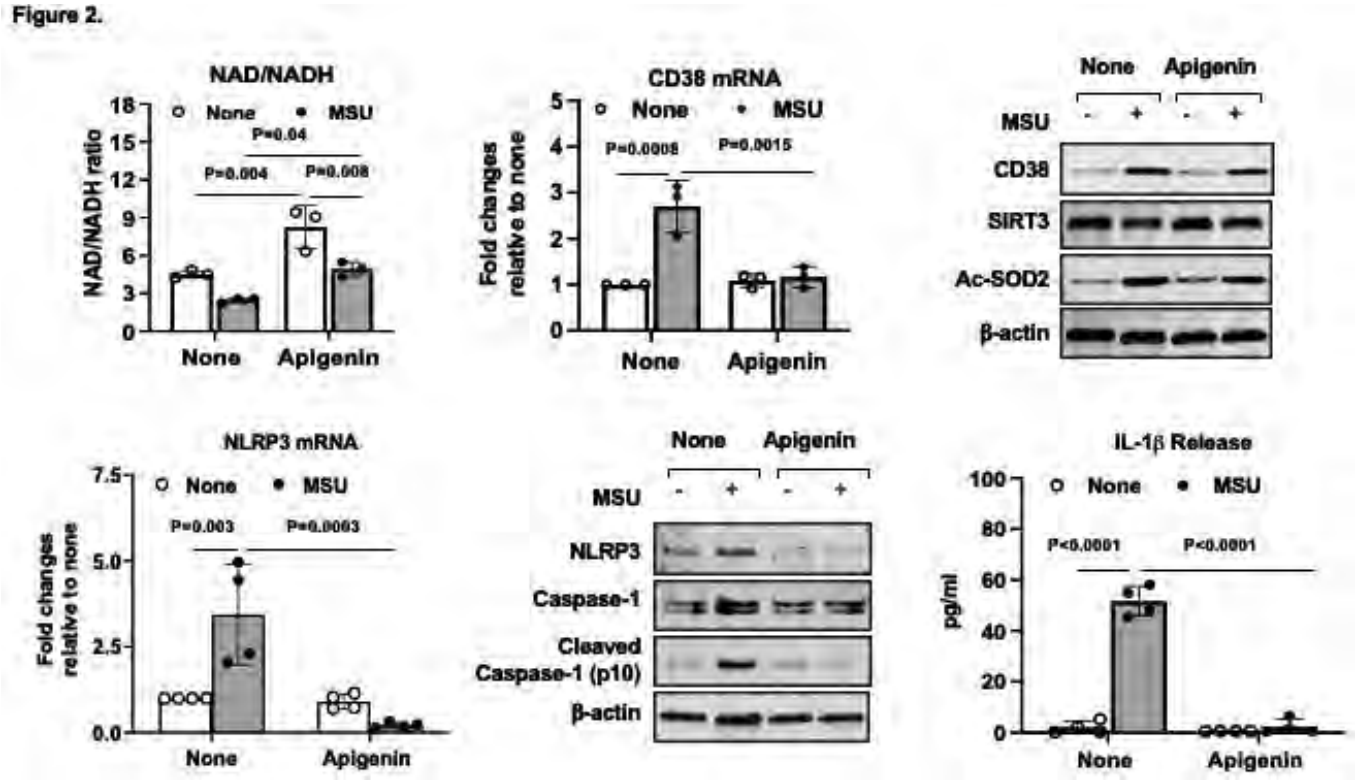

Figure 2. Apigenin inhibited CD38 expression, prevented a decrease in NAD/NADH ratio, prohibited a decrease in expression of SIRT3 and an increase in expression of acetylated SOD2, suppressed NLRP3 expression at both mRNA and protein levels, inhibited expression of cleaved casepase-1, and attenuated IL-1b release in response to MSU crystals in macrophages.

($log_2FC \leq 1$). KEGG Pathway enrichment analysis revealed several inflammatory pathways including cytokine-cytokine receptor interaction, chemokine, TNF, NF-κB, JAK-STAT, HIF-1α, TLR and MAPK signaling. Interestingly, a top differentially expressed gene six-transmembrane epithelial antigen of prostate 4 (Steap4) was upregulated in WT+MSU BMDMs ($log_2FC=8.14$) but was downregulated in WT+MSU+apigenin BMDMs ($log_2FC= -7.18$) and CD38KO+MSU BMDMs ($log_2FC= -4.43$). Steap4 is a metalloreductase that has the ability to reduce both Fe(3+) to Fe(2+) and Cu(2+) to Cu(1+), using NAD(+) as acceptor. Increased Steap4 expression has been shown to lead to mitochondrial iron accumulation and enhanced reactive oxygen species production. Thus, downregulation of Steap4 expression induced by MSU crystals through inhibition of CD38 may help maintain mitochondria homeostasis.

Conclusion: Inhibition of CD38 can attenuate inflammatory response to MSU crystals in macrophages by prohibiting NAD decline and preventing mitochondrial dysfunction.

Session Date: Monday, November 8, 2021
Session Title: Innate Immunity Poster (0992–1006)
Session Type: Poster Session C
Session Time: 8:30AM–10:30AM

Background/Purpose: Prior work demonstrates that macrophages (MØs) from patients with Systemic Sclerosis (SSc) produce fibrotic and pro-inflammatory mediators and that cocultured MØs and SSc fibroblasts engage in reciprocal activation. However, the factors responsible for pro-fibrotic MØ activation in SSc are unknown. Given the proximity of MØs and fibroblasts in SSc patient skin, we hypothesize that fibroblast-derived mediators contribute to SSc MØ activation. In this study, we identify SSc dermal fibroblast-derived exosomes as inducers of MØ activation and demonstrate that exosome-activated MØs stimulate fibroblast production of inflammatory cytokines and extracellular matrix (ECM) components (Figure 1).

Methods: Fibroblasts were isolated from skin biopsies obtained from 9 SSc patients or 7 healthy age and gender-matched control subjects following written informed consent. $CD14^+$ monocytes were purified from PBMCs obtained from whole blood of 7 healthy consented donors. Dermal fibroblasts were cultured with 5 ng/ml TGF-beta in media supplemented with exosome-depleted FBS for 72 hours prior to exosome isolation from cell supernatants. Exosomes were quantified using NanoSight and exosome purity was assessed by immunoblot for canonical markers. Monocytes were differentiated into MØs by incubation with M-CSF for 5 days and then were cultured with exosomes

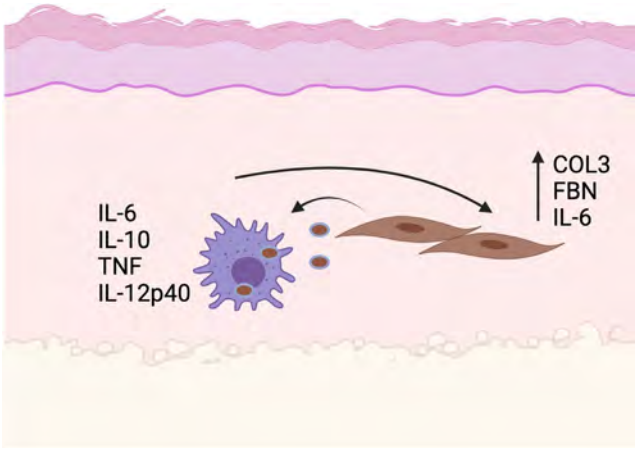

Figure 1. Model of SSc Fibroblast-derived Exosome-mediated Induction of MØ Activation in SSc. In our model, dermal fibroblasts from SSc patients release exosomes containing miR cargo that are internalized by MØs. Uptake of SSc fibroblast-derived exosomes induces pro-inflammatory and pro-fibrotic MØ activation, resulting in release of cytokines and fibrotic mediators by MØs that further stimulate SSc fibroblast activation. Cooperative activation results in dermal inflammation and increased ECM deposition.

from control or SSc fibroblasts for an additional 48 hours. MØs were immunophenotyped using flow cytometry, qRT-PCR and multiplex. For mutual activation studies, exosome-activated MØs were co-cultured with SSc fibroblasts using Transwells.

Results: MØs activated with dermal fibroblast-derived exosomes from SSc patients upregulate surface expression of CD163, CD206, and MHC Class II compared with MØs incubated with healthy control fibroblasts (Figure 2). This pattern of expression is consistent with the previously identified surface marker profile established for human SSc MØs. In addition, SSc fibroblast-derived exosomes elicit elevated levels of secreted IL-6, IL-10, IL-12p40, and TNF from MØs (Figure 3). Exosome cargo from SSc and healthy control fibroblasts was sequenced and differential expression of microRNAs (miRs) was noted between the cell types, which may account for the enhanced inflammatory activation of SSc MØs. Co-culture studies demonstrate that exosome-stimulated MØs and SSc fibroblasts engage in reciprocal activation, as production of collagen and fibronectin is significantly increased in fibroblasts receiving signals from SSc exosome-stimulated MØs.

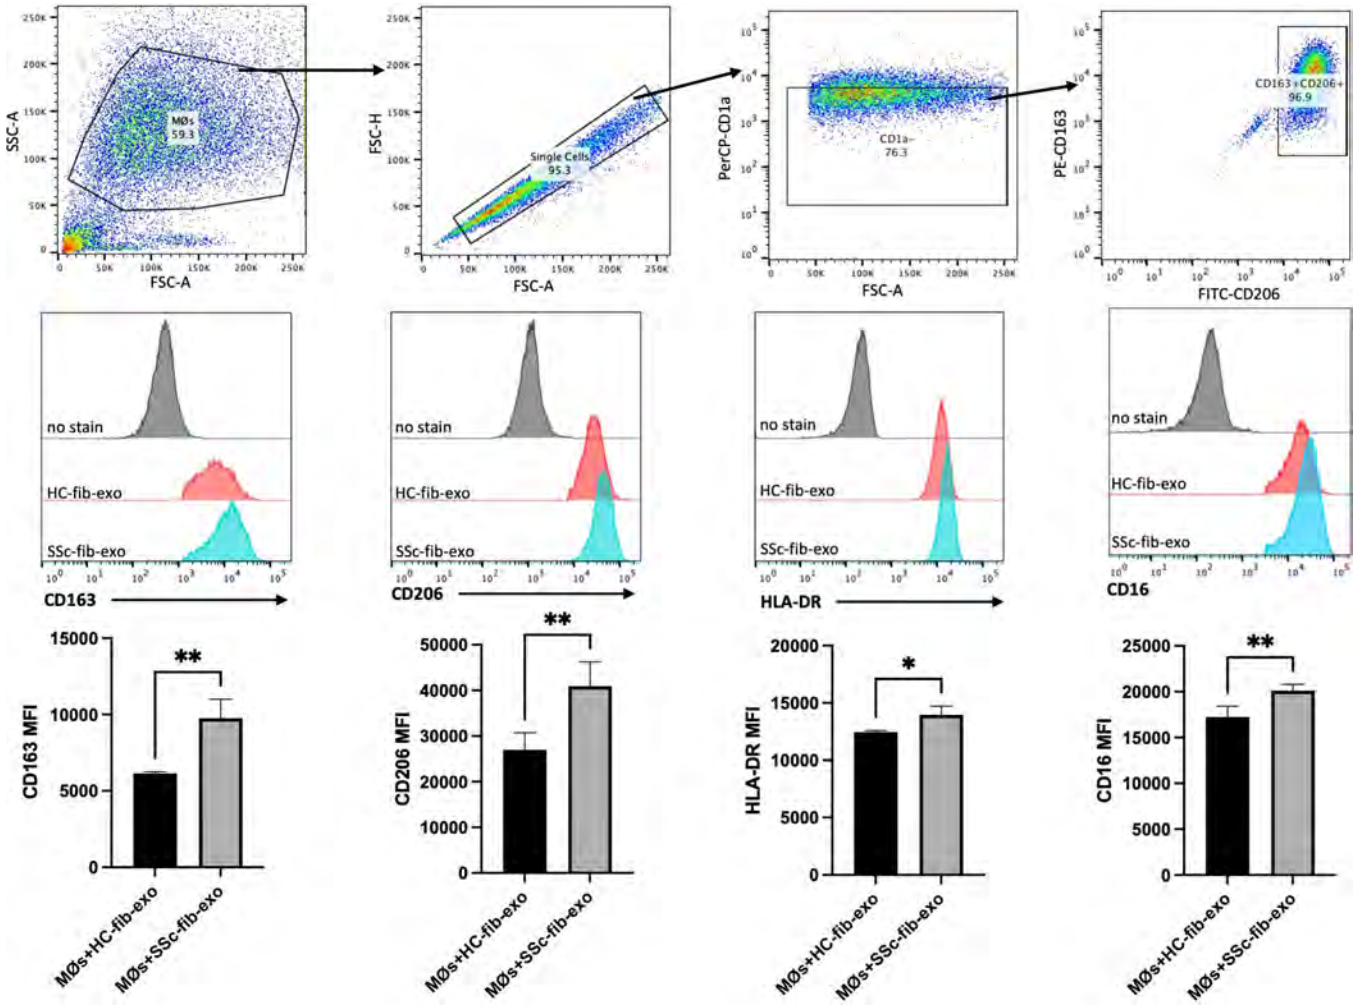

Figure 2. Induction of Surface Marker Expression on MØs by SSc Fibroblast-derived Exosomes. MØs were incubated with exosomes released from TGF-beta-stimulated SSc dermal or healthy control fibroblasts for 48 hours. Exosome uptake was verified in MØs using immunofluorescence, and activated MØs were immunophenotyped using flow cytometry. As demonstrated, internalization of SSc fibroblast-derived exosomes upregulated surface marker expression of CD163, CD206, and MHC Class II, which were previously identified as characteristic of pro-fibrotic SSc MØs.

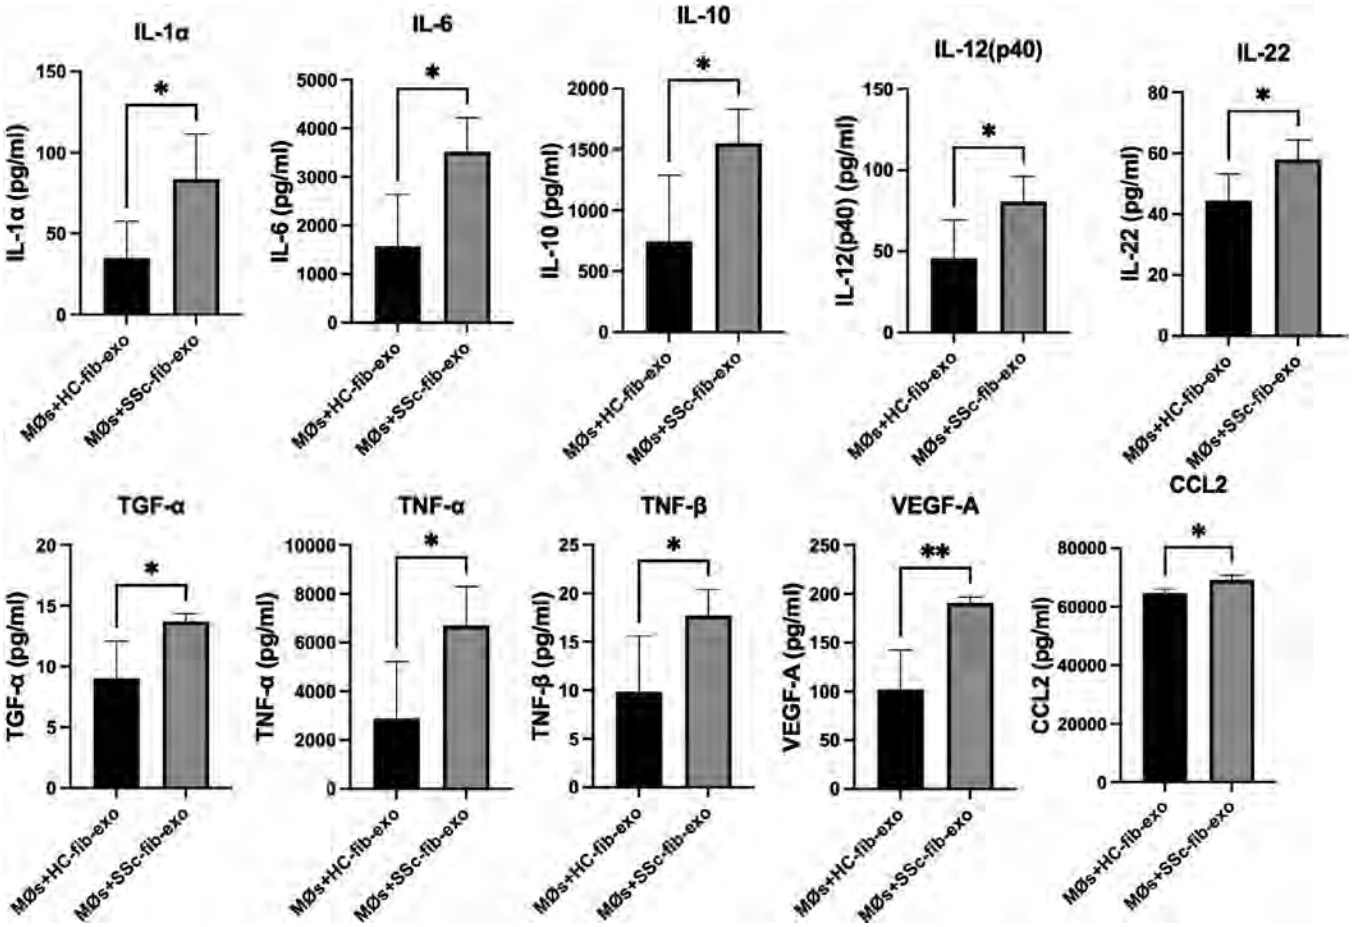

Figure 3. Pro-inflammatory and Pro-fibrotic Cytokines Are Induced in MØs Activated with SSc-Fibroblast-derived Exosomes. Exosomes were isolated from the supernatant of TGF-beta stimulated SSc or healthy control fibroblasts and cultured with MØs for 48 hours. Exosome uptake was confirmed using immunofluorescence and MØ surface phenotype was monitored by flow cytometry. Supernatants were collected from activated MØs and analyzed using multiplex analysis.

Conclusion: In this work, we demonstrate for the first time that human SSc dermal fibroblasts can mediate MØ activation through exosomes. Consistent with prior studies, we show that MØs express surface markers and release mediators associated with both alternative and inflammatory MØ activation. Our findings suggest that MØs and fibroblasts engage in cross-talk in SSc skin that results in mutual activation, inflammation, and ECM deposition. Collectively, these studies implicate MØs and fibroblasts as cooperative mediators of fibrosis in SSc and suggest dual therapeutic targeting of these cell types may provide maximal benefit in ameliorating disease in SSc patients.

Nerve and Airway-associated Tissue Resident Pulmonary Macrophages Limit Infiltration and Alter Phenotype of Infiltrating Monocytes and Fibrocytes to Reduce Pulmonary Fibrosis

Robert Freilich[1] and Kamal Khanna[2], [1]New York University Department of Rheumatology, New York, NY, [2]New York University Department of Rheumatology & Microbiology, New York, NY

SESSION INFORMATION
Session Date: Monday, November 8, 2021
Session Title: Innate Immunity Poster (0992–1006)
Session Type: Poster Session C
Session Time: 8:30AM–10:30AM

Background/Purpose: Macrophages and monocytes are increasingly implicated in the pathogenesis of autoimmune induced pulmonary fibrosis. In addition to the well-recognized classes of tissue resident macrophages alveolar macrophages (AMs) and interstitial macrophages (IMs), recent studies have identified a novel class lung tissue resident macrophage termed CD169+ Nerve and Airway-associated Macrophages (NAMs) whose role in autoimmune pulmonary pathology is unclear. Further, recent studies have demonstrated monocytes playing a critical role in the progression of pulmonary fibrosis. Interestingly, monocytes can be further subdivided into classical, non-classical, intermediate and fibrocytes, that are thought to play a key role in fibrosis/wound healing, but whose exact roles in autoimmune induced pulmonary fibrosis are unknown.

Methods: We utilized the bleomycin-induced murine model of pulmonary fibrosis in C57BL/6 wild-type (WT) mice in combination with transgenic murine models that selectively deplete AMs, NAMs, or both AMs/NAMs upon Intraperitoneal injection of diphtheria toxin (DT). DT injection (1000ng) were given 16 hours prior to bleomycin treatment (2.5u/kg). Mice were sacrificed on days 4, 11, 18 and 42. Lungs were fixed, sectioned and stained for IF or disassociated into a single cell suspension, stained, and analyzed by flow cytometry for both surface and intracellular targets, including a-Smooth Actin (aSMA)/Collagen-1a (Col1a).

Results: Bleomycin-treated mice whose NAMs were depleted were sicker than WT littermates, with greater weight loss (34% vs. 24%), reduced survival (35% vs 65%) and increased lung dry weight (67.7mg vs 55.9mg) Interestingly, NAM depletion resulted in increased monocytic infiltration compared to WT bleomycin-treated littermates. We further characterized the infiltrating monocytic compartment, via flow cytometry, as either 'true' monocytes (CD45+,CD11b+,CD140a-,SMA-,Col1a-), putative fibrocytes (CD45+,CD11b+,CD140a+,aSMA+, Col1a+) or a transitioning population (CD45+,CD11b+,CD140a+,aSMA+, Col1a-). Our analyses demonstrates that depletion of NAMs alters the infiltrating monocytic compartment in two key ways. First, we observed a 39% increase in the numbers of infiltrating monocytes that are (CD45+,CD11b+,CD140a-) (p=0.0195). However, these monocytes were noted to have more fibrocytic phenotype with higher levels of aSMA or Col1a expression, 23% (aSMA+/Col1a-) (p=0.0426), and 16% (aSMA+/Col1a+) (p=0.0292).

Conclusion: Depleting tissue-resident macrophages led to an increase in infiltrating monocytes skewed towards a more pro-fibrotic phenotype and resulting in a poorer clinical outcome. Taken together, these findings potentially provide insight into the mechanisms of inflammatory pulmonary fibrosis in autoimmune diseases.

Significant Enrichment of Pathogenic CD206+CD163+ Macrophages in Rheumatoid Arthritis Synovial Tissue with Distinct Transcriptional Signatures

Megan Hanlon[1], Mary Canavan[2], Nuno Neto[3], Qingxuan Song[4], Phil Gallagher[5], Ronan Mullan[6], Conor Hurson[7], Barry Moran[3], Michael Monaghan[3], Sunil Nagpal[8], Douglas Veale[9] and Ursula Fearon[3], [1]Molecular Rheumatology, Dublin, Ireland, [2]Trinity College, Santry, Ireland, [3]Trinity College Dublin, Dublin, Ireland, [4]Janssen Research & Development LLC, Spring House, PA, [5]St Vincent's Hospital, Dublin, Ireland, [6]Tallaght University Hospital, Dublin, Ireland, [7]St Vincents University Hospital, Dublin, Ireland, [8]Janssen Research, Collegeville, PA, [9]University College Dublin, Dublin, Ireland

SESSION INFORMATION
Session Date: Monday, November 8, 2021
Session Title: Innate Immunity Poster (0992–1006)
Session Type: Poster Session C
Session Time: 8:30AM–10:30AM

Background/Purpose: Synovial tissue macrophages are an exquisitely plastic pool of innate cells that play a key role in RA disease progression. However, the precise nature, diversity, and function of macrophage subsets within the inflamed joint remains unexplored. Therefore, the aims of this study are to phenotypically, transcriptionally and functionally characterise synovial tissue macrophages residing within the inflamed joint.

Methods: Rheumatoid Arthritis (RA), Psoriatic Arthritis (PsA), Osteoarthritis (OA), Arthralgia and healthy control synovial tissue biopsies and synovial fluid mononuclear cells were analysed using the following panel (CD40,-CD45,-CD64,-CD68,-CD163,-CD206,-CD253,-CCR4,-CCR7,-CXCR1,-CXCR3). CD206+CD163+ and CD206-CD163- macrophages were sorted from RA synovial-tissue by FACSAria sorter; RNAseq and FLIM analysis, autologous T-cell co-culture and heathy synovial fibroblast experiments were performed. Cytokine expression was measured by MSD.

Results: A spectrum of macrophage activation states exists within the inflamed synovium. Within this spectrum, significant enrichment of dominant CD206+CD163+ macrophage subtype is present in synovial-tissue versus fluid ($p< 0.05$). CD206+CD163+ synovial tissue macrophages express significantly more CD40 than synovial fluid ($p< 0.0003$), positively correlating with disease activity ($r=0.6$, $p< 0.01$), with baseline levels predicting response to therapy ($p< 0.05$). Moreover, CD206+CD163+CD40+ macrophages are enriched in RA synovial tissue compared to PsA and OA pathotypes ($p< 0.05$). While the CD206+CD163+ subset is present in healthy synovial tissue, expression of CD40 is completely absent in healthy synovium ($p< 0.05$). Protective barrier-like CX_3CR1-expressing macrophages are depleted in RA synovial tissue and this occurs prior to clinical manifestations. RNA-seq analysis indicates that CD206+CD163+ population is transcriptionally distinct from synovial tissue CD206-CD163-, synovial fluid CD206+CD163+, and RA monocyte-derived M1/M2 macrophages, with unique tissue-resident gene signatures. Moreover, differing metabolic demands between CD206+CD163+ and CD206-CD163- subsets was demonstrated by RNAseq and FLIM analysis. Finally, CD206+CD163+ macrophages spontaneously secrete high levels of key pro-inflammatory mediators (reversed through inhibition of CD40 signalling) which in turn can activate healthy synovial fibroblasts, thus further contributing to the local inflammatory response.

Conclusion: This data identifies for the first-time enrichment of a previously undescribed dysfunctional dominant and transcriptionally distinct macrophage subtype in RA synovial tissue. Taken together, this data provides a greater understanding of the critical role tissue-resident macrophages play in perpetuating inflammation in RA. Further investigation of the molecular patterns and cues that shape specific synovial macrophage subsets may provide opportunities to reinstate RA joint homeostasis.

Background/Purpose: Infiltration of monocyte-derived macrophages into the synovial tissue (ST) is a hallmark of rheumatoid arthritis (RA). These infiltrating cells lead to inflammation, local joint effusion, and joint damage via the production of inflammatory cytokines. Macrophages express an array of co-stimulatory receptors, particularly those of the B7 protein family, including the programmed death protein 1 (PD-1) ligands, PD-L1 and PD-L2, and the B7-related protein VSIG4.

In the healthy state, interaction between PD-1 and its ligands results in an inhibitory signalling cascade in the PD-1 expressing T cell, which can in turn inhibit cell proliferation and cytokine release. However, in RA, PD-L1 is conspicuously absent from the ST (Guo, et al., 2018), leaving disease-driving cells expressing PD-1 (such as T peripheral and T follicular helper cells) unchecked. This imbalance in PD-1 signalling may contribute to disease progression and may provide a target for treatment.

Herein, we investigate the potential of 'reprogramming' inflammatory synovial fluid macrophages to upregulate inhibitory co-signalling molecules such as PD-L1 and PD-L2, to provide a proof-of-concept study into using these cells as a future cellular-based therapy. Such a therapy may provide a locally administered, anti-T cell based therapeutic approach.

Methods: Synovial fluid mononuclear cells (SFMC) were obtained from patients with active early RA (< 1 year; fulfilling 2010 classification criteria). Cryopreserved SFMCs were cultured for 48 hours in the presence of 10 ng/mL interferon (IFN)-γ or 50 ng/mL dexamethasone, or neither. Following culture, cells were stained for flow cytometry using antibodies against CD14, CD16, CD68, CD163, CD45, PD-L1, PD-L2 and VSIG4 (BD Biosciences), and the viability dye Zombie NIR (BioLegend). Cells were analysed using a Beckman Coulter CytoFLEX flow cytometer and data interpreted using FlowJo software.

Results: SF macrophages were characterised by their expression of CD14, CD16, CD68 and CD163. Flow cytometric analysis revealed that SF macrophages were amenable to phenotypic modulation by exogenous mediators. As ex-

pected, Dexamethasone resulted in an increase in a CD163$^+$, M2 like phenotype. Comparison of unstimulated control SF macrophages and those cultured with IFNγ showed significantly elevated levels of PD-L1 and PD-L2, and significantly reduced expression of VSIG4. Conversely, SF cells stimulated with dexamethasone exhibited significantly reduced levels of PD-L1, and significantly elevated levels of VSIG4.

Conclusion: Our findings demonstrate, for the first time in RA, the phenotypic plasticity of SF macrophages *in vitro*. Specifically, we found that culture of RA SF macrophages in the presence of IFNγ increased the expression of PD-L1 and PD-L2, demonstrating the potential of these cells to 'rebalance' the PD-1 pathway. Interestingly, these cells exhibited decreased surface protein levels of VSIG4, a B7 family related protein with overlapping function with PD-L1 and PD-L2. Culture with dexamethasone induced the opposite. These findings suggests that while PD-L1, PD-L2 and VSIG4 have similar regulatory characteristics, these proteins may exert differential functions in specific environments.

SESSION INFORMATION
Session Date: Monday, November 8, 2021
Session Title: Innate Immunity Poster (0992–1006)
Session Type: Poster Session C
Session Time: 8:30AM–10:30AM

Background/Purpose: Dendritic cells (DCs) are a heterogeneous population of professional antigen-presenting cells which are at the interface between innate and adaptive immunity. A specific subset of DCs is known to derive from monocyte and has a key role in inflammation and infection.

This study aimed to identify and characterize the CD209$^+$/CD14$^+$ DC subset and evaluate their characteristics in the periphery of patients with inflammatory arthritic (IA) together with their enrichment and activation at the site of inflammation, the joint of rheumatoid (RA) and psoriatic arthritic (PsA) patients.

Methods: Peripheral blood and synovial fluid mononuclear cells (PBMC and SFMC) were isolated by Ficoll density gradient from healthy subjects (HC), RA and PsA patients. Single-cell synovial tissue suspension (ST) from RA and PsA patients was obtained by enzymatic digestion. PBMC, SFMC and ST were analysed by flow cytometry to identify the CD209$^+$/CD14$^+$ DC subset, its frequency and the expression of chemokines receptors (CCR6, CCR7/CXCR3/CXCR4/CXCR5) and activation markers (CD40 and CD80) on the surface of the DC subset. In addition, PBMC were

stimulated with different TLR (LPS, CPG, Poly I:C) and intracellular staining for IL12/TNFα/IL1β/IL6 was performed. $CD209^+$ DC were isolated with a two-step isolation protocol. Lineage negative cells ($CD3/CD19/CD56^-$) were stimulated with GMCSF/IL4 in the presence or absence of the JAK/STAT inhibitor Tofacitinib or the TNF inhibitor Humira and the $CD209^+/CD14^+$ DC was evaluated by flow cytometry.

Results: We identified, for the first time, the $CD209^+/CD14^+$ DC population in PBMC of RA and PsA patients, with similar frequency observed when compared to HC. However, we observed activation of circulating $CD209/CD14^+$ DC from both RA and PsA patients, with higher production of cytokines (IL12/TNFα), in addition to expression/co-expression of chemokine receptors (CCR6/CCR7/CXCR3/CXCR4/CXCR5). Interestingly, we observed that this DC population was enriched at the site of inflammation, in SFMC and ST and displayed a mature phenotype, with a significant increase in CD40 and CD80 and co-expression of specific chemokine receptors, displaying unique patterns between PsA and RA. We developed a protocol of magnetic isolation for $CD209^+$ DC from blood and observed that culturing HC CD209+DC with IA synovial fluid SF was sufficient to induce the development of $CD209/CD14^+$ DC, leading to a poly-mature phenotype. Finally, we observed that JAK/STAT inhibition, but not TNF inhibitor, reduced the generation and development of $CD209^+/CD14^+$ DC.

Conclusion: We identified, for the first time, a monocyte-derived DC population characterized as $CD209^+/CD14^+$ DC in the periphery of RA and PsA patients. This population was enriched at the site of inflammation displaying a unique chemokine receptor profile and activation markers, suggesting cells, already activated in the periphery of IA patients, are then recruited activated further into the joint of IA patients. We observed that IA SF induce the development of $CD209/CD14^+$ DC and their maturation. In addition, we demonstrated that the $CD209^+/CD14^+$ DC development is sensitive to JAK/STAT, but not TNF inhibition.

MAA Modified and/or Citrullinated Proteins Stimulate Macrophages and Human Fibroblast-Like Synoviocytes to Increase the Secretion/Expression of Fractalkine Ligand (CX3CL1) and Fractalkine Receptor (CX3CR1)

Nozima Aripova, Michael Duryee, Peter Maloley, Bryant England, James O'Dell, Ted Mikuls and Geoffrey Thiele, University of Nebraska Medical Center, Omaha, NE

SESSION INFORMATION
Session Date: Monday, November 8, 2021
Session Title: Innate Immunity Poster (0992–1006)
Session Type: Poster Session C
Session Time: 8:30AM–10:30AM

Background/Purpose: In rheumatoid arthritis (RA) synovium, activated synovial fibroblasts and macrophages release inflammatory mediators that affect surrounding cells and accelerate disease progression. One such chemokine axis, we and others have shown to be present in RA, is CX3CL1/Fractalkine ligand and its receptor CX3CR1(Fractalkine receptor). Malondialdehyde and acetaldehyde adducts (MAA) and/or citrullinated (CIT) proteins in isolation or in combination induce inflammatory and fibrotic responses by macrophages and fibroblasts. Recent preliminary

data from our laboratory using the VARA cohort (N=2342) suggests that anti-MAA antibodies negatively correlated with serum CX3CL1 levels (R=-0.04123, p< 0.05). Therefore, it was the purpose of this study to evaluate the effects of MAA and/or CIT modified proteins on the expression of CX3CL1 and CX3CR1 by macrophages (U937 cells), and human fibroblast-like synoviocytes from RA synovium (HFLS-RA).

Methods: Both HFLS-RA and U937 cells, separately, were stimulated with MAA, CIT, and MAA-CIT modified or unmodified human serum albumin (HSA) or fibrinogen (FIB) for 24 hours. Afterward, supernatants were assayed using a cytokine capture assay for CX3CL1. CX3CR1 expression was measured using both PCR and flow cytometry. In a separate experiment, U937 cells were incubated with previously collected HFLS-RA supernatants (following antigen stimulation as above) and mRNA was isolated to evaluate inflammatory markers with PCR: TNF-α, IL-1β. One-way ANOVA with Tukey's-b post-hoc was used to compare normalized values across exposure groups to appropriate native proteins.

Results: U937 cells do not secrete the CX3CL1, and HFLS-RA cells do not express the CX3CR1 in response to any modification of HSA or FIB. However, stimulation of U937 with modified antigens significantly increased CX3CR1 expression by flow cytometry [**Fig.1A,B**]. Stimulation with dually modified (MAA-CIT) HSA and FIB demonstrated the highest CX3CR1 expression by PCR [**Fig.1C**]. Treatment of HFLS-RA with HSA-MAA had the highest significant CX3CL1 release, followed by HSA-MAA-CIT [**Fig.2A**]. Treatment with FIB-MAA-CIT significantly increased levels of CX3CL1 release, followed by FIB-CIT [**Fig.2B**]. When U937 cells were stimulated with HSA-MAA-CIT [**Fig.3A**] or FIB-CIT [**Fig.3B**] supernatants from HFLS-RA cells, mRNA levels of TNF-α and IL-1β increased, but to a significantly lesser extent than respective stimulations without HFLS-RA supernatants. HSA-MAA treated HFLS-RA supernatants significantly increased U937 mRNA levels for TNF-α and considerably, to a lesser extent, IL-1β as compared to direct stimulation of U937 with HSA-MAA antigen without HFLS-RA supernatants [**Fig.3A**].

Conclusion: Our data demonstrate for the first time that fibroblasts and macrophages can express CX3CL1 and CX3CR1, respectively, in response to HSA and FIB modified proteins. Macrophages showed significantly diminished inflammatory responses when exposed to supernatants from stimulated HFLS-RA cells. These studies suggest that the CX3CL1-CX3CR1 axis could link immune cells and fibroblasts, thereby regulating inflammatory mediators in response to MAA and/or CIT modified proteins.

SESSION INFORMATION

Session Date: Monday, November 8, 2021
Session Title: Pediatric Rheumatology – Basic Science Poster (1007–1013)
Session Type: Poster Session C
Session Time: 8:30AM–10:30AM

Background/Purpose: Juvenile dermatomyositis (JDM) is a systemic vasculopathy associated with metabolic derangements and possible increased risk for premature atherosclerosis. Oxidation of low-density lipoprotein (LDL) in the endothelial wall of blood vessels is an early step in atherosclerotic plaque formation. The primary aim of this study was to compare deposition of oxidized LDL in the vasculature of muscle biopsies (MBx) from patients with untreated JDM compared to pediatric controls.

Methods: After informed consent, MRI-directed MBx were obtained from 20 female patients with JDM (mean age = 6.3+/-2.2) before the start of therapy and 5 female controls (mean age = 14.4+/-1.8). Frozen muscle sections were stained with DAPI and fluorescently labeled antibodies against von Willebrand factor (vWF) and LDL oxidized by copper (oxLDL) and were imaged by a Leica DMR-HC upright microscope. ImageJ (NIH, Bethesda, MD) was used to identify blood vessel areas, defined by the presence of vWF, and measure the fluorescence of the area and intensity of oxLDL within the vessel walls. For each vessel visualized, the intensity of oxLDL was calculated for the area of the vessel and corrected for background intensity. The total fluorescence for each muscle biopsy was calculated by dividing the sum of the intensities of the individual vessels by the sum of the area of the vessels. Data was analyzed using t-tests and Pearson correlation.

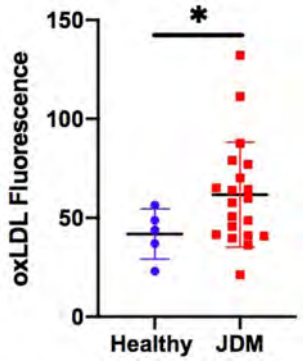

Figure 1. Fluorescence of oxLDL (intensity/area) in the walls of muscle vasculature is increased in JDM muscle biopsies compared to healthy controls (p=0.03). The mean value is indicated by the line, and the standard deviation is indicated by the whiskers. JDM patients, n=20, and healthy controls, n=5.

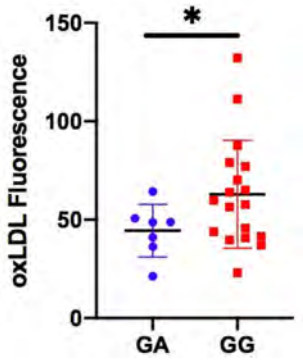

Figure 2. Fluorescence of oxLDL (intensity/area) in the walls of muscle vasculature is increased in subjects with the GG polymorphism at the TNFa-308 gene locus compared to subjects with the GA polymorphism (p=0.04).

Results: Children with untreated JDM demonstrated higher fluorescence of oxLDL in the walls of muscle vasculature compared to healthy children (p=0.03, Figure 1). Secondary analysis revealed significantly higher oxLDL fluorescence in muscle biopsies of patients with the TNF-a-308 G allele compared to biopsies of patients with the A allele (p=0.04, Figure 2). Within the JDM cohort, there was a trend towards increased oxLDL fluorescence with longer duration of untreated disease at time of MBx. There was no significant correlation found between oxLDL fluorescence and markers of disease activity including disease activity (DAS) scores, nailfold capillary end row loops, muscle enzymes, serum vWF antigen, or neopterin.

Conclusion: Increased deposition of oxLDL within blood vessels of children with JDM supports the concern that these children are at increased risk for premature atherosclerosis. Additional longitudinal studies are needed to better understand the long term impact on morbidity and mortality.

Synovial Fluid IL-36γ in Patients with Enthesitis Related Arthritis (ERA) Correlates with Disease Activity and Leads to Production of IL-6 by Fibroblast Like Synoviocytes

Amita Aggarwal, **Sanjukta Majumder** and Shivika Guleria, Sanjay Gandhi Post Graduate Institute of Medical Sciences, Lucknow, India

SESSION INFORMATION
Session Date: Monday, November 8, 2021
Session Title: Pediatric Rheumatology – Basic Science Poster (1007–1013)
Session Type: Poster Session C
Session Time: 8:30AM–10:30AM

Background/Purpose: IL-36 has been implicated in the pathogenesis of spondyloarthropathies (SpA) like psoriasis and IBD. Enthesitis related arthritis (ERA) category of juvenile idiopathic arthritis (JIA) is a form of juvenile SpA; however, no data is available regarding the role of IL-36 in this disease. Thus, we studied the involvement of IL-36 in ERA.

Methods: 84 patients with ERA (ILAR criteria), 20 patients with rheumatoid arthritis (RA) and 24 healthy subjects were enrolled in the study after ethics approval and informed consent.

IL-36α, β, γ and IL-36R was determined in PBMCs and SFMCs at the mRNA levels using RTqPCR; and IL-36α, γ, IL-36Ra, IL-6 and IL-17 levels were measured in serum and synovial fluids (SF) by ELISA. Fibroblast like synoviocytes (FLS) were stimulated with recombinant IL-36γ, IL-6, IL-17, IL-6+IL-17 and TNF-α as well as with SF from patients with ERA in presence or absence of IL-36Ra. For ELISA, cells were stimulated for 8 h and supernatants were removed, cells were washed and further cultured for 16 h. Post stimulation expression of IL-6 and IL-36γ levels were measured at mRNA and protein levels. All results are expressed as median ±IQR.

Results: Among 84 JIA-ERA patients, 77 were boys. Their mean age was 16.8 ± 3.5 years and mean disease duration was 60.3 ± 48.8 months. All had active disease with mean ESR of 62.3 ± 34.9 mm and mean Juvenile Spa disease activity score of 3.4 ± 1.4.

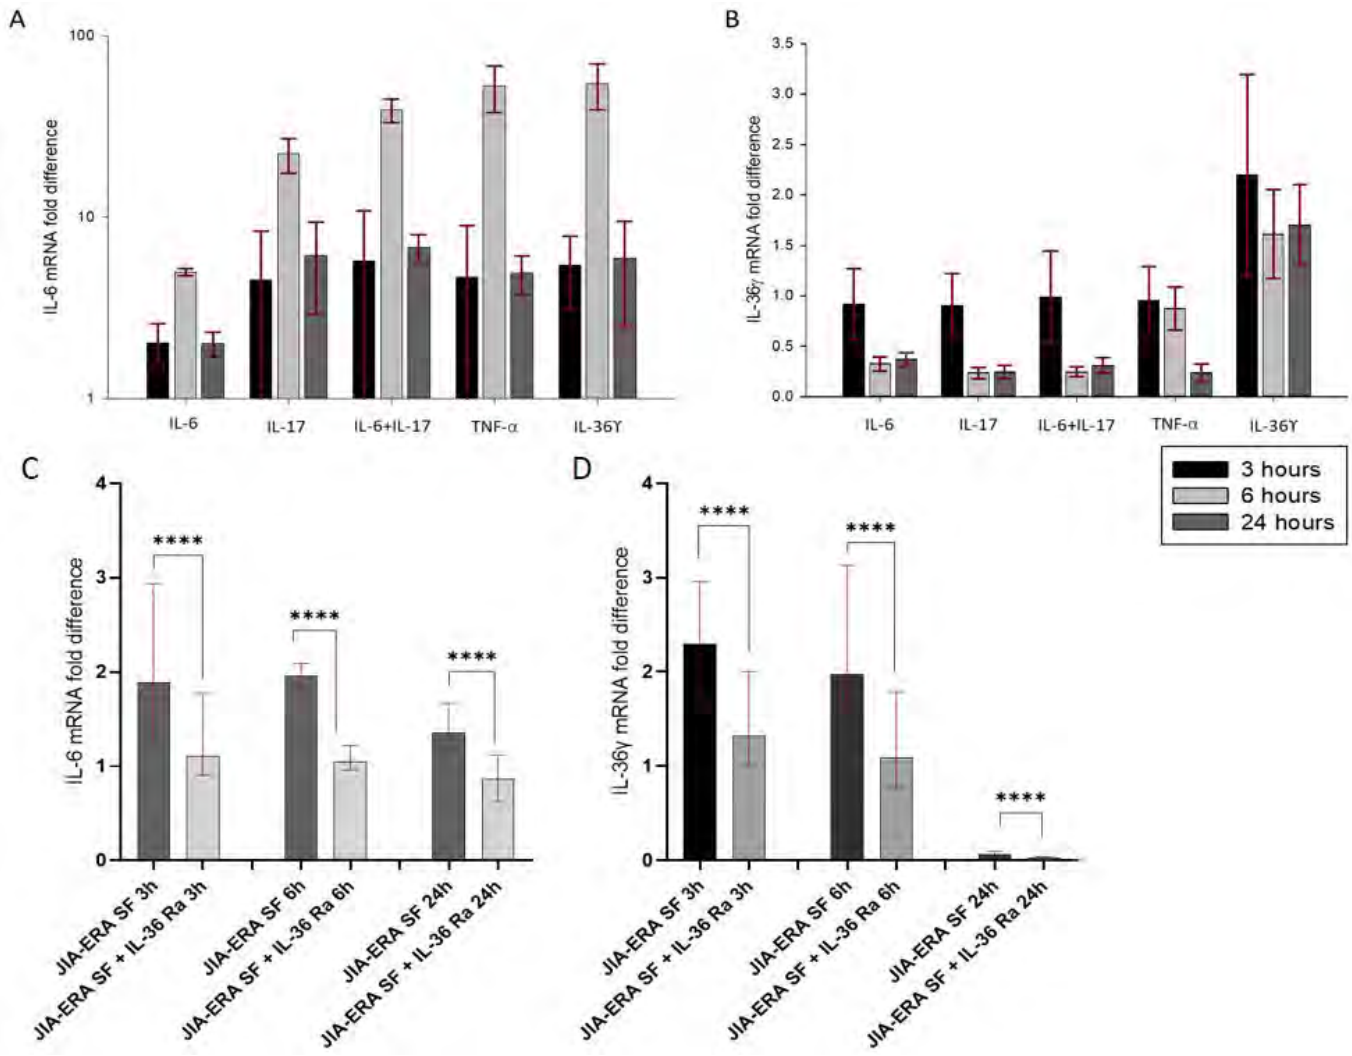

Figure. Fold difference in mRNA expression of IL-6 and IL-36**γ** in FLS post stimulation. (A) mRNA expression of IL-6 upon stimulation of FLS with pro-inflammatory cytokines. (B) mRNA expression of IL-36**γ** upon stimulation of FLS with pro-inflammatory cytokines. (C) mRNA expression of IL-6 in FLS upon stimulation with SF from JIA-ERA patients in presence or absence of IL-36Ra. (D) mRNA expression of IL-36**γ** in FLS upon stimulation with SF from JIA-ERA patients in presence or absence of IL-36Ra.

mRNA levels of IL-36α, IL-36γ and IL-36R were increased in PBMCs of ERA patients as compared to healthy controls. However, at protein level only IL-36γ was detectable in a significant proportion of subjects and was higher (0 ± 42.1 pg/mL) than controls (0 ± 0) ($p< 0.01$) but lower than RA patients (198.2 ± 672.9 pg/mL).

In SFMCs, all 4 mRNA were detectable with levels lower than RA patients. SF levels of IL-36γ were also enhanced (0 ± 26.78 pg/mL) but were lower than RA patients (460 ± 1345 pg/mL). SF IL-36γ levels correlated significantly with disease activity (JSpaDA) ($r=0.51$, $p< 0.0001$), and with SF levels of IL-6 ($r=0.4$, $p= 0.0063$) and IL-17 ($r=0.57$, $p=0.0018$). Patients on treatment with DMARDs had significantly lower SF IL-36γ levels than those not receiving DMARDs.

When FLS were stimulated with IL-36γ and other pro-inflammatory cytokines, mRNA expression of IL-36γ; and mRNA and protein expressions of IL-6 were found increased. Protein expression of IL-36γ was not detectable by ELISA in cell supernatants and no expression of IL-17 at RNA or protein level was noted.

When FLS were stimulated with SFs from JIA-ERA patients (n=5), increased expressions of IL-36γ mRNA and IL-6 mRNA and protein were seen, compared to controls. However, in presence of IL-36Ra, expressions of both cytokines were significantly reduced ($p< 0.0001$ in all cases).

Conclusion: The data suggests that pro-inflammatory cytokines aid in upregulation of IL-36γ which in turn upregulates expression of IL-6 and this might lead to a positive feedback loop leading to amplification of inflammation in ERA. Association of SF levels of IL-36g with disease activity further supports this possibility.

Expanded B Cell-Helper T Cells in ANA+ Oligoarticular Juvenile Idiopathic Arthritis

Amelie Jule[1], Maria Taylor[2], Kacie Hoyt[3], Kevin Wei[4], Maria Gutierrez-Arcelus[1], Siobhan Case[1], Mia Chandler[1], Margaret Chang[2], Ezra Cohen[1], Fatma Dedeoglu[1], Olha Halyabar[1], Jonathan Hausmann[5], Melissa Hazen[1], Erin Janssen[1], Jeffrey Lo[2], Mindy Lo[1], Esra Meidan[2], Jordan Roberts[1], Mary Beth Son[1], Robert Sundel[2], Pui Lee[6], Talal Chatila[1], Peter Nigrovic[1], Deepak Rao[4] and Lauren Henderson[7], [1]Boston Children's Hospital, Boston, MA, [2]Division of Immunology, Boston Children's Hospital, Harvard Medical School, Boston, MA, [3]Virginia Tech Carilion School of Medicine, Roanoke, VA, [4]Brigham and Women's Hospital, Boston, MA, [5]Beth Israel Deaconess Medical Center, Boston, MA, [6]Boston Children's Hospital, Newton, MA, [7]Division of Genetics and Genomics, Boston Children's Hospital, Harvard Medical School, Boston, MA

SESSION INFORMATION
Session Date: Monday, November 8, 2021
Session Title: Pediatric Rheumatology – Basic Science Poster (1007–1013)
Session Type: Poster Session C
Session Time: 8:30AM–10:30AM

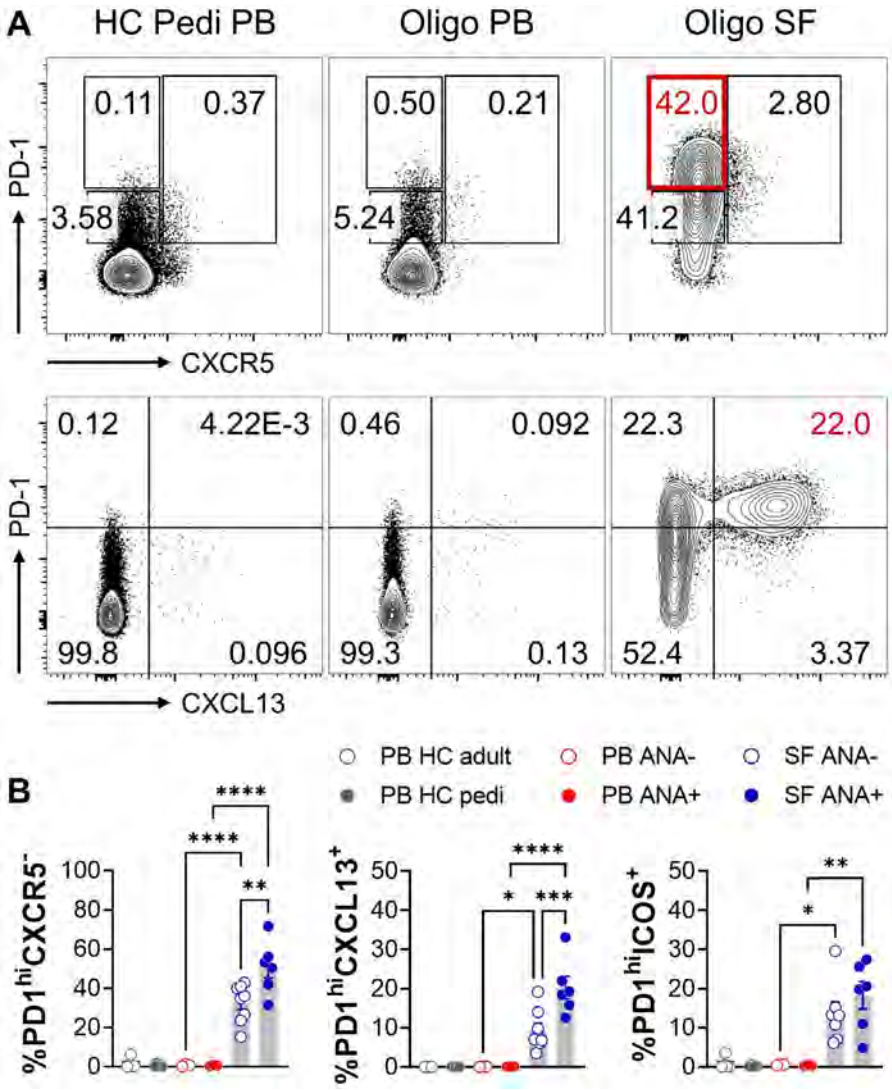
Background/Purpose: Oligoarticular juvenile idiopathic arthritis (oligo JIA) is defined by limited joint involvement (< 5 joints) in the first 6 months of disease. A subgroup of patients presents with distinct clinical features, including early age at disease onset (< 6 years), female sex, increased risk for uveitis and antinuclear antibody (ANA) positivity. The biological processes that drive clustering of these clinical features in ANA^+ oligoarthritis are not understood. The presence of autoantibodies in this oligo JIA subgroup suggests a role for abnormal B cell responses. To better understand interactions between T and B cells in oligo JIA, we characterized $CD4^+$ T cells with a B cell-helper T cell profile in ANA^+ and ANA^- oligo JIA.

Methods: Synovial fluid (SF) and, where possible, paired peripheral blood (PB) samples were collected from oligo JIA patients, defined by ILAR criteria. PB was obtained from healthy controls (HC). PB and SF mononuclear cells were evaluated with flow cytometry. T effector ($CD4^+CD25^-$, Teff) and T regulatory ($CD4^+CD25^+CD127^{lo}$) cells were sorted from the SF of 2 patients (one ANA^+ and one ANA^-), stained with hashing antibodies, pooled together in equal ratio, and processed for single-cell RNA sequencing (scRNA-seq) coupled with T cell receptor (TCR) repertoire using 10X. Transcriptomic data were analyzed in R using Seurat v3.1.5.

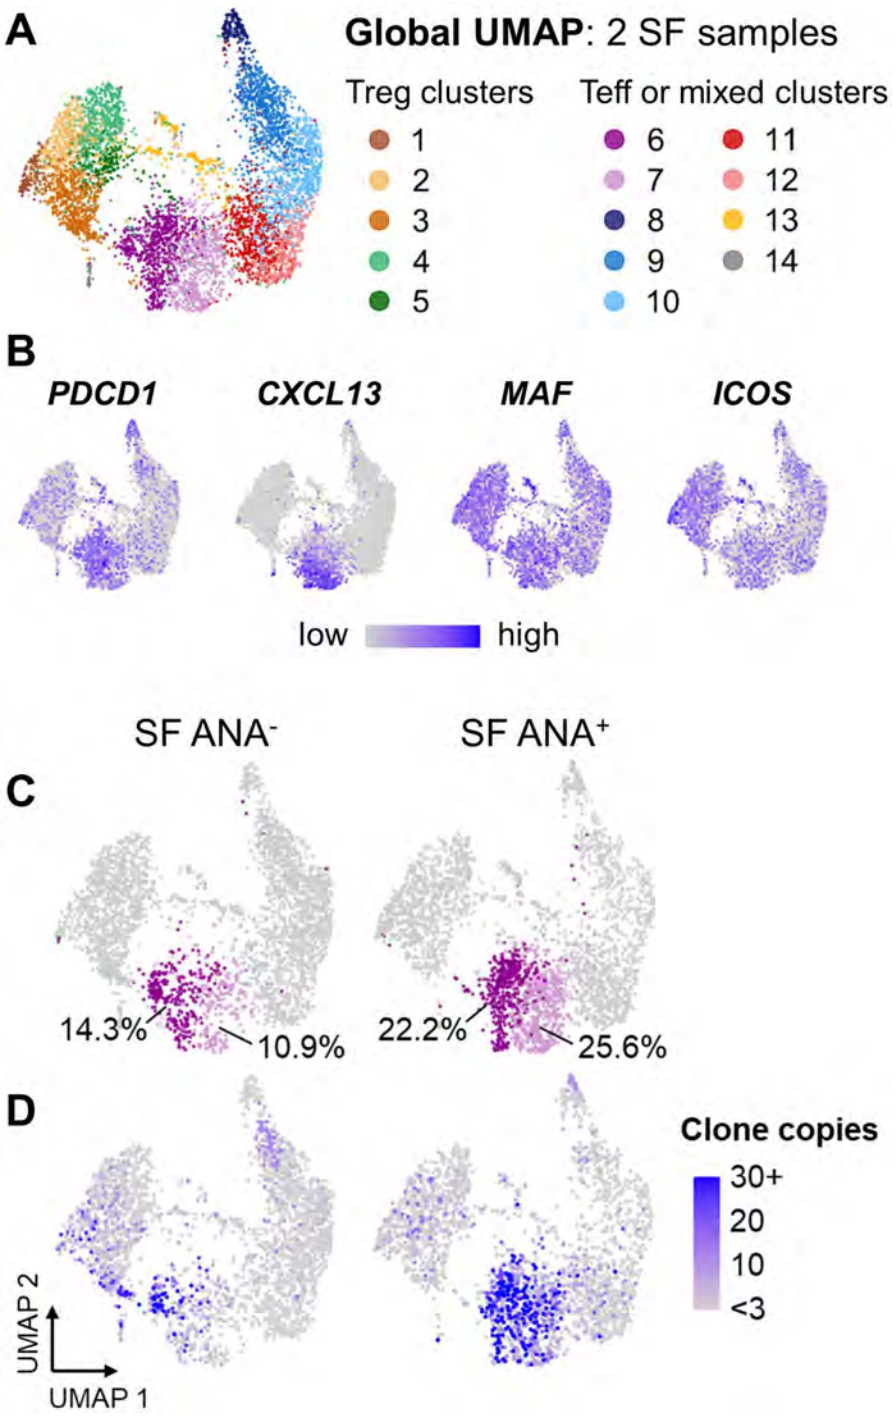
Results: 14 oligo JIA patients and 10 controls were studied. T follicular helper cells ($CD4^+PD\text{-}1^{hi}CXCR5^+$, Tfh) are found in secondary lymphoid organs and express factors (PD1, ICOS, IL-21, CXCL13) promoting B cell maturation and antibody production. Compared to the PB of controls and patients, Tfh cells were not significantly enriched in the SF of ANA^+ or ANA^- oligo JIA. In peripheral tissues, B cells are driven to mature and generate autoantibodies by T peripheral helper cells ($CD4^+PD\text{-}1^{hi}CXCR5^-$, Tph). Flow cytometry studies showed a significant enrichment of Tph cells in the SF of oligo JIA patients. ANA^+ patients had the highest proportion of Tph cells, with 50.8% ± 5.5 (mean ± SEM) of Tph

among total CD4⁺ T cells, compared to 32.5% ± 3.4 in ANA⁻ patients. In contrast, Tph cells were rare in the PB of patients and controls (< 6.5% of CD4⁺ T cells). Tph cells in SF expressed markers of B cell-helper T cells, including ICOS and the B cell chemoattractant CXCL13. scRNA-seq studies of SF CD4⁺ T cells revealed 2 clusters with Tph features, including cells co-expressing high levels of *PDCD1* (gene encoding PD1) and *CXCL13* alongside transcription factors previously identified in Tph cells (*MAF* and *BATF*). A greater proportion of Teff cells from the ANA⁺ patient (48%) compared to the ANA⁻ patient (25%) was found in Tph clusters. TCR repertoire analysis showed that clonally expanded T cells (with at least 3 clonal TCR copies) concentrated in Tph clusters and were mostly observed in the ANA⁺ patient.

Conclusion: Our results show that T cells with features of B cell-helper T cells preferentially accumulate in the joints of children with ANA⁺ oligo JIA. These results suggest that beyond the clinical features that characterize early-onset, ANA⁺ oligo JIA, disordered T cell-mediated help to B cells may further define this patient subset. Further studies are needed to delineate the functionality of Tph cells in oligo JIA.



T peripheral helper (Tph) cells are enriched in the synovial fluid (SF) of ANA+ oligo JIA. A) Representative flow cytometry dot plots gated on live CD3+CD4+ T cells. Frequencies of Tph cells (PD1hi, CXCR5-) and of the B-cell chemoattractant CXCL13 in oligo JIA SF are highlighted in red. B) Mean frequency ± SEM of CD3+CD4+ T cells expressing the corresponding markers. Statistical testing: ANOVA with correction for multiple comparisons; p-value <0.05 *; <0.01 **, <0.001 ***, <0.0001 **** (for readability, not all significant comparisons are shown).



Single-cell RNA sequencing of SF CD4+ T cells reveal clonally expanded cells with features of Tph cells in ANA+ oligo JIA. Sorted Tregs (CD4+CD25+CD127lo) and Teffs (CD4+CD25-) from the SF of 2 oligo JIA patients were studied with 10X. A) Uniform manifold approximation and projection (UMAP) of global dataset (both subjects, 6190 cells), color-coded by cluster. Clusters 6 & 7 contain Tph cells. B) UMAP of global dataset, showing gene expression levels of key Tph cell markers. C) UMAP of dataset, split by patient. The percent of T effector cells found in each Tph cluster for each patient is shown. D) UMAP projection, split by patient, highlighting T cell clones with strictly more than 3 copies across the dataset (expanded clones). A clone is defined by its paired TCRα and TCRβ chain.

Proton Pump Inhibitors Suppress IL-1 Mediated Carditis in a Murine Model of Kawasaki Disease

Paul Tsoukas[1], Melissa Kleinau[2], Lysa Langevin[2], Lily Morikawa[3], Trang Duong[1], Suzanne Tam[4] and Rae Yeung[5], [1]Hospital for Sick Children, Toronto, ON, Canada, [2]University of Toronto, Toronto, ON, Canada, [3]The Hospital for Sick Children, Toronto, ON, [4]Hospital for Sick Children, Toronto, ON, [5]The Hospital for Sick Children, Toronto, ON, Canada

SESSION INFORMATION
Session Date: Monday, November 8, 2021
Session Title: Pediatric Rheumatology – Basic Science Poster (1007–1013)
Session Type: Poster Session C
Session Time: 8:30AM–10:30AM

Background/Purpose: Kawasaki disease (KD), is the leading cause of acquired heart disease in childhood. Up to 20% of patients may develop coronary artery lesions (CAL) despite standard of care treatment with intravenous immunoglobulin (IVIg).

Murine and patient data indicate Interleukin-1 (IL-1) contributes to CALs. Proton pump inhibitors (PPI), a class of medications used to limit gastric acid secretion, have also been shown to have anti-inflammatory properties: 1) decreasing macrophage IL-1β secretion in vitro and 2) improving clinical outcomes in IL-1 mediated murine models.

This study aims to determine if PPIs inhibit IL-1β production and resulting CAL in the Lactobacillus casei cell wall extract (LCWE) induced coronary arteritis murine model of KD.

Methods: Bone marrow derived macrophages (BMDMs) were obtained from adult mice and stimulated with Pam-3Cys and Lactobacillus casei cell wall extract (LCWE), in the presence or absence of PPIs. To exclude toxic effects, viability was tested via flow cytometry and trypan blue exclusion. Electrolyte flux was measured via fluorescent imaging plate reader. In vivo, KD was induced by intraperitoneal LCWE injection. Mice were injected with LCWE alone, LCWE+PPI, saline or PPI alone. Coronary artery inflammation was scored by a blinded pathologist. Using ELISA, serum IL-1β and NT-proBNP were measured.

Results: Following stimulation with either Pam3Cys or LCWE, PPIs inhibited BMDM IL-1β production in a dose-dependent and drug class independent manner. Inflammasome activation was prevented by PPI inhibition of signal two. In vivo, compared to untreated KD diseased mice, those treated with PPI were shown to have significantly reduced coronary artery inflammation.

Conclusion: IL-1 is essential for the development of LCWE induced murine KD and anti-IL-1 therapy have been shown to prevent myocardial inflammatory changes. Our data indicate that PPIs have extra-gastrointestinal anti-inflammatory properties in a murine KD model preventing IL-1 induced coronary artery inflammation. PPIs may be a novel inexpensive, oral, and safe adjuvant anti-IL-1 medication to treat KD.

Session Title: Pediatric Rheumatology – Basic Science Poster (1007–1013)

Session Type: Poster Session C

Session Time: 8:30AM–10:30AM

Background/Purpose: Splice site variants in *IKBKG* that lead to exon 5 deletion cause NEMO-deleted exon 5 autoinflammatory syndrome (NEMO-NDAS). NEMO-NDAS clinically mimics the interferonopathy chronic atypical neutrophilic dermatosis with lipodystrophy and elevated temperature (CANDLE) but treatment with JAK inhibitors provides only partial benefit. Because an *IKBKG* pseudogene complicates the genetic diagnosis of NEMO-NDAS by standard methods, we developed and validated a bioinformatics approach to diagnose these patients (pts). We further characterized the complex immunodysregulation present in NEMO-NDAS.

Methods: A bioinformatics pipeline to mask the *IKBKG* pseudogene was refined using splice prediction tools (SpliceAi, TraP and MaxEntScan). Screening of *IKBKG* exon 5 ± 30bp was validated in 701 samples from subjects enrolled in an IRB-approved protocol, and in internal (n=2655, whole exome sequencing (WES)) and public (n=2498, whole genome sequencing (WGS)) databases. The variants detected were validated by Sanger or amplicon deep sequencing (seq) and spliced product was confirmed by Western blot, cDNA seq and RNA-seq. Nanostring gene expression, PBMC stimulation and cytokine assays were performed. CRISPR generated U937 cell line clones were functionally assessed.

Results: 13 pts (9 females and 4 males) had 9 different de novo splice site variants in *IKBKG*. cDNA seq (12/12) or Western blot (5/5) confirmed the splice product in all pts tested. RNA-seq (n=12) showed a high frequency of exon 5 skipping (median 55% (35-80%)). *IKBKG* exon 5 splice site variants were screened in internal and public WES/WGS databases (n=5149) and 11 variants in 22 subjects passed filters. Sanger seq confirmed 1 of the 11 variants (9%);

amplicon deep seq is pending. The most common clinical features in NEMO-NDAS pts were panniculitis with systemic inflammation (100%), ectodermal dysplasia (83%), hepatosplenomegaly (77%) and B-cell lymphopenia (80%). Compared to CANDLE pts (n=5), NEMO-NDAS pts' skin biopsies (n=7) showed histiocytic panniculitis, vacuolar interface changes and dyskeratosis. Liver biopsies (n=3) showed granulomatous hepatitis; 2 other pts had portal hypertension. All pts were steroid-dependent with partial responses to anti-TNF (n=9) or JAK inhibition (n=9). Nanostring IFN and NF-κB scores were elevated in all 13 pts. Pts with NEMO-NDAS had higher serum levels of IFN-γ, IL-12p40, IL-17 and IL-23 than seen in CANDLE pts ($p< 0.0001$ for all). Stimulated M1 and M2 macrophages from NEMO-NDAS pts (n=3) produced higher levels of CCL3/4 (MIP1-α/β) than healthy control (HC) cells (n=7)($p< 0.05$). NEMO-NDAS pts (n=2) had normal T and B cell proliferation, and Fas-induced T cell death was comparable to HC. U937 cell line clones lacking exon 5 normally degraded IκBα upon LPS stimulation and mutant U937 clones showed enhanced TNF induced cell death compared to wildtype and PSMB8-/- clones.

Conclusion: Our bioinformatics pipeline masking *IKBKG* pseudogene provides a sensitive diagnostic tool for the early recognition of NEMO-NDAS pts. The role of cytokine dysregulation and TNF induced cell death in the specific pathogenesis of NEMO-NDAS is being evaluated to improve therapeutic options.

Altered T Cell Responses, and Synergistic Regulation of Synovial Fibroblasts Function in Children with Down's Syndrome-Associated Arthritis

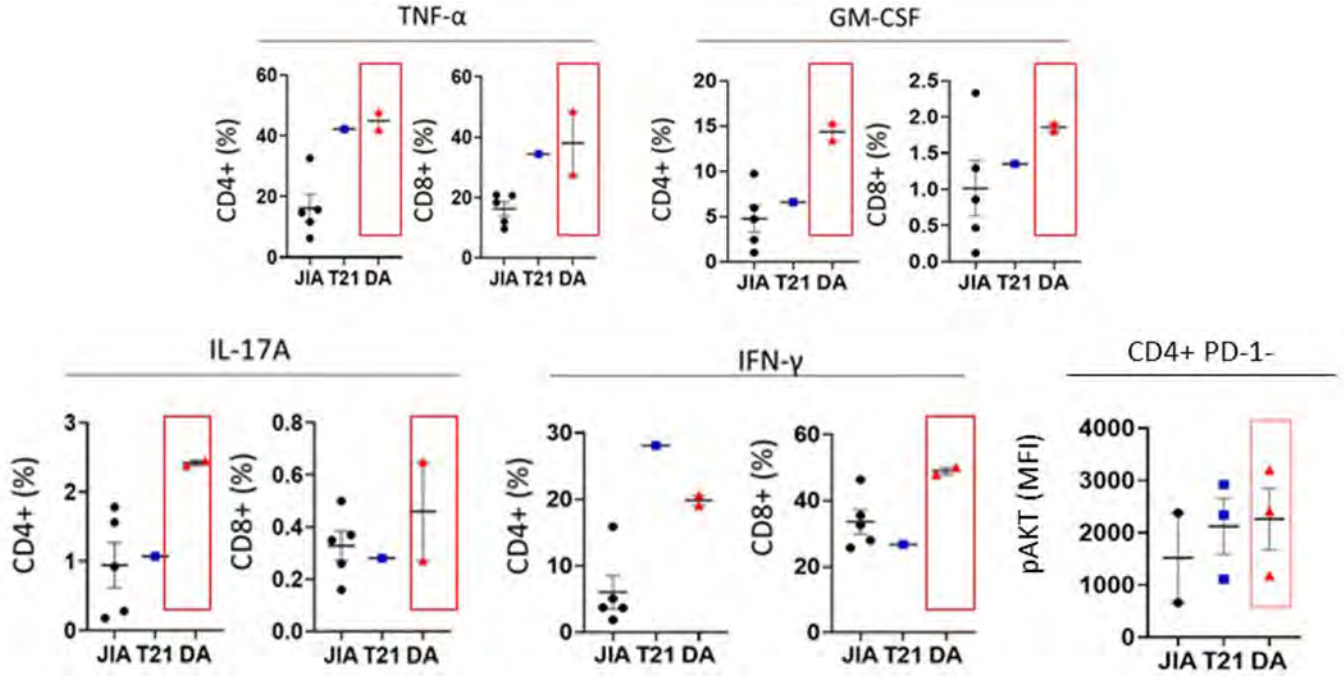
SESSION INFORMATION
Session Date: Monday, November 8, 2021
Session Title: Pediatric Rheumatology – Basic Science Poster (1007–1013)
Session Type: Poster Session C
Session Time: 8:30AM–10:30AM

Background/Purpose: Juvenile idiopathic arthritis (JIA) was thought to be the most common inflammatory arthritis in children. However an aggressive, erosive arthritis of little-known immunologic mechanism occurs 20 times more frequently in children with Down's syndrome. This study was undertaken to characterize the distinct immune cell responses and synovial fibroblast invasiveness in children with Down's syndrome-associated arthritis (DA) in comparison to JIA.

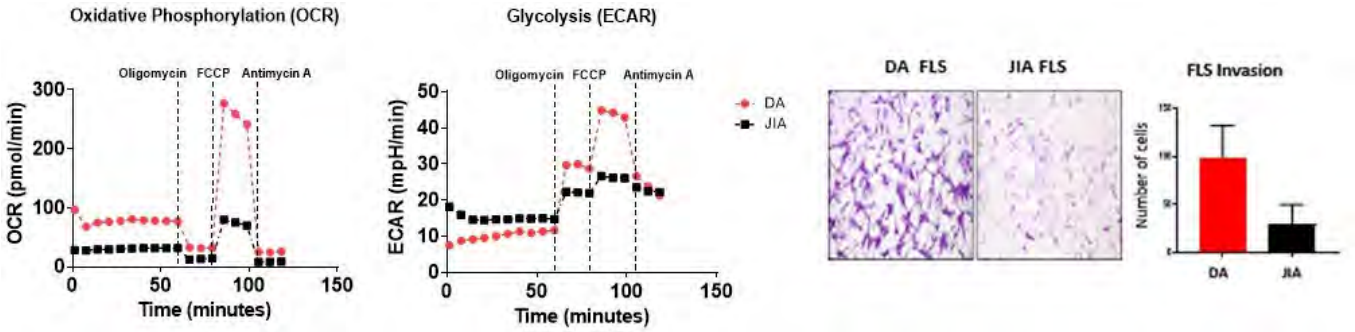
Methods: Multiparametric flow cytometric analysis was used to examine peripheral blood T cell, B cell and monocyte populations. In addition, T cell cytokine responses and their metabolic profile in children with DA, JIA, Down's Syndrome (trisomy 21 [T21]), and in healthy controls were assessed. The function of DA primary synovial fibroblasts (FLS) was assessed in response to stimulation with pro-inflammatory mediators alone and in combination (TNF-α, IL-17a, IFN-γ, GM-CSF). The two major energy pathways glycolysis (ECAR) and oxidative phosphorylation (OCR) were quantified by the Seahorse XFe96 Analyser. Migration, adhesion, invasion and cytokine/chemokine secretion were quantified wound repair scratch assays, Transwell collagen invasion chambers, adhesion binding assays, flow cytometry and ELISAs.

Results: T cell frequencies were higher in DA compared to JIA and T21 in contrast to B cell frequencies which were decreased. T cell responses in DA were characterized by increased frequencies of CD4+ and CD8+ TNF-a, IFN-g and GM-CSF producing T cells. The frequency of T peripheral helper cells were elevated in children with DA compared to all other groups, paralleled by an increase in their metabolic profile evident by higher phosphorylation of mTOR pathway component, AKT. Comparison of DA and JIA FLS demonstrated that DA FLS display a more invasive/migratory capacity and are more metabolically active. Based on the increased cytokine profile from DA T cells, we next examined the effect T cell derived cytokines TNF-α, IL-17a, IFN-γ and GM-CSF alone and in combination on DA FLS function. TNF-α, IL-17a and IFN-γ elevated IL-6, RANTES and MCP-1, with no effect observed for GM-CSF. Furthermore, TNF-α, and IL-17a induced DA FLS migration and increased PBMC adhesion to DA FLS. Finally, IL-17a and IFN-γ potentiated the effects TNF-α had on IL-6 and MCP-1 secretion compared to stimulation alone.

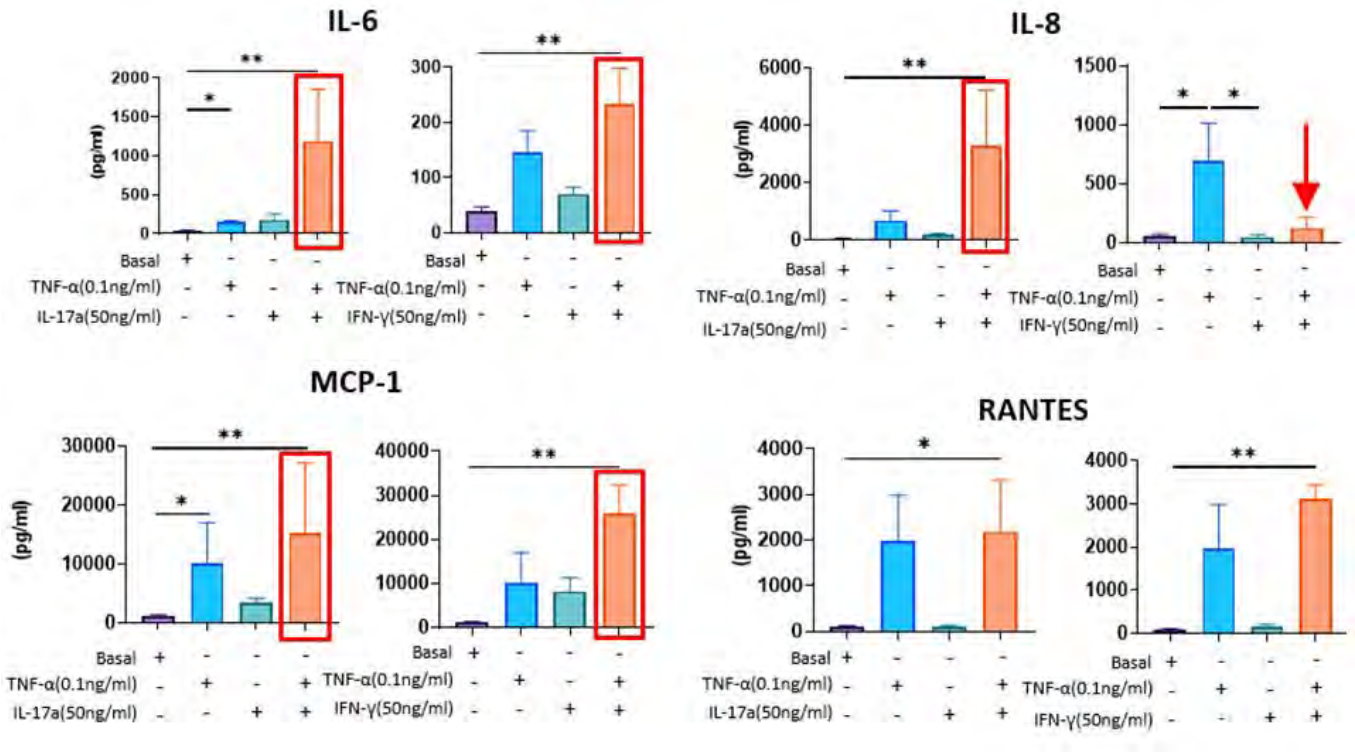
Conclusion: DA is a more common and aggressive form of arthritis compared to JIA. It is characterized by increased T cell responses and a more invasive FLS phenotype compared to that of JIA, with T cell derived cytokines alone and in combination further inducing the DA FLS pathogenic mechanisms. This suggests a synergistic relationship between cytokines. These effects mirror the increased erosive disease observed clinically.



CD4+ and CD8+ T cells in DA expresses higher TNF-α, GM-CSF and IL-17a. CD8+ T cells from DA show increased IFN-γ expression while DA CD4+ PD-1- T cells have elevated pAKT compared to JIA and T21.



Higher metabolic profiles and higher invasive capacity in DA FLS compared to JIA FLS.



Cytokine synergy between TNF-α, IL-17a and IFN-γ induces proinflammatory mediators in DA FLS.

Session Title: Pediatric Rheumatology – Basic Science Poster (1007–1013)

Session Type: Poster Session C

Session Time: 8:30AM–10:30AM

Background/Purpose: Multi-system Inflammatory Syndrome in Children (MIS-C) is a severe disease that affects a small proportion of children exposed to Severe Acute Respiratory Syndrome Coronavirus 2 (SARS-CoV-2). Differences in SARS-CoV-2 antibody responses and immune gene expression between SARS-CoV-2-infected children who develop MIS-C and those who do not may provide insight into the mechanism of MIS-C.

Methods: Healthy children presenting for elective surgery and those with MIS-C were recruited between 22 June 2020 and 5 November 2020 from a single paediatric hospital during the first wave of SARS-CoV-2 in the region. Clinical data, whole blood RNA and serum were collected. Titres of SARS-CoV-2 spike-specific antibody (SAb) and their capacity to perform neutralization, antibody-dependent cellular phagocytosis (ADCP) and antibody dependant cellular cytotoxicity (ADCC) were measured. Whole blood RNA gene expression was measured using multiplex Fluidigm quantitative Polymerase Chain Reaction (qPCR) with a panel of 84 immune genes. Principal component analysis was performed to assess for differences in gene expression. A linear regression model was developed with a forward stepwise model selection method to assess which genes associated with C-reactive protein (CRP) in MIS-C after controlling for the neutrophil to lymphocyte ratio (NLR).

Results: Twenty-three children with MIS-C and 25 healthy children were recruited. Nine healthy children had detectable SARS-CoV-2 serum antibodies (healthy exposed). No children had preceding clinical disease related to SARS-CoV-2 infection. Comparing children with MIS-C and healthy exposed children showed no difference in SAb binding responses (p=0.372) or ADCC (p=0.992). Increased neutralisation titre (p=0.084) and ADCP (p=0.086) in children with MIS-C was observed although was non-significant. Antibody function or titre did not change over time or with treatment in MIS-C. There was a clear distinction in immune gene expression between healthy children and those with MIS-C. Immune gene expression in MIS-C resolved to become indistinct from healthy children with time. Whole blood immune gene expression associated with an abundance of neutrophils in MIS-C. In a model that accounted for 66% of the variance in CRP (adjusted R^2 = 0.66) the expression of the gene for interleukin 27 (*IL27)* accounted for 64% of the model effect (B=35; p< 0.001) followed by NLR (15%, B=6.6, p=0.002) and the expression of the gene for monocyte chemoattractant protein 2 (*MCP2)* (11%, B=-14.59, p=0.008).

Conclusion: Comparing children infected with SARS-COV-2 from the same time period and region with or without MIS-C provides unique mechanistic insight into the disease. A trend towards higher SAb titres and ADCP implies a distinct humoral immune response to SARS-COV-2 in children with MIS-C, although further studies are required to validate this observation. The resolution of the abnormal immune gene expression in MIS-C implies a monophasic immune perturbation. The association of *IL27* and *MCP2* with CRP suggests that these may be important targets in future studies for possible pathogenicity and as potential biomarkers in MIS-C.

Enhanced Expression of Rheumatoid Arthritis Related Autoantibodies Following Airborne Endotoxin Exposure in the Setting of Collagen-Induced Arthritis

Ted Mikuls[1], Rohit Gaurav[1], Geoffrey Thiele[1], Bryant England[1], Madison Wolfe[1], Brianna Shaw[1], Kristina Bailey[1], Amy Nelson[1], Michael Duryee[1], Carlos Hunter[1], Debra Romberger[1], Dana Ascherman[2] and Jill Poole[1], [1]University of Nebraska Medical Center, Omaha, NE, [2]University of Pittsburgh, Pittsburgh, PA

SESSION INFORMATION
Session Date: Monday, November 8, 2021
Session Title: RA – Animal Models Poster (1014–1021)
Session Type: Poster Session C
Session Time: 8:30AM–10:30AM

Background/Purpose: In addition to inflammatory arthritis, collagen-induced arthritis (CIA) recapitulates cardinal features of rheumatoid arthritis (RA) including autoreactive T cells, peptidyl-arginine deiminase expression, and citrullination of synovial antigens. However, CIA is not characterized by robust ACPA expression, a key limitation of this model since ACPA are highly disease specific and play a pathogenic role in RA. Airborne biohazards such as cigarette smoke have been linked with airway generation of citrullinated antigens, ultimately leading to tolerance loss and ACPA production. In prior work, we have shown that combining the inhalant exposure of lipopolysaccharide (LPS; a component of relevant environmental/occupational exposures in RA) with CIA amplifies arthritis and shifts airway inflammation seen with LPS alone towards lung fibrosis. In this study, we examined the effect of repetitive exposure to airborne LPS on airway formation of autoantigens and circulating autoantibodies in CIA.

Methods: DBA/1J male mice were assigned to 4 groups: 1) Sham (saline injection/saline inhalation); 2) CIA alone (CIA injection/saline inhalation); 3) LPS alone (saline injection/LPS 100 ng inhalation); and 4) CIA+LPS (CIA injection/LPS inhalation). Serum and lung tissues were harvested at 5 weeks. ACPA (IgG) and antibody to malondialdehyde-acetaldehyde (IgG anti-MAA [also increased in RA] and anti-MAA-CIT antibody) were measured using ELISA. Lung tissues were examined for citrulline (CIT), MAA adducts, and extracellular matrix proteins (fibronectin, vimentin) using immunohistochemistry. Pearson R^2 values were calculated as measures of tissue co-localization.

Results: Serum ACPA, anti-MAA, and anti-MAA-CIT antibodies were strikingly potentiated in CIA+LPS vs. all other groups ($p< 0.01$; **Figure 1**). Both CIT- and MAA-modified lung proteins were significantly increased in CIA, LPS, and CIA+LPS vs. Sham, with the highest expression in CIA+LPS ($p< 0.01$ vs. all other groups) (**Figure 2**). CIT and MAA

Serum levels of IgG anti-citrullinated protein antibody (ACPA) levels to citrullinated (CIT) peptides, IgG antibody to malondialdehyde-acetaldehyde (MAA)-modified proteins, and combined anti-MAA-CIT autoantibodies. Statistical difference versus sham (#p<0.05, ###p<0.001, ####p<0.0001) and between groups as noted by lines (**p<0.01, ****p<0.0001).

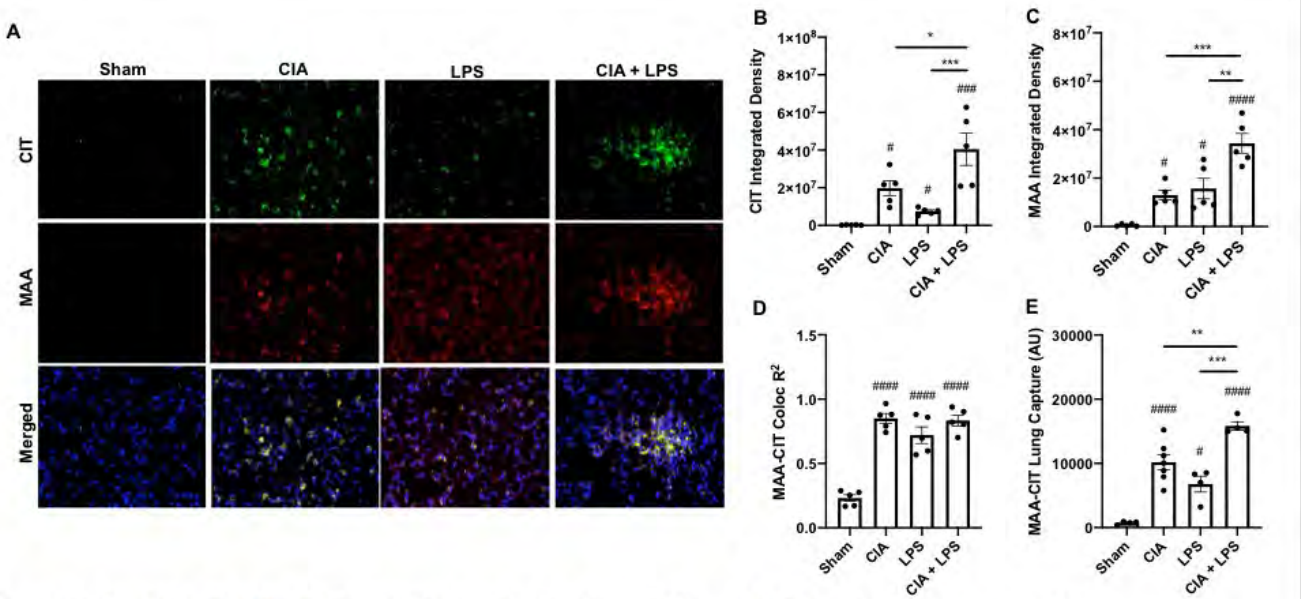

Figure 2. Combined CIA+LPS modeling modulates lung CIT and MAA autoantigen expression.
(A) Confocal images of lung tissue from treatment groups stained for citrulline (CIT; green) and malondialdehyde-acetaldehyde (MAA; red) modified proteins and merged with nuclei staining (DAPI, blue) shown at 40x magnification. Images were analyzed using Zen 2012 software (Zeiss). Scatter plots depict integrated density with SE bars of (**B**) CIT and (**C**) MAA-modified proteins quantified per each mouse. (**D**) R^2-values demonstrating co-localization of MAA-CIT within each treatment group. (**E**) Co-capture of MAA-CIT from lung tissue homogenates by sandwich ELISA (AU; arbitrary units). Statistical difference versus sham (#p<0.05, ###p<0.001, ####p<0.0001) and between groups as noted by lines (*p<0.05, **p<0.01, ***p<0.001).

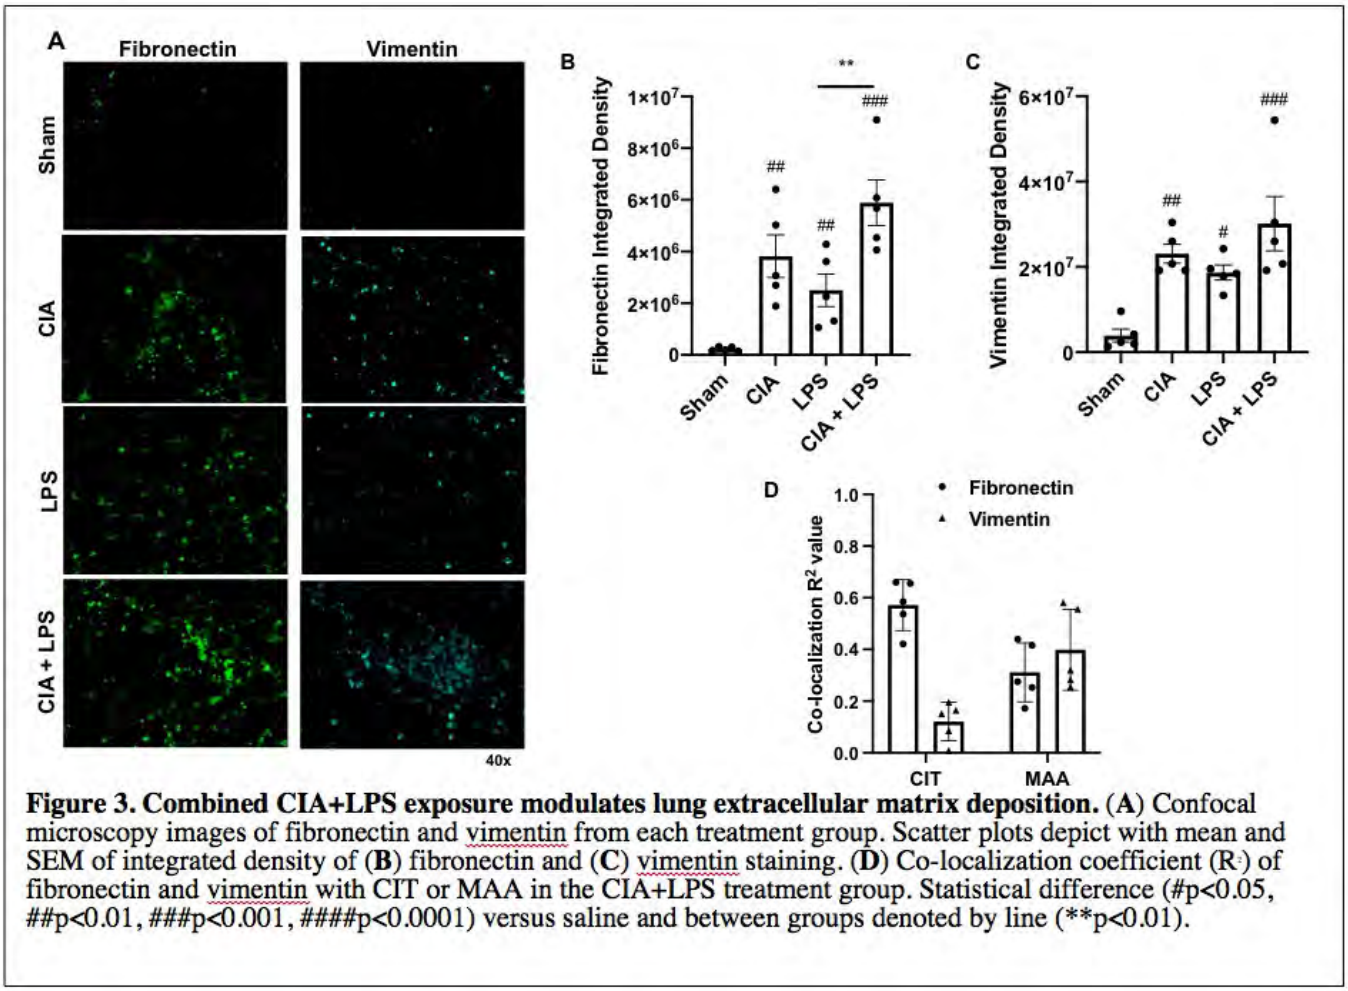

Figure 3. Combined CIA+LPS exposure modulates lung extracellular matrix deposition. (**A**) Confocal microscopy images of fibronectin and vimentin from each treatment group. Scatter plots depict with mean and SEM of integrated density of (**B**) fibronectin and (**C**) vimentin staining. (**D**) Co-localization coefficient (R^2) of fibronectin and vimentin with CIT or MAA in the CIA+LPS treatment group. Statistical difference (#p<0.05, ##p<0.01, ###p<0.001, ####p<0.0001) versus saline and between groups denoted by line (**p<0.01).

co-localization were similarly increased across groups vs. Sham. Lung fibronectin was increased with CIA and LPS and its expression was enhanced in CIA+LPS (**Figure 3**). Vimentin expression was increased in CIA, LPS, and CIA+LPS vs. Sham, but there were no differences between treated groups. In CIA+LPS lung tissues, CIT co-localized with fibronectin (R^2=0.6) but not vimentin (R^2=0.12), whereas MAA co-localized with both fibronectin (R^2=0.3) and vimentin (R^2=0.4).

Conclusion: In the context of arthritis induction, exposure to endotoxin (a ubiquitous airborne biohazard) led to substantial increases in the lung expression of post-translationally modified proteins implicated in RA. Moreover, these combined exposures led to striking increases in serum autoantibodies including a >30-fold increase in ACPA and a 6-fold increase in anti-MAA antibody, yielding an autoantibody profile more closely mimicking human disease. These results emphasize that an underlying predisposition to autoimmunity plus a "second hit" such as an airborne biohazard exposure could be driving tolerance loss and autoimmunity that characterize RA.

Session Title: RA – Animal Models Poster (1014–1021)
Session Type: Poster Session C
Session Time: 8:30AM–10:30AM

Background/Purpose: Improved management of rheumatoid arthritis (RA) and psoriatic arthritis (PsA) remains an unmet need. Salt-inducible kinases (SIKs) modulate immune cells by a dual mechanism of action (MoA) in inflammatory conditions.[1–3] SIK2/SIK3 inhibition governs a molecular transcriptional switch resulting in reduced expression of pro-inflammatory mediators coupled with enhanced immunoregulatory activity. GLPG3970 is a first-in-class SIK2/SIK3 inhibitor in development for inflammatory indications. We evaluated the therapeutic activity of GLPG3970 in murine arthritis models.

Methods: GLPG3970's selectivity and potency were profiled in biochemical and target-based cell assays. The dual MoA of SIK2/SIK3 inhibition with GLPG3970 was evaluated in LPS-stimulated human whole blood measuring TNFα and IL-10 release and by performing RNA sequencing. Functional enrichment analysis of KEGG pathways among the differentially expressed genes (DEGs) was performed using a standard hypergeometric test.

Three doses of GLPG3970 treatment were evaluated in two murine models of arthritis: the IL23-induced PsA model and the collagen-induced-arthritis (CIA) model. First, B10.RIII mice received hydrodynamic i.v. injection of 0.1 µg mIL-23 enhanced Episomal Expression Vector to induce PsA disease. Efficacy of 5 weeks of treatment with GLPG3970 was evaluated by clinical score analysis and X-ray imaging (analysis of osteophyte formation). Inflammatory media-

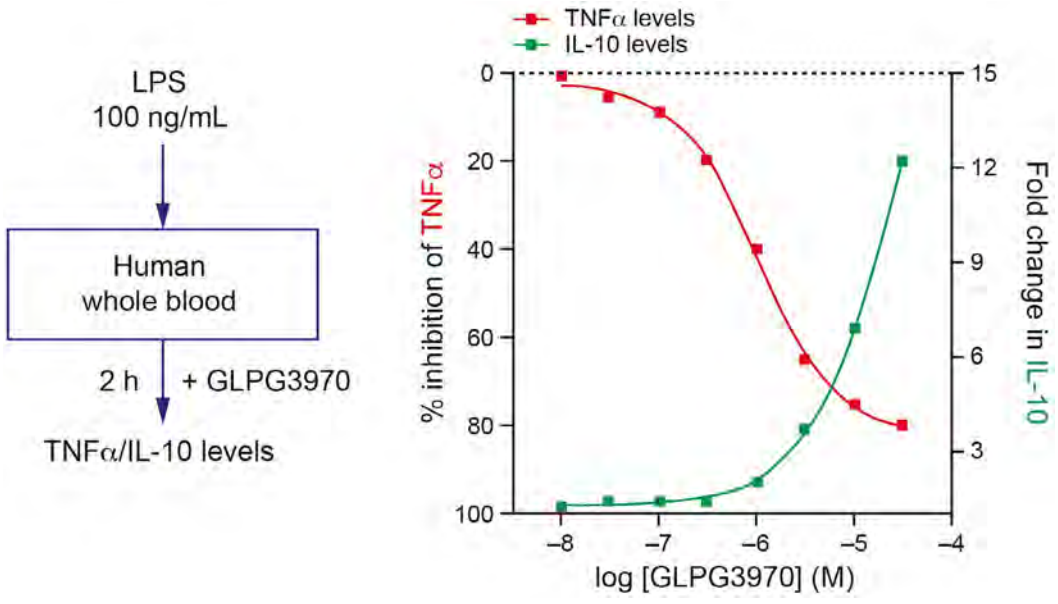

Figure 1. GLPG3970 activity in LPS-stimulated human whole blood assay (mean values, n=52, healthy donors).

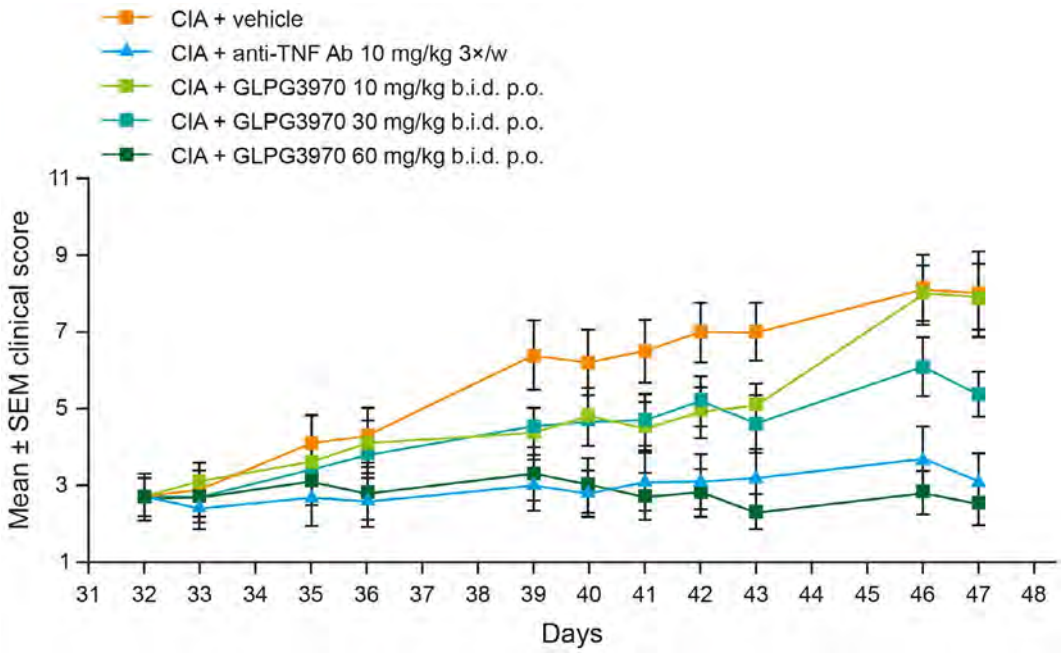

Figure 3. Clinical score over time in RA model (therapeutic CIA model).

tors were quantified in paws. Second, in the CIA model, DBA1J mice were classically immunized with a type II bovine collagen emulsion on day 1 and day 21. Efficacy of GLPG3970 treatment from day 32–47 was compared with an anti-TNF agent (Enbrel®) and evaluated by clinical score analysis and bone erosion (Larsen score after X-ray imaging). Anti-collagen type-II antibodies were quantified in serum.

Results: GLPG3970 was shown to inhibit SIK2/SIK3 with high selectivity against a panel of 372 kinases. Activity in LPS-stimulated whole blood led to dose-dependent reduction of TNFα levels coupled with increased IL-10 release (Fig 1). GLPG3970 DEGs in LPS-stimulated whole blood were functionally enriched with RA as part of the top 3 most

statistically significant pathways from the KEGG database. GLPG3970 treatment in the PsA model decreased clinical score (Fig 2), osteophyte formation and pro-inflammatory mediators. GLPG3970 reduced clinical score in the CIA model (Fig 3). The highest dose effect was comparable with anti-TNF treatment and correlated with reduced Larsen score and anti-collagen type-II antibody levels.

Conclusion: This study associates the underlying mechanism of SIK2/SIK3 inhibition with RA and highlights the therapeutic activity of GLPG3970 in murine arthritis models, supporting GLPG3970 as a promising novel approach for the treatment of arthritis. GLPG3970 is being tested in a phase 2a study in patients with RA (NCT04577781).

Assessment of Pre-Inflammatory Mesenchymal (PRIME) Cells as a Biomarker of Tumor Necrosis Factor-Induced Arthritis in Mice

Kiana Chen[1], Xi Lin[1], Lianping Xing[2], H. Mark Kenney[3], Richard Bell[4], Edward Schwarz[5] and Homaira Rahimi[5], [1]University of Rochester School of Medicine and Dentistry, Rochester, NY, [2]University of Rochester Medical Center, Webster, NY, [3]University of Rochester Medical Center, Rochester, NY, [4]Hospital for Special Surgery, New York, NY, [5]University of Rochester, Rochester, NY

SESSION INFORMATION
Session Date: Monday, November 8, 2021
Session Title: RA – Animal Models Poster (1014–1021)
Session Type: Poster Session C
Session Time: 8:30AM–10:30AM

Background/Purpose: Recently, CD45–CD31–Podoplanin (PDPN)+ synovial fibroblast-like cells, termed pre-inflammatory mesenchymal (PRIME) cells were found to be differentially expressed and circulate in the blood of rheumatoid arthritis (RA) patients before an arthritic flare (1). PRIME cells are hypothesized to be stimulated from an inflammatory trigger and recruited to the synovium from blood to facilitate flares, suggesting that their presence in circulating blood can be a biomarker for inflammatory arthritis. However, the presence of a PRIME cell population in rodent animal models of RA has yet to be determined. TNF-transgenic (TNF-Tg) mice are a model of RA in which the constitutive expression of pro-inflammatory cytokines characterizes a persistent inflammation during disease development. Identification of PRIME cells in rodent models, and specifically in the TNF-Tg mice, may be utilized to further elucidate the role of PRIME cells in inflammatory arthritis. Thus, we hypothesized that arthritic TNF-Tg mice express a population of circulating PRIME cells that are increased compared to wild-type (WT) controls.

Methods: Flow cytometry analysis of peripheral blood and bone marrow was performed on 6-9-month-old TNF-Tg and WT male littermates (n=3 mice/group). PRIME cells were determined as CD45-CD31-PDPN+ gated cells, and for each experimental sample, populations were compared with the percentage of gated cells and the total count

of PRIME cells (Fig 1). Groups were analyzed using unpaired t-tests, and values are reported as mean ± standard deviation.

Results: At 6-9 months, both TNF-Tg and WT mice showed PRIME cell populations in circulating blood (2.28 ± 1.98% TNF-Tg vs 2.21 ± 3.52% WT; 31.33 ± 45.88 TNF-Tg vs 31.33 ± 53.41 WT) and bone marrow (7.70 ± 13.34% TNF-Tg vs 12.11 ± 20.98% WT; 25 ± 43.3 TNF-Tg vs 35.33 ± 61.20 WT). There was no significant difference in PRIME cell populations between TNF-Tg and WT mice.

Conclusion: These preliminary results suggest that PRIME cells can be detected in blood and bone marrow of both TNF-Tg mice with advanced arthritis and their WT littermates. However, by late stage arthritis, the PRIME cell population in TNF-Tg mice is not greater than that found in WT controls, and therefore ineffective as a biomarker of chronic disease in this model. Future studies looking at early disease and flare are warranted to further clarify the use of PRIME cells as biomarkers in TNF-induced arthritis.

Osteoclast-Specific Transmembrane Protein (OC-STAMP) Regulates Osteoclastogenesis and Inhibits Inflammation in an Acute Arthritis Model

Maria de la Luz Garcia-Hernandez[1], Javier Rangel-Moreno[1], Ananta Paine[1], Jacob R. Jones[1], Marc Nuzzo[1], Lidsay N. Schnur[2] and Christopher Ritchlin[1], [1]Division of Allergy, Immunology, and Rheumatology, School of Medicine and Dentistry, University of Rochester Medical Center, Rochester, NY, [2]University of Rochester, Rochester, NY

SESSION INFORMATION
Session Date: Monday, November 8, 2021
Session Title: RA – Animal Models Poster (1014–1021)
Session Type: Poster Session C
Session Time: 8:30AM–10:30AM

Background/Purpose: Dendritic Cell (DC)-Specific Transmembrane Protein (STAMP) expressed by osteoclast precursors is required for cell-cell fusion in the formation of the osteoclast (OC) polykaryon. Genetic ablation of DC-STAMP results in mononuclear OCs and an osteopetrosis phenotype. Absence of DC-STAMP in the TNF-Tg arthritis model markedly reduces synovitis and inflammatory bone loss. OC-STAMP is another molecule required for cell-cell fusion and absence of either DC or OC-STAMP blocks multinucleation. To date, it is unknown if both molecules have redundant or cooperative functions and if their combined absence results in decreased bone damage and synovitis in inflammatory arthritis. We hypothesize that dual absence of OC-STAMP and DC-STAMP will ameliorate inflammation and bone erosion in a mouse model of acute arthritis (K/BxN).

Methods: OC-STAMP floxed mice were crossed with DC-STAMP$^{-/-}$ and global B6-Cre mice to generate OC-STAMP$^{-/-}$ and OC-STAMP$^{-/-}$ x DC-STAMP$^{-/-}$ animals. We injected WT, OC-STAMP$^{-/-}$ and OC-STAMP$^{-/-}$ x DC-STAMP$^{-/-}$ mice with serum collected from 8-week old K/BxN mice to induce acute inflammatory arthritis. We evaluated bone loss and local inflammation by micro-CT scan and histology, respectively. We isolated CD115^{+} cells, macrophages, neutrophils, dendritic cells (DCs), T cells and differentiated M1/M2 macrophages from WT mice to assess OC-STAMP expression by quantitative qPCR. We also quantified mRNA changes in IL13, IL10 and arginase I in WT and OC-STAMP deficient M2 macrophages.

Results: k/bxn-treated OC-STAMP deficient mice demonstrated extensive bone loss in the tibia (10 ± 0.9 Vs 22 ± 2, p = 0.0001), femur (12 ± 1 Vs 26 ± 2.5, p = 0.0001), talus (53 ± 2 Vs 58 ± 2, p = 0.0001), and increased pannus infiltration compared to WT mice. Surprisingly, the absence of DC-STAMP in OC-STAMP deficient mice treated with k/bxn sera was associated with decreased bone resorption in femur (16.3 ± 5, p = 0.05), tibia (15 ± 5, p =0.01) and ankle (51 ± 3.6, p = 0.02), compared to WT but bone loss was significantly lower than observed previously in DC-STAMP$^{-/-}$ TNF-Tg mice. We assessed OC-STAMP expression by quantitative PCR in immune cells and found that OC-STAMP is expressed by spleen macrophages (51.9 ± 0.6, p ≤ 0.001), DCs (304 ± 24, p = 0.002), neutrophils (126 ± 13, p = 0.003), M2 macrophages (350 ± 17, p = 0.001), CD4 (1.8 ± 0.014) and CD8 T cells (7.9 ± 0.5, p = 0.0002). Its expression was low or absent in M1 macrophages (4.5 ± 0.01, p ≤ 0.0001) and CD115^{+} cells (1 ± 0.01, p ≤ 0.001), respectively. OC-STAMP deficient M2 macrophages showed impaired expression of IL13 (14.5 ± 1.6 Vs. 0.1 ± 0.005, p = 0.004), arginase I (55 ± 6.7, Vs. 1.3 ± 0.07, p = 0.006) and IL10 (0.056 ± 0.03, Vs 79 ± 1.9, p ≤ 0.001) compared with WT macrophages.

Conclusion: Ablation of OC-STAMP in the K/RxN arthritis model dramatically enhanced synovitis and bone loss in direct contrast to the findings observed with DC-STAMP knockout mice. OC-STAMP modulates synovial inflammation

by inducing the expression of immunosuppressive cytokines and factors expressed by M2 macrophages. In the DC-STAMP/OC-STAMP knockout the arthritis phenotype is dominated by the absence of OC-STAMP.

Joint-Draining Popliteal Lymphatic Vessels Exhibit Lymphatic Muscle Cell Dysfunction in TNF-Tg Mice with Inflammatory Arthritis

H. Mark Kenney[1], Yue Peng[1], Karen de Mesy Bentley[1], Chad Galloway[1], Homaira Rahimi[2], Lianping Xing[3], Christopher Ritchlin[4] and Edward Schwarz[2], [1]University of Rochester Medical Center, Rochester, NY, [2]University of Rochester, Rochester, NY, [3]University of Rochester Medical Center, Webster, NY, [4]Division of Allergy, Immunology, and Rheumatology, School of Medicine and Dentistry, University of Rochester Medical Center, Rochester, NY

SESSION INFORMATION
Session Date: Monday, November 8, 2021
Session Title: RA – Animal Models Poster (1014–1021)
Session Type: Poster Session C
Session Time: 8:30AM–10:30AM

Background/Purpose: Lymphatic dysfunction is a factor in the onset and progression of rheumatoid arthritis (RA) (1). Our prior studies demonstrated reduced lymphatic clearance in the hands of symptomatic RA patients vs. healthy controls (2). We reported similar findings in the tumor necrosis factor transgenic (TNF-Tg) mouse model of RA, which exhibits reduced contractility of joint-draining popliteal lymphatic vessels (PLVs) (3,4). Remarkably, anti-TNF therapy in flaring TNF-Tg mice recovers PLV contractions concomitant with amelioration of arthritis (4). Based on this result, we hypothesize that PLV dysfunction correlates with arthritis and is caused by: 1) chronic TNF-mediated lymphatic muscle cell (LMC) damage (4), and/or 2) paracrine factors known to inhibit lymphatic contractions from accumulated peri-lymphatic inflammatory cells during chronic inflammation (5). To specifically assess LMC tissue damage, herein we tested the hypotheses that: 1) alpha-smooth muscle actin ($\alpha SMA)^+$ PLV-LMC coverage is reduced in TNF-Tg mice with severe arthritis, and 2) anti-TNF therapy recovers LMC integrity by promoting turnover of bromodeoxyuridine $(BrdU)^+$ PLV-LMCs associated with return of lymphatic and joint homeostasis.

Methods: BrdU (0.1mg/g/day/i.p.) was administered to 8-month-old wild-type (WT, n=8 mice) and TNF-Tg (placebo or anti-TNF therapy, n=5 mice each; i.p. 10mg/kg/week) mice for 6-consecutive weeks, followed by whole mount immunofluorescent microscopy for αSMA^+ and $BrdU^+$ PLV-LMCs, as previously described (6). Talus bone volumes were measured by μCT longitudinally every 3-weeks as a biomarker of ankle arthritis. Preliminary scanning electron microscopy (SEM) was performed on WT PLVs (n=2 mice) to assess the feasibility of evaluating LMC coverage with ultrastructural analysis.

Results: αSMA^+ PLV-LMC coverage was reduced in TNF-Tg placebo mice vs. WT littermates (61.32±23.47% placebo vs 84.99±10.79% WT; $p< 0.0001$). However, anti-TNF therapy failed to recover αSMA^+ PLV-LMC coverage (68.86±20.41%) **(Figure 1)**, consistent with no change in LMC turnover (< 2% $BrdU^+/\alpha SMA^+$ cells for all groups) **(Figure 2)**. In contrast, anti-TNF therapy restored talus bone volume, and there was no relationship with αSMA^+ PLV-LMC coverage and bone volume (R^2=0.1106) **(Figure 1)**. SEM of PLVs confirmed the ability to further interrogate LMC coverage with ultrastructural imaging, and also unexpectedly identified a predominant peri-lymphatic mast cell population that may explain previous findings of increased peri-lymphatic cells in TNF-Tg mice **(Figure 3)**.

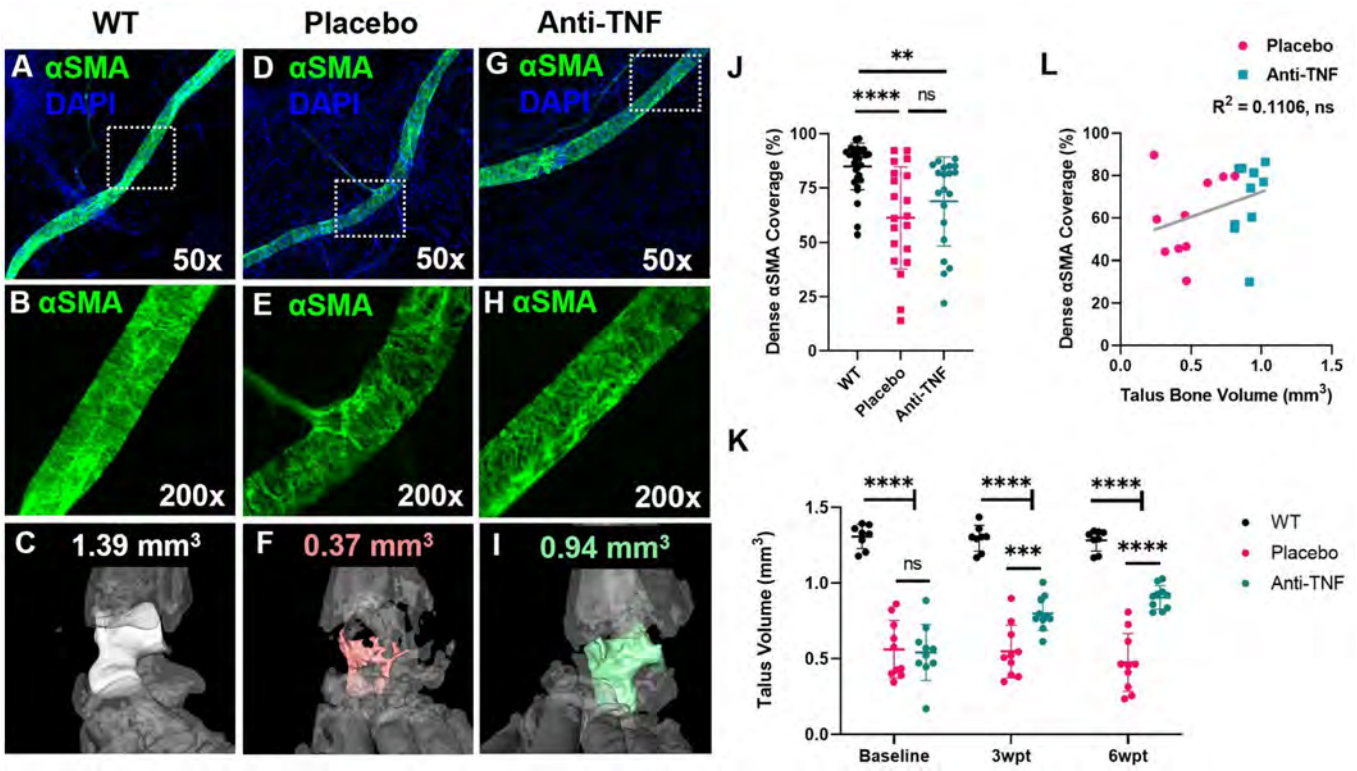

Figure 1. 6-weeks of anti-TNF therapy ameliorates bone erosions despite persistence of reduced PLV-LMC **α**SMA coverage in TNF-Tg mice. TNF-Tg mice (8-month-old) were treated with anti-TNF or placebo (10mg/kg/week, i.p.) for 6-consecutive weeks, while WT littermates received volume-matched vehicle PBS. Following treatment, PLVs were harvested and processed for whole mount immunofluorescent microscopy. Talus bone volumes were evaluated longitudinally at 3-week intervals by **μ**CT. Representative images of **α**SMA+ PLV-LMC coverage (green) and segmented taluses (colored bone within the remaining transparent grey ankle joint) (WT A-C; TNF-Tg D-F; anti-TNF G-I) with quantification of **α**SMA coverage (J, **α**SMA coverage as a percent of total PLV area), talus bone volumes (K), and the correlation between these outcomes (L) are shown for all groups. Note the similar reduction in intensity of **α**SMA signal for both placebo and anti-TNF treated TNF-Tg cohorts despite talus bone recovery with anti-TNF therapy. Each data point for **α**SMA coverage represents individual PLVs, while correlation with talus bone volumes was performed with the average between the two PLVs present in each limb. Statistics: All data is reported as mean ± standard deviation (SD). One-Way ANOVA (J; **** $p < 0.0001$, ** $p < 0.01$); Two-Way ANOVA (K; **** $p < 0.0001$, *** $p < 0.001$); and linear regression (L; no significance (ns) $p > 0.05$).

Conclusion: Chronic inflammation reduces αSMA⁺ PLV-LMC coverage. While 6-weeks of anti-TNF therapy reverses bone loss in TNF-Tg mice, this short-course does not enhance αSMA investiture or LMC turnover in damaged PLVs. Thus, future work will focus on the recent discovery of mast cell accumulation in the peri-lymphatic tissue of joint-draining PLVs during chronic inflammation, known to inhibit LMC contractility.

3. Scallan et al. *BioRxiv*. 2020.
4. Bouta et al. *A&R*. 69(6):1187-1193. 2017.
5. Li et al. *A&R*. 65(1):130-138. 2013.
6. Kenney et al. *Sci Rep*. 10(1):18088. 2020.

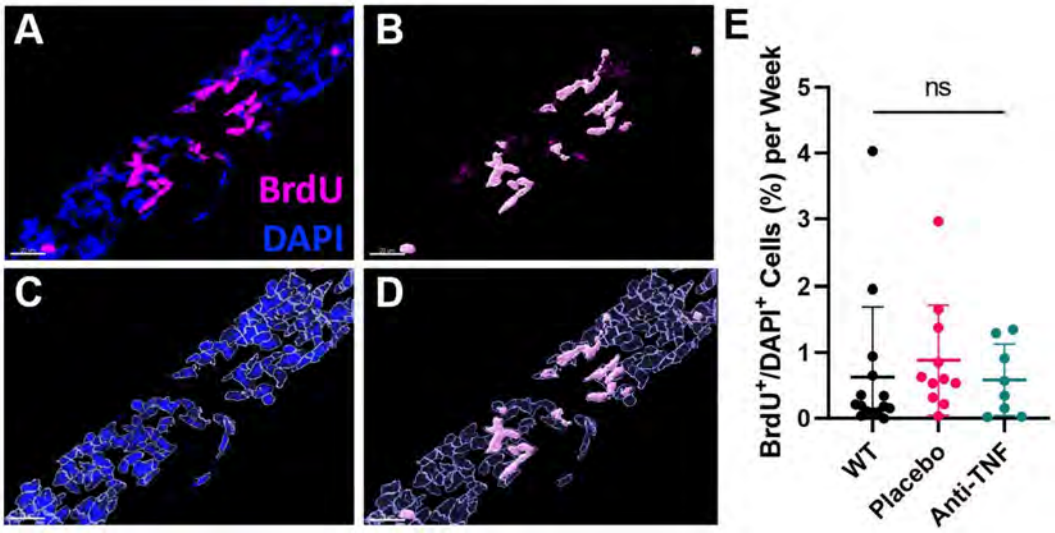

Figure 2. LMC turnover of joint-draining PLVs is unchanged during inflammation or therapy. Imaris software was used to analyze DAPI+/BrdU+ cell colocalization within an **α**SMA+ mask in 200x confocal stacks across the entire length of PLVs (~5mm) (A). Segmentation of individual BrdU+ (B) and DAPI+ nuclei (C) was performed to evaluate the ratio of BrdU+/DAPI+ cells (D). WT and TNF-Tg (placebo or anti-TNF as in Figure 1) were treated with BrdU for 6-consecutive weeks (0.1mg/g/day, i.p., as previously described (6)), and quantification of BrdU labeled cells in the PLVs indicates no difference in PLV cellular turnover between groups (E). Each data point represents a single PLV. Statistics: All data is reported as mean ± SD. One-Way ANOVA (E; ns $p > 0.05$ all comparisons).

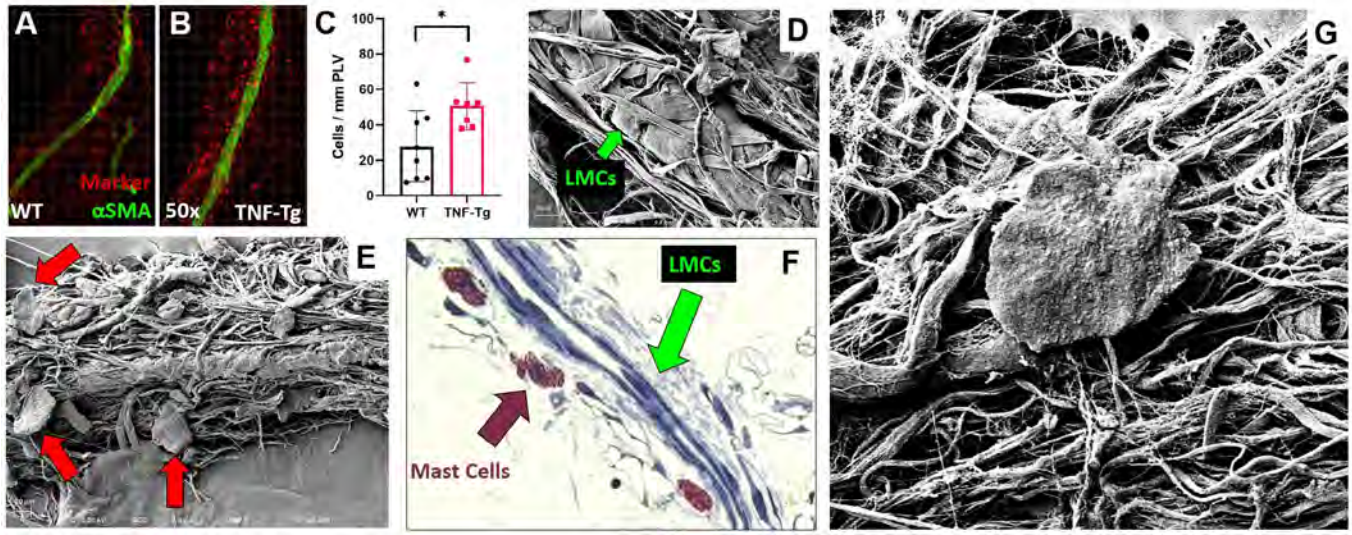

Figure 3. Increased mast cell numbers around PLVs in TNF-Tg mice with inflammatory arthritis. PLVs harvested from TNF-Tg mice exhibited increased cell accumulation in the peri-lymphatic region compared to those of WT controls by whole mount immunofluorescent microscopy (A,B), and the number of positive cells is quantified for each PLV (C). To elucidate the identity of these cells, scanning electron microscopy (SEM) was performed on WT PLVs, which identified LMCs (1,000x) (D) with mast cells embedded within the peri-lymphatic tissue (500x) (E), which was validated by histologic staining using toluidine blue (F). These findings suggest that during chronic inflammation, mast cells accumulate in the peri-lymphatic region surrounding joint-draining PLVs and inhibit lymphatic contractility associated with progression of arthritis in the afferent ankle. Future studies will target these identified mast cells (5,000x) (G) to further elucidate the mechanisms of lymphatic dysfunction in inflammatory arthritis. Statistics: All data is reported as mean ± SD. Unpaired t-test (C; * $p < 0.05$).

Cigarette Smoking Induces Post-translational Protein Modifications in Both *in Vitro* and *in Vivo* Models of Rheumatoid Arthritis-associated Interstitial Lung Disease

Alyssa Gregory[1], Corrine Kliment[1], Geoffrey Thiele[2], Michael Duryee[2], Ted Mikuls[2], Bryant England[2], Jill Poole[2] and **Dana Ascherman**[3], [1]University of Pittsburgh School of Medicine, Pittsburgh, PA, [2]University of Nebraska Medical Center, Omaha, NE, [3]University of Pittsburgh, Pittsburgh, PA

SESSION INFORMATION

Session Date: Monday, November 8, 2021

Session Title: RA – Animal Models Poster (1014–1021)

Session Type: Poster Session C

Session Time: 8:30AM–10:30AM

Background/Purpose: Cigarette smoking has been epidemiologically linked to the development of ACPA+ rheumatoid arthritis (RA) and, by extension, RA-associated interstitial lung disease (RA-ILD). Providing strong evidence for the contribution of gene-environment interactions to disease pathogenesis, the risk for ACPA+ RA is increased

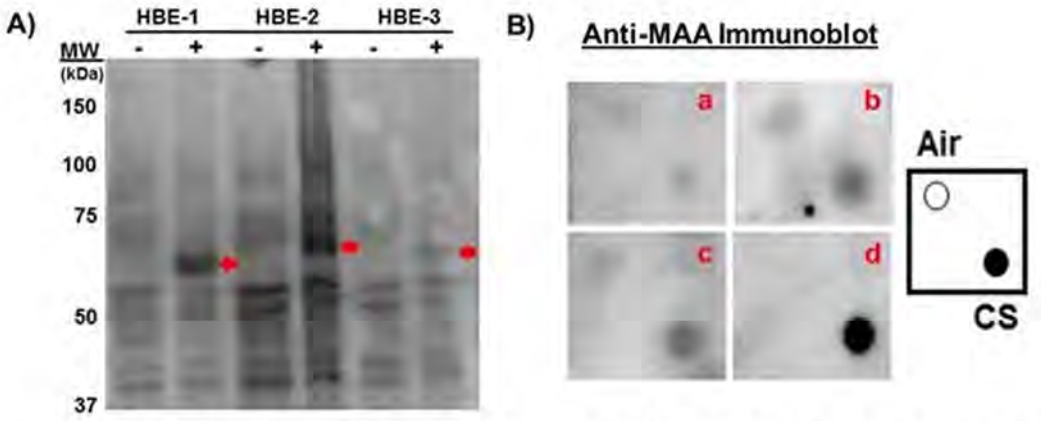

Figure 1. Cigarette smoke-induced PTMs in Human Bronchial Epithelial cells (HBEs) exposed to cigarette smoke. (**A**) Paired lanes depict equal amounts of HBE cell extract probed with anti-modified citrulline antibody (EMDMillipore) 18 hours after exposure to air (-) vs. cigarette smoke (+). Arrowheads designate specific proteins citrullinated in response to an 8 cigarette dose. (**B**) Panels a-c depict dot blots of paired extracts derived from HBE cells exposed to air (upper left) vs. cigarette smoke (4-8 cigarette dose, lower right). Specificity of the polyclonal anti-MAA antibody used to probe these blots is shown in panel d comparing recognition of unmodified (upper left) vs. MAA-modified human serum albumin (1 μg). Results are representative of at least two independent experiments for each extract.

more than 20 fold in cigarette smokers who also possess HLA-DRB1*0401 or other shared epitope alleles. This link between smoking, the shared epitope, and risk of RA/RA-ILD is thought to arise from immune responses targeting *in situ*, smoking-induced post-translational modifications (PTMs) such as citrullination. However, because most of the data linking smoking and PTMs has been "associative," we examined the ability of cigarette smoke to directly induce PTMs in both *in vitro* and *in vivo* model systems.

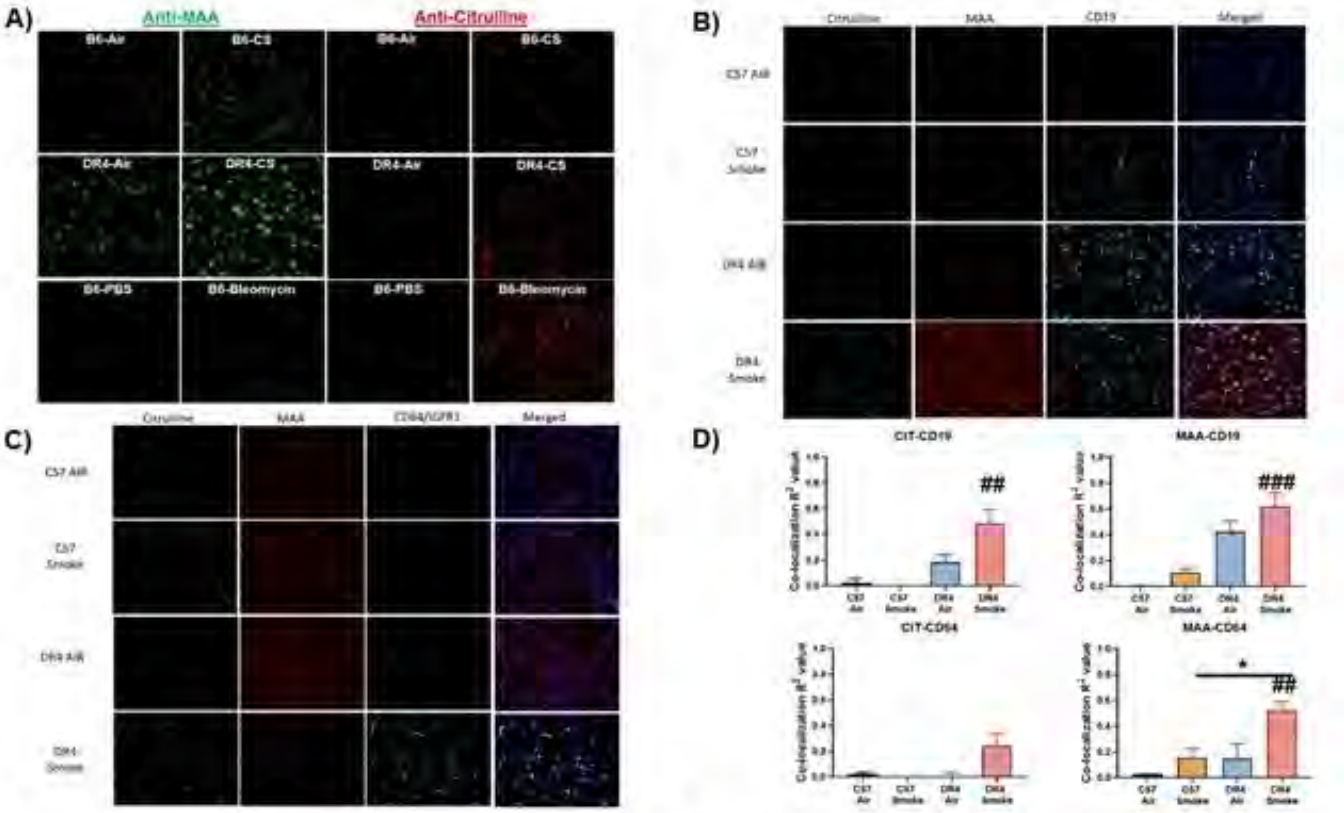

Figure 2. Cigarette smoke-induced PTMs in mouse lung tissue. A) Immunohistochemical staining of mouse lung tissue derived from C57BL/6 WT and HLA-DR4 transgenic mice following exposure to cigarette smoke demonstrates increased MAA-modified (columns 1-2) and citrullinated (columns 3-4) proteins relative to air-exposed lungs. Lung tissue from B6 WT mice following administration of intraperitoneal PBS versus bleomycin is shown for comparison. Panels B-C demonstrate co-localization of anti-MAA, anti-Cit, anti-CD19 (B), and anti-CD64 (C) staining. D) Corresponding grafts depict the degree of co-localization (represented by R^2 values) for these PTMs and CD19+ B cells or CD64+ macrophages. While significant differences between smoking groups and C57 WT-air are indicated by # symbols (#p<0.05, ##p<0.01, ###p<0.001), differences between DR4-smoking and C57 WT-smoking are denoted by asterisks and lines (*p<0.05).

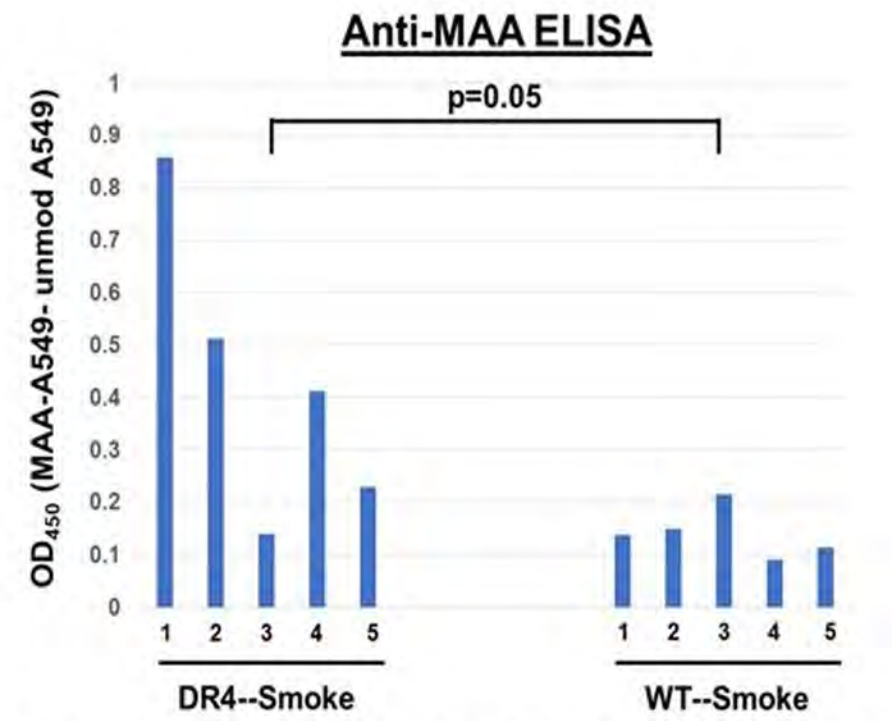

Figure 3. Cigarette smoke-induced anti-MAA antibody formation. Bars represent relative titers of antibodies targeting MAA-modified A549 lung epithelial cell extract in individual DR4 TG vs. B6 WT mice exposed to daily cigarette smoke for 2 months; negligible error bars are not shown.

Methods: Primary human bronchial epithelial cells (HBEs) were isolated, cultured at the air-liquid interface, and robotically exposed to defined doses of cigarette smoke vs. air prior to harvesting and preparation of cell extracts. Following SDS-PAGE, separated proteins were transferred to nitrocellulose membranes and probed with anti-modified citrulline antibody (EMD Millipore). Alternatively, extracts were transferred directly to membranes and probed with polyclonal antibody recognizing malondialdehyde-acetaldehyde (MAA)-modified proteins. Complementing these *in vitro* studies, HLA-DR4 transgenic (DR4) and C57BL/6 (WT) mice were exposed to daily cigarette smoke for 2 months and then harvested for immunofluorescence (IF) staining of lung tissue and ELISA-based analysis of PTM-targeted autoantibody production. Lung tissue from WT mice with bleomycin-induced pulmonary fibrosis was used as a control for PTM formation.

Results: Immunoblots of HBE cell extracts demonstrated smoke-induced citrullination as well as MAA-modification (**Figure 1**). Similarly, *in vivo* administration of cigarette smoke induced both citrullination and MAA modification of lung tissue, particularly in DR4 TG mice (**Figure 2A**). Additional IF staining revealed that these PTMs co-localized with CD19+ B cells and CD64+ macrophages (**Figure 2B-D**), both of which were increased in the lung tissue of cigarette smoke-exposed DR4 TG mice ($p < 0.01$ for CD19+ cells and < 0.0001 for CD64+ cells, DR4 TG-smoke vs. WT-smoke). ELISAs also demonstrated preferential formation of anti-MAA antibodies in the serum of DR4 TG mice exposed to cigarette smoke (**Figure 3**), but a limited profile of ACPA were not detected. Mice showed no evidence of overt arthritis in any of the treatment groups.

Conclusion: *For the first time*, these studies *directly* demonstrate that cigarette smoke can induce PTMs such as citrullination and MAA modification in lung tissue/cells. Corresponding development of PTM-targeted immune responses in DR4 TG mice support a paradigm in which cigarette smoke triggers a breach of immune tolerance in immunogenetically predisposed hosts as a foundation for the development of RA/RA-ILD.

Abstract Number: 1020

Enhancing Endothelial Cell Barrier Function via Sphingosine -1 Phosphate Receptor 1 (S1PR1) – a Novel Treatment for Experimental Arthritis

Nathalie Burg, Ryan Malpass, Carl Blobel and Jane Salmon, Hospital for Special Surgery, New York, NY

SESSION INFORMATION
Session Date: Monday, November 8, 2021
Session Title: RA – Animal Models Poster (1014–1021)
Session Type: Poster Session C
Session Time: 8:30AM–10:30AM

Background/Purpose: S1PR1 signaling plays critical roles in EC barrier function and vascular health, but until now, research on S1PR1 modulation in autoimmune rheumatic disease has been focused on lymphocyte trafficking. Importantly, endothelial cells have never been targeted for the treatment of autoimmune rheumatic disease. In prior work, we showed that S1PR1 modulators attenuated immune complex (IC) mediated vascular injury in skin and lung. In vitro, S1PR1 agonists rescued EC barrier function and decreased loss of VE-cadherin expression in human umbilical vein ECs (HUVEC) challenged with IC activated neutrophils. In this study we asked whether EC S1PR1 signaling limits experimental arthritis and whether it does so, at least in part, by limiting VE-cadherin shedding.

Methods: Mice with an EC specific S1PR1 KO or gain of function (GOF) were subjected to K/BxN serum induced arthritis (SIA) by injecting 100 µl of serum days 0 and 2. To determine how pharmacologic modulation of S1PR1 signaling affected SIA, WT animals were treated with S1PR1 agonist, CYM-5442 or antagonist NIBR-0213 30 mg/kg or vehicle controls. Clinical scores were obtained daily after day 2 in a blinded manner and mice were sacrificed on days 2-3 or on day 8. Synovial fluids from arthritic ankles obtained on days 2-3 were assessed by ELISA and western blot for soluble VE-cadherin. H&E-stained paraffin sections were scored by a pathologist in a blinded manner. HUVECs treated with S1PR1 inhibitor NIBR-0213 or vehicle control were assessed by western blot.

Results: S1PR1 ECKO mice had augmented arthritis at earlier time points and mice with EC S1PR1 GOF had delayed disease compared to controls (n=7-8 animals/group, $p< 0.05$; Fig 1). Similarly, the S1PR1 agonist CYM-5442 delayed the onset of arthritis (n= 7 mice/group $p< 0.05$; Fig 2), while an S1PR1 antagonist NIBR induced earlier and more severe disease (n=4 animals/group p= 0.05). Synovial fluid from S1PR1 ECKO mice showed increased VE-cadherin shedding (n= 6; $p \leq 0.01$) and Evans blue extravasation (n=6; p= 0.1) at early time points after SIA compared to controls, suggesting that increased vascular permeability via VE-cadherin shedding contributed to arthritic damage. S1PR1 ECKO mice also showed increased VE-cadherin shedding in their bronchoalveolar lavage fluid at baseline, suggesting that S1PR1 signaling inhibits VE-cadherin at homeostasis. To determine whether blockade of S1PR1 signaling induce VE-cadherin shedding in vitro, we treated HUVEC with NIBR-0213 (Fig 3). There was a marked increase

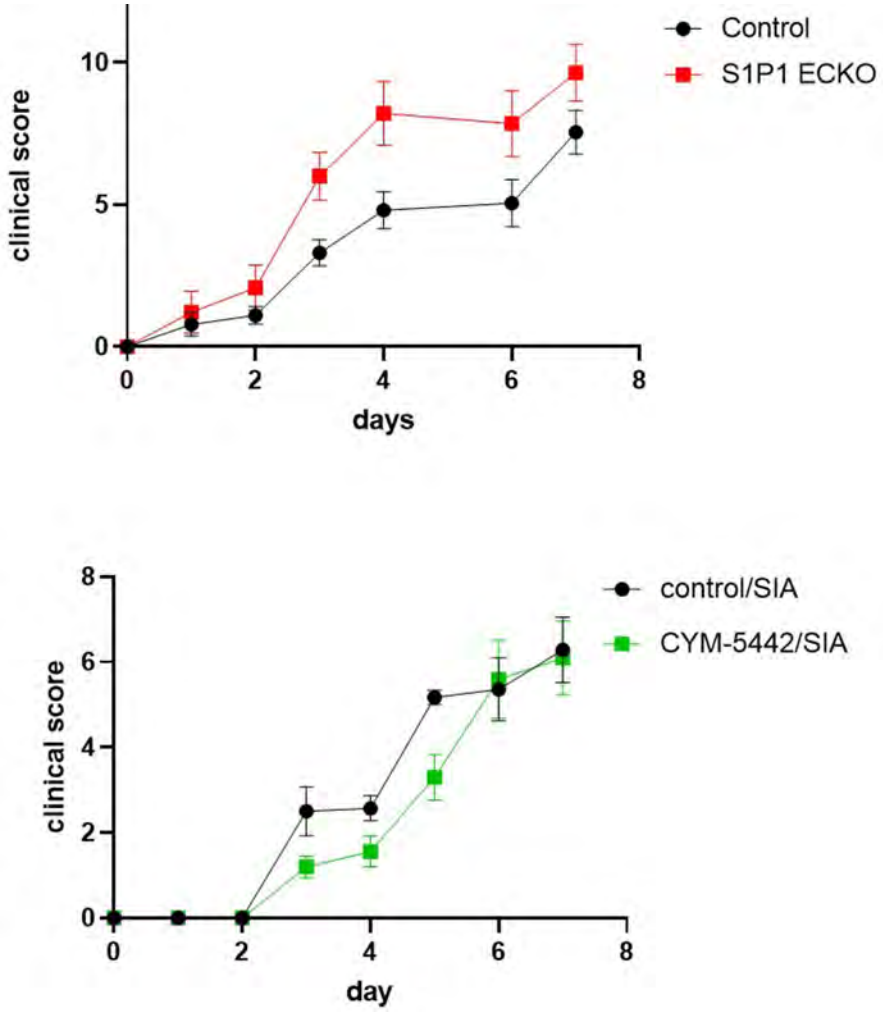

Figure 1. S1PR1 ECKO mice show increased inflammatory injury in response to SIA.
Figure 2. The S1PR1 agonist CYM-5442 delays SIA in WT mice.

in VE-cadherin shedding which was blocked by non-specific metalloprotease inhibitor marimastat (MM). Human RA single cell RNA seq data in ECs from the Accelerated Medicine Partnership (AMP) show that expression of EC S1PR1 and EC Sphingosine kinase 1, a key enzyme for the production of the endogenous ligand, S1P, are both statistically significantly lower than in OA controls.

Conclusion: Our data reveal that S1PR1 signaling restrains VE-cadherin shedding and maintains EC vascular barrier function and thereby attenuates arthritis. Augmenting EC S1PR1 signaling is a potential novel, non-immunosuppressive approach to treat inflammatory arthritis.

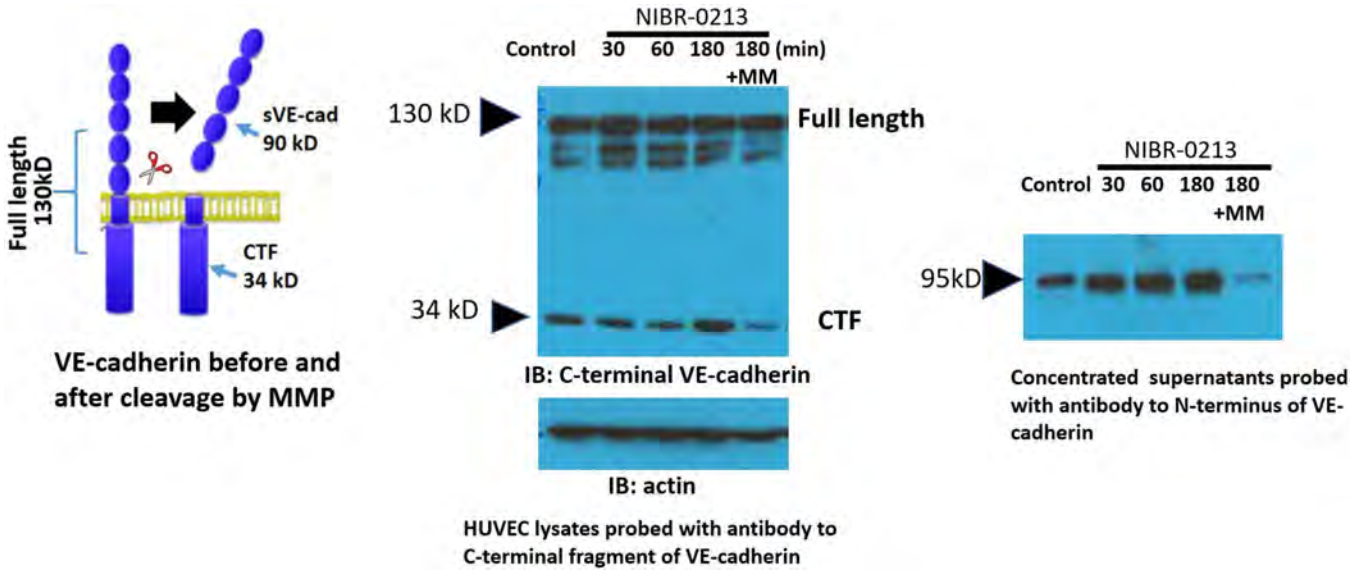

Figure 3. S1PR1 antagonist NIBR-0213 induces shedding of VE-cadherin in HUVEC that is blocked by the MMP inhibitor Marimastat (MM).

Session Type: Poster Session C
Session Time: 8:30AM–10:30AM

Background/Purpose: Environmental and occupational exposures have been epidemiologically linked to the development of rheumatoid arthritis-associated interstitial lung disease (RA-ILD). Previous investigation and modeling have also suggested that airborne inflammatory biohazards can trigger post-translational modifications (PTMs) capable of stimulating immune response against neo-epitopes. For PTMs such as citrullination, this immune response is strongly associated with HLA-DRB1*0401 and other shared epitope alleles. To further elucidate mechanisms linking environmental insults, immunogenetic background, and PTM-targeted immune responses to the development of RA-ILD, we utilized the established organic dust extract (ODE) airway inflammatory exposure model in HLA-DR4 transgenic (DR4 TG) versus C57BL/6 wild type (WT) mice.

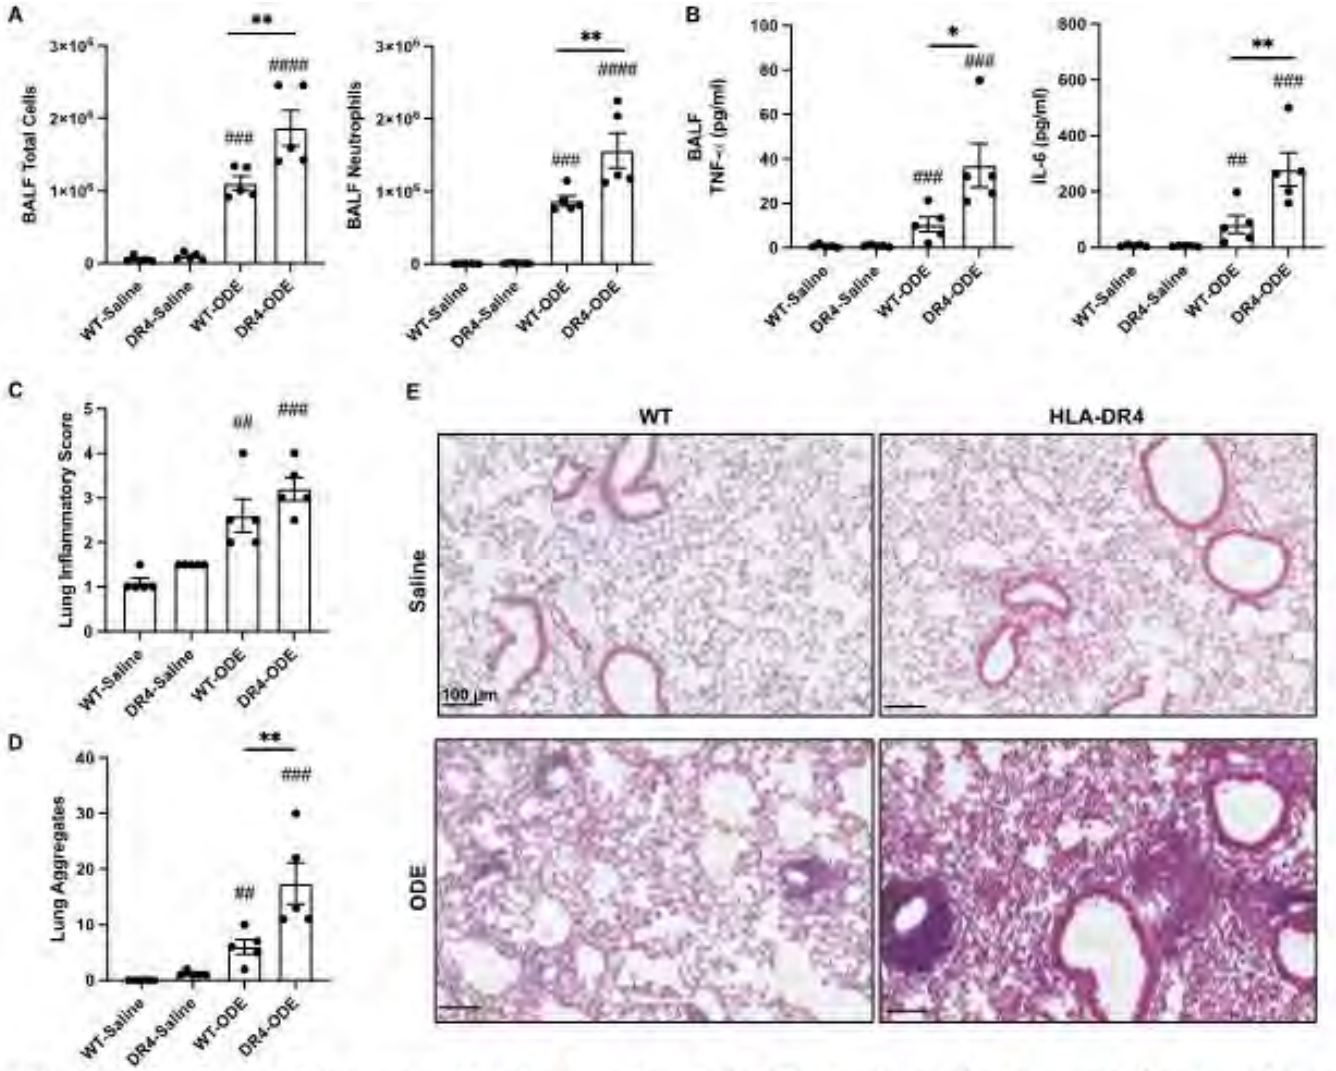

Figure 1. Repetitive organic dust extract (ODE)-induced airway inflammatory response is increased in HLA-DR4 transgenic mice. Scatter plots depict mean with standard error of (**A**) total cell and neutrophil influx and (**B**) levels of TNF-α and IL-6 in bronchoalveolar lavage fluid (BALF). (**C**) Semi-quantitative lung inflammatory score and (**D**) number of ectopic lung lymphoid aggregates are depicted; n=5 mice/group. (E) A representative H&E-stained lung section of one mouse per treatment group. While significant differences between ODE treatment groups and WT-saline are indicated by # symbols (##p<0.01, ###p<0.001, ####p<0.0001), differences between WT-ODE and DR4 TG-ODE are denoted by asterisks and lines (*p<0.05, **p<0.01).

Methods: WT and DR4 TG mice were exposed to intranasal inhalation of ODE (12.5%) versus sterile saline (n=5 mice/treatment group/strain) on a daily basis for 4 weeks. Following this 4 week treatment period, bronchoalveolar lavage fluid (BALF) was collected for cellular and cytokine analysis. Serum was also collected for ELISA-based assessment of autoantibodies targeting citrullinated and MAA (malondialdehyde-acetaldehyde)-modified substrate antigens. Lung tissue was subjected to immunofluorescence (IF) staining using antibodies recognizing peptidyl-

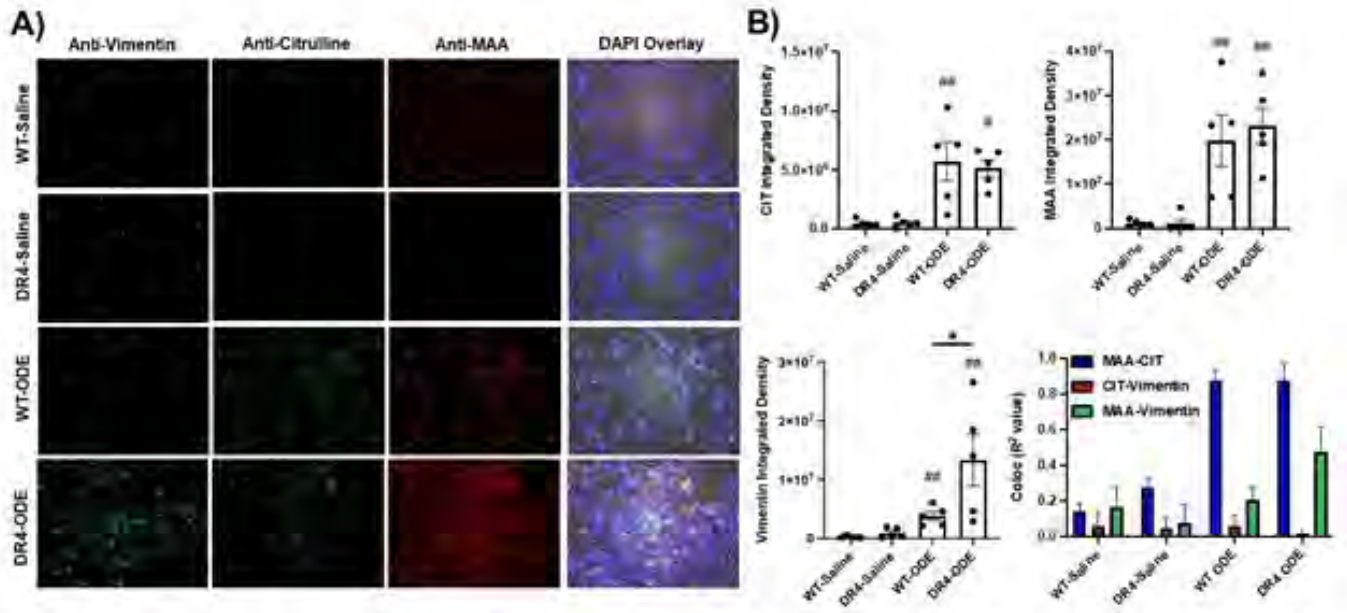

Figure 2. Post-translational protein modifications induced by repetitive ODE exposure. A) Representative images demonstrate immunofluorescent staining of lung tissue derived from WT and DR4 TG mice exposed to saline versus ODE using antibodies against vimentin, citrulline, and MAA. B) Corresponding grafts depict fluorescent signal intensity (image density) as well as the degree of co-localization (represented by R^2 values) for these proteins/PTMs. While significant differences between ODE treatment groups and WT saline are indicated by # symbols (#p<0.05, ##p<0.01), differences between WT-ODE and DR4 TG-ODE are denoted by asterisks and lines (*p<0.05).

citrulline (clone F95, EMDMillipore), MAA-modified proteins (rabbit polyclonal), and vimentin (Bioss). Quantitative scoring of fluorescence in combined regions of interest was compared using one-way ANOVA and Student's t-tests.

Results: ODE-induced airway cellular influx driven by neutrophils was significantly increased in DR4 TG versus WT mice, with corresponding increases in BALF levels of TNF-a and IL-6 ($p< 0.01$ for both cytokines, DR4 TG-ODE vs. WT-ODE) (**Figure 1A-B**). Lung histopathology demonstrated an increased number of ectopic lymphoid aggregates as well as overall lung inflammation in DR4 TG relative to WT mice after repetitive ODE exposure (**Figure 1C-E**). Corresponding IF staining of lung tissue showed that PTMs such as citrullination and MAA modification were strikingly enhanced in both DR4 TG-ODE and WT-ODE mice (**Figure 2**). Additional analysis revealed increased co-localization of vimentin and MAA staining that was most pronounced in DR4 TG mice (**Figure 2A-B**). Custom ELISAs demonstrated an increase in anti-MAA modified protein antibodies (including anti-MAA-vimentin antibodies) following ODE treatment that was amplified in DR4 TG mice ($p< 0.05$, **Figure 3**). Mice demonstrated no evidence of arthritis and had no detectable ACPA.

Conclusion: ODE-induced lung inflammation is more pronounced in DR4 TG relative to WT mice. This disease phenotype is accompanied by enhanced PTM formation and humoral immune responses targeting post-translationally-modified proteins. Overall, these results support a model in which environmental insults trigger PTM formation that,

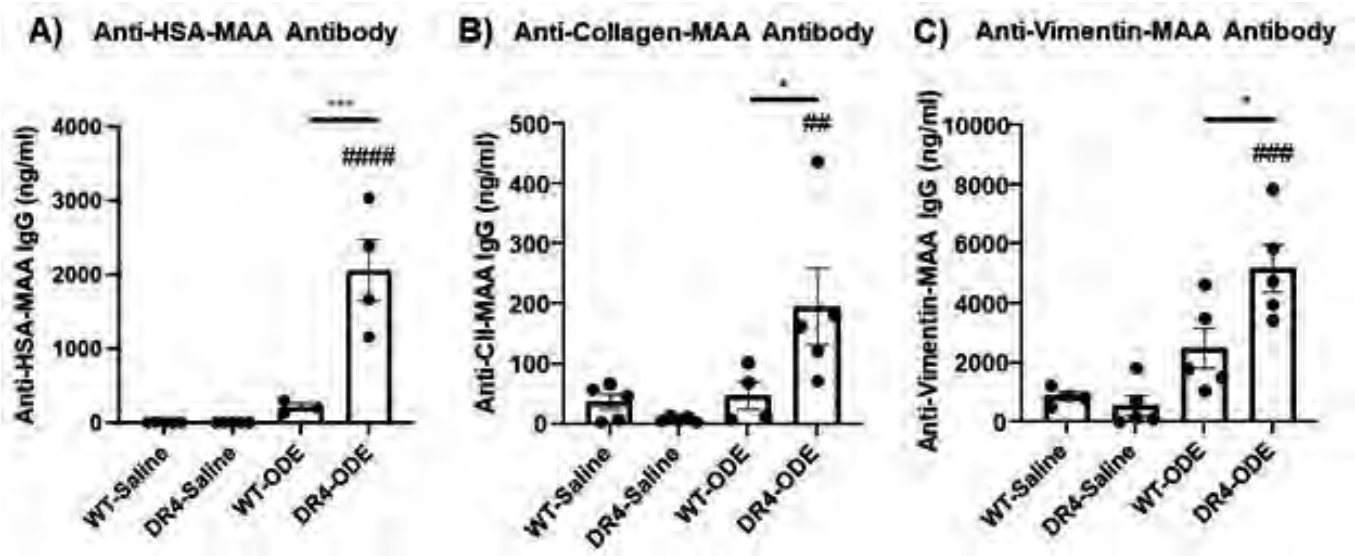

Figure 3. Anti-MAA modified protein antibody responses following repetitive ODE exposure. Panels A-C depict titers (ng/ml) of IgG anti-MAA modified protein antibodies detected in the serum of WT and DR4 mice repetitively exposed to inhaled ODE vs. Saline. While significant differences between ODE treatment groups and WT-saline are indicated by # symbols (##p<0.01, ###p<0.001, ####p<0.0001), differences between WT-ODE and DR4 TG-ODE are denoted by asterisks and lines (*p<0.05, ***p<0.001). HSA=human serum albumin.

in the selected immunogenetic background of HLA-DR4 TG mice, generates lung-centered, PTM-targeted immune responses and a tissue phenotype sharing immunopathological features with RA-ILD.

Abstract Number: 1022

Incidence of Antisynthetase Syndrome and Risk of Malignancy in a Population-based Cohort (1998-2019)

Caitrin Coffey[1], Li Wang[1], Stephanie Duong[1], Cassondra Hulshizer[1], Cynthia Crowson[2], Jay Ryu[1] and Floranne Ernste[1], [1]Mayo Clinic, Rochester, MN, [2]Mayo Clinic, Eyota, MN

SESSION INFORMATION

Session Date: Monday, November 8, 2021

Session Title: Epidemiology & Public Health Poster III: Other Rheumatic & Musculoskeletal Diseases (1022–1060)

Session Type: Poster Session C

Session Time: 8:30AM–10:30AM

Background/Purpose: The antisynthetase syndrome (ASSD) is a distinct subgroup of the idiopathic inflammatory myopathies characterized by myositis, interstitial lung disease, inflammatory arthritis, Raynaud's phenomenon and an aminoacyl tRNA synthetase autoantibody. Population-based epidemiology studies are lacking. Our aims were to determine the incidence and prevalence of ASSD in a well-defined geographic area over a 22-year period, and to assess malignancy risk among incident ASSD patients within 3 years of diagnosis.

Methods: A retrospective, population-based cohort of adult patients with incident ASSD in a geographically well-defined area from Jan 1, 1998 to Dec 31, 2019 was assembled. Fulfillment of Solomon et al. criteria (1) and clinical data were collected by manual chart review via a validated medical records linkage system. Malignancy was defined by physician diagnosis in the medical record. Patients were followed until death, migration from the area, or December 31, 2019. Incidence rate was age- and sex-adjusted to the 2010 U.S. white population. Point prevalence rate was obtained on Jan 1, 2015.

Results: 13 patients with ASSD who fulfilled Solomon et al. criteria were identified in the 22-year study period. 7 (54%) were female, 13 (100%) Caucasian, median age 44.9 years (IQR: 41.9, 58.3) at time of meeting criteria.

At time of meeting criteria, 11 (85%) of patients had interstitial lung disease diagnosed by a physician. Of these 8 patients (73%) had an NSIP pattern. 11 patients (85%) had myositis: 6/12 (50%) had a positive EMG, 1 (8%) with a positive muscle MRI. 5 patients had muscle biopsy performed, and 100% demonstrated inflammatory myopathy. 13 (100%) had positive anti-nuclear antibody; 12 (92%) had positive Jo-1 antibody. A myositis-specific panel was positive in 1 out of 4 patients showing PL-7 antibody.

The age- and sex-adjusted incidence of ASSD was 0.56 (95% CI: 0.25-0.87) per 100,000 population. The age-adjusted incidence was 0.59 (95% CI: 0.15-1.03) per 100,000 for females, and 0.52 (95% CI: 0.10-0.94) per 100,000 for males. Incidence rate was highest in the 50-59 age group, at 1.01 per 100,000 population. Age- and sex- adjusted prevalence of ASSD on Jan 1, 2015 was 9.2 per 100,000 (95% CI: 3.4-15.0).

2/13 (15%) were diagnosed with a malignancy (Hodgkin's lymphoma, leiomyosarcoma) within the follow-up interval; none within 3 years of ASSD diagnosis. Mean time to malignancy diagnosis from ASSD criteria was 52 (range: 40-64) months.

At a median 11.9 (IQR: 7.0, 13.4) years of follow-up, 12/13 (92%) of patients were alive.

Conclusion: Antisynthetase syndrome is rare, with incidence of 0.56 per 100,000 population and prevalence of 9 per 100,000. Incidence appears similar in our cohort between males and females, differing from previous estimates of higher incidence in females, and highest in persons age 50-59. None of the patients in this cohort developed malignancy within 3 years of ASSD diagnosis.

SESSION INFORMATION

Session Date: Monday, November 8, 2021

Session Title: Epidemiology & Public Health Poster III: Other Rheumatic & Musculoskeletal Diseases (1022–1060)

Session Type: Poster Session C

Session Time: 8:30AM–10:30AM

Background/Purpose: Ensuring adequate representation of racial/ethnic minorities in research necessitates understanding the prevalence of rheumatic and musculoskeletal diseases in these populations. We sought to evaluate the relative prevalence of 8 rheumatic diseases across racial and ethnic groups within the National Patient-Centered Clinical Research Network (PCORnet), an integrated partnership of diverse health systems across the US that incorporate electronic health record data to answer clinical questions affecting patients' lives.

Methods: We queried electronic health records from 50 health systems of PCORnet from January 1, 2013 to December 31, 2018 and identified adult patients having ≥ 2 encounters separated by 90 days with diagnosis codes for rheumatoid arthritis (RA), systemic lupus erythematosus (SLE), osteoporosis (OP), or several types of vasculitis (eosinophilic granulomatosis with polyangiitis (EGPA), granulomatosis with polyangiitis (GPA), microscopic polyangiitis (MPA), giant cell arteritis (GCA), and Takayasu's arteritis (TAK)). We restricted to patients with race/ethnicity data and excluded those reporting more than one race or other. To assess representativeness of PCORnet data we com-

Note: White used as reference group for all comparisons of race

pared racial/ethnic distributions in PCORnet to 2015 US census data. We then compared prevalence of rheumatic conditions across racial/ethnic groups to the PCORnet population and used univariable logistic regression to assess associations between race/ethnicity with different rheumatic diagnoses within PCORnet.

Results: A total of 28,059,546 adult PCORnet patients were included. Among the PCORnet patients with race/ethnicity data, 21% were non-white race and 13% Hispanic, similar to US Census data (Table 1). Compared to the wider PCORnet population, a higher percentage of adults with OP (89%) were white, while a higher percentage of patients with SLE (34%) were black/African-American (Table 1). African-American patients were more likely than white patients to have a diagnosis of SLE (OR 2.43, 95% CI 2.39-2.46, Table 2). American Indian/Alaska Native patients were more likely than white patients to have a diagnosis of RA (OR 1.15, 95% CI 1.09-1.22) and of SLE (OR 1.39, 95% CI 1.25-1.53), and Asian patients were more likely to have a diagnosis of Takayasu's Arteritis than were white patients (OR 1.43, 95% CI 1.00-2.03).

Conclusion: Certain rheumatic diseases disproportionately affect people of color in the US population, and PCORnet, a data resource potentially useful for studying the epidemiology and outcomes of rheumatic and musculoskeletal diseases, mirrored these expected differences. An improved understanding of the demographics and epidemiology of rheumatic disease among patients of different races and ethnicities presents an opportunity to enroll patients into research studies in a more inclusive and representative manner, and will provide an improved framework for studies of genetic and/or environmental differences, and of clinical outcomes.

Medical Care Seeking Is Frequent and Associated with Overuse of Low-Value Care for Low Back Pain in Portugal: Results from a Nationwide Population-Based Study

Luís Antunes Gomes[1], Eduardo Brazete Cruz[2], Ana Rita Henriques[1], Jaime Branco[3], Helena Canhão[4] and Ana Maria Rodrigues[3], [1]EpiDoC Unit, Comprehensive Health Research Centre (CHRC), Lisbon, Portugal, [2]Comprehensive Health Research Centre (CHRC), Setubal, Portugal, [3]EpiDoC Unit, CEDOC, Nova Medical School, Comprehensive Health Research Centre (CHRC), Lisbon, Portugal, [4]EpiDoC Unit, Comprehensive Health Research Centre (CHRC), Lisboa, Portugal

SESSION INFORMATION
Session Date: Monday, November 8, 2021
Session Title: Epidemiology & Public Health Poster III: Other Rheumatic & Musculoskeletal Diseases (1022–1060)
Session Type: Poster Session C
Session Time: 8:30AM–10:30AM

Background/Purpose: Low back pain (LBP) constitutes an important cause of disability and morbidity in general population. Appropriate care for LBP includes non-pharmacological interventions based on a biopsychosocial framework of patient education and advice. World Health Organization recommends that excessively medical solutions should be avoided. This study aimed to estimate prevalence of medical care seeking and characterize diagnostic workup and management procedures for LBP in the adult Portuguese population. We also aim to compare the medical framework for LBP diagnostic and management between primary and secondary care.

Methods: The present study was conducted under the scope of EpiReumaPt (2011-2013), a population-based study including a representative sample of non-institutionalized Portuguese adults (n=10,661 habitants). A sample of individuals who self-reported history of medical care seeking for LBP within the previous 12 months (n=2,618) were considered. Patients' self-reported data collected through a structured questionnaire was explored to characterize medical care seeking, and diagnostic and management procedures for LBP. Prevalence was computed as weighted proportions, and inference statistics used to compare medical procedures between different levels of care.

Results: A prevalence of medical care seeking for LBP of 38.0% (95%IC, 35.9 to 40.1%) was found. Primary care in isolation (45.3%), multiple care (primary plus secondary care) (28.8%) and secondary care in isolation (25.9%) were the sought levels of care for LBP. Emergency departments (25.9%) and orthopedics (19.4%) were the secondary medical specialties most used. Several distinct structural-based diagnosis and specific/ serious underlying diseases were diagnosed by physicians, mainly supported by laboratory and imaging tests performed to 91.1% of individuals. Disc herniation (20.4%) and osteoarthritis (19.7%) were the most frequent diagnosis, while x-rays (63.7%), clinical history/ observation (44.4%), blood tests (38.2%), urinalysis (34.4%), and CT scans (32.4%) were the most frequent diagnostic procedures. Only 8.5% of individuals were evaluated based on a clinical history/ observation procedure in isolation. Lastly, 75.1% of individuals self-reported being treated for LBP by their physician, 80.4% with oral medication/ pills and 15.3% with injectables. The mean duration of pharmacological treatment was 104.24 (266.80) days. The use of structural-based diagnosis, laboratory and imaging tests, and pharmacological treatment were generally aggravated when secondary care, in isolation or complementarily with primary care, was considered compared with primary care in isolation ($p< 0.05$).

Conclusion: Our results show that medical seeking for LBP is frequent and is associated to overdiagnosis through a diagnostic label despite there being no reliable way of determining the pathoanatomical source of pain for the great majority of patients. Medical seeking is also associated with overuse of pharmacological treatment. Funding and delivery actions should be prioritized to assure appropriate care of LBP and reduce this low-value care overuse within local health systems.

Survival of Patients with Idiopathic Inflammatory Myopathy in Slovenia

Alojzija Hocevar[1], Andrej Virscek[2], Monika Krosel[1], Matija Tomšič[3] and Ziga Rotar[3], [1]UKC Ljubjana, Ljubjana, Slovenia, [2]Statistical Office of the Republic of Slovenia, Ljubljana, Slovenia, [3]Department of Rheumatology, University Medical Centre Ljubljana, Ljubljana, Slovenia

SESSION INFORMATION
Session Date: Monday, November 8, 2021
Session Title: Epidemiology & Public Health Poster III: Other Rheumatic & Musculoskeletal Diseases (1022–1060)
Session Type: Poster Session C
Session Time: 8:30AM–10:30AM

Background/Purpose: Idiopathic inflammatory myopathies (IIM) are a group of rare systemic diseases associated with significant morbidity and mortality. The aim of our study was to study for the first time the survival of IIM patients in Slovenia.

Methods: We included IIM patients diagnosed between January 2005 and December 2020, and followed at our secondary/tertiary rheumatology center. To evaluate mortality the censor date of April, 14 2021 was set. Kaplan–Meier analysis was used to analyze mortality. A standardized mortality ratio (SMR) was calculated using data of age and sex matched Slovenian population as the reference. Logistic regression was used to study prognostic risk factors in IIM.

Results: During the 16-year observation period, we identified 174 new IIM patients (121 (69.5%) females, median (IQR) age 63.5 (52.1-73.1) years, range 22 to 94 years). We diagnosed polymyositis, dermatomyositis, antisynthetase syndrome, other overlap IIM, necrotizing myopathy and inclusion body myositis in 15 (8.6%), 66 (37.9%), 47 (27.0%), 23 (13.2%), 21 (12.1%), and 2 (1.1%) patients, respectively.

Patients were followed for a median (IQR) 56.6 (20.8 – 107.0) months. During follow up 57/174 (32.8%) IIM patients deceased. The causes of death were cancer (18/57 (31.6%)), infections (13/57 (22.8%)), cardiovascular disease (14/57 (24.6%)), and active IIM (4/57 (5.3%)). In 9 patients the cause of death was unknown. One- and five-year survival rate was 86.7% and 71.6%, respectively. We found no significant sex related differences in the net survival estimates during the first five years of follow up (p=0.13). Figure 1 shows the survival curve of IIM patients and general population as a comparator according to Kaplan–Meier analysis. The mortality of patients with IIM patients was significantly higher compared to matched general population. In the table 1 the standardized mortality ratios in IIM patients are presented. In the first year following IIM diagnosis the SMT was almost 8-times higher compared to the

Table 1. The standardized mortality ratio of IIM patients

Time of FU	Observed deaths	Expected deaths	SMR (95% CI)	P value
1 year	23	2.9	7.95 (5.04-11.93)	<0.01
2 years	7	2.6	2.74 (1.1-5.64)	0.033
3 years	2	2.4	0.84 (0.09-3.02)	0.852
4 years	6	2.4	2.51 (0.92-5.46)	0.071
5 years	6	1.9	3.19 (1.17-6.95)	0.026

Legend: FU follow up; SMR Standardized mortality ratio; CI confidence interval

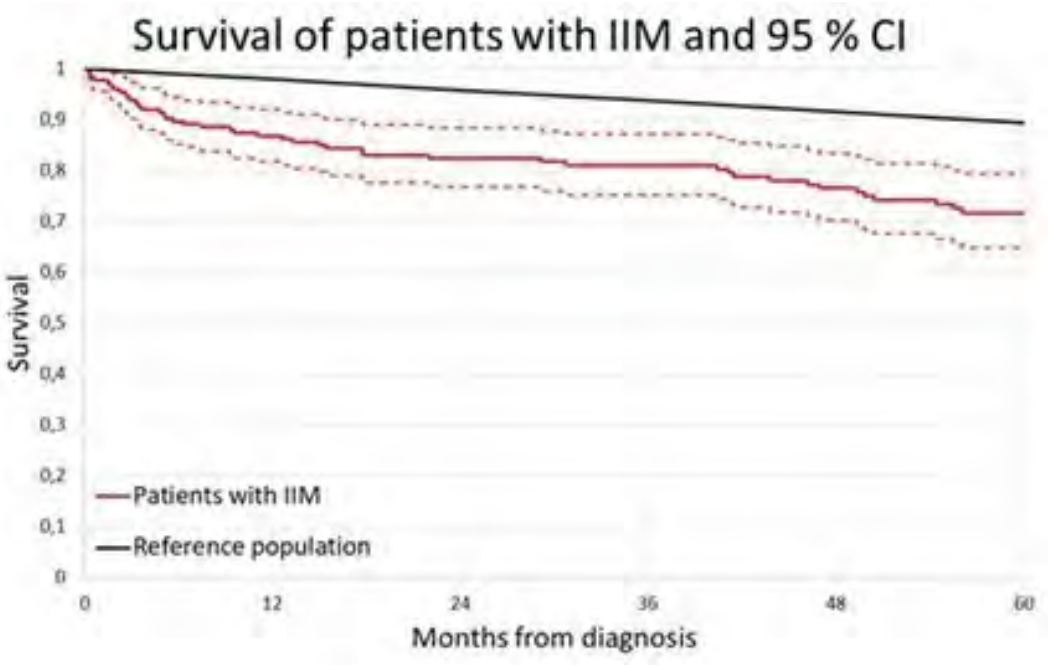

Figure 1. Survival curve according to Kaplan–Meier analysis in IIM.

general population (SMR 7.95 (95%CI 5.04-11.93). The risk remained higher also during the following four years. As prognostic risk factors emerged increasing age (OR 1.08 (95%CI 1.05-1.12); p< 0.001), antisynthetase syndrome (OR 2.61 (95%CI 1.09-6.28); p< 0.032), Raynaud phenomenon (OR 0.21 (95%CI 0.07-0.66); p< 0.007), and cancer (OR 6.21 (95%CI 2.29-16.85); p< 0.001).

Conclusion: The survival of patients with IIM patients was substantially worse compared to matched general population. Cancer was the leading cause of death in our IIM cohort.

Factors Impacting Likelihood of Discontinuing Immunosuppression in Adult Dermatomyositis: A Single-Center Study

Sung Kyung Cho[1], Lorinda Chung[2] and David Fiorentino[3], [1]University of Texas Southwestern, Dallas, TX, [2]Stanford University, Palo Alto, CA, [3]Stanford University, Redwood City, CA

SESSION INFORMATION

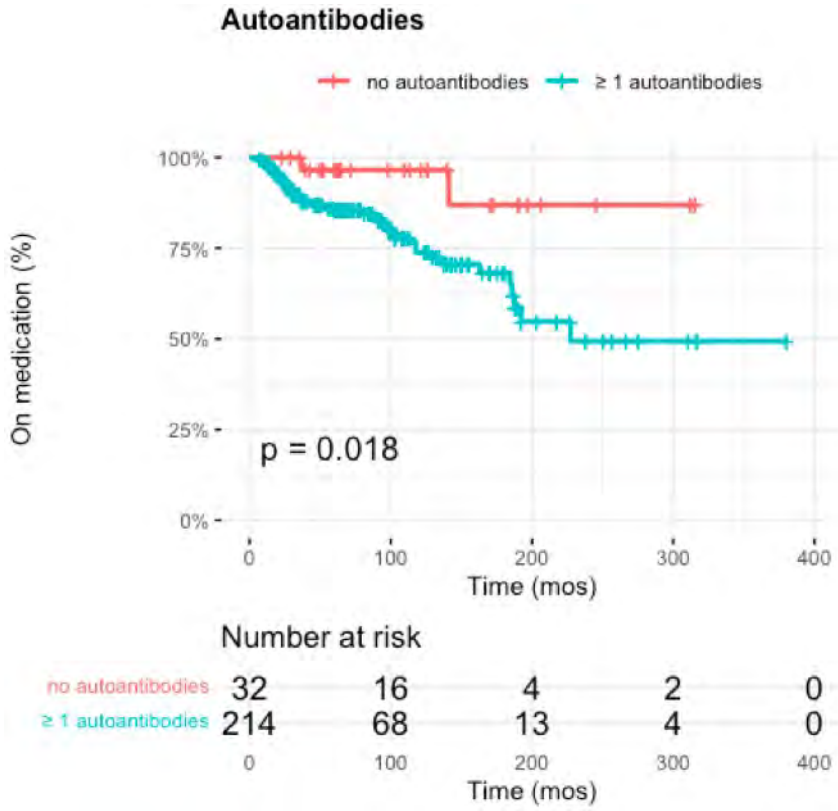
Session Date: Monday, November 8, 2021

Session Title: Epidemiology & Public Health Poster III: Other Rheumatic & Musculoskeletal Diseases (1022–1060)

Session Type: Poster Session C

Session Time: 8:30AM–10:30AM

Background/Purpose: Dermatomyositis (DM) is a chronic idiopathic inflammatory myopathy with variable clinical course, but little is known regarding factors associated with remission of disease. We conducted a retrospective cohort study of 246 adult patients at Stanford to determine the rate of discontinuation of systemic immunosuppressive therapy as a proxy for clinical remission.



Factor associated with medication cessation in patients with dermatomyositis. Patients with at least one myositis specific autoantibody had a significantly shorter time to medication cessation.

Methods: Inclusion criteria included patients diagnosed with DM after 18 years of age and seen for at least one clinic visit at the Stanford multidisciplinary rheumatology/dermatology clinic between January 1, 2013 to December 31, 2020. Included patients were exposed to at least one immunosuppressive medication for at least 3 months. Patients not returning to clinic were contacted via phone or email to determine status of medication use. Survival analysis was performed using Kaplan-Meier curves and log rank analyses. Variables significantly associated with medication cessation or with p-value < 0.15 on univariable analysis were used to perform multivariate analysis using Cox proportional-hazards models.

Results: 47 patients (19%) discontinued medications over a median follow-up time from disease onset of approximately 7 years. The median time to medication cessation from disease onset was approximately 3 years. Log rank analysis indicated that patients with at least one DM-specific autoantibody ceased all medication use significantly earlier than those without (p= 0.018) (Figure 1). In particular, those with anti-MDA5 autoantibodies had significantly shorter time to medication cessation compared with the negative autoantibody group (p=0.03). Multivariable modeling was performed including demographic features, specific organ involvement, and autoantibody status as covariates. Clinically amyopathic patients were 2.6-fold (CI 1.29-5.27) more likely to discontinue medications than those with muscle disease. In addition, those with anti-MDA5, anti-NXP2, and anti-SAE1 antibodies had increased likelihood of medication cessation with hazard ratios of 11.4 (CI 2.42-53.7), 12.0 (CI 2.31-62.7), and 10.2 (CI 2.07-50.3) respectively when compared to patients with no DM-specific autoantibodies.

Conclusion: We found that almost 20% of our DM cohort were able to discontinue immunosuppressive medications over the course of several years. Those with clinically amyopathic disease, anti-MDA5, anti-NXP2, and anti-SAE1 antibodies were associated with a higher likelihood of medication cessation.

SESSION INFORMATION

Session Date: Monday, November 8, 2021

Session Title: Epidemiology & Public Health Poster III: Other Rheumatic & Musculoskeletal Diseases (1022–1060)

Session Type: Poster Session C

Session Time: 8:30AM–10:30AM

Background/Purpose: Background: Patients with rheumatologic immune-mediated diseases (R-IMID) with Latent tuberculosis infection (LTBI) requiring biologic therapy (BT) are at an increased risk of active tuberculosis (TB). Screening of LTBI with tuberculin skin test (TST) and/or Interferon (IFN)-γ release assays (IGRA) is recommended before starting of BT.

Purpose: In patients with R-IMID previously to BT our aim was to assess a) prevalence of LTBI, b) importance of using a booster test in negative TST and c) to compare TST with the IGRA test.

Methods: Cross-sectional single University Hospital study including all patients diagnosed with R-IMID who underwent a TST and/or IGRA in the last five years (2016-2020).

Table. Results of TST (+booster) and IGRA test

		IGRA				
		Positive	Negative	Indeterminate	Unavailable	Total
TST (+Booster)	Positive	89	142	45	48	324
	Negative	30	500	130	133	793
	Total	119	642	175	181	1117

* Cohen's kappa coefficient: 0.381

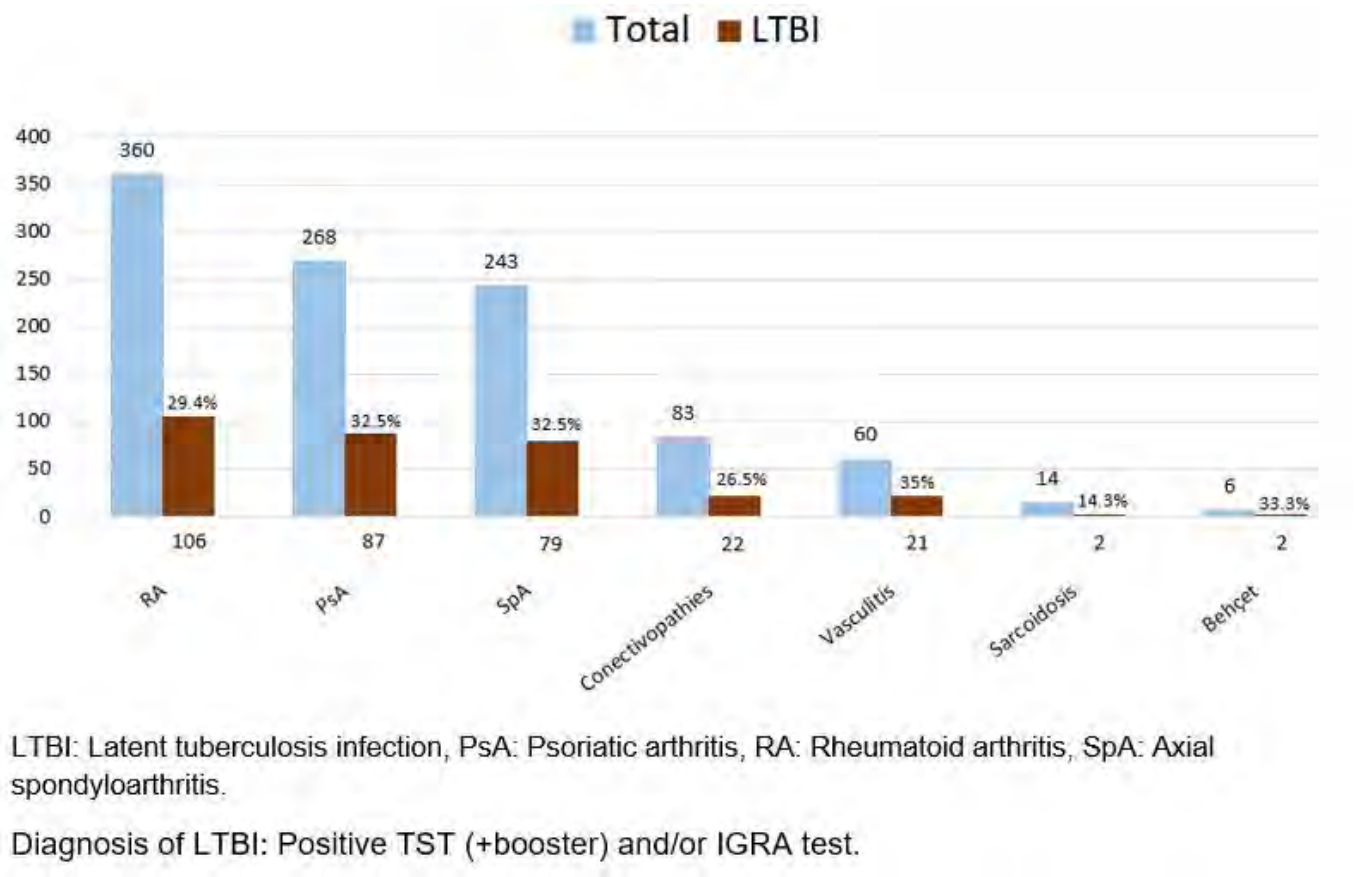

FIGURE. Prevalence of LTBI in different underlying R-IMID.

TST was performed by a subcutaneous injection of 0.1 ml of purified protein derivative (PPD) with a reading after 72 hours. TST was considered positive with an induration of more than 5 mm of diameter. If the first TST was negative, a new TST (Booster) was performed between 1 and 2 weeks after the first TST.

LTBI was diagnosed by a positive IGRA and/or TST and absence of active TB (Chest radiograph). Diagnosis with IGRA vs TST was compared (Cohen's kappa coefficient).

Results: We included 1117 patients (741 women/376 men), mean age 53±15 years with LTBI. Chest radiograph was normal in most of the patients, only 39 patients (3.5%) presented signs of previous TB infection, mostly granuloma. Total LTBI prevalence was 31.7% (354/1117). LTBI prevalence in different underlying R-IMID ranges from 35% in vasculitis up to 26.5% in conectivopathies (FIGURE).

Booster was positive in 66 patients (7.7%) out of 859 patients with a negative simple TST. Results of TST (+booster) and IGRA tests are shown in TABLE. TST (+booster) was positive in 187 patients (22.9%) out of 817 with a negative or indeterminate IGRA test. IGRA test was positive in 30 (3.8%) out of 793 patients with a negative TST (+booster). Cohen's Kappa coefficient between TST (+booster) and IGRA, was 0.381.

Conclusion: LTBI is frequent between patients with R-IMID. Booster after negative simple TST may be useful, since it can detect false negatives for LTBI. IGRA and TST(+booster) show a low grade of agreement. Therefore, performing both tests before BT may be recommendable.

Knee Osteoarthritis and Mortality: The Osteoarthritic Initiative

Jane Cauley[1], Michael Nevitt[2], Kai Sun[3], Jason Maeda[3], C. Kent Kwoh[4], Leena Sharma[5], Rebecca Jackson[6], Susan Rubin[3] and Marc Hochberg[7], [1]University of Pittsburgh Graduate School of Public Health, Pittsbugh, PA, [2]University of California San Francisco, Orinda, CA, [3]University of California San Francisco, San Francisco, CA, [4]University of Arizona College of Medicine, Tuscon, AZ, [5]Northwestern University, Chicago, IL, [6]Ohio State University, Columbus, OH, [7]University of Maryland School of Medicine, Baltimore, MD

SESSION INFORMATION

Session Date: Monday, November 8, 2021

Session Title: Epidemiology & Public Health Poster III: Other Rheumatic & Musculoskeletal Diseases (1022–1060)

Session Type: Poster Session C

Session Time: 8:30AM–10:30AM

Background/Purpose: A recent international individual participant data (IPD) meta-analysis (n=10,723) reported a 35-37% increased mortality risk among individuals with painful knees (no radiographic OA) and symptomatic radiographic knee OA (Leyland K et al 2021). We examined whether these results could be replicated in the Osteoarthritis (OAI) cohort (not included in the international IPD) using complete, long-term data on participant deaths from the OAI.

Methods: The OAI is a prospective cohort study investigating risk factors and biomarkers associated with the development and progression of knee OA. A total 4,796 adults age 45-79 years with or at high risk of developing knee OA were recruited at five US clinical sites. A National Death Index search was initiated to identify all deaths from 2004-2018. We used OAI baseline data on radiographic knee OA (K-L grade >=2), knee symptoms (pain on most days of a month in past year) and symptomatic OA (radiographic OA and symptoms in the same knee) to classify participants into four groups: symptomatic OA in one or both knees; no symptomatic OA but has radiographic OA in one or both knees; no radiographic OA but has symptoms in one or both knees; no radiographic OA or symptoms in either knee (referent group). Cox proportional hazards models were used to calculate hazard ratios (HR) for mortality, and their 95% confidence Intervals (CI), adjusted for covariates, in each group compared to the referent group. We excluded those who had a knee replacement at baseline (n=63) and missing data on covariates.

Table: Risk of Mortality by Baseline Radiographic Knee Osteoarthritis (OA) and Symptom Status

	Number of Deaths/N (%)	Model 1[a] Hazard ratio (95% CI)	Model 2[b] Hazard ratio (95% CI)
No Radiographic OA; no symptoms	117/1201 (9.7)	1.0 referent	1.0 referent
No Radiographic OA; with symptoms	64/784 (8.2)	1.13 (0.83, 1.53)	1.08 (0.79, 1.47)
Radiographic OA[c]; no symptoms	166/1243 (13.3)	0.92 (0.72, 1.16)	0.91 (0.72, 1.17)
Symptomatic radiographic OA	168/1348 (12.5)	1.28 (1.00, 1.62)	1.26 (0.99, 1.61)

[a] Model 1= age, sex, race, site

[b] Model 2=Model 1 + alcohol consumption, body mass index, cardiovascular disease, diabetes and smoking.

[c] K-L score $\geq$ 2 in either knee

Results: The mean age of the cohort at baseline was 61 years; 80% were white; 58% were women. Over an average follow-up of 9.2 years, 515 (11.3%) died. Of those with no radiographic OA and no symptoms, 9.7% died; no radiographic OA with symptoms, 8.2% died; radiographic OA and no symptoms, 13.4% died and radiographic OA and symptoms, 12.5% died, p< 0.0005, See Table. In multivariable adjusted models there was a marginally significant 28% increase in mortality (p=0.065) in participants with symptomatic knee OA at baseline. The association with mortality was stronger in those with symptomatic knee OA with a K-L grade 3 or 4 HR= 1.32 (1.00, 1.73) compared with those symptomatic OA with K-L score of 2, HR=1.17(0.85, 1.63). We also examined the association between frequent knee symptoms in either knee, adjusting for K-L grade; those with frequent knee pain had an increased risk of death, HR= 1.19 (0.99, 1.43).

Conclusion: These results with complete long-term follow-up data from the OAI cohort are consistent with those from the individual level meta-analysis showing increased mortality among those with symptomatic knee OA.

SESSION INFORMATION
Session Date: Monday, November 8, 2021
Session Title: Epidemiology & Public Health Poster III: Other Rheumatic & Musculoskeletal Diseases (1022–1060)
Session Type: Poster Session C
Session Time: 8:30AM–10:30AM

Background/Purpose: The Manhattan Lupus Surveillance Program (MLSP) is a multi-racial/ethnic population-based registry with the primary goal to determine the prevalence and incidence of Systemic Lupus Erythematosus (SLE). In this study, we compare the three most commonly used classification criteria for SLE (1997 revised ACR, Systemic Lupus International Collaborating Clinics (SLICC) and the recent EULAR/ACR classification criteria) to identify cases that fulfilled only one of the classification criteria and explore each criteria set's unique cases. In addition, we used the EULAR/ACR criteria to determine the incidence and prevalence of SLE in Manhattan.

Methods: MLSP cases were identified from Manhattan-based hospitals and rheumatologists, and state population databases. For this analysis, SLE cases were defined as fulfilling 1) the 1997 ACR classification criteria, 2) the SLICC criteria or 3) EULAR/ACR classification criteria. We quantified the number of cases that uniquely associated with each classification criteria and the number that fulfilled all three classifications. Prevalence (2007) and incidence

Table 1. Explanations for patients meeting ACR criteria only

PATIENTS MEETING ACR CRITERIA ONLY (N=50)	Number	Example
REASONS FOR NOT MEETING EULAR/ACR CRITERIA:		
No ANA for entry:	N=35	
ANA unknown/not documented:	N=15	
Sufficient points to meet EULAR/ACR if ANA known/positive:	N=15 [points range 10-23, mean 15.1]	*e.g. malar, arthritis, leukopenia, proteinuria*
ANA documented negative:	N=20	
Sufficient points to meet EULAR/ACR if ANA was positive:	N=18 [points range 10-21, mean 14.38]	*e.g. malar, oral ulcer, arthritis, pericarditis*
Insufficient points to meet EULAR/ACR criteria if ANA was positive:	N=2 [points range 6-8, mean 7]	
Unique criteria:	N=2	*e.g. serositis, [lymphopenia], anti-cardiolipin, [non-RBC casts]*
Overlapping criteria within same domain:	N=1	*e.g. malar, photosensitivity, discoid, oral ulcer*
ANA <1:80, not sufficient for entry:	N=6	
Sufficient points to meet EULAR/ACR if ANA titer was sufficient:	N=4 [points range 10-12, mean 10.75]	*e.g. ANA, malar, photosensitivity, dsDNA*
Insufficient points to meet EULAR/ACR if ANA titer was sufficient:	N=2 [points range 5-6, mean 5.5]	*e.g. ANA, arthritis, [anti-cardiolipin], [lymphopenia]*
ANA positive/sufficient titer for entry, not meeting points threshold ≥ 10:	N=9 [points range 0-9, mean 6.1]	
Unique criteria	N=7	*e.g. ANA, [lymphopenia], malar, [photosensitivity]*
REASONS NOT MEETING SLICC CRITERIA:		
No immunologic criteria:	N=35	
ANA unknown/not documented:	N=15	
< 4 criteria met – unique criteria:	N=2	*e.g. photosensitivity, arthritis, pleuritis, [lymphopenia]*
< 4 criteria met – combined criteria:	N=1	*e.g.* ***malar, photosensitivity****, arthritis, lymphopenia*
ANA negative:	N=20	
< 4 criteria met:	N=2	*e.g. malar, oral ulcer, arthritis, [lymphopenia]*
Immunologic criteria met:	N=15	
ANA <1:80, < 4 criteria met:	N=6	
Lymphopenia not met by SLICC:	N=5	
APL not met by SLICC:	N=2	
Malar/photosensitivity combined in SLICC:	N=1	
ANA ≥ 1:80, <4 criteria met:	N=9	
Lymphopenia not met by SLICC:	N=3	
APL not met by SLICC:	N=3	
Renal not met by SLICC:	N=2	
Malar/photosensitivity combined in SLICC:	N=1	

Bolded font: overlapping criteria falling within the same domain
[Brackets]: criteria not part of, or does not meet, the specified classification system

rates (2007-2009) using the EULAR/ACR classification criteria and associated 95% confidence intervals (CI) were calculated using denominators obtained from the US Census data (revised 2000-2009 intercensal population files) for Manhattan.

Results: Overall 1,568 cases fulfilled at least one of the three classification criteria. Of those, 1008 (64.3%) cases fulfilled all three classification criteria, 166 (10.5%) fulfilled only the SLICC criteria, 50 (3.2%) fulfilled only the 1997 ACR criteria and 36 (2.3%) fulfilled the EULAR/ACR criteria with the remaining cases fulfilling a combination of two classification criteria. Cases that only met one of the classification criteria, and the reasons why they did not meet the other two classification criteria with example cases, are detailed in Tables 1-3. Based on the EULAR/ACR classification criteria, the age-adjusted overall prevalence and incidence rates of SLE in Manhattan were 59.8 (n=1,029, 95%CI:56.1- 63.6) and 4.9 (n=245, 95%CI 4.3-5.5) per 100,000 population. Prevalence was 9 times higher and incidence was 6.9 times higher among females compared to males. The age-adjusted prevalence per 100,000 was highest among non-Hispanic Black females (198.9), followed by Hispanic females (133.1), non-Hispanic Asian/Pacific Islander females (97.7) and non-Hispanic White females (59.8). Age-adjusted incidence rates per 100,000 were highest in non-Hispanic Black females (15.8), followed by Hispanic females (7.5), non-Hispanic Asian/Pacific Islander females (7.3) and non-Hispanic White females (6.3). Prevalence and incidence rates for males followed a similar pattern.

Conclusion: Applying the three commonly used classification systems to a multi-racial/ethnic population-based registry allowed for identifying unique cases of SLE who only fulfilled one classification system. The EULAR/ACR classification criteria revealed similar prevalence and incidence estimates and gender and racial/ethnic disparities to the previously published results from the MLSP using the 1997 revised ACR and SLICC classification criteria.

Table 2. Explanations for patients meeting SLICC criteria only

PATIENTS MEETING SLICC CRITERIA ONLY (N=166)	Number	Example
REASONS FOR NOT MEETING EULAR/ACR CRITERIA:		
No ANA for entry:	N=53	
ANA unknown/not documented:	N=28	
Sufficient points to meet EULAR/ACR if ANA known/positive:	N=24 [points range 12-29, mean 18.75]	*e.g. dsDNA, low complement, malar, Class IV LN, leukopenia*
Insufficient points to meet EULAR/ACR criteria if ANA known/positive:	N=3 [points range 7-8, mean 7.3]	*e.g. APL, arthritis, [neuropathy], [lymphopenia]*
Sufficient points to meet EULAR/ACR, but immunologic criteria only:	N=1	*e.g. dsDNA, Smith, APL, low C4, [urinary casts]*
ANA documented negative:	N=25	
Sufficient points to meet EULAR/ACR if ANA was positive:	N=21 [points range 10-21, mean 13.95]	*e.g. dsDNA, alopecia,* ***leukopenia, thrombocytopenia***
Insufficient points to meet EULAR/ACR if ANA was positive:	N=4 [points range 7-9, mean 8]	
Overlapping criteria:	N=3	*e.g. low complement, oral ulcer, [neuropathy],* ***leukopenia, thrombocytopenia***
Unique Criteria:	N=2	*e.g. low complement, [photosensitivity], leukopenia [lymphopenia], thrombocytopenia, [DAT]*
ANA <1:80, not sufficient for entry:	N=17	
Sufficient points to meet EULAR/ACR if ANA titer was sufficient:	N=4 [points range 10-12, mean 10.75]	
Overlapping criteria within same domain:	N=2	*e.g. ANA (1:40), Sm, alopecia,* ***leukopenia****, [lymphopenia],* ***thrombocytopenia***
Unique criteria:	N=1	*e.g. ANA (1:40), arthritis, [peripheral neuropathy], leukopenia, [lymphopenia]*
Insufficient points to meet EULAR/ACR criteria if ANA titer was sufficient:	N=13 [points range 0-9, mean 6.7]	
Overlapping criteria within same domain:	N=7	*e.g. ANA (1:40),* ***malar, discoid, alopecia***
Unique criteria:	N=6	*e.g. ANA (1:40), [photosensitivity], [neuropathy], [lymphopenia]*
ANA positive, sufficient titer, but not meeting point threshold of ≥ 10:	N=95 [points range 2-9, mean 6.9]	
Overlapping criteria:	N=30	*e.g. ANA, discoid,* ***leukopenia, thrombocytopenia***
Unique criteria:	N=35	*e.g. ANA, low C3, [panniculitis], alopecia, leukopenia, [lymphopenia]*
ANA positive, sufficient points, but immunologic criteria only:	N=1	*e.g. ANA, DNA, low complement, [RBC casts]*
REASONS NOT MEETING ACR CRITERIA:		
3 criteria only:	N=102	
Low complement - not part of ACR:	N=40	*e.g. [low complement], arthritis, pericarditis, [lymphopenia]*
Alopecia - not part of ACR:	N=37	*e.g. ANA, malar, [alopecia], leukopenia, [lymphopenia]*
Unique NPSLE criteria not part of ACR:	N=24	*e.g. ANA, arthritis, [peripheral neuropathy], leukopenia*
Unique cutaneous criteria not part of ACR:	N=0	
Lymphopenia not met by ACR:	N=10	*e.g. ANA, APL, arthritis, [lymphopenia – NON-ACR]*
≤ 2 criteria only:	N=64	
Low complement - not part of ACR:	N=34	*e.g. ANA, [low C3],* ***lymphopenia, thrombocytopenia***
Alopecia - not part of ACR:	N=30	*e.g. dsDNA, [alopecia],* ***leukopenia, thrombocytopenia***
Unique NPSLE criteria not part of ACR:	N=22	*e.g. [low complement], photosensitivity, arthritis, [peripheral neuropathy]*
Unique cutaneous criteria not part of ACR:	N=3	*e.g. ANA, [bullous lesions], oral ulcer, [alopecia], [lymphopenia]*
Lymphopenia not met by ACR:	N=7	*e.g. ANA, malar, [neuropathy], [lymphopenia]*

Critical Illness in Modern Rheumatology: Analysis of Admissions to Australian and New Zealand ICUs

Robyn Lambert[1], Shailesh Bihari[2], Mihir Wechalekar[3], David Pilcher[4] and Eliza Pontifex[2], [1]Flinders University, South Australia, Adelaide, Australia, [2]Flinders Medical Centre, Southern Adelaide Local Health Network, Adelaide, Australia, [3]Flinders Medical Centre, Southern Adelaide Local Health Network, Bedford Park, Australia, [4]Alfred Health, Melbourne, Australia

SESSION INFORMATION

Session Date: Monday, November 8, 2021

Session Title: Epidemiology & Public Health Poster III: Other Rheumatic & Musculoskeletal Diseases (1022–1060)

Session Type: Poster Session C

Session Time: 8:30AM–10:30AM

Background/Purpose: Patients with systemic rheumatic diseases (SRD) have an increased risk of admission to the Intensive Care Unit (ICU) relative to the general population, secondary to SRD chronicity, expanding options for concomitant immunosuppression, co-morbidities, deconditioning, and multi-organ disease. Despite this, there is paucity of data within this population regarding outcomes of ICU admission over time, and whether subgroups of patients with SRD exhibit differential outcomes. This study aims to further the understanding of SRD in the context of critical

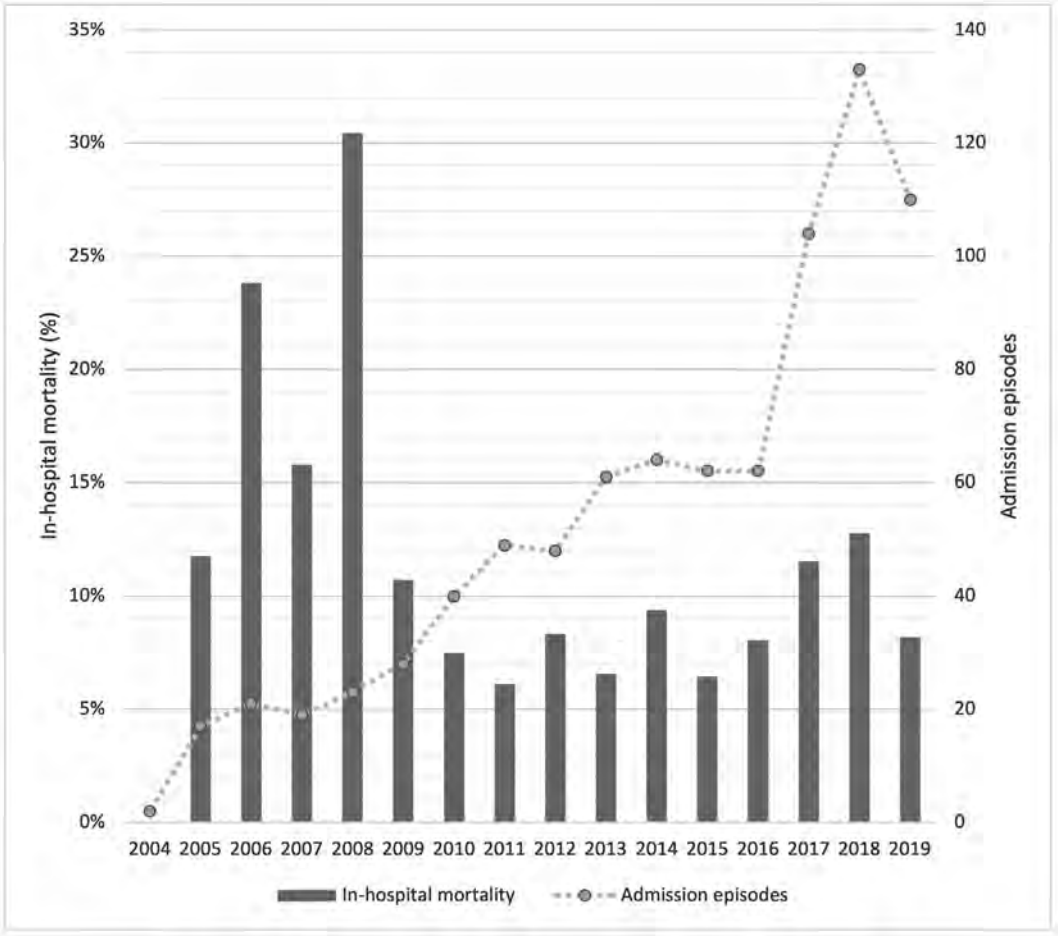

Figure 1. Admission episodes and in-hospital mortality over time.

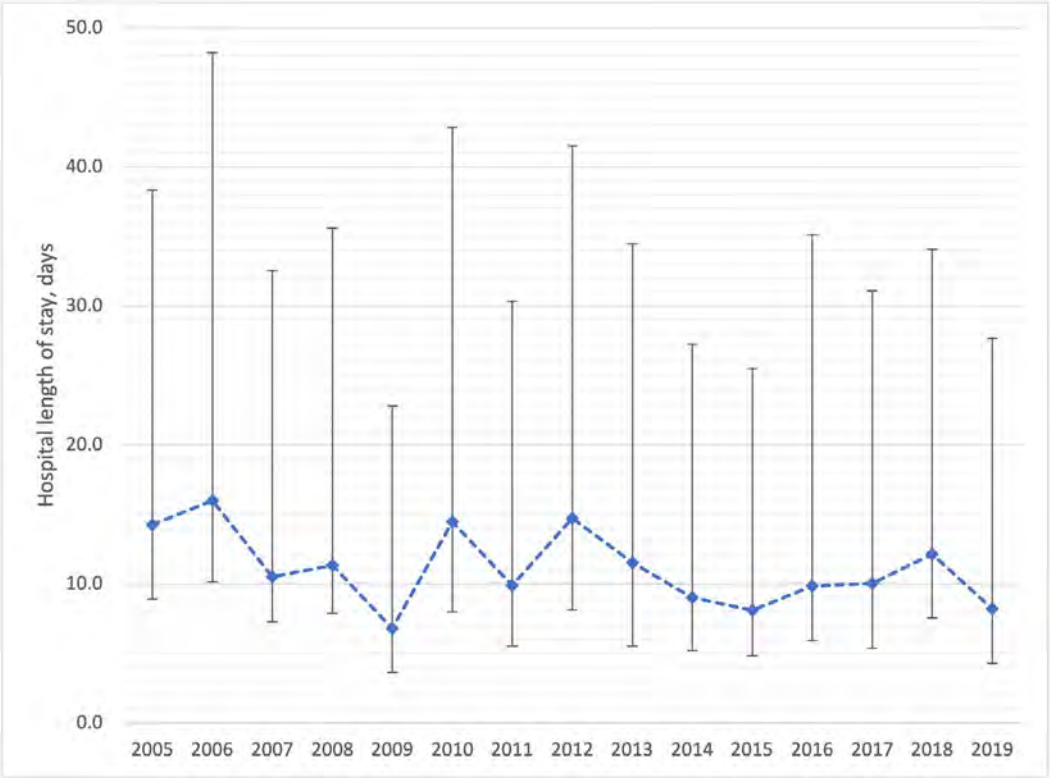

Figure 2. Median (IQR) length of hospital stay by year.

illness by examining a population-based registry, the Australia New Zealand Intensive Care Society Adult Patient Database (ANZICS-APD).

Methods: The ANZICS-APD mandates disease-category based reporting across all ICUs in ANZ, including mortality and length of stay both within ICU and hospital. Retrospective data (2004-2019) from ICU admissions across hospitals in Australia and New Zealand was analysed. Eligible records were those where the primary reason for admission was SRD. These were identified through the use of database specific codes and excluded sepsis, rhabdomyolysis and viral myositis. We sought to analyse the trends over time, mortality and length of stay across SRDs. Severity of critical illness on ICU admission was measured by the Australian and New Zealand Risk of Death (ANZROD) score.

Results: 1,478 admission episodes (52% females) were included, from 155 Australian sites (95%) and 16 New Zealand sites (5%). Reasons for admission were musculoskeletal/skin (42%), musculoskeletal medical (38%), vasculitis (7%), connective tissue disease (5%), SLE (3%), scleroderma (2%) and rheumatoid arthritis (RA; < 2%). Predicted mortalities for each diagnosis (derived from the ANZROD scoring system) were: connective tissue disease 17%, vasculitis 17%, SLE 15%, musculoskeletal-medical 10%, scleroderma 10%, musculoskeletal-skin disease 9.3% and RA 5.2%. Considering temporal changes, annual ICU admissions with SRD increased in a linear fashion from 2004 to 2019, consistent with growth in the size of the database over time. Change in hospital mortality over time was not statistically significant and remained stable or decreased over this period (Figure 1). Median length of hospital stay did not demonstrate a temporal trend (Figure 2). In-hospital mortality by SRD category was connective tissue disease (17%), vasculitis (10%), SLE (9%), musculoskeletal-medical (9%), scleroderma (20%), musculoskeletal/skin (7%) and RA (4%).

Conclusion: Analysis of a large dataset from Australian and New Zealand ICUs reveals that: 1) There has been a large increase in the number of patients with SRD admitted to ICUs each year since 2004, a change reflected in the ANZICS-APD more broadly 2) In-hospital mortality in this cohort remained stable or decreased over time; 3) No tem-

poral trend with respect to length of ICU stay is apparent; 4) Patients with connective tissue disease, vasculitis and SLE are sicker on presentation relative to other SRD diagnoses; and 5) In-hospital mortality is greatest in patients with scleroderma or connective tissue disease.

Clinical and Humanistic Burden of Dermatomyositis and Polymyositis in the United States: A Systematic Literature Review

Swamy Venuturupalli[1], Namita Goyal[2], Nathalie Fortune[3], Richard Leff[4], Konrad Pisarczyk[5], Izabela Aleksanderek[6], Kiruthi Palaniswamy[7] and Noreen Henig[8], [1]Cedars-Sinai Medical Center, Beverly Hills, CA, [2]University of California Irvine, Irvine, CA, [3]Attune Health, Beverly Hills, CA, [4]Richard L Leff MD LLC, Chadds Ford, PA, [5]Maple Health Group, Krakow, Poland, [6]Maple Health Group, Toronto, ON, Canada, [7]Kezar Life Sciences, Los Angeles, CA, [8]Kezar Life Sciences, Inc, Foster City, CA

SESSION INFORMATION
Session Date: Monday, November 8, 2021
Session Title: Epidemiology & Public Health Poster III: Other Rheumatic & Musculoskeletal Diseases (1022–1060)
Session Type: Poster Session C
Session Time: 8:30AM–10:30AM

Background/Purpose: Dermatomyositis (DM) and polymyositis (PM) are rare heterogenous systemic autoimmune disorders of the skin, muscles, and other organs that may have a devastating impact on patients and care partners life. The objective of this study was to systematically review and synthesize evidence on clinical and humanistic burden and unmet needs in the management of DM/PM.

Methods: A systematic literature review (SLR) was conducted in MEDLINE and Embase databases to identify studies in children and adults with DM/PM, published in the English language between 2011–2021. Only primary studies of any design enrolling 10 or more patients were included, irrespective of country or region. The current abstract summarizes preliminary SLR results on the clinical and humanistic burden of DM/PM in the United States (US).

Results: A total of 3624 records were retrieved from medical databases, 393 records underwent full-text review, and 210 were included in data abstraction. An additional 8 papers were included from searching reference lists of identified studies. There were 32 US studies that reported on the natural history of the disease and/or comorbidities (n=27) and quality of life (QoL) of patients or caregivers (n=8). There were 24 retrospective and 8 prospective studies, with a sample size ranging from 17 to more than 160,000 patients. Patients with DM/PM had an increased risk of comorbidities, including various types of infections (19–42%), malignancies (6–17%) and cardiovascular-related disorders (1–20%), compared to unmatched or matched non-DM/PM controls. Concerns about malignancy risk contributed to increased depression and anxiety. Remission occurred in only 33–38% of adult DM patients. About 26–50% of patients with juvenile DM/PM (JDM/JPM) often had a chronic course of disease characterized by persistently active disease, and a 36% rate of active disease 10-years post-diagnosis. Diseases flares were reported by 73% of patients within the past year and their increased frequency trended with a longer mean duration of illness ($p< 0.001$). Disease flares significantly contributed to poorer QoL due to increased disability and pain ($p< 0.001$). Adult patients with DM, compared to other dermatologic disorders such as cutaneous T-cell lymphoma and non-melanoma skin cancer/actinic keratoses, had a significantly worse Skindex-29 emotional subscore, worse SF-36 role-emotional, physical, and social functioning subscore, and greater fatigue compared to healthy controls ($p< 0.05$). DM had a detrimental

impact on QoL which correlated with skin disease activity. JDM affected the entire family with difficulties in family functioning, communication problems, sibling distress, and increased number of conflicts. Parents of patients with JDM reported higher levels of worry, anger, depression, and reduced physical functioning, than parents of children with chronic diseases.

Conclusion: DM/PM are associated with multiple comorbidities affecting multiple QoL domains, especially in the physical and social/emotional realm. Despite various therapies available, a notable proportion of patients seem not to achieve sustainable remission indicating a high residual unmet need.

Causes of Death Among Populations with Systemic Lupus Erythematosus by Race and Ethnicity

Tiffany Taylor[1], Christine Anastasiou[1], Stephanie Rush[1], Laura Trupin[2], Maria Dall'Era[3], Patricia Katz[1], Kamil Barbour[4], Jinoos Yazdany[1] and Milena Gianfrancesco[1], [1]University of California San Francisco, San Francisco, CA, [2]UC San Francisco, San Francisco, CA, [3]University of California San Francisco, Corte Madera, CA, [4]Centers for Disease Control, Atlanta, GA

SESSION INFORMATION
Session Date: Monday, November 8, 2021
Session Title: Epidemiology & Public Health Poster III: Other Rheumatic & Musculoskeletal Diseases (1022–1060)
Session Type: Poster Session C
Session Time: 8:30AM–10:30AM

Background/Purpose: Systemic lupus erythematosus (SLE) is a multi-system autoimmune disease with manifestations that vary widely in severity. Data indicate that minority populations are at higher risk of developing SLE and have more severe outcomes, including mortality. However, whether specific causes of death vary by race and ethnicity has largely been unexplored, particularly for Asians and Hispanics.

Methods: The California Lupus Surveillance Project identified potential SLE cases using community rheumatology and nephrology clinics, community hospitals, and integrated healthcare systems among individuals who were residents of San Francisco County, CA during January 1, 2007 – December 31, 2009. SLE cases were defined using American College of Rheumatology Classification Criteria (≥4 of the 11 revised criteria as defined in 1982 and updated in 1997) or two alternative definitions: SLE diagnosed by the patient's treating rheumatologist plus 3 ACR criteria; or lupus-related kidney disease (World Health Organization class II-VI lupus nephritis upon biopsy or documented record of SLE diagnosis and dialysis or renal transplantation). Cases were matched to the 2007-2017 National Death Index (NDI) data, which included the underlying cause of death for each individual. Chi-squared tests were used to examine differences in underlying cause of death by race (white, Black, Asian), ethnicity (Hispanic, non-Hispanic), and sex (female, male). Age-standardized mortality ratios (SMRs) between SLE patients and the general San Francisco county population were calculated for the leading cause of death, and estimated observed versus expected deaths by sex, race, and Hispanic/Latino ethnicity.

Results: During the study time period, 812 deaths related to SLE were identified. Cardiovascular disease (CVD) was the leading cause of death among SLE patients overall (33%), and across all racial and ethnic groups. Other top

Table 1. Standardized mortality ratios of cardiovascular disease (CVD) in SLE patients compared to the general San Francisco county population, age-standardized, 2007-2017

		CVD as Underlying Cause of Death		
	Total SLE Population #	Observed CVD Deaths in CLSP	Expected CVD Deaths*	SMR (95% CI)
Overall	809	45	12.4	3.63 (2.65, 4.86)
Race				
White	311	13	5.3	2.43 (1.29, 4.16)
Black	164	16	5.5	2.89 (1.65, 4.70)
Asian	294	14	3.7	3.83 (2.09, 6.42)
Ethnicity				
Hispanic	123	7	1.1	6.45 (2.59, 13.29)
Non-Hispanic	604	36	10.6	3.39 (2.37, 4.69)
Sex				
Female	728	40	8.6	4.65 (3.32, 6.34)
Male	81	5	1.4	3.48 (1.13, 8.12)

SMR= Age-standardized mortality ratio
#Three patients excluded from SMR analyses, as rates from CDC Wonder were not available for ages < 15 years.
*Expected rate calculated from age-specific crude mortality rates from cardiovascular disease in San Francisco county

causes included rheumatic disease (18%) and hematological/oncological conditions (18%) overall, and across all racial groups. Overall, CVD as the underlying cause of death was over three times higher among SLE cases than in the general population of San Francisco County (SMR=3.63) (Table 1). CVD deaths for those with SLE were nearly four times higher for Asians and over six times higher for Hispanic/Latinos. CVD deaths were also elevated for females (SMR=4.7) and males (SMR=3.5) with SLE compared with their non-SLE counterparts.

Conclusion: These findings indicate that CVD is the leading underlying cause of death among SLE patients across various racial and ethnic groups, and that SLE patients experience a disproportionate burden of CVD mortality compared with the general population.

Session Title: Epidemiology & Public Health Poster III: Other Rheumatic & Musculoskeletal Diseases (1022–1060)

Session Type: Poster Session C

Session Time: 8:30AM–10:30AM

Background/Purpose: Arthritis is associated with reduced physical activity (PA). PA can improve functional status, brain health, and weight management, reduce pain, prevent chronic disease, falls, and premature mortality, and prevent or delay disability. Arthritis is frequently comorbid with numerous chronic conditions for which PA is recommended for disease management, but information on physical activity among adults with arthritis across a range of comorbid chronic conditions is limited. We examined physical inactivity prevalence, stratified by arthritis status, among adults with 9 chronic conditions for which clinical guidelines recommend physical activity for disease management.

Methods: We analyzed 2019 Behavioral Risk Factor Surveillance System data from 49 states and District of Columbia for adults ≥18 years (n=380,418). Physical inactivity was no leisure-time PA in the past month. Arthritis was "yes" to "Have you ever been told by a doctor or other health care professional that you have arthritis, rheumatoid arthritis,

[1] Due to BRFSS's complex sampling design, sampling weights, derived using iterative proportional fitting (raking), were applied to make estimates representative of each state.

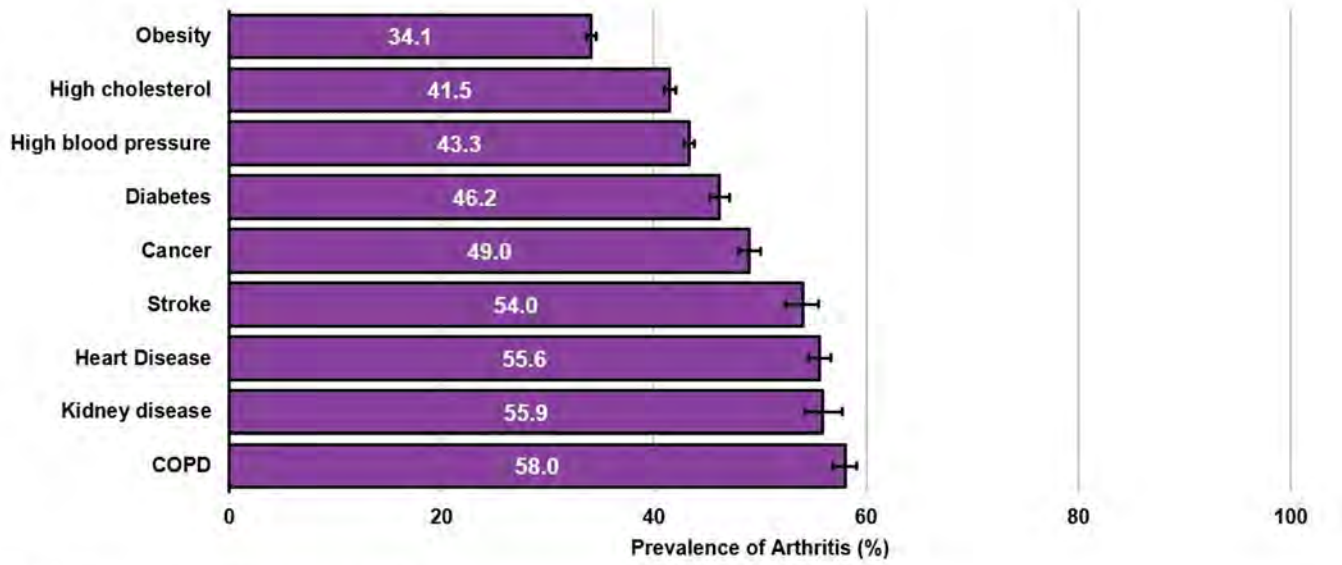
[2] Values may not sum to 100.0 because of rounding.

[3] Study inclusion criteria were: adults ≥18 years who reported age, arthritis status, and physical activity status.

[4] Arthritis was defined as "yes" in response to "Have you ever been told by a doctor or other health care professional that you have arthritis, rheumatoid arthritis, gout, lupus, or fibromyalgia?"

[5] 49 states and DC were studied. In 2019, New Jersey did not collect sufficient data to meet the minimum requirement for inclusion in the BRFSS public-use dataset.

[6] Due to missing data, number of respondents (n) for each variable does not sum to the total n.



COPD: chronic obstructive pulmonary disease
[1] Due to BRFSS's complex sampling design, sampling weights, derived using iterative proportional fitting (raking), were applied to make estimates representative of each state.
[2] Arthritis was defined as "yes" in response to "Have you ever been told by a doctor or other health care professional that you have arthritis, rheumatoid arthritis, gout, lupus, or fibromyalgia?"
[3] Study inclusion criteria were: adults ≥18 years who reported age, arthritis status, and physical activity status.
[4] Physical activity is recommended as part of the management of each of these 9 chronic conditions.
[5] 49 states and DC were studied. In 2019, New Jersey did not collect sufficient data to meet the minimum requirement for inclusion in the BRFSS public-use dataset.

Figure. Weighted(1) prevalence and 95% confidence intervals of arthritis(2) among adults aged ≥18 years(3), across each of 9 chronic conditions(4), 49 states and District of Columbia(5), Behavioral Risk Factor Surveillance System, 2019.

gout, lupus, or fibromyalgia?" The 9 comorbid conditions were cancer (excluding skin), chronic obstructive pulmonary disease (COPD), diabetes, heart disease, high blood pressure, high cholesterol, kidney disease, obesity, and stroke. We estimated chronic condition-specific prevalence of 1) arthritis; and 2) physical inactivity (unadjusted and age-standardized), by arthritis status. We compared age-standardized estimates by arthritis status using t-tests (α=0.05).

Results: Distributions of sociodemographic characteristics by arthritis status differed most for age and employment status (Table 1). In 2019, the chronic condition-specific arthritis prevalence was highest for adults with COPD (58.0%), kidney disease (55.9%), and heart disease (55.6%) (range: 34.1%–58.0%) (Figure). Unadjusted physical inactivity prevalence among adults with a specific chronic condition and arthritis was highest for COPD (46.8%), stroke (44.0%), and diabetes (44.0%) (range: 33.0%–46.8%) (Table 2). Age-standardized physical inactivity prevalence was higher for adults with each chronic condition and arthritis versus those without arthritis ($p < 0.05$ for 6 conditions). Percentage point differences ranged from 3.7–9.0; largest differences were high cholesterol (9.0), diabetes (8.9), and high blood pressure and cancer (both 7.7).

Conclusion: Adults with arthritis had a notably higher physical inactivity prevalence for all comorbid chronic conditions; the pattern was significant for 6 of the 9. Observed differences may be attributed to arthritis-related barriers that need to be addressed. Health care providers can help their patients address arthritis-specific and generic PA barriers by recommending PA and chronic disease self-management education programs. Community organizations delivering these programs may be ideal partners for referrals, and expanded program delivery could reduce PA barriers and improve quality-of-life and health outcomes.

Table 2. Weighted(1) unadjusted and age-standardized(2) prevalence of physical inactivity(3) among adults(4) aged ≥18 years, overall and for each of 9 chronic conditions(5), by arthritis(6) status, 49 states and District of Columbia(7), Behavioral Risk Factor Surveillance System, 2019

Racial/ethnic Differences in Lupus Pregnancy Outcomes over 1 Decade: A US National Study

Bella Mehta[1], Yiming Luo[2], Deanna Jannat-Khah[3], Jiehui Xu[4], Lisa Sammaritano[3], Jane Salmon[3], Michael Lockshin[1], Susan Goodman[3] and Said Ibrahim[5], [1]Hospital for Special Surgery, Weill Cornell Medicine, New York, NY, [2]National Institutes of Health, Bethesda, MD, [3]Hospital for Special Surgery, New York, NY, [4]Weill Cornell Medicine, New York, NY, [5]Weill Cornell Medicine, Cleveland, OH

SESSION INFORMATION
Session Date: Monday, November 8, 2021
Session Title: Epidemiology & Public Health Poster III: Other Rheumatic & Musculoskeletal Diseases (1022–1060)
Session Type: Poster Session C
Session Time: 8:30AM–10:30AM

Background/Purpose: Systemic lupus erythematosus (SLE) disproportionately affects women and minorities of childbearing age. Although maternal and fetal outcomes of pregnancy among women with SLE have improved over time, it is not known whether the improved outcomes are shared equally among different racial/ethnic groups.

Methods: We used the National Inpatient Sample to conduct a retrospective cross-sectional analysis of SLE pregnancy related admissions from 2008 to 2017. Patients were identified using ICD-9/10 codes. Race/ethnicity was the primary exposure variable (Caucasian, African American, Hispanic, Asian/Native American/Others). We studied pregnancy outcomes including in-hospital maternal mortality, fetal mortality, non-delivery related admissions and Cesarean section (C-section). We performed multiple imputation to account for missing data on race. Weights were applied to represent the nationwide estimates.

Results: From 2008 to 2017, there were a total of 61,012 SLE pregnancy related hospitalizations (Table 1). African American and Hispanic pregnant women (29 yrs) with SLE were younger compared to Caucasian (30 yrs) and Asians (31 yrs). Similarly, they were more likely to be on Medicaid (51% for African American, 49% for Hispanic, 30% for Caucasian and 33% for Asian/Native American/Other). During the 10-year study period, fetal mortality, and non-delivery related admissions and C-section rates improved in all racial/ethnic groups (Figure 1). Maternal mortality rates were very low throughout the study period, with none observed among Caucasians. Overall fetal mortality declined in all racial/ethinic groups, with a numerically greater reduction in Hispanic (from 291 in 2008-2009 to 101 in 2016-2017 per

The ELSA-Brasil Musculoskeletal Cohort (ELSA-Brasil MSK): Design, Implementation and Prevalence of Chronic Musculoskeletal Pain and Radiographic Knee Osteoarthritis at Baseline

Rosa Weiss Telles[1], Luciana Machado[2], Luciana Costa-Silva[3] and Sandhi Maria Barreto[1], [1]Universidade Federal de Minas Gerais, Belo Horizonte, Brazil, [2]Clinical Hospital, Universidade Federal de Minas Gerais, Belo Horizonte, Brazil, [3]Instituto Hermes Pardini. Hospital das Clínicas, Universidade Federal de Minas Gerais, Belo Horizonte, Brazil

SESSION INFORMATION
Session Date: Monday, November 8, 2021
Session Title: Epidemiology & Public Health Poster III: Other Rheumatic & Musculoskeletal Diseases (1022–1060)
Session Type: Poster Session C
Session Time: 8:30AM–10:30AM

Background/Purpose: Musculoskeletal (MSK) disorders, including low back pain and osteoarthritis (OA), are ranked among the top causes of years lived with disability and increased risk-attributable disability-adjusted life-years. ELSA-Brasil MSK is an ancillary study of the ELSA-Brasil that investigates the incidence and risk factors for MSK disorders. Here we briefly describe the design and implementation of the cohort and presented prevalence of chronic musculoskeletal pain (CMP) and knee OA at baseline.

Table 1. Prevalence of chronic musculoskeletal pain according to sociodemographic and general health characteristics at baseline of ELSA-Brasil MSK (n=2,901, 2012-2014).

Characteristics	CMP ≥1 site N=1,597 (55.1%) %	Multisite CMP N=553 (19.1%) %	Generalized CMP N=299 (10.3%) %
Sex			
Male	44.6	11.6	5.57
Female	64.3	25.9	14.6
Age, years			
38 – 44	45.0	12.1	6.2

Table 2. Tibiofemoral compartment according to Kellgren-Lawrence score, ELSA-Brasil MSK (n=5,638 knees, 2012-2014)

Tibiofemoral Kellgren-Lawrence score	N (%)
0	3,526 (62.5)
1	1,452 (25.8)
2	430 (7.6)
3	170 (3.0)
4	60 (1.1)

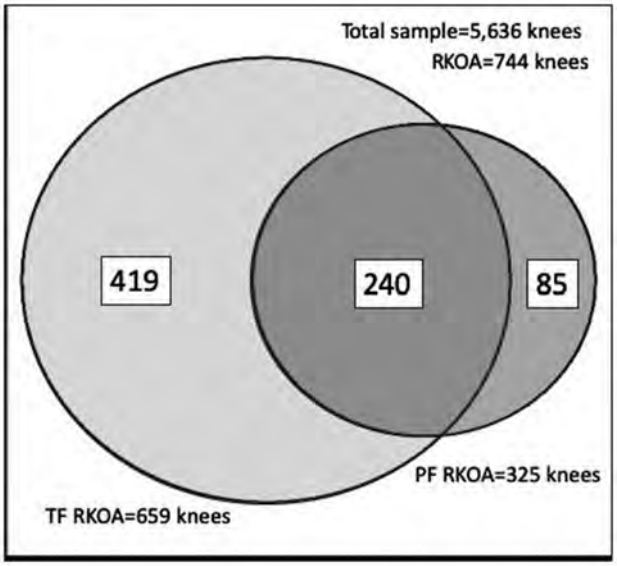

Figure 1. Venn Diagram of radiographic OA in ELSA-Brasil MSK (n=5,636 knees*, 2012-2014) *n=5,636 knees tibiofemoral and patellofemoral radiographic images.

Methods: ELSA-Brasil MSK includes active and retired civil servants from one of the investigation centers (IC) of ELSA-Brasil (IC-Minas Gerais) who completed assessments on five different domains concerning MSK health (rheumatic diseases and symptoms; disability and physical functioning; mechanical risk factors; personal beliefs; care seeking) at study baseline (2012-2014). Cohort surveillance has been performed through annual telephone interviews and return visits (scheduled every 4 years after enrollment), collecting extensive information on exposures, subclinical and clinical outcomes. A total of 2,901 participants were assessed for CMP (≥ 6 months in the past year) at nine body sites: neck, shoulders, upper back, elbows, lower back, wrists/hands, hips/thighs, knees, ankles/feet. CMP was described as multisite (>3 sites) and generalized (3 regions: upper + lower limbs + axial skeleton). 2,830 participants underwent hand and/or knee radiography for the diagnosis of OA along with the assessment of frequent hand/knee pain (pain on most days of at least 1 month). Radiographic knee OA (RKOA) was defined as the presence of tibiofemoral (TF) (KL ≥2) and/or patellofemoral (PF) (definitive osteophyte ≥2 or joint space narrowing ≥2 +bone abnormality) OA and symptomatic knee OA (SKOA) as the presence of RKOA + frequent knee pain in the corresponding knee.

Results: Participants were aged between 38 and 79 years old (mean 56.0 SD 8.9), 52.9% were women. CMP in at least one site was observed in 55.1% of participants and there was a high prevalence of multisite (19.1%) and generalized (10.3%) CMP. CMP was more commonly observed among females and participants who were older, non-white, less educated, retired, with depression, and those with higher body mass index and number of comorbidities (Table 1). The prevalence RKOA and SKOA was 18.1% and 7.8%, respectively. TF compartment was scored as KL in 2 in 7.6%, 3 in 3.0% and 4 in 1.1% of 5,638 knee images (Table 2). Most knees with RKOA (n=740) showed isolated TF OA (56.6%), with isolated PF OA in 11.4% of knees (Figure 1).

Conclusion: The high prevalence of CMP and knee OA indicates a large burden of MSK disorders in Brazil. Future longitudinal analyses in ELSA-Brasil MSK will provide an unique opportunity to fill current knowledge gaps about psychosocial and biological determinants of these disorders in a middle-income country.

Funding: ELSA-Brasil is supported by the Brazilian Ministry of Health and of Science and Technology (FINEP and CNPq-BR), (Grants 01 06 0010.00 RS, 01 06 0212.00 BA, 01 06 0300.00 ES, 01 06 0278.00 MG, 01 06 0115.00 SP, 01 06 0071.00 RJ). The Association of Patient Uncertainty with Mental Health in Systemic Autoimmune Rheumatic Diseases

Zachary Wallace[1], Claire Cook[2], Lucy Finkelstein-Fox[3], Xiaoqing Fu[3], Flavia Castelino[3], Hyon K. Choi[4], Cory Perugino[3], John Stone[5], Elyse Park[6] and Daniel Hall[7], [1]Massachusetts General Hospital, Newton, MA, [2]Division of Rheumatology, Allergy, and Immunology, Mass General Hospital, Boston, MA, [3]Massachusetts General Hospital, Boston, MA, [4]Massachusetts General Hospital, Lexington, MA, [5]Massachusetts General Hospital Rheumatology Unit, Harvard Medical School, Boston, MA, [6]Psychiatric Oncology and Behavioral Sciences, Massachusetts General Hospital, Harvard Medical School, Boston, MA, [7]Behavioral Medicine, Department of Psychiatry, Massachusetts General Hospital, Boston, MA

SESSION INFORMATION
Session Date: Monday, November 8, 2021
Session Title: Epidemiology & Public Health Poster III: Other Rheumatic & Musculoskeletal Diseases (1022–1060)
Session Type: Poster Session C
Session Time: 8:30AM–10:30AM

Background/Purpose: Patients with systemic autoimmune rheumatic diseases (SARDs) face uncertainty regarding disease flare or progression, management, how to interpret physiologic changes in their bodies, and new roles, including when and how to engage in medical visits and tests. ANCA-associated vasculitis (AAV), systemic sclerosis (SSc), and IgG4-related disease (IgG4-RD) are prototypic SARDs with differing treatments, natural histories, and manifestations that may lead to differences in the impact of illness-related uncertainty. Little is known about the psychological profiles and psychosocial and health needs of illness-related uncertainty among adults with these unique SARDs.

Methods: We invited English-speaking patients with AAV, SSc, and IgG4-RD from a single center to participate. Participants provided details of sociodemographics and SARD history and completed surveys: Mishel Uncertainty in Illness Scale (MUIS, (range 22-110), Patient Health Questionnaire depression scale (PHQ-8, range 0-12), General Anxiety Disorder (GAD-7, range 0-21), Sickness Impact Profile (SIP, range 0-22), and a survey of psychosocial needs.

Participants could complete surveys by paper, electronically, or by phone. We assessed the correlation of MUIS with PHQ-8, GAD-7, and SIP using Pearson's correlation coefficient. The association of psychological measures with self-reported needs were assessed using P-for-trend analyses. A two-sided p-value < 0.05 was considered significant.

Results: Of 368 patients invited, 132 (36%) with AAV (41, 31%), IgG4-RD (61, 46%), or SSc (30, 23%) participated (**Table 1**). The mean (SD) age was 65 years (11) and the majority (n=69, 52%) were female and white (n=110, 83%).

Table 2: The Association of Uncertainty with Mental Health

	Correlation coefficient	p-value
Overall		
MUIS and PHQ-8	0.426	<.0001
MUIS and GAD-7	0.332	<.0001
MUIS and SIP	0.280	0.0012
AAV		
MUIS and PHQ-8	0.559	0.0001
MUIS and GAD-7	0.451	0.0031
MUIS and SIP	0.565	0.0001
IgG4-RD		
MUIS and PHQ-8	0.168	0.1992
MUIS and GAD-7	0.217	0.0932
MUIS and SIP	0.012	0.9260
SSc		
MUIS and PHQ-8	0.595	0.0007
MUIS and GAD-7	0.250	0.1834
MUIS and SIP	0.593	0.0005

AAV: ANCA-Associated Vasculitis; IgG4-RD: IgG4-Related Disease; SSc: Systemic Sclerosis; MUIS: Mishel Uncertainty in Illness Scale; PHQ-8: Patient Health Questionnaire depression scale; GAD-7: General Anxiety Disorder (GAD-7), SIP: Sickness Impact Profile

Fifty-six (42%) reported remission and 42 (32%) active disease. The median [IQR] MUIS, PHQ-8, GAD-7, and SIP scores were 55.0 [48.0, 62.0], 3.0 [1.0, 6.0], 2.0 [0.0, 5.5], and 1.0 [0.0, 6.0]; 46 (35%) had at least mild depression and 42 (32%) had at least mild anxiety. We observed variations in these measures across SARDs. Across the full sample, illness-related uncertainty was positively correlated with depression (PHQ-8, r=0.43, p=< 0.0001), anxiety (GAD-7, r=0.33, p= < 0.0001), and sickness impact (SIP, r=0.28, p=0.001). We further observed variations in these measures across SARDs, such that uncertainty was more strongly associated with depression and sickness impact for individuals with AAV or SSc as compared to individuals with IgG4-RD (**Table 2**). Most commonly, patients endorsed needing help with physical symptoms (n=70, 53.0%), emotional concerns (n=32, 24.2%), and strategies to increase self-care (n=49, 37.1%), with greater needs significantly positively correlated with illness-related uncertainty (**Table 3**).

Conclusion: For rheumatology patients with prototypic SARDs, illness-related uncertainty is a significant correlate of levels of depression, anxiety, and sickness impact, as well as their chief psychosocial needs. Considering the relatively stronger associations among patients with AAV and SSc rather than IgG4-RD, there may be key differences in natural history and needs for targeted interventions to address uncertainty and patient-reported needs.

Comparisons of continuous variables were performed with the use of one-way analysis of variance, comparisons of categorical variables were performed with the use of logistic regression.

Background/Purpose: Total Knee Arthroplasty (TKA) is an effective treatment option for end-stage knee osteoarthritis. The US is well known for having striking wealth-based disparities in healthcare access and outcomes. While it is assumed that disparities in the US are larger than in other countries, there are few population-based studies that directly compare wealth-based disparities in the US with other high income countries. Our objective was to examine the relationship between neighborhood income and TKA utilization and outcomes in the US and Canada.

Methods: We used population-based administrative data fromPennsylvania(PA), USA and Ontario(ON) Canada to identify all patients age >18 who were hospitalized for primary TKA between 2012 to 2018 using ICD-9/10 codes. We linked patient-level data from each jurisdiction to community median household income using zip code of residence. In each country we independently stratified patients into neighborhood income quintiles. The primary outcome of interest was age and sex standardized per capita utilization of TKA (per 10,000 population per year) for patients in each country stratified by income quintile. Secondary outcomes included 90-day mortality, 90-day readmission, and 1-year revision rates.

Results: We identified 161,244 primary TKAs in ON and 208,016 TKAs in PA (Table 1). TKA utilization per 10,000 population per-year was significantly higher in PA than ON (29.5 vs. 22.8, $p < 0.001$). Across all income groups, utilization

Table 2: Outcomes in patients who underwent primary TKA in Ontario and Pennsylvania*

TKA Outcomes	Lowest quintile community income			2nd – 4th quartile community income			Highest quintile community income		
	Ontario N=26,393	Pennsylvania N = 35,096	p	Ontario N=102,788	Pennsylvania N = 113,577	p	Ontario N=32,063	Pennsylvania N = 59,343	p
Utilization rate, per 10,000 per year	17.5	31.4	<.001	24.4	26.1	<.001	22.8	37.5	<.001

*TKA = total knee arthroplasty

Comparisons of continuous variables were performed with the use of one-way analysis of variance, comparisons of categorical variables were performed with the use of logistic regression.

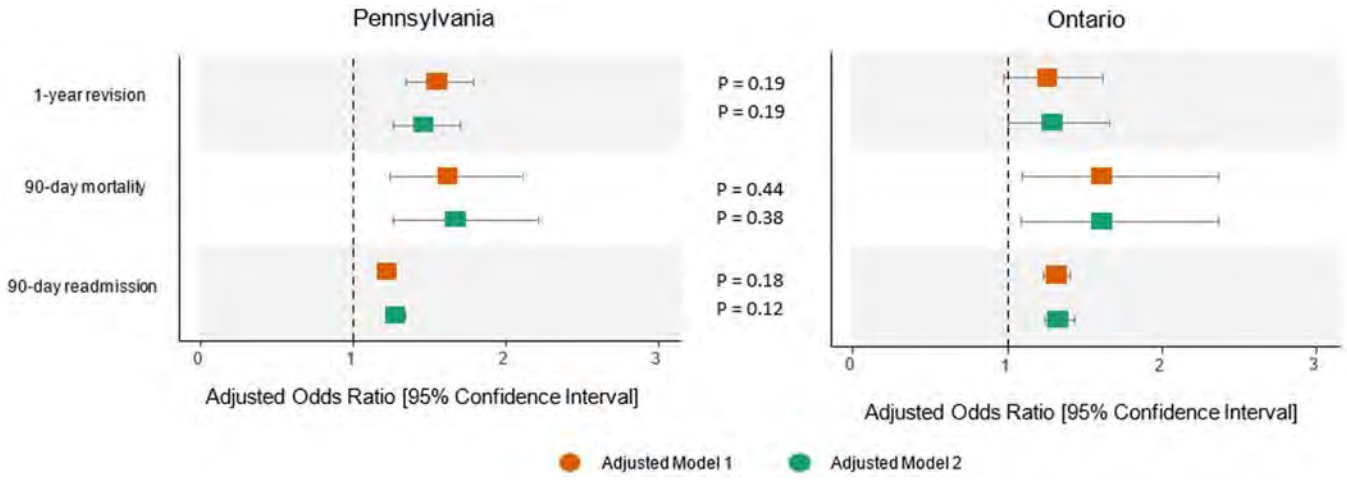

Figure 1. Adjusted odds ratio of three TKA outcomes (1-year revision, 90-day mortality, 90-day readmission) for patients who lived in the lowest income quintile compared to patients living in the highest income quintile in Pennsylvania and Ontario. Adjusted model 1 adjusted for age, sex, hospital volume of cases, rural/urban Adjusted model 2 adjusted for age, sex, hospital volume of cases, rural/urban, Elixhauser Index Comparison tests for country differences based on model estimates.

rates were significantly higher in PA compared to ON (31.4 vs. 17.5, p < 0.001 in lowest income quintile; 37.5 vs. 22.8, p < 0.001 in highest income quintile). (Table 2). In both PA and ON, those in the highest income quintile, had significantly increased odds of 90-day mortality (aOR = 1.58 in PA, 1.47 in ON) and 90-day readmission (aOR = 1.24in PA, 1.30 in ON) compared to lowest income quintile. For 1-year revision were only significant in PA (aOR = 1.44) (Figure 1)

Conclusion: The population-based utilization of TKA is higher in PA, USA compared to ON, Canada. We observed significantly lower rates of TKA for residents of lower income neighborhoods in both the US and Canada and the relative difference between low and high income communities is similar in both countries. In the context of the ongoing debate over healthcare reform in the US, our findings suggest that a single-payer system is unlikely to eliminate income-based disparities.

Abstract Number: 1038

Outcomes of Hydroxychloroquine Screening for Retinopathy in a Cohort of Patients with Rheumatological Conditions

Ghazala Tehseen[1], Alexandra Chadwick[2], Sarah Wills[2] and Audrey Low[2], [1]Faculty of Biology, Medicine and Health. The University of Manchester, Manchester, UK, Manchester, United Kingdom, [2]Rheumatology Department, Salford Royal NHS Foundation Trust, Manchester, United Kingdom

SESSION INFORMATION
Session Date: Monday, November 8, 2021
Session Title: Epidemiology & Public Health Poster III: Other Rheumatic & Musculoskeletal Diseases (1022–1060)
Session Type: Poster Session C
Session Time: 8:30AM–10:30AM

Background/Purpose: Hydroxychloroquine (HCQ) is used to treat rheumatoid arthritis (RA), connective tissue disease (CTD) and other inflammatory conditions. In 2018, the United Kingdom Royal College of Ophthalmologists (RCOphth) published new screening guidelines to monitor the risk of HCQ associated retinopathy, recommending patients be referred for screening if patients had been on HCQ for ≥5 years and included a list of risk factors to guide the screening process: dosage >5mg/kg/day absolute body weight (ABW), concurrent tamoxifen use and impaired renal function (eGFR < 60ml/min/1.73m²). This report aims to audit the 1) HCQ dosing based on RCOphth 2018 guidelines 2) the number of patients appropriately referred for screening and 3) the outcome of screening.

Methods: In July 2018 (when the RCOphth guidelines were published), a list of all patients started on HCQ from April 2013-2014 and received the first prescription from hospital was obtained from hospital pharmacy records. These patients' electronic patient records were reviewed between Jul-Oct 2018 to extract data on demographic and clinical parameters, drug persistence including reason for cessation of drug and suitability for referral for HCQ retinopathy monitoring if they continued the drug. Referral for eye screening took place between Oct 2018-May 2019. These patients were followed until the most recent follow-up visit by May 2021 to determine the outcome of screening (Figure 1).

Results: 100 patients were identified. The median age of the cohort was 57 years (46-70), with 67% of the cohort being female. Many patients (67%) were started on HCQ for RA, 16% for SLE and 17% for other rheumatological diagnoses. The median HCQ dose was 4.6mg/kg/day (3.4-5.7). 37% of patients were prescribed a starting dose of > 5mg/kg/day. 9 patients had an eGFR of < 60 ml/min/1.73m^2. No patients were on concurrent tamoxifen (Table 1).

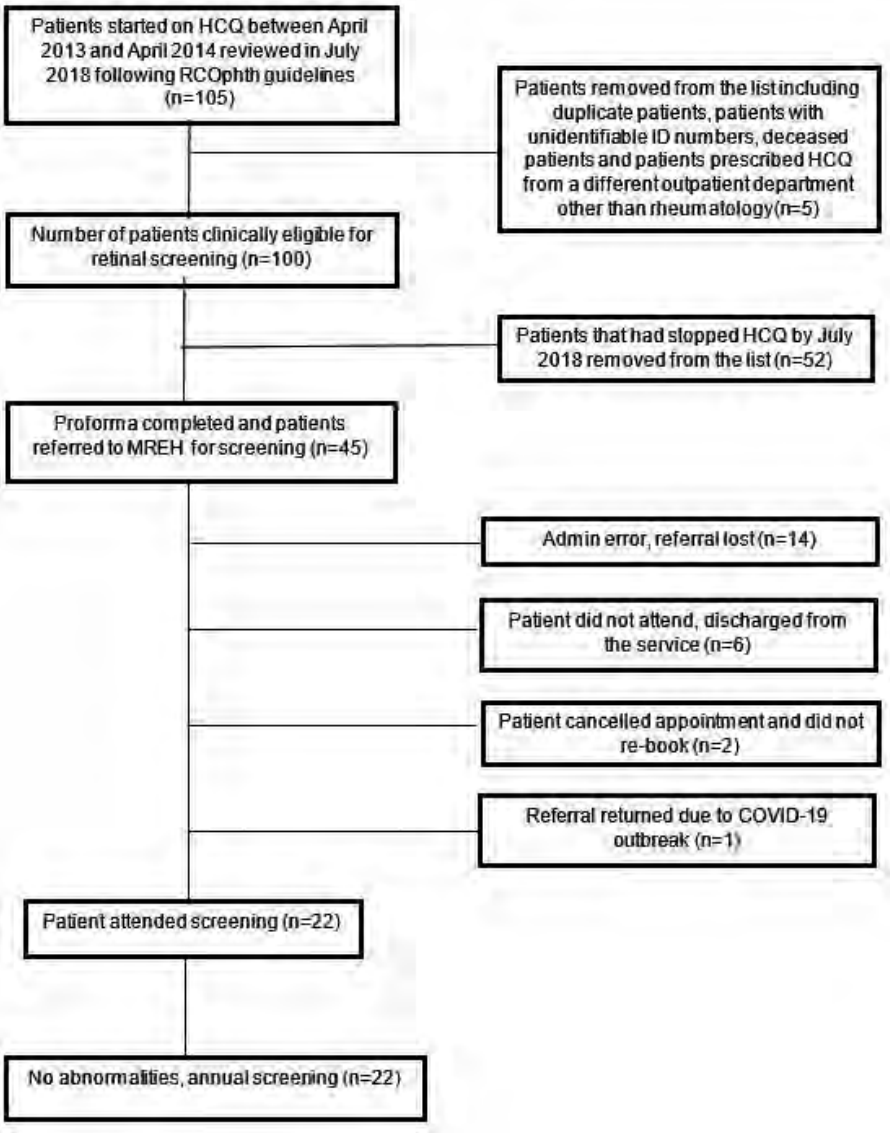

Figure 1. Flowchart showing the process of filtering patients who were clinically suitable to be referred for HCQ retinopathy screening and the outcome of screening (HCQ=hydroxychloroquine).

By July 2018 (median 5 years of follow-up from 2013), 48% of patients remained on HCQ. 52% of patients were no longer on HCQ for a variety of reasons including side effects (33%) and ineffectiveness (10%). Of the 48 patients that remained on HCQ, 3 died before they could be referred and the remaining 45 were referred for eye screening. Of the 45 who were referred, 22 were screened and all showed no evidence of retinopathy, 14 referrals were lost, 6 did not attend and were discharged, 2 cancelled and did not rebook and 1 referral was returned due to the COVID-19 outbreak (Figure 1). Of the 22 patients with normal screening, 2 had renal impairment and 7 were prescribed ≥5mg/kg/day and 2 had both renal impairment and were dosed over 5mg/kg.

Conclusion: After 5 years of follow-up, the drug survival for HCQ is 50%. By knowing the number of patients prescribed and started on HCQ annually and stop therapy after 5 years, this will influence screening service capacity issues. Of those patients who attended for screening after 5 years of therapy, none had evidence of HCQ retinopathy which is reassuring including 11 patients who were either dosed ≥5mg/kg/day (n=7) or had renal impairment (n=2) or both (n=2). In 2013, over a third of patients were started on a HCQ dose >5mg/kg/day, we need to ensure that dosage is appropriate and monitor for other factors to reduce their risk of developing HCQ retinopathy.

Table 1. Baseline characteristics of cohort that started HCQ between April 2013-2014 (ABW = absolute body weight, HCQ=Hydroxychloroquine, IQR= interquartile range, RA=Rheumatoid Arthritis, SLE= Systemic Lupus Erythematous, BMI= Body Mass Index, eGFR= estimated Glomerular Filtration Rate).

Healthcare Resource Utilization and Costs of Dermatomyositis and Polymyositis in the United States: A Systematic Literature Review

Rohit Aggarwal[1], Kelly Gwathmey[2], Richard Leff[3], Konrad Pisarczyk[4], Izabela Aleksanderek[5], Kiruthi Palaniswamy[6] and Noreen Henig[7], [1]University of Pittsburgh, Pittsburgh, PA, [2]Virginia Commonwealth University Health system, Richmond, VA, [3]Richard L Leff MD LLC, Chadds Ford, PA, [4]Maple Health Group, Krakow, Poland, [5]Maple Health Group, Toronto, ON, Canada, [6]Kezar Life Sciences, Los Angeles, CA, [7]Kezar Life Sciences, Inc, Foster City, CA

SESSION INFORMATION

Session Date: Monday, November 8, 2021

Session Title: Epidemiology & Public Health Poster III: Other Rheumatic & Musculoskeletal Diseases (1022–1060)

Session Type: Poster Session C

Session Time: 8:30AM–10:30AM

Background/Purpose: Dermatomyositis (DM) and polymyositis (PM) are rare heterogenous systemic autoimmune disorders with primary target of muscle, skin, but can also impact multiple other organs. The objective of this study was to systematically review and synthetize evidence on healthcare resource utilization (HCU) and cost of treating DM/PM in the United States (US).

Methods: A systematic literature review was conducted using MEDLINE and Embase databases. Primary studies of any design enrolling 10 or more patients with DM/PM, published in the English language between 2011–2021 were included irrespective of country or region. Each eligible article was independently reviewed by two reviewers. The title and study abstracts were reviewed to assess eligibility for full-text review. Data on the clinical, humanistic, and economic burden in DM/PM patients in the US were extracted. The economic burden data is presented below.

Results: A total of 3624 records were retrieved from medical databases, 393 records underwent full-text review, and 210 were included in data abstraction. Additional 8 papers were included from searching reference lists of identified studies. HCU and/or costs related to DM/PM in the US were reported in 13 studies. Patients with DM/PM had a significantly higher number of medical visits (>50% directly related to DM/PM care), inpatient admissions, emergency room visits, as well as visits to rheumatologists, neurologists and physical therapy care, compared to matched controls (Table 1). When hospitalized, patients with DM/PM required more specialized tests and procedures, typically with 1.11 to 1.88-day longer length of stay, compared to controls. The total annual cost of hospitalization due to DM

• Myositis-related time impaired while working/past week (presenteeism), mean (SD) [% of workdays][6]	215	DM/PM	NA	**22.15% (23.07%); Increasing trend with increasing disease flare freq. (4% - none to 32.5% - ≥4 flares/past year, p<0.001)**	

in the US was estimated at $49 million and $168 million for juvenile and adult patients, respectively, with a substantial cost increase to $644 million for hospitalizations due to various morbidities or comorbidities in adult patients (DM as secondary inpatient diagnosis). These costs were increased by 27–64% when compared with inpatients without DM. On average, mean hospital costs to payers were $55,000, which was $13,000 higher relative to inpatients without DM/PM (Table 2). Two studies evaluated indirect costs related to DM/PM and showed an increased, disease-related productivity loss (on average, 2 workdays loss vs matched controls, or 27.65% missed workdays/week) that was also associated with disease flare frequency.

Conclusion: Most of the published evidence focuses on direct hospital care suggesting DM/PM generate significant costs to the healthcare system. Moreover, there is significant direct and indirect economic burden related to the treatment of DM/PM, suggesting unmet need for exploring novel therapeutics in clinical trials to safe and efficacious therapies. Given the limited evidence on the HCU and associated costs of DM/PM in the US, additional research on this topic is warranted.

Monoclonal Gammopathy in Autoimmune Diseases: Analysis and Follow-up of 160 Cases in a Tertiary Center in China

Huazhen Liu, Pengchong Li, Ketian Li, Ziyue Zhou, Lidan Zhao and Xuan Zhang, Peking Union Medical College Hospital, Beijing, China (People's Republic)

SESSION INFORMATION
Session Date: Monday, November 8, 2021
Session Title: Epidemiology & Public Health Poster III: Other Rheumatic & Musculoskeletal Diseases (1022–1060)
Session Type: Poster Session C
Session Time: 8:30AM–10:30AM

Background/Purpose: Monoclonal gammopathy (MG) in patients with autoimmune diseases (AID) is pretty common, but the outcomes and predictors for hematological neoplasm (HN) progression have not been well characterized.

Methods: Patients diagnosed of AID complicated with MG in Peking Union Medical College Hospital from January 2010 to June 2017 were systematically reviewed, and followed up. Recognition of HN was set as the primary observational endpoint. Cox proportional hazard regression analysis was applied to identify possible risk predictors.

Results: Of 160 patients with AID and MG, the median time between AID diagnosis and MG diagnosis was 0.6 months (IQR: 0-42.3 months) with 87 (54.4%) patients diagnosed with AID and MG simultaneously. The most common AID was primary Sjögren's syndrome (37, 23.1%), followed by rheumatoid arthritis (28, 17.5%) and systemic lupus erythematosus (25, 15.6%). About 62.5% (n=100) of AID patients in our cohort were having active disease at the detection of M protein. Thirty-nine (24.4%) patients developed HN during the follow-up (median: 3.7 years, IQR: 0.3-5.5 years) including multiple myeloma (22, 56.4%), lymphoma (9, 23.1%), macroglobulinemia (4, 10.3%), amyloidosis (3, 7.7%), and plasmacytoma (1, 2.6%) (Table 1.). The cumulative probability of HN progression was 21.8% at 1 year, 22.6% at 3 years, and 29.3% at 6 years after the finding of MG, respectively (Fig. 1A). High levels of monoclonal protein (M protein > 14.35% of total serum protein) (HR 11.71, 95%CI: 5.37-25.54, p< 0.001), significant weight loss (HR 6.24, 95%CI: 2.87-13.59, p< 0.001), and reduction of other types of immunoglobulins (HR 3.02, 95%CI: 1.40-6.48, p=0.005) were independent risk indicators. Types of M protein (Fig. 1B), disease activity, and treatment of AID (Fig. 1C) seemed unrelated to HN in our cohort.

Conclusion: Around one-fourth of MG in patients with AID develop HN, indicating that though MG mostly is a benign process in patients with AID, it can be the prelude for HN in certain group of this population. High levels of M protein, weight loss, and the reduction of other immunoglobulins are predisposing factors that warrant vigorous follow-up and monitoring.

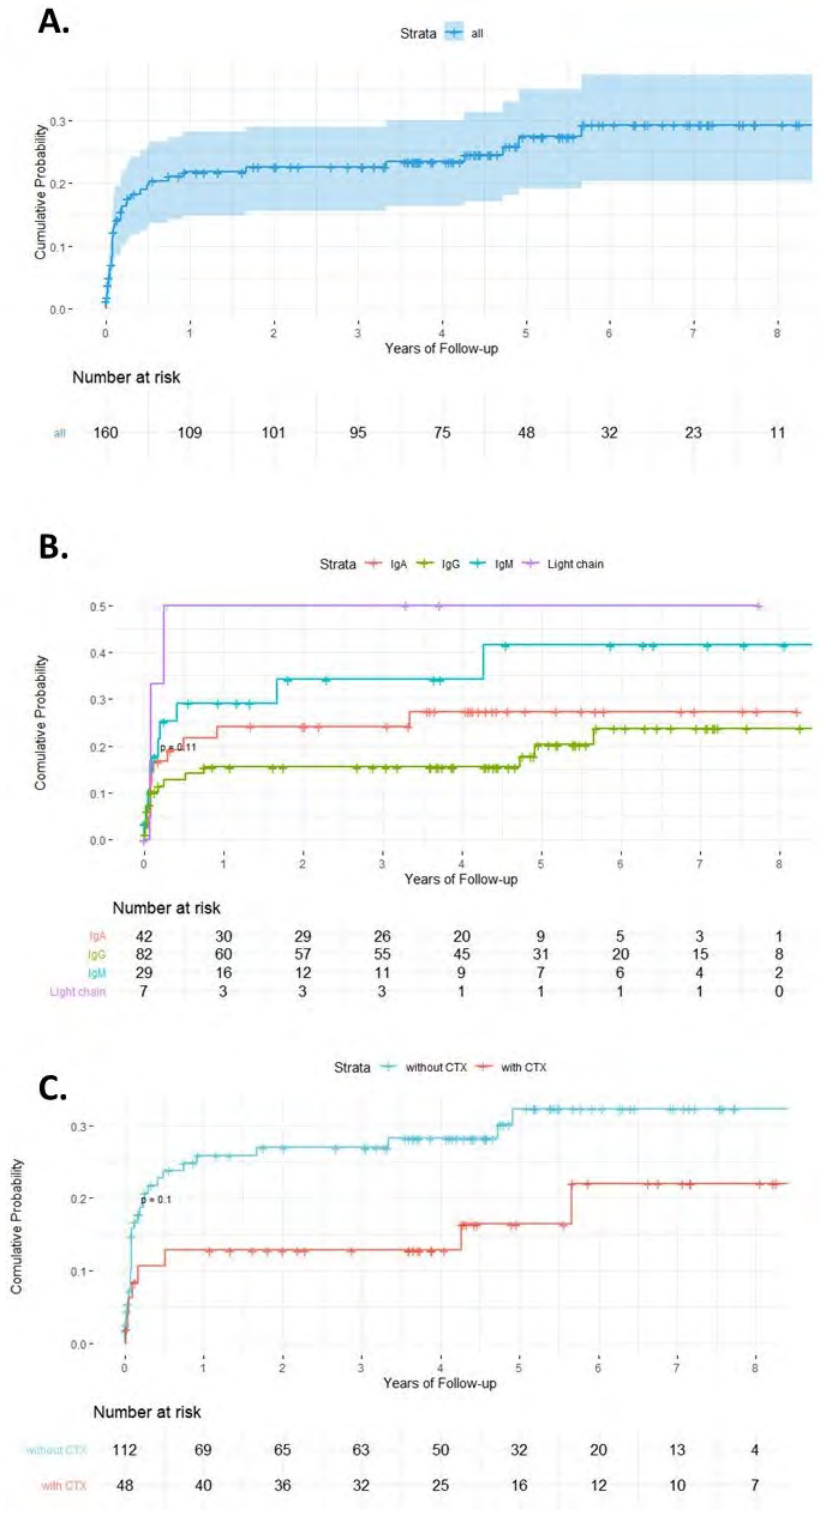

Figure 1. Survival analysis of patients with autoimmune diseases (AID) and monoclonal gammopathy. (A) Kaplan-Meier HN cumulative probability of monoclonal gammopathy patients with AID. (B) Kaplan-Meier hematological neoplasm (HN) cumulative probability of patients stratified with the type of M protein. (C) Kaplan-Meier HN cumulative probability of patients stratified with the use of cyclophosphamide. CTX: cyclophosphamide.

Table 1. Demographics of the autoimmune disease patients who developed hematological neoplasms during follow-up.

	Total	Plasma cell neoplasms		Lymphoma	Other plasma cell neoplasms

SESSION INFORMATION

Session Date: Monday, November 8, 2021

Session Title: Epidemiology & Public Health Poster III: Other Rheumatic & Musculoskeletal Diseases (1022–1060)

Session Type: Poster Session C

Session Time: 8:30AM–10:30AM

Background/Purpose: Cancer is a comorbidity of concern for the long-term prognosis in autoimmune disease (AID) patients. This study investigated cancer incidence and risks in five major AIDs in a large cohort of Chinese patients, compared with the general population.

Methods: The cohort retrospectively enrolled 8120 AID inpatients with SLE, RA, SS, SSc, or IIM admitted to Peking Union Medical College Hospital from January 2006 to April 2015. Cancer occurrences were consecutively followed

Table 1. Demographics, follow-up, and cancer occurrence of the cohort and AID-CA patients

Variables	All CTDs n=8120	SLE n=3794	RA n=1658	SS n=1329	IIM n=964	SSc n=375
Median age at cohort entry (years) (median, IQR)	43.8 (29.8-57.9)	31.2 (21.1-41.4)	57.8 (48.9-66.8)	53.7 (43.6-63.7)	48.3 (38.2-58.4)	48.8 (38.8-58.4)
Gender ratio (Female/Male)	4.82 (6726/1394)	6.66 (3299/495)	3.02 (1246/412)	9.55 (1203/126)	2.31 (673/291)	4.36 (305/70)
Follow-up time (person-years)	58726.53	19601.91	6787.29	6390.49	6144.29	1802.58
Observed cancer (n)	430	90	162	84	67	27
Expected cancer*	127.42	34.92	40.64	29.18	15.53	7.16
SIR (95%CI)	3.37 (3.06-3.71)	2.58 (2.07-3.17)	3.99 (3.40-4.65)	2.88 (2.30-3.56)	4.31 (3.34-5.48)	3.77 (2.49-5.49)
Incidence rate (per 100,000 person-years)	1110.35	459.14	2386.82	1314.45	1616.68	1497.85
Age at cancer diagnosis, median (IQR) (years)	57.5 (48.8-66.2)	49.1 (39.8-58.5)	61.5 (53.3-69.6)	61.6 (51.8-71.3)	59.7 (52.5-67)	49.2 (43.1-55.3)
Gender ratio of AID-CA patients (Female/Male)	4.58 (353/77)	21.50 (86/4)	2.77 (119/43)	15.80 (79/5)	2.05 (45/22)	8.00 (24/3)
Time interval between AID and CA diagnosis, Median (IQR) (months)	79.8 (14.2-145.4)	115.2 (62.4-166.8)	121.2 (48.0-194.4)	54.0 (4.8-103.2)	7.2 (0-20.4)	42.0 (3.6-80.4)

*Expected cancer was calculated by multiplying person-years and the cancer incidence of general Chinese population. The estimated cancer incidence rates were age, gender, and site-specific rates in 2006-2015, reported by the National Central Cancer Registry (NCCR) of China.
Abbreviations: AID, autoimmune diseases; SLE, systemic lupus erythematosus; RA, rheumatoid arthritis; SS, Sjögren's syndrome; IIM, idiopathic inflammatory myopathies; SSc, systemic sclerosis. IQR: interquartile range; SIR, standardized incidence ratio, CI: confidence interval.

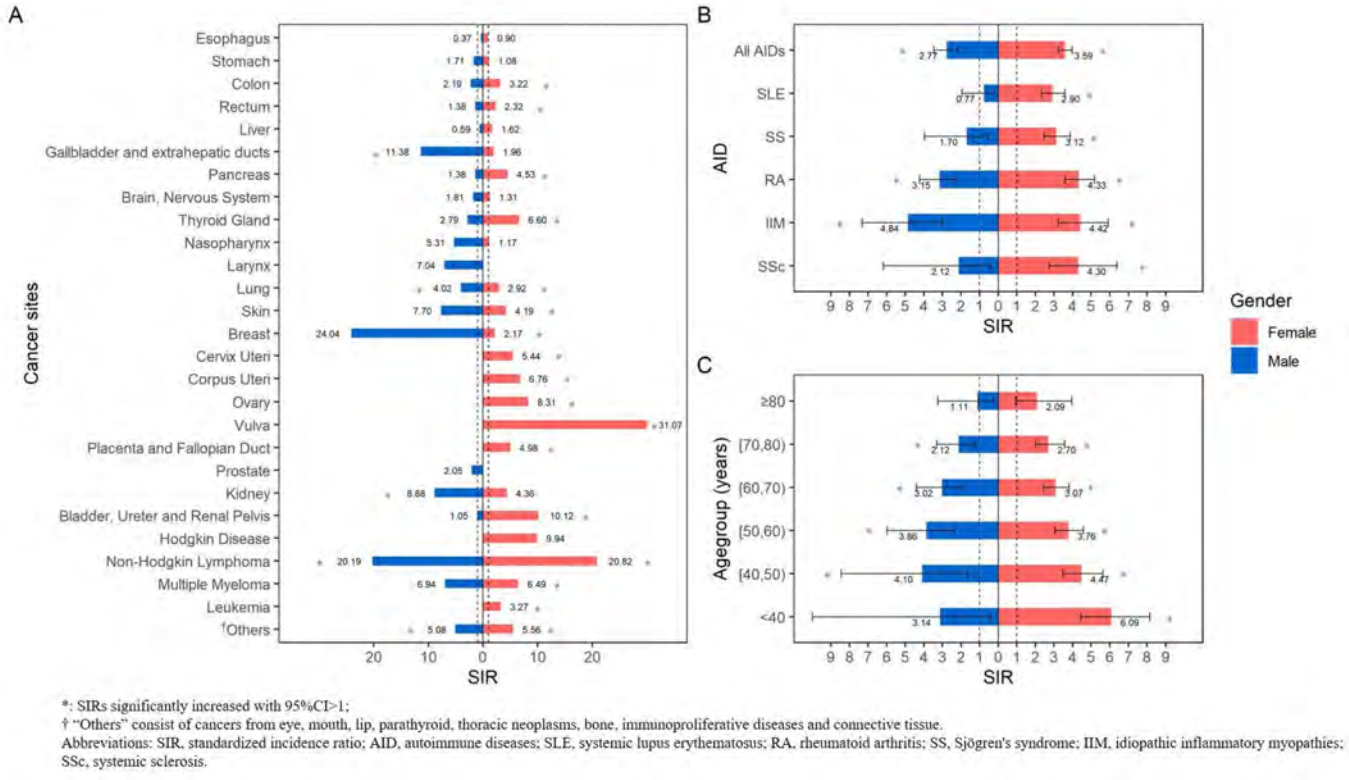

Figure 1. Gender- and age-specific standardized incidence ratios (SIRs) in AID patients and subgroups. (A) SIRs of site-specific cancers for female and male. (B) SIRs in all and each type of AID patients for female and male. (C) SIRs in different age groups (every 10 years) for female and male.

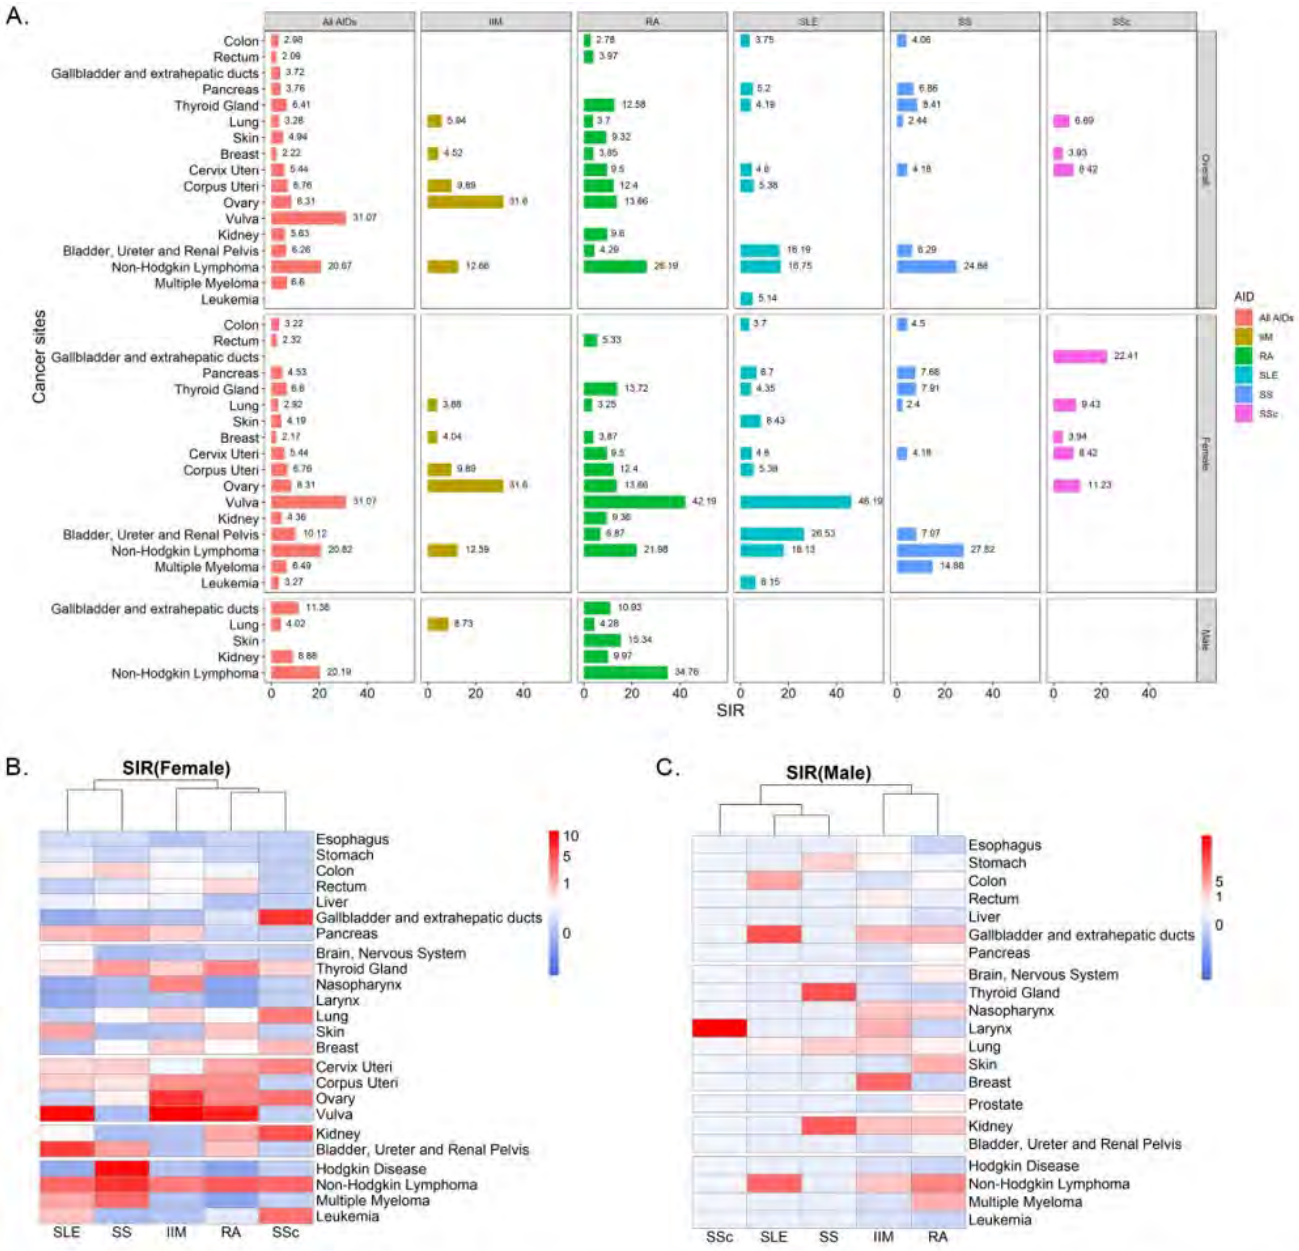

Abbreviations: SIR, standardized incidence ratio; AID, autoimmune diseases; SLE, systemic lupus erythematosus; RA, rheumatoid arthritis; SS, Sjögren's syndrome; IIM, idiopathic inflammatory myopathies; SSc, systemic sclerosis.

Figure 2. Site-specific standardized incidence ratios (SIRs) in AID patients and subgroups. (A) Significantly increased SIRs for high-risk cancer in all AID and five types of AID patients. (B) Heatmaps of SIRs in female patients clustered by type of AID. (C) Heatmaps of SIRs in male patients clustered by type of AID.

up by direct contact with the attending clinician or telephone. The demographics, distributions, and standardized incidence ratios (SIRs) were analyzed and compared among the five AIDs.

Results: During 38726.55 person-years of follow-up, 430 (5.3%) patients developed cancer, with a median age of 57.5 (IQR: 48.8-66.2) years and disease duration of 79.8 (IQR: 14.2-145.4) months after the diagnosis of AID (Table 1.). The estimated SIR in all AIDs was 3.37 (95%CI: 3.06-3.71), with the highest in IIM (4.31, 95%CI 3.34-5.48), followed by RA (3.99, 95%CI 3.40-4.65), SSc (3.77, 95%CI 2.49-5.49), SS (2.88, 95%CI 2.30-3.56) and SLE (2.58, 95%CI 2.07-3.17). Gender discrepancy of cancer risks existed, with SIR for female patients (3.59, 95% CI 3.23-3.99)

higher than male (2.77, 95% CI: 2.19-3.46) (Fig. 1A, Fig. 1B). And SIR for younger patients (age< 50) was generally higher than older patients (age≥50) (Fig. 1C). Compared among the five major AIDs, each AID had distinctive features related to cancer (Fig. 2A-C). SLE had significantly increased SIRs of hematologic malignancies and solid tumors located in the urinary tract, female genital organs, pancreas, thyroid, and colon. SS also had a high SIR of non-Hodgkin's lymphoma (NHL). IIM was closely associated with cancer, with 74.6% of cancers diagnosed within 3 years and had increased SIRs of ovarian, corpus uteri, lung, breast, and NHL. In RA populations, a wide distribution of cancers was detected after 15 years since the diagnosis of RA. For SSc, increased SIRs were observed in cervix uteri, lung, and breast cancers.

Conclusion: AID patients in China had an overall increased cancer risk than the general population, with varied site-specific cancer risks in gender, age groups, and AID types.

Multimorbidity Prevalence in Systemic Lupus Erythematosus: A Population-Based Study

Ali Duarte-Garcia[1], Maria Valenzuela-Almada[2], Mehmet Hocaoglu[3], Jesse Dabit[1], Shirley-Ann Osei-Onomah[1], Sebastian Vallejo-Ramos[1], Kurt Greenlund[4], Tina Gunderson[1], Kamil Barbour[4] and Cynthia Crowson[5], [1]Mayo Clinic, Rochester, MN, [2]Division of Rheumatology, Mayo Clinic, Rochester, MN, [3]University of Maryland Medical Center, Midtown Campus, Baltimore, MD, [4]Centers for Disease Control, Atlanta, GA, [5]Mayo Clinic, Eyota, MN

SESSION INFORMATION
Session Date: Monday, November 8, 2021
Session Title: Epidemiology & Public Health Poster III: Other Rheumatic & Musculoskeletal Diseases (1022–1060)
Session Type: Poster Session C
Session Time: 8:30AM–10:30AM

Background/Purpose: Patients with systemic lupus erythematosus (SLE) have a 3-fold increase in all-cause mortality, compared to the general population. Young patients with SLE are 40 and 60 times more likely to have cardiovascular disease and end-stage renal disease, respectively, and have at least twice the risk for psychiatric comorbidities (e.g., depression) than people of comparable age without SLE (Manzi et al. AJE 1997; Choi et al. Medicine 2019)). These and other chronic conditions have emerged as factors contributing to the excess morbidity and shorter lifespan of patients with SLE. To date, characterization of age-, disease- and treatment-related comorbidities associated with SLE has relied almost exclusively on individual comorbidity assessment. We aimed to compare the prevalence of multimorbidity in SLE patients with the general population.

Methods: Prevalent cases of SLE who met the ACR/EULAR classification criteria and were residents in a 27-county area of the United States on January 1, 2015 were included in the study. SLE patients were age-, sex-, race-, and county-matched to subjects from the same underlying population. Diagnosis codes within a five-year lookback period were used to determine the presence of comorbidities; 2 or more codes at least 30 days apart were used to define a comorbidity. A previously published list of 44 comorbidities was considered (England et al. ARD 2020). SLE and cutaneous lupus codes were excluded from the analysis. We defined multimorbidity as the presence of 2 or more comorbidities (excluding SLE) and substantial multimorbidity as the presence of 5 or more comorbidities. Logistic regression models adjusted for age and sex were performed.

Table. Prevalence on 1-1-2015 and odd ratios of comorbidities and multimorbidity (2 or more, 5 or more) in 479 patients with systemic lupus erythematosus (SLE) compared to 479 patients without SLE.

Outcome/Comorbidity	Non-SLE N (%)	SLE N (%)	OR [95%CI] SLE vs non-SLE

Parkinson's Disease	3 (0.6)	1 (0.2)	0.32 [0.02-2.6]

*Percentages reflect sex-specific totals for Non-Inflammatory Gynecologic Disorders (N=394 each group) and Prostatic Hyperplasia (N=85 each group).

Results: A total of 479 SLE patients were matched to 479 non-SLE comparators. The mean age was 53.2 (SD 16.2) years and 82.3% were female. 86% were non-Hispanic White. Patients with SLE had 5.3 comorbidities compared to 2.9 among non-SLE subjects. Multimorbidity was present in 78.5% SLE vs. 57.8% non-SLE subjects (OR 2.96; 95%CI 2.2-4.0) and substantial multimorbidity was present in 47.6% SLE patients vs. 25.5% non-SLE subjects (OR 3.06; 95%CI 2.28-4.1). Of the 44 conditions examined, 27 were more common in SLE than in non-SLE (Table).

Conclusion: In this population-based cohort, patients with SLE were 3 times as likely to suffer from multimorbidity and substantial multimorbidity compared to the general population. Most comorbidities were overrepresented in SLE patients. These findings highlight the complex care needs of SLE patients.

Prevalence of Multimorbidity in Cutaneous Lupus Erythematosus: A Population-Based Study

Mehmet Hocaoglu[1], Mark Davis[2], Maria Valenzuela-Almada[3], Jesse Dabit[2], Shirley-Ann Osei-Onomah[2], Sebastian Vallejo-Ramos[2], Tina Gunderson[2], Kurt Greenlund[4], Kamil Barbour[4], Cynthia Crowson[5] and Ali Duarte-Garcia[2], [1]University of Maryland Medical Center, Midtown Campus, Baltimore, MD, [2]Mayo Clinic, Rochester, MN, [3]Division of Rheumatology, Mayo Clinic, Rochester, MN, [4]Centers for Disease Control, Atlanta, GA, [5]Mayo Clinic, Eyota, MN

SESSION INFORMATION
Session Date: Monday, November 8, 2021
Session Title: Epidemiology & Public Health Poster III: Other Rheumatic & Musculoskeletal Diseases (1022–1060)
Session Type: Poster Session C
Session Time: 8:30AM–10:30AM

Background/Purpose: Cutaneous lupus erythematosus (CLE) patients report impaired quality of life due to cutaneous and psychological morbidity. Previous literature on the prevalence of comorbidities in CLE patients is scarce and the extent of multimorbidity is uncertain. In this population-based study, we aimed to characterize the prevalence of multimorbidity in CLE patients.

Methods: Prevalent CLE cases from a well-defined 27-county region in the United States were included in our study. Cases with concomitant systemic lupus erythematosus (SLE) meeting ACR/EULAR 2019 criteria were excluded. Subjects identified as CLE were age-, sex-, race-, and county-matched to non-CLE subjects from the same population. A five-year lookback period was used for diagnostic codes to determine the presence of comorbidities. Two or more codes ≥30 days apart were used to define a comorbidity. A previously published list of 44 comorbidities was considered (England et al. ARD 2020). CLE and SLE codes were excluded from the analysis. Two or more comorbidities were defined as multimorbidity, 5 or more as substantial multimorbidity. Logistic regression models adjusted for age and sex were used.

Results: 303 CLE patients were matched to 303 non-CLE controls from the same population. The mean age was 59.4 (SD 15.7) years. 72.9% were female. 90.8% were White. CLE patients had 4.7 comorbidities on average compared to 4.0 of non-CLE subjects. Multimorbidity was present in 79.5% CLE vs. 65.7% non-CLE (OR:2.27; 95CI:1.53-3.38) and substantial multimorbidity was present in 43.9% CLE patients vs. 34.3% non-CLE subjects (OR:1.65; 95CI:1.14-2.38). Fibromyalgia, liver disease, chronic obstructive pulmonary disease (COPD), hypertension, anemia, and hypothyroidism were significantly more common in CLE patients compared to controls (Table).

Conclusion: In this population-based study, CLE patients were 2 times more likely to have multimorbidity compared to the general population. It is unclear if the driver of multimorbidity in CLE is the disease itself, treatments, or a combination thereof.

Table. Prevalence on 1-1-2015 and odd ratios of comorbidities and multimorbidity (2 or more, 5 or more) in 303 patients with cutaneous lupus erythematosus (CLE) compared to 303 patients without CLE.

Outcome/Comorbidity	Non-CLE N (%)	CLE N (%)	OR [95%CI] CLE vs non-CLE

Abstract Number: 1044

Older Patients with Rheumatic Disease Are Commonly Prescribed Potentially Inappropriate Medications

Christine Anastasiou, Michael Evans, Gabriela Schmajuk and Jinoos Yazdany, University of California San Francisco, San Francisco, CA

SESSION INFORMATION

Session Date: Monday, November 8, 2021

Session Title: Epidemiology & Public Health Poster III: Other Rheumatic & Musculoskeletal Diseases (1022–1060)

Session Type: Poster Session C

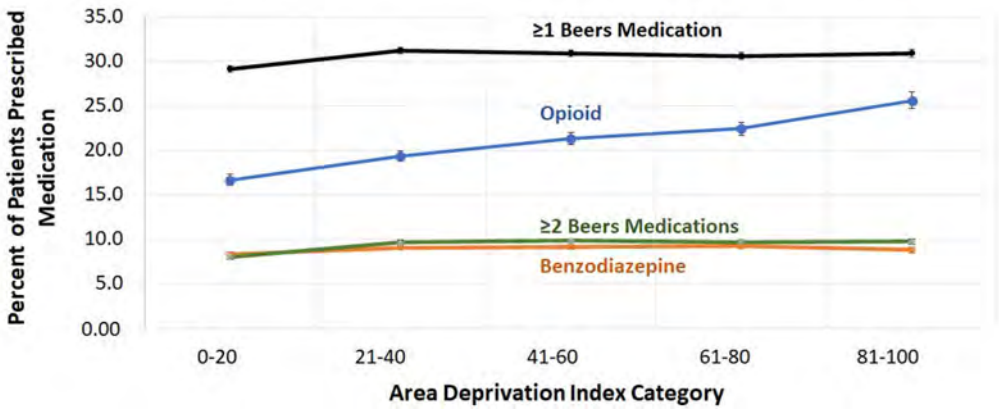
Session Time: 8:30AM–10:30AM

Background/Purpose: Reducing exposure to potentially inappropriate medications (PIMs) in older adults may minimize adverse drug events. The American Geriatrics Society (AGS) Beers Criteria® of Potentially Inappropriate Medication Use provides guidance regarding medications that should be avoided in older adults. Since opioids are associated with an increased risk of cognitive impairment, falls with fracture, and adverse drug-drug interactions in older adults, we also included opioids in the analysis. We used a population-based sample of older adults seen by rheumatologists to assess PIM use and identify risk factors.

Methods: Adult patients ≥ 65 years old with ≥ 2 visits in 2018 at a clinical rheumatology practice participating in the RISE registry were included. We focused on patients with 6 rheumatic diseases commonly associated with pain: OA, gout, RA, PsA, SLE, and SSc. Diagnosis was defined by ≥ 2 ICD-10 CM codes ≥ 30 days apart. Each patient was given one diagnosis for this analysis based on a simple predetermined hierarchy (OA, gout, RA, PsA, SLE, SSc). Medications of interest were those listed by the AGS Beers Criteria® with a 'strong recommendation to avoid', or opioids. The frequency and percent of patients with these medications listed on their medication list was determined. We developed several logistic regression models in which the outcome estimated the odds of patients taking these medications (≥1 Beers Medication, ≥2 Beers Medication, opioid, or benzodiazepine) and covariates included patient area deprivation index, age, gender, rheumatic diagnosis, Deyo-Charlson comorbidity index, insurance, and race/ethnicity. Marginal predictions and 95% confidence intervals were obtained.

Results: We included 178,833 older adults (mean age 75+/-7) from 217 practices. Forty percent of older adults seen in these rheumatology practices had a PIM on their medication list. Rates differed slightly between diseases (45% OA, 37% gout, 37% RA, 39% PsA, 42% SLE, 40% SS). Patients were most likely to have a prescription for opioids (17%), NSAIDs (12%), benzodiazepines (7%), or anticholinergics (4%). Older adults living in more socioeconomically disadvantaged neighborhoods were more likely to have an opioid prescription. Other factors associated with a higher odds of opioid prescription included female gender; OA, gout or PsA diagnosis; Medicaid insurance; and American Indian or Alaskan Natives race/ethnicity. Lower odds of opioid prescription was associated with older age and Asian race/ethnicity. Area deprivation index was not associated with other assessed PIM use (Figure).

Figure. Percent of Older Adults with Potentially Inappropriate Medication Use Based on Area Deprivation Index



Conclusion: Older adults with rheumatic disease were more likely to have an opioid prescription if they lived in a socioeconomically disadvantaged area. In contrast, other PIM prescriptions assessed did not vary based on the level of disadvantage in the area of residence. Future research should evaluate ways to reduce potentially harmful medications such as opioid and benzodiazepine use in older patients with rheumatic disease, and determine what factors are driving the increased opioid prescriptions associated with living in more deprived areas.

Beers Medication refers to medications listed in the American Geriatrics Society (AGS) Beers Criteria® with a strong recommendation to avoid. Marginal predictions and 95% confidence intervals from several logistic regression models with outcomes shown (≥1 Beers Medication, ≥2 Beers Medication, Opioid, or Benzodiazepine) based on patient area deprivation index and including age, gender, rheumatic diagnosis, Deyo-Charlson comorbidity index, insurance, and race/ethnicity as covariates.

Abstract Number: 1045

Composition of Phospholipid Fatty Acids in Erythrocyte Membranes from Patients with Ankylosing Spondylitis

Junming Chen, Xuechan Huang, Qidang Huang, Zhixiang Huang, Yukai Huang, Yuqi Liu, Lixin Huang, Shanmiao Sun, Zhuyi ji and Tianwang Li, Guangdong Second Provincial General Hospital, Guangzhou, China (People's Republic)

SESSION INFORMATION
Session Date: Monday, November 8, 2021
Session Title: Epidemiology & Public Health Poster III: Other Rheumatic & Musculoskeletal Diseases (1022–1060)
Session Type: Poster Session C
Session Time: 8:30AM–10:30AM

Background/Purpose: To investigate the composition of phospholipid fatty acids in erythrocyte membranes from patients with ankylosing spondylitis (AS), and determine the correlations between the percentage of fatty acids and inflammation level, disease activity and functional capacity in a cross-sectional study.

Methods: Fatty acids in erythrocyte membranes of 20 healthy subjects and 59 patients with AS, who fulfilled the modified New York criteria, were measured using gas chromatography-mass spectrometric (GC-MS). Inflammation level was measured by the erythrocyte sedimentation rate (ESR) and C-reactive protein (CRP). Disease activity was quantified using Bath Ankylosing Spondylitis Disease Activity Index (BASDAI) and Ankylosing Spondylitis Disease Activity Score (ASDAS), and functional capacity was Bath Ankylosing Spondylitis Functional Index (BASFI).

Results: Lower docosahexaenoic acid (DHA) and higher palmitic acid and dihomo-γ-linolenic acid (DGLA) were found in erythrocyte membranes from patients with AS compared with healthy subjects (Table 1). There were negative correlations of palmitic acid with BASDAI and BASFI ($r=-0.38$ and $r=-0.36$, respectively, $p<0.05$; Table 2), and there were positive correlations of DGLA with ESR, CRP and ASDAS ($r=0.36$, $r=0.35$ and 0.47, respectively, $p<0.05$). DHA was negatively correlated to ESR and CRP ($r=-0.38$ and $r=-0.35$, respectively, $p<0.05$).

Table 1. Composition of phospholipid fatty acids in erythrocyte membranes from 20 healthy controls and 59 patients with ankylosing spondylitis

Risk of Ocular Comorbidities and Blindness Among Patients with Behçet's Disease: A Nationwide Population-based Cohort Study in Korea

SE RIM CHOI[1], Anna Shin[2], Joo Young Shin[3], Hokyung Choung[3], You-Jung Ha[2], Yun Jong Lee[4], Eun bong Lee[1], Jin Kyun Park[1] and Eun Ha Kang[2], [1]Seoul National University Hospital, Seoul, Republic of Korea, [2]Division of Rheumatology, Department of Internal Medicine, Seoul National University Bundang Hospital, Seongnam, Republic of Korea, [3]Department of Ophthalmology, Seoul National University College of Medicine, SMG-SNU Boramae Medical Center, Seoul, Republic of Korea, [4]Seoul National University Bundang Hospital, Seongnam-si, Republic of Korea

SESSION INFORMATION
Session Date: Monday, November 8, 2021
Session Title: Epidemiology & Public Health Poster III: Other Rheumatic & Musculoskeletal Diseases (1022–1060)
Session Type: Poster Session C
Session Time: 8:30AM–10:30AM

Background/Purpose: To examine the risk of ocular comorbidities in a nation-wide cohort of patients with Behçet's disease (BD) compared to general population in Korea.

Methods: We conducted a population-based cohort study using 2002-2017 Korean National Health Insurance Service database to examine the risk of diverse ocular comorbidities associated with BD compared to general population. Patients with BD and controls were matched on age and sex at a ratio of 1:5. The primary outcome was blindness. Secondary outcomes were uveitis, and surgical procedure requiring cataract, glaucoma, or retinal diseases. Cox proportional hazard ratio models were used to estimate the hazard ratios (HRs) and 95% confidence interval (CIs) for the outcomes comparing BD patients and controls.

Results: A total of 32,288 BD patients and 161,440 controls were included in the study. During a mean 9.38 years of follow-up, the incidence rate per 100 person-years was 0.12 in the BD group and 0.025 in the control group, respectively. The corresponding HR (95% CI) for the primary outcome was 4.92 (4.27 to 5.69). The risk of all secondary

Peripheral retinal degeneration	14	303,013	0.01 (0.002–0.007)	36	1,550,497	0.002 (0.002–0.003)	2.03 (1.10–3.77)

* The hazard ratios represent the risk for Behçet's disease patients relative to controls.

outcomes was significantly elevated among the patients with BD, with the HR (95% CI) of 6.23 (5.97 to 6.51) for uveitis, 1.80 (1.72 to 1.87) for cataract, 5.20 (4.40 to 6.14) for glaucoma, and 2.55 (2.26 to 2.88) for retinal disorders.

Conclusion: This large population-based study showed that BD patients were at higher risk of diverse ocular comorbidities compared to the general population. In particular, the risk of low vision including blindness was the 4.92 tim es.

SESSION INFORMATION

Session Date: Monday, November 8, 2021

Session Title: Epidemiology & Public Health Poster III: Other Rheumatic & Musculoskeletal Diseases (1022–1060)

Session Type: Poster Session C

Session Time: 8:30AM–10:30AM

Background/Purpose: The etiology of many IMD is largely unknown; however, available data suggest that environmental contaminants could play a role in their origin. Industrial facilities are sources of exposure to pollutants in general population. Their possible association with IMD has not been studied.

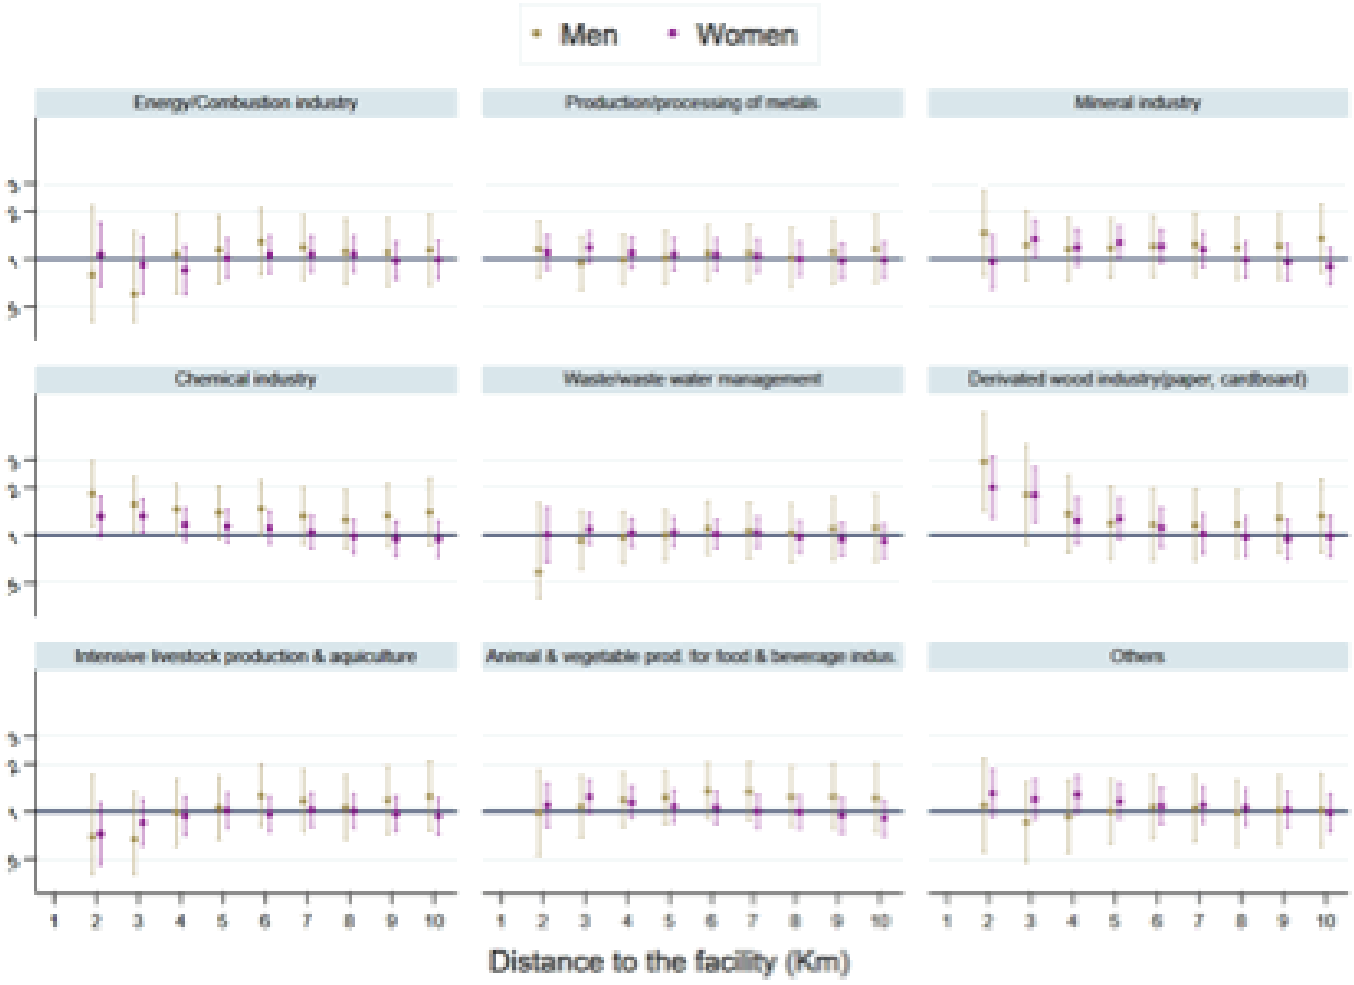

Figure 1. Mortality due to SSc related to distance of industries.

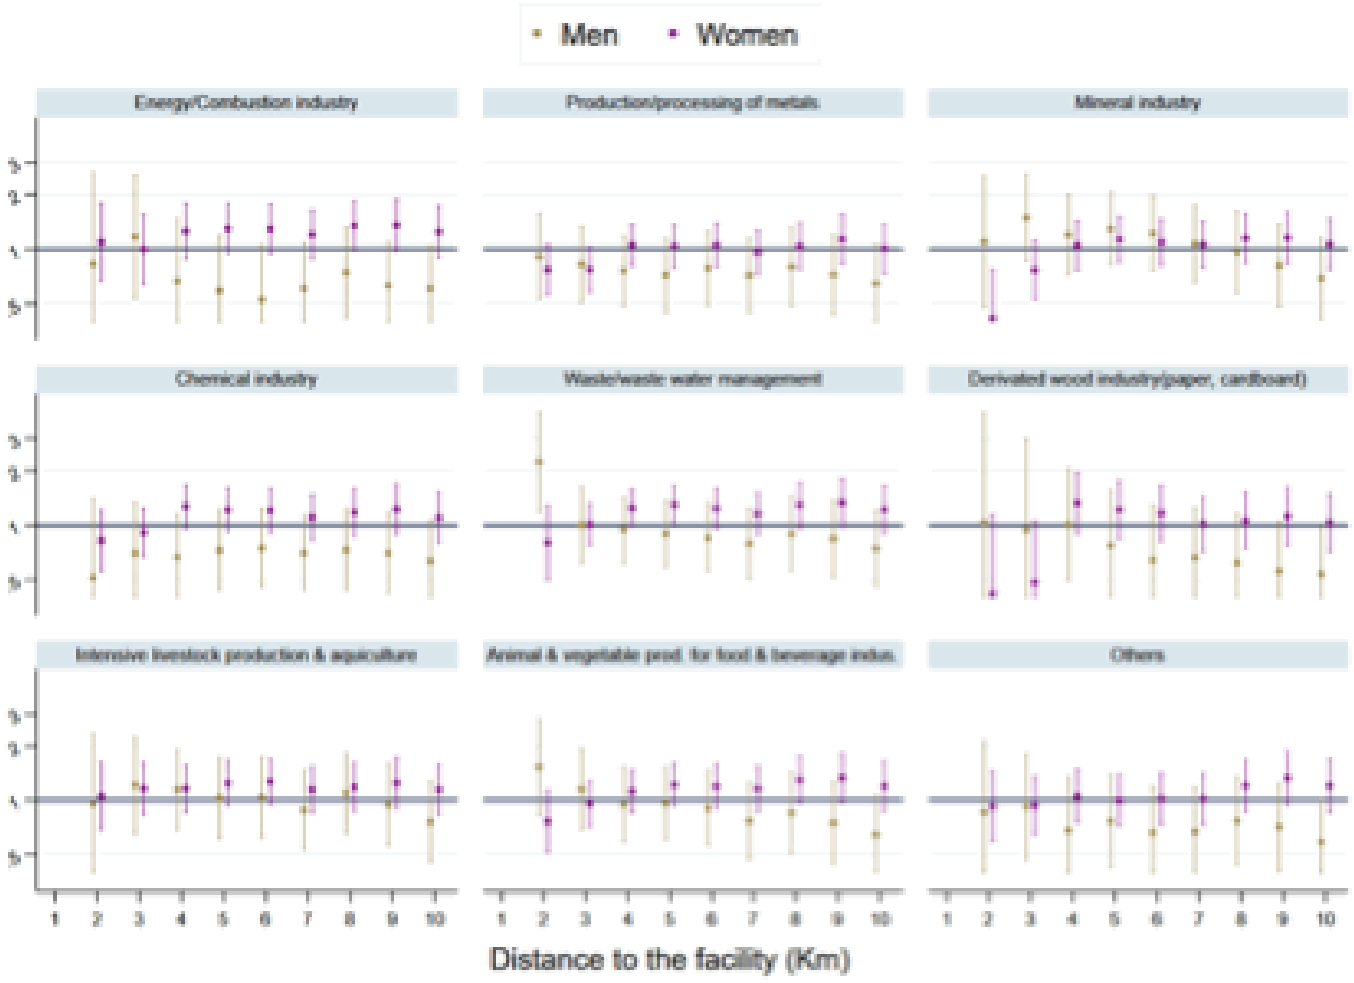

Figure 2. Mortality due to SLE related to distance of industries.

Our purpose was to study whether mortality due to SSc/SLE/Systemic Vasculitis is related to the exposure to environmental pollutants of industrial origin in Spain.

Methods: We obtained mortality due to SSc/SLE/Vasculitis & population data (2005-2014) for each municipality in Spain (8097 towns) from the National Institute of Statistics, & estimated the sex-specific age-adjusted expected deaths with Spain as reference. We collected the coordinates of a) the center of each town; and b) the industrial facilities included in the *Spanish Register of Emissions and Pollutant Sources* (https://prtr-es.es/). Then, we created concentric sectors of different radius (2-10 km) around the pollutant sources to define municipalities' exposure to industrial pollution based on the distance of their population centers to the facilities. Relative risks (RR) between exposed & unexposed municipalities were estimated with Bayesian conditional autoregressive models, using the "Integrated nested approximations" method as inference method (R-INLA library, R statistical program)

Results: SYSTEMIC SCLEROSIS (Figure 1): In both sexes, the highest risks of death due to SSc were found in the vicinity of chemical industries (RR_{men} at 2 km:1.82; 95%CI:1.13-2.94, RR_{women}:1.31;95%CI: 0.98-1.77) and near of paper and wood processing facilities (RR_{men} at 2 km:2.92; 95%CI:1.42-6.00, RR_{women}:2.00; 95%CI:1.28-3.14). In addition, they decreased with increasing distance of the pollutant sources. A less marked association was also found for males with mining industry (RR at 2km:1.21; 95%CI:0.73-2.02).

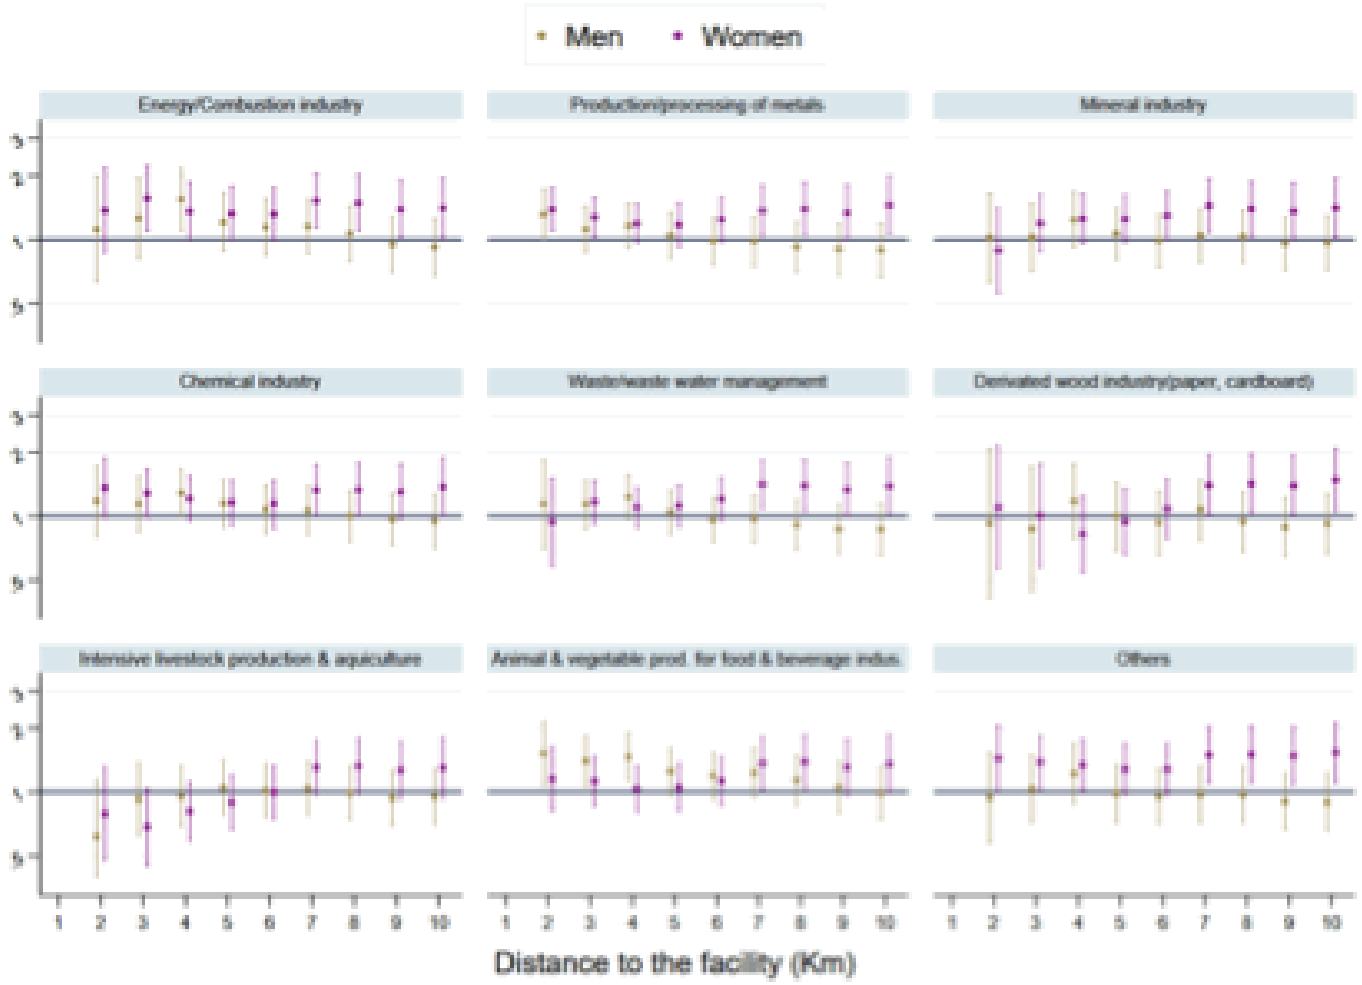

Figure 3. Mortality due to Vasculitis related to distance of industries.

SYSTEMIC LUPUS (Figure 2): In women we did not observe any association; however, in men, there were three sectors with high risks in the closeness of the industries that decreased progressively when moving away: mining facilities (RR at 3 km: 1.50; 95%CI:0.87-2.59), those related to resource and wastewater management (RR at 2 km: 2.23; 95%CI:1.18-4.19) and food industry (RR at 2 km 1.51;95%CI: 0.82-2.78).

SYSTEMIC VASCULITIS (Figure 3): In women, high risk of death was found in the industries of energy & combustion (RR at 2 km:1.38; 95%CI:0.87-2.23), metal processing (RR:1.39; 95%CI:1.10-1.76), chemical (RR:1.36; 95%CI:0.99-1.89) & "other activities" (related to use of organic solvents) (RR: 1.44; 95%CI: 1.01-2.06), but they did not decrease clearly with the distance. For men, there were high RR in the metal (RR:1.32;95%CI:1.00-1.73) and food industries (RR:1.51; 95%CI:1.08-2.14), which decreased with distance from the emitting source.

Conclusion: Residing in the vicinity of certain industries might be a risk factor for dying due to SSc/SLE/Systemic Vasculitis. These results support the possible role of environmental pollution in the origin of these diseases. However, these ecological studies are only exploratory; their results should be confirmed with other studies.

SESSION INFORMATION

Session Date: Monday, November 8, 2021

Session Title: Epidemiology & Public Health Poster III: Other Rheumatic & Musculoskeletal Diseases (1022–1060)

Session Type: Poster Session C

Session Time: 8:30AM–10:30AM

Background/Purpose: Classical statistics provide information on mortality rates for basic causes of death. Although many inflammatory rheumatic diseases decrease life expectancy, they are generally not a direct cause of death. Since 2016, the Spanish Institute of Statistics provides information on all causes appearing on certificates, in addition to the basic one; this may help to estimate the real burden of this group of diseases on mortality in Spain.

Methods: Population estimates and individual death records for inflammatory rheumatic diseases [ICD10 M05-14; M30-36; M45-46] for 2016-2018 were available from the National Institute of Statistics. We calculated age-adjusted mortality rates by sex and by age group (0-44, 45-64 and ≥ 65) a) using only the basic cause (BC) (Table 1); and b) using the certificates in which these diseases appear anywhere, either as a basic, immediate, intermediate or

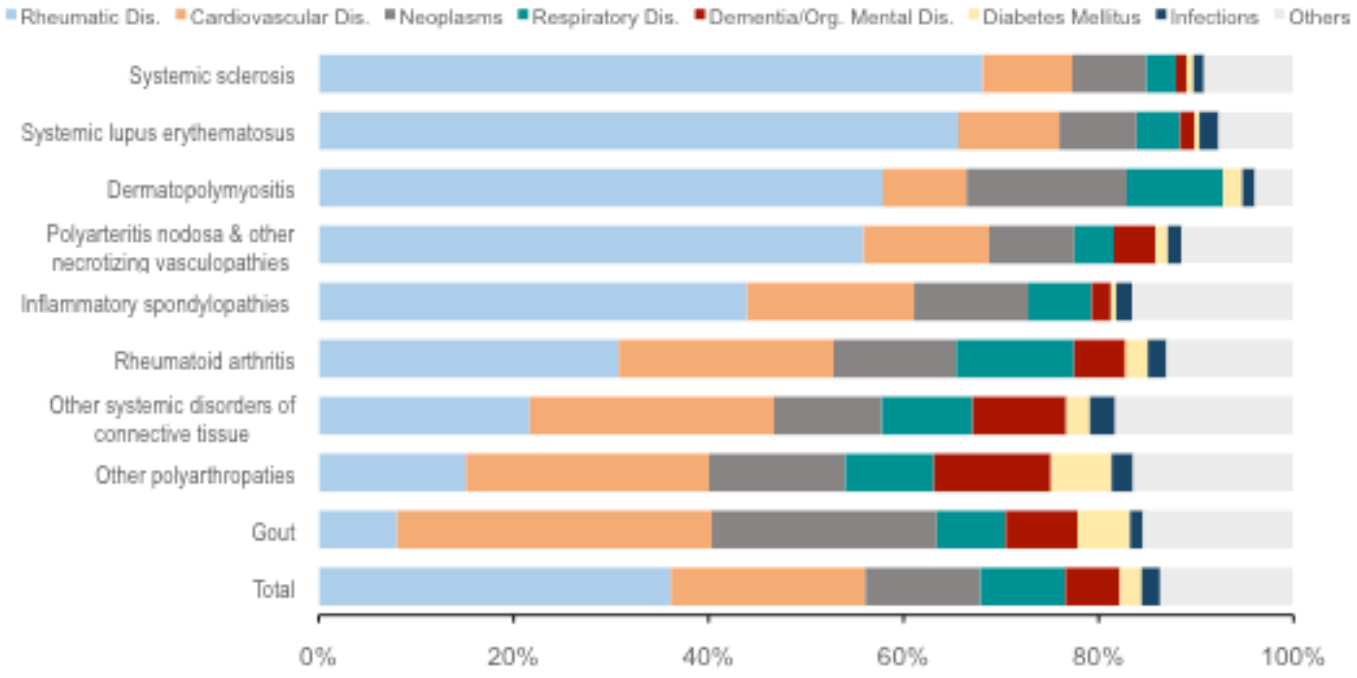

Figure 1. Basic cause of death among deceases registering inflammatory rheumatic diseases in the death certificate. Spain, 2016-2018.

* WHO World Standard Population 2001

fundamental cause (MCD) (Table 1). In the latter case, we also describe which are the non-rheumatic basic causes of death in the certificates mentioning rheumatic pathology (Figure1).

Results: Inflammatory rheumatic syndromes appeared in 6998 death certificates (2333 annual average, 63% women), although BC were considered in only 36% of them (833 deaths per year; 66% women), with age-adjusted mortality rates for MDC and BC of 1.56 and 0.64 deaths/100,000 inhabitants, respectively. In the certificates mentioning rheumatic pathology (MCD) in which this was not the basic cause, death was mainly attributed to cardiovascular disease (20%), cancer (12%) and respiratory diseases (10%).

Within age groups, the adjusted rate of MDC for deaths in those under 45 years of age was 0.17 per 100,000 (0.12 as a basic cause); 1.76 for the 45 to 64 range (0.85 as a basic cause); and 17.54 for those over 64 years of age (6.14 as a basic cause). Overall, the rates in women were somewhat higher, although the main differences between sexes were observed in systemic sclerosis and lupus (almost three times more frequent in women) and in spondyloarthritis (in which the male rates were double those of women). Rheumatoid arthritis, as expected, had the highest mortality in both sexes, with adjusted rates based on MDC more than three times higher than those calculated with BC alone (MDC: 0.56/100,000; BC: 0.17/100,000). The change in rates using MDC is rather less marked in the more aggressive entities, such as systemic sclerosis or systemic lupus erythematosus, and especially in deaths in persons younger than 45 years. In these subgroups, rheumatologic diseases are the basic cause of death in almost two thirds of the certificates in which they appear, and in almost 90% if we are talking about deaths in young people with systemic sclerosis.

Conclusion: At the population level, these syndromes have a non-negligible importance in terms of mortality, which is underestimated in the classic mortality statistics, based only on basic causes. The underestimation is less in the more severe rheumatologic processes. The rates provided here probably portray a picture closer to reality of the burden that these diseases represent in Spanish mortality.

Abstract Number: 1049

Multimorbidity Differences Between Systemic Lupus Erythematosus Patients and Comparators in Different Age Groups: A Large Nationwide US Study

Ali Duarte-Garcia[1], Herbert Heien[1], Nilay Shah[1] and Cynthia Crowson[2], [1]Mayo Clinic, Rochester, MN, [2]Mayo Clinic, Eyota, MN

SESSION INFORMATION
Session Date: Monday, November 8, 2021
Session Title: Epidemiology & Public Health Poster III: Other Rheumatic & Musculoskeletal Diseases (1022–1060)
Session Type: Poster Session C
Session Time: 8:30AM–10:30AM

Background/Purpose: Patients with Systemic Lupus Erythematosus (SLE) have an increased burden of multimorbidity. Age is strongly associated with accumulation of comorbidities. Patients with SLE may experience multimorbidity at younger ages than their non-SLE controls due to exposure to toxic treatments, disease activity or accelerated aging. We aimed to compare multimorbidity among different age groups of patients with SLE and comparators without SLE.

Methods: We used the OptumLabs Data Warehouse (OLDW), a real-world data asset with de-identified administrative claims to identify cases of SLE and matched comparators. Cases were defined as patients with ≥3 diagnoses of SLE between 1/2006 and 9/2015. Comparators were persons without SLE matched 1:1 on age, sex, race/ethnicity, and enrollment date. Race was classified as White, Black, Asian and Hispanic. Multimorbidity (2 or more comorbidities) was defined using 172 chronic comorbidities from the chronic condition indicator of the clinical classification software (healthcare cost and utilization project). Two or more ICD-9 codes at least 30 days apart were used to define a comorbidity. SLE, cutaneous lupus, and rheumatoid arthritis codes were excluded from the analysis. A secondary analysis was performed including those with 5 or more comorbidities. Conditional logistic regression models were used to estimate odds ratios (OR) with 95% confidence intervals (CI) adjusted for region.

Results: 34,752 cases with SLE and 34,752 matched non-SLE comparators were included. Mean age was 48 (SD 14.2) years, and 90.6% were female for both cohorts. 66.4% of the patients in both cohorts were White, 18.4% Black, 3.4% Asian and 18.4% Hispanic. 1.3% of patients were < 18 years old; 17% 8-34; 21.3% 35-44; 27.1% 45-54; 22.1% 55-64 and 11.2% >65 years. Patients with SLE had more multimorbidity than non-SLE subjects (58.1% vs 26.3%). Multimorbidity increased with age in both cohorts (**figure**). Multimorbidity differences between SLE and non-SLE were present throughout all the age groups, in general patients with SLE compared to non-SLE had a difference of 27-34% in the prevalence of multimorbidity on all age groups except those age >65 where the difference was 23%. Young patients with SLE had a multimorbidity burden similar to non-SLE comparators who were three decades older (SLE 18-34, 35.95%, non-SLE 55-64, 37.58%). Young patients with SLE were 6-9 times as likely to suffer from multimorbidity compared to matched non-SLE patients in the same age group (**table**), these differences decreased in older age groups but persisted even in those SLE patients that were >65 (OR 3.5, 95%CI 3.12-3.90). Secondary analysis on patients with 5 or more comorbid conditions showed similar findings (**figure and table**).

Conclusion: This large nationwide study showed increased occurrence of multimorbidity in SLE versus non-SLE patients, with substantial burden of multimorbidity through all age groups and even persistent during elderhood. Young

Figure. Prevalence of multimorbidity by age groups in SLE and non-SLE patients. Top panel, 2 or more comorbidities. Bottom panel, 5 or more comorbidities.

patients with lupus have a multimorbidity burden of similar to individuals 3 decades older. This study highlights the striking comorbidity burden patients with lupus endure. The effects of multimorbidity on compliance, healthcare burden and outcomes deserve further research.

Table. Comparison of multimorbidity prevalence by age group between patients with SLE and non SLE		
	Multimorbidity (2+ conditions) Odds ratio*	Multimorbidity (5+ conditions) odds ratio*

SESSION INFORMATION

Session Date: Monday, November 8, 2021

Session Title: Epidemiology & Public Health Poster III: Other Rheumatic & Musculoskeletal Diseases (1022–1060)

Session Type: Poster Session C

Session Time: 8:30AM–10:30AM

Background/Purpose: Ophthalmological involvement is one of the most feared manifestations of Behçet's disease. The aim of this study was to define the main demographic and clinical features of ophthalmological involvement in a well-defined cohort of patients with Behçet's disease.

Methods: Descriptive study of a cohort of 120 patients diagnosed with Behçet's disease from January 1, 1980 to December 31, 2019. Finally, following the 2014 International Criteria for Behçet's Disease (ICBD) (J Eur Acad Dermatol Venereol 2014; 28:338-47) 94 patients were chosen for this study.

Results: 50 patients (28 men/22 women; male to female ratio of 1:0.8) had ocular involvement. Mean age at diagnosis was 37.6±11.8 years. Mean ICBD score was 5.8±1.3 points. Neurological involvement was the most frequent

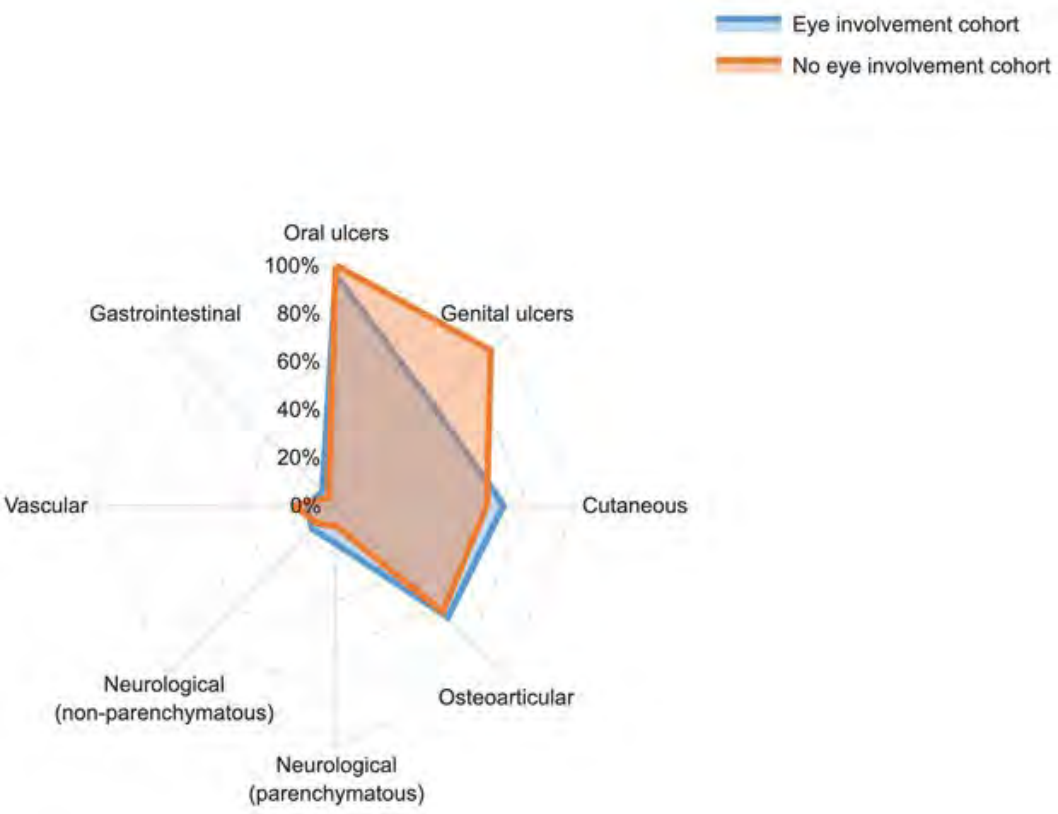

Figure. Comparison between clinical domains in patients with and without ophthalmological involvement.

Table. Clinical characteristics of ocular Behçet's disease

	n (%)	Unilateral, n (%)	Bilateral, n (%)
Uveitis	44 (88.0)	26 (59.1)	18 (40.9)
Anterior	17 (38.6)	13 (76.5)	4 (23.5)
Intermediate	2 (4.5)	-	2 (100)
Posterior	14 (31.8)	9 (64.3)	5 (35.7)
Panuveitis	11 (25.0)	4 (36.4)	7 (73.6)
Retinal vasculitis	5 (10.0)	-	-
Dry eye	5 (10.0)	-	-
Cystoid macular edema	4 (8.0)	-	-
Episcleritis	3 (6.0)	3 (100)	-
Optic neuritis	2 (4.0)	-	-

manifestation in this group. Genital ulcers were more frequent in the non-ophthalmological involvement group. Systemic clinical domains are shown in **Figure**.

The most frequent ocular manifestations were uveitis (n=44, 88.0%), retinal vasculitis (n=5, 10%) and dry eye (n=5, 10%). Likewise, the most frequent type of uveitis was anterior (n=17, 38.6%), followed by posterior uveitis (n=14, 31.8%). 26 (59.1%) of all uveitis were unilateral. Panuveitis was more frequent among patients under 60 years. Similarly, anterior uveitis was predominant in patients older than 70 years. There were no remarkable differences between genders. Main clinical features are shown in **Table**.

Conclusion: Ophthalmological involvement in Behçet's disease was more frequent in men. Uveitis and retinal vasculitis were the most frequent ocular manifestation. No remarkable differences in clinical features were observed between genders.

Variance of Joint Space Width Across the Tibiofemoral Joint on Knee Radiographs: A Novel Measure of Structure and Progression

Kent Kwoh[1], Erin Ashbeck[2], Edward Bedrick[1], Xiaoxiao Sun[1] and Jeffrey Duryea[3], [1]University of Arizona, Tucson, AZ, [2]University of Arizona Arthritis Center, Tucson, AZ, [3]Brigham and Women's Hospital, Boston, MA

SESSION INFORMATION
Session Date: Monday, November 8, 2021
Session Title: Epidemiology & Public Health Poster III: Other Rheumatic & Musculoskeletal Diseases (1022–1060)
Session Type: Poster Session C
Session Time: 8:30AM–10:30AM

Background/Purpose: The FDA accepts medial minimum joint space width (mJSW) in the tibiofemoral (TF) compartment as the standard for structural change in clinical trials of potential disease modifying OA drugs (DMOADs) for knee osteoarthritis (OA). Historical and novel imaging biomarkers of knee OA should be investigated in terms of their ability to predict clinically important outcomes. Quantitative radiographic OA scores (QROS), software developed to read fixed-flexion knee radiographs based on an anatomical coordinate system, generates medial mJSW and other quantitative measures. Our objective was to compare the clinical relevance of QROS-generated radiographic measurements based on their contributions to predicting time to knee replacement, and to assess a novel measure of structure, variance of JSW across the TF joint.

Methods: We selected knees with a baseline radiograph graded Kellgren-Lawrence (KL) 2 or 3 and QROS assessment at baseline and year 2, from the Osteoarthritis Initiative, a longitudinal observational study. QROS was used to measure medial mJSW and corresponding location, JSW measured at fixed locations across the joint (Figure 1), femoral tibial angle, width of the femoral condyles, distance from the tibial plateau to the tibial rim closest to the femoral condyle as a measure of knee positioning, and x-ray beam angle. We calculated the variance of fixed JSW measurements across the joint. Participants reported knee replacements up to 10 years following the year 2 clinic visit, confirmed by medical records and/or radiographs.

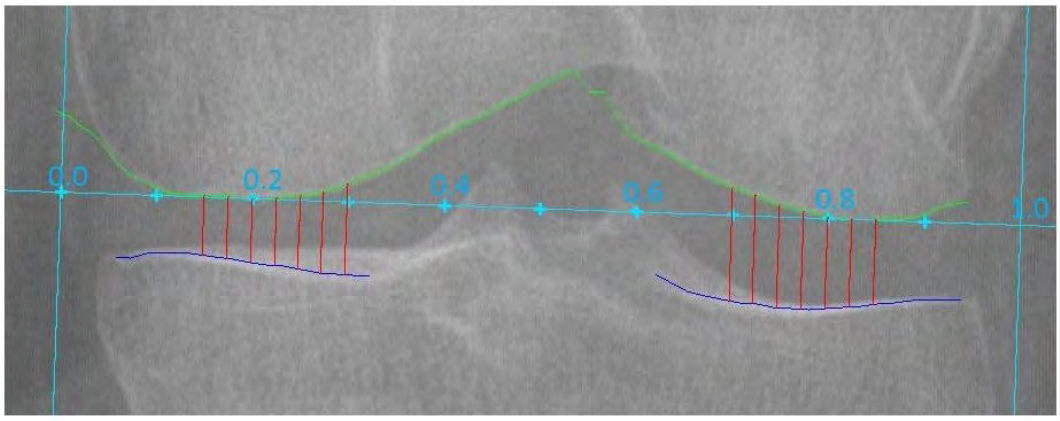

Figure 1. Fixed-location joint space width (JSW) measurements provided by quantitative radiographic OA scores (QROS) software. The variance of fixed-location JSW across the tibiofemoral joint (TF) may reflect degree of bone curvature, asymmetry of cartilage thickness in the TF joint, and/or uneven joint loading.

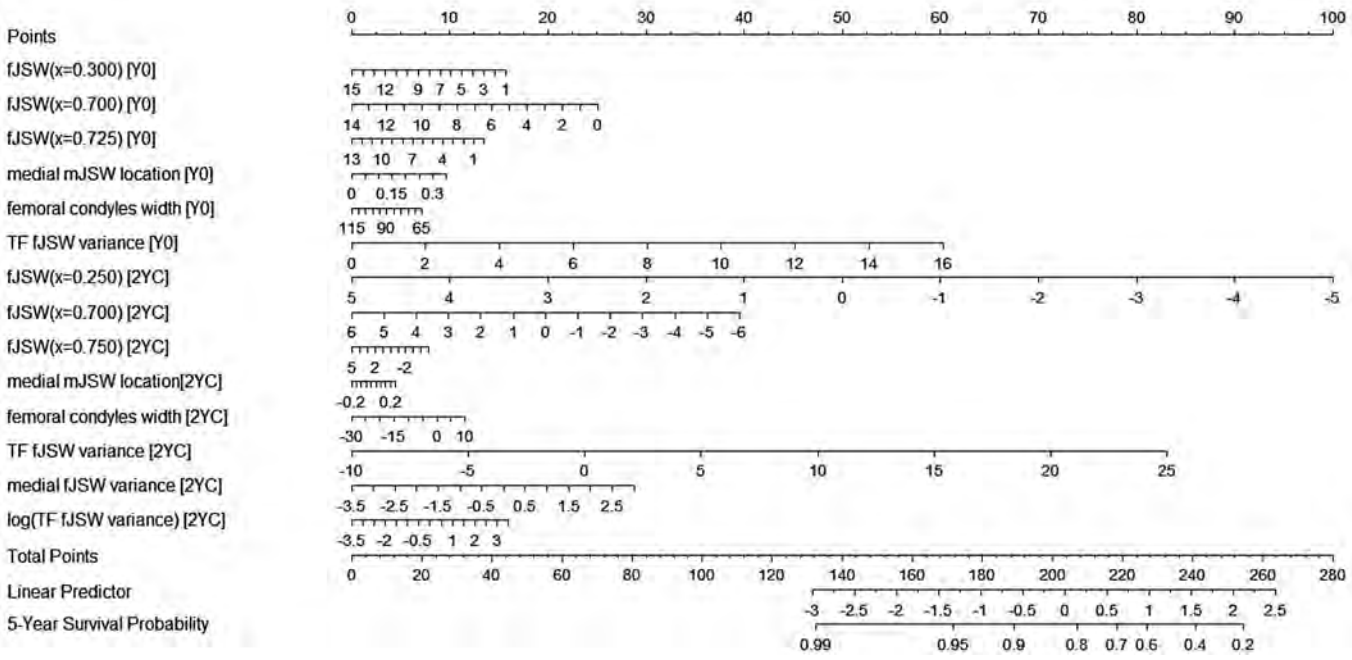

Figure 2. QROS predictors of 5-year survival. Nomogram visualization of exploratory analysis shows model-based points for lasso-selected predictors and mapping between total points and 5-year probability of survival from knee replacement. Y0 indicates OAI year 0 (baseline), and 2YC indicates 2-year change (from baseline to year 2).

We fit lasso penalized Cox models, including baseline measurements and change over 2 years, selecting the penalty parameter that achieved a partial log-likelihood deviance within one standard error of the minimum in 10-fold cross validation. Technical problems prevented some measurements in up to 9% of knees; we used multivariate imputation by chained equations to account for uncertainty in missing values. Model discrimination was evaluated with a bootstrap estimate of the time-dependent area under the receiver operating characteristic curve (AUC), and model calibration was visually inspected by plotting predicted versus observed survival probabilities.

Results: The sample included 3,082 KL 2,3 knees with 327 knee replacement outcomes over a median of 6.9 years, contributed by 2,101 participants. Lasso-selected predictors of time to knee replacement are shown in Figure 2. Important predictors included baseline and 2-year change of fJSW at specific locations in the TF joint, baseline and 2-

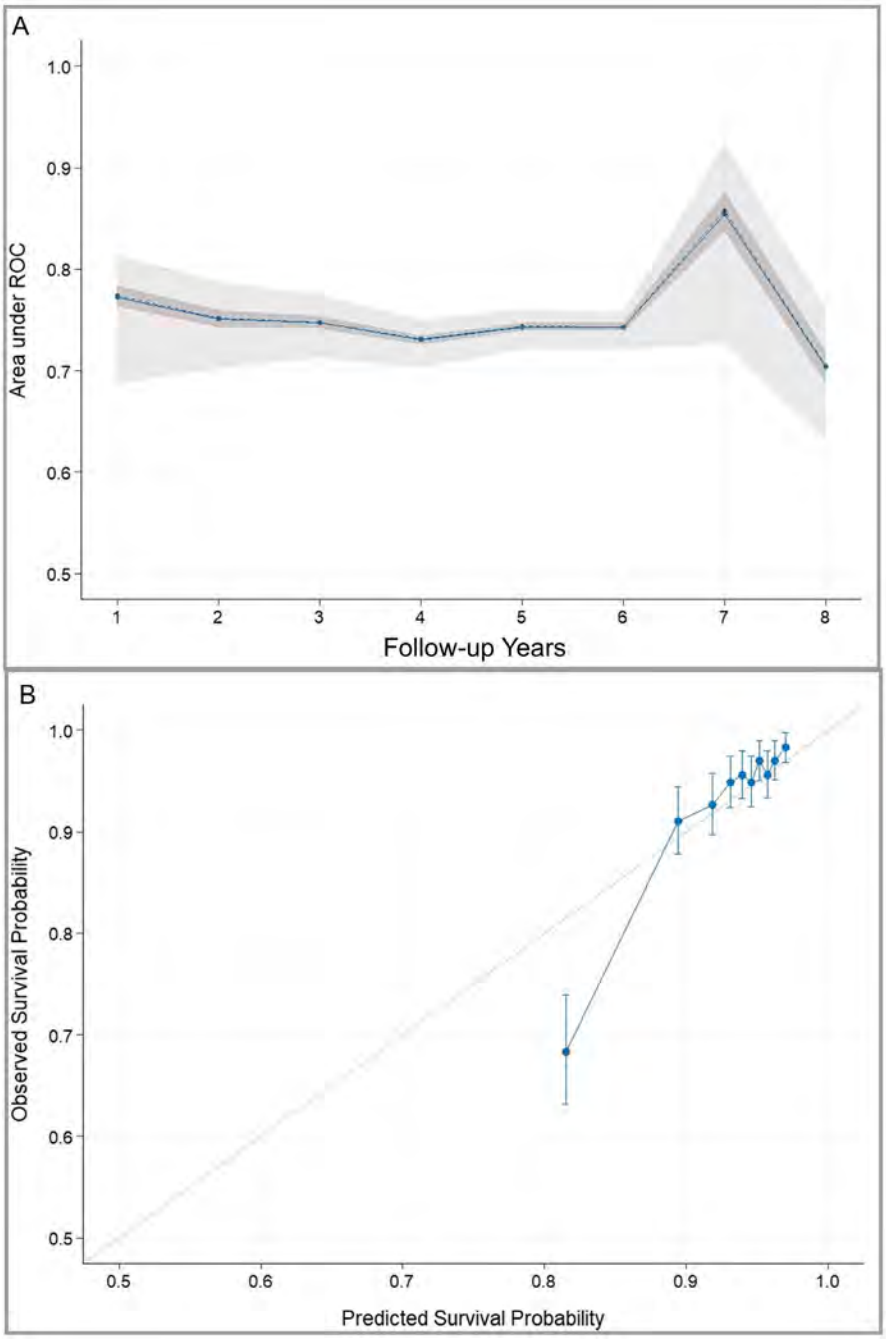

Figure 3. Model Performance. A) Discrimination: Time-dependent area under the receiver operating characteristic curve (AUC), estimated with a bootstrap. The darker interval in the plot shows the 25% and 75% quantiles and the lighter interval shows the minimum and maximum AUC from the bootstrap samples. B) Calibration: Predicted vs observed knee replacement survival at 5 years of follow-up, in 10 model-based risk groups. Bars represent 95%CI for survival probability estimated by Kaplan-Meier method.

year change of TF fJSW variance, baseline and 2-year change of medial mJSW location as well as 8 other variables. Model performance, as summarized by model discrimination and model calibration, is shown in Figure 3.

Conclusion: We developed an innovative measure of knee OA structure and progression, TF fJSW variance, which may reflect degree of bone curvature, asymmetry of cartilage thickness, and/or uneven joint loading. Baseline and 2-year change of TF fJSW variance, as well as other quantitative measures from QROS, were identified as important predictors of time to knee replacement. Further work needs to be done to validate TF fJSW variance as a potential imaging biomarker of knee OA progression.

Female Reproductive Factors and Risk of Joint Replacement Arthroplasty of the Knee and Hip Due to Osteoarthritis in Postmenopausal Women: A Nationwide Cohort Study of 1.36 Million Women

Yeonghee Eun[1], Jung Eun Yoo[2], Kyungdo Han[3], Dahye Kim[3], Jaejoon Lee[1], Dong-Yun Lee[1], Dae-Hee Lee[1], Dong Wook Shin[1] and Hyungjin Kim[1], [1]Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul, Republic of Korea, [2]Healthcare System Gangnam Center, Seoul National University Hospital, Seoul, Republic of Korea, [3]Soongsil University, Seoul, Republic of Korea

SESSION INFORMATION
Session Date: Monday, November 8, 2021
Session Title: Epidemiology & Public Health Poster III: Other Rheumatic & Musculoskeletal Diseases (1022–1060)
Session Type: Poster Session C
Session Time: 8:30AM–10:30AM

Background/Purpose: Previous studies of the relationships between female reproductive factors and osteoarthritis (OA) have shown conflicting results. In this study, we aimed to explore the relationships between reproductive factors and joint replacement arthroplasty of the knee (TKRA) and hip (THRA) in a large nationwide population-based cohort of postmenopausal Korean women.

Methods: We included 1,218,257 subjects who participated in national health examinations in 2009 in the study. The study outcomes were incident THRA or TKRA due to severe hip or knee OA. The relationships between reproductive factors and THRA or TKRA were evaluated using a multivariate-adjusted proportional hazards model.

Results: During a mean follow-up duration of 8.2 years, 1,733 incident THRA cases and 65,108 incident TKRA cases were observed. Later age at menarche, longer breastfeeding, HRT and OC use were associated with increased risk of TKRA for severe knee OA, while later age at menopause and longer reproductive span were associated with decreased risk. With regard to THRA for severe hip OA, later menarche, longer breastfeeding, and HRT more than 5 years were associated with higher risk. The associations between reproductive factors and severe OA were more pronounced in underweight and younger subjects.

Conclusion: We found that shorter estrogen exposure was associated with higher risk of joint replacement therapy due to severe OA, and such associations were more pronounced in underweight and younger subjects.

Temporal Trends and Geographic Variations of Premature Mortality Related to Musculoskeletal(MSK) and Connective Tissue Disorders in the United States: A 20-Year Analysis from WONDER Database

Ikwinder Kaur[1], Mohsin Mughal[2], Hasan Mirza[3], Harjot Jagdey[4], Pankaj Bansal[5], Eugenio Capitle[6] and Fawad Aslam[7], [1]Monmouth Medical Center, an affiliate of Rutgers health system, Long Branch, NJ, [2]Monmouth Medical Center, Long Branch, NJ, [3]Berkshire Medical Center, Pittsfield, MA, [4]BronxCare Hospital, Bronx, NY, [5]Mayo Clinic Health System, Eau Claire, WI, [6]Rutgers New Jersey Medical School, New Brunswick, NJ, [7]Mayo Clinic College of Medicine, Scottsdale, AZ

SESSION INFORMATION
Session Date: Monday, November 8, 2021
Session Title: Epidemiology & Public Health Poster III: Other Rheumatic & Musculoskeletal Diseases (1022–1060)
Session Type: Poster Session C
Session Time: 8:30AM–10:30AM

Background/Purpose: Musculoskeletal system and connective tissue disorders (arthropathies, systemic connective tissue disorders, soft tissue disorders) may contribute to premature mortality likely due to associated comorbidities related to disease and treatment. Worldwide MSK-related mortality rate showed a downward trajectory between 1986 and 1997, an uptrend till 2001, again followed by a decrease thereafter in both sexes (1). However, data regarding premature MSK-related mortality is lacking. We sought to analyze the temporal trends and geographical variations of MSK-related premature mortality (age ≤ 65 years) over the last 20 years in the United States (U.S.). We hypothesized that increased surveillance, early diagnosis or improvement of treatment, and increased survival would have led to a downward trend in premature mortality during the last two decades.

Methods: Death certificate data were retrieved from the Centers for Disease Control and Prevention's Wide-Ranging Online Data for Epidemiologic Research (WONDER) database for 1999-2018. WONDER database is publicly available de-identified data collected by CDC that reports the underlying cause of death across the United States. Premature mortality, for MSK and connective tissue disease (ICD-10 code M00-M99) as an underlying cause of death, for age<

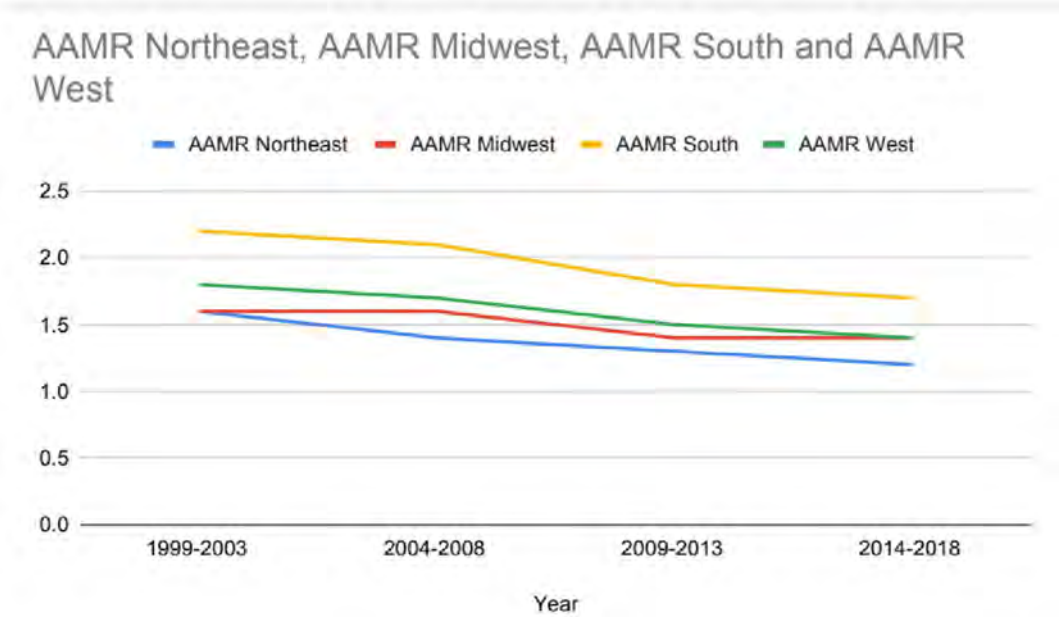

Figure 1. Illustrates temporal trends and regional MSK and connective tissue related AAMRs from 1999-2018.

Table 1. Regional age-adjusted MSK and connective tissue related mortality rate in the U.S Census regions

Census region	Year	Deaths	Population	Crude mortality rate	Age adjusted mortality rate (95% CI)	% of total deaths
Northeast CR1	1999-2003	2862	178,310,928	1.6 (1.5-1.7)	1.6 (1.5-1.6)	16.20%

	2009-2013	3,999	245,003,898	1.6 (1.6-1.7)	1.5 (1.4-1.5)	21.90%
	2014-2018	4,064	254,179,315	1.6 (1.5-1.6)	1.4 (1.4-1.5)	22.10%
Overall	1999-2003	17631	944,847,854	1.9 (1.8-1.9)	1.9 (1.8-1.9)	100%
	2004-2008	18,911	1,002,129,870	1.9 (1.9-1.9)	1.8 (1.7-1.8)	100%
	2009-2013	18,257	1,042,268,012	1.8 (1.7-1.8)	1.6 (1.5-1.6)	100%
	2014-2018	18,418	1,064,785,064	1.7 (1.7-1.8)	1.5 (1.5-1.6)	100%

Table 2. All-cause mortality in the United States

Year	All-cause AAMR	Deaths	Population	Crude mortality rate	Age adjusted mortality rate (95% CI)	Standard error for AAMR
1999-2003	300.7	3,602,568	1,158,686,801	310.9	300.7 (300.4 - 301.0)	**0.2**
2004-2008	289.2	3,110,657	1,002,129,870	310.4	289.2 (288.9 - 289.5)	0.2
2009-2013	275.3	3,235,557	1,042,268,012	310.4	275.3 (275.0 - 275.6)	0.2
2014-2018	285.5	3,490,246	1,064,785,064	327.8	285.5 (285.2 - 285.8)	0.2

65 years was queried. This duration was further stratified into five-year periods. Age-adjusted mortality rate (AAMR) per 100,000 population was calculated with 95% CI for the four U.S. census regions (CR1 Northeast, CR2 Midwest, CR3 South, and CR4 West). Figure 1 illustrates the regional trends.

Results: A total of 73,217 premature MSK and connective tissue deaths occurred among individuals aged 15-65 years in the last 20 years. Overall, AAMR per 100,000 deaths declined by 22% during the study period. From 1999-2018 AAMR for Northeast declined from 1.6 to 1.2; for Midwest 1.6 to1.4; for West 1.8 to 1.4; for South 2.2 to 1.7 (Figure-1) Regional AAMR declined by 25% in the Northeast, 22.7% in the South, 22.2% in the West, and 12.5% in Midwest. Table 1 gives Total deaths and crude mortality rates in each region. All-cause AAMR declined (~5%) from 300.7 to 285.5 per 100,000 during 1999 to 2018 (Table 2).

Conclusion: This analysis of nationally representative data shows a decline in the AAMR for premature MSK and connective tissue diseases. Overall and regional AAMR showed a downward trajectory from 1999-2018. Our study underscores the importance of high-quality and evidence-based practices in rheumatology that may have played a significant role in decreasing MSK and connective tissue disorders compared with overall all-cause mortality. The regional disparities in premature mortality among different census regions warrant further investigations. Study limitations include inherent weaknesses of database studies that misclassify the cause of mortality.

SESSION INFORMATION

Session Date: Monday, November 8, 2021

Session Title: Epidemiology & Public Health Poster III: Other Rheumatic & Musculoskeletal Diseases (1022–1060)

Session Type: Poster Session C

Session Time: 8:30AM–10:30AM

Background/Purpose: Patients with rheumatic diseases (RMD) face an increased cardiovascular (CV) mortality compared to the general population. Still, risk stratification based on traditional cardiovascular risk factors fail prediction in these patients. Particular metabolites and lipid homeostasis are of high interest as both are described to play a crucial role in cardiovascular disease (CVD) development.

In this pilot study, we aimed to identify a metabolite profile in patients with systemic lupus erythematodes (SLE), ANCA-associated vasculitis (AAV) or psoriatic arthritis (PsA) that identifies patients at cardiovascular risk, which in future can be adapted and used independently from traditional risk factors.

Methods: Plasma samples of patients with PsA (n=21), AAV (n=16) and SLE (n=16) were analyzed with a combined approach using targeted LC-MS/MS-analysis for low-concentrated lipid mediators, non-targeted LC-HRMS analysis for abundant lipids and the Biocrates MxP Quant 500 Kit a total of 685 metabolites and lipids could be detected. Compounds of interest for discrimination of patients with CV risk were selected using machine-learning with random forest algorithm, whereas 70% of the data was used for training and 30% for testing using stratified randomization. Prior training a Spearman correlation matrix and recursive feature elimination were applied to reduce the number of metabolites.

Included patients had a comparable low disease activity at inclusion with a DAS28-CRP of 2.31±0.9 (PsA), a BVAS of 2.37 ±1.45 (AAV) and a SLEDAI-2K of 2.37±1.96 (SLE). 31 of the 53 included patients had a traditional CV risk factor or a CVD, with a proportion of 22.58% male in patients with CVD and 36.36% in patients without CVD.

Patients with CVD had a mean age of 60.83 years (yrs) ±11.58 and a mean RMD duration of 16.83±12.82 yrs, compared to non-CVD patients with 43.81yrs±9.98 of mean age and 15.61±25.36 yrs of disease duration.

Results: Our machine-learning model can classify patients with and without CVD or CV risk with an accuracy of 86.67% and an ROC-AUC of 0.963 (77.78% sensitivity, 100% specificity). This model based on 14 metabolites including different amino acids, kynurenine, hexoses, acylcarnitine, palmitoyl ethanolamine, phospholipids and trigylcerides.

Conclusion: In this pilot study, we identified a panel of metabolites that can stratify patients with PsA, AAV and SLE based on CVD and traditional CV risk factors with a high sensitivity and specificity. The identified panel and a machine-learning model will be validated in larger cohorts to assess a risk stratification that is independent from traditional CV risk factors. Furthermore, the role of the selected metabolites in the pathophysiology of CVD might help to better understand the complex interaction of pathways leading to CVD development in patients with RMD.

SESSION INFORMATION

Session Date: Monday, November 8, 2021

Session Title: Epidemiology & Public Health Poster III: Other Rheumatic & Musculoskeletal Diseases (1022–1060)

Session Type: Poster Session C

Session Time: 8:30AM–10:30AM

Background/Purpose: The use of online surveys as a recruitment tool for clinical research has increased during the COVID-19 pandemic and will likely continue to expand. However, good practice guidance for investigators and steering committees to optimize their digital recruitment strategies is still needed. The aim of this study was to identify the most effective strategies for digital recruitment (e-recruitment) in an international Arab online study about the perceptions of patients with rheumatic diseases regarding the COVID-19 vaccination.

Methods: This is a post hoc analysis of the ARCOVAX (Arab League of Associations for Rheumatology (ArLAR) COVID Vaccination) study, which included patients with rheumatic diseases and health care professionals (HCPs, serving as a control group). The ARCOVAX questionnaire was an anonymous web survey adapted from the VAXICOV study (Felten et al. Lancet Rheumatol. 2021 Apr;3(4):e243-e245) and disseminated in Arabic, English, and French from April 13th until May 11th, 2021 by an ArLAR special interest group (Arab Adult Arthritis Awareness (AAAA) group), through multiple social media channels. The steering committee conducted 6 different actions to boost recruitment: promoting on social media and WhatsApp groups, sharing recruitment status on AAAA WhatsApp group, sending personalized WhatsApp messages to recruiters, disseminating e-posters and QR codes, addressing recruiters' technical issues (technical support), and announcing count-down for survey closing through a promotional video. The impact of each action was correlated with the number of enrolled participants, first in the whole population then by countries stratified according to the Gross Domestic Product (GDP) level as per the World Bank Classification.

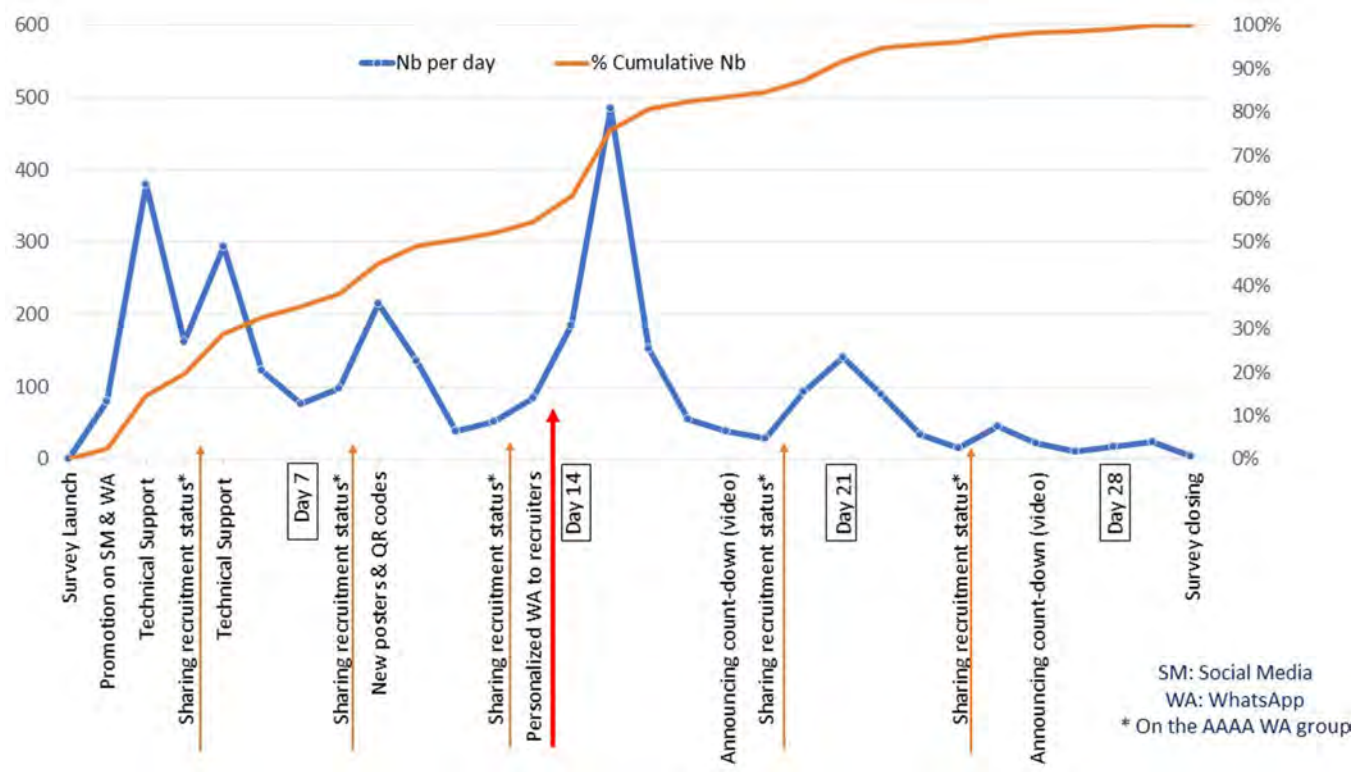

Figure 1. Enrollment of Patients For the e-Survey and Correlation with the Recruitment Strategies.

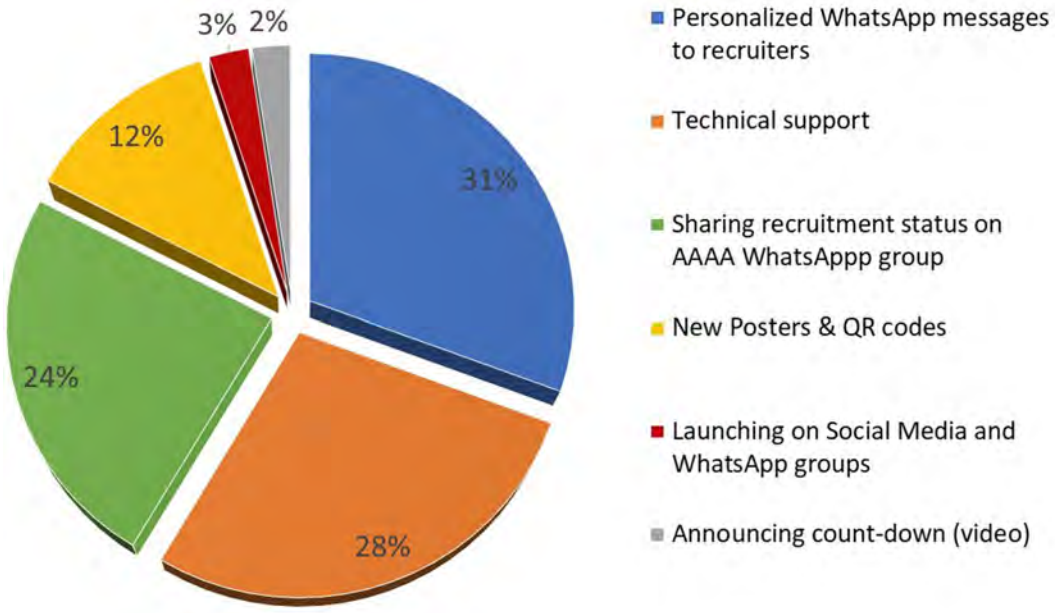

Figure 2. Percentage of recruited participants with regards to the strategy.

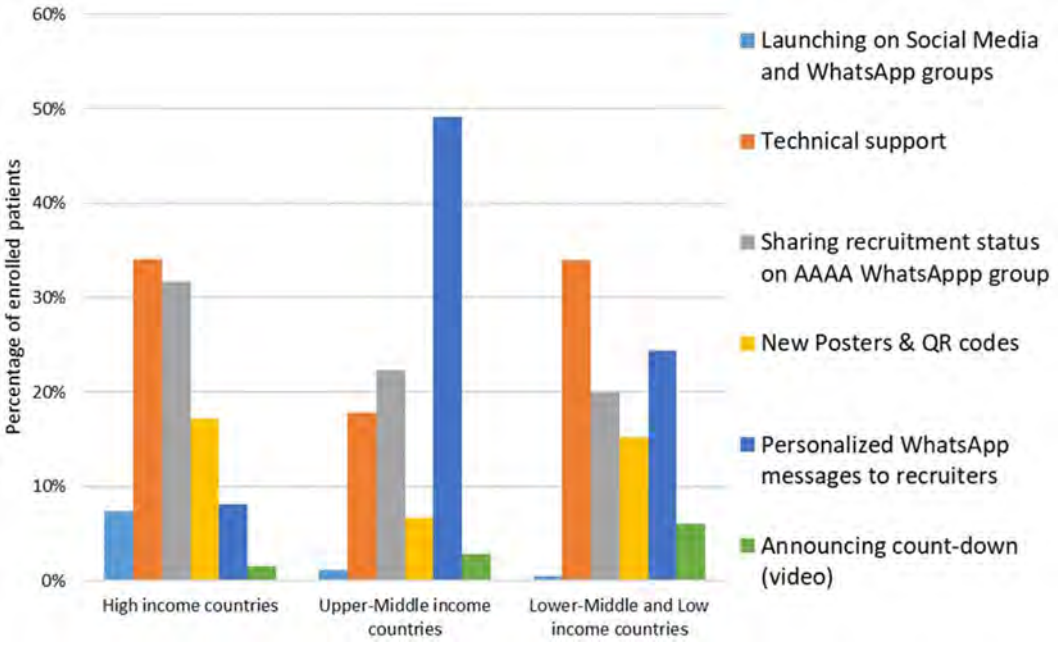

Figure 3. Impact of recruitment strategies on the number of enrolled participants by Gross Domestic Product.

Results: A total of 3,176 participants from 19 Arab countries completed the survey (1,594 patients and 1,517 HCPs). The enrollment of participants was highly fluctuating (Figure 1) and the e-recruitment strategies had different impacts: 31% of participants were recruited after sending personalized WhatsApp messages to recruiters in different countries, 28% after prompt technical support by the steering committee to resolve issues faced by the recruiters, 24% after sharing recruitment status on AAAA WhatsApp group, 12% after disseminating e-posters and QR codes via

social media and WhatsApp groups, 3% after initially launching on social media and WhatsApp groups and 2% after sharing a motivational video announcing the count-down of the last week of recruitment (Figure 2). The impact of these strategies was different according to the countries' GDP level, where technical support and sharing recruitment status had the most impact in high-income countries, and personalized messages resulted in higher recruitment in the upper-middle-income countries (Figure 3).

Conclusion: The most effective strategy was the use of personalized WhatsApp messages to the recruiters. The research team must be active (mobilizing teams to participate), reactive (prompt technical support), and proactive (sharing updates regularly). Further studies are needed to identify the appropriate action for each phase of e-recruitment and for each specific region.

Session Title: Epidemiology & Public Health Poster III: Other Rheumatic & Musculoskeletal Diseases (1022–1060)

Session Type: Poster Session C

Session Time: 8:30AM–10:30AM

Background/Purpose: This study evaluated the patterns of care, access and direct costs related to the management and treatment of patients with systemic lupus erythematosus (SLE) in Brazil.

Methods: This cross-sectional study (GSK Study 207353) assessed patients ≥18 years of age with SLE (ACR, 1997 classification criteria) who had been receiving SLE care for ≥1 year at 5 SLE reference facilities. The study period was 12 months. Patients retired or on leave owing to another illness were excluded. Clinical information and resources used in clinical practice were obtained by interviewing patients and medical records. Direct resources were categorized as: (1) health-related hospital resources: consultations, tests, medications, hospitalization; (2) non–health-related hospital resources: transportation, home adaptation, spending on caregivers. The drugs were categorized as: (1) specific for SLE, according to coverage by the Brazilian public system; (2) adjuvants, used in the management of

comorbidities. Costs were calculated at the unit value of each resource in relation to the quantity consumed. A multivariate regression model sought to explore cost predictors in this group of patients.[1]

Results: Three hundred patients with SLE (92.3% female, mean [standard deviation, SD] duration of disease of 11.8 [7.9] years) were included. Overall, the time (mean [SD]) between the onset of the first symptoms and the start of treatment was 21.6 (39.6) months (**Table 1**). Forty-six (15.3%) patients stopped schooling because of the disease and 33.3% were retired or on sick leave because of SLE. Mean (SD) travel time from home to a care facility was 4.4 (12.6) hours. Antimalarials were the drugs most used by patients (n=222 [74.0%]) followed by mycophenolate mofetil (n=90 [30.0%]). The mean total cost for SLE in Brazil was US$3123.53 per patient per year (median [interquartile range, IQR] US$1618.51 [678.66; 4601.29]). The main item that contributed to the expenditure was medication, with

Note 2: The conversion of the values to USD was made from the average of the values of the dollar for the 4 quarters in the period of the study (2019-2020) provided by the Central Bank of Brazil. Available at https://www.bcb.gov.br/conversao (last accessed April 4, 2021). Based on this, US$1.00 is equivalent to 4.24 BRL.

a median (IQR) cost of US$910.62 (460; 4033.51), followed by hospitalization (US$900.60 [382.10; 2,106.41]; **Table 2**). According to the regression model, mycophenolate use increased the cost by 3.664 times ($p< 0.001$). Also, inflammatory monitoring (erythrocyte sedimentation rate [ESR] or C-reactive protein) reduced expenditure by 0.381 times ($p< 0.001$; **Table 3**).

Conclusion: The cost of SLE in Brazil is driven by the use of immunosuppressants or by its frequent monitoring, and hospitalization.

Impact of Osteoarthritis in Younger Adults

Elizabeth Badley[1], Jessica Wilfong[2] and Anthony Perruccio[1], [1]Schroeder Arthritis Institute, University Health Network, Toronto, ON, Canada, [2]Shcroeder Arthritis Institute, University Health Network, Toronto, ON, Canada

SESSION INFORMATION
Session Date: Monday, November 8, 2021
Session Title: Epidemiology & Public Health Poster III: Other Rheumatic & Musculoskeletal Diseases (1022–1060)
Session Type: Poster Session C
Session Time: 8:30AM–10:30AM

Background/Purpose: OA is a disease frequently perceived as a disease of the elderly and an inevitable result of aging. Consequently, epidemiological and clinical studies of OA are often restricted to older adults and there is limited information on OA in the younger population. The current study takes advantage of available population-based OA data to describe OA across a wide age range comparing younger and older adult age groups.

Methods: Data source: 2009 Survey on Living with Chronic Diseases in Canada - Arthritis (SLCDC-A), a nationally representative survey of Canadians aged 20+ years who reported diagnosed arthritis in the 2008 Canadian Community Health Survey (CCHS). Analyses were restricted to individuals reporting OA and no other kind of arthritis (n=1614). Comparisons to the general population used CCHS data.

Age categories: 20-44/45-54/55-64/65-74/75+ years. SLCDC-A respondents reported OA characteristics including painful joints in the past month, severity (1-10 scale) and frequency of pain and fatigue, arthritis-attributed limitations in daily activities, and extent to which arthritis affected their lives. Both SLCDC-A and CCHS respondents also reported their life satisfaction and physical and mental well-being.

Results: The average age at diagnosis of OA was 50 years: 30.4% were diagnosed before the age of 45. At the time of the survey 27.1% of respondents reporting OA were younger than 55, with 7.2% aged 20-44 years.

Table 1. Characteristics and severity of OA by age

	Age groups				
	20-44	45-54	55-64	65-74	75+
Mean number of painful joints	3.5	3.1	3.5	3.9	3.5
Joint pain - Severe and frequent*	31.4%	22.4%	25.9%	28.6%	29.3%
Fatigue - Severe and frequent*	27.2%	26.2%	16.4%	18.4%	18.0%
Limited in bathing/dressing (yes)	36.1%	32.0%	36.8%	40.2%	40.0%
Limited in getting around the house (yes)	52.9%	39.6%	33.9%	41.1%	46.0%
Limited in doing household chores (yes)	58.9%	49.2%	58.0%	53.7%	57.8%
Limited in running errands/shopping (yes)	55.0%	48.6%	46.3%	52.1%	56.3%
Limited in recreation, leisure, hobbies or social activities (yes)	78.5%	60.8%	66.0%	57.9%	59.8%
Overall effect of OA on life					
Not at all	8.4%	12.6%	8.2%	10.4%	11.4%
A little bit/Moderately	58.9%	60.2%	71.7%	71.0%	58.7%
Quite a bit/Extremely	32.6%	27.2%	20.1%	18.6%	29.9%

*Severe joint pain was defined as pain intensity seven or more out of ten and was considered frequent if experienced "always" or "often". Severe and frequent fatigue was defined analogously.

Table 2. Health status of people with OA compared to the general population (Pop)

	Life satisfaction*		Self-rated health†		Self-rated mental health‡		Life stress§	
Age	OA	Pop	OA	Pop	OA	Pop	OA	Pop
20-44	15.2%	2.0%	30.0%	6.6%	18.3%	6.6%	35.6%	24.6%
45-54	7.6%	3.3%	25.7%	10.5%	18.5%	7.0%	28.2%	29.1%
55-64	7.9%	3.9%	23.9%	15.3%	13.4%	6.9%	20.6%	21.5%
65-74	6.7%	3.0%	29.5%	17.7%	5.3%	5.2%	12.1%	11.8%
75+	4.1%	3.9%	32.8%	25.9%	2.9%	5.9%	11.4%	4.2%

*Dissatisfied or very dissatisfied; †Fair or poor self-rated general health; ‡Fair or poor self-rated mental health; §Quite a bit or extremely stressful

The characteristics of OA for the younger and older respondents were remarkably alike, with a similar number of reported painful joint sites and similar proportions with severe and frequent joint pain, and most activity limitations (Table 1). Younger individuals were more likely to report having severe and frequent fatigue and being limited in recreation, leisure, hobbies or social activities.

The proportion of individuals in the 20-44 and 45-54 age groups reporting that their arthritis affected their life quite a bit/extremely was similar to those in the 75+ year age group. Overall, only 10% of respondents with OA reported that their OA had no effect on their lives.

Compared with the general population, in the 20-44 age group those with OA had a nearly 8-fold higher proportion reporting low life satisfaction; a nearly 5-fold higher proportion reporting low self-rated general health; and a nearly 3-fold higher proportion reporting low self-rated mental health (Table 2). Differences between individuals with OA and the general population were considerably smaller among older respondents.

Conclusion: OA is not an uncommon experience among young and middle aged adults in Canada, despite the frequently held perception that it is a condition predominantly of older people. Findings for young and middle aged adults in this study are likely to represent the initial experience of the disease for a substantial proportion of all people with OA. It appears that irrespective of age, OA is accompanied by a similar degree of symptoms and severity, suggesting that younger individuals with OA live for many years with the 'full' consequences of OA. Given the relatively little attention that has been paid to OA in young age groups, more epidemiological and clinical attention is warranted.

Sex-Specific Associations Between Knee Synovial Fluid Biomarkers and Knee Osteoarthritis Pain

Anthony Perruccio, Elizabeth Badley, J Denise Power, Mayilee Canizares, Nizar Mahomed, Kahlid Syed, Rajiv Gandhi, J. Roderick Davey, Mohit Kapoor, Christian Veillette and Y Raja Rampersaud, Schroeder Arthritis Institute, University Health Network, Toronto, ON, Canada

SESSION INFORMATION

Session Date: Monday, November 8, 2021

Session Title: Epidemiology & Public Health Poster III: Other Rheumatic & Musculoskeletal Diseases (1022–1060)

Session Type: Poster Session C

Session Time: 8:30AM–10:30AM

Background/Purpose: Sex has received limited attention in osteoarthritis (OA) clinical studies assessing relationships between biomarkers and pain. In prior work we reported sex-specific associations between knee pain and systemic inflammatory biomarkers. The current study investigated associations with knee synovial fluid (SF) biomarkers, focusing on whether associations differed by sex.

Methods: Patients (n=180) with knee OA scheduled for total joint arthroplasty at a tertiary care hospital in Toronto, Canada. Eligibility: 35+ years of age. Exclusions: acute trauma/injury or inflammatory arthritis. Health questionnaires and blood draws were completed in-clinic and knee SF drawn prior to surgical incision. Questionnaire data included knee pain (WOMAC subscale), sex, age, height and weight (BMI was calculated), comorbidity, and symptomatic joints. SF (and blood) biomarker analyses included leptin (adipokine), IL-8 (pro-inflammatory cytokine) and MMP-1 and -2 (matrix metalloproteinases) using Luminex bead-based ELISA assays. Concentration values were log-transformed for analyses. Two linear regression models were estimated (dependent variable: knee pain score). The first included each of the SF biomarkers, adjusted for sex, age, BMI, comorbidity and symptomatic joint count. The second added interaction terms between sex and factors found to have sex-specific influences.

Results: Mean age of the sample was 64 years (range 43-89), 56.2% were female. Females had higher comorbidity and joint counts, and worse knee pain scores than males. Median marker concentrations for leptin and MMP-1 were higher in females. No difference was found for IL-8 and MMP-2. In adjusted analyses, initially without sex-specific consideration, none of the biomarkers were associated with pain scores. When sex-specific effects were assessed, all biomarkers were significantly associated with pain, but differently for males and females. The association between leptin and pain was positive in males, negative in females (p=0.004). For IL-8, a negative association was found in males (p=0.022) but none in females. For MMP-2, a negative association was found only in females (p=0.008). Finally, MMP-1 was similarly positively associated with pain in males and females. Sensitivity analyses: additional adjustment for corresponding systemic biomarkers showed a positive association between systemic IL-8 and pain in males and negative association in females (p=0.002); SF biomarker associations were unchanged.

Conclusion: Findings provide evidence of sex-specific associations between SF biomarkers and knee OA pain, suggesting drug targets for OA symptom management may need to be sex-specific. They further highlight that sex considerations in OA clinical/epidemiological studies are essential.

Session Date: Monday, November 8, 2021
Session Title: Epidemiology & Public Health Poster III: Other Rheumatic & Musculoskeletal Diseases (1022–1060)
Session Type: Poster Session C
Session Time: 8:30AM–10:30AM

Background/Purpose: The primary symptom of arthritis is chronic pain which has widespread consequences on an individual's sleep and mental health. Research suggests that sleep and chronic pain may synergistically impact depression. However, to date no study has examine the joint effect that sleep and chronic pain may have on the development of depressive symptoms.

Methods: Data for this study was utilized from the 2010-2016 waves of Health and Retirement Survey (HRS). The study included data from 6,933 individuals with arthritis and were free of depressive symptoms at the baseline (2010). We performed a multivariable-adjusted Cox proportional hazards regression to estimate the hazard ratio for the joint effect of pain and sleep problem relative to having neither conditions on the development of depressive symptoms (CES-D≥3). Sex, gender, race, smoking status, comorbidity count, physical activity limitation, and BMI were all con-

Pain Only	0.95	[0.47,1.93]			1.88	[1.14,3.12]		
Neither	1.00	Referent			1.00	Referent		

*adjusted for age, smoking status, comorbidity count, race, arthritis limiting activity; RERI- Relative excess risk due to interaction; AP- Attributable proportion due to interaction

sidered for our modeling procedures. We calculated the relative excess risk due to interaction, comparing the joint effect with that of pain alone and sleep problem alone. Analysis was further stratified by sex.

Results: There was evidence of a synergistic effect of pain and sleep on risk of depressive symptoms adjusted-HR (95% CI):2.87(2.80,4.99) and RERI of 0.38. When stratified by sex, a similar synergistic effect was observed in men with adjusted-HR(95% CI):3.30(2.16,5.05) and RERI of 1.43.

Conclusion: Findings from this study suggest that sleep and pain are synergistically linked to the development of depressive symptoms. Understanding the joint effect of pain and sleep on individuals' increased risk of depressive symptoms can help target treatment options for arthritis patients.

Abstract Number: 1060

Temporal Trends of Arthropathies Related Mortality in the United States and Its Regional Variations from 1999-2018

Hafsa Akbar[1], Waqar Mughal[2], Hasan Mirza[3], Ikwinder Kaur[4], Harjot Jagdey[5] and Mohsin Mughal[6], [1]Abington Jefferson Hospital, Abington, PA, [2]University of Gujrat, Gujrat, Pakistan, [3]Berkshire Medical Center, Pittsfield, MA, [4]Monmouth Medical Center, an affiliate of Rutgers health system, Long Branch, NJ, [5]BronxCare Hospital, Bronx, NY, [6]Monmouth Medical Center, Long Branch, NJ

SESSION INFORMATION
Session Date: Monday, November 8, 2021
Session Title: Epidemiology & Public Health Poster III: Other Rheumatic & Musculoskeletal Diseases (1022–1060)
Session Type: Poster Session C
Session Time: 8:30AM–10:30AM

Background/Purpose: Temporal trends of arthropathies-related mortality in the United States are not well studied. Arthropathies include Infectious arthropathies, Inflammatory poly-arthropathies, osteoarthritis, and other joint disor-

Table 1. shows crude and age-adjusted mortality rate with 95% CI, from 1999-2018 for arthropathies as the underlying cause of death in four U.S census regions

Census region	Year	Deaths	Population	Crude rate, 95% CI	Age adjusted rate	% of total deaths
Northeast CR1	1999-2003	3,384	269,332,043	1.3 (1.2 - 1.3)	1.1	15.50%
	2004-2008	3,184	272,926,710	1.2 (1.1 - 1.2)	1	15.50%
	2009-2013	3,036	277,676,103	1.1 (1.1 - 1.1)	0.9	15.80%
	2014-2018	2,916	281,227,394	1.0 (1.0 - 1.1)	0.8	16.70%
Midwest CR2	1999-2003	6,287	323,564,615	1.9 (1.9 - 2.0)	1.9	28.80%
	2004-2008	5,692	330,130,356	1.7 (1.7 - 1.8)	1.6	27.80%
	2009-2013	5,153	335,698,460	1.5 (1.5 - 1.6)	1.3	26.70%
	2014-2018	4,683	340,082,035	1.4 (1.3 - 1.4)	1.1	26.80%
South CR3	1999-2003	7,593	508,781,830	1.5 (1.5 - 1.5)	1.5	34.80%
	2004-2008	7,152	545,314,353	1.3 (1.3 - 1.3)	1.3	34.90%
	2009-2013	6,672	579,791,769	1.2 (1.1 - 1.2)	1.1	34.60%
	2014-2018	5,810	611,686,927	0.9 (0.9 - 1.0)	0.8	33.20%
West CR4	1999-2003	4,557	321,485,667	1.4 (1.4 - 1.5)	1.6	20.90%
	2004-2008	4,448	343,655,563	1.3 (1.3 - 1.3)	1.4	21.70%
	2009-2013	4,413	363,985,531	1.2 (1.2 - 1.2)	1.2	22.90%
	2014-2018	4,094	383,293,645	1.1 (1.0 - 1.1)	1	23.40%

Table 2. shows overall AAMR for arthropathies as the underlying cause of death in the U.S from 1999-2008

Overall	Year	Deaths	Population	Crude rate, 95% CI	AAMR	Percentage deaths
	1999-2003	21,821	1,423,164,155	1.5 (1.5 - 1.6)	1.6	100.00%
	2004-2008	20,476	1,492,026,982	1.4 (1.4 - 1.4)	1.3	100.00%
	2009-2013	19,274	1,557,151,863	1.2 (1.2 - 1.3)	1.1	100%
	2014-2018	17,503	1,616,290,001	1.1 (1.1 - 1.1)	0.9	100%

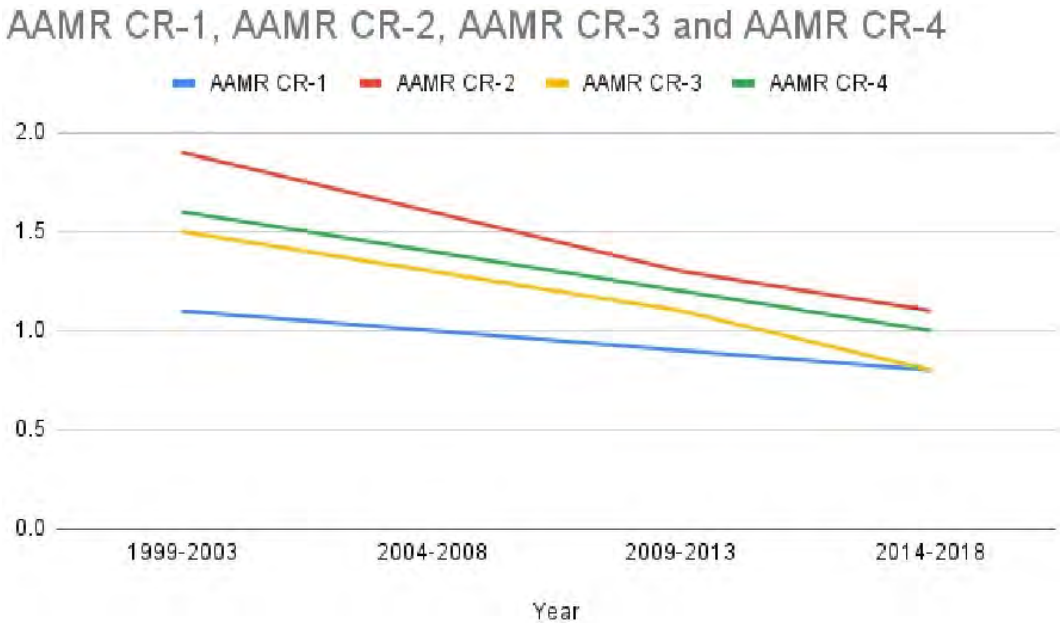

Figure 1. illustrates the age-adjusted mortality rate per 100,000 population due to arthropathies (M00-M25) in four U.S census regions from 1999-2018

ders. It is reasonable to speculate that with the advancement in the field of rheumatology, availability of new immune therapies, and persistent guideline-based high-quality treatment, arthropathies-related mortality rates would have trended down over the last two decades. We wanted to investigate the mortality rates and temporal trends of arthropathies related mortality in the United States using nationwide data.

Methods: In this retrospective study death certificate data were retrieved from the Center for Disease Control and Prevention's Wide-Ranging Online Data for Epidemiologic Research (WONDER) database for 1999-2018. WONDER database is publicly available de-identified data collected by CDC that reports the underlying cause of death across the United States. Mortality, for arthropathies (M00-M25) as an underlying cause of death, was queried. This duration was further stratified into five-year periods from 1999-2018. Age-adjusted mortality rate (AAMR) per 100,000 population was calculated with 95% CI for the four U.S. census regions (CR1 Northeast, CR2 Midwest, CR3 South, and CR4 West).

Results: From 1999-2018 overall arthropathies-related age-adjusted mortality rate (AAMR) declined by 43.75%. Arthropathies-related AAMR for Northeast (CR-1) declined by 18.18 %, for Midwest (CR-2) declined by 42.10%, for South (CR-3) declined by 46.66%; for West (CR-4) declined by 37.5%. Regional and overall crude rates with 95% CI, are reported in Table-1; and Table 2. Temporal trends are illustrated in Figure-1.

Conclusion: Our study shows a downward trajectory of arthropathies-related mortality in all U.S census regions. Regional variations warrant further discovery. This data reinforces the continuation of high-quality care and evidence-based practices that may have played a role in declining AAMR for arthropathies-related mortality in the U.S. Major limitation of our study is the inherent weakness of the WONDER database and the inability to report AAMR for different MKS related disorders (SLE, rheumatoid arthritis).

Abstract Number: 1061

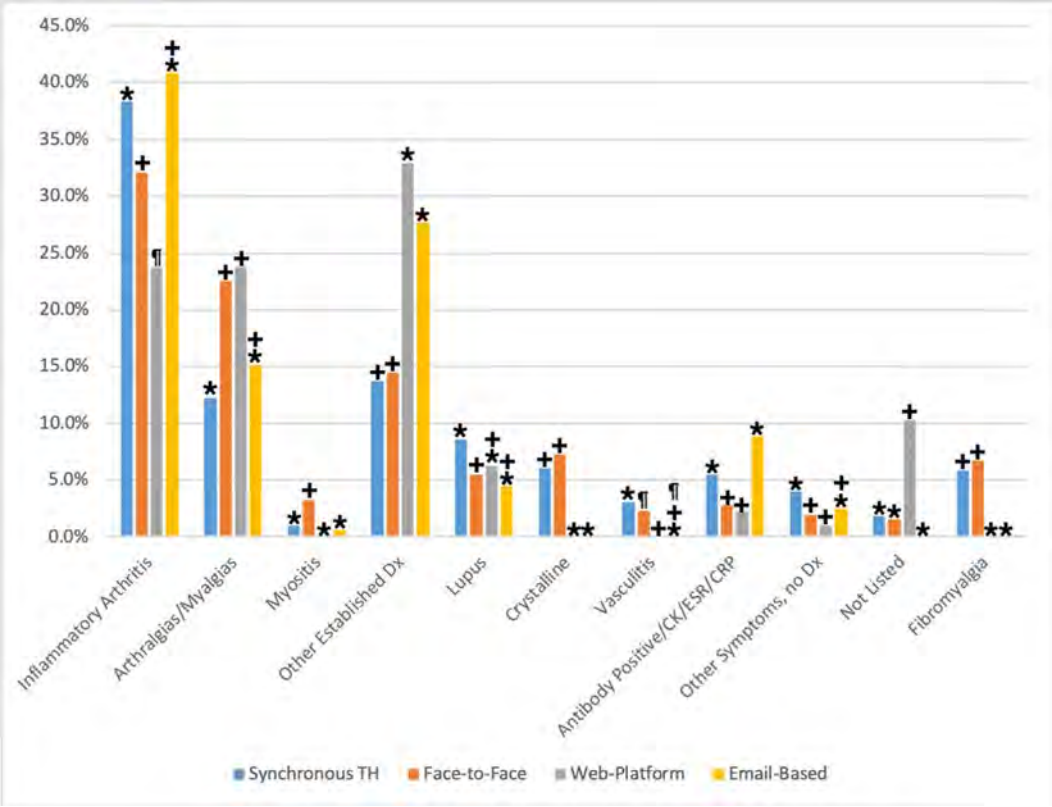
Comparing Consultation Patterns Across Telehealth Platforms and Face-to-Face Clinic in the Military Health System

Michael Loncharich, David DeSena, Angelique Collamer and Jess Edison, Walter Reed National Military Medical Center, Bethesda, MD

SESSION INFORMATION
Session Date: Monday, November 8, 2021
Session Title: Health Services Research Poster II: Care Models and Innovation (1061–1082)
Session Type: Poster Session C
Session Time: 8:30AM–10:30AM

Background/Purpose: Rheumatic diseases are often diagnostically challenging not only due to rarity, but also because symptoms can develop piecemeal before the diagnosis is clear. Access to care is another hurdle. By 2025 the majority of the US population will have only 0.5-1 rheumatologist per 100,000 people despite an aging population, resulting in an estimated shortage of 3,269 rheumatologists and increasing to a shortage of 4,133 by 2030. Practice in the military health system (MHS) adds additional challenges—transitions of care and practice in austere environments. Multiple telehealth modalities have been implemented to mitigate these challenges.

Methods: We conducted a retrospective review comparing face-to-face consults during 2019 with telehealth consults from three virtual systems in the MHS: an asynchronous email-based system from May 2006 to Feb 2018, a web-based platform from 2014 to 2018, and synchronous telehealth consults from March 2020 to March 2021. We review the diagnosis resulting from consultation and if face-to-face follow up or medical evacuation was required.



Results: Leading diagnoses across platforms were inflammatory arthritis, noninflammatory arthritis, and a composite of other diagnoses. Inflammatory arthritis was the leading diagnosis for the email-based model (65 cases, 40.9%), synchronous telehealth model (429 cases, 38.4%), and face-to-face consultations (1416 cases, 32.0%). Chi-square testing revealed that inflammatory arthritis comprised significantly more consults in the synchronous telehealth and email-based models than in the web-based and face-to-face models. The composite of other diagnoses was the leading diagnosis for the asynchronous web-based model (164 cases, 32.9%), which did not differ proportionately from the asynchronous email model and was significantly more than the synchronous telehealth and face-to-face systems.

Considering outcomes, in the email-based model consultation resulted in medical evacuation in 15.7% of cases and prevented 5 unnecessary evacuations. In the web-based model, consultation prompted medical evacuation in 20.1% of cases. In the synchronous model, face-to-face follow up was recommended in 15.0% of cases.

Conclusion: Modality of rheumatology consultation influences the type of cases are seen. In the asynchronous models, there were fewer referrals for crystalline arthropathies, fibromyalgia, vasculitis, and composite of other diagnoses, suggesting a qualitative difference in referral patterns in different telehealth mediums. Despite these differences, both synchronous and asynchronous telerheumatology models were able to answer consult questions without referral for face-to-face evaluation in 79.9-85.0% of cases, suggesting teleconsultation is a viable method to increase access to high-quality rheumatology care.

Proportion of diagnosis across consultation platforms. Matching symbols indicate that proportions are not statistically different across platforms; different symbols indicate a statistically significant difference.

Telemedicine Enriched Care Model to Optimize Care for Patients with Autoinflammatory Diseases

Lea Oefelein[1], Jens Klotsche[2], Susanne Benseler[3], **Jasmin Kuemmerle-Deschner**[1] and Tatjana Welzel[1], [1]Pediatric Rheumatology and Autoinflammatory Reference Center, University Children's Hospital Tuebingen, Tuebingen, Germany, [2]German Rheumatism Research Center, Berlin, Germany, [3]University of Calgary, Calgary, AB, Canada

SESSION INFORMATION
Session Date: Monday, November 8, 2021
Session Title: Health Services Research Poster II: Care Models and Innovation (1061–1082)
Session Type: Poster Session C
Session Time: 8:30AM–10:30AM

Background/Purpose: Autoinflammatory diseases (AID) are severe potentially life-threatening conditions requiring personalized therapy and monitoring which only few expert centers can provide. Long travel distances impede health equity and optimal AID care, especially in emergencies. Individualized care models based on integrative telemedicine consultations (video-c) with AID experts for primary care providers and patients could optimize AID care "close to patients' homes". Data on the acceptance of such care models for AID are scarce. The aim of this study was to evaluate the acceptance and influencing factors of a telemedicine enriched AID care model (video-c).

Methods: This prospective study investigated the influence of usefulness and ease of use on attitude and intention to use video-c in "close to home" AID care. Primary care providers caring for AID patients with ≥1 AID-center visit since

01/2019 were included. Personal expertise, desire for support in AID care and acceptance of video-c were recorded. Acceptance was assessed based on the Technology Acceptance Model (TAM; 7-point Likert scale) with 1 meaning no agreement and 7 meaning strong agreement. Influencing factors were tested by structural equation modeling (SEM). Analysis was performed using IBM SPSS Statistics 26 and MPLUS 7.

Results: The response rate was 54% (62/115). 87% of participants were pediatricians, 10% family physicians, and 3% internal medicine physicians; 40% were female. In AID treatment, 27.4% felt (very) unexperienced, 27.4% (very) experienced; 45.2% neutral. More support from AID experts was desired by 71%. Technical equipment for video-c was available to 56% of primary care providers. 64% indicated a positive attitude (≥5/7 points) towards video-c for AID care "close to home"; 60% would use video-c in practice (≥5/7 points). SEM confirmed acceptable model fitting (WRMR=0.81, CFI/TLI=0.98/0.98). Ease of use showed a significant association with perceived usefulness (β=0.66, p< 0.001). Perceived usefulness was positively associated with attitude towards video-c (β=0.98, p< 0.001). Ease of use and usefulness explained 94% of the variance in attitude towards video-c (R2=0.94). Perceived usefulness combined with attitude explained 93% of the variance in intention to use a video-c (R2=0.93).

Conclusion: Three out of four primary care providers wished for more expert support in AID patient care "close to patients' home". Integrative telemedicine enriched care models (video-c) for primary care providers and patients with AID experts can optimize local AID care. Perceived usefulness and ease of use are significant influencing factors that should be considered when conceptualizing video-c and implementing such care models.

Use of Telemedicine for Rheumatology Practice in Queensland, Australia: Experiences Before and During the COVID-19 Pandemic

Divita Jhaveri[1], Faith Alele[2], Aleisha Strom[3], Theophilus Emeto[2] and Helen Benham[4], [1]Rheumatology Department, Princess Alexandra Hospital, Woolloongabba, Australia, [2]Public Health & Tropical Medical, College of Public Health, Medical & Veterinary Sciences. James Cook University, Townsville, QLD, Australia, [3]Internal Medicine Department, Townsville University Hospital, Angus Smith Dr, Douglas, QLD 4811, Townsville, Australia, [4]Faculty of Medicine, The University of Queensland, Herston, Australia

SESSION INFORMATION
Session Date: Monday, November 8, 2021
Session Title: Health Services Research Poster II: Care Models and Innovation (1061–1082)
Session Type: Poster Session C
Session Time: 8:30AM–10:30AM

Background/Purpose: In Australia there is a nationwide rheumatologist shortage potentially translating to poorer clinical outcomes for those living with rheumatic diseases. [1] A possible solution to improve patient care in this setting is telemedicine (TM). During the COVID-19 pandemic TM consultations increased significantly resulting in an opportunity to review rheumatologists' use of TM. The aim of this study was to examine the utilisation and provider perceptions of TM in rheumatology. This study investigated the usage of TM by rheumatologists before and during the COVID-19 pandemic and explored the models of care utilised and the challenges experienced.

Methods: A sequential mixed-methods study design was adopted and rheumatologists completed a questionnaire including demographics, clinical practice, TM uptake, models of care applied and clinician perceptions of TM. The

qualitative phase utilised purposeful sampling of active users of TM through in-depth semi-structured interviews. The impact of COVID 19 pandemic on TM use for rheumatology practise was explored.

Results: Thirty Queensland rheumatologists participated in surveys with 76.7% actively utilising TM. Usage of TM was limited prior to the COVID-19 with 9.5% seeing more than 5 patients per week. Patient populations served by TM included capital city (n=16, 53.3%), regional (n=19, 63.3%) and rural/remote (n=7, 23.3 %). A significant association between rheumatologists (n=29) having ever practised in a rural/remote setting (n=19, 65.5%) and use of TM within the last 24 months (n=17, 58.62%), p=0.030 was seen with no association found for formal training in TM or years of experience as a rheumatologist and TM usage. Of the active TM users prior to the COVID-19 pandemic 90% commenced conventional DMARDs and 55% biological DMARDS through TM. One of the major barriers to wider usage included low to medium confidence with joints assessments through TM (n= 15/19). Qualitative analysis further identified barriers to TM uptake including limited distribution of technology, administrative and peripheral clinical staff involvement and lack of financial incentives particularly in the private sector. During the COVID-19 pandemic, a significant expansion of TM as telephone calls occurred with rheumatologists reporting low confidence and satisfaction with this, whilst identifying that telephone calls and TM may be an acceptable model for monitoring stable patients with low disease activity.

Conclusion: Familiarity with TM exists in this rheumatology cohort, however its usage in routine practise is limited due to multiple barriers. The COVID 19 pandemic highlighted lower confidence in telephone calls as a form of TM and concerns regarding new or unstable patients.

Pharmacist-Led Multidisciplinary Approach to Opioid Tapering in a Private Rheumatology Practice: Patient Outcomes

Jessica Farrell[1], Mitchell Miller[2], Kelsey Hennig[3], Kaitlyn McCarthy[4], Christ Ange Katche[5] and Jacqueline Cleary[6], [1]Albany College of Pharmacy and Health Sciences, Steffens Scleroderma Foundation, Albany, NY, [2]Bassett Medical Center, Albany, NY, [3]Binghamton University, New Lebanon, NY, [4]Center for Rheumatology, Albany, NY, [5]Albany College of Pharmacy & Health Sciences, Guilderland, NY, [6]Albany College of Pharmacy & Health Sciences, Albany, NY

SESSION INFORMATION
Session Date: Monday, November 8, 2021
Session Title: Health Services Research Poster II: Care Models and Innovation (1061–1082)
Session Type: Poster Session C
Session Time: 8:30AM–10:30AM

Background/Purpose: With the evolution of disease modifying anti-rheumatic drugs medications, the need for opioids in the treatment of rheumatic diseases has decreased. However, rheumatology professionals are often presented with patients in whom chronic opioid therapy was started prior to the availability of newer DMARDs and may require reductions in opioid doses. Current guidelines suggest opioid tapering should be considered in patients with chronic noncancer pain on ≥90 mg morphine equivalent daily dose (MEDD) daily or in combination with other high-risk medications.

Methods: The pharmacy team developed a three phased program starting in June 2019 including provider/staff education, updates to workflows, and implementation of individualized patient taper plans. Patients identified by providers are enrolled in the pharmacy service. The pharmacy team serves as a continuous resource to providers and works directly with patients enrolled in the service. Baseline characteristics, historical data on opioid related efficacy/side effects, and daily morphine equivalents are collected/tracked for each patient.

Results: Provider and staff education sessions led by the pharmacy team occurred in June 2019, October 2019 and December 2019. Controlled substance contract workflow changes were implemented in December 2019. The number of signed contracts reportable at baseline was 0. To date, a total of 253 signed controlled substance contracts (including tramadol and pregabalin) are documented in TCFR electronic health record. As of April 2021, a total of 124 patients have active prescriptions (defined as a refill in the last 3 months) for opioids including codeine, hydrocodone, oxycodone, methadone, and morphine. Since implementation of our program, 6, 33, and 10 patients have discontinued opioids prescribed by TCFR providers in the years 2019, 2020, and 2021. A total of 19 patients have been enrolled in the pharmacist-led opioid taper service. All patients are co-managed by the pharmacist and the provider. Daily initial starting doses ranged from 20 to 200 MEDD. A total of 5 patients (26%) have successfully tapered off opioids. Nine patients (47%) have had reductions in MEDD. Five patients (26%) have remained on the same initial dose. A total of 9 patients enrolled in the service had an MEDD ≥ 90. Of those patients, 56% reduced MEDD ≤90, of which 2 patients are no longer on opioids. The average MEDD percent reduction for all patients enrolled in the service was 48%. The average duration of all patients enrolled with the service is 11 months with a range from 5-20 months. The duration of taper for patients who have successfully tapered off opioids ranged from 1 to 3 months.

Conclusion: Successful opioid tapering is a time intensive process and requires a multidisciplinary approach. This provides an opportunity for pharmacists to play an essential role as part of a team-based approach to ensure a successful opioid taper or discontinuation while minimizing adverse events.

Abstract Number: 1065

Optimizing Joint Pain EConsult Referrals in an Underserved Region of Southern California

Neha Chiruvolu[1] and Vaneet Sandhu[2], [1]UC Riverside School of Medicine, Riverside, CA, [2]Loma Linda University Health, Loma Linda, CA

SESSION INFORMATION
Session Date: Monday, November 8, 2021
Session Title: Health Services Research Poster II: Care Models and Innovation (1061–1082)
Session Type: Poster Session C
Session Time: 8:30AM–10:30AM

Background/Purpose: Electronic consultations (eConsults) are increasingly utilized to supplement or replace face to face (FTF) visits in different medical specialties. They are especially valuable in underserved communities where timely access for a FTF visit with a rheumatologist is limited by various factors including transportation and limited rheumatology workforce in the area. Further, eConsult assistance with obtaining rheumatology diagnostic evaluations prior to FTF visits expedites patient care. Unfortunately, care is delayed if vital information is not included in eConsults to rheumatology. This study was thus designed to identify gaps in the eConsult referral process for chief complaints of joint pain through the Inland Empire Health Pan (IEHP), the largest insurance plan in an underserved region of Southern California.

Methods: Seven rheumatologists at Loma Linda University Health were surveyed on what information in the eConsult interface would provide the rheumatologist with necessary information to triage the patient into 3 categories: 1. Close for FTF visit, 2. Change in specialty, 3. Hold on FTF pending trial of medication or further diagnostics. 100 eConsult referrals to rheumatology for joint pain were then randomly selected and retrospectively reviewed for this information,

Table 1. Information provided in history of personal illness

Which joints?	
Joints specified	54
Joint pain indicated as "generalized"	12
Not specified	34
Description of joint pain	34
Whether or not pain/stiffness worse in morning	12
Whether or not patient has stiffness	17
Whether pain/stiffness improved or worsened with physical activity	3
Whether or not patient has joint swelling	21

Table 2. Pertinent workup ordered for joint pain

Lab	Ordered (*N*)	Result available at time of referral (*N*)
CRP	56	45
ESR	65	54
RF*	78	66
CCP**	56	48
Uric Acid	21	17
ANA	68	59
Xray	39	29

*RF: Rheumatoid Factor
**CCP: Cyclic citrullinated peptide Ab
Note: CCP was ordered along with RF in 54 patients. Solitary CCP was ordered in 2 patients.

which included: description of joint pain in patient's history of personal illness (HPI; to include description of involved joints, inflammatory vs mechanical pain, presence of swelling, stiffness, association with physical activity), laboratory workup, and x-rays of affected joints.

Results: Among 100 referrals for joint pain, affected joints were specified in 54 and generalized joint pain noted in 12 (Table 1). Information to differentiate between inflammatory vs mechanical joint pain was only provided in 34 consults with presence or absence of swelling noted in 21(62%) of these patients. Rheumatoid factor was ordered in 78 patients, of whom 54 (69%) also had a serum CCP evaluated (Table 2). ANA was ordered in 68 patients, however only seven of these patients had symptoms or indications of connective tissue disease noted in their HPI: 5 with rash, 1 with alopecia and rash, 2 with shortness of breath, 1 with anemia. X-rays were ordered in 39 patients and results were available in 29 at the time of rheumatology appointment. In total, 84 referrals were triaged to a FTF visit, 6 resulted in a change in referral specialty, and 10 were recommended trial of medication or further diagnostics prior to FTF visit.

Conclusion: We find that joint pain referrals made through the IEHP eConsult interface lack important information to guide rheumatologists in their diagnosis and appropriate triage of patients. This can potentially lead to delays in treatment. To optimize the process, a checklist can be displayed in the interface at time of referral to assure that joint pain is thoroughly described in the HPI, associated symptoms are included, and related labs and imaging are ordered in a timely manner. We plan to expand this study to include referrals for positive immunological markers such as ANA.

Abstract Number: 1066

Evaluation of a Non-Face to Face Multidisciplinary Health Care Model in a Population with Rheumatoid ArthritisVulnerable to Covid-19 in a Health Emergency Situation

Pedro Santos-Moreno[1], Rosangela Casanova[2], Gabriel-Santiago Rodríguez-Vargas[2], Laura Villareal[1], Jaime-Andrés Rubio[2], Josefina Chávez-Chávez[2], Diana Patricia Rivera-Triana[2], Ruth Alexandra Castiblanco-Montañez[2], Sandra Milena Hernández-Zambrano[2] and Adriana Rojas-Villarraga[2], [1]BIOMAB IPS, Bogotá, Colombia, [2]Fundación Universitaria de Ciencias de la Salud-FUCS, Bogotá, Colombia

SESSION INFORMATION
Session Date: Monday, November 8, 2021
Session Title: Health Services Research Poster II: Care Models and Innovation (1061–1082)
Session Type: Poster Session C
Session Time: 8:30AM–10:30AM

Background/Purpose: The COVID-19 pandemic impacted everyday practice pattern of health care in rheumatoid arthritis (RA) patients. The objective was to evaluate the implementation of a tele-consultation program in adult population with RA

Methods: This was an analytical observational study-prospective cohort (Clinical trials NCT04768413) that evaluated the effectiveness of a teleconsultation model compared with a face-to-face consultation model in RA adult patients. Patients were followed 12 weeks (Jul-Oct 2020) at a RA center of excellence in Colombia. Simple random sampling was done. Two groups were included: Group A, patients who assisted to tele-consultation care and Group B, those who wish to continue with the usual face-to-face consultation. Data regarding activity of disease (Week 0,6,12) [Patient Activity Scale (PAS) in both groups and DAS28 in group B], and Quality of life [EQ-5D-3L], disability [Health Assessment Questionnaire (HAQ)], therapeutic adherence [Morisky-Green Adherence Scale (MGLS)] and self-care capacity [Appraisal of Self-care Agency Scale -Revised (ASA-R)] was evaluated (weeks 0-12). Outcomes regarding COVID-19 were evaluated. Bivariate analysis was done (StataV-13; P-value< 0.05)

Results: 218 adults were included: (109 in Group A and 109 in Group B). The groups did not differ in general characteristics (See Figure-Table). In Group A: (n=71), no statistically significant differences were observed in the median scores of VAS global, VAS pain, PAS, HAQ, EQ-5D and ASA-R, while increase in adherence was demonstrated (MGLS, without statistical significance), during follow-up. In Group B: (n=18), a significant decrease in adherence (MGLS, p= 0,019) and increase in self-care (ASA-R, p= 0,0077) were found, no other differences were found (including DAS-28). A third group was conformed by patients (n=129) that transited between the two models during follow-up (See figure). An increase in in self-care (ASA-R) was demonstrated in the group presential >remote >presential (p=0,0001), the same result was documented in the group presential >remote >presential, with a decrease in adherence (p=0,033). 7 patients developed COVID-19 (one patient hospitalized/group A and one patient died/mixed model)

Conclusion: The teleconsultation model favors that patients remain without deteriorating their commitment to RA, without major differences compared to the face-to-face model. It is important to know these results due to the impact they have given the changes that will follow in the care of RA patients due the current pandemic. Studies with a longer follow-up period are required to corroborate the results

Table. Main characteristics of patients

Variable		Teleconsultation n=109*		Face to Face n=109*		p-valor
Age		61.1	12.6	61.9	12.5	0.6079

Experiences of Self-Care During the COVID-19 Pandemic Among Individuals with Rheumatoid Arthritis: A Qualitative Study

Jenny Leese[1], Catherine L. Backman[1], Jasmin Ma[1], Cheryl Koehn[2], Alison Hoens[3], Kelly English[3], Eileen Davidson[4], Shanon McQuitty[3], James Gavin[5], Jo Adams[5], Stephanie Thierren[6] and Linda Li[1], [1]University of British Columbia, Vancouver, BC, Canada, [2]Arthritis Consumer Experts, Vancouver, BC, Canada, [3]Arthritis Research Canada Arthritis Patient Advisory Board, Vancouver, BC, Canada, [4]Arthritis Research Canada Arthritis Patient Advisory Board, Burnaby, BC, Canada, [5]University of Southampton, Southampton, United Kingdom, [6]Arthritis Research Canada, Richmond, BC, Canada

SESSION INFORMATION

Session Date: Monday, November 8, 2021

Session Title: Health Services Research Poster II: Care Models and Innovation (1061–1082)

Session Type: Poster Session C

Session Time: 8:30AM–10:30AM

Background/Purpose: The COVID-19 pandemic poses new challenges for individuals with rheumatoid arthritis (RA) to manage their self-care, such as being physically active, maintaining emotional wellbeing, and accessing necessary medications. The aim of this qualitative study was to explore how the pandemic influenced self-care from the perspectives of individuals living with RA.

Methods: The study was jointed designed and conducted with patient partners living with RA. Between March and October 2020, we conducted one-to-one semi-structured interviews (30-60 mins) with participants with RA. These participants were purposively sampled from two ongoing randomized controlled trials (RCT) testing a web-based self-care intervention. To be eligible for either RCT, participants must have had: 1) a physician confirmed diagnosis of RA; 2) no joint surgery in the past 6 months; 3) no history of acute injury to any joints in the past six months; 4) an email address and daily access to a computer or mobile device. In the present qualitative study, we aimed for maximum variation in age, sex, and education among participants. An inductive thematic analysis approach was used. Preliminary findings were shared during consultations with 5 local patient partners and 13 patient partners living with RA in a different country to explore transferability of findings.

Results: Twenty-six of 33 eligible participants (aged 27-73; 23 females) agreed to be interviewed. Eighteen (69%) held a university degree or trade certificate. We identified 3 main themes: 1) *Adapting to maintain self-care* described how participants took measures to continue self-care activities while preventing virus transmissions. While spending more time at home, some participants reported improved self-care; 2) *Managing emotions* describes resilience-building strategies such as keeping perspective, positive reframing, and avoiding negative thoughts. Participants described both letting go and maintaining a sense of control to accommodate difficulties and emotional responses; 3) *Changing communication with health professionals* outlined positive experiences of remote consultations with health professionals, particularly if good relationships had been established pre-pandemic. Consultations with patient partners in a different country indicated experiences typically resonated across these different geographical, political and health service contexts that experienced a total or partial lockdown during the pandemic.

Conclusion: Findings describe the adaptations that adults with RA used to maintain their self-care and overall well-being. Insights gained may serve to inform researchers and clinicians in supporting adaptation and resilience among persons with arthritis more broadly during the pandemic and beyond. Findings also reveal opportunities to further examine remote consultations to optimize patient engagement and care.

Analysis of Tweets Containing Information Related to Rheumatological Diseases on Twitter

Adrian abbasi[1], Miguel Álvarez-Mon[2], Carolina Donat-Vargas[3], ana Perez[4], julio suarez[1], lorena montano[1], emilio rico[1] and melchor Alvarez de Mon[1], [1]Hospital Universitario Príncipe de Asturias, Madrid, Spain, [2]Hospital Universitario Infanta Leonor, Madrid, Spain, [3]IMDEA Food, Cardiovascular and Nutritional Epidemiology Group, Madrid, Spain, [4]Hospital Universitario Príncipe de Asturias. Rheumatology. Medicine Faculty. Alcala University Department., Madrid, Spain

SESSION INFORMATION

Session Date: Monday, November 8, 2021

Session Title: Health Services Research Poster II: Care Models and Innovation (1061–1082)

Session Type: Poster Session C

Session Time: 8:30AM–10:30AM

Background/Purpose: Twitter is an indicator of the interests of its users in the real world, and therefore, is an appropriate setting to assess the content on rheumatological diseases related tweets. The objective of this research was to analyze the content of the tweets referring to rheumatological diseases.

Methods: We analyzed the content of the tweets published between the 25 of January and 20 February, 2020, in English or Spanish, out of six rheumatological diseases: vasculitis, systemic lupus erythematosus (SLE), rheumatoid arthritis (RA), Sjögren's syndrome (SS), osteoarthritis (OA) and spondyloartopathies, including spondylitis, ankylosing spondylitis, psoriatic arthritis and reactive arthritis. At least 10% of tweets were randomly selected from each disease. It was classified as medical content (diagnosis, treatment or other aspects of the disease) or non-medical (conversation between users, request for help, etc.). It also has been evaluated the type of user and the suitability of the medical content -appropriate or fake.

Results: 15,250 original tweets were published, selecting 1,628: 1,093 classified as medical, 421 as non-medical and 168 as unclassifiable (Figure 1). We analyzed a total of 1,039 tweets: 1,093 classified as medical and 421 as non-medical.

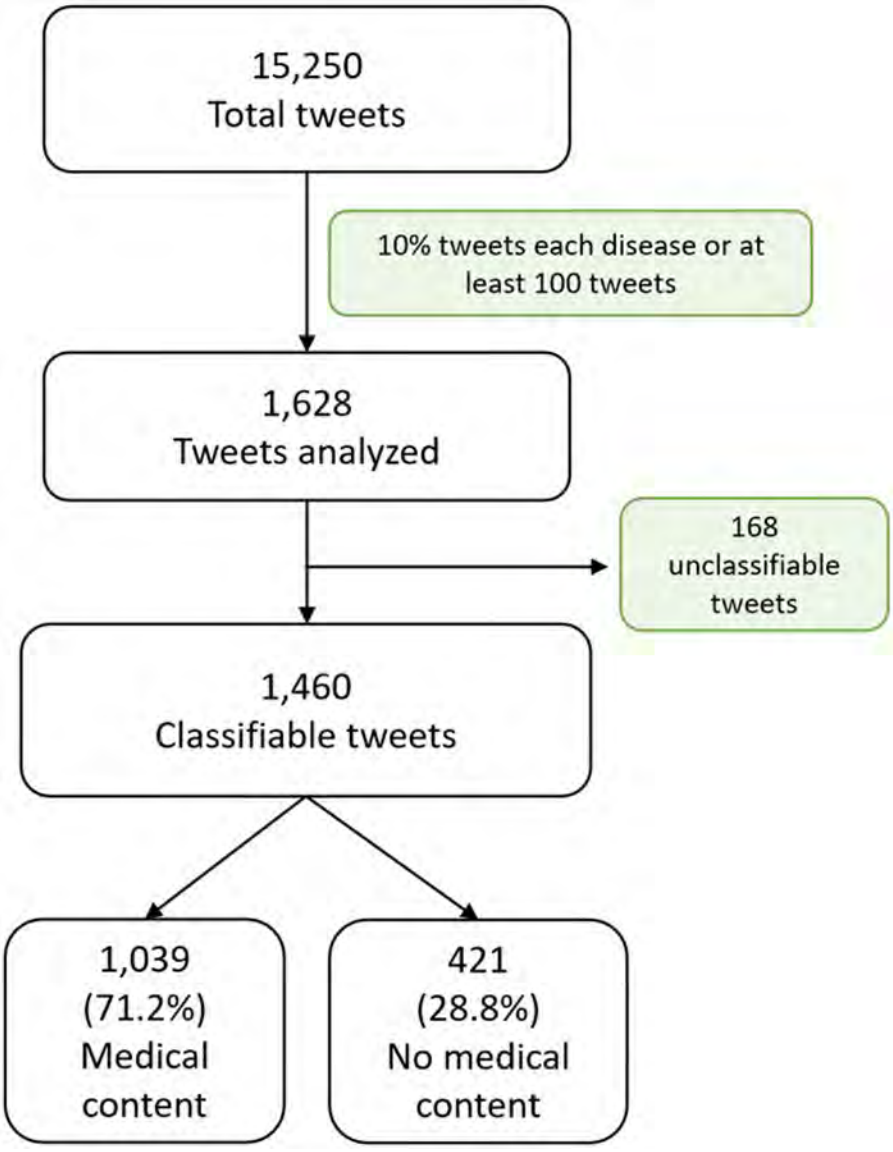

Figure 1. Flowchart illustrating the process followed for the analysis of the tweets, along with the number of tweets included and excluded.

Table 1. Number of tweets with medical contents and of those with fake information related to the rheumatic diseases

	Total tweets with medical content		Fake tweets	
Related to specific rheumatic diseases	**n**	**% of total tweets**	**n**	**% of total tweets with medical content**
Vasculitis	73	67.0%	0	0.0%
Systemic lupus erythematosus (SLE)	108	90.0%	0	0.0%
Spondyloarthropathy	171	60.0%	4	2.3%
Osteoarthritis	337	75.6%	18	5.3%
Rheumatoid arthritis	313	70.7%	24	7.7%
Sjogren's syndrome	37	64.9%	0	0.0%
Total	1039	71.2%	46	4.4%
Area of medical content	**n**	**% of total tweets**	**n**	**% of total tweets with medical content**
Diagnosis	71	6.8%	0	0.0%
Therapeutic	275	26.5%	16	5.8%
Comorbidities	69	6.6%	1	1.4%
Radiology	20	1.9%	0	0.0%
Information for patients	158	15.2%	2	1.3%
Pathophysiology	68	6.5%	0	0.0%
Other	378	36.4%	27	7.1%
Total	1039	100.0%	46	4.4%
Type of user that posted the tweet	**n**	**% of total tweets**	**n**	**% of total tweets with medical content**
Patient/Family member	32	3.1%	3	9.4%
Health professional	186	17.9%	0	0.0%
Health institutes	59	5.7%	0	0.0%
Other	762	73.3%	43	5.6%
Total	1039	100.0%	46	4.4%

The p-value of the Chi square test for the differences between the number of fake tweets by medical content, rheumatic diseases, and type of user were $p = 0.002$, $p = 0.001$ and $p = 0.001$, respectively

As shown in Table 1, medical tweets related to RA and OA accounted for 62%, followed by tweets regarding SpA.

Next, we investigated the content of the tweets (Table 1 and Figure 2). Concerning the specific medical contents, it was found that most of the tweets were related to the treatment of the disease (26.5%) followed by information for patients (15.2%). The percentage of tweets with contents referred to the diagnosis, comorbidities and pathophysiology were minor. Within the medical tweets, the content of these varied according to the disease. The specific analysis of the type of medical content among the investigated diseases showed a significative heterogenous distribution ($p< 0.001$). Contents related to diagnosis were mainly observed in those of vasculitis and SS, and were marginal in those of OA and RA. In contrast, the percentage of treatment related tweets were markedly elevated in those of OA and RA and minimum in those of SS.

Finally, we analyzed the fake content of the tweets (Table 1). Interestingly, a low percentage of tweets with fake content regarding RA, OA and SpA was observed. Furthermore, it was observed that the content of theses fake tweets was mainly focused in the treatment of the diseases. In fact, 5.8 % of the tweets related to treatment showed wrong information. The fake content came from unidentified users. Notably, no fake tweets were encountered among those posted by health professionals or health institutions.

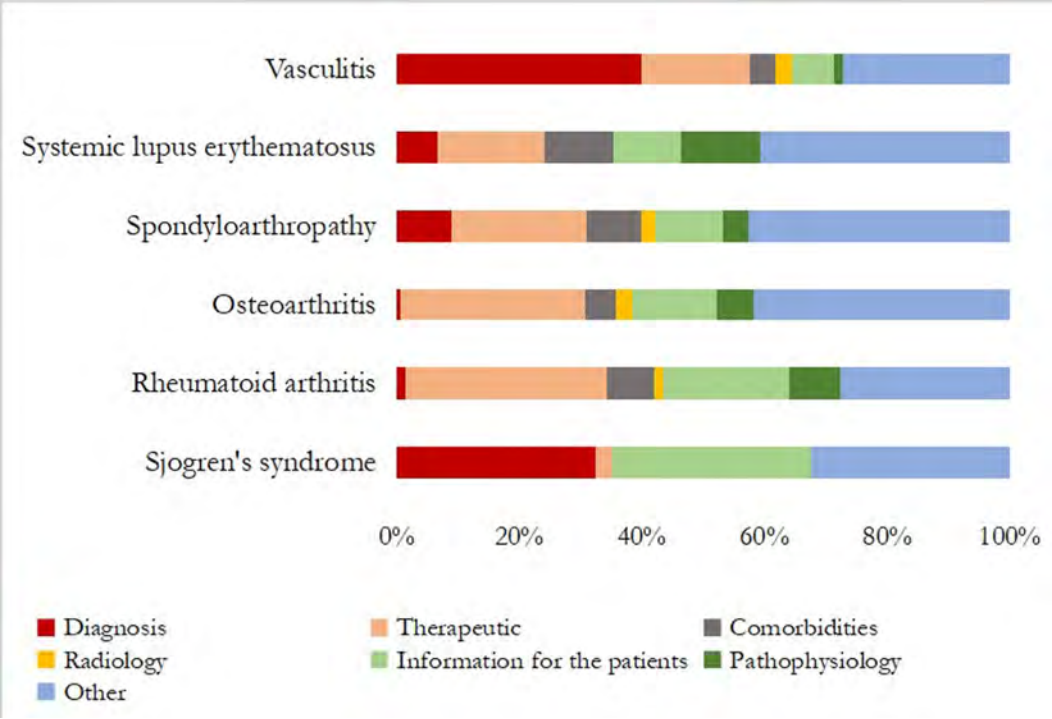

Figure 2. Proportion of the different medical contents among the tweets related to each rheumatic disease.

Conclusion: The data show that the interest of Twitter community in rheumatic diseases is high according to the number of tweets. The diseases with more tweets were the most prevalent. Given the interest raised by medical content posted on Twitter, the involvement of health institutions and health care providers in medical related conversations over social media appears to be desirable. However, the content posted by healthcare professionals is always appropriate, although there is some spreading of fake content by unidentified users.

Supporting Patient-Centered Care in the Pediatric Rheumatology Setting: Patient, Family and Provider Experiences with OurNotes

Uptej Khalsa[1], Rajdeep Pooni[2], Christy Sandborg[1], Imelda Balboni[1], Karen Wayman[3] and Tzielan Lee[4], [1]Stanford University, Palo Alto, CA, [2]Stanford Children's Health, Palo Alto, CA, [3]Stanford Children's Health, Palo Alto, CA, [4]Stanford University School of Medicine, Palo Alto, CA

SESSION INFORMATION

Session Date: Monday, November 8, 2021
Session Title: Health Services Research Poster II: Care Models and Innovation (1061–1082)
Session Type: Poster Session C
Session Time: 8:30AM–10:30AM

Background/Purpose: Health information transparency enabled by the widespread adoption of patient portals and open notes has truly transformed the way healthcare is delivered. However, broader applications of this technology are needed to promote meaningful team-based collaboration in a way that is interactive, personalized to the patient

Empowering Patients and Families as Partners
• "It made us feel like a little team all together. Our voices can be heard, and we feel like we're part of her journey, her treatment journey, whether it's good or bad we can be involved." (Parent 8)
• "I definitely see that it facilitates that structure and helps develops that collaboration which is great." (Parent 2)
• "I think it's important to think about long term goals and speaking up for how I want my medical journey to look like in the future. So, I think that goal setting is a very important thing that I hadn't thought about before, but I'm glad that the survey helps me think about it." (Patient 6)
• "I think it just goes back to the, I have a say in this, and I've got a little bit more control. It's not just the doctor, it's all of us. We have an opportunity to contribute, and I think can only be a positive thing." (Parent 6)
• "I think it's really helpful for me to get my questions out there…just to kind of gather any kind of information to help me better understand her diagnosis. I just want to make sure I cover all bases, so I can better provide care and be more attentive to what she may need, to get these questions answered I can at least kind of accommodate her through the good days and bad days." (Parent 9)
• "I think it just feels like we mean something, we're not just a number. We're not just another patient, like they've taken time to really understand our current situation, what's top of mind for us. So, I just think that improves that relationship." (Parent 6)
• "I feel like it makes the patient feel like they're actually being valued during their doctor's visits, that their doctors actually like taking into consideration their portion of the visit, like knowing that they're being heard and there's concerns are valid…it gives me as a patient more confidence. I felt like we're more connected together than just, you know, a doctor and patient. I felt like my doctor actually knew me so well." (Patient 5)
• "I think it's important because a lot of times your health is more complex than just test results and maybe clinical observations. I guess in some sense, it just adds like more data points to better inform like treatment options and things like that. So, I guess you're getting a more like holistic picture than maybe if you just had the perspective of the doctor." (Patient 1)
• "…it helps my provider kind of see my personality and just see how living with the condition affects me on a daly to day life, and so I think it had kind of a personal aspect to it." (Patient 6)
• "I think it's a positive thing because there's things that come up on the day to day that are part of just how she's doing and how she's feeling that are important to consider in her case as well…not just the clinical stuff but also just the little things that come up, and so I like that what we're seeing is also being included in her medical record. I think it just completes the picture." (Parent 14)
Impact on Care Delivery
• "I feel like our needs and specific questions got answered without me having to like rapid fire at her at the end. [The provider] kind of came in prepared knowing what I wanted to ask and where our visit was going to go, which was really great". (Parent 1)
• "If you if you're a person who has questions and…you just feel like intimidated bringing them up or whatnot, then I think this is a good avenue." (Parent 4)
• "I think it was helpful, because I'm kind of the type of patient who doesn't really say much. I think it was helpful to let my provider know what my problems were for that specific visit because if she doesn't ask, I usually don't say it. I've been with this doctor for a long time, but it's little more sensitive for me to talk about like mental health. So, it was beneficial that I could share that without having to say it to her in the moment." (Patient 2)
• "Instead of going through like more general like topics, it's like easier to pinpoint what exactly would be the best use of time, to go over what areas are you having like more trouble with. I thought it made it a little more targeted, not that it was like unproductive before." (Patient 1)
• "…just knowing that then [provider name] could process that information before we showed up, made the in-person conversation that we had during our visit much more efficient. That's what I found to be the most beautiful." (Parent 2)
• "It's a good way to organize your thoughts and be prepared for the doctor's visits, so you're not wasting the doctors time, you're not wasting your own time. I would hope that it's something that would make the appointment more efficient, and you would get more information than if you just kind of walked in blindly without any notes or thinking of anything in advance.
Especially as a parent with young kids, you're trying to make sure they're behaving themselves and sitting still you know? You're trying to focus on what the doctor is saying. I think for me having all my questions listed out beforehand…I know she's making sure we cover everything. It's like one less thing to worry about." (Parent 12)
• "Without sitting down to think about it or have some time to think about it, I can envision or probably have forgotten some of those components when you're in a in-person meeting or asked a question, right? Maybe something's more top of mind than others. So, having some time to think about things in a less time constrained format is helpful." (Parent 11)
• "You're sort of like forced to like go a little bit deeper and think about your answers like in a more meaningful way." (Patient 1)
• "There is a like a limited amount of time the doctor can spend with us right, so in that sense, having this questionnaire filled in and then the doctor reviewing it before the appointment, I think it helps to make sure that we are kind of on the same page, and that we have the same objectives for that appointment. I think we can go to the appointment with more like clarity, what we want to know, what we want to ask, what our goals are going forward." (Parent 16)
• "It does help me to kind of sit down and put my thoughts down before we all meet…we often have a lot of questions, so it's good to kind of have, okay, what are the top three things that we want to know, that we were concerned about. So, I think it was helpful to sit down and prioritize and have this thought process before we met the doctor." (Parent 14)
• "The questions on the questionnaire I feel were pointed in a constructive way, they kind of got my gears thinking in the right direction." (Parent 2)

Themes and Illustrative Quotes

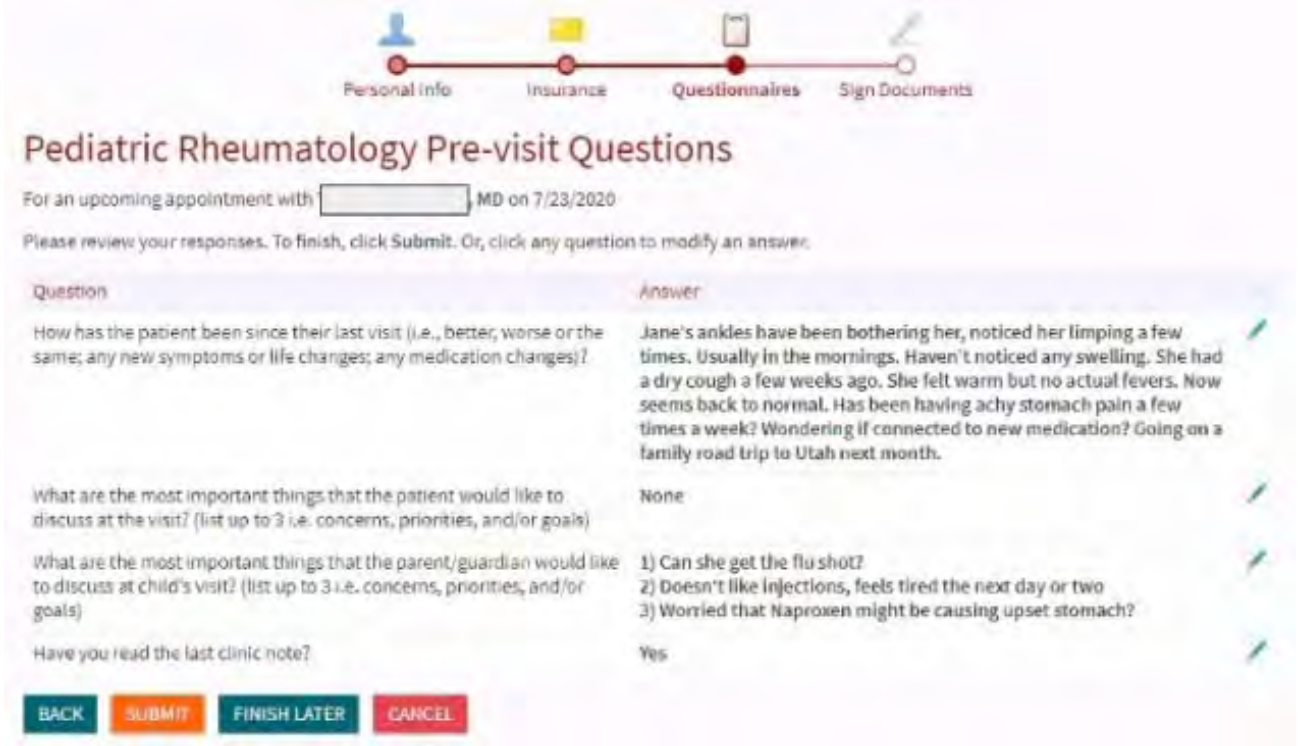
encounter, and facilitates joint decision-making regarding complex decisions. These aspects of care are particularly relevant in improving health outcomes among those with pediatric rheumatic conditions and aid in reducing the growing burden of disease in this population. Through this study, we introduced OurNotes, a portal-based pre-visit tool that leverages patient-generated health data, enabling patients and caregivers to actively contribute to their medical record and the co-generate clinical notes with their provider. We conducted a qualitative study exploring patient and caregiver experiences and attitudes related to the adoption of OurNotes in the pediatric rheumatology setting.

Methods: Patients and/or their caregivers were recruited as a convenience sample across four pediatric rheumatology ambulatory sites at Stanford Children's Health, a tertiary care academic medical center. We conducted individual semi-structured interviews following participants' clinic or telemedicine visits. Interviews were recorded and transcribed, and we employed an inductive reflexive thematic analysis approach outlined by Braun and Clark to analyze the data.

Results: Twenty-four participants (7 adult patients, 17 patient-caregiver dyads) were invited to participate in semi-structured interviews following their clinic or telemedicine visits. Patient diagnoses included juvenile idiopathic arthritis (JIA), systemic lupus erythematosus (SLE), juvenile dermatomyositis (JDM), and localized scleroderma, Inflammatory Bowel Disease-associated spondyloarthropathy. We identified four major themes and ten sub-themes that characterized patient and caregiver experiences, attitudes and perceptions on how OurNotes may foster strategies for enhancing their rheumatology care experience. Major themes included *Empowering Patients and Families as Partners, Impact on Care Delivery, Information Impact, and User Experience*. The results are summarized concisely in Table 1 with supportive illustrative excerpts.

Information Impact
• "When I read providers chart notes versus the notes that I take, it's kind of like a check and balance to make sure that this is what we are going to do, this is our plan. This is what I understood and that's what you guys understood. That way, there's no mishap or incorrect diagnosis or incorrect miscalculation of medication. So, it's definitely helpful for me to just make sure that, yes, we are on the same page. And if we're not, or if I don't see something in in your guys' notes like, you know, I'll email you guys and just be like, hey, you know, I noticed I was going through your notes, and you didn't say anything about so and so or whatever it is. Is this still the plan?" (Parent 9)
• "I just think it's good to have a central place to kind of look back at all of the notes from different appointments. Sometimes it's hard because we have some outside providers, so if the information is being transferred back and forth, it's just nice to refer back to the notes. Especially if I'm speaking to someone else and telling what happened in that appointment." (Parent 5)
• "I actually thought that that was helpful information to have access to. It was just very factual, and kind of a summary of where she was at. I thought it was interesting to read [the provider's] perspective on where things were in her words. I think it was it's just helpful sometimes to hear things you know just in a different way…I think it just added more clarity." (Parent 14)
• "Yes, I always try to read the doctor's notes either after the visit or before the next visit. I think it's always important that I know my health history and that I'm aware of everything in the doctor's notes, and I think it always helps me prepare questions for the next visit. It's also great to see the evolution of my health history over time, I think it's very important." (Patient 6)
• "I think what it helps is that during the appointment we talk, but we don't remember everything, right? So, basically what the doctor says, especially certain medications that are discontinued or no longer used or for example if there is any lab result, we need to be paying more attention to. What I find in the notes is that everything is written and captured, so I can go and review it and relate back to what we discussed during the appointment. So, in that sense it's kind of, rather than kind of just having that ambiguity in that what was discussed during the visit, the written note makes it more concrete" (Parent 16)
• "I find it helpful if I need to go back and reference something that they said that I couldn't remember. The amount of information, you get in an appointment is overwhelming and if you're juggling a small kid, it's hard to take notes, and so I think it is nice sometimes to go back. I mean, probably not everything is in there, but majority of stuff you could probably find, or I have found answers to in the past by having access to that." (Parent 12)
• "I think it's a good idea that this questionnaire gets integrated into the doctor notes. I think it's nice for both, us, and the provider, to review on both sides. So, in the future when you want to look back and see what our concerns were at a certain point in time, and what the doctor decided the plan was going to be, it may be helpful." (Parent 16)
• "It's so many different medicines and this disease is extremely complicated. A lot goes into it on a day-to-day basis and changes happen rapidly. I just to like to stay on board and you don't want to do the wrong thing. So, it's good to have a reference and then you know sometimes if you have to call your doctor's office, sometimes they're busy and you get a machine and then you gotta wait for them to call you back. So, this like provides clear messages, what the doctor said, and how to do things. It's very thorough and it's an amazing system, I think." (Parent 4)
• "…I really want to focus on him and we're there. I try to give him all my attention to help him manage his emotions and manage what he's going through. So, having my attention divided, I can sometimes miss something. I try to take notes in the moment, but it doesn't always happen. I've been able to look over his notes and make sure that I know where we're going with his treatment plan, and I know what to expect in the future." (Parent 1)
User experience
• "I'm so comfortable with everything now, and so familiar with everything we went through, but in the beginning, there was so much that I think that having this would have even made me feel more comfortable and confident in going into every appointment." (Parent 8)
• "I think that the only drawback is my time, like the effort that I'm willing to put in, and I think that it really did put the pressure, not pressure, but like just enough for me to feel like I really need to prepare and make sure that I'm walking in knowing what's going on. So, I enjoyed that. I think maybe for some people the time might be an issue." (Parent 1)
• "It depends on the week. The week that we had it, we had time to sit and go over it. Sometimes things just get crazy and busy, and it might just be another thing to do, but I think it's beneficial if you take the time to do it." (Parent 7)
• "I think I did get a little nervous. I was like oh, I better make sure that this sounds intelligent. But I realized like, it's just it's a document like any other and it's there for communication and record keeping. So, anything that I share is I think adds value, you know, and so I chilled out about it. Yeah, I find it really exciting that I get to contribute to his file." (Parent 1)
• "I think it's a great idea for parents to be able to put in their concerns. Sometimes I think I can be over worried, so that would be my only concern, listing things that may not be of immediate concern. If it's going to be solidified in the notes, I would want it to just be accurate and not my worries. I would just be afraid that would clutter up the actual detail of the note." (Parent 17)
• "I think that the questionnaire seemed very secure, and I feel like I would have been comfortable expressing any concerns in the survey, because I know that it's through a safe website and it's going directly to my provider and to people within the system that care about my health and well-being." (Patient 6)
• "I'm a very open person. So, I kind of feel like all cards are on the table, and I would put it in the chart if it's important to me and if I feel like I really need to discuss it, even though it may be embarrassing. I'm mindful, for the fact that I'm an adult, and nobody has access to my MyHealth or MyChart except for me, but if I was like a teenager who wanted to talk about something that my parents might have access to, I don't know if I would feel comfortable putting it in there." (Patient 7)
• "The only thing that I can think of would be just access. If people don't have access, right? The mobile version is more robust in some ways, but it's less user friendly. If you only have access through your cell phone, I don't think that you could do the question nearly as easily. I did it on my laptop, and so just, you know, having access to the Internet and access to a device is needed. What if you're not tech savvy?" (Parent 2)

Themes and Illustrative Quotes



Conclusion: OurNotes represents a novel application of the electronic health record that has the potential to bridge inefficiencies in care among patients and families with chronic rheumatic conditions by enhancing information flow, fostering active collaboration and supporting more personalized and productive care interactions. Clinical transparency and inclusivity afforded by this approach empowered patients and families to effectively participate in care with greater autonomy in decision-making. Participants also endorsed a better understanding of their care, improved dialogue during visits and greater trust and satisfaction with their providers. More research is needed to demonstrate the best practices of OurNotes, paying special attention to clinical workflow integration, equitable access, and patient privacy and confidentiality.

Experiences of Wearable Technology by Persons with Knee Osteoarthritis Participating in a Physical Activity Counselling Intervention Study: A Relational Ethics Lens

Jenny Leese[1], Graham Macdonald[1], Anne Townsend[2], Catherine L. Backman[1], Laura Nimmon[1] and Linda Li[1], [1]University of British Columbia, Vancouver, BC, Canada, [2]Lancaster University, Lancaster, United Kingdom

SESSION INFORMATION
Session Date: Monday, November 8, 2021
Session Title: Health Services Research Poster II: Care Models and Innovation (1061–1082)
Session Type: Poster Session C
Session Time: 8:30AM–10:30AM

Background/Purpose: Current evidence indicates wearable physical activity trackers could support persons with knee osteoarthritis (OA) to be more physically active. Recent empirical evidence also identifies, however, some persons with arthritis experience guilt or worry while using a wearable if they are not as active as they should be. Questions remain around how persons with knee OA experience benefits or downsides in using a physical activity wearable in their everyday lives. Better understanding of these experiences are needed if wearable technology is to be incorporated in arthritis self-management in ways that are ethically aware. Our aim was to use an ethics lens to describe a range of experiences (positive or negative) from persons with knee OA who used a wearable as part of a physical activity counselling intervention study.

Methods: This is a secondary analysis of qualitative interviews (60-90 mins) nested within a randomized controlled trial (RCT). Guided by phenomenography, we explored the experiences of persons with knee OA, following their participation in a physical activity counselling intervention. The intervention consisted of participants attending a 1.5-hour education session about physical activity, using a Fitbit Flex, and receiving 4 biweekly phone calls for activity counselling with a study physiotherapist (PT) in an 8-week period. All PTs were trained in the Brief Action Planning approach, whereby they guided participants to identify activity goals, develop an action plan, and identify barriers and solutions. Benefits or downsides in participants' experiences of using the wearable were identified using a relational ethics lens, with attention paid to any impacts on their relationships with themselves (i.e., their self-perception) or the study PT.

Results: Interviews with 21 participants (12 females; 9 males) aged 40-82 years were analyzed. Education ranged from high school graduate (n=4) to bachelor's degree or above (n=11). Three categories of description were identified: 1) Participants experienced their wearable as a motivating or nagging influence to be more active, depending on how freely they were able to make autonomous choices about physical activity in their everyday lives; 2) Some participants felt a sense of accomplishment from seeing progress in their wearable data, which fuelled motivation. One participant experienced negative emotions (e.g., self-blame) if his wearable data indicated physical activity goals were not met; 3) For some participants, sharing wearable data helped to build mutual trust in their relationship with the study PT. They also expressed, however, there was potential for sharing wearable data to undermine this trust if, for example, they perceived the data as inaccurate.

Conclusion: To our knowledge, this is the first qualitative study that uses a relational ethics lens to explore how persons with arthritis experienced changes in their relationship with a health professional when using a wearable during research participation. Findings also provide an early glimpse into positive and negative emotional impacts of using a wearable that can be experienced by participants with knee OA when participating in an RCT to support physical activity participation.

Experiences Using Wearable Technology by Persons with Rheumatoid Arthritis Participating in a Physical Activity Counselling Intervention Study: A Relational Ethics Analysis

Jenny Leese[1], Siyi Zhu[2], Anne Townsend[3], Catherine L. Backman[1], Laura Nimmon[1] and Linda Li[1], [1]University of British Columbia, Vancouver, BC, Canada, [2]Sichuan University, Chengdu, China (People's Republic), [3]Lancaster University, Lancaster, United Kingdom

SESSION INFORMATION
Session Date: Monday, November 8, 2021
Session Title: Health Services Research Poster II: Care Models and Innovation (1061–1082)
Session Type: Poster Session C
Session Time: 8:30AM–10:30AM

Background/Purpose: Using wearables to self-monitor physical activity is a promising approach to support self-management among persons with arthritis. Evidence indicates, from perspectives of persons with arthritis, using a wearable influences interaction with health professionals in positive and negative ways. Questions remain about benefits and downsides that may be experienced by persons with arthritis in relationships with themselves (i.e., self-perception) and others, if using a wearable in self-management. Relational ethics is a suitable conceptual lens to explore positives or negatives encountered in these relationships. Our aim was to use this ethics lens to better understand how persons with rheumatoid arthritis (RA) experience their use of a wearable as part of a physical activity counselling intervention study involving a physiotherapist (PT).

Methods: A constructivist grounded theory design and a relational ethics lens guided data collection and analysis. A sample of persons with RA took part in an initial and follow-up interview following participation in an 8-week randomized controlled trial. Participants used a Fitbit-Flex-2 paired with a new web-based application to self-monitor physical activity, received education and counselling from a study PT and received 4 biweekly calls from the PT. We

took a systematic approach of coding transcripts, and forming concepts and key categories to construct a conceptual framework underpinned by concepts of relational ethics.

Results: Initial interviews took place with 14 participants (12 female; 2 male) aged 29-71 years. Of these, 11 took part in a follow-up interview. A conceptual framework was developed to illustrate key categories identified in analysis. These categories describe positive and negative influences of using a wearable with the PT on how participants constructed a valued moral identity: 1) Participants expressed how being active intertwined with moral values placed on self-control within cultural norms in which they lived. For some, using a wearable helped to "do something right" by reaching step goals or sitting less. Some, however, felt ambivalent (feeling both justified and at fault) when they could not reach a physical activity goal; 2) Participants described how their distrust of wearable data raised moral tensions in their relationship with the PT, which had implications for how mutual trustworthiness was negotiated; 3) Participants conveyed being active as a means of preserving or regaining respect for themselves as an independent and productive person. Some described how interpreting wearable data with the PT helped them to affirm this valued sense of self.

Conclusion: This study contributes a situated relational ethics conceptual framework grounded in empirical evidence to sparse literature on how persons with arthritis experience their use of a physical activity wearable positively or negatively. It brings to light salient ethical issues pertaining to autonomy, mutual trust, and respect for further study in the context of everyday self-management. It is a key step to informing how to incorporate wearable-enabled programs that support physical activity participation in ways that are ethically aware.

Abstract Number: 1072

The Multidisciplinary Approach with Patient Collaboration Improve the Clinical Effectiveness of the Intervention

Carlos González[1], Luis Menchén-Viso[1], Ofelia Baniandres-Rodriguez[1], Carmen Lobo-Rodríguez[1], Ana Herranz-Alonso[1], Ignacio Marín-Jiménez[1], Juan Carlos Nieto[2], Lucia Ibares-Frias[1], Indalecio Monteagudo[1], Esther Chamorro de Vega[1], Javier Torresano-Bruno[1], Amparo Lopez-Esteban[1], Arantza Ais-Larisgoitia[1], Paloma Morales de los Ríos Luna[1], ana Lopez-Calleja[1], Sonia Garcia de San Jose[3] and Jose Maria Alvaro-Gracia[3], [1]CEIMI, Hospital General Universitario Gregorio Marañón, Madrid, Spain, [2]Hospital General Universitario Gregorio Marañón, Madrid, Spain, [3]Hospital General Universitario Gregorio Maranón, Madrid, Spain

SESSION INFORMATION
Session Date: Monday, November 8, 2021
Session Title: Health Services Research Poster II: Care Models and Innovation (1061–1082)
Session Type: Poster Session C
Session Time: 8:30AM–10:30AM

Background/Purpose: We have developed a multidisciplinary unit for patients in treatment with biological therapies (BT) with the collaboration of Dermatology (Der), Gastroenterology (GE), Rheumatology (Rheu), Ophthalmology (Oft), Endocrinology , M Preventive, Nursing and Pharmacy. Diseases: rheumatoid arthritis (RA), spondyloarthritis (SpA), psoriatic arthritis (PsA), inflammatory bowel disease (IBD) and psoriasis (Ps). Patients collaborate in the management of the unit.

Objective: To check the changes that the new model can offer in accessibility, efficiency effectiveness, and quality of life, as well as delving into the concept of multidisciplinarity.

Table 1: effectiveness results

	Rheu		GE		Der	
	2019	2020	2019	2020	2019	2020
Patients clinical remission (%)	52.3	62.4	67.3	72.6	78.4	82.8
Hospital admissions, any cause (%)	10.7	6.4	15.9	9.8	3.8	4.3
ER admissions, any cause (%)	25.6	20.3	37.4	24.5	17.1	12.4

Methods: Unit began in January 2019 and results of 2020 have been compared with 2019. Indicators: number of patients attended, patients starting BT, patients from another health area, proportion of patients who need to be attended by more than a specialty, proportion of patients in clinical remission, percentage of patients admitted to hospital or emergency room for any cause, annual cost of BT per patient, proportion of patients on biosimilar, EuroQol, hospital scale of depression and anxiety (HAD), labor productivity questionnaire (WPAI).

Results: In 2020, 8,156 medical consultations, 11,014 nursing consultations, 2,311 pharmaceutical care and 4,093 treatments were carried out in the day hospital. 2020 and (2019) indicators: Accessibility: 2,940 (2,280) patients, patients starting BT: 145 (140); BT patients: Rheu 1011 (868), digestive 640 (652), dermatology 210 (211); patients from another healthcare area: Rheu 43.8% (40.1%), GE 46.6% (41.9%), Der 30.8% (25.0%). The effectiveness results are shown in the attached table. Efficiency: average annual cost BT, RA € 5,747 (€ 6,371), SpA € 5,757 (€ 6,371), PsA € 6,331 (€ 6,895), IBD € 7,977 (€ 8,693), Ps 6,945 € (€ 7,210); Patients on biosimilar treatment, RA 55.2% (55.7%), SpA 38.0% (28.4%), PsA 34.7% (31.9%), EII 57.3% (48, 9%), Ps 25.9% (13.6%). Quality of life: Median EuroQol (IQR): Rheu: 75 (60-85) vs 70 (50-80) in 2019; GE 80 (60-86) vs 75 (69-80) in 2019; Der 80 (70-90) vs 77.5 (67.5-90.0) in 2019. Median HAD (IQR): Rheu 13 (-22) vs 11 (6-18) in 2019; GE 8 (5-16) vs 9 (7-10) in 2019; Der 6 (3-7) vs 5.5 (4-11) in 2019. WPAI hours / week, mean (SD): Rheu 3.9 (11.1) vs 4.3 (11.6); GE 3.9 (10.5) vs 2.7 (6.9), Der 0 vs 0.8 (2.1). Multidisciplinariety in 2020: Reu 23.3%, GE 20.5%, Der 46.8%, Oft 24.6%.

Conclusion: We observed an improvement in the quality of care in our multidisciplinary unit for patients treated with biological therapies with their collaboration in the management. Noteworthy was the improvement in the effectiveness of BT, measured by the percentage of patients in clinical remission and the decrease in patients admitted to hospital or to the emergency room. However, the improvement in the quality of life with the instruments used is not so evident. We need to deepen the analysis of the indicators used and the procedures of our model to confirm this improvement.

Abstract Number: 1073

In Favor of the Subspecialty Clinic Model for Rheumatoid Arthritis

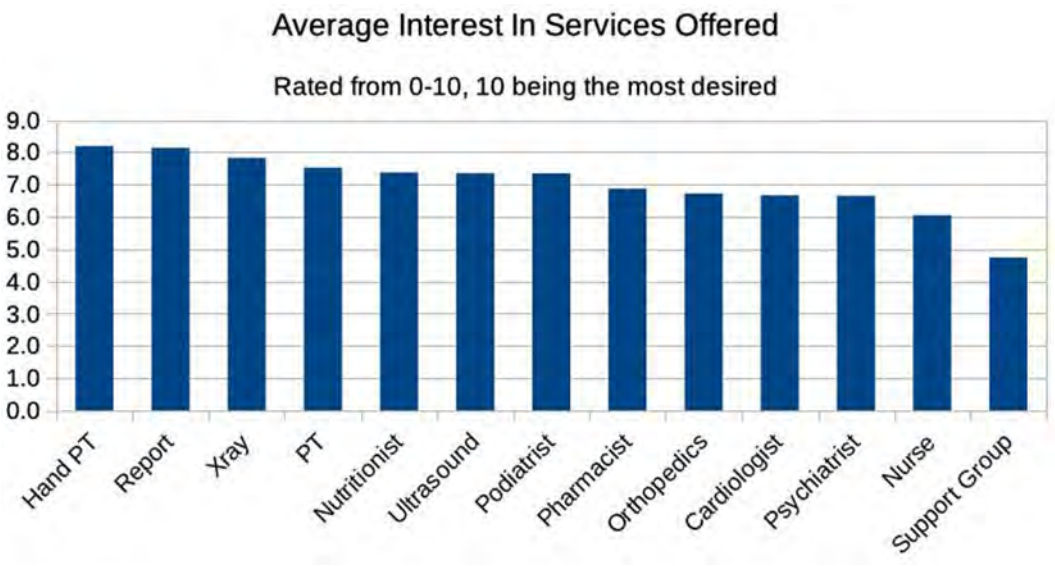
Jasmine Thai[1], Roshan Patel[1], Yeohan Song[1] and Sheryl Mascarenhas[2], [1]Ohio State University, Columbus, OH, [2]Ohio State University Hospital, Columbus, OH

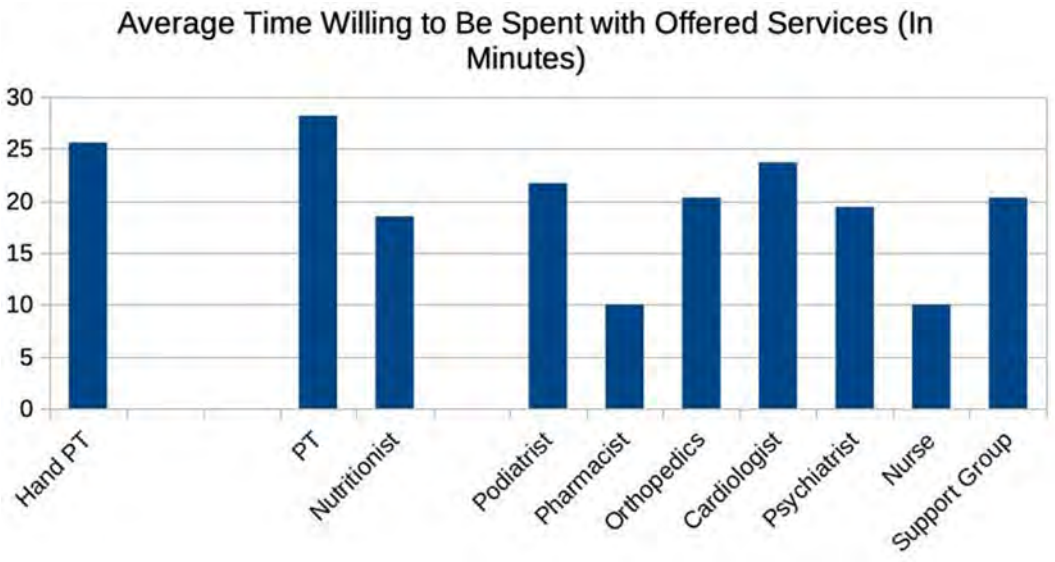
SESSION INFORMATION
Session Date: Monday, November 8, 2021
Session Title: Health Services Research Poster II: Care Models and Innovation (1061–1082)
Session Type: Poster Session C
Session Time: 8:30AM–10:30AM

Background/Purpose: The Subspecialty Clinic Model (SCM) which seeks to allow for collaborative care and services by stratifying patients with a particular disease or need to a specialized clinic has been growing in popularity in rheumatology. This model has been shown to not only improve patient satisfaction but also patient outcomes. While the SCM is popular in other rheumatologic diseases such as lupus, it is less popular for rheumatoid arthritis. In this study, we sought to collect patients' perspectives on a SCM for RA. **To our knowledge, this is the first study to take into account patient perspectives in designing a RA subspecialty clinic**.

Methods: 54 adult patients with a diagnosis of RA based on ICD-10 diagnostic codes were surveyed at an outpatient rheumatology clinic. Participants were asked to complete a survey rating their interest (0-10, with 10 being the most desired) in having a service (pharmacist, nurse, physical therapist, hand therapist, orthopedics, podiatrist, psychiatrist, cardiologist, support group, xray, ultrasound), the time (0, 5, 15, 20, 30, 45, 60 minutes) they were willing to have with said services, whether they would agree to be billed for the services, how often they would attend a clinic under the SCM, and if they would transfer care to a SCM. Statistical measures of location were used to analyze the data.

Results: Among those surveyed, 88% of respondents were interested in having at least one of the services that were described. Almost all participants (94%) expressed interest in getting an annual report. Having a psychiatrist help improve pain perception was the least popular service, but over half the respondents still expressed interest (62%). Among respondents who were interested in a service, the service that evoked the strongest interest was hand physical therapy (average of 8.19). The service that evoked the weakest response was a support group (average of 4.74). Participants were willing to spend the most time with a physical therapist (average 28 minutes) and the least time





with a pharmacist and nurse (average 10 minutes). More than 75% of respondents were willing to be billed for xrays, ultrasound, physical therapy, hand therapy, and orthopedics. Less than 60% of respondents were willing to be billed for the remaining services. 74% of participants reported that they would attend a clinic under the SCM at least yearly and 50% were willing to transfer their care in order to access these services.

Conclusion: Patient perspective and satisfaction has recently become a focus in medicine as it often positively correlates to patient outcomes. The response from our participants were strongly in favor of the SCM for rheumatoid arthritis. This indicates that movement to the SCM may be advisable.

Session Type: Poster Session C
Session Time: 8:30AM–10:30AM

Background/Purpose: Learning collaboratives (LC) have been used widely for quality improvement in healthcare, and a recent 9-month in person LC was found effective for improving treat to target (TTT) in RA (1). However, there is relatively little information about the experiences of participants in a virtual LC and little qualitative data or participant feedback on how this format can be improved.

Methods: During the COVID pandemic, we conducted a virtual LC with 18 rheumatology practices. The LC focused on implementing TTT in RA and included a virtual kick-off meeting (run over 5-6 hours) and monthly webinars. The

kick-off meeting introduced topics and discussed plan-do-study-act (PDSA) cycles as a main tool for quality improvement. Practices prepared for the monthly webinars with 20-25 chart reviews and submission of PDSA cycles. At the end of the collaborative, leaders of each practice received an anonymous 12 question survey on site characteristics. All 45 participants, including site leads, received a separate anonymous survey focused on their experience in the LC. These questions asked participants to reflect on their participation and evaluate the LC. The following analyses describe the survey responses.

Results: All 18 active rheumatology practices and 35 of 45 participants (78%) responded to the site and individual surveys, respectively. Characteristics of the practices are shown in **Table 1** and included multiple practice types, with 12 academic rheumatology practices, 2 academically affiliated practices, and 4 non-academic practices. The number of RA patients seen regularly at participating practices ranged widely from < 450 RA patients to > 1000. The number of participants in the LC at practices ranged from 1 to 8. As noted in **Table 2**, 63% of respondents indicated they attended 5 or 6 of the monthly webinars. 97% of respondents indicated they were somewhat or very active in monthly PDSA planning and approximately 77% of clinicians submitted chart reviews for 5 or 6 months of the collaborative.

Table 3: Future Learning Collaborative Suggested Medium and Topics Based on Individual Surveys (N = 35)

	Type of Collaborative	N (%)
Preferred Collaborative Medium	Virtual	13 (37%)
	Hybrid	18 (51%)
	In-Person	4 (11%)
	Topic	N (%) "Very Interested/Interested"
Future LC Topics with High Reported Levels of Interest ("Interested/Very Interested")	Improving Management of Steroid Induced Osteoporosis	29 (83%)
	Improving Adherence to Vaccination Schedules	24 (69%)
	Cardiovascular Risk Factor Management	26 (74%)
	Reproductive Health Counseling	27 (77%)
	Laboratory Monitoring for Drugs and Diseases	30 (86%)
	Obesity and Weight Management	25 (71%)

Table 2 shows that 94% of respondents indicated they were either somewhat or very satisfied with the LC, and 94% of respondents said they would recommend a similar LC to a colleague. Regarding LC format, 37% of respondents indicated they would prefer a virtual LC, and 51% indicated they would prefer a hybrid (virtual and in-person) model (**Table 3**). Respondents noted that they would be very interested in future LCs on a range of rheumatology-specific topics (**Table 3**), including improving management of glucocorticoid induced osteoporosis, cardiovascular risk factor management, reproductive health counseling, and laboratory monitoring for drugs and diseases.

Conclusion: Virtual multi-center LCs are feasible, and participants were very satisfied with the virtual format. Virtual LCs are highly valued by rheumatologists, trainees, and their practice staffs. Potential topics were identified for future LCs that could improve the quality of care delivered to rheumatology patients.

Abstract Number: 1075

The Impact of an Integrated Care Management Program on Acute Care Use for Potentially Avoidable Conditions Among High-Risk Patients with SLE

Jessica Williams[1], Kreager Taber[1], Weixing Huang[1], Jamie Collins[1], Rebecca Cunningham[1], Katherine Concannon[1], Christine Vogeli[2], Lisa Wichmann[1] and Candace Feldman[1], [1]Brigham and Women's Hospital, Boston, MA, [2]Massachusetts General Hospital, Boston, MA

SESSION INFORMATION
Session Date: Monday, November 8, 2021
Session Title: Health Services Research Poster II: Care Models and Innovation (1061–1082)
Session Type: Poster Session C
Session Time: 8:30AM–10:30AM

Background/Purpose: Patients with SLE are disproportionately from populations with lower socioeconomic status and poorer access to health care, placing them at risk for potentially avoidable acute care use (emergency department [ED] visits and hospitalizations that could be avoided if high-quality outpatient care were provided). We defined potentially avoidable acute care conditions using the Agency for Healthcare Research and Quality's 10 prevention quality indicators for adults and a recently published set of 25 SLE-specific, ambulatory care-sensitive outcomes[1] (**Table 1**). A nurse-led, primary care-based integrated care management program (iCMP) at our multihospital system coordinates care for patients at high-risk for frequent acute care use due to comorbidities, demographics, and prior use patterns. We studied whether iCMP was effective at decreasing rates of potentially avoidable ED visits and hospitalizations among patients with SLE.

Methods: We identified adults with SLE enrolled in iCMP from January 2012-February 2019. We then used electronic health record (EHR) data linked to insurance claims to compare incidence rates of potentially avoidable ED visits (composite variable and individual conditions) and potentially avoidable hospitalizations (composite variable and individual conditions) during iCMP enrollment vs. during the 12-months prior to iCMP enrollment. We used Poisson regression to compare incidence rate ratios (IRR) during iCMP versus pre-iCMP for each utilization measure, adjusted for age, sex, race/ethnicity, number of comorbidities, and calendar year, accounting for within-patient clustering. All upper gastrointestinal (GI) bleeds and osteoporotic fractures were considered potentially avoidable as we did not have information about whether patients were taking GI protectants or osteoporosis therapy.

Results: We identified 67 iCMP enrollees with SLE and linked EHR-claims data. Sixty-one of 67 met 1997 ACR criteria for SLE; 4 met 2012 SLICC criteria and 2 did not meet criteria but were diagnosed by a rheumatologist. The mean age was 60 years; 93% were female, 55% were white, 25% Black, 16% other race, and 3% Asian; 21% were Latinx. Median iCMP enrollment time was 33 months. During iCMP enrollment, there was a decrease in the overall rate of potentially avoidable ED visits (IRR 0.50; 95% CI 0.28-0.88; see **Table 2**) and potentially avoidable hospitalizations

Table 1. Potentially Avoidable Conditions for Emergency Department Visits or Hospitalizations Among Patients with SLE[1]

Infections
Community-acquired pneumonia
Influenza
Herpes zoster
Urinary tract infection
Hepatitis B
Meningococcal disease
Pneumococcal disease
Pneumocystis pneumonia while receiving moderate-to-high dose glucocorticoids
Cardiovascular Disease
Hypertension
Congestive heart failure
Angina without procedure
Recurrent myocardial infarction
Pulmonary Disease
Chronic obstructive pulmonary disease
Asthma
Renal Disease
Chronic kidney disease or end-stage renal disease among patients with known lupus nephritis
Thromboembolic Disease
Vascular thrombosis among SLE patients with antiphospholipid antibody syndrome
Embolic stroke among SLE patients with antiphospholipid antibody syndrome
Vascular thrombosis among SLE patients with positive antiphospholipid antibodies receiving estrogen-based contraception
Diabetes Mellitus-Related
Diabetes long-term complication
Diabetes short-term complication
Uncontrolled diabetes
Complications from uncontrolled glucocorticoid-induced diabetes mellitus
Lower-extremity amputation among patients with diabetes
Medication-Related
Vision loss from hydroxychloroquine toxicity
Chronic opioid use
Opioid overdose
Osteoporotic fracture among patients with SLE receiving glucocorticoids
Avascular necrosis among patients with SLE receiving prolonged glucocorticoids
Gastrointestinal bleed on glucocorticoids, non-steroidal anti-inflammatory drugs, or anticoagulation
Obstetrics/Gynecology-Related
Fetal anomalies on teratogenic medications
Neonatal lupus/congenital heart block in the offspring of a patient with positive anti-Ro or anti-La antibodies
Spontaneous abortion in an SLE patient receiving teratogenic medications
Obstetrical complications among SLE patients with antiphospholipid syndrome
Premature ovarian insufficiency/infertility in a patient following standard dose cyclophosphamide
High-grade cervical dysplasia/cervical cancer
General Preventive Care
Lupus flare in the absence of ultraviolet light protection

SLE=systemic lupus erythematosus 1. Feldman CH et al. Development of a Set of Lupus-Specific, Ambulatory Care-Sensitive, Potentially Preventable Adverse Conditions: A Delphi Consensus Study. Arthritis Care Res (Hoboken). 2021; 73: 146-57.

(IRR 0.37; 95% CI 0.21-0.65; see **Table 3**). We also found that during iCMP enrollment, there was an increase in the rate of ED visits for upper GI bleed (IRR 1.28; 95% CI 1.15-1.42).

Conclusion: We found that a nurse-led, primary care-based integrated care management program is effective at decreasing the rate of potentially avoidable ED visits and hospitalizations among high-risk SLE patients. We hypothesize that this is due to optimization of outpatient care. ED visits for upper GI bleeds also increased during iCMP, possibly due to medication use (for example, steroids). Further multicenter studies of integrated care management programs are needed to confirm these findings.

Table 2. Incidence Rate Ratios (IRR) for Potentially Avoidable Emergency Department (ED) Visits During the Integrated Care Management Program (iCMP) as Compared to Pre-iCMP (Reference)

Primary Discharge Diagnosis	Pre-iCMP IR* (95% CI)	During iCMP IR* (95% CI)	IRR (95% CI) (Ref=pre-iCMP)
All potentially avoidable conditions	12.0 (4.0-32.0)	6.0 (2.0-15.0)	**0.50 (0.28-0.88)**

Combining Fuzzy Logic with Time-Driven Activity Based Costing Within the Rheumatoid Arthritis Care Cycle: Insights from a Dutch Hospital

Fiona Koster[1], Deirisa Lopes Barreto[2], Marc Kok[3] and Angelique Weel-Koenders[1], [1]Maasstad Hospital Rotterdam, Rotterdam, Netherlands, [2]Maasstad Hospital Rotterdam, Rotterdam, [3]Maasstad Hospital, Rotterdam, Netherlands

SESSION INFORMATION

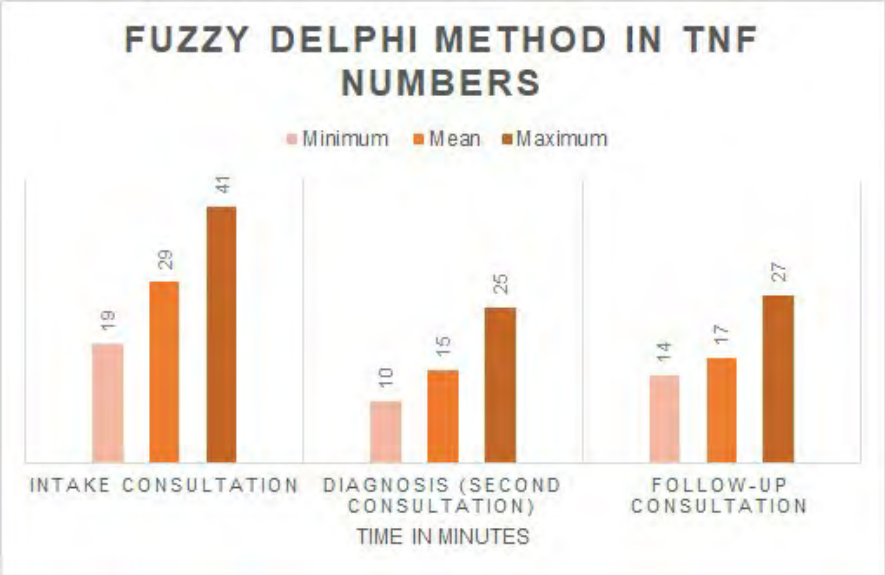
Session Date: Monday, November 8, 2021

Session Title: Health Services Research Poster II: Care Models and Innovation (1061–1082)

Session Type: Poster Session C

Session Time: 8:30AM–10:30AM

Background/Purpose: Transparency and management of healthcare costs is warranted for rheumatoid arthritis (RA) as the disease places a great economic burden on a patient and societal level. Time-Driven Activity Based Costing (TDABC) is a cost accounting method that may support value-based healthcare (VBHC) management programs. A flaw of TDABC is the inaccuracy of the time estimates due to heterogeneity in patients' care needs, presence of



Graph 1. Results of fuzzy Delphi method displayed in TNF numbers.

(multi)morbidity and the variety of providers. Thus, we aimed to gain knowledge in the costs of the RA care cycle and improve the accuracy of the cost estimates with the fuzzy logic method.

Methods: The data was retrieved from the outpatient department of rheumatology at Maasstad hospital. The care delivery value chain (CDVC) and the corresponding process map serves as a base for the assessment of the costs of the RA care cycle. To correct for the imprecision and ambiguity of the parameters in the TDABC model, the fuzzy logic Delphi method was applied and expressed in triangular fuzzy numbers (TNF). The average TNF numbers were obtained by focus groups and surveys for consultations with the medical team; rheumatologists, nurse practitioners, physician assistants, rheumatology nurses and doctor's assistants. Minimum, average and maximum time estimates were compared to the standard time frames of the procedures and finally, utilized to calculate the total costs of the RA care cycle.

Results: Conducting the Delphi method gave insight in the time estimations of staff members. With respect to the rheumatologists, a distinction was made between the intake, diagnosis and the follow-up consultations. Graph 1 shows the results of the fuzzy Delphi method concerning the average estimates of the rheumatologists. With respect to the first consultation, the estimates of the physicians were considerably lower compared to the standard determined value of 50 minutes. The highest estimate, namely 45 minutes for the maximum TNF, is not even close to the standard time for the intake consult. Remarkable is the fact that the diagnosis consult is valued at 25 minutes regarding the maximum time needed. No distinction is made between the diagnosis and follow-up consult with respect to the standard time values, despite the fact that the time of the diagnosis consultation is significantly lower compared to the follow-up consultations (i.e. 40 minutes). The spread concerning time estimates are on average lowest for the follow-up consultations.

Conclusion: Fuzzy logic was combined with TDABC to encounter the deficiencies related to the TDABC methodology. To provide an accurate and precise estimate of the costs concerning the RA care cycle, time estimates of the complex and expensive procedures are calculated as TNF numbers. The results will depict the resource costs of the RA care cycle in three ways, namely the minimum costs of the care cycle, the mean costs and the maximum costs. Hence, the fuzzy logic estimates reflect reality more properly. As TDABC is still in its infancy, this research contributes to the investigation of a convenient cost accounting method concerning care cycles.

*SMD = standardized mean difference, CI = confidence interval, RMDs = rheumatic and musculoskeletal diseases, *inflammatory RMDs, degenerative RMDs, mixed populations or unspecified , SL = sick leave, NA = not available*

Background/Purpose: Despite improvements in the treatment of rheumatic and musculoskeletal diseases (RMDs), reduced work participation persists when compared to the general population. A Task Force within the European Alliance of Associations for Rheumatology (EULAR) aimed to establish Points to Consider to support people with RMDs in healthy and sustainable work participation. Non-pharmacological interventions could have an important role in this regard. The objective of the evidence synthesis was to summarize the effectiveness of non-pharmacological interventions to promote work participation in people with RMDs.

Methods: Randomized controlled trials (RCTs) and observational studies assessing non-pharmacological interventions until August 2020 were eligible. Records addressing people with any non-work-related RMD and assessing at least one work participation outcome domain (sick leave, work status, presenteeism) were eligible. Two reviewers screened titles, abstracts and full-texts. Data on study, population and intervention characteristics, and effectiveness were extracted for qualitative and quantitative synthesis. For quantitative synthesis per outcome domain, standardized mean differences (SMDs) were used as effect size measure, with a negative SMD favoring intervention. RCTs were included in Mixed Effects Meta-Regression Analyses and a fixed effect for the specific study, stratifying for population and intervention characteristics.

Results: Out of 8,864 records, 73 were included for extraction and analysis. These 73 records described 64 studies of 71 interventions. Studies included a mixed population of RMDs (42%), followed by musculoskeletal pain (36%). Sick leave was the most frequently assessed outcome domain (88% of studies). The majority of interventions were conducted in a clinical setting (62%) and had multiple components (80%), such as vocational support (46%) and physical training (61%). In the qualitative synthesis, including 64 studies, 30%/50%/29% of interventions were considered to be possibly effective (interpretations of reviewers) on sick leave/work status/presenteeism, respectively. In the quantitative synthesis, 37 RCTs (42 interventions) were included. Their population and intervention characteristics were largely similar to those of the total sample. Interventions showed significant, but small to moderate effect sizes, favoring intervention over comparator: SMD=-0.23 (95%CI -0.33 to -0.13) for sick leave, SMD=-0.38 (-0.63 to -0.12) for work status and SMD=-0.25 (-0.39 to -0.12) for presenteeism (Table). Stratified analyses showed that interventions were effective in both populations not at risk and populations at risk or already on sick leave. Both single- and multiple-component interventions had a small positive effect on sick leave and presenteeism respectively. Of note, there was substantial heterogeneity between studies.

Conclusion: Overall, non-pharmacological interventions may have a small effect on sick leave, work status and presenteeism in RMDs. This effect varies substantially between subgroups. This synthesis suggests tailoring non-pharmacological work-related support to individuals' needs and contextual factors.

Abstract Number: 1078

Rural Veterans with Gout – "Rheum" for Improvement

Jennifer Barton[1], Elizabeth Hooker[2], Christopher Larsen[2], Rachel Matsumoto[2] and Allison O'Neill[2], [1]VA Portland Health Care System/OHSU, Portland, OR, [2]Center to Improve Veteran Involvement in Care/VA Portland Health Care System, Portland, OR

SESSION INFORMATION

Session Date: Monday, November 8, 2021
Session Title: Health Services Research Poster II: Care Models and Innovation (1061–1082)
Session Type: Poster Session C
Session Time: 8:30AM–10:30AM

Background/Purpose: Gout is a form of inflammatory arthritis that can be "cured" with appropriate urate-lowering therapy to achieve a goal uric acid of 6mg/dL or lower. Rheumatology specialty care is associated with improved control, however access to specialty care for rural Veterans can be a challenge. Our objectives were to explore factors associated with poorly controlled gout among rural Veterans and the impact of dose among those receiving allopurinol.

Methods: Veterans residing in VISN 20 in rural areas were identified using the Corporate Data Warehouse (CDW). Inclusion criteria: in 2019, Veterans: 1) received care from VA, 2) had ≥ 2 ICD codes for gout, 3) were age 18 years or older, and 4) had at least 1 serum uric acid (sUA) measurement. Data on gender, age, race/ethnicity, body mass index (BMI), and visit type (primary care or rheumatology) were extracted from CDW. Controlled status over the course of a panel-year was determined as follows: no sUA elevation (≤6 mg/dl) and no diagnosis code for tophus. Gout med-

Table. Observed and predicted percentages of rural VA patients in VISN 20 with controlled gout^ in 2019

[a] Mixed logistic regression with clustering for site
[b] Model 1: Adjusted for patient characteristics, clustered for site
^ controlled gout defined as: no serum uric acid (≤6 mg/dl), no diagnosis code for tophus

ications included any receipt of urate lowering therapy (allopurinol or febuxostat), colchicine, prednisone and non-steroidal anti-inflammatories (NSAIDs) within 2019. Descriptive statistics are presented for patient characteristics. Mixed logistic regression models with clustering for site were run to examine the association between age, race/ethnicity, BMI, and controlled gout.

Results: A total of 2,421 Veterans were identified as having gout and received care at VA in 2019 with VISN 20, 896 (37%) of whom resided in a rural area. Among rural-residing Veterans, 311 (35%) met the definition of controlled gout compared with 31% of urban Veterans. The majority of the rural population were male (98%), between 65 and 80 years old (55%), white (82%) and overweight or obese (68%). In a model with age, race, and BMI, rural Veterans in all age groups over 50 years old were significantly more likely to have controlled gout compared with those under 50 years old (predicted percentage (PP) controlled gout (95% CI): Age < =50 years: 23.3% (14.3-32.2); Age >80 years: 37.8% (28.2-47.4); p= 0.03). There was no significant variation by race or BMI category. Urate lowering therapy with allopurinol was common (76.0%) among rural Veterans with many fewer receiving febuxostat (6.4%). In an unadjusted model, Veterans with receipt of any allopurinol in 2019 had a significantly higher likelihood of controlled gout compared to those without any allopurinol receipt (PP 17% (95% CI 10.3, 23.7).

Conclusion: In this study of rural Veterans who receive care in VA, only one third had controlled gout using serum urate levels. Interventions that share rheumatology best practices and expertise for managing gout with VA primary care teams, such as the VA Rheumatology ECHO program and expansion of telehealth within VA rheumatology, should be developed and tested to enhance quality of care for rural Veterans.

SESSION INFORMATION
Session Date: Monday, November 8, 2021
Session Title: Health Services Research Poster II: Care Models and Innovation (1061–1082)
Session Type: Poster Session C
Session Time: 8:30AM–10:30AM

Background/Purpose: Patient portals provide patients and caregivers the opportunity to be more engaged in their healthcare, as it promotes autonomy and encourages patients and caregivers to take an active role in their care. The adoption of patient portals in the pediatric population compared to the adult population is complex as healthcare providers need to balance the privacy of the patient whilst providing information access to the caregiver. Since the implementation of an electronic medical record system at our pediatric institution in 2018, the enrollment and activation of patients/caregivers profiles to the patient portal has been low. The objectives of this quality improvement project were a) to double the patient/caregiver enrollment and activation of the patient portal profiles from the baseline rate

over one-year period; b) to understand barriers to enrollment and activation; and c) to identify and create systems to facilitate enrollment and activation of the patient portal.

Methods: Iterative Plan-Do-Study-Act (PDSA) cycles were used to create culture change amongst the healthcare team to promote increased patient portal enrollment and activation. Strategies were initially launched with the quality improvement team champions and were later spread to other members of the healthcare team. Results from the PDSA cycles were reviewed and shared with the healthcare team on regular intervals. Feedback from the team were used to inform each successive iterative cycle.

Results: Strategies employed during PDSA cycles that were directed at the healthcare team included educational sessions, pre-clinic identification of patients with inactive profiles, reminders within the electronic medical record, email reminders, and weekly updates. Strategies targeted to patients/caregivers in PDSA cycles included the creation of patient/caregiver activation instructions, and placement of the registration link in email signatures of healthcare team members, after visit summaries, and appointment reminder emails.

The combined strategies increased enrollment and activation from the baseline rate of 15% to 41% over a one-year period. Using a multi-pronged strategy, which informed patients about the opportunity to enroll at various points of contact with the clinic, created a redundancy mechanism that also facilitated enrollment. Barriers to enrollment and activation included patients/caregivers not activating their profile within the eligible period, patient/caregivers not wanting to enroll due to privacy concerns, healthcare team forgetting to offer enrollment, activation emails being misdirected to patients'/caregivers' spam, and the need for patients to re-enroll at ages 12 and 16.

Conclusion: Strategic planning and education of stakeholders are important in the implementation of new programs. Designing small changes that stakeholders are willing to adopt into their daily routine also facilitates this process. Helping stakeholders understand the benefit of patient portal access augmented their willingness to assist enrolling patients/caregivers. Similarly, patients/caregivers were eager to enroll after understanding the functionalities of the application.

SESSION INFORMATION
Session Date: Monday, November 8, 2021
Session Title: Health Services Research Poster II: Care Models and Innovation (1061–1082)
Session Type: Poster Session C
Session Time: 8:30AM–10:30AM

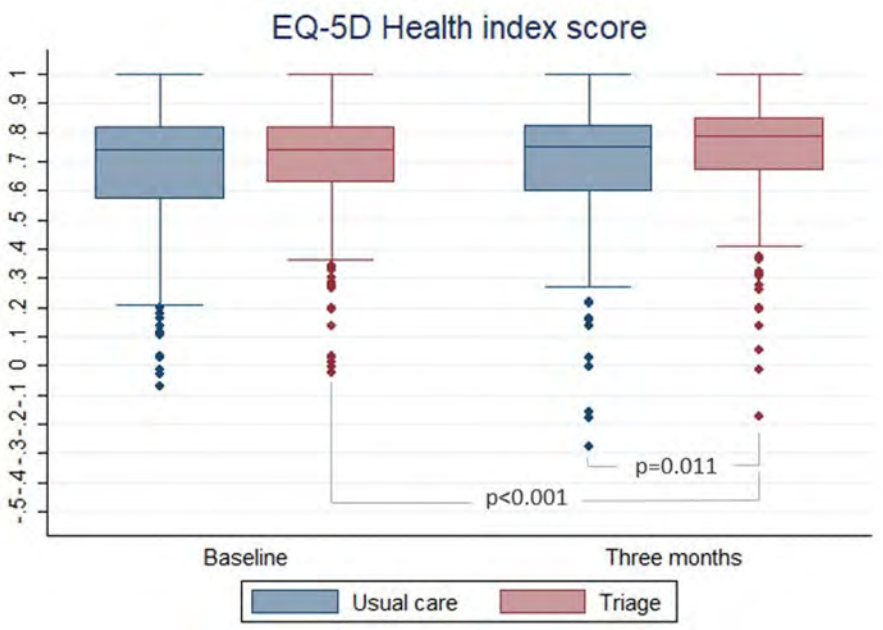

Figure 1. Change of quality of life measured by the health index score over three months after initial visit to rheumatologist.

Background/Purpose: General practitioners have difficulties recognising inflammatory rheumatic diseases (IRD), reflected by a low incidence rate of IRD in newly referred arthralgia patients. On the other hand, IRD needs to be diagnosed and treated as early as possible to overcome progression.

The objective of this study is to assess whether triage by a rheumatologist in a primary care setting effectively increases the number of appropriately referred patients to secondary care and to investigate its impact on health care utilization and patient experience.

Methods: This study follows a cluster randomized controlled trial design and is performed in the Netherlands. Triage by an experienced rheumatologist in a primary care setting will be compared to usual care where patients are referred to a rheumatologist in secondary care by advice of their own general practitioner. The primary outcome was the percentage of IRD diagnoses in referred patients as assessed by a rheumatologist. Health care utilization (iMCQ), quality of life (EQ-5D) and quality of care (CQI) were determined after three months of follow-up.

Results: A total of 544 participants were included with a mean age of 51.4 years and 24% were men. Of all referred patients, 51% had an IRD in the triage group versus 21% in the usual care group (OR 3.85, p< 0.001). After three months, triage patients showed to have a lower health care utilization (p=0.009) mainly regarding secondary care, and higher quality of life (p=0.011), without a decline in quality of care (p=0.712).

Conclusion: Triage by a rheumatologist in primary care provides appropriate care at the right place with good quality for patients with MSC. While these results are encouraging, more long term evidence is needed of value on cost-effectiveness before implementing this strategy in daily practice.

Improving Rheumatology Resource Utilization and Access to Specialty Care for Patients with Early Inflammatory Arthritis Through Enhanced Triage

Kristina Roche[1], John Hanly[1], Jennifer MacKinnon[2], Susan Parlee[2], Trudy Taylor[1], Volodko Bakowsky[1], Cheri Gunn[2], Nikolas Harris[3] and Janet Roberts[4], [1]Dalhousie University, Halifax, NS, Canada, [2]Nova Scotia Health Authority, Halifax, NS, Canada, [3]The Arthritis Society, Halifax, NS, Canada, [4]Dalhousie University, Halifac, NS, Canada

SESSION INFORMATION
Session Date: Monday, November 8, 2021
Session Title: Health Services Research Poster II: Care Models and Innovation (1061–1082)
Session Type: Poster Session C
Session Time: 8:30AM–10:30AM

Background/Purpose: In many health care jurisdictions the demand for rheumatology consultation exceeds the capacity to provide timely access for all referrals. This has highlighted the importance of enhanced triage to ensure timely access to care for those with the most urgent need. The purpose of this project was to design and evaluate a systematic centralized triage system to improve identification of patients with new onset inflammatory arthritis.

Methods: In this prospective randomized study, half of new referrals received for arthritis at a single academic health care centre with 10 attending staff rheumatologists were assigned to the "enhanced" centralized triage process (intervention); the other 50% of referrals were assessed using the "standard" current triage system (control). Referrals were randomly assigned to a triage arm using a randomization schedule generated through REDCap. In the intervention arm, referrals were triaged based on the probability of inflammatory arthritis using a combination of laboratory data including rheumatoid factor, anti-cyclic citrullinated peptide antibodies, C-reactive protein twice the upper limit of normal and a scoring algorithm using a validated early inflammatory arthritis questionnaire. Referrals in the control arm were triaged by individual rheumatologists as per their usual practice. Data regarding referral content, patient

Table 1: Demographic and Referral Data for the 198 Patients Included in the Study

		Enhanced (n=99)	Standard (n=99)
Average Age		52.667	53.040
Sex	Female	69 (69.7%)	72 (72.7%)
	Male	30 (30.3%)	27 (27.3%)
Referral Source	Family Physician	85	81
	Nurse Practitioner	3	3
	Specialist	5	14
	Other	6	1
Referral Declined		24	9
Telephone Consult Between Referring Physician and Rheumatologist		2 (1 went on to be booked as urgent)	3
Total Number of Patients Managed Without an Initial In-Person Appointment		25	12
Triage Category Assigned	Urgent	68	64
	Semi-Urgent	6	23

Table 2: Diagnosis and Time to Assessment for Urgent Referrals

	Enhanced (n=68)	Standard (n=64)
Inflammatory Arthritis	37	30
Crystalline Arthritis	6	7
Diagnosis Unclear	1	1
Connective Tissue Disease	0	4
Non-inflammatory Condition (tendonitis/fibromyalgia/OA etc.)	24	22
Average time from referral to first assessment for patients with Inflammatory Arthritis (days)	70.24	87

demographics, diagnosis, triage category, disease activity and time from receipt of referral to first assessment were collected and entered into a REDCap database.

Results: 198 patients were included in the study, 99 patients in each arm (Table 1). A higher percentage of patients requiring urgent assessment were confirmed to have inflammatory arthritis in the intervention arm compared to the control arm (54.4% vs .46.9%) although this did not reach statistical significance (P = 0.384). More patients in the intervention arm compared to the control arm (25 vs 12; P = 0.018) were managed without requiring an in-person clinic appointment, in which case initial treatment recommendations were sent directly to the referring physician. This reduced in person clinic visits and avoided prolonged delays in treatment implementation. In addition, wait times for rheumatology assessment for those with inflammatory arthritis was 17 days shorter in the intervention arm (70.2 vs. 87 days) although this did not reach statistical significance (P = 0.191).

Conclusion: For patients referred for suspected inflammatory arthritis, a systematic centralized triage system may lead to improved outcomes; these include better agreement between triage suspected diagnosis and rheumatologist confirmed diagnosis of inflammatory arthritis, improved wait times and more referrals managed without an unnecessary rheumatology assessment.

SESSION INFORMATION
Session Date: Monday, November 8, 2021
Session Title: Health Services Research Poster II: Care Models and Innovation (1061–1082)
Session Type: Poster Session C
Session Time: 8:30AM–10:30AM

Background/Purpose: A rheumatology workforce survey conducted in Canada in 2015 predicted a looming critical shortage of rheumatologists, with one third of surveyed rheumatologists indicating plans to retire between 2020-2025[1]. Moreover, the demographics of the available workforce are changing as females and millennials now comprise a larger proportion of practicing rheumatologists. The Canadian Rheumatology Association (CRA) distributed the 2020 Workforce and Wellness Survey to update the Canadian rheumatology workforce characteristics. As the survey was launched during the COVID-19 pandemic, it provided the opportunity to understand the impact of the pandemic on rheumatologists' practices and burnout.

Methods: The survey was developed from the 2015 iteration and expanded to include the additional aims. It consisted of 26 questions including demographic and practice information, how the pandemic impacted practice, and the Mini-Z questionnaire[2] was used to assess burnout. After pilot testing by 8 rheumatologists, French and English versions of the electronic survey were distributed to CRA members with 12 email reminders. The survey was open for responses from 10/14/2020-03/05/2021. We estimated the number of full-time equivalent (FTE) rheumatologists per 75,000 population from the median proportion of time in clinical practice multiplied by provincial rheumatologist numbers from the Canadian Medical Association.

Results: The response rate was 43% (183/430) of expected practicing rheumatologists (149 adult and 34 pediatric). The median age was 47 years, 62% were female, and 28% planned to retire within the next 5-10 years. Rheumatologists spent a median of 70% of their time in clinical practice, holding a median of 6 (IQR 3-7) half-day clinics, with 6 (IQR 4-12) new consultations and 40 (IQR 25-60) follow-ups seen per week. We estimated between 0 and 0.70 FTE rheumatologists per 75,000 population in each province/territory and 0.62 per 75,000 population in Canada. This represents a deficit of 1 to 78 FTE rheumatologists per province/territory and a total of 194 FTE rheumatologists needed in Canada to meet the CRA recommendation of 1 rheumatologist per 75,000 population.

As a result of the pandemic, rheumatologists were more engaged in virtual care (97% increase). There was a reported reduction in the number of half-day clinics per week, with fewer new and follow-up patients seen per week, and more time spent on clinical paperwork.

Over half of rheumatologists (51%) reported burnout. Women were at 2.86 (95%CI 1.42, 5.93) increased odds of burnout. Age was protective against burnout, with a decrease in odds of 0.95% (95%CI 0.92, 0.99) per year of age.

Conclusion: We highlight the ongoing shortage of rheumatologists in Canada and that this is likely to worsen in the near future without increasing new graduates to cover retirements. This problem may be compounded by the threat of burnout to the retention and productivity of the current workforce. The pandemic has significantly impacted patient volume, likely affecting rheumatologist remuneration and contributing to delayed care.

Session Date: Monday, November 8, 2021

Session Title: Miscellaneous Rheumatic & Inflammatory Diseases Poster II: Clinical Features & Diagnostics (1083–1117)

Session Type: Poster Session C

Session Time: 8:30AM–10:30AM

Background/Purpose: The exaggerated inflammatory responses to the SARS-CoV-2 virus and the paucity of data on COVID-19 infection risk in systemic autoinflammatory disease (SAID) patients posed many unanswered questions, in addition to the profound overall impact of the pandemic.

The aim of this study is to determine if SAID patients had any changes in flare frequency or fevers during the COVID-19 pandemic, and to assess the outcome of SAID patients infected with the SARS-CoV-2 virus.

Methods: The CARRA Autoinflammatory Working Group collaborated with the Autoinflammatory Alliance to conduct an anonymous online survey which was distributed via social media and online autoinflammatory patient groups globally. Data collection was carried out from January 2021 through May 2021.

Results: A total of 647 surveys were completed. In those, 452 of the surveyed listed a specific SAID affecting them and/or their children. (Table 1)

Data for 593 patients showed that the frequency of flares (compared to pre-pandemic) were unchanged in 56% (n=334) of patients overall. The distribution of our data included 57% of patients from the United States, US territories and Canada and 70% of the international patients. Globally 54% of individuals reported that fevers during flares were either lower (n=31) or absent (n=58) since March 2020, and (n=31) found that their fevers were higher with flares.

Specific Diagnosis of Autoinflammatory Diseases of Subjects in the Survey			
	US territories, Canada	Other countries	Total
CAPS (all forms)	77	32	109
unclassified SAID	58	12	70
PFAPA	49	15	64

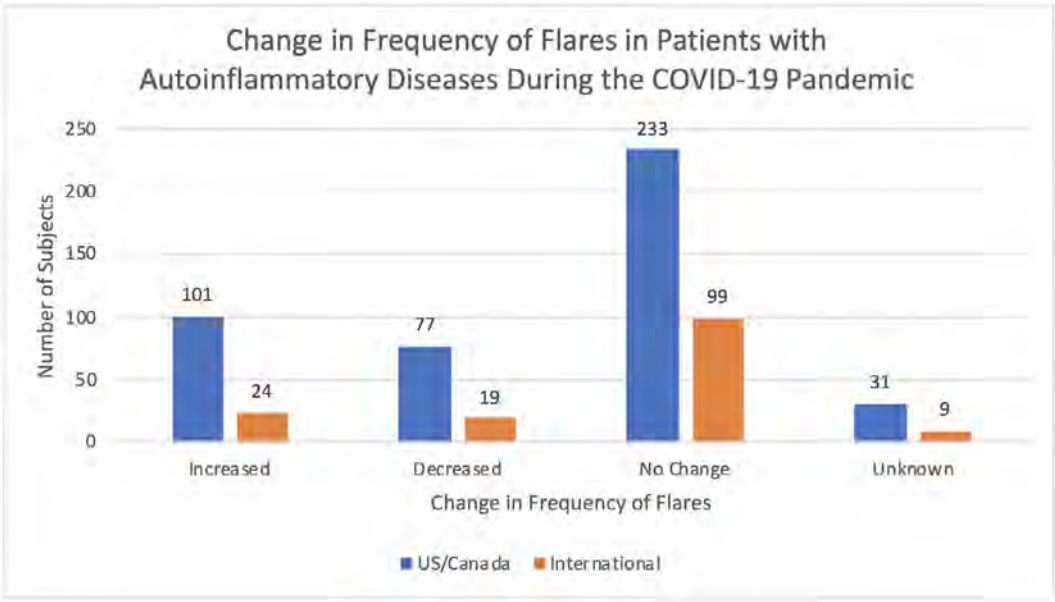
TRAPS	25	7	32
FMF	23	8	31
Behçet's	21	8	29
MKD/HIDS	13	6	19
NLRP12 (FCAS2)	8	3	11
CRMO/CNO/SAPHO	5	3	8
NOD2 (not Blau)	7	0	7
Others*	22	13	35
Totals	**339**	**113**	**452**

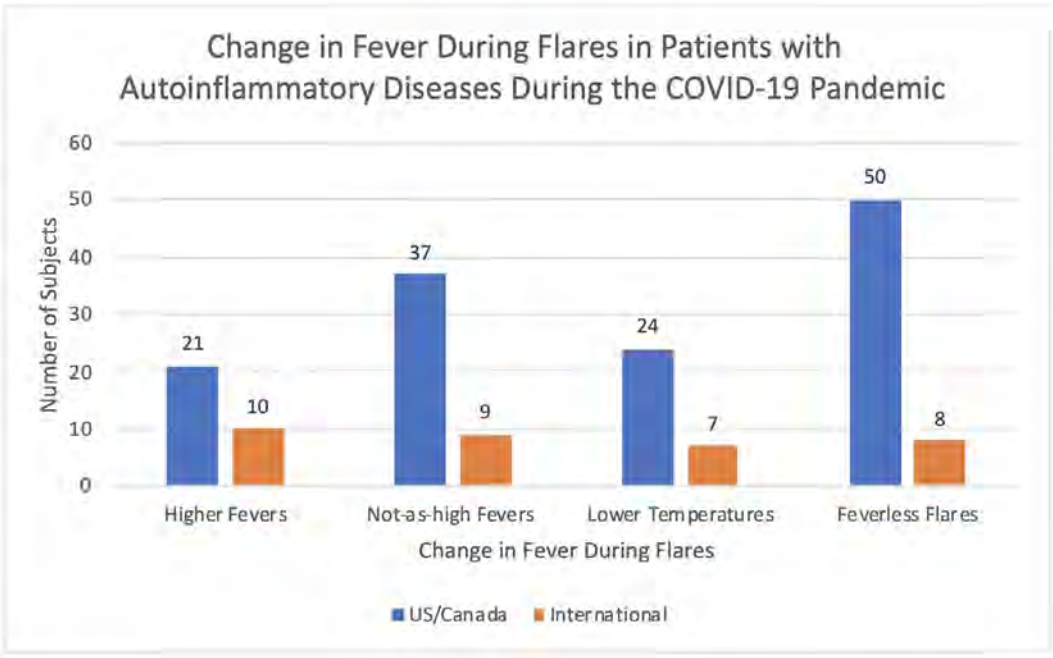
CAPS: Cryopyrin-associated periodic syndrome; PFAPA: Periodic Fever, Aphthous Stomatitis, Pharyngitis, and cervical Adenitis; SJIA: Systemic Juvenile Idiopathic Arthritis; TRAPS: Tumor necrosis factor receptor-associated periodic syndrome; FMF: familial Mediterranean fever; MKD: mevalonate kinase deficiency; HIDS: Hyper-IgD syndrome; *NLRP12*: NOD-like receptor family pyrin domain containing-3; FCAS2: Familial cold autoinflammatory syndrome-2; CRMO: Chronic Recurrent Multifocal Osteomyelitis; CNO: Chronic Non-bacterial Osteomyelitis; SAPHO: Synovitis Acne Pustulosis Hyperostosis Osteitis; *NOD2*: Nucleotide-binding oligomerization domain-containing protein- 2.

* Each diagnosis had between 1 and 4 subjects and include: autoinflammatory syndrome familial Behçet's-like (AIBSL/HA20); Aicardi Goutières; Chronic atypical neutrophilic dermatosis with lipodystrophy and elevated temperature (CANDLE); Deficiency of adenosine deaminase- 2 (DADA2); Deficiency of IL-1 receptor antagonist (DIRA); Hidradenitis suppurativa; *LPIN* mutation with periodic fevers; pyogenic sterile arthritis, pyoderma gangrenosum and acne syndrome; PAPA- PASH; PAPASH; *PLCG2* associated antibody deficiency and immune dysregulation (PLAID or FCAS3); STING-associated vasculopathy with onset in infancy (SAVI); Schnitzler syndrome; Sweet syndrome; Trisomy 8 related autoinflammatory disease (TRIAD).

(Graphic 1) Most individuals were sheltering from work or school and 50% had no changes in their medication for SAID.

SARS-CoV-2 positivity occurred in 35 subjects. 20% (n=7) were asymptomatic, 40% (n=14) had mild infection, 31% (n=11) suffered with moderate illness at home and three (8%) were hospitalized in the regular ward. From the patients who contracted SARS-CoV-2, 31% (n=11) had a flare of their underlying SAID, either concurrently (20%, n=7) or after recovering from COVID-19 infection (11%; n=4). (Table 2) Ten (29%) SARS-CoV-2 positive patients reported lingering symptoms after resolution of acute COVID-19, such as headaches, fatigue, respiratory issues, myalgia and joint pain. Twenty patients reported physician-diagnosed presumed COVID-19, including a Neuro-Behçet's patient requiring intensive care (ICU). Of these, 60% (n=12) had persistent symptoms post-COVID. One case of Multisystem Inflammatory Syndrome in children (MIS-C) and one case of Multisystem Inflammatory Syndrome in adults (MIS-A) with macrophage activation syndrome (MAS) occurred in patients with physician-diagnosed presumed COVID-19.





Conclusion: These data reflect the largest known global cohort of SAID patients' experiences during the COVID-19 pandemic. Most patients had no change in flare frequency from their baseline SAID but many had a reduced intensity of their fevers during flares. The majority of SAID patients with COVID-19 infection reported mild to moderate illness with approximately a third who presented with an exacerbation of their baseline SAID with COVID-19 and lingering symptoms.

Outcomes of Patients with SAID who had Confirmed or Presumed COVID-19 infection by Specific SAID Diagnosis

COVID-19 Among Patients with Inflammatory Arthropathies Participating in the RHUMADATA Clinical Database and Registry

Denis Choquette[1], Louis Bessette[2], Loïc Choquette Sauvageau[1], Boulos Haraoui[1], Isabelle Ferdinand[1], Frédéric Massicotte[1], Valerie Nadon[1], Jean-Pierre Pelletier[1], Jean-Pierre Raynauld[1], Marie-Anaïs Rémillard[1], Diane Sauvageau[1], Edith Villeneuve[1] and Louis Coupal[3], [1]Institut de Rhumatologie de Montréal, Montréal, QC, Canada, [2]Centre de l'Ostoporose et de Rhumatologie de Qubec, Québec City, QC, Canada, [3]Institut de Rhumatologie de Montréal, Saint-Lambert, QC, Canada

SESSION INFORMATION

Session Date: Monday, November 8, 2021

Session Title: Miscellaneous Rheumatic & Inflammatory Diseases Poster II: Clinical Features & Diagnostics (1083–1117)

Session Type: Poster Session C

Session Time: 8:30AM–10:30AM

Background/Purpose: The COVID-19 pandemic has hit the world since 2019. The province of Québec in Canada has not escaped this plague. Our goal is to compare inflammatory arthropathies patients with and without COVID-19 and compare the cumulative rate of COVID-19 infections in our cohort to that of reference populations.

Methods: RHUMADATA® clinical database and registry collect patient data that includes socio-demographics, patient-reported outcomes, disease activity indices, laboratory variables, clinical exam data, concomitant medications, inflammatory disease treatments, comorbidities, and infections. Patients followed either in person or by phone were systematically asked about their COVID-19 status since March 2019. More specifically, patients were asked about signs and symptoms of COVID-19, actual positive/negative test results and history of contact and travels. We

matched four patients without COVID-19 (controls) to each patient with COVID-19. The matching was made based on primary diagnosis, gender, age at diagnosis, and year of last treatment. The analyses were performed on data extracted on May 11, 2021. We used the number of reported COVID-19 infections to develop estimates of the burden of infection in our cohort. We further compared these estimates to that of reference populations.

Results: Fifty-four patients are known to have had COVID-19 in the RHUMADATA cohort. The crude rate of confirmed COVID- 19 cases among active RHUMADATA patients is estimated at 1324 per 100,000 (95% CI = [1021,1715]) or alternatively 13.9 cases per 1000 person-years of follow-up (95% CI = [10.5,18.0]). The treatment, clinical, and comorbidity profiles of patients with COVID-19 were like their matched controls. Overall, most subjects were women (68%). Three deaths were observed in our cohort; two occurred in the COVID-19 group and were attributed to COVID-19. As of May 27, 2021, the estimated cumulative rate of confirmed COVID-19 cases in the province of Québec is 4302 per 100,000, the second-highest rate among Canadian provinces. The reported rates from "local service networks" located around Montréal (Montréal, Laval, Montérégie) ranged from 2573 to 9214 cases per 100,000.

A matched cohort study using national Veterans Affairs data compared COVID-19 rates of RA and non-RA patients (1). Estimated rates were of 27.3 [25.5, 29.2] and 20.5 [19.0, 22.1] per 1000 person-years.

A recent seroprevalence study produced by *Héma Québec* estimated that 15% of the Québec population developed COVID-19 antibodies (10% because of an infection and 5% due to vaccination).

Conclusion: The rate of COVID-19 infections in the RHUMADATA cohort is lower than rates observed in the general population in the region of Montreal and among VA RA and non-RA patients. These differences may result from under-reporting, gender-ethnic-cultural differences, adherence to protective measures due to efficacy beliefs, and methodological differences.

SESSION INFORMATION

Session Date: Monday, November 8, 2021

Session Title: Miscellaneous Rheumatic & Inflammatory Diseases Poster II: Clinical Features & Diagnostics (1083–1117)

Session Type: Poster Session C

Session Time: 8:30AM–10:30AM

Background/Purpose: COVID19 may present different degrees of severity. It is generally thought that viral infections in patients with rheumatic inflammatory diseases (R-IMID) or receiving immunosuppressive treatment tend to present more severe disease. However, data comparing the severity of the disease between R-IMID and the general population are scarce.

Our aim was to assess the predisposing factors, clinical-analytical features and severity of COVID-19 infection in R-IMID compare to patients without R-IMID.

TABLE. Main clinical and analytical features of patients with R-IMID and matched controls

	R-IMID patients (n=274)	Controls (n=274)	P
Age	59.1±18	58.8±17.3	0.842
Sex F/M, n, (%)	185/89 (67.5/32.5)	185/89 (67.5/32.5)	1
Comorbidities (n,%)			
Hypertension	119 (43.4)	84 (30.7)	**0.0026***
Dyslipidemia	119 (43.4)	79 (28.8)	**0.0005***
Obesity	49 (17.9)	49 (17.9)	1
Diabetes mellitus	36 (13.1)	37 (13.5)	1
Pulmonary disease	29 (10.6)	32 (11.7)	0.79
Cardiovascular disease	45 (16.4)	33 (12)	0.18
Severity of the disease (n, %)			
Mild	209 (76.3)	204 (74.5)	0.69
Moderate	35 (12.8)	47 (17.2)	0.19
Severe	9 (3.3)	14 (5.1)	0.39
Critical	21 (7.7)	9 (3.3)	**0.04***
Deaths	17 (6.2)	7 (2.6)	**0.0076***
Analytical values, median [IQR]			
CRP	4.7 [2-9.3]	3.9 [1-7.3]	0.176
Creatinine (mg/dl)	0.91 [0.7-1.1]	0.79 [0.7-1.1]	0.214
Lymphocytes (x10^3 /µL)	1 [0.6-1.5]	1.1 [0.8-2.5]	0.711
Platelets (x10^3 /µL)	179 [141-237]	174 [155-211]	0.722
D-Dimer (ng/mL)	999 [342-1417]	548 [336-997]	**0.032***

CRP: C-reactive protein.

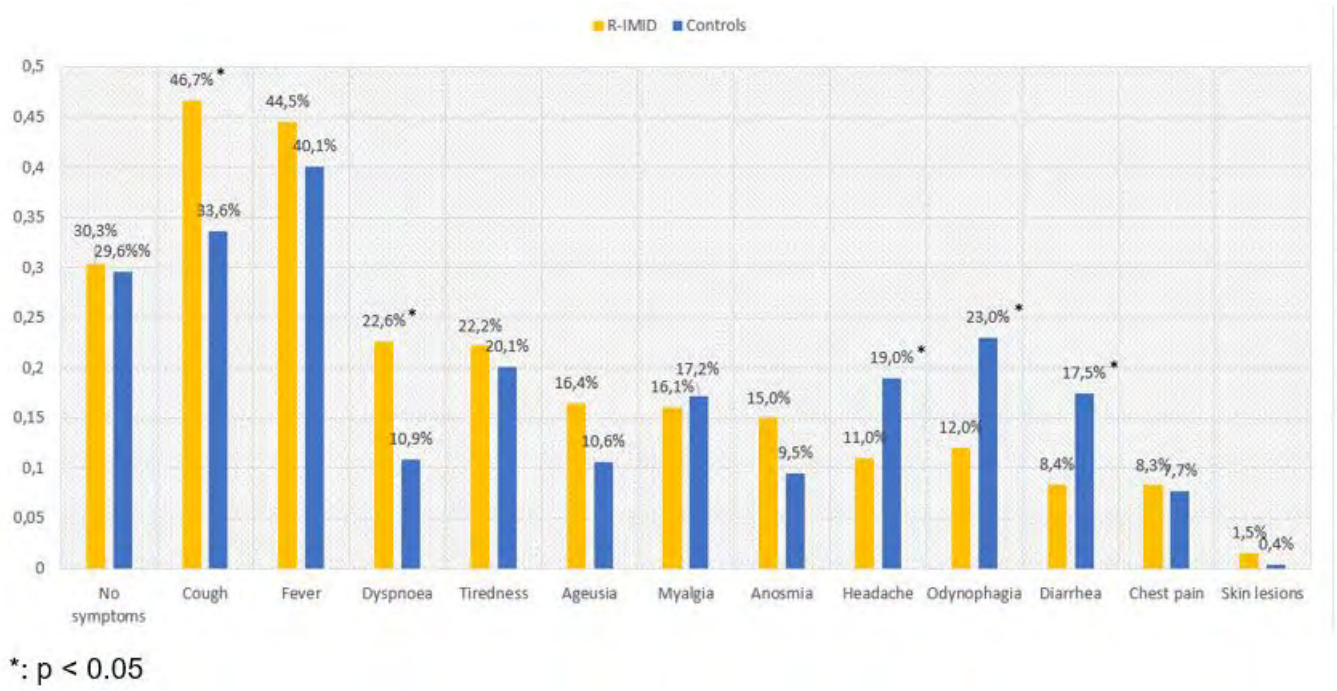

FIGURE. Symptoms in R-IMID patients and matched controls.

Methods: Case-control study in a single University Hospital. We included all consecutive patients with a diagnosis of a R-IMID and a positive test for COVID-19 up to March 31st, 2021.

A total of 274 controls were selected for each case, and matched by sex, age (± 5 years), and without previous diagnosis of R-IMID or use of immunosuppresive therapy.

Confirmed infection was defined if the patient had a positive nasopharyngeal swab for SARS-CoV-2.

COVID-19 case severity was divided into mild, moderate, severe and critical according to the United States National Institute of Health (NIH) COVID-19 guidelines. Mild/moderate COVID19 was compared with critical.

Results: We included 274 patients (185 women/89 men), mean age 59.1 18 years.

More frequent R-IMID were: Rheumatoid arthritis (RA) (n=87, 31.8%), Axial spondyloarthritis/ Psoriatic arthritis (SpA/PsA) (n=90, 32.8%), Polymyalgia Rheumatica (PMR) (n=22, 8%) and Systemic Lupus Erythematosus (SLE) (n=22, 8%)

We also included 274 age and matched controls. Main characteristics of patients with R-IMID and controls are shown in **TABLE**.

Concerning comorbidities, hypertension and dyslipidemia were more frequent in patients with R-IMID ($p< 0.05$).

COVID-19 symptoms' distribution is shown in **FIGURE**.

Cough and dyspnoea were more frequent and headache, odynophagia and diarrhea were less frequent in the R-IMID group.

The only analytical difference was D-Dimer that was significantly higher in patients with R-IMID.

Although most of the cases were mild, critical cases and deaths were more frequent in R-IMID ($p < 0.05$).

Conclusion: Most of the patients present a mild COVID-19. However, a more severe syndrome was observed in R-IMID

Abstract Number: 1086

Lack of Effect of SARS-CoV-2 Vaccination on Cell Bound Complement Activation Products (CB-CAPs), Multianalyte Assay Panel (MAP) with Algorithm, and Inflammatory Biomarkers

Mark Rudolph, Anja Kammensheidt and Roberta Alexander, Exagen Inc., Vista, CA

SESSION INFORMATION
Session Date: Monday, November 8, 2021
Session Title: Miscellaneous Rheumatic & Inflammatory Diseases Poster II: Clinical Features & Diagnostics (1083–1117)
Session Type: Poster Session C
Session Time: 8:30AM–10:30AM

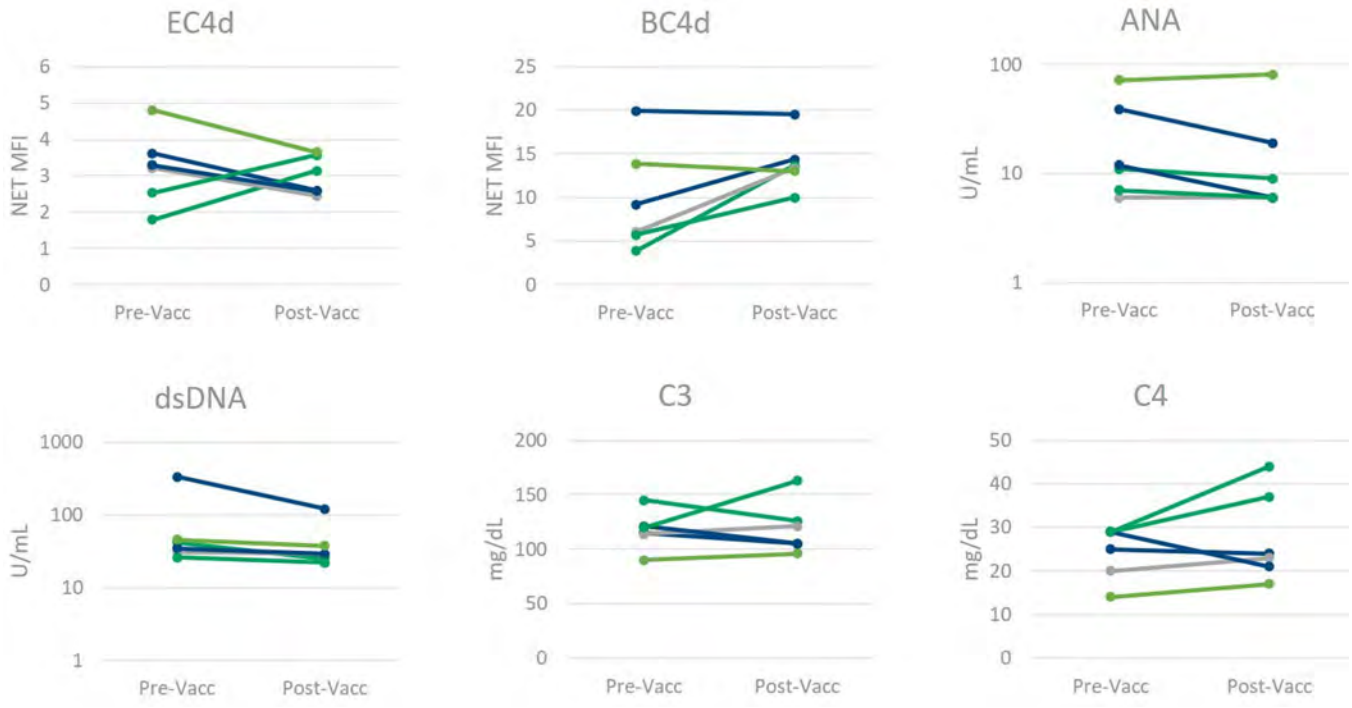

Figure 1. Multianalyte Assay Panel (MAP) components remain constant following SARS-CoV-2 Vaccination. The levels of erythrocyte- and B-cell bound C4d (measured by flow cytometry, reported as Net MFI), anti-nuclear antibodies (ANA) and anti-dsDNA (measured by ELISA, reported in Units/mL), and complement proteins C3 and C4 (measured by immunoturbidimetry, reported as mg/dL) do not significantly change in normal healthy individuals following SARS-CoV-2 vaccination. (Confirmed by paired, two-tailed homoscedastic t-test for all but anti-dsDNA (heteroscedastic).

Table 1. Normal healthy median and interquartile range values pre- and post-SARS-CoV-2 vaccination. Results of EC4d and BC4d (Net MFI), ANA and anti-dsDNA (U/mL), C3 and C4 concentration (mg/dL), and cytokine concentrations (interferon-gamma (IFN**γ**), interleukins (IL)-6, -8, -10, -17A, and 18, tumor necrosis factor-alpha (TNF**α**), IFN**γ**-induced protein-10 (IP-10), interferon-alpha-2a (IFN-**α**2a), and monocyte chemoattractant protein-1 (MCP-1) (pg/mL) in normal healthy volunteers prior to and following SARS-CoV-2 vaccination. Multianalyte Assay Panel (MAP) score is calculated by a combination of CB-CAP and auto-antibody test results, and where a score below 0 is determined to be a negative result

Unit	Biomarker	Pre-Vacc Median (IQ)	Post-Vacc Median (IQ)	p-value
NET MFI	EC4d	3.25 (2.35 – 3.92)	2.86 (2.54 – 3.59)	0.655
	BC4d	7.62 (5.26 – 15.40)	13.53 (12.25 – 15.63)	0.162
U/mL	ANA	11.5 (6.75 – 47.25)	7.5 (6.0 – 34.5)	0.841
	Anti-dsDNA	38.5 (29.75 – 118.25)	29.0 (24.25 – 59.0)	0.456 (unequal var.)
mg/dL	C3	117.5 (108.0 – 127.0)	113.0 (102.8 – 135.3)	0.883
	C4	27.0 (18.5 – 29.0)	23.5 (20.0 – 38.75)	0.517
	MAP Score	-2.5 (-3.325 - -1.25)	-2.3 (-2.425 - -1.575)	0.627
pg/mL	IFNγ	27.2 (17.45 – 42.43)	27.1 (18.6 – 51.55)	0.710
	IL-6	2.86 (2.34 – 3.78)	3.76 (3.0 – 3.83)	0.310
	IL-8	5.88 (4.13 – 17.61)	5.21 (3.94 – 10.73)	0.597
	IL-10	0.65 (0.43 – 0.89)	0.60 (0.40 – 1.11)	0.769
	TNFα	5.73 (5.25 – 6.64)	5.99 (5.12 – 6.43)	0.919
	IP-10	615.0 (443.3 – 771.8)	661.0 (546.5 – 895.5)	0.500
	IFN-α2a	3.66 (2.26 – 5.16)	3.97 (2.66 – 4.94)	0.880
	IL-18	1135.0 (1023.0 – 1238.8)	980.0 (827.5 – 1219.5)	0.390
	MCP-1	215.0 (145.5 – 260.5)	228.0 (155.5 – 328.0)	0.573
	IL-17A	6.41 (3.72 – 8.16)	6.22 (5.60 – 7.11)	0.850

Table 2. EC4d and BC4d positivity rates in April 2019 versus April 2021. Positivity of EC4d (≥ 15 NET MFI) and BC4d (≥ 61 NET MFI) among clinical samples run prior to the SARS-CoV-2 pandemic (April 2019) and amid the public rollout of SARS-CoV-2 vaccines (April 2021).

	April 2019		April 2021	
CB-CAP Assay	Positivity Ratio	Percentage	Positivity Ratio	Percentage
EC4d (≥15 NET MFI)	548/9057	6.05%	689/11542	5.97%
BC4d (≥61 NET MFI)	393/8571	4.58%	543/11542	4.70%

Background/Purpose: SARS-CoV-2 infection can lead to severe inflammation including increased complement activation (Ma, Kulkarni 2021) and the production of several proinflammatory cytokines. The rapid deployment of novel, effective vaccines against SARS-CoV-2 allow for more in-patient visits across the medical landscape, but little is known about the short-term impact the SARS-CoV-2 vaccines may have on immunological testing. This study examined a mutlianalyte assay panel (MAP), including cell-bound complement activation products (CB-CAPs), as well as levels of cytokines in normal healthy volunteers before and shortly after SARS-CoV-2 vaccination, to explore any impact immunization may have on complement activation, canonical connective-tissue disease markers, or the cytokine milieu.

Methods: Normal healthy volunteers (n = 6; 3 females, 3 males) were tested before and within two weeks (2 subjects each 6-, 11-, and 14-days post-vaccination) of receiving their second SARS-CoV-2 vaccination (Moderna mRNA-1273). Serum C3 and C4 levels were measured using immunoturbidimetry and CB-CAPs were measured from EDTA blood using flow cytometry and expressed as net mean fluorescence intensity (MFI). Autoantibodies were measured by ELISA and anti-dsDNA positivity was confirmed by *Crithidia luciliae* immunofluorescence. Cytokines were measured in plasma or serum by electrochemiluminescence on the Meso Scale Discovery platform. F-tests were performed to describe variance, and p-values were determined by paired, two-tailed t-test.

Results: There were no significant differences between pre (4-22 months prior)- and post-vaccination in the levels of erythrocyte-bound C4d (EC4d), B-cell bound C4d (BC4d), anti-nuclear antibodies (ANA), C3, or C4, as measured by

a 2-tailed equal variance t-test (Figure 1). Accounting for unequal variance found between populations (f-test = 0.02), anti-dsDNA also showed no significant differences pre- and post-vaccination (note: the one anti-dsDNA positive result was not *Crithidia* positive). The CB-CAPs remained well below the positivity threshold of 15 net MFI for EC4d and 61 net MFI for BC4d, regardless of vaccination status (Figure 1). Additionally, levels of inflammatory biomarkers were similar pre- and post-vaccination (Table 1).

Conclusion: Although COVID-19 induces robust inflammation and complement activation, SARS-CoV-2 vaccination does not appear to affect levels of serum complement, complement activation, or cytokine milieu in the 2 weeks post-vaccination. In particular, as erythrocytes circulate for up to 90 days, EC4d can be measured for up to 3 months. If robust complement activation were to occur following vaccination, one might expect increased EC4d in those receiving the SARS-CoV-2 vaccine, thus distorting its diagnostic value. Notably, CB-CAPs positivity rate has remained stable among routinely ordered testing pre-pandemic and post-vaccine rollout time periods (Figure 2). Together, these findings should increase the confidence of any physician ordering a diagnostic MAP containing CB-CAPs even in patients who received the SARS-CoV-2 vaccine.

Abstract Number: 1087

The Humoral Immunity of mRNA-Based SARS-CoV2 Vaccine in Autoimmune Rheumatic Disease Patients Receiving Immunomodulators

Omar Alsaed, Eman Satti, Bassam Muthanna, Safna Veettil, Hadil Ashour, Einas Alkuwari and Samar Al Emadi, Hamad Medical corporation, Doha, Qatar

SESSION INFORMATION
Session Date: Monday, November 8, 2021
Session Title: Miscellaneous Rheumatic & Inflammatory Diseases Poster II: Clinical Features & Diagnostics (1083–1117)
Session Type: Poster Session C
Session Time: 8:30AM–10:30AM

Background/Purpose: Since the spread of different SARS-CoV2 vaccines over the world, there was an uncertainty of the efficacy and safety of these vaccines in autoimmune rheumatic disease (ARD) patients receiving immunomodulators. Patients with ARD were not included in the vaccines phase 3 trials. Qatar national COVD19 vaccine campaign started in Jan 2021. BNT162b2 vaccine was the first to be introduced followed by mRNA-1273 vaccine.

The aim of this study was to evaluate the humoral immunity response of mRNA-based vaccines in ARD patients receiving immunomodulators.

Methods: SARS-CoV2 infection naïve ARD patients who underwent serological testing for anti-SARS-Cov2 S (Elecsys, Roche) were identified and their electronic medical records were reviewed retrospectively to capture demographic data, underlying ARD and the used immunomodulator agents. We included patients who completed two doses of the vaccine in Qatar and underwent anti-SARS-Cov2 S at least fourteen days post the 2nd dose of the vaccine. The test was considered non-reactive when the titer was zero and poorly reactive when the titer was < 132 U/ml which is the cut off used by American Association of Blood Bank to qualify COVID19 convalescent plasma donor. We ran a descriptive analysis comparing the immunogenic response on each immune modulator used in the cohort.

Medications	Reactive Ab titer > 0 n (90)	Non-reactive Ab titer = 0 n (6)	p value	Reactive Ab titer ≥ 132 n (78)	Poor reactive Ab titer < 132 n (18)	p value
Methotrexate monotherapy	23(25.6%)	0(0)	0.333	22(28.2%)	1(5.6%)	0.063
Methotrexate combination therapy	42(46.7%)	2(33.3%)	0.684	35(44.9%)	9(50%)	0.694

Ab: Antibody, ARD: Autoimmune Rheumatic Disease

Results: 96 subjects were included in the analysis, 60 (60.2%) were females and median age was 46.7 years (std 12.0). 65.6% were Arab, 22.9% were Asian and 11.5% were from other ethnicities. ARDs distribution was as the following: rheumatoid arthritis 54 (56.3%), axial spondyloarthropathy18 (18.8%), psoriatic arthritis 10 (10.4%), systemic lupus erythematosus 5 (5.2%), vasculitis 3 (3.1%) Sjogren's disease 2 (2.1%) and other ARD 4 (4.1%). In our cohort, the test was non-reactive in 6 patients and poorly reactive in 18 patients. Rituximab, glucocorticoid and mycophenolate were associated significantly with no reaction (p value 0.000, 0.001 and 0.003) and poor reaction (p value 0.015, 0.011 and 0.034), respectively. Methotrexate, hydroxychloroquine, sulfasalazine, leflunomide, anti-TNF alfa, JAK inhibitors and tocilizumab were associated with normal humoral response to mRNA-based SARS-COV 2 vaccines.

Conclusion: The majority of patients on CsDMARDs, anti TNF-alfa, JAK inhibitors and tocilizumab had adequate serologic response to m-RNA based vaccines. Poor vaccine reactivity was mainly associated with Rituximab, glucocorticoid and mycophenolate use. Further analysis in larger matched cohorts is needed to identify the factors associated with poor immune response in this category of patients.

The immunomodulators used in ARD patients stratified according to humoral response post 2 doses of mRNA-based SARS-CoV2 vaccines

Abstract Number: 1088

The Association Between Anti-Type II Collagen Antibodies at the Time of Diagnosis and Recurrence in Relapsing Polychondritis

Osamu Iri, Keisuke Nishimura, Daisuke Waki, Kohei Yo, Ryuta Inaba, Shintaro Yamamoto, Kaoru Mizukawa, Tomohiro Yoshida, Hiroyuki Murabe and Toshihiko Yokota, Department of Endocrinology and Rheumatology, Kurashiki Central Hospital, Kurashiki, Japan

SESSION INFORMATION

Session Date: Monday, November 8, 2021

Session Title: Miscellaneous Rheumatic & Inflammatory Diseases Poster II: Clinical Features & Diagnostics (1083–1117)

Session Type: Poster Session C

Session Time: 8:30AM–10:30AM

Background/Purpose: Serum titers of anti-type II collagen (anti-CII) antibodies were reported to rise at the recurrence of relapsing polychondritis (RP). It remains to be identified whether anti-CII antibodies at the time of diagnosis are risk factors for relapse. The aim of this study is to investigate the association between anti-CII antibodies at diagnosis and relapse.

Methods: We conducted a retrospective study of patients diagnosed with RP in our hospital between April 2006 and June 2020. Relapse was defined as aggravation of manifestations or worsening of imaging findings which require intensified treatments. Anti-CII antibodies were assayed by a clinically certificated ELISA test.

Results: Eighteen patients were included in this study. The median age at diagnosis was 68.2 years (IQR 56.4-72.7 years), and 55.6% were females. The median period of observation was 40.9 months (IQR 20.7-57.1 months). Seven patients had relapses (38.9%). The median time to the first relapse was 161 days (IQR 135-394 days). The anti-CII antibodies were tested in 13 patients. Tracheobronchial involvement and nasal chondritis were more frequent in the relapse group compared to the non-relapse group (71.4% vs 18.2%, p = 0.049; 85.7% vs 9.1%, p = 0.002, respectively). The relapse group had higher levels of anti-CII antibodies at diagnosis [median (IQR) : 66.8 EU/mL(38.9-131.8 EU/mL) vs 14.5 EU/mL(10.7-18.7 EU/mL), p = 0.001] (**Figure 1**). Comparing for initial treatments, the relapse group tended to receive higher dose of prednisolone (median (IQR) 45.0mg (25.0-50.0 mg) vs 30.0mg (1.5-40.0 mg), p = 0.055). Immunosuppressive drugs and biologics were more often used in the relapse group (57.1% vs 0%, p = 0.011). Kaplan-Meier estimates of the relapse-free survival showed the anti-CII antibodies positive group was significantly more likely to relapse than the negative group (Log-rank p = 0.009; HR = 1.017, 95% CI 1.004-1.031) (**Figure 2**).

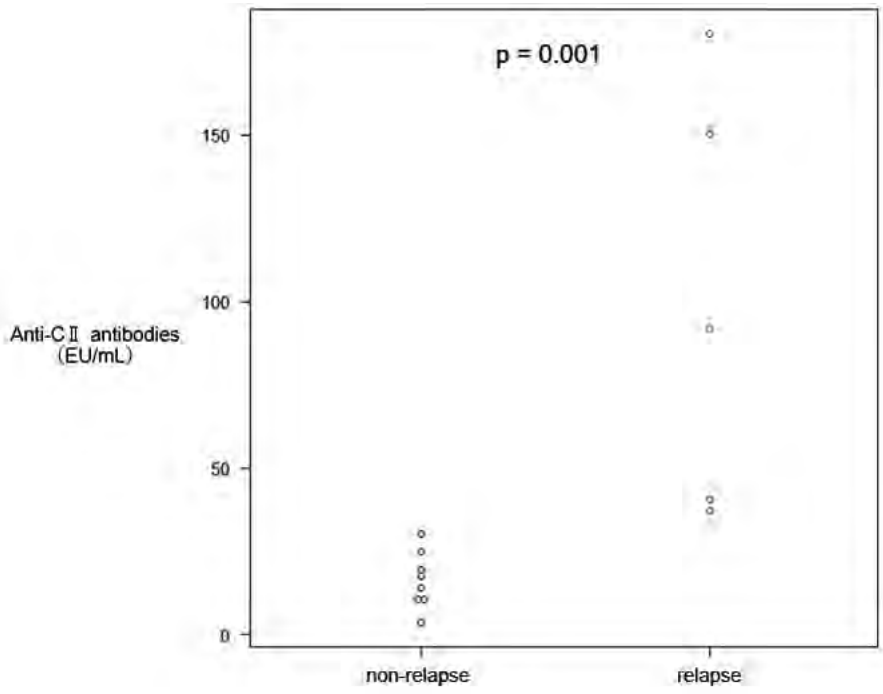

Figure 1. Anti-CII antibody titers of the relapse and non-relapse groups.

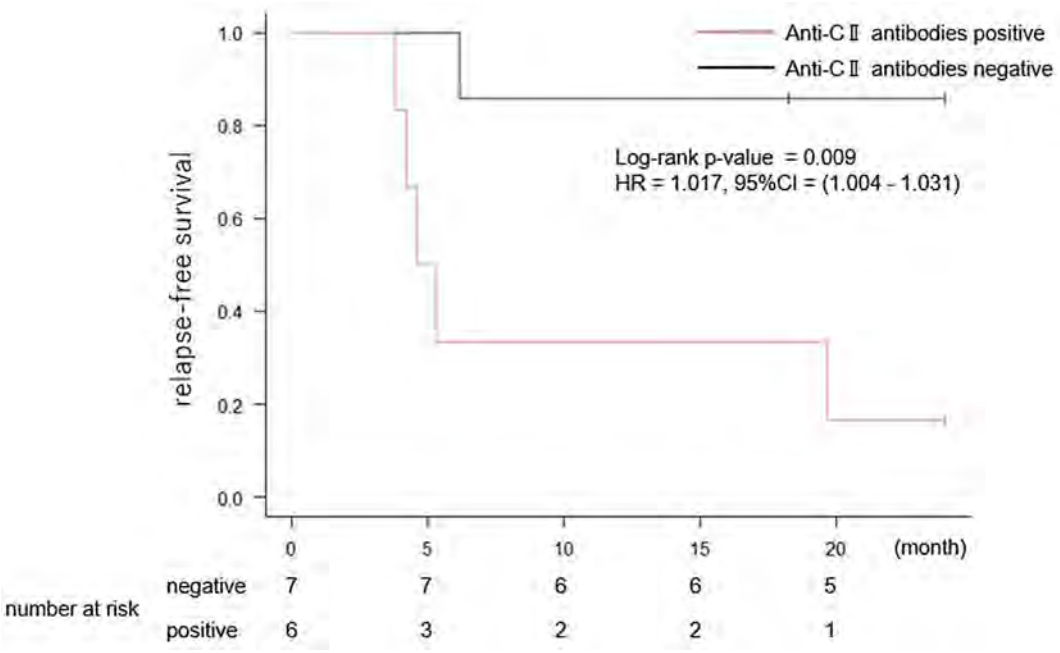

Figure 2. Kaplan-Meier survival curve for relapse in the Anti-CII antibodies positive and negative groups.

Conclusion: High titers of anti-CII antibodies at the time of diagnosis are the risk factors for relapse. This study shows that tracheobronchial involvement may also be a factor associated with relapse. We plan to measure anti-CII antibodies in consistent intervals and discuss whether routine anti-CII antibodies monitoring is useful for predicting future relapse.

Session Type: Poster Session C

Session Time: 8:30AM–10:30AM

Background/Purpose: Anti-SSA/Ro antibodies (Abs) can target Ro60 and Ro52 antigens. The presence of anti-Ro60 Abs has been widely described in patients with systemic autoimmune rheumatic diseases (SARDs). However,

	Anti-Ro52+Ro60- (n=11)	Anti-Ro52+Ro60+ (n=27)	Anti-Ro52+Ro60+ with other Abs (n=19)
Age (years), mean ± SD	53.8 ± 18.0*	65.7 ± 10.0	61.7 ± 13.6
Sex (females), n (%)	10 (90.9) *	19 (70.4)	14 (73.7)
Clinical manifestations at anti-Ro52 determination, n (%)			
Arthralgias/arthritis	7 (63.6)	18 (66.7)	14 (73.7)

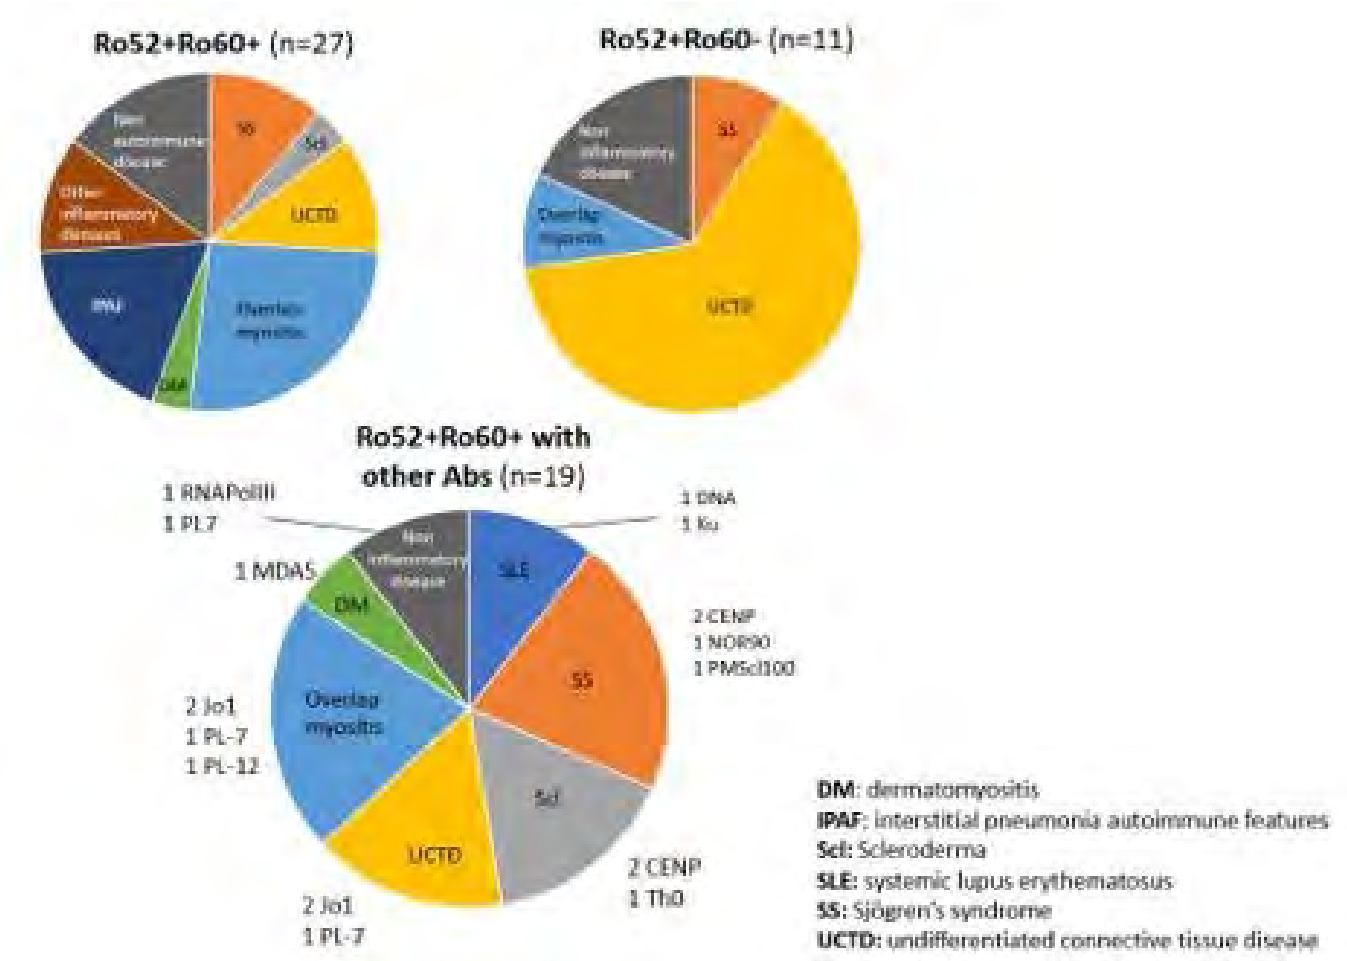
*** p< 0.05** (Ro52+Ro60+ *vs* Ro52+Ro60-)

**** p< 0.05** (Ro52+Ro60+ *vs* Ro52+Ro60- *vs* Ro52+Ro60+ with other Abs)

the clinical implication of anti-Ro52 Abs for the diagnosis and management of SARDs remains unclear. We aimed to assess the clinical associations of anti-Ro52 antibodies in patients with high clinical suspicion of SARDs.

Methods: We retrieved the clinical records of all patients with positive anti-Ro52 Abs tested in our hospital between November 2017 and September 2020. Patients were divided into 3 groups: 1) anti-Ro52+Ro60+ 2) antiRo52+Ro60- 3) antiRo52+Ro60+ with other Abs. A comparative study between groups was performed.

Results: 57 patients (43 women/14 men; mean age 62.1±13.6 years) with antiRo52+ Abs were identified. Final diagnosis were: undifferentiated connective tissue disease (UCTD) (n=13), anti-synthetase/overlap myositis (n=12), Sjögren's syndrome (n=7), interstitial pneumonia with autoimmune features (IPAF) (n=6), scleroderma (n=4), systemic lupus erythematosus (n=2), dermatomyositis (n=2), other systemic inflammatory diseases (n=3). In 8 (14%) patients the diagnosis of inflammatory diseases was finally ruled out. 27 patients were classified in the Ro52+Ro60+ group, 11 in the Ro52+Ro60- group and 19 Ro52+ with other Abs. Patients with Ro52+Ro60- were younger and more often women than patients with Ro52+Ro60+.Interstitial lung disease (ILD) was less frequent in patients with Ro52+Ro60- **(Table)**. Isolated Ro52 Abs were more frequently associated with UCTD, while IPAF was more commonly found in patients with anti-Ro52+Ro60+ Abs **(TABLE and FIGURE)**.



Conclusion: Anti Ro52 Abs determination has clinical implications in the diagnosis of SARDs

SESSION INFORMATION

Session Date: Monday, November 8, 2021

Session Title: Miscellaneous Rheumatic & Inflammatory Diseases Poster II: Clinical Features & Diagnostics (1083–1117)

Session Type: Poster Session C

Session Time: 8:30AM–10:30AM

Background/Purpose: Immunoblot assays are increasingly used in clinical practice as part of the diagnostic armamentarium of systemic autoimmune rheumatic diseases (SARDs). Our aim was to assess the contribution of an extended scleroderma/myositis-related antibodies (Ab) determination by immunoblot to the diagnosis of patients with SARDs.

Methods: We reviewed all medical records of patients with positive scleroderma/myositis-related Ab line blot determinations (Euroimmune AG, Lübeck, Germany) in our center from November 2017 to September 2020. These assays were requested due to high suspicion of SARDs in patients presenting with non-specific symptoms.

Results: 134 patients (37men/97women; mean age 59.6 ± 14.8 years) were positive for at least 1 Ab, 25 of them were positive for 2 Abs. Main clinical features at the time of immunoblot requests were: arthralgia/arthritis (n=88), Raynaud's phenomenon (n=59), rash (n=27), sicca syndrome (n=20), myopathy (n=18). During follow-up, 28 patients were diagnosed with undifferentiated connective tissue disease (UCTD), 26 scleroderma, 23 overlap myositis, 18 interstitial pneumonia with autoimmune features (IPAF), 8 other inflammatory diseases, 8 Sjögren's syndrome, 7 systemic lupus erythematosus, 5 dermatomyositis, 1 necrotizing myositis. In 10 patients the diagnosis of SARD was finally ruled out **(Figure)**. Interstitial lung disease (ILD) was present in 50 patients, being particularly frequent in those with anti-PL12, anti-PL7 and anti-MDA5 Abs. Cancer was detected in 9 (6.7%) patients, 6 of them were anti-Ro52 + **(Table)**.

	Mi-2 (n=5)	PL-7 (n=6)	PL-12 (n=4)	Jo-1 (n=6)	MDA5 (n=1)	Ro-52 (n=57)	SRP (n=3)	Scl-70 (n=12)	CENP (n=14)	Th (n=2)	Ku (n=14)	Fibrilarina (n=2)	PM-Scl75/100 (n=23)	NOR90 (n=8)	RNA pol III (n=2)
Dermatomyositis	2 (40)	0	0	0	1 (100)	2 (3.5)	0	0	0	0	0	0	1 (4.3)	0	0

Undifferentiated CTD	1 (20)	0	1 (25)	3 (50)	0	13 (22.8)	0	3 (25)	0	0	4(28.6)	0	5 (21.7)	2 (25)	1 (50)
Sjögren	0	0	0	0	0	7 (12.3)	0	0	2 (14.3)	0	0	1 (50)	1 (4.3)	1(12.5)	0
IPAF	0	0	0	0	0	6 (10.5)	0	0	1 (7.1)	0	4 (28.6)	0	3 (13)	4 (50)	0
Other systemic inflammatory disease	0	0	0	0	0	3 (5.3)	2 (66.7)	0	0	1 (50)	0	0	2 (8.7)	0	0
Non-autoimmune disease	1 (20)	1 (16.7)	0	0	0	8 (14.0)	0	0	0	0	0	0	1(4.3)	0	1 (50)

	Mi-2 (n=5)	PL-7 (n=6)	PL-12 (n=4)	Jo-1 (n=6)	MDA5 (n=1)	antiRo52 (n=57)	SRP (n=3)	Scl-70 (n=12)	CENP (n=14)	Th (n=2)	Ku (n=14)	Fibrilarina (n=2)	PM-Scl75/100 (n=23)	NOR90 (n=8)	RNA pol (n=2)
ILD	0	4 (66.7)	4 (100)	3 (50)	1 (100)	19 (33.3)	0	7 (58.3)	1 (7.1)	0	7 (50)	1 (50)	9 (39.1)	5 (62.5)	0
Cancer	1 (20)	0	0	0	0	6 (10.5)	1 (33.3)	0	0	0	1 (7.1)	0	0	0	0

Conclusion: Immunoblot assays are of great help in the diagnosis of patients with high clinical suspicion of SARDs. While some Abs, such as anti-Ro52, anti-Ku and anti-PMScl75/100, remain to be nonspecific, other Abs including anti-PL12, anti-PL7 or anti-MDA5 are particularly helpful in detecting SARDs patients with associated ILD.

SESSION INFORMATION

Session Date: Monday, November 8, 2021

Session Title: Miscellaneous Rheumatic & Inflammatory Diseases Poster II: Clinical Features & Diagnostics (1083–1117)

Session Type: Poster Session C

Session Time: 8:30AM–10:30AM

Background/Purpose: Elderly-onset RA (EORA) and polymyalgia rheumatica (PMR) are common rheumatic diseases in the elderly, but their pathogenesis is not yet fully understood. Seronegative EORAneg and PMR have similar clinical characteristics making them difficult to distinguish based on clinical features. The aim of this study was to explore the differences in the serum metabolome using 1H-nuclear magnetic resonance (NMR) to identify potential biomarkers of PMR vs EORAneg.

Methods: ARTIEL (Arthritis in the Elderly) is a cohort that consists of newly diagnosed arthritis in patients older than 60 years. Blood samples were collected at baseline (pre-treatment), along with physician and patient outcome measures throughout a 12-month period. Patients were compared with controls who were random individuals of the same age and gender. A Bruker Avance 700 MHz spectrometer was used to acquire NMR spectra of serum samples. Chenomx NMR suite 8.5 was used for metabolite identification and quantification. IL6 and TNF levels were determined by ELISA. SPSS v.27 and MetaboAnalyst 4.0 were used for statistical and pathway analysis.

Results: From the 66 patients included, 20 were diagnosed with PMR, with an average age of 76.40±4.99, 15% were males, and an average CRP level of 31.56±28.27 mg/dL; 28 patients were diagnosed of EORAneg patients with

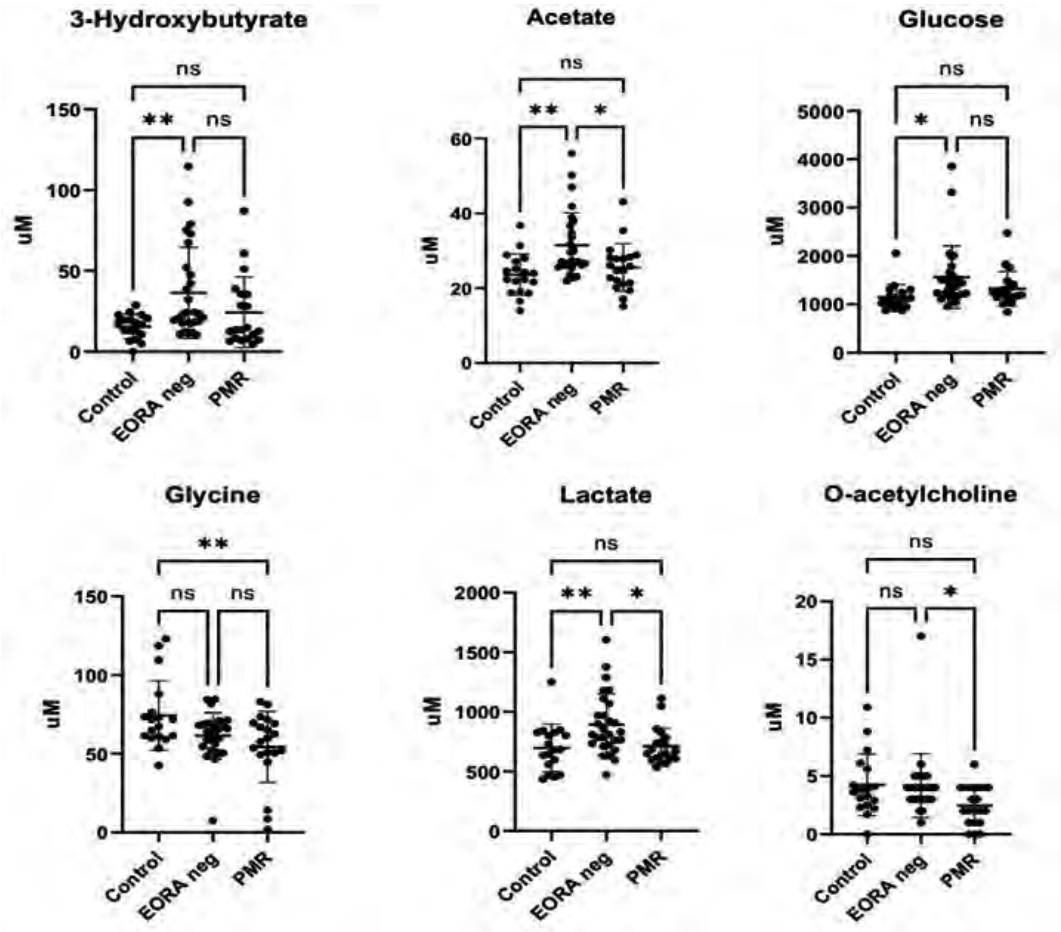

Figure 1. Concentrations of polar metabolites identified with 1H-NMR in control group, elderly-onset seronegative rheumatoid arthritis (EORAneg) and polymyalgia rheumatica (PMR) at baseline. *p<0.05, **p<0.01, ns= not statistically significant.

an average age of 76.75±6.99, 57% males, and an average CRP level of 41.57±52.14 mg/dL; and 18 controls with an average age of 75.39±6.04, 39% males, and an average CRP level of 4.10±6.78 mg/dL. At diagnosis, EORAneg patients had a mean DAS28ESR of 6.21±1.00. One hundred percent of PMR patients reported shoulder pain, and 90% reported pelvic pain. Fifty-eight polar metabolites were identified. 3-Hydroxybutyrate, acetate, glucose, glycine, lactate, and O-acetylcholine were significantly different between the 3 groups. Of these, 3-hydroxybutyrate, acetate, glucose, and lactate were elevated in EORAneg while glycine and O-acetylcholine were lower in PMR compared to control group (Figure 1). Of interest, TNF and IL-6 correlated with different metabolites in PMR and EORAneg suggesting different inflammatory activated pathways (Figure 2). Finally, a logistic regression analysis identified two metabolites, o-acetylcholine and acetate, that contributed to the separation of PMR from EORAneg with 80% sensibility and 96.4% specificity (Figure 3).

Conclusion: EORAneg and PMR have a different serum metabolomic profile that can be used as biomarker to discriminate between both diseases. Further metabolic profiling studies is needed to properly identify significant metabolites in EORAneg vs PMR, and to better understand elements of inflammation pathobiology in these populations.

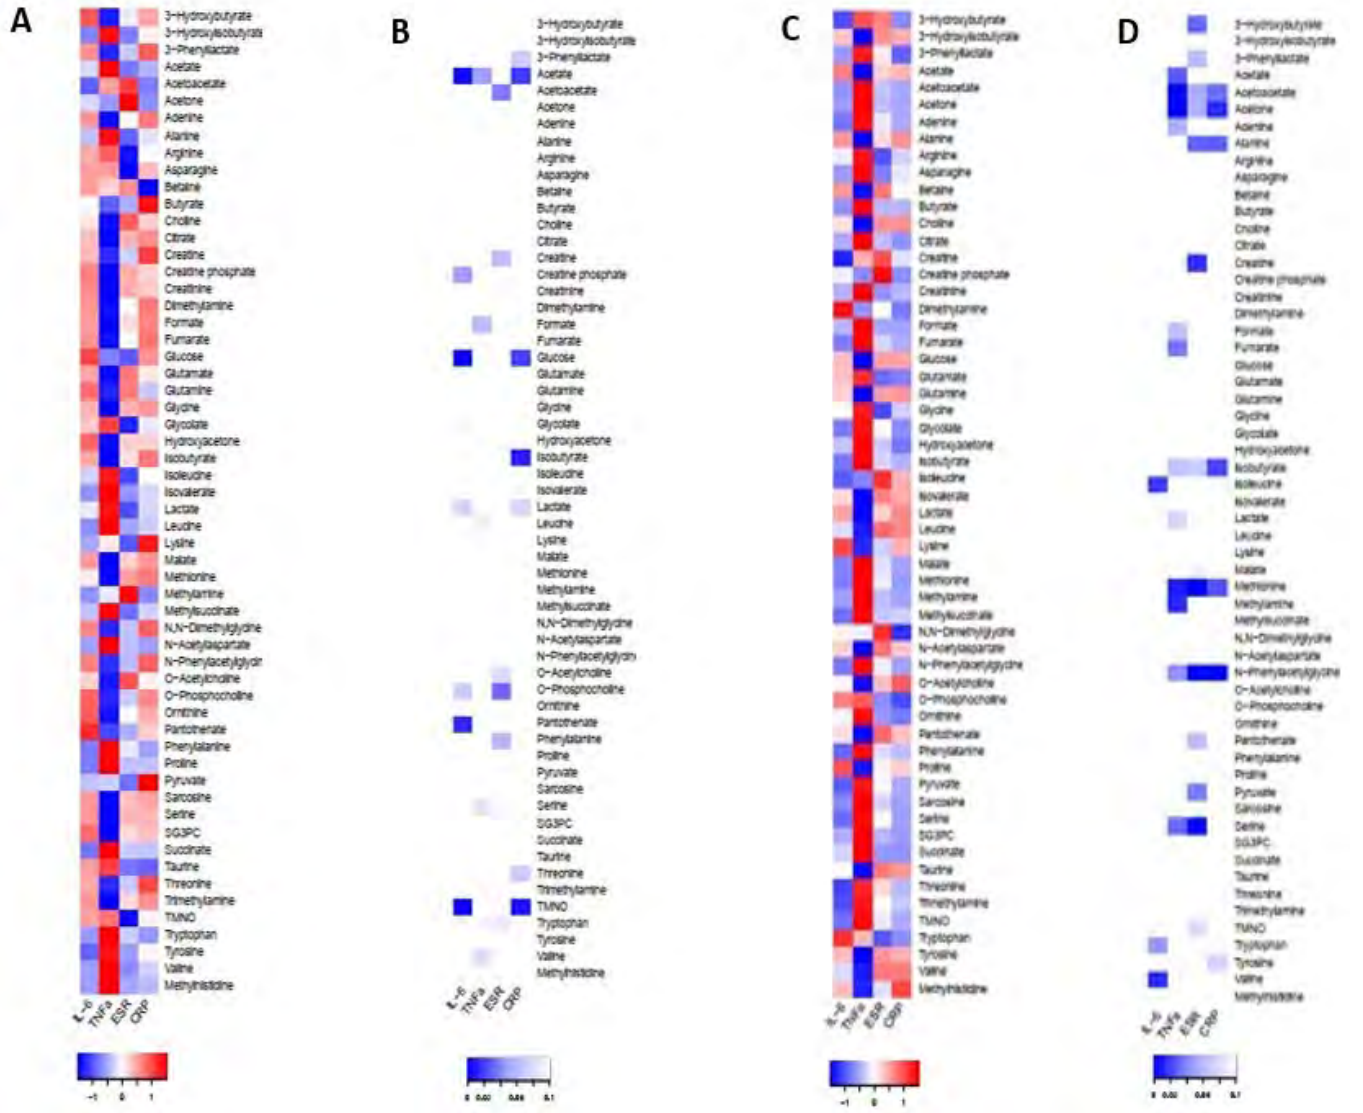

Figure 2. Pearson correlation adjusted by age, gender and BMI (body mass index) at baseline between proinflammatory cytokines and metabolites obtained by 1H-NMR. A) The strength of association of each pair were used to form a cluster heatmap to lend insight into which cytokine were correlated with which group of polar metabolites in patients with PMR or C) EORA neg. B) Correlation significant p-values for PMR or D) EORA neg.

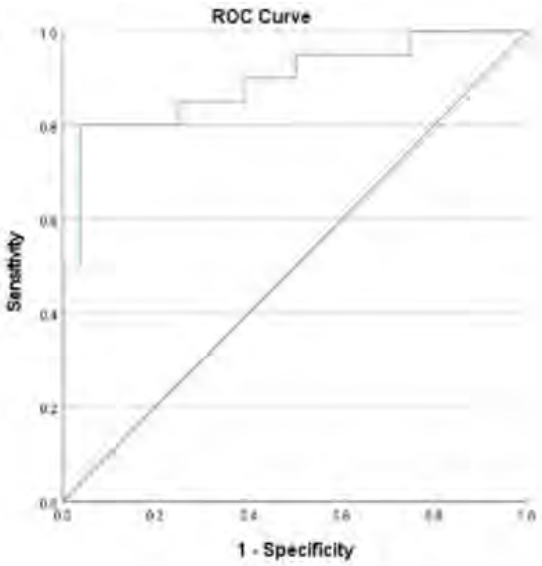
A



B

	B	SE	Wald	Sig	Exp (B)
Acetate	-0.206	0.377	5.881	0.015	0.813

Altered Metabolic Pathways in Synovial Fibroblasts of Individuals at Risk of Developing Rheumatoid Arthritis

Tineke de Jong[1], Simone Denis[1], Paul Tak[2], Riekelt Houtkooper[1] and Lisa van Baarsen[1], [1]Amsterdam UMC, Amsterdam, Netherlands, [2]Candel Therapeutics, Cambridge, United Kingdom

SESSION INFORMATION

Session Date: Monday, November 8, 2021

Session Title: Miscellaneous Rheumatic & Inflammatory Diseases Poster II: Clinical Features & Diagnostics (1083–1117)

Session Type: Poster Session C

Session Time: 8:30AM–10:30AM

Background/Purpose: Cellular metabolism has been studied in fibroblast-like synoviocytes (FLS) of rheumatoid arthritis (RA) and osteoarthritis (OA) patients and raises the question whether observed metabolic alterations appear in response to chronic inflammation or whether primary changes in cellular metabolism might underlie disease pathogenesis. Previously, we showed that genes involved in lipid metabolism are significantly lower expressed in synovial

tissue from RA-risk individuals that eventually develop RA. Here we investigated whether metabolic changes in FLS are already observed before onset of RA.

Methods: We included individuals with arthralgia who were IgM rheumatoid factor (RF) and/or anti-citrullinated protein antibody (ACPA) positive but without any evidence of arthritis (RA-risk individuals, n=6), RA patients (n=6), OA patients (n=6) and controls without inflammatory disease (n=6). Synovial tissues were collected during orthopedic surgery or individuals underwent mini-arthroscopic synovial tissue sampling of a knee joint. Subsequently, FLS were cultured after synovial tissue digestion. Cellular metabolism was assessed using qPCR, flow cytometry, the XFe96 Seahorse Analyzer and mitochondrial β-oxidation was measured using tritium-labelled oleate.

Results: Real-time analysis of mitochondrial function revealed that basal respiration is significantly lower in FLS from RA-risk individuals and RA patients compared with FLS from controls. When investigating the three main fuel pathways of cellular respiration (glucose, glutamine and fatty acids), basal respiration from all FLS largely depended on fatty acid oxidation, whereas glucose was only highly used by RA FLS. FLS from controls were flexible to switch to another fuel when the other fuel pathways were inhibited, whereas FLS from RA-risk individuals, RA and OA patients were less flexible. When cellular respiration was challenged to maximum capacity, respiration from RA-risk FLS and RA FLS was significantly lower compared with FLS from controls. This was reflected in all three fuel pathways. Based on these data we were able to define the energy profile of our cells. This showed that FLS from controls are relatively more energetic while FLS from RA-risk individuals and RA patients are more quiescent. In addition, mitochondrial β-oxidation was significantly impaired in RA-risk individuals, RA and OA patients compared with FLS from controls. Flow cytometry showed that mitochondrial reactive oxygen species (ROS) production and mitochondrial mass was increased in RA FLS compared with controls.

Conclusion: In this exploratory study, mitochondrial dysfunction and metabolic alterations are already detected in FLS from RA-risk individuals compared with controls, suggesting that these alterations start before clinical manifestation of disease and contribute to disease pathogenesis.

PsA/AS group is referent. Apolipoprotein A1, (ApoA1); Apolipoprotein B (ApoB); BNP, N-terminal prohormone BNP; HDL-c; high density lipoprotein cholesterol, high-sensitivity troponin-T, (hs-TnT); Lipoprotein A (LpA), LDL-c, low density lipoprotein cholesterol; bDMARDs, biologic disease modifying antirheumatic drugs; BMI, body mass index; csDMARDs, conventional synthetic disease modifying antirheumatic drugs; CRP, C-reactive protein; ESR, HAQ, health assessment questionnaire, CDAI, clinical disease activity index; tsDMARDs, targeted synthetic disease modifying antirheumatic drugs, VAS, visual analog scale

Methods: A cross-sectional study of consecutive patients enrolled in the University of Toronto Cardio-Rheumatology Network from 2017 to 2020 was performed. This is a primary CVD prevention program with structured clinical and laboratory assessments to diagnose and treat CVD. Patients are eligible if they have rheumatoid arthritis (RA) or spondyloarthropathy (SpA, psoriatic arthritis or ankylosing spondylitis), and no documented CVD. We included patients with baseline data for 5 cardiac biomarkers and examined the prevalence of abnormal biomarkers according to site-specific lab cut-offs: high-sensitivity troponin T (hs-TnT) (≥15 ng/L), N-terminal prohormone BNP (NT-proBNP, ≥35 pmol/L or 100 pg/mL), Apolipoprotein A1 (ApoA1, ≤1.96 g/L), Apolipoprotein B (ApoB, ≥1.17g/L or ≥1.46g/L) and Lipoprotein a (Lp(a) ≥9.7mg/dL or ≥30mg/dL). We performed logistic regression to evaluate the association with IA diagnosis and each biomarker, adjusted for demographic, clinical and CVD risk factors.

Results: A total of 376 participants were included. The majority had RA (58%), followed by PsA (33%) and AS (9%). Mean (SD) age of the sample was 59 (10.5) years and 70% were female. Disease activity and acute phase reactants reflected well controlled disease and treatment consisted primarily of csDMARDs (63%) or bioDMARDs (39%) (Table 1). At least 1 CVD risk factor was present in 77% of subjects, most commonly current/ever smoking (47%), obesity (35%), hypertension (33%) or dyslipidemia (27%). Thirteen percent had elevated hs-TnT and 17% had elevated NT-proBNP (Table 2). Abnormal lipid biomarkers occurred in 45%, primarily due to abnormal Apo A1 (90%) and to a lesser degree abnormal Lp (a) levels (29%, Table 2). Subjects with RA were more likely to have abnormalities in NT-proBNP and ApoB, but had more favourable HDL-c, non-HDL-c and triglyceride profiles compared to the PsA/AS group (Table 2). In multivariate analyses, increasing age was significantly associated with abnormal hs-TnT and NT-proBNP but negatively associated with ApoB. Female sex was associated with greater odds for abnormal Lp (a) but lower values of hs-TnT and NT-proBNP (Table 3). No other IA disease-specific or CVD risk factors were consistently associated with cardiac biomarkers (Table 3).

Conclusion: Abnormalities in cardiac and lipid biomarkers are common even in well-controlled IA patients with no known CVD. Additional research is needed to determine if biomarkers may help with CVD risk re-classification beyond traditional clinical risk score approaches. In addition, it will be important to understand whether CVD biomarkers

are responsive to changes in disease activity or particular therapies, which may be another rationale for a treat-to-target approach in IA.

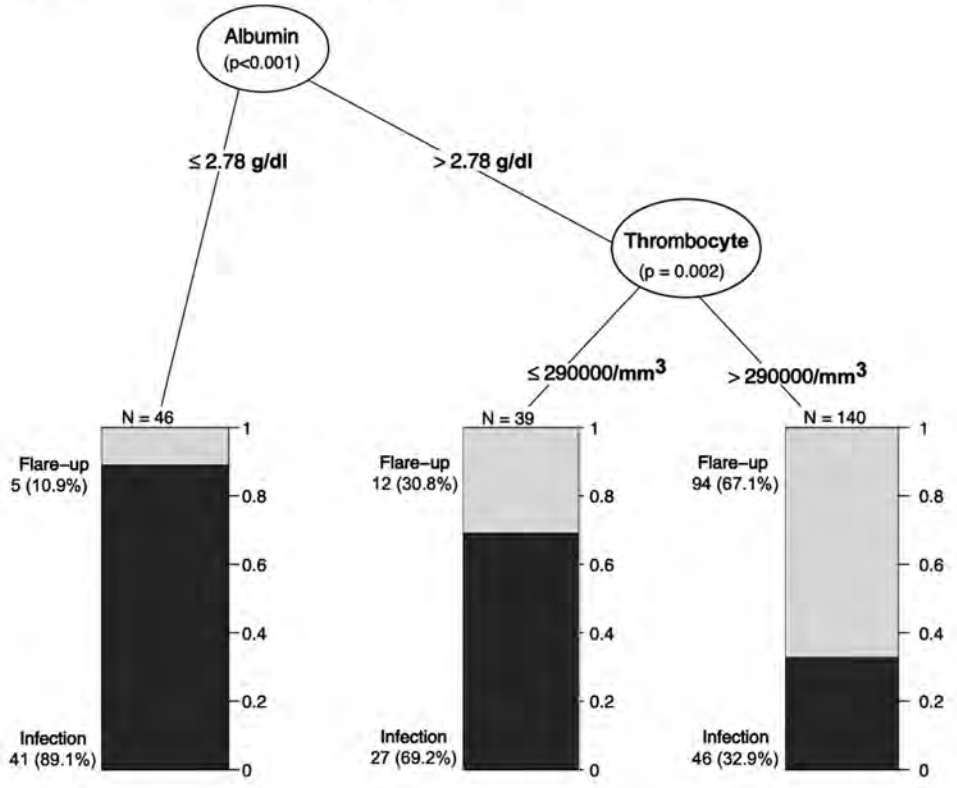
AST: Aspartate aminotransferase, ALT: Alanine aminotransferase, ALP: Alkalene phosphatase, CRP: C-reactive protein, GGT: Gamma-glutamyl transferase, MCV: Mean corpuscular volume, MPV: Mean platelet volume, RDW: Red Cell Distribution Width
Data were given as median(minimum-maximum) or n(%), if otherwise specified.

Figure. Decision tree to discriminate patients with flare-up and infection



Background/Purpose: To compare the laboratory characteristics of patients who had rheumatic diseases and presented with extremely elevated ESR (≥100 mm/h) and had either disease flare-up or documented infection and to find factors which may help to differentiate patients with disease flare-up and infection.

Methods: In this retrospective analyses, patients -either inpatient or outpatient- with ESR≥100 mm/h between 2015 and 2020 were identified. Patients with a certain diagnosis of inflammatory rheumatic disease and had either disease flare-up or documented infection were included in the analysis. Flare-up was defined as need of newly prescribed immunosuppressive (IS) agents or increment of dose of the already prescribed IS agents and NOT prescription of any kind of antibiotics. Infection was defined as documentation of possible infective agent via culture or imaging finding AND prescription of any kind of antibiotics. Available laboratory data temporarily nearest to ESR≥100 mm/h were recorded. Decision tree by R (package *party*) was used to construct a clinician-friendly algorithm for the discrimination of disease flare-up and infection by using routine laboratory tests.

Results: Of 311 patients with ESR≥100 mm/h and rheumatic diseases, 225 were included. 111 (49.3%) patients had disease flare-up and 114 (50.7%) patients had infection. In flare-up group, 93 (83.8%) had inflammatory arthritis [57 RA, 31 SPA, 2 JIA, 2 crystal arthritis, 1 adult Still's disease], 11 (9.9%) had vasculitis [5 large-vessel, 4 small-vessel, 2 PMR] , 7 (6.3%) had connective tissue disorder (CTD) [5 SLE, 1 overlap syndrome and 1 SSc]; however, in infection group 65 (57.0%) had inflammatory arthritis [25 RA, 22 SpA, 6 crystal arthritis, 6 FMF, 4 adult Still's disease, 2 JIA], 22 (19.3%) had vasculitis [12 small-vessel, 5 large-vessel vasculitis, 2 PMR, 1 relapsing polychondritis, 1 Behcet's syndrome and 1 PAN] and 27 (23.7%) had CTD [12 SLE, 5 SSc, 3 Sjögren's syndrome, 3 sarcoidosis, 2 myositis, 1 retroperitoneal fibrosis, 1 granulomatous mastitis]. Thrombocyte, MCV, albumin and total protein were significantly lower in infection group, however; neutrophil, MPV, CRP and ferritin were significantly lower in flare-up group (**Table**). Lipids, vitamin B12 and complement levels were similar. In decision tree, serum albumin ≤2.78 g/dl was the

first branch (89.1% for infection vs. 10.9 for flare-up). If serum albumin >2.78 g/dl, thrombocyte ≤290/mm6 was the second branch (thrombocyte count≤290/mm^6; 69.2% for infection vs. 30.8% for flare-up // thrombocyte >290/mm6; 32.9% for infection vs. 67.1% for flare-up) (**Figure**). In multivariable analysis factors were associated with infection over flare-up (reference level): thrombocyte count (per 1/mm^6 increment) (aOR: 0.997 (0.995-0.999)), albumin (per 1 gr/dl increment) (aOR: 0.37 (0.22-0.63)), CRP (1 mg/dl increment) (aOR: 1.044 (1.011-1.044)).

Conclusion: Extremely elevated ESR is an alarming finding for clinicians who follow-up patients with rheumatic diseases. Flare-up of the underlying rheumatic disease and infections should be kept in mind in patients with such presentation. We have generated a simple and clinician-friendly decision tree in which albumin level and thrombocyte count were key elements.

Non-Effusive Knee arthrocentesis with and without pneumatic compression (302% increase in yield, p > 0.0001)

SESSION INFORMATION
Session Date: Monday, November 8, 2021
Session Title: Miscellaneous Rheumatic & Inflammatory Diseases Poster II: Clinical Features & Diagnostics (1083–1117)
Session Type: Poster Session C
Session Time: 8:30AM–10:30AM

Background/Purpose: Arthrocentesis is critical for diagnosis and therapy of joint disease; however, it is very difficult to obtain diagnostic fluid from an arthritic but clinically non-effusive knee – the so-called "dry tap". In the era of synovial fluid biomarker analysis to diagnose and classify diseases, obtaining at leastsome fluid is of increasing importance.

To use external pneumatic compression on the non-effusive knee to improve arthrocentesis success and synovial fluid yield.

Methods: As a Quality Improvement (QI) Initiative in the Rheumatology Injection Clinic, we instituted standard mechanical compression of the knee during arthrocentesis and determined quality measures before and after. In this IRB approved study conducted from 2018 to 2021, we instituted a modified Arthrocentesis QI program using a flexed knee approach and an inexpensive standard pneumatic thigh blood pressure cuff over the suprapatellar bursa and compared quality measures before and after the procedure.

103 consecutive patients with non-effusive osteoarthritic knees were included in the QI intervention.

Knee aspiration with pneumatic external compression of non effusive knee

Exclusion criteria:

The exclusion of a knee effusion was determined clinically by palpation for suprapatellar bursa distention, ballottement of a floating patella, and fluid shift with asymmetric compression.

Inclusion criteria

1) the presence of no clinically palpable knee effusive,

2) indications for therapeutic-diagnostic joint needle procedure,

3) formal signed consent of the patient to undergo the procedure,

4) knee osteoarthritis.

103 consecutive patients underwent arthrocentesis with the knee in the flexed position with an uninflated thigh blood pressure cuff over the suprapatellar bursa (Figure 1) until fluid return ceased, and then the cuff was inflated to 100 mm Hg and arthrocentesis quality measures were again determined.

Quality Measures:

1) Pain was measured with Visual Analogue Pain Scale,

2) Arthrocentesis success in obtaining at least 2 ml of diagnostic fluid and 0.5 ml for biomarker analysis,

3) Fluid yield in milliliters before and after compression.

Results: Pneumatic compression of the knee markedly improved clinical arthrocentesis success (≥ 2 ml) and sufficient fluid for biomarker analysis (≥ 0.5 ml) while increasing overall synovial fluid yield by 302% (Figure 1, Table 1).
Conclusion:• This study demonstrates consistent improvement in arthrocentesis diagnostic success and synovial fluid yield using external pneumatic compression of the clinically non-effusive knee.

- Compression of the non-effusive knee with an inexpensive standard suprapatellar pneumatic leg blood pressure cuff markedly improves the success and fluid yield of arthrocentesis in the non-effusive knee.
- **Arthrocentesis of the knee with pneumatic compression can be used in all patients who can sit and is especially useful in patients who wish to remain seated or who cannot extend their knee due to flexion contracture, wheelchair confinement, or with pain or severe arthritis.**
- Improving synovial fluid yield from the clinically non-effusive knee will have increasing importance as synovial fluid biomarker analysis is further integrated into the classification schemes of various forms of noninflammatory and inflammatory arthritis.

CSF-specific CD8 T Cell Clonal Expansion in Neurosarcoidosis

Michael Paley[1], Brandi Baker[2], Steven Dunham[3], Nicole Linskey[3], Elisha Roberson[3], David Clifford[3] and Wayne Yokoyama[3], [1]Washington University in St. Louis, Olivette, MO, [2]Washington University in St. Louis, St. Louis, MO, [3]Washington University School of Medicine, St. Louis, MO

SESSION INFORMATION
Session Date: Monday, November 8, 2021
Session Title: Miscellaneous Rheumatic & Inflammatory Diseases Poster II: Clinical Features & Diagnostics (1083–1117)
Session Type: Poster Session C
Session Time: 8:30AM–10:30AM

Background/Purpose: Neuroinflammation is a severe manifestation of the systemic inflammatory disorders. Sarcoidosis, which leads to neurologic disease in 5-10 % of cases, has traditionally been thought to be driven by CD4 T cells. However, this model has been inferred by studies in pulmonary disease and has not been directly evaluated in the central nervous system (CNS). Here, we evaluated T and B cell clonal expansion in neurosarcoidosis to identify putative antigen-driven T or B cell responses.

Methods: We performed single-cell RNA-sequencing to obtain an unbiased gene expression survey of cerebral spinal fluid (CSF) and blood immune cells in participants with neurosarcoidosis and controls. This analysis allowed quantification, cell type identification, and transcriptional profiling of individual lymphocytes within the inflamed CNS as compared to cells in circulation, along with T cell receptor and B cell receptor sequencing to determine clonotype distribution.

Results: The plurality of CSF cells were CD4 T cells followed by CD8 T cells, with smaller and variable contributions of B cells, NK cells, and myeloid cells. Unexpectedly, B and T cell receptor sequencing revealed robust CD8 T cell clonal expansion specific to the CSF in neurosarcoidosis participants, with minimal CD4 T and B cell clonality. These

CSF-specific CD8 T cells expressed higher levels of CD27 and granzyme K and lower levels of CX3CR1, granzyme B, and granulysin, consistent with reduced cytotoxicity and similar to CD8 T cells seen in uveitis and rheumatoid arthritis. Finally, a core transcriptional signature of CSF-specific CD8 T cells was predominantly composed of interferon-stimulated genes, suggestive of a potential therapeutic target.

Conclusion: These data suggest that neurosarcoidosis may be driven by clonally expanded CD8 T cells that mediate inflammation not via direct cytotoxicity but rather through pro-inflammatory cytokines. As inhibition of interferon signaling with JAK inhibitors has been efficacious in published cases of cutaneous and pulmonary sarcoidosis, this strategy may also be effective in patients with neurologic disease.

Abstract Number: 1097

Gastrointestinal Malignancies in Sarcoidosis: A Nationwide Analysis

Rawish Fatima, Ashu Acharya, Saffa Iftikhar and Joan N Gekonde, University of Toledo Medical Center, Toledo, OH

SESSION INFORMATION
Session Date: Monday, November 8, 2021
Session Title: Miscellaneous Rheumatic & Inflammatory Diseases Poster II: Clinical Features & Diagnostics (1083–1117)
Session Type: Poster Session C
Session Time: 8:30AM–10:30AM

Background/Purpose: Sarcoidosis is a multisystem disorder that can involve any organ system. It can involve organs like the lungs, skin, eyes, nose, muscles, heart, liver, spleen, bowel, kidney, testes, nerves, lymph nodes, joints, and brain. There has also been some evidence of sarcoidosis causing lymphoma. The prevalence of gastrointestinal (GI) disorders and malignancies have been rarely studied in patients with sarcoidosis. We attempted to answer this retrospectively using the Nationwide Inpatient Sample (NIS) database analysis.

Methods: We queried the 2017 NIS database using ICD-10-CM diagnosis codes to identify all adult patients admitted with a diagnosis of sarcoidosis. We also identified various gastrointestinal disorders and malignancies using ICD-10 codes. Outcomes assessed were association between sarcoidosis and (A) GI disorders and (B) GI malignancies. A multivariate logistic regression was done adjusting the age, gender, comorbidities, insurance status, race and various hospital characteristrics, and comparative analysis was performed between patients with and without sarcoidosis, Odds Ratio (OR) with 95% confidence interval (CI) and p-values were obtained. A p-value of < 0.05 was considered statistically significant for all outcomes. Statistical analysis was performed using STATA software (StataCorp, College Station, Texas).

Results: The 2017 NIS database yielded a total 30.4 million patients, of which 82,060 (mean age 60.03 years and females 61.6%) were identified with a diagnosis of sarcoidosis and the remaining were grouped as non-sarcoidosis. The following GI signs and symptoms were significantly increased in patients with sarcoidosis compared to patients without sarcoidosis: diarrhea (4.79% vs 3.93%, $p < 0.01$), colitis (3.0% vs 2.3%, $p < 0.01$), gastritis (1.9% vs 1.5%, < 0.05), weight loss (1.0% vs 0.5%, $p < 0.01$), dyspepsia (0.6% vs 0.4%, $p < 0.01$), gastroesophageal reflux (28.5% vs 18.6%, $p < 0.01$), diverticulitis (3.1% vs 2.9%, $p < 0.01$), and celiac disease (28.6% vs 18.6%, $p < 0.01$). A somewhat lower prevalence of the following malignancies were noted in patients with sarcoidosis: esophageal cancer (0.06% vs 0.13%, $p < 0.05$), colon cancer (0.4% vs 0.6%, $p < 0.01$), rectal cancer (0.1% vs 0.3%, $p < 0.01$), and pancreatic cancer (0.3% vs 0.4%, $p < 0.01$)

Table 1. Patient Characteristics

	Variable	Sarcoidosis (82,060) N (%)	No Sarcoidosis N(%)	P-value
1.	Female	61.61%	57.73%	<0.01
2.	Mean Age	60.03	57.93	<0.05
3.	***Race***			
	White	46.7%	67.32%	<0.01
	Black	45.71%	15.14%	
	Hispanic	4.15%	11.11%	
	Asian or Pacific Islander	0.88%	2.76%	
	Native American	0.33%	0.62%	
	Other	2.23%	3.06%	
4.	***Charlson comorbidity score***			
	0	15.59%	35.77%	<0.01
	1	21.49%	19.49%	
	2	19.81%	14.49%	
	>3	43.11%	30.25%	
5	***Median income in patient zip code***			
	$1–$38,999	36.11%	30.49%	<0.01
	$39,000–$47,999	24.25%	26.58%	
	$48,000–$62,999	21.64%	23.43%	
	$63,000	18.00%	19.5%	
6.	***Insurance***			
	Medicare	56.82%	49.26%	<0.01
	Medicaid	14.88%	19.16%	
	Private	26.08%	27.56%	
	Uninsured	2.22%	4.02%	
	Hospital Location			
	Rural	7.09%	9.26%	<0.01
	Urban	92.91%	90.74%	
	Hospital size			
	Small	18.92%	20.11%	<0.01
	Medium	27.41%	29.57%	
	Large	53.67%	50.31%	
	Teaching hospital	74.56%	67.71%	

Conclusion: We highlighted a spectrum of GI signs and symptoms which were significantly more prevalent in patients with sarcoidosis. Of these, the most prevalent were gastroesophageal reflux and celiac disease. Interestingly, GI malignancies were significantly less prevalent in patients with sarcoidosis than those without. These results should be evaluated and confirmed in future studies.

Table 2. GI disorders in Sarcoidosis

Disorder	Sarcoidosis	No Sarcoidosis	OR (95% CI)	p-value
Diarrhea	4.79%	3.93%	1.22 (1.14-1.32)	<0.01
Peptic Ulcer	0.6%	0.67%	0.89 (0.72-1.09)	0.27
Colitis	3.00%	2.31%	1.30 (1.19-1.43)	<0.01
Gastritis	1.89%	1.53%	1.23 (1.09-1.38)	<0.01
Weight Loss	0.97%	0.53%	1.83 (1.57-2.13)	<0.01
Nausea/vomiting	2.32%	2.06%	1.12 (1.01-1.25)	<0.05
Constipation	7.24%	5.67%	1.29 (1.21-1.38)	<0.01
Anorexia	0.54%	0.42%	1.28 (1.05-1.57)	<0.05
Hematemesis	0.26%	0.4%	0.65 (0.48-0.88)	<0.01
Rectal bleeding	0.96%	0.90%	1.06 (0.90-1.25)	0.43
Dyspepsia	0.62%	0.42%	1.48 (1.21-1.80)	<0.01

Abstract Number: 1098

Does Cancer Masquerade as Sarcoidosis?

Daniel Albert, Dartmouth-Hitchcock, Etna, NH

SESSION INFORMATION
Session Date: Monday, November 8, 2021
Session Title: Miscellaneous Rheumatic & Inflammatory Diseases Poster II: Clinical Features & Diagnostics (1083–1117)
Session Type: Poster Session C
Session Time: 8:30AM–10:30AM

Background/Purpose: Several case reports have suggested that cancer can present occultly as a granulomatous inflammatory disease consistent with sarcoidosis. These cases illustrate a problem of potential misdiagnosis leading to adverse outcomes. However, there has not been a study to examine the frequency and circumstances of this issue.

Methods: A retrospective chart review of all the cases of sarcoidosis presenting to Dartmouth-Hitchcock Medical Center from 10/1/2015 to 9/30/2020 were examined for those patients who subsequently developed a malignancy.

Results: Of 1029 individual cases of sarcoidosis 50 patients had a malignancy diagnosed subsequent to the initial determination of sarcoid. 36 of these patients had pulmonary involvement characterized by pulmonary nodules, hilar, paratracheal or mediastinal lymphadenopathy. Of the 14 without pulmonary involvement 2 had CNS, 5 skin, 2 liver, 1 breast, 1 arthritis, 1 inguinal lymphadenopathy and 2 cardiac. 30 of the 50 had biopsy confirmation and the rest imaging consistent with sarcoidosis. 14 of the pulmonary cases had other organ involvement including bone, lymph nodes, skin, pericardial, liver and spleen. Neither of the two CNS cases were confirmed by biopsy and one had a subsequent change of diagnosis to squamous cell of the head and neck. The other had pachymeningitis with elevated CSF ACE levels and no change in diagnosis. Other possible contributing disorders included tuberous sclerosis, Sjogren's Syndrome, Celiac Disease, Crohn's Disease, Lynch Syndrome and Psoriasis. In 36 of the 50 cases the malignancy was unrelated to sarcoidosis primarily breast, thyroid, endometrial, squamous cell, basal cell and melanoma. 7 cases the subsequent diagnosis of cancer might have been related to the therapy for sarcoid including AML after mycophenolate, melanoma after Adalimumab, B cell lymphoma after Adalimumab, CTCL after infliximab and methotrexate, squamous cell and basal cell after methotrexate and adenocarcinoma after methotrexate. In one case treatment for the malignancy (Hodgkin's) probably resulted in the condition labelled sarcoid but was changed to granulomatous disease associated with CVID.7 cases the diagnosis of sarcoidosis appeared to delay the eventual cancer diagnosis by a range of 1 month to 2 years and included cases of Hodgkin's Lymphoma, a MALT tumor, lymphomatoid granulomatosis, squamous cell of the head and neck, seminoma, and CTCL. In one case sarcoidosis delayed the correct diagnosis of MAC by about 2 months. In every case where a malignancy was eventually found the original diagnosis of sarcoidosis was confirmed by biopsy.

Conclusion: Cancer can masquerade as sarcoidosis but it is very rare occurring in 7 of our 1029 (0.7%) cases resulting in a delay in diagnosis usually a matter of months but in 2 cases more than 1 year for seminoma and lymphomatoid granulomatosis. Conversely, immunosuppressive therapy for sarcoid may increase risk for malignancy. In both circumstances clinical vigilance rather than biopsy characteristics is the best guarantee for a good outcome.

Characteristics and Outcomes of Myocardial Infarction in Patients with Rheumatoid Arthritis, Systemic Lupus Erythematosus, Systemic Sclerosis, Gout and Osteoarthritis Patients Using the National Inpatient Sample Database from 2002-2018

Sonia Gupta[1], Vinay thallapally[2], Sarah Aurit[2], Rouhin sen[3] and Joseph Nahas[2], [1]Creighton University School of Medicine, Omaha, NE, [2]Creighton University, Omaha, NE, [3]Colorado University Anschutz Medical Campus, Denver, CO

SESSION INFORMATION
Session Date: Monday, November 8, 2021
Session Title: Miscellaneous Rheumatic & Inflammatory Diseases Poster II: Clinical Features & Diagnostics (1083–1117)
Session Type: Poster Session C
Session Time: 8:30AM–10:30AM

Background/Purpose: Patients with the autoimmune rheumatic disease have an increased risk of acute myocardial infarction (MI). Our study was designed to compare the prevalence, characteristics and in-hospital outcomes among patients with Rheumatoid Arthritis (RA), Systemic lupus erythematosus (SLE), Systemic Sclerosis (SSc), Gout and Osteoarthritis (OA), who developed acute myocardial infarction during 2002- 2018 in a national cohort of US hospitalizations.

Methods: We used the National Inpatient Sample (NIS) database to identify hospitalizations of patients with MI and autoimmune rheumatic diseases including RA, SLE, SSc, Gout. We compared the baseline characteristics, comorbidities, and age-adjusted mortality of patients among the study groups; OA hospitalizations with MI served as a control population. Comparisons of continuous and discrete data were made with ANOVA and the Rao-Schitt chi-square test, respectively. All analyses utilized SAS 9.4 and incorporated the NIS sampling design.

Results: Between 2002- 2018, there was a total of 844,427 MI hospitalizations with RA, SLE, SSc, Gout, and OA (RA: 87,637, SLE: 25,067, SSc: 5,523, Gout: 197,845, and OA: 528,355). Several differences were observed; females were disproportionately higher in SLE, SSc, and RA groups compared to OA (80.6%, 80.3%, 62.6% vs 55%). There was no statistically significant difference in Charlson Comorbidity Index for readmission and mortality among the groups studied. Patients with SLE (60 years; 95% CI: 50 years to 70 years) and SSc (67 years; 95% CI: 58 years to 76 years) had an early age of admission for inpatient hospitalization in comparison to OA (76 years; 95% CI: 66 years to 80 years). The average age of morality is lower in patients with SLE (66 years; 95% CI: 56 years to 76 years) and SSc (72 years; 95% CI: 60 years to 79 years) compared to OA (83 years; 95% CI: 76 years to 89 years). Refer to Table 1 for full characteristics as described above. Inpatient mortality was higher in those admitted with SSc, RA, and SLE in comparison to OA (10.2%, 5.4%, 5.2% vs 4.6%) (Table 2). However, Gout had decreased inpatient mortality compared to OA (4.3% vs 4.6 %) (Table 2).

Conclusion: This is the most updated NIS study comparing the clinical baseline hospitalization characteristics of patients with four autoimmune rheumatic diseases with acute myocardial infarction. Acute MI in SLE and SSc develop at an earlier age compared to other groups. We also observed increased mortality in patients with SSc compared with RA/ SLE/ Gout or OA. There is not much literature on outcomes of MI in patients with SSC and our study demonstrates that this patient group is an independent risk for in-hospital mortality. Therefore, further studies need to be done to evaluate the causes of higher mortality in this group.

Table 1. Clinical characteristics of hospitalized patients with four different systemic rheumatic diseases with myocardial infarction and Osteoarthritis patients with myocardial infarction

Characteristic	RA + MI (N = 87,637)	SLE + MI (N = 25,067)	SSc+ MI (N = 5,523)	Gout + MI (N = 197,845)	OA + MI (N =528,355)	*P*-value

Pulmonary Arterial Hypertension in Adult-Onset Still's Disease: A Case Series of 13 Patients

Stéphane Mitrovic[1], athénaïs Boucly[2], Estibaliz Lazaro[3], Nicolas SCHLEINITZ[4], Coralie Bloch-Queyrat[5], Christine Christides[6], Jacques Pouchot[7], marc humbert[2], David Montani[2], laurent savale[2], Xavier Jaïs[2], Olivier Sitbon[2] and Bruno Fautrel[8], [1]Pitié Salpêtrière Hospital - Institut Mutaliste Montsouris, Paris, France, [2]Pneumology Department, Bicêtre Hospital, Assistance Publique – Hôpitaux de Paris, Kremlin-Bicêtre, France, [3]Internal Medicine Department, CHU Bordeaux, Pessac, France, [4]Internal Medicine Department, Hôpital Timone, APHM, Marseille, France, [5]Internal Medicine Department, Avicennes Hospital, APHP, Bobigny, France, [6]Internal Medicine Department, CH Avignon, Avignon, France, [7]AP-HP, RUEIL-MALMAISON, France, [8]Pitié Salpêtrière Hospital, APHP, Sorbonne Université, Paris, France

SESSION INFORMATION

Session Date: Monday, November 8, 2021

Session Title: Miscellaneous Rheumatic & Inflammatory Diseases Poster II: Clinical Features & Diagnostics (1083–1117)

Session Type: Poster Session C

Session Time: 8:30AM–10:30AM

Background/Purpose: Pulmonary Arterial Hypertension (PAH) is a rare but potentially fatal complication of Adult-Onset Still's Disease (AOSD). To date, only isolated observations have been published. Our objective was to establish the largest case series of AOSD patients with PAH, and to describe their clinical profile, evolution and response to treatments.

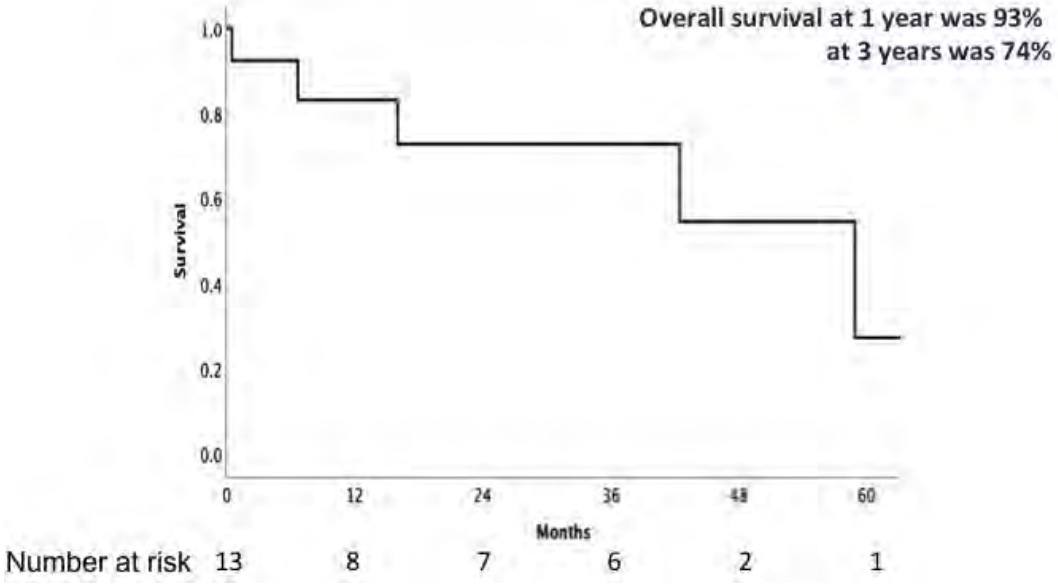
Methods: Cases were retrospectively identified from the French PAH network database and from an online call of the "Club Rhumatismes et Inflammation" (http://www.cri-net.com). To be included, all patients had to fulfil the Yamaguchi or Fautrel criteria for AOSD and PAH had to be confirmed by right heart catheterization. The data were collected using a standardized questionnaire.

Results: Thirteen patients were identified. All cases of PAH occured after the diagnosis of AOSD was made. All were female, the mean age at PAH diagnosis was 32± 12 years, 2 (15%) patients were Caucasian, 6 (46%) from Sub-

Table. Initial PAH therapeutic management

Treatment	*n (%)*
Inotropic therapy	6 (46%)
PAH treatment	10 (77%)
Monotherapy	3
Initial oral dual combination therapy	3
Dual combination therapy including IV prostacyclin	1
Upfront triple combination therapy including IV prostacyclin	3
High-dose corticosteroids	11 (85%)
Interleukin-1 inhibitors initiation	2 (15%)
Interleukin-6 inhibitors initiation	1 (0.7%)
Switch from IL-1 to IL-6 inhibitors	4 (30.7%)

Figure. Overall survival after PAH diagnosis in patients with AOSD



Saharan Africa, 1 (8%) from Asia and 4 (31%) from West Indies. Only 2 (15%) patients were smokers. All patients had a systemic onset of AOSD, 12 had a polycyclic and 1 a chronic articular evolution, and the mean delay between AOSD and PAH diagnosis was 2.9 (range 1.7 -5.4) years. PAH diagnosis was concomitant of AOSD flare in 11 (85%) patients. At PAH diagnosis, patients were receiving the following treatments: 13 (100%) corticosteroids (median dose 12 mg [interquartile range (IQR) 10-20]), 4 (31%) methotrexate, 9 (69%) interleukin (IL)-1 inhibitors (exposure median duration 7.1 months [IQR 4.4-10.1]), none IL-6 inhibitors, 2 (15%) TNF inhibitors. PAH was severe at diagnosis: 2 (15%), 7 (54%) and 4 (31%) patients were in NYHA functional class II, III and IV, respectively, with a median 6-minute walk distance of 289 m [IQR 0-448], a mean pulmonary arterial pressure of 41 ± 12 mmHg, a mean pulmonary arterial occlusion pressure of 6 ± 3 mmHg, a mean cardiac output of 3.9 ± 1.2 L/min, a mean cardiac index of 2.5 ± 0.9 L/min/m^2 and a median pulmonary vascular resistance of 7 Wood Units [IQR 6-11]. The treatment prescribed after PAH diagnosis is detailed in the table. The median follow-up was 34 months [IQR 10-42]. Five patients (38.5 %) died. The haemodynamic response to PAH treatment seemed to be dissociated from the prognosis since three patients died while their haemodynamic had improved or almost normalized. Three patients died during an AOSD flare with disseminated intravascular coagulation. Figure 1 shows the overall survival which was 93% at 1 year and 74% at 3 years.

Conclusion: PAH is a rare but potentially severe complication of AOSD. It affected exclusively women in our case series. AOSD remission should be physicians' objective, since PAH seems to occur when the underlying disease is not controlled.

Session Title: Miscellaneous Rheumatic & Inflammatory Diseases Poster II: Clinical Features & Diagnostics (1083–1117)

Session Type: Poster Session C

Session Time: 8:30AM–10:30AM

Background/Purpose: Once specific etiologic factors have been ruled out, the majority of patients with chronic interstitial pneumonia (IP) can be classified as idiopathic pulmonary fibrosis (IPF) or as connective tissue autoimmune disease (CTD) associated. Being usual interstitial pneumonia (UIP) the reference radiographic pattern of IPF, a non-UIP pattern is one of the most robust indicators of an alternative diagnosis. In this regard, Fischer's criteria of IP with autoimmune features (IPAF) include either a non-UIP radiographic pattern or the coexistence with alterations at other compartments. However, some patients presenting with UIP could have an autoimmune IP (AIP) and remain unclassified (UAIP). As it has been recently suggested, the involvement of the superior anterior lobe, an exuberant honeycombing and a straight edge between affected and unaffected regions could suggest an AIP diagnosis in patients with UIP. We set a retrospective study to describe the appearance of these atypical UIP signs in our clinic of AIP patients.

Methods: Two radiologists performed independent evaluations of CT scan images from our patients with AIP and an UIP pattern. Concordance was evaluated with kappa index. Epidemiological data, clinical diagnosis and process-associated variables were collected from clinical charts. Comparisons were assessed with non-parametric tests.

Results: Agreement between observer 1 (expert) and observer 2 (trainee) was fair as regards to the identification of the upper anterior lobe sign (p 0.001) and the straight edge ($p < 0.001$), while there was little concordance in the exuberant honeycombing scoring (p 0.7). We subsequently carried out the analysis using observer 1 scoring. There were 9 out of 33 p (27%) showing exuberant honeycombing, 5 p with involvement of the upper anterior lobe (15%) and 2 p with the straight edge sign (6%), irrespectively from the clinical diagnosis. The appearance of at least one of the signs was 62% in the CTD group, 43% in IPAF, and 30% in UAIP. In the UAIP cohort, 2 p had the anterior superior lobe sign. One of them did not fulfil the serological IPAF domain. The second one did not show involvement of other compartments, and had an ACPA titre of 264 IU. The third patient had an exuberant honeycombing, but no additional compartment involvement, along with a > 1/320 ANA titre. The last 2 patients would therefore change classification to IPAF if these signs were taken into account in the classification criteria. On the other hand, 2 patients had high rheumatoid factor but none had the atypical signs and would consequently remain unclassified. There was no association between atypical signs and inflammatory markers, such as glass-grounded opacities or acute phase reactants. Neither was there a relationship between these signs and disease duration time from or the extension of fibrosis. Interestingly, patients with emphysema were more likely to have any of the atypical UIP signs (p 0.047). We did not find associations between these signs and markers of epithelial injury. However, there was an inverse relationship with C'4 (p 0.041).

Conclusion: The new radiographic signs may help characterize a subgroup of patients with AIP, although more studies are necessary.

Comorbidities and Causes of Hospitalizations in a Cohort of IgG4-Related Disease Patients from a Single Center

David Faz-Muñoz, Eduardo Martin-Nares, Alejandra Hernández-Delgado and Gabriela Hernandez-Molina, Department of Immunology and Rheumatology, Instituto Nacional de Ciencias Médicas y Nutrición Salvador Zubirán, Mexico City, Mexico

SESSION INFORMATION
Session Date: Monday, November 8, 2021
Session Title: Miscellaneous Rheumatic & Inflammatory Diseases Poster II: Clinical Features & Diagnostics (1083–1117)
Session Type: Poster Session C
Session Time: 8:30AM–10:30AM

Background/Purpose: The frequency and types of comorbidities, causes of hospitalization, and the differences among clinical phenotypes in patients with IgG4-related disease (IgG4-RD) have not been explored thoroughly.

We aimed to disclose the types of comorbidities and causes of hospitalizations and their impact in a cohort of IgG4-RD patients.

Methods: We performed a retrospective study. IgG4-RD patients had to fulfill the Comprehensive Diagnostic Criteria for IgG4-RD and/or the Consensus Statement on Pathology and/or the 2019 ACR/EULAR Classification Criteria for IgG4-RD. Clinical variables, comorbidities and causes of hospitalizations were retrieved from the medical charts in a standardized manner. Patients were classified in clinical phenotypes: Group 1 (pancreato-hepato-biliary), Group 2 (retroperitoneal/aortic), Group 3 (head and neck-limited), Group 4 (Mikulicz/systemic) and Group 5 (undefined). The Charlson Comorbidity Index (CCI) and the Rheumatic Disease Comorbidity Index (RDCI) were calculated at last follow-up.

Table 1. Comorbidities in IgG4-related disease patients

Table 1. Comorbidities in IgG4-related disease patients	
Comorbidity, n (%)	**N = 89**
Type 2 diabetes	8 (9)
Type 3c diabetes	7 (7.9)
Hypertension	24 (27)
Obesity	11 (12.4)
Dyslipidemia	15 (16.9)
Osteoporosis	12 (13.5)
Tobacco use	23 (25.8)
Inflammatory/autoinmune diseases	16 (18)
Atopy	17 (19.1)
History of thrombosis	7 (7.9)
Thyroid disease	12 (13.5)
Malignancies	9 (10.1)

Table 2. Differences among IgG4-related disease phenotypes

	Group 1	Group 2	Group 3	Group 4	Group 5	P
Male, n (%)	17 (70.8)	6 (66.7)	4 (16)	15 (62.5)	5 (71.4)	<0.001
Age, median (IQR), years	51.6 ± 14	39.1 ± 16.8	50.9 ± 19.5	52.2 ± 10.8	42.8 ± 19.2	0.17
Comorbidities, n (%)	23 (95.8)	9 (100)	22 (88)	24 (100)	7 (100)	0.27

Damage at last follow-up, n (%)	15 (62.5)	4 (44.4)	12 (48)	14 (58.3)	3 (42.9)	0.75
CCI at last follow-up, median (IQR)	3 (1-4)	2 (1-5)	2 (0-4)	3 (2-4)	1 (0-2)	0.56
RDCI at last follow-up, median (IQR)	1 (1-2)	2 (0-4)	1 (0-2)	1 (1-2.5)	0 (0-2)	0.79
Follow-up, median (IQR), months	30.5 (18-64)	34 (26-40)	24 (12-53)	35.5 (19-99)	29 (12.5-36)	0.76

CCI: Charlson Comorbidity Index; IQR: interquartile range; RDCI: Rheumatic Disease Comorbidity Index

Results: We included 89 patients with a mean age at diagnosis of 49.6 ± 16 years, 47 (52.8) were male. Twenty-four (27%) belonged to Group 1, 9 (10.1%) to Group 2, 25 (28.1%) to Group 3, 24 (27%) to Group 4 and 7 (7.9%) to Group 5.

At least one comorbidity was detected in 85 (95.5%) patients (Table 1). Type 2 diabetes was more frequent in Group 4, type 3c diabetes in Group 1 and 4, obesity in group 3 and 5, thrombosis in Group 5 and malignancies in Group 1 (Table 2).

Forty-five (50.6%) patients were hospitalized during follow-up, 22 (24.7%) once, 15 (16.9%) twice and 8 (9%) ≥ 3 times. Causes of first hospitalization (non-exclusive) were: relapse in 28 (62.2%), infection in 16 (35.6), treatment complications in 5 (11.1%) and others in 5 (11.1%). The median days of hospitalization was 1 (IQR 0-11.5). Ten (22.2%) patients were taking prednisone at the time of hospitalization with a median dose of 20 mg (IQR 7.5-45) and 6 (14%) immunosuppressants. Only 4 patients required intensive care unit admission. Hospitalization was more common in patients from Group 1 and 5. Group 5 had the longest days of hospitalization.

The median score of the CCI and RDCI at last follow-up was 3 (IQR 1-4) and 1 (IQR 0-2), respectively. Patients who ever had a hospitalization were more likely to have damage attributed to IgG4-RD at last follow-up (OR 2.8, 95% CI 1.2-6.8, p=0.02). Two patients died during a median follow-up of 30 (IQR 18-63) months.

Conclusion: Comorbidities are very frequent in patients with IgG4-RD and differed according to clinical phenotype. Relapses were a common cause of hospitalization. Hospitalization was more frequent in patients from Group 1 and 5, and they were associated with damage accrual.

Receiving allergy immunotherapy, n (%)	4 (2.1)	0 (0.0)	4 (2.9)

IgG4 = immunoglobulin G4; ULN = upper limit of normal; IQR = interquartile range; BMI = body mass index.

Table 2. Distribution of patients with a serum IgG4 level >5x ULN by disorder

Disorder	*n* (%)	IgG4 (mg/dL), median [IQR]
Definite IgG4-RD	128 (67.0)	1014.5 [678.5, 1419.9]
Probable IgG4-RD	10 (5.2)	980.3 [807.8, 1207.5]
Atypical IgG4-RD	2 (1.0)	653.2 [609.6, 696.9]
Possible IgG4-RD	4 (2.1)	623.0 [561.5, 824.1]
B cell lymphoma	4 (2.1)	1275 [1213.8, 1489]
B cell leukemia	2 (1.0)	1105.0 [1067.5, 1142.8]
Systemic lupus erythematosus	2 (1.0)	760.0 [756.0, 764.0]
EGPA	3 (1.6)	923.0 [751.3, 1847.2]
Hypereosinophilic syndrome	3 (1.6)	540.0 [511.6, 2702.4]
Histiocytic disease	2 (1.0)	2077.0 [1676, 2478.0]
Unknown	11 (5.8)	923.0 [751.3, 1847.2]
Other*	21 (11.0)	579.0 [534.0, 1834.0]

IgG4 = immunoglobulin G4; ULN = upper limit of normal; IQR = interquartile range; IgG4-RD = IgG4-related disease; EGPA = eosinophilic granulomatosis with polyangiitis.
*Other includes single cases of multiple myeloma, cholangiocarcinoma, food allergies, acute disseminated encephalomyelitis, spondyloenchondrodysplasia with immune dysregulation, POEMS syndrome, cystic fibrosis, MSSA bacteremia and osteomyelitis of the femur, cholangiocarcinoma, T cell lymphoma, bronchiolitis obliterans, postinfectious inflammatory disease, chronic eosinophilic pneumonia, monoclonal gammopathy of undetermined significance, pulmonary mycobacterial infection, sarcoidosis, pediatric autoimmune neuropsychiatric disease associated with Streptococcal infection, lymphadenopathy, small fiber neuropathy

Table 3. Manifestations of IgG4-RD in patients with a serum IgG4 level >5x ULN

IgG4-RD Manifestations	*n* (%)
Number of organs involved, median [IQR]	3 [2,3]
Single-organ involvement	22 (15.3)
Multi-organ involvement	118 (81.9)
Lacrimal gland	48 (33.3)
Salivary gland	71 (49.3)
Orbital	25 (17.4)
Pancreas	72 (50.0)
Biliary	34 (23.6)
Liver	14 (9.7)
Renal	43 (29.9)
Retroperitoneal fibrosis	13 (9.0)
Aorta/large vessel	9 (6.3)

IgG4 = immunoglobulin G4; IgG4-RD = IgG4-related disease; IQR = interquartile range.

Background/Purpose: Serum IgG4 concentrations are used as part of the evaluation for suspected IgG4-related disease (IgG4-RD), but the specificity of this test, especially at very high levels, remains uncertain. Indeed, the ACR/EULAR Classification Criteria for IgG4-RD place high weight on elevated serum IgG4 concentrations; of the 20 points required to be classified as IgG4-RD, 11 are assigned if the patient has an IgG4 concentration ≥ 5x the upper limit of normal (ULN).[1] We sought to evaluate the association of very high serum IgG4 concentrations with a diagnosis of IgG4-RD.

Methods: The data warehouses at two large academic medical centers—Stanford University and Mass General Brigham—were queried for all IgG subclass test results. Patients with any serum IgG4 concentration ≥ 5x the ULN were included. Demographics, medical history, and other laboratory test results of interest were extracted from the electronic medical record of each patient. A diagnosis of IgG4-RD was determined using the ACR/EULAR Classification Criteria for IgG4-RD. The positive predictive value (PPV) of a serum IgG4 concentration ≥ 5x the ULN for the diagnosis of IgG4-RD was estimated. Other conditions associated with very high serum IgG4 concentrations, and specific features of the IgG4-RD patients, were characterized.

Results: Of 34,391 patients with serum IgG subclasses tested, 2,294 (7%) had an elevated serum IgG4 concentration, and 191 (0.6%) had an IgG4 concentration ≥ 5x the ULN. The combined cohort had a median age of 66 years, was predominately male (72%), and was racially diverse (**Table 1**). The PPV of an IgG4 concentration ≥ 5x the ULN for a diagnosis of definite (67%), probable (5%), or atypical (1%) IgG4-RD was 73%. The median [IQR] IgG4 concentration among patients with definite IgG4-RD (*n* = 128) was 1014.5 mg/dL [678.5, 1419.9] (**Table 2**). Other diseases associated with a very elevated serum IgG4 concentration included B cell lymphoma and leukemia, eosinophilic granulomatosis with polyangiitis and other hypereosinophilic syndromes, systemic lupus erythematosus, histiocytic disease, and systemic infections or post-infectious syndromes (**Table 2**). Among IgG4-RD patients with an IgG4 concentration ≥ 5x the ULN, the majority (82%) had multi-organ involvement, with the pancreas (50%), salivary glands (49%), lacrimal glands (33%), and kidneys (30%) being the most commonly involved organs (**Table 3**).

Conclusion: The majority of patients with a serum IgG4 concentration ≥ 5x the ULN in this study had IgG4-RD, with a PPV of 73% for IgG4-RD. These data support the significant weight placed on very elevated serum IgG4 in the IgG4-RD Classification Criteria. However, it is notable that 27% of patients with an IgG4 concentration ≥ 5x the ULN had no identifiable cause or an alternative diagnosis, underscoring the importance of the Classification Criteria's entry and exclusion criteria when evaluating a patient with a very high IgG4 concentration for IgG4-RD. These findings highlight the broad differential to consider when evaluating a patient with a very high IgG4 concentration.

Pathogenic *UBA1* Variants in Japanese Patients with Relapsing Polychondritis

Naomi Tsuchida[1], Yosuke Kunishita[2], Yuri Uchiyama[1], Yohei Kirino[3], Kaoru Takase-Minegishi[1], Ryusuke Yoshimi[1], Hideaki Nakajima[1] and Naomichi Matsumoto[1], [1]Yokohama City University Graduate School of Medicine, Yokohama, Japan, [2]Yokohama City University Graduate School of Medicine, Yokohama, Kanagawa, Japan, [3]Yokohama City University, Yokohama, Japan

SESSION INFORMATION

Session Date: Monday, November 8, 2021

Session Title: Miscellaneous Rheumatic & Inflammatory Diseases Poster II: Clinical Features & Diagnostics (1083–1117)

Session Type: Poster Session C

Session Time: 8:30AM–10:30AM

Background/Purpose: Pathogenic somatic variants in the ubiquitin like modifier activating enzyme 1 gene (*UBA1*) were discovered in individuals with systemic inflammation of cartilage, skin, and blood vessels accompanied by hematological abnormalities, named VEXAS (vacuoles, E1 enzyme, X-linked, autoinflammatory, somatic) syndrome, affecting only male patients. Some patients with VEXAS were reported to have a relapsing polychondritis (RP) phenotype. To determine clinical and genetic features of individuals with RP likely caused by pathogenic somatic variants in *UBA1*.

Methods: Fourteen patients with RP who met the Damiani and Levine classification criteria were recruited (12 men, 2 women; median onset age [interquartile range] 72.1 years [67.1–78.0]). Sanger sequencing of *UBA1* was performed using genomic DNA from peripheral blood leukocytes or bone marrow tissue. Droplet digital PCR (ddPCR) and peptide nucleic acid (PNA)-clamping PCR were used to detect low-prevalence somatic variants. Clinical features of the patients were investigated retrospectively. Clinical features were compared pathogenic *UBA1* variant-positive and negative patients. Categorical variables were analyzed using the chi-square test and exact unconditional z-pooled test. Continuous variables were examined using the Mann–Whitney U test. A p-value < 0.0028 (= 0.05/18) was considered statistically significant using Bonferroni's corrected p-value for multiple testing (N=18).

Results: *UBA1* was examined in 13 of the 14 patients; 73% (8/11) of the male patients had somatic *UBA1* variants (c.121A >C, c.121A >G, or c.122T >C resulting in p.Met41Leu, p.Met41Val, or p.Met41Thr, respectively). All the variant-positive patients had systemic symptoms, including a significantly high prevalence of skin lesions. ddPCR detected low-prevalence (0.14%) of somatic variant (c.121A >C) in one female patient, which was subsequently confirmed by PNA-clamping PCR.

Conclusion: Genetic screening for pathogenic *UBA1* variants should be considered in patients with RP, especially male patients with skin lesions.

Session Date: Monday, November 8, 2021
Session Title: Miscellaneous Rheumatic & Inflammatory Diseases Poster II: Clinical Features & Diagnostics (1083–1117)
Session Type: Poster Session C
Session Time: 8:30AM–10:30AM

Background/Purpose: Monogenic systemic inflammatory diseases (MSID) are a heterogeneous group of rare conditions caused by single gene variants leading to immune dysregulation. Diagnostic yield of targeted gene panels in these patients is limited. Whole exome sequencing (WES) has been used in pediatric populations to identify a growing number of genes implicated in MSID. Such approaches to studying MSID in adults are rare in the literature. Here, we have clinically and genetically characterized a case series of adult patients with suspected MSID.

Methods: Our study included 14 adults with suspected MSID and non-diagnostic gene panels, assessed at St Michael's Hospital, Toronto. We excluded patients with inflammation due to non-genetic causes.

Clinical and laboratory data were extracted and entered into a database. Targeted gene (n=31) panel testing on an exome backbone was performed at Genome Diagnostics, SickKids, using paired end sequencing on Illumina HiSeq 2500 platform to an average depth of ~120X following enrichment with the Agilent Clinical Research Exome V1 kit. After obtaining consent, sequence data was analyzed in a research setting using BWA aligner followed by variant calling with GATK, SAMtools, FreeBayes, and Platypus. Annotation was performed using SnpEff, Vcfanno, and custom scripts. Variants were filtered and prioritized using minor allele frequency < 0.01 in gnomAD, in silico prediction tools (CADD, SIFT, Polyphen, Vest3, Revel), conservation, segregation where parental data was available, and associations with known disorders or immunological pathways.

A *definitive* molecular diagnosis was provided if a likely pathogenic or pathogenic variant (as classified by the 2015 American College of Medical Geneticists criteria) was identified in a patient with a fully compatible phenotype. A *probable* diagnosis was defined as a variant of uncertain significance (VUS) in a gene associated with a condition identified in a patient with a compatible phenotype. A *possible* diagnosis was defined as a VUS in a gene involved in immune processes, but without a known associated condition.

Results: The majority of patients were male (64%) and European (57%). Age at study enrollment was between 22-52 years, with 36% having symptom onset before the age of 18. 42% had a family history of an immune-mediated disorder. WES provided one *definite* diagnosis (Aicardi Goutières Syndrome Type I; *TREX1* homozygous deletions) and one *probable* diagnosis (Proteasome Associated Autoinflammatory Syndrome; digenic missense variants in *PSMB4*/*PSMB8*). *Possible* diagnoses were found in eight (57%) patients (VUS's in *STYK1, FAIM3, ARHGAP26, FGD2, IKBKAP, BLK, ASAP1, RRTOR, LILRA6, RNF21)*.

Conclusion: In a series of adults with suspected MSID, exome analysis identified variants leading to a probable or definite diagnosis in 14%, and possible diagnoses in 57% of patients. Our work shows that exome sequencing identifies potential genetic causes of systemic inflammatory disease in patients with negative gene panels. Future studies would include family-based analyses and functional validation of candidate variants. Larger multicenter studies will further define the role of WES in this population.

Phenotypes and Genotypes of NLRP3-AID in Chinese Adult Patients

Na Wu, Di Wu, Junke Miao, Mengzhu Zhao and Min Shen, Peking Union Medical College Hospital, Chinese Academy of Medical Sciences & Peking Union Medical College, Beijing, China (People's Republic)

SESSION INFORMATION
Session Date: Monday, November 8, 2021
Session Title: Miscellaneous Rheumatic & Inflammatory Diseases Poster II: Clinical Features & Diagnostics (1083–1117)
Session Type: Poster Session C
Session Time: 8:30AM–10:30AM

Background/Purpose: NLRP3-associated autoinflammatory disease (NLRP3-AID, OMIM 606416), previously called cryopyrin-associated periodic syndrome (CAPS), is a spectrum of autosomal dominant inherited diseases associated with NLRP3 gene mutations, leading to the overactivation of NLRP3 inflammasome and the excessive release of interleukin (IL)-1β. NLRP3-AID encompasses three conditions of of increasing severity: familial cold-induced autoinflammatory syndrome (FCAS), Muckle-Wells syndrome (MWS), and chronic infantile neurological cutaneous articular syndrome (CINCA). We aim to report a cohort of Chinese adult NLRP3-AID patients.

Methods: This single-center study included fifteen adult patients diagnosed with NLRP3-AID at Department of Rheumatology, Peking Union Medical College Hospital between July 2015 to September 2020. Demographic informa-

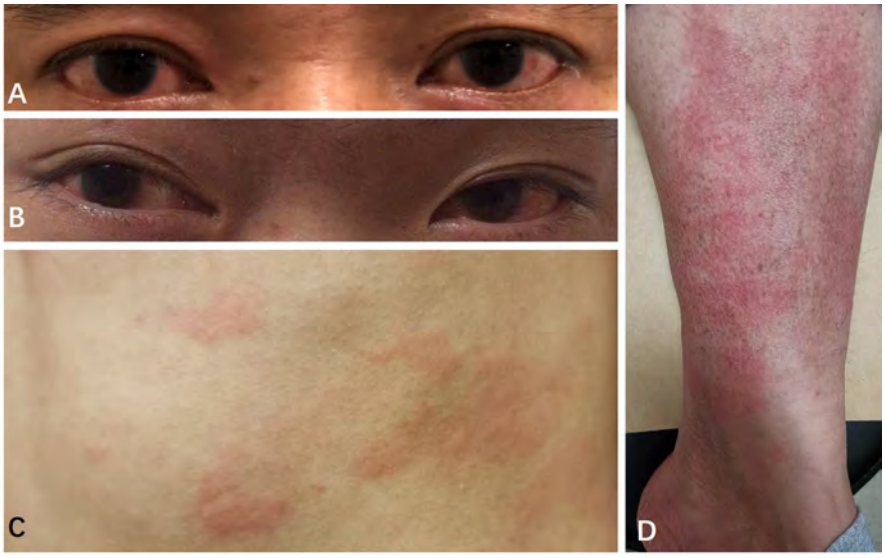

Figure 1. A.&B. Ocular inflammatory manifestations in Patient 9 and Patient 11; C. Erythematous rashes on the trunk of patient 5; D. Papules on the right lower limb of Patient 10.

tion and detailed clinical records were carefully documented and studied. Whole-exome sequencing using next-generation sequencing was performed in each patient.

Results: These 15 patients were all diagnosed as MWS. Of them, the gender ratio of male to female was 3:2. All patients were of Chinese Han ethnicity. The median age of disease onset was 16 (0-46) years old, and adult-onset was observed in 4 patients (26.7%). The median time of diagnosis delay was 20 (0–39) years. 5 patients (33.3%) had positive family history of similar symptoms. The most common clinical manifestations were fever (93.3%), arthritis (80.0%), rash (73.3%), myalgia (66.7%), hearing loss (60.0%) and central nervous system involvement (53.3%). No patient developed renal amyloidosis. Acute phase reactants (CRP 80.3 ±51.0 mg/L and ESR 52 ± 28 mm/h) elevated during flares in all patients and normalized during intervals. Rarely, a 38-year-old female patient presented with positive ANA and antiphospholipid antibodies, which were negative in the other patients. Heterozygous NLRP3 variants confirmed in these patients were T348M (n=3), Q703K, V70M, K131R, M116I, P38S, V444I, D303G, G328E, A439V, K831T, L632F and V198M (n=1, separately). Patients with T348M mutation showed more severe organ damage, including the eyes and the central nervous system. Glucocorticoids were given to 7 patients with partial symptom relief in 6 patients (71.4%). Due to the unavailability of IL-1 inhibitors in China, TNF-α inhibitors (etanercept and adalimumab) were used in 7 patients with effective responses (100%).

Conclusion: We reported a large case series of Chinese adult NLRP3-AID patients. The distinct symptoms of NLRP3-AID patients suggest the heterogeneity of disease. K131R, M116I, P38S, V444 and K831T are identified as novel NLRP3 mutations. These data expanding the clinical phenotype and genotype profile of NLRP3-AID.

§ : n=159; NA: not available; IBD: Inflammatory bowel disease; ESR: erythrocyte sedimentation rate; CRP: C-reactive protein; ANA: antinuclear antibodies; HLA: human leukocyte antigen; NSAIDs: non-steroid anti-inflammatory drugs; DMARDs: disease-modifying anti-rheumatic drugs; TNF: tumor necrosis factor;

Figure 3. Comparison of clinical features of CNO patients in the Chinese and French cohorts.

Methods: Ten adult patients (≥16 years) were diagnosed and followed up during April 2015 to February 2021, at the Department of Rheumatology, Peking Union Medical College Hospital. Clinical and genetic features of these patients were evaluated and compared with those from the French cohort.

Results: The median age of disease onset was 19 (6-64) years old, and adult-onset was observed in 6 (60%) patients. The mean time of diagnosis delay was 92±78 months. The common symptoms were bone pain (10, 100%), fever (9, 90%), and arthritis (6, 60%). Five patients (50%) had mucocutoneous disorders, manifested as palmoplantar pustulosis, psoriasis, eczema, and apthous stomatitis. In total, there were 54 skeletal lesions, and each patient had no less than 2 lesions. The most frequently affected sites included lower limbs (20.5%), mandible, vertebrae and pelvis (17.5%, separately), followed by ribs (13%), skull, and radius (5.6%, respectively). In contrast, in the French cohort which mainly consisted of pediatric CNO patients, lower limbs and pelvis were the most commonly involved sites. Variants of 3 genes were detected in our study including *COL1A1*, *PSTPIP1* and *LRP5*. A combination therapy containing tumor necrosis factor (TNF) α inhibitors was proved to be effective.

Conclusion: This is the first and largest case series of CNO in Chinese adult patients. CNO should be considered in the differential diagnosis of adult patients with long disease course and recurrent multifocal osteomyelitis of unknown cause. Pathological and etiological examination through bone biopsy is critically helpful. A combination therapy containing TNFα inhibitors is recommended.

SESSION INFORMATION
Session Date: Monday, November 8, 2021
Session Title: Miscellaneous Rheumatic & Inflammatory Diseases Poster II: Clinical Features & Diagnostics (1083–1117)
Session Type: Poster Session C
Session Time: 8:30AM–10:30AM

Background/Purpose: Familial Mediterranean Fever (FMF), an autoinflammatory disease, is characterized by self-limited inflammatory attacks. A significant proportion of patients with FMF experience episodes of acute monoarthritis, however 5 % of patients have chronic arthritis, usually of hips or knees. In this study we aimed to evaluate clinical and laboratory characteristics, genotype/phenotype correlation, outcome and biological DMARD responses in patients with FMF-associated SpA (FMF/SpA) who followed up in our tertiary referral clinic.

Methods: One hundred and twenty-four patients with FMF who fulfilled Tel Hashomer criteria and coexisting SpA were evaluated. After exclusion of 13 patients with missing data, 111 patients included into the analysis. Diagnosis of SpA was made by ASAS and/or modified New York criteria (mNYC). Axial radiographic changes were evaluated and scored according to Bath Ankylosing Spondylitis Radiology Index (BASRI) in plain radiography.

Table 1: Comparison of clinical and laboratory findings of patients between FMF/SpA and SpA control group

Clinical and laboratory variables	FMF/ SpA group (n=111)	Control group (n=216)	p value
Age (years) (mean±SD) (IQR)	43.5±12.3 (18)	43.3±10.6 (17)	0.9
Sex (n, %)			
Male	52 (46.8)	104 (48.1)	0.8
Female	59 (53.2)	112 (51.9)	
Duration of SpA (years) (mean±SD) (IQR)	15.5±9.95 (12.75)	14.9±9.2 (12)	0.6
Age onset of SpA (years) (mean±SD) (IQR)	24.8±10.8 (15)	28.5±8.3 (10)	***0.003 ****

While 79 results were available, most frequent MEFV variant was M694V homozygote (44.3%). Hip involvement was higher in patients who had two MEFV variants compared to one copy and M694V homozygous compared to others. Need for TJR was higher in M694V homozygous compared to other MEFV variants. Radiographic sacroiliitis was lower in patients with FMF/SpA compared to control group but similar both in patients who had two MEFV variants compared to one copy and M694V homozygous compared to other MEFV variants. HLA-B27 positivity was lower in patients with FMF/SpA compared to control group (table 2)

Table 3: Comparison of clinical and laboratory features of patients with switchers and no switchers

Variables	Switch		
	Yes	No	p value
Age (mean±SD) (IQR)	48.3±9.1 (13)	43.5±12 (18)	0.2

Yes (n=17)	5 (29.4)	12 (70.6)	0.08
No (n=52)	6 (11.5)	46 (88.5)	
Hip involvement (n, %)			
Yes (n=44)	11 (25)	33 (75)	***0.01 (OR:6.6)***
No (n=22)	0	22 (100)	
Peripheral arthritis (n, %)			
Yes (n=58)	11 (19)	47 (81)	0.2
No (n=8)	0	8 (100)	

Average BASRI hip scores were higher in patients with FMF/SpA compared to SpA only (p=0.01) and also higher both had two MEFV variants compared to one copy (p=0.01) and M694V homozygous compared to other MEFV variants (p< 0.001). Average BASRI-spine scores were higher in patients with SpA compared to FMF/SpA group (p=0.02); but did not differ among various MEFV variants. Average BASRI-total scores did not differ in patients with FMF/SpA and control group and only higher in patients had M694V homozygous compared to other MEFV variants (p=0.035) (table 2).

Conclusion: In our study, hip involvement and need for TJR were associated with MEFV carriage rather than HLA-B27 positivity and higher in patients with FMF/SpA compared to the patients with SpA alone. Our study indicates that the patients with FMF/SpA had more severe disease course including worse outcome and destructive hip involvement than those with SpA alone, especially in patients carrying two copy MEFV variants and M694V homozygous.

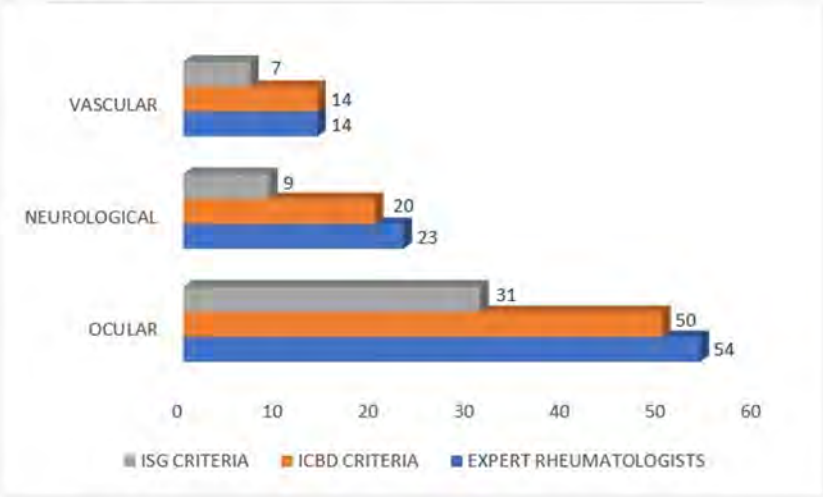
Figure: Number of patients with vascular, neurological or ocular manifestations diagnosed with BD by different criteria.



Abbreviations: ITRC-ICBD: International Team for the Revision of the International Criteria for BD; **ISG:** International Study Group for Behçet Disease.

Background/Purpose: Behçet disease (BD) is characterized by painful recurrent oral aphthosis genital ulcers and skin lesions. Nevertheless, the major causes of morbidity result from ocular, vascular and neurological involvement. Diagnosis of BD is usually performed according to the International Study Group (ISG*) (Lancet 1990; 335:1078-80).* Recently, criteria proposed by the International Team for the Revision of the International Criteria for BD (ITR-ICBD) have demonstrated a higher sensitivity *(J Eur Acad Dermatology Venereol 2014;28:338-47)*.

The aim of the present study was to assess **a)** the concordance and differences between ISG and ICDB criteria **b)** sensitivity in diagnosing severe manifestations (ocular, vascular and neurological).

Methods: The study included 120 patients diagnosed with definitive or possible BD by expert rheumatologists. They were diagnosed at a well-defined population in Northern Spain between January 1980 and December 2019. The ISG and ICBD diagnostic criteria for BD were applied to all patients and compared among them.

Results: 120 patients (62 men/ 58 women) were studied. Mean age at diagnosis was 37.6±13.8 years. 59 (49.2%) patients fulfilled ISG criteria and 96 (80%) ICBD criteria. Concordance between both criteria was moderate (Kappa 0.41). ICBD criteria diagnosed more patients with neurological (χ^2=49.1, p< 0.01), vascular (χ^2= 56.7, p< 0.01) and ocular manifestations (χ^2=84.4 p< 0.01) **(Figure)**.

Conclusion: ICBD criteria are more likely to diagnose BD and classify more patients with severe manifestations of the disease.

SESSION INFORMATION

Session Date: Monday, November 8, 2021

Session Title: Miscellaneous Rheumatic & Inflammatory Diseases Poster II: Clinical Features & Diagnostics (1083–1117)

Session Type: Poster Session C

Session Time: 8:30AM–10:30AM

Background/Purpose: CAPS is a rare, heterogenous inflammasomopathy associated with gain-of-function mutations in *NLRP3* that encodes cryopyrin. Mutations in NLRP3 result in excessive IL-1ß production that may underlie wide range of symptoms. IL-1 blockade demonstrated complete responses to treatment which has been life-changing in this monogenic inflammasomopathy.

Methods: Patients followed-up in GOSH and NAC specialist CAPS clinics from 2005 to 2021 were identified. Data on following parameters collected: disease subtype, presenting symptoms, CAPS disease activity scores, serum amyloid A (SAA) and CRP levels, MRI brain; and treatment. Descriptive statistical analysis was performed by GraphPad Prism version 9.1.1.

Results: A total of 48 patients [female (n=20, 42 %), male (n=28, 58 %)] with CAPS diagnosis in childhood/adolescence were identified. Median age at disease presentation was 3.50 years (range: 0.20 – 16.23). Disease subtypes were: CINCA (n=4), MWS (n=37), FCAS (n=6), CAPS-like disease (n=1). Two of 6 patients with FCAS harboured *NLRP3* variants of unknown significance (VUS) and were discharged since they ultimately proved asymptomatic after review. Clinical symptoms were recorded, and CAPS disease activity score was calculated in each clinic visit. There was a significant drop in the mean CAPS activity scores between first and last visits (8.66/20 (±2.59), 1.12/20 (±1.29), respectively). Median treatment duration was 5.83 years (range:0.17–15.83). Mutations could not be detected by sanger in 6/48 (12,5 %) patients, although clinical characteristics of CAPS were identified. Two/6 patients had NGS that showed no evidence of mosaicism. The commonest mutation was p.A439V in *NLRP3* gene (19/48), followed by p.V198M (3/48), p.T348M (3/48) and p.R488K (3/48) mutations. CRP and SAA levels were checked prior to treatment and at each clinic visit. 45 of 48 patients (94 %) were on anti-IL1 treatment: 42/45 (93 %) canakinumab, 27 of whom were switched from anakinra; and 3/45 (7 %) on anakinra. Two FCAS patients were discharged from clinic without any treatment, 1 patient with compound heterozygous *IRAK4* mutations in addition to *NLRP3* p.E457D was switched from canakinumab to tocilizumab, with complete clinical and serological response. Median CRP before and after treatment were 5.0 mg/L (range:1.0-83.0) and 5.0 mg/L (range:1.0–51.0). Median SAA before and after treatment were 8.5 mg/L (range:2.4–680.0) and 3.50 mg/L (range:2.0–222.0). Thirteen of 48 (27 %) patients underwent MRI brain due to neurological involvement, mainly due to recurrent headaches, with no abnormalities identified in 9/13 (70 %); whereas 4 patients (3 with CINCA) had changes on their MRI brain. None of the patients experienced deterioration neither in their clinical symptoms nor in their MRI brain scans after starting treatment with anti-IL1.

Conclusion: Anti-IL1 treatment has had a major impact in paediatric patients for the prevention and treatment of CAPS symptoms. Treatment efficacy was observed by improved CAPS clinical disease activity scores; and normalised inflammatory markers. In our cohort, neurological symptoms including sensorineural hearing loss have improved and MRI brain scans have remained stable with anti-IL1 therapies.

SESSION INFORMATION

Session Date: Monday, November 8, 2021

Session Title: Miscellaneous Rheumatic & Inflammatory Diseases Poster II: Clinical Features & Diagnostics (1083–1117)

Session Type: Poster Session C

Session Time: 8:30AM–10:30AM

Background/Purpose: Amyloidosis is characterized by accumulation of insoluble fibrils composed of different monomers in extracellular spaces of different organs, and demonstration of deposits by non-invasive methods is important especially for organs difficult to sample. Transient elastography (fibroscan) is a diagnostic method being used to measure liver stiffness (LS) in different chronic liver diseases. We herein aimed to test the place of fibroscan method for detecting increased LS associated with amyloid deposition in patients with amyloidosis.

Methods: Six categories of patients enrolled into this cross-sectional study; AA amyloidosis (AA-a), AL amyloidosis (AL-a), Familial Mediterranean Fever (FMF) patients without amyloidosis, cirrhotic chronic liver disease, non-cirrhotic chronic hepatitis B infection (CHB) and healthy controls (HC). LS assessment by fibroscan were categorized as normal for kPa< 7, significant stiffness for kPa≥7, advanced stiffness for kPa≥9.5 and kPa≥F4 stiffness. FIB-4 and APRI scores were calculated for each patient when they indicated chronic liver disease. Patients with known chronic liver disease and viral hepatitis excluded from amyloidosis and FMF groups.

Results: A total of 165 patients (AA-a, n=65; AL-a, n=15; FMF, n=20; cirrhotic patients, n=16; CHB, n=22; HC, n=27) constituted the study group. Clinical and laboratory features of patients are given in Table 1. Average age was higher in the AL-a group compared to others. Median LS was highest in cirrhotic patients, and it was also higher in AA-a and AL-a patients compared to FMF and HC. Median LS was numerically higher in AL-a compared to AA-a, but it did not reach statistical significance. Median LS was also higher in FMF patients compared to HC. FIB-4 and APRI scores were lower compared to cirrhotic patients in AA-a and AL-a. ALP levels were higher in AA-a and AL-a groups com-

pared to FMF, CHB and HC. FIB-4 and APRI scores, ALP and GGT levels were correlated with LS both in AA-a, AL-a and FMF-AA groups (Table 2). The scores of amyloid depositions were higher in non-FMF-AA-a patients compared to FMF-AA-a. In FMF-AA-a group, median LS, FIB-4 score, GGT, creatinine, cardiac septal wall thickness (CSWT) and frequency of advanced stiffness were higher in patients who had one exon 10 MEFV variant compared to those with two variants. Frequency of advanced and F4 stiffness, GIS involvement and CSWT were lower in M694V homozygous compared to other MEFV variants.

Higher patient age, age at diagnosis of amylodosis, FIB-4 and LS scores, ALP levels, non-FMF causes of AA were associated with hepatic AA amyloid involvement in biopsy-proven patients. A cut-off value 12.05 kPa of LS provided 100% sensitivity and 85.5% specificity (LR=6.9, AUC=0.901, 95% CI 0.81-0.99) for patients with AA-a.

Conclusion: In our single center cohort, we showed a higher median LS by fibroscan in both AL-a and AA-a patients compared to CHB, FMF and HC. Additionally, hepatic amyloid involvement and median LS was higher in non-FMF-AA-a compared to FMF-AA-a, and in FMF-AA-a patients with one exon 10 MEFV variant compared to those with two variants suggesting presence of amyloidogenic genetic factors additional to pathogenic MEFV variants.

SESSION INFORMATION

Session Date: Monday, November 8, 2021

Session Title: Miscellaneous Rheumatic & Inflammatory Diseases Poster II: Clinical Features & Diagnostics (1083–1117)

Session Type: Poster Session C

Session Time: 8:30AM–10:30AM

Background/Purpose: Amyloidosis is characterized by accumulation of insoluble fibrils composed of different monomers in extracellular spaces of different organs, and demonstration of deposits by non-invasive methods is important especially for organs difficult to sample. Transient elastography (Fibroscan) is a diagnostic method of measuring liver stiffness (LS) being used in chronic liver diseases.

Table 1: Baseline clinical and laboratory characteristics of study participants

Variables	Amyloidosis (n=19)	Control group (n=16)	p value
Age (years) (median; IQR)	48 (22)	51 (11)	0.4

IQR: Interquartile range, FMF: Familial Mediterranean Fever, BMI: Body mass index, DM: Diabetes mellitus, kPa: kilopascal, CRF: Chronic renal failure, ESRD: End stage renal disease, GIS: Gastrointestinal system, b-DMARD: Biological disease modifying antirheumatic drug, CNI: Calcineurin inhibitors

We herein aimed to search potential of fibroscan detecting kidney stiffness (KS) associated with amyloid deposition in patients with AA who received kidney transplants.

Methods: Renal transplant recipients (RTR) because of AA amyloidosis-related kidney failure (amyloidosis group; AG) and RTR due to other underlying diseases (control group; CG) enrolled into this study. KS and LS were measured by the same physician blinded to diagnosis. The stiffness results were expressed in kilopascals (kPa). Local ethics committee approval and patient consents were obtained.

Results: Nineteen AG and 16 CG patients included into the study. Baseline clinical and laboratory characteristics of participants are summarized in Table 1. Patient age, gender, body mass index (BMI), donor type, donor gender and donor age, frequency of rejection history and graft loss did not show significant difference between two groups. Frequency of diabetes mellitus (DM), median creatinine and proteinuria, median LS scores were higher in AG group than CG. Although median KS was higher in CG group, the difference was not significant. Baseline clinical and laboratory features were similar in AG patients with recurrent-amyloidosis (n=6) and non-recurrent AG patients (n=13) (Table 2). Median KS score was higher in recurrent compared to non-recurrent AG patients ($p< 0.001$). However median LS did not differ between two groups ($p=0.4$). In multivariate analysis only KS was associated with renal recurrence of AA ($p=0.031$; OR=1.18, 95% CI 1.015-1.362). In ROC analysis, a cut-off value of 24.55 kPa provided 83.3% sensitivity and 92.3% specificity (LR=10.8, AUC=0.936, $p=0.003$). Median KS was higher in patients with a history of rejection both among the patients with AG and CG, but the difference was not significant. Additionally, LS scores were similar between two groups.

In FMF-associated AA, median KS was higher in patients with one MEFV variant compared to those with two variants and tended to be higher in other MEFV variants compared to M694V homozygotes ($p=0.027$ and $p=0.08$, respectively). There was no correlation between the patient age, disease duration, duration of renal transplantation, donor age, BMI, LS, creatinine, CRP, proteinuria, and KS both in patients with AG and CG.

Conclusion: Median KS scores were similar between AG and CG groups; however it was higher in AG patients with recurrent kidney amyloidosis than those without recurrent disease, which may support using the fibroscan method as a useful screening method for establishing AA recurrence. Additionally, higher KS scores in patients with one MEFV variant compared to those with two variants need further studies to be able to identify other yet unidentified amyloidogenic factors.

SESSION INFORMATION

Session Date: Monday, November 8, 2021

Session Title: Miscellaneous Rheumatic & Inflammatory Diseases Poster II: Clinical Features & Diagnostics (1083–1117)

Session Type: Poster Session C

Session Time: 8:30AM–10:30AM

Background/Purpose: The 2019 ACR/EULAR classification criteria (2019 AECC) for IgG4-related disease (IgG4-RD) have been validated in cohorts mainly composed of Caucasian and Asian patients. Its performance in Latin American patients is not known. We aimed to explore the performance of the 2019 AECC for IgG4-RD in a real-world cohort of Latin American patients.

Methods: We performed a retrospective multicenter study. Participating centers belonged to the Latin American Group for the study of IgG4-RD from Argentina, Chile, Mexico, Peru and Uruguay. Investigators were asked to submit information about patients and mimickers in a standardized fashion. IgG4-RD patients had to fulfill the Comprehensive Diagnostic Criteria for IgG4-RD and/or the Consensus Statement on Pathology. Mimickers were those diseases with overlapping features with IgG4-RD that were evaluated by the investigators. We retrospectively applied the 2019 AECC.

Results: We included 300 patients of which 153 (51%) were male. Mean age was 52 ± 15.3 years. One hundred and eighty (60%) had IgG4-RD and 120 (40%) a mimicker condition. The diagnoses of the mimickers are shown in Table 1.

Table 1. Mimickers

Table 1. Mimickers	
Mimicker conditions, n (%)	**N = 120**
Autoimmune hepatobiliary diseases	16 (13.3)
Sjögren's syndrome	14 (11.7)
Histiocytosis	13 (10.8)
ANCA-associated vasculitis	12 (10)
Idiopathic sclerosing conditions	12 (10)
Chronic pancreatitides	9 (7.5)
Solid malignancies	9 (7.5)
Lymphoma (Hodgkin and non-Hodgkin)	8 (6.7)
Systemic lupus erythematosus	5 (4.2)
Graves' orbitopathy	3 (2.5)
Sarcoidosis	2 (1.7)
Others*	17 (14.2)
Other mimickers: pachymeningitis secondary to systemic autoimmune diseases (2), lymphoid hyperplasia (1), membranoproliferative glomerulonephritis (1), carotid cavernous fistula (1), POEMS syndrome (1), hypereosinohilic syndrome (1), multiple myeloma (1), intersticial pneumonia with autoimmune features (1), organizing pneumonia (1), VEXAS syndrome (1), idiopathic dry eye (1), sclerosing angiomatoid nodular transformation of the spleen (1), immune check point inhibitor-induced hypophysitis and cholangitis (1), lymphocytic hypophysitis (1), lymphocytic dacryoadenitis (1), salivary gland benign tumor (1)	

After applying the 2019 AECC, 180 patients were classified as IgG4-RD (66.7%). Of the 60 false-negative cases (33.3%), 13 did not fulfill the entry criteria; of the remaining 47, 23 fulfilled one exclusion criteria; the remaining 24 did not achieve sufficient inclusion criteria scores.

Fourteen out of the 23 patients fulfilling exclusion criteria were positive for a disease-specific autoantibody, 6 of whom have overlapping autoimmune diseases (2 ANCA-associated vasculitis, 2 systemic sclerosis, 2 rheumatoid arthritis). The other 8 patients had no evidence of another autoimmune disease during follow-up; all of them had multiorgan involvement (median: 6 organs).

The true-positive cases had more involved organs and more frequently an available biopsy and were more likely to be of the Mikulicz/systemic and the proliferative phenotypes (Table 2).

Of the 120 mimickers, 20 (16.7%) did not fulfill the entry criteria, 71 (59.2%) fulfilled at least one exclusion criteria, and the remaining 29 (24.1%) did not achieved a score of 20, resulting in no mimickers fulfilling the 2019 AECC. Four mimickers achieved sufficient inclusion criteria scores (Rosai-Dorfman disease, systemic lupus erythematosus, sarcoidosis, and pancreatic cancer).

Table 2. Comparison of true-positive cases and false-negative cases

Table 2. Comparison of true-positive cases and false-negative cases			
	True positives (n=120)	**False negatives (n=60)**	**P**
Male, n (%)	69 (57.5)	32 (53.3)	0.59
Age at diagnosis, median (IQR), years	53.3 ± 14	50.6 ± 17.5	0.26
Mestizo, n (%)	98 (81.7)	54 (90)	0.14
Caucasian, n (%)	21 (17.5)	5 (8.3)	0.09
CSP, n (%)			
Highly suggestive, n (%)	52 (43.3)	19 (31.7)	0.13
Probable, n (%)	33 (27.5)	17 (28.3)	0.90
Insufficient, n (%)	20 (16.7)	11 (18.3)	0.78
CDC, n (%)			
Definitive, n (%)	53 (44.2)	18 (30)	0.06
Probable, n (%)	32 (26.7)	20 (33.3)	0.35
Possible, n (%)	35 (29.2)	22 (36.7)	0.30
Mono-organic, n (%)	16 (13.3)	18 (30)	0.007
2 involved organs, n (%)	22 (18.3)	15 (25)	0.29
≥ 3 involved organs, n (%)	82 (68.3)	27 (45)	0.003
Number of involved organs, median (IQR)	4 (2-6)	2 (1-4)	0.003
Pancreato-hepato-biliary, n (%)	25 (20.8)	10 (16.7)	0.50
Retroperitoneal/aortic, n (%)	9 (11.7)	7 (11.7)	0.35
Head and neck-limited, n (%)	40 (33.3)	23 (38.3)	0.50
Mikulicz/systemic, n (%)	38 (31.7)	8 (13.3)	0.008
Undefined, n (%)	8 (6.7)	12 (20)	0.007
Proliferative, n (%)	89 (74.2)	36 (60)	0.05
Fibrotic, n (%)	31 (25.8)	24 (40)	0.05
Overlapping systemic autoimmune disease, n (%)	1 (0.8)	6 (10)	0.006
Biopsy, n (%)	106 (88.3)	46 (76.7)	0.04
High IgG4 levels, n (%)	86 (76.8)	38 (66.7)	0.15
Serum IgG4 levels, median (IQR), mg/dL	300.5 (150.5-680)	251 (88-481)	0.17
Inclusion criteria score, median (IQR)	34 (27.5-43.5)	18 (12-32)	<0.001
CDC: Comprehensive diagnostic criteria; CSP: Consensus statement on pathology; IQR: interquartile range			

The performance of the criteria was: sensitivity 66.7%, specificity: 100%, PPV 100%, NPV 66.7%. In a sensitivity analyses where all exclusion criteria were removed the sensitivity increased to 77.8% and the specificity decreased to 96.6%. When only removing the disease-specific autoantibody items, the sensitivity was 73.3% and the specificity 100%.

Conclusion: Application of the 2019 ACR/EULAR classification criteria for IgG4-RD in a real-world Latin American population confirms its high specificity in excluding those without the disease. The sensitivity was lower than the one reported in other cohorts. The presence of concomitant autoimmune diseases and clinically not significant disease-specific autoantibodies excludes a significant number of patients from fulfilling the criteria.

Pachymeningitis: The Mayo Clinic Experience

Emily Gilbert[1], Mina Al-Awqati[2], Tina Gunderson[3] and Florentina Berianu[1], [1]Mayo Clinic, Jacksonville, FL, [2]University of Illinois, Chicago, IL, [3]Mayo Clinic, Rochester, MN

SESSION INFORMATION
Session Date: Monday, November 8, 2021
Session Title: Miscellaneous Rheumatic & Inflammatory Diseases Poster II: Clinical Features & Diagnostics (1083–1117)
Session Type: Poster Session C
Session Time: 8:30AM–10:30AM

Background/Purpose: Pachymeningitis is a rare disorder defined by localized or generalized inflammatory thickening of the dura. It can be associated with infections, malignancy, autoimmune disorders, or can be idiopathic. The clinical presentation is dependent on the location of dural involvement and regional structures affected. Typical symptoms include chronic headaches, seizures, facial pain, ataxia, and cranial neuropathies. Case series have reported clinical characteristics and outcomes in patients with pachymeningitis; however, large series are lacking. In our retrospective study, we report the clinical presentation, demographics, etiology, imaging features, laboratory data, treatment, and outcome in 153 patients with pachymeningitis referred to our tertiary care center.

Table 1. Neurologic symptoms of subjects with Pachymeningitis. The top 10 categories by prevalence are shown.

Neurologic Symptoms	N(%)
HEADACHES	103 (67.3%)
HEARING ISSUES	39 (25.5%)
VISUAL CHANGES	39 (25.5%)
OTHERS	31 (20.3%)
DIZZINESS	25 (16.3%)
SENSORY LOSS	22 (14.4%)
NAUSEA	18 (11.8%)
PARESIS	18 (11.8%)
SEIZURES	12 (7.8%)
IMBALANCE	11 (7.2%)

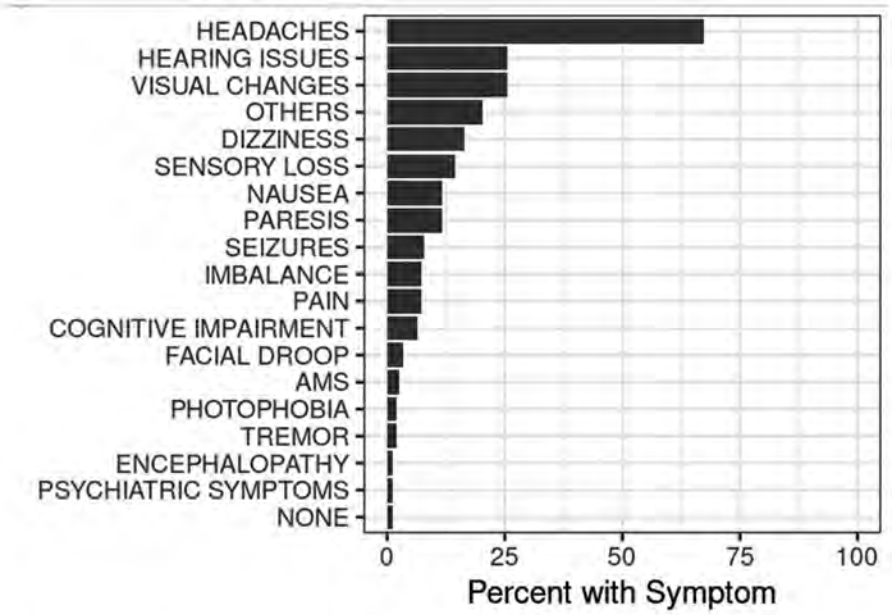

Figure 1. Neurological symptoms of Pachymeningitis.

Table 2. Etiology of Pachymeningitis. The top 10 categories by prevalence are shown.

Etiology	N(%)
IDIOPATHIC	45 (29.4%)
CSF HYPOTENSION SYNDROME/SPONTANEOUS CSF LEAK	29 (19%)
SARCOIDOSIS	19 (12.4%)
INFLAMMATORY UNDETEREMINED	16 (10.5%)
OTHERS	11 (7.2%)
INFECTIOUS	8 (5.2%)
GPA	7 (4.6%)
CANCER	6 (3.9%)
RA	5 (3.3%)
IGG4	5 (3.3%)

Methods: Medical records for all patients with pachymeningitis between 01/01/1990 and 11/01/2019 at our institution were reviewed. Pachymeningitis was defined as focal or diffuse dural thickening or enhancement on magnetic resonance imaging (MRI) of the brain or spinal cord and/or characteristic inflammation on histologic analysis of dura mater tissue samples. Clinical features, laboratory data, radiologic features, pathological findings, and therapeutic data were studied.

Results: 163 cases of potential pachymeningitis were examined, and 10 patients were excluded for not meeting pachymeningitis definition. The cases were 52.3% female (80/153) and 47.7% male (73/153). Mean age at diagnosis was 60 years (range 21 to 87) with mean age at onset of symptoms 58 years (range 17 to 87). Nearly all patients (98.7%) experienced at least one neurological symptom with headache being the most prevalent (N=103/67.3%; Table 1 and Figure 1). CSF analysis via lumbar puncture was performed in 118 patients with opening pressure being high in 19 of 90 patients. Dural thickening and enhancement was more common on MRI than either radiological finding alone, 56.2% versus 3.9% dural thickening alone or 37.9% enhancement alone (without dural thickening). The majority of cases presented with diffuse pachymeningitis on MRI (62.1%). Biopsy of the cranial or spinal parenchyma or meninges was performed in 42.5% (65/153). Etiology of pachymeningitis was idiopathic in 29.4% (45/153). The top 10 categories of etiology by prevalence are shown in Table 2. 60.1% of patients (92/153) received at least one thera-

peutic agent. 51.6% of cases received treatment with corticosteroids. Other treatments depending on etiology of the pachymeningitis included methotrexate, blood patch, antimicrobial therapy, rituximab, and azathioprine with highest prevalence. Complete clinical response and complete initial radiologic response were observed in 12.4% (19/153).

Conclusion: We report the largest series of pachymeningitis patients to date. Etiology may be idiopathic or secondary to infections, malignancy, or autoimmune disorders; therefore, appropriate workup is necessary to guide treatment strategy. Limited number of patients demonstrate complete clinical response.

SESSION INFORMATION
Session Date: Monday, November 8, 2021
Session Title: Miscellaneous Rheumatic & Inflammatory Diseases Poster II: Clinical Features & Diagnostics (1083–1117)
Session Type: Poster Session C
Session Time: 8:30AM–10:30AM

Background/Purpose: Inflammatory bowel disease (IBD), which includes Crohn's disease (CD), and Ulcerative colitis (UC) are related to Spondyloarthritis (SpA). Ocular manifestations (OM) are well-stablished in axial SpA but not in IBD. It has been classically reported that whereas uveitis with axial SpA is predominantly anterior, unilateral, acute, and non-recurrent; in IBD it is bilateral, posterior, insidious, and chronic.

In a large unselected series of IBD, our aim was to assess **a)** epidemiology and clinical features of uveitis associated to IBD, **b)** to compare patients who developed uveitis and those who did not, and **c)** its relationship with biological treatment used in IBD.

Methods: Study of all consecutive patients from a single University Hospital during the last 40 years with**: a)** IBD (CD and UC), and **b)** uveitis according to Standarization Uveitis Nomenclature (SUN) Working Group. Demographic features, clinical findings, occurrence of other extraintestinal manifestations and treatment were recorded.

Results: We studied 1449 (714 women/735 men) patients with IBD, mean age of 55.2±15.9 years.

Uveitis was present in 23 (1.6 %) (38 eyes) of 1449 IBD patients. The most common pattern of uveitis was typically anterior (n=18; 78.3%), unilateral (n=19; 82.6%), acute (n=19; 82.6%), and non-recurrent (n=12; 52.2%).

The comparative study between patients with and without uveitis showed a significant predominance of women (**TABLE)** in patients with uveitis, as well as erythema nodosum, hidradenitis suppurativa and joint involvement.

TABLE. General features of 1449 patients with IBD with and without uveitis.

	Overall (n=1449)	Uveitis (n=23)	Non uveitis (n=1426)	P
Main general features				
Age, years, mean±SD	55.2±15.9	49.1±14.6	55.2±15.9	0.8
Sex, women/men, n, (% of women)	714 / 735 (49.3)	17 / 6 (73.9)	697 / 729 (48.9)	**0.02***
IBD duration, years, mean±SD	13.2 ± 9.7	17.4 ± 10.2	13.1 ± 8.9	0.08
IBD Severity				
Surgical Interventions, n (%)	289 (19.9)	2 (8.7)	284 (19.9)	0.7
Conventional Immunosuppressive drugs, n (%)	878 (60.6)	14 (60.9)	863 (60.5)	0.5
Biological Therapy, n (%)	384 (26.5)	7 (30.4)	378 (26.5))	0.9
TNFi monoclonal antibodies	384 (26.5)	7 (30.4)	378 (26.5)	0.9
Ustekinumab	27 (1.9)	1 (4.3)	27 (1.9)	0.5
Other	23 (1.6)	1 (4.3)	22 (1.6)	0.3
Extraintestinal manifestations				
Cutaneous manifestations, n (%) (TOTAL)	125 (8.6)	9 (39.1)	121 (8.7)	0.1
Erythema nodosum, n (%)	26 (1.8)	6 (26.1)	24 (1.7)	**0.009***
Pyoderma gangrenosum, n (%)	13 (0.9)	1 (4.3)	13 (0.9)	0.7
Hidradenitis suppurativa, n (%)	2 (0.1)	1 (4.3)	1 (0.1)	**0.0001***
Joint involvement, n (%) (TOTAL)	131 (9)	10 (43.5)	121 (8.5)	**0.0001***
Axial pattern, n (%)	65 (4.5)	4 (17.4)	58 (4.1)	**0.0001***
Peripheral pattern, n (%)	64 (4.4)	4 (17.4)	63 (4.4)	0.9

Regarding IBD severity, in terms of surgical interventions, and conventional and biological immunosuppressive treatments, there were no significant differences.

Conclusion: Although uveitis is more infrequent in IBD than in axial SpA, it is also anterior, unilateral, acute, and non-recurrent in contrast with published data from selected series. Patients with uveitis do not seem to represent more severe phenotype of IBD.

Disease Characteristics of Steroid-Induced Spinal Epidural Lipomatosis: A Systematic Review

Haseeb Chaudhary[1], Usama Nasir[2], Khezar Syed[3], Abigayle Sullivan[3], Shilla Zachariah[3], Christian AkemDimala[3], Muhammad Khan[4] and Anthony Donato[3], [1]Tower Health System, Reading, PA, [2]Reading Hospital, Tower Health System, Reading, PA, [3]Reading Hospital, Tower Health System, Reading, PA, [4]University of Kentucky, Lexington, KY

SESSION INFORMATION

Session Date: Monday, November 8, 2021

Session Title: Miscellaneous Rheumatic & Inflammatory Diseases Poster II: Clinical Features & Diagnostics (1083–1117)

Session Type: Poster Session C

Session Time: 8:30AM–10:30AM

Background/Purpose: Steroid-induced epidural lipomatosis (SEL) is a rare phenomenon causing neuronal compression from adipose tissue deposition in the epidural space. We analyzed the available literature in a systematic review to determine the patient demographics, underlying disease, oral steroid doses, intervention, and outcomes of SEL.

Methods: A comprehensive database search was performed for articles reporting spinal epidural lipomatosis from oral steroid therapy from conception to May 26, 2021. Full-text articles in English language meeting our predefined criteria were analyzed for review (Figure 1).

Results: We included 36 articles for our systematic review including data of 45 patients. The mean age of patients presenting with SEL was 50.1 (27-75) years with male predominance (80.0%). The most common presenting symptom was paraparesis 82.0% (n= 35), followed by back pain 44.4% (n=25). One-third (31.1%) of the patient population had an inflammatory rheumatological indication for chronic steroid therapy. Rheumatoid arthritis was the most common inflammatory disorder in these (57%). The median oral steroid dose was 20.0 (9.75-45.8) mg/day with a median duration of 24.0 (12.0-57.0) months before the diagnosis of SEL. Thoracic spine was affected in 55.8% (n=24), lumbar spine in 34.8% (n=15) and both in 9.3% Laminectomy was performed in 73.3% (n=33) of cases. Case outcomes were variable, however the majority reported recovery to ambulation (65.2%).

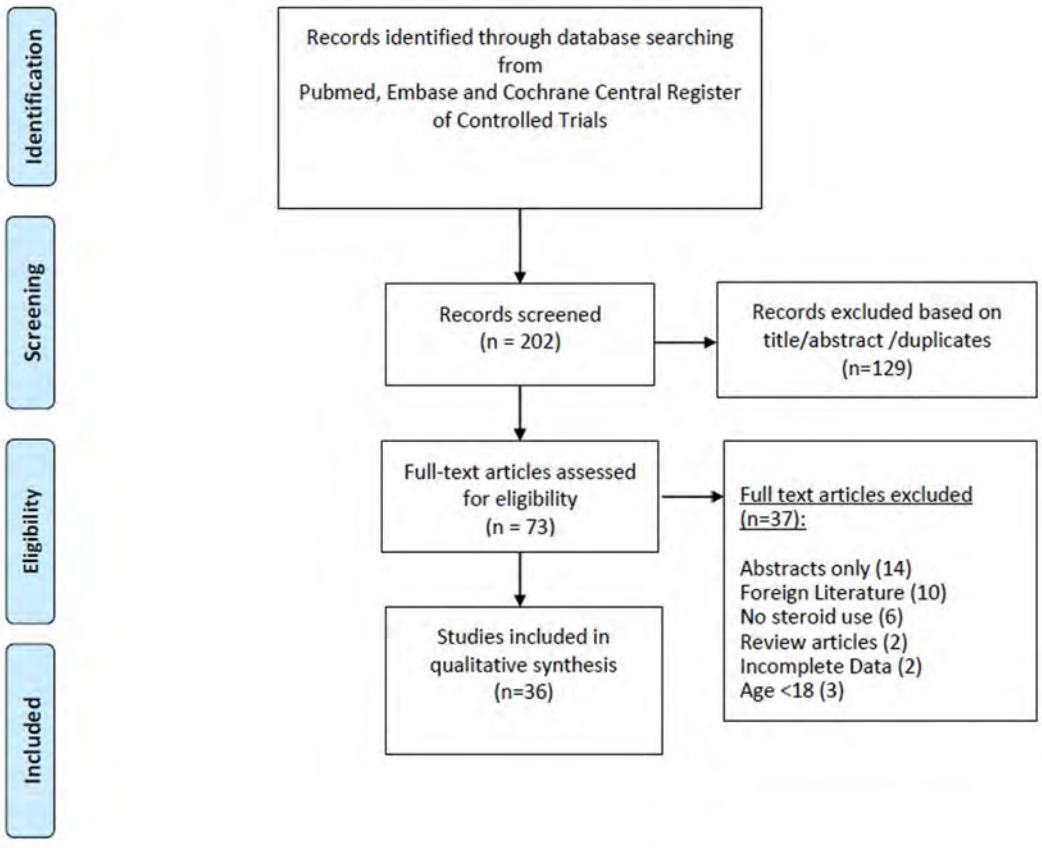

Figure 1. PRISMA flow diagram.

Conclusion: SEL should be considered as a possible etiology for lower limb weakness in patients on chronic oral steroid therapy. Our review highlights this rare association that may further increase the morbidity in patients with underlying rheumatological diseases.

SESSION INFORMATION
Session Date: Monday, November 8, 2021
Session Title: Miscellaneous Rheumatic & Inflammatory Diseases Poster II: Clinical Features & Diagnostics (1083–1117)
Session Type: Poster Session C
Session Time: 8:30AM–10:30AM

Background/Purpose: Ocular scleral pathology (OSP) includes episcleritis and scleritis. Episcleritis is generally a benign disease with a self-limited course, while scleritis is a more severe ocular condition. In some severe and refractory cases systemic therapy may be required.

In a wide series with OSP our aim was to assess **a)** underlying diseases and **b)** systemic treatment.

Methods: Study of unselected all consecutive patients studied in a single University Hospital during the last ten years with**: a)** episcleritis and **b)** scleritis diagnosed by clinical features and slit-lamp (Watson and Hayreh criteria). Best corrected visual acuity (BCVA) and intraocular pressure (IOP) were measured at diagnosis and after systemic treatment.

Results: We studied 175 patients (106 women/ 69 men) /212 affected eyes with OSP (episcleritis=135; scleritis=40); mean age 48.9±14.2 years.

OSP was unilateral in 138 (78.9%), recurrent in 74 (42.9%) and chronic in 21 (12%). Most of them were idiopathic (n=81, 46.3%) while associated with IMID were 43.4% **(TABLE).** The most important underlying IMID were spondyloarthritis and inflammatory bowel disease, without significant differences between scleritis and episcleritis. Granulomatosis with polyangiits and systemic lupus erythematosus were more frequent in scleritis, not reaching statistical significance.

Regarding treatment, topical treatment was used in all patients. 41.1% received systemic treatment, including systemic glucocorticoids, cDMARDS and bDMARDs. Systemic glucocorticoids and Methotrexate were used more frequently in scleritis **(TABLE)**. The main indication for biologic therapy was related to underlying IMID in both groups, but 7 bDMARDs in scleritis were indicated for systemic and ocular compromise.

BVCA and IOP improved significantly after systemic treatment in scleritis **(FIGURE)**.

Conclusion: OSP is a relatively frequent entity. It is necessary to exclude an underlying systemic disease to establish correct systemic treatment.

The Association of Hand OA with Paid an Unpaid Work Impairment and Related Costs: The Hand Osteoarthritis in Secondary Care Cohort

Sietse Terpstra[1], Lotte van de Stadt[1], Annelies Boonen[2], Frits Rosendaal[1] and Margreet Kloppenburg[1], [1]Leiden University Medical Center, Leiden, Netherlands, [2]Department of Internal Medicine, Division of Rheumatology, Maastricht University Medical Centre+ (MUMC+), Maastricht, Limburg, Netherlands

SESSION INFORMATION
Session Date: Monday, November 8, 2021
Session Title: Osteoarthritis – Clinical Poster III (1118–1134)
Session Type: Poster Session C
Session Time: 8:30AM–10:30AM

Background/Purpose: Rheumatic musculoskeletal diseases (RMDs) can cause impairment at paid and unpaid work and contributes to societal burden and costs. However, data on this topic concerning hand osteoarthritis (OA) is scarce.

Therefore, we aimed to investigate the association of hand OA with paid and unpaid work participation, as well as socio-demographic and disease characteristics related to productivity loss and societal costs.

Table 1. Characteristics of the HOSTAS population of our present study (n=382)

General patient characteristics	
Age, years	60.9 (8.4)
Sex, women, *n (%)*	320 (84%)
BMI, kg/m²	27.6 (4.9)
Education level, high, *n (%)*	101 (26%)
Hand-specific characteristics	
Fulfilling Altman et al. hand OA criteria, *n (%)*	344 (90%)
Erosive hand OA⁺, *n (%)*	113 (30%)
Symptom duration, years^	0.76 (0.27; 2.65)
AUSCAN hand pain (0-20)	9.4 (4.2)
AUSCAN hand function (0-36)	15.7 (8.2)
Tender joint count (0-30)^	3 (1; 6)
KL ≥ 2 joint count (0–30)^	13 (5; 21)
General burden	
Comorbidities, any comorbidity present, *n (%)*	157 (41%)
Amount of comorbidities^	0 (0; 1)
Work characteristics	
Paid work, *n (%)*	181 (47%)
Hours of paid work per week	25.9 (11.8)
Retired, *n (%)*	117 (31%)
Full work disability, *n (%)*	24 (6.3%)
Full work disability due to hand OA, *n (%)*	16 (4.2%)

Table 2. Outcomes of the Health and Labour Questionnaire in patients having paid work (181 out of 382 patients), concerning the last two weeks

Absence	
Absence due to hand OA, n (%)	13 (7%)
Hours of absence due to hand OA, if any (n=11)	42 (24; 54)
Unproductiveness at work	
Unproductiveness due to hand OA, n (%)	28 (15%)
Hours of unproductiveness due to hand OA, if any (n=28)	4 (2; 6)
Work production loss (= absence + unproductiveness)	
Any work production loss, n (%)	35 (19%)
Hours of work production loss due to hand OA, if any (n=38)	11 (4; 35)
Complaints at work due to hand OA	
Any hinder at work due to hand OA	120 (66%)
Hinder score of paid work complaints (6 - 24)	7 (6; 8)

Numbers represent median (IQR), unless otherwise specified. Abbreviations: OA = osteoarthritis.

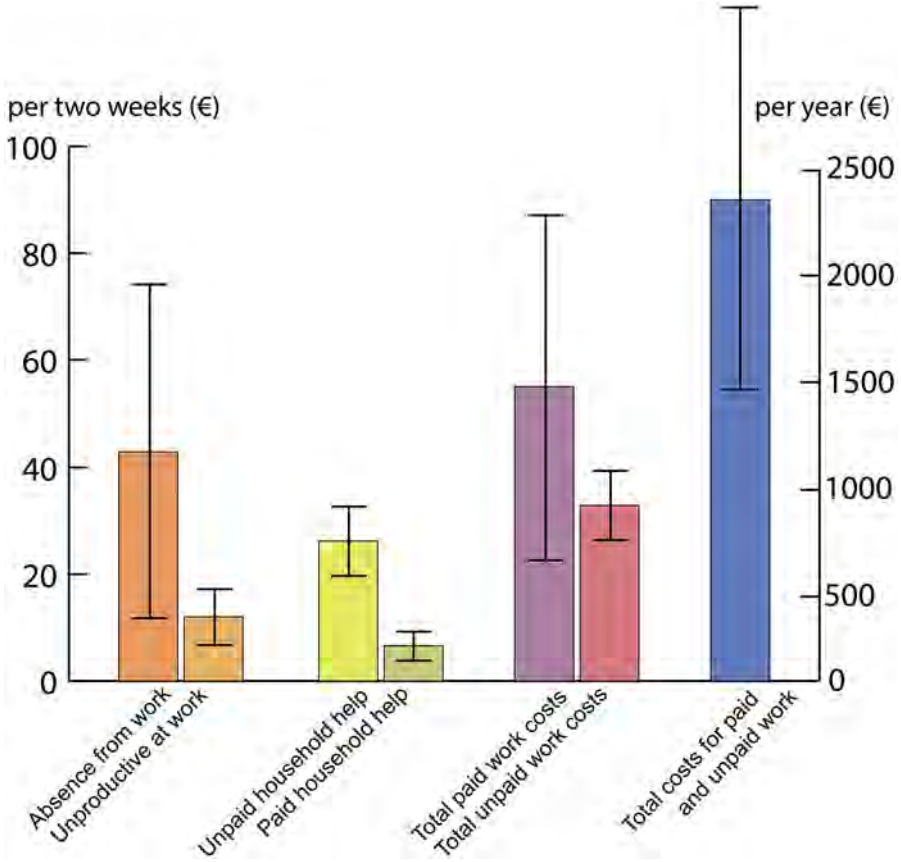

Figure 1. Mean societal costs associated with hand OA per patient in our total cohort, with 95% confidence interval.

Methods: We used data of the Hand OSTeoArthritis in Secondary care (HOSTAS) cohort. A diagnosis of hand OA by the treating rheumatologist was the case definition. Patient and OA characteristics were assessed by validated standardized questionnaires and tests. The Health and Labour Questionnaire (HLQ) was assessed on the last two weeks and related to hand OA for paid work hinder score (6 – 24), production loss while at work and hours of sick leave, as well as unpaid work replacement and hinder score (4 – 16). Self-reported income was collected to estimate income inequality compared to the Dutch age-gender-education matched population without hand OA

Societal costs (€) of paid work were estimated by multiplying number of hours of production lost due to hand OA (while present or absent form work) by the average hourly societal costs of paid work in The Netherlands. Societal costs of unpaid work were estimated by multiplying the hours of unpaid work replaced by others by the Dutch gross

average hourly salary of a household help. Costs were adjusted to 2019 values using consumer price indices. Costs per two weeks were extrapolated to costs per year by a using a conversion factor (26.09).

Results: HLQ data was available for 382 patients (mean age 60.9, 86% women, mean BMI 27.6 and 41% having any comorbidity, **table 1**). Of these persons, 16 (4%) had full work disability due to hand OA, 117 (30%) were retired and 181 (47%) had paid work. Thirteen employed persons (7.2%) reported sick leave due to hand OA, in which case a median of 42 work hours (IQR 24; 54) were lost in the past two weeks (**table 2**). Hinder at work was reported by 120 out of 181 working patients (66%), with a hinder score of 7 (6; 8). Unproductive hours while at work were reported by 28 (15%) patients, with a median of 4 hours (2; 6) in those experiencing unproductive time. Unpaid work hinder score was 8 (7; 10). Replacement of unpaid work was necessary in 180 patients (47%), with a median of 3 hours (2;7) per patient requiring help replaced.

Mean total societal costs per hand OA patient in the cohort (n=382) were estimated €90.00 (95% CI 55.20; 124.81), translating to 2343 euros (1964; 5724) per year (**figure 1**). Furthermore, patients showed a lower yearly and hourly income than a matched general Dutch population aged 55 to 65.

Conclusion: Hand OA is associated with significant hinder in paid and unpaid work participation, which translates in substantial societal costs of lost productivity. Future research should investigate prevention of hand OA sickness, absence and unproductiveness, as well as interventions to adapt the work environment to the hand OA patient.

Abstract Number: 1119

Systematic Review of Non-surgical Therapies for Hand Osteoarthritis

Haonan Mi, Christopher Oh and Tanveer Towheed, Queen's University, Kingston, ON, Canada

SESSION INFORMATION
Session Date: Monday, November 8, 2021
Session Title: Osteoarthritis – Clinical Poster III (1118–1134)
Session Type: Poster Session C
Session Time: 8:30AM–10:30AM

Background/Purpose: This systematic review evaluated all published randomized controlled trials (RCTs) assessing pharmacological and non-pharmacological therapies in patients with hand osteoarthritis (HOA).

Methods: The following electronic data sources were searched from inception to December 2020: MEDLINE, EMBASE, AMED, Clinicaltrials.gov and EBM reviews, including the Cochrane Database of Systematic Reviews (CDSR), Database of Abstracts of Reviews of Effectiveness (DARE), ACP Journal Club, and the Central Cochrane Database. RCTs were included if they evaluated a non-surgical, therapeutic intervention in adult subjects with HOA. The trial must have explicitly stated that a randomized method of allocation to a treatment group was used. RCTs evaluating OA at multiple sites were only included if efficacy data was presented separately for the hand. Exclusion criteria included: RCTs evaluating a surgical therapy, conference proceedings, unpublished RCTs, and non-English RCTs if their English abstracts did not contain sufficient details on trial methodology and outcomes. Study quality was evaluated using the Jadad's scoring checklist. A meta-analysis would be completed if possible.

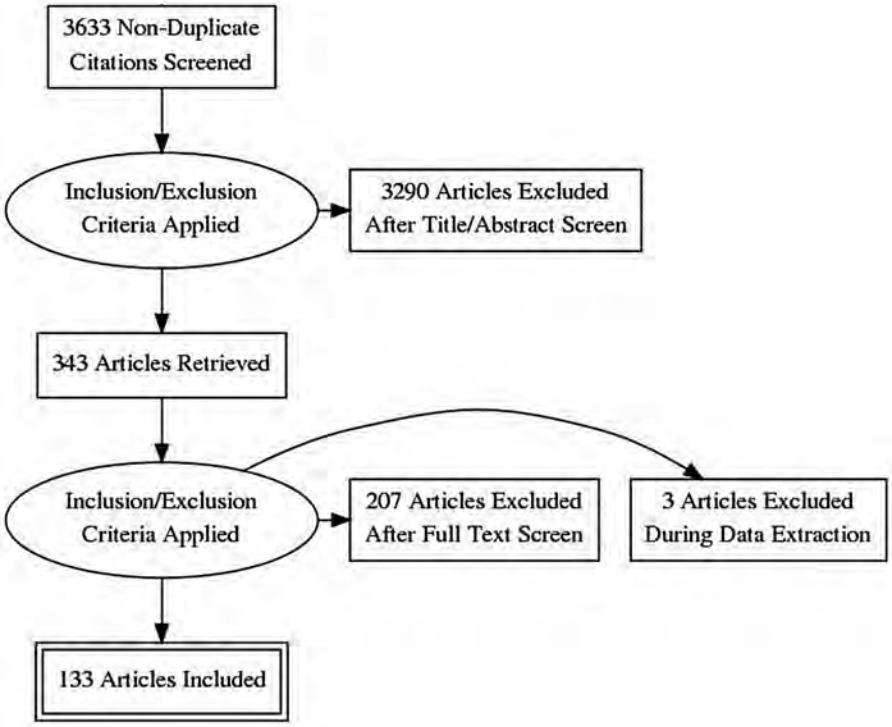

Figure 1. PRISMA diagram summarizing search strategy, study identification and retrieval.

Results: 133 RCTs were analyzed in this systematic review. There was no consistent definition of hand OA used in the RCTs, with most trials (N = 102) not explicitly distinguishing between primary (idiopathic) and secondary OA. Sixty-one RCTs used a validated hand OA classification scheme for study entry, with the most common being the ACR classification criteria (N = 54). Radiographs were taken at baseline in seventy-seven RCTs. Most studies described their methods for randomization, blinding and allocation concealment. However, studies underreported features specific to HOA, such as pattern of joint involvement and number of affected joints. Standardized outcome assessments for pain and function were commonly presented, but measures of other HOA specific outcomes, such as health-related quality of life and patient global assessments, were underreported. The mean Jadad score for all entries was 3.08. Increasing Jadad scores were noted over time. A meta-analysis was not completed due to significant heterogeneity amongst high quality RCTs and limited quantity of data.

The following pharmacologic therapies demonstrated efficacy across multiple RCTs: systemic NSAIDs, topical NSAIDs, intramuscular and intravenous clodronate, topical capsaicin, topical trolamine salicylate, oral chondroitin sulfate. Non-pharmacologic therapies that demonstrated efficacy across multiple studies include splints, joint strengthening exercises, mobilization, paraffin baths and multidisciplinary combined intervention. The remainder of the therapies had mixed or negative results, were compared to other therapies in single studies, or efficacy compared to placebo was only demonstrated in a single study.

Conclusion: HOA is a complex area in which to study the efficacy of therapies. Future trials should consistently report on HOA specific features and outcome assessments to make clinically relevant conclusions about the efficacy of the diverse treatment options available.

Knee ROM (parameters not specified) Pain during walking (VAS) Baseline and 2 weeks

Data not available if not displayed in Table.

AROM: Active ROM; HOOS: Hip disability and osteoarthritis outcome score; KL: Kellgren and Lawrence radiographic grading scale; KOOS: Knee disability and osteoarthritis outcome score; PROM: passive ROM; ROM: range of motion; VAS: Visual analogue scale; WOMAC: Western Ontario and McMaster Universities Osteoarthritis Index.

OA-affected joints is lacking. Our objective is to perform a systematic review and meta-analysis evaluating the effectiveness of stretching and/or bracing protocols on native (non-operated) joint ROM in people with radiographically-diagnosed OA.

Methods: We searched 7 databases CENTRAL, DARE, HTA, Medline, Embase, CINAHL, SCI-EXPANDED and PEDro. We included English-language studies evaluating stretching or bracing in participants with radiographically-

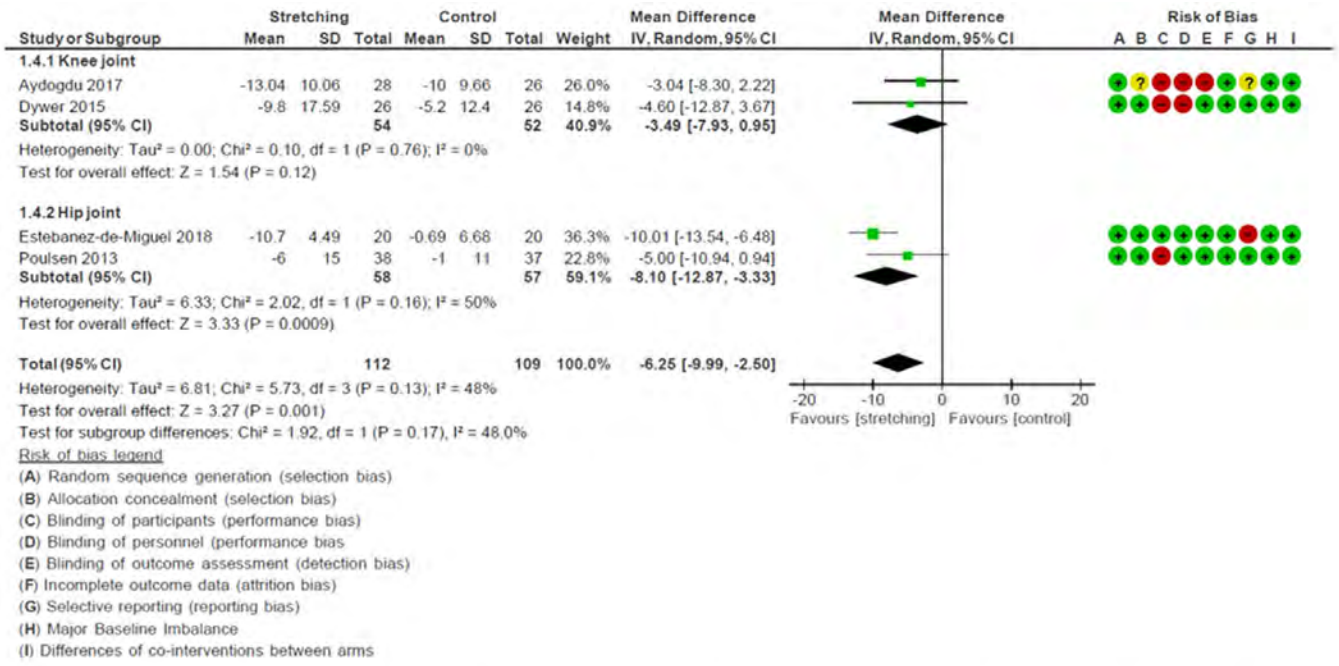

Figure 2. Meta-analysis and risk of bias for RCTs evaluating flexion range of motion following stretching intervention for the knee and hip. While knee flexion remains unchanged, hip flexion improves with stretching. Risk of bias was considered low overall for hip stretch RCTs.

diagnosed OA in any joint, prior to arthroplasty. Two reviewers independently screened titles and abstracts for inclusion and assessed risk of bias in included randomized controlled trials (RCTs) using the Cochrane Risk of Bias tool. Primary outcomes were ROM, pain and adverse events (AEs). A random-effects meta-analysis was performed when appropriate.

Results: We identified 4282 articles through database searching. Eight RCTs and 1 non-RCT met our eligibility criteria and provided adequate data for analysis (Figure 1, Table 1). Of these studies, 5 involved the knee joint, two the hip, and one the hand distal interphalangeal (DIP) joint. Three RCTs found no changes in knee flexion or extension after stretching while 1 reported increased ROM without specifying direction. Meta-analysis (n=2 studies, 1 using long-axis distraction mobilization and 1, manual therapy) showed improvement in hip flexion of 8.1° (95% CI 3.3,12.9°; Figure 2), and 1 RCT reported increased hip extension (7.8°; 95% CI 4.8,10.9°), abduction (6.2°; 95% CI 3.5,8.9), internal (7.6°; 95% CI 4.2,11.1°) and external (6.6°; 95% CI 3.6,9.5°) rotation using manual therapy. In 1 study, mean visual analogue pain reduction in the knee of 2.2 (95% CI –3.3,-1.1). One non-RCT showed that hand DIP joint splinting improved ROM. One study evaluating the hip reported an odds ratio of 4.5 (95% CI 0.9,23.0) for incurring an AE for manual therapy versus control. Risk of bias was generally rated low for studies showing improvement in ROM.

Conclusion: Stretching may be an effective strategy for improving ROM in the hip joint, while knee ROM may be more resistant to treatment. Differences in joint anatomy and biomechanical factors contributing to contractures may play a role in the observed outcomes. Stretching may also help OA-related pain. Stretching and bracing are appropriate conservative treatment options to improve OA outcomes prior to arthroplasty.

Association of Healthcare Costs and Utilization with Increasing Severity of Pain in Osteoarthritis Patients: An 18-Year Retrospective Study

Jove Graham[1], Tonia Novosat[1], Haiyan Sun[1], Brian Piper[1], Joseph Boscarino[1], Melissa Kern[1], Vanessa Duboski[1], Eric Wright[1], Craig Beck[2], Rebecca Robinson[3], Edward Casey[4], Jerry A. Hall[3] and Patricia Schepman[4], [1]Geisinger, Danville, PA, [2]Pfizer, Inc., London, [3]Eli Lilly and Company, Indianapolis, IN, [4]Pfizer, Inc., New York, NY

SESSION INFORMATION
Session Date: Monday, November 8, 2021
Session Title: Osteoarthritis – Clinical Poster III (1118–1134)
Session Type: Poster Session C
Session Time: 8:30AM–10:30AM

Background/Purpose: Osteoarthritis (OA) is a disease with complex pathogenesis, and it is important to understand a patient's level of severity in order to plan and stage treatment interventions. Prior studies have documented the health and economic burdens of patients with OA compared to those without OA. The goal of our study was to further stratify OA patients based on pain severity and compare healthcare utilization and cost.

Methods: This was a retrospective study using electronic health records and insurance claims from 2001-2018 at Geisinger, an integrated health system in Pennsylvania serving over 500,000 patients per year. Patients age 18 or older were included if they had ≥1 month of insurance coverage and ≥1 numerical pain score (NPS) after receiving a diagnosis code for OA (ICD-9: 715.*, ICD-10 M15-19) on an encounter, problem list, or OA-related procedure (hip/knee replacement, arthroscopy or injection). Pain episodes were defined as periods of time starting with an NPS (mild pain 0-3, moderate 4-6, severe 7-10) and ending when 90 days had elapsed with no new NPS. For each episode, claims were examined for the number of all-cause outpatient visits (OP), emergency department visits (ED) and inpatient days hospitalized (IP), total allowed medical cost, and total allowed pharmacy cost; these were converted to per-member-per-year (PMPY) rates or means. These statistics were compared among mild, moderate and severe pain episodes to look for differences, using generalized linear regression models adjusting for age and sex, with $p < 0.05$ considered statistically significant. Costs were normalized to 2010 US$ based on the Consumer Price Index. Claims containing a diagnosis, procedure, or national drug code related to OA were classified as OA-related and re-analyzed as a subset to examine OA-related utilization and cost.

Results: We identified 92,576 eligible patients with 306,200 pain episodes (43% mild, 32% moderate, 25% severe). For all types of OA-related utilization, moderate and severe pain episodes were associated with significantly higher rates relative to mild pain episodes (OP: 0.84 vs. 1.39 vs. 1.70 visits PMPY for mild, moderate and severe, respectively; ED: 0.13 vs. 0.21 vs. 0.41; IP: 0.10 vs. 0.22 vs. 0.26). All-cause OP and ED utilization also significantly increased with increased pain severity, but IP days did not (OP: 11.09 vs. 11.98 vs. 13.71; ED: 1.05 vs. 1.12 vs. 1.89; IP: 2.77 vs. 2.57 vs. 3.39). Similarly, we observed significant increases in OA-related costs for every category during moderate and severe pain episodes relative to mild pain (pharmacy: $669 vs. $943 vs. $1,207; medical: $1,345 vs. $2,320 vs. $2,429). Increasing pain severity was positively associated with all-cause pharmacy costs, but not all-cause medical costs (pharmacy: $7,729 vs. $9,143 vs. $10,068; medical: $27,571 vs. $22,802 vs. $20,876).

Conclusion: We observed that pain, an important symptom of OA, was strongly associated with patients' OA-related utilization and costs, and to a lesser extent, all-cause utilization and costs. With a better understanding of when and how patients become more expensive and challenging, we can develop better approaches for managing disease burden in the future.

Abstract Number: 1122

Patient-perceived Solutions to the Treatment Barriers in Knee Osteoarthritis: A Qualitative Study from a Diverse Patient Group Including Racial/ethnic Minorities

Jasvinder Singh, University of Alabama at Birmingham, Birmingham, AL

SESSION INFORMATION
Session Date: Monday, November 8, 2021
Session Title: Osteoarthritis – Clinical Poster III (1118–1134)
Session Type: Poster Session C
Session Time: 8:30AM–10:30AM

Background/Purpose: Knee osteoarthritis (OA) has worse outcomes in racial/ethnic minorities. Yet, most of the qualitative studies include primarily Caucasian people with knee OA, with minimal or no representation of racial/ethnic minorities. Therefore, our objective was **t**o examine patient perceived solutions to barriers to treatment of knee OA, in a diverse racial/ethnic group of people.

Methods: Nominal groups were conducted with consecutive patients with knee OA at a medical center clinic, oversampling for African Americans with knee OA. Participants discussed potential solutions and rank-ordered their concerns.

Results: Fourteen nominal groups with 48 knee OA patients were conducted with mean age, 60.6 years (standard deviation, 9.8) and knee OA duration, 7.8 years (sd, 5.4); 25% were men, and 46% were African American. The most frequently cited highly-ranked solutions were as follows:

1. *More Research, New medications/treatments that are more effective and/or safer, and Restoration of the joint cartilage*: Eight of the 14 groups listed this among their top concerns, and nine groups ranked this concern. It received 15% of all votes (43/288).

2. *Early diagnosis*: Two of the 14 groups listed this among their top concerns, and four groups ranked this concern. It received 7% of all votes (20/288). at an earlier stage.

3. *Better and more effective Communication*: Five of the 14 groups listed this among their top concerns, and five ranked this concern. It received 10% of all votes (29/288).

4. *Public and in-clinic patient Education*: Four of the 14 groups listed this among their top concerns, and five ranked this concern. It received 8% of all votes (22/288).

5. *Motivation/behavioral modification*: Four of the 14 groups listed this among their top concerns, and nine ranked this concern. It received 9% of all votes (26/288).

6. *Team Approach*: One of the 14 groups listed this among their top concerns, and four ranked this concern. It received 1% of all votes (2/288).

7. *Personalized medicine*: Six of the 14 groups listed this among their top concerns, and ten ranked this concern. It received 8% of all votes (24/288).

8. *Cheaper and more affordable medications and treatments*: Three of the 14 groups listed this among their top concerns, and four ranked this concern. It received 5% of all votes (15/288).

Conclusion: A diverse group of participants with knee osteoarthritis, including racial/ethnic minorities, identified several solutions to barriers to the effectiveness of current knee OA treatments. These solutions provide new knowledge. These solutions can also lead to the development of future interventions to improve the outcomes of people with knee OA.

Abstract Number: 1123

"It's a Dance Between Managing Both [Diabetes and Osteoarthritis]": A Qualitative Study Exploring Perspectives of Persons with Knee Osteoarthritis and Type 2 Diabetes Mellitus on the Impact of Osteoarthritis on Diabetes Management and Daily Life

Lauren King[1], Esther Waugh[1], Crystal McKay[1], Ian Stanaitis[2] and Gillian Hawker[1], [1]University of Toronto, Toronto, ON, Canada, [2]Women's College Hospital, Toronto, ON, Canada

SESSION INFORMATION
Session Date: Monday, November 8, 2021
Session Title: Osteoarthritis – Clinical Poster III (1118–1134)
Session Type: Poster Session C
Session Time: 8:30AM–10:30AM

Background/Purpose: The links between osteoarthritis (OA) and other common chronic conditions, such as type 2 diabetes mellitus (T2DM), are increasingly being appreciated in epidemiological studies. However, patient perceptions of the impact of concomitant knee OA on their ability to engage in chronic disease management remains unknown. Using qualitative methods, we sought to explore individuals' experiences living with knee OA and T2DM, with a focus on the impact of OA on T2DM management and daily life.

Methods: Semi-structured telephone interviews were conducted with persons with symptomatic knee OA and T2DM recruited from a hospital-based diabetes clinic and a community OA program (Arthritis Society) in Ontario, Canada. The methodology of qualitative description was used. Interview transcripts were coded by a team of researchers and

data were analysed using thematic analysis to identify major themes. Interviewing stopped after no new themes or subthemes were identified.

Results: Eighteen participants were interviewed: n=9 women, n=9 aged ≥70 years, n=8 urban region, n=9 ≥10 years since diabetes diagnosis, and n=13 ≥10 years since OA diagnosis. Three overarching themes were constructed: 1. *OA impacts diabetes control*: Painful and disabling OA made it difficult for participants to engage in physical activity prescribed for T2DM, and they perceived that lack of physical activity negatively impacted their blood sugar control. Joint pain, and its effect on sleep and emotional health, were also seen to negatively impact blood sugar control. 2. *OA as a health priority due to its effects on quality of life:* Participants, who often had other chronic conditions in addition to T2DM, viewed OA as a health priority. OA-related pain and functional limitations reduced ability to participate in valued activities, e.g., work, and negatively impacted emotional well-being. 3. *Minimization of OA by health professionals and taking personal responsibility for OA care:* Participants perceived a disproportionately greater attention by health professionals to their T2DM compared to their OA. As a result, many participants described being left to coordinate and advocate for their own OA care.

Conclusion: These findings shed light on patients' experiences of living with symptomatic knee OA in the context of T2DM. OA-related pain, functional limitations, poor sleep and mental health were perceived as negatively impacting diabetes control and engagement in daily life activities. While considered important to patients, often these concerns were not being actively addressed by health professionals. Greater recognition by health professionals of the impact of knee OA in persons with T2DM has potential to improve both diabetes care and overall quality of life.

Abstract Number: 1124

Examining the Relationships Between Treatment and Pain and Physical Function Outcomes in Patients with Osteoarthritis: A Mediation Modeling Approach

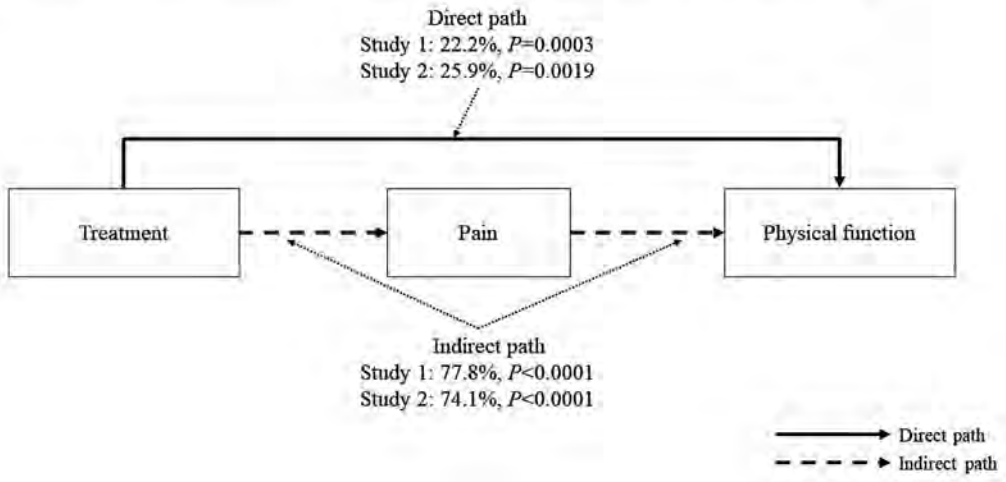
Lucy Abraham[1], Robert Dworkin[2], Dennis C. Turk[3], John D. Markman[2], David A. Williams[4], Andrew G Bushmakin[5], Jerry A. Hall[6], David C. Semel[7], Joseph C Cappelleri[5] and Ruoyong Yang[8], [1]Pfizer Ltd., Tadworth, United Kingdom, [2]University of Rochester, Rochester, NY, [3]University of Washington, Seattle, WA, [4]University of Michigan, Ann Arbor, MI, [5]Pfizer Inc, Groton, CT, [6]Eli Lilly and Company, Indianapolis, IN, [7]Pfizer, New York, NY, [8]Pfizer Inc., New York, NY

SESSION INFORMATION
Session Date: Monday, November 8, 2021
Session Title: Osteoarthritis – Clinical Poster III (1118–1134)
Session Type: Poster Session C
Session Time: 8:30AM–10:30AM

Background/Purpose: To better understand the complex relationships between treatment and pain and physical function (PF) outcomes, we investigated a set of mediation models of osteoarthritis (OA) patients' responses to tanezumab, an antibody against nerve growth factor that is in development for the treatment of OA.

Methods: Data came from two randomized clinical trials of tanezumab (Study 1: NCT02697773, JAMA. 2019;322:37-48 and Study 2: NCT02709486, Ann Rheum Dis. 2020;79:800-810); in both trials tanezumab provided greater pain relief and improvements in PF than placebo in patients with OA (all patients satisfied the American College of Rheumatology criteria for OA). A set of mediation models was used to explore the interrelationships among treatment, PF as measured by the Western Ontario and McMaster Universities Osteoarthritis Index (WOMAC*) PF scores, and

Figure. Estimated direct and indirect effects (steady-state longitudinal models)



pain (WOMAC Pain scores) as a mediator of the effect of treatment on PF: (a) cross-sectional mediation models, (b) longitudinal mediation models, and (c) pseudo steady-state longitudinal mediation models. The cross-sectional mediation models include the following variables: treatment (tanezumab vs placebo), pain and PF scores (models were assessed separately at weeks 2, 4, 8, 12, 16, or 24). The longitudinal mediation models estimate relationships using data from all weeks simultaneously and include treatment, pain and PF scores at weeks 2, 4, 8, 12, 16, and 24. The longitudinal steady-state mediation model also uses all available data at weeks 2, 4, 8, 12, 16, and 24 with the assumption that relationships among variables in the model are the same at all time points.

*© 1996 Nicholas Bellamy. WOMAC® is a registered trademark of Nicholas Bellamy (CDN, EU, USA).

Results: The results of the cross-sectional and longitudinal mediation models showed that the indirect effect of treatment through pain on PF was stable across time (cross-sectional: 78.8–95.1%, all $P< 0.0001$; longitudinal: 70.5–86.6%, all $P< 0.0001$), indicating that a pseudo steady-state model is appropriate. The results of the longitudinal steady-state mediation models showed that the indirect effect of the treatment on PF was 77.8% in Study 1 and 74.1% in Study 2 ($P< 0.0001$, respectively), while the direct effect of the treatment on PF was 22.2% for Study 1 ($P=0.0003$) and 25.9% for Study 2 ($P=0.0019$) (Figure).

Conclusion: At least 75% of the treatment effect of tanezumab on physical functioning can be explained by the improvements in pain. However, tanezumab has an additional effect on physical functioning (approximately 25%), which is independent of improvements in pain. Research is needed to explain this effect and evaluate additional mediators (e.g., sleep, fatigue, method variance) that may contribute to the observed direct effect.

(Figure 1), is an important component of synovial inflammation in OA. Altered joint loading is hypothesized to contribute to synovial inflammation in OA and may provide sufficient physiological stress to induce perivascular edema. Our objective was to investigate the association between synovial perivascular edema and surrogate measures of knee load during walking in patients with knee OA and medial compartment joint space narrowing.

Methods: Patients undergoing total knee arthroplasty or high tibial osteotomy for symptomatic, radiographic knee OA based on the American College of Rheumatology Classification Criteria, and neutral to varus alignment participated in this cross-sectional study. All participants underwent 3D gait analysis before surgery. Synovial biopsies were obtained intra-operatively for histopathological assessment of perivascular edema (presence/absence). We investigated the association between external knee moments (sagittal, frontal, and transverse planes) and the presence of synovial perivascular edema using a series of multivariate linear regression and polynomial mixed-effects regression models, while adjusting for age, sex, BMI, and gait speed.

Results: Our cohort was composed of 92 patients with complete gait and histopathological data (Table 1). The presence of perivascular edema was associated with lower peak knee flexion moment (β= -7.72 Nm [95%CI -14.18, -1.27]) and greater peak knee extension moment (β= -8.08 Nm [95%CI -15.26, -0.89]). Mixed-effects polynomial regression identified that patients with edema demonstrated higher knee adduction moments between 16-74% of stance (Figure 2A), and lower knee flexion moments from 15-92% of stance (Figure 2B). The largest differences in knee moments during walking between patients with vs. without perivascular edema occurred at 33% of stance for knee adduction (β= 6.87 Nm [95%CI 3.02, 10.72]), and 60% of stance for knee flexion (β = -10.80 [95%CI -16.20, -5.40]).

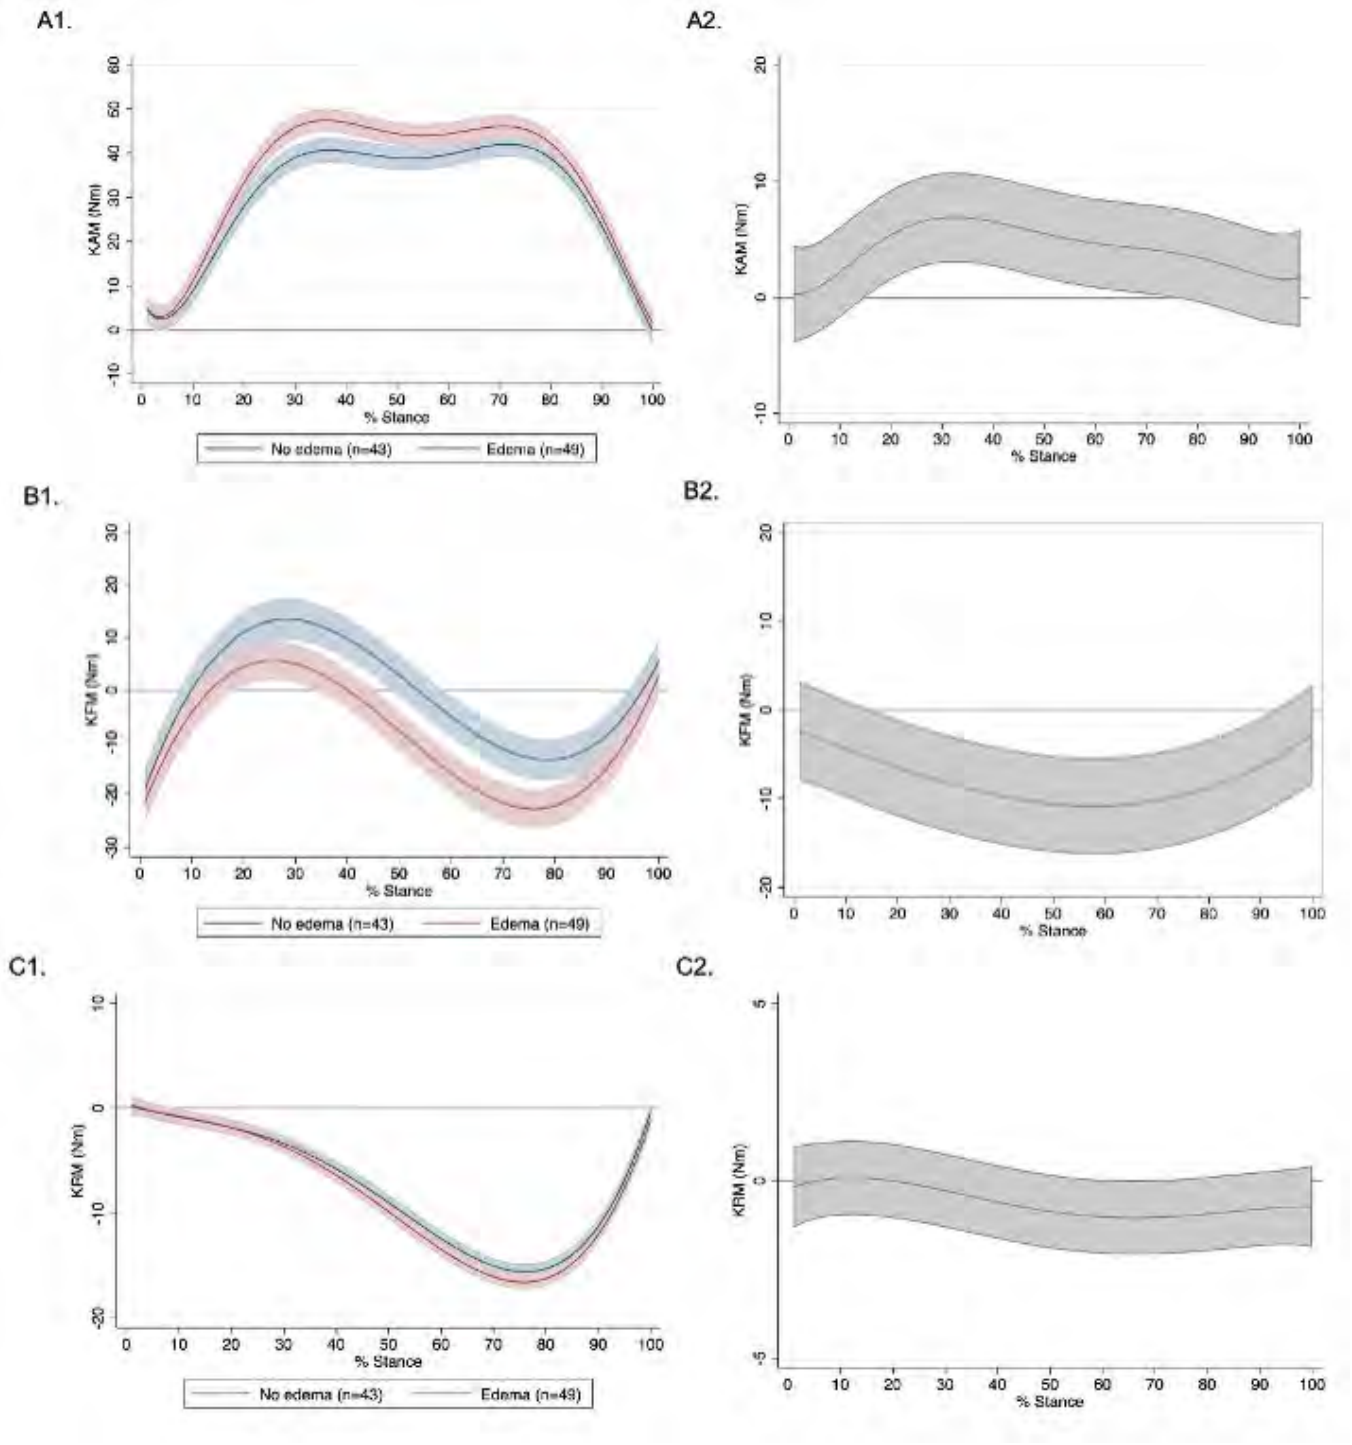

Figure 2. Marginal effects and contrasts for external knee moments over 100% of stance phase in patients with perivascular edema and no perivascular edema. Marginal effect estimates (± 95% CIs) for external knee moments by group are shown in left panels (A1-C1) and marginal contrasts (± 95% CIs) for external knee moments between patients with perivascular edema (n=49) and no perivascular edema (n=43) are shown in the right panels (A2-C2). Separate graphs for A) knee adduction moment (KAM), B) knee flexion-extension moment (KFM), and C) knee external-internal rotation moment (KRM). No perivascular edema is represented in blue and perivascular edema is represented in red. No perivascular edema is the reference group for the marginal contrasts (right panels: A2-C2); therefore, along stance phase, where the 95% CIs no longer includes 0, indicates a significant difference between groups.

Conclusion: Although causal inference is not possible, the association of synovial perivascular edema with increased gait-based proxy measures of knee loading throughout all phases of stance supports the hypothesis that abnormal

joint biomechanics contribute to synovial inflammation in knee OA. Future research is needed to identify direct or indirect mechanisms linking altered joint loading to the development of synovial perivascular edema.

Synovial Cell Dysfunction in Obese Patients May Contribute to Poor Outcomes in Knee Osteoarthritis

Holly Philpott[1], Trevor Birmingham[2], Nicole Aye[2], Benoit Fiset[3], Logan Walsh[3], Brent Lanting[2] and Tom Appleton[2], [1]Western University, London, ON, Canada, [2]University of Western Ontario, London, ON, Canada, [3]McGill University, Montréal, QC, Canada

SESSION INFORMATION
Session Date: Monday, November 8, 2021
Session Title: Osteoarthritis – Clinical Poster III (1118–1134)
Session Type: Poster Session C
Session Time: 8:30AM–10:30AM

Background/Purpose: Obesity is a major risk factor for poor outcomes in knee osteoarthritis (OA) and may involve both mechanical and physiological stresses on joint tissues. In the synovium, macrophages and fibroblasts are important for maintaining joint homeostasis and adaptive responses to joint stressors. However, the impact of obesity on synovial cellular mechanisms are not well understood. Our objectives were 1) to investigate the association of obesity and synovial histopathological features, and 2) to explore the effect of obesity on synovial cell gene expression in people with knee OA.

Methods: Patients (n=107) diagnosed with clinical knee OA based on the American College of Rheumatology (ACR) criteria were included in this cross-sectional analysis. All patients had severe symptoms and radiographic damage (KL grade 3 or 4), and were undergoing surgery for knee OA. Lateral suprapatellar synovial tissue biopsies were obtained during surgery. Routine synovial histopathology was scored (grade 0-3; None-Severe) in six domains. Multivariate linear regression was used to evaluate the association between median histopathology component scores and BMI, while adjusting for age and sex. Single cells dissociated from whole synovium biopsies were sorted into CD14+ (macrophage/monocyte) and CD90+ (stromal) cell compartments for RNA isolation and sequencing. Quantification of genes was performed in featureCounts and DESeq2 was used to normalize counts. Gene set enrichment was assessed using mSigDB Hallmark gene sets between patients with BMI < 30kg/m^2 (n=7) and BMI >35kg/m^2 (n=6).

Results: Elevated BMI was associated with lower median synovial vascularization (β = -1.35, [95%CI -2.43, -0.27]) and fibrin deposition (β = -3.80, [95%CI -6.98, -0.62]) histopathology scores. In normal to overweight patients (BMI < 30kg/m^2), CD14+ macrophage gene expression showed significant enrichment scores for immune cell signaling (*e.g*. TNF-α signaling, IFN-γ and IFN-α response, IL6/JAK/STAT3 signaling) and cell metabolism pathways (*e.g*. fatty acid metabolism, adipogenesis, oxidative phosphorylation, mTOR signaling). CD90+ stromal cell gene expression also showed significant enrichment scores for response to pro-inflammatory signaling pathways and cell metabolism pathways. In obese patients (BMI >35kg/m^2), synovial macrophage and stromal cell compartments both showed enrichment of cell stress and degenerative pathways (*e.g*. p53 pathway, unfolded protein response, apoptosis, hypoxia, epithelial-mesenchymal transition, hedgehog signaling, Wnt/β-catenin signaling, TGF-β signaling).

Conclusion: Obesity was associated with reduced signs of inflammation in synovial tissues (vascularization and fibrin), and with less inflammatory signaling, impaired cellular metabolism, and greater cellular stress in synovial macrophages and stromal cells. Our results suggest synovial inflammation and vascularization may be adaptive responses to OA-related joint stresses, and that obesity may impair these adaptive synovial processes.

Synovial Fluid Cytokines, Chemokines, and MMPs in Osteoarthritis Patients with Knee Pain Compared to RA Patients and Normal Knees

Richard Meehan[1], Elizabeth Regan[1], Eric Hoffman[1], Molly Wolff[1], Mary Gill[1], James Crooks[2], Presant Parmar[3], Richard Scheuring[4], John Hill[5], karin Pacheco[6] and Vijaya Knight[7], [1]National Jewish Health, Denver, CO, [2]National Jewsih Health and Colorado School of Public Health, Denver, CO, [3]St Joeseph hospital/NJH, Denver, CO, [4]NASA/JSC, Houston, TX, [5]University of Colorado Sports Medicine, Denver, CO, [6]Nationals Jewish Health, Denver, CO, [7]Children's Hospital Department of Immunology, Denver, CO

SESSION INFORMATION
Session Date: Monday, November 8, 2021
Session Title: Osteoarthritis – Clinical Poster III (1118–1134)
Session Type: Poster Session C
Session Time: 8:30AM–10:30AM

Background/Purpose: A major limitation of synovial fluid (SF) biomarker studies in osteoarthritis (OA) has been difficulty in obtaining SF (SF) in patients with small effusions. There is growing evidence that osteoarthritis is not simply a degenerative process but rather cartilage loss is associated with low grade inflammation which can damage chondrocytes and the extra cellular matrix. There is also little information on WBC counts, or the levels of cytokines, MMPs and other proteins in SF from normal knees. To compare differences, a panel of 16 protein biomarkers was measured in knee SF from osteoarthritis (OA) patients, rheumatoid arthritis (RA) patients and normal knees.

Methods: SF was obtained prior to an intra-articular therapeutic injection or a diagnostic arthrocentesis from 21 OA, 27 RA patients as well as 3 normal subjects, using ultrasound (US) guidance and an external pneumatic compression device. All subjects were consented to have remaining SF placed into an IRB approved SF biomarker research protocol. RA patients were categorized as active (n= 20) or controlled (n= 7) disease based upon their SF white blood cell counts (> or < 300 cells/mm^3). Samples were cryopreserved and analyzed by multiplex fluorescent bead assays (Luminex) within 60 minutes of aspiration. Between group differences were identified using ANOVA on log10 transformed concentrations with p values adjusted for multiple testing.

Results: The demographic and clinical features from the 4 groups of subjects are presented in Table 1 including age, gender, BMI, serology, SF WBC counts and drugs taken at the time of knee aspiration. The SF log 10 concentrations of each of these 16 proteins from the 4 groups of subjects are presented in Figure 1. The first 6 panels display p values differences between Active RA and PA patients. Six of the biomarkers were significantly higher in SF from active RA compared to OA (TNF –alpha, IL-1 beta, IL-7, MMP-1, MMP-2, MMP 3) whereas none of the other 10 cytokines, chemokines, MMPs and other proteins (IGFBP-3, MMP-3, IL-6, IL-1ra, IGFBP-4, IL-18, IL-2, IL-4, G-CSF and IL-15) were significantly deferent between OA and Active RA patients. The lack of statistical differences in some of these

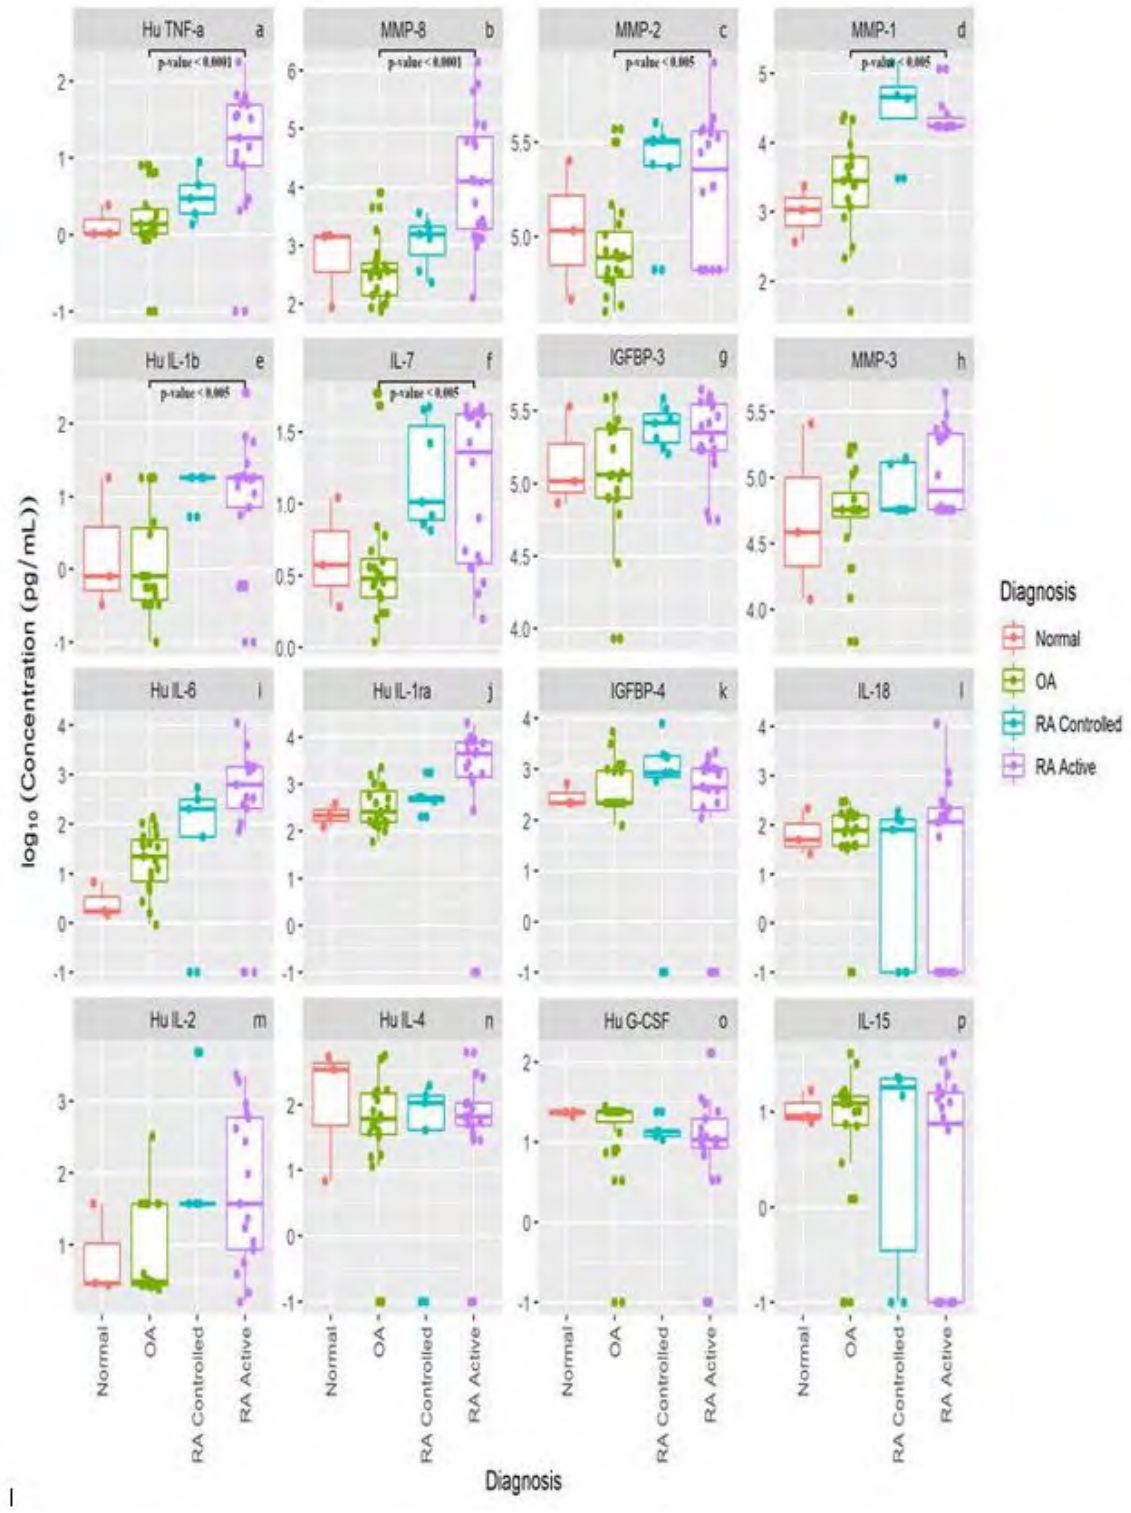
Demographics and immunomodulatory drug use among patients with OA, RA active, RA controlled and normal subjects

proteins is most likely due to the large variance in levels from several individual patients and possibly due to medications taken at the time of aspiration as listed in Table 1. SF MMP-8 levels was the only protein which correlated with WBC counts ($p < 0.001$).

Conclusion: The fact that only 6 of 16 proteins were significantly higher in SF from Active RA patients compared to those with OA is additional evidence that a pro inflammatory process in OA may lead to further cartilage loss in additional to mechanical factors and genetic predisposition. The results of this small study suggest that normal knee SF may not have any WBCs and that IL 4 as well as other cytokines and even MMPS might be important in maintaining cartilage homeostasis. SF collection using US guidance with external compression combined with a multiplex biomarker panel may help distinguish clinical subtypes and enhance development of disease modifying drugs for OA.



Synovial fluid cytokine, chemokine, MMP and other proteins levels from patients with OA compared to patients with RA active, RA controlled and normal subjects.

Inter-relationships Between Multiple Joint Osteoarthritis and Collagen Biomarkers in Men: The Johnston County Osteoarthritis Project

Amanda Nelson[1], Liubov Arbeeva[1], Duncan Lascelles[2], Jordan Renner[1], Yvonne Golightly[1], Morten Karsdal[3], Anne-Christine Bay-Jensen[3] and Richard Loeser[4], [1]University of North Carolina at Chapel Hill, Chapel Hill, NC, [2]North Carolina State University, Raleigh, NC, [3]Nordic Bioscience, Herlev, Denmark, [4]University of North Carolina, Chapel Hill, NC

SESSION INFORMATION

Session Date: Monday, November 8, 2021

Session Title: Osteoarthritis – Clinical Poster III (1118–1134)

Session Type: Poster Session C

Session Time: 8:30AM–10:30AM

Background/Purpose: To determine inter-relationships between blood-based collagen formation and degradation biomarkers and multiple joint osteoarthritis (MJOA) phenotypes in a community-based cohort.

Methods: Data were from Johnston County OA Project participants with baseline (BL, T1/T1*) and follow-up (FU, T2) data, initially selected based on available knee radiographs scored for Kellgren-Lawrence Grade (KLG), and subsequently analyzed for radiographic MJOA outcomes including MJOA-1 (≥1 IP node and ≥2 other sites), MJOA-3 (≥5 joint sites), and MJOA-8 (≥3 joint sites, doi: 10.1016/j.semarthrit.2018.10.001).

Table 1. Description of 3 MJOA types, age, BMI, and biomarkers by clusters derived from multilevel functional principal components analysis among MEN

	Cluster1 *N=109*	Cluster2 *N=43*	Cluster3 *N=64*
MJOA subtypes			
MJOA-1 (N, %)	49 (45%)	15 (35%)	21 (33%)
MJOA-3 (N, %)	57 (52%)	2 (5%)	20 (31%)
MJOA-8 (N, %)	84 (77%)	11 (26%)	37 (58%)
Baseline variables and Biomarker levels (T1)			
Age, years (SD)	66.4 (7.6)	52.3 (3.0)	61.2 (6.3)
BMI, kg/m^2 (SD)	27.7 (2.8)	30.5 (2.5)	36.2 (3.3)
C1M	33.0 (39.9)	29.0 (16.5)	29.7 (17.0)
C2M	0.43 (0.19)	0.43 (0.13)	0.45 (0.26)
C3M	9.2 (3.03)	9.4 (2.1)	9.4 (2.6)
CRPM	7.6 (2.6)	7.1 (2.4)	6.6 (2.5)
PRO-C3	16.0 (13.3)	13.3 (4.6)	14.2 (7.2)
PRO-C6	9.5 (4.2)	9.3 (3.2)	10.6 (9.4)
Col10neo	3349.6 (1153.9)	3616.4(1013.5)	3196.1(919.0)
Biomarker levels at Follow-up (T2)			
C1M	29.8 (16.6)	44.4 (44.6)	31.6 (14.5)
C2M	0.42 (0.17)	0.44 (0.15)	0.45 (0.27)
C3M	9.4 (3.6)	10.5 (3.5)	9.9 (3.6)
CRPM	7.2 (2.9)	7.5 (2.4)	7.2 (2.6)
PRO-C3	17.3 (14.0)	15.9 (13.0)	16.5 (8.1)
PRO-C6	10.1 (4.6)	9.0 (3.7)	12.0 (10.5)
Col10neo	3576.5(1133.6)	3556.4(876.9)	3440.6(1271.0)

MJOA:multiple joint osteoarthritis; BMI:body mass index; MJOA-1: ≥1 IP node and ≥2 other sites; MJOA-3: ≥5 joint sites; MJOA-8: ≥3 joint sites; SD: standard deviation; see text for biomarker definitions.

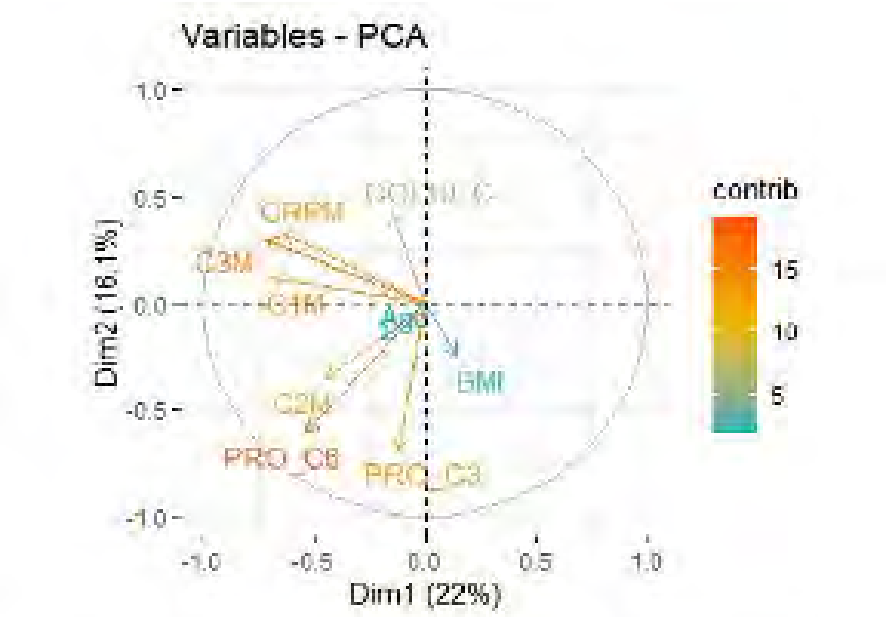

Figure 1. The loadings describe how much each variable contributes to a particular principal component (positive or negative). PC1 (Dim1) and PC2 (Dim2) explain 22% and 16% of variation among participants, respectively.

Serum biomarkers measured included: neo-epitopes of MMP mediated type I, II, and III collagen degradation (C1M, C2M, and C3M, respectively); neo-epitope of MMP-1 and -8 mediated degradation of C-reactive protein (CRPM); N-terminal pro-peptide of C3 (PRO-C3); c-terminal of released C5 domain C6 α3 chain (PRO-C6); and c-terminus of collagen type X release of C10 from cartilage (Col10neo). These represent putative markers of: fibrosis (PRO-C3, -C6); inflammation (C1M, C3M, CRPM); and cartilage degeneration (C2M, Col10neo). Biomarker values were transformed (Box-Cox) and standardized for scale. Multilevel principal component analysis (mPCA) was performed using 7 biomarkers, age, and BMI at BL and FU. Cluster analysis based on PCA-transformed data was used to search for and descriptively analyze MJOA phenotypes.

Results: Results for 225 men are reported; relationships between biomarkers and MJOA were not observed in women (n=503). At BL, C1M, C3M and CRPM clustered together, as did PRO-C3, PRO-C6 and C2M (**Fig 1**); Col10neo was distinct. MPCA identified 3 clusters (**Fig 2**). Cluster 1 had the highest frequencies of MJOA-1, -3, and -8. Cluster 2 had a very low frequency of MJOA-3 and lower frequencies of both MJOA-1 and -8 compared with Cluster 1 (**Table 1** and **Fig 2**). Clusters 2 and 3 demonstrated similar frequencies of MJOA-1. Cluster 3 had intermediate frequencies of MJOA-3 and -8 compared with Clusters 1 and 2.

Men in Cluster 1 were older with a lower BMI compared with the other clusters. This cluster was characterized by higher BL C1M which decreased at FU, higher PRO-C3 at BL and FU, and an increase in Col10neo from BL to FU (i.e., higher but declining inflammation, higher fibrosis, and increasing cartilage degeneration). Men in Cluster 2 were the youngest with intermediate BMI. This cluster had the lowest BL C1M and PRO-C3, which increased at FU; this cluster had the highest C1M at FU (i.e., increasing inflammation). Men in Cluster 3 were of an intermediate age with a much higher BMI. This group had a low BL CRPM and Col10neo, which increased at FU; they also had the highest FU PRO-C6 levels (i.e., low inflammation, increasing cartilage breakdown, and high fibrosis).

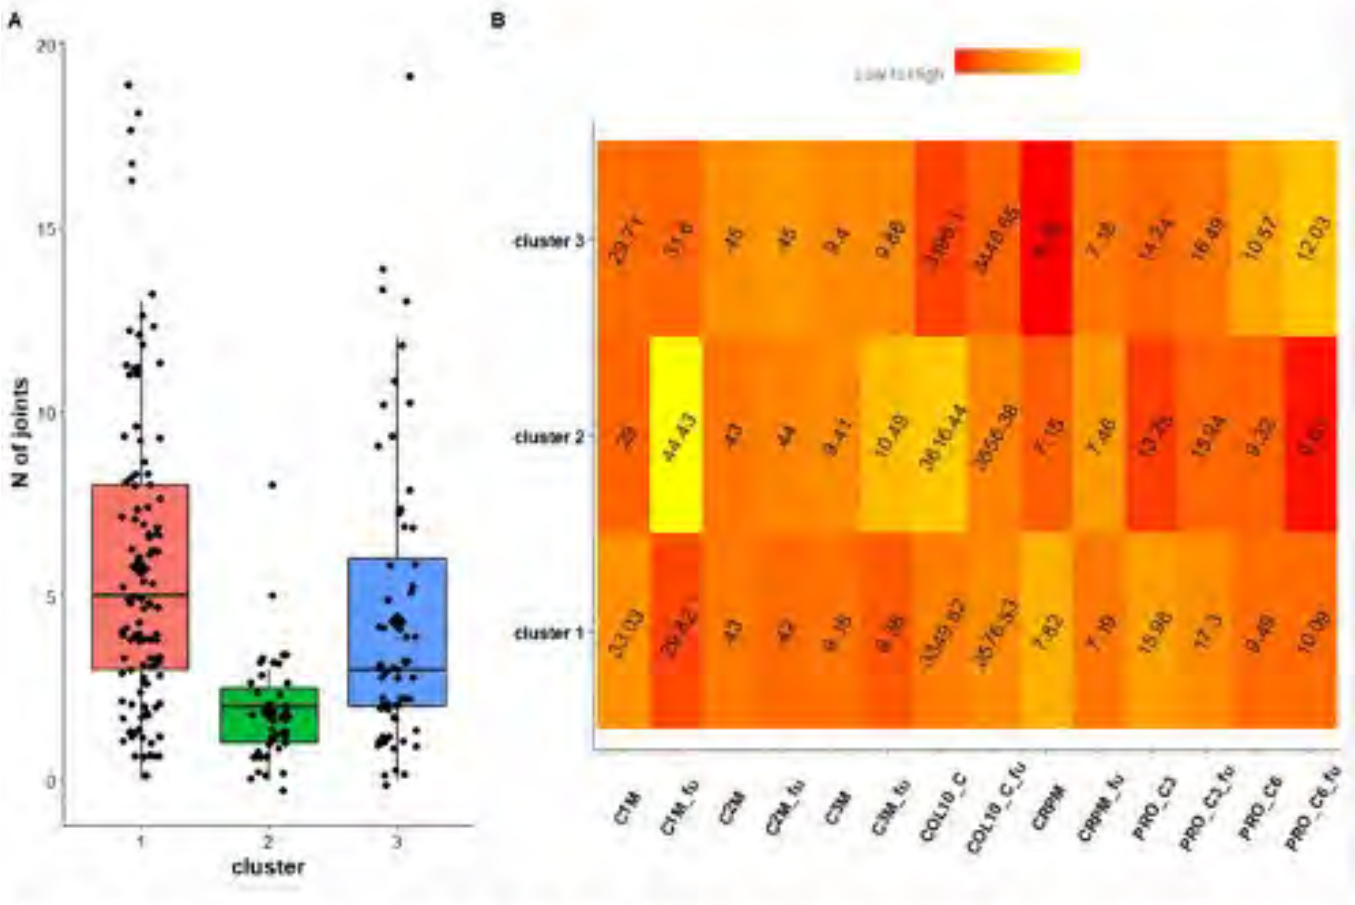

Figure 2. A: Number of joints with OA (KLG>=2) in 225 men from 3 clusters identified by mPCA. The boxplots show the mean (◇) and median (horizontal line drawn within the box); the dots are individual data points. The "whiskers" (the lines extending parallel from the boxes) indicate variability outside the upper and lower quartiles. **B:** heat map showing mean biomarker values in 3 clusters at baseline and follow-up (_fu).

Conclusion: This exploratory analysis utilized combinations of collagen and MMP-mediated degradation biomarkers at 2 time points, identifying clusters in men but not women, characterized by different frequencies of MJOA involvement at FU. This work highlights the importance of sex in OA and may provide novel insights into specific biomarkers and their change in different phenotypes of MJOA.

Cost-effectiveness of Weight Loss Interventions Prior to Total Knee Replacement for Patients with Advanced Knee Osteoarthritis and Class III Obesity

Aleksandra Kostic[1], Valia Leifer[2], Tuhina Neogi[3], David Hunter[4], Lisa Suter[5], Faith Selzer[6], Jeffrey Katz[1] and Elena Losina[7], [1]Brigham and Women's Hospital, Brookline, MA, [2]The Orthopaedic and Arthritis Center for Outcomes Research (OrACORe) at Brigham and Women's Hospital, Boston, MA, [3]Boston University School of Medicine, Boston, MA, [4]Institute of Bone and Joint Research, University of Sydney, St Leonards, Australia, [5]Yale School of Medicine, New Haven, CT, [6]Brigham and Women's Hospital, Amesbury, MA, [7]Brigham and Women's Hospital, Boston, MA

SESSION INFORMATION
Session Date: Monday, November 8, 2021
Session Title: Osteoarthritis – Clinical Poster III (1118–1134)
Session Type: Poster Session C
Session Time: 8:30AM–10:30AM

Background/Purpose: Class III obesity, defined by BMI >40kg/m^2, is linked to increased risk of complications post total knee replacement (TKR). This has led to recommendations for weight loss before TKR and even institutional BMI cutoffs for TKR. Surgical and nonsurgical weight loss (NSWL) programs show variable efficacy, but the cost-effectiveness of alternative weight loss interventions prior to TKR has received little study.

Methods: We used the Osteoarthritis Policy Model, a validated widely published microsimulation of knee osteoarthritis (OA), to evaluate the cost-effectiveness of weight loss interventions for patients with advanced knee OA and class III obesity planning to undergo TKR. We considered five strategies: 1) no weight loss intervention, no TKR; 2) immediate TKR; 3) NSWL+TKR; 4) Laparoscopic Sleeve Gastrectomy (LSG)+TKR; 5) Roux-En-Y Gastric Bypass (RYGB)+TKR. In strategies 3-5, patients were evaluated for TKR one year after weight loss intervention start. We followed subjects in the model until death, recording quality-adjusted life years (QALYs) accrued, lifetime medical costs, and TKR utilization. We examined a cohort with WOMAC pain consistent with literature pre-TKR pain (WOMAC Pain (0-100): mean 54, SD 15). We used national databases and published data to estimate weight loss strategy efficacy (initial BMI lost: NSWL 0-20%; LSG 18-38%; RYGB: 23-47%), TKR efficacy (mean WOMAC Pain reduction: 16-38 points, stratified by pre-operative WOMAC pain), surgical costs (LSG $16,099; RYGB $18,042; TKR $18,642-$19,300, stratified by BMI), and costs and risks of complications and mortality attributable to LSG, RYGB, and TKR.

Table. Cost-effectiveness of weight loss interventions prior to TKR in patients with advanced KOA and Class III obesity

Strategy	QALE*	Costs	ICER ($/QALY)	% TKR utilization
No intervention	9.19	$337,010	--	0%
NSWL → TKR	10.03	$358,250	Extended dominance**	91.0%
Immediate TKR	10.05	$358,563	Extended dominance**	99.2%
LSG → TKR	10.86	$381,568	Extended dominance**	85.5%
RYGB → TKR	11.14	$386,139	$25,100	85.4%

*QALE: Quality-adjusted life expectancy
**Extended dominance indicates interventions that have an ICER greater than that of a more effective intervention. An intervention with a higher QALE and a lower ICER is preferred, as there is a greater improvement in QALE with a lower cost per QALY.

In sensitivity analyses we varied: cost of health consequences of class II and III obesity, BMI cutoff and pain thresholds for TKR eligibility, LSG/RYGB pain efficacy, likelihood of complications from LSG/RYGB, and maximum years weight loss is maintained following LSG/RYGB. We discounted costs and QALYs at 3%/year and conducted analysis from a healthcare perspective. We calculated incremental cost-effectiveness ratios (ICERs) as the ratio of change in costs to change in QALYs for competing strategies in 2019 USD.

Results: Among patients with advanced knee OA and class III obesity, undergoing RYGB followed by TKR, if eligible, added 1.95 QALYs and $49,129 in medical costs in comparison to no interventions, resulting in an ICER of $25,100/QALY (Table). All other weight loss interventions were less economically efficient. Weight loss affected TKR usage; the percent of patients undergoing TKR ranged from 99.2% with immediate TKR (< 100% due to contraindications and mortality), 91.0% with NSWL, 85.5% with LSG, and 85.4% with RYGB (Table). ICERs were sensitive to the number of years weight loss was sustained, costs of obesity, LSG complication rates, and LSG/RYGB pain efficacy.

Conclusion: RYGB prior to TKR is a cost-effective strategy for addressing knee pain and obesity in patients with advanced knee OA and Class III obesity. TKR alone and NSWL or LSG prior to TKR are less economically efficient options compared to RYGB prior to TKR.

Osteoarthritis Patients Feel Their Tissue Remodeling

Anne-Christine Bay-Jensen[1], Yi He[2], Christian Thudium[1] and Morten Karsdal[3], [1]Nordic Bioscience, Herlev, Denmark, [2]Nordic Bioscience A/S, Herlev, Denmark, [3]Nordic Bioscience, Herlev

SESSION INFORMATION
Session Date: Monday, November 8, 2021
Session Title: Osteoarthritis – Clinical Poster III (1118–1134)
Session Type: Poster Session C
Session Time: 8:30AM–10:30AM

Background/Purpose: Osteoarthritis (OA) is a chronic disease characterized by pain and disability. Central to the revised FDA guidelines for the approval of a disease modifying OA drug are patient reported outcomes (PROs). There is a need in drug development to understand how biomarkers of tissue remodeling objectively relate to PROs, or even predict changes in PROs. Recently, it was shown that levels of the CRP metabolite (CRPM), but not CRP, with concentrations of above 9 ng/mL were prognostic of knee OA progression assessed by X-ray. Moreover, that 1/3 of OA patients had levels of CRPM like that of RA patients. While several biomarkers of tissue modeling correlate to disease activity score in RA, this information is missing in OA. The joint comprises of multiple connective tissues which consist of collagen such as type I, II, III and IV. Biomarkers have been developed which measures the remodeling of collagens. We hypothesis that such markers may provide the missing link between OA pathology and PROs. We differentiated an OA population in high and low CRPM and investigate the relationship to PROS to serological biomarker of tissue turnover.

Methods: 111 knee OA patients, 62% women, from the placebo arm of a phase III study with knee OA were included: mean (SD) age, 32(10); mean (SD) BMI, 27(4); NSAID users, 32%; and radiographic OA (KL≥2) 68%. PROs were: VAS_{pain} and WOMAC total, pain, stiffness, and function at baseline (BL). 19 healthy individuals were included as refer-

ence. Median (IQR) were 39 (13-69) and 37 (13-52) for BL VAS_{pain} and $WOMAC_{pain}$. Eight serum biomarkers of type I, II, III and IV collagen degradation (C1M, C2M, C3M, C4M) and formation (PRO-C1, PRO-C2, PRO-C3 and PRO-C4) as well as two inflammatory biomarkers CRPM and hsCRP, were assessed. Log2 transformed data was adjusted for race, gender, age, and BMI.

Results: None of the collagen formation or degradation markers were on average higher or lower in OA than healthy controls (adjusted for age, gender, race, and BMI). No correlations between collagen markers and PROs were observed. We confirmed the previous identified cut-off and found an AUC of 0.61 (p=0.078, cut-off of 8.7). In patients with low CRPM: PRO-C2 was positively correlated with VASpain (r=0.53) WOMAC total and pain (r=0.22) and PRO-C4 negatively with WOMACpain (r=-0.26). In patients with high CRPM: PRO-C4 was positively correlated with VASpain (r=0.29), WOMACtotal, pain and stiffness (r=0.28, 0.3 and 0.22). C1M was correlated with VASpain (r=0.20), WOMACtotal, pain, stiffness and function (r=0.32, 0.24, 0.29, 0.30). C2M was negatively correlated with VASpain (r=-0.28), WOMACtotal, pain, stiffness and function (r=-0.49, -0.43, 0.44, -0.43). C3M was also negatively correlated with VASpain (r=-0.44), WOMACtotal, pain, stiffness and function (r=-0.51, -0.42, -0.55, -0.49).

Conclusion: Biomarkers of tissue remodeling did not correlate to PROs in the undifferentiated OA population. In contrast, the two distinct subpopulations of ether low or high CRPM had multiple correlation between tissue turnover and PROs. The data provide the first insights into objective tissue turnover biomarkers and PROs, which is essential for successful drug development, and in the understanding of the processes in the OA joint causing pain.

Abstract Number: 1131

Interleukin 6 Concentration in Synovial Fluid and Its Clinical Significance

Ivars Veckalns and Anna Mihailova, Riga Stradins University, Riga, Latvia

SESSION INFORMATION
Session Date: Monday, November 8, 2021
Session Title: Osteoarthritis – Clinical Poster III (1118–1134)
Session Type: Poster Session C
Session Time: 8:30AM–10:30AM

Background/Purpose: Inflammatory arthritis (IA) treated with disease modifying antirheumatic drugs lead to secondary osteoarthritis (OA) due to inflammation, aging, and other factors. Inflammatory arthritis can start in middle-aged adults with OA. Discrimination between these two conditions can pose a significant challenge, especially when there are no makers for inflammatory arthritis.

Table 1. Primary diagnosis and final diagnosis crosstabulation

			Final diagnosis		Total (%)
			OA	IA	
Primary diagnosis	OA	Count (%)	13 (18.8%)	5 (7.2%)	18 (26.1%)
	IA	Count (%)	20 (29.0%)	31 (44.9%)	51 (73.9%)
Total (%)			33(47.8%)	36 (52.2%)	69 (100%)

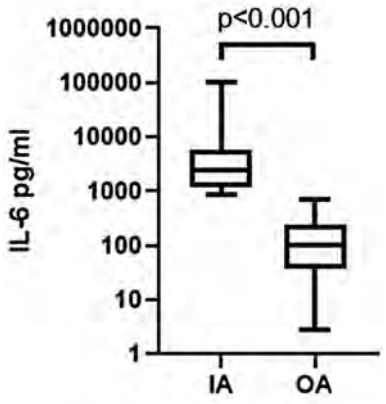

Figure 1. IL-6 concentration comparison in OA and IA patient groups.

The aim is to clarify the importance of IL6 concentration in synovial fluid for treatment purposes.

Methods: Sixty-nine patients with symptomatic swelling of the joints were undergone aspiration of synovial fluid. All patients received intraarticular steroid injections for therapeutic purposes. Then decision about treatment was depended on the IL6 concentration level in synovial fluid. IL6 concentration was determined by immunochemical luminescence method. Patients with low IL6 concentration continued therapy as OA or secondary OA patients with physiotherapy, without DMARD escalation, but high IL6 concentration DMARD treatment was prescribed or adjusted.

Primary diagnosis was made based on classification criteria for certain diseases (RA, PsA, AS, OA), and the conclusion was based on clinical presentation, current lab results, and IL6 level in synovial fluid.

Results: Primarily 51 patients were classified as having IA (AS-1; RA-1; Undifferentiated IA-2; JIA-2; ReA-32; PsA-7; RA-6). 18 patients were classified as having OA. After IL6 analysis 36 patients were re-classified as having IA (Undifferentiated IA-1; JIA-1; ReA-24; PsA-4; RA-6) and 33 patients were re-classified as having OA. Out of these 33 OA patients, 20 patients were previously classified as having IA and 5 patients of the 36 IA patient's group were previously classified as having OA. (Table 1). In 33 OA patients, the median IL6 concentration was 100 pg/ml (IQR 41.0 to 204.0). In 36 IA patients, the median was 2430.5 pg/ml (IQR 1277.0 to 5552.0). The Mann-Whitney U test showed a statistically significant difference ($p< 0.001$) between these two groups. (Figure 1). In the 20 patients, primarily diagnosed as IA and then classified as OA, the median IL6 concentration was 75.1 pg/ml (IQR 38.9 to 169.5). In the five patients, primarily diagnosed as OA and then classified as IA, the median IL6 concentration was 1800 pg/ml (IQR 1394.0 to 7738.0). In this group three patient were without any serological and genetic markers for inflammatory arthritis such as RF, anti-CCP, HLA-B27.

Conclusion: IL6 concentration in synovial fluid is different between IA and OA and may be helpful as an additional factor in the decision-making process.

ROA, radiographic osteoarthritis; OR, odds ratio; CI, confidence interval.

[a] This analysis used a logistic regression model to obtain the OR.

[b] Crude OR.

[c] Adjusted for age, gender and body mass index.

[d] Adjusted for age, gender, body mass index, smoking status, alcohol consumption, and educational level.

Table 1. Association between serum selenium levels and radiographic knee, hip or hand ROA (1,032 participants)

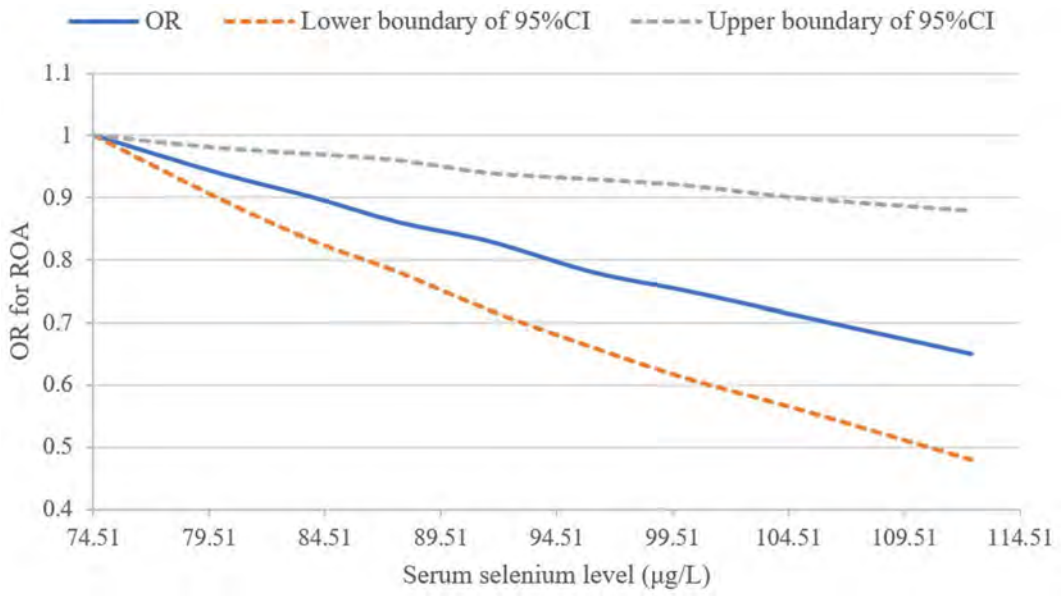

Figure 1. Dose-response relationship between serum selenium level and the odds ratio (OR) for radiographic knee, hand or hip radiographic osteoarthritis (ROA). CI, confidence interval.

Background/Purpose: Selenium plays an indispensable role in the process of antioxidant and antiinflammation. Oxidative stress and inflammation have been hypothesized to be involved in the pathogenesis of cartilage degeneration. We sought to explore the association between serum selenium levels and the prevalence of radiographic osteoarthritis (ROA) in a large population-based study.

Methods: Subjects aged 50 years or older were from the Xiangya Osteoarthritis (XO) Study, a community-based observational study. Serum selenium concentration was measured by inductively coupled plasma-dynamic reaction cell-mass spectrometry. ROA was defined as a Kellgren/Lawrence score ≥ 2 for at least one knee, hip or hand joint. The association between serum selenium levels and ROA were evaluated by conducting logistic and spline regression.

Results: A total of 1,032 participants (women: 52.5%; mean age: 63.1 years; ROA prevalence: 45.4%) were included. Compared with the lowest tertile, odds ratios (ORs) for ROA were 0.69 (95% confidence interval [CI]: 0.51 to 0.93) and 0.56 (95% CI: 0.41 to 0.75) in the second and third tertiles of serum selenium, respectively (P for trend < 0.05) (**Table 1**). Adjusting for potential confounders did not change the results materially. In addition, subjects with lower serum selenium levels had a higher prevalence of OA in a dose-response-relationship manner (P = 0.005) (**Figure 1**).

Conclusion: Subjects with lower levels of serum selenium, even within the normal range, had higher prevalence of ROA in a dose-response relationship manner, suggesting that selenium may have a preventive or therapeutic potential for OA.

The Relation of Serum Urate to Radiographic Knee Osteoarthritis in 2 Cohorts: The ELSA-Brasil MSK and the Original Cohort of the Framingham Heart Study

Ana Beatriz Vargas-Santos[1], Tuhina Neogi[2], Luciana Machado[3], Isabela Beseñor[4], Luciana Costa-Silva[5], David Felson[6], Sandhi Barreto[7] and Rosa Telles[8], [1]Universidade do Estado do Rio de Janeiro, Rio de Janeiro, Brazil, [2]Boston University School of Medicine, Boston, MA, [3]Clinical Hospital, Universidade Federal de Minas Gerais, Belo Horizonte, Brazil, [4]Faculdade de Medicina, Universidade de São Paulo, São Paulo, Brazil, [5]Instituto Hermes Pardini. SESSION INFORMATION

Session Date: Monday, November 8, 2021

Session Title: Osteoarthritis – Clinical Poster III (1118–1134)

Session Type: Poster Session C

Session Time: 8:30AM–10:30AM

Background/Purpose: Hyperuricemia may contribute to the development and/or progression of knee osteoarthritis (OA), based on increased inflammation associated with elevated serum urate (SU). Because hyperuricemia and OA are both associated with obesity, the direction and magnitude of the relation between them need to be thoroughly evaluated, taking the body mass index (BMI) into account. The identification of SU as a modifiable factor in the pathogenesis of OA could lead to the trial use of urate-lowering drugs as potential adjuvant therapy for OA. Therefore, we evaluated the relation of SU to radiographic knee OA (ROA) in two large cohorts unselected for OA, accounting for BMI.

Methods: This was a cross-sectional analysis of the Brazilian Longitudinal Study of Adult Health – Musculoskeletal Study (ELSA-Brasil MSK) cohort, mirroring a previous analysis performed on the original cohort of the Framingham Heart Study (FHS), comparing the results of these two populations. The ELSA-Brasil MSK is an ancillary study of ELSA-Brasil and comprises 2,901 individuals with data on musculoskeletal health at baseline, including knees and hands radiographs. For the present analysis, we selected subjects ≥50 years older. In the ELSA-Brasil MSK, SU was assessed at visit 1 (2008-2010) and ROA at visit 2 (2012-2014); in the FHS, SU was assessed at exams 20 and 21 (1986-1992) and ROA at exam 22 (1990-1994) in original cohort. ROA of each tibiofemoral joint was defined as KL ≥2. SU was categorized as: < 5mg/dL, 5-< 6mg/dL, 6-< 7mg/dL, 7-< 9mg/dL, and ≥9mg/dL. The sex-specific relation of SU to the prevalence of knee ROA was evaluated using logistic regression, adjusted for age and BMI, with generalized estimating equations to account for the correlations of joints within individuals. The same analyses were performed with SU as a continuous variable.

Table 1. Age and body mass index by sex in the two cohorts.

Framingham Heart Study				
Men	105/497 (21.1)	1.06 (0.90-1.25)	1.05 (0.88-1.25)	0.576
Women	207/796 (26.0)	1.18 (1.03-1.37)	1.10 (0.93-1.31)	0.268

*Adjusted for age and body mass index. OA: osteoarthritis; OR: odds ratio; CI: confidence interval.

Results: SU and radiographic data were available for 972 men and 1,124 women from the ELSA-Brasil MSK cohort and 329 men and 575 women from the FHS. Of those, 191, 229, 89, and 156 had knee OA, respectively. Age and BMI are shown in Table 1. In both cohorts after adjusting for age and BMI, men with SU ≥ 9 mg/dL had a significantly higher prevalence of knee ROA compared with those with SU < 5 mg/dL: OR 2.46 (CI 1.09-5.52, p=0.029) in the ELSA-Brasil MSK cohort and OR 3.31 (CI 1.28-8.55, p=0.013) in the FHS. In the analyses with SU as a continuous variable, the prevalence of knee ROA among men and women was 1.1 times higher for each mg/dL increment of SU in both cohorts, reaching statistical significance among men from the ELSA-Brasil MSK cohort (Table 2).

Conclusion: There seemed to be a threshold effect of SU to ROA at least among men, although this could not be properly evaluated among women due to the small number of subjects in the female highest stratum of SU.

SESSION INFORMATION

Session Date: Monday, November 8, 2021
Session Title: Osteoarthritis – Clinical Poster III (1118–1134)
Session Type: Poster Session C
Session Time: 8:30AM–10:30AM

Background/Purpose: Osteoarthritis (OA) is a highly prevalent disease resulting in joint pain and impaired function. Allergic pathways, including mast cell activation, may play a key role in the pathogenesis of OA.[1] The association between atopic disease and the development of OA is not well understood. The objective of this study was to determine the incidence of OA in patients with atopic disease compared with the general population.

Table 2. Baseline characteristics of patients in the STARR cohort.

	Total Cohort (*n* = 114434)	Control (*n* = 70705)	Asthma (*n* = 11101)	Atopic Dermatitis (*n* = 23855)	Asthma and Atopic Dermatitis (*n* = 8773)

OA = osteoarthritis; *IR = incidence rate per 1,000 person-years; †OR = adjusted odds ratio; 95% CI = 95% confidence interval. Incidence rate 95% CI were estimated using IR +/- 1.96 IR/($n^{0.5}$).

Table 3. Incidence of osteoarthritis in patients with atopic disease compared to non-atopic control patients

Methods: We conducted a retrospective cohort study using claims data from the Optum Clinformatics™ Data Mart and electronic health record data from the Stanford Research Repository (STARR). We included adult patients with more than 5 years of continuous enrollment and excluded patients with preexisting OA or a history of inflammatory arthritis. The exposed group included patients with a diagnosis of incident atopic disease, including asthma and atopic dermatitis. The control group included patients without atopic disease. The primary outcome was the development of OA, defined as two or more ICD-9 or -10 codes for OA separated by seven days or more. In the Optum cohort, the relationship between atopic disease and the development of OA was evaluated using logistic regression, adjusting for age, sex, race/ethnicity, Charlson comorbidity score, education, duration of follow-up, and frequency of outpatient visits. In the STARR cohort, we additionally adjusted for body mass index (BMI), and we were unable to adjust for education.

Results: The Optum cohort included 35,097 patients with asthma, 77,854 patients with atopic dermatitis, 4,395 patients with both asthma and atopic dermatitis, and 2,242,901 control patients without atopic disease (**Table 1**). The STARR cohort included 11,101 patients with asthma, 23,855 patients with atopic dermatitis, 8,773 patients with both asthma and atopic dermatitis, and 70,705 control patients without atopic disease (**Table 2**). There was a higher incidence of OA in patients with asthma (24.7% in Optum; 17.6% in STARR), atopic dermatitis (20.2% in Optum; 15.4% in STARR), and both asthma and atopic dermatitis (32.0% in Optum; 15.2% in STARR) compared to non-atopic control patients (13.7% in Optum; 8.9% in STARR) (**Table 3**). In the Optum cohort, there was an 84% increased risk of developing OA for patients with both asthma and atopic disease compared to non-atopic control patients (adjusted odds ratio (OR) 1.84; 95% CI, 1.71-1.97; p< .001) (**Table 3**). In the STARR cohort, after additionally adjusting for BMI, there was a similarly increased risk of OA in patients with both asthma and atopic dermatitis compared to controls, with an adjusted OR of 1.54 (95% CI, 1.44-1.65; p< 0.001) (**Table 3**).

Conclusion: This study demonstrates an increased incidence of OA in patients with atopic disease compared to the general population. The association between atopic disease and OA is supported by recent observations that mast cells and type II cytokines play important roles in the pathogenesis of OA. Our findings provide further evidence that allergic pathways may contribute to the development of OA, and future interventional studies could consider targeting these pathways for the treatment of OA.

SESSION INFORMATION

Session Date: Monday, November 8, 2021

Session Title: Osteoporosis & Metabolic Bone Disease – Basic & Clinical Science Poster (1135–1149)

Session Type: Poster Session C

Session Time: 8:30AM–10:30AM

Background/Purpose: A rapid loss of bone mass and an increase in fractures have been described in the first six months after liver transplantation. This phenomenon occurs in patients with a previous diagnosis of osteoporosis, but also in those with normal bone mass. Several factors, such as corticosteroids and others, may explain the increased risk of fractures. Treatment with bisphosphonates may help halt bone loss, improve lumbar bone mass, and reduce fractures. This study aims to evaluate characteristics, bone health, and risk of fracture of patients included in the liver transplantation pre-assessment at a tertiary center. Also, to ascertain the indication for antiresorptive therapy and the development of bone complications after transplantation.

Methods: A descriptive cross-sectional study of patients enrolled for a multidisciplinary assessment before liver transplantation from February 2019 to March 2021, with a follow-up of 6 and 12 months after transplantation. Sex, age, body mass index (BMI) and alcohol and tobacco consumption were collected. DXA-based osteopenia or osteoporosis diagnoses, the number of bone fragility fractures, and radiographic vertebral fractures were evaluated. FRAX index adapted for the Spanish population was calculated to estimate the 10-year risk of major osteoporotic fracture and hip fracture. Additionally, the indication for antiresorptive treatment and the occurrence of clinical fracture after liver transplantation were registered. Categorical variables are expressed as frequencies and percentages, and continuous variables with normal data distribution, as mean and standard deviation (SD).

	N (%)
NORMAL BONE MINERAL DENSITY (BMD)	19 (19.6%)
OSTEOPENIA by DXA T SCORE -1 to -2,5	57 (58.8%)
OSTEOPOROSIS by DXA T SCORE < -2.5	21 (21.6%)
FRAGILITY FRACTURE	3 (3.1%)
RADIOGRAPHIC VERTEBRAL FRACTURE	15 (15.5%)
OSTEOPOROSIS T SCORE < -2.5 or fragility fracture or radiographic vertebral fracture	30 (30.9%)
FRAX® 10-YEAR RISK ≥ 3% for hip fracture or ≥ **10%** (without BMD) / ≥ **7.5%** (with BMD) **for major osteoporotic fracture***	15 (15.5%)

*Reumatol Clin 2019; 15:188-210.

Results: A total of 97 patients (77.3% men) were included, with a mean age of 60 years (SD 7.5) and a mean BMI of 28.2 kg/m^2 (SD 4.8). 68% were smokers, and 72% had a background of moderate-severe alcohol consumption. 3.1% presented a fragility fracture, and in 15.5%, a vertebral fracture was diagnosed as seen by radiography. 58.8% had osteopenia, and 30.9% osteoporosis by DXA. 91% had a deficiency of 25-OH vitamin D (< 30 ng/ml). The mean 10-year risk of major fracture was 3.9% (SD 3) and 1.6% (SD 2.1) for hip fracture. Lastly, 31 (32.0%) would meet treatment criteria according to FRAX scores, DXA results and background of fragility fractures (**Table**). Adding osteopenia as a criterion for initiating antiresorptive therapy, the number of patients candidates was 75 (77.3%). 66 (68%) finally received treatment (52.6% with IV zoledronate). In the follow-up, 50 received liver transplantation. Twenty-one of them has been followed six months and 17 a year. Two patients have developed a clinical fracture (one case of L2 fracture at five months, and the other a hip fracture at nine months), despite treated at baseline with bisphosphonates.

Conclusion: In this study, many candidates for liver transplantation candidates showed risk factors for the development of fragility fractures, but half of the patients who received antiresorptive drugs would not meet the usual criteria for treatment. Nonetheless, the risk of fracture in the months after transplantation supports the need to optimize bone mineral treatment and to carry out close follow-up.

SESSION INFORMATION
Session Date: Monday, November 8, 2021
Session Title: Osteoporosis & Metabolic Bone Disease – Basic & Clinical Science Poster (1135–1149)
Session Type: Poster Session C
Session Time: 8:30AM–10:30AM

Background/Purpose: Patients with systemic sclerosis (SSc) are at high risk for osteoporosis (OPO) and fragility fractures, although their exact prevalences are unknown. This might be due to traditional risk factors for OPO, such as previous fragility fractures, low BMI, use of glucocorticoids. However, the impact of SSc disease-specific characteristics remains unclear. The aim of this study was to estimate the prevalence of OPO and fragility fractures in a large cohort of SSc patients and to identify risk factors.

Methods: We performed a cross-sectional study involving patients fulfilling ACR/EULAR 2013 SSc classification criteria followed prospectively in two European university hospital cohorts between 2004 and 2020. We used databases prospectively collecting SSc related variables including clinical phenotype, organ involvement, autoantibodies, pulmonary function tests, and biological parameters. Bone health parameters were added retrospectively including bone densitometry (DXA), history of fragility fractures and anti-osteoporotic treatment. OPO was defined by a femoral or

Chi square test for all parameters except: * Fisher's exact test, † Student T-test, ‡ Mann-Whitney test.
SLE: Systemic Lupus erythematosus; DXA : dual X-ray absorptiometry ; DLCO: diffusing capacity for carbon monoxide ; TLC: total lung capacity.

Results: Of 932 SSc patients with a mean age of 59.6 years (20.1-90.5). Of the patients 40% had an interstitial lung disease (ILD) and 12% pulmonary hypertension, respectively. Diffuse cutaneous SSc was present in 226 patients (24%); anti-topoisomerase antibodies were detected in 28%. A DXA scan was available in 38% of the patients. The prevalence of osteoporotic fractures and anti-osteoporotic treatments was 14% and 21%, respectively. Overall, 28% of the cohort was identified as having OPO.

Table 2 compares SSc patients with or without OPO. Besides age and low BMI as strong risk factors, the use of proton-pump inhibitors (OR 1.94, 95%CI 1.38-2.74) and glucocorticoids (OR 3.48, 95%CI 2.57-4.70) were statistically associated with OPO. Cutaneous diffuse form (OR 2.67, 95%CI 1.95-3.76), mRSS above 10 (OR 2.10, 95%CI 1.48-2.96), and anti-topoisomerase antibodies (OR 1.77, 95%CI 1.29-2.41) were associated with OPO. ILD (OR 2.61, 95%CI 1.29-2.41) or symptoms such as NYHA III and IV functional classes (OR 2.13, 95%CI 1.54-2.94), were also positively associated with OPO. The ILD severity, estimated through DLCO alteration and restrictive lung disease, was also associated with OPO. We did not identify any significant association between OPO and calcinosis or vasculopathy, nor oesophageal or gut involvement. CRP and ESR levels were significantly higher in the OPO group ($p = 0.004$ and $p < 0.001$, respectively), while haemoglobin levels were significantly lower ($p < 0.001$).

Conclusion: The prevalence of OPO and fragility fractures in patients with SSc was 28% and 20%, respectively. Beyond classical risk factors, our study suggests that disease severity (as reflected by cutaneous subset, organ involvement, autoantibodies and inflammatory markers) was also associated with bone health in SSc patients.

REMS Technology for the Assessment of Bone Health in a Male Population

Delia Ciardo[1], **Paola Pisani**[1], Fiorella Anna Lombardi[1], Marco Di Paola[1], Roberto Franchini[1], Maurizio Muratore[2], Francesco Conversano[1] and Sergio Casciaro[1], [1]National Research Council, Institute of Clinical Physiology, Lecce, Italy, Lecce, Italy, [2]Vito Fazzi Hospital, ASL-LE, O.U. of Rheumatology, Lecce, Italy, Lecce, Italy

SESSION INFORMATION
Session Date: Monday, November 8, 2021
Session Title: Osteoporosis & Metabolic Bone Disease – Basic & Clinical Science Poster (1135–1149)
Session Type: Poster Session C
Session Time: 8:30AM–10:30AM

Background/Purpose: This study aimed to evaluate the diagnostic accuracy of the ultrasound-based densitometric technology called Radiofrequency Echographic Multi Spectrometry (REMS) in the diagnosis of osteoporosis in a population of adult male patients based on lumbar spine scans, compared to Dual-energy X-ray Absorptiometry (DXA), considered as a reference.

Methods: Inclusion criteria were: Caucasian male patients, aged between 30 and 90 years, body mass index (BMI) less than 40 kg/m^2, no significant walking impairments, referral for lumbar spine DXA. Signed informed consent was obtained. The patients underwent a lumbar spine scans with both DXA and REMS.

The correlation between REMS and DXA-measured BMD was expressed by Pearson correlation coefficient. Bland-Altman plot was also obtained. Patients were classified as "with osteoporosis" or "without osteoporosis" on the base of the T-score value using the conventional threshold (-2.5) for both techniques independently. Considering the DXA outcome as reference, the accuracy of the diagnostic classification was assessed as sensitivity, specificity, Cohen's K and 3-classes diagnostic concordance.

Results: Three hundred and thirteen patients were considered, with mean age of 57.7 years (range: 30 to 87 years). The Pearson correlation coefficient between REMS- and DXA-measured BMD values was r=0.92 (r^2=0.85). At Bland-Altman analysis, bias ± 2 standard deviations were -0.002 ± 0.092 g/cm^2.

The agreement in diagnostic classification performed by REMS and by DXA was very high, with a sensitivity of 89.1% and specificity of 90.7%. Cohen's K was 0.71. Considering the 3 diagnostic classes (normal bone, osteopenia, osteoporosis), the diagnostic concordance between technologies was 81.5%.

Conclusion: REMS, applied to the lumbar spine site, is a reliable technology for the diagnosis of osteoporosis in men, thus confirming the diagnostic performance already observed in studies carried out in female populations [1, 2].

Abstract Number: 1138

Assessing Trends in Dual Energy X-Ray Absorptiometry (DXA) Utilization Among Medical Providers in the United States

Timothy Edgil[1], Kenneth Saag[2], Jeffrey Curtis[3] and Maria I. Danila[2], [1]Division of General Internal Medicine, University of Alabama at Birmingham, Birmingham, AL, [2]University of Alabama at Birmingham, Birmingham, AL, [3]Division of Clinical Immunology and Rheumatology, Department of Medicine, Department of Epidemiology, University of Alabama at Birmingham, Birmingham, AL

SESSION INFORMATION
Session Date: Monday, November 8, 2021
Session Title: Osteoporosis & Metabolic Bone Disease – Basic & Clinical Science Poster (1135–1149)
Session Type: Poster Session C
Session Time: 8:30AM–10:30AM

Background/Purpose: The twenty first century has seen falling reimbursement rates for dual energy X-ray absorptiometry (DXA) testing coupled with a rising elderly population in the U.S. The purpose of this study was to assess trends in performing DXA scans among U.S. medical providers and the resulting potential impact of reduced DXA availability on access to care.

Methods: A retrospective review was performed on publicly available data Medicare provider utilization and payment data between 2012 and 2018. Data was accessed from the CMS website and filtered for CPT codes used for reimbursement of DXA testing. This data included information on provider (name and identifier), city, state, zip code, sex, procedure type, location (office-based providers vs hospital-based providers), and provider specialty. Provider zip codes were compared to the Federal Office of Rural Health Policy (FORHP) designation as rural areas.

Results: From 2012-2018 the standardized number of DXA tests per 100,000 women decreased from 5,641 to 4,899 DXA tests per 100,000 women with a nadir of 4,307 DXA tests per 100,000 women in 2015. The number of DXA providers reimbursed located in a rural zip code decreased 41.3% (from 2,945 to 1,728), similar to the relative decrease

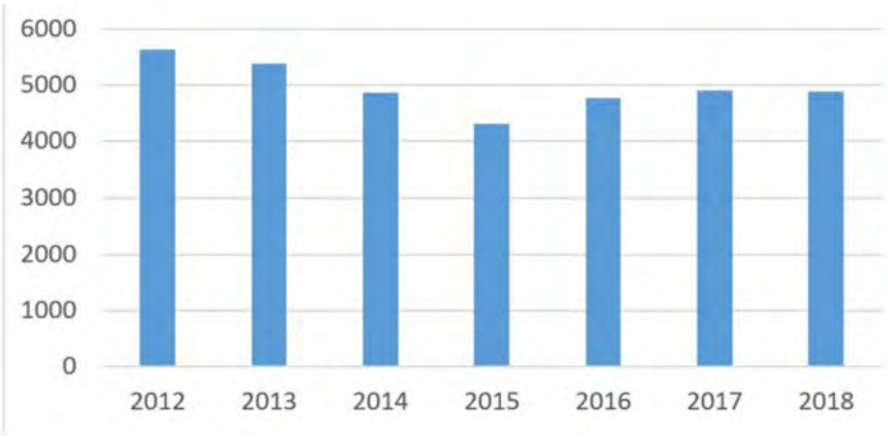

Figure 1. Standardized Number of DXA Scans Per 100,000 Women by Year.

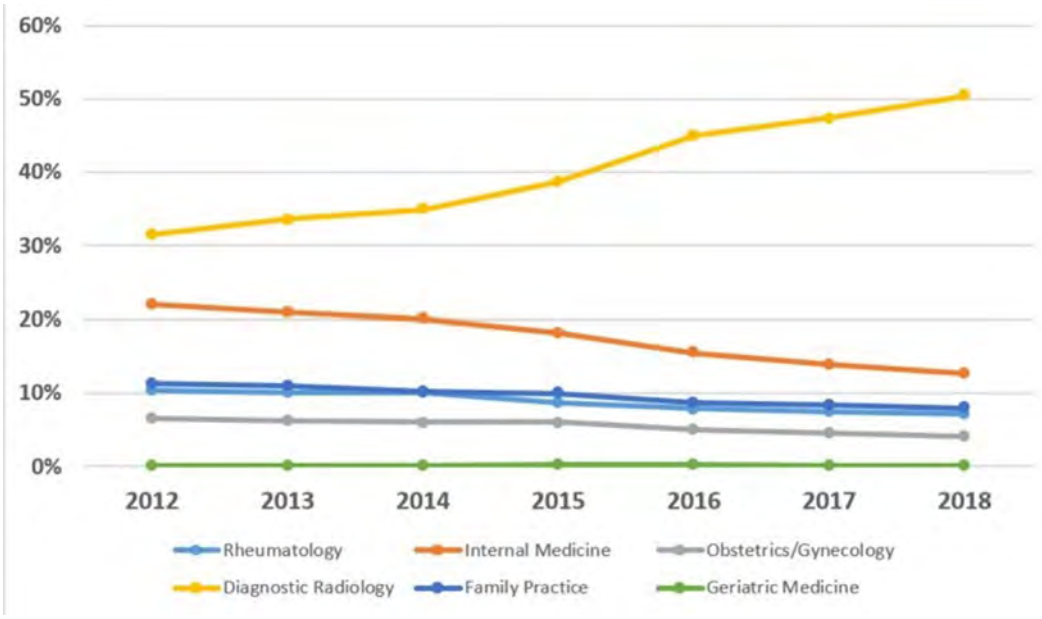

Figure 2. Yearly Trends in Percentages of DXA Testing by Specialty and Year.

in the proportion of rural providers (from 14.2% to 9.0%). The percentage of reimbursed DXA scans performed by rheumatologists decreased from 10.3% to 7.1%, internal medicine from 22.0% to 12.7%, obstetrics/gynecology from 6.5% to 4.2%, and family practice from 11.3% to 8.0%; diagnostic radiology, which are hospital-based providers, increased from 31.6% to 50.4% during the same time period.

Conclusion: The standardized number of DXA tests per 100,000 women Medicare enrollees decreased between 2012 and 2018. During the same time period, the claims for DXA testing for office-based specialties decreased, while the claims for DXA testing performed by diagnostic radiology increased. Both the number and proportion of both rural and primary care providers submitting claims for DXA testing have decreased, leading to likely decreased access to

Specialty	Total, 2012	Standardized	Total, 2018	Standardized

Fracture Liaison Service Outcomes at a Southern California County Hospital Highlights Need for Health System Improvements

Muntarin Karim[1], lorien ahn[2], Jordan Thompson[1], Christina Downey[3], Lorena Salto[4] and Karina Torralba[5], [1]Loma Linda University, Redlands, CA, [2]loma linda university medical center, Loma Linda, CA, [3]Loma Linda University Medical Center, Redlands, CA, [4]Loma Linda University Health, Loma Linda, CA, [5]Division of Rheumatology, Department of Medicine, Loma Linda University Healthcare, Loma Linda, CA

SESSION INFORMATION

Session Date: Monday, November 8, 2021
Session Title: Osteoporosis & Metabolic Bone Disease – Basic & Clinical Science Poster (1135–1149)
Session Type: Poster Session C
Session Time: 8:30AM–10:30AM

Background/Purpose: Osteoporosis causes significant morbidity and mortality in the elderly. Despite the benefits of treatment, < 25% of elderly patients who fracture receive treatment. A fracture liaison service (FLS) provides a systematic way to address secondary fracture prevention. An FLS was implemented at our county-affiliated hospital. There is limited data overall on FLS Outcomes at county hospital systems where the majority of patients are indigent, and access to services may be limited. A prior study highlighted worse outcomes in our county population vs a university hospital population. The purpose of this study is to determine the impact of an FLS at a county hospital during its first year of implementation on improving osteoporosis treatment initiation and DXA testing and to identify areas of improvement.

Methods: We performed a retrospective electronic medical chart review on 282 patients diagnosed with osteoporosis based on relevant ICD-10 codes; 144 patients were seen prior to (pre-FLS) and 138 patients seen after (post-FLS) the establishment of an FLS. Age, ethnicity, BMI, calcium and vitamin D supplementation, treatment initiation (with bisphosphonates or biologics), DXA testing, and adherence to outpatient follow-up were collected. We used Pearson's chi-square to test for independence in the demographic and clinical categorical outcome variables while independent samples t-test was used to compare mean differences in the demographic and clinical continuous outcome variables. In the post-FLS group only, we tested treatment initiation, DXA testing, calcium and vitamin D supplementation before admission and after discharge using McNemar's test statistic. We set alpha equal to 0.05 for statistical significance.

Results: The pre-FLS group tended to be slightly younger (p= 0.022) and had a higher percentage of Hispanics (p= 0.021) than the post-FLS group (Table 1). A higher percentage of the post-FLS group was female (76% vs 67%). Smoking and alcohol-use status, and BMI were independent of FLS group status.

No statistically significant differences in mean length of stay, days until next encounter (any) between FLS subgroups were noted (Table 2). While only 14% of FLS patients were seen in Rheumatology clinic, primary care physicians (PCPs) were notified of patient's fracture risk via the FLS. In the post-FLS group, more patients were treated (20 additional patients, p=0.004) and prescribed calcium (66 additional patients, p< 0.001) and vitamin D (66 additional patients, p< 0.001) after discharge in paired outcome analysis (Table 3). No statistically significant changes in DXA orders from pre-admission to post-discharge were noted.

Table 1. Patient Demographic Characteristics by Fracture Liaison Service Group Status, *n*=282

	Patient Group Treated Before Fracture Liaison Service was Established, *n*=144

BMI=Body Mass Index. Percentages are shown by column (Fracture Liaison Service group) and may not add to 100 due to rounding. Based on valid data where missing data varies by characteristic. *p-value based on the chi-square statistic for categorical variables and independent samples t-test for continuous variables, *p-value < 0.05.

Conclusion: Assessment of FLS outcomes highlighted inadequacies in osteoporosis management within the county health system. Interdisciplinary efforts to improve DXA access and PCP awareness of fracture risks are currently underway. Initial efforts have proven successful in increasing the number of patients treated after a fragility fracture in this population.

Table 2. Clinical Characteristics by Fracture Liaison Service Group Status, n=282.

Fracture Risk in DXA-Appropriate Patients on Glucocorticoids: Is Everyone Tested According to Screening Guidelines?

Alexandra Chop[1], Rajesh Kupuraju[1], Ruchi Patel[1], Kristen Salava[1], Madhuri Duggirala[1], Aparna Baburaj[1], Andrea Berger[2], Jason Brown[1] and David Bulbin[3], [1]Geisinger Medical Center, Danville, PA, [2]Department of Population Health Sciences, Geisinger Medical Center, Danville, PA, [3]Geisinger Health System, Danville, PA

SESSION INFORMATION
Session Date: Monday, November 8, 2021
Session Title: Osteoporosis & Metabolic Bone Disease – Basic & Clinical Science Poster (1135–1149)
Session Type: Poster Session C
Session Time: 8:30AM–10:30AM

Background/Purpose: Glucocorticoids are commonly prescribed for a multitude of indications, yet have many side effects, one of which is glucocorticoid induced osteoporosis (GIOP). The 2017 ACR GIOP guidelines were developed to help improve screening and management of osteoporosis for this specific population. In this study, we investigated if patients at a large rural academic center receiving glucocorticoids were appropriately monitored with DXA based on the 2017 ACR screening guidelines.

Methods: Through a retrospective electronic chart review we evaluated patients in a rural tertiary medical center in central Pennsylvania who met specific inclusion criteria: 40 years or older who received a prescription for 2.5mg of a prednisone equivalent ≥ 90 days starting January 1, 2018 – December 31, 2019. Patients that met criteria were reviewed for DXA orders between 2018 – 2020, the department that ordered the steroids, the DXA ordering department,

Figure 2. Table A – source of steroid order by department, if DXA was ordered and completed. Table B – source of steroid order comparing rheumatology vs all other departments combined.

and if a DXA had been completed. Logistic regression models were used to test for overall and pairwise associations between steroid ordering departments and whether DXAs were ordered and whether DXAs were completed.

Results: The total number of charts that met the initial electronic screening criteria was 6022. Of those, 1000 charts were randomly selected for manual review via a computer generated simple random sample. Of those 1000 patients, 673 met the inclusion criteria. Overall, 262 of 673 patients (38.9%) had DXAs ordered in the three-year period and 187 had DXAs completed (27.8%). If the most recent steroid order was from a rheumatology provider, 45.1% of patients had a DXA ordered and 34.0% had a DXA completed. Patients whose steroid was ordered by rheumatology had significantly more DXAs ordered than patients whose steroid orders came from all other departments combined (45.1% vs. 33.8%, p = 0.0028). In pair-wise comparisons against individual departments, patients from rheumatology had more DXA orders than hematology/oncology (45.1% vs 12.8%, p = 0.0005), and primary care (45.1% vs 35.1%, p = 0.0354). There were no statistically significant differences between rheumatology, gastroenterology, neurology, surgery, or pulmonary medicine. Patients whose steroid was ordered by rheumatology had significantly more DXAs completed than patients whose steroid orders came from all other departments combined (34.0% vs. 22.6%, p = 0.0011).

Conclusion: There was significant variability between different specialties in ordering of DXA scans. While the rheumatology department was more compliant with ACR guidelines when all other departments are combined, they still are screening fewer than 50% of patients who meet the ACR guidelines. This demonstrates a care gap in osteoporosis screening in this population. We plan to analyze the remaining 5022 patient charts to determine how many meet criteria for DXA screening and expound on our preliminary results. We also hypothesize that the observed trends in

interdepartmental differences will lead to more robust conclusions when analysis is completed with the full population. Additionally, we intend to implement a medical chart notification that would alert providers to consider DXA screening in appropriate patients.

Table 1. Demographic data, risk associated factors, laboratory test, bone densitometry divided by patients with fragility fracture and patients without fragility fracture.

Patient	Age	Gender	Femoral Neck Bone Mineral Density (gr/cm2)	Localization of Fracture	Severity of Fracture	Time to fracture diagnosis
Patient 1	65	Male	0,714	D6,D8,D10,D11, L1	3 Mild 2 Moderate	2 years prior SM diagnosis
Patient 2	81	Female	0,437	D4,D8,D12, L1	1 Mild 3 Severe	2 years after SM diagnosis
Patient 3	65	Female	0,767	D4,D11	Unknown	2 years prior SM diagnosis
Patient 4	42	Male	0,832	D7,D8,D9,D11,D12, L1,L2,L3,L5	3 Mild 3 Moderate 3 Severe	At time of SM diagnosis

Table 2. Characteristics of Fragility Fracture in four patients with Systemic Mastocytosis

osteoporosis (OP) resulting in fragility fracture (FF) in around 5 -37% of patients. FF affect lumbar spine (LS) more frequently in young men. Alcohol consumption, high serum tryptase level, and low femoral T score have been described as risk factors but there are some discrepancies between studies. [1-2] Our primary objective was to identify factors associated with FF in patients with SM.

Methods: We analysed all consecutive patients attending a multidisciplinary clinic up to April 2021. This clinic has been recently established by experts from Allergy and Rheumatology departments at our Centre, patients with SM diagnosis according to the 2001 WHO criteria are included. We collected demographic data, general risk factors for OP, and clinical characteristics including cutaneous involvement, bone involvement and laboratory data as serum tryptase level. Bone involvement is defined as densitometric OP (T score ≤ - 2.5) or FF. Normally distributed variables are described as means (SD) and dichotomous variables as number and frequencies. Comparison between patients with and without FF is performed using t-test and Chi^2 when needed.

Results: Seventeen patients with SM are included in this preliminary analysis. Four patients (24%) presented a FF, all of them vertebral fractures identified by plain radiographies (most of them multiple, located in dorsal vertebrae). Two men and two women presented FF, they were older versus patients without FF (Table 1), and without general risk factors for OP, including alcohol consumption and tobacco use. All of them have a high basal serum tryptase and most of them presented other MS symptoms (cutaneous, anaphylaxia). FRAX tool was useful in only one patient to predict FF risk. The two men with FF diagnosis do not met criteria for densitometric OP, specific characteristics for these patients are presented in Table 2.

Conclusion: In our cohort of SM, about 25% of patients present FF, in most cases multiple, located in dorsal spine, and without densitometric diagnosis of OP. Our patients are older versus other population described previously in the literature. FRAX may underestimate the risk of FF in patients with SM. We could not identify variables associated to higher risk of FF in this group of patients. SM should always be considered in differential diagnosis in the presence of FF, especially in men with no OP or another risk factor associated.

Abstract Number: 1142

For Vulnerable Population Treated at a Community Health Center (CHC), Primary Care Physician (PCP) Turnover Should Be Included in Social Determinants of Health (SDH) on Non-completing Osteoporosis Treatment

Yu Na Kim[1] and Julie Crosson[2], [1]DotHouse Health, Boston, [2]DotHouse Health, Boston University, Boston

SESSION INFORMATION
Session Date: Monday, November 8, 2021
Session Title: Osteoporosis & Metabolic Bone Disease – Basic & Clinical Science Poster (1135–1149)
Session Type: Poster Session C
Session Time: 8:30AM–10:30AM

Background/Purpose: Unexplained interruptions in treatment are common among patients with osteoporosis, but it is not well studied how PCP turnover affects incompletion of osteoporosis treatment for the high risk SDH patient population in a CHC setting. We sought to evaluate if provider change, in addition to epidemiologic features and clinical comorbidity, increases risk for the treatment incompletion.

Methods: We defined PCP turnover as a patient having a PCP who has worked at the clinic < 5 years, and treatment incompletion as no treatment or being treated < 3 years with no clear reason for the discontinuation and used Charlson Comorbidity Index (CCI) to assess clinical comorbidity. We used electronic health record (EHR) data from a CHC primary care clinic and identified patients with a diagnosis of osteoporosis who have seen for the last 42 months at the clinic and still alive. The patients who have since established care in another clinic or haven't had a visit for more than 2 years are excluded. The study included 381 patients with 232 identifying as Asian (60.9%), 60 White (15.7%), 59 Black (15.5%), 15 Hispanic (3.9%), 13 Pacific Islanders (3.4%), and other race/ethnicity (0.5%). Average age was 79.9. The study population by sex, preferred language, PCP turnover rate, and CCI score are men(30, 7.9%) vs women(351, 92.1%), Vietnamese(215, 56.4%) vs English(95, 24.9%) vs Spanish(45, 11.8%) vs Cape Verdean Creole(13, 3.4%) vs other language (13, 3.4%), no PCP turnover(228, 59.8%) vs PCP turnover(153, 40.1%), CCI score 1-2(56, 14.7%) vs CCI score 3-4(164, 43%) vs CCI score ≥5 (161, 42.2%).

Results: 25 patients (6.5%) did not complete their osteoporosis treatment. The characteristics of the 25 patients consist of Asian (12, 48%), Black (9, 36%), White (2, 8%), Hispanic (2, 8%) with preferred language of Vietnamese (12, 48%), English (8, 32%), Spanish (3,12%), and Cape Verdean Creole (2, 8%). For PCP turnover, 13 out of 25(52%) patients have not experienced PCP turnover, and 12 patients (48%) have experienced. This cohort's CCI scores are 1-2(3, 20%) vs 3-4(11, 73%) vs ≥ 5(11, 73%). Compared to the patient population at the CHC with osteoporosis diagnoses, relative risk(RR)s for incomplete treatment are ①PCP turnover(RR 1.29, P=0.2) vs no turnover(RR 0.9, P=0.7); ② ethnicity, White (RR 0.54, P=0.3) vs Asian (RR 0.86, P=0.5) vs Black (RR 2.0, P=0.02) vs Hispanic (RR 2.0, P=0.4); ③ language, Vietnamese (RR 0.9, P=0.7) vs Spanish(RR 0.7,P=0.6), vs English (RR 1.2, P=0.5) vs Cape Verdean creole (RR 2.2, P=0.3); ④ CCI score, 1-2(RR 0.84, P=0.7),vs 3-4(RR 1.0, P=1.0)) vs ≥5 (RR 1.0 P=0.9).

Conclusion: Among CHC population of patients with diagnoses with osteoporosis and SDH-related needs, we looked at how PCP turnover, epidemiologic factors and clinical complexity affect treatment incompletion. Patients who experienced PCP turnover are 29% less likely to complete their treatment (RR 1.29). Black and Hispanic population and Cape Verdean Creole speaking patients are at almost doubled risk for treatment incompletion (RR ~2.0). In this study, CCI did not significantly affect Osteoporosis treatment incompletion(R~1.0). These findings highlight the impact of PCP turnover and ethnic difference/language barrier on the incompletion of osteoporosis treatment.

Predictors of Engagement in Bone Health Care Among Rural Veterans at Risk for Osteoporosis

Karla Miller[1], Kimberly McCoy[2], Christopher Richards[2], Aaron Seaman[3] and Samantha Solimeo[4], [1]Department of Internal Medicine, Rheumatology Section, Veterans Affairs Salt Lake City Health Care System; Division of Rheumatology, University of Utah School of Medicine, Salt Lake City, UT, [2]VA Office of Rural Health, Veterans Rural Health Resource Center-Iowa City; Comprehensive Access & Delivery Research and Evaluation, Department of Veterans Affairs, CADRE, Iowa City VA HCS, Iowa City, IA, [3]VA Office of Rural Health, Veterans Rural Health Resource Center-Iowa City (VRHRC-IC); Division of Genera l Internal Medicine, Department of Internal Medicine, University of Iowa Carver College of Medicine, Iowa City, IA, [4]VA Office of Rural Health, Veterans Rural Health Resource Center-Iowa City; Comprehensive Access & Delivery Research and Evaluation; and Primary Care Analytics Team Iowa City (PCAT-IC), Department of Veterans Affairs, CADRE, Iowa City VA HCS Division of General Internal Medicine, Department of Internal Medicine, University of Iowa Carver College of Medicine, Iowa City, IA

SESSION INFORMATION

Session Date: Monday, November 8, 2021

Session Title: Osteoporosis & Metabolic Bone Disease – Basic & Clinical Science Poster (1135–1149)

Session Type: Poster Session C

Session Time: 8:30AM–10:30AM

Background/Purpose: A virtual bone health team (BHT) model was implemented to identify, screen, and treat rural Veterans at risk for osteoporosis. This study was conducted to identify social determinants of health and clinical factors associated with osteoporosis screening through enrollment in the BHT clinic and with osteoporosis medication initiation among those with a treatment indication.

Methods: Eligibility for BHT included: ages 50 to 99; enrollment in VA primary care; and either medication, age, or osteoporosis self-assessment tool score- based risk. A cross-sectional cohort design was utilized with a generalized estimating equation (GEE) and logit link function to account for facility-level clustering. Fully saturated and reduced models were fit using backward selection. Given population size and high percentage of medication initiators, contingency tables were constructed, and the Fisher's exact test was performed to understand medication initiation.

Results: The cohort comprised 6985 rural Veterans. Twenty-two percent accepted dual-energy X-ray absorptiometry (DXA) and were male (94%), white (95%), and married (69%), with a mean age of 76 (Table 1). Multivariate models suggest that age, distance from VA services, race, marital status, co-payment, prior fracture, or history of rheumatoid arthritis are significantly associated with DXA acceptance (Table 2). Of those with indication for medication (N=453), most were male and white, with mean age of 77 (Table 3). Few had prior DXA or osteoporosis medication, one-third had prior corticosteroid use. Fisher's exact test results suggest that a history of 2 or more falls in the prior year, current smoking, weight-bearing exercise, and parental history of hip fracture are all associated with osteoporosis medication initiation.

Sociodemographic and Clinical Characteristics of Eligible Veterans by Decision to Enroll

Conclusion: The BHT model facilitated DXA for rural Veterans at their nearest VA or non-VA facility, but cost and travel remain barriers to DXA in addition to other social determinants of health such marital status, race, and gender. Some known osteoporosis risk factors were associated with lower acceptance of DXA. Age, distance, marital status, and race were not associated with medication initiation, while the proportion of rural Veterans with a history of falls or smoking was greater for those who initiated medication. Further efforts are needed to gain insight into how clini-

Abstract Number: 1144

Underestimation of the Fracture Risk by the FRAX Formula in Chronic Glucocorticoid Users: A 10-year Longitudinal Validation Study

Chi Chiu Mok[1], Ling Yin Ho[2], Sau Mei TSE[2] and Kar Li Chan[3], [1]Tuen Mun Hospital, Hong Kong, China, [2]Tuen Mun Hospital, Hong Kong, Hong Kong, [3]Tuen Mun Hospital, Hong Kong

SESSION INFORMATION
Session Date: Monday, November 8, 2021
Session Title: Osteoporosis & Metabolic Bone Disease – Basic & Clinical Science Poster (1135–1149)
Session Type: Poster Session C
Session Time: 8:30AM–10:30AM

Background/Purpose: To compare the actual fracture incidence over 10 years in a longitudinal cohort of patients using glucocorticoids (GCs) with the risk prediction from FRAX (fracture risk assessment tool).

Methods: Adult patients who attended our out-patient rheumatology clinics between 2007 and 2009 who had underlying rheumatic diseases requiring prednisolone treatment (≥5mg/day) and had a DXA scan performed were included. The predicted rates of major osteoporotic and hip fractures were estimated using FRAX (China database) based on the clinical data at the time of DXA, with adjustment when daily dose of prednisolone ≥7.5mg according to the ACR recommendation. The actual observed incidence of symptomatic vertebral and non-vertebral fractures at 10 years (in years 2017-2019) follow-up was retrieved by medical record review and compared with the estimated rates by FRAX. Factors associated with symptomatic clinical fractures at 10 years were studied by logistic regression.

Results: 89 patients were studied (age 49.3±8.8 years at DXA examination; 98% women). The underlying rheumatic diseases were systemic lupus erythematosus (69%), rheumatoid arthritis (17%) and others (14%). The mean daily dose of prednisolone at baseline was 7.7±6.5mg (38% patients had daily dose ≥7.5mg). History of personal fracture was present in 4(4.5%) patients and 22% of female patients had menopause before the age of 45 years. The mean body mass index (BMI) was 23.5±3.3kg/m^2 (4.5% ≤18kg/m^2). Osteoporosis (bone mineral density [BMD] T score ≤-2.5) of the hip, femoral neck and lumbar spine occurred at a frequency of 11.2%, 13.5% and 25.8%, respectively at baseline (32% at any of the 3 sites). 30(34%) patients received anti-osteoporotic treatment (oral bisphosphonates in 25, raloxifene in 3 and denosumab in 2 patients). The estimated mean 10-year risk of major osteoporotic and hip fractures using the BMD data and other risk factors in the FRAX formula, adjusted for prednisolone dose, was 4.3% and 1.0%, respectively. After a follow-up of 10 years, one patient had a hip fracture, 3 patients had humerus fractures and 9 patients had symptomatic vertebral fractures. The actual observed major osteoporotic and hip fracture incidence was 14.6% and 1.1%, respectively (0.146 and 0.011 per 10 patient-years). The observed major clinical fracture rate was significantly higher than that estimated by FRAX (14.6% vs 4.3%; p=0.04). Logistic regression revealed that the only factor independently associated with major clinical fracture at 10 years was BMD T score ≤-2.5 at spine, hip or femoral neck at baseline (OR7.11[1.73-29.2]; p=0.007). Age, prednisolone daily dose, BMI, history of fracture, chronic smoking, having underlying SLE vs not and early menopause were not significantly associated with new clinical fractures.

Conclusion: Despite adjustment for prednisolone dosage, the FRAX formula underestimates the major clinical fracture risk in patients using long-term GCs. The deleterious effect of GCs on bone quality, high proportion of SLE patients, disease activity and use of additional doses of GCs and other immunosuppressive drugs during follow-up are among the contributing factors for this underestimation.

Prevalence of and Risk Factors for Vertebral Fractures and Low Bone Mass Density Among Women Aging with HIV in Peru

Diego Cabrera[1], Mijahil P. Cornejo[2], Rebecca Slotkin[3], Yvett Pinedo[4], Wei Yu[5], Wenmin Guan[5], Patricia J. Garcia[6] and Evelyn Hsieh[7], [1]Yale School of Medicine, Lima, Peru, [2]Grunenthal peruana, Lima, Peru, [3]Yale New Haven Hospital, New Haven, CT, [4]Hospital Nacional Arzobispo Loayza, Lima, Peru, [5]Department of Radiology, Chinese Academy of Medicine Sciences and Peking Union Medical College Hospital, Beijing, China (People's Republic), [6]Universidad Peruana Cayetano Heredia, Lima, Peru, [7]Yale School of Medicine, New Haven, CT

SESSION INFORMATION

Session Date: Monday, November 8, 2021

Session Title: Osteoporosis & Metabolic Bone Disease – Basic & Clinical Science Poster (1135–1149)

Session Type: Poster Session C

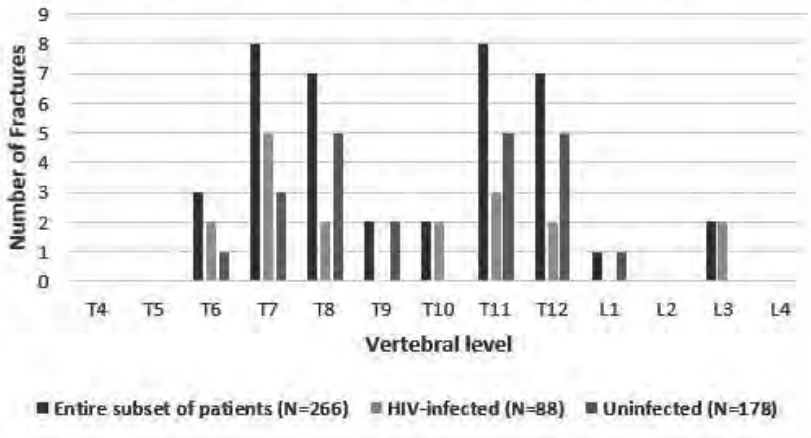
Session Time: 8:30AM–10:30AM

Background/Purpose: Few studies in Latin America and the Caribbean have evaluated osteoporosis and fracture epidemiology among populations at increased risk for secondary osteoporosis, such as women with HIV. We aimed to explore the prevalence of vertebral fracture (VF) and low bone mineral density (BMD) among women aging with HIV in Peru, in order to identify risk factors for osteoporosis and fracture in this population.

Methods: We enrolled HIV-infected and uninfected women aged ≥40 years from a large HIV clinic in Lima, Peru between October 2019 and March 2020. All participants completed a survey regarding sociodemographic, clinical and fracture-associated risk factors, and obtained a dual X-ray absorptiometry (DXA) scan to assess BMD at the lumbar spine, femoral neck and total hip. A subset of patients also obtained lateral thoracolumbar X-rays. Presence of VF was determined using the Genant semiquantitative method. Linear and logistic regression analyses were used to model associations between key risk factors and BMD at each site.

Results: A total of 104 HIV-infected and 212 uninfected women were enrolled with a mean age of 52.4±8.2 and 56.4±8.8 years ($p< 0.001$) and BMI of 26.4±5.1 and 27.6±4.1 kg/m^2 ($p=0.03$), respectively. Among postmenopausal women (257/316, 81.3%), 26.3% of HIV-infected and 25.9% of uninfected had osteoporosis. Among the subset of 88 HIV-infected and 178 HIV-uninfected who obtained thoracolumbar x-rays, 12.5% and 6.2% respectively had at least one VF. Both of these comparisons were not statistically significant. The mean 10-year FRAX risk of major osteo-

Figure. Counts of fracture by vertebral level



porotic fracture and hip fracture was 2.65% and 0.59% among women with HIV. Based on DXA and the FRAX score, 22/104 HIV-infected women met criteria for osteoporosis treatment according to national guidelines, however, none were on treatment. Unadjusted logistic regression analysis among the pre and postmenopausal HIV-infected showed that age ($p< 0.001$), postmenopausal status ($p=0.04$) and years of antiretroviral therapy ($p=0.05$) were predictors for lower BMD. Adjusted linear regression analysis showed that BMD was negatively correlated with older age and positively correlated to higher BMI.

Conclusion: In this study, HIV-infected women had increased VF prevalence compared to the slightly older uninfected group. Age and BMI were independent predictors for BMD at the lumbar spine, hip and femoral neck among women with HIV, and there was a treatment gap among osteoporosis diagnosed women. Larger prospective studies are needed in this region to identify individuals at risk for fracture and to inform prevention guidelines.

Study of Vertebral and Femur Fracture Prevalence and Scanographic Bone Attenuation Coefficient of the First Lumbar Vertebra in an Academic Hospital Setting

Zareen Vaghaiwalla[1], Paul Wasserman[1] and Gurjit Kaeley[2], [1]University of Florida College of Medicine Jacksonville, Jacksonville, FL, [2]University of Florida, Jacksonville, FL

SESSION INFORMATION
Session Date: Monday, November 8, 2021
Session Title: Osteoporosis & Metabolic Bone Disease – Basic & Clinical Science Poster (1135–1149)
Session Type: Poster Session C
Session Time: 8:30AM–10:30AM

Background/Purpose: Patients with osteoporosis are prone to suffer fragility fractures leading to an increased risk of future fractures. Detection of osteoporosis has been led by dual energy-ray absorptiometry (DEXA) as the gold standard. However, in acute fracture incidents, DEXA imaging is typically unavailable, and treatment is often delayed. In recent years scanographic bone attenuation coefficient of the first (SBAC-L1) on incidental computed tomography (CT) scans of the lumbar spine has been utilized as an alternative assessment of bone density. In particular, SBAC-L1 $\leq$ 145 HU correlates with osteoporotic bone density on DEXA imaging.

This study aims to assess the SBAC-L1 in HU of incidental CT scans in patients presenting with vertebra or femur fragility fractures in an academic hospital as it relates to osteoporosis.

Methods: We conducted a retrospective chart review of patients aged $\geq$ 45 admitted to an academic hospital for active vertebral or femur fracture between 1/1/2017- 1/31/2019, excluding traumatic and pathological fractures. Measurement of SBAC-L1 in HU was obtained on incidental CT scan imaging. Sex, race, prior and post diagnoses of osteoporosis, prior and post DEXA scan orders, use of calcium, vitamin D, and steroids were abstracted.

Results: There were 297 patients with vertebral or femur fractures from 1/1/2017- 1/31/2019. Of 297 patients, 85 deemed appropriate after excluding pathological, traumatic fractures, and lack of CT scan on the admission for fracture.

	Total Patients [n=85]	Caucasian Patients [n=67]	AA Patients [n=16]	Male Patients [n=31]	Female Patients [n=54]

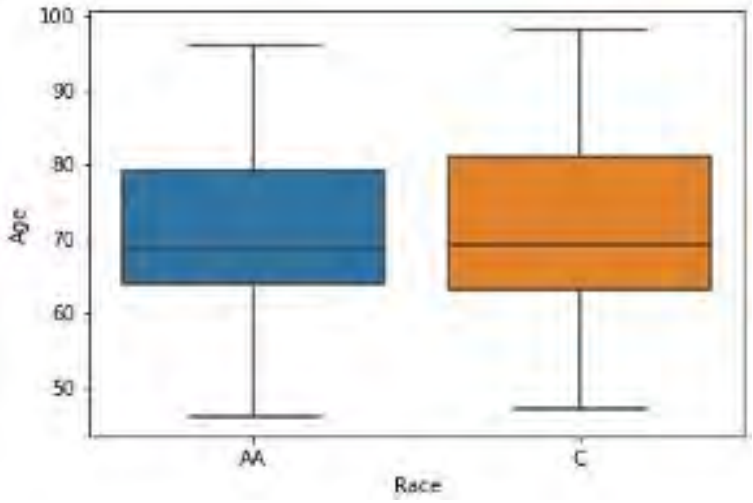
DEXA after	7	4	1	2	5

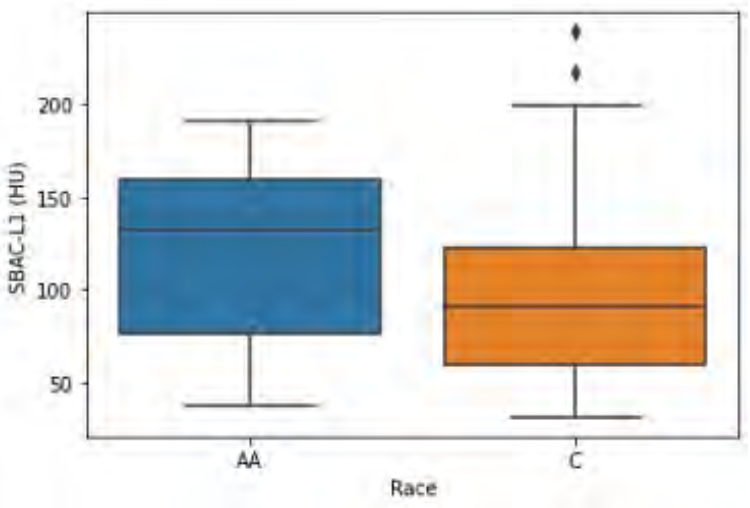
Study Characteristics



Comparison in Age for African American (AA) patients and Caucasian (C) patients

Average SBAC-L1 for all patients was 100.4 ± standard deviation (SD) of 46.5 HU. 82% of all patients had SBAC-L1 ≤ 145 HU. Caucasian patients had a lower average SBAC-L1 [99.4 HU] than African American (AA) patients [122.1 HU]. More Caucasian [n=15] had prior diagnoses of osteoporosis than AA [n=2]. Caucasian patients were prescribed Calcium and Vitamin D more often [n=39] than AA [n=3]. DEXA scan orders were placed more often in Caucasian patients [n=4] than AA patients [n=1]. Osteoporosis medications were prescribed more often in Caucasian patients [n=8] than AA patients [n=0].

Male average SBAC-L1 was 97.4 HU compared to females at 106.3 HU. Females were prescribed calcium and vitamin D more often [n=38] than males [n=8]. DEXA scan orders were placed more frequently in females [n=5] than males [n=2]. Osteoporosis medications were prescribed more often in females [n=9] than male patients [n=0].



SBAC- L1 (HU) in African American (AA) and Caucasian (C) races

Conclusion: 70 of 85 patients with incidental fragility fractures exhibited SBAC-L1 ≤ 145 HU. This is consistent with osteoporotic bone density on DEXA imaging supporting the use of SBAC-L1 measurement to corroborate the diagnosis osteoporosis. SBAC-L1 ≤ 145 HU can be utilized to increase inpatient diagnostic confidence of osteoporosis in the setting of acute fragility fractures to allow initiation of treatment prior to awaiting outpatient DEXA imaging.

The results here also highlight health disparities present among African Americans and males of all races when considering bone health.

Abstract Number: 1147

Therapeutic Inertia and Low Patient Compliance: Major Contributors to Low Treatment Rates in Patients with Osteoporosis with Clinical Vertebral Compression Fractures

Shiva Malaty, Paramvir Sidhu, Rustan Sharer and Soo Yeon Kim, HonorHealth Internal Medicine Residency, Scottsdale, AZ

SESSION INFORMATION
Session Date: Monday, November 8, 2021
Session Title: Osteoporosis & Metabolic Bone Disease – Basic & Clinical Science Poster (1135–1149)
Session Type: Poster Session C
Session Time: 8:30AM–10:30AM

Background/Purpose: Treatment rates with pharmacologic therapy after osteoporotic vertebral fracture are very low in the United States. Underlying causes of these low treatment rates are poorly understood. Poor communication between acute care teams and primary care providers (PCP), a lack of acknowledgement of vertebral compression fracture as an osteoporotic fragility fracture by PCPs, and a reluctance by patients to start therapy due to concerns regarding side effects have been proposed as possible driving factors. The objective of this study was to define major underlying causes of low treatment rates of osteoporosis in patients with clinical vertebral fractures in our community.

Methods: Medical records of 862 patients seen for new-onset clinical vertebral fractures were retrospectively analyzed to determine if a diagnosis of osteoporosis was recognized by the PCP and if appropriate pharmacotherapy was initiated by the PCP once a diagnosis of osteoporosis was recognized. Subsequent PCP visit records were analyzed to determine if patients started therapy once prescribed.

Results: Total of 862 patients were seen at our health system for new clinical vertebral fractures in the year 2020. A majority of these patients (615 =71%) were seen by their PCP for clinic follow-up within six months of the fracture. PCPs recognized occurrence of clinical vertebral compression fracture in the interim and diagnosed patients with osteoporosis in most cases, (595 patients =96%). However, less than half of these patients (254=40%) were started on pharmacologic treatment for osteoporosis by their PCP. Of the patients that were prescribed this treatment, less than half (105 =41%) decided to proceed with this treatment resulting in an overall treatment rate of around 12 percent at six months of follow up.

Conclusion: Despite regular identification of vertebral compression fractures, therapeutic inertia by PCPs and low compliance by patients were the most important factors contributing to low treatment rates for osteoporosis after these clinical vertebral fractures were identified in this population.

Prevalence and Risk Factors of Insufficiency Fractures of the Foot and Ankle Joint in Rheumatic and Musculoskeletal Diseases

Bjoern Buehring[1], Nadine Al-Azem[1], Ioana Andreica[1], David Kiefer[2], Uta Kiltz[1], Styliani Tsiami[1], Xenofon Baraliakos[1] and Juergen Braun[1], [1]Rheumazentrum Ruhrgebiet Herne, Ruhr-Universität Bochum, Herne, Germany, [2]Rheumazentrum Ruhrgebiet Herne, Ruhr-Universität Bochum, Essen, Germany

SESSION INFORMATION
Session Date: Monday, November 8, 2021
Session Title: Osteoporosis & Metabolic Bone Disease – Basic & Clinical Science Poster (1135–1149)
Session Type: Poster Session C
Session Time: 8:30AM–10:30AM

Background/Purpose: Unlike fragility fractures, high-trauma and insufficiency fractures (IF) are not classically considered osteoporotic fractures. Patients with rheumatic and musculoskeletal diseases (RMD), especially those with rheumatoid arthritis (RA), are at increased risk of IF due to factors associated with reduced bone quality including chronic inflammation, medication, and altered biomechanics. IF frequently occur in ankle joints and feet. These fractures are often not detected in conventional radiographs, magnetic resonance imaging (MRI) is thought to be more sensitive.

The aim of this study was (i) to determine the frequency of IF in symptomatic ankles and feet of patients presenting to a tertiary hospital, to (ii) identify possible risk factors and (iii) to compare the IF detection rate of radiographs and MRI.

Methods: Using a retrospective study design, data of patients who had undergone MRI scans of the ankle/foot region between 2016 and 2018 were analyzed. Patients with IF were matched with 2 control subjects based on sex, age, and diagnosis and pertinent data was extracted from their medical records. Statistical analyses included T tests, chi-square tests, and regression analyses.

Patient demographics

		Group			
		Insufficieny fracture (A)		Control (B)	
		Column N %	Mean	Column N %	Mean
Sex	female	82,9%		80,8%	
	male	17,1%		19,2%	
Age (years)			58,59		57,72
BMI			28,03		29,67 A
Illness	RA	42,6%		46,3%	
	PsoA	16,3%		18,8%	
	other CIRD	21,7%		19,7%	
	non-CIRD	19,4%		15,3%	
Current glucocorticoids	yes	48,1%		44,5%	
	no	51,9%		55,5%	
MTX	yes	42,6% B		27,9%	
	no	57,4%		72,1% A	
Smoking	yes	37,2% B		23,1%	
	no	62,8%		76,9% A	
Osteoporosis	yes	42,6% B		16,2%	
	no	57,4%		83,8% A	
Lowest T-score			-1,78		-1,20 A
History of fracture	yes	34,9% B		8,8%	
	no	65,1%		91,2% A	

Results are based on two-sided tests. For each significant pair, the key of the category with the smaller column proportion appears in the category with the larger column proportion.
Significance level for upper case letters (A, B, C): ,05 [1]

1. Tests are adjusted for all pairwise comparisons within a row of each innermost subtable using the Bonferroni correction.

Patient demographics BMI - body mass index, RA - rheumatoid arthritis, PsoA - psoriatic arthritis, CIRD - chronic inflammatory rheumatic disease, MTX - methotraxate

Results: In a total of 1471 foot and 281 ankle joint MRIs, 129 (7.4%) IF were detected. The mean age of patients with IF was 59 years, 82.9% were women. Among patients with IF 80,6% had a chronic inflammatory rheumatic disease (CIRD) which was significantly more frequent than non-CIRD diseases (19,4%, p< 0,001). Potential risk factors for IF were: low bone density indicative of osteoporosis (IF 42.6% vs. controls 16.2%, p< 0.001), history of previous fracture

(34.9% vs. 8.6%, p< 0.001), smoking (37.3% vs. 23.1%, p=0.005) and current methotrexate (MTX) therapy (42.6% vs. 27.9%, p=0.005). Of the 96 (74.4%) IF patients who also had x-rays of the ankle/foot region, 24 (25%) had an IF diagnosis in the x-ray report.

Conclusion: With a frequency of 7.4%, IF are a relatively common cause of foot/ankle pain in patients with RMD who underwent MRI after presenting to a tertiary rheumatology hospital. Risk factors for IF largely corresponded to established risk factors for osteoporosis. The potential negative influence of MTX needs further research. Future studies should investigate whether the occurrence of IF represents an indication for anti-osteoporotic therapy and whether such treatment improves fracture healing and lowers the risk of future fractures.

Abstract Number: 1149

Efficacy of Alendronate for Prevention of New Fractures and Vertebral Deformities in Patients with Rheumatologic Disorders on Chronic Glucocorticoid Therapy: A Systematic Review and Meta-analysis

Saffa Iftikhar[1], Waleed Khokher[2], Ashu Acharya[1], Joan Gekonde[3], Nithin Kesireddy[2], Rawish Fatima[1] and Nezam Altorok[2], [1]University of Toledo Medical Center, Toledo, OH, [2]University of Toledo, Toledo, OH, [3]University of Toledo, Sylvania Township, OH

SESSION INFORMATION
Session Date: Monday, November 8, 2021
Session Title: Osteoporosis & Metabolic Bone Disease – Basic & Clinical Science Poster (1135–1149)
Session Type: Poster Session C
Session Time: 8:30AM–10:30AM

Background/Purpose: Glucocorticoids are commonly used in patients with rheumatologic conditions including but not limited to Rheumatoid Arthritis, Polymyalgia Rheumatica, Systemic Lupus Erythematous and so on. There is increased rate of bone resorption after the first few months of initiating glucocorticoid therapy. The risk of bone fractures increase before a decrease in bone mineral density is observed. One of the most common side effects include new fractures and vertebral deformities. Interventions to reduce the risk of fractures involve the use of Alendronate. Alendronate is a bisphosphonate that works by inhibiting the osteoclast mediated bone resorption. It is important to study the benefit of Alendronate on fractures and vertebral deformities in patients who are on long term steroid therapy.

Methods: We conducted a systematic review and meta-analysis of studies that investigated the efficacy of Alendronate for prevention of new fractures and vertebral deformities. We performed a comprehensive search of PubMed/MEDLINE, Embase, and the Cochrane Central Register of Controlled Trials from 2006-2016. We considered randomized control trials. We excluded abstracts, animal studies, case reports, reviews, editorials, cohort studies, case-

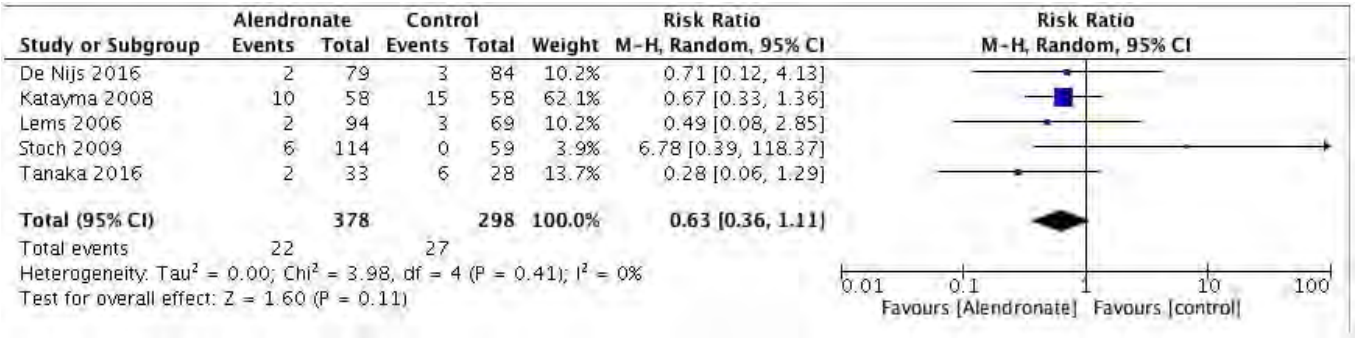

Figure 1.1 Forest plot - Rates of fracture when using Alendronate versus Control.

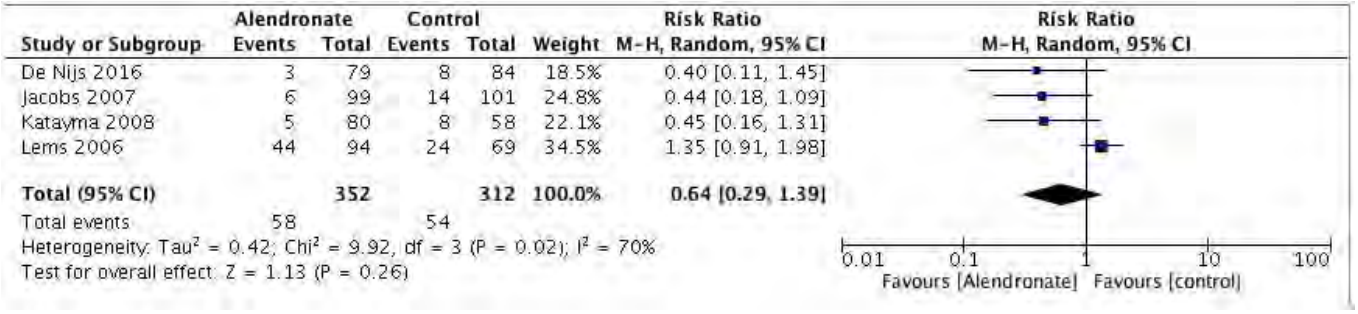

Figure 1.2. Forest Plot- Rate of Vertebral Deformities in Patients with Alendronate versus Control.

control studies, case series and letters to editors. From each study, we collected the number of patients who received Alendronate and other forms of bone protective measures including vitamin D and calcium. The primary outcome was the rate of new fractures. The secondary outcome was rate of vertebral deformities. The random-effects model was used to calculate the risk ratios (RR), mean differences (MD), and confidence intervals (CI). A p value < 0.05 was considered statistically significant. Heterogeneity was assessed using the Higgins I^2 index.

Results: Six randomized control involving 898 patients were included in the meta analysis. Five studies showed that there was no significant difference in the rate of new fractures between the Alendronate group in comparison to the control group (5.8% vs. 9.06% ;RR 0.63, 95% CI 0.36-1.11, p=0.11, I^2 = 0%). Four studies were analyzed to assess for new vertebral deformities in patients receiving Alendronate versus control. There was no significant difference between the rate of vertebral deformities between the two groups (16.5% vs. 1.6%; RR 0.64, 95% CI 0.29-1.39, p=0.26, I^2 = 70%).

Conclusion: Our meta-analysis demonstrated that the use of Alendronate versus control in patients with rheumatologic conditions on chronic prednisone therapy, did not display any significant reduction in new fractures and vertebral deformities. Further randomized control trials with larger sample sizes are needed to confirm our findings.

Abstract Number: 1150

Use of Energy Conversation Strategies as a Result of the Fatigue Management Education for Individuals with Systemic Sclerosis (FAME-iSS)

Janet Poole[1], Deirdre Connolly[2] and Kristine Carandang[3], [1]University of New Mexico, Albuquerque, NM, [2]Trinity Centre for Health Sciences, Dublin, Ireland, [3]Independent, San Diego, CA

SESSION INFORMATION
Session Date: Monday, November 8, 2021
Session Title: Patient Education/Community Programs Poster (1150–1152)
Session Type: Poster Session C
Session Time: 8:30AM–10:30AM

Background/Purpose: Fatigue remains an understudied symptom of systemic sclerosis (SSc). For other diagnoses, increasing the use of energy conservation strategies, especially pacing. has been associated with reduction in fatigue. The purpose of this ongoing study is to understand the use of energy conservation strategies after participation in a new program, Fatigue and Activity Management Education for Individuals with Systemic Sclerosis (FAME-iSS).

Methods: Adult participants were recruited from the Scleroderma Foundation chapters to participate in a 6-week, virtual, occupational therapist-led group program focused on SSc-related fatigue. Eligible participants had a minimum score reflecting moderate to high fatigue experienced, severity, and distress (scales: 1-10). At baseline, participants completed a demographic questionnaire, the Self-Efficacy for Performing Energy Conservation Strategies Assessment (SEPESCA) to measure their confidence in their ability to use energy conservation strategies. At post-intervention and 3-month follow-up, participants also completed the Energy Conservation Strategies Survey to identify use and effectiveness of 14 energy conservation strategies (e.g. changing body positions, planning and prioritizing, communicating needs) and a qualitative interview to contextualize their responses. Descriptive statistics were analyzed; medians and ranges for assessment scores are reported.

Results: Preliminary analysis includes four participants (75% White women; 51.8±12.1 years old) with established SSc (disease duration= 12±8.0 years). All participants completed 100% of FAME-iSS sessions. At post-intervention, all energy conservation strategies were being used by at least 50% of participants, and 7/14 strategies were being used by 75% of participants. Participants perceived effectiveness of strategies as high [8 (3-10)]. The most common cited reason for not adopting a new strategy after the intervention was that it was already in use (17/21 items; 81%). At 3-month follow-up, 11/14 strategies were used by at least 50% of participants, and 5/14 strategies were used by 75% of participants. Perceived effectiveness slightly decreased [7 (2-10)]. While not statistically significant, participants trended toward improved self-efficacy scores for energy conservation strategies (baseline: 8.3 (5.4-8.0); post-intervention: 9.2 (8.3-9.2); 3-month follow-up: 9.6 (4.4-10)]. Participants qualitatively reported that FAME-iSS led to the sharing of new fatigue management strategies and increased attention to their daily activities.

Conclusion: Despite longer disease duration and familiarization with self-management strategies, participants with SSc experienced persistent and disruptive fatigue symptoms. Following completion of FAME-iSS, participants with established SSc adopted new behaviors that they perceived to effectively reduce fatigue. A second round of the intervention is in progress to diversify the participant sample and continue assessing the relationship between FAME-iSS, energy conservation strategies, and quality of life constructs.

Table 1. Patients' Experiences of Living with Lupus

Theme	Subtheme	Quote
Lived Experiences	Before & after lupus	*"I have this disease too, and it makes me sad that I used to be very active, and now it's tough for me to do my activities. I have systemic lupus erythematosus and other health issues that come with it. I follow my treatment faithfully. Five years in remission, ten years since the diagnosis. It took a lot of work, but I made it. I've gone through several stages over the years, from fear, anguish, uncertainty, and finally acceptance."*
		"It hits you hard at first, and it's a condition they don't know much about, but I've learned to stop seeing it as my enemy, and little by little, I've been learning to live with lupus. It's true that it's not easy, but it's also true that if you follow the recommendations, change your lifestyle a bit and take care of yourself, you can lead a reasonably normal life."
	Good and bad days: Fluctuation and uncertainty	*"I've had lupus for eight years. I've gone through highs and lows; up until now, I'm fine, and I can say that I've fought it off twice. It's not just any disease; you suffer a lot, you can't lead a normal life like before, you can't have a good quality of life, but I fall, and I get back up again to keep going for my children. The only advice I can give is that you need to push forward without turning back and that you need to become friend with the disease because that's how you can overcome everything that lupus, "THE WOLF THAT ATTACKS YOU," deals you."*
		"There are days when I have lots of energy and other days when the pain in my legs and joints doesn't let up–that's when I think I can't take it anymore. I'm a very positive person, but there are days the pain is overwhelming, and you don't want to get out of bed, and it's depressing, and worst of all, people think it's not that big of a deal."
	The bodily experience of lupus	*"I went through some really tough times; in my case, it [lupus] affected everything, the only thing it didn't affect were my kidneys; I went through a lot, my lupus was pretty aggressive, all my hair fell out."*
		"It's an immune disorder; in other words, the person's own body is attacking itself; it's painful, there are times when it shows up on your face, you can have intense swelling in your legs or feet; other times it attacks the brain, it swells, and that's where it all ends."
	The invisibility of lupus	*"Some people think I'm pretending to be sick, not to work when I feel weak or get dizzy spells out of nowhere. Some people don't understand what I'm going through because they're not in my shoes. I hope these people go through what I'm going through; sooner or later, everything that goes around comes around in this life."*
		"I feel so alone; my husband says there's nothing wrong with me... Dozens of studies have proven otherwise, but I think he's already fed up with me."
	Hope	*"I've had SLE for almost 30 years, now in remission; it affected my nervous system, joints, sight, hearing, and skin. I can hardly walk, the nerves on my left side are damaged. I have very bad days, those days I try to beat the disease, and when they're not so bad, I try to enjoy those days to the fullest. I think without a doubt that my faith in GOD and the support of my family, my husband, and daughters, are what give me strength on the worst days to hope against hope that I'll be better."*

All quotes were extracted from public comments written in Spanish. Quotes were further translated to English by one of the authors (IPB) and independently proofread by a native English-speaker women with a diagnosis of lupus, and a native English-speaker physician (EC) who is fluent in Spanish.

SESSION INFORMATION

Session Date: Monday, November 8, 2021

Session Title: Patient Education/Community Programs Poster (1150–1152)

Session Type: Poster Session C

Session Time: 8:30AM–10:30AM

Background/Purpose: SLE disproportionately affects Latin Americans, and outcomes are worse amongst them compared to non-minority populations. Understanding patients' views of living with SLE is critical to provide proper care and inform culturally competent self-care education programs. However, little is known about illness experiences and perspectives among Latin Americans with lupus. This qualitative study describes the lived experiences and perceived meanings regarding lupus, which have been shared by Latin American patients and their relatives on an open Facebook page.

Methods: Let's Talk About Lupus (*Hablemos de Lupus*) is a public Facebook page that provides reliable and culturally competent education to Spanish speakers living with lupus. Launched in May 2017, the page has gathered nearly 100,000 followers by May 2021. Users often share their stories, questions, and thoughts organically with peers and a team of rheumatologist educators. For this study, we used the Facepager application to extract de-identified narratives posted as a reaction to the most popular resources published within the first 2 years (6 animated videos and 6 patients' testimonials). We conducted a thematic analysis using ATLAS.ti v8, with further triangulation to verify concordance and aid in an interpretative medical anthropology framework.

Table 2. Meanings of Living with Lupus

Theme	Subtheme	Quote
Religious & spiritual thoughts	Grateful to God	*"My life [goal of living] with lupus is to enjoy the moments when I'm well, and I thank God and life for one more day; sometimes, I fall into the deepest darkness, and it seems impossible to move forward. God, the universe, life, gives me another chance, and I am thankful for every moment of my life!!!!!."*
		"... I have lupus; they've just diagnosed it... It was a really difficult process for me; my life changed entirely overnight, but thanks to Jehovah God, who has given me strength and trust in Him, right now I'm doing very well; I lead a normal life, I'm still working, taking my treatment as I should and am grateful to Jehovah God for one more day of life."
	Lupus control by God	*"I've had this disease for over ten years; it's become a part of me, and I have so much faith in God that I feel healthy because only He has control of everything. [I] Put this disease in His hands, and you'll see that everything will be better... I don't even take treatment anymore."*
Metaphors	The purple butterfly	*"Not long ago at night, a dark butterfly stopped at my window. One just like the butterfly my friends with lupus put on their logos and posters to indicate that there, under that poster or inside the purple butterfly T-shirt, there is a survivor (because that's what you do when you have lupus) who wants to go on, who's strong, who loves and dances and runs even if her body and science tell her that she can no longer do so. Well, let's say that sometimes I'm like this, a bit, like the dark butterfly who has lost her way, who turns and turns until she lands on someone's leg asking for help because, in confusion, she doesn't remember and feels that she has nothing left but to trust... She'll just readjust and then go on with her flight, and we have to keep being happy and live each day as if it were the last, so seize the day, keep fighting warrior, butterfly."*
	Not belonging	*"I have that "curse" sometimes it [the disease] punishes me a lot, sometimes it lets up... you have to push through day to day!!!"*
	Bellicose discourse	*"Today I feel strong, with the attitude of an implacable warrior, yearning for victories, every battle won strengthens my spirit. I continue the struggle; every day, I learn to endure it with hope and attitude."*
Heredity	Genetic/ hereditary disease	*"No one in my town knew how to take care of my brothers. I lost three of them and my mother when I was five. Ours is genetic. But I came to the capital [city] and with [the help of] immunologists and different studies, and controls you can have a good life..."*
Experience by Family & Friends	Compassion	*"As a mother, I can tell you that it's horrible to see your daughter with this condition since there's no cure, and I have nothing but admiration for my daughter; she hardly complains at all and has been sick."*

All quotes were extracted from public comments written in Spanish. Quotes were further translated to English by one of the authors (IPB) and independently proofread by a native English-speaker women with a diagnosis of lupus, and a native English-speaker physician (EC) who is fluent in Spanish.

Results: We analyzed 1717 independent comments. Five core themes emerged: lived experiences of lupus (Table 1), religious/spiritual thoughts, lupus metaphors, lupus heredity, and family/friends' experiences (Table 2). Being diagnosed with lupus is perceived as a life-changing event. The fluctuating course of the disease causes uncertainty among patients, and the perception of invisibility within the patient's social circle generates feelings of being misunderstood. Faith and spiritual thoughts are used to cope with living with lupus. Patients use metaphors to communicate the disease's meaning and their lived experiences (e.g., the purple butterfly, not belonging, a hidden enemy, and bellicose discourse). The lupus experience extends to the family, and relatives are negatively impacted by their loved one's suffering.

Conclusion: Latin American patients experience lupus as an unpredictable condition that brings about suffering trajectories to patients, relatives, and friends. Inheriting lupus is a concern shared by patients and families. Patients use metaphoric language to foster empathy and sympathy within their social context. Metaphors are also used to overcome the challenges in communicating the illness experience, which many perceive as an 'invisible illness.' Religion is as important as medical treatment in coping with the disease. These findings can be used to improve physician-patient communication and public health campaigns to serve Latin Americans with lupus.

Abstract Number: 1152

A Follow-Up Evaluation of a Longstanding Telephone Peer Counseling Service for People with Systemic Lupus Erythematosus and Their Loved Ones

Priscilla Toral, Roberta Horton and Jillian Rose, Hospital for Special Surgery, New York, NY

SESSION INFORMATION
Session Date: Monday, November 8, 2021
Session Title: Patient Education/Community Programs Poster (1150–1152)
Session Type: Poster Session C
Session Time: 8:30AM–10:30AM

Background/Purpose: With technology rapidly evolving, studies still reinforce the value of telephone peer support for people living with chronic illness. A follow-up evaluation was conducted with participants of a national phone peer counseling service. Ongoing since 1988, this service provides emotional support & education for people with SLE & their loved ones. The program's evolution has been presented at prior ACR meetings, including the psychosocial impact of the service on the volunteers themselves.

Methods: A 62-item online survey, with Likert scale & open-ended questions was administered to callers who used the service for > 6 months during 2020-2021.The survey assessed overall satisfaction & impact, including the relationship/satisfaction with the peer counselor match. Other areas assessed included specific changes in feelings & actions taken as a result of the service.

Results: Of 43 users outreached to, 29 (67%) completed the survey. Most (89%) respondents were female, 28% identified as Black/African-American, 40% White, 23% Hispanic & 20% some other race. Callers' ages ranged from 30-80 with 78% ages 30-59. 52% were employed/self-employed & 19% were unable to work. All respondents had SLE mean year since diagnosis was 12.

Almost all (93%) identified emotional support & coping/SLE management as their initial reasons for calling. When asked about initial expectations of their counselor, callers shared “to gain information & receive emotional support.” Most callers (86%) agreed these expectations were met. When asked how their peer counselor met these expectations, participants shared: “non-judgmental & knowledgeable about SLE”. About half (45%) had > 12 calls with their peer counselor; 97% were very satisfied/satisfied with their match.

Regarding coping, 82% indicated they have coped better with their SLE since using the service & 74% agreed they had a better understanding of SLE. When asked about depression, 59% reported feeling less depressed since joining the service with most callers (81%) crediting the service for this change. Regarding anxiety, 70% reported feeling less anxious since using the service with 74% attributing this to the program. Most (89%) reported feeling less isolated with 78% crediting this to the service.

Over half (60%) indicated their communication with their doctor improved since using the service & 73% attributed this to the program. When asked about the single most helpful part of using the service responses included: “being connected to someone with lived experience with SLE” & “the consistency of the counselor & supervisor.” Almost all (96%) would recommend the service & 92% indicated they are very satisfied/satisfied with the service overall.

Conclusion: Despite limitations of a small sample size, results indicate ongoing satisfaction & positive impact, with slight increases since last evaluation in overall service satisfaction & peer match. Results point to the continued benefit of an accessible telephone support service that connects people with SLE & their loved ones to trained peers. The study highlights further opportunities for research on the impact of phone peer model programs, as traditional in person support forums are limited due to the pandemic.

The Influence of Companions on a Patient’s Decision to Transition to a Biosimilar: A Randomized Controlled Trial

Chiara Gasteiger[1], Katie Groom[1], Maria Lobo[2], Urte Scholz[3], Keith Petrie[1] and Nicola Dalbeth[1], [1]University of Auckland, Auckland, New Zealand, [2]Auckland District Health Board, Auckland, New Zealand, [3]University of Zurich, Zurich, Switzerland

SESSION INFORMATION
Session Date: Monday, November 8, 2021
Session Title: Patient Outcomes, Preferences, & Attitudes Poster III: Patient Preferences (1153–1169)
Session Type: Poster Session C
Session Time: 8:30AM–10:30AM

Background/Purpose: Involving patients in treatment decisions is commonplace in healthcare, but patients are frequently accompanied by a support person (companion). Companions are often actively involved in medical consultations, yet their impact on decisions to change medications is unknown. This study aimed to examine the influence of companions on a patient’s decision to transition to a biosimilar.

Methods: Seventy-nine patients with rheumatic diseases taking an originator biologic who regularly attend clinical appointments with a companion were randomized to receive a video explanation alone or with their usual companion. The video explanation included information on the hypothetical transition to a biosimilar and was presented by the same physician to ensure consistency. The information included the manufacturing process, efficacy, safety, and cost

benefits of biosimilars. Patients who received the explanation with their companion had some time to discuss the information before making a decision. After receiving the explanation, participants reported their willingness to transition, risk perceptions, difficulty understanding and received social support. Decisional conflict (uncertainty about the decision) and satisfaction with the decision were also measured.

Results: Companions did not influence decisions to transition to biosimilars, with accompanied (n = 21, 53%) and unaccompanied (n = 22, 56%) patients reporting similar willingness to transition (p = 0.73). There was also no significant difference between accompanied and unaccompanied patients' cognitive risk perceptions (mean (SD) 45.9 (23.4) vs. 43.9 (26.8), p = 0.72) or affective risk perceptions (54.7 (29.3) vs. 46.5 (30.9), p = 0.23). Unaccompanied patients reported finding it easier to understand the explanation compared to accompanied patients (8.2 (1.9) vs. 6.9 (2.4), p = 0.006). Accompanied patients also thought it was more important to receive information with companions than unaccompanied patients (8.3 (2.6) vs. 6.8 (3.2), p = 0.023). Companions did not impact decision satisfaction (p = 0.12) or decisional conflict (p = 0.86). Receiving emotional, but not practical support, was associated with less decisional conflict in accompanied patients (β = -0.63, p = 0.038).

Conclusion: The presence of companions does not influence risk perceptions or decisions about transitioning to biosimilars but may impact patients' reporting of their ability to understand treatment explanations.

What Do Patients Know About Biosimilars and How Satisfied Are They with the Educational Process? - A Systematic Comparison Between Rheumatologists and Nurse Specialists, Including Effects of Multiswitching

Sabina Gall, **Uta Kiltz**, Tanja Kobylinski, Ioana Andreica, Kristina Vaupel, Xenofon Baraliakos and Jürgen Braun, Rheumazentrum Ruhrgebiet Herne, Ruhr-Universität Bochum, Herne, Germany

SESSION INFORMATION
Session Date: Monday, November 8, 2021
Session Title: Patient Outcomes, Preferences, & Attitudes Poster III: Patient Preferences (1153–1169)
Session Type: Poster Session C
Session Time: 8:30AM–10:30AM

Background/Purpose: The market share of biosimilars (bsDMARDs) is steadily growing, not only in rheumatologic care. Although data on efficacy, efficiency and safety have been generated in the last years, not much is known about patients' views on bsDMARDs and also the experience with multiple switching in a non-medical switch scenario is limited. The aim of this project was to study differences in patient satisfaction after education by rheumatologists or nurse specialists, and to learn more about patients' knowledge and their view on biosimilars.

Methods: The non-medical switch to adalimumab MSB 11022 was taken as an opportunity to study patients' knowledge and views on bsDMARDs and their satisfaction with the information they had received on this subject. Adult patients of a tertiary hospital with chronic inflammatory rheumatic diseases (CIRD) such as rheumatoid arthritis (RA), axial spondyloarthritis (axSpA) and psoriatic arthritis (PsA) were included in this randomised controlled trial after obtaining informed consent and followed up for 3 months. Patients with other serious diseases and language problems

NLC = nurse led clinic; RLC = rheumatologist led clinic
* values are mean (SD)
# values of 1 indicate dissatisfaction

were excluded. Patients were randomized into two groups using block randomization: Group 1: educational process by nurse specialist (nurse led clinic (NLC)), Group 2: educational process by rheumatologist (rheumatologist led clinic (RLC)). Standard assessments using validated outcome parameters for disease activity and physical function were used. Patient's satisfaction with care was assessed by the Leeds Satisfaction Questionnaire (LSQ) which contains items on 5 subscales: provision of information, empathy with and attitude to the patient, access to and continuity with

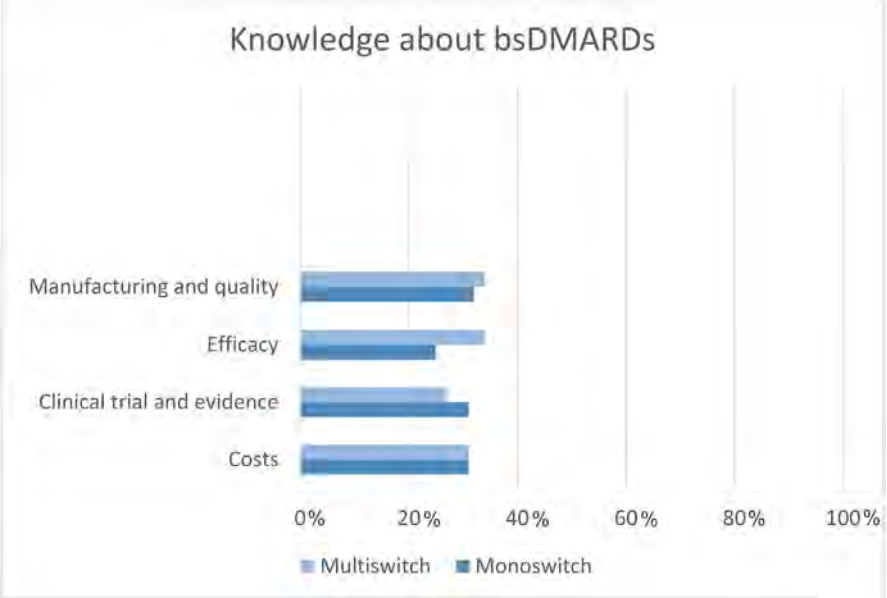

Figure 1. Knowledge about bsDMARDs. bsDMARDs: biosimilar disease-modifying anti-rheumatic drugs.

the care giver, technical competence and a general satisfaction scale. A structured questionnaire was used to assess patient's knowledge of the manufacturing, effectiveness and safety, acceptance and cost of bsDMARDS.

Results: A total of 102 patients were included, 40 (39.2%) by the rheumatologist and 62 (60.8%) were seen by the nurse specialist. Fifty patients (49%) had undergone one and 52 multiple switches (51%). Patient demographics, disease characteristics and the results including patients' knowledge about bsDMARDs and satisfaction with the information process are shown in Table 1. Scores of disease activity and physical function obtained at week 12 remained unchanged for 3 months. Less than one third of patients was able to correctly answer questions about manufacturing, efficacy and safety, approval and costs of bsDMARDs (Fig.1). Patients were generally satisfied with care irrespective of whether information about bsDMARDs and switching had been given by the nurse or the rheumatologist.

Conclusion: This study shows that the satisfaction and the outcomes of patients informed on bsDMARDs by a nurse were not different from information provided by the rheumatologist. Multiswitching did not lead to reduced satisfaction with care in patients on bsDMARDs, and the number of switches did not have a negative impact on patients' satisfaction. However, patients' knowledge on bsDMARDs was limited.

Pregnancy Experiences and Unmet Needs for Women of Childbearing Age with Chronic Rheumatic Disease in China

xinping tian[1] and yongfei fang[2], [1]Peking Union Medical College Hospital, beijing, China (People's Republic), [2]The First Hospital Affiliated to AMU (Southwest Hospital), Chongqing, China (People's Republic)

SESSION INFORMATION
Session Date: Monday, November 8, 2021
Session Title: Patient Outcomes, Preferences, & Attitudes Poster III: Patient Preferences (1153–1169)
Session Type: Poster Session C
Session Time: 8:30AM–10:30AM

Background/Purpose: Recent European research on patients with chronic rheumatic diseases (CRDs) revealed that women of childbearing age (WoCBA) have many fears and misconceptions about their journey to the motherhood. It is critical for patients to obtain accurate information around their disease management. However, there is limited related research in China. This study aimed to understand pregnancy experiences and unmet needs for WoCBA with CRD in China.

Table 1. Medication discontinuation and changes in disease severity during pregnancy and postpartum

Medication (monotherapy or combination) discontinuation		Numbers (%) of patients discontinued medication
csDMARDs	**Patients base**	**110**
	Never discontinue	20 (18.18%)
	Partially discontinue	16 (14.55%)
	Completely discontinue	74 (67.27%)
Biologic agents	**Patients base**	**30**
	Never discontinue	4 (13.33%)
	Partially discontinue	0
	Completely discontinue	26 (86.67%)
Change in disease severity		**Numbers (%) of patients**
Disease condition during pregnancy	**Patients base**	**157**
	Improved a lot	37 (23.57%)
	Improved a little	36 (22.93%)
	Stayed the same	50 (31.85%)
	Worsened a little	27 (17.20%)
	Worsened a lot	7 (4.46%)
Disease condition after childbirth	**Patients base (delivered a child)**	**149**
	Improved a lot	8 (5.37%)
	Improved a little	17 (11.41%)
	Stayed the same	25 (16.78%)
	Worsened a little	59 (39.60%)
	Worsened a lot	40 (26.85%)

Methods: A cross-sectional online survey was sent to a sample of WoCBA (18-49 years old) drawn from the Chinese Rheumatism Data Center 2019 with physician-diagnosed as moderate or severe CRD (RA AS and PsA). This study was approved by Ethics Committee of Peking Union Medical College Hospital.

Results: Total 1037 WoCBA patients were involved. 157 patients were diagnosed with CRD before pregnancy. Of which 110 and 30 patients took csDMARDs and bDMARDs (TNFi) before the index pregnancy, respectively. During their whole pregnancy, 74 (67.27%) and 26 (86.67%) patients discontinued medications completely, respectively (Table 1). The most common reason for stopping medication was that patients were concerned about the adverse effect of medications on their fetus. Of all the 157 patients, 34 and 99 patients reported that the symptoms worsened during pregnancy and postpartum respectively. Of 157 patients, 19.11% reported that they received inconsistent medication advice from rheumatologists and obstetricians during pregnancy, and 17.83% did not receive any advice.

Conclusion: Our survey indicates that women with CRDs have a wide range of unmet information and needs in relation to pregnancy in China. There is a strong need to reach a multi-disciplinary consensus on treatment recommendations to ensure that WoCBA can obtain consistent advice through all their journey to motherhood.

Impact of Treatment Experience on Patient Preferences and Disease Burden in Psoriatic Arthritis: Results from a Rheumatology Patient Research Registry

Jessica Walsh[1], Kelley Myers[2], Carol Mansfield[2], William Tillett[3], Peter Nash[4], Colton Leach[2], William Nowell[5], Kelly Gavigan[5], Patrick Zueger[6], Erin McDearmon-Blondell[7] and Alexis Ogdie-Beatty[8], [1]Salt Lake City Veteran Affairs Medical Center (VAMC)/University of Utah Hospital, Salt Lake City, UT, [2]RTI Health Solutions, Research Triangle Park, NC, [3]Royal National Hospital for Rheumatic Diseases, Bath, United Kingdom, [4]Griffith University, Brisbane, Australia, [5]Global Healthy Living Foundation, Upper Nyack, NY, [6]AbbVie Inc., Mettawa, IL, [7]AbbVie Inc., Elmhurst, IL, [8]University of Pennsylvania, Philadelphia, PA

SESSION INFORMATION

Session Date: Monday, November 8, 2021

Session Title: Patient Outcomes, Preferences, & Attitudes Poster III: Patient Preferences (1153–1169)

Session Type: Poster Session C

Session Time: 8:30AM–10:30AM

Background/Purpose: To optimize patient-provider shared decision-making, it is important to understand patients' experience with psoriatic arthritis (PsA) and its treatment, including how treatment experience may impact their preferences. We evaluated PsA symptom burden, the most important impacts of disease, and therapy preferences based on past biologic disease-modifying antirheumatic drug (bDMARD) experience among PsA patients from the ArthritisPower registry.

Methods: A cross-sectional, web-based survey was developed and administered to adults with a self-reported diagnosis of PsA recruited from a United States rheumatology patient-centered research registry, ArthritisPower. Object case best-worst scaling (BWS) was used to evaluate the relative burden of 11 PsA symptoms and the relative importance of improvement in 9 PsA-related disease impacts. BWS data were analyzed using a random parameters logit model stratified by past bDMARD experience. Additional survey questions and analyses assessed the impact of prior treatment experience on patients' experience with methotrexate (MTX) and preference for mode of treatment administration as well as overall treatment satisfaction.

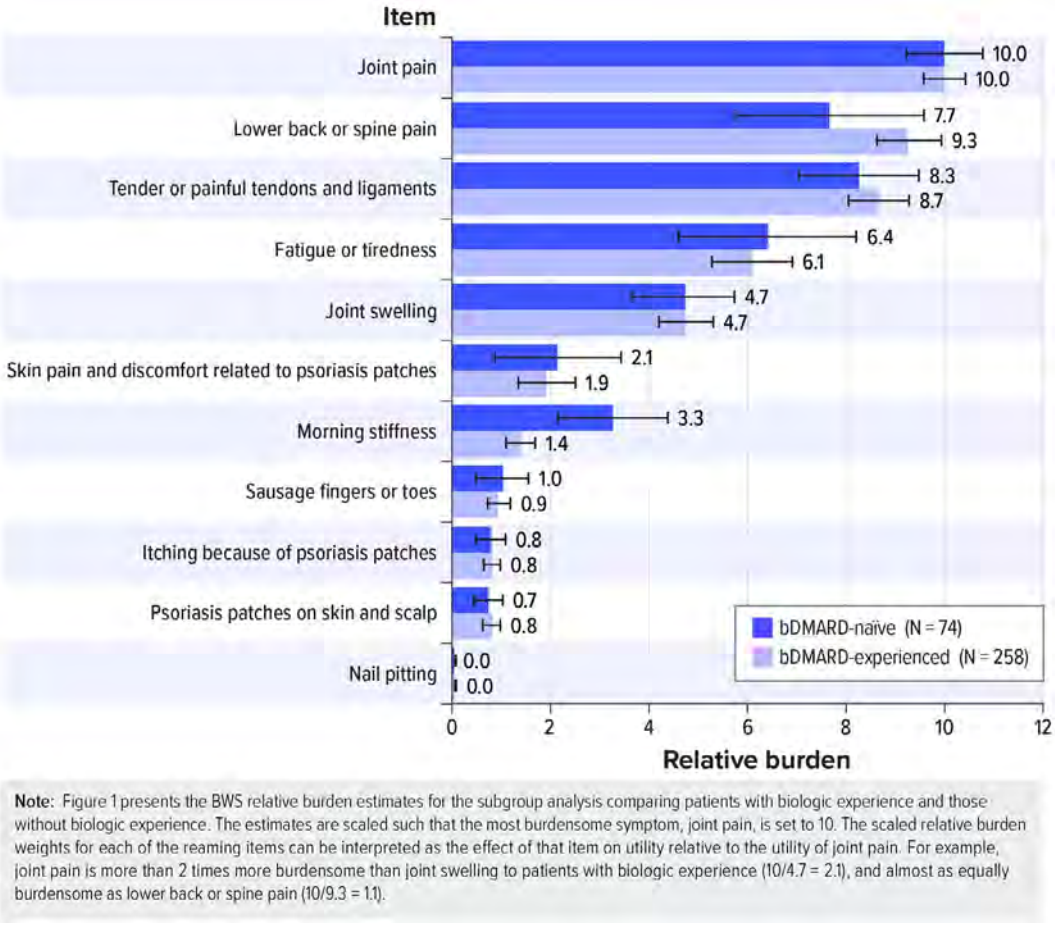

Figure 1. Relative Burden of PsA Symptoms by Biologic Treatment Experience.

Results: Among 332 respondents, 74 (22.3%) were bDMARD-naïve and 258 (77.7%) were bDMARD-experienced. In both groups, musculoskeletal pain-related symptoms were reported as most bothersome while the least bothersome symptoms were psoriasis-related (Figure 1). Patients who were bDMARD-naïve rated morning stiffness as more bothersome than bDMARD-experienced patients. The ability to perform physical activities was reported as the most important disease impact to improve by both groups, while bDMARD-naïve patients rated improvement in sleep quality as more important compared to bDMARD-experienced patients (Figure 2). Among patients with MTX experience, a similar proportion of bDMARD-naïve patients (40%) and bDMARD-experienced patients (34%) were satisfied with MTX. A significantly greater proportion of bDMARD-naïve patients felt that mode of administration was an important factor when deciding to start a new therapy compared to bDMARD-experienced patients (57% vs. 42%, $p< 0.05$). When asked to choose among four different ways of taking their PsA medication (oral once or twice per day, injection every 2 weeks or every month), a once daily oral tablet was the most commonly chosen mode by both bDMARD-naïve (39%) and -experienced patients (38%). Overall satisfaction with current treatment was higher among patients taking an advanced therapy (bDMARDs or tofacitinib) compared with those taking conventional DMARDs only (72% vs 39%, $p< 0.05$).

Conclusion: Among patients with PsA, musculoskeletal pain-related symptoms were ranked as most bothersome, and improvements in physical function were ranked as most important, regardless of bDMARD treatment experience. Though mode of administration was rated as more important among bDMARD-naïve patients, both bDMARD-naïve and -experienced patients preferred a once daily oral route of administration. These findings may serve to optimize patient-provider treatment discussion and decision making across PsA patient populations.

Patient Perspective on the Non Medical Switch of Originator to Its Biosimilar in Inflammatory Arthritis Using a Social Media Survey

David Vega Morales[1], Alejandro Garza-Alpirez[2] and **Carlos Andrés Díaz-Garza**[2], [1]Hospital Universitario, Garcia, Mexico, [2]Tecnologico de Monterrey, Escuela de Medicina y Ciencias de la Salud, San Pedro, Mexico

SESSION INFORMATION

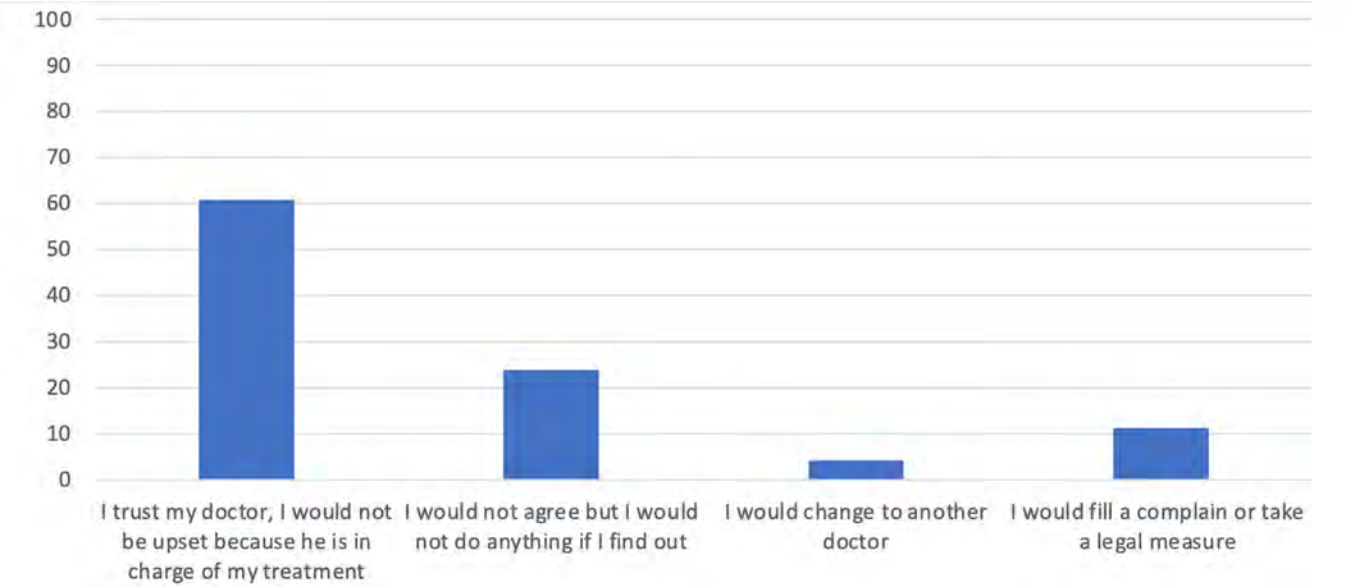
Session Date: Monday, November 8, 2021
Session Title: Patient Outcomes, Preferences, & Attitudes Poster III: Patient Preferences (1153–1169)
Session Type: Poster Session C
Session Time: 8:30AM–10:30AM

Background/Purpose: The use of biosimilars instead of its originator is a controversial subject with many implications. It is considered that a non medical switch should not occur and that pts and physicians must be involved in the decision of choosing the adequate medication.

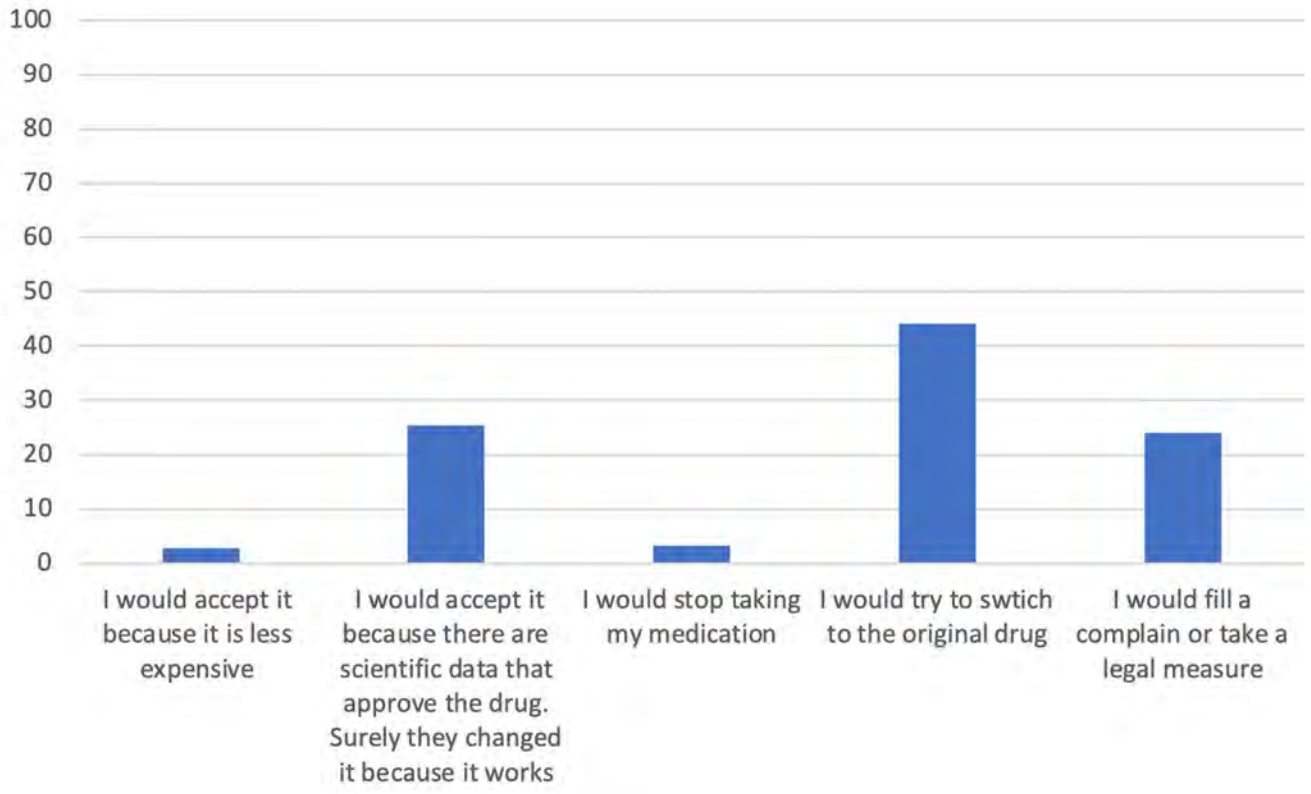
Methods: A social media survey via The Mexican Foundation for Rheumatic Patients (FUMERAC) (Facebook [FB] and Twitter) was conducted in Mexico from November 2020 to January 2021. An opening question to ascertain the consent Pts were eligible if they were >18 years of age and if they had any inflammatory or non inflammatory rheumatic condition and the use of biologics/biosimilars was not mandatory.

Results: A total of 165 pts completed the survey. 81% were women and 79% had high school or higher education. The most frequent diagnoses were RA (56.4%), AS (13.9%), PsA (11.5%) and Lupus (9.1%). DMARD monotherapy was the most common treatment representing 30% of pts. 57% reported prior or current use of biologics. Sixty four percent of pts had never heard the term biosimilar. 38% would accept the change from an originator to its biosimilar if the opinion of the patient and physician was taken into account. 24% of pts would take a legal measure or file a complaint if a NMS was to happen. The subjects asked to pts in order to reduce their inconformity were: treatment effectiveness (65.5%), adverse effects (60%), reason for change (54.4%), treatment duration (29%) and other pts experience (19.3%)

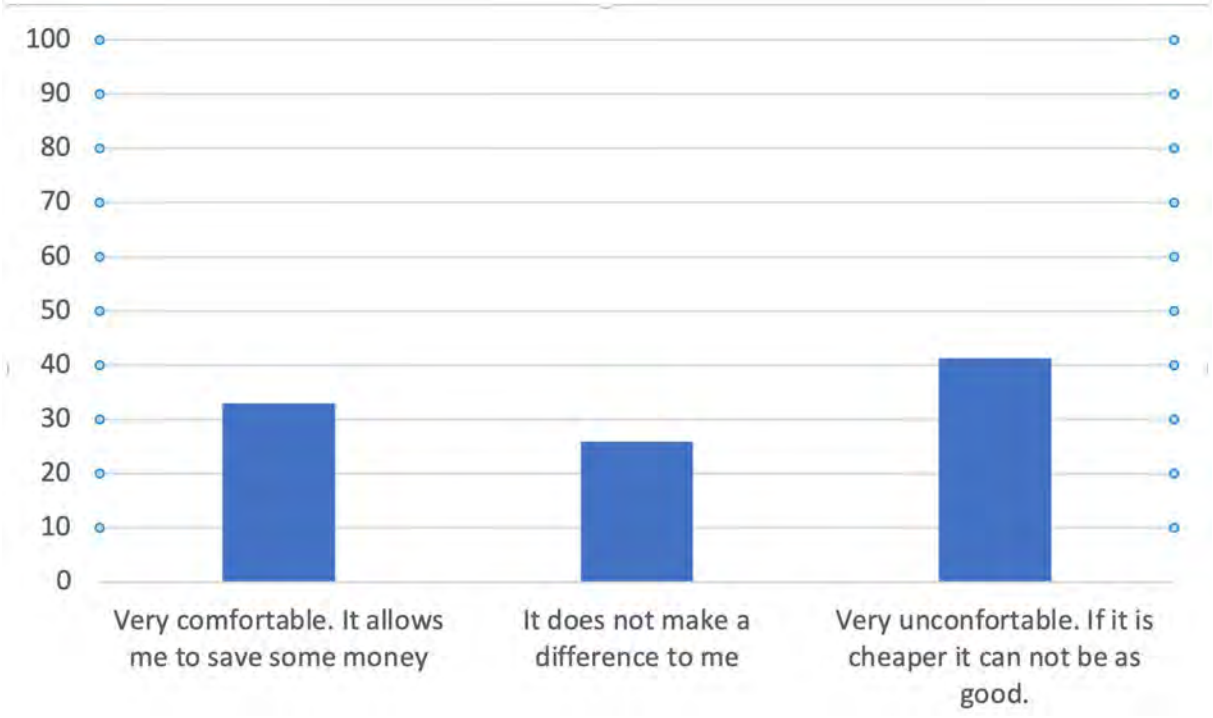
Conclusion: In Mexico the concept of biosimilars is barely known. Most of patients (76%) would not take any measure if they where changed from an originator to its biosimilar. There is still a great amount of confidence from the pts to their physician regarding the management of their medications.



What would you think if your physician changed your originator to its biosimilar without asking nor explaining you?



What would you think if your pharmacist or health insurance policy changed your medication to its biosimilar without informing you or your physician?



Do you think changing your biologic drug to its more economic biosimilar can have a consequence?

Resistance of Patients with Rheumatoid Arthritis to Changing Therapy: A 15-year Follow-up

Kaleb Michaud[1], Sofia Pedro[2], Victoria Jasion[3], Holly Budlong[4], Jessica Suboticki[5], Frederick Wolfe[6] and Patricia Katz[7], [1]University of Nebraska Medical Center, Omaha, NE, [2]Forward, The National Databank for Rheumatic Diseases, Wichita, KS, [3]AbbVie, Overland Park, KS, [4]AbbVie, Minneapolis, MN, [5]AbbVie Inc., North Chicago, IL, [6]National Data Bank for Rheumatic Diseases, Wichita, KS, [7]University of California San Francisco, San Francisco, CA

SESSION INFORMATION

Session Date: Monday, November 8, 2021

Session Title: Patient Outcomes, Preferences, & Attitudes Poster III: Patient Preferences (1153–1169)

Session Type: Poster Session C

Session Time: 8:30AM–10:30AM

Background/Purpose: Treatment options for rheumatoid arthritis (RA) have increased dramatically over the past 15 years. The objective of this study was to investigate whether willingness to change treatment and reasons for not changing have shifted by repeating a pivotal study questionnaire 15 years later.[1]

Methods: Data are from participants with RA enrolled in FORWARD, The National Databank for Rheumatic Diseases, a longitudinal registry of individuals with rheumatic diseases. Patients answered 9 questions on treatment satisfaction and preferences in 2006 (Y06) and/or 2021 (Y21). Questions included an overall assessment of likelihood to change therapy (Q1, "As long as I don't get worse I wouldn't want to change my arthritis medications," rated as true-false)

Table 1. Treatment predictors and preference for not changing therapy

	Questionnaire 2006 (Y06)				Questionnaire 2021 (Y21)			
	Responses according to whether question 1, "As long as I don't get worse I wouldn't want to change my arthritis medications," was answered "true" or "false"							
Questions	% n=6283	TRUE* 64%	FALSE* 36%	% difference§ (true-false)	% n=1632	TRUE* 50.9%	FALSE* 49.1%	% difference§ (true-false)
2. I don't need new medications because I am satisfied with the control I have over my arthritis.	53.2	73.44	17.25	56.1 (54.1 - 58.2)	36.6	56.83	15.62	41.2 (37.3 - 45.1)
3. I don't want the risk of side effects that might come from taking new medications.	72.4	87.13	46.00	41.1 (38.6 - 43.7)	42.7	61.06	23.62	37.4 (32.7 - 42.1)
4. I want to follow my doctor's suggestions, and my doctor thinks I don't need to change medications.	71.3	84.39	47.93	36.4 (34.1 -38.7)	38.1	54.27	21.53	32.7 28.5 - 36.8)
5. I am concerned that new treatments might not work as well and that I might lose control of my arthritis.	67.9	80.74	45.29	35.4 (33.0 - 37.8)	42.3	57.06	26.91	30.0 (24.7 - 35.4)
6. I don't think there are medications currently available that are better than the medications I am using now.	66.2	75.83	48.59	27.1 (24.6 - 29.7)	36.3	46.73	25.53	21.1 (16.4 - 25.8)
7. I don't want to take treatments that require injections or IVs.	35.9	41.75	25.40	16.3 (14.0 -18.5)	16.4	21.09	11.49	9.8 (5.8 - 13.7)
8. I can't afford the cost of new medications.	54.8	45.71	37.89	7.9 (5.2 - 10.5)	28.8	30.14	26.37	3.6 (-0.05 -12.2)
9. Getting approval from my insurance company and the hassle of tests and medical visits for new drugs are important problems for me.	54.8	56.04	52.22	3.8 (1.5 - 6.1)	29.1	33.70	24.34	9.3 (4.8 - 13.7)

§The greater the difference, the stronger the association with unwillingness to change.

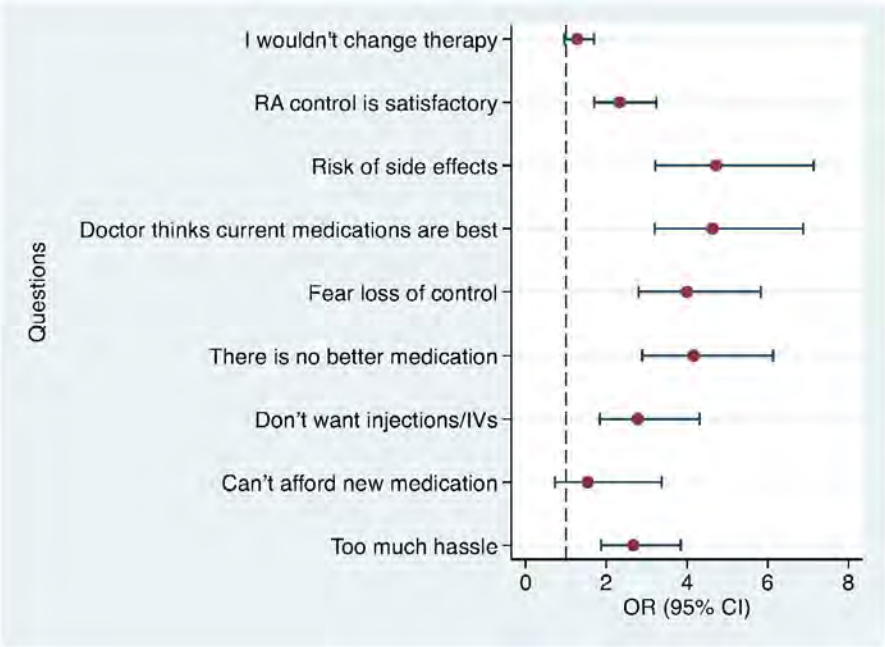

Figure 1. Odds (95% CI) of being unwilling to change medications at Y21 if unwilling to change at Y06.

and 8 (Q2-Q9) evaluating reasons for (un)willingness to change (Table 1). Paired McNemar tests were performed in the subset who answered the questionnaire at both Y06 and Y21 to estimate the likelihood of willingness to change therapy at Y21 based on response at Y06. Logistic regression was used to identify predictors at both time points of responses to Q1.

Results: In 2006, 6282 responders had a mean age of 63 years, 17 years RA duration, and exposure to 3 (IQR 2-5) DMARDs. As of April 2021, 1632 responders had a mean age of 66 years, 24 years RA duration, and exposure to 4 (IQR 3-5) DMARDs. Overall for Y06, 64% did not want to change therapy as long as their condition didn't get worse, compared with 51% from Y21. However, when looking at responses of those who completed both Y06 and Y21 questionnaires (n=442), there were no significant differences in willingness to change therapy. The primary reasons for unwillingness to change therapy over time (Y06 vs Y21) were as follows: satisfaction with medication (53% vs 37%), risk of side effects (72% vs 43%), and doctor recommendation (71% vs 38%) (Table 1). In the paired group, those who provided a reason for not changing in Y21 (eg, side effects) were more likely to have provided the same reason in Y06 (eg, 4.7-fold increase for side effects; Figure 1). Predictors of unwillingness to change therapy in Y06 and Y21 included the following: satisfactory control of RA, risk of side effects, fearing loss of control, doctor thinking current medications were best, and lower levels of pain (Table 2). Predictors related to cost or insurance were associated with unwillingness to change in Y06, but not in Y21.

Conclusion: While the overall proportion of respondents who were unwilling to change therapies was lower in 2021 than in 2006, analysis of those who responded to both questionnaires showed little change. In addition, the major reasons given for not wanting to change therapies did not change from 2006 to 2021, although cost and hassle with insurance companies were no longer significant predictors in 2021. Further data are needed to understand whether the correlation between (un)willingness to change treatments and disease activity and clinical outcomes has evolved over time.

Improving Healthcare Transition Implementation: Recommendations from Young Patients with Rheumatic Conditions

Courtney Wells[1], Peter Chira[2], Dana Guglielmo[3], Stacy Ardoin[4], Katelyn Melcher[5], Meghan Trimble[6] and Kristine Carandang[7], [1]University of Wisconsin-River Falls, White Bear Lake, MN, [2]Pediatric Rheumatology, University of California San Diego, Rady Children's Hospital, San Diego, CA, [3]Student, Atlanta, GA, [4]Nationwide Children's Hospital, Columbus, OH, [5]Patient Partner, Ankeny, IA, [6]Patient Partner, Minneapolis, MN, [7]Independent, San Diego, CA

SESSION INFORMATION
Session Date: Monday, November 8, 2021
Session Title: Patient Outcomes, Preferences, & Attitudes Poster III: Patient Preferences (1153–1169)
Session Type: Poster Session C
Session Time: 8:30AM–10:30AM

Background/Purpose: Implementation of structured healthcare transition processes remains elusive for most US rheumatology clinics (Johnson et al., 2021). Although research studies have proposed models and best practices for decades, barriers to successful healthcare transition persist, such as systemic procedures and rheumatologists' lack of time and resources (Chira et al., 2014; Zisman et al., 2019). In this study, we identified adolescent and young adult (AYA) patients' recommendations about how to deliver healthcare transition and examined their openness to various methods of implementation.

Methods: Participants aged 16-28 years old with a self-reported diagnosis of a rheumatic condition were recruited from patient organizations and social media. This mixed methods study used a two-phase exploratory sequential design. In phase one, experienced researchers led 90-minute focus groups to elicit AYAs' reactions to principles and resources of the Six Core Elements of Healthcare Transition™ (Sabbagh et al., 2018). Audio transcripts were analyzed using rapid analysis to develop a quantitative survey and later using in-depth content analysis. In phase two, an online quantitative survey was distributed to understand AYAs' willingness to engage in various healthcare transition modalities. Descriptive statistics were performed using SAS v9.4

Results: In phase one, 39 AYAs (20.8 ± 2.9 years old; 82.1% female; 92.3% White; 48.7% using pediatric rheumatology services; 84.6% arthritis) participated in 7 focus groups. Participants discussed the need for a systematic educational care plan that is purposefully introduced and reinforced within regular healthcare encounters. Participants suggested techniques to increase the effectiveness of transition-related discussions, such as pairing transitional skills with developmental milestones and acknowledging the role of parents/caregivers. While AYAs emphasized that rheumatologists ideally should be part of this process, they also provided ideas for how to structure transition education using other team members or outside time-limited rheumatology appointments. In phase two, 137 AYAs (22.9 ± 3.3 years old; 89.1% female; 75.0% White; 19.0% see pediatric-only rheumatologist; 50.4% lupus) completed the quantitative survey. Most participants reported that to learn transition skills, they would be likely or very likely to engage in programs provided by a provider outside of their regular rheumatologist (81.8%); via a patient portal (77.2%), additional telehealth appointment (74.5%), additional in-person appointment (66.4%); or in a group setting (65.7%).

Conclusion: AYA patients desired structured opportunities to discuss transition skills with multidisciplinary health care team members in the clinic and beyond. Results suggest potential for collaborations with community providers or organizations outside of the traditional healthcare system. Incorporating AYAs' expertise and preferences into the refinement of healthcare transition models may improve the feasibility of implementation and uptake by patients.

Session Time: 8:30AM–10:30AM

Background/Purpose: Despite being used for more than 70 years as a conventional (cs) DMARD, very little is known about the overall side effect (SE) profile of hydroxychloroquine (HCQ). In 2020 HCQ became well-known due to the COVID 19 pandemic. We set out to understand the patient-reported side effect of HCQ use in adults with RA, SLE, and other RMDs (excluding Osteoarthritis and Fibromyalgia).

Methods: Data provided by participants in the Forward Databank observational registry from 1999 through 2020. HCQ use was measured at enrollment and every 6 months with follow up questionnaires. Incident HCQ users were defined as new users (no HCQ use documented in a prior questionnaire) or having a 6-month maximum HCQ dura-

Table 2. HCQ use and experience of side effects due to HCQ of the last side effect (multiple infections)

Mono HCQ	6679.0 (481)	72.0 (65.9 -78.7)	2559.2 (157)	61.3 (52.5 – 71.7)	684.3 (62)	90.6 (70.6 – 116.2)
HCQ + csDmards	10907.0 (603)	55.3 (51.0 –59.9)	1465.6 (81)	55.3 (44.5 – 68.7)	247.4 (11)	44.5 (24.6– 80.4)
HCQ + bDmards	8592.2 (374)	43.5 (39.3 -48.2)	257.8 (13)	50.4 (29.3 – 86.8)	96.0 (5)	52.1 (21.7 – 125.2)
SE stopping HCQ	573	20.1 (18.6 –21.9)	79	17.6 (14.1 –21.9)	24	22.7 (15.2 – 33.8)
Mono HCQ	6679.0 (149)	22.3 (19.0 – 26.2)	2559.2 (42)	16.4 (12.1 – 22.2)	836.2 (19)	23.4 (14.3 – 38.2)
HCQ + csDmards	10907.0 (245)	22.5 (19.8 – 25.5)	1777.6 (33)	21.8 (15.4 – 30.9)	304.4 (8)	24.3 (10.9 – 54.0)
HCQ + bDmards	8592.2 (176)	20.5 (17.7 – 23.7)	318.5 (5)	19.4 (8.1 – 46.6)	128.5 (2)	22.7 (15.2 – 33.8)
SE causing hospitalization	10	0.35 (0.19 -0.65)	5	1.11 (0.46-2.70)	0	–

tion prior to FORWARD entry. Prevalent HCQ users were any user irrespective of duration of HCQ treatment. These questionnaires asked about all SEs to medications, including severity of side effect, certainty of medication as cause of side effect, and affected body systems. We analyzed incident rates of side effects overall and by HCQ categorical use: monotherapy, HCQ with concomitant use of another csDMARD, or HCQ with concomitant use of a biologic (b) DMARD or targeted synthetic (ts) DMARD.

Results: Overall, 5,685 patients were included in the initiator group and 13,018 patients were included in the prevalent group, with the majority of patients taking HCQ for RA and SLE. In both the initiator and prevalent cohorts, the majority of patients with RA were on HCQ and another DMARD. In the other RMD and SLE groups, the majority of patients were on HCQ monotherapy. Eighty four percent of patients taking HCQ for any cause did not experience any side effects in both initiator and prevalent groups. Sixteen percent of all RA patients, 16.5% of SLE and 18% of other RMD patients noted a side effect from HCQ in the initiator group, vs 16.2% of RA, 18.8% of SLE and 17.5% of other RMD noted in the prevalent group. Of those patients, 55% in the RA, 41% in the SLE and 39.3% in the other RMD groups discontinued the medication in the initiator group, with very similar results noted in the prevalent group. Hospitalization secondary to a hydroxychloroquine side effect was observed in 1% of RA patients, 2.5% of SLE patients and no patients with other RMDs in the initiator group vs 1% of RA, 2.8% of SLE and no patients with other RMD's noted in the prevalent group. In both the prevalent and initiator groups, the predominant last reported side effects in annualized incidence rates per 1000 patient-years were gastrointestinal (GI; e.g., nausea, diarrhea, 12.35 prevalent, 12.84 initiator), integumentary (e.g., rash, itching, 7.61, 8.6), and ocular (e.g., visual disturbance, 8.54, 7.42), respectively over all 3 disease groups.

Conclusion: This is the largest study of its kind conducted that reviews patient reported side effects over a 20-year period. Our findings confirm the overall low incidence of reported serious side effects from short and long- term hydroxychloroquine use for the treatment of SLE, RA and other RMDs.

Abstract Number: 1161

Patient Preferences for Hydroxychloroquine in Systemic Lupus (SLE)

Jennifer Dollinger[1], Celline Brasil[1], Marcus Wong[1], Glen Hazlewood[2], Ryan Dollinger[1], Wendy Singer[3], Christian Pineau[4], Evelyne Vinet[5], Ann Clarke[2], Jennifer Lee[1] and **Sasha Bernatsky**[4], [1]Research Institute of the McGill University Health Centre, Montréal, QC, Canada, [2]University of Calgary, Calgary, AB, Canada, [3]McGill University Health Centre, Montréal, QC, Canada, [4]McGill University, Montréal, QC, Canada, [5]McGill University Health Centre, Mont Royal, QC, Canada

SESSION INFORMATION

Session Date: Monday, November 8, 2021

Session Title: Patient Outcomes, Preferences, & Attitudes Poster III: Patient Preferences (1153–1169)

Session Type: Poster Session C

Session Time: 8:30AM–10:30AM

Background/Purpose: Although hydroxychloroquine (HCQ) has been shown to reduce SLE flares, concerns exist regarding side effects from long-term use. Very little information is available on patient preferences regarding decisions to continue, lower, or stop the drug. To address these knowledge gaps, we evaluated patient experiences and preferences for HCQ therapy and qualitatively assessed themes underlying these preferences.

Methods: Telephone interviews were conducted with patients recruited from two Canadian SLE clinical cohorts. The interviews were conducted in English and French using a standardized script. The interview recordings were transcribed, and French transcripts were translated to English. Two reviewers conducted a thematic analysis by individually generating codebooks and mutually ruling out discrepancies.

Results: We completed a thematic analysis of 42 interviews. The majority (N=38, 90%) of subjects were female. Average age was 55.7 (SD 13.0) and most subjects (N=32, 76%) were Caucasian; the rest were Black (N=4, 10%), Asian (N=4, 10%) and other races/ethnicities (N=2, 5%). Concepts emerging from interviews centred around past experiences with dose changes, who (patient/physician) makes those decisions, and current patient preferences (Table 1). Over the course of SLE, 35.7% of patients had stopped and 52.4% had lowered HCQ. Most decisions were made by physicians, but almost a fourth of patients had made a decision to lower or stop HCQ without communicating with their doctor. Though most patients preferred their dose at status quo (to avoid flares), over a third were interested in lowering, stopping, or increasing HCQ. Themes around preferences included SLE control, trust in the provider's

Table 1. Concepts discussed during the interviews

	% of patients (N=42)
Past experiences*	
Never changed HCQ dose	28.6%
Lowered HCQ	52.4%
Stopped HCQ temporarily	26.2%
Stopped HCQ permanently	9.5%
Decision-maker	
Physician +/- patient	76.2%
Patient alone	23.8%
Current preferences	
Status quo	54.7%
Lower HCQ dose	23.8%
Stop HCQ	9.5%
Augment HCQ dose	4.8%
Do not know/no preference	7.1%

*Categories are not mutually exclusive.

Table 2. Themes around preferences

Themes	Quote examples
SLE control	"[I wouldn't change the dose]. Anytime I get any medication change, I usually get flare-ups." (Female, 63 years) "If there would be a way to stop taking the medication, I would like to. If there's no risk, if it's good of course, I would stop." (Patient, 34)
Trust in the provider's decision	"I have been staying on [HCQ] mainly because I have great trust and a great relationship with doctor Y… [who] is very intelligent and very up to date." (Female, 69 years) "If the doctor said that I should change my dose, I would." (Male, 81)
Management of other medications	"I am trying to lower the dose of prednisone, and [HCQ] allows me to have my lupus under control." (Female, 36 years) "If I [didn't have] to take prednisone, I would consider lowering [my dose]." (Female, 36)
HCQ safety	"I am a little concerned about heart and vision issues long-term. I was quite eager to get off of [HCQ]." (Female, 69 years) "[I wouldn't change the dose]. I've never had any side effects. It always went well." (Female, 46 years)
HCQ effectiveness	"I don't see any improvements pain wise. I don't think [HCQ] helps. I would prefer to stop it altogether." (Female, 42) "[On HCQ], I think my [symptoms] are lessened. My major problems are less frequent and controlled." (Female, 62)

Table 3. Preferences according to patient characteristics

Characteristics	Preferences			
	Status quo	Lower dose	Stop HCQ	Other*
Sex				
Female (n=38)	57.9%	21.1%	10.5%	10.5%
Male (n=4)	25.0%	50.0%	0	25.0%
Race/ethnicity				
Caucasians (n=32)	50.0%	25.0%	12.5%	12.5%
Non-Caucasians (n=10)	80.0%	10.0%	0	10.0%
Age				
Youngest (n=10)	60.0%	20.0%	20.0%	0
Oldest (n=10)	30.0%	30.0%	10.0%	30.0%
Language				
English (n=32)	59.4%	21.9%	9.4%	9.4%
French (n=10)	40.0%	30.0%	10.0%	20.0%
SLE clinic				
Montreal (n=32)	53.1%	25.0%	6.3%	15.6%
Calgary (n=10)	60.0%	20.0%	20.0%	0
SLE duration				
Shortest (n=10)	50.0%	50.0%	0	0
Longest (n=10)	60.0%	10.0%	10.0%	20.0%

*Includes augmenting the dose or not knowing what their preferences are.

decisions, management of other medications, HCQ safety, and HCQ effectiveness (Table 2). We observed some differences in preferences across patient characteristics (Table 3). A higher proportion of non-Caucasians (80% vs 50% of Caucasians) and of the 10 youngest patients (60% vs 30% of the 10 oldest patients) preferred maintaining their current dose. Concerns about toxicities emerged in the interviews (Table 2). A limitation of our study is that most of our patients had long-established disease, with only about 10% having more recent-onset disease.
Conclusion: In this sample, most patients preferred maintaining their current HCQ dose to avoid SLE flares. However, concerns about toxicities emerged in the interviews, and several patients would prefer decreasing or stopping treatment, but respected physician recommendations. Awareness of these results may help patients and physicians navigate shared decision making. Studies like ours could also contribute to making SLE treatment guidelines more patient-centred and personalized.

Abstract Number: 1162

Exploring Cannabis Use and Perspectives Among Psoriatic Disease Patients

Jackie Tsang[1], Orli Silverberg[1], Rohan Machhar[2], Remy Pollock[3], Mitchell Sutton[4], Daniel Pereira[3], Dafna Gladman[5] and Cheryl Rosen[1], [1]University of Toronto, Toronto, ON, Canada, [2]Krembil Research Institute, University Health Network, Toronto, ON, Canada, [3]University Health Network, Toronto, ON, Canada, [4]Centre for Prognosis Studies in the Rheumatic Diseases, Krembil Research Institute, Toronto Western Hospital, University Health Network, Toronto, ON, Canada, [5]Schroeder Arthritis Institute, Krembil Research Institute, Toronto Western Hospital, Toronto, ON, Canada

SESSION INFORMATION
Session Date: Monday, November 8, 2021
Session Title: Patient Outcomes, Preferences, & Attitudes Poster III: Patient Preferences (1153–1169)
Session Type: Poster Session C
Session Time: 8:30AM–10:30AM

Background/Purpose: We aimed to assess the correlation between cannabis use and psoriatic disease severity, health-related quality of life, pain, and psychosocial outcomes in psoriasis without arthritis (PsC) and psoriatic arthritis (PsA) patients.

Methods: PsC and PsA patients enrolled in the International Psoriasis and Arthritis Research Team (IPART) program were surveyed on cannabis use and were asked to provide a serum and urine sample. Demographic and clinical variables were compared between users and non-users using Student's t-test or Mann-Whitney U test for continuous variables, and chi-square or Fisher's exact test for categorical variables.

Results: Of 151 respondents, 30.5% reported current cannabis use within the last year. Compared to non-users, cannabis users were younger ($P = 0.008$), had a shorter PsA duration ($P = 0.024$), and poorer mental health as measured by the SF-36 ($P = 0.046$). Other measures of health-related quality of life and pain were comparable between the groups. Cannabis users felt more hesitant inquiring about cannabis with healthcare professionals prior to its legalization ($P = 0.017$), but were more likely to want cannabis information from their healthcare providers than non-users ($P < 0.001$). Respondents' primary perceived benefits of cannabis use were aid in sleep and arthritis pain relief. Only patients who were taking cannabis had THC detected in the urine. Serum concentrations of IL-23 were significantly

elevated in cannabis non-users (P = 0.0026) (Table). There were no other significant differences in concentrations of measured analytes between the groups.

Table 5: Median (IQR) of urine THC and serum biomarker concentrations compared between cannabis users (n=34) and non-users (n=65)

Variable	Users (n=34)	Non-Users (n=65)	*P*-value
Urine THC (ng/ml)[§]	19.7 (147.9)	0 (0)	< 0.001
INF-gamma (pg/ml)[§]	13.9 (72.8)	46.0 (155.4)	0.26
IL-10 (pg/ml)[§]	0.5 (0)	0.5 (0.3)	0.17
IL-23 (pg/ml)[§]	39.8 (52)	65.3 (408.8)	0.0026
IL-6 (pg/ml)[§]	1.3 (1.7)	1.4 (1.2)	0.46
TNF-alpha (pg/ml)[§]	2.2 (4.7)	2.9 (5.4)	0.26

[§]Median (IQR) Mann-Whitney U test

Conclusion: This study shows that 30.5% of 151 patients used cannabis within the past year and 54.3% of users reported use of cannabis for arthritis pain relief. Knowledge of the patient demographics of cannabis users can help guide clinicians in counselling patients and aid in the development educational materials to promote responsible use.

Rosen**, None.

Abstract Number: 1163

Patients' Insights About Hydroxychloroquine, and Patient-Recommended Strategies to Target Nonadherence

Shivani Garg[1], Betty Chewning[1], Noah Kaitz[1], Shelby Gomez[1] and Christie Bartels[2], [1]UW Madison, Madison, WI, [2]University of Wisconsin School of Medicine and Public Health, Madison, WI

SESSION INFORMATION
Session Date: Monday, November 8, 2021
Session Title: Patient Outcomes, Preferences, & Attitudes Poster III: Patient Preferences (1153–1169)
Session Type: Poster Session C
Session Time: 8:30AM–10:30AM

Background/Purpose: Hydroxychloroquine (HCQ) is the cornerstone of SLE therapy as it improves damage-free survival in all SLE patients. Yet, in new users, as few as 17% of SLE patients took HCQ as recommended for a year increasing risk of poor SLE outcomes and early death. Moreover, Black patients and those from disadvantaged backgrounds have a 2-fold higher HCQ nonadherence rate, which contributes to worse SLE outcomes and health disparities. This highlights that diverse SLE patients could have different perspectives about HCQ and unique barriers to adherence. Yet, most adherence interventions lack diverse patients' insights or tailored strategies addressing their unique challenges with HCQ. Therefore, using qualitative descriptive analysis we aimed to examine diverse SLE patients' perspectives on: insights and priorities about HCQ adherence, and the most valuable and actionable adherence strategies.

Methods: We recruited 11 patients with SLE from Madison (28% non-White; 17% living in poverty) and Milwaukee, Wisconsin (56% non-White; 40% living in poverty) who were identified with a history of nonadherence or actively struggling with taking HCQ. We used purposeful sampling to recruit diverse SLE patients (e.g., age, sex, race/ethnici-

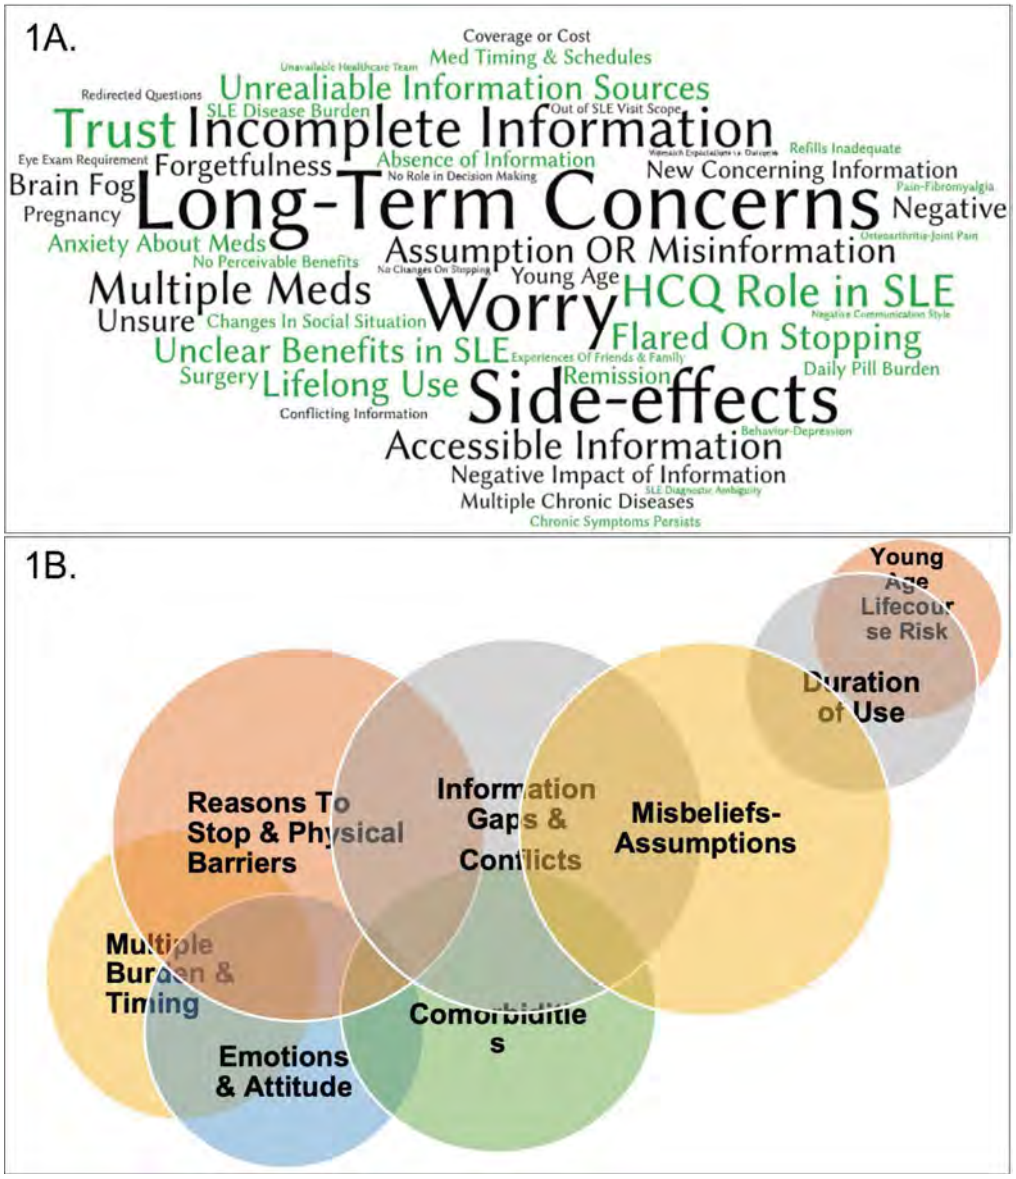

Figure 1. 1A. Patient perspectives and insights about HCQ. The size of the word/phrase matches the listed frequency. 1B. Conceptual scheme showing inter-relationships between themes from analysis of patients' insights about HCQ adherence during four 90-minute focus group meetings (n=11 patients). Note that the size of circles reflects frequency of each theme and the overlap area between circles represents the frequency when both themes were referenced within a quote.

ty, social challenges identified by using social determinants of health documented in the EHR.). Using four 90-minute semi-structured focus groups, facilitators first asked patients to share their perspectives on HCQ, insights and concerns about HCQ that lead to reduced adherence. Next, patients participated in discussing and prioritizing strategies to address their concerns and improve their adherence. All meetings were audio-recorded and transcribed. Using content analysis, we analyzed transcripts from each meeting.

Table 1. Eight Themes Highlighting Patients' Insights And Concerns About HCQ

Themes*	Sub-Categories For Each Theme**	Illustrative Quotes (1-3)
Information gaps & conflicts about medication	Incomplete med information	"Nobody told me that I could take both HCQ doses together. If I would have known, I would not have missed so many HCQ doses."
	Unreliable sources	"I had to go to the internet, which is not a great place to get information!"
	Negative impact of information	"I read drowsiness as a side-effect from HCQ. It was very concerning."
	Absence of information	"My providers did not talk with about what to expect, med response. I never knew if my symptoms from med or lupus."
	Concerning or conflicting information	"I saw on the med source that HCQ is an anti-malarial drug. I freaked out."
Reasons for stopping or physical barriers	Side effects	"I had extremely bad nausea with the medication, I had to stop for few days." "I get hair loss from HCQ." "I get upset stomach every time I take it."
	Multiple meds	"I have to take 8 different meds at 3 different times. I work 3 shifts a day. Sometimes I forget taking the morning doses, but then I wonder if I can take it with the afternoon pills or not."
	Unclear benefits in lupus & lack of perceivable benefits	"What does HCQ do for me or my disease?", "I have not noticed much difference with HCQ." "prednisone helps, but I cant say the same for HCQ."
	Forgetfulness	"Lupus affects memory and causes overwhelming fatigue. I sleep often to ease off some of my symptoms and when I wake up, I forget if I took HCQ or not."
	Changes in social situation	"I was in between providers and I could not get medications as prescribed. It was overwhelming." "I lost insurance, I could not afford HCQ"
	Cost or refills inadequate	"I was in between insurance, I could not get my meds and ended up in the hospital." "I am not sure why we cannot get 90-day fill and several refills."
Misbeliefs-Assumptions	Long-term concerns about HCQ	"I am worried about losing vision with HCQ use", "I am worried about the long-term side effects from this medication on my organs and eyes.", "Dark urine, concerns me if HCQ is affecting my kidneys."
	Assumption-Misinformation	"I got cataracts, I have increased power of my glasses. This is HCQ related, got to be.", "As I undergo regular urine tests, I am concerned about kidney or other organ damage from HCQ.", "I have more blemishes after starting HCQ."
	Unclear HCQ role in lupus	"I think I get confused about HCQ and SLE, not sure how long it will be in their system, what exactly it is doing, and how it is helping."
Emotions & attitude	Worry	"I am worried about losing vision with HCQ use", "Will HCQ be safe for long-term use, I need more reassurance."
	Negative or unsure	"I started having several allergic reactions. I did not know what it really was coming from.", "When I started HCQ, my hair fell off. I was not sure if it was HCQ or something else."
	Experiences of family or friends	"It was hard for me to start HCQ, as my mother had suffered from muscle weakness after taking HCQ."
Comorbidities	Multiple chronic diseases	"I need to know if HCQ could interact with my other chronic diseases?", "My fatigue and pain is still there. I am not sure if HCQ is working or not."
	Brain fog-cognitive issues	"I often forget taking my HCQ doses due to brain fog."
	SLE disease burden	"I had severe disease and my SLE led to kidney disease, blood clots, skin rashes, and heart disease. I take several medications. It is overwhelming."
Medication Burden & Timing	Med schedules & daily pill burden	"My medication timing and schedules are skewed. If I miss a medication then it is very hard for me to pick back up.", " I stopped HCQ as it was honestly hard to keep up with the medications at different times of the day."
	Anxiety about meds	"I find it annoying to take 1.5 tabs a day. I am worried if this will change medication effects.", "I am worried if my eyesight changes are related or not."
Duration of Use	Lifelong use	"I was distraught with the idea that I have to take a medication for the rest life."
Young Age	Life course Risk	"The idea of taking a medication for the rest of my life was unsettling."

**Themes arranged from most common to least common listed frequency. **Only top key sub-categories for each theme shown.*

Results: Eleven patients participated in focus group meetings (attendance - 100% meetings 1-3, 90% 4th meeting); 60% were age ≤ 40 years, 10% male, 40% had disease duration ≤5 years, 70% were non-White, 40% with social challenges, 50% Milwaukee area, and 40% had severe CNS or renal SLE.

"Long-term concerns" and "worry", and "side-effects from HCQ" were the most frequently mentioned words or phrases during the initial focus group meeting where patients shared their perspectives and insights about HCQ (Figure 1A). Qualitative analysis identified eight themes regarding adherence based on patients' discussions about their insights and concerns about HCQ; sub-analysis revealed inter-relationships schematically shown in Figure 1B. The most commonly coded themes and subcategories are in Table 1. Finally, we categorized all patient-suggested strategies, which were ranked by patients from most valuable to least valuable in addressing underlying concerns and barriers in the real world (Table 2).

Table 2. Six Themes Highlighting Patient-Suggested & Ranked Strategies To Address Patient Concerns & Barriers

Themes*	Sub-Categories For Each Theme**	Illustrative Quotes (1-3)
Motivators (People, situations, things that motivate taking meds)	Positive med response	"After taking HCQ, I get less easily tired and have energy. I think HCQ response motivates me to take my medication."
	Fear of disease or hospitalization	"I take my medications, I don't want to be admitted again with SLE flare." "I do not want flares, so I take it." "I just want to feel normal so I take HCQ."
	Knowledge about HCQ role	"I was taking I think you know it did help, you know contribute to helping my body be remission" "I think it reduces flare-ups and pain, and prevents damage."
	Dialogue with healthcare team about concerns or side effects	"I was in remission and I stopped taking HCQ. It was hard for me to talk with my doctor but I did discuss with my rheumatologist about my concerns and if I need to start it or if we can monitor for now."
	Family support	"I take meds regularly so that I feel less tired and I can play with my daughter.", "My husband accepted my disease so, I accepted it as well."
	Better SLE labs	"I think the biggest thing for me was really, you know, seeing the positive test results knowing that you know, these medications were actually doing something good."
Filling Information Gaps & Resolving Conflicts	Validating information sources	"I think people have to be cautious with social media sites because even on lupus sites, people are commenting, but we have to be careful because they're not professionals and they're just giving their opinion."
	Positive impact of information	"I got diagnosed at a young age. I wanted to have kids, and was concerned with medications. My doctor said that HCQ will not be an issue. It alleviated my stress."
	Complete Adequate Med Information	"My rheumatologist and my pharmacist they work together and they kind of give me all med details, like take meds with food, take omeprazole on empty stomach."
Facilitators (Strategies that facilitate taking meds)	Personalization of strategies	"I have different alarm tunes for different meds scheduled to be taken at different time of the day." "I leave pillbox lid open so that I remember to take the med." "I keep meds need toothbrush so that I take it in the morning.", "I keep water near my pillbox."
	Attentive, knowledgeable & resourceful Healthcare team	"My rheumatologist told me that it would be the best option for me to see a lupus specialist, and he would not send me if he was not confident that I would be in good hands. He was right, things have been smooth. I owed him a bit of gratitude for this."
	Increased awareness/knowledge about lupus and meds	"There was some correlation between taking meds and me feeling better." "So, basically it came down to the lesser of two evils, med is a lot less bad than disease."
	Easier schedules	"I was told to take meds at the end of the day, I take HCQ as the last thing after I crawl into my bed. Works for me", "I was told to take both tablets together, so much easy."
	Reassurance on safety	"I would like my healthcare team to reassure me that HCQ is safe and the long-term use would not affect my organs."
	Connectivity through EMR & multidisciplinary clinics	"I pick up my medications if I've got questions, I message and their response is right there.", "I like the one-stop clinic, if I need a nephrologist or pharmacist or a social worker - they have it, its easy!"
Physical & personal reminders	Personalize reminders	"I have different alarm tunes for different meds throughout the day." "I leave pillbox lid open so that I remember to take the med." "I keep meds near toothbrush so that I take it in morning.", "I keep water near my pillbox to remind me to take meds."
	Simple strategies	"Taking both tablets together." "Using a pillbox."
	Reinforcement (using 2 reminders)	"I have a pillbox and I always have an alarm on my phone."
Improving clinician-patient & team communication	Attentive provider & focus on patient	"My rheumatologist makes sure I get my eyes checked regularly so they can kind of look at those results and make sure that they're [eyes] ok."
	Non-judgmental & positive communication	"I think, if the clinicians starts with open questions like what's going on? Any stress? Can I help? It would help patients to open up."
	Acting Promptly & Advocacy for patients	During shortage, my rheumatologist acted very quickly and got me adequate med supplies.
	Team engagement	"Both times I was pregnant and was high risk pregnancy. I think my OB and my rheumatologist were talking a lot"
	Tailored patient relevant details	"I only take questions to medical professionals as they know me and they tailor discussions pertaining to me and my lupus."
Building rapport & trust	Trust	"I trust my caregiver and their knowledge and experience, I think building that trust is very important for all lupus patients."
	Personal link with healthcare team	"We had that relationship, when he [rheumatologist] could just look at me and say you're not feeling good today right?"

**Themes ranked from most valuable to least valuable by patients. **Only top key sub-categories for each theme shown.*

Conclusion: Our study provide new insights regarding inter-related themes and insights about HCQ adherence, and patient-suggested and prioritized strategies will be most valuable for future interventions. Our study brings diverse patient voices to redesign adherence intervention in SLE by using a multifaceted patient-insight informed approach and patient-recommended strategies.

Abstract Number: 1164

A Survey of Treatment Satisfaction with Intravenous Immunoglobulin Among Patients with Inflammatory Myositis

Alan Zhou, Nancy Maltez and Catherine Ivory, University of Ottawa, Ottawa, ON, Canada

SESSION INFORMATION
Session Date: Monday, November 8, 2021
Session Title: Patient Outcomes, Preferences, & Attitudes Poster III: Patient Preferences (1153–1169)
Session Type: Poster Session C
Session Time: 8:30AM–10:30AM

Background/Purpose: Intravenous Immunoglobulin (IVIg) is used to treat rheumatic conditions such as Inflammatory Myositis. Subcutaneous Immunoglobulin (SCIg) is an alternative route of administering Immunoglobulin. Studies have demonstrated that home-based SCIg therapies are cost-effective with similar outcomes and less adverse events compared to IVIg. To date, there have been no studies that have investigated patient satisfaction with respect to IVIg use in myositis. Our objective was to characterize patient satisfaction regarding IVIg in the treatment of their myositis, and to explore their perceptions of SCIg and interest in transitioning to SCIg.

Methods: Adult patients (age 18+) receiving IVIg for Inflammatory Myositis at a Tertiary Centre in Ottawa, Canada were approached and provided informed consent to participate. An adaptation of the validated Treatment Satisfaction Questionnaire for Medication (TSQM) was administered to collect data on patient satisfaction of IVIg across 4 domains (effectiveness, convenience, side effect burden, and global satisfaction) and to gauge interest in SCIg. Data was collected using a 5 or 7-point Likert scale. Results were anonymized and summarized descriptively with means reported. Ethics approval was obtained from the Ottawa Health Science Network Research Ethics Board.

Results: Indications for IVIg included Dermatomyositis (50%), Polymyositis (12.5%), Anti-Synthetase Syndrome (12.5%), and other Inflammatory Myositis (25%). 50% of participants had received IVIg for more than 3 years, 37.5% had received for less than 1 year, and 12.5% had received for 1-3 years. On average, participants were satisfied with the effectiveness of IVIg (5.6/7). Participants were somewhat dissatisfied with the convenience (4.7/7) but satisfied with the ease of planning when treatments occur (5.6/7). 87.5% of participants had experienced side effects including headache (75%), fatigue (37.5%), nausea (25%), chills (25%), and cramps (12.5%). Side effects were rated as somewhat bothersome. Overall, participants were somewhat dissatisfied with their experience of IVIg (4.9/7). Scores across all 4 domains were similar regardless of diagnosis or treatment duration. 87.5% of participants had not heard about SCIg previously. Participants were somewhat uncomfortable with the idea of SCIg (4/7) with 37.5% citing lack of knowledge. 37.5% were willing to switch to SCIg, 12.5% were not, and 50% were unsure. Those willing to switch to SCIg had on average received IVIg for a shorter duration.

Conclusion: Our results suggest that participants are satisfied with the effectiveness of IVIg in treating their myositis but somewhat dissatisfied with the convenience. This discrepancy has been previously reported in other diseases treated with IVIg, with the inconvenience being attributed to the frequency and duration of infusion appointments. We hypothesize that inconvenience, in addition to somewhat bothersome side effects, may be driving down the global satisfaction score in our study. SCIg may offer a solution to the inconvenience of IVIg, though unfamiliarity with SCIg

may be a barrier to patient buy-in. Further patient education on SCIg as a treatment option in Inflammatory Myositis is required.

"What Matters": Patient and Clinician Perspectives in Psoriatic Arthritis Care

Philip Mease[1], Dan Furst[2], Evan Siegel[3], Vibeke Strand[4], Melissa Mcilraith[5], Elaine Husni[6] and M. Cameron Hay[7], [1]Swedish Medical Center/Providence St. Joseph Health and University of Washington, Seattle, WA, [2]University of California Los Angeles, Los Angeles, CA, [3]Arthritis and Rheumatism Associates, Potomac, MD, [4]Stanford University School of Medicine, Portola Valley, CA, [5]M.Mc. Consulting, Dallas, TX, [6]Cleveland Clinic, Cleveland, OH, [7]Miami University (Ohio), Oxford, OH

SESSION INFORMATION

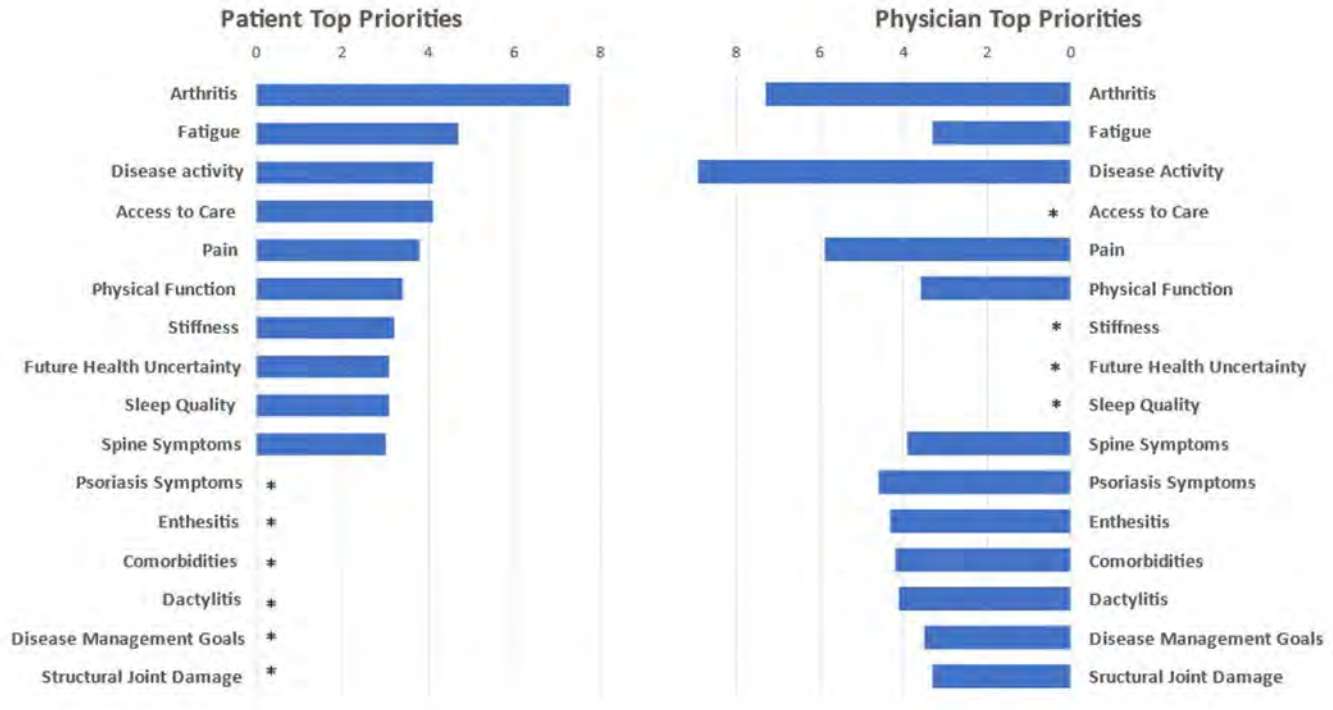
Session Date: Monday, November 8, 2021

Session Title: Patient Outcomes, Preferences, & Attitudes Poster III: Patient Preferences (1153–1169)

Session Type: Poster Session C

Session Time: 8:30AM–10:30AM

Figure 1. Top Patient and Physician Priorities



*Not in set of highest ranked items for that group

Background/Purpose: Recent psoriatic arthritis (PsA) treatment recommendations (1), highlight the importance of shared decision making; this ideally requires the clinician understands "what matters" to each patient regarding their disease. Concurrently, patient research partners have been incorporated into projects for the OMERACT core domain set (2) and measures of physical function and (health related) quality of life (3). However, less is known about the similarities and differences between patient and clinician perspectives regarding "what matters" in routine clinical care.

Methods: A comprehensive list of items describing the PsA patient experience was generated in medical anthropologist-designed (CH) peer-to-peer discussions in 4 patient focus groups across the United States (Seattle, Cleveland, Washington, DC). These items were combined with those from the GRAPPA-OMERACT PsA Outcomes patient-physician consensus project (2). A PsA physician and patient steering committee reviewed and revised the list with additional topics considered to be of importance. The final list of 51 items went through a 3 round Delphi process starting with 53 PsA patients and a 2 round Delphi with 13 PsA expert rheumatologists. In each round, participants rated each item for level of importance out of 100 total points.

Results: Top priority items for each group are depicted in Figure 1. Both patients and physicians rated 'Arthritis -Joint pain and swelling' in the top two. Five additional items were included for both groups but with different scores; all related to disease manifestations or physical consequences. 10 items received disparate priority between groups. In this set, patients included two unique items: access to care and future health uncertainty. Other items affecting everyday function were noted. Physician priorities included specific disease manifestations and physical/functional outcomes, and the topic of "disease management goals", focusing on patient-physician communication regarding a treatment plan.

Conclusion: Patients and physicians were in consensus that arthritis disease activity, pain and fatigue are key features of the patient's experience of PsA. Differences appeared in other domains; physicians ranked clinical domains such as enthesitis, dactylitis, and skin disease more highly, patients considered items such as access to care, future health uncertainty and sleep quality to be most important. This study highlights the need for physicians to ask and address "what matters" with patients and to educate patients about potential differences in physicians' areas of concern to optimize shared decision making.

Yes, but would like more information	6	26

mendations, and those that exist have mixed findings (Hauser, Journal of Pain 2017). Providers need to understand the prevalence of marijuana use among patients and their views regarding its use so that patients can be guided appropriately. This study assesses rheumatology patients' and rheumatologists' perspectives on marijuana use at an urban academic medical clinic.

Methods: Randomly selected patients from an academic rheumatology clinic were consented and enrolled to complete an IRB approved survey. An anonymous survey was given to rheumatology physicians in the same clinic to evaluate their perspectives on marijuana use. Quantitative statistics were used to analyze the data.

Table 3. Rheumatology Provider Responses

Rheumatology Provider Responses (N=12)

Measure	*n*	%
Estimated Percentage of Patients that Use Marijuana		
Less than 20 Percent	8	67
20 to 50 Percent	4	33
Over 50 Percent	0	0
Age of Patients that Use Marijuana (Multiple Answers Accepted)		
Less than 40 years old	8	57
Over 40 years old	6	43
Helpful to have Medical Marijuana Use in EMR		
Yes	10	83
No	2	17

Results: Forty-five patients completed the survey. Their demographics and pain assessment are in Table 1. Of the survey responses, 57% of patient had tried marijuana, with 50% using it weekly. Marijuana use was greater in patients over the age of 40 (p=0.05) and in those with a pain score greater than 6 (65%, p=0.01). Patients with no college degree used marijuana more than those with at least a college degree (p=0.02). Of marijuana users, 81% of patients stated that marijuana decreased their pain; 65% reported a decrease in pain medication use. There was no association between marijuana use and ethnicity, diagnosis, or employment status. The majority, 57%, of non-marijuana users were interested in trying it. Table 2 includes patient responses to the survey.

The results of the rheumatologists' survey are in Table 3. The physician survey found that 66.7% of the rheumatologists believed less than 20% of their patients were using marijuana and a majority felt that younger patients (less than 40) were more likely to use marijuana. Most rheumatologists felt that adding marijuana use to the electronic medical record would be helpful.

Conclusion: At an academic medical center, marijuana use was more common than providers expected and interestingly, more common in older patients. A majority of the patients who were not using marijuana, were interested in trying it. Given that marijuana use is increasing and may now even exceed tobacco use in many practices, it is important to ask about this in all patients. These results also highlight the need for high quality studies on the safety and effects of marijuana use in patients with rheumatic diseases.

Abstract Number: 1167

Rheumatoid Arthritis Patients' Treatment Goals Relate to Disease Activity and Rheumatology Experiences

Kelly O'Neill[1], Pamela Sinicrope[2], Kathryne Marks[3], Elena Myasoedova[2], Cynthia Crowson[4] and John Davis[2], [1]Rheumatoid Patient Foundation, Lutz, FL, [2]Mayo Clinic, Rochester, MN, [3]Rheumatoid Patient Foundation, Boston, MA, [4]Mayo Clinic, Eyota, MN

SESSION INFORMATION

Session Date: Monday, November 8, 2021

Session Title: Patient Outcomes, Preferences, & Attitudes Poster III: Patient Preferences (1153–1169)

Session Type: Poster Session C

Session Time: 8:30AM–10:30AM

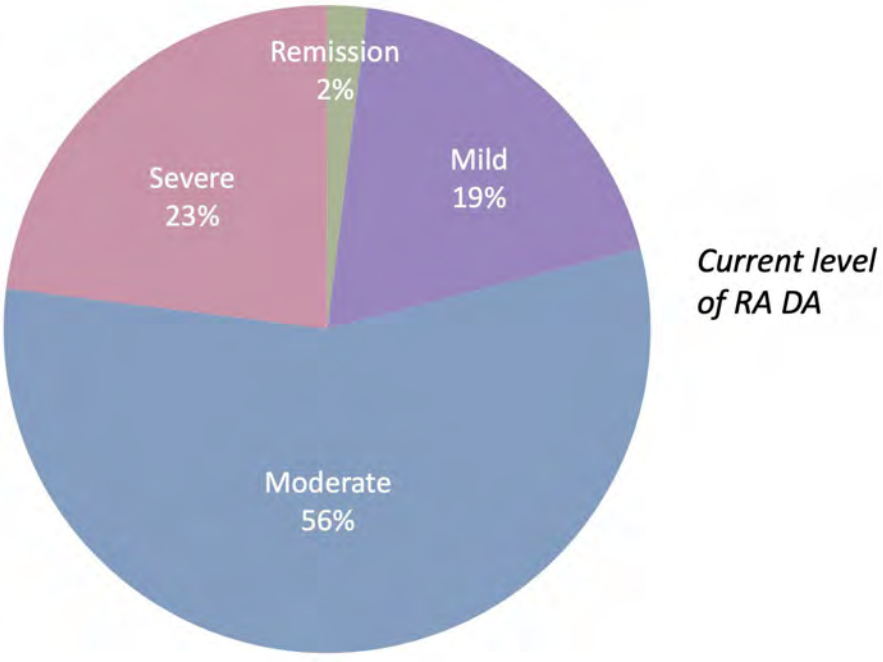
Background/Purpose: Shared decision making and treat to target are recognized guidelines to treat Rheumatoid Arthritis (RA). We previously reported associations of shared treatment goal discussions to greater disease activity (DA) improvement and satisfaction with rheumatology care. Further, only 37% of RA patients surveyed recall having shared goal discussions with providers. Building on our previous reports, we aimed to gain insight to the nature of patient treatment goals and their role in RA management.

Methods: An anonymous online questionnaire was presented in 2019 on a secure survey system. Participants were U.S. residents ≥18 years of age with a self-reported RA diagnosis by a medical professional. They responded to questions on demographics, RA disease activity, diagnosis and DMARD history, improvement from treatment, and

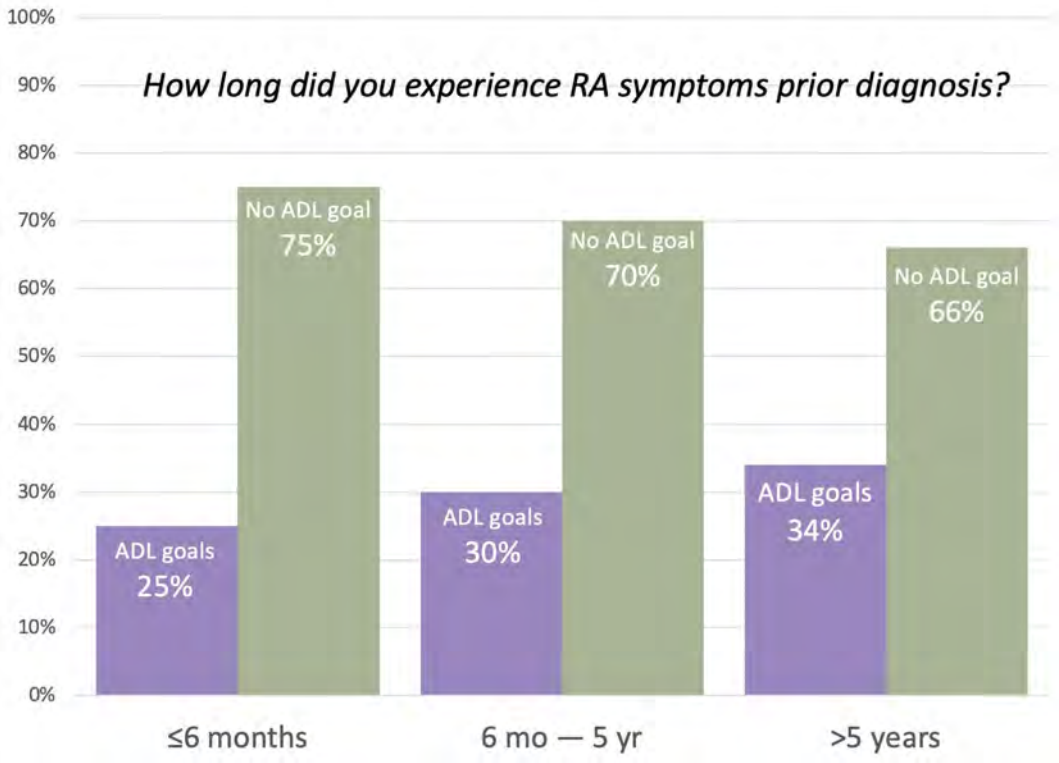
Parameter	Pain	Stop dz progress	Function: ADL	Function: Active	Function: Lifestyle
Current DA	Higher	Lower	Higher	Lower	Lower
Goal discussions	*	More likely	More likely	More likely	More likely
Remission	Less	More	Less	More	Less
No treatment plan	More likely	More likely	Less likely	More likely	Less likely
Time to treatment	Longer	Longer	Longer	Shorter	Shorter
Patient satisfaction	Less	*	Less	Higher	*
# DMARDs tried	More	More	*	Fewer	*

* No clear trend

Parameters that associate with patients' top RA treatment goals With certain parameters, particular RA treatment goals are more likely.



RA Patients Whose Treatment Goals Are Related to Pain: Figure 1. Respondents describing their RA treatment goals using "pain" (or a synonym for pain) are divided by their replies to the question "What is your current level of RA DA?"



Frequency of ADL Goals by Time Before RA Diagnosis: Figure 2. Patients describing their RA treatment goals as relating to activities of daily living (ADLs) were asked how long they had RA symptoms prior to diagnosis.

RA treatment goals. Patients' treatment goals were thematically coded and verified for reliability by a team using qualitative content analysis. If >1 goal was conveyed, both were coded; "To be able to do daily activities without so much pain" mentioned both ADL and pain goals.

Results: The questionnaire was completed by 907 RA patients (90% women, 10% men), with 58 (11) years mean (SD) age and 11 (10) years since diagnosis. In response to the question "What are your goals for RA treatment?", 95% recorded responses (n=861). Fifteen themes were identified, 8 of them present in ≥20% of respondents. Major themes were *function* 59%, *pain* 53%, *stopping disease progression* 30%, *extra-articular disease effects* 26%, *medication* 21%, *communication with providers* 21%, *remission* 20%, and *less disease activity* 20%. Function goals included 3 subthemes: *activities of daily living* (ADL) 31%, *lifestyle* 18%, and *being active* 10%. Subthemes in extra-articular goals included *constitutional health* 17%, *overall health* 5%, and *organ involvement* 4%. Minor themes included *very modest goals* 7%, *nontraditional medicine* 4%, *understanding* 3%, *story but no goal* 2%, *cure* 1%, *hopelessness* 1%, and *hope* 0.7%. Major themes associated with DA levels, time to treatment, shared goal discussions, and presence of treatment plans. Higher DA associated with goals related to pain or ADL; lower DA related to goals of lifestyle, being active, and stopping disease progression. Examples of typical treatment goals: "Significant pain reduction"; "Limit joint damage"; "Able to maintain all independence."

Conclusion: This RA patient survey found previously unreported themes in patients' treatment goals, which associated with aspects of rheumatology care such as presence of a treatment plan or a shared goal discussion as well as RA disease activity. Our study is unique in coding patient treatment goals by common themes. Further research should seek greater understanding of patient treatment goals and investigate their significance in RA outcomes.

Abstract Number: 1168

Barriers to Effectiveness of Non-surgical Treatments for Knee Osteoarthritis in a Diverse Racial/Ethnic Population: A Nominal Group Qualitative Study

Jasvinder Singh, University of Alabama at Birmingham, Birmingham, AL

SESSION INFORMATION
Session Date: Monday, November 8, 2021
Session Title: Patient Outcomes, Preferences, & Attitudes Poster III: Patient Preferences (1153–1169)
Session Type: Poster Session C
Session Time: 8:30AM–10:30AM

Background/Purpose: Knee osteoarthritis (OA) has worse outcome in racial/ethnic minorities, who also have more severe pain, disability and worse outcomes. However, most qualitative studies include primarily Caucasian people with knee OA. Therefore, our objective was **t**o examine patient experience, views and opinions of reasons for why the current knee OA treatments are not working for them in a diverse racial/ethnic group of people.

Methods: Nominal groups were conducted with consecutive clinic patients with knee OA at a medical center, oversampling African Americans. Patients discussed and rank-ordered their concerns.

Results: Fourteen nominal groups with 48 knee OA patients were conducted with mean age, 60.6 years (standard deviation, 9.8) and knee OA duration, 7.8 years (sd, 5.4); 25% were men, and 46% were African American. The most frequently cited highly-ranked concerns, divided into 3 categories as follows:

A. Medication-related: (1) side effects (9 groups); (2) limited efficacy (9 groups); (3) medication not targeting underlying disease; (4) lack of personalized medication use; and (5) temporary benefit;

B. Exercise/Physical therapy related: (1) exacerbation of joint pain (8 groups); (2) difficulty in doing exercises (6 groups); (3) lack of motivation (8 groups); (4) technical challenges/lack of personalized exercise regimens (1 group); (5) cost (3 groups); and

C. Weight loss related: (1) difficulty in achieving weight loss (7 groups); (2) motivation (2 groups); and (3) limited efficacy for symptom improvement (1 group).

Conclusion: Participants with knee osteoarthritis, consisting of a diverse racial/ethnic representation, identified several barriers to the effectiveness of current knee OA treatments. This new knowledge provides insights for making the current treatment options potentially more usable and/or more effective. Given the significant consequences of knee OA, limited/no disease-modifying drugs this strategy can potentially improve clinical care and patient outcomes.

Disclosure: J. Singh, Crealta/Horizon, 2, Medisys, 2, Fidia, 2, PK Med, 2, Two labs Inc, 2, Adept Field Solutions, 2, Clinical Care options, 2, Clearview healthcare partners, 2, Putnam associates, 2, Focus forward, 2, Navigant consulting, 2, Spherix, 2, MedIQ, 2, Jupiter Life Science, 2, UBM LLC, 2, Trio Health, 2, Medscape, 2, WebMD, 2, Practice Point communications, 2, the National Institutes of Health, 2, the American College of Rheumatology, 2, TPT Global Tech, 11, Vaxart pharmaceuticals, 11, Charlotte's Web Holdings, Inc., 11, Amarin pharmaceuticals, 11, Viking pharmaceuticals, 11, Moderna pharmaceuticals, 11, speaker's bureau of Simply Speaking, 6, member of the executive of Outcomes Measures in Rheumatology, 4.

Abstract Number: 1169

Patient Preferences for Outcome Measures for a Pragmatic Knee Osteoarthritis (OA) Clinical Trial: Results of a Cross-Sectional Patient Survey That Included Racial/Ethnic Minorities

Jasvinder Singh, University of Alabama at Birmingham, Birmingham, AL

SESSION INFORMATION

Session Date: Monday, November 8, 2021

Session Title: Patient Outcomes, Preferences, & Attitudes Poster III: Patient Preferences (1153–1169)

Session Type: Poster Session C

Session Time: 8:30AM–10:30AM

Background/Purpose: Many effective treatments are available for knee osteoarthritis (OA), however comparative effectiveness research (CER) of various treatments to each other is limited. One of the key challenges to conducting knee OA trials is the choice of primary trial outcome, that is sensitive to change and is relevant to patients as the key stakeholders. Therefore, we conducted a cross-sectional study to examine the outcomes most relevant to patients with knee OA in a sample that included racial/Ethnic minorities.

Methods: We enrolled consecutive patients with a clinical diagnosis of knee OA at a tertiary medical center clinic, oversampling for African Americans with knee OA, during regular clinic visit. Participants ranked various knee OA outcomes in response to the question: "How important is the assessment of the following outcomes in a study of people with knee osteoarthritis?"

Results: In a pilot study of 58 people with knee OA (mean age, 57 years; 72% female; 69% White) at regular clinic visits, the respondents ranked the following outcomes as extremely, very or moderately important for this study: knee pain (95%); function (86%); sleep (87%); fatigue (92%); patient acceptable symptom state (89%); social participation (77%); anxiety/depression (86%). Only 37% of patients were satisfied or very satisfied with current knee OA treatment.

Conclusion: This patient-focused study identified that a large group of patients were unsatisfied with current knee OA treatments. The chosen study outcomes reflect a range of components and outcomes important to patients and other key stakeholders. Identification of patient-relevant and patient-important study outcomes will make outcome selection practical for a pragmatic clinical trial.

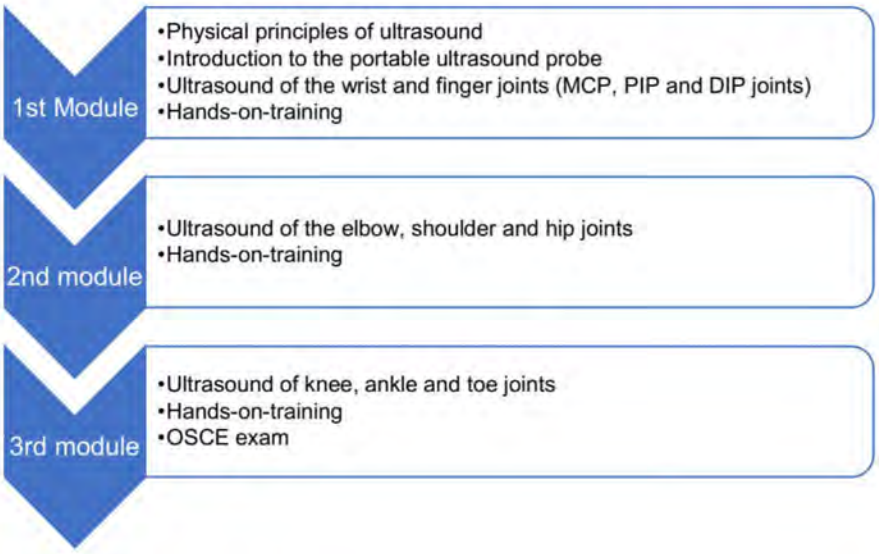
Abstract Number: 1170

Establishment and Validation of a Didactic Musculoskeletal Ultrasound Course for Dermatologists Using an Innovative Handheld Ultrasound System

Jakub Grobelski[1], Florian Recker[2], Pantelis Karakostas[1], Dagmar Wilsmann-Theis[3], Wolfgang Hartung[4], Peter Brossart[5] and **Valentin Schäfer**[1], [1]Clinic of Internal Medicine III, Oncology, Haematology, Rheumatology and Clinical Immunology, University Hospital Bonn, Bonn, Germany, [2]Centre for Obstetrics and Gynecology, University Hospital Bonn, Bonn, Germany, [3]Department for Dermatology and Allery, University Hospital Bonn, Bonn, Germany, [4]Department of Rheumatology and Clinical Immunology, Asklepios Clinic, Bad Abbach, Germany, [5]Department of Internal Medicine III, Oncology, Hematology and Rheumatology, University Hospital Bonn, Bonn, Germany



Graphic 1. Ultrasound Course Module Structure

SESSION INFORMATION
Session Date: Monday, November 8, 2021
Session Title: Professional Education Poster (1170–1195)
Session Type: Poster Session C
Session Time: 8:30AM–10:30AM

Background/Purpose: In the early detection of arthritis, such as psoriatic arthritis, ultrasound (US) of painful joints plays an important role in diagnosis. Pathological findings can be missed during clinical examination, especially if conducted by physicians who are not trained. Furthermore several publications undermine the importance of early psoriatic arthritis detection in psoriasis patients and the key role of the dermatologists in this process. The objective of this study was to examine a pilot musculoskeletal ultrasound (MSUS) course designed specifically for dermatologists.

Methods: To assess the degree of US expertise of the participants, a questionnaire was conducted before the course. The course concept covered only the most important US sections of all joints and focused on the detection of joint effusion and hyperperfusion. The course consisted of 3 modules and was carried out over 6 months. Graphic 1 shows the modular course concept. A portable US system in combination with a tablet was provided, to enable practice between the courses. The final teaching evaluation was carried out as an objective structured clinical examination (OSCE)(5) consisting of 3 stations, each representing 1 of the course modules. Graphic 2 shows exemplary the course teaching sessions. According to the following grade scoring system, the performance rating was checked: < 60 % failed, ≥ 60 - < 70 % sufficient, ≥ 70% - < 80 % satisfying, ≥ 80% - < 90 % good, ≥ 90 % very good.

Results: Twelve dermatologists participated. The mean age of our cohort was 39 years (SD ± 9.99 years) with 9 females (75 %). Eight were specialists in dermatology in mean for 11.4 years (SD ± 11 years). Four were assistant physicians practicing dermatology in mean for 3.06 years (SD ± 0.97 years).

The survey revealed no prior knowledge of MSUS. The overall mean score of all participants in the OSCE was 21.86 (SD ± 2.12) (87.44%) out of a total of 25 points resulting in a good grade. There was no statistically significant difference between the assistant physicians and the specialists in dermatology regarding the OSCE results. Table 1 shows the OSCE results.

Graphic 2. Practical exercises during the course

Table 1. Objective structured clinical examination results for all three stations in mean Module 1: representing the first OSCE station, Module 2: representing the second OSCE station, Module 3: representing the third OSCE station, overall: the mean result for all OSCE modules

Module	Mean absolute	Standard Deviation	Confidence Interval	Mean percentage	Standard Deviation	Confidence Interval	Grade
1	18.92	+/- 3.07	16.97-20.87	75.67 %	+/-12.27%	67.87-83.46 %	Sufficient
2	23.83	+/-0.99	23.21-24.46	95.33 %	+/-3.94 %	92.83-97.84 %	Very good
3	22.83	+/-0.37	22.60-23.07	91.33 %	+/-1.49 %	90.39-92.28 %	Very good
overall	21.86	+/-2.12	16.59-27.13	87.44 %	+/-8.49 %	66.36-108.53 %	Good

Conclusion: The innovative teaching concept MUDE was able to demonstrate, that it is appropriate for the training of dermatologists in MSUS, independently of their age, experience in dermatology and US.

Abstract Number: 1171

Needs Assessment of a Rheumatology Curriculum for Internal Medicine Residents

Laura Arneson[1], Biana Modilevsky[2], Kaitlin Lima[1], Sarah Fantus[1] and Anisha Dua[3], [1]Northwestern University Feinberg School of Medicine, Chicago, IL, [2]Swedish Hospital, NorthShore University HealthSystem, Chicago, IL, [3]Northwestern University, Chicago, IL

SESSION INFORMATION
Session Date: Monday, November 8, 2021
Session Title: Professional Education Poster (1170–1195)
Session Type: Poster Session C
Session Time: 8:30AM–10:30AM

Background/Purpose: The rheumatology workforce faces a shortage in the decade ahead. Internal Medicine (IM) residents comprise the pipeline of physicians who will care for rheumatology patients in general medicine, rheumatology, and other specialties. However, many IM residencies lack formal training on rheumatologic diseases. This needs assessment investigated IM residents' interest, competence, and preferred format of learning rheumatology topics. Results will guide the development of a curriculum to enhance rheumatology teaching for medicine trainees.

Methods: The study population consisted of IM residents at a university hospital (Program A, n=116) and a community hospital (Program B, n= 23). Residents' objective knowledge of rheumatology was assessed via In-Training Exam (ITE) scores from 2020. Their confidence and interest in clinical rheumatology was assessed through an anonymous survey. The survey queried residents' confidence in and interest in learning about six skills: conducting a rheumatology review of systems, performing a large joint exam, performing a small joint exam, ordering appropriate labs for

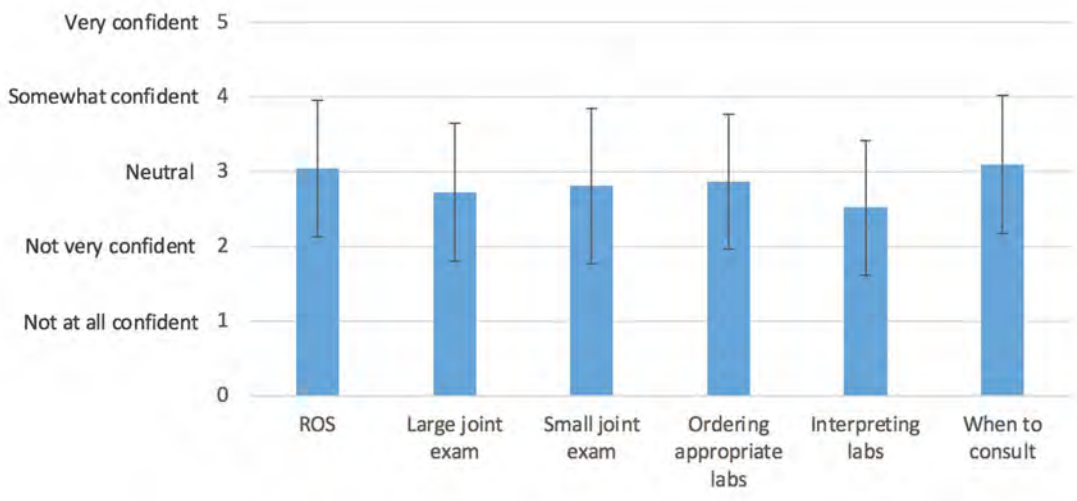

Figure 1. Residents' confidence in rheumatology skills (n=73). Average scores on a 5-point Likert scale are presented, with error bars indicating one standard deviation.

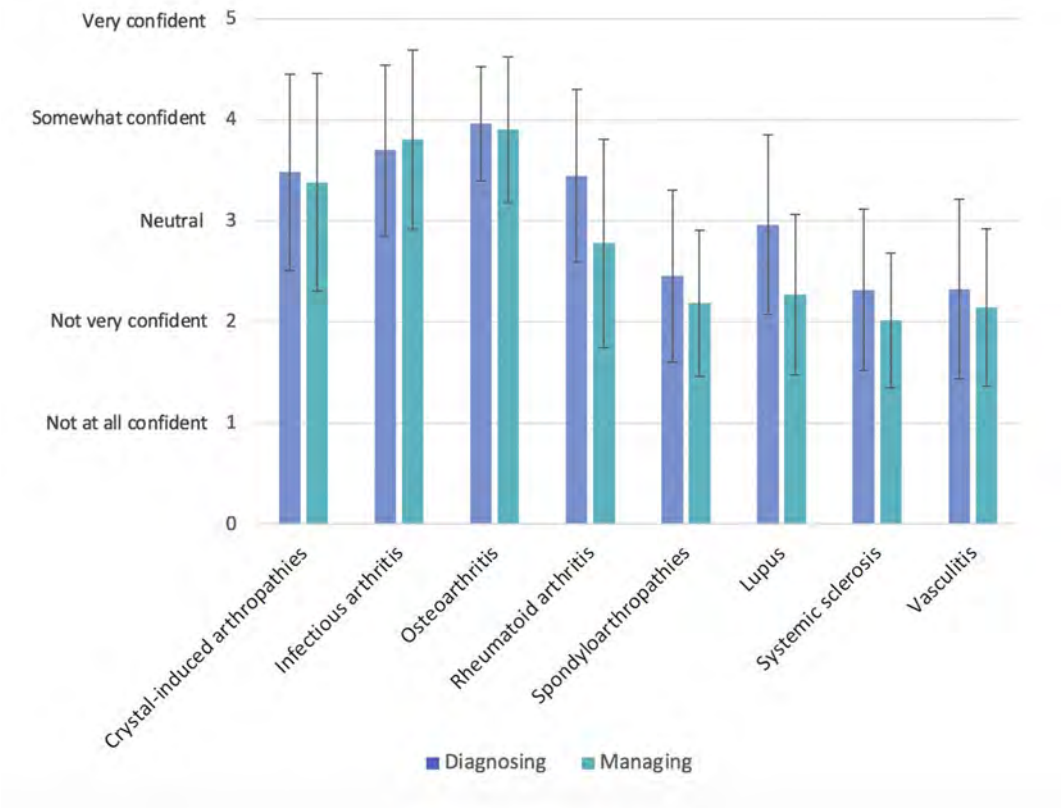

Figure 2. Residents' confidence in diagnosing (left bar) and managing (right bar) rheumatologic conditions (n=73). Average scores on a 5-point Likert scale are presented, with error bars indicating one standard deviation.

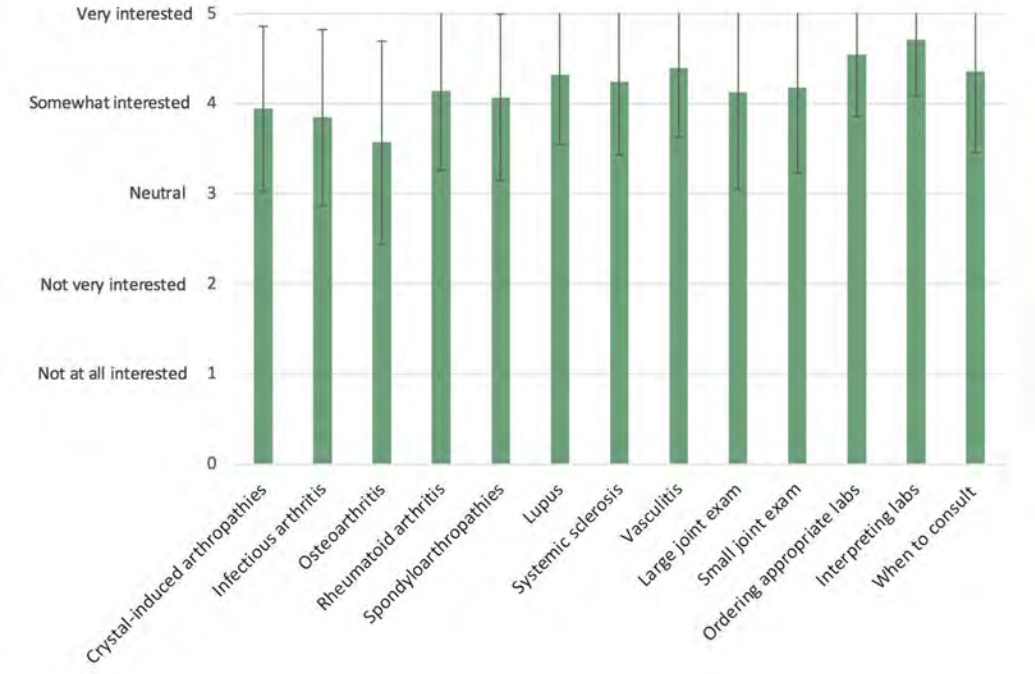

Figure 3. Residents' interest in learning about rheumatology topics (n=72). Average scores on a 5-point Likert scale are presented, with error bars indicating one standard deviation.

autoimmune diseases, interpreting labs for autoimmune diseases, and deciding when to consult rheumatology. It also assessed residents' confidence in diagnosing and managing, and interest in learning about, eight rheumatologic disease categories: crystal-induced arthropathies, infectious arthritis, osteoarthritis, rheumatoid arthritis, spondyloarthropathies, lupus, systemic sclerosis, and vasculitis. Survey questions were presented on five-point Likert scales.

Results: On the 2020 ITE, rheumatology was the subspecialty with the lowest average score for residents nationwide (59%), at Program A (60%), and tied for lowest at Program B (48%). Surveys were completed by 53/116 (46%) of residents at Program A and 20/23 (87%) of residents at Program B. Responses were similar between Program A and B across all questions, and are presented as aggregate scores. Average interest in learning about rheumatology was 3.8/5, between "neutral" and "somewhat interested." Average rating of the amount of rheumatology training received in residency was 2.3/5, between "somewhat inadequate" and "neutral." Confidence in rheumatology skills is presented in Figure 1. Confidence in diagnosing and managing specific rheumatologic conditions is presented in Figure 2. Interest in learning about rheumatology topics is presented in Figure 3. Topics for which residents expressed lowest confidence and highest interest included: ordering and interpreting labs for autoimmune diseases, lupus, vasculitis, and systemic sclerosis. Residents identified noon conference and online self-paced modules as the preferred curriculum formats.

Conclusion: IM residents at both programs demonstrated objective deficits in rheumatology knowledge on the ITE, as well as self-reported need and interest in more rheumatology training. ITE scores and our survey results highlight the urgent need to better address rheumatology training for IM residents nationwide. The study team is developing a series of noon conference sessions for IM residents on the topics identified above, to be recorded and archived for future use.

Disclosure: L. Arneson, None; **B. Modilevsky**, None; **K. Lima**, None; **S. Fantus**, None; **A. Dua**, Abbvie, 1, 2, 6, Novartis, 2, Chemocentryx, 2.

Abstract Number: 1172

Podcast-Based Learning, a Valuable Tool for Learning Rheumatology

Akrithi Udupa[1], Sophia Weinmann[2] and David Leverenz[3], [1]Duke University Hospital, Durham, NC, [2]Duke University Medical Center, Durham, NC, [3]Duke University, Durham, NC

SESSION INFORMATION
Session Date: Monday, November 8, 2021
Session Title: Professional Education Poster (1170–1195)
Session Type: Poster Session C
Session Time: 8:30AM–10:30AM

Background/Purpose: The onset of the COVID-19 pandemic disrupted the delivery of medical education to trainees, compelling educators to utilize virtual learning platforms. The purpose of this project is to assess the educational value, accessibility, and impact of podcast-based learning as a complementary learning tool for medical trainees rotating on an inpatient rheumatology service at a single academic institution.

Methods: From July 2020 to April 2021, medical trainees (physician assistant student, medical students, residents) rotating on an inpatient rheumatology consult service were given access to a podcast comprised of educational conversations between a fellow and an attending on various topics in Rheumatology, stored on a password protected server. All podcast episodes were less than 25 minutes in length. Access statistics from the server included "previews" (when a trainee listened to an episode directly on the server) and "downloads" (when a trainee downloaded

Table 1. Podcast episode engagement among survey respondents and direct access stats from the podcast server

Podcast episode	Survey respondents	Direct access statistics*	
	n (%)	Previews (n)	Downloads (n)
Systemic Lupus Erythematosus	18 (90%)	51	43
Myositis Part 1	14 (70%)	65	43
Myositis Part 2	8 (40%)	NA†	NA†
Arthrocentesis	8 (40%)	14	19
Giant Cell Arteritis	13 (65%)	43	23
Gout Part 1	10 (50%)	16	13
Gout Part 2	9 (45%)	16	17

Table Notes:
*Trainees could preview or download each episode multiple times, therefore percentages could not be calculated.
†Access statistics were not available for these episodes.

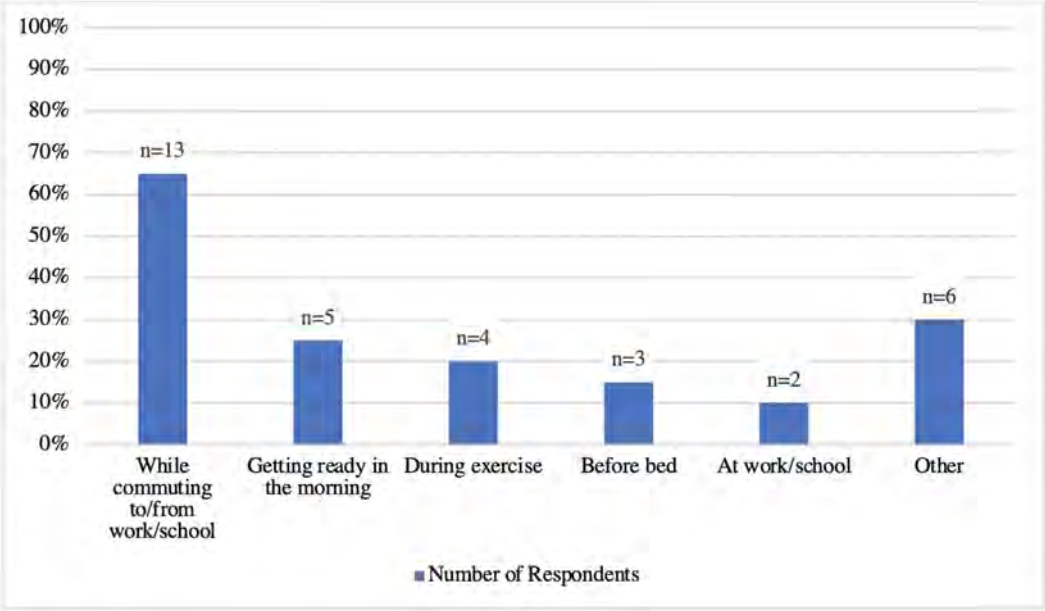

Figure 1. Number of survey respondents who reported listening to the podcast at particular times.

an episode to a device). Participants were surveyed on prior podcast listening, engagement with the rheumatology podcast intervention, perceptions of the podcast's appropriateness of educational content, learning, enjoyment, accessibility, and direct impact on clinical care of rheumatic patients. Data were examined using descriptive statistics.

Table 2. Survey results among 20 respondents regarding podcast educational content, enjoyment, impact, and accessibility.

	Strongly Disagree n (%)	Disagree n (%)	Agree n (%)	Strongly Agree n (%)
The educational content in the podcasts was appropriate for my level of training	1 (5%)	0 (0%)	6 (30%)	13 (65%)
I enjoyed listening to the podcasts	1 (5%)	0 (0%)	4 (20%)	15 (75%)
I learned a lot from the podcasts	1 (5%)	0 (0%)	6 (30%)	13 (65%)
Listening to the podcasts directly changed my approach to evaluation, diagnosis and treatment of patients with rheumatic disease	1 (5%)	0 (0%)	8 (40%)	11 (55%)
It was easy to access and listen to the podcasts	0 (0%)	6 (30%)	2 (10%)	12 (60%)

Results: Of the 41 trainees who received a survey, 20 (48.87%) responded, including 1 physician assistant student, 7 medical students, 5 interns, 3 second-year internal medicine residents, and 4 third-year residents. Prior to this study, 7/20 (35%) spent greater than two hours per week listening to podcasts on any topic and 2/20 (10%) did not listen to any podcasts. Regarding the rheumatology podcast intervention, all respondents reported listening to at least one podcast episode, 12/20 (60%) listened to at least half of the episodes, and 5/20 (25%) listened to all episodes. As shown in Table 1, more than half the respondents listened to episodes on systemic lupus erythematosus, myositis (part 1), and giant cell arteritis; these episodes also received the most "previews" and "downloads" from the podcast server. The preferred podcast episode length was between 10 and 30 minutes for 17/20 (85%) of respondents. As shown in Figure 1, respondents most often played the podcast while commuting to and from school or work (n = 13, 65%). As shown in Table 2, 19/20 (95%) respondents agreed or strongly agreed that the educational content of the podcast was appropriate for level of training, enjoyable and educational, and directly impacted their approach to evaluating, diagnosing, and treating patients with rheumatic disease. Although 14/20 (70%) agreed or strongly agreed that the podcast was easily accessible, 6/20 (30%) disagreed with this statement.

Conclusion: Medical education podcasts are emerging as a supplementary learning tool at all stages of training. Our study demonstrates that medical trainees voluntarily listened to our Rheumatology podcast and the majority of survey respondents found the podcast to be educational, enjoyable, and impactful for rheumatology patient care. Reported difficulty with playing the podcast on the server emphasizes the importance of accessibility in successful podcast learning.

Bringing Reproductive Health Guidelines into Fellowship Training: A National Survey of Adult and Pediatric Rheumatology Fellows and Program Directors to Assess Educational Need and Inform Curriculum Development

Megan Clowse[1], Stacy Ardoin[2], Elise Berlan[2], Kristine Carandang[3], Kate Chiseri[4], Arthur Kavanaugh[5], Whitney White[6], Kelly Wise[7], Andrew Wong[8] and Michael Battistone[9], [1]Duke University, Chapel Hill, NC, [2]Nationwide Children's Hospital, Columbus, OH, [3]Independent, San Diego, CA, [4]American College of Rheumatology, Atlanta, GA, [5]University of California San Diego, La Jolla, CA, [6]Birmingham VA Medical Center, Birmingham, AL, [7]Nationwide Children's Hospital, Hilliard, OH, [8]Olive View-UCLA Medical Center, Sylmar, CA, [9]Salt Lake City VA, Salt Lake City, UT

SESSION INFORMATION

Session Date: Monday, November 8, 2021

Session Title: Professional Education Poster (1170–1195)

Session Type: Poster Session C

Session Time: 8:30AM–10:30AM

Background/Purpose: In 2020, the American College of Rheumatology (ACR) published clinical practice guidelines addressing reproductive health for patients with rheumatic diseases. The guidelines are the culmination of a 5-year, multi-specialty, interprofessional effort, now known as the Reproductive Health Initiative (RHI). The 2-fold purpose of this study was to (Part I) design national surveys of rheumatology fellows and fellowship program directors (PDs) to inform development of curricula and programs relating to RHI guidelines, and to examine evidence of validity of these surveys using Messick's framework prior to (Part II) future implementation of an ACR sponsored national survey project, coordinated through the Committee on Training and Workforce.

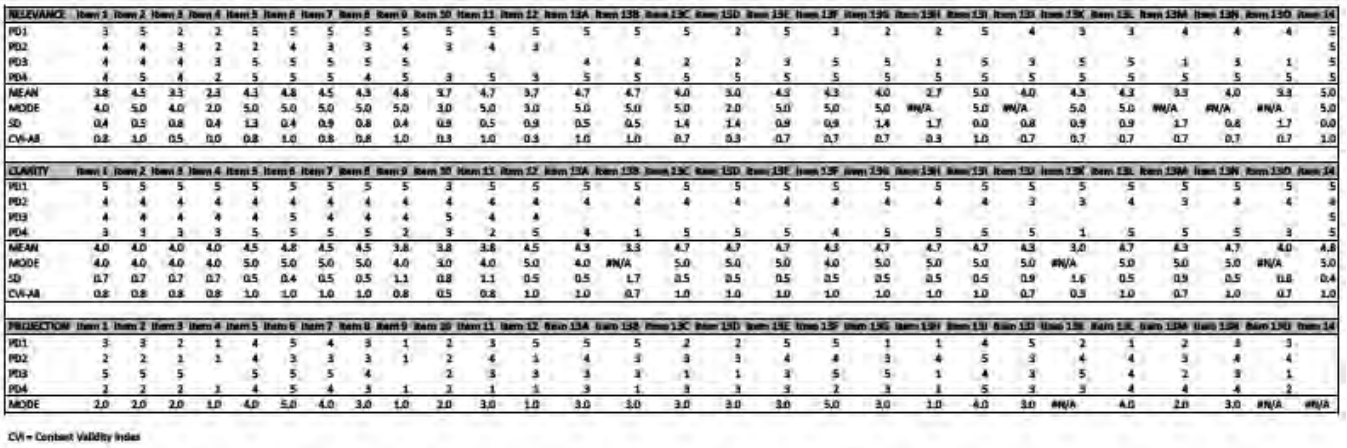
CVI = Content Validity Index

Table 2. Expert Review Ratings - Program Directors Survey



CVI = Content Validity Index

Constructs of interest were defined through literature review and refined by reflective critique from 8 RHI members, facilitated by a former PD working with a member of the ACR administrative staff. A panel of 9 outside expert reviewers (5 rheumatology fellows and 4 PDs) evaluated survey items for relevance to the constructs and clarity of communication. Descriptive statistical analyses of ratings were performed, and content validity index (CVI) for each item was calculated. Items with CVI < 0.7 were discarded.

Response Process

Cognitive interviewing, consisting of "think aloud interviewing" in which a participant was asked to verbalize their understanding of items through paraphrase, was used to clarify the mental model emerging through survey use.

Results: The construct of interest was defined as "interest in curriculum", and was considered separately for fellows and PDs. Both fellow and PD constructs were conceptualized as 4 dimensions: 1) **confidence** in the current curriculum relating to RHI guidelines; 2) **personal interest** in the topic; 3) **opinions of the importance** of the topic; and 4) **interest in a range of learning materials and educational experiences**. Initial surveys consisted of 27 items for fellows and 28 items for PDs. Expert review ratings are shown in Table 1 (fellow survey) and Table 2 (PD survey), and led to discarding 9 items for fellows and 6 items for PDs; 5 of these were corresponding questions shared across the 2 surveys. Cognitive interviewing suggested that fellows considered questions relating to their level of interest in reproductive health as connecting to a sense of ownership or responsibility for addressing these issues. Final versions of the surveys consisted of 18 items for fellows and 22 items for PDs and are being sent to 753 fellows and 179 program directors representing adult and pediatric rheumatology fellowships.

Conclusion: Validity evidence from content and response process sources support national distribution of the surveys to rheumatology fellows and fellowship PDs. Data collected through (Part II) this ACR sponsored national survey will be of value to educational leaders in developing curricula and programs to improve reproductive health for patients with rheumatic disease.

Teaching and Reproducibility of a Pediatric Musculoskeletal Ultrasound Scoring System

Ysabella Esteban[1], Jackeline Rodriguez-Smith[2], Marie Tominna[2], Arthur Meyers[2], Michael Henrickson[2], Amy Cassedy[2], Tracy Ting[2] and Patricia Vega-Fernandez[2], [1]Cincinnati Children's Hospital and Medical Center, Cincinnati, OH, [2]Cincinnati Children's Hospital Medical Center, Cincinnati, OH

SESSION INFORMATION
Session Date: Monday, November 8, 2021
Session Title: Professional Education Poster (1170–1195)
Session Type: Poster Session C
Session Time: 8:30AM–10:30AM

Background/Purpose: Localized musculoskeletal ultrasound (MSUS) examination is used in adult rheumatology clinics and has been shown to be a valid and feasible method for assessing joint inflammation in rheumatoid arthritis. Pediatric MSUS continues to be an evolving topic of research within the field, with ongoing standardization of protocol and scoring systems. The purpose of this study is to determine the time and resources necessary to reliably train pediatric MSUS sonographers of differing specialties and levels of expertise to reliably utilize a recently proposed 12-joint MSUS scoring protocol in children.

Methods: Physicians of varying degrees of MSUS experience were recruited, including a second-year pediatric rheumatology fellow, a third-year pediatric rheumatology fellow, a pediatric rheumatologist, a pediatric radiology fellow, and a pediatric radiology attending with expertise in musculoskeletal imaging. The group then underwent educational and calibration exercises led by a pediatric rheumatology attending with expertise in musculoskeletal ultrasound,

Table 1. Intraclass correlation between scorers using a pre-existing pediatric musculoskeletal scoring system.

	B-Mode		PD	
Joint/Tendon Area	ICC	Lower CI – Upper CI	ICC	Lower CI - Upper CI
Anterior Elbow	0.93*	0.89 – 0.95*	0.88*	0.77 - 0.94*
Posterior Elbow	0.93*	0.89 - 0.95*	0.77	0.61 - 0.87
Distal Radioulnar Joint	0.87*	0.78 - 0.92*	0.93*	0.87 - 0.96*
Dorsal Medial - Wrist	0.86*	0.80 - 0.90*	0.96*	0.94 - 0.97*
Dorsal Ulnar – Wrist	0.80	0.65 - 0.89	0.90	0.71 - 0.97
Tendons – Wrist	0.74	0.58 - 0.84	0.66	0.35 - 0.84
Talonavicular joint	0.66	0.41 - 0.82	0.91	0.8 - 0.96
Midline Tibiotalar Joint	0.92*	0.88 - 0.95*	0.87*	0.75 - 0.93*
Lateral Tibiotalar Joint	0.86*	0.74 - 0.93	-**	
Medial Tibiotalar Joint	0.82	0.67 - 0.91	-**	
Medial Subtalar Joint	0.77	0.63 - 0.86	0.83	0.59 - 0.94
Lateral Subtalar Joint	0.73	0.57 - 0.84	-**	
Tendons – Ankle	0.53	0.26 - 0.73	0.55	0.1 - 0.81

*Desired reliability attained. **Insufficient data to assess.

detailing the normal anatomy and pathologic variations related to arthritis of the elbow, metacarpal-phalangeal joint, wrist, knee, and ankle in B-mode and power doppler (PD) – mode. The scoring system is based on a semiquantitative scale with grading from 0-3 (0 being normal, 3 being severe pathology), utilizing both B- and PD-mode images. Each participant then scored ultrasound images from an image bank including B- and PD-mode of each joint of varying pathology. The inter-rater reliability, using the intraclass correlation (ICC), was assessed, with a goal of 0.75 or higher for the lower CI for each joint.

Results: A 26- to 39-minute educational and calibration exercise was performed for each selected joint. Participants then completed a reliability exercise for each joint (Table 1). There was good to excellent interrater reliability for the anterior elbow B-mode and PD-mode, posterior elbow B-mode, distal radioulnar joint B-mode and PD-mode, dorsal medial view of the wrist B-mode and PD-mode, talonavicular joint PD-mode, and midline tibiotalar joint B-mode and PD-mode. The remainder of the joint and tendon views demonstrated need for improvement, when considering the goal of 0.75 or higher for the lower CI. At the time of submission, the results for the knee scoring are pending, and there are ongoing training activities looking to improve the reliability of this diverse group. Repeat calibration and scoring exercises will continue to occur until excellent reliability is reached for all views/joints in this group.

Conclusion: Undergoing a single round of educational and calibration sessions facilitated the upskill of a diverse group of academic pediatric ultrasonographers, who demonstrated good to excellent interrater reliability for some joints using a recently proposed pediatric 12-joint MSUS scoring system. There is need for continued improvement in reproducibility and interrater reliability, perhaps via repeated interactive educational and calibration exercises.

Session Title: Professional Education Poster (1170–1195)

Session Type: Poster Session C

Session Time: 8:30AM–10:30AM

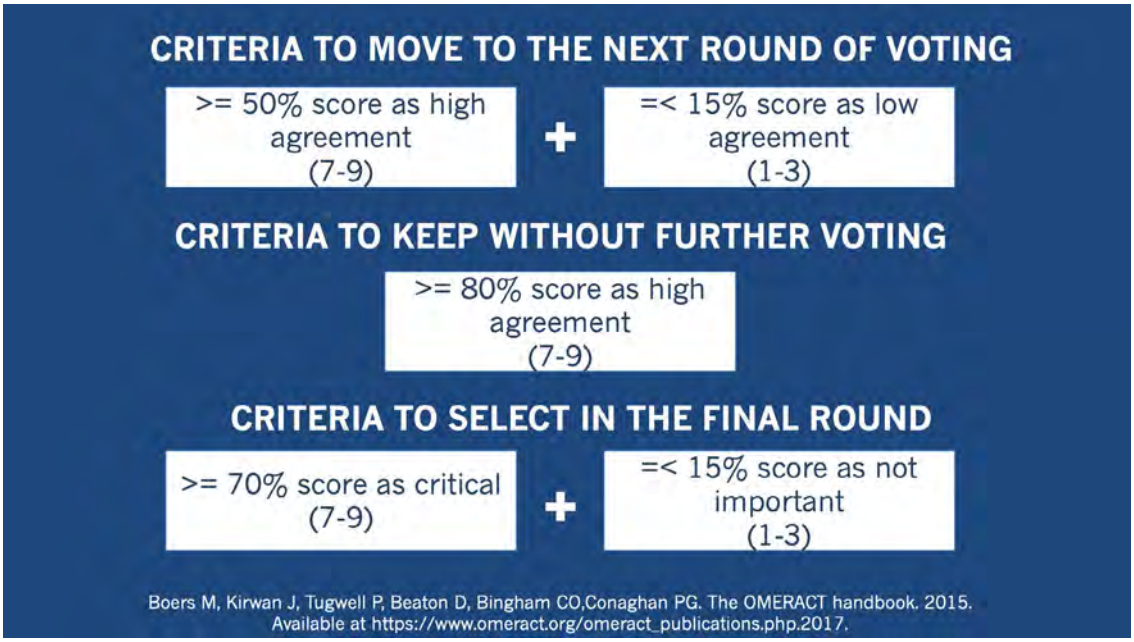

Figure 1. Criteria for selecting statements for final Best Practice Guidelines.

Background/Purpose: The need for telehealth is increasing and will undeniably play a role in the field of health care services, even beyond the COVID-19 era. Best practice guidelines (BPG) are required as they add credibility, standardize approaches, decrease liability and facilitate reimbursement. The objectives of this project were to: (1) develop BPG for the use of Telehealth In Rheumatology in the Arab region (TIROL) and (2) identify the barriers and facilitators of telehealth.

Methods: The BPG were developed under the umbrella of the Arab League of Associations for Rheumatology (ArLAR), in line with the Appraisal of Guidelines for REsearch & Evaluation (AGREE II) instrument. A computerized literature search of four sources (PubMED, American College of Rheumatology (ACR), American Telemedicine Association and World Health Organization) was performed. Guidelines and statements were drafted by a core steering committee, and levels of evidence were indicated according to the Oxford Centre for Evidence-Based Medicine. The draft was reviewed by the ArLAR scientific committee, a law firm advisor and an ACR telemedicine expert. A multidisciplinary task force, including 18 rheumatologists (from the Arab Adult Arthritis Awareness (AAAA) group and ArLAR advisors), 2 patients with rheumatic diseases, 2 regulators and payers from 15 Arab countries was convened and assessed the BPG using 3 rounds of voting by modified Delphi process. Task force members reported their level of agreement and were able to give qualitative comments. The first two Delphi rounds were performed through live online meetings and the last round used asynchronous voting through the Surveylet platform. All votes were anonymous and weighted equally. The criteria for moving from one Delphi round to another and for selecting the final statement was guided by the OMERACT recommendations **(Figure 1)**. The voting on barriers and facilitators was done by one round of anonymous voting using ranking by importance.

Results: The steering committee formulated 4 General Principles and 12 Statements in line with the literature search. All 22 (100 %) task force members participated to each of the 3 rounds. The final BPG are presented in **Table 1**. A consensus of > 80 % was achieved for all statements by the end of round 3. A teleconsultation was defined specifically for the purpose of these guidelines. The possibility of choice of telehealth was highlighted with a particular emphasis on patient's confidentiality, medical information security, rheumatologist's clinical judgment and jurisdictional

Table 1. General Principles and Best Practice Guidelines statements for Telehealth in Rheumatology

General Principles		Level of Evidence*	Consensus** (%)	Level of Agreement*** Arithmetic Mean (SD)/ Median
A Definition of a teleconsultation	A rheumatology teleconsultation is a synchronous exchange of medical information‡ between a patient and a rheumatologist via audio or audio-visual electronic communication, to improve the patient's health status.	5	100	8.14 (0.77) 8
B Access and Continuity of Care	Telehealth may improve the access and continuity of care for patients with rheumatic diseases who are home-bound, live in remote areas or under-served communities, or who need to adhere to social distancing restrictions.	3	100	8.41 (0.80) 9
C Improving disease outcomes	Telehealth can help some patients adhere to the management plan and this is likely to improve disease outcomes in some selected disease states.	2	86.36	7.86 (1.21) 8
D Quality of medical care	Rheumatologists need to use professional experience and judgment to assess whether telehealth is suitable in each situation.	5	95.45	8.14 (0.89) 8
Best Practice Statements				
1 Informed consent	Before the teleconsultation visit, an informed consent should be obtained from the patient, in writing or verbally; it should include an explanation, in a simple language, of the benefits and risks of telehealth encounters, as well as the conditions under which telehealth services may be terminated and a referral made to in-person care.	5	90.91	7.86 (1.28) 8
2 Confidentiality	The use of telehealth services must ensure the patient's information security and confidentiality.	5	100	8.82 (0.50) 9
3 Documentation	The provision of telehealth services should be well documented in the patient's file, similarly to any in-person medical visit. The decision to assess the patient remotely should be justified and recorded in the patient's file.	5	100	8.77 (0.43) 9
4 Shared decision and choice	The choice of using telehealth services should be based on a shared decision between the patient and the physician. Patients should have a choice of their provider of medical teleconsultation.	5	100	8.36 (0.73) 8.5
5 Patient's physical examination	Some parts of the physical exam might be performed remotely, like inspection and evaluation of the range of motion. The patient should be instructed on how to be prepared for a remote physical exam, using appropriate educational material.	2	90,91	7.77 (1.02) 8
6 Patient-reported outcomes	In some chronic rheumatic diseases, the use of patient-reported outcomes by means of self-completed questionnaires adapted for telehealth can help the physician make informed clinical decisions and improve the quality of care.	3	100	7.73 (0.77) 8
7 Safe Prescription	The prescription should be transmitted in a safe and confidential manner to the patient with a particular attention to avoiding abuse ((of opioids and narcotics' prescriptions in particular).	5	95.45	8.05 (0.90) 8
8 Fees and reimbursement	The teleconsultation is subject to medical fees and reimbursement similarly to the in-person visit. Any fees should be set before the teleconsultation.	5	100	8.45 (0.60) 8.5
9 Ethical considerations	Telehealth practice should conform to the same professional ethics that govern in-person care and comply with local jurisdictional laws and regulations of the physician's location.	5	100	8.59 9 (0.60)
10 Rheumatologist training	The rheumatologists are encouraged to receive proper training through seminars, workshops, and conferences to familiarize with the advantages and disadvantages of telehealth and to acquire strategies about the most productive approach to remote medical care.	5	95.45	8.18 (1.05) 8.5
11 Technical infrastructure and equity	The technical infrastructure should be improved for patients and physicians to enable an efficient and equitable access to telehealth services across the countries and in vulnerable populations.	5	100	8.41 (0.73) 9
12 Research	Local and regional research projects to assess the implementation of telehealth and the resulting disease outcomes in the Arab region are strongly encouraged.	5	95.45	8.32 (1.04) 9

* *Level of Evidence: according to* the Oxford Centre for Evidence-Based Medicine
***Consensus : % with score ≥ 80%*
*** *Level of agreement from 1 to 9, with 9 being the highest agreement.*
‡Exchange of medical information includes medical history, physical exam, review of paraclinical results and final prescription.

Table 2. Top Physician- and Patient-related Barriers- and Facilitators to Telehealth in Rheumatology in the Arab region

Choice Rank	Top Physician-related Barriers to Telehealth in Rheumatology in the Arab region
1	Concern about the quality of care (impossible to do a complete clinical exam, lack of non-verbal communication, patient distraction during the visit).
2	External technical difficulties such as poor internet connection or suitable equipment.
3	Internal technical difficulties such as lack of familiarity with e-Health, and lack of trained staff.
4	Lack of motivation (lack of reimbursement).
5	Absence of legal framework: inter-country licensure laws, need for credentialing at multiple sites, and liability concerns.

Choice Rank	Top Physician-related Facilitators to Telehealth in Rheumatology in the Arab region
1	Lack of alternatives when social distancing measures are needed.
2	Better time management, reducing crowded waiting rooms and waiting lists.
3	Less appointment cancellation and no-shows.
4	Better quality of care for close monitoring of chronic diseases.
5	Efficient triage of patients.

Choice Rank	Top Patient-related Barriers to Telehealth in Rheumatology in the Arab region
1	Concern about the quality of care or proper communication
2	Internal technical difficulties such as lack of familiarity with technology.
3	External technical difficulties such as poor internet connection or unsuitable equipment.
4	Resistance to change.
5	Lack of motivation or unclear benefit (patient lives near the healthcare facility, elderly patient with more spare time).

Choice Rank	Top Patient-related Facilitators to Telehealth in Rheumatology in the Arab region
1	Increased access to care and/or possibility to obtain specialist medical opinion from remotely based expert physicians.
2	Lack of alternatives when social distancing measures are needed.
3	Less travel costs.
4	Quick communication and reassurance from the physician.
5	Better time management.

laws and regulations of each country. **Table 2** shows the results of the top 5 Physician- and Patient-related barriers- and facilitators ranked by importance.

Conclusion: These BPG were developed to provide rheumatologists with a series of strategies about the most reliable, productive, and rational approaches to practice telehealth in the rheumatology clinic. Rheumatologists will also need to use their professional experience and judgment to assess whether telehealth is suitable in each situation while ensuring that the services provided are in compliance with the laws and regulations of their respective countri es.

Experience from TheMednet: Online Rheumatology Physician Social Network

Yuliya Afinogenova[1], Mithu Maheswaranathan[2], Nadine Housri[3] and Sarah Fantus[4], [1]Yale School of Medicine, Hamden, CT, [2]Duke University, Durham, NC, [3]Yale University, New Haven, CT, [4]Northwestern University Feinberg School of Medicine, Chicago, IL

SESSION INFORMATION
Session Date: Monday, November 8, 2021
Session Title: Professional Education Poster (1170–1195)
Session Type: Poster Session C
Session Time: 8:30AM–10:30AM

Background/Purpose: Expert opinion is valuable in clinical rheumatology practice, especially given the rapid expansion of medical information and limitations of existing data to guide evidence-based medical decision making. However, organized, effective, and accurate platforms for exchange of knowledge among physicians are often lacking. TheMednet is an electronic portal that allows for dissemination of expert knowledge and opinions in a searchable, private, and moderated question and answer format. Originally established in Oncology in 2014, involving over 12,000 US oncologists, we sought to establish the feasibility of this platform among rheumatologists.

Methods: TheMednet was piloted in Rheumatology starting in July 2020. Questions were posted by registered rheumatologists via an 'Ask Question' button. Questions were then reviewed and revised by a team of physician editors and sent to appropriate content experts in Rheumatology. Expert responses were reviewed for accuracy. Rheumatologist engagement was measured in question and citation clicks, logins, and searches.

Results: From 7/2020 to 5/2021, 837 rheumatologists registered to theMednet (35% academic physicians, 58% community physicians, and 7% rheumatology fellows) from 87 institutions. Three hundred and fifteen questions were asked (Figure 1). Two-hundred and fifty-nine questions were approved by a team of editors, and 234 questions were answered by 103 experts (80% academic practice, 20% community practice). Expert geographic locations are detailed in Figure 2. Expert answers included 210 citations to published literature. The most common question topics by the number of views included rheumatoid arthritis (20%), vasculitis (20%), systemic lupus erythematosus (16%), general rheumatology (16%), and myositis (6%). Top 10 most viewed questions are shown in Figure 3. Approximate-

Figure 1: Type of Practice Distribution among Rheumatologists on TheMednet

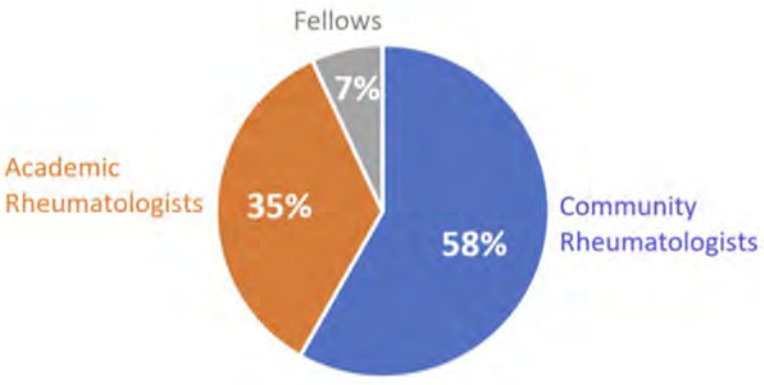

Figure 2: Geographic Distribution of TheMednet Experts in Rheumatology

Figure 3: Top 10 Most Viewed Rheumatology Questions on TheMednet

Views	Question
508	What is your initial treatment of choice in patients with RA and associated interstitial lung disease?
413	Are you recommending the mRNA COVID-19 vaccines to your patients with immune mediated inflammatory diseases?
299	Do you routinely check G6PD level prior to initiation of hydroxychloroquine?
286	How do you counsel rheumatic patients on DMARD therapy about COVID-19 vaccination?
274	What is your threshold for number of alcoholic drinks per week before reconsidering prescribing methotrexate/leflunomide?
273	How do you manage patients who are Hepatitis B core antibody positive/surface antigen negative and starting a biologic DMARD (other than rituximab)?
269	How long do you continue steroid-sparing agents such as tocilizumab for GCA once the disease is in remission off steroids?
264	What is your approach to a patient with an isolated positive rheumatoid factor, negative anti-CCP antibody, and no clinical or imaging evidence of rheumatoid arthritis?
258	Which ANCA vasculitis patients are better candidates for cyclophosphamide rather than rituximab?
255	What do you use to treat uveitis refractory to conventional synthetic DMARDs and TNF inhibitors?

ly 45% of registered rheumatologists were active each month. Over 24,000 question and answer views have been registered to date.

Conclusion: TheMednet is becoming a widely used and effective platform for academic and community rheumatologists to engage in an online network, providing insight on clinical practice and exchanging viewpoints on difficult management decisions. Future initiatives include expansion of the platform to enable exchange of information between rheumatologists and other specialists such as dermatologists, pulmonologists, and ophthalmologists who share in the management of patients with complex, multi-system rheumatic diseases.

Assessing Resident Needs and Faculty Perceptions for Rheumatology Curriculum Development

Lauren He[1], Kichul Ko[1], Laarni Quimson[2], David Leverenz[3], Shannon Martin[1] and Didem Saygin[1], [1]University of Chicago, Chicago, IL, [2]University of Chicago, Oak Park, IL, [3]Duke University, Durham, NC

SESSION INFORMATION
Session Date: Monday, November 8, 2021
Session Title: Professional Education Poster (1170–1195)
Session Type: Poster Session C
Session Time: 8:30AM–10:30AM

Background/Purpose: The goal of rheumatology rotation during internal medicine (IM) residency is to develop competency in work-up and treatment of common rheumatological conditions. IM residents spend less time in rheumatology compared to other subspecialties, necessitating a well-structured curriculum tailored towards resident needs and various clinical settings. In this study, we aimed to identify resident learning needs and preferences during inpatient and outpatient rheumatology rotations to improve the curriculum.

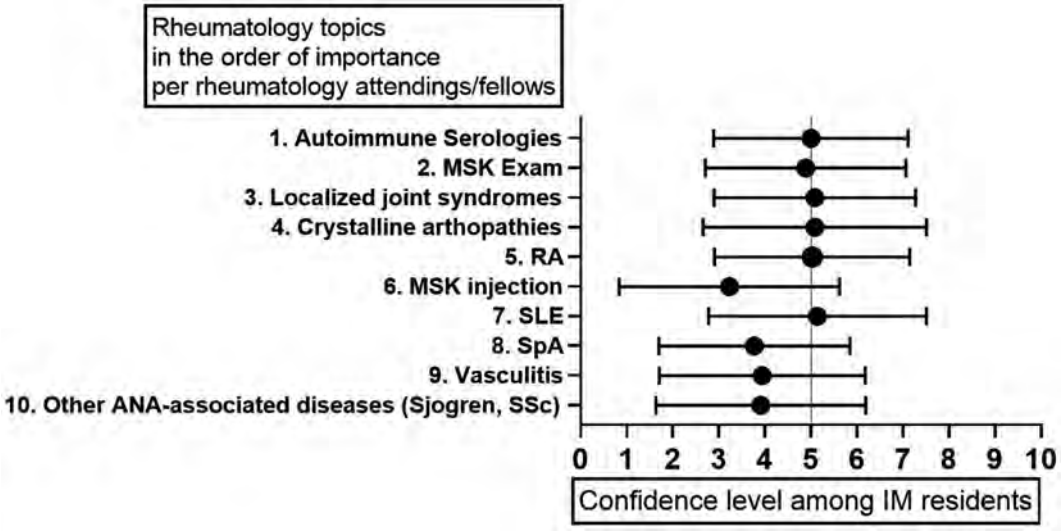

Figure 1. Most important rheumatology topics to learn during rheumatology rotation per rheumatology faculty/fellows and confidence level among residents for each topic [median with IQR].

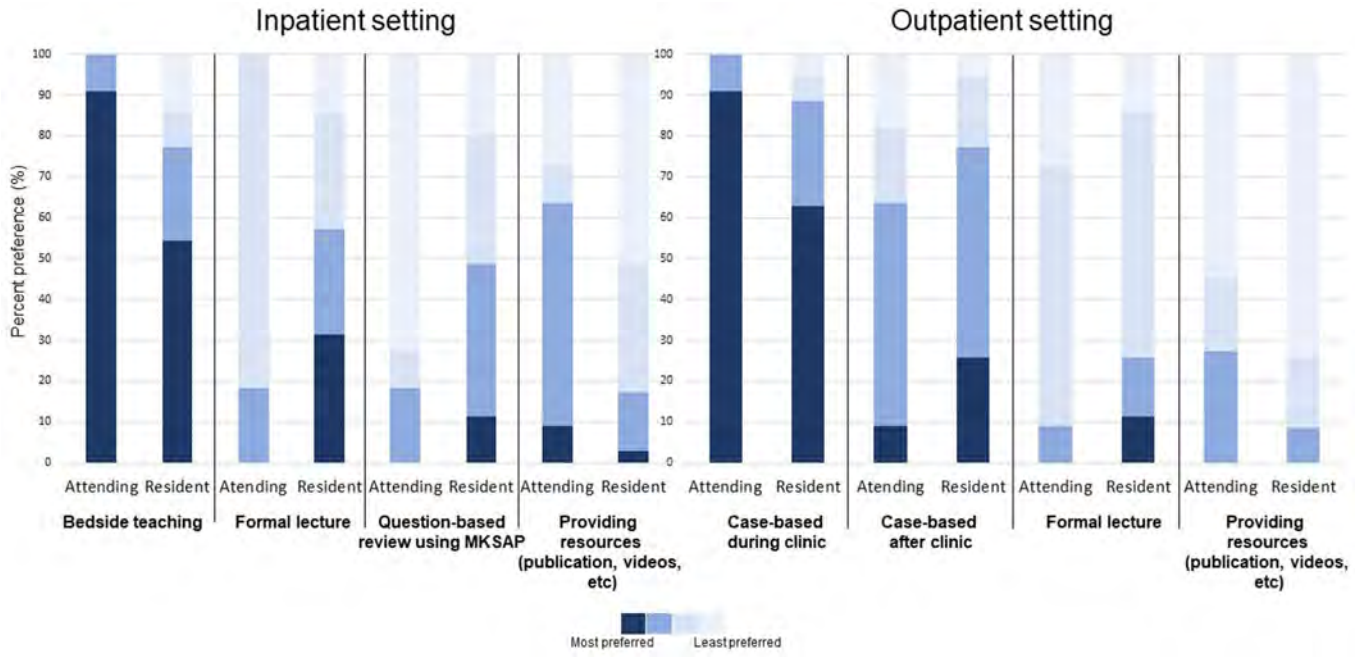

Figure 2. Preferred learning/teaching modalities for rheumatology faculty/fellows and medicine residents in inpatient and outpatient settings.

Methods: We distributed surveys to all the current IM residents at the IM Residency Program and rheumatology faculty/fellows in the Section of Rheumatology via email. Rheumatology faculty/fellows were asked to rank 10 rheumatology topics based on the importance. The resident survey assessed confidence in caring for patients with rheumatologic condition in inpatient and outpatient settings on a 10-point Likert scale. Both resident and attending/fellow surveys assessed respondent to rank their preferred learning modality in inpatient and outpatient settings. No validated instruments were available for these purposes; therefore, we created the surveys used in this study.

Results: Out of 13 rheumatology faculty/fellows, 11 (7/4; 84%) completed the survey. Out of 124 residents, 35 (28.2%) including 8 PGY-1, 13 PGY-2, 10 PGY-3, 3 PGY-4 and 1 PGY-5 completed the survey. Among respondents, 37% had rheumatology rotation in medical school and 66% in residency. Four residents (11%) were interested in rheumatology fellowship, and majority (77%) had interest in learning more about rheumatology.

The most important topics to learn during rheumatology rotation per faculty/fellows were knowing when to order and how to interpret autoimmune serologies, followed by musculoskeletal exam and crystalline arthritis (Figure 1). Median confidence level [IQR] among residents for caring for patients with rheumatological conditions was 6 [3.6-7.5] for inpatient and 5 [3.7-6.5] for outpatient settings (10 being very confident). Topics with least reported confidence included joint injections, spondyloarthritis, and other ANA-associated disorders.

Among attendings/fellows, the most preferred outpatient teaching modality was case-based and least preferred was directing trainees to relevant resources. On the inpatient side, directing to relevant resources was the 2nd most preferred modality after bedside teaching (Figure 2). Among residents, the most preferred learning modality was bedside/case-based learning (54-63%) and the least preferred was being directed to resources for self-learning (51-74%) in both settings. Formal lectures were preferred more by residents than attendings/fellows in both settings.

Conclusion: This study showed that average confidence level of residents for most rheumatology topics was moderate (5 out of 10). There was a high degree of concordance between residents and rheumatology faculty/fellows for their preferred education modality in outpatient setting, whereas discordance existed on inpatient setting. Being

directed to relevant resources for self-learning was not preferred among residents, while faculty/fellows preferred this option commonly in the inpatient setting.

Abstract Number: 1178

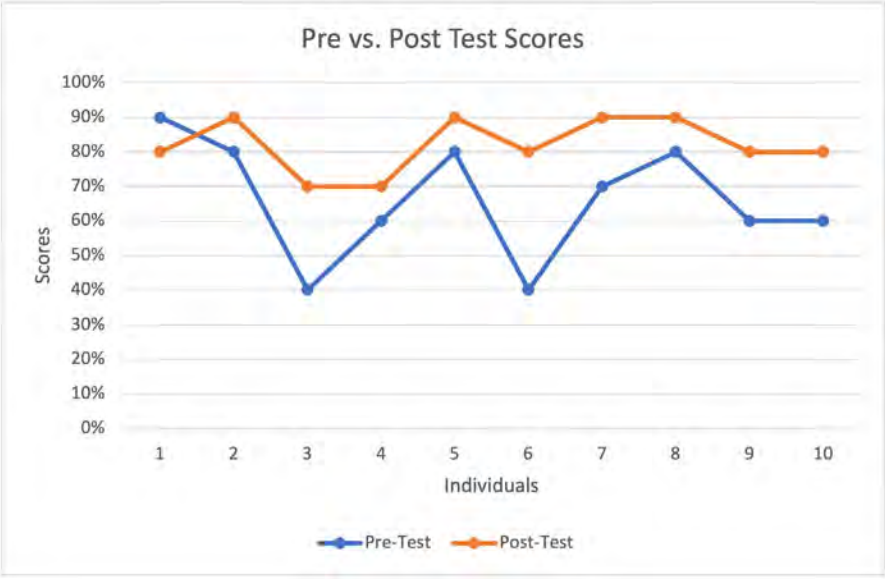
Implementation of a Dermatologic Manifestations of Connective Tissue Disease Learning Module Including All Skin Tones and Social Determinants of Health for Medical Students: A Pilot Study

Mavra Masood, Fnu Nutan, Julia Nunley and Beth Rubinstein, Virginia Commonwealth University, Richmond, VA

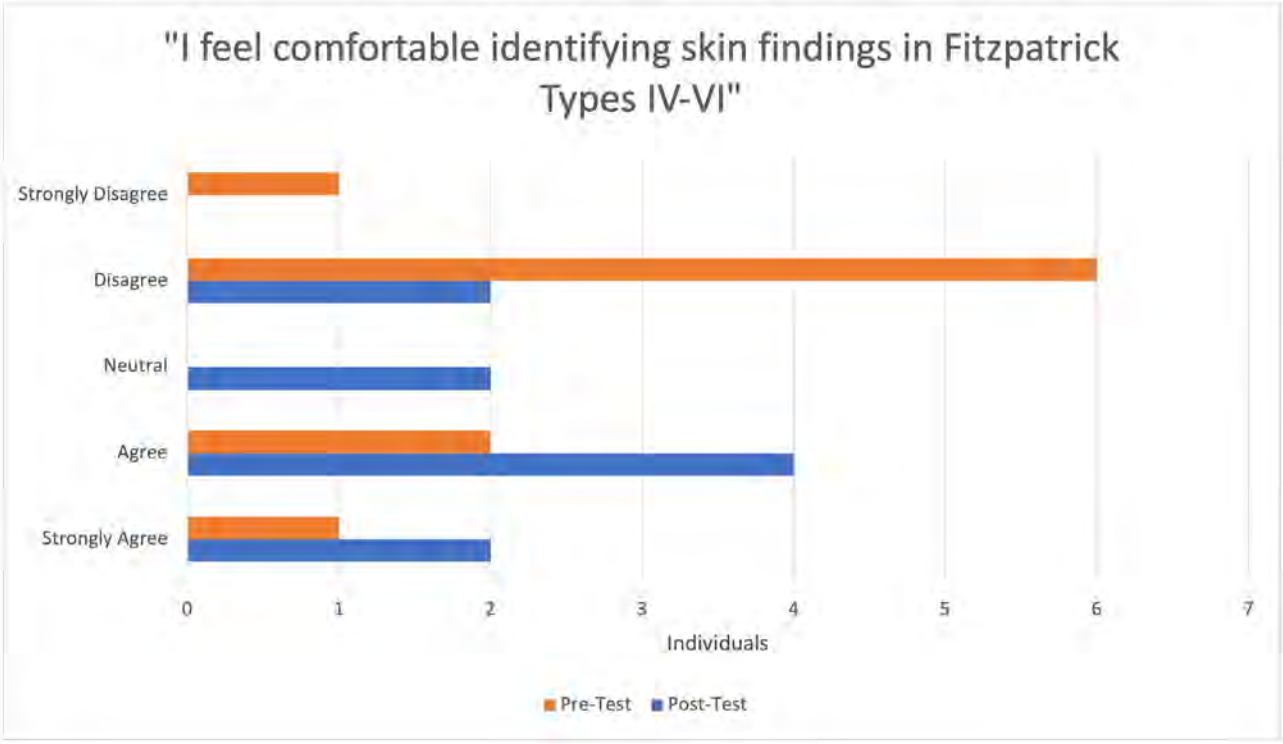
SESSION INFORMATION
Session Date: Monday, November 8, 2021
Session Title: Professional Education Poster (1170–1195)
Session Type: Poster Session C
Session Time: 8:30AM–10:30AM

Background/Purpose: There is a dearth of resources for medical students on identifying skin findings of autoimmune disorders in skin of color. Considering how several rheumatologic diseases disproportionally affect communities of color and can present with dermatologic findings, an opportunity arises to address a gap. The lack of materials educating future physicians has significant repercussions on delivering care equitably to an increasingly diverse US population.

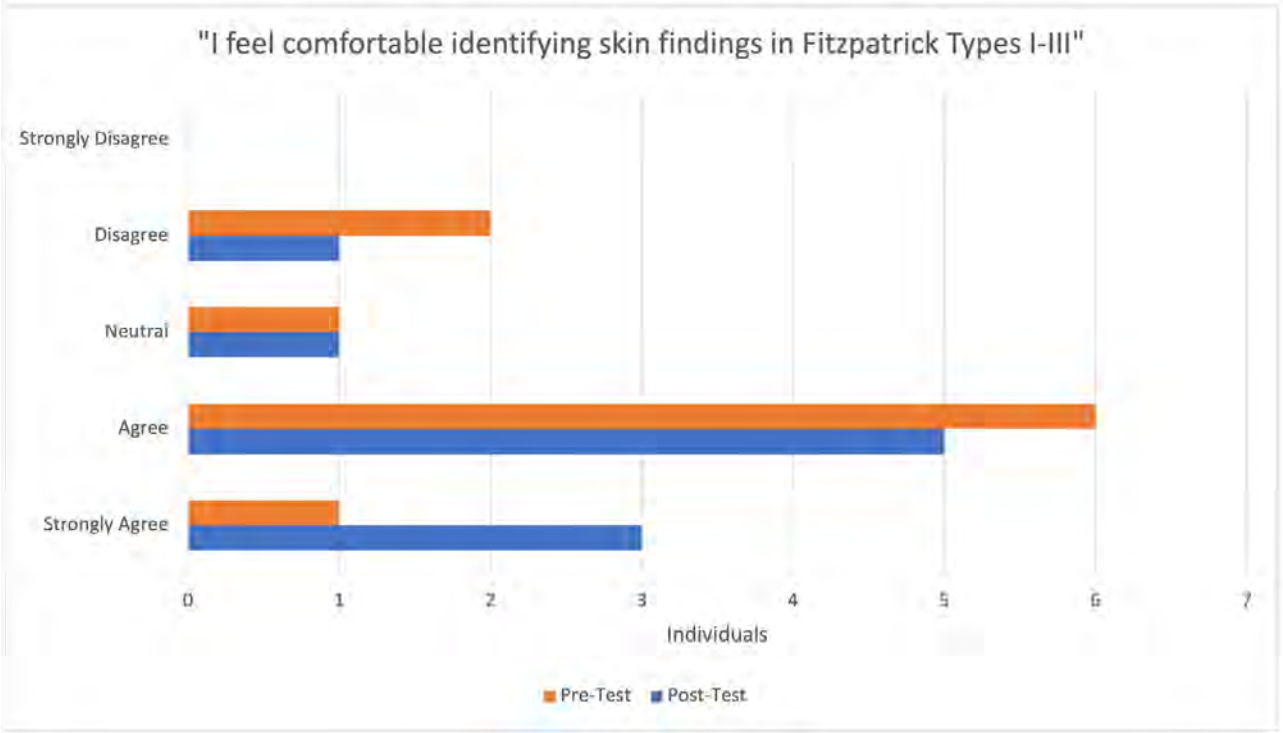
We sought to create a brief module that addresses dermatologic findings in connective tissue disease (CTD) in all skin tones for medical students. Our purpose was to assess whether this module would 1) increase learner comfort



Pre vs. Post Test Module Completion Scores



Pre vs. Post Test comfort level scores with identifying skin findings in Fitzpatrick types IV-VI



Pre vs. Post Test comfort level scores with identifying skin findings in Fitzpatrick types I-III

in identifying dermatologic findings in all skin tones and 2) increase learner knowledge of appropriate workup and lab findings in CTD.

Methods: The study was conducted at our institution's medical school. We developed a PowerPoint-slide based module with pre- and post-tests with three fictional patient scenarios detailing systemic lupus erythematosus, dermatomyositis, and systemic sclerosis. Second through fourth year medical students were asked to complete our module. The pre-test was done immediately prior to the module and the post-test immediately following completion of the module. The test included ten questions evaluating lab and physical exam findings in CTD as well as six questions assessing learner comfort with identifying physical exam findings. De-identified data was collected and stored on a cloud-based program, then analyzed using a paired two tailed student's t-test.

Results: A total of ten medical students completed the pilot module with the pre-test and post-test. Five of the trainees were rising third-year students, four were rising fourth-year students, and one was a rising second-year student. Baseline mean pre-test scores were 66% correct and the mean post-test score was 82%. Completion of the CTD module led to significant improvement from pre- to post-test scores with a mean improvement of 16.20% (P-Value = 0.00456). 80% of students in the post test had at least a 1-point increase in comfort level (i.e., neutral to agree) of identifying skin findings in Fitzpatrick types IV-VI (medium to very dark brown skin tones) and 50% of students had a 1-point increase in comfort level of identifying skin findings in all skin types.

Conclusion: Our pilot study suggests that implementing a CTD module as a part of the medical school rheumatology curriculum results in immediate improvement in medical knowledge and comfort with identifying physical exam findings in Fitzpatrick types IV-VI. Additionally, all students answered, "strongly agree" with this statement: "It is important to learn about how social determinants of health affect outcomes." This suggests that students are interested in learning about the social implications affecting patients as they are treated for their disease. Re-testing after 12 months to evaluate knowledge retention as well as implementing a photo quiz at the end of the module to assess objective improvement are future directions. This module will be implemented as a part of a larger curriculum serving to educate learners on dermatologic manifestations of rheumatologic disease for our students.

Determining Faculty vs. Fellow Preferences for ROSCE Milestone Assessments; Is It Time for a Change in Needs Assessment?

Sharon Banks[1], Seema Malkana[2] and Aruni Jayatilleke[3], [1]Penn State Health, Hershey, PA, [2]Rutgers Robert Wood Johnson Medical School, New Brunswick, NJ, [3]Temple University, Philadelphia, PA

SESSION INFORMATION

Session Date: Monday, November 8, 2021

Session Title: Professional Education Poster (1170–1195)

Session Type: Poster Session C

Session Time: 8:30AM–10:30AM

Background/Purpose: The Pennsylvania Rheumatology Objective Structured Clinical Examination (ROSCE) is an annual assessment of rheumatology fellows' skills in different standardized patient (SP) encounters involving a variety of topics related to communication issues. We previously mapped our ROSCE assessment tools to align with Accreditation Council of Graduate Medical Education (ACGME) internal medicine subspecialty milestones in 2018. In 2020, we conducted our ROSCE entirely online. Seventeen trainees from 8 rheumatology programs in the region participated in 6 SP scenarios and were observed by faculty raters. We aim to better tailor our cases and evaluation forms to address milestones of greatest utility to participants. In this study, we surveyed 2020 ROSCE fellow partici-

Milestone	Description
ICS1	**Avoiding jargon; talking on a patient level with patients and their caregivers**
MK2	**Diagnostic testing accuracy review and interpretation**
PBLI1	Working with teams to improve patient care
PC1	**Gathers and synthesizes essential information to define a complaint**
PC3	**Formulate a comprehensive action plan**
PC4	**Discussion of treatment based upon a patient's own unique needs**
PROF2	Exhibits integrity and ethical behavior
PROF4	Professional interactions with patients, peers and staff
SBP1	Recognizes system error and tries to fix it
SBP2	**Transitions patients across systems**
SBP3	Advocates for cost effective care, understands barriers to cost effective care

Table 1. Milestones presented in the survey; items in **bold** are represented in the ROSCE

pants and program directors (PDs) regarding their perceptions of the most important competencies for rheumatology fellows to master in order to become excellent clinical rheumatologists.

Methods: We created an online survey using survey monkey asking participants to rank 11 ACGME subspecialty milestones in order of their perceived importance to attaining clinical excellence in rheumatology (Table 1). Content validity was determined by consensus of 5 rheumatology fellowship PDs and key clinical faculty. Participants were invited via email; all 2020 ROSCE fellow participants and regional PDs were invited to respond. Milestones rated in the top 3 and bottom 3 for both faculty and fellows are reported in aggregate. We also mapped our 2020 ROSCE evaluation questions to current ACGME subspecialty milestones.

Results: Five fellow participants and 9 PDs completed the survey (response rate 29% and 56%, respectively). Results were similar for faculty and fellows, with MK2, PC1, PC3, PC4, and PROF2 ranked in the top 3 by at least 25% of both groups (Figure 1a), addressing test interpretation, history-taking, forming a plan, therapeutics, and ethical behavior. Conversely, milestones ranked more frequently in the lowest 3 related to jargon use, system error recognition, transitions across health systems, and cost-effective care (Figure 1b). The 2020 ROSCE evaluation questions included 39 Likert scale questions (in addition to narrative comments) (Table 1). All milestones rated as important by faculty and fellows are represented in evaluations except PROF2.

Conclusion: We surveyed rheumatology faculty and fellows to gauge their perceptions of the most important areas to assess in the ROSCE. We observed a low response rate among fellows, possibly due to survey fatigue. In general, faculty and fellow preferences aligned with respect to "top" and "bottom" ranked milestones, though numbers were small. Nearly all top-ranked milestones, dealing predominantly with patient care, are addressed in our ROSCE cases and evaluations, suggesting that it is well-suited to address these areas. PROF2, addressing ethical conduct, was reported to be of high importance but was not included in prior ROSCE cases. We aim to further tailor our ROSCE cases and evaluations to align with these preference needs, thus providing more meaningful information to PDs and fellows for formative feedback.

Figure 1. Faculty and fellow survey rankings of the top 3 (a) and bottom 3 (b) milestones by importance

Better Websites, Better Match: Assessing Quality of Rheumatology Fellowship Websites

Hiral Patel[1], D. Benjamin Riffe[1] and Rachel Wolfe[2], [1]Wake Forest School of Medicine, Winston Salem, NC, [2]Wake Forest Baptist Health, Winston-Salem, NC

SESSION INFORMATION
Session Date: Monday, November 8, 2021
Session Title: Professional Education Poster (1170–1195)
Session Type: Poster Session C
Session Time: 8:30AM–10:30AM

Background/Purpose: The internet has become an indispensable tool for residency and fellowship recruitment. Prospective applicants rely on publicly available information to learn about the application process and each program. A previous study has shown that applicants considered an easily navigated website important to their application decision-making process.[1] We evaluated adult rheumatology fellowship websites for accessibility and content

Table 1. Quality of content of rheumatology fellowship websites

Domain	N	%
Accessibility		
Functional website	120	96.00%
Social media links on the website	14	11.20%
Overview		
Program Description	117	93.60%
Coordinator's Information	106	84.80%
Director's Name	106	84.80%
Program Address	93	74.40%
Phone Number	105	84.00%
Email Address	106	84.80%
Name of Current Fellows	80	64.00%
Current Fellow's Residency Information	64	51.20%
Name of Past Fellow	46	36.80%
Faculty	104	83.20%
Salary	70	56.00%
Application Process		
Application ID/Program number	14	11.20%
Application Requirement	89	71.20%
Number of Letters of Recommendation Required	63	50.40%
Application Deadlines	29	23.20%
Education		
Didactics	109	87.20%

Call Responsibility	10	8.00%
Conference	102	81.60%
Ultrasound Curriculum	92	73.60%
Diversity		
Specific Text Regarding Diversity, Representation, and Minority in Reference to Fellows	25	20.00%
Link to/Descriptions of Diversity Resources	27	21.60%
Organization Dedicated to Diversity	30	24.00%
Overall Completeness (>70%)	29	23.20%

regarding program overview, application process, education, and diversity. The aims of the study are two-fold: to assess each Rheumatology Fellowship program's website for content completeness and to elucidate the specific areas on each program's websites that need to be updated to aid applicants in making informed decisions regarding their training options.

Methods: The American Medical Association Fellowship and Residency Electronic Interactive Database (FREIDA) was used to obtain a complete list of Accreditation Council for Graduate Medical Education (ACGME) accredited adult Rheumatology Fellowships. Information regarding accessibility of the websites, description of the program, application process, fellow education and diversity was collected from the publicly available websites with in a month period from January 4th – February 1st, 2021. Information within the five domains was analyzed via descriptive analysis.

Results: Only 23.2 % (N= 29/125) websites were >= 70.0% completed and 20.8% of websites were lacking more than 50% of the content (Table 1). Links to social media accounts were present on 11.2% of websites. Websites were lacking information regarding current program director (15.0%), names of current rheumatology fellows (36.0%), and previous research done at the institution (63.2%). Only 20.0% (N=25) of the program websites mentioned specific text regarding diversity in reference to their fellows and recruitment process.

Conclusion: The findings of our study reveal that rheumatology fellowship websites differ substantially in the details and amount of content they contain. Websites lack essential information such as program's director's name, current fellow's names, and educational programing each program offers. Most strikingly, the majority of the websites do not include specific text regarding diversity. Given the importance of healthcare organizations striving to improve diversity, equity, and inclusion within medicine, showcasing current efforts of each program on the website is vital. Rheumatology fellowship websites need to be revamped to promote what each program has to offer and to provide accurate and updated information to the future fellowship applicants, especially in the age of virtual recruitment. We hope that this study motivates institutions to keep the content of their fellowship program website well maintained and up to date to provide applicants with the most accurate information and to allow a better program-to-applicant match.

Self Directed Learning Among Internal Medicine Residents: Incorporating a New Teaching Module on Calcium Pyrophosphate Deposition in the Rheumatology Curriculum

Bassel Bou Dargham, Abhishek Nandan, Beth Rubinstein and Stamatina Danielides, Virginia Commonwealth University, Richmond, VA

SESSION INFORMATION
Session Date: Monday, November 8, 2021
Session Title: Professional Education Poster (1170–1195)

Session Type: Poster Session C
Session Time: 8:30AM–10:30AM

Background/Purpose: Medical knowledge is evolving at a fast pace, and it is important for medical students and residents to develop self-directed learning skills that will help them apply evidence-based medicine (EBM) in their clinical practice. As future practicing physicians, they should be able to incorporate new literature and updated guidelines into everyday clinical decisions. For that reason, there is a huge emphasis on introducing self-directed learning into undergraduate and medical school curriculums. In fact, the Liaison Committee on Medical Education (LCME) now requires medical schools to engage their students in self-directed learning activities. In this study, we aim to develop an interactive module that briefly covers important concepts and treatment guidelines on a specific topic. We will then assess learners' knowledge acquisition and their ability to apply these concepts in their clinical decision making.

Methods: The study was conducted at Virginia Commonwealth University Health Systems (VCUHS). We developed a module on calcium pyrophosphate deposition (CPPD), and internal medicine residents were asked to complete it as part of their rheumatology rotation. The module included a pre-test, followed by a PowerPoint presentation with case scenarios and interactive questions. Learners were then asked to solve a post-test immediately after finishing the presentation. Same questions were included in both tests, and they were presented in the same order. This process did not include directed learning methods. Data was analyzed using a student's t-test. We compared pre and post-test mean scores for every participant, and further analyzed the percentage of learners answering each question correctly before and after the completing the module (Figure 1).

Results: A total of 10 internal medicine residents completed our pilot module and filled the pre and post-tests. 8 learners were 2nd year internal medicine residents, and 2 learners were 3rd year residents. The tests were comprised of

A: Percentage of learners with a correct answer on each question before and after completing the module; B: Total score (out of 100) of pre and post-tests among different learners.

10 multiple choice questions including 3 case scenarios and 3 EBM questions. There was a significant improvement among learners when comparing their pre and post-test mean scores (30% increase in mean scores with $p< 0.0001$). We also compared the number of learners answering each question correctly in the pre and post-tests. Overall, the percentage of learners choosing the correct answer significantly increased in the post test ($p< 0.0001$). Improvement was mainly noticed in case scenarios (Q8 and Q10), and EBM based concepts (Q2 and Q3).

Conclusion: This study suggests that integrating self-directed learning modules in the rheumatology curriculum of our internal medicine residency program can help residents improve their knowledge base and comfort level with EBM and case-based concepts. The next step is to include medical students rotating on our rheumatology rotation into the participating pool of learners, with the hope that it could be integrated into their own curriculum. A larger group analysis of multiple modules will help develop a comprehensive learning course for all our rotating medical students and residents.

Pilot Health Literacy Curriculum Addressing Skills and Content Knowledge for Adult and Pediatric Rheumatology Fellows

Gabriel Tarshish[1], Heather Archer-Dyer[2], Pablo Joo[3], Dawn Wahezi[4], Tamara Tanner[5], Rhonda Acholonu[4], Tamar Rubinstein[6] and Irene Blanco[7], [1]Children's Hospital at Montefiore, New York, NY, [2]Albert Einstein College of Medicine, Bronx, NY, [3]UC Riverside School of Medicine, Riverside, CA, [4]Children's Hospital at Montefiore, Bronx, NY, [5]Montefiore Medical Center, Bronx, NY, [6]Albert Einstein College of Medicine, White Plains, NY, [7]Albert Einstein College of Medicine, Cresskill, NJ

SESSION INFORMATION
Session Date: Monday, November 8, 2021
Session Title: Professional Education Poster (1170–1195)
Session Type: Poster Session C
Session Time: 8:30AM–10:30AM

Background/Purpose: 36% of adults in the US have a basic to below basic level of health literacy. Studies show that limited health literacy (LHL) has deleterious effects on patient outcomes and act as a contributing case to health disparities across all of medicine, including rheumatology. Despite the prevalence of LHL, there is a lack of education on this topic for medical trainees. Therefore, we designed a module focused on LHL in patients with rheumatic diseases with an overall goal to help pediatric and adult rheumatology fellows build a foundational knowledge and toolkit addressing LHL in the clinical setting.

Methods: This module was piloted with fellows from the adult and pediatric rheumatology programs from Montefiore and NYU Medical Centers, NY, NY. Participants provided signed consent and pre-course and post-course evaluations were completed anonymously. The evaluations identified changes in the learners' knowledge base, clinical comfort level, and likelihood to integrate these interventions into their practice. The post-course evaluation also elicited feedback of the course. The teaching module consisted of: (1) video of a poor patient-provider interaction to allow for introspection, (2) formal didactic presentation, (3) role play scenario for fellows to practice skills using LHL checklist, (4) exercises to evaluate patient education materials.

Results: The session was held in May 2021 with 7 adult and pediatric rheumatology fellows. 4 fellows were 2nd years and the average age of the participant was 33.7y. Racial and ethic make up of the fellows was broad and 3 of 7

fellows were international medical school graduates. While 6 of 7 fellows had been taught the Teach-back Method (a common technique to assess understanding), 4 of 7 had not received formal education on health literacy. In addition, 5 of 7 fellows had never evaluated distributed patient materials to ensure appropriate reading level. All fellows felt that a patient's LHL impacted treatment plans. Nevertheless, only 2 fellows "agreed" that LHL was regularly discussed with faculty in clinical settings; where 4 of 7 fellows were "neutral" or "disagreed" that faculty were equipped to discuss the issue. After the module, all 7 fellows "agreed" or "strongly agreed" that LHL and the strategies to mitigate it were presented effectively. 6 of 7 "agreed" or "strongly agreed" that LHL should be incorporated into rheumatology education and 5 of 7 "agreed" or "strongly agreed" that faculty would benefit from this module. All 7 of the fellows "plan to modify their practice" based on this content of this module. Several quotations from feedback include: *"[I] never realized what a high reading level some of the information we give to patients can really be*". "*This is a really useful pertinent module*".

Conclusion: Participants reported increased skills in addressing LHL in their practice. Data from this study will help guide improvements to the module with plans to incorporate learner feedback into subsequent teaching sessions. The long-term goal of this work is to design a module that can be used by fellowships broadly to improve health literacy assessments leading to interventions as a means to improve overall health outcomes particularly in LHL who are at risk for disparate care.

Disclosure: G. Tarshish, None; **H. Archer-Dyer**, None; **P. Joo**, None; **D. Wahezi**, None; **T. Tanner**, None; **R. Acholonu**, None; **T. Rubinstein**, None; **I. Blanco**, None.

Abstract Number: 1183

Efficacy of Rapid Transition of a Musculoskeletal/Rheumatology/ Dermatology Course to Online Learning During COVID-19 Pandemic

Elise Belilos and **Megan Bader**, NYU Long Island School of Medicine, Mineola, NY

SESSION INFORMATION
Session Date: Monday, November 8, 2021
Session Title: Professional Education Poster (1170–1195)
Session Type: Poster Session C
Session Time: 8:30AM–10:30AM

Background/Purpose: The COVID-19 pandemic created unprecedented challenges for medical students and faculty with the abrupt transition to online learning in March 2020. At NYU Long Island School of Medicine (LISOM), a new accelerated 3-year primary care medical school, this transition occurred during the charter class's five-week Musculoskeletal/Rheumatology/Dermatology (MSK/Rheum/Derm) course. The core components of LISOM's curriculum, including didactic lectures and longitudinal courses in problem-based learning (PBL), health systems science (HSS), practice of medicine (POM), anatomy/histology/pathology/radiology (M4), and ethics, were rapidly restructured to be delivered either through prerecorded sessions (released in the afternoon on the day prior to the scheduled time) or live classes hosted virtually on WebEx.

Methods: A survey was designed on Qualtrics and distributed to second-year NYU LISOM students. Students could then voluntarily and anonymously opt to participate. All participant information was de-identified. Questions explored the students' perceived efficacy of various components of the MSK/Rheum/Derm curriculum including prerecorded lectures, Q&A sessions, case-based activities, exam review sessions, and longitudinal courses.

Results: 79% (N=19/24) of students in NYU LISOM's charter class participated in this survey. 84% of students rated prerecorded lectures as "extremely" or "very" effective and 89% of students felt that they learned as much from prerecorded lectures as in-person lectures. 52% of students began watching prerecorded lectures prior to their scheduled time and another 37% watched them during the scheduled time. Dedicated Q&A sessions addressing each lecture topic were largely underutilized by students, with 84% students attending < 5 sessions. In spite of this, 89% of students agreed that they were able to have all questions arising from lectures answered. Students felt that problem-based learning (PBL) was the most effective longitudinal course during online learning, with 79% of students rating it as 'extremely' or 'very' effective. Students also felt that MSK/Rheum/Derm lecture material was highly integrated with PBL, M4, and POM. The most difficult subjects to learn virtually were anatomy and histology (M4). Students cited the most effective M4 sessions included prerecorded lectures and the use of 3D modeling. One of the notable challenges of online learning was the development of strong student-faculty relationships with 89% of students indicating that they did not get to know the faculty well. A clear benefit of online learning was the increased flexibility and autonomy to pursue individual study styles with 100% of students agreeing that they had more time for independent study.

Conclusion: To our knowledge, the rapid and successful conversion of the entire MSK/Rheum/Derm curriculum to virtual learning at NYU LISOM during the COVID-19 pandemic was the first of its kind in that it was accomplished within a framework of a unique, compressed 3-year primary care medical school curriculum and is a viable model for remote online rheumatology learning in the setting of a public health emergency.

Abstract Number: 1184

Voluntary Online Gout Module: Housestaff Utilization and Efficacy

Sarah Tarplin[1], Susan Kroop[2] and **Catherine Deffendall**[2], [1]Vanderbilt Universty Medical Center, nashville, TN, [2]Vanderbilt University, Nashville, TN

SESSION INFORMATION
Session Date: Monday, November 8, 2021
Session Title: Professional Education Poster (1170–1195)
Session Type: Poster Session C
Session Time: 8:30AM–10:30AM

Background/Purpose: All Internal Medicine (IM) physicians should be competent in gout diagnosis and management. The purpose of this study is to assess learner engagement with a voluntary online gout diagnosis and management curriculum and to assess the impact on their knowledge and skills in the treatment of patients with gout.

Methods: We developed an online interactive module, comprised of clinical vignettes related to the diagnosis and management of gout for IM residents (hereafter described as trainees). The curriculum was published via QuizTime and delivered to trainees during their two-week outpatient or elective rheumatology rotation. QuizTime is an online platform created at Vanderbilt University Medical Center that delivers to learners one teaching quiz question at a set interval (1-2 questions per day) via an email or text link. Learners click the link and are taken to the platform with the clinical vignette quiz and possible answers. If a learner selects a correct response, they are directed to a screen confirming the correct choice and a detailed explanation. If an incorrect answer is chosen, the correct response is displayed along with the same explanation and an option to reengage with the question for up to 48 hours to reinforce new knowledge. Thus, QuizTime employs spaced interval learning and "test-enhanced learning" to reinforce concepts. The module is a supplement to standard teaching including attending clinics with preceptors, suggested readings and core IM didactics.

Half of the trainees received access to the module while the control group received standard teaching only. Pre and post rotation assessments were distributed to all trainees rotating on rheumatology and were used to compare gout knowledge between the two groups. This study was IRB exempt as it involved normal educational practices that was unlikely to adversely impact learners.

Results: Nine trainees received standard teaching in addition to access to the QuizTime Module. Ten trainees were assigned to the control teaching group. Of the nine that received access, only five answered any questions (56%). The five trainees that interacted with the module answered between 1 and 5 out of the 18 questions (2.8 to 5.6%). Three of these five trainees read any explanations (up to 50% of the questions they answered). None of the trainees that were given access to the QuizTime module took the post rotation assessments at the time of abstract submission limiting the evaluation of efficacy of the curriculum.

Conclusion: Approximately half of IM housestaff rotating on Rheumatology accessed a voluntary, online, quiz-based learning module on gout. Of the trainees that engaged with the module, very few questions were answered (2.8 to 5.6%). Data on the efficacy of the curriculum is limited by poor engagement with pre and post assessments. It is disappointing that so few engaged with a voluntary curriculum. This may be due to lack of interest in the topic, competition for housestaff time and attention, feeling that current teaching is sufficient for gout management and/or difficulty engaging with the QuizTime platform. Further study and data collection of knowledge retention is ongoing.

Disclosure: S. Tarplin, None; **S. Kroop**, None; **C. Deffendall**, None.

A New Virtual Reality: Needs Assessment and Gains in Current Trainees Experience with a Novel Video-Based Post Rheumatology Rotation Intervention

Ami Purohit[1], Camille Hawkins[2], Meenakshi Jolly[2] and Sonali Khandelwal[3], [1]Rush University Mediccal Center, Chicago, IL, [2]Rush University Medical Center, Chicago, IL, [3]Rush University, Chicago, IL

SESSION INFORMATION
Session Date: Monday, November 8, 2021
Session Title: Professional Education Poster (1170–1195)
Session Type: Poster Session C
Session Time: 8:30AM–10:30AM

Background/Purpose: Though trainees see patients at varying stages of their diagnostic course on subspecialty electives, there is often no organized opportunity for residents to follow these patients after the elective has ended. Furthermore, the lack of longitudinal follow-up on subspecialty cases may hamper the educational experience of trainees and future interest in a particular area. There is paucity of literature on strategies to foster trainee experience including increasing continuity in care (Francis, Journal of Graduate Medical Education, 2018). Herein we present preliminary results of needs assessment and virtual systematic intervention in a rheumatology elective. This intervention was designed and implemented to bolster education and continuity in an asynchronous format after the elective concluded.

Methods: Informed consent was obtained from all rotating residents in the rheumatology elective from August 2020 to April 2021. Residents completed a pre-intervention survey for needs assessment delineating current perceptions of continuity, level of exposure in their subspecialty clinics, and willingness to participate in the follow-up intervention.

Participating residents chose a patient case they had seen while on the elective to discuss at a scheduled virtual meeting 4-6 weeks following the end of their elective with a rheumatology faculty member. Participating residents completed a post-intervention survey assessing their satisfaction, changes in perception and medical knowledge, and impact on their choice of subspecialty as a career option. Descriptive statistics and one-sided Fisher exact test were undertaken.

Results: Of the 49 residents that completed the needs assessment pre-survey, 85.7% stated they never had structured continuity in their subspecialty clinics, 75.5% were interested in a structured way to follow-up patients, and 77.6% were open to the intervention. Twenty-six residents completed the intervention and post-survey, which revealed 69.2% of residents felt the intervention added to their medical knowledge and clinical experience with 26.9% felt it helped somewhat; 65.4% of the residents believed this intervention created a positive change in perception of this subspecialty rotation while none noted a negative assessment of the intervention. All trainees (n=7) that noted a positive change in perception of the subspecialty clinic following the intervention, also reported an increased consideration for rheumatology as a career ($p < 0.05$)**Conclusion:** Needs assessment confirmed there is lack of structured programs to provide trainees with longitudinal follow-up on patient encounters seen in a rheumatology elective. There was a high level of interest in an asynchronous intervention strategy to improve longitudinal learning that resulted in increased continuity, medical knowledge, clinical experience, and consideration for the subspecialty as a career. This novel intervention maximizes the use of experiential learning trainees have within their rheumatology rotation even after it has concluded; continuing such measures in the future may enhance subspecialty ambulatory training as the realm of virtual learning continues to be an integrated part of education for trainees.

Abstract Number: 1186

The Kardashian Index of Rheumatology Program Directors: Comparing Scholarly Activity and Twitter Use of Rheumatology Fellowship Program Directors in the United States

Aakanksha Khanna[1], Keerthy Gopalakrishnan[2], Dawid Czarny[1], Brian Quigley[1] and Alysia Kwiatkowski[1], [1]State University of New York at Buffalo, Buffalo, NY, [2]S.R.M. Medical College Hospital and Research Center, Buffalo, NY

SESSION INFORMATION
Session Date: Monday, November 8, 2021
Session Title: Professional Education Poster (1170–1195)
Session Type: Poster Session C
Session Time: 8:30AM–10:30AM

Background/Purpose: Social media has changed the way we communicate and disseminate information. Program directors (PDs) can use social media to boost visibility for professional networking, collaboration, program promotion, recruitment, and medical education at a global scale. Major rheumatology conferences, such as American College of Rheumatology, are beginning to employ social media ambassadors and hashtags to engage followers. Tweets© have been used to discuss findings published in manuscripts, enhancing peer and patient engagement. Increased social media publicity allows researchers to discover useful citations which they may have missed. The Kardashian index (K-index) can be used to study the correlation between the number of citations for a physician and the number of followers they have on Twitter©. The goal of this study was to analyze the presence and use of Twitter© by rheumatology PDs in the United States (US).

Methods: The Accreditation Council for Graduate Medical Education website was accessed to obtain a list of accredited rheumatology fellowships in the US and all PDs were included. Demographic data, publications, citations and h index were collected using publicly available sources: program websites, Doximity©, Healthgrades© and Scopus©. A Twitter-based search was conducted to collect numbers of followers. The K-index = Ft/F, Ft is the number of followers a physician has on Twitter©, and F is the number of followers a physician should have based on the that physician's number of citations (C). The F factor = 43.3 $(C)^{0.32}$. Nonparametric statistics including Mann-Whitney U and Kruskal-Wallis tests were used to compare differences between groups.

Results: A total of 121 PDs were included. The average age was 52.69±9.17 years, 61 (50.4%) were females, 33 had Twitter© accounts, 11 had more than 100 followers and 10 had less than 10 followers. Active followers ranged from 0 to 1964. The mean±standard deviation (median) number of publications, citations and h-index for PDs were 31.98±45.47 (14), 1344.21±3035.96 (384) and 11.94±13.05 (8). There was no statistical difference between male and female PDs as well as between American and international medical graduates with regards to the distribution of publications (p=0.108; p=0.261), citations (p=0.204; p=0.367) and h-index (p=0.12; =0.337). Their average K-index was 0.864 (SD = 1.75) with a range from 0 to 7.72. There was no significant difference between male and female PDs with Twitter© on their K-index (MW U = 103.00, p = 0.287) or based on location of training (MW U = 108.50, p = 0.434).

Conclusion: A higher K-index suggests a physician may be over celebrated due to his/her active presence on social media. Physicians with a K-index > 5 are considered to be "Kardashians" of the academic world. As only 1 PD had an index > 5, we observed that with most PDs, the Kardashian phenomenon does not exist. Lack of social media presence represents an underutilized resource for PDs, as having an active professional Twitter© account can be used for program highlights, networking and professional advancement.

Abstract Number: 1187

Is Your Program Website Optimized for Recruitment? An Evaluation of Rheumatology Fellowship Program Websites

Temitope Ajayi, Aakanksha Khanna, Brian Quigley and Alysia Kwiatkowski, State University of New York at Buffalo, Buffalo, NY

SESSION INFORMATION
Session Date: Monday, November 8, 2021
Session Title: Professional Education Poster (1170–1195)
Session Type: Poster Session C
Session Time: 8:30AM–10:30AM

Background/Purpose: A program's website is a helpful source of information for a prospective applicant whose decision on where to apply is influenced by the data provided on the internet. During the pandemic, as the applicants were unable to physically visit desired programs, there was an increased reliance on information gathered virtually to make crucial decisions. The purpose of this study was to assess the helpfulness of information provided on program websites for prospective applicants.

Methods: The Accreditation Council for Graduate Medical Education website was accessed to obtain a list of all accredited rheumatology fellowships in the United States (US). Publicly available program websites were accessed

via a Google© search to collect data on presence or absence of 10 categories of recruitment and education related content relevant to applicants. Chi-Square tests were used to compare differences between regional groups and p-value of < 0.05 was considered significant.

Results: As of May 2021, 122 accredited programs were identified and all had functional websites. The program director's description and content was provided for 44.6%, while 71.1% provided the coordinator's information and contact. Research opportunities (59.5%), details about current fellows (52.9%) and educational curriculum (52.9%), were among the most frequently described features. Visa offers (39.6%), number of fellows (38.8%), international medical graduates' acceptance (38.0%), salary or benefits (33.9%), Doctor of Osteopathic Medicine acceptance (29.8%), fellow yearly schedule (17.4%), board pass rate (6.6%) and interview day itinerary (5.0%) were the least frequently described features. Regional differences were examined between 5 areas of the country: the Northeast (n = 36), South (n= 41), Midwest (n =25), Mountain (n= 5), and Pacific (n= 14). Salary was more frequently listed in the Pacific states while curriculum was more commonly listed in the Mountain states, although the Mountain states were least likely to list benefits.

Conclusion: Despite the value that a program's website could provide to applicants when making decisions during the application process, this study revealed there is a lack sufficient, relevant, and standardized information. Improving the content, accessibility and uniformity across all rheumatology websites will reduce inappropriate applications, attract the most suitable applicants, reduce the amount of email inquiries, and could also lessen the financial burden for applicant's applying out of state. Fellowship programs could expand upon the content included, particularly with respect to providing contact information, board pass rates, types of visas offered, schedules and interview day itineraries.

Abstract Number: 1188

Sifting Through Complexity in a Methodological Manner: Identifying Key Items in Teaching Lupus to Medical Students Through Consensus

Julie Thomas[1], Michael Battistone[2], Kyle Register[1] and Andrea Barker[2], [1]University of Utah, Salt Lake City, UT, [2]Salt Lake City VA, Salt Lake City, UT

SESSION INFORMATION
Session Date: Monday, November 8, 2021
Session Title: Professional Education Poster (1170–1195)
Session Type: Poster Session C
Session Time: 8:30AM–10:30AM

Background/Purpose: Creating a curriculum for teaching lupus to medical students is a challenge given the complexities and nuances of this systemic disease. Because lupus spans multiple complex systems, educators outside of rheumatology hold stake in determining what elements of lupus a graduating medical student should be familiar with; this adds further complexity to curricular design. Unfortunately, the literature offers little guidance. The aim of this study is to use consensus methodology involving various stakeholders to identify key lupus curricular items that medical students should learn about during their four year education.

Methods: 86 faculty and housestaff members from the University of Utah (UU) were invited to participate in a 3 step Delphi consensus process. Housestaff members included 3 Rheumatology fellows and 3 Internal Medicine chief

Table 1. List of Identified Key Items meeting >80% Total Group Consensus

Item	Identified Items Meeting >80% Total Group Consensus
	Definitions
1	Recall the definition of autoimmunity
2	Recall the definition of innate and adaptive immunity*
	Pathophysiology
3	Identify SLE as an autoimmune disease
4	Identify SLE as a systemic disease
	Clinical Features
5	Identify mucocutaneous features of SLE
6	Identify discoid lupus
7	Identify that pleurisy is a feature of SLE
8	Identify that inflammatory arthritis is a feature of SLE
9	List SLE as part of a differential for neurological and psychiatric pathology
10	Identify features of lupus nephritis clinically
11	Identify serositis as a clinical feature of SLE including pleuritis, pericarditis, and peritonitis*
12	Identify pulmonary manifestations of SLE including DAH, ILD, thromboembolic disease*
13	Discuss anti-phospholipid antibody syndrome as a component of SLE including features of hypercoagulability and pregnancy complications*
	Lab Abnormalities
14	Identify autoimmune hemolysis as a feature of SLE
15	Identify leukopenia as a feature of SLE
16	Identify thrombocytopenia as a feature of SLE
17	Name ANA as a screening test for SLE
18	Name DSDNA and Smith as specific antibodies for SLE
19	Identify hypocomplementemia as feature of SLE
20	Identify ANA as a screening test and not a diagnostic test (i.e., +ANA without lupus/rheumatic disease symptoms)*
21	Understand ANA is not specific for diagnosis*
22	Correctly identify patients who should be tested for SLE (should receive an ANA test)*
23	Identify the utility of dsDNA and Smith Ab in evaluation for SLE*
24	Identify that antiphospholipid antibody syndrome can overlap with SLE*
25	Identify the utility of urine analysis and urine protein in evaluating/screening of lupus nephritis*
	Treatment
26	Identify hydroxychloroquine as a treatment for SLE
27	Identify immunosuppression as a treatment for SLE
28	Recognize the use of prednisone as a treatment and describe potential side effects, including CV risk*
	Epidemiology*
29	Identify the sex and age associations with SLE prevalence*
30	Identify ethnic association with SLE prevalence*
	Morbidity and Mortality*
31	Recognize life threatening SLE complications, such as nephritis or catastrophic anti-phospholipid syndrome*
32	Identify the risk of arterial/venous clots and need for APS testing in SLE patients with blood clots and miscarriages*

* Additional items proposed by consensus group

residents. Step 1 involved reviewing the 21 current items in the UU medical school curriculum and requesting suggestions for additional items. In step 2, each participant rated every item's importance to be included in the medical school curriculum using a 5-point Likert scale (1 = not at all important; 5 = extremely important). In the 3rd step, participants were given the group's mean and mode rating for each item, reminded of their own initial rating, and asked to make a final 5-point rating. Individual responses to each step remained anonymous. After the final step, items rated ≥4 ("very important" or "extremely important") by at least 80% of participants were retained; these identified items defined the set of lupus curricular elements representing the consensus of the group.

Results: 44 participants accepted the invitation to join our consensus project (51%); 31 participants completed all steps (37% of invited members, 70% of accepted participants). The majority were rheumatologists (16, 52%), 4

Table 2. List of Additional Key Items recommended by >80% Rheumatologists within Total Consensus Group

Item	Additional Items Recommended by >80% of Rheumatologists within total Consensus Group
	Clinical features
1	Identify features of lupus nephritis histo-pathologically
2	Understand Libman-Sacks endocarditis as well as other cardiac manifestation of lupus*
3	Describe neurological and psychiatric presentations of SLE*
4	Discuss common causes of drug-induced lupus*
5	Understand the difference between classification versus diagnostic criteria*
	Lab abnormalities
6	Identify antiphospholipid antibodies such as lupus anticoagulant, anticardiolipin, beta-2 glycoprotein*
	Treatment
7	Identify the role for steroid sparing agents*
	Morbidity and Mortality
8	Identify relation of sex, age, ethnic, economic differences to lupus severity*
9	Identify increased risk for certain co-morbidities in patients with SLE, such as CAD, CVA, cervical cancer, thrombotic events/DVT/PE, pulmonary hypertension and osteoporosis*

* Additional items proposed by consensus group

participants were from internal medicine, and 11 participants were medical school educators (6 of these medical educators also had internal medicine backgrounds).

In step 1, 61 items were added as suggestions to the curriculum leading to a total of 82 items to be rated. The consensus process eliminated 50 items, leaving 32 in the final list of identified important key teaching elements for lupus (see Table 1). In a post-hoc analysis of ratings provided by rheumatologists within the larger consensus group, 9 additional elements were identified though these did not meet total group consensus (see Table 2).

Conclusion: Using a systematic consensus exercise, a diverse group of educators participating in the lupus consensus project identified key teaching items to prioritize during medical school education. The next steps will include developing learning objectives mapped to these identified items in the development of curriculum to educate medical students about lupus.

Abstract Number: 1189

Ultrasound Online: A Novel Approach to Teaching Rheumatology Focused Musculoskeletal Ultrasonography to Resident Physicians in Training

Andrew Long[1], Bethany Marston[1], Homaira Rahimi[1], Norman Madsen[2] and William Novak[1], [1]University of Rochester, Rochester, NY, [2]University of Rochester, NY, Rochester, NY

SESSION INFORMATION

Session Date: Monday, November 8, 2021
Session Title: Professional Education Poster (1170–1195)
Session Type: Poster Session C
Session Time: 8:30AM–10:30AM

Background/Purpose: Musculoskeletal point of care ultrasound (MSK POCUS) can assess for joint effusions, synovitis and crystalline arthropathy and is increasingly utilized by generalists working in various clinical settings. Generalists are able to perform focused ultrasound (US) exams to answer specific clinical questions with accuracy similar

Table 1

Question	Pretest Correct (%)	Posttest Correct (%)
Which probe position shown is most likely to show a knee effusion if one is present?	N/A	4/4 (100%)
Drag each image to the corresponding pathology label.	0/4 (0%)	4/4 (100%)
In musculoskeletal ultrasound, anisotropy is most likely to be encountered in which tissue type?	1/4 (25%)	3/4 (75%)
Which of the following can be reliably detected with ultrasound used by an experienced operator?	1/4 (25%)	1/4 (25%)

to that of experts after brief instruction, although it is estimated that 2/3 of internal medicine (IM) programs lack a formal US curriculum. At our institution, a 2-week POCUS elective is available for IM residents, however MSK POCUS has not been formally incorporated. A needs assessment survey of residents who previously completed the POCUS elective found that 92% of residents wanted to learn POCUS to assess for joint inflammation or crystalline arthropathy. As the onset of the COVID-19 pandemic necessitated physical distancing, an online electronic learning (eLearn) module was developed to train residents to acquire and interpret MSK POCUS images of the knee. Here we present preliminary results of this model of MSK POCUS instruction for teaching IM residents.

Methods: Three high yield US views of the knee were chosen for their ability to show pathology and ease in demonstrating transducer placement pictorially including the suprapatellar long and short axis views with the knee in neutral position (for joint effusion and synovial thickening) and suprapatellar short axis view with the knee in maximal flexion (for crystalline arthropathy and osteoarthritis changes). The module was developed in Adobe Captivate, hosted on the institution's learning management system (LMS) and made available to residents in the POCUS elective. US images in each view showing normal anatomic landmarks were coupled with graphics to show transducer placement. Common pathology in each view was shown in interactive exercises. US physics, pertinent artifacts, and indications for use were reviewed. To reinforce learning, the module featured interactive elements including simulated transducer placement and point-and-click structure identification items as well as traditional quizzing elements such as drag and drop and matching exercises to provide immediate feedback to learners. Results of a pre and post test were exported to the LMS.

Results: Four residents completed the module between February and May 2021 and serve as a validation cohort. Post-test data show 100% of participants were able to identify correct transducer placement for the highest yield US view to assess for knee effusion and were also able to accurately identify images showing effusion, OA, the double contour sign of gout, and chondrocalcinosis (Table 1).

Conclusion: We present a novel eLearn module to teach targeted MSK POCUS of the knee to IM residents within the context of an existing POCUS elective. The module was effective in teaching appropriate transducer placement and image interpretation in a validation cohort. Future work will assess effects on image acquisition with observed scanning sessions after module completion, demonstrate effect in increasing MSK POCUS utilization among residents over time, and expand this model to additional joint regions and to pediatric subjects.

Abstract Number: 1190

Rheumatology Continuing Professional Development for Primary Care Providers: A Systematic Review

Rachel Robbins[1], Joseph Maciuba[2], Lauren Maggio[3] and Anita Samuel[3], [1]Walter Reed National Military Medical Center, Germantown, MD, [2]Walter Reed National Military Medical Center, Bethesda, MD, [3]Uniformed Services University, Bethesda, MD

SESSION INFORMATION
Session Date: Monday, November 8, 2021
Session Title: Professional Education Poster (1170–1195)
Session Type: Poster Session C
Session Time: 8:30AM–10:30AM

Background/Purpose: The 2015 workforce study conducted by the American College of Rheumatology estimated that in 2030, the United States (US) alone will have a shortage of about 4,700 rheumatologists. As such, primary care providers (PCPs) may find themselves taking the initial steps to diagnose and treat some rheumatologic disorders. PCPs can participate in rheumatology-focused continuing professional development (CPD), which may help mitigate this shortfall. However, there is no recent synthesis of the literature describing these initiatives or their efficacy. This risks the use of suboptimal instructional methods and missed opportunities for providers.

Methods: The authors conducted a systematic review of CPD in rheumatology for primary care. PubMed, Embase, Web of Science, ERIC, CINAHL, PsycINFO were systematically searched by a medical librarian. Studies were limited to those performed in the US and Canada. Studies prior to 1995 were excluded to allow the authors to build on a previous review published that year. An extraction form, including the Medical Education Research Study Quality Instrument, was created through an iterative process and applied to the included articles.

Results: 725 studies were retrieved, of which 9 met inclusion criteria. Preliminary results showed that CPD was directed more at non-inflammatory arthritis than inflammatory arthritis. Additionally, 4 studies at least partially focused on teaching arthrocentesis. Autoimmune diseases were underrepresented; rheumatoid arthritis was discussed in 4 studies and an additional study discussed rheumatologic topics more broadly.

In rheumatology CPD, the underrepresentation of autoimmune disease may contribute to questions in diagnosing and referring patients to rheumatology further accentuating the shortfall of rheumatologists. Newer research tended to include multi-component approaches that combine strategies (such as didactics and active learning), whereas older research was less focused on interactive learning modalities. This is consistent with a move towards more active learning in CPD. Cost considerations are important in CPD, though few articles discuss it. Though e-learning is increasing in popularity, identified interventions were predominantly face-to-face with few examples of e-learning. E-learning may continue to evolve, particularly given the impact of COVID-19 on education.

Conclusion: Rheumatology CPD is moving towards more interactive teaching methods and is typically conducted in person through virtual options in rheumatology CPD should be explored to improve access to CPD. Autoimmune disease is an uncommon topic in CPD and may be an area for future expansion.

Abstract Number: 1191

Introduction of a Joint Injection and Ultrasound Workshop for Internal Medicine Trainees

Lucia Milla, Daniel Lindstrom, Elena Gkrouzman, Jeevarathna Subramanian, Elizabeth Murphy and Jonathan Cheah, University of Massachusetts Medical School, Worcester, MA

SESSION INFORMATION
Session Date: Monday, November 8, 2021
Session Title: Professional Education Poster (1170–1195)
Session Type: Poster Session C
Session Time: 8:30AM–10:30AM

Background/Purpose: There is increasing interest in procedural training at all levels of medical education. While point of care ultrasound (POCUS) and joint injection are not specific requirements of Internal Medicine (IM) training curricula, they are at times included. The aim of this study was to assess the feasibility of an integrated approach to delivering musculoskeletal (MSK) POCUS and joint injection education to Internal Medicine trainees.

Methods: A pilot workshop for IM trainees was created. The workshop consisted of pre-session materials (videos and step-by-step guides to both ultrasound of the knee and knee aspiration and injection), a pre- and post-session knowledge check consisting of two identical multi-sectional cases involving the use of POCUS and joint aspiration/injection in a clinical context and three, 30-minute hands-on small groups sessions on 1: knee ultrasound, 2: knee aspiration and injection and 3: data interpretation/clinical context. Paired t-test was used to compare the pre- and post-session knowledge check scores with a value $p< 0.05$ deemed significant. In addition, post-workshop, feedback in the form of a five-point Likert scale (1 = not at all, 5 = extremely) on each component of the workshop and free text comments were solicitated from participants.

Results: Sixteen IM trainees participated in the pilot workshop (7 Post-Graduate Year (PGY)-1, 4 PGY-2, 4 PGY-3, 1 PGY-4). Eleven subjects had improvement in their test scores after the workshop, three scored the same pre- and post-workshop and one had a lower score post-workshop (Figure 1). The mean test score increased from 5.5 pre-workshop to 7.3 post-workshop ($p=0.001$). Feedback from the group was overall positive with the majority rating

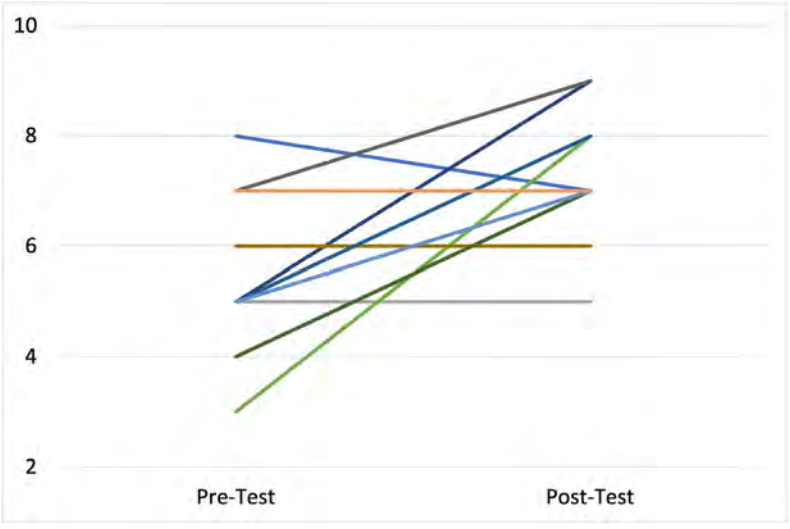

Figure 1. Scores for pre-test cases and post-test cases.

Table 1. Post-workshop feedback (%)

Helpfulness	Pre-session materials	Ultrasound	Aspiration/injection	Data interpretation
Extremely	33	73	53	33
Very	47	27	40	53
Moderately	20	0	7	13
Slightly	0	0	0	0
Not at all	0	0	0	0

each distinct aspect of the workshop either extremely or very useful (Table 1). The three most common feedback comments included 1: obtaining models for different joints in addition to the knee 2: more time to practice MSK POCUS and 3: more examples of pathological states.

Conclusion: An integrated workshop combining ultrasound, aspiration and injection of the knee joint in combination with education around the clinical use and context of these procedures was feasible. In addition, participants found the workshop valuable, leading to increased knowledge post-workshop. Future work is planned to expand this workshop to an entire IM residency program.

Abstract Number: 1192

Palliative Care for the Rheumatologist: An Educational and Patient Care Intervention

Alexandra Saltman[1], Charles Brian Serapio[2], Rebecca Colman[3] and Leah Steinberg[3], [1]University Health Network and Sinai Health System, University of Toronto Faculty of Medicine, Toronto, ON, Canada, [2]University of Toronto Faculty of Medicine, Toronto, ON, Canada, [3]Sinai Health System, University of Toronto Faculty of Medicine, Toronto, ON, Canada

SESSION INFORMATION
Session Date: Monday, November 8, 2021
Session Title: Professional Education Poster (1170–1195)
Session Type: Poster Session C
Session Time: 8:30AM–10:30AM

Background/Purpose: Patients with advanced systemic rheumatic diseases such as systemic sclerosis, inflammatory myositis and vasculitis often have a high burden of symptoms and limited life expectancy. However, these patients have limited access to palliative care. The results of a survey sent out by the Canadian Rheumatology Association revealed that rheumatologists self-report discomfort with, and inadequate knowledge of, palliative care topics including how to engage in advance care planning and goals of care (ACP and GOC) conversations suggesting a gap in training. This study assesses the impact of an education session designed for rheumatologists and trainees.

Methods: A group of rheumatologists and trainees participated in a didactic session and hands on practice with standardized patients based on a structured ACP and GOC Conversation Guide. A post-workshop survey assessed participants' practice patterns and the workshop's impact on participants' comfort with these conversations. Results were analyzed using descriptive statistics.

Results: 12 rheumatology faculty and trainees participated in the workshop and 8 completed the post-workshop survey. Of the participants who completed the survey, 63% (n=5) reported that 5% or more of inpatients that they cared for had advanced rheumatologic diseases with significant functional limitation and/or an estimated prognosis of less than 1 year. 88% (n=7) felt that the workshop was useful to their clinical practices. 75% (n=6) reported that they will be more comfortable in engaging in goals of care conversations with patients following the workshop. 63% (n=5) reported that the workshop raised awareness of the importance of palliative care for patients with life-limiting systemic rheumatic diseases. 63% (n=5) reported that the insights acquired will facilitate challenging aspects of patient care.

Conclusion: We piloted and evaluated a rheumatology-specific advance care planning and goals of care conversation training module delivered to rheumatology residents and faculty. Preliminary results point to participants' increased comfort with these conversations and increased awareness of palliative care's role for patients with end-stage rheumatologic conditions. Further study on a larger scale is required to better assess the value of such educational interventions, and their long-term impact on promoting interdisciplinary models of care for patients with life-limiting rheumatic diseases.

Musculoskeletal Ultrasound Instruction in US and Canadian Pediatric Rheumatology Fellowship Programs

Clara Lin[1], Edward Oberle[2], Megan Curran[3], Johannes Roth[4], Patricia Vega-Fernandez[5], Deidre DeRanieri[6], Tracy Ting[5], Heather Benham[7], Lorena Salto[8] and Karina Torralba[9], [1]Children's Hospital Colorado, Aurora, CO, [2]Nationwide Children's Hospital, Columbus, OH, [3]University of Colorado, Aurora, CO, [4]University of Ottawa, Ottawa, ON, Canada, [5]Cincinnati Children's Hospital Medical Center, Cincinnati, OH, [6]Lurie Children's Hospital, Chicago, IL, [7]Scottish RIte Hospital, North Richland Hills, TX, [8]Loma Linda University Health, Loma Linda, CA, [9]Division of Rheumatology, Department of Medicine, Loma Linda University Healthcare, Loma Linda, CA

SESSION INFORMATION
Session Date: Monday, November 8, 2021
Session Title: Professional Education Poster (1170–1195)
Session Type: Poster Session C
Session Time: 8:30AM–10:30AM

Background/Purpose: Musculoskeletal ultrasound (MSUS) has value in the evaluation of both pediatric and adult rheumatic diseases. It is taught by at least 94% of adult rheumatology fellowship programs based on a 2017 survey. The objective of the present study is to assess the current teaching of MSUS in Canadian and American pediatric rheumatology fellowship training programs, including surveying the teaching methods being employed.

Methods: A core group of pediatric and adult rheumatologists with at least 5 years of experience in medical education and/or in ultrasound convened to develop a survey that assessed for faculty training in ultrasound, access to equipment, financial support for faculty training and equipment, curricular implementation including educational resources, teaching and assessment of competency in ultrasound. Qualtricsâ was utilized to distribute the survey through email to program directors using an anonymous link, with a follow up email sent in two weeks to non-responders. A list of fellowship programs in the USA (36) and Canada (3) were obtained through the American Medical Association Freida™ Online Residency Program Database and the Royal College of Physicians and Surgeons' Canadian Accreditation of Residency Education (CanEra) website, respectively.

Table 1. Characteristics of Pediatric Rheumatology Fellowship Programs, Faculty Descriptors, *(n=27)*

	n (%)[a]
Respondent Role (indicate all that apply)	
Program Director (PD)	**23 (85%)**
PD & Lead US Faculty, Key Clinical Faculty	2 (7%)
PD & Division Director	3 (11%)
Other	**4 (15%)**
Lead US Faculty, Key Clinical Faculty	3 (11%)

US=Musculoskeletal Ultrasound. Percentages may not add to one-hundred due to rounding.

We list the cross-sectional descriptive frequencies and percentages to summarize the data provided by the 27 respondents who completed the survey by May 24, 2021.

Results: We garnered a 69% response rate thus far, with 27 responses. Majority of the survey respondents self-identified as program directors [23 (85%)] (Table 1). 20 (74%) respondents affirmed that their programs offered some level of MSUS training but the majority (17, 63%) surveyed did not have a formal MSUS curriculum. 12 (44%) indicated that they have 1-2 faculty members that actively teach MSUS to fellows. Most programs covered normal and abnormal sonoanatomy, image optimization and knobology, US guided procedures, and documentation and billing as content; and utilized various teaching methods (Table 2). Most programs also did not name any formal assessment methods of proficiency but did cite the use of direct observation and feedback, and use of procedure logs.

US=Musculoskeletal Ultrasound. Percentages may not add to one-hundred due to rounding.

The highest ranked barrier identified was “inadequate time or clinic space to perform MSUS in clinic” with 14 votes for it as a minor barrier and 10 votes for it as a major barrier and accounting for 89% of the total respondent ratings (Table 3). “Inadequate number of faculty to teach” [22 (82%)], and “lack of time or clinic space to include MSUS in clinics and didactics” [21 (78%)] were the next highly rated minor or major barriers.

Conclusion: Out of 27 responses, 85% of Canadian and American pediatric rheumatology fellowship programs are teaching MSUS to fellows. Competency assessment methods are needed. Barriers related to curricular integration include needing faculty who can teach and having the time and space to perform MSUS and include MSUS in clinic teaching and didactics. Further faculty development not only to inculcate MSUS skill sets but also to gain MSUS teaching and assessment skill sets and curriculum development are needed.

Table 3. Perceived Barriers to Complete Curricular Integration in Pediatric Rheumatology Fellowship Programs, *n=27* (%)[a]

	Not a Barrier	Minor Barrier	Major Barrier
Lack of ease of access to equipment	15 (56%)	7 (26%)	5 (19%)

Abstract Number: 1194

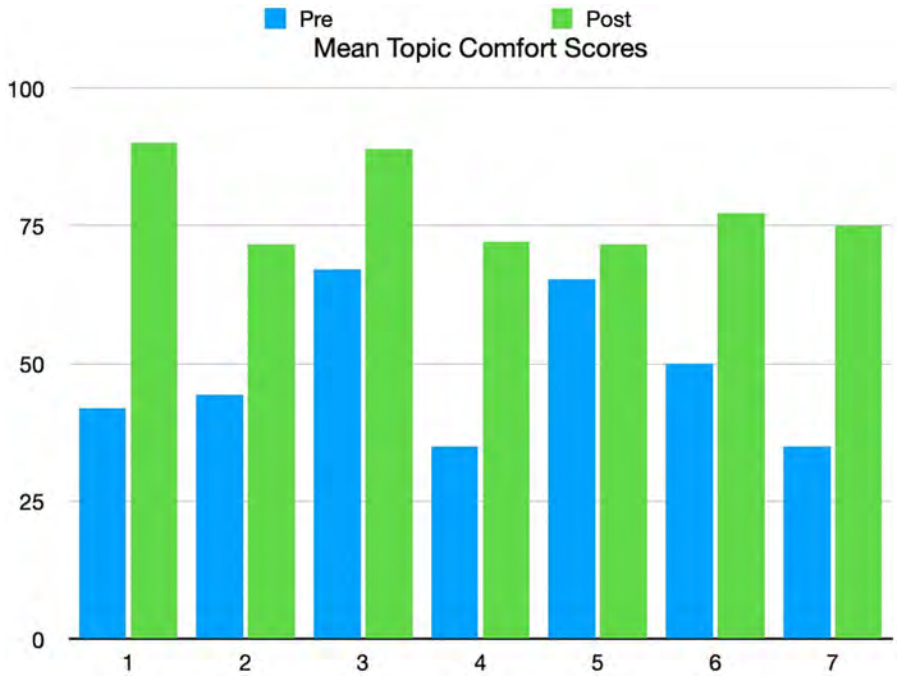
A Module on Large Vessel Vasculitis for Learners in Rheumatology

David Shoemaker[1], Stamatina Danielides[1], Abhishek Nandan[1], Huzaefah Syed[2], Beth Rubinstein[1] and Seema Patel[1], [1]Virginia Commonwealth University, Richmond, VA, [2]Virginia Commonwealth University Medical Center, Richmond, VA

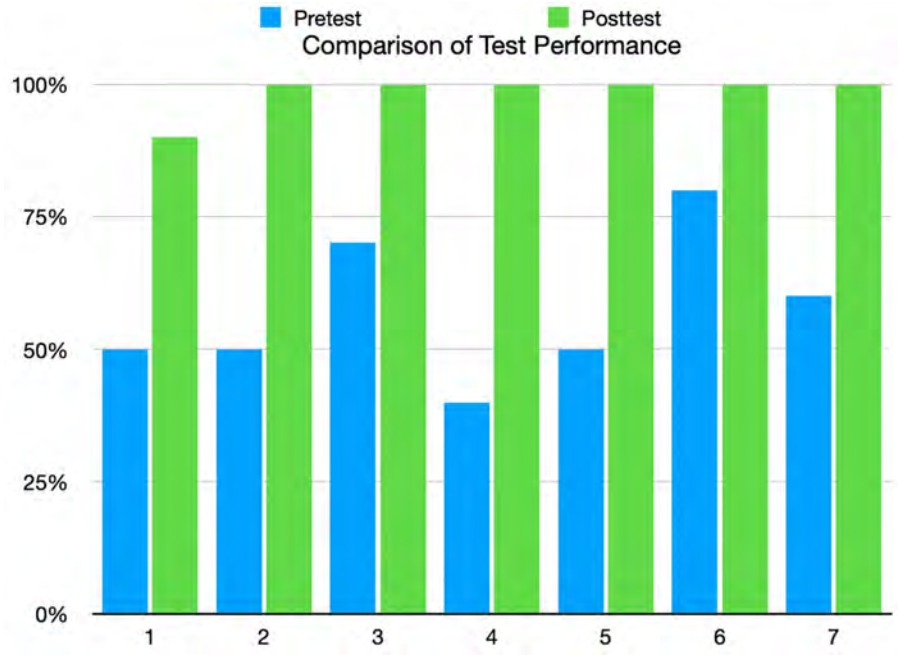
SESSION INFORMATION
Session Date: Monday, November 8, 2021
Session Title: Professional Education Poster (1170–1195)
Session Type: Poster Session C
Session Time: 8:30AM–10:30AM

Background/Purpose: Of the rheumatic disorders that learners are expected to know, the vasculitides are among the hardest to grasp. Their pathogenesis is not well-established, they have many overlapping clinical features and they are rarely encountered in general medical practice. Additionally, the consequences of missed diagnosis and delayed treatment can be catastrophic. Therefore, "vasculitis" is a frequently requested topic for teaching from rotating learners. There also have been important advancements in diagnostic methods, guidelines and available treatments that our rotating learners should know about but may not yet have encountered in training.

This module focused on large vessel vasculitis (LVV), namely giant cell arteritis (GCA) and Takayasu arteritis (TAK). It is part of a larger module-based Rheumatology curriculum undergoing development at Virginia Commonwealth University School of Medicine (VCU SOM). The primary goal of this module is to provide learners with a short, effective



Results of each participant's topic comfort rating before and after completing the educational content.



Results of each participant's test scores before and after completing the educational content.

learning tool to improve their understanding of the clinical features, diagnostic methods and treatment options of LVV in preparation for the cases they may encounter on tests and in clinical practice.

Methods: The study was conducted at VCU SOM. A brief slide-based topic overview was created using Apple Keynote that succinctly covered GCA and TAK. Slides contained high yield characteristics of the background, presentation, exam findings, diagnosis and treatment of these disorders. A test was created and administered for self-assessment and data collection via a secure online, cloud-based program. The test included 10 multiple choice

questions to assess knowledge of the clinical presentations, preferred diagnostic techniques and treatment for LVV. A brief topic comfort survey was also created to compare the learner's confidence in the material before and after the module. Learners rated their confidence in three domains on a scale 1-100 (clinical features, exam findings, diagnostic modalities). Learners were asked to take the test and survey just prior to proceeding with the topic overview and again upon completion of the content. Data were analyzed using the unpaired *t*-test.

Results: Seven participants completed the module. Learners reported a greater degree of confidence after completing the module compared to baseline (mean topic comfort scores of 78.1 and 48.4, respectively; improvement of 29.7 points, 16.9 — 42.5, $p = 0.0003$). This corresponded with significant improvement in test performance—mean pretest score was 57.1%, compared with mean posttest score of 98.6% (improvement of 41.5%, 29.6% — 53.2%, $p = < 0.0001$).

Conclusion: While sample size was small, the results show that this module helped learners significantly improve confidence in their knowledge of large vessel vasculitis, which corresponded with significant improvement in test score performance. Plans for future study involve testing participants again after one month to assess the durability of these effects.

NLP-Based Clustering Methods Can Efficiently Categorize Scientific Abstracts for Medical Conferences

Jeffrey Curtis[1], yujie Su[2], Fenglong Xie[2], cassie Clinton[2], Janet Pope[3], Vivian Bykerk[4], Kenneth Saag[2], Josef Smolen[5], Dan Furst[6] and Lauren Davis[7], [1]Division of Clinical Immunology and Rheumatology, Department of Medicine, Department of Epidemiology, University of Alabama at Birmingham, Birmingham, AL, [2]University of Alabama at Birmingham, Birmingham, AL, [3]University of Western Ontario, London, ON, Canada, [4]Division of Rheumatology, Hospital for Special Surgery, New York City, NY, [5]Medical University of Vienna, Vienna, Austria, [6]University of California Los Angeles, Los Angeles, CA, [7]American College of Rheumatology, Atlanta, GA

SESSION INFORMATION
Session Date: Monday, November 8, 2021
Session Title: Professional Education Poster (1170–1195)
Session Type: Poster Session C
Session Time: 8:30AM–10:30AM

Background/Purpose: Expanding scientific discovery has resulted in increased challenges to organize and categorize medical knowledge. Dozens or hundreds of abstracts are submitted each year to more than 40 American College of Rheumatology (ACR) Convergence Annual Meeting Abstract Submission Categories. Numerous ACR abstract review teams then are charged to group similar types of abstracts into the many poster and oral sessions (i.e. subcategories), to be presented across Convergence meeting days. This manual process of grouping relies on subject matter expertise to identify similar content across abstracts and is exceedingly time consuming. We developed and implemented an automated approach to sub-categorize similar abstracts within each ACR Abstract Submission Category to increase the efficiency of the grouping process.

Table: Results from Method Used to Subcategorize 2020 ACR Convergence Abstracts using Clustering Algorithm with Natural Language Processing

ACR Convergence Abstract Category	# of abstracts to be sub-categorized	Results: # of clusters, and abstracts/cluster			
		# of clusters	Median	Min	Max
33: Rheumatoid arthritis – Diagnosis, manifestations, outcomes	136	13	10	8	12
34: Rheumatoid arthritis – Treatments	142	14	10	7	14
36: Spondyloarthritis - Diagnosis, manifestations, outcomes	133	11	12	9	16
36: Spondyloarthritis – Treatments	129	12	10	6	18
38: SLE - Diagnosis, manifestations, outcomes	136	12	11	8	14
39: SLE – Treatments	58	6	9	8	12
30: Pediatric Rheumatology – Clinical	106	11	10	7	12
Total # of Abstracts; Median # Clusters, and # Abstracts/Cluster	**840**	**12**	**10**	**8**	**14**

Methods: The corpus of all accepted abstracts to seven of the largest 2020 ACR Convergence Abstract Categories was parsed and processed using natural language processing (NLP) tools from the National Library of Medicine. After filtering stop words, parsing the data, and applying n-grams for tokenization, a bag of words approach was used to identify all terms and multi-word concepts in both the title and body of all abstracts. We counted term and concept frequencies, weighted by the inverse of their frequency across all abstracts. Concepts also were tagged with their semantic type using UMLS. K-means clustering was used to derive abstract category subclusters, optimizing the cluster convergence criterion (CCC) metric to identify the optimal number of subclusters (i.e. abstract session subcategories). An iterative, automated approach subsequently was applied that required the clustering algorithm to select the next number of clusters (also based on the CCC) if the first solution did not meet constraints defined by varying parameters on the size of the subcategories (i.e. min/max number of clusters, and the min/max number of abstracts per cluster).

Results: A total of 840 abstracts distributed across 7 ACR 2020 Convergence categories were analyzed and yielded 156,778 unique concepts derived from 24,990 unique terms. For each of the 7 Abstract Submission Categories and with no constraints applied, the method yielded 6 – 14 subcategory clusters. The min and max number of abstracts per cluster subcategory ranged from 6 - 18 (Table). Applying additional constraints on both the number of clusters and min/max number of abstracts per cluster yielded convergence within 1-4 iterations.

Conclusion: Clustering methods combined with NLP tools has the ability to greatly reduce the time spent by ACR Convergence meeting review teams and has applicability to other scientific meetings to automatically subgroup abstracts into sessions or to pre-categorize them as a basis for further manual refinement.

Abstract Number: 1196

Morning Stiffness Already Associates with Systemic Inflammation and Subclinical Joint Inflammation in the Pre-RA Phase of Arthralgia

Doortje Krijbolder[1], Fenne Wouters[1], Elise van Mulligen[2] and Annette H.M van der Helm-van Mil[1], [1]Leiden University Medical Center, Leiden, Netherlands, [2]Erasmus Medical Center, Rotterdam, Netherlands

SESSION INFORMATION
Session Date: Monday, November 8, 2021
Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster III: Prediction, Biomarkers, & Treatment Response (1196–1222)
Session Type: Poster Session C
Session Time: 8:30AM–10:30AM

Background/Purpose: Morning stiffness (MS) is characteristic for Rheumatoid Arthritis (RA) and associates with markers of systemic and local inflammation in RA-patients. In patients with arthralgia, MS is a cardinal symptom to recognize arthralgia at-risk for RA-development (i.e. clinically suspect arthralgia, CSA). In CSA, MS is also assumed to reflect inflammation, but this has never been studied. Therefore we aimed to study whether MS in CSA-patients is associated with systemic- and subclinical joint-inflammation.

Methods: 575 patients presenting with CSA underwent laboratory investigations and contrast-enhanced 1.5T-MRI of hand and forefoot (scored according to the RAMRIS-method). Associations of MS (duration ≥60 minutes) with presence of subclinical synovitis, tenosynovitis and osteitis with increased CRP (≥5 mg/L) were determined with logistic regression. Additionally, the effect of MS-duration (≥30, ≥60, ≥120 minutes) was studied.

Results: The mean age of the study population was 44 years (SD 13), 439 patients (76%) were female, median tender joint count (TJC68) was 5 (IQR 2-10), and 79 (14%) patients were ACPA-positive. 195 (34%) CSA-patients experienced MS. These patients more often had subclinical synovitis (34% versus 21%, OR 1.95 (95%CI 1.32-2.87)), subclinical tenosynovitis (36% versus 26%, OR 1.59 (1.10-2.31)) and increased CRP (31% versus 19%, OR 1.93 (1.30-2.88)) than patients without MS. In multivariable analyses, subclinical synovitis (OR 1.77 (1.16-2.69)) and CRP (OR 1.78 (1.17-2.69)) remained independently associated with MS. In CSA-patients who later developed RA, and thus in retrospect were 'pre-RA' at time of CSA, MS was more strongly associated with subclinical synovitis (OR 2.56 (1.04-6.52)) and CRP (OR 3.86 (1.45-10.24)). Furthermore, associations increased with longer MS-durations.

Conclusion: Inflammation indeed contributes to MS, already in the CSA-phase that preceded clinical arthritis. These results increase understanding of MS when assessing arthralgia in clinical practice.

Abstract Number: 1197

Periodontal Status Before Diagnosis in Patients with Rheumatoid Arthritis Predicts Cumulative Disease Activity in Years After Treatment Inititation

Adelina Plachokova[1], Jill Hadisurya[1], Julia van Bergen[2] and **Rogier Thurlings**[3], [1]Radboudumc, department of Dentistry (Implantology & Periodontology), Nijmegen, Netherlands, [2]Radboudumc, department of Dentistry (Implantology & Periodontology), Nijmegen, [3]Radboud University Medical Centre, Nijmegen, Netherlands

SESSION INFORMATION
Session Date: Monday, November 8, 2021
Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster III: Prediction, Biomarkers, & Treatment Response (1196–1222)
Session Type: Poster Session C
Session Time: 8:30AM–10:30AM

Background/Purpose: Transversal cohort studies demonstrated a possible association between periodontal disease (PD) and rheumatoid arthritis (RA). However it is unknown how this association evolves during the disease course. In this study we aimed to compare the severity of PD in RA patients versus non-RA healthy controls prior to clinical diagnosis of RA and thereafter. Additionally, the correlation was analyzed between RA disease activity and PD severity and progression in the same period.

Methods: Data (retrospective with a follow-up of 10 years) of 98 RA patients from general practices and matched healthy control patients from the University Dental College were analyzed. Medical files and dental treatment records were evaluated. PD was analyzed via radiographic assessment using the new periodontal classification system from 2017. Primary outcome measures were the severity and extent of periodontitis (Stage and Grade) and the RA disease activity (DAS28, cumulative DAS28-score). Secondary analytes were gender, year of birth and age at diagnosis, smoking habits, frequency of dental visits for check-up, frequency and duration of periodontal debridement and the presence of rheumatoid factor (RF) and anti-cyclic citrullinated protein antibodies (Anti-CCP). Statistical analyses were performed with IBM SPSS Statistic 25. Depending on the variables Chi-Square Test, Mann-Whitney U Test, Wilcoxon Signed Rank Test, Spearman Correlation and ANOVA were used.

Results: More RA patients had severe periodontitis (stage III/IV) compared to matched healthy controls. The fraction of RA patients with severe PD increased 23% before diagnosis to 43% 5-10 years after diagnosis. The largest part of these patients developed a severe PD with a moderate risk/rate of progression. The proportion of patients that regularly visited the dentist increased from 70% before diagnosis to 80% for patients with mild PD and 94% of patients with severe PD 5-10 years after diagnosis. Development of PD did not differ between sexes or between seronegative and seropositive RA. Patients with severe PD and patients with a high risk of PD progression before RA diagnosis had a higher cumulative DAS28-score than patients with mild PD in the first 7 years after RA treatment initiation.

Conclusion: PD occurs in a proportion of RA patients before diagnosis and in an increasing proportion of patients in the years after diagnosis. PD is associated with decreased response to anti-rheumatic treatment in the years after diagnosis. A proportion of RA patients with radiographic PD infrequently undergoes dental follow up for PD treatment, especially in the years before RA diagnosis.

Ultrasonography of the Median Nerve in Patients with Rheumatoid Arthritis Under Suspicion of Carpal Tunnel Syndrome

Styliani Tsiami[1], Efthymia Ntasiou[2], Christos Krogias[2], Ralf Gold[2], Jürgen Braun[1], Michael Sarholz[3] and Xenofon Baraliakos[1], [1]Rheumazentrum Ruhrgebiet Herne, Ruhr-Universität Bochum, Herne, Germany, [2]St. Josef-Hospital, Bochum and Ruhr-University Bochum, Germany, Bochum, Germany, [3]Klinik fuer Rheumatologie, St. Marien-Hospital Vreden, Vreden, Germany

SESSION INFORMATION

Session Date: Monday, November 8, 2021

Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster III: Prediction, Biomarkers, & Treatment Response (1196–1222)

Session Type: Poster Session C

Session Time: 8:30AM–10:30AM

Background/Purpose: Carpal tunnel syndrome (CTS) is the most common nerve compression syndrome and a common extra-articular manifestation of rheumatoid arthritis (RA). Different causes of CTS are known, among them inflammatory and non-inflammatory pathologies. Electroneurography (ENG) of the median nerve, the method of choice to diagnose CTS, measures impairment of nerve conduction velocity without explaining its underlying cause. However, because the electrical stimulation is often not well tolerated, ENG results may come out inconclusive. Using greyscale ultrasonography (GS-US) provides anatomic information including a structural representation of the carpal tunnel. The aim of this study is to investigate the performance of nerve GS-US in the diagnosis of CTS in patients with RA.

Methods: Consecutive patients with active RA under suspicion of CTS presenting to a large rheumatologic center were included. Both hands were examined by an experienced neurologist including ENG and a GS-US (ML linear probe with 6-15 Hz) of the median nerve. An established grading system for ENG (1), and an established system for GS-US based on cut-offs for the nerve cross sectional area (CSA) [mild: 0,11-0,13cm², moderate: 0,14-0,15 cm², severe: > 0,15 cm² CTS (2)] were used. In addition, the Boston Carpal Tunnel Syndrome Questionnaire (BCTSQ) was used to assess CTS symptoms (3).

Results: Both hands of 58 patients with active RA (n=116) and clinical suspicion of CTS (in 38 cases bilaterally) were included. After clinical examination, CTS was suspicious in 96 hands (82.8%), and 59 of all hands had a final diagnosis of CTS (50.9%). Of the latter, 43 hands (72.9%) had a positive ENG and 16 (27.1%) a positive GS-US finding only, while 30 hands (50.8%) were positive in both examinations.

There was a good correlation of the cross-sectional area (CSA) as well as the CSA-ratio to the ENG findings: the larger the CSA, the more severe was the CTS as assessed by ENG (Spearman's rho=0.554; p< 0.001). The more severe

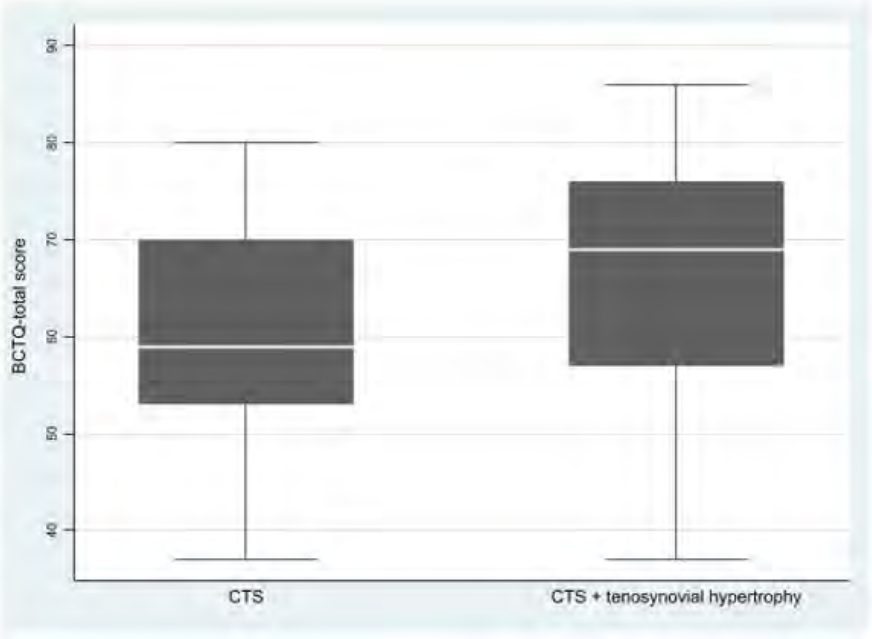

Figure. BCTSQ scores in patients with diagnosis of CTS and absence or presence of RA-related tenosynovial hypertrophy.

the GS-US findings of CTS were, the more definite were the distal motor latency (Spearman's rho=0.554; p< 0.001) and sensible nerve conduction velocity of the median nerve (Spearman's rho=-0.5411; p< 0.001).

In the 46 hands positive in GS-US, tenosynovial hypertrophy of the flexor tendons was detected in 19 hands (41.3%), 7 of which (36.8%) also showed an additional cystic mass. In these 19 patients, clinical complains were more severely present than in patients with non-inflammatory CTS, as assessed by the BCTSQ with a total score of 68.8±13.4 vs. 59.3±13.7, respectively (p=0.007).

Conclusion: In patients with active RA and clinical complains of CTS, ultrasound examinations provide additional information about inflammation which is helpful for a diagnosis of CTS. Thus, ENG and nerve GS-US should be used complementary for a diagnostic workup of CTS in RA patients with a suspicion of CTS. Power-Doppler may further improve the diagnostic performance of GS-US.

Ultrasound in Clinically Suspect Arthralgia: The Role of Power Doppler to Predict Rheumatoid Arthritis Development

Katerine López[1], Isabel Castrejón[1], Juan Carlos Nieto[1], Javier Rivera[1], Teresa González[2], Fernando Montero[1], Carlos González[3], Jose Maria Alvaro-Gracia[1] and Juan Molina[4], [1]Hospital General Universitario Gregorio Marañón, Madrid, Spain, [2]H Gregorio Maraon, Madrid, Spain, [3]CEIMI, Hospital General Universitario Gregorio Marañón, Madrid, Spain, [4]Hospital General Universitario Gregorio Maran, Madrid, Spain

SESSION INFORMATION
Session Date: Monday, November 8, 2021
Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster III: Prediction, Biomarkers, & Treatment Response (1196–1222)
Session Type: Poster Session C
Session Time: 8:30AM–10:30AM

Background/Purpose: It is of great importance to identify patients with clinically suspect arthralgia (CSA) who will develop rheumatoid arthritis (RA) or other inflammatory arthritis (IA) because an early diagnosis and initiation of DMARD therapy of these patients is associated with better long term outcomes. Thus, a prompt detection of inflammation and identification of predictors factors of RA is desirable. Our objective is to determine the usefulness of power Doppler (PD) ultrasound (US) to predict RA development in patients with CSA.

Methods: Retrospective analysis of a US unit cohort over a one-year period. Patients with CSA and no previous diagnosis of IA were included for analysis. All underwent bilateral US examination of hands and/or feet according to

Table 1. Predictive factors to rheumatoid arthritis: univariate and multivariate analysis.

the EULAR guidelines. All US examinations were performed by the same rheumatologist, unaware of the physical exam by the referring rheumatologist. The presence of synovitis and tenosynovitis was assessed on a semiquantitative scale (0-3) for gray scale (GS) and PD, respectively. Active US inflammation was defined as synovitis and/or tenosynovitis with PD signal grade ≥1 at any location. RA diagnosis according to clinician criteria 6 months after the US examination was checked. Univariate and multivariate logistic regression models were employed to investigate possible predictive factors of RA development.

Results: A total of 110 CSA patients (80 females, mean age 53.6 years) were included for analysis., Baseline characteristics of the patients with and without development of RA are shown in Table 1. US active inflammation was

present in 38 (34.5%) patients (28.2% showed PD synovitis and 19.1% PD tenosynovitis) (Table 2). After 6 months of follow up, 14 (36.8%) of the patients with US active inflammation at baseline evolved toward RA, while none of the patients without PD findings (p< 0.01) had the same evolution. In those patients who evolved to RA, the presence of GS and PD findings at US examination were significantly higher at baseline versus those who did not (100% vs 35.4%, p >0.001 and 100% vs 25%, p >0.001, respectively). Higher ACPA levels, but not RF, were also found to be associated with RA development (462±693.4 vs 30.2±127.6, p< 0.001). In the multivariate analysis, only ACPA (OR 1.004; 95%CI 1-1.007) and the presence of PD US findings at baseline (OR 13.1; CI 1.07-161.04) were found to be independent predictive factors of an evolution towards RA.

Conclusion: US is able to detect features of subclinical inflammation in CSA patients. Both ACPA and the presence of PD findings at baseline US assessment are independent predictors of RA development in CSA patients.

SESSION INFORMATION
Session Date: Monday, November 8, 2021
Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster III: Prediction, Biomarkers, & Treatment Response (1196–1222)
Session Type: Poster Session C
Session Time: 8:30AM–10:30AM

Background/Purpose: Rheumatoid Arthritis (RA) is a chronic inflammatory condition often associated with joint destruction, disability, and reduced life expectancy. Before RA diagnosis, some patients may present with seropositive arthralgia characterised by pain and/or stiffness without any clinical evidence of inflammation.

Seropositive arthralgia patients RA defined as joint pain without swelling, positive anti-citrullinated peptide antibodies (ACPA) or IgM rheumatoid factor (RF) are 'at risk' of developing RA. In this study we examine the knee arthroscopy and synovial biopsy features of 'at risk' patients for evidence of subclinical inflammation and assess its ability to predict progression to RA.

Methods: Seropositive arthralgia patients underwent needle arthroscopy and synovial biopsy of a knee joint. . The degree of synovitis and vascularity were recorded on a 0-100mm visual analogue scale. The synovium was examined by routine histology of H&E staining. Patients were followed up at regular intervals (3 months, 6 months and1 year) with a clinical assessment and laboratory investigations to evaluate if they developed RA according to the ACR/EULAR 2010 criteria.

Table 1. Baseline demographics and scope data

Demographic		
Female gender, n (%)		31 (67.4)
Age, mean (S.D.) years		57 (14.2)
Risk factors

Inflammatory infiltrate, n(%)		

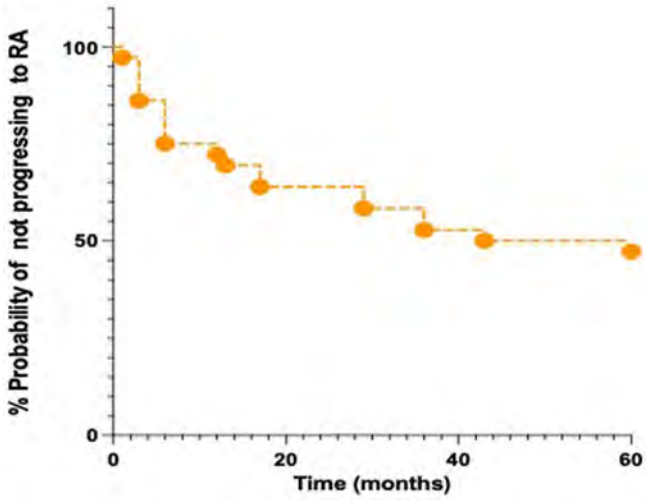

Figure 1. Kaplin-Meier Curve of the timeline of patients converting to RA.

Results: A total of 46 patients were recruited, 78% developed RA. X length of follow up. Patient demographics are outlined in Table 1. Family history, smoking and early morning stiffness were not predictive of developing RA. A statistically significant correlation was found between ACPA levels of >340 and the development of RA (P=.03). A synovitis or vascularity score of greater than 50% at arthroscopy significantly correlated with RA development (P=.04; P=.002,

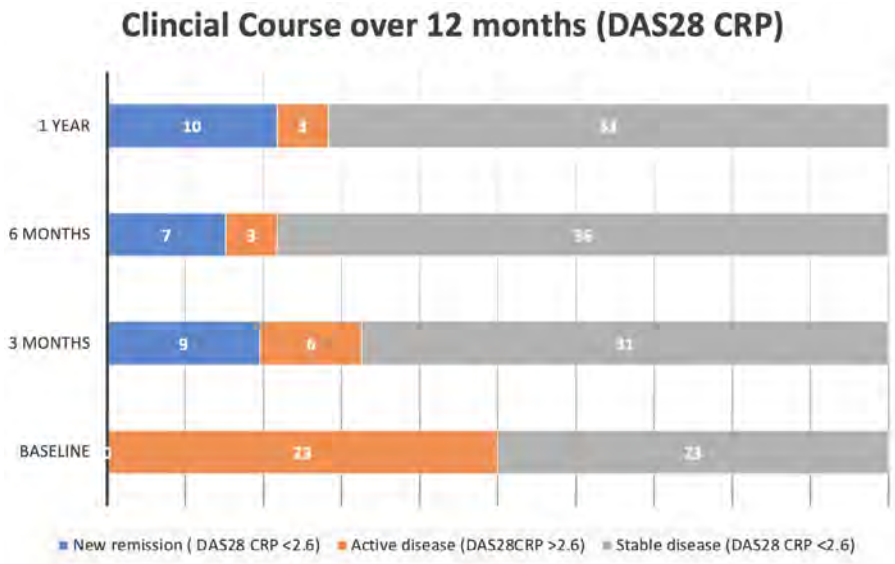

Figure 2. Clinical course over 12 months from scope (T1).

respectively). If a patient had both synovitis and vascularity score of 50%, it was strongly associated with progression to RA (P< .001).

If treated with conventional synthetic(cs) DMARDs for arthralgia, the median time for developing RA was 12 months compared to 3 months in those who did not receive treatment. Figure 1 outlines time to developing RA. The clinical course of the patients over 12 months is outlined in Figure 2.

Conclusion: Seropositive arthralgia patients 'At risk' of developing RA demonstrate >50% macroscopic synovitis or vascularity score at knee arthroscopy. ACPA titre > 340 is associated with progression and csDMARD treatment may delay, but not prevent, onset of RA .

2-year DAS28 ESR	2.8 (2.0)	211 / 26	2.9 (2.1)	280 / 56	0.03

Background/Purpose: RA is a complex multisystem disease, which, untreated, results in debilitating joint damage, excess morbidity, and premature mortality. Previous research has demonstrated an association between early treatment and improved outcomes; however, there is often a delay between symptom onset and diagnosis. We investigated the demographic and clinical features associated with delay in RA diagnosis and the impact of delayed diagnosis on disease activity in U.S. Veterans.

Methods: We studied patients in the Veterans Affairs Rheumatoid Arthritis (VARA) registry which prospectively captures RA disease activity and severity measures from 12 VA Medical Centers. We included patients who reported a date of symptom onset within 5 years of RA diagnosis to avoid bias related to inaccurate recall. Patient demographics, date of symptom onset and diagnosis (collected by self-report at the time of enrollment); and the results of RF, Anti-CCP, CRP, and tender and swollen joint counts were extracted from the registry. Disease activity measures at

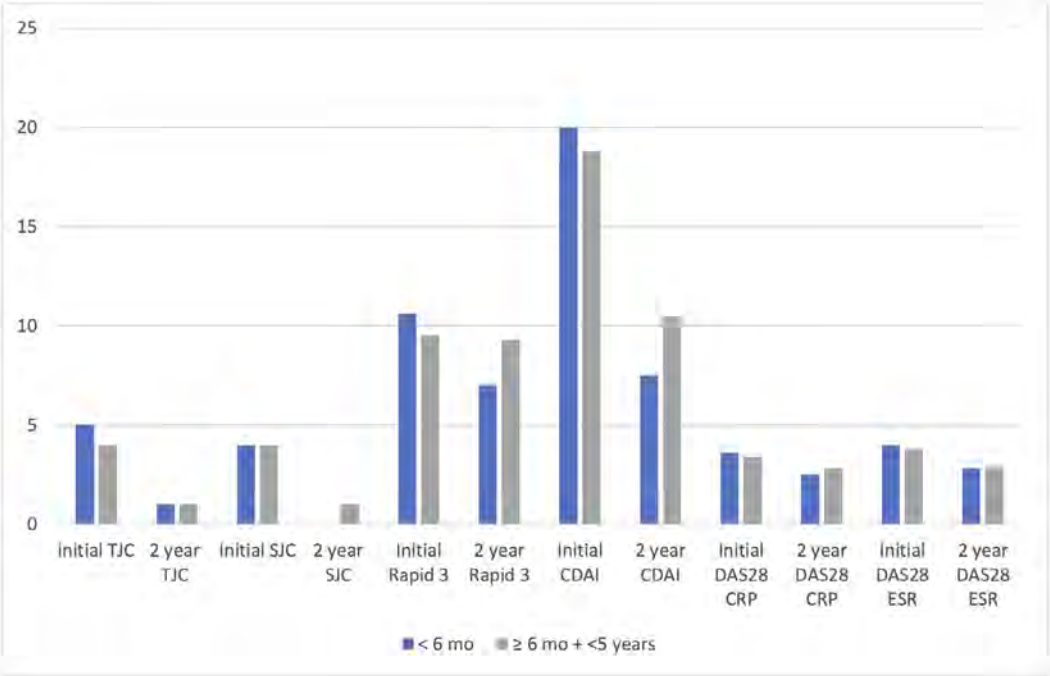

Figure 1. Baseline and 2-year Disease Activity Measures in Early vs Delayed Diagnosis.

enrollment, and 2-years after diagnosis, for RAPID3, CDAI, DAS28ESR and DAS28CRP were calculated. Early diagnosis was defined as diagnosis within 6 months of symptom onset. The relationship between pre-hypothesized study variables and the time to diagnosis was evaluated using contingency analysis and Kruskal-Wallis or Wilcoxon tests for non-normative data. Two-year post-diagnosis disease activity scores were averaged to estimate influence of a delay in diagnosis on subsequent disease control.

Results: At the time of the study there were 2,996 patients eligible for the study and 1,454 were included. The primary reasons for exclusion were patients unable to recall symptom onset date (1,169) and diagnosis date that was greater than 5 years after onset date (373). Of those included, 485 veterans were diagnosed within 6 months and 969 were diagnosed between 6 months and 5 years. Delayed diagnosis was associated with younger age, 53.7 years vs 56.2 years. (Table 1) Those with delayed diagnosis also had higher rates of current smoking. There were no significant differences in terms of family history of RA, education level, or race. No difference was noted in enrollment TJC, SJC, CRP, disease activity scores or rates of RF or CCP positivity. TJC and SJC also did not differ between groups at 2 years, however, there were lower median RAPID3 and CDAI scores in the early diagnosis group, as well as a larger change from baseline scores. No statistical difference was noted in the DAS28CRP scores at 2 years while the DAS-28ESR slightly favored the early group.

Conclusion: In this veteran cohort, where the model of access to care is substantially different from typical U.S. healthcare systems, traditional predictors of delay in RA diagnosis (older age, race, and education level) were not noted to contribute. While 2-year post diagnosis TJC and SJC were not different between the groups, differences in RAPID3 and CDAI suggest that earlier diagnosis may result in better long-term patient-reported outcomes. Additional research is needed to understand why younger age and smoking might lead to delayed diagnosis.

Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster III: Prediction, Biomarkers, & Treatment Response (1196–1222)

Session Type: Poster Session C

Session Time: 8:30AM–10:30AM

Background/Purpose: During the COVID pandemic assessments of RA disease activity (DA) have relied on virtual assessments by patient report. It is unknown whether non-articular pain might influence these. We sought to determine if patient reported Non-Articular Pain (NAP) by body pain diagram (BPD) influences the agreement of change in

Table 1: Baseline characteristics of 210 Patients Stratified by Non-Articular Pain and Pattern by Body Pain Diagram Reported at 6 Months

Variable [Mean (SD) or Frequency (%)]	No pain (N=122)	Regional pain (N=65)	Widespread pain (N=23)

Controlled Disease activity based on MD CDAI score of ≤ 10 at 6 months

Table 3: Change in MD and PT CDAI Scores between 3M and 6M timepoints in Patients Grouped by Non-Articular Pain at 6 months

NAP Group (N=210)	Difference in MD CDAI	Difference in PT CDAI	Difference in Change Scores
No NAP (N=122)	4.5 (9.3)	2.0 (10.3)	2.5 (9.5)
ICC (95% CI)		**0.51 (0.37, 0.63)**	
Regional pain (N=65)	3.6 (12.5)	1.8 (11.7)	1.8 (9.9)
ICC (95% CI)		**0.66 (0.49, 0.77)**	
Widespread pain (N=23)	1.1 (10.3)	1.30 (12.9)	-0.2 (14.5)
ICC (95% CI)		**0.25 (-0.17, 0.59)**	

clinical disease activity index (CDAI) scores over 3 months as rated by rheumatologist (MD) and patient (PT), comparing a previously validated PT CDAI and the standard MD CDAI. We hypothesized agreement would be similar for PT- and MD- CDAI ratings in patients without NAP or regional NAP (RP) but would be worse in patients with widespread NAP (WSP).

Methods: Data were from patients with early RA (Symptoms < 1 year) who were enrolled in CATCH between Mar 2017 and Mar 2021. All had complete data at 3- and 6- month (M) visits to calculate MD- and PT- CDAI scores. Patients had to have completed a BPD at each visit. Patients were classified as having regional RP (1 or 2 regions of pain on BPD), or WSP (3 or more regions of pain on BPD) at their 6M Visit. In CATCH MDs and patients separately identify tender/painful and swollen joints using a 28-joint count homunculus, and both report global assessments (GA) (NRS 0-10) at each visit. The PTCDAI score was the sum of PT-rated TJC28, SJC28, MDGA and PTGA (0-76). We compared PT and MD CDAI scores at 3M and 6M visits in all patients and in subgroups based on presence of and type of NAP. We then compared change in MD and PT CDAI scores between 3M to 6M visits stratified by NAP report and further stratified by disease activity control between 3M and 6M defining controlled as low disease activity or remission (LDA/REM) using a standard cut point of ≤ 10 by MD CDAI at 6M and active uncontrolled disease activity (high or moderate disease activity (HDA/MDA)). Simple Kappa and one way ICC were used to assess agreement for categorical and continuous measures.

Results: The sample included 210 participants with a mean (SD) age of 57 (13), symptom duration of 5.3 (2.8); 80% met RA criteria, 81% were white, 65%/60% were ACPA/RF positive. At 6 months 58% reported no NAP, 31% Regional Pain and 12% Widespread Pain. Patients with any NAP were older, mostly female, with more comorbidities, and higher PT CDAI scores compared to MD CDAI scores. More pts with WSP smoked and received glucocorticoids (Table 1). Agreement between PT and MD CDAI scores at 3M and 6M single time points, regardless of DA control was high for patients without NAP and with RP, but lower for patients reporting WSP (Table 2). Agreement for the change in MD and PT CDAI scores between 3M and 6M visits was high-moderate to high for pts without NAP, and RP but low for pts with WSP (Table 3).

Conclusion: PT CDAI scores at single time points, and the difference in scores between 3- and 6- month visits, were similar to MD CDAI scores for patients without NAP or with regional pain with good agreement, but agreement was poor for patients with WSP. These data suggest using caution in interpreting a PTCDAI in patients with a competing widespread pain disorder. It is possible regional NAP may represent RA-related inflammation such as tendinitis and may explain why agreement is still high in PT- and MD- CDAI scores.

SESSION INFORMATION

Session Date: Monday, November 8, 2021

Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster III: Prediction, Biomarkers, & Treatment Response (1196–1222)

Session Type: Poster Session C

Session Time: 8:30AM–10:30AM

Table 1. Comparison of Overall Change in MD CDAI and PT CDAI scores between the 3 and 6 month follow up visits in 937 participants with complete data

Visit Month	3M	6 M	Change between 3M and 6M
MD CDAI	11.9 (10.9)	9.2 (9.7)	2.7 (10.3)
PT CDAI	15.2 (13.2)	13.1 (12.6)	2.2 (11.9)
ICC (95% CI)	0.65 (0.61, 0.68)	0.65 (0.61, 0.69)	0.59 (0.55, 0.63)

CDAI Scores are mean (SD). Scores and change in scores were compared using one-way random effects, single measure intraclass correlation coefficient (ICC) (95%CI)

Table 2: Mean differences of change in MD and PT CDAI disease activity ratings from 3M to 6M, stratified by change in disease control over 3 months

Disease Activity	Improved to Controlled			Worsened to Active			Remained Active			Remained Controlled		
MD-PT Δ differences	(N=184; 20%)			(N=84; 9%)			(N=227; 24%)			(N=442; 47%)		
	Δ	95% CI	SD	Δ	95% CI	SD	Δ	95% CI	SD	Δ	95% CI	SD
MD CDAI	14.1	(12.7,15.4)	9.2	-12.2	(-14.1, -10.3)	8.8	2.2	(0.8, 3.6)	11.1	1.0	(0.7, 1.3)	3.5
PtCDAI	11.1	(9.5, 12.7)	11.1	-11	(-13.9, -8.1)	13.3	1.3	(-0.4, 3.0)	13.2	1.2	(0.5, 1.9)	7.8
MD-PT CDAI	3.0	(1.3, 4.7)	11.5	-1.2	(-3.7, 1.4)	11.7	0.9	(-0.7, 2.6)	12.7	-0.2	(-0.8, 0.4)	6.8

Change in Disease activity Control: defined as Improved (HDA/MDA to REM/LDA), Worsened (REM/LDA to MDA/HDA), No change remaining active (in HDA/MDA) or remaining controlled (REM/LDA) at both visits

Table 3: Agreement for differences between MD and Patients 3M to 6M Change Scores showing the ICC (95% CI) stratified by changes in control of disease activity in RA

	Improved to Controlled Disease	Worsened to Active Disease	Remained in Active Disease	Remained in Controlled Disease
Difference in MD – PT CDAI 3M to 6M Change Scores	0.34 (0.20, 0.46)	0.46 (0.28, 0.61)	0.45 (0.34, 0.55)	0.36 (0.28, 0.44)

One-way random effects, single measure ICC (95%CI) measures shown, Stratifications of change in disease activity states as controlled (REM/LDA) or uncontrolled (MDA/HDA) disease activity

Background/Purpose: The Clinical Disease Activity Index (CDAI) is a frequently used composite measure by rheumatologists (MD) in routine care used to guide target-based treatment decisions. During the COVID19 pandemic treatment decisions were made during telemedicine visits relying on patient (pt) reports. Virtual care will likely be used in future. We previously showed high agreement between MD- and PT- CDAI scores and control of disease activity (score ≤10) suggesting the PTCDAI can inform if a pt has achieved RA treatment targets. Our goal here was to determine if change scores in a proposed PTCDAI between 3M and 6M visits were similar to those of the reference MD CDAI, amongst patients with differing changes of disease activity to further assess the validity of a PTCDAI for use in virtual care. We hypothesized that differences between MD and PT CDAI change scores over 3 months will be similar whether or not patients remain in controlled/uncontrolled disease activity or not.

Methods: Data were from 937 pts with new onset inflammatory arthritis (Symptoms < 1 year) meeting criteria or MD diagnosis of RA, enrolled between Nov 2011 and July 2020 into the Canadian early ArThritis CoHort (CATCH) study. Eligible pts were all treated for RA and had complete data at 3- and 6- month (M) visits to calculate both CDAI scores. MDs and PTs independently rated 28-tender/painful and 28-swollen joint counts (TJC28/SJC28) using a homunculus, and provided respective global assessments (GA) (NRS 0-10). The PTCDAI score was the sum of Pt rated TJC28, SJC28, MDGA and PtGA (0-76). Changes in MD-CDAI and PT-CDAI scores were compared between 3M and 6M visits. The MD-CDAI cut point of ≤10 was used to identify pts with controlled [remission/low DA (REM/ LDA)] vs. uncontrolled (active) [high/moderate DA (MDA/HDA)] RA. Descriptive statistics were used to summarize and compare 3M and 6M change measures. A simple kappa or one-way, random effects, single measure ICC was used to assess agreement of change.

Results: At baseline, 937 pts had a mean (SD) age of 56 (15), symptoms of 5.5 (2.9) (mos), comorbidity score 1.2 (1.3); 70% were female, 81% white, 14% smokers, 30% BMI ≥ 30, 80% met RA criteria, 65%/60% ACPA+/RF+. CDAI scores were: MD CDAI 25.0 (14.1), PtCDAI 27.5 (15.9). All were treated with csDMARDs (73% methotrexate). There was high agreement between change in either CDAI (Table1). The change in MD- and PT-CDAI scores from 3M to 6M, stratified by a change or not in disease control were numerically similar and as clinically expected (Table 2). Agreement between MD and Pt CDAI change scores over 3M to 6M was moderate across disease control strata. As disease state improved or worsened, or when disease remained active, ratings of change in MD and PT-CDAI were well aligned but there was more variability in change ratings as disease activity improved, with patients rating less improvement than the MDs (Table 3).

Conclusion: These data provide additional evidence for the reliability of change in PTCDAI scores between 2 visits and warrant evaluation of the PT CDAI in future studies of outcomes for use in virtual care and telemedicine.

SESSION INFORMATION

Session Date: Monday, November 8, 2021

Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster III: Prediction, Biomarkers, & Treatment Response (1196–1222)

Session Type: Poster Session C

Session Time: 8:30AM–10:30AM

Background/Purpose: In a cohort of early rheumatoid arthritis (eRA) patients, we recently showed that early and aggressive treatment led to remission and limited erosive progression at 11 years. Anti-citrullinated protein antibody (ACPA), a high degree of inflammation (DAS28crp) and MRI bone marrow oedema predicted long term radiographic progression at 11 years (Scand J Rheumatol 2018, 48: 1-8). In this cohort, we investigated plasma levels of CXCL13, and its ability to predict radiographic joint destruction.

Methods: In a post-hoc study, a serial set of plasma samples was obtained from the investigator-initiated CIMESTRA study (n=117). CXCL13 was measured at baseline and after 1 year. Patients were characterized and monitored by C-reactive protein (CRP), erythrocyte sedimentation rate (ESR), Disease Activity Score in 28 joint (DAS28), swollen joint count in 28 joints (SJC28), health assessment questionnaire (HAQ) and global visual analogue scales (VAS). IgM-rheumatoid factor (IgM-RF) and ACPA status was recorded at baseline. Cumulative dose of glucocorticoid injections was recorded. Radiographic status and progression were assessed by total Sharp Score (TSS) at baseline and 11 years. Data were analysed using Wilcoxon matched pairs-signed rank test (Median (25-75 percentile), multivariate regression analysis (coefficient +/- standard error), Spearman correlation (rho) and ROC curves, determining the threshold for radiographic damage as a score of 5, applicable for TSS and deltaTSS.

Results: In eRA patients, plasma levels of CXCL13 were increased (60 pg/ml (39-102) and decreased after one year of treatment (31 pg/ml (23-49) ($p< 0.0001$). By Spearman correlation analyses, baseline levels of CXCL13 were associated with CRP (0.50), ESR (0.49), ACPA (0.39), IgM-RF (0.38), VAS Global (0.27), HAQ (0.38), and DAS28CRP (0.27), all $p< 0.05$.

In a multivariate regression analysis, adjusting for smoking status, age, gender, ACPA status, CRP, number of glucocorticoid injections, SJC28 and ESR, baseline CXCL13 was associated with both TSS (0.11 +/- 0.04, p=0.004) and deltaTSS (0.07 +/- 0.03, p=0.042) after 11 years of treatment (Figure 1). The predictive value of baseline CXCL13 for

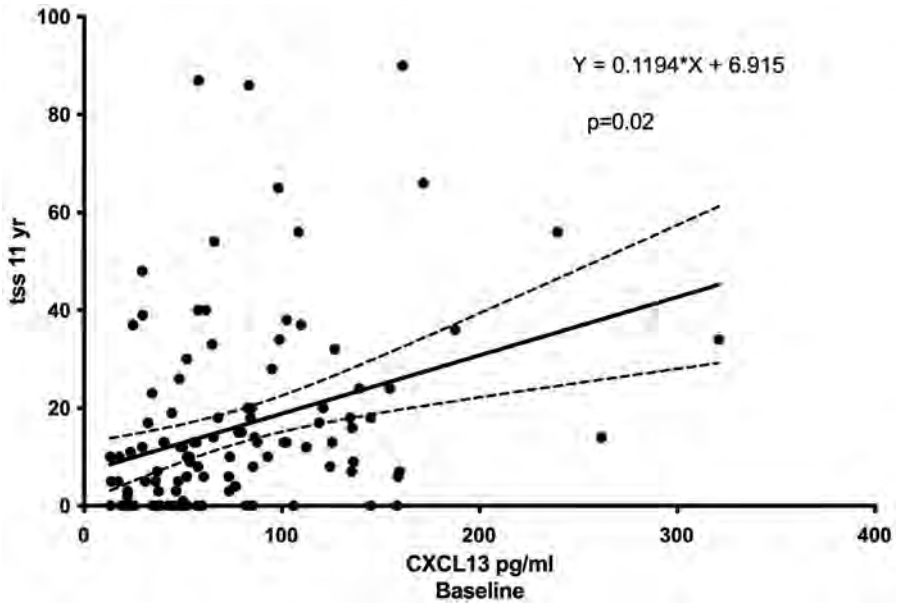

Figure 1. Plot of baseline CXCL13 and TSS after 11 years of treatment.

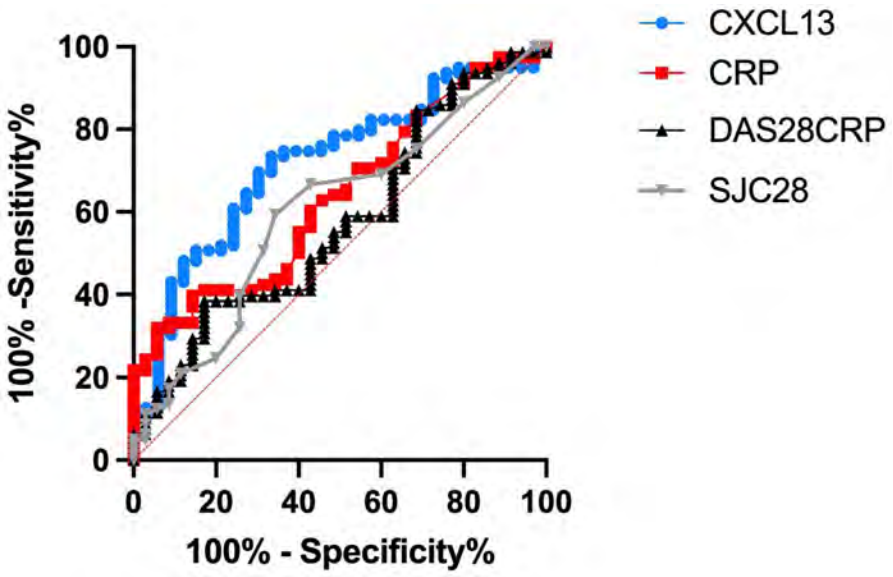

ROC curves of CXCL13, CRP, DAS28CRP and SJC28 predicting TSS above 5 after 11 years of treatment. A TSS score of 5 or above is considered as significant radiographic progression, as this accounts for one destroyed joint.

TSS >5 at 11 years was illustrated in the ROC curve with an area under curve (AUC) of 0.72, p< 0.001 (Figure 2). AUC for DAS28CRP was: 0.58, p=0.2, for CRP: 0.64, p=0.02 and for ACPA: 0.59, p=0.34. Based on the ROC curve, selecting the highest possible sensitivity and specificity of both 70%, CXCL13 levels above 53 pg/ml predicted significant radiographic destruction after 11 years with a likelihood ratio of 2.3.

Numbers of glucocorticoid injections did not differ between patients with an 11-year TSS< 5 and TSS >5.

A similar analysis was done for baseline CXCL13 and deltaTSS at 11 years, also supporting a predictive value of baseline CXCL13 for radiographic progression (AUC=0.62, p=0.03).

Conclusion: Predicting long-term radiographic destruction in patients with newly diagnosed RA remains challenging. Here, we suggest plasma CXCL13 as a reliable marker of long-term disease severity in RA, especially predicting significant radiographic destruction after more than 10 years of treatment.

SESSION INFORMATION

Session Date: Monday, November 8, 2021

Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster III: Prediction, Biomarkers, & Treatment Response (1196–1222)

Session Type: Poster Session C

Session Time: 8:30AM–10:30AM

Background/Purpose: The patient's global assessment (PGA) and physician global assessment (PhGA) are important outcomes and commonly used in rheumatoid arthritis (RA) clinical practice. Both measures are included as a part of activity indices and core sets. Up to half of patients have been reported to have discordant results between the two measurements, depending on the cut-off value. PGA was usually higher than PhGA. Understanding the reasons of this discrepancy might be important to decide treatment strategy. We aim to evaluate frequency and predictors of discordance between PGA and PhGA in patients with RA.

Methods: Two hundred-thirty three consecutive RA patients were recruited to this single center cross-sectional study. All participants met the ACR 2010 classification criteria. Demographics, clinical parameters and laboratory

Table 1. Demographics and disease characteristics of study groups

Variables	Discordance ≥30 mm (n:35)	Discordance <30 mm (n:198)	P
Age, mean (SD)	56.7 (12.2)	56.4 (11.1)	0.763
Female gender, n (%)	24 (68.6)	161 (81.3)	0.086

Table 3. Predictors of discordance between PGA and PhGA

Variables	Univariable Analyses			Multivariable Analyses		
	OR	95 % CI	p	OR	95 % CI	p
Gender (Male vs Female)	1.9	0.89-4.4	0.090	**2.8**	**1.1-6.9**	**0.020**
TJC (Absent vs Present)	1.6	0.80-3.5	0.164	1.9	0.77-4.6	0.158
SJC (Absent vs Present)	2.4	0.90-6.6	0.076	2.2	0.74-6.9	0.147
VAS pain (≥40mm vs <40 mm)	2.9	1.09-7.9	0.032	**4.4**	**1.4-13.0**	**0.007**
CRP (<5.0 mg/L vs ≥5.0 mg/L)	2.7	1.1-6.2	0.019	**3.0**	**1.2-7.7**	**0.019**

data were collected by using a structured form. Tender (TJC) and swollen joint count (SJC) was assessed by the same rheumatologist. Disease activity was evaluated by using clinical disease activity index (CDAI) and disease activity score 28 -C-reactive protein (DAS28-CRP). PGA, PhGA and pain were measured on a visual analog scale (VAS) ranging between 0 to 100 mm. Discordance was defined as more than 30 mm differences between PGA and PhGA. Spearman correlation and logistic regression analyses were used for association and predictors of discordance. In the multivariable model, we used independent variables which were found to have a p value of < 0.20 in univariate analyses.

Results: One hundred eighty-five (79.3 %) of the 233 patients were female, and the mean age was 56.7 ± 11.4 years. The frequency of discordance was found 15% (35/233) cut-off for ≥30 mm and 59.7% (139/233) for ≥20 mm. Age and gender were found similar in patient with or without discordance and the other demographics and clinical characteristics were summarized in table 1. Patients with discordant assessments had less tender and swollen joint count with less pain score on VAS. And also, discordance was found lower in remission and high disease activity group according to the CDAI. Difference between PGA and PhGA had been shown positively correlated with pain VAS but negatively with SJC and CDAI (Table 2). In multivariable model, male sex, having higher pain VAS and normal CRP levels were found to be predictors of discordance on PGA and PhGA (Table 3).

Conclusion: Discordance between patient and physician was more common in the absence of objective findings such as TJC, SJC and CRP. However male sex, higher VAS pain and normal level of CRP might independently predict disagreement. The majority of the problem was observed in patients with low and moderate disease activity. This can be affected the treatment decision of physician.

SESSION INFORMATION

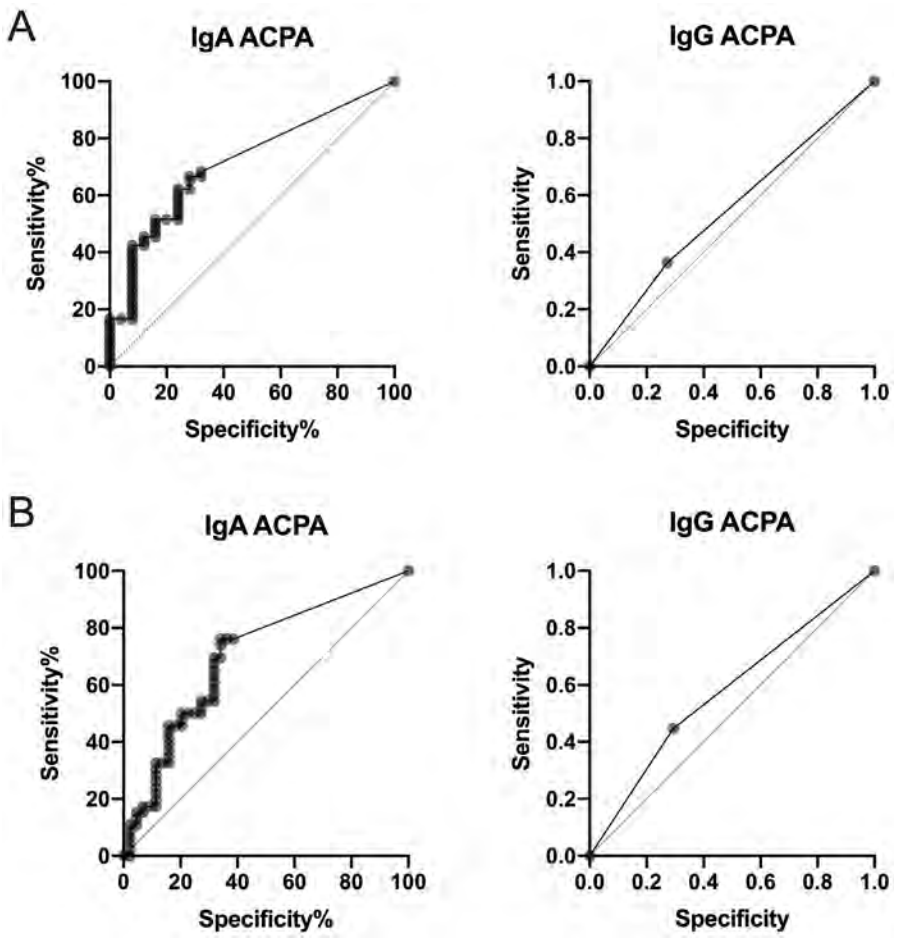
Session Date: Monday, November 8, 2021

Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster III: Prediction, Biomarkers, & Treatment Response (1196–1222)

Session Type: Poster Session C

Session Time: 8:30AM–10:30AM

Background/Purpose: Rheumatoid arthritis (RA) is characterized by polyarticular synovitis and frequent occurrence of autoantibodies, playing a central role in disease progression. Anti-citrullinated peptide antibodies (ACPA) are as-



ROC curves showing sensitivity vs specificity for IgA ACPA and IgG ACPA. Panel A shows data from TSS, and panel B shows data from ΔTSS. A cut-off value for no radiographic changes was set to 5.

sociated with periodontitis, smoking and upper respiratory tract infections, suggesting a breach of tolerance on mucosal surfaces. Early and aggressive treatment is important to limit long-term disease severity in RA, and seropositivity for APCA IgG is generally considered to be associated with a more aggressive disease. Here, we report the seroprevalence of ACPA IgA and its subtypes in patients with early (e), untreated RA and their association with long-term radiographic outcome.

Methods: The patients (n=121) included in this post hoc analysis participated in the investigator-initiated, double-blinded, placebo-controlled CIMESTRA study were treated with methotrexate and intraarticular glucocorticoids cyclosporin according to a treat-to-target protocol (Scand J Rheumatol 2018, 48: 1-8). Patient characteristics, IgM rheumatoid factor (IgM-RF) and IgG ACPA were recorded at baseline. Disease activity parameters included C-reactive protein (CRP), health assessment questionnaire (HAQ) and visual analogue scale (VAS), Disease Activity Score in 28 joints (DAS28) and swollen joint count in 28 joints (SJC28). Furthermore, structural joint damage was assessed with van der Heijde modified Total Sharp Score (TSS). All parameters were assessed at baseline and after 2 and 11 years. Total IgA, IgA1 and IgA2 ACPA were measured by ELISA at baseline and after 2 years. Statistical analyses and graphs were done using Prism 9 (GraphPad, Software). Correlations were tested using Spearman's rho (ρ).

Results: At baseline and after two years' treatment, total IgA, IgA1 and IgA2 ACPA were detectable in serum. Levels did not differ between baseline and 2 years. Baseline levels of ACPA IgA was associated to: IgG ACPA ($\rho = 0.62$), IgM rheumatoid factor ($\rho = 0.37$), gender ($\rho = 0.24$) and tender joints ($\rho = -0.20$), all p-values < 0.05. We considered a change in TSS ≥ 5 as significant radiographic progression. Using this cutoff, high baseline levels of total serum IgA (AUC = 0.71, $p = 0.002$) and IgA1 ACPA (AUC = 0.65, $p = 0.03$) predicted increased radiographic changes after 11 years, while IgA2 did not ($p = 0.12$). High baseline levels of total serum IgA (AUC = 0.70, $p = 0.001$) or IgA1 ACPA (AUC = 0.64, $p = 0.026$) also predicted high ΔTSS score (> 5). By contrast, total serum IgG ACPA did not predict a worsening of neither TSS ($p = 0.67$) nor ΔTSS ($p = 0.37$) after 11 years (Figure 1).

Conclusion: Our study confirms a role for IgA ACPA in patients with eRA and indicate that seropositivity for IgA ACPA is associated with a poor 11-year radiographic outcome in patients with eRA as measured by TSS. ACPA IgA and IgA1 are superior to ACPA IgG in predicting long-term rapid radiographic progression suggesting that there is a potential clinical gain by measuring ACPA IgA-subclasses in patients with eRA.

A Systematic Review Looking at the Relationship Between Serum Calprotectin and Ultrasound Parameters in Rheumatoid Arthritis

Andrea Hui Ling Low[1], **Fang Yi Lim**[2] and Margaret Ma[3], [1]National University of Singapore, Singapore, Singapore, [2]National Univeristy of Singapore, Singapore, Singapore, [3]National University Hospital, Singapore, Singapore

SESSION INFORMATION

Session Date: Monday, November 8, 2021

Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster III: Prediction, Biomarkers, & Treatment Response (1196–1222)

Session Type: Poster Session C

Session Time: 8:30AM–10:30AM

Background/Purpose: Serum Calprotectin level has been shown to correlate with disease activity, ultrasound (US) parameters, treatment response and clinical remission in rheumatoid arthritis (RA). The purpose of this study is to systematically review the existing literature on the relationship of calprotectin and ultrasound parameters in RA.

Methods: RA studies reporting serum calprotectin levels and US parameters published between 1 January 1988 to 26 December 2020 were included. A literature search was performed on Medline, Embase, CINAHL and Cochrane which yielded a total of 93 articles. After removing duplicates, screening remaining articles and selecting for full-texts, 11 articles were identified by 2 independent reviewers (Figure 1).

Results: A summary of the studies is shown in tables 1 and 2. Ten studies have shown associations between US findings and calprotectin levels in RA patients, seven of which used Spearman's correlation coefficient to show significant correlation between US power doppler (PD) and grey scale (GS) scores with calprotectin. When examining calprotectin in the context of treatment, calprotectin was shown to have a weak but significant correlation with US scores before and after treatment in Jonsson 2017 6. In patients monitored over their course of treatment with bDMARDs, (Nordal 2017 4) the strongest correlation was found between calprotectin and US sum scores at baseline. Calprotectin had the strongest correlation with US sum scores among patients started on etanercept and rituximab.

Figure 1. PRISMA chart

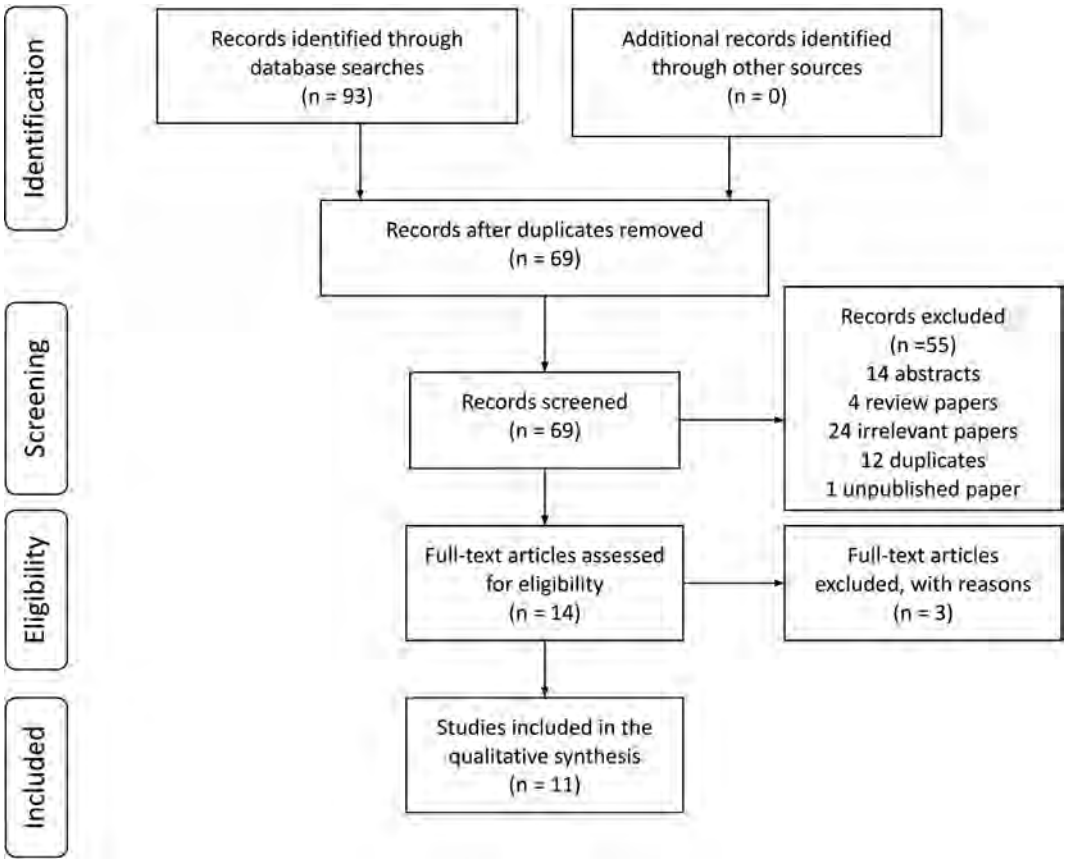

Table 1. Study Characteristics

Study	Year	Study Design	n	Inclusion/Exclusion Criteria	Sample	Ultrasound for Synovitis	Results
Jarlborg et al[1]	2020	CC	969	NR	Serum	4-point scale GS score of +/= 10 or PD score >/= 1 for 22 joints constitute positive SONAR score	Calprotectin (R2 = 0.10, p < 0.001) were associated with elevated USPD scores. Calprotectin could better predict positive SONAR score in disease duration <5 years with AUC 0.72 (95% CI 0.73-0.83) vs AUC 0.65 (95% CI 0.57-0.73) in all patients.
Sakellariou et al[2]	2019	CS	78	Include: -Fulfil CASPAR criteria -Present at EAC of IRCCS Policlinico San Matteo Foundation, Pavia -Present before May 2014 -Morning stiffness >30mins, swelling of 3 or more joints, positive squeeze test	Serum	4-point scale GS and PD >0, pre-specified GS and PD>1 in case of frequent low grade US abnormalities in healthy subjects defined as synovitis: with overall scores of 0 to 36 from sum of single sites	In regression analysis, calprotectin did not predict GS or PD score (R2 0.037, p=0.139 for GS; R2 0.017, p=0.319 for PD).
Nordal et al[3]	2017	Cohort	141	On bDMARD	Plasma Serum	4-point scale 36 joints and 4 tendon sheaths	At baseline, plasma and serum calprotectin showed significant correlation with sum GS. (Plasma = 0.59, p<0.001; serum calprotectin = 0.43, p<0.001). In concordance with sum PD score, plasma = 0.62, p<0.001 and serum = 0.46, p<0.001.
Nordal et al[4]	2017	CS	141	NR	Serum	4-point scale 36 joints and 4 tendon sheaths Weighting of joint according to method of Lansbury	Spearman rank coefficient correlation of serum calprotectin and US parameters at baseline showed strongest association, with 0.59 for sum GS scores, 0.62 for sum PD scores.
Mansour et al[5]	2017	CC	44	NR	Plasma	4-point scale	ANOVA analysis showed US B-mode scores had a statistically significant positive correlation with serum calprotectin levels in RA patients, with F test = 8.050 (p < 0.001).
Jonsson et al[6]	2017	CS	215	Include: -Fulfil ACR/EULAR criteria -DMARD-naïve with indication for DMARD therapy	Plasma	4-point scale 32 joints Ultrasound remission defined as no PD signal in any examined joint	Calprotectin was weakly to moderately correlated with ultrasound scores before treatment onset (US GS = 0.46, p<0.001; US PD = 0.42, p<0.001) and after 12 months of treatment (US GS = 0.20, p<0.01; US PD = 0.27, p<0.001).
Hurnakova et al[7]	2017	CS	150	NR	Serum	4-point scale Modified German US7 score	Calprotectin was significantly correlated with GS (r = 0.379, p<0.001) and PD synovitis scores (r = 0.419, p<0.001).
Inciarte-Mundo et al[8]	2016	CS	42	Exclude: DAS28-ESR >3.2	Serum	4-point scale Active synovitis defined as PD signal in any examined synovial tissue and SH grade >/=2	Calprotectin positively correlated with ultrasound scores (all r coefficients >0.50 in RA). Calprotectin had an AUC of 0.826 in predicting PDUS synovitis.
Hurnakova et al[9]	2016	CC	70	NR	Serum	4-point scale Modified German US7 score Ultrasound remission defined as GS 0-1 AND PD = 0.	Calprotectin correctly distinguished ultrasound remission (AUC DAS28-ESR = 0.692; AUC DAS28-CRP = 0.712) from subclinical activity in 70% of patients.
Hurnakova et al[10]	2015	CS	37	NR	Serum	4-point scale Modified German US7 score	Calprotectin was significantly associated with GS (r = 0.359, p < 0.05) and PD synovitis scores (r = 0.497, p < 0.005).
Hammer et al[11]	2011	Cohort	20	NR	Plasma	4-point scale 78 joints and 56 tendonn/tendon groups	Calprotectin had the highest correlation coefficients with the total BM and PD sum scores (median (range) 0.59 (0.37 to 0.76) for BM and 0.56 (0.38 to 0.72) for PD) as well as the highest Standardised Response Mean (0.84 at one month).

CC = case control, CS = cross sectional, NR = not reported, GS = grey scale, PD = power doppler, SH = synovial hypertrophy.

refer to table 1 legend

When calprotectin was evaluated in its utility for defining ultrasound remission, it was found to be superior in its ability to distinguish ultrasound-defined active synovitis (UdAS) and non-UdAS compared to C-reactive protein (CRP) and erythrocyte sedimentation rate (ESR) Inciarte-Mundo 20168. Hurnakova 20169 also showed its ability to distinguish between patients in US remission and those with subclinical US disease activity. There was a significantly lower median calprotectin levels in patients with US remission at 1, 3 and 12-month interval. Additionally, Jalborg 20201 reported calprotectin could better predict positive SONAR score in patients with disease progression of less than 5 years [AUC 0.72 (95% CI 0.73-0.83) in all patients compared to AUC 0.65 (95% CI 0.57-0.73) in disease duration less than 5 years]

Sakellariou 2019 was the only study which showed no significant correlation between calprotectin levels and US PD and GS scores. In this study, calprotectin level was also unable to predict ultrasound synovitis2. Finally, Nordal 20173 analyzed plasma and serum calprotectin levels and showed a stronger correlation between plasma calprotectin and US parameters when compared to serum calprotectin.

Conclusion: The majority of studies found that calprotectin correlates with ultrasound synovitis in RA patients; some of which found that calprotectin was a better biomarker compared to traditionally used biomarkers such as ESR and CRP. Calprotectin was also found to be an independent predictor of ultrasound synovitis and was able to distinguish those in ultrasound remission from subclinical synovitis. This suggest that there is a role for serum calprotectin to help define a deeper remission state in RA.

Composite Articular Index Including Acute Phase Reactants Should Not Be Used in Patients with Rheumatoid Arthritis Treated with Il6 Inhibitors but May Be Useful in Those Receiving Jak Inhibitors: Ultrasound Evidence

SESSION INFORMATION
Session Date: Monday, November 8, 2021
Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster III: Prediction, Biomarkers, & Treatment Response (1196–1222)
Session Type: Poster Session C
Session Time: 8:30AM–10:30AM

Background/Purpose: IL6 inhibitors (IL6i) have a dramatic effect on the reduction of C reactive protein (CRP) that does not always correlate with a significant improvement in synovial inflammation in rheumatoid arthritis (RA). Measurement of inflammatory activity with composite articular indices including acute phase reactants (APR) in RA patients treated with IL6i is considered inadequate. Since Jak inhibitors (Jaki) also affect IL6 activity, the performance of these indices in correctly assessing disease activity has been questioned. Joint ultrasound is not included in the composite indices used in RA but is widely used in clinical practice and has a greater sensitivity than clinical exam in detecting active synovitis.

To compare inflammatory activity measured by joint ultrasound with the composite disease activity indices and APR in patients with RA treated with IL6i or Jaki.

Methods: Observational, cross-sectional study in consecutive RA patients (ACR/EULAR 2010) treated with IL6i (tocilizumab, sarilumab) or Jaki (tofacitinib, baricitinib). We evaluated demographic and serologic (autoantibodies, ESR, ultrasensitive (us) CRP) data, composite disease activity indices (DAS28, SDAI, CDAI, RAPID3), HAQ and therapies. Joint ultrasound of both hands was evaluated and graded according to Szudlarek's(1). A synovial hypertrophy (SH) score, power Doppler ultrasound (PDUS) and a total score (SH+PDUS) was obtained. A definition of active synovitis

developed was considered (SH ≥ 2 plus PD ≥1)(2). We compared the variables between IL6i and Jaki patients. Spearman`s correlation test was used to correlate ultrasound scores and clinical and laboratory parameters.

Results: We included 63 patients (92.1% female, median age 58.6 years, median disease duration 14.4 years, 93% seropositive (RF and/or ACPA). 42 patients were treated with IL6i and 21 with Jaki. Therapy duration was significantly lower in Jaki patients. No significant differences were observed in activity indices, although DAS28 was higher in Jaki patients. No significant between-group differences were observed in ultrasound scores [Table 1].

Active ultrasound synovitis (AUS) (SH ≥ 2 plus PD ≥ 1) in ≥ 1 joint was achieved by 30 IL6i patients and 16 Jaki patients (71% vs. 76% respectively). IL6i patients with AUS had a higher SJC and PhGA score than those without. Jaki patients with AUS had higher SJC, PhGA and usCRP (Table 2).

In IL6i patients, the total ultrasound score significantly correlated only with the SJC28 (r=0.605; p< 0.001) and PhGA (r=0.392; p=0.011), although the CDAI showed a non-significant trend (r=0.279 p=0.07), which was significant when evaluating the PD score (r=0.320; p=0.039). The total ultrasound score in Jaki patients significantly correlated

SESSION INFORMATION
Session Date: Monday, November 8, 2021
Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster III: Prediction, Biomarkers, & Treatment Response (1196–1222)
Session Type: Poster Session C
Session Time: 8:30AM–10:30AM

Background/Purpose: IL6 inhibitors (IL6i) have a dramatic effect on acute phase reactants (AFR) such as C reactive protein (CRP) in rheumatoid arthritis (RA). However, CRP serum levels do not correlate with inflammatory activity in RA patients under IL6i therapy. JAK inhibitors (JAKi) also partly inhibit IL6 signaling. Calprotectin is a protein that correlates closely with inflammatory activity and may be a biomarker that accurately reflects the disease status in IL6i and JAKi treated RA patients.

Methods: Cross-sectional study in RA patients (ACR/EULAR 2010) treated with IL6i (tocilizumab, sarilumab) or JAKi (tofacitinib, baricitinib). Demographic, serological data (autoantibodies, ESR, ultrasensitive CRP (usCRP), composite activity indices (DAS28, SDAI, CDAI, RAPID3), disability (HAQ) and therapy were evaluated. Plasma calprotectin levels were measured by ELISA (CALPROLAB ALP Menarini). Hand ultrasound was studied to calculate synovial hypertrophy (SH), power Doppler signal (PD) score and total ultrasound activity score (SH+PD) graded according to Szudlarek's(1) . We compared plasma calprotectin and clinical and ultrasound variables in patients receiving IL6i and JAKi using Spearman's correlation test.

TJC: tender joint count; SJC: swollen joint count; PGA: patient global assessment PhGA: physician global assessment; VAS visual analogue scale SH: synovial hypertrophy on ultrasound: PD power Doppler signal on ultrasound. Data expressed as median and (ranges)

Results: We included 78 patients (91% female, median age 58.9 years, median RA duration 14.5 years, 88.5% seropositive (RF and/or ACPA). Fifty two patients were treated with IL6i and 26 with JAKi [Table 1]. Ultrasound studies were made in 63 patients (42 receiving IL6i and 21 JAKi).

No significant between-group differences were observed in the TJC28, SJC28, CDAI, SDAI, and HAQ. DAS28 was higher in JAKi patients. There were no differences in ultrasound scores. The median (range) of plasma calprotectin was 0.36 µg/ml (0.12-2.39) in IL6i patients and 0.65 µg/ml (0.19-5.51) in JAKi patients (p=0.083) [Table 1].

In IL6i patients, plasma calprotectin weakly correlated with SJC28 but not with composite activity indices or with AFR (usCRP or ESR), although there was a significant correlation with all ultrasound scores (SH, PD and SH+PD) that

Tabla 2 Correlation between calprotectin and clinical, laboratory and ultrasound activity parameters				
	IL6 inhibitors (n=52)		JAK inhibitors (n=26)	
	rho	P value	rho	P value

Hemoglobin	0.24	0.09	0.186	0.373
CDAI	0.168	0.239	0.087	0.68
SDAI	0.172	0.228	0.098	0.64
DAS28	0.157	0.271	0.132	0.529
HAQ	0.201	0.158	0.143	0.494
RAPID3	0.115	0.42	0.114	0.587
SH	.391*	0.01	.630**	0.002
PD	.349*	0.023	.703**	0
SH+PD	.383*	0.012	.700**	0

Rho: Spearman's correlation coefficient

was not found with usCRP or ESR. In JAKi patients, calprotectin showed a non-significant trend to correlation with TJC28, and a high correlation with all ultrasound scores (SH, PD and SH +PD) and usCRP levels, but not with activity indices [Table2].

Classification according to CDAI ≤10 vs. CDAI >10 showed no significant differences in calprotectin values: median (range) 0.33µg/ml (0.14-5.51) vs 0.59 µg/ml (0.12-5.50) p= 0.121). Classification according to ultrasound activity (ultrasound synovitis (SH ≥ 2 + PD≥1) in ≥ 1 joint showed -higher calprotectin levels in patients with ultrasound synovitis: median 0.70 µg/ml (0.18-5.03) vs 0.29 µg/ml (0.19-0.69) p< 0.001).

Conclusion: Plasma calprotectin in patients with low-moderate disease activity treated with IL6i or JAKi did not identify patients according to the degree of inflammation measured by the composite activity indices. However, in both groups and specially in patients treated with JAKi, calprotectin was related to ultrasound synovitis scores. Plasma calprotectin might be a biomarker of active synovitis in these patients.

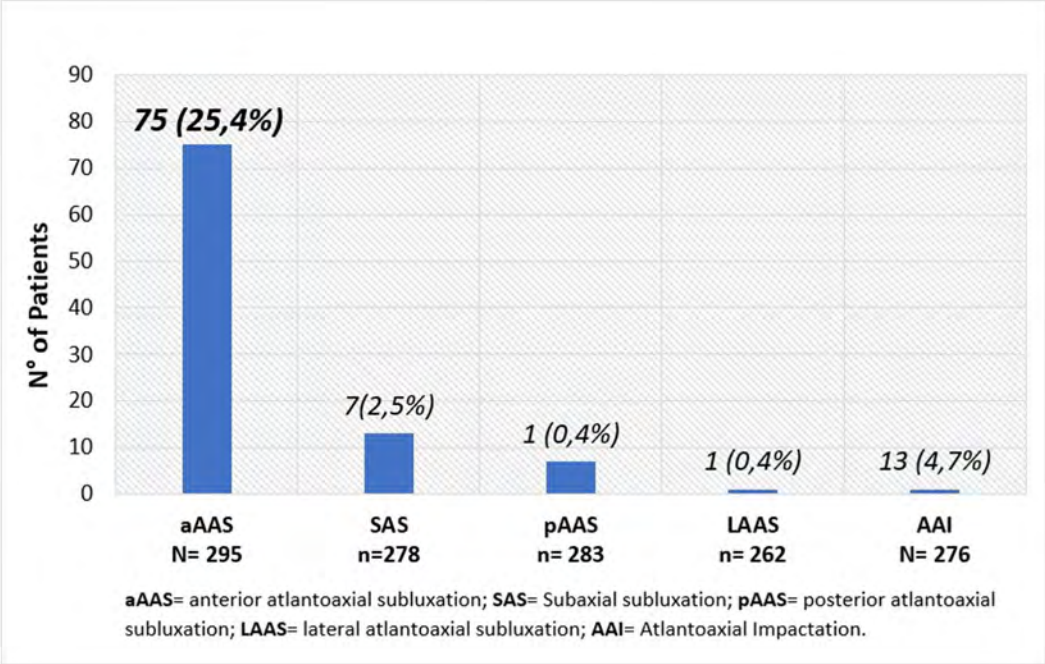

Figure 1. Frecuency of cervical spine involvement.

SESSION INFORMATION

Session Date: Monday, November 8, 2021

Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster III: Prediction, Biomarkers, & Treatment Response (1196–1222)

Session Type: Poster Session C

Session Time: 8:30AM–10:30AM

Background/Purpose: According to some series, cervical spine is the second most affected region in Rheumatoid arthritis (RA). Cervical involvement was reported in 80% of RA patients, being anterior Atlanto-Axial subluxation (aAAS) the most frequent one. Other less frequent types are Subaxial Subluxation (SAS), posterior Atlanto-Axial subluxation (pAAS), lateral Atlanto-Axial subluxation (LAAS) and Atlanto-Axial impaction (AAI). The aim of this study was to describe the frequency of aAAS in a cohort of patients with RA and to evaluate its association with demographic and disease characteristics.

Methods: Multicenter, observational, cross-sectional, descriptive, and analytical study. Patients ≥ 18 years old with diagnosis of RA (ACR-EULAR 2010) and at least one flexion lateral cervical spine radiograph were included. aAAS was defined when anterior Atlanto-Axial distance (aAAD) was ≥ 3mm. The other forms of cervical spine involvement were also reported. All the radiographs were assessed by 3 experienced rheumatologists. Statistical analysis: Descriptive statistics was done. Sociodemographic and disease characteristics of patients with and without aAAS were compared using Student's T test, Chi2 and Fisher's exact test. The aAAD was assessed according to disease characteristics, symptom presence, and disease duration at the time of diagnosis of the aAAS using Spearman correlation, Student's T test, Kruskal Wallis and Wilcoxon test.

Results: A total of 295 patients from 13 centers were included. Sociodemographic and RA characteristics are shown in Table 1. The frequency of aAAS was 25.4% and the average aAAD 4.5 mm (SD 2.4). Their frequency and that of the other types of cervical spine involvement can be observed in **figure 1**. The median disease duration at the time of diagnosis of aAAS was 128 months (IQR 82.5-196). The most frequent reported symptom was radicular pain in 20% of patients, and 6% of them required surgical intervention. Patients with aAAS had longer disease duration (119 months [45-174] vs 76 [43-102] months, $p < 0.05$) and higher frequency of extra-articular manifestations (97.3% vs.

40.9%, p < 0.001). The frequency of pAAS was much higher in the group with aAAS (8.6% vs. 0.5%, p < 0.001). In patients with aAAS, the median of the aAAD was higher in symptomatic patients (5 mm [IQR 3.7-6.5] vs 3 mm [IQR 3-5], p=0.011), and it was particularly associated with radicular pain (5 mm [IQR 4-7] vs 3 mm [IQR 3-5], p=0.009).

Conclusion: The frequency of aAAS in this cohort of RA patients was 25.4%. The prevalence of pAAS was much higher in the group with aAAS. The aAAD was greater than 5 mm in patients with neurological symptoms (especially with radicular pain).

Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster III: Prediction, Biomarkers, & Treatment Response (1196–1222)

Session Type: Poster Session C

Session Time: 8:30AM–10:30AM

Background/Purpose: Spinal involvement in Rheumatoid arthritis (RA) is limited to the upper region of the cervical spine which leads to cervical spine instability (CSI); anterior atlantoaxial subluxation (aAAS), vertical subluxation (VS), and subaxial subluxation (SAS). In this study, we aimed to evaluate the frequency of cervical involvement and the associated risk factors in patients with RA.

Methods: Two hundred-forty RA patients were recruited consecutively in this single center cross-sectional study. All participants met the ACR 2010 classification criteria. Demographics, laboratory data, patient and physician reported outcomes were collected using by a structured form. Tender and swollen joint count was assessed by the same rheumatologist. Radiographs of the cervical spine were obtained in flexion, extension, neutral position of the neck at the same visit. The presence of erosions on the hand and foot radiographs in the last year was also assessed. A diagnosis of aAAS was based on the distance between the anterior aspect of the dens and, the posterior aspect of the anterior arch of the atlas was > 3 mm during flexion (Figure 1). Vertical subluxation was recorded as present if the tip of the odontoid peg lay more than 4.5 mm above the line described by McGregor. SAS is diagnosed if a vertebra

Table 2. Evaluation of risk factors of AAS

	Univariable analyses			Multivariable analyses		
Variables	**OR**	**95 % CI**	**P value**	**OR**	**95 % CI**	**P value**
Disease duration, years (≥10 vs <10)	**2.92**	**1.2 - 7.0**	**0.017**	1.4	.52 - 3.9	0.49

Figure1. Measurement of aAAS on the cervical lateral flexion graph.

has moved 3 mm or more in relation to the next vertebra when measured from the posterior line of the vertebral bodies. All cervical spine radiographs were evaluated separately by two readers blinded to all clinical data of patients at the end of the study. There was very good agreement between the two readers [interobserver reliability: intraclass correlation coefficent (ICC) for GA: 0.88 (95% CI: 0.43 - 0.97), ICC for HC:0.80 (95% CI: 0.14 - 0.95); intraobserver reliability: ICC:0.89 (95 % CI: 0.47-0.97)].

Results: One hundred ninety-one (79.6 %) of the 240 patients were female, and the mean age was 56.4 ± 11.4 years with a mean of 10.2 ± 8.5 years of mean disease duration. Two hundred and three (84.6 %) of the participants were seropositive (RF or anti CCP) and erosion was detected in 93 patients' hand or foot radiographs. aAAS was reported in 25 (10.4 %) patients. Only one patient had combination of aAAS and VS. We could not detect any SAS. Age and gender were found similar in patient with or without aAAS and the other demographics and clinical characteristics were summarized in table 1. One in three patients with aAAS had no neck pain. Biologic drugs treatment and presence of osteoporosis was more common in the aAAS group but not reach a statistical difference (32% vs 20%, p:0.19; 28% vs 20%, p:0.37, respectively). Patient with aAAS had longer disease duration, more frequently erosion, joint restriction and history of joint prostheses (Tablo1 and 2). In the multivariate regression model, joint restriction [OR: 5.8 (95% CI: 2.1-16.0)], and history of joint prostheses [OR:3.6 (95% CI: 1.2-10.5)] was found independently predictors of the presence of aAAS.

Conclusion: aAAS was found the most common cervical involvement type in RA in this study. Longer disease duration, presence of erosion, joint restriction and prostheses was associated with aAAS. Even if there is no neck pain, cervical involvement should be kept in mind especially in the established disease.

SESSION INFORMATION

Session Date: Monday, November 8, 2021

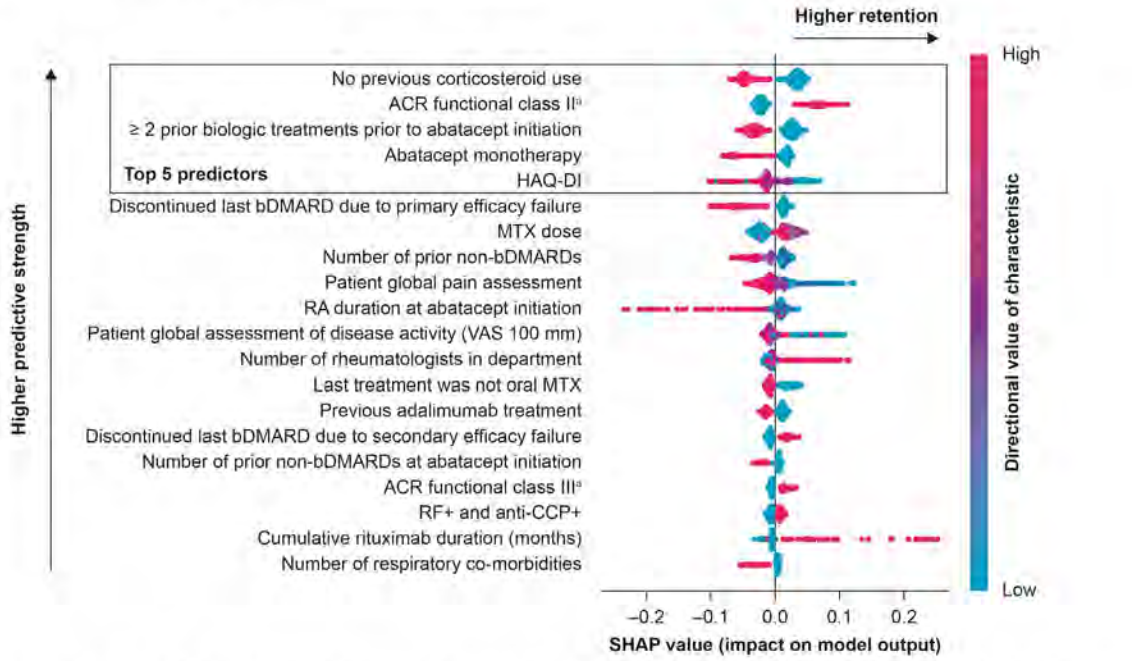
Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster III: Prediction, Biomarkers, & Treatment Response (1196–1222)

Session Type: Poster Session C

Session Time: 8:30AM–10:30AM

Background/Purpose: In the ACTION study (NCT02109666), previous multivariable Cox proportional-hazards regression models showed that predictors of 1-year retention to intravenous abatacept treatment included: patient

Figure 1. Overall variable importance in ACTION, using SHAP



The box highlights the 5 most important predictors of retention. Colors indicate the value of the variable: pink represents higher and blue represents lower. The bulges in the plot indicate more patients with that value; each dot represents a single patient. Higher SHAP values indicate a higher likelihood of retention.
[a]Compared with other ACR functional classes.
bDMARD, biologic DMARD; HAQ-DI, HAQ-disability index; SHAP, SHapley Additive exPlanations.

global pain assessment, country, reason for stopping last biologic, number of prior biologic treatments, abatacept monotherapy, RF/anti-CCP status, previous neoplasms, psychiatric disorders, and cardiac disorders.[1] Machine learning techniques, using the gradient-boosting model, identified additional predictors of abatacept retention in patients with moderate-to-severe RA enrolled in ACTION; however, the analysis did not show whether the variables predicted reduced or increased retention (directionality).[2] The objective of this analysis was to assess the clinical importance and directionality of each patient demographic or disease characteristic for predicting retention.

Methods: The gradient-boosting model was used to identify predictors of abatacept retention at 1 year in the ACTION study.[2] Retention was defined as treatment for > 365 days or ≤ 365 days in patients who achieved remission or major clinical response (using EULAR response criteria, based on DAS28). This analysis expanded on the previous model, adding SHapley Additive exPlanations (SHAP), a mathematical framework, to show how important each characteristic was for predicting abatacept retention. Higher SHAP values indicate a higher likelihood of retention. Every characteristic's contribution in the model's prediction (except country) was computed for each data point to capture the impact of each individual characteristic. This enabled interpretation for level of importance and directionality at a patient level.

Results: Using data from 2350 patients enrolled in ACTION (May 2008 to December 2013), the mean abatacept retention rate at 1 year was 59.3% (n = 1393). **Figure 1** shows how important each characteristic was for predicting retention. Lower treatment retention was predicted by no previous corticosteroid use, ≥ 2 prior biologic treatments prior to abatacept initiation, abatacept monotherapy, and a higher HAQ-disability index score at baseline, whereas higher treatment retention was predicted by ACR functional class II (vs functional classes I, III, and IV).

Conclusion: Adding SHAP to the gradient-boosting model allowed for a more clinically relevant analysis to be performed, showing how the identified variables impacted retention, either positively or negatively. The most important

baseline characteristics that were predictive of abatacept retention at 1 year were no previous corticosteroid use, which was associated with lower patient retention in the study, and ACR functional class II, which was associated with higher retention. Machine learning offers an innovative and complementary approach to biostatistics and could be used to identify treatment response predictors at an individual patient level, leading to a more personalized treatment approach.

SESSION INFORMATION
Session Date: Monday, November 8, 2021
Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster III: Prediction, Biomarkers, & Treatment Response (1196–1222)
Session Type: Poster Session C
Session Time: 8:30AM–10:30AM

Background/Purpose: Pain is the symptom with the most significant impact on patients' lives in rheumatoid arthritis (RA), whereas 17% of German RA patients report severe pain [1, 2]. Although RA patients may no longer report pain due to an articular, inflammatory origin, neuropathic pain (NP) may compromise anti-rheumatic treatment success as well.

The data-analysis presented aimed to investigate the proportion of RA patients with persisting pain and suggest clinical practice implications given specified patient-reported outcomes.

Methods: The PAIN-CONTROL study is a prospective, non-interventional, multicenter study in specialized rheumatology centers across Germany. Patients had to fulfill these inclusion criteria: 2010 ACR/EULAR classification criteria for RA, disease duration < 8 yrs, Disease Activity Index 28 (DAS28) ≥ 3.2, SJC ≥ 3, CRP above the reference range, and a visual analog scale (VAS, 0-100) pain rating ≥ 50. Eligible subjects had to be scheduled for initiation or escalation of anti-inflammatory treatment. At wk 24, clinical outcomes were evaluated, and subjects were allocated to three subgroups: Group 1 (reference): DAS28 improvement > 1.2 or DAS28 ≤ 3.2, VAS pain < 50; group 2

Table 1. Disease-related and patient-reported outcomes of the PAIN-CONTROL study (preliminary data analysis)

	Week 0	Week 24				Week 48		
	Total sample (N = 263)	Reference (N = 133)	Non-responders (N = 58)	Persisting pain (N = 72)	N(missing)/ N(total)	Reference/ Non-responders	Persisting pain (N = 51)	N(missing)/ N(total)
DAS28(CRP) (mean ± SD)	5.3 ± 0.8	2.0 ± 0.5	4.9 ± 1.1	3.4 ± 1.0	53/263 (20.2%)	-	2.9 ± 1.2	10/51 (19.6%)
PD-Q ≥ 19 n (%)	68 (25.9%)	9 (6.8%)	15 (25.9%)	18 (25.0%)	76/263 (28.9%)	-	10 (19.6%)	14/51 (27.5%)
RAID ≤ 2 n (%)	8 (3.0%)	65 (48.9%)	2 (3.4%)	6 (8.3%)	24/263 (9.1%)	-	12 (23.5%)	1/51 (2.0%)
PHQ-9 ≥ 10 n (%)	86 (32.7%)	8 (6.0%)	12 (20.7%)	10 (13.9%)	27/263 (10.3%)	-	7 (13.7%)	1/51 (2.0%)

(non-responders): DAS28 improvement ≤ 1.2 or DAS28 > 3.2 with or without alleviation of pain; group 3 (persisting pain): DAS28 improvement > 1.2 or DAS28 ≤ 3.2, VAS pain ≥ 50. For subjects in groups 1 and 2, the study ended at wk 24, subjects in group 3 continued until wk 48. This descriptive, interim analysis includes subjects having completed the study until Sept. 30th 2020, and informs about subjects classified as having NP by a painDETECT questionnaire (PDQ) score of ≥ 19. The attainment of a patient acceptable symptom state (i.e., Rheumatoid Arthritis Impact of Disease (RAID-PASS) score ≤ 2), and the proportion of patients with moderate depressive symptoms or worse according to the Patient Health Questionnaire 9 (i.e., PHQ-9 ≥ 10) were specified as secondary outcomes of interest. Descriptive results are presented as mean±SD or n (%), respectively.

Results: Sample characteristics (N=263) at baseline were as follows: Age 57.6 ± 13.0 yrs, disease duration 2.4 ± 2.6yrs, DAS28(CRP) 5.3 ± 0.8 with 174(66.2%) female subjects. At wk 24, the proportion of subjects who tested positive for NP in group 3 (persisting pain) was similar to group 2 (non-responder), (N=18; 25.0%) vs. (N=15; 25.9%). The number of patients with NP in group 3 decreased until wk 48, (N=10; 19.6%). Between wks 24 and 48, the number of subjects in group 3 attaining RAID-PASS increased from N=6 (8.3%) to N=12 (23.5%). Simultaneously, their DAS28(CRP) decreased from 3.4 ± 1.0 to 2.9 ± 1.2, respectively. During this period of the study, the proportion of patients in group 3 with moderate depressive symptoms or worse hardly changed (wk 24: 10(13.9%), wk 48: 7(13.7%)). For details see table 1.

Conclusion: NP is a frequent underrated challenge in RA patients either not responding to anti-inflammatory treatment or patients with persisting pain. These patient groups are likely to benefit from a multi-disciplinary treatment approach, including tailored pain management.

Examining the Relationship Between Shared Epitope, ACPA Seropositivity, and Real-World Drug Effectiveness in Patients with Rheumatoid Arthritis

Kristin Wipfler[1], Joshua Baker[2], Harlan Sayles[3], Xue Han[4], Sang Hee Park[4], Keith Wittstock[4], Ted Mikuls[3] and Kaleb Michaud[3], [1]FORWARD, The National Databank for Rheumatic Diseases, Omaha, NE, [2]University of Pennsylvania, Philadelphia, PA, [3]University of Nebraska Medical Center, Omaha, NE, [4]Bristol Myers Squibb, Princeton, NJ

SESSION INFORMATION
Session Date: Monday, November 8, 2021
Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster III: Prediction, Biomarkers, & Treatment Response (1196–1222)
Session Type: Poster Session C
Session Time: 8:30AM–10:30AM

Background/Purpose: The shared epitope (SE) is an amino acid sequence motif coded by several HLA-DRB1 alleles that are overrepresented among people with rheumatoid arthritis (RA). SE-positivity is associated with the production of anti-citrullinated protein antibodies (ACPA), RA risk, and possibly a more severe disease course. Recent studies showed ACPA positivity to be associated with a significantly greater response to abatacept treatment. Given these prior observations, the purpose of this study was to determine if there is an association between SE status, ACPA status, and the effectiveness of drugs used to treat RA in a real-world setting.

Methods: Data were provided by participants with RA in FORWARD, The National Databank for Rheumatic Diseases, that had known SE and ACPA status. FORWARD participants complete comprehensive questionnaires every six months that include information on medication use and health status. Inclusion criteria required initiation of a TNFi, abatacept, or JAKi during the study period. These individuals had a baseline observation (prior to medication start) and a follow up observation (after medication start) approximately six months later. Descriptive statistics were calculated by drug exposure group for each SE/ACPA cohort. Change in patient activity scale II (PAS-II; a composite index composed of HAQ-II and visual analog scales for pain and patient global) scores between baseline and follow up was calculated and classified as improved (≥1 point improvement), no change (within 1 point), or worsened (≥1 point worsening). Adjusted linear regression models were generated for each medication group to determine the relationship between SE/ACPA group and change in PAS-II, using the SE–/ACPA– group as the reference. For models with a significant relationship between SE/ACPA group and change in PAS-II, an additional model was created using the SE+/ACPA+ group as reference.

Results: Baseline characteristics of the 404 included participants are presented in Table 1 (200 TNFi, 122 abatacept, and 82 JAKi initiators) and the distribution of participants by medication group and by SE/ACPA status is presented in Figure 1. In models for TNFi and JAKi, there was no significant relationship between SE/ACPA status and change in PAS-II (Table 2). Among abatacept initiators, the two ACPA+ groups were more likely to experience an improved PAS-II score compared to the SE–/ACPA– group (B [95% CI] for SE–/ACPA+ : 1.6 (0.6, 2.6), p=0.002; for SE+/ACPA+: 1.3 [0.6, 2.1], p=0.001) and the two ACPA– groups were more likely to experience a worsened PAS-II score compared to the SE+/ACPA+ group (for SE–/ACPA–: -1.3 [-2.1, -0.6], p=0.001; for SE+/ACPA–: -0.7 [-1.4, 0], p=0.050). Change in PAS-II did not vary significantly by SE status.

Table 1. Baseline characteristics by medication initiator group.

	TNFi	Abatacept	JAKi
	n = 200	n = 122	n = 82
Participant Characteristics			
Age (years)	58.1 (11.8)	59.8 (11.0)	59.6 (8.4)
Female, %	90.5	91.8	91.5
White, %	94.0	93.4	95.1
Hx smoking, %	37.5	44.3	39.0
BMI (kg/m²)	29.1 (6.9)	29.8 (7.0)	27.5 (6.6)
Disease duration (years)	13.7 (11.4)	17.6 (13.9)	17.0 (11.9)
RDCI, 0-9	2.1 (1.6)	2.7 (1.9)	2.5 (1.9)
Hx DMARD count	4.1 (2.3)	5.5 (2.4)	6.0 (2.4)
Laboratory Measures			
SE positive, %	69.5	68.9	67.1
ACPA positive, %	54.0	59.8	46.3
RF positive, %	50.0	50.0	41.5
CRP high (≥0.8 mg/dL), %	18.0	14.8	12.2
SE / ACPA Group			
SE- / ACPA -, %	19.0	18.0	25.6
SE- / ACPA+, %	11.5	13.1	7.3
SE+ / ACPA-, %	27.0	22.1	28.1
SE+ / ACPA+, %	42.5	46.7	39.0
Patient-Reported Outcomes			
Baseline PAS-II, 0-10	3.6 (1.9)	4.2 (1.9)	4.0 (2.0)
Follow up PAS-II, 0-10	3.4 (2.0)	3.9 (2.0)	3.8 (2.1)

Values are mean (standard deviation) unless otherwise specified.

TNFi=tumor necrosis factor inhibitor; JAKi=Janus kinase inhibitor; BMI=body mass index; RDCI=Rheumatic Disease Comorbidity Index; SE=shared epitope; ACPA=anti-citrullinated protein antibodies; RF=rheumatoid factor; CRP=C-reactive protein; PAS-II=Patient Activity Scale II.

Conclusion: Using a US-wide, real-world registry, we observed a greater improvement in patient reported RA disease activity after initiation of abatacept in ACPA+ individuals. Neither SE status nor ACPA status predict response to TNF or JAKi, suggesting that the predictive value of ACPA is more specific to abatacept users. This provides early evidence that ACPA status, rather than correlative SE status, may be the stronger predictor of abatacept response among individuals with RA.

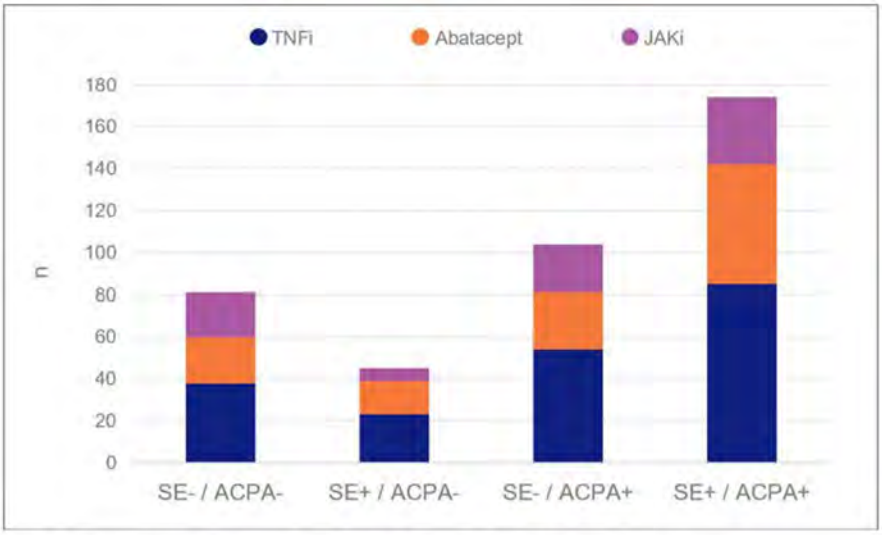

Figure 1. Distribution of participants by medication group and by SE/ACPA status.

Table 2. Linear regression models by medication group for change in PAS-II between baseline and follow up.

	TNFi n=200		Abatacept n=122				JAKi n=82	
	B (95% CI)	p	B (95% CI)	p	B (95% CI)	p	B (95% CI)	p
SE- / ACPA-	reference	-	reference	-	-1.31 (-2.05, -0.56)	0.001	reference	-
SE- / ACPA+	0.51 (-0.23, 1.26)	0.177	1.61 (0.61, 2.60)	0.002	0.30 (-0.57, 1.17)	0.494	-0.22 (-1.94, 1.50)	0.798
SE+ / ACPA-	0.15 (-0.44, 0.74)	0.621	0.60 (-0.25, 1.46)	0.163	-0.70 (-1.41, 0.001)	0.050	0.09 (-1.08, 1.27)	0.877
SE+ / ACPA+	0.24 (-0.30, 0.79)	0.381	1.31 (0.56, 2.05)	0.001	reference	-	0.12 (-0.96, 1.20)	0.825

Model was adjusted for age, sex, race/ethnicity, history of smoking, date, disease duration, BMI, prednisone use, methotrexate use, biologic use, RDCI, and baseline PAS-II score. Positive values indicate improvement, and negative values indicate a worsening in PAS-II score.

SESSION INFORMATION
Session Date: Monday, November 8, 2021
Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster III: Prediction, Biomarkers, & Treatment Response (1196–1222)
Session Type: Poster Session C
Session Time: 8:30AM–10:30AM

Background/Purpose: RA patients who respond inadequately to first-line DMARDs usually progress to a biologic DMARD. Treatment response to both DMARDs and biologics is heterogeneous within RA patients. Choosing the right treatment early is vital, but prediction models from the literature are largely based on complex biomarkers such as genetics. Here, we develop a prediction model, using only clinical baseline covariates, to predict 3-month treatment response to the commonly used anti-TNF-α drug Etanercept (ETN).

Methods: Using data from the Biologics in RA Genetics and Genomics Study Syndicate (BRAGGSS), we identified patients treated with ETN or biosimilars. Patients were included for analysis if they had complete data to calculate a Disease Activity Score of 28 Joints (DAS28) at baseline and 3 months. DAS28 was then used to calculate EULAR response groups. We retained patients with complete baseline data as poor-responders if they stopped treatment early due to inefficacy. We created two datasets, containing all samples with complete CRP (N = 778), and ESR data (N = 693), respectively. Samples with complete CRP and ESR data, appear in both datasets. Multivariable logistic regression models were fitted using baseline clinical covariates, to differentiate poor (y = 1) from good and moderate (y = 0) responders at 3 months. Table 1 shows the baseline statistics of the covariates included in the models, for both created datasets. Multiple imputation by chained equations was used to impute missing data, and models

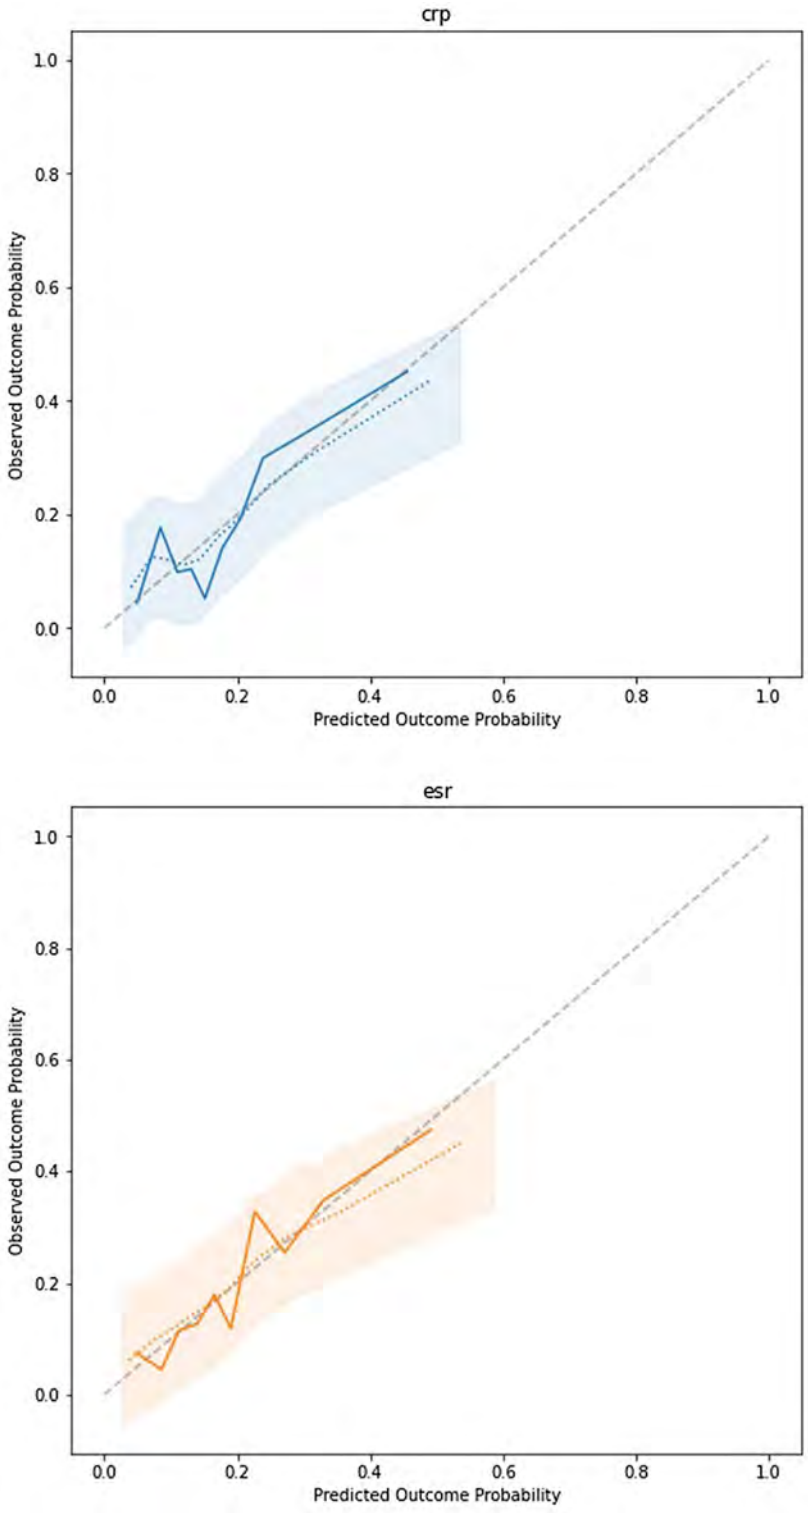

Figure 1. Calibration curves for the fitted models. The dotted line and shaded area represent the average bootstrap calibration curve and its standard deviation.

were internally validated via bootstrapping. We report model discrimination as measured by the area under the ROC curve (AUC), and model calibration via the calibration slope. Model parameters are described using β coefficients and odds-ratios (ORs).

Table 2. Model parameters and their respective odds ratio (OR)

	CRP		ESR	
	β	OR	β	OR
Intercept	1.2956	-	2.7053	-
SJC	-0.0547	0.95	-0.0631	0.94
TJC	0.0088	1.01	-0.0118	0.99
CRP	-0.0079	0.99	-	-
ESR	-	-	-0.0165	0.98
GHVAS	-0.0183	0.98	0.0191	0.98
HEIGHT	-0.0080	0.99	-0.0126	0.99
WEIGHT	-0.0009	1	0.0028	1
AGEONSET	0.0107	1.01	0.0121	1.01
DISDUR	-0.0137	0.99	-0.0157	0.98
HAQ	0.8930	2.44	0.8528	2.35
HAD-Anxiety	0.0331	1.03	0.0023	1
HAD-Depression	-0.0563	0.95	-0.0640	0.94
Concurrent DMARD	-0.1158	0.89	-0.5053	0.60
SEX	-0.2045	0.82	0.0602	1.06
SERO Positive	-0.3835	0.68	-0.0906	0.91
FIRSTBIO	-0.7991	0.45	-0.7278	0.48

Results: Both models are well calibrated with moderate discriminatory ability. Adjusted for optimism, the CRP model achieves an AUC of 0.658 (IQR 0.655-0.66), with a calibration slope of 0.767 (IQR 0.753-0.781). The ESR model shows a slightly higher AUC of 0.671 (IQR 0.67-0.672), with a marginally worse calibration slope of 0.759 (IQR 0.751-0.767). The calibration curve (figure 1) shows predictions are accurate, but that the models rarely predict high probabilities of poor response, which helps explain the moderate AUCs. Model parameters are mostly similar across the two models, and show HAQ to have the biggest impact, with β coefficients of 0.893 (OR 2.44) and 0.8528 (OR 2.35). Additionally, if this is their first biologic treatment, a patient's odds of having a poor response are significantly reduced (OR 0.45 and 0.48 for CRP and ESR, respectively).

Conclusion: Though competitive with existing genetic models from the literature, clinical features alone have insufficient discriminatory ability to predict response to ETN. These models serve as a baseline to investigate and evaluate the use of more complex models incorporating biomarkers to further improve prediction of treatment outcomes in RA. All model parameters are provided (see table 2) to facilitate external validation as well as the further development required to create models that can eventually inform treatment decisions.

SESSION INFORMATION
Session Date: Monday, November 8, 2021
Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster III: Prediction, Biomarkers, & Treatment Response (1196–1222)
Session Type: Poster Session C
Session Time: 8:30AM–10:30AM

Background/Purpose: Local inflammation may cause synovial fibroblasts to become sensitized, resulting in higher susceptibility to arthritis. Longitudinal assessment of joint involvement in rheumatoid arthritis (RA) might show if clinical arthritis tends to recur in the same joints.

Methods: Data from the BeSt study were used, a treat-to-target (disease activity score ≤2.4) study in 508 newly diagnosed RA (ACR 1987 criteria) patients. During 10 years, three-monthly 68-joint assessments (swelling yes/no and Ritchie Articular Index) were done by trained nurses.

We analyzed the association between local joint swelling at baseline and later swelling of the same joint using a multilevel mixed-effects logistic regression model, adjusted for joint location and for timepoint, with joints clustered within patients. A sensitivity analysis was done for the 25% joints that were most often swollen in the study population (MCP 1-3, PIP 2-3, wrists and MTP 2-4).A permutation test was performed to assess if over time joint swelling was better predicted (indicated by a p-value of < 0.05) by baseline swelling of the same joint than by baseline swelling of randomly selected other joints. This was repeated for the joints that were most often swollen.

The association between baseline joint swelling and the number of joint swelling episodes during follow-up was evaluated using a multilevel Poisson regression model, adjusted for joint location and follow-up duration, clustered within patients.

All models were repeated to account for missing data in two ways. First, all missing joint evaluations until end of follow-up were regarded as not swollen. Second, last observation was carried forward for one missing time point if the joint evaluation (swelling yes/no) at the time point before a missing evaluation was the same as at a subsequent time point after the missing evaluation.

Results: At baseline, 8,137/34,423 (24%) assessed joints were scored as swollen. Swelling recurred at least once in 46% of the joints with baseline swelling. Baseline swelling was significantly associated with swelling in the same joint during follow-up (odds ratio 2.37, 95% CI 2.30-2.43, $p< 0.001$). This association also was found in the 25% most swollen joints (OR 2.11, 95% CI 2.03 to 2.19, $p< 0.001$). Local joint swelling (in all joints and in the most susceptible joints) was better predicted by baseline swelling of that particular joint than by baseline swelling of other joints

(p< 0.001). Baseline joint swelling was also predictive for the number of joint swelling episodes in that joint during follow-up (incidence rate ratio 1.48, 95% CI 1.37 to 1.59, p< 0.001). When accounted for missing data, using the two different methods described before, all models showed similar results.

Conclusion: In RA patients treated to target DAS ≤ 2.4, joint swelling tends to recur locally in the joints swollen at presentation. This suggests that local factors influence the manifestation of joint inflammation over time and might indicate that joints that are swollen at disease onset may require additional monitoring and treatment.

Discontinuation Rate of Tofacitinib Is Similar When Compared to TNF Inhibitors in Rheumatoid Arthritis Patients: Pooled Data from Two Rheumatoid Arthritis Registries in Canada

Mohammad Movahedi[1], Denis Choquette[2], Louis Coupal[2], Angela Cesta[3], Xiuying Li[3], Edward Keystone[4] and Claire Bombardier[5], [1]Toronto General Hospital Research Institute, University Health Network, Toronto, ON, Canada, [2]Institut de Rhumatologie de Montréal, Montréal, QC, Canada, [3]Toronto General Hospital Research Institute, UHN, Toronto, ON, Canada, [4]Keystone Consulting Enterprises Inc., Toronto, ON, Canada, [5]University of Toronto - Toronto, Toronto, ON, Canada

SESSION INFORMATION
Session Date: Monday, November 8, 2021
Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster III: Prediction, Biomarkers, & Treatment Response (1196–1222)
Session Type: Poster Session C
Session Time: 8:30AM–10:30AM

Background/Purpose: Tofacitinib (TOFA) is an oral, small molecule drug used for rheumatoid arthritis (RA) treatment as the first or an alternative option to biologic disease- modifying antirheumatic drugs (bDMARDs), including tumor necrosis factor inhibitors (TNFi). The similarity in retention of TNFi and TOFA was previously reported separately by the Ontario Best Practices Research Initiative (OBRI) and the Quebec cohort RHUMADATA. To increase the study power, we propose to evaluate the discontinuation rate (due to any reason) of TNFi compared to TOFA, using pooled data from both these registries.

Methods: RA patients enrolled in the OBRI and RHUMADATA initiating their TOFA or TNFi between 1st June 2014 (TOFA approval date in Canada) and 31st Dec 2019 were included. Time to discontinuation was assessed using adjusted Kaplan-Meier (KM) survival and Cox regression models. To deal with confounding by indication, we estimated propensity scores for covariates with a standard difference greater than 0.1. Models were then adjusted using stratification and inverse probability of treatment weight (IPTW) methods. Multiple imputation (Imputation by Chained Equation method, N=20) was used to deal with missing data for covariates at treatment initiation.

Results: A total of 1318 patients initiated TNFi (n=825) or TOFA (n=493) with mean (SD) disease duration of 8.9 (9.3) and 13.0 (10.1) years, respectively. In the TNFi group, 78.8% were female and mean age (SD) at treatment initiation was 57.6 (12.6) years. In the TOFA group, 84.6% were female and mean (SD) age at treatment initiation was 59.5 (11.5) years. The TNFi group was less likely to have prior biologic use (33.9%) than the TOFA group (66.9%). At treatment initiation, the mean (SD) CDAI was significantly (p< 0.05) lower in the TNFi group [20.0 (11.7)] compared to the

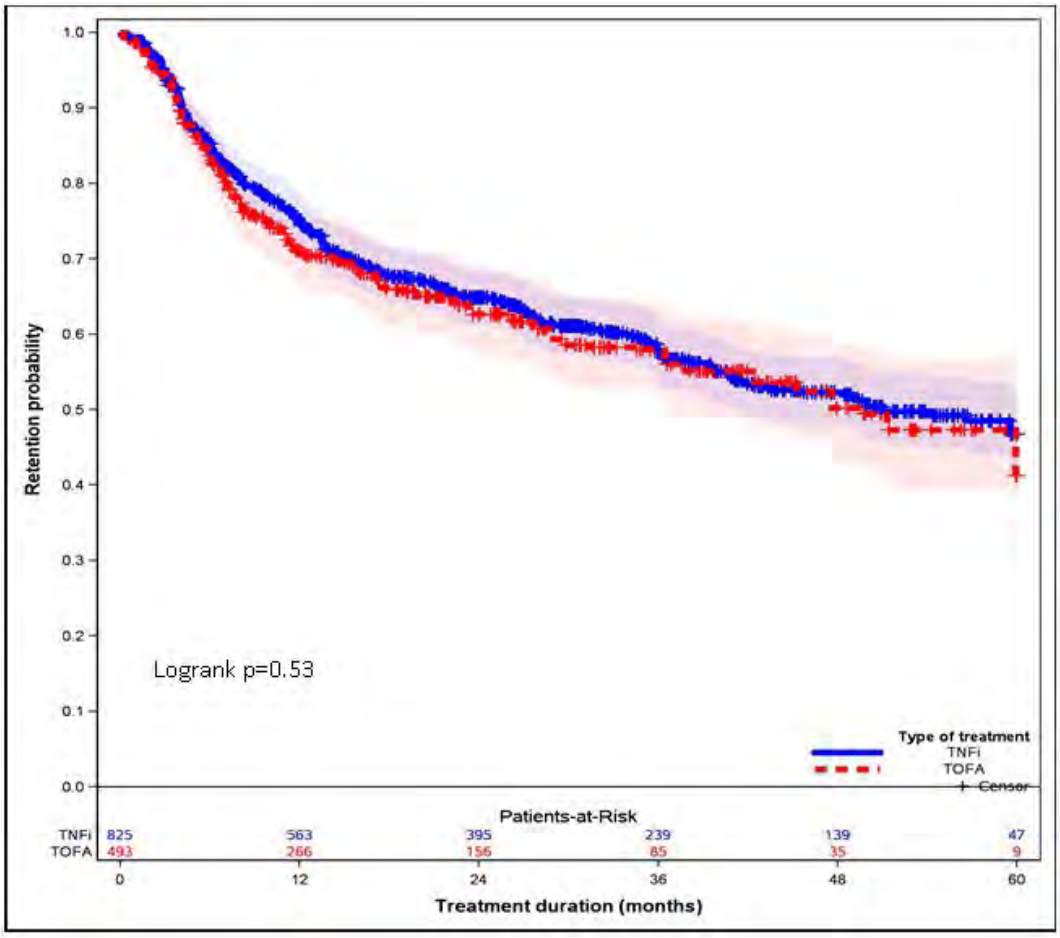

Figure 1. Propensity Score Weighted (IPTW) Survival Curves was performed using one imputed dataset.

TOFA group [22.1(12.4)]. Physical function measured by HAQ-DI was also significantly lower ($p< 0.05$) in the TNFi compared to the TOFA group (1.2 vs.1.3).

Over a mean follow-up of 23.2 months, discontinuation was reported in 309 (37.5%) and 182 (36.9%) of all TNFi and TOFA patients, respectively. After adjusting for propensity score deciles across 20 imputed datasets, there was no significant difference in discontinuation between treatment groups (adjusted HRs: 0.96, 95% CI: 0.78-1.18; p=0.69). The results were similar for two propensity adjustment methods. Figure 1 shows IPTW adjusted KM survival curves comparing discontinuation rates in patients treated with TNFi and TOFA.

Conclusion: In this pooled real -world data study, we found that TNFi and TOFA retention is similar in patients with RA. In the next step we will analysis the data for specific reasons of discontinuation. We will also repeat analysis comparing discontinuation in the first users versus those after one or more biologic failure.

Unsupervised Clustering Identifies Unique Subsets of Patients in a Racially and Ethnically Diverse Rheumatoid Arthritis Cohort

Gabriella Lui[1], Namrata Singh[2], James Andrews[3], Jonathan Graf[4] and Katherine Wysham[5], [1]University of Washington Department of Bioengineering, Seattle, WA, [2]University of Washington, Bellevue, WA, [3]University of Washington, Seattle, WA, [4]Ucsf, San Francisco, CA, [5]VA Puget Sound/University of Washington, Seattle, WA

SESSION INFORMATION
Session Date: Monday, November 8, 2021
Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster III: Prediction, Biomarkers, & Treatment Response (1196–1222)
Session Type: Poster Session C
Session Time: 8:30AM–10:30AM

Background/Purpose: Single biomarkers have limited utility to date in guiding clinical care in RA. There is growing interest in applying machine learning algorithms to combine demographic, clinical, and biomarker data to better identify and stratify RA patient outcomes. We aimed to determine if unsupervised machine learning methods can be employed in a racially and ethnically diverse RA cohort to identify clusters of patients with different disease activity trajectories, as measured by DAS28ESR.

Methods: Data are derived from the longitudinal, observational University of California, San Francisco RA Cohort from years 2011-2018. Along with routine labs, medication use and disease activity assessments, a multiple biomarker of disease activity (MBDA) panel was obtained at each clinical encounter. The MBDA measures 12 unique serum biomarkers. All observations were collapsed to create a cross-sectional dataset before clustering. Missing data were imputed using multiple imputation with chained equations. Data were standardized in preparation for clustering. Patient clusters were identified by unsupervised K-prototype clustering. Longitudinal disease activity (DAS28ESR) trajectories and 95%CIs were plotted for each cluster. Lasso regression was used to identify biomarkers independently associated with DAS28ESR within the whole cohort and by cluster.

Results: Three distinct clusters were identified in our dataset. Cluster 1 (C1) was our smallest cluster (N=56, 20%), with the oldest age (59±14.4), highest proportion of Hispanic/Latino participants (n=43, 77%), the longest disease duration (11.4±8.9) and highest proportion of biological DMARD exposure (N=41, 73%) (Table 1). C1 also had the highest disease activity measured by DAS28ESR of 5.4±0.8. C2 and C3 both had 109 (40%) participants with similar ages 55.2±12.5 and 54.0±14.0, respectively. C3 had the highest proportion of Asian participants of the clusters (N=91, 33%) and the highest BMI of the cohort at 31.8±7.4. Notably, C2 had the lowest DAS28ESR of 3.2±0.7 (Figure 1). C1 had the highest mean DAS28ESR trajectory over time, whereas C3 had high disease activity that decreased over time. C2 had the lowest disease activity throughout the observation period. CRP and matrix metalproteinase-3 (MMP3) both had significant positive associations with DAS28ESR in our lasso regression model of the whole cohort (Table 2). No significant biomarker associations with DAS28ESR were found in C1. IL-6 had a negative association with DAS28ESR in C2 whereas IL-6 had a positive association and TNF-receptor inhibitor had a negative association with DAS28ESR in C3.

Conclusion: Using machine learning methods, we identified 3 clusters of patients in a racially and ethnically diverse longitudinal RA cohort. Each cluster had distinct disease activity trajectories and biomarker associations. This project demonstrated that machine learning methods can be applied to a moderate size RA cohort. Future work will be focused on evaluating baseline data to predict disease activity overtime and validating our findings in an external cohort.

Table 1. Demographics and clinical characteristics of the RA cohort by cluster.

	Cluster 1 (N=56, 20%)	Cluster 2 (N=109, 40%)	Cluster 3 (N=109, 40%)	Overall (N=274)

Machine Learning Based Prediction Model for Responses of bDMARDs in Patients with Rheumatoid Arthritis and Ankylosing Spondylitis

Seulkee Lee, Seonyoung Kang, Yeonghee Eun, Hyungjin Kim, Jaejoon Lee, Eun-Mi Koh and Hoon-Suk Cha, Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul, Republic of Korea

SESSION INFORMATION
Session Date: Monday, November 8, 2021
Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster III: Prediction, Biomarkers, & Treatment Response (1196–1222)
Session Type: Poster Session C
Session Time: 8:30AM–10:30AM

Background/Purpose: Few studies on rheumatoid arthritis (RA) have generated machine learning models to predict biologic disease-modifying antirheumatic drugs (bDMARDs) responses; however, these studies included insufficient analysis on important features. Moreover, machine learning is yet to be used to predict bDMARD responses in ankylosing spondylitis (AS). Thus, in this study, machine learning was used to predict such responses in RA and AS patients.

Methods: Data were retrieved from the Korean College of Rheumatology Biologics therapy (KOBIO) registry. The number of RA and AS patients in the training dataset were 625 and 611, respectively. We prepared independent test datasets that did not participate in any process of generating machine learning models. Baseline clinical characteristics were used as input features. Responders were defined as those who met the ACR 20% improvement response criteria (ACR20) and ASAS 20% improvement response criteria (ASAS20) in RA and AS, respectively, at the first follow-up. Multiple machine learning methods, including random forest (RF), were used to generate models to predict bDMARD responses, and we compared them with the logistic regression model.

Results: The RF model had superior prediction performance to logistic regression model (accuracy: 0.726 [95% confidence interval (CI): 0.725–0.730] vs. 0.689 [0.606–0.717], area under curve (AUC) of the receiver operating characteristic curve (ROC) 0.638 [0.576–0.658] vs. 0.565 [0.493–0.605], F1 score 0.841 [0.837–0.843] vs. 0.803 [0.732–0.828], AUC of the precision-recall curve 0.808 [0.763–0.829] vs. 0.754 [0.714–0.789]) with independent test datasets in patients with RA (Figure 1). However, machine learning and logistic regression exhibited similar prediction performance in AS patients. Furthermore, the patient self-reporting scales, which are patient global assessment of disease

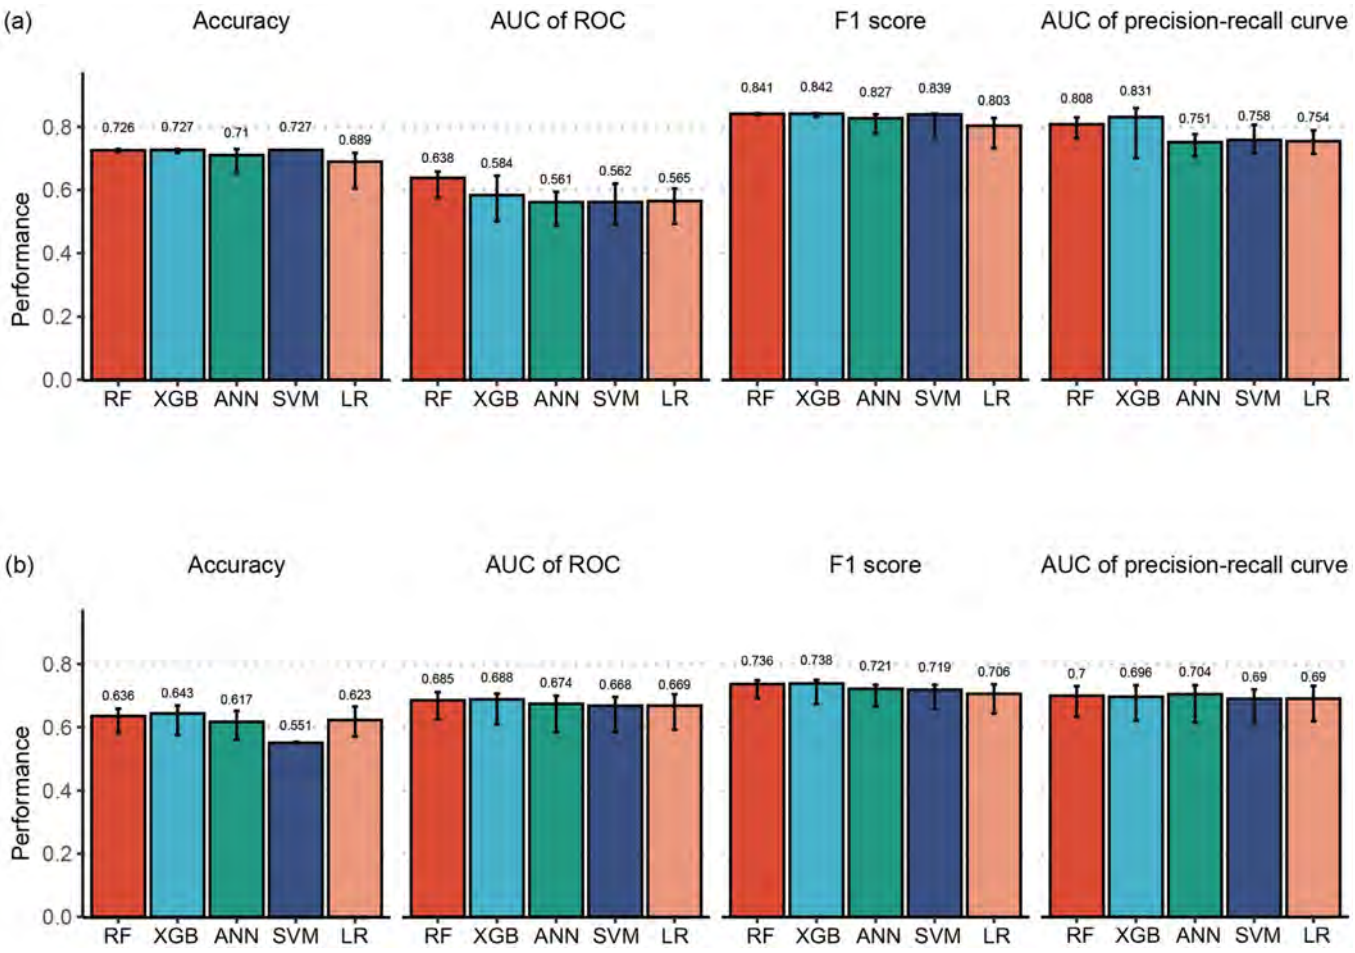

Figure 1. Performances of models trained using various methods (RF, XGBoost, ANN, SVM, and logistic regression) with independent test dataset, in terms of accuracy, AUC of the ROC curve, F1 score, and AUC of the precision-recall curve. (a) RA patients. (b) AS patients. RF, random forest; XGBoost, extreme gradient boosting; ANN, artificial neural network; SVM, support vector machine; LR, logistic regression.

activity (PtGA) in RA and Bath Ankylosing Spondylitis Functional Index (BASFI) in AS, were revealed as the most important features in both diseases (Figure 2).

Conclusion: RF exhibited superior prediction performance for responses of bDMARDs to a conventional statistical method, i.e., logistic regression, in RA patients. In contrast, despite the comparable size of the dataset, machine learning did not outperform in AS patients. The most important features of both diseases, according to feature importance analysis were patient self-reporting scales.

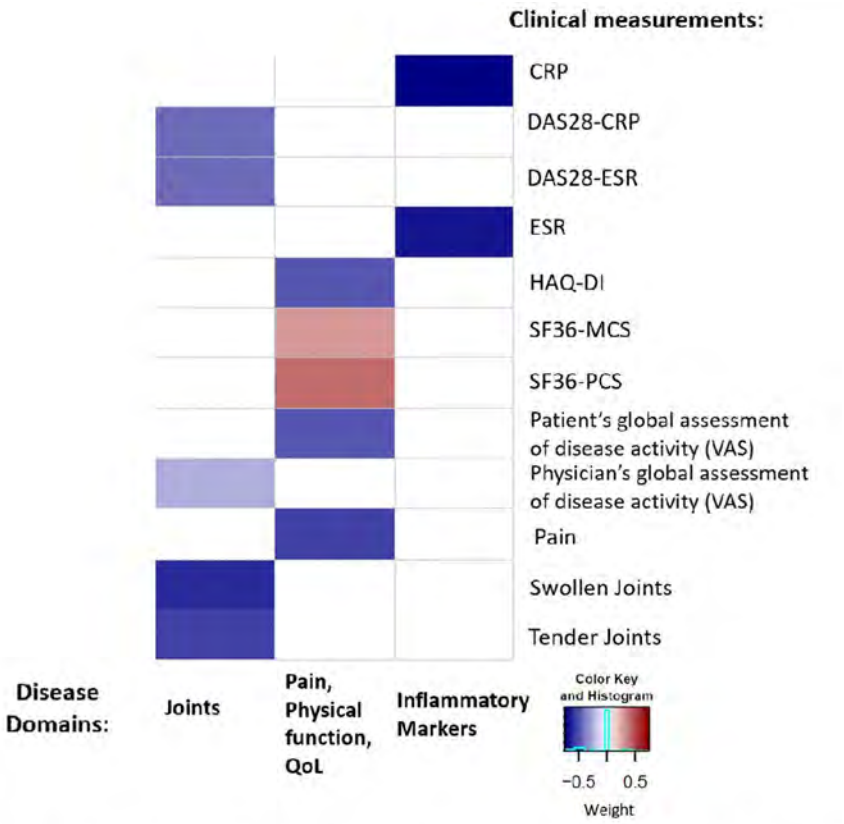
SESSION INFORMATION
Session Date: Monday, November 8, 2021
Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster III: Prediction, Biomarkers, & Treatment Response (1196–1222)
Session Type: Poster Session C
Session Time: 8:30AM–10:30AM

Background/Purpose: Secukinumab is a fully monoclonal antibody approved for the treatment of several related autoinflammatory diseases, including psoriasis, psoriatic arthritis (PsA) and ankylosing spondylitis.[1] While a single clinical endpoint may be chosen to evaluate treatment effect, the natural extension of this sets out to capture a clinical trial's entire longitudinal response profile, made up of multifaceted signs and symptoms. The objective of this analysis is to characterize disease progression and treatment response to secukinumab, across a wide range of clinical variables, thereby complementing traditional analyses of standard endpoints in PsA and rheumatoid arthritis (RA).

Methods: A novel longitudinal latent factor approach was developed and applied across PsA and RA indications. The method identifies underlying (latent) factors that quantify the contribution of each clinical variable to the major sources (axes) of variation in patient response.[2] More importantly, it bundles several clinical endpoints into a small number of concise clinical domains that jointly characterize disease progression. Data from three Phase II RA studies, three Phase III RA studies, and six Phase III PsA studies were pooled, yielding a dataset of 4906 patients; 3464 treated with secukinumab and 1442 treated with placebo. Twelve efficacy endpoints were analyzed up to Week 16 including joint stiffness or swelling, pain, patient-reported outcomes, and alterations in inflammatory markers and quality of life.

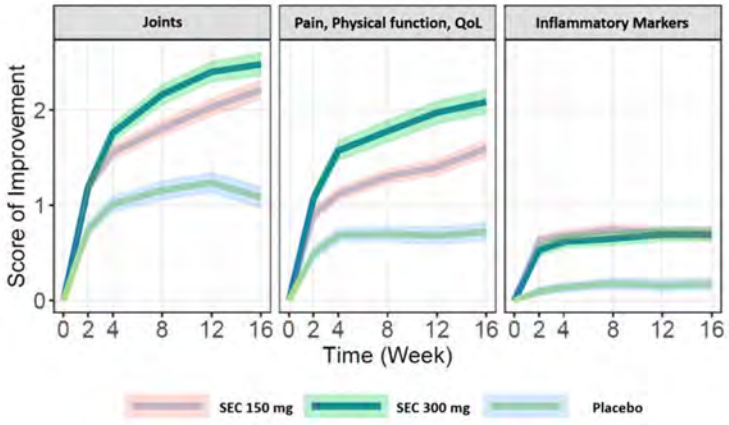
Results: The method summarized the 12 efficacy endpoints in three succinct disease domains, each with a distinct clinical interpretation and role in a multi-dimensional remission [3,4] concept (**Figure 1**). The first disease domain focuses on joint-related symptoms; the second on pain, patient's disease global assessment, and quality of life; and the third on inflammatory laboratory markers. Together, these three disease domains explain three quarters of the variability in the data across both diseases. **Figure 2** displays the trajectory of these latent factors over time. All three disease domains show a numerical separation and greater effect over placebo, with the third separating from placebo as early as Week 4.

Conclusion: The longitudinal latent factor method provided insights into key clinical variables that impact on underlying disease progression and led to better characterization of treatment response. This application has the potential to enhance our understanding of existing composite endpoint methods, as well as to catalyze the development of novel and more robust clinical endpoints.



The heat map depicts the relative weights of efficacy measurement in the disease domains. The color intensity represents the absolute weight of each measurement in a disease domain. The blue color in the histogram represents a negative weight, i.e. the factor tends to increase/improve as that clinical measurement decreases. The red color denotes positive weight, i.e. the factor tends to increase/improve as that clinical measurement increases.

CRP, C-reactive protein; DAS, disease activity score; ESR, erythrocyte sedimentation rate; HAQ-DI, Health Assessment Questionnaire-Disability Index; MCS, mental component score; PCS, Physical component score; SF-36, 36-Item Short Form Survey; VAS, visual analogue scale; QoL, quality of life



Longitudinal responses for each treatment arm (curves) in each disease domain (panels). SEC 150mg represents pooled data for treatment regimens of Secukinumab 150 mg s.c and Secukinumab i.v. (10 mg/kg)-150mg. Each panel depicts the trajectory of improvement of the latent factor at each disease domain over time. Each line represents the mean response of each treatment in induction stage from baseline to Week 16. The color band represents the 95% confidence interval of response in each treatment. SEC, secukinumab; QoL, Quality of life.

Association of Neutrophil Lymphocyte and Platelet Lymphocyte Ratios with Joint Inflammation in Rheumatoid Arthritis

Diyu Pearce-Fisher[1], Dana Orange[2], Bella Mehta[3], Deanna Jannat-Khah[1] and Susan Goodman[1], [1]Hospital for Special Surgery, New York, NY, [2]The Rockefeller University, New York, NY, [3]Hospital for Special Surgery, Weill Cornell Medicine, New York, NY

SESSION INFORMATION
Session Date: Monday, November 8, 2021
Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster III: Prediction, Biomarkers, & Treatment Response (1196–1222)
Session Type: Poster Session C
Session Time: 8:30AM–10:30AM

Background/Purpose: It can be challenging to determine whether rheumatoid arthritis (RA) patients who require arthroplasty have ongoing inflammation, in addition to damage in the affected joint on clinical exam. C-reactive protein (CRP), erythrocyte sedimentation rate (ESR), neutrophil-lymphocyte (NLR) and platelet-lymphocyte ratios (PLR) are all blood biomarkers that have been reported to associate with disease activity.

Table 1. Multivariate ordered logistic regression predicting SLI in all RA patients

	OR	SE	P>|t|	95% Confidence Interval
CRP	1.18	0.102	0.055	(0.997, 1.399)
ESR	**1.02**	**0.008**	**0.035**	**(1.00, 1.03)**
PLR	**1.003**	**0.002**	**0.050**	**(0.9999, 1.007)**
Removed from model as insignificant (p>0.1): DAS28-ESR, SJC, TJC, MD global, NLR				
*bold values significant p<0.05; OR=odds ratio; SE=standard error; CRP = C Reactive Protein; ESR = erythrocyte sedimentation rate; NLR = neutrophil lymphocyte ratio; PLR = platelet lymphocyte ratio; TJC = tender joint count; SJC = swollen joint count				

Table 1. Multivariate ordered logistic regression predicting SLI in all RA patients

	OR	SE	P>|z|	95% Confidence Interval
TJC	0.941	0.030	0.056	(0.885, 1.002)
ESR	**1.025**	**0.011**	**0.016**	**(1.005, 1.046)**
MD Global	1.221	0.135	0.071	(0.983, 1.516)
PLR	**1.006**	**0.003**	**0.044**	**(1.0002, 1.011)**
Removed from model as insignificant (p>0.100): NLR, DAS28-ESR, SJC, CRP				
*bold values significant p<0.05; OR=odds ratio; SE=standard error; ESR = erythrocyte sedimentation rate; NLR = neutrophil lymphocyte ratio; PLR = platelet lymphocyte ratio; TJC = tender joint count; SJC = swollen joint count				

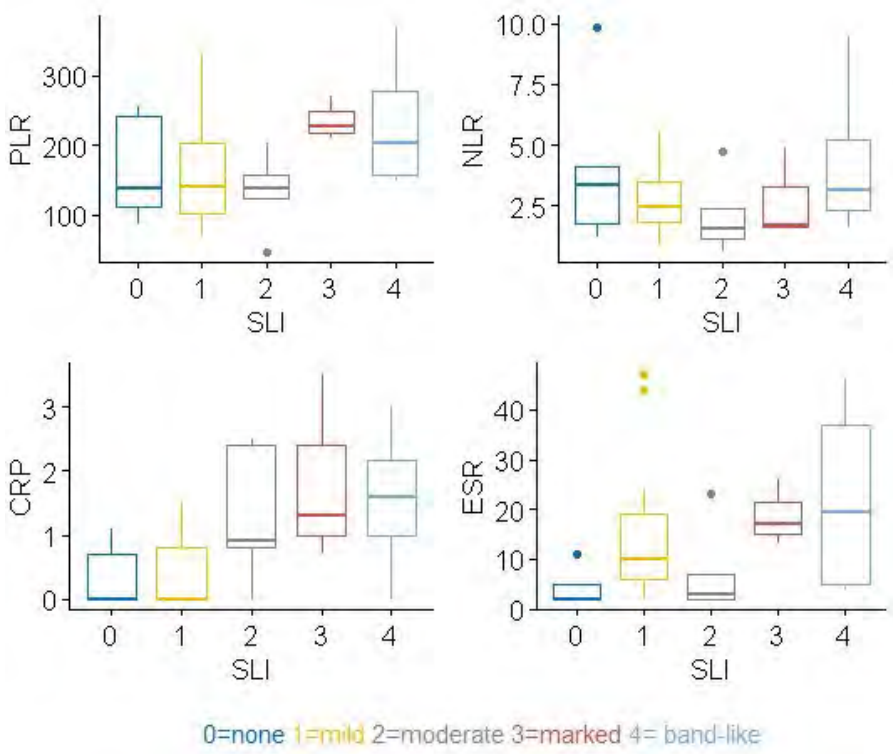

Figure 1. Blood biomarkers by SLI in RA patients with DAS<3.2 not on GCs.

Methods: 239 patients meeting ACR/EULAR 1987 and/or 2010 RA criteria and 162 OA patients were recruited prior to elective total hip, knee, elbow, or shoulder arthroplasty. Disease characteristics and blood samples were collected pre-operatively. Hematoxylin and eosin (H&E) stains of the synovium were prepared and scored by a pathologist. Mann-Whitney and Kruskal Wallis tests were used to compare biomarkers among groups. Stata's backward stepwise regression and multivariable ordered logistic regression was performed to predict synovial lymphocytic inflammation on (1) 239 RA patients, (2) 146 RA patients not on GCs, and (3) 52 RA patients with low disease activity (DAS28-ESR< 3.2).

Results: RA patients (median [IQR] = 159.6 [103.1]) had higher PLR than OA patients (median [IQR] = 138.9[76.5]) (p< 0.001). RA patients (median [IQR] = 2.73 [2.34]) also had a slightly higher NLR compared to OA patients (median [IQR] = 2.45[1.90]) (p=0.052). Additionally, RA patients on glucocorticoids (GCs) had higher NLR (p< 0.001) and PLR (p=0.04) than those not on GCs. In all models predicting SLI in RA, PLR was significantly associated with SLI but not DAS28-ESR or CDAI **(Table 1 and Table 2)**. Patients with DAS28-ESR< 3.2 and high SLI had higher PLR (p=0.01) and CRP (p=0.02) **(Figure 1)** than those with low SLI. PLR was not associated with SLI in OA patients.

Conclusion: Platelet lymphocyte ratio is associated with synovial lymphocytic inflammation in rheumatoid arthritis patients of all disease activity levels. This suggests that inexpensive, routinely performed blood tests may be a useful blood biomarker of RA synovial inflammation, including subclinical synovitis.

Drug Response Is Associated with Changes in Specific MicroRNAs in Patients with Rheumatoid Arthritis

Qiong Wu[1], Sheau-Chiann Chen[1], Fei Ye[1], Joseph Solus[1], S. Louis Bridges, Jr.[2], Jeffrey Curtis[3], C. Michael Stein[1] and Michelle Ormseth[1], [1]Vanderbilt University Medical Center, Nashville, TN, [2]Hospital for Special Surgery, New York, NY, [3]Division of Clinical Immunology and Rheumatology, Department of Medicine, Department of Epidemiology, University of Alabama at Birmingham, Birmingham, AL

SESSION INFORMATION
Session Date: Monday, November 8, 2021
Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster III: Prediction, Biomarkers, & Treatment Response (1196–1222)
Session Type: Poster Session C
Session Time: 8:30AM–10:30AM

Background/Purpose: MicroRNAs are markers and mediators of disease and drug response. Prior studies have proposed several miRNAs for prediction of drug response or monitoring drug effect in patients with RA. Our objective was to determine if baseline or change in concentrations of these plasma miRNAs are associated with clinical response to several key disease modifying antirheumatic drugs (DMARDS): methotrexate, adalimumab and tocilizumab.

Methods: We developed a list of candidate miRNAs which are associated with response to a DMARD based on literature: let-7a-5p, let-7b-5p, miR-126-3p, miR-132-3p, miR-146a-5p, miR-16-5p, miR-22-3p, miR-223a-3p, miR-23a-3p, miR-24-3p, and miR-27-3p. Candidate miRNAs were measured in plasma from 70 patients with RA in the TETRAD repository before and 6-months after starting a new DMARD by qPCR. The miRNA concentration was determined from a standard dilution curve of a known DNA mimic concentration. MiRNAs were log2 transformed due to skewness. The relationship between change in miRNA concentration and DAS28-ESR before versus after DMARD was assessed by Spearman correlation and using a two-step linear regression with 6-month DAS28-ESR as the outcome and baseline DAS28-ESR and the log2-transformed residualized miRNA as predictors. The residualized miRNA reflects the baseline adjusted miRNA at 6-months, thus enabling adjustment for both baseline miRNA and DAS28-ESR in the final analysis. The predictive capacity of the baseline concentrations of miRNAs adjusted for baseline DAS28-ESR to predict DAS28-ESR at 6 months was assessed by linear regression. Pathway analysis of the miRNA predicted targets was performed using MSigDB Reactome gene sets.

Table 1. Clinical characteristics of all patients with rheumatoid arthritis initiating methotrexate, adalimumab, or tocilizumab

	all RA (n= 70)	Methotrexate (n = 24)	Adalimumab (n = 23)	Tocilizumab (n = 23)
Age, years	54 (45, 62)	54 (45, 56)	54 (46, 63)	53 (46, 63)
Race, # Caucasian	56 (80)	18 (75)	18 (78)	20 (87)
Gender, # female	57 (81)	18 (75)	19 (83)	20 (87)
Disease duration, years	4.24 (0.34, 12.10)	0.19 (0.08, 1.20)	5.19 (1.81, 10.91)	12.65 (4.80, 21.88)
CCP, # positive	42 (60)	17 (71)	11 (48)	14 (61)
RF, # positive	43 (61)	15 (62)	12 (52)	16 (70)
Baseline DAS28-ESR, units	4.91 (3.61, 5.62)	4.78 (3.34, 5.43)	4.99 (3.78, 5.97)	4.89 (3.69, 5.92)
Concomitant MTX, # yes	30 (43)	-	19(83)	11(48)
Concomitant corticosteroids, # yes	37(65)	13 (87)	12 (60)	12 (55)
EULAR response, # yes	51 (73)	16 (67)	16 (70)	19 (83)

Data presented at median (interquartile range) or number (%). Disease duration= time since symptom onset. CCP= anti-cyclic citrullinated peptide antibody. RF= rheumatoid factor. DAS28-ESR= disease activity based on 28 joints and erythrocyte sedimentation rate. MTX= methotrexate. EULAR= European League Against Rheumatism. EULAR response= moderate to good.

Table 2. Relationship between change in log2_miRNA with change in DAS28-ESR between baseline and 6-months after initiation of new DMARD

	Spearman Rho (comparing change in miRNA and change in DAS28-ESR)	Baseline adjusted P*
let-7a-5p	-0.20	0.02
let-7b-5p	-0.28	0.004
miR-126-3p	-0.18	0.049
miR-132-3p	-0.15	0.38
miR-146a-5p	-0.19	0.04
miR-16-5p	-0.23	0.02
miR-22-3p	-0.17	0.03
miR-223a-3p	-0.10	0.26
miR-23a-3p	-0.18	0.12
miR-24-3p	-0.23	0.07
miR-27-3p	-0.13	0.26

Adjusted P value is the result of the residualized miRNA analyses which adjust for baseline miRNA concentrations and baseline DAS28-ESR scores.

Results: The 70 patients with RA had a median age of 54 years; 80% were Caucasian, 81% were female, median baseline DAS28-ESR was 4.91 units; after 6-months 73% had a moderate to good EULAR response (Table 1). Increasing plasma concentrations between baseline and 6-months of six of the miRNAs (let-7a-5p, let-7b-5p, miR-126-3p, miR-146a-5p, miR-16-5p, and miR-22-3p) were significantly associated with decreasing DAS28-ESR after 6-months of new DMARD treatment in the residualized miRNA analyses (Table 2, all $p< 0.05$), although mean miRNA concentrations did not significantly change before versus after treatment. There was no significant interaction based on the DMARD initiated (all $p >0.2$), and baseline miRNA concentrations did not predict drug response (all $p >0.05$). Pathway analysis demonstrated that the six miRNAs which are associated with change in DAS28-ESR are predicted

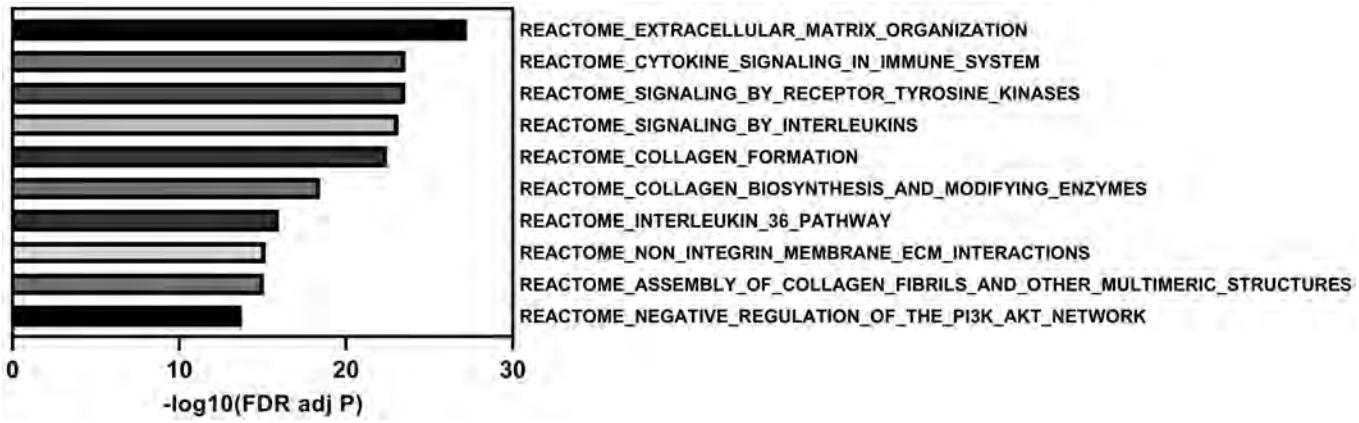

Figure. Reactome pathways which are significantly enriched among miRNA predicted targets.

to target pertinent functions like cytokine signaling, and signaling by receptor tyrosine kinases (Figure), which could contribute to drug response.

Conclusion: Increasing concentrations of six of the eleven miRNAs were significantly associated with greater improvement in RA disease activity 6-months after starting a new DMARD. Pathway analysis demonstrates that these miRNAs, while being markers of drug response may play a direct role in resolution of inflammation. Further studies will be needed to confirm this.

A Multinational, Prospective, Observational Study in Patients with Rheumatoid Arthritis Receiving Baricitinib, Targeted Synthetic or Biologic Disease-Modifying Therapies: 6-Month Effectiveness and Patient Reported Outcome Data from the European Cohort

Gerd Burmester[1], Bruno Fautrel[2], **Rieke Alten**[3], Marco Matucci-Cerinic[4], Jean hugues Salmon[5], Thorsten Holzkaemper[6], Inmaculada de la Torre[7], Pedro Lopez-Romero[8], Walid Fakhouri[8] and Anja Gentzel-Jorczyk[8], [1]Charité University Medicine Berlin, Berlin, Germany, [2]Pitié Salpêtrière Hospital, APHP, Sorbonne Université, Paris, France, [3]Schlosspark-Klinik University, Berlin, Germany, [4]University of Florence, Florence, Italy, [5]Rheumatology, CHU Maison blanche, Reims, Reims, France, [6]Eli Lilly and Company, Bad Homburg, Germany, [7]Eli Lilly and Company, Alcobendas, Spain, [8]Eli Lilly and Company, Indianapolis, IN

SESSION INFORMATION
Session Date: Monday, November 8, 2021
Session Title: RA – Treatments Poster II: PROs, Biomarkers, & Systemic Inflammation (1223–1256)
Session Type: Poster Session C
Session Time: 8:30AM–10:30AM

Background/Purpose: Baricitinib (BARI) is a JAK1/2 inhibitor approved for the treatment of adults with moderately to severely active rheumatoid arthritis (RA) and the treatment of adult atopic dermatitis in Europe and Japan.

RA-BE-REAL is a 3-year, prospective, observational study of adult RA patients (pts) evaluating adherence to treatment in clinical practice.

The purpose of this abstract is to report the proportion of European pts with RA that discontinue treatment following 3- and 6-months (M) of either BARI, biologic (b)DMARDs or any other targeted synthetic (ts)DMARDs (b/ tsDMARDs) after starting that treatment for the first time. To report the percentage of pts achieving remission and low disease activity (LDA) based on Clinical Disease Activity Index (CDAI) at 6M. To assess changes from baseline in CDAI and to describe changes in patient reported outcomes (PROs) related to quality of life, pain, and physical functioning at 6M.

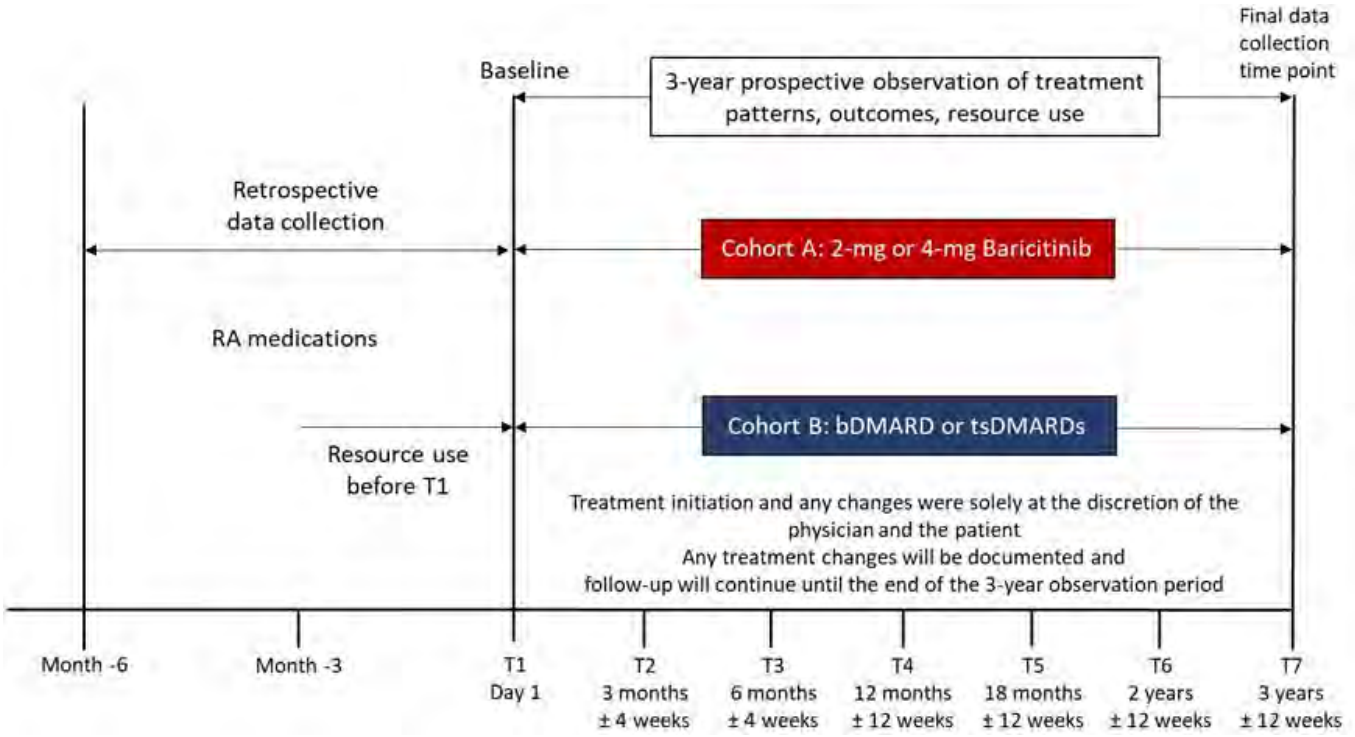
Methods: The primary endpoint is the discontinuation rate of initial RA treatment for all causes (excluding sustained clinical response) over a 24M period. Two pt cohorts are assessed: cohort A, started treatment with BARI (2mg or 4mg), and cohort B, any biologic or any other tsDMARD (Fig. 1). Treatment initiation and changes are at the discretion of the pt or physician. In this interim analysis we report descriptive baseline, 3M and 6M data.

Results: Between October 2018 and March 2020, 1074 adult RA pts were enrolled from France, Germany, Italy, Spain, and UK. At time of enrollment 50.9% of pts in cohort A and 31.2% of pts in cohort B commenced treatment as a monotherapy (Table 1). A similar proportion of pts in cohort A (52/392 pts; 13.3%) and cohort B (59/425; 13.9%) discontinued treatment at 3M. At 6M pts in cohort A (63/336; 18.8%) were less likely to have discontinued their initial RA treatment than pts in cohort B (93/370; 25.1%) (Fig.2A). At 6M a higher percentage of cohort A pts had achieved CDAI remission (cohort A; 25.6%, cohort B; 18.5%) (Fig.2B). Pts in cohort A experienced a greater decrease in disease activity as assessed by CDAI with a mean reduction in disease activity scores of -13.9 (-11.8 for pts in cohort B) (Table 2). With respect to PROs, a similar improvement from baseline in HAQ-DI, pain (VAS), and EQ-5D-5L scores was observed for both cohorts (Table 2).

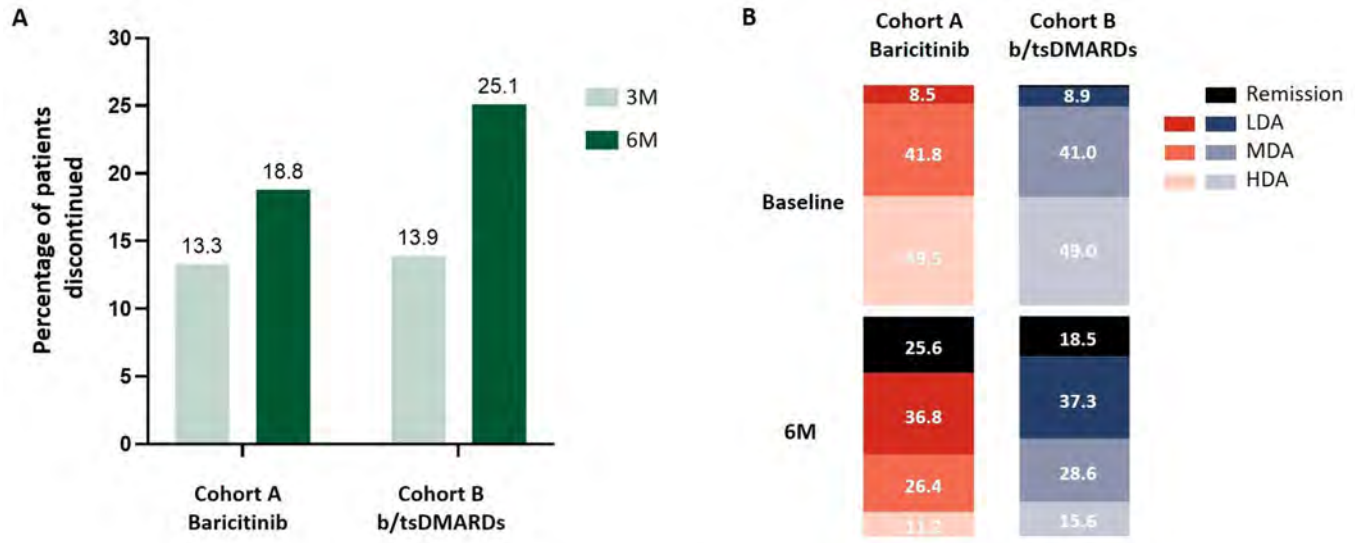
	Cohort A Baricitinib (n=509)	Cohort B b/tsDMARDs (n=565)
Concomitant use of csDMARDs n (%)		
with any csDMARD	250 (49.1)	389 (68.8)
as a monotherapy	259 (50.9)	176 (31.2)
Age in years (SD)	59.1 (13.2)	57.0 (13.9)
Disease duration in years (SD)	10.0 (9.1)	8.9 (9.6)
Oral GCCs at time of enrollment n (%)		
Yes	218 (42.8)	249 (44.1)
No	291 (57.2)	316 (55.9)
b/tsDMARDs treatment any time before enrollment n (%)		
Naive	245 (48.1)	344 (60.9)
1 b/tsDMARD	67 (13.2)	57 (10.1)
2 b/tsDMARDs	110 (21.6)	79 (14.0)
>2 b/tsDMARDs	87 (17.1)	85 (15.0)

Data presented side-by-side for descriptive purposes only. csDMARD; conventional synthetic disease-modifying antirheumatic drugs, GCCs; glucocorticoids, SD; standard deviation

Conclusion: Overall, these observational study results highlight that pts receiving baricitinib are less likely to discontinue treatment and more likely to achieve remission than pts receiving a biologic or any other tsDMARDs.



Study Design. Participants entered cohort A or B based on their treatment decision for BARI or another b/tsDMARD, pts in each cohort were with/without concomitant csDMARDs.



Footnote: M; months, LDA; low disease activity, MDA; moderate disease activity, HDA; high disease activity. Values are presented as a percentage of the population.

A. Percentage of pts that discontinued initial RA treatment at 3M and 6M, B. Percentage of pts in cohort A and cohort B achieving remission and LDA status at 6M.

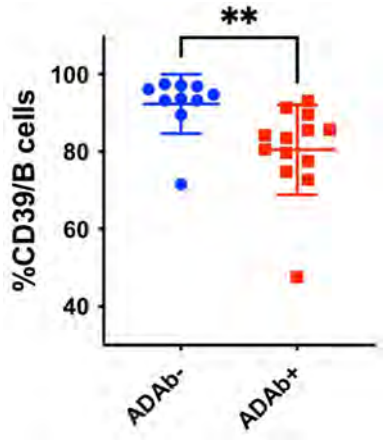
SESSION INFORMATION

Session Date: Monday, November 8, 2021

Session Title: RA – Treatments Poster II: PROs, Biomarkers, & Systemic Inflammation (1223–1256)

Session Type: Poster Session C

Session Time: 8:30AM–10:30AM



Background/Purpose: Anti-Drug antibodies (ADAb) are well studied and have an impact on response to treatment with monoclonal anti-TNF biologics. Rituximab treatment has an important immunogenic potential as it is a chimeric antibody. Most recent studies on biosimilars have identified low rates of ADAb among rituximab-treated patients without impact on treatment efficacy. The lack of sensitivity in the detection of ADAb might explain discrepancies between TNFi and rituximab. Methotrexate has been associated with less occurrence of ADAb when co-administered with adalimumab. CD73 and CD39 are ectoenzyme involved in the pathway of adenosine production, a known mechanism of action of methotrexate. The objective of this study was to characterize if CD39 and CD73 expression on B cells was a predictor of occurrence of ADAb in a population of RA patients treated with rituximab.

Methods: ABIRISK is an IMI-2 European consortium designed to identify predictors of ADAb among rheumatoid arthritis (RA) patients and inflammatory bowel disease (IBD) patients. Prospective assessment of ADAb was performed using sensitive technique based on Meso Scale diffusion. Response to rituximab was assessed at 6 months using delta DAS 28. Patient's PBMCs at baseline were assessed for B cell lineage markers and CD73 and CD39 using flow cytometry.

Results: Among the 23 analyzed RA patients treated with rituximab, 13 became ADAb+ and 10 remained ADAb negative. There was no difference in the proportion of patients with concomitant methotrexate in both groups with 77 % and 80% in ADAb+ and ADAb- respectively. B cells lineage markers did not vary between patients' groups. Baseline levels of CD73 expression on B cells were similar among patients who later became ADAB+ or negative. At baseline lower levels of CD39 expression on B cells was significantly predictive of the future appearance of ADAb (see figure). There was a trend of correlation between pre-treatment CD39 expression levels and delta DAS 28 at 6 months indicating a potential diminished response to treatment in patients with lower CD39 expression (p= 0,059).

Conclusion: Pre-treatment lower CD39 expression levels on B cells is predictive of the future appearance of ADAb directed against rituximab in RA patients. CD 39 levels trended to negatively correlate with less treatment efficacy. Since the number of patients co-treated with methotrexate is not significantly different between ADAb+ and ADAb- patients, we might hypothesize that the level of CD39 accounts for the occurrence of ADAb. This suggests that the level of adenosine that might be modulated by methotrexate or by the level of CD39 expression may impact the occurrence of anti-rituximab antibodies in RA patients.

Session Title: RA – Treatments Poster II: PROs, Biomarkers, & Systemic Inflammation (1223–1256)

Session Type: Poster Session C

Session Time: 8:30AM–10:30AM

Background/Purpose: Predictive biomarkers reflecting RA processes and treatment (tmt) efficacy are urgently needed to inform medical options. Markers of bone remodeling and extracellular matrix (ECM) turnover may serve as disease-relevant, surrogate biomarkers indicative of synovial joint pathophysiology.[1,2] We evaluated baseline (BL) correlations of biomarkers with disease activity (DA), their predictive value for efficacy, and pharmacodynamic (PD) changes during subcutaneous (SC) abatacept (ABA) tmt in a phase 3b study in MTX-naive, ACPA+ patients (pts) with early RA (AVERT-2; NCT02504268).[3]

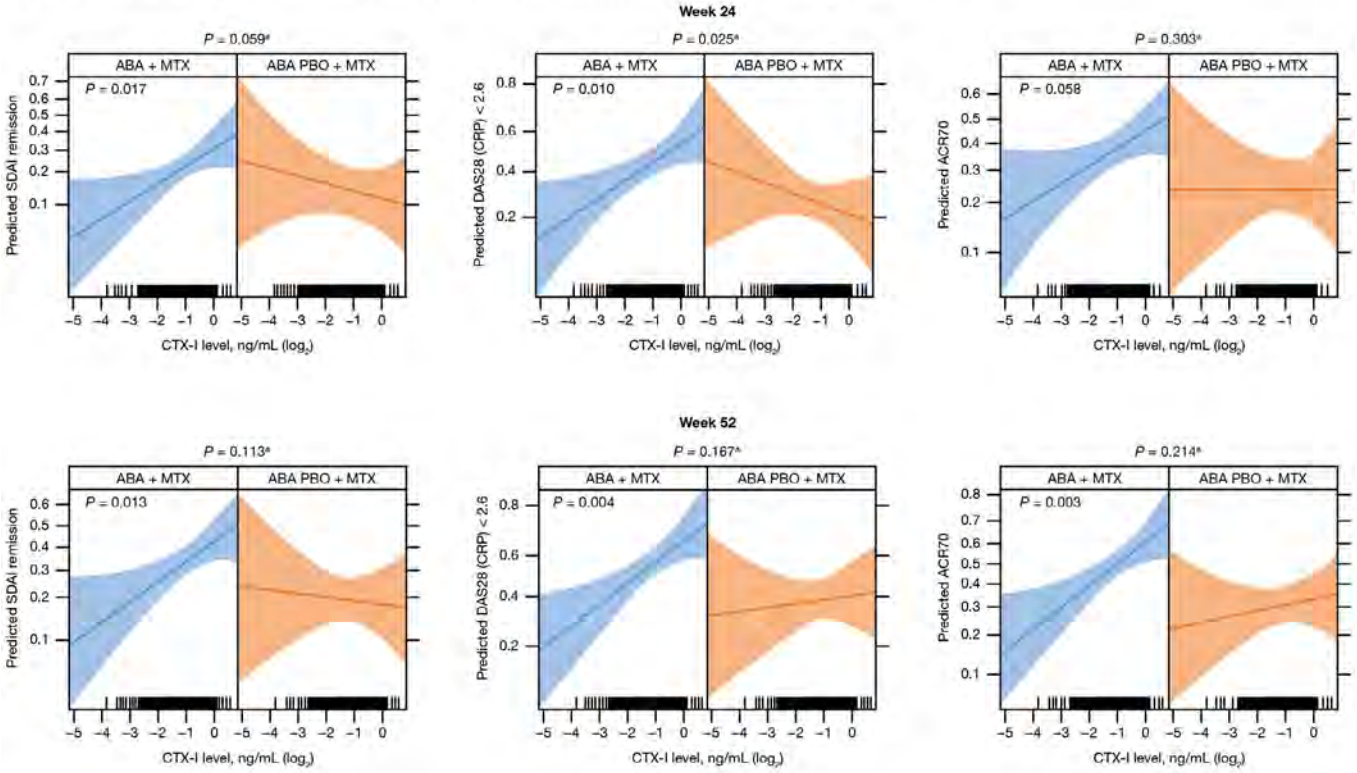
Methods: Pts with early RA (ACR/EULAR 2010)[4] were randomized to SC ABA 125 mg QW or SC ABA placebo (PBO) both with oral MTX for 56 weeks (wks). A subgroup of the overall population (intention-to-treat) was included. Linear correlations were assessed using BL levels of 8 ECM serum biomarkers (Nordic Biosciences) including MMP-mediated degradation products of type III and IV collagen (C3M, C4M), neo-epitope of MMP-mediated degradation of CRP (CRPM), and neo-epitope of cathepsin-mediated degradation of type I collagen (CTX-I), with DA measures.

Table 1. Baseline characteristics in the overall (ITT) population and the ECM biomarker subgroup by treatment arm

	ITT population			ECM biomarker subgroup		
	Abatacept + MTX (n = 451)	Abatacept placebo + MTX (n = 301)	*P* value	Abatacept + MTX (n = 330)	Abatacept placebo + MTX (n = 205)	*P* value
Age, mean (SD)	49 (13)	49 (14)	0.69	48 (13)	47 (14)	0.52
Sex, female, n (%)	349 (77)	243 (81)	0.31	266 (81)	171 (83)	0.48
Race, n (%)						
Asian	77 (17)	52 (17)	0.99	61 (18)	41 (20)	0.96
Black	20 (4)	15 (5)		13 (4)	9 (4)	
Other	39 (9)	25 (8)		31 (9)	19 (9)	
White	315 (70)	209 (69)		225 (68)	136 (66)	
SDAI, mean (SD)	38 (14)	39 (14)	0.25	39 (14)	39 (14)	0.87

ECM, extracellular matrix; ITT, intention to treat; SD, standard deviation; SDAI, Simplified Disease Activity Index.

Figure 1. Probability of achieving efficacy outcomes at weeks 24 and 52 with ABA + MTX or ABA PBO + MTX as predicted by baseline CTX-I level



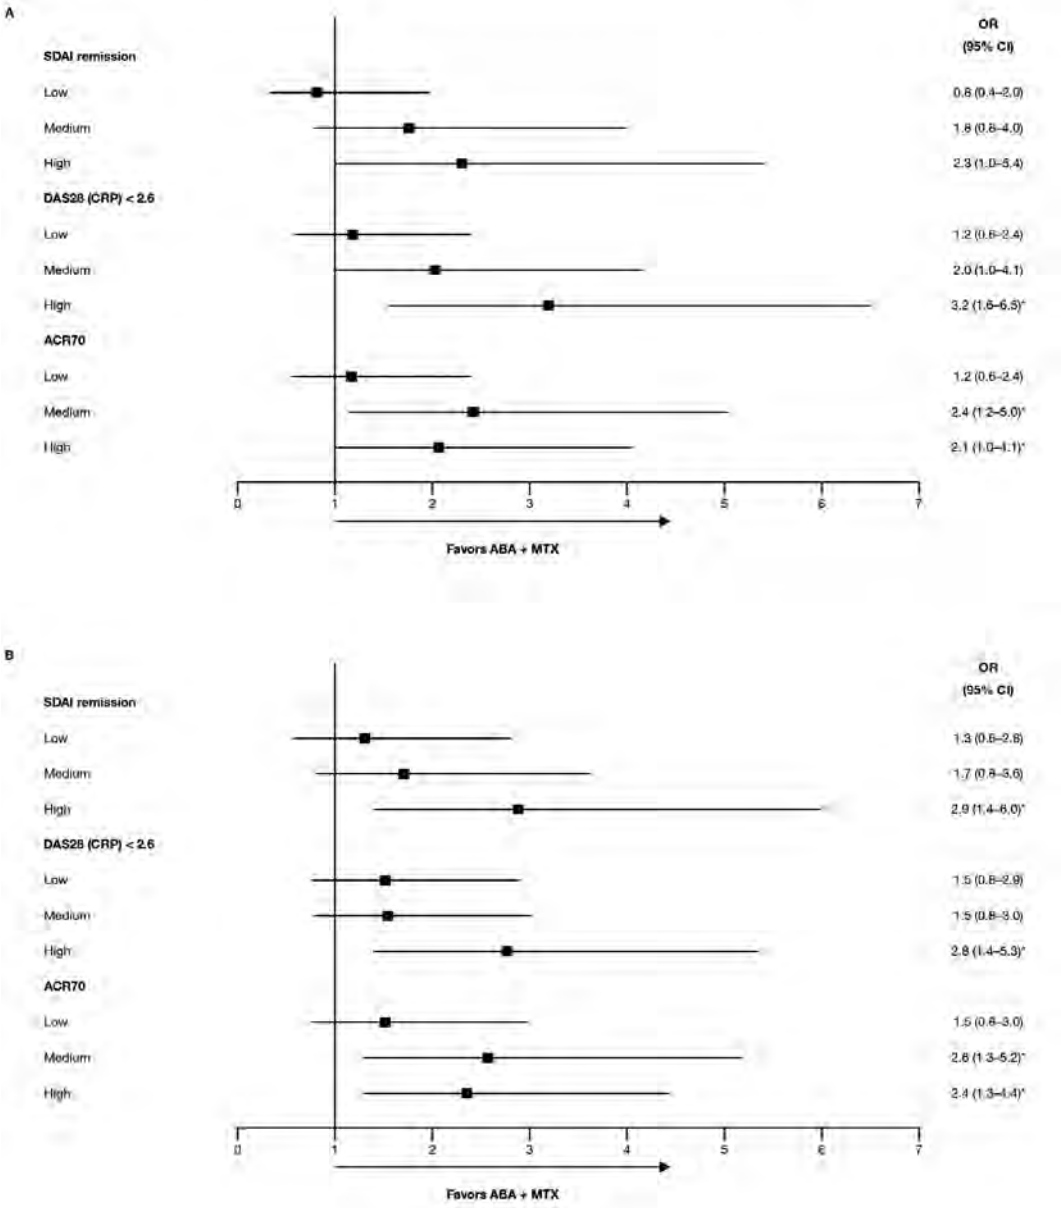
Age, baseline SDAI, and baseline erosion score were used as covariates.
A total of 8 biomarkers were tested: C3M: neo-epitope of MMP-9 mediated degradation of type III collagen; C4G: neo-epitope of granzyme B mediated degradation of type IV collagen; C4M: neo-epitope of MMP-2, -9, and -12 mediated degradation of type IV collagen α1 chain; CPa9-HNE: neo-epitope of human neutrophil elastase (HNE) mediated degradation of calprotectin; CTX-I: neo-epitope of cathepsin-mediated degradation of type I collagen; CRPM: neo-epitope of MMP-1 and -8 mediated degradation of CRP; N-MID: N-MID osteocalcin; VICM: neo-epitope of MMP-2, -8, and trypsin mediated degradation of citrullinated vimentin.
[a]Interaction effect for ABA + MTX versus ABA PBO + MTX.
ABA, abatacept; PBO, placebo; SDAI, Simplified Disease Activity Index.

Logistic regression predictive models were used to evaluate BL bone remodeling markers in predicting clinical efficacy (SDAI remission, DAS28 [CRP] < 2.6, ACR70) at wks 24 and 52 with biomarker levels defined as a continuous variable or categorically (low, medium, high tertiles). For biomarkers with data at wks 24 and 52, PD changes were assessed using a linear mixed-effects model with repeated measures.

Results: BL pt characteristics were similar between the overall population and the ECM biomarker subgroup, and across tmt arms (**Table 1**). BL biomarker levels were generally similar between tmt arms. Of biomarkers tested, BL C3M, C4M, and CRPM showed greatest correlations with BL DA measures; CTX-I showed weak correlation with BL DA. Probability of wk 24 and 52 efficacy as predicted by BL CTX-I showed differential response between ABA + MTX and ABA PBO + MTX tmt arms at both time points (**Figure 1**). This was not seen with BL CRP (data not shown). Categorical analysis showed greater tmt differences for ABA + MTX vs ABA PBO + MTX in pts with medium/high vs low BL CTX-I (**Figure 2**). PD analysis showed significant tmt differences in adjusted change from BL in C3M and C4M (wk 24 and 52) and CRPM (wk 24) with ABA + MTX vs ABA PBO + MTX (data not shown).

Conclusion: In ACPA+ pts with early RA, BL levels of cartilage biomarker CTX-I predicted differential SDAI remission or DAS28 (CRP) < 2.6 with abatacept + MTX vs abatacept PBO + MTX, with higher levels of CTX-I associated with a greater probability of achieving efficacy endpoints for abatacept + MTX; this relationship was not observed with abatacept PBO + MTX. Tmt differences were greatest in pts with medium/high BL CTX-I levels. Significant PD effects of abatacept tmt on C3M, C4M, and CRPM were seen. Additional studies of BL CTX-I as a predictive biomarker of abatacept tmt response are warranted.

Figure 2. Treatment differences in efficacy outcomes at (A) week 24 and (B) week 52 by baseline CTX-I levels (low, medium, high)



Low, medium, and high CTX-I categories are based on tertiles T1 (n = 178, 0.028–0.324 ng/mL), T2 (n = 177, 0.325–0.525 ng/mL), and T3 (n = 178, 0.526–1.570 ng/mL), respectively. Age, baseline SDAI, and baseline erosion score were used as covariates.
*$P < 0.05$ for comparison of ABA + MTX versus ABA PBO + MTX.
ABA, abatacept; CI, confidence interval; CTX-I, neo-epitope of cathepsin-mediated degradation of type I collagen; OR, odds ratio; PBO, placebo; SDAI, Simplified Disease Activity Index.

SESSION INFORMATION
Session Date: Monday, November 8, 2021
Session Title: RA – Treatments Poster II: PROs, Biomarkers, & Systemic Inflammation (1223–1256)
Session Type: Poster Session C
Session Time: 8:30AM–10:30AM

Background/Purpose: RA is an inflammatory disease that results in pain and loss of function, especially in the hands and wrists. Brief self-assessment tools that can reliably and precisely quantify hand/wrist function are needed to assess inflammatory activity when a physical exam is not feasible and to capture day-to-day experience of living with RA. Neuro-QoL is part of the PROMIS family of self-report measures created using a patient-centred approach and IRT methodology. The Neuro-Qol Upper Extremity Function (UEF) scale measures ability across fine motor and ADLs involving digital, manual and reach-related function and self-care. Little is known about its performance in RA. Our goal was to evaluate the validity and responsiveness of the 8-item Neuro-QoL UEF in adults with RA and compare its performance with legacy measures of physical function. We hypothesized scores would be strongly (r >0.7) associated with MHAQ, MD-HAQ, and PROMIS PF, and moderately (r=0.4 to 0.7) with symptoms, disease activity, and QoL indicators, and be responsive to change in disease activity and PF.

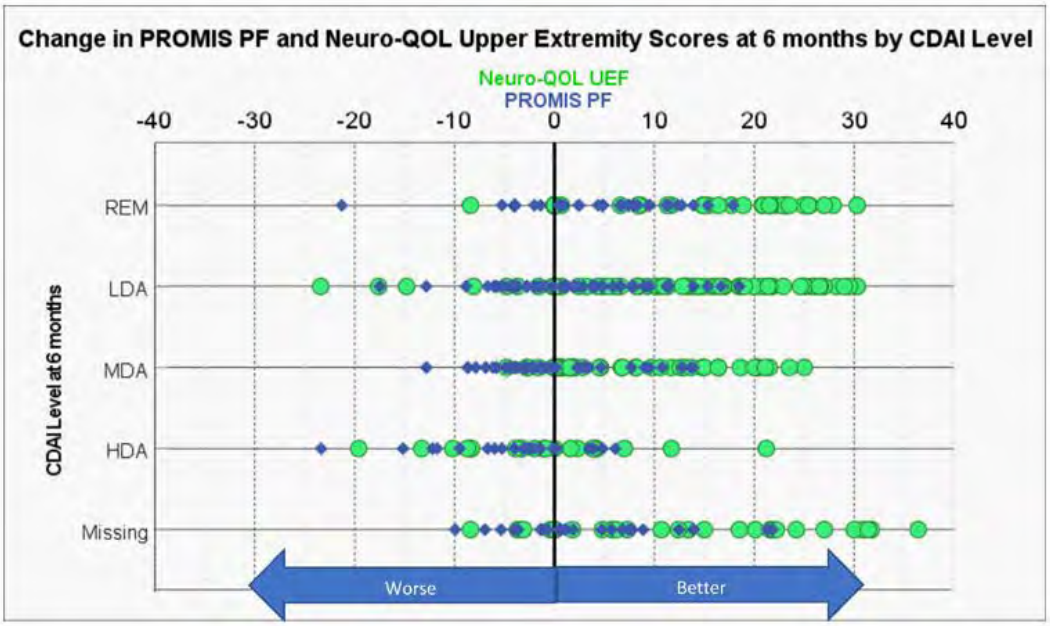
Methods: Data were from the 0 and 6-month visits of adults with early RA (symptoms < 1 yr) enrolled in the Canadian Early Arthritis Cohort, a prospective real-world study at 16 sites across Canada. Participants completed the Neuro-QoL UEF, MHAQ, MDHAQ, PROMIS-29, and PT Global at each visit. Rheumatologists recorded joint counts and

Table 1. Summary statistics of physical function and RA disease activity indices at 6 months

	Mean	SD	Mdn	25%	75%	(Min, Max)
Physical Function						
Neuro-Qol UEF	46.5	9.7	53.8	37.5	53.8	(21.8, 53.8)
MHAQ (0-3)	0.29	0.43	0.13	0.00	0.38	(0.00, 2.25)
MD-HAQ (0-10)	1.39	1.64	0.70	0.00	2.00	(0.00, 8.00)
PROMIS-PF	46.4	8.5	46.2	39.5	56.0	(23.3, 56.0)
RA Disease Activity						
CDAI	9.3	9.9	6.0	3.0	13.0	(0.0, 56.0)
SDAI	10.7	10.9	6.8	3.1	15.2	(0.0, 57.0)
Patient Global	3.0	2.5	3	1	5	(0, 10)
MD Global	1.8	2.2	1	0	3	(0, 9)
Swollen Joints (28)	2.1	3.7	0	0	2	(0, 20)
Tender Joints (28)	2.4	3.9	1	0	3	(0, 24)

Table 2. Mean scores (95% CI) at 6 months by CDAI level

	REM	LDA	MDA	HAD
NeuroQol UEF	52.8 (51.8, 53.7)	48.1 (46.6, 49.7)	42.0 (39.4, 44.6)	33.8 (30.5, 37.1)
MHAQ (0-3)	0.05 (0.02, 0.09)	0.19 (0.14, 0.24)	0.45 (0.34, 0.57)	0.90 (0.63, 1.17)
MD-HAQ (0-10)	0.31 (0.17, 0.46)	1.11 (0.90, 1.32)	2.15 (1.71, 2.59)	3.56 (2.56, 4.56)
PROMIS-PF	52.8 (51.4, 54.2)	46.8 (45.3, 48.2)	42.3 (40.4, 44.2)	38.0 (34.4, 41.6)



MD Global. To evaluate content validity, we examined descriptive statistics across CDAI disease activity levels, and Pearson correlations between the Neuro-QOL UEF, legacy measures, CRP & ESR. Responsiveness was assessed by correlating change scores from visits 0-6 between Neuro-QoL UEF, disease activity and legacy PF scores.

Results: The 262 participants were mostly white (83%) women (71%) with a mean (SD) age of 55 (13). Summary statistics at 6-months are shown in Table 1. Neuro-QOL UEF was moderately-strongly correlated with MHAQ, MDH-AQ, PROMIS-PF (|r|=0.63-0.75) and moderately correlated with pain and stiffness, (|r|=0.59, -0.64), and CDAI, SDAI,

Patient & MD Global, TJ & SJ (|r|=0.39-0.58). Neuro-QOL UEF was moderately correlated with PROMIS QoL domains Pain, Fatigue, Anxiety, Depression, Sleep & Participation (|r|=0.39-0.60).

Neuro-QOL scores decreased in a dose-response manner across worsening CDAI DA states reflecting increasing impairment (Table 2). Persons with HDA reported the highest disability, scoring nearly 0.5 SD lower on the Neuro-QoL UEF than PROMIS PF. Change from baseline to 6 months in Neuro-QoL UEF was moderately correlated with changes in PROMIS PF, MHAQ, Patient Global, and CDAI (|r|=0.44-0.65). The mean change and range from 0-6 months in Neuro-QoL was significantly larger than in PROMIS (8.9 [95% CI 7.5, 10.4] vs. 5.4 [95% CI 4.4, 6.4])(see Figure).

Conclusion: Clinicians, researchers, and patients benefit from practical self-report tools that reliably and precisely monitor hand function in RA. Results offer initial evidence of validity and responsiveness and support use of Neuro-QoL UEF to self-assess inflammatory activity in the hands and day-to-day experiences of living with RA.

Clinical Predictors of Response to Methotrexate in Patients with Rheumatoid Arthritis: A Machine Learning Approach Using Clinical Trial Data

Stephanie Duong[1], Cynthia Crowson[2], Elizabeth Atkinson[1], Arjun Athreya[1], John Davis[1], Eric Matteson[3], Richard Weinshilboum[1], Liewei Wang[1] and Elena Myasoedova[1], [1]Mayo Clinic, Rochester, MN, [2]Mayo Clinic, Eyota, MN, [3]Mayo Clinic College of Medicine and Science, Rochester, MN

SESSION INFORMATION
Session Date: Monday, November 8, 2021
Session Title: RA – Treatments Poster II: PROs, Biomarkers, & Systemic Inflammation (1223–1256)
Session Type: Poster Session C
Session Time: 8:30AM–10:30AM

Background/Purpose: Methotrexate (MTX) is the preferred initial disease-modifying drug (DMARD) for rheumatoid arthritis (RA). However, up to 50% of patients respond inadequately to MTX. Clinically useful predictors that effectively identify patients with RA who are likely to respond to MTX are lacking. We aimed to identify clinical predictors of response to MTX among DMARD-naïve patients with RA using machine learning methods.

Methods: Using the resources of the Clinical Study Data Request Consortium (CSDR) we identified 14 randomized clinical trials (RCT) involving 3,003 patients with RA who were randomized to MTX monotherapy or placebo plus MTX. Data were accessed through the Vivli Center for Global Clinical Research Data. Studies with available Disease Activity Score with 28-joint count (DAS28) at baseline, 12 and 24 weeks were included, resulting in exclusion of one RCT. Patients on prior conventional or biologic DMARDs were excluded. Latent class mixed modeling of response to MTX was applied. Patient groups with similar trajectories were compared by pretreatment baseline characteristics: socio-demographics (age, sex, race), baseline DAS28 with erythrocyte sedimentation rate [ESR] and its individual parameters, C-reactive protein, 66 swollen joint count (SJC66), 68 tender joint count (TJC68), RA duration, baseline use of glucocorticoids, health assessment questionnaire [HAQ] score, and serologic status (positive for rheumatoid factor [RF] or anticitrullinated protein antibodies [ACPA]). Proximity imputation was used to impute missing values. Lasso analysis and random forests were used to identify predictors of MTX treatment response. RCT study indicators were included in the model to adjust for heterogeneity among studies.

Results: A total of 1,478 DMARD-naïve patients from 13 RCTs were included. Mean age 50.5 years, 79% female, 84% RF positive, 87% ACPA positive, median RA duration 1.9 years, mean baseline DAS28-ESR 6.7, mean baseline HAQ 1.6. We identified 3 trajectory groups of response to MTX based on mean change in DAS28-ESR between baseline and 24 weeks: Class 1, “responders”, >1.2 unit change per 3 months; Class 2 and 3 “non-responders” < 1.2 unit change per 3 months in each. Using Lasso methods, RA duration, baseline DAS28-ESR, ESR, CRP, SJC66, age, and patient global assessment of disease activity (PtGA) were important predictors of response to MTX. The discrimination of responders from non-responders was acceptable: area under the curve (AUC) 0.70. Concordantly, using Random forests, the top five predictors of response to MTX were baseline DAS28-ESR, RA duration, SJC66, TJC68 and PtGA (AUC 0.69). Sex, race, HAQ score, seropositivity and use of glucocorticoids were not predictive of response to treatment with MTX.

Conclusion: Several baseline clinical characteristics, including DAS28-ESR, RA duration, PtGA, SJC66 were predictive of response to MTX and should be considered during the decision-making when initiating MTX in DMARD-naïve patients with RA.

Session Title: RA – Treatments Poster II: PROs, Biomarkers, & Systemic Inflammation (1223–1256)

Session Type: Poster Session C

Session Time: 8:30AM–10:30AM

Background/Purpose: A treat-to-target approach for RA management is recommended, with the aim of achieving remission.[1,2] The Abatacept SubCutaneOus in Routine clinical practicE (ASCORE; NCT02090556) study assessed efficacy and safety of subcutaneous (SC) abatacept for the treatment of patients with moderate-to-severe active RA; month 12 retention and clinical response rates were better in patients receiving abatacept as a first- versus later-line biologic (b)DMARD.[3] This post hoc analysis of ASCORE investigated the association of baseline variables with the achievement of DAS28 (CRP), Simplified Disease Activity Index (SDAI), and Clinical Disease Activity Index (CDAI) remission following treatment with SC abatacept in patients with RA.

Methods: Patients from ASCORE (recruited between February 2013 and April 2017) who initiated SC abatacept 125 mg once weekly were included. Analysis of baseline factors predictive of DAS28 (CRP; < 2.6), SDAI (≤ 3.3), and CDAI (≤ 2.8) remission at month 12 was conducted by treatment line (first- and ≥ second-line) and in the overall population. Variables found to be significant ($P < 0.2$) in univariate logistic regression analysis were selected as covariates in a multivariate backward elimination logistic regression model. Odds ratios (95% confidence intervals) and *P* values were calculated. Standardized values were used for the continuous baseline predictors.

Results: Overall, 2892 patients were included (first-line, n = 1198; ≥ second-line, n = 1694). Baseline mean (standard deviation) age was 57.7 (12.7) years, BMI was 27.2 (5.8) kg/m^2, and HAQ-disability index (DI) score was 1.4 (0.7); 78.6% were female, 61.7% were double seropositive (RF+ and ACPA+), and 18.6% were either RF+ or ACPA+. For patients treated with abatacept as first-line therapy, double/single seropositivity (vs negativity) was a predictor of

All variables with $P \leq 0.05$ are shown.
[a]Overall, country was shown to impact remission however the OR varied by individual countries; [b]Related or not related to RA; [c]Voluntarily not in employment; [d]Including looking for a position; [e]Continuous variables were standardized prior to multivariate analysis; [f]Inverted directionality versus univariate analysis due to interaction between variables in the multivariate model.
CDAI, Clinical Disease Activity Index; CI, confidence interval; HAQ-DI, HAQ-disability index; OR, odds ratio; SDAI, Simplified Disease Activity Index.

CDAI (**Figure 1**) and SDAI remission (**Figure 2**). For patients treated with abatacept as ≥ second-line therapy, double seropositivity (vs negativity) was a predictor of DAS28 (CRP) (**Figure 3**), SDAI, and CDAI remission. For the overall population, double/single seropositivity (vs negativity) was a predictor of DAS28 (CRP), SDAI, and CDAI remission. Active (vs inactive) employment status, low BMI, no previous bDMARD use, and low HAQ-DI were predictive of achieving remission in the overall population.

Conclusion: In this post hoc analysis of the real-world ASCORE study, several baseline characteristics were associated with remission in patients with RA treated with SC abatacept. Patients with seropositive RA, no previous bDMARD use, low HAQ-DI, and low BMI at baseline were more likely to achieve remission when treated with abatacept. Seropositivity was associated with remission regardless of abatacept treatment line. Early identification of patients with seropositive RA may facilitate a precision medicine approach to treatment.

Does BMI Influence the Efficacy of Subcutaneous or Intravenous Abatacept in Patients with RA in Routine Clinical Practice? A Post Hoc Analysis of Two Real-world Observational Studies

Rieke Alten[1], Xavier Mariette[2], Melanie Chartier[3], Christiane Rauch[4], Yedid Elbez[5], Karissa Lozenski[6] and Vadim Khaychuk[6], [1]Schlosspark-Klinik University, Berlin, Germany, [2]Université Paris-Saclay, AP-HP, Hospital Bicêtre, Paris, France, [3]Bristol Myers Squibb, Rueil-Malmaison, France, [4]Bristol Myers Squibb, Munich, Germany, [5]Deepscover, Puteaux, France, [6]Bristol Myers Squibb, Princeton, NJ

SESSION INFORMATION
Session Date: Monday, November 8, 2021
Session Title: RA – Treatments Poster II: PROs, Biomarkers, & Systemic Inflammation (1223–1256)
Session Type: Poster Session C
Session Time: 8:30AM–10:30AM

Background/Purpose: BMI has been shown to affect treatment response and may influence the development of optimal individualized treatment plans in patients with RA.[1] The extent to which treatment response is influenced by BMI varies across biologic DMARDs and may be associated with mechanism of action.[1] We evaluated the impact of BMI on disease activity scores in patients receiving intravenous (IV) or subcutaneous (SC) abatacept as reported in the real-world AbataCepT In rOutiNe clinical practice (ACTION)[2] and Abatacept SubCutaneOus in Routine Clinical PracticE (ASCORE)[3] studies in order to determine the impact of BMI on abatacept efficacy.

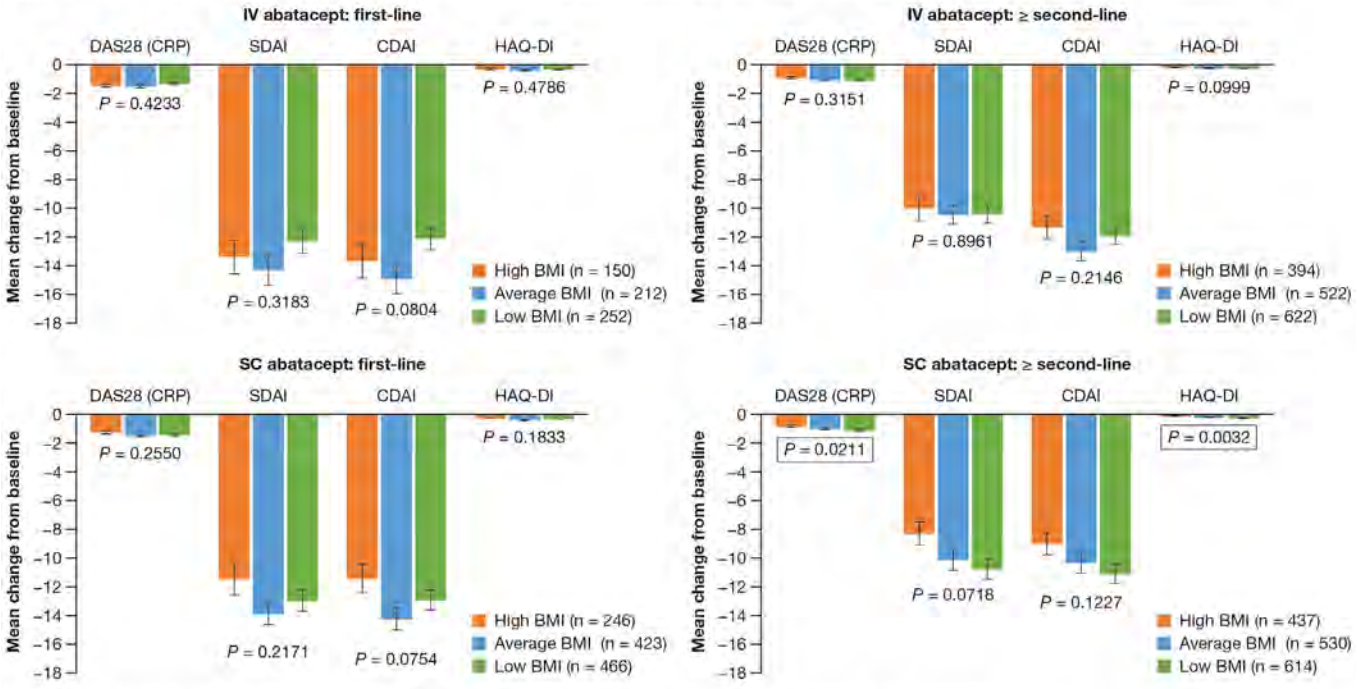
Methods: ACTION (NCT02109666) and ASCORE (NCT02090556) were international observational studies of patients with moderate-to-severe RA receiving IV (body weight–adjusted dosing) or SC (fixed dosing at 125 mg once weekly) abatacept, respectively, over 2 years.[2,3] In this post hoc analysis, patients were stratified by baseline BMI (high, ≥ 30 kg/m^2; average, 25–< 30 kg/m^2; low, < 25 kg/m^2); patients were also stratified by abatacept treatment

Table 1. Baseline disease activity scores (all patients)

	IV abatacept			SC abatacept		
	High BMI (n = 544)	Average BMI (n = 734)	Low BMI (n = 874)	High BMI (n = 683)	Average BMI (n = 953)	Low BMI (n = 1080)
DAS28 (CRP)	5.12 (1.05)	4.95 (1.10)	4.82 (1.13)	4.92 (1.10)	4.70 (1.17)	4.51 (1.16)
SDAI	32.43 (12.93)	31.07 (13.17)	29.40 (12.91)	29.67 (12.78)	27.64 (12.99)	26.36 (12.42)
CDAI	30.82 (12.51)	29.40 (12.54)	27.52 (11.94)	28.24 (12.45)	26.25 (12.42)	25.00 (11.87)
HAQ-DI	1.59 (0.65)	1.46 (0.69)	1.37 (0.67)	1.61 (0.69)	1.37 (0.72)	1.24 (0.72)

Data are presented as mean (SD). BMI groups are defined as high, ≥ 30 kg/m^2; average, 25–< 30 kg/m^2, and low, < 25 kg/m^2.
CDAI, Clinical Disease Activity Index; HAQ-DI, HAQ-disability index; IV, intravenous; SC, subcutaneous; SD, standard deviation; SDAI, Simplified Disease Activity Index.

Figure 1. Mean change from baseline disease activity at 12 months in patients receiving IV or SC abatacept by treatment line



BMI groups are defined as high, ≥ 30 kg/m^2; average, 25–< 30 kg/m^2; and low, < 25 kg/m^2. Patients with missing data for baseline BMI are excluded.
Last observation carried forward imputation method was applied for missing data. *P* value is from an ANOVA test comparing the three BMI groups.
CDAI, Clinical Disease Activity Index; HAQ-DI, HAQ-disability index; IV, intravenous; SC, subcutaneous; SDAI, Simplified Disease Activity Index; SE, standard error.

line (first-line; ≥ second line; all patients). Assessments were performed at month (M)6 and M12 and included mean (standard error) change from baseline in DAS28 (CRP), Clinical Disease Activity Index, Simplified Disease Activity Index, and HAQ-disability index (DI) scores. A last observation carried forward imputation method was applied for missing data. Differences between the three BMI categories were assessed using ANOVA test.

Results: 4868 patients were evaluated. Patient numbers and baseline disease activity scores were similar across BMI groups in both studies. Most patients had low BMI at baseline (**Table 1**). In patients receiving IV abatacept, there were no significant M12 differences across BMI groups for mean change from baseline across all measures of disease activity and physical function (HAQ-DI) in both treatment lines (**Figure 1**). In patients receiving SC abatacept, there were no significant M12 differences across BMI groups for mean change from baseline across all measures of disease activity and HAQ-DI in the first-line treatment group. However, in the ≥ second-line treatment group, significant differences across BMI groups were recorded for DAS28 (CRP) (P = 0.0211) and HAQ-DI scores (P = 0.0032).

Conclusion: BMI status did not significantly impact clinical efficacy in patients treated with IV abatacept. There were no significant differences between BMI categories for patients receiving IV abatacept as first- or ≥ second-line therapy. For SC abatacept, no significant differences across BMI groups were seen in the first-line group, but significant differences were seen in for DAS28 (CRP) and HAQ-DI scores in the ≥ second-line group. While results from clinical trials have shown that BMI has no impact on abatacept clinical efficacy, BMI was shown to significantly impact clinical responses in patients receiving abatacept as ≥ second- line therapy in a real-world observational setting.

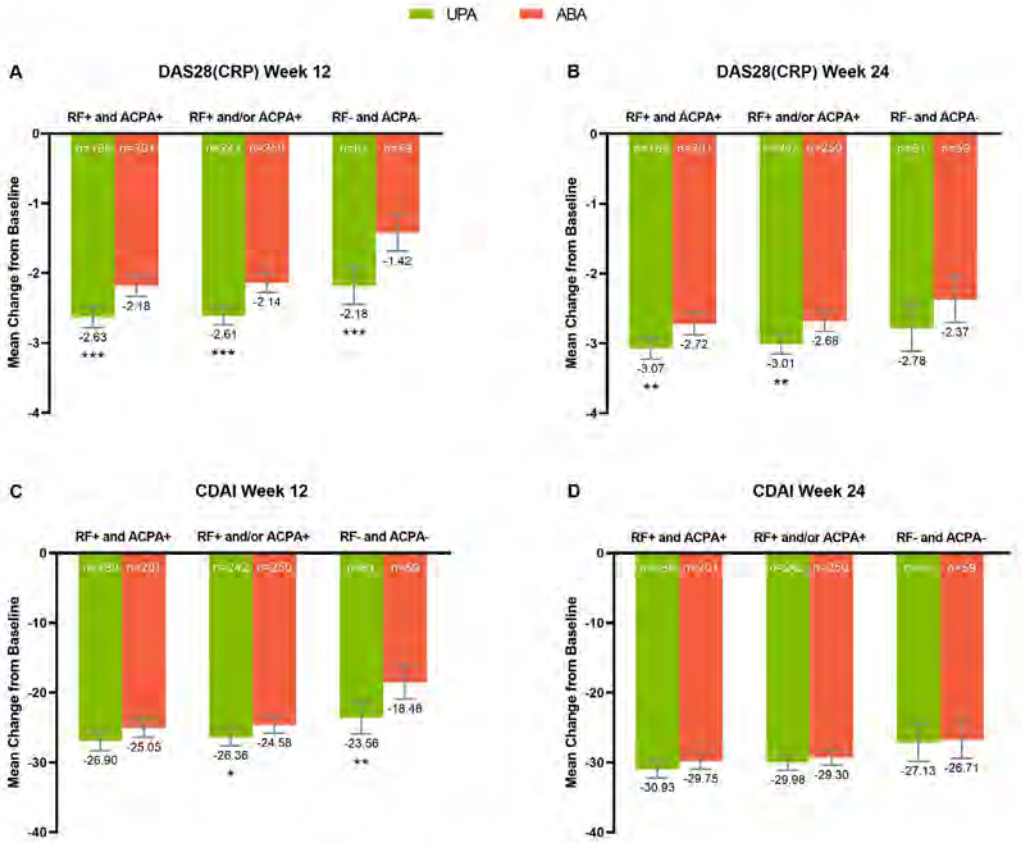
Session Title: RA – Treatments Poster II: PROs, Biomarkers, & Systemic Inflammation (1223–1256)
Session Type: Poster Session C
Session Time: 8:30AM–10:30AM

Background/Purpose: In patients with RA who had a prior inadequate response or intolerance to biologic DMARDs, the oral Janus kinase inhibitor, upadacitinib (UPA), demonstrated superiority in change from baseline in DAS28(CRP) and DAS28(CRP)< 2.6 at week 12 and improved responses across additional endpoints compared to abatacept (ABA) in the phase 3 SELECT-CHOICE study.[1] Seropositive patients have been reported to respond better to treatment than seronegative patients;[2] therefore, the objective of this sub-group analysis was to evaluate clinical responses with UPA versus ABA among RA patients based on serologic status.

Methods: In SELECT-CHOICE (24-week, phase 3, double-blind, controlled trial), RA patients were randomized to oral UPA (15 mg once daily) or intravenous (IV) ABA (at day 1 and weeks 2, 4, 8, 12, 16, and 20; < 60 kg, 500 mg; 60-100 kg, 750 mg; >100 kg, 1000 mg).[1] UPA patients also received IV placebo and ABA patients also received oral placebo. All patients continued stable background conventional synthetic DMARDs. Starting at week 12, background RA medications were adjusted or added if patients did not experience ≥20% improvement compared to baseline in tender and swollen joint counts at two consecutive visits. For this sub-group analysis, patients were categorized as follows: RF+ and ACPA+, RF+ and/or ACPA+, and RF- and ACPA-. Mean change from baseline in DAS28(CRP), Clinical Disease Activity Index (CDAI), ACR responses, HAQ-DI, patient's assessment of pain, and Functional Assessment

Figure: Mean Change from Baseline in DAS28(CRP) and CDAI with UPA 15 mg or ABA Across Serologic Status Sub-Groups at Weeks 12 (A, C) and 24 (B, D)†



ABA, abatacept; ACPA, anti-cyclic citrullinated peptide antibodies; CDAI, Clinical Disease Activity Index; DAS28(CRP), 28-joint Disease Activity Score based on C-Reactive Protein; RF, rheumatoid factor; UPA, upadacitinib

*P<0.05; **P<0.01; ***P<0.001 UPA vs. ABA; nominal P-values are presented and were not adjusted for multiple comparisons
†Multiple imputation was used for missing data; LS means with 95% confidence intervals are shown

of Chronic Illness Therapy - Fatigue scale (FACIT-F) were evaluated at weeks 12 and 24. Statistical inference was conducted using Chi-square tests or analysis of covariance (ANCOVA) with non-responder imputation or multiple imputation used for missing data and nominal *P*-values shown.

Results: Of the total population (N=612), the majority of patients were seropositive for RF and/or ACPA at baseline (80.4%) (**Table**). Most patients were female (~80%), ~55 years old, and one-third had previously experienced ≥2 biologic DMARDs. Mean change from baseline in DAS28(CRP) and CDAI were numerically higher with UPA vs ABA at weeks 12 and 24 across all sub-groups (**Figure**). Regardless of serologic status, UPA demonstrated numerically higher responses vs ABA for ACR 20/50/70 and proportions of patients in low disease activity and remission at both timepoints (**Table**). Mean change from baseline in the HAQ-DI and the patient's assessment of pain was numerically higher with UPA compared to ABA across all sub-groups and timepoints. Clinical responses were generally numerically higher at week 24 compared to week 12, and for the seropositive groups compared to the seronegative group, with both UPA and ABA.

Conclusion: Across serologic statuses, clinical responses with UPA 15 mg vs ABA were numerically higher at weeks 12 and 24 among RA patients with prior inadequate response or intolerance to biologic DMARDs. In addition, clinical responses were numerically higher for seropositive patients compared to seronegative patients across all endpoints assessed, although the seronegative group had a smaller sample size in this post-hoc analysis.

SESSION INFORMATION
Session Date: Monday, November 8, 2021
Session Title: RA – Treatments Poster II: PROs, Biomarkers, & Systemic Inflammation (1223–1256)
Session Type: Poster Session C
Session Time: 8:30AM–10:30AM

Background/Purpose: Biomarkers play an important role in RA and can help guide treatment decisions. Previous studies have suggested differential treatment efficacy of abatacept (ABA) in patients with biomarker-seropositive RA,[1–4] including differential treatment impact of ABA on ACR20/50/70 among patients with SeroPositive Early & Active RA (SPEAR) in historic randomized controlled trials (RCTs).[5] In this study, we analyzed clinical outcomes among patients with SPEAR and non-SPEAR to understand the differential treatment impact of ABA on each ACR core measure.

Methods: Individual patient data (IPD) from 2087 patients in 4 phase 3, early RA ABA RCTs (AGREE [NCT00122382], AMPLE [NCT00929864], AVERT [NCT01142726], AVERT-2 [NCT02504268]) were pooled. Patients were classified as SPEAR at baseline if they: 1) were RF+ and ≥ 3 times the upper limit of normal on an anti-CCP test (ACPA+), 2) had a disease duration ≤ 12 months, and 3) had DAS28 (CRP) ≥ 3.2. Patients were treated with either ABA (monotherapy or with MTX) or a comparator (MTX or adalimumab + MTX). Outcomes of interest included mean change from baseline to week 24 in ACR core measures (e.g., HAQ-DI score, CRP value, patient global assessment). IPD mixed-effects regressions for each outcome used trial fixed effects, baseline measures of the outcome, and SPEAR status as covariates in the ABA-treated population. In the analysis of the full population, treatment type was added as well as an interaction term of treatment type and SPEAR status. Sensitivity analyses using an alternative SPEAR definition restricted to criterion 1 were also conducted.

[a]Comparators included MTX and adalimumab + MTX.

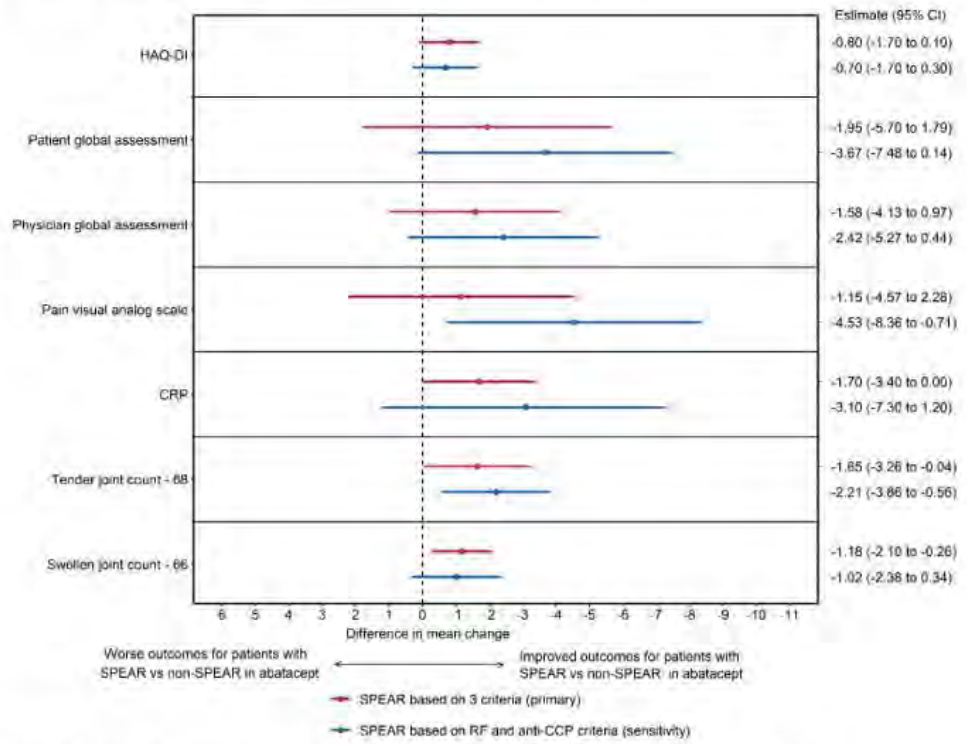
[b]All patients (N = 2057); patients with SPEAR on abatacept (n = 773); patients with SPEAR on comparators (n = 531); patients with non-SPEAR on abatacept (n = 383); patients with non-SPEAR on comparators (n = 370).

SPEAR, SeroPositive Early & Active RA.

Results: A total of 1328 (64%) SPEAR and 759 (36%) non-SPEAR were included. For patients with non-SPEAR, around half were RF+ and three-quarters were ACPA+, while DAS28 (CRP) was high for all patients (**Table 1**). Among ABA-treated patients, outcomes were more favorable for patients with SPEAR compared to patients with non-SPEAR across all outcomes, either statistically or directionally (**Figure 1**). The differences in outcomes between patients with SPEAR vs non-SPEAR were larger for ABA than for comparators across all outcomes with the exceptions of HAQ-DI and pain, where the differences continued to be directionally favorable for ABA (**Figure 2**). The results were consistent in the sensitivity analysis.

Conclusion: This study compared clinical outcomes of patients with enriched autoantibody biomarkers and early RA (SPEAR) to patients with non-SPEAR and found a differential treatment impact of abatacept across all ACR core measures in the RCTs analyzed. These findings corroborate prior studies and further suggest that the differential treatment impact of abatacept is not limited to a subset of core measures but affects all dimensions including laboratory values, joint counts, functional status, patient reported outcomes, and physician global assessment.

Figure 1. Comparison of mean change from baseline to week 24 in ACR core measures between SPEAR vs non-SPEAR groups among patients receiving abatacept



HAQ-DI and CRP were rescaled to 0.1 points and mg/10ml, respectively, for visual clarity.

ABA, abatacept; SPEAR, SeroPositive Early & Active RA.

Patients were classified as SPEAR at baseline if they: 1) were RF+ and $\geq$ 3 times the upper limit of normal on an anti-CCP test (ACPA+), 2) had a disease duration $\leq$ 12 months, and 3) had DAS28 (CRP) $\geq$ 3.2.

Synovial Tissue Lymphoid Aggregates Are Associated with Response to Rituximab Therapy in Rheumatoid Arthritis Patients

Matthew Turk[1], Candice Low[2], Carl Orr[3], Richard Conway[4], Kieran Murray[5], Ursula Fearon[6] and Douglas Veale[7], [1]St. Vincents University Hospital, Dublin, Ireland, [2]St. Vincent's University Hospital, Dublin, Ireland, [3]St Vincent's Hospital, Dublin, Ireland, [4]St. James's University Hospital, Dublin, Ireland, [5]Saint Vincent's University Hospital, Dublin, Ireland, [6]Trinity College Dublin, Dublin, Ireland, [7]University College Dublin, Dublin, Ireland

SESSION INFORMATION

Session Date: Monday, November 8, 2021
Session Title: RA – Treatments Poster II: PROs, Biomarkers, & Systemic Inflammation (1223–1256)
Session Type: Poster Session C
Session Time: 8:30AM–10:30AM

Background/Purpose: Activated B lymphocytes and plasma cells are implicated in the pathogenesis of rheumatoid arthritis (RA). The anti-CD20 monoclonal antibody therapy (Rituximab) is an effective therapy in some RA patients. The goal of this study was to evaluate the clinical and laboratory factors associated with long-term responses to Rituximab therapy in patients with RA.

Methods: One hundred and fourteen RA patients received Rituximab (1g doses x 2, 2 weeks apart), at a single centre, between 2003-2016. Prior to treatment, arthroscopy and synovial biopsy was performed on patients in this cohort who had active knee arthritis. Demographic, clinical and outcome data were collected prospectively and immunohistology was subsequently performed on synovial tissue biopsies. Clinical and laboratory outcomes were evaluated using linear and binary logistic regression.

Results: The median (IQR) disease duration was 13.5 (7, 24.3) years. The number of prior csDMARDs was 1 (0, 2), and biologic DMARD was 1 (0, 2). Rituximab monotherapy was used in 34 patients, while 80 patients received rituximab-csDMARD combination therapy. Forty-four patients underwent an arthroscopy and synovial biopsy prior to treatment. Synovial tissue lymphoid aggregates (LA) were observed in 21 subjects, of which 17 (81%) showed complete or partial remission in response to treatment with Rituximab. The presence of LA was significantly associated with remission in these patients treated with rituximab (p=0.007, OR=7.286 [1.737-30.555]). A significant association was also shown between LA and CD138 plasma cell staining in the synovial biopsies ($p< 1.0x10^{-4}$, OR=22.667 [3.979-129.119]). 73% of patients were female, 85% were rheumatoid factor (RF) positive, 64% anti-citrullinated protein antibody (ACPA) positive, 59% double positive, and 11% seronegative. Rituximab treatment follow-up time had a median (IQR) of 3.1 (1.8, 6.1) years and median number of treatment courses was 3 (2, 5). Sixty-eight patients (60%) reached sustained remission, while 14 (12%) were primary non-responders, 25 (22%) were secondary non-responders, and 7 (6%) stopped due to adverse events. Twenty-six of the 68 patients in remission (38%) received Rituximab monotherapy and 42/68 (62%) received combination therapy with a csDMARD. Twenty-four of 39 (62%) biologic naïve patients achieved remission on treatment with rituximab. There was no significant association between any other clinical or laboratory markers and remission in patients treated with rituximab.

Conclusion: These data show significant evidence for lymphoid aggregates as a predictive marker for response to treatment with rituximab. Rituximab is an effective long-term treatment for RA, with high remission rates that are associated with synovial lymphoid aggregates.

Physician and Patient Reported Effectiveness Outcomes Are Similar in Tofacitinib and TNF Inhibitors in Rheumatoid Arthritis Patients: Data from a Rheumatoid Arthritis Registry in Canada

Mohammad Movahedi[1], Angela Cesta[2], Xiuying Li[2], Edward Keystone[3] and Claire Bombardier[4], [1]Toronto General Hospital Research Institute, University Health Network, Toronto, ON, Canada, [2]Toronto General Hospital Research Institute, UHN, Toronto, ON, Canada, [3]Keystone Consulting Enterprises Inc., Toronto, ON, Canada, [4]University of Toronto - Toronto, Toronto, ON, Canada

SESSION INFORMATION
Session Date: Monday, November 8, 2021
Session Title: RA – Treatments Poster II: PROs, Biomarkers, & Systemic Inflammation (1223–1256)
Session Type: Poster Session C
Session Time: 8:30AM–10:30AM

Background/Purpose: Tofacitinib (TOFA) is an oral, small molecule drug used for rheumatoid arthritis (RA) treatment as an alternative option to biologic disease modifying antirheumatic drugs (bDMARDs) including tumor necrosis factor inhibitors (TNFi). We aimed to evaluate physician and patient reported effectiveness outcomes in TNFi compared to TOFA, using real-world data from the Ontario Best Practices Research Initiative (OBRI).

Methods: RA patients enrolled in the OBRI initiating their TOFA or TNFi (Adalimumab, Certolizumab, Etanercept, Golimumab, Infliximab, and Biosimilars) between 1st June 2014 (TOFA approval date in Canada) and 31st Dec 2019 were included. Patients were required to have physician and patient reported effectiveness outcomes data available at treatment initiation and 6-month (± 2 months) follow-up. These included clinical disease activity index (CDAI), rheumatoid arthritis disease activity index (RADAI), HAQ-DI, sleep problem, and anxiety/depression scores. Multiple imputation (Imputation Chained Equation, N=20) was used to deal with missing data for covariates at treatment initiation. To deal with confounding by indication, we estimated propensity scores for covariates with an absolute standard difference greater than 0.1 between the two treatment groups.

Results: A total of 419 patients were included. Of those, 226 were initiating a TNFi and 193 TOFA, and had a mean (SD) disease duration of 8.0 (8.7) and 12.6 (9.6) years, respectively. In the TNFi group, 81.9% were female and mean age (SD) at treatment initiation was 56.6 (13.4) years. In the TOFA group, 85% were female and mean (SD) age at treatment initiation was 60.3 (11.2) years. The TNFi group was less likely to have prior biologic use (21.7%) compared to the TOFA group (67.9%). At treatment initiation, physical function measured by HAQ-DI was significantly lower in TNFi compared to the TOFA group (1.2 vs.1.4).

The rate of CDAI LDA/remission at 6 months was 33.6% and 26.4% in TNFi and TOFA group, respectively. The generalized linear mixed models (GLMM) adjusting for propensity score quantile, showed that there was no significant difference in CDAI LDA/remission (ORs: 0.85, 95% CI: 0.51, 1.43), RADAI (β-coefficient: 0.48, 95% CI: -0.18, 1.14), HAQ-DI (β-coefficient: -0.01, 95% CI: -0.18, 0.16), sleep problems (β-coefficient: -0.25, 95% CI: -0.95, 0.45), and anxiety/depression scores (β-coefficient: 0.12, 95% CI: -0.35, 0.58) between the two treatment groups (TOFA used as reference).

Conclusion: In this real-world data study, we found that, physician and patient reported effectiveness outcomes are similar in the TNFi and TOFA groups 6 months after treatment initiation in patients with RA.

Routine Assessment of Patient Index Data 3 (RAPID3) in Patients with Rheumatoid Arthritis Treated with Long-Term Upadacitinib Therapy

Martin Bergman[1], Maya Buch[2], Yoshiya Tanaka[3], Gustavo Citera[4], Sami Bahlas[5], Ernest Wong[6], Yanna Song[7], Namita Tundia[7], Jessica Suboticki[7] and Vibeke Strand[8], [1]Martin Jan Bergman, MD, Ridley Park, PA, [2]University of Leeds, Leeds, United Kingdom, [3]University of Occupational and Environmental Health, Kitakyushu, Japan, [4]Instituto de Rehabilitación Psicofísica, Buenos Aires, Argentina, [5]Medicine, King Abdulaziz University, Jeddah, Saudi Arabia, [6]Rheumatology, Queen Alexandra Hospital, Portsmouth, United Kingdom, [7]AbbVie Inc., North Chicago, IL, [8]Stanford University School of Medicine, Portola Valley, CA

SESSION INFORMATION

Session Date: Monday, November 8, 2021

Session Title: RA – Treatments Poster II: PROs, Biomarkers, & Systemic Inflammation (1223–1256)

Session Type: Poster Session C

Session Time: 8:30AM–10:30AM

Background/Purpose: Routine Assessment of Patient Index Data 3 (RAPID3) is a pooled index of 3 patient-reported measures: patient global assessment, pain, and physical function. RAPID3 was shown to correlate with other composite measures of disease activity[1] and is recommended by the American College of Rheumatology for use in clinical practice.[2] The objective of this analysis was to evaluate the impact of upadacitinib (UPA) versus comparators on RAPID3 over 60 weeks, as well as the correlation of RAPID3 scores with other disease measures in the UPA phase 3 SELECT clinical program.

Methods: This post hoc analysis included placebo-controlled (SELECT-NEXT, -BEYOND, and -COMPARE) and active comparator-controlled (SELECT-EARLY, -MONOTHERAPY, and -COMPARE) trials. Patients received UPA as monotherapy or in combination with conventional synthetic disease-modifying antirheumatic drugs (csDMARDs). Mean change from baseline in RAPID3 and the proportion of patients reporting RAPID3 remission (≤3), low (LDA, >3 to ≤6), moderate (MDA, >6 to ≤12), and high disease activity (HDA, >12) were assessed. Correlations between absolute scores for RAPID3 and Clinical Disease Activity Index (CDAI), Simplified Disease Activity Index (SDAI), and 28-joint Disease Activity Score with C-reactive protein (DAS28[CRP]) were assessed using Spearman correlation coefficients. All data are as observed.

Results: A total of 661, 498, 648, 1629, and 945 patients were included from SELECT-NEXT, -BEYOND, -MONOTHERAPY, -COMPARE, and -EARLY. At baseline, the majority of patients across all studies were in RAPID3 HDA (mean baseline RAPID3 [across all studies], 17.2–19.2) (**Table** and **Figure**). Improvements from baseline in RAPID3 were observed with UPA 15 mg and 30 mg through Week 60, with numerically greater improvements observed with UPA compared with active comparators (**Table**). Across studies, mean improvements in RAPID3 exceeded the minimal clinically important difference (MCID) with UPA and adalimumab (ADA) treatment (MCID=3.8[3]). By Week 60, approximately one-half of UPA-treated patients were in RAPID3 remission or LDA, with only 10–25% remaining in HDA, except for the more refractory population in SELECT-BEYOND, in which ~38% of patients remained in

Table Change from BL in RAPID3 at Week 60 (as observed)

Phase 3 study	Group	n[a]	Mean (SD) BL score	Mean (SD) change from BL[b]
SELECT-EARLY[c] (MTX-naïve)	MTX	236	18.5 (5.6)	−9.6 (7.5)
	UPA 15 mg QD	269	18.9 (5.6)	−12.0 (7.6)
	UPA 30 mg QD	253	18.2 (5.6)	−13.4 (7.2)
SELECT-NEXT (csDMARD-IR)	UPA 15 mg QD	172	17.7 (5.1)	−11.1 (7.3)
	UPA 30 mg QD	172	17.6 (5.3)	−10.4 (6.8)
SELECT-MONOTHERAPY (MTX-IR)	UPA 15 mg QD	172	17.4 (5.8)	−9.6 (7.4)
	UPA 30 mg QD	180	17.2 (5.9)	−10.6 (7.2)
SELECT-COMPARE[c] (MTX-IR)	UPA 15 mg QD	552	18.5 (5.5)	−10.2 (7.1)
	ADA 40 mg EOW	264	18.7 (5.4)	−8.8 (6.7)
SELECT-BEYOND (bDMARD-IR)	UPA 15 mg QD	133	19.2 (5.1)	−8.6 (6.8)
	UPA 30 mg QD	118	18.5 (5.3)	−9.3 (7.3)

b, biologic; BL, baseline; EOW, every other week; IR, inadequate response; MTX, methotrexate; QD, once daily; SD, standard deviation

[a]Number of patients with RAPID3 values at both BL and Week 60. [b]Negative values indicate improvement from BL. [c]Observed data include patients rescued to UPA and/or ADA; treatment effect may include both the randomized and switch treatments in these patients

HDA (**Figure**). RAPID3 scores moderately to strongly correlated with CDAI (ρ=0.69–0.83), SDAI (ρ=0.69–0.82), and DAS28(CRP) (ρ=0.58–0.77), across all studies, at Week 60 (all $p< 0.001$).

Conclusion: UPA, as monotherapy or in combination with csDMARDs, was associated with improvements in patient-reported disease activity, pain, and physical function, as assessed by RAPID3 over 60 weeks in the phase 3 SELECT clinical program. RAPID3 continues to be an important tool in clinical practice to assess disease activity, as it was shown to correlate to other disease activity measures and allows for rapid scoring.

Treatment Effect of Baricitinib on Fatigue: Mediation Analysis Results from Two Phase 3 Trials

Bruno Fautrel[1], Bochao Jia[2], Jianmin Wu[3], Ju Ji[2], Julie Birt[2], Ewa Haladyj[2] and Tsutomu Takeuchi[4], [1]Pitié Salpêtrière Hospital, APHP, Sorbonne Université, Paris, France, [2]Eli Lilly and Company, Indianapolis, IN, [3]Eli Lilly and Company, Indianaplolis, IN, [4]Div. Rheumatology, Keio University, Tokyo, Japan

SESSION INFORMATION

Session Date: Monday, November 8, 2021

Session Title: RA – Treatments Poster II: PROs, Biomarkers, & Systemic Inflammation (1223–1256)

Session Type: Poster Session C

Session Time: 8:30AM–10:30AM

Background/Purpose: Fatigue is very common in rheumatoid arthritis (RA) and impairs patient quality of life. Baricitinib (BARI) improved fatigue, pain and other patient-reported outcomes (PROs) in patients with active RA and an inadequate response (IR) to conventional synthetic DMARDs (csDMARDs), or to ≥1 tumor necrosis factor inhibitors or other biological DMARDs (bDMARDs).[1-3] The aim of the current analysis was to investigate the effects of BARI on fatigue that are influenced by disease activity and those that are independent of disease activity in patients from the RA-BEAM and RA-BEACON trials.

Methods: Data were analyzed from two phase 3 studies, RA-BEAM (NCT01710358, methotrexate (MTX)-IR patients) and RA-BEACON (NCT01721044, bDMARD-IR patients). All trial patients had a diagnosis of adult-onset RA as defined by the ACR/EULAR 2010 Criteria for the Classification of RA.[4] Fatigue was assessed by the Functional Assessment of Chronic Illness Therapy-Fatigue scale (FACIT-F). In a mediation analysis, the dependent variable was the change from baseline to week 12, 16, 20 or 24 for FACIT-F. The treatment (BARI 4-mg vs. placebo (PBO) or adalimumab (ADA) vs. PBO) was the independent variable. Changes in Clinical Disease Activity Index (CDAI) from baseline to week 12, 16, 20 or 24 were used as the mediator variables. The total treatment effect on fatigue over PBO that can be accounted for by changes in CDAI is the "indirect" or mediation effect; whereas the total treatment effect that cannot be accounted for by the mediation effect is the "direct" effect. The random-intercept cross-lagged panel model (RI-CLPM) was applied for mediation analysis.[5]

Results: In MTX-IR patients (RA-BEAM trial), disease activity-mediated effect accounted for 50-60% of the fatigue improvement in both BARI 4-mg and ADA over PBO. The total effect, direct effect (i.e., those not associated with disease activity), and mediation effect of treatment on fatigue relief continuously increased in BARI 4-mg group from Week 12 to Week 24 (Table 1). Additionally, the total effect and mediation effect of BARI 4-mg over PBO on FACIT-F were numerically greater than that of ADA over PBO from Week 12 to 24. The direct fatigue relief effect of BARI 4-mg over placebo was significant starting Week 16, but that of ADA was not. In bDMARD-IR patients (RA-BEACON trial), about 20-30% of the effects of BARI 4-mg on FACIT-F were independent of disease activity.

Table 1: Mediation analysis results from RA-BEAM.

RA-BEAM	Week 12		Week 16		Week 20		Week 24	
	ADA vs PBO	BARI 4 mg vs PBO	ADA vs PBO	BARI 4 mg vs PBO	ADA vs PBO	BARI 4 mg vs PBO	ADA vs PBO	BARI 4 mg vs PBO

Conclusion: Irrespective of being MTX-IR or bDMARD-IR, BARI 4-mg had a proportion of effects on fatigue that were independent of disease activity in patients with active RA. The direct fatigue relief effect of BARI 4-mg over placebo was significant starting Week 16, whereas that of ADA was not.

Pain in Patients with Rheumatoid Arthritis Who Did or Did Not Achieve Treatment Response Based on Improvement in Swollen Joints with Baricitinib Clinical Trials

Anthony Sebba[1], Duzhe Wang[2], Bochao Jia[2], Jason Troutt[2], Julie Birt[2], Amanda Quebe[3] and Peter C Taylor[4], [1]Division of Rheumatology, University of South Florida, Tampa, FL, [2]Eli Lilly and Company, Indianapolis, IN, [3]Eli Lilly and Company, Indanapolis, IN, [4]University of Oxford, Oxford, United Kingdom

SESSION INFORMATION

Session Date: Monday, November 8, 2021
Session Title: RA – Treatments Poster II: PROs, Biomarkers, & Systemic Inflammation (1223–1256)
Session Type: Poster Session C
Session Time: 8:30AM–10:30AM

Background/Purpose: Baricitinib (BARI) is a Janus kinase (JAK)1/JAK2 inhibitor which provides improvements to clinical signs, symptoms, and patient-reported outcomes (PROs) in patients with rheumatoid arthritis (RA), with a notable effect on pain.[1,2,3] Pain in RA is multifactorial, with inflammation being an important, but not exclusive, cause.

Methods: Data for these analyses were derived from the Phase 3 study RA-BEAM (NCT01710358). Changes in pain from baseline to week (W)12 and W24 were evaluated using a 0-100 mm visual analog scale. To assess the relationship between pain and inflammation, results were compared between patients receiving BARI 4-mg + MTX and those receiving adalimumab (ADA) + MTX in both patients who achieved ≥ 50% improvement in swollen joint count (SJC) and those who did not at W12 and W24. At each visit, the analysis of covariance (ANCOVA) model was applied which includes the change from baseline of pain as the response variable and baseline pain, region, baseline joint erosion status, treatment, SJC 50% improvement subgroup and the interaction of treatment and subgroup as the explanatory variables. *P*-values were calculated for both treatment comparisons and the interaction term and were not adjusted for multiplicity.

Results: Consistent with previously reported clinical efficacy, most patients achieved SJC 50% improvement when treated with BARI + MTX (365/487, 74.9%) and ADA + MTX (228/330, 69.1%) at W12. For patients who did not achieve 50% improvement in SJC at W12, those treated with BARI 4-mg + MTX reported significantly greater improvements in pain (-24.3 vs -13.4, $p< 0.001$) than ADA + MTX (Fig 1A). This difference was not observed consistently in the group achieving SJC 50% (Fig 1B). The significant interaction test ($p=0.008$) between treatment and subgroup defined by SJC 50% improvement at W12 implies a differential effect of BARI on pain not associated with the improvement in inflammation. A similar trend was found at W24 (Fig 2). Additionally, at W12, the magnitude of pain reduction difference between BARI + MTX and ADA + MTX in the groups achieving or not achieving SJC 20% improvement was directionally similar to results using SJC 50% as the threshold, but this analysis is limited by small sample size in the non-responder group.

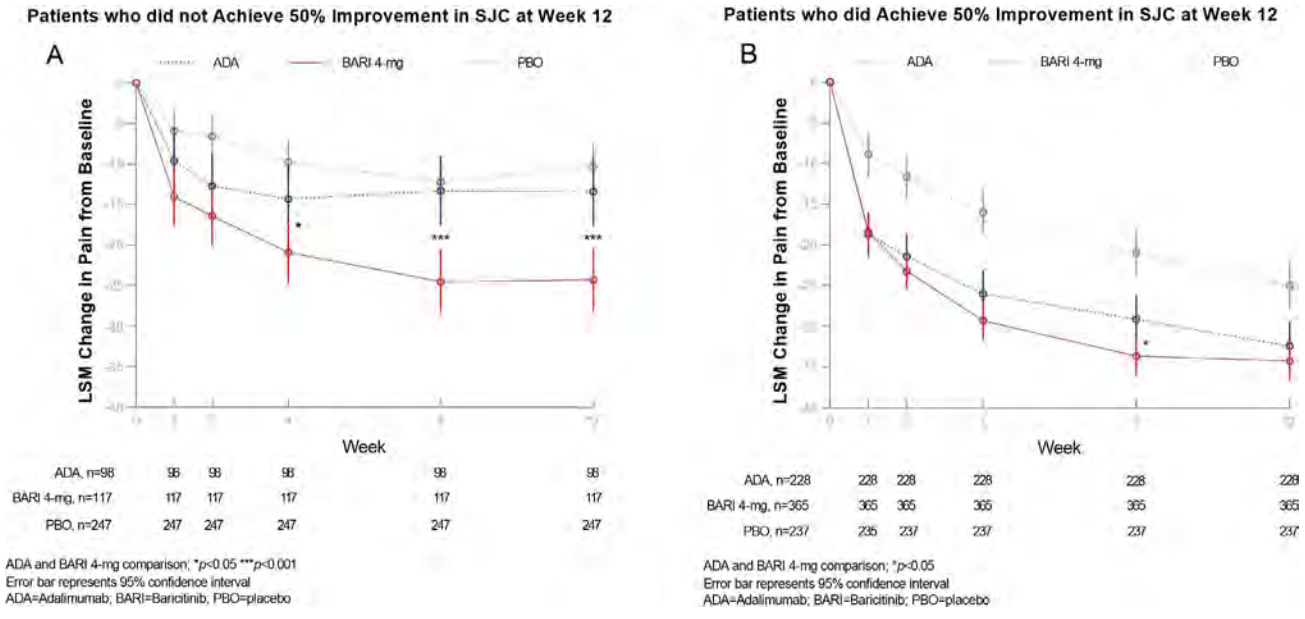

Figure 1. Least Square Mean Change in Pain Score from Baseline to Week 12.

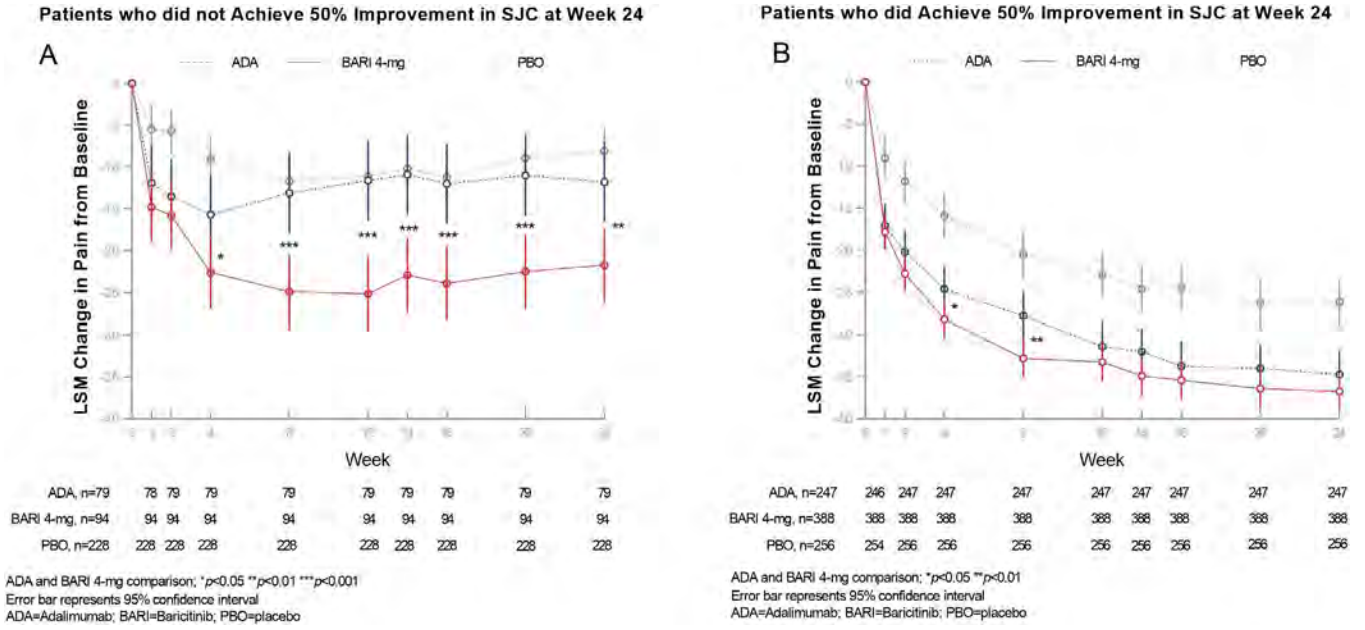

Figure 2. Least Square Mean Change in Pain Score from Baseline to Week 24.

Conclusion: BARI 4-mg + MTX treatment provided superior pain relief compared to ADA + MTX in patients with RA who did not achieve ≥ 50% improvement in SJC at W12 and W24. These results may point toward a differential effect of BARI on pain mediated outside of the inflammatory pathway.

SESSION INFORMATION

Session Date: Monday, November 8, 2021

Session Title: RA – Treatments Poster II: PROs, Biomarkers, & Systemic Inflammation (1223–1256)

Session Type: Poster Session C

Session Time: 8:30AM–10:30AM

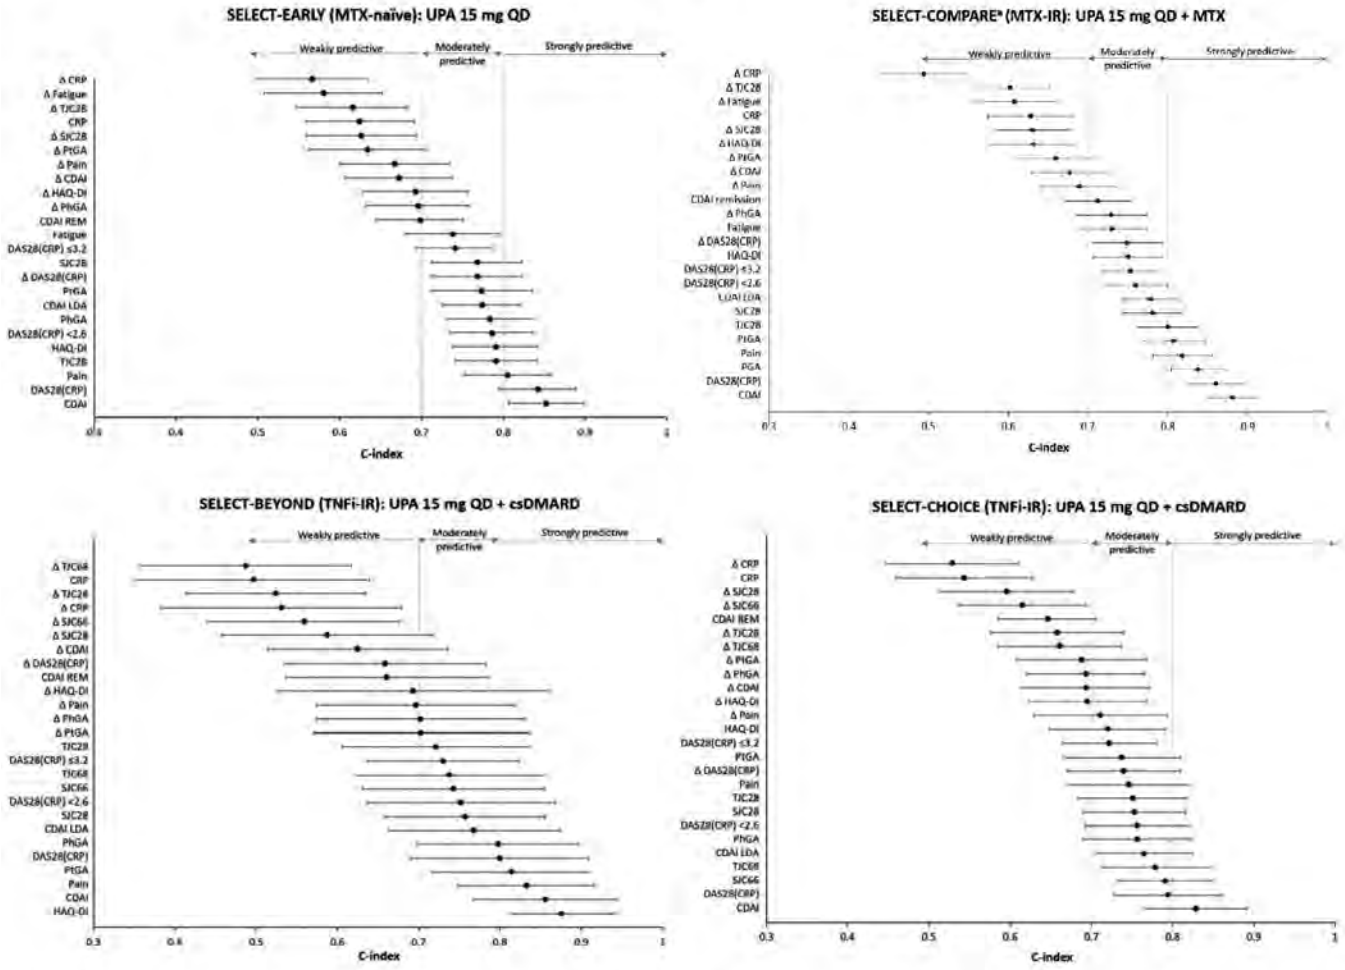
Background/Purpose: Early prediction of response to treatment with upadacitinib (UPA) 15 mg once daily (QD) could help optimize therapy in patients (pts) with RA.[1-4] The objective of this analysis was to identify baseline (BL) characteristics or Week (Wk) 12 disease activity measures that may predict the achievement of remission (REM) or low disease activity (LDA) at 6 months in pts with RA.

Table Achievement of CDAI LDA and REM at Wk 24/26[a]

	SELECT-EARLY	SELECT-COMPARE	SELECT-BEYOND	SELECT-CHOICE
Patient population	MTX-naïve	MTX-IR	TNFi-IR	TNFi-IR
Treatment	UPA 15 mg monotherapy (n=317)	UPA 15 mg + MTX (n=651)	UPA 15 mg + csDMARD (n=146)	UPA 15 mg + csDMARD (n=263)
Efficacy at Wk 24/26[a], n (%)				
CDAI REM (≤2.8)	90 (28.4)	150 (23.0)	16 (11.0)	60 (22.8)
CDAI LDA (≤10)	178 (56.2)	343 (52.7)	73 (50.0)	154 (58.6)

[a] Wk 26 for SELECT-COMPARE only

Figure Wk 12 predictors[a] for CDAI remission at Wk 24/26[b]



[a]Determined by a univariate logistic regression model. C-statistics provide a C-index value from 0.5 (chance prediction) to 1 (perfect prediction). Error bars indicate 95% CI. [b]Wk 26 for SELECT-COMPARE only.
CRP, C-reactive protein; DAS28(CRP), Disease Activity Score in 28 joints using C-reactive protein; HAQ-DI, Health Assessment Questionnaire-Disability Index; PhGA, Physician Global Assessment; PtGA, Patients Global Assessment; SJC28/66, swollen joint count in 28/66 joints; TJC28/68, tender joint count in 28/68 joints.

Methods: This ad hoc analysis included pts randomized to UPA 15 mg QD, as monotherapy in MTX-naïve pts (SELECT-EARLY) or in combination with conventional synthetic DMARDs (csDMARDs), in pts with inadequate response (IR) to MTX (SELECT-COMPARE) or ≥1 tumor necrosis factor inhibitors (TNFis) (SELECT-BEYOND and SELECT-CHOICE). Association of BL characteristics (age, disease duration, prior/concomitant treatments, C-reactive protein [CRP], seropositivity, and disease activity) and Wk 12 disease activity parameters with achievement of Clinical Disease Activity Index (CDAI) REM (≤2.8) or LDA (≤10) at Wk 24 (or Wk 26 in SELECT-COMPARE) was assessed by concordance statistics (C-statistics), or area under the receiver operator characteristic curve. C-index values and 95% confidence intervals were calculated by fitting a univariate logistic regression model for: demographic and BL characteristics, Wk 12 disease activity measures, and change from BL at Wk 12 in disease activity measures. A multivariate logistic regression with stepwise model selection was also performed. Proportion of pts achieving Wk 24/26 CDAI REM/LDA was stratified by ≥50% improvement from BL in swollen and/or tender joint count in 66/68 joints (SJC66/TJC68).

Results: A total of 1377 pts were included. Across the 4 studies, CDAI REM and LDA were achieved in 11.0–28.4% and 50.0–58.6% of pts, respectively (**Table**). BL demographics and disease characteristics were weakly predictive

(C-index < 0.70) of Wk 24/26 CDAI REM (C-index 0.49–0.69) or LDA (C-index 0.47–0.65), except for BL disability index of HAQ (HAQ-DI) in SELECT-BEYOND, which was moderately predictive of CDAI REM (C-index 0.73). Changes from BL in disease activity measures at Wk 12 were weakly or moderately predictive of Wk 24/26 CDAI REM (**Figure**) or LDA. CDAI value at Wk 12 was strongly predictive (C-index >0.80) of Wk 24/26 CDAI REM or LDA. Disease Activity Score in 28 joints using CRP and pain at Wk 12 were strongly predictive of Wk 24/26 CDAI REM (except in SELECT-CHOICE). Physician's global assessment at Wk 12 was the only common predictor in multivariate regression models for CDAI REM/LDA at Wk 24/26 across studies. Greater proportion of pts achieving ≥50% improvement in SJC66 and TJC68 at Wk 12 achieved CDAI REM (16.5–37.8% vs 0–9.4%) or LDA (66.0–72.8% vs 20.9–35.7%) at Wk 24/26 than those who did not.

Conclusion: BL characteristics did not strongly predict response to UPA, but composite disease activity scores at Wk 12 predicted Wk 24/26 REM/LDA with UPA 15 mg QD across MTX-naïve, MTX-IR, and TNFi-IR pts. ≥50% improvement in SJC/TJC at Wk 12 was also associated with Wk 24/26 REM/LDA.

SESSION INFORMATION

Session Date: Monday, November 8, 2021

Session Title: RA – Treatments Poster II: PROs, Biomarkers, & Systemic Inflammation (1223–1256)

Session Type: Poster Session C

Session Time: 8:30AM–10:30AM

Background/Purpose: According to ACR and EULAR recommendations, patients with rheumatoid arthritis (RA) who persist in remission (REM) should consider tapering RA therapy. Identification of clinical factors that are associated with a patient remaining in REM following tapering is of value. Since low disease activity (LDA) is an acceptable disease state, we utilized multivariate logistic regression to assess baseline (BL) factors associated with remaining in REM or LDA during methotrexate (MTX) monotherapy, etanercept (ETN) monotherapy, or combination therapy (combo).

Methods: SEAM-RA was a phase 3, multicenter, randomized withdrawal, double-blind, controlled study in patients with RA on MTX + ETN (combo) who had very good disease control for 6 months prior to study entry. If REM (primary endpoint, Simplified Disease Activity Index [SDAI] ≤3.3) was sustained through a 24-week open-label period, patients then entered a 48-week, double-blind period and were randomized 2:2:1 to receive MTX monotherapy, ETN monotherapy, or combo therapy. We evaluated >60 covariates in a step-wise approach to identify BL factors associated with REM or LDA at the end of 48 weeks without disease-worsening. A *P* value of ≤0.25 was required to enter the regression model, and covariates remained in the multivariate model if $P \leq 0.15$ or if commonly of clinical interest in studying RA. Interaction terms for all covariates per treatment arm were also assessed during variable selection to

Table 1. Multivariate logistic regression estimates for SDAI REM or LDA

BL Factor	Parameter Estimate (SE)	Odds Ratio [95% CI]	*P* Value

[a]Odds ratios for covariates that have interactions with others are evaluated in Table 2. **P* value based on Wald joint test. BL = baseline; BMI = body mass index; CCP = cyclic citrullinated peptide; Combo = MTX + ETN; CRP = C-reactive protein; ETN = etanercept; Mg = magnesium; MTX = methotrexate; PhGA = Physician Global Assessment of Disease Activity; PtGA = Patient Global Assessment of Disease Activity; RA = rheumatoid arthritis; RF = rheumatoid factor; SDAI = Simplified Disease Activity Index.

Table 2. Odds Ratios for SDAI REM or LDA for Covariates With Varying Magnitudes of Association Dependent on Treatment

BL Factor	Odds Ratio [95% CI]		
	MTX	ETN	Combo
1 unit (mg/dL) increase of Mg	0.18 [0.01, 5.14]	0.01* [<0.001, 0.18]	2.58 [0.08, 79.55]
0.1 unit (mg/dL) increase of Mg	0.84 [0.60, 1.18]	0.61* [0.50, 0.84]	1.10 [0.78, 1.55]
≤5 years with RA vs >5 years	5.28* [1.73, 16.05]	0.75 [0.24, 2.33]	1.67 [0.37, 7.63]

BL Factor	≤5 Years RA Odds Ratio [95% CI]	>5 Years RA Odds Ratio [95% CI]
ETN vs MTX at 1.6 mg/dL Mg	5.41 [0.33, 89.31]	38.09* [2.49, 583.16]
Combo vs MTX at 1.6 mg/dL Mg	0.43 [0.02, 8.70]	1.34 [0.08, 22.01]
ETN vs MTX at 2.1 mg/dL Mg	1.07 [0.31, 3.64]	7.51* [2.92, 19.29]
Combo vs MTX at 2.1 mg/dL Mg	1.63 [0.38, 7.03]	5.13* [1.72, 15.31]
ETN vs MTX at 2.6 mg/dL Mg	0.21 [0.02, 2.45]	1.48 [0.15, 14.54]
Combo vs MTX at 2.6 mg/dL Mg	6.21 [0.46, 83.49]	19.58* [1.64, 233.11]

*Significant at the level of $P<0.05$. BL = baseline; Combo = MTX + ETN; ETN = etanercept; LDA = low disease activity; Mg = magnesium; MTX = methotrexate; RA = rheumatoid arthritis; REM = remission; SDAI = Simplified Disease Activity Index.

consider varying magnitudes of association by treatment arm. Score selection with best subset was used to confirm the model.

Results: In total, 253 patients with RA were included in the analysis. BL rheumatoid factor (RF) and Patient Global Assessment of Disease Activity (PtGA) showed strong association with SDAI REM or LDA (Table 1). After adjusting for other factors, patients with a 1-point higher PtGA (0-100 scale) at BL were 0.93 times more likely to maintain SDAI REM/LDA at Week 48. RF-positive patients were less than half as likely (OR, 0.46) as RF-negative patients to remain in REM/LDA at Week 48. Longer RA duration in the MTX arm and shorter duration of ETN treatment strongly decreased the odds of SDAI REM/LDA (Tables 1 and 2). An association was also found between lower CRP at BL and REM/LDA (Table 1). There was a trend for non-obese patients to be more likely to remain in REM than obese patients, although significance was not achieved. In addition, MTX and ETN patients with higher magnesium levels at BL had lower odds of maintaining REM/LDA, with an especially strong association within ETN monotherapy (Table 2). The area under the curve for the receiver operating characteristic of the model was 0.78.

Conclusion: These findings indicate patients with overall lower disease activity are more likely to remain in SDAI REM/LDA after tapering RA therapy. RF-negative status and lower PtGA scores in particular were strongly associated with likelihood of remaining in REM/LDA with MTX or ETN monotherapy. The role of magnesium in disease control warrants further exploration.

SESSION INFORMATION

Session Date: Monday, November 8, 2021

Session Title: RA – Treatments Poster II: PROs, Biomarkers, & Systemic Inflammation (1223–1256)

Session Type: Poster Session C

Session Time: 8:30AM–10:30AM

Background/Purpose: Patients with RA in remission (REM) may experience disease-worsening (DW) following therapy change or withdrawal. The change in patient-reported outcomes (PROs) after therapy withdrawal has not been well described. This analysis examined PRO changes in RA patients in REM at baseline from a clinical trial enacting medication withdrawal.

Methods: SEAM-RA was a phase 3, multicenter, randomized withdrawal, double-blind controlled study in patients with RA on methotrexate (MTX) + etanercept (ETN) (combo) who were in REM (Simplified Disease Activity Index [SDAI] ≤3.3). After randomization to either MTX or ETN withdrawal, patients who experienced an SDAI score >11 at any time following randomization or SDAI >3.3 and ≤11 during 2 consecutive visits ≥2 weeks apart or on ≥3 separate visits were considered to have DW. Patients with DW resumed or continued MTX + ETN (rescue therapy). Patient Global Assessment of Disease Activity (PtGA), Patient Assessment of Joint Pain (PtJP), Health Assessment Questionnaire-Disability Index (HAQ-DI), and the 36-item Short-Form Health Survey (SF-36) were administered at baseline and Weeks 24 and 48 and also at Weeks 12 and 36 for PtGA and PtJP. Over the 48-week period, PROs were

Table 1. Cumulative Proportion of Patients Whose Patient- and Physician-Reported Outcome Scores Worsened Over 48 Weeks

Change From Baseline in Outcome Score	DW (N = 121) n/N (%)	REM (N = 132) n/N (%)
PtGA		
≥20	76/121 (62.8)	21/131 (16.0)
>10	90/121 (74.4)	36/131 (27.5)
PtJP

>10	89/121 (73.6)	42/131 (32.1)
PhGA		
≥20	59/121 (48.8)	6/131 (4.6)
>10	80/121 (66.1)	24/131 (18.3)
HAQ-DI		
≥0.35	54/120 (45.0)	31/130 (23.8)
SF-36 MCS		
≤−2.5	69/120 (57.5)	58/130 (44.6)
SF-36 PCS		
≤−2.5	82/120 (68.3)	62/130 (47.7)

PtGA, PtJP, and PhGA on a 0–100 scale. Differences between DW and non-DW groups were significant at the level of $P<0.0001$ for all outcome measures. n = number of patients reporting worsening reaching MCID (≥20 or >10); N = number of patients with non-missing data; MCS = Mental Component Summary; PCS = Physical Component Summary.

Table 2. Cumulative Proportion of DW Patients Whose PtGA, PtJP, and PhGA Scores Worsened and Subsequently Improved by Receipt of Rescue Therapy Over 48 Weeks

Change From PRO Worsening Point, n/N (%)	Patients Receiving Rescue Therapy	Patients Not Receiving Rescue Therapy
PtGA		
≥20[a]	45/62 (72.6)	1/14 (7.1)
>10[b]	64/73 (87.7)	1/17 (5.9)
PtJP		
≥20[a]	47/57 (82.5)	0/13 (0.0)
>10[b]	59/73 (80.8)	0/16 (0.0)
PhGA		
≥20[a]	43/51 (84.3)	0/8 (0.0)
>10[b]	56/65 (86.2)	0/15 (0.0)

[a]Improvement defined as change from the first time of worsening ≥MCID up to an improvement of ≤−20.
[b]Improvement defined as change from the first time of worsening ≥MCID up to an improvement of <−10.
PtGA, PtJP, and PhGA on a 0–100 scale. MCID = minimal clinically important difference.

Table 3. Proportion of Patients Whose Week 48 PROs Did Not Worsen More Than an MCID

Change from Baseline in PRO Score, n/N (%)	DW (N = 121)	REM (N = 132)
PtGA		
≥20	82/105 (78.1)	115/121 (95.0)
>10	72/105 (68.6)	106/121 (87.6)
PtJP		
≥20	85/105 (81.0)	115/121 (95.0)
>10	71/105 (67.6)	105/121 (86.8)
PhGA		
≥20	97/105 (92.4)	119/120 (99.2)
>10	89/105 (84.8)	114/120 (95.0)

PtGA, PtJP, and PhGA on a 0–100 scale. Data are observed cases.

evaluated by a change (worsening or improvement) greater than the minimal clinically important difference (MCID) for the instrument/domain. We present cumulative data for patients with PRO change ≥MCID from baseline. Among these patients experiencing DW, we also present improvement after time of worsening.

Results: Of 253 enrolled patients, 132 maintained REM and 121 experienced DW. A greater proportion of DW than REM patients had worse PtGA scores at a ≥20-point change from baseline (62.8% vs 16.0%) and at a >10-point change from baseline (74.4% vs 27.5%) (Table 1). This pattern also was observed for PtJP and Physician Global Assessment of Disease Activity (PhGA) (Table 1). Median time to PtGA worsening >MCID (>10) was 169 days in DW patients and was shorter than median time to overall DW (198 days in the MTX group, not evaluable due to cumulative probability of DW always < 50% in the ETN and combo groups). A higher percentage of patients in DW vs REM deteriorated >MCID on the HAQ-DI (≥0.35) (45.0% vs 23.8%), SF-36 Mental Component Summary (≤–2.5) (57.5% vs 44.6%), and SF-36 Physical Component Summary (≤–2.5) (68.3% vs 47.7%) scores (Table 1). Among DW patients with a ≥20-point change from baseline in PtGA and PtJP, a greater proportion of those who received rescue therapy improved their scores than those who did not receive rescue therapy (72.6% vs 7.1% and 82.5 vs 0.0%, respectively) (Table 2). At Week 48, a higher proportion of REM vs DW patients were closer to their baseline values (< MCID) for PtGA (95.0% vs 78.1%) (Table 3); similar trends were observed for PtJP and PhGA.

Conclusion: Patients who experience a loss of REM also experience deterioration in their patient-reported global health assessment and additional joint pain. The changes in patient outcomes are experienced by more DW patients than those remaining in REM. Median time to PtGA worsening more than an MCID is shorter than median time to

overall DW. DW patients who receive rescue therapy can regain their outcomes, but to a lesser extent than those remaining in REM.

Biomarker Driven Dissection of Inflammation Modulatory Effects of Upadacitinib versus Abatacept in Patients with Active Rheumatoid Arthritis Refractory to Biologic DMARDs

Fang Cai[1], Thierry Sornasse[2], Feng Hong[3], Heidi Camp[4], Koji Kato[5] and **Iain McInnes**[6], [1]AbbVie, Redwood City, CA, [2]AbbVie Inc, Redwood City, CA, [3]AbbVie, Worcester, MA, [4]AbbVie Inc., North Chicago, IL, [5]AbbVie Inc, Shinagawa- Ku, Japan, [6]University of Glasgow, School of Medicine, Glasgow, Scotland, United Kingdom

SESSION INFORMATION
Session Date: Monday, November 8, 2021
Session Title: RA – Treatments Poster II: PROs, Biomarkers, & Systemic Inflammation (1223–1256)
Session Type: Poster Session C
Session Time: 8:30AM–10:30AM

Background/Purpose: In patients with active rheumatoid arthritis (RA) refractory to biologic DMARDs (bDMARD-IR), a phase 3, double-blind and active-controlled study (SELECT-CHOICE) demonstrated that upadacitinib (UPA) 15 mg QD was superior to abatacept (ABA) IV in driving change from baseline in DAS28-CRP and achievement of clinical remission at week 12.[1] The objective of this analysis was to compare the effects of UPA versus ABA on inflammatory biomarkers in bDMARD-IR RA patients, and to assess the dynamic relationship of such biomarkers with disease activity.

Methods: A subset of patients was randomly selected from the SELECT-CHOICE study cohort that consented sample collection for exploratory research (UPA: n = 99; ABA: n = 100). Plasma biomarker levels were assessed at baseline, week 2 and week 12 using the *Olink Explore 384 Inflammation* panel. Change from baseline was expressed as $\log_2$ fold change ($\log_2$FC). A Repeated Measure Mixed Linear Model identified biomarkers differentially modulated from baseline. Statistical tests were corrected for multiple comparison using the Benjamini – Hochberg False Discovery Rate (FDR) method. Downstream biological effects were predicted with Ingenuity Pathway Analysis. Responders in this analysis were defined by achieving DAS28-CRP Low Disease Activity (≤3.2) at week 12.

Results: Overall, 58 out of 368 biomarkers assessed were significantly modulated by UPA or ABA at week 12 (Table 1). Compared to ABA, treatment with UPA resulted in faster and broader modulation of inflammatory mediators implicated in RA pathogenesis in bDMARD-IR RA patients. Predictive analysis of downstream biological processes showed overlapped inhibitory effects by UPA and ABA on lymphocytes, myeloid cells, antigen presenting cells, and phagocyte activities, indicating a functional convergence of UPA and ABA mechanisms of action (MOA). IL-6, CCL7,

CSF1 and HSD11B1 were identified as DAS28-CRP-related biomarkers in this analysis. The levels of IL-6, CCL7, CSF1, and HSD11B1 significantly correlated with DAS28-CRP at the baseline, and the changes in these biomarkers significantly correlated with changes in DAS28-CRP at week 12. UPA had significantly greater modulation effects on IL-6, CCL7, CSF1 and HSD11B1 compared to ABA; these were more profound in responders than in non-responders.

Conclusion: The results of inflammatory biomarker modulation by UPA and ABA treatment demonstrates their MOA in bDMARD-IR RA patients, consistent with previous findings.[2,3] The more profound modulation of DAS28-CRP-related biomarkers by UPA may provide a mechanistic rationale for the superior efficacy of UPA compared to ABA, which warrants further investigation.

Comparison of the Effects of Upadacitinib Monotherapy with MTX on Protein Biomarkers in MTX-Naïve and MTX-Inadequate Responders in Patients with Active Rheumatoid Arthritis: Results from the SELECT-EARLY and SELECT-MONOTHERAPY Phase 3 Studies

Thierry Sornasse[1], Heidi Camp[2], Fang Cai[3], Justin Klaff[2] and **Iain McInnes**[4], [1]AbbVie Inc, Redwood City, CA, [2]AbbVie Inc., North Chicago, IL, [3]AbbVie, Redwood City, CA, [4]University of Glasgow, School of Medicine, Glasgow, Scotland, United Kingdom

SESSION INFORMATION
Session Date: Monday, November 8, 2021
Session Title: RA – Treatments Poster II: PROs, Biomarkers, & Systemic Inflammation (1223–1256)
Session Type: Poster Session C
Session Time: 8:30AM–10:30AM

Background/Purpose: In MTX-naïve patients (SELECT-EARLY/M13-545 Phase 3 study) UPA 15 mg QD monotherapy (UPA Mono) demonstrated significant and clinically meaningful improvements in RA signs and symptoms vs MTX.[1] In MTX-IR patients (SELECT-MONOTHERAPY/M15-555 Phase 3 study), switching to UPA Mono showed significant improvements in RA signs and symptoms versus continuing MTX.[2] These study populations offer excellent opportunities to dissect disease and therapeutic mechanisms using biomarker analysis. The objective of this analysis was to compare the biological activity of MTX and UPA Mono in MTX-naïve and MTX-IR RA patients, via evaluation of circulating protein biomarkers related to inflammation compared with clinical disease activity.

Methods: Patients from the SELECT-EARLY (MTX, n = 96; UPA 15 mg QD, n = 96) and SELECT-MONOTHERAPY (MTX, n = 79; UPA 15 mg QD, n = 99) studies were randomly selected from the subsets of patients with available plasma samples. The levels of 92 inflammation related proteins were analyzed using the Olink platform; change from baseline in protein levels were expressed as Log_2 Fold Change; a Repeated Measure Mixed Linear Model identified proteins differentially modulated by MTX and UPA compared to Baseline. Pathway analysis was performed with Ingenuity Pathway Analysis.

Results: In MTX-naïve RA patients, both UPA Mono and MTX modulated a broad range of protein biomarkers associated with key pathways implicated in RA pathogenesis. UPA Mono had a faster onset of effect than MTX (Table 1) determined by impact on protein biomarker levels. Moreover, UPA Mono had a more profound effect on biomarkers that are significantly associated with baseline disease activity measures. In MTX-IR RA patients, only UPA Mono exerted significant effects on a subset of the biomarkers identified above, whereas continued treatment with MTX had no measured effect. Pathway analysis indicated that in MTX-naïve RA Patients, UPA Mono and MTX were predicted to elicit similar effects on adaptive, innate immune cells and on non-immune bone, connective tissue, and angiogenesis related pathways; but UPA Mono did so faster than MTX. In MTX-IR RA patients, only UPA Mono was predicted to affect those pathways, although to a lesser extent than in MTX-naïve RA patients.

Conclusion: UPA Mono exerted significant effects on protein biomarkers in both MTX-naïve and MTX-IR patients, whereas MTX did so only in MTX-naïve patients. The more profound and rapid effects of UPA Mono in MTX-naïve

patients provide a possible mechanism for the superior clinical efficacy of UPA Mono over MTX. Overall, treatment with UPA monotherapy resulted in the normalization of key pathways associated with the pathobiology of RA in both MTX-naïve and MTX-IR patients, consistent with our previous observations on the effect of UPA in combination with csDMARDs in csDMARD-IR RA patients.[3,4]

SESSION INFORMATION

Session Date: Monday, November 8, 2021

Session Title: RA – Treatments Poster II: PROs, Biomarkers, & Systemic Inflammation (1223–1256)

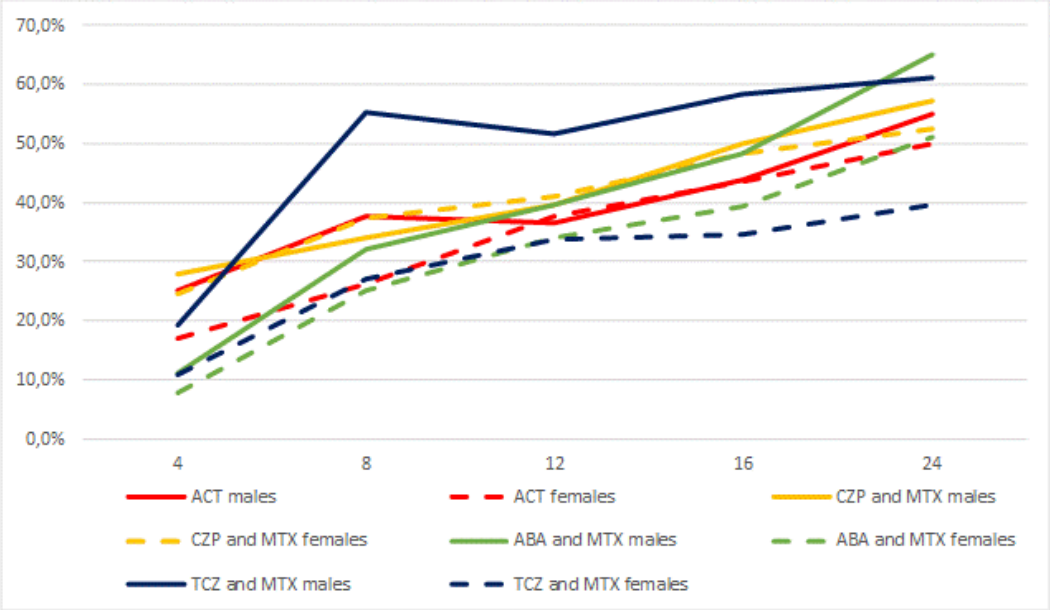
Session Type: Poster Session C

Session Time: 8:30AM–10:30AM

Background/Purpose: To investigate sex differences in clinical response to three different biological treatments in combination with methotrexate (MTX) versus MTX plus corticosteroids (active conventional treatment; ACT), in early RA. We hypothesized that men and women differ in their response to one or several treatments.

Methods: DMARD-naïve patients with symptom duration < 2 years, moderate to severe disease activity (DAS28-CRP >3.2) and RF or ACPA positivity, or increased CRP (≥10 mg/L) were randomized in the phase IV NORD-STAR trial (NCT01491815) on 1:1:1:1 ratio, stratified by country, sex and ACPA status to 1)ACT; 2)certolizumab pegol (CPZ); 3)abatacept (ABA); 4)tocilizumab (TCZ)[1]. Remission outcomes were analyzed with longitudinal logistic generalized estimating equations analysis. The model included treatment, time (4, 8, 12, 16, and 24 weeks) and sex. The primary and secondary clinical results of the trial after 24 weeks have been published[1]. For this sub-study, the co-primary

Figure 1 Crude clinical disease activity index (CDAI) remission rates over 24 weeks in percentage



ACT=active conventional treatment (methotrexate and corticosteroids); CZP=certolizumab pegol; ABA=abatacept; TCZ=tocilizumab; MTX=methotrexate

outcomes were differences in clinical disease activity index remission (CDAI≤2.8) over 24 weeks and at 24 weeks with ACT as the reference. Sex differences were assessed by interaction terms (males vs. females within each treatment comparison).

Results: This study included all 812 patients in the NORD-STAR trial (251 men and 561 women). The mean age was 56.5 (SD 14.0) and 53.2 (SD 15.0) years in males and females, respectively. Corresponding baseline DAS28-CRP was 5.0 (SD 1.0) and 5.0 (SD 1.1) and CDAI 27.5 (SD 11.6) and 28.1 (SD 12.0).

The crude CDAI remission rates at 24 weeks were 55.0% in males and 50.0% in females for ACT, 57.1% and 52.4% for CZP, 65.0% and 51.1% for ABA and 61.1% and 39.6% for TCZ (Figure 1). The analyses were adjusted for the stratification variables, age, BMI and DAS28-CRP at baseline. Using ACT as the reference, the adjusted overall odds ratios (OR) for achieving CDAI remission (95% confidence intervals, CI) with CZP were 1.26 (0.73-2.19) and 1.26 (0.88-1.81) in males and females, respectively, with ABA 1.25 (0.74-2.13) and 0.86 (0.60-1.24) and with TCZ 1.70 (1.01-2.87) and 0.76 (0.51-1.13). Corresponding odds ratios at 24 weeks with CZP were 1.41 (0.62-3.18) and 1.12 (0.66-1.89), with ABA 2.19 (0.96-4.97) and 1.04 (0.62-1.73) and with TCZ 1.54 (0.68-3.49) and 0.66 (0.38-1.14). For the primary and several secondary outcomes, women responded significantly poorer than men to TCZ compared with ACT (Table 1).

The percentage of males and females who experienced at least one adverse event with ACT was 85.7% and 86.1%, respectively, with CZP 82.5% and 82.7%, with ABA 70.3% and 84.3% and with TCZ 93.2% and 96.0%. The percentage of men and women who stopped treatment early with ACT was 6.3% and 11.1%, respectively, with CZP 12.5% and 10.8%, with ABA 6.3% and 5.0% and with TCZ 6.8% and 14.0%.

Conclusion: After 24 weeks, higher remission rates were observed in men than in women for all four treatment arms, suggesting that this generalized sex difference is related to the disease itself rather than to the treatments. In contrast, a distinctly lower treatment response was seen in female patients treated with tocilizumab versus conventional treatment, suggesting a sex-effect that is specific for IL-6 blockade.

Table 1 Adjusted remission and response outcomes over 24 weeks, at 12 and 24 weeks. Values are odds ratios (95% confidence intervals) with active conventional treatment (methotrexate plus corticosteroids) as the reference

Real World Validation of a Rule to Predict Response to Sarilumab in Patients with Rheumatoid Arthritis: Analysis from the RISE Registry

Huifeng Yun[1], Jeffrey Curtis[2], Lang Chen[3], cassie Clinton[3], Hubert van Hoogstraten[4], Stefano Fiore[4], Markus Rehberg[5] and Ernest Choy[6], [1]University of Alabama Birmingham, Birmingham, AL, [2]Division of Clinical Immunology and Rheumatology, Department of Medicine, Department of Epidemiology, University of Alabama at Birmingham, Birmingham, AL, [3]University of Alabama at Birmingham, Birmingham, AL, [4]Sanofi, Bridgewater, NJ, [5]Sanofi, Franfurt, Germany, [6]CREATE Centre, Cardiff University, Cardiff, Wales, United Kingdom

SESSION INFORMATION
Session Date: Monday, November 8, 2021
Session Title: RA – Treatments Poster II: PROs, Biomarkers, & Systemic Inflammation (1223–1256)
Session Type: Poster Session C
Session Time: 8:30AM–10:30AM

Background/Purpose: Accurately identifying patients who may respond better to a specific drug or mechanism of action could improve rational selection of medications to optimize clinical response, reduce irreversible damage, and ameliorate long term outcomes. Using a machine learning approach, previous work using data from clinical trials has found that patients with positive ACPA status (ACPA+) and CRP >12.3 mg/L responded better to sarilumab than patients who did not meet this criterion. However, the average disease activity and CRP levels for most patients initiating sarilumab in real-world settings is often lower than in clinical trials. Therefore, we validated the stratification rule in a national real-world rheumatology based electronic health record (EHR) registry. We hypothesized that sarilumab initiators who are rule-positive (seropositive [RF, ACPA] with CRP levels >12.3 mg/L) are more likely to achieve treatment targets compared with rule-negative patients.

Methods: Using 2017–2020 ACR's Rheumatology Informatics System for Effectiveness (RISE) registry, we identified sarilumab initiators who had ≥1 prescription of sarilumab on or after 5/22/2017 (FDA approval date). The first prescription date was the index date. Eligible patients were required to be 18 years of age, ≥1 rheumatologist diagnosis for RA prior to index, clinical disease activity index (CDAI) >10 within 30 days prior to or 7 days after index, with CRP value within 90 days prior to index, and ≥1 CDAI within 6 ± 3 months after index. Based on the CDAI and CRP levels at the index date, we categorized the cohort into 4 groups, 1) Seropositive and CRP >12.3 mg/L, 2) Seropositive and CRP ≤12.3 mg/L, 3) Seronegative and CRP >12.3 mg/L, 4) Seronegative and CRP ≤12.3 mg/L. Logistic regression models were used to compare the odds of achieving CDAI low disease activity (LDA) or Remission (CDAI < 10), and MCID (minimum clinical important difference; CDAI improvement ≥12 if baseline CDAI >22 or CDAI ≥6 if baseline 10< CDAI < 22) between rule positive and negative patients. Sensitivity analyses using CRP >5 mg/L (rather than 12.3 mg/L) as the rule positive cutoff point were also conducted.

Results: We identified 205 sarilumab users who met all required inclusion and exclusion criteria. Baseline demographic and clinical characteristics are shown in **Table 1**; most characteristics of these patients were equally distributed across the four groups, except that seropositive patients were more likely to be of black race and less likely to have previous Janus kinase inhibitor use. Logistic regression showed that compared with rule negative patients, rule positive patients were more likely to reach LDA/remission and MCID (**Table 2**). The mean difference in Δ CDAI

All the numbers in the table are n (%) unless indicated otherwise.
Group 1: Seropositive and CRP >12.3 mg/L,
Group 2: Seropositive and CRP ≤12.3 mg/L,
Group 3: Seronegative and CRP >12.3 mg/L,
Group 4: Seronegative and CRP ≤12.3 mg/L.
Seropositive patients were defined as those with a history of anti-CCP positive status or RF positive status or any ICD-10 diagnosis code of M05.
CDAI, clinical disease activity index; csDMARD, conventional synthetic DMARD; ICD, International Classification of Diseases; JAKi, Janus kinase inhibitors; RX, prescription; TNFi, tumor necrosis factor inhibitors.

between rule positive and rule negative patients was 1–4 units (p=0.16). Results from sensitivity analyses (CRP >5 mg/L) yielded a better response in rule positive patients as in the main analysis.

Conclusion: Patients with seropositive status and elevated CRP (>12.3 mg/L, or >5 mg/L) had a better response to sarilumab compared with patients who did not meet these two criteria in real-world settings. Seropositivity seemed to be a stronger driver for response in this data set and validation of an optimal CRP cutoff may require more data.

SESSION INFORMATION

Session Date: Monday, November 8, 2021

Session Title: RA – Treatments Poster II: PROs, Biomarkers, & Systemic Inflammation (1223–1256)

Session Type: Poster Session C

Session Time: 8:30AM–10:30AM

Background/Purpose: Many patients with controlled rheumatoid arthritis (RA) continue to report high levels of disease activity (PGA), as well as other disturbing patient-related outcomes (PROs), such as depression and anxiety. Aiming to improve PGA and PROs in a pragmatic pilot study, Mindfulness-Based Stress Reduction (MBSR), an eight-week non-pharmacological approach, was offered to patients with controlled RA but elevated negative PROs.

Methods: Patients in clinical remission on stable treatment at their regular visit were referred to research assistants to determine their interest in the study. Recruitment strategies (Table 1) were based either on elevated Center for Epidemiologic Studies Depression scale (CES-D) scores or on a differenre ≥2/10 (Delta) between PGA and Physician General Assessment (EGA). Patients were evaluated 1-4 weeks before MBSR and 6 and 12 months after MBSR's end. Scores were compared between baseline and 6 and 12 months. Differences within and between groups were calculated with linear mixed regression models for continuous outcomes or with generalized estimating equation for dichotomic outcomes. Some participants were interviewed about their experience after the 6-month assessment to complete a qualitative evaluation.

Results: Out of 325 tagged patients, 224 were identified as candidates by rheumatologists, 67 were proposed MBSR, 39 (58%) agreed to participate, 31 took part to 1 of 4 MBSR groups provided over 18 months, and 28 (42%) completed both the baseline and the 6- and/or 12-month evaluation (Table 2). Timing (day vs evening), frequency of the group meetings, distance from home, severe depression, extremes of age and comorbidities were examples of barriers to participation.

Results showed a significant improvement from baseline to 12 months post-MBSR for depression (CES-D; estimate (95% CI)=(-9.21 (-13.96 to -4.41), p=0.004), anxiety (GAD-7; -3.18 (-5.15 to -1.22), p=0.004), emotional coping (-5.18

Table 1. Inclusion and exclusion criteria

	Groups with criteria
Inclusion criteria (both required):	
1. ≥18 year-old patient with DMARD- and/or biologic-treated RA (meeting 1987/2010 ACR classification criteria) and stable arthritis treatment for at least 3 months (expected to be stable over the following months)	All groups
2. ≤2/66 SJC Both ≤2/66 SJC and CRP ≤8 mg/L	First group Other groups
3. CES-D score ≥16 CES-D score ≥16 and/or Δ(PGA – EGA) ≥2cm	First group Other groups
Exclusion criteria (both required):	
1. Inability to consent (e.g. not fluent in French, dementia) or to participate in groups at pre-specified times (e.g. travel difficulties or distance);	All groups
2. Active vasculitis	All groups
3. Untreated active bipolar disease, severe depression with suicidality risk, or psychosis, as determined upon chart review or during patient encounters	All groups

DMARD: Disease Modifying Anti-Rheumatic Drugs, SJC=swollen joint count, CRP: C-reactive protein, CES-D: Center for Epidemiologic Studies Depression scale, PGA: Patient global assessment, EGA: Evaluator Global Assessment of activity

Table 2. Patient characteristics at baseline

	Baseline	
	n	Value
Age (years), mean ± SD	28	61.8 ± 13.6
Women, n (%)	28	24 (85.7)
Disease duration (years), median (IQR)	28	9.8 (4.7-12.5)
Seropositive status, n (%)	26	15 (53.6)
Body mass index (kg/m2), mean ± SD	28	27 ± 5.6
Education (number of years), mean ± SD	28	12.9 ± 3.2
Caucasian, n (%)	28	27 (96.4)
Marital status, n (%)

Non-steroidal anti-inflammatory drug, n (%)	28	3 (10.7)
Antidepressants, n (%)	28	7 (25.0)

SD: Standard deviation, IQR: Interquartile range (25th-75th percentiles)

(-7.82 to -2.53), p=0.004), sleep (-2.06 (-3.12 to -0.99), p=0.004) and function (M-HAQ; -0.28 (-0.43 to -0.12), p=0.009) (Table 3). At baseline, PGA was significantly correlated with function (r=0.54) but not depression (r=0.18) or anxiety (r=0.19). At 6 months, PGA showed a higher correlation with function (r=0.72) and became significantly correlated with depression (r=0.60) and anxiety (r=0.44). Emotional coping strategy was the only one significantly modified by MBSR; this maladaptive approach to illness is critical to quality of life. Qualitative interviews at 6 months in 10 patients indicated persistent subjective patient benefits including integration of MBSR techniques and effective coping strategies into daily life.

Conclusion: Offering MBSR to RA patients with high negative PROs is both feasible and helpful. MBSR had lasting benefits on outcomes that are important to patients, particularly anxiety, depression, and function. MBSR helped empower patients to practice self-management and enabled them to use fewer emotional coping strategies. MBSR did not appear to improve PGA, despite PGA correlations with function, depression, and anxiety at 6 months. The reasons for this apparent PGA disconnect require further studies.

SESSION INFORMATION

Session Date: Monday, November 8, 2021

Session Title: RA – Treatments Poster II: PROs, Biomarkers, & Systemic Inflammation (1223–1256)

Session Type: Poster Session C

Session Time: 8:30AM–10:30AM

Background/Purpose: In recent decades, the therapeutic arsenal in RA has dramatically expanded. Baricitinib (BARI) and Tofacitinib (TOFA) were the first JAK inhibitors (JAKi) to be recommended for moderate-to-severe RA after conventional synthetic DMARD failure. Several alerts have arisen concerning an increased risk of veinous thromboembolism (VTE) with these drugs. In May 2019, the European Medicines Agency (EMA) sent a warning about an interim post-marketing analysis revealing a significant increase in the number of VTE with TOFA at the dose of 10 mg twice daily. The first objective of this study was to compare the characteristics of patients initiating a JAKi before versus after EMA's warning to determine if use restrictions were currently applied in daily practice. The second objective was to compare the persistence of BARI and TOFA in real-world.

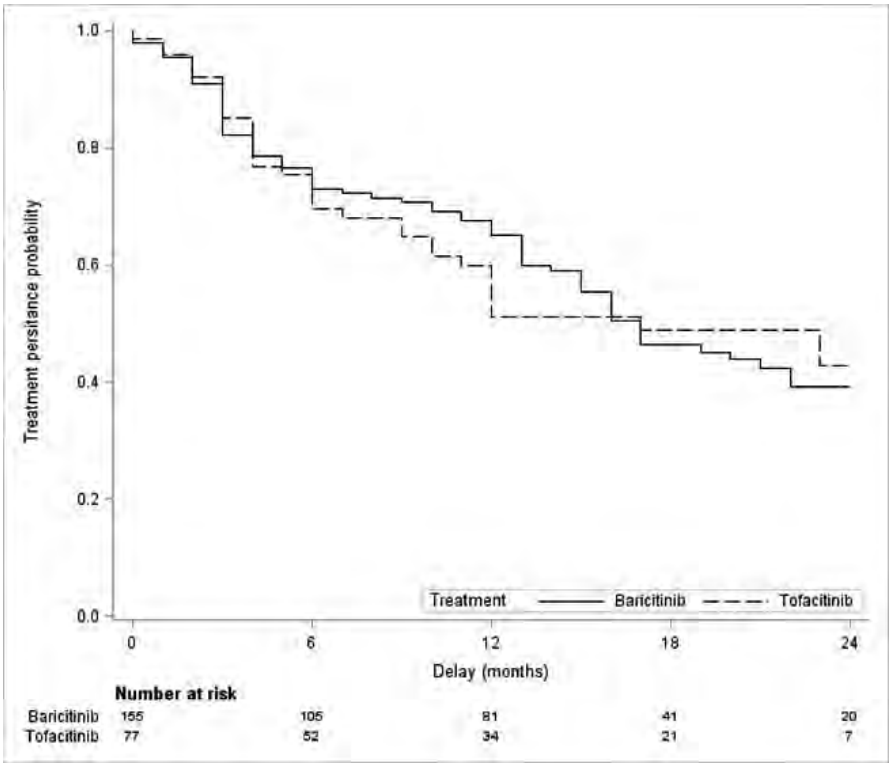

Figure 1. Two-year follow-up treatment persistence with Baricitinib (BARI) and Tofacitinib (TOFA).

Methods: A retrospective multicentric cohort study was conducted. Patients with RA were included if they fulfilled the 2010 ACR/EULAR RA classification criteria and initiated BARI or TOFA between October 2017 and September 2020. Patients were JAKi-naïve. Patient characteristics regarding VTE risk factors were compared between the two periods (before and after May 2019) by using pre-specified statistical tests. Comparison of persistence was assessed by using pre-specified propensity-score methods.

Results: 232 patients were included: 155 with BARI and 77 with TOFA (**Table 1**). Mean age was 59.6±14.2 years old for BARI and 56.7±13.4 years old for TOFA. Median duration of RA was 11 years (IQR, 4 to 20). The proportion of bDMARD-naïve patients was 14.8% with BARI and 9.1% with TOFA. Combination with a csDMARD was reported in 38.7 % (BARI) and 37.4 % (TOFA) of patients. The baseline characteristics of patients regarding VTE risk factors were not statistically different when JAKi was initiated before versus after EMA's warnings although a trend towards a lower proportion of thromboembolic personal history was observed (**Table 2**). The overall median persistence was 17 months (IQR, 13 to 22). Persistence rate at 2 years was 39.3% (BARI) and 42.8% (TOFA) with no significant difference between the two drugs in the propensity score analysis: hazard ratio 0.96; 95% Confidence Interval: 0.52 to 1.74; p=0.89 (**Figure 1**). BARI and TOFA were discontinued due to inefficacy in 64% and 60% of cases, respectively. Both drugs were discontinued due to an adverse event in 30.7% (BARI) and 31.4% (TOFA) of cases. 5 VTE events occurred during our study, 4 with BARI, 1 with TOFA. 4/5 events occurred in patients who initiated JAKi before May 2019. There has been no incident neoplasia nor myocardial infarction reported.

Conclusion: In conclusion, our study revealed that EMA's warnings have not significantly changed RA patient characteristics initiating a JAKi. BARI and TOFA have a similar persistence in our study. The tolerance profile is consistent with post-marketing and real-world data. VTE risk remains a concern in current practice. This study provides additional data and is a hot topic pending the publication of the ORAL-surveillance study (NCT02092467). Monitoring of new marketed JAKi will help understand if there are specific efficacy and safety profiles among JAKi according to the selectively targeted Janus Kinases.

The Effect of Tocilizumab on miR-146a-5p and EMMPRIN/CD147 in Rheumatoid Arthritis Patients

Devy Zisman[1], Mirna Safieh[1], Elina Simanovich[1], Joy Feld[2], Amalia Kinarty[1], Liron Zisman[1], Tal Gazitt[3], Amir Haddad[4], Muna Elias[1], Itzhak Rosner[5], Lisa Kaly[6] and Michal A Rahat[7], [1]Carmel Medical Center, Haifa, Israel, [2]Carmel and Zvulun Medical Centre, Haifa, Israel, [3]Carmel Hospital, Haifa, Israel, [4]Carmel Medical Centre, Haifa, Israel, [5]Rheumatology Unit, Bnai Zion Medical Center, Haifa, Israel, [6]Bnei Zion Medical Center, Haifa, Israel, [7]Carmel Medical Center/Ruth and Bruce Rappaport Faculty of Medicine, Technion-Israel Institute of Technology, Haifa, Israel

SESSION INFORMATION
Session Date: Monday, November 8, 2021
Session Title: RA – Treatments Poster II: PROs, Biomarkers, & Systemic Inflammation (1223–1256)
Session Type: Poster Session C
Session Time: 8:30AM–10:30AM

Background/Purpose: Angiogenesis is an important contributor to the development of rheumatoid arthritis (RA). Tocilizumab (TCZ), an anti-IL-6 receptor antibody used in the treatment of RA patients, has been shown to exert anti-inflammatory effects. However, its effects on angiogenesis are not fully elucidated, and the molecular mechanisms regulating this effect are unknown.

We aimed to evaluate the expression levels of several microRNA molecules and the concentrations of pro- and anti-angiogenic factors in sera of RA patients before and after the initiation of TCZ treatment and to explore the mechanisms of TCZ action in an *in vitro* co-culture system.

Methods: Sera from 40 RA patients before and 4 months after the initiation of TCZ treatment were collected. Using commercial ELISA kits, the concentrations of the pro-angiogenic factors EMMPRIN, VEGF, MMP-9, IL-6, NGAL, and of the anti-angiogenic factors endostatin and thrombospondin-1 (Tsp-1) were measured, as were the expression levels of microRNA molecules miR-16-5p, miR-21-5p, miR-132-3p, miR-146a-5p, miR-150-5p, miR-155-5p, miR-203a-3p, miR-221-3p, and miR-323a-3p. In vitro, the levels of secreted EMMPRIN, VEGF MMP-9 and Tsp-1 were measured in a co-culture system of HT1080 fibroblasts and U937 monocytes with and without addition of anti-EMMPRIN blocking antibody.

Results: The mean age of RA patients was 57.5±11.1 years, 33 (82.5%) females, mean disease duration 7.7±5.6 years. Of these patients, 25/40 (62.5%) were classified as "responders" based on EULAR criteria.

Statistically significant reduction in the level of EMMPRIN/CD147 ($p=0.035$), without significant changes in serum levels of MMP-9, VEGF, MMP-3, MMP-7 and of the anti-angiogenic factors Tsp-1 and endostatin were found 4 months after TCZ treatment. The ratio between EMMPRIN and Tsp-1 calculated for each patient 4 months after initiating TCZ decreased significantly ($p=0.031$), most notably in responding patients versus non-responders ($p=0.033$), while the levels of VEGF, MMP-9, Tsp-1, and EMMPRIN were unchanged. Of microRNA, only miR-146a-5p and miR-150-5p levels were significantly increased after 4 months of TCZ treatment relative to treatment initiation ($p=0.0178$, $p=0.0028$ respectively), with no difference noted in microRNA levels between patients considered responders and non-responders to TCZ.

In vitro, the accumulation of EMMRPIN, VEGF and MMP-9 in the supernatants was increased by co-culturing the HT1080 fibroblasts and the U937 monocytes ($p< 0.05$, $p< 0.05$, $P< 0.001$ respectively), while the accumulation of the anti-angiogenic factor thrombospondin-1 (Tsp-1) ($p< 0.001$) and the expression levels of miR-146a-5p were reduced ($p< 0.001$). Transfection of the miR-146-5p mimic reduced EMMPRIN, VEGF and MMP-9 levels by 1.3, 2.3 and 2.2-fold, respectively ($p< 0.05$).

Adding anti-EMMPRIN antibody to the co-culture reduced the accumulation of VEGF and MMP-9 in the supernatants by 1.8 and 1.4, respectively ($p< 0.05$).

Conclusion: Our findings implicate miR-146a-5p in the regulation of EMMPRIN and suggest that TCZ affects angiogenesis through its effects on EMMRPIN and miR-146a-5p.

Plasma Cell-free DNA Is a Useful Biomarker for Tocilizumab Therapy in Rheumatoid Arthritis

Teppei Hashimoto[1], Yuichi Yokoyama[2], Takahiro Yoshikawa[3], Tetsuya Furukawa[4], Naoto Azuma[5], Akira Hashiramoto[6] and Kiyoshi Matsui[7], [1]Hyogo College of Medicine, Kobe, Hyogo, Japan, [2]Pathology and Laboratory Medicine, University of Pennsylvania Perelman School of Medicine, Philadelphia, [3]Hyogo College of Medicine, Nishinomiya, Japan, [4]Hyogo college of Medicine, Nishinomiya, Hyogo, Japan, [5]Division of Rheumatology, Department of Internal Medicine, Hyogo College of Medicine, Nishinomiya, Hyogo, Japan, [6]Kobe University, Kobe, Japan, [7]Hyogo College of Medicine, Nishinomiya-city, Hyogo, Japan

SESSION INFORMATION

Session Date: Monday, November 8, 2021

Session Title: RA – Treatments Poster II: PROs, Biomarkers, & Systemic Inflammation (1223–1256)

Session Type: Poster Session C

Session Time: 8:30AM–10:30AM

Background/Purpose: Endogenous DNA derived from nuclei is released into the blood circulation as cell-free DNA (cfDNA) following cell damage or death. cfDNA is associated with various pathological conditions. In patients with rheumatoid arthritis (RA), cfDNA levels in peripheral blood and synovial fluid are increased. In addition, cfDNA induces joint inflammation via Toll-like receptor 9 (TLR9) pathways both *in vitro* (Dong C, et al. Front Immunol 2020) and *in vivo* (Liang H, et al. Nat Commun 2018). We have previously reported that the amounts of cfDNA released from synovial cells in RA are significantly suppressed with tocilizumab treatment *in vitro*, although they remain unchanged with etanercept (Hashimoto N, et al. ACR 2016 Annual Meeting). This study aimed to evaluate the clinical significance of cfDNA in RA treated with biological disease-modifying antirheumatic drugs (bDMARDs), specifically tocilizumab and tumor necrosis factor inhibitor (TNF-I).

Methods: We enrolled 126 patients with RA who initiated treatment with bDMARDs, including 72 with tocilizumab and 54 with TNF-I (10 with etanercept, 7 with adalimumab, 22 with certolizumab pegol, and 15 with golimumab).

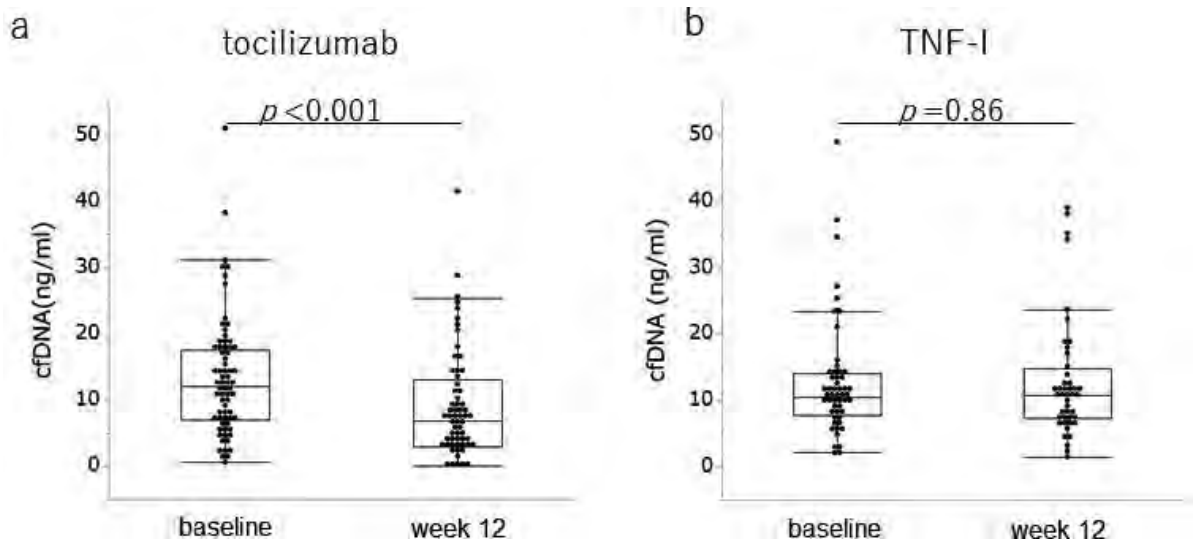

Figure1. cfDNA levels at baseline and week 12 with tocilizumab therapy (a) and with TNF-I (b).

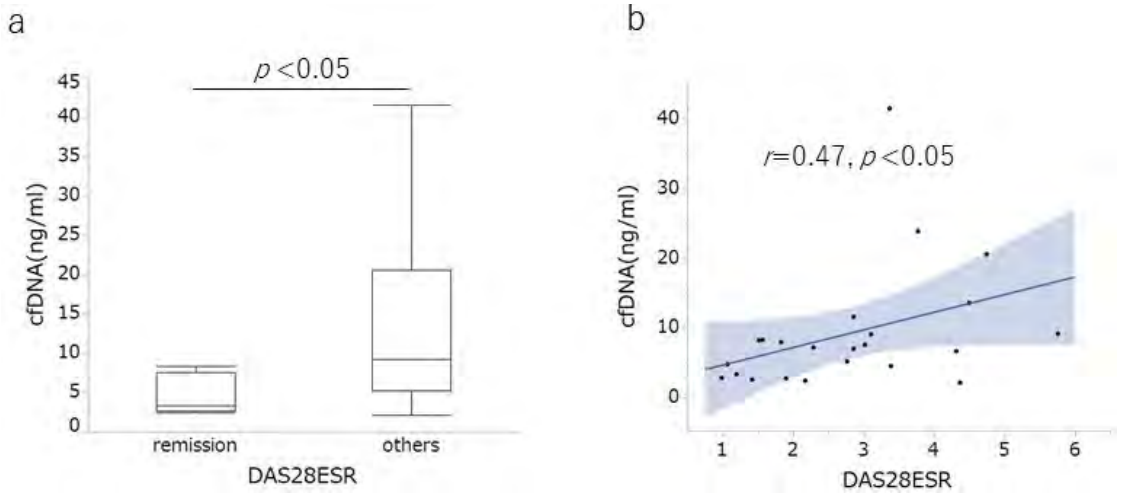

Figure 2. cfDNA levels and DASESR in the biological treatment-naïve patients with tocilizumab therapy. (a) cfDNA levels in DAS28ESR remission patients and others at week 12. (b) Correlation between cfDNA and DAS28ESR at week 12.

Plasma cfDNA levels were measured at baseline, week 4, and week 12 using quantitative polymerase chain reaction (qPCR) assays. Disease activity was also evaluated at the same timepoint, using the disease activity score 28 erythrocyte sedimentation rate (DAS28ESR).

Results: The DAS28ESR at baseline was not different between those who received tocilizumab and TNF-I (median [interquartile range, IQR]: 5.22 [4.35–6.49] and 4.91 [3.92–5.79], respectively), and it was significantly improved in both biological groups at week 12 (median [IQR]: 2.86 [1.82–4.01] and 3.34 [2.74–3.67], respectively). However, cfDNA levels in plasma were significantly decreased with tocilizumab at week 12, but not with TNF-I (Figure. 1). In particular, in the biological treatment-naïve patients with tocilizumab at week 12, cfDNA levels were significantly lower in patients with DAS28ESR remission than those in others (median [IQR]: 3.37 ng/mL [2.69–7.59] and 9.18 ng/mL [5.22–20.6], p< 0.05, respectively) (Figure.2a) and correlated with the DAS28ESR (r=0.47, p< 0.05) (Figure.2b). Meanwhile, there was no difference between remission and others in the biological treatment-naïve patients with TNF-I (median [IQR]: 8.49 ng/mL [7.03–16.4] and 11.2 ng/mL [7.50–18.1], p=0.26, respectively), with no association with the DAS28ESR (r=0.15, p=0.42).

Conclusion: Tocilizumab reduced cfDNA levels in patients with RA, like that in the *in vitro* study. Plasma cfDNA is a possible biomarker for tocilizumab therapy in biological treatment-naïve patients. In addition, tocilizumab may suppress inflammation via the TLR9 pathway by decreasing cfDNA levels.

Session Date: Monday, November 8, 2021

Session Title: RA – Treatments Poster II: PROs, Biomarkers, & Systemic Inflammation (1223–1256)

Session Type: Poster Session C

Session Time: 8:30AM–10:30AM

Background/Purpose: Previous studies have found differential treatment efficacy of abatacept (ABA) for the treatment of RA based on biomarker-seropositivity.[1-4] An earlier study found a differential treatment impact of ABA among SeroPositive Early & Active RA (SPEAR) patients in historic randomized controlled trials (RCTs).[5] In this study, we add to this evidence and test the robustness of the differential treatment impact of ABA among patients with SPEAR to adjustment for patient characteristics.

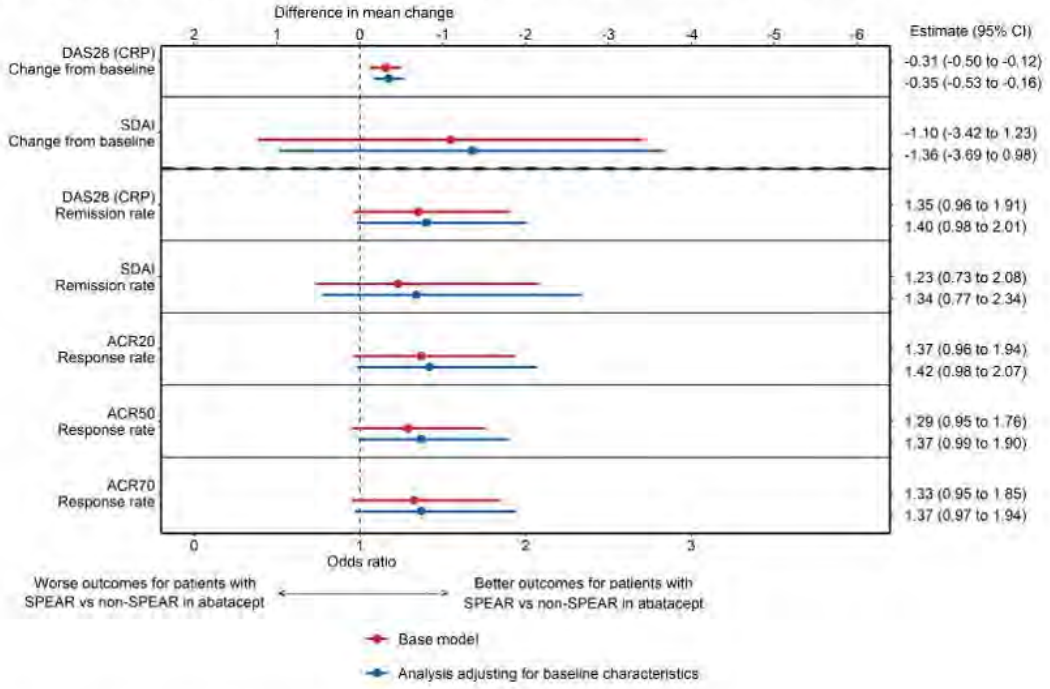
Table 1. Baseline characteristics

	All patients	Abatacept		Comparators[a]	
		Patients with SPEAR	Patients with non-SPEAR	Patients with SPEAR	Patients with non-SPEAR
	N = 2087	n = 784	n = 385	n = 544	n = 374
Trial, n (%)					
AGREE	492 (23.6)	177 (22.6)	68 (17.7)	155 (28.5)	92 (24.6)
AMPLE	509 (24.4)	45 (5.7)	206 (53.5)	41 (7.5)	217 (58.0)
AVERT	339 (16.2)	157 (20.0)	68 (17.76)	79 (14.5)	35 (9.4)
AVERT-2	747 (35.8)	405 (51.7)	43 (11.2)	269 (49.5)	30 (8.0)
Demographics & Disease characteristics					
Age, mean (SD), years	49.3 (12.9)	48.6 (12.5)	49.4 (12.6)	49.2 (13.5)	50.6 (12.9)
Female, (%)	79.3	77.2	81.3	77.9	83.4
Race, n (%)					
Asian	206 (9.9)	104 (13.3)	19 (4.9)	71 (13.1)	12 (3.2)
Black	118 (5.7)	35 (4.5)	30 (7.8)	32 (5.9)	21 (5.6)
Other	146 (7.0)	52 (6.6)	32 (8.3)	27 (5.0)	35 (9.4)
White	1,617 (77.5)	593 (75.6)	304 (79.0)	414 (76.1)	306 (81.8)
Disease duration, mean (SD), months	8.5 (12.5	2.4 (2.8	19.9 (15.9	2.4 (2.9	18.3 (15.1
RF positive, %	91.0	100	74.2	100	76.1
Anti-CCP positive, %	81.8	100	52.2	100	47.3
DAS28 (CRP), mean (SD)	5.71 (1.13)	5.68 (1.09)	5.72 (1.19)	5.76 (1.08)	5.66 (1.20)
CRP Value, mean (SD), mg/dl	2.16 (3.09)	2.22 (2.85)	1.85 (2.42)	2.45 (3.73)	1.92 (3.15)

[a]Comparators included MTX and adalimumab + MTX.

SPEAR, SeroPositive Early & Active RA.

Figure 1. Comparison of SPEAR vs non-SPEAR groups among patients receiving abatacept



SPEAR, SeroPositive Early & Active RA.

Comparators included MTX and adalimumab + MTX.

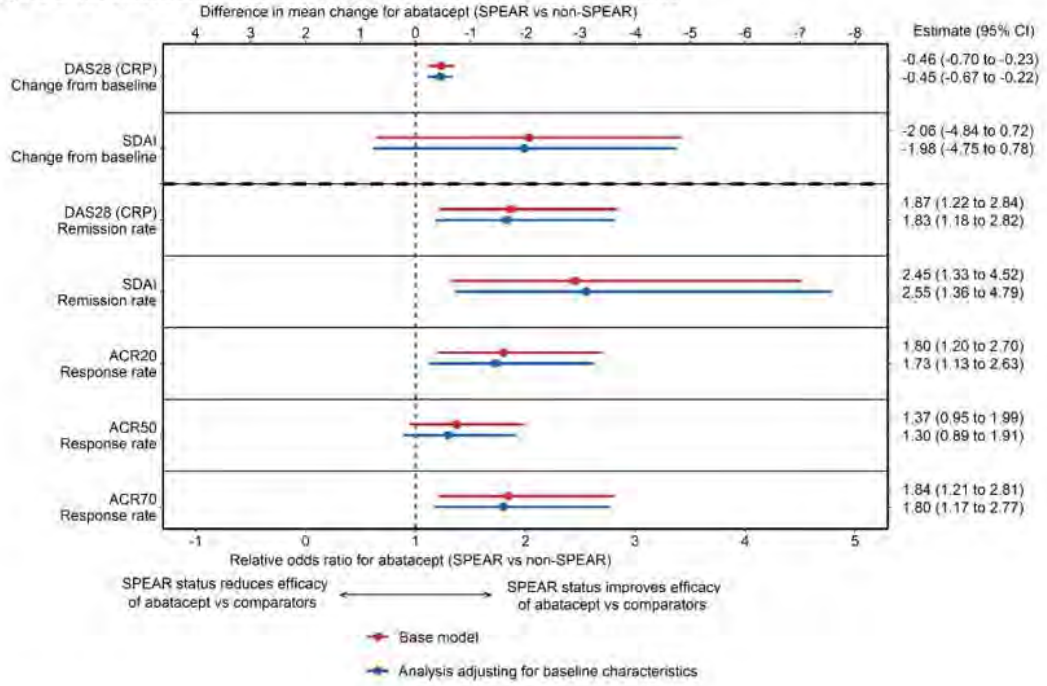
The base model included trial fixed effects, SPEAR status, baseline measures of the outcome (for DAS28-CRP or SDAI outcomes), and treatment type and an interaction between treatment type and SPEAR status (when analyzing the full population).

The analysis adjusting for baseline characteristics included baseline demographics (age, gender, race (White, Non-White), region (North America, Europe, Other)) and baseline ACR core measures as covariates.

Methods: Pooled patient data from 2087 patients from 4 phase 3, early-RA ABA RCTs (AGREE [NCT00122382], AMPLE [NCT00929864], AVERT [NCT01142726], AVERT-2 [NCT02504268]) were analyzed. Patients were defined as SPEAR if they satisfied the following baseline criteria: 1) RF+ and ≥ 3 times the upper limit of normal on an anti-CCP test (ACPA+), 2) disease duration ≤ 12 months, and 3) DAS28 (CRP) ≥ 3.2. Outcomes included DAS28-CRP and SDAI mean change from baseline to week 24 and remission (< 2.6 or ≤3.3, respectively), and ACR 20/50/70 at week 24. Patients were treated with either ABA (monotherapy or ABA+MTX) or a comparator (MTX or adalimumab + MTX). Analyses were conducted separately among ABA-treated patients (comparing SPEAR vs non-SPEAR) and the full population (estimating how the efficacy of ABA vs comparators is modified by SPEAR status). For each outcome, two separate analyses were conducted: the base model included trial fixed effects, SPEAR status, baseline measures of the outcome (for DAS28-CRP or SDAI outcomes), and treatment type and an interaction between treatment type and SPEAR status (when analyzing the full population). In a further adjusted model, baseline demographics (age, gender, race (White, Non-White), region (North America, Europe, Other)) and baseline ACR core measures were added as covariates. Sensitivity analyses defining SPEAR status using only ACPA+ and RF+ were conducted.

Results: This study analyzed 1328 (64%) SPEAR and 759 (36%) non-SPEAR patients. Roughly half of patients with non-SPEAR were RF+ and three-quarters ACPA+; while all patients had high DAS28 (CRP) (**Table 1**). The estimated differential treatment efficacy of ABA among SPEAR patients for both analyses - improved outcomes for ABA-treated SPEAR patients vs non-SPEAR patients, and improved relative efficacy for ABA vs comparators among SPEAR patients vs non-SPEAR patients - was robust to including additional baseline characteristics across all outcomes, with only small changes to effect sizes and precision (**Figures 1 & 2**). Findings were consistent in sensitivity analyses.

Figure 2. Modification of ABA vs comparator efficacy by SPEAR status



SPEAR, SeroPositive Early & Active RA.

Comparators included MTX and adalimumab + MTX.

The base model included trial fixed effects, SPEAR status, baseline measures of the outcome (for DAS28-CRP or SDAI outcomes), and treatment type and an interaction between treatment type and SPEAR status (when analyzing the full population).

The analysis adjusting for baseline characteristics included baseline demographics (age, gender, race (White, Non-White), region (North America, Europe, Other)) and baseline ACR core measures as covariates.

Conclusion: This analysis compared clinical outcomes of RA patients with enriched autoantibody biomarkers and early disease stage (SPEAR) to non-SPEAR, and found that the differential efficacy of ABA was robust to adjustment for baseline demographics and disease status.

In Rheumatoid Arthritis, Inhibition of the Lactate Monocarboxylate Transporters-1, and -4 in Pathological Fibroblast-Like Synoviocytes Led to Decreased ChemokineProduction

Morten Aagaard Nielsen[1], Maithri Aspari[2], Klaus Frommer[3], Malene Hvid[2], Tue Kragstrup[2] and Bent Deleuran[2], [1]Aarhus University / Aarhus University Hopital, Aarhus, Denmark, [2]Aarhus University, Aarhus, Denmark, [3]Justus-Liebig-University Giessen, Bad Nauheim, Germany

SESSION INFORMATION
Session Date: Monday, November 8, 2021
Session Title: RA – Treatments Poster II: PROs, Biomarkers, & Systemic Inflammation (1223–1256)
Session Type: Poster Session C
Session Time: 8:30AM–10:30AM

Background/Purpose: Pathological subsets of fibroblast-like synoviocytes (FLS) have recently been identified as key players in the aggravation of both persistent joint inflammation and destruction in rheumatoid arthritis (RA). In RA, these FLS are considered responsible for the acidification of the synovial fluid through local lactate production and secretion. Lactate transporters such as monocarboxylate transporter-1 (MCT1) and -4 (MCT4) are upregulated on FLS in RA. This facilitates a local build-up of lactate that influence cells in their vicinity. Inhibiting MCT4 in CIA mice led to amelioration of arthritis. In this study, we hypothesized that pathological FLS could be directly targeted by MCT inhibitors to decrease their cytokine production. We investigated the effect of therapeutically inhibiting MCT-1 and -4 in human pathological RA FLS cultures.

Methods: Synovial fluid derived FLS (SF-FLS) were isolated from the synovial fluid of patients with RA (n=6) and evaluated at passage 4, and compared with normal healthy dermal fibroblasts (NHDF). These cells were analyzed by flow cytometry for expression of the surface proteins CD34, CD45, thymocyte differentiation antigen-1 (Thy-1) and podoplanin (PDPN) and additionally evaluated by light microscopy. Subsequently, they were cultured with or without added INFg or TNFa (both 10 ng/mL) and a specific inhibitor of MCT-1 (AZD3965; 1 μM) or MCT-4 (syrosingopine; 10 μM) for 24 hours. The supernatants were analyzed with an Iscus microdialyzer and ELISA.

Results: The homogeneous subpopulations of unstimulated L/D^{neg}+$CD45^{neg}$ FLS, isolated from the synovial fluid, were positive for both Thy-1 and PDPN [94.6%, (79.9-97.4]). Without stimulation, RA SF-FLS showed substantial lactate secretion [2.567 mmol/L, (2.113-3.020)] with a factor of 1.2 more than healthy dermal fibroblasts. These levels did not increase significantly after the cells were stimulated with either INFγ or TNFα. Unstimulated pathological FLS also secreted substantial amounts of MCP-1 [2107 pg/mL, (98-4117)], elevated by a factor of >12 compared with healthy dermal fibroblasts (n=3) ($p< 0.05$). Furthermore, the levels between lactate and MCP-1 in the supernatant showed a significant positive correlation [rho = 0.89, (0.27-0,99)] ($p< 0.02$). Only when the MCT inhibitors were combined, a significant reduction in lactate secretion was detected after 24 hours. This was seen in unstimulated ($p< 0.05$) and INFγ stimulated cells ($p< 0.05$) but not after TNFα stimulation (ns) of FLS cultures. Concomitantly we detected a decrease in MCP-1 production in pathological FLS by a factor of 0.8 (0.6-0.9) ($p< 0.05$). This reduction in MCP-1 secretion was not seen if the cells were pre-stimulated with either INFγ or TNFα prior to MCT inhibition. The reduction in both lactate and MCP-1 levels were not detectable in the NHDF cultures.

Conclusion: In pathological RA FLS the production of lactate and MCP-1 were strongly correlated and blocking the transport of lactate across the cellular membrane in these cells let to decreased chemokine production. Overall, this

human in vitro study supports that targeting metabolic lactate-transporters could be a useful and promising therapeutic strategy in RA, directly affecting pathological FLS.

SESSION INFORMATION

Session Date: Monday, November 8, 2021

Session Title: RA – Treatments Poster II: PROs, Biomarkers, & Systemic Inflammation (1223–1256)

Session Type: Poster Session C

Session Time: 8:30AM–10:30AM

Background/Purpose: Our goal was to assess histological and transcriptomic effects of Abatacept (ABA) on RA synovium, and to compare them with previously published data obtained by our group using the same study design on other DMARDs: Tocilizumab (TCZ), Rituximab (RTX), Methotrexate (MTX) and Adalimumab (ADA).

Methods: Synovial tissue was obtained using ultrasound-guided biopsy from affected joints before (W0) and 16 weeks (W16) after treatment with subcutaneous Abatacept 125mg per week on a MTX background. Paraffin-sections were stained for CD3, CD20 and CD68 and scored by a pathologist for T cell, B cell and macrophage infiltration. Transcriptional profiling was performed using GeneChip Human Genome U133 Plus 2.0 arrays (Affymetrix), and analyzed on Genespring GX (Agilent). Pathway analyses were performed on Genespring GX, Metascape and EnrichR. Protein-Protein Interaction (PPI) networks were generated on STRING.

Results: 14 RA patients were included (female: 9, ACPA/RF positive: 8, erosive disease: 12, median disease duration in years (± SD): 11.7 (± 8.1), median DAS28CRP (± SD): 4.78 (± 1.11)). Median DAS28CRP significantly decreased between W0 and W16, as did US GS score. Evaluation of histological slides (n=11 pairs of samples) showed no significant effect of Abatacept on T cell, B cell or macrophage infiltration. Gene expression analysis (n=10 pairs of samples) identified 304 transcripts differentially expressed (129 downregulated, 175 upregulated) between W0 and W16 (FC≥1.5 and $p< 0.05$, paired Mann-Whitney). Downregulated genes were significantly enriched for immune processes and included several key T cell regulatory genes (*IL2RA, CD28, IL7, IL7R*), strongly overlapping with data from previous studies on TCZ (n= 12 pairs), RTX (n=12 pairs), MTX (n=8 pairs) and ADA (n=8 pairs). Thus, each treatment shares 31 to 48% of its downregulated genes with the others, with genes downregulated by at least three involved in key RA-associated pathways such as *leukocyte activation*, *NF-kappa B signaling*, *TNF signaling and JAK-STAT signaling*. Given their seemingly overlapping effects, data were pooled across these studies, markedly improving power thanks to their paired-design. This revealed that genes downregulated by DMARDs (n=573, Benjamini-Hochberg corrected p-value< 0.05, paired Mann-Whitney) were significantly enriched for both *T cell* and *myeloid leukocyte activation* pathways. Interestingly, DMARDs seem to have a coordinate effect on the two pathways (correlation of

mean Log_2FC: r=0.8558, p< 0.0001), with a stronger impact (Log_2FC_{W16-W0}) in good responders to therapy (n=17) as compared to moderate (n=20) and to non-responders (n=13) (p< 0.0001, Mann-Whitney). Finally, Transcription Factor enrichment and PPI network analyses point to a central role for molecules including JAK/STATs as mediators of all studied therapies.

Conclusion: We provide evidence that the effects of five DMARDs on RA synovium culminate in the same pathways (namely, *T cell* and *myeloid leukocyte activation*). This confirms previous studies suggesting the existence of common mediators downstream of DMARDs, independent of their primary targets, and suggests attractive new therapeutic targets.

Abstract Number: 1251

Serum B Cell Activating Factor Reflects Good EULAR Response to TNF Inhibition in Patients with Rheumatoid Arthritis

Borja Hernandez-Breijo[1], Ioannis Parodis[2], Chamaida Plasencia-Rodríguez[3], Mariana Díaz-Almirón[4], Ana Martínez-Feito[5], Marta Novella-Navarro[3], Dora Pascual-Salcedo[1] and Alejandro Balsa[3], [1]Immuno-Rheumatology Research Group, Hospital La Paz Institute for Health Research-IdiPAZ, Madrid, Spain, [2]Division of Rheumatology, Department of Medicine Solna, Karolinska Institutet, Karolinska University Hospital, Stockholm, Sweden and Department of Rheumatology, Faculty of Medicine and Health, Örebro University, Örebro, Sweden, [3]Immuno-Rheumatology Research Group, Hospital La Paz Institute for Health Research-IdiPAZ, Rheumatology, La Paz University Hospital, Madrid, Spain, [4]Biostatistics Unit, Hospital La Paz Institute for Health Research-IdiPAZ, Madrid, Spain, [5]Immuno-Rheumatology Research Group, Hospital La Paz Institute for Health Research-IdiPAZ, Immunology Unit, La Paz University Hospital, Madrid, Spain

SESSION INFORMATION

Session Date: Monday, November 8, 2021

Session Title: RA – Treatments Poster II: PROs, Biomarkers, & Systemic Inflammation (1223–1256)

Session Type: Poster Session C

Session Time: 8:30AM–10:30AM

Background/Purpose: The latest breakthroughs in the pathophysiology of rheumatoid arthritis (RA) highlighted the activation of B cells as a trigger of the joint flare initiation and therefore, implicated a central role for B cells in RA pathogenesis. B cell activating factor (BAFF) is essential for B cell activation, differentiation and survival. The main objective of this study was to investigate the role of BAFF in the progression of rheumatoid arthritis during treatment with TNF inhibitors (TNFi) and its association with treatment response.

Methods: This was a prospective study including 158 patients with RA initiated at the first TNFi and followed-up for 6 months (m). Disease activity was assessed using the Disease Activity Score 28 (DAS28) at baseline and 6m of treatment. Clinical response at 6m of treatment was defined according to the EULAR criteria for good responders. BAFF concentration was measured in serum samples collected at baseline and 6m. Associations between the EULAR response at 6m and clinical/serological variables were evaluated using univariable and multivariable logistic regression models. Receiver operating characteristic (ROC) analysis was performed to determine the optimal threshold of serum BAFF concentration portending EULAR response at 6m of TNFi treatment, determined as the highest Youden index.

Results: After 6m of TNFi treatment, 38/158 (24%) of patients attained good EULAR response (GR). These patients had lower body mass index (BMI) (p=0.02), lower baseline DAS28 (p=0.02) and lower serum BAFF concentration at baseline and at 6m compared with patients who did not attain GR. To further investigate the role of BAFF, the cohort was stratified by anti-citrullinated protein antibody (ACPA) seropositivity. 134 (85%) patients were ACPA positive and 24 (15%) were seronegative. After 6m of TNFi treatment, seropositive patients who attained GR had lower serum BAFF concentration compared with patients who did not attain GR (median [IQR]: 793 [712-956] pg/mL vs. 955 [808-1176] pg/mL; p=0.006) (Figure 1). However, there were no differences in ACPA negative patients (Table 1). Therefore, the optimal threshold value for serum BAFF concentration associated with GR at 6m of TNFi treatment was evaluated in seropositive patients. Serum BAFF< 968 pg/mL at 6m represented the concentration likely to best discriminate between GR and non-GR at 6m of TNFi treatment (AUC: 0.67; 95% CI: 0.56-0.78; p=0.009; sensitivity: 50%, specificity: 81%; PPV: 89%, NPV: 35%), yielding a positive likelihood

Table 1. Patient characteristics. The table shows mean±SD, median (IQR) or absolute number (percentage) for patients included (n=158). The results are stratified by ACPA positivity. Statistically significant differences between good responders and non-responders are indicated as p<0.05 (*) or p<0.01 (**). Serum BAFF at 6m (pg/mL)	890 (722-1074)	917 (792-1044)	793 (715-956) (*)	799 (700-992)	856 (697-992)	758 (715-1090)	903 (776-1104)	955 (808-1176)	793 (712-956) (**)

ratio of 2.7 (Figure 2). Then, a logistic regression analysis adjusted by patient characteristics with p-value≤0.1 in univariable analysis (disease duration, BMI and baseline DAS28) was performed. We found that a serum BAFF< 968 pg/mL at 6m was significantly and independently associated with GR attainment in seropositive patients (OR: 5.28; 95% CI: 1.72-16.17; p=0.004).

Conclusion: Our results show that serum BAFF concentrations reflect clinical response to TNFi after 6m of treament, mainly in ACPA positive patients. These results suggest that BAFF may be considered a biomarker of clinical response to TNFi in patients with RA.

SESSION INFORMATION
Session Date: Monday, November 8, 2021
Session Title: RA – Treatments Poster II: PROs, Biomarkers, & Systemic Inflammation (1223–1256)
Session Type: Poster Session C
Session Time: 8:30AM–10:30AM

Background/Purpose: A 23-feature blood-based molecular signature response classifier[1] (MSRC) identifies rheumatoid arthritis (RA) patients who are unlikely to respond to tumor necrosis factor-α inhibitor (TNFi) therapies. This study evaluated treatment outcomes over a 12-month period among patients prescribed TNFi therapies as a first targeted treatment and stratified according to MSRC results.

Methods: RA patients (N=175)[1] from the CERTAIN study[2] were followed 12-months following initiation of TNFi therapy. The MSRC evaluated patient gene expression data, anti-CCP and clinical metrics (sex, BMI, patient global assessment) prior to starting TNFi therapy to predict which patients were unlikely to respond to TNFi therapies. Prescription choices, response to therapies, and time on TNFi were assessed at 6, 9 and 12 months following TNFi treatment initiation. Response was measured using the ACR50 criteria.

Results: Relative to those without a molecular signature of non-response to TNFi therapies (n=93), a larger proportion of patients with high (n=26) and very high (n=47) signature of non-response discontinued their first TNFi therapy within the 12-month monitoring period (29.1% vs 42.3% and 59.6%, respectively). When a reason for discontinuation was provided, 63.6% reported issues with efficacy and 22.7% reported safety concerns. Predicted inadequate responders who did not reach ACR50 spent an average of 279 days (interquartile range 200-370) receiving TNFi therapy. Disease activity measures (DAS28-CRP, clinical disease activity index [CDAI], tender joint count and swollen joint counts) assessed at 6, 9 and 12 months following TNFi treatment initiation indicated less improvement from baseline among predicted inadequate responders compared to patients without a molecular signature of inadequate response. Among the 22 patients with more than one reported treatment cycle none (0/6) of the twelve PrismRA predicted inadequate responders achieved an ACR50 response to a second cycle TNFi therapy; however, 33% (2/6) achieved an ACR50 response to a non-TNFi treatment.

Conclusion: The molecular signature predictive of inadequate response to TNFi correlated with more discontinuation to TNFi therapy by 12 months, mostly due to lack of effectiveness; and despite this inactivity patients remained on TNFi treatment for 279 days on average.

Acupuncture in Rheumatoid Arthritis Activity

Diana Seixas[1], Fátima Farinha[2], Marcos Pacheco da Fonte[3], Manuel Laranjeira[1] and Marília Rua[4], [1]ICBAS, Porto, Portugal, [2]CHUP-HSA, Porto, Portugal, [3]CHEDV, Santa Maria da Feira, Portugal, [4]University Aveiro, Aveiro, Portugal

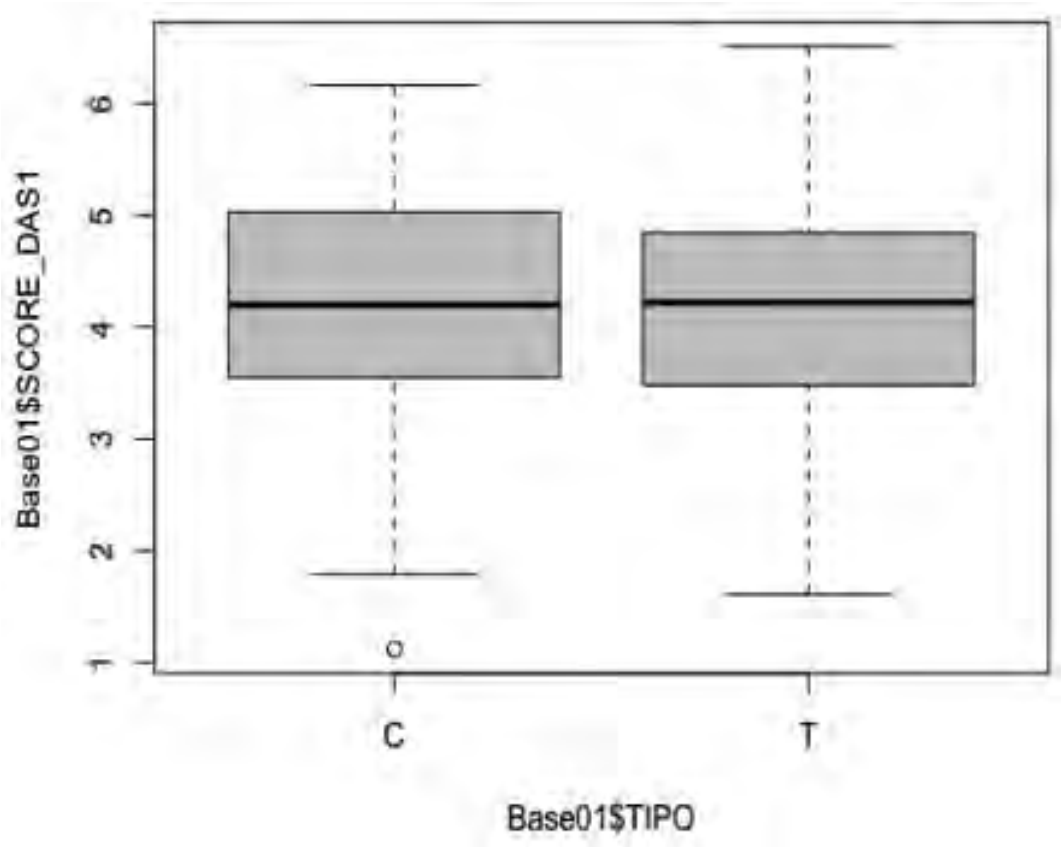
SESSION INFORMATION
Session Date: Monday, November 8, 2021
Session Title: RA – Treatments Poster II: PROs, Biomarkers, & Systemic Inflammation (1223–1256)
Session Type: Poster Session C
Session Time: 8:30AM–10:30AM

Background/Purpose: High activity rates of Rheumatoid Arthritis (RA) lead to an increased risk of mortality. RA patients have a high incidence of comorbidities, associated with the chronic inflammatory process, with joint inflammation and deformity, loss of functional capacity and quality of life. Although over time it is difficult to sustain low disease activity/remission rates, associated with a decrease in functional disability and therefore a better quality of life, reaching these goals in a timely manner leads to better functional and quality of life outcomes for patients (1). The objective of the study was to investigate the effect of acupuncture, combined with the pharmacological treatment instituted, on RA activity, through DAS28-CRP.

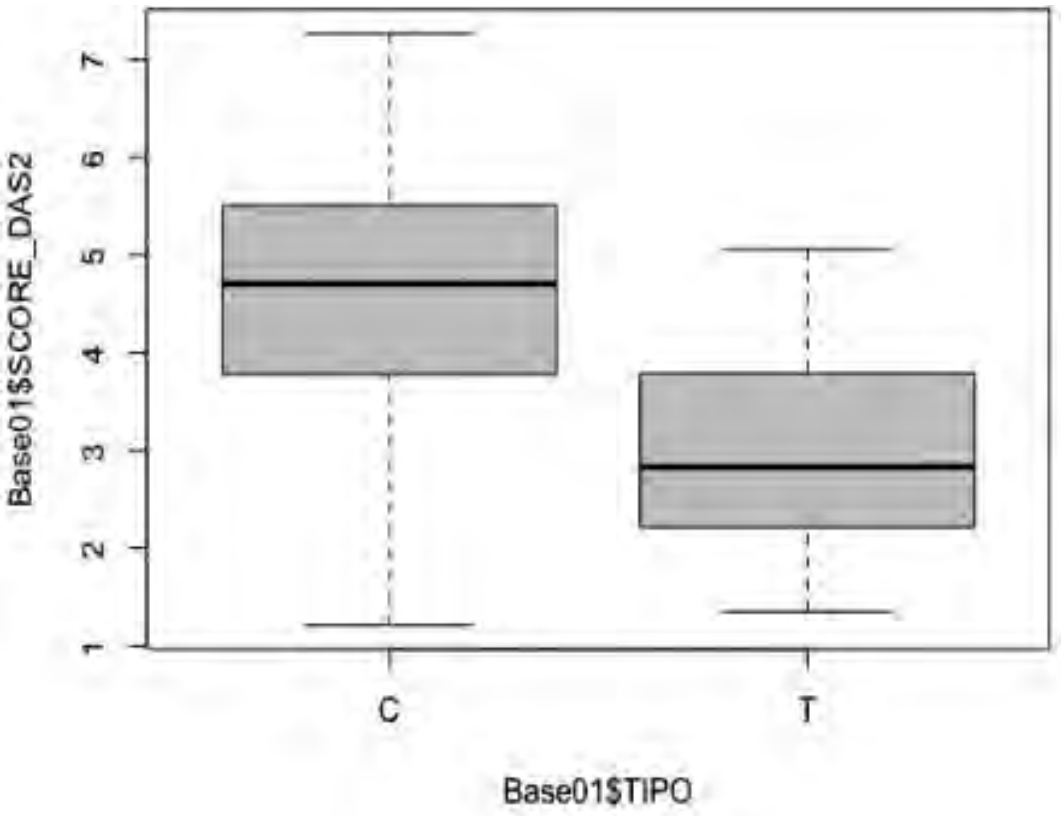
1 Scott IC, Ibrahim F, Panayi G, Cope AP, Garrood T, Vincent A, et al. The frequency of remission and low disease activity in patients with rheumatoid arthritis, and their ability to identify people with low disability and normal quality of life. *Seminars in Arthritis and Rheumatism* 49 (2019) 20-26

Methods: Randomized, prospective and controlled experimental study. Patients were submitted one acupuncture session per week for 8 consecutive weeks, with DAS28-CRP evaluation immediately before the 1st acupuncture session and another evaluation one week after the last acupuncture session. The 101 patients were randomly assigned to an Experimental Group (EG), submitted to acupuncture (n=50) and Control Group (CG), not submitted to acupuncture (n=51). All maintained pharmacological treatment in progress, not initiating any another pharmacological and/or non-pharmacological treatment during the present study.

Results: The results obtained in the first evaluation were similar between the study groups, with no significant differences that allow them to be distinguished from each other, mean (4,129 versus 4,245) and median (4,220 versus 4,200), classifying them as EG and CG, respectively, with moderate activity, defined by DAS28-CRP. In the evaluation carried out after treatment with acupuncture for EG patients, it was obtained through the DAS28-CRP score, mean (2,993) and median (4,541). CG patients, in the last evaluation, presented different and very significant results, namely the mean (4,541) and median (4,705). According to the definition by DAS28-CRP, after treatment with acupuncture, the EG decreased the disease activity index, defining itself with low activity, in contrast to the CG that maintained



Graph 1. Boxplot DAS28-CRP scores: 1st Review Experimental Group and Control Group.



Graph 2. Boxplot DAS28-CRP scores: 2nd Review Experimental Group and Control Group.

values very close to those of the first evaluation, with a moderate disease activity index. This statistical evidence is graphically explained in Graph 1 and Graph 2.

Conclusion: The effect of acupuncture was evident in patients whose treatment was combined with the pharmacological treatment already in place. The decrease in the DAS28-CRP score was clearly visible, and it's possible to inform that acupuncture, when combined with treatment already underway, allows to decrease RA activity. Thus, acupuncture may be a non-pharmacological intervention to start early, when diagnosing RA, as a way of managing and treating the disease, based on the individual needs of each patient.

Abstract Number: 1254

The Role of Regulatory T Cells (CD4+CD25+FOXP3) in Methotrexate Unresponsiveness in a Cohort of Naive Rheumatoid Arthritis Patients

Anna Abou-Raya, Darwish ELHallous, Mohamed Ossama, Nahla Farahat, Mohamed Khaled and Suzan Abou-Raya, Faculty of Medicine, Alexandria University, Alexandria, Egypt

SESSION INFORMATION
Session Date: Monday, November 8, 2021
Session Title: RA – Treatments Poster II: PROs, Biomarkers, & Systemic Inflammation (1223–1256)
Session Type: Poster Session C
Session Time: 8:30AM–10:30AM

Background/Purpose: Rheumatoid Arthritis (RA) is a chronic immune-mediated heterogenous disease characterized by a defect in the compartment of regulatory CD4+Foxp3+ T cells (Treg) which are essential for maintenance of self-tolerance and exert a suppressive effect. The first-line anchor drug for RA is low-dose methotrexate (MTX). However, 46% of RA patients started on MTX therapy discontinue treatment by 3 years and our ability to predict who will experience a good response versus non response remains very limited. Accordingly, the aim of the present study was to evaluate the role of (CD4+ CD25+ FOXP3) regulatory T cells in MTX unresponsiveness in naïve RA patients and to examine their correlation with the traditional clinical and serological markers of disease activity.

Methods: Fifty random early untreated RA patients diagnosed according to the ACR/EULAR 2010 criteria of RA, naïve to disease-modifying anti-rheumatic drugs (DMARDS) were enrolled. Information on disease duration, disease activity, presence and duration of morning stiffness, articular and extra articular complaints, smoking habits and comorbidities was recorded. The British version of the Health Assessment Questionnaire (HAQ) was performed to assess functional status. Disease activity with DAS-28 activity score was calculated for all patients. Peripheral blood (CD4+ CD25+ FOXP3) Tregs were determined in all RA patients before and after MTX treatment using multi-color flow cytometry. All patients received MTX monotherapy at a dose of 15 to 20 mg/week, maintained for at least four weeks before peripheral blood collection. Patients were stratified according to their response to MTX therapy into two groups: **Unresponsive:** (UR-MTX), treated with MTX by a dose of ≥ 15mg/week for at least 6 months and still presented active disease (DAS28 >4.0) and **Responsive:** (R-MTX), treated with MTX by a dose of ≥ 15mg/week for at least 6 months and presented remission (DAS28 < 3.0) using the EULAR response criteria.

Results: Six months after MTX monotherapy, 30 patients were classified as responders and 20 as non-responders. The mean value of CD4+ CD25+ FOXP3 Treg cells % was significantly higher in the (R-MTX) group; 0.63 ± 0.57, than in the (UR-MTX) group; 0.18 ± 0.14, p< 0.001. In the (R-MTX) group, the absolute change of (CD4+ CD25+ FOXP3)

Tregs % was inversely correlated to DAS-28 score (r_s = -0.652, p< 0.001), ESR (r_s = -0.654, p< 0.001), CRP (r_s = -0.840, p< 0.001), VAS (r_s = -0.550, p=0.002), and HAQ score. (r_s = -0.548, p=0.002), but directly correlated to serum Hb levels (r_s = 0.535, p=0.002).

Conclusion: MTX responsiveness is directly related to the expansion of (CD4+ CD25+ FOXP3) Tregs % after 6 months of MTX monotherapy, likely via the ADO/A2aR pathway. The absolute change of Tregs % correlates inversely with disease activity in responsive patients, which suggests an important role of (CD4+ CD25+ FOXP3) Treg cells in the pathogenesis of disease activity and flares. Our data also suggest that, low expression of (CD4+ CD25+ FOXP3) Treg cells after 6 months of MTX monotherapy, could be a biomarker for predicting unresponsiveness to MTX in RA patients.

A Molecular Signature Response Classifier Predicts the Likelihood of Non-response to TNF Inhibitor Therapies in RA at 3 Months

Stanley Cohen[1], Theodore Mellors[2], Lixia Zhang[3], Alex Jones[3], Erin Connolly-Strong[4], Dimitrios Pappas[5], Joel Kremer[6], Johanna Withers[3] and Viatcheslav Akmae[3], [1]Metroplex Clinical Research Center, Dallas, TX, [2]Scipher Medicine, Waltham, TX, [3]Scipher Medicine, Waltham, MA, [4]Scipher Medicine, Austin, TX, [5]CorEvitas, LLC, Waltham, MA, [6]Albany Medical College, Latham, NY

SESSION INFORMATION
Session Date: Monday, November 8, 2021
Session Title: RA – Treatments Poster II: PROs, Biomarkers, & Systemic Inflammation (1223–1256)
Session Type: Poster Session C
Session Time: 8:30AM–10:30AM

Background/Purpose: Most people with rheumatoid arthritis (RA) are prescribed a TNF inhibitor (TNFi) as their first targeted therapy. A blood-based molecular signature response classifier (MSRC) was shown to predict inadequate response to TNFi therapies, before treatment initiation.[1] Identification of likely inadequate responders has the potential to reduce the time spent on trial-and-error approaches for treatment selection. Incorporating this test into clinical workflows could result in improved patient outcomes, reduced patient burden and potentially reduced disease progression.[2,3] In a treat-to-target treatment approach, 3-months post treatment initiation is an important decision point for assessment of response;[4] therefore, further validation of the MSRC at timepoints earlier than 6 months are warranted.

Methods: The MSRC uses data collected at baseline before starting targeted therapy, including gene expression features, laboratory tests (anti-CCP) and clinical metrics (sex, BMI, patient global assessment) to determine if patients have a molecular signature predictive of inadequate response to TNFi. The MSRC was used to evaluate RA patients (N=96) from the CERTAIN study[5] who were initiating a TNFi as their first targeted therapy. None of these patients were included in previous MSRC validation studies, and only baseline and 3-month follow-up visit data were available. MSRC prediction of inadequate response were compared to treatment response, ACR50, reported at 3 months. Odds ratios and area under the receiver operating characteristic curve (AUC) were used to evaluate the ability of the MSRC test to predict inadequate response to TNFi therapy at 3 months.

Results: Of the 96 RA patients described in Table 1, 51.0% (49/96) had a molecular signature of non-response. An ACR50 response at 3 months to a TNFi therapy was observed in 20.8% (20/96) of patients. Patients were stratified

Table 1. Patient demographics

Characteristic	RA patients (N = 96)
Age, median (SD)	54 (13.7%)
Female, n (%)	74 (77.1%)
CCP positive, n (%)	57 (59.3%)
RF positive, n (%)	57 (59.3%)
TNFi use, n (%)	
Adalimumab	38 (39.6%)
Etanercept	26 (27.1%)
Infliximab	18 (18.8%)
Certolizumab pegol	11 (11.5%)
Golimumab	3 (3.1%)

according to detection of a molecular signature of non-response to TNFi therapy with an AUC of 0.63. Patients with a molecular signature of non-response were 3 times less likely to satisfy the ACR50 response criterium at 3 months compared to patients lacking the molecular signature (odds ratio 3.0, 95% confidence interval 1.1-8.8).

Conclusion: The MSRC identified RA patients who did not fulfill the ACR50 response criteria to TNFi therapies by 3 months post-treatment initiation. Minimal response to treatment at 3 months is indicative of poor treatment response targets at later timepoints.[6,7] Thus, MSRC test results received prior to treatment could support targeted therapy treatment selection in treat-to-target management strategies.

Factors Associated with the Use of Biologic Disease-modifying Antirheumatic Drugs in Patients with Rheumatoid Arthritis

Roya Hosseini[1], Souhiela fawaz[2] and Enrique Seoane-Vazquez[2], [1]Chapman University School of Pharmacy, Aliso Viejo, CA, [2]Chapman University School of Pharmacy, Irvine, CA

SESSION INFORMATION
Session Date: Monday, November 8, 2021
Session Title: RA – Treatments Poster II: PROs, Biomarkers, & Systemic Inflammation (1223–1256)
Session Type: Poster Session C
Session Time: 8:30AM–10:30AM

Background/Purpose: Rheumatoid arthritis (RA) is a chronic autoimmune inflammatory disease characterized by polyarthritis of small and large joints. RA is the second most common type of autoimmune arthritis. RA treatment has been revolutionized by the development of biologic disease-modifying antirheumatic drugs (bDMARDs), which are increasingly used after the introduction of biosimilar products. This study evaluates the association between biologic DMARDs use and the social demographic characteristics of the RA patient population and assesses changes in biologic DMARDs utilization in the RA patient population after biosimilars market entry.

Methods: In this retrospective analysis of Medical Expenditure Panel Survey (MEPS) data from 2010 to 2018, the study population includes RA patients diagnosed using the International Classification of Disease. Logistic regression will be conducted to measure the association between biologic DMARD use and the study population's social demographic characteristics. Linear regression will also be used to assess changes in biologic DMARDs utilization in the RA patient population after biosimilars market entry.

Results: A total of 1620 patients were diagnosed with RA in 2010-2015, of which 72% of RA patients were females, and 28% were males. Most patients were aged 45-70 years (63.3%) with a mean±SD age of 58.5±15.2 and a range of 6 to 85 years old. RA patients were predominantly white (61.2%) and non-Hispanic (78.7%). Private and public health insurance covered 41% and 52% of the patient population, respectively, and 7% were uninsured. bDMARDs were used by 20% and cDMARDs by 80% of the patients. Methotrexate, among cDMARDs, was the drug more often prescribed. Adalimumab and etanercept, among bDMARDs, had a similar percentage of prescriptions. The results of the regression analyses will be also presented.

Conclusion: Biologic disease-modifying antirheumatic drugs play a crucial role in managing and treating rheumatoid arthritis. Thus, it is essential for clinicians, healthcare providers, and policy-makers to understand the association of the social demographic characteristics of RA patients and the utilization of DMARDs to improve RA patients' outcomes.

SESSION INFORMATION

Session Date: Monday, November 8, 2021

Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster III: Outcomes (1257–1303)

Session Type: Poster Session C

Session Time: 8:30AM–10:30AM

Background/Purpose: Laboratory tests are routine in the management of SLE. In clinical trial endpoints, data from laboratory tests contribute to responder status, but this is captured using discrete thresholds rather than continuous data. We investigated whether the trajectory of abnormal laboratory tests in patients with active SLE, measured as continuous data, corresponds with conventional measures of clinical improvement.

Methods: We used clinical and laboratory data from a large multinational prospectively followed longitudinal cohort. Eligible patients had active disease (SLEDAI-2K ≥6), and at least one abnormal routine laboratory test (haemoglobin, white cell count, lymphocytes, platelets, ESR, albumin, C3, C4, anti-dsDNA, and urine protein, red cells or white cells), at a visit designated as baseline. At 12 months thereafter, for each laboratory test we classified improvement from individual patient baselines as complete response (CR; 100% improvement i.e. restoration to normal range), partial response (PR; ≥ 20-< 100% improvement) or no response (NR; < 20% improvement)) and assessed associations with a range of improvement outcomes: modified SLE responder index (omitting BILAG criteria) (mSRI4), physician global assessment (PGA) improvement ≥ 0.3, attainment of lupus low disease activity state (LLDAS (Golder, 2019)), SLE flare index (SFI) and SLICC/ACR damage index accrual (SDI increase >0), using logistic regression.

Results: 1,525 patients were included, with separate subsets for each individual abnormal laboratory test. Most patients were female (93%), Asian (88%) and had established SLE. Associations (odds ratios, 95% confidence inter-

vals and significance) of laboratory variable CR and PR with clinical outcomes at 12 months are shown in Figure 1. Improvement in proteinuria, albumin, haemoglobin, ESR and platelets had the strongest associations with clinical improvement measures, including increased odds of LLDAS attainment and protection against damage accrual. In contrast, serology was associated only with the less stringent outcomes of PGA improvement and mSRI4. White cell count and lymphocytes had the weakest associations with improvement measures. Although CR had stronger associations, PR of certain laboratory tests also conferred benefit.

Laboratory test and definition of abnormal	Laboratory test improvement at 12 months	Modified SRI4	Improved PGA ≥0.3	Presence of flare (SFI)	LLDAS attainment	Damage accrual (increased SDI)

Odds ratio (95% CI) | p>0.1 | p=0.05-1.0 | p<0.05

Figure 1. Associations of partial and complete improvement in abnormal laboratory tests between baseline and 12 months, and corresponding clinical improvement outcomes.

Conclusion: Improvements in abnormal laboratory tests were predictive of clinical outcomes at 12 months, with a discrepancy between tests currently incorporated in clinical trial endpoints, such as serology, and those with the strongest associations with clinical outcomes. Associations with improved clinical outcomes were associated with improvement thresholds less stringent than complete resolution for some tests. The selection, weighting and threshold-based use of laboratory tests in lupus trial endpoints should be revised.

Measurement of Specific Organ Domains in Lupus Randomised Controlled Trials

Kathryn Connelly[1], Jeevan Vettivel[2], Vera Golder[2], Rangi Kandane-Rathnayake[2] and Eric Morand[3], [1]Monash University, Camberwell, Australia, [2]Monash University, Clayton, Australia, [3]Monash University, Melbourne, Australia

SESSION INFORMATION
Session Date: Monday, November 8, 2021
Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster III: Outcomes (1257–1303)
Session Type: Poster Session C
Session Time: 8:30AM–10:30AM

Background/Purpose: Randomised controlled trials (RCTs) in SLE typically adopt composite responder definitions as primary efficacy endpoints, however outcomes within individual organ domains are also important to understand in order to infer the efficacy profile of a new treatment. The aim of this study was to evaluate how, and how consistently, organ-specific disease activity and therapeutic responses have been measured and reported in lupus RCTs.

Methods: We conducted a scoping review in accordance with the Johanna Briggs Institute Guidance and 2018 PRISMA statement. We systematically searched MEDLINE, EMBASE, Cochrane registry and clinicaltrials.gov. Eligible studies were RCTs investigating efficacy of an immune-directed drug therapy in active SLE, published January 2000-March 2021, excluding studies limited to lupus nephritis. Data items for each eligible RCT were general study/patient characteristics, and clinician-reported outcome measures of organ-specific disease activity at baseline and

treatment response definitions at the primary endpoint. Data were extracted independently in duplicate into a pre-established form and summarised descriptively.

Results: A total of 34 RCTs were included (PRISMA diagram, Figure 1). Nine non-renal organ domains were measured using a limited number of instruments. Table 1 summarises the frequency of organ-specific involvement at baseline, and different response definitions used, across the RCTs. Study populations had a high, although variable, frequency of baseline musculoskeletal and mucocutaneous activity and low but also variable representation of other domains. Definitions of organ-specific responses were inconsistent, even within individual instruments. Response in most organ domains were evaluated using BILAG and SLEDAI components but meaningful comparison between treatment arms was limited by small subgroups analysed in post-hoc fashion. Outcome measures using Cutaneous Lupus Erythematosus Disease Area and Severity Index activity scores (CLASI-A) and joint counts (tender, swollen and/or active) were also commonly used, including within pre-specified organ-specific endpoints, which discriminated between treatment arms in some studies.

Conclusion: Mucocutaneous and musculoskeletal manifestations predominate in SLE RCTs. Organ-specific outcome measures are commonly reported, but definitions of involvement and response are inconsistent between trials. Research into the development of new outcome measures for key organ domains, and validation and comparison of response definitions using existing instruments is needed, to facilitate evaluation of the efficacy of novel therapies and ensure the validity, consistency, and comparability of individual organ responses within and between trials.

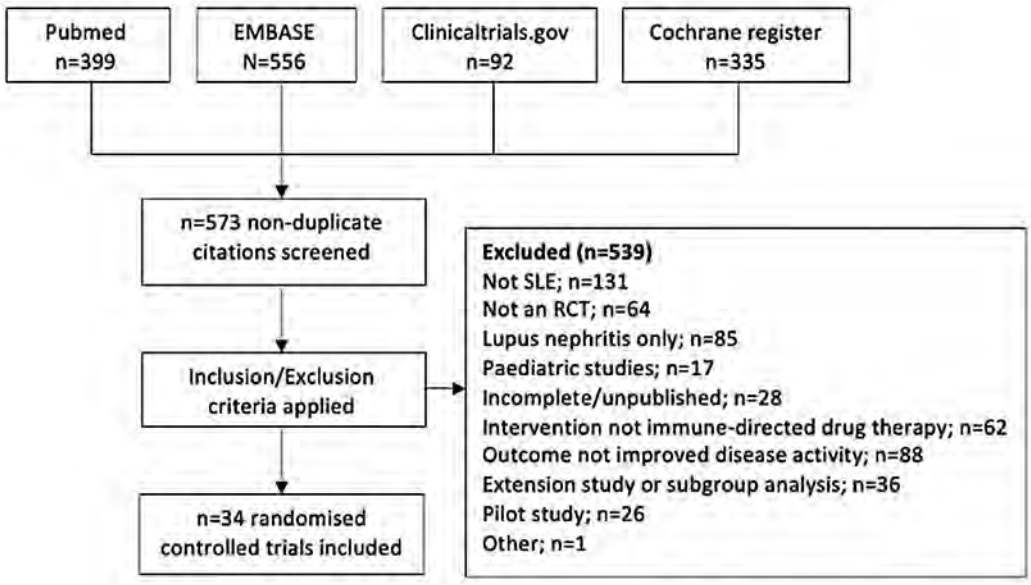

Figure 1. PRISMA diagram demonstrating study selection.

Table 1. Definition and rates of organ-specific activity and treatment responses in the included RCTs, according to instruments employed in at least one study

Domain	Instrument	Rates of organ involvement	Response definitions
Muco-cutaneous	SLEDAI	Mucocutaneous SLEDAI (11 studies): 82-96%	Reduction in score from mucocutaneous items (7 studies)
	BILAG	BILAG A/B (14 studies): 49-86% BILAG A (5 studies): 15-33%; B (4 studies): 57-72%	Reduction in mucocutaneous letter grade from A/B (5 studies) Reduction in mucocutaneous letter grade from A/B/C (1 study) Resolution in mucocutaneous letter grade to BILAG D (2 studies)
	CLASI-A	Mean CLASI-A (8 studies): 3.8-13.6	Reduction ≥50% from baseline ≥10 (4 studies) Reduction ≥50% from baseline ≥4 (1 study) Reduction ≥4 from baseline ≥10 (1 study) Difference in mean change from baseline (3 studies)
Musculo-skeletal	SLEDAI	Musculoskeletal SLEDAI (12 studies): 59-96%	Reduction in score from musculoskeletal items (6 studies)
	BILAG	BILAG A/B (14 studies): 27-98% BILAG A (5 studies): 9-32%; B (4 studies): 51-63%	Reduction in musculoskeletal letter grade from A/B (5 studies) Resolution in musculoskeletal letter grade to BILAG D (2 studies)
	Joint count	Mean 28-SJC (8 studies): 2.7-8.6 Mean 28-TJC (8 studies): 7.3-20.1 Mean 28-active joint count (2 studies): 6.8-7.9	Reduction ≥50% in TJC and SJC from baseline ≥6 (1 study) Reduction ≥50% in TJC and SJC from baseline ≥8 (3 studies) Reduction ≥50% in TJC and SJC from baseline ≥4 (1 study) Difference in mean change in TJC from baseline (3 studies) Difference in mean change in SJC from baseline (3 studies) Difference in mean change in active joints from baseline (3 studies)
Haematologic	SLEDAI	Haematological SLEDAI (10 studies): 5-13%	Reduction in score from haematological items (6 studies)
	BILAG	BILAG A/B (10 studies): 0-24% BILAG A (4 studies): 0-2%; B (3 studies): 0-22%	Reduction in haematological letter grade from A/B (5 studies) Resolution in haematological letter grade to BILAG D (1 study)
Cardio-Respiratory	SLEDAI	Cardio-respiratory SLEDAI (8 studies): 1-9%	Reduction in score from cardio-respiratory items (5 studies)

SESSION INFORMATION

Session Date: Monday, November 8, 2021

Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster III: Outcomes (1257–1303)

Session Type: Poster Session C

Session Time: 8:30AM–10:30AM

Background/Purpose: The SLE Responder Index (SRI) is a composite responder definition employed as a clinical trial endpoint in SLE. Despite its widespread adoption, recent discrepant trial results have questioned its performance as an efficacy endpoint, and there is limited validation of the SRI against long-term clinical outcomes. The aim of this study was to investigate longitudinal associations of SRI attainment with key clinical outcomes.

Methods: We used data from a large multi-centre longitudinal SLE cohort. Eligible patients had active disease (SLEDAI-2K ≥6) at a visit designated as baseline. Attainment of a modified version of the SLE Responder Index (mSRI; excluding BILAG criteria) defined as a reduction in SLEDAI-2k ≥4 with no worsening in physician global assessment (PGA) ≥0.3 was determined at 1-year intervals from baseline (up to 5 years). The associations between mSRI attainment and a range of clinical outcomes (longitudinal disease activity, steroid use, flare, damage accrual, attainment of lupus low disease activity state (LLDAS (Golder 2019)), clinical remission on therapy (CROT (van Vollenhoven 2017)) and mortality) were determined using univariable linear and logistic regression.

Results: A total of 2,024 patients had an eligible baseline visit. Baseline characteristics are summarised in Table 1. mSRI response was attained by 55.5% of patients at 1 year, with similar rates (54-57%) at subsequent annual visits. Associations of mSRI response with clinical outcomes were similar at each of the annual time points; Table 2 presents results at years 1, 3 and 5 post baseline. Attainment of mSRI was associated with significantly lower disease activity over follow-up.

Table 1. Baseline characteristics (n=2024)

Baseline characteristic	Median (interquartile range) or n (%)
Age at enrolment	37 (28, 47)
Age at diagnosis	27 (21, 37)
Female	1868 (92.3%)
Asian ethnicity	1783 (88.4%)
SLEDAI-2K score	8.0 (6.0, 10.0)
Physician global assessment (PGA)	1.0 (0.5, 1.5)
Prednisolone (mg/day)	7.5 (5.0, 15)
Mild/moderate flare	871 (45.3%)
Severe flare	331 (17.2%)
SLICC-ACR damage index (SDI) >0	777 (41.8%)

Table 2. Associations between mSRI attainment and clinical outcomes at follow up years 1, 3 and 5

Outcome	Year 1 (n=1567)			Year 3 (n=936)			Year 5 (n=522)		
	mSRI responder			mSRI responder			mSRI responder		
	No n=671	Yes n=838	RC or OR p-value	No n=399	Yes n=472	RC or OR p-value	No n=213	Yes n=282	RC or OR p-value

SELENA-SLEDAI flare mild/moderate (ever)	408 (61%)	477 (57%)	1.51 p=0.128	265 (67%)	341 (73%)	1.33 p=0.057	158 (75%)	221 (78%)	1.22 p=0.364
SELENA-SLEDAI flare severe (ever)	223 (33%)	248 (30%)	1.42 p=0.13	172 (44%)	226 (49%)	1.19 p=0.202	110 (53%)	158 (57%)	1.18 p=0.38
Damage accrual after baseline visit (SDI)	68 (10%)	65 (8%)	2.94 p=0.106	101 (26%)	92 (20%)	**0.71 p=0.037**	74 (36%)	86 (31%)	0.82 p=0.32
Lups low disease activity state (LLDAS) (ever)	203 (30%)	525 (63%)	**2.16 p<0.001**	245 (62%)	366 (79%)	**2.24 p<0.001**	141 (67%)	243 (86%)	**3.14 p<0.001**
Clinical remission on therapy (CROT)	138 (21%)	362 (43%)	**5.37 p<0.001**	184 (47%)	167 (29%)	**2.36 p<0.001**	123 (59%)	216 (77%)	**2.31 p<0.001**
Death	0 (0%)	2 (0.2%)	N/A	0 (0%)	0 (0%)	N/A	1 (0.5%)	0 (0%)	N/A

Note patients with unknown PGA were excluded when defining mSRI responder status

Damage accrued in 9% of patients at 1 year and 32% by 5 years, with rates numerically lower in mSRI responders at all time points (significant at years 2 and 3). mSRI response was also significantly associated with attainment of LLDAS and clinical remission on therapy. Prednisolone doses at follow-up visits were consistently lower in the mSRI responder group, but time-adjusted mean dose had no significant differences. mSRI response was not associated with significant protection against flare. There were insufficient deaths for meaningful between-group comparison.

Conclusion: In a longitudinal cohort of SLE patients with baseline SLEDAI ≥6, attainment of a modified SRI responder index at annual visits up to 5 years was associated with clinical benefit including lower disease activity, reduced damage accrual and higher attainment of treat-to-target endpoints.

Factors That Impact Medication Adherence in Hospitalized Patients with Systemic Lupus Erythematosus

Prarthana Jain[1], Mithu Maheswaranathan[2], Holly Mitchell[3] and Diane Kamen[1], [1]Medical University of South Carolina, Charleston, SC, [2]Duke University School of Medicine, Durham, NC, [3]Ralph H Johnson VA Medical Center, Charleston, SC

SESSION INFORMATION

Session Date: Monday, November 8, 2021

Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster III: Outcomes (1257–1303)

Session Type: Poster Session C

Session Time: 8:30AM–10:30AM

Background/Purpose: Systemic lupus erythematosus (SLE) is an autoimmune disease, characterized by episodes of flares, often involving multiple organ systems. Medication nonadherence remains a significant problem, reported by 43% to 75% of patients with one third self-discontinuing treatment after 5 years. Medication nonadherence has been linked to increased morbidity and hospital readmission. In addition to known predictors of nonadherence, including low socioeconomic status and side effects of medications, we hypothesized that pill burden, medical/psychiatric comorbidities and patient beliefs also play a role. Using survey methodology, our study examines factors that impact medication adherence among hospitalized patients with SLE. By characterizing these factors qualitatively and quantitatively, we hope to identify ways to decrease barriers to nonadherence.

Methods: This study was approved by the local Institutional Review Board. Hospitalized patients with SLE were identified and invited to participate. Demographics, education level, employment, insurance status, and self-reported outpatient medication use were obtained by patient interview. Patient-reported medication use was compared to outpatient prescriptions from the medical record to determine pill burden and adherence. Qualitative information was collected on beliefs surrounding medications and the presence of family and community support. Patients were

instructed to complete the STOFHLA health literacy questionnaire. Two-sample t-tests for continuous variables and Fisher's exact test for categorical measures were performed as appropriate.

Results: 20 patients with SLE met eligibility criteria and consented to participate. Most of our patients were black (n=18, 90%) and all were female, with a mean age of 36.4 ± 15.3. In his cohort, 55% of patients reported lack of medication adherence within 2 weeks of hospitalization. Nonadherent patients were more likely to have 3 or more additional medical/psychiatric comorbidities ($p< 0.01$). Nonadherent patients were also more likely to report that taking their medication was a hassle or inconvenience ($p< 0.05$). Factors such as age, employment, insurance status, or self-reported presence of family and/or community support were not significantly associated with adherence. There was no statistical difference in hospital length of stay (7.4 vs. 8.1 days) or pill burden per week (135 vs. 123 pills/week) between adherent and nonadherent patients. Health literacy, as measured by the STOFHLA, was not significantly different between adherent and nonadherent patients.

Conclusion: Within this predominantly African American female cohort of patients with SLE, there was high pill burden and prevalence of medication nonadherence prior to hospitalization. Despite the small sample size, this ongoing study provides insight into barriers important to patients and modifiable risk factors that healthcare providers can target when treating patients with SLE and addressing nonadherence.

SESSION INFORMATION

Session Date: Monday, November 8, 2021

Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster III: Outcomes (1257–1303)

Session Type: Poster Session C

Session Time: 8:30AM–10:30AM

Background/Purpose: Health-related quality of life (HRQoL) is considered one of the most important outcomes in clinical trials of systemic lupus erythematosus (SLE), along with reduction in disease activity and safety. We studied the duration and consecutiveness of remission or low disease activity throughout a 52-week long period on standard therapy plus belimumab or placebo in relation to HRQoL outcome.

Methods: We analysed pooled 52-week data from the BLISS-52 (N=865) and BLISS-76 (N=819) phase III trials. We determined remission using the prevailing Definitions of Remission in SLE (DORIS) definition (1) and low disease activity using the Lupus Low Disease Activity State (LLDAS) (2). Remission required clinical (c)SLEDAI-2K=0, PhGA (0–3) <0.5, and prednisone ≤5 mg/day. LLDAS required SLEDAI-2K ≤4, PhGA (0–3) ≤1, and prednisone ≤7.5 mg/day. HRQoL was measured with the SF-36 physical and mental component summary (PCS and MCS), and EQ-5D-3L. Minimal clinically important difference (MCID) at week 52 for PCS and MCS was set to 2.5, and for EQ-5D-3L utility index to 0.040. Associations were assessed using quantile regression analysis. Adjustments for demographics, disease duration, organ damage and baseline status were incorporated.

Results: The minimum cumulative attainment of remission to achieve a benefit in PCS ≥MCID at week 52 was four visits (corresponding to 16 weeks) (β=0.63), while 7 visits (28 weeks) were required for MCS differences ≥MCID (β=0.37). Correspondingly, 9 visits in LLDAS (36 weeks) were required for achieving differences ≥MCID in both PCS (b=0.28) and MCS (β=0.29). Table 1 shows 95% confidence intervals and p values. When analysing the impact of sustained remission and LLDAS, four consecutive visits in remission (16 weeks) were required for PCS ≥MCID (b=0.70), whereas six visits (24 weeks) were required for MCS ≥MCID (b=0.46). Sustained LLDAS for nine consecutive visits (36 weeks) was needed for PCS and MCS ≥MCID (b=0.31 and 0.31, respectively). For EQ-5D ≥MCID to be reached, a cumulative total of seven visits (28 weeks) in remission (b=0.006), or eight visits (32 weeks) in LLDAS (b=0.005) was required, whereas if sustained, remission for six visits (24 weeks; b=0.008) or LLDAS for seven visits (28 weeks; b=0.006) were sufficient.

Conclusion: Attainment of remission or LLDAS in the BLISS-52 and BLISS-76 trials of belimumab was associated with improved HRQoL. Less time was required in remission than in LLDAS to achieve clinically important differences in multiple HRQoL aspects. Clinically important differences in HRQoL required shorter total time if the remission or LLDAS was sustained. Clinically important differences in mental aspects of HRQoL required longer time in remission than physical aspects. The impact of cumulative and sustained remission or LLDAS on HRQoL adds evidence on the clinical importance of these treat-to-target endpoints.

Associations with:	PCS β (95% CI) P value	MCS β (95% CI) P value	EQ-5D β (95% CI) P value
≥2 cumulative visits in remission	0.63 (4 visits) (0.31–0.95) P<0.001	0.37 (7 visits) (0.12–0.62) P=0.004	0.006 (7 visits) (0.002–0.010) P=0.002
≥2 cumulative visits in LLDAS	0.28 (9 visits) (0.13–0.43) P<0.001	0.29 (9 visits) (0.10–0.47) P=0.002	0.005 (8 visits) (0.003–0.007) P<0.001

SESSION INFORMATION
Session Date: Monday, November 8, 2021
Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster III: Outcomes (1257–1303)
Session Type: Poster Session C
Session Time: 8:30AM–10:30AM

Background/Purpose: Omega-3 fatty acid-derived "specialized pro-resolving mediators" (SPM) are low-abundance lipid mediators (LM) central to inflammation resolution. In this cross-sectional study, we investigated whether fish oil (FO) supplementation was associated with pro-inflammatory and pro-resolving LM in SLE patients compared to matched non-SLE controls.

Methods: Within the Mass General Brigham Biobank, we identified 16 patients with SLE taking FO, who were matched by age, sex, and race to 16 patients without SLE taking FO. Another 16 patients with SLE not taking FO were matched on the same factors to 16 non-SLE patients not taking FO. Demographic and clinical data were obtained by medical record review (**Table 1**). Targeted liquid chromatography-tandem spectroscopy was performed on plasma to quantify 27 omega-3-derived LM, identified with >6 diagnostic ions by tandem mass spectrometry (MS-MS). Multivariable linear analyses examined whether SLE, FO, and the interaction between SLE and FO were associated with LM levels (log-transformed to improve normality), adjusting for smoking status, body mass index and medications. In SLE case-only analyses, we additionally adjusted for C-reactive protein or erythrocyte sedimentation rate (normal/elevated), anti-double stranded DNA (dsDNA positive/negative), C3 and C4 (normal/low), and presence of lupus nephritis. We adjusted for multiple comparisons using a False Discovery Rate (FDR) with a cut-off of 0.05. For missing data, we used multiple imputation.

Table 1. Baseline characteristics of SLE patients and age, sex, and race matched controls				
Characteristic	**Not taking Fish Oil**		**Taking Fish Oil**

Abbreviations: BMI, body mass index; HCQ, hydroxychloroquine; SD, standard deviation; SLE, systemic lupus erythematosus

1. Pravastatin, atorvastatin, lovastatin, rosuvastatin, simvastatin
2. Methotrexate, leflunomide, sulfasalazine, cyclophosphamide, cyclosporine, mycophenolate mofetil, etanercept, adalimumab, rituximab, infliximab, belimumab, tofacitinib, tocilizumab

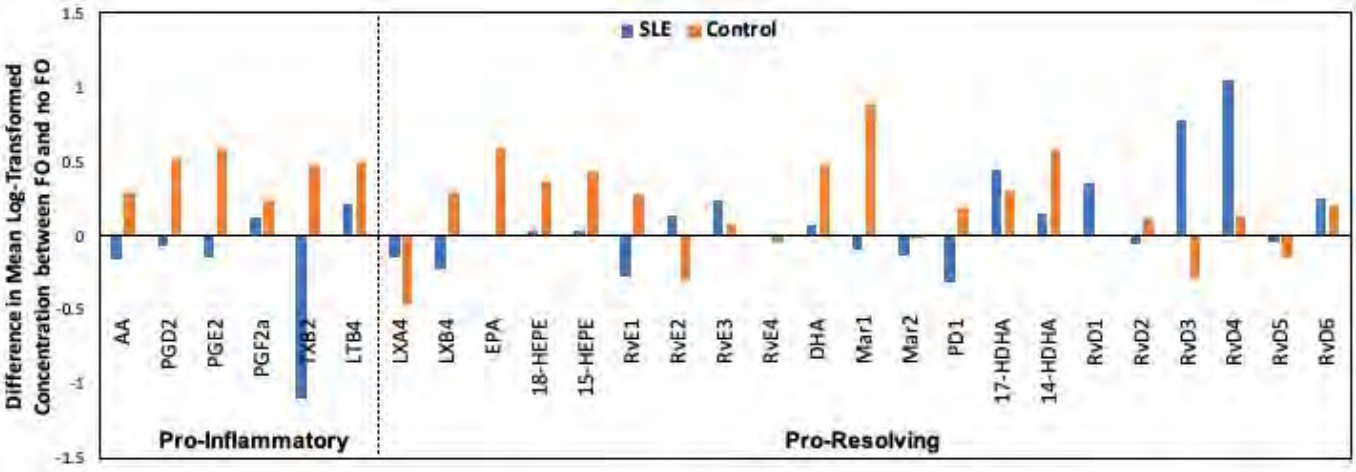

Figure 1. Difference in mean log-transformed Omega-3 fatty acid derived lipid concentration between taking vs. not taking fish oil supplementation among SLE and controls. No statistically significant differences were found after adjustment for multiple comparisons was performed using false discovery rate of 0.05. Abbreviations: LTB4, Leukotriene B4; LXA4, Lipoxin A4; LXB4, Lipoxin B4; MaR1-2, maresin 1-2; PGD2, Prostaglandin D2; PGE2, Prostaglandin E2; PGF2a, Prostaglandin F2 alpha; TXB2, Thromboxane B2; PD1, protectin D1; RvD1-6, resolvin D-6; RvE1-4, resolvin E1-4; 14-HDHA, 14-hydroxy-docosahexaenoic acid; 15-HEPE, 15-hydroxyeicosapentaenoic acid; 17-HDHA, 17-hydroxy-docosahexaenoic acid; 18-HEPE, 18-hydroxyeicosapentaenoic acid.

Results: Among SLE patients, lower levels of arachidonic acid (AA) and most (60%) of its pro-inflammatory derivatives were observed in those taking vs. not taking FO, whereas, among the controls, higher levels of AA and all of its pro-inflammatory derivatives were observed in those taking vs. not taking FO (**Figure 1**). However, after adjustment for multiple comparisons, there were no significant differences for any LM between SLE compared to matched controls, taking or not taking FO. Among controls, taking FO was associated with higher levels of eicosapentaenoic acid (adjusted ß coefficient 0.67 (95% CI: 0.28-1.07), FDR = 0.04) (**Table 2**). Taking FO was not associated with SPM levels among SLE patients even after adjusting for markers of disease activity. The interaction between SLE and FO was not statistically significant.

Conclusion: In this cross-sectional study, FO supplementation among SLE patients was not significantly associated with higher levels of several pro-resolving SPMs. This may be related to a higher level of inflammatory burden in SLE patients at baseline, reduced ability to biosynthesize SPMs, or failure to take regular and adequate doses of FO. As FO preparations and doses were not controlled in this observational study, further larger controlled studies should pursue these observations.

Table 2. Effects of dietary fish oil supplements on Omega-3 Fatty Acid derived Lipid Mediators, adjusted for smoking, BMI, medications (prednisone, immunomodulators, and statins) and markers of SLE disease activity (for SLE cases only)

	Lipid	Among SLE taking FO (n=16) vs. not taking FO(n=16)			Among Control Subjects taking FO (n=16) vs. not taking FO (n=16)

Treatment of Pediatric Lupus Is Associated with Significant Re-Organization of B Cell Chromatin

Joyce Hui-Yuen[1], Kaiyu Jiang[2], Susan Malkiel[3], Betty Diamond[3] and James Jarvis[4], [1]North Shore LIJ Health System, Great Neck, NY, [2]University at Buffalo, Buffalo, NY, [3]Northwell Health, Manhasset, NY, [4]University at Buffalo Jacobs School of Medicine, Buffalo, NY

SESSION INFORMATION
Session Date: Monday, November 8, 2021
Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster III: Outcomes (1257–1303)
Session Type: Poster Session C
Session Time: 8:30AM–10:30AM

Background/Purpose: Systemic lupus erythematosus (SLE) may be triggered by gene-environment interactions. Data remain scarce on how epigenetic variance contributes to disease risk in pediatric SLE (pSLE). Our objectives were to identify differences in chromatin architecture in treatment-naïve pSLE compared to healthy children (HC) and pSLE patients after induction therapy.

Methods: We used assays for transposase-accessible chromatin-sequencing (ATACseq) in 8 pSLE patients pre- and post-induction therapy and 5 HC to investigate whether regions of open chromatin unique to pSLE patients demonstrate enrichment for transcriptional regulators, using standard computational approaches and a false discovery rate of < 0.05.

Results: The mean age of onset was 13.75 (range 7-17) years in pSLE, and mean SLEDAI was 12.8 (range 6-24). We identified 245 differentially accessible regions (DAR) around peaks unique to treatment-naïve pSLE patients, of which over 50% appear to be more accessible in pSLE than HC, and are located more than 100kb from the nearest transcription start site (nTSS), implying transcription factors (TF) may be acting on distal enhancers to regulate transcription. pSLE DAR were enriched for enhancer marks. In DAR encompassing TF binding sites, pSLE samples, but not HC, were enriched for disease-associated single nucleotide polymorphisms (SNPs) previously identified in lupus genome-wide association studies. Variant calling within DAR found 3864 genes belonging to 129 different biologic processes, including cellular activation in immune response and responses to external stimuli. In contrast, over 80% of peaks unique to pSLE patients post-induction therapy are located distal to nTSS. Induction therapy for pSLE patients included corticosteroids in all patients, cyclophosphamide in 5, and mycophenolate in 3. DAR from pSLE patients post-induction therapy were not enriched for enhancers or disease-associated SNPs.

Conclusion: We demonstrate an epigenetically-distinct profile in pSLE B cells when compared to HC, indicating pSLE B cells are predisposed for disease development. Pathways of significance analyses identified immunologic pathways important in the pro-inflammatory response in treatment-naïve pSLE patients. These pathways were absent in analyses from the same pSLE patients post-induction therapy. Thus, increased chromatin accessibility in genomic regions controlling activation of inflammatory and immune responses suggest transcriptional dysregulation of key players in immune cell activation plays an important role in pathogenesis of SLE. Treatment with corticosteroids and immunosuppressive medication changes this epigenetic profile, making pathways responsible for inflammation and B cell activation less accessible.

Racial Differences in Chronic Glucocorticoid Use in Patients with SLE: A Cross Sectional Study

James Sullivan[1] and Emily Littlejohn[2], [1]Cleveland Clinic Lerner College of Medicine, Cleveland Heights, OH, [2]Cleveland Clinic, Cleveland, OH

SESSION INFORMATION
Session Date: Monday, November 8, 2021
Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster III: Outcomes (1257–1303)
Session Type: Poster Session C
Session Time: 8:30AM–10:30AM

Background/Purpose: Black patients with systemic lupus erythematosus (SLE) face higher rates of morbidity and mortality compared to White patients. Long-term glucocorticoid use has been associated with worse health outcomes among patients with SLE. We sought to quantify chronic glucocorticoid use among Black and White patients with SLE within a prospective registry.

Methods: Using a registry at a large academic institution, we compared chronic glucocorticoid use among participants with SLE that self-identify as Black or White race. SLE was defined by either Systemic Lupus International Collaborating Clinics or American College of Rheumatology criteria. At the time of registry enrollment, demographic and disease specific variables, including age, sex, Systemic Lupus Erythematosus Disease Activity Index 2000 (SLEDAI-2k), hospitalization in the year before registry enrollment, disability status, and current SLE-related medications were captured. Chronic glucocorticoid utilization was defined as both documentation of current glucocorticoid use by participant self-report and physician documentation of steroid use as part of SLE treatment at the time of registry enrollment. Multivariable logistic regression of race and chronic glucocorticoid use was performed, adjusting for covariates exhibiting a bivariate association with chronic glucocorticoid use at significance level $p < 0.10$.

Results: 114 White participants (mean age 45; standard deviation (SD) 15) and 59 Black participants (mean age 42; SD 14) were analyzed. White participants had mean SLEDAI-2K score of 3.7 (SD 5.2). Black participants had mean SLEDAI-2K scores of 6.3 (SD 6.0). Among Black participants, 43 (72%) utilized glucocorticoids compared to White participants 39 (34%) (unadjusted odds ratio (OR) 5.17; 95% confidence interval (CI) 2.59-10.33). We did not observe differences between unadjusted hydroxychloroquine (OR 0.69; 95% CI 0.28-1.65) or conventional disease-modifying anti-rheumatic drug (cDMARD) (OR 1.07; 95% CI 0.57-2.01) utilization among Black and White participants. SLEDAI-2K, disability, recent hospitalization, and past or present hydroxychloroquine or cDMARD use were included in a logistic regression model. Adjusting for covariates, Black participants were more likely to be on glucocorticoids (adjusted OR 5.69; 95% CI 2.17-14.96); p=0.0004).

Conclusion: Adjusting for disease activity and other medications, Black patients had greater exposure to chronic glucocorticoids than White patients in a prospective SLE registry while cDMARD use remained the same. These patients may face increased glucocorticoid-related morbidity, which could contribute significantly to long-term health outcomes and utilization of health care resources. Future research in larger, more diverse registries should be conducted to further characterize patterns of glucocorticoid use.

Table 1. Demographics of White and Black participants in the SLE registry.

Variable	White (N = 114)	Black (N = 59)
Mean age (years; standard deviation)	45 (15)	42 (14)
Hispanic ethnicity (N, %)	8 (7%)	2 (3%)
Currently disabled (N, %)[a]	23 (21%)	16 (31%)

Annual Income		
<$25,000	24 (41%)	28 (47%)
$25,000 – $75,000	44 (39%)	17 (29%)
>$75,000	28 (25%)	3 (5%)
Student	5 (4%)	2 (3%)
Missing	13 (11%)	9 (15%)
Total SLEDAI-2K[b] (mean, SD)	3.7 (5.2)	6.3 (8.0)
+Total SLEDAI-2K[b] ≥ 6 (N, %)	23 (20%)	32 (54%)
Hospitalized in the past year (N, %)[a]	20 (20%)	20 (37%)
Median SLE medications (median, interquartile range)[a]	2 (1-3)	2 (2-3)

[a]Indicates missing data: Disabled N = 161; Hospitalized N = 152; Median medications N = 168

[b]SLEDAI-2K stands for systemic lupus erythematosus disease activity index 2000

Table 2. Current SLE medication use among White and Black participants

Medication	White (n = 114)	Black (n = 59)	P-value[a]	Odds ratio (95% confidence interval)
Chronic oral corticosteroids	39 (34%)	43 (73%)	**< 0.0001**	5.17 (2.59-10.33)
NSAIDs[b]	35 (31%)	20 (34%)	0.62	1.19 (0.51-2.33)
Hydroxychloroquine	100 (88%)	49 (83%)	0.40	0.69 (0.28-1.65)
Conventional DMARDs[c,d]	58 (51%)	31 (53%)	0.84	1.07 (0.57-2.01)
Biologic DMARDs[e]	8 (7%)	3 (5%)	0.75[f]	0.71 (0.18-2.78)

[a] All statistical tests performed utilized Pearson's Chi Squared Test except where indicated
[b] NSAIDs stands for non-steroidal anti-inflammatory drugs
[c] DMARD stands for disease-modifying anti-rheumatic drug
[d] Conventional DMARDs consist of methotrexate, azathioprine, mycophenolate leflunomide, cyclophosphamide
[e] Biologic DMARDs consist of rituximab, belimumab
[f] Fischer's Exact Test

Table 3. Multivariable logistic regression of odds of chronic glucocorticoid use among White and Black participants in the SLE registry. Independent variables include race, hospitalization in the last year, total SLEDAI-2K dichotomized at 6, disability, no current or prior hydroxychloroquine, and current or prior conventional disease-modifying anti-rheumatic drugs (methotrexate, azathioprine, mycophenolate, leflunomide, cyclophosphamide). Odds ratios and significance are Wald based.

Variable	Estimate	Odd ratio (95% confidence interval)	P-value
Intercept	-2.51		<0.0001
Race (Black)	1.74	5.69 (2.17-14.96)	0.0004
Hospitalization	-0.52	0.60 (0.21-1.69)	0.33
Total SLEDAI-2K[a] ≥ 6	1.73	5.66 (1.93-16.56)	0.002
Disabled	1.34	3.81 (1.45-10.07)	0.007
Never used hydroxychloroquine	1.24	3.44 (0.59-19.33)	0.17
Ever used cDMARD[b]	1.75	5.76 (2.20-15.04)	0.0004

Overall model p-value <0.0001; Overall model N = 145

[a]SLEDAI-2K stands for systemic lupus erythematosus disease activity index 2000

[b]cDMARD stands for conventional disease-modifying anti-rheumatic drug (methotrexate, azathioprine, mycophenolate, leflunomide, cyclophosphamide)

Paradoxical Effect of Vitamin D on Bone Mineral Density in SLE

Michelle Petri[1], Jessica Li[2] and Daniel Goldman[1], [1]Johns Hopkins University School of Medicine, Baltimore, MD, [2]Johns Hopkins University, Baltimore, MD

SESSION INFORMATION
Session Date: Monday, November 8, 2021
Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster III: Outcomes (1257–1303)
Session Type: Poster Session C
Session Time: 8:30AM–10:30AM

Background/Purpose: Osteoporosis with fractures is consistently one of the top three items in the SLICC/ACR Damage Index in cohort studies internationally. As vitamin D insufficiency and deficiency are common in SLE, we asked whether 25(OH) vitamin D levels were associated with bone mineral density.

Methods: We took the first DXA scan after the first 25(OH) vitamin D blood level measurement. 1099 SLE patients (meeting SLICC or EULAR/ACR classification criteria) had a DXA scan done after a 25(OH) vitamin D measurement. We examined bone mineral density in two ways: 1) binary – osteoporosis or not; and 2) continuous variable of lumbar spine t-score.

Table 1. Association of Patient Demographic Variables with Osteoporosis

Results: 1012 (92%) were female, 459 (42%) were African American, 529 (48%) were Caucasian. The mean age at their DXA scan after vitamin D level measurement was 45 years (SD=13.1). There were 83 patients with spine t-score < =-2.5. Table 1 shows demographic variables and their association with osteoporosis. Smoking was strongly associated. Next we looked at the first 25(OH) vitamin D, the mean, and most recent levels versus both osteoporosis AND the lumbar spine t-score (Table 2). These analyses showed a U-shaped relationship centered at 25(OH) vitamin D levels of 30-40. Both lower levels and some higher levels were associated with osteoporosis and with lower lumbar spine t-scores.

Conclusion: Vitamin D has a surprisingly paradoxical relationship to bone health in SLE. The Ideal 25(OH) vitamin D level appears to be 30-40 ng/mL. Vitamin D is not truly a "vitamin" but should be considered a sterol hormone, which may contribute to its complicated role in bone health. As 40 ng/mL is also the ideal level for renal lupus, this appears to be the best 25(OH) vitamin D target in SLE management.

Quality of Life Measures and Physical Activity in Childhood Systemic Lupus Erythematosus

Meghan Nelson[1], Lori Ponder[2], Sinclair Gibson[3], D. Sofia Villacis- Nunez[1], Lai Hin Kimi Chan[3], Lakshmi Moorthy[4] and Sampath Prahalad[5], [1]Department of Pediatrics, Emory University School of Medicine, Atlanta, GA, [2]Children's Healthcare of Atlanta, Atlanta, GA, [3]Children's Healthcare of Atlanta, Atlanta, GA, [4]Rutgers Robert Wood Johnson Medical School, New Brunswick, NJ, [5]Emory + Children's Pediatric Institute, Atlanta, GA

SESSION INFORMATION

Session Date: Monday, November 8, 2021

Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster III: Outcomes (1257–1303)

Session Type: Poster Session C

Session Time: 8:30AM–10:30AM

Background/Purpose: Childhood systemic lupus erythematosus (cSLE) is a life-long disease with significant morbidity and mortality, and with associated significant impact on health-related quality of life (HRQOL). Prior research has shown that SLE patients' physical activity level is lower than that of healthy individuals. Increased physical activity is associated with improved wellbeing in SLE.There is a paucity of literature examining relationship between physical activity and HRQOL in cSLE. We sought to describe the physical activity and determine the relationship between exercise, SLE activity and treatment modalities and HRQOL in cSLE. To our knowledge, this is the first study investigating the relationship between the Physical Activity Questionnaire (PAQ) and Simple Measure of the Impact of Lupus Erythematosus in Youngsters (SMILEY) total scores (both used in our study).

Methods: Children < 18 years of age with SLE and their parents were enrolled and completed corresponding child and parent SMILEY reports, and the PAQ for Children (PAQ-C) or Adolescents (PAQ-A). Through retrospective chart review we assessed disease activity (SLE Disease Activity Index). Descriptive statistics as well as Pearson's correlation coefficients were performed with the data obtained, with the patients stratified into two cohorts of lower and higher levels of physical activity (PAQ score < 2 and ≥ 2) and based off the average PAQ score of 2, with median PAQ score of 1.8 (range 1.0- 4.7). We utilized a conservative estimate of PAQ scoring, with previous studies identifying normative PAQ scores in a healthy pediatric population ranges between a minimum of 2.7-2.9 based on age and gender, respectively.

Results: Forty-four children and their parents were enrolled; clinical data, SMILEY and PAQ-C or PAQ-A scores of cSLE subjects were evaluated. The most frequently reported exercise modality was walking (61.4%), with mean frequency of 3.7 ± 1.8 days/week, and a median of 3.5 days/week. Running was the second most frequent exercise reported (54.5%), with mean frequency of 3.1 ± 2.0 days/ week, and a median of 1.5 days/week. Our patients had an overall lower frequency of Cyclophosphamide use and higher frequency of Mycophenolate and Rituximab use. Patients with hypocomplementemia at diagnosis, current prednisone use, Class IV/V lupus nephritis, and Cyclophosphamide use had a higher proclivity towards less activity (PAQ score < 2). There was a mild correlation between SMILEY total score and PAQ [cSMILEY and PAQ (Pearson correlation=0.2), and pSMILEY scores (Pearson correlation=0.3; p=0.05*)]*. cSLE patients with PAQ≥ 2 had higher child and parent SMILEY scores but the difference was not statistically significant. There was a strong correlation between child and parent-SMILEY scores (Pearson correlation=0.7; p= < .00001).

Conclusion: Patients with cSLE prefer walking followed by running. cSLE patients with higher physical activity appeared to have better HRQOL, lower steroid use, and less cyclophosphamide use. We need larger samples to un-

Frailty and Emergency Department Utilization in Systemic Lupus Erythematosus: An Administrative Claims Data Analysis

Sarah Lieber[1], Iris Navarro-Milln[2], Musarrat Nahid[2], Mangala Rajan[2], Sebastian Sattui[1] and Lisa Mandl[1], [1]Hospital for Special Surgery, New York, NY, [2]Weill Cornell Medicine, New York, NY

SESSION INFORMATION

Session Date: Monday, November 8, 2021
Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster III: Outcomes (1257–1303)
Session Type: Poster Session C
Session Time: 8:30AM–10:30AM

Background/Purpose: Emergency department (ED) utilization is associated with worse quality of care and health-related quality of life (HRQoL) in systemic lupus erythematosus (SLE). While frailty is a risk factor for adverse health outcomes in SLE, whether frailty is a risk factor for ED utilization in SLE is unknown. We aimed to study frailty prevalence in adults with SLE < 65 years of age compared to age- and gender-matched comparators without systemic rheumatic disease (SRD) using two validated claims-based frailty indices (CFIs) [1-2] and to assess the risk of ED utilization in frail patients with and without SLE, as well as in frail patients without SRD, compared to non-frail patients without SRD.

Methods: We conducted a longitudinal study using the Centers for Medicare and Medicaid Services Medicaid subset of the Truven Health MarketScan dataset from 2011-2016. We identified patients with SLE 18-65 years of age by ≥3 ICD-9 CM codes for SLE (710.0) ≥30 days apart during the baseline period (2011), as well as age- and gender-matched non-SRD comparators [1:4]. Baseline frailty status was determined using two CFIs validated by Segal et al. and Kim et al. [1-2]. We identified patients who were frail according to one ("frail discordant") or both ("frail concordant") CFIs or non-frail according to both CFIs. Agreement between CFIs was evaluated with a kappa statistic. During the follow-up period (2012-2016), we examined the risk of ED utilization in the following groups: non-frail patients without SRD (referent), non-frail with SLE, frail concordant and discordant without SRD, and frail concordant and discordant with SLE. Cox proportional hazard models were calculated, adjusting for baseline hydroxychloroquine, glucocorticoid, and immunosuppressive medication use.

Results: We identified 2262 patients with SLE and 9048 matched comparators without SRD (Table 1). Baseline frailty prevalence in patients with SLE was higher than in patients without SRD according to each CFI (Segal's definition: 38.3% versus 21.6%; Kim's definition: 50.4% versus 18.6%), with moderate agreement between CFIs (κ=0.47, p< 0.0001). 28.8% of patients with SLE and 11.6% of comparators without SRD were frail according to both CFIs (Table 1). Patients with SLE who were frail concordant were older and less commonly on hydroxychloroquine and immunosuppressive medication at baseline than non-frail patients with SLE (Table 1). Compared to non-frail patients without SRD, non-frail patients with SLE had a 2.1 times higher hazard of ED utilization (Table 2). Frail patients with SLE, using either frailty definition, had a 3.4 times higher hazard of ED utilization than non-frail patients without SRD (Table 2).

Table 1. Baseline sociodemographic features and SLE-related medication use in frail and non-frail patients with SLE and non-systemic rheumatic disease (SRD) comparators

	Patients with SLE (N=2262)		Non-SRD comparators (N=9048)	
N (%), unless otherwise specified	Frail* (N=651)	Non-frail** (N=904)	Frail* (N=1050)	Non-frail** (N=6458)
Age in years, mean (SD)	50.8 (8.0)	35.2 (9.5)	54.3 (5.8)	37.2 (10.1)
Female	610 (93.7)	842 (93.1)	982 (93.6)	578 (91.2)
Race				
Black or African American	354 (54.4)	447 (49.5)	324 (38.6)	1817 (28.1)
White	216 (33.2)	320 (35.4)	595 (56.7)	3723 (57.7)
Other	42 (6.5)	62 (6.9)	66 (6.3)	481 (7.5)
Unknown	39 (6.0)	28 (3.1)	19 (1.8)	245 (3.8)
Hydroxychloroquine use	239 (36.7)	544 (60.2)	0 (0)	10 (0.15)
Glucocorticoid use	367 (56.4)	548 (60.6)	768 (11.9)	768 (11.9)
Immunosuppressive medication use	119 (18.3)	335 (37.1)	3 (0.5)	21 (0.33)

*Frail according to both claims frailty indices.
**Non-frail according to both claims frailty indices.

Table 2. Hazard of emergency department visits according to baseline frailty status and presence of SLE from 2011 to 2016

Patient group	Unadjusted hazard ratio (95% confidence interval)	Adjusted† hazard ratio (95% confidence interval)
Non-frail* non-SRD**	Referent group	Referent group
Non-frail SLE	2.0 (1.8-2.3)	2.1 (1.8-2.4)
Frail concordant‡ SLE	3.6 (3.1-4.0)	3.4 (2.9-3.9)
Frail discordant‡‡ SLE	3.5 (3.1-4.0)	3.4 (2.9-3.9)
Frail concordant‡ non-SRD**	2.3 (2.0-2.5)	2.1 (1.9-2.4)
Frail discordant‡‡ non-SRD**	1.7 (1.5-1.9)	1.7 (1.5-1.8)

*Non-frail according to both claims frailty indices.
**Non-systemic rheumatic disease.
‡Frail according to both claims frailty indices.
‡‡Frail according to one claims frailty index.
†Adjusted for baseline hydroxychloroquine, glucocorticoid, and immunosuppressive medication use.

Conclusion: Frailty prevalence in young and mid-aged patients with SLE exceeded that in age- and gender-matched patients without SRD in this sample of Medicaid beneficiaries. Both SLE and frailty appear to be associated with a higher hazard of ED visits. Frailty may identify a subset of patients with SLE at increased risk of ED utilization and serve as a novel target for interventions to improve HRQoL in SLE.

Abstract Number: 1268

Predicting Adverse Pregnancy Outcomes in Women with Systemic Lupus Erythematosus: A Comparison of Machine Learning Methods

Melissa Fazzari[1], Marta Guerra[2], Jane Salmon[2] and Mimi Kim[3], [1]Albert Einstein College of Medicine, Bronx, NY, [2]Hospital for Special Surgery, New York, NY, [3]Albert Einstein College of Medicine, Larchmont, NY

SESSION INFORMATION
Session Date: Monday, November 8, 2021
Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster III: Outcomes (1257–1303)
Session Type: Poster Session C
Session Time: 8:30AM–10:30AM

Background/Purpose: Nearly 20% of pregnancies in patients with Systemic lupus erythematosus (SLE) result in an adverse pregnancy outcome (APO); early identification of women with SLE who are at high risk of APO is vital. We previously derived a risk model for APO using logistic regression and data from the PROMISSE Study, a large multi-center, multi-ethnic/racial study of APO in women with mild/moderate SLE and/or aPL. While this highly interpretable regression model showed promising predictive performance, we sought to determine if novel and increasingly popular machine learning (ML) approaches would enhance APO risk prediction using all available predictors and potential complex relationships such as interactions or higher order terms. We compared logistic regression modeling to LASSO, a regression approach that handles high-dimensionality and correlated predictors through shrinkage of estimated coefficients, as well as several "black box" ML algorithms. ML techniques are well-suited to high-dimensional data, require no variable selection, and unlike regression-based approaches are able to explore complex relationships without explicit input by the user.

Methods: We used the original PROMISSE data (41 predictor variables from 385 subjects) with APO (71/385, 18.4%) defined as preterm delivery due to placental insufficiency or preeclampsia, fetal or neonatal death, or fetal growth restriction. Logistic regression with stepwise selection (LR-S) was compared to LASSO, random forest (RF), neural network (NN) with 2 hidden neurons, support vector machines with RBF kernel (SVM_{RBF}), and gradient boosting (GB). To summarize discrimination we present cross-validated area under the receiver operating curve (AUC), along with sensitivity (Sn) and specificity (Sp) at an optimal cut-point.

Results: Regression based classifiers confirmed the predictors of APO identified in our previously reported model: non-white race, use of anti-hypertensive medication, low platelets, SLE disease activity, lupus anticoagulant (LAC) +, and high diastolic blood pressure (DBP). RF additionally revealed two novel interaction variables that increased APO risk: LAC+ with anti-b2GPI IgM, high DBP with low C3. LR-S and LASSO were observed to have similar overall discrimination (AUC=0.75 vs. 0.77) but LASSO had higher sensitivity (Sn=0.71 vs. 0.65). ML classifiers RF and SVM_{RBF} had similar good performance (AUC=0.77-0.78), while NN and GB were inferior.

Table 1: Summary of 5x10 fold cross-validation results

Model	*AUC*	*sensitivity*	*specificity*
LR-S	0.75	0.65	0.78
LASSO	0.77	0.71	0.75
NN	0.71	0.70	0.61
RF	0.77	0.77	0.78
GB	0.72	0.72	0.72
SVM-RBF	0.78	0.78	0.73

Conclusion: Several popular ML algorithms did not provide meaningful improvements to the previously identified model for APO prediction. The strong relative performance of regression-based models with this large and well-characterized clinical data set is notable as these models are highly interpretable, well-understood, and generally require fewer variables to generate a risk prediction. New clinical and laboratory markers may improve predictions in the future.

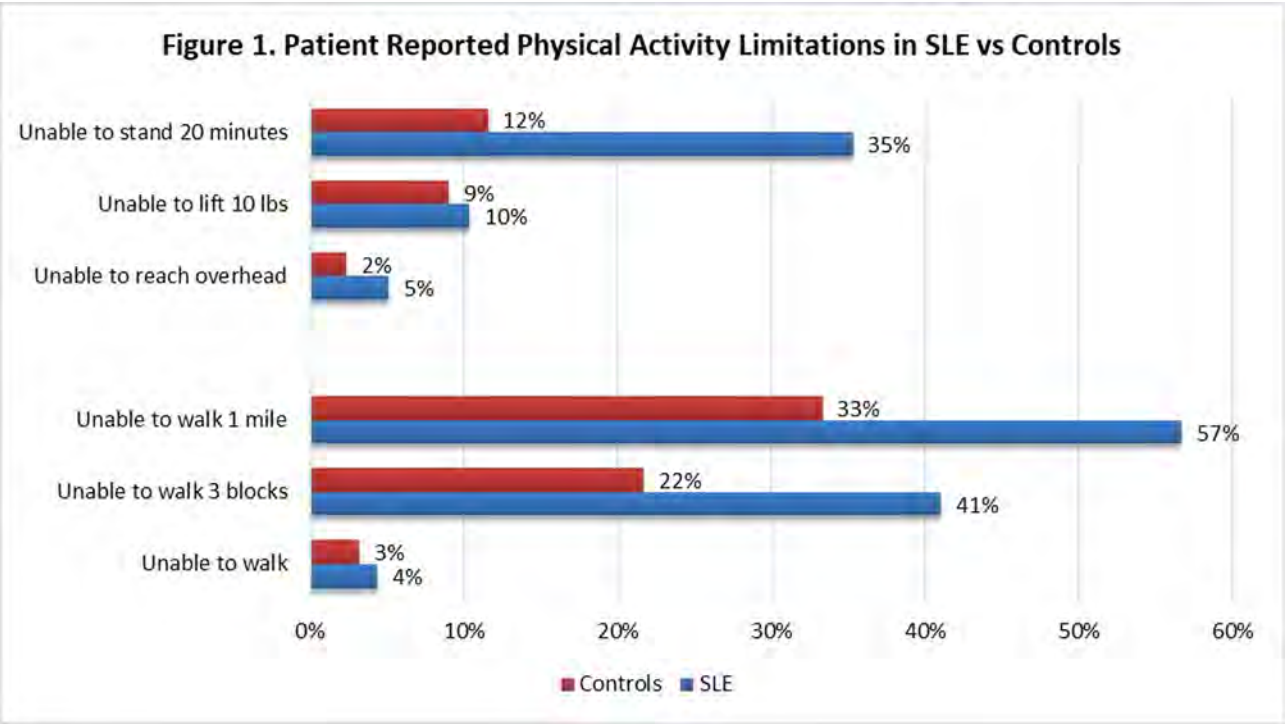
The Burden of Systemic Lupus Erythematosus Patients in the United States – Evidence from the Medical Expenditure Panel Survey (2016-2018)

Shannon Grabich[1], Eilleen Farrelly[2], Robert Ortmann[3], Michael Pollack[4] and Sandra Sze-jung Wu[4], [1]Xcenda, Durham, NC, [2]Xcenda, Carrollton, TX, [3]AstraZeneca, Greenwood, IN, [4]AstraZeneca, Wilmington, DE

SESSION INFORMATION
Session Date: Monday, November 8, 2021
Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster III: Outcomes (1257–1303)
Session Type: Poster Session C
Session Time: 8:30AM–10:30AM

Background/Purpose: Due to the heterogeneity of systemic lupus erythematosus (SLE), clinical characteristics, quality of life (QOL), social determinant of health (SDOH), health care utilization (HRU), and cost are important metrics in evaluation of treatment efficacy. Our study sought to use a generalizable real-world data source to characterize SLE patient characteristics compared to the general population.

Methods: We analyzed 2016 - 2018 Medical Expenditure Panel Surveys (MEPS). MEPS is an annual survey designed to represent the US civilian non-institutionalized population. SLE patients were identified using ICD-10 M32 and had to have either/or SLE-related medication and rheumatologist visit. A non-SLE (referent) cohort from the general MEPS population was 1:5 matched using matching without replacement to SLE patients on index year, age, gender, and geographic region. Data were pooled across all three years. Continuous variables and proportions were compared with t-tests or Chi-square tests, respectively. Logistic models were used to evaluate the odds ratio (OR) of SLE vs controls for HRU and QOL outcomes. Generalized linear models (GLM) were used to assess mean cost differences



comparing adults with SLE to controls. The 95% confidence intervals (CI) were reported for all models adjusted for race, payer, and key comorbidities.

Results: 154 (0.16%) respondents among 96,996 adults who reported annual data in MEPS met our criteria for SLE. After applying weights to generate nationally representative estimates, SLE adults were more likely to be publicly insured (35% vs. 18%), have lower median family income ($46,925 vs. $70,624), and higher unemployment (50%

Table 1. Weighted annualized all-cause HCRU data in SLE compared to the control population

	SLE (n=490,385)		Controls (n=2,625,427)		*p*-value
	n	%	n	%

Total prescription expense	**$4,512**	$510	$1,952	$547	0.0007

vs. 34%); however, education level did not differ compared to the non-SLE cohort. Comorbidities were significantly higher in SLE vs. non-SLE adults, including joint pain (63% vs. 33%), arthritis (61% vs 29%), hypertension (39% vs 26%), asthma (27% vs. 13%) and heart disease (24% vs. 8%). 17% percent of SLE respondents reported they were "unable to work due to illness/disabled" compared to only 3% of non-SLE adults. More SLE adults reported "delaying getting necessary care" (14% vs. 5%) and "unable to pay family medical bills" (16% vs. 5%) than the non-SLE cohort. The adjusted odds ratio of "pain limited work" was significantly higher in SLE adults vs. controls (2.5 (95% CI: 1.4,4.3)). Adults with SLE were significantly more likely to report perceived poorer physical and mental health, including a higher OR of depression (2.1 (95% CI: 1.3, 3.3)). SLE adult had a higher HRU of outpatient and ER visits with approximately twice as many annual visits. All-cause healthcare and prescription expenses were significantly higher in SLE adults compared to non-SLE patients ($17,270 vs $8,350 and $4,512 vs $1,952 respectively).

Conclusion: This study characterizes adults with SLE compared to the general non-SLE population in a nationally representative weighted data source. Overall, comorbidity, QOL, HRU and cost burden was higher in SLE compared to non-SLE adults. It is essential to understand both direct and indirect factors in HRU and cost, including patient experience, to make treatment recommendations and decrease disease burden.

Disease Severity and Healthcare Costs Associated with Chronic Kidney Disease in Patients with Systemic Lupus Erythematosus

Shirley Huang[1], Amy Guisinger[2], Carlyne Averell[1] and **Christopher Bell**[1], [1]GlaxoSmithKline, Research Triangle Park, NC, [2]US Value, Evidence and Outcomes, GlaxoSmithKline, Research Triangle Park, NC

SESSION INFORMATION
Session Date: Monday, November 8, 2021
Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster III: Outcomes (1257–1303)
Session Type: Poster Session C
Session Time: 8:30AM–10:30AM

Background/Purpose: Lupus nephritis (LN) is a severe manifestation of systemic lupus erythematosus (SLE), occurring in approximately 40% of SLE patients (pts) and often resulting in the development of chronic kidney disease (CKD) and permanent kidney damage.[1] CKD is categorized by progressive disease stages (1-5) based on kidney biopsy, ultimately resulting in end-stage kidney disease (Stage 5). While healthcare costs of CKD by stage for broad CKD populations have been quantified,[2,3] few studies have examined CKD costs among SLE pts. This study described and compared disease severity and healthcare costs for SLE pts with and without CKD in the United States of America.

Methods: A retrospective analysis (GSK Study 217378) was conducted using claims data from the Optum Research Database. Adults who had ≥2 outpatient medical claims or ≥1 inpatient claim for SLE from January 1, 2018, to December 31, 2018 (identification period), were assessed. During the identification period, SLE pts with CKD were identified based on ≥1 CKD International Classification diagnosis code and were subsequently categorized based on their highest diagnosed CKD stage (date of highest CKD stage=index). SLE pts without CKD were required to have no CKD diagnoses (date of their first SLE diagnosis=index). Pts' characteristics and disease severity were assessed for

the baseline period (12 months pre index). Healthcare costs (in 2019 US$) were assessed for the observation period (January 1, 2019, to December 31, 2019) for SLE pts with CKD (overall and by CKD stage) and SLE pts without CKD.

Results: A total of 2666 SLE patients with CKD and 9488 SLE patients without CKD met study criteria. Patients were mostly female (CKD: 86.6%; no CKD: 91.1%) with a mean (standard deviation, SD) age of 63.9 (14.1) (CKD) and 57.8 (14.5) (no CKD) years. During the baseline period, SLE patients with CKD had greater disease activity than SLE patients without CKD (moderate-severe disease: 93.9% vs 66.4%; ≥1 flare of any severity: 96.5% vs 92.0%; mean [SD] number of flares: 5.9 [3.1] vs 4.7 [2.8]). Also, 4.1% of SLE patients with CKD had evidence of biopsy versus 0.2% of SLE patients without CKD, and 76.9% had LN versus 3.0% of SLE patients without CKD. During the observation period, mean (SD) annual healthcare costs were substantially higher for SLE patients with CKD versus those without CKD ($59,956 [100,785] vs $31,652 [57,781]). In addition, costs increased with advancing stages of CKD, from $36,417 ($56,028) (Stage 1) to $152,169 ($177,656) (Stage 5) (**Figure**).

Conclusion: SLE patients with CKD had more severe disease and incurred higher annual healthcare costs compared with SLE patients without CKD. Among SLE patients with CKD, healthcare costs increased with each CKD stage progression. These results demonstrate the substantial burden of CKD in patients with SLE and highlight the need to manage SLE to prevent progression to CKD.

Healthcare Resource Utilization and Costs Associated with Systemic Lupus Erythematosus After Diagnosis of End-Stage Kidney Disease: Evidence from Two United States Databases

Shirley Huang[1], Amy Guisinger[2] and **Christopher Bell**[1], [1]GlaxoSmithKline, Research Triangle Park, NC, [2]US Value, Evidence and Outcomes, GlaxoSmithKline, Research Triangle Park, NC

SESSION INFORMATION
Session Date: Monday, November 8, 2021
Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster III: Outcomes (1257–1303)
Session Type: Poster Session C
Session Time: 8:30AM–10:30AM

Background/Purpose: Approximately 40% of patients with systemic lupus erythematosus (SLE) develop lupus nephritis (LN), of whom up to 20% may progress to end-stage kidney disease (ESKD).[1] Despite this substantial clinical burden, data on healthcare resource utilization (HCRU) and healthcare costs of ESKD among patients with SLE are limited. This study describes HCRU and costs for patients with SLE in the 12 months after ESKD diagnosis in the United States (US).

Methods: This was a retrospective analysis (GSK Study 215295) of two US administrative claims databases (IBM MarketScan [DB#1]; Optum Research Database [DB#2]), conducted between March 2011 and December 2019. The study population comprised adults with SLE who were newly diagnosed with ESKD between March 1, 2012, and December 31, 2018 (diagnosis based on International Classification of Disease [ICD-9/10] diagnosis codes for SLE and ESKD). HCRU and costs (2019 US Dollars) were reported for patients with 12-month continuous enrolment post ESKD diagnosis.

Results: Overall, 1356 and 425 patients with SLE and ESKD were identified in DB#1 and DB#2, respectively. Mean (standard deviation, SD) age was 46.7 (12.32) years (DB#1) and 46.3 (13.95) years (DB#2), and the majority of patients were female (DB#1: 81.8%, DB#2: 79.3%). A total of 805 (DB#1) and 261 (DB#2) patients had 12-month continuous enrollment post-ESKD diagnosis. The mean (SD) annual cost post-ESKD diagnosis was $179,914 ($272,011) (DB#1) and $160,284 ($200,000) (DB#2). Mean (SD) costs were greatest at 1 month post-ESKD diagnosis and stabilized thereafter (**Figure**). In the 12 months following ESKD diagnosis, HCRU was similar across databases: 97.9% (DB#1)

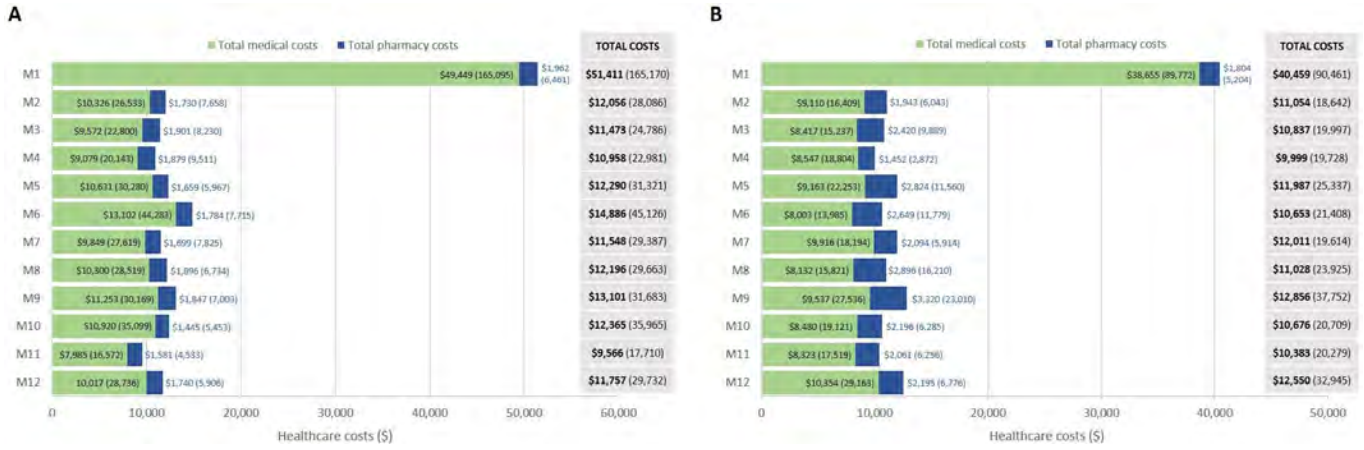

Figure. Mean (SD) healthcare costs (in 2019 US dollars) within 12 months following ESKD diagnosis. A. DB#1 (N=805), B. DB#2 (N=261).

Table 1. HCRU within 12 months following ESKD diagnosis

All-cause HCRU, n (%)	DB#1 (N=805)	DB#2 (N=261)
Any visit	805 (100.0%)	261 (100.0%)
Ambulatory	804 (99.9%)	255 (97.7%)
Physician office	788 (97.9%)	251 (96.2%)
Outpatient	747 (92.8%)	234 (89.7%)
Inpatient	553 (68.7%)	186 (71.3%)
Emergency room	383 (47.6%)	144 (55.2%)
Other*	644 (80.0%)	226 (86.6%)
Pharmacy fills	702 (87.2%)	258 (98.9%)

*Other includes ambulance, assisted living facilities, comprehensive rehabilitation facilities, custodial care facilities, hospice/home care services, intermediate care facilities, psychiatric facilities, and skilled nursing facilities

Table 2. SLE-related medications within 12 months following ESKD diagnosis

Medications, n (%)	DB#1 (N=805)	DB#2 (N=261)
Antimalarials	318 (39.5%)	110 (42.2%)
Oral corticosteroids	522 (64.8%)	194 (74.3%)
Immunosuppressants	416 (51.7%)	153 (58.6%)
Methotrexate	15 (1.9%)	4 (1.5%)
Mycophenolate	276 (34.3%)	94 (36.0%)
Cyclophosphamide	52 (6.5%)	26 (10.0%)
Azathioprine	72 (8.9%)	32 (12.3%)
Cyclosporine	27 (3.4%)	7 (2.7%)
Tacrolimus	143 (17.8%)	45 (17.2%)
Biologics	55 (6.8%)	12 (4.6%)
Rituximab	40 (5.0%)	7 (2.7%)
Belimumab	15 (1.9%)	6 (2.3%)

and 96.2% (DB#2) of patients had at least one physician office visit, 68.7% (DB#1) and 71.3% (DB#2) had an inpatient visit, and 47.6% (DB#1) and 55.2% (DB#2) had an emergency room visit (**Table 1**). SLE-related medications in the 12 months post-ESKD diagnosis included oral corticosteroids (DB#1: 64.8%, DB#2: 74.3%), immunosuppressants (DB#1: 51.7%, DB#2: 58.6%), antimalarials (DB#1: 39.5%, DB#2: 42.2%), and biologics (DB#1: 6.8%, DB#2: 4.6%) (**Table 2**).

Conclusion: Patients with SLE and newly diagnosed with ESKD had high healthcare costs and utilization 12 months post-ESKD diagnosis. Study results reflect the considerable clinical and economic burden associated with newly diagnosed ESKD among patients with SLE.

Characterizing Patient and Physician Perceptions of Systemic Lupus Erythematosus (SLE) Disease Burden Using Traditional Rheumatoid Arthritis Outcomes Measures

Christopher Bell[1], Shirley Huang[1], Meg Wang[2], Maral DerSarkissian[2], Mei Sheng Duh[2], Bhavna Dhillon[3], Carlyne Averell[1], Bernie Rubin[1] and Daniel Wallace[4], [1]GlaxoSmithKline, Research Triangle Park, NC, [2]Analysis Group, Boston, MA, [3]United Rheumatology, Hauppauge, NY, [4]Cedars-Sinai, Los Angeles, CA

SESSION INFORMATION

Session Date: Monday, November 8, 2021
Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster III: Outcomes (1257–1303)
Session Type: Poster Session C
Session Time: 8:30AM–10:30AM

Background/Purpose: SLE is a chronic, autoimmune disease affecting multiple organ systems, and characterized by fluctuating disease activity. Many SLE disease measures may be impractical for routine clinical practice due to administrative burden and delay in scoring while awaiting laboratory results. Patients may also feel discouraged if their laboratory results indicate improvement while their physical/mental well-being has not improved. Rheumatoid arthritis (RA)–specific disease measures are widely used to assess patients with RA. This study evaluated the use of RA disease measures among patients with SLE in United Rheumatology's community-based physician network in the United States.

Methods: A retrospective, observational analysis (GSK Study 213818) was conducted using the United Rheumatology Normalized Integrated Community Evidence (UR NICE) electronic medical records database. Patients ≥5 years of age diagnosed with SLE (≥1 encounter with an SLE International Classification of Disease-9 or 10 code) between January 1, 2010 and December 31, 2014 were assessed (date of first SLE diagnosis = index date). At least 5 years of clinical activity post-index was required. Patient characteristics were reported at index date, and certain RA disease measures were assessed during a 5-year follow-up period (Patient/Physician Global Assessment [PtGA/PGA]; Pain Index; tender/swollen joint counts [TJC/SJC]; Health Assessment Questionnaire [HAQ]; Routine Assessment of Patient Index Data 3 [RAPID3]), as counts and percentages, or means and standard deviations.

Results: Overall, 5990 patients with SLE and 5 years' follow-up met the inclusion criteria (20–59 years of age, 73.8%; female, 91.8%; commercial insurance, 63.7%; comorbid RA post-index, 9–11%) (**Table 1**). The most frequently used RA assessments included: Pain Index; TJC/SJC; HAQ, PtGA; PGA; and RAPID3. In Year 1, use of RA measures ranged from 2.0% for PGA to 36.1% for Pain Index; use increased in Year 5 (ranging from 20.0% for PGA to 59.2% for Pain Index). Across the 5-year follow-up period, mean PtGA scores were consistently higher (indicating greater

Mean (SD) score	4.3 (2.2)	3.9 (2.3)	3.8 (2.3)	3.6 (2.2)	3.7 (2.3)
Remission or low disease activity, n (%)	93 (18.0)	167 (25.7)	256 (27.6)	392 (30.4)	546 (27.9)

*Scale: 0–10, where higher scores indicate higher level of disease activity.

†Scale: 0–28, where higher scores indicate higher level of disease activity.

disease activity) than PGA scores. Mean scores for Pain Index and TJC/SJC were relatively stable throughout the 5-year period (Pain Index, 4.1 to 4.2; SJC, 0.9 to 1.1; TJC, 3.2 to 3.5). Similar findings were observed for HAQ and RAPID3 (HAQ: 1.5 to 2.0; RAPID3: 3.6 to 4.3). However, the proportion of patients classified as in remission or low disease activity by RAPID3 increased over the 5-year period (Year 1, 18.0%; Year 5, 27.9%) (**Table 2**).

Conclusion: RA disease measures were used, albeit infrequently, to assess patients with SLE in a rheumatology physician network. PtGA scores consistently indicated greater disease activity than the PGA scores, which may correspond to the discordance of Pain Index and TJC/SJC results over the 5-year period. Further research is needed to better understand the utility of various RA assessments for evaluating patients with SLE. However, they may ultimately represent an efficient approach to measuring patient outcomes and improving care.

SESSION INFORMATION

Session Date: Monday, November 8, 2021

Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster III: Outcomes (1257–1303)

Session Type: Poster Session C

Session Time: 8:30AM–10:30AM

Background/Purpose: Fatigue in SLE patients is ubiquitous and is reported as one of the most debilitating symptoms. Yet mechanisms underlying the pathophysiology of SLE-related fatigue are not well understood. Data from our group and others have shown that fatigue is independent of SLE disease activity. One mechanism proposed to explain fatigue is impairment in mitochondrial metabolism. Impaired mitochondrial metabolism lead to abnormal T-cell activation and effector function contributing to immune dysregulation. Type I IFN were shown to downregulate mitochondria-derived genes and metabolic pathways causing increased apoptosis of $CD8^+$ T-cells contributing to SLE pathogenesis. Regulation of mitochondrial transmembrane potential ($\Delta\psi m$) and blocking mammalian target of rapamycin (mTOR) in T-cells was shown to improve SLE disease activity and fatigue. The purpose of this study is to characterize the responses to an aerobic exercise program in SLE patients and to understand mechanisms underlying fatigue.

Methods: Sixteen female SLE patients with SELENA-SLEDAI < 4 that self-reported the presence of significant fatigue (Fatigue Severity Scale=FSS > 3) were enrolled in a supervised, aerobic exercise training program of treadmill exercise for 30 minutes, thrice a week for 12 weeks. The primary outcome measure was the time to reach the anaerobic threshold(tAT) during a cardiopulmonary exercise test (CPET). Secondary outcomes included 10 Minute

Walk Test (10MWT) distance, and self-reported changes in fatigue and health related quality of life from the FSS and the Patient-Reported Outcomes Measurement Information System (PROMIS) scores, respectively. Extracellular flux studies were done to measure mitochondrial dysfunction (MiD) by Oxygen Consumption Rate (OCR) / ExtraCellular Acidification Rate (ECAR) ratio before and after administering mitochondrial respiratory inhibitors and interferon stimulated genes (ISGs) signature by nanostring.

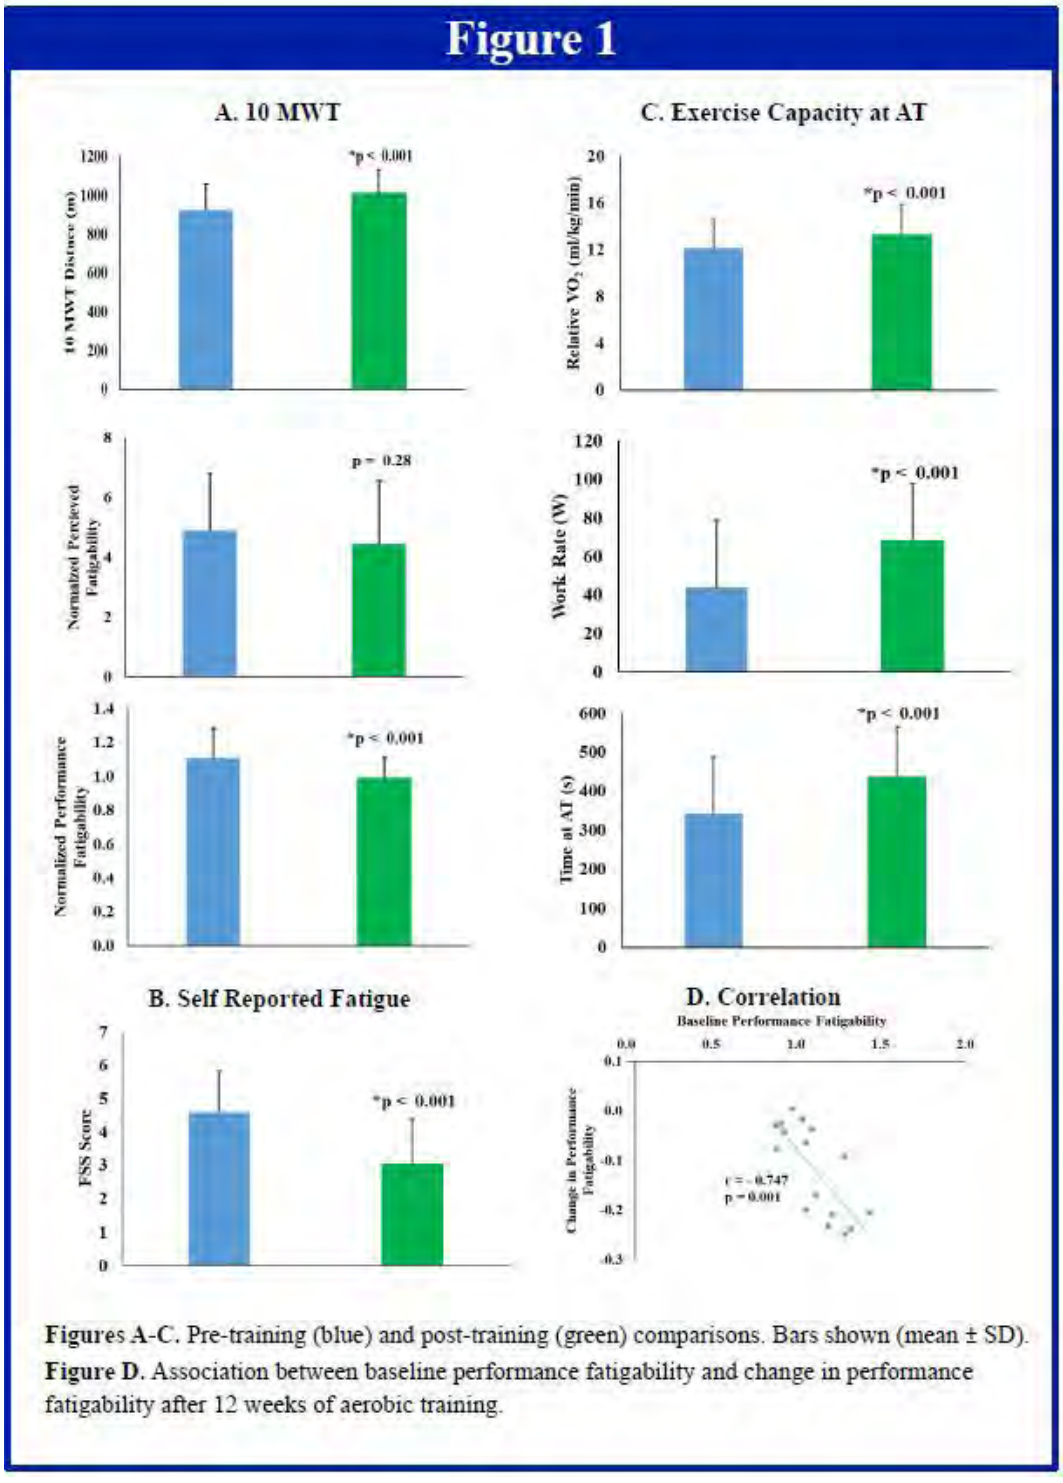

Figure 1. Pre-Exercise and post-exercise of Anaerobic Threshold(AT), 10MWT, FSS, and.

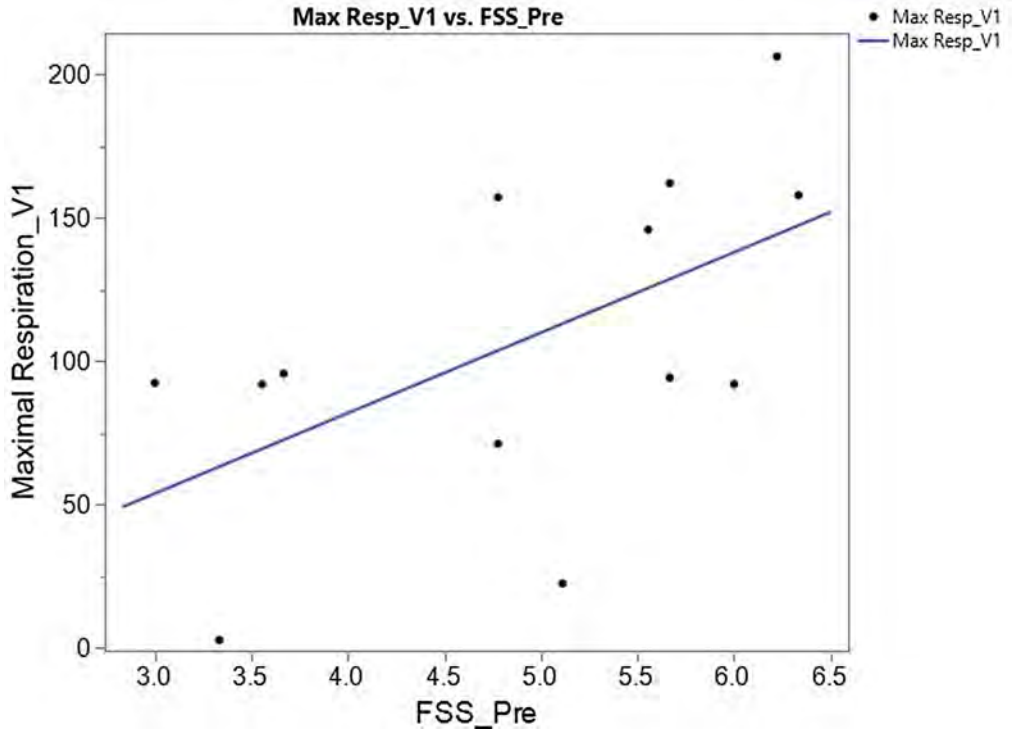

Figure 2. FSS correlates with mitochondrial maximal respiration. r = 0.59, p =0.03.

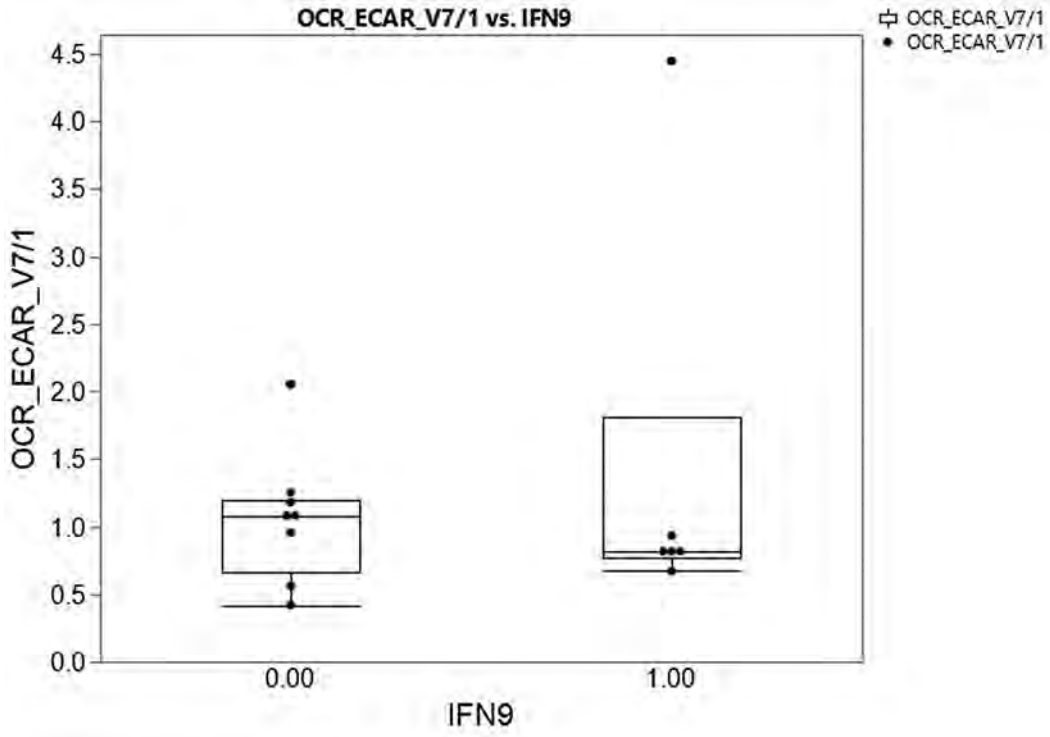

Figure 3. The 9 patients with improved IFN signature had higher increases in OCR/ECAR ratio from V1 to V7. V7-V1 indicates the difference in values between the 2 timepoints. V7/V1 indicates the ratio. p = 0.013.

Results: The mean ±SD age of subjects was 42.0 (± 10.3) years with the duration of disease 9.1 (± 6.5) years, 8/16 (50%) of subjects were Hispanic. The baseline SELENA-SLEDAI and FSS scores were mean (±SD)1.4 (± 1.9) and 4.6 (± 1.2) respectively. There were significant improvements in tAT ($p< 0.001$), 10 MWT ($p< 0.001$), total FSS score($p< 0.0001$), and most of the PROMIS domains(Figure 1). The disease activity remained unchanged throughout the study. The pre and post-exercise decrease in FSS scores correlated with increases in OCR/ECAR ratio ($r=-0.59$, $p=0.03$) (Figure 2). A subset of subjects (9/16) had significant reductions in post-exercise ISGs expression ($p=0.007$) accompanied by a significant increase in OCR/ECAR ratio ($p=0.013$)(Figure3).

Conclusion: In this study a 12- week exercise program resulted in significant improvements in physiological reserve and self-reported fatigue. Fatigue correlated with MiD which improved with exercise. The ISGs scores improved with a corresponding improvement in MiD. Larger studies are needed to confirm the role of MiD in the pathogenesis and its therapeutic targeting in management of fatigue in SLE.

Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster III: Outcomes (1257–1303)

Session Type: Poster Session C

Session Time: 8:30AM–10:30AM

Background/Purpose: Flares in SLE patients, regardless of their severity, have been associated with damage accrual. However, their impact on HRQoL has not been fully evaluated. In fact, disease activity is only minimally associated with HRQoL. The aim of this study is to determine the association between flares and HRQoL.

Methods: Patients from the Almenara Lupus Cohort were included. Visits occurring between December 2015 and February 2020 were included. Flares were defined as an increase on the SLEDAI-2K of at least 4 points; severe flares were those with a final SLEDAI-2K higher than 11 and mild-moderate flares all the others. HRQoL was measured using the LupusQoL. Univariable and multivariable generalized estimating regression equations were performed, adjusting for possible confounders. Confounders were determined at one visit whereas the outcome was determined on the subsequent visit; flares were determined based on the variation of the SLEDAI-2K between these visits.

SE: Standard error of the estimate. SDI: SLICC/ACR damage index

Results: Two hundred and seventy-seven patients were included; 256 (92.4%) were female, mean age at diagnosis was 36.0 (SD: 13.3) and a mean disease duration at baseline was 9.1 (SD: 7.1) years. Patients had mean of 4.8 (SD: 1.9) visits and a mean follow-up of 2.7 (1.1) years. Out of 1098 visits, 115 (10.5%) flares were defined, 17 were severe and 98 mild-moderate. After adjustment for possible confounders, only severe flares were associated with a poorer HRQoL in pain, planning, emotional health and fatigue (table 1).

Conclusion: Severe flares, but not mild-moderate flares are associated with poorer HRQoL.

SESSION INFORMATION

Session Date: Monday, November 8, 2021

Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster III: Outcomes (1257–1303)

Session Type: Poster Session C

Session Time: 8:30AM–10:30AM

Background/Purpose: Patient-reported outcome measures (PROMs) provide the physician with an important insight into the patients' perception of lupus disease activity. Technology and the widespread use of digital platforms have made it possible for patients to access and respond to disease specific PROMs from home using their own device.

This study aims to assess agreement in various PROMs, with Systemic Lupus Erythematosus Activity Questionnaire (SLAQ) global health as primary outcome, between a web application (app) on the patient's own smartphone/tablet and an outpatient touchscreen among patients with SLE.

Methods: The study was a randomised, crossover, agreement trial (NCT04411407). Patients diagnosed with SLE for ≥ 12 months was assessed for eligibility. Participants were randomised in a 1:1 ratio to: 1) Group web app → touch-screen i.e. PROMs answered on the web app and after a "washout period" on the outpatient touchscreen or 2) Group touchscreen → web app i.e. vice versa. The "washout period" was pre-specified to be one to two days to minimise recall bias. Agreement between the two device types was assessed using mixed linear models.

Results: In total, 34 patients were enrolled as visualised in **Figure 1**.

An excellent agreement for SLAQ global health between the two device types was observed, visualised in the Bland-Altman plot (**Figure 2**). Mean difference in SLAQ global health between the two device types was -0.21, (95% confidence interval [95% CI]: -0.65 to 0.23) (**Table 1**); thus, equivalence was demonstrated as the 95%CI was within the pre-specified equivalence margin of ± 0.75. Furthermore, equivalence was proven for all other PROMs except Visual Analogue Scale (VAS) global health. However, the observed difference in VAS global health is within the limits of the pre-specified minimum clinically important difference (MCID); thus, not anticipated to have any clinical relevance.

Thirty-one (91.2%) patients preferred the DANBIO web app over the outpatient touchscreen.

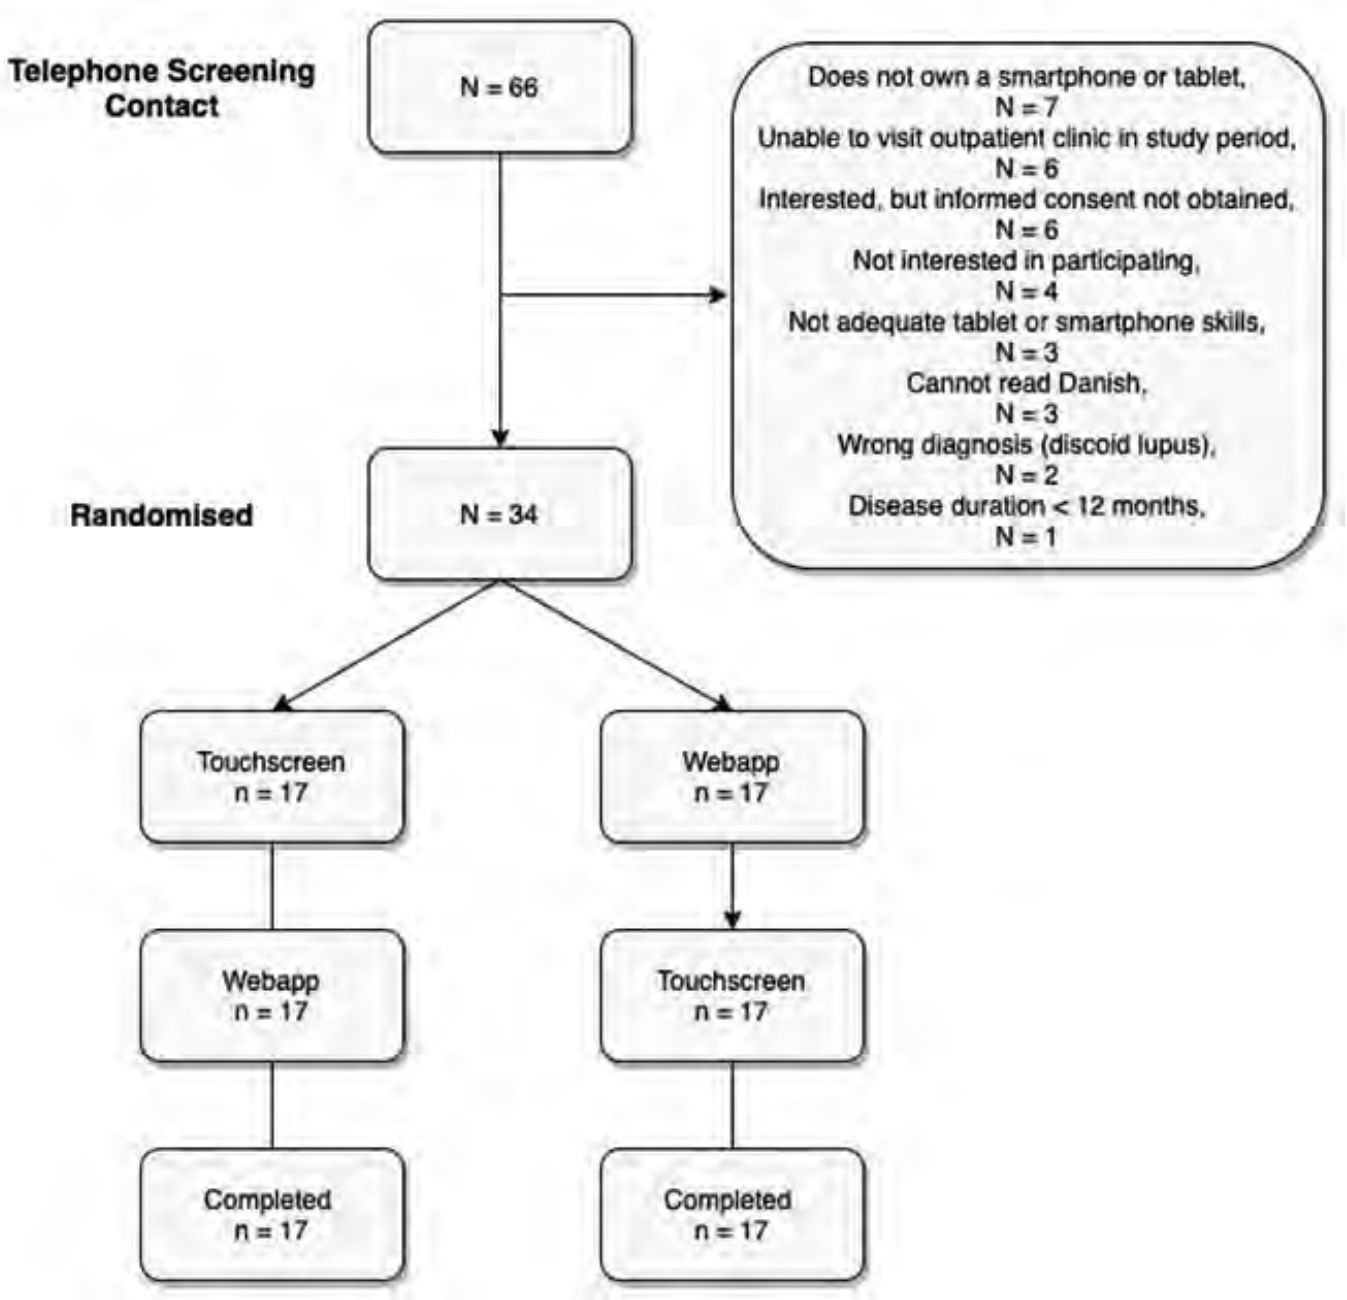

Figure 1. Flow diagram of patient recruitment.

Conclusion: To our knowledge, equivalence between two electronic device types has not previously been demonstrated for a collection of various PROMs among patients with SLE. A very high patient preference for the web app was observed. Implementation of the device is expected to be of great value for patients with SLE; thereby, improving management of their disease.

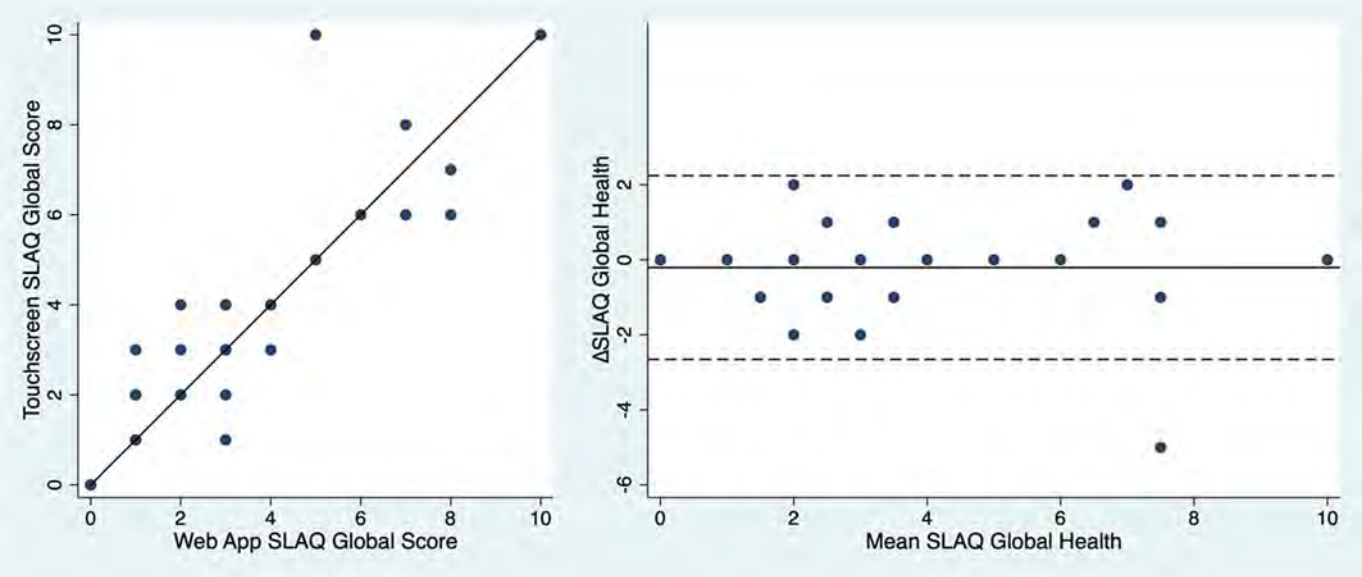

Figure 2. Bland-Altman plot on SLAQ global health registered on the two device types.

SESSION INFORMATION

Session Date: Monday, November 8, 2021

Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster III: Outcomes (1257–1303)

Session Type: Poster Session C

Session Time: 8:30AM–10:30AM

Background/Purpose: Remission and LLDAS have been proposed as the goals for the treatment of SLE patients. However, the predictors of each state remain unknown. The aim of this study was to determine predictors of remission and LLDAS.

Methods: We studied patients from a long-term longitudinal multinational, multiethnic SLE inception cohort followed for a mean of 6.5 years; eligible patients were those completing at least two annual visits. Three outcomes were established: 1. Remission off treatment, defined as a SLEDAI-2K (excluding serology) =0, without prednisone (PDN) and immunosuppressive drugs (IS). 2. Remission on treatment, defined as a SLEDAI-2K (excluding serology) =0, PDN≤5

mg/d and maintenance IS drugs (based on the 2017 DORIS definition). 3. LLDAS, defined as a SLEDAI-2K≤4 with no activity in major organ systems, with no new features of lupus disease activity compared to the previous assessment, PDN≤7.5 mg/d and maintenance IS drugs (based on the Asia Pacific Lupus Consortium definition). Antimalarials were allowed in all groups. Possible predictors included were sex, age at diagnosis, ethnicity, educational level, SLEDAI-2K at cohort entry, disease duration at baseline, highest PDN dose before baseline, number of methylprednisolone (MP) IV pulses as well as mean dose per pulse before baseline. Antimalarial use and the SLICC/ACR damage index (SDI) were time-dependent covariates. Three outcome groups were defined after exclusion of patients who had already achieved the outcome at baseline. Univariable and multivariable interval-censored survival regression models for each outcome (stepwise selection procedure, including age at diagnosis and sex in all models) were used. Alternative models including SLEDAI-2K's domains instead of the global score were performed.

Results: Remission off treatment was achieved in 367 of 1243 patients (29.5%), remission on treatment in 749 of 1185 patients (63.2%), and LLDAS in 833 of 1151 patients (72.4%). Non-Caucasian ethnicity (in particular African) as well as a higher SLEDAI-2K scores and glucocorticoid (GC) dose (oral PDN as well as MP pulses) were associated with a lower probability of achieving these states. Older age at diagnosis and antimalarial use during the follow-up period were associated with a higher probability of remission on treatment and LLDAS. Disease duration at baseline was associated with a lower probability of remission off treatment. Sex, educational level, and the SDI were not associated with any of these states. These data are summarized in Table 1. In the alternative models, the SLEDAI-2K domains associated with a lower probability of achieving at least one of the outcomes were mucocutaneous (all outcomes), renal (remission off treatment and LLDAS), fever (remission off treatment) and musculoskeletal and neurological (LLDAS).

Conclusion: Older age at diagnosis and antimalarial use during follow-up were associated with a higher probability of achieving these treatment goals; on the other hand, non-Caucasian ethnicity (in particular African), a higher

SESSION INFORMATION

Session Date: Monday, November 8, 2021

Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster III: Outcomes (1257–1303)

Session Type: Poster Session C

Session Time: 8:30AM–10:30AM

Background/Purpose: The Type 1 & 2 SLE Model was developed to better characterize the signs and symptoms of SLE. Type 1 SLE consists of inflammatory manifestations like arthritis, nephritis, and rashes; Type 2 SLE includes symptoms of fatigue, myalgia, mood disturbance, and cognitive dysfunction. In this study, we explored patient experiences living with Type 2 SLE symptoms.

Methods: Semi-structured in-depth interviews were conducted among adult participants meeting ACR or SLICC criteria for SLE. Participants were purposefully selected for age, race, sex, and nephritis history. All interviews were audio-recorded and transcribed. Data were analyzed through episode profile analysis. Two rheumatologists and a lupus researcher independently read transcripts, summarized patterns of Type 1 & 2 SLE symptoms described by participants, and identified broader themes about the relationship between Type 1 & 2 SLE symptoms. Through this process, two patterns of Type 2 SLE symptoms were identified. The two patterns were then descriptively compared.

Results: We interviewed 42 patients with SLE (93% female, 52% Black, mean age 45 years, mean disease duration 15 years). All but two participants reported experiencing Type 2 SLE symptoms at some point during their disease course.

Type 2 SLE Pattern: Two patterns of Type 2 SLE were identified: intermittent or resolving (n=18) and persistent or pervasive (n=24). Patients with intermittent Type 2 often experience Type 2 symptoms in tandem with or as a result of Type 1 symptoms. In these patients, Type 2 symptoms improve and are often not present when Type 1 disease is inactive, leaving these patients feeling generally well. In contrast, patients with persistent Type 2 experience Type 2 symptoms regardless of Type 1 symptoms. For these patients, Type 2 symptoms are always present, although the severity may fluctuate.

Demographics: Compared to patients with persistent Type 2, patients with intermittent Type 2 were typically younger (39 vs. 50 years old) and more often Black (67% vs. 42%).

Self-Reported Symptoms during Disease Course: A majority of participants in both groups reported they had experienced brain fog and depression, and all but two participants reported experiencing fatigue. Almost all had experienced traditional lupus symptoms of joint pain, hair loss, and rash. Participants in the persistent Type 2 group were more likely to describe experiencing anxiety, muscle pain, and widespread pain.

Clinical Criteria: Almost all participants met musculoskeletal and mucocutaneous SLE criteria. However, more patients with intermittent Type 2 met renal, hematologic, and immunologic criteria.

Conclusion: Almost all patients in our study experienced Type 2 symptoms, and we found two unique patterns of Type 2 SLE: intermittent and persistent. Patients with intermittent Type 2 SLE have more internal SLE manifestations and feel generally well when Type 1 is inactive. Patients with persistent Type 2 always experience Type 2 symptoms despite inactive Type 1. We hypothesize some degree of Type 2 symptoms in each group might be inflammation-driven; however, the persistence of Type 2 in one group suggests different underlying pathophysiology.

Clinical Outcomes in a Cohort of Puerto Ricans with Systemic Lupus Erythematosus After SARS CoV-2 Infection

Ariana González-Meléndez[1] and Luis Vilá[2], [1]University of Puerto Rico Medical Sciences Campus, San Juan, PR, [2]University of Puerto Rico Medical Sciences Campus, San Juan, Puerto Rico

SESSION INFORMATION
Session Date: Monday, November 8, 2021
Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster III: Outcomes (1257–1303)
Session Type: Poster Session C
Session Time: 8:30AM–10:30AM

Background/Purpose: The coronavirus disease 2019 (COVID-19) pandemic is of particular concern for people with autoimmune rheumatic diseases and for those who are immunosuppressed given the risk for complications during and after the acute infection. Some studies on SLE have been reported, but most have evaluated the clinical manifestations, complications, and outcomes of COVID-19 rather than the impact on lupus. As seen for other viral infections, COVID-19 could induce an exacerbation of lupus. Therefore, we studied the short- and mid-term clinical outcomes after COVID-19 in a cohort of lupus patients.

Methods: A cohort of adult Puerto Ricans with SLE (per 1997 American College of Rheumatology classification criteria) was studied from March 2020 to May 2021. Demographic parameters, COVID-19 manifestations, SLE manifestations, disease activity (per Systemic Lupus Erythematosus Disease Activity Index ([SLEDAI]), disease damage (per Systemic Lupus International Collaborating Clinics/American College of Rheumatology Damage Index [SDI]), pharmacologic treatment, SLE exacerbations, emergency room (ER) visits, and hospitalizations were ascertained. SARS CoV-2 infection was confirmed by polymerase chain reaction test. The proportion of COVID-19 cases was compared to the entire population of Puerto Rico per data provided by the Department of Health.

Results: Of the entire SLE cohort (n=337), 18 patients (5.3%) had COVID-19. During the same study period, 3.7% of the adult population of Puerto Rico had COVID-19, but this was not statistically different from that observed for SLE patients (p=0.11). The mean (standard deviation [SD]) age of SLE patients that had COVID-19 was 43.7 (8.9) years; 94.4% were female. Except for one patient who had COVID-19 pneumonia requiring hospitalization and oxygen therapy, the rest had mild symptoms (77.8%) or were asymptomatic (22.2%). The main COVID-19 manifestations were anosmia (50.0%), myalgias (50.0%), polyarthralgia (35.7%), headaches (35.7%), fever (22.6%), and fatigue (22.6%). At the time of COVID-19, patients had mean (SD) SLEDAI and SDI scores of 0.7 (0.3) and 1.0 (1.1), respectively, and were receiving therapy with hydroxychloroquine (72.2%), corticosteroids (66.7%), mycophenolate mofetil (50.0%), tacrolimus (11.1%), and azathioprine (11.1%). Patients were followed for a mean (SD) period of 6.8 (2.8) months. During the follow-up, none had disease exacerbations, ER visits, hospitalizations, or worsening of disease activity or damage accrual.

Conclusion: In this group of Puerto Ricans with SLE, 5.3% had COVID-19. All patients had low disease activity or were in clinical remission at the time of infection. After a mean follow-up of nearly 7 months after infection, none had disease exacerbations or damage accrual. This study suggests that COVID-19 does not have a negative impact in the short and mid-term clinical outcomes of these patients.

Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster III: Outcomes (1257–1303)

Session Type: Poster Session C

Session Time: 8:30AM–10:30AM

Background/Purpose: Systemic lupus erythematosus (SLE) is an autoimmune disease characterized by multiple and heterogeneous clinical manifestations that may negatively affect these patients' quality of life (QoL) and their levels of activity and productivity, despite overall progress in treatment of the disease. The aim of this study is to assess lupus quality of life (LupusQol) and work productivity and activity impairment (WPAI) of daily life in a SLE multicenter Latin American cohort (GLADEL 2.0, *Grupo Latino Americano De Estudio del Lupus*) among patients with active lupus nephritis (LN) versus those without LN (never) and/or currently inactive LN.

Methods: The GLADEL 2.0 cohort enrolled SLE patients >18 years of age, from three different subsets: Group I: SLE patients, without renal involvement (never); Group II: SLE patients with prevalent renal involvement (at any time during their disease course), currently inactive; Group III: SLE patients with prevalent or incident renal involvement, currently

Table 1. Demographic and Clinical Characteristics of SLE Patients from the GLADEL 2.0 Cohort

Lupus QoL questions within each domain were categorized as: never or present at different degree					

Lupus QoL questions within each domain were categorized as: never or present at different degree Percentages reflect positive responses (i.e., present) on the QOL questions

Table 3. Evaluation of Work Productivity with the WPAI in GLADEL 2.0 Cohort Patients from the Different Groups

WPAI n (%)	Total 795 (93.64)	Group I LN never 324 (94.19)	Group II Inactive LN 200 (97.56)	Groups III Active LN 271 (90.33)	p_value
Question 1 *Currently employed, n (%)*	357 (44.91)	144 (44.44)	105 (52.50)	108 (39.85)	0.024
Question 5* *Degree health affected productivity while working, median (IQR)*	2 (0-5)	1.5 (0-4.25)	0 (0-3)	4 (0-7)	<0.001
Question 6* *Degree health affected regular activities, median (IQR)*	4 (0-6)	3 (0-6)	1.5 (0-5)	5 (2.25-8)	<0.001
*Questions 5 and 6 measures a scale from 0 to 10 being 10 the highest involvement					

*Questions 5 and 6 measures a scale from 0 to 10 being 10 the highest involvement

active. Disease activity was ascertained with the Systemic Lupus Erythematosus Disease Activity Index (SLEDAI-2k) and the Physician Global Assessment (PGA) and damage with the SLICC/ACR Damage Index (SDI). The differences in the baseline Lupus QoL (questions were categorized as never or present at different degree) and WPAI-Lupus [Questions 1 (Currently employed), 5 (Degree health affected productivity while working) and 6 (Degree health affected regular activities)] were analyzed among these three groups. We particularly were interested in examining in more detail Question 6 of the WPAI, that focus on activities of daily living and which is answered by everybody regardless of

whether they are working or not. Numeric variables are reported as medians (interquartile ranges IQR) and compared using Wilcoxon test; categorical variables are reported as frequencies (percentages) and compared using Chi-square or Fisher test, as appropriate. To evaluate the impact of active versus inactive LN in WPAI (Question 6), a multivariate analysis (MV) was adjusted for possible confounders such as: sex, age, socioeconomic level, ethnicity, education, activity and damage in a negative binomial model.

Results: A total of 849 patients with a diagnosis of SLE were included; 344 in Group I, 205 in Group II and 300 in Group III. Their main sociodemographic and clinical features are shown in Table 1. Patients with active LN (group III) had a higher proportion of male patients, were younger at diagnosis, had a shorter disease duration and higher SLEDAI and PGA scores. This group of patients also presented greater impact in all LupusQoL domains (Table 2) and in the WPAI (Table 3). Moreover, the MV analysis for Question 6 of the WPAI demonstrate a significant higher degree health regular activities impairment and active LN after adjusting for confounders (p=0.02) (Data not shown).

Conclusion: In this cohort, we have shown that active LN significantly affects the patients' QoL especially in their physical health, emotional health, body image and fatigue. In addition, an impact in work productivity and activity impairment was observed in this group.

SESSION INFORMATION

Session Date: Monday, November 8, 2021

Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster III: Outcomes (1257–1303)

Session Type: Poster Session C

Session Time: 8:30AM–10:30AM

Background/Purpose: Lupus nephritis (LN) is an autoimmune disease characterized by inflammation of the kidneys, a severe manifestation of systemic lupus erythematosus (SLE) that occurs in approximately 50% of SLE patients. To evaluate treatment benefit effectively, it is critical that patient-reported outcome (PRO) measures are fit-for-purpose and have strong evidence of content validity in the specific context of use, to serve as trial endpoints and support product label claims. SF-36, Lupus-QoL, and FACIT-Fatigue are commonly used clinical trial endpoints in SLE populations, with demonstrated evidence of content validity in this population. Similar evidence of their content validity in an LN population is lacking. A prior qualitative literature and online blog review and concept elicitation interviews with LN patients identified key symptoms (i.e., skin rash, joint pain, joint stiffness, and swelling of the legs/feet) and symptom properties (i.e., severity) not adequately assessed by these three PRO measures. Novel PRO symptom severity items were developed to address conceptual gaps. This study aimed to evaluate the content validity of SF-36, Lupus-QoL, FACIT-Fatigue, and novel PRO items in a sample of LN patients.

Methods: Qualitative, semi-structured, telephone cognitive interviews were conducted with 20 US adult patients with a diagnosis of LN. To evaluate the content validity of the existing PRO measures, participants' understanding and relevance of the concepts to their experience of LN was assessed. Participants completed the novel PRO items using a 'think aloud' process. Questioning explored understanding and relevance of item wording, instructions, different recall periods (24-hour vs 7-day), and response scales (numeric rating scale (NRS) vs verbal response scale). Interviews were conducted in two rounds to allow for modifications to novel PRO items and subsequent re-testing. Qualitative analysis of verbatim interview transcripts was performed.

Results: Symptom and impact concepts assessed by SF-36, Lupus-QoL, and FACIT-Fatigue were well understood, with most considered relevant by the majority of participants asked. Symptoms assessed by the novel PRO items were considered relevant to most participants. Participant feedback informed modifications to the novel PRO items and instructions to improve clarity and understanding between rounds. Each iteration of the item wording and instructions were understood and interpreted consistently by all participants asked. The selected 7-day recall period and NRS in the final iteration of the PRO items were understood, relevant, and appropriately endorsed.

Conclusion: Findings support the content validity of the symptom and impact concepts assessed by SF-36, Lupus-QoL, FACIT-Fatigue in LN patients, providing evidence of their suitability as supportive efficacy endpoints in LN randomized controlled trials. Content validity evidence was also generated for the novel PRO items in LN patients, supporting their suitability to address conceptual gaps in existing PRO measures. Further research is required to establish the psychometric validity of the novel PRO items in a LN population.

Longitudinal Association of Baseline Frailty with Patient-Reported Outcome Measures

Sarah Lieber[1], Musarrat Nahid[2], Mangala Rajan[2], Medha Barbhaiya[1], Lisa Sammaritano[1], Robyn Lipschultz[1], Myriam Lin[1] and Lisa Mandl[1], [1]Hospital for Special Surgery, New York, NY, [2]Weill Cornell Medicine, New York, NY

SESSION INFORMATION
Session Date: Monday, November 8, 2021
Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster III: Outcomes (1257–1303)
Session Type: Poster Session C
Session Time: 8:30AM–10:30AM

Background/Purpose: Frailty has been associated with disability and mortality in systemic lupus erythematosus (SLE). While frailty is known to be associated with worse patient-reported outcome measures (PROMs) cross-sectionally, the extent to which frailty, particularly the self-reported FRAIL scale (FS) [1], predicts poor health-related quality of life (HRQoL) longitudinally in SLE is not well understood. We aimed to assess the association of baseline frailty according to two validated metrics, the FS and the Fried phenotype (FP) [2], with PROMs at 1 year in a single center prospective cohort of women with SLE.

Methods: Women 18 to 70 years old with SLE validated according to the 1997 Update of the 1982 American College of Rheumatology Revised Classification Criteria and mild or moderate disease activity were identified prospectively at a single center. Multiple measures were obtained at baseline and 1 year, including frailty (FS, an entirely self-reported instrument, and the FP, including objective and self-reported components); physician-reported disease activity and damage; and PROMs (including Patient-Reported Outcomes Measurement Information System (PROMIS) computerized adaptive tests and Valued Life Activities (VLA) self-reported disability). Differences between frail and non-frail participants according to each frailty metric were evaluated using Fisher's exact or Wilcoxon rank sum tests and the association of baseline frailty with disability (as defined by the upper quartile of VLA scores) at 1 year using logistic regression.

Results: Of 72 women enrolled at baseline, 1-year follow-up data were available for 51 women (71%). Among these 51 women, 24% and 16% were frail at baseline according to the FS and the FP, respectively (Table 1). Frail women had greater disease damage at baseline than non-frail women (FS: $p< 0.01$; FP: $p=0.02$); compared to non-frail women, frail women according to the FS had lesser educational attainment ($p=0.05$) while frail women according to the FP were more often Black or African American ($p< 0.01$), had greater comorbidity burden ($p=0.04$), and were more commonly smokers over their lifetime ($p=0.04$) (Table 1). Women who were frail at baseline had worse PROMIS measures related to mobility (FS and FP: $p< 0.01$), physical function (FS and FP: $p< 0.01$), pain interference (FS: $p< 0.01$; FP: $p=0.01$), and fatigue (FS: $p< 0.01$; FP: $p=0.02$) and greater VLA disability (FS and FP: $p< 0.01$) at 1 year than women who were not frail at baseline (Table 2). Baseline frailty according to either metric was not associated with VLA disability at 1 year (FS: Odds ratio (OR) 2.1, 95% confidence interval (CI) 0.5-8.9; FP: OR 4.0, 95% CI 0.8-19.5).

Conclusion: Women with SLE who were frail at baseline had worse HRQoL at 1 year than non-frail women. Baseline frailty was not longitudinally associated with self-reported disability at 1 year according to either frailty metric in this small sample of women with SLE. Longitudinal follow-up is underway to determine whether frailty status trajectory may be a more informative predictor of self-reported disability.

Table 1. Baseline characteristics of women with SLE by frailty classification

Characteristic (Median and interquartile range unless otherwise specified)	FRAIL Scale (N=51)			Fried Definition (N=51)

Abstract Number: 1282

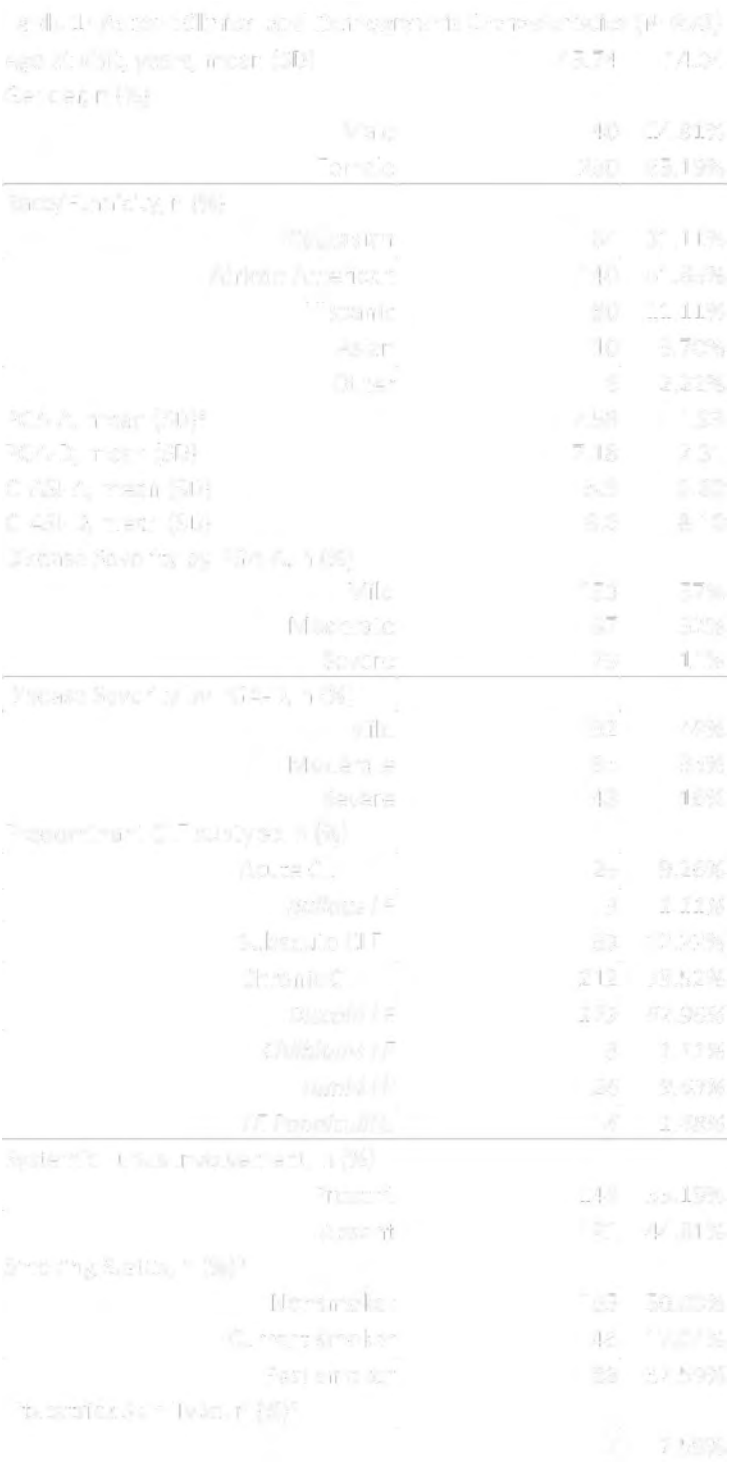
Classification of Disease Activity and Damage in Cutaneous Lupus

Laila Abbas, Karabi Nandy and Benjamin Chong, University of Texas Southwestern Medical Center, Dallas, TX

SESSION INFORMATION
Session Date: Monday, November 8, 2021
Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster III: Outcomes (1257–1303)
Session Type: Poster Session C
Session Time: 8:30AM–10:30AM

Background/Purpose: The Cutaneous Lupus Disease Area and Severity Index (CLASI) can quantify disease activity and damage in Cutaneous Lupus Erythematosus (CLE). Classification of CLASI scores provides standardized clinical context for patients and providers. A prior study used a small patient cohort to classify CLASI activity (CLASI-A) scores into mild, moderate and severe categories, but was limited by small sample size.[1] The objectives of the present study were to classify both CLASI-A and CLASI damage (CLASI-D) scores into mild, moderate, and severe categories using a large, heterogeneous cohort of CLE patients, and determine risk factors for different categories of activity and damage.

Table 1. Patient Clinical and Demographic Characteristics (N=270)



Methods: This was a single-center, cross-sectional study involving patients seen in the outpatient dermatology clinics at University of Texas Southwestern and Parkland Health and Hospital System from April 2009 to January 2020. Table 1 shows demographic and clinical features of participants. Skin severity measurements including CLASI and Physicians' Global Assessment (PGA) of Activity and Damage were scored for all patients. The anchoring outcome measure was the PGA-A and PGA-D, which classified patients into mild, moderate, and severe categories for sub-

Table 2. Percent sensitivity, specificity, and correctly classified for CLASI category ranges

		Sensitivity (%)	Specificity (%)	Correctly Classified (%)
New Disease Activity Category Ranges	Mild (0-6)	96	68	80
	Moderate (7-14)	49	93	78
	Severe (15-70)	72	96	70
Previous Disease Activity Category Ranges[a]	Mild (0-9)	99	44	70
	Moderate (10-20)	26	91	59
	Severe (21-70)	38	99	85
Disease Damage Category Ranges	Mild (0-5)	86	96	95
	Moderate (6-16)	73	83	69
	Severe (17-56)	65	90	56

[a] Klein R, Moghadam-Kia S, LoMonico J, et al. Development of the CLASI as a tool to measure disease severity and responsiveness to therapy in cutaneous lupus erythematosus. Arch Dermatol. 2011;147(2):203-208. doi:10.1001/archdermatol.2010.435

Figure 1: Characteristics associated with different categories of activity and damage.

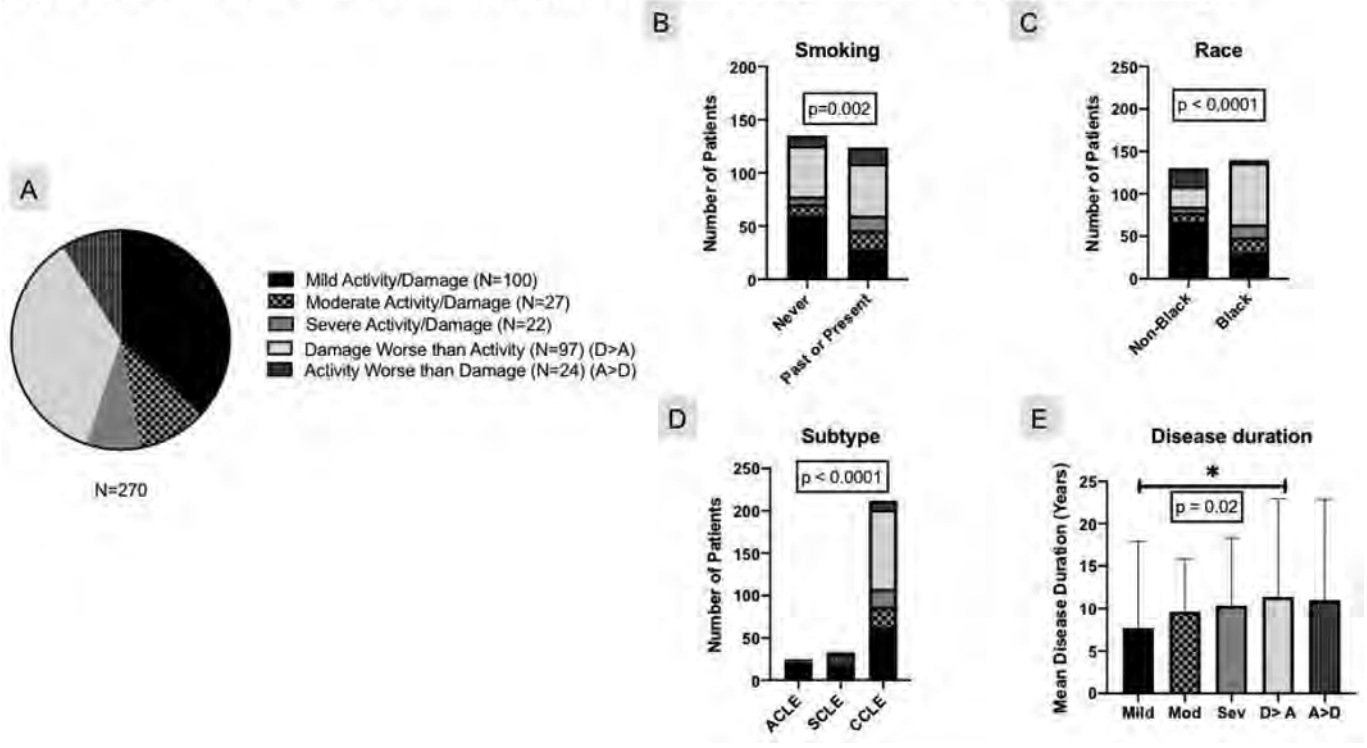


Figure 1. Characteristics associated with different categories of activity and damage.

sequent analysis with CLASI scores. Severity strata were evaluated using receiver operating characteristics (ROC) curves. Skindex-29+3 scores were collected to evaluate patient quality of life.

Results: 270 patients with CLE (**Table 1**) met recruitment criteria. CLASI-A scores of 0-6, 7-14, and 15-70 corresponded to mild, moderate, and severe disease activity. These performed better than previously published strata[1] by sensitivity,

specificity, and percent correctly classified (**Table 2**). CLASI-D scores of 0-5, 6-16, and 17-56 corresponded to mild, moderate, and severe disease damage. Patients had significantly more impaired quality of life with more severe categories of both activity and damage ($p< 0.0001$). About half (55%) of patients had matching disease activity and damage categories, with the other half having discrepant categories. Smoking ($p=0.002$), race ($p< 0.0001$), CLE subtype ($p< 0.0001$), and disease duration ($p=0.02$) were factors that were significantly different amongst the groups of activity and damage (**Figure 1**). Black race, chronic CLE, and longer disease duration were associated with disease damage disproportionately worse than disease activity. Smoking was associated with worsening severity of both activity and damage.

Conclusion: CLASI-A and CLASI-D scores can be classified into mild, moderate, and severe categories with high specificity and sensitivity using a large, diverse cohort. This will allow providers to have greater context of disease severity using CLASI scores for prognostic, clinical, and research use. Future studies across multiple cohorts will help validate these ranges.

Reduction in Glucocorticoid Use in Patients with Systemic Lupus Erythematosus Treated with Belimumab: A Large Pooled Analysis of 5 Placebo-Controlled Studies

Karen Costenbader[1], Yoshiyuki Abe[2], Laurent Arnaud[3], George Bertsias[4], Norma Lynn Fox[5], Mathew Gibb[6], Anne Hammer[5], Alexa Meara[7], Holly Quasny[8], David Roth[5] and Tania Gonzalez-Rivera[5], [1]Brigham and Women's Hospital, Belmont, MA, [2]Juntendo University School of Medicine, Tokyo, Japan, [3]Department of Rheumatology, French National Reference Center for Autoimmune Diseases (CRMR RESO), Strasbourg, France, [4]Rheumatology, Clinical Immunology and Allergy, University of Crete School of Medicine, Heraklion, Greece, [5]GlaxoSmithKline, Collegeville, PA, [6]Veramed Ltd., Twickenham, United Kingdom, [7]Ohio State University Wexner Medical Center, Columbus, OH, [8]GlaxoSmithKline, Research Triangle Park, NC

SESSION INFORMATION
Session Date: Monday, November 8, 2021
Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster III: Outcomes (1257–1303)
Session Type: Poster Session C
Session Time: 8:30AM–10:30AM

Background/Purpose: Glucocorticoids (GC) play an important role in rapid systemic lupus erythematosus (SLE) symptom relief. However, chronic GC use increases organ damage risk; and treatment recommendations are to minimize/discontinue GC use when clinically possible.[1] Belimumab (BEL) is a disease-modifying SLE treatment that demonstrated a consistent efficacy profile in 4 Phase 3 trials.[2–5] This study analyzed pooled SLE data to assess whether GC reduction occurred more rapidly in patients (pts) randomized to BEL versus placebo (PBO).

Methods: Belimumab Summary of Lupus Efficacy (Be-SLE) analyzed data from 5 double-blind, PBO-controlled BEL studies in SLE: BLISS-76, BLISS-52, BLISS-NEA, BLISS-SC, and EMBRACE. The analysis compared BEL (10 mg/

kg intravenous [IV] or 200 mg subcutaneous [SC]) versus PBO (IV and SC) pooled data, collected every 4 weeks from baseline to Week 52. Although GC tapering was recommended for pts responding well to treatment, GC adjustments were at the investigator's discretion. GC use was converted to prednisone-equivalent dose (mg/day). A ≥25% GC reduction from baseline to ≤7.5 mg/day at Week 52 was a key GC endpoint in all trials. Odds ratios (OR) and 95% confidence intervals (CI) for GC dose changes were calculated using a logistic regression model with covariates of treatment, study, baseline GC dose, and (SELENA-SLEDAI score (≤9 versus ≥10).

Results: The analysis included 1869 and 1217 pts receiving BEL and PBO, respectively. Most pts were female (94.4%), with a median age of 36.0 years (range 18–77 years); baseline demographics and disease characteristics were balanced between groups. Most pts (BEL 88.2% [n=1648]; PBO 88.7% [n=1079]) received GC at baseline; mean baseline GC dose for BEL and PBO was 12.3 and 12.2 mg/day, respectively. A ≥25% GC reduction from baseline to ≤7.5 mg/day during Week 40 through Week 52 was achieved by 16.9% (n=202) of BEL recipients versus 11.9% (n=91) of PBO patients (OR: 1.52 [95% CI: 1.16–1.99], p=0.0024).

At Week 52, 33.9% of pts receiving BEL had a GC decrease from baseline, versus 27.4% with PBO (OR: 1.41 [95% CI: 1.18–1.70], p=0.0002; **Figure**). Conversely, 11.1% and 16.2% of BEL and PBO pts had a GC increase, respectively (OR: 0.65 [95% CI: 0.52–0.81], p=0.0001; **Figure**). Statistically significant differences in GC use between BEL and PBO were observed as early as Week 12 for *"any increase in GCs*," and by Week 24 for *"any decrease in GC"* (**Figure**). Mean (standard deviation) cumulative GC dose over 1 year was 4495 mg (4018.8) with BEL and 5096 mg (5641.6) with PBO (p=0.024 by analysis of covariance).

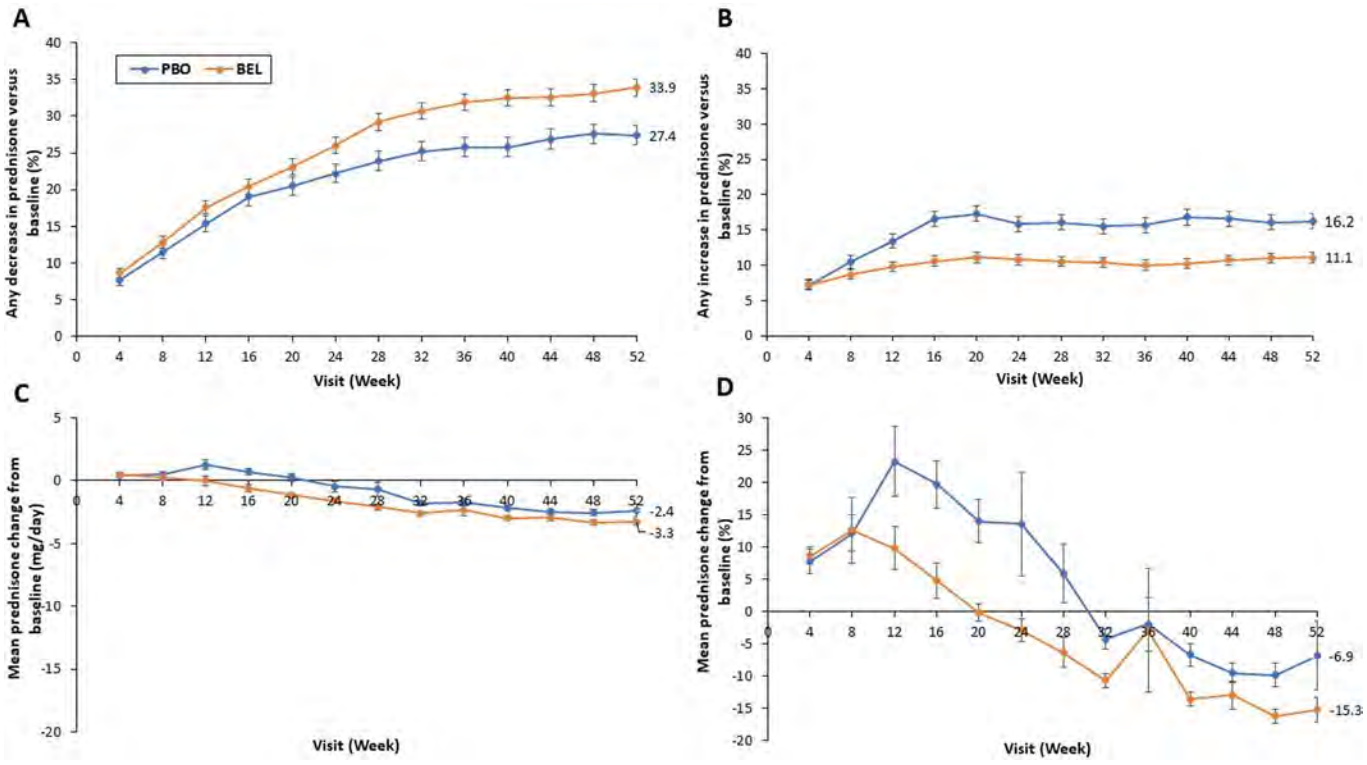

Figure. Percentage of pts with a decrease in GC dose compared with baselinea at each visit (A), percentage of pts with an increase in GC dose compared with baselineb at each visit (B), mean change from baselineb in GC dose (mg/day) at each visit (C); mean percentage change from baselinea in GC dose at each visit (D) Error bars represent the standard error. Numerical values shown represent data at Week 52. aAnalysis of pts receiving GCs at baseline bAnalysis of all pts, including those receiving GCs at baseline.

Conclusion: BEL was associated with significantly greater reductions in GC dose from baseline, and a lower cumulative GC dose over 1 year versus PBO. GC reductions with BEL occurred early in the 52-week treatment period despite no forced taper in the original studies. These data further support the role of BEL as a GC-sparing treatment in SLE management.

One Third of Lupus Nephritis Patients Classified as Complete Responders Continue to Accrue Progressive Renal Damage Despite Resolution of Proteinuria

Emma Weeding[1], Andrea Fava[2], Daniel Goldman[3] and Michelle Petri[3], [1]Johns Hopkins Hospital, Baltimore, MD, [2]Johns Hopkins University, Baltimore, MD, [3]Johns Hopkins University School of Medicine, Baltimore, MD

SESSION INFORMATION
Session Date: Monday, November 8, 2021
Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster III: Outcomes (1257–1303)
Session Type: Poster Session C
Session Time: 8:30AM–10:30AM

Background/Purpose: Up to 40% of individuals with lupus nephritis (LN) develop chronic kidney disease (CKD). Biopsy studies have revealed that patients with SLE can have active class III, IV, or V LN even in the absence of proteinuria or an abnormal glomerular filtration rate (GFR). We hypothesized that some patients with LN might be classified as treatment responders based on proteinuria, yet continue to accrue kidney damage. We sought to characterize early CKD in LN, and assessed the ability of traditional prognostic features, such as renal biopsy class and resolution of proteinuria, to identify patients likely to accrue progressive renal damage.

Methods: We conducted a single center retrospective study of SLE patients diagnosed with their first episode of biopsy-proven class III, IV, and/or V LN (n = 37). Participants with fewer than five years of clinical follow-up data were excluded, as were participants diagnosed with LN before 2004, so as to reflect modern outcomes. For each participant, eGFR calculated by CKD-EPI was graphed over time from date of renal biopsy to five years thereafter. Participants were divided into those with progressive GFR loss (GFR slope < -5 mL/min/1.73 m^2 per year) versus

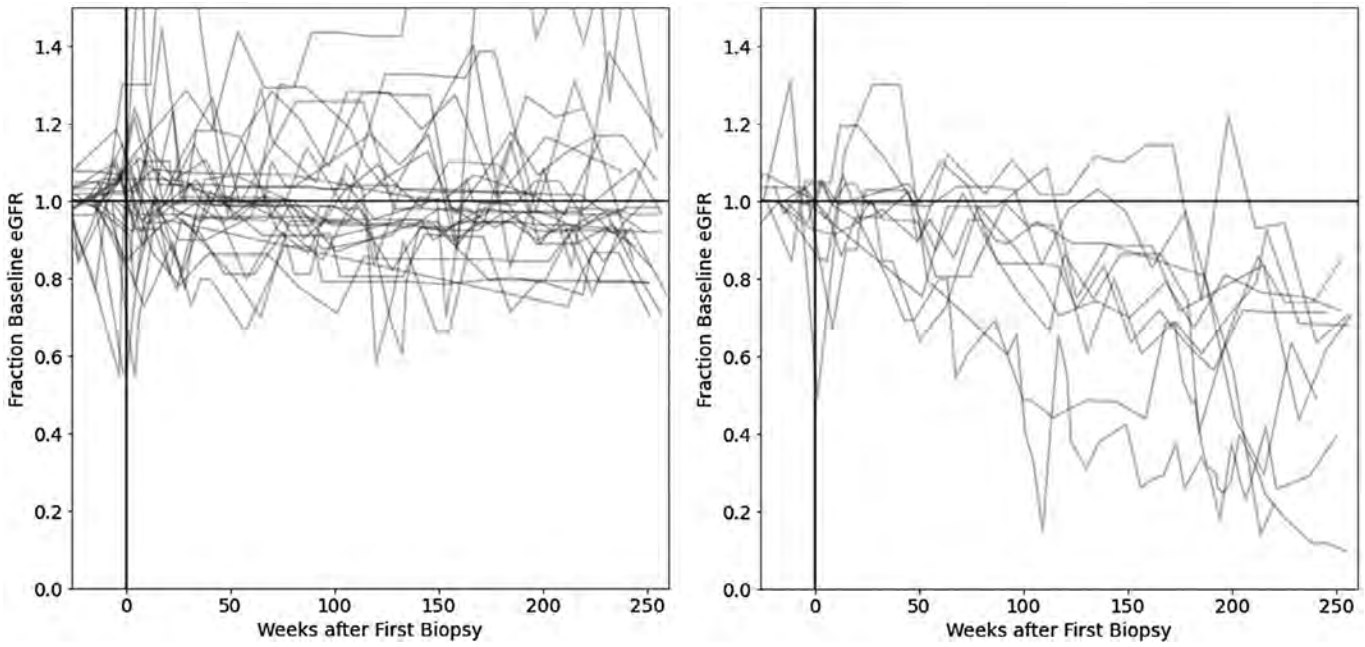

Figure 1. GFR trajectories of participants who maintained a stable GFR (left panel; n = 26) versus those who progressively lost GFR (right panel; n = 11). Each line represents the GFR values for one participant over time. To facilitate comparison between participant trajectories, GFR values were normalized to each participant's pre-LN baseline GFR.

Table 1. Baseline or other early characteristics of the GFR trajectory groups. Unless otherwise noted, average values are shown

Baseline Characteristic	GFR Trajectory Group		P Value
	Stable (n = 26)	Decline (n = 11)	
Sex, female	77%	91%	0.65
Race, black	77%	55%	0.24
Age at biopsy, years	31.9	37.7	0.14
BMI	26.7	28.5	0.34
Baseline GFR, mL/min/1.73 m^2	111	115	0.77
Urine protein (semi-quant), median	2+	2+	1.0
LN class, any proliferative	77%	82%	1.0
Activity index, median*	5	4	0.47
Chronicity index, median*	3	2	0.41
dsDNA, positive	69%	82%	0.69
C3	76	71	0.60
C4	14	11	0.37
RVVT >40	23%	10%	0.65
IgG aCL, positive	4%	0%	1.0
IgM aCL, positive	0%	0%	1.0
IgA aCL, positive	4%	0%	1.0
Hydroxychloroquine use at time of biopsy	89%	82%	0.62
Maximum prednisone dose, mg/kg	0.30	0.31	0.89
Induction therapy, MMF	77%	82%	1.0
ACEi or ARB use	50%	46%	1.0
History of hypertension**	31%	36%	1.0
History of diabetes**	0%	0%	1.0

* Activity and chronicity indices were available for 20 participants
** Prior to diagnosis of LN. No patients developed diabetes within the first year after biopsy.

Table 2. Response status (based on proteinuria < 500 mg/mg) at one year versus GFR trajectory group. Resolution of proteinuria at one year did not associate with ultimate GFR trajectory (p = 1.0). Response status could not be calculated for two participants in the stable GFR group (excluded from this table) due to missing clinical information at one year

Response Status at One Year	GFR Trajectory Group		
	Stable	Decline	
Responder	12	6	33% with GFR decline
Non-responder	12	5	29% with GFR decline
	50% classified as responders	55% classified as responders	

those who maintained a stable GFR (GFR slope not meeting the above threshold). Baseline demographics, renal biopsy features, immunologic status, treatment regimen, and comorbidities were compared between GFR trajectory groups using the Student's t-test, Wilcoxon rank-sum test, or Fisher's exact test as appropriate. Finally, proteinuria was assessed at one year after renal biopsy, and participants were classified as complete responders if urine protein was < 500 mg/mg at this time.

Results: Among these participants diagnosed with their first episode of LN, 30% (n = 11) accrued progressive renal damage despite standard of care therapy over the first five years following renal biopsy (**Figure 1**). There were no significant differences in baseline characteristics between GFR trajectory groups, including no association between progressive GFR loss and renal biopsy class, chronicity index, prednisone dosage, induction regimen, ACE inhibitor or ARB initiation, or prevalence of pre-existing hypertension or diabetes (**Table 1**). Likewise, resolution of proteinuria at one year did not differentiate between GFR trajectory groups (**Table 2**). Notably, 55% of participants with progressive GFR loss (n = 6 of 11) would be classified as complete responders based on < 500 mg/mg urine protein at one year after biopsy, and 33% (n = 6 of 18) of complete responders based on this urine protein threshold continued to accrue renal damage.

Conclusion: We have identified an understudied category of patients with LN who accrue progressive renal damage despite apparent response to standard of care therapy. Roughly half of the participants in this study with a worrisome GFR trajectory would be misleadingly classified as complete responders at one year based on resolution of proteinuria. These findings indicate that definitions of LN treatment response based on proteinuria can fail to identify patients who continue to accrue renal damage despite treatment. Better definitions and biomarkers of response are needed to improve long-term renal outcomes and trial design.

Major Determinants of Prolonged Remission in Systemic Lupus Erythematosus: Retrospective Study over a 41-Year Period

Goncalo Durao-Carvalho[1], Raquel Fernandez[2], Bethan Goulden[3], Filipa Farinha[4] and David Isenberg[5], [1]Servico de Medicina Interna, Centro Hospitalar do Oeste – Unidade de Caldas da Rainha, Caldas da Rainha, Portugal, Caldas da Rainha, Portugal, [2]Servicio de Medicina Interna, Hospital Universitario de Ourense, Ourense, Spain, [3]Department of Rheumatology, University College London Hospitals, London, United Kingdom, [4]Department of Rheumatology, University College London Hospitals and Centre for Rheumatology, University College London, London, United Kingdom, [5]Centre for Rheumatology, University College London, London, United Kingdom

SESSION INFORMATION

Session Date: Monday, November 8, 2021

Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster III: Outcomes (1257–1303)

Session Type: Poster Session C

Session Time: 8:30AM–10:30AM

Background/Purpose: Disease activity is a major determinant of mortality whereas prolonged remission contributes to improving health outcomes in SLE patients (pts). Remission is thus a key target, however, different definitions have been used.

Our aim was to investigate predictors of sustained complete remission for at least 3 and 5 years.

Methods: Retrospective observational study from Jan.1978-Dec.2019. Pts attending the Lupus Clinic in a tertiary care hospital for a period of at least three years. All pts fulfilled either the 1997 update of the 1982 American College of Rheumatology (ACR) revised criteria for classification of SLE or the 2019 EULAR/ACR criteria. To be included in the study, pts had to have been attending the clinic at least once a year. At each visit, disease activity was assessed using the BILAG index (also sensitive to detect flares) and blood test were done.

Complete remission (CR) was defined as no clinical activity (BILAG score C, D or E only), taking no steroids or immunosuppressants (antimalarials were permitted) and no serological activity (normal dsDNA antibodies and C3 levels) for a minimum of 3 consecutive years. Pts were **serologically active clinically quiescent (SACQ)** if there was no clinical activity, but an active serological profile (low C3 and/or high dsDNA) for at least 3 consecutive years; and in **serological remission (SR)** if there was no serological activity but persistent clinical activity (BILAG score A or B and/or treatment with steroids or immunosuppressive drugs) for at least 3 consecutive years. Pts not meeting the remission definitions were included in a **no-remission group**.

After testing for normality, we compared continuous numerical variables with Kruskal-Wallis test. For categorical variables, we compared groups using Pearson's chi-squared test. Kaplan-Meier curves were used to investigate cumulative survival. Pts were censored if they were lost to follow-up or reached the end of the study. Cox regression analysis was performed to investigate predictors of sustained remission. For continuous numerical variables showing a significant result, we used ROC curves to find a cut-off for each variable. All variables with a significant result in univariable analysis were included in the multivariable model. Statistical significance for P value < 0.05.

Results: 564 pts included. 15% achieved CR; 7% SACQ; 15% SR. 63% attained no remission.

Table 1. Comparison between patients who achieved different levels of sustained remission (at least 3 years) and no remission

Antiphospholipid Syndrome, N (%)	56 (10)	3 (4)	7 (18)	11 (13)	35 (10)	0.048
Sjogren's syndrome, N (%)	76 (14)	15 (17)	8 (21)	15 (18)	38 (11)	0.084
Myositis	19 (3)	1 (1)	3 (8)	3 (4)	12 (3)	0.298
Rheumatoid arthritis	26 (5)	2 (2)	0	9 (11)	15 (4)	0.020
Deaths, N (%)	65 (14)	4 (7)	1 (3)	5 (7)	55 (18)	0.007

SLE: Systemic Lupus Erythematosus; y: years; IQR: interquartile range; ITP: immune thrombocytopenia. The p value refers to the comparison between the 4 groups (except in duration of remission - only 3 groups).

Pts who did not reach any kind of sustained remission died significantly earlier ($p < 0.001$). Cumulative survival figures at 5, 10, 20 and 30 years were 100, 100, 94 and 90%, respectively, for pts who achieved CR and 96, 93, 77 and 58%, respectively, for pts in the no-remission group.

	N total	N deaths	Cumulative survival %			
			5 y	10 y	20 y	30 y
Total	468	65	98	95	84	75
Complete Remission	57	4	100	100	94	90
Clinical Remission	31	1	100	100	100	100
Serological Remission	72	5	100	96	89	89
No remission	308	55	96	93	77	58

Figure 1. Kaplan-Meier curves showing cumulative patient survival in patients who reached different levels of sustained remission (for at least 3 years).

Significant predictors of CR were white ethnicity, adjusted hazard ratio (HR) 2.16 [95% CI 1.30-3.59] p=0.003; older age at diagnosis (>32-years), HR 1.92 [1.24-2.97] p=0.003; absence of renal involvement, HR 2.55 [1.39-4.67] p=0.002; and no concomitant antiphospholipid syndrome (APS), HR 4.92 [1.55-15.59] p=0.007.

Conclusion: Pts not achieving any kind of sustained remission have a higher risk of early mortality. White ethnicity, older age at diagnosis, absence of renal involvement and of APS were significantly associated with CR.

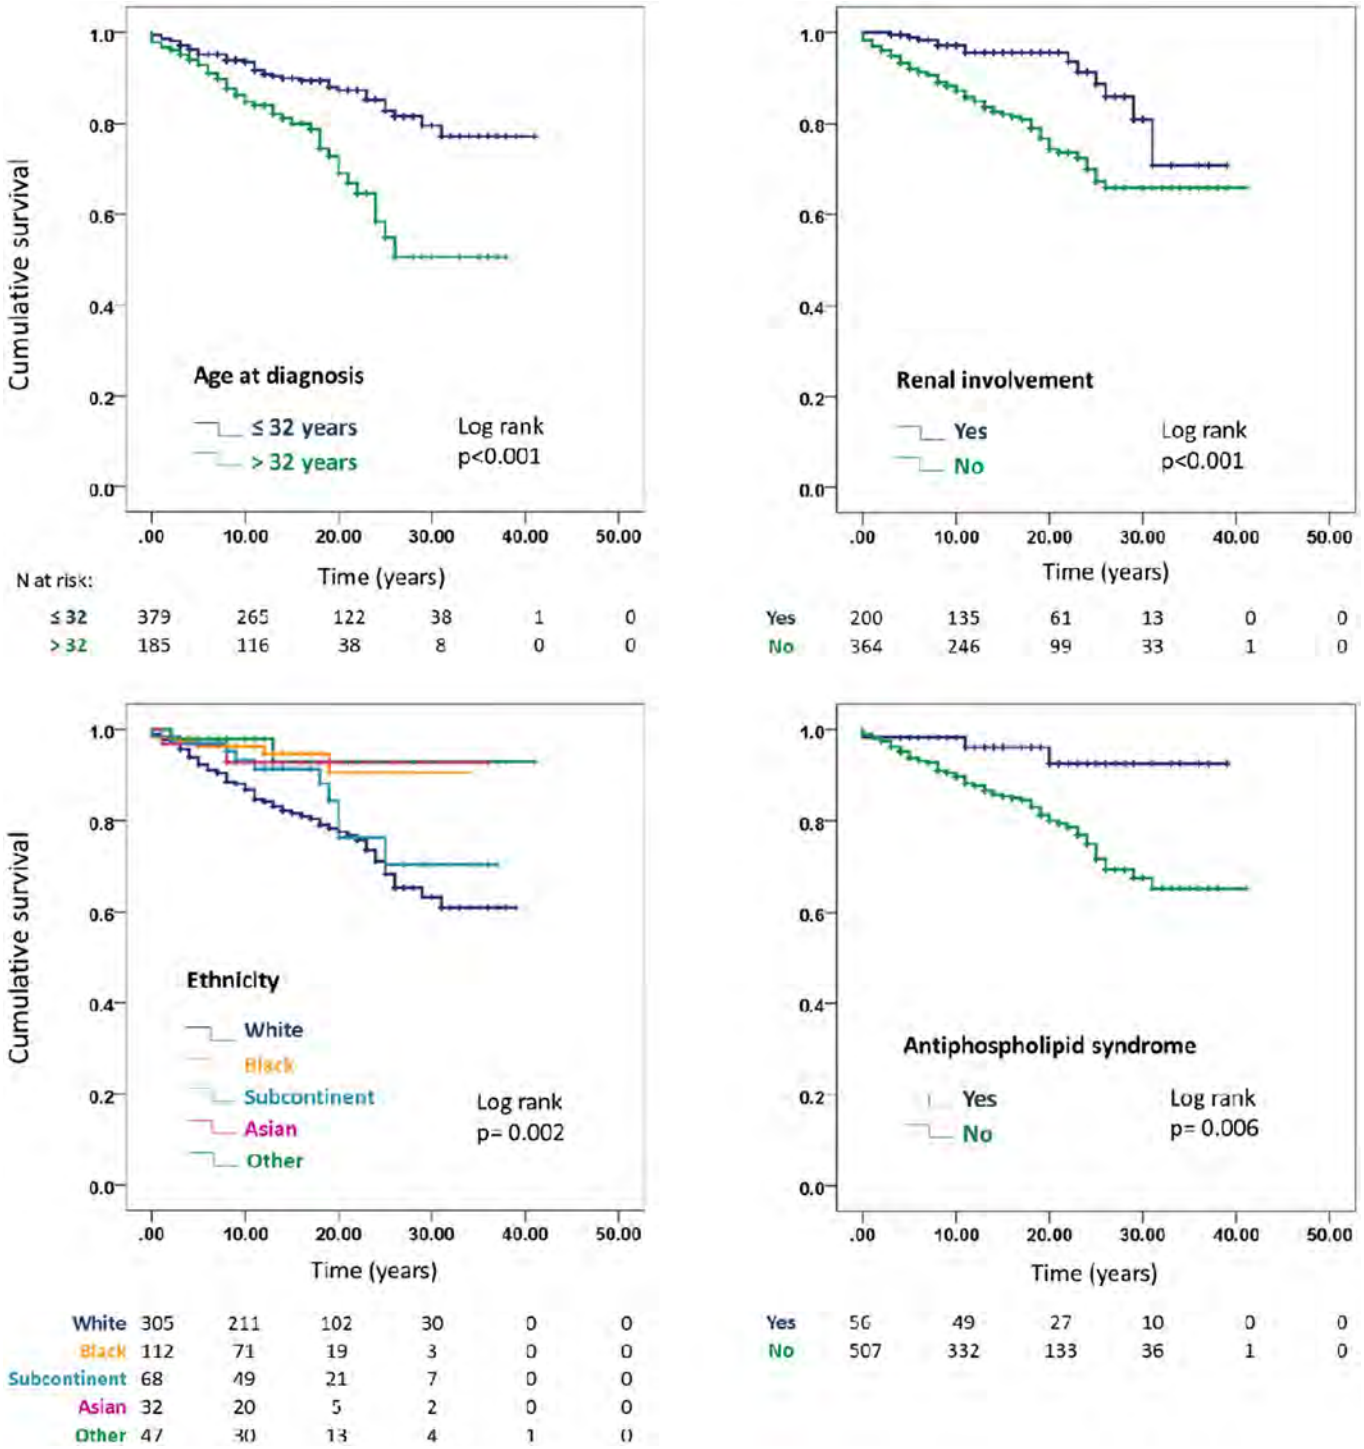

Figure 2. Kaplan-Meier curves showing cumulative survival free of complete sustained remission (at least 3 years), in different groups of patients, after the diagnosis of SLE.

Twenty-Year Trends in Systemic Lupus Erythematosus All–Cause Mortality in Mexico: A Nationwide Health Registry

Claudia Mendoza-Pinto[1], Ivet Etchegaray-Morales[2], Mario García-Carrasco[2], Pamela Munguía-Realpozo[2] and Socorro Méndez-Martínez[3], [1]Instituto Mexicano del Seguro Social, San Andres Cholula, Mexico, [2]Benemérita Universidad Autónoma de Puebla, Puebla, Mexico, [3]Instituto Mexicano del Seguro Social, Puebla, Mexico

SESSION INFORMATION
Session Date: Monday, November 8, 2021
Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster III: Outcomes (1257–1303)
Session Type: Poster Session C
Session Time: 8:30AM–10:30AM

Background/Purpose: Marked regional variation in systemic lupus erythematosus (SLE) mortality may be due to different spectra of local environmental factors. There have been no large population-based studies of SLE mortality trends in Mexico. The aim of this study was to assess mortality trends in adults with SLE using a nationwide health registry.

Methods: Data came from the Dynamic Cubes of the General Direction of Health Information from 1998-2017 for mortality. In patients aged ≥ 15 years, SLE as the principal cause of death was defined according to the International Classification of Diseases (ICD)-10 code M32 and was classified by sex and age. Information was provided by the National Institute of Statistics, Geography and Informatics on mortality in the general population during the study period. Joinpoint trend analyses of annual age-standardized mortality rates (ASMR) (Table) for SLE patients and non-SLE people were carried out.

Results: From 1998 through 2017, we identified 11,449 SLE deaths and 9,911, 323 non-SLE deaths. The mean age of deaths for SLE was 37 years. The proportion of deaths among women was higher for SLE than for non-SLE. Over this period, SLE ASMR increased more than non-SLE ASMR, with a 53.8% cumulative increase in the ratio of SLE to non-SLE.

Whereas the non-SLE ASMR remained relatively stable throughout the 20 years (either overall or by sex), the SLE ASMR significantly increased between 1998 and 2008 (annual percentage change of 6.4 [95% CI 4.7 to 8.0]), decreased not significantly between 2008 and 2011 and not significantly increased there after. Similar pattern was seen for women with SLE and for men with SLE an increased between 2003 to 2017 was identified. Both women and men had large cumulative increase in the ratio of the SLE to the non-SLE ASMR (73.8% and 191.3%, respectively). Moreover, of the 11,449 deaths, 445 (3.8%) were in geographical areas where ≥ 40% of the population is indigenous, 6552 (57.6%) in areas with ≥ 5,000 indigenous inhabitants, and 4452 (38.6%) occurred in areas with no or very small indigenous inhabitants.

Conclusion: SLE mortality rates have increased since 1998 and remain high compared with non-SLE mortality: significant sex disparities persist.

The same method was used to calculate ASMR for all years from 1998 to 2017 and for all subpopulation based con sex.

Direct age standardization calculation for SLE mortality in Mexico female population for 2017

Association of Limited Health Literacy with Patient-Provider Communication in Systemic Lupus Erythematosus

Ann Barr[1], Catherine Howe[2], Jennifer Rogers[1], Jayanth Doss[1], Rebecca Sadun[1], Lisa Criscione-Schreiber[3], Megan Clowse[4], Kai Sun[3] and Mithu Maheswaranathan[3], [1]Duke University, Durham, NC, [2]Duke University Hospital, Durham, NC, [3]Duke University School of Medicine, Durham, NC, [4]Duke University, Chapel Hill, NC

SESSION INFORMATION
Session Date: Monday, November 8, 2021
Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster III: Outcomes (1257–1303)
Session Type: Poster Session C
Session Time: 8:30AM–10:30AM

Background/Purpose: Low health literacy is common among US adults, including patients with SLE, and is associated with higher disease activity and worse patient-reported outcomes. The complex nature of managing lupus puts SLE patients with low health literacy at even greater risk of poor outcomes. Limited health literacy has also been associated with worse patient-provider communication in other chronic diseases, though this has not been evaluated in SLE. Our study aimed to explore the relationship between health literacy and patient-provider communication in patients with SLE.

Methods: Patients with SLE meeting ACR/SLICC criteria were recruited from a university lupus clinic. Patient-provider communication data, as measured by the Interpersonal Processes of Care (IPC-29) survey, with a 0-5 range, were collected 7/2018-1/2019. On the IPC-29 survey, we considered a difference of ≥ 0.5 points by median score as clinically significant for each individual question. Health literacy was assessed using the Newest Vital Sign (NVS), a validated 6-item measure of reading comprehension and numeracy; limited health literacy was defined as NVS < 4. The NVS was administered from 9/2020-2/2021 during routine clinic visits and over video call. We compared charac-

teristics median IPC-29 scores between limited and adequate health literacy groups by descriptive statistics, and we stratified the IPC-29 domains by race.

Results: The study included 58 SLE patients (48% white, 48% Black, 5% Hispanic). Median age was 41 years; 97% were female, 59% had at least a college education, and 57% had Medicare or Medicaid, and 45% were on disability. 26% of our cohort was found to have limited health literacy.

Compared to adequate health literacy, those with limited health literacy were more likely to be Black, have Medicare/Medicaid, be on disability, have less than a college education, and have an annual income of ≤$50,000. Patients with limited health literacy were more likely to rate their providers as speaking too quickly, using difficult words, not finding out concerns, and not involving the patient in treatment decisions (Table 1).

Non-Black patients with limited health literacy reported lower provider eliciting of patient concerns, higher discrimination and worse physician compassion and respect compared to those with adequate health literacy. On the other hand, among Black patients, those with limited health literacy reported lower patient-centered decision making (Table 2).

Conclusion: Our results show that low health literacy is common, affecting 1 in 4 patients with SLE. While we did not find major differences in overall perceived communication based on level of health literacy, there were some notable differences in the eliciting concerns, patient-centered decision-making, and compassionate/re-

Table 1: Interpersonal Processes of Care (IPC-29) survey results by Health Literacy group

Interpersonal Processes of Care Domain	Total Median (IQR)	Limited Health Literacy	Adequate Health Literacy	p-value
Hurried Communication	1.2 (1.0-1.6)	1.4 (1-2)	1.2 (1.0-1.4)	0.4
• How often did doctors speak too fast?	1 (1-2)	**2 (1-3)**	**1 (1-2)**	
• How often did doctors use words that were hard to understand?	1 (1-2)	**2 (1-3)**	**1 (1-2)**	
Elicited Concerns, Responded	5 (4.3-5)	4.8 (4-5)	5 (4.7-5)	0.6
• How often did doctors really find out what your concerns were?	5 (4-5)	**4.5 (4-5)**	**5 (4-5)**	
Explained Results and Medications	4.75 (4.25-5)	4.9 (4.25-5)	4.75 (4.25-5)	0.8

First Year Infection Risk in SLE Patients Treated with Rituximab versus Standard of Care Treatment: Results from the British Isles Lupus Assessment Group Biologics Registry (BILAG-BR)

Mia Rodziewicz[1], Sarah Dyball[1], Stephen McDonald[1], Emily Sutton[1], Ben Parker[1], The British Isles Lupus Assessment Group[2] and Ian N. Bruce[1], [1]University of Manchester, Manchester, United Kingdom, [2]Lupus Trust, London

SESSION INFORMATION

Session Date: Monday, November 8, 2021

Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster III: Outcomes (1257–1303)

Session Type: Poster Session C

Session Time: 8:30AM–10:30AM

Background/Purpose: Individuals with systemic lupus erythematosus (SLE) have an increased risk of infection compared to the general population. We aimed to assess the early risk of infection following rituximab therapy in a large national biologics register.

Methods: Patients receiving rituximab (RTX) or standard of care (SoC) treatment recruited to the UK national SLE biologics registry (2010-21) were included. Demographic, clinical and laboratory data were recorded at recruitment

Table 1. Baseline characteristics of patients receiving rituximab and standard of care treatment

and during follow up. Information relating to infection and mortality were collected from study centres and the UK Office for National Statistics in the first 12-months after treatment initiation. Serious infections were defined as those requiring intravenous antibiotic treatment, hospital admission, resulting in disability or death.

Statistical analysis was performed using Stata (v14). Baseline variables were compared using Chi-squared or Mann-Whitney U tests. A logistic regression model adjusted for age and sex was used to test the association of baseline variables with serious infection within the first year.

Results: We included 931 patients (764 RTX and 167 SoC). In the SoC arm, commonest prescribed recent therapies included mycophenolate (n=126, 75%), azathioprine (n=46, 28%) and/or cyclophosphamide (n=38, 23%).

Baseline characteristics were similar between the two groups but RTX patients had a longer disease duration, higher number of previous immunosuppressants, more obstructive airways disease and lower maintenance steroid dose and baseline serum IgG (Table 1). In the first year following treatment initiation, 259 infections were reported in 143 (15%) patients, including 106 (41%) serious infections. In the RTX group, 127 (17%) individuals reported an infection compared to 16 (10%) in the SoC group, *p=0.022*. There was no difference in the number of serious infections between groups, 58 (8%) and 10 (6%) patients in RTX and SoC groups respectively, *p=0.471*. Recurrent serious infections occurred in 21 (2%) patients and were not significantly different between RTX and SoC groups (2.5% Vs 1.2%, *p=0.309*).

After adjusting for age and gender in the RTX group, number of comorbidities (OR 1.34 95% CI 1.08-1.65), maintenance steroid dose (OR 1.05 CI 1.01-1.08) and hypogammaglobulinaemia (IgG < 6.0 g/L) (OR 2.35, 95%CI 1.06-5.18) were associated with increased risk of infection (Table 2).

The commonest sites of serious infection were respiratory (n=24, 23%), bone/soft tissue (n=14, 13%), ENT (n=11, 10%) and urinary tract (n=8, 8%). One RTX-treated individual died of an infection (sepsis) within a year of treatment initiation.

Conclusion: RTX-treated SLE patients do not demonstrate an increased risk of serious infections compared to those on SoC treatment. Baseline hypogammaglobulinaemia, higher number of comorbidities and usual oral steroid dose correlate with infection risk in RTX-treated patients.

SESSION INFORMATION

Session Date: Monday, November 8, 2021

Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster III: Outcomes (1257–1303)

Session Type: Poster Session C

Session Time: 8:30AM–10:30AM

Background/Purpose: Lupus nephritis can occur as an isolated component of disease activity or be accompanied by diverse extrarenal symptoms that can adversely affect a patient's quality of life (QOL). Whether renal disease absent other activity is sufficient to decrease QOL is unknown. A lack of reported QOL impairment may place patients at risk for delayed diagnosis of nephritis or medication noncompliance yet nephritis trials have largely neglected QOL. As such, this study leveraged the multi-center multi-racial Accelerating Medicines Partnership (AMP) lupus nephritis cohort to assess QOL measured by PROMIS-29.

Methods: Patients (n=182) fulfilling ACR or SLICC criteria for SLE with a uPCR ≥ .5 and biopsy Class III, IV, V, or mixed were consecutively enrolled in AMP at the time of renal biopsy and clinical history, PROMIS-29, and disease activity as assessed by the hybrid SELENA-SLEDAI were recorded. Patients were determined to have extrarenal clinical activity if, after excluding all laboratory parameters from the SLEDAI, the score remained ≥ 1. Raw PROMIS-29 scores were transformed to t-scores with the mean of 50 ± 10 representing the US population and a difference of 5 points considered clinically meaningful. PROMIS-29 physical and mental health summary scores were calculated according to published formulas.

Results: Forty-three percent of patients (n=78) had extrarenal clinical manifestations including vasculitis (4%), arthritis (39%), rash (45%), alopecia (42%), mucosal ulcers (13%), pleurisy (12%), pericarditis (8%), and fever (4%). Patients with isolated renal disease (n=104, 57%) did not have PROMIS-29 scores that differed clinically from the US population whereas patients with extrarenal disease reported deficits in physical functioning, fatigue, social functioning, and pain (Table 1). Patients with extrarenal disease had significantly lower physical health summary scores compared to patients with isolated disease (median [IQR]: 40.31 [35.79, 47.02] p< 0.001 vs. 48.6 [40.14, 57.08]) and significantly lower mental health summary scores (44.12 [38.63, 51.39], p=0.024 vs. 48.67 [40.51, 55.07]). Female and African American patients and those with nephrotic range proteinuria or undergoing first biopsy had significantly lower physical health summary scores, but mental health summary scores did not differ by these variables. Patients on greater than 20 mg of prednisone had both significantly lower physical and mental health summary scores compared to those on lower doses. PROMIS-29 scores did not differ by low complements, anti-dsDNA, or anti-Ro antibodies. Stepwise multivariable linear regression analysis demonstrated that the association between extrarenal disease and lower PROMIS-29 summary scores was primarily driven by arthritis and independent of potential confounders (Tables 2 and 3).

Table 1. PROMIS-29 scores among patients with isolated renal vs extrarenal disease.

Category	Isolated Renal n=104	Extrarenal n=78	P-value
Physical functioning <	48.3 [40.5-57.0]	41.2 [36.7-48.3]	**<0.0001**
Anxiety >	53.7 [40.3-59.5]	51.2 [40.3-59.5]	0.87
Depression >	45.0 [41.0-55.7]	45.0 [41.0-57.3]	0.88
Fatigue >	53.1 [46.0-62.2]	57.9 [48.6-64.6]	**0.009**
Sleep >	54.3 [48.9-57.9]	54.3 [48.4-59.8]	0.80
Social functioning <	51.9 [44.2-64.2]	44.2 [42.3-51.9]	**0.002**
Pain >	55.6 [41.6-61.2]	61.2 [55.6-66.6]	**0.0002**
Pain intensity >	3.0 [1.0-5.8]	6.0 [3.0-8.0]	**<0.0001**

Results are presented as median [IQR], Mann-Whitney U test of significance
< lower scores indicate worse outcome
> higher scores indicate worse outcome

Table 2. Stepwise multivariable linear regression analysis of extrarenal manifestations and PROMIS-29 physical health summary scores

	Physical health summary scores <	
Predictors	**Estimate (95% CI)**	**p-value**
Arthritis (yes vs. no)	-8.68 (-12.32 ,-5.03)	**<.0001**
Rash (yes vs. no)	-2.24 (-5.65 ,1.17)	0.196
Prednisone>20mg	-4.68 (-7.4 ,-1.97)	**0.0008**
Sex: female	-3.05 (-6.5 ,0.4)	0.0827

< lower scores indicate worse outcome

Table 3. Stepwise multivariable linear regression analysis of extrarenal manifestations and PROMIS-29 mental health summary scores

	Mental health summary scores <	
Predictors	**Estimate (95% CI)**	**p-value**
Arthritis (yes vs. no)	-5.93 (-9.47 ,-2.38)	**0.0012**
Rash (yes vs. no)	-1.9 (-5.29 ,1.49)	0.2699
Prednisone>20mg	-2.39 (-5.11 ,0.33)	0.0848
Non-Hispanic Caucasian	-4.13 (-7.76 ,-0.49)	**0.0266**

< lower scores indicate worse outcome

Conclusion: The majority of patients had isolated renal disease and report a QOL similar to that of the general population. In contrast, those with extrarenal manifestations report significantly worse QOL outcomes. These results reinforce the critical importance of routine laboratory surveillance and medication compliance for nephritis even in patients with seemingly quiescent clinical disease.

Abstract Number: 1290

Validation of a Novel Lupus Multivariable Outcome Score as an Outcome Measure for Systemtic Lupus Erythematosus Trials

Michal Abrahamowicz[1] and **Peter Lipsky**[2], [1]McGill University, Montréal, QC, Canada, [2]AMPEL BioSolutions, Charlottesville, VA

SESSION INFORMATION
Session Date: Monday, November 8, 2021
Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster III: Outcomes (1257–1303)
Session Type: Poster Session C
Session Time: 8:30AM–10:30AM

Background/Purpose: Development of effective new Systemic Lupus Erythematosus (SLE) treatments requires a validated responder index responsive to clinically meaningful change and relevant to clinical practice. To address this challenge, we have recently developed a new Lupus Multivariable Outcome Score (LuMOS) to optimize discrimination between outcomes of actively treated patients *versus* those randomized to placebo [1]. We now report on external validation of LuMOS in two independent SLE clinical trials.

Methods: Validation was carried out in the Illuminate trials used to evaluate tabalumab (TB) in SLE. All participants in both Illuminate 1 and 2 clinical trials met the ACR classification criteria for SLE and all were included in our analyses. To adapt LuMOS for use with laboratory results assessed on different platforms than used in the trials of belimumab employed to generate the original LuMOS outcome score [1], we calculated a standardized score using z-score transformation. For validation, in each of the Illuminate trials, we calculated LuMOS scores at week 52 for all participants receiving either placebo or one of 2 dosage regimens of TB. Cohen D Effect Size (ES), with 95% confidence intervals (CI), assessed the ability of LuMOS to discriminate between outcomes in active treatment groups *versus* placebo, and compared it with SRI-5 responder index used in the trials.

Results: LuMOS using standardized z-score transformed laboratory data worked comparably to the original LuMOS model in the original data from the belimumab trials and was then applied to the Illuminate data sets. LuMOS-based ES for both TB groups in both trials indicated highly significant ($p < 0.0001$), moderately strong treatment effects (ES

Table 1

Trial	Group (n)	**LuMOS: Effect Size (95% CI)**	**SRI-5: Effect Size (95% CI)**
ILLUMINATE-1	TB-q4weeks (n=378)	**0.44 (0.30; 0.59)**	**0.13 (- 0.02; + 0.27)**
ILLUMINATE-1	TB-q2weeks (n=381)	**0.42 (0.27; 0.56)**	**0.05 (- 0.09; + 0.20)**
ILLUMINATE-2	TB-q4weeks (n=376)	**0.54 (0.39; 0.68)**	**0.15 (+0.01; +0.30)**
ILLUMINATE-2	TB-q2weeks (n=372)	**0.69 (0.53; 0.83)**	**0.23 (+0.08; +0.37)**

Comparison of Effect Sizes of LuMOS vs. SRI-5 for discrimination between TB-treated and placebo groups n Illuminate-1/-2 trials

>0.4), in contrast to weak effects (ES< 0.25) based on SRI-5, that were statistically *non*-significant for Illuminate-1, as reflected by the 95% CI's that included 0 (Table).

Conclusion: LuMOS improves the ability to detect statistically significant treatment effects. Further validation in SLE trials of non-B cell directed treatments is necessary to document utility as an outcome measure independent of drug mechanism.

Risk of Bleeding-related Complications After Kidney Biopsy in Patients with Systemic Lupus Erythematosus

Eun Song Kang[1], Ji Seon Oh[2], Soo Min Ahn[1], Yong Gil Kim[1], Chang-Keun Lee[1], Bin Yoo[3] and Seokchan Hong[3], [1]Asan Medical Center, Seoul, Republic of Korea, [2]Asan Medical Center, Ulsan, Republic of Korea, [3]Asan Medical Center, Seoul, South Korea

SESSION INFORMATION
Session Date: Monday, November 8, 2021
Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster III: Outcomes (1257–1303)
Session Type: Poster Session C
Session Time: 8:30AM–10:30AM

Background/Purpose: Kidney biopsy is essential for the diagnosis and classification of lupus nephritis in patients with systemic lupus erythematosus (SLE). Even though the risk of bleeding-related complications is not low in such patients, data on the risk of percutaneous kidney biopsy in SLE patients are limited. Thus, we investigated the rate of bleeding-related complications and examined the risk factors for complications of kidney biopsy in patients with SLE.

Methods: We retrospectively reviewed the medical records of SLE patients who underwent ultrasound-guided percutaneous kidney biopsy between 2002 and 2020 at a tertiary referral center. Major complications included bleeding events that required interventions (e.g., blood transfusion, angiographic embolization, surgery) after biopsy. Minor complications included hematoma, oozing at the biopsy site, and passing hematuria without a need for intervention. Statistical analysis with a multivariate logistic regression model was performed to identify the risk factors associated with complications.

Results: In a total of 165 SLE patients, the rate of overall bleeding-related complication after kidney biopsy was 25% (major: 8%, minor: 17%). In terms of the details of major complications, 86% (12/14) of patients needed a blood transfusion alone without embolization or surgery, and the remaining two patients needed embolization for bleeding control. Patients with any kind of complication had a significantly lower platelet level than did those without complications (p< 0.001). Univariate analysis showed that the levels of hemoglobin (OR 0.81; 95% CI, 0.66–0.99), platelet (OR 0.99; 95% CI, 0.99–1.00), aPTT (OR 1.05; 95% CI, 1.00–1.11), and proteinuria (OR 1.00; 95% CI, 1.00–1.00) were significantly associated with the risk of complications. Multivariate analysis revealed that low platelet count (OR 0.99; 95% CI, 0.98–0.99) was significantly associated with the risk of bleeding-related complications after kidney biopsy.

Conclusion: Percutaneous kidney biopsy was accompanied by the risk of bleeding-related complications, although the majority of events did not require vascular intervention for bleeding control. Low levels of platelet counts had a significantly increased risk of complications after kidney biopsy in patients with SLE.

Table 1. Clinical and laboratory characteristics of SLE patients with and without complication after kidney biopsy

Characteristics	Complication group (n=42)	Non-complication group (n=123)	p-value
(1) Clinical features

Systemic Lupus Erythematous Readmissions Has Reduced in the Last Decade in the United States: A 9- year Longitudinal Study of the Nationwide Readmission Database

Ehizogie Edigin[1], Precious Eseaton[2], Chinenye Osuorji[3], Ajayi Temitope[4], Oluwafeyi Adedoyin[5], Nneka Chukwu[6] and Augustine Manadan[7], [1]Internal Medicine, John H Stroger Jr. Hospital of Cook County, Chicago, IL, [2]University of Benin, Benin, Nigeria, [3]Internal Medicine, Burrell College of Osteopathic Medicine, Las Cruces, NM, [4]Internal Medicine, University of Buffalo, Buffalo, NY, [5]Internal Medicine, Englewood Hospital and Medicine Center, Englewood, NJ, [6]Nuvance Health Internal Medicine Residency, Poughkeepsie, NY, [7]Rush University Medical Center, Chicago, IL

SESSION INFORMATION

Session Date: Monday, November 8, 2021

Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster III: Outcomes (1257–1303)

Session Type: Poster Session C

Session Time: 8:30AM–10:30AM

Background/Purpose: Longitudinal data on trends of Systemic Lupus Erythematous (SLE) readmissions is scarce. Our study aims to study trends of 30-day readmissions of patients admitted for SLE flare in the United States (US) from 2010-2018. We also aim to highlight the most common reasons for 30-day readmissions of patients admitted for SLE flare in the last decade.

Methods: Data were obtained from the Nationwide Readmission Database (NRD). NRD includes nested and weighted discharge data stratified in clusters to produce national estimates. We performed a retrospective 9-year longitudinal trend analysis of NRD 2010 – 2018 databases. Every other year was sampled during the study period. We searched for index hospitalizations for patients aged ≥ 18 years with "principal" diagnosis of SLE using ICD 9 & 10 codes ("7100" & "M32" respectively) for the corresponding year. The principal diagnosis is the main reason for hospitalization, hence index hospitalizations with SLE as the principal diagnosis are defined as SLE flare hospital-

Table 1. Characteristics and longitudinal trends of 30-day readmissions following index hospitalization for Systemic Lupus Erythematous flare Abbreviations: Readmit: Readmissions, d, days, LOS: Hospital length of stay, Cost: total hospital cost, CCI: Charlson comorbidity index score, USD: United States dollars, yr: years SLE: Systemic Lupus Erythematous, AKI: Acute kidney injury, UTI: Urinary tract infection. p-value <0.05 is statistically significant. *We included hospitalizations with a "principal" diagnosis of SLE. **Readmission cost for each year was adjusted for inflation using 2018 US dollars according to the medical expenditure panel survey-based factor for hospital care

Variables	2010	2012	2014	2016	2018	Adjusted p-trend

0-2	57.8	57.7	54.8	50.8	45.7	
≥3	42.2	42.3	45.2	49.3	54.4	
Most common reasons for Readmit						
	SLE	SLE	SLE	SLE Glomerulonephritis	SLE Glomerulonephritis	
	Pneumonia	Pneumonia	Pneumonia	SLE, unspecified	SLE, unspecified	
	Sepsis	Sepsis	Sepsis	Sepsis	Sepsis	
	AKI	Chest pain	AKI	AKI	AKI	
	UTI	UTI	Pericardial disease	SLE with unspecified organ or system involvement	SLE with unspecified organ or system involvement	

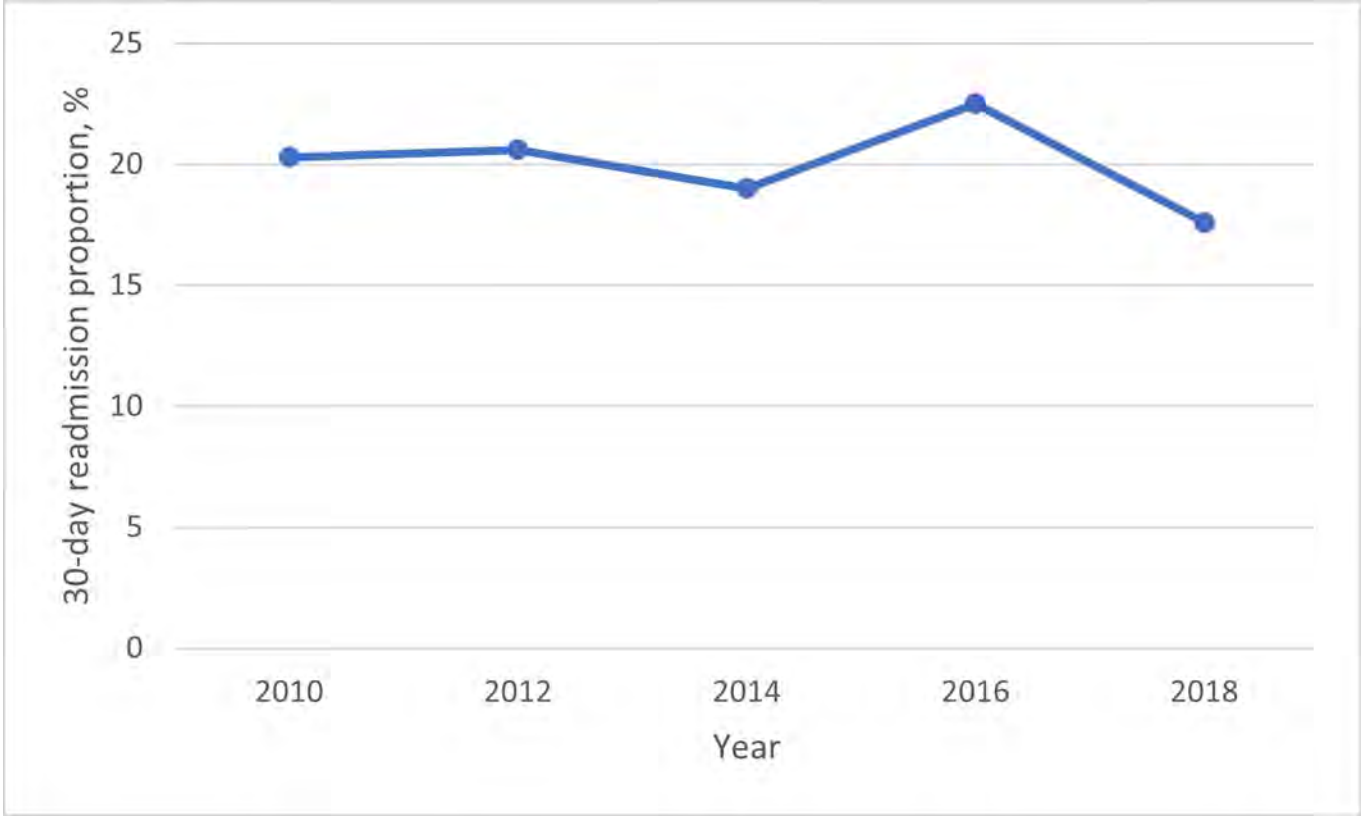

Figure 1. Proportion of 30-day readmissions following index admission for SLE flare from 2010-2018.

izations. Elective and traumatic readmissions were excluded. The 5 most common principal diagnoses or reasons for readmissions for each sampled year were highlighted. Multivariable logistic and linear regression analyses were used to calculate adjusted p-trend for categorical and continuous outcomes, respectively. We adjusted for change in demographics and Charlson comorbidity index (CCI) score over the years. Analysis was performed using STATA, 16.

Results: 30-day readmissions following admissions for SLE flare decreased from 20.3% in 2010 to 17.6% in 2018 (adjusted p-trend=0.009). See Figure 1. Readmission mortality reduced from 2.5% to 2% (adjusted p-trend=0.317, hospital length of stay (LOS) reduced from 6.7 days to 6 days (adjusted p-trend=0.045), and total hospital cost reduced from $15,843 to $14,619 (adjusted p-trend=0.052) from 2010 to 2018. Proportion of readmissions with CCI score ≥3 increased from 42.2% to 54.4% (adjusted p-trend< 0.0001) during the study period. SLE, sepsis and infections were common reasons for 30-day readmissions across the years (table 1).

Conclusion: About 1 in 5 SLE flare admission results in 30-day readmission. 30-day readmissions following hospitalization for SLE flares have reduced in the last decade. Although readmission LOS reduced, CCI score has increased over time. Decreasing readmission rates over time may reflect improved discharge care and outpatient flare management. Infection control strategies are important in reducing 30-day readmissions following admissions for SLE flare.

SESSION INFORMATION

Session Date: Monday, November 8, 2021

Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster III: Outcomes (1257–1303)

Session Type: Poster Session C

Session Time: 8:30AM–10:30AM

Background/Purpose: Systemic Lupus Erythematosus (SLE) has a high prevalence of cognitive impairment (CI) (38% (95% confidence interval: 33-43%)). Patient reported outcomes (PROs) capture patient perceptions of their health condition, mood, health related quality of life (HRQoL) and other aspects. We aimed to determine if self-reported fatigue, anxiety, depression, perceived deficits questionnaire (PDQ-20), HRQoL, disease activity scores and cognitive neuro-battery (NB) cluster into distinct groups in SLE patients. We assessed if patients changed clusters at 1 year of follow-up.

Methods: This is a retrospective analysis of consecutive consenting patients, aged 18-65 years, who attended a single center (Jul 2016 – Mar 2019) and completed baseline and 1 year follow-up visits. Patients completed a comprehensive NB evaluating six cognitive domains: manual motor speed and dexterity, simple attention and processing, visual spatial construction, verbal fluency, learning and memory (verbal and visuospatial) and executive function. We derived a total score for the NB. Patients completed the Beck anxiety, Beck depression, fatigue severity score (FSS), Short Form Health Survey (SF-36) physical (PCS) and mental scores (MCS), and the PDQ-20 (subjective cognitive function). Disease activity was assessed by SLEDAI-2K. Ward's method was used for clustering and Principal Component Analysis (PCA) was used to confirm the number of clusters. Clusters were grouped based on symptom intensity, defined as those that had high, medium, and low PROs scores relative to one another. We assessed the stability and movement of clusters at 1 year. Stability was assessed with kappa statistic.

Results: 142 patients were included, 89.4% comprised of females. The mean age and SLE duration at enrolment were 43.1 ± 12.1 and 15.3 ± 10.1 years, respectively.

Three clusters were found: **Cluster 1** had low symptom intensity, **Cluster 2** had moderate symptom intensity and **Cluster 3** had high symptom intensity (**Figure 1**). In Cluster 3, the most severe scores for fatigue, depression, anxiety, PDQ-20, and SF-36 MCS were found. NB scores in Cluster 3 were similar to Cluster 2. SLEDAI-2K was similar in Clusters 1 and 3 and more active in Cluster 2.

At 1 year follow-up, 49% of patients (69/142) remained in their baseline cluster; a fair agreement of stability (Kappa statistic 0.35;95% confidence interval 23.0-47.3) was found. Cluster 1 had the highest stability (77% of patients stayed in the same cluster), followed by Cluster 3 (51%) and Cluster 2 had the lowest stability (3%; Table 1). A minor-

ity of patients from Cluster 1 moved to Cluster 3 (19%). In Cluster 3, a larger number moved to Cluster 2 (40%) and less to Cluster 1 (9%).

Conclusion: Three distinct clusters of symptom intensity were defined by PCA in SLE patients in association with cognitive function with Cluster 3 displaying the highest symptom severity and worse cognitive function versus Cluster 1 having the lowest symptom burden and better cognitive function. Patients remained in the same cluster at one year, particularly in Cluster 1 and Cluster 3, and there was a low tendency to move between these two Clusters.

Figure 1. Clusters plotted against eight measurements, demonstrating symptom severity.

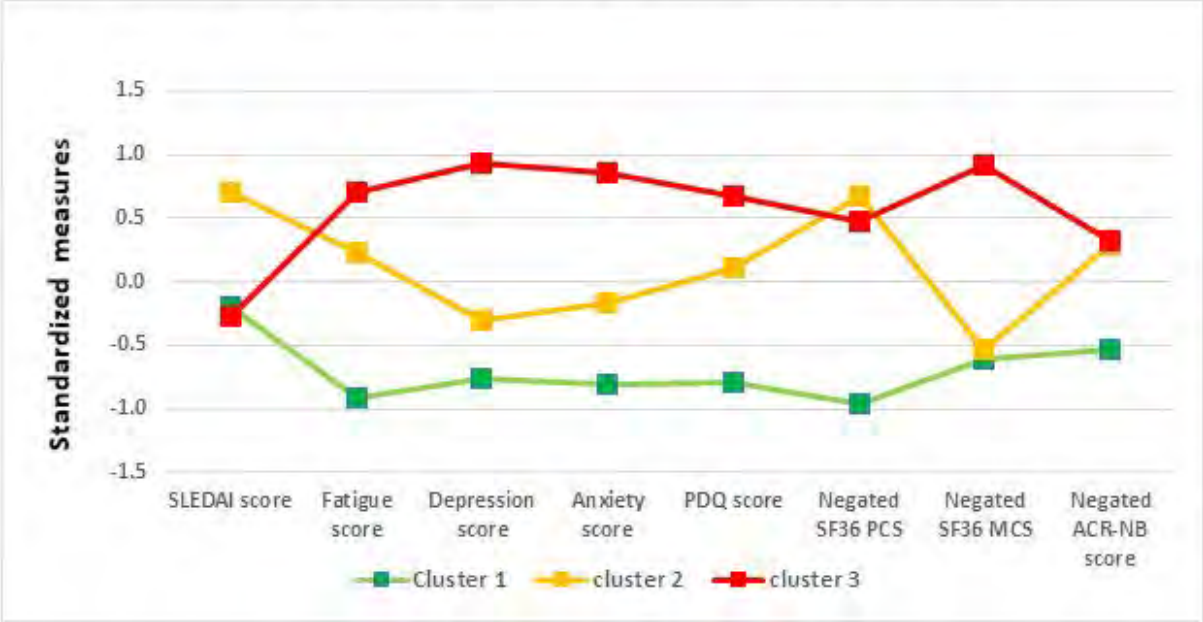

Table 1. Stability and dynamic of clusters at baseline compared to at year 1

Baseline Clusters	Clusters on follow up at year 1		
	Cluster 1 Patients' numbers (%)	Cluster 2 Patients' numbers (%)	Cluster 3 Patients' numbers (%)
Cluster 1	**40 (77%)**	2 (4%)	10 (19%)
Cluster 2	10 (28%)	**1 (3%)**	24 (69%)
Cluster 3	5 (9%)	22 (40%)	**28 (51%)**

Interpretation for the table: e.g. In Cluster 1, 77% of patients remained in this cluster at year 1 while 4% moved to Cluster 2 and 19% to Cluster 3.

SESSION INFORMATION

Session Date: Monday, November 8, 2021

Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster III: Outcomes (1257–1303)

Session Type: Poster Session C

Session Time: 8:30AM–10:30AM

Background/Purpose: Several novel SLE therapies are in development. Precision medicine aims to improve treatment practices and real-world outcomes. Certain factors, however, will likely reflect overall good outcomes even with current standard of care (SOC). Such factors need to be considered when assessing treatment-specific response markers in trials of novel therapies. Using an international SLE cohort, we aimed to identify factors associated with attaining favourable response states in SLE.

Methods: Patients were recruited into an international inception SLE cohort from 11 countries. To mimic a trial setting, we selected patients at the first visit in which they fulfilled a definition of active disease, comparable to a level reflecting entry to a clinical trial using 'classic' BILAG i.e. >=1 BILAG A and/or >= 2 BILAG B scores.

The first visit where the BILAG criteria were met was classified as their baseline visit. We examined the rates of, and factors associated with achieving outcomes at 12 months namely, 'Major Clinical Response' (MCR, defined as reduction to BILAG C in all domains, steroid dose of < = 7.5mg & SLEDAI < = 4) and 'Improvement' (defined as reduction to < = 1B score in previously active organs & no new BILAG A/B, stable or reduced steroid dose & no increase in SLEDAI). Univariate and multi-variate logistic regression with Least Absolute Shrinkage and Selection Operator (LASSO) and cross-validation in randomly split samples were used to build prediction models. Variables were ranked by the percentage of times selected by LASSO.

Results: In total, 924 patients (51% of the cohort) met criteria for active disease, including 820 (89%) women. The median [IQR] age and SLE disease duration were 30.6 [23.2 - 41.3] and 0.34 [0.12 - 0.71] years respectively. Common

Table 1. Univariate odds ratios for predictors of major clinical response (selected by LASSO in >=50% of the prediction models) in the active disease cohort

Predictors	Point of Reference	Odds Ratio	95% Confidence Interval
Anti-malarial use	yes vs. no	2.273	1.406 – 3.676
Hypertension	yes vs. no	0.573	0.371 – 0.884
Low C3 or C4	yes vs. no	0.481	0.310 – 0.746
Number of BILAG A or B	>= 2 vs. 1	0.439	0.288 – 0.668
Haematology (BILAG)	A or B vs. C, D or E	0.617	0.404 – 0.941
SLEDAI	1-unit increase	0.884	0.844 – 0.926
Oral steroid dose	Moderate (>7.5 -30mg/day) vs. low (<= 7.5mg/day)	0.327	0.174 – 0.617
Immunosuppressant use	yes vs. no	0.441	0.292 – 0.668

BILAG-2004 organ systems for which patients scored an A or B were renal (n = 480, 52%), haematological (n = 406, 44%), musculoskeletal (n = 335, 36%) and mucocutaneous (n = 317, 34%).

Outcome data at 12 months were available in 759 (82%) patients; MCR and Improvement were achieved in 114 (15%) and 261 (34%) respectively. Factors associated with a higher or lower probability of achieving MCR (selected by LASSO in >= 50% of the prediction models) are shown in Table 1.

Factors associated with a lower probability of achieving improvement in the active disease cohort were residence in Mexico (versus Canada), Hispanic and African (versus Caucasian) race/ethnicity, immunosuppressant use, low C3 or C4 and a higher SLEDAI score.

Conclusion: In active SLE receiving SOC, several factors are associated with the likelihood of achieving MCR and Improvement. Such factors are important to consider, potentially as stratification or minimisation factors, when designing clinical trials or precision medicine studies. Imbalances in geography, demographics, disease characteristics or background therapy may influence the interpretation of such trials.

Belimumab Reduces Severe Flares in Systemic Lupus Erythematosus Across Multiple Patient Subgroups: Results of a Large Integrated Analysis

Michelle Petri[1], Norma Lynn Fox[2], Mathew Gibb[3], Tania Gonzalez-Rivera[2], Anne Hammer[2], Holly Quasny[4], Ronald van Vollenhoven[5] and David Roth[2], [1]Johns Hopkins University School of Medicine, Baltimore, MD, [2]GlaxoSmithKline, Collegeville, PA, [3]Veramed Ltd., Twickenham, United Kingdom, [4]GlaxoSmithKline, Research Triangle Park, NC, [5]Department of Rheumatology and Clinical Immunology, Amsterdam University Medical Center, Amsterdam Rheumatology Center, Amsterdam, Netherlands

SESSION INFORMATION

Session Date: Monday, November 8, 2021

Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster III: Outcomes (1257–1303)

Session Type: Poster Session C

Session Time: 8:30AM–10:30AM

Background/Purpose: Belimumab (BEL) is a disease-modifying systemic lupus erythematosus (SLE) treatment that inhibits B-lymphocyte stimulator. BEL has demonstrated a consistent efficacy profile across 4 pivotal Phase 3 trials[1-4] and has improved renal outcomes in active LN and reduced SLE organ damage progression[5,6]. In 2011, BEL became the first biologic approved for SLE treatment in the USA[7] with additional approvals in >70 countries. Severe flares in SLE are linked to poor long-term outcomes and increased healthcare resource utilization[8]. BEL has been shown to decrease severe flare risk[2]; however, data are lacking for specific patient (pt) subgroups. This analysis evaluated the role of BEL in preventing severe flares across a large pooled population as well as by subgroups.

Methods: The Belimumab Summary of Lupus Efficacy (Be-SLE) analysis assessed data from 5 double-blind, placebo (PBO)-controlled BEL studies: BLISS-76, BLISS-52, BLISS-NEA, BLISS-SC, and EMBRACE. Data from pts receiving BEL (10 mg/kg intravenously or 200 mg subcutaneously) were compared with PBO; both groups received also standard therapy (ST). Data were collected every 4 weeks from baseline until Week 52. Severe flare was defined using the Safety of Estrogens in Lupus Erythematosus National Assessment (SELENA)-SLE Disease Activity Index (SLEDAI) flare index. The number of pts and time to first severe flare (days) were determined for both groups. Time to first severe flare was evaluated by the following subgroups: SLE International Collaborating Clinics (SLICC)/American College of Rheumatology (ACR) Damage Index (SDI) score, disease duration, anti-double stranded deoxyribonucleic acid (dsDNA), serum levels of C3 and C4 proteins, steroid use, and immunosuppressant use. Hazard ratios (HR) for severe flare risk between groups were calculated using Cox proportional hazards model, adjusted for study and baseline SELENA-SLEDAI score.

Results: The analysis included 1869 pts receiving BEL and 1217 pts receiving PBO. Mean age (~37 years) and percentage of females (~94%) were similar between treatment groups. Over 52 weeks, 13.8% (n=258) of pts receiving BEL had severe flares versus 22.2% (n=270) of pts receiving PBO. BEL yielded a 39% reduction in the risk of severe flares versus PBO (HR: 0.61; 95% confidence interval [CI]: 0.51, 0.72). BEL also consistently reduced the risk of severe flares versus PBO across various pt subgroups (**Figure**); risk reductions appeared greater in pts with anti-dsDNA+ and ≥C3/C4, or SDI=0.

Conclusion: Pts receiving BEL had a reduced risk of severe flares versus pts receiving PBO. Some subgroups had greater risk reduction; these pts in particular may benefit from BEL. These results reinforce the advantage of BEL in ST in the treatment of SLE.

Funding: GSK

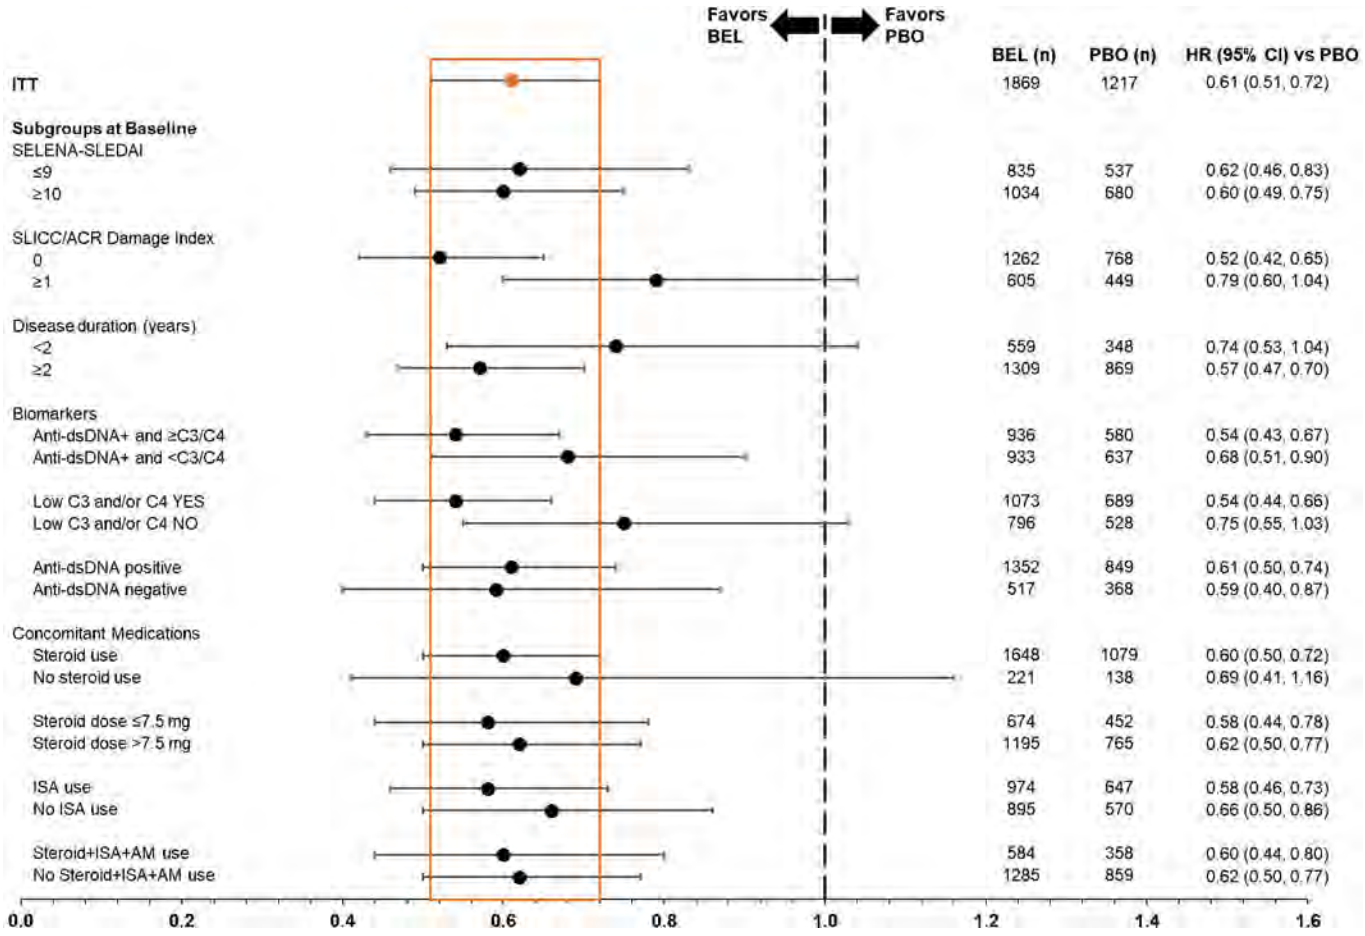

Figure Risk of severe flares HR for BEL versus PBO for various pt characteristic subgroups AM, antimalarial; ISA, immunosuppressant The orange box denotes the 95% CI for the overall (intention-to-treat) HR.

SESSION INFORMATION

Session Date: Monday, November 8, 2021

Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster III: Outcomes (1257–1303)

Session Type: Poster Session C

Session Time: 8:30AM–10:30AM

Background/Purpose: The mortality in lupus patients is 2–3 times higher than the general population. However, survival in these patients has improved significantly and it is currently 95% at 5 years according to several studies. Since the last 20 years, there are no new reports on this issue in Argentina. Objetive: To analyze the factors associated with mortality, survival and causes of death in SLE patients.

Methods: Ten rheumatology argentinian centers participated in this longitudinal - multicenter study. Patients with SLE (ACR 1997 and / or SLICC 2012 criteria) with a minimum follow-up of 6 months between january 2008 and december 2018 were included. Demographic, clinical, laboratory, therapeutic variables (treatments received during the evolution of the disease and within 60 days prior to death or last control); mortality, causes of death and survival at 5, 10 and 20 years were evaluated. Statistical analysis: descriptive statistics, Kaplan-Meier survival curves and Cox regression model.

Results: Three hundred and eighty two patients were included; 90% women and 82% mestizos. Mean disease duration was 4.1 ± 6.7 years. Mean age was 37.2 ± 12.7 years, SLEDAI 3.2 ± 4.2 and SLICC 1.2 ± 1.9 at the last control or death. During the evolution the main manifestations were: mucocutaneous (90.6%), osteoarticular (76%), hematological (55.2%) and renal (55%) involvement. Ninety two percent of the patients received treatment with hydroxychloroquine (HCQ), for an average time of 53 ± 59 months, 43% methylprednisolone pulses, 38% cyclophosphamide and 28% mycophenolate.

Mortality rate was 12% (95% CI [8-15]) and the causes of death were: Infections (27), cardiovascular disease (6), SLE activity (3), catastrophic antiphospholipid syndrome (2) and other causes (8). According to Cox regression models, the variables that increased the risk of death significantly were: renal involvement (RR 3.3), cardiac involvement (RR 2.7), central nervous system involvement (RR 2.1), arterial thrombosis (RR 2.3), hyperlipemia (RR 2.4), number of infections (RR 1.2) and last SLEDAI (1.1). Osteoarticular involvement had a protective effect on the risk of death in all of them.

The use of hydroxychloroquine for more than 36 months decreased the risk of death in this cohort (40%, p= 0.03) and was a mortality protection factor (RR 0.4). Cyclophosphamide was a risk factor for death (RR 5.2).Prednisone was not associated with mortality (p NS).

Patients who died from infection had less disease duration (Me 2.25 years) than those who died due to cardiovascular causes (Me 10 years) or SLE activity (Me 15 years), p= 0.017. In this cohort, survival was 93% at 5 years, 88% at 10 years and 72% at 20 years.

Conclusion: Mortality in argentinian lupus patients was 12% and infection was the main cause of death. The use of HCQ decreased the risk of death.

Factors Associated with Employment and Work Disability in Patients with SLE: A Nested Case-control Study

Connor Maddock[1], Behdin Nowrouzi-Kia[2], Jiandong Su[3] and Zahi Touma[4], [1]University College Dublin, Dublin, Ireland, [2]University of Toronto, Toronto, ON, Canada, [3]University Health Network, Toronto, ON, Canada, [4]University of Toronto, Mississauga, ON, Canada

SESSION INFORMATION
Session Date: Monday, November 8, 2021
Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster III: Outcomes (1257–1303)
Session Type: Poster Session C
Session Time: 8:30AM–10:30AM

Background/Purpose: Systemic lupus erythematosus (SLE) is a chronic autoimmune disease that can affect multiple organ systems and can vary in its manifestations between individuals. SLE can range in severity, resulting in some patients being unable to continue working while others can remain employed.

The purpose of this study is to analyze and compare factors including SLE disease activity between work disabled and employed patients with SLE to elucidate variables associated with unemployment.

Methods: This is a cross-sectional study focused on the status of last employment reported in the data on 1110 adult SLE patients followed at a single centre where 746 patients were categorized as “Employed” and 364 as “Unemployed” (work disability or Sick Leave). In the employed group, 478 patients were matched to 297 patients in the unemployed group by 2:1 matching. Patients were matched on gender, inception status (whether patient was first seen at clinic within 12 months of SLE diagnosis), disease duration at last visit (+/- 3 years), ethnicity (Caucasian or non-Caucasian) and highest education level obtained. Associations between variables and employment status were assessed using univariate and multivariate conditional logistic regressions in a nested case-control study. Greedy matching algorithm was used to assemble the cases and controls. Patients’ characteristics were compared by paired t-test and McNemar’s test in matched cohorts, and a conditional logistic regression was performed to examine patients’ demographics, last five years’ disease activity, organ damage, disease burdens and treatment to the last em-

Table 1: Patient characteristic data of the Unemployed and Employed groups

Variable in the last 5 years	Value	Unemployed (N=297)	Employed (N=478)	P-value
Inception Patients	Yes (%)	122 (41.1%)	194 (40.6%)	N/A[1]

[1] Hypertension defined as blood pressure ≥140/90 mmHg or treated with antihypertensive

[2] Dyslipidemia defined as abnormal total cholesterol or Low-density Lipoprotein levels or treated with antidyslipidemic agents

ployment status. Step-down variable selection method was adopted in the multivariable model building with Akaike Information Criterion (AIC) used as the model fitting statistics.

Results: The demographics of 775 patients were represented in Table 1. Patients in the unemployed group showed significantly greater disease activity (higher adjusted mean SLEDAI-2K and SLEDAI-K Glucocorticoid index (SLEDAI-2KG) in the past five years and greater damage by SDI). Patients were also found to have a significantly higher prevalence of myocardial infarction, stroke, fibromyalgia, hypertension, and higher daily and cumulative glucocorticoid use. In the multivariable analysis (Table 2), age at SLE diagnosis (OR, 95% CI: 1.04,1.02-1.06), adjusted mean SLEDAI-2KG in past five years (OR, 95% CI: 1.07, 1.03-1.12), SDI (OR, 95% CI: 1.59, 1.40-1.80) and prevalence of fibromyalgia (OR, 95% CI: 3.84, 2.52, 5.86) were associated with the increased risk of unemployment. We conducted additional modeling where adjusted mean SLEDAI-2KG was substituted by adjusted mean SLEDAI-2K and cumulative glucocorticoid dose in the past five years, and the results were similar to the previous model.

Conclusion: High disease activity, damage and use of glucocorticoids were associated with an increased likelihood of patients being unemployed. Similarly, fibromyalgia was strongly associated with a patient being unemployed. Employment status may be improved by better control of SLE disease activity and management of fibromyalgia and other risk factors.

Abstract Number: 1298

Clinical Characteristics of Patients with Pre-pubertal Onset SLE and Disease Outcome Throughout Puberty: A Multicenter North American Longitudinal Study

Martha Rodriguez[1], Kiana Rachele Johnson[2] and Kathleen O'Neil[1], [1]Riley Hospital for Children at Indiana University, Indianapolis, IN, [2]East Tennessee state University, Johnson, TN

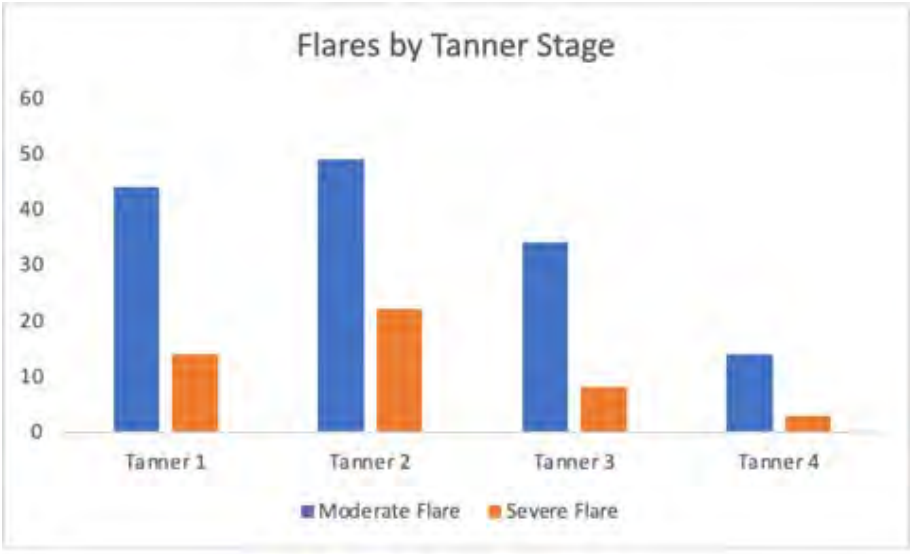
SESSION INFORMATION
Session Date: Monday, November 8, 2021
Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster III: Outcomes (1257–1303)
Session Type: Poster Session C
Session Time: 8:30AM–10:30AM

Background/Purpose: Pediatric Onset SLE is associated with higher disease activity and higher risk of damage. There is limited information on prepubertal patients with SLE and how disease activity varies throughout puberty. With the increasing life expectancy and yet subsequent cumulative damage it is paramount to characterize the clinical manifestations, disease activity, organ damage and quality of life in these patients. The aims of this study are to describe the clinical characteristics, disease activity pattern, frequency and classification of flares and organ damage of patients with prepubertal onset SLE and to evaluate the association of disease outcome as they relate to pubertal progress and hormonal changes.

Methods: This database represents 63 subjects (51 girls and 12 boys) from 12 CARRA sites followed every 3 months from late pre-puberty through completion of maturation process or study completion. Collected data included comprehensive medical history, physical examination findings, Tanner stage, SLEDAI-2k activity scores and MD-global assessments. Analytes measured in serum: Sex *Hormones* – Prolactin, estradiol, testosterone; adipose derived hormones *Adipokines* – leptin, adiponectin, resistin, visfatin. Flares were determined by SELENA-SLEDAI flare index. Two generalized estimating equations were calculated using SLEDAI and PGA as predictors in two different models. Multivariable models were adjusted for possible confounders.

Results: A total of 484 follow-up visits were included. Mean length of study involvement was 21 months. Arthritis, hematologic and renal manifestations were predominant among this group of subjects. Results of the of GEE analysis of hormones predicting disease activity indicated the main effects of adiponectin (Wald $c^2 = 14.25$, $p < .001$) and estradiol (Wald $c^2 = 6.04$, $p < .01$) significantly predicted disease activity as measured by the SLEDAI. Interactions between Tanner stage and adiponectin (Wald $c^2 = 22.64$, $p< .001$) and Tanner stage and Estradiol (Wald $c^2 = 7.187$, $p< .001$) predicted disease activity as indicated by higher SLEDAI scores. In our second model, the main effects of leptin (Wald $c^2 = 8.14$, $p < .01$), adiponectin (Wald $c^2 = 15.88$, $p < .001$), visfatin (Wald $c^2 = 9.61$, $p < .001$), and progesterone (Wald $c^2 = 12.64$, $p < .001$) predicted disease activity as indicated by PGA scores.

Conclusion: The activity level of SLE and risk of disease flare rise as soon as the first signs of puberty are apparent, a time referred to as the start of Tanner 2. Changes of adiponectin and estradiol significantly predicted disease activity as measured by the SLEDAI. Disease activity and flare risk declined once the child was sexually mature. Treatment algorithms based on these factors may help to improve long-term outcomes in childhood SLE.



Flares vs Tanner Stages

SLEDAI model	Wald χ^2	p-value
Adiponectin	14.25,	$p < .001$
Estradiol	6.04	$p < .01$
Tanner stage X adiponectin	22.64	$p < .001$
Tanner stage X Estradiol	7.187	$p < .001$
PGA Model		
leptin	8.14	$p < .01$
adiponectin	15.88	$p < .001$
visfatin	9.61	$p < .001$
progesterone	12.64	$p < .001$
tanner stage X leptin	16.47	$p < .001$
tanner stage X adiponectin	17.85	$p < .001$
tanner stage X visfatin	19.65	$p < .001$
tanner stage X progesterone	8.23	$p < .05$

Table 1. Response Rates in AMP LN

N = 121	Baseline	Wk 12	Wk 26	Wk 52
CR	0	16	28	34
% CR	0.0%	13.2%	23.1%	28.1%
PR	0	19	24	28
CR and PR	0	35	52	62
% CR and PR	0.0%	28.9%	43.0%	51.2%

Figure 1. Heat Map Displaying Longitudinal CR and PR Responses in AMP LN

Background/Purpose: The Accelerating Medicines Partnership (AMP) Lupus Network was established with the goal of applying novel technologies to the interrogation of blood and tissue samples from patients with lupus nephritis (LN). In contrast to global LN clinical trials, the AMP LN cohort affords an opportunity to generate outcome data representative of a US multicenter multi-ethnic real-world experience. In this analysis, the AMP clinical dataset was investigated to determine the percentages of patients who attained prespecified definitions of partial or complete responses at 52 weeks. In addition, incorporation of response rates at weeks 12 and 26 to the analysis provided longitudinal patterns of response to standard of care.

Methods: Patients with LN who were undergoing kidney biopsies as part of standard of care were eligible to enroll in the AMP LN study. Response definitions were only applied to cases whose baseline spot urine protein/creatinine (UPCR) ratios were > 1.0. Complete response (CR) required: 1) UPCR < 0.5; and 2) normal creatinine (< 1.3 mg/dL) or, if abnormal at baseline, < 125% of baseline; and 3) prednisone < 10 mg/day at the time of the study visit. Partial response required: 1) >50% reduction in UPCR without meeting UPCR criterion for CR; and 2) normal creatinine (< 1.3 mg/dL) or, if abnormal, < 125% of baseline; and 3) prednisone dose < 15 mg/day at the time of the study visit. Patients who did not achieve a CR or PR at the specific timepoints were considered non-responders (NR). Only patients with renal biopsies that demonstrated ISN/RPS classes III, IV, V or combined III or IV with V and data available at all four timepoints (baseline, weeks 12, 26 and 52) were included in this analysis. Cross-sectional and longitudinal analyses of responses were performed, and heat maps were generated to graphically display response patterns.

Results: Data on 121 patients with LN enrolled in AMP were included in this analysis. Cross-sectional response rates at 52 weeks were: CR: 28.1%; PR: 23.1%; NR: 48.8% (Table 1). Response rates at weeks 12 and 26 are additionally displayed in Table 1, and Figure 1 is a heat map demonstrating longitudinal responses of our patients. All patients were considered NR at baseline. Only 7.4% of patients had week 12 CR responses sustained through week 52, whereas 19% had attained PR or CR at all 3 visits. An additional 14.9% achieved a PR or CR at 26 weeks which was sustained at 52 weeks. Overall, 36.4% of patients were NR at all time points.

Conclusion: Clinical data from the AMP Lupus Network revealed rates of 52-week CR and PR that were consistent with placebo response data from recently conducted LN trials. Low sustained CR rates not only underscore the need for more efficacious therapies but highlight how critically important it is to understand the molecular pathways that are associated with response and non-response.

Effect of Time in Clinical Remission on Damage Accrual in Systemic Lupus Erythematosus

Konstantinos Tselios[1], Dafna Gladman[2], Jiandong Su[3] and Murray Urowitz[4], [1]McMaster University, Hamilton, ON, Canada, [2]Schroeder Arthritis Institute, Krembil Research Institute, Toronto Western Hospital, Toronto, ON, Canada, [3]University Health Network, Toronto, ON, Canada, [4]Center for Prognosis Studies in the Rheumatic Diseases, Toronto Western Hospital, University of Toronto, Lupus Clinic, Toronto, ON, Canada

SESSION INFORMATION

Session Date: Monday, November 8, 2021

Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster III: Outcomes (1257–1303)

Session Type: Poster Session C

Session Time: 8:30AM–10:30AM

Background/Purpose: We have previously shown that prolonged clinical remission for ≥10 years is associated with significantly less damage accrual in inception patients with systemic lupus erythematosus (SLE)[1]. However, most lupus patients (approximately 70%) will follow a relapsing-remitting disease course pattern with greatly varying duration of remission over time. The aim of the present study was to assess the optimal duration of clinical remission in inception lupus patients and investigate its effect on damage accrual.

Methods: Inception SLE patients (time from diagnosis to first clinic visit ≤18 months) with at least 10 years of follow-up who had a relapsing-remitting pattern (≥2 distinct clinical flares over that decade) were retrieved from our long-term longitudinal database. Optimal duration of remission during the first decade of disease for the outcome of new damage accrual was established from a Logistic regression analysis (Receiver Operating Characteristic curve, ROC). Subsequently, subjects were divided into two groups according to the optimal remission duration (defined as clinical SLEDAI-2K=0 regardless of therapy). Groups were compared for percentage of patients with new damage accrual at 10 years, mean Damage Index, atherosclerotic vascular events (AVEs), osteonecrosis, osteoporosis and cumulative glucocorticoid dose. Outcomes were compared by Student's t-test for mean values and Chi-Square test for binary variables.

Results: Two hundred patients were retrieved. Remission duration of 7.1 years yielded the best threshold based on the ROC analysis using Youden index as the selection criterion (specificity 82%, sensitivity 33%). Patients were divided into groups A (time in remission ≤7.1 years) and B (>7.1 years). Patients in group A had significantly less mucocutaneous involvement; there were no significant differences regarding the other demographic, clinical, immunological and therapeutic variables at baseline (Table 1). Outcomes are shown in Table 2. Group B received significantly less glucocorticoids than group A and accrued significantly less damage. Osteoporosis was significantly less frequent in these patients. The prevalence of atherosclerotic vascular events and osteonecrosis was also less although insignificantly.

Conclusion: Among inception patients with SLE, clinical remission of at least 7.1 years is associated with significantly less damage over 10 years than shorter remission. While the difference in AVEs was not statistically significant, this comorbidity usually manifests later in disease course.

Early Increase in Circulating Memory B Cells Portends Clinical Response to Treatment in Pooled Data from Three Phase III Trials of Belimumab

Ioannis Parodis[1], Alvaro Gomez[2], Julius Lindblom[2], Alexander Borg[2], Sharzad Emamikia[2] and Mariele gatto[3], [1]Division of Rheumatology, Department of Medicine Solna, Karolinska Institutet, Karolinska University Hospital, Stockholm, Sweden and Department of Rheumatology, Faculty of Medicine and Health, Örebro University, Örebro, Sweden, [2]Division of Rheumatology, Department of Medicine Solna, Karolinska Institutet, Karolinska University Hospital, Stockholm, Sweden, [3]Department of Rheumatology, University of Padua, Padua, Italy

SESSION INFORMATION

Session Date: Monday, November 8, 2021

Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster III: Outcomes (1257–1303)

Session Type: Poster Session C

Session Time: 8:30AM–10:30AM

Background/Purpose: Belimumab blocks soluble B cell activating factor (BAFF) and is the only to date approved targeted treatment for systemic lupus erythematosus (SLE). Identification of biological predictors of response occurring earlier upon treatment would provide measurable tools to improve patient monitoring and stratification according to likelihood of response. We investigated early changes in B lymphocyte subsets in relation to response to standard therapy plus belimumab or placebo given to patients with active SLE and mainly musculoskeletal and mucocutaneous symptoms.

Methods: We analyzed pooled data from belimumab phase III clinical trials including BLISS-76 (N=819) and BLISS-SC (N=836); in addition, 60 patients from the BLISS North-East Asia trial were included in the analysis. B lymphocyte subsets were determined with flow cytometry. Treatment response was assessed using the composite measure SLE Responder Index 4 (SRI-4), defined as decrease in SLEDAI by ≥4 points, no worsening in the physician's global assessment by >30% and no new British Lupus Isles Assessment Group (BILAG) index (≥1 A or ≥2 B), at week 52. Additionally, persistence of SRI-4 through week 52 was evaluated. We investigated B cell changes relative to baseline using logistic or proportional hazards regression analysis, as appropriate.

Results: We found an association between an early expansion of $CD19^+CD20^+CD27^+$ memory B cells from baseline through week 8 and attainment of SRI-4 response at week 52 (OR: 1.5; 95% CI: 1.18–1.89; P=0.001), or for relative increases >10% (OR: 1.5; 95% CI: 1.17–1.83; P=0.001). Expansion above this threshold of 10% was also associated with increased probability or shorter time to achieve SRI-4 response that was maintained through week 52 (HR: 1.4; 95% CI: 1.15–1.61; P< 0.001). Notably, belimumab treatment (any dose) yielded an 11.5-fold increased probability of memory B cell expansion through week 8 compared with placebo (95% CI: 8.74–15.02; P< 0.001). No association with SRI-4 response was observed for early changes in $CD19^+CD20^+$ B cells, $CD19^+CD20^+CD27^-$ naïve B cells, $CD19^+CD20^+CD69^+$ activated B cells, $CD19^+CD20^-CD27^{bright}$ short-lived plasma cells, $CD19^+CD20^-CD138^+$ long-lived plasma cells, or $CD19^+CD38^{bright}CD27^{bright}$ SLE-associated plasma cells.

Conclusion: Early increases in memory B cells through the first 8 weeks of therapy, mainly driven by belimumab, portended good and sustained clinical response within one year from treatment initiation. Early immunological changes preceding the clinical outcome and may prove useful in early evaluation of belimumab therapy.

*Patients in the post-treatment follow-up period are no longer receiving study treatment.

MedDRA, Medical Dictionary for Regulatory Activities; SOC, system organ class.

Background/Purpose: Belimumab (BEL) is a recombinant IgG1λ monoclonal antibody that is approved for treatment of systemic lupus erythematosus (SLE). Although clinical studies of BEL have demonstrated a favorable benefit–risk profile, varying incidence rates of mortality and adverse events of special interest, including malignancies, warrant further consideration. The Belimumab Assessment of Safety in SLE (BASE) placebo- (PBO)-controlled trial was conducted to assess long-term safety following BEL exposure.[1]

Methods: This was a post-treatment follow-up of the Phase 4, double-blind BASE study (GSK Study BEL115467; NCT01705977).[1] A total of 4003 adults with active, autoantibody positive SLE received BEL (10 mg/kg IV) or PBO, plus standard therapy (ST) for 48 weeks. Following the treatment period, patients entered a Year 2–5 follow-up period in which they received physician-directed ST. All patients were contacted annually by telephone, including patients who discontinued treatment during the study. Mortality and new primary malignancies (including nonmelanoma skin cancer [NMSC]) were the only endpoints collected and rates were summarised. We present the data for the Year-3 follow-up by treatment received during the 52-week double-blind treatment period (Year 1).

Results: Baseline characteristics at the start of the 52-week treatment for the Year-3 follow-up population (N=3266) were similar to those of the Year-1 double-blind study population (N=4003). By the Year-3 follow-up, cumulatively 12.0% and 10.9% of patients in the original BEL and PBO Year-1 treatment groups had received BEL as part of physician-directed care, respectively. In total (for both treatment groups), crude mortality rates were similar across Year 1 (0.87%), Year 2 (0.89%), and Year 3 (0.80%), whilst crude malignancy rates for Year 3 (0.52%) were numerically higher than Year 2 (0.30%), but similar to Year 1 (0.47%) (**Table 1**). Mortality and malignancy rates were lower in the BEL versus PBO Year-1 treatment group. Cumulative rates are shown in **Table 2**.

Table 2. Cumulative deaths and new primary malignancies by follow-up year

	BEL Year-1 treatment group N=2002	PBO Year-1 treatment group N=2001	Total N=4003
Cumulative deaths by Year 1, n (%)	13 (0.65)	22 (1.10)	35 (0.87)
Incidence rate per 100 patient years	0.66	1.11	
Cumulative deaths by Year-2 follow-up*, n (%)	22 (1.10)	43 (2.15)	65 (1.62)
Incidence rate per 100 patient years	0.60	1.18	0.89
Cumulative deaths by Year-3 follow-up*, n (%)	31 (1.55)	60 (3.00)	91 (2.27)
Incidence rate per 100 patient years	0.58	1.14	0.86
Cumulative new primary malignancies by Year 1, n (%)	9 (0.45)	10 (0.50)	19 (0.47)
Incidence rate per 100 patient years for malignancies (excluding NMSC)†	0.25	0.35	
Incidence rate per 100 patient years for NMSC†	0.20	0.15	
Cumulative new primary malignancies by Year-2 follow-up*, n (%)	12 (0.60)	17 (0.85)	29 (0.72)
Incidence rate per 100 patient years	0.34	0.48	0.41
Cumulative new primary malignancies by Year-3 follow-up*, n (%)	20 (1.00)	25 (1.25)	45 (1.12)
Incidence rate per 100 patient years	0.39	0.49	0.44

*Year-2 and Year-3 follow-up populations were off-study treatment; †As summarized for Year 1.

Conclusion: Post-treatment follow-up results in Year 3 from BASE, the largest study of patients with SLE to date, provide continued support for the safety profile of BEL and remained consistent with the Year-2 follow-up data. No new safety concerns for BEL were identified in patients with active, autoantibody-positive SLE receiving ST.

Abstract Number: 1303

Associations Between Early Changes in Circulating B Cell Subsets and Severe Flare in Systemic Lupus Erythematosus – Results from Three Phase III Trials of Belimumab

Ioannis Parodis[1], Alvaro Gomez[2], Julius Lindblom[2], Alexander Borg[2], Sharzad Emamikia[2] and Mariele gatto[3], [1]Division of Rheumatology, Department of Medicine Solna, Karolinska Institutet, Karolinska University Hospital, Stockholm, Sweden and Department of Rheumatology, Faculty of Medicine and Health, Örebro University, Örebro, Sweden, [2]Division of Rheumatology, Department of Medicine Solna, Karolinska Institutet, Karolinska University Hospital, Stockholm, Sweden, [3]Department of Rheumatology, University of Padua, Padua, Italy

SESSION INFORMATION

Session Date: Monday, November 8, 2021
Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster III: Outcomes (1257–1303)
Session Type: Poster Session C
Session Time: 8:30AM–10:30AM

Background/Purpose: Belimumab is the only approved targeted treatment for systemic lupus erythematosus (SLE). Identification of early predictors of response or non-response to therapy is imperative to optimize surveillance and decision-making. We studied early changes in B cell subsets in relation to flare during standard therapy plus belimumab or placebo given to patients with active SLE within the frame of three phase III clinical trials of belimumab.

Methods: We analyzed pooled 52-week data from BLISS-76 (N=819), BLISS-SC (N=836), and BLISS North-East Asia (N=60). B cell subsets were determined with flow cytometry. Severe flare was evaluated according to the SELENA-SLEDAI Flare Index every fourth week. We investigated B cell changes relative to baseline using proportional hazards regression analysis.

Results: Early decreases in $CD19^+CD20^-CD138^+$ long-lived (HR: 0.7; 95% CI: 0.56–0.98; P=0.034) and $CD19^+CD38^{bright}CD27^{bright}$ SLE-associated plasma cells (HR: 0.7; 95% CI: 0.50–0.87; P=0.003) from baseline through week 24 were negatively associated with the development of a severe flare during the study period, i.e. through week 52 from treatment initiation. A similar trend was seen for decreases in naïve $CD19^+CD20^+CD27^-$ B cells (HR: 0.7; 95% CI: 0.56–1.00; P=0.051). No such association was observed for early changes in the total $CD19^+CD20^+$ B cell pool, or in $CD19^+CD20^+CD27^+$ memory B cells, $CD19^+CD20^+CD69^+$ activated B cells, $CD19^+CD20^+CD138^+$ cells or $CD19^+CD20^-CD27^{bright}$ short-lived plasma cells. The association with $CD19^+CD38^{bright}CD27^{bright}$ SLE-associated plasma cells held true for patients treated with belimumab (any dose) (HR: 0.7; 95% CI: 0.47–0.97; P=0.032) but not placebo, while placebo receivers showing reductions in $CD19^+CD20^-CD138^+$ long-lived plasma cells displayed a lower probability to flare (HR: 0.6; 95% CI: 0.38–0.87; P=0.009).

Conclusion: Early decreases in long-lived circulating plasma cells were negatively associated with severe flares in patients with active SLE treated with standard immunosuppression with or without add-on belimumab, while reductions in circulating $CD19^+CD38^{bright}CD27^{bright}$ SLE-associated plasma cells may prove a useful early biological marker of favorable response to belimumab therapy.

Increased Risk of Vertebral Fracture Among Patients with Psoriatic Arthritis: A Systematic Review and Meta-analysis

Patompong Ungprasert[1], Nipith Charoenngam[2], Ben Ponvilawan[3], Jerapas Thongpiya[4] and Pitchaporn Yingchoncharoen[3], [1]Cleveland Clinic, Cleveland Heights, OH, [2]Mount Auburn Hospital, Boston, MA, [3]Mahidol University, Bangkok, Thailand, [4]Mahdiol University, Bangkok, Thailand

SESSION INFORMATION

Session Date: Monday, November 8, 2021

Session Title: Spondyloarthritis Including PsA – Diagnosis, Manifestations, & Outcomes III: Comorbidities, Extra-muskuloskeletal Manifestations, & Related Conditions (1304–1328)

Session Type: Poster Session C

Session Time: 8:30AM–10:30AM

Background/Purpose: Increased risk of vertebral fracture (VF) has been documented in several autoimmune diseases as a result of excessive inflammatory burden and use of corticosteroids. The risk is well-established in several autoimmune diseases with high inflammatory burden such as rheumatoid arthritis and systemic lupus erythematosus. However, the risk among patients with autoimmune diseases of less inflammatory burden, including psoriatic arthritis (PsA), is unclear.

Methods: Potentially eligible studies were identified from MEDLINE and EMBASE database from inception to December 2020 using search strategy that comprised of terms for “Psoriatic Arthritis” and “Vertebral Fracture”. Eligible study must be cohort study that consists of one cohort of patients with PsA and another cohort of comparators without PsA. Then, the study must investigate for the prevalence of VF in both groups. Odds ratio (OR) with 95% confidence intervals (95% CIs) comparing prevalent VF between the groups or sufficient raw data to calculate this OR must be provided. Point estimates with standard errors were retrieved from each study and were combined together using the generic inverse variance method. Funnel plot was used to assess for the presence of publication bias.

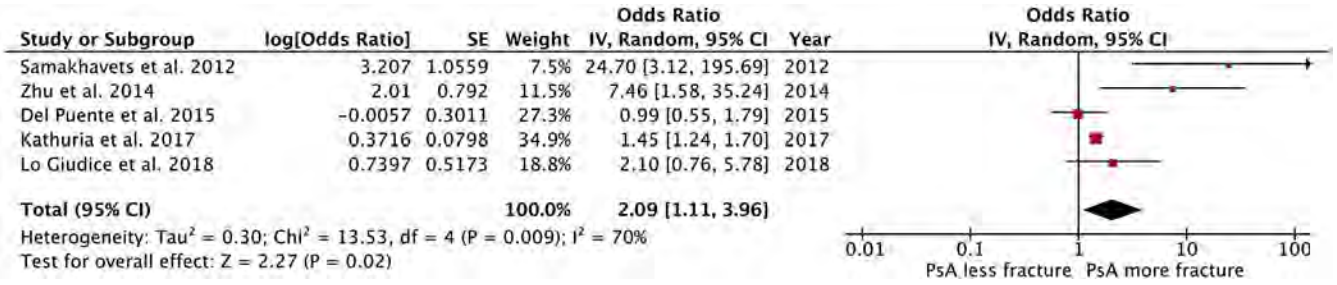

Figure 1. Forest plot of this meta-analysis.

Results: A total of 26,090 articles were identified. After two rounds of independent review by three investigators, five cohort studies met the eligibility criteria and were included into the meta-analysis. PsA is significantly associated with VF with the pooled odds ratio of 2.09 (95% CI, 1.11 – 3.96; I^2 70%) (Figure 1). The funnel plot was fairly symmetric and was not suggestive of publication bias.

Conclusion: This systematic review and meta-analysis found a significantly increased risk of prevalent VF among patients with PsA.

Undiagnosed Depression in Axial Spondyloarthropathy and the Negative Impact on Patient Outcomes: Results of a Screening Study

Sinead Maguire[1], Phil Gallagher[2] and Finbar (Barry) O'Shea[1], [1]St James's Hospital, Dublin, Ireland, [2]St Vincent's Hospital, Dublin, Ireland

SESSION INFORMATION

Session Date: Monday, November 8, 2021
Session Title: Spondyloarthritis Including PsA – Diagnosis, Manifestations, & Outcomes III: Comorbidities, Extra-muskuloskeletal Manifestations, & Related Conditions (1304–1328)
Session Type: Poster Session C
Session Time: 8:30AM–10:30AM

Background/Purpose: Previous research in axial spondyloarthropathy(axSpA) has shown this population to have a high prevalence of depression. This co-morbidity has been previously shown to impact disease activity in patients with rheumatic disease.

The purpose of this study was to screen for early signs of depression using two validated tools, the Patient Health Questionaire-9 (PHQ-9) and the Hospital Anxiety and Depression Scale for depression (HADs-D) in patients with known axSpA.

Methods: AxSpA patients attending the Rheumatology department in St James' Hospital between February and October 2020 were invited to take a self-administered survey which included the PHQ-9 and the HADs-D. Scores from the HADs-D yielded a numerical result which was then categorised as normal, borderline or abnormal. PHQ-9 numerical results were categorised as normal, mild, moderate, moderate/severe or severe. Patients with a known

diagnosis of depression were excluded. In addition to baseline demographics, patient reported outcomes from the clinic visit were also recorded.

Data analysis was performed using IBM SPSS version 26. Continuous variables were recorded as means, categorical variables as frequencies with percentages. A one-way analysis of variance analysis (ANOVA) was used to determine significance of variation in outcomes between patient outcomes as determined by the HADs-D and PHQ-9. A p-value of < 0.05 was deemed significant. Informed consent was obtained prior to participation. Approval for this study was received from the St James'/Tallaght Hospital Joint Ethics Committee.

Results: In total 71 axSpA patients took part in the survey. The population was 70.4%(50) males and 29.5%(21) female, with an average age 47.9 years and mean disease duration 19.7 years (mean outcomes: BASDAI 4.08, BASFI

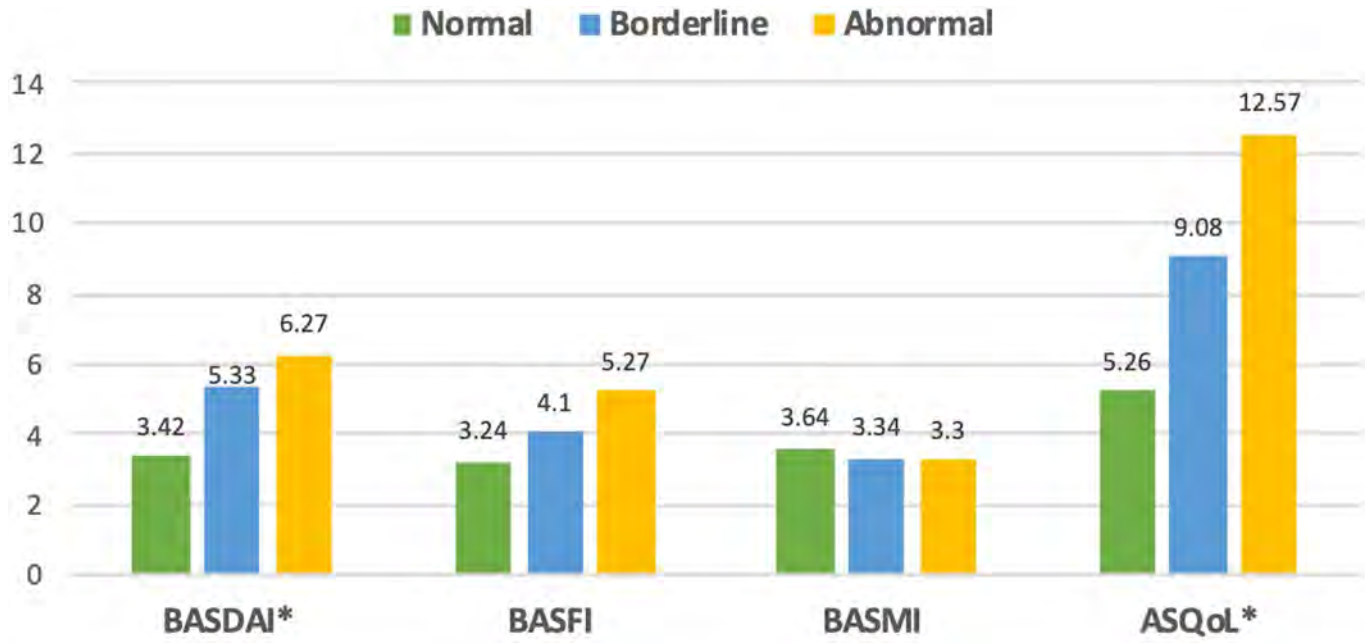

Figure 1. Patient outcomes by HADs-D scores (*indicates significant differences at the p<0.05 level).

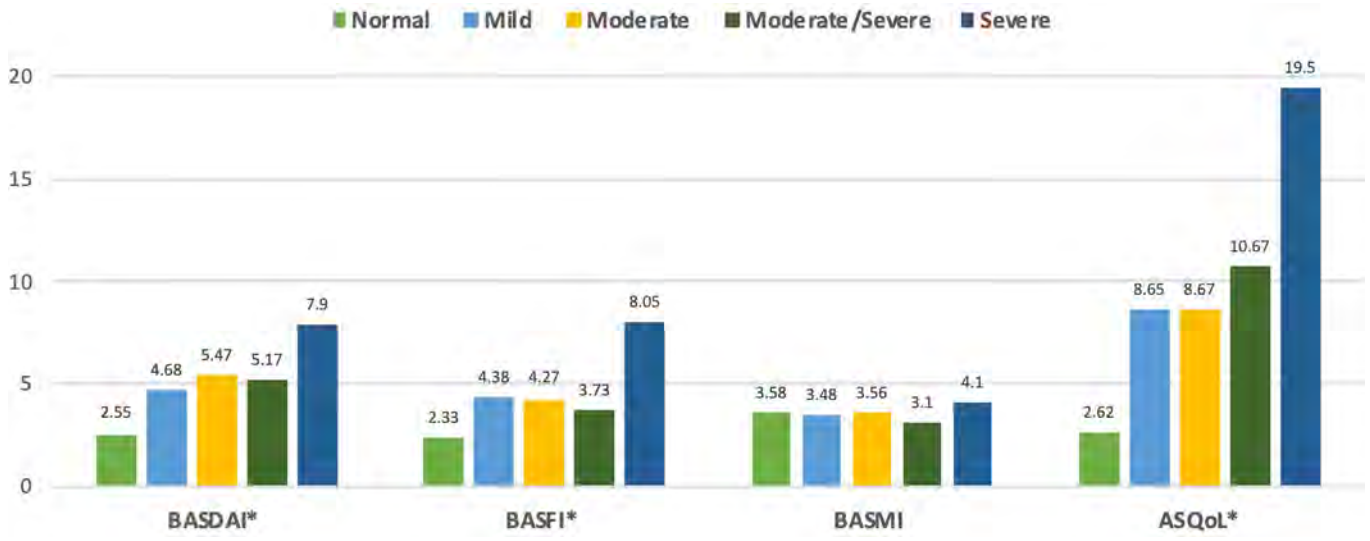

Figure 2. Patient outcomes by PHQ-9 scores (*indicates significant differences between normal, mild and severe groups at the p<0.05 level).

3.62, BASMI 3.54, ASQoL 6.79). Overall, 7 (9.9%) participants recorded abnormal HADs-D scores, while 17 (23.9%) recorded moderate to severe PHQ-9 scores indicative of underlying depression. AxSpA females had higher mean HADs-D scores (7.5 vs 4.8, p=0.01) than males, with abnormal scores in 19%(4) of females and 6% (3) of males. No significant differences were found in PHQ-9 scores between genders.

Analysis revealed significantly worse BASDAI (6.27 vs 3.42, p< 0.01) and AQoL scores (12.57 vs 5.26, p< 0.01) in axSpA patients with abnormal compared to normal HADs-D scores (figure 1). No significant differences were noted in BASFI, BASMI or baseline demographics. A similar pattern was noted on analysis of PHQ-9 scores, with significantly worse BASDAI (7.9 vs 2.55, p< 0.01), BASFI (8.05 vs 2.33, p< 0.01) and ASQoL (19.5 vs 2.62, p< 0.01) noted in those scoring as severe compared to normal (figure 2). No significant differences were detected in BASMI scores or baseline demographics.

Conclusion: A high percentage of axSpA patients recorded high HADs-D and PHQ-9 scores concerning for undiagnosed depression. These patients were noted to have significantly worse disease activity and quality of life as compared to patients with normal scores. Clinicians treating axSpA should consider actively screening for depression in this population.

Clinical and Imaging Characteristics of Spondyloarthritis Among Crohn's Disease Patients

Laarni Quimson[1], Nisa Oren[2], Catherine Burns[3] and Reem Jan[2], [1]University of Chicago, Oak Park, IL, [2]University of Chicago, Chicago, IL, [3]Indiana University, Indianapolis, IN

SESSION INFORMATION

Session Date: Monday, November 8, 2021

Session Title: Spondyloarthritis Including PsA – Diagnosis, Manifestations, & Outcomes III: Comorbidities, Extra-muskuloskeletal Manifestations, & Related Conditions (1304–1328)

Session Type: Poster Session C

Session Time: 8:30AM–10:30AM

Background/Purpose: Inflammatory bowel disease (IBD) affects up to 1.3% of the population and is associated with musculoskeletal manifestations including spondyloarthritis (SpA). Axial SpA (axSpA) is estimated to occur in 3-10% of IBD patients, but variation in imaging modalities and diagnostic criteria may underestimate the prevalence. Early recognition and identification of inflammatory changes on imaging can influence treatment that can alleviate symptoms, prevent radiographic progression, and improve quality of life. The aim of this study is to determine the prevalence of inflammatory changes on imaging in the Crohn's disease (CD) population utilizing routine magnetic resonance enterography (MRE) or magnetic resonance imaging (MRI) and to identify patient characteristics that can assist in early recognition of axSpA.

Methods: This is a retrospective chart review of patients with a diagnosis of CD at our institution between 2014 and 2020. Inclusion criteria included patients with CD, 18 years of age or older, with MRE or MRI pelvis studies available for review. Exclusion criteria included patients with ulcerative colitis, less than 18 years of age, and those without imaging. Images were reviewed by a blinded radiologist using the Assessment of Spondyloarthritis international Society criteria including abnormal enhancement on T1- weighted fat-saturated images and bone marrow edema on T2-weighted fat-saturated images as well as inflammatory structural lesions such as fat deposits, erosions, sclerosis,

Table. Patient characteristics and medical history. BMI: Body mass index; CD: Crohn's Disease; B1p: nonstricturing perianal disease; B2p: stricturing perianal disease; B3p: penetrating perianal disease

Characteristic	All patients (n = 48)	No imaging abnormalities (n=36)	Imaging abnormalities (n = 12)	Imaging abnormalities with back pain (n =4)	Imaging abnormalities without back pain (n = 8)

Values expressed as median (interquartile range) or (percentage)

or ankylosis. Demographics, medical history, medications, and labs at the time of imaging were recorded. Patients were assessed by a questionnaire for rheumatologic symptoms including inflammatory back pain and peripheral joint manifestations.

Results: 48 patients met the inclusion criteria. 41 had MREs and 7 had MRIs of the pelvis. 12 patients (25%) were identified with imaging abnormalities, all of which were found on MREs. 7 had structural lesions indicating prior inflammation and 5 were noted to have abnormal enhancement or bone marrow edema in the sacroiliac joints. From the 12 patients with imaging abnormalities, 8 (67%) were asymptomatic with no reported back pain or stiffness, 9 (75%) were female, 8 (67%) had stricturing or penetrating CD (Table). 3 patients (25%) were seeing a rheumatologist. From all the patients surveyed, 13 (30%) reported back pain, 26 (59%) reported previous joint pain or swelling, 13 (30%) had previous entire digit swelling, and 16 (36%) reported previous heel pain.

Conclusion: This study reveals that among Crohn's disease patients at our institution, the prevalence of abnormal sacroiliac joint findings on MRE and MRI is 25%. Majority of these patients did not report back pain, were female, and had intestinal complications of CD. Only 25% were following with a rheumatologist. Asymptomatic or subclinical axSpA in Crohn's disease patients remains under diagnosed and our study suggests that MREs should be routinely evaluated for musculoskeletal abnormalities. Furthermore, female sex and sticturing or penetrating CD may be risk factors for axSpA. Patients with these characteristics should be formally evaluated for the presence of inflammatory back pain as part of their clinical care.

SESSION INFORMATION

Session Date: Monday, November 8, 2021

Session Title: Spondyloarthritis Including PsA – Diagnosis, Manifestations, & Outcomes III: Comorbidities, Extra-muskuloskeletal Manifestations, & Related Conditions (1304–1328)

Session Type: Poster Session C

Session Time: 8:30AM–10:30AM

Background/Purpose: Uveitis is the most frequent extra-musculoskeletal manifestation in Spondyloarhtritis (SpA). Moreover, up to 50% of patients with an acute episode of uveitis develop recurrent anterior uveitis. Recently, the prevalence of history of uveitis reported in ASAS perSPA study (PERipheral involvement in SpondyloArthritis) was similar in axial and peripheral SpA (21.6% and 17.3%, respectively). However, it is not well known whether the clinical characteristics of patients with uveitis and recurrent uveitis differ between patients with axial and peripheral SpA. The primary objective was to compare the clinical characteristics of axial and peripheral SpA patients who have ever suffered from uveitis. Secondary objective was to compare the clinical characteristics of axial and peripheral SpA patients with a single episode of uveitis versus SpA patients with recurrent uveitis.

Methods: This is a post-hoc analysis of the ASAS-PerSpA study which included 3465 patients with SpA, 2910 patients fulfilling ASAS axSpA criteria and 555 patients fulfilling peripheral ASAS criteria. Recurrent uveitis was defined as the presence of 2 or more episodes of uveitis ever. Univariable and multivariable binary logistic regression analyses were conducted to identify factors associated with the presence of uveitis ever and the presence of recurrent uveitis.

Results: In the multivariable analysis, the presence of uveitis was significantly associated with the presence of HLA-B27 and disease duration, OR 2.88 (CI95% 2.15 - 3.91) and OR 1.05 (CI95% 1.04 - 1.06) respectively. Furthermore, the presence of inflammatory bowel disease ever is increased in patients with uveitis, OR 1.60 (CI95% 1.04 - 2.44). Nevertheless, the presence of psoriasis is decreased in patients with uveitis, OR 0.43 (CI95% 0.31 - 0.59). Patients from Latin America region were more likely to present uveitis in comparison with European patients, OR 1.42 (CI95% 1.02 - 1.94). Importantly, the presence of uveitis was not significantly different in patients with axSpA

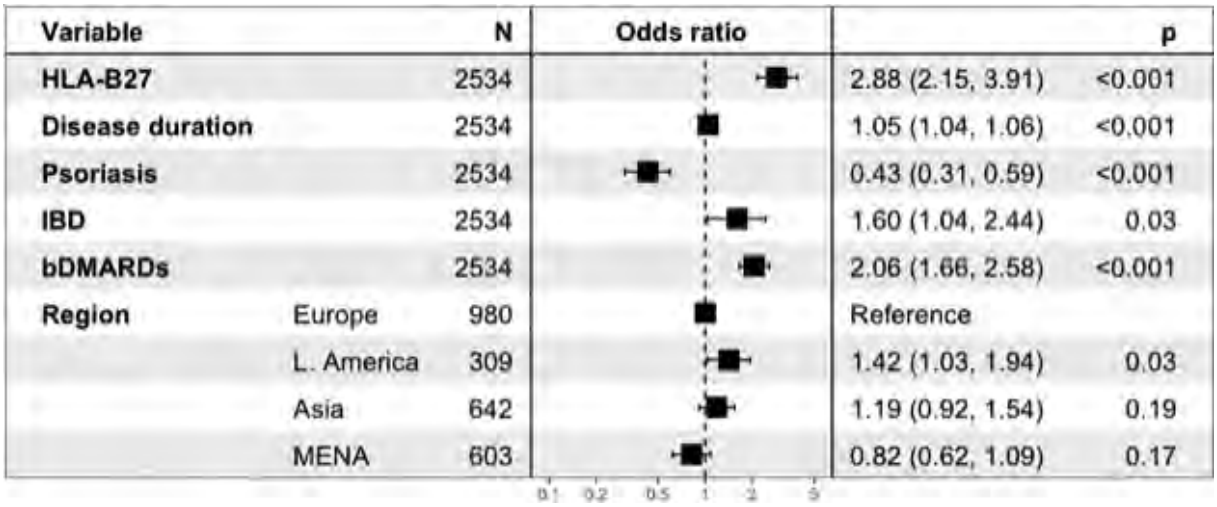

Figure 1. Multivariable analysis of 2534 patients with Spondyloarthritis to identify factors associated with the presence of uveitis ever. IBD, inflammatory bowel disease; HLA-B27, human leucocyte antigen B27; bDMARDs, biological disease-modifying antirheumatic drugs.

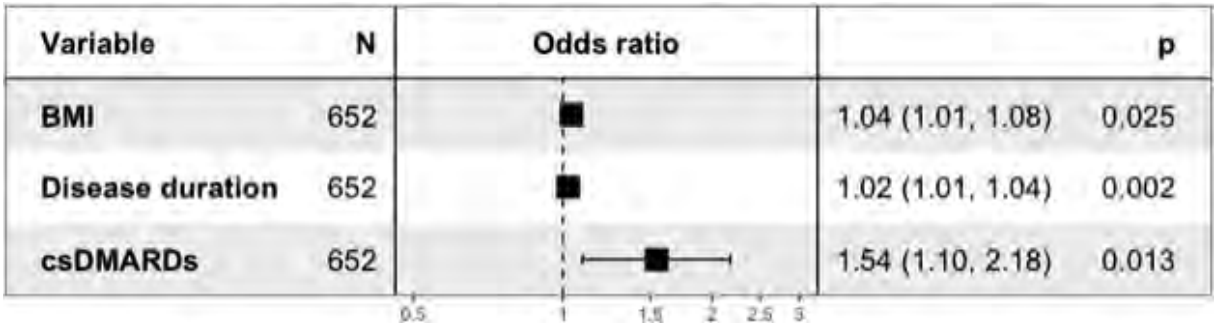

Figure 2. Multivariable analysis of 2534 patients with Spondyloarthritis to identify factors associated with the presence of recurrent uveitis. BMI, body mass index; csDMARDs, conventional synthetic disease-modifying antirheumatic drugs.

as compared to patients with pSpA (Figure 1). One the other hand, only disease duration and body mass index (BMI) was significantly associated with the presence of recurrent uveitis, OR 1.04 (CI95% 1.01-1.08) and OR 1.02 (CI95% 1.01-1.04) (Figure 2).

Conclusion: The prevalence of uveitis was not significantly higher in patients with axSpA as compared to patients with pSpA. HLA-B27 positivity is associated with the presence of uveitis, but not with recurrent uveitis in SpA patients. Hence, further biomarkers are needed to identify patients at risk of recurrent uveitis

SESSION INFORMATION
Session Date: Monday, November 8, 2021
Session Title: Spondyloarthritis Including PsA – Diagnosis, Manifestations, & Outcomes III: Comorbidities, Extra-muskuloskeletal Manifestations, & Related Conditions (1304–1328)
Session Type: Poster Session C
Session Time: 8:30AM–10:30AM

Background/Purpose: Psoriatic arthritis (PsA) is a chronic inflammatory arthropathy associated with cardiovascular abnormalities. The echocardiography is a non-invasive tool useful in the detection of cardiac abnormalities, which may be the only manifestation of cardiac involvement preceding a global dysfunction. However, echocardiographic differences between PsA patients, rheumatoid arthritis (RA) patients, and controls have not yet been well described. Therefore our objective was to analyze the echocardiographic parameters in PsA patients and to compare them with RA patients and controls.

Methods: This case-control study included thirty-six patients (nineteen in each group), aged 40-75 years, with PsA and RA who fulfilled the CASPAR (Classification criteria for Psoriatic Arthritis) and ACR/EULAR 2010 classification criteria, respectively, matched by age, gender and comorbidities with nineteen healthy controls. Exclusion criteria were a poor echocardiographic window, patients with a previous atherosclerotic cardiovascular disease (ischemic heart disease, cerebrovascular accident or peripheral arterial disease), and pregnancy. A Transthoracic echocardiogram was performed and reviewed by 2 board-certified cardiologists, in all study subjects. Comparisons were done with X^2, Kruskall Wallis or ANOVA.

Results: There were not any statistically significant differences found in the demographic characteristics (Table 1). When comparing echocardiographic findings a statistically significant difference was found in the prevalence of di-

Table 1. Comparison of demographic characteristics between patients with PsA, RA and controls.

	PsA (n=19)	RA (n=19)	Controls (n=19)	*p-value*

LV, left ventricular; LVEF, left ventricular ejection fraction; TAPSE, tricuspid annular plane systolic excursion.

astolic dysfunction, being more prevalent in PsA and RA patients compared with controls (52.6% vs 52.6% vs 5.3%, *p=0.002),* likewise the presence of mild mitral valve regurgitation was higher (84.2% vs 53.6% vs 10.5%, *p=0.001*) and mild pulmonary valve regurgitation (68.4% vs 10.5% vs 0%, *p=0.001*). Prevalence of abnormal left ventricular geometry was higher in PsA and RA patients than controls (68.4% vs 63.2% vs 21.1%, *p=0.006)*. Results are shown in Table 2.

Conclusion: This study shows the high prevalence of echocardiographic alterations in PsA patients compared to the general population, of the same magnitude as patients with RA. We emphasize the value of an echocardiogram for a complete cardiovascular evaluation and early detection of cardiac abnormalities in these patients.

Abstract Number: 1309

Impact of the Number of Comorbidities on the Outcome Measures and on the Retention Rate of the First Anti-TNF in Patients with Ankylosing Spondylitis: Two-year Follow-up REGISPONSER-AS

Mara ngeles Puche Larrubia[1], M.Lourdes Ladehesa-Pineda[1], Pilar Font[2], Alejandro Escudero Contreras[3], Eduardo Collantes-Estevez[2] and Clementina López Medina[4], [1]Hospital Universitario Reina Sofía, Córdoba, Spain, [2]IMIBIC/Reina Sofia Hospital/University of Córdoba, Córdoba, Spain, [3]Hospital Universitario Reina Sofía/IMIBIC/Universidad de Córdoba., Cordoba, Spain, [4]Department of Rheumatology, Reina Sofia Hospital, IMIBIC, University of Cordoba, Cordoba, Spain/Department of Rheumatology, University of Paris, Cochin Hospital, Paris, France

SESSION INFORMATION

Session Date: Monday, November 8, 2021

Session Title: Spondyloarthritis Including PsA – Diagnosis, Manifestations, & Outcomes III: Comorbidities, Extra-muskuloskeletal Manifestations, & Related Conditions (1304–1328)

Session Type: Poster Session C

Session Time: 8:30AM–10:30AM

Background/Purpose: a) To evaluate the impact of the number of comorbidities on the outcome measures after two years of follow-up in patients with ankylosing spondylitis (AS) and b) to determine whether the number of comorbidities influences the retention rate to the first anti-TNF alpha.

Methods: Observational and prospective study during 2 years of follow-up that includes a subgroup of 749 patients with AS (REGISPONSER-AS) from the REGISPONSER study (Spanish Rheumatology Spondyloarthritis Registry). The patients were divided into three groups according to the number of comorbidities at baseline (0, 1 or ³2 comorbidities). The Patient Reported Outcomes (PROs) evaluated were the Global VAS, BASDAI, ASDAS, BASFI and the mental and physical components from the SF12 questionnaire. Linear regression models were performed using the PROs as the dependent variable and the three groups of patients according to their comorbidities as the explanatory variable. Since disease duration may influence both the number of comorbidities and the PROs, additional models adjusting for this variable were explored. After that, the impact of the number of comorbidities on PROs over two years of follow-up was evaluated using mixed models for repeated measures (MMRM) adjusting for disease duration. Finally, we compared the retention rate to the first anti-TNF alpha across the three groups of patients using a Kaplan-Meier curve and a Log-rank test.

Results: 749 patients were included (mean age 48.37 ± 12.2 years, of which 75.3% were men). The association between the number of comorbidities and the PROs is shown in Table 1. We found that patients with 2 or more comorbidities showed an increase (b coefficient) in all PROs compared with patients without comorbidities. The impact of the number of comorbidities on the PROs after two years of follow-up is shown in Figure 1. In general, patients with two or more comorbidities showed higher scores during the two years of follow-up in Global VAS, BASDAI, ASDAS, BASFI and worse levels of the physical component from the SF12.

Table 1. Association of the number of comorbidities with PROs

	Global VAS		BASDAI		ASDAS	
	Crude β (95%CI)	β (95%CI) adjusted for disease duration	Crude β (95%CI)	β (95% CI) adjusted for disease duration	Crude β (95%CI)	β (95%CI) adjusted for disease duration
1 comorbidity vs. 0 comorbidities	0.21 (-0.07 to 0.49)	0.15 (-0.14 to 0.43)	0.03 (-0.43 to 0.48)	-0.01 (-0.46 to 0.45)	0.09 (-0.08 to 0.25)	0.06 (-0.11 o 0.23)
2 or more comorbidities vs. 0 comorbidities	0.78 (0.52 to 1.05)	0.63 (0.35 to 0.91)	1.12 (0.69 to 1.56)	1.04 (0.59 to 1.50)	0.49 (0.33 to 0.64)	0.42 (0.26 to 0.58)
	BASFI		SF12 Physical component		SF12 Mental component	
	Crude β (95%CI)	β (95%CI) adjusted for disease duration	Crude β (95%CI)	β (95%CI) adjusted for disease duration	Crude β (95%CI)	β (95%CI) adjusted for disease duration
1 comorbidity vs. 0 comorbidities	0.59 (0.20 to 0.98)	0.41 (0.02 to 0.80)	-1.27 (-2.40 to -0.13)	-1.09 (-2.24 to 0.05)	0.32 (-0.98 to 1.63)	0.13 (-1.19 to 1.45)
2 or more comorbidities vs. 0 comorbidities	1.68 (1.31 to 2.05)	1.25 (0.87 to 1.64)	-2.23 (-3.33 to -1.14)	-1.70 (-2.83 to -0.56)	1.52 (0.26 to 2.78)	1.08 (-0.23 to 2.39)

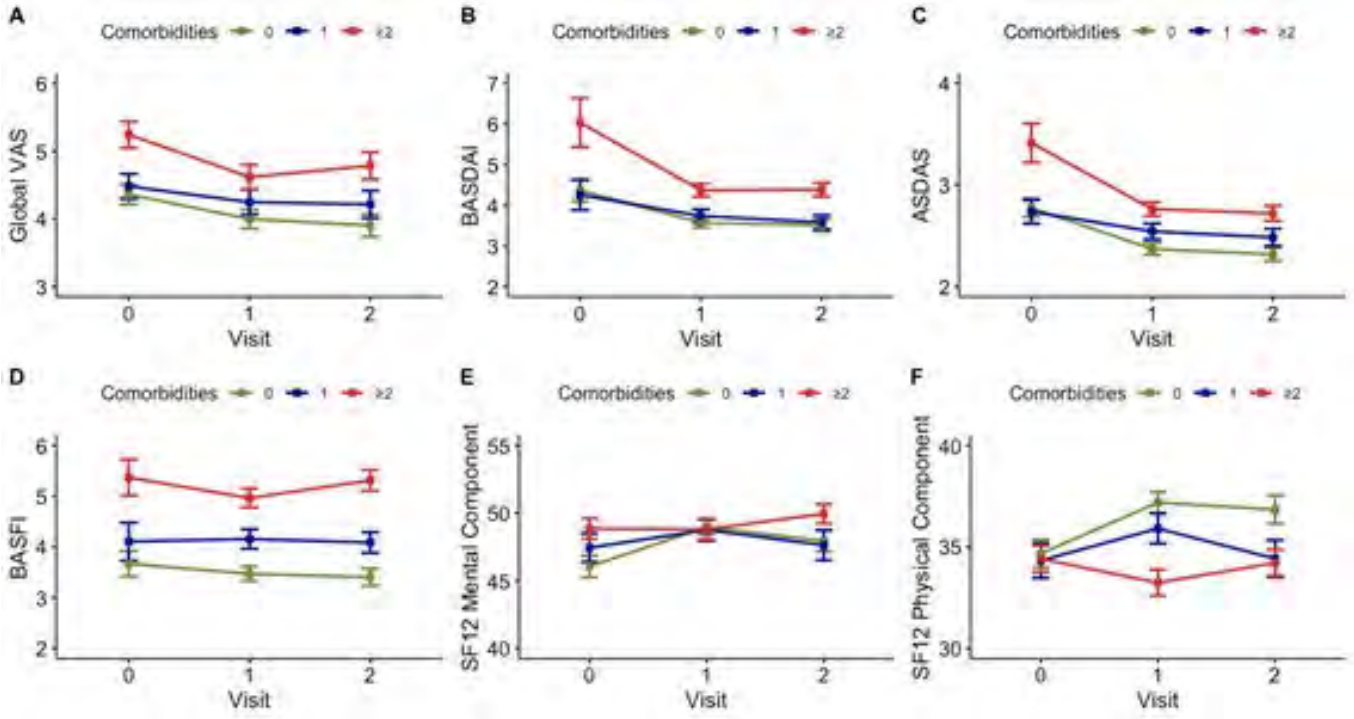

Figure 1. Impact of the number of comorbidities on PROs over two years of follow-up.

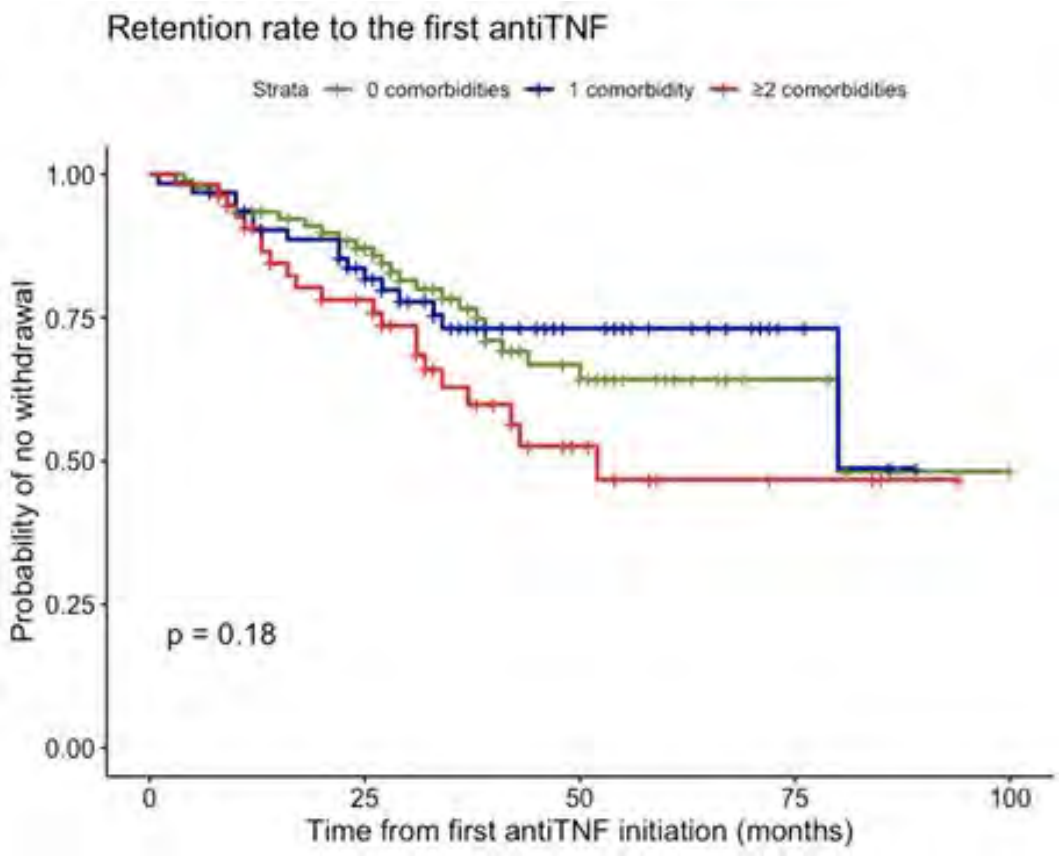

Figure 2. Impact of the number of comorbidities on the adherence to the first TNF-alpha blocker.

The impact of the number of comorbidities on the retention rate of the first anti-TNF is shown in Figure 2. We found a higher probability of discontinuation of the first anti-TNF in patients with 2 or more comorbidities compared with the other two groups (38.2% vs. 26.6% vs. 25.4% for 2 or more comorbidities, 0 and 1 comorbidity, respectively), although these differences were not significant (Log-rank test: p-value = 0.180).

Conclusion: In patients with AS, the presence of 2 or more comorbidities was associated with poorer scores on the outcome measures after two years of follow-up, in comparison with patients without comorbidities. Despite the three groups showed a similar use of anti-TNF alpha, a greater tendency of discontinuation of the first anti-TNF was observed in patients with 2 or more comorbidities.

Session Title: Spondyloarthritis Including PsA – Diagnosis, Manifestations, & Outcomes III: Comorbidities, Extra-muskuloskeletal Manifestations, & Related Conditions (1304–1328)

Session Type: Poster Session C

Session Time: 8:30AM–10:30AM

Background/Purpose: A recent study reports that gut inflammation is linked to degree of bone marrow edema in sacroiliac joints in patients with axial spondyloarthritis (SpA). SpA patients with concomitant inflammatory bowel disease (IBD) typically have more severe disease requiring aggressive treatment. However, the clinical characteristics of SpA patients with IBD has not been shown in a large cohort and there are few descriptions of regional differences.

Table 1. Clinical Characteristics of SpA patients with IBD

The purpose of this study is to clarify the clinical characteristics of SpA patients with IBD compared to those SpA patients without IBD. In addition, we aim to determine the phenotype of patients given a definitive diagnosis of IBD-associated SpA by their treating rheumatologist.

Methods: Using ASAS-PerSpA data, an observational study, we analyzed information on demographics and disease characteristics, dichotomizing patients by IBD status. SpA patients with IBD were further categorized by region; Japan, non-Japan Asia, and non-Asian countries. SpA patients with IBD were also categorized as IBD-associated SpA or other SpA with IBD by their rheumatologists.

Results: Among 4465 SpA patients included in the study, 287 were identified with IBD. Compared to those without IBD, SpA patients with IBD were less likely male (54.0 vs 61.5%) and more likely to have experienced diagnostic delay (5.1 vs 2.9 years) (Table 1). SpA patients with IBD had lower prevalence of positive HLA-B27 (37.2% vs 68.0%) and less dactylitis (9.1% vs 15.8%) despite similar rates of other peripheral signs. Disease activity, radiographic sacroiliitis and inflammation on MRI were similar in the two groups. csDMARDs and bDMARDs use was higher in SpA patients with IBD.

With respect to regional differences, SpA patients with IBD was more common in Japan than in both non-Japan Asia and non-Asian countries (13.2, 1.7 and 7.1%, respectively). SpA patients with IBD in Japan experienced more diagnostic delay (12.8, 0.3 and 5.0 years, respectively), had lower prevalence of positive HLA-B27 (0, 81.8 and 36.2%, respectively) and less axial symptom (inflammatory back pain: 57.7, 84.6 and 81.9%, radiographic sacroiliitis: 23.1,46.2 and 60.9%, sacroiliitis on MRI: 33.3, 83.3 and 71.3%, respectively).

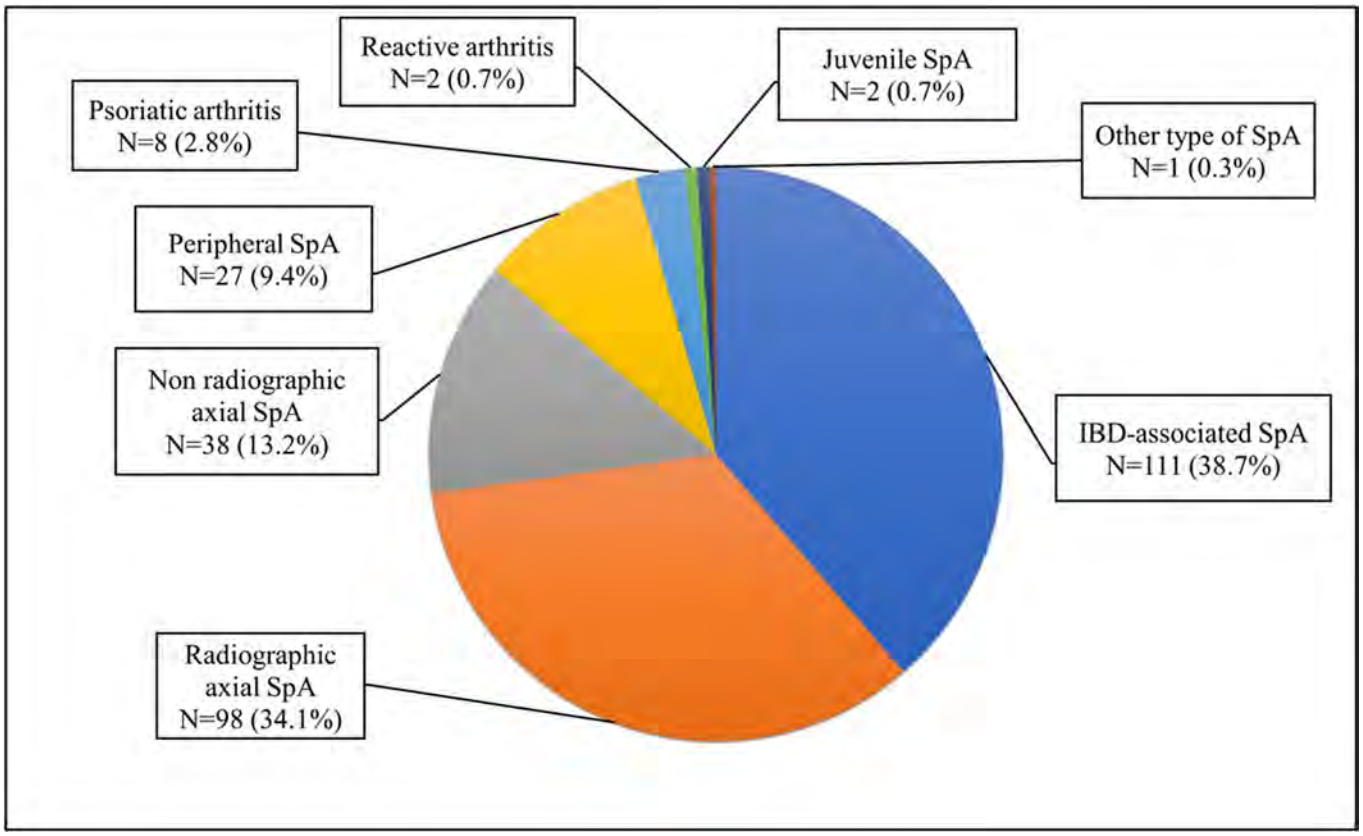

Figure 1. Final clinical diagnosis of SpA patients with IBD patients by rheumatologists. (N=287).

Table 2. Clinical Characteristics of IBD-associated SpA compared to other SpA patients with IBD

csDMARDs (Ever)	108 (97.3)	146 (83.0)	**<0.001**
bDMARDs (Ever)	74 (66.7)	137 (77.8)	0.051

Values are expressed as n (%) or median [IQR] unless otherwise indicated.

SpA patients with IBD were categorized by rheumatologists into their respective clinical diagnoses, of which 111 were diagnosed with IBD-associated SpA (Figure 1). IBD-associated SpA patients, compared to those diagnosed as primarily SpA patients with IBD but not IBD-associated SpA, had lower prevalence of both HLA-B27 (19.3 vs 45.2%) and family history of SpA (24.3 vs 39.8%) (Table 2). IBD-associated SpA patients had fewer axial symptom and signs, and were more likely to have peripheral arthritis - especially oligoarthritis. In IBD-associated SpA patients, IBD appears more often as the first symptom of SpA, and IBD-specific treatment was needed more frequently. csDMARDs use was higher in IBD-associated SpA.

Conclusion: SpA patients with IBD required more specific treatments than those without IBD. In SpA patients with IBD, rheumatologists tended to diagnose IBD-associated SpA in those without axial signs but with peripheral signs, and those with IBD as the initial symptom and requiring IBD-specific treatment.

De Novo Psoriasis Can Be Reported at Any Timepoint in Early Axial Spondyloarthritis: An Analysis of 6 Years of Follow-up of the DESIR Cohort

Florian LUCASSON[1], Pascal Richette[2], krystel aouad[1], Adeline RUYSSEN-WITRAND[3], Daniel Wendling[4], Bruno Fautrel[5] and Laure Gossec[6], [1]Sorbonne Université, INSERM, Institut Pierre Louis d'Epidémiologie et de Santé Publique, Paris, France, [2]Lariboisiere Hospital, Paris, France, [3]Toulouse University Hospital, Centre d'Investigation Clinique de Toulouse CIC1436, Inserm, Paul Sabatier University,, Toulouse, France, [4]Service de rhumatologie, CHU de Besançon, Besançon, France, [5]Pitié Salpêtrière Hospital, APHP, Sorbonne Université, Paris, France, [6]Sorbonne Université; APHP, Rheumatology Department, Pitié-Salpêtrière Hospital, Paris, France

SESSION INFORMATION

Session Date: Monday, November 8, 2021

Session Title: Spondyloarthritis Including PsA – Diagnosis, Manifestations, & Outcomes III: Comorbidities, Extra-muskuloskeletal Manifestations, & Related Conditions (1304–1328)

Session Type: Poster Session C

Session Time: 8:30AM–10:30AM

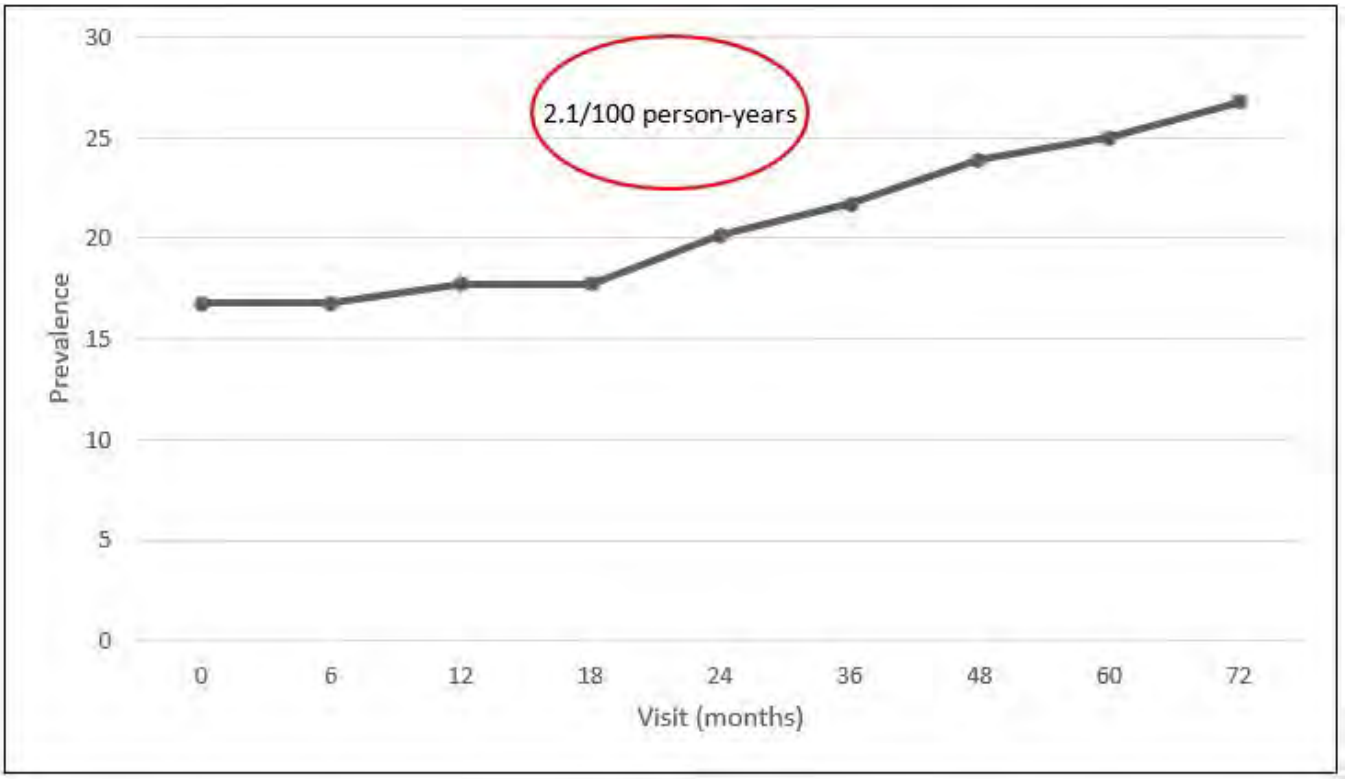
Background/Purpose: Psoriasis is a frequent extra-articular manifestation in axial spondyloarthritis (axSpA) with a prevalence in established axSpA around 9% and consequences on the disease course. In recent axSpA, prevalence and consequences of psoriasis are unclear.

The objectives were to determine the prevalence and the impact of psoriasis in recent axSpA over 6 years of follow-up.

Methods: This was an analysis of the first 6 years of the French prospective cohort DESIR (NCT01648907) which recruited adult patients with inflammatory back pain for less than 3 years suggestive of SpA(4). Psoriasis was recorded at baseline and at each visit (once or twice per year) through the rheumatologist's reporting. Functional assessment (HAQ-AS, BASFI) and disease activity were assessed at each time point. Cumulative prevalence of psoriasis at each time point and cumulative incidence were calculated. Baseline characteristics associated with cumulative psoriasis were assessed by univariable analysis. Patients with versus without psoriasis were compared at 5 years for sacroiliac and spine SPARCC inflammatory score and at 6 years, for HAQ-AS, BASFI, ASDAS-CRP and MASES enthesitis index, in univariable then multivariable analysis adjusted on demographic variables and baseline values of each score. Patients with complete data for ASDAS-CRP at 6 years were included in this analysis. There was no imputation of missing data.

Results: After 6 years, 589/708 (83.2%) patients were followed-up: mean age 40.5±8.7 years, 45.8% men. The cumulative prevalence of psoriasis increased from 99/589 (16.8%) at baseline to 158/589 (26.8%) at 6 years (Figure), leading to an incidence of 2.1/100 patient-years. As expected, patients with psoriasis had more peripheral arthritis and a higher BMI at baseline. After 6 years of follow-up, for 343 patients with complete data, there was no significant impact of psoriasis on functional capacity (BASFI, HAQ), on disease activity (similar ASDAS-CRP score), enthesitis or MRI.

Conclusion: Psoriasis is frequent in early axSpA and is often concomitant to the diagnosis of axSpA. Over 6 years of follow-up, de novo psoriasis may be detected at any time point, necessitating regular work-ups. In this analysis, outcomes did not appear worse for patients with psoriasis than without. Further research to explore impact of psoriasis on axSpA is needed.



Cumulative prevalence and incidence of psoriasis in 589 axial SpA patients over 6 years of follow-up

Session Date: Monday, November 8, 2021

Session Title: Spondyloarthritis Including PsA – Diagnosis, Manifestations, & Outcomes III: Comorbidities, Extra-muskuloskeletal Manifestations, & Related Conditions (1304–1328)

Session Type: Poster Session C

Session Time: 8:30AM–10:30AM

Background/Purpose: The diagnostic delay remains long in patients with spondyloarthritis (SpA), thus effective screening/referral strategies for early recognition are needed. Up to 40% of patients presenting with acute anterior uveitis (AAU) have an undiagnosed SpA [1]. The Dublin Uveitis Evaluation tool (DUET) was presented as a referral tool for ophthalmologists [1]. The objective of this study was to compare the performance of the DUET with a screening strategy based on the Assessment of SpondyloArthritis International Society (ASAS) referral recommendations in AAU patients (figure, [2]).

[1] Haroon M, et al. Ann Rheum Dis 2015;74:1990-5.

[2] Poddubnyy D, et al. Ann Rheum Dis 2015;74:1483-7.

Methods: A total of 207 consecutive patients with non-infectious AAU seen in the ophthalmology clinic and ophthalmological private practices were included, 189 of them completed a standardized rheumatological examination in the specialized center including imaging of sacroiliac joints (MRI performed in 185 patients, X-rays performed in 116 patients) allowing for a definite conclusion on the presence/absence of SpA. The sensitivity, specificity and positive predictive value of both referral tools were calculated. Mann Whitney U and Fisher's exact tests were used for comparison between AAU patients with and without SpA.

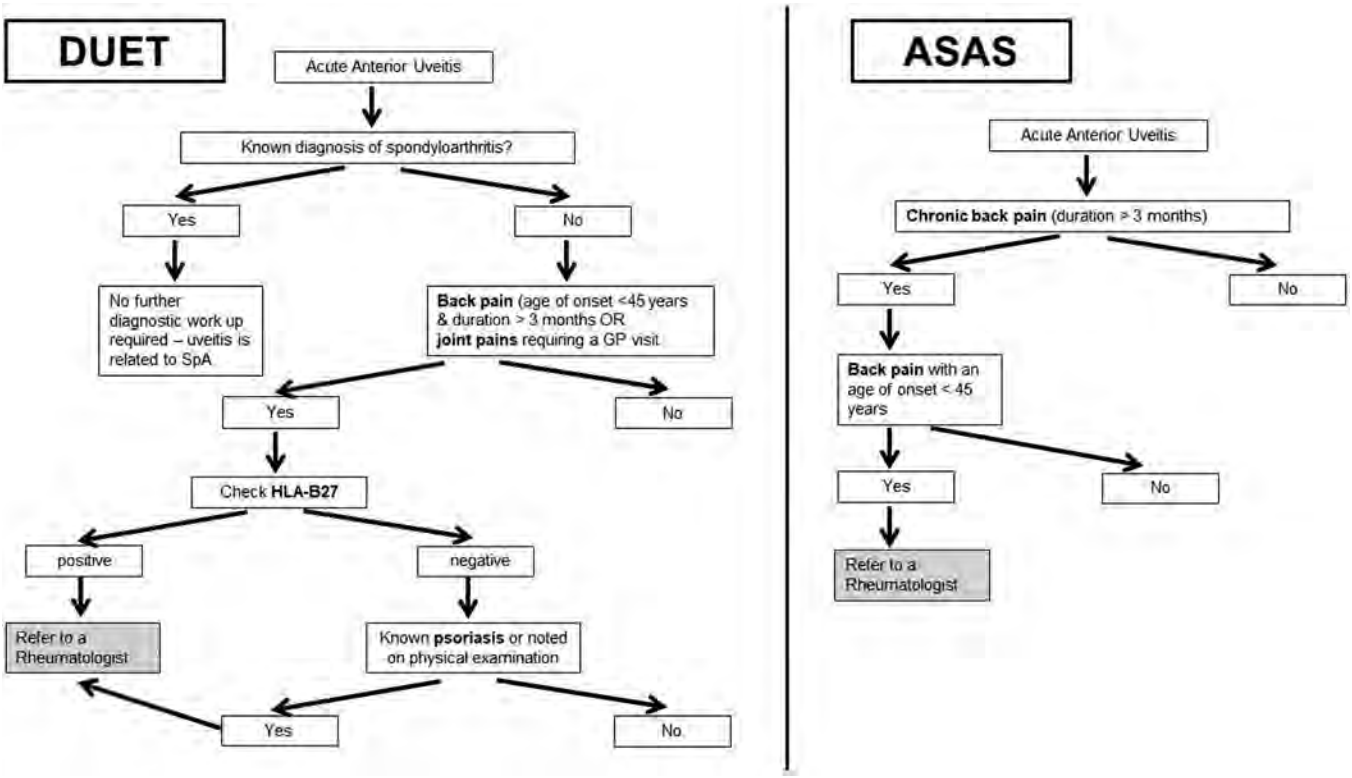

Figure: DUET and ASAS referral tool, modified after [1,2].

Table 1. Demographic and clinical parameters of the 189 included patients with acute anterior uveitis with and without spondyloarthritis (SpA). * Mann Whitney U test for numerical and Fisher's exact test for categorical variables. Table 2. Performance of referral tools in all patients (N=180) and only patients without a previously diagnosed spondyloarthritis (N=148): Dublin Uveitis Evaluation Tool (DUET) versus an adaption of the Assessment of SpondyloArthritis International Society referral tool (ASAS)

	ASAS, n/N (%)	DUET, n/N (%)	ASAS, patients without a known diagnosis of SpA, n/N (%)	DUET, patients without a known diagnosis of SpA, n/N (%)
Sensitivity	83/97 (85.6%)	80/97 (82.5%)	55/68 (80.9%)	52/68 (76.5%)
Specificity	23/83 (27.7%)	34/83 (41.0%)	23/80 (28.8%)	33/80 (41.3%)
Positive predictive value	83/143 (58.0%)	80/129 (62.0%)	55/112 (49.1%)	52/99 (52.5%)
Prevalence of SpA	97/180 (53.9%)		68/148 (45.9%)	

Results: Out of the 189 AAU patients, 105 (56%) were diagnosed with SpA: the majority of them (n=100, 95%) had predominantly axial SpA, 5 patients solely peripheral SpA. 33 of the included 189 patients had a previous external diagnosis of SpA, however, in three out of them SpA was excluded after rheumatologist evaluation as part of the study.

Patients with underlying SpA were more often male, HLA-B27 positive and had predominantly unilateral uveitis (table 1). Though back pain was frequent in the overall study population, back pain present at inclusion as well as inflammatory back pain were significantly more prevalent in the AAU patients with SpA. Moreover, SpA patients had higher disease activity parameters and elevated inflammatory markers (both CRP and ESR) as well as reduced spinal mobility compared to patients without SpA. Patients with SpA presented more frequently with psoriasis and peripheral arthritis.

The ASAS referral tool showed a higher sensitivity (86% vs. 83%) but a lower specificity (28% vs. 41%) compared to the DUET. The positive predictive value was 58% for the ASAS tool and 62% for the DUET (table 2). Similar performances were observed when analyzing only patients without a known diagnosis of SpA (table 2).

Conclusion: We revealed a high prevalence of undiagnosed SpA in patients with acute anterior uveitis. As anticipated, the DUET strategy also including psoriasis and HLA-B27 positivity showed higher specificity for recognition of SpA than the ASAS referral tool focusing on back pain, which showed a higher sensitivity. Given the high prevalence of SpA in AAU patients, we recommend referring all AAU patients with relevant back pain for a rheumatologic evaluation.

Abstract Number: 1313

The Impact of Comorbidities on Patients with Axial Spondyloarthritis: A Cluster Analysis

Seulkee Lee, Seonyoung Kang, Yeonghee Eun, Hyungjin Kim, Hoon-Suk Cha, Eun-Mi Koh and Jaejoon Lee, Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul, Republic of Korea

SESSION INFORMATION

Session Date: Monday, November 8, 2021

Session Title: Spondyloarthritis Including PsA – Diagnosis, Manifestations, & Outcomes III: Comorbidities, Extra-muskuloskeletal Manifestations, & Related Conditions (1304–1328)

Session Type: Poster Session C

Session Time: 8:30AM–10:30AM

Background/Purpose: Previous study using cluster analysis technique analyzed the association between comorbidities and various outcome measures in patients with axial spondyloarthritis (axSpA). Due to the cross-sectional nature of the study, however, prognostic information about each group were not provided. Using the data retrieved from Korean College of Rheumatology Biologics (KOBIO) registry, which includes longitudinal data of axSpA patients using anti-TNF agents, this study aims to perform cluster analysis to differentiate axSpA patients in terms of comorbidities and to examine the differential treatment outcomes of these groups.

Methods: Clinical characteristics and demographic data of axSpA patients in KOBIO registry were analyzed using an agglomerative hierarchical cluster analysis. The optimum number of clusters was determined by the pseudo-F statistic. After clustering, baseline clinical characteristics and treatment outcomes were compared between isolated axSpA and classified comorbidity groups using multivariable linear models and mixed linear models, respectively.

Results: 1,207 patients were included in the study. At least one comorbidity was seen in 464 (38%) axSpA patients. Compared with those with isolated axSpA, patients with comorbidity were older, longer disease duration, and reported higher patient global assessment of disease activity (PtGA, $p = 0.019$), and BASFI ($p < 0.001$), but did not have significantly different BASDAI, ESR, and CRP levels (Table 1). The most common comorbidities were hypertension (14.4%), hyperlipidemia (13.0%), and obesity (4.5%). The hierarchical cluster analysis classified patients in 21 groups. We combined clusters 17-21 for further evaluation due to the small size of clusters (< 5 patients). In multivariable linear models for baseline clinical characteristics, we found that patients in the hypothyroidism, asthma, and headache clusters reported poorer PtGA, BASDAI, or BASFI, and the weight loss cluster had higher level of CRP, compared with patients with isolated axSpA even after adjustment of patient demographic data (Table 2). After 1-year treatment of anti-TNF agents, the patients in the hypothyroidism and weight loss clusters decreased greater amounts of BASDAI and BASFI scores and ESR/CRP levels, respectively, compared with patients with isolated axSpA (Table 3). However, the degree of improvement in asthma and headache clusters, which had higher disease activities at baseline, was similar with isolated axSpA. Therefore, they still had higher disease activity scores at the 1-year follow-up.

Conclusion: Comorbidity could affect the treatment outcomes in patients with axSpA in certain subgroups. Thus, we should also pay attention to the comorbidities when treating axSpA.

SESSION INFORMATION

Session Date: Monday, November 8, 2021

Session Title: Spondyloarthritis Including PsA – Diagnosis, Manifestations, & Outcomes III: Comorbidities, Extra-muskuloskeletal Manifestations, & Related Conditions (1304–1328)

Session Type: Poster Session C

Session Time: 8:30AM–10:30AM

Background/Purpose: Axial spondyloarthritis (axSpA) is a chronic inflammatory rheumatic disease mainly affecting sacroiliac joints and spine. Peripheral arthritis, dactylitis and enthesitis may also occur. Acute anterior uveitis (AAU) is the most frequent extra musculo-skeletal manifestation of axSpA which may lead to severe functional impairment. Moreover, an AAU attack can be the presenting symptom that may lead to diagnosis of axSpA. However, there is limited data regarding the factors predicting the development of AAU attacks in patients with axSpA.

Purpose: To examine the factors associated with the AAU attacks in patients with axSpA in a longitudinal axSpA cohort.

Methods: In total 469 axSpA patients (272 [58%] male; 297 [63%] with AS and 172 [36%] with non-radiographic (nr)-axSpA) who have followed up to three years were included in this observational study. Baseline disease characteristics and follow-up data including the development of AAU attacks, concurrent disease activity, serum CRP levels, usage of conventional synthetic and biological disease modifying anti-rheumatic drugs (cs-DMARD, bDMARD) were collected on 3, 6, 12, 24 and 36th months. The longitudinal relationship between AAU attacks (dependent) and potential predictive factors (independent) tested by using generalized estimating equations (GEE) which is a technique for longitudinal data analysis allowing the use of all available data even deviated from normality.

Results: Overall, 99 (%21) of 469 patients had experienced at least one AAU attack (77 [78%] on history and 31 of them also in follow up, 11 patients [11%] presented with AAU in their first visits and 11 have developed their first AAU attacks on follow up) (Table 1). In total 89 AAU attacks were observed during follow up (35 attacks on presentation, 10 attacks at 3nd month, 4 attacks at 6th month, 12 attacks at 12ndmonth, 16 attacks at 24th month and 12 attacks at 36th months of follow up). At baseline patients with the AAU history were older (p=0.001), had more peripheral arthritis (p< 0.001), higher BASMI score (p=0.007), and higher serum CRP levels (p=0.016). Those patients with a positive AAU history have been also using cs- and bDMARD more commonly. Univariate longitudinal analysis revealed that the development of AAU attacks was significantly associated with the history of AAU, male gender, the presence of extraspinal involvement, concomitant cs-DMARD usage, BASDAI scores, ASDAS-CRP, and PGA of disease activity. However, multivariate analysis showed that the presence of AAU history and concurrent disease activity assessed by BASDAI were the only independent determinants of the development of AAU attacks in axSpA patients (Table 2).

Table 1. Baseline characteristics of axSpA patients with and without history of uveitis

	All group N=469	Patients with a history of AAU N=77	Patients without a history of AAU N=392	*p*
Age, years median (IQR)	43 (18)	47.5 (18)	42 (16)	**0.001**
Sex, male, %	58	54.5	58.7	0.53
HLA-B27 positivity, %	60.5	66.7	59.4	0.38
The presence of extraspinal involvement history (arthritis or dactylitis or enthesitis)	58.5	70.8	56.1	**0.021**
Peripheral arthritis, %	32.6	51.4	28.9	**<0.001**
Enthesitis, %	47.5	51.7	46.8	0.57
Dactylitis, %	3.1	1.4	3.4	0.71
Psoriasis, %	4.3	5.2	4.3	1
Inflammatory bowel disease, %	3.3	5.1	3	0.42
BASDAI (0 to 10), median (IQR)	4 (3)	3.3 (3.4)	3.6 (3.1)	0.22
BASFI (0 to 10), median (IQR)	2.8 (4.2)	2.1 (4)	2.4 (3.6)	0.65
BASMI (0 to 10), median (IQR)	2 (3)	3 (3)	2 (3)	**0.007**
CRP (mg/dl), median (IQR)	1 (8)	4 (8)	1 (4.3)	**0.016**
PGA of disease activity (0 to 100), median (IQR)	40 (40)	35 (50)	40 (40)	0.36
Current cs-DMARD use, %	25.8	45.2	22	**<0.001**
Current bDMARD use, %	67	45.5	30.6	**0.007**

Conclusion: Our results showed that AAU attacks were significantly higher in axSpA patients who had history of AAU and higher disease activity. Moreover, the presence of AAU might have an impact on treatment in axSpA patients.

Session Title: Spondyloarthritis Including PsA – Diagnosis, Manifestations, & Outcomes III: Comorbidities, Extra-muskuloskeletal Manifestations, & Related Conditions (1304–1328)

Session Type: Poster Session C

Session Time: 8:30AM–10:30AM

Background/Purpose: Systemic inflammation in psoriatic arthritis (PsA) patients accelerates the process of atherosclerosis; this increases the risk of presenting a major cardiovascular (CV) event than the general population. The carotid ultrasound (US), a non-invasive diagnostic tool, has the ability of detecting subclinical atherosclerosis, but it is not available to all patients.

The aim of this study was to determine which is the best CV risk (CVR) algorithm to predict the presence of carotid plaque (CP) in PsA patients.

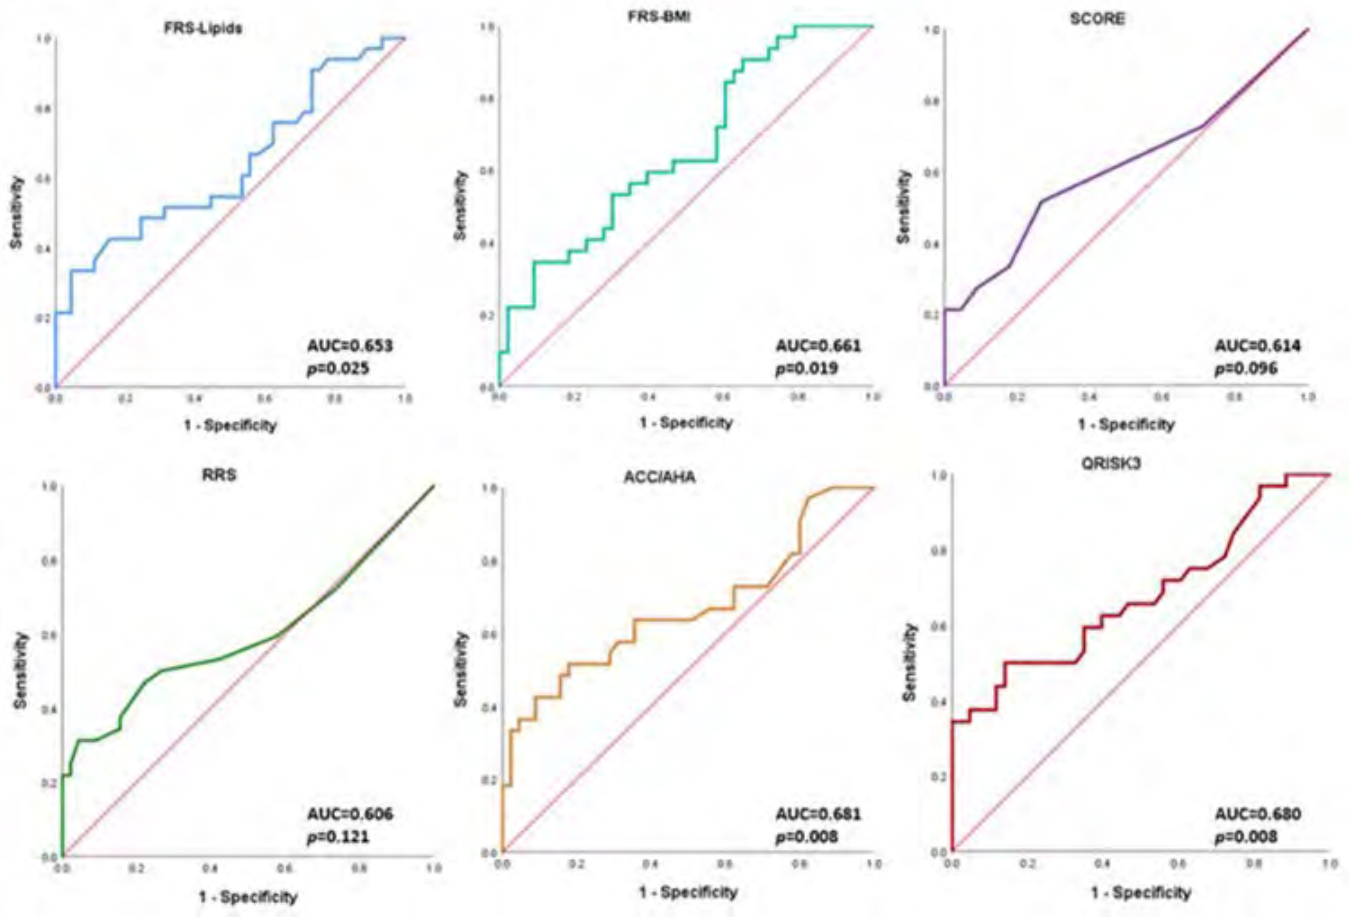
Methods: This was a cross-sectional and observational study. A total of 78 patients aged 40-75 years, who fulfilled the 2006 CASPAR classification criteria for PsA were included. The CVR of each patient was assessed by six different CVR algorithms, including: Framingham Risk Score (FRS)-lipids, FRS-body mass index (FRS-BMI), American College of Cardiology and American Heart Association (ACC/AHA) Risk Algorithm, Systematic Coronary Risk Evaluation (SCORE), QRISK3 and Reynolds Risk Score (RRS). A carotid US was performed in all study subjects to identify the presence of CP. A ROC-curve analysis was done to establish the cut-off points of each algorithm to predict the presence of CP, calculating sensitivity, specificity and area under the curve (AUC) to determine the discriminative capacity. A p-value < 0.05 was considered statistically significant.

Table 1. ROC curve analysis of the cardiovascular risk algorithms.

Cardiovascular risk algorithms (cut-off points)	AUC	CI 95%		p	Sensitivity	Specificity	Likelihood ratio	
		Inferior limit	Superior limit				+	-
FRS-lipids (11.55)	0.653	0.523	0.783	**0.025**	51.5%	68.9%	1.66	0.70
FRS-BMI (13.8)	0.661	0.536	0.786	**0.019**	59.4%	60.5%	1.50	0.67
SCORE (1.5)	0.614	0.478	0.750	0.096	-	-		
RRS (3.5)	0.606	0.467	0.745	0.121	-	-		
ACC/AHA (4.8)	0.681	0.551	0.812	**0.008**	63.6%	64.4%	1.79	0.56
QRISK3 (5.15)	0.680	0.551	0.810	**0.008**	62.5%	60.5%	1.58	0.62

AUC, area under the curve; FRS, Framingham Risk Score; BMI, body mass index; SCORE, Systematic Coronary Risk Evaluation; RRS, Reynolds Risk Score; ACC/AHA, American College of Cardiology and American Heart Association.

Figure 1. ROC-curve of the six cardiovascular algorithms.



Results: Most patients were women (55.1%) with a mean age of 53.46 (±10.86) years. The prevalence of CP was 42.3%. Four of the six CVR algorithms showed the capacity of predicting CP in PsA patients. FRS-lipids showed an AUC 0.653 (0.523-0.783), p=0.025, a cut-off point ≥11.55, a sensitivity of 51.5% and specificity of 68.9%. FRS-BMI showed an AUC 0.661 (0.536-0.786), p=0.019, a cut-off point ≥13.8, sensitivity of 59.4% and specificity of 60.5%. ACC/AHA showed an AUC 0.681 (0.551-0.812), p=0.008, a cut-off point ≥4.8, sensitivity of 63.6% and specificity of 64.4%. QRISK3 showed an AUC 0.680 (0.551-0.810), p=0.008, a cut-off point ≥5.15, sensitivity of 62.5% and specificity of 60.5% (Table 1, Figure 1).

Conclusion: The best CVR algorithm to predict CP in PsA patients was the ACC/AHA risk score. However, there is a need of lower cut-off points to have the capacity of identifying patients classified in the low-moderate risk, according to these algorithms, with subclinical atherosclerosis, who would benefit from an opportune treatment.

SESSION INFORMATION

Session Date: Monday, November 8, 2021

Session Title: Spondyloarthritis Including PsA – Diagnosis, Manifestations, & Outcomes III: Comorbidities, Extra-muskuloskeletal Manifestations, & Related Conditions (1304–1328)

Session Type: Poster Session C

Session Time: 8:30AM–10:30AM

Background/Purpose: There are increasing data about vitamin D immunomodulatory potential in different rheumatologic disorders. Deficiency of vitamin D is frequent in patients with spondyloarthritis (SpA) but studies about the role of vitamin D in disease activity and functional impairment are controversial. This study aims to assess whether vitamin D deficiency is associated with increased disease activity and functional impairment in patients with SpA.

Methods: Our cross-sectional study included patients with SpA according to Assessment of Spondyloarthritis International Society classification criteria. All study patients were treated with biologic disease-modifying antirheumatic drug (bDMARD). Disease activity was assessed using Bath Ankylosing Spondylitis Disease Activity Index (BASDAI) and Ankylosing Spondylitis Disease Activity Score (ASDAS) and functional impairment using Bath Ankylosing Spondylitis Functional Index (BASFI). Serum 25-hydroxyvitamin D [25(OH)D] levels were measured in SpA patients after 6 months of bDMARD therapy. Vitamin D deficiency was defined as 25(OH)D< 30ng/mL. Vitamin D deficient patients were compared with non-deficient patients using Student's t-test for Gaussian.

Results: We included 190 patients with axial and peripheral SpA, 98 were females (51.6%) and 41 current smokers (21.6%). Mean age was 42.7±12.1 and mean disease duration 8.0±9.1 years. Non-steroidal anti-inflammatory drugs were used by 102 patients (53.7%). Seventy patients (36.8%) were treated with conventional syntheticDMARDs and all patients were on bDMARD therapy (189 patients with tumor necrosis factor inhibitors and one with interleukin-17 inhibitor. The mean concentration of 25(OH)D was 27.2±13.4 ng/ml and 118 patients (62.1%) had 25(OH)D levels below the recommended threshold (< 30 ng/ml). Vitamin D supplementation was used by 75 patients (39.5%). Sub-

Table 1: Differences in BASDAI, ASDAS e BASFI in SpA patients with (<30 ng/ml) and without (≥30 ng/mL) vitamin D deficiency

25(OH)D concentration ng/mL	BASDAI (mean±SD)	ASDAS (mean±SD)	BASFI (mean±SD)
<30	4.28±2.41	2.48±1.01	4.82±2.97
≥30	3.16±2.23	2.09±1.00	3.41±2.51
* Student's t-test	p= 0.007*	p= 0.02*	p=0.004*

groups analysis of SpA patients with low 25(OH)D concentration (< 30ng/ml) compared to higher 25(OH)D concentration show that mean BASDAI (4.28 vs 3.16), ASDAS (2.48 vs 2.09) and BASFI (4.82 vs 3.41) were all significantly higher in patients deficient for vitamin D (p< 0,05).

Conclusion: The group of patients with vitamin D deficiency has significantly higher levels of activity and functional impairment than the group of patients with normal vitamin D concentration. According to these data vitamin D can therefore play an immunomodulating and anti-inflammatory role and can be considered a co-adjuvant in the treatment of these patients.

Session Title: Spondyloarthritis Including PsA – Diagnosis, Manifestations, & Outcomes III: Comorbidities, Extra-muskuloskeletal Manifestations, & Related Conditions (1304–1328)

Session Type: Poster Session C

Session Time: 8:30AM–10:30AM

Background/Purpose: There is certain evidence that neuropsychiatric changes occur in systemic lupus(1) and rheumatoid arthritis (2). However, there is little knowledge about possible cognitive changes in axial spondyloarthritis (axSpA). The aim of this study ist to evaluate patients with axial spondyloarthritis regarding cognitive impairments.

Methods: 101 consecutive patients with axial spondyloarthritis attending two rheumatology practices were routinely evaluated by different rheumatologists and underwent a computer-based memory and attention test (MAT) described elsewhere (3, 4). The results of short-term memory and working memory were analyzed compared with an age-, sex- and education-matched control group of healthy subjects.

Results: Patients' characteristics are displayed in table 1. Patients with axSpA revealed a decreased working memory (table 2) as analysed by Wilcoxon signed-rank test (table 3).

Conclusion: The MAT computerized testing is a highly feasible test and was well accepted by patients. It showed a clinically meaningful decrease in working memory in patients with axial spondyloarthritis. Further work-up is required to characterise possible causes or associations of this cognitive impairment.

Table 1. Patients' characteristics

Session Date: Monday, November 8, 2021

Session Title: Spondyloarthritis Including PsA – Diagnosis, Manifestations, & Outcomes III: Comorbidities, Extra-muskuloskeletal Manifestations, & Related Conditions (1304–1328)

Session Type: Poster Session C

Session Time: 8:30AM–10:30AM

Background/Purpose: The Covid-19 pandemic has been especially challenging for patients with inflammatory diseases including spondyloarthritis (SpA). Patients with rheumatic and musculoskeletal diseases (RMDs) remain at an increased risk of morbidity and mortality from vaccine preventable infections, often as a result of disease activity, comorbidities, and immunosuppressive medication.[1] Susceptibility and severity of Covid-19 was addressed with an online survey of patients with a diagnosis of SpA established by a physician.

Methods: We conducted a web-based survey of SpA distributed to approximately 40,000 individuals (mostly in North America) who had registered with the Spondylitis Association of America. Additional surveys were distributed based on lists provided by the Axial Spondyloarthritis International Federation (ASIF). The survey was translated into 15 additional languages to accommodate ASIF members.

Results: Responses from 4723 subjects with SpA and 450 household contacts of these subjects. Most from the US (64.9%), Canada (8%), and the rest from 72 other countries. 63% of the were female. Median age was male 54 and females 49. Several forms of SpA were identified, with 83.5% as ankylosing spondylitis. Respondents reported being exposed to Covid-19 (19.6%) with 384 (8.2%) reported being infected. Of those infected 295 had a confirmatory positive test. Table 1 indicates that none of the treatments appeared to affect the likelihood to develop Covid-19 or the subjective rating of the severity of Covid-19. Some classes of medications such as anti-malarials and JAK inhibitors were not commonly used by the respondents so the statistical meaning of the results could be confounded by the limited size of the database. Patients with SpA were not statistically significantly different from household controls.

Conclusion: Based on survey results, SpA does not affect susceptibility or severity of Covid-19. Medications commonly used to treat spondyloarthritis do not affect susceptibility or severity of Covid-19.

We cannot exclude confounding because patients taking certain medications such as a biologic might exercise greater care to socially distance and minimize exposure.

Session Title: Spondyloarthritis Including PsA – Diagnosis, Manifestations, & Outcomes III: Comorbidities, Extra-muskuloskeletal Manifestations, & Related Conditions (1304–1328)

Session Type: Poster Session C

Session Time: 8:30AM–10:30AM

Background/Purpose: Patients with psoriatic arthritis (PsA) have a higher risk of developing a cardiovascular (CV) event than the general population. This could be attributed to a higher prevalence of traditional CV risk (CVR) factors and to disease characteristics such as systemic inflammation. There are multiple algorithms to estimate the CVR for the general population, however there is not one for PsA patients.

The aim of this study was to compare the CVR reclassification using six CVR algorithms and a carotid ultrasound (US) in PsA patients and controls.

Methods: This was a cross-sectional, observational, and comparative study. A total of 75 patients aged 40-75 years old, who fulfilled the 2006 CASPAR criteria and 75 controls without PsA matched by age (±5 years), gender and comorbidities were recruited for this study. Initially CVR was evaluated according to six CVR algorithms, including Framingham Risk Score (FRS)-lipids, FRS-body mass index (BMI), American College of Cardiology and American Heart Association (ACC/AHA) Risk Algorithm, Systematic Coronary Risk Evaluation (SCORE), QRISK3 and Reynolds Risk Score (RRS). Posteriorly a carotid US was performed in all subjects to identify the presence of subclinical atherosclerosis, defined as the presence of carotid plaque (CP) or an increased carotid intima media thickness (cIMT) which was considered as a value ≥0.8mm. CP was defined as a cIMT ≥1.2mm or a focal narrowing of the surrounding lumen ≥0.5mm. Patients with presence of CP but classified in the low-moderate risk by the CVR algorithms were re-classified to a higher risk category. Distribution was evaluated with the Kolmogorov-Smirnov test. Comparisons were done using χ^2 test for qualitative variables, and Student's t test and Mann-Whitney's U test for quantitative variables. A p-value < 0.05 was considered statistically significant.

Results: Mean age was 53.89 ± 10.59 in PsA patients and 54.25 ± 7.08 in the control group (p=0.807), 57.3% were women in both groups. There were no significant differences in traditional CVR factors between PsA patients and controls. A difference was found in the presence of CP, being more prevalent in PsA patients (44.0% vs 26.7%, p=0.026) and in the presence of subclinical atherosclerosis overall (52.0% vs 34.7%, p=0.032) (Table 1). When comparing the CVR reclassification to a higher risk category a difference was found in five of the six CVR algorithms. The reclassification was more prevalent in PsA patients: 29.3% vs 13.3%, p=0.017 with FRS-lipids; 26.7% vs 10.7%, p=0.012 with FRS-BMI; 40.0% vs 21.3%, p=0.013 with SCORE; 33.3% vs 17.3%, p=0.024 with QRISK3; and 36.0% vs 21.3%, p=0.047 with RRS (Table 2).

Table 1. Demographic characteristics and ultrasound findings.

cIMT ≥0.8mm, n (%)	14 (18.7)	9 (12.0)	NS
Subclinical atherosclerosis, n (%)	39 (52.0)	26 (34.7)	**0.032**

PsA, psoriatic arthritis; NS, not significant; T2DM, type 2 diabetes mellitus; HTN, hypertension; BMI, body mass index; DAPSA, disease activity for psoriatic arthritis; cIMT, carotid intima media thickness.

Conclusion: The CVR algorithms underestimate de real CVR of PsA patients. This could be attributed to the fact that these algorithms do not include disease characteristics that can affect the CV prognosis of PsA patients. For this reason, a carotid US should be done to correctly classify the CVR of PsA patients and identify those who would benefit from an opportune treatment.

[1] Pearson's Chi-squared test, [2] Kruskal-Wallis rank sum test

SpA: Spondyloarthritis, BASDAI: Bath ankylosing spondylitis disease activity index, ASDAS: Ankylosing Spondylitis Disease Activity Score, FIRST: Fibromyalgia Rapid Screening Tool, NSAID: Non-steroidal anti-inflammatory drugs, cDMARDs: conventional disease-modifying antirheumatic drugs

Background/Purpose: Obese patients with spondyloarthritis (SpA) had more functional limitations, higher subjective disease activity, fewer benefits of exercise, and showed less response to drug therapy. This study aims to explore the relationship of obesity with clinical manifestations and disease burden including biologic/targeted DMARD (btDMARD) burden, SpA-related surgery burden, labor loss, and patient-reported health status.

Methods: An ancillary analysis of ASAS-PerSpA cross-sectional study from 24 participating countries. The ASAS-PerSpA study included the data of diagnosis, demographics, disease duration, clinical manifestations (ie, inflammatory back pain, sacroiliitis, enthesitis, psoriasis, uveitis, fatigue, and fibromyalgia assessment), disease activity, ongoing treatment and treatment history (ie, ongoing btDMARDs use, ever btDMARDs use, number of btDMARDs kinds ever-prescribed, number of btDMARD discontinuation, and the reasons for discontinuation), SpA-related surgery (ie, spinal vertebrectomy, total hip replacement, peripheral joint surgery), work productivity and activity impairment (WPAI) questionnaire, ASAS Health Index (ASAS-HI), Bath Ankylosing Spondylitis Functional Index (BASFI), and global wellbeing (on a visual analog scale). In addition to the current BMI (BMI_c), the 20-year-old BMI (BMI_{20}) data were also noted. Patients were divided into three groups according to the BMI_c and comparisons between the obese patients ($BMI_c \geq 30$ kg/m^2), overweights ($BMI_c \geq 25$ to < 30 kg/m^2), and normal weights ($BMI_c < 25$ kg/m^2) were performed

Table 2. Burden associations with the current BMI

Burden		Normal weight	Overweight	Obese	p	$p^{adj\ (N\text{-}OW)}$	$p^{adj\ (N\text{-}Ob)}$

**The count of data is not sufficient for statistical model construction.*

for the above-mentioned parameters. In addition, the same population was also divided into different three groups according to their BMI_{20} and they have compared again in themselves.

Results: A total of 4449 patients with the BMI_c values were included. The mean age was 44.4 (SD 14.0) and 61.0% were male. The mean disease duration was 14.3 (SD 11.3) years and 42.6% of them were ever-smokers. Demographics and patient characteristics were demonstrated in Table 1. Comparisons of the disease burden according to the BMI_c (Table2) and BMI_{20} (Table 3) documented the statistical significances between the groups.

Conclusion: Obesity is related to a biological (or targeted) therapy burden, labor loss, and worse patient-reported health status.

Uveitis in Patients with Psoriatic Arthritis – a Database Analysis

Nizar Hijaze[1], Tal Gazitt[2], Amir Haddad[3], Muna Elias[4], Idit Lavi[4], Ilan Feldhamer[5], Arnon Dov Cohen[5], Shaul Sar[4], Oren Tomkins Netzr[4] and Devy Zisman[4], [1]Carmel medical centre, Tamra, Israel, [2]Carmel Hospital, Haifa, Israel, [3]Carmel Medical Centre, Haifa, Israel, [4]Carmel Medical Center, Haifa, Israel, [5]Clalit Health Services, Tel Aviv, Israel

SESSION INFORMATION

Session Date: Monday, November 8, 2021

Session Title: Spondyloarthritis Including PsA – Diagnosis, Manifestations, & Outcomes III: Comorbidities, Extra-muskuloskeletal Manifestations, & Related Conditions (1304–1328)

Session Type: Poster Session C

Session Time: 8:30AM–10:30AM

Background/Purpose: Psoriatic arthritis (PsA) belongs to the group of spondyloarthropathies in which uveitis is an associated disease . The prevalence of uveitis among PsA patients especially in the era of biologic treatment is not well established.

Methods: A retrospective database study was conducted on 6,147 adult PsA patients who were newly diagnosed with PsA between January 1, 2005 (start date) and 31 December 2020 (end date) with date of diagnosis considered the index date compared to 23,999 randomly selected control subjects matched for age, sex, ethnicity, and index date. Both groups were followed from the index date until the first episode of uveitis, death, or end of follow-up, whichever came first. Demographic variables, smoking status, socioeconomic status (SES), body mass index (BMI), presence of selected chronic comorbidities, and medication use including conventional and biologic disease-modifying anti-rheumatic drugs (c/b DMARD) were extracted in both groups.

Descriptive statistics was applied as appropriate. Marginal model with robust covariant estimate counting for the matching was used to estimate the crude and adjusted hazard ratio (HR) for the association between PsA and uveitis. Within the group of PsA patients, Cox proportional hazard regression time dependent models were used to calculate the risk of uveitis given demographic variables, SES, smoking, selected comorbidities, and c/bDMARD. All tests were 2-sided; p values of ≤ 0.05 were considered statistically significant.

Results: PsA cohort consisted of 53.1% females with mean age of 51.75±15.39. In the PsA group, 107 patients (1.7%) were diagnosed with uveitis, compared to 187 patients (0.8%) in the control group ($p< 0.0001$, HR 2.25, CI 1.78-2.86). Compared to the control group with uveitis, patients with PsA and uveitis were more often female (64.5% vs 51.9% p=0.036), of a younger age (54.49±16.2 vs 58.89±14.8, p=0.02).

Within the PsA group, patients with uveitis had a previous history of uveitis (HR 33.56 CI 20.76- 54.25), and were more often treated with cDMARDS (83.2% vs 67.1%, $p< 0.0001$), monoclonal anti-Tumor Necrosis Factor-a (anti-TNF-a) agents (68.2% vs 38.6%, $p< 0.0001$) and etanercept (37.4% vs 20.8%, $p< 0.0001$). No difference in uveitis occurrence was noted regarding treatment with anti-IL-17 or anti IL12/23 agents or with regards to demographic characteristics and comorbidities.

No difference in uveitis occurrence was noted regarding treatment with anti-IL-17 or anti IL12/23 agents or with regards to demographic characteristics and comorbidities.

Conclusion: The hazard ratio for uveitis was significantly higher in the PsA group relative to the general population. A high index of suspicion for uveitis is warranted in PsA patients with previous episode of uveitis. Uveitis was reported in patients treated with TNFα blockers irrespective of their mode of action.

Body Mass Index (BMI) Underestimates Obesity in Females with Axial Spondyloarthropathy

Sinead Maguire[1], Wilson Fiona[2], Phil Gallagher[3] and Finbar (Barry) O'Shea[1], [1]St James's Hospital, Dublin, Ireland, [2]Discipline of Physiotherapy, Trinity College Dublin, Dublin, Ireland, [3]St Vincent's Hospital, Dublin, Ireland

SESSION INFORMATION
Session Date: Monday, November 8, 2021
Session Title: Spondyloarthritis Including PsA – Diagnosis, Manifestations, & Outcomes III: Comorbidities, Extra-muskuloskeletal Manifestations, & Related Conditions (1304–1328)
Session Type: Poster Session C
Session Time: 8:30AM–10:30AM

Background/Purpose: Worldwide prevalence of obesity has been steadily increasing, despite public health campaigns to raise awareness. In axial spondyloarthropathy (axSpA) obesity has been shown to be associated with higher levels of disease activity and decreased response to treatment. The waist to hip ratio (WtHpR) is a tool to screen for abdominal obesity. Abdominal deposition of adipose tissue is associated with increased risk of cardiovascular disease, type II diabetes and premature death. Abdominal obesity is more common in males, with females more prone to gluteal-femoral fat deposition. The Ankylosing Spondylitis Registry of Ireland (ASRI) is a source of epidemiological data of axSpA patients in Ireland. The aim of this study was to capture the prevalence of abdominal obesity in a large cohort of axSpA patients and assess for variation in prevalence between sexes.

Methods: Participants were analysed on the basis of gender and presence of obesity by BMI and WtHpR. Obesity was defined by body mass index (BMI) with a result of >30 categorised as obese as per CDC definitions. Abdominal obesity was assessed by WtHpR and defined as per WHO guidelines (table 1). Categorical variables were tested for statistical significance with a chi^2 test for independence, while continuous variables were tested with an independent t-test or Mann Whitney U test. A Spearman's correlation analysis was run to assess the strength of association between BMI and WtHpR. A p-value of < 0.05 was deemed significant. IBM SPSS version 26 was used for statistical analysis.

Table 1. Waist to Height Ratio definitions for Abdominal Obesity as per the World Health Organisation (WHO) guidelines

	Males	Females
Normal	< 0.9	< 0.8
Overweight	0.9-0.99	0.8-0.84
Obese	> 1.0	> 0.85

Table 2. Assessment of Obesity by Sex

	Males	Females	p value
n	77.7% (538)	22.3% (154)	
Weight (kg)	84.98	72.76	*<0.01*
BMI (kg/m²)	28.08	27.69	*0.45*
Underweight	0.9% (5)	0.06% (1)	*0.49*
Normal Weight	29.2% (157)	36.4% (56)	
Overweight	39.2% (211)	34.4% (53)	
Obese	29.9% (161)	28.6% (44)	
Waist Circumference (cm)	97.43	90.03	*<0.01*
Hip Circumference (cm)	102.11	101.27	*0.56*
Waist to Hip Ratio	0.956	0.890	*<0.01*
Normal Weight	23.8% (128)	17.5% (27)	*<0.01*
Overweight	46.3% (249)	14.3% (22)	
Obese	29.9% (161)	68.2% (105)	

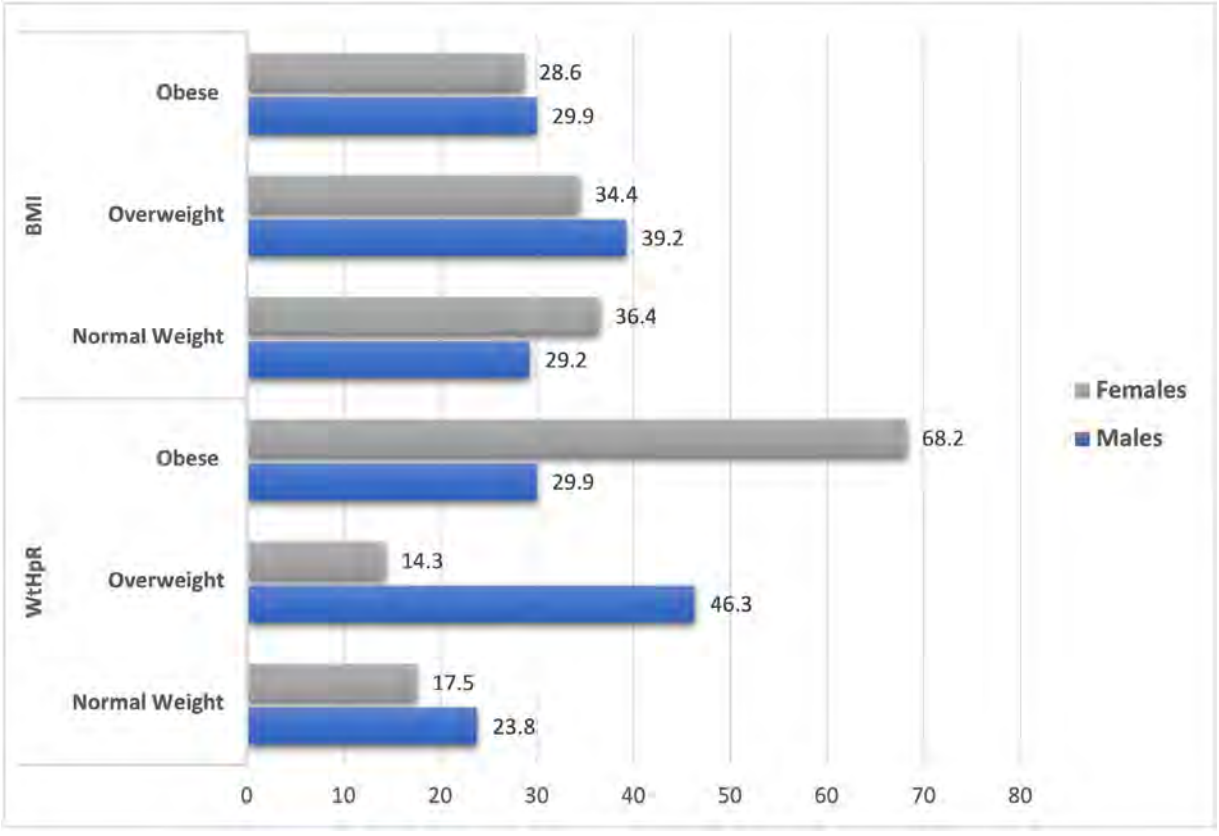

Figure 1. Prevalence of Obesity (%) in AxSpA as detected by Body Mass Index (BMI) and Waist to Hip Ratio (WtHpR) within each sex.

Results: At the time of analysis, physical measurements were available on 692 patients in the ASRI made up of 96.2% (666) Caucasians with 22.3% (154) females and 77.7% (538) males. The average age was 45.9 years with a mean disease duration of 18.8 years (mean scores: BASDAI 4.09, BASFI 3.71, BASMI 3.99, HAQ 0.54, ASQoL 6.72). 80.9% (560) of patients had radiographic sacroiliitis while 49.1% (340) had sacroiliitis on MRI.

Overall 29.5% (215) patients were obese based on BMI results, while 37.5% (274) were centrally obese as per the WtHpR. Analysis on the basis of sex revealed no significant variation in mean BMI (28.1 vs 27.7, p=0.45) or prevalence of obesity as assessed by BMI (29.9% vs 28.6%, p=0.49) between males and females (table 2). As expected, analysis of WtHpR revealed higher mean ratios in males compared to females (0.96 vs 0.89, p< 0.01), however there was a significantly higher prevalence of abdominal obesity in females (29.9% vs 68.2%, p< 0.01) (figure 1).

A moderate positive correlation was detected between BMI and WtHpR (r_s =0.454, p< 0.01). When cases were analysed within each sex the correlation was noted to be stronger in males than females (r_s = 0.543 vs 0.304, p< 0.01).

Conclusion: There is a high prevalence of abdominal obesity as assessed by WtHpR in axSpA, especially in females with axSpA. BMI can underestimate obesity in axSpA women, as the association between BMI and WtHpR is stronger in axSpA males. Use of WtHpR should be considered when screening for obesity in axSpA.

SESSION INFORMATION

Session Date: Monday, November 8, 2021

Session Title: Spondyloarthritis Including PsA – Diagnosis, Manifestations, & Outcomes III: Comorbidities, Extra-muskuloskeletal Manifestations, & Related Conditions (1304–1328)

Session Type: Poster Session C

Session Time: 8:30AM–10:30AM

Background/Purpose: Uveitis is the most common ocular manifestation of psoriatic arthritis (PsA). It has been described that uveitis in PsA tends to be insidious, chronic, posterior and bilateral onset, unlike uveitis in spondyloarthritis (SpA), which tends to be of sudden onset, acute course, unilateral and recurring. The use of TNF inhibitory agents (TNFi), especially monoclonal antibodies, has been shown to be effective in the prevention and treatment of refractory non-infectious uveitis.

In a large unselected series of patients with PsA, our objectives were to evaluate a) the epidemiology and clinical characteristics of uveitis associated with PsA, b) the differences between patients with and without uveitis and c)the relationship of uveitis with the biological treatment used.

Methods: Cross-sectional study of patients with PsA from a single referral hospital. They were classified according to the CASPAR criteria. Those with ocular manifestations were evaluated by expert ophthalmologists for the presence of uveitis. Demographic characteristics, clinical findings, complementary tests, presence of other extra-articular manifestations and treatment used were recorded.

Results: We studied 406 (202 women/204 men) patients with PsA; mean age of 46.3±12.3 years. The mean duration of the disease was 9.9±8.2 years.

Uveitis was observed in 20 of 406 (4.9%) patients (12 women/8 men); mean age of 43.1±14.5 years). Uveitis was characterized by being of acute onset (100%), anterior (80%), unilateral (80%) and recurrent (50%).

The comparison between patients with PsA who developed uveitis and those who did not is shown in the Table. The patients who present uveitis were characterized by a higher frequency of HLA-B27 (45%), sacroiliitis on MRI (25%) and ocular surface pathology (10%). The result of PsAID (Psoriatic Arthritis Impact of Disease) (median 5.9 [IQR 2.1-6.8]) and the BASFI index (Bath Ankylosing Spondylitis Functional Index) (median 4 [IQR 1.6-5]) was higher in patients with PsA and uveitis.

Table. General features of 406 patients with PsA. Comparison between patients with and without uveitis

	Overall (n=406)	Uveitis (n=20)	Non uveitis (n=386)	p value

Previous treatments				
Etanercept	31(7.6)	1(5)	30(7.8)	0.999
TNFi monoclonal antibodies	160(39.4)	12(60)	148(38.3)	0.053
Secukinumab	48(11.8)	1(5)	47(12.2)	0.158
Other	41(10.1)	1(5)	40(10.4)	0.708

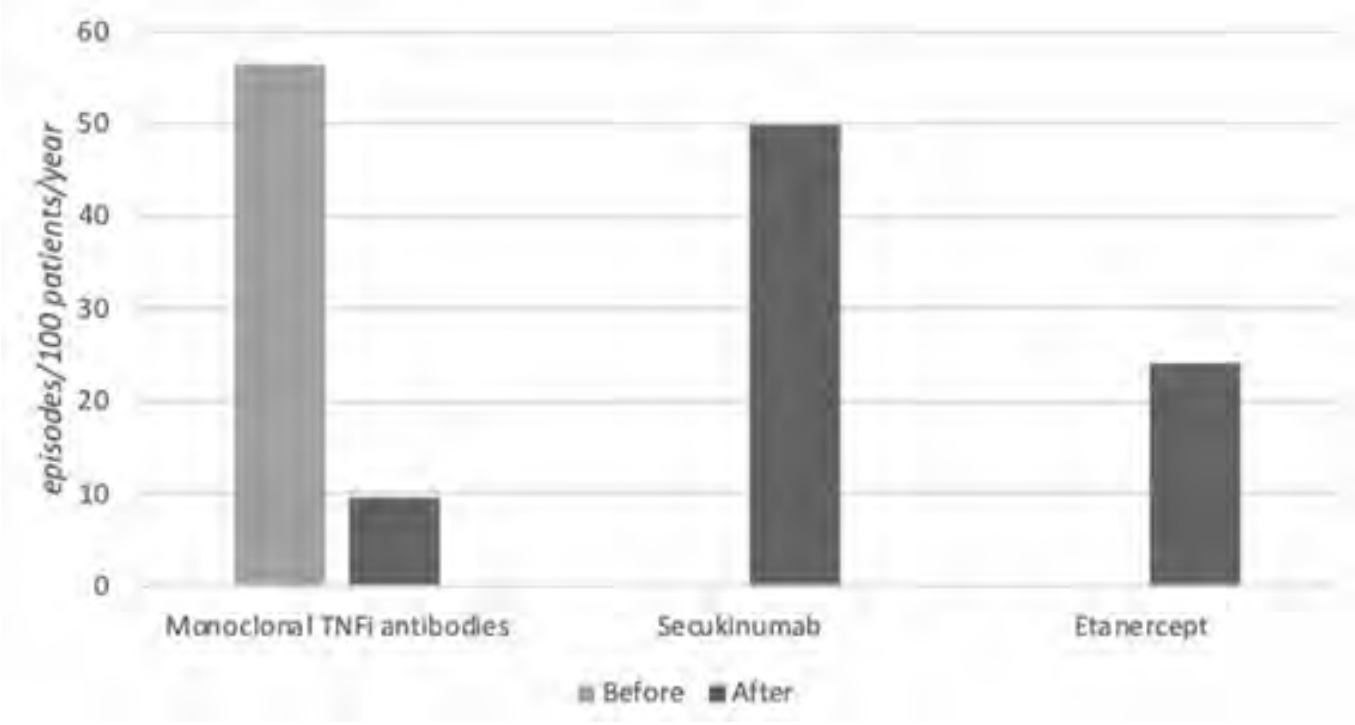

Figure. Uveitis incidence rate before and after biological therapy.

The incidence of uveitis prior to treatment with monoclonal antibodies TNFi and ETN was 56.3 and 6.03 episodes/ 100 patients/year respectively (Figure). Once the treatment was established, the incidence of uveitis in patients with monoclonal antibodies TNFi became 9.4 episodes/ 100 patients/ year while in those treated with ETN and SECU was 24.2 and 50 episodes/100 patients/year respectively.

Conclusion: In our study, the prevalence of uveitis in patients with PsA was 4.9%. The pattern was similar to that observed in axSpA with acute onset and anterior and unilateral pattern. Patients who developed uveitis more frequently presented HLA-B27 positivity, sacroiliitis in MRI and ocular surface pathology, in addition to a higher PsAID score and the BASFI index. The uveitis rate decreased with the monoclonal antibodies TNFi, while an increase was recorded with ETN or SECU.

SESSION INFORMATION

Session Date: Monday, November 8, 2021

Session Title: Spondyloarthritis Including PsA – Diagnosis, Manifestations, & Outcomes III: Comorbidities, Extra-muskuloskeletal Manifestations, & Related Conditions (1304–1328)

Session Type: Poster Session C

Session Time: 8:30AM–10:30AM

Background/Purpose: Uveitis is the most common extra-articular manifestation of axial spondyloarthritis (axSpA). It is characterized by sudden onset, acute, anterior and unilateral. The most widely used biological drugs for its treatment are TNF inhibitors (TNFi), especially monoclonal antibodies.

Our objectives were to evaluate a) epidemiological and clinical characteristics of patients with axSpA and uveitis, and b) the biological treatment received.

Methods: Cross-sectional study of patients with axSpA from a single referral hospital. They were diagnosed of axSpA according to the ASAS criteria. Demographic characteristics, clinical findings including extra-articular manifestations, and the treatment used were recorded. Those with ocular manifestations were evaluated by expert ophthalmologists for diagnosis and characterization of uveitis.

Results: We studied 301 patients with axSpA, 72.1% of them met New York criteria for Ankylosing Spondylitis (AS) and the remaining 27.9% met ASAS criteria for non-radiographic axSpA (nr-axSpA). 59.1% were male and the mean age was 52.16± 12.50 years. At the time of the study, 44 patients (14.6%) had developed at least one episode of uveitis (36 AS and 8 nr-axSpA). The uveitis pattern was anterior and acute (AAU) in all cases and 93% presented unilateral involvement.

The comparison of baseline characteristics between patients with axSpA with and without uveitis is shown in the Table. The group of patients with uveitis showed a higher delay in diagnosis (median [IQR]: 8.5[1-21] Vs 4[1-10], p=0.08) and a higher prevalence of HLA-B27 (84.1% Vs 59.5%, p=0.002).No differences were found in the other clinical characteristics collected (presence of peripheral arthritis, enthesitis and dactylitis throughout the disease, or BASDAI, BASFI or BASMI values at the time of the study). The presence of other extra-articular manifestations was also comparable in patients with and without AAU.

17 (38.6%) patients with AAU were treated with TNFi agents versus 115(44.7%) patients without AAU, with no differences between the diferents agents used. In both groups, the most widely used TNFi agents were Adalimumab,

Table. General baseline characteristics of 301 patients with axSpA.Comparison between patients with and without uveitis

Osteoporosis in Psoriatic Arthritis

Sara M. Rojas Herrera[1], Ignacio Braña Abascal[1], Maria Priego Fernanddez-Martos[1], Delia Fernandez Lozano[1], Lara M. Chaves Chaparro[1], Raul Veroz Gonzalez[1], Juan J. Aznar Sanchez[2] and Eugenio Chamizo Carmona[1], [1]Hospital de Mérida, Mérida, Spain, [2]Hospital de Mérida, Merida, Spain

SESSION INFORMATION

Session Date: Monday, November 8, 2021

Session Title: Spondyloarthritis Including PsA – Diagnosis, Manifestations, & Outcomes III: Comorbidities, Extra-muskuloskeletal Manifestations, & Related Conditions (1304–1328)

Session Type: Poster Session C

Session Time: 8:30AM–10:30AM

Background/Purpose: Osteoporosis (OP) is a frequently underestimated comorbidity in immune-mediated inflammatory diseases (IMIDs). Its association with IMIDs is worse characterized in Psoriatic Arthritis (PsA) than in rheumatoid arthritis (RA). The objective of the study was determine the densitometric values in lumbar spine (LS) and femoral neck (FN) of our cohort of PsA patients to estimate the frequency of OP and analyze the factors associated with a lower bone mineral density (BMD).

Methods: Cross-sectional study in patients (pts) with PsA from a monographic consultation of recent-onset PsA who were invited to perform a DXA densitometry (GELunar Prodigy®). SPSS25 was used for statistical analysis.

Results: 155 PsA pts was screened with DXA. Osteopenia was observed in 84/155 (54.2%) pts: femoral neck (FN) in 74/155 (47,7%) pts and lumbar spine (LS) in 51/152 (33,5%) pts (3 pts could not have lumbar spine determination by previous surgery). OP was observed in 19 (12.3%) pts: LS in 11/152 (7.2%), and FN in 11/155 (7.1%) pts. The

	Osteopenia			Osteoporosis (OP)			Femoral OP

25OHD3 < 20ng/dl	0,03	0,23	0,82	0,07	0,53	0,60	0,14	1,22	0,23
Age DMO (year)	0,37	2,64	0,01	0,15	1,02	0,31	0,10	0,78	0,44
Disease evolution (years)	0,26	2,05	0,04	0,12	0,92	0,36	-0,05	-0,40	0,69
Ischemic heart disease	0,05	0,39	0,70	0,29	2,08	0,42	0,38	3,17	0,002

mean (SD) age at DXA was 47.1 (12.9) years (y). The mean evolution time was 10.2y (6.2) from diagnosis to DXA; median 9y (6;13). OP, in general, and FN OP, were associated with age, but not with the average evolution time of PsA: OP 55.3y (10.0) vs 45.9y (12.8) (p=0.003) and NF OP 58.5y (10.2) vs 46.2y (12.7), (p=0.002). LS OP was not associated with any of the parameters studied. LS osteopenia was more frequent in women 32/76 (42.1%) than men 19/76 (25%) [OR 1,515 (1,020;2,249); p=0.026]. Hyperuricemic pts were less likely to have vertebral osteopenia (OR 2.525 (1.027;6.205) than non-hyperuricemic. Inflammatory bowel disease (IBD) was associated with LS osteopenia [OR 8.511 (0.926;78.247), p=0.044]. FN OP was more frequent in males 9/79 (11.4%) than females 2/76 (2.6%) OR=4.75 (0.99; 22.8) p(fisher)=0.057. We found association of FN OP with axial involvement [OR 3.882 (1.115;13.518); p=0.024], hypertension [OR 9,9 (2,055;47,689); p< 0.001], ischemic heart disease (IHD) [OR 7.657 (1.914;30.630), p< 0.001] and vitamin D deficiency (< 20ng/dl) [26/75 (16,8%) pts; OR 8.727 (0.921;82.691), p=0.046, but not with the rest of the PsA domains, comorbidities or cardiovascular risk factors (CVRF). Femoral osteopenia was only associated with hypertension but more weakly than FN OP. We found no association between the presence of OP and current or previous treatments. Pts who received DMARDs had a lower tendency to present osteopenia [OR 3.28 (0.98; 10.96), p=0.04]. Forty-three pts had received steroids, 141 DMARDs, 129 conventional syinthetic-DMARDs (122 methotrexate), 69 biological-DMARDs with a total of 119 cycles (mainly, TNFi) and 20 targeted synthetic-DMARDs. In the multivariate analysis, we found a positive correlation with OP and IHD (OR= 2.08; 0.42) as in femoral OP (OR=3.17; 0.002), and negative with hyperuricemia (p=0.002). Osteopenia is associated with age (OR=2.64; 0.01), axial involvement and time of disease evolution (not significant).

Conclusion: In our cohort, OP is more frequent in men, it is associated with age despite the time of evolution of the disease. Femoral OP is more frequent in patients with axial involvement, hypertension, heart ischemic disease and vitamin D deficiency.

Session Title: Spondyloarthritis Including PsA – Diagnosis, Manifestations, & Outcomes III: Comorbidities, Extra-muskuloskeletal Manifestations, & Related Conditions (1304–1328)

Session Type: Poster Session C

Session Time: 8:30AM–10:30AM

Background/Purpose: Psoriasis, a chronic immune-mediated skin disease affecting 2-4% of the US population, is increasingly recognized as a *systemic inflammatory disorder* associated with cardiometabolic and other comorbidities. Additionally, psoriasis frequently precedes the development of psoriatic arthritis (PsA) and among patients with psoriasis, certain comorbidities may be risk factors for development of PsA. The objectives of this study were to: 1) investigate the prevalence of comorbidities in an *incident* cohort of psoriasis patients compared to age- and

sex-matched controls, and 2) compare the prevalence of comorbidities in mild psoriasis with moderate to severe psoriasis at diagnosis.

Methods: A population-based incidence cohort of psoriasis subjects ≥18 years of age and first diagnosed between 2000 and 2010 was identified. Complete medical records of all potential psoriasis subjects were reviewed, and psoriasis was defined as a confirmatory diagnosis in the medical record, either by a dermatologist or a physician's

Table. Prevalence of 44 comorbidities in patients without and with psoriasis and in mild psoriasis compared to moderate/severe psoriasis at psoriasis incidence date. (* SMD of >0.1 signifies potentially meaningful difference)

	No Psoriasis (N=849)	Psoriasis (N=817)	*SMD PsO vs no PsO	Mild (N=120)	Moderate to Severe (N=561)	*SD mild vs mod/severe PsO
