SESSION INFORMATION

Session Date: Sunday, November 7, 2021

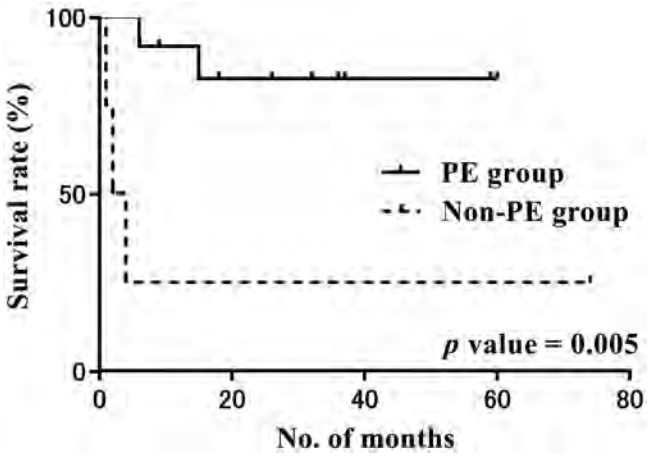
Session Title: Muscle Biology, Myositis & Myopathies Poster (0683–0722)

Session Type: Poster Session B

Session Time: 8:30AM–10:30AM

Background/Purpose: This study was extended report from our previous study that "Successful treatment of anti-MDA5 antibody-positive refractory interstitial lung disease with plasma exchange therapy" (Rheumatology (Oxford) 59(4):767-71, 2020). Anti-melanoma differentiation-associated gene 5 (MDA5) antibodies are a type of myositis-specific autoantibody. Anti-MDA5 antibodies are closely related to interstitial lung disease (ILD). Intensive immunosuppressive therapy with combination calcineurin inhibitor, and intravenous pulse cyclophosphamide was developed, because rapid progressive-ILD (RP-ILD) with anti-MDA5 antibodies is refractory and fatal. Intensive immunosuppressive therapy was shown to improve patient survival and prognosis. However, 20–30% of cases were still fatal, and we reported that the effectiveness of plasma exchange (PE) therapy for refractory RP-ILD. We aimed to reveal the effect of PE on survival in patients with refractory RP-ILD with anti-MDA5 antibodies.

Methods: We added 6 RP-ILD patients who were positive of anti-MDA5 antibodies with PE. Refractory RP-ILD was defined as radiological progression and/or oxygenation exacerbation within 4 weeks after intensive immunosuppressive



Kaplan-Meier curves for survivability comparing the overall PE group and non-PE group. The result of the log-rank test was P = 0.005. PE: plasma exchange therapy.

therapy. Study approval was obtained from the ethical committee of Juntendo University Hospital (approval number 17-274).

Results: The PE group included 6 former patients and 6 new patients such as 1 with newly refractory cases, 3 with relapsed refractory cases, and 2 with newly severe hypoxia cases that P/F ratio was less than 200. A total of 12 patients were included in the PE group. The 1-year survival rate of the PE group was significantly higher than that of the non-PE group (92% and 25%, respectively, P = 0.03). One patient who showed severe hypoxia at the start of treatment was improved from respiratory failure, but he died of candidemia due to vascular catheter infection.

Conclusion: We revealed the higher 1-year survival rate of PE for refractory or severe hypoxia RP-ILD in patients positive for anti-MDA5 antibodies. Physicians may consider that adding PE in refractory or severe hypoxia RP-ILD patients positive for anti-MDA5 antibodies.

Adipokines and Loss of Lean Mass Among Patients with Rheumatoid Arthritis

Joshua Baker[1], Jon Giles[2], Patrick Gould[1] and Patricia Katz[3], [1]University of Pennsylvania, Philadelphia, PA, [2]Columbia University Irving Medical Center, Division of Rheumatology, New York, NY, [3]University of California San Francisco, San Francisco, CA

SESSION INFORMATION

Session Date: Sunday, November 7, 2021
Session Title: Muscle Biology, Myositis & Myopathies Poster (0683–0722)
Session Type: Poster Session B
Session Time: 8:30AM–10:30AM

Background/Purpose: Rheumatoid arthritis (RA) is associated with loss of muscle mass and quality that can have significant impacts on physical functioning and quality of life. Adipokines are fat and muscle-secreted hormones that

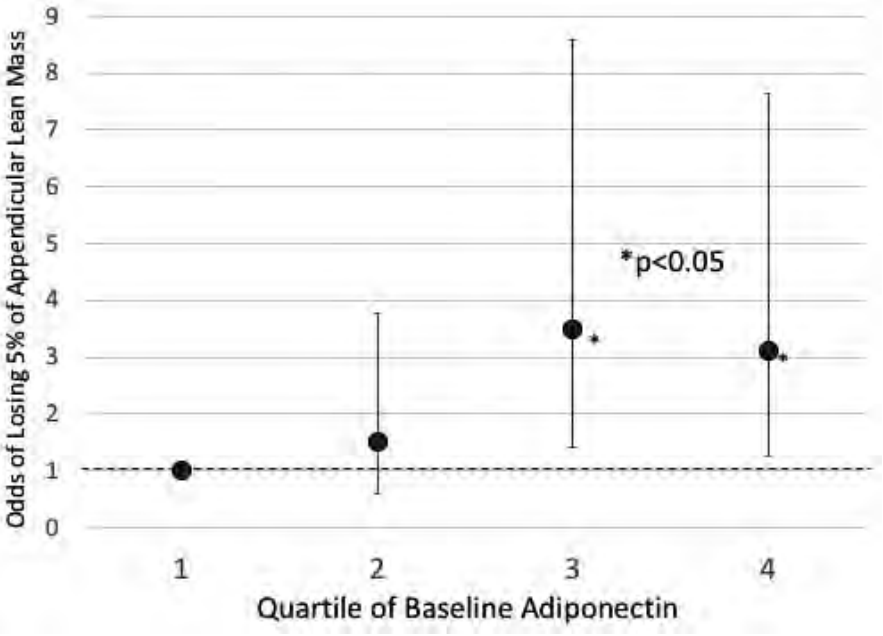

Figure. Adjusted odds of losing 5% of ALMI during follow-up by adiponectin quartile.

play a role in regulating metabolism and energy homeostasis and may play a role in the worsening of skeletal muscle deficits in RA. We determined whether adiponectin, leptin, and Fibroblast Growth Factor(FGF)-21 could predict significant declines in skeletal muscle mass over 2-3 years.

Methods: This study combined data from three longitudinal RA cohorts with assessments of whole-body dual-energy absorptiometry (DXA) measures including appendicular lean mass index (ALMI) and fat mass index (FMI). We

Table. Association between individual adipokines and their changes over follow-up and the adjusted odds of losing 5% of lean mass over follow-up

	Loss of 5% Lean Mass (individual adipokines)	
	OR (95% CI)	P
Baseline Adipokines*		
Adiponectin (per 1 SD)	1.55 (1.14, 2.49)	0.005
Leptin (per 1 SD)	0.82 (0.51, 1.30)	0.40
FGF-21 (per 1 SD)	1.82 (1.15, 2.88)	0.01
Change in Adipokines**		
Adiponectin (per 1 SD change)	2.36 (1.32, 4.23)	0.004
Leptin (per 1 SD change)	0.65 (0.37, 1.14)	0.13
FGF-21 (per 1 SD change)	0.67 (0.34, 1.35)	0.27

*Each adipokine is analyzed in a separate model and adjusted for age, sex, race, baseline ALMI, baseline FMI, study cohort, and follow-up time.
**as above and further adjusted for baseline adiponectin/leptin/FGF-21 levels.

defined a loss of lean mass as a decrease in ALMI of 5% or more and a loss of FMI as a decrease in FMI of 5% or more. Adiponectin, leptin, and FGF-21 were measured on stored samples. Values were log-adjusted and standardized so that one unit represents a 1 SD change in the exposure. Associations between adipokines at baseline and the change in adipokines during follow-up with long-term changes in ALMI and FMI were assessed using multivariable linear regression, adjusting for demographics, study cohort, and baseline body composition.

Results: A total of 75 (22%) out of 338 participants lost more than 5% of ALMI and 93 (28%) lost >5% of FMI by the time of their follow-up visit over a median (IQR) follow-up of 3 years (2, 3). Those who lost 5% of ALMI had higher adiponectin (per SD) levels at baseline [Mean (SD): 0.40 (1.10) v. -0.048 (1.06), p=0.001], but had similar levels of leptin [Mean (SD): 0.001 (1.04) v. 0.02 (0.96), p=0.87]. In a smaller cohort with FGF-21 levels, levels were higher (per SD) among the 31/159 (16%) who lost ALMI [Mean (SD): 0.28 (0.14) v. -0.17 (0.081), p=0.02]. A higher level of adiponectin (per 1 SD) was associated with a higher probability of losing 5% of ALMI (Figure 1). In multivariable models, participants with higher adiponectin levels had a significantly higher odds of losing 5% of ALMI [OR (per 1 SD): 1.55 (1.14, 2.10) p=0.005] (Table 1). Higher FGF-21 levels were also associated with a higher odds [OR: 1.82 (1.15, 2.88) p=0.01]. Leptin levels were not associated in similar models [OR (per 1 SD): 0.82 (0.51, 1.30), p=0.40]. In addition, after adjusting for baseline adiponectin levels, an increase in adiponectin during follow-up was associated with higher odds of losing 5% of ALMI [OR (per 1 SD change): 2.48 (1.37, 4.50), p=0.004]. Associations between adipokines and changes in ALMI were not attenuated by adjustment for C-Reactive Protein, pain scores, or results of the Health Assessment Questionnaire at baseline (not shown). Adipokines were not associated with loss of FMI.

Conclusion: Elevated adiponectin and FGF-21 levels as well as increasing levels of adiponectin are associated with declines in lean mass over long-term follow-up. These observations support the hypothesis that alterations in adipokines including elevations in adiponectin are associated with an adverse metabolic phenotype in patients with RA and may identify patients at risk of sarcopenia or cachexia. Further study is needed to determine whether elevations in adiponectin are associated with other long-term clinical outcomes in RA.

SESSION INFORMATION

Session Date: Sunday, November 7, 2021

Session Title: Muscle Biology, Myositis & Myopathies Poster (0683–0722)

Session Type: Poster Session B

Session Time: 8:30AM–10:30AM

Background/Purpose: Multiple diagnostic methods have been used to investigate muscle involvement in patients with idiopathic inflammatory myositis (IIM) such as electromyography (EMG) and muscle MRI. 18F-FDG PET-CT has been used to screen malignancy, and may also be beneficial in the investigation of myositis [1].

In this study, we aimed to evaluate the muscle involvement with PET – CT, which was performed for malignancy screening, and its association with clinical and laboratory parameters in patients with IIM.

Table 1: Comparison of PET-CT findings between patients with IIM and control group

Variables	IIM (n=34)	Control (n=14)	p value
Liver (SUV-max) (mean±SD; range)	3.1±1.2 (0.38-7.30	3.6±0.55 (2.6-4.6)	0.14
Mediastinum (SUV-max) (mean±SD; range)	2±0.85 (0.3-5.2)	2.1±0.36 (1.4-2.8)	0.7
Lumbar longus muscle (LLM) (SUV-max) (mean±SD; range)	1.28±0.6 (0.15-2.7)	1.13±0.3 (0.7-1.6)	0.4

Ɨ Fisher's exact test, *Man Whitney U test, **kappa test SD: Standard deviation, CK: Creatinine kinase, LDH: Lactate dehydrogenase, ESR: Erythrocyte sedimentation rate, CRP: C-reactive protein, MRI: Magnetic resonance imaging

Methods: IIM patients who fulfilled EULAR/ACR classification criteria and had PET-CT scans during the active phase of myositis included into the study. PET-CT scans of IIM patients and non-IIM patients with malignancy as controls were assessed retrospectively by two experienced nuclear medicine specialists and decisions were made by consensus. Positive PET-CT for myositis was defined as higher FDG muscle uptake compared to liver, mediastinal vascular structures (mediastinum) and lumbar longus muscle (LLM). Univariate and multivariate analysis were performed according to FDG uptake compared to mediastinum which was found to have higher diagnostic accuracy.

Results: One hundred and sixty IIM patients were screened and 34 patients (of 64.7 % female) whose PET-CT results were available and 14 non-IIM patients included into the study. Mean age of the IIM patients was 55±13 (25-85). Median disease duration of IIM patients was 12 months. Liver, mediastinum and LLM uptakes were similar in patients with IIM and non-IIM groups; higher muscle uptake was observed in proximal and distal upper ($p=0.001$, $p< 0.001$, respectively) and lower extremity ($p=0.003$, $p< 0.001$, respectively) in patients with IIM compared to non-IIM. Sensi-

tivity and specificity of positive FDG muscle uptake were 37.1 % and 100 %, 65.7 % and 92.9 %, 91.4 % and 7.1 % compared to liver, mediastinum and LLM uptakes, respectively (Table 1).

In univariate analysis; increased CK, LDH and CRP levels (p=0.026, p=0.028 and p=0.032 respectively) and positive muscle MRI (p=0.04; OR:4.1) were associated with PET-CT positivity. There was significant agreement between PET-CT positivity and muscle MRI findings (κ=0.412; p=0.04) (Table 2). In multivariate analysis, high baseline CRP (p=0.017, CI 95%: 1.03-1.36, OR:1.18) and LDH (p=0.029, CI 95%: 1.001-1.017, OR:1.01) levels were associated with PET-CT positivity. Baseline muscle strength (r=-0.411, p=0.04) was negatively correlated with muscle FDG uptake.

Conclusion: In patients with active IIM, median muscle FDG uptake with PET-CT was higher compared to non-IIM and significantly increased compared to liver and mediastinum. Muscle FDG values compared to mediastinum had the highest sensitivity. PET-CT findings are correlated with biomarkers of inflammation and clinical activity. PET-CT may be used for the evaluation of extent and activity in patients with IIM although further prospective research is needed.

Abstract Number: 0687

Clinical Features and Prognosis of a Large North American Cohort of Adult MDA5+ Dermatomyositis

Christopher Mecoli[1], Eleni Tiniakou[2], William Kelly[2], Jemima Albayda[2], Julie Paik[2], Brittany Adler[2], Andrew Mammen[3], Cheng Ting Lin[1], Sonye Danoff[4], Livia Casciola-Rosen[5] and Lisa Christopher-Stine[2], [1]Johns Hopkins University School of Medicine, Baltimore, MD, [2]Johns Hopkins University, Baltimore, MD, [3]National Institutes of Health, Bethesda, MD, [4]Johns Hopkins Medicine, Baltimore, MD, [5]Johns Hopkins, Baltimore, MD

SESSION INFORMATION
Session Date: Sunday, November 7, 2021
Session Title: Muscle Biology, Myositis & Myopathies Poster (0683–0722)
Session Type: Poster Session B
Session Time: 8:30AM–10:30AM

Background/Purpose: We describe a single-center North American adult cohort of MDA5-positive DM, with emphasis on the subgroup of patients that experience drug-free long-term remission.

Methods: From our entire IIM cohort, 52 patients were included that (1) Met either Bohan and Peter or 2017 American College of Rheumatology/European League Against Rheumatism classification criteria for dermatomyositis and (2) Were positive for anti-MDA5 autoantibodies by two methods: Euroimmun line blot (16 Ag IgG, Germany) and ELISA (MBL, Japan). All patients underwent structured telephone research interviews in 2019-2020 to update clinical status including symptoms and DM-specific therapies. Remission was defined as being off all immunosuppressive and immunomodulatory therapies > 1 year while remaining asymptomatic.

Results: Demographic and disease characteristics for the 52 MDA5-positive DM patients can be found in Table 1. Thirty-eight (73%) of the patients were women with a median age at DM symptom-onset of 47 (IQR 40-54). Twenty-five (48%) percent of patients were white, 16 (30%) were African American, 3 (6%) were Asian and 8 (16%) were other/declined to provide race. All patients had either Heliotrope or Gottron's sign, 29 (56%) had synovitis, and 18 (35%) had calcinosis. The majority of patients had interstitial lung disease, defined by fibrotic changes on HRCT (83%). With

Table 1. Demographic and Disease Characteristics of MDA5-positive DM Cohort, as well as those who experienced clinical remission. Physical examination findings are reported as ever/never recorded throughout longitudinal follow-up

	Total N=51	Chronic Course (n=42) Median (IQR)	Remission (n=9) Median (IQR)	p-value

Nadir TLC over longitudinal follow-up	68.5 (59.0-79.0)	70.0 (59.0-80.0)	61.0 (58.0-72.5)	0.320
Nadir DLCO over longitudinal follow-up	62.5 (45.5-78.5)	62.0 (45.5-79.5)	68.0 (51.0-78.0)	0.600
Ulcerations (composite) (digital ulcers, cutaneous ulcers, and mucosal ulcers)	67%	71%	44%	0.140
Ischemic digital ulcers on examination or pits	31%	31%	33%	1.000
Mucosal ulcerations (tongue, larynx, Vocal cords, mouth, NOT attributable to MTX or H!	35%	34%	43%	0.690
Cutaneous ulcerations on skin (hands or rest of body)	63%	67%	44%	0.270
Required intubation for rapidly progressive ILD (excludes elective/BAL/bx)	12%	14%	0%	0.570
Spontaneous pneumothorax or pneumomediastinum	8%	10%	0%	1.000
Proximal muscle weakness on examination	73%	79%	44%	0.093
Received pulse dose solumedrol	35%	40%	11%	0.130
Death	10%	12%	0%	0.570

regards to disease severity, 35% of patients required pulse-dose solumedrol at some point in their treatment course, 8% experienced a spontaneous pneumothorax or pneumomediastinum, 12% required intubation, and 10% died.

Over longitudinal follow-up, the median of which was 3.5 years (IQR 1.3-5.9), a total of 9 patients (18%) achieved clinical remission. One patient lost to follow-up could not be reached to ascertain clinical status. For the 9 patients that achieved clinical remission, the median time from DM-symptom onset to clinical remission was 4 years (IQR 2.4-5.0, range 1.8-5.6). The median duration of remission at the time of this study was 3.5 years (range 1.4-7.8). There were no demographic or disease characteristics that were significantly associated with clinical remission. There was no association between baseline MDA5 titer as obtained by MBL ELISA and clinical remission (median MBL MDA5 139 vs 140 units, Wilcoxon rank sum p=0.82). In patients who went into remission, there was no clear association with receiving more immunosuppression: A history of combination therapy use was equally likely in remission and non-remission groups, with a median number of concurrent medications of 3 throughout follow-up. Similarly, patients who went into remission had the same interval between DM-symptom onset to 1st immune-suppressing medication prescribed (median 0.25 years vs 0.25 years, rank sum p=0.185).

Conclusion: In a single center, tertiary referral population of MDA5+ DM, the largest North American cohort reported to date, approximately 20% of patients experienced long-term drug-free remission. No demographic, clinical sign/

symptom or laboratory factors were associated with remission. Future studies investigating other candidate biomarkers are warranted to identify this patient subgroup.

Background/Purpose: Whether the likelihood of a cancer diagnosis in idiopathic inflammatory myopathy (IIM) patients differs by autoantibody type is not fully characterized. To inform cancer surveillance in IIM patients, in a large, tertiary referral IIM cohort, we determined whether cancer occurrence differs by autoantibody type from that expected based on the general US population.

Methods: Patients enrolled in our myositis cohort was retrospectively reviewed from 2007-2020 for adult patients who met one of these criteria: (i) Probable or definite DM/PM by Peter and Bohan, (ii) IMNM by the 2003 ENMC Criteria, (iii) Classic DM rash (Gottron's/heliotrope) and consistent histopathology on skin biopsy. Myositis specific and associated autoantibodies were determined systematically in our research lab using Euroimmun line blot (16 Ag IgG), ELISA (Mi2 and TIF1y by MBL, HMGCR by INOVA Diagnostics), and in-house immunoprecipitation (NXP2). Three time windows were analyzed: cohort enrollment onward, IIM symptom-onset onward, and within 3 years of IIM symptom onset (-3 to +3 years). The Surveillance, Epidemiology, and End Results (SEER) registry was used to compare the observed number of cancers to the expected number of cancers in the general population, adjusted for calendar year, age, sex, and race. Standardized prevalence ratios of cancer (SPR) – the observed/expected prevalence of cancer over an interval of time - were determined.

Results: 1174 patients, including 201 (17%) with a history of cancer, were studied. Median (IQR) time from IIM symptom onset to enrollment was 1.68 (0.75-3.8) yrs. From enrollment onward (5.21 [2.64-8.64] yrs; 89 diagnosed with cancer), patients with TIF1y autoantibodies (>6 units) had higher than expected cancer period prevalence (SPR=1.73, 95%CI 1.12-2.56), whereas patients negative for anti-TIF1y did not (SPR=1.04, 95%CI 0.68-1.51) [Table 1]. From IIM symptom onset onward (7.95 [4.92-11.86] yrs; 131 diagnosed with cancer, 25.2% within 0-1 yr, 28.2%

Table 3. Number of IIM patients, person-years of follow-up, and cancer standardized prevalence ratio in each autoantibody stratum. Time period is -3 to +3 years surrounding IIM symptom onset. TIF1γ was considered positive by two different MBL thresholds: >32 units per manufacturer, and >6 units (4 standard deviations above healthy control cohort mean)

>1-3 yrs, 14.5% >3-5 yrs, 32.1% >5 yrs), patients with anti-TIF1γ had higher than expected period prevalence of cancer, mainly breast (SPR=2.95, 95%CI 1.69-4.70) and ovarian (SPR=16.63, 95%CI 6.10-36.19). Patients with anti-SAE also had higher than expected cancer period prevalence (SPR=4.04, 95%CI 1.48-8.79). Patients with anti-Mi2 had higher than expected period prevalence of gastrointestinal cancers (SPR=6.03, 95%CI 1.24-17.61) [Table 2]. Within 3 yrs of IIM symptom onset (93 diagnosed with cancer), patients with anti-TIF1γ had higher than expected period prevalence of breast and ovarian cancer [Table 3]. Patients with DM autoantibodies (Mi2, SAE, or NXP2) had higher than expected cancer period prevalence.

Conclusion: In this tertiary referral center cohort, anti-TIF1γ was associated with higher occurrence of breast and ovarian cancers. Other DM-specific autoantibodies (Mi2, SAE, or NXP2) were associated with higher cancer occurrence. No cancer association (positive or negative) was observed for antisynthetase antibodies. These data suggest that intensive cancer surveillance is not needed in all IIM patients, and that autoantibody type may inform cancer occurrence, site and timing. Funded in part by NIAMS K23AR075898.

SESSION INFORMATION
Session Date: Sunday, November 7, 2021
Session Title: Muscle Biology, Myositis & Myopathies Poster (0683–0722)
Session Type: Poster Session B
Session Time: 8:30AM–10:30AM

Background/Purpose: Previous epidemiologic studies defined dermatomyositis (DM) using international codes of diseases (ICD) codes or Bohan & Peter 1975 criteria, and most were not population-based. Therefore, we aimed to determine the population-based incidence, prevalence, and mortality of DM, all using the new European League Against Rheumatism (EULAR)/American College of Rheumatology (ACR) 2017 DM classification criteria to define patients with DM.

Methods: This population-based cohort study included incident DM from 1/1/1995 and 12/31/2019 among all residents in a single geographical location. We used ICD codes for DM (710.3, M33.0-1, M33.9) and polymyositis (710.4, M33.2) to identify individuals with possible DM, and manually reviewed all to determine if they met criteria for DM by EULAR/ACR criteria (primary), rheumatologist/dermatologist physician diagnosis, and/or Bohan & Peter 1975 criteria. We defined index date of DM as date of EULAR/ACR 2017 criteria fulfilment. For incidence and prevalence, we age- and sex-adjusted our estimates to the United States White year 2000 population and provided 95% confidence intervals (CI). We estimated prevalence on 1/1/2015. For mortality calculations, we compared the survival of our cohort to expected survival rates from local life tables by age, sex, and year using standardized mortality ratios.

Table 1. Age- and sex-specific dermatomyositis incidence rates from 1995 to 2019

	Female		Male		Total	
Age	N	Rate (per 100,000)	N	Rate (per 100,000)	N	Rate (per 100,000)
18-29	1	0.29	0	0.0	1	0.2
30-39	4	1.5	1	0.4	5	0.9
40-49	4	1.6	0	0.0	4	0.8

80+	4	5.1	0	0.0	4	3.2
Total	26	1.8 (1.2,2.6)*	3	0.2 (0.0,0.5)*	29	1.1 (0.7,1.5)**

*Age-adjusted to the US White 2000 population
**Age- and sex-adjusted to the US White 2000 population

Table 2. Age- and sex-specific dermatomyositis prevalence rates on 1 January 2015

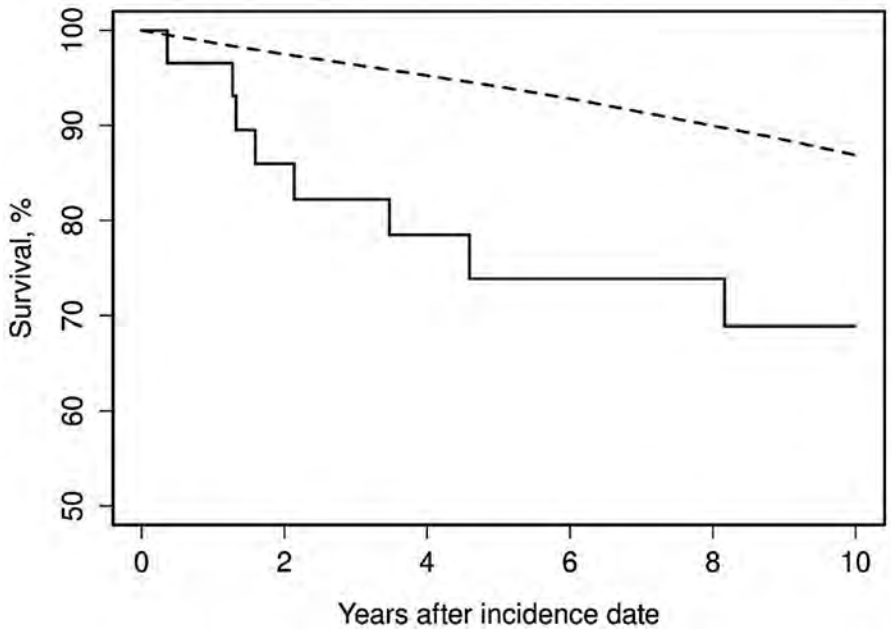
	Female		Male		Total	
Age	N	Rate (per 100,000)	N	Rate (per 100,000)	N	Rate (per 100,000)
18-29	0	0	0	0	0	0
30-39	1	9	0	0	1	4
40-49	2	22	0	0	2	11
50-59	2	18	1	10	3	14
60-69	2	25	1	14	3	20
70-79	4	81	0	0	4	44
80+	2	56	0	0	2	34
Total	13	21 (10,33)*	2	3.0 (0,7.2)*	15	13 (6,20)**

*Age-adjusted to the US White 2000 population

**Age- and sex-adjusted to the US White 2000 population

Results: We identified 40 cases of verified DM meeting at least one of the three DM criteria. Of those, 29 cases were incident DM in the study geographical location from 1995 to 2019 (mean age 57 years, 90% female). Median follow-up time was 8.2 years with interquartile range (IQR) 3.5 to 16.3 years. Of the 29, 17 (59%) had clinically myopathic DM, and 12 (41%) had clinically amyopathic DM (CADM). After age- and sex-adjusting to the US White 2000 population, the overall incidence of DM was 1.1 (95% CI 0.7 to 1.5) per 100,000 person-years (Table 1), and prevalence was 13 (95% CI 6 to 20) per 100,000 (Table 2). During the study period, 6 individuals with myopathic DM and 3 with CADM died (overall 10-year survival 69%; 95% CI 48-96%). Mortality of this DM cohort was higher than expected for their age-, sex-, and year-matched peers (Figure 1). The standardized mortality ratio was significantly elevated among the myopathic DM cases (3.1, 95% CI 1.1 to 6.8) but not CADM cases (1.1, 95% CI 0.2 to 3.3).

Conclusion: This population-based study using validated DM classification criteria found incidence and prevalence on the higher end of previous reports. Though confidence intervals were wide, mortality was significantly elevated for myopathic DM but not for CADM.



Overall survival of residents with incident dermatomyositis in 1995-2019 compared to expected rates from local lifetables

Impact of Achieving 2016 ACR/EULAR Response Criteria on Patient Centered Outcome Measures in Myositis

Didem Saygin[1], Siamak Moghadam-Kia[2], Chester Oddis[2], Dana Ascherman[2], Nicole Neiman[2], Diane Koontz[2] and Rohit Aggarwal[2], [1]University of Chicago, Chicago, IL, [2]University of Pittsburgh, Pittsburgh, PA

SESSION INFORMATION
Session Date: Sunday, November 7, 2021
Session Title: Muscle Biology, Myositis & Myopathies Poster (0683–0722)
Session Type: Poster Session B
Session Time: 8:30AM–10:30AM

Background/Purpose: The 2016 ACR/EULAR Myositis Response Criteria represent a composite measure that is increasingly being used as a primary end point in myositis clinical trials. The total improvement score (TIS) is calculated using differentially-weighted changes in six myositis core set measures, with thresholds for minimal, moderate and major improvement. It is unclear if achievement of these improvement levels truly reflects changes in symptoms, physical function, and physical activity in myositis patients. In this study, we examined the impact of achieving ACR-EULAR response criteria on patient-centered outcome measures.

Methods: Myositis patients were consecutively enrolled in an observational study with baseline, 3- and 6-month visits where six core set measures [extra-muscular, patient global, and physician global disease activity, manual muscle testing, HAQ-DI, and creatine kinase levels] were evaluated and TIS was calculated for each visit (https://www.niehs.nih.gov/research/resources/imacs/response_criteria/adult.html). The patient centered outcome measures included fatigue (VAS, SF-36), pain (VAS, SF-36), muscle strength (dynamometry), patient reported physical function (PROMIS PF-20, SF-36), task oriented physical function tests [sit-to-stand, timed up-and-go, and six-min walk test] and physical activity (Actigraph). Wilcoxon signed-rank test was used to assess significance of change in outcome measures over 3- and 6-months. Relative changes in outcome measures were compared between patients with improvement vs. those without improvement by using Mann-Whitney U test. Spearman correlation was used for correlations between TIS and changes in specified outcome measures.

Results: Fifty myositis patients were enrolled [mean age: 52, 60% female, 94% white], including 6 PM, 24 DM, 9 necrotizing myopathy and 11 with anti-synthetase syndrome. As per ACR/EULAR criteria, 22 patients had TIS scores satisfying criteria for improvement (13 minimal, 7 moderate, 2 major) at 3-months. Patient centered outcome measures including fatigue, pain, muscle strength, patient reported, and task oriented physical function measures demonstrated significantly greater changes in patients who met ACR/EULAR response criteria of at least minimal improvement compared to those who did not (Table 1). TIS correlated moderately-strongly with relative changes in most patient-centered outcome measures (Table 2). Similar results were noted at 6-months (n=39). Percentage agreement of improvement per TIS was 62% with patient-reported improvement and 90% with physician-reported improvement at 6-months. Patients who had at least minimal improvement also demonstrated significant improvement in pain, fatigue, muscle strength, PROMIS-PF, and task-oriented physical function tests over 6-months.

Vector magnitude per minute	-13.4 [(-27.5) – 0.7]	1.3 [(-10.9) – 34.7]	0.02

Conclusion: Achieving improvement using the ACR/EULAR myositis response criteria was accompanied by significant improvement in several patient centered outcome measures including fatigue, pain, muscle strength, physical function, and physical activity. Our results reinforce the validity of the ACR/EULAR myositis response criteria and support their use as a clinically meaningful metric of improvement.

esis and be used as biomarkers for prognostication, monitoring disease activity, and treatment response. We aimed to identify serum cytokine profiles of patients with active disease as compared to patients in remission and healthy controls, and explored correlations of these cytokines with clinical myositis outcome measures.

Methods: This was a prospective study of 3 clinical groups: (1) myositis patients with active disease, (2) patients in remission, and (3) healthy controls. All myositis patients fulfilled the Bohan-Peter criteria for DM/PM. Active disease was defined as requiring escalation of therapy within 6-months of screening. There were 3 study visits at baseline, 3- and 6-months. Plasma concentrations (pg/l) of 51 cytokines/chemokines/MMPs were obtained by utilizing a bead-based multiplex cytokine assay (Luminex). Physician- and patient-reported clinical outcome measures, functional measures, and creatine kinase levels were obtained for all the patients at each visit. T-test and false discovery rate for baseline differences as well as LASSO and random forest models were utilized to identify markers that best discriminate patients from controls, and patients with active disease from those in remission. GeneOntology was used for pathway analysis. Spearman correlation was used to assess correlations between cytokine levels and clinical outcome measures.

Results: 11 myositis patients in remission, 21 with active disease (including 10 enrolled in the open label trial of repository corticotropin injection) and 10 healthy controls were included in the study (Table 1). Results of the T-test,

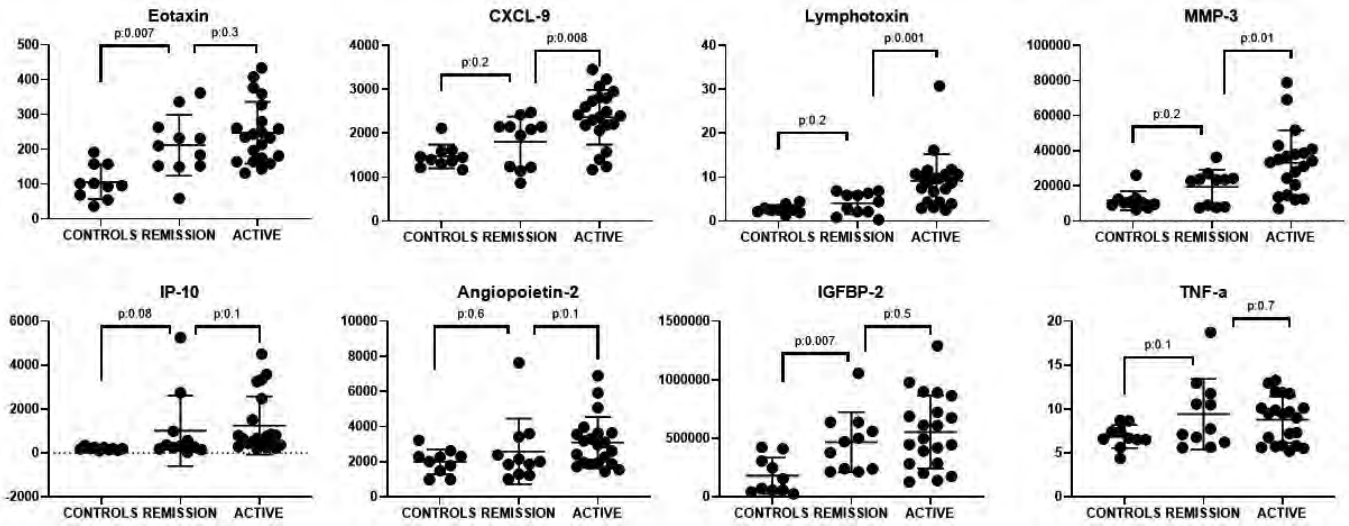

Figure 1. Distribution of cytokines/chemokine concentrations (pg/ml) among healthy controls, myositis patients with active disease and in remission.

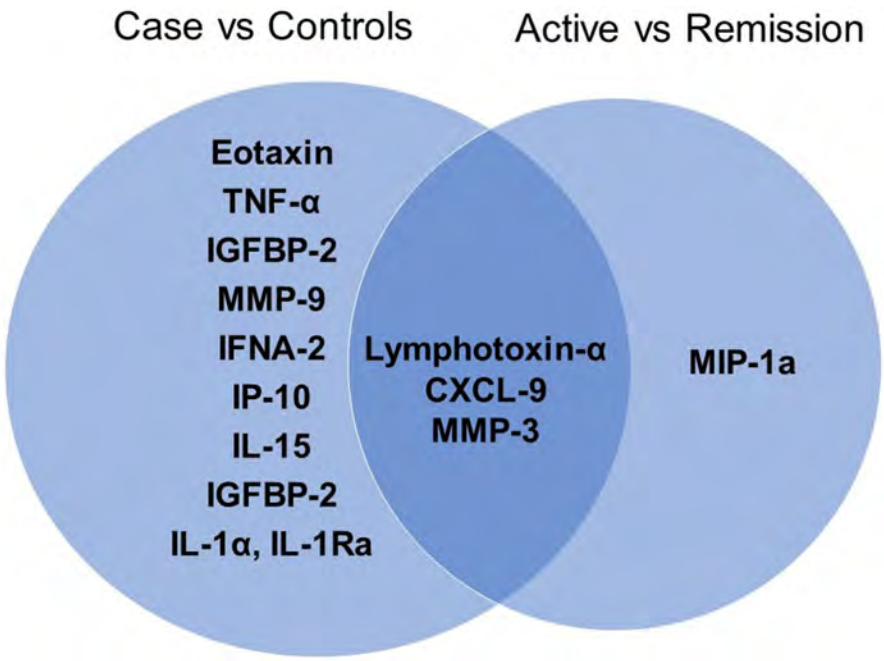

Figure 2. Upregulated cytokines that best differentiate cases from controls and patients with active disease from those in remission at baseline.

LASSO and random forest models revealed similar results. Myositis patients had elevated levels of chemokines that attract eosinophils (eotaxin) and dendritic cells, NK cells, cytotoxic T cells and monocytes/macrophages (CXCL-9, IP-10), cytokines that drive T-helper 1 responses (TNF-a, IL-1a, IL-1Ra, lymphotoxin-a, IFNA-2, IL-15), matrix degrading enzymes (MMP-3 and -9), and IGFBP-2 compared to healthy controls (Figure 1,2). Myositis patients with active disease had higher levels of lymphotoxin-a, CXCL-9, MIP-1b and MMP-3 than patients in remission. The pathways related to increased levels of these cytokines include chronic inflammatory responses, regulation of IL-1 mediated signaling, myoblast fusion, and tyrosine phosphorylation of STAT proteins. Eotaxin and CXCL-9 correlated with cutaneous and extramuscular global disease activity, IP-10 corelated with manual muscle strength test, and IL-1 correlated with HAQ as well as functional tests.

Conclusion: We identified key cytokines and chemokines that distinguish myositis patients from healthy controls as well as different disease activity states. Some cytokines correlated with clinical outcome measures, suggesting their potential use as biomarkers. Longitudinal analysis for the comparative changes in key cytokines and chemokines among different groups is currently ongoing. Larger longitudinal studies are needed to validate our findings.

Immunophenotyping of Inclusion Body Myositis Blood T Cells: Pathogenic and Biomarker Implications

Namita Goyal[1], Jonathan Cauchi[1], Tyler Irani[1], Nadia Araujo[1], Leo Wang[2], Marie Wencel[1], Vivian Li[3], **Steven Greenberg**[4] and Tahseen Mozaffar[1], [1]University of California Irvine, Irvine, CA, [2]University of Washington, Seattle, WA, [3]University of California, Irvine, CA, [4]Brigham and Women's Hospital Department of Neurology, Boston, MA

SESSION INFORMATION
Session Date: Sunday, November 7, 2021
Session Title: Muscle Biology, Myositis & Myopathies Poster (0683–0722)
Session Type: Poster Session B
Session Time: 8:30AM–10:30AM

Background/Purpose: The recent discovery of highly differentiated, killer cell lectin-like receptor subfamily G member 1 (KLRG1)+ T cells in the muscle of inclusion body myositis (IBM) patients raises the potential of targeting KLRG1 for therapeutic intervention. High-resolution mapping of blood KLRG1+ T cells and the broader T cell compartment of IBM patients is lacking. Here, we report the deep immunophenotyping of IBM blood T cell compartments and the relationship of derived biomarkers to IBM diagnosis, disease duration, and disease severity.

Methods: Patients providing informed consent who met the European Neuromuscular Centre (ENMC) criteria for clinically defined or probable IBM were included. Functional data and quality of life questionnaires were collected. Serological testing for NT5C1A antibodies and analysis of markers of T cell and NK subsets including KLRG1 isolated from peripheral blood through multiplex flow cytometry were done and compared with data from age-matched healthy donors.

Results: Data were obtained from 51 IBM patients and 19 healthy donors. A population of KLRG1+ T effector memory (TEM) and T effector memory re-expressing CD45RA (TEMRA) cells was expanded in both the CD4+ and CD8+ T cell subpopulations of IBM patients (Figure 1). KLRG1 expression in CD8+ T cells increased with T cell differentiation with the lowest levels in naïve T cells and highest in highly differentiated TEMRA and CD56+CD8+ T cells in IBM. The CD8+ TEMRA and KLRG1+ CD8+ TEMRA proportions were not associated with IBM disease severity, but modestly positively associated with disease duration. The KLRG1+CD4+ cells in IBM patients vs healthy controls had high

Table 1. Diagnostic performance of blood biomarkers of IBM

Biomarker	AUC	p-value
CD4% of CD3	0.70	0.0078

KLRG1+ % of NK	0.68	0.0191

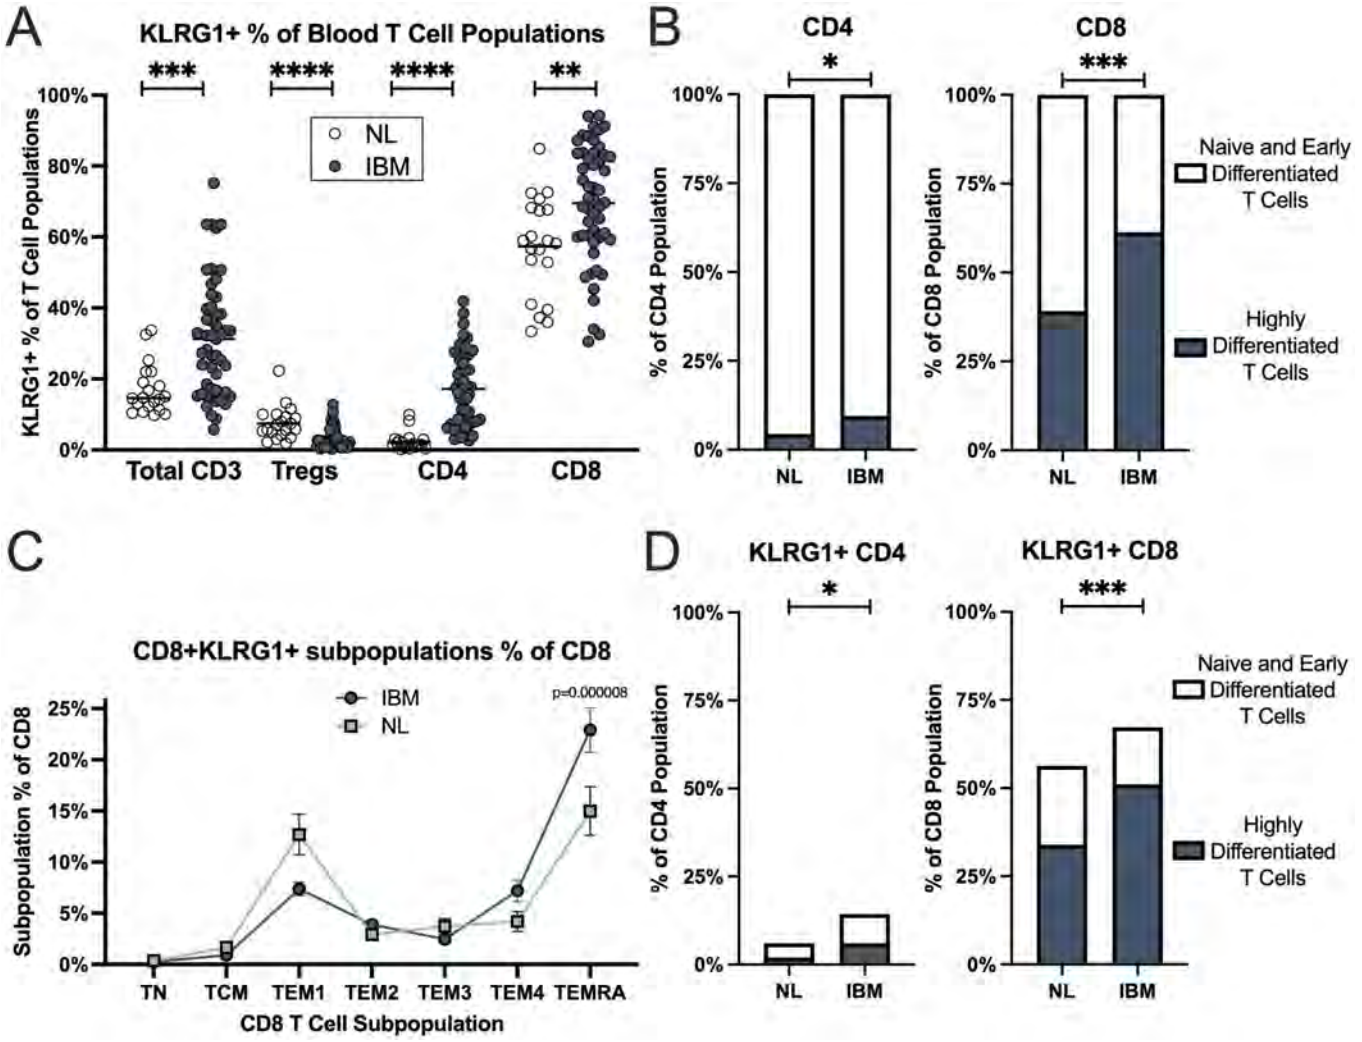

Figure 1. Skewed distribution of the blood T cell population in IBM towards highly differentiated CD8+ cytotoxic T cells. (A) Expansion of the KLRG1+ populations among total CD3+ T cells, Tregs, CD4+ T cells, and CD8+ T cells. (B) The proportion of blood naïve and early differentiated T cells (CD57-CD28+) and heterogenous highly differentiated T cells (CD57-CD28-; CD57+CD28-; CD57+CD28+) among CD4+ Tconv and CD8+ T cells. (C) KLRG1 expansion within and CD8+ TEM4 and TEMRA populations. (D) Expansion of the KLRG1+ T cell population lies largely within the highly differentiated compartments.

diagnostic performance (area under the curve=0.96; p< 0.0001) (Table 1). Minimal KLRG1 expression was present on regulatory T cells (3%) and no apparent alterations in NK cell phenotypes were identified in IBM.

Conclusion: Our findings reveal an expansion of blood KLRG1+ CD4+ and CD8+ TEMRA and TEM cells in IBM. Lack of association with disease activity suggests these cells may have a pathogenic role throughout the entire disease course. Measurement of these cells potentially allows for new blood diagnostic biomarkers.

Abstract Number: 0693

Discovery of Antigen Specific CD4+ T Cells in Anti-HMGCR-positive Immune Mediated Necrotizing Myopathy

Eleni Tiniakou[1], Andrew Mammen[2] and Erika Darrah[1], [1]Johns Hopkins University, Baltimore, MD, [2]National Institutes of Health, Bethesda, MD

SESSION INFORMATION
Session Date: Sunday, November 7, 2021
Session Title: Muscle Biology, Myositis & Myopathies Poster (0683–0722)
Session Type: Poster Session B
Session Time: 8:30AM–10:30AM

Background/Purpose: Anti-3-hydroxy-3-methylglutaryl coenzyme A reductase (HMGCR)-positive immune mediated necrotizing myopathy (anti-HMGCR+ IMNM) is a unique myopathy characterized by IgG autoantibodies against HMGCR and a strong association with a specific HLA class II allele (*HLA-DRB*1*11:01). Although this implicates HMGCR-specific CD4+ T cells in disease pathogenesis, no such cells have been identified thus far. In this study, we aimed to define HMGCR T cell epitopes using a natural antigen processing assay (NAPA).

Methods: Monocyte-derived dendritic cells (MoDCs) from 6 patients with anti-HMGCR+ IMNM were incubated with the C-terminal portion of HMGCR protein (amino acids 340-888) and presented peptides were identified using NAPA. Briefly, HLA-DR/peptide complexes were isolated by immunoprecipitation, and bound HMGCR peptides were sequenced by mass spectrometry. HMGCR peptides corresponding to the putative CD4+ T cell epitopes were synthesized and used to stimulate peripheral blood mononuclear cells (PBMCs) from 6 patients with anti-HMGCR+ IMNM and 6 patients with dermatomyositis, as negative controls. HMGCR-reactive CD4+ T cells were identified by flow cytometry based on activation status (CD154 upregulation).

Results: A total of 7 different naturally processed HMGCR peptides were identified using NAPA (Table 1). The number of distinct peptides presented per patient ranged from 1 to 5, with 5 epitopes being presented by at least two patients. All naturally presented HMGCR peptides elicited robust CD4+ T cell responses in the 6 anti-HMGCR+ IMNM

Table 1. Naturally processed HMGCR peptides identified by mass spectrometry. The naturally processed HMGCR peptides presented by each patient are indicated (+ = detected, - = not detected my mass spectrometry)

HMGCR+ Patient ID	1	2	3	4	5	6	7	#Peptides
9184	-	-	-	+	-	+	-	2
11054	-	+	-	+	-	-	+	3
12133	-	-	+	+	+	+	-	4
12168	+	+	-	+	+	-	+	5
13125	-	-	-	-	+	-	-	1
16024	-	-	-	+	-	+	-	2
#Patients	**1**	**2**	**1**	**5**	**3**	**3**	**2**	

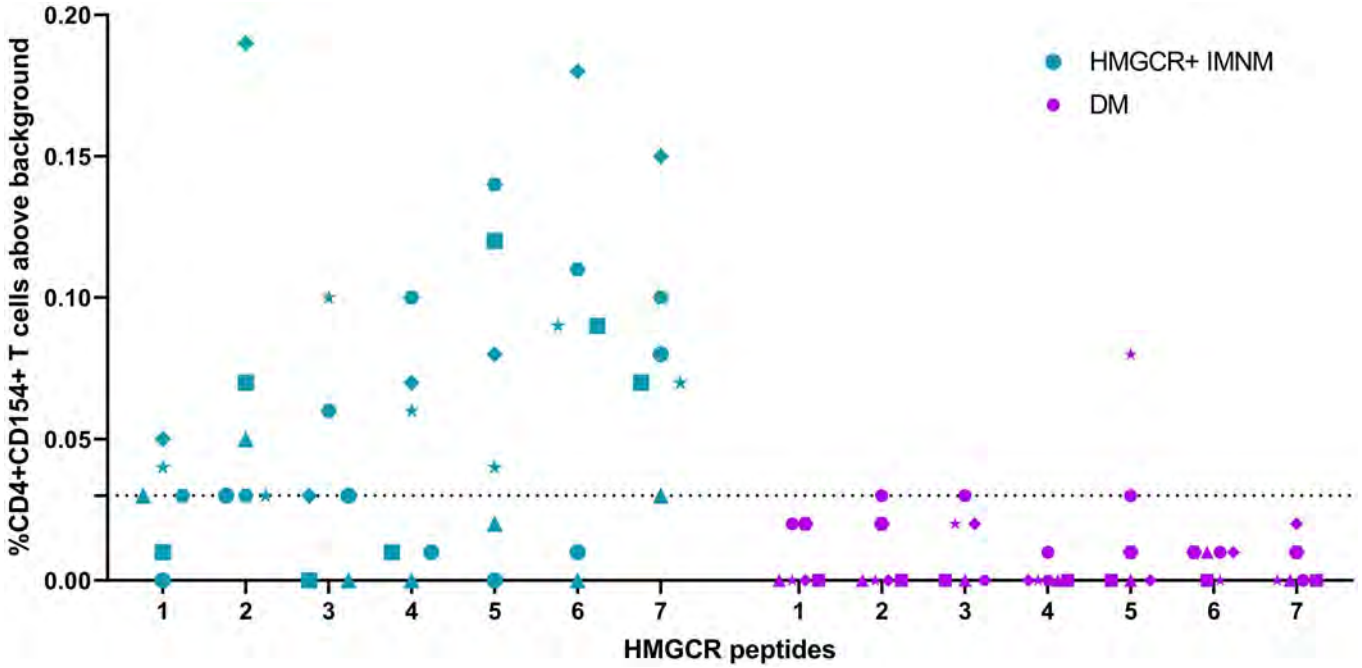

Figure 1. Anti-HMGCR+ IMNM patient T-cell responses to naturally processed HMGCR peptides. PBMCs from 6 anti-HMGCR+ IMNM patients were stimulated with the HMGCR peptides identified by NAPA and the % of CD4+CD54+ T cells above background observed with media alone was measured. Positive responses were considered those above the 95th percentile of the response of dermatomyositis (DM) controls (dotted line).

patients, compared to only 2/6 patients with dermatomyositis (p=0.014). All anti-HMGCR+ IMNM patients responded to 3-7 peptides (median 5.5) (Figure 1), and the T cell responses were significantly higher than those observed in patients with dermatomyositis (p< 0.0001).

Conclusion: Our findings represent the first report of antigen-specific CD4+ T cells in anti-HMGCR+ IMNM. Leveraging NAPA, we were able to define a core set of HMGCR peptides naturally presented by MoDCs from patients with anti-HMGCR+ IMNM, defining precise immunologically relevant autoantigenic CD4+ T cell epitopes. Definition of these epitopes is key in understanding disease pathogenesis and will aid in the future development of antigen-specific research and therapeutic tools.

Glucagon-like Peptide-1 Receptor Agonist Suppresses Muscle Fiber Necroptosis and Muscle Inflammation and Ameliorates Muscle Weakness in Experimental Polymyositis

Mari Kamiya[1], Fumitaka Mizoguchi[1], Hirokazu Sasaki[2], Natsuka Umezawa[1] and Shinsuke Yasuda[3], [1]Department of Rheumatology, Graduate School of Medical and Dental Sciences, Tokyo Medical and Dental University (TMDU), Tokyo, Japan, [2]Department of Lifetime Clinical Immunology, Graduate School of Medical and Dental Science, Tokyo Medical and Dental University (TMDU), Tokyo, Japan, [3]Tokyo Medical and Dental University (TMDU), Tokyo, Japan

SESSION INFORMATION
Session Date: Sunday, November 7, 2021
Session Title: Muscle Biology, Myositis & Myopathies Poster (0683–0722)
Session Type: Poster Session B
Session Time: 8:30AM–10:30AM

Background/Purpose: While glucocorticoids (GC) are the cornerstone of the treatment for polymyositis (PM), GC-induced myopathy is inevitable, which deteriorates muscle weakness. Therefore, novel therapeutic strategy that not only suppresses muscle inflammation but also improves muscle strength is awaited. Glucagon-like peptide-1 receptor (GLP-1R) agonists, which have been developed as an anti-diabetic therapy, have pleiotropic actions including anti-inflammatory effects, suppression of muscle wasting, and inhibition of cell death. We showed that the cell death of injured muscle fibers in PM is FASLG-mediated necroptosis, a form of regulated cell death accompanied with release of inflammatory mediators such as HMGB1. We also found that inhibition of necroptosis or HMGB1 ameliorated the muscle weakness and muscle inflammation in C protein-induced myositis (CIM), a murine model of PM. Accordingly, we hypothesized that GLP-1R agonists have beneficial effects on PM to recover muscle strength and to suppress muscle inflammation. The aims of this study are to examine the role of GLP-1R in PM and the effect of a GLP-1R agonist on PM models in vivo and in vitro.

Methods: Muscle specimens of PM patients and CIM were examined with immunohistological staining for the expression of GLP-1R. The effect of PF1801 (ImmunoForge, Seoul, South Korea), a GLP-1R agonist, on CIM was examined in monotherapy or in combination with prednisolone (PSL). C2C12-derived myotubes were treated with FAS ligand (FASLG) to induce necroptosis and used as an in vitro model of PM. The levels of HMGB1, TNF-α and IL-6 in the serum of CIM and the culture supernatant were measured by ELISA. The effect of PF1801 on the myotube necroptosis was examined using time lapse imaging and its effect on the activation of AMP-activated protein kinase (AMPK) and the expression of PGAM5 was assessed with western blotting. The levels of reactive oxygen species (ROS) were analyzed with CellROX® assay in vitro. The effect of PF1801 on the expression of antioxidant molecules was analyzed with quantitative real-time PCR in vitro.

Results: GLP-1R was expressed on the inflamed muscle fibers of PM and CIM. The treatment with PF1801 in monotherapy or in combination with PSL suppressed CIM-induced muscle weakness and the muscle weight loss as well as the severity of histological myositis while the monotherapy with PSL did not suppress muscle weakness and muscle weight loss. PF1801 decreased the levels of HMGB1, TNF-α and IL-6 in the serum of CIM. In vitro, PF1801 inhibited FASLG-induced myotube necroptosis and decreased the levels of HMGB1, TNF-α and IL-6 in the supernatant. The inhibitory effect of PF1801 on myotube necroptosis was dependent on the activation of AMPK. PF1801 activated AMPK and decreased the levels of PGAM5, which was crucial for FASLG-induced necroptosis of the myotubes. Furthermore, PF1801 upregulated the expression of antioxidant molecules including *Nfe2l2, Hmox1, Gclm,* and *Nqo1* and suppressed FASLG-induced ROS accumulation in the myotubes.

Conclusion: GLP-1R agonist could be a novel therapy for PM that recover muscle weakness and suppress muscle inflammation through suppressing muscle fiber necroptosis.

SESSION INFORMATION
Session Date: Sunday, November 7, 2021
Session Title: Muscle Biology, Myositis & Myopathies Poster (0683–0722)
Session Type: Poster Session B
Session Time: 8:30AM–10:30AM

Background/Purpose: Dermatomyositis (DM) is a chronic systemic autoimmune disease with characteristic skin rash and muscle weakness. Intravenous immunoglobulin (IVIg) has long been used as adjuvant treatment for DM and its efficacy was recently shown in a double-blind, randomized, placebo-controlled, phase III clinical trial (ProDERM study). The aim of this sub-analysis of the ProDERM study was to present detailed safety and tolerability data of IVIg in DM subjects.

Methods: The trial enrolled adults with definite or probable DM (Bohan & Peter criteria) with active disease and muscle weakness (MMT < 142/150). In the double-blind, placebo-controlled First Period, subjects were randomized 1:1 to either high dose IVIg (2g/kg every 4 weeks) or placebo.

After week 16, all patients on placebo and patients without clinical worsening while on IVIg entered the open label Extension Period, receiving 2 g/kg IVIg infusions every 4 weeks for an additional 24 weeks period. IVIg was given in equally divided doses over 2-5 consecutive days (=1 infusion cycle) every 4 weeks.

Results: A total of 95 adult DM patients (mean age: 53 years; 75% females) were enrolled and received at least one dose of IVIg. Baseline clinical characteristics were balanced between the 2 arms. Overall 96% and 73% patients completed the first and extension period, with 3 (3%) and 9 (10%) subjects discontinuing due to adverse events (1 of 3 and 6 of 9 due to IVIg related events), respectively.

A total of 664 infusions cycles were administered and 545 adverse events (AEs) were reported. Of these AEs, 282 in 62 (65%) subjects were assessed as being related to study drug. The majority of related AEs were mild (73.4%, 207), some were moderate (23.4%, 66) or severe (3.2%, 9). Most were infusion reactions (92%, 260). Headache (42% of subjects), pyrexia (19%) and nausea (16%) were the most common AEs (Table 1). Premedication for infusions was required by only 21.3% of patients before IVIg administration.

The incidence of serious AEs was similar in the two treatment groups during the First Period: 3 subjects (5.8%) experienced 5 serious AEs after IVIg and 2 subjects (4.2%) experienced 4 serious AEs after placebo.

Table 1. Related AEs reported > 2% of subjects (First and Extension Period)

Adverse event	% of subjects (N=95)
Headache	42.1
Fever	19
Nausea	15.8
Vomiting	8.4
Chills	7.4
Musculoskeletal pain	7.4
Blood pressure increased	6.3
Coombs test positive	5.3
Dizziness	4.2
Tachycardia	4.2
Infusion site condition	3.2
Haemoglobin decreased	3.2
Dyspnoea	3.2
Asthenia	2.1
Fatigue	2.1
Pain	2.1
Peripheral swelling	2.1
Arthralgia	2.1
Muscle spasms	2.1
Pain in extremity	2.1
Pulmonary embolism	2.1
Anaemia	2.1
Lymphopenia	2.1
Vision blurred	2.1

Overall, serious AEs were reported in 16 patients (Table 2). In 7 patients these were assessed as related to IVIg including thromboembolic events (TEE) in 5 subjects. All subjects with TEE had 1 or more other risk factors for TEE in addition to DM. During the study the exposure-adjusted incidence rate for TEE was efficiently lowered from 1.54 events per 100 patient months to 0.54 by reducing the maximum allowed infusion rate from 0.12 mL/kg/min to 0.04 mL/kg/min.

Conclusion: The safety and tolerability profile for high dose IVIg administration in patients with active DM was as expected with headache, pyrexia and nausea being most commonly reported during or after the infusions. Patients should be monitored for TEE (especially those with additional risk factors) with risk mitigation by using a low maxi-

Anti-Transcriptional Intermediary Factor 1-gamma Antibodies in Dermatomyositis with and Without Cancer - A Longitudinal Study

Lara Dani[1], Sandra Selickaja[2], Angeles Shunashy Galindo-Feria[3], John Svensson[4], Paulius Venalis[5], Dag Leonard[6], Malin Hemberg[7], Balsam Hanna[8], Ingrid E Lundberg[9] and Marie Holmqvist[4], [1]Karolinska Institutet and Karolinska University Hospital, Stockholm, Sweden, [2]State Research Institute for Innovative Medicine and Vilnius university hospital Santaros Klinikos, Vilnius, Lithuania, [3]Karolinska Institutet, Karolinska University Hospital, Stockholm, Sweden, [4]Karolinska Institutet, Stockholm, Sweden, [5]Center for Molecular Medicine, Department of Medicine, Karolinska Institutet, Stockholm, Sweden, [6]Department of Rheumatology, Uppsala University, Uppsala, Sweden, [7]Rheumatology Unit, Falu Lasarett, Falun, Sweden, [8]Department of Rheumatology, Sahlgrenska University Hospital, Gothenburg, Sweden, [9]Karolinska Institutet, Karolinska University Hospital, Division of Rheumatology, Department of Medicine Solna, Stockholm, Sweden, Stockholm, Sweden

SESSION INFORMATION

Session Date: Sunday, November 7, 2021

Session Title: Muscle Biology, Myositis & Myopathies Poster (0683–0722)

Session Type: Poster Session B

Session Time: 8:30AM–10:30AM

Background/Purpose: To longitudinally follow the levels of anti- transcriptional intermediary factor (TIF)1-gamma autoantibodies in patients with dermatomyositis with and without cancer.

Methods: We identified sera from 128 patients diagnosed with dermatomyositis (DM) between 1996 and May 2018 from a national myositis cohort. DM diagnosis was based on the new 2017 Eular/ACR classification criteria for inflammatory myopathies. Serum samples taken at DM diagnosis and after one and three years were tested for anti-TIF1-gamma autoantibodies by Enzyme-Linked ImmunoSorbent Assay (ELISA). Clinical data on DM and cancer was extracted from medical records, National Rheumatology Quality Register, National Myositis Network, International Myositis Register and National Cancer Register. Patients were grouped based on cancer within +/-3 years and anti-TIF1-gamma status into four mutually exclusive groups: DM negative or positive for anti-TIF1-gamma autoantibody

Table 1: The mean value and standard deviation (SD) in optical density (OD) of anti-TIF1-gamma autoantibodies at baseline 0, and after 1 year and 3 years from dermatomyositis (DM) diagnosis in patients with DM and cancer associated DM (CADM).

Time yr	Mean DM	SD DM	Mean CADM	SD CADM	P-value
0	2,07	0,91	2,49	0,88	0,171
1	1,37	0,86	1,75	0,96	0,444
3	1,02	0,84	1,22	0,71	0,651

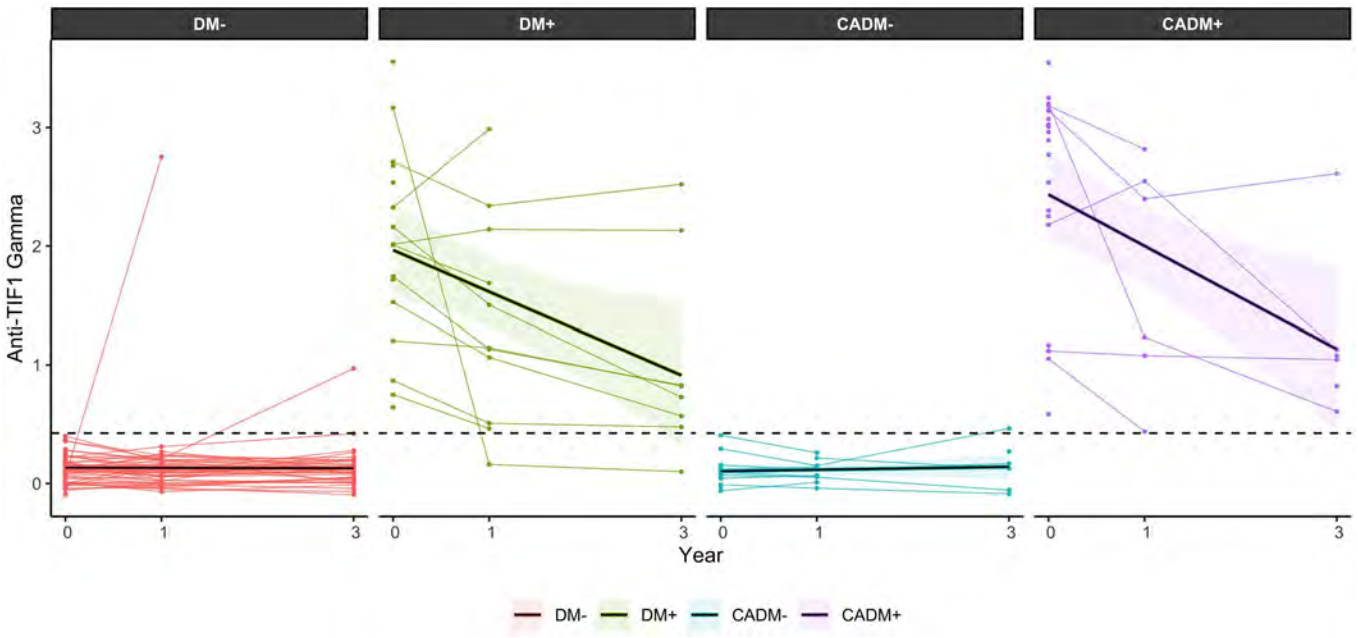

Figure 1. The mean value (one thin coloured line for each patient at baseline 0, 1 year and 3 years) and the overall slope (thick line) of anti-TIF1-gamma antibody. The filled area represents standard error. Dashed line = tif1gamma cutoff.

without cancer +/-3 years (DM- and DM+) and DM with cancer +/-3 years (CADM) negative or positive for anti-TIF1-gamma autoantibody (CADM- and CADM+). Levels of antibody over time were compared with healthy controls and between subgroups.

Results: For 41 patients only one serum sample was available, while 87 had longitudinal samples: 33 patients had 2 serum samples and 54 patients had 3 serum samples. Of all 128 patients, 34 (27%) had cancer within 3 years from myositis diagnosis and 36 (28%) of 128 were positive for anti-TIF1-gamma autoantibodies. We found 78 DM- (61%), 17 DM+ (13%), 19 CADM+ (15%) and 15 CADM- (12%). The mean serum level of anti-TIF1-gamma autoantibodies at baseline and after one and three years was higher in CADM+ patients compared to DM+ (table 1 and figure 1). Patients who tested positive at diagnosis for anti-TIF1-gamma autoantibodies, regardless of cancer status, lightly decreased in serum levels over time but remained in general persistently positive. During the observation time, only two patients changed their anti-TIF1-gamma autoantibody status from negative to positive and one from positive to negative.

Conclusion: The variation of anti-TIF1-gamma autoantibody levels over time did not differ in patients with DM with or without cancer and change in antibody status is rare, indicating that repeated serological tests might not be helpful in the clinical practice.

Detection of Autoantibodies Against Muscle-Specific Four-and-a-Half-LIM Domain 1 (FHL1) in Inflammatory Myopathies: Results from a Single-Center Cohort

Angeles Shunashy Galindo-Feria[1], Begum Horuluoglu[1], Jessica Day[2], Catia Cerqueira[3], Edvard Wigren[4], Susanne Gräslund[4], Susanna Proudman[5], Ingrid E Lundberg[4] and Vidya Limaye[6], [1]Karolinska Institutet, Karolinska University Hospital, Stockholm, Sweden, [2]Rheumatology Unit, Royal Adelaide Hospital, Adelaide, Australia and Discipline of Medicine, University of Adelaide, Adelaide, Australia, [3]4Dcell, Montreuil, France, [4]Karolinska Institutet, Karolinska University Hospital, Division of Rheumatology, Department of Medicine Solna, Stockholm, Sweden, Stockholm, Sweden, [5]University of Adelaide, Medindie, Australia, [6]Royal Adelaide Hospital, Adelaide, Australia

SESSION INFORMATION
Session Date: Sunday, November 7, 2021
Session Title: Muscle Biology, Myositis & Myopathies Poster (0683–0722)
Session Type: Poster Session B
Session Time: 8:30AM–10:30AM

Background/Purpose: Autoantibodies targeting a muscle-specific autoantigen, four-and-a-half-LIM-domain 1 (FHL1), have been previously identified in patients with idiopathic inflammatory myopathies (IIM) (1).

The aim of this study was to determine the prevalence and associations of anti-FHL1 antibody in South Australian patients with histologically-confirmed IIM and autoimmune disease control group (systemic sclerosis (SSc)).

Methods: Sera from patients with IIM (n=267) from the South Australian Myositis Database (SAMD), and SSc (n=174) from the Australian Scleroderma Cohort Study (ASCS) followed at the Royal Adelaide Hospital, and healthy con-

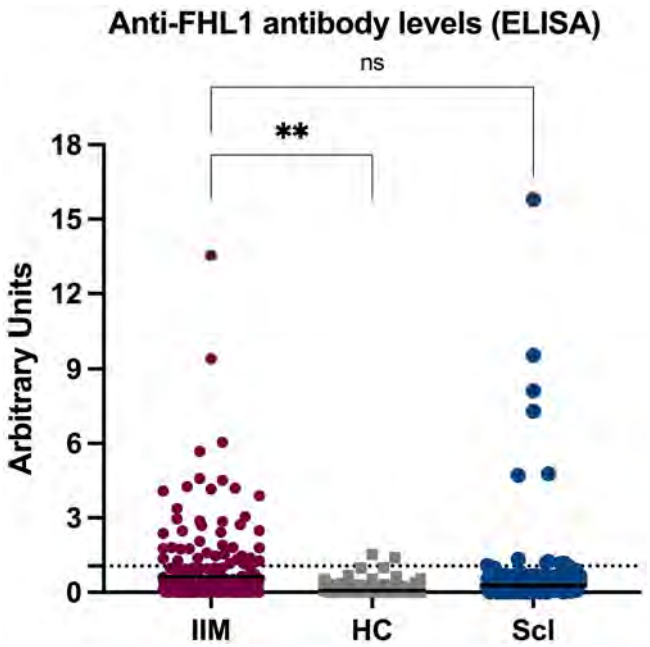

Figure 1. Sera from patients with IIM (DM, PM, IBM, IMNM and MNOS; n=267), SSc (n=174) and HC (n=100) were analyzed by ELISA using recombinant His-tagged FHL1. A cut-off value of 1.06 AU was calculated using a receiver operating characteristic (ROC) curve based on the HC, with an area under the curve (AUC) of 0.62 (CI 95% 0.56-0.68), sensitivity 15.52%, specificity 98%, and a likelihood ratio (LR) of 7.52. IIM, idiopathic inflammatory myopathy; HC, healthy controls; SSc, systemic sclerosis.

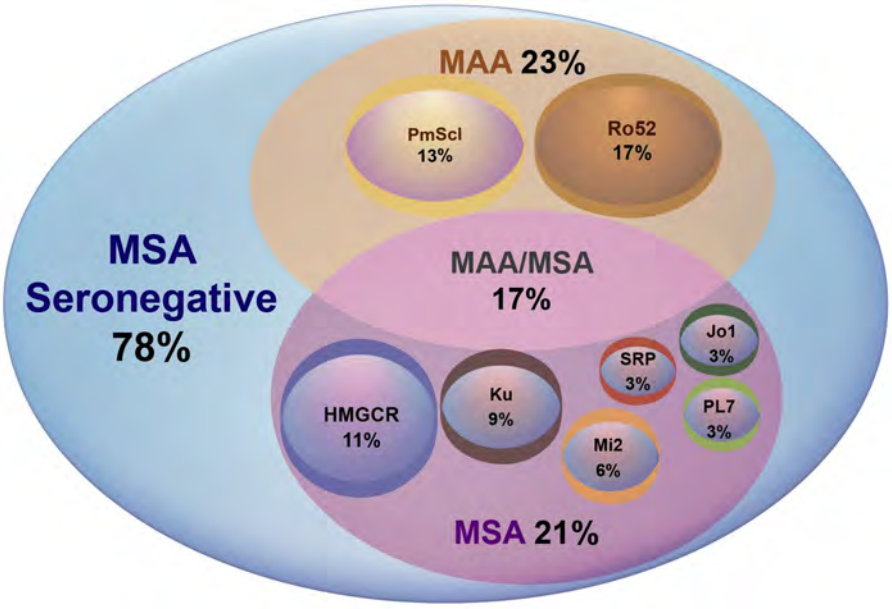

Figure 2. Frequency of IIM patients presenting MSA and MAA in anti-FHL1+ group. MSA, myositis-specific autoantibodies; MAA, myositis-associated autoantibodies

trols (HC, n=100) were analyzed for anti-FHL1 autoantibodies by Enzyme-Linked ImmunoSorbent Assay (ELISA) and transformed to Arbitrary Units (AU). Clinical, serological, and histological details were retrieved from the SAMD and the ASCS.

Results: Autoantibodies to FHL1 were more frequent in patients with IIM (37/267, 13.8%) compared with SSc (12/174, 7%) ($p< 0.02$) and HC (2/100, 2%) ($p< 0.001$) (Figure 1). There were no other myositis-specific autoantibodies (MSA) present in 28/37 (75%) anti-FHL1$^+$ patients (Figure 2). When analyzing the IIM subgroups, the presence of anti-FHL1 autoantibodies was more frequently found in the subgroups polymyositis (PM, 11/37) and Inclusion Body Myositis (IBM, 9/37) (Figure 3). In anti- FHL1$^+$ patients that were seronegative for other MSA (n=28), we found a higher frequency of vessel inflammation and marked fiber atrophy in muscle biopsies, less myalgia, lower CK median levels, and lower cellularity in the biopsy compared to anti-FHL1$^-$ patients. Objective weakness and marked fiber atrophy y in muscle biopsies was more frequent in anti-FHL1$^+$ compared to anti-FHL1- IBM patients. In the SSc patients, the

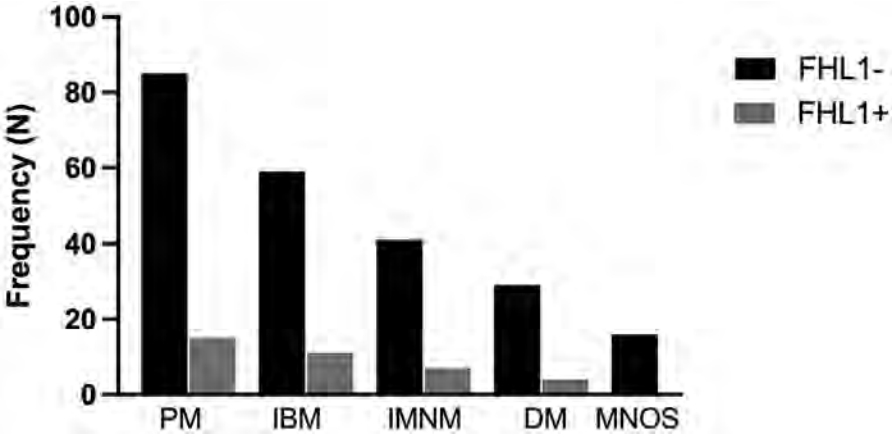

Figure 3. Frequency of IIM patients by disease subsets according to the presence of anti-FHL1+ or anti-FHL1- autoantibodies. IIM, idiopathic inflammatory myopathy; DM, dermatomyositis; PM, polymyositis; IBM, inclusion body myositis; IMNM, immune-mediated necrotizing myopathy; MNOS, myositis not-otherwise-specified

presence of anti-FHL1 autoantibodies was more frequent in limited compared to diffuse SSc, but did not have more frequent clinical diagnosis of myositis or atrophy in the muscle biopsy compared to anti-FHL1$^-$ patients.

Conclusion: The presence of anti-FHL1 autoantibodies was confirmed in a cohort of histologically-defined adult IIM of mixed ethnicity, and most anti-FHL1 positive cases were negative for known MSAs. We confirmed a clinical phenotype dominated by skeletal muscle involvement in patients with anti-FHL1 autoantibodies. We also found the presence of anti-FHL1 in SSc, and this finding warrants investigation in further SSc cohorts.

Abstract Number: 0698

Flow Cytometry and Sorting of Single Antibody Secreting Cells from Frozen Muscle Tissue

Andrew Zlobin, Peter Pytel and **Vladimir Liarski**, University of Chicago, Chicago, IL

SESSION INFORMATION
Session Date: Sunday, November 7, 2021
Session Title: Muscle Biology, Myositis & Myopathies Poster (0683–0722)
Session Type: Poster Session B
Session Time: 8:30AM–10:30AM

Background/Purpose: Idiopathic inflammatory myopathies (IIM) – dermatomyositis (DM), polymyositis, and inclusion body myositis - are poorly understood autoimmune muscle disorders. Isolation of relevant immune cell populations is made difficult by most protocols requiring fresh tissue. Our objective was to develop an approach to obtain intact antibody secreting cells from clinical samples of cryopreserved muscle biopsies.

Methods: Recent publications described the ability to isolate intact cells from frozen biopsies of human lupus nephritis and rheumatoid arthritis. These relied on collecting material in HypoThermosol FRS (HT), followed by freezing using CryoStor CS10 (CS) medium (both STEMCELL Technologies, Cambridge, MA) – a method not currently used in clinical practice. The authors achieved non-inferior results compared to fresh tissue. We integrated the above approach with published methods of preparing non-human primate muscle and tested tissue processing, freezing, and storage methods. Paired deidentified 1 cm^3 tonsil samples were subjected to variable collection media [HT or normal saline (NS)], freezing method [CS or liquid nitrogen-cooled isopentane (IP)], and digestion protocols. Flow cytometry was used to identify major antibody secreting cell subsets. Stored clinical DM and IBM samples were subjected to the final validated protocol and CD138$^+$ cells were sorted into 96-well plates. PCR was performed to confirm expression of heavy and light chain and PRDM1 and Bcl6.

Results: We recovered similar proportions of CD19$^+$ cells and downstream CD27$^+$IgD$^-$ and CD138$^+$ cell subsets by flow cytometry from tonsil collected with NS (**Fig. 1A**). Quantitation of our data showed that IP freezing was non-inferior to CS with statistically greater recovery of CD19$^+$ ($p=0.002$) and CD138$^+$ ($p< 0.001$) cells compared to fresh tissue (**Fig. 1B**). IP freezing outperformed CS conditions for CD19$^+$ ($p=0.001$) and CD27$^+$IgD$^-$ cells ($p=0.002$). Substitution of HT for NS did not alter results (data not shown).

Figure 1

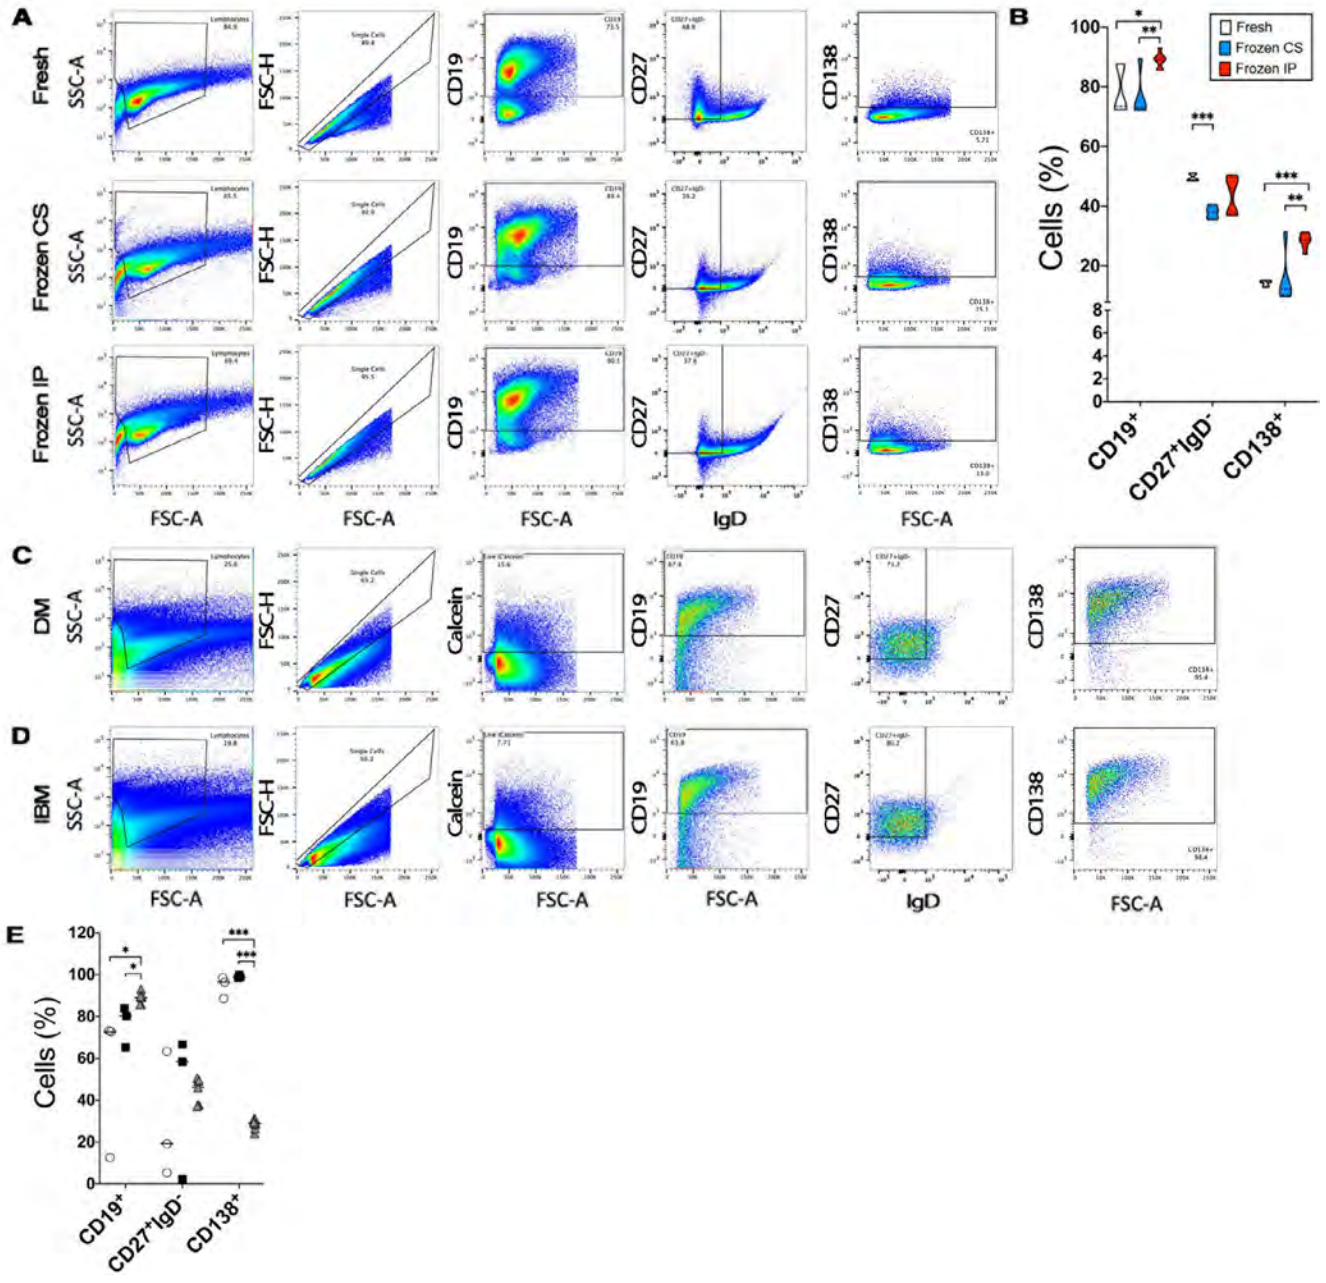

Figure 1. Development and validation of a frozen human tissue digestion protocol. (A) Representative flow cytometry plots performed on cell suspensions derived from digestion of fresh, CryoStor CS-10 (CS) frozen, or Isopentane (IP) frozen human tonsil tissue, collected in normal saline (NS). (B) Standard violin plot quantifying results in (A); fresh tonsil – white; CS – blue; IP – red. Total of 4 independent experiments. (C-D) Representative flow cytometry plots performed on cell suspensions derived from digestion of frozen biopsies of dermatomyositis (DM) (C) or inclusion body myositis (IBM) (D) patients. Calcein was added to confirm cell viability. (E) Quantitation of results in C and D for CD19+ B cells and indicated cell subsets in dermatomyositis (open circle), inclusion body myositis (closed square), and IP-frozen tonsil (closed grey triangle) samples, all collected in NS. Total of 3 independent experiments. * $P < 0.05$, ** $P < 0.01$, *** $P < 0.001$, unpaired two-tailed t test. Central horizontal lines denote mean in E; median in B.

Applying the digestion protocol to 6 muscle biopsies (3 DM, 3 IBM) showed similar proportions of live $CD19^+$ B cells and downstream populations (**Fig. 1C and D**). All samples had recoverable cells despite an average sample age of 6.5 years. A quantitative comparison revealed no statistically significant differences in isolated cell populations between DM (open circle) and IBM (black square), while both disorders exhibited significantly greater proportions

Figure 2

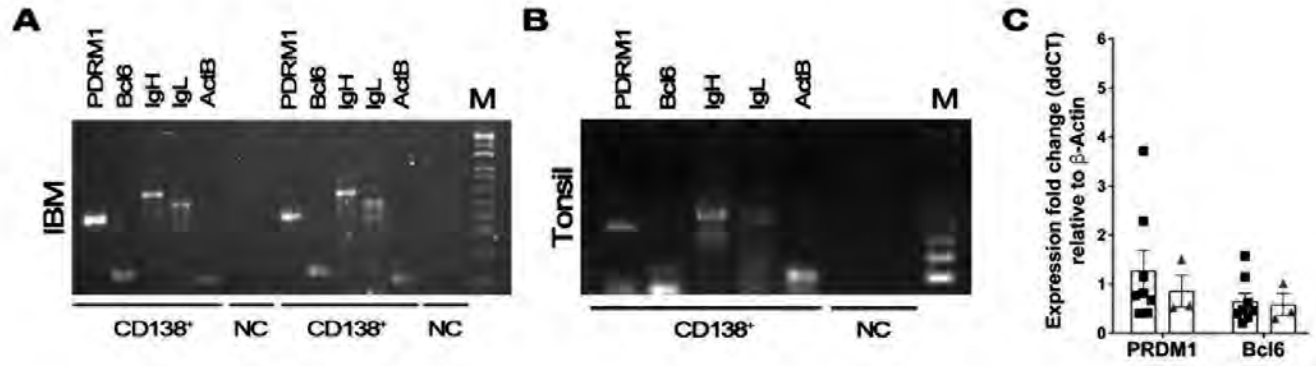

Figure 2. Confirmation of antibody secreting cell phenotype by PCR. Single sorted cells from inclusion body myositis (IBM) (A) or tonsil (B) were subjected to PCR for gene targets as labeled. Negative controls (NC) were performed on empty wells from the last two rows of collection plates. IgH: immunoglobulin heavy chain, ~550 bp; IgL: immunoglobulin light chain, ~400 bp; ActB: **β**-Actin; M: molecular weight marker. (C) Gel densitometry quantitative comparison of representative images A and B. CD138+ cells from IBM (black square) and tonsil (grey triangle) were analyzed. Values are expressed as fold change relative to **β**-Actin (ddCT). Total of 3 independent experiments. Error bars denote standard error.

of CD138$^+$ cells compared to tonsil ($p < 0.001$) (**Fig. 1E**). When subjected to PCR, examined single cells from IBM expressed immunoglobulin heavy and light chains (**Fig. 2A**). Levels of PDRM1 and Bcl6 from IBM (black square) were similar to tonsil controls (grey triangle) (**Fig. 2B)**.

Conclusion: By making it feasible to use stored samples of frozen muscle tissue, the diagnosis and histology of which are known, our approach serves to make a large impact on human translational research of myositis. A major benefit is that the derived muscle digestion protocol does not require specialized collection or freezing media and is compatible with standard clinical samples. We plan to use this approach in the study of antibody repertoire and *in situ* immune response in IIM.

Abstract Number: 0699

Clinical Characteristics of Idiopathic Inflammatory Myositis Manifesting with Myoglobinuria: A 15 Year Retrospective Review

Lilian Vilar, William Moore and Ian Ward, Dwight D Eisenhower Army Medical Center, Fort Gordon

SESSION INFORMATION
Session Date: Sunday, November 7, 2021
Session Title: Muscle Biology, Myositis & Myopathies Poster (0683–0722)
Session Type: Poster Session B
Session Time: 8:30AM–10:30AM

Background/Purpose: The Idiopathic Inflammatory myopathies (IIM) are characterized by muscle damage and progressive weakness. Myoglobin is not typically released in high levels in IIM and myoglobinuria is more typically found in rhabdomyolysis. Myoglobinuria has been rarely described in inflammatory myositis. This study aims to describe the frequency, significance, and associated clinical characteristics of myoglobinuria in IIM patients receiving care through the military healthcare system.

Table 1. Demographics and Initial Labs at Time of Diagnosis

	Urine Myoglobin Positive N = 20	Urine Myoglobin OR Urine Hemoglobin positive N=44	IIM Cohort N=99	P-value
Age of onset, years, mean (range)	50.3 (19-72)	54.9 (19-87)	49.3 (18-82)	NS

Necrotizing features on biopsy	13 (92.8%) *n=14	21 (72.4%) *n=29	20 (43.5%) *n=46	0.014

Methods: We performed a retrospective chart review of patients diagnosed with an inflammatory myositis within the Department of Defense (DoD) between January 2006 and December 2020. Patients were identified by ICD-10 diagnosis codes for inflammatory myositis and included if diagnosed at one of fifteen medical facilities within the DoD. All patients met either the Bohan and Peter 1975 or EULAR/ACR classification criteria for definite or probable myositis. Demographic and laboratory data were identified at initial presentation. Myositis complications and treatment regimens were collected during the follow up period. Clinical outcomes were based on the most recent documentation by the evaluating physician. We identified clinical evidence of myoglobinuria (urine myoglobin positivity or urinalysis with moderate to large blood and < 2 red blood cells on microscopy) at onset of disease and compared demographic, clinical and serologic parameters, treatments and outcomes with those patients without myoglobinuria. We performed Chi square tests to analyze categorical variables and Student's t-tests for continuous variables between groups.

Results: One hundred and forty three patients were included with follow-up time between 1 and 180 months. Forty four patients (30.8%) presented with evidence of myoglobinuria (Table 1) and were more likely to be males (p=0.002) and less likely to be of Caucasian race (p=0.014). Immune mediated necrotizing myopathy (IMNM) was the most common IIM subtype (p< 0.001) and muscle necrosis on biopsy was associated with myoglobinuria (p=0.014). Higher levels of creatine kinase (p< 0.0001), aldolase (p< 0.0001), and lactate dehydrogenase (p=0.016) at onset correlated with myoglobinuria, and these patients were more likely to have HMGCoA antibodies. Dysphagia and myocarditis were not associated with myoglobinuria, but there was significantly less incidence of interstitial lung disease (p=0.02).

Myoglobinuria was associated with less ongoing active disease at last follow up (p=0.03), but number of immunosuppressive agents needed was similar between groups.

Conclusion: We demonstrated that myoglobinuria occurs in over thirty percent of IIM. Non-Caucasian ethnicity, male sex, and IMNM were all more likely to present with myoglobinuria. These patients presented with more profound muscle involvement, but surprisingly had higher remission rates at follow up. The clinical profile identified herein will allow for recognition of severe but potentially highly treatment responsive myositis. We hypothesize this population, when recognized early, may respond well to treatment.

Table 2. Inflammatory Myositis Subtypes and Complications

	+ Urine Myoglobin N = 20	+ Urine Myoglobin OR + Urine Hemoglobin N = 44	Control N=99	P-value

Clinical Outcomes in Idiopathic Inflammatory Myositis Within the Military Health System: A 15 Year Retrospective Review

David Mecham[1], William Moore[1] and Ian Ward[2], [1]Dwight D Eisenhower Army Medical Center, Fort Gordon, [2]United States Army, Evans, GA

SESSION INFORMATION
Session Date: Sunday, November 7, 2021
Session Title: Muscle Biology, Myositis & Myopathies Poster (0683–0722)
Session Type: Poster Session B
Session Time: 8:30AM–10:30AM

Background/Purpose: The Idiopathic Inflammatory Myopathies (IIM) are often difficult to treat, require chronic steroid therapy, and can remain active despite multiple treatment regimens. The objective of this study is to identify clinical characteristics at time of diagnosis and follow on treatment strategies which have prognostic value related to disease outcomes.

Methods: We performed a retrospective chart review of patients diagnosed with an inflammatory myopathy within the Department of Defense (DoD) between January 2006 and December 2020. Identified by the ICD-10 diagnosis codes for inflammatory myositis, patients were included if diagnosed at one of fifteen hospitals within the DoD. All patients met either the Bohan and Peter 1975 or EULAR/ACR classification criteria for definite or probable myositis. Demographic and laboratory data were identified at initial presentation. Myositis complications and treatment regimens were collected during the follow up period. Clinical outcomes were based on the most recent evaluation. Patients were categorized into one of five clinical outcome groups. We used ANOVA modeling to identify significant parameters and performed Chi square tests for categorical variables and Student's t-tests for continuous variables within groups.

Results: Two hundred and eleven patients were followed between 2 and 180 months. Steroid free remission was achieved in 126 (59.7%) of which 39 (18.5%) achieved drug free remission. Thirty-eight patients (18.0%) remained with clinically active disease at end of study. African American ethnicity was associated with persistent disease activity ($p< 0.001$) (Table 1). There was no significant outcome associations for the subtypes of IIM, age, gender, and BMI. ESR was significantly lower in patients reaching steroid free remission compared to remission with steroids ($p=0.016$), but not with the active disease cohort. No other laboratory values correlated with outcomes. Dysphagia, but not interstitial lung disease or myocarditis, was associated with worse disease outcomes (Table 2). Patients who achieved any form of disease remission were more likely to see a 90% reduction in creatine kinase (CK) levels at 12 months of therapy than those with active disease (OR 2.7, CI 1.1 – 6.5). There was a trend with CK reduction of 87% at 3 months and end of study remission (OR 2.29, CI 0.99 – 5.24). Treatment regimens at final assessment did not correlate with specific outcomes, but historical exposure to second line agents mycophenolate ($p=0.03$), azathioprine ($p=0.008$), intravenous immunoglobulin (IVIg) ($p=0.007$) or rituximab ($p=0.002$) was associated with active disease (Table 3).

Conclusion: Steroid free remission was achieved in nearly 60% of the IIM population, but chronic steroid exposure and poor clinical outcomes were still common. African American ethnicity, dysphagia, and second line therapies were all associated with worse outcomes, identifying a need for more effective treatments strategies. Creatine kinase at time of onset did not correlate with outcomes, but a dramatic drop (>90% at 12 months) may have prognostic implications for remission, suggesting a need for a treat to target strategy.

Table 1. Clinical Characteristics at Time of Diagnosis

SESSION INFORMATION

Session Date: Sunday, November 7, 2021

Session Title: Muscle Biology, Myositis & Myopathies Poster (0683–0722)

Session Type: Poster Session B

Session Time: 8:30AM–10:30AM

Background/Purpose: To inform guidance for cancer surveillance in patients with idiopathic inflammatory myositis (IIM), we conducted a retrospective cohort study in a single tertiary referral center to evaluate the use and yield of computed tomography (CT) for cancer surveillance within distinct myositis-specific autoantibody strata from 2007 through 2020.

Table 1. Time window of cohort enrollment onwards. Autoantibody, number of patients, # of cancers, and CT scans performed

Methods: In 2020, we reviewed the electronic medical records of all patients who previously enrolled in our Myositis Research Registry to identify those who met the following criteria**:** (i) Probable or definite DM/PM by Peter and Bohan, (ii) IMNM by the 2003 ENMC Criteria, (iii) Classic DM rash (Gottron's/heliotrope) and consistent histopathology on skin biopsy. Myositis specific and associated autoantibodies were assayed using Euroimmun line blot (16 Ag IgG), ELISA (anti-Mi2 and anti-TIF1y [MBL], anti-HMGCR [INOVA Diagnostics]), and in-house immunoprecipitation (anti-NXP2). We also reviewed their charts and outside medical records for any CT chest and abdomen/pelvis studies ordered for cancer surveillance/screening purposes. Our myositis center's strategy for malignancy screening/surveillance includes at least one CT chest, abdomen, and pelvis upon IIM diagnosis. Data on CT imaging was collected with researchers blinded to both myositis-specific autoantibody and cancer status. Two time periods were analyzed: Cancer screening tests performed (i) after cohort enrollment, and (ii) after IIM-symptom onset, both through 12/31/2020.

Results: Among 1174 patients, 1054 patients had at least one myositis specific or associated autoantibody. From cohort enrollment onwards, the number of cancers that occurred within 0-3 yrs, 3-5 yrs, and >5 yrs after IIM symptom onset was 35, 15, and 34, respectively. The number/% of CT chest scans that were positive for cancer were 6/1.34% (0-3 yrs), 2/1.18% (3-5 yrs), and 3/1.38% (>5 yrs). The number/% of CT a/p positive for cancer was 9/2.90% (0-3 yrs), 0/0% (3-5 yrs), and 3/1.91% (>5 yrs). Of the 35 cancers diagnosed within 0-3 yrs from IIM symptom onset, more than half were diagnosed by methods other than CT chest, abdomen and pelvis imaging. Amongst 273 anti-TIF1g-positive patients, 181 CT chest or a/p scans were performed, 5 (2.7%) of which were positive within 0-3 yrs. In contrast, amongst 248 patients with Jo1, PL12, PL7, OJ, or EJ autoantibodies, 178 CT chest or a/p scans were performed, 1 (< 1%) of which was positive.

From IIM symptom onset onwards, the number of IIM patients diagnosed with cancer that occurred within 0-3 yrs, 3-5 yrs, and >5 yrs after IIM symptom onset was 70, 16, and 36. The percent of screening/surveillance CT chest and CT a/p scans that were positive for cancer was comparable to the time window from cohort enrollment onwards (Table 2).

Conclusion: In a tertiary referral center population, the number of patients needed to be screened by CT imaging to detect one cancer within the first 3 yrs of IIM was approximately 70 for CT chest and 40 for CT a/p. CT imaging is of higher yield in patients with anti-TIF1y antibodies compared to patients with antisynthetase autoantibodies. Whether CT imaging leads to improvement in cancer or IIM outcomes remains to be determined. Funded in part by NIAMS K2 3AR075898.

Abstract Number: 0702

Performance of Commercial Autoantibody Testing in Comparison to Recognized Gold Standards in Myositis Autoantibody Testing

Sarvar Nazir[1], Lisa Rider[2], Ira Targoff[3], Stanley Naides[4], Andrew Mammen[5], Steven Greenberg[6] and Adam Schiffenbauer[5], [1]NIEHS, NIH, Bethesda, MD, [2]NIEHS, NIH, Garrett Park, MD, [3]Oklahoma Medical Research Foundation, Oklahoma City, OK, [4]Self, Dana Point, CA, [5]National Institutes of Health, Bethesda, MD, [6]Department of Neurology, Brigham and Women's Hospital, Harvard Medical School, Boston, MA

SESSION INFORMATION

Session Date: Sunday, November 7, 2021

Session Title: Muscle Biology, Myositis & Myopathies Poster (0683–0722)

Session Type: Poster Session B

Session Time: 8:30AM–10:30AM

Background/Purpose: The idiopathic inflammatory myopathies (IIM) are a heterogenous group of autoimmune conditions. The presence of myositis-specific autoantibodies (MSAs) and myositis-associated autoantibodies (MAAs) in patients are important for diagnosis and prognosis. The currently accepted gold standards for autoantibody testing are time consuming and difficult to perform. Commercial testing may offer a more cost-effective and time-efficient method for autoantibody testing. However, the relative performance characteristics of commercial testing methods are not well known. We sought to determine the relative performance characteristics of autoantibody (Abs) testing from a widely-used commercial lab compared to gold standard methodologies.

Methods: Laboratory testing by protein and RNA immunoprecipitation (IP) and IP-immunoblotting methods performed by the Oklahoma Medial Research Foundation (OMRF) was used as the gold standard for anti-Jo1, OJ, EJ, PL-7, PL-12, Mi-2, SRP, Ku, MDA5, P155, PM/Scl, and MJ autoantibodies. Testing by ELISA and confirmation by IP in the Mammen laboratory was used as the gold standard for anti-HMGCR autoantibodies. Immunoblotting results from Mammen and Greenberg labs were used as gold standards for the CN1A autoantibody. Commercial antibody testing was performed on archived samples by a commercial lab using laboratory developed ELISAs for HMGCR and CN1A assays and a laboratory developed line blot method for the remaining autoantibodies. Up to 10 adults and juveniles positive by gold standard testing for each autoantibody were selected to be evaluated in the commercial lab.

Results: Samples from 198 patients with diagnosed IIM were used, of which 137 were adult and 61 were juvenile.

Across those autoantibodies with more than 5 gold standard positive (GSP) test results, sensitivities were greater than 0.95 for Jo1 (0.96, 22 GSP), EJ (1.0, 6 GSP), PL-12 (1.0, 10 GSP), and Ku (1.0, 8 GSP), and > 0.85 for Mi-2 (0.89, 9 GSP), MDA-5 (0.95, 19 GSP), and SRP (0.88, 20 GSP). PM/Scl (0.75, 8 GSP), MJ (0.74, 19 GSP), HMGCR (0.7, 10 GSP), P155 (0.48, 23 GSP), CN1A (0.37, 21 GSP), OJ (0, GSP) exhibited sensitivities under 0.85.

Two autoantibodies had specificities under 0.95: SRP (0.88) and Mi-2 (0.89). All other autoantibodies tested had a specificity above 0.95.

Subgroup analysis by age showed differences in sensitivity greater than 0.2 between CN1A Abs in adult (0.83) and juvenile IIM (0.15) ($p = 0.004$) and in anti-HMGCR Abs in adult (0.4) and juvenile IIM (0.15) ($p = 0.038$).

Conclusion: Of the autoantibodies with at least 5 positive gold standard positive results, there was a large variation in the sensitivities among the Abs. Sample storage may have impacted commercial test sensitivity. However, the specificities were strong overall. Our results show that commercial testing can be used as a tool for initial autoantibody testing in myositis patients, but the gold standards still provide value for autoantibody groups with low sensitivities, including P155, CN1A, and OJ. Further research is needed to explain sensitivity differences between age groups.

CD8 Positron Emission Tomography (PET/CT) Imaging with 89Zr-Df-IAB22M2C in Patients with Inclusion Body Myositis

Colin Quinn[1], Kelsey Moulton[1], Ron Korn[2], William Le[3], Niti Goel[4], Michael Farwell[5] and Steven Greenberg[6], [1]Department of Neurology, University of Pennsylvania, Philadelphia, PA, [2]ImaginAb, Inglewood, CA, [3]ImaginAb, Inc, Inglewood, CA, [4]Abcuro, Inc., Newton,, MA, [5]Department of Radiology, University of Pennsylvania, Philadelphia, PA, [6]Brigham and Women's Hospital Department of Neurology, Boston, MA

SESSION INFORMATION

Session Date: Sunday, November 7, 2021

Session Title: Muscle Biology, Myositis & Myopathies Poster (0683–0722)

Session Type: Poster Session B

Session Time: 8:30AM–10:30AM

Background/Purpose: Inclusion body myositis (IBM) is a slowly progressive autoimmune skeletal muscle disease for which no effective pharmacological therapy is available. A prominent feature of autoimmunity seen on microscopy is effector cytotoxic CD8+ T cells invading myofibers. Pathophysiologically, a quantitative approach to detection of CD8+ T cell burden in muscle would potentially distinguish IBM from other muscle diseases and provide a biomarker predicting disease progression, stratification for clinical trials, or a surrogate outcome for T cell directed therapies.

[89]Zr-Df-IAB22M2C is positron emission tomography (PET) tracer with high affinity for the CD8 glycoprotein.

In this pilot study we evaluated the safety, muscle distribution and sensitivity of [89]Zr-Df-IAB22M2C, to detect CD8+ T cell inflammation in the skeletal muscle of IBM patients.

Methods: Five patients with IBM from the University of Pennsylvania who met European Neuromuscular Center Criteria (ENMC) for probable IBM and were able to walk at least 10 feet without an assistive device were recruited. Patients on any immunomodulatory therapy or investigational agent were excluded. Screening and formal clinical evaluation by a neuromuscular neurologist (CQ) was performed within 28 days of imaging.

Table 1. Clinical Characteristics 1. Subject 1 was not included as this subject decided against imaging after clinical evaluation 2. IBM-FRS = IBM Functional Rating Scale. The IBM-FRS is a 10 question survey of functional status, including swallowing, arm and leg tasks. Each question is scored 0-4. The maximum score is 40. 3. IBM MRC Sum= A sum of medical research council grading scores, converted to a 10-point scale. This is a non-validated score measuring shoulder abduction, elbow flexion, elbow extension, long finger flexion (digit 2), long finger flexion (digit 4), hip flexion, knee extension, ankle dorsiflexion and ankle plantarflexion bilaterally

Subject[1]	Age (Years)	Gender	Disease Duration (Months)	IBM-FRS[2]	IBM MRC Sum[3]
2	77	M	132	22	124
3	61	F	132	26	148
4	60	M	7	34	154
5	64	F	121	25	117
6	73	M	23	20	118

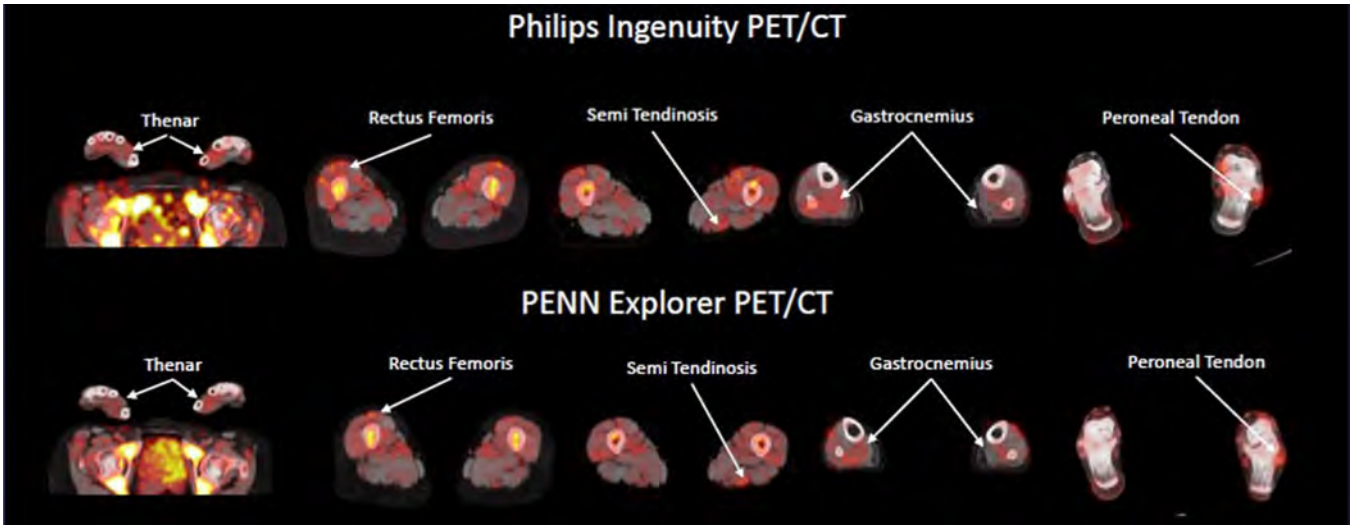

Figure 1. Representative PET/CT images from subject 4 demonstrating 89Zr-Df-IAB22M2C signal in the hands, anterior thigh and gastrocnemius muscles.

	Paraspinal muscle	Lt Thigh	Rt Thigh	Lt Calf	Rt Calf	Lt Upper Ext	Rt Upper Ext	Lt Forearm	Rt Forearm	Lt Hand	Rt Hand
01-002	0.3	0.3	0.5	0.9	0.5	0.6	0.6	0.6	0.3	0.5	0.8
01-003	0.2	0.3	0.3	0.8	0.6	0.5	0.4	0.5	0.5	0.3	0.2
01-004	0.4	0.3	0.4	0.3	0.5	0.3	0.3	0.3	0.3	0.2	0.3
01-005	0.3	0.6	0.7	0.4	0.6	0.5	0.8	0.8	0.6	0.4	0.3
Oncology	0.4	0.2	0.2	0.3	0.3	0.3	0.3	0.0	0.0	0.0	0.0

Figure 2. Muscle SUVmean. Subjects 2, 3, 4, 5 have been analyzed. A comparison control oncology patient is included. The highest uptake was seen in the calf (average SUVmean 0.58, SD 0.20), upper extremities (average SUVmean 0.50, SD 0.17), and forearms (average SUVmean 0.49, SD 0.18). The uptake in the paraspinal muscles (average SUVmean 0.30, SD 0.08) was similar to the control population.

Patients were imaged 24 h after administration of 0.7-1.1 mCI of ^{89}Zr-Df-IAB22M2C on both a standard clinical PET/CT scanner (Ingenuity TF; Philips Healthcare) and the PennPET Explorer, a whole-body scanner with approximately 40 times the sensitivity of a standard PET/CT instrument.

Outcome measures included safety and tolerability and a standard uptake value (SUV)-based quantitative analysis of tracer uptake in various muscle regions. SUV means were compared to a preexisting dataset from an oncology population where available.

Results: To date all 5 patients have undergone clinical assessment and PET imaging. Four patients have been analyzed. Clinical details of each patient are detailed in Table 1.

^{89}Zr-Df-IAB22M2C was well tolerated. One patient dropped out prior to receiving the tracer due to claustrophobia. A second patient experienced a fall the day after receiving the tracer deemed unrelated to the tracer, but the resulting delayed PET/CT evaluation left time for only PennPET Explorer imaging.

^{89}Zr-Df-IAB22M2C signal was detectable in the muscles of all patients (Figures 1 and 2). In all of the extremities assessed, the average muscle uptake was higher than in our control population, though some individual muscles were similar to control uptake. The highest uptake was seen in the calf (average SUVmean 0.58, SD 0.20), upper extremities (average SUVmean 0.50, SD 0.17), and forearms (average SUVmean 0.49, SD 0.18). The uptake in the paraspinal muscles (average SUVmean 0.30, SD 0.08) was similar to the control population.

Conclusion: ^{89}Zr-Df-IAB22M2C appears safe and well tolerated. This pilot study demonstrated clear uptake of ^{89}Zr-Df-IAB22M2C in the muscles of IBM patients at an intensity greater than the control population. Further studies should examine ^{89}Zr-Df-IAB22M2C uptake in other diseases and correlation with longitudinal changes related to measures of disease progression.

nostic role and use in risk assessment. The aim of this analysis was to describe ILD spectrum and pulmonary function tests (PFTs) in IIM patients in relation to anti-SSa/SSb and anti-Ro52 positivity.

Methods: We queried the Northwell Myositis Center database for patients with IIM between 1/1/2007 to 4/6/2018. Patients were selected if they met 2017 European League Against Rheumatism /American College of Rheumatology classification criteria for IIM and had anti-SSa/SSb data available. Results of commercially available anti-SSa/SSb and anti Ro52 immunoassays were used. Anti-SSb was only found in association with anti-SSa in this cohort and anti-SSa/SSb were combined and analyzed as a single group. ILD was defined by the presence of NSIP, COP/BOOP, UIP and unspecified ILD patterns on CT chest. PFTs variables were collected. Statistical analyses included Chi-

Table 3. Frequency of ILD and PFT results in anti-Ro52 positive and negative patients

	anti-Ro52 +	anti-Ro52 -	p-value
ILD n (%)	N=25	N=35	
ILD present	16 (64 %)	9 (25.7%)	**0.004** **
No ILD	9 (36 %)	26 (74.3%)	
PFT %	N 14	N 19	
FEV1 median (min-max)	66 (33-105)	81 (42-131)	0.1165
FVC median (min-max)	64 (27-97)	80 (40-117)	0.1770
DLCO median (min-max)	47 (21-77)	68 (18-102)	**0.0226** **
** statistically significant difference			

square, Fisher's Exact test, and Wilcoxon Rank Sum test to determine statistical differences in group distributions and McNemar's test was performed to compare groups.

Results: 118 IIM adult (age ≥ 18) patient records were reviewed. 15 with no anti-SSa/SSb and anti-Ro52 data and 9 anti-SSa/SSb negative patients with low positive Ro52 antibodies were excluded. Of 94 patients included in the analysis 35.1% (33 /94) were anti-SSa/SSb positive. Of 60 patients with available anti-Ro 52 41.6% % (25/60) were positive. The anti-SSa/SSb positive (n=33) and negative (n=61) groups and anti-Ro52 positive (n=25) and negative (n=35) groups had similar distribution for age, gender, and race, as well as subtypes of IIM. Demographics, clinical characteristics are listed in Table1.

56% of patients with anti-SSa/SSb positive IIM had ILD compared to 44% of patient with negative anti-SSa/SSb (p = 0.003) regardless of anti-Ro52 status. 64% of patients with positive anti-Ro52 had ILD as compared with 36% of patient with negative anti-Ro52 (p= 0.004). NSIP and non-specified ILD were most reported irrespective of serological status, UIP was only seen in anti-SSa/SSb negative group. There was no statistically significant difference observed in FEV1, FVC, or DLCO between anti-SSA positive and anti-SSa negative patients. Interestingly, patients with positive Ro52 antibodies had a lower DLCO (47% vs. 68%; p = 0.003) than in anti-Ro52 negative patients, while there was no difference in FEV1 and FVC between groups.

Conclusion: While anti-SSa/SSb positivity is associated with higher rate of ILD, independent of anti-Ro 52 status, it does not confer an increased risk of ILD severity as measured with PFTs. DLCO in anti-Ro52+ group was significantly lower than that in anti-Ro52- group, indicating that anti-Ro 52 positivity is likely more applicable in predicting ILD severity than anti-SSa/SSb. This suggests that while both assays are useful in defining risk for ILD, anti-Ro52 is superior to the anti-SSa/SSb in determining severity of ILD in myositis patients.

Mitochondrial Calcification-Induced Inflammation in Human Skeletal Muscle and Immune Cells

Bhargavi Duvvuri[1], Lauren Pachman[2], TING WANG[1], Payton Hermanson[1] and Christian Lood[1], [1]University of Washington, Seattle, WA, [2]Northwestern's Feinberg School of Medicine. Ann and Robert H. Lurie Children's Hospital of Chicago; Stanley Manne Children's Research Institute of Chicago, Lake Forest, IL

SESSION INFORMATION
Session Date: Sunday, November 7, 2021
Session Title: Muscle Biology, Myositis & Myopathies Poster (0683–0722)
Session Type: Poster Session B
Session Time: 8:30AM–10:30AM

Background/Purpose: Children with juvenile dermatomyositis (JDM) have decreased autophagy, as also confirmed by our RNA seq data in JDM muscle, which may contribute to accumulation of harmful agents. Consistent with that interpretation, our prior work demonstrated accumulation of calcified mitochondria in degenerated muscle fibers of JDM patients. In further mechanistic studies, we demonstrated mitochondrial reactive oxygen species (mtROS) as the main driver of mitochondrial calcification in human skeletal muscle cells. However, what remains to be explored is the effect of mitochondrial calcification on inflammation in calcifying skeletal muscle cells and in phagocytosing immune cells that may participate in clearance of calcified extruded mitochondria.

Methods: Mitochondrial calcification was induced in human skeletal muscle cells (RH30 cells) by addition of moderately high calcium-phosphate medium (Ca-P), and detected by fluorescent stain osteoimage. MtROS was measured using MitoSOX. Targeted metabolomics was performed on RH30 cells to identify potential pathways enriched upon mitochondrial calcification. Inflammation in RH30 cells was measured by RT-qPCR and ELISA. Mitochondrial DNA was measured using qPCR. Cardiolipin exposure was measured by flow cytometry. THP-1 monocytes were used to investigate the inflammatory potential of calcified mitochondria.

Results: Consistent with the role of calcium in mitochondrial metabolism, we found a significant increase in mtROS of calcified RH30 cells compared to untreated cells ($p< 0.01$). Pathway enrichment analysis on metabolites significantly downregulated in Ca-P treated cells revealed several mitochondrial-related pathways including mitochondrial respiration. In RH30 cells, upon mitochondrial calcification, there is a significant induction of interferon-stimulated gene expression and release of inflammatory cytokines including IL-1β (135 pg/mL vs. 75 pg/mL, $p=0.0002$). Further, cellular supernatants from calcified RH30 cells enriched in mtDNA could induce interferon responses in an interferon reporter cell line suggesting the extrusion of inflammatory mitochondria-derived components upon calcification of skeletal muscle cells. Consistent with these findings, investigation on isolated calcified mitochondria demonstrated a propensity of calcified mitochondria to release significant amounts mtDNA compared to non-calcified mitochondria (2,233,494 copies/mL vs. 581,655 copies /mL, $p< 0.0001$) and a trend for increased cardiolipin exposure (aCL MFI 18,500 vs. 10,271, $p=0.07$), suggesting destabilization of calcified mitochondria. Consistent with the proinflammatory nature of calcified mitochondria, THP-1 monocytes stimulated with calcified mitochondria but not non-calcified mitochondria secreted significant levels of IL-1β.

Conclusion: Mitochondrial calcification, as occurs in JDM, contributes to inflammation in skeletal muscle cells as well as in phagocytosing immune cells.

Mycophenolate Mofetil and Methotrexate Efficacy in Dermatomyositis

Madison Grinnell[1], Emily Keyes[2], DeAnna Diaz[2], Thomas Vazquez[3], Rui Feng[4] and Victoria Werth[2], [1]Department of Dermatology, Perelman School of Medicine at the University of Pennsylvania and Philadelphia VAMC, OMAHA, NE, [2]Department of Dermatology, Perelman School of Medicine at the University of Pennsylvania and Philadelphia VAMC, Philadelphia, PA, [3]FIU Wertheim College of Medicine, Virginia Beach, VA, [4]University of Pennsylvania Department of Biostatistics, Philadelphia, PA

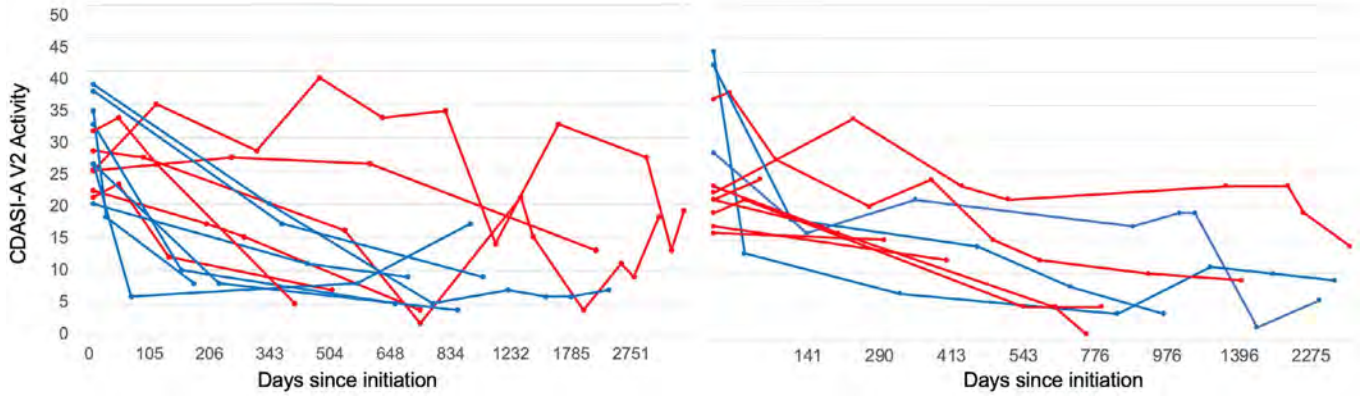
SESSION INFORMATION

Session Date: Sunday, November 7, 2021
Session Title: Muscle Biology, Myositis & Myopathies Poster (0683–0722)
Session Type: Poster Session B
Session Time: 8:30AM–10:30AM

Background/Purpose: Treatment of dermatomyositis (DM) typically follows a stepwise sequence starting with either methotrexate (MTX) or mycophenolate mofetil (MMF) after an inadequate response to antimalarial therapy. However, data is scarce regarding the effectiveness of MTX and MMF.

Methods: A cohort of 24 patients with currently skin-predominant DM was identified using data from a prospective database at The University of Pennsylvania. Included patients took MTX or MMF and had ≥ two study visits within a retrospective observation period from October 2008 until February 2021. The Cutaneous Dermatomyositis Disease Area and Severity Index (CDASI) was used to assess severity and outcomes. Patients with mild disease activity, defined as a CDASI activity (CDASI-A) score < 14 (maximum sub-score of 100), were excluded from the analysis as were any patients on any other medications used to treat DM aside from MTX or MMF, with the exception of chronic antimalarials or topical medications.

Results: For both MMF (n=13) and MTX (n=11), there was no baseline difference in CDASI-A scores at initiation. There was no significant difference in the degree of improvement on either medication, with a mean difference in daily CDASI-A change between MTX and MMF of -0.0028 ± 0.0024 (p=0.2400) using a mixed linear effects model.



MMF Takers (Left) and MTX Takers (Right) CDASI Activity Scores (*Responders at first follow up displayed in blue, nonresponders displayed in red)

MMF		MTX	
Avg Age	62	Avg Age	62
Sex	10 Female, 3 Male	Sex	10 Female, 1 Male
Race	11 Caucasian, 2 Asian	Race	10 Caucasian, 1 Asian
Amyopathic	11	Amyopathic	8
Classic	2	Classic	3
# Switched	6	# Switched	1

Demographics

For MTX, the median percentage change in CDASI-A between the first and last study visit was -74%. For MMF, the median percentage change was -76%. A decrease of 40% or greater in the CDASI-A score has previously been associated with a meaningful change in quality of life (1). Defining responders as having a 40% or greater improvement in their CDASI-A score between their first and second observations (see Figure 1), 27% of the patients taking MTX were responders while 54% of patients taking MMF were responders. The range of time varied between the first and second visits with 50% of patients having a second study visit within 150 days. By last follow-up, 55% of patients taking MTX were considered responders and 77% of patients taking MMF met criteria to be considered responders. For MTX, the median follow-up for the second visit was 178 days and for the last visit was 776 days. For MMF, the median follow up was similar—147 days for the second visit, and for the last visit was 787 days. Of note, 7 patients in total had taken both MMF and MTX at some point in their disease course. More patients switched from taking MTX to MMF (see Table 1).

Conclusion: Although we do not have a large enough sample size to make a properly powered conclusion, MTX trended to a slightly delayed effect compared to MMF. Either MMF or MTX may be added to treatment plans for patients with DM who have not responded to antimalarial therapy. Moreover, our data suggest that responders continued to improve over many months (even years for some) while most non-responders showed little improvement at first follow-up (ranging from 2-6 months) during the observation period. Large cross over studies with safety data are needed to evaluate patient response to MMF and MTX in DM.

Association of Pneumomediastinum with Poor Prognosis in Patients with Myositis-Associated Interstitial Lung Disease

Kazuki Hirano[1], Azusa Kojima[1], Akira Ishii[1], Mai Sugiyama[1], Yuto Izumi[1], Noriko Sasaki[2], Yuji Hosono[1], Chiho Yamada[1] and Shinji Sato[3], [1]Tokai University School of Medicine, Isehara, Japan, [2]tokai university, sagamihara-city, Japan, [3]Tokai University, Isehara, Japan

SESSION INFORMATION
Session Date: Sunday, November 7, 2021
Session Title: Muscle Biology, Myositis & Myopathies Poster (0683–0722)
Session Type: Poster Session B
Session Time: 8:30AM–10:30AM

Background/Purpose: Pneumomediastinum is an important complication in patients with myositis-associated interstitial lung disease (ILD). Patients with myositis and ILD who had pneumomediastinum during the disease course have a poor outcome, often fatal, especially in the case of rapidly-progressive ILD (RP-ILD). The purpose of this study was to establish the clinical features and risk factors for mortality in patients with myositis-associated ILD accompanied by pneumomediastinum.

Methods: Retrospective study of patients attending Tokai University Hospital between 2011 and 2020, with idiopathic inflammatory myopathies (IIMs) satisfying the ACR/EULAR classification criteria and with ILD diagnosed based on the clinical course of respiratory symptoms, function and computed tomography. Patients´ sera were screened for autoantibodies using protein immunoprecipitation assays. Clinical features and prognostic risk factors were compared between patients with or without pneumomediastinum using univariate and multivariate analyses and multiple logistic regression models.

Results: Of 164 patients with IIMs accompanied by ILD, 23 (12 female, 11 male; mean age 58.6, range 36-80 years) developed pneumomediastinum during their clinical course. Seven of these patients had classic dermatomyositis (DM) and 11 had clinically amyopathic DM (CADM), 3 had polymyositis (PM) and 2 had anti-aminoacyl-tRNA synthetase (ARS) antibody syndrome. Twelve possessed antibodies specific for melanoma differentiation-associated gene 5 (MDA5) and 8 had anti-ARS antibodies (3 with anti-PL-7, 3 with anti-EJ, and 2 with anti-PL-12 antibodies). Frequencies of smoking and anti-MDA5 antibody-positivity were significantly higher in patients with pneumomediastinum than in those without (61% vs. 36%, P=0.027; 52% vs. 20%, P=0.001, respectively). By univariate analysis, pneumomediastinum during the clinical course was identified as an initial factor associated with subsequent mortality due to ILD. However, multiple regression analysis revealed that anti-MDA5-positivity, but not pneumomediastinum during the clinical course, was an independent factor associated with mortality due to ILD (HR= 4.84, 95% CI: 2.3, 10.7, P=0.01; HR= 2.42, CI: 1.0, 5.4, P=0.11, respectively).

Conclusion: These results indicate that pneumomediastinum frequently coexists with anti-MDA5-positivity and that the presence of anti-MDA5 antibody might be a potential confounding factor for pneumomediastinum with regard to mortality due to ILD in patients with myositis-associated ILD.

Session Date: Sunday, November 7, 2021

Session Title: Muscle Biology, Myositis & Myopathies Poster (0683–0722)

Session Type: Poster Session B

Session Time: 8:30AM–10:30AM

Table 1: Baseline characteristics

	IIM (n = 39)	HC (n = 39)
Gender, n (%): female / male	32 (82) / 7 (18)	32 (82) / 7 (18)
Age (years); median (IQR)	56.0 (47.7 – 64.1)	56.0 (48.3 – 64.2)
BMI (kg/m²); median (IQR)	25.9 (23.2 – 31.1)	27.5 (23.9 – 31.7)
Disease subtype, n (%): DM / PM / IMNM	14 (36) / 18 (46) / 7 (18)	
Disease duration (years); median (IQR)	4.84 (1.96 – 8.83)	
Disease activity (MITAX); median (IQR)	0.13 (0.06 – 0.29)	
Disease damage (MDI); median (IQR)	0.05 (0.03 – 0.08)	
MMT-8; median (IQR)	64 (54 – 70)	
CRP (mg/L); median (IQR)	3.0 (1.4 – 5.0)	
ESR (mm/h); median (IQR)	13 (8 – 25)	
CK (µkat/L); median (IQR)	3.0 (1.3 – 9.4)	
LD (µkat/L); median (IQR)	3.7 (3.4 – 5.2)	
Myoglobin (µg/L); median (IQR)	93.6 (60.4 – 250.2)	
Glycaemia (mmol/L); median (IQR)	5.2 (4.8 –5.8)	
Current dose of GC - prednisolone equivalent dose (mg/day); median (IQR)	6.5 (3.75 – 15)	
IIM-associated clinical manifestations, n (%): MW / OD / SR / MH / RP / A / ILD / CI	35 (88) / 7 (18) / 5 (13) / 8 (21) / 10 (26) / 5 (13) / 16 (41) / 3 (8)	
Autoantibodies (positive), n (%): ANA / Mi-2 / TIF-1γ / CADM-140 / SAE / p140 / SRP / Jo-1 / PM-Scl / RNP / Ku / Ro / HMGCR	24 (62) / 3 (8) / 3 (8) / 0 (0) / 0 (0) / 0 (0) / 3 (8) / 10 (26) / 5 (13) / 5 (13) / 0 (0) / 16 (41) / 3 (8) / 2 (5)	
Treatment, n (%): GC / MTX / AZA / CSA / CPA / LEF / MMF	36 (92) / 11 (28) / 8 (21) / 5 (13) / 2 (5) / 2 (5) / 1 (3)	
Arterial hypertension (treated), n (%)	15 (38)	
Diabetes mellitus, n (%): Untreated / PAD / Insulin treatment	3 (8) / 1 (3) / 1 (3)	
Statin use, n (%): Current / Previous / Other current hypolipidemic drugs	0 (0) / 4 (10) / 1 (3)	
Smoking (current), n (%)	0 (0)	

Acronyms: IIM, idiopathic inflammatory myopathies; DM, dermatomyositis; PM, polymyositis; IMNM, immune mediated necrotising myopathy; HC, healthy controls; MITAX, Myositis Intention to Treat Activity Index; MMT-8, manual Muscle Testing-8; CRP, C-reactive protein; ESR, erythrocyte sedimentation rate; CK, creatine kinase; LD, lactate dehydrogenase; MW, muscle weakness; OD, oesophageal motility disorder; SR, skin rash; MH, mechanic's hands; RP, Raynaud's phenomenon; A, arthritis; ILD, interstitial lung disease; CI, cardiac involvement ANA, antinuclear antibodies; Mi-2, anti-nuclear helicase 218/240 kDa; p155-140, anti-TIF1 (transcription factor-1); CADM-140, anti-MDA5 (antigen associated with melanoma differentiation); SAE, anti-SUMO1 (small ubiquitin-like activating enzyme); p140, anti-NXP2 (nuclear matrix protein); SRP, anti-signal recognition particles; Jo-1, anti-histidyl-tRNA synthetase; PM-Scl, anti-Pm-Scl (anti-core complex 11-16 proteins); RNP, anti-ribonucleoprotein; Ku, anti-Ku (against the nuclear DNA-protein kinase subunit); Ro, anti-Ro (52 / 60kDa, against cytoplasmic RNA and associated peptides); GC, glucocorticoids; MTX, methotrexate; AZA, azathioprine; CSA, cyclosporin A; CPA, cyclophosphamide; LEF, lefunomide; MFF, mycophenolate mofetil; PAD, per oral antidiabetic drugs

Background/Purpose: Idiopathic inflammatory myopathies (IIM) are associated with systemic inflammation, limited mobility, and glucocorticoid treatment, which can have a negative impact on metabolic disease, atherogenesis, and cardiovascular risk. The aim of this study was to assess the cardiovascular risk in IIM patients and healthy controls (HC) and the association with disease-specific features.

Methods: 39 patients with IIM (32 females; mean age 56; disease duration 4.8 years; DM 14 / PM 18 / IMNM 7) and 39 age-/sex-matched HC (32 females, mean age 56) without rheumatic diseases were included. DM and PM patients fulfilled the Bohan/Peter criteria, IMNM patients fulfilled the ENMC criteria. In both groups manifest cardiovascular disease (angina pectoris, myocardial infarction, cerebrovascular, and peripheral arterial vascular events) were excluded by case history. Disease activity and damage were evaluated by MITAX and MDI, muscle involvement by manual muscle testing (MMT-8), and comorbidities and current treatment were recorded. All participants underwent an examination of carotid intima-media thickness (CIMT), pulse wave velocity (PWV), ankle-brachial index (ABI), body composition (densitometry: iDXA Lunar, bioelectric impedance: BIA2000-M). Physical activity was evaluated by Human Activity Profile (HAP) questionnaire. The risk of fatal CV risk events was evaluated by SCORE (charts for the European population). Data are presented as median (IQR).

Table 2: Cardiovascular (CV) parameters in patients with idiopathic inflammatory myopathies (IIM) and healthy controls (HC)			
Parameters of CV risk	**IIM** (n = 39)	**HC** (n = 39)	**p-value**
MAP (mmHg); median (IQR)	**95** (86 - 103)	**97.7** (89.3 - 107)	0.497
ABI; median (IQR)	**0.995** (0.92 – 1.06)	**1.05** (0,89 – 1.10)	0.265
PWV (m/s); median (IQR)	**8.0** (6.05 – 9.40)	**8.0** (7.05 – 9.38)	0.484
CIMT (mm) ; median (IQR)	**0.7** (0.6 – 0.8)	**0.7** (0.6 – 0.8)	0.356
Plaque; n (%)	**14** (35.9)	**10** (25.6)	0.462
Plaque thickness (mm); median (IQR)	**1.4** (1.3 – 1.8)	**1.6** (1.2 – 2)	0.978
BMI (kg/m²); median (IQR)	**25.9** (23.2 – 31.1)	**27.5** (23.9 – 31.7)	0.893
HAP; median (IQR)	**58.3** (47.8 – 69.8)	**83** (79 – 90.8)	**<0.001**
SCORE (%); median (IQR)	**2** (1 – 5)	**3** (1 – 5)	0.990

Acronyms: MAP, mean arterial pressure; ABI – ankle-brachial index; PWV – pulse wave velocity; CIMT – carotid intima-media thickness; BMI – body mass index; HAP, Human activity profile questionnaire; SCORE, systematic Coronary risk evaluation – risk of fatal cardiovascular event in 10 years (%)

Results: In IIM, baseline characteristics, disease activity, the dose of glucocorticoids, prevalence of comorbidities were evaluated (Table 1). Compared to HC, there was no significant difference in IIM regarding blood pressure, ABI, PWV, CIMT and risk of fatal CV events by SCORE. In IIM, there was a higher frequency of plaques, but no difference in the plaque thickness. IIM group recorded significantly lower physical activity (Table 2). In IIM, blood pressure (represented as MAP) correlated positively with age, BMI, parameters of inflammation (CRP, C3), triglycerides, atherogenic index and body fat %, but negatively with albumin and HDL-C. Decreased (unfavourable) values of ABI were associated with low HDL-C. Increased PWV was associated with higher age, longer disease duration, decreased disease activity (MITAX), and unfavourable parameters of body composition and nutritional status (decreased phase angle and cell quota, and higher extracellular/body-cell-mass ratio). Increased (unfavourable) values of CIMT and plaque thickness were associated with longer disease duration (Table 3).

Conclusion: No significant differences in cardiovascular risk parameters between our IIM patients and healthy age-/sex-matched individuals were detected. However, in IIM, cardiovascular risk factors were associated with age, disease duration, dose of glucocorticoids, and parameters of lipidogram and body composition. No association with decreased physical activity was observed.

Lower HDL-associated Apolipoprotein A-I Levels Associate with Presence of Calcinosis in Adult Dermatomyositis

Sangmee Bae[1], Ani Shahbazian[2], Jennifer Wang[2] and Christina Charles-Schoeman[2], [1]University of California Los Angeles, Los Angeles, CA, [2]Department of Medicine, University of California, Los Angeles, Los Angeles, CA

SESSION INFORMATION
Session Date: Sunday, November 7, 2021
Session Title: Muscle Biology, Myositis & Myopathies Poster (0683–0722)
Session Type: Poster Session B
Session Time: 8:30AM–10:30AM

Background/Purpose: Calcinosis is a sequelae of juvenile and adult dermatomyositis (DM) associated with significant morbidity and poor quality of life. It is hypothesized that inflammatory vasculopathy may lead to dystrophic mineral deposition. Apolipoprotein A-I (apoA-I) is the major apolipoprotein component of HDL which normally prevents inflammation in the vessel wall. The current study aims to identify clinical and laboratory features associated with calcinosis in a cohort of adult patients with idiopathic inflammatory myopathies (IIM).

Methods: A cross sectional study was performed in 288 adult patients with IIM recruited at the University of California, Los Angeles between 2008-2020. Clinical and laboratory features including myositis autoantibodies were compared between patients with and without calcinosis. HDL-associated ApoA-I levels (HDL-apoA-I) were measured using sandwich ELISA. Patients were divided into HDL-apoA-I tertiles to compare the association of calcinosis with low (tertile 1) vs high (tertial 3) HDL-apoA-I. Stepwise multivariate logistic models were constructed to obtain odds ratios (ORs) that related calcinosis to various variables. Statistically significant bivariate variables were considered as predictors for the stepwise model. The final stepwise model was selected to minimize the Bayes Information Criterion (BIC).

Results: We identified 27 (9.3%) patients with calcinosis in our IIM cohort. All patients with calcinosis had dermatomyositis (DM), (12.6 % of DM cohort with calcinosis), with the exception of 1 patient who had polymyositis overlap with CREST syndrome. Five (19%) of the patients with calcinosis had juvenile onset DM. Patients with calcinosis were older and had significantly longer disease duration, higher MD global damage scores and lower total cholesterol (TC), LDL-cholesterol (LDL-C), and CPK levels. Among myositis autoantibodies, NXP2, SAE and PM-scl ab were more frequently seen in patients with calcinosis. In contrast, antisynthetase, HMGCR and SRP ab were less frequently seen in patients with calcinosis. None of the patients with calcinosis had a history of cancer compared to 28% in patients without calcinosis. Low (vs high) HDL-apoA-I levels were associated with calcinosis, and the association remained strong in multivariate analysis in addition to older age and longer disease duration. In fact, IIM patients with low HDL-apoA-I were 11.5 times more likely to have calcinosis compared to patients with high HDL-apoA-I.

Table 1. Clinical and laboratory features in IIM patients with and without calcinosis Values reported as mean±SD or N(%) unless specified *p <0.05 comparing calcinosis vs no calcinosis group using student's t test or Wilcoxon rank sum test. † Patient with polymyositis and overlap with CREST ‡ Myositis autoantibody testing results were available in 209/288 patients § Patients were divided into HDL-apoA-I tertiles: tertile 1 including patients with lowest apoA1, and tertile 3 including patients with highest apoA1 levels

Abstract Number: 0710

Patients with Recent Onset, Active Polymyositis (PM), Dermatomyositis (DM) and Antisynthetase Syndrome (ASS) Have Reduced Muscle Endurance but Not Reduced Muscle Strength Compared to Patients with Established, Low-active Disease

Kristofer Andreasson[1] and Helene Alexanderson[2], [1]Karolinska Institute, Stockholm, Sweden, [2]Karolinska Institutet, Stockholm, Sweden

SESSION INFORMATION

Session Date: Sunday, November 7, 2021
Session Title: Muscle Biology, Myositis & Myopathies Poster (0683–0722)
Session Type: Poster Session B
Session Time: 8:30AM–10:30AM

Background/Purpose: To analyze for differences in quadriceps maximal isometric voluntary contraction (MVIC), muscle endurance (ME), muscle mass and fat mass (m. vastus lateralis, mid-thigh) in patients with recent onset PM/DM and established PM/DM.

Table 1. Patient characteristics

	Recent onset PM/DM/ASS (n=8)	Established PM/DM/ASS (n=8)
Diagnosis, PM/DM/ASS, n	2/4/2	3/4/1
Age	54.5 (20-64)	53 (19-67)
Sex, n, M/F	1/7	1/7
Disease duration	5.5 (3-6) months	7.5 (6-36) years
Physical activity, min/week	225 (<30 - >300)	120 (60 - >300
Exercise, min/week	90 (0 - >120	120 (20 - >120)
Prednisone, mg/d	13.75 (2.5-30)	3.75 (0-8.75)
Physician VAS	20 (12-40)[1]	0 (0-20)[1]
Extra-muscular VAS	18 (0-50)[3]	0 (0-20)[1]
HAQ	0.63 (0-2.25)[1]	0.3 (0-1.38)[1]

All values in median (min-max) if not stated otherwise. Superscripted numbers showing numbers of cases with missing data.

Methods: All patients diagnosed with PM, DM or ASS during September 2017 to January 2020 at Karolinska University Hospital or Akademiska Hospital who met the inclusion criteria were asked to participate (n=16). So far 8 patients with established PM/DM/ASS have been identified to match 8 of the patients with recent onset disease, by age and gender. A dynamometer from Biodex was used to assess MVIC and ME starting with three warm-up 4-sec. contractions followed by three maximal contractions, all with a 3-minute rest in-between. Thereafter six sets of twelve submaximal contractions, starting on 20 % of MVIC and increasing by 10 % for each set, finishing on 70 % of MVIC. Each set ended with a new maximal contraction registered as percentage of initial MVIC. Muscle and fat mass was assessed by MRI. A blinded, experienced radiologist analyzed the muscle mass in m. vastus medialis and lateralis (distance femur - outer edge of the muscle) and fat mass (outer edge of muscle - inner edge of skin) in millimeters (mm). Examinations of muscle function and MRI were conducted at most two weeks apart.

Results: Patients with recent onset PM/DM had a median MVIC of 73 (53-93) Nm and established PM/DM had 75 (41-118) Nm (p=0.65). Median ME was 85 (63-89) % and 90.5 (83-98) % for the 8 patients with recent onset disease and established disease, respectively (p=0.007). Median muscle mass for patients with recent onset PM/DM was 38.5 (26-47) mm and 33 (20-55) mm for patients with established disease (p=0.41). Patients with recent onset disease had a median fat mass of 13 (7-21) mm and patients with established PM/DM had 10 (7-23) mm (p=0.49).

Conclusion: Patients with recent onset, active PM/DM/ASS had a significantly reduced muscle endurance (ME) compared to matched patients with established disease. No significant differences were found between the groups regarding maximal voluntary isometric contraction (MVIC), muscle mass or fat mass. Further data collection is needed to reach statistical power.

Suppression of HDL-associated Apolipoprotein A-I (apoA-I) Levels in Patients with Idiopathic Inflammatory Myopathies

Sangmee Bae[1], Ani Shahbazian[2], Jennifer Wang[2] and Christina Charles-Schoeman[2], [1]University of California Los Angeles, Los Angeles, CA, [2]Department of Medicine, University of California, Los Angeles, Los Angeles, CA

SESSION INFORMATION
Session Date: Sunday, November 7, 2021
Session Title: Muscle Biology, Myositis & Myopathies Poster (0683–0722)
Session Type: Poster Session B
Session Time: 8:30AM–10:30AM

Background/Purpose: Patients with idiopathic inflammatory myopathies have accelerated vascular disease, which contributes to higher disease morbidity and mortality. Apolipoprotein A-I (apoA-I) is the major protein component of HDL, which suppresses vascular inflammatory responses through promotion of cholesterol efflux and prevention of low density lipoprotein (LDL) oxidation. The current work assessed HDL-associated ApoA-I levels (HDL-apoA-I) in IIM patients compared to healthy controls, and evaluated associations of HDL-apoA-I with specific IIM disease characteristics.

Methods: HDL-apoA-I levels were measured by sandwich ELISA using a primary HDL antibody. HDL-apoA-I levels, demographic variables and traditional cardiovascular risk factors were compared in 122 IIM patients and 110 healthy controls (HC). HDL-apoA-I levels were also assessed separately in a large IIM extended patient cohort (n=274) in

Table 1. Clinical and laboratory characteristics of IIM patients and controls Values are mean±SD or N(%) unless specified *P<0.05, **P<0.0001 by student's t test and Wilcoxon rank sum test ‡Defined as first degree relative with MI at age <55 for male and <65 for female Abbreviations: MI, myocardial infarction; TIA, transient ischemic attack; BMI, body mass index; FHx, family history; hsCRP, high sensitivity C-reactive protein

relation to clinical and laboratory IIM disease characteristics. Multivariate linear regression analyses were performed to further assess predictors associated with HDL-apoA-I while adjusting for statistically significant univariate variables.

Results: HDL-apoA-I levels were significantly lower in IIM patients compared to HC (Table 1). The association between low HDL-apoA-I and IIM diagnosis remained strong after multivariate adjustment (Table 2). In linear regression analysis of the extended IIM patient group (Table 3), higher MD global disease activity scores by visual analog and likert scales as well as the presence of dermatomyositis (vs polymyositis or inclusion body myositis) and the presence of certain myositis specific autoantibodies (ab) (MDA5 and TIF1< ![if !msEquation] >< ![if !vml] >< ![endif] >< ![endif] > ab) were associated with lower HLD-apoA-I levels. In multivariate analysis, the presence of MDA5 or TIF1γ ab remained significantly associated with lower HDL-apoA-I levels (regression coefficient β= -1.35, p< 0.001 and β= -0.81, p=0.01 respectively).

Table 2. Multivariate Regression Analysis of Variables associated with HDL-apoA-I† activity in IIM patients and Healthy Controls (n=232) †Log transformation was used for skewed variables (apoA-I, hsCRP)

Conclusion: HDL-apoA-I levels were significantly lower in IIM patients compared to HC, and inversely associated with the presence of MDA5 and TIF1γ ab. Our results indicate a potential mechanism for the microvascular inflammation and damage in IIM, particularly in patients with MDA5 and TIF1γ ab.

SESSION INFORMATION

Session Date: Sunday, November 7, 2021

Session Title: Muscle Biology, Myositis & Myopathies Poster (0683–0722)

Session Type: Poster Session B

Session Time: 8:30AM–10:30AM

Background/Purpose: Immune checkpoint inhibitor (ICI)-related adverse events (irAE) recently emerged as new diseases in the field of auto-immunity. Among them, ICI-related myotoxicity has the highest fatality rate and is the second most frequent musculosketal irAE. Ir-myositis differs from its idiopathic counterpart by frequent oculomotor and bulbar symptoms as well as respiratory dysfunction. In addition, the presence of acetylcholine receptor antibodies (AchR Abs) in a subset of patients may suggest concurrent neuromuscular junction disorder. A comprehensive understanding of disease pathology underlying overlapping features of ir-myositis and ir-myasthenia gravis (MG) remains elusive, complicating disease stratification and management. Our study aimed to clarify the ir-myositis pathophysiology.

Methods: An observational, monocentric cohort study was conducted. Inclusion criteria were history of malignancy, ICI exposure, pathologically confirmed myositis, available AchR antibody testing and repetitive nerve stimulation, and absence of dermatomyositis skin rash. Post-mortem histopathology of the orbital muscles and diaphragm was examined in one and three patients, respectively.

Results: Twenty-two patients were enrolled. Median age was 71 [IQR 62-79] years; 14 patients (64%) were male. Two patients reported history of autoimmune disease. Lung (n=9/22), skin (n=3/22) and kidney (n=3/22) cancers were the most frequent indications for ICI therapy. Patients received anti-PD1 or anti-PDL1 monotherapy (77%; n=17/22) or combination therapy (23%; anti-LAG-3, n=1/22 and anti-CTLA4, n=4/22). Time to symptom onset was 25 [19-43] days. Clinical manifestations included proximal and axial muscle weakness (86%; n=19/22) and myalgia (63%; n=14/22). CK level was 3467 [1836-7659] U/L.

Additionally, patients frequently displayed diplopia and/or ptosis (45%; n=10/22) and dysphagia (53%; n=12/22). Respiratory failure requiring ventilatory assistance (invasive or non invasive) occured in a third of cases.

AchR Abs were detected at diagnosis in three patients (14%). We examined serum obtained prior to ICI exposure for presence of antibodies and retrieved positive results in all three cases. Electromyography showed a myopathic pattern in 13 patients (57%), whereas decrement on repetitive nerve stimulation was never observed.

Intensive care unit admission was required in 20 cases (91%). At follow-up (87 [36-255] days), mortality was 50%; death was related directly to myotoxicity in three patients (14%).

Post-mortem examination revealed muscle inflammation of both the oculomotor muscles and diaphragm.

Conclusion: Neuromuscular (oculomotor, bulbar and respiratory) signs typically observed in MG are frequent in ir-myositis and AchR Abs pre-exist in 14% of patients. In our cohort, based on electromyographic analysis, no evidence supports that the neuromuscular signs were related to a neuromuscular junction disorder. Necropsy findings may suggest that muscle inflammation underlies both oculomotor and respiratory dysfunction in ir-myositis patients. AchR Abs could be a biomarker of disease, however their pathogenic role is unclear.

MDA5 Helicase Domains Identified as the Main Targets of Anti-MDA5 Autoantibodies in European Dermatomyositis Patients

Eveline Van Gompel[1], Catia Cerqueira[2], Karine Chemin[3], Begum Horuluoglu[1], Angeles Shunashy Galindo-Feria[4], khaled amara[5], Edvard Wigren[6], Susanne Gräslund[6], Ellen De Langhe[7], Olivier Benveniste[8] and Ingrid E Lundberg[6], [1]Karolinska Institutet, Stockholm, Sweden, [2]4Dcell, Montreuil, France, [3]Division of Rheumatology, Center for Molecular Medicine, Karolinska Institutet, Stockholm, Sweden, [4]Karolinska Institutet, Karolinska University Hospital, Stockholm, Sweden, [5]Karolinska Institutet and Karolinska University Hospital, Stockholm, Sweden, [6]Karolinska Institutet, Karolinska University Hospital, Division of Rheumatology, Department of Medicine Solna, Stockholm, Sweden, Stockholm, Sweden, [7]KU Leuven, Leuven, Belgium, [8]UPMC, Paris, France

SESSION INFORMATION
Session Date: Sunday, November 7, 2021
Session Title: Muscle Biology, Myositis & Myopathies Poster (0683–0722)
Session Type: Poster Session B
Session Time: 8:30AM–10:30AM

Background/Purpose: The presence of anti-melanoma differentiation associated protein 5 (MDA5) autoantibodies in myositis patients is associated with mucocutaneous ulcerations, (rapidly progressing) interstitial lung disease (RPILD), arthritis and mild muscle involvement. There are no biomarkers to identify patients that will develop RPILD, although early initiation of treatment is essential to rescue patients from respiratory failure. The aetiology is unresolved and it is unknown which domain of the MDA5 protein is the main elicitor of an immunogenic response.

The aim of this study is to identify the domains in the MDA5 protein that are the target of autoantibodies, which could lead to more insight into the disease mechanism.

Methods: The reactivity in sera from MDA5+ dermatomyositis patients at baseline (n=20, Karolinska Institutet) and purified IgG were measured in ELISA (OD). IgG were isolated from MDA5+ plasmapheresis samples (n=9, from

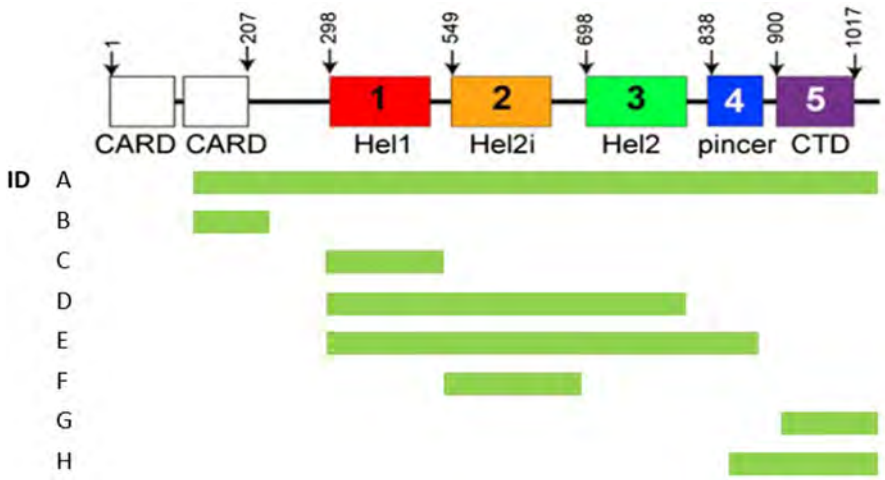

Figure 1. Graphical presentation of the MDA5 construct, each construct representing different (combinations of) domains of the MDA5 protein.

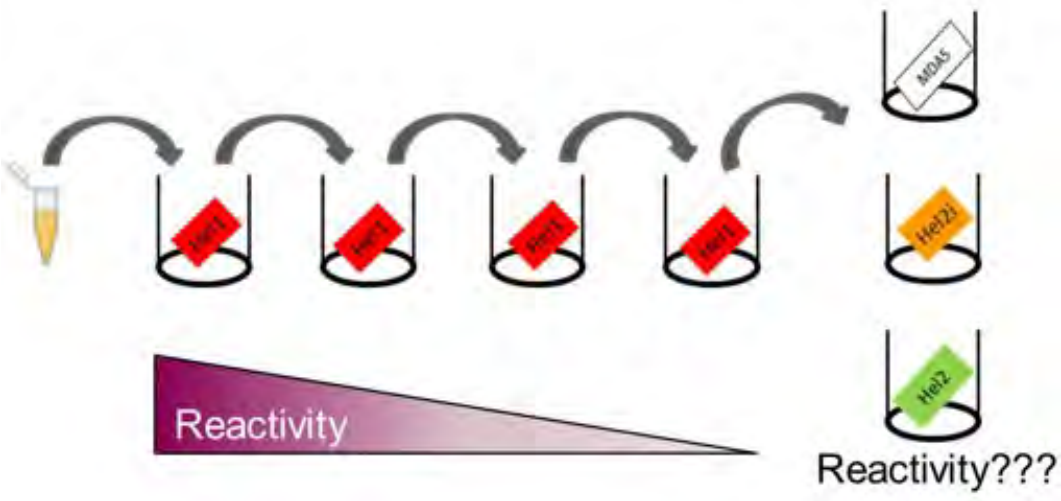

Figure 2. Graphical representation of the depletion ELISA. Samples were incubated with a primary construct to deplete all specific autoantibodies and then transferred to a secondary construct to assess if there were still specific antibodies towards the second construct.

France, Sweden and Belgium) by affinity chromatography as previously described (1). All target proteins, MDA5 constructs (UniProt ID Q9BYX4, *Figure 1*) and RIG-I (UniProt ID O95786), were produced in *E.coli*. A depletion ELISA was developed to assess the specificity of the reactivity towards the different domains. Briefly, the reactivity towards one construct was depleted in several incubation steps before the purified IgG were transferred to another construct to measure the remaining reactivity (*Figure 2*). The RIG-I protein was used as a negative control.

Results: All MDA5+ patients (n=20) showed reactivity towards the helicase (Hel) domains at the center of the MDA5 protein, but reactivity towards construct B was significantly lower compared to construct A (median OD 0.940 vs 3.13, $p< 0.0001$) and reactivity towards construct G varied between patients (median OD=2.285 [1.057-3.109]). There was no reactivity towards the RIG-I protein (0/29). After depleting antibodies that target Hel1 (or Hel2i), the reactivity towards Hel2i and Hel2 (or resp. Hel1 and Hel2) persisted.

Conclusion: Anti-MDA5 autoantibodies in plasma of dermatomyositis patients mainly target the helicase domains of the MDA5 protein. Our depletion experiments suggest that patients can have specific autoantibodies towards each

helicase domain, which implies that multiple epitopes are present on the MDA5 protein. The absence of reactivity towards construct B possibly suggests the structure of the autoantigen might differ from the endogenous MDA5 protein, but further experiments are necessary. The potential usage of anti-MDA5 reactivity as a biomarker for RPILD will be explored in an extended cohort.

SESSION INFORMATION
Session Date: Sunday, November 7, 2021
Session Title: Muscle Biology, Myositis & Myopathies Poster (0683–0722)
Session Type: Poster Session B
Session Time: 8:30AM–10:30AM

Background/Purpose: The skeletal muscle biopsy is the gold standard for idiopathic **i**nflammatory myopathies (IIM) diagnosis. Myositis specific antibodies are diagnostic biomarkers for IIM but are present in only 60-70% of cases. Another non-invasive procedure: the electromyogram (EMG) maybe useful for IIM diagnosis but its diagnostic accuracy has been poorly investigated.

We aim to define the sensitivity, the specificity, and the positive and negative predictive values of EMG for IIM diagnosis.

Methods: We conducted a single-center retrospective study between January 2018 and October 2020. We selected all consecutive patients referred to the neuropathology department for a suspicion of IIM. Patients were enrolled if an EMG was performed in our department before the muscle biopsy.

Patients were diagnosed as IIM based on myopathological finding. Patients were subclassified into dermatomyositis (DM), anti-synthetase syndrome (ASyS), overlap myositis (OM), immune mediated necrotizing myopathy (IMNM), Inclusion body myositis (IBM) and immune checkpoint inhibitor induced myositis (ICI) based on ENMC criteria.

Results: Two hundred and thirty-one patients were screened and 182 patients were included. Patients were 57.8 ± 15.8 years and 62.6% were female.

	DM	ASyS	Overlap	IMNM	IBM	ICI myositis

Short MUP	27 (90)	15 (93.8)	40 (85.1)	19 (95)	23 (85.2)	5 (29.4)

EMG was described as myogenic in 74.1% of cases. Patients were diagnosed as IIM in 86.2% of cases.

The sensitivity was 82.2%, and the specificity was 76%. The positive likelihood ratio was 3.4. The positive predictive value was 95.6% and the negative predictive value 40.4%.

The presence of EMG abnormality was highly dependent on the IIM subgroup. The sensitivity was high in DM (90%), ASyS (93.8%) and IMNM (95%). The sensitivity also high in sIBM (85.2%) and in OM (85.1%) but low in ICI myositis (29.4%) (Table1).

Statistical analysis showed that factors associated with a false negative EMG (patients; n=28) were the use of corticosteroids prior to EMG (21.7% vs 46.4% p=0.01) and the absence of myositis specific antibody (68% vs. 88.9% p=0.03).

Conclusion: EMG was sensitive and specific for IIM diagnosis but its accuracy decrease with the use corticosteroids.

Session Title: Muscle Biology, Myositis & Myopathies Poster (0683–0722)

Session Type: Poster Session B

Session Time: 8:30AM–10:30AM

Background/Purpose: The idiopathic inflammatory myopathies (IIM) are a clinically heterogeneous group of conditions affecting the skin, muscle, joint, and lung in various combinations. This study aims to investigate the immunologic heterogeneity through detailed immunophenotyping of peripheral blood mononuclear cells (PBMCs) in IIM patients and healthy controls.

Methods: We collected PBMCs from 17 patients with a clinical diagnosis of inflammatory myositis in the inpatient or outpatient setting and 18 healthy controls. Immunophenotyping was performed using mass cytometry by time of flight (CyTOF) to simultaneously characterize B, T, and myeloid cell subsets. Data were analyzed using a combination of supervised biaxial gating and unsupervised clustering algorithms including t-distributed stochastic neighbor em-

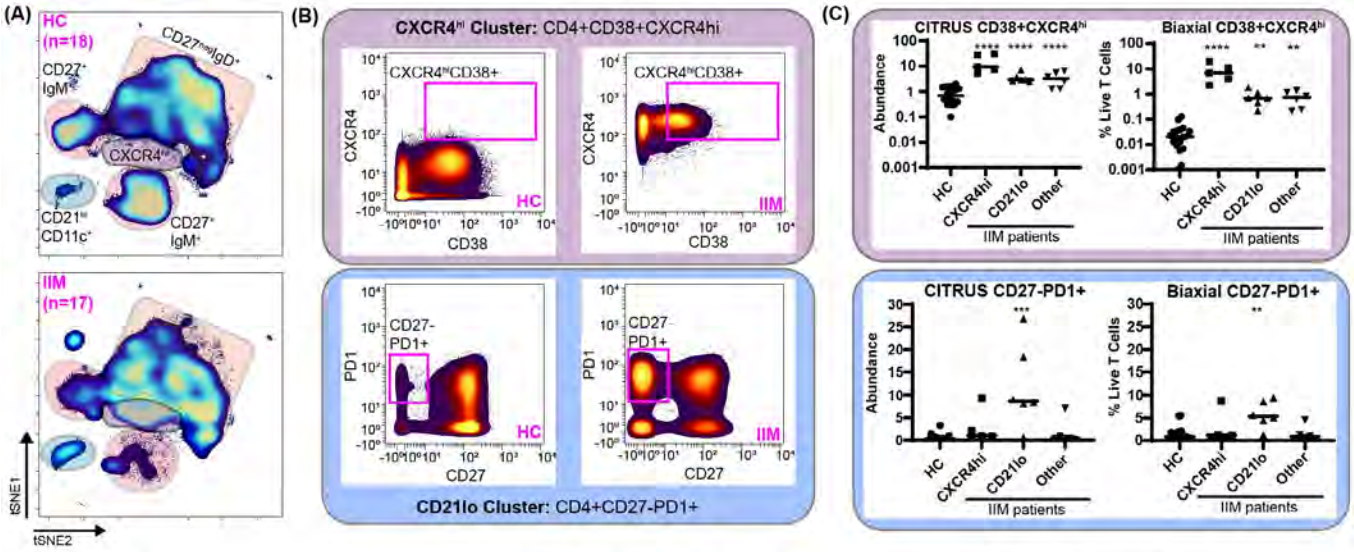

Figure 1. Preliminary immunophenotypes in the idiopathic inflammatory myopathies (IIM). (A) Density contour tSNE maps of concatenated CD19+ cells from healthy controls (HC) and IIM patients showing the increased CXCR4hi and CD21lo islands in IIM compared to healthy controls. (B) Biaxial flow cytometry plots of the CITRUS identified CD38+CXCR4hi and CD27-PD1+ CD4+T cell clusters. (C) CITRUS determined abundance and corresponding biaxial gating frequency for both the T cell clusters stratified by their B cell immunophenotype.

bedding (tSNE), cluster identification, characterization, and regression (CITRUS), and marker enrichment modeling (MEM).

Results: Patient demographics are shown in Table 1. We identified two distinct immune signatures amongst IIM patients (Figure 1). In one signature, increased CD19+CXCR4hiCCR7hi cells correlated with increased CD3+CXCR4hiCD38hi (Spearman r=0.62, p=0.009) and CD14+CD16-CXCR4+CD38+HLADR- (Spearman r=0.61, p=0.01) populations. Three out of five patients with a significant CD19+CXCR4hiCCR7hi island were critically ill with respiratory failure, a fourth was admitted with inability to swallow. In the second signature, increased CD19+CD21loCD11c+ cells correlated with an increased CD3+CD4+PD1+ (Spearman r=0.60, p=0.01) population. Of the six patients with a dominant CD19+CD21loCD11c+ island, four were Pm/Scl positive.

Conclusion: Based on circulating B cell phenotype, we identified two distinct immunologic signatures in IIM patients. Future work is needed to determine the significance of these immune signatures for clinical manifestations and treatment responses.

SESSION INFORMATION

Session Date: Sunday, November 7, 2021

Session Title: Muscle Biology, Myositis & Myopathies Poster (0683–0722)

Session Type: Poster Session B

Session Time: 8:30AM–10:30AM

Background/Purpose: Scleromyositis (SM) is an emerging subset of autoimmune myositis (AIM) in patients with features of systemic sclerosis (SSc). SM patients may present without characteristic SSc skin thickening and without known SSc autoantibodies. We previously reported that SM was characterized by marked capillary basement membrane (BM) reduplication, even in patients with mild SSc features. The objective of this study was to confirm this histopathological finding in an independent cohort.

Methods: A standardized review of an independent cohort of SM cases and AIM controls was performed by 2 reviewers. In the absence of a gold standard, SM cases were selected based on clinicoserological features by a consensus of ≥2 experts. All stains recommended by the European NeuroMuscular Center (ENMC) for histopathological assessment of inflammatory muscle biopsy were performed. Muscle biopsies from SM cases and AIM controls were categorized using the ENMC criteria. Collagen IV immunofluorescence was performed to assess endomysial capillary abnormalities (dropout and/or mural thickening and/or luminal dilation) and electron microscopy to examine capillaries for BM reduplication (mild, 2-3 layers; marked, ≥4 layers).

Results: Twenty-four SM cases and 17 AIM controls (4 dermatomyositis (DM), 5 anti-HMGCR+ immune-mediated necrotizing myopathy (IMNM), 5 inclusion body myositis (IBM) and 3 antisynthetase syndrome) were reviewed. SM cases were predominantly females (63%) and mean age at diagnosis was 58 years (range, 27-81). Proximal muscle weakness was present in 74% of SM cases and mean CK level was 2561 IU/L (range, 180-9239). Eighty-three percent (19/23) of SM cases fulfilled the ACR/EULAR SSc criteria at the time of myositis diagnosis. SSc features supporting the diagnosis of SM in the 4 remaining cases included: Raynaud's phenomenon (n=4), positive ANAs and/or SSc-associated autoantibodies (n=3), SSc-type nailfold capillaroscopy (n=3), interstitial lung disease (n=2) and puffy fingers (n=1). Using the ENMC criteria, SM cases were mainly categorized as IMNM (54%), non-specific myopathic changes (17%), non-specific myositis (13%), unclassifiable (8%), IBM (4%) or polymyositis (4%). When using complementary techniques for capillary assessment, immunofluorescence identified abnormal capillaries in 95% (20/21) of SM cases vs 56% (5/9) of controls (p=0.0195), and electron microscopy demonstrated capillary BM reduplication in 83% of SM cases vs 35% of controls (p=0.0028). This difference in BM reduplication between SM and controls was even higher when only marked BM reduplication (≥4 layers) was considered (71% of SM vs 12% of controls,

p=0.0003). In SM patients who did not fulfill the ACR/EULAR criteria for SSc, 100% (4/4) showed BM reduplication; and in SM patients without known SSc autoantibodies, 83% (5/6) showed BM reduplication.

Conclusion: In this validation study, we confirmed that marked BM reduplication is the hallmark histopathological feature of SM. Ultrastructural evaluation of muscle capillaries is useful to support an accurate diagnosis of SM.

Association of Fatigue with Disease Activity in Myositis

Tissa Bijoy George[1], Anjana Chandrasekhara Pillai[2], Siamak Moghadam-Kia[3], Nicole Neiman[4], Dana Ascherman[3], Chester Oddis[3], Dianxu Ren[4] and Rohit Aggarwal[3], [1]UPMC McKeesport, Monroeville, PA, [2]UPMC, Pittsburgh, PA, [3]University of Pittsburgh, Pittsburgh, PA, [4]University of Pittsburgh Medical Center, Pittsburgh, PA

SESSION INFORMATION
Session Date: Sunday, November 7, 2021
Session Title: Muscle Biology, Myositis & Myopathies Poster (0683–0722)
Session Type: Poster Session B
Session Time: 8:30AM–10:30AM

Background/Purpose: The Idiopathic inflammatory myopathies are a heterogeneous group of rare systemic autoimmune diseases with muscle as the primary target. Fatigue is one of the most common and prominent symptoms reported by myositis patients. Activities of daily living are frequently affected by fatigue. In this study, we investigated the cross-sectional and longitudinal association of fatigue in myositis with established clinical outcome measures.

Methods: Myositis patients [Dermatomyositis (DM), necrotizing myopathy (NM), Polymyositis(PM), and anti-synthetase syndrome (AS)] evaluated at the University of Pittsburgh Myositis Center were prospectively enrolled. Patients with active disease (defined as the escalation of immunosuppressive therapy in the previous 6 months) and inactive disease were assessed at 0, 3, and 6 months. At each of these visits, myositis core set measures (CSMs) [muscle enzymes, manual muscle testing (MMT), patient and physician global disease activity, extra-muscular disease activity, and HAQ], task-oriented functional measures [Timed up and go (TUG), Sit to Stand (STS), 6 Minute Walk Distance (6-MWD)], and patient-reported outcomes [Patient-Reported Outcomes Measurement Information System-physical function (PROMIS-PF), Short Form- 36 (SF-36) physical and mental component summary (PCS, MCS)] were evaluated. Fatigue was evaluated using the vitality domain (energy/fatigue) of the SF-36 and a 10 cm Visual Analog Scale (VAS) for fatigue (mild 0-3; moderate 3-7; severe 7-10). The phenotypic and disease activity measures of the cohort were correlated with fatigue measures using Spearman at the baseline visit. Longitudinal changes were associated with clinical improvement (per 2016 ACR/EULAR myositis response criteria) as well as physician and patient global assessment of change using the Chi-square test.

Results: Fifty patients [mean age, 51.6 (±14.9); 60% females] were studied: 6 PM, 24 DM, 9 NM, and 11 AS (without clinical myositis). The mean (SD) severity of fatigue (0-10) was 4.2 (3), with most patients having moderate (51%) or severe (16%) fatigue at baseline. No difference was observed with respect to gender, disease subtypes (DM, non-DM), or age at enrollment. However, at baseline, fatigue (both VAS and SF-36 domain) was significantly associated with active myositis and having muscle weakness. Fatigue measures showed moderate to strong correlation with several

Table 2. Association of 6-month longitudinal change in fatigue (VAS and SF-36) with 2016 ACR/EULAR response criteria, physician-reported change and patient-reported change

	ACR/EULAR Improvement			Physician reported Improvement			Patient reported Improvement		
	No (n=26)	Yes (n=13)	p value	No (n=21)	Yes (n=15)	p value	No (n=27)	Yes (n=7)	p value
Change in Fatigue VAS (mean, SD)	0.28 (2.3)	-3.20 (4.3)	0.007	-1.95 (3.9)	0.40 (2.7)	0.03	-0.68 (2.8)	0.64 (4.0)	0.26
Change in SF 36 Fatigue domain (mean, SD)	-2.70 (16.6)	27.5 (26.1)	0.004	17.33 (23.6)	-6.66 (17.6)	0.005	9.60 (22.1)	15.83 (18.5)	0.03

myositis disease activity measures including CSMs, pain, and patient-reported outcomes of physical function (table 1). Physical function measures such as PROMIS-PF, HAQ-DI, SF-36 PCS, and MCS also had a statistically strong correlation with fatigue. The longitudinal analysis over the 6-month study period suggested that fatigue improved

significantly with improvement in myositis disease activity as assessed by 2016 ACR/EULAR response criteria as well as physician and patient-reported assessment of change in disease activity.

Conclusion: Fatigue is common in myositis and has a moderate to strong correlation with disease activity measures, muscle strength, and functional outcome measures. Further, an improvement in fatigue is associated with the clinical response using the ACR/EULAR myositis response criteria.

SESSION INFORMATION
Session Date: Sunday, November 7, 2021
Session Title: Muscle Biology, Myositis & Myopathies Poster (0683–0722)
Session Type: Poster Session B
Session Time: 8:30AM–10:30AM

Background/Purpose: Although pain is one of the most common and highest priority symptoms reported by people with autoimmune inflammatory myopathies (AIM), large descriptive studies on pain in AIM are lacking. The objective of this study was to assess the prevalence, severity, functional impact, and clinical correlates of pain in AIM.

Methods: We undertook a cross-sectional study of adult AIM subjects in a large multicenter cohort. Standardized clinical histories, medical examinations, and self-administered questionnaires were collected at baseline study visit. Severity of pain was assessed using a Numeric Rating Scale (NRS; scores ranging from 0 (no pain) to 10 (very severe pain)). Pain interference with work (including both work outside the home and housework) was measured using the Short Form 36 (SF-36) (5-point Likert scale: not at all, a little bit, moderately, quite a bit, extremely). Global and skin disease activity were rated by the study physician using a NRS ranging from 0 (no activity) to 10 (maximum severity). Physical functioning was assessed using the Health Assessment Questionnaire (HAQ; scores ranging from 0 (no disability) to 3 (severe disability)). Ordinal logistic regression models were generated to determine the association between pain severity at baseline and selected clinical predictors.

Results: The study included 143 AIM subjects (69% female, median disease duration 1.6 years and mean age at diagnosis 56 years) with dermatomyositis (DM; 33%), overlap myositis (OM; 35%), anti-synthetase syndrome (ASS; 13%), inclusion body myositis (IBM; 13%), immune-mediated necrotizing myopathy (IMNM; 5%), and polymyositis/unspecified (PM/UNS; 2%) (Table 1). At baseline, 27% of subjects had myalgia, 59% active myositis, 39% interstitial

DM, dermatomyositis; OM, overlap myositis; ASS, anti-synthetase syndrome; IBM, inclusion body myositis; IMNM, immune-mediated necrotizing myopathy; PM, polymyositis; UNS, unspecified; CK, creatine kinase; ab, autoantibodies; NRS, numerical rating scale; SD, standard deviation; IQR, interquantile range.
†Present at time of baseline visit as per Myosiits Disease Activity Assessment Tool (MDAAT).

lung disease, 12% arthritis and 34% Raynaud's phenomenon (Table 1). At baseline, mean (SD) skin activity was 1.1 (1.6), and mean (SD) global disease activity 2.7 (2.0). Mean (SD) creatine kinase (CK) was 1380 UI/L (6120). Median (IQR) HAQ score was 1 (0.3-1.9) indicating moderate functional disability.

Median (IQR) pain severity was 3 (1-7), with 64% of subjects reporting some level of pain (13% severe, 21% moderate, 30% mild pain) (Table 2). Pain interference with work affected 73% of patients (10% extremely, 27% moderately, 16% quite a bit, 20% a little bit). Among the AIM subsets, a higher percentage of patients with DM, OM, and ASS reported severe pain compared to other subsets. The IBM subjects reported more severe pain interference than in any other subset.

Univariate and multivariate logistic ordinal regressions showed statistically significant associations of baseline pain severity with age at diagnosis and arthritis (Table 3). After adjustment, patients with arthritis were almost 3 times more likely to report higher pain level than those without (OR [95%CI] 2.77 [1.04-7.48], p-value 0.04). By contrast, for every one-year increase in age at diagnosis, the odds of having pain decreased by 4% (OR [95%CI] 0.96 [0.94-0.99], p-value 0.008).

Increased Risk of Venous Thromboembolism in Adult Patients with Idiopathic Inflammatory Myopathies

Gözde Kübra Yardımcı[1], Arzu Taghiyeva[2], Enes Erul[2], Bayram Farisogulları[3], **Levent Kilic**[1] and Sule Apraş Bilgen[1], [1]Hacettepe University, Faculty of Medicine, Department of Internal Medicine, Division of Rheumatology, Ankara, Turkey, [2]HACETTEPE UNIVERSITY, Ankara, Turkey, [3]Division of Rheumatology, Department of Internal Medicine Faculty of Medicine, Hacettepe University, Ankara, Turkey

SESSION INFORMATION

Session Date: Sunday, November 7, 2021

Session Title: Muscle Biology, Myositis & Myopathies Poster (0683–0722)

Session Type: Poster Session B

Session Time: 8:30AM–10:30AM

Background/Purpose: Idiopathic inflammatory myopathies (IIMs) patients have a higher risk of venous thromboembolism (VTE) [1]. We aimed to assess the incidence of thrombosis and associated factors in IIMs patients.

Methods: 93 IIMs patients (44 dermatomyositis and 49 polymyositis) were retrospectively reviewed to identify patients who had experienced a thrombosis during the follow-up period. The patients' clinical characteristics, association with cancer, presence of thrombophilia, APSL autoantibodies, and intravenous immunoglobulin (IVIG) therapy were systematically analysed.

Results: 93 cases with IIMs (64.5% female) were followed median 27.6 (IQR:11.6-75.4) months. The incidence of a thrombotic event in the total cohort was 8.6%. Median time to development of venous thromboembolism was 4 (IQR:1-28,75) months and 75% of the thrombotic events developed during the first year after IIM diagnosis (Table). Venous thromboembolism was not associated with age, sex, cancer or IVIG therapy.

Conclusion: The prevalence of thrombotic events was 8.6% in our cohort and the risk of VTE is highest in the first year of disease. Further studies are needed to identify high-risk patients and to test the role of thromboprophylaxis.

Table. Patients with polymyositis/dermatomyositis and venous thromboembolism

Patient	Diagnosis/ Onset age, years	Time from diagnosis to first thrombotic event, months	VTE	Malignancy	Thrombophilia	APSL autoantibodies
1	PM/35	6	Sinus thrombosis	No	Negative	Negative
2	PM/57	2	DVT	No	Not available	Negative
3	PM/67	0	Massive PE	No	Not available	Negative
4	PM/55	1	DVT/PE	No	Negative	Negative
5	DM/47	1	Iliac vein	No	Negative	Negative
6	PM/56	36	Portal vein	Breast	Not available	Negative
7	DM/63	7	Right cephalic vein, external iliac vein, vena saphena magna	Breast	Not available	Not available
8	PM/61	50	Popliteal vein	No	Negative	Negative

Abbreviatoins: PM: Polymyosisits; DM:Dermatomyositis; VTE: venous thrombosis; DVT: Deep vein thrombosis; PE: Pulmonary embolism,; Thrombophilia: include Factor V Leiden and prothrombin gene mutation; MTHFR gene mutation, homocysteine, antithrombin, Protein C, Protein S and Factor VIII, APSL: antiphospholipid

Abstract Number: 0720

The Clinical Significance of anti-PC4 and SFRS1 Interacting Protein 1 Antibody in Polymyositis and Dermatomyositis Patients

Yuji Hosono[1], Azusa Kojima[1], Akira Ishii[1], Yuto Izumi[1], Kazuki Hirano[1], Noriko Sasaki[2], Chiho Yamada[1] and Shinji Sato[3], [1]Tokai University School of Medicine, Isehara, Japan, [2]tokai university, sagamihara-city, Japan, [3]Tokai University, Isehara, Japan

SESSION INFORMATION
Session Date: Sunday, November 7, 2021
Session Title: Muscle Biology, Myositis & Myopathies Poster (0683–0722)
Session Type: Poster Session B
Session Time: 8:30AM–10:30AM

Background/Purpose: Many kinds of myositis specific autoantibodies are detected in sera from polymyositis (PM) and dermatomyositis (DM). Screening for autoantibodies is essential in the diagnostic workup of systemic autoimmune rheumatic diseases (SARD). It is noteworthy that recent reports suggest anti- PC4 And SFRS1 Interacting Protein 1 (PSIP1) are more prevalent in healthy individuals compared to SARD, especially systemic lupus erythematosus. However, it is still unclear its significance in PM/DM. Thus, we investigated the frequency of anti-PSIP1 Ab and the clinical features in PM/DM.

Methods: Adult Japanese PM/DM (N=87), SLE (N=17) patients who were treated at Tokai University hospital from 2012 to 2020 and healthy controls/non-SARD (N=41) were enrolled. Anti-ARS, SRP Ab were screened by RNA-immunoprecipitation and anti-MDA5, anti-TIF-1 Ab were detected by immunoprecipitation with [^{35}S]methionine-labeled HeLa cells. anti-PSIP1 Ab and anti-MDA5 Ab titers were measured using enzyme-linked immunoabsorbent assay (ELISA). Clinical data was retrospectively collected.

Results: The frequency of anti-PSIP1 Ab was 27.6% (24/87) in PM/DM, 7.3% (3/41) in healthy controls/non-SARD and 11.8% (2/17) in SLE.

Of note, the prevalence of anti-PSIP1 Ab was significantly higher in PM/DM compared to healthy control/non-SARD and SLE ($p < 0.05$). The prevalence of anti-PSIP1 Ab in PM/DM patients with anti-ARS, SRP, TIF1-γ and MDA5 Ab were 35.7% (10/28), 11.1% (1/9), 40% (4/10) and 22.5% (9/40), respectively. Among anti-ARS Ab positive PM/DM, none of anti-OJ (0/5) or anti-PL-7 (0/5) were positive for anti-PSIP1, while 66.7% (4/6) of anti-Jo-1 and 50% (6/12) of anti-PL-12 were. In addition, the change of anti-PSIP1 Ab titers were seemed to be correlated with those of anti-MDA5 Ab in the disease course.

Conclusion: In our study, anti-PSIP1 Ab was frequently detected in PM/DM, compared to healthy control/non-SARD and SLE. In addition, measurement of anti-PSIP1 Ab titers may be an indicator of disease activity in DM with anti-MDA5 Ab.

Timed Function Tests as Measures of Disease Activity and Functional Outcome in Inflammatory Myositis

saikumar dunga[1], Chengappa Kavadichanda[2] and VirSingh Negi[3], [1]Jawaharlal Institute of Postgraduate Medical Education and Research, Puducherry, India, [2]JIPMER, Pondicherry, India, [3]Jawaharlal Institute of Postgraduate Medical Education and Research (JIPMER), Puducherry, India

SESSION INFORMATION
Session Date: Sunday, November 7, 2021
Session Title: Muscle Biology, Myositis & Myopathies Poster (0683–0722)
Session Type: Poster Session B
Session Time: 8:30AM–10:30AM

Background/Purpose: Manual muscle testing (MMT) and Functional index 2(FI-2) are the usual methods in assessing disease activity and functional status in IIM[1]. Limitations of MMT8 include low sensitivity to change and floor/ceiling effect[2] .FI-2 takes a longer time to administer. Several Timed function tests (TFTs) namely 2-minute walk test (2MWT), 30s raise from a chair test and 30s 1kg arm rise test have potential to measure both these aspects[2] and needs to be evaluated in IIM.

Our objective was to evaluate the performance of TFT in assessing muscle diseases at baseline and to evaluate the performance of TFTs to detect the longitudinal change in muscle power and endurance at 3 and 6 months.

Methods: This was an observational cohort study which included 42 patients with polymyositis and dermatomyositis satisfying EULAR/ACR classification criteria. MMT8, FI-2, FI-3 and TFTs were done at baseline, 3 months and 6 months. Individuals with a stable MMT-8 over last 1 month with no evidence of extra muscular disease activity were classified as inactive and the others as active disease.

Table 1. Mean MMT8, F-2, FI-3, and Timed function tests in active and inactive disease groups at baseline, 3 months, and 6 months

	Baseline (n=42)		3 months (n=42)		6 months (n=39)	
	Active disease (n=18)	Inactive disease (n=24)	Active disease (n=16)	Inactive disease (n=23)	Active disease (n=18)	Inactive disease (n=24)
Mean MMT8	62.6 ± 14.19	73 ± 2.2	69.7 ±8.6	75.1 ± 1.6	73.8 ±7.5	75.8 ± 2.1
Mean Fi-2	3.48±2.53	5.85±2.4	6.85±1.8	7.5±2.6	8.6 ± 2.3	7.8 ± 1.9
Mean Fi-3	1.24±0.53	3.65±1.4	2.8±0.84	3.8±0.62	3.6 ± 0.4	3.8 ± 1.2
Mean 30s rise from chair test	12±7.2	15±4.5	14.8±6.9	16±4.7	18 ± 5.4	17.3 ± 4
Mean 30s 1kg arm rise test	14.3±8.2	17±5.7	17.5±7.3	18.6±5.9	22.1 ± 4	20.1 ± 3
Mean 2MWD	82±5.1	128±30.3	105±45.3	134±26.8	126 ± 38	137 ± 24.2

MMT8- Manual muscle testing 8, Fi- Functional index, 2MWD- 2 Minute walk distance

Table 2. Correlation between TFT and MMT8, FI-2 & FI-3 at baseline in the study population

		Total study population (n=42)	Active disease (n=18)	Inactive disease (n=24)
Correlation of MMT8 with TFTs	**30s rise form chair**	**0.709***	0.581	**0.841***
	30s1kg arm lift	**0.699***	0.574	**0.762***
	2MWD	**0.806***	**0.781***	**0.649***
Correlation of FI-2 with TFTs	**30s rise form chair**	**0.755***	**0.811***	**0.658***
	30s1kg arm lift	**0.829***	**0.801***	**0.796***
	2MWD	**0.811***	**0.790***	**0.766***
Correlation of FI-3 with TFTs	**30s rise form chair**	**0.711***	**0.657***	**0.649***
	30s1kg arm lift	**0.804***	**0.621***	**0.769***
	2MWD	**0.789***	**0.709***	**0.779***

MMT8- manual muscle testing 8, Fi- Functional index, 2MWD- 2 Minute walk distance
*indicates p value<0.05

Results: All 42 [11 (27%) polymyositis, and 31 (73%) dermatomyositis] completed three month follow-up assessment and 39 underwent evaluation at 6 months. The mean MMT8 of the total study population at 59±12, 67 ±8 and 71 ± 9 at baseline, 3 and 6 months respectively. In the active disease subgroup the MMT-8 was 62.6 ± 18, 69.7 ± 9 (n=42), 73.8 ± 9.6 (n=39)at baseline, 3 and 6 months respectively. The 3 TFTs had moderate to high correlation with MMT8 and FI-2 adn FI-3 at baseline (Table 2). The change in TFTs showed a moderate to strong correlation with the change in FI-2 as well as FI-3 among the study population at three months and six months (Table 3). Among the TFTs 2MWD had the best performance with moderate correlation with both MMT8, FI-2 and FI-3 in active disease suggesting a role in assessing both disease activity and endurance.

Conclusion: Using timed function tests can be an excellent alternative to FI-2/3 in assessing muscle endurance. 2-minute walk distance could be a better alternative to conventional muscle testing as it measures both power and endurance, is simple to perform and could be a valid patient reported outcome measure.

Table 3. Correlation of change in TFT with change in composite MMT8, FI-2 at 3 months and 6 months

		At 3 months (n=42)		At 6 months (n=39)	
		Active disease (n=18)	Inactive disease (n=24)	Active disease (n=16)	Inactive disease (n=23)

Myostatin in Idiopathic Inflammatory Myopathies: Seric Assessment and Disease Activity

Alexandrine Mahoudeau[1], Céline Anquetil[2], Nozomu Tawara[1], Hossein Khademian[1], Damien Amelin[1], Yves Allenbach[3] and Olivier Benveniste[3], [1]Center of Research in Myology, Sorbonne University, Paris, France, [2]Center of Research in Myology, Sorbonne University - AP-HP, Pitié-Salpêtrière Hospital, Department of Clinical Immunology and Internal Medicine, Paris, France, [3]Sorbonne University - AP-HP, Pitié-Salpêtrière Hospital, Department of Clinical Immunology and Internal Medicine, Paris, France

SESSION INFORMATION

Session Date: Sunday, November 7, 2021

Session Title: Muscle Biology, Myositis & Myopathies Poster (0683–0722)

Session Type: Poster Session B

Session Time: 8:30AM–10:30AM

Background/Purpose: In Idiopathic Inflammatory Myopathies (IIM) disease activity is very difficult to assess and IIM may induce severe muscle damage, especially in immune-mediated necrotizing myopathies (IMNM). We hypothesize that myostatin, a negative regulator of muscle mass, could be a new biomarker of disease activity and/or muscle damage.

Methods: Prospective assessment of myostatin protein level in 447 IIM sera samples (dermatomyositis (DM), n=157; inclusion body myositis (IBM), n=72; immune-mediated necrotizing myopathies, n=125; anti-synthetase syndrome (ASyS), n=93) and 59 healthy donors (HD) was performed by ELISA. A gene transcript analysis was also carried out on 18 IIM muscle biopsies and 6 HD to analyze the expression of myostatin and myostatin pathway genes.

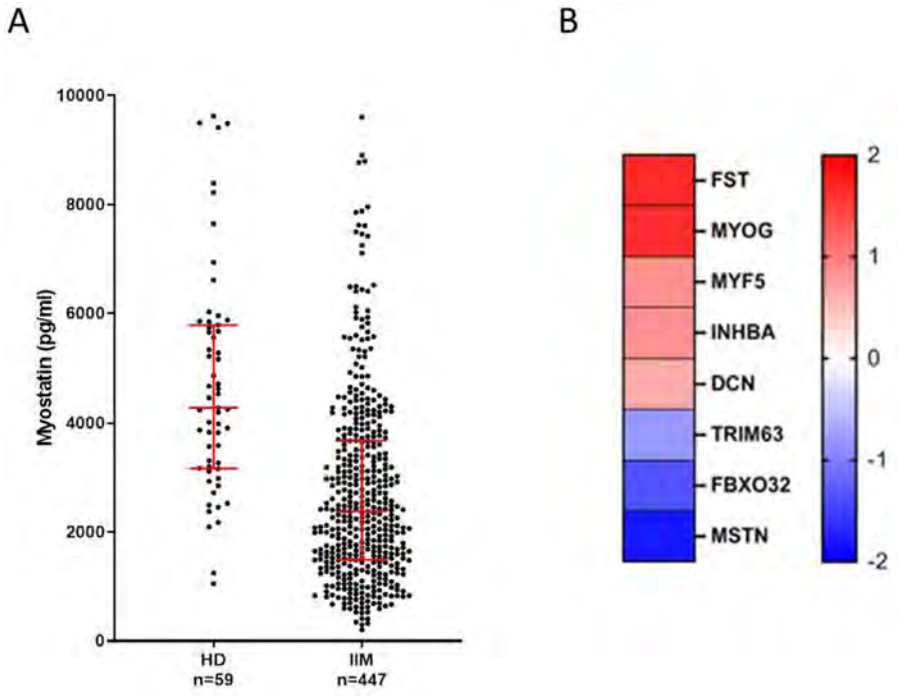

Figure 1. Quantification of circulating myostatin (A) and expression (Log2FC) of genes implicated in the myostatin pathway in IIM (B) compared to HD FST: follisatin, MYOG: myogenin, MYF5: myogenic factor 5, INHBA: inhibin A, DCN: decorin, TRIM63: Tripartite Motif Containing 63, FBXO32: F-box Protein 32, MSTN: myostatin.

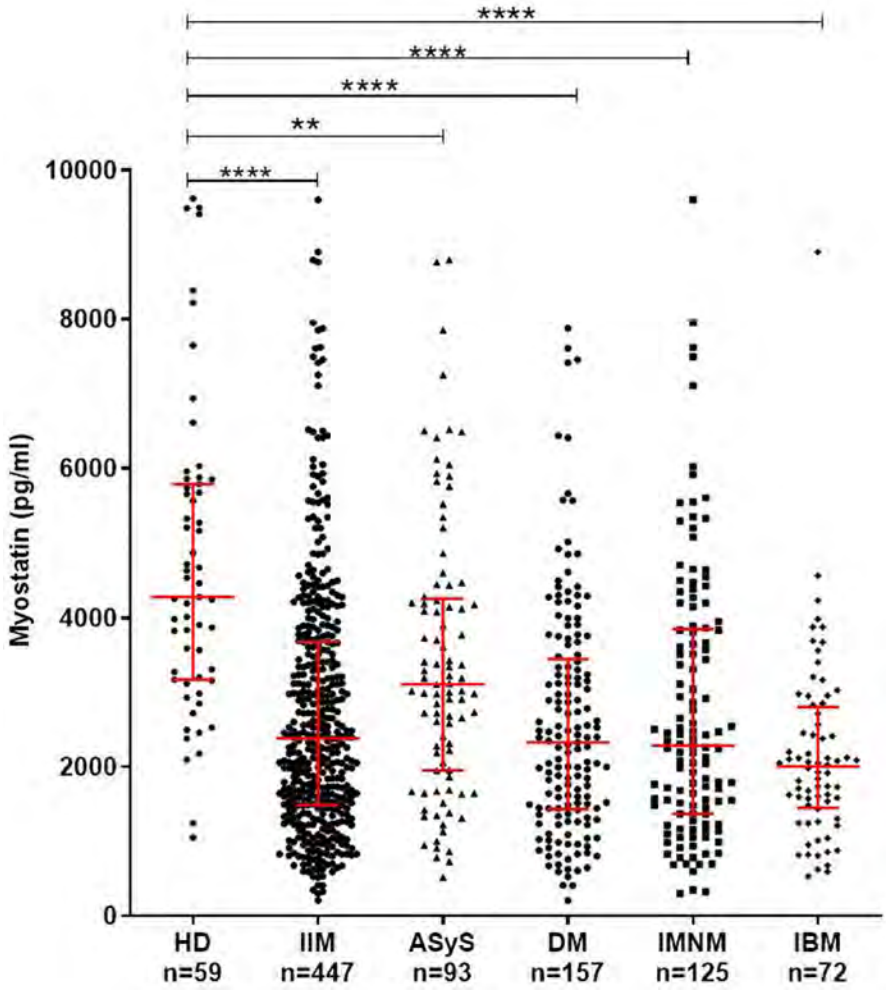

Figure 2 . Circulating myostatin levels in IIM subgroups.

Results: IIM patients had lower myostatin circulating protein levels and gene expression compared to HD (2379 [1490; 3678] pg/ml vs 4281 [3169; 5787] pg/ml; p< 0.0001 and log2FC=-1.83; p=0.0005 respectively) (Fig1). Myostatin-related genes expression varied accordingly. Myostatin circulating levels were then assessed for each subgroups. Myostatin levels were lower in ASyS (3109 [1952; 4258] pg/ml; p=0,001), DM (2327 [1431; 3446] pg/ml; p< 0.0001),

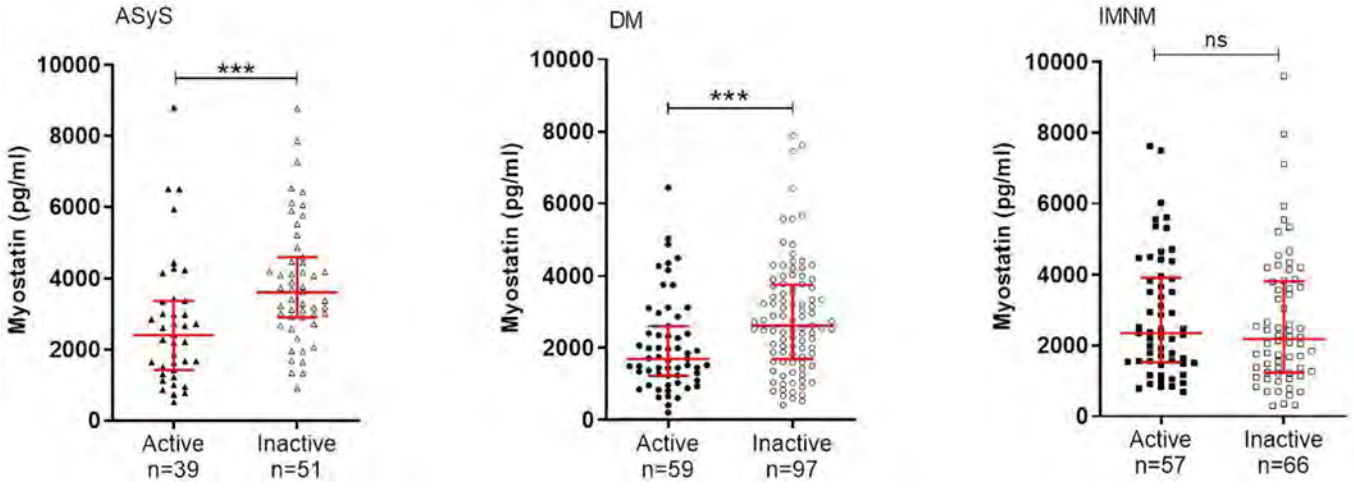

Figure 3 . Circulating myostatin levels in active vs inactive IIM patients.

IMNM (2285 [1371; 3851] pg/ml; p< 0.0001) and IBM (2005 [1449; 2803] pg/ml; p< 0.0001) compared to HD (4281 [3169; 5787] pg/ml) (Fig2). Based on the Physician Global Activity score, inactive IIM patients had higher myostatin levels than active ones. This was the case for all IIM subgroups, except IMNM patients where low myostatin levels were maintained (2186 [1235; 3815] vs 2349 [1518; 3922] pg/ml; p=0.4) even during remission (Fig3).

Conclusion: Myostatin protein and RNA levels are decreased in all IIM patients and circulating protein levels are correlated with disease activity. Inactive ASyS and DM patients have higher level of myostatin than active patients. Myostatin could be a marker of disease activity in these two subgroups. However, IMNM patients do not have a significant increase in myostatin levels after disease remission. This observation may highlight a new pathological disease mechanism in IMNM patients.

Abstract Number: 0723

Size of Regression to the Mean in First-Line Interventions for Osteoarthritis: An Illusion of Effectiveness

Martin Englund and Aleksandra Turkiewicz, Lund University, Lund, Sweden

SESSION INFORMATION
Session Date: Sunday, November 7, 2021
Session Title: Osteoarthritis – Clinical Poster II (0723–0738)
Session Type: Poster Session B
Session Time: 8:30AM–10:30AM

Background/Purpose: Persons who seek treatment for osteoarthritis (OA) are likely doing so when experiencing a flare-up in pain. Due to natural fluctuation of pain, this will lead to regression to the mean (RTM), i.e. on average less pain at follow-up. In contrast to placebo response, RTM is deceiving as it constitutes *no* treatment response. Using reported results from two nation-wide exercise and education interventions, we estimated the size of the reported average improvement that could be attributable to RTM.

Methods: From the annual reports 2019, we retrieved average pain levels and reported improvement for knee OA patients enrolled in the Good Life with osteoArthritis in Denmark (GLA:D®) and Better Care for OA (BOA), Sweden. Both programs are similar first-line exercise and education programs for patients with OA.

To estimate mean levels of pain in subjects with symptomatic knee OA, i.e. the underlying population of GLA:D® and BOA, we used cohort data from the Osteoarthritis Initiative (OAI), USA, and the Malmoe OA study (MOA), Sweden. From OAI we included subjects with radiographic knee OA at baseline, 12 or 24 months, who reported knee pain, aching or stiffness on most days of at least one month the past 12 months at the baseline visit. MOA consisted of two parts: First, subjects responded to a postal questionnaire. Later, they had a clinic visit when knee X-rays were obtained. We included subjects who had signs of OA on X-rays and reported knee pain in the postal questionnaire. For OAI, we report pain values at both 12 and 24 months, and for MOA we report pain assessed at the clinic visit.

We used OAI data to estimate variability in pain over time, i.e. we determined the intra-class correlation coefficient (ICC) of two measurements (Table 1). To estimate the size of RTM expected in GLA:D®/BOA, we used a known formula: (1 - ICC)*($mean^{Pop}$ – $mean^{Int}$), where $mean^{Pop}$ is mean pain in the underlying population and $mean^{Int}$ is mean pain

Table 1. Standard deviation (SD) and intra-class correlation coefficient (ICC) of NRS pain over 12 months in OAI participants with radiographic knee OA (Kellgren Lawrence grade =2) and reporting knee pain, aching or stiffness on most days of at least one month the past 12 months knee pain on at least one follow-up between baseline and 48 months.

	NRS pain		
Visits	Between subjects, SD	Within subjects, SD	ICC (95%CI)*
12 months & 24 months	1.9	2.0	0.49 (0.46, 0.53)
36 months & 48 months	2.1	1.9	0.56 (0.52, 0.59)

*Based on these results, in RTM estimation using bootstrapping we sampled ICC from normal distribution with mean of 0.53 and standard deviation of 0.02.

in the intervention cohort at baseline. We assumed the difference in NRS pain between the underlying population and GLA:D®/BOA participants at baseline to vary from 0.4 to 1.3 (Table 2). To also address the uncertainty around the value of ICC we used bootstrapping. As a sensitivity analysis we evaluated the change in pain from baseline to 12 months in OAI.

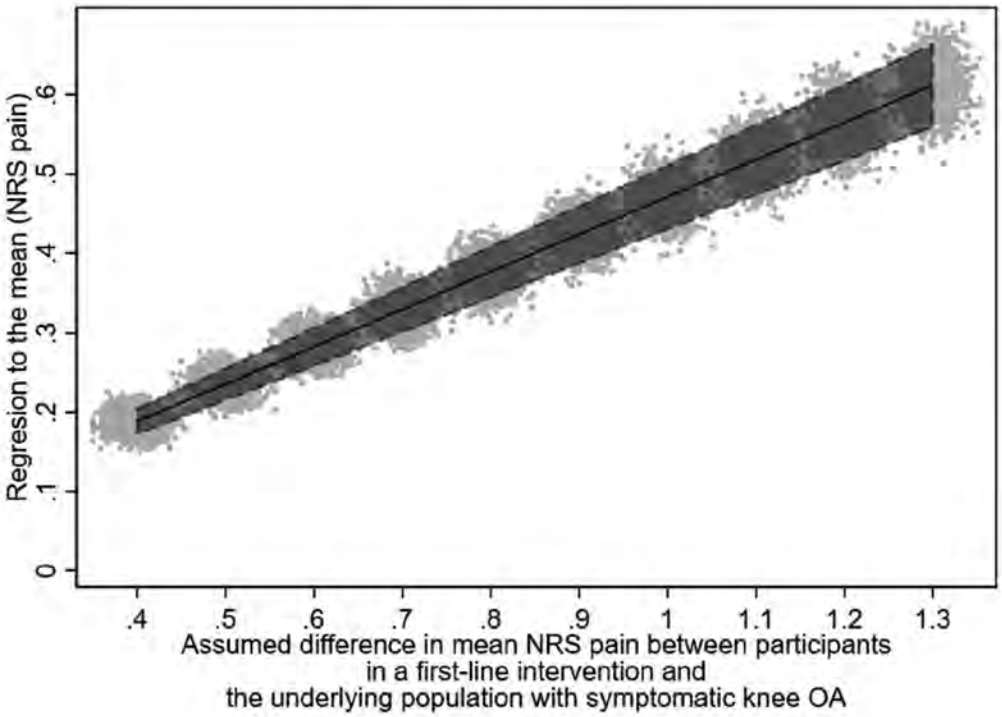
Results: The mean NRS pain levels at baseline in GLA:D® and BOA participants were *worse* than in persons with symptomatic knee OA from both the OAI and MOA (Table 2). An average ICC for NRS was ~0.53 (Table 2). We estimated the absolute improvement attributable to RTM in GLA:D®/BOA to range from 0.2 to 0.6 NRS points, depending on the assumptions (Figure 1) in line with the 0.5 NRS point improvement observed in OAI. The reported improvement in NRS from baseline to 12 months in GLA:D® was 1.3 and in BOA 1.0. Thus, in relative terms RTM ranges from 15% to 60% of the reported improvement in NRS pain.

Table 2. Key descriptive statistics for the OAI, MOA, GLA:D® and BOA participants.

	Persons with symptomatic knee OA, on a scheduled study visit			Knee OA patients self-enrolling in a first-line OA intervention	
	OAI, 12 months visit, n=1085	OAI, 24 months visit, n=1044	MOA, n=486	GLA:D®, baseline visit n=10 000*	BOA, baseline visit n=28 882*
Age, mean years	61	61	73	65	66
% women	56	56	65	68	69
BMI, mean kg/m^2	29	29	29	29	28
KOOS pain, mean	73	74	69	N/a	N/a
NRS pain, mean	3.9	4.0	4.3†	4.7§	5.2

N/a = Not available; data not collected or not presented in the annual report.
* Numbers as reported in each annual report 2019 for GLA:D® and BOA, respectively.
† The association between KOOS pain subscale and NRS pain in OAI data in persons with knee OA was linear with the formula: NRS=9.68-0.078*KOOS pain value. Thus, we used this formula to convert the mean KOOS pain in MOA of 69 to NRS value of 4.3.
§ We converted VAS values reported in GLA:D® to NRS values, by dividing by 10.

Figure 1. Size of the regression to the mean (in absolute NRS value), median (solid line), 2.5 and 97.5 percentile (dashed outer lines) of the estimated values (sampling 95% confidence intervals), depending on the difference in mean NRS pain in persons included in the first-line education and exercise programs and the underlying population with knee OA.



Conclusion: RTM in knee OA patients enrolled in a first-line intervention likely explains between 15% to 60% of the reported average improvement at 12 months. Results from OA interventions without control group(s) should not be inferred to as treatment effectiveness in reporting or marketing because the improvement is inflated by RTM which is neither an effect of the intervention, nor part of placebo response.

Dose (Exposure) Efficacy Response of Tanezumab Following Intravenous and Subcutaneous Administration Across Phase 2 and Phase 3 Studies in Patients with Osteoarthritis of Hip and Knee

Martin Boucher[1], Kenneth Verburg[2], Puneet Gaitonde[2] and Scott marshall[1], [1]Pfizer R&D Ltd., Sandwich, United Kingdom, [2]Pfizer Inc., Groton, CT

SESSION INFORMATION

Session Date: Sunday, November 7, 2021
Session Title: Osteoarthritis – Clinical Poster II (0723–0738)
Session Type: Poster Session B
Session Time: 8:30AM–10:30AM

Background/Purpose: Tanezumab is a humanized monoclonal antibody against nerve growth factor that has been evaluated for relief of chronic osteoarthritis pain by subcutaneous (SC) or intravenous (IV) administration every 8

Table. Predicted multiple imputation treatment differences (95% CI)

Endpoint	Tanezumab 2.5 mg vs placebo	Tanezumab 5 mg vs placebo	Naproxen vs placebo	Naproxen vs placebo (sensitivity analysis)
WPS	−0.75 (−0.84, −0.69)	−0.90 (−0.98, −0.84)	−0.25 (−0.36, −0.13)	−0.49 (−0.79, −0.19)
WOMAC Pain	−0.85 (−0.92, −0.79)	−1.00 (−1.10, −0.95)	−0.40 (−0.51, −0.30)	−0.52 (−0.84, −0.20)
WOMAC Physical Function	−0.91 (−1.00, −0.85)	−1.00 (−1.10, −0.97)	−0.28 (−0.43, −0.17)	−0.47 (−0.77, −0.17)

CI, confidence interval; WOMAC, Western Ontario and McMaster Universities Osteoarthritis Index; WPS, weekly average pain score.

weeks. The current objectives were to (1) characterize the dose-response relationship between assigned dose and selected measures of efficacy at Week 16, (2) determine if average plasma tanezumab concentrations between 12 and 16 weeks ($C_{av12–16}$) could explain variability in the exposure-response, and (3) compare dose-response characterization for phase 2 vs phase 3 studies.

Methods: Data were pooled from 7 placebo-controlled clinical studies of tanezumab (2.5, 5, or 10 mg) administered via SC or IV routes in patients with osteoarthritis. Two of the 7 studies also included an active-controlled naproxen arm. Weekly average pain score (WPS), Western Ontario and McMaster Universities Osteoarthritis Index (WOMAC*) Pain subscale score, and WOMAC Physical Function subscale score were evaluated. Population modeling analyses were conducted, using stepwise covariate modeling and multiple imputation methods consistent with the primary efficacy analysis to account for dropout. Sensitivity analyses used estimates of naproxen vs placebo, with study as an additional covariate on placebo response.

Results: Maximum effect models adequately described the dose-response relationship at Week 16 for all 3 endpoints; E_{max} point estimates (95% confidence interval [CI]) were: WPS −1.12 (−1.49, −0.76), WOMAC Pain −1.21 (−1.55, −0.87), and WOMAC Physical Function −1.22 (−1.55, −0.90). Model-based estimates of the treatment differences at Week 16 are shown in the **Table**; a 5 mg dose would provide only a 10–20% increase in effect over a 2.5 mg dose. Sensitivity analysis estimates (95% CI) of treatment differences for naproxen vs placebo for comparison with final model estimates are shown in the Table. Age was a significant covariate on E_{max} for all 3 endpoints; older patients had larger treatment effects compared with placebo than younger patients: between −0.15 and −0.24 for 75th age percentile and 25th age percentile, respectively. Exposure ($C_{av12–16}$) was not a significant covariate on E_{max} and route of administration (SC vs IV) was not a significant treatment effect modifier at Week 16 for any endpoint. The phase 2 study had a significantly lower placebo response and higher E_{max} compared with phase 3 studies for WPS and WOMAC Pain endpoints; after correcting for these differences, the estimated dose-response adequately covered the observed data across the phase 2 and phase 3 dose ranges.

Conclusion: Model-based simulations of E_{max} showed useful efficacy of pain relief with tanezumab 2.5 mg, with an increase in effect over naproxen. There was little effect gain at a higher tanezumab dose of 5 mg, and comparable efficacy between SC and IV routes of administration.

Efficacy of Subcutaneous Tanezumab for the Treatment of Osteoarthritis of the Knee or Hip: A Post Hoc Subgroup Analysis of Patients from a Randomized, NSAID-Controlled Study with a History of Depression, Anxiety, or Insomnia

Philip Mease[1], Theresa Mallick-Searle[2], Elizabeth Johnston[3], Lars Viktrup[3], Dominique Menuet[4], Ruoyong Yang[5] and Robert Fountaine[6], [1]Swedish Medical Center/Providence St. Joseph Health and University of Washington, Seattle, WA, [2]Stanford Health Care, Redwood City, [3]Eli Lilly and Company, Indianapolis, IN, [4]Pfizer SAS, Paris, France, [5]Pfizer Inc., New York, NY, [6]Pfizer Inc., Groton, CT

SESSION INFORMATION
Session Date: Sunday, November 7, 2021
Session Title: Osteoarthritis – Clinical Poster II (0723–0738)
Session Type: Poster Session B
Session Time: 8:30AM–10:30AM

Background/Purpose: Tanezumab is a monoclonal antibody directed against nerve growth factor that is under study to treat moderate to severe chronic pain associated with osteoarthritis (OA) in adults for whom other treatments are ineffective or not appropriate. Phase 3 clinical trials have demonstrated the efficacy of subcutaneous (SC) tanezumab vs placebo for pain and function outcomes over various timepoints. Largely similar change from baseline was demonstrated in an oral NSAID-controlled study.[1-3] The efficacy of some other OA therapies can be dampened in patients with depression, anxiety, or insomnia.[4-6] A post hoc analysis explored efficacy of SC tanezumab after 16 weeks of treatment, as compared to oral NSAID, in patients with OA and a history of depression, anxiety, or insomnia at baseline.

Methods: A randomized, double-blind, double-dummy, active-controlled phase 3 study (NCT02528188) of tanezumab SC 2.5 or 5 mg every 8 weeks vs twice daily oral NSAID in patients (aged ≥18 y) with radiographically confirmed moderate to severe hip or knee OA (KL grade ≥2).[3] Co-primary efficacy endpoints were change from randomization to Week 16 in WOMAC Pain and Physical Function subscale scores (both ≥5/10 at baseline; higher scores indicate increasing pain/disability) and PGA-OA (≥3/5 at baseline; higher scores indicate poorer condition). Patients had a history of inadequate pain relief with acetaminophen; inadequate pain relief with/intolerance/contraindication to tramadol or opioids, or unwillingness to take opioids. Patients were on a stable dose of NSAID for ≥30 days before screening. Data are presented as least squares (LS) mean change from baseline to Week 16 for the whole population and subgroups of patients with/without a history of depression, anxiety, or insomnia at baseline. Statistical analysis by ANOVA (P not adjusted for multiplicity). This exploratory analysis was not prespecified or included in any sample size calculations; comparisons between treatment arms or patient subgroups should be interpreted with caution.

Results: Overall, 2996 patients were randomized and received at least one dose of study treatment (SC tanezumab 2.5 mg: n=1002; 5 mg: n=998; oral NSAID: n=996). In patients with or without a history of anxiety, depression, or insomnia, all treatments were associated with notable and largely similar magnitude improvements in WOMAC Pain and Physical Function and PGA-OA at Week 16 (Figure). Across treatment groups, differences in LS mean change from baseline in patients with and without a history of depression, anxiety, or insomnia ranged between 0–0.34 for WOMAC Pain and Physical Function and 0–0.19 for PGA-OA.

Conclusion: Patients with a history of depression, anxiety, or insomnia did not appear to experience dampened improvements in pain or function with tanezumab or NSAID vs those without.

Abstract Number: 0726

Joint Safety of Tanezumab versus NSAIDs; A Combined Assessment of Benefit and Harm

Robert Fountaine[1], Robert Dworkin[2], Anne Hickman[1], Glenn Pixton[3], Ed Whalen[4], Christine West[1] and Kenneth Verburg[1], [1]Pfizer Inc., Groton, CT, [2]University of Rochester, Rochester, NY, [3]Pfizer Inc., Morrisville, NC, [4]Pfizer Inc., New York, NY

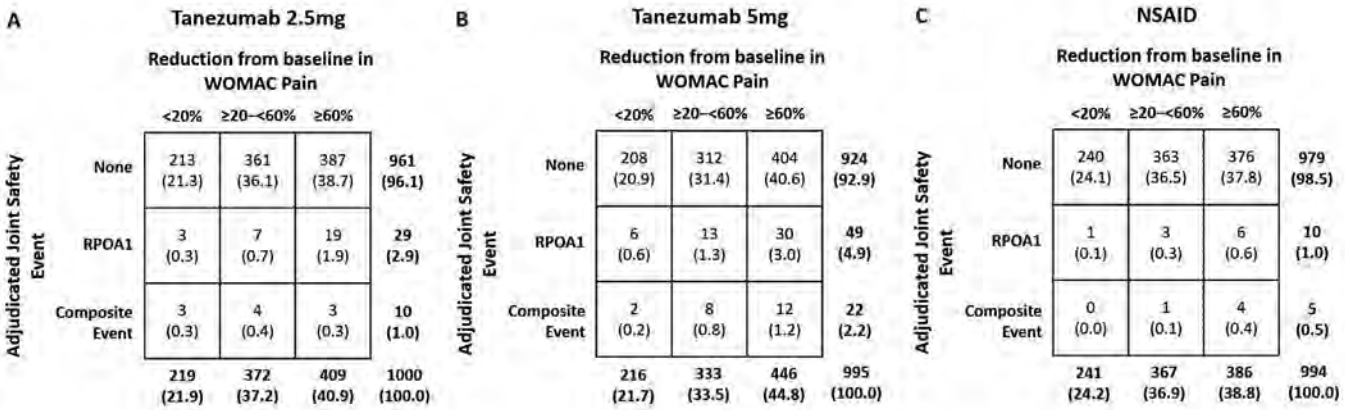
SESSION INFORMATION
Session Date: Sunday, November 7, 2021
Session Title: Osteoarthritis – Clinical Poster II (0723–0738)
Session Type: Poster Session B
Session Time: 8:30AM–10:30AM

Background/Purpose: Tanezumab, a monoclonal antibody against nerve growth factor, is in development for the relief of signs and symptoms of moderate to severe osteoarthritis (OA) in adult patients (pts) for whom use of other analgesics is ineffective or not appropriate. Previously, tanezumab has been associated with an increased incidence of joint safety events versus nonsteroidal anti-inflammatory drugs (NSAIDs)[1]. Our aim was to investigate the benefit/harm relationship for tanezumab and NSAIDs using the OMERACT 3x3 scale[2].

Methods: The study (NCT02528188) included pts with moderate to severe hip or knee OA with a history of inadequate pain relief with acetaminophen; inadequate pain relief with/intolerance to tramadol or opioids; or unwillingness to take opioids. Pts were randomized to subcutaneous tanezumab 2.5mg or 5mg every 8 weeks or twice daily oral NSAIDs for a total of 56 weeks, with a 24-week post-treatment follow-up period. Benefit was assessed using 3 categories of reduction from baseline in Western Ontario and McMaster Universities Osteoarthritis Index (WOMAC)* Pain in the index joint at the primary efficacy endpoint of Week 16; < 20% (minimal improvement), ≥20–< 60% (moderate–substantial improvement) or ≥60% (very substantial improvement). Harm was assessed by considering 3 categories of joint safety outcomes; none (no adjudicated joint safety endpoints), rapidly progressive OA type 1 (RPOA1) or having an adjudicated composite joint safety endpoint (primary osteonecrosis, RPOA type 2, subchondral insufficiency fracture or pathological fracture) in any joint up to the end of the follow-up period or 26 weeks after the end of the treatment period, whichever was later.

Results: In the tanezumab 2.5mg group (n=1,000), 387 pts (38.7%) had the most favorable outcome of ≥60% improvement in WOMAC Pain with no joint safety events. 3 pts (0.3%) had the least favorable outcome of < 20% improvement in WOMAC Pain and a composite event (Figure 1A). In the tanezumab 5mg group (n=995), 404 pts

Figure 1. Assessment of benefit and harm using the OMERACT 3x3 scale



Patients, n (%), with each combination of outcomes is reported for the tanezumab 2.5mg (n=1,000), 5mg (n=995) and NSAID (n=994) groups. The total number and percentage of patients within each outcome category is presented at the end of the respective column or row.

Reduction from baseline in WOMAC Pain was assessed for the index joint at the primary study timepoint of Week 16. Adjudicated joint safety events were recorded for any joint up to the end of the follow up period or 26 weeks after the end of the treatment period, whichever was later.

NSAIDs, nonsteroidal anti-inflammatory drugs; RPOA1, rapidly progressive OA type 1; WOMAC, Western Ontario and McMaster Universities Osteoarthritis Index.

(40.6%) had the most favorable outcome and 2 pts (0.2%) had the least favorable outcome (Figure 1B). In the NSAID group (n=994), 376 pts (37.8%) had the most favorable outcome and 0 pts had the least favorable outcome (Figure 1C). Across all treatment groups, the incidence of RPOA1 increased with the category of benefit. The number of pts meeting the composite event increased with the category of benefit in the tanezumab 5mg and NSAID groups.

Conclusion: These analyses showed that ≥37.8% of pts had the most favorable outcome and ≤0.3% had the least favorable outcome; the proportion of pts with these outcomes was not notably different across treatments. An increased incidence of adjudicated joint safety events was associated with more favorable efficacy responses across treatments, with the exception of the composite event in the tanezumab 2.5mg group.

This study was sponsored by Pfizer and Eli Lilly. Medical writing support was provided by Steven Moore, PhD, of Engage Scientific Solutions and was funded by Pfizer and Eli Lilly.

Session Title: Osteoarthritis – Clinical Poster II (0723–0738)

Session Type: Poster Session B

Session Time: 8:30AM–10:30AM

Background/Purpose: Tanezumab (TNZ) is an antibody against nerve growth factor that has demonstrated efficacy in the management of osteoarthritis (OA). Due to the potential risk of rapidly progressive OA (RPOA), recent phase 3 studies of subcutaneous (SC) TNZ have included a comprehensive prospective assessment of joint safety. This analysis summarizes data on patients (pts) who underwent total joint replacement (TJR) in the recent phase 3 OA TNZ studies.

Table 1: Summary of Total Joint Replacements — Patient Level

		Tanezumab			
	Placebo n=514	2.5 mg n=1530	2.5/5 mg n=219	5 mg n=1282	NSAID n=996
Patients with ≥1 TJR, n (% pts in each treatment group)	23 (4.5)	84 (5.5)	15 (6.8)	100 (7.8)	26 (2.6)
TJRs during study, no. (% pts with TJR)					
1	20 (87.0)	77 (91.7)	13 (86.7)	87 (87.0)	25 (96.2)
≥2	3 (13.0)	7 (8.3)	2 (13.3)	13 (13.0)	1 (3.8)
TJR of index joint, no. (% pts with TJR)	20 (87.0)	74 (88.1)	14 (93.3)	77 (77.0)	22 (84.6)
Adjudicated joint safety outcomes, no. (% pts with TJR)					
RPOA1	0	4 (4.8)	1 (6.7)	8 (8.0)	2 (7.7)
RPOA2	0	3 (3.6)	0	10 (10.0)	1 (3.8)
Primary osteonecrosis	0	0	0	1 (1.0)	0
Pathological fracture	0	0	0	0	0
Subchondral insufficiency fracture	0	0	0	3 (3.0)	1 (3.8)
Normal progression of OA	21 (91.3)	73 (86.9)	14 (93.3)	73 (73.0)	22 (84.6)
Insufficient information to determine rapid vs normal progression of OA	0	2 (2.4)	0	0	0
Other joint outcome[a]	2 (8.7)	2 (2.4)	0	5 (5.0)	0

Includes TJR or adjudicated event up to the end of the follow-up period or 26 weeks after the end of the treatment period, whichever is later.

RPOA1 (rapidly progressive osteoarthritis type 1) is defined as a significant loss of joint space width ≥2 mm (predicated on optimal joint positioning) within ~1 year, without gross structural failure.

RPOA2 (rapidly progressive osteoarthritis type 2) is defined as abnormal bone loss or destruction, including limited or total collapse of ≥1 subchondral surface, that is not normally present in conventional end-stage osteoarthritis.

[a] Includes post-traumatic/post-procedure events and pre-existing conditions.

[a]KL grading was not conducted for shoulder joints.

KL, Kellgren-Lawrence; no., number of events; NSAID, nonsteroidal anti-inflammatory drug; TJR, total joint replacement.

Methods: In NCT02697773, pts with OA received placebo (PBO), TNZ 2.5 mg or 2.5 mg then 5 mg (TNZ 2.5/5 mg) for 16 weeks. In NCT02709486, pts received PBO or TNZ 2.5 or 5 mg for 24 weeks. In NCT02528188, pts received TNZ 2.5 or 5 mg or NSAIDs for 56 weeks. TNZ and matching PBO were given SC every 8 weeks; NSAID and matching PBO were taken orally twice daily. All studies had a 24-week safety follow-up period. Subgroup analyses were performed to explore potential associations between the incidence of TJR and baseline (BL) demographic/clinical characteristics or post-BL outcomes. In all studies, TJRs were adjudicated by a blinded external Adjudication Committee to determine any association with joint safety events including RPOA type 1, RPOA type 2, subchondral insufficiency fracture (SIF), primary osteonecrosis, or pathological fracture. For each pt, the most painful hip or knee joint with radiographic OA was selected as the index joint. Pain was assessed in all joints but efficacy assessments were only for the index joint. Pts could also have had OA in non-index joints.

Results: Across the 3 studies (N=4541 pts), 248 pts had ≥1 TJR (26 ≥2 TJRs) with an incidence of 2.6–7.8% across groups (**Table 1**). In all, 83% of pts with a TJR had surgery on their index joint, the proportion of which was similar in the PBO, TNZ 2.5 mg, and NSAID groups (84.6–88.1%), lower in the TNZ 5 mg (77.0%) group, and higher in the TNZ 2.5/5 mg (93.3%) group (**Table 1**). Most TJRs occurred in joints with Kellgren-Lawrence (KL) grade 3 or 4 at BL (**Table 2**). In the TNZ 5 mg group, 2 pts had TJR of a joint that was KL grade 0 at BL: 1 was adjudicated to be associated with RPOA2 and 1 as a post traumatic subchondral fracture following an accidental fall. The majority (73.3–81.0%) of pts across treatment groups had no prior history of TJR. Of the 275 TJRs reported across groups, 50.0–60.4% occurred in a knee, 38.5–50.0% in a hip and 0–3.7% in a shoulder (**Table 2**). Among PBO, TNZ 2.5 mg, TNZ 2.5/5 mg and NSAID groups, incidences of an adjudicated outcome of normal progression of OA were similar (84.6–93.3%; lower with TNZ 5 mg [73.0%]). The TNZ 5 mg group had the highest percentage of pts with a TJR with an adjudicated outcome of RPOA1, RPOA2 or SIF (**Table 1**). Subgroup analyses did not reveal any associations between BL demographic or clinical characteristics and the incidence of TJR (**Table 3**).

Conclusion: Pts treated with TNZ 5 mg had a greater incidence of TJR than those receiving TNZ 2.5 mg, PBO or NSAID. The occurrence of TJR in the index joint in pts receiving TNZ 2.5 mg was similar to those receiving PBO or

Table 3: Subgroups Analyzed for Potential Association With Total Joint Replacement

Subgroups	Details	Association with TJR
Demographic factors	• Age: <65 vs ≥65, <75 vs ≥75 • Gender: Male vs female • BMI: <25, 25 to <30, 30 to <35, ≥35	No association
Baseline disease severity	• Maximum KL grade (2, 3, or 4) at baseline • No. of joints with baseline KL grade ≥2 • Prior history of TJR • WOMAC[a] Pain subscale score at baseline (<7, ≥7) • WOMAC Physical Function subscale score at baseline (<7, ≥7) • Patient's global assessment at baseline (Fair, Poor/Very Poor)	No association
Adverse events	• Selected adverse events up to end of study: ○ Arthralgia or joint swelling ○ Arthralgia or joint swelling prior to TJR ○ Any adverse event of abnormal peripheral sensation[b] ○ Peripheral edema ○ Any fracture ○ Fracture of the lower limb ○ Any post-baseline fall	No association
Efficacy response: WOMAC Pain and Physical function	• Change from baseline in WOMAC Pain and Physical function scores at Week 16 and Week 56 (NCT02528188 only) for the index joint	No association
Other factors	• Use of intra-articular hyaluronic acid in year prior to study • Use of intra-articular corticosteroid in year prior to study • Any concomitant use with NSAID, cardiovascular prophylactic aspirin, intra-articular corticosteroid, bisphosphonate, or acetaminophen	No association
Concomitant NSAID use	• Use of NSAID prior to occurrence of TJR	No association
Baseline bone health	• Including history of osteopenia or osteoporosis	No association

Intra-articular Canakinumab (anti-interleukin-1β) for Treatment of Symptomatic Knee Osteoarthritis: A Randomized, Double-blind, Placebo and Naproxen-controlled Phase II Study

Philip Conaghan[1], Xavier Chevalier[2], Linda Mindeholm[3], Ursula Schramm[3], Jens Praestgaard[3], Abdelkader Seroutou[3], Ronenn Roubenoff[3] and Matthias Schieker[3], [1]Leeds Institute of Rheumatic and Musculoskeletal Medicine, University of Leeds, Leeds, United Kingdom, [2]Henri Mondor University Hospital and Paris University XII, UPEC, Créteil, France, Créteil, France, [3]Novartis Institutes for Biomedical Research, Basel, Switzerland, Basel, Switzerland

SESSION INFORMATION
Session Date: Sunday, November 7, 2021
Session Title: Osteoarthritis – Clinical Poster II (0723–0738)
Session Type: Poster Session B
Session Time: 8:30AM–10:30AM

Background/Purpose: Knee osteoarthritis (OA) is a common musculoskeletal disease associated with pain and functional impairment. There are few effective therapies, often limited by side-effects.[1] This phase II study investigated the efficacy, safety, and pharmacokinetics of canakinumab, an anti-interleukin-1β antibody, in patients (pts) with knee OA (NCT01160822).

Methods: The study had a single placebo (PBO)-controlled ascending dose period assessing the safety of intra-articular (i.a.) canakinumab, and an 18-week randomized, double-blind, double-dummy PBO and naproxen-controlled period. Pts (N = 136) with symptomatic knee OA (VAS pain ≥40, Kellgren/Lawrence [K/L] grade 2 or 3) were enrolled to receive a single i.a. injection of canakinumab 600 mg or matched PBO at baseline (BL), and naproxen 500 mg twice daily or matched PBO. Co-primary endpoints were change from BL in knee OA pain (VAS 0-100] at Day 4 and in Western Ontario and McMaster OA Index (WOMAC) pain (scale 0-20) at Day 29.

Results: Canakinumab i.a was generally safe and well tolerated and had a short resident time in the joint with an early detection (1 hour) in the circulation after i.a. injection. The co-primary efficacy endpoints were not met. The rapid and clinically significant decreases from BL in VAS pain and WOMAC pain scores were largely comparable between canakinumab, PBO and naproxen (Figure 1A). In a post hoc analysis of pts with BL elevated high sensitive C-reactive protein (hsCRP) levels (≥2 mg/L), canakinumab had a more pronounced inhibitory effect on pain than PBO or naproxen (-2.56 [-5.16; 0.04], P = 0.11; adjusted mean (90% CI) from a mixed-effect model repeated measures [MMRM]) at Day 57. Furthermore, this subpopulation showed a (-1.24 [-3.87; 1.39], P = 0.44) reduction of WOMAC pain at Day 85 compared to PBO or naproxen (Figure 1B).

Conclusion: The effect of canakinumab on pain in a population with knee OA was not different from PBO or naproxen. An effect of canakinumab on pain was observed in a subpopulation with elevated BL hsCRP levels. In addition to the data published previously on the CANTOS study[2], these findings underscore the need to identify specific populations of pts with knee OA, who may benefit from anti-inflammatory treatment.

Session Title: Osteoarthritis – Clinical Poster II (0723–0738)
Session Type: Poster Session B
Session Time: 8:30AM–10:30AM

Background/Purpose: Lorecivivint (LOR), a novel intra-articular (IA) CLK/DYRK inhibitor that modulates Wnt and inflammatory pathways, is in development as a knee osteoarthritis (OA) treatment. To further evaluate the safety and exploratory efficacy of a single LOR injection that was administered into the target knee joint of subjects with moderate to severe knee OA from two consecutive Phase 2 trials, an extension study was performed with the primary objective of evaluating serious adverse events (SAEs), as well as analyzing safety data for all doses and efficacy data for the (pivotal) 0.07 mg LOR dose.

Methods: This was a 5-year, Phase 3, multicenter, observational, extension study of completer subjects (NCT02951026) from a 12-month Phase 2a (Yazici, Y. et al. *Arthritis Rheumatol*. 72, 1694–1706 (2020)) and a 6-month Phase 2b (Yazici, Y. et al. *Osteoarthr. Cartil*. In Press, (2021)) trial of LOR. The study was terminated in Year 3 as relevant long-term safety information became limited in the absence of repeated LOR administration. Subjects received a single LOR or vehicle placebo (PBO) injection at their Phase 2 parent-trial baseline visit (Month 0). Pooled data from clinic visits at 6, 12, 24, and 36 months were used to analyze safety outcomes (serious AEs, knee-related AEs, and AEs of newly diagnosed conditions needing treatment). A post hoc baseline-adjusted ANCOVA on 0, 3, 6, 12, and 18-month data points (across current and parent trials) was used to compare changes from baseline in a subject subgroup (unilat-

^Control= Placebo, Sham, and 2 PBO subjects with dose of PBO not specified by protocol

eral symptoms, no widespread pain, 18-month post-injection radiograph at study termination) in WOMAC Pain and Function subscores and medial joint space width (mJSW) between 0.07 mg LOR and PBO groups.

Results: Of 703 subjects, 119 (17%) subjects discontinued prior to study termination. Subject characteristics are shown in Table 1. The safety analysis set included 495 LOR-treated subjects and 208 control subjects (Table 2). Four AEs in 3 (0.6%) subjects across LOR groups were considered related to the study drug; no subjects withdrew from the study due to a treatment-related AE. Incidence was similar between LOR and PBO groups. Sixty-eight SAEs in

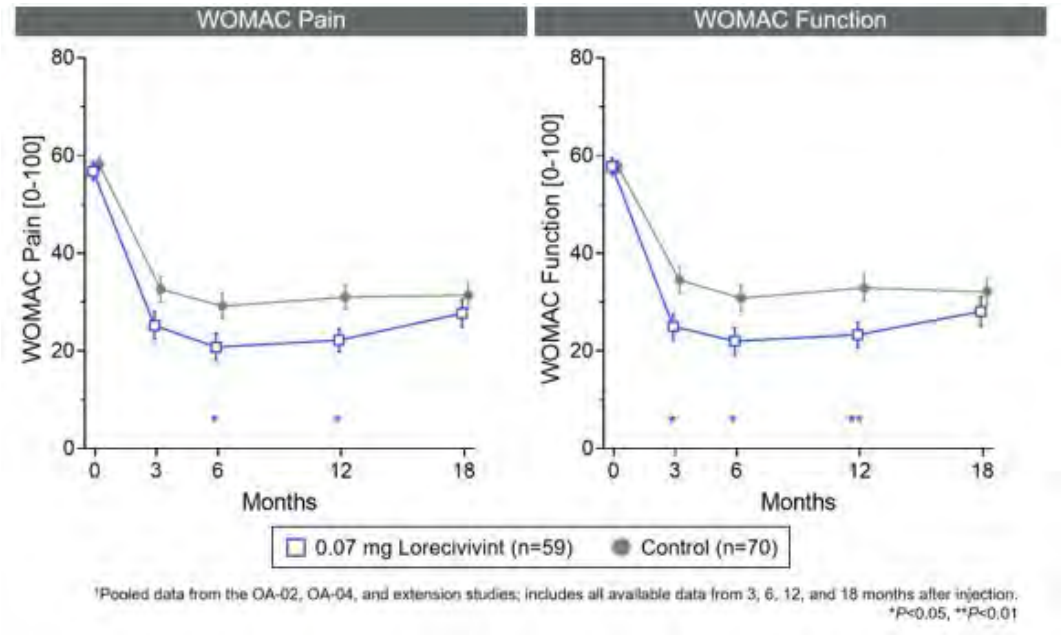

Figure 1. WOMAC Pain and Function scores over time in unilateral completers treated with intra-articular LOR (lorecivivint) or vehicle placebo (Control). Month 0 (baseline) is the subject's day of knee injection. Lower scores denote improvements. Statistical significance (asterisks) is shown for the groupwise comparison of mean changes from baseline for LOR and Control groups.

38 (5.4%) subjects were reported with none considered related to treatment by investigators. One death occurred in the control group. Post hoc efficacy analyses demonstrated that subjects in the 0.07 mg LOR group (n=59) showed greater mean improvements from baseline in both WOMAC Pain and Function at 6 (Pain: -8.16, 95% CI [-15.60, -0.71], *P*=0.032; Function: -9.47 [-17.09, -1.84], *P*=0.015) and 12 (Pain: -8.51 [-15.17, -1.85], *P*=0.013; Function: -9.62 [-16.83, -2.42], *P*=0.009) months vs. subjects in the control group (n=70) (Figure 1). No mJSW progression was observed in any group over 18 months. Limitations included using subjects (completers) more likely to be responders and not controlling for other treatments in the extension study period.

Conclusion: LOR appeared safe and well tolerated. Efficacy analyses on the described subset of completer subjects demonstrated durable symptom improvements in WOMAC Pain and Function for up to at least 12 months vs. contr ols.

Abstract Number: 0730

Safety, Tolerability, and Pharmacokinetics of an Intra-articular Corticosteroid Injection Administered 7 Days Before or After Intra-articular Lorecivivint Injection into the Same Knee of Healthy Volunteers: An Open-Label, Parallel-Arm Study

Amy Halseth[1], **Nancy Lane**[2], Sarah Kennedy[3], Christopher Swearingen[1], Victor Lopez[1], Ismail Simsek[1], Mark Fineman[1] and Yusuf Yazici[4], [1]Biosplice Therapeutics, Inc., San Diego, CA, [2]University of California Davis, Hillsborough, CA, [3]Biosplice Therapeutics, Inc, San Diego, CA, [4]New York University School of Medicine, La Jolla, CA

SESSION INFORMATION
Session Date: Sunday, November 7, 2021
Session Title: Osteoarthritis – Clinical Poster II (0723–0738)
Session Type: Poster Session B
Session Time: 8:30AM–10:30AM

Background/Purpose: Knee osteoarthritis (OA) is a painful condition leading to joint damage and impaired function. Intra-articular (IA) corticosteroid injections are frequently prescribed to treat pain. Lorecivivint (LOR), a novel IA CLK/DYRK inhibitor that modulates Wnt and inflammatory pathways, appeared safe and demonstrated patient-reported outcome pain and function improvements compared with placebo in a Phase 2b knee OA trial (Yazici, Y. et al. *Osteoarthr. Cartil*., 2021). While lorecivivint is proposed for stand-alone use, in clinical practice, providers might administer lorecivivint in close time proximity to IA corticosteroid. This open-label, parallel-arm, healthy volunteer study was conducted to assess potential safety and tolerability (primary objectives), and pharmacokinetic (PK) interactions (secondary objective), between lorecivivint and triamcinolone acetonide (TCA) when the two medications were administered 7 days apart.

Methods: Healthy volunteers were randomized to Treatment Arm 1 (IA 40 mg TCA on Day 1 followed by IA 0.07 mg lorecivivint on Day 8) or Treatment Arm 2 (IA 0.07 mg lorecivivint on Day 1 followed by IA 40 mg TCA on Day 8). All injections were performed on the right knee. For each treatment arm, treatment-emergent adverse events (TEAEs) were categorized by “epoch”, with Epoch 1 spanning from first until second injection, and Epoch 2 spanning from second injection until end of study. In Treatment Arm 1, plasma TCA levels were assessed on Days 1 (before TCA

Table 1. Treatment-emergent adverse events (TEAEs) by preferred term in the safety analysis set

	Treatment Arm 1				Treatment Arm 2			
	TCA (Epoch 1) (n=20)		TCA + LOR (Epoch 2) (n=20)		LOR (Epoch 1) (n=20)		LOR + TCA (Epoch 2) (n=20)	
Preferred Term	n (%)	Total Number of Events	n (%)	Total Number of Events	n (%)	Total Number of Events	n (%)	Total Number of Events
Total TEAEs	4 (20.0)	5	3 (15.0)	8	2 (10.0)	2	3 (15.0)	3
Injection site bruising	4 (20.0)	4	0	0	1 (5.0)	1	2 (10.0)	2
Injection site pain	0	0	1 (5.0)	2	0	0	0	0
Back pain	1 (5.0)	1	0	0	0	0	0	0
Flank pain	0	0	1 (5.0)	1	0	0	0	0
Musculoskeletal discomfort	0	0	1 (5.0)	1	0	0	0	0
Pain in extremity	0	0	1 (5.0)	1	0	0	0	0
Headache	0	0	1 (5.0)	1	1 (5.0)	1	0	0
Hypersensitivity	0	0	0	0	0	0	1 (5.0)	1
Skin abrasion	0	0	1 (5.0)	1	0	0	0	0
Adnexa uteri pain	0	0	1 (5.0)	1	0	0	0	0

All subjects in the safety analysis set received both study injections in a randomized manner in either Treatment Arm 1 (TCA then lorecivivint) or Treatment Arm 2 (lorecivivint then TCA). Epoch 1 spans the duration from the first injection until just prior to the second injection. Epoch 2 spans the duration from the second injection until the end of study phone visit/early termination. TEAEs were coded using MedDRA v23.1.
Abbreviations: LOR, lorecivivint; TCA, triamcinolone acetonide

dosing and up to 12 h after), 2 (24 h after), 3, 5, 8 (before lorecivivint dosing and up to 8 h after), 11, and 15. Plasma lorecivivint concentrations were assessed on Day 8 (before lorecivivint dosing and up to 8 h after). In Treatment Arm

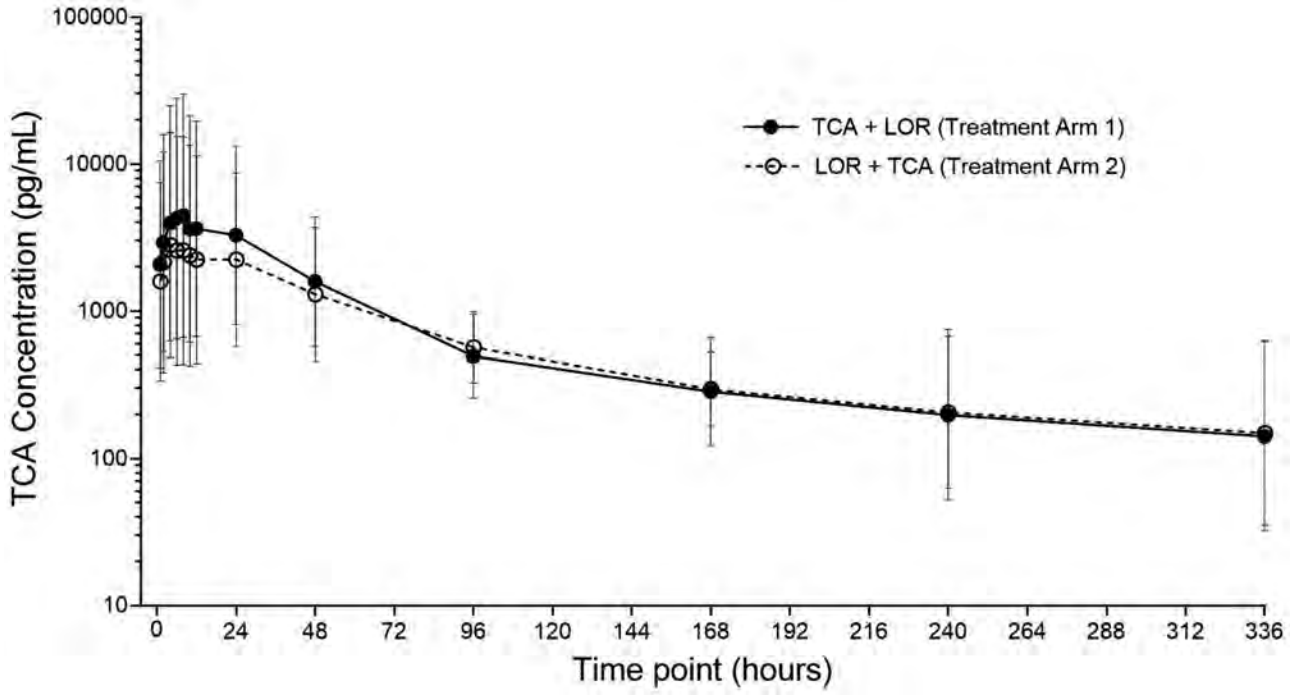

Figure 1. Plasma concentration of triamcinolone acetonide (TCA) following intra-articular (IA) knee injection (40 mg) 7 days before (Treatment Arm 1) and after (Treatment Arm 2) IA lorecivivint (LOR) (0.07 mg). Values shown are geometric means (geometric SD) for all post-injection time points. Values reported below the lower limit of quantification (LLOQ=20.0 pg/mL) were set to ½ × LLOQ.

2, plasma lorecivivint levels were assessed on Days 1 (before lorecivivint dosing and up to 8 h after), 8 (up to 8 h after TCA dosing), 9 (24 h after), 10, and 12. Plasma TCA levels were assessed on Days 8 (before TCA dosing and up to 12 h after), 9 (24 h after), 10, 12, 15, 18, and 22.

Results: Forty subjects (n=20/arm; age 41.3±7.2 years; BMI 27.8±2.98 kg/m^2; female 40.0%) were evaluated. A total of 18 TEAEs were reported by 11 (27.5%) subjects (Table 1). TEAEs were similar between arms and there were no serious adverse events. In all subjects and at all time points, plasma lorecivivint concentrations were below the limit of quantification (0.1 ng/mL). Geometric mean concentrations (Figure 1) and PK parameters for TCA were similar between treatment arms.

Conclusion: There were no quantifiable plasma concentrations of lorecivivint in either treatment arm, and the PK of TCA was unaffected by previous lorecivivint injection. No safety signals were observed. These results suggest that IA administration of lorecivivint and triamcinolone in close proximity (7 days apart) should not pose a safety concern.

SESSION INFORMATION
Session Date: Sunday, November 7, 2021
Session Title: Osteoarthritis – Clinical Poster II (0723–0738)
Session Type: Poster Session B
Session Time: 8:30AM–10:30AM

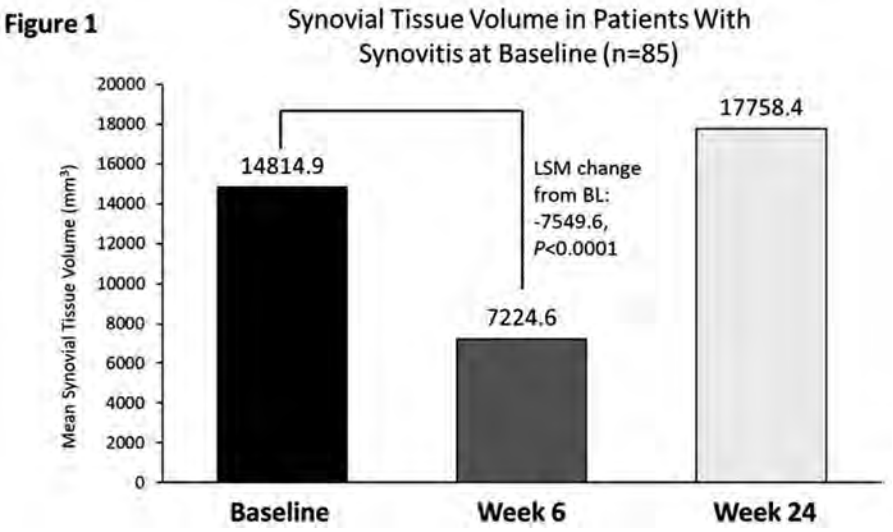
Background/Purpose: Synovial inflammation is common in knee osteoarthritis (OA) and is associated with pain and disease severity. Previous studies have suggested short-term (approximately 2 weeks) effects on synovial tissue from intra-articular (IA) steroid injection. This open-label Phase 3b study evaluated a single 32 mg intra-articular (IA) injection of triamcinolone acetonide extended release (TA-ER) on synovial tissue volume (STV), pain, stiffness, function, and quality of life (QOL) (NCT03529942).

Methods: Patients with KL grade 2-3 painful (Western Ontario and McMaster Universities Osteoarthritis Index (WOMAC)-A total sum score ≥ 6) knee OA received TA-ER at baseline (BL). Assessments occurred at BL, Weeks 6, 12, 18, and 24, and included gadolinium MRI at BL, Weeks 6 and 24 using automated segmentation. MRIs were used to determine STV, with synovitis at BL defined as STV ≥3000 mm^3. Patients who had quality MRI data available at BL

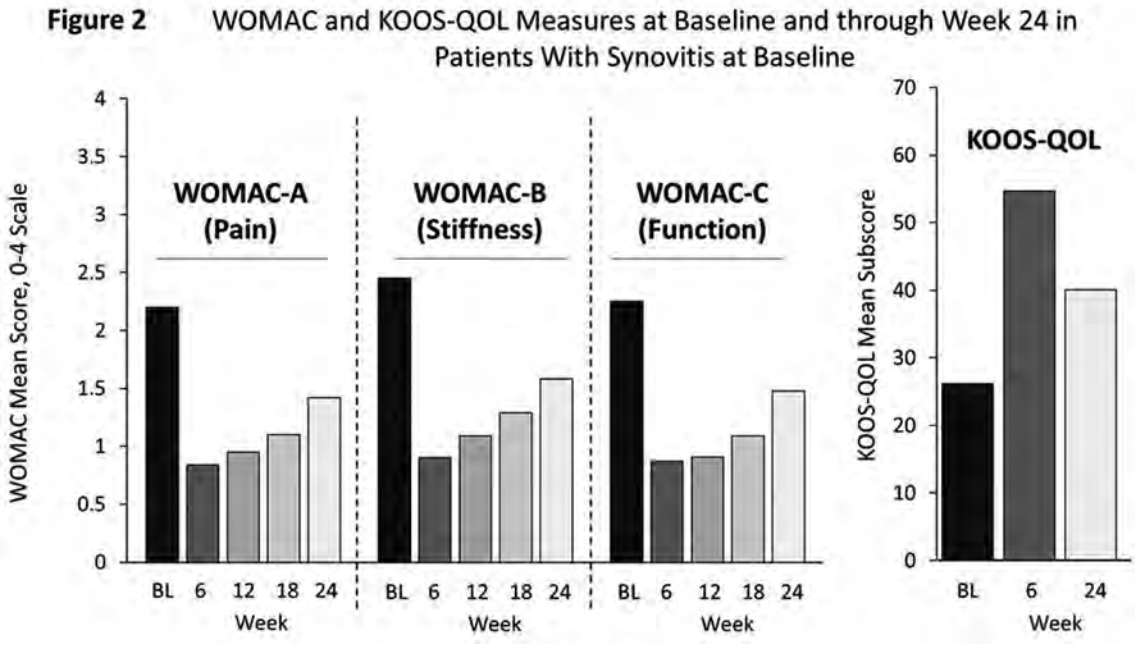
Parameter	Statistics	All Patients (N=129)	Patients With Synovitis* at BL (n=102)
Age, years	Mean (SD)	61.2 (8.0)	61.7 (7.9)
Female	%	62.8	61.8
BMI, kg/m^2	Mean (SD)	30.3 (4.7)	30.6 (4.5)
Years since diagnosis	Mean (SD)	9.0 (8.9)	8.9 (8.6)
Days with pain/month	Mean (SD)	29.2 (2.7)	29.2 (2.7)
Bilateral OA	%	69.8	65.7
Prior index knee surgery	%	26.4	30.4
Prior IACS	%	41.1	43.1
Prior IAHA	%	11.6	13.7
KL grade 2	%	48.8	40.2
KL grade 3	%	51.2	59.8
Joint space width, mm	Mean (SD)	4.7 (1.4)	4.5 (1.5)
WOMAC-A (pain)	Mean (SD)	2.2 (0.6)	2.2 (0.6)
WOMAC-B (stiffness)	Mean (SD)	2.4 (0.7)	2.5 (0.6)
WOMAC-C (function)	Mean (SD)	2.2 (0.6)	2.3 (0.6)
KOOS-QOL	Mean (SD)	27.2 (16.3)	26.2 (16.5)
Baseline STV, mm^3	Mean (SD)	11,876.6 (10,681.6)	14,814.9 (10,337.9)

*Synovitis was defined as STV ≥3000 mm^3 (3 mL) at baseline determined using gadolinium MRI.
BL, baseline; BMI, body-mass index; IACS, intra-articular corticosteroid; IAHA, intra-articular hyaluronic acid; KL, Kellgren-Lawrence; KOOS-QOL, Knee Injury and Osteoarthritis Outcome Score – Quality of Life; OA, osteoarthritis; SD, standard deviation; STV, synovial tissue volume; WOMAC, Western Ontario and McMaster Universities Osteoarthritis Index.

Figure 1



and at least one post-baseline timepoint were included in the Imaging Population. The primary study endpoint was mean standardized change in STV from BL to Week 6. Additionally, WOMAC-A (pain), WOMAC-B (stiffness), and WOMAC-C (function) were assessed at BL and Weeks 6, 12, 18, and 24; the Knee injury and Osteoarthritis Outcome Score – QOL (KOOS-QOL) was assessed at BL, Weeks 6 and 24. Treatment-emergent adverse events (TEAEs) were recorded.



Results: We enrolled 129 patients with typical knee OA characteristics (Table); 102 (79%) demonstrated BL synovitis (STV ≥3000 mm^3; range 3,005-45,113 mm^3). In patients with BL synovitis who were part of the Imaging Population (n=85), STV was significantly reduced at Week 6 ($P< 0.0001$; (Figure 1). The primary endpoint was met: standardized least squares mean (LSM) STV change at Week 6 was −0.90 (95% CI, −1.06 to −0.73; $P< 0.001$); at Week 24, STV change was 0.20 (95% CI, 0.04 to 0.36). In patients with BL synovitis following TA-ER, WOMAC-A, B, and C improved from BL at Weeks 6, 12, 18, and 24; also, KOOS-QOL improved from BL at Weeks 6 and 24 (Figure 2). Although STV returned to BL by Week 24, the clinical improvements observed in WOMAC and KOOS measures persisted through Week 24. Thirty-one patients (24%) experienced TEAEs; 9 (7.0%) patients had ≥1 index-knee TEAE. Most TEAEs were considered mild or moderately severe, however, one severe adverse event of nephrolithiasis occurred. None of the TEAEs were considered related to the study drug.

Conclusion: In patients with knee OA and BL synovitis, a single IA injection of TA-ER improved six-week synovitis, measured as reduced STV. TA-ER reduced OA symptoms of pain and stiffness and improved function and OA-related quality of life through Week 24. Overall, a single IA injection of TA-ER was well tolerated.

Topical Rofecoxib for OA of the Knee

Bruce Register[1], Nancy Lane[2], Lee Simon[3], John Newsam[4], Edward Kisak[4], Jed Pheneger[5], John Galvin[5], Jeffrey Klein[6] and Marc Hochberg[7], [1]BriOri BioTech, Inc., Newport Beach, CA, [2]University of California Davis, Hillsborough, CA, [3]SDG LLC, West Newton, MA, [4]Tioga Research, Inc, San Diego, CA, [5]Inotiv, Boulder, CO, [6]Sinclair Research Center, Auxvasse, MO, Canada, [7]University of Maryland School of Medicine, Baltimore, MD

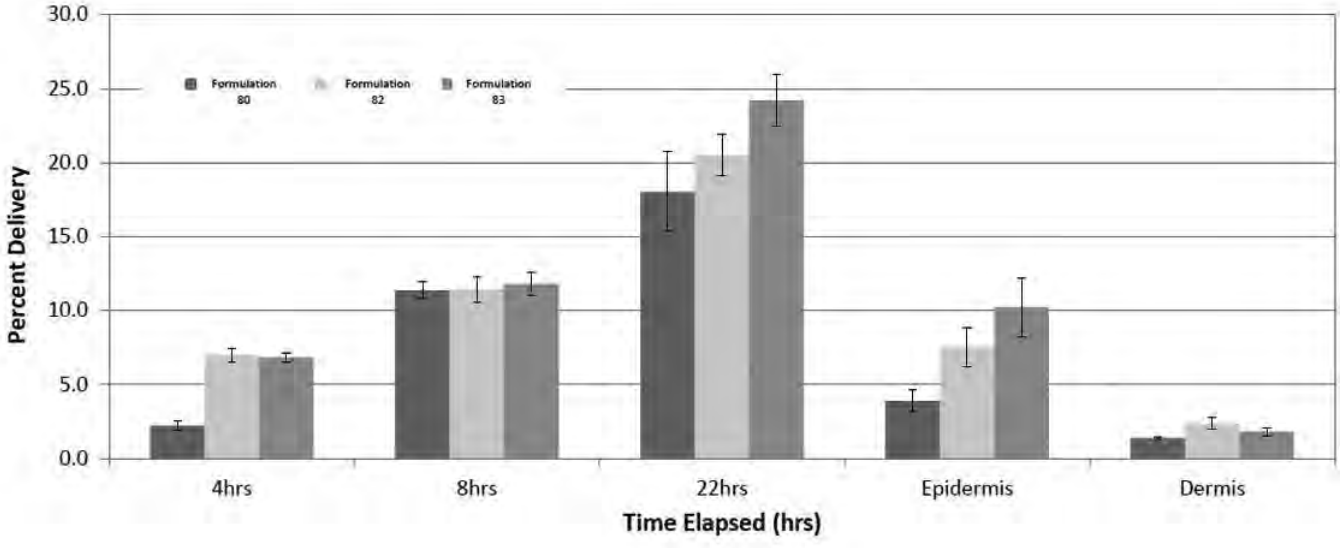
SESSION INFORMATION
Session Date: Sunday, November 7, 2021
Session Title: Osteoarthritis – Clinical Poster II (0723–0738)
Session Type: Poster Session B
Session Time: 8:30AM–10:30AM

Background/Purpose: Osteoarthritis remains a highly prevalent disease in the elderly, and there are currently no approved treatments that can modify the disease course. Currently, both oral and topical nonsteroidal anti-inflammatory drugs (both COX-1 and COX-2 inhibitors) are frequently utilized to reduce pain and joint inflammation. These studies were done to demonstrate that rofecoxib topical may be an effective topical pain therapy.

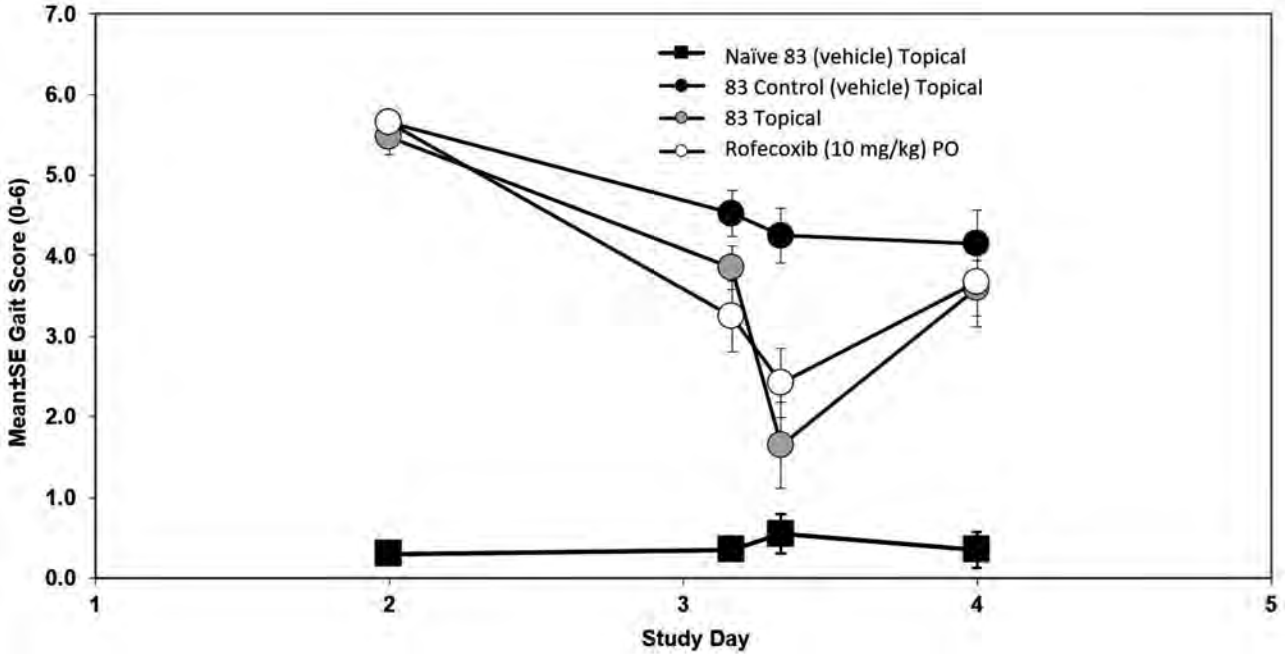
Methods: Three non-clinical experiments were performed to assess the utility of this newly formulated rofecoxib topical. The first experiment studied permeation across human cadaver skin, the second assessed the pain relief obtained in a rat inflammatory joint model, while a third experiment studied the dermal irritation and bioavailability of the topical drug.

Results: Human skin Franz diffusion cell studies (Figure 1) were performed using human cadaver skin. Rofecoxib transferences of 6% at 4 hours and up to 24% at 22 hours were measured. Topical Rofecoxib was tested in an

Figure 1



Human skin permeation of rofecoxib topical formulations.



Rat inflammatory joint model of rofecoxib topical.

adjuvant-induced model (Figure 2) of pain in Rats. Day 0. Rats were weighed and randomized by body wight. The animals were then anesthetized and injected with Freund's complete adjuvant into right rear joint to create severe joint inflammation and pain. Day 2. Rats were randomized by gait into groups of 10 with a score of "0" (normal) to "6" (hopping or carrying the leg). Day 3. Rats were dosed on the skin over the joint with: A. Ointment control (no API) on naive rats 100ul B. Ointment control (no API) C. Ointment with 2% API on test rats 100ul (1mg) D. Oral rofecoxib 10mg/kg. Following dosing the rats were gated for pain at 4, 8 and 24 hours. As shown in figure 2 at 8 hours topical rofecoxib showed efficacy equal to or greater than a super dose of oral rofecoxib. Study 3 was a Seven-Day Skin Irritation and Bioavailability Mini-Pig PK study (Table 1). Hanford miniature swine were dosed with topical rofecoxib for bioavailability. On day one 1.25ml of a 2% ointment was applied (25mg) to the 10% of the mini-pigs skin and a 24-hour pk study was done. On days 2 – 7 two applications of 1.25ml of the 2% ointment were applied and a 24-hour pk study was done on day 7. Draize scores for all animals through the end of the study on day 7 were all 0. One set of minipigs was dosed with 0.1mg/kg oral rofecoxib equivalent to a 12.5mg human dose of rofecoxib. The Day 1 t_{max} was the same as the oral rofecoxib demonstrating rapid absorption through the skin. The C_{max} on Day 1 was 15%

Table 1

C_{max} ng/ml	Day 1	% of Oral	Day 7	% of Oral
Oral (0.2mg/kg)	91.0		141.0	
Releven 2%[a]	14.5	15.9%	29.9	20.9%
AUC (ng*hours/ml)	**Day 1**	**% of Oral**	**Day 7**	**% of Oral**
Oral	610		579	
Releven 2%	39.5	6.4%	237	41.0%
t_{max} (hours)	**Day 1**		**Day 7**	
Oral	4.0		2.0	
Releven 2%	4.0		14.0	

Bioavailability of the topical rofecoxib.

of the oral and the AUC 6.4% of oral which will provide sufficient rofecoxib to the local area of inflammation for pain relief. The Day 7 C_{max} and AUC are significantly below the oral dose of rofecoxib reducing systemic exposure and potential side effects. No skin irritation was observed.

Conclusion: These data demonstrate that that topical rofecoxib diffuses through human skin rapidly resulting in a dose that provides pain relief in a rat model of inflammatory arthritis. In addition, the topical dosing in mini pigs has been shown to have a lower systemic exposure then oral rofecoxib given at the lowest approved human dose. These results suggest topical rofecoxib may be an effective topical analgesic.

A New Wearable Transcutaneous Electrical Nerve Stimulation Device (actiTENS®) Is More Efficient and Better Tolerated Than Weak Opioids in the Treatment of Knee Osteoarthritis Pain

Emmanuel Maheu[1], Sandrine Soriot-Thomas[2], Eric Noël[3], Hervé Ganry[4], Eric Lespessailles[5] and Bernard Cortet[6], [1]Saint-Antoine Hospital, Paris, France, [2]CHU Amiens Picardie, Amiens, France, [3]Santy Orthopaedic Center, Lyon, France, [4]Hergan Consulting 4U, Amiens, France, [5]CH Orléans, ORLEANS, France, [6]CHU Lille, Lille, France

SESSION INFORMATION
Session Date: Sunday, November 7, 2021
Session Title: Osteoarthritis – Clinical Poster II (0723–0738)
Session Type: Poster Session B
Session Time: 8:30AM–10:30AM

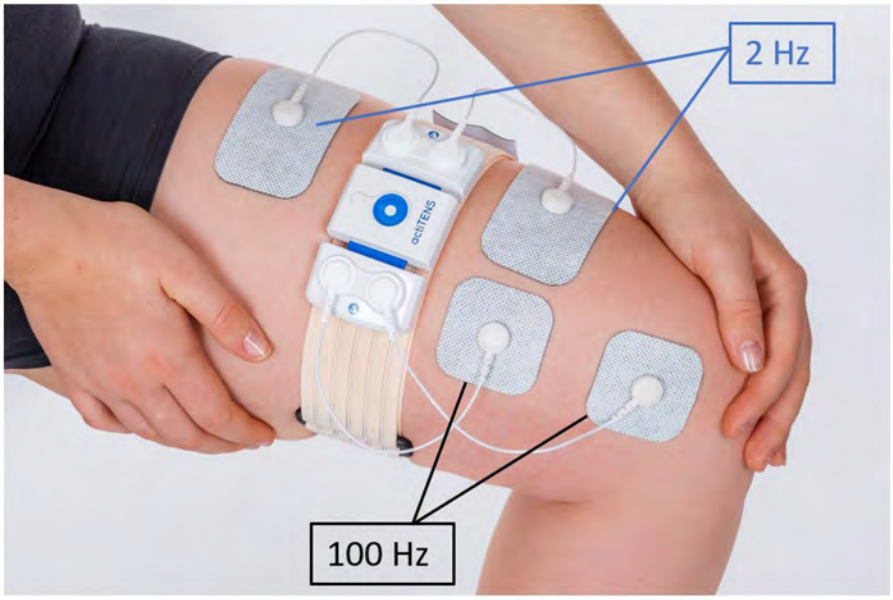
Background/Purpose: Knee osteoarthritis (KOA) is a frequent disease for which therapeutic possibilities are limited. In current recommendations, the first-line analgesic is acetaminophen. However, its low efficacy frequently leads to the use of weak opioids (WO) despite their poor tolerance, especially in elderly patients.

The primary objective was to compare the analgesic efficacy and safety of a new wearable transcutaneous electrical nerve stimulation (W-TENS) to weak opioids (WO) in the treatment of moderate to severe, nociceptive, chronic pain in KOA patients.

Methods: ArthroTENS study is a non-inferiority, multicentric, prospective, randomized, single-blinded for primary efficacy outcome, controlled, 2-parallel groups, clinical study. It compared W-TENS to WO over a 3-month controlled period with an additional optional non-controlled 3-month follow-up in W-TENS group.

Patients had KOA (ACR criteria) with baseline pain intensity (PI) ≥4 on a numerical rating scale (NRS), after failure to level 1 analgesics/NSAIDs, a Kellgren-Lawrence grade ≥2 and were assessed at baseline, M1 and M3.

The co-primary outcomes were PI at 3-month and the number of treatment-related adverse events (TRAEs) over 3 months. Secondary outcomes included WOMAC function, EuroQol, responder rates defined by PI reduction ≥30 and ≥50% and OMERACT-OARSI response criteria. The non-inferiority margin was defined as 0.825 on PI reduction.



Standardized positioning of W-TENS electrodes.

Measure population	W-TENS	WO	W-TENS - WO	
PP population				
n	52	47		Non inferiority demonstrated 95% CI < 0.825
Mean (SD)	3.87 (2.12)	4.65 (2.37)	-0.79 (0.44)	
95% CI	[3.28, 4.46]	[3.96, 5.35]	[-1.65, 0.08]	
ITT population				
n	55	55		Non inferiority demonstrated 95% CI < 0.825
Mean (SD)	3.84 (2.08)	4.73 (2.28)	-0.92 (0.40)	
95% CI	[3.27, 4.40]	[4.11, 5.35]	[-1.71, -0.12]	

Non-inferiority analyses on PI at M3. PP and ITT populations.

In W-TENS group, an advanced, mobile app enabled, wearable TENS was used. 100Hz and 2 Hz frequency stimulations were delivered via electrodes with standardized positioning (Figure 1).

Results: The non-inferiority of W-TENS was demonstrated in both the PP and ITT populations (Table 1). At M3, PI in PP population was 3.87 (2.12) compared to 4.66 (2.37) (delta: -0.79 (0.44); 95% CI (-1.65; 0.08)) in W-TENS and WO groups, respectively. Since the absolute value of the 95% CI of the between-treatments mean PI difference [-1.71, - 0.12] was above 0 in ITT set, the planned superiority analysis was performed, demonstrating that W-TENS was significantly superior to WO at M3 (P=0.0124).

In the ITT population, the number of potentially TRAEs was significantly lower (p< 0.001) in the W-TENS group (n=7) than in the WO group (n=36) during the 3-month controlled follow-up. The AEs observed in the W-TENS group were mainly local cutaneous reactions (erythema: 5.5%) due to the TENS technique, while those observed in the WO group were systemic and well known (dry mouth: 1.8%; vomiting: 1.8%; pruritus: 3.6%; dizziness: 5.5%; drowsiness: 7.3%; nausea: 10.9% and constipation: 12.7%) and limit their use and effectiveness in clinical practice. Thirty-nine (70.9%) patients wished to extend W-TENS treatment for 3 additional months. The efficacy was maintained throughout this additional therapeutic period. All secondary outcomes favored the W-TENS group at M1 and M3.

Conclusion: W-TENS was more effective and better tolerated than WO in the treatment of nociceptive KOA chronic pain and could represent an interesting non-pharmacological analgesic alternative for patients.

Primary Total Knee Arthroplasty for Knee Osteoarthritis Among Younger versus Older Individuals: Cross-sectional Study of Surgical Appropriateness and Surgeon Decision-Making

Gillian Hawker[1], Eric Bohm[2], Michael Dunbar[3], Allyson Jones[4], Tom Noseworthy[5] and Deborah Marshall[5], [1]University of Toronto, Toronto, ON, Canada, [2]Concordia Hip & Knee Institute, Winnipeg, MB, Canada, [3]Dalhousie University, Halifax, NS, Canada, [4]University of Alberta, Edmonton, AB, Canada, [5]University of Calgary, Calgary, AB, Canada

SESSION INFORMATION
Session Date: Sunday, November 7, 2021
Session Title: Osteoarthritis – Clinical Poster II (0723–0738)
Session Type: Poster Session B
Session Time: 8:30AM–10:30AM

Background/Purpose: Rising rates of total knee arthroplasty (TKA) in younger adults with knee osteoarthritis (OA) has prompted concern about surgical appropriateness. We compared patient appropriateness for TKA, using previously validated criteria, and surgeons' recommendations for TKA, by patient age.

Methods: This cross-sectional study recruited patients with knee OA referred for TKA consultation to two centralized provincial arthroplasty intake centers in Alberta, Canada. Patients aged 30 years or older and determined by the surgeon to have primary knee OA on physical examination and imaging were eligible. Individuals with inflammatory arthritis were excluded. To examine age effects, recruitment continued until there was at least 200 individuals aged 30-59, 60-69 and ≥ 70 years. A pre-consult questionnaire assessed measures of patients' TKA appropriateness (need: knee symptoms, prior OA treatment; readiness/willingness to undergo TKA; health status; expectations) and contextual factors. Post-consultation, surgeons reported if TKA had been recommended and if not, why. Using multivariable logistic regression, we assessed the relationships between patient age (< 60 versus ≥ 60) and TKA appropriateness and receipt of surgeon recommendation for TKA.

Results: Of 2,064 participants, 26.0% were < 60 years of age, 68.0% female, 35.6% employed. Compared to older participants, younger participants reported significantly worse knee symptoms, higher use of OA therapies and similar TKA readiness/willingness. They were also more likely to have BMI >40 kg/m^2, smoke and endorse return to exercise/sports as a very important TKA outcome. TKA was offered to 1,525 individuals (73.9%). In multivariable analyses, controlling for TKA appropriateness, we found no relationship between patient age and surgeons' recommendations for TKA (OR, odds ratio, 0.81; 95% CI, confidence interval, 0.59 to 1.10). Surgeons were significantly

more likely to recommend TKA to those with TKA need, willingness and for whom improved ability to perform daily activities was very important. They were less likely to recommend surgery to smokers and for whom return to exercise/sport was important.

Conclusion: Among individuals referred for surgical consultation regarding TKA for knee OA, we found that younger patients (< 60 years old) had comparable TKA need, readiness and willingness as those aged 60 years or older. However, younger individuals were more likely to be obese, smoke, and desire to return to sport after TKA, which may increase risk for complications, including early revision. Incorporation of TKA appropriateness criteria into patient referral and patient-surgeon decision-making regarding TKA has potential to facilitate a balanced consideration of TKA benefits alongside the risks in a growing population of young, obese individuals with knee OA.

Abstract Number: 0735

Walking Ability 12 Months After Total Knee Arthroplasty for Osteoarthritis – Gap Between Expectations and Reality: The BEST Knee Cohort Study

Lauren King, Esther Waugh and Gillian Hawker, University of Toronto, Toronto, ON, Canada

SESSION INFORMATION
Session Date: Sunday, November 7, 2021
Session Title: Osteoarthritis – Clinical Poster II (0723–0738)
Session Type: Poster Session B
Session Time: 8:30AM–10:30AM

Background/Purpose: Improved ability to walk is a key driver for people with knee osteoarthritis (OA) to seek total knee arthroplasty (TKA). However, the extent to which patients' expectations of walking improvement are met following TKA is unknown. In individuals with knee OA undergoing primary TKA, we assessed: 1) pre-TKA expectations about walking ability and gait aid use after TKA; 2) TKA patient-reported improvement in walking ability and gait aid use pre-TKA and 12 months post-TKA; and 3) whether gender differences were present.

Methods: Participants with knee OA completed standardized questionnaires 1 month prior to and 12 months after primary, elective TKA. Pre-TKA, we assessed sociodemographic and clinical characteristics and patients' expectations for TKA (Hospital for Special Surgery Expectations Survey). Participants were asked to indicate how important "improved ability to walk" and "removed need for a gait aid" were to them as TKA outcomes (very important, yes/no). Both pre- and post-TKA, we assessed for perceived walking limitation (yes/no), gait aid use (yes/no) and walking ability (unlimited, 6-10 blocks, 1-5 blocks, < 1 block). At 12 months post-TKA, we assessed perceived change in walking ability (8-point Likert scale from "extremely worse" to "extremely better"). Values pre- and post-TKA were compared using McNemar tests. Chi-square tests compared gender differences in walking expectations pre-TKA and perceived walking ability at 12 months.

Results: 278 participants were included: mean age 67 years (SD 8.5), and 65.5% female. Pre-TKA, 97.5% indicated it was "very important" that TKA improve ability to walk and, of these, 98.1% desired to be able to walk medium-to-long distances. Of 68 (24.5%) who were using a gait aid pre-TKA, 84.0% indicated it was "very important" that TKA remove their need for one. At 12 months post-TKA, 73.6% reported walking "a lot" or "extremely better". Overall,

Table 1. Walking ability 1 month prior to and 12 months after total knee arthroplasty (n=278)

Variable	Pre-TKA	12mo post-TKA	p-value
Patient-reported walking ability			
Perceived distance can walk continuously, n (%)			<0.001
Unlimited	17 (6.16)	102 (37.09)	
6-10 blocks	55 (19.93)	85 (30.91)	
1-5 blocks	160 (57.97)	76 (27.64)	
<1 block	44 (15.94)	12 (4.36)	
Reported usual need for gait aid with waking, n (%)	81 (29.14)	50 (18.00)	0.002
Perceived limitation in walking ability, yes, n (%)	232 (83.45) *Of these 216 (93.51%) indicate due to knee*	90 (32.37) *Of these, 19 (21.11%) indicate due to knee*	<0.001
Patient reported change in walking ability after TKA			
Perceived change in walking ability, n (%)			
Extremely worse		-	
A lot worse		2 (0.72)	
Somewhat worse		6 (2.17)	
No change		20 (7.25)	
A little better		14 (5.07)	
Somewhat better		31 (11.23)	
A lot better		93 (33.70)	
Extremely better		110 (39.86)	

68.0% reported they could walk 6 or more city blocks, 60.5% of gait aid users pre-TKA no longer required one, and 67.6% reported no walking limitation; of those who did, only 21.1% ascribed the walking limitation to their operated knee (**Table 1)**. Pre-TKA, women and men had similar expectations of TKA to improve their ability to walk, but post-TKA, women were less likely to report being "unlimited" in walking ability compared to men (32.4% vs 46.2%, $p< 0.03$) and more likely to require a gait aid (21.4% vs 11.46%, $p< 0.04$).

Conclusion: This study confirmed the importance of improved ability to walk as a surgical outcome to patients undergoing TKA for knee OA, and elucidated that most expected TKA to enable walking medium to long distances. However, only two-thirds reported the ability to walk long distances post-TKA. A better understanding of causes of persistent walking limitation after TKA, as well as ways in which this can be addressed, are needed to support individuals with knee OA in meeting their walking expectations.

Abstract Number: 0736

Decrease in Prevalence of Self-Reported Anxiety or Depression in Persons with Osteoarthritis After Total Knee Arthroplasty: The BEST KNEE Cohort Study

Owen Krystia, Lauren King, Esther Waugh and Gillian Hawker, University of Toronto, Toronto, ON, Canada

SESSION INFORMATION
Session Date: Sunday, November 7, 2021
Session Title: Osteoarthritis – Clinical Poster II (0723–0738)
Session Type: Poster Session B
Session Time: 8:30AM–10:30AM

Background/Purpose: While anxiety and depression are highly prevalent in persons with symptomatic knee osteoarthritis (OA), few studies have assessed the effect of treatment of knee OA on these mood disorders. Further, it remains unclear which individuals will continue to have persistent anxiety and/or depression after OA treatment, limiting targeted intervention. Thus, the objectives of this study were to, in individuals with knee OA undergoing primary total knee arthroplasty (TKA): (1) describe the proportion of patients who report being anxious or depressed (A/D) pre TKA, 6 months post TKA, and 12 months post TKA; and (2) determine, in those with self-reported A/D pre TKA, the factors associated with persistence of mood disorder at 12 months post TKA.

Methods: In this prospective cohort study, patients with knee OA were assessed one month pre- and 6 and 12 months post-TKA. Questionnaires assessed sociodemographic factors, knee OA symptoms, comorbidities, and psychosocial factors. We assessed prevalence of self-reported A/D using the Anxiety/Depression dimension of the EQ-5D-3L. Self-reported A/D was defined as reporting being moderately or extremely anxious or depressed. Among individuals with self-reported A/D pre TKA, multivariable Poisson regression with a robust error variance was used to assess the association of sociodemographic factors, comorbidities, psychosocial factors, and knee OA symptoms with persistence of self-reported A/D at 12 months post TKA.

Results: 1259 patients were included: mean age 67.2 years, 60.8% female, mean pre TKA WOMAC pain 57.6 (SD 17.4) /100, and mean pre TKA KOOS-PS physical function 53.3 (SD 17.3)/100 (higher scores worse). The mean change from pre TKA to 12 months post TKA in WOMAC pain was -42.7 (SD 21.9), and in KOOS-PS was -29.6 (SD 21.5). Prevalence of self-reported A/D pre TKA was 624 (49.6%), at 6 months was 278 (22.1%), and at 12 months was 254 (20.2%). Of the 624 participants with self-reported A/D pre TKA, 197 (31.6%) self-reported A/D 12 months post TKA. In multivariable regression, persistence of A/D at 12 months post TKA was associated with reporting higher levels of knee OA pain post TKA (RR per WOMAC unit 1.02, 95% CI 1.01 to 1.03), greater knee OA functional impairment post TKA (RR per KOOS-PS unit 1.01, 95% CI 1.00 to 1.03), less pre TKA self-efficacy (RR per unit General Self-Efficacy Scale 0.97, 95% CI 0.94 to 0.99), and the presence of a pre TKA depression diagnosis (RR 1.89, 95% CI 1.44 to 2.48). Analyses stratified by sex, age (< 60/≥60 years), obesity, and reporting a prior diagnosis of depression were not appreciably different from the primary model.

Conclusion: A large proportion of individuals with knee OA report being anxious or depressed pre TKA. Of these individuals, greater than two-thirds report resolution of their mood disorder by 12 months post TKA. We found a higher risk of persistence in individuals with worse knee OA symptoms post TKA and among those with less self-efficacy. However, the strongest factor associated with persistence of A/D was a previous diagnosis of depression suggesting a group of individuals whose depression may not be related to their OA and would benefit from targeted mental health interventions to improve mood outcomes.

SESSION INFORMATION

Session Date: Sunday, November 7, 2021

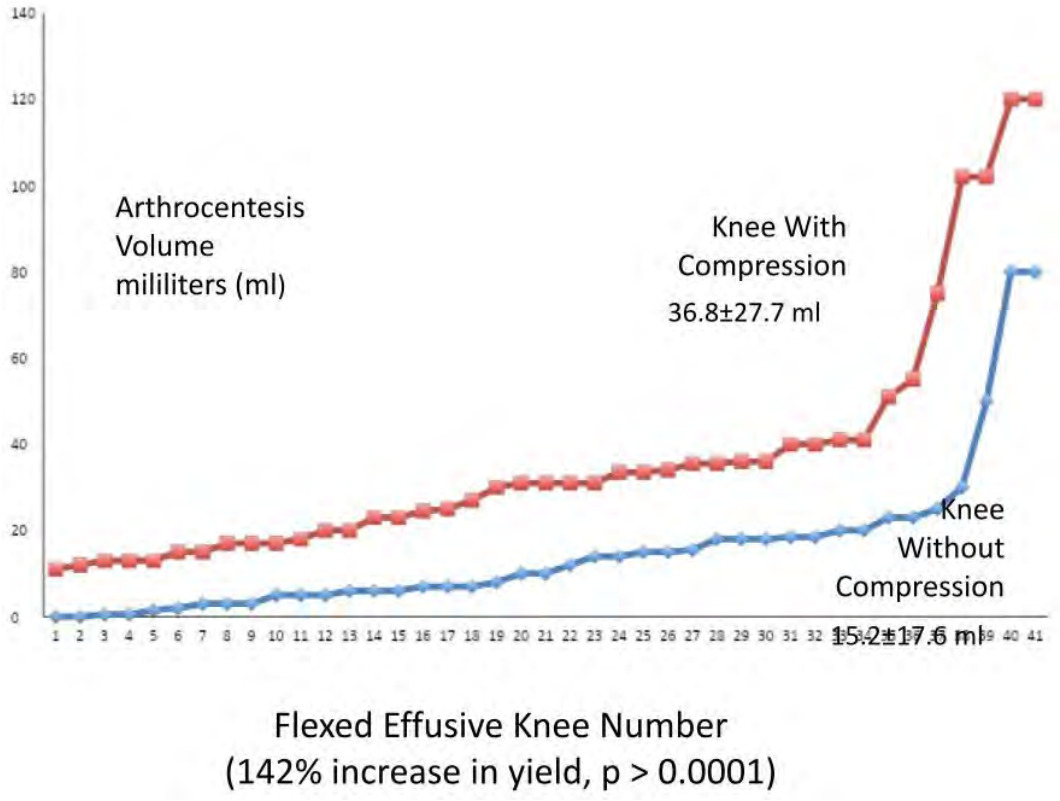
Session Title: Osteoarthritis – Clinical Poster II (0723–0738)

Session Type: Poster Session B

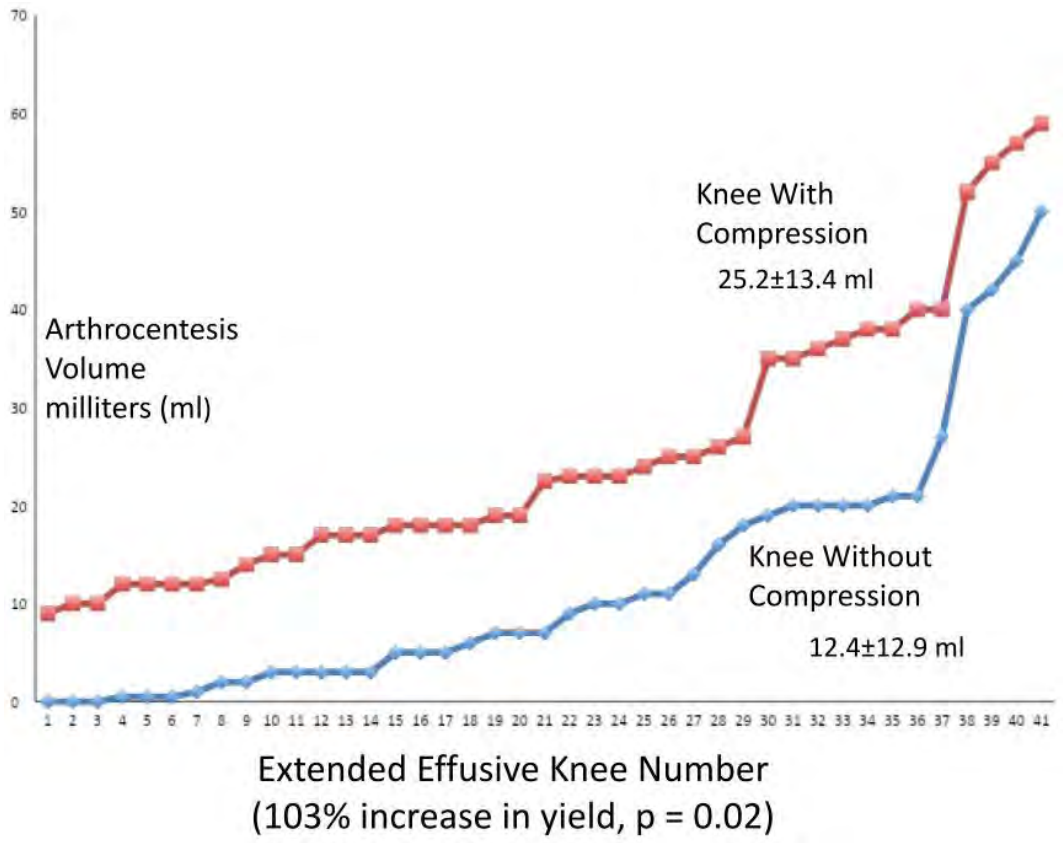
Session Time: 8:30AM–10:30AM

Background/Purpose: To explore an alternative to standard extended knee arthrocentesis using pneumatic compression of the flexed knee.

Methods: Using a paired sample design, 41 consecutive effusive knees underwent arthrocentesis in the flexed knee position first without and then with pneumatic compression of suprapatellar bursa. Arthrocentesis success and fluid yield in milliliters (ml) were measured. For comparison 41 consecutive patients who had undergone extended knee arthrocentesis without and with compression were also studied.



These graphs demonstrate the fluid yield with and without pneumatic compression of the flexed knee using the inferiolateral portal. Pneumatic compression causes a marked increase in fluid yield.



These graphs demonstrate the fluid yield with and without mechanical compression of the extended knee using the superiolateral portal (suprapatellar approach). Mechanical compression causes a marked increase in fluid yield similar to the increase in fluid yield with pneumatic compression shown in Figure 1.

Results: Successful diagnostic arthrocentesis (≥ 3 ml) of the effusive flexed knee was 85% (35/41) without compression and increased significantly to 100% (41/41) with pneumatic compression (p=0.027). Synovial fluid yields were significantly greater with pneumatic compression (36.8±27.7 ml) than without compression (15.2±17.6 ml) (increase of 142% or 21.6±17.6 ml more; 95% CI: 13.0 < 23.4< 33.8, p< 0.0001). Arthrocentesis yield for the extended knee position without compression (12.4±12.9 ml) was similar to the flexed knee without compression (15.2±17.6 ml; 95% -9.9412 < -3.1< 3.7412 (Wald) p=0.36). Arthrocentesis yield for the extended knee with compression (25.2±13.4 ml) was enhanced by 108% (12.8±13.2 ml) similar to the flexed knee with compression (142%, 21.6±17.6 ml).

Conclusions: Compression of the effusive flexed knee with a suprapatellar pneumatic cuff markedly improves the success and fluid yield of arthrocentesis and is non-inferior to standard extended knee arthrocentesis with or without compression. Arthrocentesis of the flexed knee with pneumatic compression is especially useful in patients who wish to remain seated or who cannot extend their knee due to flexion contracture, wheelchair confinement, pain or severe arthritis.

Conclusion: For individuals with knee contractures, the obese, wheelchair-bound individuals, the elderly, or those apprehensive individuals who involuntarily and forcefully contract the quadriceps muscles during a procedure, the standard extended knee superiolateral approaches for arthrocentesis can be difficult and/or inconvenient. Compression of the effusive flexed knee with a suprapatellar pneumatic cuff markedly improves the success and fluid yield of arthrocentesis and is non-inferior to standard extended knee arthrocentesis with or without compression. This pneumatic compression method that permits the patient to remain in the sitting position or equivalent with a flexed knee, but provides high levels of arthrocentesis success and fluid yield will be of obvious clinical utility.

Table 1. Clinical and Research Characteristics of the Study Populations

	Extended knee	Extended knee with compression	Flexed Knee	Flexed Knee with Compression
Number of Subjects	41	41	41	41

Session Date: Sunday, November 7, 2021
Session Title: Osteoarthritis – Clinical Poster II (0723–0738)
Session Type: Poster Session B
Session Time: 8:30AM–10:30AM

Background/Purpose: Oral Chinese patent medicine (CPM) has been deemed to have analgesic and anti-inflammatory effects and is widely used as the first-line treatment for osteoarthritis (OA) in Asia countries. Despite this enthusiastic use of CPM for knee OA, its clinical efficacy remains unclear. We conducted an updated review to determine the effects of these therapies to inform clinical practice.

Methods: We performed a comprehensive search on PubMed, Cochrane Library, EMBASE, Biomedical Databases, National Knowledge Infrastructure, Wanfang, and VIP through May 2021. We included randomized controlled trials (RCTs) of oral CPM therapies as the first-line treatment in adults with knee OA. Knee OA was defined by the American College of Rheumatology criteria or the Chinese orthopedic association criteria. We also accepted the composite outcome criteria developed by the Chinese National Institute of Rheumatology as an endpoint (total effective rate,

[a] N= number of patients included; [b] Age reported in years as a mean; [c] Six oral CPM with the Chinese herbs have potential benefits in knee pain relief and physical function; [d] Between group comparisons. Visual Analogue Scale (VAS, range 0-10), Western Ontario and McMaster Universities Arthritis Index pain scores (WOMAC pain, range 0-20) and the Lequesne index (range 0-24), where a lower score indicates a better outcome (less pain or better physical function).

between 0-100%, higher score = better outcome), which assesses the overall pain, physical function and wellness. We extracted information on study characteristics, population characteristics, type, duration, frequency of interventions, and outcomes. Study quality was assessed in RevMan5.3 software using the Cochrane Risk of Bias Tool. The differences between treatment groups were reported as mean change or percentage improvement (P-value).

Results: We identified 1096 potentially relevant studies. Eighteen with a total of 2474 subjects (59% female, mean age = 59 years, mean pain duration = 3 years) met eligibility criteria. Seventeen studies were conducted in China and one in Thailand. **Table 1** summarized the eighteen RCTs concerned with the effectiveness of oral CPMs for knee OA. Six types of oral CPMs including Jintiange Capsule, Jinwu Gutong Capsule, Zhuanggu Guanjie Capsule, Biqi Capsule, Xianling Gubao Capsule and Duhuo Jisheng Pill were prescribed as the first-line treatment based on the syndrome differentiation. The treatment varied duration from one to three times per day and lengths of the treatment ranged from 4 to 24 weeks. The control group treatments included oral non-steroidal anti-inflammatory drugs (17 studies) and placebo (1 study). Ten studies showed significant pain relief compared to the controls (std, Mean Difference [SMD] = -0.50; 95% CI, -0.86 to -0.13; $p< 0.05$). Thirteen studies reported a significant improvement in overall clinical symptoms on both pain and function (RR = 1.15; 95% CI, 1.09 to1.22; $p< 0.00001$). There were no significant differences in Lequesne index between the groups in six studies (MD = -1.11; 95% CI, -2.57 to 0.34; p=0.13). No serious adverse events occurred. Constipation was the most common adverse reaction in the oral CPM group, followed by dizziness, nausea, stomach discomfort and rash, and the incidence of adverse events was significantly lower than the controls.

Conclusion: This review showed promising results for oral CPM that is a safe and potential beneficial effects for knee OA. Further high-quality randomized controlled trials with longer follow-up periods are warranted.

Abstract Number: 0739

Contextual Factors Should Complete the Assessment of Functioning in Patients with Axial Spondyloarthritis (axSpA)

Uta Kiltz[1], Eerik Ahomaa[2], Björn Buehring[1], Xenofon Baraliakos[1], David Kiefer[1], Jaclyn-Dalisay Leicht[1] and Jürgen Braun[1], [1]Rheumazentrum Ruhrgebiet Herne, Ruhr-Universität Bochum, Herne, Germany, [2]St. Franziskus-Hospital, Department of Orthopedic Surgery, Cologne, Germany

SESSION INFORMATION
Session Date: Sunday, November 7, 2021
Session Title: Patient Outcomes, Preferences, & Attitudes Poster II: Measurements (0739–0763)
Session Type: Poster Session B
Session Time: 8:30AM–10:30AM

Background/Purpose: Functioning of axSpA patients (pat.) is influenced by many factors, but how contextual factors influence functioning isn't well studied. According to the International Classification of Functioning, Disability and Health (ICF), functioning is a complex interaction between health status and contextual factors such as social support, relationships and attitudes. Resulting from impaired functioning, pat. reporting barriers might face definite limitations in participation. Thus, limitations in participation as well as barriers and facilitators of contextual factors need to be investigated in axSpA pat.

Methods: axSpA pat. were standardized assessed, thereby collecting pat. and disease characteristics, patient-reported outcomes (ASDAS, BASFI, BASMI, PHQ-9, ICF Measure of Participation and ACTivities questionnaire

Table 1. Presence of contextual factors, stratified for global functioning categories Table legend (below table): values given as number (%), Reference: 1 Kiltz et al. Ann Rheum Dis 2013;72(s3):572

ICF category	EFIS Item	Correlation between EFIS item and ASAS HI sum score	Global Functioning (ASAS HI 0-17)		
			Good ≤ 5 (n= 69)	Moderate <5 to <12 (n= 106)	Poor ≥ 12 (n= 25)
e3, Support and relationship	EFIS 1: As a result of my rheumatic disease, the children take more responsibility for household tasks.	0.5	11 (15.9)	55 (51.9)	21 (84)
e3, Support and relationship	EFIS 2: I don't like the way my friends act around me.	0.4	0 (0)	15 (14,2)	12 (48,0)
e3, Support and relationship	EFIS 3: I can't count on my relatives to help me with my problems	0.2	11 (15,9)	24 (22,6)	9 (36)
e1 Products and technologies	EFIS 4: I modify my home and work environments.	0.2	16 (23,2)	47 (44,3)	9 (36)
e5, Health services, disease control	EFIS 5: I have difficulties getting worsening of my disease acknowledged by a health care professional	0.4	3 (4,3)	21 (19,8)	16 (64)
e5, Health services, time constraints	EFIS 6: Treatment of my rheumatic disease is taking up time	0.4	22 (31,9)	73 (68,9)	22 (88)
e4, Attitudes friends, negative	EFIS 7: My friends expect too much of	0.2	1 (1,4)	18 (17,0)	7 (28)
e4, Attitudes family	EFIS 8: No one pays much attention to me at home	0.1	10 (14,5)	20 (18,9)	7 (28)
e4, Attitudes friends, positive	EFIS 9: My friends understand me	-0.1	56 (17,4)	83 (78,3)	12 (48)

values given as number (%), Reference: 1 Kiltz et al. Ann Rheum Dis 2013;72(s3):572

(IMPACT-S (0-100%)), ASAS Health Index (ASAS HI and environment factor item set (EFIS) (1). The EFIS contains 9 dichotomous questions addressing ICF categories of products and technologies (e1), support and relationship (e3), attitudes (e4) and health services (e5). Prior to the analysis, EFIS 1, 4 and 8 were assumed to act as facilitators. Validated cut-offs of ASAS HI were used to categorize global functioning: good ≤ 5, moderate < 5 to < 12, poor ≥ 12.

Results: A total of 200 axSpA pat. were included: 69% males, 44.3±12.5 years, symptom duration 17.9±12.6 years, ASDAS 2.5±1.1, BASFI 4.0±2.7, BASMI 3.5±1.8, ASAS HI 7.0±4.1. Pat. reported limitations in the IMPACT-S activity and participation domain (82.3% (15.2) and 83.5% (16.8)), respectively. The majority of pat. reported that treatment of axSpA requires time (e4, 58.5%) as a barrier. Some pat. reported needs such as (a) the support by family members (e3, 43.5%), (b) to modify home and work environment (e1, 39.5%) and (c) the inreliability of family members for help (e3, 22%) as barriers. Some pat. (< 20%) reported (a) comprehension problems with health care professionals when experiencing a flare (e5, 18.5%), (b) inadequate care of pat. at home (e4, 18.5%), (c) disliking friends' behavior toward them (e4, 13.5%), and (d) too demanding friends (e4, 13%) as barriers. The majority of pat. (e4, 75.9%) identified attitudes of friends as the only and major facilitator. All pat. reporting at least one barrier, had significantly worse global functioning (ASAS HI, IMPACT-S), and depression (PHQ-9) compared to pat. reporting no barriers in the respective ICF categories ($p < 0.01$). Similarly, pat. with poor functioning are more likely to report barriers in contextual factors compared to pat. with good functioning (Table 1). Pat., who have to ask for more support from their families, expressed the feeling that they cannot rely on that.

Conclusion: Barriers of contextual factors are more present in axSpA pat. than facilitators. This study shows that barriers of contextual factors are more common in pat. with impairments in self-reported and performed functioning as in those without impairments, underlining the importance of contextual factors in the management of axSpA pat. The controversial response to EF-Items 1, 4 and 8 suggests relevant differences in the individual interpretation of these questions.

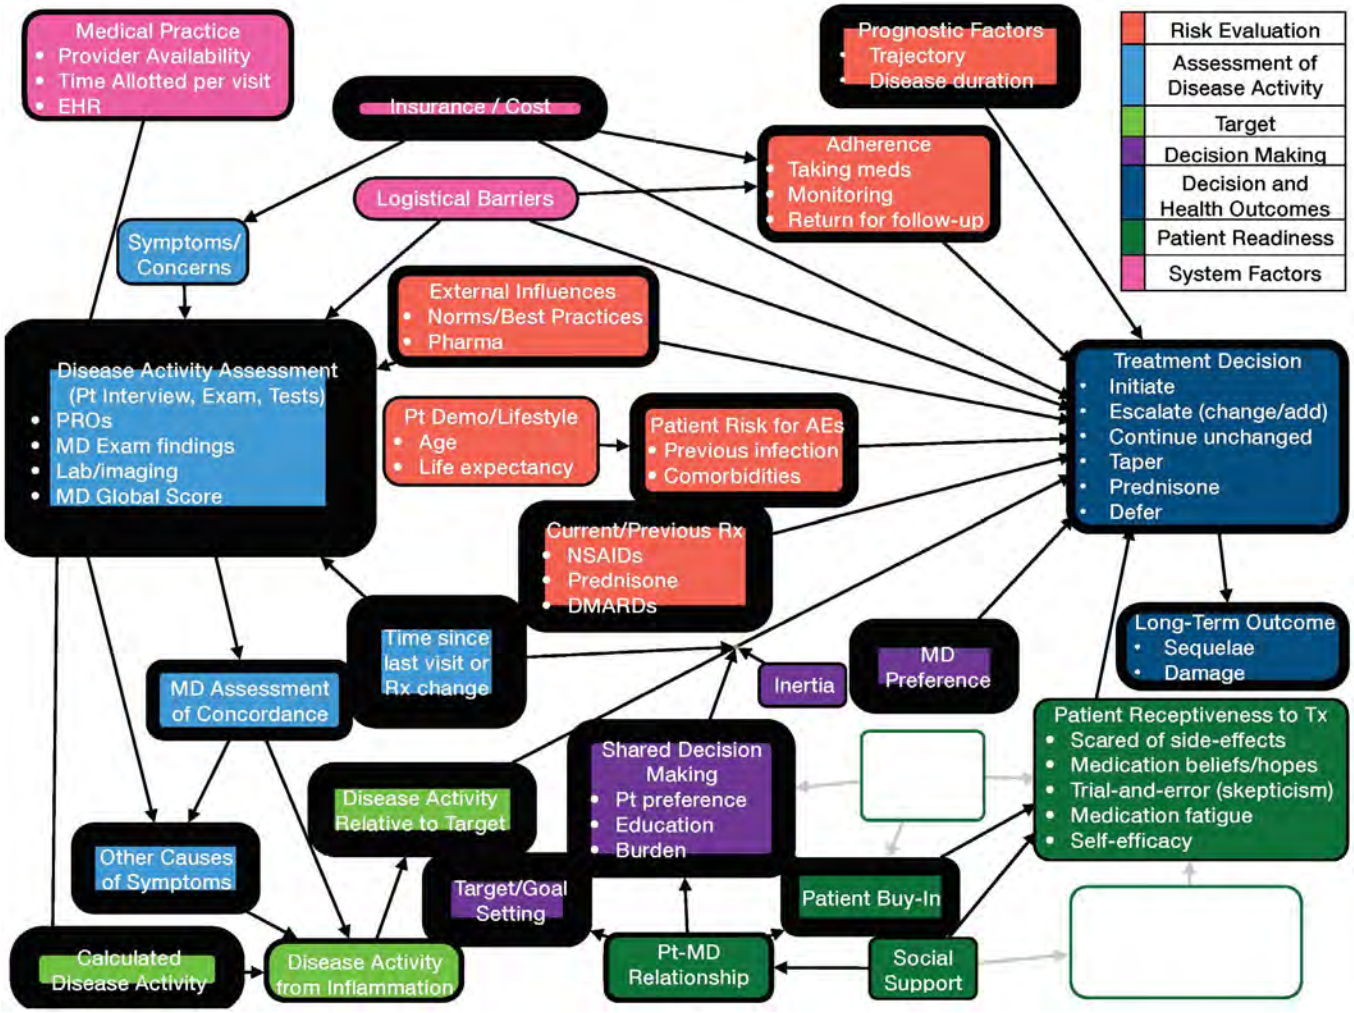
• Barrier of paperwork	43%	13%

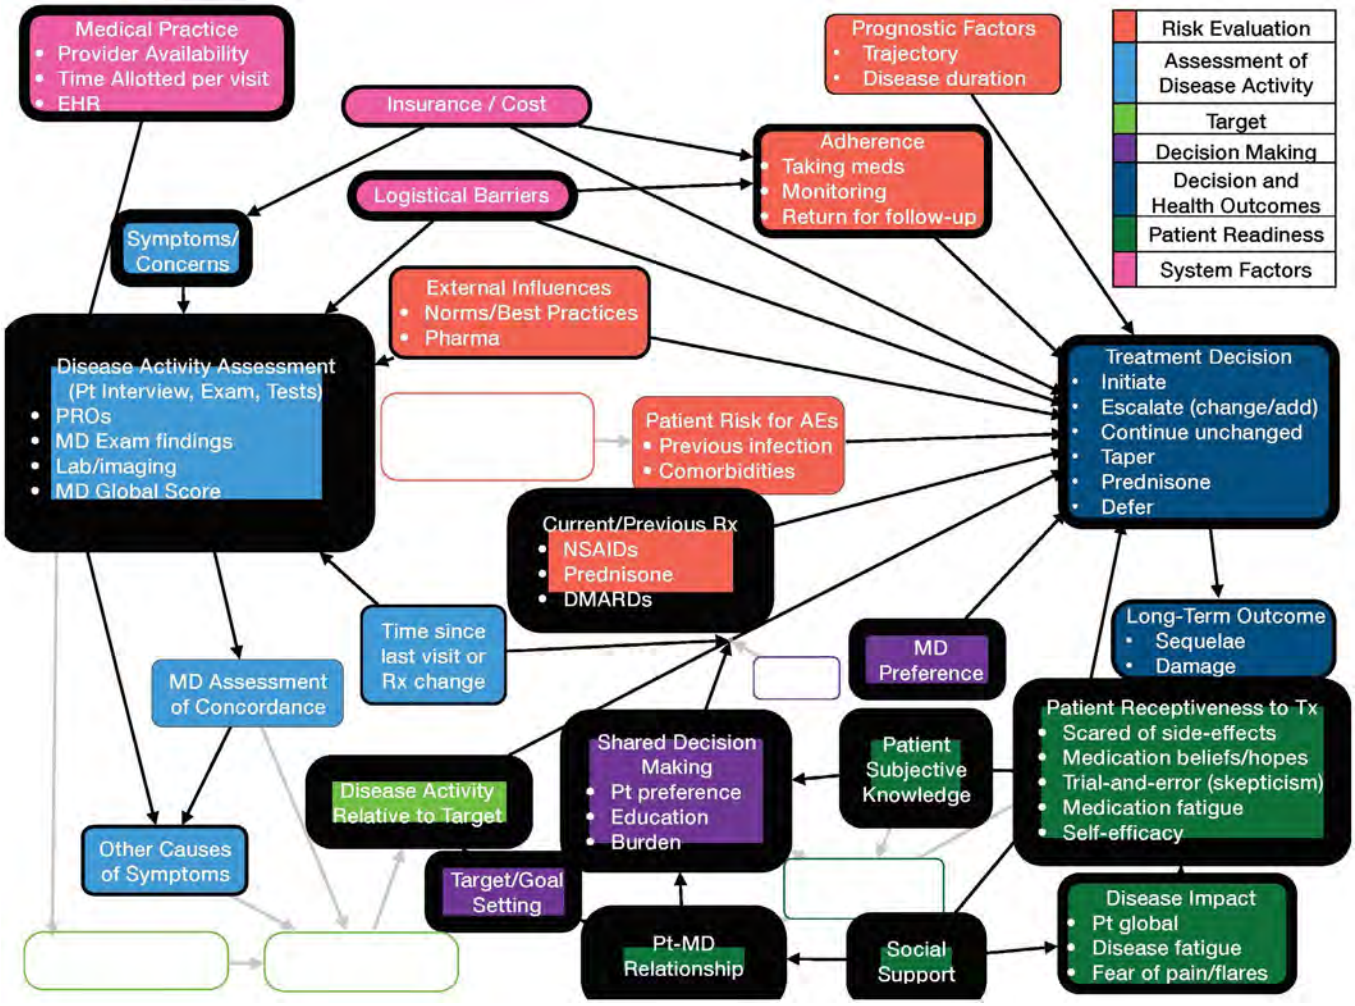


Physician Mental Model

Background/Purpose: Fewer than 50% of patients with rheumatoid arthritis (RA) are treated using a TTT strategy. The purpose of this study was to better understand rheumatologists' and patients' decision making regarding TTT using the Mental Models Approach to Risk Communication (MMARC). The MMARC provides a rigorous framework to develop interventions that address critical discrepancies between the mental models held by different populations, in this context, rheumatologists and patients.

Methods: We conducted semi-structured interviews with 14 rheumatologists and 30 patients to elicit respondents' views regarding treatment decisions in RA, with a focus on TTT. Interviews were transcribed and coded independently by two researchers. Final agreement between coders was high (kappa > 95%). We report the prevalence of each concept mentioned using the corresponding code. Because some ideas may not be expressed, these proportions represent a lower bound of their prevalence in people's mental models.

Results: Table 1 presents all factors raised in the interviews. Based on the codes assigned to each set of interviews, we created one model representing how rheumatologists conceptualize TTT (Figure 1) and another representing how patients conceptualize their treatment (Figure 2). Border thickness represent the frequency with which concepts were raised. Empty shapes highlight discrepancies between the rheumatologist and patient models. Several physicians stated that treatment decisions should be made based on overall trajectory of disease rather than at the point-of-care. They also described the importance of adherence and response to previous DMARDs on their decision making. Physicians recognized system barriers at the patient level (e.g., inadequate transportation), practice level, and insur-



Patient Mental Model

ance. Physicians also described how their own preferences and pharmaceutical company influences might affect their treatment decisions.

Notably absent from the patients' mental model is the cornerstone of TTT, i.e., disease activity measurement using validated instruments. Patients' anticipation of future experience on new medications. They described the necessity of feeling adequately informed, including from sources outside of their rheumatologist, in order to make treatment changes. Several discussed the burden of making treatment decisions. The uncertainty regarding whether one will benefit from a new DMARD and the risk of new side effects was frequently mentioned as an adverse aspect of changing medications. Concerns of the influence of pharmaceutical companies on rheumatologists' recommendations were also raised.

Conclusion: The TTT model of care is specific and prescriptive: measure disease activity and adjust treatment to achieve or maintain a predefined target using shared decision making. However, rheumatologists' and patients' mental models of treatment decision making in RA are much more complex and explain the low rates of TTT implementation. We found several discrepancies primarily related to differences in how patients and physicians value trade-offs that can serve as specific targets to improve patient-physician communication and ultimately inform interventions to improve uptake of TTT.

Abstract Number: 0741

Assessing the Relationship of Patient Global Assessment of Disease Activity and Health Related Quality of Life by SF-36 with Other Patient-Reported Outcomes in Rheumatoid Arthritis: Post Hoc Analyses of Data from Phase 3 Trials of Baricitinib

Vibeke Strand[1], Anthony Sebba[2], Savannah Scardo[3], Amanda Quebe[4], Liliana Zaremba-Pechmann[5] and Peter C Taylor[6], [1]Stanford University, Portola Valley, CA, [2]Division of Rheumatology, University of South Florida, Tampa, FL, [3]Eli Lilly and Company, Indianapolis, IN, [4]Eli Lilly and Company, Indanapolis, IN, [5]HaaPACS, Schriesheim, Germany, [6]University of Oxford, Oxford, United Kingdom

SESSION INFORMATION

Session Date: Sunday, November 7, 2021

Session Title: Patient Outcomes, Preferences, & Attitudes Poster II: Measurements (0739–0763)

Session Type: Poster Session B

Session Time: 8:30AM–10:30AM

Background/Purpose: Improvements in patient-reported outcomes (PROs) were demonstrated in randomized controlled trials (RCTs) of baricitinib (BARI), an oral Janus kinase (JAK)1/JAK2 inhibitor, for the treatment of rheumatoid arthritis (RA). In these post-hoc analyses of BARI RCT data at baseline and 24 weeks, we examined the relative importance of PROs on the Patient Global Assessment of Disease Activity (PtGA) and health-related quality of life (HRQoL) and whether these differ in patients with good disease control compared with those not in low disease activity (LDA) or remission in different patient populations.

Methods: We analyzed data from three BARI phase 3 studies: 1) RA-BEGIN (NCT01711359) included 588 conventional synthetic DMARD-naive patients randomized 4:3:4 to receive methotrexate (MTX) monotherapy, BARI 4 mg, BARI + MTX; 2) RA-BEAM (NCT01710358) included 1307 MTX-inadequate response (IR) patients randomized 3:3:2 to placebo (PBO), BARI 4 mg, or adalimumab 40 mg; and 3) RA-BEACON (NCT01721044) included 527 biologic DMARD-IR patients randomized 1:1:1 PBO, BARI 2 mg, or BARI 4 mg. PtGA was measured by a visual analog scale (VAS, 0 to 100 mm) and HRQoL was measured by SF-36 physical component summary (PCS) and mental component summary (MCS) scores. PROs included pain (VAS, 0 to 100 mm), Functional Assessment of Chronic Illness Therapy-Fatigue (FACIT-F), duration of morning joint stiffness (AMJtS), and Health Assessment Questionnaire-Disability Index (HAQ-DI). Good disease control was defined as either LDA or remission by Clinical Disease Activity Index (CDAI, ≤10 and ≤2.8, respectively). Within each RCT, treatment-agnostic correlation analyses at all time points from baseline to Week 24 were performed. Multiple regression analyses for the overall population and for patients in LDA, remission, or nonresponse were conducted; we present standardized parameter estimates from the regression analyses for each PRO to assess their relative importance on the PtGA, PCS score and MCS score.

Results: Across RCTs, pain strongly correlated with PtGA (r: 0.9); FACIT-F moderately correlated with PtGA, PCS, and MCS scores (r: 0.6 to 0.7; FACIT-F and PtGA are negatively correlated); and HAQ-DI moderately-to-strongly correlated with PtGA and PCS score (r: 0.6 to 0.8; HAQ-DI and PCS are negatively correlated). Duration of AMJtS was weakly correlated with the other PROs (r: -0.2 to -0.3 for PCS and MCS and 0.3 to 0.4 for PtGA). In regression

analyses across RCTs at baseline and Week 24 for the overall populations, the most significant factors were pain with PtGA (Table 1), HAQ-DI with SF-36 PCS score (Table 2]), and FACIT-F with SF-36 MCS score (Table 3). Similar results were observed in patients in LDA, remission, or nonresponse.

Conclusion: These results confirm prior findings, such as high correlations of pain with PtGA. We, however, observed that the relationships between other PROs with PtGA, PCS, or MCS scores were stable across time points over the first 6 months of treatment in differing patient populations, ranging from early to later disease. PtGA, PCS, and MCS scores were each associated with different PROs, indicating the importance of collecting multiple PROs in RCTs and real-world clinical practice.

Healthline	8	4.13	0.57	1	0
CDC	4	3.30	0.82	0.63	0.25

*Score range 1-5 for each question; average of all questions was calculated for each website
**Score range 0= "not met", 1= "met" for each of 4 core standards; average of all core standards was calculated for each website

Background/Purpose: The internet is a significant source of information for health-related topics. Given the complexity of rheumatic diseases, rheumatologists may find their patients searching online for information related to their diagnosis, including treatment options and complications. Often, what patients find on the internet can steer their decisions on treatments and issues they discuss with their provider, regardless of how varied the quality and reliability of this information may be. This study was thus designed to critically evaluate the information found on common rheumatic diseases through Google search using two instruments (Table 1): Four core standards presented by the *Journal of American Medical Association* (JAMA) to promote accountability for information written on the internet and the DISCERN instrument which is the first standardized quality index developed to judge the quality of written consumer health information.

Methods: Google search was performed for 10 diseases commonly evaluated by rheumatologists: ankylosing spondylitis, fibromyalgia, gout, lupus, osteoarthritis, psoriatic arthritis, rheumatoid arthritis, scleroderma, Sjogren's, and vasculitis. The first 10 website search results for each diagnosis were included in the study to yield a total of 100 websites. All websites were classified into major medical information websites (websites that disseminate information on a wide variety of health topics) and non-major websites. Websites were then assessed using JAMA and DISCERN. Primarily descriptive statistics were utilized. One-way analysis of variance and two tailed t-tests were performed to assess differences in scores.

Results: Average DISCERN quality score and JAMA score for all 100 websites were 3.48 (SD 0.66) and 0.66 (SD 0.29), respectively. Only 24 websites scored ≥ 4 on the DISCERN instrument. Risks of no treatment was the most missed question on the DISCERN instrument and authorship was the most missed core standard on the JAMA in-

strument (Table 1). While there was no statistically significant difference in DISCERN scores and JAMA scores for the 10 different diagnoses (P =0.36 for DISCERN, P=0.91 for JAMA), websites on ankylosing spondylitis numerically scored highest on the DISCERN instrument and rheumatoid arthritis scored highest on the JAMA instrument (Table 2). We observed that the major medical information websites (n=49) scored higher than non-major websites (n=51, $P < 0.0001$) on both instruments with eMedicineHealth scoring highest on the DISCERN instrument (4.33, SD 0.31) (Table 3).

Conclusion: Information on common rheumatic conditions procured through Google searches is of moderate quality and lacks essential aspects such as authorship, sources, and thorough explanation of treatment options. Not surprisingly, major medical information websites present more reliable information than non-major websites. If patients are looking for information on the internet, rheumatologists should guide them towards more reliable resources for further reading.

SESSION INFORMATION
Session Date: Sunday, November 7, 2021
Session Title: Patient Outcomes, Preferences, & Attitudes Poster II: Measurements (0739–0763)
Session Type: Poster Session B
Session Time: 8:30AM–10:30AM

Background/Purpose: People living with idiopathic inflammatory myositis (IIM) suffer impairments in health-related quality of life (HRQL), especially in the domains of pain interference, fatigue, and physical function. In 2021, the OMERACT Myositis Working Group 2021 Survey of PROM Construct Validity and Reliability was developed to evaluate specific patient-reported outcome measures (PROMs). The goal was to assess the measurement properties of construct validity and test-retest reliability for the Patient Reported Outcome Information System (PROMIS) Pain Interference 6a v1.0, Fatigue 7a v1.0, and Physical Function 8b v2.0 instruments.

OMERACT DOMAIN	Working Definition	Selected Instrument
Pain Interference	Aching, soreness, or tenderness attributable to IIM relating to the joints, muscles, and/or skin causing interference with routine daily function.	PROMIS Pain Interference 6a v1.0
Fatigue	A feeling of [extreme] tiredness or exhaustion attributable to IIM, interfering with usual and meaningful daily activities.	PROMIS Fatigue 7a v1.0
Physical Function	The ability to perform basic and desired activities of daily living that is affected by decreased use of muscles or other organ systems affected by IIM.	PROMIS Physical Function 8b v2.0

Table 1. OMERACT Core Domains of Interest.

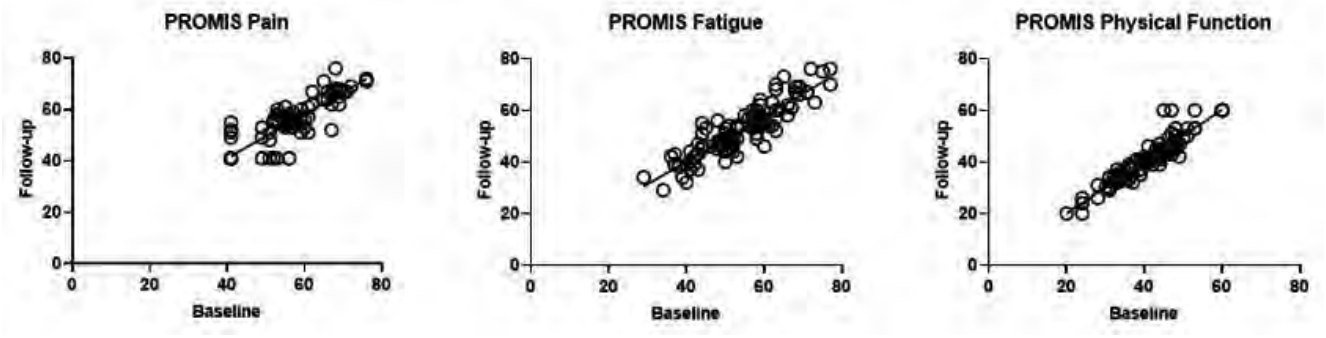

Figure 1. Test-Retest Correlation Matrices.

Methods: Formalized definitions of each domain were developed per methodological guidance from the OMERACT Instrument Selection Filter 2.2 (Table 1). PROMs for each domain of interest were deployed via Redcap to adult patients with confirmed IIM at a large tertiary care referral site (Baltimore, MD). Patient demographics and PROMIS v1.0 4a anxiety, depression, sleep disturbance, and social participation questionnaires were also administered, and identical questionnaires were given 7 days later. In addition, data from Sweden, Australia, South Korea, The Netherlands and the USA that was collected as part of the OMERACT Myositis Working Group 2019 Survey of PROM Content Validity and Feasibility was used which additionally included the Pain Disability Index (PDI), International Physical Activity Questionnaire (IPAQ), and Myositis Activities Profile (MAP). Raw PROMIS scores were converted to T-score measures and normalized to a score of 50 with a standard deviation of 10; higher scores indicate more of the concept being measured. Test/Retest reliability was calculated using intraclass correlation coefficients (ICC) and correlation matrices were constructed. Construct validity was determined via formulation of *a priori* hypotheses generated by working group members (Table 2); >75% member agreement was required for each hypothesis. Pearson's correlation was calculated for each construct pair.

Results: Domain definitions were formalized based on patient/expert consensus (Table 1). There were 287 adult participants with IIM who completed the baseline 2021 survey and 97 participants who completed the retest; the number of participants who completed the 2019 survey as relevant to this exercise varied (Table 2). Participants from the 2021 baseline survey were 76% female with a mean (SD) age of 60 (12). Test-retest reliability was high for pain interference, fatigue, and physical function with an ICC (95% CI) of 0.878 (0.823-0.917), 0.886 (0.822-0.925), and

Table 2. Construct Validity Assessment

OMERACT Myositis Working Group 2021 Survey of PROM Construct Validity and Reliability					
Construct	***A priori* hypothesis-expected correlation**	**Consensus Exercise, % Agreement of Group Members**	**Expected Results**	**Observed Pearson's rho**	**Hypothesis confirmed?**
PROMIS Pain Interference 6a v1, PROMIS Sleep Disturbance 4a v1: Pain interference should correlate moderately with one's sleep	Moderate	93%	r >0.25 but < 0.75	0.35	yes
PROMIS Pain Interference 6a v1, Pain Intensity (NRS): Pain interference should relate to pain intensity but not perfectly correlate.	Moderate-High	100%	r >0.50 and <0.90	0.87	yes
PROMIS Fatigue 7a v1, PROMIS Anxiety 4a v1.0: Fatigue is a complex symptom that should be partially driven by emotional distress.	Moderate	93%	r >0.25 but < 0.75	0.58	yes
PROMIS Fatigue 7a v1, PROMIS Sleep Disturbance 4a v1.0: Fatigue is a complex symptom that should moderately correlate to sleep disturbance but not to a high degree	Moderate	100%	r >0.25 but < 0.75	0.54	yes
PROMIS Physical function 8b v2.0, PROMIS Depression 4a v1: Physical function, or the perception of one's physical function, should be impacted by negative emotion.	Moderate (negative)	93%	r >0.25 but < 0.75	-0.49	yes
OMERACT Myositis Working Group 2019 Survey of PROM Content Validity and Feasibility					
PROMIS Pain interference 8a v1, sex: Pain interference should not differ between sexes	Low	57%	Item dropped	Item dropped	N/A
PROMIS Pain Interference 8a v1, age: Age should not be driving pain interference. N=65 observations.	Low	93%	r < 0.25	-0.18	Yes
PROMIS Pain interference 8a v1, Pain Disability Index (PDI): Pain interference and disability attributed to pain should be very similar in IIM. N=100 observations.	High	100%	r > 0.75	0.63	No
PROMIS Fatigue 7a v1, sex: Fatigue from IIM should not be related to sex. N=68 observations.	Low	100%	r < 0.25	0.17	Yes
PROMIS Fatigue 7a v1, age: Age should not be driving the degree of fatigue in IIM. N=68 observations.	Low	100%	r < 0.25	-0.18	Yes
PROMIS Physical function 8b v2.0, sex: Physical Function from IIM should not be impacted by sex. N=79 observations.	Low	100%	r < 0.25	-0.01	Yes
PROMIS Physical function 8b v2.0, age: Age should not be driving physical function in IIM. N=79 observations.	Low	100%	r < 0.25	-0.11	Yes
PROMIS Physical function 8b v2.0, International Physical Activity Questionnaire (IPAQ): One's physical activity should be related to/depend on one's physical function. N=100 observations.	Moderate	86%	r > 0.5	-0.134	No
PROMIS Physical Function 8b v2.0, Physical Activity: Myositis Activities Panel (MAP): One's physical activity should be related to/depend on one's physical function. N=100 observations.	Moderate	86%	r > 0.5	0.77	Yes

0.943 (0.917-0.962), respectively (Figure 1). For the construct validity exercise, member consensus was met for 12 of 13 *a priori* hypotheses. Hypotheses were correct for 3 out of the 4 available constructs for pain interference, 4 out of 4 constructs for fatigue, and 4 of 5 constructs for physical function (Table 2).

Conclusion: Both test-retest reliability and construct validity are high for pain interference, fatigue, and physical function when used in this IIM population. Further longitudinal validation is ongoing in Sweden, Australia, South Korea, The Netherlands and the USA.

Anxiety (0-5.5)	-0.44	0.44	0.48	0.74	0.70	0.45	-0.44	0.37
Depression (0-5.5)	-0.45	0.46	0.48	0.71	0.77	0.47	-0.47	0.41
Sleep (0, 1.1, 2.2, 3.3)	-0.49	0.55	0.51	0.46	0.45	0.74	-0.48	0.56
Participate (0-5)	-0.72	0.61	0.49	0.40	0.43	0.39	-0.65	0.52
PATGL (0-10)	-0.65	0.76	0.53	0.41	0.46	0.44	-0.59	0.83
RAPID3 (0-30)	-0.75	0.82	0.57	0.46	0.52	0.50	-0.64	0.88
60-symptom checklist (0-60)	-0.53	0.56	0.64	0.53	0.54	0.53	-0.53	0.53
RADAI (0-54)	-0.56	0.62	0.45	0.46	0.48	0.45	-0.48	0.63

Background/Purpose: PROMIS-29 (patient-reported outcome measurement information system) has been extensively validated in many diseases according to standard deviations from normalized T-scores for 7 domains. It was developed through literature review, investigator consensus, item response theory analysis and expert review of scaling results from multiple PROMIS data sets. The domains are physical function, pain interference, fatigue, anxiety, depression, sleep quality and ability to participate, and it has construct validity and reliability in many diseases, including RA and other rheumatic diseases (Katz P et al Arth Care & Res. 2017;69:1312-21). An MDHAQ (multidimensional health assessment questionnaire) queries similar domains having been developed in clinical care by continuous quality improvement cycles. MDHAQ scores may be more intuitively understood by health professionals, and MDHAQ includes 3 indices which agree 80-90% with reference indices that require additional measures and are less feasible in busy clinical settings: RAPID3 (routine assessment of patient index data) to assess patient status; FAST4 (fibromyalgia assessment screening tool) to screen for fibromyalgia (Gibson, J Rheumatol. 2020;47:761-9); and DEP2 (Morla, Arth Care & Res 2021;73:120-9) to screen for depression (Dep). High correlations have been reported between PROMIS T-scores vs RAPID3 (Yun et al Arth Care & Res. 2020;72:553-60), suggesting a hypothesis that 7 PROMIS-29 vs MDHAQ domains may provide similar information, as studied here.

Methods: Both PROMIS-29 and MDHAQ were completed at the same routine rheumatology encounter. PROMIS-29 T-scores were obtained by submitting the data to the HealthMeasures Scoring Service, powered by Assessment Center^{SM} (https://www.assessmentcenter.net/ac_scoringservice). MDHAQ scores and indices were computed in the clinic. MDHAQ and PROMIS T-scores were compared in all patients, rheumatoid arthritis (RA) and non-RA patients by Spearman correlations and a series of linear regressions in which each PROMIS-29 T-score served as a dependent variable and MDHAQ scores as independent variables, and vice versa. Scores were also compared according to FAST4 status; (1 point each for pain >6/10, fatigue >6/10, symptom checklist >16/60, and self-report painful joint count >16/54 where 3/4 =FM).

Results: PROMIS-29 and MDHAQ were completed at the same visit by 571 patients, 225 with RA and 346 with other diagnoses. All 7 MDHAQ and PROMIS-29 domains were correlated significantly (rho=-0.65 to 0.82, $p< 0.001$) in all patients (Table), similar in RA and non-RA patients. Significantly poorer status was seen in both RA and non-RA patients with FM vs no FM according to FAST4 (data not shown). Regressions explained 53-81% of the variation in PROMIS T-scores by MDHAQ domains and 44%-82% of the variation in MDHAQ domains by PROMIS T-scores.

Conclusion: MDHAQ and PROMIS-29 give similar information in rheumatology patients. PROMIS has advantages for clinical research, while MDHAQ provides additional clinical information and is intuitive for busy clinical settings.

PATGL = Patient Global Assessment, RADAI = Rheumatoid Arthritis Disease Activity Index, RAPID3 = Routine Assessment of Patient Index Data 3. Participate (0-5) = Participate in Recreational Activities or Sports (0-3) + Social activity in 60-symptom (0 for No, 2 for Yes). Anxiety (0-5.5) = Anxiety (0-3.3) + Anxiety in 60-symptom (0 for No, 2.2 for Yes). Depression (0-5.5) = Depression (0-3.3) + Depression in 60-symptom (0 for No, 2.2 for Yes).

Patient-reported Outcomes and Safety Measures in Patients with Rheumatic Diseases Who Switched from Reference or Other Biosimilar Etanercept to Biosimilar Etanercept GP2015 and in Biologic-naïve Patients Starting a Treatment with GP2015: 12-month Interim Analysis from a Real-world Study

Ayman Askari[1], Marc Schmalzing[2], Slawomir Jeka[3], Javier De Toro Santos[4], Eduardo Collantes-Estevez[5], Fabricio Furlan[6], Sohaib Hachaichi[6] and Herbert Kellner[7], [1]The Robert Jones and Agnes Hunt Orthopaedic Hospital, Shropshire, United Kingdom, [2]Rheumatology/Clinical Immunology, Department of Internal Medicine II, University of Wuerzburg, Wuerzburg, Germany, [3]Clinic and Department of Rheumatology and Connective Tissue Diseases, University Hospital No 2 in Bydgoszcz Collegium Medicum UMK in Toruń, Bydgoszcz, Poland, [4]University Hospital Coruña, Servicio de Reumatología, A Coruña, Galicia, Spain, [5]IMIBIC/Reina Sofia Hospital/University of Córdoba, Córdoba, Spain, [6]Hexal AG (A Sandoz company), Holzkirchen, Germany, Holzkirchen, Germany, [7]Hospital Neuwittelsbach, Center for Rheumatology and Gastroenterology, Munich, Germany, Munich, Germany

SESSION INFORMATION
Session Date: Sunday, November 7, 2021
Session Title: Patient Outcomes, Preferences, & Attitudes Poster II: Measurements (0739–0763)
Session Type: Poster Session B
Session Time: 8:30AM–10:30AM

Background/Purpose: GP2015 is a biosimilar of etanercept (ETN). COMPACT is an ongoing, non-interventional study, evaluating the effectiveness, safety, and quality of life with GP2015 treatment in patients (pts) with rheumatoid arthritis (RA), axial spondyloarthritis (axSpA) or psoriatic arthritis (PsA) in real-world conditions.[1] Herein we present the pt-reported outcomes (PROs) and safety data focusing on pts who were either in treatment with reference ETN or biosimilar ETN (initial ETN; iETN) other than GP2015 and switched to GP2015 or biologic-naïve pts who started GP2015 as a first biologic therapy.

Methods: Pts aged ≥18 years who initiated treatment with GP2015 were enrolled. They were categorized based on prior treatment status.[1] PROs assessments through 12 months included 12-Item Short Form Survey (SF-12) score for mental/physical health and physical function as Health Assessment Questionnaire Disability Index (HAQ-DI) score. PROs and safety data are presented for switched pts (on clinical remission or low disease activity under treatment with iETN and switched to GP2015) and biologic-naïve pts (considered uncontrolled with conventional therapy and started with GP2015).

Results: A total of 1437 pts were recruited (analysis cut-off date: 16 Oct 2020), comprising 828 (57.6%) with RA as primary indication, 325 (22.6%) with axSpA, and 284 (19.8%) with PsA. There were 292, 159, and 116 switched pts; and 439, 124, and 134 biologic-naïve pts with RA, axSpA, and PsA, respectively. Comorbidities (switched and biologic-naïve pts) were more frequent in RA (70.2% and 65.8%), followed by PsA (58.6% and 59.7%) and axSpA (49.7% and 54.8%), respectively. After 12 months treatment with GP2015, we observed comparable HAQ-DI, SF-12 mental, and SF-12 physical scores between the switched and biologic-naïve pts (**Figure 1 A-C**). Incidences of adverse events (AEs) and serious AEs in pts with RA were 37.3% and 6.5% in switched, 43.7% and 7.3% in biologic-naïve; in pts with axSpA they were 25.8% and 3.1% in switched, 46.8% and 7.3% in biologic-naïve; and in pts with PsA they were 33.6% and 1.7% in switched, 43.3% and 6.0% in biologic-naïve. Injection-site pain was low across the groups (RA: 2.1% and 0.7% in switched and biologic-naïve pts; axSpA: 1.3% and 1.6% in switched and biologic-naïve pts; PsA: 0 and 0.7% in switched and biologic-naïve pts, respectively).

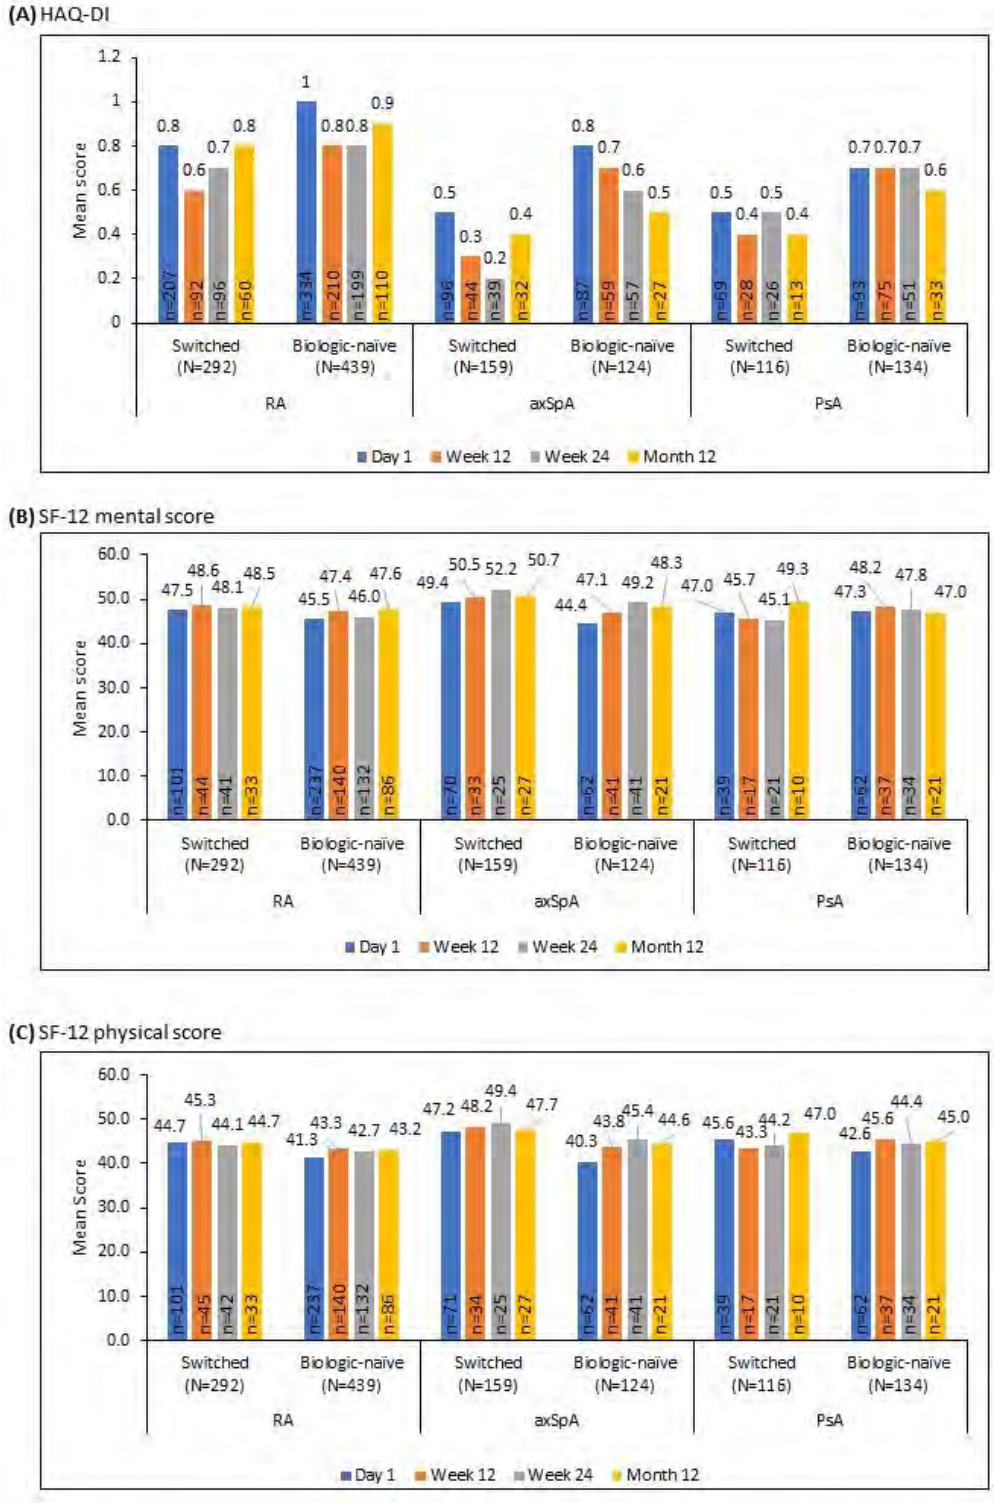

Figure 1. PROs in pts who switched from iETN to GP2015 and biologic-naïve started on GP2015.

Conclusion: This analysis shows comparable PRO scores obtained after 12 months of observation in pts under treatment with iETN who switched to GP2015 and in pts who were biologic-naïve and started GP2015 as a first-line biologic therapy, without any new safety signals in real-world conditions.

setting of telehealth encounters. Likewise, completion of physician-reported measures of disease activity may not be possible via telehealth because, for example, joint examinations and global assessments cannot be conducted reliably. In both cases, acceptable proxies are needed for use in telehealth as this method of care delivery remains widely used. We examined the relationship between (1) simple, single-item ratings of pain, function, and fatigue with validated scales measuring the same constructs, and (2) patient and physician ratings of disease activity in patients with rheumatoid arthritis.

Methods: Analysis 1 uses data from FORWARD, The National Databank for Rheumatic Diseases, a longitudinal registry of individuals with rheumatic diseases. Data are regularly collected via semi-annual questionnaires. Within each questionnaire, pain, function, and fatigue are assessed by both single-items and validated scales (Table 1). Spearman correlations examine the associations between single-item and scales for each construct at 4 different questionnaire administrations and between 6-month changes in item and scale responses. Analyses were conducted separately for rheumatoid arthritis (RA), systemic lupus erythematosus (SLE), and osteoarthritis (OA). Analysis 2 uses data from a study of people with rheumatoid arthritis in which both the Clinical Disease Activity Index (CDAI) and patient-reported Rheumatoid Arthritis Disease Activity Index (RADAI) were completed. Spearman correlations examine associations between CDAI and RADAI scores and components (global assessments, joint counts).

Results: Analysis 1: Participants with RA (n=7478) had mean age 68±11 years, were 92% white and 83% female; those with SLE (n=893) had mean age 63± 13 years, were 83% white, and 94% female; and those with OA (n=3371) had mean age 70± 10 years, were 95% white, and 86% female. Cross-sectional correlations between single items and scales were uniformly medium to large (Table 1). Correlations between change scores, however, were small (Table 2)..

Table 3. Correlation between CDAI and RADAI total scores and components (n = 48)	
	correlation
Total score	0.70
Components	
RADAI painful joints, CDAI swollen joints	0.36
RADAI painful joints, CDAI tender joints	0.71
Patient global, physician global	0.57

Analysis 2: Participants (n=48) had mean age 58 ± 12 years, were 76% female, 36% white, 7% Asian, 14% Black, and 43% other/multi-racial, and 36% LatinX ethnicity. Correlations between CDAI and RADAI total scores was 0.70, RADAI painful joint count and CDAI tender joints 0.71, and RADAI and CDAI global assessments 0.57.

Conclusion: Cross-sectional group associations between single-item and scale responses were high suggesting the potential for usefulness in telehealth settings where rheumatologists may not have sufficient time to complete longer validated measures nor data from a physical exam. Correlations in changes, however, were low, perhaps reflecting reduced precision of the single-item measures, which might limit the usefulness of these measures for following patients over time. The moderate-high associations between CDAI and RADAI scores and components suggests that remote patient-completed assessments of disease activity may be useful in telehealth settings.

Understanding Heterogeneity in Patients' Conceptualization of Treatment for Rheumatoid Arthritis: A Cluster Analysis

Betty Hsiao[1], Julie Downs[2], Mandy Lanyon[2], Leslie Harrold[3], Jeffrey Curtis[4], Susan Blalock[5], Carole Wiedmeyer[6], SHILPA VENKATACHALAM[7], William Nowell[8] and Liana Fraenkel[9], [1]Yale-New Haven Medical Center, New Haven, CT, [2]Carnegie Mellon, Pittsburgh, PA, [3]Corrona, LLC, Northborough, MA, [4]Division of Clinical Immunology and Rheumatology, Department of Medicine, Department of Epidemiology, University of Alabama at Birmingham, Birmingham, AL, [5]Chapel Hill, Chapel Hill, NC, [6]Global Healthy Living Foundation, Nyack, NY, [7]Global Healthy Living Foundation, New York, NY, [8]Global Healthy Living Foundation, Upper Nyack, NY, [9]Berkshire Medical Center, Lenox, MA

SESSION INFORMATION
Session Date: Sunday, November 7, 2021
Session Title: Patient Outcomes, Preferences, & Attitudes Poster II: Measurements (0739–0763)
Session Type: Poster Session B
Session Time: 8:30AM–10:30AM

Background/Purpose: Uptake of treat to target strategies for the management of rheumatoid arthritis (RA) is low. While there are known system-related barriers to accessing treatment, poor primary (starting) and secondary (continuing) adherence are prevalent causes of suboptimal care. The objective of this study was to better understand the heterogeneity in patients' conceptualization of treatment of RA in order to inform interventions aimed at improving appropriate utilization of DMARDs.

Methods: Participants were recruited from an online research registry. Those meeting eligibility criteria [physician diagnosed RA currently being treated with DMARD(s)] rated 56 items (coded on 5-point scales with appropriate anchors) reflecting concepts raised during preparatory in-depth individualized patient interviews. To combine similar items for ease of analysis and interpretation we conducted a principal components analysis using Varimax rotation. We then entered mean scores, weighted by how heavily each item loaded onto each factor, into a k-means cluster analysis. We examined whether demographic characteristics differed across clusters using ANOVA and chi-square for continuous and categorical variables, respectively.

Results: Participants (N= 621) ranged in age from 22 to 93, with a mean of 57 years old (SD= 11.5). Most (89%) were female and reported themselves to be non-Hispanic white (89%); 27% reported having a post-graduate degree. A

Table 1. List of Items

Survey Item Text *(items with scores of 6 or higher are listed)*	Factor Loading	Mean (SD)
1. Access to high quality care and support (Variance Explained: 12.10%, Items: 21)		
Difficulty getting clear, complete answers in a timely manner from my rheumatologist (by email or telephone) in-between appointments if I have questions or concerns. (Reverse)	-0.72	1.83 (1.11)
Difficulty scheduling an appointment with my rheumatologist right away if my disease flares up. (Reverse)	-0.70	2.30 (1.24)
I feel like I don't have much of a say in making decisions about treating my RA. (Reverse)	-0.65	2.03 (1.11)
My rheumatologist gives me enough time to ask questions during my visits.	0.65	4.25 (0.89)
My rheumatologist wants me to stay on a medication even though I want to switch. (Reverse)	-0.63	1.72 (1.00)
My rheumatologist gives me enough information to decide which medication to take.	0.62	3.99 (1.10)
I feel like I have enough information from all sources to make good decisions about my medication.	0.60	3.91 (0.98)
2. Comfortable adding/switching DMARDs (Variance Explained: 9.73%, Items: 14)		
I worry about changing medication because I don't know if I will get new (or more) side effects. (Reverse)	-0.78	3.49 (1.31)
I worry about changing medication because I don't know if a new medication will work as well or any better than the one(s) I'm already taking. (Reverse)	-0.75	3.32 (1.30)
It is hard to decide whether to switch medication. (Reverse)	-0.65	2.93 (1.19)
It is hard to decide whether to add medication to the ones I am already taking. (Reverse)	-0.63	2.89 (1.21)
3. Perceived favorable DMARD risk/benefit ratio (Variance Explained: 8.74%, Items: 15)		
Medication is needed to keep my RA under control.	0.66	4.60 (0.69)
My life would be a real challenge without my RA medication.	0.63	4.50 (0.83)
4. Confidence that testing reflects disease activity (Variance Explained: 6.20%, Items: 6)		
Blood work shows whether I need more or different medication.	0.75	2.77 (1.23)
Blood work shows whether my medication is working.	0.69	2.90 (1.21)
Blood work shows if my RA is progressing. (Agree)	0.66	2.93 (1.31)
X-rays show whether I need more or different medication. (Agree)	0.66	2.37 (1.15)
X-rays show whether my medication is working. (Agree)	0.64	2.44 (1.12)
X-rays show if my RA is progressing. (Agree)	0.62	3.22 (1.15)

scree plot revealed that a 4-factor solution explaining 36.8% of the variance would provide desirable interpretability, with a discontinuous drop in eigenvalues for additional factors slowly tapering and adding little discriminability between later solutions. The four factors (% variance explained, number of items) were: 1) Access to high quality care and support (12.10%, n= 21); 2) Comfortable adding/switching DMARDs (9.73%, n= 14); 3) Perceived favorable

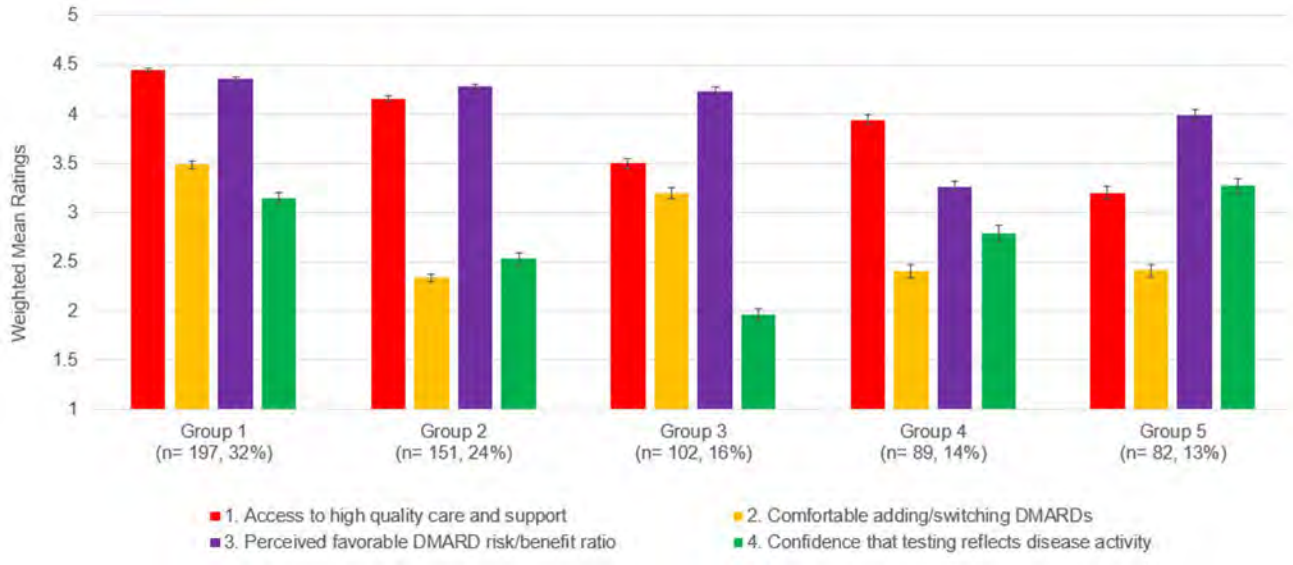

Figure 1. Weighted Ratings per Cluster.

Table 2. Participant Characteristics Across Groups

	Group 1 (n = 197)	Group 2 (n = 151)	Group 3 (n = 102)	Group 4 (n = 89)	Group 5 (n = 82)	p value
Age, mean (SD)	60.7 (9.6)	54.7 (11.6)	54.2 (11.8)	57.0 (12.7)	53.3 (11.3)	p= 0.1
Female, n (%)	173 (87.8%)	132 (87.4%)	93 (91.2%)	77 (86.5%)	75 (91.5%)	p= 0.6
White, Non-Hispanic n (%)	184 (93.4%)	137 (90.7%)	95 (93.1%)	72 (80.9%)	67 (81.7%)	p= 0.002
College degree or more, n (%)	111 (56.3%)	87 (57.6%)	61 (59.8%)	51 (57.3%)	33 (40.2%)	p= 0.01

DMARD risk/benefit ratio (8.74%, n= 15); and 4) Confidence that testing reflects disease activity (6.20%, n= 6). Table 1 lists the mean ratings for items with factor loading scores of 6 or greater. A 5-cluster solution showed the most stable convergence of cluster centers after 10 iterations. Figure 1 shows the weighted mean scores for each factor across clusters. While four out of the five groups perceived a favorable DMARD risk/benefit ratio, all groups voiced some discomfort with adding or changing DMARDs, with Groups 2, 4 and 5 having particularly low scores. Level of comfort adding/switching DMARDs was not mitigated by access to high quality care and support. There were a greater number of non-white participants in Groups 4 and 5, and less well-educated participants in Group 5 (Table 2). No differences in age or sex across groups were observed.

Conclusion: Patients' conceptualization of RA treatment varies. However, adding/switching DMARDs appears to be ubiquitous regardless of the perceived benefits associated with DMARDs and access to high quality care and support. Interventions outside of the traditional physician-patient relationship are needed to facilitate treatment escalation in patients with RA. Further research is required to understand residual variance not explained by our model.

Abstract Number: 0748

Performance of Standardized Scores for Disease Assessment and Pain in Patients Withspondyloarthritis and Fibromyalgia

Xenofon Baraliakos, Styliani Tsiami, Maria Claudia Gkelaki, Piet Dukatz, Uta Kiltz and Jürgen Braun, Rheumazentrum Ruhrgebiet Herne, Ruhr-Universität Bochum, Herne, Germany

SESSION INFORMATION
Session Date: Sunday, November 7, 2021
Session Title: Patient Outcomes, Preferences, & Attitudes Poster II: Measurements (0739–0763)
Session Type: Poster Session B
Session Time: 8:30AM–10:30AM

Background/Purpose: The pathogenesis of spondyloarthritis (SpA) including axial SpA (axSpA) and psoriatic arthritis (PsA) differs from fibromyalgia (FM). However, symptoms partially overlap and both patient groups suffer from pain and stiffness. In addition, SpA patients may also develop a secondary form of FM. Classification criteria for SpA and

Table 1. Baseline characteristics of all diagnosis subtypes and comparison (p-values) to primary FM diagnosis. '+' : diagnosis with concomitant FM, '-': diagnosis without concomitant FM

Table 1	FM	axSpA-	*p-value*	axSpA+	*p-value*	PsA-	*p-value*	PsA+	*p-value*

diagnostic criteria for FM are used to differentiate between these subsets. Patient reported outcomes (PRO) often generated by questionnaires are used to assess severity and other disease features. We aim to study whether PROs developed for axSpA, PsA, and related physician-based information behave in a similar way in patients diagnosed with FM without an additional chronic inflammatory rheumatic disease (CIRD) as in patients with a primary diagnosis of SpA without or with secondary FM.

Methods: Patients were consecutively recruited. The main inclusion criterion was a clinical diagnosis of FM (without CIRD), axSpA or PsA (without or with secondary FM) and the indication for a treatment adaptation (escalation or change within the same class) for any reason, based on the judgement of experienced rheumatologists. Standardized assessment tools and lab parameters (BASDAI, ASDAS-CRP, DAPSA, patient´s and global assessment (NRS), CRP, BASFI, Fibromyalgia Impact questionnaire (FIQ), Leeds Enthesitis Index (LEI), Maastricht Ankylosing Spondylitis (MASES) and SpA Research Consortium of Canada (SPARCC) Enthesitis Score were assessed and compared between subgroups.

SPARCC	9.4±3.4	3.5±3.4	*<0.001*	7.7±3.8	*0.139*	5.1±3.7	*<0.001*	8.1±3.9	*0.412*

Results: The baseline demographics of 300 recruited patients (100 FM. 100 axSpA and 100 PsA) are shown in Table 1. All patients with FM (primary or secondary to SpA) showed the highest scores in almost all assessments, and this was independent of the main diagnosis (Table 2). In comparison, patients with axSpA or PsA without secondary FM showed significantly lower scores in all PROs as compared to those with primary and secondary FM, with exception of (i) scores of ASDAS-CRP and (ii) duration of morning stiffness (Question 6 of BASDAI), which were not affected by the presence of secondary FM (Table 2).

Conclusion: Secondary FM is leading to significantly higher levels of SpA-specific scores. ASDAS-CRP was the only score that was not influenced by the presence of secondary FM in patients with axSpA even though it was also increased in patients with primary FM, while similar results were found for the duration but not the level of morning stiffness. On the other hand, FM-specific questionnaires also showed high scores in patients with axSpA and PsA with concomitant FM but not in those without.

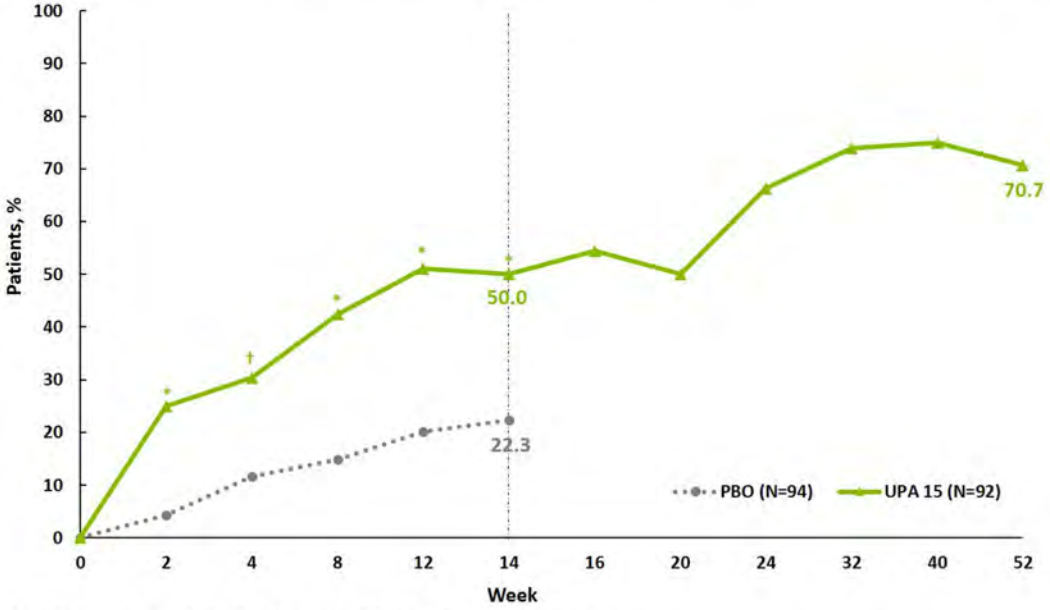
SESSION INFORMATION
Session Date: Sunday, November 7, 2021
Session Title: Patient Outcomes, Preferences, & Attitudes Poster II: Measurements (0739–0763)
Session Type: Poster Session B
Session Time: 8:30AM–10:30AM

Background/Purpose: Back pain is the hallmark disease feature for patients (pts) with AS. However, the relationship between back pain and other patient-centric outcomes and disease activity measures has not been well characterized. The purpose of this study was to examine the association between meaningful back pain improvement and quality of life, disease activity, physical functioning, fatigue, sleep, and work productivity in pts with AS treated with upadacitinib (UPA) or placebo (PBO) in the phase 2/3 SELECT-AXIS 1 trial[1].

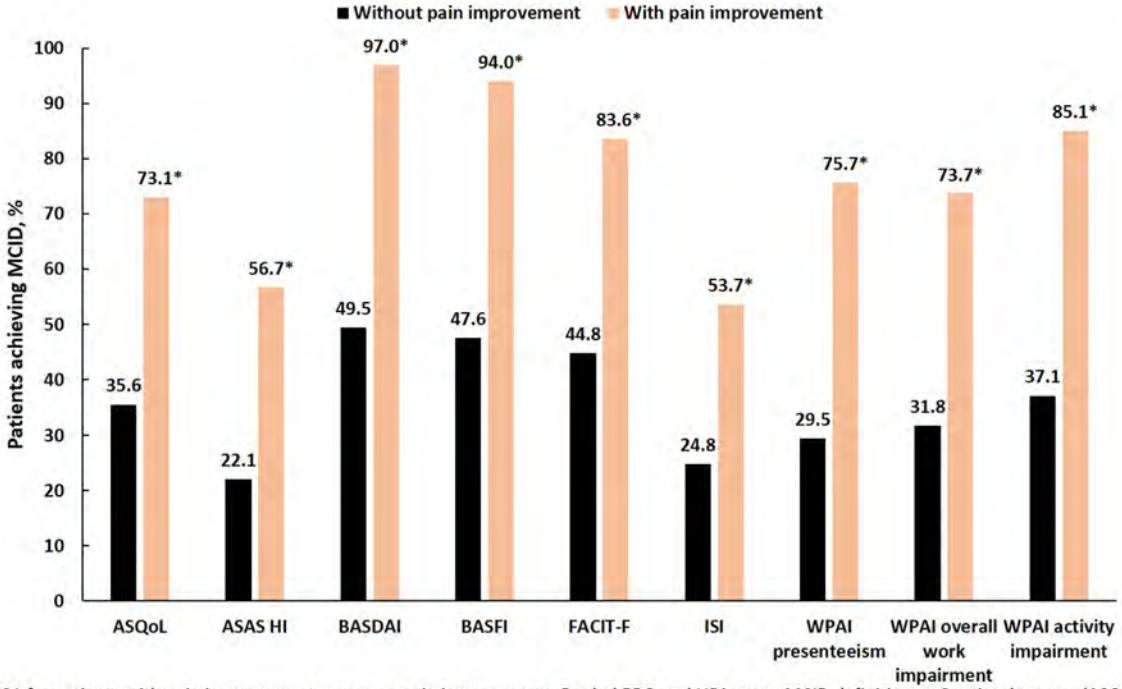
Methods: Active AS pts with an inadequate response to NSAID therapy received UPA 15 mg once daily or PBO for 14 weeks, followed by a 90-week open label extension period. Clinically meaningful back pain improvement was defined as achieving a score of < 4 and ≥2-point decrease from baseline in Patient's Assessment of Total Back Pain score

Figure 1. Proportion of patients achieving meaningful back pain improvement through Week 52 with treatment



*P<0.0001 vs placebo. †P<0.001 vs placebo. PBO, placebo; UPA, upadacitinib.

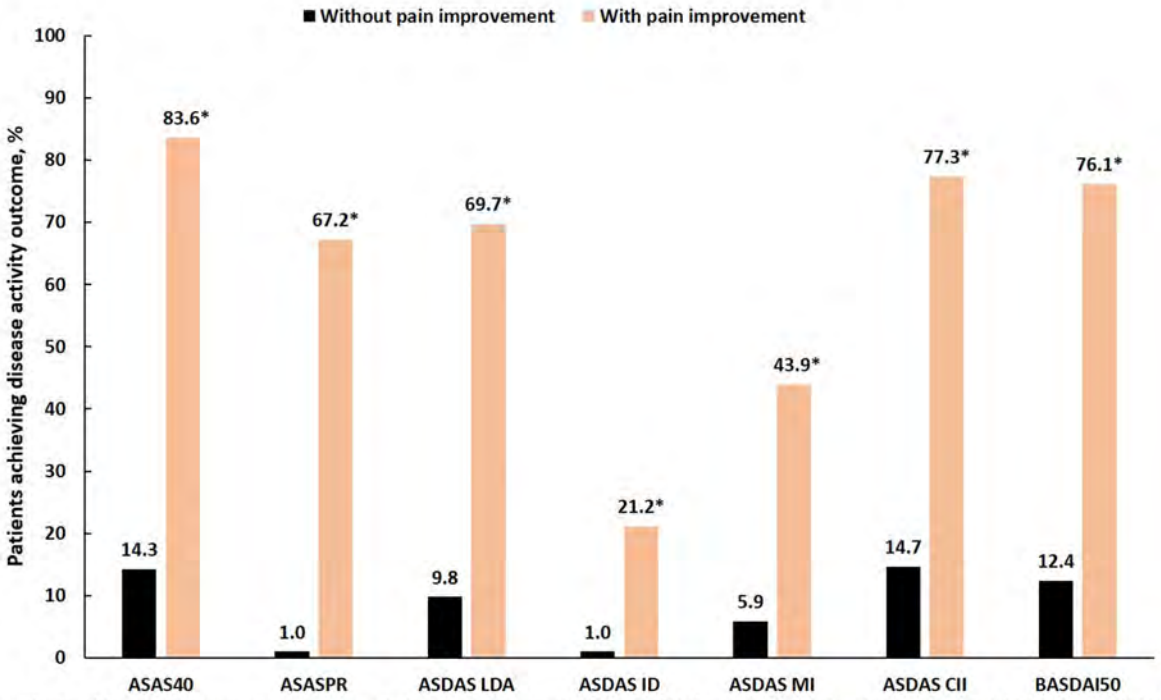
Figure 2. Proportion of patients with and without meaningful back pain improvement achieving MCID in PRO at Week 14



*P≤0.0001 for patients with pain improvement versus no pain improvement. Pooled PBO and UPA arms. MCID definitions: ≥3-point decrease (ASQoL and ASAS HI), ≥1.1-point decrease (BASDAI), ≥0.6-point decrease (BASFI), ≥4-point increase (FACIT-F), ≥6-point decrease (ISI), ≥20% decrease (presenteesism and activity impairment), and ≥15% decrease (overall work impairment).

ASAS HI, Assessment of SpondyloArthritis international Society-Health Index; ASQoL, Ankylosing Spondylitis Quality of Life; BASDAI, Bath Ankylosing Spondylitis Disease Index; BASFI, Bath Ankylosing Spondylitis Functional Index; FACIT-F, Functional Assessment of Chronic Illness Therapy-Fatigue; ISI, Insomnia Severity Index; MCID, minimum clinically important difference; PRO, patient-reported outcomes; WPAI, Work Productivity and Activity Impairment.

Figure 3. Proportion of patients with and without meaningful back pain improvement achieving disease activity outcomes at Week 14



*$P \leq 0.0001$ for patients with pain improvement versus no pain improvement. Pooled PBO and UPA arms. ASDAS thresholds: <2.1 (ASDAS LDA), <1.3 (ASDAS ID), ≥2-point decrease (ASDAS MI), and ≥1.1-point decrease (ASDAS CII). ASAS, Assessment of SpondyloArthritis international Society; ASASPR, ASAS partial remission; ASDAS, Ankylosing Spondylitis Disease Activity Score; ASDAS CII, ASDAS clinically important improvement; ASDAS ID, ASDAS inactive disease; ASDAS LDA, ASDAS low disease activity; ASDAS MI, ASDAS major improvement; BASDAI, Bath Ankylosing Spondylitis Disease Activity Index.

on a numeric rating scale and was assessed at all time points up to Week 52. The proportions of pts maintaining Week 4 meaningful back pain improvement at Week 14 and the proportion of pts at Week 14 in the pooled UPA and PBO arms reporting values ≥ minimum clinically important differences (MCID) in patient-reported outcomes (PROs: BASFI, BASDAI, BASFI, Assessment of SpondyloArthritis international Society-Health Index [ASAS HI], AS Quality of Life [ASQoL], Functional Assessment of Chronic Illness Therapy – Fatigue [FACIT-Fatigue], Insomnia Severity Index [ISI] scores, and Work Productivity and Activity Impairment [WPAI; presenteeism, overall work impairment, and activity impairment]), and achieving disease activity outcomes (ASAS40, ASAS partial remission, AS Disease Activity Score [ASDAS; low disease activity, inactive disease, major improvement, and clinically important improvement], and BASDAI50) as a function of meaningful back pain improvement were also assessed. Analyses were performed using either the Cochran-Mantel-Haenszel test, adjusting for high-sensitivity C-reactive protein with non-responder imputation for comparison between treatments, or Chi-Square test with as observed analysis for comparison between responders/non-responders. *P*-values < 0.05 were nominal.

Results: Meaningful improvement in back pain was achieved by a significantly greater proportion of pts with AS receiving UPA versus PBO starting at Week 2 ($P < 0.001$), with further improvements in the UPA group between Week 14 and Week 52 (Figure 1). Of pts achieving back pain improvement at Week 4, 92.9% of pts on UPA 15 compared to 54.5% of pts on PBO maintained this response at Week 14 ($P < 0.05$). A significantly greater proportion of pts who attained meaningful back pain improvement at Week 14 vs those who did not reported values ≥MCID in all PROs and had greater response across all disease activity outcomes ($P \leq 0.0001$, Figures 2 and 3).

Conclusion: A significantly greater proportion of pts with AS achieved meaningful improvement in back pain with UPA compared to PBO starting at Week 2, with continued improvement through 52 weeks of treatment. Meaningful

back pain improvement was associated with meaningful improvement in other PROs and achievement of important measures of AS disease activity.

Effect of Deucravacitinib on the Psoriatic Arthritis Impact of Disease Questionnaires 12 and 9: Analysis of a Phase 2 Study of Active Psoriatic Arthritis

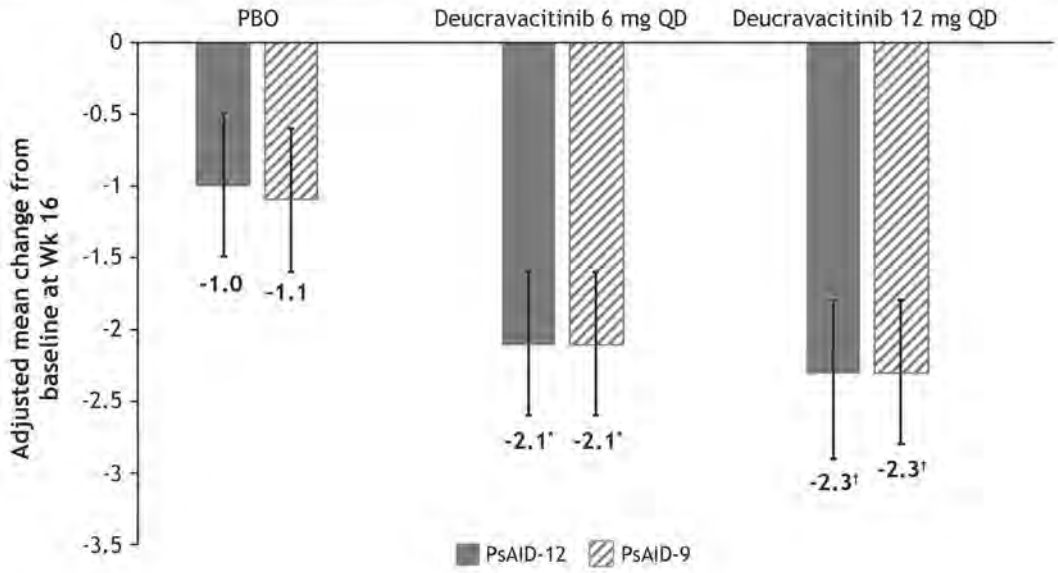
Laure Gossec[1], Laura Coates[2], Alexis Ogdie-Beatty[3], Philip Mease[4], Tom Lehman[5], Miroslawa Nowak[5], Lan Wei[5], June Ye[5], Jiyoon Choi[5], Joe Zhuo[5] and Brandon Becker[5], [1]Sorbonne Université; APHP, Rheumatology Department, Pitié-Salpêtrière Hospital, Paris, France, [2]Nuffield Department of Orthopaedics, Rheumatology and Musculoskeletal Sciences, University of Oxford, Oxford, United Kingdom, [3]University of Pennsylvania, Philadelphia, PA, [4]Swedish Medical Center/Providence St. Joseph Health and University of Washington, Seattle, WA, [5]Bristol Myers Squibb, Princeton, NJ

SESSION INFORMATION
Session Date: Sunday, November 7, 2021
Session Title: Patient Outcomes, Preferences, & Attitudes Poster II: Measurements (0739–0763)
Session Type: Poster Session B
Session Time: 8:30AM–10:30AM

Background/Purpose: Tyrosine kinase 2 (TYK2) is an intracellular kinase that mediates signaling by cytokines, such as IL-23, IL-12, and IFNα/β, involved in the pathogenesis of PsA and other immune-mediated diseases. Deucravacitinib is a novel, oral selective inhibitor of TYK2 via the TYK2 nonconserved regulatory domain. Phase 2 results showed deucravacitinib was efficacious and well tolerated versus placebo (PBO) in patients (pts) with active PsA. The Psoriatic Arthritis Impact of Disease (PsAID) questionnaire is a validated instrument designed to specifically assess the impact of PsA on health-related quality of life from the pt's perspective and is available as separate versions for clinical practice (PsAID-12) and clinical trials (PsAID-9)[1] This analysis compared the effect of deucravacitinib vs PBO on PsAID-12 and PsAID-9 responses and assessed the relationships between PsAID scores and clinical and pt-reported outcome (PRO) measures.

Methods: In this 1-year, double-blind, Phase 2 trial (NCT03881059), pts with active PsA were randomized 1:1:1 to deucravacitinib 6 mg or 12 mg once daily (QD), or PBO for 16 weeks (Wk). PsAID-12 and PsAID-9, other PROs, and clinical response outcomes were assessed at baseline (BL) and Wk 16. Mean changes from BL in PsAID-12 and PsAID-9 total scores at Wk 16 were determined for each treatment group as well as by response outcomes (ie, achievement of response at Wk 16 for PROs and select clinical response outcomes). Spearman correlations between PsAID-12 and PsAID-9 scores and clinical and PRO measures were also assessed .

Figure. Adjusted mean change from baseline in PsAID-12 and PsAID-9 total scores at Wk 16



*$P \leq 0.002$ vs PBO; †$P \leq 0.0005$ vs PBO.
PBO, placebo; PsAID-9, 9-item Psoriatic Arthritis Impact of Disease questionnaire; PsAID-12, 12-item Psoriatic Arthritis Impact of Disease questionnaire; QD, once daily.

Results: Of 203 pts randomized, 180 (89%) completed 16 Wks of treatment (deucravacitinib 6 mg QD, 63/70 [90%]; deucravacitinib 12 mg QD, 59/67 [88%]; PBO, 58/66 [88%]). Demographic and BL disease characteristics were similar across groups. Mean age was 49.8 years and median PsA duration since diagnosis was 4.5 years. Adjusted mean changes from BL in PsAID-12 and PsAID-9 scores at Wk 16 were significantly greater in the deucravacitinib groups vs PBO (**Figure**). Significant improvements with deucravacitinib vs PBO were also observed in pts who achieved response for PROs and for Psoriatic Arthritis Disease Activity Score low disease activity and ≥75% improvement from BL in Psoriasis Area and Severity Index response (**Table**). In contrast, adjusted mean changes from BL were generally similar with deucravacitinib vs PBO in nonresponders. Spearman correlation analysis revealed significant correlations at BL and Wk 16 between PsAID-12 and PsAID-9 scores and clinical and PRO measures ($P < 0.0001$).

Conclusion: With deucravacitinib vs PBO, PsAID-12 and PsAID-9 scores were significantly improved vs BL at Wk 16. Both PsAID scores detected additional improvements among pts achieving response for multiple other PROs and select clinical outcome measures.

SESSION INFORMATION
Session Date: Sunday, November 7, 2021
Session Title: Patient Outcomes, Preferences, & Attitudes Poster II: Measurements (0739–0763)
Session Type: Poster Session B
Session Time: 8:30AM–10:30AM

Background/Purpose: Psoriatic Arthritis (PsA) affects multiple attributes of patient health; to assess treatment effectiveness a compilation of Patient Reported Outcomes (PRO) have been utilized. While useful, most of these were originally created for other diseases and only later validated or adapted for use in PsA. More recent efforts have focused on development of PsA specific PRO tools, with inclusion of patient input and relevance for use in both clinical research and clinical care (1). Our research subjected a broad set of currently used PROs to patient assessment, giving clinicians insight into their usefulness in the clinic and informing ongoing efforts for optimization of PROs in PsA.

Methods: Four focus groups were conducted across three regionally-diverse areas in the United States from March 2016 to October 2016. Patients represented a range of disease history, symptoms, and severity. After trained facilitators encouraged open conversation about PsA, including symptoms, challenges and feelings about disease and treatment, patients were given time to review 13 currently utilized PROs and rate relevance of these instruments to reporting their disease experiences on a 3 point scale of Relevant, Somewhat Relevant, and Irrelevant. Verbal discussion followed on the merits and challenges of each rated PRO.

Results: PRO instruments ranged from overall global assessments to disease specific assessments (Table 1). The PROs received a variety of ratings, with Functional Assessment of Chronic Illness Therapy - Fatigue (FACIT-F) and Psoriatic Arthritis Impact of Disease (PsAID) judged as Very Relevant by the largest number of patients, followed by Health Assessment Questionnaire-Spondyloarthropathies (HAQ-S) and Pain VAS (Figure 1). Instruments receiving the most assessments of Not Really Relevant were Pt Global and PsA Quality of Life (PsAQOL). In the qualitative portion of the research, major patient critiques across PROs were the time frames listed on the questionnaires; some were too restrictive and disallowed reporting important recent disease activity. Preferences were for questions asked as '...since your last visit...'. Multiple participants also agreed that a visual tool allowing patients to circle specific joints to indicate pain would be useful.

Conclusion: Currently utilized PROs in PsA evaluating domains of fatigue, function, pain, and disease specific manifestations were all important regarding new therapeutic agents. However, some are more relevant than others to patients, most notably FACIT-F and PsAID, the latter being an important example of a patient-led and disease-specific development effort. Allowing reporting of items of concern without restrictive time periods is important to patients. These preferences and comments can be utilized to better understand the value of PROs in clinical settings to optimize patient-clinician communications.

Intervening on Adverse Childhood Experiences in SLE—Self-Efficacy as a Potential Target

Kimberly DeQuattro[1], Andrea Seet[1], Laura Trupin[2], Stephanie Rush[1], Kamil Barbour[3], Maria Dall'Era[4], Jinoos Yazdany[1] and Patricia Katz[1], [1]University of California San Francisco, San Francisco, CA, [2]UC San Francisco, San Francisco, CA, [3]Centers for Disease Control, Atlanta, GA, [4]University of California San Francisco, Corte Madera, CA

SESSION INFORMATION
Session Date: Sunday, November 7, 2021
Session Title: Patient Outcomes, Preferences, & Attitudes Poster II: Measurements (0739–0763)
Session Type: Poster Session B
Session Time: 8:30AM–10:30AM

Background/Purpose: Modifiable adaptations to adversity such as resilience (the ability to recover from difficulty) and self-efficacy (the belief in one's ability to succeed in a situation) may be protective for those with SLE who experience stress. We previously reported that patients with a history of adverse childhood experiences (ACEs) demonstrate worse patient-reported outcomes. There are gaps in how to ameliorate poor outcomes among patients who experienced ACEs. We seek to identify patterns of adaptations to adversity as potential targets for future interventions in this population.

Methods: Data are from the California Lupus Epidemiology Study (CLUES), a diverse sample of adult SLE patients with confirmed diagnosis of SLE (met (a) ≥4/11 ACR 1982/1997 criteria for the classification of SLE, (b) 3/11 ACR 1982/1997 criteria and treating rheumatologist's diagnosis of SLE, or (c) diagnosis of SLE nephritis). Participants completed a 10-item ACE questionnaire (range 0-10), a 4-item Brief Resilience Coping Score (BRCS, range 0-12), and the PROMIS self-efficacy survey. We examined associations for patient-reported measures of disease activity (SLAQ) and depression (PHQ-8) as well as ACEs with BRCS and self-efficacy using ANOVA and linear regression, controlling for age, gender, race/ethnicity, education, and disease duration. We also tested for interactions between ACE scores and resilience/self-efficacy.

Results: Of the 205 participants, 91.7% were female and 69.3% were non-white, with a mean ACE score of 1.76 (SD 2.1). Resilience was at the middle of the scale range (mean 8.4, SD 2.0) and the self-efficacy PROMIS measure was near the mean for the population distribution (mean 49.0, SD 9.1). There were similar levels of resilience and self-efficacy across ACE score categories (Table 1). As depicted (Table 2), there were significantly worse SLAQ and PHQ scores for people with higher ACE scores compared to people in the low ACE score category (0-1). Resilience showed no significant independent effect on SLAQ or PHQ, but self-efficacy was associated with better PHQ scores and SLAQ scores, although the latter did not reach statistical significance. Interactions between ACE score and resilience/self-efficacy were not statistically significant.

Table 1. Resilience, self-efficacy, disease activity, and depression among individuals with SLE (N=205) by Adverse Childhood Experience Score Category

	Adverse Childhood Experience Score Category			
	Low (0-1) (mean, sd) N = 121	Medium (2-3) (mean, sd) N = 44	High (4+) (mean, sd) N = 40	ANOVA p-value
Resilience	8.3 (2.0)	8.4 (2.0)	8.9 (1.8)	0.14
Self-Efficacy	48.6 (9.3)	49.2 (8.8)	49.2 (9.3)	0.67
SLAQ	7.6 (6.7)	10.9 (7.5)	14.0 (8.1)	<0.01**
PHQ-8	5.3 (4.6)	7.8 (5.8)	8.7 (5.1)	<0.01**

SLAQ - Systemic Lupus Activity Questionnaire; PHQ-8 - Patient Health Questionnaire depression scale

Resilience	0.32 ± 0.25	0.20	-0.16 ± 0.18	0.38
Self-Efficacy	-0.11 ± 0.06	0.06	-0.13 ± 0.04	<0.01**

SLAQ - Systemic Lupus Activity Questionnaire; PHQ-8 - Patient Health Questionnaire depression scale
[1]Adjusted for age, gender, race, disease duration, education level.
Self-Efficacy is a 4-item PROMIS subscale normed as T-scores with a population mean of 50 and standard deviation of 10

Conclusion: Individuals with SLE with the highest ACEs exposures reported high disease activity and depression. Resilience did not show protective effects on the outcomes examined in this cohort. However, self-efficacy, for which interventions have been developed, was associated with less depression, suggesting the potential for interventions targeting self-efficacy to improve outcomes. Experiencing ACEs did not affect whether a participant was more or less resilient or self-efficacious. Additional targets for interventions, such as social support, merit exploration to better bolster SLE patients with a history of ACEs.

Abstract Number: 0753

Patient-Reported Burden of Adverse Drug Reactions Attributed to the Use of Adalimumab and Etanercept in Patients with Inflammatory Rheumatic Diseases

John Davelaar[1], Naomi Jessurun[2], Sander Tas[3], Mike Nurmohamed[4], Bart van den Bemt[5] and Harald Vonkeman[6], [1]Netherlands Pharmacovigilance Centre Lareb, Utrecht, Netherlands, [2]Netherlands Pharmacovigilance Centre Lareb, 's-Hertogenbosch, Netherlands, [3]Amsterdam UMC, locatie AMC, Utrecht, Netherlands, [4]Reade; Amsterdam Rheumatology & Immunology Center, Amsterdam, Netherlands, [5]Sint Maartenskliniek; Radboud University Medical Center, Ubbergen, Netherlands, [6]Medisch Spectrum Twente; University of Twente, Enschede, Netherlands

SESSION INFORMATION
Session Date: Sunday, November 7, 2021
Session Title: Patient Outcomes, Preferences, & Attitudes Poster II: Measurements (0739–0763)
Session Type: Poster Session B
Session Time: 8:30AM–10:30AM

Background/Purpose: Health care professionals tend to focus on adverse drug reactions (ADRs) with the highest clinical impact. Subsequently, ADRs with less obvious clinical impact but with a high impact on patient's daily lives, might be overlooked. These ADRs may occur frequently and therefore constitute a considerable part of the total perceived burden of ADRs. To develop strategies to reduce the burden of ADRs, it is important to know which ADRs have the highest impact on patients' lives. The aim of the study was to gain insight into which patient-reported ADRs contribute most to the total experienced ADR burden attributed to the use of etanercept (ETN) and adalimumab (ADA).

Methods: Data of the Dutch Biologic Monitor (DBM) was used. In the DBM, immune-mediated inflammatory disease patients using biologicals were asked to fill out bimonthly questionnaires on experienced ADRs attributed to the biologic and the burden of the ADR using a five-point Likert-type scale ranging from 1 (no burden) to 5 (very high burden). Inclusion criteria for the present study were: patients with rheumatoid arthritis, psoriatic arthritis or spondyloarthritis using ADA or ETN, reporting an ADR with a burden score of 2 or higher. The ADRs reported for ADA and ETN were grouped into system organ classes (SOCs) according to the Medical Dictionary for Regulatory Activities. Every ADR in the SOC is multiplied with the corresponding burden score, summating the experienced burden per SOC. The total experienced burden of ADA and ETN is the sum of the experienced burdens of all SOCs. The proportion of the burden per SOC is calculated by dividing the burden per SOC by the total burden of all SOCs. ADRs per SOC were further stratified by ADA and ETN use, and analysed separately to identify possible differences.

Results: A total 196 patients met the inclusion criteria, of which 95 patients (48%) reported an ADR for adalimumab (575 ADRs) and 101 patients (52%) reported and ADR for ETN (793 ADRs), see Table 1. The proportion of experi-

Table 1 Demographics and characteristics of patients

Drug-induced ADR burden (mean ± SD)	3.09 ± 0.56	3.04 ± 0.66	2.95 ± 0.49
Number of completed questionnaires (mean ± SD)	4.2 ± 7.0	3.6 ± 4.0	4.7 ± 9.0

[a]Patients could report more than one indication

Table 2 The proportion of burden of ADRs per system organ class (SOC) for adalimumab and etanercept

SOC	Proportion of the burden (%)	Mean burden	Number of reports
General disorders and administration site conditions	26,7	2,6	408
Infections and infestations	19,4	3,2	241
Skin and subcutaneous tissue disorders	13,1	2,9	177
Gastrointestinal disorders	9,5	2,8	133
Musculoskeletal and connective tissue disorders	8,1	3,2	98
Respiratory, thoracic and mediastinal disorders	6,6	2,7	95
Nervous system disorders	5,2	2,9	69
Eye disorders	4,3	3,2	54
Psychiatric disorders	1,7	3,1	21
Vascular disorders	1,3	2,6	20

enced burden attributed to ADA and ETN is summarized in Table 2. The ADRs that account for the highest proportion are general disorders (such as fatigue) and administration site conditions (such as injection site pain), infections and infestations (such as respiratory tract infections and nasopharyngitis), skin and subcutaneous tissue disorders (such

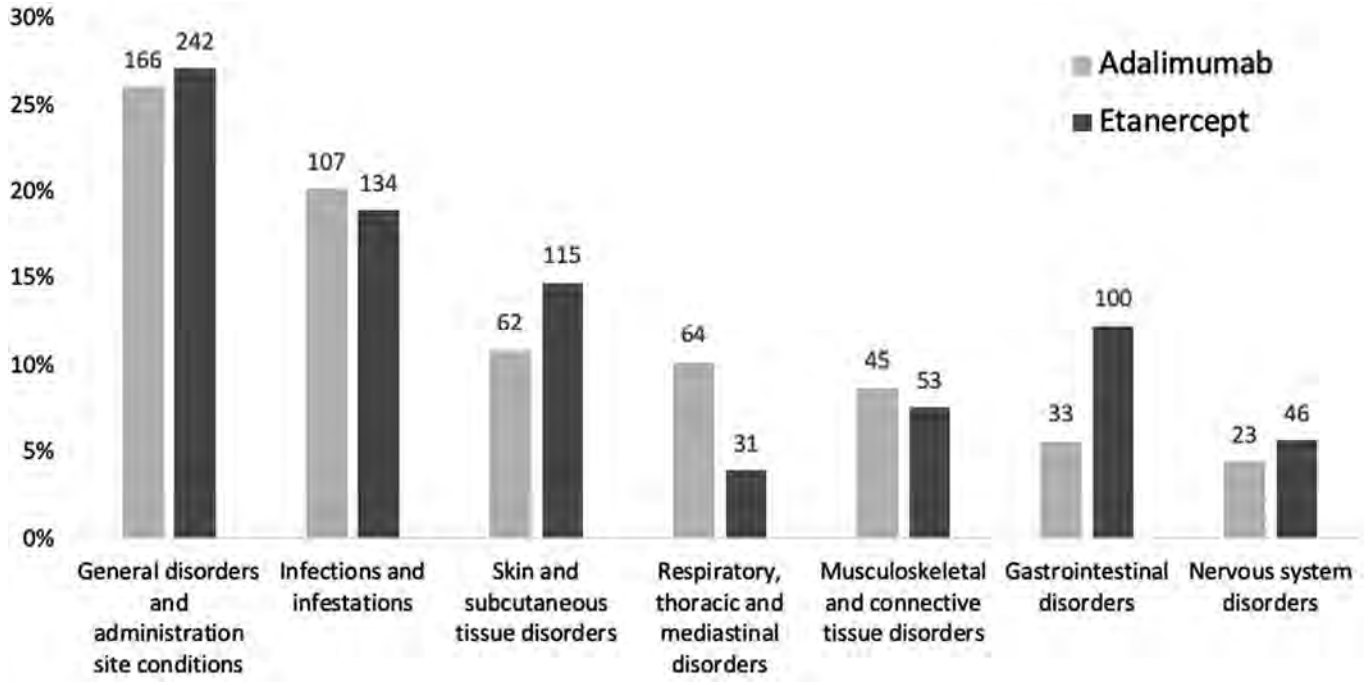

Figure 1. Proportion of experienced burden of adverse drug reaction per system organ class for adalimumab (575 ADRs) and etanercept (793 ADRs) with each their respective ADR count represented at the top of the bars.

as dry skin and pruritus). The proportion of burden of ADRs for ADA and ETN are comparable, except for skin and subcutaneous tissue disorders, respiratory, thoracic and mediastinal disorders, gastrointestinal disorders and vascular disorders (see Figure 1).

Conclusion: ADRs belonging to the SOCs General disorders and infections are the foremost contributors to the ADR burden. These ADRs are well-known and this outcome is as expected. Less known and new is information the high proportion of burden attributed to ADRs in the SOC skin and subcutaneous tissue disorders. Addressing these ADRs offers opportunities to reduce the burden associated with the use of ADA and ETN. Furthermore, although ADA and ETN are clinically considered comparable, our findings point to differences in proportions of experienced burden of ADRs grouped per SOC.

Bridging the Gap Between Patient-Reported Outcomes and Disease-Related Outcomes in Lupus – a Feasibility Study

Shivani Garg[1] and Christie Bartels[2], [1]UW Madison, Madison, WI, [2]University of Wisconsin School of Medicine and Public Health, Madison, WI

SESSION INFORMATION

Session Date: Sunday, November 7, 2021

Session Title: Patient Outcomes, Preferences, & Attitudes Poster II: Measurements (0739–0763)

Session Type: Poster Session B

Session Time: 8:30AM–10:30AM

Table 1. Patient Demographics.

Patient-Visits, No. of Patients	250 visits; 75 patients
Age (mean±SD)	37±19 years
Racial/Ethnicity	
White	52 (69%)
Other*	23 (31%)
Gender	
Female	70 (93%)
Male	5 (7%)
PROMIS-Physical Health (mean±SD)	12.7±1.9
PROMIS-Mental Health (mean±SD)	11.9±2.3
LupusQOL-Total Domain Score (mean±SD)	560±170
SLEDAI (mean±SD)	2.3±2.6
SLICC-DI (mean±SD)	0.82±1.03

Background/Purpose: Patients with SLE have significantly worse health-related quality of life (QOL) at an earlier age compared to patients with other chronic diseases. This highlights the importance of measuring and addressing patient-reported outcomes (PROs) to improve outcomes and QOL in SLE. Yet, QOL tools are lengthy and offer limited guidance to clinicians on use to impact disease-related outcomes in SLE. There is a need to improve feasibility such as using global short-form QOL measures. Therefore, we examined the feasibility of collecting global and lupus specific QOL measures in an academic SLE center and their correlation with disease-related outcomes.

Methods: Our study included all consecutive SLE follow-up visits at the UW SLE Clinic between 3/2019-5/2021. At each visit: 1) patients completed both the Patient Reported Outcome Measure Information System (PROMIS) Global Short Form and the LupusQOL; 2) physicians completed SLE disease activity index (SLEDAI) and SLICC-ACR damage index (SLICC DI). We calculated Pearson's correlation between PROMIS – Global physical and mental health scores, and LupusQOL domain scores and a total LupusQOL score. Next, we tested correlation between SLEDAI and PROMIS – global physical and mental health scores and LupusQOL domain and total scores, and SLICC-DI and both QOL scores.

Results: Between 1/1/19-4/1/21, there were 250 consecutive follow-up patient-visits of 75 patients with confirmed SLE at our clinic. Patients (Table 1) were 93% female, 69% White, and mean age at SLE diagnosis was 37 years. We noted that LupusQOL was completed in 106 patient visits (43%), PROMIS – Global was completed in 100 patient visits (40%), and SLEDAI, SLICC-DI completion rates were each 72%.

We found moderate correlation between both PROMIS-Global physical and mental health scores and total LupusQOL domain score ($r = 0.55$, $p < 0.001$; $r = 0.52$, $p < 0.001$) (Table 2). Further, PROMIS-Global physical health scores had moderate correlation with LupusQOL pain ($r = 0.56$, $p < 0.001$) and physical health (0.60, $p < 0.001$) domains (Table 2). While PROMIS-Global mental health scores only moderately correlated with all LupusQOL domains except the

Table 2. Correlations Between PROMIS Global Physical and Mental Health Scores & LupusQOL Domain Scores, n = 250 patient-visits

PROMIS Global Short-Form (Physical & Mental Health)	LupusQOL (8 domains)	Correlation Coefficient (95% CI)	p-value
PROMIS - Physical Health	**Pain**	**0.56 (0.41, 0.68)**	**<0.001**

PROMIS - Mental Health	Body Image	0.41 (0.22, 0.56)	<0.001
PROMIS - Mental Health	Intimate Relationship	0.34 (0.15, 0.51)	<0.001
PROMIS - Mental Health	Planning	0.48 (0.31, 0.62)	<0.001
PROMIS - Mental Health	**Total Domain Score**	**0.52 (0.34, 0.65)**	**<0.001**

Moderate correlations shown in bold font.

burden domain. Next, we noted statistically significant correlation between high SLEDAI and low total LupusQOL scores (r = -0.31, p 0.0029), low LupusQOL emotional health scores (r = -0.30, p 0.004) and low LupusQOL fatigue scores (r=-0.31, p 0.002) (Table 3). We noted statistically significant but low correlation between high SLICC-DI and low LupusQOL pain score (r = -0.30, p 0.0023) (Table 3.). No correlations were noted between PROMIS and SLEDAI, and PROMIS and SLICC-DI.

Conclusion: Our findings highlight that specific LupusQOL domains correlate with disease-related outcomes which could be targeted in busy clinical settings to improve QOL. Further, the PROMIS global short-form moderately correlates with key LupusQOL domains thus, this could be utilized in busy practices to assess QOL. Given a moderate QOL completion rate, future studies are required to develop short, actionable tools to incorporate key specific LupusQOL domains that correlate with disease scores to improve disease and patient outcomes in SLE.

Abstract Number: 0755

Satisfaction with the Process versus Outcome of Care in Total Hip and Knee Arthroplasty

J. Alex Gibbons[1], Cynthia Kahlenberg[1], Bella Mehta[2], Vinicius Antao[1], Emily Ying Lai[1], Huong Do[1], Linda Russell[1], Peter Sculco[1], Mark Figgie[1] and Susan Goodman[1], [1]Hospital for Special Surgery, New York, NY, [2]Hospital for Special Surgery, Weill Cornell Medicine, New York, NY

SESSION INFORMATION
Session Date: Sunday, November 7, 2021
Session Title: Patient Outcomes, Preferences, & Attitudes Poster II: Measurements (0739–0763)
Session Type: Poster Session B
Session Time: 8:30AM–10:30AM

Background/Purpose: Patient satisfaction, both with the process of care and the outcome of care, is critical for measuring the quality and value of elective procedures such as arthroplasty, leading the Centers for Medicare and Medicaid (CMS) to include patient satisfaction with the process of care in their payment models. The purpose of this study was to evaluate the association between patient-reported early postoperative satisfaction with the process of care and 2-year satisfaction with the outcome of care after primary total hip (THA) and total knee arthroplasty (TKA).

Methods: We identified patients that underwent primary THA or TKA from an institutional arthroplasty registry which administered a survey measuring satisfaction with the outcome of care to patients 2-years post-operatively. An overall satisfaction score was calculated using a previously validated score. Patient satisfaction with the process of care, as measured by the Press Ganey (PG) inpatient survey administered to patients shortly after discharge, was obtained and linked to the registry data. Both satisfaction measures have a range of 0-100, with higher scores indicating greater satisfaction. Spearman rank correlation coefficients were calculated to evaluate the association between satisfaction with the process of care (PG score) and the outcome of care (2-year score).

Results: The cohort included 721 TKA patients and 760 THA patients who underwent surgery at our institution and completed both the PG survey and 2-year satisfaction questionnaire (**Table 1)**. The mean age was 65.1 years, mean BMI was 28.8, and 56% were female. Satisfaction was high for both measures, with a mean PG score of 88.2 and a mean 2-year score of 95.6. Correlation between the two measures was fair to poor, with Spearman rank correlation coefficients of 0.23 for TKA patients ($p < 0.001$) and 0.13 for THA patients ($p < 0.001$). Bubble charts showing the distribution of patients by PG score and 2-year score for TKA and THA are presented in Figures 1a and 1b, respectively.

Conclusion: We found weak correlation between measurements of satisfaction with the process of care surrounding joint arthroplasty using the PG survey and satisfaction with the outcome of care after hip and knee arthroplasty using a validated 2-year satisfaction score. Policymakers should consider both facets of patient satisfaction when considering hospital performance and the value of elective surgical procedures.

Validation of Two Simple Patient-centered Outcome Measures for Virtual Monitoring of Patients with Idiopathic Inflammatory Myositis

R Naveen[1], Darpan R Thakare[2], Vikas Agarwal[2], Rohit Aggarwal[3] and Latika Gupta[1], [1]Sanjay Gandhi Post Graduate Institute of Medical Sciences, Lucknow, India, [2]Sanjay Gandhi Postgraduate Institute of Medical Sciences, Lucknow, India, [3]University of Pittsburgh, Pittsburgh, PA

SESSION INFORMATION

Session Date: Sunday, November 7, 2021

Session Title: Patient Outcomes, Preferences, & Attitudes Poster II: Measurements (0739–0763)

Session Type: Poster Session B

Session Time: 8:30AM–10:30AM

Background/Purpose: Changing landscape of patient care from in-person to virtual telemedicine-based consultation in times of a global pandemic has necessitated a wider use of patient-centered outcomes measures (PCOMs) and device-based measures for objective disease assessment. We prospectively validated 2 novel task based PCOMs for physical function, namely Arm Lift test (AL) & Two-Minute Walk Distance (2MWD) in idiopathic myositis (IIM) patients.

Methods: This was a prospective observational study with enrolment of adult patients with IIM in the MyoCite cohort (2017 ACR/EULAR criteria). Both active and inactive disease patients were enrolled. Active disease was defined as escalation of immunosuppression within 3 months, elevated muscle enzymes, physician VAS ≥2, skin disease worsening or fall in MMT8< 76 (any 2).

Two novel tests were performed at baseline; AL: Time taken for arm abduction ten times & 2MWD: distance walked in 2 minutes. We also evaluated all myositis core set measures [MMT 8, patient and physician global disease activity (PtGA and PhGA), HAQ-DI, extra-muscular disease activity as well as MDAAT & MDI]. Test-discriminant validity was tested between active and inactive myositis.

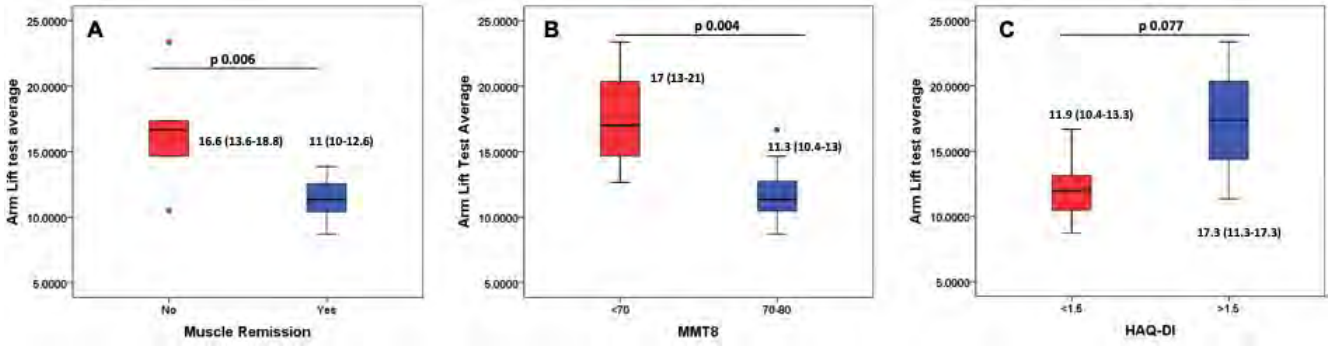

Figure 1. Arm lift test variation based on muscle disease remission (A), MMT8 (B) and HAQ-DI (C).

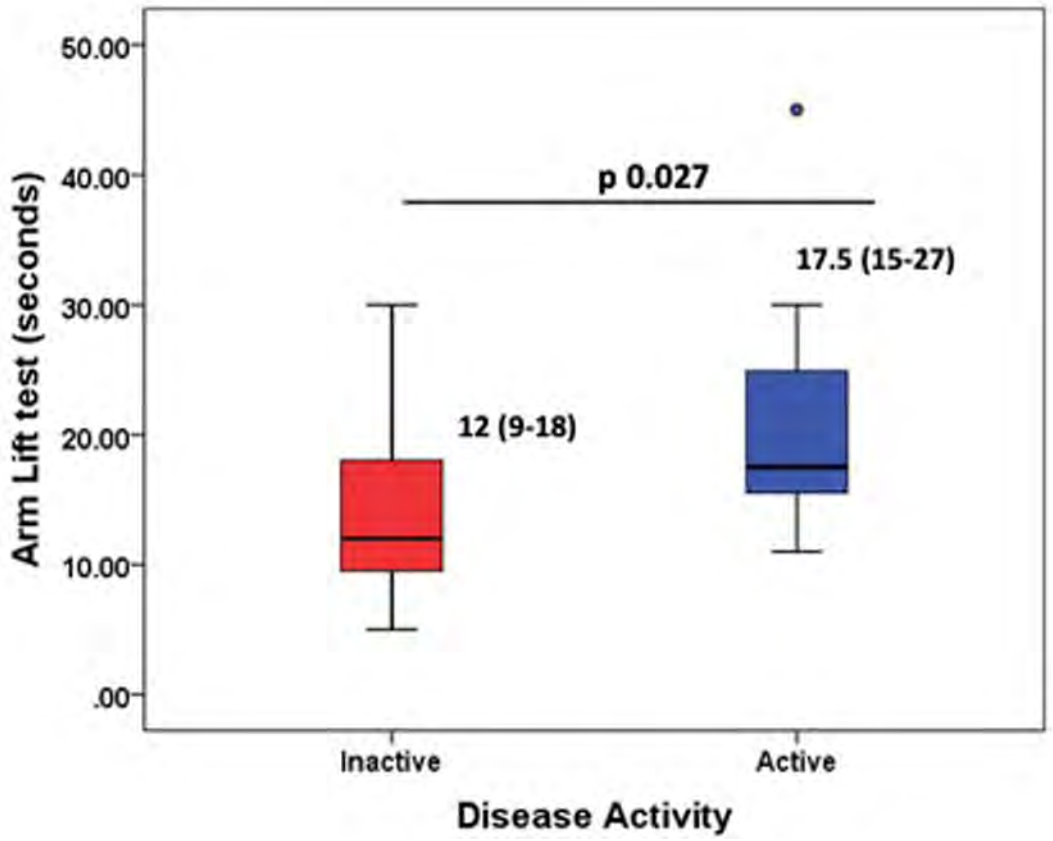

Figure 2. Arm Lift test in active versus inactive disease in Validation cohort (47 patient visits).

The results were validated in a larger Teleconsultation-based cohort to differentiate active vs. inactive disease. All values are in median(IQR).

Results: *Observation cohort*

22 adult IIM patients (68% female) of age 30.5 (19-62) years were enrolled. Median AL time, 2MWD and MMT-8 were 11.9 (10.5-14) seconds, 198 (167-225) metres and 79 (74-80) respectively.

AL and 2MWD showed excellent test-retest reliability (Cronbach's alpha 0.987 & 0.99 respectively, n=12). AL test had moderate to strong correlation all myositis core set measures including MMT8, PtGA, PhGA, HAQ-DI, Extra-muscular global (Ex-MuscGA), muscle enzyme (LDH, AST, ALT) and MYOACT (trend), but not with CK levels and MDI (table 1). In addition it showed moderately strong association with muscle disease VAS and muscle disease remission. In contrast, 2MWD had huge variability and no significant association with any of the core set or other measures except a moderate correlation with muscle VAS.

A higher AL time discriminated active and inactive myositis (16.6 vs 11 seconds, p=0.006) and discriminated between patients with and without muscle weakness (significant) and HAQ (non-significant trend) (Figure 1 A-C). However, 2MWD didn't discriminate based on muscle disease activity or other measures.

AUC for active versus inactive disease was 0.882 (p 0.006) with AL test. A cut-off of 12.8 seconds had 94% negative predictive values for active muscle disease (83% sensitivity, 83% specificity).

Table 1. Correlation of Arm lift test and 2MWD with disease parameters (Construct Validity) in observation cohort (n=22)

Validation cohort

In 47 patient visits among 26 patients (81% female, 33 years median age), AL significantly differentiated between active vs. inactive patients (Figure 2).

Conclusion: AL correlated well with myositis disease activity measures including muscle weakness providing preliminary evidence for its role as PCOM in IIM especially in clinical trials and telemedicine consultation. 2MWD was not a good test for outcome evaluation of IIM patients. Larger longitudinal studies are needed to further validate these findings.

Different Versions of the Patient Global Question in Rheumatoid Arthritis – Does It Really Matter? – Results of a Multi-center Observational Study

Paul Studenic[1], Aliaksandra Baranskaya[2], Stanley Cohen[3], Nancy Shadick[4], Christine Iannaccone[5], Maria Dahl Mjaavatten[6], Elisabeth Lie[7], Tore Kvien[8], Josef Smolen[9], Daniel Aletaha[10] and Helga Radner[9], [1]Karolinska Institute; & Medical University of Vienna, Stockholm, Sweden, [2]Queen Elizabeth Hospital Birmingham, University Hospitals Birmingham NHS Foundation Trust, Birmingham, United Kingdom, [3]Metroplex Clinical Research Center, Dallas, TX, [4]Brigham & Women's Hospital, Boston, MA, [5]Brigham and Women's Hospital, Topsfield, MA, [6]Diakonhjemmet Hospital, Haslum, Norway, [7]Diakonhjemmet Hospital, Oslo, Nepal, [8]Diakonhjemmet Hospital, Oslo, Norway, [9]Medical University of Vienna, Vienna, Austria, [10]Medical University Vienna, Vienna, Austria

SESSION INFORMATION
Session Date: Sunday, November 7, 2021
Session Title: Patient Outcomes, Preferences, & Attitudes Poster II: Measurements (0739–0763)
Session Type: Poster Session B
Session Time: 8:30AM–10:30AM

Background/Purpose: The patient global assessment (PGA), typically assessed as *'Considering all of the ways your arthritis has affected you, how do you feel your arthritis is today?'* should reflect the patient's perception of disease activity. It is incorporated as core set measure of disease activity in rheumatoid arthritis (RA) but has been criticized to not adequately fulfill its construct validity.

We explore different versions of the PGA and assess agreement, factors of variance, change over time and effect on disease activity classification.

Methods: In a multicenter study (4 centers in US & Europe), RA patients were asked to score on global health (GH) and 6 differently phrased PGA questions using visual analogue scale covering 2 aspects: (1) providing more detailed explanation on disease activity *("Active arthritis can cause joint swelling OR stiffness, pain OR discomfort in your joints. WITH ACTIVE ARTHRITIS, You CAN BE tired during the day, even when you've slept well"* (ePGA) compared to traditional phrasing (tPGA); and (2) reference to 3 time periods: *today (TD), last week (LW)* or *last month (LM)*. This generated 3 tPGA versions (TD/LW/LM) and 3 ePGA versions (TD/LW/LM). Agreement was calculated with intra-class correlation (ICC) and comparisons between PGA were done with paired-analyses. The empirical variation coefficient (eVC: (SD/mean)/SQRT(n)) was calculated per patient. The influence of disease duration, HAQ >0.5 or ≤0.5, SJC28, TJC28, fatigue and evaluator global assessment (EGA) on scoring of PGA versions were assessed and the resulting variations in disease activity classification.

Results: At baseline (BL) 189 patients (82% female, 45%≥1 comorbidity, mean disease duration ±SD: 16.6±10.8, mean PGA: 31.8±22.7, mean eVC 0.15±0.15, mean SJC28: 1.6±2.3) and 138 with follow-up (FU) were subjected to analyses. In paired analyses ePGA were scored higher than tPGA ($p \leq 0.001$) and in both, scores were higher in longer reference periods. When comparing in between reference periods (Table 1), ICCs were all ranging >0.8. Changes in PGA between BL and FU reached high agreement, except for TD versus LM. Poor to moderate agreement both for BL, as well as change scores, were found between versions of PGA and GH (Table 1). BL to FU PGA changes correlated highly with changes in pain and moderately with changes in EGA. The difference between PGA and GH (LW, LM versions) increases with more swollen joints. Differences between phrasings were less pronounced in patients with HAQ >0.5 or with comorbidities. The variance in scores between questions was lower in people with higher disease

Intra-Class Correlation

ePGA LW > GH	8.5%	2.6%	7.4%
ePGA TD > ePGA LM	4.8%	1.6%	11.1%
tPGA TD > tPGA LM	3.2%	1.6%	14.8%
CDAI: clinicial disease activity index			
tPGA: traditional PGA; ePGA: explained PGA;			
TD: today; LW: last week; LM: last month			

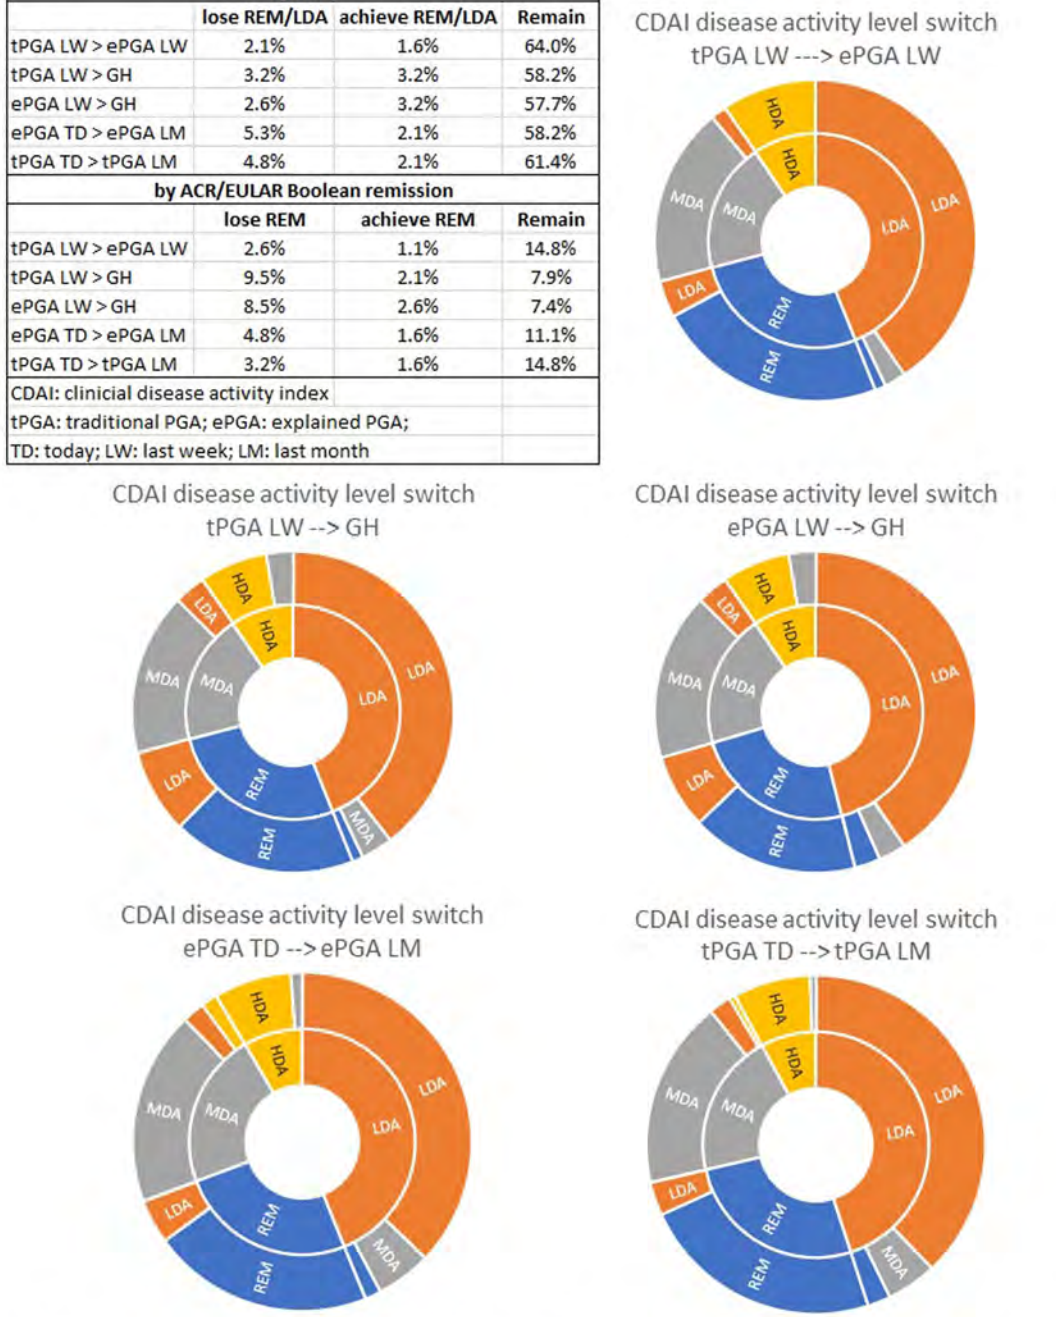

Figure 2: Sunburst Diagrams - Shift of classification of the patient in disease activity levels (measured by the clinical disease activity index – CDAI) when applying different versions of the Patient Global Assessment (PGA) or Global Health (GH).

activity. Higher mean PGA, fatigue, TJC, SJC and EGA correlated moderately with smaller eVC (Figure 1). The rate of patients switching CDAI disease activity level is around 8% when comparing tPGA with ePGA, but between 15% to 20% in PGA/GH and around 14% in TD/LM (Figure 2). Only up to 3% less achieve REM/LDA CDAI when switching to ePGA, however GH use instead of PGA coincides with 5 to 7% of patients less in Boolean remission.

Conclusion: Different versions of the PGA show high correlation, implicating that a more detailed phrasing would not increase construct validity. GH performs differently than PGA and may not be used interchangeably.

Outcome Reporting in Self-management Interventions for Inflammatory Arthritis Trials: A Systematic Review of Outcome Measures Covering Self-management Domains

Charlotte Hansen[1], Bente Esbensen[1], Robin Christensen[2], Annette De Thurah[3] and Pernille Cromhout[1], [1]Rigshospitalet, Glostrup, Denmark, [2]Section for Biostatistics and Evidence-Based Research, the Parker Institute, Bispebjerg and Frederiksberg Hospital, Copenhagen & Research Unit of Rheumatology, Department of Clinical Research, University of Southern Denmark, Copenhagen, Denmark, [3]Aarhus University Hospital, Aarhus, Denmark

SESSION INFORMATION
Session Date: Sunday, November 7, 2021
Session Title: Patient Outcomes, Preferences, & Attitudes Poster II: Measurements (0739–0763)
Session Type: Poster Session B
Session Time: 8:30AM–10:30AM

Background/Purpose: A significant heterogeneity exists across outcome domains and outcome instruments measuring the effect of self-management interventions targeting people with inflammatory arthritis (IA). Thus, it is currently difficult to perform evidence synthesis assessing the effect of self-management interventions, and variability in the quality of the applied outcome measurement instruments exists. The objective of this study was to identify outcome measure instruments applied to measure the effect of self-management interventions targeting patients with IA.

Methods: Measures of self-management in IA were identified through an informative systematic literature review as described by OMERACT (1) and the Core Outcome Measures in Effectiveness Trials (COMET) (2) which focus on mapping outcome domains from earlier studies to inform the development of a COS. Trials were eligible for inclusion if the intervention was described as "self-management intervention", and the study population comprised of people with any IA: RA, PsA or SpA. Two authors independently assessed trials for eligibility and extracted information on study characteristics, outcome domains, and outcome measurement instruments reported. With discrepancies, discussion among all authors was conducted. Outcome domains and the outcome measurement instruments were sorted and categorized into domains and sub-domains using the OMERACT Framework based on 3 core areas: (*i*) Death, (*ii*) Life Impact, and (*iii*) Pathophysiological manifestations, plus resource use/economical evaluation which is highly recommended, but not defined as a mandatory core area.

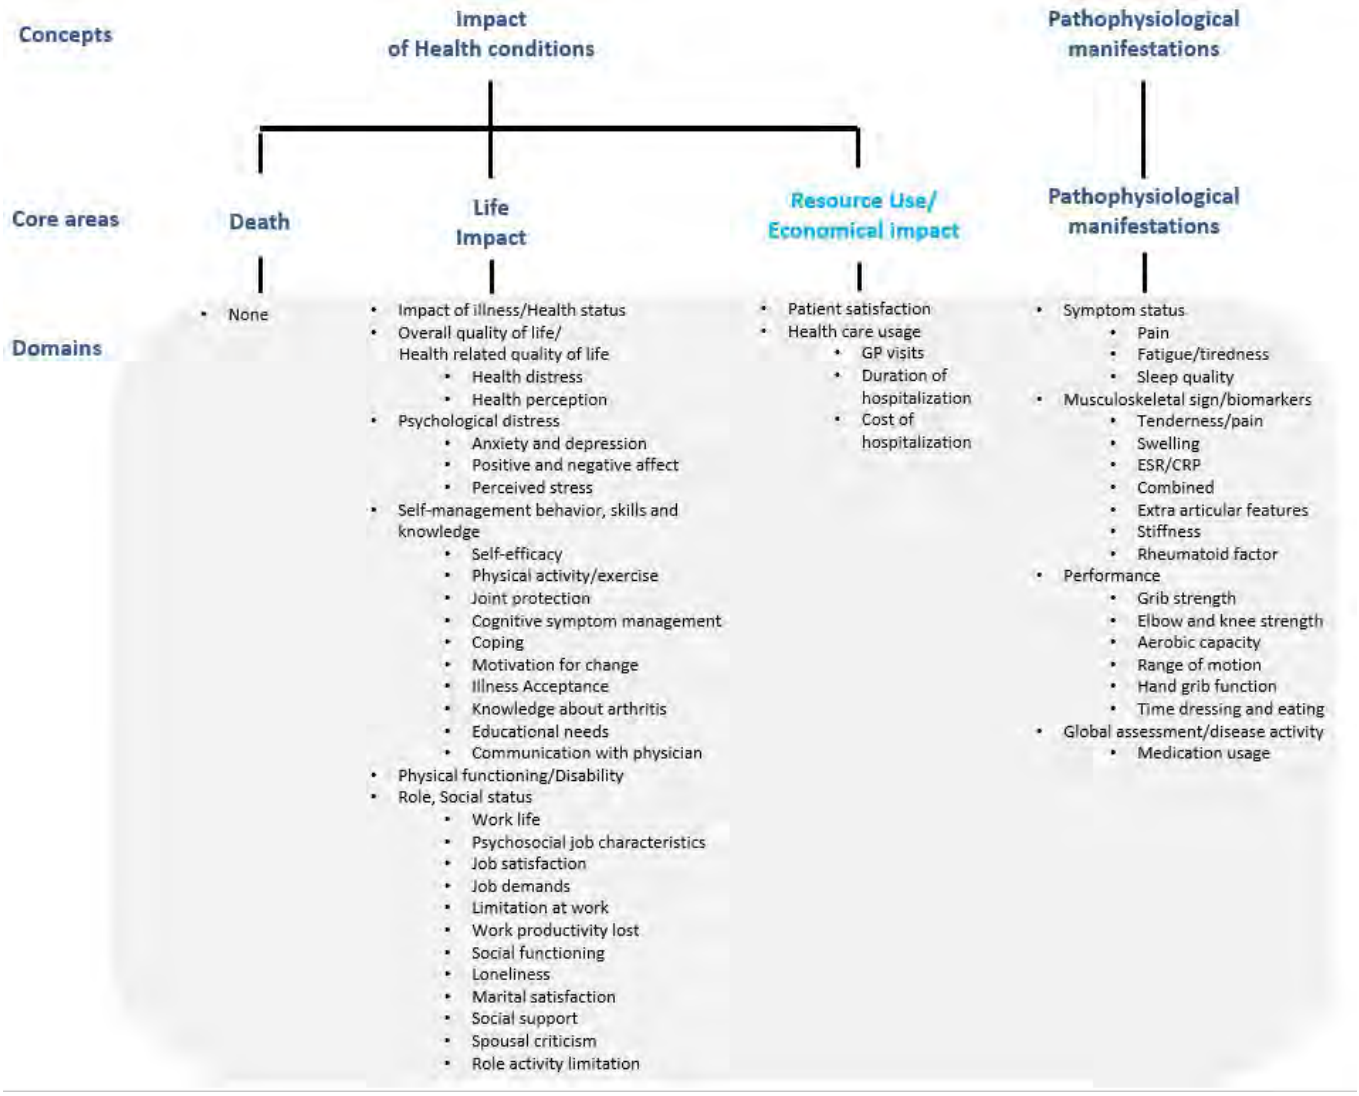

Figure 1. Overview of outcome domains and outcome sub-domains extracted from the 38 trials.

Results: From a total of 2502 records, we included 38 trials, published between 1988 and 2021. The studies most often based their self-management intervention on cognitive behavioral therapy and/or self-efficacy theory focusing on education of arthritis, medication, lifestyle, and self-management skill training involving problem-solving and goal setting. Across the trials, we identified 12 different outcome domains and 47 sub domains, comprising 128 different measurement instruments. The outcome domains and outcome sub-domains are illustrated in Figure 1. The identified outcome domains were primarily within the 'Life impact' core area. Self-efficacy and health-related quality of life was the most commonly applied domains in 30 and 16 studies, respectively. The domains and measurement instrument within the 'Life impact' core area are listed in Table 1.

Conclusion: The outcome domains and measurement instruments reported in self-management interventions including IA population, were widely diverse. This study provides a foundation for the development of a core outcome set for use in future trials.

The Patient as Assessor of Disease Status: A Graphical Evaluation of Relations Between Patient-Reported Outcomes in Early Rheumatoid Arthritis

Diederik De Cock[1], Gert Verhavert[1], Sofia Pazmino[1], Delphine Bertrand[1], Michal Doumen[1], Rene Westhovens[2] and Patrick Verschueren[3], [1]KU Leuven, Leuven, Belgium, [2]University Hospitals KU Leuven, Maaseik, Belgium, [3]University Hospitals Leuven - KULeuven, Leuven, Belgium

SESSION INFORMATION

Session Date: Sunday, November 7, 2021

Session Title: Patient Outcomes, Preferences, & Attitudes Poster II: Measurements (0739–0763)

Session Type: Poster Session B

Session Time: 8:30AM–10:30AM

Background/Purpose: Current EULAR-guidelines recommend treating Rheumatoid Arthritis (RA) early, intensively and to-target. Patient-Reported Outcomes (PROs) can be important contributors for remote monitoring of disease status in patients with (early) RA to guide the interventions needed. However, which PROs are vital for such purposes is unknown. Therefore, we aimed to investigate the direct and indirect relations between different PROs in the Care in Early RA (CareRA) trial.

Methods: In CareRA, patients were asked to register the following PROs at baseline (BL), week 52 (W52), and week 104 (W104): Multi-Dimensional Fatigue Index (MF), Short Form 36 (SF36), Illness perception questionnaire (IPQ), Utre-

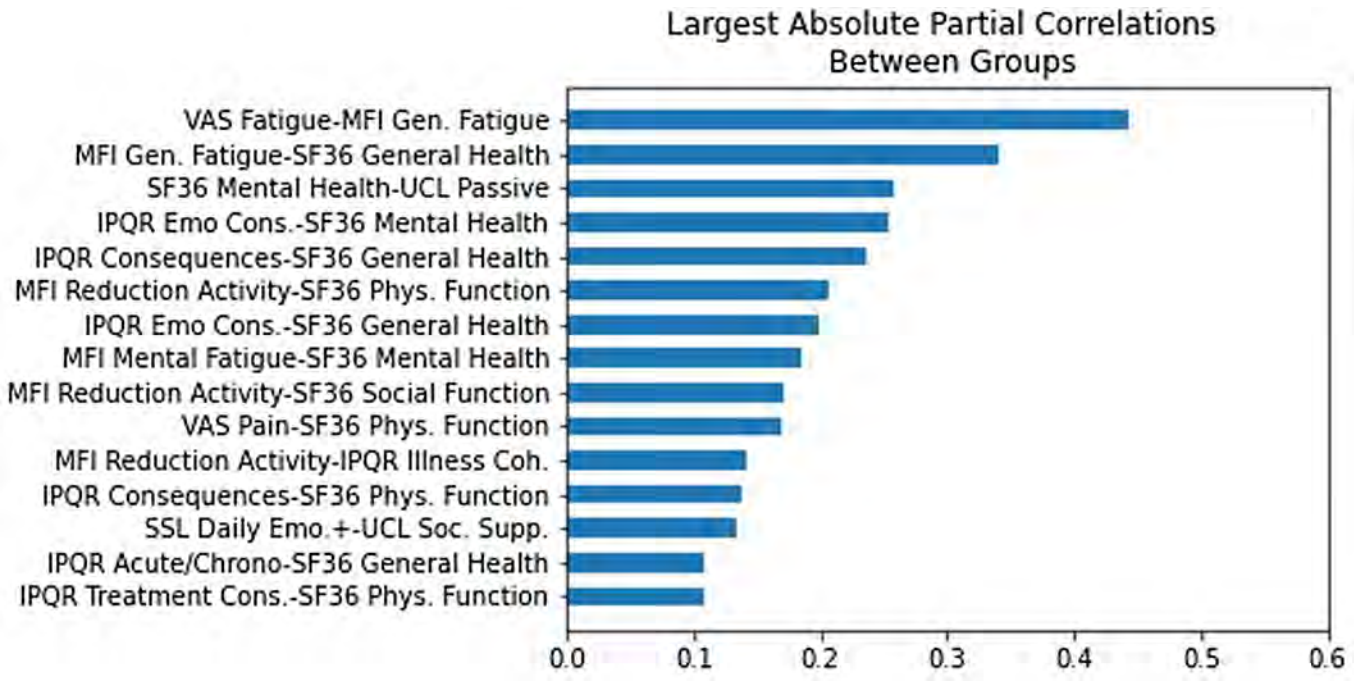

Figure 1 Estimated absolute (penalized) partial correlations between the (sub)scores at W104.

cht Coping List (UCL), Social Support List (SSL), Pittsburgh Sleep Questionnaire (PSQ), RA Quality of Life (RAQOL) and global health, pain and fatigue as measured by Visual Analogue Scale (VAS). Most questionnaires consist of different subdomains or subscores. Where applicable, these subscores were used, else the total score per questionnaire was used. The graphical lasso (GLASSO) method was used to estimate relations between PRO (sub)scores. GLASSO provides both an overview on indirect relations (via correlation) and on direct relations (via precision matrix). The GLASSO was run at BL, W52 and W104 to check for consistency over time.

Results: The GLASSO procedure suggested 168 direct relations out of 561 possible relations (±30%) at W104. Similar results were obtained at BL and W52. Fig 1 shows the 15 relations with the highest partial correlations between

Figure 2 Estimated direct relations (edges) between (sub)scores (nodes) at W104.

subscores from different PROs at W104. Absolute values of relationship strength showed slight variations, but the correlation scores appeared robust over time. Analyzed (sub)scores and relations estimated at W104 are presented in Fig 1. Three distinct groups of PROs were clearly identifiable from the GLASSO procedure. A first group consisting only of SSL subscores, a second group consisted only of UCL subscores and the last group consisted of all other PROs. There were many connections within each group and few between groups. This suggests that each group relates to a different underlying dimension.

Conclusion: Using the GLASSO-approach, we distinguished three distinct groups of PRO dimensions. Coping and social support constructs seem distinct from another heterogeneous group representing both mental and physical health topics. Correlation between these disease-activity-related PROs suggests not all PROs are required to get a representative view of patient health.

The Performance of RA Disease Activity and Patient-Reported Outcomes in Rheumatoid Arthritis-Associated Interstitial Lung Disease in a Prospective Trial Using Pirfenidone in RA ILD (TRAIL1)

Paul Dellaripa[1], Tracy Doyle[2], Sonye Danoff[3], Hillary Goldberg[1], Martin Kolb[4], Daniel Chambers[5], Felix Woodhead[6], Cathy Spino[7], Ivan Rosas[8] and Joshua Solomon[9], [1]Brigham and Women's, Boston, MA, [2]Brigham and Women's Hospital, West Roxbury, MA, [3]Johns Hopkins Medicine, Baltimore, MD, [4]McMaster University, Hamilton, ON, Canada, [5]University of Queensland, Brisbane St Lucia, Australia, [6]University of Leicester, Leicester, United Kingdom, [7]University of Michigan, Ann Arbor, MI, [8]Baylor College of Medicine, Houston, TX, [9]National Jewish Health, Denver, CO

SESSION INFORMATION
Session Date: Sunday, November 7, 2021
Session Title: Patient Outcomes, Preferences, & Attitudes Poster II: Measurements (0739–0763)
Session Type: Poster Session B
Session Time: 8:30AM–10:30AM

Background/Purpose: Both rheumatoid arthritis (RA) and idiopathic pulmonary fibrosis (IPF) have established measures of disease severity and patient reported outcomes (PROs) that measure health-related quality of life (HRQL). In IPF, established PROs correlate with severity of lung disease. In patients with interstitial lung disease (ILD) associated with RA, it is unknown if established RA disease severity indices and PROs correlate with ILD severity and available PROs used in IPF, which have been adapted for use in the TRAIL1 trial. Using baseline data collected in the TRAIL1 trial, we sought to examine correlations between PROs, measures of RA disease severity and severity of ILD and correlations between PROs used in RA and IPF.

Methods: Baseline data from 123 subjects randomized to the TRAIL1 trial were used for this analysis. All subjects underwent pulmonary function testing (PFT), baseline high-resolution computed tomography (HRCT) to determine extent of fibrosis and administration of PROs at enrollment. Disease severity for joint disease was measured with the disease activity score (DAS)28 in RA and disease severity for ILD was measured using forced vital capacity (FVC)%, diffusing capacity for carbon monoxide (DLCO)% and extent of fibrosis in ILD. PROs examined include the

Footnote: SGRQ=St. George's Respiratory Questionnaire, DAS=Disease Activity Score. r=Spearman correlation, p=p-value				

Correlations between RAPID3, DAS28 and Lung-Specific PROs.

Results: Table 1 shows the baseline characteristics of the subjects randomized for the TRAIL1 trial. Most subjects were Caucasian males over 55 years old with a moderate amount of fibrosis. Baseline PROs revealed moderate RA activity; dyspnea and pulmonary-specific HRQL (as measured by the SGRQ) showed moderate impairment that was comparable to that seen in IPF. There was no association between DAS28 or PROs and disease severity for ILD (Table 2). There were strong correlations between the RAPID3 and the ILD-specific PROs (SQRQ and Dyspnea-12) (Table 3).

Conclusion: No correlations between joint-disease activity and RA-ILD disease severity as measured by PFTs and extent of fibrosis on HRCT were shown. Additionally, no correlations were apparent between ILD-specific PROs and severity of lung disease in RA-ILD, as is seen in IPF. While the small patient numbers may impact the results, these data suggest that RA-ILD has features that are unique compared to IPF, perhaps related to the systemic nature of the disease as well as the multicompartmental lung involvement that can be seen in RA. These differences may require the development of specific PROs that better correlate with lung function in the assessment of patients with RA-ILD. Furthermore, the correlation between RA and ILD-specific PROs may be important in the clinical management of patients with RA-ILD and requires further study.

Abstract Number: 0761

Development of a Symptom Diary for Use in Patients with Sjogren's Syndrome

Briana Ndife[1], Sheri Fenel[2], Sandy Lewis[2] and Neetu Agashivala[3], [1]Novartis, East Hanover, NJ, [2]RTI Health Solutions, Research Triangle Park, NC, [3]Novartis Pharmaceutical Corporation, East Hanover, NJ

SESSION INFORMATION
Session Date: Sunday, November 7, 2021
Session Title: Patient Outcomes, Preferences, & Attitudes Poster II: Measurements (0739–0763)
Session Type: Poster Session B
Session Time: 8:30AM–10:30AM

Background/Purpose: Sjögren's Syndrome (SS) is a systemic autoimmune disease associated with a wide range of symptoms and long-term complications. While clinical indices are useful in diagnosis and assessment of disease activity, patient-reported outcome (PRO) measures are needed to measure the severity of symptoms from a patient perspective. The objective of this study was to develop a patient-reported diary for use in clinical trials to assess the severity of key symptoms of SS in alignment with Food and Drug Administration (FDA) PRO guidance documents.

Methods: Development began with targeted reviews of the literature and relevant PRO measures to identify symptoms of SS which are both highly prevalent in the patient population and have the potential to improve within the context and timeframe of a clinical trial. Following the development of an item pool addressing the initially identified symptoms, semi-structured interviews were conducted with clinical experts (n=2) to gather feedback on this preliminary item pool and to identify any additional concepts of importance. Following minor revisions to the draft items based on clinician feedback, three iterative sets of hybrid concept elicitation (CE) and cognitive debriefing (CD) interviews were conducted with a total of 17 patients with primary SS (64.7% female; median age 58.0 years [range 28-70 years]) to refine the diary and further assess its content validity.

Results: Based on the targeted literature review, the most prevalent symptoms of importance to patients with SS included dryness of the eyes, mouth, skin, and female genitalia along with fatigue and muscle or joint pain. While additional symptoms that tend to occur at later stages of the disease process were identified (e.g., brain fog, neuropathic pain), these symptoms would not be relevant across the full disease spectrum and thus were not included in the preliminary item pool. While the clinical experts generally endorsed the initial content of the diary, they recommended the exclusion of skin dryness, noting that this was not a common complaint among their patients.

The symptoms most commonly reported by patients participating in the qualitative interviews were consistent with those addressed in the preliminary item pool and final diary, including dry eyes (100%), dry mouth (100%), dry skin (47%), genital dryness (46% of female participants), fatigue (77%), and muscle or joint pain (53%). Of note, while the concept of skin dryness was not fully endorsed by the clinical experts, patients supported its inclusion in the final measure. With minor modifications, patients also indicated that the diary items were easy to understand and answer. Finally, no concept of importance was identified as missing from the diary by more than 3 of the 17 interview participants, and many of these were impacts rather than symptoms of SS (e.g., dental decay, depression).

Conclusion: The Sjögren's Syndrome Symptom Diary is a content valid measure designed for use in clinical trials to assess the severity of the symptoms most commonly experienced by patients with SS. Following psychometric evaluation, this measure will have the potential to support product labeling claims.

Abstract Number: 0762

Validity of the Musculoskeletal Health Questionnaire: Real World Analysis of Data Collection via an Electronic Patient Reported Outcome Platform

Amy Boalch[1], Sam Norton[1], Sophia Steer[2], Nicky Wilson[2] and James Galloway[3], [1]King's College London, London, United Kingdom, [2]King's College Hospital, London, United Kingdom, [3]Kings College London, London, United Kingdom

SESSION INFORMATION
Session Date: Sunday, November 7, 2021
Session Title: Patient Outcomes, Preferences, & Attitudes Poster II: Measurements (0739–0763)
Session Type: Poster Session B
Session Time: 8:30AM–10:30AM

Background/Purpose: The Musculoskeletal Health Questionnaire (MSK-HQ) is a patient reported outcome measure (PROM) validated to assess disease outcomes in patients with MSK disorders. This study evaluates the validity of the MSK-HQ in an ePROM system as part of routine care in rheumatology. We assess reliability and validity of the MSK-HQ across different conditions and evaluate correlation of the total score and activity score with other PROMs.

Methods: Data were extracted via the King's College Hospital IMPARTS ePROM system which sends an SMS link 24hrs before a clinic appointment to complete PROMs tailored to the patient condition. The MSK-HQ includes 14 items summed to give a total score (0-56, higher scores indicate better quality of life) and a final item for physical activity in the past week. In addition, data were extracted for mental health (PHQ9 & GAD7), functional limitation (HAQ), and disease specific measures (BASDAI & DLQI). Data are reported as mean±SD with Pearson correlations estimated to test association and linear regression to test group differences.

Results: Data was available for 1323 encounters between 06/20 and 01/21. The MSK-HQ was completed on 1216 (92%) occasions (31.4±13.9). RA had the greatest impact compared to AS and PsA (RA: 30.3±14.4; AS:36.0±13.1; 33.3±12.8; other:31.1±13.6; $p < .001$). Chronbach's alpha coefficients indicated excellent reliability of the MSK-HQ total score (alphas:overall=.95;RA=.96;PsA=.96;AS=.95). Factor analysis confirmed a unidimensional solution supporting use of the total score.

Across all encounters patients reported 2.3±2.3 active days in the last week. Patients with RA, AS and PsA were active on 2.0± 2.2, 2.9± 2.3 and 2.6± 2.4 days respectively again suggesting RA has greater disease impact ($p < .001$). MSK-HQ scores were positively correlated with active days ($r=.36$, $p < .01$).

The MSK-HQ total score demonstrated good convergent validity with condition specific PROMs. BASDAI and BASFI in AS ($r=-.89$ $p < .001$ & $r=-.81$ $p < .001$ respectively) and DLQI in PsA ($r=-.44$, $p < .001$). BASDAI and BASFI strongly correlated with active days ($r=-.30$ $p < .05$ & $r=-.37$ $p < .05$ respectively) however DLQI didn't show significant correlation ($r=-.07$, $p=.42$).

Good convergent validity was demonstrated against HAQ. There was a $r=-.38$ correlation ($p < .05$) with active days per week. A HAQ score ≤1 was associated with a mean of 3.01 active days compared to a HAQ score >1 associated with a mean of 1.44 active days ($t=8.81$, $p < .05$).

Both MSK-HQ total score and number of active days could discriminate between those with and without mental health symptoms. The correlation between PHQ9 and GAD7 score and active days was $r=-.27$ and $r=-.19$ (both $p < .01$). Individuals with mild depressive symptoms were active 0.9 days less per week compared to those without

symptoms (t -4.06, p< .01). Individuals with probable major depression were active 1.4 days less per week compared to those with no symptoms (t -7.99, p< .01).

Conclusion: This study demonstrated acceptability and validity for both the MSK-HQ total score and activity score delivered via an ePROM system. The activity score in isolation discerned patients with and without symptoms of anxiety or depression highlighting the value of using this PROM in the healthcare setting.

Herrera[3], Clara Malagon[4], Olga Arguedas[5], Amparo Ibanez Estrella[6], Nicola Ruperto[7], Angelo Ravelli[8] and Alessandro Consolaro[9], [1]Università degli Studi di Genova Genoa, Italy, Genova, Italy, [2]Istituto Giannina Gaslini, Genova, Italy, [3]Hospital de Ninos Roberto Gilbert Elizalde, Rheumatology, Guayaquil, Ecuador, Paediatric Rheumatology International Trials Organisation (PRINTO), Guayaquil, Ecuador, [4]Hospital Universitario Simon Bolivar, Clinica infantil Colsubsidio, Facultad de Medicina, Post Grado Reumatologia Pediatrica, Universidad El Bosque, Bogota, Colombia, Paediatric Rheumatology International Trials Organisation (PRINTO), Bogotà, Colombia, [5]Hospital Nacional de Ninos Dr Carlos Saenz Herrera, Servicio de Immunologia y Reumatologia pediatrica, San Josè, Costa Rica, Paediatric Rheumatology International Trials Organisation (PRINTO), San Josè, Costa Rica, [6]National Institute Salud del Nino, Rheumatology Service, Brena, Lima, Peru, Paediatric Rheumatology International Trials Organisation (PRINTO), Lima, Peru, [7]Istituto Giannina Gaslini, Paediatric Rheumatology International Trials Organisation (PRINTO), Genova, Italy, [8]Istituto Giannina Gaslini, Genoa, Italy, [9]Istituto Giannina Gaslini, Università degli Studi di Genova, Genova, Italy

SESSION INFORMATION
Session Date: Sunday, November 7, 2021
Session Title: Patient Outcomes, Preferences, & Attitudes Poster II: Measurements (0739–0763)
Session Type: Poster Session B
Session Time: 8:30AM–10:30AM

Background/Purpose: Parent- and child-reported outcomes (PCROs) reflect the parent and child perception of rheumatic disease course and effectiveness of therapeutic interventions. Among PCROs for the assessment of patients with juvenile idiopathic arthritis (JIA), the most widely adopted is the parent/patient global evaluation or well-being visual analogue scale (WB-VAS). Several studies in JIA have highlighted the discrepancies in the assessment of the disease status between the physician and the parent/patient. This difference might be due to the WB-VAS measuring a broader construct than the physician global assessment (PGA). Aim of this study is to evaluate in a large multinational sample of JIA patients the disease characteristics of subjects with a PGA score of 0 and with an increased WB-VAS score.

Methods: Data from the multinational dataset of patients in the Epidemiology Treatment and Outcome of Childhood Arthritis study were analyzed. We have included only subjects with a PGA score of 0. PCROs were collected through the juvenile arthritis multidimensional assessment report. We compared demographic features, socio-economic sta-

tus, level of education, subtype of JIA diagnosis and the main PCROs (pain level, presence of morning stiffness, count of joints with swelling or pain, functional ability, disease activity level, ongoing therapy, presence of medications side effects and health related quality of life between subjects with WB-VAS ≤ 1 and > 1.

Results: a total of 3537 patients were sorted into two groups according to the WB_VAS score: 2862 subjects were included in a first group (WB_VAS ≤1); 675 in a second one (WB-VAS >1). Respectively, 17,6% vs 18,1% of families belonged to the lower socio-economic status, 70,5% vs 71% to the intermediate, 11,9% vs 10,8% to the higher. The percentages of patients in the three levels of education was not different in the two groups:20,2% and 22% in the lower, 48,9% and 50,1% in the intermediate, 30,8% and 27,9% in the higher level of education. No significant difference was observed in the distribution of JIA categories in the two groups. Subjects in first group were younger at disease onset (5.6 vs 6.4 years). Comparison of main PCROs results is presented in the table.

PCROs	**WB_VAS ≤1**	**WB_VAS >1**	**p**
VAS_Pain (average)	0.3 (0.9)	2.4 (2.4)	< 0.001
Presence of morning stiffness (%)	227 (8.0)	285 (42.4)	< 0.001
Patients under treatment (%)	1919 (67.2)	540 (80.2)	< 0.001
Reporting side effects (%)	421 (22.1)	236 (43.9)	< 0.001
Juvenile Arthritis Functionality Scale (JAFS)Total Score (average)	0.5 (1.6)	3.0 (4.4)	< 0.001
JIA Quality of Life (JQL) Total Score (mean)	1.6 (2.3)	6.4 (4.4)	< 0.001
VAS-Disease Activity (average)	0.4 (1.3)	2.3 (2.4)	< 0.001
Count of active joints (average)	0.2 (0.7)	1.4 (2.2)	< 0.001

Conclusion: we have analyzed the variables that might determine a difference between the physician's assessment of inactive disease and the parent's/patient's perception of well-being. In particular, socio-economic status, level of education, and gender representation seem not to impact on the general perception of well-being, while pain seems to have the greatest influence on the parent/patient quality of life assessment. Finally, children with lower WB-VAS score had a younger disease onset.

SESSION INFORMATION

Session Date: Sunday, November 7, 2021

Session Title: Pediatric Rheumatology – Clinical Poster II: SLE, JDM, & Juvenile Scleroderma (0764–0785)

Session Type: Poster Session B

Session Time: 8:30AM–10:30AM

Background/Purpose: Juvenile systemic sclerosis (jSSc) is a rare disease with a prevalence of around 3 in 1,000,000 children. To better capture the clinical manifestations of jSSc the juvenile systemic sclerosis inception cohort (jSScC) has been prospectively enrolling patients with predetermined clinical variables over the past 12 years. One of the goals is to study the demographic, clinical features, and physician and patient reported outcome differences between those with juvenile limited cutaneous (lc) compared to diffuse cutaneous (dc) disease subtypes, to determine if characteristics are similar or different between dc and lc jSSc.

Methods: Demographic, physical examination, organ system evaluation, autoantibody profile, treatment, and patient and physician reported outcome variables were evaluated from the jSSc Inception cohort and summary statistics applied using chi-square test and Mann Whitney U-test comparing lcjSSc and dcjSSc subtypes.

Results: At the time of data extraction, 187 jSSc patients were enrolled in the cohort, 80% were Caucasian and 80% female. Diffuse cutaneous jSSc subtype predominated (72%). Median Disease duration was 2.5 years (1 – 4.4). Median age at Raynaud´s was 10.4 years (7.2 – 13.1) and median age of first non-Raynaud´s was 10.9 (7.4 – 13.5). Significant differences were found between dcjSSc versus lcjSSc, regarding several clinical characteristics. Patients with diffuse cutaneous subtype had significantly higher modified Rodnan skin score ($p< 0.001$), presence of sclerodactyly ($p=0.003$), presence of Gottron's papules ($p=0.008$), presence of telangiectasia ($p=0.005$), history of digital tip ulceration ($p=0.001$). Cardiac involvement was significantly higher in limited cutaneous jSSc subtype ($p=0.001$). Diffuse cutaneous jSSc patients had significantly worse scores for Physician Global Assessment of disease activity (35 vs 20; $p< 0.001$) and disease damage (30 vs 15; $p< 0.001$).

Conclusion: Results from this large international cohort of jSSc patients demonstrate significant differences between dcjSSc and lcjSSc patients. According to the general organ involvement and physician global scores, the dcjSSc patients had significantly more severe disease. These observations strengthen our previous findings of the unique organ pattern of pediatric patients.

Male Juvenile Systemic Sclerosis Patients Have More Severe Disease: Results from the International Juvenile Scleroderma Inception Cohort

SESSION INFORMATION

Session Date: Sunday, November 7, 2021

Session Title: Pediatric Rheumatology – Clinical Poster II: SLE, JDM, & Juvenile Scleroderma (0764–0785)

Session Type: Poster Session B

Session Time: 8:30AM–10:30AM

Background/Purpose: Juvenile systemic sclerosis (jSSc) is a rare disease with a prevalence of around 3 in 1,000,000 children. To better capture the clinical manifestations of jSSc the juvenile systemic sclerosis inception cohort (jSScC) has been prospectively enrolling patients with predetermined clinical variables over the past 12 years. One of the goals is to study the demographic, clinical features, and physician and patient reported outcome differences between male and female patients, to determine if characteristics are similar or different.

Methods: Demographics, organ involvement, laboratory evaluation, patient reported outcomes and physician assessment variables were compared between male and female jSSc patients enrolled in the prospective international juvenile systemic sclerosis cohort (jSScC) at their baseline visit.

Results: 175 jSSc patients were evaluated, 142 female and 33 male. Race, age of onset, disease duration, and disease subtypes (70% diffuse cutaneous) were similar between males and females. Active digital ulceration, very low body mass index, and tendon friction rubs were significantly more frequent in males. Physician global assessment of disease severity and digital ulcer activity was significantly higher in males. The composite pulmonary involvement was also more frequent in males, though not statistically significantly.

Conclusion: In this cohort, jSSc had a more severe course in males. This reflects the adult-onset SSc cohort data and parallels it in regards to increased digital ulcers, interstitial lung disease, and global severity. Differences from adult findings include no increased signal of pulmonary arterial hypertension or heart failure in male pediatric patients. While monitoring protocols of organ involvement in jSSc need to be identical for males and females, our findings suggest a higher index of suspicion of certain organ involvement in males.

Baseline Characteristics and Patient Reported Outcomes from a Juvenile Dermatomyositis Registry Inception Cohort

Jessica Neely[1], Kaveh Ardalan[2], Adam Huber[3] and Susan Kim[4], [1]University of California San Francisco, San Francisco, CA, [2]Duke University Medical Center, Durham, NC, [3]Dalhousie University, Halifax, NS, Canada, [4]UCSF Benioff Children's Hospital, San Francisco, CA

SESSION INFORMATION

Session Date: Sunday, November 7, 2021

Session Title: Pediatric Rheumatology – Clinical Poster II: SLE, JDM, & Juvenile Scleroderma (0764–0785)

Session Type: Poster Session B

Session Time: 8:30AM–10:30AM

Background/Purpose: Juvenile dermatomyositis (JDM), the most common inflammatory myopathy of children, is rare, with an estimated incidence of 2-4 in 1 million children. Given the challenges of studying JDM, large observa-

tional cohort studies are invaluable resources for disease characterization, long-term monitoring, and comparative effectiveness studies, to ultimately improve the care and outcomes of children with JDM.

The Childhood Arthritis and Rheumatology Research Alliance (CARRA) Registry, designed a longitudinal inception cohort that includes the systematic data collection, including patient reported outcomes, planned over 10 years.

Table 1. Demographics, Diagnostic and Clinical Features

Age at diagnosis in years, median (IQR)	8 (4.0-11.5)
Age at disease onset in years, median (IQR)	7 (3.5-7.5)
Time to diagnosis in months, median (IQR)	3 (1-6.5)
Female, N (%)	76 (63.4)
Race, N (%)	
White	86 (72.3)
Hispanic, Latino, or Spanish origin	22 (18.5%)
Black, African American, African, or Afro-Caribbean	9(7.6)
Asian	7(5.9)
Native American, American Indian or Alaskan Native	3 (2.5)
Middle Eastern	3 (2.5)
Unknown	3 (2.5)
Other	4 (3.4)
Skin Predominant JDM, N (%)	38 (31.9)
History of, N (%)	
Proximal Muscle Weakness	86 (72.3)
Rash (Heliotrope or Gottron's)	110(92.4)
Elevated muscle enzymes	99(83.2)
EMG abnormality (n=4)	4
Muscle Biopsy abnormality (n=19)	18
MRI (81)	66
Autoantibodies, proportion	
ANA	75/96 (78.1%)
Myositis-specific antibodies	
Anti-MJ/NXP2	11/49 (22.4%)
Anti-p155/140/TIF1-γ	7/53 (13.2%)
Anti-Mi2	6/55 (10.9%)
Anti-MDA5	4/51 (7.8%)
Anti-Jo1	2/67 (3.0%)
Myositis-associated antibodies	
Anti-PM-Scl	3/43 (7.0%)
Anti-Smith	1/56 (1.7%)
Muscle Enzyme Elevation, N (%)	99 (83.2)
MMT8, median (IQR)	63.5 (51.0-75.0), N=32
CMAS, median (IQR)	43.5 (30.5-51.0), N=34
Skin Manifestations, N (%)	
Gottron's papules or sign	90(75.6)
Malar or facial erythema	78(65.5)
Periungal capillary loop changes	70(58.8)
Heliotrope Rash	64(53.8)
Linear Erythema	33 (27.7)
Cuticular overgrowth	24(20.2)
Non-sun exposed erythema	23(19.3)
Extensive cutaneous erythema	17(14.3)
Shawl Sign	13(10.9)

Table 2. Patient/Parent-Reported Outcome Measures

Global Assessments:	Median (IQR)	High symptom/low function scorers, n (%)*
Global Assessment of Disease Activity (patient), n=48	3 (1.75-5.25)	-
Global Assessment of Disease Activity (parent), n=33	3 (1-7)	-
PROMIS Pediatric Global Health 7 (patient), n=48	38.8 (33.6-42.1)	19 (39.6)
PROMIS Pediatric Global Health 7 (parent), n=34	34.6 (29.4-37.9)	18 (52.9)
Physical Function:

Pain Intensity Past 7 Days (patient), n=48	3 (1-6)	-
Pain Intensity Past 7 Days (parent), n=35	2 (0-6)	-
Pain Frequency, # Days in Past 14 Days (patient), n=46	5 (1.25-13.25)	-
Pain Frequency, # Days in Past 14 Days (parent), n=30	4 (0.25-14)	-
PROMIS Pain Interference (patient), n=40	55.65 (50.33-61.4)	15 (37.5)
PROMIS Pain Interference (parent), n=30	62 (51.5-66.5)	21 (77.8)

*N=119 unless indicated in the table where missing data reduced the total number of patients analyzed

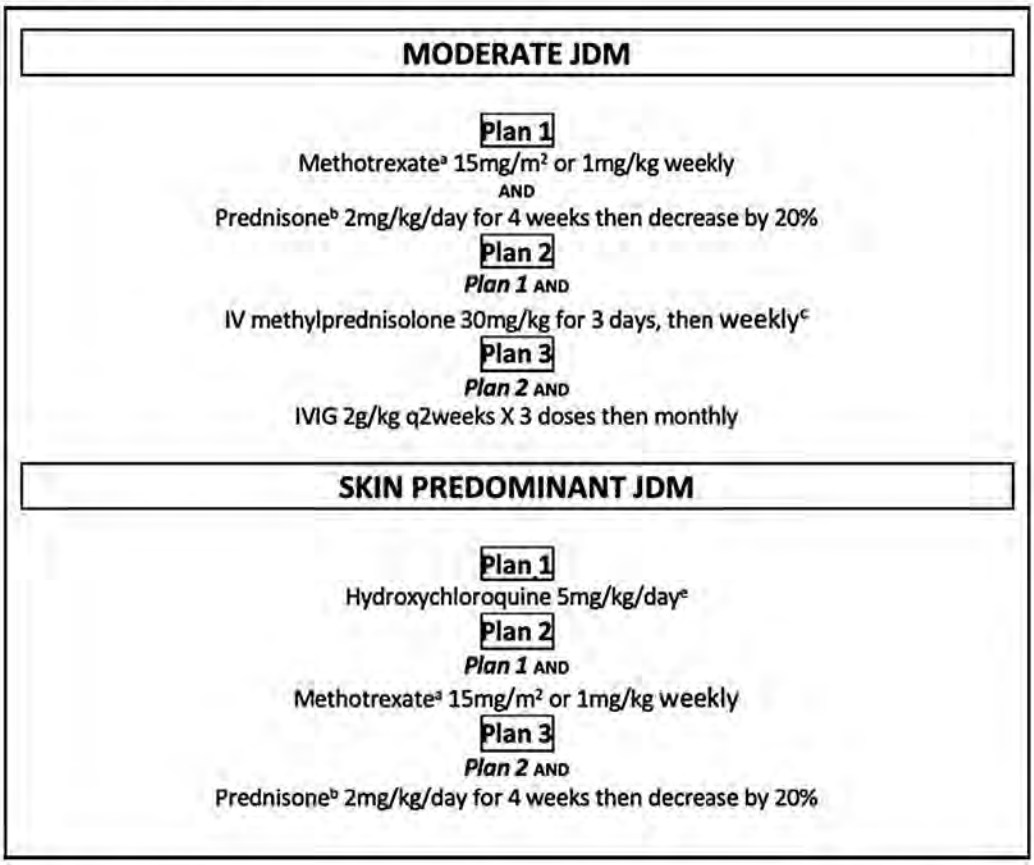
Here, we describe the baseline patient demographics, disease characteristics, initial assessments, patient/parent-reported outcomes and treatments for an inception cohort of children with JDM enrolled to the registry in the first year.

Methods: The CARRA Registry began enrollment of JDM subjects in January 2019. Eligible subjects were < 18 years of age at disease onset and diagnosed with JDM based on clinical judgement of the treating rheumatologist. Enrolled subjects had disease for < 6 months and treatment naïve or treated with systemic therapy for < 12weeks. This Registry is approved by Duke University Institutional Review Board (IRB) and each participating site. Consent/assent was obtained from eligible participants by the local investigators.

Results: 119 JDM subjects were enrolled from 41 sites. Most were female (63.4%), and white (72.3%) with a median diagnosis age 8.0 years (IQR 4.0-11.5), and median age of disease onset 7.0 years (IQR 3.5-7.5) (Table 1). They had characteristic rashes (92.4%), elevated muscle enzymes (83.2%), physician global score 4.0 (IQR 2.5-5.0) and manual muscle testing score 63.5 (IQR 51.0-75.0). Calcinosis (3%) and interstitial lung disease (< 1%) were uncommon.

CHAQ results (median 0.75, IQR 0.03-1.875), and patient/parent global assessments of disease activity (median 3, patient IQR: 1.75-5.25; parent IQR: 1-7) showed mild-moderate disability. PROMIS® Pediatric Global Health 7

Figure 1: Published Consensus Treatment Plans for JDM patients with Moderate, and Skin predominant disease



[a] Lesser of 15 mg/m² or 1 mg/kg (max 40 mg), [b] max 60mg, [c] optional, [d] max 70 grams, [e] max 400mg, [f] max 1500mg bid, [g] higher doses based on toxicity, efficacy

Published Consensus Treatment Plans for JDM patients with Moderate, Skin predominant disease.

scores, PROMIS measures for pain interference, physical function scores for mobility, and upper extremity function were commonly worse than 95% of the general pediatric population based on published normative data (Table 2).

Approximately half of subjects, 54.6% (n=64), were treated according to a Consensus Treatment Plans (CTP) (Figure 1).

Conclusion: In its first year 119 JDM patients were successfully enrolled into the CARRA Registry. They were similar to historic cohorts, with a trend toward earlier time to diagnosis and milder disease. PROs were also collected successfully, and our findings reveal moderate to severe patient and parent-reported disease impact. Published CTPs were also used to treat over half of the enrolled patients, suggesting that pragmatic trials may be feasible in the CARRA Registry.

This growing registry provides infrastructure to advance future clinical research and paired specimens in the CARRA biorepository will enable future translational research. Together, these efforts enhance trial readiness for future therapeutic studies, including comparative effectiveness trials which will help to advance care and outcomes for JDM.

Medication Use in Pediatric Lupus in the Childhood Arthritis and Rheumatology Research Alliance Registry

Jordan Roberts[1], Laura Berbert[1] and Mary Beth Son[2], [1]Boston Children's Hospital, Boston, MA, [2]Boston Children's Hospital, Brookline, MA

SESSION INFORMATION
Session Date: Sunday, November 7, 2021
Session Title: Pediatric Rheumatology – Clinical Poster II: SLE, JDM, & Juvenile Scleroderma (0764–0785)
Session Type: Poster Session B
Session Time: 8:30AM–10:30AM

Background/Purpose: Black and Hispanic children with pediatric lupus (pSLE) have higher morbidity and mortality, but the extent to which differences in outcomes may be related to disparities in treatment, including in medication regimens, is unknown. We aimed to characterize medication use in a large cohort of children with pSLE and determine whether use of steroids, antimalarials and rituximab in pSLE is associated with self-reported race and ethnicity.

Methods: We included patients with pSLE in the Childhood Arthritis and Rheumatology Research Alliance (CARRA) Registry enrolled from 2017-July 2020 with demographic, disease activity and medication data available at baseline visit. Central nervous system (CNS) lupus was defined as documented organic brain syndrome, psychosis, cerebrovascular accident, visual disturbance, cranial neuropathy, or seizure. Large versus small site of care was also included. Summary statistics were used to describe disease and demographic features and medication use in the cohort. We analyzed specific medication use: (1) use versus non-use of antimalarials (2) use of high (≥ 15mg or 0.3mg/kg prednisone equivalent daily) versus low/no prednisone dose at time of baseline visit and (3) use versus non-use of rituximab in the first year of Registry enrollment. Univariate logistic regression analysis was used to identify sociodemographic and disease-related factors associated with each medication outcome. Multivariable logistic regression was used to compare medication outcomes in Black and Hispanic patients to those of non-Black and non-Hispanic patients while adjusting for these covariates.

Results: We identified 572 patients with pSLE enrolled in the CARRA Registry with complete data at baseline visit and 273 patients with at least 1 year of follow up. Patient and disease characteristics are presented in Table 1. Median disease duration at baseline visit was 5.8 months. Overall, 90% of patients were prescribed an antimalarial at baseline visit and 49% were on high-dose steroids versus 51% on no or lower-dose steroids (Table 2). Of those with at least 1 year of follow up, 7.7% received rituximab. In multivariate regression, patients with lupus nephritis and those treated at large centers had increased odds of high-dose steroid regimens at their baseline visits; a trend toward higher dose was also seen in lower income patients (Table 3). Black race was associated with over three-fold higher odds of rituximab use within the first year of Registry enrollment even when controlling for disease activity. Antimalarial use at baseline was significantly associated with private insurance.

Conclusion: High dose steroid regimens were associated with higher SLEDAI score, lupus nephritis and large center size. Rituximab use was uncommon and associated with Black race and higher SLEDAI. Antimalarial use was high, though not universal, in this pSLE cohort, and use was associated with private insurance. Further research is needed to understand reasons for this variation and its impact on pediatric lupus outcomes.

Poverty and Length of Stay in Children Hospitalized with Pediatric Systemic Lupus Erythematosus: An Analysis of the 2016 Kids' Inpatient Database

William Soulsby, Erica Lawson and Matthew Pantell, University of California San Francisco, San Francisco, CA

SESSION INFORMATION
Session Date: Sunday, November 7, 2021
Session Title: Pediatric Rheumatology – Clinical Poster II: SLE, JDM, & Juvenile Scleroderma (0764–0785)
Session Type: Poster Session B
Session Time: 8:30AM–10:30AM

Background/Purpose: Prior studies have demonstrated alarming health disparities in adult patients with SLE, including higher disease severity and activity among Hispanic and Black patients. Pediatric studies have demonstrated similar racial disparities, including associations between Hispanic and Black race and end stage renal disease, increased health utilization, and death among hospitalized patients. Importantly, prior studies do not focus on modifiable risk factors of socioeconomic status (SES), such as income level, particularly important as exiting poverty demonstrated potential reversibility of disease damage in an analysis of the Lupus Outcomes Study. Our study aims to use the most recent iteration (2016) of the Kids' Inpatient Database (KID) – the largest all-payer pediatric inpatient care database in the U.S. – to investigate the relationship between income level and hospital length of stay (LOS) via cross-sectional analysis.

Methods: SLE hospitalizations were identified for children ages 2-20 by a primary ICD-10 diagnosis code of M32. Those with neonatal lupus (ICD-10 M32.8) were excluded. Baseline characteristics were compared by income level (Quartile 1, 2, 3, and 4) using descriptive statistics (ANOVA and Pearson's chi-squared exact tests, as appropriate). Negative binomial regression was used to analyze the effect of income level (by median income for zip code divided into quartiles) on length of stay unadjusted, then adjusted for sex and age, and finally adjusted for other covariates of interest (race/ethnicity, primary payer status) and confounders (APRDRG severity of hospitalization, presence of severe lupus features, and location/teaching status of hospital). Using this adjusted model, a marginal mean length of stay was calculated at each income quartile.

Results: A total of 1,586 primary lupus hospitalizations were identified (Table 1). The mean age at admission was 16 with a female predominance (84%). This cohort represented a diverse patient population (36% Black, 27% Hispanic, 8% Asian/Pacific Islander vs 14% White) with higher proportions of minority populations in the lower compared to upper income quartiles (i.e. Black 50% in Quartile 1 & 31% in Quartile 2 vs 27% in Quartiles 3 & 4). Private insurance coverage was more common in the highest income quartile (62% in Quartile 4 vs 26% in Quartile 1). In unadjusted analysis, income level was not associated with increased LOS though adjusted analysis did demonstrate an association with prolonged increased length of stay at the 2nd income level (IRR 1.17, p-value 0.032 – Table 2). Adjusted mean length of stay was higher than the mean for those with lower income levels (Quartile 1 and 2 - Figure 1).

Conclusion: Lower income level may be associated with prolonged LOS among children hospitalized with SLE though this association was only significant at the 2nd level of income quartile. This may reflect that those of lowest income are supported by resources not available to others in poverty who miss strict guidelines for assistance, such as housing support. Future work will include income as a predictor of readmissions and recurrent ED visits.

SESSION INFORMATION

Session Date: Sunday, November 7, 2021

Session Title: Pediatric Rheumatology – Clinical Poster II: SLE, JDM, & Juvenile Scleroderma (0764–0785)

Session Type: Poster Session B

Session Time: 8:30AM–10:30AM

Background/Purpose: Lupus nephritis is a frequent manifestation in childhood-onset systemic lupus erythematosus (cSLE) and has a great potential for chronic kidney disease (CKD), requiring dialysis and kidney transplantation, with great loss in health-related quality of life. The objective of this study was to analyze renal outcomes and CKD in cSLE and to assess its association with cumulative clinical and laboratory features, current disease activity and damage, cumulative treatments, and outcomes.

Methods: This is a multicenter, nationwide observational study of a cohort of 1,528 cSLE patients followed in 27 Brazilian pediatric rheumatology tertiary centers. All patients fulfilled the American College of Rheumatology (ACR) 1997 criteria for classification of SLE, with disease onset before 18 years of age. In this study, we investigated cumulative risk factors for KF in a large sample of cSLE patients.

Results: A total of 59/1528 (3.9%) of patients presented CKD. After Bonferroni´s correction for multiple comparisons ($p^{c}0.0013$), determinants significantly associated with CKD were urinary sediment alterations, neuropsychiatric involvement, higher scores of current SLEDAI-2K and SLICC/ACR-DI (especially renal involvement), as well as cumulative use of intravenous methylprednisolone, cyclophosphamide, and rituximab. In regression models, arterial hypertension (HR=15.42, 95%CI=6.12-38.83, $p \leq 0.0001$) and biopsy-proven proliferative nephritis (HR=2.83,

Table 1 – Demographic data, clinical and laboratorial features, disease activity and disease damage score, and treatment during follow-up in 1528 childhood-onset systemic lupus erythematosus (cSLE) patients with and without chronic kidney disease (CKD).

Results are presented in n (%) and median (min-max).
The bold numbers express the p value that are statistically significant. *p value according to Bonferroni correction for multiple comparisons (p<0.0013).
CKD – chronic kidney renal disease, LN – Lupus Nephritis, SLEDAI-2K – Systemic Lupus Erythematosus Disease Activity Index 2000, SLICC-ACR/DI – Systemic Lupus International Collaborating Clinics/ACR-Damage Index, g – gram.

95%CI=1.70-4.72, p≤0.0001) increased the risk of CKD. The Kaplan-Meier overall curves showed significantly worse patient survival in cSLE patients with biopsy-proven proliferative nephritis (p=0.02) and CKD (p≤0.0001).

Conclusion: This study showed that cSLE patients with arterial hypertension and biopsy-proven proliferative nephritis exhibited higher hazard rates of progression to poor outcomes. Therefore, those patients could benefit from strict blood pressure control during follow-up, and better drug treatment for aggressive management of active lupus nephritis.

Evaluation of the Lupus Low Disease Activity State (LLDAS) vs. the Systemic Lupus Erythematosus Disease Activity Index (SLEDAI)-2K Score in a Pediatric Systemic Lupus Erythematosus Cohort

Bridget Wilson, Tingting Qiu, Angela Merritt, Bin Huang and Hermine Brunner, Cincinnati Children's Hospital Medical Center, Cincinnati, OH

SESSION INFORMATION
Session Date: Sunday, November 7, 2021
Session Title: Pediatric Rheumatology – Clinical Poster II: SLE, JDM, & Juvenile Scleroderma (0764–0785)
Session Type: Poster Session B
Session Time: 8:30AM–10:30AM

Background/Purpose: Systemic Lupus Erythematosus (SLE) is a chronic autoimmune disease which can affect any organ system, and ongoing disease activity leads to organ damage. The Lupus Low Disease Activity State (LLDAS) has been evaluated in adult patients, but not yet in pediatrics. In adults, achieving LLDAS was shown to decrease morbidity and mortality and was associated with improved quality of life. The Systemic Lupus Erythematosus Disease Activity Index (SLEDAI)-2K is a weighted scale measuring presence of SLE activity in nine organ systems. In children with SLE, disease activity measured by the SLEDAI-2K ≤ 4 (low SLEDAI-status) is considered to reflect good disease control currently. The purpose of the study was to compare LLDAS and low SLEDAI-status in children with SLE.

Table 1. Patient Demographics

DEMOGRAPHICS	Patients (N=117) N (%) or Mean±SD
Age at diagnosis (yrs)	15.02±2.96
Number of visits per patient	10.31±8.51
Gender	
Female	97 (82.91%)
Male	20 (17.09%)
Race	
White	56 (47.86%)
Black	48 (41.03%)
Other	11 (9.4%)
Unknown	2 (1.71%)
Ethnicity	
Non Hispanic	114 (97.44%)
Hispanic	3 (2.56%)

Table 2. Clinic Visits Achieving Low SLEDAI-2K Status and LLDAS

	Low SLEDAI-Status	Not Low SLEDAI-Status	
LLDAS	312	---	
Not LLDAS	473	---	
	785 (65%)	419 (35%)	1204 total visits

Methods: LLDAS metrics were recorded for 1204 clinic visits from 117 patients (83% female; 41% black) enrolled in the SLE Database at Cincinnati Children's Hospital Medical Center (see table 1). Visits with incomplete data to score the LLDAS were omitted. LLDAS criteria include: (1) low SLEDAI-status, without activity in major organ systems; (2) no new SLE disease activity compared with previous assessment; (3) physician global assessment (PGA) ≤1 (range 0-10); (4) current prednisolone (or equivalent) dose ≤ 7.5 mg/day; and (5) well tolerated standard maintenance doses of immunosuppressive drugs or approved biological agents, excluding investigational drugs.

Results: The majority (65%, 785/1204) of visits met low SLEDAI-status criteria, of which only 40% (312/785) met the LLDAS criteria (see table 2). Of those visits meeting low SLEDAI-status but not meeting LLDAS (N=473), 51% (N=241) presented new SLE activity from the previous visit; 50% (N=238) had current prednisolone (or equivalent) dose >7.5 mg daily, and 44% (N=209) had PGA >1 (see figure 1).

Conclusion: LLDAS is more stringent than low SLEDAI-status, which is the current treatment target. If confirmed that children with SLE accrue less disease damage with LLDAS versus low SLEDAI-status, this would change treatment targets, hence the standards of clinical care. The study also suggested the need to refine LLDAS for pediatric patients, particularly the criteria for prednisolone dosage.

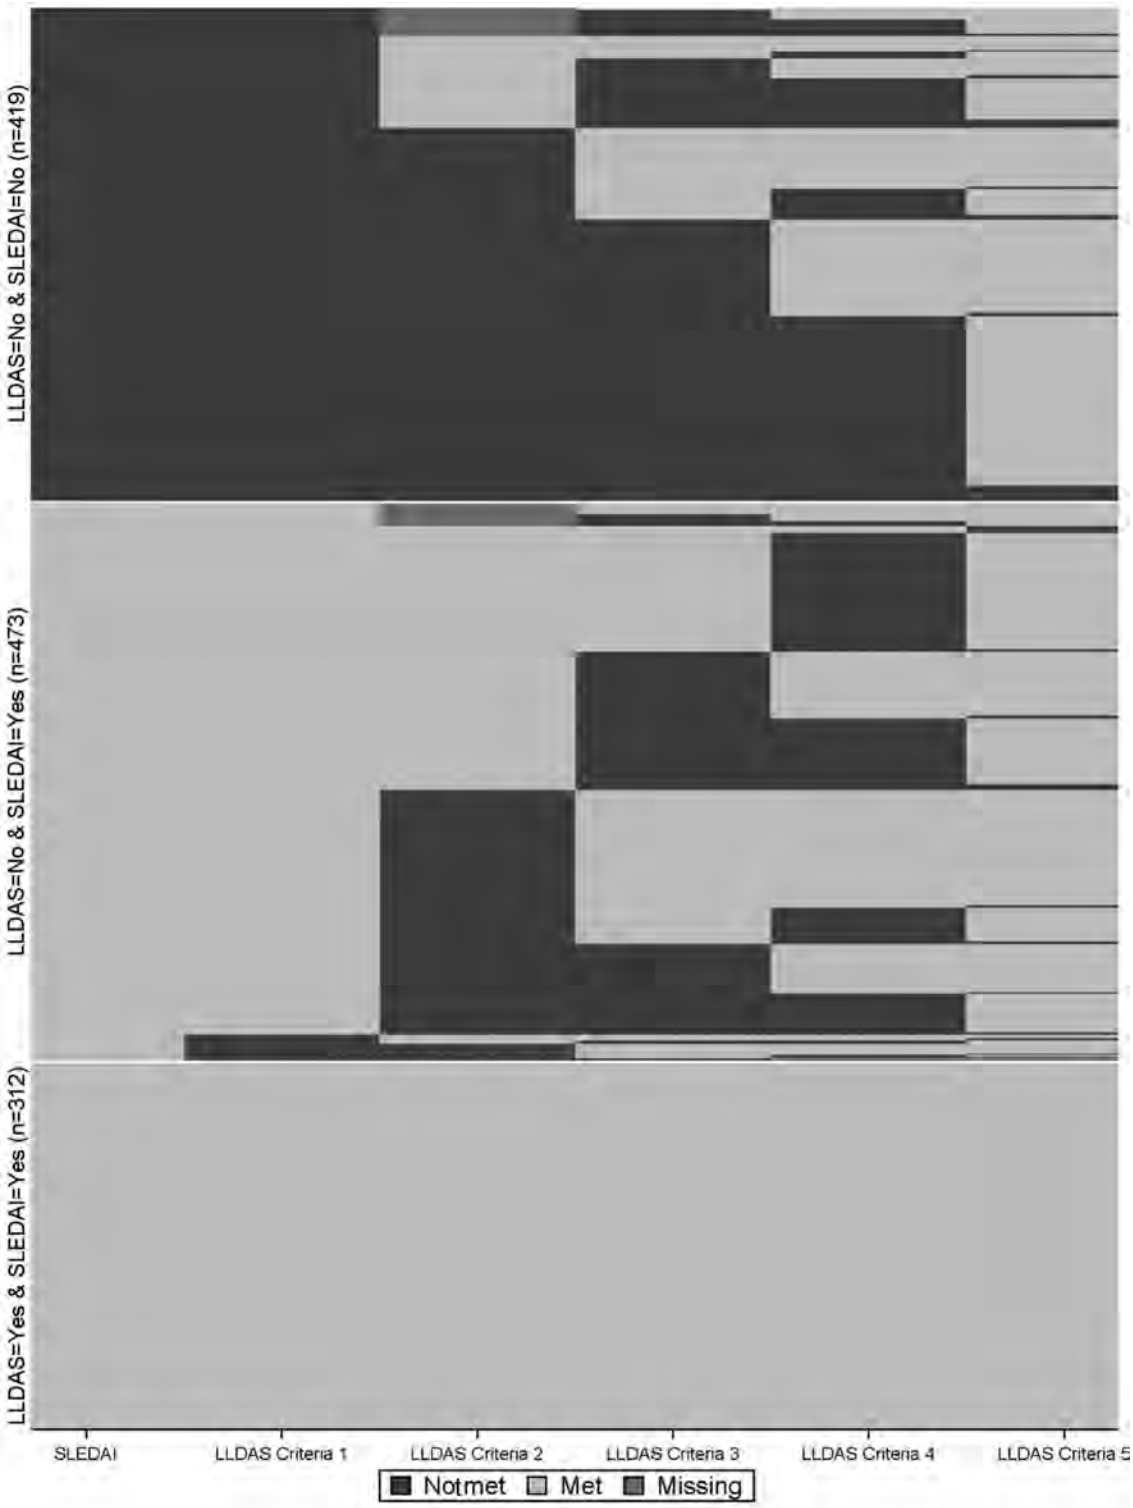

Figure 1. Heat Map of Clinic Visits Showing Low SLEDAI-2K Status and Particular LLDAS Criteria Met.

Session Date: Sunday, November 7, 2021
Session Title: Pediatric Rheumatology – Clinical Poster II: SLE, JDM, & Juvenile Scleroderma (0764–0785)
Session Type: Poster Session B
Session Time: 8:30AM–10:30AM

Background/Purpose: The association of race/ethnicity with childhood-onset systemic lupus erythematosus (cSLE) outcomes has been well described, with non-White individuals experiencing a more severe disease phenotype including increased damage accrual and higher rates of renal involvement. However, there are limited data regarding patient-reported outcomes (PROs) across race and ethnic groups in cSLE. This study assesses the association of race/ethnicity with Pediatric Global Health [PGH-7], Pain Interference, and Physical Function Mobility as measured

Table 1. Characteristics by race/ethnicity in cSLE patients

	Features by race/ethnicity						P-value**

** P-value global comparison across races/ethnicities
[1]Parental educational level (high school not completed)
[2]cSLE features and PROs at baseline visit
[3]PLN (proliferative lupus nephritis): 81/108 individuals had kidney biopsy consistent with PLN at baseline visit

by the Patient-Reported Outcomes Measurement Information System (PROMIS®) in cSLE patients at enrollment in the Childhood Arthritis and Rheumatology Research Alliance (CARRA) Registry.

Methods: The CARRA Registry is a convenience cohort of pediatric patients with rheumatic diseases including cSLE. Sites are primarily North American. This study included cSLE patients enrolled in the CARRA registry within two years from cSLE diagnosis between May 2017 to January 2020 who met ≥ 4/11 ACR classification criteria and/or ≥ 4/11 SLICC classification criteria for lupus. Baseline demographics, laboratory, and disease features as well as PROs were

obtained. Analysis of variance (ANOVA) was used to assess the difference in the PROMIS summary T-score means across races/ethnicities. Relationships between SLEDAI and PRO scores were analyzed using Pearson's correlation coefficients. Multivariable linear regression analysis was used to examine the association of race and ethnicity with PROMIS scores at baseline. P-values < 0.05 were considered statistically significant.

Results: At the time of data extraction, 588 cSLE patients met inclusion criteria: 84% were female, 24.2% non-Hispanic White, 23% African American, and 19% Hispanic. The mean age at diagnosis was 13.2 years (SD 3.1). Household income and highest parental education varied by race/ethnic group, as did frequency of rash, leukopenia, and positive anti-Sm antibody (Table 1). The cohort had low-moderate baseline disease activity, with a mean SLEDAI of 6.14 (SD 6.8). There was no difference in disease activity across races/ethnicities in one-way ANOVA analysis. The overall PROMIS PHG-7 mean T-score was 38.6 (SD 6.4), which is more than 1 SD below the general population mean of 50. The mean Pain Interference T-score of 54 (SD 10) was slightly above, and the Physical Function Mobility mean T-score of 47.5 (SD 10.13) was slightly below the population mean of 50. There was a negative moderate correlation between PROMIS Pain Interference and Physical Function Mobility (Pearson correlation coefficient: - 0.52). There was no association between race/ethnicity and PROMIS scores in multivariable linear regression analysis.

Conclusion: In this large multiethnic CARRA pediatric lupus cohort, global health (PGH-7), pain interference, and physical function mobility as measured by PROMIS did not vary across races/ethnicities. The relatively low baseline disease activity may explain this lack of association. Long-term follow-up data is needed to assess for associations between PROs and race/ethnicity over time.

Abstract Number: 0772

Pediatric Craniofacial Scleroderma: Assessing Handheld 3D Stereophotogrammetric Imaging Feasibility and Reliability

Daniel Glaser[1], Kaila Schollaert-Fitch[2], Christopher Liu[1], Jesse Goldstein[1] and Kathryn Torok[2], [1]UPMC Children's Hospital of Pittsburgh, Pittsburgh, PA, [2]University of Pittsburgh, Pittsburgh, PA

SESSION INFORMATION
Session Date: Sunday, November 7, 2021
Session Title: Pediatric Rheumatology – Clinical Poster II: SLE, JDM, & Juvenile Scleroderma (0764–0785)
Session Type: Poster Session B
Session Time: 8:30AM–10:30AM

Background/Purpose: Craniofacial scleroderma (Cf-LS), also known as Parry-Romberg Syndrome or scleroderma *en coup de sabre*, is a subtype of localized scleroderma (morphea). Diagnosis and monitoring of Cf-LS is challenging due to the spectrum of clinical manifestations and lack of robust standardized assessment tools. Digital 3D facial maps help to provide objective assessment of longitudinal facial tissue changes between clinical visits. Traditional stationary camera systems are large, expensive, and require specialized training to use. In contrast, handheld 3D cameras are portable, low-cost, and easy to use. Handheld 3D cameras have been shown to produce reliably high-quality 3D facial maps in adults both with and without craniofacial differences. We set out to determine if the same holds true for children with Cf-LS.

Table 1. Baseline Enrollment Demographics and Characteristics (N = 22).

	n (%)
Female	13 (59)
Male	9 (41)
Diagnosis	
En coup de sabre (ECDS)	17 (77)
Parry-Romberg Syndrome (PRS)	3 (14)
Overlap (PRS+ECDS)	2 (9)
Facial Level Involvement*	
Top third	18 (82)
Middle third	13 (59)
Bottom third	8 (36)
	Median (IQR)
Age (years)	13.9 (9.8 – 16.7)
Disease Duration (years)	6.1 (4.6 – 14.0)
Height (centimeters)	155 (140 – 166)
Weight (kilograms)	51.7 (32.7 – 55.6)
Body Mass Index	19.4 (18.1 – 22.6)
Tri-ponderal Mass Index	13.7 (11.7 – 15.4)

*Facial involvement is defined by landmarks. Top third is the area superior to a horizontal line passing through nasion, middle third the area inferior to a horizontal line passing through nasion and superior to a horizontal line passing through subnasale, lower third inferior to a horizontal line passing through nasion and superior to a horizontal line passing through gnathion.

Methods: Digital facial images were obtained on 22 clinically stable Cf-LS patients < 23 years of age (IRB #19080205). Each subject was photographed with a handheld Vectra H2 (Canfield Scientific) and stationary 3dMD.head.t camera systems (3dMD), with a randomized order of acquisition. Number of trials and acquisition time to obtain a satisfactory image were recorded. Descriptive statistics were reported. Consensus facial landmarks (FaceBase Consortium) were digitally applied to each map by two trained individuals. Linear and curvilinear distances between landmarks were measured (VAM software). Reliability statistics and magnitude of error between instruments were calculated.

Results: Subjects ranged in age from 3.5 – 21.5 years with a median disease duration of 6.1 years (Table 1). Mean total image acquisition time was not significantly different between the 3dMD and Vectra camera systems (3dMD =

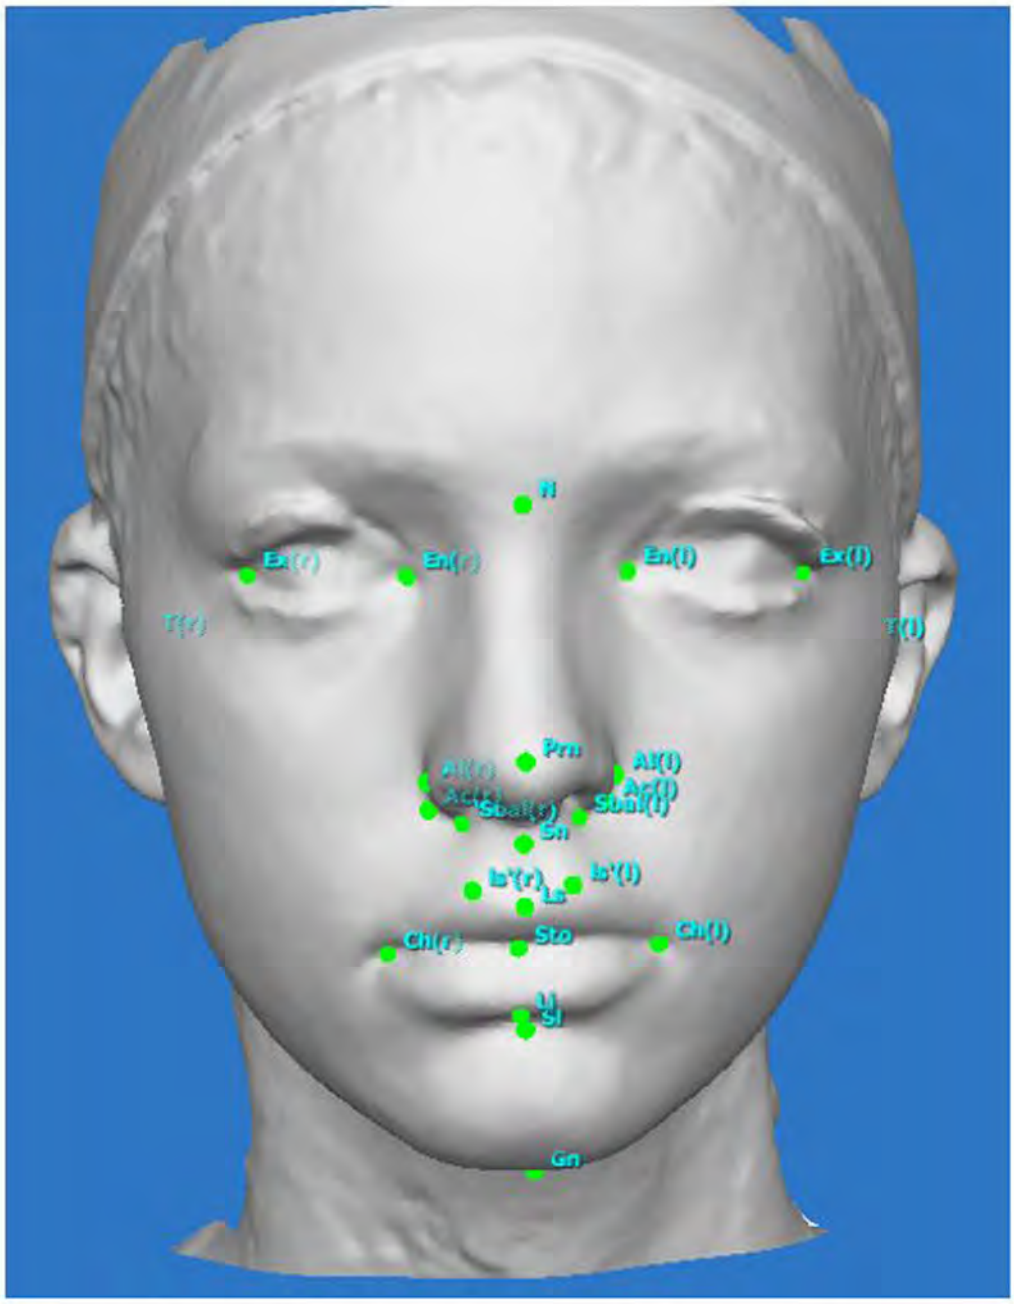

Figure 1. Twenty-four facial landmark locations for linear analysis on a representative 3D mesh. Inter-landmark distances were calculated using 3D coordinate positions of these landmarks.

59 seconds vs. Vectra = 61 seconds, p=0.71). Age was poorly related to acquisition time for both Vectra (Pearson r = -0.07) and 3dMD (Pearson r = -0.32) systems. Height was poorly related to acquisition time for the Vectra system (Pearson r = -0.21) but moderately related for the 3dMD system (Pearson r = -0.41).

Comparing the digital facial maps (Figure 1) from 3dMD and Vectra across 19 inter-landmark linear distances and 2 raters, the median technical error of measurement (TEM) was 1.91mm (range 0.6 – 9.08mm) and the median relative TEM (rTEM) was 3.85% (range 0.80% - 26.42%) (Table 2). Measurements with the highest TEM and rTEM values

Table 2. Single rater results for inter-landmark measurements comparing 3dMD to Vectra digital facial maps.

Landmarks	Mean Difference (mm)	Mean Signed Difference (mm)	TEM (mm)	rTEM (%)	Agreement Category*
Tragion(L) - Gnathion	1.42	0.12	1.03	0.80	Excellent
Gnathion - Tragion(L)	1.42	0.12	1.03	0.80	Excellent
Tragion(L) - Nasion	1.47	-0.17	1.11	0.99	Excellent
Tragion(L) - Subnasale	1.51	0.17	1.21	1.04	Very Good
Exocanthion(R) - Exocanthion(L)	1.73	-1.58	1.46	1.77	Very Good
Nasion - Stomion	1.34	-0.47	1.23	1.78	Very Good
Nasion - Gnathion	2.28	-1.28	2.04	1.83	Very Good
Alare(R) - Alare(L)	0.63	0.35	0.60	1.93	Very Good
Endocanthion(R) - Endocanthion(L)	0.87	-0.20	0.70	2.13	Very Good
Subnasale - Gnathion	2.26	0.78	2.00	3.27	Very Good
Nasion - Subnasale	2.52	-1.86	1.97	3.74	Very Good
Chelion(R) - Chelion(L)	2.05	-0.12	1.81	4.06	Good
Stomion - Gnathion	2.08	-0.81	1.84	4.10	Good
Sublabiale - Gnathion	2.35	-0.29	2.24	7.55	Moderate
Subnasale - Stomion	1.88	1.58	1.59	9.56	Moderate
Labiale superius - Stomion	1.06	0.68	0.92	12.16	Poor
Subnasale - Labiale superius	1.56	1.21	1.34	12.73	Poor
Stomion - Sublabiale	2.05	-0.52	2.01	13.09	Poor
Stomion - Labiale inferius	1.96	-0.60	2.28	26.42	Poor

* rTEM agreement categories include: < 1% (Excellent), 1 – 3.9% (Very Good), 4 – 6.9% (Good), 7 – 9.9% (Moderate), ≥ 10% (Poor).

usually involved oral and/or peri-oral landmarks. Only 36% of subjects had Cf-LS involvement of the lower third of the face. Measurements with the lowest TEM and rTEM values typically included landmarks along the midline of the face.

Conclusion: Handheld 3D cameras are easy to use and generate high quality digital facial maps in children as young as 3 years of age with craniofacial scleroderma, which are overall equivalent to images obtained by stationary cameras. Age and height did not impact the ease of obtaining handheld camera images. Measurements utilizing oral and peri-oral landmarks are most vulnerable to variation due to subtle changes in facial expression between acquisition on both camera systems. Future work will explore the accuracy of longitudinal digital facial maps for disease monitoring in the same population.

Janus Kinase (JAK) Inhibition with Baricitinib: Dosing and Patient-Reported Outcomes in Refractory Juvenile Dermatomyositis

Hanna Kim[1], Ly-Lan Bergeron[2], Samantha Dill[2], MIchelle O'Brien[2], Xiaobai Li[3], Jomy George[3], April Brundidge[2], Michelle Millwood[2], Lisa Rider[4] and Robert Colbert[5], [1]Juvenile Myositis Pathogenesis and Therapeutics Unit, NIAMS, National Institutes of Health, Bethesda, MD, [2]Office of Clinical Director, NIAMS, National Institutes of Health, Bethesda, MD, [3]Clinical Center, National Institutes of Health, Bethesda, MD, [4]NIEHS, NIH, Garrett Park, MD, [5]NIH/NIAMS, Bethesda, MD

SESSION INFORMATION

Session Date: Sunday, November 7, 2021

Session Title: Pediatric Rheumatology – Clinical Poster II: SLE, JDM, & Juvenile Scleroderma (0764–0785)

Session Type: Poster Session B

Session Time: 8:30AM–10:30AM

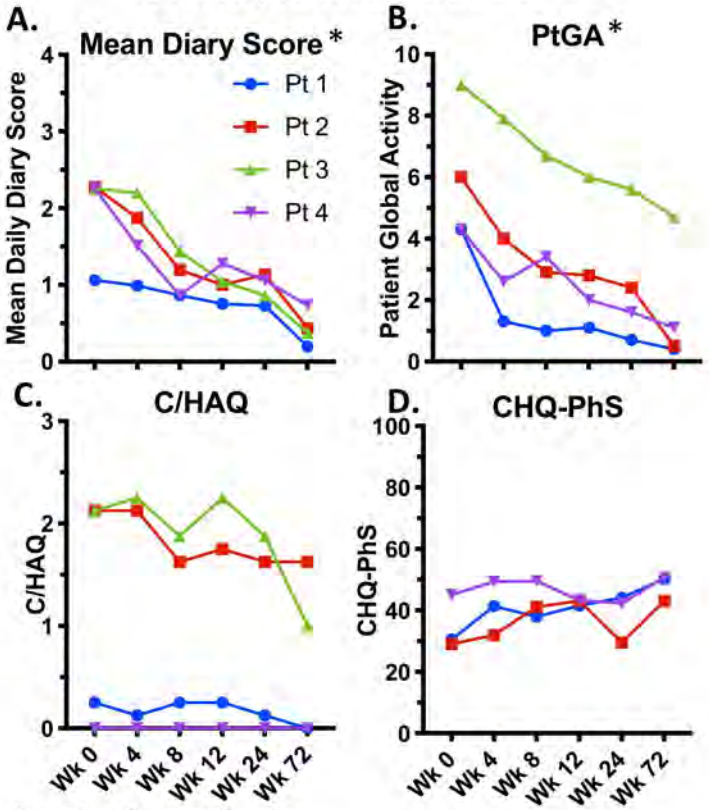
Background/Purpose: Juvenile dermatomyositis (JDM) is a systemic autoimmune disease with a prominent interferon (IFN) signature. Treatment often requires prolonged high-dose steroids and other immunosuppressive medications. In a compassionate use program, we assessed baricitinib (JAK 1/2 inhibitor) in active, refractory JDM and recently demonstrated efficacy by clinically relevant improvements in validated disease activity assessments and decreased IFN markers by 24 weeks.(1) Here we report patient-reported outcomes (PRO) and dosing with extended follow-up.

Methods: Baricitinib was dosed based on weight and renal function, with options to adjust dose based on established dosing and pharmacokinetics in pediatric interferonopathies.(2) One of the primary outcomes was reduction in symptom daily diary score (DDS) of weakness, fatigue, musculoskeletal pain, and rash. Each symptom was graded based on impact from 0 (no impact, not present) to 4 (maximal impact, highest grade), with symptom categories averaged for diary scores. DDS were collected for at least 2 weeks prior to starting investigational drug and then daily throughout the program. Other PROs included Patient/Parent Global Assessment (PtGA) by visual analog scale, (Childhood) Health Assessment Questionnaire (C/HAQ), and Childhood Health Questionnaire–Physical Summary Score (CHQ-PhS). Linear mixed models were used to compare measures to baseline. Safety and tolerability were assessed.

Results: Four patients with JDM (5.8-20.7 years old) were enrolled (NCT01724580), with at least 72 weeks of follow-up data collected. Patient diaries were collected for a total of 2167 days, with 2163 (99.8%) days of diary entries completed. At 72 weeks, DDS changed from a mean of 2.0/4.0 (range 1.1-2.3) to 0.4 (0.2-0.7; 68-83% decrease, $p< 0.01$) (Fig 1A). PtGA decreased from a mean of 5.9/10.0 (4.3-9.0) to 1.7 (0.4-4.7; 48-92% decrease, $p< 0.01$) (Fig 1B). C/HAQ decreased from mean 1.13/3.0 (range 0.0-2.13) to 0.66 (0.0-1.63, 0-100% decrease), indicating less disability (Fig 1C). CHQ-PhS (n=3) increased from mean 34.9/100 (29.1-45.0) to 48.0 (43.0-50.7; 13-65% increase), indicating improved physical function-related quality of life (Fig 1D). Patients were started on baricitinib 4-8mg PO per day divided BID or TID, and at last time point were on 5-12 mg/day divided BID. Dose adjustments were made based on renal function, safety laboratories, and/or efficacy in three patients. Baricitinib was generally well tolerated. There were no serious adverse events (AEs). Infections were the most common AE; Most common infection was upper respiratory infection. No AEs required holding/discontinuing baricitinib.

Conclusion: Patient-reported outcome data using baricitinib in four patients with refractory JDM supports shows continued improvement in symptoms with less disability and better physical function-related quality of life. Minor baricitinib dosing adjustments within the dosing range for pediatric interferonopathies were generally well tolerated.

Figure 1: Patient-reported outcomes in refractory JDM on baricitinib



*: p-value <0.1 versus baseline.

Patient-reported outcomes shown at baseline (week or wk 0), and then at week 4, 8, 12, and 24, and 72 for (A) mean Daily Diary score (DDS) out of 4, (B) Patient Global Activity (PtGA) out of 10, (C) Childhood Health Assessment Questionnaire (CHAQ) for 3 pediatric patients and Health Assessment Questionnaire (HAQ) for 1 adult patient out of 3, and (D) Childhood Health Questionnaire – Physical Function Summary Score (CHQ-PhS) out of 100 for 3 pediatric patients. A decrease indicates improvement for A-C, while an increase indicates improvement for D.

Disclosures: Baricitinib provided by Eli Lilly & Company, expanded access program sponsor. Other support: IRP of NIH, NIAMS, NIEHS, CC.

The Impact of Patient/Provider Discordance on Changes on Mood and Behavior in Adolescents with Systemic Lupus Erythematosus

Zanab Mian[1], Terrence Calistro[2], Kimberly Rapoza[2], Shari Berkowitz[2], Tamar Rubinstein[3], Kathleen Kenney-Riley[2] and Joyce Hui-Yuen[4], [1]Cohen Children's Medical Center, New Hyde Park, NY, [2]Mercy College, Dobbs Ferry, NY, [3]Albert Einstein College of Medicine, White Plains, NY, [4]Cohen Childrens Medical Center, New Hyde Park, NY

SESSION INFORMATION
Session Date: Sunday, November 7, 2021
Session Title: Pediatric Rheumatology – Clinical Poster II: SLE, JDM, & Juvenile Scleroderma (0764–0785)
Session Type: Poster Session B
Session Time: 8:30AM–10:30AM

Background/Purpose: Discordance between physicians' and patients' perceptions of disease severity can negatively impact treatment and disease outcomes; this has not yet been studied in children and adolescents with systemic lupus erythematosus (SLE). Neuropsychiatric symptoms, including depression and anxiety, can be present in up to 65% of adolescents with SLE. We propose to investigate the incidence of mood and behavioral changes, and its association with discordance between patient and physician perceptions of disease severity.

Methods: This is a multicenter pilot study conducted between September 2019 and April 2021. Patients over 12 years of age, diagnosed with SLE before their 19th birthdays, and who met ACR or SLICC Lupus classification criteria, were enrolled from two tertiary pediatric rheumatology centers in NY (one urban and one suburban). Data including demographics, disease manifestations, medications, and disease severity were collected. Patients completed standardized surveys assessing depression and various measures of quality of life. Global scores were obtained from individual patients and providers, analyzed via two-tailed t-tests, and compared with survey data using Pearson's correlations. A p-value of < 0.05 was considered significant.

Results: A total of 58 patients were enrolled, 40 from the urban center and 18 from the suburban center. Overall, the mean age at enrollment was 19 (13-23) years, with 81% female. The two cohorts identified ethnicity and race as 47% Hispanic, 38% Black, 6% White, and 3% as Alaskan Native/American Indian. There were no differences between the two cohorts on administered Kidscreen-52, Adverse Childhood Experience, and most Promis-25 survey subsections specifically focused on psychosocial factors, fatigue, mood, and cognition. However, the suburban cohort demonstrated higher depression scores on CES-D (mean 24.05, $p=0.008$), indicative of severe depression, and higher emotional scores on PedsQL (mean 9.58, $p=0.01$). The overall mean patient global score was 3.0 (range 0-9), and physician global was 1.44 (range 0-7). Patient/physician discordance was noted to be higher in the urban-based institution (p=NS), possibly indicating that patient perception of disease was often more severe than provider assessment. Discordance was also associated with items from PedsQL school ($r=0.41$, $p< 0.05$) and PROMIS depression subsections ($r=0.34$, $p< 0.05$).

Conclusion: We found that pediatric SLE patients in an urban based center demonstrated higher patient/physician discordance when compared to a suburban cohort. However, adolescents with SLE demonstrated higher rates of depression and emotional changes at a suburban-based center, despite physician perception of stable disease.

SESSION INFORMATION

Session Date: Sunday, November 7, 2021

Session Title: Pediatric Rheumatology – Clinical Poster II: SLE, JDM, & Juvenile Scleroderma (0764–0785)

Session Type: Poster Session B

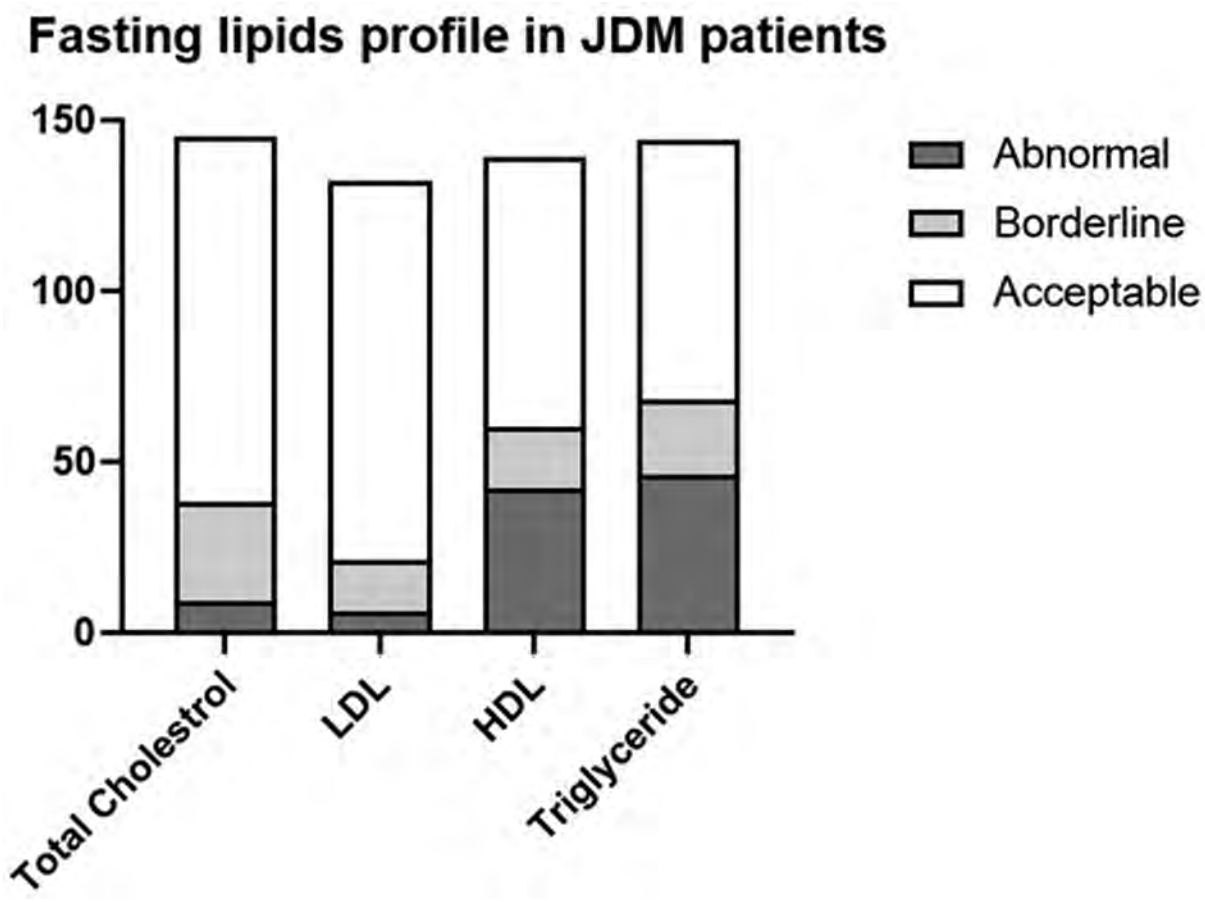
Session Time: 8:30AM–10:30AM

Background/Purpose: Juvenile Dermatomyositis (JDM) is the most common inflammatory myopathy of childhood and is characterized by chronic inflammation targeting muscle and skin. Older patients who had JDM in childhood have a higher risk of atherosclerosis, documented by increased intima-media thickness. Paraoxonase 1 (PON1) is a hydrolytic enzyme associated with HDL and essential to protecting against LDL oxidation. Lower PON1 activity is linked with increased CAD risk. We hypothesize that, in JDM, dyslipidemia and HDL's antioxidant function is associated with the severity of systemic inflammation. We focused on the association of neopterin and dyslipidemia because TNF alpha, a proinflammatory cytokine produced by activated macrophage, can lead to dyslipidemia; elevated neopterin levels document macrophages activation.

Methods: This IRB-approved retrospective study was conducted at the Ann and Robert H. Lurie Children's Hospital of Chicago. All JDM patients (n= 143) who had fasting lipid profile, disease activity score (DAS), and neopterin level at the same visit were included. Normal, borderline and abnormal lipid profile values for children was defined based on the American Academy of Pediatrics guideline. HDL's antioxidant function evident by paraoxonase, lactonase, and arylesterase activity was measured by Dr. Charles-Schoeman's lab on 42 untreated JDM and 42 controls.

Results: Of 143 JDM patients included, 75% were female, and 70% were white. Only 12% of the subjects had lipid profiles before steroid treatment. While 88% of the untreated subject had low or borderline HDL and 75% had high or borderline triglycerides , only 13% had high or borderline LDL. Of the study population (n=143) 24% had elevated neopterin levels. Those with elevated neopterin levels had significantly lower mean HDL levels at 38.6 +/- 14.7 than JDM with normal neopterin at 51.6 +/- 14.9 and $p < 0.0001$. There was a significant negative correlation between HDL and various disease activity marker such as Neopterin ($R2=0.17$, $p < 0.0001$), DAS-total ($R2=0.16$ $p < 0.0001$), DAS-Muscle Weakness ($R2=0.19$, $p < 0.0001$) and DAS-Skin ($R2=0.07$, $p = 0.001$). We then examined the HDL antioxidative ability in 42 untreated JDM and age-matched control. JDM patients showed significantly lower lactonase activity (19.1 U/ml vs 23.9 U/ml p =0.005) and arylesterase activity (165.3 U/ml vs 189.4 U/ml p=0.04). Furthermore, there was a significant correlation between arylesterase enzyme activity and various disease activity markers such as Neopterin ($R2=0.22$, $p =0.004$), DAS-total ($R2=0.18$ p 0.005), DAS-Muscle Weakness ($R2=0.19$, $p =0.004$) and CMAS ($R2=0.16$, $p =0.01$). A similar correlation was found between lactonase as disease activity markers.

Conclusion: JDM patients have an increased prevalence of elevated TG and low HDL, especially before treatment. JDM patients with low HDL levels have more disease activity, as evidenced by DAS and elevated neopterin. Of note, the antioxidant capacity of HDL appeared to be reduced in JDM compared to control, and the degree of reduction



was associated with disease activity indicators. These findings suggest that early control of inflammation in JDM might improve HDL levels and their function.

Genetics of Neonatal Lupus Erythematosus Risk and Specific Manifestations

Melissa Misztal[1], Fangming Liao[2], Talia Diaz[2], Zeynep Baskurt[2], JingJing Cao[2], Daniela Dominguez[2], Deborah Levy[2], Andrea Knight[3] and Linda Hiraki[2], [1]The Hospital for Sick Children, Oakville, ON, Canada, [2]The Hospital for Sick Children, Toronto, ON, Canada, [3]Hospital for Sick Children, Toronto, ON, Canada

SESSION INFORMATION
Session Date: Sunday, November 7, 2021
Session Title: Pediatric Rheumatology – Clinical Poster II: SLE, JDM, & Juvenile Scleroderma (0764–0785)
Session Type: Poster Session B
Session Time: 8:30AM–10:30AM

Background/Purpose: Neonatal lupus erythematosus (NLE) is a passively acquired autoimmune disease in infants, secondary to the transplacental passage of maternal autoantibodies against Ro and/or La. The presence of anti-Ro

and/or La antibodies are necessary for NLE, but insufficient for disease suggesting additional risk factors. Genetics may impact NLE risk. We analyzed systemic lupus erythematosus (SLE) susceptibility loci in infants and their anti-Ro antibody positive mothers, with NLE risk and NLE specific manifestations.

Table 1. Cohort Demographics and NLE Manifestations. a Data includes 21 infants with self-reported ethnicity instead of genetically inferred ancestry, and 2 infants without genetically inferred or self-reported ethnicity. b Percentage of total cardiac NLE cases. c Percentage of total hematologic NLE cases. d Percentage of total rheumatic disease diagnoses.

Infants	n=287 (%) [a]
Female (%F)	148 (52)
Ethnicity	
European	118 (41)
East Asian	53 (18)
South Asian	45 (16)
Amerindian	22 (8)
African	21 (7)
Admixed	26 (9)
First born children	154 (54)
Previous sibling with NLE	24 (8)
NLE	156 (54)
Cardiac	20 (7)
Complete Heart Block	17 (85) [b]
Cutaneous	36 (13)
Hepatic	88 (31)
Neurologic	13 (5)
Hematologic	67 (23)
Neutropenic	61 (91) [c]
Thrombocytopenic	7 (10) [c]
Mothers	n=233 (%)
Rheumatic Disease Diagnosis	168 (72)
SLE	112 (67) [d]
Sjogren's Syndrome	32 (19) [d]
Hydroxychloroquine use during pregnancy	90 (39)

Table 2. Association between SLE-PRS and NLE Outcome. a a Models adjusted for PCs, prior NLE affected infants, maternal rheumatic disease and maternal hydroxychloroquine use during pregnancy.

	OR (95% CI) *P*-value		
	Infant PRS (n=264)	Mother PRS (n=423)	Mother-Infant PRS (n=212)
NLE	0.99 (0.79,1.26) 0.99	0.92 (0.71,1.19) 0.52	0.98 (0.74,1.30) 0.89
Cardiac NLE	1.04 (0.63,1.73) 0.87	1.19 (0.70,2.02) 0.52	1.20 (0.71,2.04) 0.49
Cutaneous NLE	0.83 (0.58,1.20) 0.33	0.87 (0.59,1.28) 0.48	1.22 (0.79,1.90) 0.37

Methods: We recruited infants born to anti-Ro positive mothers from the NLE clinic at The Hospital for Sick Children. Infants and mothers underwent genotyping on the Illumina Global Screening Array. Ancestry was genetically inferred from principal components (PCs) and Admixture, or self-reported based on Canada census categories. We created additive non-HLA SLE polygenic risk scores (PRSs) using 70 common SLE-risk SNPs from the largest SLE genome wide association study to date. Outcomes were defined as (1) any NLE, (2) cardiac NLE and (3) cutaneous NLE. We tested the association between SLE PRSs in the infant and in the mother with NLE outcomes, in logistic regression models using Generalized linear Mixed Model Association Tests (GMMAT). GMMAT enables inclusion of first-degree relatives in analyses by accounting for relatedness. In order to examine the degree of discordance between maternal and infant PRS, we regressed the difference between mother and infant PRS on NLE outcomes. Models were adjusted for PCs, prior NLE affected infants, maternal rheumatic disease status and hydroxychloroquine use during pregnancy.

Results: The study included 287 infants born to 233 anti-Ro positive mothers, with 212 genotyped maternal-infant pairs. The majority of infants were European (41%) or East Asian (18%), 52% were female, and 8% had a prior NLE affected sibling. Over half of the infants in the cohort had NLE (54%), including 7% with cardiac NLE and 13% with cutaneous NLE. Of the mothers, 41% were European and 21% were East Asian. A total of 168 mothers (72%) had a rheumatic disease diagnosis and 90 mothers (39%) were on hydroxychloroquine during pregnancy (Table 1).

We did not observe a significant association between infant, maternal or maternal-infant SLE-PRSs and any NLE, cardiac NLE or cutaneous NLE in adjusted GMMAT models (Table 2).

Conclusion: In our multiethnic cohort of infants born to Ro positive mothers, we did not identify a significant association between SLE genetics and risk of NLE or its manifestations. Additional studies are required to replicate our findings.

Potential Biomarkers of Cognitive Impairment in the Context of Childhood-Onset Systemic Lupus Erythematosus

Santiago Arciniegas[1], Sarah Mossad[2], Tala El Tal[3], Lawrence Ng[4], Paris Moaf[4], Helen Branson[4], Adrienne Davis[4], Linda Hiraki[4], Deborah Levy[4], Ashley Danguecan[2] and Andrea Knight[2], [1]University of Toronto/The Hospital for Sick Children, Toronto, ON, Canada, [2]Hospital for Sick Children, Toronto, ON, Canada, [3]University of Toronto/Hospital for Sick Children, Toronto, ON, Canada, [4]The Hospital for Sick Children, Toronto, ON, Canada

SESSION INFORMATION

Session Date: Sunday, November 7, 2021

Session Title: Pediatric Rheumatology – Clinical Poster II: SLE, JDM, & Juvenile Scleroderma (0764–0785)

Session Type: Poster Session B

Session Time: 8:30AM–10:30AM

Background/Purpose: Cognitive complaints are common in children with childhood-onset systemic lupus erythematosus (cSLE), but neuropsychiatric lupus (NPSLE) remains challenging to diagnose and treat. To increase understanding of contributing mechanisms, we examined the association between cognitive function, disease measures and structural neuroimaging metrics.

Methods: We examined a cross-sectional sample of 24 patients with cSLE (ages 12-17) meeting ACR or SLICC classification criteria. Patients completed standardized traditional neurocognitive tests quantifying domains of attention and inhibition (CPT-3, Conners' Continuous Performance Test 3rd ed), working memory (WISC-V, Wechsler Intelligence Scale for Children 5th ed), and cognitive flexibility (D-KEFS, Delis-Kaplan Executive Function System). Cognitive impairment was defined as a score of 1.5 standard deviations below the mean in any domain. T1-weighted brain magnetic resonance images (MRI) were obtained using a 3T scanner. Advanced structural MRI analysis was used to extract volume, cortical thickness, and surface area metrics for brain segments. Demographic and disease measures were extracted from medical records. We used Partial Least-Squares Regression (PLS2), to examine the association between cognitive function (continuous outcome) and its potential predictors, comprised of structural brain metrics as well as disease and demographic measures. PLS2 analysis enables description of interactions between multivariate and potentially collinear data with a relatively small sample size. Each predictor's relevance criteria (i.e., stability and significance) were based on the bootstrapped sample distribution of its variable importance in projection (VIP) value, which measures the relative weight of a predictor across all outcome variables.

Results: Cognitive impairment was present in 42% (10/24) of patients; only one subject had a diagnosis of NPSLE (Table 1). In PSL2 analysis (Figure 1), 52 predictors were found to be relevant in the estimation of cognitive function (CI = 95%, VIP > 1.18). Of these, 50 were brain structure variables, with the most highly associated brain measures deriving from the frontal lobe (n=19), temporal lobe (n=11), occipital lobe (n=9) and cingulate cortex (n=7). The surface area and volume of the mid-posterior corpus callosum, total left and bilateral cortical volumes, the level of CRP and the age of patients at study visit were also found to be relevant predictors of cognitive function.

Conclusion: Objective cognitive impairment was prevalent in >40% of patients with cSLE. Impairment was strongly associated with several structural brain metrics, most of which derived from the frontal lobe. Only one disease-related factor (CRP) and one demographic factor (patient age) were found to be relevant predictors of cognitive function. Our results suggest that computational modeling has the potential to enhance diagnosis of NPSLE. Further study is needed to identify robust disease biomarkers that can be linked to functional and structural brain metrics with the use of machine learning models.

Table 1: Summary of demographic and lupus disease features in the cSLE cohort (n=24)	
Sex (Female, %)	20 (83%)
Age in years, Mean ± SD	15.4±1.7
Race (n, %)	
Asian	8 (33%)
White	8 (33%)
Black or African American	2 (8%)
Hispanic	2 (8%)
Mixed	2 (8%)
American Indian or Alaskan Native	1 (4%)
Middle Eastern	1 (4%)
Highest Household Education, n (%)	
College Diploma	6 (25%)
High School Diploma	6 (25%)
Bachelor's Degree	5 (21%)
Advanced Degree (Master's, Doctoral, Professional)	4 (16%)
Some College/University	3 (13%)
Household income (n, %)	
$90,000 or more	7 (29%)
$40,000 - <$90,000	13 (54%)
$15,000 - <$40,000	4 (17%)
Disease Measures	
Age at diagnosis of SLE in years, median (IQR)	13 (11-15)
Age at study visit in years, median (IQR)	16 (14-16)
Disease duration in years, median (IQR)	1.8 (1.0-3.1)
SLEDAI at study visit, median (IQR)	2 (1.5-4.2)
Mean SLEDAI in preceding year per patient, median (IQR)	3 (1.2-7)
Physician Global Assessment Scale (PGA) at study visit, median (IQR)	0.5 (0-2)
Level of C-Reactive Protein (CRP) at study visit, median (IQR)	0.6 (0.2-1.8)
Erythrocyte Sedimentation Ratio (ESR) at study visit, median (IQR)	17 (7-31)
Level of anti-double stranded DNA (anti-dsDNA) at study visit, median (IQR)	26.1 (9.8-130.7)

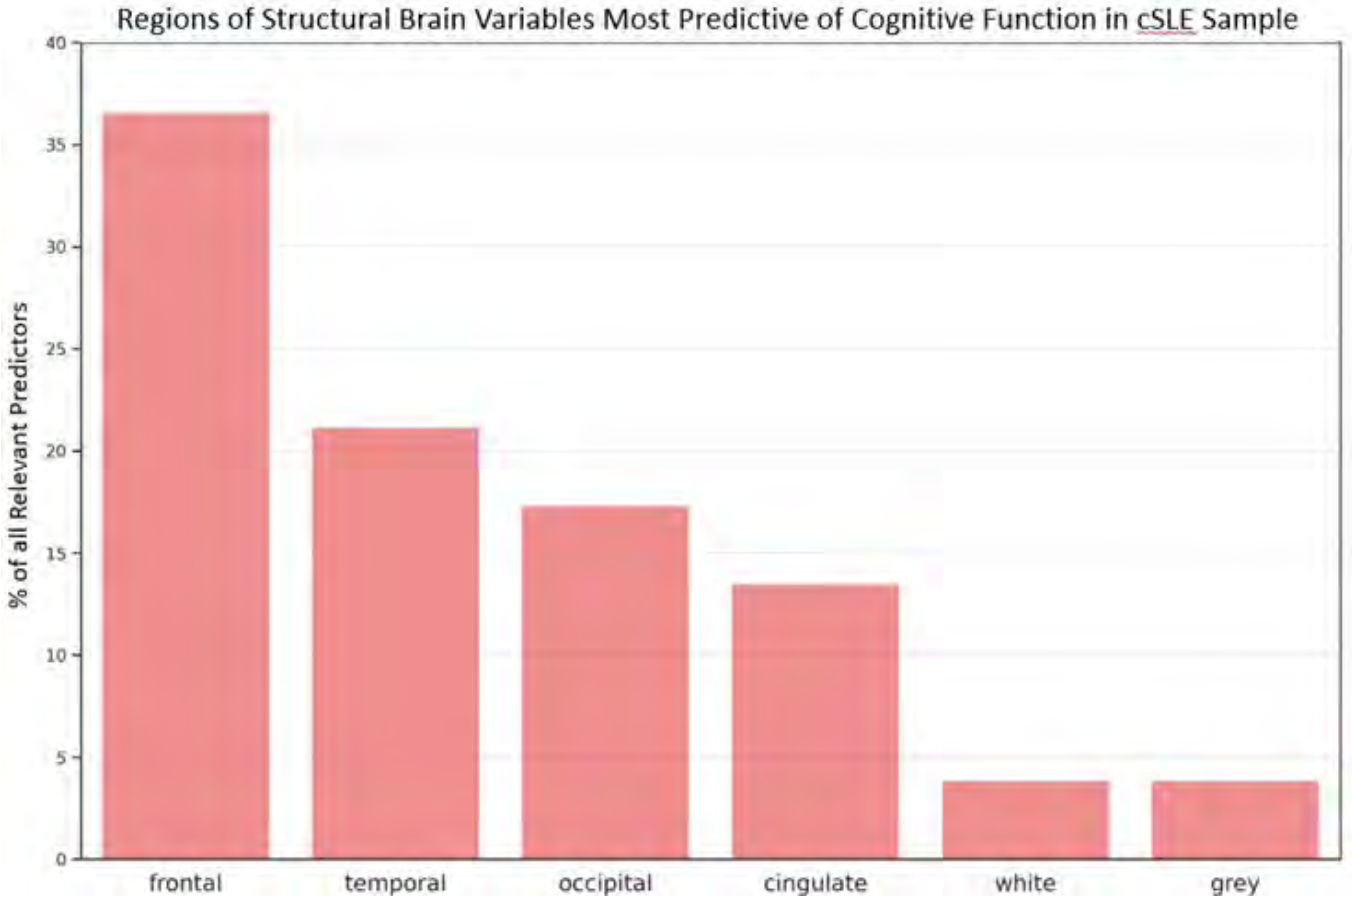

Figure 1. Shown is the distribution of the most relevant structural predictors of cognitive function in cSLE patients. Predictors are grouped per category and reported as a percentage of the all relevant predictors found in partial least squares analysis. Relevant white matter predictors are the area and volume of the mid-posterior corpus callosum. Relevant grey matter predictors are the total left and bilateral cortical volumes. No relevant predictors were found in the parietal lobe, subcortical structures, cerebellum or brainstem.

Autologous Stem Cell Transplantation with CD34-Selected Peripheral Blood Stem Cells in Patients with Treatment-Resistant Juvenile-Onset Systemic Sclerosis

Kathryn Torok[1], Franziska Rosser[2], Kirsten Rose-Felker[1], Vibha Sood[1], Geoffrey Kurland[1], Adam Olson[1], Meghan Frost[1], Vickie Vandergrift[1], Shawna McIntyre[1], Alisha Maslanka[3], Kaila Schollaert-Fitch[1], Jessie Barnum[1] and Paul Szabolcs[1], [1]University of Pittsburgh, Pittsburgh, PA, [2]UPMC Children's Hospital of Pittbsurgh, Pittsburgh, PA, [3]University of Pittsburgh, Pittsburgh

SESSION INFORMATION
Session Date: Sunday, November 7, 2021
Session Title: Pediatric Rheumatology – Clinical Poster II: SLE, JDM, & Juvenile Scleroderma (0764–0785)
Session Type: Poster Session B
Session Time: 8:30AM–10:30AM

Background/Purpose: Juvenile-onset systemic sclerosis (jSSc) is a rare autoimmune disease associated with life-threatening multi-organ inflammation and fibrosis. As in adults, jSSc organ involvement includes vascular, cutaneous, gastrointestinal, pulmonary, and musculoskeletal systems. Treatment options are limited for aggressive and recalcitrant SSc, however advances in adult SSc therapies support Autologous Stem Cell Transplant (ASCT) as a safe option to reset the immune system and prevent eminent decline. Our center has developed reduced intensity conditioning protocols for both pediatric and adult onset SSc using CD34-selected peripheral blood ASCT, including our Immune Transplant and Therapy Center (ITTC) protocol (ClinicalTrials.gov Identifier: NCT03630211). We report initial safety and clinical response of three jSSc patients who received ASCT at our center (Table 1) with comorbidities too advanced even for our trial.

Methods: Patients with severe and progressive disease referred to our center were evaluated by pediatric rheumatologist (KT) and referred to BMT (PS, JB) if deemed to be refractory to standard clinical care. A dedicated multidisciplinary team evaluated the patients (Rheum, BMT, Cards, Pulm, GI) to determine baseline status and eligibility for an existing protocol (ITTC) or an Investigational New Drug (IND) application if more suitable. After IRB approval and consent, patients underwent ASCT with standardized safety, clinical outcome, and patient reported measures collected at baseline (pre-ASCT), 6, and 12 months-post ASCT.

Results: Three jSSc patients were eligible to receive ASCT by the multi-disciplinary team (Table 1); all failed to meet ITTC eligibility criteria due to poor respiratory function (FVC < 45% and/or DLCO < 40%; and 6MWT < 400m; see Table 1) and had individual INDs approved for ASCT. All consisted of Cyclophosphamide 120 mg/kg, total body irradiation (6 Gy in 3 fractions with liver and kidney shielding) and ATGAM. At time points of 15 months-post ASCT, 6 months-post ASCT, and engraftment for patients 1, 2, and 3, respectively, only patient 2 had a major safety concern, a significant ATGAM reaction requiring a brief ICU stay for increased supportive needs, with protocol resumption within 48 hours. Patient 3 had a milder ATGAM reaction. There have been no serious infections or organ dysfunction to date. All patients showed improvement in clinical outcomes of mRSS, range of motion, physical functioning (HAQ), and several PRO domains including dyspnea, Raynaud's phenomenon, and gastrointestinal symptoms (Table 2).

Conclusion: Our preliminary data supports the safety and efficacy of ASCT with CD34-Selected Peripheral Blood Stem Cells in jSSc. Two subjects had 7+ years of duration: one with more limited skin disease, and the other with overlap disease with myositis, both with positive outcomes. Expansion of ASCT eligibility to include children, adolescents and young adults and those with clinical features beyond classic early diffuse cutaneous SSc should be considered while maintaining an acceptable safety profile.

Table 1. Caption: a Clinical variables that would have failed adult SSc entry criteria ASCT trials: Autologous Stem Cell Transplantation International Trial (ASTIS) (van Laar et al JAMA 2014; 311(24)) and Scleroderma: Cyclophosphamide or Transplantation (SCOT) (Sullivan et al NEJM 2018; 378(11)). b Additional clinical variables that would have failed adult SSc entry criteria ITTC trial (6MWT >400). c Values represent percent predicted based on GLI2012 prediction equations for FVC and DLCO Quanjer et al. Eur Respir J 2012;40(6), and Rosenthal et al. Thorax 1993;48(8) for TLC. d Percent predicted based on Geiger et. al. J Pediatrics 2007; 150(4), pediatric prediction equations. e SpO2 was monitored continuously during 6MWT via forehead probe. Abbreviations: dcSSc (diffuse cutaneous systemic sclerosis); lcSSc (limited cutaneous systemic sclerosis); Scl-70 (scleroderma-70 anti-topoisomerase antibody); PM-Scl (polymyositis-scleroderma overlap antibody); ILD (interstitial lung disease); PHTN – (pulmonary hypertension)

Abbreviations: ASCT (autologous stem cell transplant); VAS (Visual Analog Scale); HAQ (Health Assessment Questionnaire); LES (lower esophageal sphincter); GIT (scleroderma gastrointestinal tract instrument); FVC (forced vital capacity); DLCO (diffusing capacity for carbon monoxide); 6MWT (6 minute walk test). GLI2012 prediction equations used for both FVC and DLCO. * Indicates a patient reported outcome. VAS scale on HAQ, GIT, CHAQ are 0 to 3; higher number reflects more interference of disease with function. a Comparability to prior tests is limited as patient's home portable oxygen concentrator, used on prior tests, was unavailable thus the patient carried a portable oxygen tank. 6MWT values here are likely not fully reflective of patient's ability.

SESSION INFORMATION

Session Date: Sunday, November 7, 2021

Session Title: Pediatric Rheumatology – Clinical Poster II: SLE, JDM, & Juvenile Scleroderma (0764–0785)

Session Type: Poster Session B

Session Time: 8:30AM–10:30AM

Background/Purpose: Childhood-onset Systemic lupus erythematosus (cSLE) is an inflammatory autoimmune disease known for its complex and variable clinical presentation and disease course. Its severity may vary according to different organs involved and is usually life-threatening and have poorer outcome compared to adults (aSLE), leading to significant morbidity and mortality. The objectives of this study were to identify predictors of mortality of cSLE and to evaluate their association with clinical manifestations, laboratory features, disease activity and damage, current treatment, survival and causes of death.

Methods: This is a multicenter, nationwide observational study of a cohort of 1,528 cSLE patients followed in 27 Brazilian pediatric rheumatology tertiary centers. In this study, we investigated cumulative risk factors for mortality in a large sample of cSLE patients. We also compared its association with cumulative clinical and laboratory features, as well as disease activity and damage, cumulative treatment, outcome and causes of death.

Results: Mortality between patients was 4.1% (63/1528), occurring in a median period of 3.2 years after diagnosis, with predominance of girls (84.1%). The most frequent causes of death were sepsis/infectious disease in 29/63 (29%) and cSLE activity in 8/63 (12.7%). In 12/63 (19%) the cause was unknown. After Bonferroni´s correction for multiple comparisons ($p<0.0017$), determinants significantly associated with mortality were constitutional symptoms, skin vasculitis, pericarditis, arterial hypertension, acute renal injury, chronic kidney disease (CKD), neuropsychiatric (NP-SLE), thrombocytopenia, higher score of SLEDAI-2K at last visit or death, and SLICC/ACR-DI especially in renal domain. The use of intravenous methylprednisolone, cyclosporine, cyclophosphamide, and rituximab at last visit or death were also more frequent. In the multivariate regression model analysis, NP-SLE ($p=0.001$) and CKD ($p=<0.0001$) were significant factors associated to death. Patients with NP-SLE had 2.6 times higher risk of death (HR=2.56, 95%CI=1.48-4.42) compared to cSLE patients who did not present NP-SLE, and the risk of death in patients with CKD increases 4.3 times (HR=4.33, 95%CI=2.33-8.04). The Kaplan-Meier overall curve showed worse survival in patients with NP-SLE ($p=<0.0001$), proliferative nephritis ($p=0.02$) and CKD ($p=<0.0001$). Overall patient survival after diagnosis at 1, 5 and 10 years were 98.5%, 97% and 95.4% respectively.

Table 1 – Demographic data, clinical and laboratorial features, disease activity and disease damage score, and treatment at last visit/death in 1528 cSLE patients dead and alive.

Results are presented in n (%) and median (min-max).
The bold numbers express the p value that are statistically significant. *p value according to Bonferroni correction for multiple comparisons (p<0.0017).
NA: not analyzed.
CKD – Chronic kidney disease, LN – lupus nephritis, SLEDAI-2K – Systemic Lupus Erythematosus Disease Activity Index 2000, SLICC-ACR/DI – Systemic Lupus International Collaborating Clinics/ACR-Damage Index, VDRL – venereal disease research laboratory, g – gram.

Conclusion: This study showed that cSLE patients with CKD and NP-SLE exhibited higher hazard rates of progression to poor outcomes. Therefore, those patients could benefit from early aggressive management of active lupus nephritis and NP-SLE, especially within the first years after diagnosis.

High Adolescent Health Needs and Relationship to Disease in Patients with Childhood-Onset Systemic Lupus Erythematosus

Chelsea DeCoste[1], Paris Moaf[1], Lawrence Ng[1], Dragana Ostojic-Aitkens[1], Fatima Faruq[2], Byran Maguire[3], Deborah Levy[1], Linda Hiraki[1], Alene Toulany[1] and Andrea Knight[4], [1]The Hospital for Sick Children, Toronto, ON, Canada, [2]University of Toronto, Toronto, ON, Canada, [3]Research Institute, The Hospital for Sick Children, Toronto, ON, Canada, [4]Hospital for Sick Children, Toronto, ON, Canada

SESSION INFORMATION

Session Date: Sunday, November 7, 2021

Session Title: Pediatric Rheumatology – Clinical Poster II: SLE, JDM, & Juvenile Scleroderma (0764–0785)

Session Type: Poster Session B

Session Time: 8:30AM–10:30AM

Background/Purpose: Childhood-onset systemic lupus erythematosus (cSLE), with typical onset in adolescence, is a chronic life-threatening disease. In addition to dealing with cSLE, these adolescents endure the unique psychosocial and physical health challenges of this life stage. We aimed to characterize the burden of adolescent health issues faced by patients with cSLE, as well as demographic and disease characteristics associated with adverse adolescent health.

Methods: We conducted a retrospective cohort study of adolescents age 12-18 years with cSLE (meeting ACR and SLICC classification criteria) who were seen by Adolescent Medicine (AM) specialists in the Lupus Clinic at SickKids Hospital, between July 2018-July 2020. As part of our cSLE care model, patients presenting with adolescent health issues were routinely seen by AM in the clinic. Adolescent health issues were characterized using the HEADDSS framework (**H**ome, **E**ducation/**e**mployment, peer group **A**ctivities, **D**rugs, **S**exuality, and **S**uicide/depression), which was standardly recorded for all AM visits. Issues were classified as presenting and/or identified problems at each visit. Adolescent health burden was tabulated as the number of individual adolescent issues identified per patient. Multiple Poisson regression was used to examine associated patient factors, including age, gender, material deprivation score (measure of social marginalization that accounts for income, housing quality, educational attainment, and family structure), SLE disease activity and damage indices, and high-dose glucocorticoid exposure (>3 months and any-time dose of >30mg prednisone equivalent).

Results: 226 adolescents with cSLE were seen in the Lupus Clinic during the observation period, of which 106 (47%) were seen by AM. Of these, 88 (83%) were female. Median age at first visit was 14 years (IQR 13, 16). Additional patient characteristics are shown in Table 1. Patients had a median of 2 (1, 3) visits with AM over the study period. Figure 1 shows the range of adolescent health issues described across all visits, of which mood was identified as the top adolescent issue (presenting problem in 22%, and identified issue in 51% of patients). Patients had an average adolescent health burden of 2.8 ± 2.31, defined as the number of separate adolescent health issues identified over the study period. In multiple regression analyses, higher adolescent issue burden was associated with higher glucocorticoid exposure (RR=1.72, 95% CI 1.32-2.24), presence of damage (RR=1.30, 95% CI 1.30, 95% CI 0.99-1.70), higher material deprivation (RR=1.16, CI 1.03-1.29), and lower disease activity (RR=0.96, 95% CI 0.92-0.99). The most common service provided by AM was psychoeducation at 54% (Table 2).

Conclusion: Adolescents with cSLE experience a wide range of physical, emotional, and social issues in addition to their underlying disease. We found that increased cSLE disease severity and social marginalization put teens at higher risk of worse adolescent health issues. This highlights the need to discuss adolescent health during rheumatology clinic visits, and the importance of integrating AM specialists into routine cSLE care.

Table 1. Demographics & Disease Characteristics of Patients with cSLE in Adolescent Medicine Care (n=106)

SESSION INFORMATION

Session Date: Sunday, November 7, 2021

Session Title: Pediatric Rheumatology – Clinical Poster II: SLE, JDM, & Juvenile Scleroderma (0764–0785)

Session Type: Poster Session B

Session Time: 8:30AM–10:30AM

Background/Purpose: Juvenile localized scleroderma (jLS) is a rare chronic inflammatory and fibrosing disease associated with a high risk for morbidity in children. Methotrexate (MTX) has been identified as effective treatment, but data is limited as to the optimal duration, and need for corticosteroid (CS) treatment. The LS group of the Childhood Arthritis and Rheumatology Research Alliance (CARRA) developed standardized regimens (consensus treatment plans, CTPs) for comparative effectiveness studies. The results of a 1-year follow-up of a pilot multi-center study of treating 50 patients with a MTX-based CTP were previously reported. Of the 44 (88%) patients that completed 1 year of follow-up, 33 (66%) were rated as responders and 11 (22%) as non-responders. We now report on the long-term follow-up of these patients.

Table. Characteristics of jLS study patients. JLS patients in the pilot CTP study were followed after they initiated treatment with one of 3 MTX-based CTPs. The characteristics of all the patients that completed the first year of treatment, patients that ever experienced a treatment failure (treatment failures), and patients that responded to the CTP (responders) are shown. Numbers are shown with % in parentheses unless otherwise stated. The % for number of patients is based upon the total initial cohort (50 patients). The other % are based upon the number of patients in the specific cohort. P-value was calculated for differences between the responders and treatment failures.

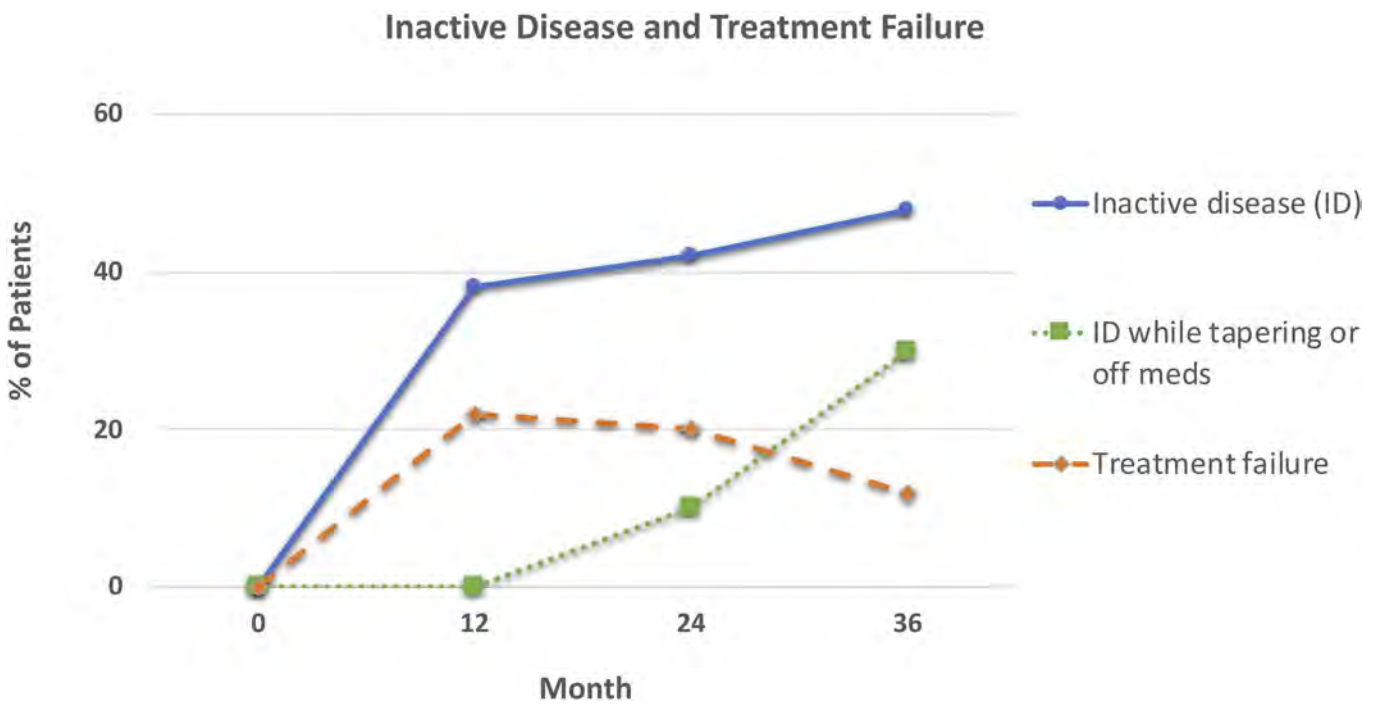

Figure 1. Percent of jLS patients achieving inactive disease or experiencing treatment failure over time. Patients initiating treatment with one of 3 MTX-based CTPs (no CS, concomitant oral CS, or concomitant intravenous CS) were followed for up to 36 months. There were 50 patients at 0 months, 44 at 12 months, 39 at 24 months, and 37 at 36 months. Inactive disease was defined as PGA-A = 0, treatment failure as active disease requiring additional treatment besides that specified by CTP.

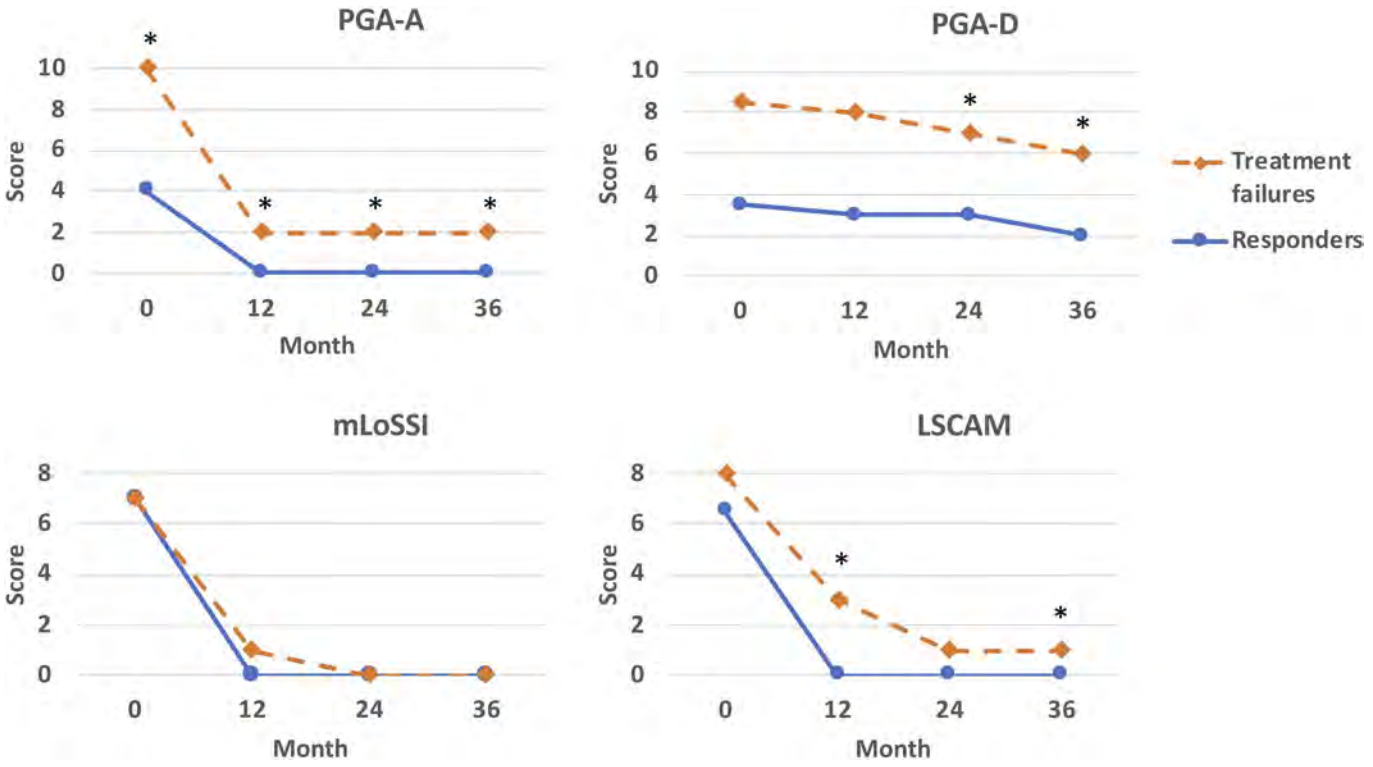

Figure 2. Comparison of scores in patients who experienced treatment failure to those who were responders to CTP. Significant differences are indicated by an * ($p < 0.05$). There were 28 patients who were responders and 16 who experienced treatment failure. mLoSSI: modified Localized Scleroderma Skin Severity Index; LSCAM: Localized Scleroderma Cutaneous Activity Measure; PGA-A: Physician global assessment of disease activity; PGA-D: physician global assessment of disease damage.

Methods: Patients enrolled in the pilot CTP study were eligible to enroll in the long-term extension, with study visits completed at 24 and 36 months. Each patient was evaluated by the same investigator for all 3 years of the study, using the same set of standardized clinical outcome measures for all visits. Treatments and adverse events that occurred since the last study visit were collected. Descriptive analysis was performed of all patients that had completed at least 12 months of follow-up, with p values calculated by Z-score or Mann Whitney U test. Inactive disease was defined as physician global assessment of activity (PGA-A) = 0, remission off medicine as PGA-A = 0 with the patient off treatment, and treatment failure as active disease requiring additional medication besides that specified in CTP. Patients who experienced treatment failures at any time during the study were compared to patients who were never treatment failures.

Results: Most patients were female (70%) and had linear scleroderma (Table). Thirty-seven (74%) of patients completed 36 months of follow-up (Figure 1). Over time, more patients achieved inactive disease, with 30% able to maintain inactive disease while tapering or discontinuing methotrexate (Figure 1). Treatment failures (TF) occurred most commonly in years 1 and 2 when ~20% of patients were non-responders. In addition to 11 patients who experienced TF in the first 12 months, 5 additional patients experienced TF by 24 months.

PGA-A and Skin scores declined significantly from 0 to 12 months for both responders and treatment failures. However, patients who experienced TF had higher PGA-A scores than responders at all visits (Figure 2). Skin activity scores, as measured by LSCAM, were also higher in patients who experienced TF at the 12- and 36-month visits than responders; no difference was identified by mLoSSI (Figure 2). PGA-Damage scores were higher at 24 and 36 months in patients who experienced TF than responders.

Conclusion: JLS patients treated with MTX-based standardized regimens were found to achieve further improvement in years 2 and 3 with continued treatment, with 20% able to achieve remission off medicine in year 3. Disease flares occurred in each year and overall, 16 (32%) patients were non-responders, with extracutaneous involvement, especially arthritis, associated with treatment failure. More work is needed to identify the at-risk patients and determine their optimal therapy.

SESSION INFORMATION

Session Date: Sunday, November 7, 2021

Session Title: Pediatric Rheumatology – Clinical Poster II: SLE, JDM, & Juvenile Scleroderma (0764–0785)

Session Type: Poster Session B

Session Time: 8:30AM–10:30AM

Background/Purpose: Depression and anxiety symptoms are prevalent in youth with childhood-onset system lupus erythematosus (cSLE). Healthcare disparities and trauma are associated with adverse mental health in adults with SLE. There is limited data on how these socioenvironmental factors impact mental health for children and adolescents with cSLE. We examined the association of socioenvironmental and disease-related factors with symptoms of depression and anxiety in a pediatric cSLE sample.

Table 1. Demographic, Socioenvironmental and Clinical Characteristics of Patients with cSLE

	Total Cohort (n=72)	Elevated symptoms of depression[a] (n=25)	Elevated symptoms of anxiety (n=28)
Demographic Characteristics			
Age, mean (SD) years	15.3(1.8)	15.8 (1.3)	15.5 (1.4)
Female, n (%)	59 (83%)	21 (84%)	24 (86%)
Race / ethnicity, n (%)	52 (75%)	17 (71%)	19 (70%)
Black/African-American	5 (7%)	1 (4%)	0 (0%)
East Asian	19 (27%)	4 (17%)	8 (30%)
South Asian	9 (13%)	6 (25%)	4 (15%)
Mixed race	4 (6%)	1 (4%)	2 (7%)
White	17 (25%)	7(29%)	8 (30%)
Other	15 (22%)	5(21%)	5 (18%)
Socioenvironmental Factors			
Exposure to traumatic experience, n (%)	25 (37%)	12 (52%)	10 (37%)
Marginalization total score, mean (SD)	2.9 (0.75)	3.1 (0.73)	2.8 (0.78)
Marginalization dimensions – % in most marginalized quartile			
Instability[b], n (%)	7(10%)	3(12%)	3(11%)
Material Deprivation[c], n (%)	14(19%)	8(32%)	6(21%)
Dependency[d], n (%)	3(4%)	2(8%)	2(7%)
Ethnic Concentration[e], n (%)	5(51%)	14(56%)	13(46%)
Clinical Characteristics			
Disease duration, mean months (SD)	45.3 (31.6)	31.8 (25.6)	44.6 (32.4)
Active disease (SLEDAI[f] > 4), n (%)	13 (18%)	5 (20%)	4 (14%)
Presence of damage (SDI[g]>0), n (%)	10 (14%)	6 (24%)	3 (11%)

[a] Elevated depression symptoms based on use of one of 3 self-rating scales

[b] The instability dimension reflects family and residential instability, which takes into account several indicators such as proportion of dwellings that are not owned and proportion of dwellings that are occupied by a single resident.

[c] The material deprivation dimension reflects the inability for residents to access basic material needs, and includes indicators such as proportion of single-parent households, proportion of population that received government transfer payments, and proportion of population that is considered low-income.

[d] The dependency dimension takes into the number of people (children, senior, adults) who do not have income from employment.

[e] The ethnic concentration dimension reflects the proportion of the population who are recent immigrants and/or belong to a 'visible minority' group.

[f] SLEDAI-2K: Systemic Lupus Erythematosus Disease Activity Index

[g] SDI: Systemic Lupus International Collaborating Clinics/ American College of Rheumatology Damage index

Table 2. Association of Patient Factors with Elevated Depression Symptoms in cSLE

	Univariate Analysis		Multivariate Analysis	
Variable	**Odds Ratio (95% CI)**	***p* value**	**Odds Ratio (95% CI)**	***p* value**
Age	1.29 (0.935-1.784)	0.120	-	-
Gender	1.11 (0.297-4.110)	0.881	-	-
Race (White/Non-White)	0.69 (0.225-2.140)	0.525	-	-
Socioenvironmental Factors				
Exposure to traumatic experience	2.60 (0.916-7.385)	0.073	1.82 (0.584-5.678)	0.302
Marginalization total score	1.93 (0.981-3.782)	0.057	1.67 (0.804-3.475)	0.169
Clinical Characteristics				
Disease duration	0.97 (0.955-0.994)	0.011	0.98 (0.956-0.999)	0.038
Active disease (SLEDAI > 4)	1.22 (0.352-4.214)	0.755	-	-
Presence of damage (SDI>0)	3.39 (0.858-13.434)	0.082	2.77 (0.491-15.669)	0.248

Shown are results of logistic regression models for predictors of elevated depression symptoms. Factors with univariate associations reaching significance of $p<0.10$ were included in the multivariate analysis.

Table 3. Association of Patient Factors with Elevated Anxiety Symptoms in cSLE

Variable	**Univariate Odds Ratio (95% CI)**	***p* value**
Age	1.08 (0.820-1.417)	0.590
Gender	1.37 (0.371-5.072)	0.636
Race (White/Non-White)	0.65 (0.214-1.960)	0.442
Socioenvironmental Factors		
Exposure to traumatic experience	0.98 (0.357-2.691)	0.969
Marginalization total score	0.68 (0.355-1.316)	0.255
Clinical Characteristics		
Disease duration	0.99 (0.984-1.014)	0.885
Active disease (SLEDAI > 4)	0.65 (0.179-2.348)	0.509
Presence of damage (SDI>0)	0.63 (0.150-2.689)	0.537

Shown are results of logistic regression models for predictors of elevated anxiety symptoms.

Methods: We examined a cross-sectional pediatric sample ages 9-17 years from a major tertiary hospital SLE outpatient clinic between August 2017 and April 2021. All patients met ACR or SLICC classification criteria for SLE. Self-report screening questionnaires for depression (one of: Center for Epidemiologic Studies Depression Scale for Children, Beck's Depression Inventory, Child Depression Inventory), and anxiety (the Screen for Childhood and Anxiety Related Disorders) were used to investigate current symptoms. Elevated depression/anxiety symptoms were determined based on established clinical cut-points. The Kiddie-Schedule for Affective Disorders and Schizophrenia (Version 5) interview recorded history of exposure to a traumatic event. Disease activity was measured by SLEDAI-2K and damage by the SLICC Damage Index (SDI). Area-level indicators of socioenvironmental disadvantage were obtained using the Ontario Marginalization Index. The association between elevated depression and anxiety symptoms

(binary outcomes), and disease-related (duration, activity, damage) and socioenvironmental (traumatic exposure, marginalization) factors were examined using univariate and multivariate logistic regression analyses.

Results: 72 youth (mean age 15.3 ± SD 1.8 years, 83% female, 75% self-identified as non-white) were included (Table 1). The mean ± SD disease duration was 46.3 ± 32.6 months. 18% had active disease (SLEDAI-2K > 4), and 14% had disease damage (SDI >0). History of traumatic exposure (e.g., witness of domestic violence) was present in 37%. The mean marginalization total score was 2.9 (range 1-5 with higher values reflecting greater marginalization). Elevated depression symptoms were present in 37% (n=25) and anxiety in 39% (n=28). In univariate analysis (Table 2), elevated depression symptoms were associated with shorter disease duration (OR=0.97, p=.011), presence of disease damage (OR=3.39, p=0.082), traumatic exposure (OR=2.60, p=.073), and higher marginalization level (OR=1.93, p=.057). Shorter disease duration was the only significant predictor in the multivariate analysis for depression. Analyses for anxiety (Table 3) did not identify any significant contributory factors.

Conclusion: In this pediatric sample of cSLE, depression and anxiety symptoms were prevalent, and levels of trauma exposure and social marginalization were high. Shorter cSLE disease duration was associated with elevated depression symptoms, which may reflect difficulty coping with the diagnosis. An approach for mental health care of youth with cSLE should consider early screening for mood problems, and underscores the need to assess the availability of psychological supports to enhance mental wellbeing.

Transmission Disequilibrium Testing Meets Next Generation Sequencing: Applying TDT to Whole Genome Data in Childhood-Onset Systemic Lupus Erythematosus

Kathleen Vazzana[1], Anthony Musolf[2], Joan Bailey-Wilson[3], Zuoming Deng[3], Mariana Kaplan[3] and Laura Lewandowski[2], [1]National Institutes of Arthritis and Musculoskeletal and Skin Diseases (NIAMS), National Institutes of Health (NIH)/ Children's National Hospital, Washington, DC, [2]NIAMS, NIH, Rockville, MD, [3]National Institutes of Health, Bethesda, MD

SESSION INFORMATION
Session Date: Sunday, November 7, 2021
Session Title: Pediatric Rheumatology – Clinical Poster II: SLE, JDM, & Juvenile Scleroderma (0764–0785)
Session Type: Poster Session B
Session Time: 8:30AM–10:30AM

Background/Purpose: Systemic lupus erythematosus (SLE) is a systemic autoimmune disorder that is more severe in children than adults. Due to aggressive disease in childhood-onset SLE (cSLE), identification of genetic associations in this population could lead to insights into pathogenesis. Transmission disequilibrium test (TDT) is a family-based genetic association test performed on trios (affected patient and two unaffected parents) to compare the rate of transmission of an associated marker allele from the heterozygous parent to an affected offspring. Trio based TDT has increased power to detect association over a wide range of allele frequencies, but the empirical significance threshold has not been established for whole genome data. This is the first study to apply TDT to whole genome sequence data in a diverse, international cSLE cohort.

Table 1. Top gene based rvTDT results

Gene	p-value
DNAH11 (dynein axonemal heavy chain 11)	0.0009
PCDHB15 (protocadherin beta 15)	0.0009
TMEM63A (transmembrane protein 63A)	0.0009
FAM160A1 (family with sequence similarity 160 member A1)	0.0011
HNRNPUL2 (heterogeneous nuclear ribonucleoprotein U like 2)	0.0013
ADCY10 (adenylate cyclase 10)	0.0018
DAB2IP (DAB2 interacting protein)	0.0018
BCAM (basal cell adhesion molecule)	0.0019
CEBPZ (CCAAT enhancer binding protein zeta)	0.0024
SLFN14 (schlafen family member 14)	0.0026

Methods: SLE subjects met at least 4 of 11 revised American College of Rheumatology classification SLE criteria. cSLE subjects had disease onset prior to age 18. Whole blood samples collected from 81 subjects and 111 parents underwent whole genome sequencing via Illumina HiSeq X Ten. TDT was performed to assess for association of each variant allele with cSLE in the parents with heterozygous genotypes. TDT was performed as SNP-based and gene-based analyses. SNP-based TDT was performed using PLINK 1.9. Gene-based TDT analyses used EPACTS to annotate each SNP into genes. We then employed rvTDT, which uses multiple gene-based burden tests adapted for TDT including the burden of rare variants (BRV) test. Statistical significance was determined empirically by permutation for both the SNP-based and gene-based analyses.

Results: The SNP-based analysis did not return any genome-wide significant SNPs. A SNP of interest close to the empirical significance threshold was found to be associated with the Transmembrane Protein 132C gene (*TMEM132C*). In the gene-based TDT analysis, many significant genes were identified (Table 1). We cross-referenced our SNP and gene-based results with results from other SLE genetic analysis. *TMEM132C* was also present in our gene-based analysis, although again it did not reach statistical significance. The *TMEM132* family encodes for cell to cell junctions in the central nervous system. *TMEM132C* has not been associated with autoimmunity in prior studies, but previous genome wide association studies have found this gene to be associated with panic disorder, oncologic conditions, and hearing loss.

Conclusion: Our study identified novel genetic mutations that were statistically significant in a diverse childhood-onset lupus cohort. While no SNP reached significance across the genome, when we clustered SNPs by gene, we found many unrelated families were enriched in variants in the same gene. Future studies should be done to explore the role of *TMEM132C* in the pathogenesis of SLE. Our study is the first in rheumatology to apply TDT methodology to whole genome data. TDT methodology allowed for a robust analysis in a diverse patient cohort. Further studies in larger cohort of cSLE patient/parent trios will allow us to better evaluate significant SNP- and gene-based associations and identify candidate causal risk genes for SLE.

Abstract Number: 0784

Use of EuroLupus Cyclophosphamide Dosing for the Treatment of Lupus Nephritis in Childhood-Onset Systemic Lupus Erythematosus in North America

Laura Cannon[1], Scott Wenderfer[2], Laura Lewandowski[3], Jennifer Cooper[4], Beatrice Goilav[5], Andrea Knight[6], Aimee Hersh[7], Stacy Ardoin[8] and Rebecca Sadun[1], [1]Duke University, Durham, NC, [2]Baylor College of Medicine, Houston, TX, [3]NIAMS, NIH, Rockville, MD, [4]University of Colorado/Children's Hospital Colorado, Denver, CO, [5]Children's Hospital at Montefiore, Bronx, NY, [6]Hospital for Sick Children, Toronto, ON, Canada, [7]University of Utah, Salt Lake City, UT, [8]Nationwide Children's Hospital, Columbus, OH

SESSION INFORMATION

Session Date: Sunday, November 7, 2021

Session Title: Pediatric Rheumatology – Clinical Poster II: SLE, JDM, & Juvenile Scleroderma (0764–0785)

Session Type: Poster Session B

Session Time: 8:30AM–10:30AM

Background/Purpose: Childhood-onset systemic lupus erythematosus (cSLE) has higher rates of lupus nephritis (LN) than adult-onset SLE, often requiring intensive immunosuppression. This study examined North American practices and preferences for the low-dose EuroLupus cyclophosphamide protocol, as compared to the high-dose National Institute of Health (NIH) cyclophosphamide protocol, to treat LN in cSLE.

Methods: A 35-item web-based survey was distributed to Childhood Arthritis and Rheumatology Research Alliance (CARRA) and Pediatric Nephrology Research Consortium (PNRC) providers. The survey assessed participant demographics, cyclophosphamide prescribing practices, perceptions of EuroLupus protocol, and LN vignette treatment decisions; one vignette was taken from a 2009 CARRA survey and responses were compared. Multivariable logistic regression analyzed provider factors associated with practices and preference for low- versus high-dose cyclophosphamide.

Results: Responses were provided by 185/421 (44%) CARRA physicians (Table 1). Among respondents who prescribed cyclophosphamide for pediatric LN over the past year (n=135), half reported using EuroLupus protocol. When presented the same vignette about an adolescent with class IV LN, 32% of pediatric rheumatologists chose EuroLupus dosing in 2020, versus only 6% in 2009 (Figure 1). Provider factors associated with choosing the low-dose regimen were familiarity with the protocol (OR 4.2, p=0.006) and greater perceived benefit (OR 1.6, p< 0.0001) (Table 2). Forty pediatric nephrologists had similar responses to the pediatric rheumatology providers. Overall, 78% of respondents perceived EuroLupus protocol efficacy to be equivalent to the high-dose protocol in cSLE LN.

Conclusion: Of pediatric specialists who prescribe cyclophosphamide for cSLE LN, more use low-dose cyclophosphamide compared to a decade prior. Nevertheless, familiarity with EuroLupus dosing remains low.

SESSION INFORMATION
Session Date: Sunday, November 7, 2021
Session Title: Pediatric Rheumatology – Clinical Poster II: SLE, JDM, & Juvenile Scleroderma (0764–0785)
Session Type: Poster Session B
Session Time: 8:30AM–10:30AM

Background/Purpose: Juvenile Dermatomyositis (JDM) is a rare pediatric autoimmune disease characterized by muscle and skin inflammation. The Pathophysiology of JDM is complex; it involves both adaptive and innate immune system dysregulation. The increase in type I and type II interferon signature is well documented in JDM patients.

IFN-α has been shown to enhance Natural Killer (NK) cell degranulation and inflammatory cytokine production. However, information about how NK cells contribute to the pathophysiology in JDM patients is lacking. This study aims to evaluate the changes in the NK cell count and its correlation with various disease activity markers.

Methods: This IRB-approved retrospective study was conducted at the Ann and Robert H. Lurie Children's Hospital of Chicago. 135 subjects (76% female, 74% white, 18.5 % Hispanic, 3% black) were included in this study. Clinical and laboratory variables, including age, race, gender, MSA, Disease Activity Scores (DAS skin, muscle, total), nailfold capillary count, neopterin, and muscle enzymes, were obtained from the Lurie Children's Juvenile Myositis Registry REDCap database. All subjects had flow cytometry (CD3, CD4, CD8, CD16/56, CD19, and HLA-Dr) before receiving treatment for JDM. To identify which NK cell subtype (CD56dim, CD56 bright) is affected in JDM, another flow cytometry was done with CD16 and CD56 on different fluorochromes in a smaller subset of the untreated JDM and control subjects.

Results: 57% of the untreated JDM children had low NK cells. Those with low NK cell count had more active disease with mean DAS-total 11.6 vs 9.6 (p= 0.001), DAS-muscle 5.8 vs 3.9 (p< 0.001), neopterin levels 22.1 vs 15.5 (p=0.003). Muscle enzymes were higher in the NK low groups as following: CPK 2733 vs 474 (p= 0.025), AST 147 vs 54(p= 0.003), LDH 491 vs 348(p= 0.006), Aldolase 23 vs 11(p= 0.013). There was no significant difference in the DAS-skin or nailfold capillary count between NK low group or normal. Among the different MSAs groups, the anti-MJ group has the Lowest mean NK cell count at 105+/- 52, and the anti P155/140 group has the highest level at 196 +/- 161; however, the difference was not statistically significant. Then we examined the NK cell subset in six JDM with low NK cells, three JDM with normal NK, and three healthy controls. CD56 dim NK cell percentage was significantly lower in NK low group than in control (0.55 % vs 4.6 % P< 0.001), whereas CD56 bright percentage did not differ significantly (0.45% vs 0.83% P=0.199).

Conclusion: Significant percentage of JDM children have low NK cells before treatment, suggesting that NK cells are likely to be contributing to the disease pathophysiology. Furthermore, JDM subjects with low NK cells show higher disease activity, especially in the muscle weakness and elevated muscle enzymes. Most of the NK cell count reduction is caused by the decreased number of the CD56 dim population, which is more cytotoxic with high perforin expression. Further studies of JDM muscle biopsies are in progress to determine if the CD56 dim NK cell counts are decreased in peripheral blood due to muscle infiltration.

Abstract Number: 0786

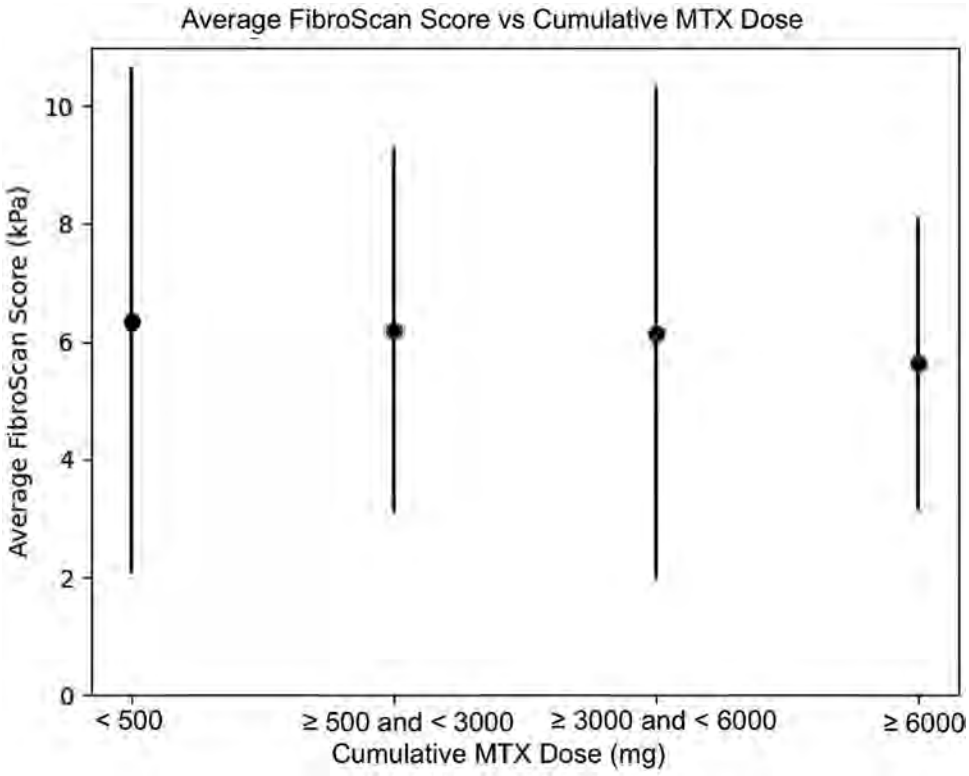
Diagnostic Utility of FibroScan in Screening for Liver Injury in Patients with Inflammatory Arthritis on Treatment with Methotrexate (MTX)

Saman Darabian[1], john Wade[2], Stefanie Wade[3], Jason Kur[2] and Maziar Badii[2], [1]University of British Columbia, North Vancouver, BC, Canada, [2]University of British Columbia, Vancouver, BC, Canada, [3]Beth Israel Deaconess Medical Center, Boston, MA

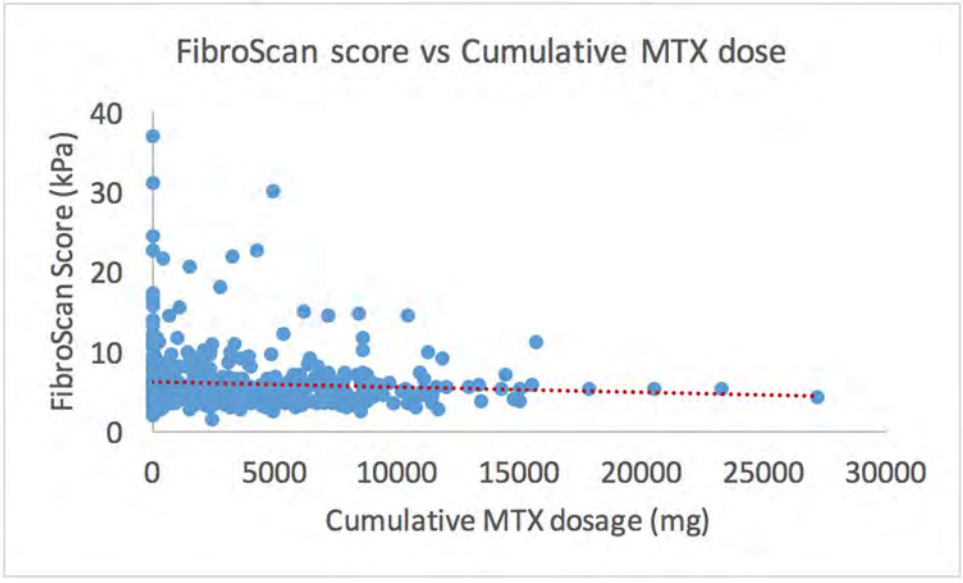
SESSION INFORMATION

Session Date: Sunday, November 7, 2021
Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster II: Miscellaneous Aspects of RA (0786–0812)
Session Type: Poster Session B
Session Time: 8:30AM–10:30AM

Background/Purpose: Methotrexate (MTX) is often the primary medication to treat various rheumatic diseases, including rheumatoid arthritis, psoriasic arthritis and many other inflammatory diseases. MTX is significantly less ex-



This table shows number (N) and percentage of participants with corresponding FibroScan scores in four cumulative MTX dosage subgroups and in the total study population. Also demonstrated are prevalence's of participants with stages F2+ and F3+ liver stiffness according to FibroScan measurements.



Scatterplot of the FibroScan score vs the cumulative MTX dosage among all participants. The plot shows that there is no significant correlation between the cumulative MTX dosage and the FibroScan score. The dotted line is the best linear fit to the data and the fact that it is almost horizontal indicates that the two variables (the cumulative MTX dosage and the FibroScan score) are almost independent from each other. Minimum cumulative MTX dosage = 0mg, maximum cumulative MTX dosage 27200mg, minimum FibroScan score = 1.5 kPa, maximum FibroScan score = 37.1 kPa.

Cumulative Dose of MTX Subgroup	Total N	F0-F1 N (%) (0.0 ≤ FS score < 7.1 kPa)	F2 N (%) (7.1 kPa ≤ FS score < 8.7 kPa)	F3 N (%) (8.7 kPa ≤ FS score < 10.4 kPa)	F4 N (%) (10.4 kPa ≤ FS score)	F2+ N (%) (FS score ≥ 7.1 kPa)	F3+ N (%) (FS score ≥ 8.7 kPa)
Group 1 (0-499 mg)	211	159 (75.4)	24 (11.4)	8 (3.8)	20 (9.5)	52 (24.6)	28 (13.3)
Group 2 (500-2999 mg)	95	73 (76.8)	6 (6.3)	10 (10.5)	6 (6.3)	22 (23.2)	16 (16.8)
Group 3 (3000-5999 mg)	104	89 (85.6)	3 (2.9)	5 (4.8)	7 (6.7)	15 (14.4)	12 (11.5)
Group 4 (6000+ mg)	110	93 (84.5)	7 (6.4)	4 (3.6)	6 (5.5)	17 (15.5)	10 (9.1)
Total	520	414 (79.6)	40 (7.7)	27 (5.2)	39 (7.5)	106 (20.4)	66 (12.7)

Average liver stiffness score per cumulative MTX dosage group. No significance difference between groups of different cumulative MTX dosage has been observed.

pensive than other alternatives and has been shown in randomized controlled trials to be effective in controlling disease activity, enhancing patient quality of life, and potentially decreasing mortality among patients with inflammatory disorders. Despite its advantages, however, a major concern has been the potential for hepatic fibrosis associated with long term MTX usage.

The present study investigates the association between cumulative MTX intake and development of liver fibrosis among patients with rheumatic diseases. We utilized non-invasive transient elastography (FibroScan) to assess for liver fibrosis among patients in a large academic outpatient rheumatology clinic.

Methods: All patients with inflammatory arthritis treated with MTX were offered screening with FibroScan. All patients who volunteered to participate were included. A certified FibroScan technician measured the liver stiffness after patients adhered to a minimal 90-minute fast. Health and medication information were collected from the patient. FibroScan measurements were recorded as both numerical values represented by the machine in kilopascal (kPa), as well as an ordinal classification from F0 (normal liver stiffness) to F4 (cirrhosis).

Results: Five hundred and twenty rheumatologic patients were included in the primary analysis. FibroScan scores ranged between 1.5 kPa and 37.1 kPa, with an average of 6.13 kPa ± 3.76 kPa. Univariate and multivariate linear and logistic regression models were used for analysis in this study. In multivariable linear regression analysis, statistically significant factors were BMI (regression coefficients: 0.060, p=0.001), waist circumference (0.041, p=0.015), male sex (0.109, p=0.004), and age (0.026, p=0.054). The population was then divided into quartiles based on the participant's cumulative dosage of MTX. The prevalence of F3/F4 liver fibrosis (i.e. FS ≥ 8.7 kPa) was 13.3% in the control group (MTX cumulative dosage < 500mg), 9.1% in subgroup 4 (MTX >6000mg) and 12.7% in the entire sample. Compared with subgroup 1 (control), MTX subgroups 2-4 were not significantly correlated with higher FS scores (p-values 0.82, 0.59, and 0.18 respectively).

Conclusion: FibroScan scores compatible with liver fibrosis were seen in all MTX subgroups; however, no significant correlation between the cumulative MTX dosage and liver stiffness was observed, even at high MTX doses. The analysis showed significant correlations between the FibroScan score and BMI, waist circumference, male sex, and age. Further studies are needed to assess agreement between liver function tests and FibroScan scores and to better

identify threshold FibroScan scores warranting methotrexate discontinuation, particularly in patients with additional risk factors such as high BMI and waist circumference.

Association of Hemoglobin Levels and Radiographic Progression in the BRASS Registry

Nancy Shadick[1], Owen Hagino[2], Amy Praestgaard[3], Stefano Fiore[2], Michael Weinblatt[4] and Gerd Burmester[5], [1]Brigham and Women's Hospital, Boston, MA, [2]Sanofi, Bridgewater, NJ, [3]Sanofi, Cambridge, MA, [4]Brigham and Women's Hospital, Boston, MA, [5]Charité University Medicine Berlin, Berlin, Germany

SESSION INFORMATION
Session Date: Sunday, November 7, 2021
Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster II: Miscellaneous Aspects of RA (0786–0812)
Session Type: Poster Session B
Session Time: 8:30AM–10:30AM

Background/Purpose: To evaluate baseline hemoglobin (Hb) and radiographic progression over time for patients in the Brigham and Women's Hospital Rheumatoid Arthritis Sequential Study (BRASS) registry.

Methods: BRASS is a prospective observational study of over 1,500 patients diagnosed with RA at the Robert Breck Brigham Arthritis Clinic in Boston, MA (NCT01793103). The study began enrollment in March 2003 and has a 4-year average follow up retention rate of 80%. An extended follow-up of up to 18 years is available for some patients. BRASS Hb data and total Sharp score (TSS) data fields were matched with the main BRASS subjects by subject ID and visit date (±15 days). Hb at baseline was categorized as low (Hb < 120 g/L for women or < 130 g/L for men) and normal (Hb ≥120 g/L for women or ≥130 g/L for men) as per WHO guidelines. The distributions of Hb at baseline overall and within current medication subgroups at baseline (anti-TNF, biologic DMARD, non-biologic DMARD) and demographics and disease characteristics overall and by low/normal Hb were summarized. Hb and TSS values and changes over time were described (overall, by low/normal Hb and current medication at baseline). All analyses were descriptive.

Results: Patients with low Hb (N=224) at baseline had longer disease duration, higher disease activity, reported more pain, had lower income levels, less education, and were less frequently Caucasian. Compared with patients with normal Hb, those with low Hb were less frequently MTX-experienced, on a combination of anti-TNF and MTX, or on a biologic DMARD at baseline; low Hb was more frequently associated with baseline use of non-biologic DMARD and NSAIDs (Table 1). Over the 10-year observation period patients with low Hb at baseline continued to have lower Hb than patients with normal Hb; although, on average, patients in the low Hb subgroup exhibited a steady increase in Hb levels. This increase in Hb was observed in all baseline treatment subgroups. A larger increase in TSS over time was observed for patients with low Hb than for patients with normal Hb. No meaningful differences potentially attributable to medication use at baseline were detected.

Conclusion: Patients with low Hb who were treated with anti-TNFs, biologic DMARDs, or non-biologic DMARDs experienced sustained improvements in Hb levels over time. Patients with lower Hb levels at baseline tended to have increased radiographic progression as measured by TSS compared to RA patients with normal Hb levels. Future analyses may evaluate constant therapy and non-constant therapy cohorts and disease severity cohorts.

Table 1. Baseline demographic and clinical characteristics by Hb subgroup

Characteristic		Low Hb (N=224)	Normal Hb (N=890)	*P*-value
Age[a], years	Number Mean (SD)	224 60.38 (14.60)	890 55.53 (13.74)	<0.0001

Red Cell Distribution Width Is Associated with Baseline 25-hydroxyvitamin D Level Before Methotrexate Therapy in Rheumatoid Arthritis

Shahdi Malakooti[1], Brigid Wilson[2], Taissa Bej[2], Lenche Kostadinova[3], Alyssa Lange[2], Megan O'Mara[2], David Zidar[2], Maya Mattar[4] and Donald Anthony[5], [1]Case Western Reserve University, UH Cleveland Medical Center, VA Medical Center, Cleveland, OH, [2]VA Medical Center, Cleveland, OH, [3]UH Cleveland Medical Center, VA Medical Center, Cleveland, OH, [4]Louis Stokes VA Medical Center, Mayfield Heights, OH, [5]Case, VA, Metro, Chardon, OH

SESSION INFORMATION
Session Date: Sunday, November 7, 2021
Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster II: Miscellaneous Aspects of RA (0786–0812)
Session Type: Poster Session B
Session Time: 8:30AM–10:30AM

Background/Purpose: Peripheral blood red cell distribution width (RDW) correlates with disease activity in rheumatoid arthritis (RA) and is associated with subsequent mortality in non-RA patient populations. Although RDW and 25-hydroxyvitamin D (25(OH)D) levels are inversely correlated in community dwelling adults, the association between 25(OH)D status and RDW in RA has not been characterized. We investigated the relationships between baseline 25(OH)D status, RDW, and methotrexate (MTX) therapy in RA.

Methods: This was a retrospective cohort study of RA patients who fulfilled 1987 ACR classification criteria for RA and had a 25(OH)D level obtained within one year prior to MTX initiation at a single center VA Rheumatology Clinic (n=167). We evaluated vitamin D levels before and after MTX therapy start and evaluated the relationships between RDW, 25(OH)D levels, and 25(OH)D supplementation (multivitamin or higher dose supplementation) using Wilcoxon Signed Rank Test for paired analyses and Spearman Rank Sum Test for analyses of correlations.

Results: Prior to MTX therapy, 41% (n=69) were receiving 25(OH)D supplementation. After MTX therapy, 85% (n=142) were receiving 25(OH)D supplementation and 55% (n=92) were still receiving MTX at the last lab value. RDW inversely correlated with 25(OH)D levels prior to MTX (n=167; r=-0.19; p=0.01). This relationship also was observed in the subgroup where patients were receiving 25(OH)D supplementation (n=69; r=-0.25; p=0.04) but not in the subgroup not receiving supplementation (n=94; r=-0.07; p=0.52) prior to MTX.

25(OH)D level after any MTX therapy was significantly higher compared to baseline level (n=167; p< 0.001), and of those patients who remained on MTX therapy at last lab value significantly higher 25(OH)D level also was observed (n=92; p< 0.001). RDW was significantly higher compared to baseline level after any MTX therapy (n=167; p< 0.001), and of those patients who remained on MTX therapy at last lab value higher RDW again was observed (n=92; p< 0.001). After start of MTX therapy, the relationship between 25(OH)D level and RDW was no longer observed (n=92; r=0.13; p=0.21).

Conclusion: RDW and 25(OH)D levels are inversely correlated in RA patients on 25(OH)D supplementation prior to initiating MTX therapy. The relationship between 25(OH)D and RDW after MTX therapy start was no longer observed,

potentially secondary to MTX-driven anemia or MTX-mediated inflammatory control. Whether this relationship reflects overlapping inflammatory pathways driving RDW and 25(OH)D levels, or whether this is a causal relationship is yet to be determined. Specifically, whether 25(OH)D is a mediator of immunologic homeostasis in RA will need to be further elucidated.

Adipokine Levels and Associations with Achievement of Low Disease Activity in Rheumatoid Arthritis

SESSION INFORMATION
Session Date: Sunday, November 7, 2021
Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster II: Miscellaneous Aspects of RA (0786–0812)
Session Type: Poster Session B
Session Time: 8:30AM–10:30AM

Background/Purpose: Adipokines are fat-secreted proteins that serve as metabolic regulators. Prior studies have identified associations between adipokines and disease characteristics such as disease activity and radiographic progression in rheumatoid arthritis (RA) suggesting a link with disease phenotype, however, they have not been evaluated as prognostic biomarkers. In this study, we determined if circulating levels of adipokines were associated with the achievement of low disease activity (LDA) and clinical remission in RA. We also evaluated whether adipokines predicted the escalation of therapy to the use of biologic or targeted synthetic DMARDs.

Methods: This study evaluated patients with rheumatologist-diagnosed RA from Veteran patients who had moderate-high disease activity at enrollment in a registry study. Serum adiponectin, leptin, and fibroblast growth factor (FGF)-21 were assessed at enrollment using a multi-analyte panel. The primary outcome was the time to achievement of LDA (DAS28< 3.2). Secondary outcomes included the achievement of remission (DAS28< 2.6), achievement of low values for DAS28 subcomponents, and the incident use of bDMARDs or tsDMARDs. We used Cox proportional hazards models to evaluate the time to LDA by quartile of each adipokine among participants not in LDA at enrollment. Cox models were also used to assess the time to the initiation of bDMARDs or tsDMARDs among patients that were naïve to these therapies at enrollment regardless of disease activity. Models were comprehensively adjusted for demographics, calendar year, body mass index (BMI), disease characteristics, and comorbidity.

Results: Among 1276 patients [Mean age (SD): 70.9 (10.3) ; 89% male] that were eligible for inclusion, 827 achieved LDA and 598 achieved remission over 2,287 and 4,096 person-years of follow-up, respectively. Higher adipokine levels were associated with significantly lower rates of LDA and remission in a dose-dependent manner independent of a number of other clinical factors including BMI (Figure 1). Adipokines were also associated with lower rates of achievement of a low patient and evaluator global score and a low tender joint count, but not swollen joint count.

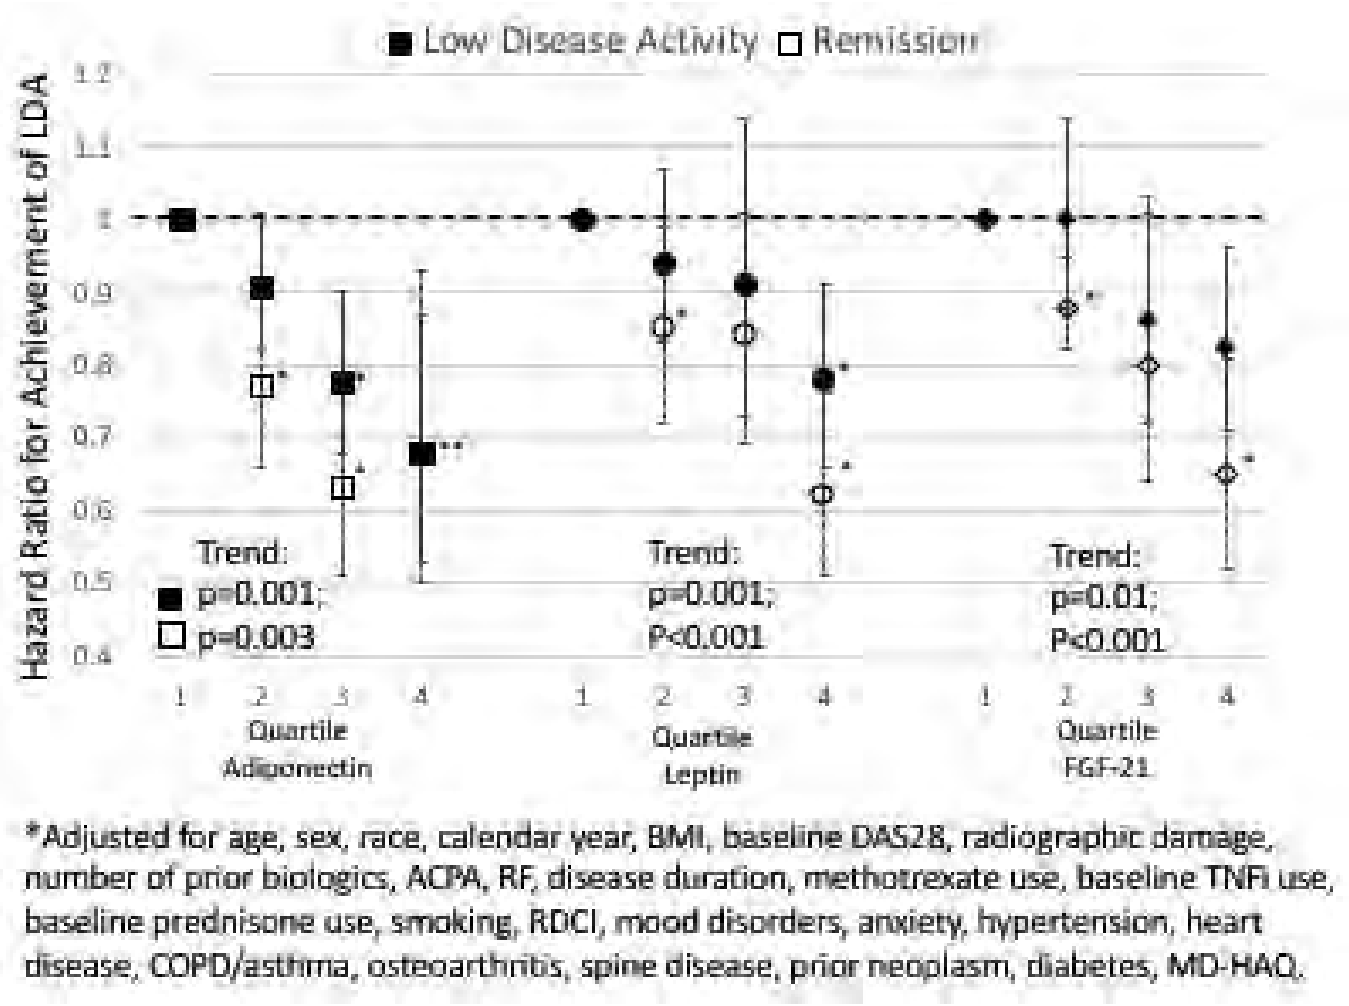

Figure 1. Adjusted risk of achieving low disease activity and remission by quartile of adipokines (adiponectin, leptin, and FGF-21).

Leptin was also associated with a lower likelihood of achievement of a low CRP. Among the 1352 biologic-naïve patients at enrollment total of 68 patients initiated a bDMARD or tsDMARD in 5,475 person-years of follow-up. Higher adipokine levels tended to be associated with a higher likelihood of initiation of new therapies (Figure 2).

Conclusion: Patients with high levels of adipokines demonstrate lower rates of achieving LDA and remission; an association that is independent of a number of clinical factors including baseline disease activity and BMI. In addition, patients with elevated adipokine levels, particularly adiponectin, might also be more likely to require escalation to a bDMARD or tsDMARD. While it remains unclear if adipokines play a causal role in promoting refractory disease, these data do support adipokines as prognostic biomarkers that may help to identify patients who are likely to experience more refractory disease over time. Further study is needed to further clarify the role of adipokines in the pathogenesis of the disease.

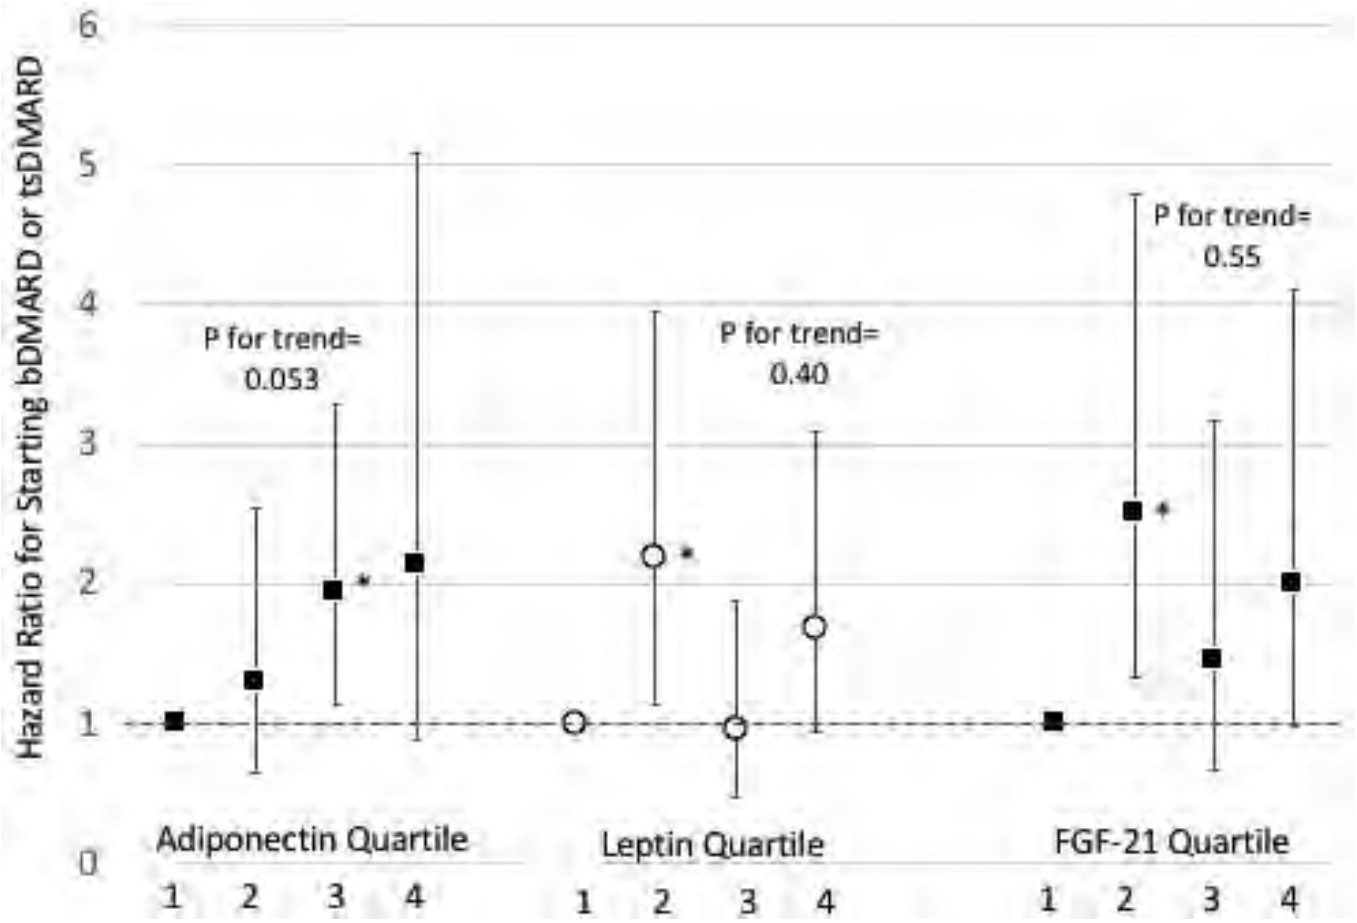

Figure 2. Hazard ratios for the risk of starting a new bDMARD or tsDMARD by adipokine quartile.

Unraveling Heterogeneity Within ACPA-negative Rheumatoid Arthritis; The Subgroup of Patients with a Strong Clinical and Serological Response to Initiation of DMARD-treatment Favor Disease Resolution

Marloes Verstappen[1], Hanna van Steenbergen[2], Pascal de Jong[3] and Annette H.M van der Helm-van Mil[1], [1]Leiden University Medical Center, Leiden, Netherlands, [2]Leiden Univeristy Medical Center, Leiden, Netherlands, [3]Erasmus MC, Hendrik Ido Ambacht, Netherlands

SESSION INFORMATION
Session Date: Sunday, November 7, 2021
Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster II: Miscellaneous Aspects of RA (0786–0812)
Session Type: Poster Session B
Session Time: 8:30AM–10:30AM

Background/Purpose: Rheumatoid arthritis (RA) is a heterogeneous disease, especially ACPA-negative-RA. This is reflected by differences in long-term outcomes, ranging from refractory RA to sustained-DMARD-free-remission(SDFR; sustained absence of synovitis after DMARD-cessation). Differentiation of RA-patients who are most likely to achieve SDFR can contribute to personalized treatment and tapering-strategies, however this subgroup remains scarcely discerned. Previous research demonstrated that RA-patients achieving SDFR are characterized by an early clinical response (DAS-remission after 4-months) after DMARD-start. We studied whether, in addition to this clinical response, a specific biomarker-response can further differentiate the subgroup of RA-patients most likely to achieve SDFR.

Methods: In 266 RA-patients, levels of 12-biomarkers(SAA/CRP/MMP-1/MMP-3/resistin/leptin/IL-6/TNF-R1/YKL-40/EGF/VEGF/VCAM-1) in the first 2-years after diagnosis, were studied in relation to SDFR, stratified for ACPA-status. Subsequently, biomarkers associated with SDFR-development were combined with early DAS-remission to study its additional value in defining subgroups. Since most biomarker-levels are not routinely measured in clinical practice, we explored how this subgroup could be recognized.

Results: ACPA-negative-RA-patients achieving SDFR(n=63) were characterized by a stronger decline in MMP-1/MMP-3/SAA/CRP 1-year after DMARD-start; respectively 1.30x/1.44x/2.12x/2.24x stronger. This effect was absent in ACPA-positive-RA. In ACPA-negative-RA, a strong biomarker-decline associated with early DAS-remission and the combination of both declines was present in a subgroup of ACPA-negative RA-patients achieving SDFR. This subgroup can be clinically recognized by the combination of high baseline CRP-levels(≥3-times ULN), and early DAS-remission ($DAS_{4\text{-months}} < 1.6$).

Conclusion: ACPA-negative RA-patients with early DAS-remission and a strong biomarker-response (or baseline CRP-levels≥3xULN) are most likely to achieve SDFR later-on. This could guide personalized treatment-decisions on DMARD-tapering/cessation in ACPA-negative-RA.

Abstract Number: 0791

Most Rheumatoid Arthritis (RA) Patients from Routine Care Reported in 2008-2021 Have Improved Outcomes vs Earlier Eras, but Most Remain in Moderate/high Disease Activity Rather Than Low Activity/remission: Are New Strategies for Earlier Treatment Needed in Addition to New Agents?

Juan Schmukler[1], Kyle Schroeder[2] and Theodore Pincus[2], [1]Mount Sinai Hospital - Rheumatology, Chicago, IL, [2]Rush University Medical Center, Chicago, IL

SESSION INFORMATION
Session Date: Sunday, November 7, 2021
Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster II: Miscellaneous Aspects of RA (0786–0812)
Session Type: Poster Session B
Session Time: 8:30AM–10:30AM

Background/Purpose: Treatment of rheumatoid arthritis (RA) has been advanced considerably by biological agents with capacity for stringent control of inflammation. A "treat-to-target" directive toward remission or low disease activity according to a quantitative index such as DAS28 (disease activity score), SDAI (simplified disease activity index), CDAI (clinical disease activity index), or RAPID3 (routine assessment of patient index data), is widely advocated, although it is recognized that the target must be adjusted in certain patients. The status of patients according to these indices in data from routine care has not been studied extensively and is analyzed here.

Methods: A PubMed search was conducted for "DAS28 categories - not trial," and for "CDAI" or "RAPID3" in lieu of DAS28 in separate searches. Many reports included several indices; if SDAI also was reported, it was included in analyses. Abstracts, reports of diseases other than RA, those that did not include index data or were restricted to subsets (e.g., elderly RA patients), were excluded. No further searches were done, with a goal to provide a general overview and not a comprehensive review. Means and medians of DAS28, CDAI, RAPID3 or SDAI were analyzed in cross-tabulations. The proportions of patients in 4 index categories – high, moderate, low, and remission - was analyzed in deciles.

Results: A total of 51 reports met inclusion criteria, including 1, 2, 3, or 4 indices; 43 reports presented only mean or median index values, 29 reports only different categories of index activity/severity, and 22 presented both types of data. In 79 available comparisons (including several indices in many studies), 18 for CDAI, 39 for DAS28, 13 for RAPID3, and 9 for SDAI, mean or median values indicated activity/severity that was high in 16 (20%), moderate in 55 (70%), low in 8 (10%), remission in none (Table 1). Similar results were seen for the 4 indices, with 56 -77% in moderate and 13-30% in high activity/severity (Table 1). In 60 available analyses of 4 categories of activity/severity (Table 2),

Table 1. Mean or median values for 4 RA indices for 4 categories of activity/severity, or remission in 79 reported comparisons

Activity	Remission	Low	Moderate	High	Total
CDAI	0	2 (11%)	11 (61%)	5 (28%)	18
DAS28	0	4 (10%)	30 (77%)	5 (13%)	39
RAPID3	0	0	9 (69%)	4 (31%)	13
SDAI	0	2 (22%)	5 (56%)	2 (22%)	9
Total		8 (10%)	55 (70%)	16 (20%)	79

Table 2. Proportion of patients in low activity or remission according to DAS28, SDAI, CDAI, and RAPID3 in 60 comparisons (2 studies "lumped" low activity and remission so no separate figure for remission)

	REMISSION					LOW ACTIVITY/REMISSION				
Percent	DAS28	SDAI	CDAI	RAPID3		DAS 28	SDA I	CDAI	RAPID3	
0-9.9	7	3	8	2	20 (34%)	2	0	0	0	2 (3%)
10-19.9	7	4	5	4	20 (34%)	5	1	3	0	9 (15%)
20-29.9	8	0	1	3	12 (21%)	3	3	3	4	13 (22%)
30-39.9	4	0	1	0	5 (9%)	10	0	3	2	15 (25%)
40-49.9	0	0	0	0	0	4	0	2	3	9 (15%)
50-59.9	1	0	0	0	1 (2%)	3	2	4	0	9 (15%)
60-69.9	0	0	0	0	0	1	1	1	0	3 (5%)
Total	27	7	15	9	58	28	7	16	9	60

remission was reported in 20% or more patients in 18/58 (31%) studies, 47%, 0%, 13%, and 33% for DAS28, SDAI, CDAI, and RAPID3, respectively. Low activity/remission was reported in 40% or more patients in 21/60 (35%) studies, 25%, 43%, 44%, and 33% for DAS28, SDAI, CDAI, and RAPID3, respectively (Table 2). Mean disease duration in all studies was 7.7 years. No differences were seen according to disease duration, or any trend toward better results between 2008 and 2021.

Conclusion: The findings indicate a considerable advance over historical results in RA treatment. Nonetheless, most patients were in moderate rather than low activity/severity or remission. This study is limited by a small number of reports, many from socioeconomically disadvantaged countries, some patients in remission may be seen rarely and not be included, and higher index scores may result from comorbid fibromyalgia and/or secondary osteoarthritis and other comorbidities. Nonetheless, the results may suggest a need for changes in treatment practices, such as strategies to see patients at shorter intervals after onset of symptoms, in addition to new agents, for optimal RA treatment.

Session Type: Poster Session B

Session Time: 8:30AM–10:30AM

Background/Purpose: The main goal of treatment for patients (pts.) with rheumatoid arthritis (RA) is to achieve remission, in order to both, preserve physical function and to stop and prevent radiographic progression. Using the treat-to-target (T2T) approach this has recently been achieved in less than 50% of pts. in an early arthritis cohort in Germany[1]. Several influencing factors such as long symptom duration, impaired physical function, and a history of

multiple DMARD therapies were identified. Remission rates over longer periods of time in a real-life setting have not been well studied.

To evaluate the remission rate in a cohort of RA pts. treated in a tertiary care center in which a large proportion of pts. present for a second opinion.

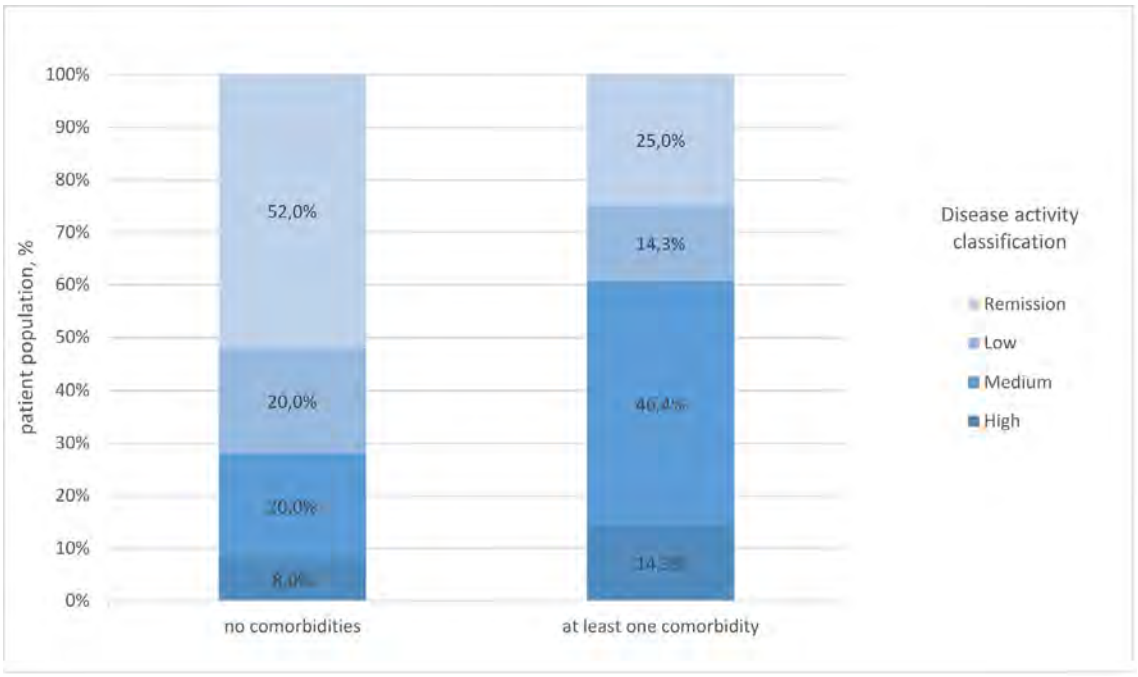

Figure 1. Disease activity DAS28-CRP at clinical visit.

Methods: Adult RA pts. were eligible for inclusion when their initial visit at our tertiary center was between January 2012 and December 2018. Patients and disease characteristics as well as standard assessments using validated outcome parameters for disease activity (DAS28-CRP, SDAI, and ACR/EULAR remission) and physical function (HAQ) were prospectively documented (clinical visit) and values were taken retrospectively from their initial visit (baseline visit) and from the visit at which remission criteria of DAS28-CRP < 2.6 occurred (remission visit).

Results: A total of 137 pts. were examined at their clinical visit between August 2020 and February 2021. Retrospective chart data were available for a follow-up of 33.7 (SD 18.0) months. One third of our cohort already had erosions and severe limitations in physical functioning (table 1). Cardiovascular comorbidities were as common as osteoporosis (both 13.1%). The vast majority of pts. (110 (80.3%)) achieved a state of clinical remission, (DAS28-CRP < 2.6) at least once in a time period of 47.9 (SD 18.9) months. At the clinical visit, 41 pts. (29.9%) were in DAS28 remission. However, using other outcome measures, 23 pts. achieved remission using SDAI (16.8%) and only 17 with Boolean criteria (12.4%), respectively. On average, remission by DAS28-CRP was reached 14.9 (SD 13.8) months after baseline visit. During the observation period pts. achieved remission for 15.8 (SD 10.4) months or 51.3% (SD 25.7) of the time, while 65 pts. (47.4%) achieved sustained remission for at least 6 months. Pts. with comorbidities reached remission less often than pts. without comorbidity (p=0.002). In accordance with the T2T strategy and EULAR recommendations, glucocorticoids were stopped in 47 pts. (34.3%) during the observation period. The remaining 53 pts. (38.7%) were still taking glucocorticoids at the clinical visit, but at a significantly lower dose than at baseline (table 2). The number of pts. on b/ts-DMARD therapy increased significantly from 14.7% at baseline to 59.1% at the clinical visit.

Conclusion: In this study pts. with RA reached remission more often when visited and observed more frequently and for longer periods of time. However, disease activity tends to come back for different reasons. This needs to be

further investigated. Moreover, the data also indicate that in a chronic disease more long term data are needed since short term results may show efficacy but this frequently changes over time in both directions.

Contributing Factors of Good Outcome in Difficult-to-treat Rheumatoid Arthritis: A Multicenter RA Ultrasound Prospective Observational Cohort Study in Japan

Shin-ya Kawashiri[1], Tohru Michitsuji[1], Yushiro Endo[1], Ayako Nishino[1], Toshimasa Shimizu[1], Remi Sumiyoshi[1], Tomohiro Koga[1], Naoki Iwamoto[1], Kunihiro Ichinose[2] and Atsushi Kawakami[1], [1]Nagasaki University Graduate School of Biomedical Sciences, Nagasaki, Japan, [2]Nagasaki University Graduate School of Biomedical Sciences, Department of Immunology and Rheumatology, Division of Advanced Preventive Medical Sciences, Nagasaki, Japan

SESSION INFORMATION
Session Date: Sunday, November 7, 2021
Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster II: Miscellaneous Aspects of RA (0786–0812)
Session Type: Poster Session B
Session Time: 8:30AM–10:30AM

Background/Purpose: The concept of difficult-to-treat rheumatoid arthritis (D2T RA) has emerged as the greatest unmet need in recent years. We have investigated the clinical characteristics and the contributing factors toward the outcome in patients with D2T RA in the real world setting using a multicenter RA ultrasound prospective observational cohort study.

Methods: We enrolled 366 RA patients from a multicenter prospective ultrasound observational cohort study [KUDOS study] who received biologic or targeted synthetic disease-modifying antirheumatic drugs (b/tsDMARDs) therapy. We evaluated the therapeutic efficacy by the patients' clinical disease activity scores and musculoskeletal ultrasound (MSUS) scores (sum of semi-quantitative evaluation from 22 joints from both wrist and finger joints) every 3 months during 12 months. We defined a D2T RA as a patient with (1) failure of ≥2 b/tsDMARDs and (2) at least moderate disease activity (DAS28-ESR >3.2 or CDAI >10) or inability to taper glucocorticoid treatment (≥7.5 mg/ day prednisone) at baseline. First, we compared characteristics between D2T RA and non-D2T RA. Second, we attempted to identify any variables that were independently contributing factors of the good outcome defined as CDAI remission and treatment continuation at 12 months from the patients' baseline characteristics and types of b/tsDMARD mode of action by performing a multivariate logistic regression analysis.

Results: Among 366 patients with RA, 74 (20.2%) were D2T RA. Disease duration, the positivity of rheumatoid factor, a complication of interstitial pneumonia, concomitant use of glucocorticoids, clinical disease activity scores and MSUS scores were significantly higher in D2T RA compared with non-D2T RA. There was no significant difference in

Table 1. Contributing factors of good outcome at 12 months in patients with D2T RA by multivariate logistic regression analysis

	Comparison	Odds ratio	95% CI	p-value
Age	1 increase	0.93	0.86-1.01	0.07
Rheumatoid factor	Positive	0.32	0.04-2.65	0.29
Concomitant use of MTX	presence	7.09	1.09-46.2	0.040
IL-6 inhibitor	presence	9.61	1.87-49.5	0.0068

the continuation rate at 12 months between D2T RA and non-D2T RA (60.8 vs 67.8%, p=0.44). Clinical and ultrasound remission (CDAI ≤2.8 and PD=0) rates at 12 months were significantly lower in D2T RA compared with non-D2T RA (9.5 vs 24.3%, p=0.0053). When good outcome at 12 months was defined as the achievement of CDAI remission with the continuation of b/tsDMARDs, 14 (18.9%) have achieved a good outcome. Multivariate logistic regression analysis showed that IL-6 inhibitor therapy (odds ratio 9.61, 95% confidence interval [CI] 1.87–49.5, p=0.0068) and concomitant use of methotrexate (MTX) (odds ratio 7.09, 95%CI 1.09–46.2, p=0.040) were independent contributors of good outcome (Table 1).

Conclusion: In our ultrasound cohort study, one-fifth of patients were classified as D2T RA at study entry. In patients with D2T RA, concomitant use of MTX and treatment with IL-6 inhibitors were associated with clinical remission and treatment continuation at 12 months.

SESSION INFORMATION
Session Date: Sunday, November 7, 2021
Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster II: Miscellaneous Aspects of RA (0786–0812)
Session Type: Poster Session B
Session Time: 8:30AM–10:30AM

Background/Purpose: The aim of this analysis was to compare between enrolment periods RA treatment outcomes and frequency of treating to target, and to assess the impact of target type on long-term function.

Methods: This is a post-hoc analysis of data from the Biologic Treatment Registry Across Canada (BioTRAC). Patients with RA who initiated treatment with infliximab or subcutaneous golimumab were included. Patients were grouped into enrolment periods: 2002-2004, 2005-2008, 2009-2012, 2013-2015, 2016-2017. Achievement of LDA (CDAI LDA or SDAI LDA or SJC≤1), remission (CDAI remission or SDAI remission or SJC=0), and sustained LDA or remission (at 6 and 12 months) were compared between enrolment periods with the Chi-square test and multivariate logistic regression. The impact of achieving LDA or remission at 6 months, 12 months, or both (sustained) on HAQ-DI at 18 months was assessed with one-way ANOVA and generalized linear models.

Results: 1420 patients treated with anti-TNFs (IFX: n=890; GLM: n=530) were included. Over calendar time, a significant decrease in baseline disease duration and disease activity scores (CDAI, SDAI, SJC28, TJC28, HAQ) was observed ($p < 0.001$).

Across enrolment periods, significant differences were observed in target achievement with higher rates observed in more recent years. Upon adjusting for baseline CDAI and prior biologic exposure, no differences between enrolment periods were observed in achieving LDA, remission or sustained LDA/remission at 6 months; however, significantly (p=0.030) higher odds of achieving remission at 12 months were observed in more recent years.

Among patients not achieving LDA at 6 and 12 months, an intervention was applied in approximately 40% of patients, without significant differences between enrolment periods. Between 6 and 12 months, the most common intervention was anti-TNF discontinuation (64.9% of non-LDA achievers), followed by DMARD addition (9.8%), NSAID addition (8.8%), or steroid addition (7.2%). Similar results were obtained post 12 months.

Patients achieving sustained LDA, followed by those achieving LDA either at 6 or 12 months had significantly lower HAQ-DI at 18 months compared to patients not achieving LDA at either timepoint (0.8 vs. 1.1 vs. 1.4; $p< 0.001$). Similar results were observed when evaluating achievement of disease remission albeit with greater impact on HAQ-DI at 18 months (0.7 vs. 1.1 vs. 1.2; $p< 0.001$). Adjustment for baseline HAQ-DI did not impact the results.

Conclusion: Target achievement has increased over time although emphasis in treating to target may be placed in the first 6 months of treatment. Achieving stricter targets was associated with better long-term patient function.

Treatment Response and Several Patient-reported Outcomes Are Early Determinants of Future Self-efficacy in Patients with Rheumatoid Arthritis

Michal Doumen[1], Diederik De Cock[1], Sofia Pazmino[1], Delphine Bertrand[1], Rene Westhovens[2] and Patrick Verschueren[3], [1]KU Leuven, Leuven, Belgium, [2]University Hospitals KU Leuven, Maaseik, Belgium, [3]University Hospitals Leuven - KULeuven, Leuven, Belgium

SESSION INFORMATION
Session Date: Sunday, November 7, 2021
Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster II: Miscellaneous Aspects of RA (0786–0812)
Session Type: Poster Session B
Session Time: 8:30AM–10:30AM

Background/Purpose: Self-efficacy (SE), or patients' confidence in their ability to control disease and its consequences, was recently prioritised in EULAR-recommendations for self-management strategies for inflammatory arthritis (1). However, it remains unclear which factors influence SE in rheumatoid arthritis (RA), particularly during early disease.

Methods: We conducted a post-hoc analysis of the 2-year RCT Care in early RA (CareRA), which studied remission-induction treatment regimens for early RA. Participants completed the Arthritis Self-Efficacy Scale (ASES), Short

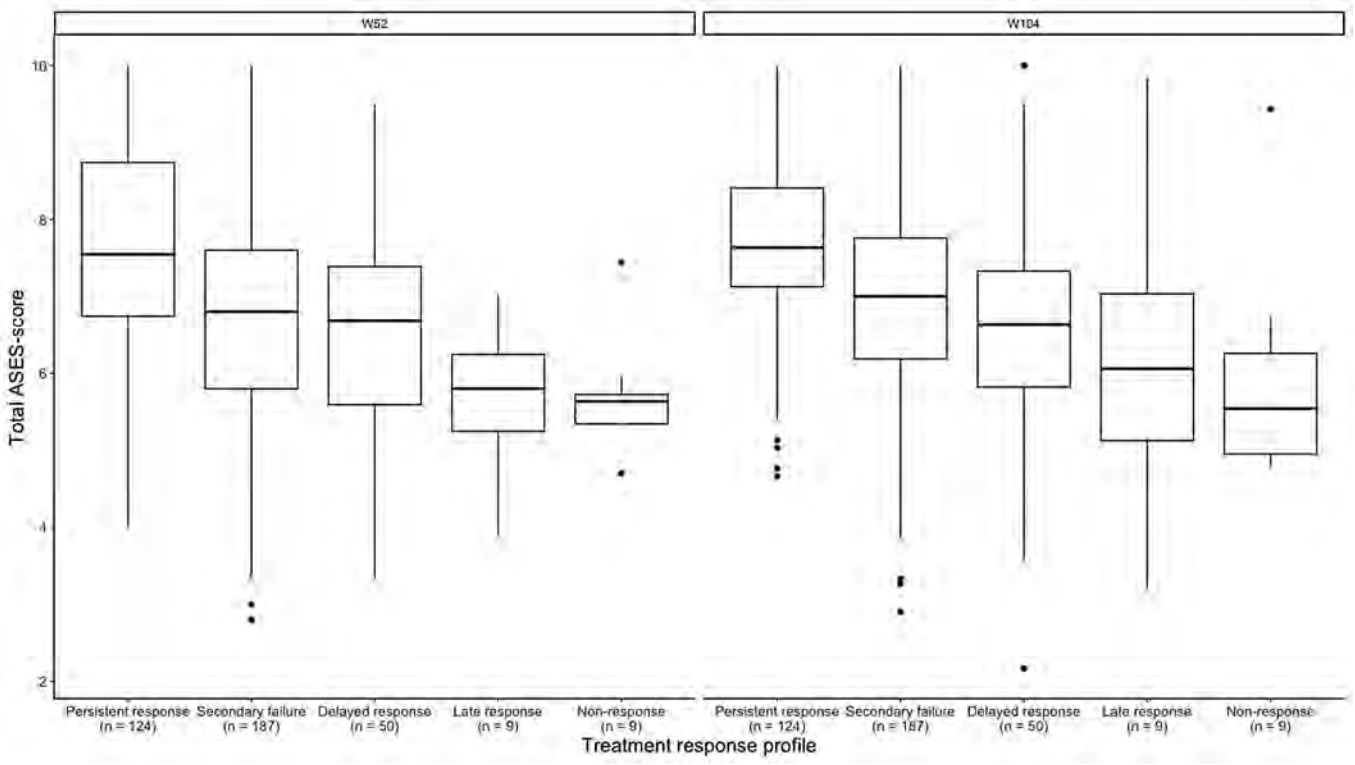

Figure 1. Total ASES-score at week 52 and week 104, stratified by treatment response profile. ASES = Arthritis Self-Efficacy Scale; Persistent response = sustained remission from week 16 to week 104; Secondary failure = loss of remission after week 16; Delayed response = first remission after week 16; Late response = first remission after week 52; Non-response = no remission within 104 weeks.

Form 36 (SF-36), Revised Illness Perception Questionnaire (IPQ-R), Utrecht Coping List (UCL), RAQoL and Health Assessment Questionnaire (HAQ). Depending on time to first remission (DAS28-CRP < 2.6) and persistence of remission, treatment response was defined as persistent response, secondary failure, delayed response, late response or non-response. The association between ASES scores and clinical/psychosocial factors was explored with Spearman correlation and multivariate linear mixed models. Baseline predictors of week 104 ASES were identified with exploratory simple linear regression followed by multiple linear regression of significant predictors adjusted for DAS28-CRP, HAQ, treatment arm, treatment response and demographic/serologic confounders. Models were adjusted for multiple comparisons, setting significance at a = 0.003.

Results: All 379 patients had a recent diagnosis of RA and were DMARD-naïve at study initiation. Most patients were women (69%) and RF/ACPA-positive (66%) and the mean (SD) age was 52 (13) years. For all tested outcome measures, better perceived health correlated with higher SE (Table 1). While patient-reported factors (HAQ, SF-36, RAQoL, IPQ-R, pain, fatigue and patient global assessment) showed moderate/strong correlations with ASES scores, correlations with physician-reported factors (physician global assessment, SJC28), TJC28 and DAS28-CRP were weak. In mixed models, only more favourable outcomes on patient-reported factors and DAS28-CRP were associated with higher ASES scores at each time point.

Table 1. Spearman-coefficients and linear mixed model output for the correlation between total ASES-score and clinical and psychosocial variables at all available time points. Bonferroni-correction for multiple comparisons was applied, setting the significance level at p < 0.003. ASES = Arthritis Self-Efficacy Scale, DAS28 = Disease Activity Score in 28 joints, HAQ = Health Assessment Questionnaire, VAS = Visual Analogue Scale, PGA = patient global assessment, SF-36 MCS = Short-Form 36 mental component score, IPQ-R = Revised Illness Perception Questionnaire, PhGA = physician global assessment, TJC28 = tender joint count in 28 joints, SJC28 = swollen joint count in 28 joints, CRP = C-reactive protein, ESR = erythrocyte sedimentation rate

Table 2. Baseline and treatment-related predictors of total ASES-score at week 104, based on multivariate linear regression. Predictors were first selected based on significance in univariate linear regression. Results were obtained from multivariate linear regression models predicting total ASES-score at week 104 by predictors that were significant in univariate analyses, and adjusting for age, gender, treatment arm and response, auto-antibody status and baseline HAQ and DAS28-CRP or its components. Bonferroni-correction for multiple comparisons was applied, setting the significance level at $p < 0.003$. ASES = Arthritis Self-Efficacy Scale, HAQ = Health Assessment Questionnaire, VAS = Visual Analogue Scale, PGA = patient global assessment, PhGA = physician global assessment, SF-36 = Short-Form 36, MCS = mental component score, IPQ-R = Revised Illness Perception Questionnaire, UCL = Utrecht Coping List

RAQoL	-0.04 (-0.07, -0.02)	**0.001**	0.203

An earlier, persistent treatment response predicted higher ASES scores at both week 52 and 104 (Fig. 1). Significant baseline predictors of week 104 ASES included HAQ; SF-36 dimensions Mental Component Score, Vitality, Mental Health and Role Emotional; IPQ-R dimensions Illness coherence, Treatment control, Emotional representations and Consequences; UCL dimension Passive reacting and the RAQoL (Table 2).

Conclusion: Patient-reported outcomes and treatment response were important early determinants of long-term SE in an early RA clinical trial. These results provide further relevance for the window of opportunity in an early treat-to-target strategy. In addition, our results could help to timely identify patients who might benefit the most from self-management treatment strategies or interventions to improve SE. Further prospective research is needed to confirm these findings.

SESSION INFORMATION

Session Date: Sunday, November 7, 2021

Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster II: Miscellaneous Aspects of RA (0786–0812)

Session Type: Poster Session B

Session Time: 8:30AM–10:30AM

Background/Purpose: Therapeutic decisions in RA patients should be based on regular disease activity assessment using scores like the Simplified Disease Activity Index (SDAI) or the Clinical Disease Activity Index (CDAI) [1]. The CDAI has the benefit of being immediately available, while the SDAI encompasses with the C-reactive protein (CRP) an acute phase reactant and therefore is the recommended score for the use in clinical trials. However, CRP

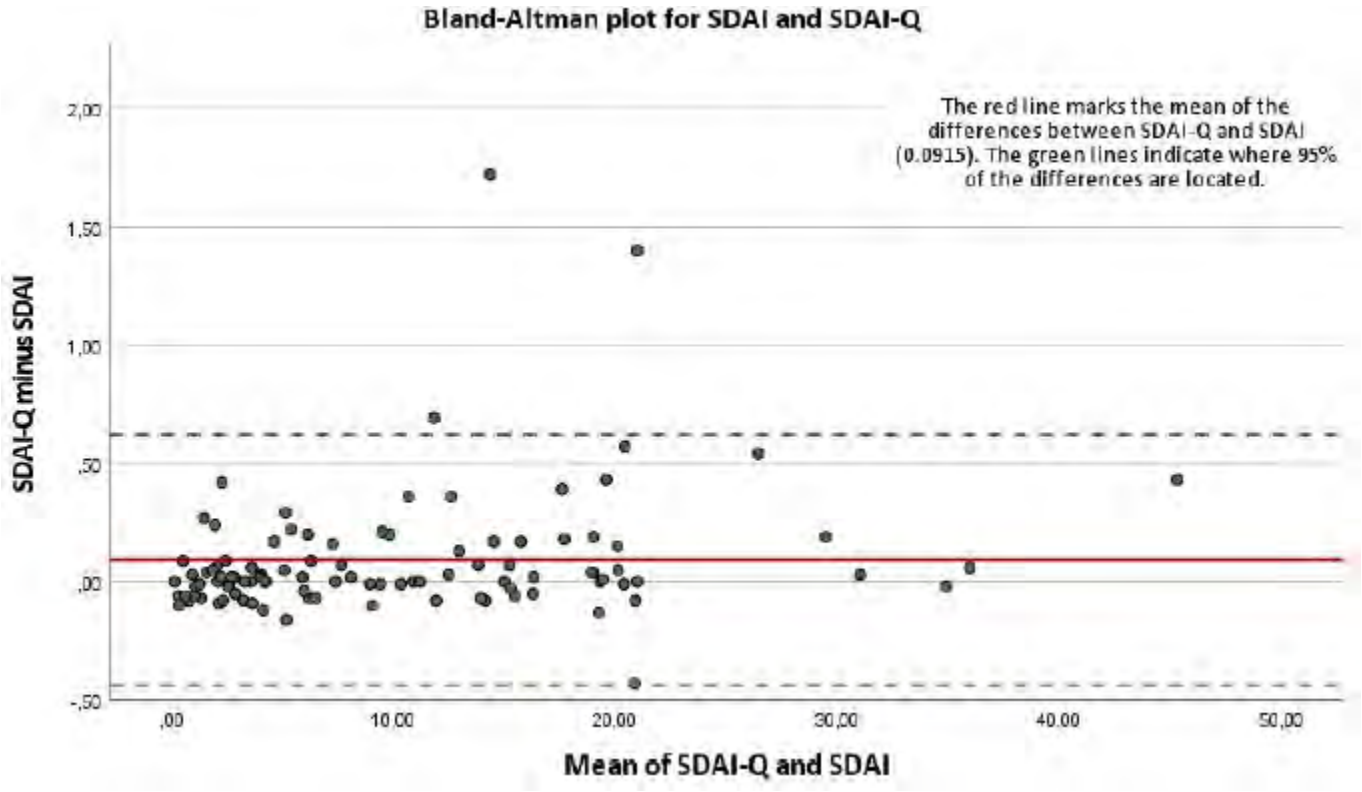
determination takes hours to days, thus hindering the treat-to-target concept using the SDAI. Quick quantitative CRP (qCRP) tests allow CRP measurement within a few minutes. Therefore, qCRP based SDAI (SDAI-Q) could combine the advantages of both scores. The objective of our study was to validate the SDAI-Q in a prospective, multicenter study of RA patients.

Table 1. A) Disease activity categories by SDAI-Q vs. SDAI; B) Disease activity categories by SDAI-Q vs.CDAI

A		SDAI-Q (n = 100)			
		Remission (≤ 3.3)	Low Disease Activity (> 3.3 and ≤ 11)	Moderate Disease Activity (> 11 and ≤ 26)	High Disease Activity (> 26)
SDAI	Remission (≤ 3.3)	28 (28.0%)			
	Low Disease Activity (> 3.3 and ≤ 11)		31 (31.0%)		
	Moderate Disease Activity (> 11 and ≤ 26)			35 (35.0%)	
	High Disease Activity (> 26)				6 (6.0%)

B		SDAI-Q (n = 100)			
		Remission (≤ 3.3)	Low Disease Activity (> 3.3 and ≤ 11)	Moderate Disease Activity (> 11 and ≤ 26)	High Disease Activity (> 26)
CDAI	Remission (≤ 2.8)	26 (26.0%)			
	Low Disease Activity (> 2.8 and ≤ 10)	2 (2.0%)	28 (28.0%)	2 (2.0%)	
	Moderate Disease Activity (> 10 and ≤ 22)		3 (3.0%)	33 (33.0%)	
	High Disease Activity (> 22)				6 (6.0%)

Fields highlighted in red indicate that disease activity categories do not match.
SDAI = Simplified Disease Activity Index;
SDAI-Q = SDAI calculated with a quick quantitative CRP assay;
CDAI = Clinical Disease Activity Index.



Bland-Altman plot for SDAI and SDAI-Q.

Methods: The study was conducted in five centers in Berlin, Germany. Consecutive adult (≥ 18 years) RA patients were included. In addition to a rheumatological assessment, including patient reported outcomes, routine CRP was measured in the local labs. Additionally, a qCRP testing with the „QuikRead go instrument“ (Aidian Oy, Finland) was performed locally (measurement range 0.5 - 200 mg/l). Statistical analysis included descriptive statistics, cross tabulation and weighted Cohen´s kappa comparing disease activity categories, Bland-Altman plots and intraclass correlation coefficient (ICC) for CRP, qCRP, SDAI, SDAI-Q and CDAI.

Results: In this study 100 RA patients were included (mean age: 60.9 years, mean disease duration: 11.4 years, 73.0% were female, 63.0% RF positive, 57.0% ACPA positive, 49.0% positive and 29% negative for both parameters). 75.0% were treated with csDMARD, 15% with tsDMARDs, 39.0% with bDMARDs and 40% with glucocorticoids (mean prednisolone equivalent: 5.4 mg prednisolone/d). Mean CRP and qCRP-levels were 6.97 and 7.89 mg/l, respectively (ICC 0.992; 95%CI: 0.987; 0.995). Comparing SDAI-Q and SDAI, all patients (100%) achieved the same disease activity status (Table 1A); weighted Cohen´s kappa was 1.000 (95%CI: 1.000; 1.000). ICC for SDAI-Q- and SDAI-values was 1.000 (95%CI: 1.000; 1.000). The agreement of SDAI-Q and SDAI is shown in a Bland-Altman plot (Figure 1). When comparing the CDAI with the SDAI-Q 93 patients (93%) were assigned to the same disease activity category (Table 1B); weighted Cohen´s kappa was 0.929 (95%CI: 0.878; 0.981). ICC for numerical values of SDAI-Q and CDAI was 0.989 (95%CI: 0.978; 0.994).

Conclusion: SDAI-Q showed an absolute agreement with SDAI on the assignment to disease activity categories with the important advantage of time. With SDAI-Q, rheumatologists could base their clinical decision-making immediately on an index-based disease activity measurement by using a composite score considering acute phase reactants. Consequently, SDAI-Q can be integrated in clinical routine and clinical trials and could be implemented into the treat-to-target concept in RA patients.

Psychosocial Wellbeing and Illness Perceptions During the Early Disease Phase Predict Sustained Remission in Rheumatoid Arthritis

Michal Doumen[1], Diederik De Cock[1], Sofia Pazmino[1], Delphine Bertrand[1], Rene Westhovens[2] and Patrick Verschueren[3], [1]KU Leuven, Leuven, Belgium, [2]University Hospitals KU Leuven, Maaseik, Belgium, [3]University Hospitals Leuven - KULeuven, Leuven, Belgium

SESSION INFORMATION
Session Date: Sunday, November 7, 2021
Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster II: Miscellaneous Aspects of RA (0786–0812)
Session Type: Poster Session B
Session Time: 8:30AM–10:30AM

Background/Purpose: Patient-reported outcomes (PROs) relating to global psychosocial wellbeing are rarely assessed in clinical trials for rheumatoid arthritis (RA), and specifically not to tailor additional interventions. Moreover, many patients with RA report ongoing pain, fatigue and suboptimal mental health despite satisfactory clinical disease control. We aimed to describe the association of early psychosocial wellbeing, coping and illness perceptions with sustained remission in early RA, and to identify patients with psychosocial unmet needs despite being in clinical remission.

Methods: Data were analysed from the 2-year randomised controlled treat-to-target trial Care in early RA (Care-RA). Patients completed the Short Form 36 (SF-36), Revised Illness Perception Questionnaire (IPQ-R) and Utrecht Coping List (UCL) among other PROs. Sustained remission was defined as continued DAS28-CRP < 2.6 from week 16 to week 104. SF-36 mental components, UCL and IPQ-R at baseline and week 16 were studied as predictors of sustained remission with multivariate logistic regression adjusting for age, gender, treatment arm, serology and 2-component DAS28 (1). Subgroups of patients in remission at week 16 were identified by Latent Profile Analysis (LPA) including significant psychosocial predictors from the regression models. Survival of remission was compared per subgroup by Kaplan-Meier analysis and Cox proportional hazards regression.

Results: All 379 included patients were recently diagnosed with RA and had not received DMARDs before study initiation. Most patients were women (69%) and RF/ACPA-positive (66%), with a mean age of 52 (SD 13) years. Sustained DAS28 CRP-remission was achieved by 124/379 (33%) patients. Sustained remission was associated with higher SF-36 scores and less passive coping at baseline, and with higher SF-36 scores and more positive IPQ-R reports at week 16 (Table 1). Among patients in DAS28-CRP remission at week 16 (n=287), two subgroups

Table 1. Psychosocial variables at baseline and week 16 predicting sustained remission. Results were obtained from multivariate logistic regression models with the specified variables as predictors and the odds of sustained DAS28-CRP-remission (from week 16 to week 104) as the dependent variable. All models contained age, gender, treatment arm, the presence of autoantibodies and 2C-DAS28 as covariates. OR = odds ratio, CI = confidence interval; SF-36 = Short Form 36, MCS = mental component score, VT = vitality, SF = social function, MH = mental health, RE = role emotional; IPQ-R = Revised Illness Perception Questionnaire; UCL = Utrecht Coping List; 2C-DAS28 = two-component Disease Activity Score in 28 joints

Personal control	1.02 (0.96 – 1.09)	0.521	1.08 (1.00 – 1.17)	**0.048**
Emotional representations	0.98 (0.94 – 1.02)	0.357	0.94 (0.90 – 0.98)	**0.005**
Consequences	0.97 (0.92 – 1.02)	0.277	0.88 (0.83 – 0.93)	**<0.001**
UCL				
Active tackling	0.99 (0.92 – 1.06)	0.841	1.07 (0.99 – 1.15)	0.156
Palliative reacting	0.98 (0.92 – 1.05)	0.685	0.97 (0.91 – 1.05)	0.303
Avoidance	0.98 (0.91 – 1.05)	0.508	0.96 (0.89 – 1.04)	0.175
Seeking social support	1.04 (0.97 – 1.12)	0.224	1.06 (0.98 – 1.15)	0.168
Passive reacting	0.92 (0.85 – 0.99)	**0.037**	0.93 (0.86 – 1.01)	0.086
Expression of emotion	1.01 (0.88 – 1.16)	0.727	1.10 (0.94 – 1.28)	0.340
Reassuring thoughts	0.98 (0.89 – 1.08)	0.666	1.03 (0.93 – 1.13)	0.625

were identified: a low-psychosocial-burden (n=231) and a high-psychosocial-burden group (n=56) (Fig. 1). The low-psychosocial-burden group retained remission longer (HR 0.51 [0.35-0.73]) (Fig. 2).

Conclusion: Suboptimal psychosocial wellbeing and illness perceptions were associated with lower odds of sustained remission in an early RA trial. Illness perceptions appeared to be more clinically relevant after 4 months of treatment. One-in-five patients still showed worse psychosocial outcomes despite being in early clinical remission, and these patients tended to lose remission earlier. Future research should focus on timely identification of unmet needs and person-centred interventions to target them.

SESSION INFORMATION

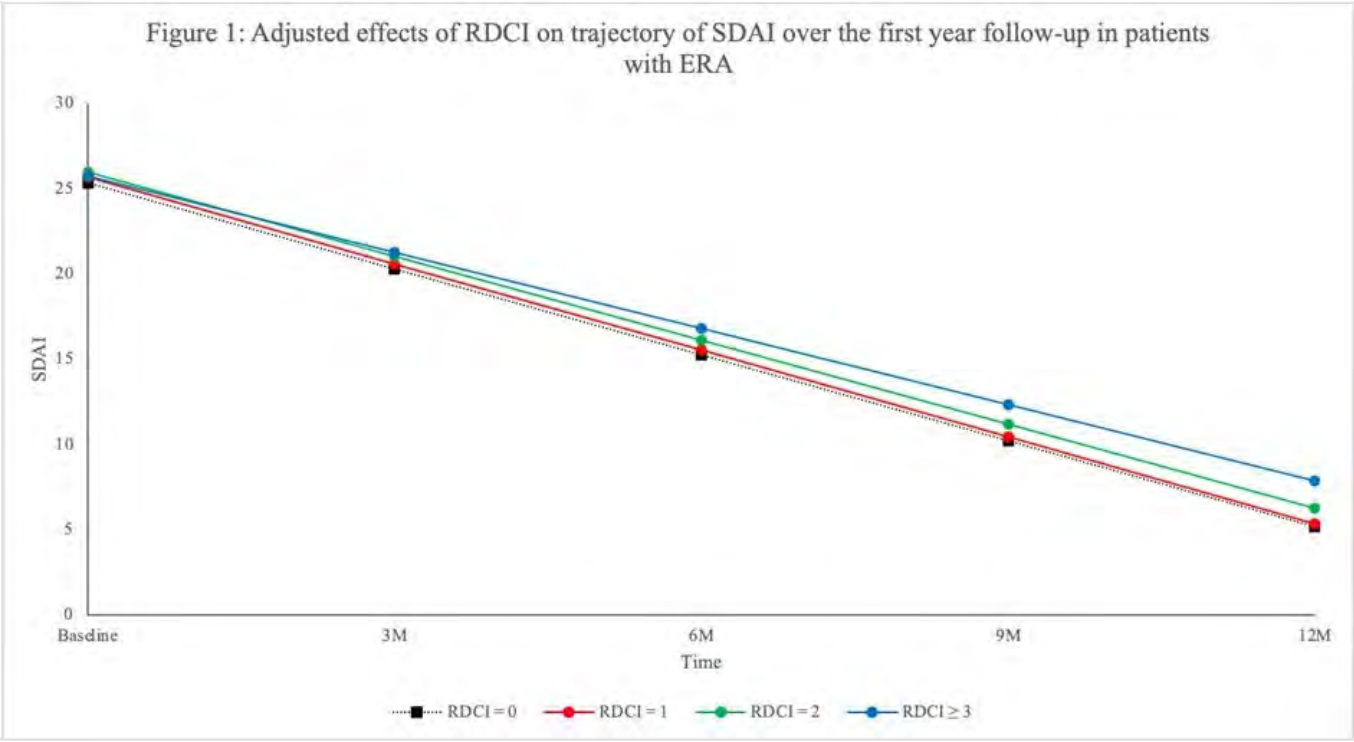
Session Date: Sunday, November 7, 2021

Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster II: Miscellaneous Aspects of RA (0786–0812)

Session Type: Poster Session B

Session Time: 8:30AM–10:30AM

Background/Purpose: Comorbid conditions have been shown to negatively influence the achievement of treatment targets in rheumatoid arthritis (RA) patients. The comorbid conditions may bias the subjective measures of the widely

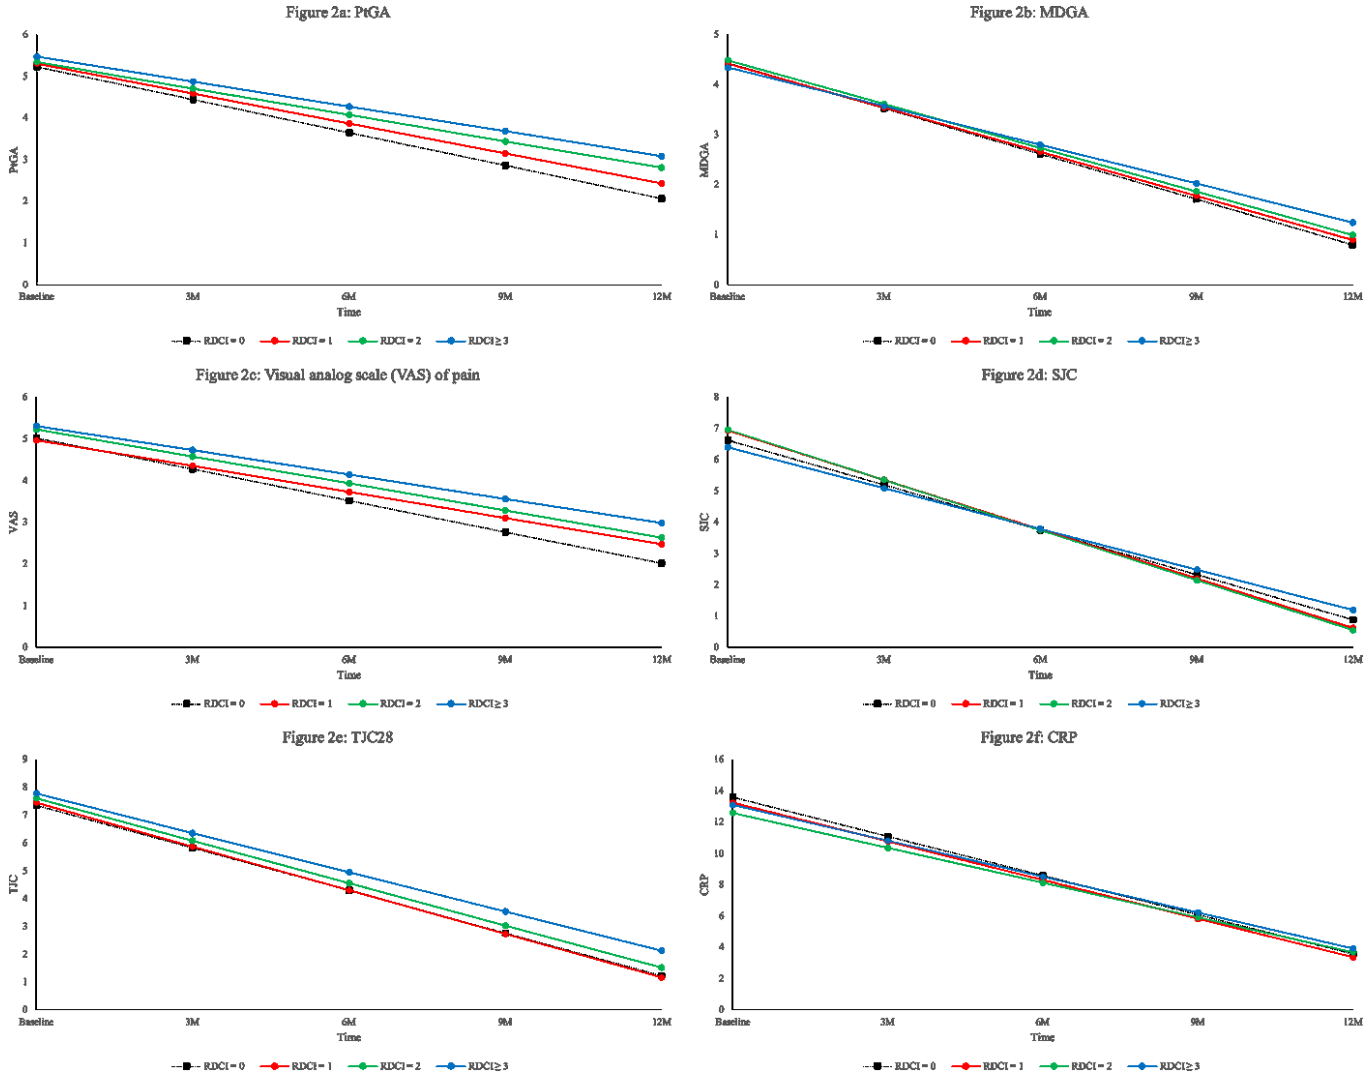


Adjusted effects of RDCI on trajectory (predictive margins) of SDAI over the first year follow-up in patients with ERA.

used indices for evaluation of disease activity. The objective is to look at the relationships between comorbidities and components of common clinical disease activity scores, such as tender (TJC) and swollen (SJC) joint count, patient global assessment (PtGA), physician global assessment (MDGA), C-reactive protein (CRP) and pain in early RA.

Methods: Using a validated tool for the assessment of comorbidity burden specifically developed for rheumatology, the Rheumatic Disease Comorbidity Index (RDCI), the influence of comorbidities on each component's trajectory in time has been assessed in early rheumatoid arthritis (ERA) patients over the first year of treatment with conventional synthetic DMARDS using data from the Canadian Early Arthritis Cohort (CATCH). The adjusted effects of RDCI scores (0, 1, 2, and ≥ 3) on the trajectory of the SDAI, on each component of the SDAI, and on pain (visual analog scale) was evaluated over the first year of follow-up with generalized estimating equations (GEE). Data were adjusted for possible confounders including baseline sociodemographic factors, disease activity and treatments.

Results: This sample size included 2248 ERA patients with a mean symptom duration (SD) of 5.71 (2.96) months; mean age (SD) was 55 (15) years old and 72% were female. At baseline, 1664 (74%) were treated with methotrexate with a mean weekly dose (SD) of 20.0 mg (4.2) and 1340 (60%) also received other conventional synthetic DMARDs. The mean (SD) SDAI at enrolment was 29 (15) and 90% were classified as having moderate-high SDAI. RDCI scores



Adjusted effects of RDCI on trajectory (predictive margins) of PtGA, MDGA, pain, and SJC over the first-year follow-up in patients with ERA.

of 0, 1, 2 or ³3 were obtained in 888 (40%), 547 (24%), 451 (20%), and 362 (16%) participants, respectively. Although disease activity did not differ by comorbidity status at baseline, patients with RDCI of 0 had better improvement (rate of change) in SDAI (Figure 1), PtGA, MDGA and pain (Figure 2a,b,c) over time relative to patients with multiple RDCI conditions ($p< 0.05$). A significant higher rate of change in SJC was observed in patients with RDCI of 1 and 2 compared with participants having higher RDCI score ($p= 0.01$) (Figure 2d). The RDCI scores were not significantly associated with the change of TJC and CRP (Figure 2e and f) over one year.

Conclusion: In this ERA cohort, having multiple comorbidities was associated with worse improvement and disease activity assessed by SDAI over the first year of treatment. SJC, PtGA, and MDGA were the components of SDAI that were most influenced by the presence of comorbidities. The results demonstrate a negative effect of having comorbidities at disease onset of RA on the evolution of both patients and physicians reported outcomes.

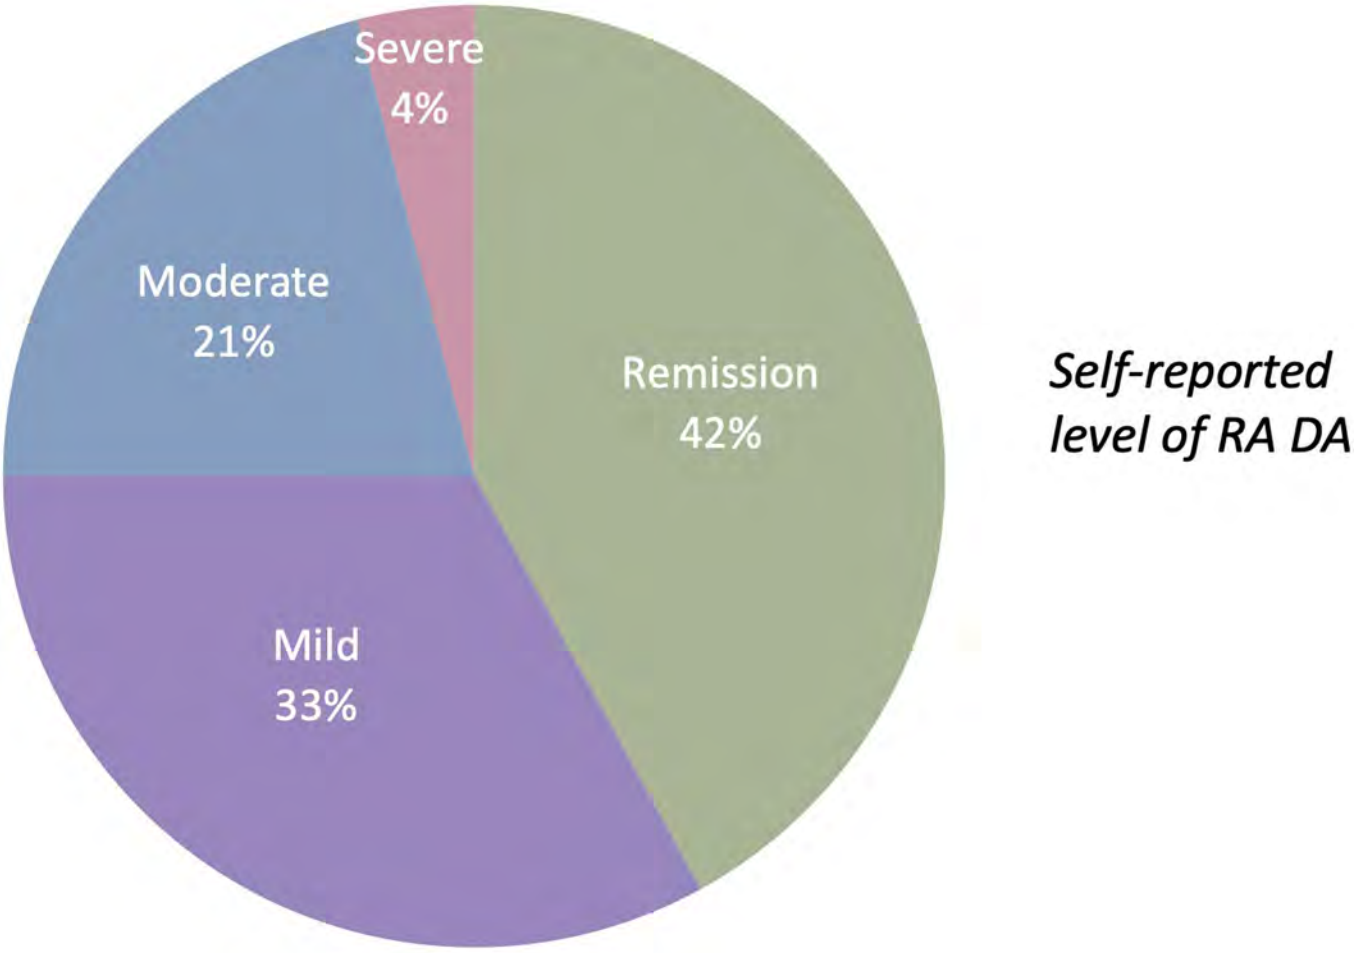
Relationships of Rheumatology Care and Patient Experiences to Rheumatoid Arthritis Remission

Kelly O'Neill[1], Kathryne Marks[2], Pamela Sinicrope[3], Cynthia Crowson[4], Elena Myasoedova[3] and John Davis[3], [1]Rheumatoid Patient Foundation, Lutz, FL, [2]Rheumatoid Patient Foundation, Boston, MA, [3]Mayo Clinic, Rochester, MN, [4]Mayo Clinic, Eyota, MN

SESSION INFORMATION
Session Date: Sunday, November 7, 2021
Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster II: Miscellaneous Aspects of RA (0786–0812)
Session Type: Poster Session B
Session Time: 8:30AM–10:30AM

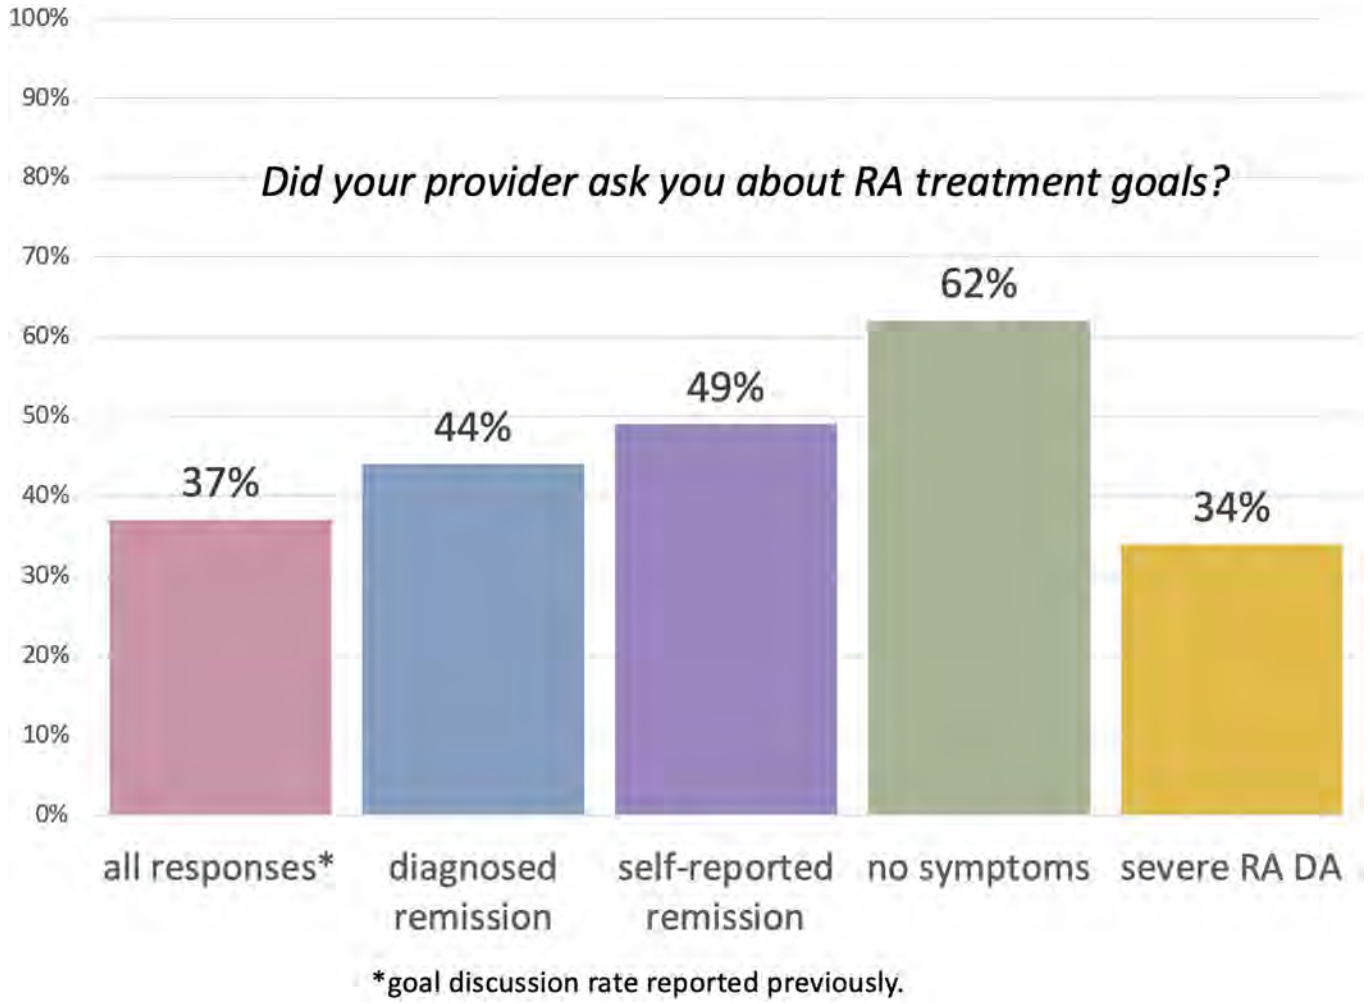
Background/Purpose: Remission is a well-established optimal outcome in rheumatoid arthritis (RA) treatment, yet a minority of patients reach this goal. There is not one recognized definition for RA remission, but several sets of criteria regarded as remission or low disease activity. Except aggressive treatment and less time between diagnosis and treatment, little is known of what factors may impact RA remission. Building on a long-term collaboration of a non-profit organization and an academic rheumatology center, we explored factors associated with RA remission.



Patient-assessed Disease Activity (DA) in Diagnosed RA Remission: Figure 1. Respondents replying "Yes" to "Does your doctor consider your RA to be in remission?" are divided by their replies to the question "What is your current level of RA disease activity?".

Methods: An anonymous survey was offered in 2019 on a secure online system. Participants were U.S. residents age ≥18 years with a self-reported RA diagnosis by a medical professional. They responded to questions on demographics, RA disease activity (DA), diagnosis and DMARD history, improvement from treatment, and RA treatment goals. Analyses included descriptive statistics with chi-square and rank sum tests for comparisons. Treatment goals were thematically coded and verified for reliability by a team using qualitative content analysis.

Results: The questionnaire was completed by 907 RA patients (90% women, 10% men), with 58 (11) mean (SD) years age and 11 (10) years since diagnosis. About twice as many reported being given an explicit diagnosis of RA remission (n=102; 11%) as patients who rated their DA as "in remission" (n=49; 5%). Patients rating their DA as in remission tried fewer different DMARDs than patients with more active disease (mean: remission 3.3; mild 4.2; moderate 5.7; severe DA 8.8). Those with diagnosed remission tried fewer mean DMARDs (4.7) than all respondents (5.8). Both self-reported remission and diagnosed remission were associated with less time between symptom onset and DMARD treatment. In both groups, about 35% were treated < 6 months of onset, but in all respondents, only 24% were treated this early. Both remission groups were associated with older current age and older age at diagnosis. Both remission groups were more likely to have had discussions with providers about RA treatment goals (diagnosed, 44% self-report, 51%) than all patients surveyed (37%).



RA Remission and Shared Treatment Goal Discussions: Figure 2. Patients in each category were asked whether their providers had discussed RA treatment goals with them.

Conclusion: This survey found previously unreported associations between remission and aspects of rheumatology care including time from symptom onset to treatment, age at diagnosis, and frequency of shared treatment goal discussions, independent of whether remission was clinically diagnosed or based on patient-reported DA levels. Our study is unique in that diagnosed remission is compared to self-reported DA "in remission," the former being twice as frequent. Further research should seek greater insight on patient experiences in remission and explore how factors associated with remission may be used to increase the rate of remission in people with RA.

Survey questions	Reported DA "in remission" n=49	Diagnosed remission n=102	All respondents n=907
Current age mean (SD)	60.3 (11.4)	60.1 (10.1)	57.9 (10.8)
Age at diagnosis mean (SD)	50.2 (13.3)	47.9 (15.2)	46.9 (12.9)
Years from diagnosis to treatment mean (SD)	1.7 (7.2)	1.4 (5.9)	0.9 (3.8)
Years since diagnosis mean (SD)	9.8 (8.6)	11.9 (10.8)	11.1 (10.1)
How many different DMARDs used mean (SD)	3.3 (3)	4.7 (3.7)	5.8 (4.4)
Highest level of improvement with DMARDs			
<20% improvement	1 (2%)	3 (3%)	129 (14%)
~20% improvement	2 (4%)	5 (5%)	157 (17%)
~50% improvement	2 (4%)	24 (24%)	277 (31%)
~70% improvement	13 (27%)	27 (26%)	197 (22%)
≥90% improvement	31 (63%)	43 (42%)	147 (16%)
How would you describe your current health?			
Very good	19 (19%)	17 (35%)	53 (6%)
Good	50 (49%)	23 (47%)	304 (34%)
Fair	24 (24%)	8 (16%)	355 (39%)
Poor	7 (7%)	0 (0%)	142 (16%)
Very poor	2 (2%)	1 (2%)	52 (6%)
Time from symptom onset to treatment			
<6 months (percent of group)	17 (35%)	36 (35%)	216 (24%)
6 months – 5 years	25 (51%)	42 (41%)	432 (48%)
>5 years	6 (12%)	23 (23%)	243 (27%)

Diagnosed remission in RA compared to patient-reported disease activity "in remission."

SESSION INFORMATION

Session Date: Sunday, November 7, 2021

Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster II: Miscellaneous Aspects of RA (0786–0812)

Session Type: Poster Session B

Session Time: 8:30AM–10:30AM

Background/Purpose: Sustained disease remission is the treatment goal for Rheumatoid Arthritis (RA) leading patients to be eligible to treatment tapering or discontinuation. However, disease flare is an unpredictable event after treatment change representing a burden for RA. The study aims were to assess the impact of clinical classification on synovial tissue (ST) inflammation in sustained remission RA and to identify biomarkers of disease flare after treatment modification.

Methods: 152 RA in sustained clinical (84 RA with DAS< 1.6 and 68 RA fulfilling Boolean remission criteria for at least 9 months, respectively) and ultrasound (US) remission (PDneg) under Methotrexate with or without biological-Disease Modifying Anti-Rheumatic Drug (bDMARD) underwent US guided ST biopsy and were enrolled in the study. 240 naive RA were enrolled as comparison group. For each patient, synovitis degree was determined using a H&E-based semiquantitative score[1]. Some ST samples of naive RA and RA in remission were used for digital spatial profiling (GeoMx DSP, Nanostring) to quantitate transcript abundance in spatially distinct regions of interest (ROIs) within ST. RA in remission were randomly assigned to tapering/discontinuation (TAP/DISC) group (tapering c- or b-DMARD treatment for 6 months first and discontinuing c- or bDMARD afterwards) or maintaining the therapy unchanged (CONT). Each RA was followed every 3 months to assess disease flare rate after treatment modifications for at least 6 months.

Results: Considering the whole RA cohort, despite either DAS- and Boolean-defined remission RA had significantly lower KSS than naive RA (p< 0.0001 for both), RA in Boolean remission had lower KSS compared to RA in DAS-defined remission (p< 0.0001). In particular, ST of RA in Boolean remission showed lower stromal density (p< 0.0001) and inflammatory infiltrate scores (p=0.0003) together with lower lymphocytes (p=0.003) and plasmacells presence rates (p=0.015) than ST of RA with DAS-defined remission. Among the whole cohort, 54(35.5%) RA had a disease flare regardless the treatment change. Moreover, RA with DAS-defined remission who had a disease flare within at least 6 months follow-up had, at study entry, significantly higher KSS (p=0.0005) than RA who maintained a sustained remission, regardless to the treatment change (CONT:p=0.0275 and TAP/DISC:p=0.0112, respectively). Conversely, RA in Boolean-defined remission did not differ in terms of ST inflammation at study entry in the CONT (p >0.05) as well as in the TAP/DISC (p >0.05) subgroup. However, DSP analysis revealed that ROIs in ST of RA in Boolean remission had a unique transcriptomic signature characterized by 298 differentially expressed genes belonging to 26

pathways compared with RA in DAS-defined remission, whose over-expression, identifies ROIs from ST of RA who had disease flare.

Conclusion: DAS- and Boolean-based remission definitions in RA mirror differential degree of residual subclinical synovitis and are characterized by distinct ST transcriptomic signature which identifies RA in remission at higher risk of disease flare after treatment modification.

Early Remission at 6 Months as a Predictor of Longterm Remission in New Onset Rheumatoid Arthritis

Emilie SAPART[1], Tatiana SOKOLOVA[2], Aleksandra AVRAMOVSKA[1], Paschalis SIDIRAS[3], Sandra KLEIMBERG[3], Stéphanie DIERCKX[4], Laurent MERIC de BELLEFON[5], Clio RIBBENS[6], Michel MALAISE[6], Silvana DI ROMANA[7], Valérie BADOT[8] and Patrick DUREZ[9], [1]Rhumatologie, cliniques universitaires saint-luc, Université catholique de Louvain - Institut de Recherche Expérimentale et Clinique (IREC), Brussels, Belgium, [2]Pôle de pathologies rhumatismales systémiques et inflammatoires, Institut de Recherche Expérimentale et Clinique, Université catholique de Louvain, Brussels, Belgium, [3]Rhumatologie, Hôpital Erasme, Brussels, Belgium, [4]Rhumatologie, CHU UCL Mont-Godinne, Brussels, Belgium, [5]Service de Rhumatologie, Cliniques Universitaires Saint-Luc, Brussels, Belgium, [6]Rhumatologie, CHU de Liège, Liège, Belgium, [7]Rhumatologie, CHU Saint–Pierre, Brussels, Belgium, [8]Rhumatologie, CHU Brugmann, Brussels, Belgium, [9]Pôle de Recherche en Rhumatologie, Institut de Recherche Expérimentale et Clinique, Brussels, Belgium

SESSION INFORMATION
Session Date: Sunday, November 7, 2021
Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster II: Miscellaneous Aspects of RA (0786–0812)
Session Type: Poster Session B
Session Time: 8:30AM–10:30AM

Background/Purpose: Early therapeutic intervention is crucial for patients with early rheumatoid arthritis (ERA). The goal of remission is achievable in a large proportion of ERA patients.

To evaluate the rate of patients in remission at 6 months and to correlate the 36 and 60 months remission rate in the Belgian CAP48 cohort and the UCLouvain Brussels cohort. To identify baseline characteristics differences between patients achieving remission or not.

Methods: We included patients with ERA from the CAP48 cohort and from the UCLouvain Brussels cohort who met the ACR/EULAR 2010 RA classification criteria. All patients were naïve to csDMARDs therapy. We collected patient characteristics at baseline and clinical response was analysed at 6, 36 and 60 months.

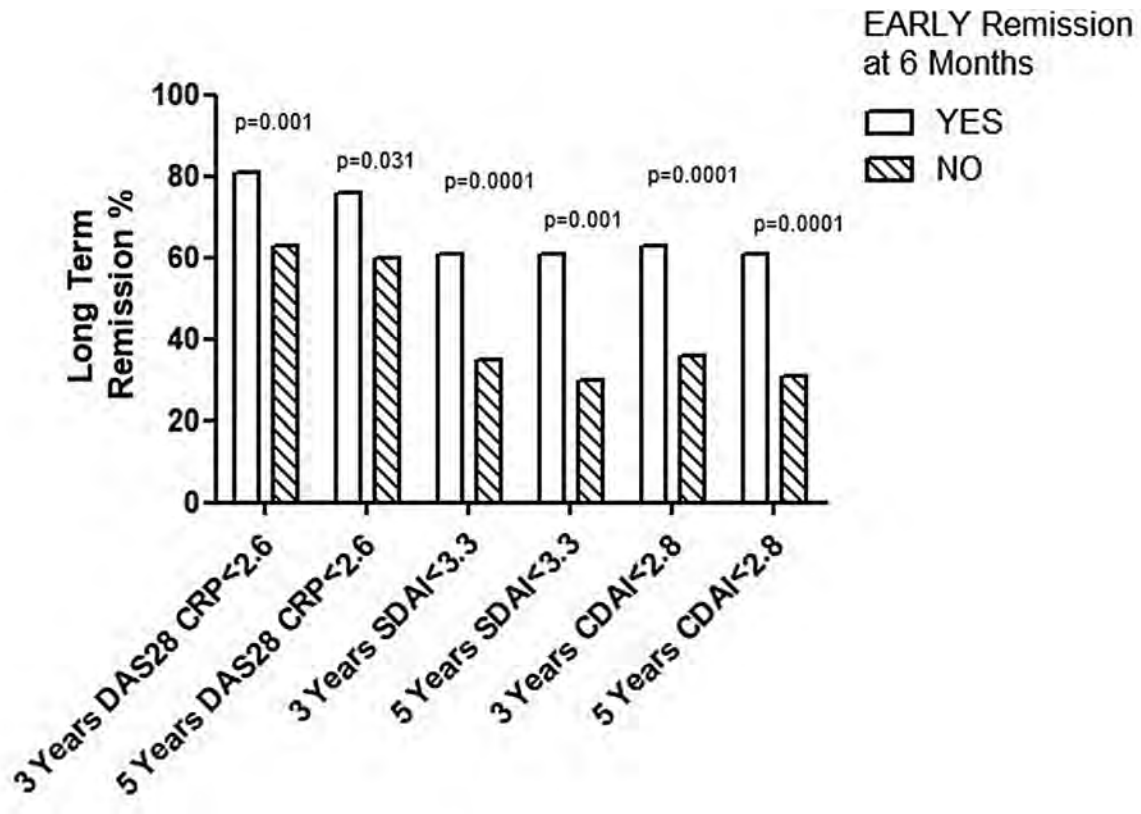
Results: 287 RA patients from our UCLouvain Brussels Cohort and the CAP48 cohort were analysed (211 Females, 76 Males, mean age 46.2 years, 43.4% with baseline erosion, 70.1% with ACPA, 70.3% with Rheumatoid Factor, mean HAQ 1.16, mean DAS28-CRP 4.67, mean SDAI 24.9 and mean CDAI 24.1).

The clinical results are summarized in the Table.

We divided the patients according to whether they achieved remission DAS28-CRP < 2.6 (group 1), or not (group 2) at 6 months.

Patient baseline characteristics were similar in the two groups respectively: age (46.7 vs 45.4 yrs); female (68.5 vs 77.3%); smoker (25.6 vs 27.0%); ACPA positive (70.1 vs 75.4%); baseline X-ray erosion (45.0 vs 54.7%).

DAS28-CRP, SDAI and CDAI at 6 months could predict long-term remission at 36 and 60 months (Figure).



In group 1 global remission (DAS28-CRP< 2.6, HAQ< 0.5 and no X-ray progression) was observed in 75.6% at 60 months. The majority of these patients (69.4%) are still treated with Methotrexate, the others were treated with combination therapy.

Conclusion: Early and long term remission is an achievable goal in our two cohorts. Early diagnosis is critical in standard of care. At 6 months, all remission index criteria are good predictor for long term remission and could be used in daily care.

Infection in Rheumatoid Arthritis Patients Treated with Golimumab

Louis Bessette[1], Proton Rahman[2], John Kelsall[3], Jane Purvis[4], Emmanouil Rampakakis[5], Allen Lehman[6], Meagan Rachich[6], Francois Nantel[7] and Odalis Asin-Milan[6], [1]Laval University, Québec City, QC, Canada, [2]Department of Medicine, Eastern Health and Memorial University of Newfoundland, St John's, NL, Canada, [3]Providence Health Care, Vancouver, BC, Canada, [4]Peterborough Education, Peterborough, ON, Canada, [5]JSS Medical Research, Montréal, QC, Canada, [6]Janssen Inc., Toronto, ON, Canada, [7]., Montreal, ON, Canada

SESSION INFORMATION
Session Date: Sunday, November 7, 2021
Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster II: Miscellaneous Aspects of RA (0786–0812)
Session Type: Poster Session B
Session Time: 8:30AM–10:30AM

Background/Purpose: Biologic use in RA is a well-characterized risk factors for infections. The aim of this analysis was to characterize the incidence of infection in RA patients treated with golimumab in Canadian routine care, as well as assess the impact of oral corticosteroid (CS) and DMARD use on infection.

Methods: This is a post-hoc analysis of the Biologic Treatment Registry Across Canada (BioTRAC). Patients with RA who initiated treatment with subcutaneous golimumab were included in this analysis. The incidence density rates (IDR) of total, serious (SI), and non-serious (NSI) infections were calculated for the overall follow-up period as well as by 6-month interval. Negative binomial and cox regressions were used to assess the impact of CS and DMARD use, as well as CS and methotrexate (MTX) dose levels. Time to first infection and time to treatment discontinuation were assessed with the Kaplan-Meier estimator of the survival function, and the impact of concomitant CS and DMARD use was assessed with the log rank test.

Results: 530 patients were included with a mean (SD) age of 57.7 (13.0) years and disease duration of 8.0 (8.3) years. Of these 74 (14.0%) were treated with ≤15mg/week MTX, 280 (52.8%) with >15mg/week MTX, while 173 (32.6%) were not on MTX. In terms of CS, 72 (13.6%) were treated with ≤5mg/day, 63 (11.9%) with >5mg/day, and 391 (73.8%) were not on CS.

Over a mean follow-up duration of 27.0 months, the IDR for total infections, NSI, and SI was 35.10 events/100 PYs, 32.90 events/100 PYs, and 2.23 events/100 PYs. Median estimated time to first infection was 52.9 months (SI: 84.9 months; NSI: 55.1 months). The incidence of total infections was 44.0, 37.3, 35.1, 29.4, 31.1, 35.7, 19.3, 7.4 and 0.0 events/100 PYs at 0-6 months, 6-12 months, 12-24 months, 24-36 months, 36-48 months, 48-60 months, 60-72

months, 72-84 months and 84-90 months, respectively. Longer follow-up duration was significantly associated with higher number of NSI (HR [95%CI]: 1.011 [1.006-1.017]) but not SI (1.011 [0.988-1.035]), while neither the use of DMARD, CS nor MTX was found to have an impact.

Conclusion: Higher IDR was observed during the first 6 months of treatment and decreasing thereafter. CS and DMARD treatment did not impact retention of golimumab treatment. These results support the notion that CS should be used concomitantly with anti-TNF for the shortest period possible to achieve remission, and then tapered.

Abstract Number: 0803

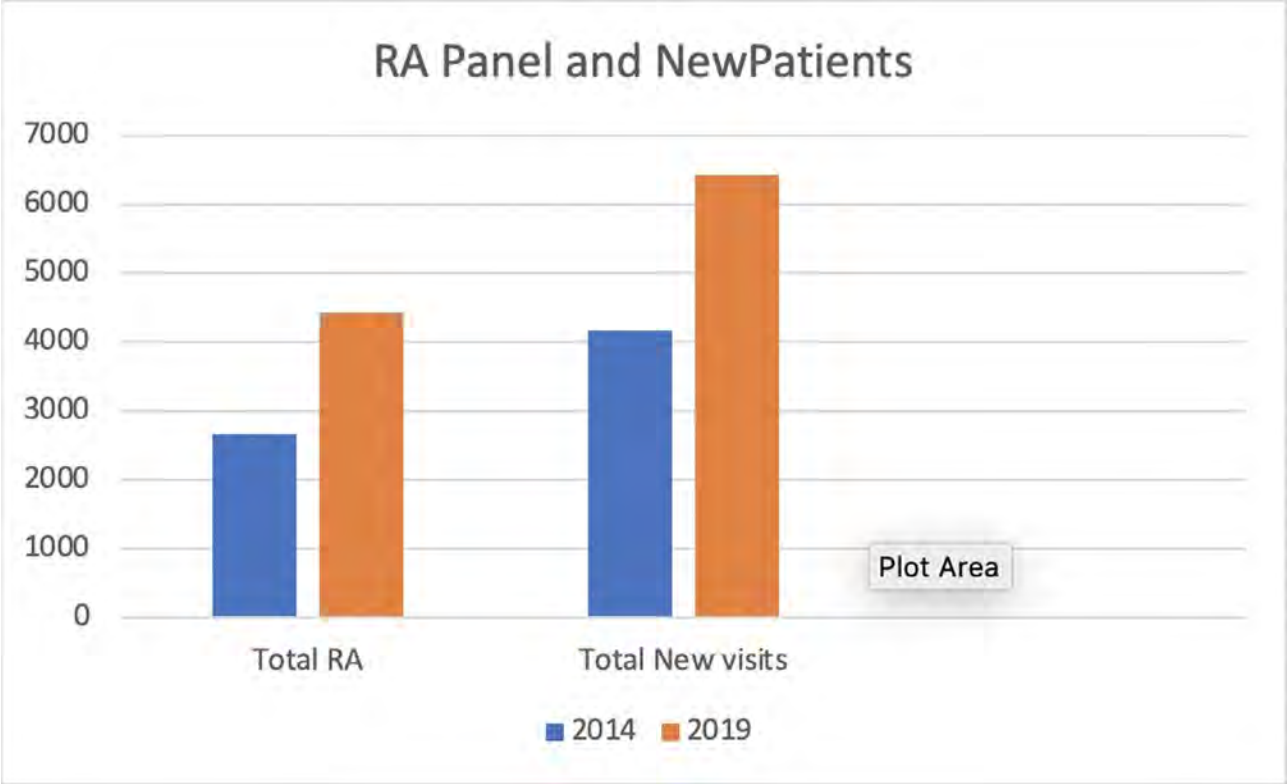
Rheumatoid Arthritis Practice Performance (RAPP) Project at 6 Years: Population Medicine (POPMED) Principles and Treat to Target (T2T) Care Yield Dramatic Improvements in Both Outcomes and Access for RA Patients and Productivity for Rheumatologists

William Arnold[1], Erin Arnold[1], David Sikes[2], Gary Crump[3], Kathleen Thomas[4] and andrew johnson[5], [1]Arnold Arthritis and Rheumatology, Wilmette, IL, [2]Florida Medical Clinic, Wesley Chapel, FL, [3]Rheumatology Associates, Louisville, KY, [4]Community Health Network, Noblesville, IN, [5]PopMed Solutions, Boyds, MD

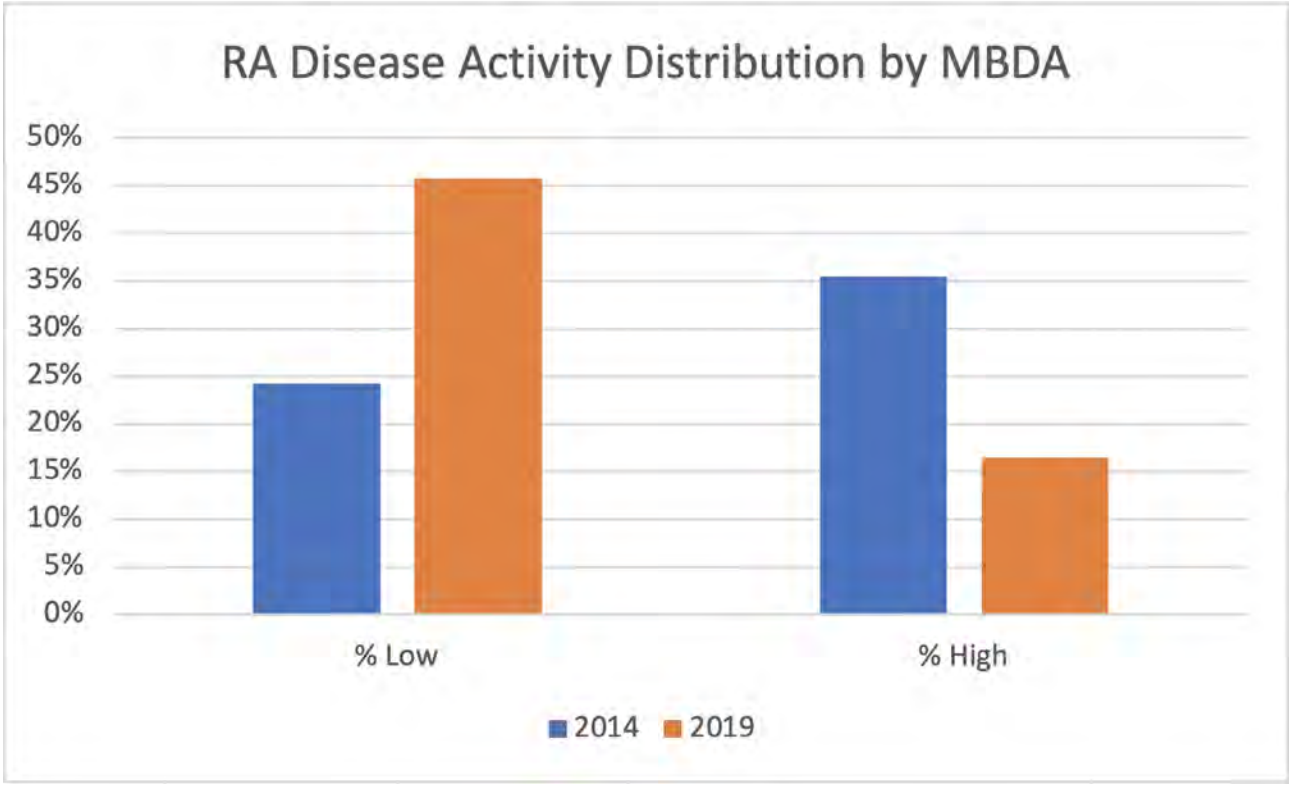
SESSION INFORMATION
Session Date: Sunday, November 7, 2021
Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster II: Miscellaneous Aspects of RA (0786–0812)
Session Type: Poster Session B
Session Time: 8:30AM–10:30AM

Background/Purpose: The RAPP quality improvement project is a voluntary consortium of practicing rheumatologists founded in 2013 by Timothy Harrington MD, MACR. The primary focus is to provide accurate, on-time disease activity assessments and necessary treatments for an entire RA population consistent with T2T recommendations. We identified a bottleneck at available physician appointments as a major impediment. To address this bottleneck, RAPP practices utilized principles of chronic disease management (POPMED) such as team care with advanced practice providers and medical assistants gathering pertinent clinical, lab and imaging data 1-2 weeks prior to the actual clinical visit with the Rheumatologist. We now report our experience with RA disease activity outcomes, timeliness of care and Rheumatologist productivity over 6 years in 4 RAPP practices that have implemented both T2T care and POPMED principles.

Methods: The 4 Rheumatology practices included in this analysis represent a spectrum of community-based, physician-owned Rheumatology providers including two large (>250 MDs) multispecialty groups, a 4 Rheumatologist practice and a solo practice. Timeliness of care was judged by fulfilling ACR/EULAR guidelines of assessments every 3 months for high or moderate disease activity (HDA) patients and 3-6 months for low or controlled disease activity (LDA) patients. RAPP practices also chose to use one or more composite disease activity profile from a panel



RA Panel and New Patients



RA Disease Activity Distribution by

(Rapid-3, CDAI, SJC, TJC, MD Global) . All or part of these were obtained by team members at each visit prior to the Rheumatologist seeing the patient. Only MBDA (Vectra) testing was utilized in all 4 practices at prescribed intervals.

Results: Over 6 years the 4 practices in total decreased the number of Rheumatologists from 11 to 10 while increasing the number of team members from 54 to 76. The added positions included 8 NP/PAs, 4 MAs and an assortment of other support staff. Total annual new patient visits increased 54% from 4165 to 6424(Image1).There was a 66% increase in the RA patient panel from 2673 (range 428 to 824) to 4428 (690-1307). MBDA scores demonstrated that initially 35% of RA patients had HDA and 42% were evaluated on time (Image 2). 6 years later only 16% of RA patients had HDA with 56% evaluated on time. A concomitant increase in RA patients with LDA from 24 to 46% was noted with on time evaluations increasing from 55% to 68%.

Conclusion: Creation of patient care teams and re-designing the patient visit into two components allowed almost 1800 additional patients with RA to access Rheumatology care despite an actual decrease in the number of Rheumatologists in the 4 practices. Associated with improved access, the number of RA patients with HDA declined dramatically (35% to 16%) and LDA increased (24 to 46%) as the timeliness of their visits improved. We conclude that Dr Harrington's vision of using T2T care and POPMED principles to improve quality and access to care for patients with RA has proven true.

Finally, the dramatic improvements in Rheumatologist productivity associated with implementing team care suggests the RAPP project can be a model to mitigate the shortage of Rheumatologists both now and projected in the future.

Validation of the 2010 ACR/EULAR Classification Criteria of Rheumatoid Arthritis (RA) in a Nursing-led Triage Clinic

Ching Man Tsang[1], Chi Chiu Mok[2], Kar Li Chan[3], Sau Mei TSE[1] and Ling Yin Ho[1], [1]Tuen Mun Hospital, Hong Kong, Hong Kong, [2]Tuen Mun Hospital, Hong Kong, China, [3]Tuen Mun Hospital, Hong Kong

SESSION INFORMATION
Session Date: Sunday, November 7, 2021
Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster II: Miscellaneous Aspects of RA (0786–0812)
Session Type: Poster Session B
Session Time: 8:30AM–10:30AM

Background/Purpose: To shorten the waiting time to see rheumatologists, a nurse-led triage clinic was established in our hospital in September 2018 to triage new referrals for peripheral joint symptoms. Patients who were assessed to fulfil the ACR/EULAR criteria for rheumatoid arthritis (RA) were channeled for an early appointment while others a routine appointment in the rheumatology clinics. The objective of this study is to validate the performance of the 2010 ACR/EULAR classification criteria of RA in a nurse-led triage clinic.

Methods: Adult patients who presented with peripheral joint pain and referred to the medical clinics of Tuen Mun Hospital, Hong Kong between October 2018 and October 2020 were studied. Patients were seen face-to-face by a designated rheumatology nurse specialist (CMT) for assessment of the medical history, fulfillment of the ACR/

Performance of ACR/EULAR criteria	Sensitivity (%)	Specificity (%)	PPV (%)	NPV (%)
All patients (n=282)	92.1 (83.6-97.1)	86.4 (81.0-90.8)	71.4 (63.8-78.0)	96.7 (93.2-98.5)
Age ≥50 years (n=210)	93.2 (83.5-98.1)	84.1(77.3-89.5)	69.5 (61.2-76.9)	97.0 (92.5-98.8)
Age <50 years (n=72)	88.2 (63.6-98.5)	92.7 (82.4-98.0)	79.0 (59.0-90.7)	96.2 (87.4-99.0)
Male patients (n= 59)	80.0 (51.9-95.7)	84.1 (69.9-93.4)	63.2 (45.4-78.0)	92.5 (81.6-97.2)
Female patients (n= 223)	95.1 (86.3-99.0)	87.0 (80.9-91.8)	73.4 (64.9-80.5)	97.9 (94.0-99.3)

EULAR RA criteria and the number of tender and swollen peripheral joints. A final clinical diagnosis of RA made by the attending rheumatologists was regarded as the standard and the performance of the ACR/EULAR criteria for RA was validated by a 2x2 contingency tables according to a diagnosis of RA ("condition positive") and criteria fulfilment ("test positive") using standard formulas (sensitivity = true positive/[true positive+false negative]; specificity = true negative/[true negative+false positive]); positive predictive value (PPV) = true positive/true positive+false positive; negative predictive value (NPV) = true negative/true negative+false negative).

Results: A total of 336 patients were seen in the nurse-led clinic during the specified period. 51 patients were excluded because they were diagnosed to have RA by other specialists or private rheumatologists. Finally, 282 patients were studied (223 women [79%]; age 55.2±11.9 years [18-88]). All except 4 patients were ethnic Chinese. 73 (25.8%) patients were anti-CCP positive, 123 (43.5%) patients were rheumatoid factor (RF) positive, and 28 (9.9%) patients had more than 10 joints involved. A total of 98 patients fulfilled the ACR-EULAR criteria, 78 (79.6%) of whom were diagnosed clinically as RA by rheumatologists. The clinical diagnosis of patients who fulfilled the ACR-EULAR criteria but not clinical RA were: osteoarthritis (n=14), psoriatic arthritis (n=3), fibromyalgia (n=3), undifferentiated connective tissue disease (n=2), lupus (n=1), scleroderma (n=1) and others (n=4). The sensitivity and specificity of ACR/EULAR criteria for RA was 92.1% and 86.4%, respectively. Subgroup analyses showed that the ACR/EULAR RA criteria was less sensitive but more specific in younger patients (< 50 years). Both the sensitivity and specificity of the ACR/EULAR criteria for RA was lower in male patients.

Conclusion: The performance of the 2010 ACR/EULAR criteria for triage purpose in our nurse-led triage clinic is satisfactory. The higher specificity and sensitivity of the criteria as compared to other European and Asian cohorts is possibly related to the longer duration of joint symptoms in our patients before nursing assessment.

SESSION INFORMATION

Session Date: Sunday, November 7, 2021

Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster II: Miscellaneous Aspects of RA (0786–0812)

Session Type: Poster Session B

Session Time: 8:30AM–10:30AM

Background/Purpose: Patients (pts) with immune-mediated rheumatic diseases and an insufficient response to previous treatment with TNFα inhibitors (TNFαi) are frequently encountered in clinical practice. This study assessed the effectiveness of golimumab (GLM) and its impact on patient-reported outcomes in this population.

Methods: GO-BEYOND was a real-world, prospective, 18-month study conducted in 25 sites in Greece. Eligible pts had active RA, PsA, or axSpA and had failed previous treatment with one TNFαi due to secondary non-response (defined as disease relapse following ≥6 months of treatment), intolerability, or inconvenience. The primary objective assessed the proportion of pts with: RA attaining low disease activity (LDA; DAS for 28 joints based on CRP [DAS28-CRP] < 3.2); PsA attaining minimal disease activity (MDA; defined by MDA criteria); and, axSpA attaining moderate disease activity (Bath Ankylosing Spondylitis Disease Activity Index [BASDAI] between 4 and 7) at 6 months. Disease activity, including inactive disease in axSpA pts (Ankylosing Spondylitis Disease Activity Score [ASDAS] < 1.3), was assessed at months 3, 12 and 18 as part of the secondary objectives, which also assessed work productivity and activity impairment (Work Productivity and Activity Impairment Questionnaire [WPAI]), QoL (EQ-5D-3L questionnaire), and healthcare resource utilization (HCRU) via a patient diary, at baseline (BL), 3, 6, 12, and 18 months in all indications. Drug persistence was evaluated using the Kaplan-Meier method.

Results: A total of 242 pts (RA: 117 [48.3%]; PsA: 63 [26.0%]; axSpA: 62 [25.6%]) were included, with a mean (SD) age of 55.1 (13.5). Most pts were female (173, 71.5%). The median (Q1-Q3) time from diagnosis to study entry was 3.6 (2.1-7.1) years. At BL, pts with RA had a median (Q1-Q3) DAS28-CRP of 4.8 (4.5-5.3), pts with PsA had a median (Q1-Q3) DAS28-CRP of 4.7 (4.3-5.1), and pts with axSpA had a median (Q1-Q3) BASDAI of 6.2 (4.7-6.9). Following 6 months of GLM treatment, 46.4% (45/97) of pts with RA achieved LDA and 57.1% (32/56) of pts with PsA achieved MDA; of pts with axSpA, 98.1% (53/54) achieved BASDAI≤7, 74.1% (40/54) achieved BASDAI < 4 and 31.3% (15/48) achieved inactive disease by ASDAS. Improvements in disease activity were also observed across each time point (3,

12 and 18 months) (Table 1). In the entire cohort (RA, PsA, and axSpA), the changes in all WPAI domain scores from BL to 3, 6, 12, and 18 months were significant ($p < 0.001$ all comparisons; Table 2), as were the respective changes in the EQ-5D-3L UK index score (Table 3). Of all pts, ~90.0% had disease-related laboratory tests performed and ~20.0% visited specialist physicians during the observation period; no hospitalizations were recorded. Finally, the persistence rates at 3, 6, 12 and 18 months were 93.7%, 89.0%, 85.1% and 85.1%.

Table 1. Disease Activity Measures by Disease Type

		Patients achieving each endpoint/ Patients with available data	%
RA patients – LDA (DAS28-CRP<3.2)			
3 months		35/108	32.4
6 months		45/97	46.4

Absenteeism	93	-3.5 (-7.7, -0.2)	
Presenteeism	93	-40.0 (-50.0, -30.0)	<0.001
Work productivity loss	93	-40.0 (-50.5, -29.9)	
Activity impairment	182	-40.0 (-60.0, -30.0)	
Median (Q1, Q3) change in domain scores from baseline to 18 months, %			
Absenteeism	83	-3.2 (-7.0, -1.4)	
Presenteeism	83	-50.0 (-60.0, -40.0)	<0.001
Work productivity loss	83	-50.0 (-58.1, -39.4)	
Activity impairment	173	-50.0 (-60.0, -30.0)	

*Number of patients with available data. §By Wilcoxon signed-rank test for paired samples. Q1, first quartile; Q3, third quartile.

Conclusion: In a real - world setting in Greece, pts with active RA, PsA or axSpA, treatment with GLM over 18 months resulted in clinically relevant improvements in disease activity, while a high persistence rate was observed. Significant improvements in work productivity, activity impairment, and QoL were observed from BL to 3, 6, 12 and 18 months. HCRU was mostly driven by laboratory tests.

SESSION INFORMATION
Session Date: Sunday, November 7, 2021
Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster II: Miscellaneous Aspects of RA (0786–0812)
Session Type: Poster Session B
Session Time: 8:30AM–10:30AM

Background/Purpose: Receiving a Rheumatoid Arthritis (RA) diagnosis presents a significant health stressor. Given that little is known about how patients cope with it, we aimed to validate for the first time the Coping with Health Injuries and Problems (CHIP) questionnaire (Endler NS et al. Psychol Assessm 1998;10:195) in early RA.

Methods: Between August 2006 and October 2020, 483 consecutive patients who met the criteria for RA were enrolled at the Centre Hospitalier Universitaire de Sherbrooke (CHUS). At baseline and at each scheduled yearly study visit, patients self-administered the CHIP questionnaire. CHIP is comprised of 32 items, with 4 subscales: Distraction, Palliative, Instrumental, Emotional. Each subscale is the sum of 8 items with a score ranging from 8 to 40. CHIP's validity was assessed for internal consistency with Cronbach's alpha, for sensitivity to change with mixed linear model with repeated measures as well as for factor structure with factorial analysis and confirmatory analysis.

Table 1. Cronbach's alpha for original subscales of the CHIP questionnaire

	Cronbach's alpha
Distraction	0.754
Palliative	0.736
Instrumental	0.763
Emotional	0.857

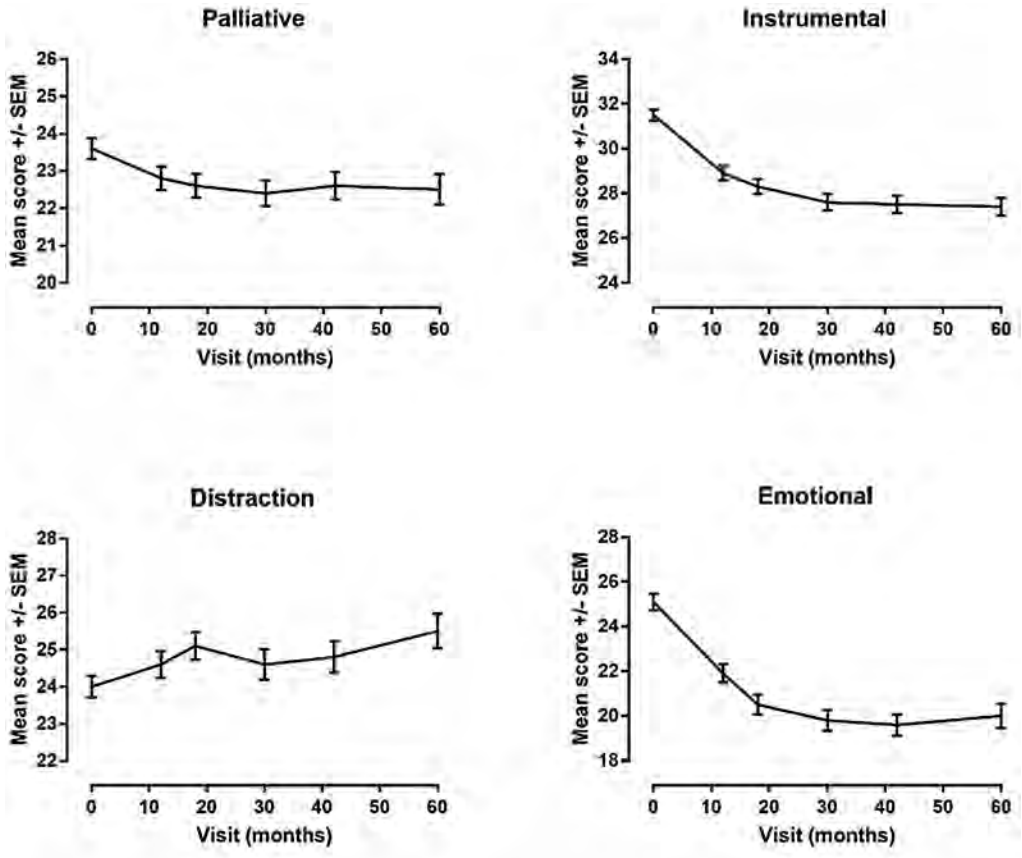

Figure 1. Evolution of CHIP subscales over the five years following RA onset

Results: A total of 420 patients were followed up to 5 years. The baseline mean (SD) of 4 subscales were 24.01 (6.46) for Distraction, 23.58 (6.07) for Palliative, 31.48 (5.35) for Instrumental and 25.10 (7.95) for Emotional. CHIP demonstrated good psychometric properties. Internal consistency (Cronbach's alpha) varied between 0.736 and 0.857 (Table 1); deleting each element separately did not improve the coefficient suggesting that each was an important contributor to the overall score. CHIP was sensitive to change with significant decreases (estimated ± SE) until 5 years for Instrumental (-4.25 ± 0.36, p< 0.001), Emotional (-5.87 ± 0.44, p< 0.001), Palliative (-1.27 ± 0.35, p< 0.001) and a significant increase for Distraction (1.15 ± 0.40, p=0.04) (Figure). Factor analysis suggested that all items were better represented on 7 subscales rather than 4; the 7-dimension solution explained 56.5% (versus 37.8%) of the total variability. The first subscale was defined by all 8 Emotional items; the second by 6 of 8 items of Distraction; five of the Instrumental items were found on dimension 3, the 3 others (linked to treatment adherence) were on dimension 5; Palliative items were split into 3 subscales (4, 6 and 7) that we called comfort, rest and well-being (Table 2). Confirmatory analyses showed that 7 subscales may be slightly better than the original 4, although Cronbach's alphas of the new 7 subscales were not improved when compared to the original 4.

Table 2. Results of factorial analysis using the 32 coping items of the CHIP questionnaire

	Fact 1	Fact 2	Fact 3	Fact 4	Fact 5	Fact 6	Fact 7

Eigenvalues	4.20	2.87	2.69	2.34	2.30	1.90	1.78
% of Variance explained	13.12	8.96	8.42	7.31	7.20	5.95	5.55
Cronbach's alpha	0.857	0.724	0.741	0.677	0.751	0.646	0.421

Conclusion: CHIP questionnaire describes patient's individual coping styles when facing recent-onset RA. Due to the prospective nature of our cohort, we could validate the questionnaire. Factor analysis suggested that coping in early RA was better characterized using 7 rather than 4 subscales, but Cronbach's alpha suggested that using the original tool might be as good, an observation that remains to be confirmed. Discussing a patient's results for CHIP may enable a rheumatologist to understand patients' perspectives and address their needs better, thereby strengthening their relationship. Results from CHIP may also be used as predictor of patients' outcomes pointing towards interventions that may help those in need to deal with their illness better.

Abstract Number: 0807

Baseline Coping Strategies as Predictors of Outcomes in Patients with Early-onset Rheumatoid Arthritis (RA)

Zafer Akman[1], Gilles Boire[2], Nathalie Carrier[3], Sophie Roux[4], Ariel Masetto[2], Artur deBrum Fernandes[5], Patrick Liang[2], Patricia L Dobkin[6] and Allard-Chamard Hugues[7], [1]Istanbul University Cerrahpasa, İstanbul, Turkey, [2]Universite de Sherbrooke, Sherbrooke, QC, Canada, [3]CIUSSS de l'Estrie - CHUS, Sherbrooke, QC, Canada, [4]Université de Sherbrooke, Sherbrooke, QC, Canada, [5]Universite De Sherbrooke, Fleurimont, QC, Canada, [6]McGill University, Montréal, QC, Canada, [7]Universit de Sherbrooke, Sherbrooke, QC, Canada

SESSION INFORMATION
Session Date: Sunday, November 7, 2021
Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster II: Miscellaneous Aspects of RA (0786–0812)
Session Type: Poster Session B
Session Time: 8:30AM–10:30AM

Background/Purpose: Patients recently diagnosed with RA employ various coping strategies. We aimed to describe these strategies over time and determine if specific strategies impacted patient outcomes.

Methods: Consecutive patients meeting the criteria for early RA identified at the Centre Hospitalier Universitaire de Sherbrooke(CHUS) self-administered the Coping with Health Injuries and Problems (CHIP) questionnaire at baseline and yearly follow-ups, up to 5 years. CHIP consists of 32 items with 4 subscales: Distraction, Palliative, Instrumental, Emotional, each containing 8 questions scored from 1 to 5. The scores (range 8-40) over time were examined by gender. Correlation between score and clinical variables at baseline were computed. Baseline scores were used to predict disease outcomes over time. The primary outcomes were: remission according to Simple Disease Activity Index (SDAI) and disability according to the Modified-Health Assessment Questionnaire (M-HAQ). CHIP scores were analyzed with the continuous scale and dichotomized according to the upper or lower third of the scale (≥30 or ≥18). P-values were calculated with linear mixed regression models for continuous outcomes or with generalized estimating equation for dichotomic outcomes.

	Distraction	Palliative	Instrumental	Emotional
p-value (Time)	<0.001	0.012	<0.001	<0.001
p-value (Gender)	<0.001	<0.001	<0.001	0.0214
p-value (Interaction)	0.038	0.033	0.199	0.374

Figure 1. Evolution of CHIP subscales over the five years according to gender.

Results: 482 patients were enrolled between August 2006 and October 2020 (61% female). Baseline mean scores (SD) were: 24.01 (6.46) for Distraction, 23.58 (6.07) for Palliative, 31.48 (5.35) for Instrumental and 25.10 (7.95) for Emotional.

Table 1. Correlation between CHIP subscales at baseline and clinicals variables at baseline

For all subscales, females scored significantly higher than males and scores varied significantly over time (Figure 1). For Distraction and Palliative, scores declined faster in males than females, with significantly different slopes (interaction: gender*time).

At baseline, Emotional subscale was significantly correlated with depressive symptoms measured with Center for Epidemiological Studies-Depression (CES-D) (r=0.58) and with M-HAQ, fatigue, pain, disease activity according to the patient and the physician (r values between 0.20 to 0.33). Palliative subscale at baseline had significant correlations with the same variables, albeit weaker (r values 0.10 to 0.28) (Table 1).

≥ 18 (Lower)	0.92 (0.61-1.41)	0.7341	0.97 (0.44-2.10)	0.9306	1.08 (0.50-2.36)	0.8298	1.11 (0.30-4.16)	0.8704
Emotional								
Continuous	0.96 (0.96-0.97)	**<0.0001**	0.94 (0.93-0.95)	**<0.0001**	0.94 (0.93-0.95)	**<0.0001**	1.08 (1.07-1.10)	**<0.0001**
≥ 30 (Upper)	0.94 (0.84-1.05)	0.2574	0.69 (0.57-0.84)	**0.0001**	0.76 (0.64-0.91)	**0.0022**	2.04 (1.58-2.63)	**<0.0001**
≥ 18 (Lower)	0.81 (0.72-0.90)	**0.0011**	0.62 (0.52-0.74)	**<0.0001**	0.66 (0.56-0.78)	**<0.0001**	3.61 (2.24-5.82)	**<0.0001**

For baseline Emotional subscale, subjects with a score of ≥18 had less SDAI remission over time (RR 95% CI: 0.62 (0.52-0.74), p< 0.001) and higher M-HAQ over time (RR: 3.61 (2.24-5.82), p< 0.001) (Table 2). For Palliative, the best cut-off for SDAI remission was lower third (RR: 0.58 (0.44-0.77), p< 0.001) and upper third for M-HAQ (RR: 2.26 (1.32-3.86), p< 0.001). For Instrumental, the mean baseline score was above the upper third cut-off (≥30); the best cut-off for both remission and M-HAQ was thus set higher at ≥35.

Conclusion: CHIP questionnaire describes coping styles when facing health challenges such as recent-onset RA. Coping strategies vary across gender, female having the highest scores at baseline and over time. When maladaptive coping strategies dominate (e.g., emotional) poor outcomes are encountered. Our results indicate that CHIP may be a novel predictor for RA outcomes. Analyzing whether coping strategies add to existing models to predict outcomes in early RA patients is warranted.

[1]Age, sex and other variables with p<0.1 are listed. [2] adjusted for age, ESR and VAS pain at baseline. ESR – erythrocyte sedimentation rate; MIP-1β - Macrophage inflammatory protein-1β; VAS – visual analogue scale

with conventional synthetic disease modification anti-rheumatic drug (csDMARDs), and eventually escalate to biologic/targeted synthetic DMARDs (b/tsDMARDs) when the target is not met. The response rate to csDMARDs varies among individuals. Currently, there are limited biomarker data in predicting csDMARDs response. If certain biomarker could predict non-response towards csDMARDs, would early initiation of b/tsDMARDs improve disease prognosis remained uncertain.

Methods: This is a 6-month pilot prospective discovery cohort in patients with ERA. Patients received T2T treatment according to a standardized protocol with every 3-monthly follow up. Patients who achieved simplified disease activity index (SDAI) remission at month 6 is defined as csDMARDs responder. Serum blood sample was collected at baseline and 48 cytokines and chemokines Bio-Rad Bioplex assay was performed.

Results: Twenty-seven patients (age: 55±15 years; female: 21(78%)) who had completed month 6 follow up were included in the current analysis. All patient received csDMARDs treatment. After 6 months, significant improvement in disease activity was observed (SDAI: 24.4±8.3 at baseline vs 8.0±6.5 at month 6, $p< 0.001$). One third of them (9/27, 33%) achieved SDAI remission at month 6 and were regarded as csDMARDs responder (DR). Patients in DR+ group were older, had lower pain score and higher Erythrocyte sedimentation rate (ESR) (Table 1). There were no statistically difference between the use of drugs across the two groups during study period. Macrophage inflammatory protein-1β (MIP-1β) is a proinflammatory chemokine produced by macrophages. Baseline serum level of MIP-1β were dateable in all patients, and the level was significantly lower in DR (DR: 393±21 ng/ml vs non-DR: 437 ±46 ng/ml, $p=0.012$). Using multivariate logistic regression, lower MCP-1 was significantly associated with csDMARDs response (OR=0.87, 95%CI: 0.77 to 0.99, $p=0.034$) after adjustment of age, ESR and pain score at baseline. MIP-1β were also positively correlated with rheumatoid factor ($r=0.559$, $p=0.02$) at baseline and SDAI at month 6 ($r=0.412$, $p=0.012$).

Conclusion: Lower serum level of MIP-1β was associated with csDMARDs response in patients with ERA. Further validation will testify current findings.

The Impact of Flares on Clinical and Patient Reported Outcomes in Rheumatoid and Undifferentiated Arthritis Patients

Johanna Maria Maassen[1], Sytske Anne Bergstra[1], PDM de Buck[2], Maikel van Oosterhout[3], Cornelia F. Allaart[1] and Tom WJ Huizinga[1], [1]Leiden University Medical Center, Leiden, Netherlands, [2]Haaglanden medical center, The Hague, Netherlands, [3]Groene Hart Hospital, Gouda, Netherlands

SESSION INFORMATION
Session Date: Sunday, November 7, 2021
Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster II: Miscellaneous Aspects of RA (0786–0812)
Session Type: Poster Session B
Session Time: 8:30AM–10:30AM

Background/Purpose: There are many definitions of flare in rheumatoid arthritis (RA). Loss of low disease activity is associated with clinically relevant deterioration. Patients in DAS remission may flare to DAS≥1.6 but still have low disease activity. How does this affect outcomes? Therefore the objective of this study was to evaluate the prevalence of disease flares in patients treated to target DAS < 1.6, and to study the impact on clinical and patient-reported outcomes (PROs).

Methods: In the IMPROVED study 610 patients with early RA or UA were treated to target DAS< 1.6 for 5 years. Flares were defined as; **A)** DAS≥1.6 regardless of the previous DAS and ≥0.6 increase; **B)** DAS≥1.6 and previous DAS< 1.6 with ≥0.6increase. Kruskal Wallis tests were used to compare mean HAQ over time, HAQ at 5y, and median SHS progression at 5y between patients with different no. of flares. The OR for a significant deterioration of ≥20mm (from the preceding visit) on a visual analogue score (VAS) for disease activity, pain and morning stiffness during flares were calculated using a generalized linear mixed model.

Results: Over time 75% of patients had ≥1 flare **A**, and 68% ≥1 flare **B**. In 55% and 69% of cases, respectively, DAS remained ≤2.4. In 55% of flares A and B, a clinically relevant increase in HAQ of ≥0.22 occurred. This significantly (p< 0.01) increased to 68% in flares A and 76% in flares B if the DAS had increased to ≥2.4. More flares A per person were associated with a higher mean HAQ over-time and at 60 months and SHS progression at 5y (table 1). Also for the patient reported outcomes, there was a significant risk for a >20 mm deterioration (ORs ≥1 with 90% confidence intervals exceeding 1) for flares A and B (table 2).

Conclusion: In most patients, significant deterioration in PROs occurred when DAS increased to >1.6, even if DAS remained ≤2.4. Regardless of previous DAS, an increase in ≥0.6 DAS points was clinically relevant. Cumulative flares were associated with loss of and radiological progression at 5 years.

Table 1. Dose-response effect of the number of flares on functional ability and radiographic damage progression

Persistent Disease Activity Impairs Work Productivity and Non-work Activity in Recent Onset Rheumatoid Arthritis

Carol Hitchon[1], Marie-France Valois[2], Orit Schieir[3], Susan Bartlett[2], Louis Bessette[4], Gilles Boire[5], Glen Hazlewood[6], Edward Keystone[7], Janet Pope[8], Carter Thorne[9], Diane Tin[10], Vivian Bykerk[11] and Canadian Early Arthritis Cohort (CATCH) Investigators[12], [1]University of Manitoba, Winnipeg, MB, Canada, [2]McGill University, Montréal, QC, Canada, [3]Canadian Early Arthritis Cohort Study, Montréal, QC, Canada, [4]Centre de l'Ostoporose et de Rhumatologie de Qubec, Québec City, QC, Canada, [5]Universite de Sherbrooke, Sherbrooke, QC, Canada, [6]University of Calgary, Calgary, AB, Canada, [7]Keystone Consulting Enterprises Inc., Toronto, ON, Canada, [8]University of Western Ontario, London, ON, Canada, [9]Southlake Regional Health Centre, Newmarket, ON, Canada, [10]The Arthritis Program Research Group, Newmarket, ON, Canada, [11]Hospital for Special Surgery, New York, NY, [12]Canadian Early Arthritis Cohort, Toronto, ON, Canada

SESSION INFORMATION

Session Date: Sunday, November 7, 2021

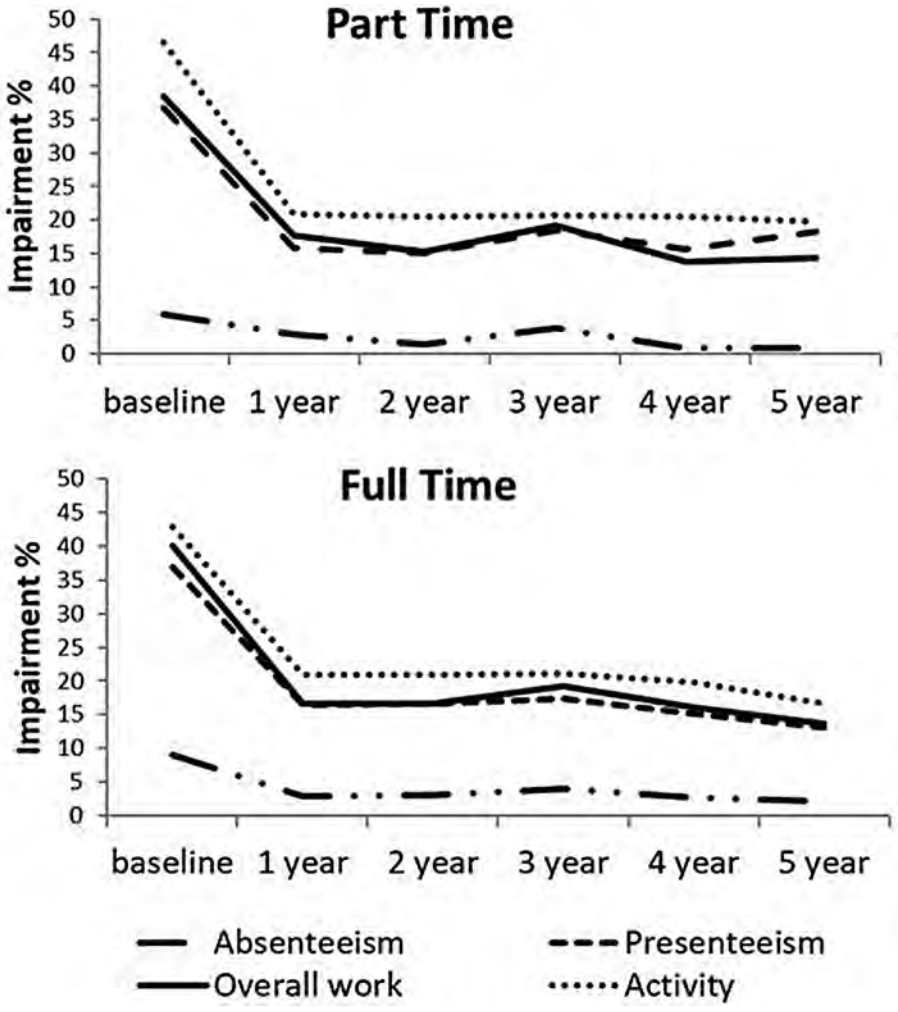
Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster II: Miscellaneous Aspects of RA (0786–0812)

Session Type: Poster Session B

Session Time: 8:30AM–10:30AM

Background/Purpose: Reduced work and activity productivity are significant contributors to the personal and societal costs associated with rheumatoid arthritis (RA). We sought to describe work productivity in newly diagnosed RA patients and to identify predictors of impaired productivity over time in patients managed according to contemporary treatment strategies.

Methods: Data were from working age, early RA patients (18-64 years; < 1 year of symptoms at baseline), followed by rheumatologists across Canada and treated with disease modifying anti-rheumatic drug therapies (DMARDs) according to Treat-2-Target guidelines. Between Nov 2011 and March 2020, participants reported baseline work status (employed, unemployed, retired) and annual work productivity was assessed using the Work Productivity and Activity Index (WPAI). WPAI scores for overall work productivity loss with subscores for absenteeism (time away from work) and presenteeism (reduced productivity at work) and scores for reduced general activity are expressed as impairment percentages (%) with higher numbers indicating greater impairment and less productivity. We used generalized estimating equations (GEE) to estimate associations between change in WPAI scores over the first five years of follow-up with time varying lagged disease activity (DAS28 at previous visit predicting WPAI at the next visit), while adjusting for baseline variables of age, sex, work commitment (full time; part-time) and comorbidity [Rheumatic Disease Comorbidity Index (RDCI; range 0-9); depression], and time-varying lagged therapy use (Methotrexate (MTX), biologic DMARDs/ JAKi, prednisone) at the previous visit.



Work productivity and activity impairment over the first five years of follow-up.

Results: At baseline, of 673 working age RA patients, 434 (65%) were employed [352 (82%) full time], 159 (24%) were unemployed and 74 (11%) were retired. Employed RA patients were mainly female (75%), Caucasian (81%), had some education beyond high school (68%) and had active RA with mean (SD) baseline DAS28 4.7(1.4) and mHAQ 0.5(0.5). At baseline, employed RA patients reported on average (SD) 39.8% (29.8) overall work impairment [absenteeism 8.4% (18.6); presenteesim 37.0 % (28.0)] and non-work activity impairment due to health of 43.5% (28.5). Work productivity scores improved after 1 year follow-up but remained relatively stable thereafter (Figure). In lagged multivariable GEE models, higher DAS28 was associated with more work impairment over time; mean change (95% confidence interval) in overall work impairment 7.1% (6.2, 7.9), absenteeism 1.9% (1.4, 2.5), presenteeism 6.6% (5.8, 7.4) and activity impairment 7.8% (7.1, 8.6). Baseline comorbidity was also associated with overall work impairment over time [RDCI mean change 1.9 % (0.1, 3.6); depression mean change 8.0 % (0.4, 15.7].

Conclusion: Patients with early RA report nearly 40% reduced work productivity, mainly from reduced effectiveness while at work, and have similar impairment in non-work activities. While work and activity productivity improve with treatment, persistent disease activity contributes to productivity impairment over time. Interventions to optimize continued engagement in work and addressing difficult to treat RA may improve productivity outcomes for RA patients and their employers.

Abstract Number: 0811

Using a Smartphone App to Detect and Characterise Real-Time Patient-Reported Flares in Rheumatoid Arthritis

Julie Gandrup, Sabine N van der Veer, John McBeth and Will Dixon, University of Manchester, Manchester, United Kingdom

SESSION INFORMATION
Session Date: Sunday, November 7, 2021
Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster II: Miscellaneous Aspects of RA (0786–0812)
Session Type: Poster Session B
Session Time: 8:30AM–10:30AM

Background/Purpose: Flares are an intrinsic part of the rheumatoid arthritis (RA) disease course and may impact clinical and patient outcomes. Severity, frequency and duration of flares matter, but the clinical assessment is limited

by patient recall. Consumer technologies make it possible to capture and explore patient-reported flares in near real time. We used smartphone app data to explore the frequency of patient-reported flare weeks and their associations with various summary features of daily symptoms reported during the preceding week.

Methods: The Remote Monitoring of Rheumatoid Arthritis (REMORA) study aimed to improve monitoring of disease severity in RA. Patients tracked daily symptoms on a 0-10 scale (pain, fatigue, function, sleep, coping, physical and emotional wellbeing) and weekly flares on the REMORA smartphone app.

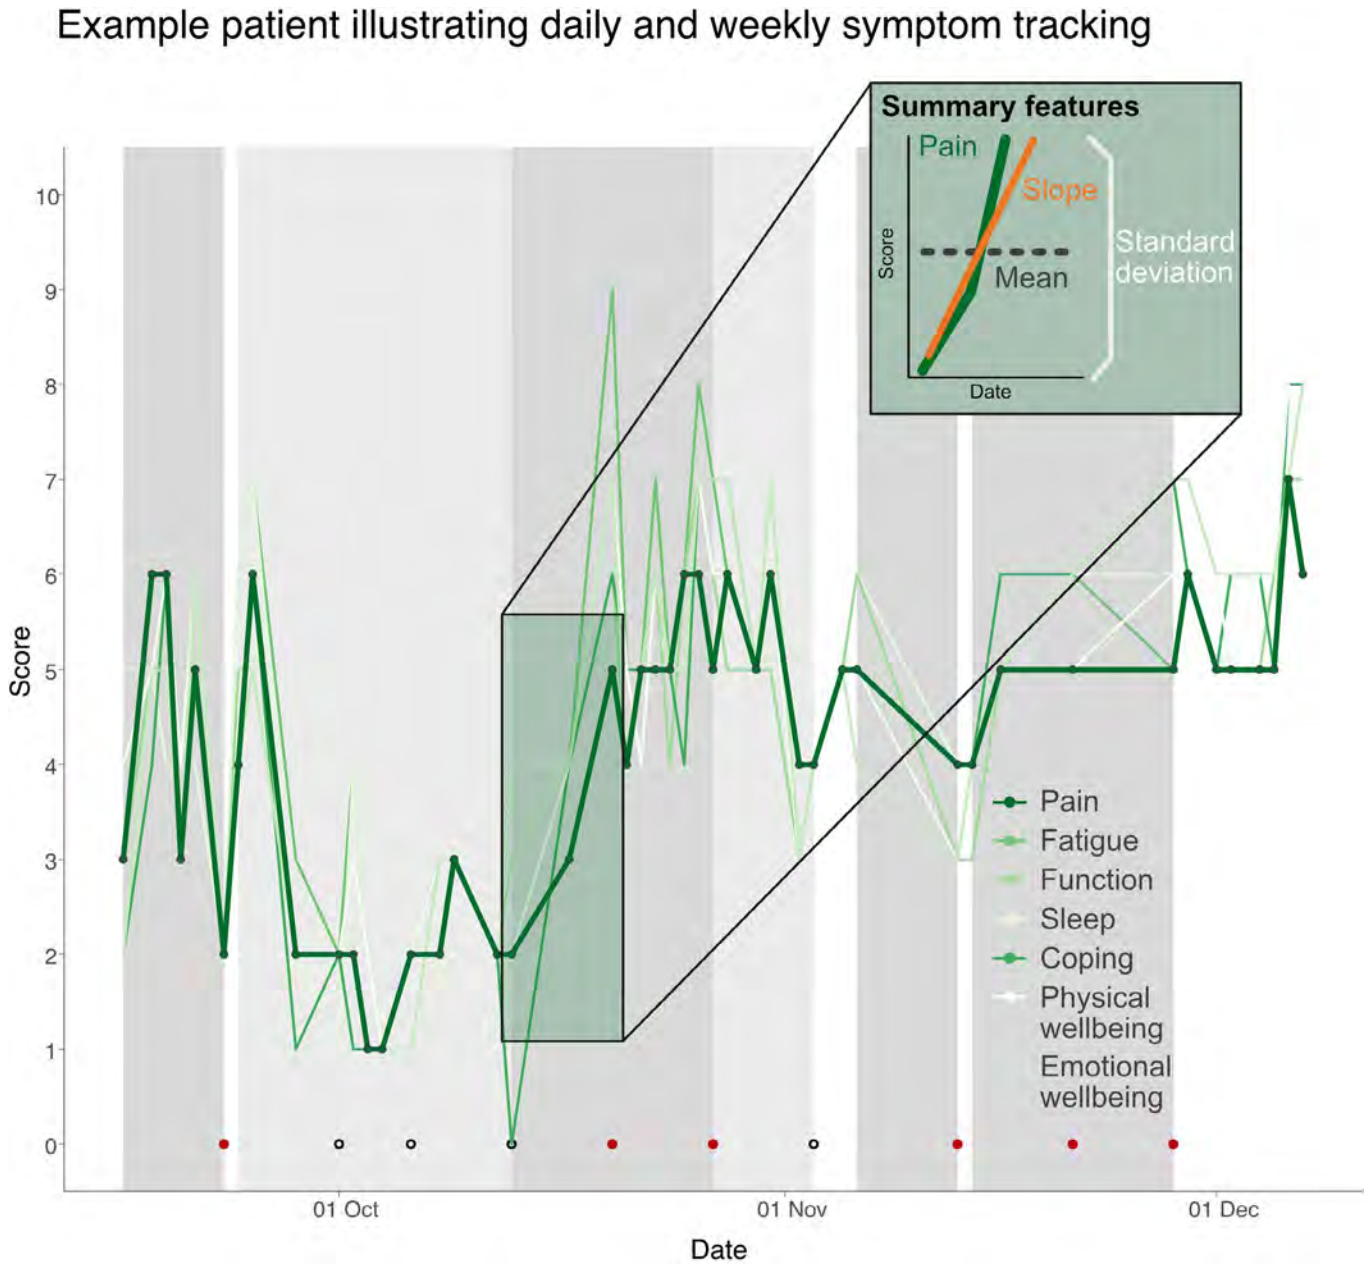

Figure 1. Example patient illustrating daily and weekly symptom tracking. The red circles indicate that the patient answered "yes" to the weekly flare question, the white circles when the patient answered "no". The seven days leading up to the flare question are marked with grey boxes to illustrate flare (darker) and non-flare (lighter) weeks. In the inset, the three summary features are highlighted for pain: 1) Mean, 2) Standard deviation, and 3) Slope.

A flare week was defined as the seven days leading up to the weekly flare-question "*Have you experienced a flare in the last week?*" where the patient answered "yes" (Fig. 1). We summarised the number of patient-reported flare weeks. Symptom scores in flare and non-flare weeks were compared.

For each week prior to a flare question, we calculated the following summary features for all daily symptoms: 1) mean score, 2) standard deviation (SD), and 3) slope (Fig. 1, inset). Mixed effects logistic regression models quantified the associations between flare weeks and each summary feature.

Results: Twenty patients tracked symptoms over three months. 60% were female, all but one were white British, and mean age was 56.9±11.1 years. The median number of days in the study was 81 (interquartile range (IQR) 80, 82). We included 168 participant weeks. In total, 15/20 participants reported at least one flare week, with 54 patient-reported flare weeks in total. Participants reported a median of two flare weeks (IQR 0.75, 3.5).

In paired analyses, all mean symptom scores were significantly higher (difference on average 0.67 (SD 0.22)) in flare weeks compared to non-flare weeks except for sleep ($p< 0.05$). The SDs, a measure of variability, were slightly higher in flare weeks, but only significantly different from non-flare weeks for emotional wellbeing. For slope, there was an increase for all symptoms in flare weeks, although only the slopes of pain, physical wellbeing, and coping were statistically significant.

Due to strong correlations between symptoms, multivariate modelling of all symptoms and their summary features was not possible. Rather, we modelled pain as an example using each of its three derived features. In the full pain model, mean pain scores appeared to be more clearly associated with a flare (odds ratio 1.83 (1.15; 2.97)) than the change in scores in the preceding week.

Conclusion: In our RA cohort, self-reported flares were frequent. Flare weeks were broadly associated with higher scores (for mean, variability, and slope) across a range of daily symptoms in the preceding week, but the absolute value seemed more important than the change. The correlation between daily symptoms made it impossible to disentangle the contribution of individual symptoms to the flare experience.

Future analysis of daily symptoms may allow us to predict imminent flares, opening the opportunity for just-in-time interventions.

Are Biologic and Targeted Synthetic Disease Modifying Anti-Rheumatic Drugs Associated with Work Participation Improvement in Early Rheumatoid Arthritis? A Systematic Review and Meta-analysis

Mary Lucy Marques[1], Alessia Alunno[2], Louise Falzon[3], Annelies Boonen[4] and Sofia Ramiro[1], [1]Leiden University Medical Center, Leiden, Netherlands, [2]University of Perugia, Perugia, Italy, [3]Center for Personalized Health, Northwell Health, New York City, NY, [4]Department of Internal Medicine, Division of Rheumatology, Maastricht University Medical Centre+ (MUMC+), Maastricht, Limburg, Netherlands

SESSION INFORMATION
Session Date: Sunday, November 7, 2021
Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster II: Miscellaneous Aspects of RA (0786–0812)
Session Type: Poster Session B
Session Time: 8:30AM–10:30AM

Background/Purpose: Treatment of early RA with DMARDs is associated with particularly effective responses, resulting in sustained beneficial outcomes, including clinical and radiographic remission and optimal health related quality of life. The benefit of treatment with biological (b) and targeted synthetic (ts) DMARDs on work participation (WP), a top social role for RA patients, has been less frequently studied. Our aim was to review the evidence of treatment with b-/tsDMARDs in patients with early RA on WP outcomes.

Methods: Following PRISMA, a systematic literature review (SLR) was conducted in key electronic databases up to December 2020. The PICOT framework was: (P) RA with disease duration ≤3y; (I) b-/tsDMARDs; (C) any treatment/placebo (PBO); (O) employment status (ES), at-work productivity loss (presenteeism) and/or absence from paid work (sick leave - SL); (T) longitudinal studies (except cost-effectiveness) with any follow-up duration. Two reviewers independently identified eligible studies and extracted data using a self-composed extraction sheet. The Cochrane risk-of-bias tool for RCTs was used for the assessment of risk of bias. Odds ratios (OR) were computed for individual studies, and a pooled OR was obtained by random-effects meta-analysis. Statistical heterogeneity was assessed by I^2.

Results: From 5979 records (65 full-text articles screened), 9 studies were included in the SLR (6 RCTs in conventional synthetic (cs)DMARDs-naïve patients; 2 RCTs in bDMARD-naïve patients with inadequate response to csDMARDs; 1 RCT of bDMARD tapering after initial combination with methotrexate (MTX)). Studies assessed WP outcomes with validated and non-validated instruments (*Table 1*). Interventions comprised 4 bDMARDs (abatacept, adalimumab, etanercept and infliximab) and 1 tsDMARD (baricitinib). Most studies had MTX monotherapy(±PBO) (n=7;78%) as active comparator; in 2 studies bDMARD(±PBO) was added to background MTX. For presenteeism and SL, most between-group comparisons showed improvement in favour of b-/tsDMARDs, but not all comparisons were statistically significant – *Table 1*. A meta-analysis for ES (weeks 56 to 104) included 3 studies (total of 1124 patients) with

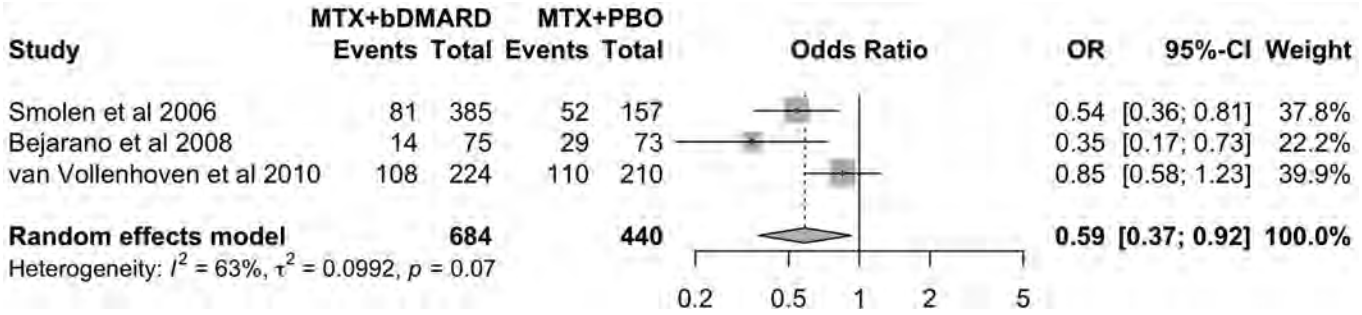

Figure 1. Random-effects meta-analysis of the employment loss in patients with early rheumatoid arthritis treated with MTX+bDMARD versus MTX in monotherapy. bDMARD – biologic disease-modifying antirheumatic drugs; MTX – methotrexate; PBO – placebo.

either adalimumab or infliximab as intervention (*Figure 1*). The pooled OR of the 3 studies showed a lower likelihood of employment loss in patients treated with MTX+bDMARDs (OR: 0.59; 95% CI:0.37 to 0.92) compared to MTX+PBO. High statistical heterogeneity was observed 63% [0.0%; 89.3%].

Conclusion: A protective effect against employment loss was observed in patients with early RA treated with MTX-+bDMARDs compared to MTX monotherapy. Although trends towards beneficial effects of b-/tsDMARDs were seen on presenteeism and SL, the methodological heterogeneity hampers clear conclusions. The additional role of b-/tsDMARD in a real world T2T approach should be further studied in long term (preferably population controlled) studies. Efforts to homogenize the design, analysis and reporting of future studies with WP as an outcome by following recently developed points to consider are crucial[1].

Abstract Number: 0813

Improvement in Clinical Disease Activity and Patient-Reported Outcomes After 6 Months of Treatment with Abatacept, Stratified by Line of Therapy, in Patients with RA: Results from a Large, US, National Observational Study

Leslie Harrold[1], Keith Wittstock[2], Sheila Kelly[2], Sang Hee Park[2], Xue Han[2], Ying Shan[1], Carla Roberts-Toler[1], Nicole Middaugh[1] and Vadim Khaychuk[2], [1]CorEvitas, LLC, Waltham, MA, [2]Bristol Myers Squibb, Princeton, NJ

SESSION INFORMATION
Session Date: Sunday, November 7, 2021
Session Title: RA – Treatments Poster I: Comparative Effectiveness, Biosimilars, Withdrawal, & the Real World (0813–0845)
Session Type: Poster Session B
Session Time: 8:30AM–10:30AM

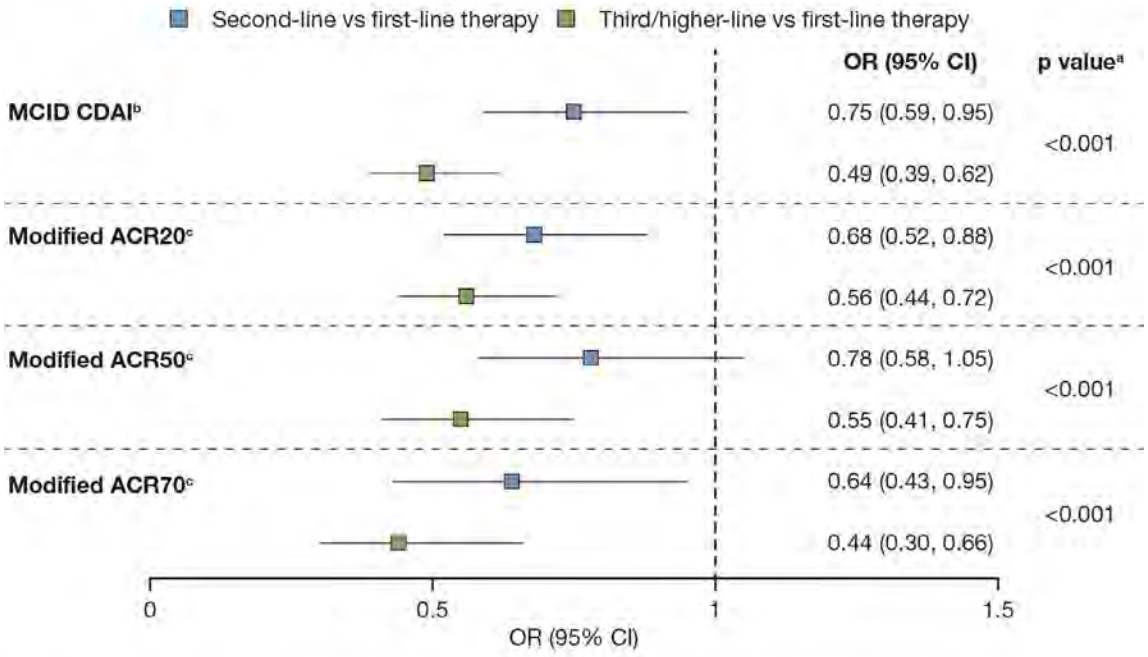
Background/Purpose: RA is more responsive to treatment in the early stages of disease, and early treatment may lead to better long-term outcomes.[1,2] Data on the effectiveness of specific drugs as first or later lines of therapy will help inform treatment sequencing. Data from patients enrolled in the Corrona RA Registry network were used to compare the effectiveness of abatacept across lines of therapy overall (primary cohort) and in a subset of patients who were ACPA+.

Table 1. Adjusted mean change in CDAI and patient-reported outcomes from BL to 6 months after initiation of abatacept by line of therapy (primary cohort)

Adjusted outcome, mean change (SE)	First-line (n = 440)	Second-line (n = 898)	Third/higher-line (n = 1515)	*P* value[a]
CDAI	−7.96 (0.33)	−7.49 (0.27)	−5.74 (0.19)	< 0.001
Patient-reported pain (VAS 0–100)	−9.43 (0.69)	−7.98 (0.47)	−7.70 (0.35)	0.074
Patient-reported fatigue (VAS 0–100)	−7.49 (0.71)	−5.87 (0.51)	−4.81 (0.36)	0.002
Patient-reported HAQ	−0.16 (0.01)	−0.12 (0.01)	−0.08 (0.01)	< 0.001

[a]Estimated by multiple linear regression model adjusted for age, sex, disease duration, work status, SC nodules, history of hypertension and depression, BL CDAI, BL patient-reported pain, and BL fatigue (factors that were identified *a priori* based on clinical experience or that differed significantly by line of therapy); *P* values reflect ANOVA overall test of differences across lines of therapy.
VAS, visual analog scale.

Figure 1. Adjusted odds ratio of achieving MCID CDAI or modified ACR20/50/70 at 6 months after initiation of abatacept by line of therapy (primary cohort)



[a]Estimated by multiple logistic regression analysis adjusted for age, sex, disease duration, work status, SC nodules, history of hypertension and depression, BL CDAI, BL patient-reported pain and BL fatigue (factors that were selected a priori based on clinical experience or differed significantly by line of therapy); p values reflect overall difference across lines of therapy.
[b]Reduction in CDAI score of 2 if BL disease activity was low (CDAI score ≤10); of 6 if BL disease activity was moderate (CDAI score >10 and ≤22); and of 11 if BL disease activity was high (CDAI score >22).
[c]Modified ACR criteria is based on 2 out of 4 measures (not using ESR or CRP).
Modified ACR20/50/70=20/50/70% improvement in modified ACR criteria; MCID=minimal clinically important difference; OR=odds ratio.

Methods: Patients with RA who initiated abatacept (January 2006 to October 2020), had 6 months' follow-up (within 4–9 months of starting abatacept), had baseline (BL) and follow-up CDAI scores available, and had BL CDAI > 2.8 were included. Outcomes were compared for first-, second- and third or higher-line therapy: 0, 1 or ≥ 2 prior biologic DMARDs or Janus kinase inhibitors, respectively. Continuous outcomes included change from BL to 6 months in mean CDAI and patient-reported pain, fatigue, and HAQ. Binary outcomes included rate of achieving minimal clinically important difference (MCID) in CDAI or modified ACR20/50/70 at 6 months. Continuous and binary outcomes were analyzed using multiple linear and logistic regression, respectively. The models included line of therapy, age, sex, disease duration, work status, SC nodules, history of hypertension and depression, BL CDAI, BL patient-reported pain, and BL fatigue. Additional subgroup analyses were carried out in patients with moderate/high disease activity (CDAI > 10) at BL.

Results: In total, 2876 patients (2327 with BL CDAI > 10; 890 ACPA+) were included; 442, 911, and 1523 patients initiated first-, second- or third/higher-line abatacept, respectively. Compared with patients on second/third/higher-line abatacept therapy, those on first-line abatacept were significantly older, had shorter disease duration, and had lower BL CDAI, pain and fatigue (all $P < 0.001$). In adjusted analyses, patients receiving abatacept as earlier lines of therapy had significantly greater improvement from BL in mean CDAI and in patient-reported fatigue and HAQ (**Table 1**). There was no significant difference between lines of therapy in change in patient-reported pain. Patients receiving first-line abatacept had significantly higher odds of achieving a MCID in CDAI or modified ACR20/50/70 response (**Figure 1**). Similar patterns were seen when the sample was limited to patients with moderate/high disease activity or in patients who were ACPA+.

Conclusion: There were significant differences in improvement in clinical disease activity and patient-reported outcomes across lines of therapy. Better treatment responses were observed with earlier lines of abatacept therapy in the overall population, in patients who were ACPA+ and in those with moderate/high BL disease activity.

SESSION INFORMATION

Session Date: Sunday, November 7, 2021

Session Title: RA – Treatments Poster I: Comparative Effectiveness, Biosimilars, Withdrawal, & the Real World (0813–0845)

Session Type: Poster Session B

Session Time: 8:30AM–10:30AM

Background/Purpose: Randomized controlled trials (RCTs) have long been considered the gold standard for clinical research, but can be complemented with real-world data (RWD) to further inform clinical decision-making. We evaluated patient (pt) characteristics, efficacy, and treatment patterns for tofacitinib monotherapy in pts with RA using RCT data and available RWD.

Methods: Three cohorts of pts receiving tofacitinib 5 mg BID monotherapy were defined for post hoc analyses of RCT data: Cohort (C)1, pts with an inadequate response to DMARDs from Phase (P)3 and P3b/4 RCTs (NCT00814307/

NCT02187055); C2, MTX-naïve pts from a P3 RCT (NCT01039688); and C3, pts who completed an index study and continued in any long-term extension study (NCT00413699/NCT00661661). Outcomes included Clinical Disease Activity Index (CDAI) low disease activity (LDA; scores ≤ 10) rates, and rates of/time to study discontinuation due to lack of efficacy or adverse events (AEs; per Kaplan–Meier plots). Across outcomes, available RWD are presented for contextualization, identified by non-systematic literature searches of PubMed, Embase, and ACR/EULAR abstracts, from 2013–2021.

Results: 1,498 pts treated with tofacitinib 5 mg BID monotherapy were included in the RCT analysis (C1, n=627; C2, n=373; C3, n=498); generally, baseline (BL) disease activity was high, most pts received concomitant glucocorticoids (GC) and were biologic (b)DMARD-naïve (Table). C1 and C2 CDAI LDA rates were ≥ 32.2% by Month (M)3 and sustained through M12 (Figure 1); C3 LDA rates ranged from 64.0–70.7% through M72 (Figure 1). In C1, C2, and C3, respectively, 4.0%, 15.6%, and 27.7% of pts discontinued due to lack of efficacy or AEs; Kaplan–Meier plots of time to discontinuation are presented in Figure 2. We identified 6 RWD publications that included tofacitinib monotherapy data; across publications, 16.6–59.2% of tofacitinib-treated pts received tofacitinib monotherapy.[1-6] Only 1 paper reported BL characteristics with tofacitinib monotherapy: median disease activity was moderate, pts had low GC use, and most were bDMARD-experienced[1] (Table 1). In the same paper, M6 CDAI LDA rates were 30.2% (Figure 1). Another paper estimated the 1-year retention rate for tofacitinib monotherapy as 59.7%.[6] While no RWD on treatment discontinuation specific to tofacitinib monotherapy were identified, 1 paper reported no significant differences in retention with tofacitinib monotherapy vs tofacitinib + conventional synthetic DMARDs (HR 1.11 [95% CI 0.91, 1.35]).[4]

Conclusion: Tofacitinib 5 mg BID monotherapy demonstrated good efficacy and persistence in post hoc analyses of RCT data. Variable monotherapy rates were seen in RWD; based on available data, tofacitinib monotherapy demonstrated good efficacy, and retention comparable with combination therapy.

SESSION INFORMATION

Session Date: Sunday, November 7, 2021

Session Title: RA – Treatments Poster I: Comparative Effectiveness, Biosimilars, Withdrawal, & the Real World (0813–0845)

Session Type: Poster Session B

Session Time: 8:30AM–10:30AM

Background/Purpose: TTT has been shown in multiple RCTs to be an effective paradigm for managing RA, however TTT has not been uniformly implemented in US rheumatology. In a prior RCT, we found improvement implementation of TTT at selected rheumatology practices during a face-to-face 9-month Learning Collaborative (LC) (1). An LC is a method for group-based quality improvement, which has been successfully used in healthcare. In the current study, we tested a 6-month virtual LC that took place during the COVID pandemic as a method for improving implementation and adherence with TTT in 18 rheumatology practices in the US.

Methods: During 2020-2021, we conducted a virtual LC for TTT in RA. All meetings used video-conferencing and a website allowed participants to share documents and data. The LC consisted of one 5-6 hour kickoff session and 6 monthly webinars. Faculty and participants discussed procedures for TTT, its rationale, and methods for quality improvement; we focused on Plan-Do-Study-Act (PDSA) cycles as a method for implementing TTT. Practices were asked to meet and carry-out PDSA cycles. Each monthly webinar discussed the PDSAs, reinforced topics from the kick-off, and demonstrated data on TTT adherence from the practices. Practices were asked to review 20-25 visit notes from RA patients and to input de-identified data into the website. The data were analyzed and shared in the monthly webinars. The webinars allowed sites to discuss the data and share best (and worst) practices. Adherence with TTT was measured as a percentage of the TTT component processes: 1) measure and document RA disease activity (any standard disease activity measure considered acceptable, e.g., CDAI, RAPID3, DAS28), 2) determine a target disease activity, 3) make treatment changes if not at target, and 4) document shared decision-making.

Results: 18 sites from 10 states (plus Washington DC) participated; they represented 45 rheumatology clinicians (MDs, nurse practitioners, and physician's assistants) who attended the kick-off and/or monthly webinars. During the 6 months, sites entered data on 1826 patient visits. Adherence with TTT improved over the six months from a mean of 50.7% at baseline to 83.7% at study completion (see **Figure 1**, p for trend < 0.001). Each aspect of TTT measured also improved (see **Figure 2**). The main reason for TTT non-adherence was that clinicians changed treatment in only 59% of visits where patients were not at target. Some reasons documented (not mutually exclusive) for not intensifying treatment when patients were not at target are shown in **Table 1**. They include patient preference (33%), clinician

Figure 1: Adherence with Treat to Target Across All Sites During the Learning Collaborative

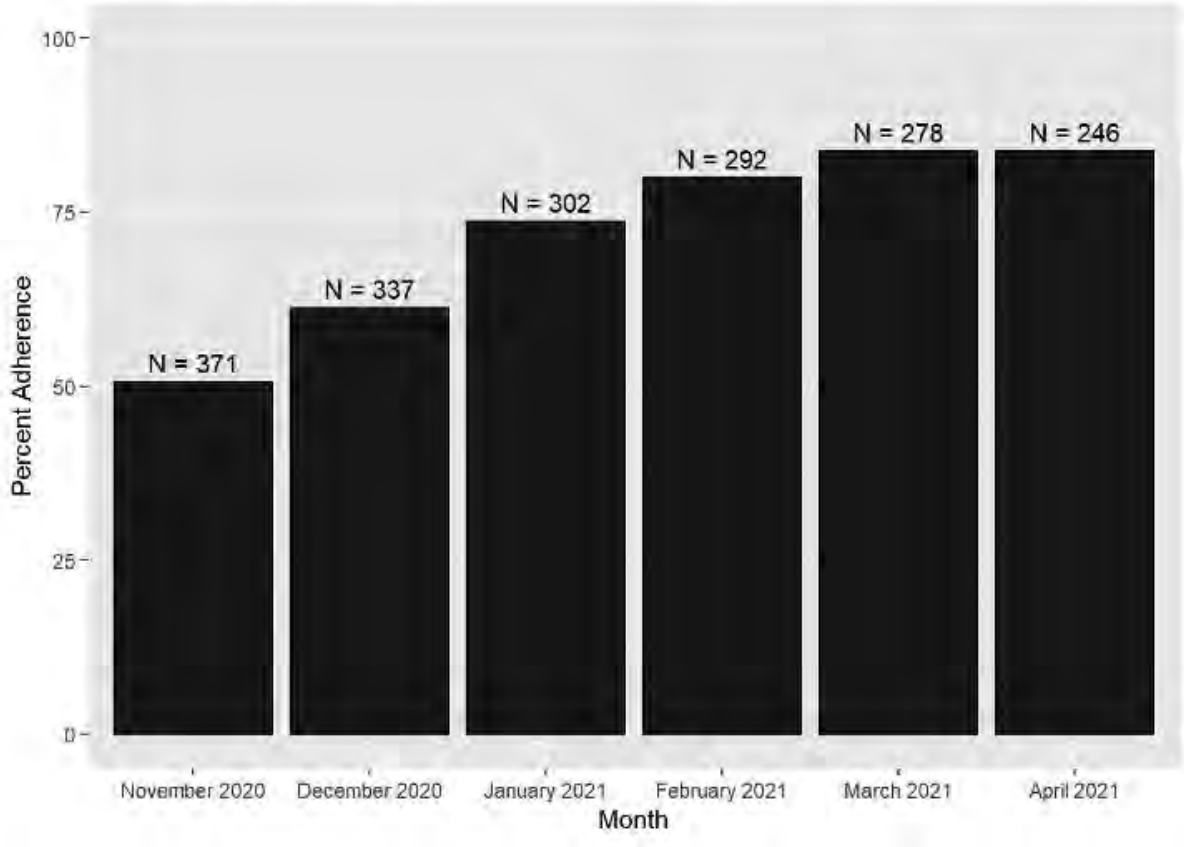

Figure 2: Adherence for the Four Components of TTT Adherence

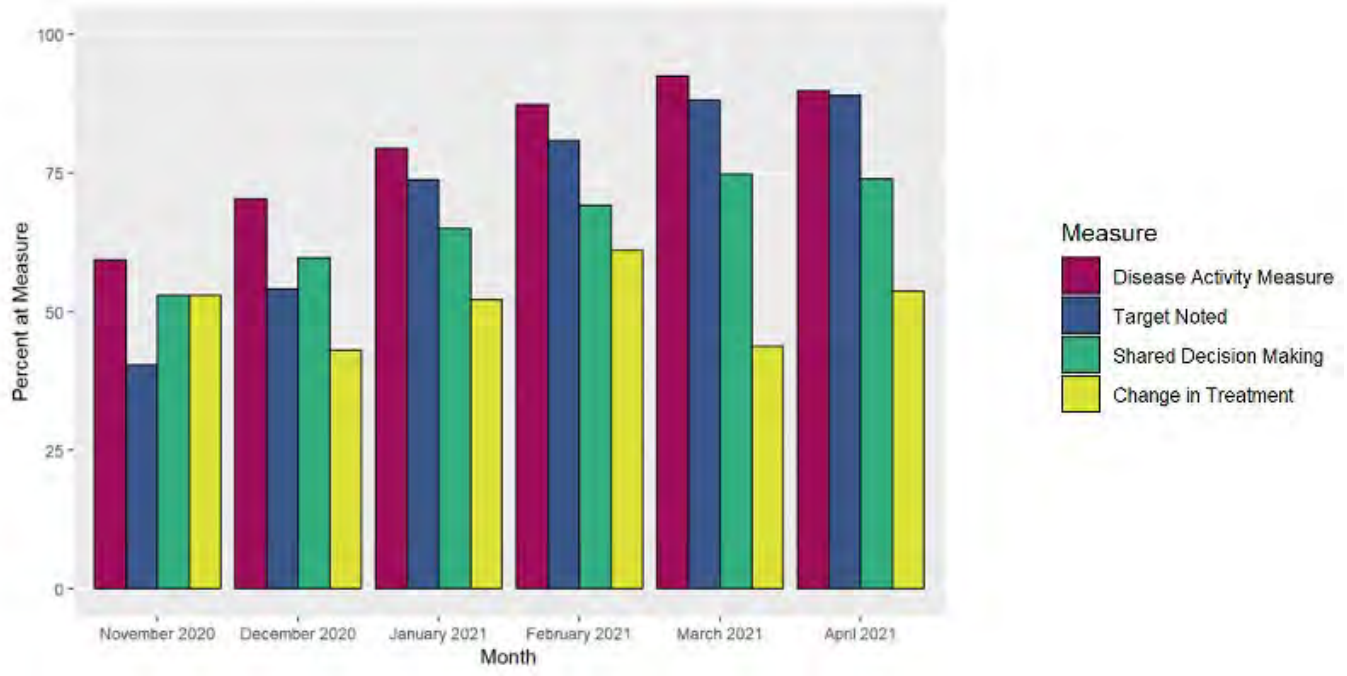

Table 1: Reasons for Not Changing RA Treatment when Patient Not at Target (n = 346)

Reasons	N (%)
Patient preference	115 (33.2)
Clinician preference	65 (18.8)
Pain not from rheumatoid arthritis	87 (25.1)
Wanted to give current treatment more time to work	65 (18.8)
Clinician/Patient did not want to make a change during COVID-19	5 (1.4)
Other reasons	9 (2.6)

preference (19%), clinician deemed symptoms were not from RA (25%), and the desire to observe the treatment effect for more time (19%).

Conclusion: Implementing TTT for RA can be improved through a relatively low-cost virtual LC. This improvement in TTT was observed despite the COVID pandemic. We would urge professional societies to experiment with implementing LC quality improvement programs virtually to facilitate wider dissemination of best practices.

SESSION INFORMATION

Session Date: Sunday, November 7, 2021

Session Title: RA – Treatments Poster I: Comparative Effectiveness, Biosimilars, Withdrawal, & the Real World (0813–0845)

Session Type: Poster Session B

Session Time: 8:30AM–10:30AM

Background/Purpose: Longer disease duration and greater number of prior DMARDs have been associated with lower treatment efficacy in patients with RA.[1] Abatacept is a biologic (b)DMARD for treatment of moderate-to-severe

RA and is available in SC formulation, which may offer convenience benefits with efficacy similar to IV administration.[2] ASCORE (NCT02090556) was a 2-year, observational, prospective, multicenter study of SC abatacept for treatment of RA in routine clinical practice.[3] This *post hoc* analysis was conducted to determine if retention and efficacy of abatacept were impacted by disease duration and/or treatment line.

Methods: Eligible patients, aged ≥18 years, with active moderate-to-severe RA (ACR/EULAR 2010 criteria[4]) who were IV abatacept-naive and initiated SC abatacept 125 mg once weekly, were enrolled into 2 cohorts: bDMARD-naive patients and those with ≥1 prior bDMARD treatment failure. This *post hoc* analysis evaluated abatacept retention using Kaplan-Meier estimates, as well as disease activity scores (DAS28 [ESR]), CDAI and SDAI in patients with disease duration of ≤2, 3–5, 6–10 or >10 years, and in patients taking abatacept as first-line or ≥ second-line treatment.

Results: Table 1 shows baseline characteristics. Mean age increased with disease duration; other characteristics were comparable across groups. Retention proportions (95% CIs) at Month 24 were 0.50 (0.4, 0.5), 0.47 (0.4, 0.5), 0.51 (0.5, 0.5) and 0.46 (0.4, 0.5) in the ≤2, 3–5, 6–10 and >10 years' duration groups, respectively. Proportion of patients (95% CI) with ≤2 years' duration retaining treatment at Month 24 were 0.51 (0.4, 0.6) among those using abatacept as first-line treatment and 0.44 (0.3, 0.6) among those using abatacept as a ≥ second-line treatment (Figure 1). Proportions (95% CI) at Month 24 were 0.51 (0.5, 0.6), 0.57 (0.5, 0.6) and 0.52 (0.5, 0.6) in first-line patients and 0.43 (0.4, 0.5), 0.48 (0.4, 0.5) and 0.44 (0.4, 0.5) in ≥ second-line patients in the 3–5, 6–10 and >10 years' duration

Table 1. Baseline characteristics (n=2872)

	RA disease duration, years			
	≤2 (n=338)	3–5 (n=655)	6–10 (n=686)	>10 (n=1193)
Age, years				
n	338	655	686	1193
Mean (SD)	55.2 (12.8)	55.6 (12.7)	56.9 (13.0)	59.9 (12.2)

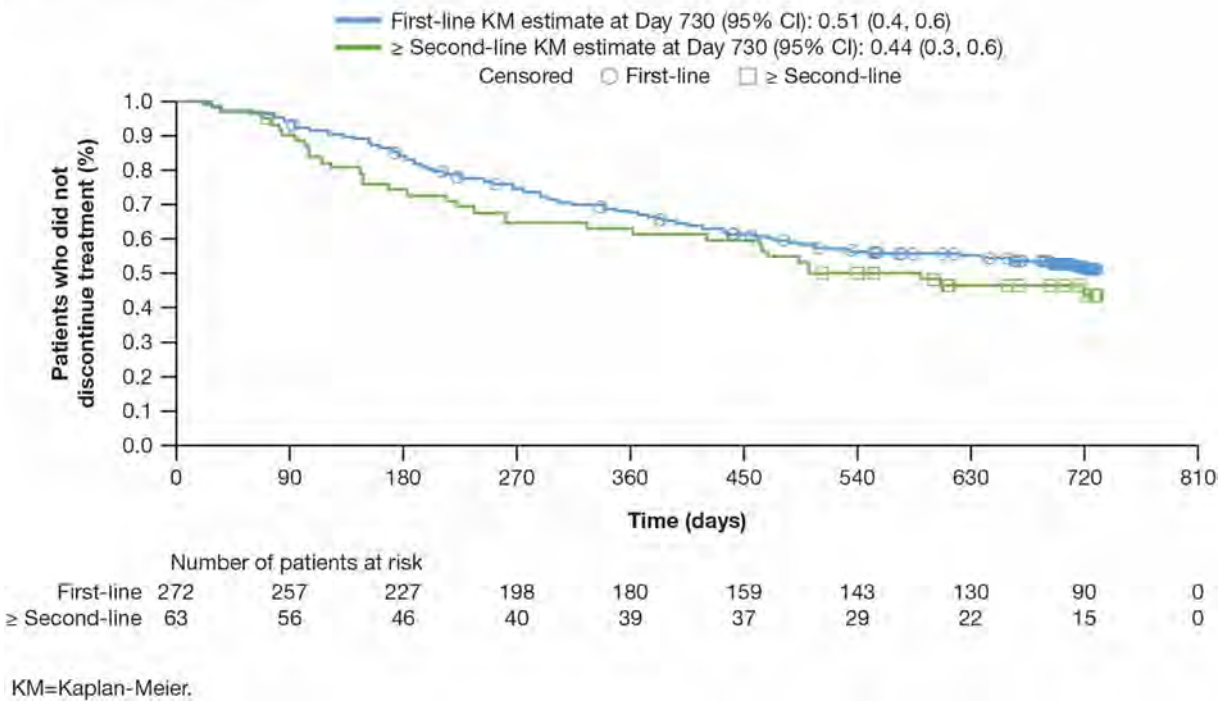
Anti-CCP status, n (%)				
Anti-CCP+	165 (48.8)	332 (50.7)	333 (48.5)	516 (43.3)
Anti-CCP–	89 (26.3)	126 (19.2)	137 (20.0)	175 (14.7)

Patients with missing duration of disease are excluded.

Figure 1. Treatment retention over 2 years among patients with RA with ≤2 years' disease duration



KM=Kaplan-Meier.

groups, respectively. Mean (SE) changes from baseline in DAS28 (ESR) at Month 24 were –2.12 (0.205), –1.86 (0.151), –2.07 (0.140) and –2.05 (0.115) in the ≤2, 3–5, 6–10 and >10 years' duration groups, respectively; respective mean (SE) changes in CDAI were –18.74 (1.604), –15.60 (1.099), –18.50 (1.038) and –17.68 (0.850); and respective mean (SE) changes in SDAI were –19.10 (1.873), –15.72 (1.345), –19.54 (1.103) and –17.07 (0.939).

Conclusion: In this *post hoc* analysis of the real-world ASCORE trial, patients with RA receiving abatacept in clinical practice as first-line therapy had better retention versus those receiving it as a ≥ second-line treatment, regardless of disease duration at baseline. Retention rates were similar across disease duration subgroups. Improvements in disease activity were seen in all duration subgroups, without consistently greater or lesser improvement seen with longer disease duration.

Biosimilar Infliximab Therapy in Rheumatoid Arthritis, Axial Spondyloarthritis and Psoriatic Arthritis: A Long-term Follow-up Study on Infliximab-naive Patients and Switched Patients from the Originator to the Biosimilar CT-P13

Hubert MAROTTE[1], Maryse Assing[2], Nadir Mammar[2], Yves Brault[3] and Bruno Fautrel[4], [1]Rheumatology department - Unisersity Hospital of Saint-Etienne, Saint-Etienne, France, [2]Inflammation & Immunology - Pfizer, Paris, France, [3]Pfizer, Paris, France, [4]Pitié Salpêtrière Hospital, APHP, Sorbonne Université, Paris, France

SESSION INFORMATION
Session Date: Sunday, November 7, 2021
Session Title: RA – Treatments Poster I: Comparative Effectiveness, Biosimilars, Withdrawal, & the Real World (0813–0845)
Session Type: Poster Session B
Session Time: 8:30AM–10:30AM

Background/Purpose: ReFLECT study has been carried out to investigate real life use of CT-P13, the first monoclonal antibody biosimilar to infliximab (IFX) originator.

Methods: ReFLECT is a multicentre, prospective, observational study conducted in France to determine the characteristics of patients (pts) receiving CT-P13, its effectiveness and safety in a real-life setting. Eligible pts were both IFX naive pts (IFX-N) starting CT-P13 and those who have been switched from infliximab originator (IFX-S) to CT-P13. Interim results in adult pts with rheumatic diseases using descriptive statistical analyses from inclusion to a 24-month-follow-up period are presented here.

Results: Among the 1370 adult pts included between October 2016 and April 2019, data were analysed for 142 pts with rheumatoid arthritis (RA; 23.9% males; mean age: 61.5±10.9 years; 80 IFX-N / 61 IFX-S), 411 with axial spondyloarthritis (axSpA; 58.9% males; 48.1±13.1 years; 228 IFX-N / 179 IFX-S), and 96 with psoriatic arthritis (PsA; 41.7% males; 53.4±14.1 years; 55 IFX-N / 40 IFX-S) after a median duration between 8.7 and 12.9 years since diagnosis. At

Figure 1. Change from 1st administration of CT-P13 in CRP and disease activity scores at month 24

Table 2. Safety results

	RA (n = 142)	axSpA (n = 411)	PsA (n = 96)
Pts with ≥ 1 adverse event (AE)	67 (47.2%)	222 (54.0%)	48 (50.0%)
Pts with ≥ 1 AE related to CT-P13	33 (23.2%)	84 (20.4%)	19 (19.8%)
Pts with ≥ 1 serious AE	19 (13.4%)	42 (10.2%)	9 (9.4%)
Pts with ≥ 1 allergic infusion reaction †	4 (2.8%)	11 (2.7%)	1 (1.0%)
Pts with ≥ 1 infection ‡	10 (7.0%)	18 (4.4%)	3 (3.1%)

† *Including acute and delayed hypersensitivity reactions*
‡ *Including severe infections, tuberculosis, opportunistic infections, hepatitis*

inclusion, 67.9%, 24.1% and 50% had a concomitant treatment with methotrexate. At the time of the first administration of CT-P13, disease had been active in 94.2%, 76.6% and 83.3% of the IFX-N pts compared with 45.3%, 24.0% and 32.0% of the IFX-S pts respectively. From the first administration of CT-P13 to month 24, both CRP levels and disease activity remained stable in the IFX-S pts and as expected, improvement was observed in the IFX-N pts (Figure 1). In naive pts, after 24 months of treatment since its first administration, CT-P13 brought both CRP and disease activity down to levels comparable to those seen in pts having switched from the IFX originator to CT-P13 (Table 1). After 24 months of follow-up, 70 to 80% of pts in each group, whether IFX-N or IFX-S, remained on treatment with CT-P13, RA naive pts aside (53.8%). Main reason for CT-P13 withdrawing was treatment failure (including primary non-response and secondary loss of response) in both naive and switched pts: 31.6% and 13.1% of RA, 18.1% and 12.8% of axSpA, 9.1% and 15.8% of PsA pts respectively. Withdrawing for intolerance involved 6.3% and 1.6% of RA, 2.2% and 1.1% of axSpA, 1.8% and 2.6% of PsA in naive and switched pts respectively. Safety results are reported in Table 2.

Conclusion: Year 2 follow-up data indicate that CT-P13 effectively induced improvement in disease activity in pts with RA, axSpA and PsA receiving infliximab for the first time and maintained stable disease activity in pts having switched from IFX originator to CT-P13. This real-life study did not highlight any new safety concerns.

Biologics Initiation in Moderate vs Severe Rheumatoid Arthritis Patients: Prospective Observational Study from a Canadian Registry

Nancy Guo[1], Xiuying Li[2], Mohammad Movahedi[3], Angela Cesta[4] and Claire Bombardier[5], [1]Kingston General Hospital, Kingston, ON, Canada, [2]OBRI at University Health Network, Toronto, ON, Canada, [3]Toronto General Hospital Research Institute, University Health Network, Toronto, ON, Canada, [4]Toronto General Hospital Research Institute, UHN, Toronto, ON, Canada, [5]University of Toronto - Toronto, Toronto, ON, Canada

SESSION INFORMATION

Session Date: Sunday, November 7, 2021

Session Title: RA – Treatments Poster I: Comparative Effectiveness, Biosimilars, Withdrawal, & the Real World (0813–0845)

Session Type: Poster Session B

Session Time: 8:30AM–10:30AM

Background/Purpose: Prior studies have shown that in the real-world setting, rheumatoid arthritis (RA) patients have lower disease activity than those studied in clinical trials. However, randomized controlled trials for biologics continue to mainly recruit patients with severe disease. To assess the implications of this practice, our study investigates the proportion of patients achieving remission (DAS28-ESR ≤ 2.6), in RA patients with moderate disease activity and severe disease activity, at 12 months' post starting their first biologic, and identifies baseline predictors of biologic response.

Methods: This study included RA patients who have never been treated with a biologic and initiated their first biologic while enrolled in the Ontario Best Practices Research Initiative (OBRI) registry, between 2008 and 2019. Patients selected had either moderate RA (DAS28 ≥ 3.2 to ≤ 5.1) or severe RA (DAS28 > 5.1). Comparisons were made between the moderate and severe disease groups using the student's t-test for continuous variables, and the chi-square test for categorical variables. Multivariable logistic regression was used to test potential predictors of remission. Backward stepwise model selection was applied to select variables with *p*-value ≤0.10. Multiple imputation (MCMC method; n=20) was used to impute missing data.

	Moderate-RA (n=264)	Severe-RA (n=219)	*P*-Value
Remission, *n* (%)	111 (50)	45 (23)	<0.0001
Low disease activity, *n* (%)	151 (59)	74 (35)	<0.0001
Change in DAS from baseline ≥ 1.2, *n* (%)	168 (66)	164 (78)	0.0049
HAQ-DI change >0.22, *n* (%)	98 (53)	83 (52)	0.7974
Change in DAS28 from baseline, mean (SD)	-1.4 (1.3)	-2.2 (1.5)	<0.0001
Change in HAQ-DI from baseline, mean (SD)	-0.29 (0.57)	-0.30 (0.66)	<0.0001
Change in fatigue from baseline, mean (SD)	-0.98 (3.2)	-1.11 (3.2)	<0.0001
Change in sleep from baseline, mean (SD)	-0.85 (3.6)	-1.05 (3.9)	0.0004

Table 1. Outcomes at 12 months among patients with RA who initiated the first biologic.

Results: Overall, 641 patients initiated their first biologic, 483 had follow up data at 12 months (moderate disease activity=264; severe disease activity=219). In the moderate group, the mean age (SD) was 55.7 (13.1) and 80% were female. In the severe group, mean age (SD) was 58.4 (12.3) and 81% were female. At time of biologic initiation, the mean DAS28 for the moderate group was 4.1 (0.5), and 6.0 (0.6) for the severe group. After 12 months of starting a biologic, the proportion of patients achieving remission was 50% in the moderate group, and 23% in the severe group ($p< 0.0001$). In contrast, the proportion of patients achieving significant clinical change from baseline (improvement in DAS28 ≥ 1.2) was 78% in the severe group, compared to 66% in the moderate group ($p=0.0049$). More specifically, the absolute improvement in DAS28 after 12 months was higher in the severe group at 2.2 (1.5), compared to a change of 1.4 (1.3) in the moderate group ($p< 0.0001$). Negative predictors of remission include female gender (odds ratio (OR), 0.57, 95% confidence interval (CI), 0.33-0.97; $p=0.039$), and higher HAQ-DI score (OR 0.49, 95% CI 0.36-0.68; $p< 0.001$). In turn, moderate disease at time of biologic initiation (OR 2.38, 95% CI 1.50-3.79; $p=0.0390$) was identified as a positive predictor of remission.

Conclusion: This prospective cohort study found RA patients with moderate disease activity are more likely to reach targeted states (remission and low disease activity), whereas severe patients have greater absolute improvements in DAS28 and HAQ-DI but are less likely to achieve remission. Moderate disease is a positive predictor for remission, whereas female gender and a higher HAQ-DI score are negative predictors.

Abstract Number: 0819

A Real-World 2-Year Prospective Study of Medication Tapering in Patients with RA in Sustained Remission in the RHEUmatoid Arthritis Medication TAPering (RHEUMTAP) Cohort

Mohamed Tageldin[1], Malavikalakshmi Attur[2], Nicole Wilson[1], Rebecca Schorr[3] and Tarun Sharma[1], [1]Allegheny Health Network, Pittsburgh, PA, [2]Drexel University School of Medicine, Philadelphia, PA, [3]Highmark Health, Pittsburgh, PA

SESSION INFORMATION
Session Date: Sunday, November 7, 2021
Session Title: RA – Treatments Poster I: Comparative Effectiveness, Biosimilars, Withdrawal, & the Real World (0813–0845)
Session Type: Poster Session B
Session Time: 8:30AM–10:30AM

Background/Purpose: Long term use of conventional synthetic DMARDs (csDMARDs) and biologics in RA has clinical risks including infection and malignancy. Patients with chronic RA remain interested in the question of medication tapering per our previous survey-based study within the RHEUmatoid Arthritis Medication TAPering (RHEUMTAP) cohort. Few RCTs and retrospective studies have systematically studied clinical outcomes of medication tapering in RA. In this study, we prospectively compared the clinical outcomes of different medication tapering groups within the RHEUMTAP cohort.

Methods: RHEUMTAP is a 2 year prospective cohort of patients with RA in sustained remission on biologics seen at Allegheny Health Network Rheumatology between 11/30/2018 and 11/30/2020 with at least 6 months follow up. Biologic tapering regimens were pre-determined based on provider consensus. Manual electronic health record (EHR) review was performed to confirm sustained remission on biologic therapy defined as CDAI≤2.8, stable RA medication

Table 1. Characteristics of Tapered and Not-Tapered groups

Variable	No taper (n=77)	Only biologic tapered (n=26)	Only csDMARD tapered (n=23)	Both biologic + csDMARD tapered (n=5)
Demographics				
Age	59.7 (±11)	60.3 (±11)	58.8 (±14)	57.8 (±12)
Female	60 (78%)	19 (73%)	22 (96%)	4 (80%)
Caucasian	70 (96%)	21 (88%)	22 (96%)	5 (100%)
BMI	29.3 (±5.8)	28.2 (±5.2)	30.5 (±7)	31.1 (±9)
Smoking history, yes	40 (52%)	11 (42%)	8 (35%)	2 (40%)
RA and Medication related variables				
Seropositive disease (RF ± CCP)	54 (70%)	17 (65%)	18 (78%)	4 (80%)
Erosive disease	21 (27%)	7 (27%)	5 (22%)	0
Baseline CDAI score	0 (0-1)	1 (0-1)	1 (0-1)	0.5 (0-1)
End visit CDAI score	4 (3-6)	8.5 (2-15)	4.5 (4-5)	18 (18-18)
Glucocorticoid use	14 (18%)	1 (3.9%)	2 (8.7%)	1 (20%)
Taper related variables				
Provider initiated taper	N/A	19 (73%)	12 (73%)	3 (60%)
Visit Taper Started				
Baseline visit	N/A	2 (7.7%)	2 (8.7%)	0
Visit#1		17 (65%)	15 (65%)	4 (80%)
Visit#2		5 (19%)	5 (22%)	1 (20%)
Visit#3		1 (3.9%)	1 (4.3%)	0
End visit		1 (3.9%)	0	0
End Visit Type, Virtual	21 (27%)	7 (30%)	9 (36%)	2 (40%)
Infection ± antibiotic use	7 (9.1%)	4 (15%)	2 (8.7%)	2 (40%)
Malignancy	1 (1.3%)	0	0	1 (20%)
Remission at end visit*	73 (95%)	20 (77%)	20 (87%)	1 (20%)
Flare*	4 (5.2%)	10 (38%)	3 (13%)	3 (60%)
Time to flare, days	305 (240-430)	29 (7-364)	98 (72-212)	297 (236-545)

Data are presented as mean (standard deviation) or median (interquartile range) for continuous variables, and frequency (percentage) for categorical variables. Variables with p value <0.05 are marked with *

use, and absence of flares for a period of at least 6 months. Taper meant a reduction in biologic and/or csDMARD dose, frequency, or discontinuation. Primary outcome was proportion of flares at the end of study period, and secondary outcome was time to flare. Flare was defined as provider diagnosed worsening RA requiring initiation, change

Table 2. Primary and secondary outcome (multivariable analyses)

	Only biologic tapered vs No-taper	p-value	Only csDMARD tapered vs No-taper	p-value	Both biologic and csDMARD tapered vs No-taper	p-value
Proportion of flares, Odds ratio (95%CI)	9.88 (2.5-39)	0.176	2.46 (0.46-13)	0.22	26.93 (2.5- 276)	0.048
Time to flare, Hazard ratio, (SE)	33.9 (1.2)	0.004	2.85 (1.1)	0.34	10.89 (0.91)	0.008

Variables with p<0.25 in univariate analysis were included in multivariable analysis. These variables included age, race, seropositive disease, and baseline DMARD use. Multivariable regression analysis was used for proportion of flares (primary outcome), and Cox regression analysis was used for time to flare (secondary outcome).

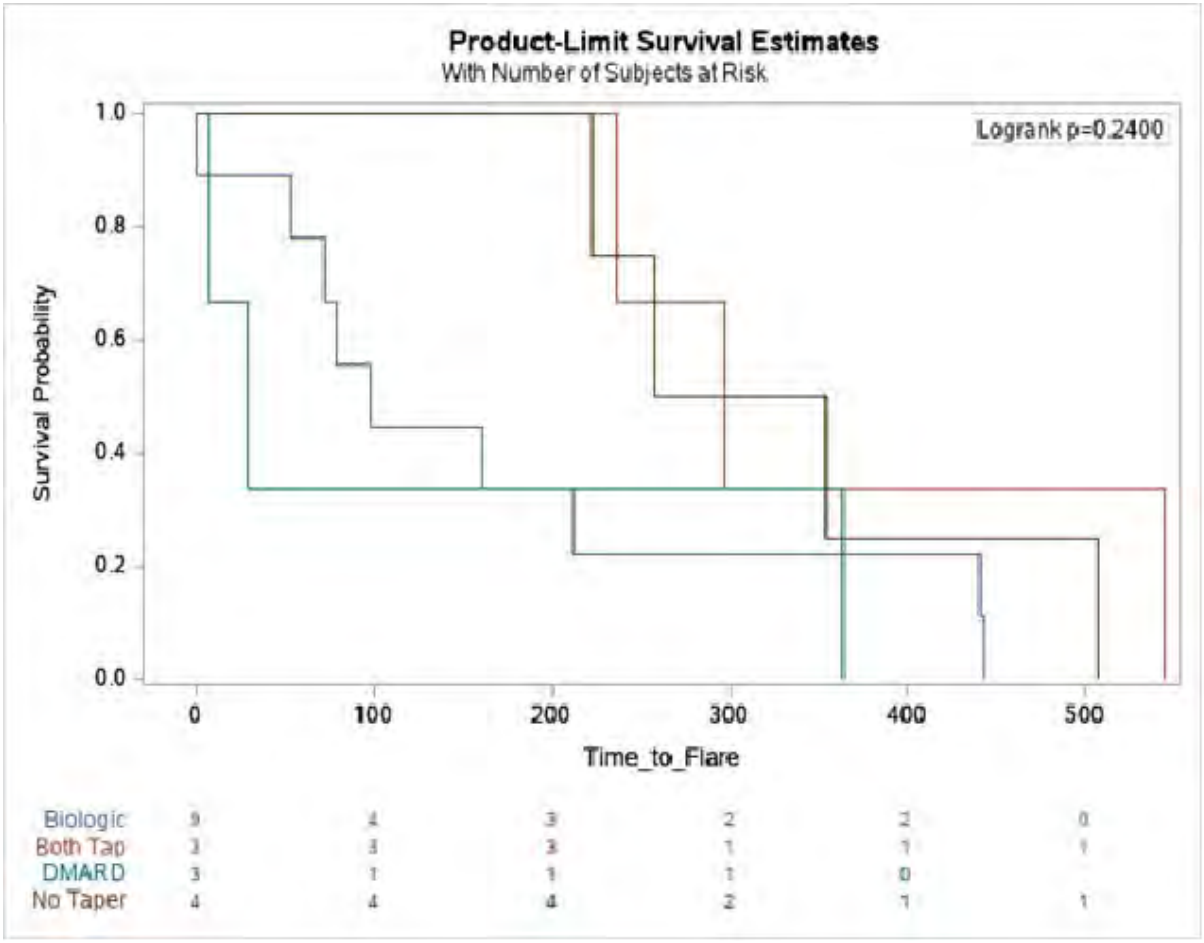

Figure 1. KM survival curve, without flare.

or increase in therapy. The 4 groups of comparison were: no taper, only biologic tapered, only csDMARD tapered, and both biologic and csDMARD tapered. Statistical analyses were completed using SAS Enterprise Guide 7.15 HF3 (SAS Institute, Inc, Cary, NC). Multivariable logistic regression analyses were used to estimate adjusted odds of flare. Kaplan Meier survival plots were created to determine the time to flare utilizing the log-rank test to determine significance.

Results: The RHEUMTAP cohort included 346 patients of which 131 patients were confirmed to have sustained remission on biologics +/- csDMARDs based on manual EHR review. Of these 131 patients, 54 patients underwent a medication taper. Flare was experienced by 20 (15%) patients during follow up period, of which 16 were in the taper groups and 4 in the no-taper group. There were no significant differences in characteristics between the groups (table 1). The most frequently tapered biologics were etanercept and adalimumab, and most frequent csDMARD tapered was methotrexate. Patients undergoing any taper (all groups combined) overall were 7.6 times more likely to experience a flare in the follow-up period compared to those not tapered (OR 7.68, 95% CI 2.4-24, p=0.0006). The both biologic and csDMARD tapered group was more likely to experience a flare (OR 26.93, 95% CI 2.5- 276, p< 0.048) and have a shorter time to flare (HR 10.89, SE 0.91, p=0.008) compared to the no-taper group (table 2).

Conclusion: RHEUMTAP is the first real-world prospective cohort study to report the outcomes of different medication tapering groups in RA in sustained remission. In our cohort, patients who tapered both biologics and csDMARDs were more likely to experience a flare and have a shorter time to flare. Larger studies are required to confirm our findings given our wide confidence intervals.

SESSION INFORMATION

Session Date: Sunday, November 7, 2021

Session Title: RA – Treatments Poster I: Comparative Effectiveness, Biosimilars, Withdrawal, & the Real World (0813–0845)

Session Type: Poster Session B

Session Time: 8:30AM–10:30AM

Background/Purpose: SB5, an adalimumab (ADL) biosimilar, received EU marketing authorisation in August 2017, based on the totality of evidence from pre-clinical and clinical Phase I and III studies that demonstrated bioequivalence and comparable efficacy, safety and immunogenicity to reference ADL. There are few published data on longer-term follow-up of the transition from reference ADL to SB5 outside the controlled, randomised, clinical trial setting and in different disease cohorts. When complete, this umbrella study aims to evaluate candidate predictors of persistence on SB5 in EU patients across multiple indications.

Table 1: Patient baseline characteristics*

Methods: This ongoing non-interventional study enrolled 1000 subjects with rheumatoid arthritis (RA), axial spondyloarthritis (axSpA) or psoriatic arthritis (PsA), ulcerative colitis or Crohn's disease who initiated SB5 as part of routine clinical practice following a minimum of 16 weeks' treatment with reference ADL, at clinics in Belgium, Germany, Ireland, Italy, Spain and the UK. Data are captured from clinic records retrospectively for the 24 weeks prior to transition, and prospectively and/or retrospectively for 48 weeks following transition. This interim analysis provides insight into baseline characteristics, disease activity scores and dose regimen up to 48 weeks post-initiation of SB5 in subjects with RA, axSpA or PsA enrolled at 35 specialist sites and followed up to the data extract date of 3rd May 2021.

Results: This interim analysis includes 510 patients: 205 with RA, 169 with PsA and 136 with axSpA. Baseline clinical characteristics are outlined in Table 1 and changes in dosing regimens and disease activity scores in Table 2.

The majority of patients were in remission or had stable disease at transition, with no meaningful difference seen in disease score by Week 48 post-transition. Almost three quarters of patients in each cohort were transitioned to the same dose regimen of SB5 as received for reference ADL prior to transition, and the great majority of patients continued the same SB5 regimen to Week 48.

Table 2: SB5 Dose Regimen and Disease Score

		RA (N=205)		axSpA (N=136)		PsA (N=169)	
Dose Regimen		**n**	**%**	**n**	**%**	**n**	**%**
Baseline	40 mg Q2W	152	74.1	122	89.7	156	92.3

*Other includes all other reported doses and/or dosing intervals: 40 mg QW, 80 mg Q2W, and unspecified frequency.
BASDAI Bath Ankylosing Spondylitis Disease Activity Index; BL Baseline; CI, Confidence Interval; DAS-28 Disease Activity Score 28; FFbH Hanover Functional Ability Questionnaire; PsARC Psoriatic Arthritis Response Criteria; Q2W every 2 weeks.

Most patients were well educated about handling and self-administration of SB5.

Nine serious adverse events were reported: 5 in the PsA cohort (myocardial infarct [2], breast carcinoma [1], COVID-19 [1], gastrostomy [1]); 4 in the RA cohort (herpes zoster [1], pneumonia [2], facial numbness [1]). Herpes zoster and one case of pneumonia were considered to be causally related to study treatment.

Conclusion: This interim analysis has shown that effectiveness is maintained at 48 weeks after switching from reference to biosimilar ADL SB5 in a large, contemporary cohort of EU patients with established RA, axSpA or PsA. No new safety signals were observed.

Baseline Characteristics Predictive of Remission in Patients with RA Following Treatment with IV Abatacept: Post Hoc Analysis of a Real-world Observational Study

Rieke Alten[1], Xavier Mariette[2], Mauro Galeazzi[3], Melanie Chartier[4], Christiane Rauch[5], Yedid Elbez[6] and Karissa Lozenski[7], [1]Schlosspark-Klinik University, Berlin, Germany, [2]Université Paris-Saclay, AP-HP, Hospital Bicêtre, Paris, France, [3]University of Siena, Siena, Italy, [4]Bristol Myers Squibb, Rueil-Malmaison, France, [5]Bristol Myers Squibb, Munich, Germany, [6]Deepscover, Puteaux, France, [7]Bristol Myers Squibb, Princeton, NJ

SESSION INFORMATION

Session Date: Sunday, November 7, 2021

Session Title: RA – Treatments Poster I: Comparative Effectiveness, Biosimilars, Withdrawal, & the Real World (0813–0845)

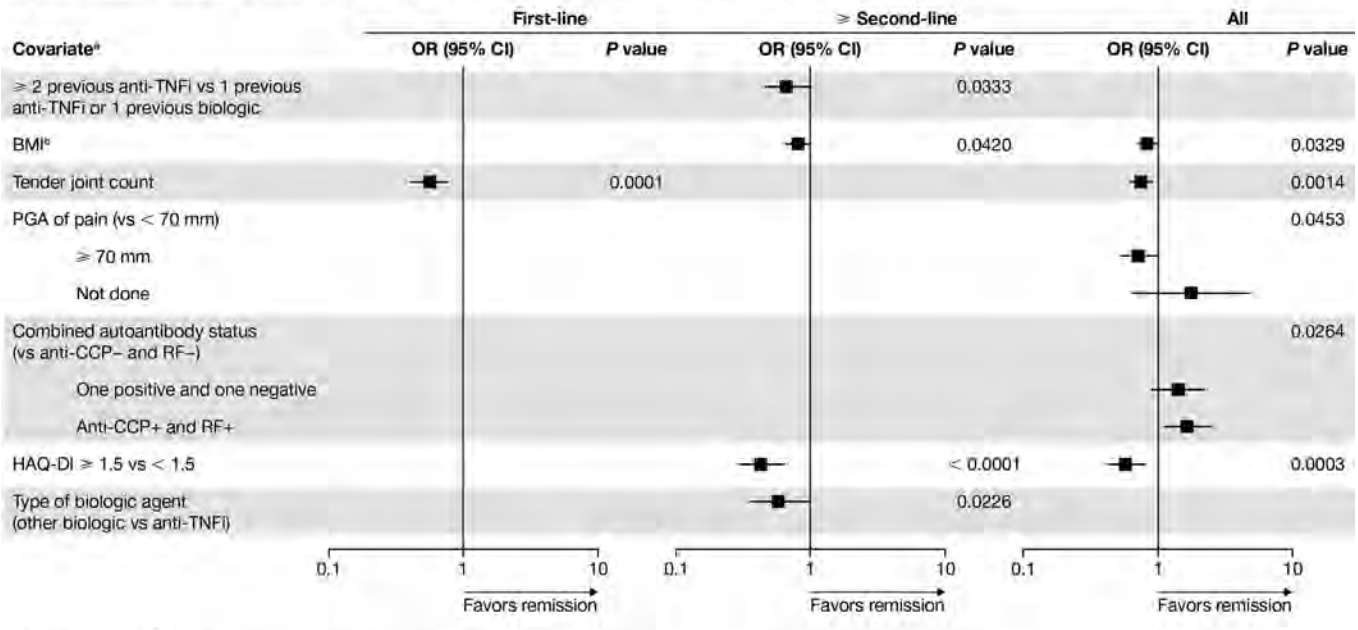
Session Type: Poster Session B

Session Time: 8:30AM–10:30AM

Background/Purpose: Identifying factors associated with treatment response and remission in patients with RA may assist with therapeutic decision-making. An international observational study evaluated efficacy and safety in patients with RA who initiated intravenous (IV) abatacept (AbataCepT In rOutiNe clinical practice [ACTION]; NCT02109666) and noted retention of 47.9% at 2 years.[1] This post hoc analysis identified baseline characteristics predictive of remission following abatacept treatment in patients with RA who participated in the real-world setting ACTION study.

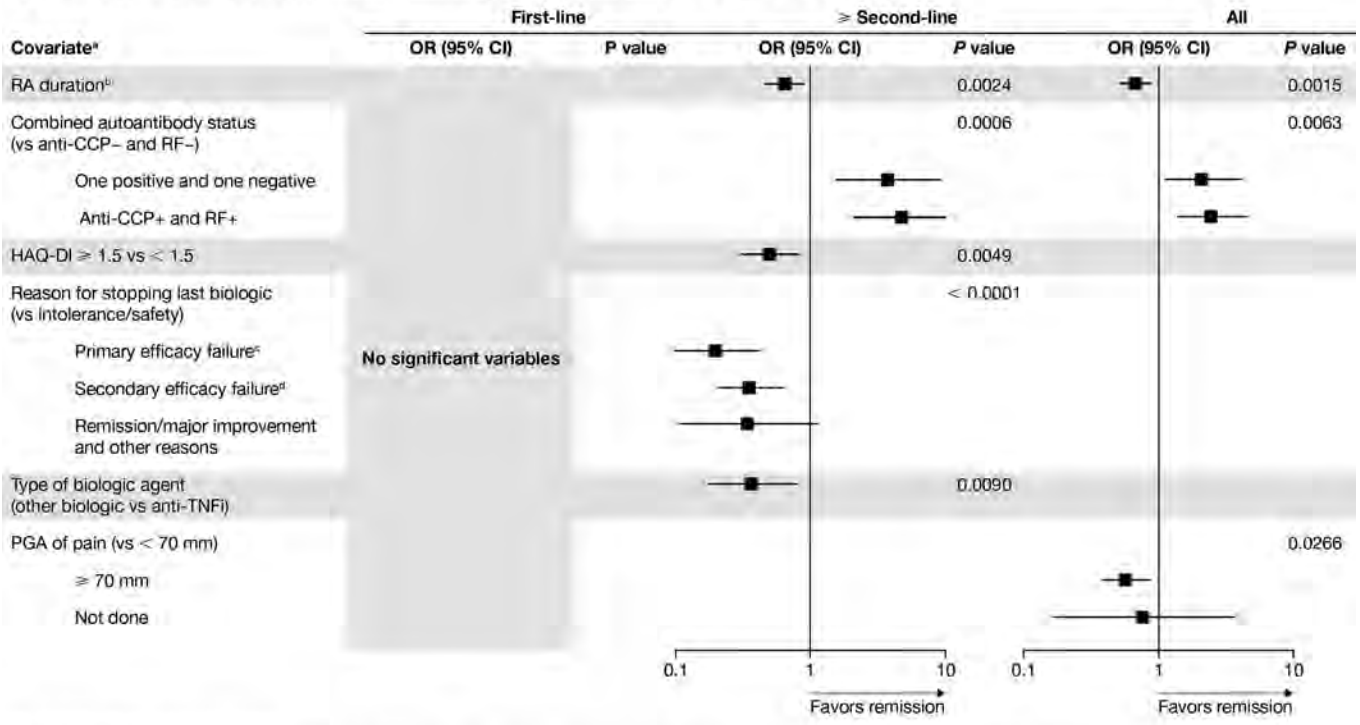
Methods: Patients (aged ≥ 18 years) with moderate-to-severe RA from ACTION who initiated IV abatacept as first- or ≥ second-line therapy and achieved DAS28 (CRP; < 2.6), Clinical Disease Activity Index (CDAI; ≤ 2.8) or Simplified Disease Activity Index (SDAI; ≤ 3.3) remission at 12 months were included. Univariate logistic regression analysis was performed to determine potential predictors of remission by treatment arm including baseline demographics, disease characteristics, serum markers, and previous treatments. Significant variables ($P < 0.2$) from the univariate analyses

Figure 1. Baseline factors predictive of DAS28 (CRP) remission by treatment line and overall, in multivariate analyses



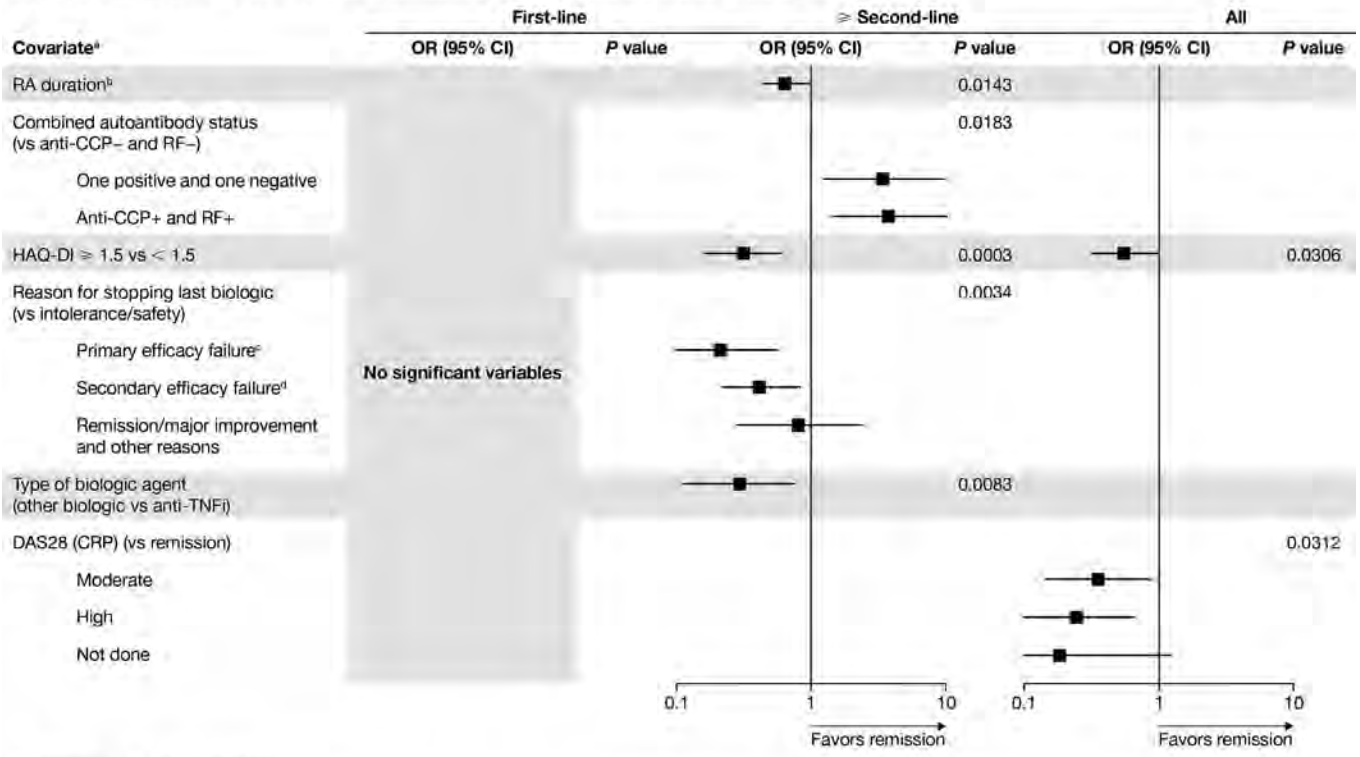
All variables with $P \leq 0.05$ are shown.
[a]Overall, country was shown to impact remission; however, the OR varied by individual countries; [b]Continuous variables were standardized prior to multivariate analysis.
CI, confidence interval; HAQ-DI, HAQ-disability index; OR, odds ratio; PGA, patient global assessment; TNFi, TNFi inhibitor.

Figure 2. Baseline factors predictive of CDAI remission by treatment line and overall, in multivariate analysis



All variables with $P \leq 0.05$ are shown.
[a]Overall, country was shown to impact remission; however, the OR varied by individual countries; [b]Continuous variables were standardized prior to multivariate analysis; [c]± secondary efficacy failure, remission, or other reasons; [d]± remission or other reasons.
CDAI, Clinical Disease Activity Index; CI, confidence interval; HAQ-DI, HAQ-disability index; OR, odds ratio; PGA, patient global assessment, TNFi, TNF inhibitor.

Figure 3. Baseline factors predictive of SDAI remission by treatment line and overall, in multivariate analysis



All variables with $P \leq 0.05$ are shown.
[a]Overall, country was shown to impact remission; however, the OR varied by individual countries; [b]Continuous variables were standardized prior to multivariate analysis; [c]± secondary efficacy failure, remission, or other reasons; [d]± remission or other reasons.
CI, confidence interval; HAQ-DI, HAQ-disability index; OR, odds ratio; SDAI, Simplified Disease Activity Index; TNFi, TNF inhibitor.

were evaluated by a multivariate backward elimination logistic regression model; odds ratios (95% confidence intervals) and *P* values were determined. Standardized values were used for the continuous baseline predictors.

Results: Overall, 2260/2364 enrolled patients were evaluable (643 first-line and 1617 ≥ second-line abatacept). For the overall population, DAS28 (CRP) (Figure 1) and CDAI remission (Figure 2) were more likely to be achieved in patients with seropositivity, while DAS28 (CRP) and SDAI remission (Figure 3) were more likely to be achieved in patients with less severe disability (HAQ-disability index [DI]). DAS28 (CRP) remission was more likely to be achieved with ≥ second-line therapy in patients who had low BMI, less severe HAQ-DI, and prior TNF inhibitor (TNFi) use (vs other biologic use). Lastly, in patients who received abatacept as ≥ second-line therapy, CDAI and SDAI remission were more likely to be achieved by patients with: seropositivity, less severe HAQ-DI, shorter RA duration, prior TNFi use (vs other biologic use), and lack of efficacy on last biologic.

Conclusion: This post hoc, multivariate analysis of the ACTION study showed several baseline factors, including seropositive RA and less severe disability (HAQ-DI), to be associated with remission at 12 months for patients treated with IV abatacept. These data support the earlier use of abatacept in patients with seropositive RA.

Session Title: RA – Treatments Poster I: Comparative Effectiveness, Biosimilars, Withdrawal, & the Real World (0813–0845)
Session Type: Poster Session B
Session Time: 8:30AM–10:30AM

Background/Purpose: Adalimumab (ADL) can be self-administered every 2 weeks as a subcutaneous (s.c.) injection in patients with rheumatoid arthritis (RA), psoriatic arthritis (PsA), and psoriasis (PsO). Conflicting evaluations of local tolerance to formulations containing citrate buffer have created insecurity among health care professionals and patients.[1,2] Here, we evaluated local tolerance of SDZ-ADL (GP2017) a biosimilar ADL with low citrate concentration (1.2 mM), in 466 healthy volunteers (HV) and 408 patients (RA: 177; PsO: 231 including PsA: 52) from 4 phase I pharmacokinetic and 2 phase III confirmatory studies.

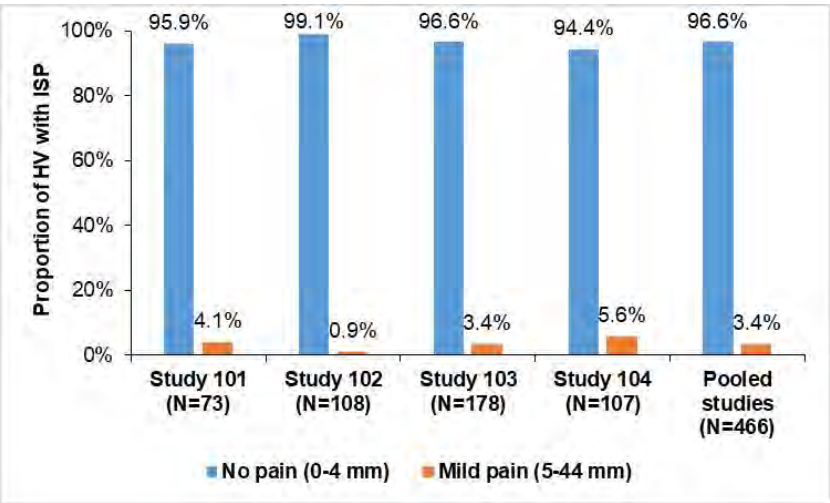

Figure. Proportion of HV with ISP in phase I PK studies.

Table. ISP and ISR results from phase I PK and phase III confirmatory studies

Phase I PK studies					
Study	**101 (N=73)**	**102 (N=108)**	**103 (N=178)**	**104 (N=107)**	**Pooled studies (N=466)**
VAS scores (mm) at 1-hour post-dose					
Mean (SD)	0.89 (2.07)	0.07 (0.52)	1.03 (1.71)	1.03 (2.49)	0.79 (1.84)
Median	0	0	1	0	0
ISR scores at 1-hour post-dose, n (%)					
None	73 (100)	106 (98.2)	178 (100)	99 (92.5)	456 (97.9)
Mild	0 (0)	1 (0.9)	0 (0)	8 (7.5)	9 (1.9)
Moderate	0 (0)	1 (0.9)	0 (0)	0 (0)	1 (0.2)

Phase III confirmatory studies				
	ADACCESS[4]* (PsO and PsA pts)		**ADMYRA[5]* (RA pts)**	
	W0–17 (N=231)	W0–51 (N=168; including pts re-randomized to continue SDZ-ADL after W17)	W0–24 (N=177)	W0–48 (N=177; all pts continued SDZ-ADL after W24)
Dosage	Induction 80 mg W0, then 40 mg EoW s.c.	40 mg EoW s.c.	40 mg EoW s.c.	40 mg EoW s.c.
Study duration, W	17	51	24	48
AEs - ISR, n (%), events	15 (6.5), 34	9 (5.4), 26	7 (4.0), 11	7 (4.0), 12
Mild	14 (6.1), 30	9 (5.4), 26	7 (4.0), 11	7 (4.0), 12
Moderate	1 (0.4), 4	0	0	0
AEs - ISP (reported as ISR), n (%)	3 (1.3)	1 (0.6)	2 (1.1)	2 (1.1)

*ADACCESS and ADMYRA were switch studies, therefore, only pts exposed to SDZ-ADL throughout the study period are included here. AEs, adverse events; EoW, every other week; ISP/ISR, injection site pain/reaction; N, number of HV or pts; HV, healthy volunteers; PK, pharmacokinetic; Pts, Patients; W, week

Methods: HV evaluated their injection site pain (ISP) using a Visual Analog Scale (VAS) of 0–100 mm. HV received a single 40 mg/0.8 mL s.c. injection and patients received SDZ-ADL every 2 week during 48–51week duration of study. Injection site reactions (ISR) as well as adverse events were assessed by investigators during the clinical studies. Detailed study designs have been reported previously.[3–6]

Results: Overall, 456 (97.9%) HV did not experience ISR while 10 (2.1%) HV experienced ISR. These were mostly of mild intensity; only 1 (0.2%) had an ISR of moderate intensity. At 1-hour post-dose, 96.6% of HV experienced no pain (VAS score, 0–4 mm) (**Figure**). In the phase III studies, a low number of mild/moderate ISR/ISP events were observed, which further decreased during the study. Detailed results are presented in the **Table**. No ISR/ISP led to treatment or study discontinuation in any study.

Conclusion: The proportion of HV and patients experiencing ISR and ISP after administration of SDZ-ADL was low, with no events leading to treatment or study discontinuation. These outcomes challenge the clinical impact of citrate in ADL formulations on the incidence and intensity of ISP/ISR.

Pharmacokinetic and Pharmacodynamic Evaluation of a Proposed Biosimilar MSB11456 versus Both the US-licensed and EU-approved Tocilizumab: Results of a Randomized, Double-blind, Parallel-group, Single-dose Trial in Healthy Adults

Christian Schwabe[1], Chris Wynne[2], **Andras Illes**[3], Martin Ullmann[3], Emmanuelle Vincent[3], Vishal Ghori[3], Corinne Petit-Frere[3], Anne-Sophie Racault[3] and Joelle Monnet[3], [1]Auckland Clinical Studies Ltd, Auckland, New Zealand, [2]Christchurch Clinical Studies Trust Ltd, Christchurch, New Zealand, [3]Fresenius Kabi SwissBioSim, Eysins, Switzerland

SESSION INFORMATION
Session Date: Sunday, November 7, 2021
Session Title: RA – Treatments Poster I: Comparative Effectiveness, Biosimilars, Withdrawal, & the Real World (0813–0845)
Session Type: Poster Session B
Session Time: 8:30AM–10:30AM

Background/Purpose: Tocilizumab, a biologic disease-modifying antirheumatic drug, is a recombinant humanized monoclonal immunoglobulin G1 antibody against the interleukin-6 receptor (IL-6R). MSB11456 is a proposed biosimilar to US-licensed tocilizumab and EU-approved tocilizumab. Prior to initiation of its clinical development program, MSB11456 was considered highly similar to the reference products based on extensive *in vitro* pharmacological testing and functional activity assays. This double-blind, parallel-group phase I study (NCT03282851) assessed the pharmacokinetic (PK) and pharmacodynamic (PD) equivalence of MSB11456 to US-licensed and EU-approved tocilizumab and provided data on the similarity of safety profiles and immunogenicity of MSB11456 and the reference products in healthy adult subjects.

Methods: Healthy adult volunteers were randomized to receive a single 162 mg subcutaneous injection of MSB11456, US-licensed tocilizumab, or EU-approved tocilizumab. Samples for PK/PD and immunogenicity analysis were taken predose, up to 29 days postdose, and at the end of study visit (day 48). Primary endpoint PK parameters were natural log transformed and analyzed using analysis of covariance (ANCOVA) methods; results were then transformed back to the original scale. Secondary PD analysis measured serum soluble IL-6R and serum C reactive protein (sCRP) parameters, and data were analyzed using a method similar to that for PK data. Safety data were collected throughout the study and analyzed descriptively.

Results: 685 subjects were randomized and treated. Results of the primary PK analysis demonstrated bioequivalence between MSB11456 and both US-licensed and EU-approved tocilizumab, as well as between the reference

Results of primary PK analysis

Parameter	Treatment	n	Ratio of geometric LSMs (%)	90% CI of ratio
MSB11456 vs US-licensed tocilizumab				
$AUC_{0-\infty}$	MSB11456	194	106.16	96.80, 116.43
	US-licensed tocilizumab	190		
AUC_{0-t}	MSB11456	230	104.15	93.58, 115.90
	US-licensed tocilizumab	226		
C_{max}	MSB11456	230	104.45	95.05, 114.77
	US-licensed tocilizumab	226		
MSB11456 vs EU-tocilizumab				
$AUC_{0-\infty}$	MSB11456	194	104.03	94.96, 113.96
	EU-approved tocilizumab	200		
AUC_{0-t}	MSB11456	230	94.78	85.15, 105.50
	EU-approved tocilizumab	224		
C_{max}	MSB11456	230	94.83	86.28, 104.22
	EU-approved tocilizumab	224		
US-licensed vs EU-approved tocilizumab				
$AUC_{0-\infty}$	US-licensed tocilizumab	190	97.99	89.40, 107.41
	EU-approved tocilizumab	200		
AUC_{0-t}	US-licensed tocilizumab	226	91.01	81.71, 101.36
	EU-approved tocilizumab	224		
C_{max}	US-licensed tocilizumab	226	90.79	82.57, 99.84
	EU-approved tocilizumab	224		

AUC, area under the serum concentration-time curve (μg·h/mL); $AUC_{0-\infty}$, AUC from time zero to infinity; AUC_{0-t}, AUC from time zero to the time of the last quantifiable concentration; C_{max}, maximum concentration (μg/mL)

Results of primary PK analysis.

products, since all corresponding 90% confidence intervals (CIs) for the geometric least squares mean (LSM) ratios were within the predefined 80.00% to 125.00% equivalence margin (Table). PD analyses also demonstrated equivalence of MSB11456 and both US-licensed and EU-approved tocilizumab, as well as between the reference products. Safety, tolerability and immunogenicity were also comparable between treatments. The incidence of tocilizumab-specific neutralizing antibodies was low (< 3% for all three products).

Conclusion: PK and PD equivalence of MSB11456, US-licensed tocilizumab, and EU-approved tocilizumab were demonstrated with comparable immunogenicity, safety, and tolerability for the three products. This study adds to the totality of evidence in support of MSB11456 as a proposed biosimilar to tocilizumab.

Physicians' Reasons for Prescribing Janus Kinase Inhibitors (JAKi) in Patients with Rheumatoid Arthritis, and Associated Alignment Between Physicians and Patients in a Real-world Clinical Setting

Peter C Taylor[1], Bruno Fautrel[2], Yves Piette[3], Susana Romero-Yuste[4], Jasper Broen[5], Martin Welcker[6], Elizabeth Holdsworth[7], Monia Zignani[8], Katrien Van Beneden[8], Roberto Caporali[9] and Rieke Alten[10], [1]University of Oxford, Oxford, United Kingdom, [2]Pitié Salpêtrière Hospital, APHP, Sorbonne Université, Paris, France, [3]AZ Sint-Jan Brugge-Oostende AV, Bruges, Belgium, [4]Complejo Hospitalario Universitario de Pontevedra, Pontevedra, Spain, [5]Maxima Medical Centre, Veldhoven, Netherlands, [6]MVZ für Rheumatologie, Planegg, Germany, [7]Adelphi Real World, Bollington, United Kingdom, [8]Galapagos, NV, Mechelen, Belgium, [9]Policlinico S. Matteo University, Pavia, Italy, [10]Schlosspark-Klinik University, Berlin, Germany

SESSION INFORMATION
Session Date: Sunday, November 7, 2021
Session Title: RA – Treatments Poster I: Comparative Effectiveness, Biosimilars, Withdrawal, & the Real World (0813–0845)
Session Type: Poster Session B
Session Time: 8:30AM–10:30AM

Background/Purpose: Shared decision making, a cornerstone of rheumatoid arthritis (RA) management[1], allows physicians and their patients to make informed decisions about their treatment goals and choice of care. As new treatments become available, it is important to understand rheumatologists' reasons for choosing Janus kinase inhibitors (JAKi), rheumatologist and patient satisfaction and alignment with this choice in patients with RA.

Methods: The Adelphi RA Disease Specific Programme™[2] is a large, multinational, point-in-time survey conducted amongst rheumatologists and their consulting patients with RA in Europe (Belgium, France, Germany, Italy, Spain, UK) between January and October 2020.

Physicians completed record forms for up to 10 consecutive RA patients, collecting demographic, clinical and treatment data, and reasons for current treatment choice. Patients were invited to complete a patient questionnaire to assess their satisfaction with ongoing treatment (5-point scale), and perceptions of shared decision making for the current treatment.

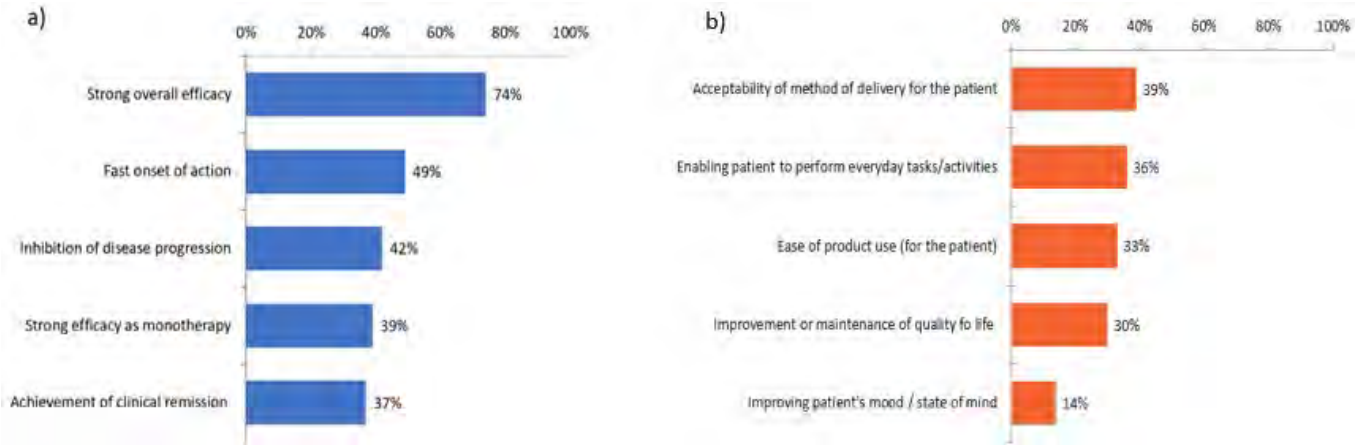

Figure 1. Physician stated reasons for prescribing a JAKi in their patients with RA, % of patients (n=397). a) Top 5 clinical reasons (Blue); b) Top 5 patient-centric reasons (Orange).

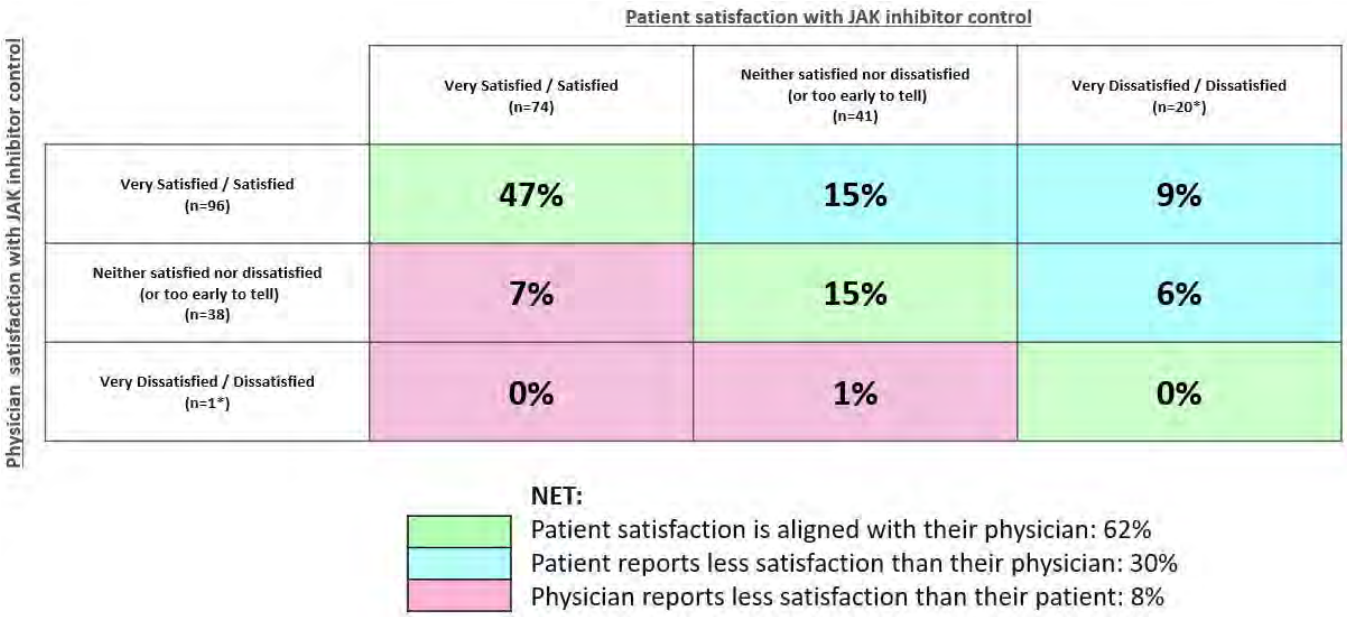

Figure 2. Level of alignment between physician and patient-reported satisfaction with JAKi.

Results: 316 rheumatologists provided data for 3121 patients, of whom 1130 (36.2%) completed patient reported questionnaires. Overall, 67% were female, mean age was 53 years (SD 14), 23% had moderate-high disease activity score (DAS28: >3.2). 68% of patients were currently receiving either a biologic or targeted synthetic DMARD (defined here as advanced therapy, AT), 72% were on first line AT.

Overall, physicians and their patients were aligned that a conversation took place about a treatment decision (n=855, 79% net alignment), and this was a shared treatment decision (n=814, 75% net alignment).

15% of patients not taking an AT were reported to have a clinical condition warranting one; reasons for not taking AT included patients' concerns about infection (24%), csDMARDs were tolerable and safe in the patient (18%), and patient dislike of infusions/injections (17%).

Of 2143 patients receiving AT, 19% were prescribed JAKi; 57% as monotherapy, 43% as combination therapy. For physician stated reasons for choice of JAKi, factors were driven by both perceptions of clinical efficacy and onset of action, as well as factors relating to patient acceptability such as method of delivery and ease of use (Figure 1).

With respect to JAKi treatment (n=135 patient-physician pairs), 62% of physicians and their patients were aligned on satisfaction, however 30% of patients reported less satisfaction than their consulting physician (Figure 2).

Conclusion: Communicating the choice of pharmacological therapy to patients with RA has become increasingly complex for physicians with expansion of approved treatments. In this subgroup of patients on JAKi, the drug attributes considered as reasons for prescribing were driven by clinical factors as well as by patient centric attributes. Although communications between patients and physicians were largely aligned, better understanding of patient expectations might serve to improve messaging about treatment options and resulting satisfaction.

SESSION INFORMATION

Session Date: Sunday, November 7, 2021

Session Title: RA – Treatments Poster I: Comparative Effectiveness, Biosimilars, Withdrawal, & the Real World (0813–0845)

Session Type: Poster Session B

Session Time: 8:30AM–10:30AM

Background/Purpose: The optimal first-line treatment of patients (pts) with early rheumatoid arthritis (eRA) is yet to be established. The main objectives were to assess and compare clinical and radiographic outcomes after 48 weeks of active conventional therapy (ACT) with conventional synthetic (cs)DMARDs plus glucocorticoid versus each of three biological (b)DMARDs with different modes of action (certolizumab pegol, abatacept and tocilicumab), all combined with methotrexate (MTX).

Methods: The NORD-STAR trial (NCT01491815) was conducted in the Nordic countries and Netherlands (1). In this investigator-initiated, randomized, open-label, blinded-assessor study pts with treatment-naïve, eRA with DAS28 >3.2, and positive RF or ACPA, or CRP >10mg/L were randomized 1:1:1:1. Methotrexate (25 mg/week) was combined with: 1) ACT: oral prednisolone (tapered quickly; discontinued at wk 36); *or*: sulphasalazine, hydroxychloroquine and mandatory intra-articular (IA) glucocorticoid (GC) injections in swollen joints; 2) certolizumab 200 mg EOW SC (CZP); 3) abatacept 125 mg/wk SC (ABA); tocilizumab 162 mg/wk SC (TCZ). IA GC was allowed in all arms except wks 20-24 and 44-48. Co-primary outcomes were clinical disease activity index remission (CDAI≤2.8) at wk 48 and change in total van der Heijde-modified Sharp Score from baseline to wk 48 ($\Delta vdHSS_{w0\text{-}w48}$).

As predefined in the statistical analysis plan, 6 primary null hypotheses were tested: no difference between ACT and each of the 3 bDMARDs for each of the two co-primary outcomes. Multiplicity was handled by Bonferroni correction of the co-primary outcomes (resulting in a 0.025 significance level per outcome), and then applying Dunnet's multiple comparison procedure with ACT as reference within each outcome. Logistic regression with non-responder imputation (NRI) (dichotomous outcomes) and analysis of covariance (ANCOVA) (ΔvdHSS) were applied with inter- or extrapolation for missing values and adjusted for baseline value (only ANCOVA), gender, ACPA status and country.

Table 1. Demographics and patient characteristics at baseline (ITT population).

Parameter	ACT (n=200)	CZP+MTX (n=203)	ABA+MTX (n=204)	TCZ+MTX (n=188) §
Demographics				
Age (years)	55 (15)	55 (15)	55 (14)	52 (15)

ΔJSN w0-w48	Reference	0 (-0.13 to 0.13)	0.08 (-0.05 to 0.21)	0.01 (-0.12 to 0.14)

[1]For dichotomous variables, values are estimated adjusted marginal proportions or estimated difference in proportions against ACT with 95% confidence limits. Confidence limits are calculated from the logistic regression model by the delta method. Missing data are imputed using worst outcome (non-responder imputation).

[2]For radiographic scores, values are estimated adjusted marginal mean change from baseline or estimated difference against ACT with 95% confidence limits from the ANCOVA model. Missing data are imputed using intra- or extrapolation.

Results are based on the intention to treat population; 17 Finnish patients allocated to tocilizumab and methotrexate group excluded([§]), since they could not receive tocilizumab because the drug was not available in the Finnish part of the study.

*Superiority of bDMARD compared with ACT was demonstrated; p=0.021. ** Superiority of bDMARD compared with ACT was demonstrated; p<0.001.

ABA: Abatacept, ACR: American College of Rheumatology, ACT: Active conventional therapy, bDMARD: Biological disease modifying anti-rheumatic drug, CDAI: Clinical disease activity index; CZP: Certolizumab pegol, DAS28: Disease activity score (28 joints, 4 variables, C-reactive protein), EULAR, European Alliance of Associations for Rheumatology, IQR: Interquartile range, JSN: Joint space narrowing, n: Number of patients, SDAI: Simple disease activity index, ITT: intention to treat, TCZ: Tocilizumab, vdHSS: van der Heijde-modified Sharp Score

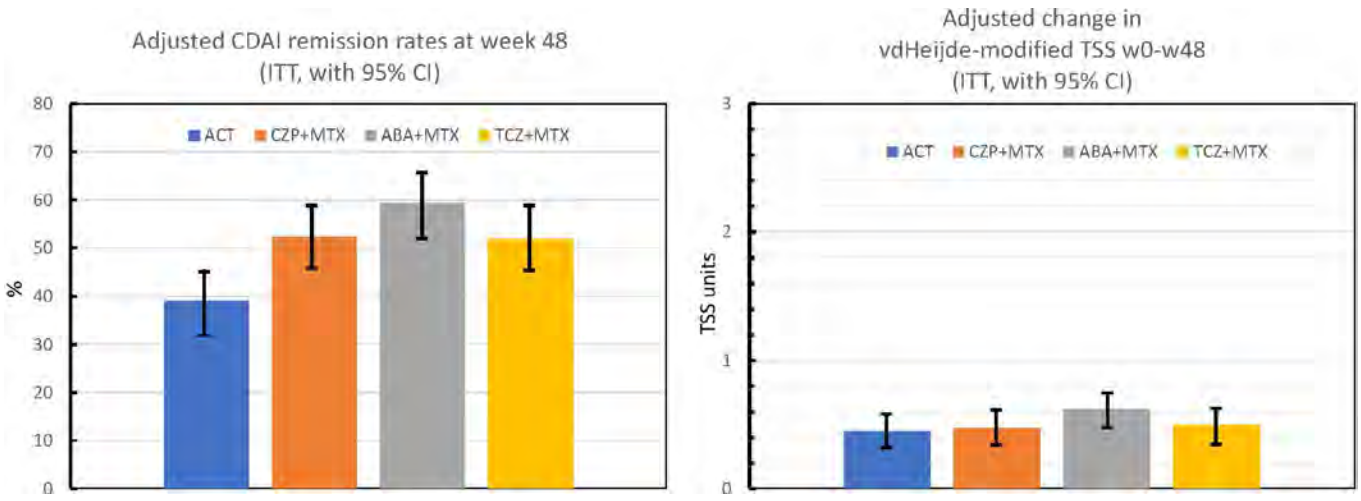

Figure 1. Adjusted CDAI remission rates at week 48 (left) and adjusted change in van der Heijde modified total Sharp score from baseline to week 48 (right).

Results: 812 pts were randomized. Table 1 shows baseline data.

Adjusted CDAI remission rates at w48 were: 59.3% (for ABA), 52.3% (CZP), 51.9% (TCZ) and 39.2% (ACT), with the null hypothesis formally rejected for ACT vs ABA (adjusted difference +20.1%; adjusted p< 0.001) and ACT vs CZP (+13.1; p=0.021), but not for ACT vs TCZ (+12.7; p=0.030). For key secondary clinical outcomes improved clinical outcomes in bDMARD groups compared to ACT were consistently found (Table 2).

Adjusted estimated mean $\Delta vdHSS_{w0\text{-}w48}$ was 0.62 (ABA), 0.47 (CZP), 0.50 (TCZ) and 0.45 (ACT), i.e consistently low. None of the radiographic null hypotheses were rejected (Table 2).

Safety profiles were as previously reported. The total number of serious adverse events (% patients with ≥1 event) were: ABA 21 (8.3%), CZP 28 (12.4%), TCZ 20 (9.2%) and ACT 23 (10.7%).

Conclusion: Compared with ACT (csDMARD+glucocorticoids), statistically significant superiority regarding CDAI remission rates was demonstrated for ABA+MTX and CZP+MTX, and not for TCZ+MTX. Radiographic progression was low, without significant differences between treatments.

Abstract Number: 0826

Diagnosis, Treatment and Utilization Changes in Rheumatoid Arthritis Patients Before and During COVID-19

Miao Wang[1], Sylvie Lardeux[2], Elisea Avalos-Reyes[3], Michele Hamburger[4] and Kjel Johnson[5], [1]CVS Health, New York, NY, [2]CVS Health, Wellesley, MA, [3]CVS Health, Irving, TX, [4]Frances Hamburger Institute, Hauppauge, NY, [5]CVS Health, Lincoln, RI

SESSION INFORMATION
Session Date: Sunday, November 7, 2021
Session Title: RA – Treatments Poster I: Comparative Effectiveness, Biosimilars, Withdrawal, & the Real World (0813–0845)
Session Type: Poster Session B
Session Time: 8:30AM–10:30AM

Background/Purpose: During the COVID-19 pandemic, individuals were encouraged to shelter in place, specifically those considered high risk for COVID-19. Rheumatoid arthritis (RA) patients are known to be particularly susceptible to infections. During the pandemic, RA patients were found to cancel appointments and alter medications. This study aimed to understand the impact of COVID-19 on RA patients' diagnosis, treatment, and utilization during the pandemic.

Methods: This is a retrospective cohort study of RA patients insured by a large Commercial and Medicare health plan in the United States. To assess the impact of COVID-19 on newly diagnosed treatment and utilization rates, we compareda pre-COVID period (March 1 to December 31, 2019) to a COVID period (March 1 to December 31, 2020) to assess how COVID-19 impacted changes. We defined a new RA diagnosis as a patient with medical insurance but no paid claim for RA for at least six months before the initial claim with an RA diagnosis. We utilized both medical and pharmacy claims to identify utilization patterns.

Results: This study included 36,019 patients in 2019 and 35,880 patients in 2020. The newly diagnosed rate increased 6% ($p = 0.002$) for Medicare but not for Commercial patients. Infusion treatments decreased 7% ($p=0.03$) for Commercial but not for Medicare patients. During this time, there was a switch in infusion site of care from the hospital setting to the office setting of 3.1% ($p=0.05$) and 5.7% ($p< 0.001$) for Commercial and Medicare patients, respectively. There was also a switch from facility to office-based biologic drug administration for Commercial (1.8%, $p= 0.03$) and Medicare patients (2.6%, $p = 0.08$). From March to May 2020, there was an 18-19% decrease ($p < 0.001$) in new RA diagnoses for Commercial and Medicare patients with a rebound in the last six months of 2020. There was an 11-17% decrease ($p < 0.001$) in utilization among existing patients during this time. Having COVID-19 increased

the odds of being newly diagnosed with RA by 1.37 in Medicare patients and 1.91 in Commercial patients (both $p < 0.001$).

Conclusion: During the COVID-19 pandemic, we observed higher RA incidence rates. Additionally, infusion treatments decreased and changed from the hospital to the office setting. While new RA diagnosis and utilization rates of existing RA patients declined during the pandemic's height, both rates quickly rebounded in the last months of 2020. As a result, patients treated for COVID-19 were more likely to be newly diagnosed with RA, likely driving the higher incidence rates observed in this study. During the pandemic, some healthcare services were compromised to meet the demands of caring for COVID-19 patients. In some cases, patients canceled appointments or delayed care due to fear of exposure. The results of this study highlight the impact of a pandemic on healthcare.

Abstract Number: 0827

Discontinuation Rate of Tofacitinib as Monotherapy Is Similar Compared to Combination Therapy with Methotrexate in Rheumatoid Arthritis Patients: Pooled Data from Two Rheumatoid Arthritis Registries in Canada

Mohammad Movahedi[1], Denis Choquette[2], Louis Coupal[2], Angela Cesta[3], Xiuying Li[3], Edward Keystone[4] and Claire Bombardier[5], [1]Toronto General Hospital Research Institute, University Health Network, Toronto, ON, Canada, [2]Institut de Rhumatologie de Montréal, Montréal, QC, Canada, [3]Toronto General Hospital Research Institute, UHN, Toronto, ON, Canada, [4]Keystone Consulting Enterprises Inc., Toronto, ON, Canada, [5]University of Toronto - Toronto, Toronto, ON, Canada

SESSION INFORMATION
Session Date: Sunday, November 7, 2021
Session Title: RA – Treatments Poster I: Comparative Effectiveness, Biosimilars, Withdrawal, & the Real World (0813–0845)
Session Type: Poster Session B
Session Time: 8:30AM–10:30AM

Background/Purpose: Tofacitinib (TOFA) is an oral, small molecule drug used for rheumatoid arthritis (RA) treatment and is prescribed alone or with methotrexate (MTX). We previously reported the similarity in retention between TOFA monotherapy and TOFA with MTX using data from two different registries separately; the Ontario Best Practices Research Initiative (OBRI) and the Quebec registry RHUMADATA.

Methods: RA patients enrolled in the OBRI and RHUMADATA initiating their TOFA between 1st June 2014 (TOFA approval date in Canada) and 31st Dec 2019 were included. Concurrent MTX use was defined as MTX use for more than 75% of the time while using TOFA. Multiple imputation (Imputation Chained Equation method, N=20) was used to deal with missing data for covariates at treatment initiation.

Time to discontinuation was assessed using Cox regression models. To deal with confounding by indication, we estimated propensity scores for selected covariates with an absolute standard difference greater than 0.1. We then adjusted Cox regression models for propensity quantile to compare the discontinuation of TOFA with MTX versus TOFA without MTX.

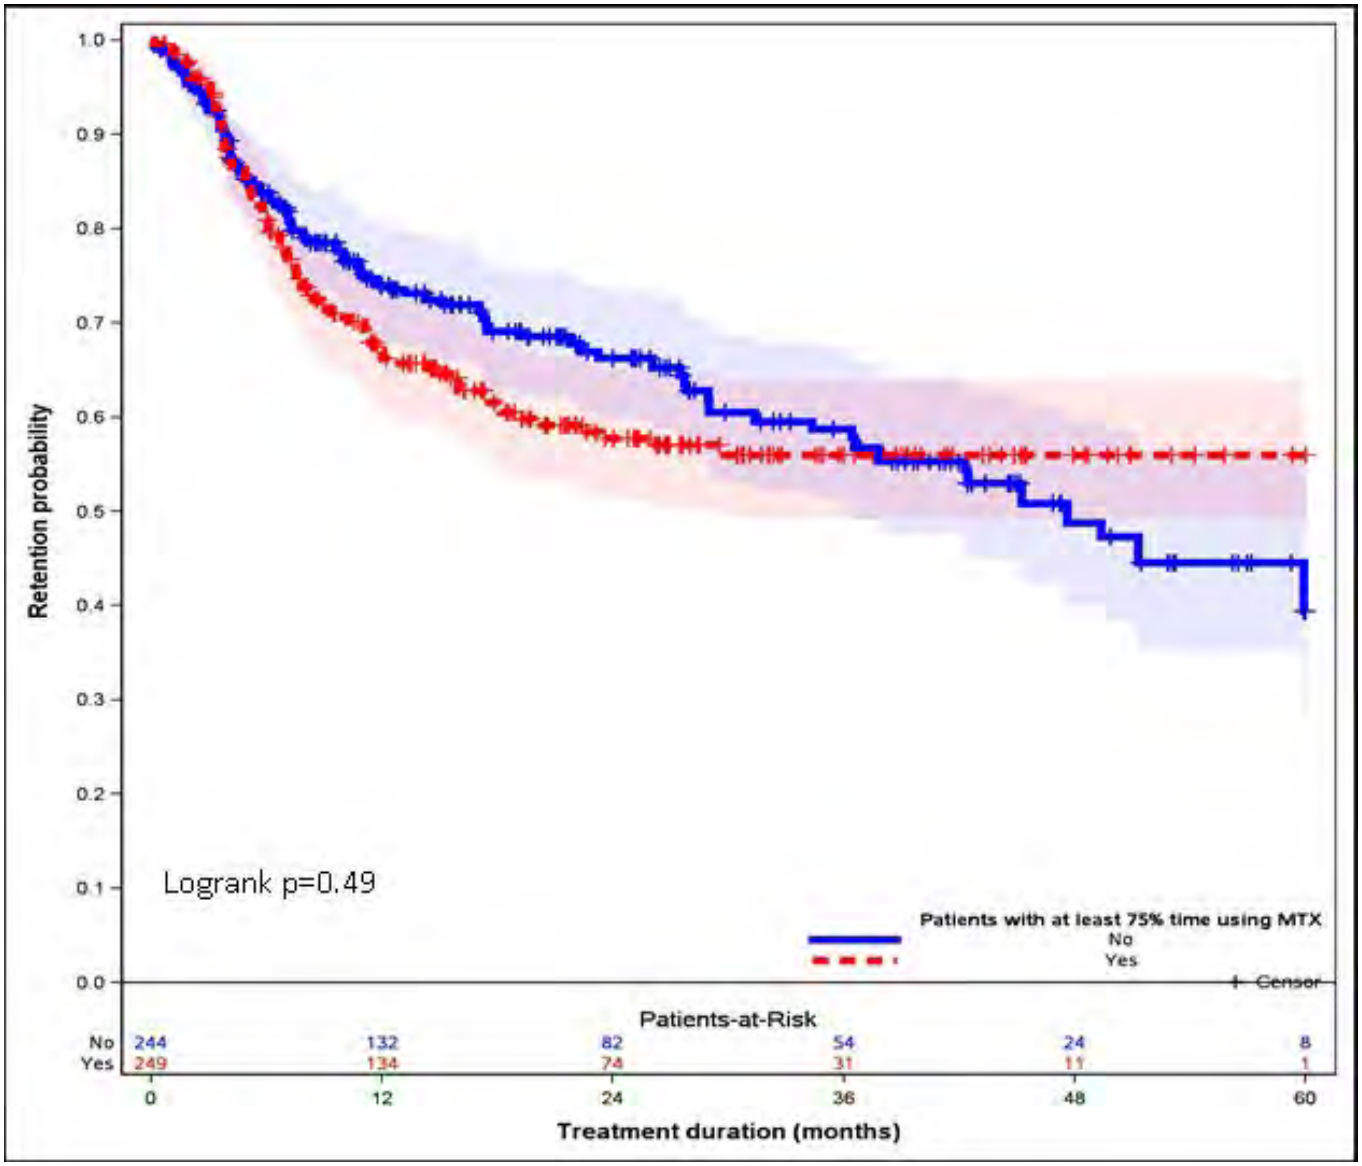

Figure 1. TOFA retention with and without MTX.

Results: A total of 493 patients were included. Of those, 244 (49.5%) and 249 (51.5%) were treated with MTX and without MTX, respectively. Compared to TOFA monotherapy, the TOFA with MTX group had a significantly lower mean HAQ-DI, fatigue score, and the number of prior biologic use at the time of TOFA initiation. A lower proportion of positive ACPA (59% vs. 66%), prevalence of hypertension (31% vs 37%), and concomitant use of Leflunomide (11% vs. 23%) were also observed for patients using TOFA with MTX.

Over a mean follow-up of 19.0 months, discontinuation was reported in 182 (36.9%) of all TOFA patients. After adjusting for propensity score quantile across 20 imputed datasets, there was no significant difference in discontinuation between treatment groups (adjusted HRs: 1.12, 95% CI: 0.83-1.51; p=0.49) (Figure 1).

Conclusion: In this pooled real-world data study, we found that in patients with RA, the retention of TOFA is similar if it is used as monotherapy or in combination with MTX.

SESSION INFORMATION
Session Date: Sunday, November 7, 2021
Session Title: RA – Treatments Poster I: Comparative Effectiveness, Biosimilars, Withdrawal, & the Real World (0813–0845)
Session Type: Poster Session B
Session Time: 8:30AM–10:30AM

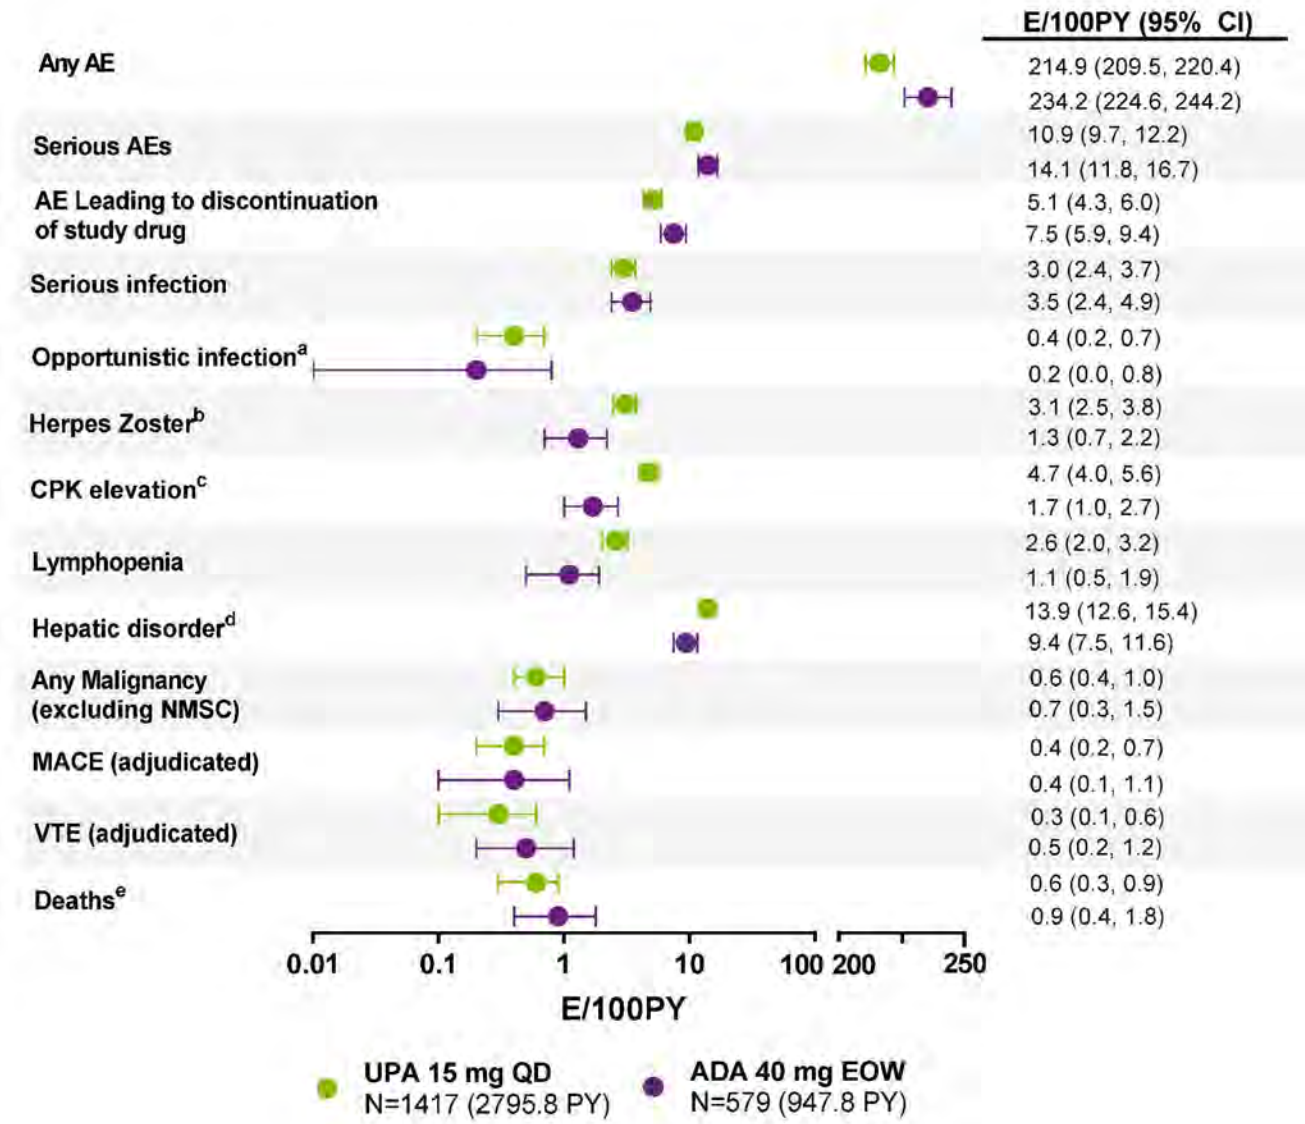
Background/Purpose: In the SELECT-COMPARE study, the Janus kinase inhibitor, upadacitinib (UPA), demonstrated significant improvement in the signs and symptoms of rheumatoid arthritis (RA) when administered at 15 mg once daily (QD) on background methotrexate (MTX) compared with adalimumab (ADA) plus MTX at Week 12 that were maintained through 72 weeks in patients with prior inadequate response to MTX.[1] The objective of this analysis was to assess the long-term safety and efficacy of UPA vs ADA over 3 years in the ongoing long-term extension (LTE).

Methods: Patients receiving background MTX were randomized 2:2:1 to UPA 15 mg QD, placebo (PBO), or ADA 40 mg every other week. Between Weeks 14-26, rescue was mandated for either lack of response (< 20% improvement in tender or swollen joint counts: Weeks 14, 18, 22) or failure to achieve a targeted disease outcome (CDAI low disease activity: Week 26). Patients who completed the 48-week double-blind period could enter an LTE for up to 10 years total. This analysis describes patients through 3 years of treatment. Treatment-emergent adverse events (TEAEs) per 100 patient years (PY), including events of special interest (AESI), were summarized up to 3 years based on exposure to UPA and to ADA. Efficacy was analyzed by original randomized groups. Patients who were rescued or prematurely discontinued study drug were categorized as non-responders for visits after rescue or discontinuation. Descriptive analyses were performed without formal statistical comparisons.

Results: In total, 651, 651, and 327 patients were randomized at baseline to receive UPA, PBO, and ADA, respectively. Between Weeks 14-26, 252 (39%) patients were rescued from UPA to ADA, 159 (49%) were rescued from ADA to UPA, and all PBO patients were switched to UPA by Week 26.[1] A higher proportion of patients randomized to UPA completed 3 years without rescue compared to those randomized to ADA (47% vs 36%, respectively). UPA was generally well-tolerated as assessed by the rates of TEAEs, including serious AEs, AEs leading to discontinuation of study drug, and AESIs, including serious and opportunistic infections, malignancies, adjudicated major adverse

cardiac events or venous thromboembolism; **Figure**). Consistent with previous analyses, the event rates of AESIs were generally comparable between the UPA and ADA groups, while herpes zoster, lymphopenia, hepatic disorder, and CPK elevation were reported at higher rates with UPA. Consistent with earlier time points, greater proportions of patients randomized to UPA achieved low disease activity and remission at 3 years based on CDAI, as well as DAS28(CRP) ≤3.2 or < 2.6, compared with patients randomized to ADA (**Table**).

Figure. Exposure-adjusted Event and Incidence Rates of Treatment-emergent AEs Over 3 Years



ADA, adalimumab; AE, adverse event; CI, confidence interval; CPK, creatine phosphokinase; EAER, exposure-adjusted event rates; EOW, every other week; MACE, major adverse cardiovascular event; NMSC, non-melanoma skin cancer; PY, patient years; QD, once daily; UPA, upadacitinib; VTE, venous thromboembolism.

Exposure adjusted incidence rates (EAIR) are reported for malignancy, MACE, VTE, and deaths; exposure adjusted event rates (EAER) are reported for the remaining events.

[a]Excluded tuberculosis and herpes zoster.

[b]Herpes zoster: majority of cases on UPA were non-serious and involved 1 or 2 dermatomes.

[c]CPK elevation: most were mild or moderate and asymptomatic, with no reports of rhabdomyolysis.

[d]Hepatic disorders: majority were transaminase elevations.

[e]Includes treatment-emergent and non-treatment emergent deaths.

Table. Efficacy Endpoints at 3 Years (NRI)

Endpoints, % (95% CI)	UPA 15 mg QD N=651*	ADA 40 mg EOW N=327*
CDAI ≤10	39 (36, 43)	29 (24, 34)
CDAI ≤2.8	24 (21, 28)	17 (12, 21)
DAS28(CRP) ≤3.2	37 (33, 41)	26 (21, 31)
DAS28(CRP) <2.6	32 (29, 36)	22 (17, 26)

ADA, adalimumab; CI, confidence interval; DAS28(CRP), Disease Activity Score for 28-joints C-Reactive Protein; CDAI, clinical disease activity index; EOW, every other week; NRI, non-responder imputation; QD, once daily; UPA, upadacitinib.
*Patients who were rescued prior to/at Week 26 were considered non-responders. 252/651 and 159/327 patients were rescued of those randomized to UPA and ADA, respectively.

Conclusion: The safety profile of UPA was consistent with the results reported previously and with the integrated Phase 3 safety analysis.[1,2] Higher levels of clinical response continued to be observed with UPA vs ADA through 3 years of treatment.

Session Title: RA – Treatments Poster I: Comparative Effectiveness, Biosimilars, Withdrawal, & the Real World (0813–0845)

Session Type: Poster Session B

Session Time: 8:30AM–10:30AM

Background/Purpose: Tapering and withdrawal of biological or targeted synthetic disease-modifying antirheumatic drugs (bDMARDs or tsDMARDs) in patients with inflammatory arthritis (IA) in remission or low disease activity (LDA) are a topic of great interest. This systematic review aimed to assess the risk of flare after tapering or withdrawing b- or tsDMARDs compared to continuation of standard dosage.

Methods: The protocol was registered at PROSPERO (CRD42019136905). Predefined search terms identified relevant articles in Cochrane Library, EMBASE, PubMed, and Web of Science (search date: 13-14/06/2019, rerun

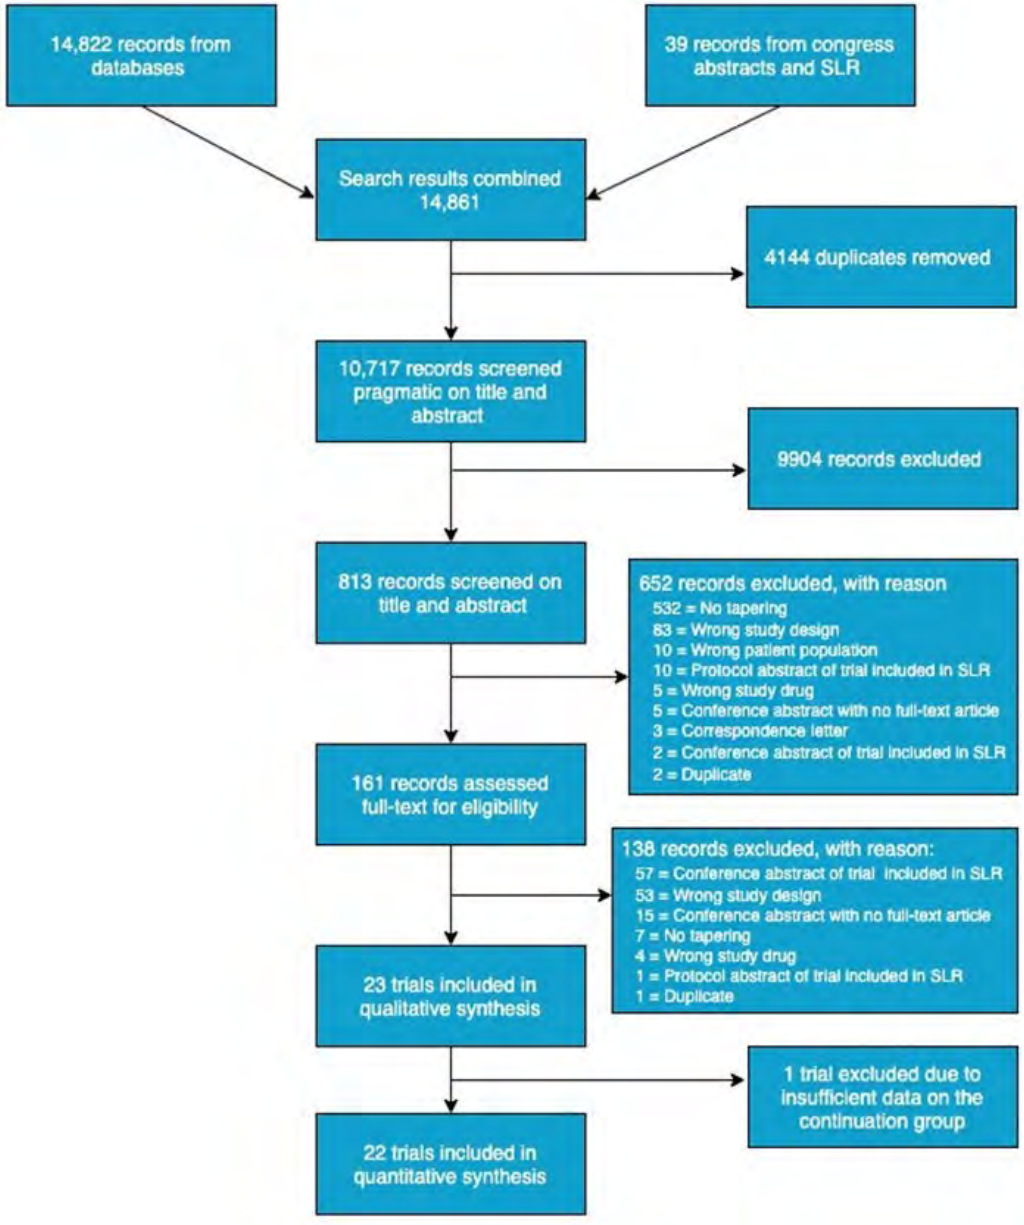

Figure 1. Flow diagram of study selection.

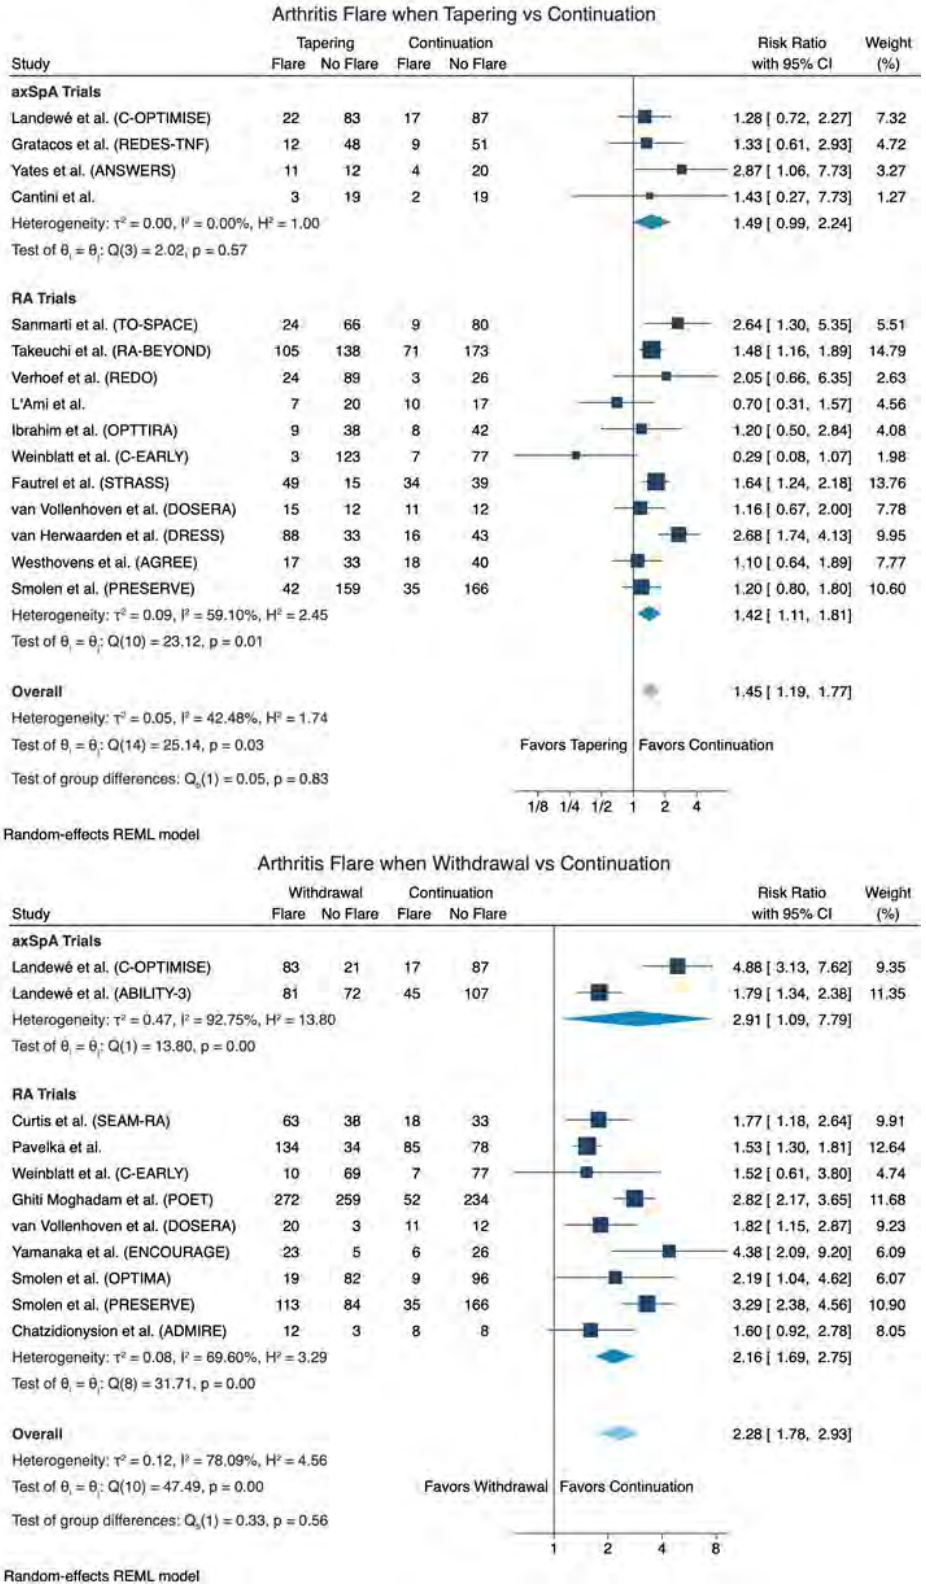

Figure 2. Meta-analysis of risk ratio with 95% confidence interval (95%CI) for flare by diagnosis (i.e. RA or axSpA) who A) Taper or B) Withdraw b- or tsDMARDs compared to continuation of standard dosage.

11/01/2021). Congress abstracts from ACR and EULAR after 01/01/2017 was evaluated for eligibility. Randomized trials comparing tapering or withdrawal of b- or tsDMARDs in patients with IA with continuation of standard dosage were included. Random-effects meta-analyses were performed to combine the risk ratio (RR) with 95% confidence interval (95%CI) for data on flare after either A) Tapering or B) Withdrawal of b- or tsDMARDs compared to continuation of standard dosage stratified by diagnosis. In trials with >1 tapering strategy, data for the different tapering strategies were combined initially before meta-analysis.

Results: 14,861 references were screened, and 22 trials were included in the meta-analyses of flare risk with data on 3,942 patients with RA and 828 patients with axSpA (*Figure 1*). An increased risk for developing flare(s) was demonstrated in the meta-analysis on 15 trials tapering of b- or tsDMARDs, RR = 1.45 (95%CI: 1.19 to 1.77; *Figure 2*). This corresponds to an absolute effect of number needed to treat (NNT [harm]) of 10 patients. Moreover, in 11 trials testing the effect of (abrupt) withdrawal of tumour necrosis factor inhibitors (TNFis), a highly evident increased risk was demonstrated, RR = 2.28 (95%CI: 1.78 to 2.93; *Figure 2*) with an absolute effect of NNT (harm) of 3 patients. As presented in *Figure 2*, no significant difference in the risk for flare was observed in subgroup meta-analyses when stratifying by diagnosis (i.e. axSpA or RA).

In summary, 431 patients (32.7%) in the tapering group had a flare and 888 patients (67.3%) did not whereas 830 patients (55.3%) in the withdrawal group experienced a flare and 670 patients (44.7%) did not. Thus, even though an increased risk for flare was demonstrated in the meta-analyses it is noteworthy that the proportion of patients with no flare was larger in the tapering group (67.3%) compared to the withdrawal group (44.7%).

Conclusion: Patients with IA who taper or withdraw their b- or tsDMARDs compared to continuation of standard dosage have an increased risk of flare with no significant risk difference between patients with axSpA or RA. However, a complete withdrawal was associated with a substantially increased flare risk; thus, the most favorable approach to reduce b- or tsDMARDs dose seems to be tapering.

Smartphone Assisted Patient Initiated Care Safely Reduces Outpatient Clinic Visits in Patients with Rheumatoid Arthritis: Results from a Randomized Controlled Trial

Bart Seppen[1], Jimmy Wiegel[1], Marieke ter wee[2], DirkJan van Schaardenburg[1], Leo Roorda[1], Michael Nurmohamed[3] and wouter Bos[4], [1]Reade, Amsterdam, Netherlands, [2]Amsterdam UMC, location VUmc, Amsterdam, Netherlands, [3]Reade and Amsterdam University Medical Center, location VUmc, Amsterdam, Netherlands, [4]Reade Amsterdam, Amsterdam, Netherlands

SESSION INFORMATION

Session Date: Sunday, November 7, 2021

Session Title: RA – Treatments Poster I: Comparative Effectiveness, Biosimilars, Withdrawal, & the Real World (0813–0845)

Session Type: Poster Session B

Session Time: 8:30AM–10:30AM

Background/Purpose: The demand on outpatient rheumatology clinics is high due to protocolised visits of rheumatoid arthritis (RA) patients, including those in low disease activity or remission. We developed a mobile phone app for patients with RA, which allows them to self-monitor their disease activity in between clinic visits by answering a weekly routine assessment of patient index data (RAPID-3). The objective of this study is to assess efficacy and safety of self-initiated care assisted by a smartphone app in patients with RA.

Methods: A randomised controlled trial was performed with a study duration of one year. Inclusion criteria were: 1) diagnosed with RA by a rheumatologist, 2) disease duration of at least two years and 3) a Disease Activity Score 28 (DAS28) below 3.2 at the start of the study. Patients were excluded if they had initiated or discontinued conventional DMARDs or a biological in the previous 6 months. Patients were randomised to either app supported self-initiated care with only one scheduled follow-up consultation after a year (app-group) or to usual care. The app warned patients that they could be flaring when RAPID-3 scores increased more than 2 points and the overall score was over 4. The co-primary outcome was mean number of consultations with a rheumatologist and non-inferiority in terms of difference in DAS28 at 12 months. The non-inferiority limit was set at 0.5 difference in DAS28 between the groups. Secondary outcomes included consultations with nurses, satisfaction with healthcare and app usage.

Results: In total, 103 patients were randomised to usual care (n=53) or to the app group (n=50). Baseline characteristics were similar in both groups (table 1). At 12 months, the mean number (±SD) of outpatient or telephone consultations with the rheumatologist was significantly lower in the app group compared with usual care (1.7±1.8 vs 3.0±1.4, p< 0.001). The same applied to the nurse outpatient or telephone consultations (0.4±1.0 vs 0.9±1.1, p=0.03; table 2). Non-inferiority was established as the 95% confidence interval of the mean difference in DAS28 between the groups was within the non-inferiority limit: -0.04 in favour of the intervention group ([95% CI], -0,39, 0.30). Satisfaction with healthcare received was high (8.6 out of 10 ±1.3) in both groups and not statistically different. On average patients completed 56% (29/52, SD13.3) of the weekly questionnaires.

Table 1. Baseline characteristics. Data are mean (SD) or percentage.

	Telemonitoring (n=50)	Usual Care (n=53)
Age, years	58.4 ±12.6	57 ±10.8
Gender, % male	44	40
BMI	25.5 ±4.4	26.1 ±4.5
Disease duration, years	12.4 ±9.4	10.8 ±8.5
DAS28	1.7 ±0.7	1.5 ±0.7
RAPID 3	2.3 ±1.5	1.9 ±1.4
ACPA, % positive	66	75
RF, % positive	58	62

Table 2. Number of consultations per group. Means and standard deviation (SD) are presented. CI: 95% Confidence Interval.

	Telemonitoring (N=49)	Usual Care (N=53)	Mean Difference (CI)	P-value
Rheumatologist				
Telephone	1.4 ±1.6	2.0 ±1.3	0.6 (0.0-1.2)	0.04
Outpatient visits	0.3 ±0.6	1.1 ±0.8	0.8 (0.5-1.0)	<0.001
Total	1.7 ±1.8	3.0 ±1.4	1.2 (0.6-1.9)	<0.001
Nurse				
Telephone	0.3 ±0.8	0.5 ±0.9	0.2 (-0.2-0.5)	0.31
Outpatient visits	0.1 ±0.3	0.3 ±0.6	0.2 (0.0-0.4)	0.02
Total	0.4 ±1.0	0.9 ±1.1	0.5 (0.0-0.9)	0.03

Conclusion: The results of this study show that self-initiated care supported with weekly RAPID3 self-monitoring via a smartphone app reduces the number of outpatient visits and telephone consultations and is non-inferior to usual care in terms of the DAS28. We propose the implementation of this approach to optimise rheumatologic care for RA patients in low disease activity.

SESSION INFORMATION

Session Date: Sunday, November 7, 2021

Session Title: RA – Treatments Poster I: Comparative Effectiveness, Biosimilars, Withdrawal, & the Real World (0813–0845)

Session Type: Poster Session B

Session Time: 8:30AM–10:30AM

Background/Purpose: ORAL Surveillance (NCT02092467) was mandated by the US Food and Drug Administration to assess the relative risk of tofacitinib vs TNF inhibitors (TNFi), based on observed increases in lipids and malignancies in patients (pts) with RA following tofacitinib treatment. This analysis compared the risks of major adverse cardiovascular (CV) events (MACE) and malignancies (excluding non-melanoma skin cancer) in pts with moderate to severe RA aged ≥ 50 yrs with ≥ 1 additional CV risk factor receiving tofacitinib or a TNFi.

Methods: This Phase 3b/4 prospective, randomized, open-label, non-inferiority study (co-primary endpoints: adjudicated MACE and malignancies) was in high-risk pts with RA (aged ≥ 50 yrs, ≥ 1 additional CV risk factor), receiving MTX. Pts were randomized 1:1:1 to receive tofacitinib 5 or 10 mg twice daily (BID) or a TNFi (adalimumab 40 mg every other week or etanercept 50 mg every week). Adjudicators were blinded to treatment. Outcome differences were analyzed using univariate Cox proportional hazard models. The primary comparison was whether the upper limit of the 2-sided 95% confidence interval (CI) for the hazard ratio (HR) for tofacitinib doses combined vs TNFi was < 1.8; the secondary comparison was whether the upper limit for tofacitinib 10 vs 5 mg BID was < 2.0. Incidence rates (IRs; unique pts with events/100 pt-yrs) were calculated for co-primary endpoints and adverse events (AEs) of special interest. Efficacy outcomes for clinical disease activity and pt-reported outcomes were captured.

Results: Between Mar 2014–Jul 2020, 1,455, 1,456, and 1,451 pts received tofacitinib 5 mg BID, tofacitinib 10 mg BID, and TNFi, respectively. Median age was 60.0 yrs. For MACE and malignancies, primary assessments were not met for tofacitinib doses combined vs TNFi (HR [95% CI] 1.33 [0.91, 1.94] and 1.48 [1.04, 2.09], respectively; upper

Figure. HRs (95% CIs)[a,b] and IRs (95% CIs) for adjudicated MACE and adjudicated malignancies (excluding NMSC)

NNH[d] vs TNFi	567	319	412	--	276	275	275	--

The definition of MACE in this study was non-fatal myocardial infarction, non-fatal stroke, and all cardiovascular deaths, excluding death due to pulmonary embolism. For adjudicated MACE, the primary censoring time was the 60-Day On-Treatment period (defined as the time from the first until last study dose + 60 days or last contact date, whichever is earlier); for adjudicated malignancies (excluding NMSC), the primary censoring time was total time (defined as last contact date)

[a]The primary comparison (all tofacitinib doses combined vs TNFi) was whether the upper limit of the two-sided 95% CI for the HR was < 1.8

[b]The secondary comparison (tofacitinib 10 vs 5 mg BID) was whether the upper limit of the two-sided 95% CI for the HR was < 2.0

[c]The tofacitinib 10 mg BID treatment group included pts that were switched from 10 to 5 mg BID as a result of a study modification in 2019

[d]NNH was the number of PY of exposure needed for a treatment to have one more event relative to the reference; calculations were performed post hoc

BID, twice daily; CI, confidence interval; HR, hazard ratio; IR, incidence rate (pts with events per 100 PY); MACE, major adverse cardiovascular events; NNH, Number Needed to Harm; NMSC, non-melanoma skin cancer; pt, patient; PY, pt-yrs; TNFi, TNF inhibitor

Table. AEs of special interest

AE, n (%), IR [95% CI]	Tofacitinib 5 mg BID (N=1455)	Tofacitinib 10 mg BID (N=1456)	TNFi (N=1451)
Serious infection	141 (9.7)	169 (11.6)	119 (8.2)
	2.86 [2.41, 3.37]	3.64 [3.11, 4.23]	2.44 [2.02, 2.92]
All herpes zoster	180 (12.4)	178 (12.2)	58 (4.0)
(non-serious/serious)	3.75 [3.22, 4.34]	3.94 [3.38, 4.57]	1.18 [0.90, 1.52]

	0.17 [0.08, 0.33]	0.50 [0.32, 0.74]	0.06 [0.01, 0.17]
Deep vein thrombosis[a]	11 (0.8)	15 (1.0)	7 (0.5)
	0.21 [0.11, 0.38]	0.31 [0.17, 0.51]	0.14 [0.06, 0.29]
Venous	17 (1.2)	34 (2.3)	10 (0.7)
thromboembolism[a]	0.33 [0.19, 0.53]	0.70 [0.49, 0.99]	0.20 [0.10, 0.37]
Arterial	47 (3.2)	45 (3.1)	41 (2.8)
thromboembolism	0.92 [0.68, 1.22]	0.94 [0.68, 1.25]	0.82 [0.59, 1.12]
All-cause mortality[a]	26 (1.8)	39 (2.7)	17 (1.2)
	0.50 [0.33, 0.74]	0.80 [0.57, 1.09]	0.34 [0.20, 0.54]

Censoring time was the 28-day on-treatment time (time from the first until last study dose + 28 days or last contact date, whichever was earlier)

[a]Adjudicated

AE, adverse event; BID, twice daily; CI, confidence interval; IR, incidence rate (pts with events per 100 PY); pt, patient; PY, pt-yrs; TNFi, TNF inhibitor

limits of CIs were > 1.8); for tofacitinib 10 vs 5 mg BID, the upper limits of 95% CIs were < 2.0 (Figure). IRs for MACE and malignancies were numerically higher for tofacitinib vs TNFi (Figure). In post hoc analyses, most MACE and malignancies occurred in pts who were aged ≥ 65 yrs or had ever smoked (MACE: 83/98 [84.7%] and 29/37 [78.4%];

malignancies: 102/122 [83.6%] and 33/42 [78.6%]; with tofacitinib and TNFi, respectively). IRs of AEs of special interest were numerically higher with tofacitinib (10 > 5 mg BID) vs TNFi (Table). Efficacy was similar across treatment arms.

Conclusion: For MACE and malignancies, the primary assessments were not met for tofacitinib doses combined vs TNFi in this high-risk population. Pts most at risk were aged ≥ 65 yrs or had ever smoked. IRs for MACE and malignancies were < 1.5 across all treatment groups, with overlapping 95% CIs. The Numbers Needed to Harm for tofacitinib 5 and 10 mg BID, respectively, vs TNFi were 567 and 319 for MACE and 276 and 275 for malignancies. Efficacy was similar across treatment arms.

SESSION INFORMATION

Session Date: Sunday, November 7, 2021

Session Title: RA – Treatments Poster I: Comparative Effectiveness, Biosimilars, Withdrawal, & the Real World (0813–0845)

Session Type: Poster Session B

Session Time: 8:30AM–10:30AM

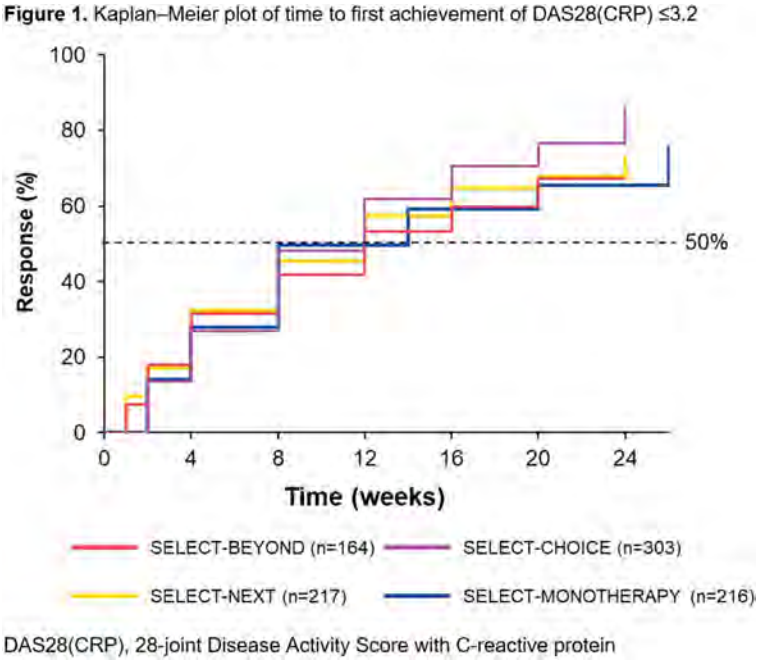

Figure 1. Kaplan–Meier plot of time to first achievement of DAS28(CRP) ≤3.2.

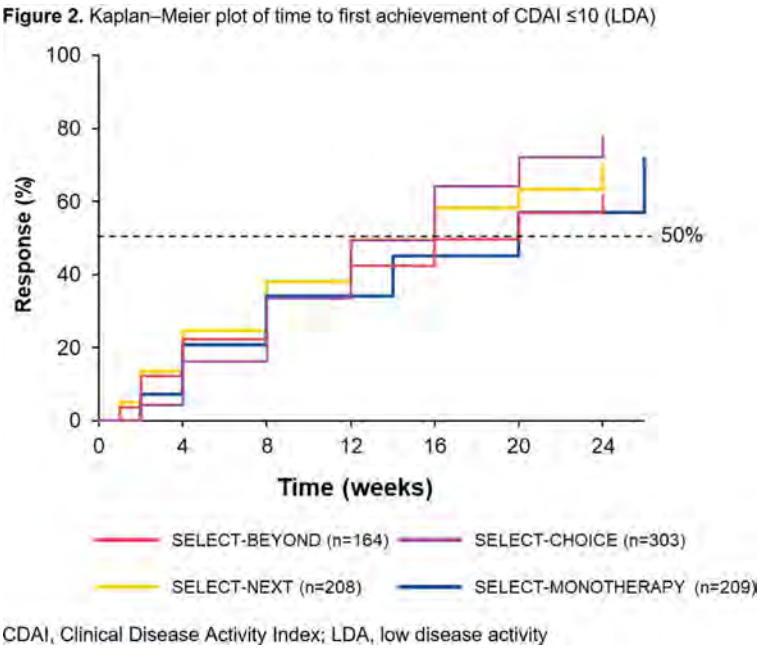

Figure 2. Kaplan–Meier plot of time to first achievement of CDAI ≤10 (LDA).

Background/Purpose: Upadacitinib (UPA) has demonstrated efficacy in patients with moderate-to-severe rheumatoid arthritis (RA) across various patient populations.[1–4] This post hoc analysis aimed to evaluate the consistency in time to achieving meaningful clinical response with UPA 15 mg + conventional synthetic (cs) DMARDs in biologic (b) DMARD-inadequate responder (IR) versus csDMARD-IR patients with RA as well as with UPA 15 mg monotherapy versus UPA 15 mg + csDMARDs in csDMARD-IR patients.

Methods: Patients originally randomized to UPA 15 mg once daily from four Phase 3 trials were included in this analysis: SELECT-BEYOND[1] and SELECT-CHOICE[2] (UPA 15 mg + csDMARDs in bDMARD-IR patients), SELECT-NEXT[3] (UPA 15 mg + csDMARDs in csDMARD-IR patients), and SELECT-MONOTHERAPY[4] (UPA 15 mg monotherapy in methotrexate-IR patients). Time to response was estimated using the Kaplan–Meier method for clinical outcomes over 24 weeks (26 weeks in SELECT-MONOTHERAPY). Clinical outcomes included achievement of 28-joint Disease Activity Score with C-reactive protein (DAS28[CRP]) ≤3.2; low disease activity (LDA) defined as Clinical Disease Activity Index (CDAI) ≤10 and Simple Disease Activity Index (SDAI) ≤11; and 50% improvement in American College of Rheumatology (ACR) core components and morning stiffness (MS) duration/severity. Data presented were as observed.

Results: Overall, 905 patients were included (SELECT-BEYOND: n=164; SELECT-CHOICE: n=303; SELECT-NEXT: n=221; SELECT-MONOTHERAPY: n=217). csDMARD-IR patients had a mean disease duration of 7.3 (SELECT-NEXT) or 7.5 years (SELECT-MONOTHERAPY); bDMARD-IR patients had a mean disease duration of 12.4 years, with a more refractory population (≥3 prior bDMARDs) in SELECT-BEYOND (23%) than SELECT-CHOICE (10%). In general, the median time to DAS28(CRP) ≤3.2, CDAI LDA, 50% improvement in ACR core components, and 50% improvement in MS duration/severity were consistent across the studies in bDMARD-IR and csDMARD-IR patients. For SELECT-BEYOND, SELECT-CHOICE, SELECT-NEXT, and SELECT-MONOTHERAPY, the median (95% CI) time to achieve DAS28(CRP) ≤3.2 was 12 (12, 16), 12 (8, 12), 12 (8, 12), and 14 (8, 14) weeks, respectively **(Figure 1)**, and the median time to achieve CDAI LDA was 20 (12, 24), 16 (12, 16), 16 (12, 16), and 20 (14, 20) weeks, respectively **(Figure 2)**. A longer median (95% CI) time to achieve SDAI LDA was observed with UPA monotherapy (20 [14, 20] weeks) versus UPA + csDMARDs (12 [12, 16] weeks) in csDMARD-IR patients. Among bDMARD-IR patients, the median (95% CI) time to 50% improvement in pain was longer in SELECT-BEYOND versus SELECT-CHOICE (16 [12, 20] versus 8 [8, 12] weeks).

Conclusion: In diverse patient populations with RA, patients treated with UPA 15 mg, as monotherapy or with csDMARDs, generally demonstrated consistent time to achieving DAS28(CRP) ≤3.2, CDAI LDA, and 50% improvement in clinical outcomes.

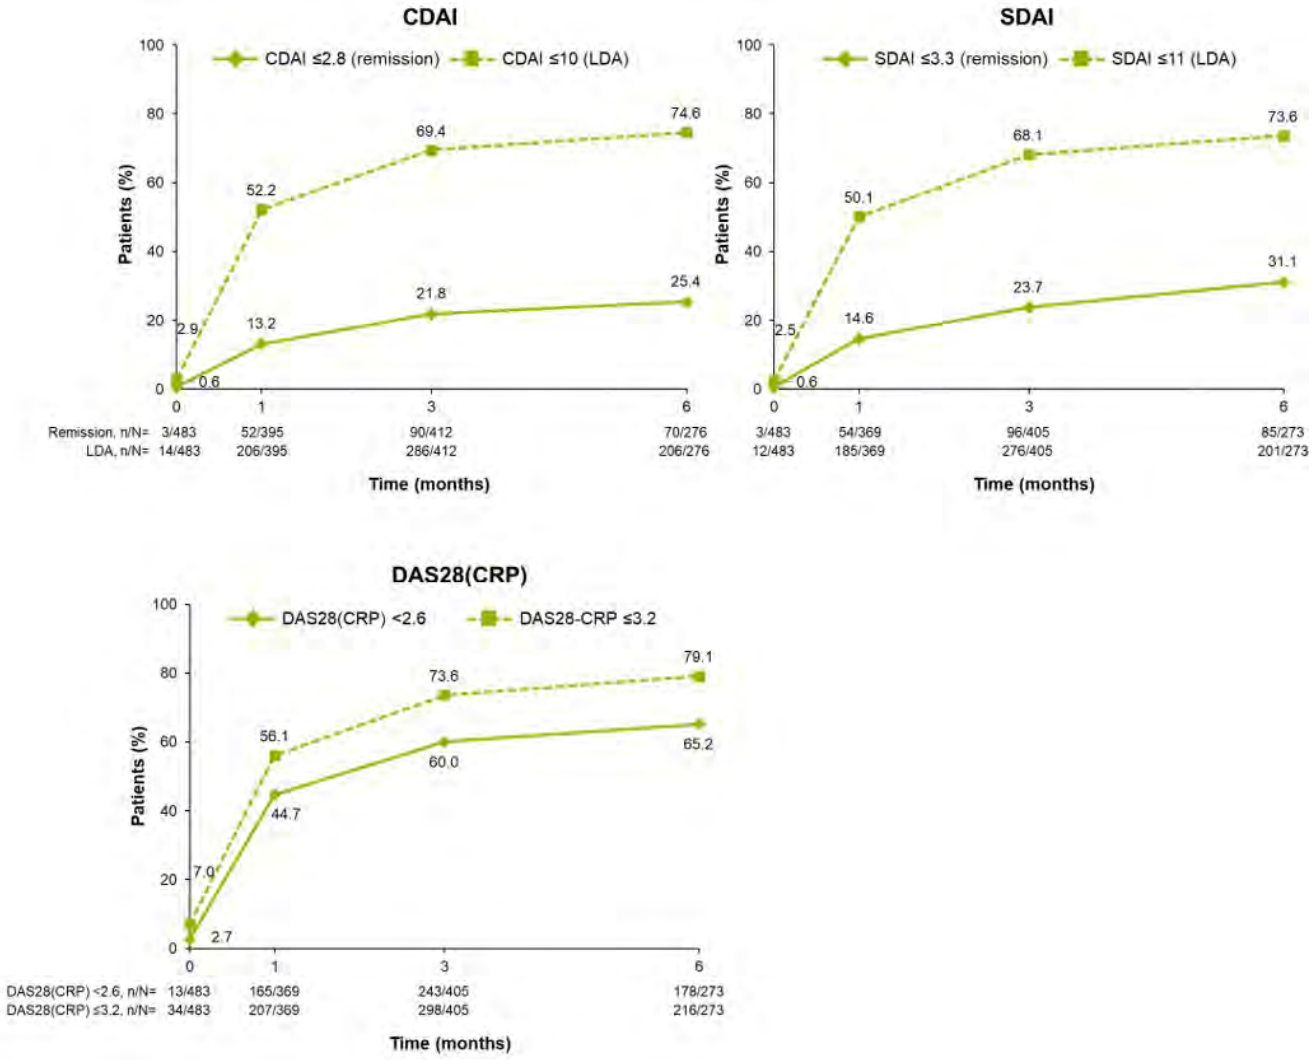
Mean GC dose, mg/day	175	5.7 (3.3)
Prior HZ vaccination, Shingrix/Zostavax, n (%)	483	37 (7.7)/3 (0.6)

[a]Mean (SD) unless otherwise stated. [b]The study enrolled around 50% of patients receiving UPA monotherapy and 50% of patients receiving UPA + MTX at baseline per protocol.
ACPA, anti-citrullinated protein antibody; bDMARD, biologic disease-modifying antirheumatic drug; CDAI, Clinical Disease Activity Index; CRP, C-reactive protein; DAS28(CRP), 28-joint Disease Activity Score using C-reactive protein; GC, glucocorticoid; HAQ-DI, Health Assessment Questionnaire-Disability Index; HZ, herpes zoster; MTX, methotrexate; QD, daily; RAID, Rheumatoid Arthritis Impact of Disease; RF, rheumatoid factor; SD, standard deviation; SDAI, Simple Disease Activity Index; SJC28/TJC28, swollen/tender joint count in 28 joints; tsDMARD, targeted synthetic disease-modifying antirheumatic drug; ULN, upper limit of normal; UPA, upadacitinib.

Background/Purpose: Upadacitinib (UPA) is a Janus kinase inhibitor that has been shown to be effective and well tolerated in patients with rheumatoid arthritis (RA) in the Phase 3 SELECT clinical trials.[1–6] However, data on the use of UPA in real-world clinical practice are limited. The UPwArds study aims to investigate the effectiveness and safety of UPA as monotherapy or in combination with methotrexate (MTX) in patients with RA in German clinical practice.



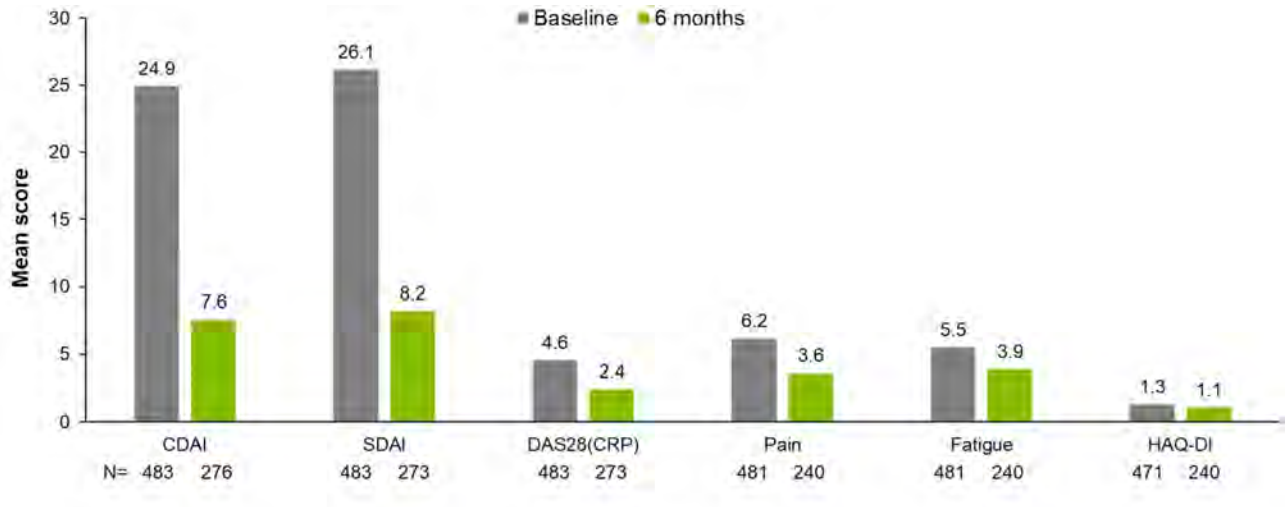
This descriptive interim analysis reports data based on observed case analyses for the patients who had completed Visit 3 (Month 6) by the cut-off date of March 22, 2021.

CDAI, Clinical Disease Activity Index; DAS28(CRP), 28-joint Disease Activity Score using C-reactive protein; LDA, low disease activity; SDAI, Simple Disease Activity Index.

Figure 1. Proportions of patients achieving CDAI remission/LDA, SDAI remission/LDA, and DAS28(CRP) <2.6/≤3.2 over 6 months of upadacitinib treatment.

Methods: UPwArds is an ongoing, prospective, multicenter, non-interventional, post-marketing study in adult patients with moderate-to-severe RA who are treated with UPA 15 mg once daily according to the product label, with the decision to initiate UPA made prior to study participation. Per protocol, the study enrolled around 50% of patients receiving UPA monotherapy and 50% of patients receiving UPA + MTX. The primary endpoint was the proportion of patients achieving remission defined as Clinical Disease Activity Index (CDAI) ≤2.8 at 6 months. Key secondary endpoints included the proportion of patients achieving CDAI ≤2.8 and ≤10, Simple Disease Activity Index (SDAI) ≤3.3 and ≤11, and 28-joint Disease Activity Score using CRP (DAS28[CRP]) < 2.6 and ≤3.2 at each visit. Changes from baseline in disease activity and patient-reported outcomes were also assessed. This descriptive interim analysis reports data for the patients who had completed Visit 3 (Month 6) by the cut-off date of March 22, 2021. Data are presented as observed and summarized descriptively, with no statistical analyses conducted.

Results: Of the 483 patients at baseline (76.4% female; mean disease duration: 9 years), 60.9% had previously been treated with biologic (b) or targeted synthetic (ts) DMARDs **(Table 1)**. Of the patients with 6-month data, 25.4% (70/276) and 74.6% (206/276) achieved CDAI remission (primary endpoint) and LDA, respectively, after 6 months of UPA 15 mg treatment **(Figure 1)**. DAS28(CRP) < 2.6 and ≤3.2 at Month 6 were achieved by 65.2% (178/273) and 79.1% (216/273) of patients, respectively. The percentage of patients achieving any definition of LDA (DAS28[CRP] ≤3.2, CDAI ≤10, or SDAI ≤11) or remission (DAS28[CRP] < 2.6, CDAI ≤2.8, or Boolean remission) at 6 months was similar among those treated with UPA monotherapy (72.9%) or UPA + MTX (74.1%). Disease activity and patient-reported outcomes (including pain, fatigue, and physical function) improved within the first 6 months following initiation of UPA 15 mg **(Figure 2)**. The safety profile of UPA 15 mg was consistent with that seen in the Phase 3 trials with no new safety signals.[1–6]



This descriptive interim analysis reports data based on observed case analyses for the patients who had completed Visit 3 (Month 6) by the cut-off date of March 22, 2021.
CDAI, Clinical Disease Activity Index; DAS28(CRP), 28-joint Disease Activity Score using C-reactive protein; HAQ-DI, Health Assessment Questionnaire-Disability Index; SDAI, Simple Disease Activity Index.

Figure 2. Disease activity and patient-reported outcomes after 6 months of upadacitinib treatment.

Conclusion: Consistent with previous clinical data, the 6-month interim results from this study suggest that UPA as monotherapy or in combination with MTX is associated with a favorable benefit–risk profile in real-world patients with RA.

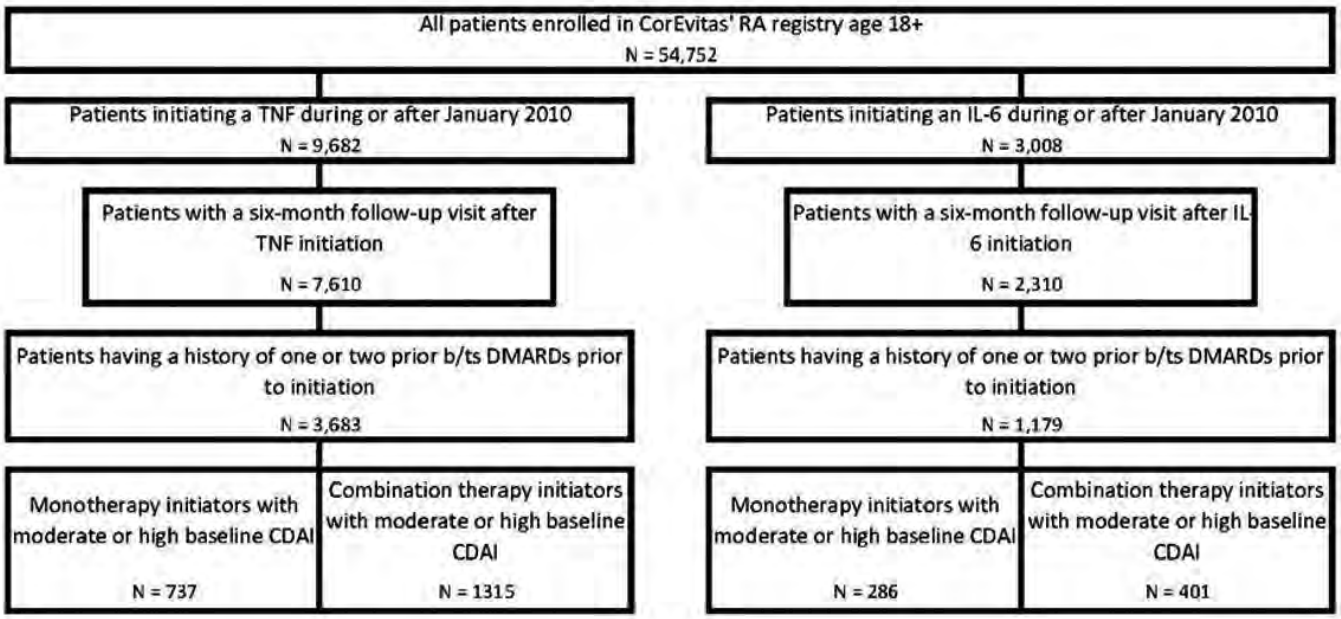
SESSION INFORMATION
Session Date: Sunday, November 7, 2021
Session Title: RA – Treatments Poster I: Comparative Effectiveness, Biosimilars, Withdrawal, & the Real World (0813–0845)
Session Type: Poster Session B
Session Time: 8:30AM–10:30AM

Background/Purpose: RA patients who fail to achieve treatment targets with conventional synthetic DMARDs (csDMARDs) can be treated with biologics. Randomized controlled trials (RCTs) have shown IL-6 receptor inhibitors (IL-6i) to be superior to TNF-α inhibitors (TNFi; adalimumab) as monotherapy in biologic-naïve patients with high disease activity. There is limited research comparing the effectiveness of TNFi vs IL-6i as monotherapy or in combination with csDMARDs in biologic-experienced RA patients with moderate/high disease activity. This real-world retrospective study based on CorEvitas' RA registry aimed to address the gap.

Methods: Adult RA patients who initiated a TNFi or IL-6i during or after January 2010 were included if they had: a history of 1 or 2 biologic/targeted synthetic DMARDs (b/tsDMARDs) prior to initiation, moderate/high disease activity at initiation, and a follow-up visit at 6 (± 3) months after initiation. Cohorts included TNFi and IL-6i initiators, both with subgroups initiating as mono- or combination (with MTX) therapy. Mixed effects regression models with random intercept for patients were used to evaluate the impact of therapy class on the following outcomes: disease burden (HAQ-DI, pain visual analog scale [VAS, 0-100], patient global assessment, and fatigue [1-item VAS, 0-100]), non-inflammatory pain (NIP; NIP1: tender joint count [TJC, 28] – swollen joint count [SJC, 28] ≥7; NIP2: SJC [28]/TJC [28] < 0.5), and clinical disease activity index (CDAI). Unadjusted and covariate-adjusted effects (β, 95% confidence interval [CI] for linear regressions and odds ratio [OR, 95% CI] for logistic regressions) were reported.

Results: Patients initiating IL-6i (n=286) vs TNFi monotherapy (n=737; **Figure 1**) were older (60.0 vs 55.4 years; *P*< 0.001), had longer history of RA (12.2 vs 10.0 years; *P*=0.001), higher CDAI at baseline (26.9 vs 24.9; *P*=0.02), and were more likely to initiate as 3rd line therapy (57.0% vs 30.9%; *P*< 0.001). IL-6i (n=401) vs TNFi (n=1315) combination therapy initiators had higher CDAI at baseline (26.7 vs 24.8; *P*=0.007) and were more likely to initiate as 3rd line therapy (56.4% vs 28.7%; *P*< 0.001; **Table 1**). There were no statistically significant differences in outcomes between IL-6i and TNFi initiators (as mono- or combination therapy). One-third of IL-6i and TNFi mono- (adjusted OR [aOR]: 0.99 [0.59, 1.67]) and combination therapy initiators (aOR: 0.96 [0.66, 1.38]) achieved low disease activity (**Table 2**).

Conclusion: In this real-world analysis, no significant differences were noted in the outcomes for IL-6i vs TNFi initiators (as mono- or combination therapy). Compared with prior RCTs, patients in this study were biologic-experienced, had lower disease activity, and were unblinded to treatment, which could have contributed to a reduced difference in effectiveness between these treatments. In addition, selection of therapy in this real-world study may be influenced by factors that cannot be measured or controlled.



b/ts DMARDs, biologic/targeted synthetic disease modifying anti-rheumatic drugs; CDAI, clinical disease activity index; IL-6, interleukin-6; N, number of patients; RA, rheumatoid arthritis; TNF, tumor necrosis factor.

Figure 1. Patient Disposition.

Table 1. Baseline demographic and clinical characteristics in monotherapy and combination therapy initiators by therapy class

Characteristic[a]	Monotherapy Initiators			Combination Therapy Initiators

SESSION INFORMATION
Session Date: Sunday, November 7, 2021
Session Title: RA – Treatments Poster I: Comparative Effectiveness, Biosimilars, Withdrawal, & the Real World (0813–0845)
Session Type: Poster Session B
Session Time: 8:30AM–10:30AM

Background/Purpose: To study in daily practice the risk of immunogenicity of patients treated with rituximab (RTX) biosimilar GP2013 for their chronic inflammatory rheumatic disorder.

Methods: A prospective routine care study was carried out between September 2018 and May 2021 in the Rheumatology department of Cochin Hospital. We consecutively included patients treated with the biosimilar RTX GP2013, systematically used in the department since March 2018. Samples were taken before each infusion to quantify anti-RTX antibodies (ADAbs) and serum RTX trough levels by ELISA (Lisa Tracker Duo Rituximab, LTR005, Theradiag).

Results: We included 170 consecutive patients treated with GP2013 (134 women, 79%) with a mean age of 59±12 years and a mean disease duration of 18±11 years. Among these 170 patients, 114 (67%) had RA and 56 had another disease (17 systemic sclerosis (SSc), 13 mixed connective tissue disease (MCTD), 7 undifferentiated polyarthritis, 5 systemic lupus (SLE), 5 inflammatory myopathies (MI), 5 overlap syndrome, and 4 primary Sjögren syndrome). 146 patients (86%) were receiving associated disease-modifying therapy (DMARD), mainly methotrexate (MTX, 109/146 patients, 75%). 129 patients (76%) were in maintenance therapy with originator RTX (RTX exposure: 77±47 months and cumulative dose of RTX: 8±6g) before the switch to GP2013 in March 2018. Originator RTX was not re-established during the entire treatment period. The other 41 patients (24%) treated with GP2013 were naïve of originator RTX. During a mean follow-up of 25±10 months, 15 patients (8%), developed ADAbs, corresponding to a rate of 4 for 100 patient years (**Figure 1A**). Among the 15 patients with ADAbs, 9 had RA, 3 MCTD, 2 SSc and 1 SLE. The mean time to ADAbs detection was 11±6 months (range: 6-27 months). ADAb concentrations ranged from 6 to >100 ng/mL, with 3 patients with high ADAb concentrations >100 ng/mL. Patients with ADAbs had undetectable serum RTX trough levels. The frequency of immunization was higher among RTX-naïve patients (8/41, 19.5%) than in patients switching from originator RTX (7/129, 5%, p=0.004). Age, gender, disease duration, concomitant treatment with MTX, a body mass index >30 and the underlying disease were not predictive of immunization. Conversely, complete B cell depletion (CD19 < 18) was identified as protective of immunization (hazard ratio 0.04, 95% confidence interval, CI, 0.09-0.33, p=0.003) (**Figure 1B**). Moreover, ADAb concentrations correlated with CD19 counts (r=0.20, p=0.021). The presence of anti-RTX antibodies was not associated with increased disease flares or RTX discontinuation (**Figure 1C**). Regarding the 3 patients with ADAb concentrations >100 ng/mL, 1 patient experienced a severe allergic reaction leading to treatment discontinuation and the two others required RTX dose escalation from 500 mg to 1 g to maintain treatment efficacy.

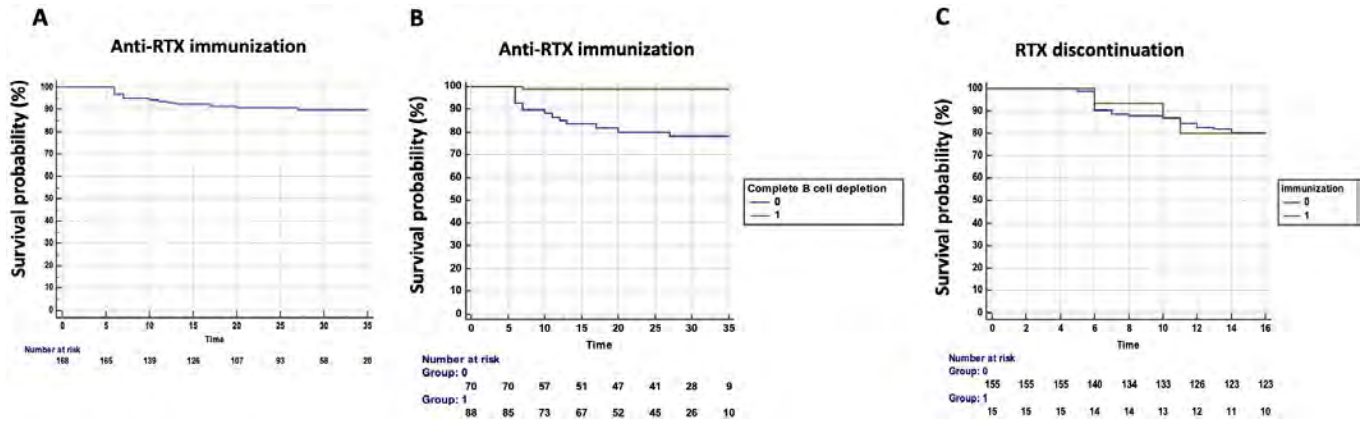

Figure 1. Kaplan Meyer Survival Analyses. A, risk of immunogenicity in patients treated with RTX biosimilar GP2013 during the follow-up period; B, risk of immunogenicity according to complete or incomplete B cell depletion and C, RTX discontinuation according to the presence of anti-RTX antibodies.

Conclusion: The immunogenicity of the biosimilar RTX GP2013 is a rare event associated with incomplete B cell depletion. Although development of anti-RTX antibodies had no impact on disease flares and treatment discontinuation, possible meaningful consequences may be observed in patients with high antibody levels.

Flare After Switching from Intravenous Tocilizumab to Subcutaneous Formulation in Patients with Rheumatoid Arthritis

Soo Min Ahn[1], Ji Seon Oh[2], Hyun Mi Heo[3], Seokchan Hong[3], Chang-Keun Lee[3], Bin Yoo[1] and Yong-Gil Kim[3], [1]ASAN MEDICAL CENTER, Seoul, South Korea, [2]Asan Medical Center, Ulsan, Republic of Korea, [3]Asan Medical Center, Seoul, Republic of Korea

SESSION INFORMATION
Session Date: Sunday, November 7, 2021
Session Title: RA – Treatments Poster I: Comparative Effectiveness, Biosimilars, Withdrawal, & the Real World (0813–0845)
Session Type: Poster Session B
Session Time: 8:30AM–10:30AM

Background/Purpose: Interleukin-6 (IL-6) plays a key role in inflammatory and immune responses. Tocilizumab (TCZ) is a recombinant humanized monoclonal antibody of the IL-6 receptor which inhibits IL-6-mediated signaling. TCZ is available as an intravenous (IV) formulation (TCZ-IV) and a subcutaneous (SC) formulation (TCZ-SC). The present study aimed to evaluate the incidence and risk factors for RA flares after switching to TCZ-SC in stable RA patients as TCZ-IV.

Methods: We retrospectively evaluated the incidence of RA flares in patients who switched from TCZ-IV to TCZ-SC in single tertiary hospital between January 2013 and April 2020. Patients were divided into two groups based on RA disease activity as assessed by Disease Activity Score in 28 joints (DAS28) after switching from TCZ-IV to TCZ-SC ("SC inefficacy group" versus "SC efficacy group"). Factors associated with RA flares were evaluated by multivariate analysis.

Table 1. Clinical characteristics of the study patients at the time of switching from intravenous to subcutaneous tocilizumab

	SC inefficacy (n=11)	SC efficacy (n=26)	Total (n=37)	p-value
Age, years, mean (SD)	57.3 (11.4)	59.3 (13.3)	58.7 (12.6)	0.660
Female, n (%)	11 (100)	21 (80.8)	32 (86.5)	0.295
Disease duration, median (IQR)	138 (36-160)	92 (51-181)	104 (50-174)	0.868
IV TCZ duration, months, median (IQR)	9.0 (6.0-23.0)	13.5 (9.5-19.5)	13.0 (7.5-21.0)	0.433
TCZ dose, mg/kg, mean (SD)	8.2 (0.3)	7.7 (0.5)	7.9 (0.5)	0.002*
TCZ > 8 mg/kg, n (%)	7 (63.6)	5 (19.2)	12 (32.4)	0.018*
Concomitant medication				
MTX use, n (%)	5 (45.5)	21 (80.8)	26 (70.3)	0.0508
Dose of MTX, mg/week, median (IQR)	0 (0-10)	8.8 (7.5-15)	7.5 (0-10)	0.033*

h/o Abatacept	6.389	1.179-34.624	0.031*	29.817	1.069-831.44	0.046**
eGFR at switching	1.038	1.003-1.073	0.032*	1.039	0.990-1.091	0.119
DAS28-ESR at switching	2.511	0.680-9.275	0.167			
Age at switching	0.987	0.931-1.045	0.651			

Results: Among 147 patients who were treated initially with TCZ-IV, 37 patients were switched to TCZ-SC after the acquisition of remission or low disease activity. The SC inefficacy and SC efficacy groups included 11 (29.7%) and 26 (70.3%) patients, respectively. At the time of switching, mean DAS28 was not different between the two groups. However, doses of TCZ-IV per weight and methotrexate were higher in the SC inefficacy group. In the multivariate analysis, the use of a high dose (more than 8 mg/kg) TCZ (odds ratio [OR] 33.441, 95% confidence interval [CI], 1.573–710.833, p=0.024), methotrexate non-user(OR 41.416, 95% CI, 1.529–1121.731, p=0.027), and history of prior abatacept use (OR 29.817, 95% CI, 1.069–831.442, p=0.046) were associated with the risk of RA flares after switching to TCZ-SC.

Conclusion: Methotrexate non-use and TCZ-IV overdose per weight were associated with a higher risk of RA flare after switching to TCZ-SC. Thus, we recommend checking these factors before switching from TCZ-IV to TCZ-SC to prevent RA flares.

Sustainability of Response Between Upadacitinib and Adalimumab in Patients with Rheumatoid Arthritis: Results Through 3 Years from the SELECT-COMPARE Trial

Peter Nash[1], Arthur Kavanaugh[2], Maya Buch[3], Bernard Combe[4], Louis Bessette[5], In-Ho Song[6], Tim Shaw[7], Yanna Song[6], Jessica Subotickí[6] and Roy Fleischmann[8], [1]Griffith University, Brisbane, Australia, [2]University of California San Diego, La Jolla, CA, [3]University of Leeds, Leeds, United Kingdom, [4]CHU Montpellier Montpellier University, Montpellier, France, [5]Laval University, Québec City, QC, Canada, [6]AbbVie Inc., North Chicago, IL, [7]AbbVie Inc., North Chicago, [8]Metroplex Clinical Research Center and University of Texas Southwestern Medical Center, Dallas, TX

SESSION INFORMATION
Session Date: Sunday, November 7, 2021
Session Title: RA – Treatments Poster I: Comparative Effectiveness, Biosimilars, Withdrawal, & the Real World (0813–0845)
Session Type: Poster Session B
Session Time: 8:30AM–10:30AM

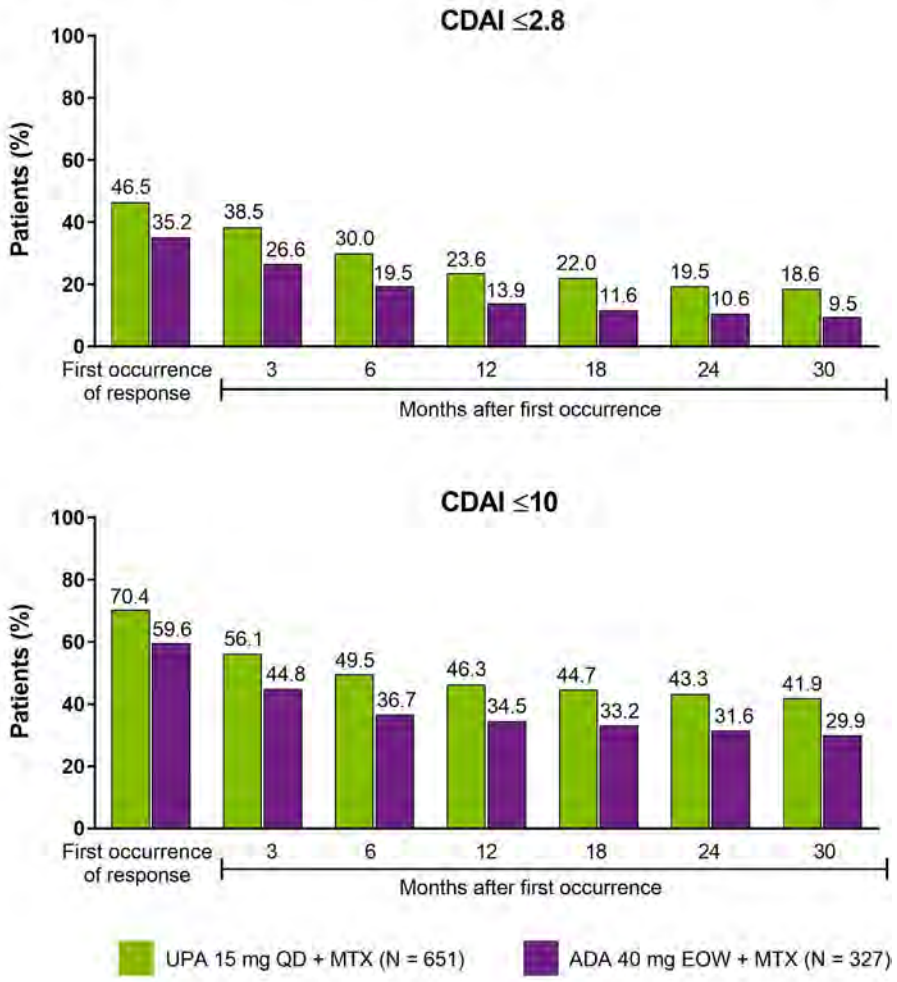
Background/Purpose: The primary treatment target for patients with active rheumatoid arthritis (RA) is sustained clinical remission (REM) or low disease activity (LDA).[1,2] A greater proportion of patients with RA and inadequate response to methotrexate (MTX) receiving the JAK inhibitor, upadacitinib (UPA), achieved REM/LDA compared with adalimumab (ADA), both with background MTX, through 26 weeks in the phase 3, SELECT-COMPARE trial.[3] Here we assessed sustainability of response over 3 years.

Methods: SELECT-COMPARE included a 26-week, double-blind, placebo (PBO)-controlled period, a 48-week, double-blind active comparator-controlled period, and an ongoing long-term extension for up to 10 years. Patients on background MTX received UPA 15 mg once daily, PBO, or ADA 40 mg every other week. Patients who did not achieve at least 20% improvements in tender and swollen joint counts (Weeks 14-22) or LDA (CDAI ≤10 at Week 26) were rescued from UPA to ADA or PBO/ADA to UPA. This post hoc analysis evaluated clinical REM (CDAI ≤2.8; SDAI ≤3.3), LDA (CDAI ≤10; SDAI ≤11), and DAS28(CRP) < 2.6/≤3.2 at first occurrence (prior to treatment switch [rescue]), as well as over 3 years following initial response in patients randomized to UPA or ADA. For those patients who achieved REM/LDA, Kaplan-Meier was used to define the time from when the response was first achieved to the earliest date at which the response was lost at two consecutive visits, discontinuation of study drug, or losing

response at the time of rescue. The predictive ability of time to CDAI REM/LDA was assessed using Harrell's concordance (c)-index (range: 0 [all predictions wrong] to 1.0 [perfect predictive ability]. Non-responder imputation was used for missing data.

Results: Through 3 years, a significantly higher proportion of patients receiving UPA + MTX vs ADA + MTX achieved CDAI REM (47% vs 35%, *P* = 0.001) as well as CDAI LDA (70% vs 60%, *P* = 0.001). At 30 months after first occurrence of response, CDAI REM/LDA was sustained in 19%/42% of patients randomized to UPA and 10%/30% of patients randomized to ADA (**Figure 1)**. Time to initial clinical response did not appear to be predictive of sustained disease control. The c-index for CDAI REM/LDA was 0.50/0.60 on UPA vs 0.49/0.56 on ADA. Through the last

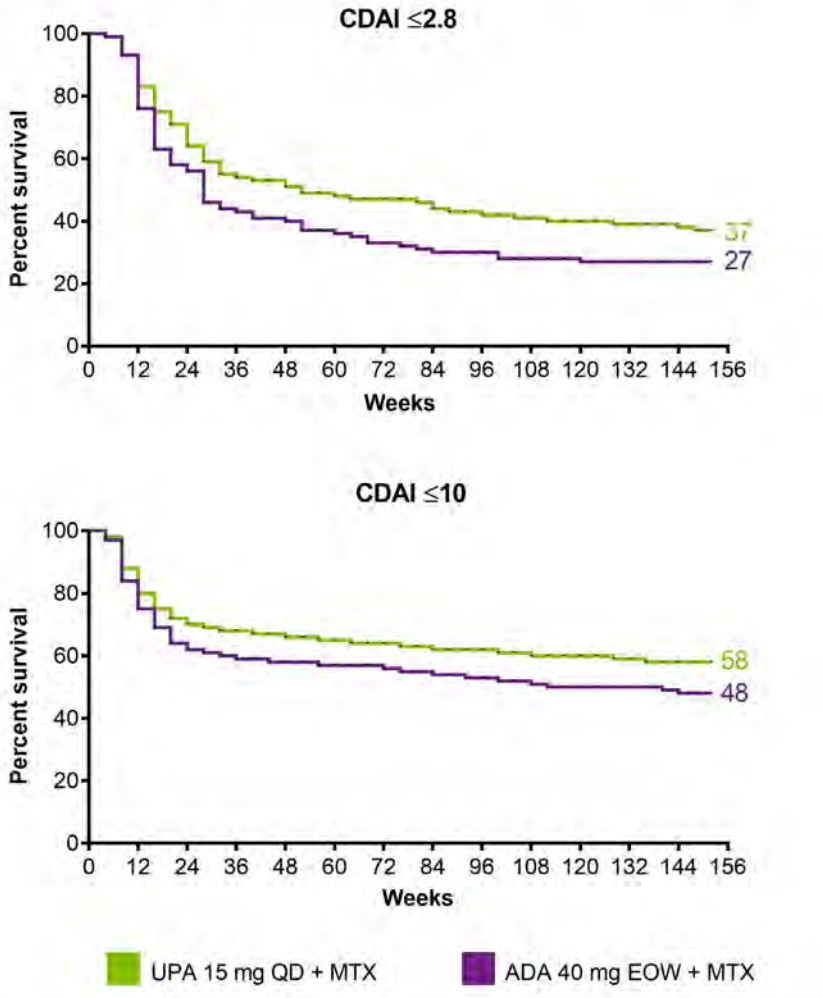
Figure 1. Proportion of Patients Sustaining CDAI Remission or Low Disease Activity Up to 30 Months After First Occurrence of Response Among the Total Randomized Population



Treatment groups are by initial randomization; non-responder imputation was used for missing data. Data are from patients who achieved initial CDAI response at any point during the 3-year study period, with 30 months post-initial response being the maximum time estimated for both treatment groups.

ADA, adalimumab; CDAI, Clinical Disease Activity Index; EOW, every other week; MTX, methotrexate; QD, once daily; UPA, upadacitinib.

Figure 2. Kaplan-Meier Analysis of Time to Loss of CDAI Remission or Low Disease Activity After the First Occurrence of Response Through 3 Years



Results are for patients who achieved CDAI clinical remission or low disease activity; treatment groups are by initial randomization. UPA 15 mg QD + MTX: CDAI ≤2.8: n = 303; CDAI ≤10: n = 458. ADA 40 mg EOW + MTX: CDAI ≤2.8: n = 115; CDAI ≤10: n = 195. Data were censored (i.e., data collection stopped) at 3 years, when all patients had reached Week 156 visit. Non-responder imputation was used for missing data. Week 0 indicates the first occurrence of response.

ADA, adalimumab; CDAI, Clinical Disease Activity Index; EOW, every other week; MTX, methotrexate; QD, once daily; UPA, upadacitinib.

follow-up visit, 37%/58% of patients receiving UPA and 27%/48% on ADA remained in CDAI REM/LDA, respectively (**Figure 2**). Of patients who lost CDAI REM, 68% on UPA and 55% on ADA remained in LDA. Additionally, roughly similar proportions on UPA and ADA recaptured CDAI REM/LDA (UPA, 40%/17%; ADA, 48%/19%). Similar results were observed for REM/LDA based on SDAI and for DAS28(CRP) < 2.6/≤3.2.

Conclusion: Among patients with inadequate response to MTX, a higher proportion receiving UPA + MTX achieved remission or LDA across disease activity measures vs ADA + MTX. UPA-treated patients demonstrated a consistently higher sustained response rate over 3 years compared to those receiving ADA. Furthermore, significant proportions of patients who lost response on either UPA or ADA were able to recapture remission or LDA.

SESSION INFORMATION

Session Date: Sunday, November 7, 2021

Session Title: RA – Treatments Poster I: Comparative Effectiveness, Biosimilars, Withdrawal, & the Real World (0813–0845)

Session Type: Poster Session B

Session Time: 8:30AM–10:30AM

Background/Purpose: Non-treatment and treatment delays contribute to suboptimal symptom control and irreversible joint damage in patients with inflammatory arthritis (IA). This investigations objective was to identify baseline patient factors associated with treatment initiation during the 12 months after the initial diagnosis of rheumatoid arthritis (RA), psoriatic arthritis (PsA), or ankylosing spondylitis (AS).

Methods: Active users of the Veteran Affairs Health System with an incident IA diagnosis between 1/1/2007 and 12/31/2019 were included (Figure 1). Data resources included the corporate data warehouse and the VA Informatics and Computing Infrastructure. Coded data were used to identify comorbidities, medications, laboratory data, provider visits and other encounters in the VA system. Natural language processing improved the accuracy of incident cohort identification and identifying erosions due to IA in the text of radiology reports. Treatment was captured during the 12 months following the initial IA diagnosis. Univariate analysis was used to explore patient factors associated with treatment. In normally distributed continuous variables means and standard deviations were compared, while medians and interquartile ranges were used for non-normally distributed variables.

Results: The study included 18,318 Veterans with incident IA (14,470 RA, 2380 PsA, 1468 AS). The mean age was 63.1 years and 90.7% were male. In the 12 month follow-up period, 40.7% did not use an IMM. VA system utilization was similar between groups (RR=1.000). Characteristics significantly associated with treatment included younger age (RR=0.9985), female gender (RR=0.9781), white race (RR=1.0179) non-Hispanic ethnicity (RR=1.0248), divorced marital status (RR=1.0118), and higher BMI (RR=1.0016). Estimates of socioeconomic status (measured by the area deprivation index [ADI]) were similar amongst patients with available data, but treatment was less frequent in patients with missing ADI (RR=1.0545). Higher comorbidity burden (RR=0.9883), alcohol dependence (RR=0.9718), heart failure (RR=0.9433), kidney disease (RR=0.9144), and osteoporosis (RR=0.9487) associated with non-treatment. Rheumatology (RR=1.2356), dermatology (RR=1.0462), gastroenterology (RR=1.0342), and orthopedic (RR=1.0232) visits were associated with treatment. Use of glucocorticoids (RR=1.1341), NSAIDS (RR=1.0785), and opiates (RR=1.0214) associated with treatment. Tests associated with therapy included: HLA-B27, RF, CCP, CRP, ESR. Positive results with RF, CCP, ESR, and articular erosions were associated with treatment (Table 2).

Conclusion: Several patient factors including certain demographics, subspecialty visits, additional medications, laboratory testing and erosions on imaging had a positive association with treatment. Other patient factors such as male gender, comorbidities and unknown addresses had a negative association with treatment. Future research with added analyses of these factors (multivariate analysis) and additional factors (health system and provider variables) may inform strategies to improve early treatment in appropriate patients with IA.

Session Type: Poster Session B
Session Time: 8:30AM–10:30AM

Background/Purpose: The variety of treatment options in RA contrasts with a lack of personalized medicine. The presence of concomitant SjS might be associated with differerences in RA pathobiology. We hypothesize that the clinical phenotype and treatment response differs in RA/SjS compared to RA alone with an inferior response to TNF-inhibitors (TNFi) over other target specific therapies.

Methods: In this retrospective observational cohort study data from the Swiss Clinical Quality Management in Rheumatic Diseases (SCQM) registry were obtained (01.01.2000-01.01.2021). All treatment courses (TC) from patients aged 18 and older with RA as diagnosed by the treating rheumatologist and definite SjS status undergoing TNFi, other modes of action (OMA) bDMARD (Abatacept, IL6-inhibitors, Rituximab) or JAK-inhibitors (JAKi) were assessed. Two group-comparison between RA/SjS and RA/non-SjS were performed. P-values are from Fisher test for nominal and Kruskal test for continuous variables. We estimated crude hazard ratios (HR) from univariate Cox models with the outcome of stop or start of a new bDMARD.

Results: A total of 9601 TCs were analyzed (5373 TNFi, 3201 OMA, 1027 JAKi). RA/SjS were more likely to be female, non-smoker, to have longer RA disease duration, a higher DAS28 and HAQ-score. Additionally, RA/SjS patients were more likely to receive OMA or concomitant steroid treatment and had a higher number of prior biologic treatments. Patients' characteristics at the start of each eligible TC are displayed in table 1. Figure 1 shows the Kaplan Meier plot for TNFi TCs (p-value corresponds to the log-rank test). Median retention time for RA/SjS versus RA/non-SjS was: TNFi 489 versus 714d; OMA 619 versus 768d; JAKi 693 versus 801d. There was evidence that RA/SjS have a higher hazard for stopping TNFi treatment than RA/non-SjS (crude HR 1.35, 95%; CI 1.05 to 1.74, p=0.02). No evidence was found for a difference in OMA (crude HR 1.13, 95% CI 0.92 to 1.39, p=0.23) or JAKi (crude HR 1.12, 95% CI 0.76 to 1.67, p=0.57).

Conclusion: The unadjusted Cox model suggests that patients with RA and associated SjS have an inferior response to TNFi than RA patients without SjS.

Table 1. Patient characteristics at the start of an eligible treatment course. Displayed are n (%) for nominal and median (Q1-Q3) for continuous variables

Variable	Levels	RA/non-SjS	RA/SjS	All patients	p value

Modelling of Disease Activity in Patients with Inflammatory Arthropathies Treated with Etanercept Originator or Biosimilar as First-Line Biologic: A Real-World Observational Study Using the OPAL Dataset

Claire Deakin[1], Geoffrey Littlejohn[2], Hedley Griffiths[3], Tegan Smith[4], Catherine OSullivan[5] and Paul Bird[6], [1]OPAL Rheumatology Ltd, Sydney, Australia, [2]Monash University, Melbourne, Australia, [3]Barwon Rheumatology Service, Geelong, Australia, [4]OPAL Rheumatology Ltd, Kogarah, Australia, [5]OPAL Rheumatology Ltd, Queenscliff, Australia, [6]University of New South Wales, Sydney, Australia

SESSION INFORMATION

Session Date: Sunday, November 7, 2021

Session Title: RA – Treatments Poster I: Comparative Effectiveness, Biosimilars, Withdrawal, & the Real World (0813–0845)

Session Type: Poster Session B

Session Time: 8:30AM–10:30AM

Background/Purpose: The availability of biosimilars as non-proprietary versions of established biologic disease-modifying anti-rheumatic drugs (bDMARDs) has increased around the world. Since April 2017 both the originator and a biosimilar for etanercept have been available for use in Australia. This study aimed to model effectiveness of etanercept originator or biosimilar in reducing DAS28CRP in patients with RA, PsA or AS treated with either drug as first-line bDMARD as well as describe persistence on etanercept originator or biosimilar as first-line bDMARD in patients with RA, PsA or AS.

Methods: Clinical data were obtained from the Optimising Patient outcomes in Australian rheumatoLogy (OPAL) dataset, derived from electronic medical records. Eligible patients with RA, PsA or AS who initiated etanercept originator (n=977) or biosimilar (n=552) as first-line bDMARD between 1 April 2017 and 31 March 2021 were identified. Propensity score matching was performed to select patients on originator (n=280) or biosimilar (n=170) with similar characteristics in terms of diagnosis, disease duration, joint count, age, sex and concomitant medications. Data on clinical outcomes were recorded at 3 months after baseline, and then at 6-monthly intervals. Outcomes data that were missing at a recorded visit were imputed and propensity scores were re-calculated to include imputed outcomes data at baseline including DAS28CRP.

Effectiveness of the originator, relative to the biosimilar, for reducing DAS28CRP over time was modelled in the matched population using linear mixed models with both random intercepts and slopes to allow for individual heterogeneity. Time was modelled as a combination of linear, quadratic and cubic continuous variables. Individuals were weighted using inverse probability of treatment weights to ensure comparability between treatment groups. The average weighted baseline DAS28CRP were 4.95 and 4.94 for the originator and biosimilar, respectively.

Persistence on the originator or biosimilar was analysed using survival analysis (log-rank test).

Results: Reduction in DAS28CRP was associated with both time and etanercept originator treatment (Table 1). The conditional R-squared for the model was 0.28. The average model-predicted DAS28CRP at 3 months, 6 months, 9 months and 12 months were 3.0 and 3.3, 2.5 and 2.8, 2.3 and 2.5, and 2.1 and 2.3 for the originator and biosimilar, respectively, indicating a clinically meaningful effect of time for patients on either drug and an additional modest improvement for patients on the originator.

Median time to 50% of patients stopping treatment was 24.6 (16.8, 35.9) months for the originator and 24.1 (15.2, 32.2) months for the biosimilar (p=0.72). An adverse event was the reason for discontinuing treatment in 39 patients (11.4%) on the originator and 20 patients (13.4%) on the biosimilar.

Conclusion: Analysis using a large national real-world dataset showed treatment with either the etanercept originator or the biosimilar was associated with a reduction in DAS28CRP over time, with the originator being associated with a further modest reduction in DAS28CRP that was not clinically significant. Persistence on treatment was not different between the two drugs.

Table 1. Model summary for prediction of DAS28CRP using time and etanercept originator (relative to biosimilar)

Fixed Effect	Estimate	95% Confidence Interval	p-value
Time (linear)	0.91	0.91, 0.92	1.4e-64
Time (quadratic)	1.00	1.00, 1.00	1.2e-30
Time (cubic)	1.00	1.00, 1.00	1.2e-17
Originator	0.92	0.87, 0.96	6.7e-04

SESSION INFORMATION
Session Date: Sunday, November 7, 2021
Session Title: RA – Treatments Poster I: Comparative Effectiveness, Biosimilars, Withdrawal, & the Real World (0813–0845)
Session Type: Poster Session B
Session Time: 8:30AM–10:30AM

Background/Purpose: The treatment strategy for rheumatoid arthritis (RA) includes achieving remission or at least low disease activity within six months of starting therapy. Active RA may be treated with either biological DMARDs (bDMARDs) or JAK inhibitors after inefficacy or intolerance of conventional DMARDs. To date, only few data are available on the persistence of the different treatment approaches in daily practice.

Methods: Regarding different mode of actions (MoA) for anti-rheumatic treatment, this analysis compares the persistence of JAK inhibitors with TNF inhibitors and other bDMARDs (nonTNFi) in RA patients from the German RheumaDatenRhePort (Rhadar) registry.

Data of 5154 RA patients from the pseudonymized Rhadar registry (Kleinert, S., P. Bartz-Bazzanella et. al. (2021). "A Real-World Rheumatology Registry and Research Consortium: The German RheumaDatenRhePort (RHADAR) Registry." J Med Internet Res 23(5): e28164.) entered by 22 rheumatologists were evaluated. Patients were included in the sample characterization if at least one registry entry was documented between July 1st, 2020, and March 31st, 2021. Only data of those patients that received a newly prescribed bDMARD or JAK inhibitor between June 1st, 2017 (shortly after the approval of tofacitinib and baricitinib in Germany) and March 31st, 2020, were compared regarding persistence. 3124 (60,6 %) of the evaluated patients suffered from a seropositive RA, 73,5% females, with a mean age of 64.5±13.9 years. 66.9% received monotherapy. The persistence of the respective MoA was calculated using Kaplan-Meier survival curves. Descriptive statistical analysis and drug survival were calculated using R (version 4.0.4) (R Core Team. R: A language and environment for statistical computing. R Foundation for Statistical Computing, Vi-

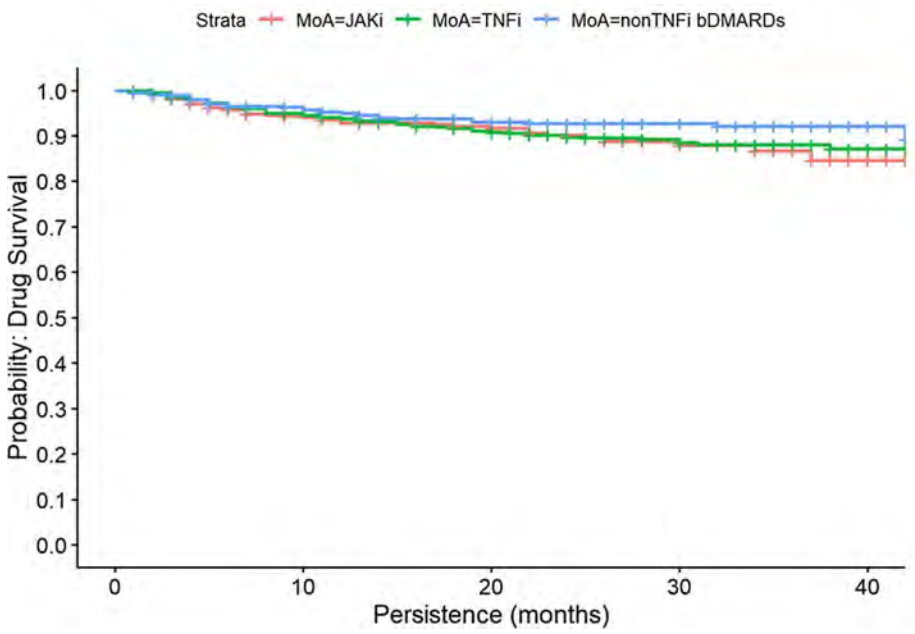

Figure 1. Persistence of the respective therapy principles (MoA = Mode of Action): (JAKi = JAK-inhibitor, TNFi = TNF-inhibitor, IL6i = IL6-receptor-inhibitor, CD20 = Rituximab, CD80/CD86 = Abatacept).

enna, Austria. 2018) and RStudio (version 1.4.1103) (RStudio Team. RStudio: Integrated Development for R. RStudio, Inc, Boston, MA. 2016).

Results: Prescription information of 4715 of the 5154 patients was available at database closure. Of these 4715 patients, 15.2% received a TNF inhibitor, 8.9% other bDMARDs and 10.0% a JAK inhibitor. JAK inhibitors were prescribed as monotherapy in 64.8%, TNF inhibitors only in 45.4% and other bDMARDs in 63.7% of the RA patients. The persistence on JAK inhibitors, TNF inhibitors and other bDMARDs was high (> 85% after 24 months) (fig. 1) and did not differ significantly between JAK inhibitors and TNF inhibitors ($p = 0.724$) or JAK inhibitors and other bDMARDs ($p = 0.084$) in a corresponding Cox proportional hazards model.

Conclusion: The persistence of therapy with JAK-inhibitors is high in daily practice, comparable to TNF inhibitors and other bDMARDs.

SESSION INFORMATION
Session Date: Sunday, November 7, 2021
Session Title: RA – Treatments Poster I: Comparative Effectiveness, Biosimilars, Withdrawal, & the Real World (0813–0845)
Session Type: Poster Session B
Session Time: 8:30AM–10:30AM

Background/Purpose: Short-term glucocorticoid (GC) bridging therapy results in rapid suppression of disease activity during the initial treatment of rheumatoid arthritis (RA) patients with DMARDs. But there are concerns that many patients may not be able to discontinue GC, risking adverse events. We reviewed the literature to investigate the success rate of GC discontinuation during 24 months of follow-up in trials using GC as bridging therapy.

Methods: A systematic literature search was conducted in PubMed, Embase, Web of Science, COCHRANE library, Emcare and Academic Search Premier to find clinical trials about RA patients treated with (also) initial GC bridging with at least 12 months follow-up. Studies were excluded according to a decision rule (see flowchart in *figure 1*). Heterogeneity was assessed based on pre-defined items, describing patient characteristics, initial GC bridging scheme, additional treatment and treatment adjustment protocols. Studies were assessed for continuation or restarting of GC after the induction scheme.

Results: The literature search identified 7160 abstracts (flowchart in *figure 1*). Based on reviewing the first 100 abstracts, we found a 97% interobserver agreement between the 3 reviewers (LO, ISN and SAB). The remaining abstracts were screened separately by the reviewers. 350 abstracts were included for full text analysis, resulting in 12 unique studies (*table 1*). The majority of included patients fulfilled the ACR/EULAR 2010 (53%) or the ACR 1987 (33%) criteria. At baseline, the mean symptom duration ranged from 4 to 7 months and the disease activity score (DAS) ranged from 3.0 to 5.2. All trials started with a DMARD at baseline next to the GC. In 83% of the studies oral GC bridging was used (initial dose ranging between 7.5 and 60 mg/day, the latter always followed by rapid tapering to 7.5 mg/day as maintenance dose, see *table 1*). Studies starting with a lower initial dose (5 studies) tapering to 5 mg/day (2/5, 40%) or directly to zero (3/5, 60%). Only 4/12 studies reported data on GC use after the GC induction phase, either at 12 (3/4) and/or at 24 (3/4) months follow-up (see *table 2*). The proportion of patients still using GC ranged from 23 to 44% at 12 months and 10 to 28% at 24 months. One study only started tapering at 12 months; at 24 months 45% of the patients were still using GCs (see *table 2*). Other outcome measures (e.g. cumulative or average GC dose, number of GC episodes) were reported in even fewer studies. Therefore, a meta-analysis was not performed.

Conclusion: The currently available data do not provide sufficient information on successful GC discontinuation after the induction phase, since initial type and dose of GC tapering schedules differed between studies and the total number of trials with pertinent data was small. However, preliminary data suggest that in the clinical trials assessed, up to 60% of patients have discontinued GCs initially at 12 months follow-up, and up to 70% at 24 months.

Session Title: RA – Treatments Poster I: Comparative Effectiveness, Biosimilars, Withdrawal, & the Real World (0813–0845)
Session Type: Poster Session B
Session Time: 8:30AM–10:30AM

Background/Purpose: Rheumatoid arthritis (RA) patients have a higher risk of developing infections as compared to the patients without the diagnosis, and this risk is further augmented by the use of biologics and immunosuppressant medications used for the treatment. This could be explained by the disease process itself, associated comorbidities, and immunomodulation as a result of the treatment modalities. We aim to identify national trends in terms of the common infectious etiologies in RA patients leading to hospitalizations in the patients admitted within a 15 year time period.

Methods: We used the Nationwide Inpatient Sample (NIS) database (years 1999-2014) and extracted all patients with Rheumatoid Arthritis using validated International Classification of Disease (ICD) codes. Further, six common hospitalized infections were identified: Urinary tract infection (UTI), Pneumonia, Skin and soft tissue infection (SSTI), Sepsis, Bacteremia, and Opportunistic infections. Data was analyzed using Statistical Analysis System (SAS) 9.4 software.

Results: A total of 1,351,284 cases of Rheumatoid arthritis were identified in the 15 year period (1999-2014). Mean age was 66.55 ± 15.34 years with females making up 74.95% (n= 1,012,532) of the patient population. As seen in Figure 1, an overall upward trend was noticed in all 6 selected infections ($p< 0.001$). It was found that UTI was the most prevalent infection in this population, which was on the rise from 10.38% in 1999 to 15.15% in 2011, with a steady decline to 14.74% in 2014, followed by Pneumonia (9.6% in 1999, 11.67% in 2014). Sepsis (3.34% in 2006 to 9.51% in 2014) and Bacteremia (3.91% in 2006 to 9.48% in 2014) had a dramatic increase since 2006.

Length of stay (LOS) in RA patients without any infection is 4.43 days and the average cost is $29,833.65 whereas in RA patients with any of the infections, LOS increases to 6.95 days and the average cost is $39,214.49.

Conclusion: The use of biological agents for the treatment of RA is associated with improved outcomes by decreasing inflammation and improving the overall mortality and morbidity in RA patients. However, at the same time, this has led to a higher rate of infections as a result of immune suppression in RA patients. It has been reported that

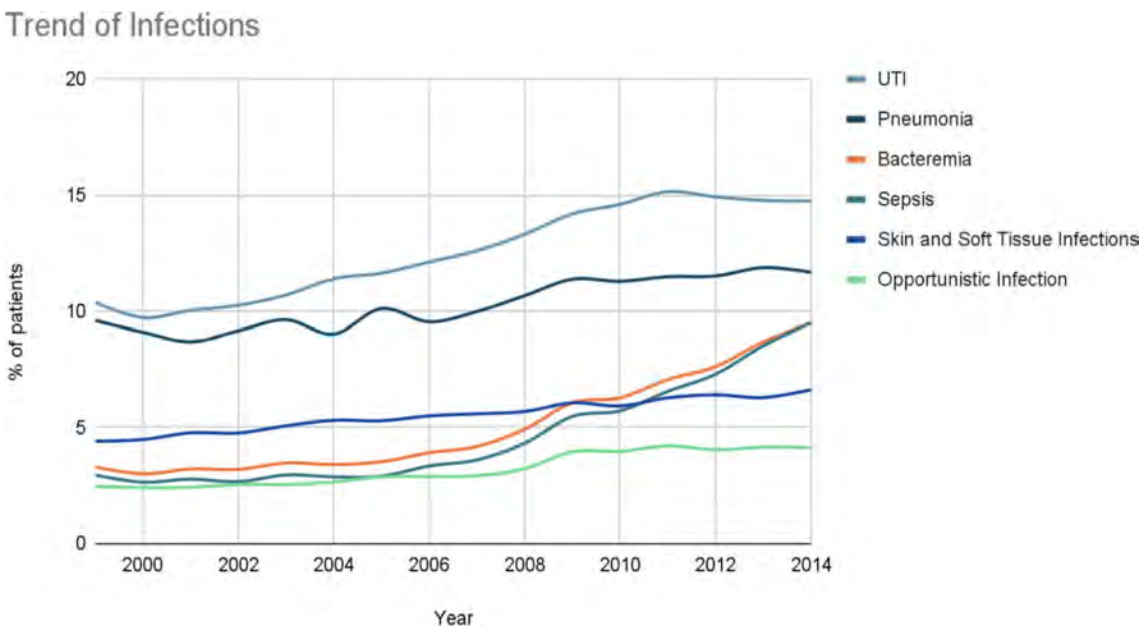

Figure 1. Trend of Infections over 15 years.

tumor necrosis (TNF) inhibitors are associated with a higher rate of infection when compared to conventional disease modifying agents, especially UTI, pneumonia and SSTI. In our study, we noticed that the common infections in hospitalized patients with RA included UTI and Pneumonia, both of which have risen since 1999. Higher UTI prevalence can also be explained by the female predominance. An increase in Sepsis was also seen which could be attributed to a higher infection rate, but maybe overestimated or correctly estimated as compared to past secondary to better coding and documentation of sepsis. Higher infection rates also contributed to longer hospital stays, thus leading to higher costs of care in these patients. Thus, there needs to be increased infection surveillance in this patient population, especially with the increasing use of biologic agents.

[a]**JAK inhibitors included**: tofacitinib and baricitinib. [b]**Anti-TNF biologic included**: etanercept, infliximab, golimumab, adalimumab and certolizumab. [c]**Other biologic** included other biologic drugs except the anti-TNFs. [d]The percentage for these variables was calculated based on the number of patients who had this test and whose lab results were known. [e]Included 10 patients exposed to methotrexate before baseline (10 non-MFAT). [f]Included 3 patients exposed to hydroxychloroquine before baseline (3 non-MFAT). [g]Included 9 patients exposed to prednisone before baseline (7 non-MFAT and 2 MFAT).

Background/Purpose: A subset of patients with rheumatoid arthritis (RA) experience refractory disease and do not attain remission imparting worse long-term outcomes. We evaluated RA patients with at least one year of follow-up on their first biologic, to identify characteristics associated with multiple failures of advanced therapies (MFAT) (biologics and/or JAK inhibitors).

Methods: The Rheumatoid Arthritis Pharmacovigilance Program and Outcomes Research in Therapeutics (RAPPORT) registry is a prospective inception cohort of northern Albertan RA patients starting their first biologic. We assessed RAPPORT patients with at least one year of follow-up on a biologic and identified RA patients with MFAT (defined as those exposed to 3 or more biologic classes or JAK inhibitors) developing over follow-up (i.e. forward from

[a]Adjusted for all variables shown. [b]**Other DMARDs Included**: chloroquine, leflunomide, gold,aAzathioprine, cuprimine, cyclophosphamide, minocycline, mycophenolate, cyclosporine and sulfasalazine. [c]**Anti-TNF biologic included**: etanercept, infliximab, golimumab, adalimumab and certolizumab. [d]**Achievement of remission** at 3-4 months or 1 year after baseline in this case (Yes/no). [e]These variables (drugs) are at time-dependant: Patients who had already taken these drugs. [f]Variable for whether or not the patient switched their biologic in the first year since the baseline in this case.

our time zero, which was from one year after biologic initiation). Cox regression analysis was performed to evaluate factors (demographics, clinical characteristics, and treatment) potentially associated with poor outcome.

Results: Of 2338 RAPPORT patients, baseline characteristics included low exposure to prednisone (12.7%), mean DAS-28-CRP 4.5 (SD 1.3), mean HAQ 1.5 (SD 0.7) and 86% with anti-TNF as their first biologic. 2107 had at least one year of follow-up on their first biologic (231 dropped out or were lost to follow-up prior to this point). Over an average of 6 years of follow-up beyond our time zero, 271/2107 (13%) of patients ultimately required ≥3 advanced therapies. Characteristics were similar between the two groups concerning age, sex, RA duration, Caucasian maternal race, body mass index, seropositivity for rheumatoid factor and anti-CCP (Table 1). Current smoker (29%) and unemployed (53%) were characteristics observed more frequently in the MFAT group. In univariate analyses, high disease activity and lower education were associated with requiring ≥3 advanced therapies, and lower risk of the outcome was seen in those with DAS28 remission at 3-4 months (HR 0.49, 95% CI 0.35- 0.68).

In unadjusted and adjusted models (Table 2), the risk of developing MFAT was associated with current smoking (time zero) (HR 1.49, 95% CI 1.06-2.09], entry into the cohort from 2011 onwards (HR 2.07, 95% CI 1.42-3.03], ever (up to time zero) used prednisone (HR 3.06, 95% CI 2.23-4.19]; and patients who switch bDMARD in the first year (HR 3.53, 95% CI 2.52-4.92). Lower risk of the outcome was associated with anti-TNF used as first biologic (HR 0.62 , 95% CI 0.40-0.98) and DAS28 remission at one year (HR 0.49, 95% CI 0.27-0.89). Results were similar when patients switching biologic in the first year were excluded. A potential limitation related to reasons for therapy changes beyond uncontrolled RA (e.g. adverse events).

Conclusion: Attaining disease remission within the first year of biologic initiation is a key factor associated with better longer-term RA outcomes. The greater risk of MFAT in early switchers may reflect the importance of personalized medicine and using the right treatment in the right patient in a timely manner. Subjects entering RAPPORT in the past decade were more likely to ultimately require ≥3 advanced therapies, possibly representing increasing therapy options and/or more aggressive approaches.

SESSION INFORMATION

Session Date: Sunday, November 7, 2021

Session Title: RA – Treatments Poster I: Comparative Effectiveness, Biosimilars, Withdrawal, & the Real World (0813–0845)

Session Type: Poster Session B

Session Time: 8:30AM–10:30AM

Background/Purpose: SB4 is an etanercept biosimilar that obtained EU regulatory approval in 2016, and became available in Greece in 2018. Due to lack of published evidence about the use of etanercept biosimilars in the Greek setting, this study aims to generate real-world data on the impact of SB4 on patient-reported physical function and disease activity in RA patients.

Methods: BENEFICIAL is an ongoing 100-week non-interventional, multicenter, prospective study conducted in Greece, studying adult patients with moderate to severe active RA and inadequate response to conventional synthetic DMARDs. Patients were newly prescribed SB4 as monotherapy or combination therapy per the approved label in routine clinical practice. Patients who initiated SB4 >2 weeks before enrollment or who were previously treated with originator etanercept were excluded. Data are collected by routine clinical assessments, including tender/swollen joint count and physician's global assessment of disease activity, acute phase reactants, and patient-reported outcomes (PROs) at baseline (SB4 treatment initiation), and at 24, 52 and 100 weeks post-baseline. PROs include the validated Greek Patient-Reported Outcomes Measurement Information System Physical Function Short Form 20a (PROMIS PF SF-20), and the patient's global assessment of disease activity, joint pain intensity, and morning stiffness using visual analogue scales. We present the results of an interim analysis performed after all patients completed the 52-week observation period.

Results: Between 2/May/2019 and 9/Dec/2019, 132 eligible patients were enrolled in 9 rheumatology centers. Baseline characteristics are shown in Tables 1 and 2. Over a median (interquartile range; IQR) treatment duration of 50.1 (48.7-52.6) weeks, a median (IQR) of 50.0 (48.0-52.0) injections were received. The baseline median (IQR) PROMIS PF SF-20 total T-score was 28.7 (25.8-34.4).

A clinically important improvement from baseline physical function (≥2 point-change in PROMIS PF SF-20 total T-score) was observed in 82.1% (95% CI: 75.1-89.0) and 92.4% (95% CI: 87.3-97.5) of the patients at 24 and 52 weeks, respectively. Median PROMIS PF SF-20 total T-score and all item scores significantly increased from baseline

Table 1. Baseline patient characteristics.

Baseline patient characteristics	N=132
Age, median (IQR), years	66.3 (56.1-73.6)

Methotrexate	78 (59.1%)
Hydroxychloroquine	45 (34.1%)
Leflunomide	19 (14.4%)
Ciclosporin	2 (1.5%)

CCP: cyclic citrullinated peptide, DAS28-ESR: disease activity score 28 with erythrocyte sedimentation rate, csDMARD: conventional synthetic disease modifying antirheumatic drug, IQR: interquartile range, N: total sample size, n: number of patients with available data, PhGA: physician's global assessment, PtGA: patients' global assessment, RA: rheumatoid arthritis, SD: standard deviation, SDAI: simplified disease activity index, SJC28: swollen joint count based on 28-joint assessment, TJC28: tender joint count based on 28-joint assessment, VAS: visual analog scale.

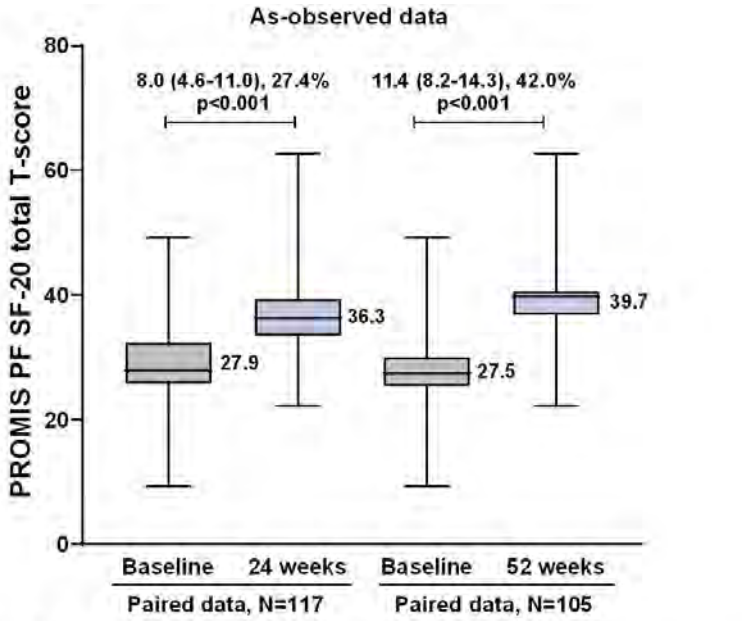

Figure 1. Change in PROMIS PF SF-20 total T-score from baseline at 24 and 52 weeks post-baseline, among patients with available paired data. Numbers next to bars indicate median values, while whiskers extend to minimum and maximum values at each timepoint. Median (interquartile range) differences and percent changes are displayed above the respective horizontal capped bars. Statistically significant increases (p<0.001, Wilcoxon signed-rank test) from baseline were observed both at 24- and 52- weeks post-baseline. N: number of patients with available data, PROMIS PF SF-20: Physical Function Short Form 20a.

Figure 1. Change in PROMIS PF SF-20 total T-score from baseline at 24 and 52 weeks post-baseline, among patients with available paired data. Numbers next to bars indicate median values, while whiskers extend to minimum and maximum values at each timepoint. Median (interquartile range) differences and percent changes are displayed above the respective horizontal capped bars. Statistically significant increases (p<0.001, Wilcoxon signed-rank test) from baseline were observed both at 24- and 52- weeks post-baseline. N: number of patients with available data, PROMIS PF SF-20: Physical Function Short Form 20a.

(9/113) of patients at 24 weeks, and by 86.8% (79/91), 58.1% (54/93) and 20.4% (19/93) at 52 weeks, respectively. The adverse event (AE) rate was 18.9% (25/132). AEs related to SB4 were reported for 3 (2.3%) patients (excluding events of 'drug ineffective') of whom one patient experienced 2 serious events.

Conclusion: These are the first real-world data on SB4 in a routine setting in Greece, indicating that the majority of patients in this study cohort demonstrated clinically meaningful improvement in their physical function and disease activity by 24 and 52 weeks post-initiation of SB4 for treatment of RA.

SESSION INFORMATION
Session Date: Sunday, November 7, 2021
Session Title: Research Methodology Poster (0846–0854)
Session Type: Poster Session B
Session Time: 8:30AM–10:30AM

Background/Purpose: Loneliness is a pervasive experience that has been associated with poorer health-related quality of life, and remains understudied in patients with systemic sclerosis (SSc). This study examined the psychometric properties of scores from the UCLA Loneliness Scale-6 (ULS-6; Neto, 1992), a self-report questionnaire not previously evaluated for SSc, and evaluated the equivalence of English and French versions.

Methods: This study used baseline data from 775 adults with SSc (89.9% female, 52.9% limited SSc, 66% English-speaking) enrolled in the Scleroderma Patient-Centered Intervention Network (SPIN) Cohort. Confirmatory factor analysis (CFA) was used to evaluate the single-factor structure of the ULS-6. Internal consistency reliability was assessed via McDonald's omega and Cronbach's coefficient alpha, and convergent validity was examined via Pearson product-moment correlations with measures of depression symptoms (PHQ-8) and social support (OSSS-3), number of people in the household, and social interaction frequency. Multiple group CFA (MGCFA) was used to determine whether the single-factor structure was supported in English and French-speaking subgroups. The MIMIC model was used to examine differential item functioning (DIF) for English versus French versions.

Results: The mean score on the ULS-6 was 7.00 (SD = 4.76, range 0-18), with a higher score representing greater loneliness. The CFA supported the expected single-factor structure (CFI = .96, SRMR = .03), although the RMSEA = .11 suggested less than adequate model fit. All standardized factor loadings for items were large and statistically significant (.62 to .86, all *p*s < .001). Omega and alpha were both 0.87, indicating high reliability. The ULS-6 total score correlated significantly (all *ps* < .001) and in expected directions with the total score for the PHQ-8 (*r* = .56), the total score on the OSSS (*r* = -.53), and frequency of social interactions with one person (*r* = -.162) and multiple people *(r* = -.24), but did not correlate significantly with number of people in the household (r = -.058, *p* = .11). The MGCFA indicated that the configural invariance model best fit the data ($\Delta\chi^2[8] = 56.14$, $p < .001$), suggesting non-equivalent factor loadings between language subgroups. However, unstandardized (.72 to 1.39, all *p*s < .001) and standardized (.48 to .90, all *p*s < .001) factor loadings were positive and statistically significant. The overall MIMIC model fit well and suggested cross-language metric equivalence (CFI = .939, SRMR = .044, RMSEA = .11). Statistically significant DIF were found for three items across language, although standardized differences were small (β(item 2) = .14, $p < .001$, β(item 4) = -.14, $p = .005$, β(item 6) = .13, $p < .001$).

Conclusion: Analyses demonstrated acceptable reliability and validity of the ULS-6 scores in English- and French-speaking adults with SSc, supporting its use to examine comparative experiences of loneliness. Although half of the items showed DIF across linguistic groups and the MGCFA did not support factor loading invariance, there were few practical implications for the total scores derived. Future studies of the ULS-6 across linguistic groups are needed to establish invariance for use with diverse SSc populations.

Abstract Number: 0847

A Psychometric Analysis of the Self-Efficacy for Managing Chronic Disease Scale in Systemic Sclerosis: A Scleroderma Patient-Centered Intervention Network Cohort Study

Alyssa Choi[1], Chelsea Rapoport[2], Linda Kwakkenbos[3], Marie-Eve Carrier[4], Karen Gottesman[5], Scott Roesch[6], Brett Thombs[7] and Vanessa Malcarne[6], [1]SDSU/UC San Diego Joint Doctoral Program in Clinical Psychology, San Diego, CA, [2]SDSU/UC San Diego Joint Doctoral Program in Clinical Psychology, La Jolla, CA, [3]Department of Clinical Psychology, Radboud University Behavioural Science Institute, Nijmegen, Netherlands, [4]Lady Davis Institute for Medical Research, Jewish General Hospital, Montréal, QC, Canada, [5]Scleroderma Foundation, Southern California Chapter, Danvers, MA, [6]SDSU/UC San Diego Joint Doctoral Program in Clinical Psychology; Department of Psychology, San Diego State University, San Diego, CA, [7]Lady Davis Institute for Medical Research, Jewish General Hospital; Department of Psychiatry, McGill University, Montréal, QC, Canada

SESSION INFORMATION
Session Date: Sunday, November 7, 2021
Session Title: Research Methodology Poster (0846–0854)
Session Type: Poster Session B
Session Time: 8:30AM–10:30AM

Background/Purpose: Self-efficacy is a key determinant of health behaviors and the target mechanism of self-management programs for patients with chronic diseases. The Self-Efficacy for Managing Chronic Disease (SEMCD) scale, a brief self-report instrument, has been widely used to measure self-efficacy in chronic disease populations and is validated in English for use in people with systemic sclerosis (SSc). However, it is essential that translations of measures be examined for psychometric equivalence across populations, and no research has yet ascertained that SEMCD scores are comparable across languages. The present study examined the cross-language measurement equivalence of the SEMCD in a sample of English- or French-speaking adults with SSc.

Methods: Adults with SSc (*N* = 2159; 87.4% female; 57.3% limited SSc; 68.3% English-speaking) from 46 centers were enrolled in the Scleroderma Patient-Centered Intervention Network (SPIN) Cohort. All participants were classified as having SSc according to the 2013 ACR/EULAR classification criteria. The SEMCD scale includes 6 items and higher scores indicate higher levels of self-efficacy. Confirmatory factor analysis (CFA) was used to confirm the single-factor structure of the SEMCD scale. Cronbach's coefficient alpha and McDonald's omega were used to evaluate internal consistency reliability. Multiple group confirmatory factor analysis (MGCFA) was used to determine whether the single-factor structure was supported in both languages. The Multiple-Indicator Multiple-Cause (MIMIC) model was used to examine differential item functioning (DIF).

Results: The mean total score on the SEMCD was 6.45 (SD = 2.26, range = 1-10). The SEMCD demonstrated good internal consistency reliability (α = .93, ω = .93). CFA indicated that a one-factor model fit well based on 2 of the 3

tested indices of model fit (Comparative Fit Index [CFI] = .96, Standardized Root Mean Residual [SRMR] = .03). The Root Mean Square Error of Approximation (RMSEA) indicated less than acceptable model fit (RMSEA = .14). Standardized factor loadings for all items were large and statistically significant (all *p*s < .001; range .755 to .879). Results from the MGCFA supported the metric invariance model as the best fit for the data ($\Delta\chi^2$ [10, *N* = 2159] = 13.32, *p* = .206), suggesting that the factor loadings are invariant across English and French language versions. The overall MIMIC model fit well and indicated that the SEMCD items demonstrate cross-language metric equivalence (CFI = .96, SRMR = .03, RMSEA = .12), although a statistically significant but small-magnitude DIF was found for one SEMCD item across language (β = .03, *p* < .05).

Conclusion: Findings support the use of the SEMCD as a reliable and valid single-factor measure of self-efficacy in SSc. SEMCD scores from English- and French-speaking individuals with SSc can be compared or combined for analysis. Future studies should examine the metric equivalence of the SEMCD across other linguistic and sociodemographic groups (e.g., race/ethnicity, sex).

Automatic Hand Segmentation from Hand X-rays Using Minimized Training Samples and Machine Learning Models

Zilong Yang[1], Juan Shan[2], Carmine Guida[2], Jordan Blackadar[1], Tino Cheung[1], Jeffrey Driban[3], Timothy McAlindon[4] and **Ming Zhang**[1], [1]Wentworth Institute of Technology, Boston, MA, [2]Pace University, New York, NY, [3]Tufts Medical Center, Boston, MA, [4]Tufts Medical Center, Arlington, MA

SESSION INFORMATION
Session Date: Sunday, November 7, 2021
Session Title: Research Methodology Poster (0846–0854)
Session Type: Poster Session B
Session Time: 8:30AM–10:30AM

Background/Purpose: In many hand osteoarthritis (OA) studies (e.g., automatic Joint Space Width measuring), accurate hand segmentation is the first step towards making further analysis. However, it would be a difficult task to use only traditional image processing techniques due to inconsistencies like bands, rings, and low contrast X-rays (see Figure 1). To train a machine learning model to segment hand X-rays, one needs to set up a training set in which each hand X-ray should be manually delineated. To minimize the effort of manual delineation, we developed a novel iterative training strategy that requires only a small number of images to be manually segmented.

Methods: 3557 hand X-rays from the Osteoarthritis Initiative (OAI) were utilized in this study, where each X-ray contains one hand. We randomly separated the dataset into a training set with 3024 X-rays and a testing set with 533 X-rays, and the testing set was not exposed to the models during the training procedure. In round 1, we applied a traditional image segmentation algorithm on the training set and selected 132 good-quality results as a training set to train model 1. Round 2, we applied to model 1 to the training set with 3024 images and selected 25 of the worst predicted segmentations from the results. We manually segmented those 25 failed images and used them to train a new U-net model (model 2). In round 3, likewise, we applied to model 2 to the training set again and picked 11 failed segmentations from the results. We manually segmented those 11 failed cases and combined them with the 25 cases from round 2 to train a new model using a total of 36 training samples (model 3). In total, we only manually segmented 36 hand X-rays (25 in round 2 and 11 in round 3). To evaluate segmentation accuracy, two research as-

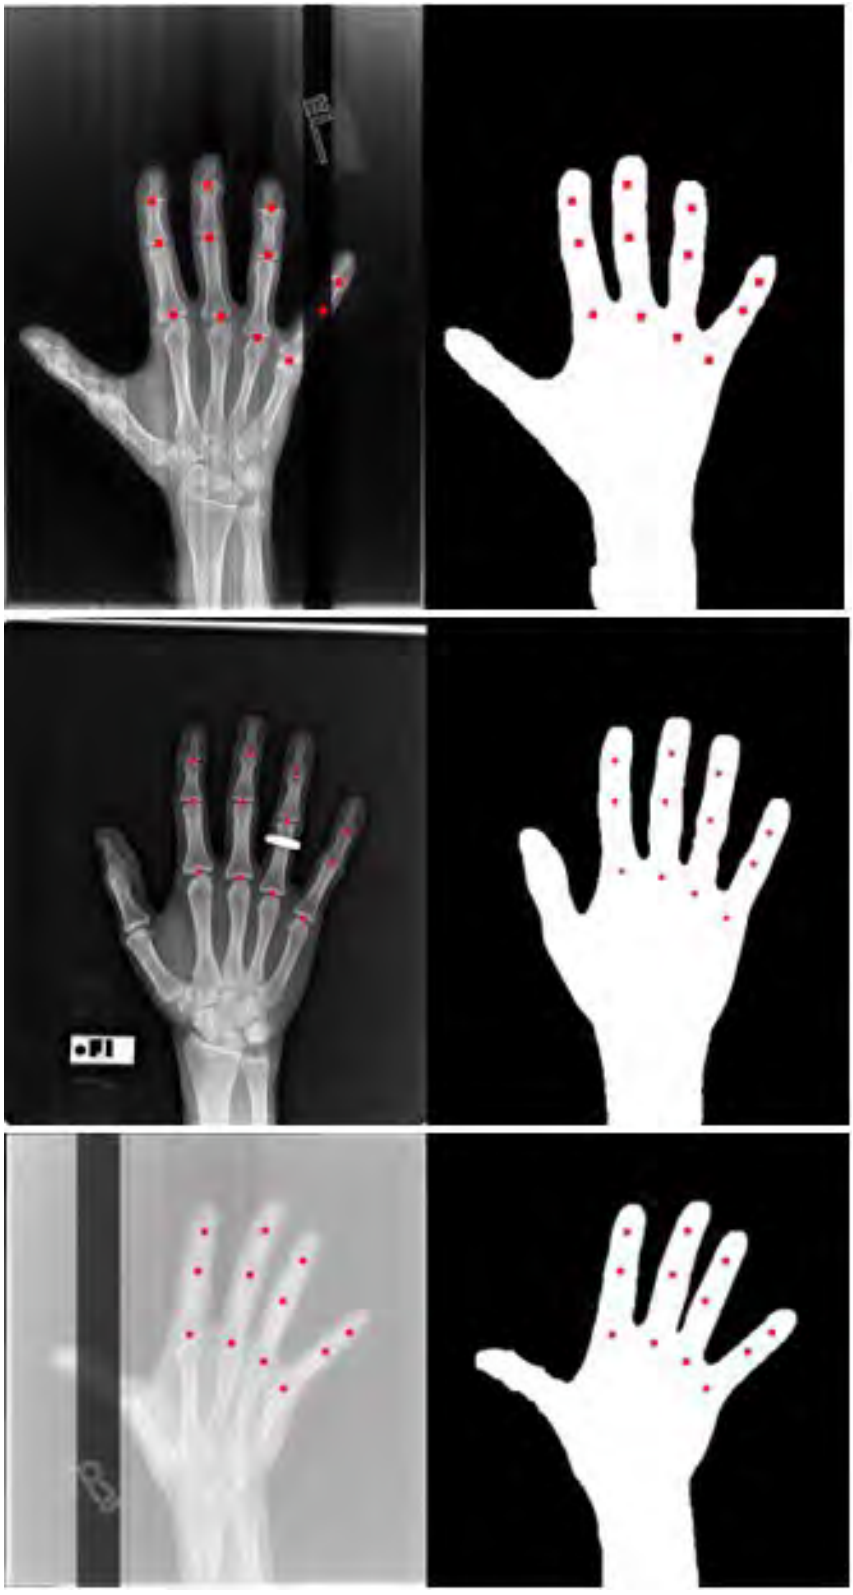

Figure 1. The first column contains challenge hand X-ray images with white bands, rings, and low contrast. The red dots are manual marks of 12 joint centers. The second column is the predicted hand masks by the machine learning model U-net (model 3).

Table 1. Hand segmentation accuracy

Model	# Training Samples	# Missing Joints / Total	Accuracy
Model 1	132	127/6396	98.01%
Model 2	25	24/6396	99.62%
Model 3	36	3/6396	99.95%

sistants manually marked the centers of 12 joints (excluding the thumb, Figure 1 red dots) on each of the 533 hands in the testing set. The reason that we used joint centers instead of segmenting the whole hand is to save labor. We evaluated the hand segmentation accuracy at the joint level: if a joint center is within the predicted hand mask, the joint is a match; otherwise, the joint is a miss. The overall accuracy of a model is equal to the number of matches divided by the number of total joints.

Results: Table 1 lists the accuracy for each model: model 1 performed the initial segmentation with the most training samples, but its accuracy was lowest; model 2 used only 25 training samples but improved the accuracy significantly; model 3 achieved the best accuracy (99.95%) with 36 training samples and only 3 joints out of 6396 joints were missed in the testing set.

Conclusion: Acquiring a large medical image dataset is a challenge in many studies and manually labeling is often a time-consuming procedure. In this paper, we proposed an iterative strategy to minimize the training samples that need to be manually labeled. In a dataset of 3557 hand X-rays, we only need to manually segment 36 images and achieved 99.95% accuracy for joint detection on the testing set. This strategy has potential usage in other medical image processing problems to save the manual labeling effort (e.g., knee cartilage segmentation, bone marrow lesion segmentation, etc.).

Myalgic Encephalomyelitis/Chronic Fatigue Syndrome: Creating a Foundation for Linking Patient Reported Outcomes Measures with the International Classification of Functioning, Disability and Health

Hannah Bailey[1], Ananya Vasudevan[1], Emily Hickey[2], **Aileen Ledingham**[3], Mary Slavin[1], Lewis Kazis[4] and Ronald Tompkins[5], [1]Boston University School of Public Health, Boston, MA, [2]University of Wisconsin, Madison, WI, [3]Boston University School of Public Health, Waltham, MA, [4]Boston University, Spaulding Hospital and Harvard Medical School, Boston, MA, [5]Harvard Medical School, Boston, MA

SESSION INFORMATION
Session Date: Sunday, November 7, 2021
Session Title: Research Methodology Poster (0846–0854)
Session Type: Poster Session B
Session Time: 8:30AM–10:30AM

Background/Purpose: Myalgic Encephalomyelitis/Chronic Fatigue Syndrome (ME/CFS) is a devastating multisystem chronic disease, estimated to affect 1.5 million adults in the United States. The disease is associated with immune, neurological, metabolic, cognitive and sleep impairments compounded principally by Post-Exertional Malaise (PEM) and dysautonomia associated with a pathological level of fatigue. Among people with ME/CFS, 70%

cannot work; 25% are home- or bed-bound, and recovery is rare. There are no FDA-approved drugs or treatments. Diagnosis of ME/CFS is challenging due to many changing and persistent symptoms and often relies on a diagnosis of exclusion. Rheumatologists are among the handful of clinicians who treat patients with ME/CFS.

The National Institutes of Health (NIH) identified 119 Common Data Elements (CDEs) for use in people with ME/CFS. However, most CDEs are not targeted specifically for those with ME/CFS. The World Health Organization (WHO) International Classification of Functioning, Disability and Health (ICF) provides a framework to understand CDE items. The aim of this study is to use the ICF to categorize ME/CFS CDE items administered as Patient Reported Outcome Measures (PROMs). This work will provide a foundation to select the most appropriate CDE assessments and guide future development of an advanced, psychometrically-sound symptom based Computerized Adaptive Test (CAT) to assist rheumatology professionals in the treatment of patients with ME/CFS.

Methods: We reviewed all CDEs and excluded those that: 1) are not PROMs; 2) provide participant socio-demographic characteristics and medical history only; 3) use visual or pictographic scales; or 4) are for pediatric patients only.

We applied ICF linking rules[1] to identify and code meaningful concepts for all items. Items were divided among five researchers for independent coding and codes were compared. Coding discrepancies were noted and discussed until a consensus was achieved (Table 1. ICF Coding Example).

Results: We identified 36 PROMs comprised of 944 items (Figure 1). All coded items fit into two ICF components: *(1) Body Function (b codes) and (2) Activity and Participation (d codes)*. Body Function codes were as follows: *Energy and drive* (most frequently used), 14.9% (n=210) of the 1413 total codes; *Sensation of pain* 14.7% (n=208); *Sleep*

Table 1. Methods example of linking ICF categories to PROM items

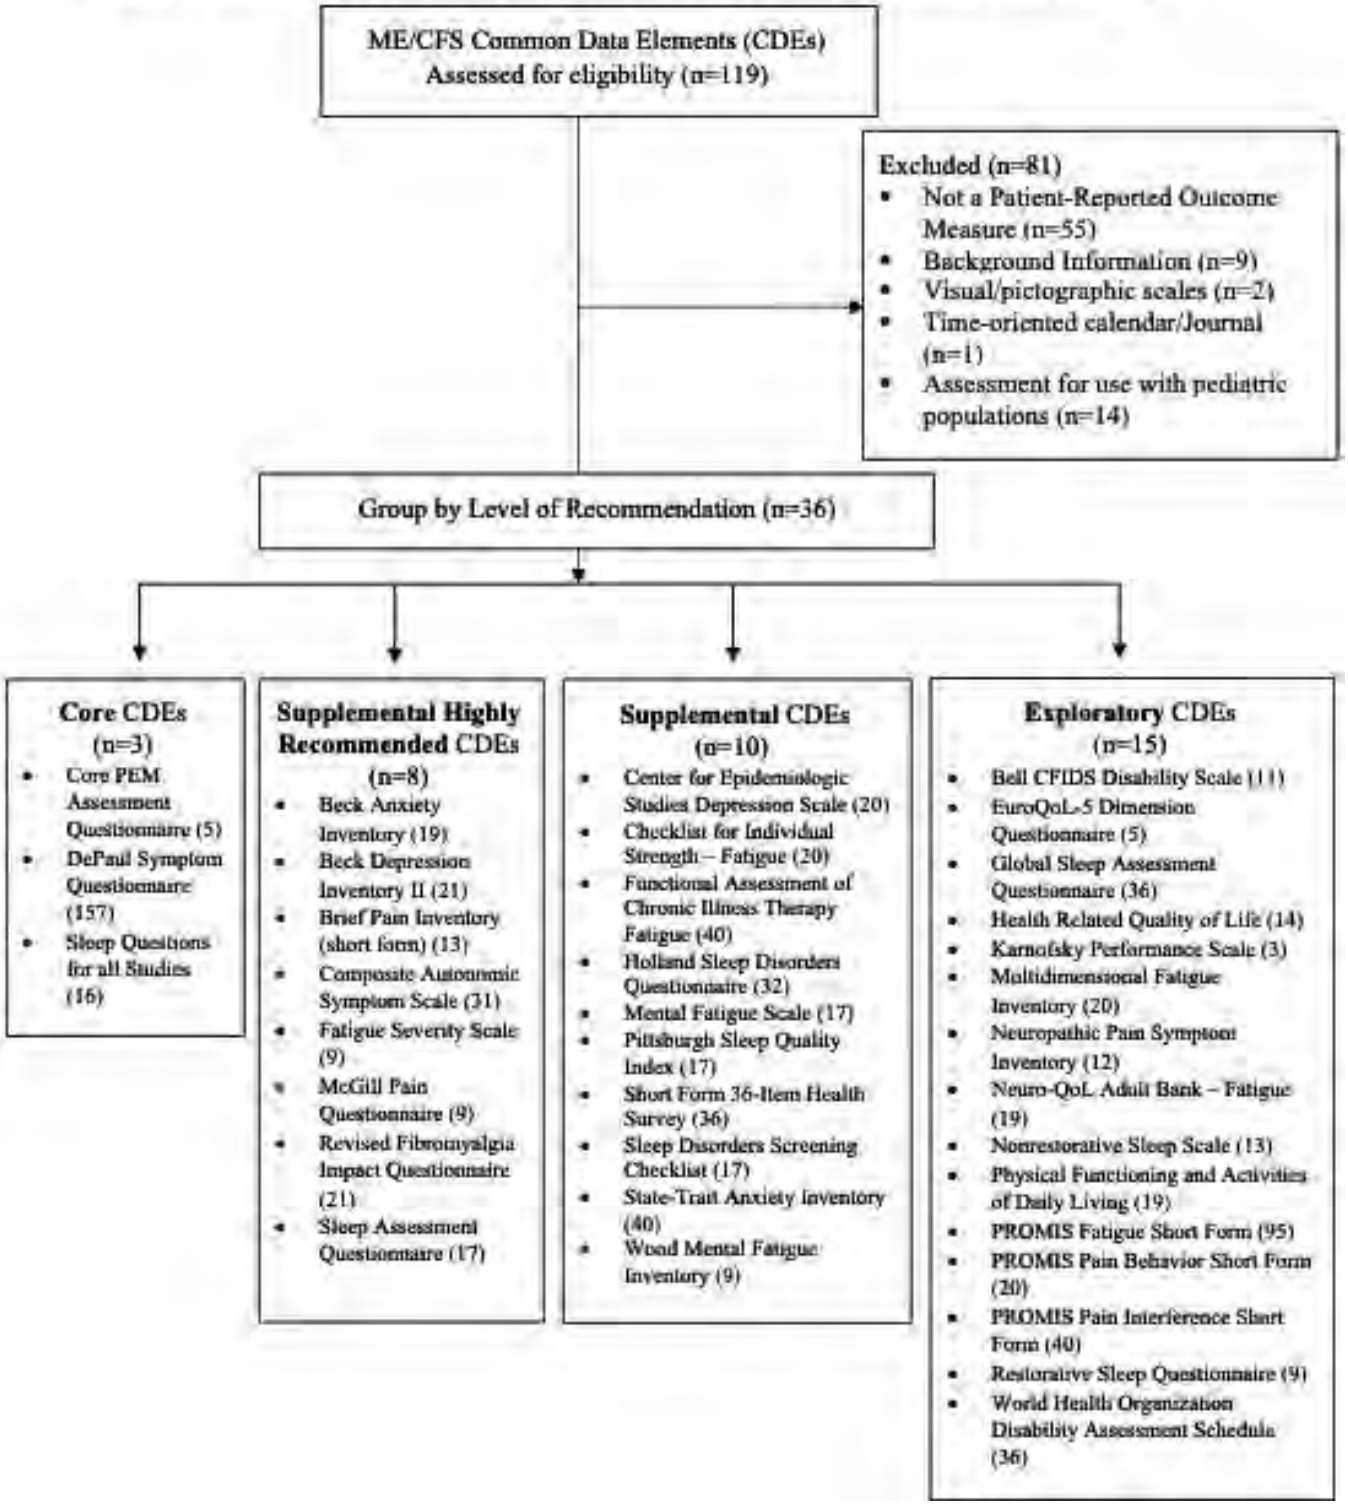
functions 11.9% (n=168); *Fatiguability* 11.5% (n=163); and *Emotional functions* 9.7% (n=137). Only 11.1% (n=157) of items were coded in the *Activity and Participation* component. Table 2 presents ICF codes for core ME/CFS symptoms and functions.

Figure 1. NIH ME/CFS Common Data Elements ICF Coding Inclusion Flow Diagram



Conclusion: NIH ME/CFS CDEs are comprised of items that assess key areas of *Body function*; however, relatively few items assess the impact of ME/CFS symptoms on *Activity and Participation*. Extreme limitation in the ability to engage in physical and cognitive activities is a hallmark of ME/CFS. Results demonstrate the value of using the ICF conceptual framework to examine item content to assist rheumatology professionals in selecting appropriate assessments for their patients and to inform the future development of item banks for psychometrically-sound assessments.

Abstract Number: 0850

Regression Methods for Modeling Western Ontario and McMaster Universities Arthritis Index (WOMAC) Pain Scores for Early Stage Knee Osteoarthritis

Benjamin Sweigart and Michael LaValley, Boston University School of Public Health, Boston, MA

SESSION INFORMATION
Session Date: Sunday, November 7, 2021
Session Title: Research Methodology Poster (0846–0854)
Session Type: Poster Session B
Session Time: 8:30AM–10:30AM

Background/Purpose: The Western Ontario and McMaster Universities Arthritis Index (WOMAC) pain score [range 0-20] is a common outcome measure for clinical trials and observational studies in knee osteoarthritis (OA). However, for early stage OA, the distribution of WOMAC pain is not symmetric, with many people reporting pain scores of 0, and very few high scores. Modeling non-symmetric outcomes with standard linear regression or t-tests can yield inaccurate estimates of association and prediction. We sought to determine whether alternative regression methods are better for modeling WOMAC pain scores for samples in early stage OA.

Methods: We analyzed WOMAC pain scores for the right knees of participants at the baseline exam of the Osteoarthritis Initiative (OAI) incidence cohort, which includes subjects at risk for symptomatic OA. We modeled the pain scores by fitting the following distributions to all participants: normal, log-normal, beta, and gamma. The log-normal and gamma distributions require values to be >0, and the beta distribution requires values to be >0 and < 1. To accommodate these restrictions, pain scores were transformed by adding 1 and dividing by 22 to range from 0.045 to 0.955. We assessed the best fits of distributions to the pain values visually, and with chi-square statistics comparing observed to expected counts after dividing the range into 10 intervals. We performed multivariable log-normal, beta and gamma regression including sex, age, and BMI as predictors of transformed pain values, and used the best fitting models to create 10,000 simulated datasets with pain score and predictor values distributed similarly to the OAI incidence cohort. We then fit log-normal, beta, gamma, and robust regression models to each simulated dataset with transformed pain as the outcome and age, sex and BMI as predictors. To measure regression accuracy and precision, we used the predicted mean on the original 0-20 WOMAC pain scale for each sex along with the 95% confidence interval coverage, average confidence interval width, bias, and mean square error of the predicted means.

Results: We included data from 3,282 individuals, 41% of whom were male, with an average age of 61.3 (SD 9.2) and BMI of 28.1 (SD 4.6). The median WOMAC pain score was 1.0 (interquartile range 0.0, 3.0). The normal and log-normal distributions were poor fits to the pain score data, while the beta and gamma distributions were better fits, both visually and from chi-square statistics (Figure 1). When simulated datasets were created using parameters from the beta regression, all of the regression models slightly under-predicted the true mean of WOMAC pain score for both males and females, but the beta regression resulted in highest coverage, shortest confidence intervals, and lowest mean square error (Table 1). Results were similar when simulated datasets were created using parameters from log-normal or gamma regressions.

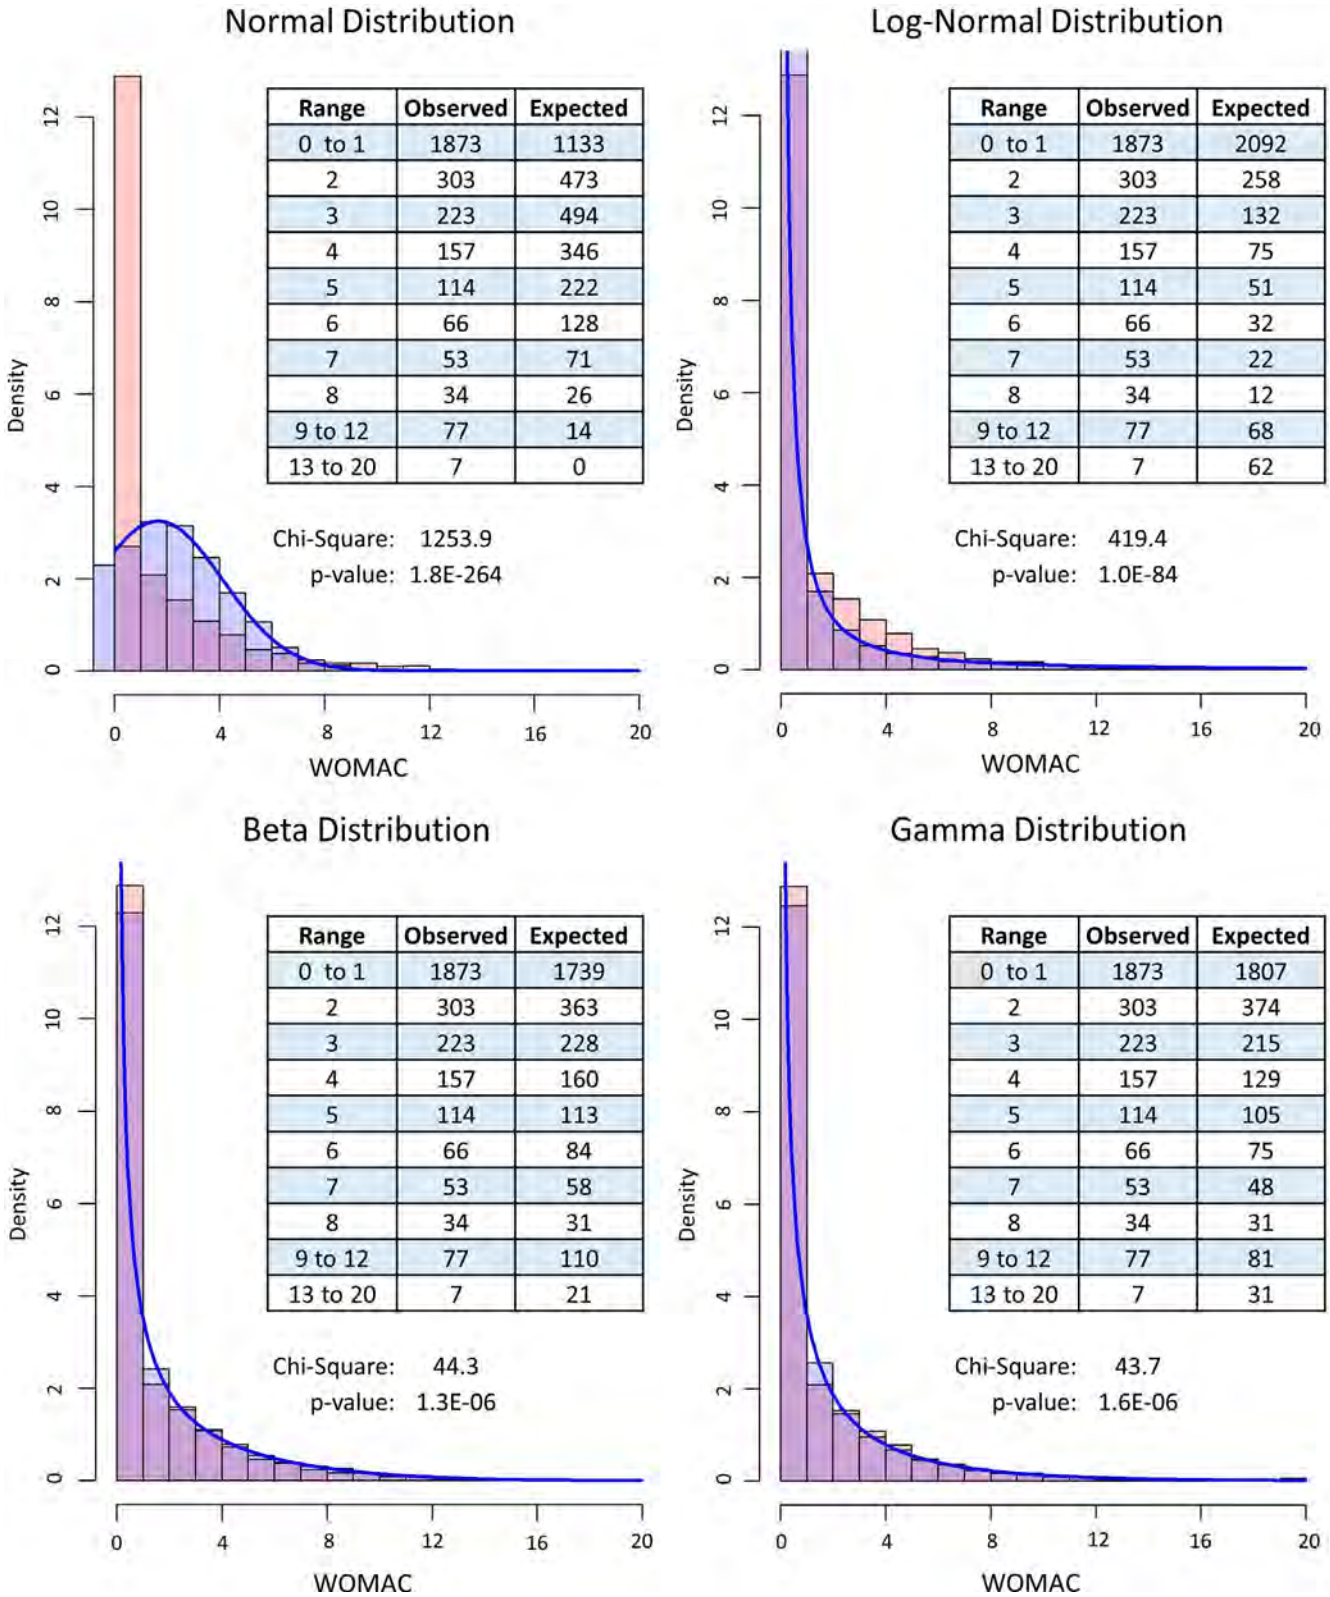

Figure 1. Goodness of fit of statistical distributions to the OAI Incidence Cohort WOMAC pain scores. Red = Actual OAI data; Blue = Fitted data; Purple = Overlap.

Table 1. Simulation results for predicted WOMAC pain score [0-20]: values for males and females, aged 60 years, with BMI 28 kg/m^2. Data were simulated from beta, gamma, and log-normal regression models and each simulated data set contained 3,282 observations. Results based on 10,000 simulations.

Data Generation Model	Regression Analysis Model	Males					Females

	Robust	**0.95**	94%	1.6	**-0.06**	0.39	1.08	93%	1.7	-0.25	0.35

Conclusion: Standard methods used to analyze WOMAC pain score data rely on assumed distributions that may poorly fit the data. For creating regression models to predict the WOMAC pain score, beta regression may have better statistical properties than either normal or log-normal regression.

SESSION INFORMATION
Session Date: Sunday, November 7, 2021
Session Title: Research Methodology Poster (0846–0854)
Session Type: Poster Session B
Session Time: 8:30AM–10:30AM

Background/Purpose: Radiographic osteoarthritis (rOA) and joint symptoms at the knee and hip are predictors of mortality. However, questions remain about the nature of the relationship and if there are other predictors, or combinations of predictors, that contribute to increased mortality. Since non-steroidal anti-inflammatory drugs (NSAIDs) have been shown to increase risk of death and are widely used by those with OA, we applied novel statistical methods to identify a set of predictors of mortality, and whether these predictors interact with NSAID use

Methods: Data were from 4,156 participants in the Johnston County Osteoarthritis Project (JoCoOA), a longitudinal community-based cohort of Black and White men and women aged ≥45 years. Vital status was assessed using the National Death Index records to capture date of death through December 2015. Clinical exams, radiographs and questionnaires were completed at baseline and at up to 3 follow-up time points. Socio-demographic and clinical characteristics, including comorbidities and joint symptoms, were considered as predictors and NSAID use was considered as an effect modifier. Multiple imputation was used for missing data.

We applied a time-varying covariate stratified cox model with recursive feature elimination (RFE). RFE searches for a subset of predictors starting with a full model including all predictors in the training dataset, and successively removing one at a time. Our model initially included 57 predictors, with NSAID use entered as an interaction term with all other predictors. A model with the smallest change in log-likelihood from the full model was selected and that predictor, along with its interaction with NSAID use, was dropped. This process was repeated until no predictors remained in the model. Using a plot of the log-likelihoods after each elimination, the final model was selected based on an inflection point prior to a notable decrease in log-likelihood (Figure 1). All observations were stratified by the time point, and hazard ratios (HR) and 95% confidence intervals (CI) were estimated.

Results: Mean age of the participants at baseline was 61 years, 63% were female and 66% were white (Table 1). More than 34% of participants reported taking NSAIDs at baseline, which increased to 51%, 67%, and 70% at the first, second, and third follow-up, respectively, over which time 1,812 deaths occurred.

In the RFE model, we found that after iterative predictor elimination, 13 predictors showed an important contribution to excess death (Figure 1, Table 2). The strongest contributors were current smoking status, cancer, diabetes and male sex. Left knee pain was associated with a 19% increased HR. We observed an NSAID-modified association with right knee injury where those with a knee injury and no NSAID use had a 30% lower hazard of mortality, whereas little association was observed for right knee injury among those who used NSAIDs.

4, n (%)	25 (0.6)	18 (0.7)	5 (0.3)	6 (1.1)
Replacement, n (%)	21 (0.5)	27 (1.1)	43 (3.0)	17 (3.1)

FU=Follow-up; SD=Standard deviation; BMI=body mass index NSAIDs=non-steroidal anti-inflammatory drugs; KL=Kellgren-Lawrence

Conclusion: We show that an application of a RFE algorithm is useful to both select the important predictors, and to quantify predictive validity, on excess mortality. The model demonstrated good performance in selecting a set of predictors and identifying characteristics most important in premature death that can be explored in future analyses.

Table 2. Final prediction model

Predictor	HR (95% CI)

Bone Marrow Lesion Segmentation Using Synthetic Data and Deep Learning Models

Barak Michaely[1], **Ming Zhang**[2] and Juan Shan[1], [1]Pace University, New York, NY, [2]Wentworth Institute of Technology, Boston, MA

SESSION INFORMATION
Session Date: Sunday, November 7, 2021
Session Title: Research Methodology Poster (0846–0854)
Session Type: Poster Session B
Session Time: 8:30AM–10:30AM

Background/Purpose: Bone marrow lesions (BML) are indicators for knee osteoarthritis (OA) and can be detected from magnetic resonance imaging (MRI). Due to the small size, low contrast, and various positions that BML may occur, it is challenging to automatically segment BMLs. Besides, not all patients with OA have BML, and for those patients with BML, not every slice has BML. The limited data becomes an obstacle to train machine learning models. In this work, we developed a novel strategy to synthesize MRI images with BML and trained deep learning models using the augmented dataset.

Methods: 300 cases from the Osteoarthritis Initiative (OAI) database were utilized in this study, where each case has sagittal intermediate weighted fat-suppressed (IWFS) sequence that is composed of a sequence of 36 MRI images. The BMLs in the dataset were manually delineated by domain experts as ground truth. We randomly separated the dataset into training, validation, and testing sets with 210/45/45 cases, respectively. To generate synthetic images with BML, we used images from the training set only. Three strategies were proposed. In strategy 1, for each image with BML in the training set, we selected a clean image without BML from the training set. We cropped out the BML from the original image and overlaid it on the clean image. To decide where to overlay it, we first calculated the center of the femur bone, the angle to the vertical direction, and the projected point on the bone edge in the original image, as shown in Figure 1. We also calculated the distance from the center to the lesion, and from the center to the bone

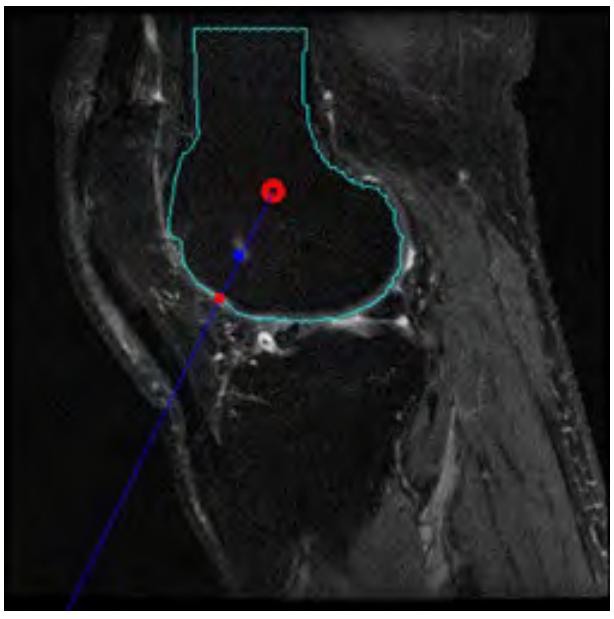

Figure 1. Bone center and projection on the edge (red point). BML is marked by the blue point.

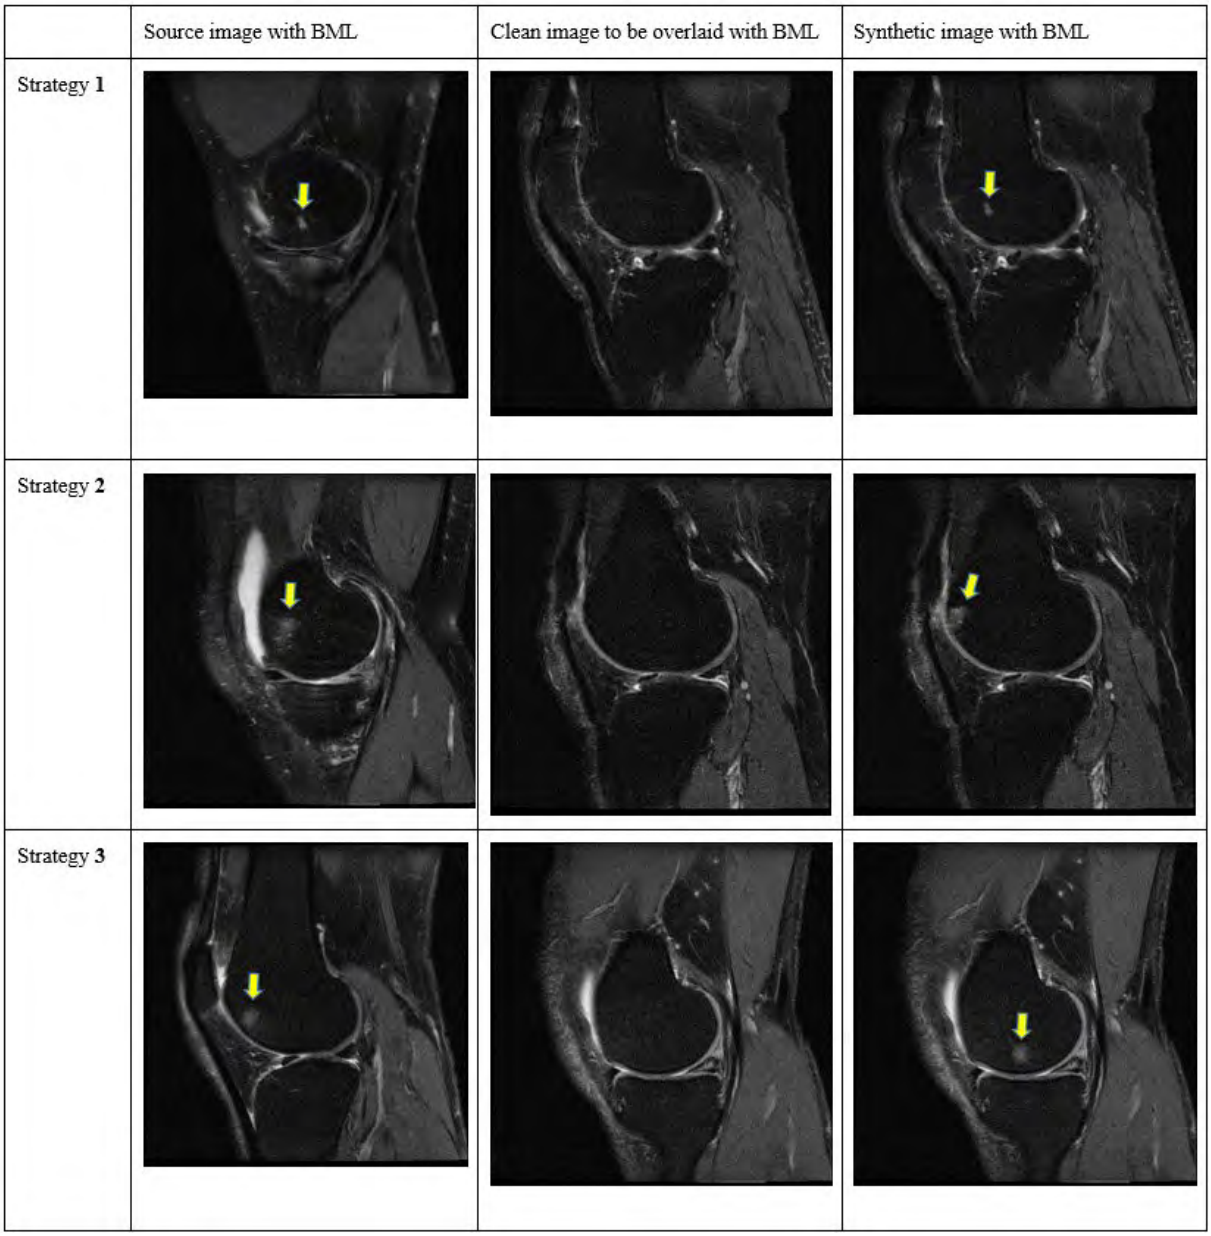

Figure 2. Example images for each strategy (the highlighted arrows mark the BML location).

Table 1. BML segmentation performance on the testing set using different augmentation strategies.

	Dice Coefficient (average)	Similarity (average)
Baseline Data (Original Images with BML)	0.4029	0.2998
Baseline Data + Synthetic Data from Strategy 1	0.5190	0.3963
Baseline Data + Synthetic Data from Strategy 2	**0.5192**	**0.3862**
Baseline Data + Synthetic Data from Strategy 3	0.4378	0.3274

edge. Then we applied the same distance percentage and same angle when overlaying the BML to the clean image. In strategy 2, everything is the same as strategy 1 except a fixed distance percentage was used to make sure the lesion is close to the bone boundary. In strategy 3, we introduced variations about the angle. A random angle from a range of -20 to +20 degrees from the vertical direction of the bone was applied when overlaying the BML. Figure 2 shows examples of the three strategies. After data generation, we first trained a deep learning model, called U-net, using the original BML images from the training set, as our baseline. Then for each strategy, a separate U-net model was trained, using the combination of original BML images plus the synthetic images.

Results: We reported the Dice coefficient and Similarity for each model in Table 1. An interesting finding is that for all the strategies, using 50% of the synthetic data produced higher accuracy than using 100% of the synthetic data. Therefore, we presented the results of using 50% of the synthetic data for each strategy. As Table 1 shows, the best accuracy was achieved by strategy 2, with more than 0.1 improvement in Dice and around 0.1 improvement in Similarity.

Conclusion: We developed an effective synthetic image generation method for BML segmentation. The accuracy was improved after adding the synthetic images to the training set. Future work could focus on refining the strategies for more realistic images and find the balanced combination between original images and synthetic images.

SESSION INFORMATION
Session Date: Sunday, November 7, 2021
Session Title: Research Methodology Poster (0846–0854)
Session Type: Poster Session B
Session Time: 8:30AM–10:30AM

Background/Purpose: As we enter the big data revolution, comprehensive informatics solutions are essential to realising precision medicine for rheumatic and other chronic disease patients, especially for curating high-quality,

large-scale and longitudinal biospecimen and linked data collections. In establishing the Australian Arthritis and Autoimmune Biobank Collaborative (A3BC), we sought to develop a low-cost, nation-scale data management system capable of managing our multi-site longitudinal biobank-registry and its complex biobank and data requirements. This included broad life-course data from adults and children across clinical/phenotypic, biological, patient-reported

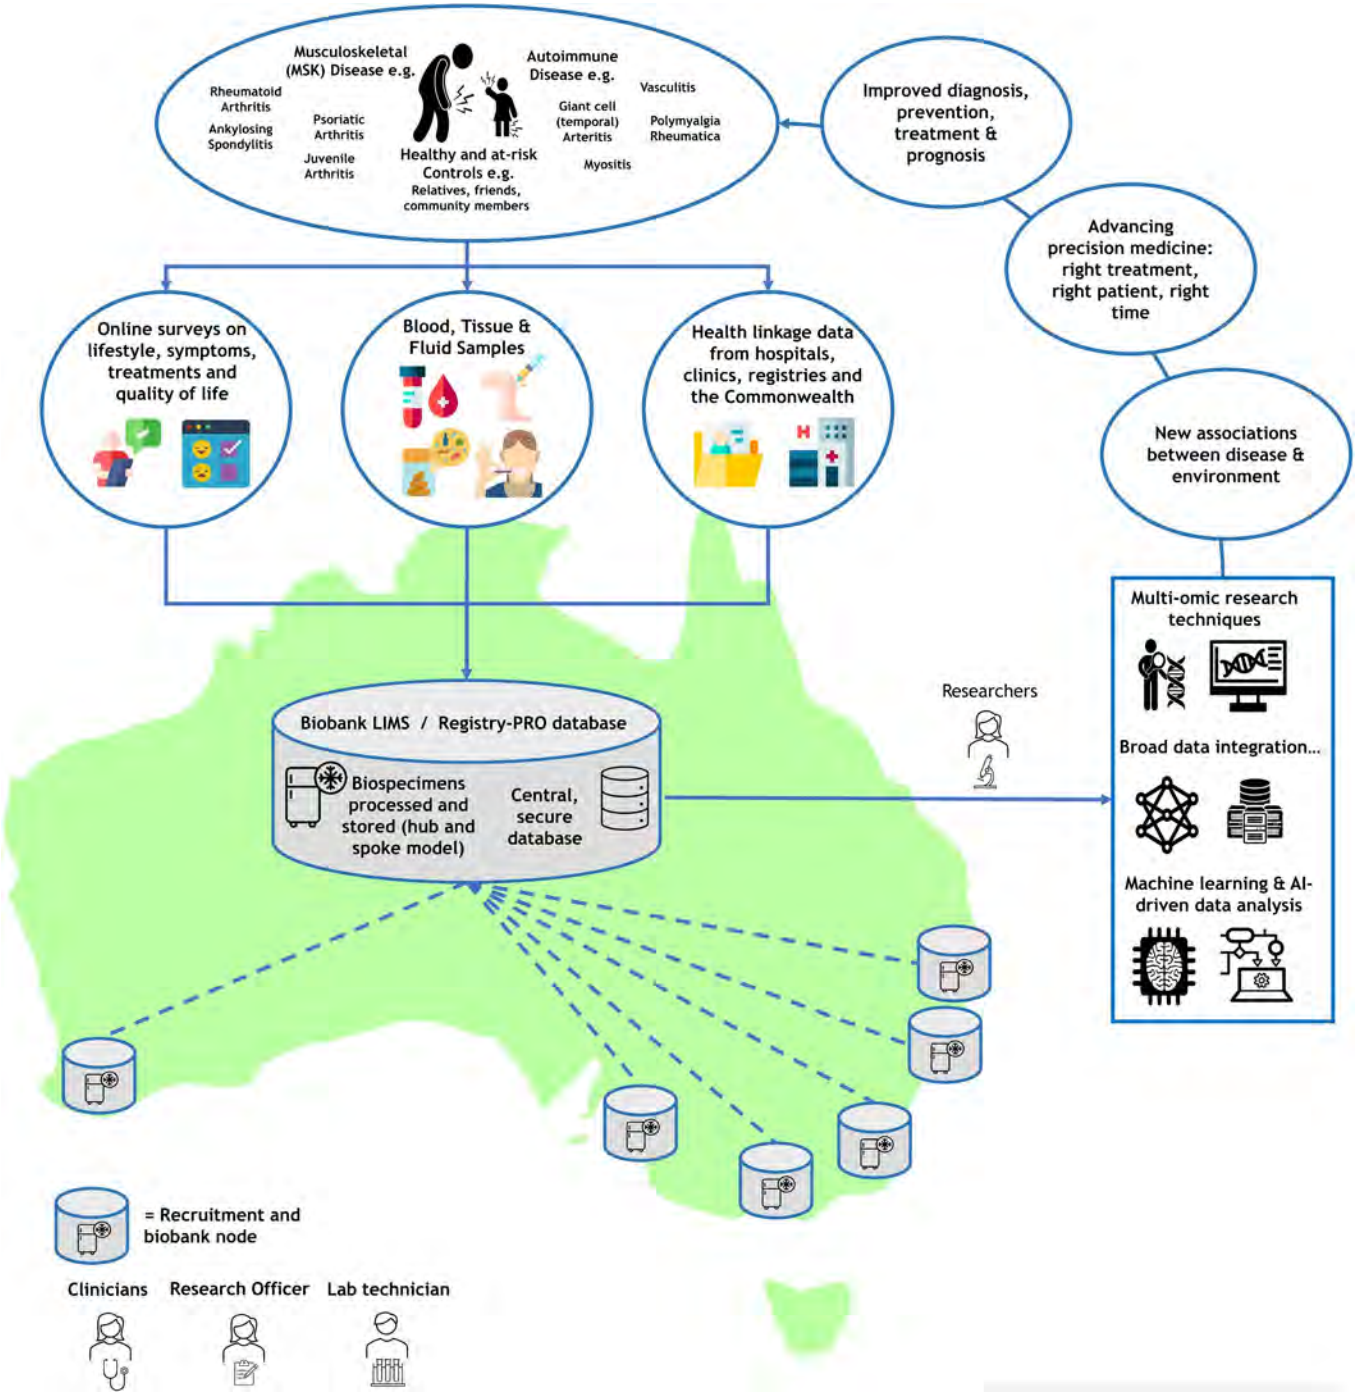

Figure 1. The A3BC is a national arthritis and autoimmune disease biobank-registry network developing state-of-the-art data collection, data linkage and big data analytics (incl. machine-learning) capabilities for better enabling and translating research discovery. It integrates a broad range of 'omic' (genomic, microbiomic etc), patient-reported (demographics, treatment, quality of life, diet etc), medical and administrative health data from people adults and children across Australia. Collected data and biological samples are deidentified and made available for ethics-approved research into understanding the causes, improving treatments or preventions, and finding cures for arthritis and autoimmune conditions.

and administrative health data domains, collected to enable holistic multidisciplinary research towards improved outcomes for people living with arthritis and autoimmune conditions (Figure 1).

Methods: We assessed several international commercial and non-profit software platforms using standardised system requirement criteria and follow-up interviews. Vendor compliance scoring was prioritised to meeting our project-critical requirements. Consumer / end-user co-design was integral to refining our system requirements for optimised adoption. Customisation of the selected software solution was performed to optimise field auto-population between participant timepoints and forms, using external modules that do not impact core code. Institutional and independent testing was used to ensure data security.

Results: We selected the widely used research web application, Research Electronic Data Capture (REDCap), which is "free" for non-profit REDCap Consortium members. REDCap is highly configurable and customisable to a variety of biobank and registry needs and can be developed/ maintained by end-users with modest IT skill, time and cost. We created a secure, comprehensive participant-centric biobank-registry database that includes best practice data security measures (incl login for multi-site access using academic and government user credentials), permission-to-contact and dynamic itemised e-consent (Figure 2A), a complete chain of custody from consent to biospecimen/data collection to publication, complex longitudinal patient-reported surveys, a fully integrated biobanking workflow (Figure 2B), disease-specific case report forms (Figure 2C), integration of record-level extracted/ linked participant data, significant form auto-population for streamlined data capture, and native dashboards for operational visualisations. The system (Figure 3) has the capacity to enrol participants with a range of diagnoses as well as healthy or at-risk controls (e.g. first degree relatives).

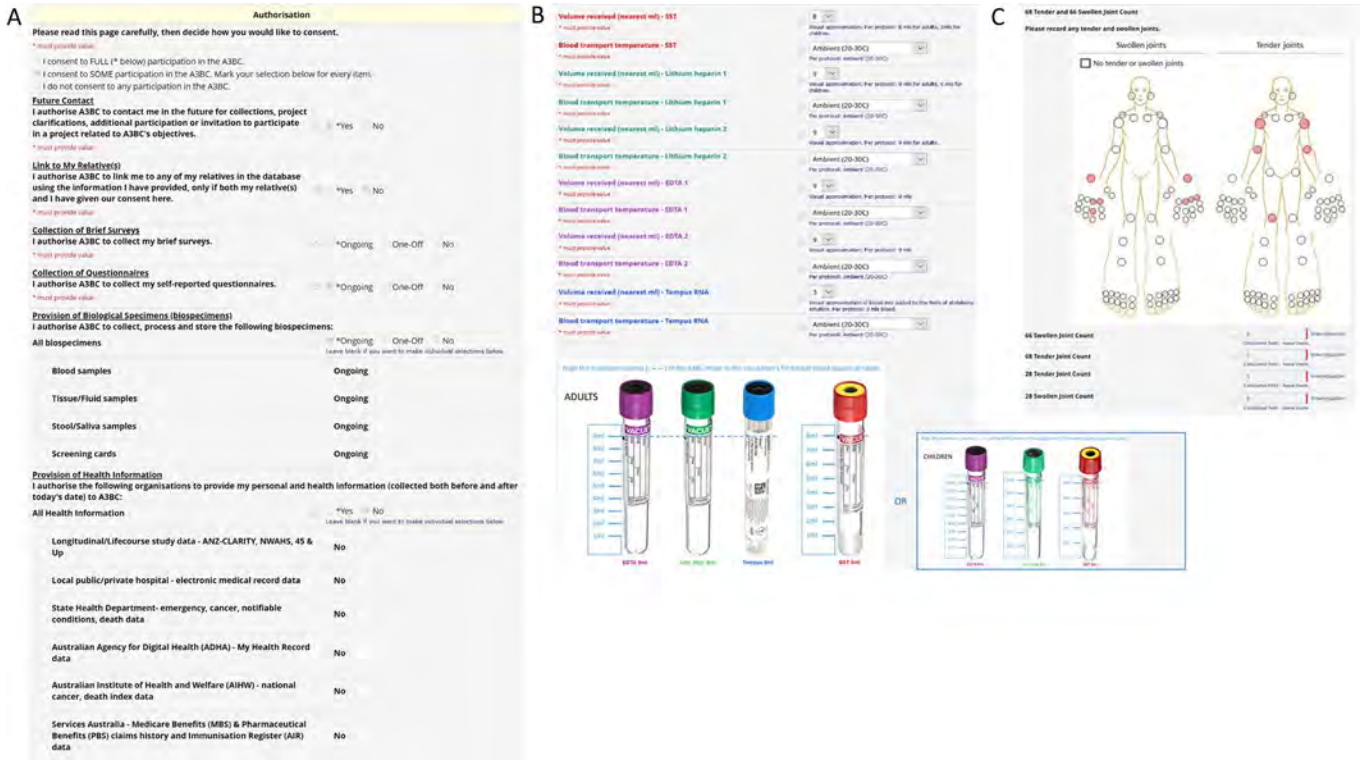

Figure 2. (A) In line with global trends in clinical research we created a Permission to Contact (PTC) and dynamic electronic consent (eConsent) strategy to maximise patient engagement in our biobank-registry. (B) We made extensive use of REDCap's action tag, smart variable and external module functionalities for defining auto-population and branching logic rules to dramatically reduce user effort in recording pre-analytical variables, an important aspect of biobank quality management and tracking for downstream applications. (C) An interactive 66 swollen / 68 tender joint count data collection tool was designed and implemented in our electronic case report form (eCRF) using the REDCap Image Map external module. Joint map image use permission granted by the Group for Research and Assessment of Psoriasis and Psoriatic Arthritis (GRAPPA)-Outcome Measures in Rheumatology (OMERACT).

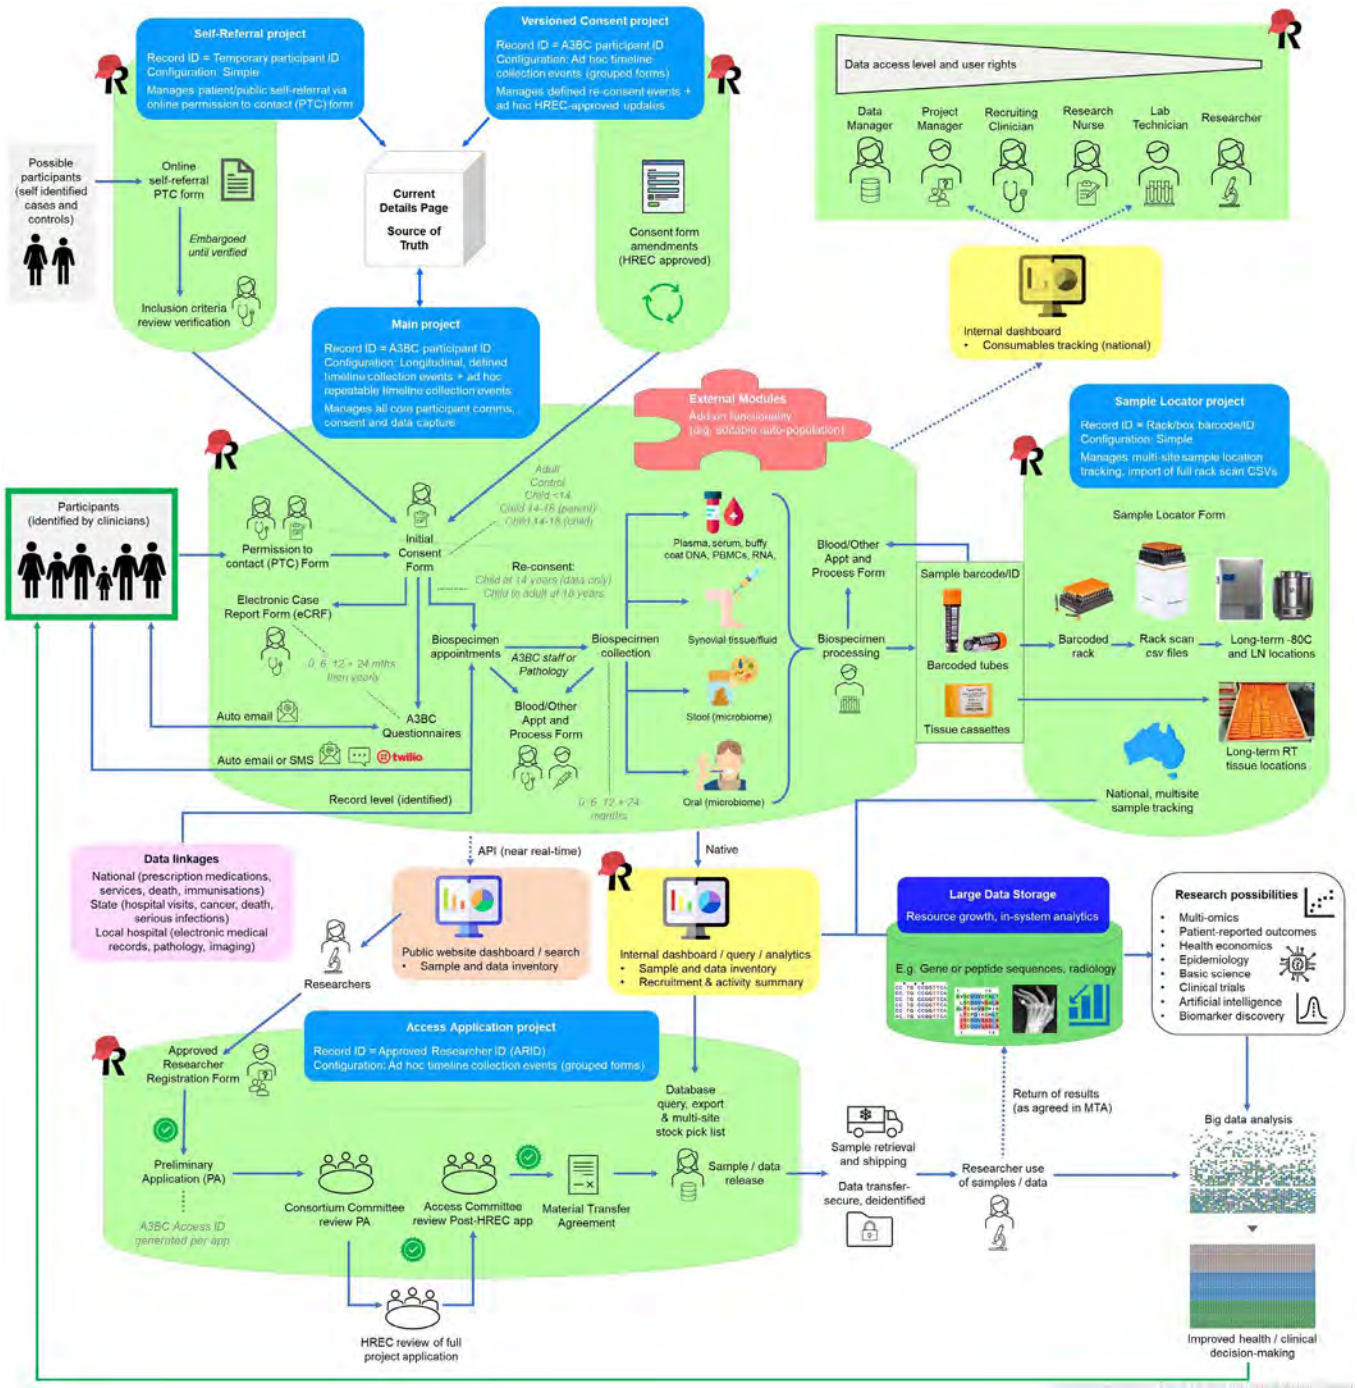

Figure 3. To enable both participant- and sample-centric functionalities, the system was designed as five linked REDCap projects, each representing a relational data table. Several unique linkage keys are used across the A3BC database tables to ensure a complete chain of custody is maintained from the point of collection through to storage, transfer, return of results and publication. Of note, we customised a 'Current Details' form as our central source of truth for participant contact details, consent status and collected samples. This form uses an underlying external module for hierarchical field auto-population to pull changes in specified fields from different locations across the Main project into a single location.

Conclusion: We utilised REDCap to develop an economical, easily-adaptable and sustainable model and recommend it for prospective chronic disease biobanks or biobank-registry projects supporting research into disease prediction, targeted treatments and prevention strategies.

Session Date: Sunday, November 7, 2021
Session Title: Research Methodology Poster (0846–0854)
Session Type: Poster Session B
Session Time: 8:30AM–10:30AM

Background/Purpose: Fatigue is a prevalent, debilitating symptom across chronic diseases that is difficult to treat and negatively impacts patients' quality of life. Patients with rheumatologic diseases, such as systemic sclerosis (SSc), report high levels of fatigue. The 29-item Fatigue Assessment Instrument (FAI) is an expanded version of the 9-item Fatigue Severity Scale (FSS). The FAI is multidimensional and yields 4 subscales measuring different components of fatigue (global severity, situation specific, psychological consequences, responds to rest/sleep), while the FSS is unidimensional and has been more widely used to assess fatigue in chronic disease populations. However, there have been few psychometric studies of the FAI and FSS in SSc, and structural validity has yet to be assessed. The present study examined the previously established 1-factor structure of the FSS and the 4-factor structure of the FAI in an SSc sample.

Methods: SSc patients (*N* = 390; 84.1% female; 59.0% diffuse SSc; 52.1% White, 26.2% Hispanic, 17.7% Black) were sampled from the *G*enetics versus *EN*vironment *I*n *S*cleroderma *O*utcome *S*tudy (GENISOS). GENISOS is a

multicenter, prospective cohort study of early SSc patients based in Texas. All patients fulfilled the ACR/EULAR classification criteria for SSc and had disease duration < 5 years at enrollment. Confirmatory factor analysis was used to assess the 1-factor structure of the FSS and the 4-factor structure of the FAI. Cronbach's coefficient alpha and McDonald's omega were used to evaluate internal consistency reliability.

Results: The 1-factor model of fatigue demonstrated good model fit for the FSS based on 2 indices (Comparative Fit Index [CFI] = .96, Standardized Root Mean Residual [SRMR] = .04). The Root Mean Square Error of Approximation (RMSEA) indicated slightly less than acceptable model fit (RMSEA = .09). All standardized factor loadings for items were statistically significant (all *p*s < .001), with values ranging from .338 to .842. The 4-factor model of fatigue demonstrated acceptable model fit for the FAI based on 2 indices (SRMR = .07, RMSEA = .08). However, the Comparative Fit Index (CFI) indicated less than acceptable model fit (CFI = .86). All standardized factor loadings for items were statistically significant (all *p*s < .001), with values ranging from .23 to .82. The FSS (α = .89, ω = .90) and the global fatigue severity subscale of the FAI had adequate internal consistency reliability (α = .92, ω = .92). The other 3 FAI subscales had Cronbach's coefficient alpha and McDonald's omega values ranging from .62 to .69.

Conclusion: Findings provided support for the expected factor structure of both the FSS and the FAI. However, given the superior model fit of the FSS, the lower internal consistency reliability of 3 subscales of the FAI, and that only 22 of the 29 items on the FAI are scored, the FSS is recommended for use as a general, more efficient measure of fatigue in SSc patients.

Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster II: Manifestations (0855–0896)
Session Type: Poster Session B
Session Time: 8:30AM–10:30AM

Background/Purpose: To date, the prevalence and prognosis of coronary artery disease (CAD) according to the coronary calcium score (CCS) and coronary artery calcification (CAC) using coronary computed tomography in patients with rheumatic diseases, including systemic lupus erythematosus (SLE), have been investigated in various studies, but with conflicting results. The latest American Heart Association and American College of Cardiology (AHA/ACC) guidelines for the primary prevention of atherosclerotic cardiovascular disease (CVD) permit the CAC score to be used in intermediate-risk patients, in whom additional individual risk-enhancing clinical factors such as chronic inflammatory disease, such as SLE are present, if the risk level is uncertain.

Table 1. Characteristics of the studies included

Author and publication year	N (SLE/Controls)	Type of controls	Ethnicity SLE%/Controls %	Type of CT scanner
Asanuma 2003	65/69	Age, sex and race-matched controls	Caucasian 72/75	EBCT

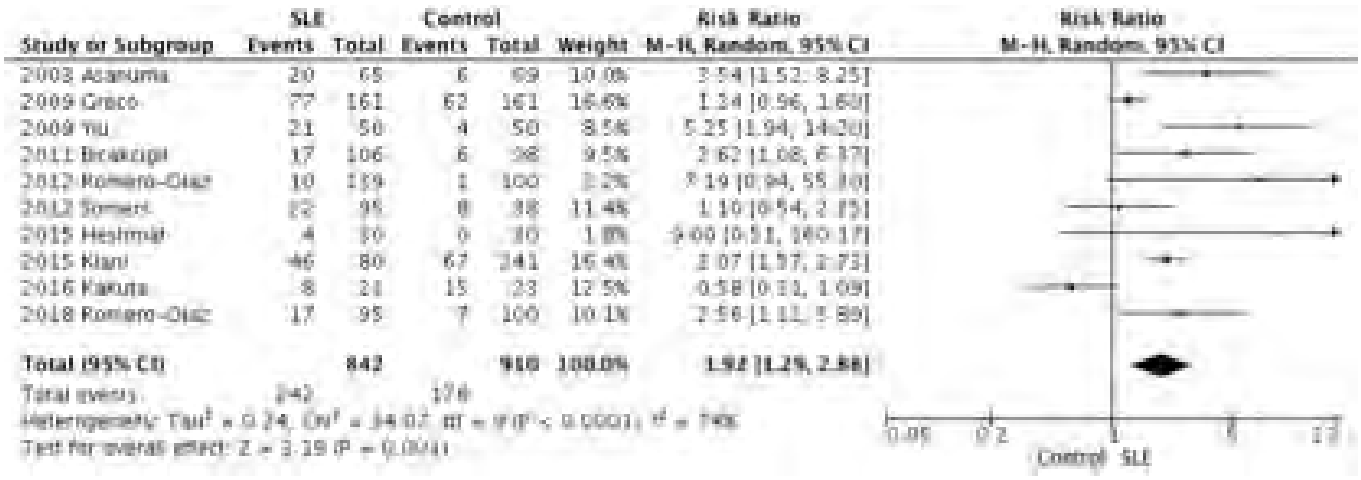
Stojan 2020	72/100	Not matched controls	Caucasians 70.8/71.3 African American 23.6/5.3	MDCT

EBCT: electron beam computed tomography; MDCT: multi-detector computed tomography; NA: not available.



Meta-analysis of the weighted mean differences (WMD) of coronary calcium score in patients with SLE compared to controls.

The aim of this systematic review and meta-analysis was to synthesize the evidence on this topic.

Methods: Relevant literature was identified and evaluated from inception until January 2021 through multiple search strategies on PubMed, Embase, Web of Science and Cochrane library. Cross-sectional or cohort (baseline data) studies reporting CAC prevalence and the extent of CAC identified by the CCS were included. Data extracted from eligible studies were used to calculate estimated effect sizes (ESs) and 95% confidence intervals (95%CI) and weighted mean differences (WMD) with 95% CI (PROSPERO registration number: CRD42021228710).

Results: The search retrieved 80 articles, of which 23 were eligible for inclusion. For the CAC prevalence, 10 studies were included (842 SLE patients and 910 controls) and the pooled prevalence of the random effect size was 28.7% (95%CI 25.7-31.9%) for SLE patients and 19.3% (95%CI 16.2-21.4%) in controls (RR 1.92, 95%CI 1.3 to 2.9; p< 0.0001) with substantial heterogeneity (I^2= 74%, p < 0.0001) (Fig 1) and there was no significant increase in the WMD for CCS (MD= 0.32, 95%CI -5.55 to 6.20, p= 0.91 and I2= 50%, p= 0.06) compared with controls (Fig 2), using data from 7 studies. Limited evidence suggests that patients with SLE had more multivessel CAD. Greater organ damage was associated with a higher CCS. Glucocorticoid use was associated with both prevalence or progression in CAC. According to two studies, coronary computed tomographic angiography showed the calcified and non-calcified plaque burden were increased in SLE patients compared with controls.

Conclusion: In patients with SLE, asymptomatic CAD by CAC is more prevalent and shows more multivessel disease compared with controls without lupus. However, the extent of CAC was not increased in SLE patients.

Abstract Number: 0856

Identifying COVID-19 Infection Rates and Outcomes in Patients with Systemic Lupus Erythematosus

Alexander Hall[1], Michael Trevisonno[1], Elizabeth Murray[1], Omoakhe Tisor[1], Emily Stanford[1], Jacob Gaines[1], Noor Anvery[1] and Ellen Ginzler[2], [1]SUNY Downstate Health Sciences University College of Medicine, Brooklyn, NY, [2]SUNY Downstate Health Sciences University, Brooklyn, NY

SESSION INFORMATION
Session Date: Sunday, November 7, 2021
Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster II: Manifestations (0855–0896)
Session Type: Poster Session B
Session Time: 8:30AM–10:30AM

Background/Purpose: The risk of COVID-19 infection among patients with Systemic Lupus Erythematosus (SLE) is poorly understood. Patients with SLE often take medications which modulate the immune system, and some were of interest as possible therapies for COVID-19. It is not fully understood if taking these medications may be associated with an increased or decreased risk of contracting COVID-19. This survey sought to investigate the rate of COVID-19 infection among our patients with SLE, identify disease severity among infected patients, and identify any correlation between ongoing treatment and the diagnosis of COVID-19.

Methods: We identified all patients with SLE seen in the Rheumatology clinic between January 2018 and March 2020. Patients were contacted via telephone from June 2020 through August 2020 to complete a questionnaire. Data were collected by chart review and by a telephone questionnaire. We recorded data on patient demographics, medication regimen, COVID-19 diagnosis and complications, and social distancing practices. A logistic regression was performed to identify possible risk factors for being diagnosed with COVID-19.

Results: 245 patients with SLE were identified. 129 (52%) completed the telephone questionnaire. The COVID-19 status was known for 137 patients, either through chart review or by the telephone survey. The most commonly used medications were hydroxychloroquine (82.2%), prednisone (45.7%), and mycophenolate mofetil (32.6%).14 (10.2%) patients were diagnosed with COVID-19. Among these patients, 4 were hospitalized, 2 received intensive care-unit level of care, and 3 died. There were no deaths attributed to active lupus in the patients that were surveyed. The odds

of being diagnosed with COVID-19 were not significantly higher in patients treated with steroids (OR 1.08, 95% CI 0.36 to 3.28), hydroxychloroquine (OR 0.84, 95% CI 0.22 to 3.27), mycophenolate mofetil (OR 0.57, 95% CI 0.15 to 2.14), belimumab (OR 2.76, 95% CI 0.51 to 14.82), leflunomide (OR 3.08, 95% CI 0.30 to 31.77) or azathioprine (OR 1.01, 95% CI 0.20 to 4.94). Known contact with someone who had COVID-19 was associated with an increased risk of being diagnosed with COVID-19 (OR 7.79, 95% CI 1.43 to 42.38). The odds of contracting COVID-19 were not increased with comorbid lung disease (OR 0.61, 95% CI 0.16 to 2.31), gender (OR 1.09, 95% CI 0.12 to 8.76), smoking history (OR 1.49, 95% CI 0.43 to 5.15), age above median (47 years, OR 0.51, 95% OR 0.16 to 1.61), or weight above median (76.7 kg, OR 1.02, 95% CI 0.34 to 3.07). The median subjective disease activity score determined by the patient on a scale of 0-10 was 3.

Conclusion: Immunosuppressive treatment was not associated with increased odds of contracting COVID-19. Our infection rate of 10.2% is within the range of percentage of total Brooklyn residents testing positive for COVID-19 (3.08% - 13.97% per the New York Times New York City Coronavirus Map and Case Count database). Patients with SLE do not appear to have an elevated risk of COVID-19 compared to the general population. Surveyed patients felt that their SLE was fairly well controlled during the pandemic.

Association of Telomere Length with Phenotypic Frailty in Systemic Lupus Erythematosus

Sarah Lieber[1], Robyn Lipschultz[1], Syed Zahid[2], Mangala Rajan[2], Myriam Lin[1], Laura Donlin[1], Neal Lue[2] and Lisa Mandl[1], [1]Hospital for Special Surgery, New York, NY, [2]Weill Cornell Medicine, New York, NY

SESSION INFORMATION
Session Date: Sunday, November 7, 2021
Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster II: Manifestations (0855–0896)
Session Type: Poster Session B
Session Time: 8:30AM–10:30AM

Background/Purpose: Frailty is a novel risk factor for adverse health outcomes in systemic lupus erythematosus (SLE). Although frailly is conceptualized as "accelerated aging," whether the frailty phenotype is associated with physiologic biomarkers of aging is unclear. Shortened telomere length reflects cellular senescence in older adults.

Table 1. Prevalence of frailty and individual components by frailty definition

Fried phenotype (N=52)		**FRAIL scale (N=52)**	
Component	N (%)	*Component*	N (%)
Weight loss	13 (25.0)	Weight loss	13 (25.0)

*SELENA-SLEDAI: Safety of Estrogens in Lupus Erythematosus National Assessment-Systemic Lupus Erythematosus Disease Activity Index. Scores range from 0-105, with higher scores indicating greater disease activity.

**SLICC/ACR Damage Index: Systemic Lupus International Collaborating Clinics/American College of Rheumatology Damage Index. Scores range from 0-46, with higher scores indicating greater damage.

†>10% missing

Although preliminary evidence suggests that telomere length is not associated with a SLE-specific cumulative deficits definition of frailty in adult women with SLE [1], to our knowledge, the relationship between telomere length and phenotypic definitions of frailty has not been assessed in women with SLE. We aimed to evaluate differences in telomere length between frail and non-frail women with SLE and to assess whether telomere length is independently associated with frailty after controlling for multiple potential confounders.

Table 3. Cross-sectional association of telomere length with frailty

Model	Fried phenotype (N=52)		FRAIL scale (N=52)	
	Odds ratio	*95% confidence interval*	*Odds ratio*	*95% confidence interval*
Unadjusted	0.19	0.06-0.65	0.60	0.25-1.46
Adjusted for age	0.26	0.07-0.96		
Adjusted for age and disease damage	0.21	0.04-1.03		

Methods: Women ≥18 years old with SLE validated according to the 2019 European League Against Rheumatism/ American College of Rheumatology Classification Criteria were enrolled at a single center. Frailty status according to both the Fried phenotype (FP), which includes objective and self-report components, and the FRAIL scale (FS), an exclusively self-report instrument, were measured at a single study visit. Telomere length was determined from whole blood drawn at the same visit using Southern analysis of terminal restriction fragments. Sociodemographic features and physician-reported disease activity and damage also were collected. Differences between frail and non-frail participants were evaluated using Fisher's exact or Wilcoxon rank sum tests. The association of telomere length with frailty was assessed using logistic regression.

Results: Data from 52 participants were available for this interim analysis. 12 (23.1%) and 13 (25.0%) of women were classified as frail according to the FP and the FS, respectively, despite median age of 50-52 years old (Tables 1 and 2). Frail women according to both metrics had greater comorbidity burden (FP: p=0.01; FS: p< 0.01), more organ damage (FP: p< 0.01; FS: p< 0.01), and a higher prevalence of cigarette smoking (FP: p=0.01; FS: p< 0.01) than non-frail women; frail women according to the FS also were taking more glucocorticoids compared to non-frail women (p=0.03) (Table 2). Telomere length was significantly shorter among frail versus non-frail women according to the FP (p< 0.01), but not the FS (p=0.18) (Table 2). Similarly, telomere length was significantly associated with frailty according to the FP (Odds ratio [OR] 0.19, 95% confidence interval [CI] 0.06-0.65), but not the FS. This relationship was attenuated for the FP after adjustment for age (OR 0.26, 95% CI 0.07-0.96) and further attenuated after adjustment for organ damage (OR 0.21, 95% CI 0.04-1.03) (Table 3).

Conclusion: Approximately a quarter of women with SLE were frail according to two validated frailty measures. Shorter telomere length was associated with frailty according to the FP, but not the FS, suggesting that the FP is a better measure of accelerated aging in women with SLE. Further study is needed to identify the longitudinal impact of frailty on the health of women with SLE.

Abstract Number: 0858

Effect of COVID Infection and COVID Vaccination on SLE Activity, Including Antiphospholipid Antibodies

Michelle Petri[1], Jessica Li[2] and Daniel Goldman[1], [1]Johns Hopkins University School of Medicine, Baltimore, MD, [2]Johns Hopkins University, Baltimore, MD

SESSION INFORMATION
Session Date: Sunday, November 7, 2021
Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster II: Manifestations (0855–0896)
Session Type: Poster Session B
Session Time: 8:30AM–10:30AM

Background/Purpose: SLE patients may have a particular propensity to some viral infections including zoster and CMV. International studies have suggested that prednisone and rituximab may be risk factors for COVID in rheumatic disease patients. One study found that 50% of hospitalized patients (not SLE) made antiphospholipid antibodies. In this study we compared disease activity, and antiphospholipid antibodies both before and after COVID-19 infection and vaccination.

Methods: Patients enrolled in a lupus cohort had data on COVID-19 testing and vaccination status prior to May, 2021 collected. A positive RNA test was required to confirm COVID-19 infection. Dates of vaccination and vaccine source were recorded. All patients met ACR and/or SLICC criteria for SLE. The lupus activity index (0-3 visual acuity scale: LAI), SELENA SLE disease activity index (SLEDAI) and laboratory values were collected at each visit. To compare the pre and post COVID infection/vaccination, paired t-test was used for continuous variables and McNemar's test was used for categorical variables.

Results: Out of 860 patients in the cohort, 65 patients had a positive COVID-19 RNA test. 38 of these patients had at least one visit within 6 months before and after the COVID date. Table 1 shows the effect of COVID-19 on disease activity and laboratory values. On average, the LAI-rash score was lower after COVID infection. Anticardiolipin (aCL) IgG and anticardiolipin IgM increase after COVID infection. 228 patients had COVID-19 vaccine: 10 had Johnson & Johnson; 94 had Moderna; 124 had Pfizer. 13 patients were positive for COVID-19 prior to vaccination. 98 patients had at least 1 visit within 6 months before vaccine and at least one visit after vaccine. Table 2 shows the effect of COVID-19 vaccination on disease activity and laboratory values.

Conclusion: : COVID infection did not lead to an increase in SLE activity. Instead there was a decrease in cutaneous activity (perhaps explained by quarantine). There was an increase in aCL IgG and IgM post infection, but COVID vaccination did not increase SLE activity and did not increase antiphospholipid antibody levels.

Table 1. Effect of COVID infection on disease activity and laboratory measurements

		Average of visits within 210 days before and after infection			Closest visit before and after infection

Evaluation of the Montreal Cognitive Assessment as a Screening Tool for Cognitive Dysfunction in Systemic Lupus Erythematosus

Sudha Raghunath[1], Yifat Glikmann-Johnston[1], Eric Morand[2], Julie Stout[1] and Alberta Hoi[3], [1]Monash University, Melbourne, Australia, [2]School of Clinical Sciences at Monash Health, Monash University Faculty of Medicine, Nursing and Health Sciences, Monash Medical Centre Clayton, Melbourne, Australia, [3]Department of Rheumatology, Monash Health & Department of Medicine, School of Clinical Sciences, Monash University, Melbourne, Australia

SESSION INFORMATION

Session Date: Sunday, November 7, 2021

Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster II: Manifestations (0855–0896)

Session Type: Poster Session B

Session Time: 8:30AM–10:30AM

Background/Purpose: Cognitive dysfunction (CD) affects approximately 40% of SLE patients (1), impacting on employment, daily function, and quality of life (2)(3). Diagnostic neuropsychological testing is time-consuming and requires specialised staff, limiting access and resulting in under-detection in routine practice. Therefore, effective screening of SLE patients in the clinical setting is essential in selecting patients for formal cognitive testing. The Montreal Cognitive Assessment (MoCA) is a brief screening tool, initially designed to screen for mild cognitive impairment (MCI) or dementia, which preliminary studies suggest may have utility in SLE. This study aimed to comprehensively evaluate the MoCA as a screening tool for CD in SLE.

Methods: We tested SLE patients (n=95) and demographically matched healthy control (HC) participants (n=48) using the MoCA and the one-hour neuropsychiatric test battery recommended by the ACR for use in SLE (4). CD in SLE patients was defined using standard deviations from the HC group mean. We compared three CD

Table 1. Multivariate Analysis of the Montreal Cognitive Assessment (MoCA), Age and Cognitive Test Results in SLE. CI = Confidence Interval, *p value <0.05 **p value <0.005. Premorbid IQ was highly collinear with MoCA score and therefore was not included in the multivariate model. 1) Impairment defined by number of cognitive domains either 1.5 or 2 SD below healthy control group mean. 2) Specific cognitive tests used for each domain are as follows: Visual Memory - Rey Ostrrieth Complex Figure Test Recall Score, Verbal Memory -California Verbal Learning Test trials 1-5, Verbal Fluency - Controlled Oral Word Association Test FAS Sum, Working Memory - Letter Number Sequencing score, Processing Speed - Coding score, Complex Attention - Trail making test B time inverse, Psychomotor speed - finger tap test dominant hand score. Test scores were expressed as Z-scores in comparison to healthy control group data.

	Cognitive Impairment Definitions[1]			**Individual Cognitive Domains[2]**						
	2 domains 1.5 SD below	1 domain 2 SD below	2 domains 2 SD below	Visual Memory	Verbal Memory	Verbal Fluency	Working Memory	Processing Speed	Complex attention	Psychomot or Speed
	Odds ratio (CI) using logistic regression			Coefficient (CI) using linear regression

definitions, all based on thresholds from the 2007 ACR response criteria for neurocognitive impairment in SLE clinical trials (5). We used regression analyses to determine associations between MoCA and cognitive test scores, and assessed sensitivity, specificity, positive predictive value and negative predictive value of various MoCA cut-offs for predicting CD. We then determined the diagnostic accuracy of MoCA cut-off thresholds using receiver operator curves.

Results: The SLE and HC groups were well matched with no significant differences in age, gender, ethnicity, premorbid IQ or education level. The median age was 45 (range 22-64), 60% were Caucasian and the rest predominantly Asian, and all had good English proficiency. The prevalence of CD in the SLE group varied from 19% to 49% depending on the definition used; the median MoCA score was 26 (range 19-30). On multivariate analysis, MoCA score correlated significantly with nine of the ten cognitive endpoints studied (all $p < 0.001$; Table 1). Receiver operator curve analysis suggested that the MoCA cut-off of < 27 yielded the highest diagnostic accuracy across the three cognitive impairment definitions (AUC 0.76-0.78; Figure 1). The MoCA cut-off of < 28 had sensitivity of 83-94% with specificity of 46-58%, depending on the impairment definition used (Table 2).

Table 2. Sensitivity, Specificity, Positive Predictive Value and Negative Predictive Value of Montreal Cognitive Assessment (MoCA) for detection of Cognitive Impairment in SLE. 1) Defined by number of cognitive domains either 1.5 or 2 SD below healthy control group mean. Acronyms: HC – Healthy Control, PPV – Positive Predictive Value, NPV – Negative Predictive Value.

Table 2a: Sensitivity and Specificity of Montreal Cognitive Assessment (MoCA) for detection of Cognitive Impairment in SLE

	Cognitive Dysfunction Definitions[1]					
	2 domains ≥1.5 SD below HC		1 domains ≥2 SD below HC		2 domains ≥2 SD below HC	
MoCA cut off	Sensitivity	Specificity	Sensitivity	Specificity	Sensitivity	Specificity
<24	21.3%	100.0%	23.1%	98.2%	38.9%	96.1%

<26	46.8%	93.8%	48.7%	89.3%	72.2%	84.4%
<27	72.3%	83.3%	74.4%	76.8%	88.9%	66.2%
<28	83.0%	58.3%	87.2%	55.4%	94.4%	45.5%
<29	91.5%	35.4%	92.3%	32.1%	100.0%	26.0%
<30	95.7%	20.8%	97.4%	19.6%	100.0%	15.6%

Table 2b: Positive and Negative Predictive Value of Montreal Cognitive Assessment (MoCA) for detection of Cognitive Impairment in SLE

	Cognitive Impairment Definitions[1]					
	2 domains 1.5 SD below		1 domains 2 SD below		2 domains 2 SD below	
MoCA cut off	PPV	NPV	PPV	NPV	PPV	NPV
<24	100.0%	56.5%	90.0%	64.7%	70.0%	87.1%
<25	94.4%	61.0%	83.3%	68.8%	61.1%	70.0%
<26	88.0%	64.3%	76.0%	71.4%	52.0%	92.9%
<27	81.0%	75.5%	69.1%	81.1%	38.1%	96.2%
<28	66.1%	77.8%	57.6%	86.1%	28.8%	97.2%
<29	58.1%	81.0%	48.7%	85.7%	19.0%	95.2%
<30	54.2%	83.3%	45.8%	91.7%	21.7%	100.0%

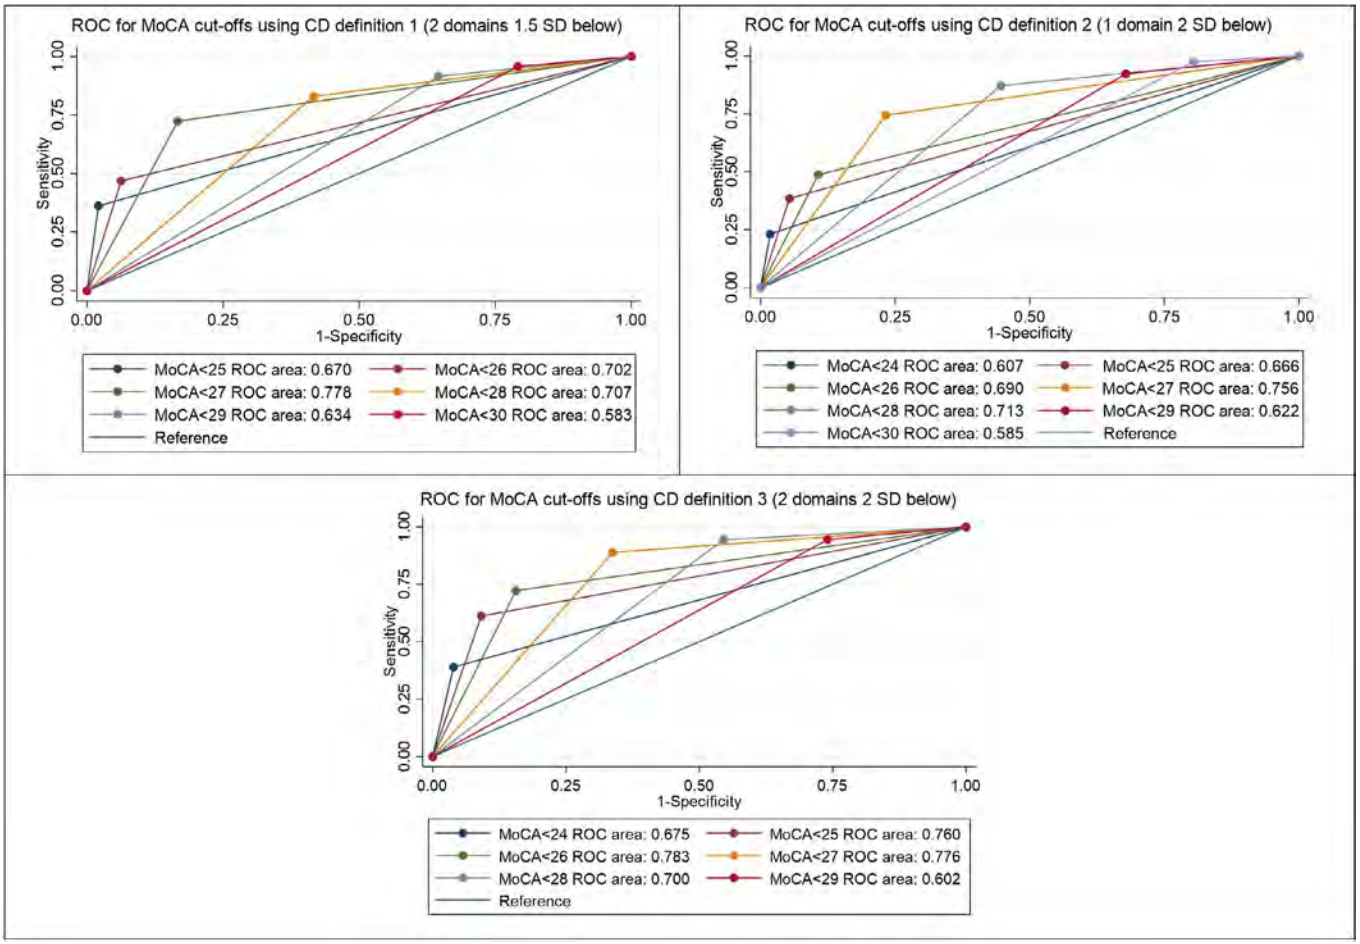

Figure 1. Receiver Operating Curves (ROC) for different Montreal Cognitive Assessment (MoCA) cut-offs by Cognitive Dysfunction (CD) Definition. Area under the curve interpretation: 0.7-0.9 = moderate accuracy, 0.5-0.7 = low accuracy, ≤0.5 = equal to chance.

Conclusion: The MoCA correlates strongly with gold-standard cognitive test results in SLE and is sufficiently sensitive for use in screening. We recommend the MoCA cut-off of < 28 as the threshold with the optimal sensitivity for screening for CD in SLE to ensure potential cases are detected. This threshold is higher than the MoCA cut-off used for MCI and dementia. This brief, freely available and practical tool for screening SLE patients for CD should be considered for inclusion in SLE management guidelines.

Associations Between Tricarboxylic Acid Cycle Plasma Metabolites and Fatigue Phenotypes in Black Females with Systemic Lupus Erythematosus: An Untargeted Metabolomics Analysis

Laura Kimble[1], Arezou Khosroshahi[1], Glenna Brewster[1], Nicole Carlson[1], Ronald Eldridge[1] and Elizabeth Corwin[2], [1]Emory University, Atlanta, GA, [2]Columbia University, New York, NY

SESSION INFORMATION

Session Date: Sunday, November 7, 2021

Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster II: Manifestations (0855–0896)

Session Type: Poster Session B

Session Time: 8:30AM–10:30AM

Background/Purpose: Systemic lupus erythematosus (SLE) occurs predominantly in women and Black women have disproportionately poorer health outcomes across the trajectory of their disease compared to women of other race/ethnicities. Specifically, Black women with SLE report higher symptom burden with pervasive impacts on quality of life. Fatigue is highly prevalent in SLE patients, and is a major driver of negative disease perception and patient difficulty with steroid therapy discontinuation. However, the underlying biochemical mechanisms of fatigue in Black women with SLE are largely unknown. We conducted untargeted metabolomic plasma profiling in Black females with SLE and Black female non-SLE controls to identify metabolites and metabolic pathways associated with SLE. We then identified which of these SLE metabolites and pathway predictors were correlated with patient-reported symptoms of fatigue.

Methods: Blood samples were collected from 23 Black female patients with diagnosis of SLE during a routine outpatient rheumatology visit and from 21 Black female non-SLE controls. SLE clinical data were obtained via EMR review and all subjects completed identical, reliable and valid measures of fatigue (Multidimensional Fatigue Inventory [MFI]) and PROMIS symptom measures. A US-based commercial metabolomics analysis company conducted

Note: * $p < .05$, TCA Cycle metabolites noted in *italics*.

Correlations Between MFI Fatigue Subscales, TCA Cycle Metabolites, Co-Occurring Symptoms, and Clinical Variables in SLE Subjects (n=21).

untargeted metabolomics on the 44 plasma samples using ultrahigh performance liquid chromatography/tandem mass spectrometry along with metabolite identification and quantification to examine differences between SLE/non-SLE groups. Metabolites and symptom data were correlated using Kendall's Tau with a two tailed alpha of $p < .05$.

Results: All SLE subjects met 2019 EULAR/ACR diagnostic criteria. SLE subjects were significantly younger (42.5 years ± 12.2 vs. 63.2 years ± 6.4), had a lower BMI (30.3 ± 9.4 vs. 34.9 ± 4.1), and greater co-morbidities (2.3 ± 1.3 vs. 1.1 ± 1.3) than non-SLE controls. Welch's two sample t-tests revealed 290 biochemicals that were significantly different ($p \leq .05$) between SLE and non-SLE groups; with Random Forest analysis yielding a predictive accuracy of 91% in differing between the two groups. While significant metabolic differences between groups were noted in biochemicals within pathways associated with glycolysis, the TCA cycle, fatty acid metabolism, branched chain amino acids, sterols, and heme catabolism, the metabolites that associated with fatigue were within the TCA cycle, also called the Kreb's Cycle, and responsible for energy production (See table). Increased MFI physical fatigue was significantly correlated with alpha-ketoglutarate, succinate, lower cognitive function, and greater BMI. Increased MFI mental fatigue was significantly associated with fumarate, depression, sleep disturbance, lower cognitive function, and increased age.

Conclusion: Metabolites from the TCA cycle, identified through untargeted metabolomics, were significantly associated with physical and mental fatigue phenotypes in Black females with SLE. Validating these findings in a larger sample would inform potential biomarkers for fatigue as well as targets for intervention.

Abstract Number: 0861

Systemic Lupus Erythematosus, a Pilot Study of a New Disease Activity Score

Daphna Paran[1], Monique Ben-Am[2], Liran Mendel[2], Ari Polachek[3], Victoria Furer[2], Ofir Elalouf[4], Jonathan Wollman[4], Shaye Kivity[5] and Nancy Agmon-Levin[6], [1]Tel Aviv Sourasky Medical Center-Ichilov Hospital, Even Yehuda, Israel, [2]Tel Aviv Sourasky Medical Center, Tel Aviv, Israel, [3]Sourasky Medical Center, Petah-Tikva, Israel, [4]Tel Aviv Medical Center, Herzliya, Israel, [5]Meir Medical Center, Kefar Saba, Israel, [6]Sheba Medical Center, Ramat Gan, Israel

SESSION INFORMATION
Session Date: Sunday, November 7, 2021
Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster II: Manifestations (0855–0896)
Session Type: Poster Session B
Session Time: 8:30AM–10:30AM

Background/Purpose: Systemic lupus erythematosus (SLE) is a heterogeneous, waxing and waning, multisystem autoimmune disease. The complexity and clinical unpredictability of SLE challenge the assessment of disease activity over time, especially in every day clinical practice. Multiple clinical disease monitoring instruments have been developed, however they are limited in ability to detect change in disease activity over time or too cumbersome to be utilized in daily practice. The aim of the study is to construct a new disease activity score which will simplify and improve disease activity assessment in daily practice, and possibly serve as a better tool for clinical studies.

Methods: The new instrument for the assessment of SLE activity is comprised of 6 visual analogue scales (VAS), which separately address the physician's global assessment and 5 organ systems including: mucocutaneous, musculoskeletal, cardiorespiratory, renal and neuropsychiatric systems. Changes in blood counts, serology, and medica-

tions are recorded. The patient's own assessment, as well as treatment changes will be included in the final score. In order to assess the reliability and validity of the new score, as well as the score's sensitivity to change in disease activity, 4 paper cases, including 2 visits for each case, were constructed. Each of the visits was scored by 5 experienced rheumatologists who were not involved in the construction of the new score, using 3 validated scoring instruments: BILAG, SLEDAI, LFA-REAL, and our proposed score. The order of the instruments utilized for each scored visit and the order of patients scored by each physician were randomized.

Results: The inter-rater reliability (i.e. agreement between physicians) of the new score was good for all systems represented in the paper cases, both for single visit scores and for the change in disease activity between 2 consecutive visits (ICC (2,1) range 0.75-0.95), except for a borderline value for changes in disease activity in the renal system (0.59). The inter-rater reliability values of the new score were comparable with those of the BILAG and the LFA-REAL scoring systems. The construct (convergent) validity of the new score, as evaluated by correlation with the other 3 validated scoring instruments was good for single visit scores (Spearman correlation coefficients range 0.48-0.94). Correlation of our proposed score with the BILAG score, regarding changes in disease activity, was good when scoring the mucocutaneous, musculoskeletal and cardiorespiratory systems (0.66, 0.75, 0.83, respectively) but was poor when scoring the renal system (0.11).

Conclusion: This paper case evaluation of the new disease activity score suggests a promising and simple tool, with overall good reliability and construct validity. Further studies are ongoing to evaluate a greater diversity of real-life patients with SLE. Further psychometric evaluation is needed to refine the score and to incorporate laboratory and medication data and patient assessment.

Prevalence and Risk Factors for Herpes Zoster Reactivation in 1542 Patients with Rheumatic Diseases

Chi Chiu Mok[1], Ling Yin Ho[2], Sau Mei TSE[2], Kar Li Chan[3] and Chi Hung To[4], [1]Tuen Mun Hospital, Hong Kong, China, [2]Tuen Mun Hospital, Hong Kong, Hong Kong, [3]Tuen Mun Hospital, Hong Kong, [4]Pok Oi Hospital, Hong Kong, Hong Kong

SESSION INFORMATION
Session Date: Sunday, November 7, 2021
Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster II: Manifestations (0855–0896)
Session Type: Poster Session B
Session Time: 8:30AM–10:30AM

Background/Purpose: To study the prevalence and risk factors of herpes zoster (HZ) infection in patients with rheumatic diseases.

Methods: Medical records of patients with rheumatic diseases who attended our out-patient rheumatology clinics between March and August, 2019 were retrospectively reviewed. Patients who were using biological or targeted DMARDs were excluded. Episodes of HZ infection were identified and the prevalence over time was calculated. Laboratory parameters (total white cell count, neutrophil-to-lymphocyte ratio, serum albumin, globulin & creatinine), history of diabetes mellitus and the highest doses of immunosuppressive medications within 6 months of the first ep-

isode of HZ infection were compared with those within 6 months of last follow-up in patients who did not have HZ infection. Cox regression analysis was performed to identify factors associated with the first HZ infection in all patients.

Results: 1542 patients were studied (88% women, age 46.4±15.0 years). The underlying diseases were SLE (38%), rheumatoid arthritis (26%) and other rheumatic diseases (36%). After a total follow-up of 11,515 patient-years since diagnosis (7.5±7.0 years), 122 (7.9%) patients developed 146 episodes of HZ infection, giving an overall prevalence of 1.27/100-patient years. The prevalence rates of HZ in SLE, RA and non-SLE/RA patients were 1.70, 0.64 and 0.76 per 100 patient-years, respectively. Patients who experienced HZ reactivation were younger (41.6±14.7 vs 46.8±15.0 years; p< 0.001), more likely to have SLE (74% vs 35%; p< 0.001) and diabetes mellitus (17% vs 7.3%; p=0.01), and had a significantly lower albumin (38.6±5.6 vs 41.3±3.5; p< 0.001) and higher neutrophil-to-lymphocyte ratio (4.9±6.2 vs 2.8±2.6; p< 0.001). More patients with HZ reactivation were treated with prednisolone (54% vs 22%; p< 0.001), azathioprine (20% vs 8%; p< 0.001), mycophenolate mofetil [MMF] (21% vs 12%; p=0.006), cyclophosphamide [CYC] (4.9% vs 0.1%; p< 0.001) and hydroxychloroquine (48% vs 34%; p=0.002) in the preceding 6 months compared with those who did not have HZ infection. Among those using immunosuppressive drugs, the doses of MMF (1.42±0.64 vs 1.02±0.31g; p=0.005) and prednisolone (15.6±15.9 vs 5.5±4.5mg; p< 0.001) were significantly higher in those with HZ infection. The cumulative risk of having HZ reactivation in SLE patients at 24 and 48 months since diagnosis was 5.9% and 8.6%, respectively, which was significantly higher than that in non-SLE patients (1.9% and 2.5%, respectively; p< 0.001 by log rank test). Cox regression analysis revealed that having a diagnosis of SLE (HR 1.97 [1.17-3.31]), albumin level (HR 0.93 [0.90-0.97] per g/L; p=0.001), serum creatinine (HR 0.995 [0.990-1.00] per umol/L), higher neutrophil/lymphocyte ratio (HR 1.08 [1.05-1.11]) and the use of CYC (HR 6.69 [2.56-17.5]) and prednisolone (HR 1.61 [1.02-2.45]) in the preceding 6 months were independently associated with the development of HZ infection.

Conclusion: Reactivation of HZ is fairly common in patients with rheumatic diseases. Underlying SLE, prednisolone/cyclophosphamide therapy and the neutrophil/lymphocyte ratio, but not age, sex or other laboratory parameters, are the major risk factors for HZ reactivation.

Serum Proprotein Convertase Subtilisin/kexin Type 9 (PCSK9) and Cardiovascular Risk in Systemic Lupus Erythematosus: A Longitudinal Cohort Study

Chi Chiu Mok[1], Ling Yin Ho[2], Kar Li Chan[3], Sau Mei TSE[2] and Chi Hung To[4], [1]Tuen Mun Hospital, Hong Kong, China, [2]Tuen Mun Hospital, Hong Kong, Hong Kong, [3]Tuen Mun Hospital, Hong Kong, [4]Pok Oi Hospital, Hong Kong, Hong Kong

SESSION INFORMATION
Session Date: Sunday, November 7, 2021
Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster II: Manifestations (0855–0896)
Session Type: Poster Session B
Session Time: 8:30AM–10:30AM

Background/Purpose: To study the predictive value of serum PCSK9 level on cardiovascular complications in Chinese patients with systemic lupus erythematosus (SLE).

Methods: Consecutive patients who fulfilled ≥4 1997 ACR criteria for SLE and consented for a biomarker study between 2009 and 2012 were included. Stored serum samples from these patients were assayed for PCSK9 using a commercial ELISA kit. New ischemic vascular events in these patients during follow-up were evaluated. ROC analysis was performed to adopt the best cut-off value of PCSK9 for the prediction of a new vascular event. Patients were divided into two groups according to this cut-off value. The cumulative incidence of new vascular event and mortality over time was studied by Kaplan-Meier's analysis and compared between the high and low PCSK9 subgroups. Cox regression was performed to study the effect of the PCSK9 subgroups on new vascular events and mortality, adjusted for other confounding factors.

Results: 539 SLE patients were studied (93% women, age 41.9±14.0 years; disease duration 106±90.4 months at entry). The mean PCSK level at baseline was 265±158ng/ml and a cut-off of 243.25ng/ml best predicted a new vascular event by the maximum Youden's index (ROC analysis: AUC 0.63[0.51-0.74]; sensitivity 69%; specificity 61%). 220 SLE patients had baseline PCSK9 level of ≥243.25ng/ml (high PCSK9) and 319 patients had level below 243.25ng/ml (low PCSK9). No significant difference in SLE manifestations and autoantibody profile was observed between the high and low PCSK9 groups except the former had a significantly higher prevalence of lupus nephritis. 31 new vascular events (13 ischemic stroke, 13 acute coronary syndrome and 5 peripheral vascular disease) developed in 29 patients over a mean follow-up of 91.3±18.6 months. Patients with a new vascular event had a significantly higher baseline PCSK9 level than those without (350±225 vs 260±153ng.ml; p=0.02). The cumulative incidence of a first vascular event at 5 years from study entry was 7.8% in the high PCSK9 group and 1.9% in the low PCSK9 group (log rank test; p=0.003, univariate hazard ratio [HR] 3.08[1.39-6.80]). At last follow-up, 40 patients succumbed (10 due to vascular event [vascular death]). Kaplan-Meier's analysis showed that the high PCSK9 group had a significant higher cumulative risk of all-cause mortality (log rank test p=0.003; HR2.68[1.39-5.14]) and vascular mortality (log rank test p=0.002; HR12.4[1.56-98.4]) over time than the low PCSK9 group. Cox regression analyses showed that high PCSK9 was significantly associated with new vascular events (HR2.56[1.10-5.99]; p=0.03) independent of age, sex, SLE duration, diabetes mellitus, hypertension, body mass index, atherogenic index, smoking, antiphospholipid antibody, past history of vascular events, and the use of statins, aspirin, hydroxychloroquine, prednisolone, mycophenolate mofetil, azathioprine and the calcineurin inhibitors at study entry.

Conclusion: A higher serum PCSK9 level is a strong risk factor for ischemic vascular events in patients with SLE, which is independent of age, sex, traditional atherosclerotic risk factors, antiphospholipid antibody and the use of statins and immunosuppressive medications.

Does Obesity Affect Disease Activity Outcomes in Systemic Lupus Erythematosus?

Konstantinos Tselios[1], Dafna Gladman[2], Jiandong Su[3] and Murray Urowitz[4], [1]McMaster University, Hamilton, ON, Canada, [2]Toronto Western Hospital, University of Toronto, Toronto, ON, Canada, [3]University Health Network, Toronto, ON, Canada, [4]Center for Prognosis Studies in the Rheumatic Diseases, Toronto Western Hospital, University of Toronto, Lupus Clinic, Toronto, ON, Canada

SESSION INFORMATION
Session Date: Sunday, November 7, 2021
Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster II: Manifestations (0855–0896)
Session Type: Poster Session B
Session Time: 8:30AM–10:30AM

Background/Purpose: Increased Body Mass Index (BMI) affects cardiovascular risk and is related to worse health-related quality of life measures in patients with systemic lupus erythematosus (SLE). However, its impact on disease activity over time is not known. The aim of the present study was to assess the impact of increased BMI on measures of disease activity in SLE.

Table 1. Demographic, clinical, serological and therapeutic characteristics of patients at baseline

VARIABLE	Normal weight BMI=18-24.9 N=257	Overweight BMI=25-29.9 N=101	Obese BMI=30 N=61	*p*

SLEDAI-2K: SLE Disease Activity Index 2000, SDI: Systemic Lupus International Collaborating Clinics Damage Index, CNS: central nervous system, BP: blood pressure, TC: total cholesterol, LDL: low-density lipoprotein, hs-CRP: high sensitivity C-reactive protein, eGFR: estimated glomerular filtration rate

Methods: Patients with documented weight and height in their first two clinic visits and at least three consecutive years of follow-up were retrieved from our long-term longitudinal database. They were divided into three groups according to their BMI (normal BMI=18-24.9, overweight with BMI=25-29.9 and obese with BMI ≥30). Patients were followed for three years for outcomes of disease activity (primary) including the time-adjusted mean SLE Disease Activity Index 2000 (AMS), number of flares (defined as any increase in SLEDAI-2K, any increase ≥4 in SLEDAI-2K and systemic treatment escalation), percentage of patients achieving clinical remission and low disease activity state (LDA, defined as clinical SLEDAI-2K 2 regardless of therapy), time spent in remission and/or LDA, cumulative glucocorticoid dose and adjusted high sensitivity C-reactive protein (hs-CRP). Secondary outcomes included new damage accrual (increase in Damage Index) as well as new atherosclerotic vascular events (AVEs), osteoporosis and osteonecrosis. Outcomes were compared among groups by ANOVA test for mean values and Chi-Square test for binary variables; post-hoc multi-testing adjustments were applied in case of statistical difference. The associated effect of obesity on AMS in three years was evaluated using Linear regression analysis.

Results: There were 419 eligible patients (257 with normal BMI, 101 overweight, 61 obese). The baseline characteristics are shown in Table 1. Obese patients had a longer disease duration and higher prevalence of hypertension and higher hs-CRP at baseline. Other variables did not differ significantly between groups. The outcomes after three years

Table 2. Primary and secondary outcomes at 3 years

VARIABLE	Normal weight BMI=18-24.9 N=257	Overweight BMI=25-29.9 N=101	Obese BMI=30 N=61	*p*
Adjusted Mean SLEDAI-2K	5.2 ± 3.6	4.4 ± 3.7	4.7 ± 4.0	0.185
Number of flares (SLEDAI-2K increase = 1)	1.5 ± 1.3	1.4 ± 1.3	1.4 ± 1.2	0.596
Number of flares (SLEDAI-2K increase =4)	0.9 ± 1.0	0.9 ± 1.1	0.8 ± 1.0	0.797
Number of flares (treatment escalation)	2.1 ± 1.8	1.8 ± 1.8	1.6 ± 1.7	0.065
Remission (clinical SLEDAI-2K=0) at 3rd year	157 (61.1%)	59 (58.4%)	38 (62.3%)	0.86
LDA (clinical SLEDAI-2K=2) at 3rd year	187 (72.8%)	75 (74.3%)	44 (72.1%)	0.946
Time in remission (y)	1.6 ± 1.0	1.6 ± 1.1	1.7 ± 0.9	0.569
Time in remission or LDA (y)	1.9 ± 1.0	2.1 ± 1.0	2.1 ± 0.9	0.283
Cumulative glucocorticoid dose (g)	13.9 ± 19.7	15.8 ± 24.4	14.7 ± 23.9	0.747
Adjusted mean hs-CRP	3.8 ± 7.1	4.1 ± 4.2	7.0 ± 7.2	0.004
SDI increase	0.5 ± 0.9	0.5 ± 0.8	0.5 ± 0.9	0.996
New AVEs in 3 years	3 (1.2%)	6 (5.9%)	3 (4.9%)	0.03
New osteonecrosis in 3 years	20 (7.8%)	6 (5.9%)	5 (8.2%)	0.808
New osteoporosis in 3 years	21 (8.2%)	6 (5.9%)	4 (6.6%)	0.741

SLEDAI-2K: SLE Disease Activity Index 2000, LDA: low disease activity, AVEs: atherosclerotic vascular events

of follow-up are shown in Table 2. There were no differences in terms of adjusted mean SLEDAI-2K, flare rate and time spent in remission and/or low disease activity after three years of follow-up between normal weight, overweight and obese patients. However, obese patients had higher time-adjusted hs-CRP. Overweight patients developed more frequently AVEs. Linear regression analysis with AMS as the dependent outcome did not confirm obesity to significantly affect this measure of disease activity.

Conclusion: Obese patients had a higher time-adjusted CRP over three years indicating persistent inflammation. However, this was not associated with increased lupus inflammatory burden. These patients more frequently developed atherosclerotic cardiovascular events that could be explained both by the persistence of inflammation (as expressed by the CRP) and traditional atherosclerotic risk factors.

SESSION INFORMATION

Session Date: Sunday, November 7, 2021

Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster II: Manifestations (0855–0896)

Session Type: Poster Session B

Session Time: 8:30AM–10:30AM

Background/Purpose: Mortality in patients with systemic lupus erythematosus (SLE) is high compared to the general population. Attainment of the Lupus Low Disease Activity State (LLDAS) is validated as protective against adverse outcomes including organ damage accrual and flare. We examined whether LLDAS attainment provided protection against mortality in patients with SLE. In addition, we examined remission (Definitions for Remission in SLE (DORIS) definitions).

Methods: Data from a 13-country longitudinal SLE cohort on patients meeting either ACR or SLICC criteria were collected between 2013 and 2020 using standard case report files. LLDAS was defined as in Golder *et al*., 2019 (SLEDAI≤4, no new activity, PGA ≤1, pred ≤7.5 mg/d, antimalarials (AM) and immunosuppressants (IS) allowed. Remission definitions were as in Vollenhoven *et al*, 2016 included clinical remission on treatment (CROT: clinical SLEDAI=0, AM and IS allowed, prednisolone ≤5 mg/d), and a variation disallowing glucocorticoid (CROT-off-steroid). Longitudinal associations of mortality were examined using survival (Cox regression) analysis.

Results: The study cohort included 4,020 SLE patients followed over a median of 2.6 years [IQR: 1.0 to 5.1] (Table 1). Ninety-one patients died during the study observation period; the crude mortality rate was ~ 7/1000 person-years. About 68% of deaths were related to infections; ~49% were related to SLE; ~24% related to cardiovascular causes and about 13% related to malignancy.

Disease activity and organ damage were strongly and independently associated with mortality. A 1 point increase in SLEDAI-2K was associated with an increased risk of mortality of 15% after accounting for confounders (adjusted HR: 1.15 (1.07, 1.23), p< 0.001). A 0.3-increase in PGA increased the risk of mortality by 33% (adjusted HR = 1.33 (1.13, 1.56), p=0.001). Every 1 unit increase in SDI score increased the mortality hazard by 53% (adjusted HR = 1.53 (1.38, 1.70), p< 0.001). While the associations of cumulative prednisolone exposure and flares with mortality were significant in univariable analysis, they attenuated in multivariable analysis.

48% of all patients achieved ≥50% observed time in LLDAS (LLDAS-50) but only 21% of those who died (Table 2). LLDAS-50 reduced mortality by 60% (adjusted HR = 0.40 (95% CI: 0.23, 0.69) p< 0.001) (Table 2). Clinical remission on treatment ≥50% of observed time (CROT-50) was achieved in 36% of patients and reduced mortality by 50% (HR = 0.50 (0.27, 0.92), p=0.026). A greater reduction in mortality was observed in patients who spent ≥50% time on CROT-off-steroid (HR=0.13 (0.02,0.96), p=0.045), but this was only achieved in 13% of patients (Table 2).

Table 1. Patient demographics of the study cohort

Patient demographics and clinical indicators	All patients N=4,020	Deceased patients N = 91
	Median [IQR] (range) or n (%)	
Age at enrolment (years)	39 (30, 50)	41 (28, 54)
Age at diagnosis (years)	29 (21, 39)	31 (21, 39)
Disease duration at enrolment (years)	8 (3, 15)	7 (3, 13)
Study duration (years)	2.6 (1.0, 5.1)	2.1 (0.7, 3.5)
Patients with ≥2 visits	3750 (93%)	80 (88%)
Females	3697 (92%)	81 (90%)
Asian ethnicity	3552 (89%)	52 (90%)
Tertiary level education	1963 (53.4%)	29 (35%)
Time adjusted mean SLEDAI-2K (AMS)	2.9 (1.3, 4.7)	5.0 (2.7, 7.1)
Time adjusted mean PGA	0.4 (0.2, 0.7)	0.8 (0.5, 1.3)
Prednisolone-ever	3417 (85%)	89 (98%)
Time adjusted mean prednisolone mg/day	5.0 (2.5, 8.8)	9.0 (5.7, 15.5)
Cumulative prednisolone dose (g)	3.6 (0.7, 9.6)	6.3 (2.1, 13.0)
Organ damage present at the end of study follow-up	1707 (47.8%)	60 (72%)
Damage accrual during study period	707 (19.8%)	27 (33%)

Table 2. Longitudinal associations of LLDAS and DORIS remission attainment with mortality

Treat-to-Target (T2T) endpoints	All patients Total=3,750	Deceased patients Total = 80	Multivariable Cox regression analysis
	N (%)	N (%)	HR[1] (95% CI), p-value
LLDAS-50[2]	1,800 (48%)	17 (21%)	0.40 (0.23,0.69), p=0.001
CROT-50[3]	1,353 (36%)	13 (16%)	0.50 (0.27,0.92), p=0.026
CROT-off-steroids-50[4]	498 (13%)	1 (1.3%)	0.13 (0.02,0.96), p=0.045

[1] *HR = Hazard ratios adjusted for GDP (PPP) and SDI score.*

[2] *Lupus Low Disease Activity State, defined as SLEDAI≤4, no new activity, PGA ≤1, prednisolone ≤7.5 mg/day, antimalarials and immunosuppressants allowed, for ≥50% of observed time*

[3] *Clinical Remission on Therapy, defined as cSLEDAI=0; antimalarials and immunosuppressants allowed; Prednisolone ≤5mg/day, for ≥50% of observed time*

[4] *Clinical Remission on Therapy but Off Steroids, defined as cSLEDAI=0; anti-malarial and immunosuppressants allowed; no corticosteroids, for ≥50% of observed time*

Conclusion: The attainment of LLDAS and DORIS remission conferred significant protection against mortality in SLE. LLDAS was more attainable than remission. Compared to LLDAS, clinical remission on treatment was not more protective, while clinical remission off steroids was maximally protective. Steroid free remission should be the goal of treatment in SLE.

SESSION INFORMATION

Session Date: Sunday, November 7, 2021

Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster II: Manifestations (0855–0896)

Session Type: Poster Session B

Session Time: 8:30AM–10:30AM

Background/Purpose: Preliminary data in people with SLE suggested that disease activity as well as SLE treatment at time of COVID-19 acquisition impact COVID-19 outcomes over and above other known risk factors. We assessed characteristics associated with poor outcomes in a global population of people with SLE and COVID-19.

Methods: People with SLE reported in the COVID-19 Global Rheumatology Alliance (GRA) physician-reported registry from March 24th 2020 to April 12th 2021 were included. Variables collected included age, gender, region [Europe, North America, South America and other (Africa, Asia and Australia)], comorbidities (chronic renal disease, cardiovascular disease, and the number of other comorbidities), physician global assessment of disease activity, calendar

Table 1: Characteristics associated with poorer COVID-19 outcomes in individuals with SLE (n=1734)*.

	OR (95% CI)
Age (per year, continuous)	1.03 (1.02, 1.04)
Gender	
Female	Ref.
Male	1.74 (1.22, 2.49)
Region	
Europe	Ref.
North America	1.26 (0.52, 3.07)
South America	1.37 (0.59, 3.19)
Other (Asia, Africa and Australia)	3.77 (1.85, 7.69)
Calendar Period	
March 24-June 15, 2020	Ref.
June 16-Sept 30, 2020	0.61 (0.42, 0.89)
Oct 1, 2020- April 12, 2021	0.42 (0.30, 0.59)
Baseline Glucocorticoid Dose	
0 mg/day	Ref.
1-5 mg/day	1.87 (1.39, 3.04)
6-9 mg/day	2.46 (1.35, 4.46)
=>10 mg/day	2.32 (1.63, 3.32)
Baseline Medication Category	
Antimalarial monotherapy for SLE	Ref.
No SLE treatment	2.05 (1.39, 3.04)
IS drugs as monotherapy (MMF, tacrolimus, cyclophosphamide, cyclosporine, azathioprine, methotrexate, leflunomide, sulfasalazine only)	1.04 (0.77, 1.42)
Biologic/targeted monotherapy	1.05 (0.45, 2.45)
Biologic/targeted monotherapy + IS	1.30 (0.82, 2.06)
Chronic renal insufficiency or end stage renal disease	3.21 (2.31, 4.46)
Cardiovascular/Hypertension	1.64 (1.24, 2.16)
Number of Comorbidities (Other than Renal/Cardiovascular/Hypertension)	1.51 (1.15, 1.98)
Physician-reported SLE Disease Activity	
Remission	Ref
Minimal or low	0.99 (0.73, 1.35)
Moderate	1.78 (1.19, 2.64)
Severe or high	4.18 (2.50, 6.97)

IS: immunosuppressive; b/ts: biologics/target synthetic; OR: Odd ratio; CI: confidence interval

*The ordinal outcomes was: 1 not hospitalized, 2 hospitalized without supplementary oxygen or with non-invasive ventilation, 3 hospitalized with mechanical ventilation/extracorporeal membrane oxygenation and 4 death. This assumed that the relationship between each pair of outcome groups is of the same direction and magnitude.

period, glucocorticoid dose, and SLE treatment at the time of COVID diagnosis. SLE treatment was categorized into five groups: antimalarials only (reference), no SLE drugs, non-biologic immunosuppressant (IS) monotherapy, biologics/target synthetic IS, and combination IS therapy. An ordinal outcome was defined as: 1) not hospitalized, 2) hospitalized without supplementary oxygen or with non-invasive ventilation, 3) hospitalized with mechanical ventilation/extracorporeal membrane oxygenation and 4) death. We constructed a multivariable ordinal logistic regression model to assess the relationship between COVID-19 severity and demographic characteristics, comorbidities, medications and disease activity.

Results: 1734 patients were included; 1567 (90.4%) were female, median age was 44.3 (SD: 14.3) years. A total of 1291 (74.5%) patients were not hospitalized; 148 (8.5%) patients were hospitalized without oxygen or with non-invasive ventilation, 195 (11.2%) patients were hospitalized with mechanical ventilation/extracorporeal membrane oxygenation and 100 (5.6%) died. In our multivariable model, more severe COVID-19 outcomes were seen in older patients (odds ratio, OR=1.03 per year), males (OR =1.74), patients outside Europe and North and South America (OR=3.77), patients on prednisone (0-5 mg/d OR=1.87, 5-10 mg/d OR=2.46, and >10 mg/d OR=2.32), no SLE therapy (OR =2.05), chronic renal disease (OR =3.21), cardiovascular disease (OR =1.64), the number of other comorbidities (OR=1.51) and moderate and high disease activity (OR =1.78 and OR=4.18, respectively). There was evidence of a calendar period effect, with worse outcomes in those with a COVID diagnosis earlier in the pandemic (before June 15, 2020); these data are summarized in Table 1.

Conclusion: These results demonstrate patterns similar to the general rheumatic disease population, and underscore the importance of controlling disease activity in people

with SLE patients during the COVID-19 pandemic.

SESSION INFORMATION

Session Date: Sunday, November 7, 2021

Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster II: Manifestations (0855–0896)

Session Type: Poster Session B

Session Time: 8:30AM–10:30AM

Background/Purpose: Systemic lupus erythematosus (SLE) is associated with enhanced cardiovascular (CV) risk linked to both traditional Framingham risk factors and lupus-specific immune dysregulation. Characterizing an immunological signature at the transcriptional and protein level that associates with subclinical vascular disease and predicts atherosclerosis progression has been challenging.

Methods: SLE patients and matched healthy controls underwent assessments of vascular stiffness (cardio-ankle vascular index (CAVI)), vascular inflammation by FDG-PET CT, and coronary artery plaque by coronary computed tomography angiography (CCTA). Whole blood RNA sequencing was performed in samples from a subset of those patients including 10 controls and 20 SLE patients. In a larger subset of these patients including 24 controls and 64 SLE patients, measurement of several inflammatory biomarkers using the Olink platform was performed. The findings were correlated with clinical and vascular assessments.

Results: In initial pathway analyses, transcriptional regulation of genes related to cell cycle processes was observed in SLE patients with more severe vascular disease compared to SLE patients with milder vascular phenotypes. Additionally, upregulation of pathways related to cytokine-mediated signaling and response to interferon-gamma was also noted between these groups but was driven by changes in expression of only a small selection of genes. Within SLE patients, proteomic analyses revealed fourteen immunologic and inflammatory-linked proteins (CCL11, IL18R1, IL20RA, IL6, IL7, LIF, CDCP1, IL22RA, LAP TGF-β1, LIFR, MCP3, TNFSF14, TRANCE, X4EBP1) which correlate with more than one cardiovascular readout. Of specific interest, these analyses reveal four proteins that correlate significantly with non-calcified plaque burden (IL6, LIFR, IL22RA1, IL4) and thirteen different proteins which correlate with dense calcified plaque burden (CCL11, IL1α, IL20, IL20RA, IL2RB, IL2, IL5, IL7, LIF, MCP3, MCP4, MMP1, TNFSF14),). Of note, decreased leukemia inhibitory factor receptor (LIFR) and increased IL6 were associated with both increased vascular inflammation, total plaque burden and non-calcified plaque burden in SLE patients.

Conclusion: Several inflammatory serum markers associate with enhanced vascular damage in SLE. Of note, dysregulation of the LIF/IL6 axis, described to be involved in regulation of the fate of T-cells, may represent both a marker of increased atherosclerotic plaque burden risk and a mechanism by which plaque burden worsens in SLE patients, potentially driven by changes in lymphocyte composition. Thus, further investigation of the influence of the LIF/IL6 axis and T-cell subsets is warranted in understanding the pathogenesis of cardiovascular disease in SLE. Additionally, given the transcriptomic data, investigation of the role of cell cycle processes in cardiovascular risk in SLE may also prove valuable.

Cell-bound Complement Activation Products (CB-CAPs) Predicts Type 1 SLE Activity

Jennifer Rogers[1], Rory Bloch[2], Amanda Eudy[1], David Pisetsky[3], Roberta Alexander[2], John Conklin[2], Kai Sun[1], Rebecca Sadun[1], Lisa Criscione-Schreiber[4], Jayanth Doss[1] and Megan Clowse[5], [1]Duke University, Durham, NC, [2]Exagen Inc., Vista, CA, [3]Duke University Medical Center, Durham, NC, [4]Duke University School of Medicine, Durham, NC, [5]Duke University, Chapel Hill, NC

SESSION INFORMATION
Session Date: Sunday, November 7, 2021
Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster II: Manifestations (0855–0896)
Session Type: Poster Session B
Session Time: 8:30AM–10:30AM

Background/Purpose: SLE is a multisystem autoimmune disease that displays diverse manifestations that can be categorized into two broad types. Type 1 SLE activity includes inflammatory manifestations such as arthritis and nephritis. Type 2 SLE activity, which has a less clear relationship to inflammation, includes findings such as fatigue and widespread pain and can be assessed using patient-reported outcome measures (PROs). Cell bound-activation products (CB-CAPs), erythrocyte-bound C4d (EC4d), and B-lymphocyte-bound C4d (BC4d) in a multi-analyte assay with algorithm (MAP) provide valuable diagnostic information in SLE. In this study, we evaluated EC4d, BC4d, and MAP as markers of current Type 1 SLE activity.

Methods: This was a cross-sectional study of SLE patients (ACR 1997 or SLICC criteria) from June 2020 to March 2021. ANA and other autoantibodies were measured by ELISA. Anti-dsDNA was determined by immunofluorescence using Crithidia luciliae. CB-CAPs were measured by flow cytometry. The multi-analyte assay panel with algorithm (MAP) was determined using a 2-tier algorithm.

We used SLEDAI, the Polysymptomatic Distress Score (PSD, patient-reported pain and symptoms), and a PGA (physician's global assessment; a 3-point visual analog scale) for Type 1 and for Type 2 SLE activity to define 3 bookended patient groups based on current SLE activity:

- Type 1 SLE activity: SLE Disease Activity Index (SLEDAI-2k) ≥6, clinical SLEDAI ≥4, renal SLEDAI ≥4 or Type 1 PGA ≥1.5, with or without Type 2 SLE activity
- Type 2 SLE: PSD score ≥8, Type 2 PGA ≥1.5, SLEDAI=0, and Type 1 PGA ≤0.5
- Minimal SLE: PSD score of ≤3, SLEDAI=0, Type 1 PGA ≤0.5 and Type 2 PGA ≤0.5.

Differences across groups were analyzed by Fisher's exact test. Logistic regression analysis examined predictors of Type 1 activity.

Results: In this bookended cohort of 52 patients (90% female, 54% Black, mean age 46 years), 50% had current Type 1 activity, 31% had Type 2 SLE without Type 1 activity, and 19% had minimal SLE activity. Patients with Type 1 activity were younger, but there was no difference in race, ethnicity, length of disease, historical renal disease, hydroxychloroquine, or immunosuppression use across the groups (Table 1). The median MAP score and BC4d and EC4d levels were significantly higher in patients with current Type 1 activity (Table 2). Additionally, BC4d, EC4d, and

EC4d (log MFI)	2.5 (0.9)	1.5 (0.6)	2.2 (0.7)	2.1 (1.3)	**0.003**
Traditional SLE Activity Biomarkers:					
dsDNA positive	8/26 (31%)	1/16 (6%)	1/10 (10%)	10/52 (19%)	0.1
Low C3 and/or C4	7/26 (27%)	0/16 (0%)	0/10 (0%)	7/52 (14%)	**0.02**
dsDNA positive and/or Low C3 and/or C4	10/26 (39%)	1/16 (6%)	1/10 (10%)	12/52 (23%)	**0.03**
Extractable Nuclear Antibodies:					
Ro-60 positive	17/26 (65%)	5/16 (31%)	0/10 (0%)	22/52 (42%)	**0.001**
Sm positive	3/26 (12%)	0/16 (0%)	1/10 (10%)	4/52 (8%)	0.4
U1RNP positive	8/26 (31%)	3/16 (19%)	4/10 (40%)	15/52 (29%)	0.5

Biomarkers and Serologies.

Ro-60 were more frequently positive in patients with current Type 1 activity. Only 39% of patients with Type 1 SLE had positive dsDNA and/or low complement. MAP positivity, Sm, and U1-RNP did not distinguish between the groups. In a predictive model, the presence of BC4d >40 or Ro-60 >20 resulted in an 84.6% sensitivity, 73.1% specificity, and diagnostic odds ratio of 14.9 for Type 1 SLE activity.

Conclusion: CB-CAPs may serve as effective biomarkers to categorize current SLE activity using the Type 1 and Type 2 model. MAP scores as well as BC4d, EC4d, and Ro-60 positivity, but not traditional SLE-related antibodies, differentiated current Type 1 SLE activity from Type 2 SLE and low disease activity patients. The addition of CB-CAPs to PROs assessing Type 2 SLE enhances the rheumatologist's ability to categorize more completely the spectrum of SLE symptomatology.

Comparison of Two Frailty Definitions in Women with Systemic Lupus Erythematosus

Sarah Lieber[1], Musarrat Nahid[2], Alexandra Legge[3], Mangala Rajan[2], Robyn Lipschultz[1], Myriam Lin[1] and Lisa Mandl[1], [1]Hospital for Special Surgery, New York, NY, [2]Weill Cornell Medicine, New York, NY, [3]Dalhousie University, Halifax, NS, Canada

SESSION INFORMATION
Session Date: Sunday, November 7, 2021
Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster II: Manifestations (0855–0896)
Session Type: Poster Session B
Session Time: 8:30AM–10:30AM

Background/Purpose: Frailty is a novel risk factor for adverse health outcomes in systemic lupus erythematosus (SLE). Multiple definitions of frailty, including the Fried definition (FD), a disease-agnostic phenotypic definition, and the Systemic Lupus International Collaborating Clinics Frailty Index (SLICC-FI), a SLE-specific cumulative deficits definition, have been used to measure frailty in SLE [1,2]. However, the relationship between these two definitions of frailty has not been evaluated. We aimed to determine the prevalence of frailty according to the FD and the SLICC-FI in a single center cohort of adult women with SLE, as well as the cross-sectional association of each frailty definition with self-reported disability.

Methods: Women 18-70 years of age with SLE validated according to the 1997 Update of the 1982 American College of Rheumatology Revised Classification Criteria were enrolled. Frailty status according to the FD and the SLICC-FI was measured at a single study visit. Agreement between frailty metrics was determined using a kappa statistic. Sociodemographic features, physician-reported disease activity and damage, Patient Reported Outcome Measurement Information System (PROMIS) computerized adaptive tests, and Valued Life Activities (VLA) self-report disability were assessed. Differences between frail and non-frail participants were evaluated using Fisher's exact, Chi-squared, or Wilcoxon rank sum tests. The cross-sectional association of frailty according to each metric and VLA disability was assessed using logistic regression.

Results: Data from 67 participants were available for analysis. 12 (17.9%) and 18 (26.7%) of women were classified as frail according to the FD and the SLICC-FI, respectively. There was moderate agreement between frailty metrics (kappa = 0.41, $p< 0.01$). Compared to non-frail women, frail women had lesser educational attainment (FD: $p=0.05$; SLICC-FI: $p=0.03$) and greater disease damage (FD and SLICC-FI: $p< 0.01$) (Table 1). Frail women according to the FD were also older ($p=0.05$) with greater comorbidity burden ($p< 0.01$) and more likely to have smoked over their

Depression	51.3 [44.7, 57.5]	56.5 [48.1, 69.5]	0.12	51.3 [44.6, 57.5]	54.7 [48.1, 65.8]	0.13
Anxiety	54.1 [50.6, 51.5]	61.2 [48.1, 69.0]	0.33	53.6 [50.4, 61.3]	61.5 [52.9, 65.1]	0.15
Valued Life Activities† disability	0.5 [0.2, 0.9]	1.2 [1.1, 1.8]	<0.01	0.4 [0.1, 0.9]	1.1 [0.9, 1.5]	<0.01

*PROMIS: Patient Reported Outcome Measurement Information System. Scored using a T score metric, with 50 representing the population mean and a difference of 5 considered clinically significant.
†Valued Life Activities: Scores range from 0-3, with higher scores indicating greater disability.
‡Defined by presence of ≥3 criteria.
‡‡Defined by SLICC-FI score >0.21.

Table 3. Cross-sectional association of frailty with disability in women with SLE

Model	Fried phenotype (N=66)		SLICC-FI (N=66)	
	Odds ratio	*95% confidence interval*	*Odds ratio*	*95% confidence interval*
Unadjusted*	6.2	1.6-23.5	5.0	1.5-16.5
Adjusted for age	4.7	1.2-18.8	4.6	1.3-15.8

*Odds of Valued Life Activities disability score in the top quartile in frail versus non-frail women.

Conclusion: Frailty prevalence was higher according to the SLICC-FI than the FD in this single center cohort of women with SLE. Agreement was moderate and clinical characteristics differed between participants classified as frail according to each metric, suggesting differences in frailty constructs. Further studies are needed to explore discrepancies in frailty metrics to determine which may best predict relevant health-related outcomes in patients with SLE.

SESSION INFORMATION

Session Date: Sunday, November 7, 2021

Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster II: Manifestations (0855–0896)

Session Type: Poster Session B

Session Time: 8:30AM–10:30AM

Background/Purpose: The pathogenesis of neuropsychiatric SLE (NPSLE) has not been fully elucidated. Recent evidence suggests impaired blood brain barrier (BBB) integrity as a possible mechanism leading to neuropsychiatric damage. We aimed to assess brain imaging patterns in patients with SLE, NPSLE and healthy controls utilizing multi-parametric MRI methods to assess cerebral atrophy, tissue and BBB integrity. We also aimed to assess correlations between imaging findings, clinical characteristics and cognition.

Methods: Twenty-three consecutive patients attending the Lupus clinic (NPSLE n=11, non-NPSLE n=12), and 20 age and gender matched healthy subjects were recruited. The MRI protocol included high-resolution T1 sequence (MP2RAGE), diffusion tensor imaging and dynamic contrast enhanced imaging utilizing a 3-Tesla MRI scanner. Brain segmentation was performed to assess volumetric changes, tissue integrity and BBB permeability in various brain regions. Clinical parameters, quality of life and cognition were assessed. Patients were divided into subgroups based on presence of NPSLE, SLE disease activity, disease duration, accrued damage and presence of antiphospholipid antibodies (aPL). Comparisons were performed between the entire patient group and the control group and between subgroups.

Results: The NPSLE group was significantly younger than the non-NPSLE group and significantly less educated compared to the healthy controls and the non-NPSLE group. The NPSLE group had significantly shorter disease duration, more accrued damage, more hypertension compared to the non-NPSLE group and a higher percentage were treated with anticoagulants.

Abnormal findings on conventional MRI (cMRI) were seen in 67% of the non-NPSLE group and 82% of the NPSLE group. Brain atrophy was seen in 43% of the patients and was not limited to NPSLE. In the NPSLE group a negative correlation was observed between the volume of grey matter and disease duration. The grey matter volume was significantly reduced in the NPSLE group and in patients with aPL as compared to healthy controls. The volume of the nucleus accumbens was significantly reduced in patients with a damage index of ≤ 1 as compared to those without damage and compared to healthy controls. Impairment of BBB integrity, as expressed by increased permeability values compared to healthy controls was seen in 5 of the SLE patients (25%), 3 of whom were non-NPSLE. Increased

permeability was detected in several cerebral grey and white matter regions. All 5 patients had significantly longer disease duration (>10years) and as a group had a smaller volume of the anterior segment of the corpus callosum. One patient with SLE underwent MRI scanning during active disease and repeat scan when the disease was better controlled showing a reduction in BBB permeability by 25% in 8 brain regions.

Conclusion: In the present study we detected abnormal cMRI findings, brain atrophy and impaired BBB integrity among patients with SLE, which was not limited to patients with NPSLE. Our results suggest that impairment of the BBB occurs in patients with long disease duration and possibly during active disease, even in patients with SLE without overt NPSLE.

The Association of Hydroxychloroquine Dosing with Adverse Cardiovascular Events in Patients with Systemic Lupus Erythematosus

Alejandra Londono Jimenez[1], Mohammad Hashim Mustehsan[1], Ana Valle[2], Jammie Law[3], Shudan Wang[2], Maria Auxiliadora Salgado Guerrero[4], David Briceno[1] and Anna Broder[1], [1]Albert Einstein College of Medicine/Montefiore Medical Center, Bronx, NY, [2]Albert Einstein College of Medicine/Montefiore Medical Center, New York, NY, [3]Montefiore Medical Center, Bronx, NY, [4]Jacobi Medical Center/Albert Einstein College of Medicine, Bronx, NY

SESSION INFORMATION
Session Date: Sunday, November 7, 2021
Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster II: Manifestations (0855–0896)
Session Type: Poster Session B
Session Time: 8:30AM–10:30AM

Background/Purpose: Current guidelines recommend use of hydroxychloroquine (HCQ) at doses not exceeding 5mg/kg based solely on the increased risk of retinopathy at higher doses. This recommendation does not consider the impact of HCQ dose in comorbidities, disease activity or outcomes. Both protective and toxic effects of HCQ on cardiovascular health have been reported but how HCQ dose influences this balance is uncertain. We aimed to determine if HCQ dose is associated with all-cause heart failure with reduced ejection fraction (HFrEF), life-threatening arrhythmia or cardiac death in SLE.

Methods: This was a retrospective cohort study of SLE patients followed at a tertiary care center in the Bronx, New York between January 2005 and January 2021. SLE patients on HCQ with at least one echocardiogram were included. HCQ weight-based doses at HCQ start date and through follow up were recorded. The primary outcome was incident all-cause HFrEF, life-threatening arrhythmia or cardiac death. HFrEF was defined as documentation of clinical heart failure and a systolic ejection fraction < 50% on echocardiogram. Arrhythmia was defined as ventricular arrhythmia, sudden cardiac death, or need for implantable cardiac device or pacemaker. We used competing risk regression to study the association of HCQ dose with the composite outcome. Due to a significant interaction between smoking and HCQ exposure, models were stratified by smoking status.

Results: Of 296 patients, 38 (13%) developed the outcome over a median (IQR) follow up time of 7.0 (3.3,11.8) years. Mean age at baseline (HCQ start date) was 33 ± 13.6 years. A total of 267 (90%) were female and 278 (94%) self-identified as Hispanic or Black. At baseline, 97 (33%) had lupus nephritis, 44 (15%) had chronic kidney disease stage

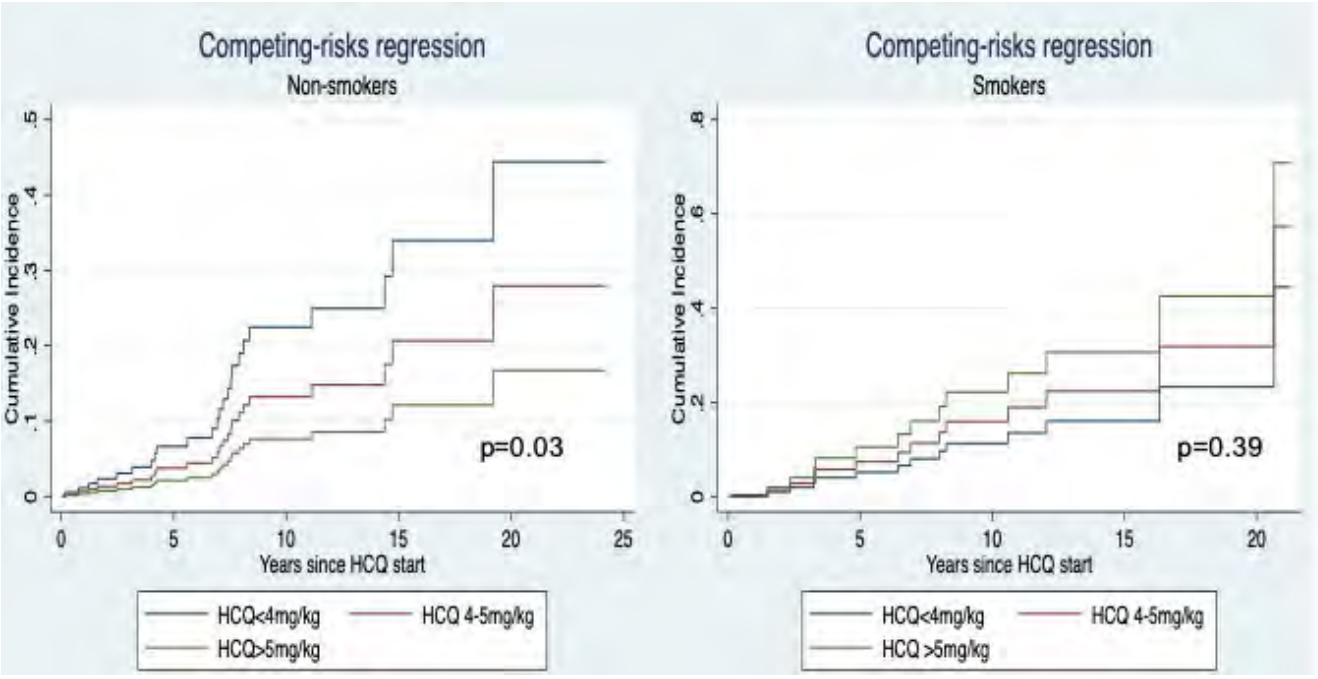
*Models adjusted for age, chronic kidney disease, thromboembolism and diabetes
** Shown models adjusted for age

Competing Risk Regression Analysis Stratified by Smoking Status.



Cumulative Incidence Curves Stratified by Smoking Status.

3 or higher, 26 (9%) had a history of thromboembolism or antiphospholipid syndrome, 101 (34%) had hypertension, 68 (23%) were smokers, 11 (4%) had diabetes and 7 (2%) had coronary artery disease. Mean HCQ weight-based dose was 5.2 ± 1.5 mg/kg at baseline and 5.1 ± 1.5 in average through follow up. Median (IQR) HCQ duration and cumulative dose were 6.5 (3.1, 11.3) years and 828 (328, 1467) grams, respectively. In non-smokers (n=225), multivariable analysis adjusted for age, chronic kidney disease, diabetes and thromboembolism showed that the risk of HFrEF or arrhythmia decreased by 28% per mg/kg of baseline HCQ dose, HR 0.72 (95% CI 0.53, 0.98), p=0.03

(Table). The cumulative incidence of the outcome was the lowest at doses >5mg/kg (Figure). Conversely, there was no significant association between higher baseline HCQ doses and the risk for the outcome among smokers (n=67), HR 1.12 (95% CI 0.77, 1.65) per mg/kg, p=0.56.

Conclusion: Higher HCQ doses were associated with a lower risk HFrEF, life-threatening arrhythmia or cardiac death among non-smoker SLE patients and no increased risk among smokers. If confirmed with future studies, these results would support the inclusion of the potential cardiovascular benefits derived from higher HCQ dosing into HCQ dosing risk-benefit considerations, beyond the risk for retinopathy.

Lack of Association Between Cognitive Test Performance and Cognitive Symptoms in Systemic Lupus Erythematosus (SLE)

Sudha Raghunath[1], Yifat Glikmann-Johnston[1], Emma Guymer[1], Eric Morand[2], Julie Stout[1] and Alberta Hoi[3], [1]Monash University, Melbourne, Australia, [2]School of Clinical Sciences at Monash Health, Monash University Faculty of Medicine, Nursing and Health Sciences, Monash Medical Centre Clayton, Melbourne, Australia, [3]Department of Rheumatology, Monash Health & Department of Medicine, School of Clinical Sciences, Monash University, Melbourne, Australia

SESSION INFORMATION
Session Date: Sunday, November 7, 2021
Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster II: Manifestations (0855–0896)
Session Type: Poster Session B
Session Time: 8:30AM–10:30AM

Background/Purpose: Cognitive dysfunction (CD) is reported to affect approximately 40% of SLE patients (1). Mood disorders have been associated with both cognitive symptoms and cognitive function in SLE, but the associations of fibromyalgia with these are unclear. We investigated the relationships between patient-reported cognitive symptoms and objective cognitive test results in SLE, and associations of fibromyalgia and mood disorders with both.

Methods: We tested SLE patients (n=87) and demographically matched healthy control (HC) participants (n=48) with the one-hour neuropsychiatric test battery recommended by the ACR for use in SLE (2) and applied three binary definitions of CD and seven cognitive test z-scores. We assessed patient-reported cognitive symptoms, mood disorder symptoms, fibromyalgia symptoms, and fatigue using the Cognitive Symptoms Inventory (CSI), Hospital Anxiety and Depression Scale (HADS), Central Sensitivity Score (CSS) derived from the 2016 ACR fibromyalgia diagnostic criteria (3) and the Functional Assessment of Chronic Illness Therapy Fatigue Scale (FACIT), respectively. We performed multivariate regression analysis to determine associations with cognitive endpoints; likelihood ratio tests were used to select for inclusion from collinear pairs. We used unpaired t tests to compare CSI scores between groups.

Table 1. Characteristics of Study Groups. 1) Sociodemographic variables were compared between the SLE and control groups using Mann-Whitney, Chi squared and T tests. 2) Premorbid IQ measured by Test of Premorbid Functioning scaled score. 3) HADs – Hospital Anxiety and Depression Scale. 4) Central Sensitivity Score = Widespread Pain Index plus Symptom Severity Score as per 2016 ACR Fibromyalgia Diagnostic Criteria. 5) Meeting 2016 ACR Fibromyalgia Diagnostic Criteria. 6) Impairment defined by number of cognitive domains either 1.5 or 2 standard deviations (SD) below healthy control group mean.

Anxiety History											3.47
FACIT total											

Results: Among SLE patients, the median (range) age was 45 (22-64). Compared to HC, CSS scores were higher (< 0.00001), fibromyalgia was more common (p 0.009) and a history of depression or anxiety was more frequent (p< 0.0001) in SLE patients (Table 1). Cognitive symptoms (CSI score) were worse in SLE patients than HC (median (range) 33 (19-52) vs. 26.5 (21-35), p < 0.0001). At all thresholds, cognitive dysfunction was also more frequent in SLE patients than HC. Age and premorbid IQ were significantly associated with multiple cognitive test endpoints but not with CSI score. On multivariate analysis, CSS, a history of depression, and HADS Anxiety each had significant associations with at least one CD endpoint, but history of anxiety or FACIT score did not. On univariate analysis, cognitive symptoms (CSI) consistently correlated with CSS, FACIT and all mood disorder covariates (CSI) (p 0.02 - < 0.001); on multivariate analysis, after selecting from collinear pairs, only CSS remained significant (p< 0.0001) (Table 2). There were no associations between cognitive symptoms and cognitive test results. Correspondingly, there was no significant difference in cognitive symptoms (CSI score) between cognitively impaired and unimpaired SLE patients at any cognitive impairment threshold (p values 0.22-0.47).

Conclusion: Cognitive impairment, and cognitive symptoms, are each common in patients with SLE, but there were no associations between patient-reported cognitive symptoms and objective cognitive test results. Depression, anxiety and fibromyalgia were more strongly associated with cognitive symptoms than with test results. The distinction between cognitive symptoms and cognitive function needs to be considered when assessing SLE patients with CD.

Clinical and Serological Characteristics of Latin American Patients with Lupus Enteritis: A Case-Control Study

Marcela Muñoz-Urbano[1], Julian Sanchez-Bautista[2], Yeison Santamaria-Alza[1], Diana C. Quintero-González[3], Andres Ramirez[2], Adriana Lucía Vanegas-García[4], Gloria M. Vasquez[1] and Luis Alonso Gonzalez[3], [1]Rheumatology section, Universidad de Antioquia, Medellín, Colombia, [2]Department of internal medicine, Universidad de Antioquia, Medellín, Colombia, [3]Division of rheumatology, Universidad de Antioquia, Medellín, Colombia, [4]Division of rheumatology, Universidad de Antioquia – Hospital San Vicente Fundación, Medellín, Colombia

SESSION INFORMATION
Session Date: Sunday, November 7, 2021
Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster II: Manifestations (0855–0896)
Session Type: Poster Session B
Session Time: 8:30AM–10:30AM

Background/Purpose: Lupus enteritis (LE) is a potentially life-threatening manifestation of systemic lupus erythematosus (SLE), with an incidence ranging from 8% to 27%. Timely diagnosis is essential for prompt treatment and the prevention of complications. As the clinical and immunological characteristics of LE have not been established in Latin American patients (1-2), we conducted a case-control study to investigate the clinical and serological characteristics compared with non-LE patients.

Methods: We performed a case-control study in SLE patients (per ACR criteria) at a tertiary care academic center from January 2012 to December 2019. Eleven patients with LE (cases) were matched with twenty-four non-LE patients (controls), who were similar in age and gender distribution to those of the group of cases. Descriptive statistics were used to compare them.

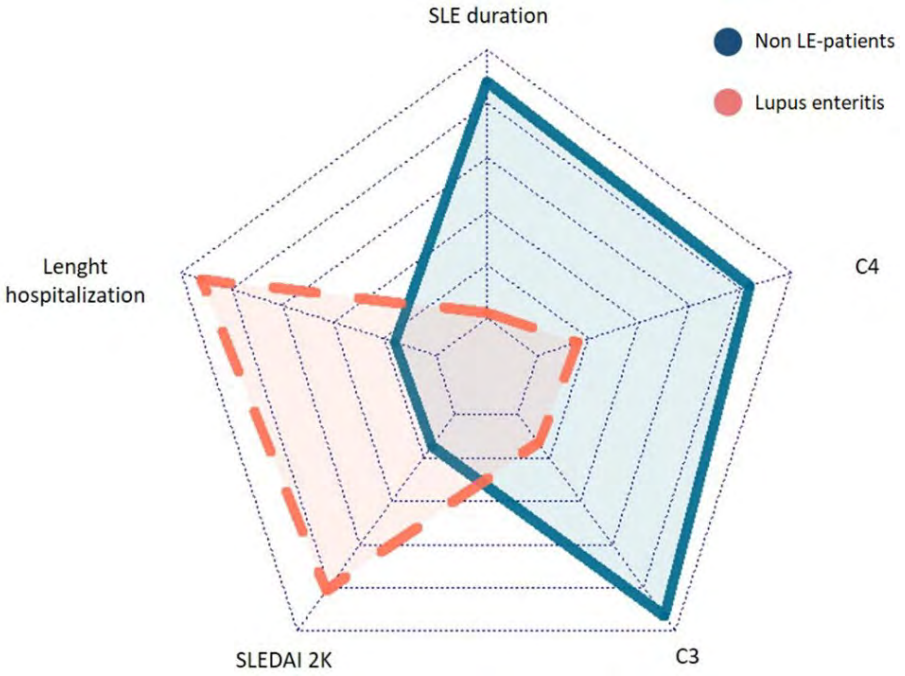

Figure 1. Spider diagram of quantitative variables with significant differences between the groups.

Table 1. Demographic, clinical, and immunological characteristics in patients with and without LE.

Variable	LE (n=11)	Non-LE (n=24)	p-value
Age, mean years ± SD	28.9±15.8	28.3±10.8	0.929
Female (%)	11 (91)	24 (96)	0.536

Concomitant skin involvement (%)	7 (64)	20 (83)	0.194
Concomitant joint involvement (%)	7 (64)	18 (75)	0.380
Concomitant hematologic compromise (%)	7 (64)	18 (75)	0.380
Concomitant serositis (%)	6 (54)	9 (37)	0.281

LE, Lupus enteritis; non-LE, non-enteric lupus; SD, standard deviation.

Results: LE patients were predominantly women (91%) and had a median age of 29 years. In seven (63.6%) patients LE was an initial presentation of SLE, 2 (18%) patients had a recurrence of LE, and 10 (90.9%) patients had concomitant lupus nephritis (LN). The most common clinical manifestations were abdominal pain (90.9%), nausea or vomiting (72.7%), fever (63.6%), and diarrhea (63.6%). Imaging studies revealed the target sign (63.6%), increased attenuation of mesenteric fat (18%), and bladder wall thickening (9.1%). Only one death was recorded and was due to sepsis. All patients received steroids as initial treatment, 82% intravenous (IV) pulses of methylprednisolone, 72.7% IV cyclophosphamide, 9.1% azathioprine, 9.1% mycophenolate mofetil, 9.1% rituximab, and 9.1% IV immunoglobulin. Among the eight patients who received cyclophosphamide, seven had LN or another severe SLE manifestation, which was the main indication for the additional immunosuppressant. LE patients had a significantly shorter disease duration (51 vs 75 months, p=0.046), longer hospital stay (28.7 vs 8.9 days, p=0.0007), higher SLEDAI-2K scores (22.3 vs 6.6, p=0.0001), lower levels of C3 (55.2 vs 85.9 mg/dL, p= 0.004) and C4 (10.4 vs 18.0 mg/dL, p= 0.014), and higher positivity of anti La antibodies (33.3% vs 0%, p= 0.042) compared to non-LE patients.

Conclusion: In Latin American patients, LE is an early SLE manifestation and often with coexistent LN. LE patients had evidence of more active disease than those without LE and had a moderate recurrence rate despite aggressive immunosuppressive therapy.

Abstract Number: 0874

Serum Galectin-9 and CXCL-10 but Not Their Urinary Levels Reflect Lupus Activity

Pankti Mehta, Pratibha Singh and Amita Aggarwal, Sanjay Gandhi Post Graduate Institute of Medical Sciences, Lucknow, India

SESSION INFORMATION
Session Date: Sunday, November 7, 2021
Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster II: Manifestations (0855–0896)
Session Type: Poster Session B
Session Time: 8:30AM–10:30AM

Background/Purpose: SLE is characterized by increased type I IFN signature in the blood and immune cells. Traditionally, type I IFN signature is measured by gene expression analysis however it is difficult to compute in routine clinical practice. IFN alpha levels are very low and need a highly sensitive assay for its measurement, thus we aimed to look at proteins affected by IFN-alpha like galectin-9 and CXCL-10 as markers of SLE activity as well as for lupus nephritis.

Methods: Patients with SLE (fulfilling SLICC criteria) were included and clinical parameters recorded. They were divided based on renal involvement and disease activity into—active (SLEDAI≥4) renal, active non-renal and inactive subgroups. 20 healthy controls (HC) were also included. Serum and urine galectin-9 and CXCL-10 levels were measured by ELISA. Urine galectin-9 and CXCL-10 were normalized with spot urine creatinine values. Follow-up serum and urine galectin-9 levels were measured for those in the active renal group at six-months. Non-parametric test like Kruskal Wallis test, Spearman's correlation coefficient, and ROC curve analysis were used.

Results: 97 patients with SLE (26 years; 89 females) were categorized into active renal disease (35), inactive disease (32) and active non-renal disease (30). 20 HC (25 years; 15 females) were enrolled.Themedian duration of disease was 24 months (6-48)and SLEDAI 2K was 9 (2-15).

Patients with SLE had higher serum galectin-9 (5.652 vs 1.702 ug/ml, p=0.0001) but not urine galectin-9 (0.538 vs 0.317 ug, p=0.7) levels as compared to HC. Serum galectin-9 but not urine galectin-9 was higher in patients with active as compared to inactive lupus (12.912 in active renal, 16.777 in active non-renal vs 3.565 ug/ml, p=0.04 and 0.005). There was no significant difference in serum or urine galectin-9 between active renal and active non-renal disease.

Patients with SLE had higher CXCL-10 (0.164 vs 0.046ug/ml, p=0.0003) and urine CXCL-10 levels (0 vs 0 ug, p=0.01) as compared to HC. Patients with active non-renal disease had higher serum CXCL-10 levels as compared to inactive lupus (0.365 vs 0.086 pg/ml, 0.02), however, urine CXCL-10 was not significantly different between active renal and

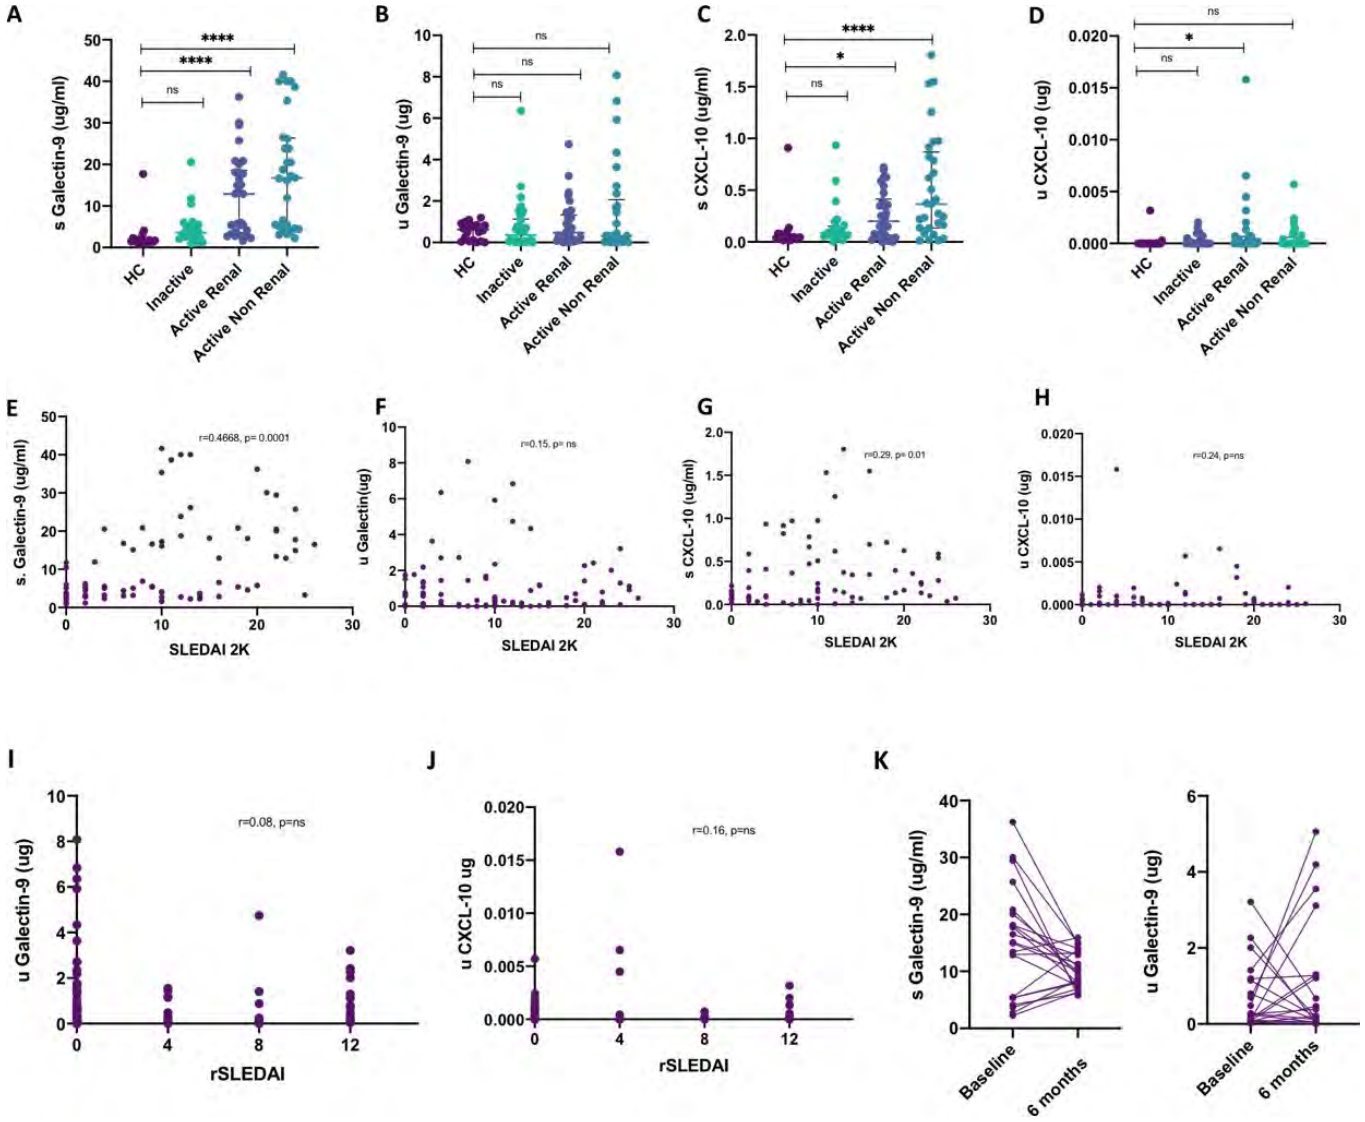

Figure 1. Comparison of serum galectin-9 (A), urine galectin-9 (B), serum CXCL-10 (C) and urine CXCL-10 (D) across active renal, active non-renal, inactive renal and healthy controls. Correlation of serum galectin-9 with SLEDAI 2K (E), urine galectin-9 with SLEDAI 2K (F), serum CXCL-10 with SLEDAI 2K (G) and urine CXCL-10 with SLEDAI 2K (H). Correlation of urine galectin-9 and CXCL-10 with renal SLEDAI (I, J). Follow up levels of serum and urine galectin 9 in the active renal subgroup at baseline and 6 months (K).

inactive subgroup. There was no difference in serum or urine CXCL-10 between active renal and active non-renal disease. [Fig 1A-D]br>

Serum galectin-9 and serum CXCL-10 showed a good association with SLEDAI2K however urinary galectin-9 and CXCL-10 had no association with SLEDAI2K [Fig 1E-H]. Serum galectin-9 and CXCL-10 levels had a modest correlation (r=0.4) with SLEDAI2K, both the urinary markers did not show any association with rSLEDAI. [Fig I-J]

In a subset of patients with active renal disease, serum galectin-9 levels significantly reduced after six-months whereas urine galectin did not show a significant fall [Fig 1K]. Serum galectin-9 showed a greater AUC than CXCL-10 (0.77 vs 0.67) in differentiating active SLE from inactive disease.

Conclusion: Serum Galectin-9 and CXCL10 are good markers of lupus activity however they do not differentiate between active renal and active non-renal disease. Urinary Galectin-9 & CXCL10 do not reflect renal activity.

Renal Function, Adherence and Low Hydroxychloroquine Dosing Predict HCQ Blood Levels and Lupus Disease Activity

Shivani Garg[1], Karen Hansen[2], Betty Chewning[1] and Christie Bartels[2], [1]UW Madison, Madison, WI, [2]University of Wisconsin School of Medicine and Public Health, Madison, WI

SESSION INFORMATION
Session Date: Sunday, November 7, 2021
Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster II: Manifestations (0855–0896)
Session Type: Poster Session B
Session Time: 8:30AM–10:30AM

Background/Purpose: Despite weight-based dosing, hydroxychloroquine (HCQ) efficacy varies between individuals. Our meta-analysis based on several studies found that low HCQ levels increased risk of lupus flare, while high levels increased the risk of macular toxicity. Aside from body weight, factors influencing HCQ levels are not well defined. Understanding such factors could guide clinicians to adjust HCQ doses, with the aim of controlling lupus disease activity while minimizing toxicity. Thus, we examined individual factors associated with variations in HCQ levels. We also evaluated the impact of HCQ levels on SLE disease outcomes.

Methods: Inclusion criteria were: a) age ≥18 years, b) 1997-ACR, 2012-SLICC or 2019-ACR/EULAR confirmed SLE, c) prescribed HCQ ≥1 month before enrollment. We measured consented patients' whole blood HCQ levels after clinic visits. We abstracted data on patients' demographics, disease characteristics, laboratory values, SLE disease activity index (SLEDAI), and patient-reported adherence (0-100% MASRI Visual analogue scale (VAS); ≥80% adherence) on the day of the visit. We measured HCQ blood levels by liquid chromatography mass spectrometry. We used linear and logistic regression models to test associations between interindividual factors and HCQ blood levels, and between HCQ levels and SLE outcomes.

Results: Patient and clinical characteristics are summarized in Table 1. Among 82 samples collected from 70 patients between 8/1/20 and 5/20/21, mean±SD HCQ levels were 813±502 ng/ml. HCQ dosing, renal function and adherence were the key variables predicting HCQ levels. We noted that regardless of adjustment for body weight, patients taking

200 mg/day had lower HCQ levels (Mean Difference -415 ng/ml, CI -134, -697; p 0.005, Table 2). We found an inverse relationship between renal function and HCQ blood levels. For every 10 mL/min increment in glomerular filtration rate (GFR), there was a 44 ng/mL decline in HCQ levels (CI -43, -84; p 0.03). Further, we found that patients with CKD stage ≥3 had significantly higher HCQ levels by 345 ng/ml (CI 42, 648; p 0.02, data not shown). Finally, we found that every 10% increase in patient-reported adherence predicted an 83 ng/ml increase in HCQ levels (CI 45, 120; p < 0.001). We found no associations between weight and HCQ levels.

HCQ levels ≥500 ng/ml predicted 40-fold higher odds of patient-reported adherence by VAS (p 0.0007, data not shown). There was a good correlation between HCQ levels and patient-reported adherence (0.55, p < 0.001, data

Table 3. Multivariable Analysis of HCQ Blood Levels Predicting Active SLE, SLEDAI ≥6 in Age, Gender, Race, and Patient-Reported Adherence Model; n = 82 blood samples

Table 3. Multivariable Analysis of HCQ Blood Levels Predicting Active SLE, SLEDAI ≥6 in Age, Gender, Race, and Patient-Reported Adherence Model; n = 82 blood samples

Variables	OR Active SLE (95% CI)	p-value
HCQ Level Categories		
<250 ng/ml	*ref*	*ref*
>250-500 ng/ml	0.77 (0.65, 8.6)	0.83
>500-750 ng/ml	1.1 (0.15, 8.8)	0.95
>750-1000 ng/ml	0.18 (0.01, 2.3)	0.21
>1000 ng/ml	**0.06 (0.002-0.77)**	**0.04**

**Includes Hispanic ethnicity; Significant findings bolded*

not shown). Finally, we noted that HCQ levels ≥1000 ng/ml predicted 94% lower odds of active SLE (SLEDAI ≥6) (OR 0.06, CI 0.002-0.77, p 0.039, Table 3) and clinically meaningful change in SLEDAI (-2.7, CI -1.1, -4.4, p 0.036).

Conclusion: We found that HCQ dose, adherence and renal function predicted significant variations in HCQ blood levels. Patients with CKD stage ≥3 had markedly higher HCQ levels, which could portend higher HCQ toxicity in this group. Conversely, prescribing lower HCQ doses could permit higher flare risk. Our findings support that individualizing HCQ dosing based on GFR could benefit SLE patients. Future work will focus on how to effectively individualize dosing to reduce toxicity and flares in diverse SLE patients.

Session Type: Poster Session B
Session Time: 8:30AM–10:30AM

Background/Purpose: Patients with Systemic Lupus Erythematosus (SLE) often receive immunosuppressive treatment for many years, resulting in higher risk of infections, including COVID-19, and infections may trigger disease flares. Patients with SLE show reduced immunogenicity against influenza and pneumococcal vaccination, however the immune response depends on immunosuppressive therapy and disease activity. Our aim was to investigate the immune response during a 24-month follow-up period in patients with SLE following COVID-19 vaccination with a two-dose regimen.

Methods: Patients with SLE (≥18 years of age) in the Region of Southern Denmark were invited to participate in the study. Blood samples were drawn approximately 3 weeks after the first vaccination and 4 and 8 weeks after

*** TNFα inhibitors, Belimumab, Rituximab.*

the second vaccination. SLEDAI-score and SLICC damage were assessed between vaccinations and 8 weeks after the second vaccination. Patients' hospital records were reviewed for clinical information and treatment data. Anti-SARS-CoV-2 Spike IgG was determined using Abbotts SARS-CoV-2 IgG II Quant. Resulting concentrations (AU/ml were converted to IU/ml using a lot-specific factor calibrated against the "First WHO International Standard for anti-SARS-CoV-2 immunoglobulin (20/136)). A positive cut off for Anti-SARS-CoV-2 Spike IgG was set at >8.7 IU/ml. Nucleocapsid IgG was determined using Abbotts SARS-CoV-2 IgG.

Results: A total of 128 patients with SLE were included in the study. We report the preliminary results of antibody response to the SARS-CoV-2 spike antigen of 90 patients who have completed the two-dose vaccine regimen in this ONGOING STUDY (Table 1). Of these, 55 (49.5%) of the participants had blood samples drawn for IgG antibodies after the first vaccination and seropositive SARS-CoV-2 spike IgG antibody titers were detected in 31 (56.4%) with an overall mean of 92.7 IU/ml (±327.6).

The response rate was increased to 93.3% (84) four weeks after the second dose with an overall mean of 1601.3 IU/ml (±1752.6). Of participants with a positive response 81 (96.4%) recieved the BNT162b2 vaccine, 2(2.4%) recieved the AZD1222 vaccine and 1(1.2%) recieved the mRNA-1273 vaccine.

The median SLEDAI score was 2 (IQR: 0-6) and SCLICC damage score was 1 (IQR: 0-2) between vaccinations, and there was no significant difference between responders and non-responders (Mann-Whitney, P=0.2113 and P=0.0623, respectively). All participants were negative for SARS-CoV-2 nucleocapsid IgG, suggesting that none of the patients had COVID-19 prior to vaccination.

Conclusion: Patients with SLE had a good antibody response after COVID-19 vaccination, without secondary flare of disease activity.

Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster II: Manifestations (0855–0896)
Session Type: Poster Session B
Session Time: 8:30AM–10:30AM

Background/Purpose: HCQ levels reflect adherence and have been shown to correlate with SLE outcomes. However, HCQ levels have not been studied in the context of a novel conceptual model which categorizes SLE activity into Type 1 (including arthritis, rash, nephritis) and Type 2 manifestations (including myalgias, mood disturbance, and cognitive dysfunction). We hypothesized that HCQ levels would inversely correlate with Type 1 but not Type 2 SLE activity.

Methods: Those meeting ACR or SLICC classification criteria for SLE were recruited from an academic lupus clinic. We measured whole blood HCQ levels using liquid chromatography coupled to mass spectrometry. Patients were categorized by HCQ levels as under-exposed (HCQ < 200 ng/ml), subtherapeutic (HCQ between 200-1000 ng/ml), or

Table 1. Comparing socio-demographics, self-reported adherence, and HCQ dosing information among patients with different HCQ levels.

	Total cohort (n=81)	Under-exposed HCQ (n=12)	Subtherapeutic HCQ (n=32)	Therapeutic HCQ (n=37)	p-value
Socio-demographics					
Age in years	42[30-49]	33[27-37]	44[32-53]	38[30-49]	0.07
Female gender	90%	92%	94%	86%	0.6
Black	73%	92%	66%	73%	0.2
Less than a College Education	51%	75%	50%	43%	0.2
Married/cohabitating	39%	33%	47%	34%	0.5
Income over $50,000	29%	8%	23%	42%	0.06
Private Insurance	58%	42%	47%	73%	0.04
Self-Reported Adherence:

Table 2. Comparing measures of Type 1 and Type 2 SLE activity among patients with different HCQ levels.

	Under-exposed HCQ (n=12)	Subtherapeutic HCQ (n=32)	Therapeutic HCQ (n=37)	p-value
Type 1 SLE Activity:				
Type 1 PGA	1[0.5-1.5]	0.5[0.1-1.3]	0.25[0-0.8]	0.04
Type 1 PGA ≥1	67%	34%	19%	0.008
SLEDAI	5[0-9]	2[0-4]	2[0-4]	0.3
Type 2 SLE Activity:				
Type 2 PGA	1.4[0.5-2]	0.5[0.3-1.1]	0.5[0.25-1.3]	0.03
Type 2 PGA ≥1	67%	34%	35%	0.1
Depression (PHQ-2)	15%	11%	17%	0.6
Polysymptomatic Distress Score[1]	16[12-23]	8[4-12.5]	8[3.5-11]	0.01
Widespread Pain Index	8[3.5-12.5]	3.5[1-7]	3[1-6]	0.07
Symptom Severity Score	7[5-10]	4[2-5]	4[1.5-6]	0.07
Fatigue[2]	67%	63%	35%	0.07
Cognitive dysfunction[2]	44%	8%	12%	0.03
Unrefreshed sleep[2]	78%	31%	25%	0.02

Footnotes: continuous variables are summarized by median [interquartile range];
[1]Polysymptomatic distress score is the sum of widespread pain index and symptom severity score; [2]Fatigue, cognitive dysfunction, and unrefreshing sleep are components of the symptom severity score; the percentage of patients reporting moderate-severe levels of these symptoms.

therapeutic (HCQ >1000 ng/ml). Type 1 SLE activity measures included Type 1 Physician Global Assessment (PGA) and SLEDAI. Type 2 SLE activity measures included Type 2 PGA, patient-reported Polysymptomatic Distress (PSD) score, and depression based on the Patient Health Questionnaire-2. SLE groups were defined as Minimal (low Type 1 and 2 activity), Type 1 (high Type 1 and low Type 2 activity), Mixed (high Type 1 and 2 activity), and Type 2 (low Type 1 and high Type 2 activity). Self-reported adherence was measured using the visual analog scale of the Medication Adherence Self-Report Inventory. We used the Chi-squared and Kruskal-Wallis tests to examine differences across patient groups.

Results: This analysis included 81 patients (median age 42, 90% female, 73% Black, 51% < college education, 39% married or cohabiting, 29% with annual household income >$50,000, and 58% with private insurance). HCQ levels were under-exposed in 15%, subtherapeutic in 39%, and therapeutic in 46% of patients (Table 1).

Patients with therapeutic HCQ levels were more likely to have private insurance and a trend for older age and higher income. Self-reported adherence was similarly high among the three HCQ groups. Patients with lower HCQ levels are more likely to have lower creatinine, but weight and HCQ dose prescribed did not appear to play a consistent role in therapeutic drug level.

Lower HCQ levels were significantly associated with both higher Type 1 and Type 2 SLE activity. Patients with lower HCQ levels self-reported a higher PSD score, more cognitive dysfunction and nonrestorative sleep. There was also a trend for patients with lower HCQ blood levels to have more fatigue, areas of pain, and higher symptom severity scores (Table 2).

Comparing HCQ levels across SLE groups, patients with Mixed SLE activity had significantly lower HCQ levels compared to all other patients (Table 3).

Conclusion: More than half of the patients had lower than therapeutic HCQ blood levels, and surprisingly, this was associated with both higher Type 1 and Type 2 SLE activity. Although Type 2 SLE manifestations are conventionally

Table 3. Comparing HCQ levels across SLE groups.

	Minimal (n=37)	Type 1 (n=11)	Mixed (n=20)	Type 2 (n=7)	p-value
HCQ level	1005 [708-1247]	1005 [660-1581]	502 [18-992]	1402 [1338-1418]	0.048
HCQ<200	3%	18%	35%	0%	0.007
HCQ 200-1000	46%	27%	40%	14%	
HCQ>1000	51%	55%	25%	86%	

Footnotes: continuous variables are summarized by median [interquartile range]

High Type 1 SLE activity is defined by: SLEDAI ≥6, clinical SLEDAI ≥4, active lupus nephritis, or Type 1 PGA ≥1.0; High Type 2 is defined by: FSS ≥8 or Type 2 PGA ≥1.0

SLE groups are defined as: Minimal (low Type 1 and 2 activity), Type 1 (high Type 1 and low Type 2 activity), Mixed (high Type 1 and 2 activity), and Type 2 (low Type 1 and high Type 2 activity).

thought to be noninflammatory, their inverse association with HCQ blood levels in patients with concurrent Type 1 SLE activity suggest that in some SLE patients, immunologic activity may contribute to these debilitating symptoms.

Abstract Number: 0878

Investigating the Neutrophil to Lymphocyte Ratio as a Marker of SLE Disease Activity, Health-Related Quality of Life and Depression

Eleni Papachristodoulou[1], Loukas Kakoullis[1], Savvas Psarelis[2], Victor Hajiroussos[3], Costas Christophi[4] and Konstantinos Parperis[1], [1]University of Cyprus Medical School, Nicosia, Cyprus, [2]Nicosia General Hospital/University of Cyprus Medical Schooll, Nicosia, Cyprus, [3]Ygia Polyclinic Hospital, Limassol, Cyprus, [4]Cyprus University of Technology, Limassol, Cyprus

SESSION INFORMATION

Session Date: Sunday, November 7, 2021

Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster II: Manifestations (0855–0896)

Session Type: Poster Session B

Session Time: 8:30AM–10:30AM

Background/Purpose: The need for readily available markers of SLE activity has led to the evaluation of laboratory parameters, such as the neutrophil to lymphocyte ratio (NLR). Our goal was to ascertain the association of NLR with SLE activity and damage, and further evaluate its association with disease specific health-related quality of life (HRQoL) and depression.

Methods: This cross-sectional study included data from 134 patients from the Cyprus SLE registry. All patients fulfilled the SLICC classification criteria 2012. The following data were captured: NLR, demographic parameters, patient self-rated health (poor/fair vs. good/excellent), SELENA-SLEDAI index (score ≥4 was defined as active disease), SLICC/ACR damage index (DI) (damage defined as score ≥1). HRQoL was assessed by the Lupus QoL, a disease specific measure that includes 8 domains (physical health, pain, planning, intimacy, burden to others, emotional health, body image, and fatigue). Each domain score ranges from 0 to 100, with higher scores indicating better QoL. Depression was evaluated by the patient health questionnaire (PHQ-9) and higher scores suggest the presence of im-

Table 1. Activity index - SELENA-SLEDAI, Damage index - SLICC/ACR DI, Lupus QoL and PHQ9 indices

% No		116 (87.9%)		81 (94.2%)		35 (76.1%)	
PHQ 9 score	131	6 [3, 11]	86	6 [2, 10]	45	7 [3, 14]	0.082

Abbreviations: SELENA-SLEDAI, Safety of Estrogens in Lupus Erythematosus National Assessment - Systemic Lupus Erythematosus Disease Activity Index; SLICC/ACR DI, Systemic Lupus International Collaborating Clinics/American College of Rheumatology Damage Index; Lupus QoL, Lupus Quality Of Life; PHQ, Patient Health Questionnaire; NLR, Neutrophil to lymphocyte ratio.

paired depressive symptoms. Scores ≥15 are consistent with severe or moderately severe depression. Patients were separated in two groups using an NLR cutoff of 2.73, which corresponds to the 90th percentile of healthy individuals. Mean ± SD and median (q1, q3) were reported for normally and not normally distributed variables and compared using the student's t-test and Wilcoxon test, respectively. Categorical variables were compared using the $\chi 2$ test of independence. Unadjusted and adjusted logistic regression models were used, adjusting for age, sex, and BMI and odds ratios (OR) with the corresponding 95% CIs and p-values were reported. All tests performed were two-tailed, using an alpha level of significance of 0.05

Results: Out of the 134 SLE patients, 47 (35%) had NLR ≥2.73 and among them the mean age was 47 years old and 85% were females. Compared to the NLR< 2.73 group, SLE patients with NLR ≥2.73 were more likely to report poor/fair self-rated health (53.2% vs. 28.7%, p=0.005) and higher activity based on the SELENA-SLEDAI-index (median

4 vs. 2, p=0.002). There was no statistically significant difference between the groups in SLICC/ACR DI (p=0.054) or presence of damage (p=0.057). Several LupusQoL domains such as physical health (p=0.012), planning (p=0.010), and body image (p=0.028), were significantly lower in the high NLR group (Table 1). While no significant difference was found in the presence of depression (PHQ ≥10) (p=0.143) or overall PHQ-9 score (p=0.082), there were significantly more patients with moderately severe or severe depression (PHQ ≥15) in the high NLR group (23.9% vs. 5.8%, p=0.002). Adjusted logistic regression models revealed a significant association between high NLR and moderately severe or severe depression (OR=7.21), poor/fair self-reported health (OR=2.79), high disease activity (SLEDAI≥4) (OR=2.23) and the presence of damage (SLIC/ACR DI ≥1) (OR=2.51).

Conclusion: High NLR in SLE patients is associated with active disease, damage, severe depression, and worse HRQoL and self-rated health.

Anti-dsDNA Antibodies Increase Systemic Lupus Erythematosus Cardiovascular Risk Impairing the Immune and Cardiovascular Systems

Carlos Pérez-Sánchez[1], Alejandra Patiño-Trives[2], Maria Angeles Aguirre[3], Laura Perez-Sanchez[3], Chary Lopez-Pedrera[3], Maria Luque-Tevar[2], Maria del Carmen Ábalos-Aguilera[3], Iván Arias de la Rosa[4], Cristobal Román-Rodriguez[3], Pedro Segui[3], Mario Espinosa[3], Pilar Font[3], Nuria Barbarroja[4], alejandro Escudero[3], Eduardo Collantes-Estevez[3], Jose Antonio Gonzalez-Reyes[5], Jose Manuel Villalba[5] and Chary lopez-pedrera[3], [1]IMIBIC, Córdoba, Spain, [2]Rheumatology Department, Reina Sofia University Hospital/ Maimonides Institute for Research in Biomedicine of Cordoba (IMIBIC)/ University of Cordoba, Cordoba, Spain, [3]IMIBIC/Reina Sofia Hospital/University of Córdoba, Córdoba, Spain, [4]University of Cordoba/IMIBIC/Reina Sofia Hospital, Cordoba, Spain, [5]Department of Cell Biology, Physiology and Immunology, University of Córdoba, Campus de Excelencia Internacional Agroalimentario, ceiA3, Cordoba, Spain

SESSION INFORMATION
Session Date: Sunday, November 7, 2021
Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster II: Manifestations (0855–0896)
Session Type: Poster Session B
Session Time: 8:30AM–10:30AM

Background/Purpose: This study aimed to delineate the role of anti-dsDNA antibodies on the alterations observed in the gene profile and the activity of immune and vascular cells in systemic lupus erythematosus (SLE) patients, as well as on their cardiovascular risk.

Methods: Eighty SLE patients were included. Extensive clinical/analytical evaluation was performed, including parameters related to cardiovascular diseases (CVD) such as endothelial function, proatherogenic dyslipidemia, and carotid intima-media thickness. Gene and protein expression profiles were evaluated in monocytes from patients positive and negative for anti-dsDNA antibodies by using Nanostring and cytokine arrays respectively. NETosis was assessed in both, neutrophils and plasma through analysis of nucleosomes, neutrophil elastase, and myeloperoxidase. The circulating inflammatory profile was also quantified by Luminex assays.

Results: Positivity and persistence of anti-dsDNA antibodies in SLE patients were found associated with endothelial dysfunction, pro-atherogenic dyslipidemia, and accelerated atherosclerotic process. In parallel, anti-dsDNA antibodies were linked to the aberrant activation of innate immune cells, so that anti-dsDNA(+) SLE monocytes showed distinctive gene and protein expression/activity profiles, and neutrophils were more prone to suffer NETosis in com-

parison with anti-dsDNA(-) patients. Anti-dsDNA(+) patients further displayed altered levels of numerous circulating mediators related to inflammation, NETosis, and enhanced CV risk. In vitro, Ig-dsDNA promoted NETosis on neutrophils, apoptosis on monocytes, modulated the expression of inflammation and thrombosis-related molecules, and induced endothelial activation, at least partially, by FcR-binding mechanisms.

Conclusion: Anti-dsDNA antibodies increase the cardiovascular risk of SLE patients by altering key molecular features that drive a distinctive and coordinated immune and vascular activation.

SESSION INFORMATION

Session Date: Sunday, November 7, 2021

Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster II: Manifestations (0855–0896)

Session Type: Poster Session B

Session Time: 8:30AM–10:30AM

Background/Purpose: The spread of COVID-19 misinformation is especially serious for individuals with complex diseases like SLE; conflicting and/or unfounded information can complicate a patient's health decision making and exacerbate stress. We assessed how SLE patients access and trust health information pre and during COVID-19.

Methods: Canadian and international patients fulfilling the ACR or Systemic Lupus International Collaborating Clinics (SLICC) Classification Criteria for SLE were recruited from 15 observational SLE research cohorts, and patients self-reporting SLE were recruited through five patient advocacy organizations. Participants completed an online survey from June 2020-April 2021 regarding the sources of health information they accessed in the 12 months preceding

(pre 03/11/2020) and during the COVID-19 (post 03/11/2020) pandemic. We calculated the percentage of patients accessing each source of information, their preferred sources, and the level of trust in each source. McNemar tests were used to compare frequencies pre and post 03/11/2020 in the Canadian and international samples.

Results: 845 Canadian and 1090 international (Asia n=201, Europe n=324, Latin America n=118, US n=447) patients completed the survey (40.4% and 21.0% response rates, respectively); 78.0% were recruited through SLE research cohorts, 92.7% were female, 35.2% reported non-white race/ethnicity, mean age at diagnosis was 32.0 years (SD 13.3) and mean disease duration was 16.6 years (SD 12.0). 76.6% of participants had completed post-secondary education, and 2.1% reported a positive COVID-19 test. Canadian and international patients accessed news media more frequently during vs pre pandemic (44.6% of Canadians accessed sometimes/often/always pre vs 52.1% during; 59.8% of international participants accessed pre vs 68.9% during), while access to family physicians, lupus specialists, pharmacists and alternative care providers decreased in both samples during the pandemic (Table 1). Lupus specialists and family physicians were ranked the most preferred information sources (Table 2) and considered the most trustworthy (Table 3) pre and during the pandemic. News media was more preferred post vs pre 03/11 (Table 2), yet was considered less trustworthy in Canada (44.5% rated online news media as somewhat/very trustworthy pre vs 41.8% post) and internationally (43.0% pre vs 40.2% post) during COVID-19 (Table 3). In both samples, patient

**Respondents who reported source as somewhat/very trustworthy*						

advocacy organizations were accessed less frequently pre and during COVID-19 than other less preferred and trusted sources (e.g., peers, social media), and trust in advocacy organizations decreased during the pandemic in both Canadian and international samples by 4.1% and 5.0%, respectively.

Conclusion: Although lupus specialists and family physicians were ranked as the most preferred and trustworthy health information sources, patients accessed these sources less frequently during the pandemic and accessed news media, a less trusted source, more frequently. To increase accessibility to preferred and trusted sources, virtual visits should be promoted where not already in place. This research will improve existing information dissemination pathways valued by SLE patients.

SESSION INFORMATION

Session Date: Sunday, November 7, 2021

Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster II: Manifestations (0855–0896)

Session Type: Poster Session B

Session Time: 8:30AM–10:30AM

Background/Purpose: Little is known about the economic burden of NP lupus. We estimated annual and cumulative direct and indirect costs (DC, IC) associated with NP events attributed to SLE and non-SLE causes using multistate modelling in a multicentre, multi-ethnic inception cohort.

Methods: Patients fulfilling revised ACR classification criteria for SLE from 31 centres in 11 countries were enrolled within 15 months of diagnosis. NP events were documented annually using ACR NP case definitions and attributed to either SLE or non-SLE causes. At each assessment and for both SLE and non-SLE events, patients were stratified into 1 of 3 NP states (no, resolved, or new/ongoing NP event). The change in NP status characterized by transition rates between states was analyzed over time, using multistate modelling for SLE attributed NP events and non-SLE attributed NP events (*Hanly. A&R 2021;* https://doi.org/10.1002/art.41876*)* (Fig 1).

At each assessment, annual DC and IC were based on health resource use and lost work-force/non-work-force productivity over the preceding year. Resource use was costed using 2021 Canadian prices and lost productivity using Statistics Canada age-and-sex specific wages. Costs associated with each SLE and non-SLE NP state were

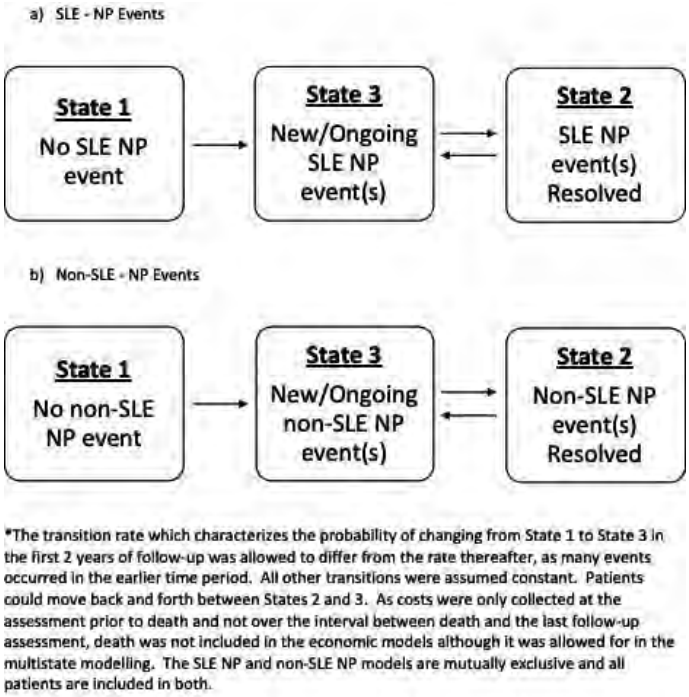

Figure 1. Reversible Multistate Patient Level Models for Observed Transitions* in a) SLE NP Events and b) Non-SLE NP Events.

Table 1. Observed Annual Unadjusted Costs (in 2021 Canadian dollars), Stratified by a) SLE NP State and b) Non-SLE NP State

a) SLE NP States

Current NP State	Patients no. *	Observations, no. (%)	Direct Costs Mean (95%CI)	Indirect Costs Mean (95%CI)
State 1**	1487	11155 (80)	6474 (5752, 7196)	24459 (23130, 25788)
State 2	235	1562 (11)	8254 (6449, 10058)	28224 (25059, 31390)
State 3	273	1270 (9)	10721 (8409, 13033)	35921 (32318, 39524)

b) Non-SLE NP States

Current Non-SLE NP State	Patients no.	Observations, no. (%)	Direct Costs Mean (95%CI)	Indirect Costs Mean (95%CI)
State 1	1280	8169 (58)	5874 (5238, 6511)	22322 (20828, 23815)
State 2	504	2922 (21)	8430 (6622, 10238)	30317 (28050, 32584)
State 3	620	2896 (21)	8789 (7381, 10198)	34454 (31638, 37271)

*The number of patients exceeds 1697 as a single patient may have multiple NP states during the study duration and will contribute observations to multiple states.

** State 1 = no NP event; State 2 = resolved NP event; State 3 = new/ongoing NP event

calculated by averaging all observations in each NP state. Multiple regressions including age at diagnosis, sex, race/ethnicity, disease duration, geographic region, and smoking adjusted for possible confounding of these variables on the association of annual DC and IC and NP state. 5 and 10-year cumulative costs for each NP state were predicted

Table 2. Predicted Annual and 5 and 10-Yr Direct and Indirect Costs (in 2021 Canadian dollars), Stratified by SLE and Non-SLE NP States*

*Values are the mean (95% CI).

** State 1 = no NP event; State 2 = resolved NP event; State 3 = new/ongoing NP event

Boldface indicates differences which are significant as the 95% CI does not include 0.

by multiplying adjusted annual costs associated with each state by the expected duration in each state, forecasted using the multistate model.

Results: 1697 patients (89% female, 51% non-Caucasian race/ethnicity, mean age at enrolment 35.1 years) were followed for a mean of 8.8 years. 1971 NP events occurred in 956 patients, 32% attributed to SLE. Across 13,987 assessments, the majority of observations were provided by patients with no NP event (Table 1.) For the SLE NP events, annual DC were higher in those with a new/ongoing vs no event ($10809 vs $6715) (Table 2). Although 5 and 10-yr cumulative DC trended higher in the new/ongoing vs no event, the differences were not significant. However, annual and 5-yr IC were higher in the new/ongoing vs no event and new/ongoing vs resolved event. (5-yr: new/ongoing vs no: $172674 vs $ $136970). For the non-SLE NP events, although all DC trended higher in the new/ongoing vs no event, the differences were not significant. However, annual IC were higher in the new/ongoing vs no

event, new/ongoing vs resolved event, and resolved vs no event and 5 and 10-yr IC were higher in the new/ongoing vs no event (10-yr: new/ongoing vs no: $342434 vs $279874). For all NP states, IC exceeded DC between 2.8 and 4-fold.

Conclusion: IC are approximately 1.3-fold higher in patients with new/ongoing vs no NP events, attributed to either SLE or non-SLE. While DC trended higher in those with new/ongoing events, they did not differ significantly. Impaired productivity associated with both ongoing and resolved NP lupus is substantial and underscores the previously documented reduced quality of life in NP lupus.

Abstract Number: 0882

COVID-19 Impact Among Patients with Systemic Lupus Erythematosus

Jose Rubio[1], Suzanne krishfield[1] and Vasileios Kyttaris[2], [1]Beth Israel Deaconess Medical Center/Harvard Medical School, Boston, MA, [2]BIDMC, Boston, MA

SESSION INFORMATION

Session Date: Sunday, November 7, 2021
Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster II: Manifestations (0855–0896)
Session Type: Poster Session B
Session Time: 8:30AM–10:30AM

Background/Purpose: Initial studies of SLE patients with COVID-19 revealed an increased risk for severe disease in people with distinct demographic features such as advanced age and/or underlying comorbidities comparable to

that of the general population. However, uncertainty remains around the real impact SARS-CoV-2 has in SLE. In this context, we conducted a cross-sectional survey in SLE patients who follow at our tertiary care lupus cohort.

Methods: We designed a questionnaire using the REDCap tool to capture information about demographics, clinical and serological variables related to SLE and COVID-19. The survey was sent between June 1st to August 31st, 2020 to 87 participants. Additional information was gathered from the lupus registry database. After the survey ended subjects underwent SARS-CoV-2 IgG antibody testing.

Results: A total of 79 subjects completed the survey. From these, 6 patients developed COVID-19 infection with many of them disclosing an epidemiologic link. All infected patients were female and the mean age was significantly higher in COVID-19 patients compared to those who did not get infected (p 0.04). We also found a significant relationship between COVID-19 status and race (p 0.02) with the majority of the infected individuals having black ancestry. COVID-19 serology was tested in 46 individuals, showing only one positive result in someone who reported COVID-19 infection. Interestingly, among 4 infected subjects whose serology was obtained only one had evidence of persistent immunity against SARS-CoV-2 10 months after the infection. Additionally, we observed a numeric trend in patients' global disease activity (60 v 41), SLE duration (17 v 12 years), SLICC-DI score (1.8 v 0.7), and mean daily dose of prednisone (3 v 2 mg) in COVID-19 patients compare to non-infected subjects, respectively. In regards to COVID-19 features in SLE, the most common symptoms were headache, shortness of breath, and cough. Despite a prolonged illness and a relative more severe SLE, the majority of infected patients presented with a favorable disease course including the patient who was hospitalized. Moreover, the use of immunosuppressive drugs was not found to be associated with severe infection. COVID-19 related hydroxychloroquine shortage affected up to 16.5% of SLE patients, but at least short-term consequences were not evident. Lastly, we identified that 69% of the respondents were

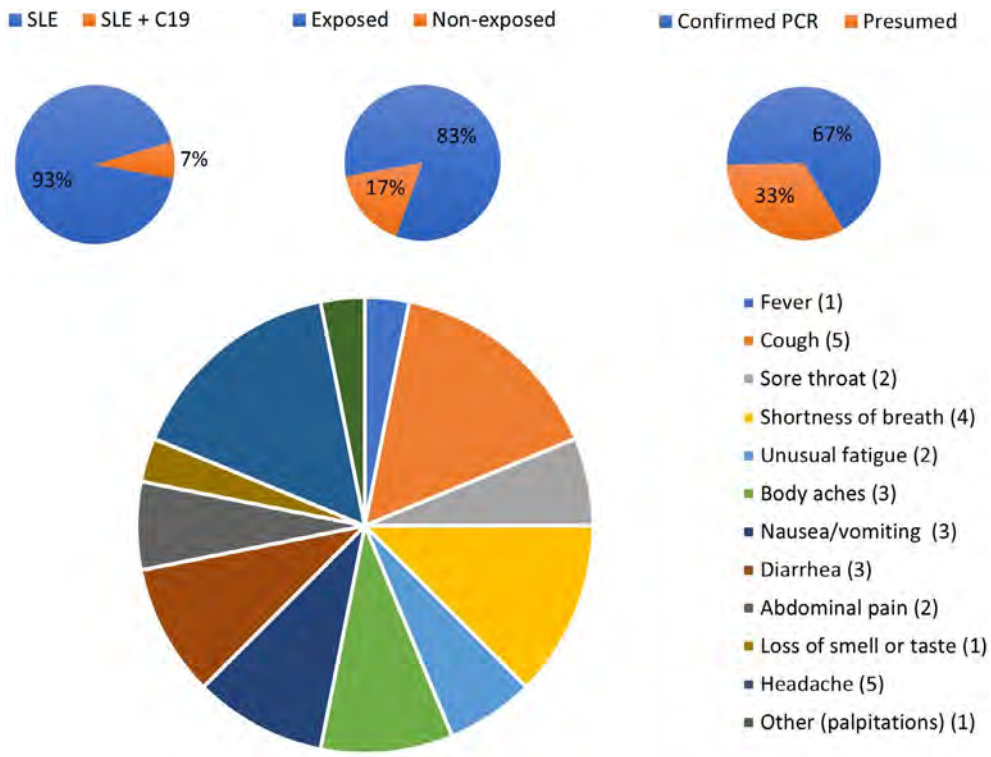

Figure 1. COVID-19 prevalence and symptoms in SLE patients. The prevalence of COVID-19 in patients with SLE (SLE, SLE+C19) is shown on the upper leftmost panel. Exposure history and PCR positivity in SLE patients with COVID-19 are plotted in the middle and rightmost panel, respectively. The prevalence of different symptoms in patients with SLE and COVID-19 are depicted in the lower panel.

Table 1. Characteristics of the surveyed SLE patients

	Total (n=79)	SLE-C19 (+) (n=6)	SLE-C19 (-) (n=73)	P value
Age, years (mean, SD)	42.6 ±12.7	52.3 ±9.7	41.8 ±12.6	**0.04**

SARS-CoV-2 IgG antibody n° (%)	46	1	45	

SLE: systemic lupus erythematosus; SLICC-DI: Systemic Lupus International Collaborative Clinics Damage Index; LEF: leflunomide; CsA: cyclosporine A; PGA: patient global assessment; C19: Coronavirus disease 2019.

able to continue medical care through telehealth during the surge, and 87% were eager to make use of telemedicine services in the foreseeable future.

Conclusion: Despite study limitations, our data confirm that age and race are important risk factors for COVID-19 infection in SLE. Importantly, we also noted that neither underlying SLE nor the use of immunosuppressive drugs was found to be risk factors for severe COVID-19 illness though further studies are needed. Finally, our results demonstrated that having COVID-19 infection does not necessarily mean prolonged immunity as this can wane over time. In any case, as the pandemic continues to unfold, rheumatologists should continue stressing preventive measures, recommending vaccination, and offering optimal virtual care when needed to avoid undesirable outco mes.

Table 2. Survey of COVID-19 in SLE

	Total (n=79)	SLE C19 (+) (n=6)	SLE C19 (-) (n=73)	P value
Employment status n° (%)				
Before the pandemic				
Employed (full/part-time)	55/9 (69/11)

Abstract Number: 0883

Multimorbidity Burden in Systemic Lupus Erythematosus: A Nationwide Study

Ali Duarte-Garcia[1], Herbert Heien[1], Nilay Shah[1] and Cynthia Crowson[2], [1]Mayo Clinic, Rochester, MN, [2]Mayo Clinic, Eyota, MN

SESSION INFORMATION

Session Date: Sunday, November 7, 2021
Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster II: Manifestations (0855–0896)
Session Type: Poster Session B
Session Time: 8:30AM–10:30AM

Background/Purpose: Patients with systemic lupus erythematosus (SLE) have an increased risk of osteoporosis, end-stage renal disease, cardiovascular disease, and other comorbidities. The presence of multiple chronic conditions (multimorbidity) is associated with disability and premature death. We aimed to compare the burden of multimorbidity in SLE patients with the general population.

Methods: An SLE cohort was assembled using OptumLabs Data warehouse (OLDW) from 1/2006-9/2015. SLE cases were identified using ≥ 3 SLE ICD-9 codes separated ≥ 30 days, the date of the third SLE code was considered the index date. SLE patients were matched to non-SLE comparators on age, sex, race, and enrollment date. Diagnosis codes from the period between enrollment and index date were used to determine the presence of comorbidities. Comorbidities were identified using the ICD-9 chronic condition indicator of the clinical classification software

Table. Top 10 most prevalent chronic conditions in SLE vs Non-SLE			
Comorbidity	SLE, N (%) 34,869	Non-SLE, N (%) 34,869	Odds ratio (95%CI)
Essential hypertension	10053 (28.8)	5411 (15.5)	2.6 (2.5-2.7)
Hyperlipidemia	6199 (17.8)	4538 (13.0)	1.5 (1.5-1.6)
Thyroid disorders	4964 (14.2)	2123 (6.1)	2.7 (2.5-2.8)
Osteoarthritis	3798 (10.9)	1092 (3.1)	4.2 (3.9-4.5)
Mood disorders	3634 (10.4)	1701 (4.9)	2.3 (2.2-2.5)
Chronic pain disorders	2989 (8.6)	713 (2.0)	4.6 (4.2-5.0)
Spondylosis; intervertebral disc disorders; other back problems	2957 (8.5)	1164 (3.3)	2.7 (2.5-2.9)
Esophageal disorders	2935 (8.4)	996 (2.9)	3.2 (3.0-3.5)
Diabetes mellitus without complication	2884 (8.3)	2158 (6.2)	1.4 (1.3-1.5)
Anxiety disorders	2117 (6.1)	1053 (3.0)	2.1 (1.9-2.3)

(healthcare cost and utilization project). SLE, cutaneous lupus, and rheumatoid arthritis ICD-9 codes were excluded from the analysis. Two or more ICD-9 codes at least 30 days apart were used to define a comorbidity. We defined multimorbidity as the presence of 2 or more comorbidities (excluding SLE) and substantial multimorbidity as the presence of 5 or more comorbidities. Conditional logistic regression models were performed.

Results: A total of 34,869 SLE patients were matched to 34,869 non-SLE comparators. The mean age was 48 (SD 14.2) years and 90.6% were female. 66.4% were White, 18.4% Black, 3.4% Asian and 18.4% Hispanic. The mean observation time from enrollment to index date was 2.3 (SD 2.4) years. Multimorbidity was present in 58.0% SLE vs. 26.3% non-SLE subjects (OR 5.0; 95%CI 4.8-5.2) and substantial multimorbidity was present in 21.2% SLE patients vs. 6.5% non-SLE subjects (OR 4.6; 95%CI 4.4-4.9). Of the 172 chronic conditions examined, 134 (78%) were more common in SLE than in non-SLE (Table).

Conclusion: In this nationwide commercial insurance database study, patients with SLE were five times as likely to suffer from multimorbidity and substantial multimorbidity compared to the general population. Most comorbidities were overrepresented in SLE patients. It is unclear if multimorbidity in SLE is driven by the disease activity, medication such as steroids, socioeconomic factors, or a combination of these.

Genetics of Longitudinal Disease Activity in Adults with Systemic Lupus Erythematosus

Linda Hiraki[1], Fangming Liao[1], Dafna Gladman[2], Ker-Ai Lee[3], Zahi Touma[4], Joan Wither[5], Richard Cook[3] and Murray Urowitz[6], [1]The Hospital for Sick Children, Toronto, ON, Canada, [2]Schroeder Arthritis Institute, Krembil Research Institute, Toronto Western Hospital, Toronto, ON, Canada, [3]Department of Statistics and Actuarial Sciences, University of Waterloo, Waterloo, ON, Canada, [4]University of Toronto, Mississauga, ON, Canada, [5]University Health Network, Toronto, ON, Canada, [6]Center for Prognosis Studies in the Rheumatic Diseases, Toronto Western Hospital, University of Toronto, Lupus Clinic, Toronto, ON, Canada

SESSION INFORMATION

Session Date: Sunday, November 7, 2021

Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster II: Manifestations (0855–0896)

Session Type: Poster Session B

Session Time: 8:30AM–10:30AM

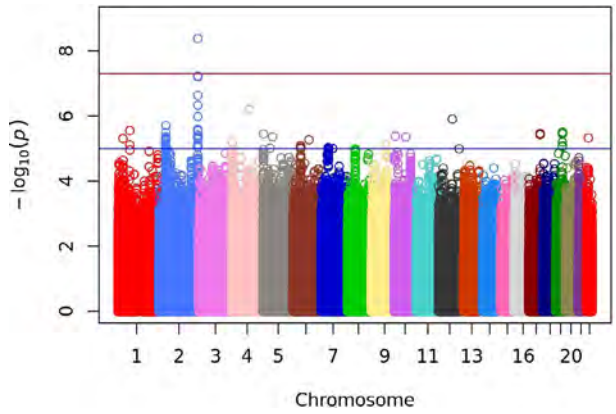

Figure. Manhattan plot for meta-genome-wide association of adjusted mean SLEDAI and corticosteroid exposure over time (AMSG).

Background/Purpose: Genetics and gene expression has been shown to correlate with systemic lupus erythematosus (SLE) disease severity. Our aim was to identify genetic risk loci for disease activity measures over time, representing disease activity burden.

Methods: The cohort study included participants from a tertiary care centre dedicated Lupus Clinic. Participants all met ≥4 of the ACR/SLICC classification criteria for SLE or 3 criteria and a positive biopsy. All participants had prospectively collected clinical data including repeated measures of disease activity evaluated with the Systemic Lupus Erythematosus Disease Activity Index 2000 (SLEDAI-2K). We restricted to participants with a first Lupus clinic visit within 3 years of SLE diagnosis and at least 2 clinic visits within 5 years. Participants were genotyped on the Illumina Multi-Ethnic Global Array, Global Screening Array or Omni 1-Quad array. Ungenotyped SNPs were imputed and ancestry was inferred using principal components (PCs) (1000 Genomes Project reference). The outcome was adjusted mean SLEDAI-2K and corticosteroids (AMSG), the calculated area under the curve of SLEDAI-2K over time, accounting for corticosteroid dose. Continuous square-root of AMS-G was the outcome of interest, transformed to improved normality. We included variants with minor allele frequency (MAF) of ≥0.01 and imputation quality r2 >0.3. Genome-wide additive allelic linear regression models were adjusted for sex and 5 PCs, stratified by array (MEGA+GSA and OMNI) and results were meta-analyzed using inverse variance weighting. A genome-wide significance threshold ($p< 5x10^{-8}$) was used to indicate statistical significance.

Results: The cohort included 538 individuals with SLE. The majority (75%) had a first clinic visit within 1 year of SLE diagnosis. The majority were of European ancestry (54%) with 16% of East Asian ancestry and 12% African ancestry. The median ASMG was 5.5 (IQR 3.2, 8.8). Meta-GWAS identified a genome-wide significant SNP for ASMG (rs4561613) on chromosome 2 intronic to *AGAP1* (Beta 0.34, SE 0.06, *P*=4.2x10-9) (Figure). The overall MAF is 0.43, with a higher risk allele frequency for increased ASMG in non-European ancestral groups (0.67 in African ancestry; 0.41 East Asian ancestry) compared to those of European ancestry (0.36).

Conclusion: We identified a genome-wide significant locus for SLE disease activity burden as measured by AMSG. Variants in *AGAP1* has been linked with body mass index and red blood cell indices. The mechanism by which AGAP1 variants impact disease activity and severity in SLE is unclear. Future studies are required to replicate these findings in independent cohorts.

SESSION INFORMATION

Session Date: Sunday, November 7, 2021

Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster II: Manifestations (0855–0896)

Session Type: Poster Session B

Session Time: 8:30AM–10:30AM

Background/Purpose: Cognitive impairment (CI) in SLE is a significant problem with limited treatment options. This is in part due to the uncertainty regarding the multifaceted cause. Factors associated with CI include depression, pain, fatigue, medications, as well as more specific SLE factors such as disease damage, autoantibodies and inflammation. We aimed to phenotype CI in SLE using machine learning techniques to better enable future personalised targeted treatments.

Methods: SLE patients aged 18-65 years attending a single lupus centre (January 2016 - October 2019) completed the ACR Neuropsychological Battery (ACR-NB) cognitive assessment. Age and gender matched normative data

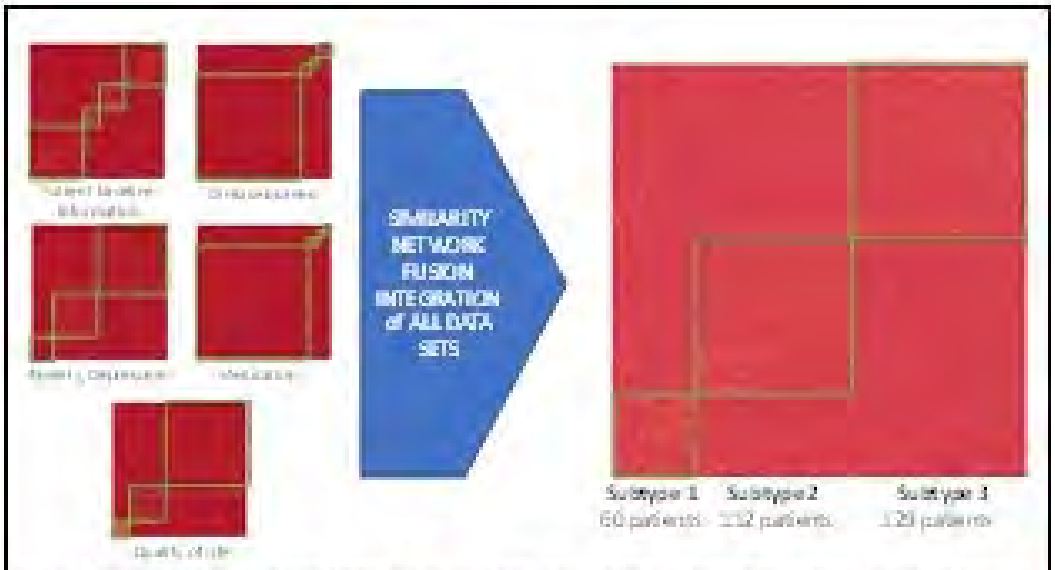

Figure 1. Similarity network fusion (SNF) for first visit data. Three subtypes defined by patterns in patient baseline information, health-related quality of life (HRQoL), depression, anxiety, fatigue, and medication usage. Demographic and clinical variables used within the patient baseline and disease burden information included; age, sex, marital and employment status, education and income level, age at diagnosis, disease damage, disease activity and fibromyalgia status.

were used to obtain z-scores on all 19 tests of ACR-NB. The ACR-NB tests were reduced using principal component analysis (PCA) to generate a factor score (CI Factor Score).

Demographic, and clinical data, and patient reported outcomes including, SF-36, LupusQoL, the PDQ-20 (perceived cognitive deficits), Beck Depression Inventory-II, Beck Anxiety Inventory, and the fatigue severity scale (FSS) were analysed using similarity network fusion (SNF) to identify patient subtypes. Differences between the SNF identified subtypes were evaluated using Kruskal-Wallis tests and chi-square tests.

Results: Of the 301 patients, 89% were women, mean age 40.9 ± 12.1 and mean disease duration 14 ± 10.1 years at study visit. The CI Factor Score accounted for 28.8% of the variance and was associated predominantly with tests of executive function and verbal memory. The SNF analysis defined **subtypes** with distinct patterns in health-related quality of life (HRQoL), depression, anxiety, fatigue, fibromyalgia, medication usage, and disease damage (**figure 1**). The CI Factor Score was significantly different between the subtypes (p=0.008). Examining specific cognitive domains revealed the most significant differences in the language processing (p=0.0008) and executive function tests (p=0.008; p=0.009; p=0.0009). Subtype 3 performed worst on the majority of the different cognitive domains (**figure 3**). Further exploration revealed statistical differences with depression, anxiety, fatigue, and fibromyalgia between the subtypes (**figure 2**). Differences were also found relating to organ involvement within the last ten years and damage within specific organs. No differences were found for SLE disease activity (**figure 2**). Subtype 3 had higher levels of all conditions and disease damage, Subtype 2 had lower levels and Subtype 1 mixed levels.

Conclusion: The subtype with the greatest psychiatric and disease burden and reduced HRQoL performed worse on cognitive testing, specifically in domains of language processing and executive function. This subtype also had more musculoskeletal (MSK) and cardiovascular involvement. MSK involvement affects pain levels, which can impact cognition. Cardiovascular damage may be linked to cerebral small vessel disease, which is known to affect cognitive function SLE patients. Overall, these results aid with phenotyping CI in SLE and provide a baseline for our future longitudinal results. This will then help to determine personalised CI trajectory and treatment options in SLE.

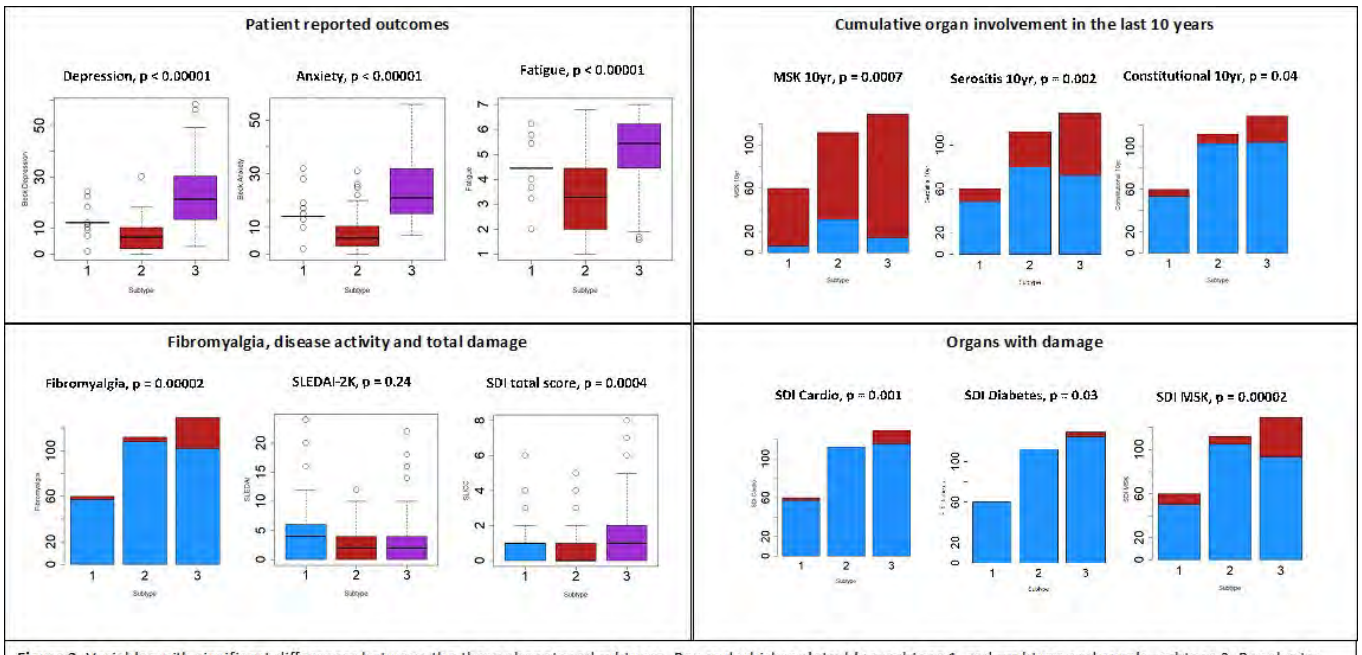

Figure 2. Variables with significant differences between the three phenotyped subtypes. Box and whisker plots: blue=subtype 1, red =subtype and purple=subtype 3. Bar charts: red=number of participants with variable and blue=number without.

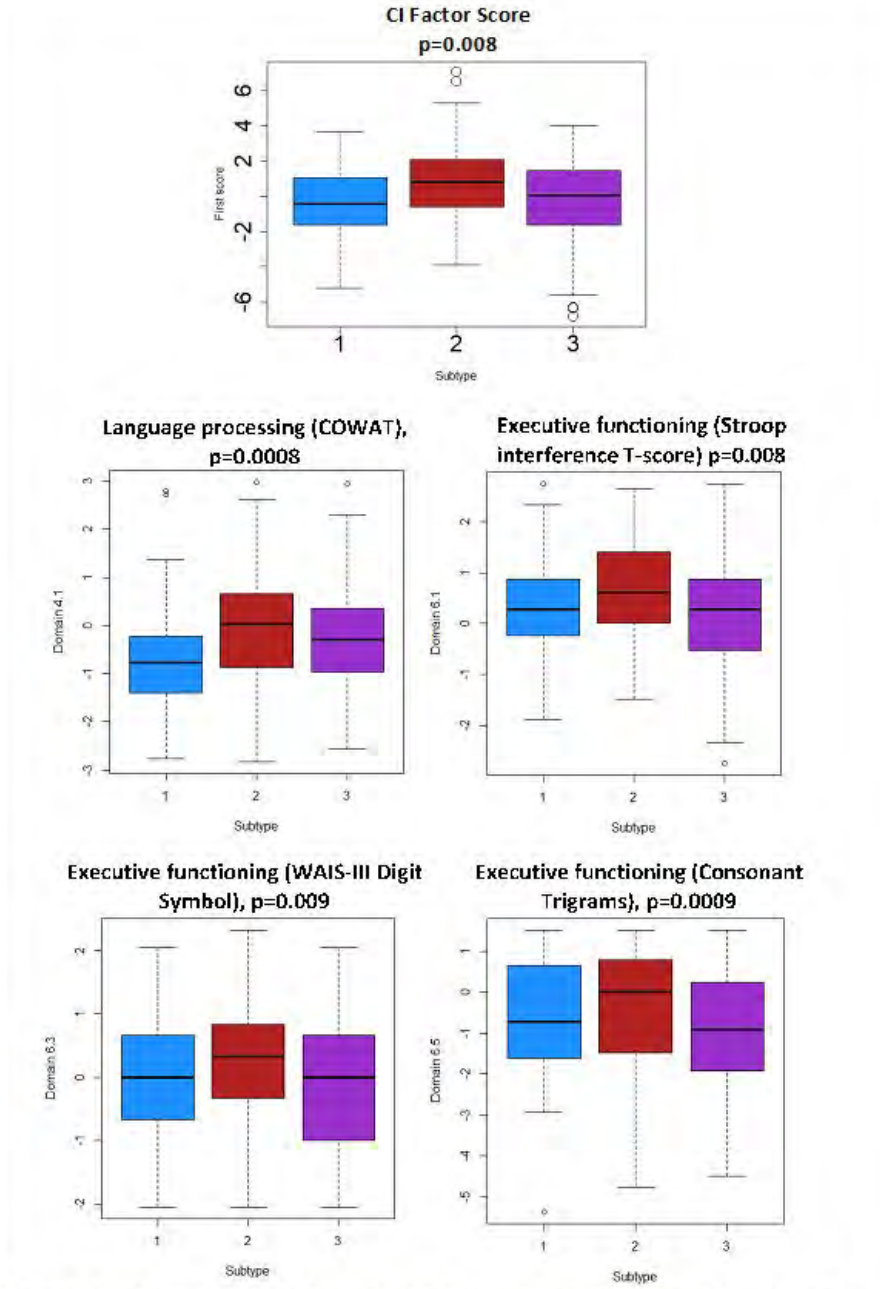

Figure 3. Significant differences between the three subtypes for the PCA determined CI Factor Score and the different cognitive domains tested. Lower score indicates greater cognitive impairment.

COWAT= Controlled Oral Word Association Test
Stroop interference T-score = Predicted interference (word and colour)
WAIS-III= Wechsler Adult Intelligence Scale
Consonant Trigrams = An average score between 0-3 was determined for repetitions of three letters after delays of 9, 18 and 36 seconds. These scores were converted to z-scores and the lowest of the three z-score is represented here.

SESSION INFORMATION

Session Date: Sunday, November 7, 2021
Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster II: Manifestations (0855–0896)
Session Type: Poster Session B
Session Time: 8:30AM–10:30AM

Background/Purpose: The spread of COVID-19 misinformation through social/news media is a health risk in SLE. We assessed the determinants of SLE patients accessing health information in social and news media, and self-reporting negative health impacts associated with accessing health information from these sources.

Methods: International patients meeting ACR or Systemic Lupus International Collaborating Clinics Classification Criteria for SLE were recruited from 15 patient cohorts, and patients self-reporting SLE were recruited from five advocacy organizations.They completed an online survey (06/2020-04/2021) about sources of health information accessed preceding (pre 03/11/2020) and during (post 03/11/2020) the COVID-19 pandemic. Logistic regression was used to explore factors (region, sociodemographics, SLE characteristics, access to/trust in sources) associated with: 1) accessing social media, 2) news media, and 3) self-reported negative impacts from health information accessed through these sources.

Results: 1935 patients (Asia n=201, Canada n=845, Europe n=324, Latin America (LA) n=118, US n=447) completed the survey (27.1% response rate): 92.7% female, 35.2% non-white race/ethnicity, mean age at diagnosis 32.0 years (SD 13.3), mean disease duration 16.6 years (SD 12.0), and 76.6% had post-secondary education. 21.6% and 37.0% accessed health information often/always from social and news media, respectively, and 17.0% reported being negatively impacted by health information accessed through these sources.

Table 1. Logistic regression results: access to social and news media often/always*+

Explanatory Variables	Social Media		News Media

Access – News Media[b]	5.78	(3.92, 8.53)	-	-
Access – Social Media[b]	-	-	4.83	(3.74, 6.22)
Trust – News Media[c]	-	-	4.33	(3.40, 5.52)
Trust – Social Media[c]	3.18	(2.45, 4.14)	0.63	(0.48, 0.83)

* Sociodemographics (region, age, gender, marital status, household size, employment status, ethnicity, post-secondary education), disease characteristics (antimalarial, steroid and immunosuppressive use, disease duration, positive COVID-19 test), number of days to survey completion since 03/11, and access to and trust in sources (family physicians, SLE specialists, pharmacists, alternative care providers, peers, advocacy organizations, social media, news media) were considered in the models. Only significant variables are presented here.

+ Variables with a – were not included in the final model. All geographic variables were forced in the model, and other variables were chosen through backwards selection.

[a]Time (years) of survey completion since March 11, 2020
[b]Respondents accessing source for health information sometimes/often/always since March 11, 2020
[c]Respondents reporting source as somewhat/very trustworthy since March 11, 2020

Respondents in Europe and LA vs Canada were more likely to access social (Europe: OR 1.46, 95% CI 1.03, 2.07; LA: OR 2.19, 95% CI 1.36, 3.56) and news media (Europe: OR 1.77, 95% CI 1.26, 2.49; LA: OR 1.71, 95% CI 1.03, 2.83), and those in the US were less likely to access social media (OR 0.58, 95% CI 0.40, 0.84) (Table 1). Females were more likely (OR 2.02, 95% CI 1.17, 3.49), while older subjects were less likely to access social media (OR 0.98, 95% CI 0.97, 0.99). Patients accessing family physicians during COVID-19 were less likely to access social (OR 0.70, 95% CI 0.54, 0.92) and news (OR 0.64, 95% CI 0.50, 0.80) media, and those reporting trust in social (OR 3.18, 95% CI 2.45, 4.14) and news media (OR 4.33, 95% CI 3.40, 5.52) were more likely to access each, respectively. Those in Asia vs Canada (OR 0.34, 95% CI 0.17, 0.66) and older participants (OR 0.97, 95% CI 0.96, 0.99) were less likely to report negative impacts, and females (OR 2.27, 95% CI 1.15, 4.47) were more likely to report negative impacts (Table 2). While subjects with post-secondary education were less likely to be negatively impacted (OR 0.60, 95% CI 0.40, 0.90), those with post-secondary education in Europe (OR 3.56, 95% CI 1.75, 7.30) and LA (OR 4.37, 95% CI 1.44, 13.30) were more likely to report negative impacts.

Conclusion: Region, age, gender, accessing family physicians, and education were associated with accessing social/news media and/or self-reporting negative impacts of accessing health information from these sources. Education was inversely associated with reporting a negative impact, yet in Europe and LA the relationship is reversed, likely due to local context. This study emphasizes the need for targeted health messaging.

Table 2. Logistic regression results: self-reported negatively impacted by accessing health information through social/news media

Abstract Number: 0887

Association of Mycophenolate and Azathioprine Use with Cognitive Function in SLE

Chrisanna Dobrowolski[1], Jiandong Su[2], John McGinley[1], Melissa Fazzari[1], Kathleen Bingham[3], Nicole Anderson[2], Dorcas Beaton[4], Lesley Ruttan[3], Joan Wither[2], Maria Tartaglia[2], Mahta Kakvan[2], Dennisse Bonilla[2], May Choi[5], Marvin Fritzler[6], Patricia Katz[7], Robin Green[2], Chaim Putterman[1] and Zahi Touma[8], [1]Albert Einstein College of Medicine, Bronx, NY, [2]University Health Network, Toronto, ON, Canada, [3]University of Toronto, University Health Network, Toronto, ON, Canada, [4]Institute for Work & Health, Toronto, ON, Canada, [5]Brigham and Women's Hospital | University of Calgary, Calgary, AB, Canada, [6]University of Calgary, Calgary, AB, Canada, [7]University of California San Francisco, San Francisco, CA, [8]University of Toronto, Mississauga, ON, Canada

SESSION INFORMATION
Session Date: Sunday, November 7, 2021
Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster II: Manifestations (0855–0896)
Session Type: Poster Session B
Session Time: 8:30AM–10:30AM

Background/Purpose: Cognitive dysfunction (CD) is a common manifestation of systemic lupus erythematosus (SLE) which can have detrimental consequences for those affected. To date, no treatments have been approved for SLE-associated CD (SLE-CD). This study aims to assess the association of azathioprine (AZA) and mycophenolate (MMF) use with SLE-CD, given that these medications have demonstrated neuroprotective qualities in prior studies.

Methods: Consecutive adult SLE patients presenting to a single center were screened. The American College of Rheumatology (ACR) neuropsychological battery (NB) for SLE, evaluating 6 cognitive domains, was administered to consenting participants at 0, 6 and 12 months. Age and gender matched normative data were used to obtain z-scores. CD was determined by a z-score of £-1.5 in ³2 cognitive domains. Non-CD was defined as no z-score £-1.5. MMF and AZA use were recorded as cumulative dose (grams per kilogram [g/kg]), duration of treatment (number of years) and current use for ³6 months from visit day. Clinical and demographic characteristics were verified at each visit. Baseline characteristics by cognitive status and medication use were documented. Mixed-effects logistic regression models were constructed to estimate the odds of CD and non-CD with respect to AZA and MMF use over the three follow-up periods.

Results: Three hundred participants representing 676 patient visits completed the study; 157 (52%) met criteria for CD at baseline. Mean age was 41.1 years (SD 12.1) and 267 participants (89.0%) were female. Table 1 outlines baseline characteristics by CD and non-CD status. There were no significant differences in mean age, glucocorticoid dose, disease duration, SLE Disease Activity Index-2000 (SLEDAI-2K) scores, or SLICC-ACR Damage Index (SDI) scores. In contrast, there were significantly more participants with CD who identified as Black or Chinese, and significantly fewer participants identifying as White. There were also fewer married participants with CD. Table 2 documents baseline characteristics by AZA and MMF use with respect to CD status. Participants taking AZA or MMF had significantly higher SLEDAI-2K scores and higher prevalence of nephritis; participants taking MMF had higher rates of hypertension, higher daily doses of glucocorticoid medications and lower rates of smoking.

Table 3 shows results of the mixed effects models for AZA and MMF use versus CD. For each g/kg of cumulative AZA, there was on average a 24% reduced odds of CD: OR 0.76, 95% CI 0.61, 0.96, p=0.02. For each year of AZA treatment there was on average a 32% reduced odds of CD: OR 0.68 (0.50, 0.94), p=0.02. AZA use as binary variable (yes versus no) demonstrated a consistent trend toward reduced odds of CD with AZA use without reaching statistical significance: OR 0.29 (0.08, 1.12), p=0.07. Cumulative AZA dose was not significantly associated with non-CD status: 1.08 (0.91, 1.27), p=0.38 (not shown). MMF use was not associated with CD or non-CD.

Conclusion: Despite higher disease activity scores in participants taking AZA compared to those not taking AZA, cumulative AZA dose and increasing AZA treatment duration were associated with significantly lower odds of SLE-CD. MMF use was not associated with SLE-CD.

1) CD: cognitive dysfunction. Defined as a z-score of ≤-1.5 on ≥2 cognitive domains, based on neuropsychological testing. 2) Completion of post-secondary schooling including a College (≥2 years) or University (≥4 years) degree. 3) Positive lupus anticoagulant testing, and/or anti-beta2glycoprotein1 IgG or IgM, and/or anti-cardiolipin IgG or IgM above laboratory specific upper limit of normal, at baseline and again after ≥12 weeks. 4) Psychosis, seizures, stroke, neuropathy and/or transverse myelitis. 5) Known risk factors for cognitive dysfunction not captured elsewhere. 6) SLICC ACR: Systemic Lupus International Collaborating Clinics / American College of Rheumatology Damage Index.

7) SLEDAI-2K: Systemic Lupus Erythematosus Disease Activity Index 2000. 8) SLEDAI-2KG: Systemic Lupus Erythematosus Disease Activity Index 2000 Glucocorticoid Index. 9) Beck Depression Inventory score of 0–13 is considered minimal, 14–19 mild, 20–28 moderate and 29–63 severe. 10) Beck Anxiety Inventory score of 0-7 is considered minimal, 8-15 mild, 16-25 moderate and 26-63 severe.

Table 1. Baseline characteristics of participants by cognitive function

	Total n=300	Non-CD[1] n=143 (47.7%)	CD[1] n=157 (52.3%)	Absolute Standardized Differences (%)	p-values

SESSION INFORMATION

Session Date: Sunday, November 7, 2021

Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster II: Manifestations (0855–0896)

Session Type: Poster Session B

Session Time: 8:30AM–10:30AM

Background/Purpose: Systemic Lupus Erythematosus is the archetypic systemic autoimmune disease in which dysbiosis in the gut microbiome has been postulated to contribute to disease development in genetically-susceptible

individuals. To investigate for dynamic-relationships between gut-microbial community shifts and disease activity, we performed taxonomic surveys using 16S rRNA gene amplicon-libraries from female patients and healthy controls (CTL).

Methods: To study the gut microbial communities in disease-affected individuals, we examined two to six sequential fecal samples obtained from 16 individual lupus patients, representing 44 samples obtained over 24-291 weeks. For comparisons, we also evaluated 72 samples from 22 healthy adult female volunteers, with 2 to 12 samples from 9 of these CTL. To assess the diversity within these bacterial communities, fecal DNA was extracted, followed by targeted amplification of a standard interval to generate 144 individual 16S rRNA gene amplicon libraries. Community-wide multivariate analysis were used to estimate subject variances in libraries from individual donors based on Jensen-Shannon Divergence with the Tw2 statistic,

Results: Lupus gut communities commonly displayed significant imbalances in alpha and beta microbiota diversity as compared to control subjects. The communities in each individual lupus patients exhibited unique differences from other patients -- a pattern of disease-associated heterogeneity in dysbiotic responses termed *the Anna Karenina Principle*. From community-wide ecological multivariate analysis, we documented significantly greater intra-individual longitudinal microbiota community instability in Lupus patients than in healthy individuals and more so in Lupus Nephritis (LN) patients. Taxonomic analyses also documented transient spikes of several potentially pathogenic bacterial species, and by far the most prevalent were blooms of *Ruminococcus blautia gnavus* documented in 4/9 LN and 1/7 non-renal patients. From libraries obtained over many months to several years, RG blooms were concordant with disease flares.

Conclusion: As many Lupus patients suffer relapsing illness despite appropriate follow-up, evaluation, and treatment, we speculate that gut blooms of pathogenic bacteria, which impair gut barrier function and stoke systemic inflammation, directly contribute to lupus immunopathogenesis. We propose that future therapeutic interventions that

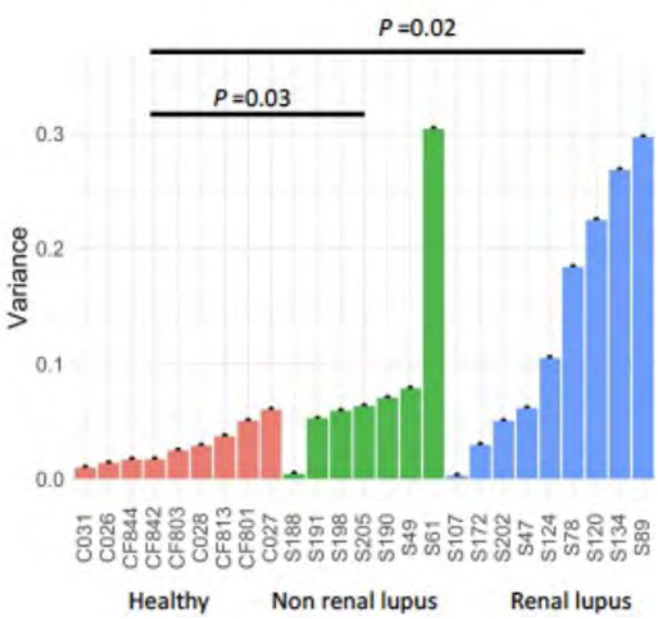

Figure 1. Lupus patients have more unstable gut microbiota than healthy individuals. To compare the overall dynamics of shifts in fecal communities sampled overtime in individual subjects, community-wide multivariate analysis were used to estimate subject variances based on Jensen-Shannon Divergence with the Tw2 statistic (Hamidi et al. (2019) Microbiome 7(1):51). Patients were assigned to the renal group was based on ACR criteria. The variance in these three groups were significantly different (Kruskal Wallis ANOVA, p = 0.03). Variance of gut microbiota in the healthy subjects were significantly different than communities in the renal lupus group, as well as the non-renal lupus group (two-sided Mann-Whitney test, p = 0.02 and p = 0.03, respectively).

are designed to promote a durable cure, consider the necessity to target both the immunologic/inflammatory abnormalities and re-establish stability in the gut microbiota community.

SESSION INFORMATION
Session Date: Sunday, November 7, 2021
Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster II: Manifestations (0855–0896)
Session Type: Poster Session B
Session Time: 8:30AM–10:30AM

Background/Purpose: Systemic Lupus Erythematosus (SLE) can lead to a number of neuropsychiatric manifestations including cognitive impairment (CI). Previous meta-analyses have reported the prevalence of CI at 38% (95% confidence interval: 33-43%), with a range of 15-79%. Comprehensive neuropsychological battery (NB) of tests is considered the gold standard when diagnosing CI. We aim to compare a subjective questionnaire, the perceived deficits questionnaire (PDQ-20) to the NB and also to other patient reported outcomes, in an SLE cohort.

Methods: This is a cross-sectional study of consecutive consenting patients, aged 18-65 years, who attended a single center (Jul 2016 – Mar 2019). Each patient completed a comprehensive NB evaluating six cognitive domains including: manual motor speed and dexterity, simple attention and processing, visual spatial construction, verbal fluency, learning and memory (verbal and visuospatial) and executive function. They also completed the 20 item PDQ-20 questionnaire (subjective cognitive function) along with other patient reported outcome questionnaires such as the Beck anxiety score, Beck depression score, fatigue severity score (FSS), Short Form Health Survey (SF-36) domains [Role Physical, Mental Health, Bodily Pain, General Health, Physical Functioning, Emotional, Social Functioning, and Vitality domains].

The variable of main interest was the total score of 19 tests in NB, along with patients' demographics, lupus disease activity, organ damage, treatment and other PROs. Mean ± std., median (interquartile range) and count (%) were calculated for these variables. Univariate and multivariable linear regressions were performed to evaluate the associated factors with total PDQ-20 scores. Least Absolute Shrinkage and Selection Operator (LASSO) method was used in the variable selection in multivariable model building process. Linear model assumptions were tested by residual density plots and quantile-quantile plots.

Results: Data on 238 patients was analysed; 89.9% were females with an average age and SLE duration at baseline visit of 41.1 ± 12.1 and 14.3 ± 10.0 years, respectively. In the univariate analysis, PDQ-20 was associated with the

Battery total score	-0.2	-0.37	-0.03	0.01	-	-	-	-

NB, SDI, fatigue severity score (FSS), BECK anxiety and depression score and all SF-36 domains (Table 1). In the multivariate analysis, PDQ-20 was significantly associated with female gender, SDI, fatigue, BECK depression and anxiety scores, SF-36 Role Emotional domain and glucocorticoid dosage. PDQ-20 was not associated with the NB. There was also no association with age at first visit, SLE disease duration, ethnicity, education level, SLEDAI score, anti-malarial or immunosuppressive treatment with the PDQ-20 score.

Conclusion: Subjective cognitive report by PDQ-20 was associated with the NB in univariate analysis but not multivariate analysis. While PDQ-20 was associated with all SF-36 domains in the univariate analysis, this association was

significant only with Role Emotional in the multivariate analysis. There was a clear association of PDQ-20 with other subjective patient reported outcomes (such as fatigue, anxiety and depression, and SF-36 Role Emotional domain).

SESSION INFORMATION
Session Date: Sunday, November 7, 2021
Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster II: Manifestations (0855–0896)
Session Type: Poster Session B
Session Time: 8:30AM–10:30AM

Background/Purpose: Systemic Lupus Erythematosus International Collaborating Clinics-Frailty Index (SLICC-FI) is a novel health measure in systemic lupus erythematosus (SLE) and was reported to have impact on outcomes including mortality. The objective of the study was to evaluate the association of depression and frailty in SLE patients.

Methods: SLE patients who fulfilled 1997 American College of Rheumatology (ACR) classification criteria were enrolled from five teaching hospitals in Korea and the participants filled out questionnaires at outpatient clinic. Electronic medical records were reviewed for laboratory results, disease activity at enrollment, medications and damage

Table 1. Risk factors of frailty in systemic lupus erythematosus patients (multivariable logistic regression analysis)

	Odd ratio (95% C.I)	P-value	
Age	1.09 (1.03-1.14)	0.002	
ESR	1.03 (1.00-1.06)	0.030	
SLEDAI-2K	1.18 (1.02-1.37)	0.026	
PHQ-9 score	1.27 (1.14-1.40)	<0.001	
SDI score	3.22 (2.00-5.32)	<0.001	

ESR, erythrocyte sedimentation rate; PHQ-9, patient health questionnaire-9; SLEDAI-2K, systemic lupus erythematosus disease activity index-2000; SDI, SLICC/ACR damage index

index score and SLICC-FI was calculated. To assess the severity of depression, patient health questionnaire-9 (PHQ-9) was used. Logistic regression analysis was used to evaluate the factors associated with frailty in SLE patients

Results: In total, 247 patients were recruited. Mean (standard deviation, SD) age of the cohort was 50.5 (1.6) and 91.9% of the cohort was female. The mean (SD) of SLE disease activity index-2000 (SLEDAI-2K) was 3.5 (4.0). According to SLICC-FI, 36 (14.6%) patients were classified as frail. Mild depression (PHQ-9 score ≥ 5) was observed in 97.2% of frail patients and 54.5% of not-frail patients. Severe depression (PHQ-9 ≥ 20) was observed in 22.2% of frail patients and 1.4% of not-frail patients. In multivariable logistic regression analysis, age (1.09), ESR (1.03), SLEDAI-2K (1.18), PHQ-9 score (1.27) and SLICC/ACR damage index (3.22) were associated with frailty (odds ratio in parenthesis).

Conclusion: Depression in SLE patients was associated with frailty. Rheumatologists should pay attention to early detection and intervention of depression in SLE patients to improve outcomes.

Quality of Life Assessment in an Indian Inception Cohort (INSPIRE) of SLE Using Lupus QoL Questionnaire

Liza Rajasekhar[1], Dhundra Bhavani[1], Sneha Tota[2], Vishnupriya Vijayalekshmi[3], Ranjan Gupta[4], Chengappa Kavadichanda[5], Vineeta Shobha[6], VirSingh Negi[7] and Amita Aggarwal[2], [1]NIMS, Hyderabad, India, [2]Sanjay Gandhi Post Graduate Institute of Medical Sciences, Lucknow, India, [3]AIIMS, New delhi, delhi, India, [4]AIIMS, New delhi, Ne Delhi, India, [5]JIPMER, Pondicherry, India, [6]Saint Johns Medical college, Bengaluru, Bengaluru, India, [7]Jawaharlal Institute of Postgraduate Medical Education and Research (JIPMER), Puducherry, India

SESSION INFORMATION
Session Date: Sunday, November 7, 2021
Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster II: Manifestations (0855–0896)
Session Type: Poster Session B
Session Time: 8:30AM–10:30AM

Background/Purpose: Lupus quality of life (Lupus QoL) questionnaire is a disease specific patient reported outcome that is available in multiple languages[1]. Indian SLE inception cohort for research (INSPIRE) is a multi-institutional cohort having patients from different parts of India who speak different languages[2]. The study aimed to assess the QOL in this cohort and study its association with measures of disease activity.

Methods: Patients satisfying the SLICC classification criteria for lupus enrolled in the INSPIRE cohort[1] were asked to fill the Lupus QoL questionnaire in their native language. Any help needed in understanding a question was provided by the study nurse or the physician. Internal consistency of the questions in the various domains of the Lupus QoL was assessed using Cronbach's Alpha. Associations between Lupus QoL domains with age, SLEDAI, and BILAG were analyzed using Spearman correlation.

Results: Seven hundred and eighty-one lupus patients answered the Lupus QoL in either Hindi, Telugu, Tamil, Kannada, Urdu, Punjabi, Bengali and English. The mean age of the patients was 28± 10 years. Disease duration was less than three years. The median (IQR) HAQ score was 0.5(0.25-1.0). The mean SLEDAI was 10.9± 8.1. The internal

Table 1. Internal consistency in different language version of LupusQoL

Domain name	Question no.	Cronbach's alpha N=781	Hindi n=197	Telugu n=197	Tamil n=193	Kannada N=72	Urdu n=22
Physical Health	1-8	0.90	0.89	0.91	0.94	0.78	0.90
Pain	9-11	0.80	0.71	0.83	0.87	0.80	0.75
Planning	12-14	0.84	0.80	0.85	0.92	0.72	0.92
Intimacy	15,16	0.91	0.82	0.94	0.89	0.94	0.92
Burden to others	17-19	0.83	0.75	0.86	0.85	0.82	0.91
Emotional health	20-25	0.90	0.83	0.90	0.95	0.93	0.94
Body image	26-30	0.81	0.80	0.84	0.91	0.62	0.91
Fatigue	31-34	0.79	0.78	0.72	0.86	0.79	0.62

Table 2. The mean scores in Lupus QOL domains across different languages

Language / LQOL domains	Hindi (n=197)	Telugu (n=197)	Tamil (n=193)	Kannada (n=72)	Urdu (n=22)
Physical Health	60.3	60.2	53.3	54.8	68.9
Pain	55.9	58.8	54.6	54.6	66.3
Planning	66.3	65.1	54.8	57.4	75.8
Intimacy	57.5	57.5	51.2	56.6	65.9
Burden to others	52.8	57.4	52	49.2	64
Emotional health	59.9	62.5	57.8	52.5	73.7
Body image	59.3	64.6	55.5	54.7	74.2
Fatigue	57.9	60.7	45.6	58.7	67

consistency of the questions in various domains of the translated LupusQOL was high with Cronbach's Alpha varying from 0.79-0.91 (Table1)

The mean scores in each domain of Lupus QoL among the patients were as follows: physical health 58.1, pain 55.9, planning 63, intimacy 54.8, burden to others 55, emotional health 59.7, body image 59.3 and fatigue 57.5 (Table 2). Higher SLEDAI scores correlated with poor LupusQoL across all domains, though the correlation was at mild.

Table 3. Correlation with clinical disease activity *p<0.05, ** p<0.01

	Physical Health	Pain	Planning	Intimacy	Burden	Motion	Body Image	Fatigue
SLEDAI	-.219**	-.184**	-.206**	-.170**	-.157**	-.164**	-.126**	-.170**

Renal	-0.058	-0.036	-.074*	-.132**	-.097**	-0.066	-0.039	-0.004
Hematological	-.117**	-.124**	-.114**	-.098*	-0.070	-.086*	-0.063	-.082*

Looking at impact of different organ involvement on LUPUS QoL Physical health was affected by constitutional and musculoskeletal(MSK) domain and pain scores correlated with MSK domain, (Table 3).

Conclusion: Hindi, Telugu, Tamil, Kannada and Urdu translations of Lupus QoL have good internal consistency. Indian lupus patients have significantly impaired quality of life. only some part of which could be accounted for by disease activity. Thus other factors contributing to poor QoL need to be addressed while managing patients.

Screening for Cognitive Impairment with the Automated Neuropsychological Assessment Metrics in Patients with Systemic Lupus Erythematosus

Ruyi Pan[1], Juan Diaz-Martinez[2], Jessica Gronsbell[1] and Zahi Touma[3], [1]University of Toronto, Toronto, ON, Canada, [2]UHN, Toronto, ON, Canada, [3]University of Toronto, Mississauga, ON, Canada

SESSION INFORMATION

Session Date: Sunday, November 7, 2021

Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster II: Manifestations (0855–0896)

Session Type: Poster Session B

Session Time: 8:30AM–10:30AM

Background/Purpose: The American College of Rheumatology Neuropsychological Battery (ACR-NB) is the standard screening test for cognitive impairment (CI) in systemic lupus erythematosus (SLE). While the ACR-NB is vali-

dated for classifying definite, indeterminate, or non-CI, it requires expensive administration by specialists that limits widespread use. Towards an accessible alternative, we developed a CI index with the Automated Neuropsychological Assessment Metrics (ANAM) in a SLE population with definite or non-CI. Although our work provided evidence for the validity of the ANAM relative to the ACR-NB, one third of SLE patients are classified as indeterminate CI in practice. In this study, we further assessed the ANAM as a screener for CI in a population more reflective of clinical settings. Our objectives were to: (i) identify ANAM subtests predictive of CI, (ii) develop an initial approach for classifying definite, indeterminate, or non-CI, (iii) evaluate performance relative to the ACR-NB.

Methods: 211 adult SLE patients were given the ACR-NB and ANAM on the same day at a single center in 2016-2018 **(Table 1)**. The ACR-NB scores across the 6 domains are standardized by age and gender to define CI as: definite: z-score ≤ -1.5 in ≥ 2 domains, indeterminate: z-score ≤ -1.5 in 1 domain, or non: z-scores in all domains > -1.5. The ANAM has 7 domains with 15 subtests scored with the mean reaction time (MR), percentage correct responses (PCT), the coefficient of variation of the MR (CV), and/or throughput (TH).

To classify ACR-NB CI status (definite/indeterminate/non-CI) with the ANAM subtests, we fit 6 models with all subtests and different score types: 4 with one score each, one with MR, CV, and PCT, and one with MR, CV, PCT, and TH. In each setting, we fit a proportional odds cumulative logit model with the adaptive elastic net penalty using the log transformed ANAM subtest scores. The penalized fitting identifies relevant subtests by shrinking coefficients of irrelevant subtests to zero. The initial estimates for penalization were obtained with ridge regression and the tuning parameter selected with cross-validation using the Akaike information criteria. Performance estimates relative to the ACR-NB were obtained with weighted 3-fold cross-validation.

Results: The best performing model included the MR, CV, and PCT scores and selected 36 subtest scores across the 7 ANAM domains for classification of CI. The estimates of the nonzero coefficients are presented in **Table 2**. **Figure 1** summarizes the overall classification accuracy of the model relative to the ACR-NB CI classifications. While the model tends to overcall the indeterminate group as definite CI and the non-CI group as indeterminate and definite CI, it performs well for definite CI compared to ACR-NB. Used as a screening test for CI relative to indeterminate or non-CI, the model has a sensitivity of 0.62 (95% confidence interval: 0.48, 0.76), specificity of 0.72 (0.60, 0.88), and area under the curve of 0.76 (0.69, 0.80).

Conclusion: This is the first study to evaluate the ANAM in discriminating definite, indeterminate, and non-CI in a real world SLE population. The ANAM holds promise as a CI screener and warrants further assessment.

Table 1: Characteristics of the patient population.

	ACR-NB CI Status		
	Non (N=42)	Indeterminate (N=69)	Definite (N=100)
Female sex(%)	40(95.2%)	59(85.5%)	86(86.0%)

Figure 1: Overall accuracy of the proportional odds cumulative logit model for classifying ACR-NB CI status based on the ANAM subtests. The rows correspond to the ACR-NB classification and the columns correspond to the model classification. The diagonal from left to right contains the percentage of patients correctly classified by the model, while the off-daigonal entries contain the percentage of misclassifications.

Trajectories of Depressive Symptoms in Systemic Lupus Erythematosus over 7 Years

Seerat Chawla[1], Jiandong Su[2], Zahi Touma[3] and Patricia Katz[4], [1]University of California Los Angeles, Los Angeles, CA, [2]University Health Network, Toronto, ON, Canada, [3]University of Toronto, Mississauga, ON, Canada, [4]University of California San Francisco, San Francisco, CA

SESSION INFORMATION

Session Date: Sunday, November 7, 2021

Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster II: Manifestations (0855–0896)

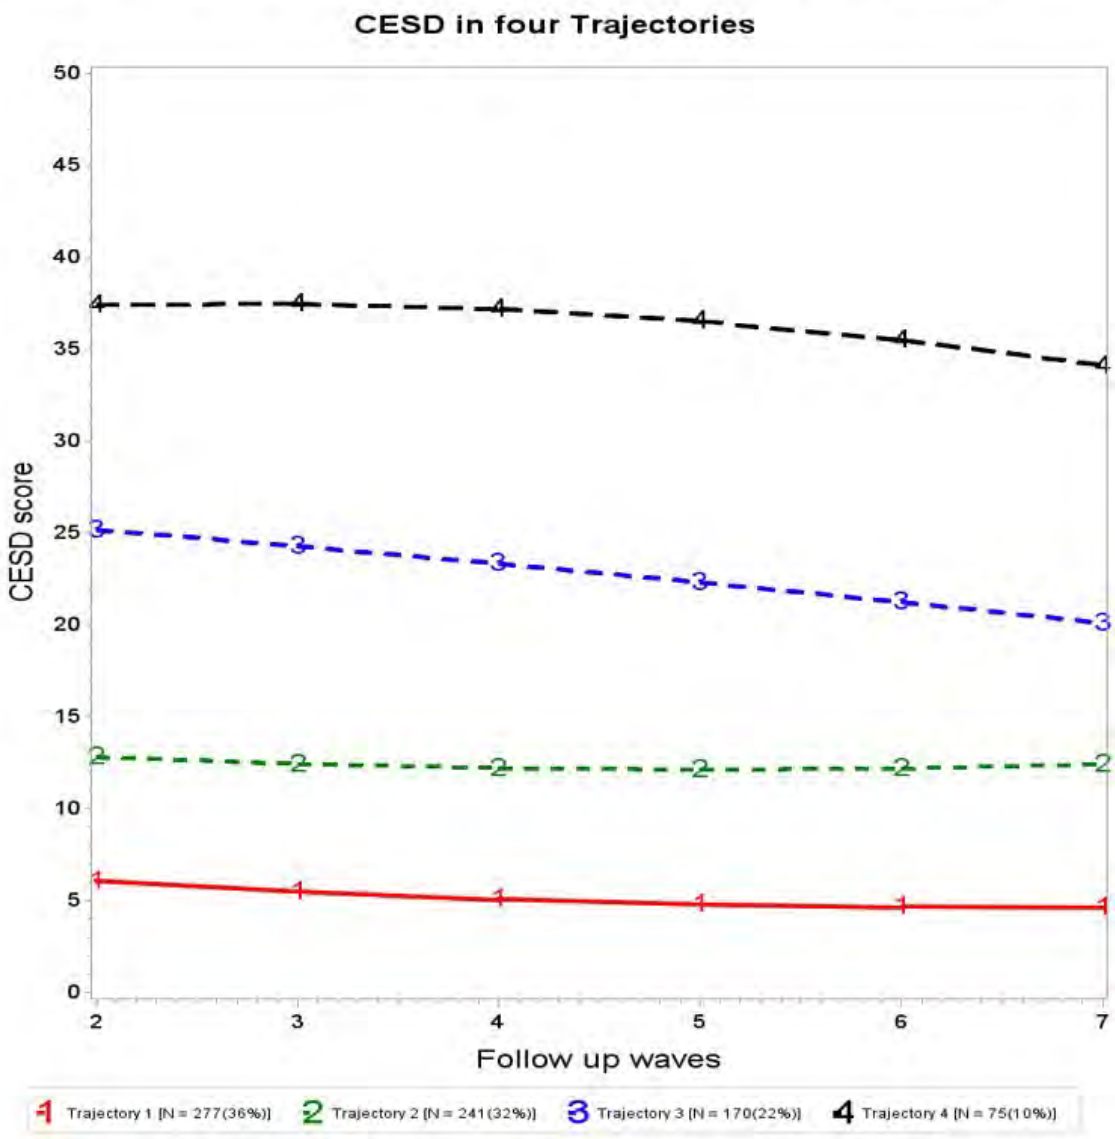
Session Type: Poster Session B

Session Time: 8:30AM–10:30AM

Background/Purpose: Depression remains one of the most frequently observed psychiatric disorders in patients with SLE with a pooled prevalence of 35.0% (95% CI: 29.9%-40.3%). Nevertheless, the trajectory of depression in this population remains uncharacterized. Our aims were to: 1) determine longitudinal trajectories of depressive symptoms in patients with SLE, 2) identify baseline factors that predict a patient's trajectory of depression.

Methods: Longitudinal data on 763 adults with SLE followed over 7 years from a single center were analyzed. Depressive symptoms were assessed with the Centre for Epidemiologic Studies Depression Scale (CESD) annually in years 2-7 providing 6 waves of observation (wave 2 is the baseline assessment for CESD). Patients with two or more

Figure 1. Membership and trajectories of four latent classes using CESD over 7 years



waves of data for CESD were included. Group-based joint trajectory modelling was used to model latent classes. Using only members with latent class posterior probability > 0.8, univariable and multivariable analyses were used to examine baseline factors association with latent classes memberships. The outcomes were the ordinal worse classes of depression represented by latent classes. The assumption of proportionality of the model was checked and satisfied between the four latent classes.

Results: Depressive symptoms were mapped into four trajectories: 1) lowest CESD scores (no depression, 36%), 2) low CESD scores (no depression, 32%), 3) high CESD scores (depression, 22%), and 4) highest CESD scores (depression, 10%). **Figure 1** shows the longitudinal trajectories of four latent classes based on their CESD values over 7 years.

Table 1 shows the baseline demographic information in four classes of patients after they were grouped into four trajectories.

Table 1. Baseline characteristics of patients by classes (n=763)					
	Descriptive	Class 1 Lowest CESD scores	Class 2 Low CESD scores	Class 3 High CESD scores	Class 4 Highest CESD scores
Variables	VALUE	N=277	N=241	N=170	N=75
Female	Yes	253 (91.3%)	220 (91.3%)	157 (92.4%)	75 (100.0%)
Ethnicity	Missing	18	8	7	4
	Caucasian	187 (72.2%)	170 (73.0%)	117 (71.8%)	48 (67.6%)
	Hispanic	17 (6.6%)	16 (6.9%)	16 (9.8%)	6 (8.5%)
	African-American	13 (5.0%)	12 (5.2%)	15 (9.2%)	7 (9.9%)
	Asian	29 (11.2%)	19 (8.2%)	9 (5.5%)	5 (7.0%)
	Other	13 (5.0%)	16 (6.9%)	6 (3.7%)	5 (7.0%)
Age	Mean ± SD	49.1 ± 13.5	50.7 ± 13.2	50.8 ± 11.1	50.6 ± 9.8
SLE Disease duration	Mean ± SD	15.9 ± 9.3	15.9 ± 8.0	14.8 ± 8.0	15.9 ± 8.8
Education	1 - Less than high school	1 (0.4%)	4 (1.7%)	3 (1.8%)	7 (9.3%)
	2 - High school graduate	20 (7.2%)	25 (10.4%)	24 (14.1%)	14 (18.7%)
	3 - Some college/no degree	68 (24.5%)	75 (31.1%)	54 (31.8%)	19 (25.3%)
	4 - Associate degree/trade or vocational school	42 (15.2%)	36 (14.9%)	34 (20.0%)	25 (33.3%)
	5 - College graduate (Bachelor's degree)	82 (29.6%)	53 (22.0%)	37 (21.8%)	5 (6.7%)
	6 - Masters/PhD/professional degree	64 (23.1%)	48 (19.9%)	18 (10.6%)	5 (6.7%)
Deceased	Yes	23 (8.3%)	33 (13.7%)	27 (15.9%)	8 (10.7%)

Data on 584 (76%) patients satisfied the posterior probability 0.8 and were analyzed in the ordinal logistic regression. In the multivariable analyses, older age at baseline, Caucasian, higher education level and less SF-36 Bodily Pain were associated with better CESD classes while higher fatigue score and SLE disease activity by SLAQ were associated with worse CESD classes (**Table 2**).

Conclusion: Four distinct trajectories for depressive symptoms were found. Baseline factors that were associated with latent classes were identified that may be helpful in identifying individuals with SLE who are at the greatest risk of developing persistent depressive symptoms over time. These results will serve as a more comprehensive guide for prognosis and clinical decisions to improve overall treatment outcomes.

Class 1) lowest CESD scores (no depression, 36%), Class 2) low CESD scores (no depression, 32%), Class 3) high CESD scores (depression, 22%), and Class 4) highest CESD scores (depression, 10%)

Table 2. Multivariable ordinal logistic regression of baseline factors of class membership, using only members with posterior probability > 0.8

Variables	Odds Ratio Estimate	Lower 95% Confidence Limit for Odds Ratio	Upper 95% Confidence Limit for Odds Ratio	P values
Age	0.98	0.96	0.99	0.007
Caucasian vs. non-Caucasian	0.67	0.45	0.99	0.046
Education levels 1 to 6, higher vs. lower level	0.84	0.74	0.96	0.010
Fatigue score at wave two (each one unit increase)	1.04	1.02	1.05	<.0001
Any of Immunosuppressives, yes vs. no	1.42	0.96	2.10	0.076
SF-36 Physical Functioning Score (higher is better, each one unit increase)	0.99	0.99	1.00	0.137
Lupus activity, scale of 0 to 10, where 0 is no activity and 10 is the most activity	1.13	1.04	1.22	0.003
Income was above or below 125% of the US federal poverty threshold, based on income and household size	1.59	0.92	2.77	0.099
Kidney problems because of lupus, Yes vs. no	1.39	0.91	2.13	0.127
SF-36 Bodily Pain score (higher is better, each one unit increase)	0.94	0.92	0.96	<.0001

Abstract Number: 0894

Help-seeking Behaviors and Treatment Preferences for Sleep Problems Among Persons with Lupus

Deborah Da Costa[1], Josée Savard[2], Elham Rahme[1] and Paul R Fortin[3], [1]McGill University, Montréal, QC, Canada, [2]Université Laval, Québec City, QC, Canada, [3]CHU de Quebec - Universite Laval, Québec City, QC, Canada

SESSION INFORMATION

Session Date: Sunday, November 7, 2021

Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster II: Manifestations (0855–0896)

Session Type: Poster Session B

Session Time: 8:30AM–10:30AM

Background/Purpose: Sleep disturbances, including difficulty initiating sleep, maintaining sleep, and/or early morning awakenings are prevalent among persons with lupus and have been shown to contribute to worsening of symptoms including fatigue, pain, depression and health related quality of life. Cognitive behavioral therapy for insomnia (CBTi) is considered first-line treatment for insomnia, but accessibility is limited. Internet delivered CBTi has the potential to overcome accessibility barriers. To guide the tailoring of an internet delivered CBTi for persons with lupus experiencing insomnia, an on-line needs assessment was conducted to identify help-seeking behaviors, strategies for managing insomnia and treatment preferences among persons with lupus.

Methods: We conducted a cross-sectional on-line survey with 119 individuals with lupus (mean age = 47.4 years ± 13.7) recruited through social media ads posted by Lupus Canada and other Canadian and provincial lupus Face-

book pages. Participants completed self-report questions assessing their sleep quality, insomnia symptoms (Insomnia Severity Index – ISI), help-seeking behaviors, barriers to help-seeking, treatment preferences for sleep problems and sociodemographics. Means, medians, and percentages were calculated for continuous values, and percentages were calculated for categorical values.

Results: Of the total sample in the past year, 46% had used at least once prescription medications and 37.2% had used over the counter medication to specifically facilitate sleep. Among participants with probable insomnia (ISI score ≥ 8, n=103), 71.3% had ever discussed their sleep problem with a health care provider and 44.6% perceived a need to talk to a health care provider about their sleep problems in the past year but decided not to seek care. Most commonly endorsed reasons for not seeking treatment were perceptions of insomnia as a problem that one should be able to handle on one's own (54.8%), that insomnia gets better by itself (50%), or that insomnia is not amenable to change (48.9%). Among patients with probable insomnia, 45.4% rated medication treatment as very acceptable, while 56.7% rated nonmedication treatment as very acceptable, and 98% reported that they would be likely or very likely to try a nonmedication approach delivered over the internet and tailored to lupus to improve sleep.

Conclusion: Given the prevalence, chronicity and adverse consequences associated with insomnia in individuals with lupus, this study suggests that efforts designed to reduce the perception of insomnia as transient and to increase awareness of the effectiveness of behavioral treatments are needed. Behavioral interventions such as CBTi are acceptable to individuals with lupus and these findings will guide the evaluation of an internet delivered CBTi program tailored to persons with lupus experiencing insomnia.

Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster II: Manifestations (0855–0896)

Session Type: Poster Session B

Session Time: 8:30AM–10:30AM

Background/Purpose: Dispersion is defined as the variability in an individual's performance across multiple tasks at a single assessment visit. This measure has been studied in a number of neurodegenerative and neurodevelopmental disorders, in which increased dispersion was generally found to be associated with cognitive dysfunction (CD). We aim to compute a dispersion score using the tests of the American College of Rheumatology Neuropsychological battery (ACR-NB) and to determine the association between this dispersion score and the risk of CD in SLE patients.

Methods: This retrospective longitudinal study included patients who attended the Lupus Clinic from January 2016 to October 2019. A total of 301 adult SLE patients were administered the ACR-NB at their initial visit, 6 months and

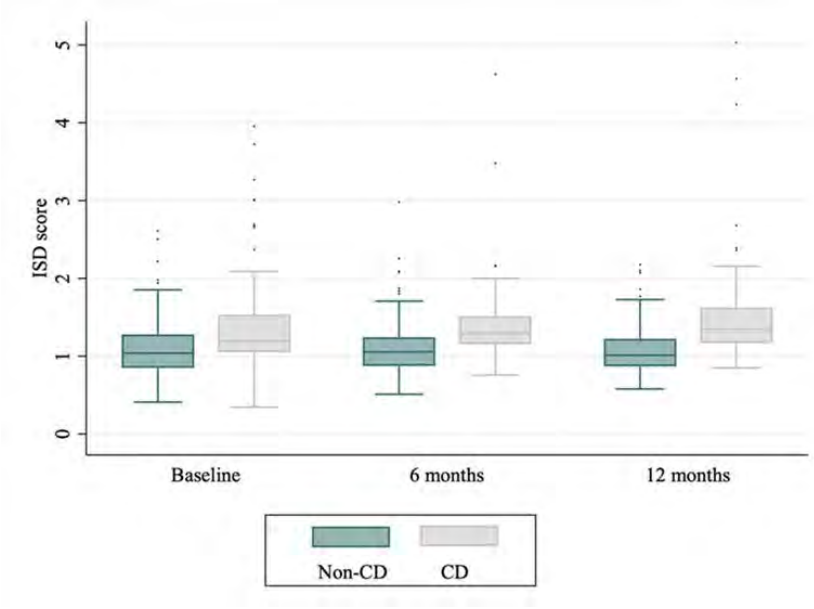

Figure 1. Intraindividual standard deviation (ISD) scores across three assessment visits for non-CD patients and CD patients.

Table 1. Multivariable random intercept logistic regression model

	Odds ratio	95% CI	P-value
ISD

Sick Leave	2.47	0.32-19.00	0.38
Looking for Work	5.18	0.33-81.38	0.22
Others	1.83	0.09-37.17	0.70

12 months. CD was defined as a z-score of ≤-1.5 on ≥2 domains or z ≤-2 on ≥1 domain. The 19 tests of the ACR-NB were used to compute a type of dispersion score, the intraindividual standard deviation (ISD). To obtain the ISD, the standard deviation of the age- and sex- adjusted z-scores was calculated for each visit, resulting in a maximum of 3 scores per patient. To estimate the association between ISD and patient's cognitive status (CD and non-CD), we used multi-level logistic regression, adjusting for clinically important covariates.

Results: CD was observed in 106 patients (35.2%) at baseline, 52 patients (27.8%) at 6 months, and 53 patients (28.0%) at 12 months. Among all observations across 3 visits, the mean age- and sex-adjusted ISD was 1.40 ± 0.55. Prior to adjustment for covariates, the mean ISD for the non-CD group was 1.10 ± 0.31 compared with 1.50 ± 0.70 for the CD group. After adjusting for ethnicity, education, employment, socioeconomic status and anxiety/depression, there was a statistically significant association between ISD and cognitive status (odds ratio [OR] for one unit increase in ISD: 13.56, 95% CI: 4.80-38.31; OR for 1/10th unit increase in ISD: 1.30, 95% CI: 1.17-1.44). Findings were robust to multiple sensitivity analyses. Multivariable random intercept logistic regression modelling is provided in **Table 1**. ISD scores across 3 assessment visits for non-CD and CD patients is provided in **Figure 1**.

Conclusion: Dispersion scores such as ISD have been explored as a pragmatic and sensitive marker of cognitive function in different patient populations. We showed that among adult SLE patients, increased ISD across the cognitive tests of the ACR-NB was associated with an increased likelihood of having CD, adjusting for important covariates. Additional research is warranted to evaluate the promise of dispersion scores in clinical practice.

Abstract Number: 0896

Systemic Lupus Erythematosus Disease Flares After SARS-CoV-2 Vaccination

Medha Barbhaiya[1], Jonah Levine[1], Caroline Siegel[1], Vivian Bykerk[2], Deanna Jannat-Khah[1] and Lisa Mandl[1], [1]Hospital for Special Surgery, New York, NY, [2]Division of Rheumatology, Hospital for Special Surgery, New York City, NY

SESSION INFORMATION
Session Date: Sunday, November 7, 2021
Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster II: Manifestations (0855–0896)
Session Type: Poster Session B
Session Time: 8:30AM–10:30AM

Background/Purpose: Vaccination against SARS-CoV-2 is particularly important for patients with systemic lupus erythematosus (SLE), who may be at increased risk of hospitalization for COVID-19. However, the most common reason for vaccine refusal in patients with SLE is fear of SLE disease flare. Additionally, the SARS-CoV-2 mRNA vaccines could potentially induce interferon production, associated with increased SLE disease activity. Thus far, no population-based data exist regarding whether SARS-CoV-2 vaccines trigger SLE flares.

Methods: We emailed a secure web-based survey on March 5, 2021 to 7,094 patients aged ≥18 years evaluated at least once between 2018-2020 by a rheumatologist at a single Rheumatology Division in New York City. We included individuals who received at least one vaccine dose. ICD-10-CM codes identified patients with SLE. A self-reported disease flare was defined as "a sudden worsening of your rheumatology condition or arthritis" within two weeks of the vaccine dose. To prevent misleading conclusions, we did not perform statistical testing on these interim results.

Results: As of March 30, 2021, 136/466 (29.2%) respondents with SLE (mean[SD] age 54.7 [13.9] years; 93.4% female; 67.7% White; 13.2% Hispanic/Latinx ethnicity) reported receiving at least one COVID-19 vaccine dose.

Table 1. Vaccine Characteristics in Outpatients with SLE, Stratified by Flare Status Post-COVID-19 Vaccination				
	1st COVID-19 Vaccine Dose N=136		2nd COVID-19 Vaccine Dose N=72

Acetaminophen	3 (33.3)	33 (26.0)	4 (80)	26 (38.8)
NSAIDs/CoX-2 inhibitors	2 (22.2)	9 (7.1)	1 (20)	6 (9)
No Medications	4 (44.4)	86 (67.7)	0 (0)	35 (52.2)
Flare defined as self-reported "sudden worsening of rheumatology condition or arthritis" within 2 weeks of COVID-19 vaccination. *Column numbers do not add up due to missing data.				

Eighty-one patients (59.6%) received Pfizer, 48 (39.3%) received Moderna, and 4 (2.9%) received Janssen. Of patients receiving Pfizer or Moderna, 72 (54.5%) received 2/2 doses. Twelve patients (8.8%) reported SLE flare within two weeks of COVID-19 vaccination. Only 1 patient (8.3%) with flare reported a history of suspected/confirmed COVID-19, similar to those without flare (8.4%). Patients reporting SLE flare were older (59.0 [14.0] vs. 54.3 [13.9] years) and White (83.3% vs. 61.1%). Flares occurred in 12.5% of patients receiving Moderna and 7.4% receiving Pfizer (6 patients each). Out of 7 patients receiving both vaccine doses, 2 flared only after the first dose, 3 flared only after the second dose, and 2 flared after both doses. Of the 14 flare episodes, 9 occurred after the first dose, and 5 occurred after the second dose. Medications were used for prevention or treatment of vaccine side effects by both the flare and non-flare groups (Table 1). Most flares after the first vaccine dose were mild (77.8%), and after the second vaccine were moderate (60%). 12/14 flares (85%) were described as "typical", predominantly characterized by joint pain, muscle aches, and fatigue (Table 2). While 8/14 flares started 1 day after vaccination, 4/14 started 4-7 days later. None started >7 days post-vaccination. Most SLE flares resolved within 7 days of onset; however, 4/14 lasted 8-21 days and 2/14 lasted >21 days.

Conclusion: Our data suggest >91% of SLE patients did not experience a disease flare post-SARS-CoV-2 vaccination; of those that did, most had mild flares. Given almost all patients reported that their post-vaccine flare was "typical" of their SLE flares, vaccine side effects alone may not explain these findings. This information can help inform vaccine decision-making among patients with SLE. Future analyses will evaluate whether modifying immunosuppressive medications to enhance vaccine efficacy increased SLE flare risk.

Table 2. Flare Characteristics in Outpatients with SLE, Stratified by Flare Status Post-COVID-19 Vaccination

Age-Stratified Trend of Spinal Radiographic Damage Progression in Patients with Ankylosing Spondylitis

Tae-Han Lee[1], Bon San Koo[2], Bora Nam[3], Seunghun Lee[4], Kyung Bin Joo[4] and Tae-Hwan Kim[3], [1]Keimyung University Dongsan Hospital, Daegu, Republic of Korea, [2]Inje University Seoul Paik Hospital, Seoul, Republic of Korea, [3]Hanyang University Hospital for Rheumatic Diseases, Seoul, Republic of Korea, [4]Hanyang University Hospital, Seoul, Republic of Korea

SESSION INFORMATION

Session Date: Sunday, November 7, 2021

Session Title: Spondyloarthritis Including PsA – Diagnosis, Manifestations, & Outcomes Poster II: Imaging in Spondyloarthritis (0897–0907)

Session Type: Poster Session B

Session Time: 8:30AM–10:30AM

Background/Purpose: Previous studies investigating the course of spinal structural progression in patients with ankylosing spondylitis (AS) using the modified Stoke Ankylosing Spondylitis Spine Score (mSASSS) have shown highly variable rates of mSASSS progression among individuals. Furthermore, a substantial radiographic progression has been noted both in young patients at an early stage of disease as well as in elderly patients at an advanced stage, indicating a within-individual variation in the progression of long-term structural damage in the spine. Thus, exploring the extent to which spinal radiographic damage worsens according to age can be helpful in providing insights into the understanding of the natural course of structural disease progression. The aim of this study was to estimate the course of spinal radiographic progression for specific age range categories using a longitudinal dataset in a real-life setting.

Methods: In total, 4016 radiographic intervals were obtained from 1125 AS patients with consecutive spinal radiographs available at a single hospital. The included radiographic intervals were categorized into five groups based on the age at each radiograph: age < 20 (n=122); 20–29 (n=1124); 30–39 (n=690); 40–49 (n=794); and ≥50 years (n=286). Radiographic progression rate was defined as the mSASSS change per year. Age-stratified mSASSS change per year was estimated using the generalized estimating equations (GEE) for longitudinal data after adjusting for predictors of radiographic progression. A subgroup analysis was performed to estimate the course of radiographic progression, stratified for identified risk factors.

Results: The mean (SD) follow-up duration was 8.4 (2.9) years and the mean number of radiographs was 4.6 (1.2) per patient. The mean radiographic progression rate of the overall intervals was 0.8 (1.9). In the GEE multivariable analysis, smoking, peripheral joint involvement, eye involvement, log-transformed C-reactive protein (CRP) values at each radiograph, and preexisting syndesmohyte were significant and independent factors for predicting structural damage progression.

GEE-estimated radiographic progression was highest at age group 30–39 (estimated mean mSASSS change per year was 1.148), followed by 40–49 (1.003), 20–29 (0.868), ≥50 (0.779), and < 20 (0.643) . However, radiographic damage scores rapidly increased among younger age groups with risk factors. The estimated mean mSASSS change per year for the age group 20–29 was 1.244 with elevated CRP levels and 2.505 with preexisting syndesmophytes, respectively.

Table 1. Characteristics of radiographic intervals, overall and by age-stratified groups

Variable	Total intervals (n=4016)		Radiographic intervals by age-stratified groups, years				
	No. with data	Value	<20 (n=122)	20–29 (n=1124)	30–39 (n=1690)	40–49 (n=794)	≥50 (n=286)
Age, years	4016	34.7 (9.5)	17.6 (1.5)	25.4 (2.8)	34.3 (2.8)	43.6 (2.8)	55.9 (5.1)
Symptom duration, years	3457	12.7 (7.8)	3.9 (3.0)	7.9 (4.6)	13.3 (6.4)	16.6 (8.2)	19.9 (11.3)
Male gender	4016	3572 (88.9%)	112 (91.8%)	1008 (89.7%)	1528 (90.4%)	696 (87.7%)	228 (79.7%)
HLA-B27 positive	4006	3878 (96.8%)	119 (98.3%)	1100 (98.2%)	1637 (97.1%)	756 (95.3%)	266 (93.0%)
Smoking ever	3860	2384 (61.8%)	35 (29.9%)	519 (48.9%)	1100 (67.7%)	555 (71.3%)	175 (62.7%)
Eye involvement ever	3564	1410 (39.6%)	21 (22.1%)	327 (33.2%)	620 (41.0%)	328 (45.8%)	114 (44.5%)
Peripheral joint involvement ever	3529	1539 (43.6%)	51 (54.8%)	433 (44.5%)	637 (42.3%)	298 (42.3%)	120 (47.4%)
CRP, mg/dL	3957	1.6 (1.9)	1.9 (2.4)	1.9 (2.2)	1.5 (1.8)	1.5 (1.9)	1.4 (1.6)
Elevated CRP	3957	1585 (40.1%)	50 (41.7%)	501 (45.4%)	656 (39.4%)	275 (35.0%)	103 (36.3%)
ESR, mm/h	3961	22.9 (25.1)	25.1 (28.8)	23.8 (26.3)	21.4 (23.4)	23.1 (25.2)	26.4 (28.1)
BASDAI (0–10)	2684	3.4 (2.2)	4.1 (2.7)	3.6 (2.3)	3.4 (2.2)	3.3 (2.1)	3.7 (2.0)
Elevated BASDAI (≥4)	2684	946 (35.2%)	21 (48.8%)	243 (38.9%)	412 (34.0%)	186 (31.4%)	84 (39.3%)
TNF inhibitor use ever	4016	2306 (57.4%)	78 (63.9%)	625 (55.6%)	957 (56.6%)	458 (57.7%)	188 (65.7%)
Sacroiliitis grade at baseline	3796	2.9 (0.9)	2.3 (0.8)	2.6 (0.9)	3.0 (0.9)	3.1 (0.9)	2.9 (0.9)
Syndesmophytes presence at baseline	4016	1146 (28.5%)	0 (0.0%)	84 (7.5%)	494 (29.2%)	397 (50.0%)	171 (59.8%)
mSASSS change/year	4016	0.8 (1.9)	0.1 (0.5)	0.5 (1.5)	1.0 (2.0)	1.1 (2.0)	0.8 (1.8)
Cervical segment	4016	0.3 (1.2)	0.0 (0.4)	0.2 (1.0)	0.4 (1.3)	0.5 (1.2)	0.3 (1.3)
Lumbar segment	4016	0.5 (1.2)	0.1 (0.3)	0.3 (0.9)	0.6 (1.3)	0.6 (1.4)	0.5 (1.5)

Continuous variables are presented as mean (standard deviation).

BASDAI, Bath Ankylosing Spondylitis Disease Activity Index; CRP, C-reactive protein; ESR, erythrocyte sediment rate; HLA, human leukocyte antigen; mSASSS, modified Stoke Ankylosing Spondylitis Spine Score; TNF, tumor necrosis factor.

Conclusion: In AS, spinal structural damage with age progresses in an increasing trend in which periods of relatively rapid increase and slow increase may alternate, and it seems to progress the most in the 30s. However, patients with risk factors show a rapid progression from under the 30s.

Table 2. Age-stratified radiographic progression rate estimated from GEE multivariable models

	Radiographic intervals by age-stratified groups, years				
	<20	20–29	30–39	40–49	≥50
Estimated mSASSS change/year	0.643 (0.484, 0.801)	0.868 (0.711, 1.026)	1.148 (1.027, 1.268)	1.003 (0.837, 1.170)	0.779 (0.519, 1.038)
Cervical segment	0.211 (0.086, 0.336)	0.316 (0.200, 0.432)	0.478 (0.375, 0.582)	0.492 (0.390, 0.594)	0.343 (0.186, 0.500)
Lumbar segment	0.324 (0.205, 0.444)	0.477 (0.374, 0.580)	0.684 (0.595, 0.773)	0.557 (0.439, 0.674)	0.511 (0.309, 0.714)

Values are balanced marginal means (95% CI) of mSASSS change/year which were averaged over the levels of independent predictors of radiographic progression (smoking, eye involvement, peripheral joint involvement, log-transformed CRP, and preexisting syndesmophyte).

CI, confidence interval; GEE, generalized estimating equations; mSASSS, modified Stoke Ankylosing Spondylitis Spine Score.

Table 3. GEE-estimated radiographic progression rate, by the presence or absence of risk factors

Session Title: Spondyloarthritis Including PsA – Diagnosis, Manifestations, & Outcomes Poster II: Imaging in Spondyloarthritis (0897–0907)

Session Type: Poster Session B

Session Time: 8:30AM–10:30AM

Background/Purpose: In previous studies vertebral corner inflammation (VCI) and vertebral corner fat deposition (VCFD) were associated with syndesmophyte formation on cervical and lumbar conventional radiography. We studied associations between patterns of VCI, VCFD and a combination of both on magnetic resonance imaging (MRI) and the development of new or grown syndesmophytes on whole spine low dose computed tomography (ldCT), thereby studying these associations also in the thoracic spine.

Methods: Patients in the Sensitive Imaging in Ankylosing Spondylitis cohort underwent MRI at baseline, 1 year and 2 years, and ldCT at baseline and 2 years. MRI lesions were scored by 3 central readers, using the SPARCC method for VCI and the CanDen method for VCFD, and coded as absent or present per timepoint and per reader. MRI patterns over time (Table) were deemed present if seen by ≥2 out of 3 readers. The patterns reflect hypothetical associations between presence and absence of VCI and VCFD, independently and combined, on ldCT detected new or grown syndesmophytes. Individual reader change scores were used for ldCT images, scored by 2 central readers with the Computed Tomography Syndesmophyte Score. New (CTSS 0 à 1, 2 or 3) and grown (CTSS 1 à 2 or 3; 2 à 3) syndesmophytes were grouped together to represent bone formation. Corners not at risk for the outcome due to presence of a bridged syndesmophyte at baseline were excluded. Multilevel generalized estimated equations were used, with separate models per MRI pattern, accounting for correlations within patients and between ldCT readers.

Results: Fifty patients were included, contributing a total of 4600 vertebral corners. Their mean age was 49.3 years (SD 9.8), 86% were male and 78% were HLA-B27+. Presence of VCI and VCFD patterns ranged from 43 (0.9%) to 3108 (67.6%) corners (Table), with the lowest frequency being for VCI preceding VCFD. Protection against syndesmophyte development was seen in case of absence of both VCI and VCFD (OR 0.35) and positive associations with ORs ranging from 1.87-2.58 were observed for various VCI/VCFD patterns. Nevertheless, out of all corners with a new or grown syndesmophyte, 47.3% of corners according to reader 1 and 43.9% according to reader 2 had neither VCI nor VCFD preceding the bone formation.

Conclusion: Presence of VCI or VCFD and combinations of the two increased odds of bone formation 2 years later, whereas absence of both VCI and VCFD decreased the odds, showing that VCI and VCFD have some role in the development of syndesmophytes. However, almost half of all bone formation occurred in corners without VCI or VCFD, suggesting the presence of these lesions in yearly MRIs does not fully explain the development of syndesmophytes.

Table. Effect of vertebral corner inflammation and vertebral corner fat deposition on syndesmophyte formation

Patterns of lesions over time on MRI	Corners with VCI/VCFD pattern N(%)	OR (95% CI)
1. VCI at any TP, irrespective of VCFD	691 (15.0%)	**2.37 (1.49-3.78)**
2. VCFD at any TP, irrespective of VCI	1080 (23.5%)	**2.58 (1.97-3.39)**
3. VCI on ≥1 TP and absence of VCFD on all TPs	372 (8.1%)	**1.90 (1.15-3.13)**
4. VCFD on ≥1 TP and absence of VCI on all TPs	754 (16.4%)	**1.87 (1.41-2.48)**
5. VCI precedes VCFD	43 (0.9%)	2.20 (0.83-5.86)
6. VCI precedes or coincides with VCFD. VCFD does not precede VCI	198 (4.3%)	**2.33 (1.47-3.69)**
7. Absence of VCI and VCFD on all TPs	3108 (67.6%)	**0.35 (0.25-0.49)**

VCI, vertebral corner inflammation; VCFD, vertebral corner fat deposition; TP, timepoint.

This study confirmed that there is an association between VCI and VCFD and bone formation also for the thoracic spine and on ldCT compared to conventional radiography.

Session Title: Spondyloarthritis Including PsA – Diagnosis, Manifestations, & Outcomes Poster II: Imaging in Spondyloarthritis (0897–0907)
Session Type: Poster Session B
Session Time: 8:30AM–10:30AM

Background/Purpose: Diagnosis of axial spondyloarthritis (SpA) is nowadays commonly made with pelvic radiography or MRI. However, there is an important inter-observer variability for radiographs, and MRI is subject to possible false positives and is not the best modality for studying structural lesions. Conversely, pelvic CT has an excellent

Table 1. Sacro-iliac CT findings using a score modified from Diekhoff et al.

Finding	AS Patients	Controls	p-value
Mean (SD) total score (range 0-108)	73.13 ± 38.07	7.51± 12.42	< 0.0001
Global positivity, n (%)	60 (89.55 %)	13 (19.40 %)	< 0.0001
Bilateral ankylosis, n (%)	39 (58.21 %)	1 (1.49 %)	< 0.0001
Positive joint space score, n (%)	59 (88.06 %)	12 (17.91 %)	< 0.0001
Positive erosion score, n (%)	18 (26.87 %)	2 (2.99%)	0.0001
Significant sclerosis, n (%)	16 (23.88 %)	10 (14.93%)	0.19
Intra-articular gas, n (%)	18 (26.87 %)	45 (67.16 %)	< 0.0001
DISH, n (%)	3 (4.48 %)	23 (34.33 %)	< 0.0001

specificity and appears to be more effective than radiography for the diagnosis of SpA. However, CT findings in patients over 50 years of age have not been studied. Therefore, we conducted a study to describe sacroiliac (SI) joint CT characteristics in patients with ankylosing spondylitis (AS), aged 50 years or older.

Methods: An observational, retrospective study was performed using medical records from Besançon University Hospital's rheumatology department, which were screened to identify patients with AS, according to the 2009 ASAS criteria. A search was then carried out for patients over 50 years old in the hospital's imaging archiving system to identify those who had undergone a CT which included the SI joints in their entirety. Non-inclusion criteria were the existence of pelvic bone lesions and a history of pelvic radiotherapy. Each patient was then matched with a control of the same age and sex, recruited through the hospital's imaging archiving system.

For each individual, CT was interpreted by two independent readers using a score previously used by Diekhoff et al.[1], dividing each SI joint into 12 regions, for each of which joint space narrowing (JSN), erosions, and sclerosis are assessed. For this study, we also observed the existence of intra-articular gas and diffuse idiopathic skeletal hyperostosis (DISH) lesions for each region. Quantitative variables are expressed as mean ± standard deviation and were compared using Student's t-test. Qualitative variables are expressed as numbers and percentages and were compared using the Chi-2 test.

Results: 67 patients and 67 controls were included. Mean age was 65.45 ± 10.62 years in the AS group and 65.34 ± 10.70 years in the control group. 44 (65.67%) were male in both groups. In the AS group, 48 (87.27%) were HLA-B27 positive. Mean disease duration was 22.57 ± 14.88 years. 23 (35.38%) had a bamboo spine. CT findings are described in table 1. The majority of AS patients had a positive JSN score, but significant erosions were found in only a minority of cases. This is partly explained by the fact that 39 (58.21%) patients had at least one complete bilateral ankylosis (and therefore no erosions) on the slices studied.

Bilateral ankylosis was associated with longer disease duration (p=0.0007) and presence of bamboo spine (p=0.0003). The distribution of patients' lesions appeared to be homogenous over all 24 regions studied (Figure 1).

The rate of significant JSN and erosion was significantly higher in the AS group. On the contrary, the rate of DISH and intra-articular gas was significantly higher in the control group.

Conclusion: CT findings in AS patients over 50 years of age are mostly represented by changes in joint space, with bilateral ankylosis present in half of the patients, and show more erosions and JSN changes, but less intra-articular gas than controls. AS appears to be a protective factor for DISH.

Session Title: Spondyloarthritis Including PsA – Diagnosis, Manifestations, & Outcomes Poster II: Imaging in Spondyloarthritis (0897–0907)

Session Type: Poster Session B

Session Time: 8:30AM–10:30AM

Background/Purpose: Ankylosing Spondylitis describes disorders of inflammation and damage to the spine and sacroiliac (SI) joints. Clinicians have observed, on occasion, AS subjects with fused SI joints but little or no spinal involvement; is there truly a subgroup with fused SI joints and long-standing disease but absent radiographically demonstrated spinal syndesmophytes? No study has assessed the subset with long standing disease with fused SI joints but no radiographic spinal disease. Using a large multi-center cohort, the purpose of this study was to identify factors associated with discordant SI joint and spinal radiographic severity in AS patients.

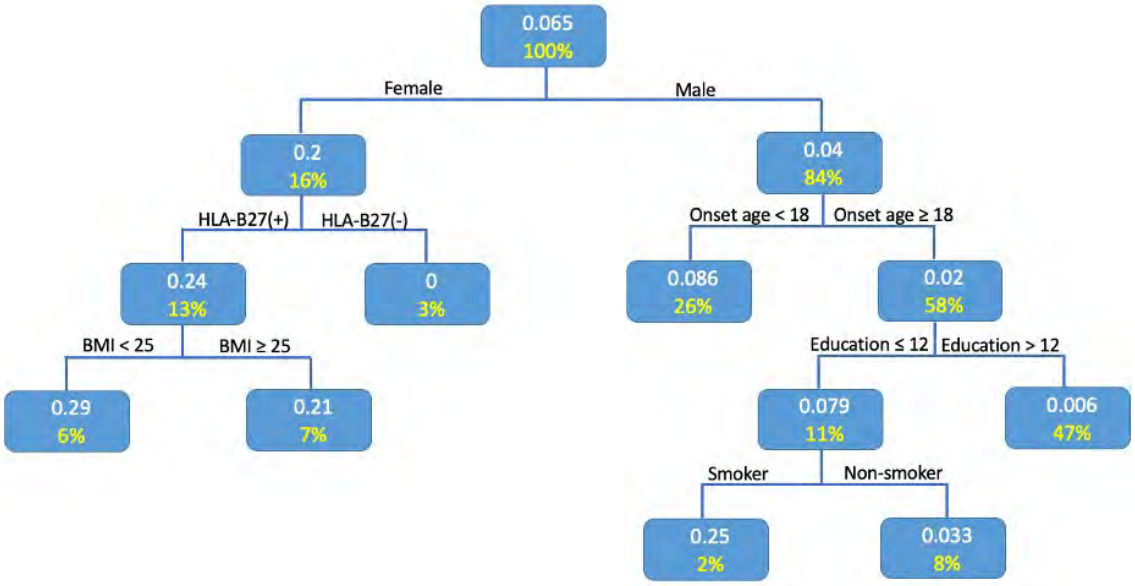

Figure 1. CART Analysis. Yellow values = percentages of the total subgroup population. White values = likelihood of not having syndesmophytes.

Table 1. Factor associated with syndesmophytes for patients with disease duration ≥20 years and grade IV sacroiliitis based on univariable logistic regression model (N=354 patients).

NA*: All patients with no-syndesmophytes have HLA-B27+
NA**: All patients with age of onset >45 have syndesmophytes

Methods: Patients met the modified New York criteria for AS. Study visits every 4-6 months included CRP levels, demographic and social information. Radiographs of the pelvis and lateral spine were performed every 2 years. We included 354 patients with fused SI joints and disease duration of at least 20 years. We employed classification and regression trees (CART) analysis to examine the subset of patients with fused SI joints but no syndesmophytes. We defined no-syndesmophytes as mSASSS< 2 at all cervical- and lumbar-spine levels, and the presence of syndesmophytes as mSASSS≥ 2. We also conducted logistic regression models.

Results: Of the 354 patients with long standing disease and fused SI joints, 6.5% did not have syndesmophytes. Gender was the strongest factor associated with lack of syndesmophytes on CART analysis. Females accounted for

Table 2. Factors associated with syndesmophytes for patients with disease duration ≥ 20 years and grade IV sacroiliitis based on multivariable logistic regression with first-order interactions (N=354 patients).

Variable	Adj. OR (95% CI)	p-value
Education level (High school or less vs. College or more)	0.33 (0.04, 2.99)	0.325
BMI (Overweight [BMI 25 to 30] vs. Normal [18.5 to <25])	1.00 (0.21, 4.68)	0.999
BMI (Obese [BMI ≥30] vs. Normal [18.5 to <25])	1.79 (0.29, 11.07)	0.532
Gender (Male vs. Female)		
Age of onset <18	1.44 (0.24, 8.68)	0.691
Age of onset ≥18	35.65 (2.81,451.60)	0.006

16% of the subgroup, and of these, 20% did not have syndesmophytes. Males were 84% of the subgroup and 4% did not have syndesmophytes (*Figure 1*). Univariable logistic regression modeling corroborated this finding with OR 5.83 (95% CI 2.43, 14.00), *p*-value was < 0.001 with females more likely to not have syndesmophytes (*Table 1*).

In men, age of onset was the next important predictor. 26% of males had age of symptom onset less than 18 years, and 8.6% of these did not have syndesmophytes (*Figure 1*). Investigating interactions between male gender and age of symptom onset, on multivariable analysis the *p*-value was 0.006 with OR 35.65 (95% CI 2.81, 451.60) (*Table 2*) with men who had age of symptom onset < 18 years being less likely to have syndesmophytes.

All 23 patients who did not have syndesmophytes were HLA-B27 positive.

Conclusion: Of our subgroup, 6.5% of patients lacked syndesmophytes. Gender was the most important variable, with women being more likely to lack syndesmophytes despite having complete SI fusion with long disease duration. Age of symptom onset may also be an important variable in male gender subjects. All of the non-syndesmophyte group were HLA-B27 positive raising the possibility that HLA-B27 positivity may be more associated with sacroiliitis than proliferative spinal bone disease. Our study is distinct in assessing this subpopulation of fused SI joints with long disease duration but no spinal disease. Further studies are needed to elucidate why AS disease behaves differently in this and other subgroups.

Session Type: Poster Session B

Session Time: 8:30AM–10:30AM

Table 1: Sensitivity, specificity, positive predictive value & negative predictive value

Variables	Readers	Sensitivity (%)	Specificity (%)	PPV (%)	NPV (%)
DECT BME compared with MRI	Reader 1	28.9	90.0	78.57	50.0
	Reader 2	35.29	87.50	75.0	56.0
MRI Erosion compared with DECT	Reader 1	85.4	81.5	87.5	78.6
	Reader 2	82.5	80.8	86.8	75

Table 2: Measure of Agreement: Kappa Analysis- inter-rater agreement between reader 1 and reader 2.

Variables	Kappa Value	Standard Error	P value
MRI BME	0.880	0.058	<0.001
DECT BME	0.57	0.12	<0.001
MRI Erosion	0.939	0.042	<0.001
DECT Erosion	0.683	0.092	<0.001

Background/Purpose: Bone marrow edema (BME) and erosions of the sacroiliac (SI) joints are key imaging features in the diagnosis of axial spondyloarthritis (axSpA). MRI with a fluid sensitive sequence is the most common technique for confirming BME but disadvantages include cost and accessibility. Traditional CT is considered superior for detection of erosions but may be limited by radiation exposure. Low dose CT is a technique associated with a similar amount of radiation as conventional radiography and low dose dual energy CT (ldDECT) may be able to detect BME without the need for higher doses of radiation.

We aim to compare the ability of ldDECT and MRI STIR for the detection of BME and erosions of the SI joints in an inception cohort of patients presenting with undiagnosed back pain and psoriasis, iritis, colitis, or positive HLA-B27.

Methods: Consecutive patients ≤ 45 years of age with ≥ 3 months of undiagnosed low back or buttock pain with any one of psoriasis, uveitis, inflammatory bowel disease, or positive HLA-B27 underwent routine clinical evaluation by a rheumatologist for axSpA followed by both MRI and ldDECT of the SI joints done within 3 months of each other.

Two musculoskeletal fellowship trained radiologists were given 17 cases for calibration which were not included in the study. MRI images were scored for presence of BME, presence of large BME lesions, erosions, number of erosions, and radiologist global assessment for presence/absence of sacroiliitis with confidence scale (0-10) blinded to clinical information and ldDECT images. ldDECT images were scored in the same manner and discordant reads were adjudicated by a third radiologist.

Results: 68 patients were recruited with 27 (39.7%) diagnosed with axSpA (mean age 33.2, male 63%, mean symptom duration 8.7 years, HLA-B27 positive 85%). Uveritis, psoriasis, and IBD were present in 20, 23, and 6% of patients respectively.

ldDECT had a sensitivity of 28.9 and 35.3% and a specificity of 90 and 87.5% between two readers for detection of BME compared with MRI (Table 1).

MRI had a sensitivity of 85 and 82.5% and a specificity of 81.5 and 80.8% between two readers for detection of erosions compared with ldDECT.

Inter-reader reliability was higher for MRI detected BME and erosions compared with DECT (Table 2).

Amongst patients who were diagnosed by a rheumatologist as having axSpA (n=27), 21 had sacroiliitis seen on both CT and MRI, 2 only on CT, 1 only on MRI, and 3 on neither.

Conclusion: ldDECT displayed a reduced sensitivity but was highly specific for BME compared to MRI STIR sequence as a reference standard. MRI revealed reasonable sensitivity and specificity for erosions compared to ldDECT as a reference standard. ldDECT has good reproducibility for the interpretation of erosions but has moderate inter-reader reliability for BME.

Amongst patients where BME was detected, 86% had evidence of erosive changes suggesting a marginal benefit with addition of dual energy scanning. Only 1 patient eventually diagnosed with axSpA had sacroiliitis on MRI not seen on ldDECT. Given the potential lower cost and accessibility of ldDECT, further studies may reveal whether utilizing ldDECT as the initial imaging modality would reduce the need for an MRI and thus increase accessibility and reduce costs.

Session Title: Spondyloarthritis Including PsA – Diagnosis, Manifestations, & Outcomes Poster II: Imaging in Spondyloarthritis (0897–0907)

Session Type: Poster Session B

Session Time: 8:30AM–10:30AM

Background/Purpose: Diagnosis and classification of axial spondyloarthritis (axSpA) relies considerably on imaging evidence of sacroiliitis which has led to the development of classification criteria which also rely on imaging. However, it has been suggested that such criteria may not be appropriate for axSpA patients presenting with other forms of

Imaging Feature	Colitis (n=30)	Psoriasis (n=19)	Iritis (n=52)	P value
Unilateral sacroiliitis (grade ≥2), N(%)	1 (3.3%)	0 (0%)	2 (3.8%)	0.69

SpA, especially psoriatic, because imaging features may vary in frequency and/or may be atypical. This hypothesis has never been tested in a prospective inception cohort of patients presenting with undiagnosed back pain. We aimed to compare the spectrum of radiographic and MRI abnormalities in the sacroiliac joint (SIJ) and spine of an inception cohort of patients presenting with undiagnosed back pain and psoriasis, iritis, and colitis.

Methods: We used data from the prospective multicenter Screening for Axial Spondyloarthritis in Psoriasis, Iritis, and Colitis (SASPIC) Study, which is aimed at early detection of axial SpA in patients referred by the respective specialist after first presenting with these disorders. Consecutive patients ≤45 years of age with ≥3 months undiagnosed back pain with any one of psoriasis, AAU, or colitis undergo routine clinical evaluation by a rheumatologist for axial SpA followed by imaging. In SASPIC I, MRI evaluation of the SIJ and whole spine was ordered per rheumatologist decision. In SASPIC II, MRI evaluation of the SIJ was ordered for all patients. Radiographs and MRI scans were assessed by two central readers and comparisons of the three groups were based on concordant assessments of imaging features. Evaluation of MRI scans included both global assessment for presence/absence of axSpA with confidence scale (-10 to +10), active and structural lesions typical of axSpA per recent ASAS definitions, and granular assessment of individual lesions according to SIJ quadrants and halves in consecutive semicoronal slices through the SIJ as well as detailed evaluation of active and structural lesions in individual discovertebral units of the spine on consecutive sagittal slices. Groups were compared by ANOVA and the chi-square test.

Results: A total of 240 patients were recruited, 143 from SASPIC I and 97 from SASPIC II, 101 (42.1%) being diagnosed with axSpA (65.3% male, mean age 34.4 years, mean symptom duration 8.7 years, B27 positive 55.4%). Mean age of colitis (N=101), psoriasis (N=61), iritis (N=78) patients were 33.4, 36.6, 34.3 years, respectively, mean symptom duration was 6.8, 7.2, 9.4 years, respectively, and % males were 45.5%, 52.5%, 51.3%, respectively. MRI scans of the SIJ were available in 101 patients and of these 41 also had MRI of the spine. There were no significant group differences for unilateral versus bilateral radiographic sacroiliitis and no significant differences in the frequencies, type,

or distribution of MRI lesions in the SIJ and spine(Table). In particular, there was not a single case where there was an MRI indicative of axSpA in the spine that was not also evident in the SIJ.

Conclusion: Data from the SASPIC prospective inception cohort does not support the view that imaging of the SIJ and spine differs in psoriatic axSpA, which appears similar to axSpA associated with iritis or colitis. These data support the umbrella concept of axSpA.

SESSION INFORMATION

Session Date: Sunday, November 7, 2021

Session Title: Spondyloarthritis Including PsA – Diagnosis, Manifestations, & Outcomes Poster II: Imaging in Spondyloarthritis (0897–0907)

Session Type: Poster Session B

Session Time: 8:30AM–10:30AM

Background/Purpose: There is no international consensus on the optimal number of slices for evaluation of MRI structural lesions in the SIJ. An "all slice" method evaluates lesions from the most anterior slice, defined as the first slice with vertical height of ≥1cm of the SIJ joint cavity, up to the most posterior slice, defined as the most posterior slice where ≥1cm vertical height of the cartilaginous portion is still visible. The SPARCC method scores the transitional slice between cartilaginous and ligamentous compartments as the first slice and then an additional 4 slices anterior to the transitional slice. We aimed to investigate inter-reader reliability, the extent of detection of lesions, and frequency of cases with a positive MRI for structural lesions when using an "all slice" approach versus the SPARCC scoring of 5 central slices.

Table 1.

MRI Lesion	"All slice"	Central 5 slices	Peripheral slices	P value central vs peripheral slices	P value "all slice" vs central slices
Mean (SD) Lesion Score Per Case

Erosion	0.54 (0.15) (0.28-0.84)	0.58 (0.13) (0.34-0.85)	0.40 (0.17) (0.10-0.66)
Fat lesion	0.61 (0.18) (0.30-0.89)	0.63 (0.16) (0.35-0.88)	0.52 (0.20) (0.19-0.82)
Sclerosis	0.73 (0.18) (0.36-0.94)	0.73 (0.16) (0.36-0.91)	0.67 (0.19) (0.27-0.94)
Backfill	0.37 (0.21) (0.10-0.85)	0.39 (0.19) (0.14-0.83)	0.18 (0.23) (0.0-0.80)
Ankylosis	0.97 (0.02) (0.91-0.99)	0.99 (0.01) (0.97-1.0)	0.85 (0.10) (0.62-0.98)

Methods: MRI T1W images with DICOM series were available from 148 cases who had MRI performed in the ASAS-Classification Cohort. Seven central readers recorded MRI lesions in an eCRF that recorded global assessments of presence/absence of changes suggestive of axSpA and structural lesions typical of axSpA. Structural lesions per the ASAS definitions were also recorded in consecutive semicoronal slices using the "all slice" approach, but also recording the transitional slice, according to their presence/absence in SIJ quadrants (erosion, fat lesion, sclerosis) or halves (backfill, ankylosis). Structural lesion frequencies were assessed descriptively according to majority agreement (≥4/7) of central readers and also any 2 central readers. Reliability for detection of MRI lesions was compared between central and local readers using the ICC.

Results: The mean (SD) (range) number of anterior and posterior slices peripheral to the 5 central slices was 1.0 (1.0) (0-4) and 2.2 (1.8) (0-6) per case, respectively. There were 2 cases (1.4%) where ≥2 readers scored structural lesions in peripheral slices but not in the 5 central slices. The mean percentage of the total structural lesion score that was captured by the 5 central slices was >75% for all types of lesions except ankylosis (59%) (Table 1). Inter-reader reliability was greater for all lesions when assessing the 5 central slices and especially for erosion and backfill (Table 2).

Conclusion: The major component of structural lesion data is captured by assessment of 5 slices, which includes the transitional slice and the subsequent 4 anterior slices. Moreover, reliability for detection of structural lesions is substantially worse in peripheral slices.

Session Title: Spondyloarthritis Including PsA – Diagnosis, Manifestations, & Outcomes Poster II: Imaging in Spondyloarthritis (0897–0907)

Session Type: Poster Session B

Session Time: 8:30AM–10:30AM

Background/Purpose: The ASAS definition of a positive MRI for inflammation in the spine (ASAS-MRI+) is intended for classification of patients as having axSpA but is often misused for diagnostic purposes. This is problematic because bone marrow edema (BME) in the spine may occur in 20-40% of both healthy individuals as well as those with mechanical back disorders. The ASAS MRI group has generated updated consensus lesion definitions that describe each of the MRI lesions in the spine. These definitions have been validated by 8 readers from the ASAS-MRI group on MRI spine images from the ASAS Classification Cohort. We aimed to identify quantitative cut-offs based on numbers of vertebral corners that define a positive MRI for axSpA, there being two gold standards: A. majority central reader decision as to the presence of spine MRI findings consistent with axSpA B. rheumatologist expert opinion diagnosis of axSpA

Methods: Eight ASAS-MRI readers recorded MRI lesions in the spine of 62 cases recruited to the ASAS classification cohort according to recently updated ASAS definitions in an eCRF that comprises global assessment (are the findings on this MRI scan consistent with axSpA? (yes/no)), and detailed scoring of lesions for all sites in the spine, including vertebral bodies, lateral and posterior elements. We calculated sensitivity and specificity for numbers of vertebral corners with BME (VC-BME) where a majority of readers (≥5/8) agreed as to the presence of MRI findings consistent with axSpA. We selected optimal cut-offs with ≥95% specificity. These cut-offs were analyzed for their predictive utility for rheumatologist diagnosis of axSpA by calculating positive and negative predictive values (PPV, NPV) and selecting those cut-offs with PPV of ≥95%. Both specificity of ≥95% for MRI consistent with axSpA as well

Table 1. Majority readers agree MRI findings consistent with axSpA are present is the gold-standard external reference

MRI cut-offs	Sensitivity (95%CI)	Specificity (95%CI)
BME in ≥1 vertebral corner	87.5(47.3 - 99.7)	83.3 (70.7 - 92.1)
BME in ≥2 vertebral corners	87.5 (47.3 - 99.7)	87.0 (75.1 - 94.6)
BME in ≥ 3 vertebral corners	87.5 (47.3 - 99.7)	94.4 (84.6 - 98.8)
BME in ≥4 vertebral corners	**75.0 (34.9 - 96.8)**	**98.2 (90.1 - 100.0)**
BME in ≥5 vertebral corners	62.5 (24.5 - 91.5)	98.2 (90.1 - 100.0)
Cases with ≥1 additional non-corner site inflammatory lesion		
BME in ≥1 vertebral corner	37.5 (8.5 - 75.5)	94.4 (84.6 - 98.8)
BME in ≥2 vertebral corners	37.5 (8.5 - 75.5)	94.4 (84.6 - 98.8)
BME in ≥3 vertebral corners	**37.5 (8.5 - 75.5)**	**98.2 (90.1-100.0)**
BME in ≥4 vertebral corners	37.5 (8.5 - 75.5)	100.0 (93.4-100.0)
BME in ≥5 vertebral corners	37.5 (8.5 - 75.5)	100.0 (93.4-100.0)
Cases with ≥2 vertebral corner fat lesions		
BME in ≥1 vertebral corner	**62.5 (24.5 - 91.5)**	**100.0 (93.4-100.0)**
BME in ≥2 vertebral corners	62.5 (24.5 - 91.5)	100.0 (93.4-100.0)
BME in ≥ 3 vertebral corners	50.0 (15.7 - 84.3)	100.0 (93.4-100.0)
BME in ≥4 vertebral corners	50.0 (15.7 - 84.3)	100.0 (93.4-100.0)
BME in ≥5 vertebral corners	37.5 (8.5 - 75.5)	100.0 (93.4 -100.0)

Table 2. Predictive values of cut-offs for number of vertebral corners with BME according to the diagnostic ascertainment of the rheumatologist

MRI cut-offs	Sensitivity (95%CI)	Specificity (95%CI)	PPV	NPV
MRI findings consistent with axSpA ≥any 2 readers	52.5 (36.1 - 68.5)	94.7 (74.0 - 99.9)	95.5 (75.3 - 99.3)	48.6 (40.2 - 57.2)
MRI findings consistent with axSpA ≥majority read	20.0 (9.1 - 35.6)	100.0 (82.4 - 100.0)	100.0	37.3 (33.7 - 40.9)
BME in ≥ 4 vertebral corners	**17.5 (7.3 - 32.8**	**100.0 (82.4 - 100.0)**	**100.0**	**36.5 (33.3 - 39.9)**
Cases with ≥1 additional inflammatory lesion				
BME in ≥ 3 vertebral corners	**10.00 (2.8 - 23.7)**	**100.00 (82.4 - 100.0)**	**100.0**	**34.5 (32.2 - 36.9)**
Cases with ≥2 vertebral corner fat lesions				
BME in ≥1 vertebral corner	**12.50 (4.2 - 26.8)**	**100.00 (82.4 - 100.0)**	**100.0**	**35.2 (32.6 - 37.9)**

as a PPV of ≥95% for rheumatologist diagnosis were considered requirements for preliminary designation of MRI cut-offs defining a positive spine MRI consistent with axSpA.

Results: MRI findings consistent with axSpA were observed in the spine by majority read in 8 (20%) of 40 cases diagnosed with axSpA, and 0 (0%) of 19 cases without axSpA. Cut-offs achieving specificity of ≥95% for MRI findings consistent with axSpA were 4 VC-BME (sensitivity 75%) for all cases, 3 VC-BME (sensitivity 37.5%) for cases with ≥1 additional location with inflammation, 1 VC-BME (sensitivity 62.5%) in cases with ≥2 vertebral corner fat lesions (Table 1). All of the above cut-offs also had very high positive predictive values (≥95%) for diagnosis of axSpA in cases diagnosed by the rheumatologist (Table 2).

Conclusion: A cut-off of BME in ≥4 vertebral corners, or ≥3 corners in the setting of additional inflammatory lesions at other locations or corner fat, are primary candidates for defining a positive MRI of the spine consistent with axSpA. The PPV performance of these MRI cut-offs for rheumatologist diagnosis of axSpA apply to typical patients referred to a rheumatologist with a high index of suspicion of axSpA and may not be appropriate in other populations.

SESSION INFORMATION

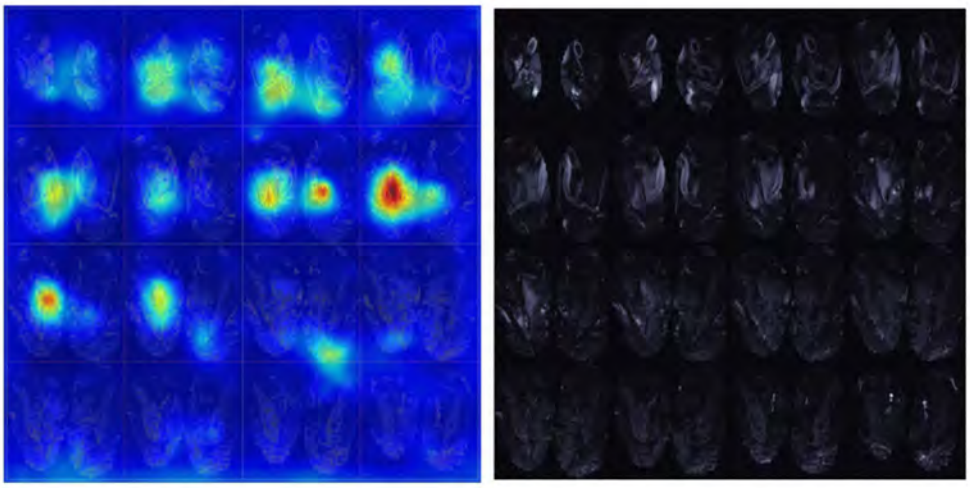
Session Date: Sunday, November 7, 2021

Session Title: Spondyloarthritis Including PsA – Diagnosis, Manifestations, & Outcomes Poster II: Imaging in Spondyloarthritis (0897–0907)

Session Type: Poster Session B

Session Time: 8:30AM–10:30AM

Figure 1. Inference of the convolutional neural network on a pre-processed 2D grid of an MRI of sacroiliac joints from the validation dataset.



This exemplary gradient-weighted class activation map (left panel) shows that the CNN correctly focusses on the periarticular bone marrow edema that is evident on a preprocessed 2D grid image of an exemplary STIR sequence (right panel).

Background/Purpose: Active inflammatory changes in sacroiliac joints (SIJ) compatible with axial spondyloarthritis - axSpA (first of all, subchondral bone marrow edema – BME / osteitis) as detected by magnetic resonance imaging (MRI) play a pivotal role in diagnostic and classification approaches. Artificial intelligence/machine learning methods such as a trained artificial convolutional network (CNN) offer a potential for the development of assistant tools to be used by radiologists and rheumatologists in clinical practice.

The present study is aimed to evaluate the possibility of detection of active inflammatory changes compatible with axSpA on MRI of SIJ.

Methods: A total of 6 trained and calibrated readers evaluated MRIs of SIJ (STIR, semicoronal views) of 476 patients with and without axSpA from 4 cohorts (GESPIC-AS, GESPIC-Crohn, GESPIC-Uveitis, and OptiRef). Readers indicated the presence or absence of active inflammatory changes compatible with axSpA and specified the type of changes. Active inflammatory changes were considered present if at least 4 out of 6 readers deemed them positive. Images with an undetermined classification were adjudicated in a consensus reading session. These results were used for the training and validation of the CNN. First, we used an object detection approach to train a 3D CNN to detect the SIJ on all available MRIs to generate dilated masks of the SIJs to focus subsequent model training to the SIJs and periarticular areas. Secondly, we used a classification task to train a 2D CNN (ResNet34) to predict the presence of active inflammatory changes compatible with SpA on these grid MRI images. MRIs from the ASAS classification Cohort annotated by 7 readers (Maksymowych WP, at al. Ann Rheum Dis 2020;79:935-942) formed the holdout dataset that was used to test for CNN generalizability.

Results: A total of 403 STIR-MRIs were included in the training, 73 in the validation sets and 122 in the holdout set. The trained classification CNN achieved an accuracy of 91.8%, a sensitivity of 88.9% and a specificity of 93.5% in detecting active inflammatory changes in SIJ compatible with axSpA in the validation set (n=73). The accuracy of MRI classification in the independent holdout set (ASAS) was 81.5% with a sensitivity of 67% and a specificity of 84.5%. Figure 1 shows an exemplary class activation map of the CNN.

Conclusion: Our study shows the principal possibility of detecting active inflammatory changes compatible with axSpA on MRI of SIJs. Detection of structural changes and overall contextual interpretation of the findings are warranted for the subsequent development steps.

Acknowledgment. The project was supported by a research grant from ASAS. We want to thank colleagues who performed annotation of the images from the ASAS classification cohort: Xenofon Baraliakos, Robert Lambert, Pedro Machado, Walter Maksymowych, Mikkel Ostergaard, Suzanne Juhl Pedersen, and Ulrich Weber.

Measurement of Vertebral Hounsfield Units in Low Dose Computed Tomography – a Reliable Methodology for Assessing Bone Mineral Density at the Vertebral Level in Patients with Radiographic Axial Spondyloarthritis

Mary Lucy Marques[1], Nuno Pereira da Silva[2], Désirée van der Heijde[3], Floris van Gaalen[1] and Sofia Ramiro[1], [1]Leiden University Medical Center, Leiden, Netherlands, [2]Radiology Department, Centro Hospitalar e Universitário de Coimbra, Coimbra, Portugal, [3]Department of Rheumatology, Leiden University Medical Center, Meerssen, Netherlands

SESSION INFORMATION

Session Date: Sunday, November 7, 2021

Session Title: Spondyloarthritis Including PsA – Diagnosis, Manifestations, & Outcomes Poster II: Imaging in Spondyloarthritis (0897–0907)

Session Type: Poster Session B

Session Time: 8:30AM–10:30AM

Background/Purpose: Bone loss paradoxically coexists with bone formation in radiographic axial spondyloarthritis (r-axSpA). Assessing bone mineral density (BMD) in r-axSpA poses challenges, namely because of possible overestimation due to ectopic bone formation. The measurement of Computed Tomography (CT) Hounsfield Units (HU) at the individual vertebral level has been shown to correlate with BMD as measured by Dual-energy X-ray absorptiometry in trauma patients.[1] However, its value in r-axSpA has never been studied. Whole spine low dose CT (ldCT) has been suggested as the ideal method to assess both bone formation and bone loss in r-axSpA. By using ldCT scans, we aimed to cross-sectionally describe HU measurements and their inter-reader reliability at the vertebral level from C3 to L5 in patients with r-axSpA.

Methods: We used ldCT scans of r-axSpA patients included in the Sensitive Imaging in Ankylosing Spondylitis (SIAS) study, a multicenter (Leiden, the Netherlands and Herne, Germany) 2-year prospective cohort. A standardized protocol was applied in both centers and automatic exposure control calibration in ldCT imaging acquisition was used. For the present study, baseline ldCT scans were independently assessed by two trained readers. The HU measurement was performed as described in *Figure 1* – using OsiriX software (v6.5.1). Inter-reader reliability was assessed using intraclass correlation coefficients (ICC) absolute agreement, applying two-way mixed effect models. Agreement was assessed using the smallest detectable difference (SDD = 1.96 x $SD_{difference}$ /(√k), in which $SD_{difference}$ is the standard deviation of the differences in status scores between two readers, and k=2 (number of readers) and Bland-Altman plots.

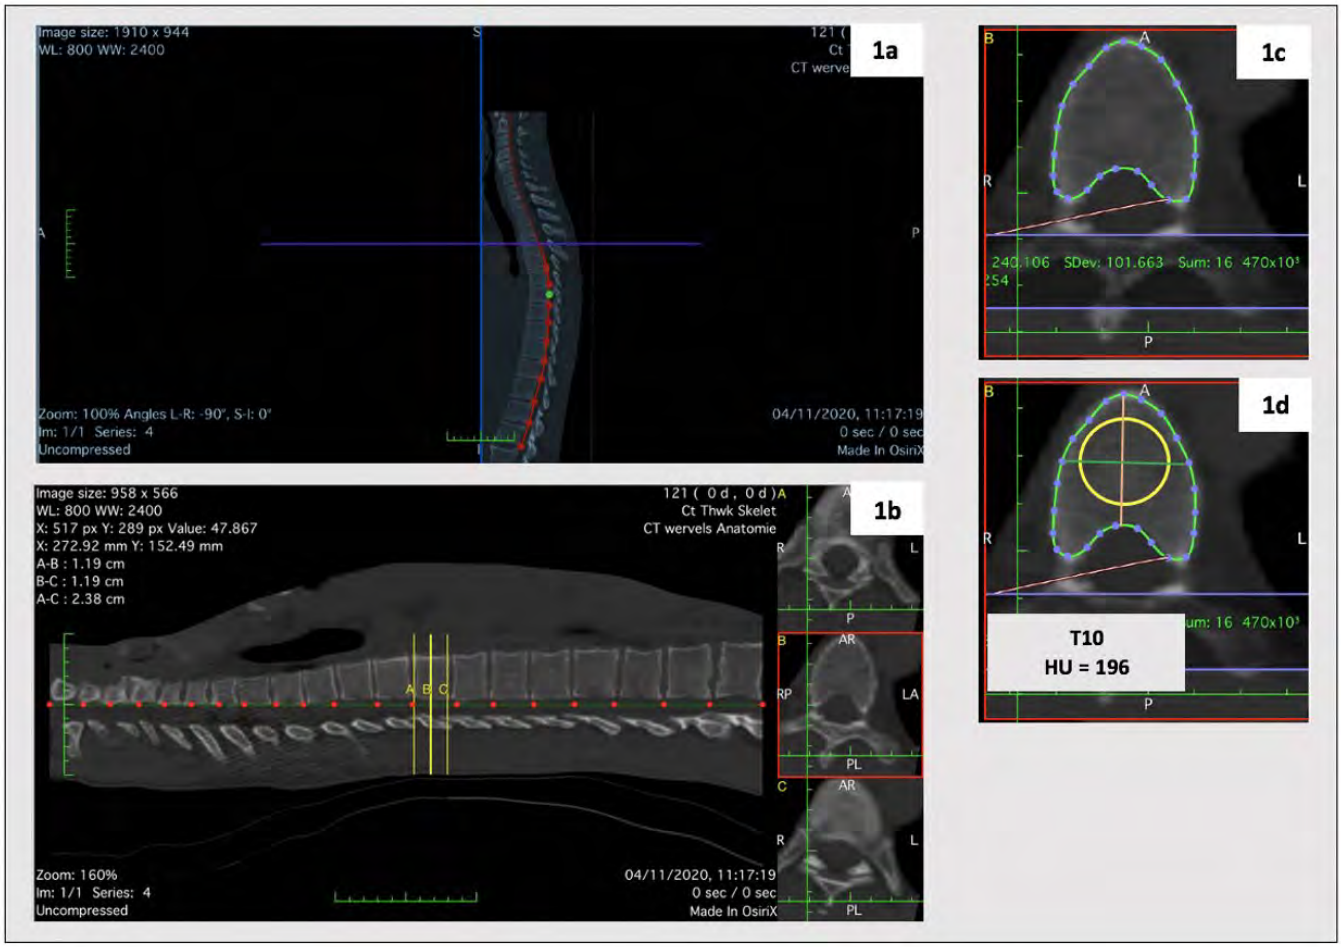

Figure 1. Methodology of Hounsfield Units (HU) measurement. Using a three-dimensional curved-multiplanar reconstruction (3D Curved-MPR) we identify the curve of the spine from the spinal canal (1a). On the obtained sagittal image, the individual vertebral levels are identified. At each vertebral level, two lines of reference are positioned at the superior (yellow line A) and inferior (yellow line C) limits of the vertebra. Equidistant to A and C, the yellow line B will be positioned at the center of the vertebral body (1b). Vertebral HU measurements are taken from a reconstructed cross-sectional slice positioned at the center of the vertebra as defined by the selection process described above (1c). A circular sample region of this slice is used, centered at the body origin and having a diameter equal to 75% of the average of distances posteroinferior-to-anteroinferior, and posterosuperior-to-anterosuperior. The density of the vertebra is calculated as the average image intensity within the sample region, reported in HU (1d).

Results: Whole spine ldCT scans from 50 r-axSpA patients (mean (SD) age of 49 (10) years; 43 (86%) male and 42 (84%) HLA-B27 positive) were included. In total, 220 cervical, 588 thoracic and 245 lumbar vertebrae were assessed by both readers. The HU values decreased from the cervical to the lumbar spine – *Table 1*. For both readers, the highest mean (SD) value for HU was obtained at C3 (354 (106) and 355(108), for reader 1 and 2 respectively), and the lowest at L3 (153 (65) and 150 (65), for reader 1 and 2 respectively). Inter-reader reliability was shown to be excellent (cervical spine ICC: 0.90 to 1.00; thoracic spine ICC: 0.97 to 1.00; lumbar spine ICC: 0.89 to 0.91). SDD varied from 4 to 8. A small degree of systematic error was observed between the two readers, i.e., for the majority of vertebrae, reader 1 scored somewhat higher than reader 2 (mean difference of scores ranging from -0.6 HU to 2.9 HU). Bland-Altman plots show homoscedasticity throughout the whole spine. Representative examples from vertebrae of each segment of the spine are presented in *Figure 2*.

Conclusion: Low dose CT measurement of HU is a reliable method to assess BMD at each vertebra from C3 to L5. This methodology can aid the future study of bone loss in r-axSpA, a disease affecting the whole spine. Further validation and longitudinal assessment of reliability are warranted in future studies.

Table 1. Descriptive statistics of Hounsfield Units (HU) per vertebral level, according to reader 1 and 2 measurements

Vertebra§	Mean (SD) HU Reader 1	Range HU Reader 1	Mean (SD) HU Reader 2	Range HU Reader 2
C3	354 (106)	162 to 643	355 (108)	158 to 647
C4	350 (113)	119 to 661	350 (113)	122 to 668
C5	333 (109)	83 to 601	333 (109)	88 to 605
C6	290 (88)	82 to 481	289 (88)	83 to 479

Radiographic Sacroiliitis Progression up to Six Years of Follow-Up in Patients with Non-Radiographic Axial Apondyloarthritis

Stan Kieskamp[1], Rick Wilbrink[2], Freke Wink[3], Reinhard Bos[4], Hendrika Bootsma[1], Suzanne Arends[1] and Anneke Spoorenberg[1], [1]University Medical Center Groningen, Groningen, Netherlands, [2]University of Groningen, Leeuwarden, Netherlands, [3]Medical Center Leeuwarden, Leeuwarden, Netherlands, [4]Department of Rheumatology, Medical Centre Leeuwarden, Leeuwarden, Netherlands

SESSION INFORMATION

Session Date: Sunday, November 7, 2021

Session Title: Spondyloarthritis Including PsA – Diagnosis, Manifestations, & Outcomes Poster II: Imaging in Spondyloarthritis (0897–0907)

Session Type: Poster Session B

Session Time: 8:30AM–10:30AM

Background/Purpose: In two years, approximately 10% of patients with non-radiographic axial spondyloarthritis (nr-axSpA) progresses to ankylosing spondylitis (AS). There are no data available of more long-term follow-up. The objective of this study was to assess the rate of progression of nr-axSpA to AS in patients with up to six years of follow-up.

Methods: Patients enrolled in the ongoing Groningen Leeuwarden Axial Spondyloarthritis (GLAS) cohort, classified as nr-axSpA at baseline with a baseline pelvic radiograph and at least one two-year follow-up radiograph, were selected for our analyses. These baseline, two-, four- and six-year radiographs were randomized with radiographs of AS patients in a three-to-one ratio and scored with known time sequence according to the modified New York (mNY) criteria by two trained readers (SK and RW). In case of discrepancy in classification, the score of a third independent reader (AS) was used. Progression to AS was defined as progression in mNY sacroiliitis score to ≥2 bilaterally or ≥3 unilaterally.

Table 1. Patients classified with nr-axSpA progressing to AS according to mNY-criteria for radiographic sacroiliitis, evaluated with two-year intervals.

Population	Size	nr-axSpA	AS	Follow-up data not yet available
Baseline	79	79	N/A	N/A
+2 years	79	71	8	N/A
+4 years	48	44	4	23
+6 years	24	21	3	20

Results: 79 patients were clinically classified as nr-axSpA at baseline confirmed by radiographic score. At baseline, mean age was 39 ± 10 years, 48% was male, median symptom duration was 6 (IQR 3-17) years, mean ASDAS was 2.8 ± 1.1, and 71% was HLA-B27+. After two, four and six years, 8/79 (10.1%), 4/48 (8.3%) and 3/24 (12.5%) nr-axSpA patients progressed to AS. In total, 23 and 20 patients did not yet reach follow at four and six years, respectively (Table 1).

Conclusion: In our observational cohort of patients with axial spondyloarthritis with up to six years of follow-up, every two years approximately 10% of patients progressed from nr-axSpA to AS. The next step will be to evaluate associations with patient and disease characteristics.

Evaluation of the Nonsteroidal Anti-Inflammatory Drug-Sparing Effect of Secukinumab in Patients with Ankylosing Spondylitis: Multicenter, Randomised, Double-blind, Phase IV Study

Uta Kiltz[1], Xenofon Baraliakos[1], Jan Brandt-Jrgens[2], Ulf Wagner[3], Sebastian Lieb[4], Christian Sieder[5], Christian Mann[5] and Jürgen Braun[1], [1]Rheumazentrum Ruhrgebiet Herne, Ruhr-Universität Bochum, Herne, Germany, [2]Rheumatologische Schwerpunktpraxis, Berlin, Germany, [3]Universitätsklinikum Leipzig, Leipzig, Germany, [4]Novartis Pharma GmbH, Immunology, Hepatology and Dermatology, Nürnberg, Germany, [5]Novartis Pharma GmbH, Nürnberg, Germany

SESSION INFORMATION
Session Date: Sunday, November 7, 2021
Session Title: Spondyloarthritis Including PsA – Treatment Poster I: Axial Spondyloarthritis (0908–0939)
Session Type: Poster Session B
Session Time: 8:30AM–10:30AM

Background/Purpose: Nonsteroidal anti-inflammatory drugs (NSAIDs) are used to treat inflammatory back pain in patients (pts) with ankylosing spondylitis (AS). However, an increased risk of side effects associated with NSAIDs and their dosage has been reported[1]. Therefore, lower doses and a dose reduction is desirable. The objective of this study is to evaluate the short-term NSAID sparing effect of secukinumab (SEC) in AS pts with NSAID intake.

Methods: In a prospective controlled trial, 211 adult pts with active AS Bath Ankylosing Spondylitis Disease Activity Index (BASDAI ≥4) and an inadequate response (IR) to at least 2 NSAIDs at the highest recommended/tolerated dose and pts with an IR, or those who were naïve/intolerant to a maximum of 2 tumor necrosis factor inhibitors (TNFi) were enrolled. NSAID intake was evaluated using the Assessment in Ankylosing Spondylitis (ASAS)-NSAID score. To be eligible, pts had to take at least 50% of the highest recommended/tolerated NSAID dose regularly. Pts were randomised (1:1:1) to receive SEC 150 mg s.c. from Week (Wk) 0 (group [gp] 1), Wk 4 (gp 2) and Wk 16 (gp 3). All groups received SEC 150 mg from Wk 16. NSAID tapering was allowed in all groups from Wk 4 onwards. The primary endpoint (PE) was an ASAS20 response of pooled gp 1 and gp 2 *vs*. gp 3 at Wk 12.

Results: There were 71 pts in gp 1, 70 in gp 2 and 70 in gp 3. Baseline (BL) characteristics were comparable across groups; mean age (SD) was 45.2 (12.3) years (yrs), time since diagnosis was 7.4 (9.8) yrs, 57.8% male, 79.0% human

AS, ankylosing spondylitis; ASAS, Assessment of SpondyloArthritis International Society; ASDAS, AS Disease Activity score; BASDAI, Bath AS Disease Activity Index; BL, baseline; CRP, C-reactive protein; IR, inadequate responder; NSAID, non-steroidal anti-inflammatory drug; N, total number of subjects in each treatment group; PBO, placebo; PR, partial remission; pts, patients; SD, standard deviation; SEC, secukinumab; TNFi, tumor necrosis factor inhibitor; Wk, week.

†p<0.001; §p<0.01 and ‡p<0.05 *vs*. gp 3; ‡‡p<0.05 *vs*. gp 2

*p-values are from a logistic regression model with treatment, TNFi status (IR / naive) and CRP status (>/ ≤ central lab ULN) as factors. Missing values were imputed as non-response.

+p-values are from MMRM with treatment, TNFi status (IR / naive), CRP status (>/ ≤ central lab ULN) and visit as factors, BL value as continuous covariate. Missing values were imputed as non-response.

Observed data (pts) for gp 1, 2, 3, respectively:

**67, 66, 62

***67, 66, 63

++67, 67, 65

‡20, 19, 20

‡‡51, 51, 50

leukocyte antigen (HLA)-B27 positive 48.6% pts had an elevated C-reactive protein (CRP) 40.8% were current/ever smoker and 72.0% were TNFi-naïve. The ASAS-NSAID (SD) scores at BL were: gp 1 *vs*. gp 2 *vs*. gp 3: 82.9 (37.7) *vs*. 79.9 (45.3) *vs*.82.3 (39.1). BASDAI and Ankylosing Spondylitis Disease Activity Score (ASDAS)-CRP scores were similar between groups: 6.0 (1.4) *vs*. 6.2 (1.5) *vs*. 6.2 (1.3), and 3.4 (0.7) *vs*. 3.3 (0.8) *vs*. 3.4 (0.7), respectively. The ASAS20 response at Wk 12 of pooled gp 1 and 2 *vs*. gp 3 was 51.1% *vs*. 44.3% but the PE was not met (p=0.35). A higher proportion of pts in gp 1 and 2 achieved ASAS40 and BASDAI50 and other secondary outcomes at Wk 16 (**Table**). More pts in gp 1 and 2 reduced their NSAID intake from BL through Wk 16 *vs*. gp 3 **(Table and Figure)**.

Conclusion: In this population of pts with AS, SEC provided clinical improvements in conventional clinical outcomes and a short-term NSAID sparing effect.

SESSION INFORMATION

Session Date: Sunday, November 7, 2021

Session Title: Spondyloarthritis Including PsA – Treatment Poster I: Axial Spondyloarthritis (0908–0939)

Session Type: Poster Session B

Session Time: 8:30AM–10:30AM

Background/Purpose: Current studies suggest that the phenotype of spondyloarthritis differs between genders and that this may influence the subsequent diagnostic approach and therapeutic decisions[1]. The German non-interventional study AQUILA provides real-world data on the influence of gender on therapeutic effectiveness and retention rate under treatment with secukinumab, a fully human monoclonal antibody that selectively inhibits interleukin-17A.

The aim of this interim analysis is to describe selected baseline (BL) demographics, to evaluate secukinumab treatment outcomes on disease activity, depressive mood and retention rate depending on the gender of PsA patients.

Methods: AQUILA is an ongoing, multi-center, non-interventional study including more than 3000 patients with active AS or psoriatic arthritis. Patients were observed from BL up to week (w) 52 according to clinical routine. Real-world data was assessed prospectively and analyzed as observed. Validated questionnaires were used to collect data on disease activity (Bath Ankylosing Spondylitis Disease Activity Index, BASDAI), global functioning and health (Assessment of SpondyloArthritis-Health Index, ASAS-HI) and severity of depressive mood (Beck´s Depression Inventory version II, BDI-II). Patient reported outcomes were reported using patient´s global assessment (PGA). In addition, retention rates (time from study inclusion until premature secukinumab treatment discontinuation) were assessed through Kaplan-Meier plots. This interim analysis focuses on the subgroups of male and female AS patients.

Results: At BL, 683 AS patients were included: 59.7% (n=408) male and 40.3% (n=275) female. Demographic data (Table 1) of male and female AS patients differed numerically in the following parameters: proportion of obese patients, smokers, pretreatment with disease-modifying antirheumatic drugs (csDMARDs), and biologicals/biosimilars (b-bsDMARDs).Mean BASDAI and PGA were comparable between male and female AS patients over time (♂: 5.2 at BL to 3.8 at w52, ♀: 5.3 at BL to 4.1 at w52 and ♂: 5.9 at BL to 4.1 at w52, ♀: 5.6 at BL to 4.3 at w52, respectively). Mean ASAS-HI over time was higher in women; nevertheless, improvements in global functioning were comparable for both genders from BL to week 52 (Fig. 1A). Severity of depressive mood was numerically lower in male patients; nevertheless, BDI-II reductions were comparable across the genders (♂: 11.2 at BL to 10.0 at w52, ♀: 13.1 at BL to 11.0 at w52). Secukinumab treatment retention rate for men was (not significantly) higher than for women (Fig. 1B).

Conclusion: In a real-world setting, secukinumab improved disease activity, global functioning and severity of depressive mood in AS patients in both men and women. Women showed overall higher disease burden. Altogether, real-world data of this interim analysis are in line with those of Phase 3 studies and show that secukinumab is an effective treatment up to 52 weeks with high treatment retention rates, irrespective of gender.

Table 1. Overview of baseline characteristics in AS patients depending on gender

Demographics*	Male (N=408)	Female (N=275)
Age, years	45.6 (12.1)	47.8 (12.2)

SESSION INFORMATION
Session Date: Sunday, November 7, 2021
Session Title: Spondyloarthritis Including PsA – Treatment Poster I: Axial Spondyloarthritis (0908–0939)
Session Type: Poster Session B
Session Time: 8:30AM–10:30AM

Background/Purpose: Ankylosing spondylitis (AS) is associated with greater cardiovascular (CV) risk than in the general population. The impact of tumor necrosis factor inhibitors (TNFi) on CV risk in AS, including on the development of hypertension, an important CV risk factor, remains unclear. We aimed to determine the association of TNFi use with incident hypertension in a longitudinal AS cohort.

Table 1. Baseline demographic and clinical characteristics of subjects without hypertension at baseline, stratified by baseline TNFi use

Variables	Whole cohort (n=630)	TNFi users (n=269)	TNFi non-users (n=361)
Age, years	39.4 ± 12.9	39.1 ± 12.2	39.6 ± 13.3
Male	72%	74%	70%
White	80%	80%	80%
Age at symptom onset, years	23.8 ± 9.2	23.8 ± 9.3	23.9 ± 9.2
BASDAI (0-10)	3.7 ± 2.4	3.3 ± 2.4	3.9 ± 2.4
Elevated CRP	37%	26%	46%
Continuous NSAID use	32%	25%	37%
Obese BMI	22%	25%	19%
Cardiovascular disease	2%	2%	3%
Diabetes	1%	2%	1%
Current smoking	10%	10%	10%

Methods: Adults with AS were enrolled in a prospective cohort during 2002-2018 and examined every 4-6 months. TNFi use during the preceding six months was ascertained at each study visit. We defined hypertension by patient-reported hypertension, anti-hypertensive medication use, or, on two consecutive visits, systolic blood pressure ≥140 mm Hg or diastolic ≥90 mm Hg. We evaluated the association between TNFi use and the development of hypertension with marginal structural models, estimated by inverse probability weighting, to account for time-dependent confounders (nonsteroidal anti-inflammatory drug use and disease activity) and informative censoring.

Results: We included 630 participants without baseline hypertension, and at least one year of follow-up. Of these, 72% were male, with a mean age at baseline of 39±13 years, and 43% used TNFi at baseline. On follow-up (median 5 years), 129 developed incident hypertension. TNFi use was not associated with incident hypertension (adjusted hazard ratio 1.11, 95% CI 0.86-1.44).

Conclusion: In this prospective AS cohort, there was no conclusive evidence to support an increased risk of incident hypertension with TNFi use, after accounting for important baseline and time-dependent confounding factors.

SESSION INFORMATION

Session Date: Sunday, November 7, 2021

Session Title: Spondyloarthritis Including PsA – Treatment Poster I: Axial Spondyloarthritis (0908–0939)

Session Type: Poster Session B

Session Time: 8:30AM–10:30AM

Background/Purpose: Biological disease-modifying antirheumatic drugs (bDMARDs) should be considered in patients with active axial spondyloarthritis (AxSpA) despite treatment with nonsteroidal anti-inflammatory drugs. The objective of this study was to compare drug retention in patients with active AxSpA treated with tumor necrosis factor inhibitors (TNFi) and secukinumab (SEC), an interleukin 17 inhibitor.

Methods: AxSpA patients from three tertiary care centers starting SEC or TNFi in 2016-2019 were included. Hazard-ratios (HR) for treatment discontinuation were calculated using propensity score and after overlap weighting.

Results: A total of 279 patients were included (TNFi 178, SEC 101). Mean (SD) age was 45.1 (13.1) years and 45.5% were women. Most of them were diagnosed with radiographic sacroiliitis (63.4%), few were bDMARD-naïve (33.7% and 14.9% for TNFi and SEC, respectively). Before matching, patients of the SEC group were older, more likely to present with peripheral joint manifestations, radiographic sacroiliitis, had a higher prevalence of male gender,

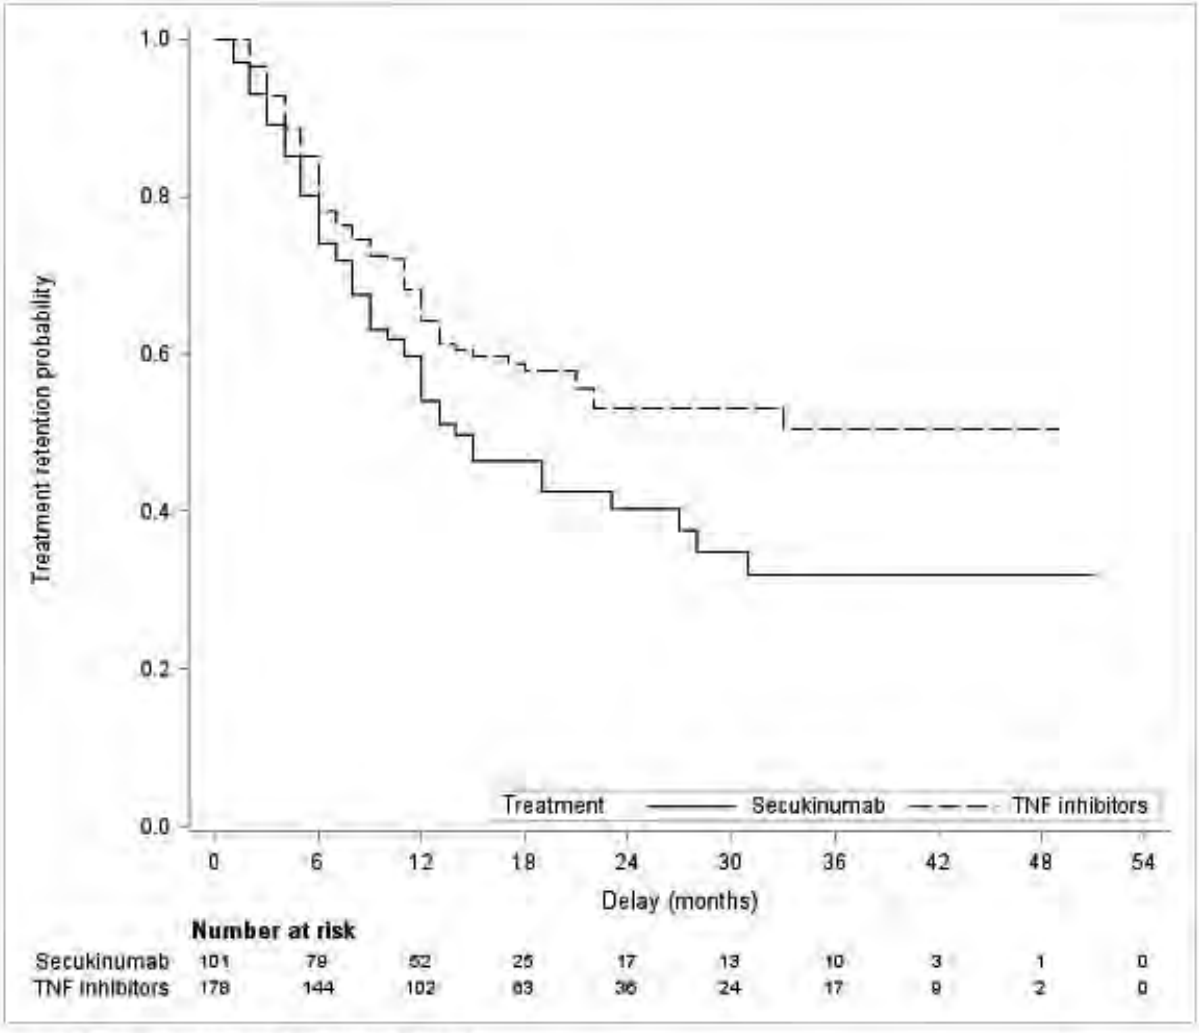

Figure 1. Persistence with SEC versus TNFi

HLA-B27 positive status, fibromyalgia and comorbidities. 77 matched pairs (mean values of the 10 imputed datasets) were found.

Out of 279 patients, 128 (45.9%) discontinued treatment (Figure 1). In unadjusted analyses, a better drug retention was observed with TNFi compared with SEC (Hazard Ratio HR for treatment discontinuation: 1.46 95% CI: 1.03 to 2.08; p=0.033). The HR for treatment discontinuation in overlap-weighting and matched cohort were 1.46 (95%CI:

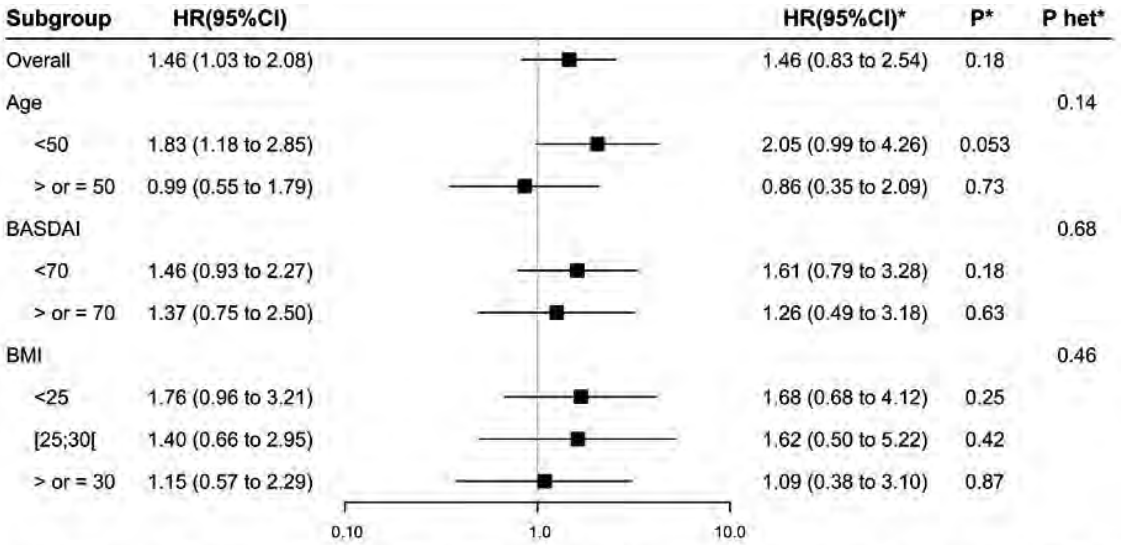

Figure 2. Treatment retention between SEC and TNFi, before and after Overlap Weighting. Abbreviations: BASDAI: Bath Ankylosing Spondylitis Disease Activity Index; BMI: body mass index; CI: confidence interval; CRP: C-reactive protein; HR: hazard ratio. Hazard ratios were calculated for patients treated with Secukinumab versus those treated with TNF inhibitors. * after overlap weighting

Other, n (%)	0 (0.0)	3 (5.5)†

* One new-onset inflammatory bowel disease

† One death not treatment related, one progression of multiple sclerosis, one progression chronic lymphocytic leukemia

0.83 to 2.54; p=0.18) and 1.46 (95%CI: 0.86 to 2.50; p=0.16), respectively. 6-month and 12-month SEC retention rates were 74% and 54%, respectively. Subgroup analyses (age, BASDAI at diagnosis, BMI) showed no difference between TNFi and SEC (Figure 2).

Reasons for discontinuation of TNFi and SEC treatments are demonstrated in Table 1. The main reason for discontinuating both treatments was inefficacy. The overall rate of adverse events leading to treatment discontinuation was similar for both treatment groups (19.2% and 20.0% for TNFi and SEC, respectively).

Conclusion: In this real-world AxSpA cohort, drug retention of SEC and TNFi were similar. In subgroups analyses, age, BASDAI at diagnosis and BMI did not favour any group. These results should be supplemented by head-to-head trials.

Abstract Number: 0912

Efficacy and Safety of Intravenous Golimumab in Ankylosing Spondylitis Patients with Early versus Late Disease Through Week 52 of GO-ALIVE Study

Atul Deodhar[1], Shelly Kafka[2], Elizabeth Hsia[3], Kim Hung Lo[4], Kim Lilianne[4], Stephen Xu[3] and John Reveille[5], [1]Oregon Health & Science University, Portland, OR, [2]Department of Immunology, Janssen Scientific Affairs, LLC, Horsham, PA, [3]Janssen Research & Development, LLC, Spring House, PA, [4]Department of Biostatics, Janssen Research & Development, LLC, Spring House, Spring House, PA, [5]Division of Rheumatology, The University of Texas Health Science Center at Houston, Houston, TX

SESSION INFORMATION
Session Date: Sunday, November 7, 2021
Session Title: Spondyloarthritis Including PsA – Treatment Poster I: Axial Spondyloarthritis (0908–0939)
Session Type: Poster Session B
Session Time: 8:30AM–10:30AM

Background/Purpose: The GO-ALIVE study assessed efficacy and safety of intravenous golimumab (IV GLM) in patients with ankylosing spondylitis (AS).[1,2] In this post hoc analysis, we assessed IV GLM efficacy and safety in AS patients with early disease (ED) vs late disease (LD) based on patient-reported duration of inflammatory back pain (IBP).

Methods: In this Phase 3, double-blind, placebo (PBO)-controlled trial, patients with active AS were randomized (1:1) to receive IV GLM 2 mg/kg at Week (W) 0, W4, then every 8 weeks (Q8W) or PBO at W0, W4, and W12 with crossover to IV GLM at W16, W20, then Q8W through W52. The primary endpoint was the Assessment of SpondyloArthritis International Society 20% improvement response (ASAS 20) at W16. In this post hoc analysis, 208 patients were grouped into quartiles based on self-reported duration of IBP symptoms. Efficacy and safety in 60 patients with ED (1st quartile) were compared with 52 patients with LD (4th quartile).

Results: For the overall study population, mean duration of IBP symptoms was 10.9 years and mean time since diagnosis was 5.5 years. For ED patients, the mean duration of IBP symptoms ranged from 2.3 years (IV GLM) to 2.6 years (PBO), and for LD patients ranged from 23.5 years (IV GLM) to 24.4 years (PBO). At W16, ASAS 20 was

Table. Efficacy Outcomes

	ED				LD			
	Week 16		Week 52		Week 16		Week 52	
	PBO (n=25)	IV GLM (n=35)	PBO→IV GLM (n=25)	IV GLM (n=35)	PBO (n=28)	IV GLM (n=24)	PBO→IV GLM (n=28)	IV GLM (n=24)
ASAS 20	32%	71%	68%	71%	21%	67%	68%	63%
ASAS 40	12%	46%	56%	60%	4%	42%	57%	42%
BASDAI 50	12%	40%	64%	60%	7%	33%	57%	42%
ASDAS inactive disease (score <1.3)	4%	17%	44%	37%	0%	8%	14%	4%
ASDAS major improvement (decrease ≥2.0)	n=24 4%	57%	n=24 54%	51%	0%	n=23 48%	46%	n=23 30%
ASDAS clinically important improvement (decrease ≥1.1)	n=24 29%	77%	n=24 75%	77%	18%	n=23 91%	61%	n=23 65%
Mean change from baseline (SD) in BASFI	n=23 -0.4 (2.0)	-2.3 (2.1)	n=23 -2.7 (2.7)	-2.8 (2.6)	n=27 -0.3 (1.8)	n=24 -2.2 (1.7)	n=27 -2.4 (2.2)	n=23 -2.3 (1.7)
Mean change from baseline (SD) in BASMI	n=23 -0.3 (0.7)	-0.4 (0.7)	n=23 -0.6 (0.7)	-0.3 (0.5)	n=27 0.01 (0.5)	n=21 -0.3 (0.6)	n=27 -0.4 (0.7)	n=20 -0.3 (0.7)
Mean change from baseline (SD) in enthesitis score	n=23 0.1 (3.6)	-2.9 (2.9)	n=23 -2.0 (4.4)	-3.2 (2.5)	n=27 -0.6 (3.4)	n=21 -2.5 (3.0)	n=27 -2.5 (3.1)	n=20 -3.5 (5.9)

ASAS=Assessment of SpondyloArthritis International Society, ASDAS=Ankylosing Spondylitis Disease Activity Score, BASDAI=Bath Ankylosing Spondylitis Disease Activity Index, BASFI=Bath Ankylosing Spondylitis Functional Index, BASMI=Bath Ankylosing Spondylitis Metrology Index, ED=early disease, GLM=golimumab, IV=intravenous, LD=late disease, PBO=placebo, SD=standard deviation

achieved by 72% IV GLM vs 32% PBO patients with ED and by 67% IV GLM vs 21% PBO patients with LD. Patients with ED had numerically better response than those with LD in Bath Ankylosing Spondylitis Functional Index (BASFI), Bath Ankylosing Spondylitis Metrology Index (BASMI), and across more stringent endpoints, including ASAS 40, Bath Ankylosing Spondylitis Disease Activity Index 50% improvement (BASDAI 50), and Ankylosing Spondylitis Disease Activity Score (ASDAS) inactive disease and major improvement (Table). Response rates at W16 among IV GLM-treated patients were generally consistent through 1 year in both ED and LD subgroups; also in ED and LD subgroups, patients crossing over to IV GLM at W16 demonstrated response at W52 consistent with patients who started IV GLM at W0. At W16, improvements in enthesitis score were similar for patients with ED (mean change -2.9 for IV GLM vs 0.1 for PBO) and LD (mean change -2.5 for IV GLM vs 0.6 for PBO); improvements were maintained at W52 for ED and LD patients. Treatment-emergent adverse events and serious adverse events through 1 year were 46% and 3% for patients with ED compared with 61% and 2% for patients with LD, respectively.

Conclusion: While IV GLM provided clinically meaningful improvements in signs and symptoms of AS in patients regardless of disease duration, response generally appeared numerically better in patients with ED than in patients with LD. This supports the principle of prompt diagnosis and early treatment.

SESSION INFORMATION

Session Date: Sunday, November 7, 2021

Session Title: Spondyloarthritis Including PsA – Treatment Poster I: Axial Spondyloarthritis (0908–0939)

Session Type: Poster Session B

Session Time: 8:30AM–10:30AM

Background/Purpose: Certolizumab pegol (CZP) has demonstrated clinical efficacy in patients with active non-radiographic axial spondyloarthritis (nr-axSpA) and objective signs of inflammation (sacroiliitis on MRI and/or elevated C-reactive protein levels) treated during the 52-week placebo-controlled period of C axSpAnd.[1] We evaluate long-term safety and changes in clinical outcomes in patients with active nr-axSpA treated with CZP for up to 3 years during the C-axSpAnd double-blind period and open-label (OL) safety follow-up extension (SFE).

Methods: C-axSpAnd (NCT02552212) was a 3-year, phase 3, multicenter study consisting of a 1-year double-blind, placebo-controlled period (Weeks 0–52) followed by a 2-year OL SFE (Weeks 52–156).[1] Patients were randomized 1:1 to placebo (PBO) or CZP (400 mg at Weeks 0, 2, 4, then 200 mg every 2 weeks [Q2W]), which they received in addition to non-biologic background medication for 52 weeks. Switching to OL CZP (or other biologics) was permitted at any point. At Week 52, patients completing the double-blind phase (on CZP, PBO or OL CZP) who enrolled into the SFE received OL CZP 200 mg Q2W for an additional 104 weeks. We report safety and clinical outcomes (Ankylosing Spondylitis Disease Activity Score [ASDAS], BASDAI and BASFI, ASDAS Major Improvement [ASDAS-MI], Assessment of SpondyloArthritis international Society 40% response [ASAS40]) up to Week 156 for patients who entered the SFE according to whether they were initially randomized to CZP or PBO. As efficacy outcomes for the SFE were assessed at Weeks 52 and 156 only, data are reported as observed case (OC).

Results: 243/317 patients who entered C-axSpAnd continued into the SFE, including 120 patients from the CZP-randomized arm and 123 from the PBO-randomized arm. During the double-blind period, prior to SFE entry, 75/123 PBO patients had switched to OL CZP, compared to 10/120 of CZP patients. In total, 102/120 (85.0%) and 104/123 (84.6%) SFE patients from the CZP- and PBO-randomized arms, respectively, completed the study up to Week 156.

Table. Safety outcomes up to Week 156 of the C-axSpAnd study

	Double-blind period Weeks 0–52		Safety follow-up extension Weeks 52–156	
n (%) [#]	CZP 200 mg Q2W (n=159)	PBO (n=158)	CZP 200 mg Q2W (n=120)	PBO → CZP 200 mg Q2W (n=123)
Any TEAE	120 (75.5) [476]	101 (63.9) [333]	73 (60.8) [193]	76 (61.8) [212]
Serious TEAEs	8 (5.0) [9]	3 (1.9) [3]	6 (5.0) [6]	9 (7.3) [14]
Subject discontinuations due to TEAEs	3 (1.9) [4]	3 (1.9) [3]	1 (0.8) [2]	4 (3.3) [4]
Permanent withdrawal of study medication due to TEAEs	3 (1.9) [4]	3 (1.9) [3]	1 (0.8) [2]	5 (4.1) [5]
Drug-related TEAEs	48 (30.2) [111]	23 (14.6) [61]	13 (10.8) [33]	23 (18.7) [46]
Severe TEAEs	5 (3.1) [5]	4 (2.5) [4]	4 (3.3) [4]	5 (4.1) [8]
Frequently reported TEAEs by preferred term [a]				
Diarrhea	8 (5.0) [11]	10 (6.3) [10]	1 (0.8) [1]	3 (2.4) [3]
Upper respiratory tract infection	30 (18.9) [38]	16 (10.1) [23]	14 (11.7) [20]	7 (5.7) [11]
Nasopharyngitis	21 (13.2) [24]	13 (8.2) [17]	18 (15.0) [23]	8 (6.5) [10]
Bronchitis	8 (5.0) [9]	5 (3.2) [5]	5 (4.2) [6]	5 (4.1) [5]
Tonsilitis	7 (4.4) [7]	2 (1.3) [2]	6 (5.0) [7]	6 (4.9) [7]
Increased blood creatine phosphokinase	8 (5.0) [9]	4 (2.5) [4]	1 (0.8) [1]	2 (1.6) [2]
Arthralgia	9 (5.7) [12]	10 (6.3) [12]	3 (2.5) [3]	3 (2.4) [3]
Axial spondyloarthritis	11 (6.9) [13]	12 (7.6) [13]	4 (3.3) [4]	1 (0.8) [1]
Headache	11 (6.9) [15]	7 (4.4) [9]	4 (3.3) [4]	5 (4.1) [7]
Cough	6 (3.8) [6]	8 (5.1) [10]	1 (0.8) [1]	2 (1.6) [2]
Deaths	0	0	0	0

For Weeks 0–52, data are reported for double-blind safety set (N=317), and for Weeks 52–156 for the SFE safety set (N=243). [a] Reported in ≥5% patients. #: number of individual TEAE occurrences; CZP: certolizumab pegol; PBO: placebo; Q2W: every 2 weeks; TEAE: treatment-emergent adverse event.

During the SFE, 405 TEAEs were reported for 149 (61.3%) patients, including 20 serious TEAEs in 15 (6.2%) patients (**Table**). Over a period of up to 3 years of CZP treatment, no new safety signal was identified.

At Week 52 (SFE baseline), using OC data, there were substantial improvements from Week 0 in ASDAS, BASDAI and BASFI, and in ASDAS-MI and ASAS40 response rates (**Figure**). As the majority of PBO-randomized patients had switched to OL CZP during the double-blind period, improvements were also observed in this arm at Week 52. Responses were maintained to Week 156 in both arms, and by Week 156, improvements across all reported efficacy outcomes in patients initially randomized to PBO were comparable to those initially randomized to CZP (**Figure**).

Conclusion: This analysis reports safety and clinical outcomes in the nr-axSpA patients who entered the C-axSpAnd SFE and received OL CZP treatment. During the SFE, CZP was shown to be well tolerated in patients with nr-axSpA, in line with 1-year data.[1] In patients receiving CZP treatment for up to 3 years, observed improvements in signs and symptoms after 1 year were maintained up to 3 years.

Response to Certolizumab Pegol in Patients with Non-Radiographic Axial Spondyloarthritis by Baseline C-Reactive Protein Cut-Offs: Post-Hoc Analysis from a Phase 3 Multicenter Study

Philip Robinson[1], Stephen Hall[2], Bengt Hoepken[3], Lars Bauer[3], Eleni Demas[4], Mindy Kim[5] and Atul Deodhar[6], [1]University of Queensland School of Clinical Medicine, Brisbane, Queensland, Australia, Herston, Australia, [2]Emeritus Research and Monash University, Melbourne, Australia, Melbourne, Australia, [3]UCB Pharma, Monheim am Rhein, Germany, [4]UCB Pharma, Slough, United Kingdom, [5]UCB Pharma, Smyrna, GA, [6]Oregon Health & Science University, Portland, OR

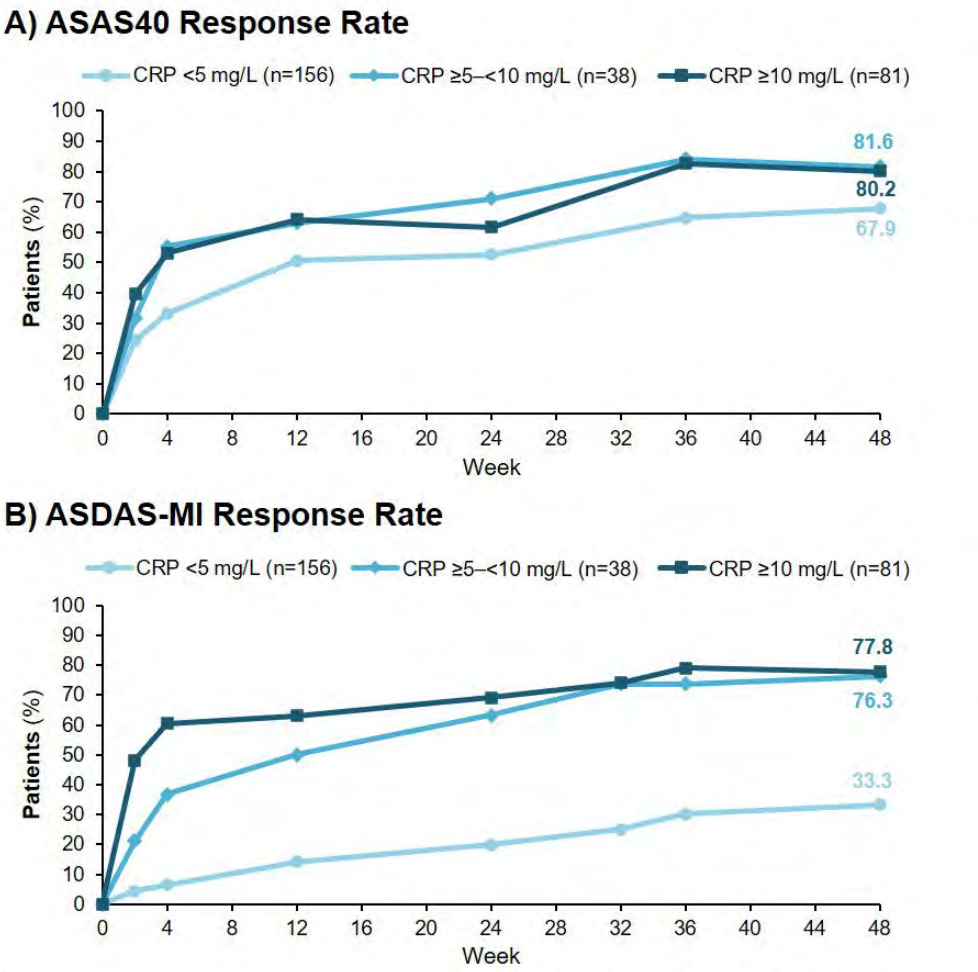
SESSION INFORMATION
Session Date: Sunday, November 7, 2021
Session Title: Spondyloarthritis Including PsA – Treatment Poster I: Axial Spondyloarthritis (0908–0939)
Session Type: Poster Session B
Session Time: 8:30AM–10:30AM

Background/Purpose: Certolizumab pegol (CZP), an Fc-free, PEGylated tumor necrosis factor (TNF) inhibitor, has previously demonstrated efficacy and safety in patients with radiographic (r) and non-radiographic (nr) axial spondyloarthritis (axSpA).[1,2] In nr-axSpA patients, CZP has demonstrated efficacy across all C-reactive protein (CRP) subgroups, including patients with normal baseline CRP levels.[3] However, the association between CZP efficacy and baseline CRP levels has not been investigated in the subset of nr-axSpA patients with positive magnetic resonance imaging (MRI+; defined as the presence of active sacroiliitis on MRI based on the Assessment of SpondyloArthritis international Society [ASAS] criteria).[4] This post-hoc analysis explores the association between baseline CRP levels and CZP efficacy in MRI+ nr-axSpA patients from the C-OPTIMISE trial.

Methods: C-OPTIMISE (NCT02505542) was a two-part, multicenter, phase 3b study in adult patients with r-axSpA or nr-axSpA.[1,2] In the open-label run-in period (0–48 weeks), patients received CZP 400 mg at Weeks 0, 2, and 4, then CZP 200 mg every 2 weeks thereafter. This analysis included the subset of MRI+ nr-axSpA patients in the C-OPTIMISE cohort who received ≥1 dose of study medication in the open-label period. Efficacy outcomes were evaluated and stratified by baseline CRP levels (<5 mg/L, ≥5– < 10 mg/L and ≥10 mg/L). The upper limit of normal of the CRP assay was defined as 9.99 mg/L by the central laboratory. The lower limit of quantification (LLoQ) was 4 mg/L; where CRP levels < LLoQ, a CRP value of 2 mg/L was used to calculate Ankylosing Spondylitis Disease Activity Score (ASDAS).[5] Outcomes included ASAS ≥40% improvement (ASAS40), ASDAS – major improvement (ASDAS-MI), ASAS partial remission (ASAS PR), ASDAS, BASDAI, and BASFI.

Results: In total, 275 MRI+ nr-axSpA patients were included in this analysis (CRP <5 mg/L: n=156; CRP ≥5– <10 mg/L: n=38; CRP ≥10 mg/L: n=81). Response rates for ASAS40 increased over the treatment period and were com-

Figure 1. (A) ASAS40 and **(B)** ASDAS-MI response rates in CZP-treated patients by baseline CRP category (non-responder imputation)



ASAS40: Assessment of SpondyloArthritis international Society ≥40% improvement; ASDAS-MI: Ankylosing Spondylitis Disease Activity Score – major improvement; CRP: C-reactive protein; CZP: certolizumab pegol.

parable across CRP subgroups (**Figure 1A**). Response rates for ASDAS-MI were higher in the CRP ≥10 mg/L and CRP ≥5– <10 mg/L subgroups than the CRP <5 mg/L subgroup (**Figure 1B**). Across other efficacy measures, improvements were observed at Week 48 compared with baseline in all CZP-treated CRP subgroups (**Table 1**).

Conclusion: Clinically relevant responses were observed in MRI+ nr-axSpA patients treated with CZP, across CRP subgroups and measured outcomes. The responses in each subgroup were consistent with those previously reported in total nr-axSpA patient group.[1] ASDAS-MI response rates were lower in the CRP <5 mg/L subgroup, however, CRP is a key factor in ASDAS derivation. It is unlikely that ASDAS-MI could be achieved in patients in the CRP <5 mg/L subgroup since most of them had CRP levels < LLoQ.

SESSION INFORMATION

Session Date: Sunday, November 7, 2021

Session Title: Spondyloarthritis Including PsA – Treatment Poster I: Axial Spondyloarthritis (0908–0939)

Session Type: Poster Session B

Session Time: 8:30AM–10:30AM

Background/Purpose: Axial spondyloarthritis (axSpA) is a chronic inflammatory disease associated with extracellular matrix (ECM) remodeling of the cartilage, bone, and connective tissues. Quantification of ECM-mediated biomarkers may be useful to determine treatment response in axSpA. The aim of this study was to identify biomarkers reflecting the pharmacodynamic effect and the treatment response of adalimumab in two placebo-controlled axSpA studies.

Methods: Biomarkers reflecting the degradation of collagen type I (C1M), II (C2M and T2CM), III (C3M), IV (C4M), VI (C6M), formation of collagen type II (PRO-C2), III (PRO-C3), IV (PRO-C4) and VI (PRO-C6) and inflammation (CRPM, PROM, and VICM) were measured in serum from the ASIM study (n=45) and the DANISH study (n=49) at baseline, week 6 or 12 (ASIM and DANISH, respectively), and week 24. Patients received treatment with adalimumab 40 mg or placebo the first 6 or 12 weeks (ASIM and DANISH, respectively) followed by adalimumab 40 mg for an additional 18 or 12 weeks (ASIM and DANISH, respectively). Differences in fold change of biomarker levels between week 6 or week 12 (ASIM and DANISH, respectively) and baseline were evaluated by a linear regression model to investigate treatment pharmacodynamics. A linear regression model adjusted by treatment (active treatment or placebo for the first 6 or 12 weeks, ASIM and DANISH, respectively) were applied to investigate treatment response. Response to treatment was evaluated as a reduction of at least 50% in BASDAI index from baseline to week 24.

Table 1. Pharmacodynamic effect of adalimumab in the ASIM (Baseline to 6 weeks) and DANISH (Baseline to 12 weeks) studies, presented as fold change of the investigated serum biomarkers.

C1M: metalloproteinase (MMP)-degraded type I collagen; C2M: metalloproteinase (MMP)-degraded type II collagen; T2CM: MMP-1 and -13 mediated degradation of type II collagen; C3M: MMP-degraded type III collagen; C4M: MMP-degraded type IV collagen; C6M: MMP-degraded type VI collagen; CRPM:C-reactive protein metabolite; PROM: MMP-1 and -13 mediated degradation of prolargin; VICM: citrullinated and MMP-degraded vimentin; PRO-C2: pro-peptide of type II collagen; PRO-C3: pro-peptide of type III collagen; PRO-C4: pro-peptide of type IV collagen; PRO-C6: pro-peptide of type VI collagen; Type 2: formation/degradation ratio of type II collagen; Type 3: formation/degradation ratio of type III collagen; Type 4: formation/degradation ratio of type IV collagen; Type 6: formation/degradation ratio of type VI collagen.

Results: In the ASIM vs. DANISH study 56% vs. 78% of the patients were male, the mean (SD) age of the patients was 37.6 (9.9) vs. 39.5 (11.2) and frequency of HLA-B27 78% vs. 88%. The 22 patients representing the primarily actively treated group in the ASIM study presented significantly lower fold change in C1M, C3M, C4M, C6M, and PRO-C4 over the first 6 weeks as compared to the placebo group ($p< 0.001$, $p< 0.001$, $p< 0.001$, $p< 0.001$, $p= 0.018$, respectively Table 1), and showed a significantly higher fold change in the ratios of formation/degradation of collagen type III, IV and VI (all $p< 0.001$). The 24 patients from the actively treated group in the DANISH study had a significantly lower fold change over the first 12 weeks in C1M, C3M, C4M, C6M as compared to the placebo group ($p=0.002$, $p=0.02$, $p=0.015$, $p=0.011$, respectively, Table 1), and had a significantly higher fold change in the ratios of formation/degradation of collagen type IV and VI ($p=0.009$, $p=0.049$, respectively). Thirty-two out of 45 patients were considered responders in the ASIM study, and 43 out of 46 patients in the DANISH study (Table 2). In the ASIM study, levels of PRO-C4 presented a significantly lower fold change in responders compared to non-responders ($p=0.042$), while in the DANISH study, levels of C3M and C4M had both a significantly lower fold change in responders compared to non-responders (both $p=0.04$, Table 2).

Conclusion: The biomarkers C1M, C3M, C4M, and C6M may have potential as pharmacodynamic biomarkers, while the biomarkers C3M and C4M were associated with response to adalimumab treatment after 24 weeks.

SESSION INFORMATION

Session Date: Sunday, November 7, 2021

Session Title: Spondyloarthritis Including PsA – Treatment Poster I: Axial Spondyloarthritis (0908–0939)

Session Type: Poster Session B

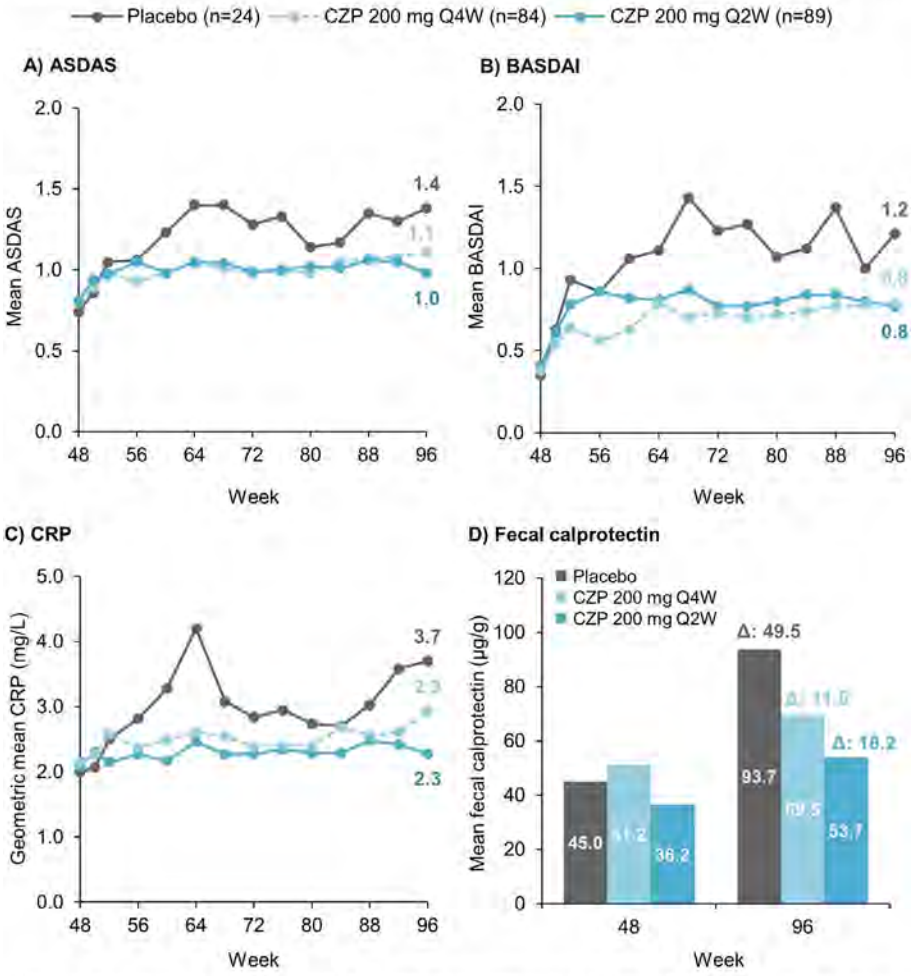
Session Time: 8:30AM–10:30AM

Background/Purpose: C-OPTIMISE was a phase 3b study investigating certolizumab pegol (CZP) maintenance dose continuation, reduction or withdrawal following achievement of sustained remission in patients with axial spondyloarthritis (axSpA). During the C-OPTIMISE maintenance period, the majority of patients randomized to CZP, either the full or reduced maintenance dose, did not experience disease flares. Conversely, in those who had CZP withdrawn, only a minority of patients remained flare-free.[1] This post-hoc analysis evaluates disease activity and clinical markers of inflammation in patients who did not experience a disease flare following randomization to CZP full maintenance dose, CZP reduced maintenance dose or placebo (PBO) during the C-OPTIMISE maintenance period (Weeks [Wks] 48–96).

Methods: C-OPTIMISE (NCT02505542) was a multicenter, double-blind, parallel-group, randomized phase 3b study with a 48-wk open-label run-in period.[1] Adult patients with early (< 5 years' symptom duration) active axSpA received open-label CZP 200 mg every 2 wks (Q2W) for the first 48 wks; from Wk 48, patients who achieved sustained remission (Ankylosing Spondylitis Disease Activity Score [ASDAS] < 1.3 at Wk 32/36 and Wk 48) were randomized 1:1:1 to double-blind CZP 200 mg Q2W (full maintenance dose), CZP 200 mg Q4W (reduced maintenance dose) or PBO for a further 48 wks (maintenance period). A flare was defined as ASDAS ≥2.1 at two consecutive visits or ASDAS >3.5 at any visit. We report ASDAS, BASDAI, and C-reactive protein (CRP) and fecal calprotectin levels during Wks 48–96 in CZP- and PBO-randomized patients who did not experience a flare (completed Wk 96 on randomized treatment). Missing data were imputed using last observation carried forward.

Results: Of 313 patients entering the maintenance period at Wk 48 (CZP 200 mg Q2W: 104; CZP 200 mg Q4W: 105; PBO: 104), 197 (62.9%) completed Wk 96 on randomized treatment without experiencing a flare; of these, 89 (85.6%) and 84 (80.0%) patients were in the CZP 200 mg Q2W and CZP 200 mg Q4W arm, respectively, with only 24 (23.1%) patients randomized to PBO not experiencing a flare. Baseline characteristics of patients are shown in the **Table**. During Wk 48–96, disease activity (ASDAS, BASDAI) and CRP levels were comparable between the CZP full and reduced maintenance dose group, and lower in both CZP arms than in PBO (**Figure A–C**). From Wk 60 up to Wk 96, PBO patients who did not flare had consistently higher mean ASDAS, BASDAI and CRP levels compared with CZP-randomized patients (**Figure A–C**). Similarly, there was a greater increase in fecal calprotectin levels between Wks 48 and 96 in the PBO arm compared with both CZP arms (**Figure D**).

Figure. (A) ASDAS, (B) BASDAI, (C) CRP and (D) fecal calprotectin in patients who did not experience a flare during the C-OPTIMISE maintenance period (Weeks 48–96)



Missing data were imputed using last observation carried forward. Δ values for fecal calprotectin show change from Week 48. ASDAS: Ankylosing Spondylitis Disease Activity Score; BASDAI: Bath Ankylosing Spondylitis Disease Activity Index; CRP: C-reactive protein; CZP: certolizumab pegol; Q2W/Q4W: every 2/4 weeks.

Table. Baseline (Week 0) characteristics of patients who did not experience flares during the C-OPTIMISE maintenance period

Median	2.8	3.5	3.9
ASDAS, mean (SD)	3.4 (0.8)	3.7 (0.8)	3.7 (0.7)
BASDAI, mean (SD)	6.3 (1.1)	6.6 (1.5)	6.4 (1.4)
CRP (mg/L), geometric mean	6.28	7.88	7.35
Fecal calprotectin (µg/g), mean (SD)	71.8 (111.4)	87.1 (110.5)	81.0 (120.0)

ASDAS: Ankylosing Spondylitis Disease Activity Score; CZP: certolizumab pegol; Q2W: every 2 weeks; Q4W: every 4 weeks; SD: standard deviation.

Conclusion: Despite not meeting the threshold for a flare, numerically higher disease activity and increases in serologic and inflammatory biomarkers were observed in PBO-randomized patients who did not experience a flare compared to those who remained on CZP. These findings confirm that patients with axSpA who achieve sustained remission benefit from continued CZP treatment, either with the full or reduced maintenance dose, over treatment withdrawal.

SESSION INFORMATION
Session Date: Sunday, November 7, 2021
Session Title: Spondyloarthritis Including PsA – Treatment Poster I: Axial Spondyloarthritis (0908–0939)
Session Type: Poster Session B
Session Time: 8:30AM–10:30AM

Background/Purpose: Human Leukocyte Antigen (HLA)-B is strongly associated with axial spondyloarthritis (axSpA); over 100 subtypes of HLA-B27 are currently recognized and designated as HLA-B*2701 to HLA-B*27106, defined by their DNA sequence.[1,2] The association of these subtypes with the clinical features of axSpA patients or their response to therapy has not been determined so far. In this post hoc analysis, we explored the potential association of the HLA-B27 subtypes with the effect of secukinumab (SEC) in axSpA patients from the SKIPPAIN trial (NCT03136861).

Methods: SKIPPAIN, a 24 week (wk), randomised, double-blind, placebo (PBO) controlled, multicenter trial, enrolled adult axSpA patients with active disease fulfilling ASAS classification criteria (Bath Ankylosing Spondylitis Disease Activity Index [BASDAI] score ≥4 and average spinal pain numerical rating scale [NRS] score >4 at baseline [BL]) and inadequate response to ≥2 NSAIDs for ≥4 wks. Patients were randomized (3:1) to receive subcutaneous SEC 150 mg or PBO wkly followed by every 4 wks (q4w) starting at Wk 4. At Wk 8, PBO patients were re-randomized to SEC 150 or 300 mg q4w up to Wk 24. HLA-B27 subtypes were tested by PCR-reverse sequence-specific oligonucleotide probe on a baseline blood sample. Average spinal pain scores were analysed using a repeated measures analysis of covariance (ANOVA) model.

Results: Overall 380 patients with axSpA (269 [70.8%] AS and 111 [29.2%] nr-axSpA) were randomised to SEC 150 mg (N=285) or PBO (N=95). Demographic and BL characteristics were previously reported.[3] Most patients enrolled in the study were HLA-B27 positive in both treatment groups (233 [81.8%] in the SEC vs. 76 [80.0%] in the PBO

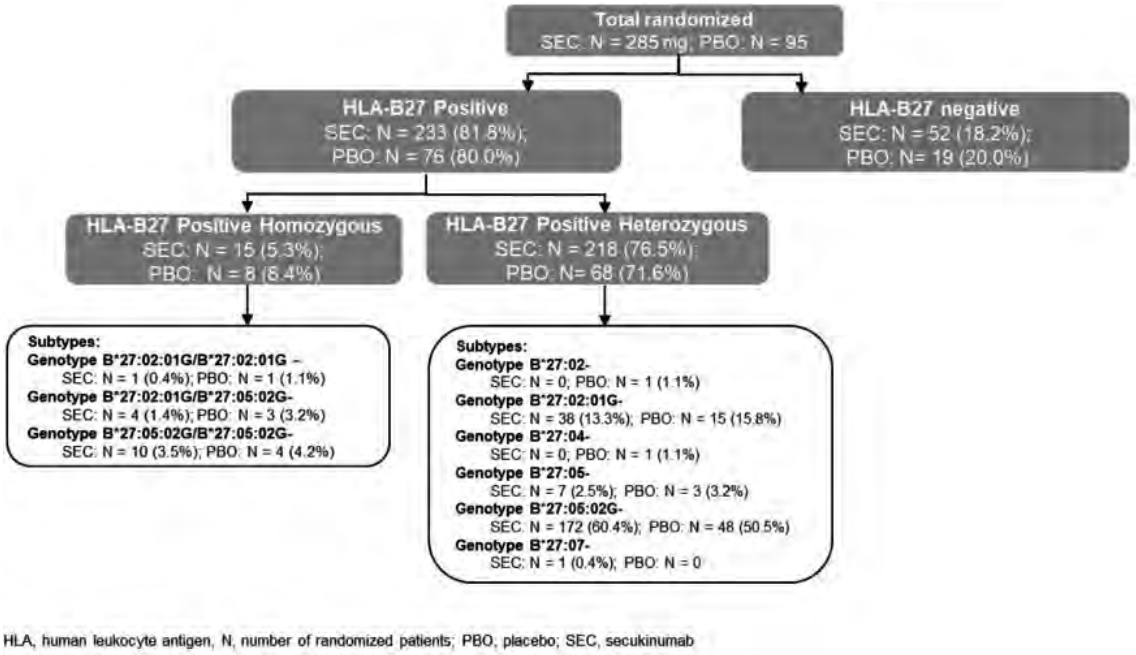

Figure 1. Distribution of HLA-B27 subtype patients.

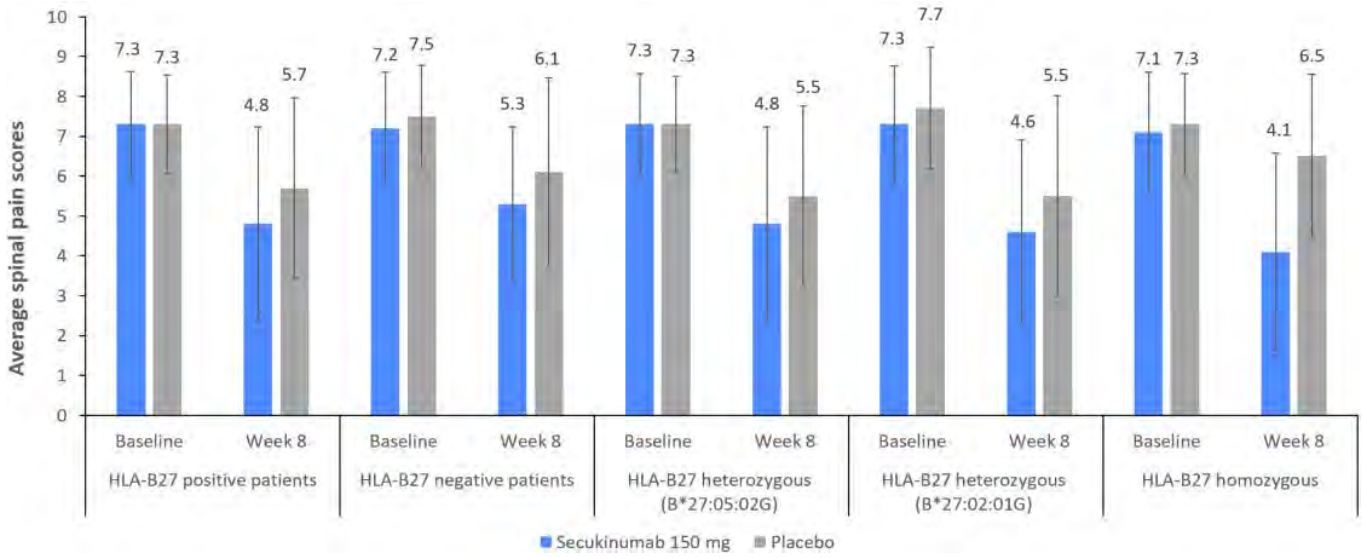

Figure 2. Average spinal pain scores in treatment groups by HLA-B27 status.

group). The distribution of HLA subtypes was consistent with what is expected in a typical European population[1], with HLA-B*27:05:02G as the most common allele **(Figure 1)**. In the HLA-B*27 homozygous group, a higher proportion of patients had uveitis, peripheral arthritis, enthesitis and a family history of spondyloarthritis, when compared to the heterozygous group; disease severity or burden of disease was similar between the two groups. Male predominance was more evident in the HLA-B*27 homozygous group who were younger by one year and reported longer duration of symptoms by an average of 8 months. Disease severity was comparable while disease burden was higher in B*27:05:02G compared with B27:02:01G heterozygous group. There were notable differences in the back pain response associated with B27 subtypes although the level of statistical significance could not always be reached due to the size of the subgroups (**Figure 2 and Table**).

Table 1. Average spinal pain scores (LS mean) at Week 8 and difference of LS Mean between the treatment groups, according to HLA-B27 status

Treatment Group	n	LS mean (SE)	LS mean difference (SE) between SEC vs PBO	95% CI	P-value
HLA-B27 positive patients					
Secukinumab 150 mg	279	5.1 (±0.19)	−0.9 (±0.27)	−1.47 to −0.42	**0.0004**
Placebo	92	6.0 (±0.27)			
HLA-B27 heterozygous (B*27:05:02G)					
Secukinumab 150 mg	167	5.1 (±0.24)	−0.9 (± 0.37)	−1.62 to −0.17	**0.0152**
Placebo	48	6.0 (±0.38)			
HLA-B27 heterozygous (B*27:02:01G)					
Secukinumab 150 mg	37	5.8 (±0.64)	−0.53 (±0.73)	−1.99 to 0.94	0.4748
Placebo	13	6.3 (±0.82)			
HLA-B27 homozygous					
Secukinumab 150 mg	15	4.7 (±1.23)	−2.45 (±1.26)	−5.23 to 0.32	0.0778
Placebo	8	7.2 (±1.45)			

Average spinal pain scores were analysed using a repeated measures analysis of covariance model with treatment, country, and the stratification factor of HLA-B27 as factors and the respective BL spinal pain score as covariate
CI, confidence interval; HLA, human leukocyte antigen; LS, least square; SE, standard error.

Conclusion: The spinal pain response after 8 weeks of treatment showed notable differences between HLA-B27 subgroups. Further studies or pooled analyses are warranted to investigate associations of the HLA-B27 subtypes with the clinical features of axSpA or of less prevalent HLA-B27 subtypes with response to treatment.

SESSION INFORMATION

Session Date: Sunday, November 7, 2021
Session Title: Spondyloarthritis Including PsA – Treatment Poster I: Axial Spondyloarthritis (0908–0939)
Session Type: Poster Session B
Session Time: 8:30AM–10:30AM

Background/Purpose: Ixekizumab (IXE), an IL-17A antagonist, is effective in patients with radiographic axial spondyloarthritis (rad-axSpA). Assessment in SpondyloArthritis International Society (ASAS) 40 response – the primary study endpoint – was achieved at week (wk) 16 by 48% of those treated with 80mg subcutaneous IXE every 4 wks (Q4W) in the phase 3 COAST V trial (NCT 02696785) [1]. Until now, no information has been available on the efficacy of IXE on the components of the ASAS40 composite endpoint. Our objective is to describe which individual components of ASAS40 drive the achievement of efficacy response.

Methods: This exploratory post-hoc analysis was based on COAST V data. Patients enrolled in COAST V met ASAS criteria for rad-axSpA and were biological disease-modifying antirheumatic drug (bDMARD)-naïve. Patients were assigned 1:1:1:1 to subcutaneous placebo (PBO), IXE Q4W, IXE Q2W or 40 mg adalimumab (ADA). Only data for approved doses are shown.

To reach ASAS40 response, patients must have an improvement of at least 40% and at least 2 units for at least 3 of 4 individual components which define response (patient global assessment of disease activity, spinal pain, inflammation (defined as the mean of Bath Ankylosing Spondylitis Disease Activity Index (BASDAI) questions 5 and 6), and function (Bath Ankylosing Spondylitis Functional Index - BASFI)), without worsening in the remaining component. We describe the percentage of patients who achieved this change, had an insufficient response, or deteriorated in each component out to wk 16 for IXE Q4W, ADA and PBO. The time course of the change from baseline in individual components of the ASAS response is depicted descriptively per treatment arm by use of the mean and standard deviation. Observed data have been utilised.

Table 1. Observed changes from baseline (CFB), percentage improvements and response status of patients enrolled in COAST V trial at wk 16

Measure	*Observed CFB (SD)*	*Observed % improvement (SD)*	*Improvement >=40% and >=2 units, n (%)*	*Insufficient response, n (%)*	*Deteriorated, n (%)*
IXE Q4W (N=78)					
Patient global assessment	-2.6 (2.9)	32.3 (51.1)	39 (50.0)	30 (38.5)	9 (11.5)
Spinal pain	-3.3 (2.7)	43.4 (34.4)	47 (60.3)	27 (34.6)	4 (5.1)
Inflammation*	-3.2 (2.5)	46.8 (32.8)	47 (60.3)	25 (32.0)	6 (7.7)
Function	-2.5 (2.3)	39.6 (31.0)	34 (43.6)	37 (47.4)	7 (9.0)
ADA (N=88)					
Patient global assessment	-2.6 (2.4)	35.2 (33.4)	35 (39.8)	48 (54.5)	5 (5.7)
Spinal pain	-2.6 (2.4)	36.8 (34.7)	38 (43.2)	44 (50.0)	6 (6.8)
Inflammation*	-2.6 (2.4)	38.4 (36.9)	42 (47.7)	37 (42.0)	9 (10.2)
Function	-2.1 (2.2)	35.2 (34.3)	31 (35.2)	48 (54.6)	9 (10.2)
PBO (N=86)					
Patient global assessment	-1.5 (2.0)	18.0 (37.9)	21 (24.4)	54(62.8)	11(12.8)
Spinal pain	-1.9 (1.9)	25.8 (26.7)	23 (26.8)	55(64.0)	8(9.3)
Inflammation*	-1.4 (1.9)	20.9 (33.9)	19 (22.1)	53 (61.6)	14 (16.3)
Function	-1.3 (1.8)	19.1 (31.6)	16 (18.6)	51 (59.3)	19 (22.1)

Inflammation is mean of BASDAI 5 (Morning stiffness severity) and BASDAI 6 (Morning stiffness duration)

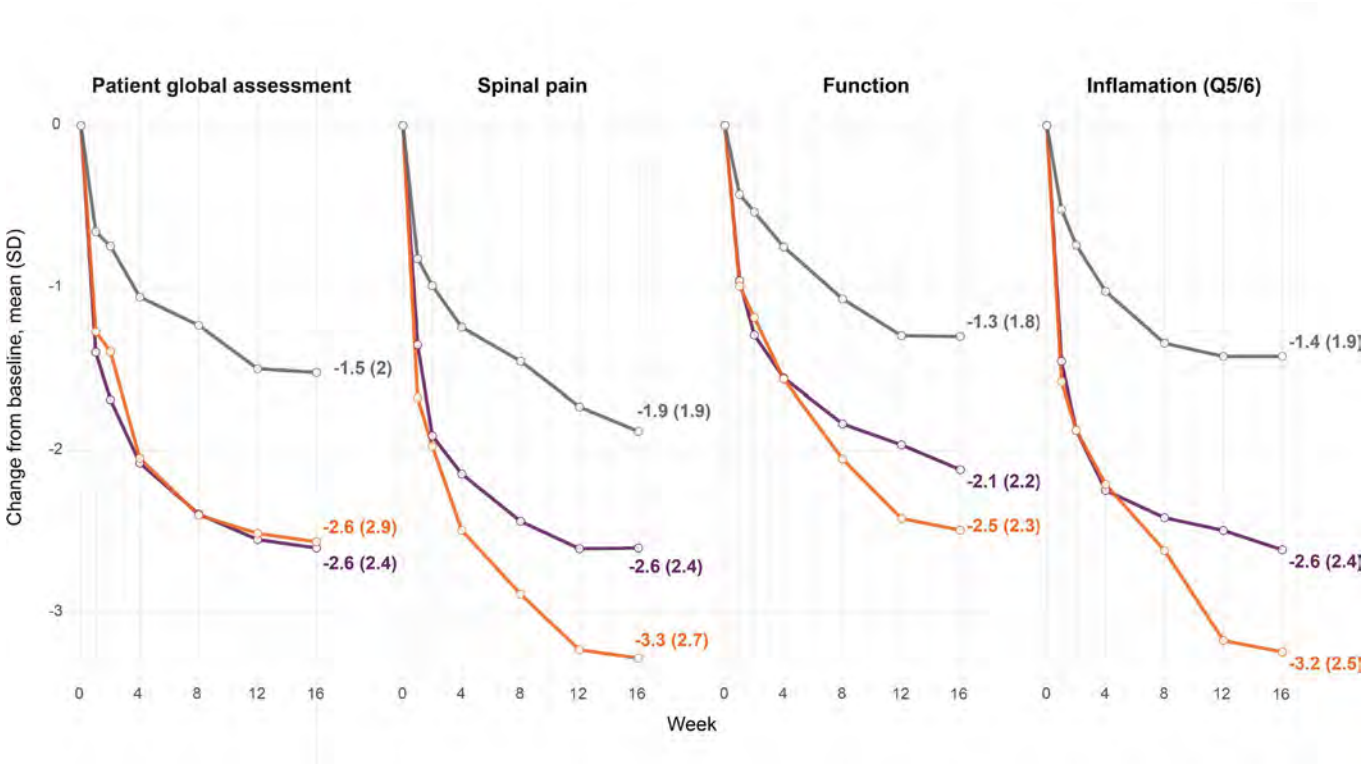

Figure 1. Mean (SD) change from baseline (observed) on individual components of ASAS 40 response by treatment arm and wk.

Results: IXE Q4W response at 16 wks was driven by all 4 individual components of the ASAS40 with the largest improvements for patients treated with IXE Q4W seen in inflammation and spinal pain (Fig. 1).

At wk 16, at least 50% of all patients treated with IXE Q4W achieved response on spinal pain (60.3%), inflammation (60.3%) and patient global assessment (50%), with 43.6% of patients meeting the response criteria for function (Table 1). The corresponding results for ADA were 43.2%, 47.7% 39.8%, and 35.2%.

Conclusion: Our findings show that meeting ASAS40 response criterion for an individual component at 16 wks by patients treated with IXE Q4W was broadly similar between individual components. However, a clinically relevant improvement was more frequently observed for the spinal pain and inflammation components.

SESSION INFORMATION
Session Date: Sunday, November 7, 2021
Session Title: Spondyloarthritis Including PsA – Treatment Poster I: Axial Spondyloarthritis (0908–0939)
Session Type: Poster Session B
Session Time: 8:30AM–10:30AM

Background/Purpose: Ixekizumab (IXE) demonstrated rapid efficacy in patients (pts) with AS at week (W) 16 in the absence of elevated inflammation as measured by baseline serum CRP values or spinal MRI Spondyloarthritis Research Consortium of Canada (SPARCC) score.[1] This analysis evaluated the improvement in pain with IXE based on longitudinal status of objective measures of inflammation by MRI, CRP value, and BASDAI 5/6 over 16W.

Methods: The Phase III COAST-V (NCT02696785) 52W, multi-center, randomized, double-blind, placebo (PBO)-controlled study examined the efficacy of IXE in pts with active AS. Adalimumab (ADA) was used as an active reference arm for the first 16W. Pts originally assigned to PBO or ADA were re-randomized to IXE at W16. Change in spinal pain at night (SP-N) and Short Form 36 Health Survey Questionnaire (SF-36) Bodily Pain were measured during study visits and analyzed while controlling for inflammation status using MRI, CRP levels and mean of BASDAI 5/6 (Q5: Duration, Q6: Intensity of morning stiffness). Observed data analyses are presented for each group stratified by treatment arm. Initial analysis: 'controlled inflammation' is defined as MRI SPARCC SI joint <4 and MRI SPARCC Spine $<3^2$ at W16, CRP < 5mg/L at every visit W4-16, or BASDAI 5/6 improvement of ≥2 points W12 and W16. 'Not Controlled' are noted in figure legends. Second analysis: control is defined as CRP < 5 mg/L at every week between W4-16 and MRI SPARCC SI joint <4 at W16 and MRI SPARCC Spine <3 at W16.

Results: When inflammation is controlled per MRI, pts treated (tx) with IXEQ4W (-3.9 $p < 0.001$) and ADA (-2.8 $p=0.02$) experienced significant reduction in SP-N vs PBO (-1.6) at W16, further improvements were experienced in pts rerandomized to IXE by W52 (Fig1A). When inflammation was not controlled per MRI, IXEQ4W (-3.5 $p < 0.01$) and ADA (-3.1 $p=0.02$) experienced significant reduction in SP-N at W16, all IXE tx pts had further reductions at W52 (Fig1B). When inflammation was controlled per MRI+CRP, IXEQ4W (-3.8 $p=0.2$) and ADA (-3.1 $p=0.4$) had reduction in SP-N at W16 vs PBO (-2.4), all IXE groups had further improvements at W52 (Fig2A). When inflammation was not controlled as measured by MRI+CRP, IXEQ4W (-3.7 $p < 0.001$) had significant reduction in SP-N vs PBO (-1.7), whereas improvement with ADA (-2.6 $p=0.06$) was not significant, all IXE tx pts had further reduction by W52 (Fig1B). For SF-36 bodily pain, improvements were observed at W16 and W52 whether inflammation was controlled or not controlled per MRI, CRP, MRI+CRP, or BASDAI 5/6 (Table 1).

Conclusion: This analysis adds support to the hypothesis that IXE improves pain in pts with and without measurable inflammation.

Session Date: Sunday, November 7, 2021

Session Title: Spondyloarthritis Including PsA – Treatment Poster I: Axial Spondyloarthritis (0908–0939)

Session Type: Poster Session B

Session Time: 8:30AM–10:30AM

Background/Purpose: Upadacitinib (UPA), an oral Janus kinase inhibitor, has demonstrated efficacy and safety through 14 weeks in the SELECT-AXIS 1 study in biologic disease-modifying antirheumatic drug-naïve patients with

Table PBO-corrected mean change from baseline (95% CI) in ASDAS(CRP) at Week 14 in patients receiving UPA 15 mg by baseline subgroups (MMRM)

		n		ASDAS(CRP)
Subgroup		**UPA 15 mg**	**PBO**	**PBO-corrected mean change from baseline (95% CI)**
Gender	Male	58	62	–1.11 (–1.37, –0.84)
	Female	26	22	–0.44 (–0.92, 0.03)
Age	<40 years	24	36	–1.00 (–1.42, –0.58)
	40–<65 years	51	46	–0.88 (–1.17, –0.59)
Body mass index	<25 kg/m²	32	37	–0.92 (–1.30, –0.55)
	≥25 kg/m²	52	47	–0.89 (–1.20, –0.59)
AS symptom duration	<5 years	16	17	–0.90 (–1.46, –0.34)
	≥5 years	68	67	–0.92 (–1.18, –0.66)
Baseline hsCRP	≤2.8 mg/L	23	19	–0.59 (–1.02, –0.15)
	>2.8–<10 mg/L	39	34	–0.59 (–0.95, –0.23)
	≥10 mg/L	22	31	–1.64 (–2.01, –1.27)
Inflammation based on SPARCC MRI scores	Positive[a]	56	57	–0.98 (–1.27, –0.69)
	Negative[b]	21	16	–0.60 (–1.08, –0.12)
HLA-B27 status	Positive	62	66	–0.97 (–1.24, –0.71)
	Negative	20	17	–0.73 (–1.28, –0.17)

[a]Spine SPARCC score ≥2 or sacroiliac joint SPARCC score ≥2. [b]Spine SPARCC score <2 and sacroiliac joint SPARCC score <2

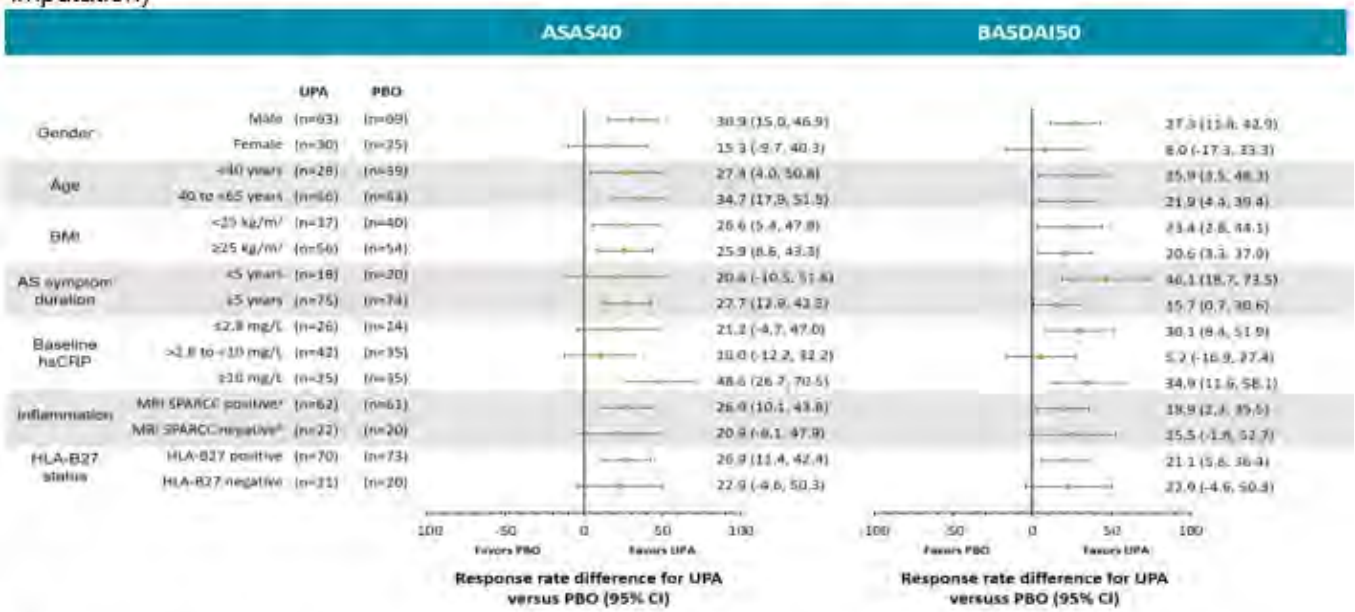
ASDAS(CRP), Ankylosing Spondylitis Disease Activity Score with C-reactive protein; CI, confidence interval; HLA-B27, human leukocyte antigen B27; hsCRP, high-sensitivity C-reactive protein; MMRM, mixed model repeated measures; MRI, magnetic resonance imaging; PBO, placebo; SPARCC, Spondyloarthritis Research Consortium of Canada; UPA, upadacitinib

active ankylosing spondylitis (AS).[1] The objective of this analysis was to evaluate the efficacy of UPA 15 mg once daily (QD) in selected subgroups of patients with AS based on different baseline characteristics.

Methods: In SELECT-AXIS 1, patients were randomized to 14 weeks of blinded treatment with UPA 15 mg QD or placebo (PBO). This post hoc analysis evaluated the proportions of patients achieving ≥40% improvement in Assessment of SpondyloArthritis International Society criteria (ASAS40), ≥50% improvement in the Bath Ankylosing Spondylitis Disease Activity Index (BASDAI50), and change from baseline in Ankylosing Spondylitis Disease Activity Score with C-reactive protein (ASDAS[CRP]) at Week 14 across subgroups based on the following baseline patient characteristics: gender, age, body mass index, AS symptom duration, C-reactive protein (CRP) levels, Spondyloarthritis Research Consortium of Canada Magnetic Resonance Imaging index, and human leukocyte antigen B27 status. For missing data, non-responder imputation analysis was used for ASAS40 and BASDAI50, and mixed model repeated measures analysis was used for ASDAS(CRP).

Results: Baseline disease characteristics were balanced between the treatment groups at randomization, as previously reported.[1] ASAS40 and BASDAI50 response rates at Week 14 were numerically higher with UPA 15 mg versus PBO across the demographic and disease characteristic subgroups evaluated (**Figure**), including some subgroups with small sample sizes, such as patients with disease duration < 5 years and female patients. Improvements from baseline in ASDAS(CRP) were also consistently greater with UPA 15 mg versus PBO across the subgroups evaluated (**Table**).

Figure Response rate difference for UPA versus PBO (95% CI) for ASAS40 and BASDAI50 responses at Week 14 in patients receiving UPA 15 mg by baseline subgroups (non-responder imputation)



[a]Spine SPARCC score ≥2 or sacroiliac joint SPARCC score ≥2. [b]Spine SPARCC score <2 and sacroiliac joint SPARCC score <2

AS, ankylosing spondylitis; ASAS40, ≥40% improvement in Assessment of SpondyloArthritis International Society criteria; BASDAI50, ≥50% improvement in Bath Ankylosing Spondylitis Disease Activity Index; BMI, body mass index; CI, confidence interval; HLA-B27, human leukocyte antigen B27; hsCRP, high-sensitivity C-reactive protein; MRI, magnetic resonance imaging; PBO, placebo; SPARCC, Spondyloarthritis Research Consortium of Canada; UPA, upadacitinib

Conclusion: Within subgroups evaluated, most patients with active AS receiving UPA 15 mg demonstrated greater improvements versus PBO in disease activity measures assessed by ASAS40, BASDAI50, and change from baseline in ASDAS(CRP). There was some evidence that gender, AS symptom duration, and baseline CRP levels seemed to influence outcomes, though results should be interpreted with caution due to small sample sizes for some subgroups.

SESSION INFORMATION

Session Date: Sunday, November 7, 2021

Session Title: Spondyloarthritis Including PsA – Treatment Poster I: Axial Spondyloarthritis (0908–0939)

Session Type: Poster Session B

Session Time: 8:30AM–10:30AM

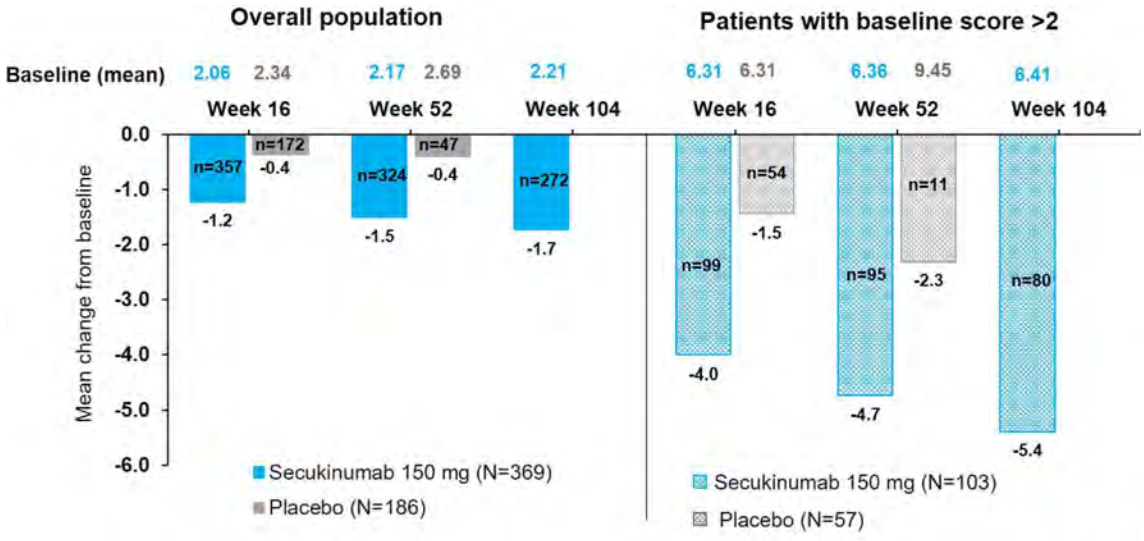
Background/Purpose: Axial spondyloarthritis (axSpA) is characterized by inflammation of the sacroiliac joints (SIJ) and the spine. Secukinumab (SEC) treatment was clinically efficacious and reduced SIJ bone marrow edema as detected by magnetic resonance imaging (MRI) in patients with non-radiographic (nr)-axSpA through 52 weeks in PREVENT (NCT02696031) study.[1] Here, we report radiographic progression and the course of inflammation as assessed by X-ray and MRI of SIJ and spine, over 2 years in the study.

Methods: Study design, key endpoints have been reported.[1] In total, 555 patients were randomized (1:1:1) to receive SEC 150mg with (LD) or without loading (NL) doses, or placebo (PBO). Switch to open-label (OL) SEC or standard of

care (SoC) was permitted after Week 20. All patients (except those who switched to SoC) received OL SEC from Week 52. Radiographs of the spine and SIJ were collected at baseline (BL) and Week 104; MR images of the spine and SIJ were collected at BL, Weeks 16, 52, and 104. Spinal radiographs were scored using the modified Stoke Ankylosing Spondylitis Spine Score (mSASSS) and SIJ radiographs according to modified New York criteria (mNYC). Spinal MR images were assessed for signs of inflammation with the Berlin score. SIJ bone marrow edema was assessed according to the Berlin Active Inflammatory Lesions Scoring. All images were evaluated in blinded fashion independently by two central readers. All data are reported from the Week 104 reading session and are presented as observed.

Results: The vast majority (98%) of patients treated with SEC 150mg (pooled LD and NL) showed no structural progression, defined as change in total mSASSS score ≤ smallest detectable change (SDC) of 0.760 (80% agreement level) over 2 years. At BL, 62 patients (43 in SEC 150mg, 19 in PBO) presented with at least one syndesmophyte (at least one vertebral unit scored by at least 1 reader). Among these patients, 9 in the SEC 150mg (20.9%) and 7 in the PBO (36.8%) groups had developed at least one new syndesmophyte by Week 104. Among 237 (SEC 150mg) and 117 (PBO) patients without syndesmophytes at BL, only 4 patients on SEC 150mg (1.7%) and 4 patients on PBO (3.4%) developed at least one new syndesmophyte by Week 104. SIJ radiographs showed that 88% (SEC 150mg) and 86% (PBO) patients had no progression in SIJ [defined as change ≤ SDC (0.458) in total mNYC score] by Week 104. No patient had an increase in that score of 2 or more. Spinal inflammation on MRI (Berlin score) was low at BL: mean 0.82 (SEC 150mg) and 1.07 (PBO) with no change at Week 104: 0.56 (SEC 150mg). SEC reduced SIJ bone marrow edema score versus PBO at Week 16 and Week 52 with sustained reduction through Week 104 in the overall patient population, with greater reduction in patients with BL score > 2 (**Figure)**.

Conclusion: Secukinumab reduced SIJ inflammation (SIJ bone marrow edema) in patients with active nr-axSpA. The majority of patients initially randomized to secukinumab or placebo showed no radiographic progression through 2 years.



Data presented are as observed. Secukinumab (pooled) included patients who continued on secukinumab to Week 104. Placebo included only patients randomized to placebo who remained on placebo to Week 52. At each time point, only patients with a value at both Baseline and that time point are included.
MRI, magnetic resonance imaging; n, number of evaluable patients; N, total number of randomized patients; SIJ, sacroiliac joint

Mean change in SIJ bone marrow edema score by MRI in the overall population and in patients with baseline score >2 through Week 104.

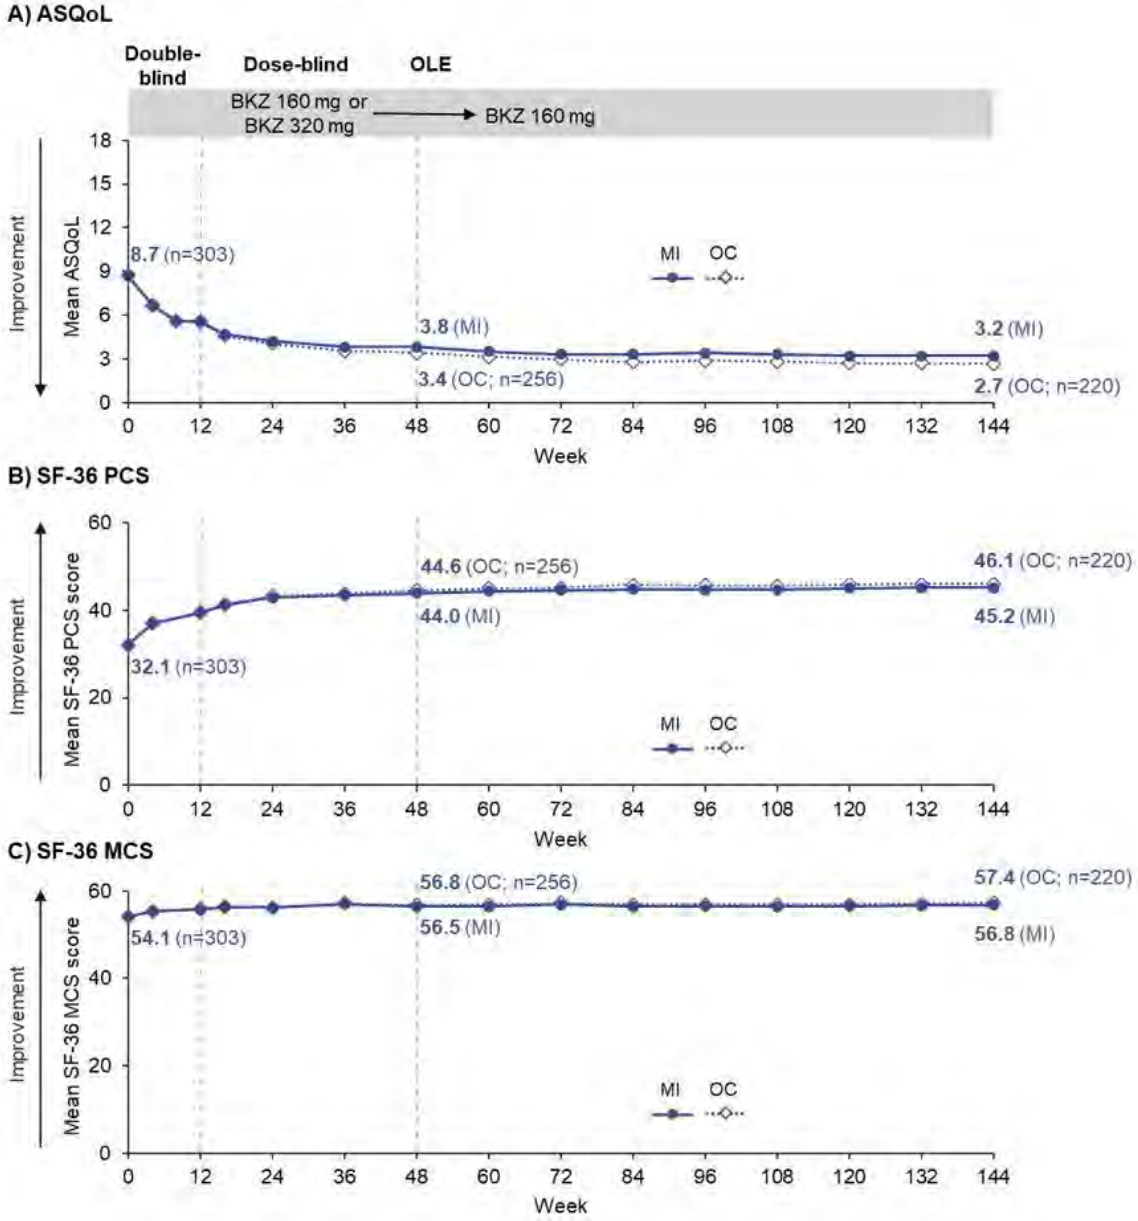
SESSION INFORMATION
Session Date: Sunday, November 7, 2021
Session Title: Spondyloarthritis Including PsA – Treatment Poster I: Axial Spondyloarthritis (0908–0939)
Session Type: Poster Session B
Session Time: 8:30AM–10:30AM

Background/Purpose: Bimekizumab (BKZ), a monoclonal IgG1 antibody that selectively inhibits both interleukin (IL)-17F and IL-17A, has been demonstrated to be efficacious and well tolerated in patients (pts) with ankylosing

spondylitis (AS) treated for up to 3 years (yrs).[1–3] We report 3-yr interim health-related quality of life (HRQoL) in pts with active AS from a 1-yr phase 2b study (BE AGILE; NCT02963506) and its ongoing 4-yr open-label extension (OLE; NCT03355573).

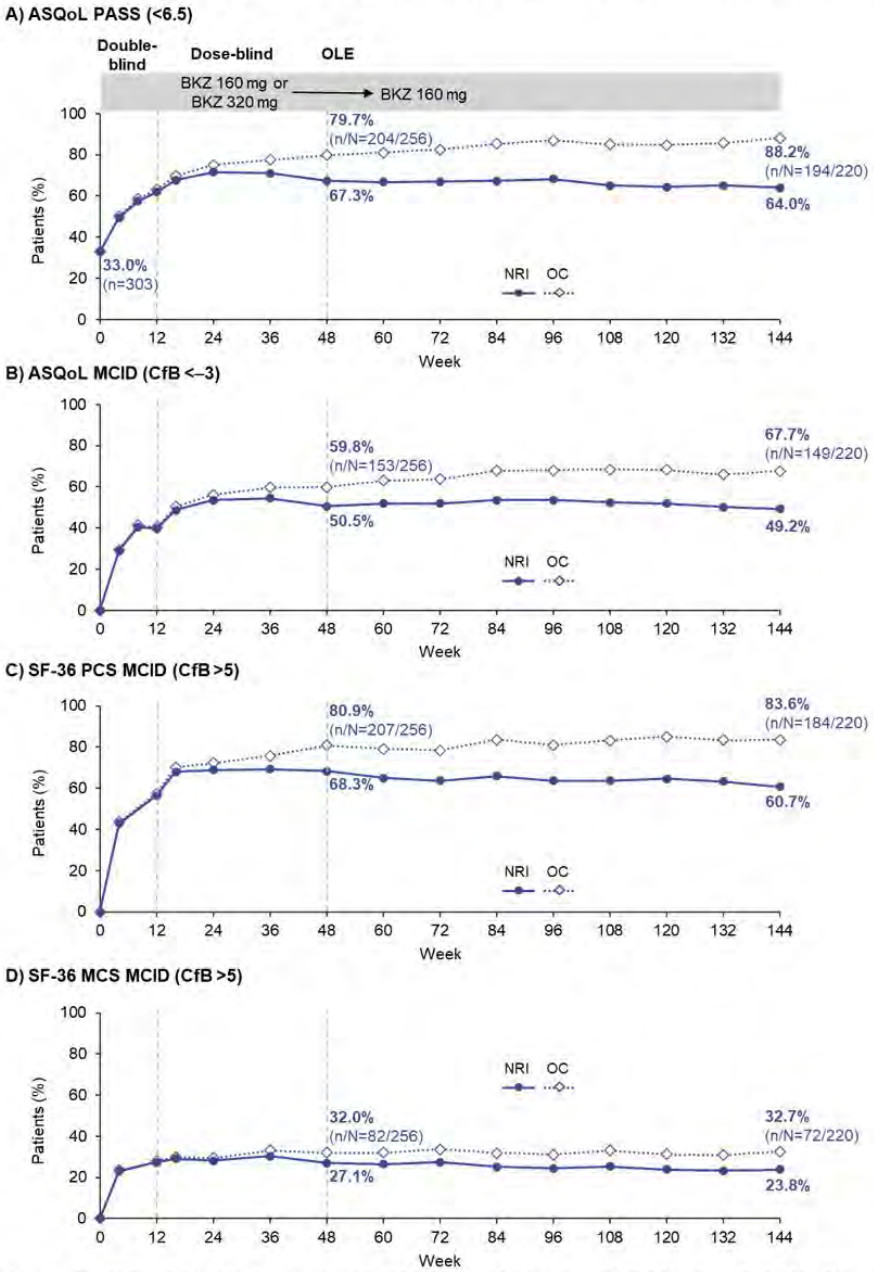
Figure 1. Change over time in HRQoL outcomes from baseline to Week 144 (multiple imputation and observed case)



Full analysis set (N=303). All patients received BKZ 160 mg during the OLE (Weeks 48–144) after completing BKZ 160 mg or 320 mg in BE AGILE. During the double-blind period (Weeks 0–12), 60/303 (19.8%) patients received placebo. MI and OC data are shown for all timepoints from BE AGILE baseline to Week 144. SF-36 MCS scores were high from baseline (≥US population normal mean score).
ASQoL: Ankylosing Spondylitis Quality of Life; BKZ: bimekizumab; HRQoL: health-related quality of life; MCS: mental component summary; MI: multiple imputation; OC: observed case; OLE: open-label extension; PCS: physical component summary; SF-36: Short Form-36.

Methods: The BE AGILE study design has been described previously.[1] Following the 12-week (wk) double-blind, placebo-controlled dose-ranging period, pts received BKZ 160 mg or 320 mg every 4 wks (Q4W) in the dose-blind period to Wk 48. Pts completing Wk 48 were eligible to enter the OLE where all pts received BKZ 160 mg Q4W.

Figure 2. Proportion of patients meeting clinically relevant thresholds for HRQoL outcomes from baseline to Week 144 (non-responder imputation and observed case)



Full analysis set (N=303). All patients received BKZ 160 mg during the OLE (Weeks 48–144) after completing BKZ 160 mg or 320 mg in BE AGILE. During the double-blind period (Weeks 0–12), 60/303 (19.8%) patients received placebo. NRI and OC data are shown for all timepoints from BE AGILE baseline to Week 144; in the NRI analyses, patients who completed BE AGILE to Week 48 but did not enter the OLE were considered non-responders from Week 48 onwards. ASQoL: Ankylosing Spondylitis Quality of Life; BKZ: bimekizumab; CfB: change from baseline; HRQoL: health-related quality of life; MCID: minimal clinically important difference; MCS: mental component summary; NRI: non-responder imputation; OC: observed case; OLE: open-label extension; PASS: patient acceptable symptom state; PCS: physical component summary; SF-36: Short Form-36.

We report HRQoL following a total of 3 yrs of treatment for the BE AGILE full analysis set (all randomized patients who received ≥1 dose of investigational medicinal product and had a valid measurement of the ASAS components at baseline). Change over time in ASQoL and SF-36 scores are reported using multiple imputation (MI) and observed case (OC) methodology. Additionally, for ASQoL, we report the proportion of pts achieving a pt acceptable symptom state (PASS) of < 6.5 and a reduction from baseline greater than a minimal clinically important difference (MCID) of 3;[4,5] for SF-36 PCS and MCS scores, we report the proportion of pts with an improvement in score greater than an MCID of 5.[6] These analyses utilized non-responder imputation (NRI) and OC methodology; for NRI, pts who did not enter the OLE were considered non-responders from Wk 48 onwards.

Results: 296/303 (97.7%) pts randomized at BE AGILE study baseline entered the dose-blind period at Wk 12; 262/303 (86.5%) pts completed Wk 48 on BKZ. At Wk 48, 256/303 (84.5%) pts entered the OLE, of whom 255 received BKZ 160 mg Q4W; 220/303 (72.6%) pts completed the HRQoL instruments at Wk 144. ASQoL and SF-36 PCS scores at baseline were indicative of impaired physical function in this patient population with long-standing disease; mean scores (both OC and MI) improved up to Wk 48 and these improvements were maintained up to Wk 144 (**Figure 1A, B**). Baseline SF-36 MCS mean was indicative of non-impaired psychological function; the slight improvement trend shown at Wk 48 was maintained over 144 wks of BKZ treatment (**Figure 1C**). At baseline, 33.0% pts were in a PASS for ASQoL (score < 6.5); this increased to 67.3% and 64.0% at Wk 48 and Wk 144 respectively in the NRI analysis, and 79.7% and 88.2% in the OC analysis (**Figure 2A**). The proportion of pts with clinically relevant improvements (≥MCID) was maintained from Wk 48 to Wk 144 for ASQoL (NRI: 50.5% to 49.2%; OC: 59.8% to 67.7%), as well as SF-36 PCS (NRI: 68.3% to 60.7%; OC: 80.9% to 83.6%) and MCS (NRI: 27.1% to 23.8%; OC: 32.0% to 32.7%; **Figure 2B–D**).

Conclusion: Clinically relevant improvements in HRQoL demonstrated at Wk 48 were sustained over 144 wks of BKZ treatment.

SESSION INFORMATION

Session Date: Sunday, November 7, 2021

Session Title: Spondyloarthritis Including PsA – Treatment Poster I: Axial Spondyloarthritis (0908–0939)

Session Type: Poster Session B

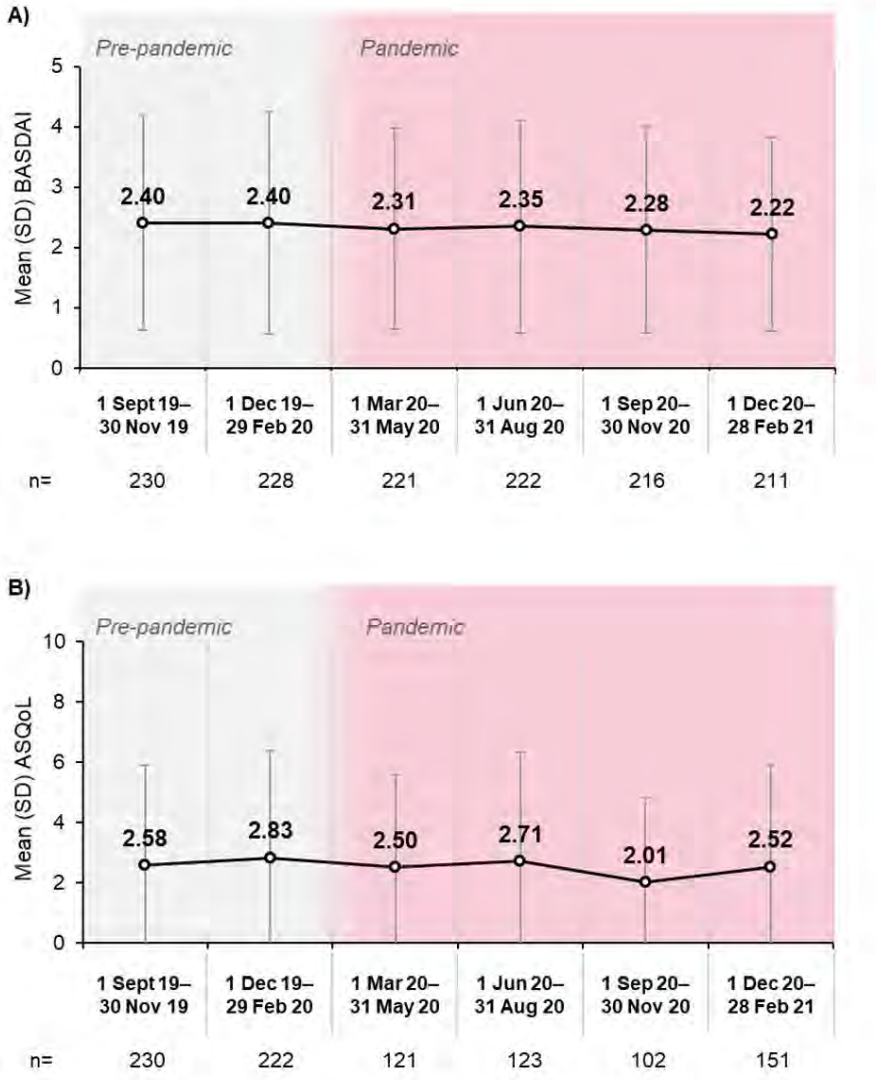
Session Time: 8:30AM–10:30AM

Background/Purpose: Bimekizumab (BKZ), a monoclonal IgG1 antibody that inhibits both interleukin (IL)-17A and IL-17F, has been demonstrated to be efficacious and well tolerated in patients (pts) with ankylosing spondylitis (AS) treated for up to 3 years in the BE AGILE study and its open-label extension (OLE).[1–3] At the start of the COVID-19 pandemic in March 2020, most pts in BE AGILE had received >3 years of BKZ treatment and outcomes were stable.[3] Findings from real-world studies evaluating the impact of the pandemic on disease activity and quality of life in pts with axial spondyloarthritis have been conflicting.[4–6] We assess whether the COVID-19 pandemic and associated societal changes have impacted pt-reported disease activity and health-related quality of life (HRQoL) among pts with active AS receiving BKZ in the ongoing OLE (NCT03355573) of a phase 2b dose-ranging study (BE AGILE; NCT02963506).

Methods: The BE AGILE study design has been described previously.[1] Pts treated with BKZ 160 mg or 320 mg every 4 weeks (Q4W) at Week 48 in BE AGILE were eligible for OLE entry. All OLE pts received BKZ 160 mg Q4W. For the OLE full analysis set, we report descriptive statistics for BASDAI (measured every 12 weeks) to show overall disease activity and Ankylosing Spondylitis Quality of Life (ASQoL; measured every 12 weeks up to Week 156, then every 24 weeks) to show HRQoL for selected time periods before and during the pandemic. For this post hoc analysis, the start of the pandemic was defined as 11 March 2020, as per the World Health Organization's declaration. Analyses included data collected between September 2019–April 2021.

Results: Of the 255 pts (safety set) who entered the OLE and received BKZ 160 mg, 229 (89.8%) were based in Eastern Europe (most were from Poland [n=89; 34.9%], the Czech Republic [n=72; 28.2%] or Russia [n=32; 12.5%]), 18 (7.1%) in Western Europe and 8 (3.1%) in North America. Study discontinuation rate was low, with 224/255 (87.8%) pts remaining in the study at Week 156; very few BKZ doses and study visits were missed for any reason. Across 3-monthly periods before and during the pandemic, BASDAI or ASQoL scores appeared to be stable (**Figure 1**). During the pandemic period between March 2020 and April 2021, there were no notable changes in these outcomes since the last pre-pandemic visit (last visit before 11 March 2020; **Figure 2**).

Figure 1. Mean (A) BASDAI and (B) ASQoL scores during the pre-pandemic and pandemic periods in patients receiving BKZ 160 mg Q4W during the BE AGILE OLE (observed data)



Data are reported for the OLE full analysis set (patients who entered the OLE and had ≥1 dose of BKZ and ≥1 valid efficacy variable measurement in the OLE; N=254). Error bars show SD. Patient numbers appear lower for ASQoL than BASDAI during the pandemic period because ASQoL assessments were conducted every 24 weeks from Week 156, whereas BASDAI assessments were conducted every 12 weeks. Data for the period 1 Mar 2021–30 Apr 2021 are not shown as data were only available for a limited number of patients at the time of writing. ASQoL: Ankylosing Spondylitis Quality of Life; BASDAI: Bath Ankylosing Spondylitis Disease Activity Index; BKZ: bimekizumab; OLE: open-label extension; SD: standard deviation; Q4W: every 4 weeks.

Conclusion: In pts with AS receiving BKZ in this OLE study, disease activity (BASDAI) and HRQoL (ASQoL) remained stable during the pandemic; there was no indication that the pandemic had a detrimental impact on these outcomes. Our findings, which differ from some recent real-world studies evaluating the impact of the pandemic on pts with rheumatic disease,[4–6] may partly reflect the clinical trial setting of this study.

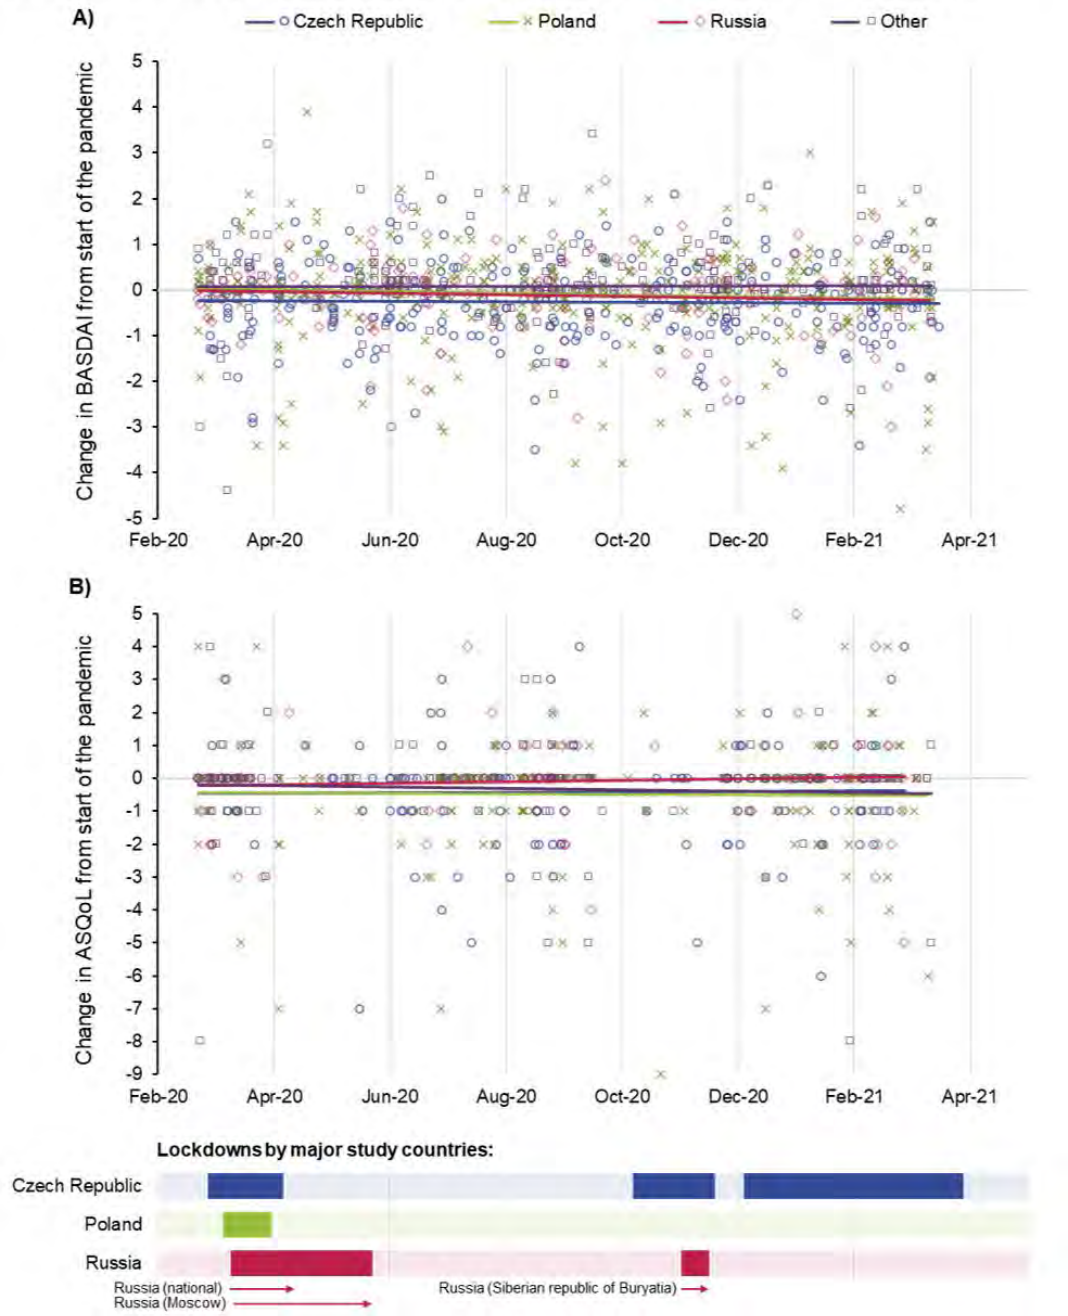
Figure 2. Change in (A) BASDAI and (B) ASQoL scores since the start of the pandemic in patients receiving BKZ 160 mg Q4W during the BE AGILE OLE (observed data)



The start of the pandemic is defined as the last visit before 11 March 2020. Each marker represents a single patient visit; linear trendlines for each of the countries/regions are shown. Data are reported for the OLE full analysis set (N=254). Patient numbers appear lower for ASQoL than BASDAI because ASQoL assessments were conducted every 24 weeks from Week 156, whereas BASDAI assessments were done every 12 weeks. Lockdowns (national, unless otherwise indicated) for the major study countries are shown by dark-colored bars. ASQoL: Ankylosing Spondylitis Quality of Life; BASDAI: Bath Ankylosing Spondylitis Disease Activity Index; BKZ: bimekizumab; OLE: open-label extension; SD: standard deviation; Q4W: every 4 weeks.

SESSION INFORMATION
Session Date: Sunday, November 7, 2021
Session Title: Spondyloarthritis Including PsA – Treatment Poster I: Axial Spondyloarthritis (0908–0939)
Session Type: Poster Session B
Session Time: 8:30AM–10:30AM

Background/Purpose: The objective of this long-term analysis of the SELECT-AXIS 1 study was to report safety and efficacy of upadacitinib (UPA) in active AS through 2 years.

Methods: SELECT-AXIS 1 (NCT03178487) included a placebo-controlled, 14-week (wk) period followed by a 90-wk open-label extension.[1] The study enrolled patients (pts) with active AS (fulfilling modified New York criteria) who had an inadequate response to NSAID therapy and were biologic DMARD naive. At baseline (BL), pts were randomized to UPA 15 mg once daily (QD) or PBO; at wk 14, pts continued to receive UPA 15 mg QD (continuous UPA) while PBO pts were switched to UPA. Efficacy assessments related to signs and symptoms included Assessment of SpondyloArthritis international Society (ASAS) 40 response, ASAS partial remission (PR) and AS Disease Activity Score (ASDAS) inactive disease (ID) and low disease activity (LDA). Imaging assessments included changes from BL in MRI Spondyloarthritis Research Consortium of Canada (*SPARCC*) spine and SI joint scores and in modified Stoke Ankylosing Spondylitis Spine Score (mSASSS) at wk 104. As observed (AO) and non-responder imputation (NRI) data for binary endpoints and mixed-effect model repeated measures for continuous efficacy endpoints are reported. UPA treatment-emergent adverse events (AEs) were monitored throughout the study.

Results: Of 187 pts randomized at BL, 178 pts (each n=89 for UPA and PBO) completed wk 14 on study drug and entered the open-label extension; 144 pts (77%) completed wk 104 (UPA, n=71; PBO to UPA, n=73). ASAS40 response was maintained through 2 years among pts receiving continuous UPA; similar results at wk 104 were observed among pts who switched from PBO to UPA at wk 14 (**Figure)**. A similar pattern and maintenance of response was

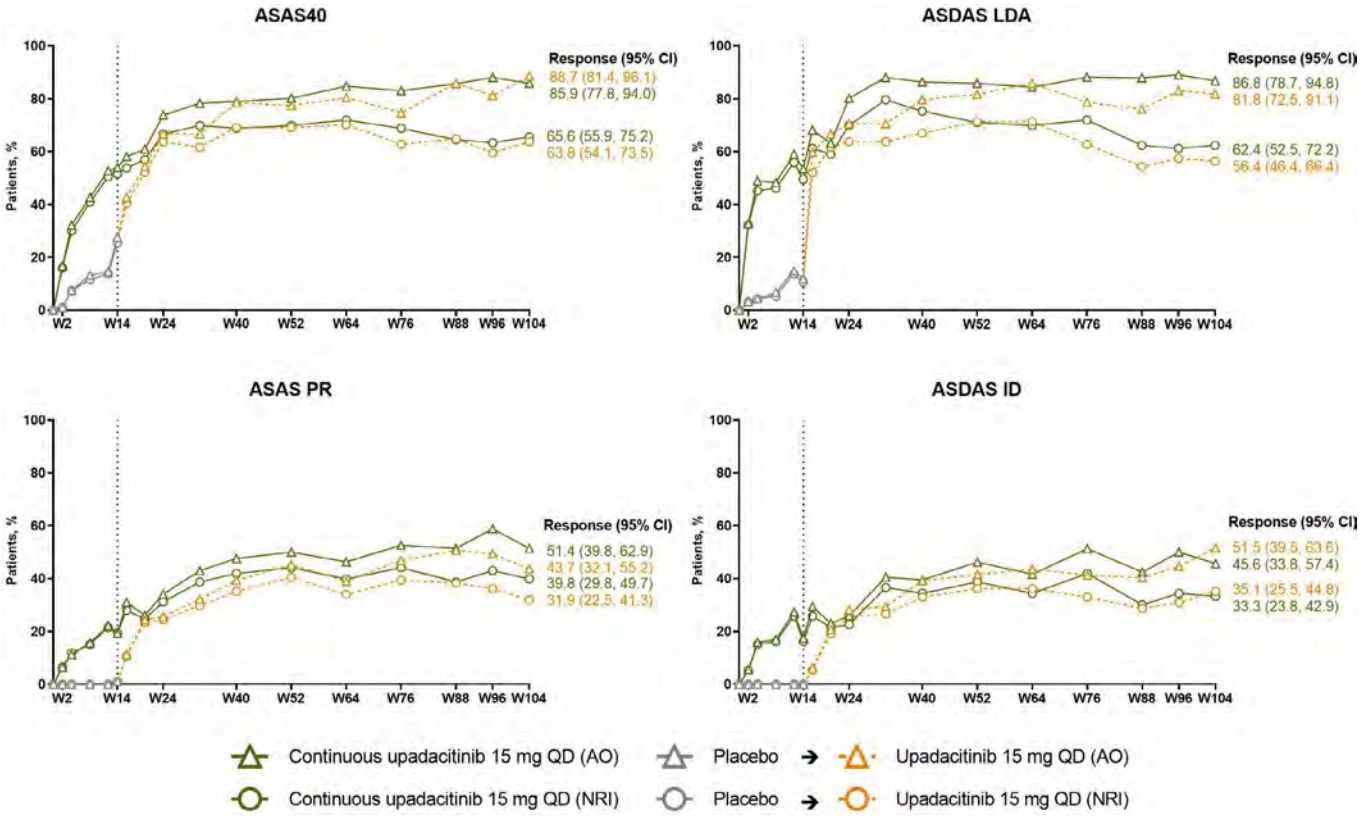

Figure 1. Clinical Efficacy Endpoints Over Time.

Table 1. Baseline Mean and Mean Change From Baseline in MRI SPARCC score and mSASSS.

Mean (95% CI)	UPA 15 mg QD	PBO to UPA 15 mg QD	Total
MRI SPARCC Spine*			
Baseline, mean (SD)	11.3 (15.4) n=85	12.7 (16.5) n=81	12.0 (15.9) n=166
Week 14, mean (95% CI) Δ	−7.2 (−10.2, −4.2) n=69	−2.0 (−3.7, −0.2) n=60	—

Δ, change from baseline; mSASSS, modified Stoke Ankylosing Spondylitis Spine Score; SPARCC, Spondyloarthritis Research Consortium of Canada.
95% CIs are calculated based on the t-distribution.
*Data were obtained in a dedicated reading session that included baseline, week 14, and week 104 images.

Table 2. Treatment-emergent Adverse Events Throughout the Study.

Events (E/100 PY)	Any UPA 15 mg QD N=182 (308.6 PY)
AE	749 (242.7)
Serious AE	19 (6.2)
AEs leading to discontinuation	17 (5.5)
Infections	246 (79.7)
Opportunistic infections excluding TB and herpes zoster*	2 (0.6)
Herpes zoster†	5 (1.6)
Creatine phosphokinase elevation‡	35 (11.3)
Hepatic disorder§	32 (10.4)
Neutropenia‖	9 (2.9)
Anemia‖	5 (1.6)
Lymphopenia‖	3 (1.0)
Malignancy¶	1 (0.3)
Adjudicated venous thromboembolic events**	1 (0.3)
Inflammatory bowel disease††	1 (0.3)
Uveitis‡‡	16 (5.2)
Deaths	0

AE, adverse events; PY, patient years; QD, once daily; TB, tuberculosis; UPA, upadacitinib
*Two non-serious events of esophageal candidiasis in the same patient.
†Five events in 4 patients (3 from Japan); all non-serious, mild or moderate, and limited to 1 dermatome.
‡All but 1 event were non-serious and none led to study drug discontinuation; majority were asymptomatic, and the 3 symptomatic patients had muscle pain due to alternative explanations, such as increased physical activity
§Majority based on asymptomatic alanine aminotransferase/aspartate aminotransferase elevations; all were non-serious and none led to study drug discontinuation.
‖All events were non-serious and none led to study drug discontinuation.
¶Squamous cell carcinoma of tongue (stage IV) in 61-year-old male former smoker (approximately 40 pack-years).
**Pulmonary embolism in 1 female patient with history of thrombosis of the lower leg prior to study entry, impaired glucose tolerance, cigarette smoking, sedentary lifestyle, and obesity.
††Event of colitis with appendix swelling in patient with no prior history of inflammatory bowel disease.
‡‡16 uveitis AEs in 10 patients; 9 patients were HLA-B27 positive, 9 patients had a history of uveitis, and 15 of 16 events were mild or moderate. Most events were transient, resolved with local treatment (corticosteroid eye drop), and did not lead to interruption of study drug or study drug discontinuation (except 1 patient with mild uveitis who discontinued the study); all were non-serious.

also observed for other efficacy endpoints (**Figure**). MRI SPARCC spine and SI joint scores decreased from BL to wk 14 and were maintained thereafter to wk 104 with continuous UPA; a similar magnitude of decrease was seen at wk 104 in pts who switched from PBO to UPA at wk 14 (**Table 1**). The mean (95% CI) change from BL to wk 104 in the mSASSS was 0.68 (0.27, 1.09) in the total group (**Table 1**). Overall UPA treatment-emergent AE rate was 242.7/100 patient-years (PY). Infections were the most common AEs; no serious infections, active tuberculosis, adjudicated major adverse cardiovascular events, lymphoma, non-melanoma skin cancer, renal dysfunction, or gastrointestinal perforations were observed. Five (1.6/100 PY) non-serious herpes zoster infections (limited to 1 dermatome), 1 event of colitis (0.3/100 PY), 16 (5.2/100 PY) non-serious uveitis events (mostly in HLA-B27 positive pts with a history of uveitis), and 35 (11.3/100 PY) mostly asymptomatic and transient events of creatine phosphokinase elevation were observed throughout the 2 years among pts receiving UPA (**Table 2**).

Conclusion: UPA 15 mg QD showed sustained and consistent efficacy over 2 years for ASAS40 (primary endpoint) and other clinically relevant endpoints (ASDAS ID, ASDAS LDA, and ASAS PR). A low rate of radiographic progression was observed based on spinal radiographs. No new safety findings were observed.

Abstract Number: 0925

Impact of Achieving ASDAS LDA on Disease Activity and Patient-Reported Outcome Measures Among Patients with Ankylosing Spondylitis Treated with Biologic DMARDs

Philip Mease[1], Robert McLean[2], Taylor Blachley[2], Maya Marchese[2], Laura Anatale-Tardiff[3], Christopher Saffore[4], Danny Quach[5], Ana Biljan[6] and Alexis Ogdie[7], [1]Swedish Medical Center/Providence St. Joseph Health and University of Washington, Seattle, WA, [2]CorEvitas, LLC, Waltham, MA, [3]CorEvitas, Waltham, MA, [4]AbbVie, North Chicago, IL, [5]AbbVie Inc., North Chicago, IL, [6]Abbvie Inc., Chicago, IL, [7]University of Pennsylvania, Philadelphia, PA

SESSION INFORMATION
Session Date: Sunday, November 7, 2021
Session Title: Spondyloarthritis Including PsA – Treatment Poster I: Axial Spondyloarthritis (0908–0939)
Session Type: Poster Session B
Session Time: 8:30AM–10:30AM

Background/Purpose: Although Ankylosing Spondylitis Disease Activity Score (ASDAS) low disease activity (LDA) is a common treatment target for disease control when managing AS, real-world research describing ASDAS LDA achievement among patients treated with biologic DMARDs (bDMARD) is limited. The aim of this study was to describe disease activity and patient-reported outcome measures (PROMs) among patients with AS who achieved and did not achieve ASDAS LDA after 6 months of bDMARD treatment.

Methods: This analysis included patients diagnosed with AS in CorEvitas' PsA/SpA Registry, a prospective, observational, disease-based registry. Eligible patients initiated bDMARD treatment (baseline) between March 2013 and March 2021, were not in ASDAS LDA at initiation, and had a 6-month follow-up visit. Baseline demographic and clinical characteristics were compared between patients who did and did not achieve ASDAS LDA (ASDAS < 2.1) at follow-up using t-tests, Wilcoxon ranked-sum tests, chi-square tests, or Fisher exact tests. Clinical outcomes at 6 months (assessment in AS [ASAS] 20, 40, and partial remission [PR]) were described for both groups.

Results: Of 130 patients, 25% (n=33) achieved ASDAS LDA 6 months after bDMARD initiation and 75% (n=97) did not. At baseline, a greater percentage of ASDAS LDA achievers were naïve to conventional DMARDs (79% vs 58%; *P*=0.03), and ASDAS LDA achievers were more likely to be naïve to bDMARDs (76% vs 44%; *P*=0.002; **Table 1**). AS-

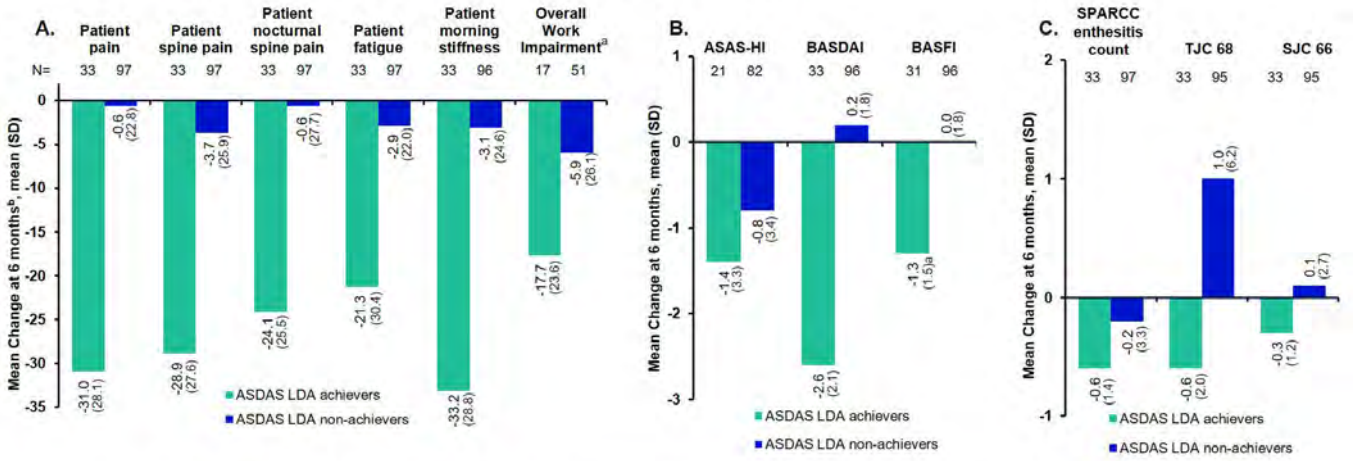
TJC 68, mean ± SD	1.7 ± 2.7	4.9 ± 8.9	0.02
SJC 66, mean ± SD	0.9 ± 1.8	1.5 ± 3.4	0.25

[a]*P*-values from two sample t-tests or Wilcoxon ranked-sum tests for continuous variables, and from chi-square or Fisher exact tests for categorical variables. [b]Defined as CRP >0.8 mg/dL. [c]Enthesitis was defined as SPARCC index score ≥1. [d]Measured using a 100-point visual analog scale. [e]Only measured for those reporting that they are working at baseline (n = 106). ASAS-HI, Assessment of Spondyloarthritis International Society Health Index; ASDAS, Ankylosing Spondylitis Disease Activity Score; AS, ankylosing spondylitis; BASDAI, Bath Ankylosing Spondylitis Disease Activity Index; BASFI, Bath Ankylosing Spondylitis Functional Index; BMI, body mass index; CRP, C-reactive protein; HLA-B27, human leukocyte antigen B27; IBD, irritable bowel disease; LDA, low disease activity; N/A, not applicable; SD, standard deviation; SJC 66, swollen joint count 66; SPARCC, Spondyloarthritis Research Consortium of Canada; TJC 68, tender joint count 68; y, year.

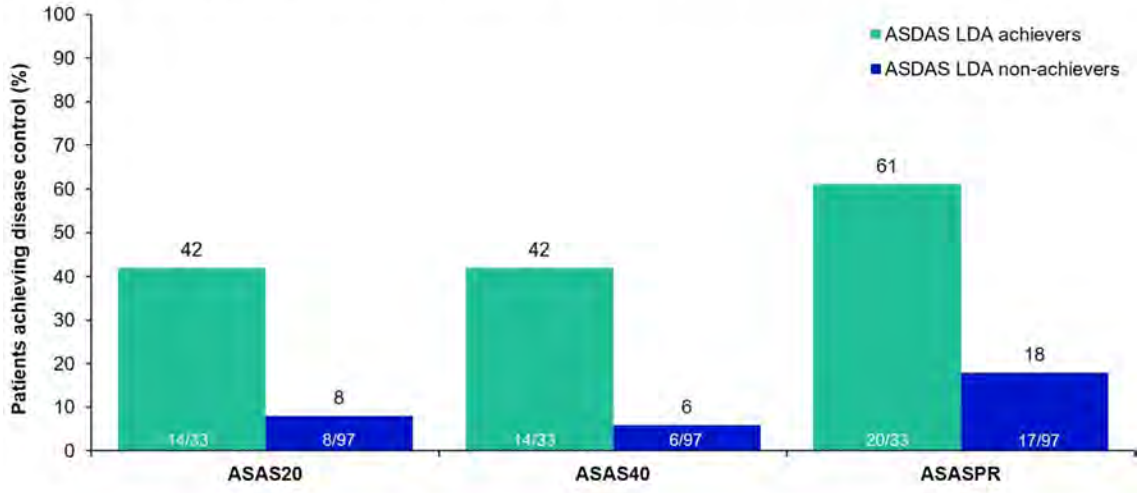
DAS LDA achievers were less likely to be women compared with the non-achiever group (34% vs 62%; *P*=0.01). A higher number of ASDAS LDA non-achievers had comorbidities such as depression, uveitis, and inflammatory bowel disease. After 6 months of bDMARD therapy, those who achieved ASDAS LDA reported substantial improvements (mean change [standard deviation]) in PROMs (measured on a 0-100-point visual analog scale), including patient-

Figure 1. Mean change in patient-reported outcome and clinical evaluation measures among ASDAS LDA achievers and non-achievers who initiated a biologic DMARD, from baseline to 6 months



[a]Overall work impairment was only assessed in patients who reported current employment. [b]All assessments are measured on a 0-100 visual analog scale (Panel A). ASAS-HI, assessment of spondyloarthritis international society health index; ASDAS, ankylosing spondylitis disease activity score; BASDAI, bath ankylosing spondylitis disease activity index; BASFI, bath ankylosing spondylitis functional index; LDA, low disease activity; SJC 66, swollen joint count 66; SPARCC, Spondyloarthritis Research Consortium of Canada; TJC 68, tender joint count 68.

Figure 2. Disease control among ASDAS LDA achievers and non-achievers who initiated a biologic DMARD, from baseline to 6 months



ASAS20, assessment in ankylosing spondylitis, 20% improvement; ASAS40, assessment in ankylosing spondylitis, 40% improvement; ASASPR, assessment in ankylosing spondylitis, partial remission; ASDAS, ankylosing spondylitis disease activity score; LDA, low disease activity.

reported pain (-31.0 [28.1]), spine pain (-28.9 [27.6]), nocturnal spine pain (-24.1 [25.5]), fatigue (-21.3 [30.4]), morning stiffness (-33.2 [28.8]), and overall work impairment (-17.7 [23.6]) (**Figure 1A**). ASDAS LDA achievers had improved clinical characteristics of peripheral arthritis, including Spondyloarthritis Research Consortium of Canada enthesitis count (mean change [standard deviation]; -0.6 [1.4]), tender joint count (-0.6 [2.0]), and swollen joint count (-0.3 [1.2]) (**Figure 1B-C**). Patients with ASDAS LDA achievement had numerically higher rates of ASAS20, ASAS40, and ASASPR attainment than non-achievers (42% vs 8%, 42% vs 6%, 61% vs 18%, respectively) (**Figure 2**).

Conclusion: Among our real-world patients with AS, those who achieved ASDAS LDA demonstrated substantial improvements in PROMs and achievement of key clinical milestones of ASAS20, ASAS40, and ASASPR, suggesting ASDAS LDA as an important target for disease control when managing patients with AS. Key patient characteristics

such as sex and comorbidities were different between patients who did and did not achieve ASDAS LDA and may need to be considered when managing patients with AS.

Predictors of 1-Year Treatment Response Among Upadacitinib-Treated Patients with Ankylosing Spondylitis: A Post Hoc Analysis

Marina Magrey[1], Sofia Ramiro[2], Marcelo Medeiros Pinheiro[3], Tianming Gao[4], Fabiana Ganz[4], In-Ho Song[4], Ana Biljan[5], Nigil Haroon[6] and Martin Rudwaleit[7], [1]Case Western Reserve University, MetroHealth Medical Center, Cleveland, OH, USA, Richfield, OH, [2]Leiden University Medical Center, Leiden, Netherlands, [3]Universidade Federal de São Paulo, São Paulo, Brazil, [4]AbbVie Inc., North Chicago, IL, [5]Abbvie Inc., Chicago, IL, [6]Division of Rheumatology, Toronto Western Hospital, University of Toronto, Toronto, ON, Canada, [7]University of Bielefeld, Klinikum Bielefeld, Bielefeld, Germany

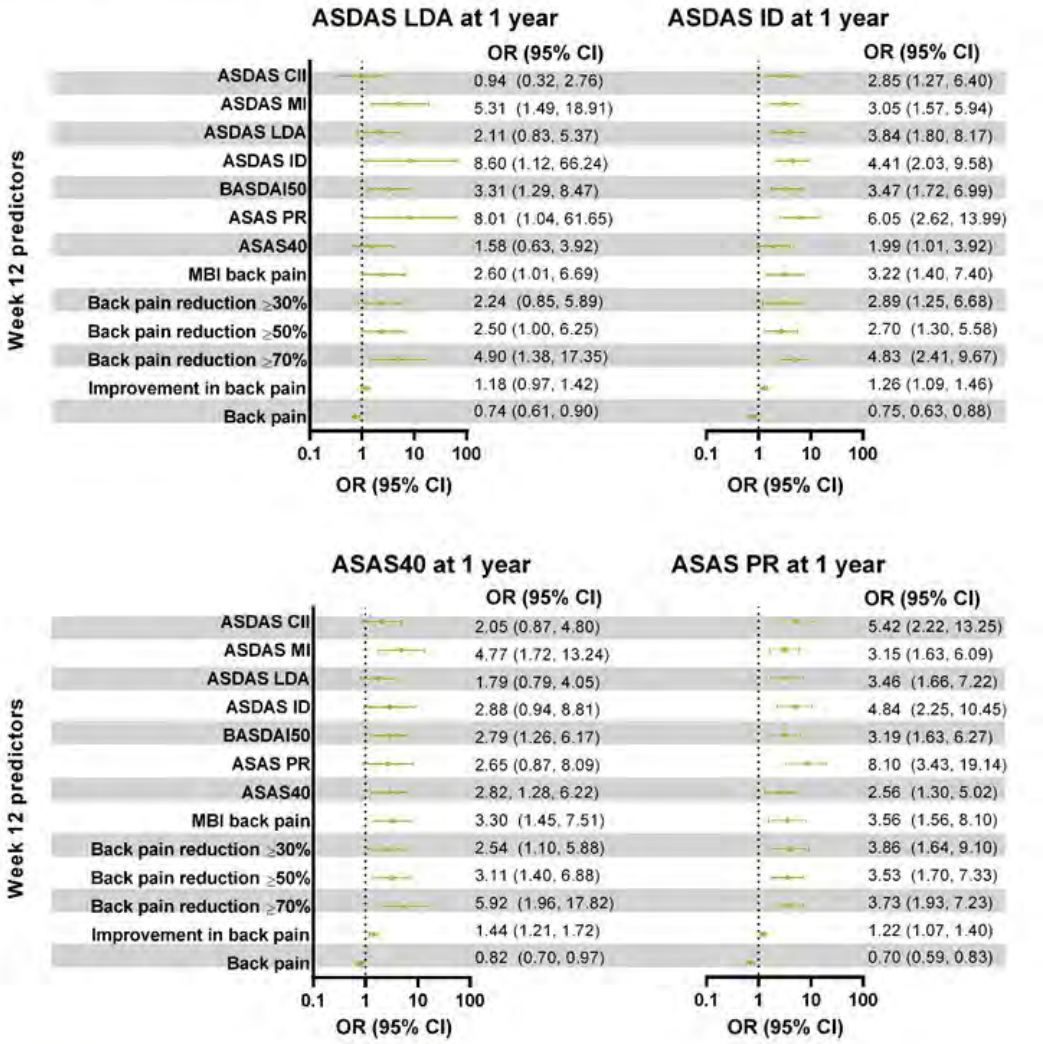
SESSION INFORMATION
Session Date: Sunday, November 7, 2021
Session Title: Spondyloarthritis Including PsA – Treatment Poster I: Axial Spondyloarthritis (0908–0939)
Session Type: Poster Session B
Session Time: 8:30AM–10:30AM

Background/Purpose: Upadacitinib (UPA) is an oral Janus kinase inhibitor that has demonstrated efficacy and safety among patients with ankylosing spondylitis (AS) in the phase 2/3 SELECT-AXIS 1 study.1 If identified, early predictors of treatment response may inform treat-to-target strategies and optimize patient outcomes in AS. The objective of this analysis was to determine whether baseline (BL) characteristics or early responses predict clinical response at 1 year in UPA-treated patients with AS.

Methods: In the double-blind, randomized, placebo (PBO)-controlled SELECT-AXIS 1 study, patients received UPA 15 mg once daily or PBO until Week 14.[1] At Week 14, PBO-treated patients switched to UPA 15 mg; patients originally randomized to UPA continued UPA therapy. Data from patients in the PBO and UPA arms were combined based on overall exposure to UPA; in the switch arm, exposure was defined as current visit minus 14 weeks (time of switch). The following outcomes were assessed at 1 year: Ankylosing Spondylitis Disease Activity Score with C-reactive protein (ASDAS[CRP]) inactive disease (ID; < 1.3) and low disease activity (LDA; < 2.1), Assessment of SpondyloArthritis International Society (ASAS) partial remission (PR), and ≥40% improvement in ASAS criteria (ASAS40) response. The ability of BL characteristics, efficacy at Week 12, and back pain at Week 12 to predict 1-year outcomes was assessed using a univariable logistic regression model generating odds ratios (ORs; 95% confidence intervals). LASSO regression was used to select the best-fitted multivariable model at Week 12 for each outcome measure.

Results: Among 187 patients who received or switched to UPA 15 mg, 70 (37.4%), 134 (71.7%), 73 (39.0%), and 131 (70.1%) achieved ASDAS(CRP) ID, ASDAS(CRP) LDA, ASAS PR, and ASAS40, respectively, following 1 year of UPA treatment. No meaningful predictors of 1-year efficacy outcomes were identified based on BL demographics

Figure Association between Week 12 response or back pain at Week 12 and achievement of efficacy outcomes at 1 year (univariable analysis)



All ASDAS scores are calculated using C-reactive protein

ASDAS CII: change from BL ≥1.1; ASDAS MI: change from BL ≥2.0; MBI back pain: ≥2-point reduction in absolute score and ≥33% reduction from BL on a 0–10 NRS

ASAS, Assessment of SpondyloArthritis International Society; ASAS40, ≥40% improvement in ASAS criteria; ASDAS, Ankylosing Spondylitis Disease Activity Score; BASDAI50, ≥50% improvement in the Bath Ankylosing Spondylitis Disease Activity Index; BL, baseline; CI, confidence interval; CII, clinically important improvement; ID, inactive disease; LDA, low disease activity; MBI, much better improvement; MI, major improvement; NRS, numeric rating scale; OR, odds ratio; PR, partial remission

(including disease duration, gender, and human leukocyte antigen B27 status) or BL disease characteristics (including ASDAS, Bath Ankylosing Spondylitis Disease Activity Index, and CRP levels). In univariable analyses, Week 12 responses based on several disease activity measures and patient-reported outcomes (PROs), including reductions

(much better improvement [MBI], ≥30/≥50/≥70% reduction, or improvement) in back pain score, along with lower scores for back pain at Week 12, were associated with the achievement of ASDAS(CRP) ID, ASDAS(CRP) LDA, ASAS PR, and ASAS40 at 1 year (**Figure**). In a multivariable analysis, improvement from BL to Week 12 in back pain score consistently predicted several efficacy outcomes at 1 year.

Conclusion: In upadacitinib-treated patients with AS, improvement in PROs and reduction in back pain score at 12 weeks predicted clinical outcomes at 1 year.

Whole Blood Transcriptional Changes Following Treatment with Filgotinib in Patients with Ankylosing Spondylitis

Denis Poddubnyy[1], Yihua Liu[2], William Barchuk[3], Robin Besuyen[4], René Galien[5], Yuan Tian[2], Vlad Malkov[2] and Angie Hertz[2], [1]Department of Rheumatology, Charité – Universitätsmedizin, Berlin, Germany, [2]Gilead Sciences, Foster City, CA, [3]Gilead Sciences, Inc., Foster City, CA, [4]Galapagos BV, Leiden, Netherlands, [5]Galapagos NV, Romainvulle, France

SESSION INFORMATION
Session Date: Sunday, November 7, 2021
Session Title: Spondyloarthritis Including PsA – Treatment Poster I: Axial Spondyloarthritis (0908–0939)
Session Type: Poster Session B
Session Time: 8:30AM–10:30AM

Background/Purpose: Ankylosing spondylitis (AS) – also referred to as radiographic axial spondyloarthritis – is a chronic inflammatory disease that affects the sacroiliac joints and spine. Inhibition of Janus kinase 1 (JAK1) has the potential to simultaneously block multiple inflammatory pathways and lessen disease severity. In the recently completed TORTUGA study, filgotinib (FIL), a preferentially selective JAK1 inhibitor, significantly reduced AS disease activity compared with placebo (PBO).[1] The current study was conducted to evaluate the impact of FIL on transcriptional biomarkers in adult patients with active AS from the TORTUGA study.

Methods: TORTUGA (Clinicaltrials.gov identifier: NCT03117270) is a phase 2 double-blind, PBO-controlled study in which 116 AS patients with an inadequate response to >1 NSAID were randomized 1:1 to receive FIL 200 mg or PBO orally once daily for 12 weeks. Whole blood samples from patients were collected in PAXgene tubes at baseline and weeks 1, 4 and 12. Illumina TruSeq Stranded mRNA (50M 100bp PE) was generated for 414 samples from 96 patients, FIL 200 (n=49) and PBO (n=47). Gene-level quantification of RNA-seq counts and transcripts/million (TPMs) was conducted using Salmon (v0.8.2, and gencode GRCh38.p7 v25). Pathway analysis was performed using single sample gene set enrichment analysis (ssGSEA) based on Hallmark 50 pathways from the MSigDB. Treatment effect was evaluated using differential expression analysis by limma.

Results: The JAK-STAT, Inflammatory Response, Complement and Coagulation Hallmark 50 pathways were significantly correlated with the C-reactive protein (CRP) levels at baseline, whereas ASDAS correlated with Inflammatory

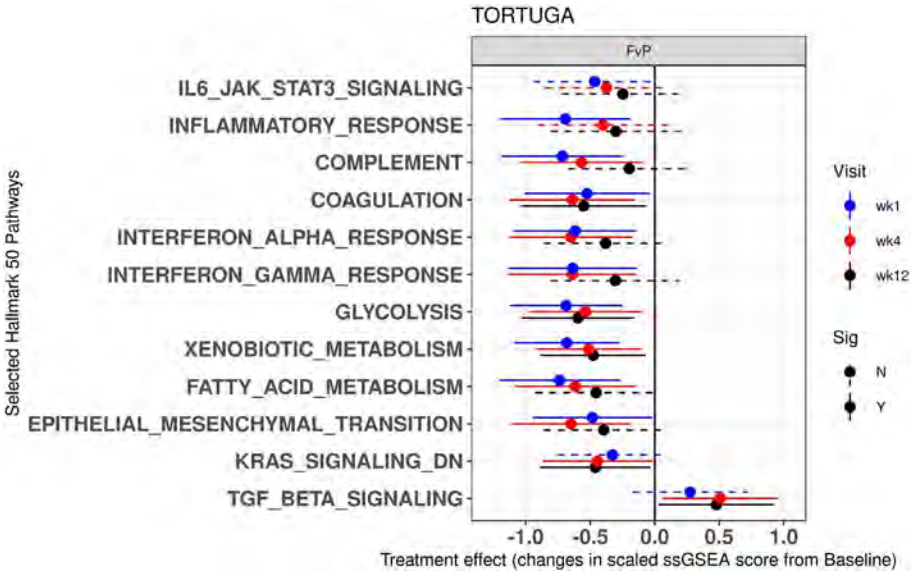

Figure 1. Filgotinib treatment effect on selected Hallmark 50 pathways. Whole blood transcriptomic analysis of PBO-subtracted FIL gene expression changes at weeks 1, 4 and 12 compared to baseline. Center dots represent the mean changes of the pathway ssGSEA scores from baseline and the horizontal bar indicate the 95% CI. Treatment effect significance at each time point is indicated by a solid line and is based on the nominal p-value generated by Limma.

Response and Coagulation pathways, among others. Treatment with filgotinib rapidly decreased several immune pathways at week 1 (Coagulation, Inflammatory Response Complement, Interferon), metabolic pathways (Glycolysis, Fatty Acid Metabolism) and increased the TGF-β Signaling pathway at weeks 4 and 12 (Figure 1). At the gene level, CRP-associated genes such as FAM20A, as well as the JAK-STAT pathway member CISH were downregulated following treatment with FIL.

Changes in circulating cellular composition were observed following filgotinib treatment comprising a decrease in percentage of neutrophils (weeks 1, 4), a transient decrease in monocytes (weeks 1, 4), an increase in B cells (weeks 4, 12) and a transient increase in lymphocytes (weeks 1, 4). These cellular fluctuations accounted for a portion of the changes in gene expression observed, including loss of some gene expression changes over time and upregulation of many genes at weeks 4 and 12.

Conclusion: In patients with active AS, FIL treatment meaningfully decreased inflammatory pathways and genes associated with disease activity in AS, and increased TGF-β signaling pathways as a result of changes in inflammatory gene expression and alterations in circulating cellular composition.

Session Title: Spondyloarthritis Including PsA – Treatment Poster I: Axial Spondyloarthritis (0908–0939)

Session Type: Poster Session B

Session Time: 8:30AM–10:30AM

Background/Purpose: Ankylosing spondylitis (AS) – also referred to as radiographic axial spondyloarthritis – is a chronic inflammatory disease that affects the sacroiliac joints and spine. In the recent TORTUGA study, filgotinib (FIL), a preferentially selective Janus kinase 1 (JAK1) inhibitor, significantly reduced AS disease activity compared with placebo (PBO).[1] JAK1 inhibition by FIL has the potential to block multiple inflammatory pathways. Thus, we analyzed circulating biomarker concentrations in samples from adult patients with active AS in TORTUGA and age, gender and BMI-matched healthy volunteers (HV) using exploratory multiplex biomarker panels and high sensitivity immunoassays to assess the impact of disease on circulating biomarkers at baseline and evaluate the effect of FIL treatment over 12 weeks.

Methods: TORTUGA (Clinicaltrials.gov identifier NCT03117270) was a 12-week, randomized, double-blind, placebo-controlled, phase 2 study. Patients were randomized 1:1 to FIL 200 mg (n=58) or PBO (n=58) once-daily and serum and plasma samples (FIL n=56, PBO n=53) were collected at baseline (BL) and weeks 1, 4 and 12. The samples were analyzed using immunoassays from Meso Scale Diagnostics (Rockville, MD, USA), EMD Millipore (Burlington, MA, USA), Nordic Biosciences (Herlev, Denmark) and Nexelis (Seattle, WA, USA). Biomarker concentration changes from BL were analyzed on paired patient data and reported for weeks 1, 4 and 12, and clustering analysis was performed. Correlation between the biomarkers and selected clinical scores were assessed by Spearman rank correlation analysis. Mean of log-fold-changes in biomarker levels from BL to week 4 and week 12 were compared between arms using PBO-adjusted estimates from a linear mixed effects model.

Results: Five clusters of biomarker response were identified based on the kinetics and magnitude of percent changes from BL with FIL treatment. As compared to PBO, a reduction in the inflammatory biomarkers CRP, SAA and IL-6 was observed, as well as a reduction in matrix metalloproteinase-degraded collagen fragments C1M, C3M, C6M and MMP1 (Figure 1). The change in several of these biomarkers correlated with changes in numerous clinical characteristics from BL to week 12, notably a correlation of MMP1, C6M and ICAM1 with Ankylosing Spondylitis Disease Activity Score (ASDAS), CRP, Spondyloarthritis Research Consortium of Canada (SPARCC) MRI spine score and patient-reported pain. Comparisons to HV were made on a subset of biomarkers and BL ICAM1 and VCAM1 were elevated in AS patients as compared to HV. However, after 1 week of treatment with FIL, both were reduced to levels comparable to HV and remained low for the 12-week duration of the study.

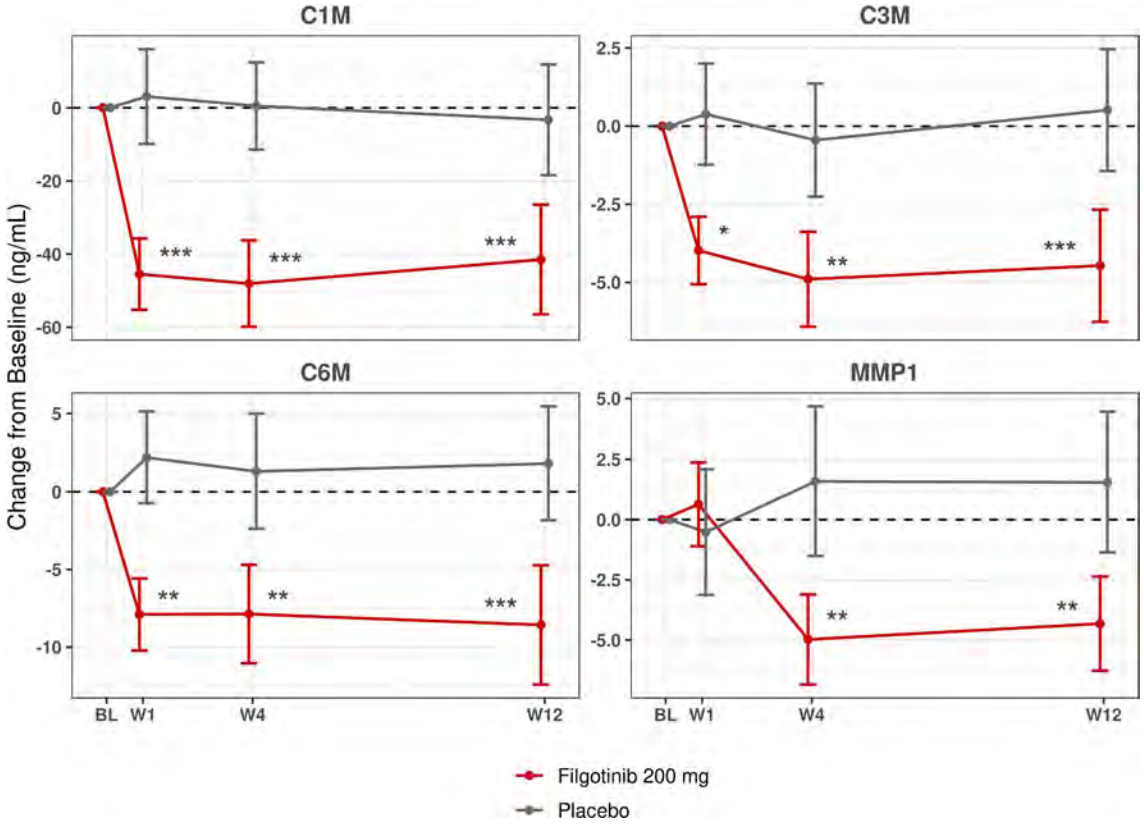

Figure 1. Circulating levels of matrix remodeling biomarkers are reduced with FIL treatment. The change from baseline resulting from PBO or FIL treatment on C1M, C3M, C6M and MMP1 levels at BL, weeks 1, 4 and 12 was calculated using a linear mixed effects model (adjusted for age, sex, BMI, BL ASDAS and BL spine SPARCC MRI scores) including a treatment by visit multiplicative interaction. The data are presented as the mean and 95% CI. FDR-corrected p-values: *Adj.p <0.05; **Adj.p <10–3; ***Adj.p <10–6.

Conclusion: In patients with active AS, FIL treatment reduced the levels of inflammatory cytokines associated with disease including systemic inflammatory cytokines, matrix remodeling biomarkers and cellular adhesion molecules. The observed decrease in biomarkers is consistent with the reduced AS disease activity in TORTUGA and suggest that FIL treatment can rapidly reduce a range of inflammatory cytokines involved in AS pathobiology.

Session Title: Spondyloarthritis Including PsA – Treatment Poster I: Axial Spondyloarthritis (0908–0939)

Session Type: Poster Session B

Session Time: 8:30AM–10:30AM

Background/Purpose: Patients with axial spondyloarthritis (axSpA) in clinical remission tapered Tumor Necrosis Factor inhibitor (TNFi) treatment according to a clinical guideline and were followed for 2-years. We aimed to investigate 1) potential 'baseline' predictors of flare within 16 weeks after tapering to 2/3, 1/2, 1/3 and 0 of standard dose and 2) if change in clinical and/or imaging variables in the previous 16-weeks (i.e. during the previous dose reduction step) could predict flare within 16 weeks after tapering to 1/2, 1/3 and 0 dose.

Methods: In all, 109 patients (78(72%) on standard dose, 31(28%) on reduced dose) in clinical remission with Bath ankylosing spondylitis disease activity index (BASDAI)< 40, physician global score< 40 and no signs of disease activity the previous year tapered TNFi to 2/3 of standard dose at baseline, 1/2 at week 16, 1/3 at week 32 and withdrew at week 48. Patients who experienced clinical, BASDAI or magnetic resonance imaging (MRI) flare stopped tapering and escalated to the previous dose. Prediction analyses were done by multivariable regression.

Results: Of 107 patients who followed the tapering algorithm for 2 years, 106 patients flared: 30 (28%) flared at 2/3 of standard dose, 20 (19%) at 1/2, 29 (27%) at 1/3 and 27 (25%) after discontinuation of TNFi (Table 1). Of the 106 patients who flared, 105 had clinical flare, 25 BASDAI flare and 23 MRI flare (Figure 1). Higher baseline physician global score was an independent predictor of flare after tapering to 2/3 (Odds ratio (OR)=1.21 (95% Confidence Interval=1.05 to1.44); p=0.007). When changes from baseline to week 16 in addition to demographics were investigated as predictors of flare, higher age predicted flare within 16 weeks after tapering to 1/2 dose (OR=1.07(1.01 to 1.15); p=0.015) (Table 2). Prediction analyses on lower dose steps were not possible due to small sample sizes.

Conclusion: In axSpA patients in clinical remission who tapered TNFi according to a clinical guideline, higher baseline physician global score was the only independent predictor of flare within 16 weeks after tapering to 2/3 of standard dose.

AUC (95% CI)				0.71 (0.57 - 0.88)		

Predictors were selected by applying backward selection in stacked imputed data. p-values by likelihood ratio tests. Bold indicates p-values<0.1 in univariate analyses. Results of final multivariable analyses were derived in non-imputed data (no missing values in selected predictors) and CIs were given as profile likelihood CIs. AUC was estimated based on internal validation by bootstrapping with 1000 samples.

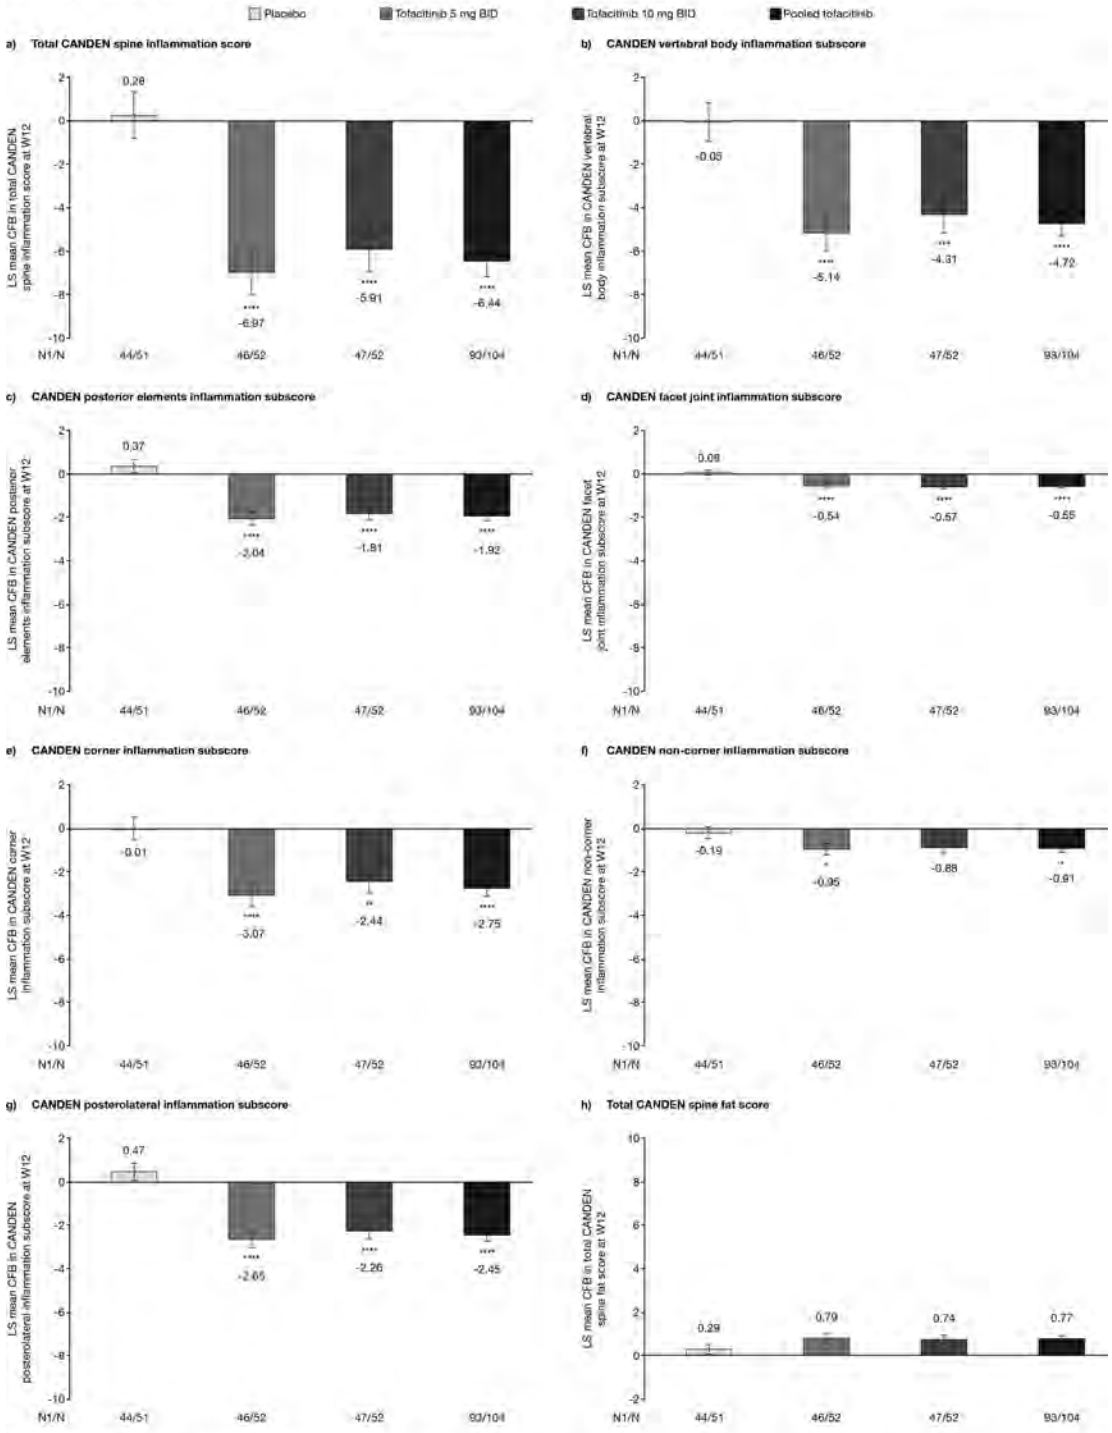
SESSION INFORMATION
Session Date: Sunday, November 7, 2021
Session Title: Spondyloarthritis Including PsA – Treatment Poster I: Axial Spondyloarthritis (0908–0939)
Session Type: Poster Session B
Session Time: 8:30AM–10:30AM

Background/Purpose: The Canada-Denmark (CANDEN) MRI scoring system enables detailed anatomy-based evaluation of inflammatory and structural lesions in spinal vertebral bodies and posterior elements in patients (pts) with AS.[1] Tofacitinib is an oral Janus kinase inhibitor under investigation for the treatment of adult pts with AS. In a Phase (P)2 dose-ranging study (NCT01786668), tofacitinib showed greater efficacy vs placebo (PBO) in reducing signs, symptoms, and inflammation based on Spondyloarthritis Research Consortium of Canada MRI SI joint and spine scores in biologic-naïve pts with AS.[2] This post hoc analysis evaluated the efficacy of tofacitinib on MRI outcomes for spinal vertebral body and posterolateral element inflammation and structural lesions in pts with AS, assessed with the CANDEN MRI scoring system.

Methods: Biologic-naïve adult pts with active AS (per modified New York criteria) were randomized 1:1:1:1 to tofacitinib 2, 5, or 10 mg twice daily (BID), or PBO in a 16-week (12-week treatment; 4-week follow-up), double-blind P2 study. Spine MRI assessments were performed at baseline (BL) and Week (W)12. This post hoc analysis comprised data from re-evaluation of MRI images in pts in the tofacitinib 5 or 10 mg BID, or PBO groups. Images were read

pairwise (both time points displayed simultaneously) by 2 independent readers blinded to time point/treatment, and scored using the CANDEN MRI scoring system. In cases of substantial disagreements between readers, a third reader adjudicated. Least squares mean changes from BL to W12 were reported for CANDEN-specific MRI outcomes, including total spine inflammation score and subscores, and total spine fat score. An analysis of covariance was

Figure. LS mean change from BL at W12 (FAS, LOCF) in CANDEN MRI scoring system: a) total spine inflammation score; b) vertebral body inflammation subscore; c) posterior elements inflammation subscore; d) facet joint inflammation subscore; e) corner inflammation subscore; f) non-corner inflammation subscore; g) posterolateral (costovertebral joints, transverse processes, spinous processes, and soft tissues) inflammation subscore; and h) total spine fat score



Data are LS mean (SE)
*p < 0.05; **p < 0.01; ***p < 0.001; ****p < 0.0001 for LS mean difference vs placebo
The pooled tofacitinib group included data from pts treated with tofacitinib 5 or 10 mg BID. An analysis of covariance with fixed effects of treatment and BL value was used. The FAS included pts who were randomized to tofacitinib 5 or 10 mg BID or placebo and received ≥ 1 dose of study drug. BL value was defined as the last observation prior to or on the date of the first dose of study drug. If a pt discontinued from the study ≥ W6, the pts' MRI was required at the early termination visit. MRI images obtained at the early termination visit were used for the W12 visit (LOCF)
BID, twice daily; BL, baseline; CANDEN, Canada-Denmark; CFB, change from BL; FAS, full analysis set; LOCF, last observation carried forward; LS, least squares; MRI, magnetic resonance imaging; N, number of pts in the FAS; N1, number of pts with both BL and W12/early termination MRI images in the FAS, evaluable by CANDEN MRI scoring system, included in analyses; pt, patient; SE standard error; W, Week

used for the primary comparison of pooled tofacitinib 5 and 10 mg BID groups vs PBO and for comparisons between tofacitinib 5 or 10 mg BID groups vs PBO. P values without adjustment to multiplicity are reported.

Results: MRI data for 137 pts were evaluated. At W12, significantly greater reductions were seen in the pooled tofacitinib group vs PBO for total CANDEN spine inflammation score ($p < 0.0001$; Fig a), and CANDEN vertebral body ($p < 0.0001$; Fig b), posterior elements ($p < 0.0001$; Fig c), facet joint ($p < 0.0001$; Fig d), corner ($p < 0.0001$; Fig e), non-corner ($p=0.0310$; Fig f), and posterolateral (costovertebral joints, transverse processes, spinous processes, and soft tissues; $p < 0.0001$; Fig g) inflammation subscores. Similar reductions were seen for these outcomes in the tofacitinib 5 or 10 mg BID groups vs PBO. Regarding fat infiltration, a numerically greater increase in total spine fat score was seen in the pooled tofacitinib group vs placebo (Fig h).

Conclusion: In biologic-naïve pts with AS, tofacitinib treatment was associated with significant reductions in MRI spinal inflammation, as assessed by the CANDEN MRI scoring system. Tofacitinib reduced inflammation in the posterolateral elements of the spine and the facet joints, which has not been described previously.

Early Improvement in Disease Activity Indices Predicts Achievement of Long-term Clinical Remissions, ASDAS Inactive Disease and Low BASDAI with Normal CRP, During TNF-α-inhibitor Therapy in Patients with Ankylosing Spondylitis

Sang Jin Lee, Na Ri Kim and Eon Nam, Kyungpook National University Chilgok Hospital, Daegu, Republic of Korea

SESSION INFORMATION
Session Date: Sunday, November 7, 2021
Session Title: Spondyloarthritis Including PsA – Treatment Poster I: Axial Spondyloarthritis (0908–0939)
Session Type: Poster Session B
Session Time: 8:30AM–10:30AM

Background/Purpose: As biologic agents including tumor necrosis factor (TNF)-α inhibitors (TNFi) have been proven to improve enormously clinical outcomes for patients with ankylosing spondylitis (AS), treat-to-target (T2T) is an emerging management strategy in AS. According to the concept of T2T strategy, clinical remission, which means

mainly achievement of ASDAS inactive disease (ASDAS-ID) or, alternatively, low BASDAI with normal CRP (BASDAI-CRP) or ASAS partial remission, should be accomplished and then be maintained throughout TNFi therapy. In this study, we evaluated to determine the possibility of achieving clinical remission and to investigate the predictors of attainment of clinical remission in AS patients treated with TNFi.

Methods: This was a retrospective observational study in 139 adult AS patients treated with TNFi up to 33 months. All outcome measures were performed at baseline and month 3, and then every six month up to month 33. Clinical remission selected were ASDAS-ID and BASDAI < 2 with normal CRP level (BASDAI-CRP). The longitudinal relationship between early improvement in clinical parameters and achievement of clinical remission was assessed using generalized estimating equations (GEEs).

Results: Responders of ASDAS-ID increased from 32.4 at month 3 to 68.9% at month 33 and that of BASDAI-CRP increased from 39.9% at month 3 to 75.2% at month 33. Patients satisfied with ASDAS-ID or BASDAI-CRP were almost redundant. The responders of ASDAS-ID or BASDAI-CRP showed a significantly better functional and metrological indices than the non-responders.

The analysis using univariable GEE model demonstrated that age [OR: 0.71 (95% confidence interval (CI), 0.54-0.92)] and all of 3-month improvement in ASDAS-CRP [OR: 1.57 (CI, 1.11-2.23)], BASDAI [OR: 1.78 (CI, 1.40-2.26)], physician's global assessment (PhGA) [OR: 1.47 (CI, 1.26-1.71)], patient's global assessment (PtGA) [OR: 1.40 (CI, 1.26-1.71)], and pain [OR: 1.32 (CI, 1.13-1.53)] were significant variables. On the multivariable GEE analysis, age [OR: 0.67 (CI, 0.49-0.93)] and 3-month BASDAI improvement [OR: 1.70 (CI, 1.19-2.41)] were associated with achievement of ASDAS-ID.

On the univariable GEE analysis, age [OR: 0.76 (CI, 0.60-0.96)], 3-month improvement in BASDAI [OR: 1.66 (CI, 1.32-2.10)], PhGA [OR: 1.23 (CI, 1.06-1.42), PtGA [OR: 1.19 (CI, 1.04-1.38)], and pain [OR: 1.25 (CI, 1.09-1.45)], and normalized ESR [OR: 2.87 (CI, 1.26-6.55)] and CRP [OR: 2.56 (CI, 1.22-5.34)] at month 3 were independent predictors of achievement of BASDAI-CRP. On the multivariable GEE analysis, age [OR: 0.75 (CI, 0.59-0.96)], 3-month BASDAI improvement [OR: 1.75 (CI, 1.29-2.36)], normalized ESR [OR: 2.93 (CI, 1.20-7.16)] and CRP at month 3 [OR: 2.98 (CI, 1.30-6.83)] were independent predictors of attainment of BASDAI-CRP.

Conclusion: The proportion of achievement of BASDAI-CRP was higher than that of ASDAS-ID during long-term TNFi therapy and patients satisfied with ASDAS-ID and BASDAI-CRP were almost redundant. On the analysis of mul-

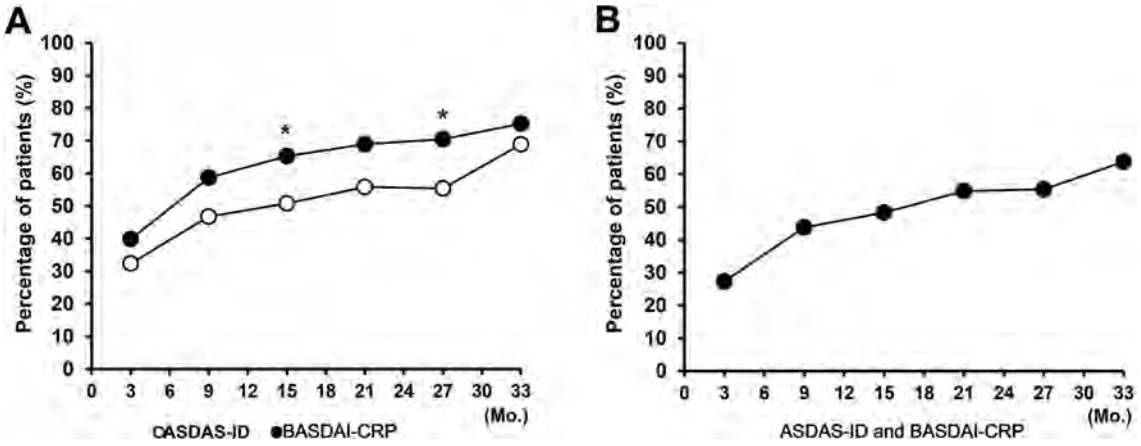

Figure. Response to TNF-α-inhibitor therapy as measured by ASDAS inactive disease (ASDAS-ID) and BASDAI + CRP criteria. These graphs show the proportion of achievement of (A) ASDAS-ID or BASDAI-CRP and (B) both ASDAS-ID and BASDAI- CRP criteria. *p <0.05.

tivariable GEE model, age and 3-month BASDAI improvement were independent predictors of achievement of both clinical remission criteria and normalized ESR and CRP at month 3 were predictors of achievement of BASDAI-CRP.

SESSION INFORMATION
Session Date: Sunday, November 7, 2021
Session Title: Spondyloarthritis Including PsA – Treatment Poster I: Axial Spondyloarthritis (0908–0939)
Session Type: Poster Session B
Session Time: 8:30AM–10:30AM

Background/Purpose: Increasing immunmodulatory treatment options are available for axial spondyloarthritis. Little is known about sequential treatment in clinical routine.

Methods: The pseudonymized RHADAR database (Kleinert, S. et al, J Med Internet Res. 2021;23(5):e28164) was analyzed with a special emphasis on patients with axSpA and with databank entries in the last 9 months before March 31st 2021. Their current and previous therapies were analyzed using the statistic software R (version 3.5.1) and RStudio (version 1.1.453). Documented therapies between 2011 and 2021 were included.

Results: Characteristics of the 1050 axSpA-patients are displayed in table 1. In 986 patients at least two timepoints of therapy could be analyzed. 77.2% stayed on the treatment of timepoint 1, 21.8% patients changed treatment at timepoint 2, and 4.2 % changed again at a 3rd timepoint.

At timepoint 1, 501 patients were on anti-TNF treatment; of which 379 (75.6%) therapy remained unchanged . At timepoint 2 57 (11,4%) changed to a different TNF blocker, 33 (6,6%) to NSAID only, 16 (3,2%) to anti-IL17 treatment, and 2 (0,4%) to treatment with a Janus kinase inhibitor.

NSAID therapy was applied in 335 patients at timepoint 1, of those, 281 (83.9%) remained on same therapy., 45 (13,4%) changed to anti-TNF treatment, 6 (1,8%) to anti-IL17 treatment at timepoint 2.

Among the 52 (5.3%) patients on anti-IL17 treatment at timepopint 1 38 (73,1%) continued their therapy unchanged, 7 changed to NSAIDs, 4 to a different anti-IL17 inhibitor, and 2 to anti-TNF treatment.

Table 1. Patients' characteristics.

	n (available)	% (available)	Mean	SD	Median	25% Quantile	75% Quantile
Age	1050	100.0	50.1	14.0	51.0	39.0	60.0
Age (female)	454	43.2	51.3	13.7	53.0	40.0	60.8
Age (male)	596	56.8	49.1	14.2	49.0	38.0	59.0
Disease duration	1041	99.1	14.4	12.2	11.0	6.0	21.0
Disease duration (female)	453	43.1	12.5	11.8	9.0	5.0	17.0
Disease duration (male)	588	56.0	15.9	12.3	13.0	6.0	22.0
BASDAI	1009	96.1	3.2	2.1	2.8	1.5	4.7
BASFI	961	91.5	2.8	2.5	2.2	0.8	4.5
BASMI	376	35.8	1.9	2.5	1.0	0.0	3.0
ASDAS	522	49.7	2.0	0.9	1.9	1.4	2.5
Treatment Timepoint 1	986						
- NSAID	335	34.0					
- Anti TNF	501	50.8					
- Anti IL17	52	5.3					
- different (Sulfasalazine, Methotrexat)	101	10.2					

Conclusion: The majority of the patients 50,8% (501/986) were treated with an TNF-inhibitor, 34% (335/986) received NSAIDs only, while 5,3% were on IL17-inhibitor at timepoint 1. Regardless of the treatment modality at timepoint 1 majority of axSpA-patients continued their therapy unchanged. The most likely explanation to this observation is the low disease activity as reflected by the disease activity indices in table 1.

The emerging immunomodulatory therapeutic options will offer further alternative pathways in the sequential treatment of axSpA patients.

Sustained Functional Remission in Axial Spondyloarthritis (axSpA): Which Are the Primary Outcomes That Should Be Targeted to Achieve This?

Walter Maksymowych[1], Robert Inman[2], Louis Bessette[3], Proton Rahman[4], Emmanouil Rampakakis[5], Odalis Asin-Milan[6], Meagan Rachich[6], Anne Marilise Marrache[6] and Allen Lehman[6], [1]Department of Medicine, University of Alberta, Alberta, Canada, Edmonton, AB, Canada, [2]University Health Network, Toronto, ON, Canada, [3]Centre de l'Ostoporose et de Rhumatologie de Qubec, Québec City, QC, Canada, [4]Department of Medicine, Eastern Health and Memorial University of Newfoundland, St John's, NL, Canada, [5]JSS Medical Research, Montréal, QC, Canada, [6]Janssen Inc., Toronto, ON, Canada

SESSION INFORMATION

Session Date: Sunday, November 7, 2021

Session Title: Spondyloarthritis Including PsA – Treatment Poster I: Axial Spondyloarthritis (0908–0939)

Session Type: Poster Session B

Session Time: 8:30AM–10:30AM

Background/Purpose: A treat-to-target (T2T) strategy has been advocated for the management of axSpA although no consensus exists as to the most appropriate target or the outcome to be monitored to achieve this target. Structural damage assessed by radiography is not a feasible target in axSpA as it is insensitive to change. Functional impairment is associated with inflammation and structural damage and is assessed in axSpA using the Bath Ankylosing Spondylitis (AS) Functional Index (BASFI). Sustained (≥6 mos duration) low BASFI (< 3) may therefore be an appropriate target for a T2T strategy in axSpA. There is also no consensus as to which outcome(s) should be monitored in a T2T strategy although there is agreement that the key domain is disease activity. The AS Disease Activity Score (ASDAS) is recommended although the Bath AS Disease Activity Index (BASDAI) is more feasible. Our objectives were to determine 1) to what degree duration of low disease activity impacts function and 2) which patient and disease characteristics predict sustained low BASFI focusing on a comparison of sustained (≥6 mos) low ASDAS versus BASDAI.

Methods: Biologic Treatment Registry Across Canada (BioTRAC) was a multi-centre, prospective, registry that collected real-world patient reported outcomes, clinical, and laboratory data on axSpA patients treated with infliximab or golimumab between 2002-2018. Data were collected every 6 mos. The impact of achieving low BASDAI (< 3) and/or ASDAS-inactive disease (ID) (< 1.3) at 6 and 12 mos, at only 6 or 12 mos, or at neither time point, and the interaction of CRP at 6 and 12 mos with BASDAI, on the BASFI score at 18 mos was analyzed by generalized linear models (GLM) adjusted for age, gender, baseline disease duration, and baseline BASFI. Generalized estimating equations (GEE) were used in univariate and multivariate analyses to test baseline patient demographic and disease character-

Table 1. Predictors of low BASFI (<3) Between 12 and 18 Months

Parameter	OR	95% CI	P-Value
BASFI-Baseline	0.7	0.6, 0.8	**<0.001**
Low BASDAI (<3): M6 and M12 vs persistent BASDAI >3	10.5	4.0, 27.2	**<0.001**
Low BASDAI (<3): M6 or M12 vs. persistent BASDAI>3	5.2	2.4, 11.1	**<0.001**
ASDAS-ID: M6 and M12 vs. persistent ASDAS>1.3	3.7	1.1, 13.1	**0.040**
ASDAS-ID: M6 or M12 vs. persistent ASDAS>1.3	2.2	0.8, 6.0	0.144

Table 2. Predictors of BASFI at 18 Months

Parameter	B*	95% CI	P-Value
BASFI-Baseline	0.30	0.19, 0.41	**<0.001**
Low BASDAI (<3): M6 and M12 vs. persistent BASDAI >3	-2.45	-3.35, -1.55	**<0.001**
Low BASDAI (<3): M6 or M12 vs. persistent BASDAI >3	-2.14	-2.88, -1.41	**<0.001**
ASDAS-ID: M6 and M12 vs. persistent ASDAS>1.3	-1.10	-2.15, -0.05	**0.041**
ASDAS-ID: M6 or M12 vs. persistent ASDAS>1.3	-0.70	-1.62, 0.22	0.136
Age (Years)	0.04	0.02, 0.07	**0.001**
Male vs. Female	0.35	-0.22, 0.92	0.228
Baseline Disease Duration (Years)	-0.02	-0.05, 0.01	0.121

**Positive Beta coefficient indicates increased BASFI score at 18 months*

istics, treatment, sustained low BASDAI and/or ASDAS-ID at 6 and 12 mos, in predicting low BASFI (< 3) between 12 and 18 mos.

Results: A total of 1620 pts were enrolled, 33.7% and 15% with sustained low BASDAI and ASDAS-ID, respectively. In univariate GEE of baseline variables, only age and baseline BASDAI, BASFI, and ASDAS were significant predictors of sustained low BASFI. In univariate GEE of follow up variables, sustained low BASDAI and ASDAS-ID were also predictors. In multivariate GEE, sustained low BASDAI and baseline BASFI were the only predictors of low BASFI (Table 1). Sustained ASDAS-ID was a weak predictor when forced into the model.

Similarly, in GLM models, sustained low BASDAI and baseline BASFI plus age were strong predictors of BASFI score at 18 mos, while sustained ASDAS-ID was a weak predictor (Table 2). A significant interaction was observed between duration of low BASDAI and normal CRP (< 5mg/L at 6 and 12 mos) with CRP remission identified as an independent predictor of function among patients on sustained low BASDAI.

Conclusion: Aiming for sustained low BASDAI (< 3) may be a valid and more feasible T2T treatment strategy than ASDAS-ID for routine care in axSpA. Further validation of these real-world findings is required to aid in achieving consensus on which outcome should be monitored in a T2T strategy.

Baseline Characteristics and Treatment Response to Ixekizumab Categorised by Sex in Radiographic and Non-Radiographic Axial Spondylarthritis Patients Through 52 Weeks: Data from 3 Phase III, Randomized, Controlled Trials

Irene van der Horst-Bruinsma[1], Rebecca Bolce[2], Theresa Hunter[3], David Sandoval Calderon[2], Danting Zhu[2], Vladimir Geneus[2], Jeffrey Lisse[4], Soyi Liu-Leage[5] and Marina Magrey[6], [1]Amsterdam UMC, Amsterdam, Netherlands, [2]Eli Lilly and Company, Indianapolis, IN, [3]Eli Lilly and Company, Indianapolis, IN, USA, Indianapolis, IN, [4]Eli Lilly and Company, Tucson, AZ, [5]Eli Lilly and Company, Neuilly sur Seine, France, [6]Case Western Reserve University, MetroHealth Medical Center, Cleveland, OH, USA, Richfield, OH

SESSION INFORMATION
Session Date: Sunday, November 7, 2021
Session Title: Spondyloarthritis Including PsA – Treatment Poster I: Axial Spondyloarthritis (0908–0939)
Session Type: Poster Session B
Session Time: 8:30AM–10:30AM

Background/Purpose: Axial spondyloarthritis (axSpA) is a chronic inflammatory disease of the axial skeleton comprising two subtypes within the same spectrum: radiographic (r-axSpA) and non-radiographic (nr-axSpA). Previous studies have shown that clinical presentation and treatment response of males and females may differ[1] despite simi-

lar disease burden.[2] Ixekizumab (IXE), a high-affinity monoclonal antibody that selectively targets interleukin-17A, has demonstrated superior efficacy to placebo in the treatment of patients with r-axSpA (COAST-V/W [bDMARD- naïve/ TNFi-experienced]) and nr-axSpA (COAST-X [bDMARD-naïve]).[3] Here we report baseline characteristics and treatment response to IXE categorised by sex in patients with r-axSpA and nr-axSpA for up to 52 weeks.

Methods: Patients fulfilled the ASAS classification criteria for r-axSpA or nr-axSpA. Patients were randomized to receive 80 mg subcutaneous IXE every 2 weeks (Q2W) or 4 weeks (Q4W), or to placebo (PBO) [16 weeks COAST-V/W; 52 weeks COAST-X]. Baseline characteristics and treatment outcomes were assessed. Patients were categorised by sex, missing data was controlled for using non-responder imputation (NRI) and modified baseline observation carried forward (mBOCF) analysis was conducted on continuous efficacy variables.

Table 1. Baseline Characteristics of Patients Categorised by Sex

	Patients with r-axSpA (COAST-V/W) (n=376)			Patients with nr-axSpA (COAST-X) (n=198)		
Characteristic	**Male (n=298)**	**Female (n=78)**	**p value**	**Male (n=99)**	**Female (n=99)**	**p value**
Age at onset (yrs), mean (SD)	26.5 (8.7)	30.1 (10.1)	**0.002***	27.9 (7.7)	32.0 (10.7)	**0.002***
Symptom duration (yrs), mean (SD)	16.7 (10.5)	17.8 (12.2)	0.420	9.5 (9.2)	12.3 (11.3)	0.057
ASDAS, mean (SD)	4.0 (0.8)	3.9 (0.7)	0.304	3.7 (0.8)	3.9 (0.8)	0.143
BASDAI, mean (SD)	7.10 (1.4)	7.4 (1.5)	0.179	6.9 (1.4)	7.4 1.4)	**0.013***
Fatigue/tiredness (BASDAI Q1), mean (SD)	7.4 (1.6)	7.8 (1.5)	**0.036***	7.0 (1.6)	7.9 (1.5)	**<0.001***
Spinal pain (BASDAI Q2), mean (SD)	7.9 (1.5)	8.0 (1.5)	0.682	7.5 (1.4)	7.9 (1.5)	**0.029***
Pain/swelling in other joints (BASDAI Q3), mean (SD)	6.5 (2.1)	6.9 (2.2)	0.129	6.6 (2.3)	7.2 (1.9)	**0.039***
Tenderness to touch/pressure (BASDAI Q4), mean (SD)	6.8 (1.8)	7.0 (1.9)	0.339	6.6 (1.9)	6.8 (1.8)	0.404
Morning stiffness (BASDAI Q5), mean (SD)	7.5 (1.6)	7.7 (1.8)	0.504	7.3 (1.7)	7.7 (1.9)	0.137
Morning stiffness duration (BASDAI Q6), mean (SD)	6.5 (2.3)	6.5 (2.8)	0.944	6.3 (2.3)	6.6 (2.5)	0.392
Spinal pain at night NRS, mean (SD)	7.4 (1.5)	7.8 (1.7)	**0.033***	7.0 (1.8)	7.6 (1.8)	**0.027***
BASFI, mean (SD)	6.8 (1.8)	7.0 (2.0)	0.466	6.2 (1.8)	6.7 (2.1)	0.108
SF-36 PCS, mean (SD)	30.9 (8.3)	28.9 (8.2)	0.075	33.1 (7.7)	32.1 (7.2)	0.348

p-value from Fisher's exact test analysis of variance (ANOVA) with sex as a factor for continuous data. Data includes pooled IXEQ2W and IXEQ4W.

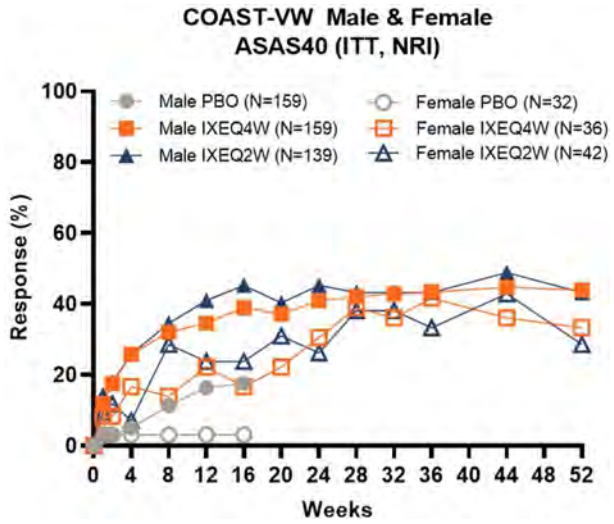

Figure 1. COAST-V/W ASAS40 (ITT, NRI) Patients initially randomized to PBO in COAST-V/W switched to IXEQ2W or Q4W at week 16 by study design; PBO data are summarised up to week 16.

Results: At baseline, females were older, with significantly higher pain and fatigue scores and peripheral joint symptoms (table 1). ASAS40 response rate with IXEQ4W was achieved in 39% of males with r-axSpA by week 16, and 44% by week 52. Females achieved 16.7% at week 16, and 33.3% at week 52. In nr-axSpA, 46% of IXEQ4W males achieved ASAS40 at week 16 and 30% at week 52. 23.9% of females achieved ASAS40 at week 16, increasing to 30.4% at week 52.

Conclusion: This analysis demonstrates that for the axSpA disease spectrum, females present with higher disease burden as reflected by higher scores in fatigue/tiredness, and spinal pain at night. Our findings indicate that males and females respond to IXE; however, females experience this benefit later in their treatment course, with a more prolonged attainment of peak response.

SESSION INFORMATION
Session Date: Sunday, November 7, 2021
Session Title: Spondyloarthritis Including PsA – Treatment Poster I: Axial Spondyloarthritis (0908–0939)
Session Type: Poster Session B
Session Time: 8:30AM–10:30AM

Background/Purpose: To evaluate the effect of treatment with ixekizumab versus placebo (PBO) on structural lesions in the sacroiliac joints (SIJ) at 16 weeks in patients with non-radiographic axial spondyloarthritis (nr-axSpA).

Methods: Patients with active nr-axSpA who were biologic-naïve (COAST-X, NCT02757352) were randomized 1:1:1 to receive double-blinded ixekizumab 80 mg every 4 (Q4W) or 2 weeks (Q2W) with an 80-mg or 160-mg starting dose at week 0 or PBO. SIJ magnetic resonance imaging (MRI) was assessed by Spondyloarthritis Research Consortium of Canada (SPARCC) SIJ structural score (SSS). Treatment comparisons used analysis of covariance based on observed cases.

Results: Of 303 randomized patients, 266 patients (Q4W: n=85, Q2W: n=91, PBO: n=90) with an MRI scan available at baseline and week 16 were included in this analysis. Mean SPARCC SSS for PBO and ixekizumab dose groups were similar at baseline (Figure 1 and Table). Significant reduction in SPARCC SSS for erosion was observed in both ixekizumab dose groups versus PBO (Fig. 1A). Increased erosion scores occurred for fewer patients in both ixekizumab dose groups versus PBO (Fig. 1B). Decreased erosion scores occurred for more patients in both ixekizumab dose groups versus PBO (Fig. 1B). Mean change from baseline in SPARCC SSS was significantly greater for ixekizumab for fat metaplasia (Q4W) and backfill (Q4W and Q2W) versus PBO (Table). Changes in ankylosis were generally not observed (Table).

Conclusion: Treatment with ixekizumab versus PBO led to significant reductions in erosions and significant increases in fat metaplasia and backfill in the SIJ in patients with nr-axSpA assessed at 16 weeks of treatment.

Session Title: Spondyloarthritis Including PsA – Treatment Poster I: Axial Spondyloarthritis (0908–0939)

Session Type: Poster Session B

Session Time: 8:30AM–10:30AM

Background/Purpose: Axial spondyloarthritis (axSpA) is a chronic inflammatory rheumatic disease affecting sacroiliac joints and spine as well as peripheral joints and entheses. Tumour necrosis factor inhibitors (TNFi) are widely used in patients with persistently high disease activity despite non-steroidal anti-inflammatory drugs. Some patients

fail to respond or loose responsiveness during therapy with TNFi. The development of anti-drug antibodies (ADA) might play a role in non-response or some adverse events. However it has never been evaluated for 2-years period.

Objectives: Therefore, the aim of the present study was to evaluate the development of ADA against TNFi longitudinally during 2-years period in axSpA patients and factors associated with it.

Methods: In total 180 axSpA patients according to ASAS classification criteria with a new TNFi prescription in the last two weeks period were included in this observational study. Clinical data and serum samples were collected at baseline and at every 12 weeks. Serum drug levels and ADAs were measured on 12, 24, 52 and 104 weeks of treatment by ELISA in one center to avoid inter-assay variability. The development of ADA over time was investigated by using generalized estimating equations (GEE) which is a technique for longitudinal data analysis allowing the use of all available data even deviated from normality.

Results: 180 biologic naive axSpA patients (116 male, median [IQR] 44,5 [14,5] years) who started anti-TNF agents (infliximab [20%], adalimumab [27,2%], etanercept [32,2%] and golimumab [20,6%]) were included in the analysis (Table 1). In comparison to baseline values BASDAI, ASDAS-CRP and CRP values were significantly decreased in third months of follow-up (Figure 1). In total 172 patients had at 12 weeks, 154 at 24, 121 at 52, and 73 at 104 week serum samples available for ADA determination. In longitudinal analysis; baseline age and TNFi type, as well as longitudinal BASDAI, ASDAS, serum CRP levels and the development of adverse events and discontinuation of the drug were found to be associated with the development of ADA. In order to determine independent association/s with the development of ADA two longitudinal multivariable models were run; (a) with ASDAS as an activity measure, (b) with BASDAI and CRP levels and produced that all the variables were independently associated with longitudinally development of anti-drug antibodies (Table 2). Antibodies to adalimumab were related with lower serum drug levels.

Conclusion: The results of the present study with up to 2 years of follow-up, revealed that the development of ADA against TNFi therapy is associated with high disease activity, the development of adverse events and treatment discontinuation in patients with axSpA. And etanercept might be negatively associated with the development of ADA.

Evaluation of the Safety of Vedolizumab in Combination with Other Immunosuppression Biological Therapy in Patients with Inflammatory Bowel Disease

Gino Chesini[1], Elizabeth Parrott[1], Lauren Fox[1], Jenna Beatty[1], Cassandra Effken[1], Na Yu[1], Florence Hosseini-Aslinia[1] and Megan Krause[2], [1]University of Kansas Medical Center, Kansas City, KS, [2]University of Kansas, Kansas City, KS

SESSION INFORMATION
Session Date: Sunday, November 7, 2021
Session Title: Spondyloarthritis Including PsA – Treatment Poster I: Axial Spondyloarthritis (0908–0939)
Session Type: Poster Session B
Session Time: 8:30AM–10:30AM

Background/Purpose: Inflammatory bowel disease (IBD) causes a wide range of symptomology frequently leading to co-management of disease activity between gastroenterologist and rheumatologists. Recently in efforts to optimize treatment, there has been interest in using combination biological therapy with vedolizumab.

Methods: A retrospective single center study was performed on individual patients, between the ages 18 to 80, treated with combination therapy with vedolizumab and any other biological (etanercept, adalimumab, golimumab, certolizumab, infliximab, ustekinumab, JAK inhibitors) between 2014 and May 2021. Patients were identified through a database search via diagnosis code and medication list review with subspecialty clinics. Individual patient charts were then reviewed to confirm IBD diagnosis and use of combination therapy during their time of follow-up at this institution. Additional data was abstracted regarding baseline characteristics, infections, cancer diagnoses, and mortality.

Results: Sixteen patients meeting the study criteria for a complete retrospective chart review were identified. The mean age at initiation of combination therapy was 39.8 years of age. 56% of the patients were male. 81.2% of the patients were diagnosed with Crohn's disease and 18.8% with ulcerative colitis. 56.25% had complaints of joint pain and 37.5% were evaluated by rheumatology. Dual biological therapy was initiated for IBD control in 75% of patients and for joint pain in 25% of patients. 69% received adalimumab, 44% received ustekinumab, and 6% received certolizumab. One of the patients received adalimumab then transitioned to ustekinumab. The mean duration of dual biological therapy was 11.9 months. 14 of 16 patients remained on dual therapy during the duration of the study. One patient developed antibodies against adalimumab which lead to discontinuation. One patient had to discontinue dual therapy due to insurance authorization. The minimum duration of combination therapy was 1 month and the maximum duration was 22 months. Seven total infections occurred in 4 patients (25%). Serious infections requiring hospitalization or IV antibiotics occurred in two patients (12.5%). None of the patients developed a new diagnosis of cancer or experienced a reoccurrence of cancer. No deaths occurred during the time of follow-up.

Conclusion: This retrospective study reviewing 16 cases of patients treated with vedolizumab and dual biological combination therapy demonstrates additional data regarding infection, cancer, and mortality rates. Further studies are needed to better characterize and evaluate the safety profile of vedolizumab combination therapy in IBD patients for intestinal and extra-intestinal manifestations.

Comparative Effectiveness and Treatment Survival of Different TNF Inhibitors for Axial Spondyloarthritis in Real-World Clinical Practice

Javier Marrugo[1], Maude Bonin[1], Gilles Boire[1], Louis Bessette[2] and Ariel Masetto[1], [1]Universite de Sherbrooke, Sherbrooke, QC, Canada, [2]Centre de l'Ostoporose et de Rhumatologie de Qubec, Québec City, QC, Canada

SESSION INFORMATION
Session Date: Sunday, November 7, 2021
Session Title: Spondyloarthritis Including PsA – Treatment Poster I: Axial Spondyloarthritis (0908–0939)
Session Type: Poster Session B
Session Time: 8:30AM–10:30AM

Background/Purpose: Tumor necrosis factor (TNF) inhibitors are the mainstay treatment for NSAID refractory axial spondyloarthritis (axSpA). However, few data exist on their use during routine clinical practice. The primary aim of

this study was to evaluate the effectiveness and treatment survival of different TNF blocking agents within a cohort of patients with axSpA.

Methods: We obtained data from patients who fulfilled the ASAS 2011 classification criteria for axSpA, who were treated with a TNF inhibitor and had clinical follow-up from 2003 to 2019. Effectiveness was evaluated based on the BASDAI50 response at 6 months of therapy. Multivariable linear regression models were used to estimate the predictors of improvement in BASDAI. Treatment persistence was analyzed using Kaplan-Meier survival analysis and Cox proportional hazards model.

TNF inhibitor during first treatment	BASDAI50 (%)
Adalimumab	39/71 (54.9%)
Certolizumab	1/3 (33.3%)
Etanercept	16/33 (48.5%)
Golimumab	24/52 (46.2%)
Infliximab	7/12 (58.3%)
Total	87/171 (50,9%)

Table 1. Percentage of patients obtaining a BASDAI50 by molecule during first TNF inhibitor treatment (n=171); p=0,812[b]

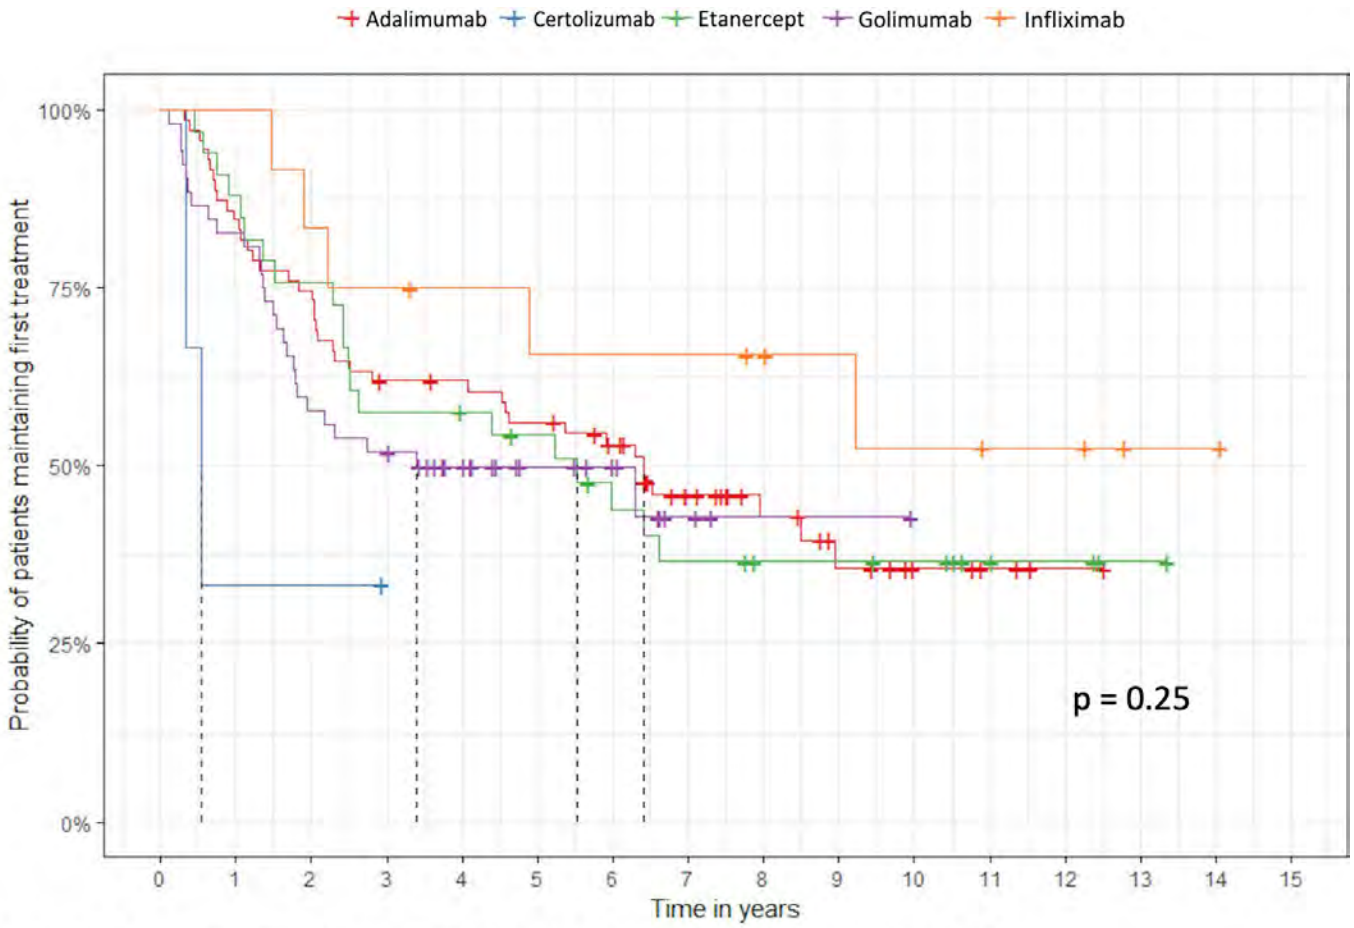

Figure 1. Drug survival for different TNF inhibitors as first treatment in axSpA

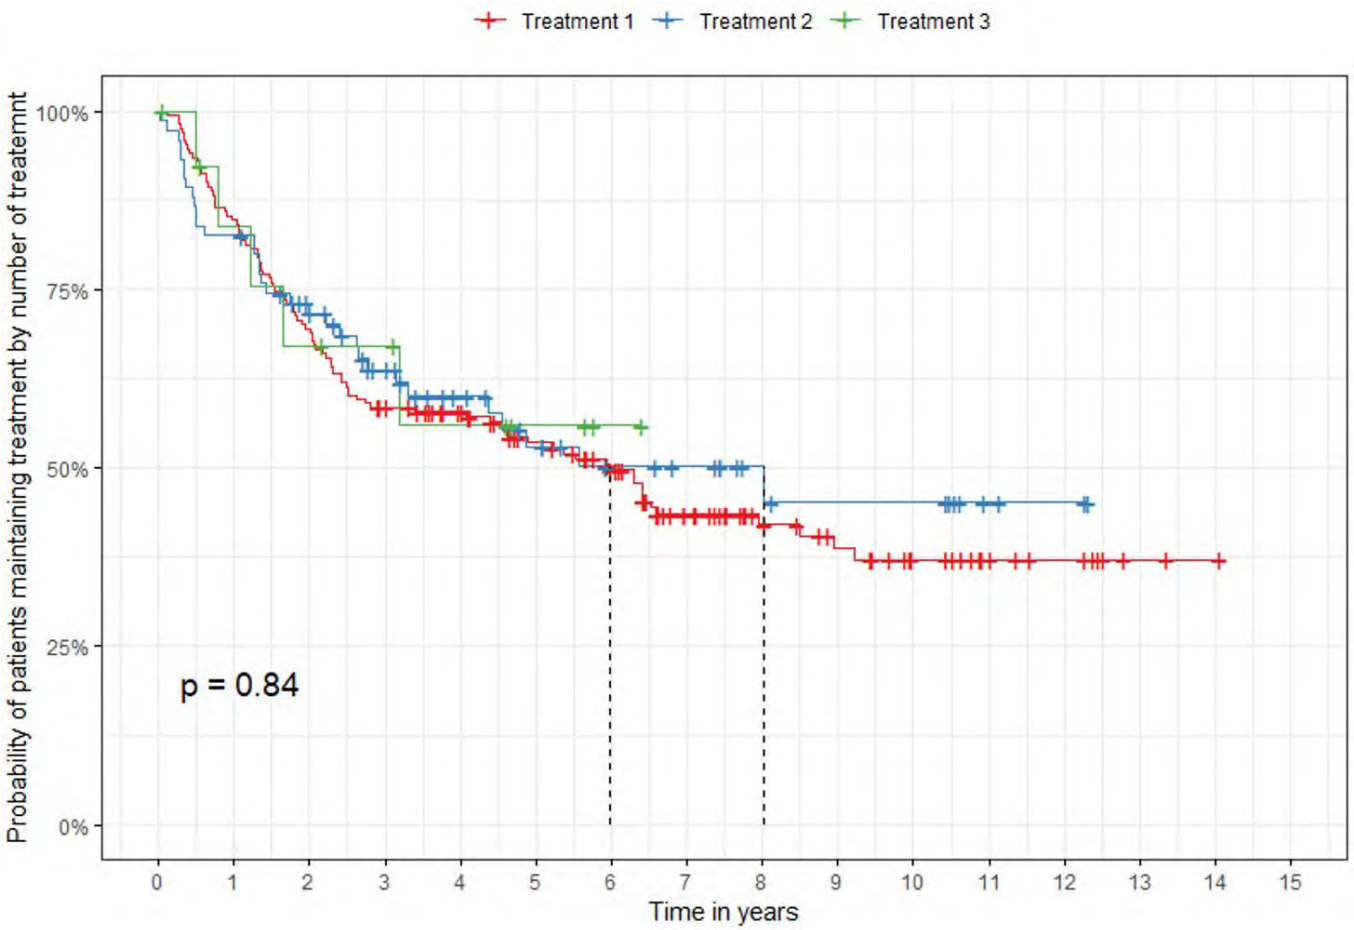

Figure 2. Drug survival of first and subsequent TNF inhibitor treatments

Results: The study comprised 171 patients. The median age was 45 years and 57% were males. Mean baseline BASDAI and BASFI were 6.1 and 5.5 respectively. At 6 months, 50.9% reached a BASDAI50 response and no differences were observed within the different TNF inhibitors **(Table 1)**. In the adjusted analysis, smokers were less likely to achieve a BASDAI50 response compared with nonsmokers HR 0.15 (95% CI 0.059 - 0.375) $p < 0.0001$. In contrast, patients with a higher baseline BASDAI score were more likely to reach a BASDAI50 at 6 months HR 1.29 (95% CI 1.072 - 1.564) $p = 0.007$. No other variables demonstrated an association with BASDAI50. The median survival for the first TNF inhibitor therapy was 5.9 years (95% CI 4.5-7.4) without significant difference in treatment survival between TNF inhibitors. There was a trend for a better survival with infliximab, but this was not statistically significant (Figure 1). In the non-radiographic (nr-axSpA) group (n=51), 57% reached a BASDAI50 response, compared to 48% in the ankylosing spondylitis (AS) group (n=119) (p=0.28) during the first TNF inhibitor treatment. The median survival, for the first TNF blocking therapy, was 5.3 years (95% CI 1.58-9.15) in the nr-axSpA group and 6,3 years in the AS group (95% CI 4.58-8.01).

After a first TNF inhibitor failure, the BASDAI50 response for subsequent second and third TNF inhibitor therapies, was 48.7% and 38.5% respectively, with no significant difference in treatment survival (Figure 2). The reasons for discontinuation of the first TNF inhibitor were primary failure 14.7%, secondary failure 61.1%, adverse events 14.7%, and others 9.5%.

Conclusion: Most patients who received TNF blocking agents for axSpA during routine clinical care showed improvement in disease activity. TNF inhibitor effectiveness and drug survival were comparable to published data.

There were no significant differences in effectiveness or treatment survival among the different TNF inhibitors. Effectiveness and drug survival was not different between nr-axSpA and AS. Failure to a first TNF inhibitor did not diminish effectiveness or drug survival of subsequent TNF inhibitor treatments. The main reason for treatment discontinuation was secondary failure.

Non-steroidal Anti-inflammatory Drug Use Is Associated with Disease Activity and Reduced Significantly in Patients with Axial Spondyloarthritis Treated with Tumor Necrosis Factor Inhibitors; Data from a Real Life Experience

Elif Ediboglu[1], Dilek Solmaz[2], Gokhan Kabadayi[3], eda otman[1], Haluk Cinaklı[1], Gulay Alp[1], Esra Erpek[1], Sercan Gücenmez[4], Mustafa Ozmen[4] and Servet Akar[2], [1]Izmir Katip Celebi University, Faculty of Medicine, Department of Internal Medicine, Division of Rheumatology, İzmir, Turkey, [2]Izmir Katip Celebi University, Faculty of Medicine, Department of Internal Medicine, Division of Rheumatology, Izmir, Turkey, [3]Cigli Education and Research Hospital, İzmir, Turkey, [4]katip çelebi university, izmir, Turkey

SESSION INFORMATION
Session Date: Sunday, November 7, 2021
Session Title: Spondyloarthritis Including PsA – Treatment Poster I: Axial Spondyloarthritis (0908–0939)
Session Type: Poster Session B
Session Time: 8:30AM–10:30AM

Background/Purpose: Bacground: Non-steroidal anti-inflammatory drugs (NSAIDs) is the first line treatment option in axial spondyloarthritis (axSpA) patients suffering from pain and stiffness. However there is only limited data regarding the concomitant use of NSAIDs during tumour necrosis factor inhibitor (TNFi) treatment.

Objectives: To evaluate longitudinal concomitant NSAIDs use with the TNFi treatment and the determinant of the ASAS-NSAID index in patients with axSpA.

Methods: In total 429 axSpA patients (253 [59%] male; 272 [63%] with AS and 157 [37%] with nonradiographic (nr)-axSpA) who have followed up one year were included in this observational study (Table 1). The data regarding disease activity and serum CRP levels were collected on 12, 24 and 52nd week. At each visit NSAID usage, type, dosage and frequency were recorded in order to calculate ASAS-NSAID index. The longitudinal relationship between NSAID-index and other factors tested by using generalized estimating equations (GEE) which is a technique for longitudinal data analysis allowing the use of all available data even deviated from normality

Results: At baseline 127/138 (92%) patients starting TNFi and 239/291 (82%) conventionally treated patients were using NSAID. Both the rate (p=0.007) and the median (IQR) ASAS-NSAID index were higher in biologic treatment group (100 [50] vs 70.8 [89.4]; $p< 0.001$). During follow-up ASAS-NSAID index was decreased significantly in patients treated with TNFi (median 100 to 8.0;$p< 0.001$), however ASAS-NSAID index was not changed in conventionally

(P values for 3rd months BASDAI<0.0001, CRP<0.001, ASDAS-CRP<0.001 respevtively)

and showed that BASDAI and patient global assessment of disease activity were independent determinants of NSAID dosage in biologic treated patients. However, in multivariate analysis there was no significant predictor for NSAID index in conventional treatment group.

Conclusion: Our results showed that NSAID prescription was significantly higher in axSpA patients who have TNFi indication. NSAID use was decreased significantly over time with TNFi and still independently determined by disease activity. However, it is stable in conventionally treated axSpA patients.

Overactivation of the Kinase IKK2 Causes a Hand Osteoarthritis-Like Phenotype in Mice

Sergio Ramirez-Perez, kyle Jones, Umesh Gangishetti and Pallavi Bhattaram, Emory University School of Medicine, Atlanta, GA

SESSION INFORMATION
Session Date: Sunday, November 7, 2021
Session Title: Abstracts: Osteoarthritis & Joint Biology – Basic Science (0940–0943)
Session Type: Abstract Session
Session Time: 9:00AM–10:00AM

Background/Purpose: Hand osteoarthritis (OA) presents the highest prevalence among rheumatic diseases. Synovitis is a defining feature in hand OA that has been associated with radiographic progression and bone erosion. Synovitis is mediated by the activation of several signalling pathways, such as the NF-κB pathway, which remain active within the synovial joint. Activation of NF-κB takes place after phosphorylation of the kinase IKK2, an event that converges in overexpression of inflammatory molecules that play a critical role in hand OA. These mediators include cytokines, chemokines, and degradative enzymes released by fibroblast-like synoviocytes (FLS), contributing to cartilage degeneration and bone erosion. Pathogenic mechanisms driving hand OA remain unclear, and no animal models exist; however, activating specific cell types within the joint could represent a better approach to elucidate disease mechanisms. In order to characterize a hand OA model, our lab induced a constitutive IKK2 activation in Prg4-expressing cells, such as FLS and superficial chondrocytes, as a strategy to study *in situ* inflammation within the synovial joint of mice paws.

Methods: The *R26Stop*^{FL}*ikk2ca-Prg4*^{CreERT2} mouse model that expresses a constitutively active form of IKK2 was used in this study. IKK2 activation was induced in the homozygous mouse model in a tamoxifen-inducible Prg4 CreER-dependent way by intraperitoneal injections to 2-month old mice. Isolation of FLS was performed after four weeks of tamoxifen injections. Bulk RNA-seq was performed from total RNA extraction obtained from FLS at passages 2 to 4. Additionally, single-cell RNA-seq was accomplished in live-sorted cells from the paws joint to identify cell clusters

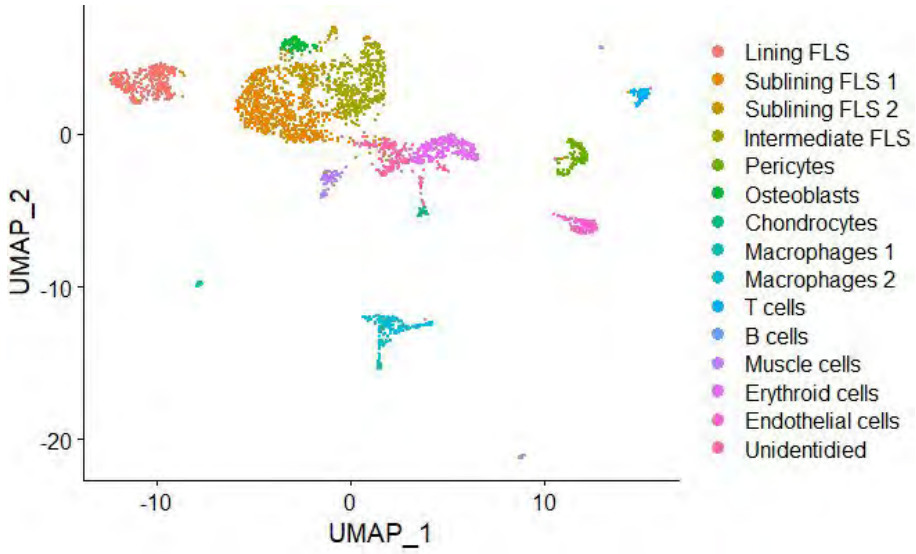

Figure 1. Single-cell RNA-seq clustering in the IKK2ca model. UMAP shows fifteen cell clusters identified in our model. Cluster names are located at the far right of the plot.

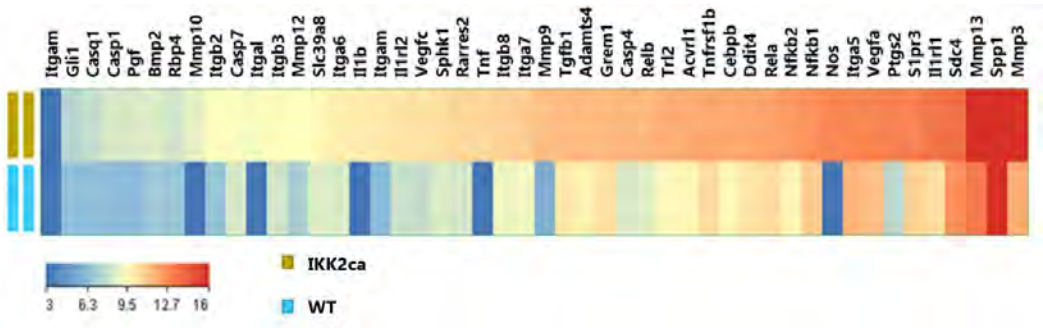

Figure 2. Top DE genes observed in the osteoarthritis signalling canonical pathway. Bulk RNA-seq from IKK2ca vs WT mice FLS was performed. IPA was carried out by using DE genes obtained from bulk RNA-seq. Top DE genes between IKK2ca and WT FLS observed in the OA signalling canonical pathway are shown in the heatmap.

in our model. Public available data was used for bioinformatics analysis to compare DE genes between paws from IKK2ca mice and hand OA [European Nucleotide Archive (ENA) codes PRJEB14422 and PRJEB14595].

Results: Bulk RNA-seq data analysis showed high expression of proinflammatory mediators in FLS obtained from IKK2ca mice compared with WT. Besides, scRNA-seq allowed us to identify fifteen cell clusters in our mice. We observed an increased number of cells in both the osteoblast and macrophage clusters when we compare IKK2ca vs WT. Differential expression (DE) gene analysis between IKK2ca and WT mice showed upregulation of MMPs and NF-κB signalling pathway activation molecules. Interestingly, ingenuity pathway analysis (IPA) from those DE genes revealed the osteoarthritis pathway as one of the top five canonical pathways in the IKK2ca model. Additionally, bioinformatics analysis revealed an overlap of key up and down-regulated genes involved in inflammation and cartilage degeneration in IKK2ca compared with hand OA.

Conclusion: Overactivation of IKK2 induced a hand OA-like phenotype characterized by overexpression of MMP's, cytokines, and NF-κB signalling molecules that contributed to cartilage degeneration.

SESSION INFORMATION
Session Date: Sunday, November 7, 2021
Session Title: Abstracts: Osteoarthritis & Joint Biology – Basic Science (0940–0943)
Session Type: Abstract Session
Session Time: 9:00AM–10:00AM

Background/Purpose: Osteoarthritis (OA) is characterized by increased cartilage thinning, bone remodeling, and inflammation. Post-traumatic OA, which develops after acute direct trauma to the joints, accounts for approximately 12% of all OA cases.[1] Current therapeutic options focus on alleviating symptoms and pain rather than disease

Table 1: OARSI scores

Week-2 injection	Sham-operated (14 weeks after surgery)	Baseline (BL) (2 weeks after surgery)	Vehicle (12 weeks after injection)	LOR (12 weeks after injection)
Total score	5.99	19.17	31.36	19.19
SEM	1.07	1.55	2.48	1.81
***P* value versus BL**				0.9999
***P* value versus vehicle**				0.0004

Week-3 injection	Sham-operated (15 weeks after surgery)	Baseline (BL) (3 weeks after surgery)	Vehicle (12 weeks after injection)	LOR (12 weeks after injection)
Total score	6.09	23.17	30.45	21.20
SEM	1.25	1.36	1.42	1.00
***P* value versus BL**				0.4522
***P* value versus vehicle**				0.0001

Week-4 injection	Sham-operated (16 weeks after surgery)	Baseline (BL) (4 weeks after surgery)	Vehicle (12 weeks after injection)	LOR (12 weeks after injection)
Total score	6.97	16.88	24.95	18.63
SEM	1.32	1.04	1.74	1.61
***P* value versus BL**				0.6257
***P* value versus vehicle**				0.0111

modification. Lorecivivint (LOR; SM04690), an intra-articular (IA), small-molecule CLK/DYRK inhibitor that modulates the Wnt pathway, has been shown in animal studies to induce chondrogenesis, protect cartilage, and reduce inflammation and, thereby, improve joint health.[2] A single IA LOR injection was evaluated in a rat model of knee instability to determine its protective and regenerative effects when injected at different timepoints after induction of post-traumatic OA.

Methods: Knee instability/post-traumatic OA was surgically induced in rats by combining anterior cruciate ligament transection with partial medial meniscus transection (ACLT+pMMx). LOR (0.3 µg) or vehicle was injected into the IA space of the damaged knee at 2, 3, or 4 weeks after induction of OA. OA-induced (n=10/group) or sham-operated (surgery without ACLT+pMMx; n=5/group) rats were sacrificed at the injection timepoint (baseline) or 12 weeks after LOR/vehicle injection (study conclusion). Histological grades were evaluated using the summed OARSI scores (stage and grade of cartilage damage)[3] of the anterior and posterior medial femoral condyle (MFC) and medial tibial plateau (MTP). Weight distribution analysis was performed using an incapacitance meter at several timepoints. Statistical analysis was performed using one-way ANOVA with Dunnett's multiple comparison test.

Results: ACLT+pMMx surgeries led to increased OARSI scores in rats by 2 weeks compared with sham surgeries. LOR treatment at Weeks 2, 3, and 4 led to significant decreases ($P< 0.05$) in total OARSI scores (Table 1) at the end of the study compared with vehicle treatment. Rats treated with LOR for 12 weeks and rats at injection baseline had similar OARSI scores, suggesting that LOR treatment arrested the progression of cartilage damage. Significant improvements ($P< 0.05$) were also observed in the weight distribution of LOR-treated rats in the 3- and 4-week groups at 6 and 12 weeks after their respective IA injections compared with vehicle-treated rats.

Conclusion: LOR exhibited cartilage-protective effects and slowed disease progression in the ACLT+pMMx model in vivo and, therefore, has potential as a structure-modifying treatment for OA.

Transcriptional Regulation of Synovial Macrophages in the Aging Joint

Shang-Yang Chen[1], Anna Montgomery[1], Anna Woo[1], Gaurav Gadhvi[1], Harris Perlman[1], Carla Cuda[1], Dawn Bowdish[2] and **Deborah Winter**[3], [1]Northwestern University, Chicago, IL, [2]McMaster University, Hamilton, ON, Canada, [3]Northwestern University Division of Rheumatology, Chicago, IL

SESSION INFORMATION
Session Date: Sunday, November 7, 2021
Session Title: Abstracts: Osteoarthritis & Joint Biology – Basic Science (0940–0943)
Session Type: Abstract Session
Session Time: 9:00AM–10:00AM

Background/Purpose: Macrophages are critical in maintaining tissue homeostasis, as well as in inflammation and immune response, but their function deteriorates with age increasing susceptibility to arthritis. In the joint synovium, we and others have shown that several distinct populations of macrophage co-exist at steady-state and differ in their ontogeny, localization, and function. Our prior work demonstrated that the epigenomic landscape of macrophages is specified by a combination of transcription factors (TFs) that become active during differentiation or in response to the local environment: however, these processes may be disrupted over time. Here, we investigate how the transcriptional regulation of synovial macrophages is altered in the aging joint.

Methods: We use young (3-6 months), old (20-24 months) mice with a C57BL/6 background. Ankles were dissected, muscle resected, and bone marrow removed. Synovium is exposed and digested into a single-cell suspension for Fluorescence-Activated Cell Sorting (FACS). Macrophages were identified as CD45+CD11B+Ly6G-Ly6C-CD64+ cells and further subdivided into four populations by expression of MHCII and CX3CR1. In addition, monocytes were sorted from the blood and bone marrow. Either RNA-seq or ATAC-seq was performed and sequenced on Illumina Nextseq. Sequencing files were demultiplexed and resulting fastq files were trimmed and aligned to mm10 followed by either mappin to genes with HTseq (RNA-seq) or peak calling and annotation with HOMER (ATAC-seq).

Results: We isolate four macrophage subpopulations which we characterize based on their steady-state identity as CX3CR1+MHCII- tissue-resident synovial lining, CX3CR1+MHCII+ newly infiltrating cells; CX3CR1-MHCII- tissue-resident interstitial, CX3CR1-MHCII+ monocyte-derived interstitial. These populations have distinct epigenomic landscapes in the young joint with the tissue-resident macrophage populations exhibiting more similar transcriptional profiles than the monocyte-derived populations. However, as the mouse ages, the gene expression of all the subpopulations converges on a transcriptional profile similar to young infiltrating macrophages. This is consistent with the observation that there are increased numbers of monocyte-derived macrophages in the joint. Moreover, our results suggest a decrease in the activity of the TF, Mef2C, associated with the expression of tissue-resident genes. By comparing the epigenomic landscape of monocytes in young and aged mice, we observe an decrease in chromatin accessibility at the binding sites of cell-type-specific TFs, such as KLF and PU.1. Thus, the dysfunction of aged synovial macrophages traces back to changes in monocytes, whose contribution increases over time.

Conclusion: These results further our understanding of how the function of different macrophage subpopulations change with age. Future studies will investigate specific targets to reprogram the synovial macrophage compartment in aging.

Metabolomic Profiling of Synovial Tissue of Patients with Osteoarthritis

Jessica Murillo Saich[1], Roxana Coras[2], Robert Meyer[3] and Monica Guma[4], [1]University of California San Diego, La Jolla, CA, [2]University of California San Diego/Department of Medicine, Autonomous University of Barcelona, San Diego, CA, [3]San Diego VA Healthcare Service, La Jolla, CA, [4]University of California San Diego/San Diego VA Healthcare Service/ Department of Medicine, Autonomous University of Barcelona, La Jolla, CA

SESSION INFORMATION
Session Date: Sunday, November 7, 2021
Session Title: Abstracts: Osteoarthritis & Joint Biology – Basic Science (0940–0943)
Session Type: Abstract Session
Session Time: 9:00AM–10:00AM

Background/Purpose: Increasing evidence indicates that osteoarthritis (OA) progression is mediated not simply by progressive degeneration of cartilage, but also by low-grade synovial inflammation (synovitis) that is associated with increased symptoms in knee OA (KOA). Ongoing inflammatory responses are associated with dramatic shifts in tissue metabolism. The objective of this work is to explore the metabolomic profiling in synovial tissue (ST) from OA patients and its association with synovial inflammation.

Methods: 37 ST samples (28 knees and 9 hips) were collected from patients with OA during hip or knee replacement. ST was either fixed in formalin for histology analysis, cultured (explants) for 24 hours to collect supernatant for cytokine analysis, or snap-frozen for metabolomic analysis. ST samples were categorized as inflammation 0-I vs II-III according

Table 1. Comparison of cytokines from explants (pg/ml) and metabolites from ST (μM) concentrations between stages of inflammation.

	Inflammation 0-I n=13	Inflammation II-III n=24	p
IL-6	22801 ± 27542	56793 ± 48175	0.06
CXCL2	756 ± 756	2229 ± 1966	0.05
Alanine	3.41 ± 1.24	5.53 ± 2.64	0.002
Fumarate	0.15 ± 0.10	0.24 ± 0.11	0.012
Glutamine	2.17 ± 1.32	3.90 ± 2.61	0.032
Glycine	1.70 ± 2.40	4.51 ± 4.18	0.014
Lactate	27.17 ± 13.53	40.63 ± 19.22	0.032
Leucine	1.80 ± 1.02	2.59 ± 1.01	0.030
Lysine	1.93 ± 1.10	3.00 ± 1.37	0.020
Methionine	0.34 ± 0.23	0.50 ± 0.39	0.019
TMNO	0.19 ± 0.10	0.36 ± 0.26	0.007
Tryptophan	0.26 ± 0.15	0.046 ± 0.21	0.017
Valine	1.36 ± 0.76	2.28 ± 1.02	0.01

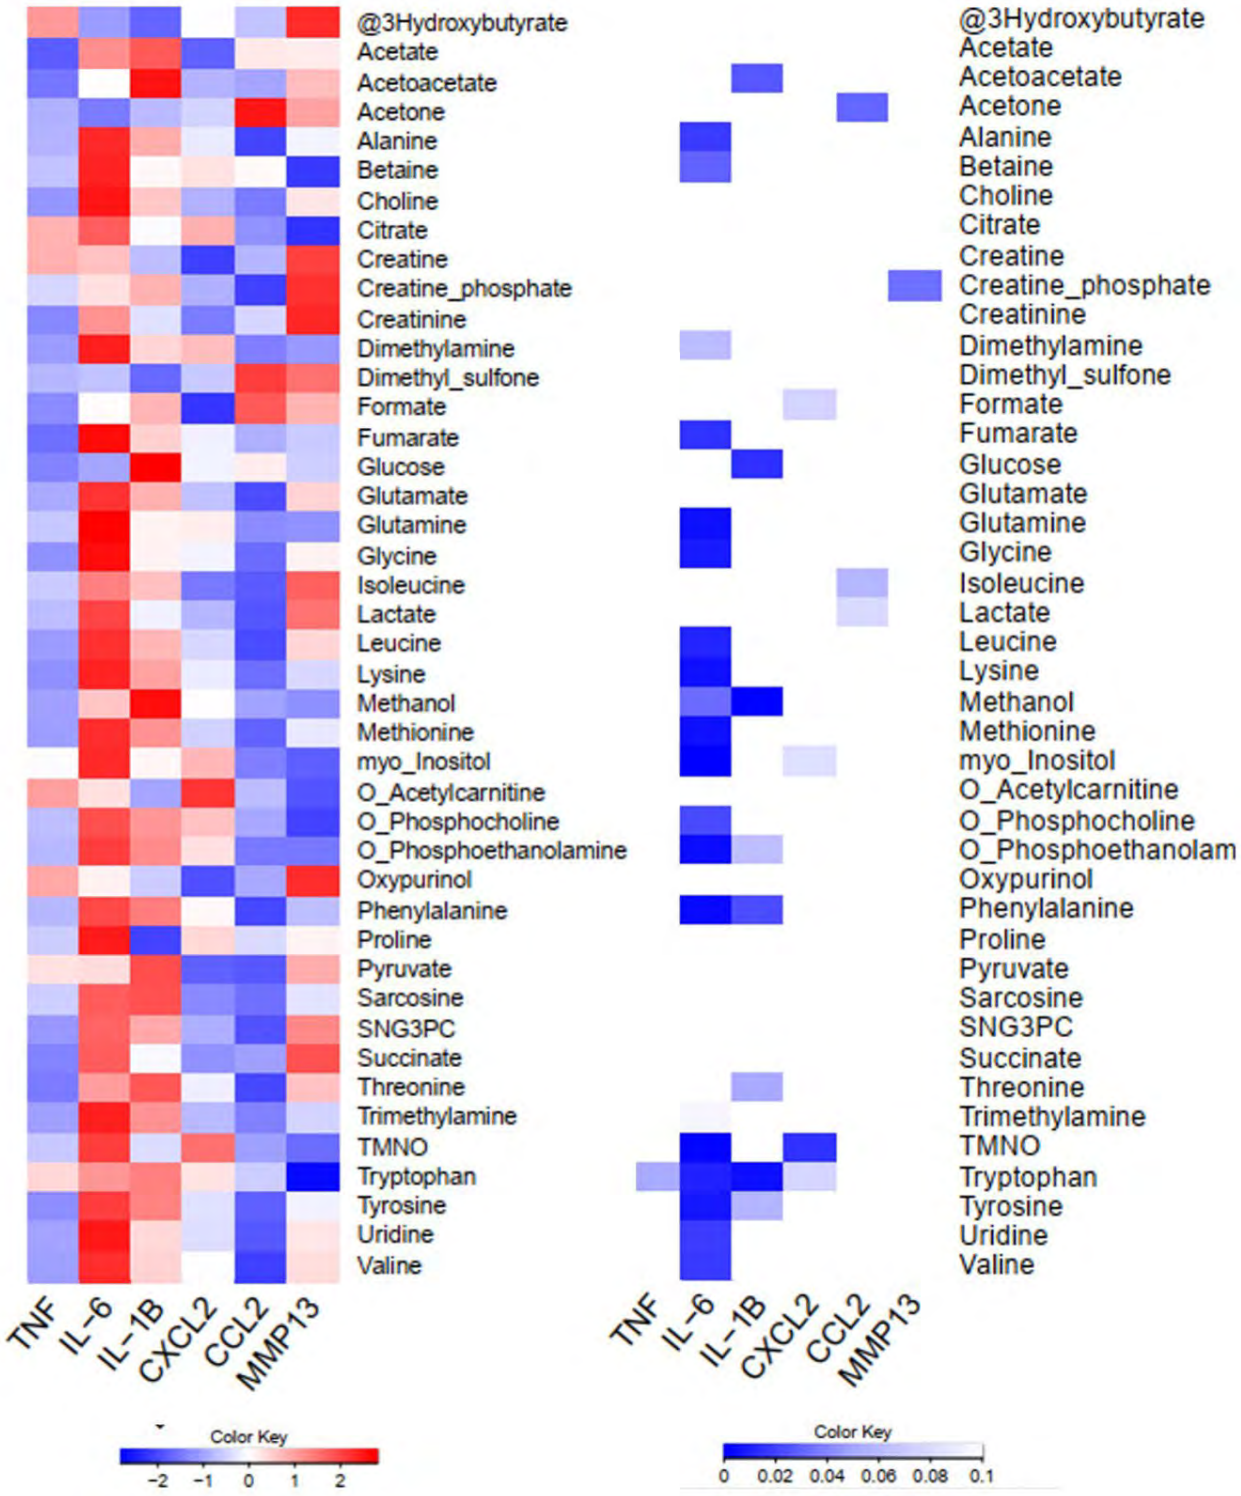

Figure 1. Pearson correlation between polar metabolites in ST obtained by 1H-NMR and proinflammatory mediators quantified from explants. A) The strength of association of each pair were used to form a cluster heatmap to lend insight into which mediator were correlated with which group of polar metabolites; B) Correlation p values are displayed in B. TNF: Tumor necrosis factor; IL-6: Interleukin 6; IL-1B: Interleukin 1β; CXCL2: Chemokine (C-X-C motif) ligand 2; CCL2: C-C motif chemokine 2; MMP13: Matrix metallopeptidase 13.

to the Krenn histopathological synovitis score. We also categorized our samples in fibrosis 0-I vs fibrosis II-III with Masson's trichrome staining. A 600 MHz Bruker Avance III spectrometer ^{1}H-NMR was used to acquire NMR spectra of ST samples. Software Chenomx NMR suite 8.5 professional was used for metabolite identification and quantifi-

cation. The samples were normalized by volume/weight and the concentrations are reported in μM. Proinflammatory mediators were measured by ELISA. Metaboanalyst 5.0, SPSS v26, and R studio were used for statistical analysis.

Results: 51 metabolites were detected in the ST by 1H-NMR. ST samples were divided in inflammation 0-I (n= 13) vs inflammation II-III (n=24), and fibrosis 0-I (n=18) vs fibrosis II-III (n=19). Only 4 metabolites were different between the 2 fibrosis categories (acetoacetate, creatine phosphate, tryptophan and proline). However, the levels of several metabolites (lactate alanine, fumarate, glutamine, glycine, leucine, lysine, methionine, trimethylamine N-oxide, tryptophan and valine) were elevated in ST with inflammation II-III compared to 0-I (Table 1). Proinflammatory mediators (TNF, IL-1b, IL6, CCL2, CXCL2 and MMP13) from ST explants (n-24, 9 with inflammation 0-I, and 15 with inflammation II-III) were measured in the supernatants. CXCL2 and IL-6 levels were higher in ST explants supernatants with inflammation II-III than with 0-I (Table 1). IL-6, but also IL-1β, correlated positively with several metabolites (Figure 1).

Conclusion: Metabolomic profiling of synovial tissue can identify metabolic changes associated with inflammation. Further studies are needed to determine whether metabolomic profiling of synovial tissue can identify new therapeutic targets in inflammatory osteoarthritis.

Student t test was used to evaluate the differences between groups. $P<0.05$ was considered significant. Continous variables are expressed in mean ± standard deviation. TMNO: Trimethyalamine N-oxide.

A Characterization of the Gut and Cutaneous Microbiome of Monozygotic Twins Discordant for Psoriatic Disease

Julia Manasson[1], Matthew Stapylton[2], Rhina Medina[1], Rochelle Castillo[3], Parvathy Vasudevanpillai Girija[1], Adriana Heguy[1], Carles Ubeda[4], Mid-Atlantic Twin Registry (MATR)[5], Jose Clemente[2] and Jose Scher[1], [1]New York University School of Medicine, New York, NY, [2]Icahn Institute for Genomics and Multiscale Biology, Icahn School of Medicine at Mount Sinai, New York, NY, [3]NYU Langone Health, New York, NY, [4]La Fundación para el Fomento de la Investigación Sanitaria y Biomédica de la Comunitat Valenciana, Valencia, Spain; CIBERESP, Madrid, Spain, [5]Virginia Commonwealth University, Richmond, VA

SESSION INFORMATION
Session Date: Sunday, November 7, 2021
Session Title: Abstracts: Spondyloarthritis Including PsA – Basic Science (0944–0947)
Session Type: Abstract Session
Session Time: 9:00AM–10:00AM

Background/Purpose: Psoriasis (PsO) is an inflammatory, immune-mediated skin disorder affecting ~3% of the population worldwide. It is associated with multiple comorbidities, including psoriatic arthritis (PsA), which occurs in up to a third of patients. While genes contribute to the pathogenesis of psoriatic disease, twin studies demonstrate substantial discordance in PsO and PsA, suggesting that epigenetics and environmental factors play a significant role. In fact, there is increasing evidence that the microbiome has an impact on psoriatic disease pathogenesis. However, prior investigations were performed in populations of unrelated individuals and could not discern environmental from genetic influences. To characterize the host-microbiome relationship, we studied the gut and skin microbiome of monozygotic (MZ) twins discordant for psoriatic disease in order to determine disease-specific microbial perturbations that are independent of host-genes.

Methods: Stool and skin swabs were collected from subjects with psoriatic disease and their unaffected MZ twin siblings (pairs=9, n=18). Non-lesional (NL) or healthy skin was swabbed at three separate sites: bicep, scalp, and elbow/forearm. Fecal samples underwent shotgun metagenomic sequencing to deeply characterize the gut microbiome taxonomy and functional pathways at high resolution. Sequences were processed with the HUMAnN and MetaPhlAn2 pipelines. Skin swab samples underwent 16S rRNA sequencing to characterize the cutaneous bacterial microbiome. Forward sequences were processed with the QIIME2 pipeline and SILVA reference database. Downstream computational analysis was performed using several libraries in R, including DESeq2.

Results: In gut samples, the relative abundance of *Ruminococcus bromii* species was significantly reduced and two pathways related to tetrahydrofolate biosynthesis were upregulated in psoriatic twins compared to their corresponding unaffected siblings (Fig 1; p< 0.05, Mann-Whitney). In NL skin samples from psoriatic twins, there was a

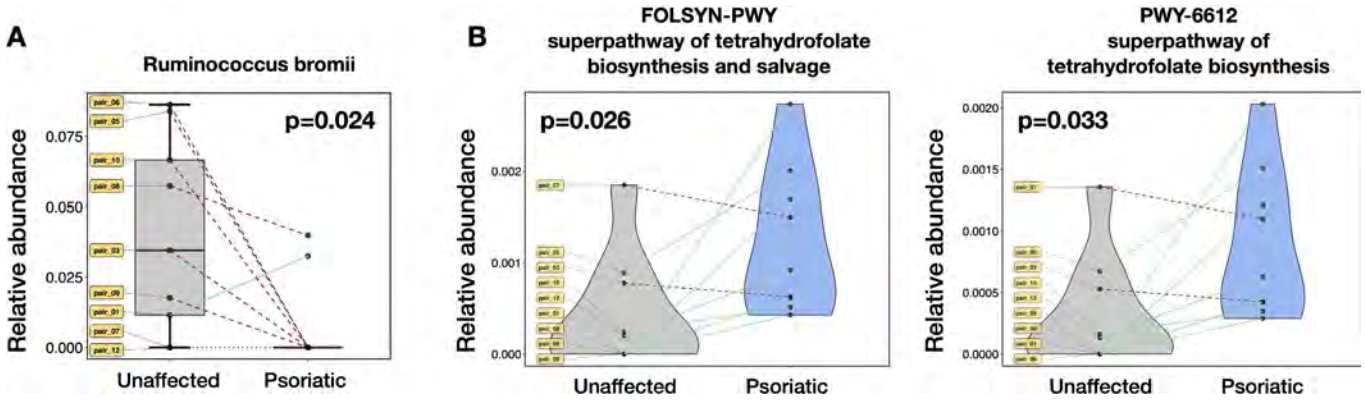

Figure 1. Monozygotic (MZ) twins discordant for psoriatic disease demonstrate differences in their gut microbial features. Psoriatic twins show a significant reduction in Ruminococcus bromii species (A), and a higher abundance of two tetrahydrofolate biosynthesis pathways (B) compared to their unaffected siblings (p<0.05, Mann-Whitney).

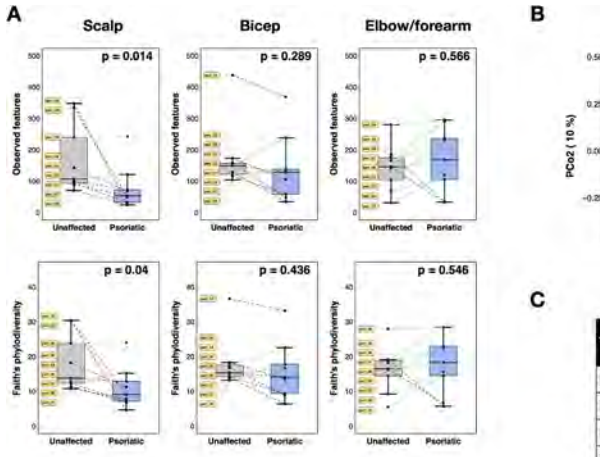

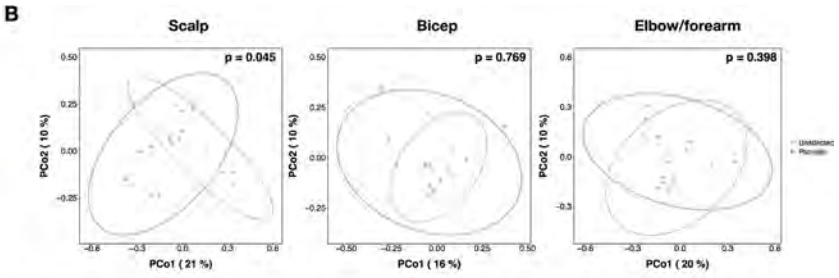

C

Taxon	Log2-fold change (Psoriatic/Healthy)	p-value	p-value with FDR adjustment	Mean relative abundance (%)
Bacilli (c)	2.831	0.001	0.018	63.661
Deinococcales (o)	-21.331	6.40E-13	2.88E-11	0.175
Fusobacteriales (o)	-3.429	0.002	0.037	0.641
Bacillales (o)	2.557	0.0007	0.016	57.615
Deinococcaceae (f)	-21.459	4.66E-13	4.05E-11	0.175
Deinococcus (g)	-21.912	1.55E-13	2.48E-11	0.175

Figure 2. The cutaneous microbiome of non-lesional (NL) skin from the scalp of monozygotic (MZ) psoriatic twins is different from corresponding healthy skin of their unaffected siblings. (A) Alpha diversity is significantly reduced in the scalp of psoriatic twins compared to their unaffected siblings (p<0.05, Mann-Whitney; observed features and Faith's phylodiversity), but not in the bicep or elbow/forearm. (B) There is a significant difference in the beta diversity of scalp microbial communities between psoriatic and unaffected twins (p<0.05, Permanova; unweighted UniFrac), but not in the bicep or elbow/forearm. (C) Differential abundance analysis with DESeq2 demonstrates a higher abundance of the Bacillales order and related taxa, and a lower abundance of the Deinococcus genus and related taxa in psoriatic twins compared to their unaffected siblings (p<0.05 with FDR correction). Prior to DESeq2 analysis, features were filtered to ensure that every feature was present in at least 2 samples in order to minimize outliers.

significant reduction in alpha diversity and beta diversity differences in microbial communities of the scalp, but not the bicep or elbow/forearm, compared to healthy samples from unaffected twins (Fig 2A-B; $p< 0.05$, Mann-Whitney and Permanova). Differential analysis of taxa in the scalp identified a higher abundance of the *Bacillales* order and related taxa, as well as a lower abundance of the *Deinococcus* genus and related taxa in psoriatic twins compared to their unaffected siblings (Fig 2C; $p< 0.05$ with FDR correction).

Conclusion: This is the first study exploring microbial differences in MZ twins discordant for psoriatic disease. In agreement with our previous results, we found that *Ruminococcus* is reduced or virtually absent in the gut of psoriatic patients, and may therefore be associated with psoriatic disease. Additionally, we discovered that even healthy-appearing NL skin of psoriatic subjects, particularly in the scalp, exhibited microbial perturbations and decreased diversity compared to unaffected twins. A further understanding of these changes and their downstream effects should shed light into the pathogenesis of psoriatic disease beyond genetic susceptibility.

SESSION INFORMATION
Session Date: Sunday, November 7, 2021
Session Title: Abstracts: Spondyloarthritis Including PsA – Basic Science (0944–0947)
Session Type: Abstract Session
Session Time: 9:00AM–10:00AM

Background/Purpose: Dysregulated endothelial cell (EC) function and altered (lympho)angiogenesis crucially contribute to synovial pathology in inflammatory arthritis. Additionally, endothelium plays a key role in the positional identity of sublining synovial fibroblasts and their pathogenic expansion in RA. Here, we utilized single-cell RNA sequencing (scRNA-seq) to characterize the diversity of synovial vascular and lymphatic ECs and functionally annotate synovial ECs across inflammatory arthritides.

Methods: We obtained synovial tissue from 12 knees, 8 wrists, 8 metacarpophalangeal and one sternoclavicular joint from 14 RA, 5 SpA, 3 PsA and 3 patients with undifferentiated arthritis (UA, 2 mono-, 1 polyarthritis) using ultrasound-guided synovial biopsy. We dissociated synovium into a single cell suspension through a combined mechanical-enzymatic dissociation. Additional tissue was formalin-fixed and paraffin-embedded for immunohistology (Krenn

synovitis score, pathotype). We created scRNA-seq libraries with 10x Genomics Chromium and sequenced them on NovaSeq6000 (min. 50'000 reads/cell). We mapped the reads to the reference genome GRCh38.p13 (transcripts from GENCODE Release 32) and analysed the scRNA-seq data with R/Bioconductor tools, including quality control, filtering, graph-based clustering, manual and computational cell-type annotation, differential abundance (DA), and differential state analysis. We visualized data using iSEE.

Results: Our dissociation protocol yielded highly viable (median 90%) single-cell suspensions from which we generated 107'438 high quality synovial single cell profiles. We could classify synovial pathotypes in 86% of the samples (24% diffuse myeloid, 29% lympho-myeloid, 33% pauci-immune). Krenn synovitis score ranged from 2 to 8 (median 4), suggesting a moderate inflammation in most synovia. ScRNA-seq analysis identified 6 principal and 4 minor synovial cell populations forming 38 distinct synovial cell clusters (Fig 1A). PECAM1^{+} ECs (n=10'231) represented 4-15% (25Q-75Q, median 9%) of all synovial cells, comprising 8 distinct cell subpopulations: ACKR1^{high} SELE^{high} ICAM1^{high} IL6^{+} venous ECs, ACKR1^{high} SELE^{high} IL6^{-} venous ECs, ACKR1^{high} SELE^{low} IL6^{-} venous ECs, COL3A1^{+} and

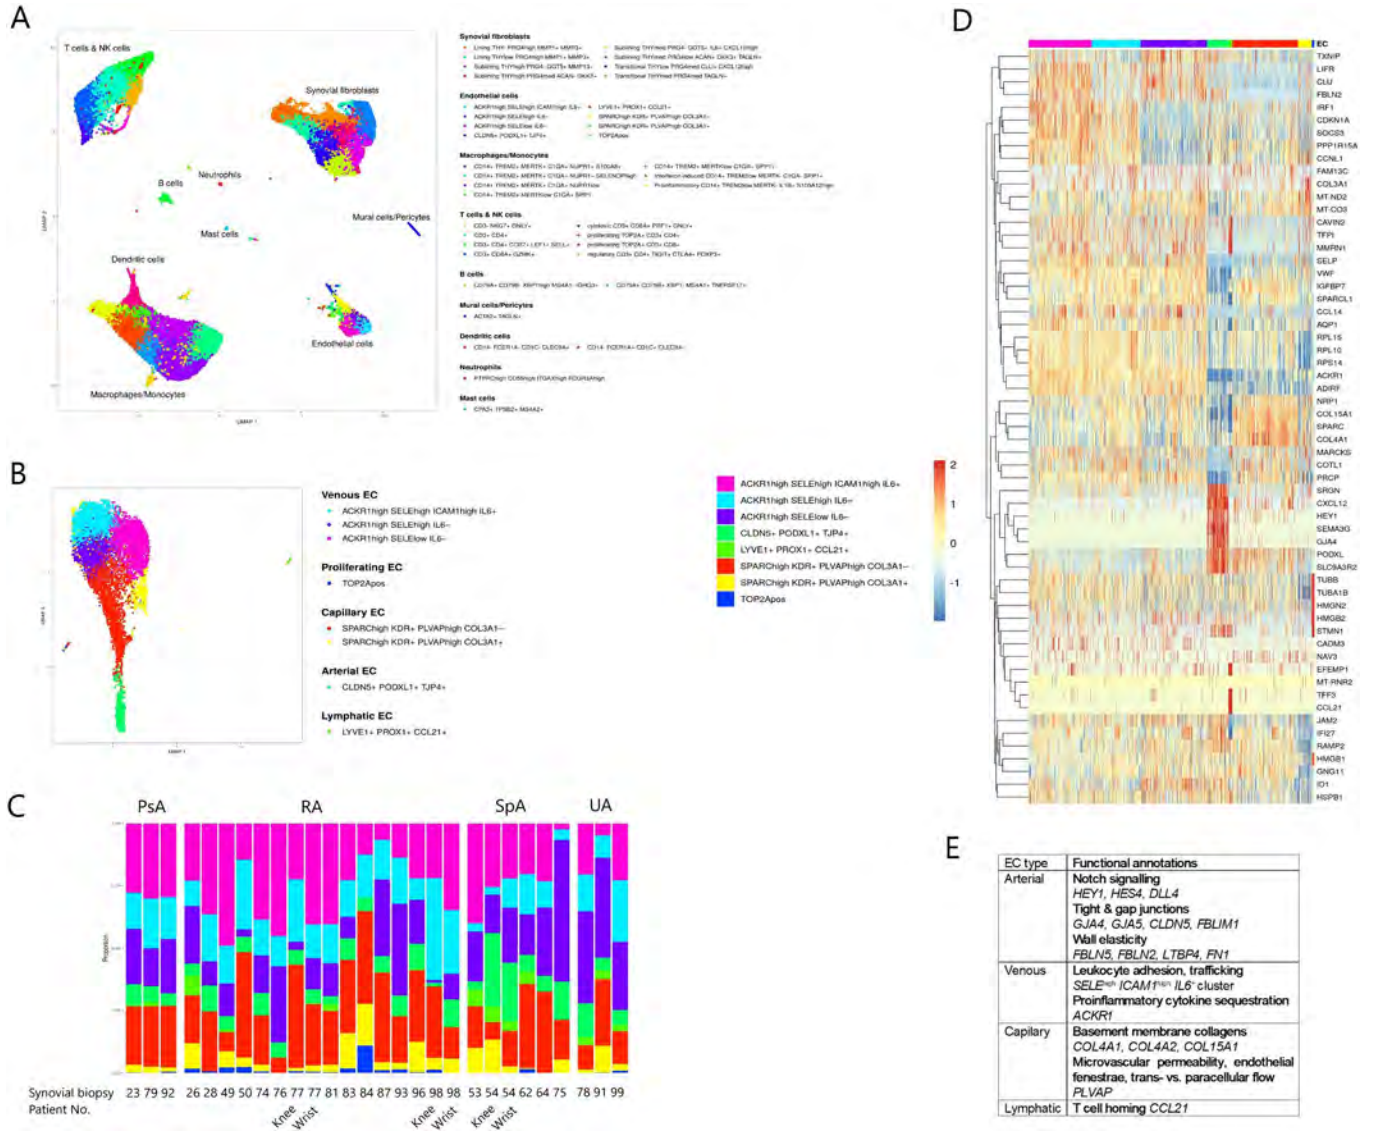

Figure 1. ScRNA-seq: UMAP plots with annotations of (A) all synovial cells and (B) ECs. (C) A heterogeneous distribution of the eight EC subpopulations across patients with PsA, RA, SpA and UA. The EC subpopulations are specified with the colour palette. (D) Top 10 cluster marker genes per each of the eight EC subpopulations. The EC subpopulations are specified with the colour palette at the top of the heatmap. (E) Core enriched genes in EC subpopulations inferring EC functions.

COL3A1^{-} SPARC^{high} KDR+ PLVAP^{high} capillary ECs, highly proliferative TOP2A^{+} ECs, CLDN5^{+} PODXL1^{+} TJP4^{+} arterial ECs and lymphatic LYVE1^{+} PROX1^{+} CCL21^{+} ECs (Fig 1B). EC subpopulations were heterogeneously distributed across patients (Fig 1C), but none of the EC subpopulations was significantly enriched in RA, PsA and SpA synovia in our patient cohort. We defined synovial pan-endothelial and subtype-specific EC markers (Fig 1D) and identified genes that infer the core EC subtype-specific functions (Fig 1E).

Conclusion: We created a comprehensive single-cell atlas of synovial ECs in patients with inflammatory arthritis. Our EC dataset comprises more than 10'000 EC profiles, representing a reference dataset for annotating synovial ECs and guiding EC subtype-specific functional studies.

SESSION INFORMATION
Session Date: Sunday, November 7, 2021
Session Title: Abstracts: Spondyloarthritis Including PsA – Basic Science (0944–0947)
Session Type: Abstract Session
Session Time: 9:00AM–10:00AM

Background/Purpose: The differential diagnosis of Rheumatoid Arthritis (RA) and Psoriatic arthritis (PsA) is often difficult due to the similarity of symptoms and the unavailability of reliable clinical biomarkers. Lipid alterations have been suggested to contribute to the pathophysiological processes in the knee joint, and chronic inflammation induces significant changes in the synovium and synovial fluid (SF) lipidome. Therefore, we aimed to evaluate whether differences in the lipid profiles from synovial membrane (SM) and SF could support the differential diagnosis of these diseases.

Methods: SM samples of patients affected by RA (n=6), PsA (n=12) and control donors (n=10) were compared using Matrix-Assisted Laser Desorption Ionization Mass Spectrometry Imaging (MALDI-MSI) for spatially resolved lipid analysis. To this end, tissue sections were measured on a RapifleX MALDI-TOF/TOF instrument. Next, a targeted approach based on multiple reaction monitoring (MRM-MS) was performed to further validate the lipidomic alterations reported by MALDI-MSI between RA and PsA tissues. In this case, lipids extracted from SF (control donors (n=4), RA (n=21) and PsA (n=27)) were analyzed in a QTRAP 4000 mass spectrometer coupled with an ExpressHT™-Ultra HPLC system for the targeted analysis of 84 lipid species. Principal component analysis (PCA) and discriminant analysis (DA) were used for data interpretation.

Results: Lipid profiles of PsA and RA synovial membranes were unequivocally distinguished by MALDI-MSI followed by PCA-DA. Interestingly, several lipid species, including sphingomyelins, phosphatidylcholines (PC) and phosphatidylethanolamines (PE), presented the greatest separation power to classify RA and PsA tissue samples. On the other hand, the lipid profile of arthritic SM samples was also discriminated from control tissues. Specifically, several lysophosphatidylcholines showed the greatest discriminative capability for separating groups. The abundance of those lipid species with discriminatory potential were further compared using ANOVA. This analysis found 35 lipid species significantly different among the study groups, where most of them were significantly increased in RA and PsA compared to controls. Particularly, 11 lipids showed higher levels in PsA tissues compared with RA, including several PC and PE such as PE 34:1 and PE 36:1. The spatial distribution of these PE species was associated with areas of the sublining layer with increased vascularity and inflammatory cell infiltrates, according to MALDI-MSI images. On the other hand, RA and PsA patients were also correctly classified based on the SF levels of all quantified lipid species

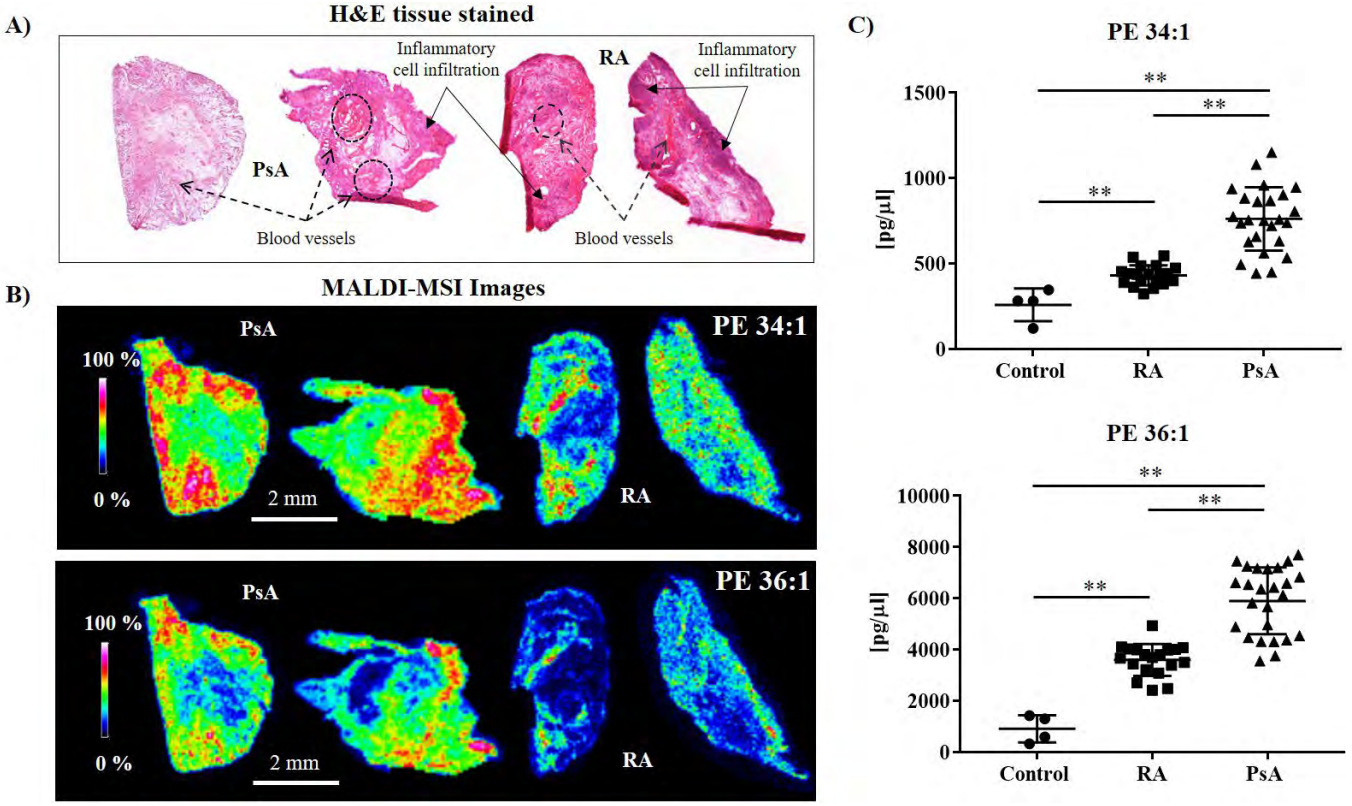

Figure 1. Increased levels of PE 34:1 and PE 36:1 in the PsA synovium and synovial fluid compared to RA. A) Images show samples from two representative RA and PsA biopsies stained with hematoxylin and eosin. B) MALDI-MSI images showing the differences in the abundance and spatial distribution of PE 34:1 and PE 36:1 in PsA synovium compared to RA samples. The colour scale at the bottom left indicates the relative abundance. Pink or white denote higher abundances, while blue or black denote lower abundances. C) SF levels of PE 34:1 and PE 36:1 are increased in PsA patients compared to RA. Y-axis represents concentrations in pg/µl. **p-value < 0.01. PE, phosphatidylethanolamine; RA, rheumatoid arthritis; PsA, psoriatic arthritis; SF, synovial fluid.

according to PCA and clustering analysis. Finally, we were able to validate the increased levels of PE 34:1 and PE 36:1 in the SF of PsA patients compared to RA (Figure 1).

Conclusion: Our study shows a distinct lipid profile between RA and PsA synovium and synovial fluid, and reports potential clinically useful lipid markers for the differential diagnosis of these diseases.

Cytokine Competent Gut-joint Migratory T Cells Contribute to Inflammation in the Joint

Adam Lefferts[1], David Claypool[1], Eric Norman[1], Uma Kantheti[1] and Kristine Kuhn[2], [1]University of Colorado, Anschutz Medical Campus, Aurora, CO, [2]University of Colorado Anschutz Medical Campus, Aurora, CO

SESSION INFORMATION
Session Date: Sunday, November 7, 2021
Session Title: Abstracts: Spondyloarthritis Including PsA – Basic Science (0944–0947)
Session Type: Abstract Session
Session Time: 9:00AM–10:00AM

Background/Purpose: Although studies have identified the presence of gut-associated cells in the enthesis of joints affected by spondyloarthritis, a direct link through cellular transit between the gut and joint has yet to be formally demonstrated. Using the KikGR transgenic mice to label in situ and track cellular trafficking from the distal colon to the joint under inflammatory conditions of both the gut and joint, we aimed to determine the relative roles of gut-trafficked T cells in the joint.

Methods: KikGR x $TNF^{DARE/+}$ mice, which spontaneously develop Crohn's like intestinal inflammation and spondyloarthritis-like joint inflammation, and KikGR x $TNF^{+/+}$ controls underwent colonoscopy-guided photo-labeling of the distal colon epithelium. At 72 hours after photo-labelling, we harvested the popliteal lymph nodes (PLNs) from both KikGR x $TNF^{DARE/+}$ and KikGR x $TNF^{+/+}$ mice. Following magnetic sorting of T cells by negative selection, T cells were stimulated with anti-CD3 anti-CD28 for 4 hours in the presence of protein transport blockade. T cells then were evaluated by flow cytometry for activation, cytokine production, and transcription factors. To assess the contribution of gut-derived T cells to disease, we reconstituted $Rag1^{-/-}$ mice with colon epithelium associated T cells from and $TNF^{DARE/+}$ and $TNF^{+/+}$ donors harvested by negative selection magnetic sorting. After 8 weeks of homeostatic proliferation, we assessed joint inflammation by histology 5 days following injection of complete Freund's adjuvant (CFA) into the left hind hock.

Results: 72 hours following photo-labeling, gut-trafficked T cells are observed in the Achilles enthesis in equal proportions (~10% of total T cells) between $TNF^{DARE/+}$ and $TNF^{+/+}$ mice. In the PLNs, photo-labeled T cells expressed markers of terminal differentiation, with 51% of labeled cells Foxp3+ and 19% Roryt+, compared to 10% and 1.7% in the unlabeled fraction, respectively ($P< 0.01$), similar in both $TNF^{DARE/+}$ and $TNF^{+/+}$ mice. Ex vivo stimulation of T cells isolated from the PLNs demonstrated significant enrichment of TNF and IL-17A production in the photo-labeled gut-derived T cells compared to unlabeled cells. As expected, gut-derived T cells derived from $TNF^{DARE/+}$ animals produced higher levels of TNF compared to littermate controls (45% vs 5%, $P=0.1$); However, while we observed a

large and significant enrichment for Il-17A positivity in greater proportion within gut-derived cells in $TNF^{+/+}$ mice (41% vs 1%, P< 0.0001) this enrichment was smaller and not significant in the $TNF^{DARE/+}$ (29% vs 5% P =0.2). Transfer of gut-derived T cells into $Rag1^{-/-}$ mice resulted in moderately increased inflammation in recipients of $TNF^{+/+}$ T cells (P=0.056), and a significant increase in inflammation in recipients of $TNF^{DARE/+}$ cells (P=0.01), compared to unmanipulated $Rag1^{-/-}$ mice, when challenged with hock injection of CFA.

Conclusion: Our data demonstrate a direct link between the gut and joint through trafficking of gut-derived T cells with the potential to be directly pathogenic through production of pro-inflammatory cytokines like IL-17 and TNF and exacerbation of joint inflammation. Altogether our data suggest a means by which gut-derived T cells may drive joint pathology.

Immunometabolism of Neutrophils in Antiphospholipid Syndrome (APS)

Ajay Tambralli[1], Alyssa Harbaugh[2], Shanea Estes[2], Srilakshmi Yalavarthi[2], Claire Hoy[2], Gautam Sule[2] and Jason Knight[2], [1]University of Michigan, Ypsilanti, MI, [2]University of Michigan, Ann Arbor, MI

SESSION INFORMATION
Session Date: Sunday, November 7, 2021
Session Title: Abstracts: Antiphospholipid Syndrome (0948–0951)
Session Type: Abstract Session
Session Time: 9:00AM–10:00AM

Background/Purpose: Neutrophil hyperactivity and neutrophil extracellular trap (**NET**) release (**NETosis**) appear to play roles in APS pathophysiology. Until recently, it was thought that neutrophils relied primarily on glucose uptake and glycolysis to fulfill their energy needs. Accumulating evidence now suggests that metabolic plasticity guides both physiologic and pathologic neutrophil functions. Our previous work characterizing the transcriptome of APS neutrophils found that genes related to glycogenolysis and the pentose phosphate pathway were markedly upregulated. We now begin to characterize how neutrophil metabolism may impact APS-relevant NETosis.

Methods: Primary human neutrophils were stimulated with phorbol myristate acetate (**PMA**), calcium ionophore A23187 (**Ca iono**), or affinity-purified anti-β_2GPI IgG (**aβ_2GPI**). PMA and Ca iono were chosen as mechanistic anchors given their divergent mechanisms for triggering NETosis (NADPH oxidase-dependent and -independent, respectively). Inhibitors included 2-deoxy-D-glucose (**2-DG**, a competitive inhibitor of glycolysis) and 6-aminonicotinamide (**6-AN**, a glucose-6-phosphate dehydrogenase inhibitor that blocks the pentose phosphate pathway). Metabolic flux analysis was conducted using a Seahorse analyzer. NETosis was quantified with SYTOX Green. APS-associated thrombosis was modeled in C57BL/6 mice via electrolytic activation of the inferior vena cava (**IVC**) endothelium.

Results: In the metabolic flux analysis, Ca iono triggered an earlier peak in oxygen consumption than did PMA (30 min vs. 90 min). Peak Ca iono-induced oxygen consumption decreased by 30% with 2-DG and by 74% with 6-AN. For PMA, the decreases were 39% (2-DG) and 47% (6-AN). Interestingly, as compared with healthy control neutrophils, neutrophils isolated from primary APS patients (n=3) demonstrated a pattern of oxygen consumption indicative of more robust mitochondrial reserve. When NETosis was considered, PMA-induced NETosis was sensitive to both 2-DG (46% reduction) and 6-AN (57% reduction). In contrast, Ca iono-induced NETosis was insensitive to both in-

hibitors. Importantly, aβ_2GPI-induced NETosis mirrored PMA and was sensitive to both 2-DG (< 0.05) and 6-AN (p< 0.05). In a mouse model of APS, transfer of IgG from APS patients into mice (n=8-10/group) doubled IVC thrombus size (mean 9.7 mm vs. 5.1 mm) at 24 hours. When APS mice were administered daily 2-DG (250-1000 mg/kg) for two weeks prior to thrombus induction, thrombus size was decreased back to the baseline of 5 mm (p< 0.0001); this was accompanied by a reduction in plasma NET remnants.

Conclusion: We demonstrate for the first time that inhibitors of glycolysis and the pentose phosphate pathway attenuate aβ_2GPI-induced NETosis. Furthermore, neutrophils isolated from patients with primary APS appear to have baseline characteristics suggestive of a more robust mitochondrial network, which may hint at metabolic plasticity *in vivo*. The potential clinical applicability of these studies are emphasized by the ability of 2-DG to restrain APS-associated thrombosis in mice. Numerous studies are now underway to further dissect these metabolic (and potentially modifiable) underpinnings of APS pathophysiology.

Single-Cell RNA Sequencing of APS Skin Reveals Endothelial Pathology and Cellular Interactions

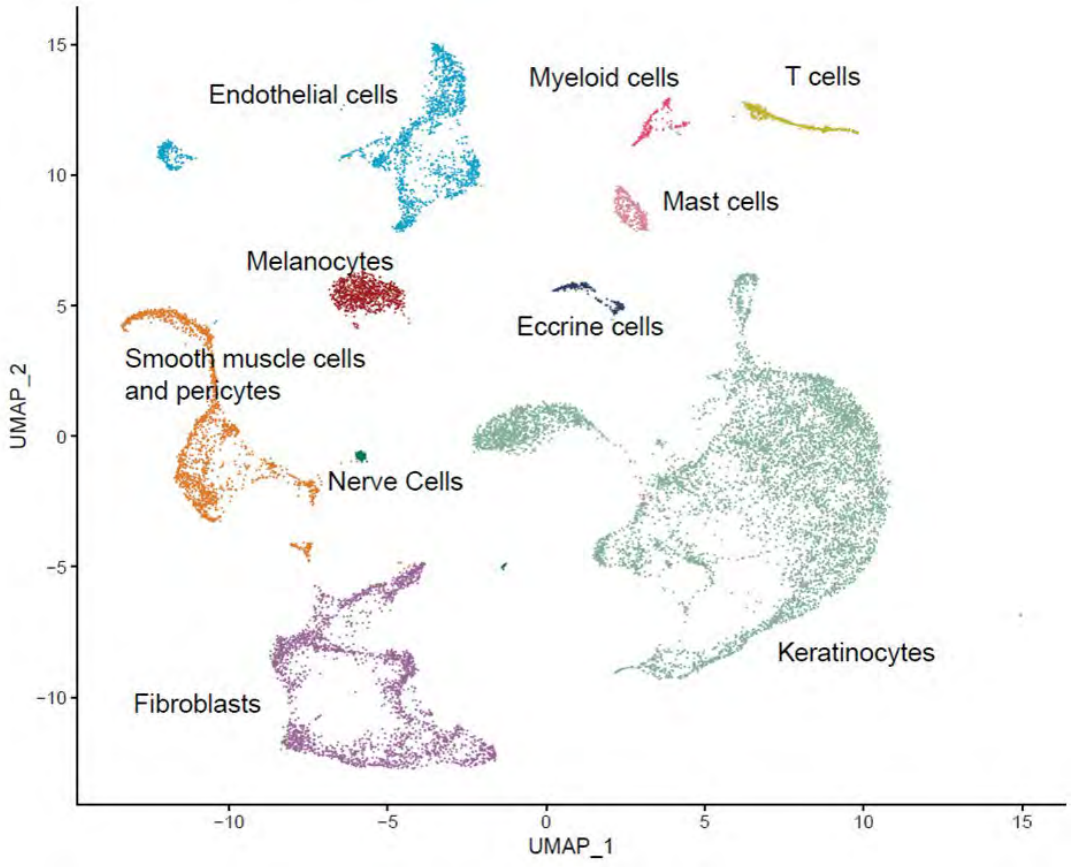
Hui Shi[1], Allison Billi[2], Rachael Wasikowski[1], Claire Hoy[3], Kelsey Gockman[1], Lam Tsoi[1], Johann Gudjonsson[2], Pei-Suen Tsou[1] and Jason Knight[1], [1]University of Michigan, Ann Arbor, MI, [2]Department of Dermatology, University of Michigan, Ann Arbor, MI, [3]University of Michigan, Ann Arbor

SESSION INFORMATION
Session Date: Sunday, November 7, 2021
Session Title: Abstracts: Antiphospholipid Syndrome (0948–0951)
Session Type: Abstract Session
Session Time: 9:00AM–10:00AM

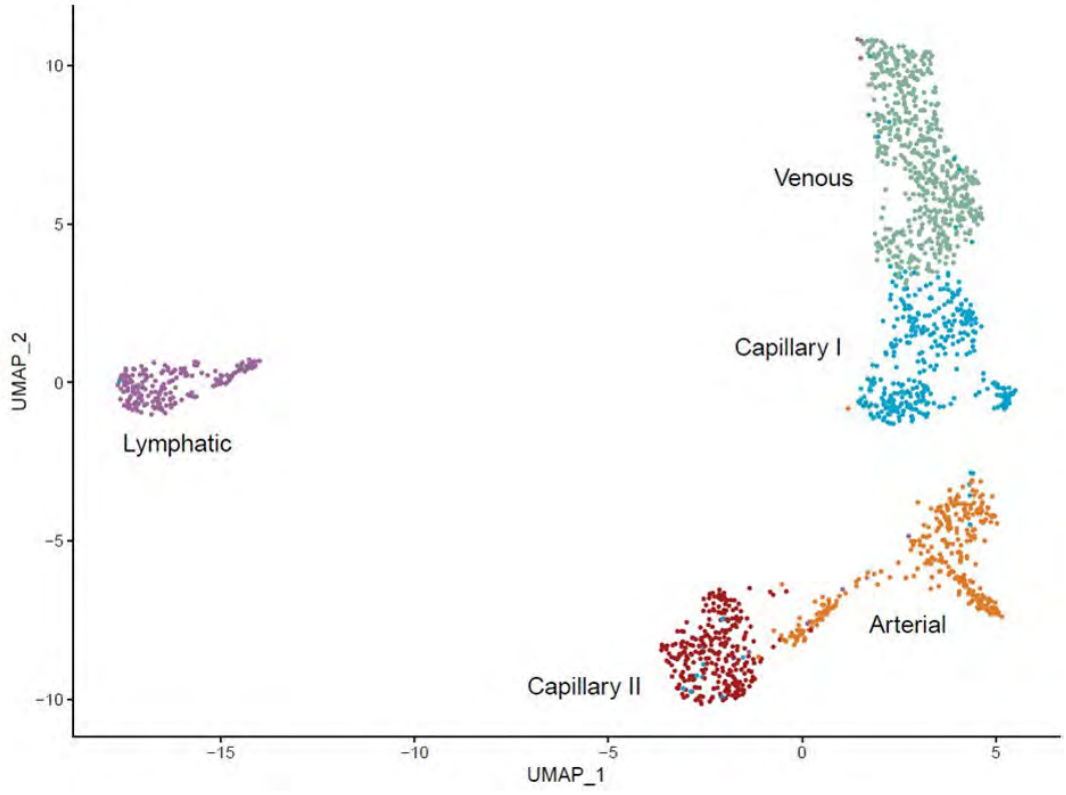
Background/Purpose: Although antiphospholipid syndrome (**APS**) regularly presents with discrete thrombotic events, many patients will also acquire organ damage over time secondary to occlusive neointimal formation in small vessels. The presence of livedo reticularis is predictive of various "internal" manifestations of APS including cerebrovascular disease. Although the interplay between antiphospholipid antibodies (**aPL**) and endothelial cells is likely a key driver of APS vasculopathy in skin and other organs, APS microvascular endothelial cells have been studied only sparsely. Here, we employed skin biopsy and sc-RNAseq to characterize APS endothelial cells with an eye toward identifying the dysregulated pathways and cellular crosstalk that may conspire to promote APS vasculopathy over time.

Methods: We applied sc-RNAseq to skin biopsies of three primary APS patients with livedo reticularis and four healthy controls with neither APS nor livedo. Uniform manifold approximation and projection (UMAP) was used to discriminate cell types, and differential gene expression analysis was identified. Pathway enrichment was determined by Ingenuity Pathway Analysis. Ligand-receptor pairs from the Database of Interacting Proteins were used to identify potential intra- and inter-cellular communication. Immunohistochemistry (IHC) was performed to verify protein expression in APS and control skin. Control human MVECs were cultured with APS sera in pursuit of discerning transcriptional expression of upregulated genes.

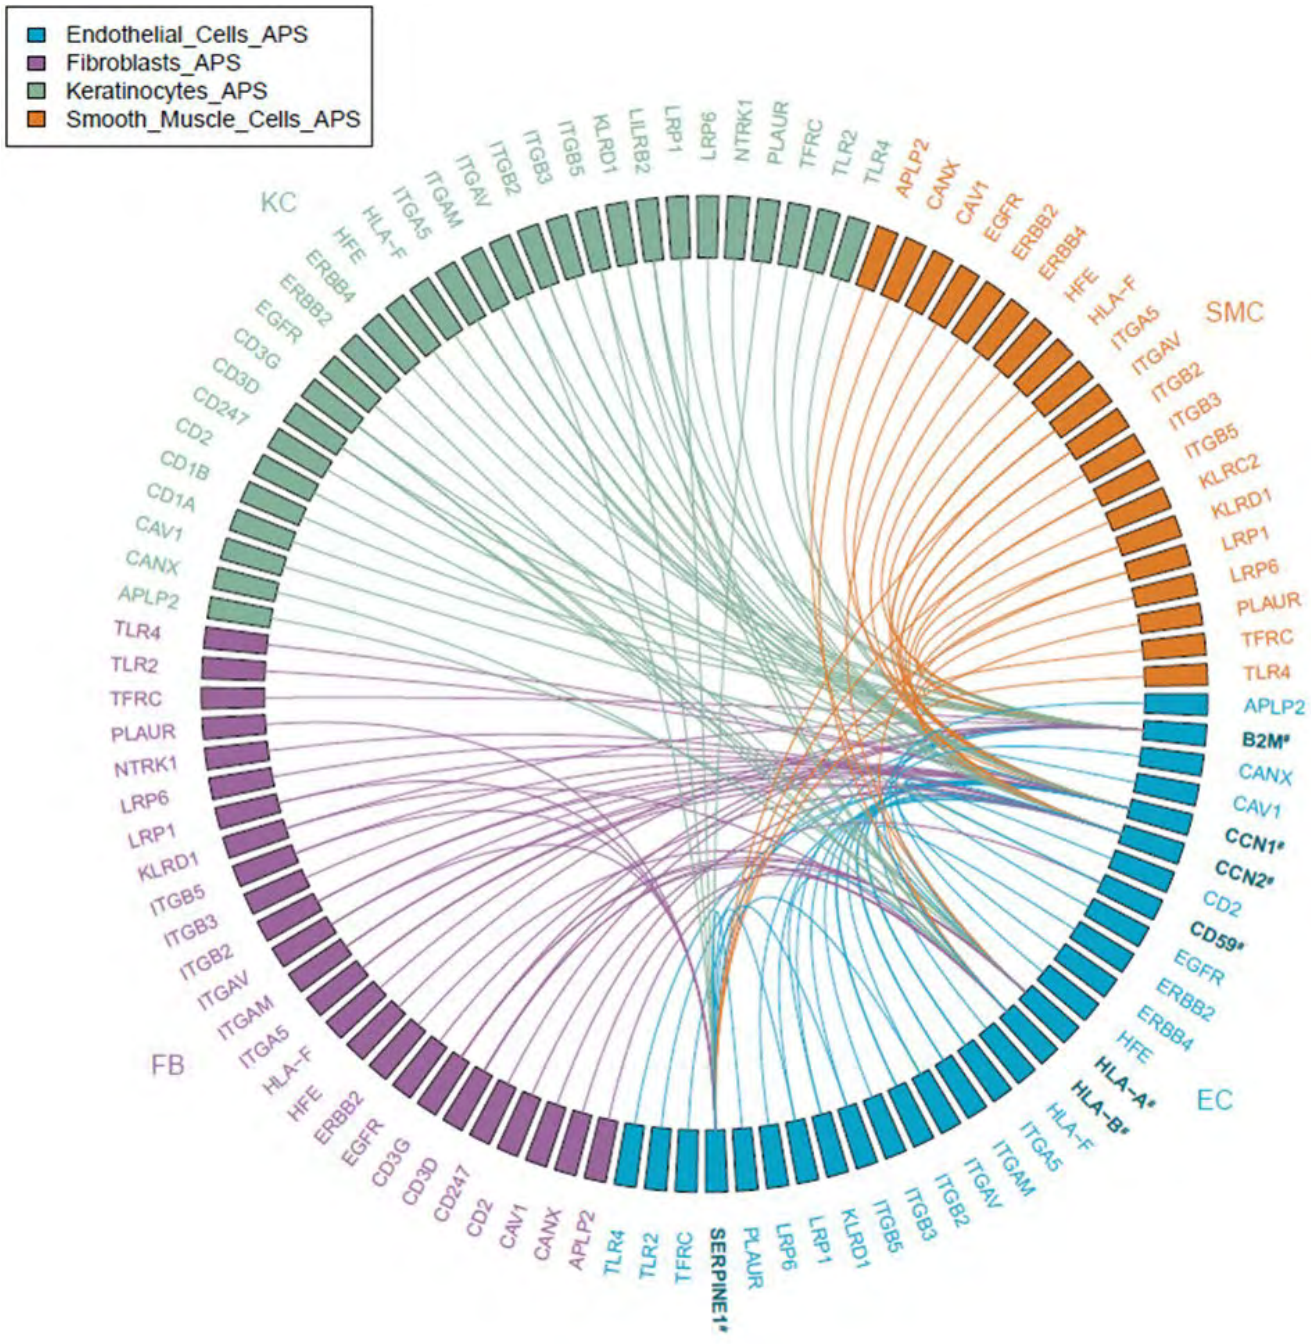
Results: We identified ten cell types in skin (**Figure 1**). Within the main endothelial cell population, there were four distinct subsets that we named Arterial, Capillary I, Capillary II, and Venous based on differential expression of key



Cell type-specific subsets in APS and control skin.



Endothelial cell subsets in APS and control skin.



Interactions between ligands upregulated in APS endothelial cells (bolded) and receptors expressed by endothelial cells and other cell types. EC=endothelial cells, SMC=pericytes/smooth muscle cells, KC=keratinocytes, and FB=fibroblasts.

genes (**Figure 2**). We compared gene expression profiles between APS and control endothelial cells and found significant upregulation of various genes associated with cell proliferation, most notably CCN1 (CYR61), CCN2 (CTGF), and SERPINE1 (PAI-1) in APS. These changes were most pronounced in the Capillary I and Venous subsets. By pathway analysis, we found the APS endothelial cell expression profile to be enriched for Hippo-YAP1/TAZ and TGF-β pathways. Anchored by differentially-expressed ligands of APS endothelial cells, interaction analysis suggested strong communication between endothelial cells (especially ligands CCN1 and CCN2) and both pericytes/smooth muscle cells and fibroblasts (**Figure 3**). IHC staining confirmed higher expression of CCN1 and CCN2 in APS skin as

compared with control skin. In these same biopsies, APS endothelial cells were more likely to display YAP1 nuclear translocation as compared with control endothelial cells. *In vitro*, culture of control MVECs with APS sera upregulated CCN1, CCN2, and SERPINE1.

Conclusion: To our knowledge, this is the first direct analysis of gene expression in APS endothelial cells and local interacting cells. These data suggest that APS endothelial cells demonstrate a pattern of ligand gene expression with potential to drive the proliferation of neighboring cells including pericytes/smooth muscle cells and fibroblasts, which may have significant relevance for the neointimal formation of APS vasculopathy.

Mammalian Target of Rapamycin (mTOR) Pathway Assessment in Antiphospholipid Antibody Positive Patients with Livedo Reticularis/ Racemosa

Ecem Sevim[1], Salma Siddique[2], Madhavi Latha Chalasani[3], Susan Chyou[4], William Shipman[3], Orla O`Shea[5], Oral Alpan[6], Stephane Zuily[7], Joanna Harp[8], Theresa Lu[3] and Doruk Erkan[3], [1]Montefiore Medical Center - Wakefield Campus, Bronx, NY, [2]Nemours/A.I.duPont Hospital for Children, Wilmington, DE, [3]Hospital for Special Surgery, New York, NY, [4]Autoimmunity and Inflammation Program, Hospital for Special Surgery, New York, NY, [5]Analytical Microscopy Core Laboratory, Hospital for Special Surgery, New York, NY, [6]O&O Alpan Medical Center, Vienna, VA, [7]Nancy Academic Hospital, Vandoeuvre-ls-Nancy, France, [8]Dermatology, Weill Cornell Medicine, New York, NY

SESSION INFORMATION
Session Date: Sunday, November 7, 2021
Session Title: Abstracts: Antiphospholipid Syndrome (0948–0951)
Session Type: Abstract Session
Session Time: 9:00AM–10:00AM

Background/Purpose: Endothelial proliferation is a key finding in antiphospholipid antibody (aPL)-positive patients with microvascular disease. The mTOR pathway plays a role in the endothelial proliferation leading to aPL-related nephropathy; however, the role of mTOR pathway is not well determined in patients with livedo, which is discolorization of the skin due to reactive dilation of peripheral dermal venules triggered by reduced blood flow in the center. Thus, our primary objective was to investigate mTOR pathway activation in the skin biopsies of aPL-positive patients with livedo reticularis/racemosa.

Methods: This cross-sectional study included patients with livedo reticularis/racemosa: a) those with aPL-positivity (LA, aCL IgG/M > 40U, and/or aβ2GPI IgG/M > 40U) with/without systemic lupus erythematosus (SLE); and b) aPL-negative SLE patients as a control group. We collected demographics and aPL-related history. We performed two 5-mm skin biopsies (epidermis) on each patient, one from the erythematous-violaceous peripheral area (lesional) and the second from the non-violaceous central area (non-lesional). Specimens were stained for phosphorylated S6 ribosomal protein (P-S6RP) and protein kinase B (AKT) as a marker of mTOR complex-1 activity. We manually counted cells in the upper superficial and lower basal layers of epidermis and compared the number of cells stained positive for mTOR between different groups (lesional and non-lesional samples in aPL-positive patients vs aPL-negative SLE controls) using chi square test.

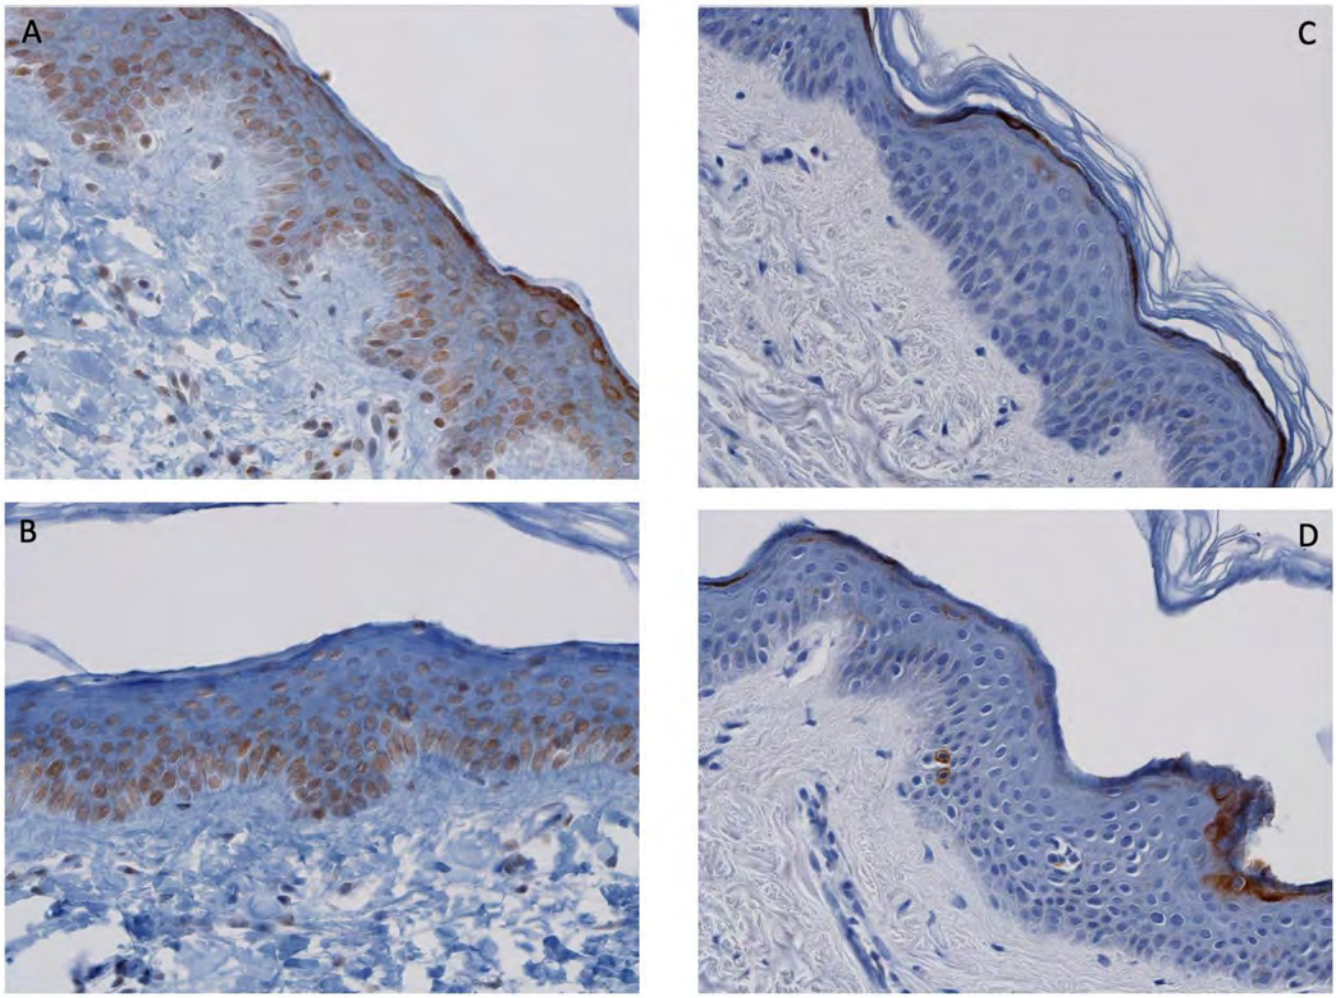

Figure. Increased mTOR Activity Suggested by the S6RP Staining (brown) in the Lesional (A) and Non-lesional (B) Skin Biopsies of an Antiphospholipid Antibody Positive SLE Patient with Livedo, (no similar mTOR activity was observed in the Lesional [C] or Non-lesional [D] skin biopsy of the aPL-negative SLE patient with livedo [C, D]).

Results: Ten patients were enrolled (aPL-positive without SLE: 4 [APS classification met: 3], aPL-positive SLE: 4 [APS classification met: 3], and aPL-negative SLE [control]: 2); nine females; all Caucasian; mean age: 45±13.6y. In all aPL-positive patients (n: 8), there was significantly increased mTOR activity in both lesional and non-lesional skin biopsies, compared to the aPL-negative SLE controls (n:2), more pronounced in the lower basal layers (Figure; Table 1). Furthermore, increased mTOR activity in aPL-positive patients was more prominent in the lesional samples, compared to non-lesional (Table 2).

Conclusion: We found increased mTOR activity in livedoid lesions of aPL-positive patients with or without SLE, compared to aPL-negative SLE patients, suggesting there is a role of mTOR pathway activation in aPL-positive patients with livedo. Our results also showed more profound mTOR activity in: a) lower basal layers of epidermis (compared to upper surface layer), more accountable to present the underlying pathology given the cellular proliferation initiates from the basal layers and the upper layer uptake might be non-specific; and b) in non-violaceous central areas (compared to erythematous-violaceous peripheral areas), consistent with the pathophysiology of livedoid lesions given the vascular stenosis occurring in arterioles located in the center leads to livedo at the periphery.

Session Title: Abstracts: Antiphospholipid Syndrome (0948–0951)

Session Type: Abstract Session

Session Time: 9:00AM–10:00AM

Background/Purpose: Several antiphospholipid antibody (aPL) profiles are associated with a higher risk for the clinical manifestations of the antiphospholipid syndrome (APS). These include "triple positivity" (lupus anticoagulant [LA], anticardiolipin antibodies [aCL], and anti-b2 glycoprotein I antibodies [ab2GPI]), and LA positivity itself. Further risk is associated with higher levels of aCL and ab2GPI, and with aPL persistence. LA test can detect antibodies to b2GPI and/or prothrombin of any isotype; ab2GPI immunoassays detect isotype-specific antibodies to human b2G-PI. Although the putative antigen in aCL tests is cardiolipin, these tests primarily detect isotype-specific antibodies to bovine b2GPI (present in the blocking buffer/sample diluent). Given that the three aPL tests do not detect discrete antibody populations, but rather partially overlapping sets of antibodies, the primary goal of this study was to further characterize the associations among aPL tests using validated APS ACTION Core Laboratory data.

Methods: The APS ACTION Registry was created to study the natural course of persistently aPL-positive patients with or without autoimmune disorders over at least 10 years. The inclusion criteria are positive aPL according to Updated Sapporo Classification Criteria tested within one year prior to enrollment. Patients are followed every 12±3 months with clinical data and blood collection for APS ACTION Core Laboratory aPL confirmation. We analyzed

Table 1: Prediction of Positive Lupus Anticoagulant (LA) Test by Anticardiolipin Antibody (aCL) and Anti-β2 glycoprotein-I (aβ2GPI) IgG/M Levels ≥ 40 (n: 351)

	OR	95% CI	p value
aCL IgG ≥40U	5.2	2, 14	.001
aCL IgM ≥ 40U	3.6	1.3, 10.5	.02
aβ2GPI IgG ≥ 40U	3.2	1.1, 9.3	.03
aβ2GPI IgM ≥ 40U	14	1.9, 103.6	.01

OR: Odds Ratio, CI: Confidence Interval. In patients with negative LA test, the frequency of all aPL ELISA titers <40 Units was 82%, while in patients with positive LA test it was 41% (p<.0001).

Table 2: Contribution of Number of Anticardiolipin Antibody (aCL) and Anti-β2 glycoprotein-I IgG/M ≥40U ("aPL Load") to Positive Lupus Anticoagulant Test (n: 351)			
	OR	95% CI	p value
At Least 1-2 aCL/aβ2GPI IgG/M ≥ 40U*	6.1	2.6, 14.2	<.001
At Least 3-4 aCL/aβ2GPI IgG/M ≥ 40U*	10.7	1.4, 80.4	.02

*OR: Odds Ratio, CI: Confidence Interval. * 47% IgG only, 30% IgM only, and 23% IgG and IgM.*

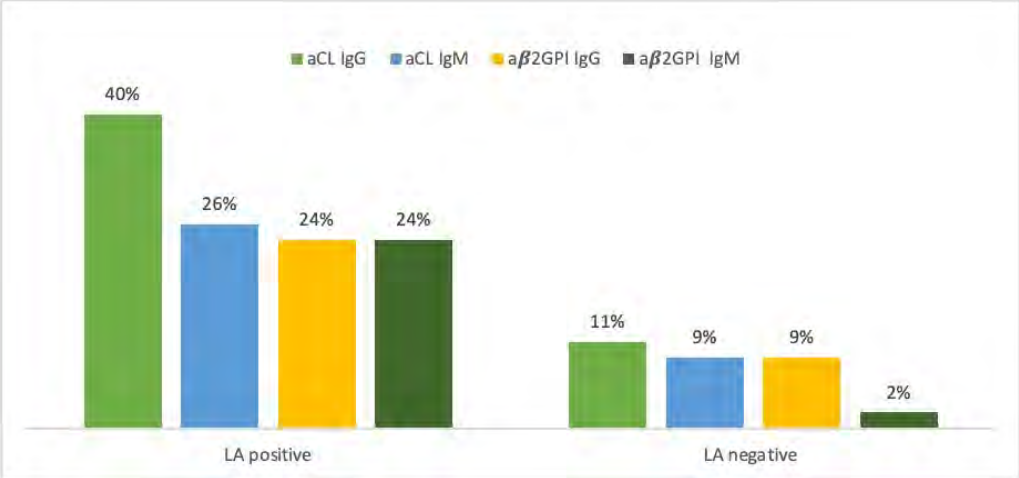

Figure 1. The Frequency of Anticardiolipin Antibody (aCL) and Anti-beta 2 glycoprotein-I IgG/M >=40U Based on the Lupus Anticoagulant (LA) Results (n=351; LA positive=306, LA negative=45).

baseline and prospective Core Laboratory aPL data for associations. Spearman's rank correlation with Bonferroni adjusted significance level for multiple comparisons was used to assess correlation between all available aPL ELISA test results (Inova Diagnostics). Univariate logistic regression was used to assess laboratory predictors of positive LA test.

Results: As of 1/2021, 854 patients were included; 567 patients had Core Laboratory aPL profiles at baseline and follow up. Based on four (aCL/ab$_2$GPI IgG/M) same sample tests (n: 1008) at baseline and follow up, a strong correlation was identified between aCL IgG and ab$_2$GPI IgG, and aCL IgM and ab$_2$GPI IgM (r=0.75, p< .001 for both). There was no correlation between IgG and IgM isotypes. Based on five (aCL/ab$_2$GPI IgG/M and LA) same sample tests at baseline, patients with: a) aCL/ab$_2$GPI IgG/IgM ≥40U had a higher chance of a positive LA test, compared to those with lower titers (Table 1); b) one or two positive tests ≥ 40U among aCL/ab$_2$GPI IgG/IgM had 6.1 times higher odds of a positive LA test; and c) three or four positive tests ≥ 40U among aCL/ab$_2$GPI IgG/IgM had 10.7 times higher odds of a positive LA test (Table 2). The frequencies of aCL IgG, ab$_2$GPI IgG, aCL IgM, and ab$_2$GPI IgM levels ≥40U in LA-positive and LA-negative patients are shown in Figure 1.

Conclusion: Using a large scale international aPL/APS database, we confirmed a strong association between aCL IgG and ab2GPI IgG and, similarly, aCL IgM and ab2GPI IgM, that is likely explained by the b2GPI dependence of aCL tests. Both aPL ELISA levels ≥ 40U and a higher number of aPL ELISA tests ≥ 40U were predictive of a positive LA test, introducing the concept of "aPL load", that may provide a mechanistic explanation of a positive LA test.

SESSION INFORMATION
Session Date: Sunday, November 7, 2021
Session Title: Abstracts: Vasculitis – ANCA-Associated (0952–0955)
Session Type: Abstract Session
Session Time: 9:00AM–10:00AM

Background/Purpose: Patients with primary systemic vasculitis (PSV) and polymyalgia rheumatica (PMR) may be at high risk for poor COVID-19 outcomes due to the treatments used, the potential organ damage caused by PSV, and demographic factors such as older age that are associated with these conditions. We investigated factors associated with COVID-19 outcomes in patients with PSV and PMR in a large multinational registry.

Methods: We analyzed PSV and PMR cases from the COVID-19 Global Rheumatology Alliance registries (12/Mar/2020-12/Apr/2021). PSV diagnoses included ANCA vasculitis (AAV), giant cell arteritis (GCA), Behçet's syndrome, and other vasculitides. The ordinal COVID-19 severity outcome was: 1) no hospitalization, 2) hospitalization without oxygen, 3) hospitalization with oxygen/ventilation, or 4) death. Relevant covariates included age, sex, race, season, number of comorbidities, BMI, smoking status, disease activity, immunosuppresive therapies (conventional synthetic and biologic/targeted synthetic DMARDs), glucocorticoid (GC) (daily dose prednisolone-equivalent), and region. Multivariable ordinal logistic regressions were used to estimate odds ratios (ORs) for being one level higher on the ordinal outcome. Analyses were also stratified by disease (GCA, AAV, or PMR).

Results: Of 1,202 included patients, 61.0% were female; mean age was 63.8 years. Diagnoses were PMR (31.1%), AAV (29.3%), GCA (15.2%), Behçet's syndrome (9.4%), and other vasculitis (15.0%). Overall, 508 (49.8%) patients

Figure 1. Global distribution of primary systemic vasculitis and polymyalgia rheumatica patients with COVID-19 infection in the COVID-19 Global Rheumatology Alliance Physician Registry

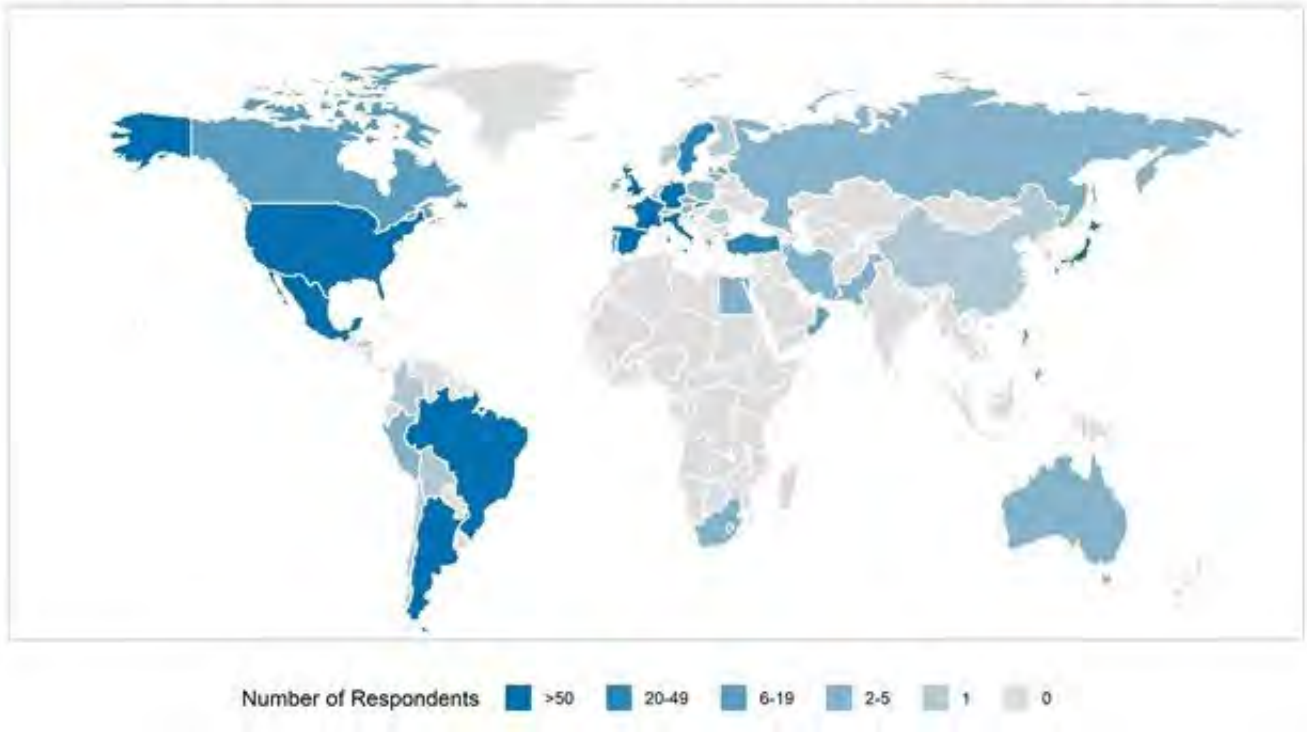

Figure 1.

Table 1.

Table 1. Frequencies and proportions of outcomes in the ordinal COVID-19 severity scale according to diagnosis*

COVID-19 Severity scale	Overall (N = 1020)	GCA (N = 158)	AAV (N = 293)	PMR (N = 323)	Behcets (N = 98)	Other vasculitis (N = 148)
Not Hospitalized	512 (50.2)	69 (43.7)	110 (37.5)	187 (57.9)	84 (85.7)	77 (52.0)
Hospitalization with No Oxygenation	114 (11.2)	19 (12.0)	30 (10.2)	30 (9.3)	11 (11.2)	20 (13.5)
Hospitalization with Any Ventilation or Oxygenation	239 (23.4)	38 (24.1)	88 (30.0)	71 (22.0)	1 (1.0)	30 (20.3)
Death	155 (15.2)	32 (20.3)	65 (22.2)	35 (10.8)	2 (2.0)	21 (14.2)

* Excluding 182 cases with missing outcome data
COVID-19, Coronavirus Disease 2019; AAV, ANCA-associated vasculitis; GCA, giant cell arteritis; PMR, polymyalgia rheumatica.

Table 2.

Table 2. Multivariable† logistic regression analysis of factors associated with the ordinal COVID-19 severity outcomes for patients with primary systemic vasculitis or polymyalgia rheumatica

Factors	OR (95% CI)	p-value
Age (per decade)	1.46 (1.33, 1.60)	<0.01**
Sex		
Female	REF	
Male	1.46 (1.12, 1.91)	<0.01**
Season		
Prior to June 15, 2020	REF	
June 16-Sept 30, 2020	1.07 (0.71, 1.61)	0.76
Oct 1,2020- April 12,2021	0.47 (0.35, 0.63)	<0.01**
Number of Comorbidities	1.38 (1.22, 1.57)	<0.01**
Smoking	0.95 (0.70, 1.28)	0.73
Obesity	1.26 (0.91, 1.75)	0.16
Glucocorticoid (prednisone equivalent)		
No glucocorticoid use	REF	
1-5 mg/day	1.14 (0.81, 1.59)	0.45
6-9 mg/day	1.30 (0.80, 2.11)	0.29
≥ 10 mg/day	2.14 (1.48, 3.09)	<0.01**
Disease Activity		
Remission/Minimal or low	REF	
Moderate/Severe or high	2.32 (1.60, 3.36)	<0.01**

†Adjusted for sex, age, region, medication category, season, number of comorbidities, disease activity, and random effects of region
* $p < 0.05$
** $p \leq 0.005$
The effect size is the odds of being one level higher on the ordinal scale than the reference group.
COVID-19, Coronavirus Disease 2019

were hospitalized, and 155 (15.2%) patients died (Table 1). Older age (OR 1.46, 95% CI 1.33-1.60), male sex (OR 1.46, 95% CI 1.12-1.91), GC dose ≥ 10 mg/day (OR 2.14, 95% CI 1.48-3.09), moderate/severe or high disease activity (OR 2.32, 95% CI 1.60-3.36) and number of comorbidities (OR 1.38, 95% CI 1.22-1.57) were associated with worse outcome (Table 2). In the disease-specific stratified analysis, 20.3% and 22.2% of patients with GCA and AAV, respectively, died. Risk factors for poorer outcomes were: for GCA patients, older age (OR 1.79, 95% CI 1.21-2.65) and obesity (OR 3.04, 95% CI 1.17-3.04); for AAV patients, older age (OR 1.45, 95% CI 1.18-1.79), rituximab (OR 2.50, 95% CI 1.33-4.68) or cyclophosphamide use (OR 6.43, 95% CI 1.48-28.01), and moderate/severe or high disease activity (OR 2.71, 95% CI 1.21-6.07); and for polymyalgia rheumatica, older age (OR 2.69, 95% CI 1.99-3.63) and higher comorbidity burden (OR 1.31, 95% CI 1.03-1.67). Overall, severe outcomes were less likely if COVID-19 infection developed between October 1, 2020, and April 12, 2021 (OR 0.47, 95% CI 0.35-0.63). This was also observed in the disease-specific analysis.

Conclusion: Patients with GCA or AAV who had COVID-19 infection had higher rates of severe outcomes compared to PMR and other vasculitis, even despite similar ages of the GCA and PMR groups. Risk factors identified for different PSV subtypes may inform mitigation strategies for these patients.

An International Delphi Exercise to Identify Items of Importance for Measuring Response to Treatment for ANCA-associated Vasculitis

Kaitlin Quinn[1], Sara Monti[2], Georgia Lanier[3], Maria Bjork Viðarsdóttir[4], Robin Christensen[5], David R.W. Jayne[6], Carol Langford[7], Alfred Mahr[8], Christian Pagnoux[9], Gunnar Tomasson[10] and Peter Merkel[11], [1]National Institute of Arthritis and Musculoskeletal and Skin Diseases (NIAMS), National Institutes of Health (NIH), Washington, DC, [2]University of Pavia, Pavia, Italy, [3]n/a, Sherborn, MA, [4]n/a, Reykjavik, Iceland, [5]Section for Biostatistics and Evidence-Based Research, the Parker Institute, Bispebjerg and Frederiksberg Hospital, Copenhagen & Research Unit of Rheumatology, Department of Clinical Research, University of Southern Denmark, Copenhagen, Denmark, [6]University of Cambridge, Cambridge, United Kingdom, [7]Cleveland Clinic, Moreland Hills, OH, [8]Kantonsspital St. Gallen, St.Gallen, Switzerland, [9]Mount Sinai Hospital, Toronto, ON, Canada, [10]University of Iceland, Reykjavik, Iceland, [11]University of Pennsylvania, Philadelphia, PA

SESSION INFORMATION
Session Date: Sunday, November 7, 2021
Session Title: Abstracts: Vasculitis – ANCA-Associated (0952–0955)
Session Type: Abstract Session
Session Time: 9:00AM–10:00AM

Background/Purpose: ANCA-associated vasculitis (AAV) is characterized by fluctuating levels of disease activity. Randomized controlled trials (RCTs) in AAV have used multiple instruments to define active disease or remission as a dichotomous outcome. However, no formal criteria exist to measure treatment response in AAV. This Delphi exercise aimed to reach consensus about which measures are considered by patients and physicians to be most important when assessing treatment response in RCTs in AAV.

Methods: An international 3-round online Delphi exercise was conducted in English. Survey participants included experts in AAV and patients with AAV. Items in the Delphi were based on a systematic literature review of outcome measures in RCTs in AAV, and suggestions from a Steering Committee comprised of vasculitis experts and patients with AAV.

Survey participants were asked to rate (on a scale of 1-9) the importance of each item when assessing response to treatment (improvement) in a RCT in AAV. Items scored 7-9 by ≥70% participants were considered to be highly important, and items scored 1-3 by ≥70% participants were considered to be of limited importance.

Results: 265 participants completed three rounds of the Delphi, including 176 physicians with expertise in AAV and 89 patients with AAV. Physicians were from six continents; the majority from Europe [n=81 (46%)] or North America [n=50 (28%)]. Most physicians specialized in rheumatology [n=105 (60%)] or nephrology [n=50 (28%)]. All physicians were in practice for at least 2 years (two-thirds >10 years) and responsible for managing ≥30 patients with AAV; over half of the physicians managed >75 patients with AAV. Patients with AAV were from four continents, with most located in North America [n=63 (71%)] or Europe [n=23 (26%)] with a diagnosis of GPA [n=71 (80%)] or MPA [n=16 (18%)]. The majority of patients with AAV were female [n=61 (69%)], ages 50-79 years [n=67 (75%)], were diagnosed in the past 10 years [n= 62 (70%)], and were currently on treatment [n=61 (69%)].

The most highly rated items of response (Table 1) involved disease activity [reduction in BVAS, extent of organ involvement, and physician global assessment] and patient-reported outcomes [patient global assessment and health-related quality of life]. Achievement of BVAS ≤1 and BVAS of 0 were highly rated more often by physicians than by patients. Pain and fatigue were highly rated by patients, but not by physicians. Changes on urinalysis and acute phase reactants were highly rated only by patients. Additional items related to organ damage, glucocorticoid tapering, and

Table 1: Results of the Delphi exercise rating importance of items to measure when assessing response to treatment in a clinical trial in ANCA-associated vasculitis. Items rated as highly important by physicians and/or patients after 3 rounds of the Delphi.

	Delphi Item	Physicians (n=176) (% rated highly important)	Patients (n=89) (% rated highly important)
Patient-reported outcomes	Improved patient global assessment	72%	73%
	Improved HRQoL measures	75%	87%
	Improved pain	28%	75%
	Improved fatigue	14%	71%
Disease activity	**BVAS**		
	≥50% reduction in BVAS	72%	76%
	BVAS ≤1	94%	70%
	BVAS of 0	94%	67%
	Kidney function		
	Improved kidney function (eGFR)	96%	83%
	No development of ESRD	97%	97%
	Ability to discontinue dialysis	84%	88%
	Resolution of hematuria on urinalysis	42%	79%
	Resolution of proteinuria on urinalysis	50%	81%
	Other		
	No new/worse major organ involvement	96%	95%
	No new/worse minor organ involvement	80%	93%
	Improved physician global assessment	80%	80%
	No rise in acute phase reactants	27%	71%
	No worsening of chest CT	70%	88%
	Survival	100%	97%
Damage	No new major organ damage	94%	97%
	No new non-major organ damage	80%	88%
Glucocorticoid taper	Ability to taper prednisone to ≤5 mg/day	88%	84%
	Ability to stop prednisone	81%	84%
Adverse events	Severe medication-related adverse events	95%	91%
	Severe infections	97%	94%

HRQoL = Health-related quality of life, BVAS = Birmingham Vasculitis Activity Score (any version), eGFR = estimated glomerular filtrate rate, ESRD = end-stage renal disease, CT = computerized tomography.

treatment-related adverse events were highly rated by both patients and physicians. There were no items rated of limited importance by both patients and physicians.

Conclusion: In this Delphi exercise, there was consensus between international experts in AAV and patients with AAV on many items considered important to measure when assessing treatment response in RCTs in AAV. There were also some items rated as highly important by only experts or only patients. These data provide insights into how to evaluate this complex form of vasculitis and will inform the next steps in the development of treatment response criteria in AAV.

Session Type: Abstract Session

Session Time: 9:00AM–10:00AM

Background/Purpose: The RAVE trial established the non-inferiority of rituximab (RTX) vs cyclophosphamide (CYC) for remission induction of ANCA-Associated Vasculitis (AAV). Patients in RAVE were followed for 18 months so little

is known regarding the long-term outcomes of these remission induction strategies in real world practice. Here, we evaluated the association of remission induction treatment strategy with the risks of end-stage renal disease (ESRD) and death, two key outcomes in AAV.

Methods: The data source was a consecutive inception cohort of PR3- or MPO-ANCA+ AAV patients assembled in a large healthcare system between 2002 and 2019. Baseline demographics and disease-specific features, including baseline manifestations and laboratory values, were extracted from the electronic health records (EHR) and data warehouse. The primary exposure was RTX- vs CYC-based remission induction regimens, ascertained by manual review. ESRD and vital status, the composite outcome of interest, were ascertained by EHR review as well as linkage to the United States Renal Data System and National Death Index, respectively. A propensity score (PS) model for treatment with RTX vs CYC was created using demographic and disease-specific variables present at baseline, including age, sex, comorbidities, ANCA type, AAV manifestations, and renal function. We first examined the association of RTX vs CYC with the risk of ESRD or death in unadjusted and multivariable adjusted Cox proportional hazard models. We then performed the same analysis after one to many matching RTX users to CYC users by PS.

Results: We identified 553 patients who received RTX- or CYC-based regimens (**Table 1**). The mean (SD) age was 59.6 (17.5) years, 236 (43%) were male, and 475 (86%) were White. The majority were MPO-ANCA+ (379, 68%) and had renal involvement (376, 68%). The mean (SD) BVAS/WG score was 5.1 (2.2). Baseline demographics were similar between RTX- and CYC-users (**Table 1**). RTX-users had a higher BVAS/WG (5.3 [2.4] vs 4.8 [1.9], p=0.004) and CYC-users had a higher creatinine (2.4 [1.2, 5.2] vs 1.2 [1.0, 3.5], p< 0.001). Over a total follow-up of 64,686 days, there were 182 events (ESRD or death). The incidence of the primary outcome was 3.0/1,000 days in RTX-users vs 2.7/1,000 days in CYC-users (**Table 2**). In the multivariable adjusted Cox model (n=553), the risk of ESRD or death was similar in RTX- vs CYC-users (1.26, 95% CI 0.89 to 1.79). Our results remained similar in analyses limited to those with renal involvement and those with any major disease. Baseline demographics and disease-specific features were

PS-Matched	1.19 (0.75-1.89)	1.0 (Ref)

Adjusted for age, sex, race, smoking; ^Adjusted for age, sex, race, smoking, ANCA type, CCI score, BVAS Score, GFR, CRP, ESR; † Adjusted for age, sex, race, smoking, ANCA type, CCI score, GFR; **Adjusted for age, sex, race, smoking, ANCA type, CCI score, GFR, BVAS

well-balanced after PS-matching. In the PS-matched analysis (n=351), the risk of ESRD or death was similar in RTX- vs CYC-users (1.19, 95% CI 0.75-1.89).

Conclusion: In this large multi-center AAV cohort, there were no significant differences in the risk of ESRD or death associated with RTX- vs CYC-based therapy for remission induction. Our observations remained consistent in analyses using propensity score matching to robustly address confounding by indication. These results will inform the care of patients with AAV for whom there remains some uncertainty regarding initial choice of immunosuppression.

Abstract Number: 0955

The Effect of Treatment with the Complement C5a Receptor Inhibitor Avacopan on Health-Related Quality of Life in ANCA-Associated Vasculitis

Vibeke Strand[1], Pirow Bekker[2], Huibin Yue[2], David R.W. Jayne[3] and Peter Merkel[4], [1]Stanford University School of Medicine, Portola Valley, CA, [2]ChemoCentryx, San Carlos, CA, [3]University of Cambridge, Cambridge, United Kingdom, [4]University of Pennsylvania, Philadelphia, PA

SESSION INFORMATION
Session Date: Sunday, November 7, 2021
Session Title: Abstracts: Vasculitis – ANCA-Associated (0952–0955)
Session Type: Abstract Session
Session Time: 9:00AM–10:00AM

Background/Purpose: Avacopan, an oral C5a receptor inhibitor, was evaluated in ANCA-associated vasculitis (AAV). Efficacy and safety results were reported previously. Health-related quality of life (HRQoL) changes are reported here.

Methods: A 52-week blinded trial (ADVOCATE) randomized 331 AAV patients 1:1 to either full-dose daily oral prednisone with taper ('Prednisone SOC'), or avacopan with no daily oral prednisone ('Avacopan Group'). Both received standard of care (SOC): rituximab induction *or* cyclophosphamide. Glucocorticoid (GC) exposure including pre-randomization tapering into the blinded treatment period, co-administration with rituximab, and flares was expected and balanced between groups. The total dose of prednisone was ~2500 mg less with avacopan treatment over the entire trial. Primary efficacy endpoints were % patients achieving disease remission at Week 26 and sustained remission at Week 52 using Birmingham Vasculitis Activity Score (BVAS). HRQoL was assessed by Short Form-36 Health Survey version 2 (SF-36), a generic measure of HRQoL that performs well across vasculitis trials, including AAV[1] and giant cell arteritis[2], and EuroQoL Group 5-Dimensions 5-Levels Questionnaire (EQ-5D-5L).

Results: Week 26 improvements in physical component summary (PCS) score with Avacopan Group: 4.5 points vs Prednisone SOC: 1.3 points (least squared means, LSM, for all analyses); statistically significant (p=0.002) and >minimum clinically important difference (MCID) = 2.5 points[3] (**Fig. 1**). Mental component summary scores (MCS) were: Avacopan Group: 4.9 points; Prednisone SOC: 3.3 points, > MCID in both groups. At Week 26 improvements in physical function (PF), role physical (RP), general health (GH), vitality (VT) and role emotional (RE) domains with Avacopan Group were large (3.1 to 16.8 points); statistically significant vs Prednisone SOC (p< 0.002 to p=0.002), and >MCID of 5.0 points in 4 domains (**Fig. 2**). This reflects improvements in physical function and activities; also fatigue, energy, emotional role limitations, and general health perceptions.

	Physical Component Score (PCS)			Mental Component Score (MCS)		
	Avacopan Group n=165	Prednisone SOC n=160	P-value	Avacopan Group n=166	Prednisone SOC n=160	P-value

Wk 26 Score	44.2	42.1	–	49.4	47.1	–
Wk 52 Change	5.0	2.6	p=0.018	4.7	6.4	ns
Wk 52 Score	44.8	43.1	–	50.9	48.8	–
MCID: minimum clinically important difference; ns: not significant; SOC: standard of care						

Least Squares Mean Improvements in SF-36 Physical and Mental Component Scores.

Week 52 improvements with Avacopan Group vs Prednisone SOC were maintained or improved. PCS score was 5.0 vs 2.6 points, clinically meaningful, and statistically significant (p=0.018). Improvements in PF and GH domains exceeded MCID and were statistically significant (p< 0.049 and p< 0.002). The health utility score, SF-6D, based on calculation across all 8 domains of SF-36, indicated broad improvements in patient-reported health status. Improvements at Weeks 26 and 52 were greater with Avacopan Group compared to Prednisone SOC **(Fig. 3)**; >MID (0.041)[3] and consistent with reported improvements in EQ-5D-5L utility score, which was statistically significant at week 52 (p=0.009).

Conclusion: Treatment of AAV with avacopan and a reduced-dose glucocorticoid regimen led to significant improvements in HRQoL compared to SOC. These findings have important clinical implications for treatment of patients with AAV.

Racial Disparities in Renal Outcomes over Time Among Hospitalized Children with SLE and Effects of Hospital Minority Composition

Joyce Chang[1], Cora Sears[2], Veronica Torres[3] and Mary Beth Son[1], [1]Boston Children's Hospital, Brookline, MA, [2]Children's Hospital of Philadelphia, Philadelphia, PA, [3]Temple University, Bucks County, PA

SESSION INFORMATION
Session Date: Sunday, November 7, 2021
Session Title: Plenary II (0956–0961)
Session Type: Plenary Session
Session Time: 10:30AM–12:00PM

Background/Purpose: Racial and ethnic minorities are disproportionately affected by pediatric-onset SLE and have worse outcomes compared to their white counterparts. With ongoing advances in pediatric SLE care, it is not known how these gaps are changing. We determined whether changes in renal outcomes over time of hospitalized children with SLE varied by race/ethnicity, and whether these trends differed by hospital minority composition.

Table 1. Characteristics of Hospitalized Children with SLE by Race/Ethnicity

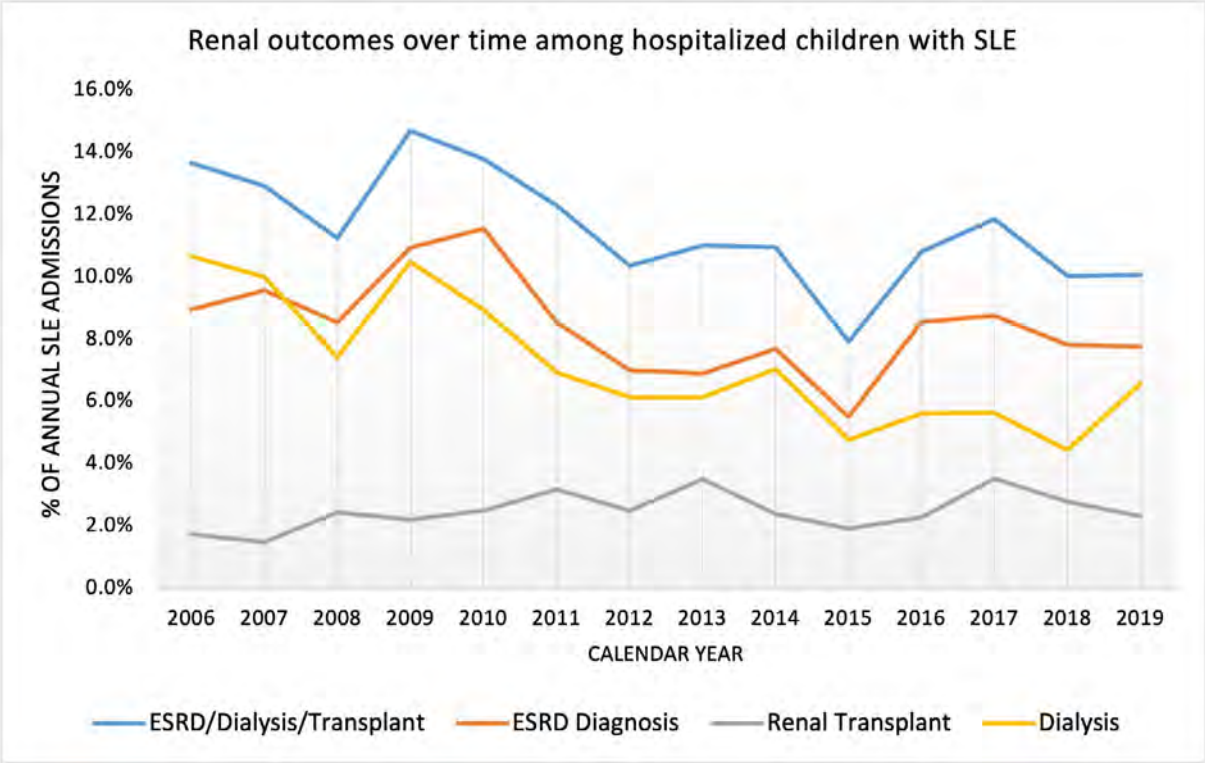

Figure 1. Proportion of SLE admissions in each calendar year that were assigned an ESRD diagnosis code, dialysis procedure code, or renal transplant procedure code, and composite outcome.

Methods: We identified patients ≤21 years old with an ICD-9/10 hospital discharge diagnosis of SLE in the Pediatric Health Information System® inpatient database from 2006-2019. Adverse renal outcomes were defined by assignment of an end-stage renal disease (ESRD) diagnosis code, dialysis procedure code, or renal transplant, analyzed separately and as a composite outcome. We used logistic regression models with fixed effects for time (calendar period), demographic and disease characteristics, and hospital-level random effects to estimate odds of a) an adverse renal outcome at any single hospital encounter or b) incident hospitalization for an adverse renal outcome, after which subsequent encounters were censored. We tested interactions between race and time to assess if change over time differed by race/ethnicity. Hospitals were further dichotomized by whether ≥50% of SLE patients were Black or ≥50% were Hispanic (Creanga et al. 2014) to test multiplicative interactions between hospital minority composition, race and time.

Results: There were 7,434 unique SLE patients with a total of 20,893 admissions at 50 hospitals. Racial/ethnic composition and patient characteristics are shown in **Table 1**. The proportion of SLE admissions with any adverse renal outcome, ESRD, or dialysis decreased over time from 2006 to 2019 (Fig. 1, $p< 0.01$ for trends). However, Black children remained significantly more likely to have an adverse renal outcome at any hospital encounter (adjusted OR 2.5, 95% CI [1.8-3.5]) over time compared to non-Hispanic whites. Black and Asian children were also more likely to have an incident hospitalization for an adverse renal outcome (OR 1.4 [1.1-1.8] and OR 1.5 [1.0-2.4], respectively). There were no significant changes in the magnitude of disparity over time. However, there were significant differences in both the magnitudes of disparities and changes in disparity levels over time between hospitals in which Black or Hispanic minorities comprised ≥50% of SLE patients vs. < 50% (p-values for interactions < 0.01). At hospitals with ≥50% Hispanic SLE patients, renal outcomes failed to improve at the same rate among Black and Hispanic white patients compared to non-Hispanic whites (**Fig. 2A/B**). At hospitals with ≥50% Black SLE patients, rates of renal outcomes improved less over time among black vs. non-Hispanic white children and worsened among Hispanic white children (**Fig. 2C/D**).

Conclusion: On average, adverse renal outcomes among hospitalized children with SLE decreased over a 13 year period, but racial disparities persisted without significant narrowing of the existing gap. There is a specific need to

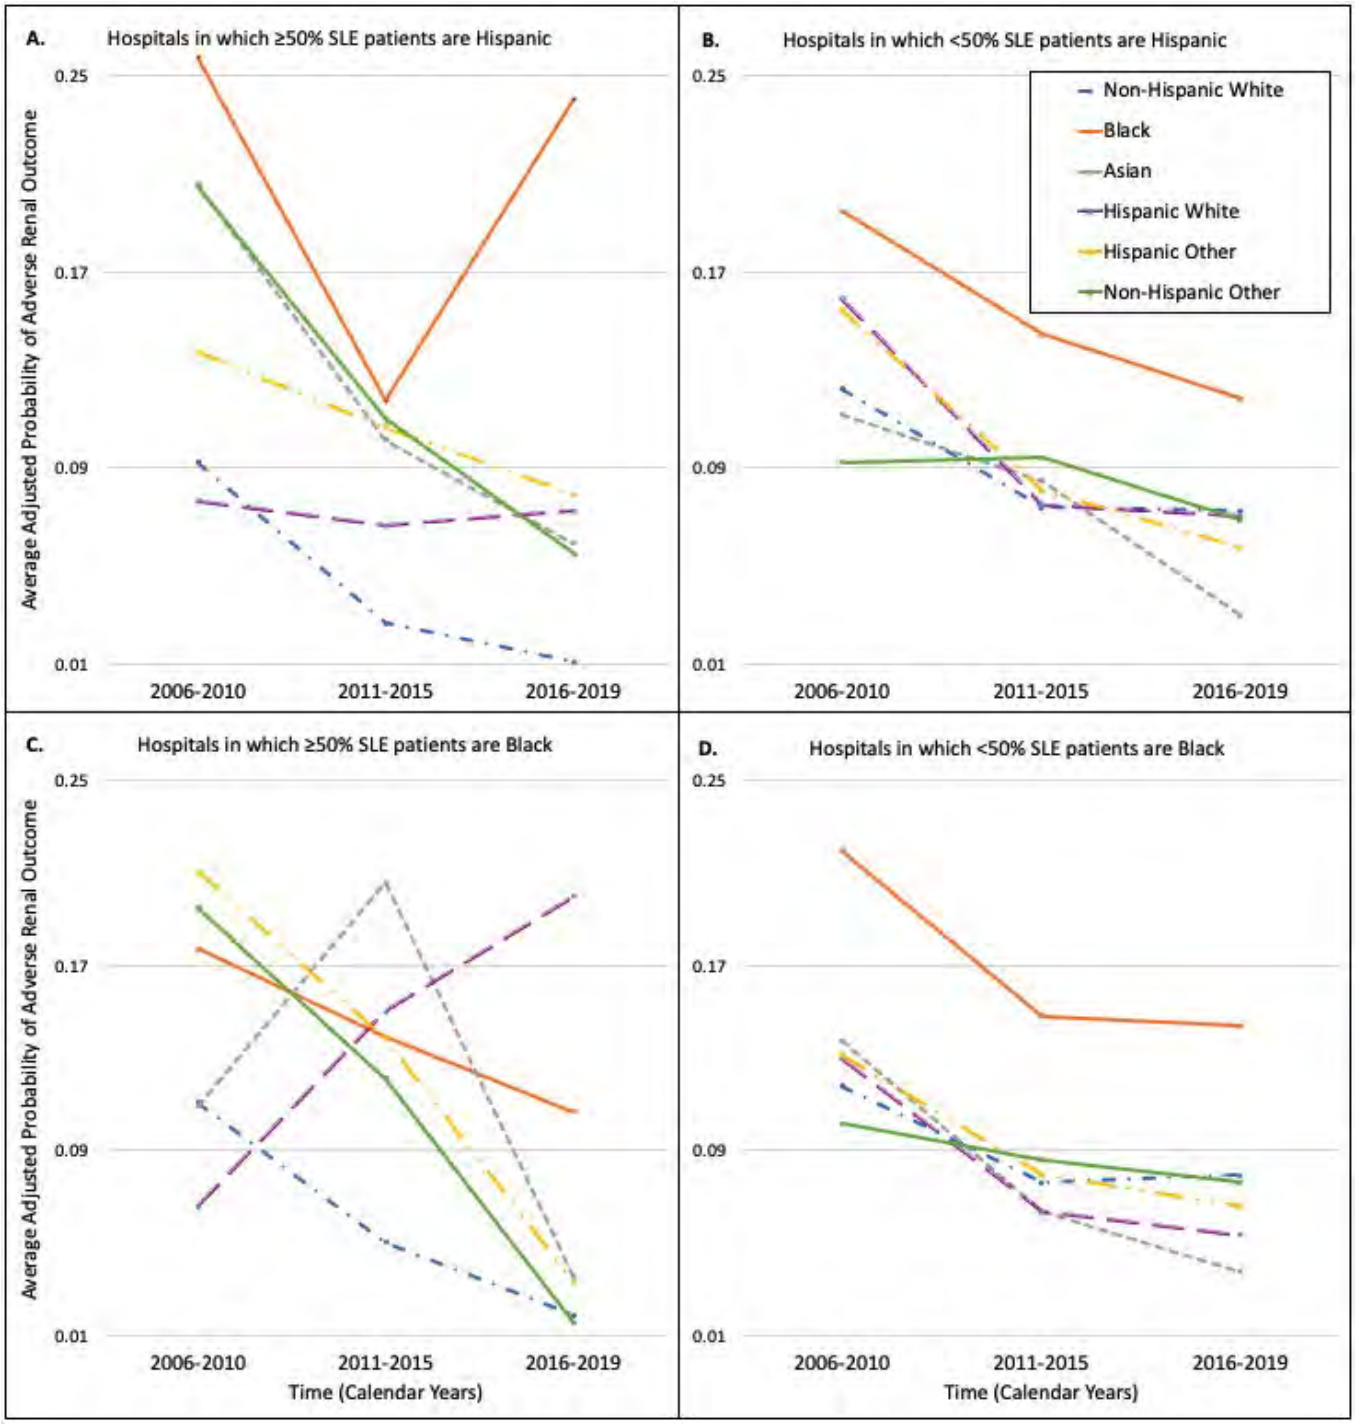

Figure 2. Marginal predictions of the average adjusted probability of adverse renal outcomes at any hospital encounter (composite of ESRD diagnosis, dialysis, renal transplant) over time by racial/ethnic category, stratified either by hospitals in which Hispanic patients comprise A) ≥50% of admitted SLE patients (N=7 hospitals) vs. B) <50% of SLE patients (N=43 hospitals), or by hospitals in which C) ≥50% of SLE patients are Black (N=18 hospitals) vs. D) <50% of SLE patients are Black (N=32 hospitals). All models are adjusted for age, census region, median household income, insurance type, APR-DRG severity of illness, and seizure.

address greater or widening disparities that are systematically concentrated in local contexts despite population level improvements.

Session Title: Plenary II (0956–0961)
Session Type: Plenary Session
Session Time: 10:30AM–12:00PM

Background/Purpose: In observational studies, vitamin D has been inconsistently associated with reduced risk of several autoimmune diseases, and a large randomized, controlled trial has been lacking. Dietary marine-derived long-chain omega-3 (n–3) fatty acids decrease systemic inflammation and ameliorate symptoms in some autoimmune diseases, but no trials have tested whether supplementation lowers risk of developing autoimmune disease. We tested both vitamin D_3 and n-3 fatty acids for the prevention of autoimmune disease within a large nationwide randomized, controlled trial.

Methods: VITamin D and Omeg**A**-3 Tria**L** (**VITAL**), a U.S. nationwide randomized, double-blind, placebo-controlled trial, enrolled men at least 50 years and women at least 55 years of age in a two-by-two factorial design. Randomiza-

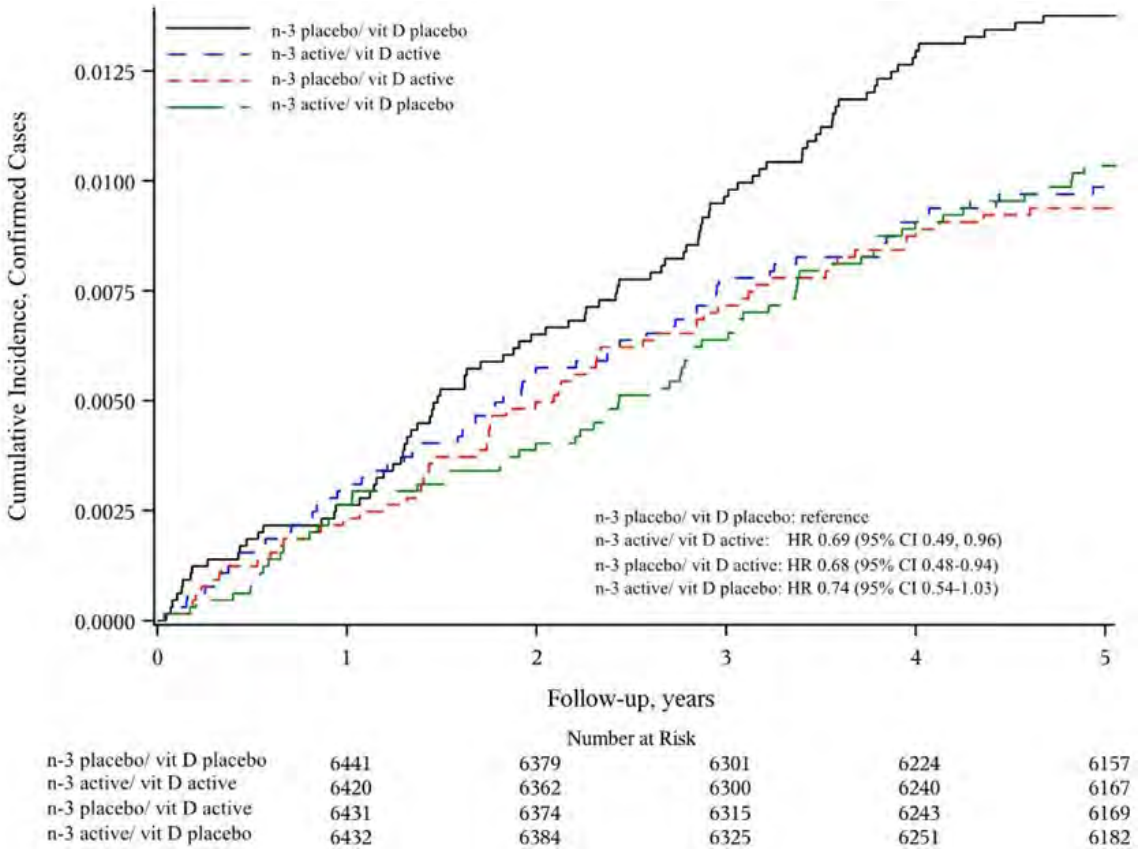

Figure 1. Incident Autoimmune Disease in the Four Arms of VITAL over 5.3 years Mean Follow-up, including Confirmed Cases.

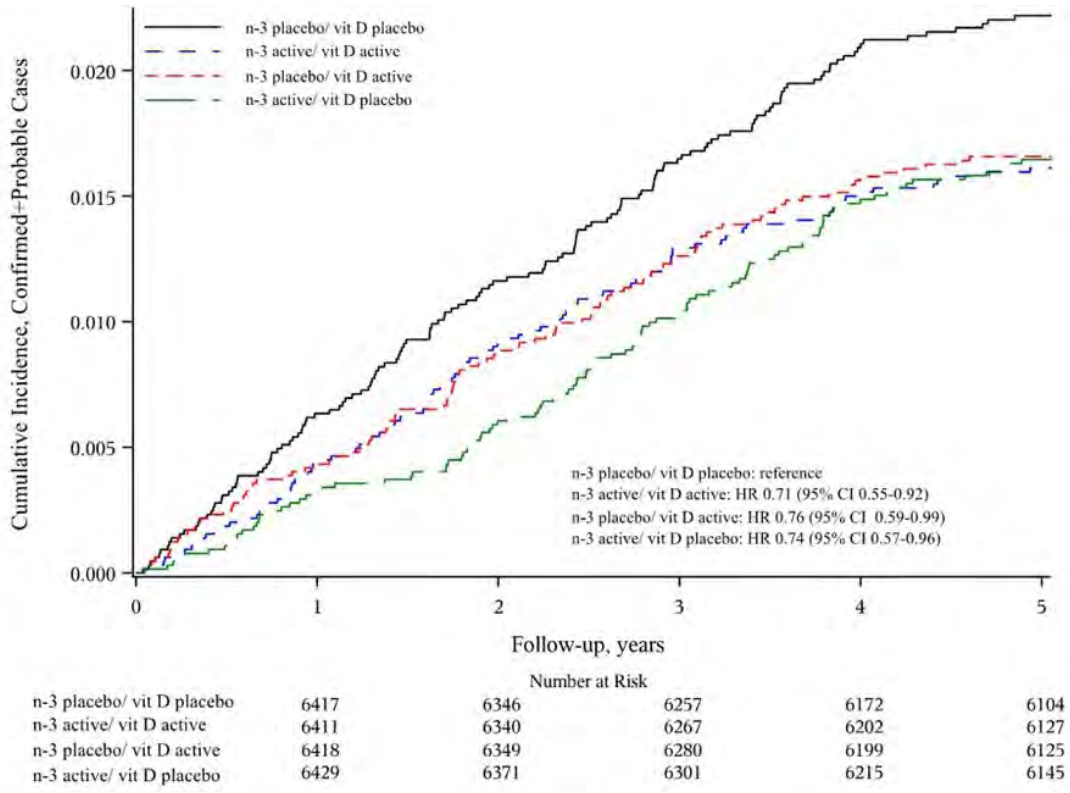

Figure 2. Incident Autoimmune Disease in the Four Arms of VITAL over 5.3 years Mean Follow-up, including Confirmed and Probable Cases.

tion to vitamin D_3 (2000 IU/d) and/or n-3 fatty acids (1000 mg/d) or placebo occurred from November 2011 to March 2014, and treatment continued through December 2017. (VITAL parent trial for cancer and cardiovascular disease prevention was reported in *NEJM*, January 3, 2019). We tested effects of vitamin D_3 and n-3 fatty acids upon autoimmune disease incidence. Incident doctor-diagnosed autoimmune diseases were reported by participants annually and confirmed by medical record review by expert physicians for classification criteria (if existing). The primary endpoint was total incident autoimmune diseases, including rheumatoid arthritis, polymyalgia rheumatica, autoimmune thyroid disease, psoriasis, and all others. Pre-specified secondary endpoints included individual most common autoimmune diseases; and probable autoimmune disease (evidence of incident autoimmune disease but lacking enough medical record data to confirm). Results were displayed in cumulative incidence curves and Cox regression models calculated hazard ratios (HR) of incident autoimmune diseases.

Results: 25,871 participants were randomized: 71% self-reported non-Hispanic Whites, 20% Black, and 9% other racial/ethnic groups, 51% women, mean age 67.1 years. During median follow-up of 5.3 years, confirmed autoimmune disease was diagnosed in 117 participants in the vitamin D_3 group and 150 in the placebo group (HR 0.78, 95% confidence interval 0.61-1.00, p=0.04). Excluding the first 2 years in pre-specified analyses of the primary endpoint, the HR for vitamin D_3 was 0.61 (0.43 - 0.86; 137 cases). Confirmed autoimmune disease was diagnosed in 123 participants in the n-3 fatty acids group and 144 in the placebo group (HR 0.85 (0.67-1.09). Excluding the first 2 years, the HR for the primary endpoint was 0.90 (0.64-1.26). (**Table 1**) When analyzed by factorial design subgroups, HRs for all three active arms vs. placebo/placebo were reduced by 25-30% (**Figures 1-2**). The number needed to treat with both agents for 5 years to prevent one autoimmune disease was 167 (94-769).

Conclusion: Supplementation for 5 years with vitamin D_3 and/or n-3 fatty acids reduced incident autoimmune disease by 25-30% in older adults vs. those who received neither supplement. The effect of vitamin D_3 appeared stronger after 2 years of supplementation.

Table 1. Hazard Ratios and 95% Confidence Intervals for the Primary and Secondary Endpoints, according to Randomized Assignment to (A) Vitamin D3 or Placebo or (B) N-3 Fatty Acids or Placebo

Table 1A. Hazard Ratios and 95% Confidence Intervals (95% CI) for the Primary and Secondary Endpoints, according to Randomized Assignment to Vitamin D_3 or Placebo[a]

SESSION INFORMATION

Session Date: Sunday, November 7, 2021

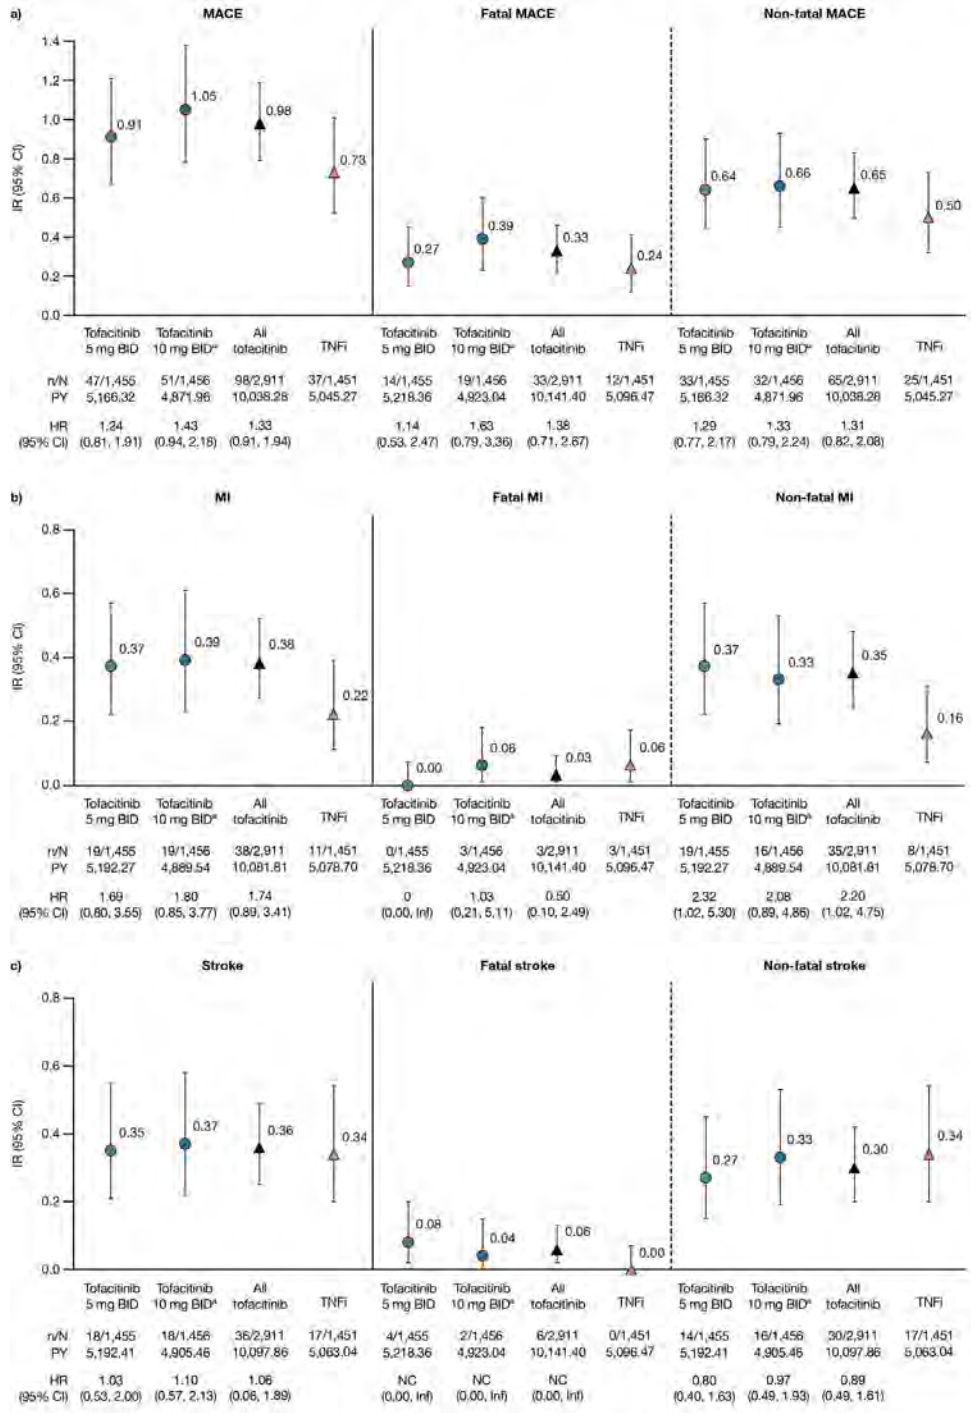
Session Title: Plenary II (0956–0961)

Session Type: Plenary Session

Session Time: 10:30AM–12:00PM

Background/Purpose: To identify independent risk factors for major adverse cardiovascular (CV) events (MACE) in ORAL Surveillance (NCT02092467), a long-term, randomized, open-label, non-inferiority, Phase 3b/4 safety study of tofacitinib vs TNFi in high-risk (aged ≥ 50 yrs with ≥ 1 additional CV risk factor) patients (pts) with RA and an inadequate MTX response.

Figure. IRs (95% CI, unique pts with events per 100 PY) and HRs (95% CI; tofacitinib vs TNFi) for a) MACE, b) MI, and c) stroke, including fatal and non-fatal events



[a]The tofacitinib 10 mg BID group included pts who were switched from tofacitinib 10 to 5 mg BID as a result of a study modification in February 2019
MACE included CV death (excluding CV death due to pulmonary embolism), non-fatal MI, and non-fatal stroke
HRs (95% CI) were based on 2 univariate Cox models (one for comparing All tofacitinib vs TNFi, and the other for comparing tofacitinib 5 and 10 mg BID vs TNFi) with treatment as the only covariate; NC is shown where HR was not calculated due to 0 events in the denominator (TNFi) of the treatment comparison
Risk period was to 60 days beyond the last dose or to the last contact date, whichever was shorter. The last contact date was the maximum of: AE start date, AE stop date, last study visit date, withdrawal date, or telephone contact date. If a pt died, the last contact date was the death date. PY included time to first event for pts with events, otherwise pts with no events were censored at the end of this risk period
AE, adverse event; BID, twice daily; CI, confidence interval; CV, cardiovascular; HR, hazard ratio; Inf, infinity; IR, incidence rate; MACE, major adverse cardiovascular events; MI, myocardial infarction; NC, not calculated; pt, patient; PY, pt-yrs; TNFi, tumor necrosis factor inhibitor

Methods: Pts on stable doses of MTX were randomized 1:1:1 to receive tofacitinib 5 or 10 mg BID or a TNFi (adalimumab 40 mg every 2 weeks or etanercept 50 mg every week). Incidence rates (IRs; unique pts with events/100 pt-yrs) and hazard ratios (HRs; tofacitinib vs TNFi) were evaluated for the co-primary endpoint of adjudicated MACE, as well as myocardial infarction (MI) and stroke; MACE was defined as CV death (excluding CV death due to pulmonary embolism), non-fatal MI, and non-fatal stroke. Across outcomes, IRs and HRs are also presented for fatal and non-fatal events. A post hoc analysis identified independent overall risk factors for MACE across treatment groups by Cox regression models. Baseline (BL) categorical covariates were initially screened in 2 univariate Cox analyses (main risk factor $p < 0.1$ and risk factor–treatment interaction $p \geq 0.2$) and were then selected in the final multivariate Cox model using backward selection, with $p < 0.1$ stay criteria. IRs and HRs for MACE were then stratified by the 4 most important risk factors identified (per largest HRs and smallest p values in the multivariate Cox model).

Results: 4,362 pts were included (tofacitinib 5 mg BID, n=1,455; tofacitinib 10 mg BID, n=1,456; TNFi, n=1,451). Median (range) age was 60.0 (50.0–88.0) yrs. MACE was reported by 47 pts, 51 pts, and 37 pts receiving tofacitinib 5 mg BID, tofacitinib 10 mg BID, and TNFi, respectively (Figure). IRs for MACE, MI, fatal and non-fatal MACE, and non-fatal MI were numerically higher with both tofacitinib doses vs TNFi (95% CIs overlapped; Figure a, b). Generally, IRs for fatal MI, and stroke (including fatal/non-fatal events), were similar across treatment groups (Figure a–c). HRs for MACE, MI, and stroke were generally > 1 for tofacitinib vs TNFi (Figure a–c); HR 95% CIs for non-fatal MI excluded 1 for tofacitinib 5 mg BID and all tofacitinib vs TNFi. BL covariates identified as the most important independent overall risk factors for MACE were current smoking, aspirin use, age ≥ 65 yrs, and male sex (Table 1). In pts with 1 of these

Table 1. Multivariate analysis of BL covariates as potential independent overall risk factors for MACE across all treatment groups

BL covariate	HR (95% CI)	p value
Current smoking	2.18 (1.50, 3.16)	< 0.0001
Aspirin use	2.11 (1.40, 3.19)	0.0004
Age ≥ 65 yrs	1.81 (1.27, 2.59)	0.0011
Male sex	1.81 (1.25, 2.61)	0.0015
History of diabetes	1.72 (1.16, 2.54)	0.0064
History of coronary artery procedures	1.71 (0.98, 2.99)	0.0598
History of hypertension	1.51 (1.00, 2.29)	0.0526
Total cholesterol/HDL-c ratio > 4	1.50 (1.06, 2.14)	0.0240

The tofacitinib 10 mg BID group included pts who were switched from tofacitinib 10 to 5 mg BID as a result of a study modification in February 2019

MACE included CV death (excluding CV death due to pulmonary embolism), non-fatal MI, and non-fatal stroke

A backward selection algorithm was used on a multivariate Cox model, which included effects of treatment (tofacitinib 5 mg BID, tofacitinib 10 mg BID, and TNFi; not subject to backward selection) and a pre-selected set of potential independent overall risk factors (ie risk factors which affect the incidence rates of an event equally across all 3 treatment groups) based on 2 Cox univariate models, where the p value for the risk factor was < 0.1 in a main effect model, and for the risk factor–treatment interaction was ≥ 0.2 in an interaction effect model. This pre-selected set of risk factors were subject to backward selection, with $p < 0.1$ stay criteria (except for treatment, which was mandatorily included in the model)

The 8 independent overall risk factors shown were selected from the backward selection algorithm; of these, the top 4 with the smallest p values were identified as the most important independent risk factors for MACE. The HR (95% CI) and p value presented for each risk factor are for Yes vs No (or the reference level)

Risk period was to 60 days beyond the last dose or to the last contact date, whichever was shorter. The last contact date was the maximum of: AE start date, AE stop date, last study visit date, withdrawal date, or telephone contact date. If a pt died, the last contact date was the death date

AE, adverse event; BID, twice daily; BL, baseline; CI, confidence interval; CV, cardiovascular; HDL-c, high-density lipoprotein-cholesterol; HR, hazard ratio; MACE, major adverse cardiovascular events; MI, myocardial infarction; pt, patient; TNFi, TNF inhibitors

Table 2. IRs (95% CI, unique pts with events per 100 PY) and HRs (95% CI; tofacitinib vs TNFi) for MACE, stratified by BL covariates identified as independent overall risk factors for MACE by Cox regression modeling

50–< 65 yrs and never smoked	7/523	0.36 (0.15, 0.75)	0.87 (0.32, 2.41)	8/493	0.45 (0.19, 0.89)	1.10 (0.41, 2.93)	15/1,016	0.41 (0.23, 0.67)	0.98 (0.42, 2.31)	8/525	0.42 (0.18, 0.82)

[a]The tofacitinib 10 mg BID group included pts who were switched from tofacitinib 10 to 5 mg BID as a result of a study modification in February 2019

MACE included CV death (excluding CV death due to pulmonary embolism), non-fatal MI, and non-fatal stroke

HRs (95% CI) were based on 2 univariate Cox models (one for comparing All tofacitinib vs TNFi, and the other for comparing tofacitinib 5 and 10 mg BID vs TNFi) with treatment as the only covariate at each level of the risk factors

Risk period was to 60 days beyond the last dose or to the last contact date, whichever was shorter. The last contact date was the maximum of: AE start date, AE stop date, last study visit date, withdrawal date, or telephone contact date. If a pt died, the last contact date was the death date

AE, adverse event; BID, twice daily; BL, baseline; CI, confidence interval; CV, cardiovascular; HR, hazard ratio; IR, incidence rate; MACE, major adverse cardiovascular event; MI, myocardial infarction; pt, patient; PY, pt-yrs; TNFi, TNF inhibitors

risk factors present, IRs for MACE were numerically higher with both tofacitinib doses vs TNFi (95% CIs overlapped; Table 2). Across treatment groups, in pts without these risk factors present, IRs for MACE were similar (Table 2). Generally, HRs for MACE were > 1 for tofacitinib vs TNFi, in pts with or without risk factors present (Table 2).

Conclusion: The incidence of MACE was numerically higher with tofacitinib vs TNFi treatment. Across treatment groups, the BL covariates, current smoking, aspirin use, age ≥ 65 yrs, and male sex were identified as independent overall risk factors in pts experiencing MACE; tofacitinib vs TNFi treatment in pts with any of these risk factors present was associated with numerically higher incidence of MACE.

SESSION INFORMATION
Session Date: Sunday, November 7, 2021
Session Title: Plenary II (0956–0961)
Session Type: Plenary Session
Session Time: 10:30AM–12:00PM

Background/Purpose: Physicians and patients often consider reducing or discontinuing hydroxychloroquine (HCQ) among SLE patients in remission or very low disease activity to limit HCQ-induced toxicity. We evaluated how disease activity status is associated with SLE flare after HCQ reduction or discontinuation, compared with HCQ maintenance.

Methods: We analyzed prospective data from the SLICC cohort (33 sites in Europe, Asia, and North America), which enrolls patients within 15 months of diagnosis and follows them annually since 1999. In patients initially receiving HCQ, we identified events of HCQ dose reduction and discontinuation. We created two cohorts of person-time, with time zero being date of first HCQ reduction in one cohort, and discontinuation in the other. For each cohort, we formed a comparison cohort of person-time on HCQ maintenance, matched on HCQ duration at time-zero (Figure

1). Patients were censored at death, lost to follow-up, end of study (April 2019), or when they started contributing person-time to the other cohorts. SLE flare was defined as either subsequent SLE therapy augmentation (steroids, immunosuppressives, HCQ, chloroquine, or biologics), increase of ≥4 points in the SLE Disease Activity Index-2000 (SLEDAI-2K) or hospitalization for SLE (information available only after 2014, for 60% of patients). We estimated crude flare rates, adjusted hazard ratios (HRs) and 95% confidence intervals (CIs) of the first flare in the HCQ reduction and discontinuation cohorts (vs HCQ maintenance). Analyses were then stratified by low disease activity state or clinical remission (see the definitions in the footnote to Table 1). All models were adjusted for demographics and clinical characteristics at time-zero.

Results: A total of 1460 patients were included (89% female, 52% Caucasian). The HCQ reduction cohort contributed 1063 person-years (N=564) and were compared with 1242 HCQ maintenance person-years (N=778). The HCQ discontinuation cohort contributed 657 person-years (N=389) and were compared with 924 maintenance person-years (N=577). We estimated that 5% of patients may have reduced HCQ therapy as result of the AAO guidelines, 55% because of low disease activity state, and the remainder (40%) for other reasons (possibly intolerance or patient preference). Among those who discontinued HCQ, 4% had retinal changes of concern, 15% were in clinical remission and the remainder stopped for unknown reasons (possibly intolerance, or patient preference). Cohorts reducing or discontinuing HCQ tended to have more SLE flares versus those maintaining HCQ (Table 1). Maintaining HCQ was associated with lower SLE flares particularly among patients already in low disease activity state or in remission at time zero (Table 1). However, patients who were not in remission or low activity state, were likely to flare if HCQ was either maintained or reduced, but the flare risk was higher if they discontinued HCQ (Table 1).

Conclusion: Maintaining HCQ was associated with a lower flare risk in all subgroups evaluated. Even among SLE patients in remission, lowering or stopping HCQ was associated with a 2-fold increase in flare risk compared to HCQ maintenance.

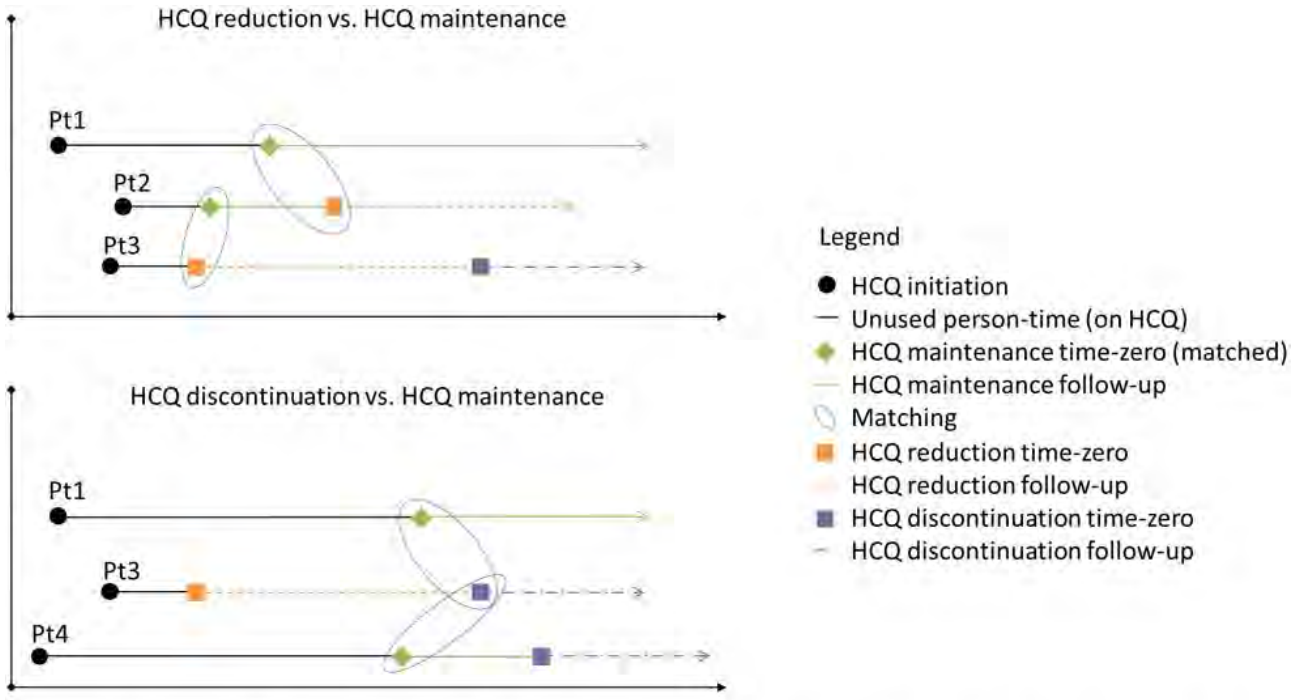

Figure 1. Example of 4 cohort patients (Pt1-4). A single patient could contribute person-time to one or more cohorts. HCQ maintenance person-time was matched (2:1) to the reduction or discontinuation groups on HCQ duration at time-zero.

Table 1. Adjusted hazard ratios with 95% confidence intervals (CIs) for SLE flares associated with HCQ reduction/discontinuation versus maintenance: main and stratified analyses

	HCQ reduction vs maintenance			HCQ discontinuation vs maintenance		
	No. of patients	Absolute flare rate/100 person-years (95% CI)	Adjusted HR (95% CI)*	No. of patients	Absolute flare rate/100 person-years (95% CI)	Adjusted HR (95% CI)*
Main analysis	1342	42.3 (38.6, 46.4) vs. 35.6 (32.4, 39.1)	1.13 (0.98, 1.30)	966	43.1 (38.3, 48.4) vs. 34.2 (30.6, 38.2)	1.41 (1.19, 1.67)
Stratified analyses:						
Low disease activity[a] state at time zero						
Yes	815	38.7 (34.2, 43.8) vs. 31.4 (27.8, 35.5)	1.26 (1.04, 1.51)	592	36.7 (31.5, 42.7) vs. 30.1 (26.0, 34.8)	1.52 (1.21, 1.91)
No	527	48.1 (41.8, 55.4) vs. 43.9 (38.0, 50.8)	1.00 (0.80, 1.23)	374	56.9 (47.5, 68.1) vs. 42.2 (35.6, 50.0)	1.37 (1.06, 1.77)
Clinical remission[b] at time zero						
Yes	196	26.2 (20.1, 34.1) vs. 13.2 (9.4, 18.4)	2.14 (1.34, 3.43)	133	24.7 (17.7, 34.6) vs. 12.2 (8.0, 18.8)	2.77 (1.46, 5.26)
No	1146	46.3 (41.9, 51.1) vs. 41.7 (37.8, 46.0)	1.07 (0.92, 1.24)	833	47.9 (42.3, 54.2) vs. 39.2 (35.0, 43.9)	1.35 (1.13, 1.62)

*Adjusted for sex, race, age at SLE diagnosis, education, geographic residence, and the following variables assessed at time zero: SLE duration, renal damage according to SLICC Damage Inex, body mass index, smoking, prednisone, immunosuppressives and biologics. The main analysis was additionally adjusted by disease activity at time zero. [a]Low disease activity state was defined as SLEDAI-2K<4 and current prednisone dose ≤7.5 mg/day. [b]Clinical remission was defined as SLEDAI-2K=0 and no prednisone or immunosuppressives use during the last year.

SESSION INFORMATION
Session Date: Sunday, November 7, 2021
Session Title: Plenary II (0956–0961)
Session Type: Plenary Session
Session Time: 10:30AM–12:00PM

Background/Purpose: The CARRA STOP-JIA study compared the effectiveness of the CARRA Consensus Treatment Plans (CTPs) in achieving clinical inactive disease (CID) in untreated polyarticular JIA (pJIA) at 12 months using a prospective, observational study design. The primary results were reported previously ["The CARRA STOP-JIA Study: A Comparative Effectiveness Study of CARRA Consensus Treatment Plans for Untreated Polyarticular JIA", Kimura et al, Arthritis Rheumatol, In press]. Patients were enrolled into the CARRA Registry, which allows for long-term follow-up of this cohort. Here we report on the impact of initial CTP choices on outcomes at 24 mo.

Methods: STOP-JIA compared 3 CARRA CTPs: 1) Step Up (SU) – starting conventional synthetic disease modifying anti-rheumatic drug (csDMARD), adding biologic (b)DMARD if needed after ≥ 3 months; 2) Early Combination (EC) - csDMARD and bDMARD started together; and 3) Biologic First (BF) – starting bDMARD monotherapy, adding csDMARD if needed after ≥ 3 months. There was no randomization. Data were collected every 3 months using the CARRA Registry for the first 12 months and every 6 months thereafter. Patients with 24 months of follow-up were included in this analysis. The primary outcome was the proportion of children achieving CID off glucocorticoids (GC) at 24 months. Propensity score (PS) weighting (linear probability model) was used to balance baseline differences in potential confounders between CTPs. Secondary outcomes included the clinical Juvenile Arthritis Disease Activity Score based on 10 joints (cJADAS10), the Pediatric ACR 70 (pACR70) and patient-reported outcomes (PROs).

Results: 291 participants had a 24 month visit (188 Step Up, 76 Early Combination, 27 Biologic First). There were significant baseline differences between CTP groups for several variables, including JIA categories, number of active joints, Physician Global Assessment of Disease Activity, and cJADAS10 scores (Table 1). Patients in CID at 24 months was 42% for SU, 52% EC, and 44% BF (at 12 months: 32%, 37%, and 24% respectively), with a statistically significant difference (p=0.006) between the SU and EC groups after PS weighting at 24 months (Table 2). There were no significant differences between proportions of patients achieving cJADAS10 inactive disease (ID) (≤2.5) or the pACR70. All groups continued to improve at 24 months compared to 12 months. At 12 months/24 months, proportion of cJADAS10 ≤2.5 in SU: 45% vs 59%; EC: 60% vs 66%; BF: 48% vs. 57%. At 12 months/24 months, proportion of

Table 2. Between Group Differences in Clinically Inactive Disease (ACR) off Glucocorticoids, Pediatric ACR 70 Scores and cJADAS10 at 24 months

*A. Between-group difference estimates in CID off GC: estimates from PS-weighted model with adjustment**

	Difference in CID	Lower 95%	Upper 95%	P-value
Biologic First vs Step Up	7.2	-17.8	32.2	0.572
Early Combination vs Step Up	19.1	4.5	33.6	0.011
Biologic First vs Early Combination	-11.8	-38.0	14.3	0.375

*B. Between-group differences in cJADAS10 Inactive Disease (ID) (≤2.5): estimates from PS-weighted model with adjustment**

	Difference in ID	Lower 95%	Upper 95%	P-value
Biologic First vs Step Up	-2.1	-27.6	23.5	0.875
Early Combination vs Step Up	10.0	-5.9	25.8	0.219
Biologic First vs Early Combination	-12.0	-38.6	14.6	0.376

*C. Between-group differences in ACR70: estimates from PS-weighted model with adjustment**

	Difference in ACR70	Lower 95%	Upper 95%	P-value
Biologic First vs Step Up	-3.8	-28.6	21.0	0.765
Early Combination vs Step Up	9.1	-3.8	22.1	0.169
Biologic First vs Early Combination	-12.9	-38.7	12.9	0.328

* Adjusted for severity factors

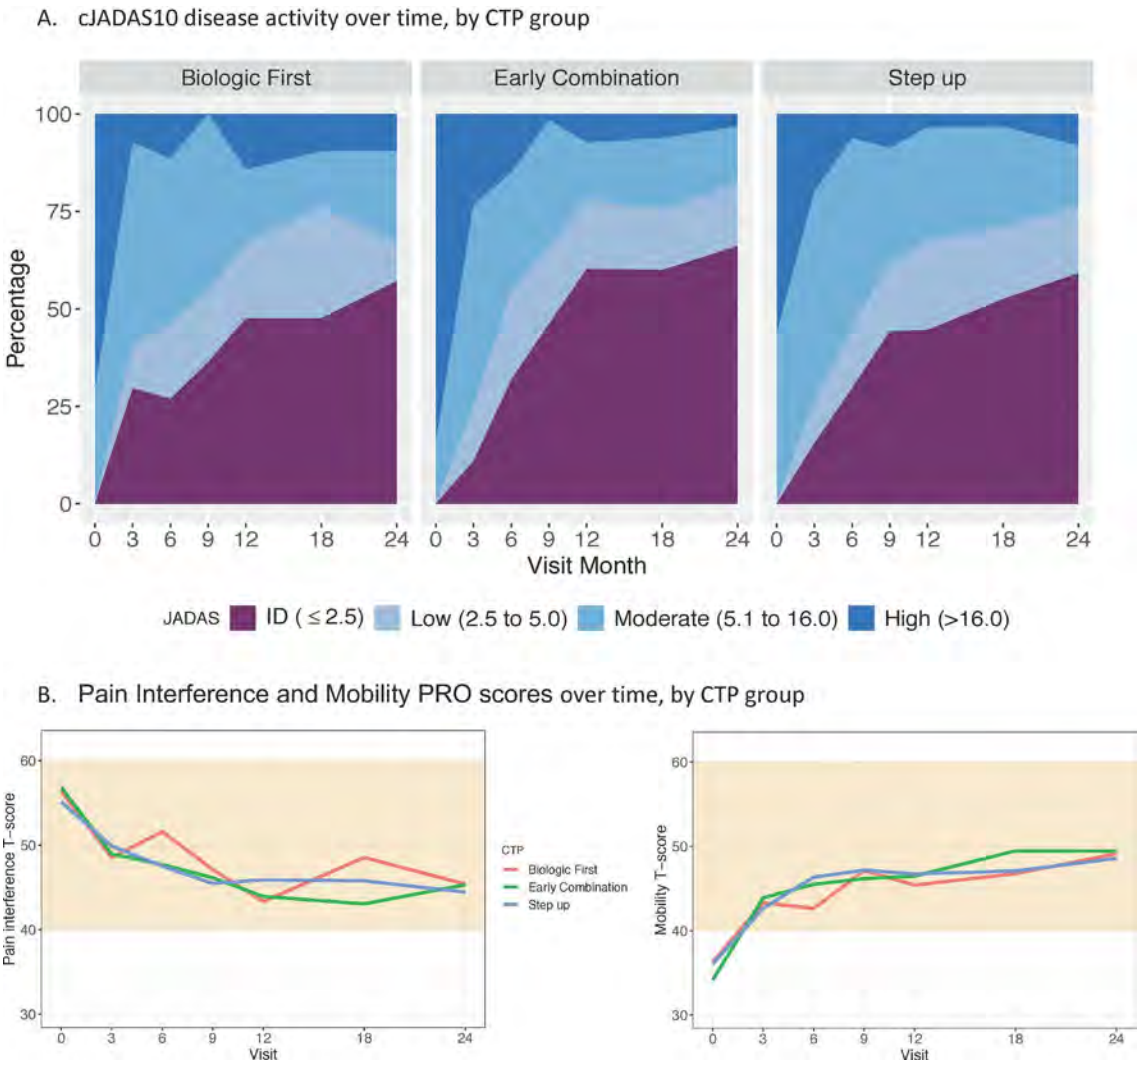

Figure 1. cJADAS10 and PRO measures over time.

pACR70 in SU: 47% vs 74%; EC: 59% vs 83%; BF: 44% vs 74%. Figure 1A shows the proportions of each group's JADAS activity over the 24 months. All groups also showed improvement in PROMIS® pain interference or mobility measures from baseline (Figure 1B). Seventeen SAEs were reported, most commonly infections.

Conclusion: While there was a significant difference in CID favoring Early Combination versus Step Up at 24 months, there were no significant differences between CTPs for other study outcomes. All groups did continue to improve in cJADAS10 and PRO measures. Additional analyses will include comparison of remission on medications (CID for 12 months) and patients ever achieving CID between CTPs.

SESSION INFORMATION
Session Date: Sunday, November 7, 2021
Session Title: Plenary II (0956–0961)
Session Type: Plenary Session
Session Time: 10:30AM–12:00PM

Background/Purpose: Multi-system Inflammatory Syndrome in Children (MIS-C) is a major complication of the Severe Acute Respiratory Syndrome Coronavirus 2 (SARS-CoV-2) pandemic in pediatric patients. Children with MIS-C present with varying degrees of cardiovascular and hyperinflammatory symptoms. We performed a comprehensive analysis of the plasma proteome of more than 1400 proteins in children with SARS-CoV-2. We hypothesized that the proteome would reflect heterogeneity in hyperinflammation and vascular injury, and further identify pathogenic mediators of disease.

Methods: Between April 2020 and October 2020, we enrolled 63 hospitalized patients with MIS-C (N=22), Severe COVID-19 ("Severe", N=15)) or asymptomatic or mild SARS-CoV-2 infection ("Minimal", N=26). In addition, we included remnant plasma samples from otherwise healthy patients ("Healthy", N=25). We utilized the Olink Explore 1536/384 protein biomarker platform to interrogate the plasma proteome of all 88 patients. All statistical analyses were performed in RStudio (RStudio, PBC, Boston, MA).57 Data were assumed to be non-parametric unless normality was demonstrated.

Results: To understand how the overall proteome of patients with MIS-C changes over time, we first created a PCA mapping all proteins and all patients. We then PCA transformed data for convalescent samples on that space. Convalescent samples shifted towards the healthy controls, implying that following treatment, the proteome in MIS-C patients returns towards a baseline state. We examined CXCL9 as the key protein associated with IFNg response and

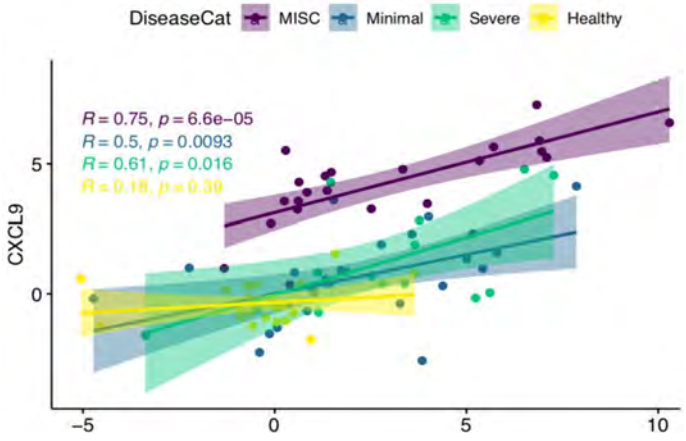

Figure 1. MISC patients are hyperresponsive to IFNg. Compared to all other groups, MISC patients make increased amounts of the IFNg responsive protein CXCL9 relative to their serum levels of IFNg.

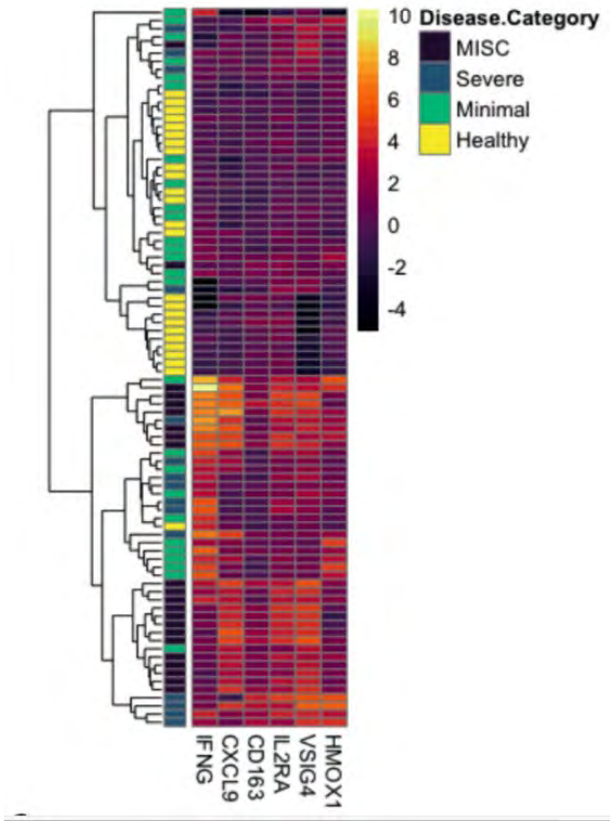

Figure 2. Clustering of patients based on MAS protein biomarkers. A panel of 6 protein biomarkers that are elevated in MAS cluster MISC patients away from healthy controls, asymptomatic SARS-CoV-2 infected patients, and severe COVID19 patients. There are two MAS/MISC clusters, one with an IFNg high signature, and one with an IFNg low signature.

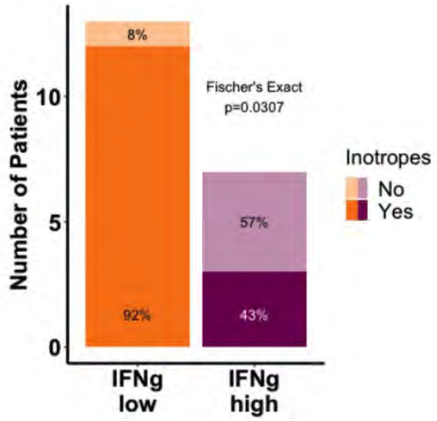

Figure 3. MISC patients with higher levels of IFNg are protected from inotrope requirement.

found that all patients with SARS-CoV-2 infection showed a positive CXCL9 response to increasing IFNg. Strikingly, MIS-C patients had a disproportionately high CXCL9 response to IFNg compared to the other groups. Consistent with a derepression of IFNg signaling, MIS-C patients expressed less TRIM21 compared to healthy controls. Unsupervised hierarchical clustering revealed two distinct groups of MIS-C patients that had elevations in multiple Macrophage Activation Syndrome (MAS) markers. These two clusters primarily differed by their IFNg expression with an IFNg-high versus IFNg-low group evident. Hierarchical clustering identified that SC5B9 correlated most highly with PLA2G2A, PDGFC, SELE, CALCA, NOS3, VWA1 and TYMP, demonstrating a signature consistent with thrombotic

microangiopathy (TMA). Patients with elevations in MAS or TMA markers were more likely to meet clinical criteria for MAS or TMA respectively. Interestingly, MISC patients with an Interferon gamma low signature were at higher risk of requiring inotropes.

Conclusion: We used proteomic analysis to begin to unravel the complex and heterogeneous pathophysiology associated with MIS-C. We identify PLA2G2A as a candidate biomarker for MIS-C and show that PLA2G2A is associated with clinical features of TMA. We demonstrate that MIS-C patients are characterized by a disproportionately high CXCL9 response to IFNg, implying a dysregulated response to IFNg. Patients with MIS-C showed heterogeneity based on IFNg expression, and surprisingly, patients with higher IFNg levels were less likely to require inotropes.

SESSION INFORMATION
Session Date: Sunday, November 7, 2021
Session Title: Abstracts: Infection-related Rheumatic Disease (0962–0965)
Session Type: Abstract Session
Session Time: 10:30AM–11:30AM

Background/Purpose: Although several studies indicate that patients with COVID-19 produce antiphospholipid antibodies (aPL), it is unclear which aPL subtype predominates and whether aPL correlates with thrombosis or severe COVID-19 outcomes. We tested aPL in a large prospective cohort of patients with and without COVID-19, and determined if aPL are associated with thromboembolic events and other severe outcomes in hospitalized COVID-19 patients.

Methods: Symptomatic patients undergoing SARS-CoV-2 nasopharyngeal PCR testing at a Canadian tertiary centre were enrolled in a prospective biobank cohort from March-July 2020. All PCR results (including those performed at other centres), demographics, medical history, hospitalization details and clinical outcomes were collected with a standard report form. Subjects were classified as COVID+ (≥1 positive PCR prior/at baseline) or non-COVID (all PCR negative prior/after enrolment). Biobanked plasma (day 0-7 after enrolment) was tested for anticardiolipin (aCL) IgM and IgG, anti-domain I of ß2-glycoprotein I (aD1ß2GP1) IgM and IgG, anti-phosphatidylserine/prothrombin (aPS/PT) IgM and IgG (Inova Diagnostics, San Diego), as well as lupus anticoagulant (LAC; Precision BioLogic, Halifax) using manufacturers' cut-offs. All plasma was also tested for SARS-CoV-2 IgM and IgG. We compared aPL prevalence (including subtypes) between COVID+ and non-COVID subjects. In hospitalized COVID+ subjects, we performed multivariate logistic regressions evaluating aPL (and subtypes) and thrombotic events (deep vein thrombosis, DVT, pulmonary embolism, PE, stroke, transient ischemic attack, TIA, myocardial infarction, MI), as well as acute kidney injury (AKI), intensive care unit (ICU) stay, mechanical ventilation, and death, adjusting for age and sex.

Table 1. Characteristics and aPL status of COVID+ and non-COVID subjects (n=656)

Characteristic	COVID + subjects n=291	Non-COVID subjects n=365
Age in years, mean (SD)	67 (18)	64 (20)
Female sex, n (%)	151 (52)	183 (50)
Hospital admission, n (%)	241 (83)	224 (61)
Prospective follow-up, mean days (SD)	70 (48)	60 (51)
Positive SARS-CoV-2 serologies IgM and/or IgG[1], n (%)	201/288 (70)	11/362 (3)

Abbreviations : AKI, acute kidney injury; ICU, intensive care unit ; aPL, antiphospholipid antibody; aCL, anticardiolipin, aD1 β2GP1, anti-domain-1 of β2-glycoprotein-1; aPS/PT, anti-phosphatidylserine/prothrombin; LAC, lupus anticoagulant

[1] each OR adjusted for age and sex

[2] analysis not performed for aD1 β2GP1 IgG+ due to too few subjects

[3] multivariate analyses for some outcomes could not be performed since no event occurred in those positive for the aPL subtype

Results: We studied 291 COVID+ and 365 non-COVID patients. The two groups were similar in age and sex, but more COVID+ patients were hospitalized (83% vs 61%) and had positive SARS-CoV-2 serology (70% vs 3%) vs non-COVID patients (Table 1). At baseline, 43% of COVID+ patients were positive for at least one aPL versus 32% of non-COVID patients (difference in proportion 11%; 95% CI 3, 18). In hospitalized COVID+ patients, 13% had a thromboembolic event, 38% developed AKI, 27% had an ICU stay, 19% had mechanical ventilation, and 17% died. In multivariate analyses, presence of any aPL was associated with AKI (OR 1.9; 95% CI 1.1, 3.3), ICU stay (OR 1.8; 95% CI 1.0, 3.5) and mechanical ventilation (OR 3.7; 95% CI 1.7, 7.8). Both aCL IgM and aCL IgG were strongly and independently associated with ICU stay and mechanical ventilation (Table 3). We saw a strong trend for more thrombotic events associated with aCL IgG (OR 2.3; 95% CI 0.9, 6.0), though the CI included the null value.

Conclusion: In this large prospective sample, over 40% of COVID-19 patients had aPL early in their clinical course. In hospitalized COVID-19 patients, aPL were associated with substantial increased risk of severe outcomes, with a strong trend for association between aCL IgG and thrombotic events. Our findings suggest that aPL, in particular aCL, might be useful markers for risk stratification in COVID-19.

Abstract Number: 0963

Immunogenicity of COVID-19 Vaccines in Patients with Autoimmune and Inflammatory Rheumatic Diseases (AIIRDs)

Gordon Lam[1], Andrew Laster[2], Sarah McCarter[2], Heather Gladue[3], Ahmad Kashif[2], Erin Siceloff[2], Victoria Lackey[3], Cheryl Robertson[3], Ashley Toci[2] and Leonard Calabrese[4], [1]Arthritis and Osteoporosis Consultants of the Carolinas, Cornelius, NC, [2]Arthritis and Osteoporosis Consultants of the Carolinas, Charlotte, NC, [3]Arthritis & Osteoporosis Consultants of the Carolinas, Charlotte, NC, [4]Cleveland Clinic, Cleveland, OH

SESSION INFORMATION
Session Date: Sunday, November 7, 2021
Session Title: Abstracts: Infection-related Rheumatic Disease (0962–0965)
Session Type: Abstract Session
Session Time: 10:30AM–11:30AM

Background/Purpose: AIIRD patients may have a blunted immune response to the COVID-19 vaccines, but this is largely uncharacterized as these individuals were not included in clinical trials. Vaccine response may be affected by patients' underlying disease processes and the systemic immunomodulatory therapies used to treat them, although the evidence for this is uncertain. To better understand the immunogenicity of the COVID-19 vaccines in this patient population and their treatment regimens, we quantified humoral responses to the SARS-CoV-2 spike protein in AIIRD patients.

Methods: This exploratory, descriptive, prospective cohort study enrolled patients from a single-specialty practice in Charlotte, NC who received the BNT162b2 (Pfizer), mRNA-1273 (Moderna) or Ad26COV2.S (Johnson & Johnson) vaccine from 3/17/21-5/14/21. Those with prior COVID-19 by self-report were excluded. We collected demographics, AIIRD diagnoses and immunomodulatory regimens of these patients. Antibody (Ab) testing was performed at least 14 days after completion of their vaccine series. SARS-CoV-2 IgG Ab levels to the S1 spike antigen RBD were measured using a semi-quantitative assay (Siemens Atellica; Quest). Associations between clinical characteristics and Ab responses were evaluated.

Results: Characteristics of 291 AIIRD patients studied are listed in Table 1. Overall, 71% developed an Ab response with a mean Ab titer of 12.72 (< 1 index). There was no difference based on gender. The likelihood of an absent Ab response increased with age, and there was a decline in mean levels with aging in Ab+ patients.

Treatment associations are listed in Table 2. Patients receiving rituximab were less likely to develop an Ab response (13%) and had a lower mean Ab titer (7.55) compared to the overall cohort. Dosing appeared to affect response rates with a single dose (1000 mg) Ab+ rate of 38% compared to a paired dose (1000 mg x2) rate of 7% (Table 3). Patients receiving abatacept IV were also less likely to develop an Ab response (45%). Detectable antibodies were seen in nearly all patients on JAKi (91%), belimumab (86%), TNFi (82%), IL-17i (80%), IL-6i (78%), IL-23i (100%) and IL-12/23i (100%).

Without concomitant targeted therapy, Ab+ rates with mycophenolate (75%) and MTX (80%) were decreased compared to sulfasalazine (100%), leflunomide (100%) and azathioprine (89%). 82% of patients receiving prednisone without biologics were Ab+ (average daily dose ≤10 mg). Overall dose effect is shown in Table 3.

Table 1. Demographics and Clinical Characteristics of Patients with Autoimmune and Inflammatory Rheumatic Disease patients

Gender				
	N	Ab (-)	Ab (+)	Mean Ab+ titer
Female	217 (75%)	63 (29%)	154 (71%)	12.82

monotherapy	5	3(60%)	2 (40%)	3.22
combination therapy	3	2 (67%)	1 (33%)	20.00
Paired dose (1000mg x 2 @2 wks)	30 (79%)	28 (93%)	2 (7%)	5.66
monotherapy	11	11(100%)	0 (0%)	0
combination therapy	19	17 (89%)	2 (11%)	5.66
Prednisone (all patients)				
Average Daily Dose (mg)	**N**	**AB (-)**	**AB (+)**	**Mean Ab titer**
≤ 5 mg	61	**21 (34%)**	40 (66%)	**12.52**
6-10 mg	12	**5 (42%)**	7 (58%)	**10.38**
11-15 mg	2	2	0	0.00
16-20 mg	1	1	0	0.00
>20 mg	1	0	1	20.00

Conclusion: A majority (71%) of AIIRD patients developed detectable anti-SARS-CoV-2 RBD Abs. Ab response rates and titers were age dependent. Patients receiving rituximab and abatacept IV were less likely to develop an Ab response with the former having a dose effect. Among csDMARDs, response rates were decreased in patients receiving MTX and mycophenolate. Low dose prednisone without biologics did not appear to influence Ab+ rates. Limitations of this study include its single center, non-randomized design and lack of residual confounder measures. Additional measures of humoral immune response and T cell function are also needed. However, this real-world study may provide further guidance for COVID-19 vaccination in patients with AIIRDs on immunomodulatory drugs.

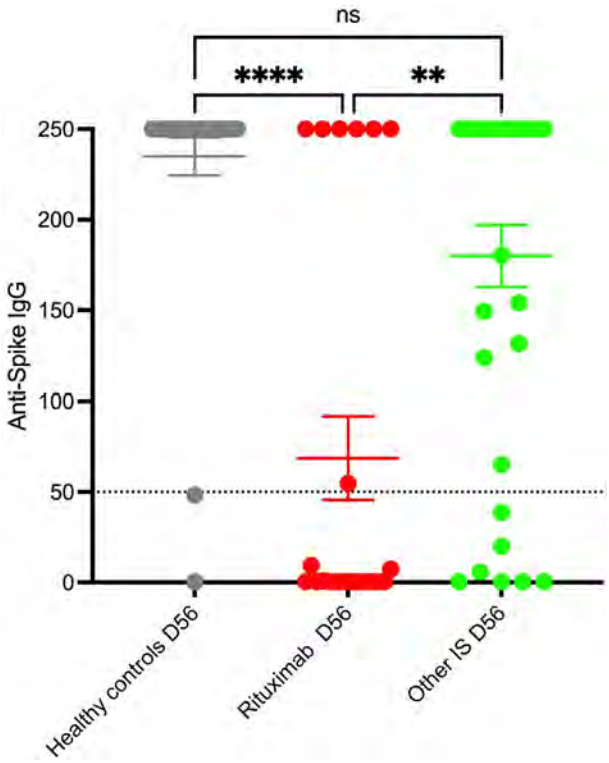
SESSION INFORMATION
Session Date: Sunday, November 7, 2021
Session Title: Abstracts: Infection-related Rheumatic Disease (0962–0965)
Session Type: Abstract Session
Session Time: 10:30AM–11:30AM

Background/Purpose: The global COVID-19 pandemic is starting to be controlled by massive vaccination. Some immunosuppressed patients have already paid a high price to the pandemic with increased risk of death in cancer patients and in autoimmune diseases patients treated with rituximab (hazard ratio of death: 4,04 (2,32-7,03). Despite the tremendous efficacy of novel mRNA vaccines, some immunocompromised patients seem not to respond at the same level compared to healthy controls to these vaccines when anti-spike antibodies are considered.

Objectives: To compare autoimmune diseases patients treated with either rituximab (RTX) or other immunosuppressants (other IS) and controls regarding response to mRNA vaccines.

Methods: Patients and healthy controls (HC) were vaccinated with BNT162b2 at days 0 and 28 and sampled at days 28 and 56. Patients with detectable levels of anti-nucleocapsid at any time points were excluded. Patients were divided into 2 groups: “RTX group” if they had received RTX ≤1 year, or “other IS group” if they were treated with other immunosuppressants. Serological assessment of vaccine response (ECLIA Cobas, Roche) and neutralization (iFlash-2019-nCoV Nab assay, Ylho) was performed. According to preliminary data, a threshold ≥ 50 of anti-Spike IgG was defined as a response to vaccine (since it is the value were patients had detectable neutralizing antibodies in the neutralization test). T-cell response against spike peptides using intra-cellular staining of TNF, IFNg, IL6, granzyme and perforine on activated CD4 and CD8 T cells will also be analyzed in all patients and will be presented at the time of the ACR meeting.

Results: 28 HC and 57 patients with autoimmune diseases were included: 24 patients in rituximab group and 33 in other IS group. On day 28, HC had significantly higher median levels of anti-Spike IgG (46.7 IQR 146) compared to



RTX and other Is : 0.4 IQR 3.8 and 4.5 IQR 20.5 respectively. At day 56, compared to both control (250 IQR 0) and other IS groups (250 IQR 141), the RTX (0.4 IQR 250) group had significantly lower median levels of anti-spike IgG (see figure). The RTX group also had a lower response rate : 29,2% in RTX group vs.79.4% in other IS group and 92,2% in HC There was no difference in anti-Spike IgG levels or percentage of response between the HC and other IS group. Within the RTX group, the median time to last RTX infusion was significantly lower in the non-responders (81 days IQR 147) compared to responders (231 days IQR 89). None of the patients having received RTX in the previous 6 months responded to the vaccine.

Conclusion: In patients with autoimmune disorders treated with immunosuppressors, responses after 1 dose of mRNA COVID vaccine were lower to that of HC. However, assessed one month after the second dose responses remained significantly impaired only in RTX treated patients (lower response rate and IgG anti-spike levels), but not in patients with patients treated with other IS. In RTX treated patients, the main factor associated with lack of response was time since last infusion. Given the low frequency of patients on RTX having a humoral response, it will be key to assess if these patients will have or not a cellular response. Data will be presented at the congress.

Anti-TNF Usage in Patients with HIV Infection 2003-2021: Long Term Safety and Followup

Benjamin Naovarat[1], Francis Williams[2], Gloria Salazar[3] and John Reveille[4], [1]University of Texas McGovern Medical School, Houston, TX, [2]Specialists for Health/Wellmed, Shavano Park, TX, [3]University of Texas Medical School at Houston/McGovern Medical School, Houston, TX, [4]Division of Rheumatology, The University of Texas Health Science Center at Houston, Houston, TX

SESSION INFORMATION
Session Date: Sunday, November 7, 2021
Session Title: Abstracts: Infection-related Rheumatic Disease (0962–0965)
Session Type: Abstract Session
Session Time: 10:30AM–11:30AM

Background/Purpose: There are concerns about using immunosuppressive agents for treatment of rheumatic diseases in patients with HIV infection due to concerns of opportunistic infection. We previously reported a series of eight HIV positive patients primarily seen at a County Outpatient Rheumatology Clinic treated with anti-TNF agents between 2003 and 2008 (Cepeda et al, Ann Rheum Dis 67: 710-12, 2008). The purpose of this study is to report the safety and efficacy of anti-TNF agents in these patients over time to the present and to update our experience with biologic agents in this setting in additional patients.

Methods: All but three of the patients were seen at the Harris County HIV Outpatient Clinic. At baseline visit, sociodemographic characteristics, CD4 counts, HIV viral load and medications were collected. Patients with rheumatoid arthritis or spondyloarthritis were initially treated with NSAIDs and nonbiologic disease modifying antirheumatic drugs(DMARDs) (methotrexate, sulfasalazine) and intra-articular/intralesional corticosteroids. Those patients with persistent disease activity despite conservative therapy were begun on anti-TNF agents, provided CD4 counts were

above 200 cells/µl and HIV viral load < 60,000 copies/ml (as per guidelines for use of immunosuppressive agents in the face of HIV infection).

Results: In total, 18 patients were treated with anti-TNF agents, including 8 treated with anti-TNF agents between 2003 and 2006 (two RA, two peripheral spondyloarthritis (SpA), of whom we have follow-up data on seven, and an additional nine treated with anti-TNF agents since then. There were no major infectious episodes that necessitated discontinuation of the medications, although one patient seen after 2006 had his adalimumab discontinued by his primary care doctor because of rising HIV viral load. The data on seven of the original eight are shown in Table 1 (one patient was seen only transiently in 2004 and was lost to followup).Of these original seven patients, four are still currently followed (of whom one is on adalimumab and one ustekinumab, the other two in remission) and all seven have been seen in the past six years. Of the nine patients begun on anti-TNF agents since 2006, all but one are currently being followed. by us, of whom six are still taking anti-TNF agents. Three had discontinued them, one due to lack of efficacy, one because of a rising HIV viral load, and one due to fears of toxicity(though no actual event was recorded).

Conclusion: In this series of 17 HIV positive patients, followed up to 18 years, the largest and longest followed reported to date, our data underscore the safety of using anti-TNF agents in patients with HIV infection over long duration, provided standard precautions of using immunosuppressive agents in the setting of HIV infection are followed.

Integrated Single Cell RNA-Sequencing Analysis of Tissue-Localized T Cells in Cutaneous Lupus and Lupus Nephritis

Garett Dunlap[1], Allison Billi[2], Feiyang Ma[3], Johann Gudjonsson[2], J. Michelle Kahlenberg[4] and Deepak Rao[5], [1]Harvard University, Somerville, MA, [2]Department of Dermatology, University of Michigan, Ann Arbor, MI, [3]University of California Los Angeles, Los Angelas, CA, [4]University of Michigan, Ann Arbor, MI, [5]Brigham and Women's Hospital, Boston, MA

SESSION INFORMATION
Session Date: Sunday, November 7, 2021
Session Title: Abstracts: T Cell Biology & Targets in Autoimmune & Inflammatory Disease (0966–0969)
Session Type: Abstract Session
Session Time: 10:30AM–11:30AM

Background/Purpose: Cutaneous lupus erythematosus (CLE) is commonly present in patients with systemic lupus erythematosus (SLE), but can also exist as an isolated manifestation without further systemic involvement. Single cell RNA-sequencing (scRNAseq) has previously been employed to define the T cell states present in SLE and lupus nephritis (LN), which has helped reveal insights into the pathogenesis of the disease. Similar scRNAseq studies targeted at skin lesions in SLE could likewise help define the cellular landscape of cutaneous lupus, and could facilitate comparisons of cell infiltrates in different target tissues in SLE. Here, we present the scRNAseq profile of T and NK cell populations within both lesional and non-lesional skin biopsies of patients with cutaneous lupus. We further integrate this dataset of skin-localized T cells with scRNAseq data from T cells from LN kidneys to compare and contrast T cell infiltrates at these two target sites.

Methods: Skin biopsies were obtained from both lesional and non-lesional sites of patients with cutaneous lupus, and from healthy donors. Single cells were encapsulated and sequenced using the 10x Genomics Chromium platform, and data were processed using the Cell Ranger pipeline (10x Genomics). Broad T/NK cell clusters were subset

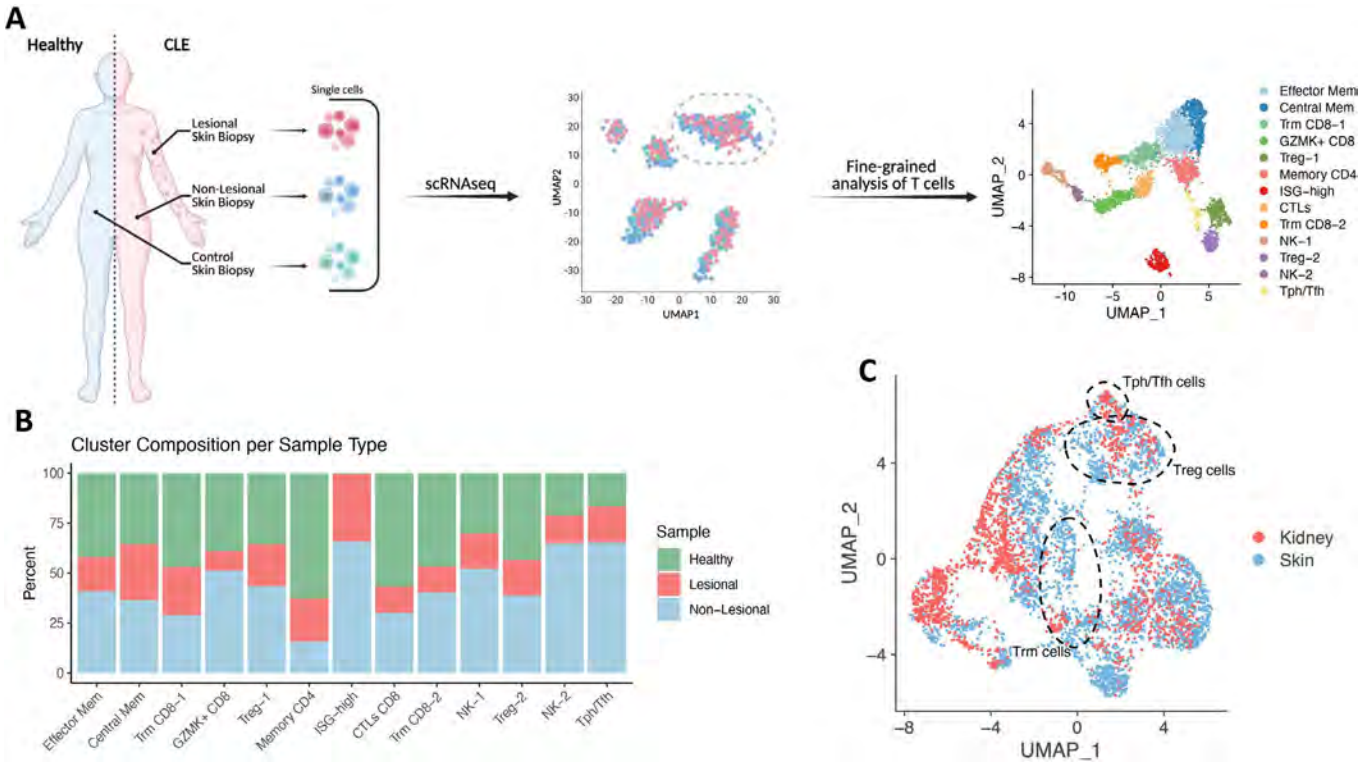

Figure 1. Analysis of T cells subsets across cutaneous lupus and lupus nephritis. (A) Graphical representation of pipeline for cutaneous lupus sample collection and analysis. (B) Breakdown of sample-type representation per cluster in the cutaneous lupus T cell dataset. (C) Integration of cutaneous lupus and lupus nephritis T cell datasets. Several conserved cell subsets, including Tregs, resident memory CD8 T cells, and Tph/Tfh-like cells, are highlighted.

from this dataset and were processed using Seurat for quality control filtering and subcluster analysis. scRNAseq data from LN T cells was obtained from the AMP RA/SLE Phase LN immune cell dataset. Integration of datasets was performed in Seurat using CCA analysis.

Results: Following filtering, paired lesional and non-lesional skin biopsies from 6 SLE patients and 1 isolated CLE patient, along with biopsies from 13 healthy donors, yielded 3,499 T and NK cells. Clustering of these cells revealed 13 subclusters. A population of strongly interferon-responding cells were present in patients with CLE but absent in healthy donors. Within CLE patients, both lesional and non-lesional cells across clusters expressed elevated levels of interferon simulated genes (ISGs), mirroring the ISG upregulation previously seen in scRNAseq studies of LN and blood T cells of lupus patients. Other populations enriched in lupus skin biopsies include a peripheral helper/follicular helper-like CD4 T cells (Tph/Tfh-like) population characterized by expression of CXCL13, MAF, and ICOS, and a population of NK cells expressing PRF1, GNLY, and GZMB. Integration of this dataset with T cells from LN samples using CCA revealed many shared T cell states, including populations of resident memory CD8 T cells, regulatory T cells, Tph/Tfh-like cells, cytotoxic CD8 T cells, ISG-high cells, and NK cells.

Conclusion: This data represents the first analysis of the transcriptomics of T and NK cells in cutaneous lupus at the single cell level. We defined the populations of T cells present in lesional skin as compared to non-lesional skin from the same patients, as well as skin from healthy controls. We identified a strong ISG upregulation in samples collected from CLE patients, and also noted an overrepresentation of helper T cells and NK cells among these samples. Integration of CLE and LN further revealed numerous conserved states, serving as a base for deeper analysis across tissues in lupus.

Antigen-specific and Bystander Autoreactive T Cell Control in Peripheral Blood of ACPA+ Rheumatoid Arthritis Patients Administered Antigen-specific Tolerising Immunotherapy

Pascale Wehr[1], Ranjeny Thomas[2], Nishta Ramnoruth[3], Swati Patel[3], Jamie Rossjohn[4] and Hugh Reid[4], [1]University of Queensland Diamantina Institute, Brisbane, Australia, [2]University of Queensland, Diamantina Institute, Brisbane, Australia, [3]University Of Queensland, Brisbane, Australia, [4]Monash University, Melbourne, Australia

SESSION INFORMATION
Session Date: Sunday, November 7, 2021
Session Title: Abstracts: T Cell Biology & Targets in Autoimmune & Inflammatory Disease (0966–0969)
Session Type: Abstract Session
Session Time: 10:30AM–11:30AM

Background/Purpose: The control of autoreactive T cells in an antigen-specific manner in autoimmune diseases is a major clinical research goal. Various regulatory immune signatures have emerged from the analysis of patients with type 1 diabetes (T1D), multiple sclerosis or allogeneic stem cell transplantation who achieve prolonged disease remission or a favorable response to immunotherapies designed to control T cells. These include CD4+CD25+CD127hi T helper (Th) cells producing Th2 cytokines, IL-10-producing CD4+ regulatory type 1 (Tr1) T cells, and EOMES+-TIGIT+KLRG1+ "partially exhausted" CD8+ T cells. Transcriptomic and T cell receptor (TCR) sequencing analysis of rheumatoid arthritis (RA) peripheral blood (PB) and synovial T cells has identified large populations of clonally expanded CD4+ and CD8+ cytotoxic T cells (CTL) in RA patients. DEN-181 is a liposome immunotherapy encapsulating 40mg/ml collagen $II_{259-273}$ (CII) peptide + 400ng/ml calcitriol, which is presented by lymph node dendritic cells after s.c. injection. Here we assessed the impact of a single ascending dose of DEN-181 on PB CII-specific and bystander citrullinated (Cit) Cit64vimentin$_{59-71}$ autoreactive T cell responses, CD4+ T cells, and CTL.

Methods: Stored PBMC from 11 ACPA+ HLA-DRB1*0401 or *0101+ RA patients who received vehicle or 3 dose levels of DEN-181, in clinical trial protocol A-RA—0081, were evaluated for number of CII- and Cit64vimentin$_{59-71}$-specific CD4+ T cells 0, 7 and 28 days post-dosing with flow cytometry using haplotype-specific tetramers in a recently-qualified assay. CD45+ leukocytes from cryopreserved PBMC of one patient per cohort at 0 and 28 days post-dose were sequenced using 5' RNA/TCR single-cell 10x Genomics kits. We identified clonally expanded TCR and mapped the clonotypes to their respective transcriptome using the Seurat package in R.

Results: The number of CII-specific T cells and Cit64vimentin$_{59-71}$-specific bystander T cells decreased at day 7 and 28 relative to baseline with similar trends in cohorts receiving 1ml or 3ml but not 0.3ml DEN-181 or placebo. Transcriptomics identified 16 unique CD3+TCR+ PB populations, including activated and exhausted CTL, naïve, Th2-like memory and regulatory CD4+ T cells. The most expanded clonotypes were CD8+ CTL. While the polyfunctional CD8+ CTL cluster decreased at day 28 after 0.3, 1 or 3ml DEN-181, exhausted CTL uniquely increased after 1ml DEN-181. In contrast to 0.3 or 3ml, all but one of the TCR clonotypes shared across time points after 1ml DEN-181 expanded its proportion of exhausted cells at day 28. Naïve-like T cells decreased and $CD4^{lo}$ central memory Th-like T cells increased uniquely after 1ml DEN-181.

Conclusion: In T1D, CTL exhaustion reflects a favorable response to T cell immunotherapy. One ml of antigen-specific tolerising immunotherapy, DEN-181, controlled antigen-specific and autoreactive bystander CD4+ T cell numbers, and enhanced bystander CTL clonal exhaustion in RA PB.

SESSION INFORMATION

Session Date: Sunday, November 7, 2021

Session Title: Abstracts: T Cell Biology & Targets in Autoimmune & Inflammatory Disease (0966–0969)

Session Type: Abstract Session

Session Time: 10:30AM–11:30AM

Background/Purpose: T cell-derived pro-inflammatory cytokines are a major driver of rheumatoid arthritis (RA) pathogenesis. While CD4 T cells have traditionally been assumed to be the main cytokine-producing T cells, CD8 T cells rival CD4 T cells in terms of both cell numbers and production of IFNγ and TNF. We found that the majority of CD8 T cells in synovial tissue and fluid are defined by high granzyme K (GzmK) expression and intermediate granzyme B (GzmB) expression, a pattern rare in blood. Here, we characterize the functions and differentiation of these tissue CD8 T cell subsets and describe the effects of GzmK on synovial fibroblasts.

Methods: Blood, synovial fluid, and synovial tissue were obtained from patients meeting the 2010 ACR criteria for RA. Single-cell RNA-seq data sets were generated by integrating new and publicly available data from synovial tissue and fluid from patients with RA and from blood from healthy controls. Synovial fibroblasts were stimulated with recombinant GzmK and/or cytokines for 24 hours prior to harvest of supernatants and RNA. Cytokine production was assessed by intracellular cytokine staining and flow cytometry or by enzyme-linked immunosorbent assay (ELISA). Gene expression changes were analyzed by RT-PCR or bulk RNA-sequencing (RNA-seq). In cross-disease analysis, GzmK and GzmB gene signatures were derived from RA synovial tissue data and applied to other tissue CD8 T cell profiles from publicly available scRNA-seq data.

Results: The vast majority of synovial CD8 T cells have a phenotype that is distinct from classic cytotoxic T lymphocytes, which express high levels of cytotoxic proteins such as granzyme B (GzmB), perforin, and granulysin (Fig. 1A). Instead, synovial CD8 T cell populations are dominated by GzmK$^+$ GzmB$^+$ CD8 T cells with low expression of perforin. Unlike GzmB, which activated caspases to induce target cell death, we find that GzmK does not induce cell death of synovial fibroblasts. Instead, we find that GzmK induces synovial fibroblasts to produce inflammatory factors such as IL-6 and CCL2. Moreover, GzmK can potentiate the effects of IFNg and TNF on synovial fibroblasts, thereby amplifying the effects of these T cell-derived cytokines in RA synovium (Fig. 1B). Using single-cell TCR repertoire studies to track sister clones among matched blood and synovial CD8 T cells, we have identified migration and differentiation pathways that lead to the accumulation of GzmK$^+$ GzmB$^+$ CD8 T cells in inflamed joints. Further, we found transcriptomically similar CD8 T cells in both healthy and diseased tissues, including bowel from patients with inflammatory bowel disease and bronchoalveolar lavage fluid from patients with severe COVID-19 (Fig. 1C).

Conclusion: These findings suggest that GzmK$^+$ GzmB$^+$ CD8 T cells form a core population of tissue-associated T cells in humans that has the potential to drive inflammation both by production of inflammatory cytokines and by direct effects of granzyme K on other cells.

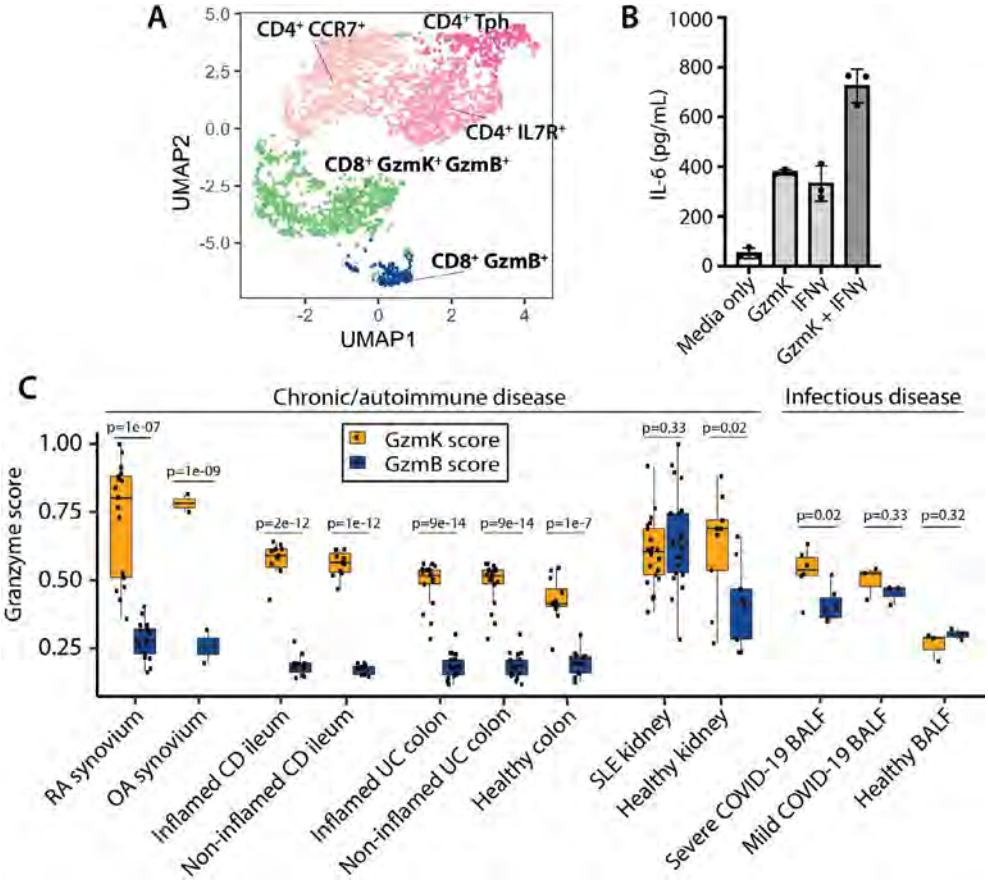

Figure 1. (A) UMAP plot of Louvain clustering of 4,111 single-cell RNA-seq profiles from synovial tissue T cells. (B) IL-6 production by synovial fibroblasts after stimulation with recombinant GzmK and/or IFNg for 24 hours. (C) GzmK and GzmB scores were derived from scRNA-seq data from CD8 T cells from RA synovial tissue and applied to publicly available scRNA-seq profiles of CD8 T cells from other healthy and diseased tissues.

Loss of Balance Between Protective and Pro-inflammatory Synovial Tissue T Cell Polyfunctionality Predates Clinical Onset of Rheumatoid Arthritis

Achilleas Floudas[1], Nuno Neto[2], Carl Orr[3], Mary Canavan[4], Phil Gallagher[3], Conor Hurson[5], Michael Monaghan[2], Nagpar Sunil[6], Ronan Mullan[7], Douglas Veale[8] and Ursula Fearon[2], [1]Molecular Rheumatology Trinity Biomedical Sciences Institute, Dublin, Ireland, [2]Trinity College Dublin, Dublin, Ireland, [3]St Vincent's Hospital, Dublin, Ireland, [4]Trinity College, Santry, Ireland, [5]St Vincents University Hospital, Dublin, Ireland, [6]Janssen R&D, Spring House, PA, [7]Tallaght University Hospital, Dublin, Ireland, [8]University College Dublin, Dublin, Ireland

SESSION INFORMATION

Session Date: Sunday, November 7, 2021

Session Title: Abstracts: T Cell Biology & Targets in Autoimmune & Inflammatory Disease (0966–0969)

Session Type: Abstract Session

Session Time: 10:30AM–11:30AM

Background/Purpose: Effective treatment of Rheumatoid arthritis (RA) patients is achievable within a short window of opportunity. T-cells are early drivers of synovial inflammation of RA, therefore, identification of pathogenic T-cell subsets at the synovial tissue of pre-RA, individuals at risk (IAR), would greatly improve our understanding of disease pathogenesis. Comparative analysis of healthy control, IAR subject and RA-patient derived synovial tissue T-cell responses will lead to the identification of pathogenic as well as protective cytokine milieu, thus enabling the identification of early therapeutic targets to help steer the immune response towards resolution.

Methods: Synovial biopsies from RA, IAR and HC by arthroscopic surgery followed by RNAseq analysis (Guo et al., PLoS One, 2018). Single cell synovial tissue cell suspensions from RA, IAR and HC and paired PBMC were stimulated *in vitro* and polyfunctional synovial T-cell subsets examined by flow cytometric analysis, SPICE visualization and FlowSom clustering. Flow-Imaging, was utilised to confirm T-cell cluster identification. Fluorescent Lifetime Imaging Microscopy (FLIM) was used to visualise metabolic status of specific T-cell populations.

Results: T-cell associated pro-inflammatory gene pathways were increased in RNAseq analysis of RA-patient and IAR compared to HC synovial tissue biopsies. Flow cytometric analysis of pro-inflammatory cytokine (TNF-a, IFN-γ, IL-2, GM-CSF, IL-17A, IL-22) production and SPICE analysis of *ex vivo* stimulated T-cells revealed marked polyfunctionality of IAR synovial T-cells, thus providing evidence for a dysregulated synovial T-cell response that pre-dates clinical onset of disease. Importantly, HC synovial tissue harbours a small, albeit surprisingly polyfunctional, CD4 T-cell population characterised by significantly increased IL-4 and GM-CSF cytokine production compared to arthralgia subject ($P< 0.001$ and $P=0.01$) and RA-patient ($P< 0.001$ and $P=0.004$) synovial tissue. However, not all polyfunctional T-cells are equal in their pathogenic potential. Therefore, in order to identify highly pathogenic synovial T-cells, cluster analysis of flow cytometric data using the unsupervised algorithm FlowSom was performed and led to the identification of specific T-cell clusters with unique polyfunctionality characteristics. Specifically a cluster of $CD4^{+}CD8^{+}$ double positive (DP) T-cells with high polyfunctionality scores was identified. Hybrid flow cytometry and imaging technique confirmed the co-expression of CD4 and CD8 by a synovial T-cell population. DP T-cells are enriched in RA-patient synovial fluid and synovial tissue and IAR synovial tissue, but are absent from HC synovial tissue. Importantly, DP T-cell synovial accumulation strongly ($P=0.002$) correlates with DAS28(CRP) of RA-patients. Utilisation of the novel, non-invasive FLIM technique for visualisation of cellular NAD, revealed that DP T-cells have a metabolic profile indicative of activated memory T-cells.

Conclusion: These data highlight a key early loss of balance between protective and pathogenic synovial T-cell polyfunctionality and the emergence of specific, highly polyfunctional and pathogenic T-cell clusters in RA.

A. FlowSom unsupervised clustering algorithm analysis of RA patient synovial CD3+ T cells for the identification of phenotypically distinct highly polyfunctional T cell clusters. Symbols indicate polyfunctional CD4+CD8+ DP T cells. B. Representative flow cytometric analysis of paired RA patient peripheral blood, synovial fluid and synovial tissue CD3+ T cells. C. Frequency of CD4+CD8+ DP T cells in the periphery (n=34), synovial fluid (n=13), and synovial tissue (n=7), of RA patients. D. Frequency of CD4+CD8+ DP T cells in the periphery and synovial tissue of HC (n=11 and n=5 respectively), IAR (n=13 and n=6 respectively), subjects and RA (n=34 and n=7 respectively) patients. E. Representative imaging flow cytometry of RA patient synovial fluid CD4+, CD8+ and CD4+CD8+ DP T cells. F. FLIM images and cumulative data of RA patient flow sorted peripheral blood CD4+ and CD4+CD8+ DP T cells, (n=5). H. Session Title: Abstracts: SLE – Etiology & Pathogenesis (0970–0973)

Session Type: Abstract Session

Session Time: 2:00PM–3:00PM

Background/Purpose: Skin inflammation and photosensitivity are common manifestations of cutaneous (CLE) and systemic lupus erythematosus (SLE), yet the mechanisms underlying heightened cell death and epidermal inflammation remain unclear. Non-lesional lupus keratinocytes (KCs) sustain an interferon (IFN)-rich, inflammatory profile even through several weeks of culture, suggesting possible epigenetic changes that drive this phenotype. Here we identify differential methylation of the Hippo signaling pathway as a novel regulator of apoptosis and photosensitive responses in lupus skin.

Methods: Genome-wide DNA methylation analysis was performed on extracted KC DNA from SLE patients and HC skin biopsies. Single-cell and bulk RNA sequencing was used to analyze RNA expression in cultured primary KCs from SLE patients and HC.*In vivo* protein and phospho-protein expression was assessed by immunofluorescent staining of HC and non-lesional lupus skin. A spontaneously immortalized KC line (N/TERTs) expressing a tetracycline inducible TEAD inhibitor (TEADi) that prevents colocalization of YAP-TEAD was used to evaluate the role of YAP signaling in apoptosis and UVB-mediated cell death. Apoptosis was analyzed via TUNEL staining and caspase 3/7 assay.

Results: Genome-wide DNA methylation analysis on cultured KC DNA from non-lesional, non-sun exposed skin biopsies of SLE patients and HC identified Hippo signaling as the top differentially-methylated pathway. We found significant hypomethylation of WWC1 in lupus KCs compared to control ($\Delta\beta$=-0.17,*P*= 4.36 X 10-9) which promotes phosphorylation and thus cytosolic sequestration of YAP, attenuating TEAD-mediated transcription of pro-proliferative target genes. To determine functional relevance, we compared IFNγ or IFNα stimulated RNA-seq samples from the KCs used for our methylation studies. We found a negative correlation between IFN responses and methylation signatures. As confirmation, we analyzed Hippo regulated genes using single-cell RNA sequencing of nonlesional KC isolated from skin biopsies of lupus vs. HC and found downregulation of pro-proliferative YAP target genes such as SLP1, MYC, and AREG. Consistent with modulation of Hippo signaling as predicted by our methylation data, WWC1 expression was significantly increased in SLE vs. HC KC ($p = 0.0142$). Further, immunofluorescent microscopy of frozen non-lesional biopsies identified a significant increase in phosphorylated YAP in lupus skin compared to controls. TEADi induction in a spontaneously immortalized KC line resulted in a robust increase in UVB-mediated apoptosis as measured by TUNEL staining and caspase 3/7 activation, suggesting that the cytoplasmic retention of YAP observed in SLE KCs may contribute to enhanced UV-mediated KC apoptosis.

Conclusion: Collectively, our work describes a novel mechanistic paradigm in lupus KC in which hypomethylation of key regulators of the Hippo pathway restrict coactivation of TEAD transcriptional activity through cytoplasmic reten-

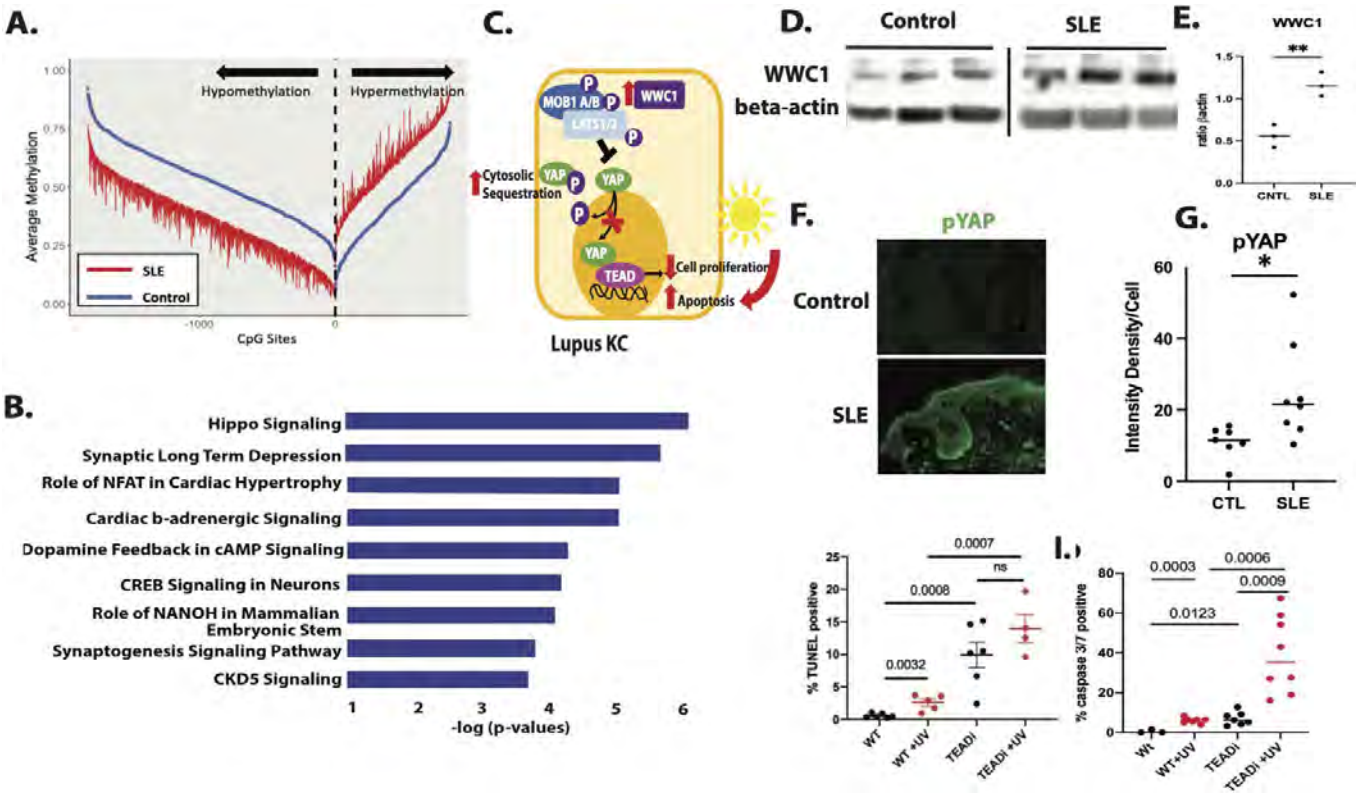

Figure 1. Deactivation of Hippo signaling in SLE KCs leads to increased UVB-mediated apoptosis. A. Illumina methylation arrays of non-lesional SLE vs. control KCs (age, sex, race matched, n=7 each) identified differential methylation in SLE KCs and B. KEGG analysis (via DAVID) revealed Hippo signaling as the top significantly differentially methylated pathway. C. Schematic of Hippo signaling in SLE KCs: increased WWC1 leads to phosphorylation of LATS1/2 which then phosphorylates YAP and leads to cytosolic retention and decreased transcription of proliferative genes and increased transcription of pro-apoptotic genes. D. Western blot of WWC1 and beta-actin in 3 healthy control and 3 SLE KC cultures. E. Quantification of WWC1 in 3 HC and 3 SLE KC lines. F. Immunofluorescent staining of healthy control and SLE non-lesional skin identifies increased phospho-YAP staining in SLE vs. HC. G. Quantification of pYAP in 3 SLE and 3 HC lines. H and I. Induction of a protein which interrupts YAP-TEAD binding results in increased UVB mediated apoptosis (treated with 50 mJ/cm2) as measured by TUNEL staining (H) and active caspase 3/7 (I).

tion of YAP. This results in a propensity for apoptosis after UVB. Thus, modulation of the Hippo pathway could serve as a novel target for abrogation of photosensitivity in SLE and CLE patients.

Longitudinal CyTOF Immunophenotyping Reveals Distinct Patterns of T cell-B Cell Dysregulation in SLE

Takanori Sasaki[1], Sabrina Bracero[1], Lin Chen[1], Ye Cao[2], Emma Stevens[1], Yujie Qu[3], Guoxing Wang[4], Joshua Keegan[1], James Lederer[5], Stephen Alves[3], Karen Costenbader[6] and Deepak Rao[2], [1]Brigham and Women's Hospital and Harvard Medical School, Boston, MA, [2]Brigham and Women's Hospital, Boston, MA, [3]Merck & Co., Inc., Boston, MA, [4]Merck & Co., Inc, Boston, MA, [5]Brigham and Women's Hospital and Harvard Medical School, Millis, MA, [6]Brigham and Women's Hospital, Belmont, MA

SESSION INFORMATION
Session Date: Sunday, November 7, 2021
Session Title: Abstracts: SLE – Etiology & Pathogenesis (0970–0973)
Session Type: Abstract Session
Session Time: 2:00PM–3:00PM

Background/Purpose: Mass cytometry (CyTOF), a powerful tool to broadly assess immuno-phenotypes, has previously revealed that T follicular helper (Tfh) cells, T peripheral helper (Tph) cells, and age-associated B cells (ABCs) are robustly expanded in patients with newly diagnosed SLE. However, how these and other immune cell populations change over time in SLE remains unclear.

Methods: We employed CyTOF with two 39 marker panels (T and B cell) in cryopreserved peripheral blood mononuclear cells (PBMCs) from 9 patients with newly diagnosed immunosuppressant-naïve SLE, 15 patients with established SLE, and 14 non-inflammatory controls. FlowSOM (Flow Self-Organizing Maps) and marker analysis by tSNE (t-distributed Stochastic Neighbor Embedding) used to identify and quantify clusters based on their 39-parameter characterization. For the newly diagnosed cohort, PBMCs were analyzed at 3 time points (A = at diagnosis, B = 6 months after the diagnosis, C = 12 months after the diagnosis). Serum samples were also analyzed to quantify 65

Figure 1

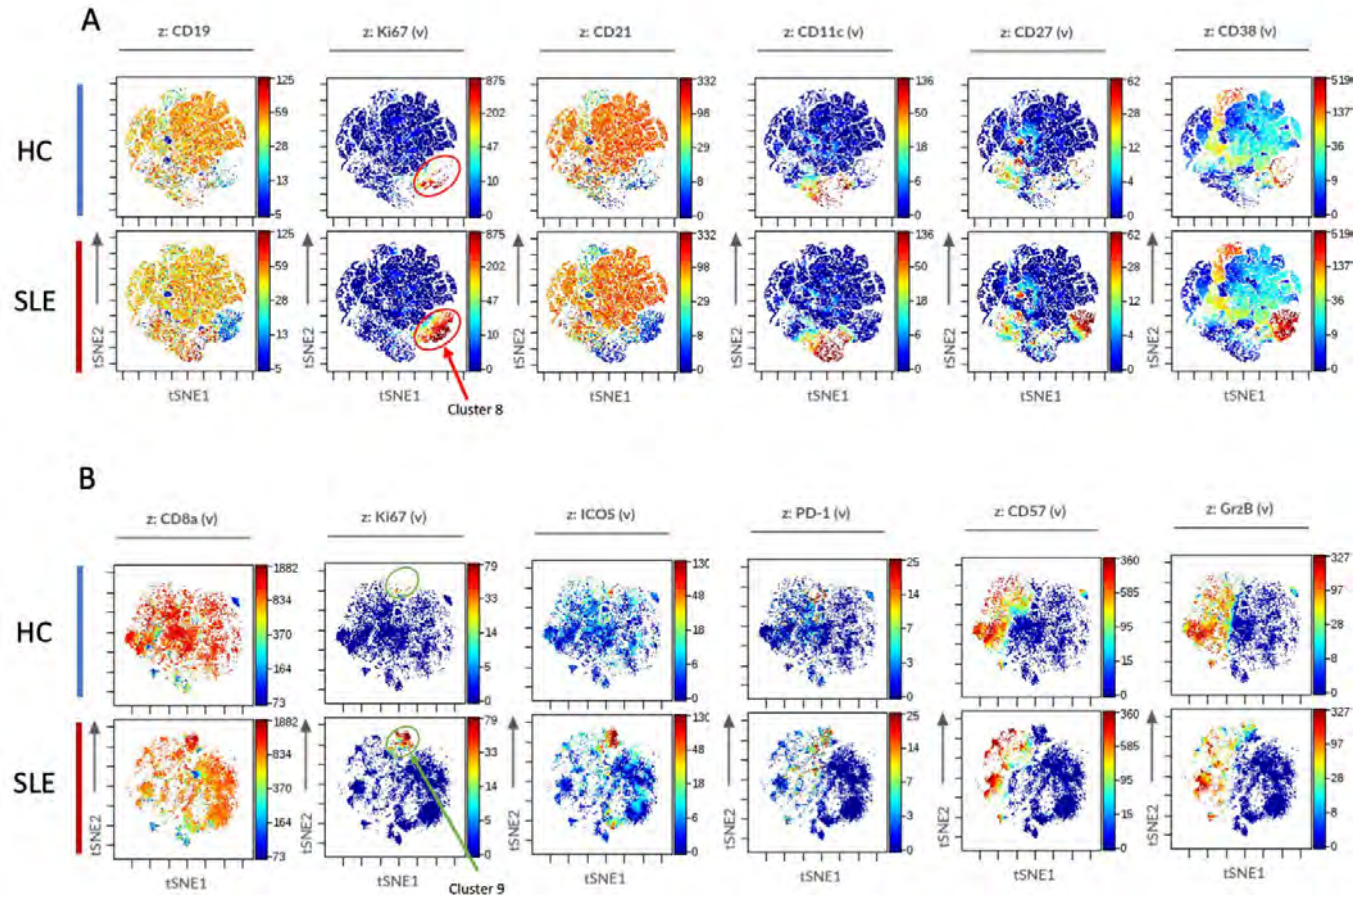

Figure 1. Expanded two Ki67+ populations in PBMCs of SLE patients. A. tSNE plot of CD19+ cells revealed that CD21low, CD11clow, CD27hi, CD38hi plasmablasts were expanded in SLE (Cluster 8). B. tSNE plot of CD8+ cells revealed that Ki67hi, ICOShi, PD-1int, CD57low, GrzBint CD8 T cells were expanded in SLE (Cluster 9).Figure 1. Expanded two Ki67+ populations in PBMCs of SLE patients. A. tSNE plot of CD19+ cells revealed that CD21low, CD11clow, CD27hi, CD38hi plasmablasts were expanded in SLE (Cluster 8). B. tSNE plot of CD8+ cells revealed that Ki67hi, ICOShi, PD-1int, CD57low, GrzBint CD8 T cells were expanded in SLE (Cluster 9).

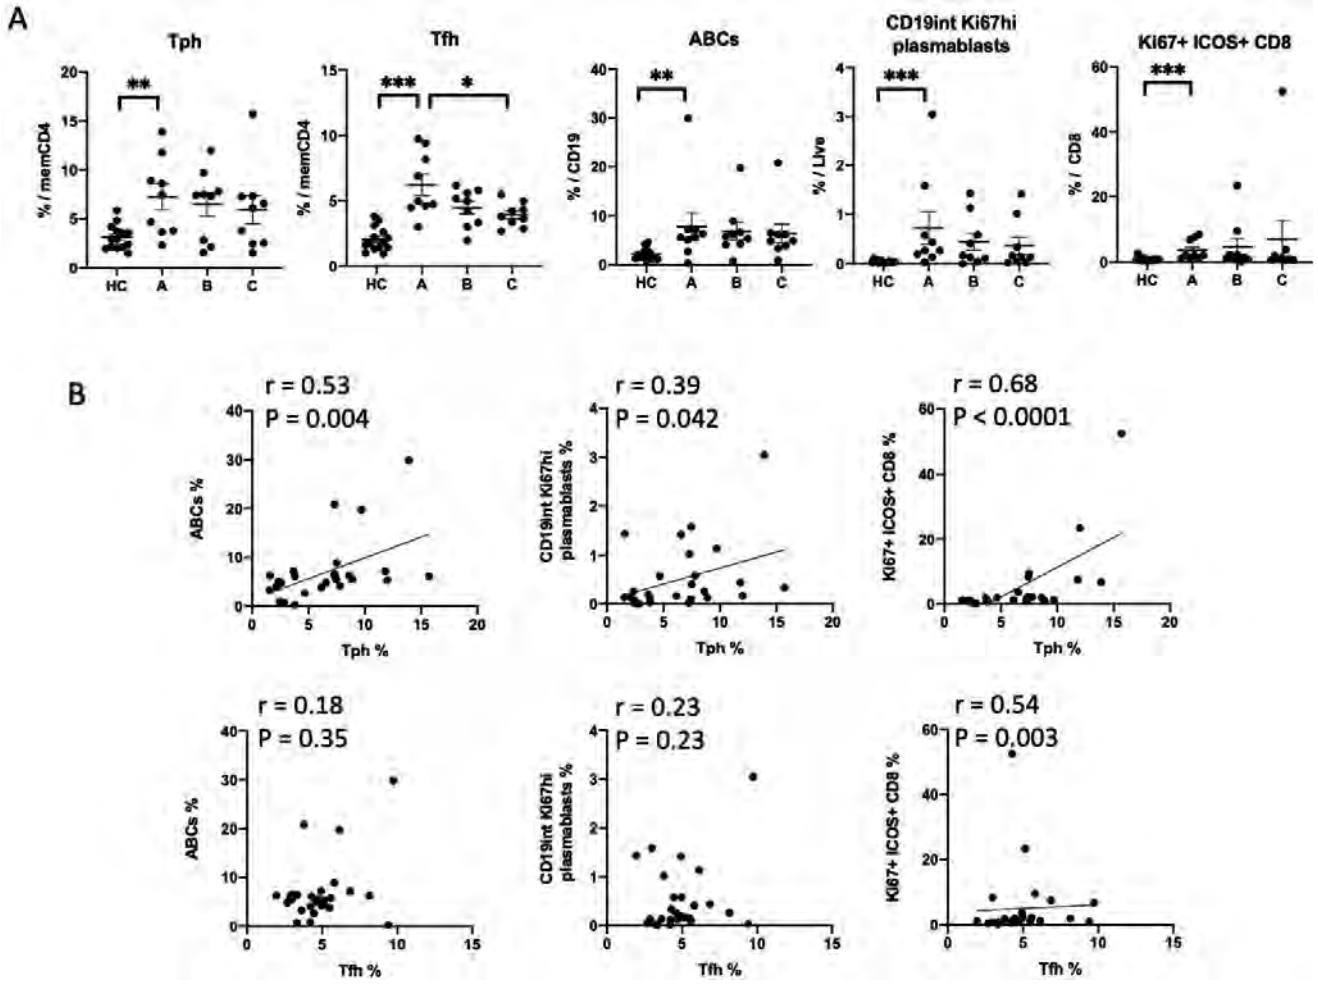

Figure 2. Longitudinal CyTOF analysis of PBMCs in SLE patients. A. Time course changes of Tph, Tfh, ABCs, CD19int Ki67hi plasmablasts, and Ki67+ ICOS+ CD8 T cells in SLE. Timepoint A = at diagnosis, timepoint B = 6 months after the diagnosis, timepoint C = 12 months after the diagnosis. B. Correlation analysis between dysregulated T cell, B cell subsets and cytokine in SLE. HC and A were compared by Mann-Whitney U test. A, B, and C were compared by Wilcoxon test. *p<0.05, **p<0.01, ***p<0.001. Correlation was assessed by Spearman's test.

cytokines by Luminex multiplex assay, and associations between cell types and cytokines assessed by Spearman correlation.

Results: We first confirmed that among CD4 T cells, Tfh cells (PD-1^{hi} CXCR5^{+} CD4^{+} T cells) and Tph cells (PD-1^{hi} CXCR5^{-} CD4^{+} T cells) were significantly increased in SLE patients. A broad analysis of B cells identified 3 clusters as significantly increased in the patients with SLE. Two of these clusters contained CD11c^{+} CD21^{-} ABCs, consistent with prior analyses. A third cluster, cluster 8, contained a CD19^{int} Ki67^{hi} B cell population. This CD19^{int} Ki67^{hi} cluster was also CD21^{low}, CD11c^{low}, CD27^{hi}, and CD38^{hi}, consistent with a Ki67^{hi} plasmablast population (**Figure1A**). Among CD8 T cells, we identified one highly expanded cluster in SLE patients compared to controls, which expressed Ki67^{hi}, ICOS^{hi}, PD-1^{int}, CD57^{low}, and granzyme B^{int} (**Figure1B**). In longitudinal analyses, the frequency of Tfh cells decreased over the first year of SLE, while Tph cells, ABCs, CD19^{int} Ki67^{hi} plasmablasts, and Ki67^{+} ICOS^{+} CD8 T cells remained elevated at 12 months (**Figure 2A**). Tph cells, but not Tfh cells, were correlated with ABCs ($r = 0.53$, $p = 0.004$) and CD19^{int} Ki67^{hi} PB ($r = 0.39$, $p = 0.042$). Ki67^{+} ICOS^{+} CD8 T cells were correlated with Tph cells and Tfh cells, but more strongly in Tph cells ($r = 0.68$, $p < 0.0001$) (**Figure 2B**). Correlation analyses including both immune cell frequencies and cytokines revealed an association of Tph cells, Ki67^{+} ICOS^{+} CD8 T cells, ABCs, and CD19^{int} Ki67^{hi} plasmablasts. These associated populations, but not Tfh cells, were also significantly correlated with CXCL13 and TSLP (**Figure 3**).

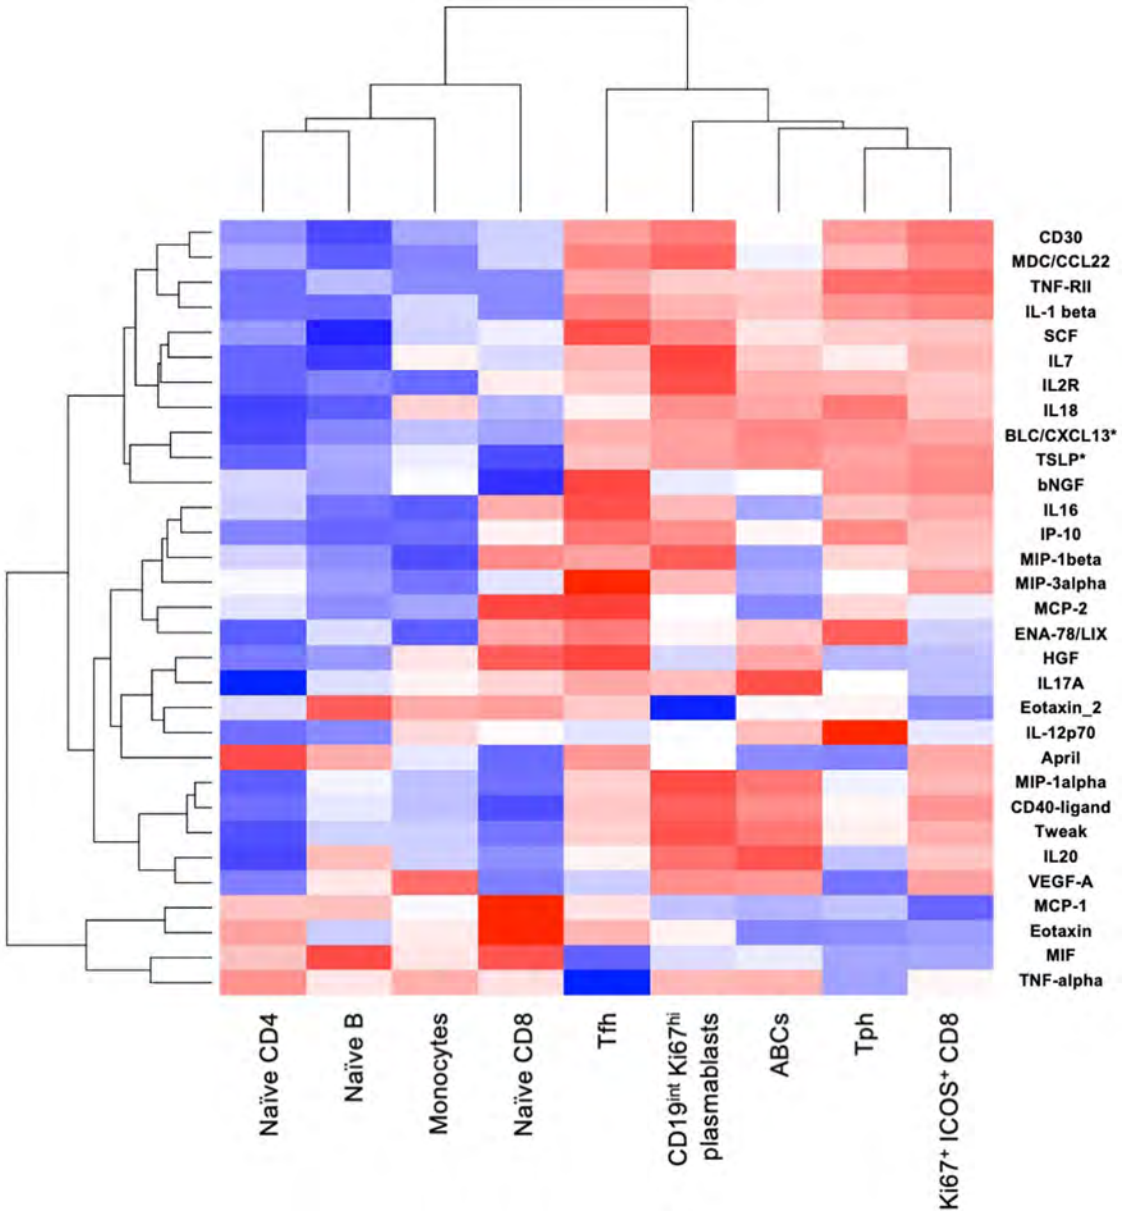

Figure 3. A hierarchical clustering heatmap with immune cell frequencies and cytokines in SLE. Among 65 cytokines, 31 cytokines were detected. Correlation coefficients calculated by Spearman's test were used for the heatmap. *p<0.05 in Tph cells, Ki67+ ICOS+ CD8 T cells, ABCs, and CD19int Ki67hi plasmablasts, but not in Tfh cells and other populations.

Conclusion: Tph cells, ABCs, and the two different Ki67^{+} proliferating populations were consistently elevated during the first year after diagnosis of SLE, while Tfh cells decreased in frequency over the same timeframe. This longitudinal immunophenotyping and cytokine profiling approach thus highlights persistent activation of a Tph-CXCL13-ABC-plasmablasts axis in both early and established phases of SLE.

Hypoxia Promotes the Expression of ADAM9 by Tubular Epithelial Cells Which Enhances TGF-β1 Activation and Promotes Tissue Fibrosis in Lupus Nephritis

Masataka Umeda[1], Abhigyan Satyam[1], Nobuya Yoshida[1], Rhea Bhargava[1], Ryo Hisada[1], Simin Jamaly[1], Caroline Owen[2] and George Tsokos[3], [1]Department of Medicine, Beth Israel Deaconess Medical Center, Harvard Medical School, Boston, MA, [2]Division of Pulmonary and Critical Care Medicine, Brigham and Women's Hospital, Harvard Medical School, Boston, MA, [3]BIDMC, Boston, MA

SESSION INFORMATION
Session Date: Sunday, November 7, 2021
Session Title: Abstracts: SLE – Etiology & Pathogenesis (0970–0973)
Session Type: Abstract Session
Session Time: 2:00PM–3:00PM

Background/Purpose: Enhanced expression of transforming growth factor-beta (TGF-β) in the kidneys of patients with lupus nephritis (LN) can lead to progressive fibrosis, resulting in end-organ damage (J Immunol. 180, 1903-1912. 2008). We previously reported that a disintegrin and metalloproteinases 9 (ADAM9) enhances Th17 cell differentiation and autoimmunity by activating TGF-β1 (PNAS. 118, 2021). We hypothesized that ADAM9 in the kidney may accelerate fibrogenesis by activating TGF-β1.

Methods: We assessed the expression of ADAM9 in kidneys from MRL/*lpr* mice and control MPJ mice and determined the expression levels of ADAM9 in kidney cells. We conducted *in vitro* experiments using tubular epithelial cells (TEC) isolated from B6 mice and explored the mechanisms responsible for the upregulation of ADAM9 in tubular epithelial cells (TEC) and the subsequent activation of TGF-β1 by ADAM9 expressed in TEC. To assess the role of ADAM9 in the development of tubular-intestinal fibrosis in LN, we generated MRL/*lpr.Adam9-/-* mice and compared the intensity of renal fibrosis between *Adam9* sufficient and deficient MRL/*lpr* mice.

Results: We identified ADAM9 to be highly expressed in tubules from MRL/*lpr* mice. The transcription factor hypoxia-inducible factor-1 alpha (HIF-1α) was found to promote the transcription of ADAM9 in TEC. TEC from *Adam9*-deficient mice exposed to the hypoxia inducer dimethyloxalylglycine (DMOG) failed to cleave the latency-associated peptide to produce bioactive TGF-β1 from latent TGF-β1. Co-culture of TEC from *Adam9*-deficient mice and fibroblasts with DMOG and latent TGF-β1 showed decreased production of type I collagen and alpha-smooth muscle actin (αSMA) by fibroblasts. *Adam9*-deficient MRL/*lpr* mice showed mitigated tubular-intestinal fibrosis.

Conclusion: Our findings have revealed that hypoxia promotes the expression of ADAM9 by TEC which is responsible for the development of interstitial fibrosis in LN by promoting the generation of fibroblast bioactive TGF-β1 [hypoxia (HIF-1α) **->** ADAM9 **->** TGF-β1 **->** production of collagen I and αSMA by resident fibroblasts].

SESSION INFORMATION
Session Date: Sunday, November 7, 2021
Session Title: Abstracts: SLE – Etiology & Pathogenesis (0970–0973)
Session Type: Abstract Session
Session Time: 2:00PM–3:00PM

Background/Purpose: The clinical heterogeneity of SLE with its complex pathogenesis remains challenging as we strive to provide optimal management. The contribution of platelets to endovascular homeostasis, inflammation and immune regulation highlights their potential importance in SLE. Prior work from our group showed that the Fcγ receptor type IIa (FcγRIIa)–R/H131 biallelic polymorphism is associated with increased platelet activity and cardiovascular risk in SLE. The study was initiated to investigate the platelet transcriptome in patients with SLE and evaluate its association across FcγRIIa genotypes and distinct clinical features.

Methods: RNA-sequencing was done on platelets isolated from 51 patients fulfilling criteria for the classification of SLE based on recent EULAR/ACR definitions, and 18 healthy controls matched on age, sex, and race. Unsupervised clustering, differential gene expression, and gene set enrichment analysis (GSEA) were used to analyze differences between SLE patients and controls, and SLE subpopulations, based on SELENA SLEDAI Hybrid disease activity, specific organ manifestations, and FcγRIIa genotype. Weighted Gene Correlation Network Analysis (WGCNA) was performed to create a modular transcriptomic framework.

Results: Our cross-sectional SLE cohort (N=51, age = 41.1±12.3, 100% female, 45% Hispanic, 24% black, 22% Asian, 51% white, SLEDAI = 4.4±4.2) was comprised of patients consecutively enrolled excluding those on aspirin or anticoagulants. Compared to the 18 controls, there were 2290 ($p.adj < 0.05$) differentially expressed genes. (**Figure 1 A,B)** GSEA revealed positive enrichment for pathways related to interferon response, TNFa signaling, and coagulation in SLE. (**Figure 1C)** WGCNA was used to create a modular transcriptomic framework. (**Figure 2A**) Modules enriched for platelet activity, immune response, and WNT signaling were significantly increased in SLE versus controls. Moreover, modules enriched for interferon response and WNT signaling paralleled increases in disease activity. (**Figure 2B)** When analyzing patients with proteinuria, modules associated with oxidative phosphorylation and platelet activity were unexpectedly decreased. **(Figure 2C)** Analyzing the ratio of fold changes between SLE/Control vs SLE Proteinuria/SLE No Proteinuria, genes increased in SLE and those with proteinuria were enriched for immune effector processes, while genes increased in SLE but decreased in proteinuria were enriched for coagulation and cell adhesion. **(Figure 2D)** The module enriched for FCR activation was decreased in SLE and was affected by the FcγRIIa genotype. **(Figure 3A)** FcγRIIa R131 and H131 patients showed significantly different platelet transcriptomes. **(Figure 3B)** The combination of SLE with an FcγRIIa R131 variant leads to a significant increase in the platelet activity module not seen in controls. **(Figure 3C)**

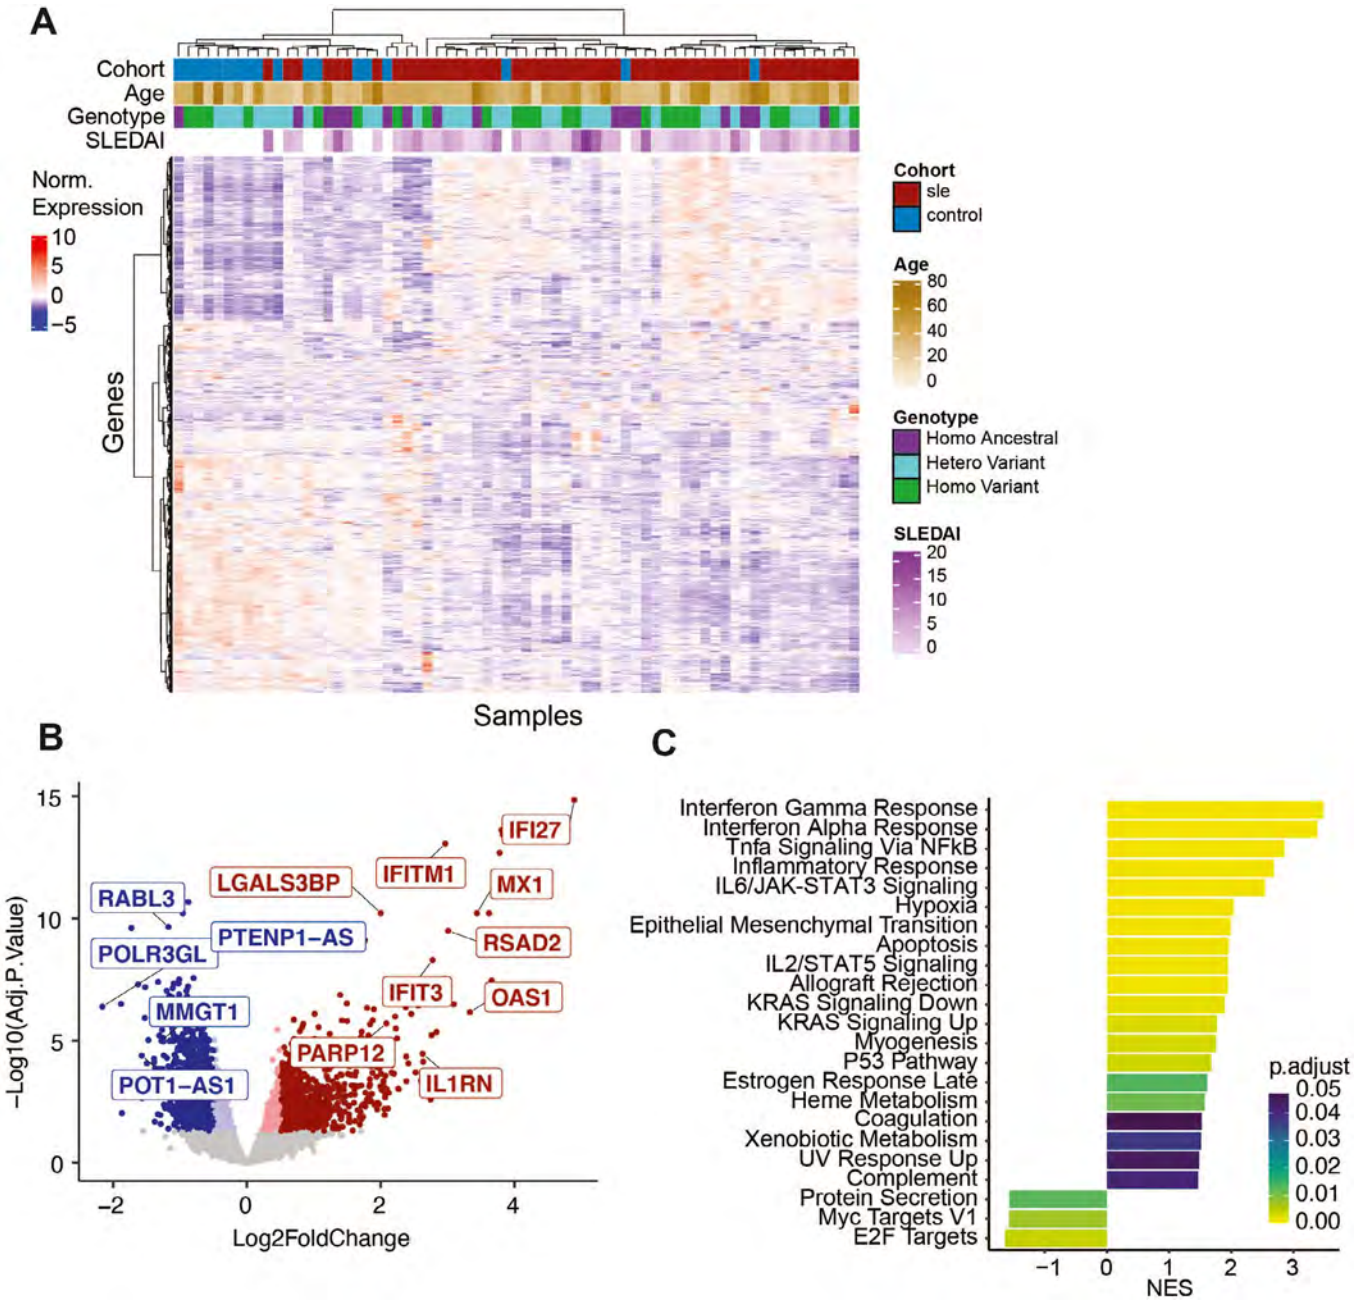

Figure 1. Transcriptomic analyses reveal differences between SLE and Control platelet transcriptomes. (A) Unsupervised clustering of out cohort based on the top 10% of varied genes. (B) Volcano plot depicting differential expression between the SLE and Control cohorts. (C) Gene Set Enrichment Analysis (GSEA) normalized enrichment scores and p values for pathways differentially enriched between our cohorts.

Conclusion: These analyses reveal that SLE patients have a significantly different platelet transcriptome from controls, different phenotypic presentations of SLE patients associate with distinct platelet transcriptomic signatures, and FCGR2a variants may differentially influence the role of platelets in the contribution to SLE disease activity.

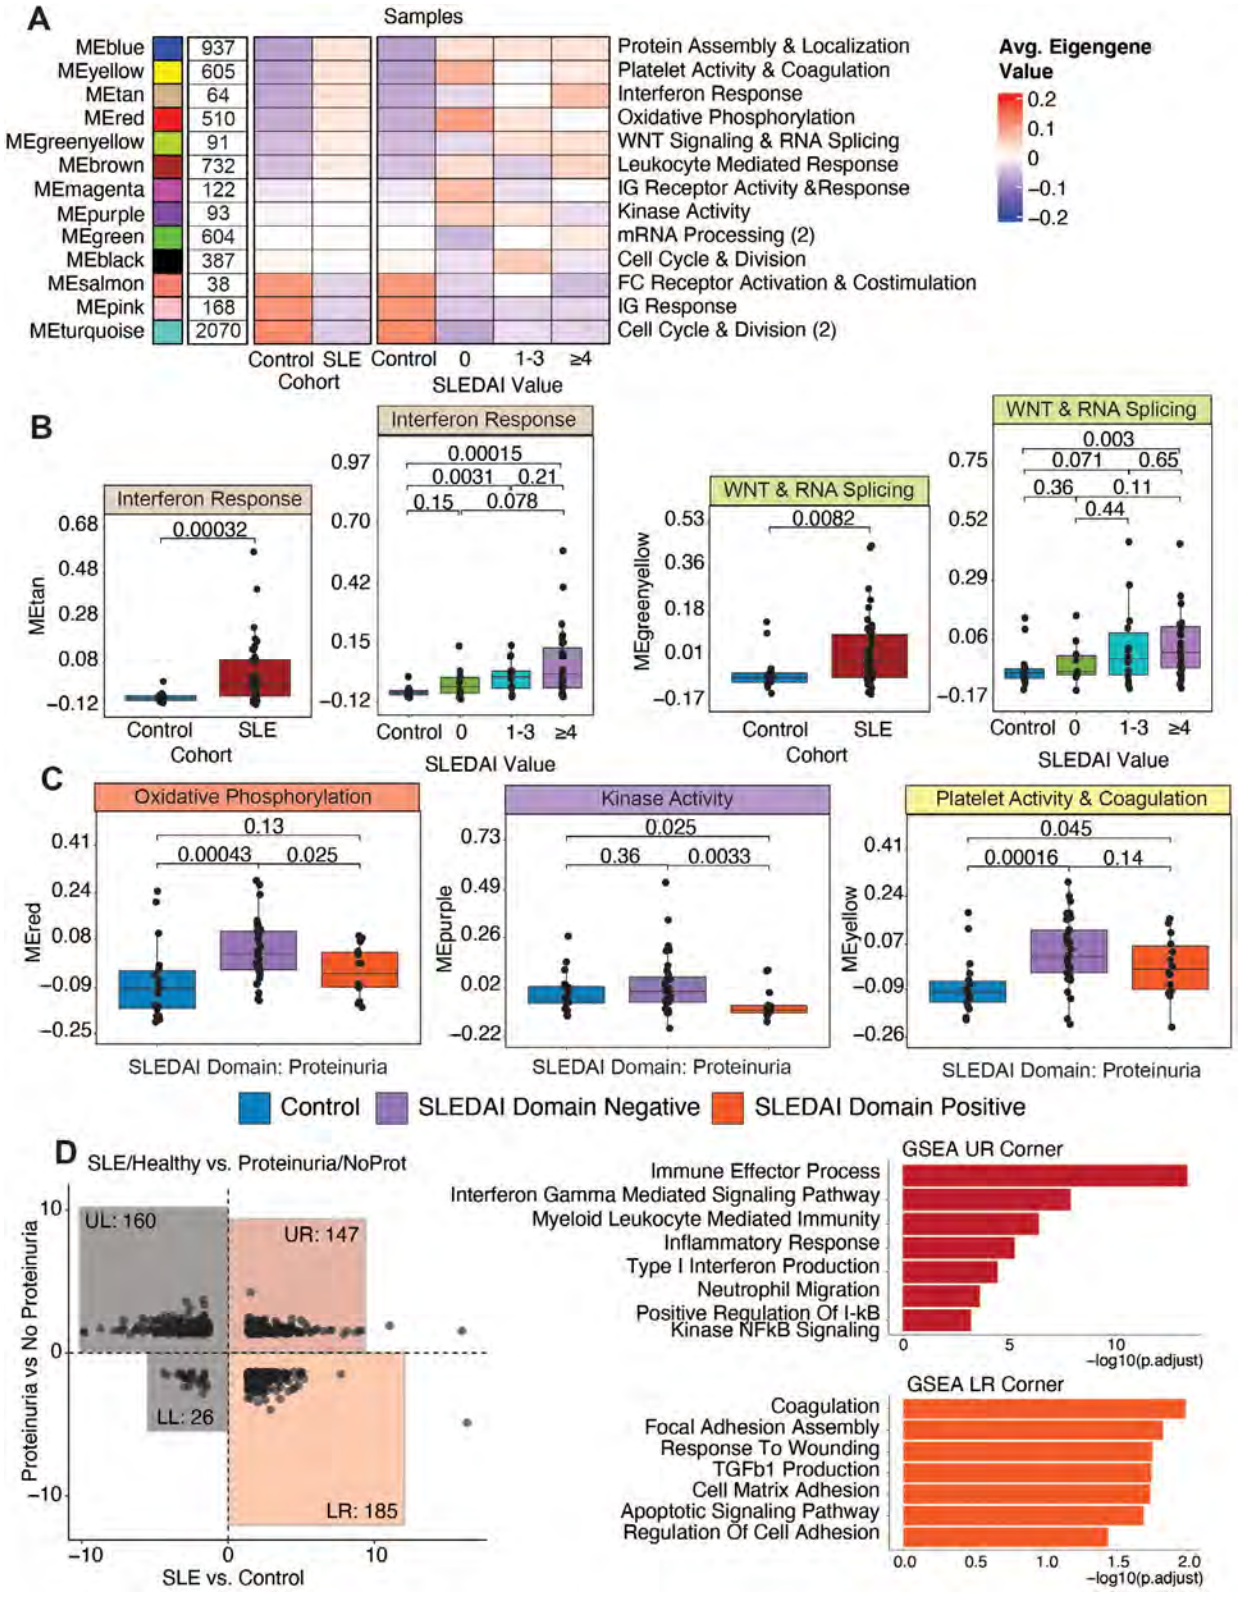

Figure 2. Modular analyses of the lupus cohort demonstrate differences between SLE patients. (A) Weighted Gene Correlation Network Analysis (WGCNA) derived modules and their average values between our control and SLE cohort, and between control and our SLE cohort when divided by SLEDAI value. (B) Boxplots for the individual patient values of the Interferon Response module and WNT & RNA Splicing modules seen in our SLE cohort. (C) Boxplots for the Oxidative Phosphorylation, Kinase Activity, and Platelet Activity & Coagulation modules seen in our cohort when separated into control, proteinuria, and no proteinuria. (D) Scatterplot of log2fc values for SLE vs control, and proteinuria vs no proteinuria, divided into quadrants associated with the directionality of the two log2fc ratios. GSEA analysis was performed on the UR (upper right) quadrant and the LR (lower right) quadrant.

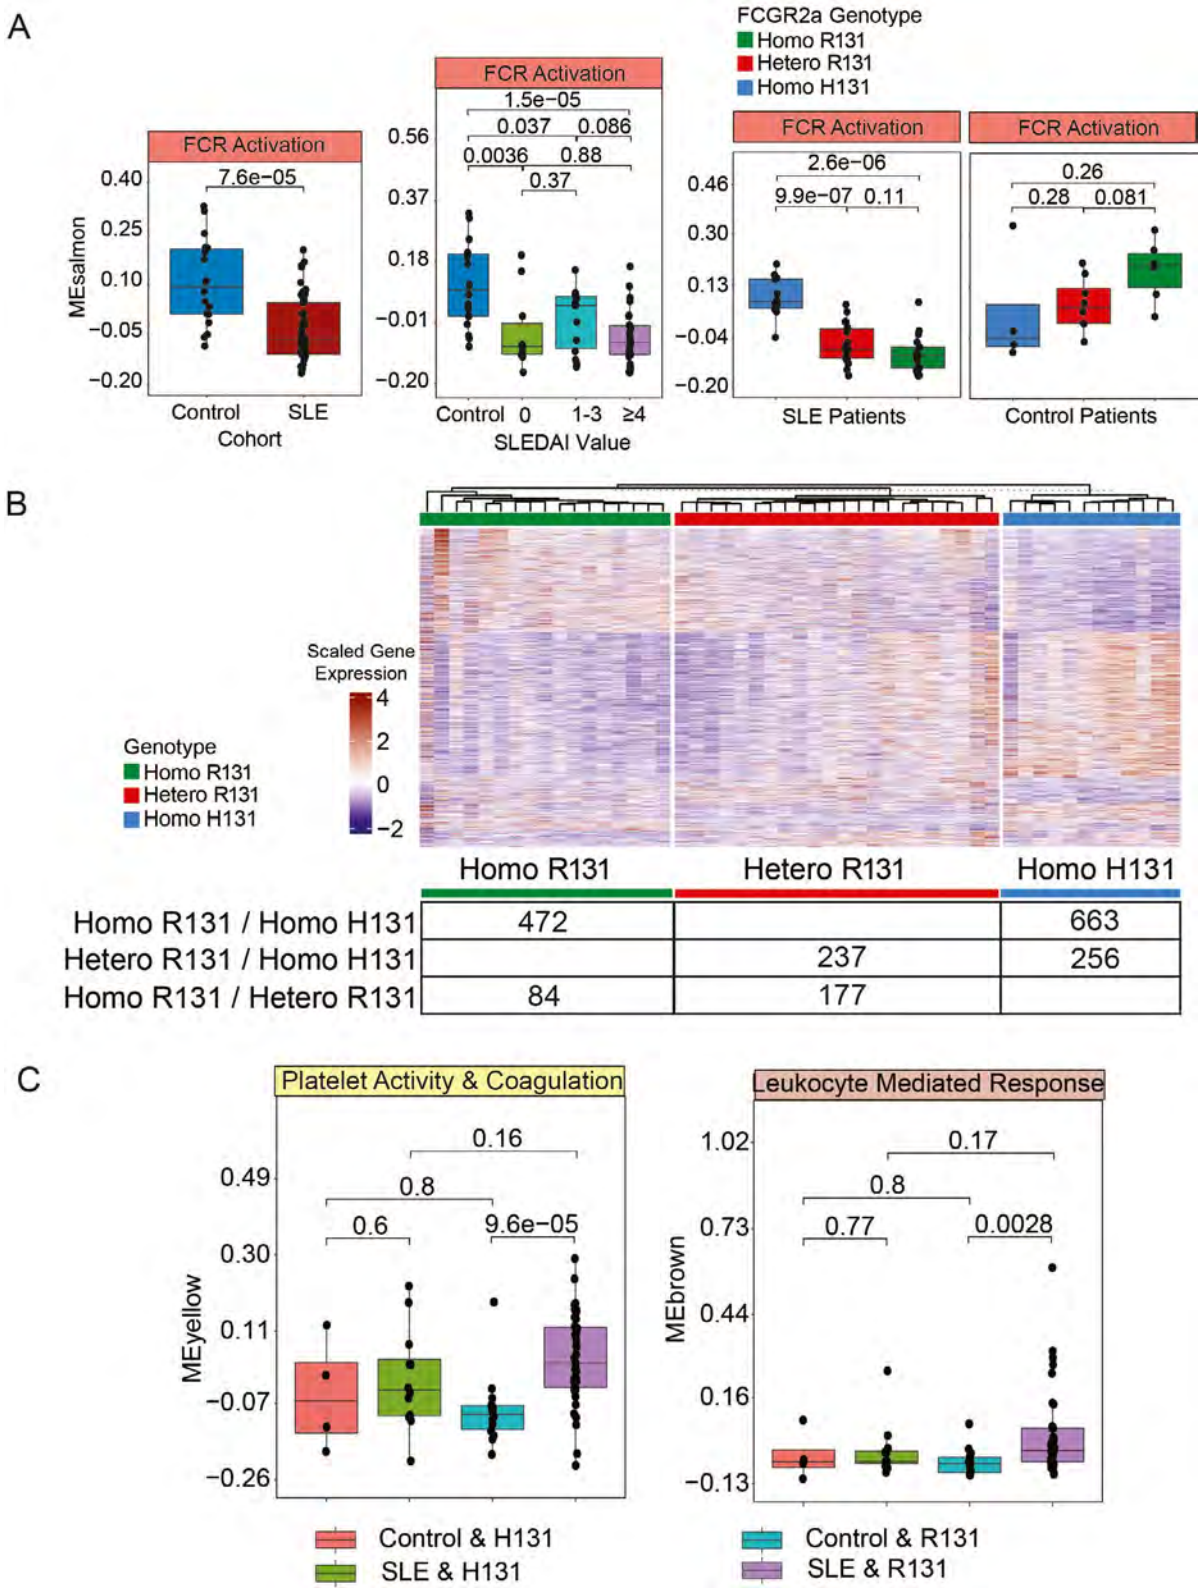

Figure 3. FCGR2a variants significantly affect the platelet transcriptome. (A) The WGCNA module enriched for FCR activation represented as boxplots when our cohort is split by (1) SLE vs control, (2) control vs SLEDAI groups, and (2) SLE and Control cohorts split by their FCGR2a genotype. (B) Heatmap of differentially expressed genes derived from the pairwise comparisons of our three genotype groups: Homozygous R131, Heterozygous R131, and Homozygous H131. The table shows number of genes up in the respective group for each pairwise comparison (e.g. Homozygous R131 / Homozygous H131 had 472 genes upregulated in Homo R131, and 663 genes upregulated in Homo H131) (C) WGCNA Modules for Platelet Activation and Leukocyte Mediated Response when split by diagnosis and FCGR2a genotype.

Use of Disease-Modifying Anti-Rheumatic Drug Associated with Lower Incidence of Anti-Tumor Necrosis Factor Induced Psoriasis in Children with Inflammatory Bowel Disease and Juvenile Idiopathic Arthritis

Katelyn Baggett[1], Timothy Brandon[1], Rui Xiao[2], Zachary Valenzuela[1], Lisa Buckley[3] and **Pamela Weiss**[1], [1]Children's Hospital of Philadelphia, Philadelphia, PA, [2]University of Pennsylvania, Philadelphia, PA, [3]Vanderbilt Children's Hospital, Nashville, TN

SESSION INFORMATION
Session Date: Sunday, November 7, 2021
Session Title: Abstracts: Pediatric Rheumatology – Clinical (0974–0979)
Session Type: Abstract Session
Session Time: 2:00PM–3:30PM

Background/Purpose: Tumor necrosis factor inhibiting (TNFi) therapies are associated with new-onset psoriasis in children with inflammatory bowel disease (IBD) and juvenile idiopathic arthritis (JIA). We aimed to compare the differential effect of three TNFi therapies and to examine whether the addition of a nonbiologic disease-modifying anti-rheumatic drug (DMARD) impacts the incidence of psoriasis in children with IBD and JIA.

Methods: This was a single-center retrospective cohort study of electronic health record data from 2008 to 2020. Inclusion criteria were: 1) 2 ICD-9 or ICD-10 codes for JIA, IBD, or chronic nonbacterial osteomyelitis (CNO); 2) age at diagnosis of under 19 years; 3) at least 2 visits with a study center rheumatologist or gastroenterologist. Subjects with psoriasis prior to the diagnosis of JIA, IBD, or CNO were excluded. TNFi exposure was defined as at least 1 prescription for infliximab, etanercept, or adalimumab (ever/never). DMARD exposure was dichotomized as ever/never and included methotrexate. The primary outcome was incident psoriasis defined as the first ICD-9/10 code for psoriasis during a visit with a study center rheumatologist, gastroenterologist, or dermatologist. Incidence rates (IRs) were calculated and stratified by underlying diagnosis, TNFi agent, and DMARD use. IRs for CNO were not calculated due to small sample size.

Results: 5088 children met inclusion criteria – 3799 (75%) had IBD, 1185 (23%), had JIA, and 104 (2%) had CNO. 1335 (66%), 304 (15%), and 382 (19%) of children were prescribed infliximab, etanercept, or adalimumab, respectively. 1430 (71%) and 593 (29%) had TNFi exposure with or without a DMARD, respectively. The number of follow-up years, cases, and IRs for the entire cohort and for each diagnosis are presented in Table 1. The IR for psoriasis was higher in patients with JIA than IBD in both the TNFi alone and TNFi plus DMARD groups with a risk difference of 7.9 and 4, respectively. Amongst all patients, the IR for psoriasis was lowest for infliximab (12.4) and similar in etanercept and adalimumab (17.1 and 17.2). The IR for infliximab remained lower than the other 2 TNFi when stratified by DMARD use but differed by underlying diagnosis. There were no IBD patients treated with etanercept and of the limited number of JIA patients treated with infliximab (N=21), none developed psoriasis. The IR of psoriasis was lower amongst children on a TNFi who were DMARD-exposed (12.2) versus those unexposed (15.1).

Conclusion: The IR of TNFi-induced psoriasis was lowest for patients exposed to infliximab, even after stratifying by DMARD exposure. For patients with exposure to any of TNFi evaluated, the IR was lower in those also exposed to DMARD.

Table 1. Incidence rates of psoriasis for entire cohort and for each underlying disease according to TNFi type and presence of methotrexate

SESSION INFORMATION

Session Date: Sunday, November 7, 2021

Session Title: Abstracts: Pediatric Rheumatology – Clinical (0974–0979)

Session Type: Abstract Session

Session Time: 2:00PM–3:30PM

Background/Purpose: Determining optimal cut-offs for active and structural imaging lesions of juvenile spondyloarthritis (JSpA) with axial disease is important for diagnosis, therapeutic management, and classification. We aimed to determine quantitative sacroiliac joint (SIJ) imaging lesion thresholds to 1. define a positive MRI for inflammatory and structural lesions typical of axial JSpA and 2. evaluate the lesions associated with assessment of axial disease by a panel of SpA experts.

Methods: Subjects were a retrospective cohort of children who had an MRI as part of their evaluation for suspected axial disease. MRI scans were reviewed by 6 central raters blinded to clinical details. Raters provided a yes/

Table 1. Performance of cut-offs for presence of definite inflammatory and structural lesions of axial disease

Cut-offs for number of SIJ quadrants (any location)	Sensitivity (95% CI)	Specificity (95% CI)
Majority (≥4/6) rater agreement for definite active lesion		
BME score ≥1	100 (95-100)	85.9 (79.7-90.7)
BME score ≥2	100 (95.0-100)	93.5 (88.7-96.7)
BME score ≥3	98.6 (92.5-100)	96.5 (92.5-98.7)
BME score ≥4	95.8 (88.3-99.1)	97.1 (93.3-99.0)
Inflammation in erosion cavity (any)	56.2 (44.1-67.8)	98.3 (95.0-99.6)
BME score ≥3 *or* inflammation in erosion cavity (any)	98.6 (92.5-100)	95.3 (90.9-97.9)
Majority (≥4/6) rater agreement for definite structural lesion		
Erosion score ≥1	97.1 (90.1-99.7)	91 (85.4-95)
Erosion score ≥2	95.7 (88-99.1)	96.8 (92.7-99)
Erosion score ≥3	91.4 (82.3-96.8)	98.7 (95.4-99.8)
Sclerosis score ≥1	74.3 (62.4-84)	95.5 (91-98.2)
Sclerosis score ≥2	62.9 (50.5-74.1)	98.1 (94.5-99.6)
Fat score ≥1	31.4 (20.9-43.6%)	96.8 (92.7-99%)
Fat score ≥2	22.9 (13.7-34.4%)	98.7 (95.4-99.8%)
Backfill score ≥1	24.3 (14.8-36)	99.4 (96.5-100)
Backfill score ≥2	20 (11.4-31.3)	100 (97.7-100)
Ankylosis score ≥1	2 (0.4-5.7)	100 (94.9-100)
Ankylosis score ≥2	1.3 (0.2-4.7)	100 (94.9-100)
Any structural lesion*	98.6 (92.3-100)	89.7 (83.9-94)
Erosion score ≥2 *plus* ≥1 of the following lesions: sclerosis, fat score, back fill, ankylosis	80 (68.7-88.6)	99.4 (96.5-100)

Table 2. Diagnostic test statistic performance for active, structural or any lesion (defined in Table 1) consistent with SpA using majority expert final assessment of case as the reference standard.

	Sensitivity (95% CI)	Specificity (95% CI)	PPV (95% CI)	NPV (95% CI)
Active lesions				
Inflammation in erosion cavity	41.2 (30.6-52.4)	95.8 (91.9-98.2)	81.4 (66.6-91.6)	78.5 (72.7 (83.6)
BME ≥3 quadrants	80.6 (69.5-88.9)	89.8 (84.1-93.9)	77.3 (66.2-86.2)	91.4 (86-95.2)
BME ≥3 quadrants *or* inflammation in erosion cavity	80.6 (69.5-88.9%)	88.6 (82.7-93%)	75.3 (64.2-84.4%)	91.3 (85.8-95.2%)
Structural lesions				
Erosion ≥2 quadrants	72.2 (60.4-82.1)	88 (81.7-92.7)	74.3 (62.4-84.0)	86.8 (80.4-91.8)
Erosion ≥2 quadrants *plus* at least one of the following: sclerosis, fat lesion, backfill, ankylosis	59.7 (47.5-71.1)	90.7 (84.8-94.8)	75.4 (62.2-85.9)	82.4 (75.7-87.9)
Erosion ≥2 quadrants *or* at least one of the following: sclerosis, fat lesion, backfill, ankylosis	80.6 (69.5-88.9)	83.3 (76.4-88.9)	69.9 (58.8-79.5)	89.9 (83.7-94.4)
Active or structural lesion combinations				
Any active *or* structural lesion^	89.3 (80.1-95.3%)	81.5 (74.8-87.1%)	68.4 (58.2-77.4%)	94.5 (89.4-97.6%)
BME ≥3 *or* erosion ≥2 quadrants	82.7 (72.2-90.4)	85.7 (79.5-90.6)	72.1 (61.4-81.2)	91.7 (86.3-95.5)

no response and confidence levels to the following parameters: 1) Are there typical active inflammatory lesions compatible with axial SpA present in the SIJs or at entheseal sites outside the SIJ? 2) Are typical chronic inflammatory lesions present in or around the SIJs? Raters assessed lesions in SIJ quadrants or halves on consecutive semi-coronal slices on a web-based interface for: a) bone marrow edema (BME), b) inflammation in erosion cavity, c) erosion, d) sclerosis, e) fat lesion, f) backfill, and g) ankylosis. Optimal sensitivity and specificity of MRI score cut-offs for each lesion were calculated using central imaging majority (≥4/6 raters) designation of high confidence (≥+3 on confidence scale from -5, "Definitely No", to +5, "Definitely Yes") in the presence of MRI active or structural lesions typical of axial SpA as the reference standard. All clinical and imaging data were assessed by 3 of 14 SpA expert panelists. JSpA experts assessed their confidence that the case was "JSpA with axial disease" with the anchors -3 (very unlikely) to +3 (very likely). Cases classified by majority (≥2/3) experts with high confidence (≥+2) were used as the reference standard. Test statistic properties of the quantitative lesion-based MRI thresholds were assessed against this reference standard.

Results: Imaging from 243 subjects, 61% male, median age 14.9 had sequences available for detailed MRI scoring. The lesion-based cut-offs achieving specificity ≥95% with the highest sensitivity for a definite active inflammatory lesion were: BME in ≥3 quadrants or ≥1 inflammation in an erosion cavity (Table 1); combining the two types of lesions did not add incremental value. For definite structural lesion, the lesion cut-offs achieving ≥95% specificity with the highest sensitivity were the following: erosion in ≥2 quadrants, sclerosis in ≥1 quadrant, fat lesion in ≥1 quadrant, and backfill in ≥1 quadrant (Table 1); combinations of the lesions did not add incremental value. PPV and NPV of the quantitative threshold definitions for active, structural, or any lesions typical of axial SpA using the majority expert final assessment as the reference standard are shown in Table 2. The PPV and specificities were highest for BME ≥3 quadrants, erosion in ≥2 quadrants or a combination of the 2.

Conclusion: We propose cut-offs for definite active and structural lesions on MRI typical of axial disease in JSpA that have high PPV and specificity for clinical assessment. These cut-offs have applicability for diagnosis, therapeutic management, and classification.

*Any structural lesion with the following score thresholds: Erosion in ≥2 quadrants, sclerosis in ≥1 quadrant, fat lesion in ≥1 quadrant, backfill in ≥1 quadrant, or ankylosis ≥1 quadrant. Erosion SIJ quadrants = upper ilium, lower ilium, upper sacrum, lower sacrum for left and right SIJ; # of quadrants = total # of quadrants with detectable BME across all slices of study. Bone Marrow edema: An ill-defined area of high bone marrow signal intensity on fluid-sensitive sequences within the subchondral bone of the ilium or sacrum compared to the signal intensity of the iliac crest, edges of the vertebrae, and triradiate cartilage and in comparison to physiological changes normally seen on MRI examinations of age- and sex-matched children, and visible in 2 planes [1]. Inflammation at the site of an erosion: Increased signal on STIR and/or T1-weighted fat suppressed (FS) post-gadolinium at the site of erosion [2]. Erosion: A defect in subchondral bone associated with full-thickness loss of the dark appearance of the subchondral cortex at its expected location, with loss of signal on a T1-weighted sequence compared with the normal bright appearance of adjacent bone marrow [2]. Sclerosis: A substantially wider than normal (of ≥ 5 mm in adolescents) area of low subarticular bone signal on T1-weighted and fluid sensitive images [1]. Fat lesion: Homogeneous increased signal intensity within the subchondral bone on T1-weighted non-FS image presenting with a distinct border of the lesion [2]. Backfill: Bright signal on a T1-weighted sequence in a typical location for an erosion or confluent erosions, with signal intensity greater than normal bone marrow, which meets the following requirements: a) associated with complete loss of the dark appearance of the subchondral cortex at its expected location. B) clearly demarcated from adjacent bone marrow by an irregular band of dark signal reflecting sclerosis at the border of the original erosion [2]. Ankylosis: Presence of signal equivalent to regional bone marrow continuously bridging a portion of the joint space between the iliac and sacral bones [1]. BME = bone marrow edema; SIJ = sacroiliac joint; CI = confidence interval.

Confidence level was reported for each case on a scale of highly confident the case is not axial disease (-3) to highly confident the case is axial disease (+3). Cases rated as high confidence by the experts in having axial disease ≥+2 were used as the reference standard. ^Bone marrow edema in ≥3 quadrants, inflammation in an erosion cavity, Erosion in ≥2 quadrants, sclerosis, fat lesion, backfill, or ankylosis. PPV = positive predictive value; NPV = negative predictive value; CI = confidence interval; BME = bone marrow edema.

Abstract Number: 0976

Cumulative Social Disadvantage Predicts an Arthritis Diagnosis: A Cross-sectional Analysis of the National Survey of Children's Health (NSCH)

William Soulsby, Erica Lawson and Matthew Pantell, University of California San Francisco, San Francisco, CA

SESSION INFORMATION
Session Date: Sunday, November 7, 2021
Session Title: Abstracts: Pediatric Rheumatology – Clinical (0974–0979)
Session Type: Abstract Session
Session Time: 2:00PM–3:30PM

Background/Purpose: The impact of social determinants of health in juvenile idiopathic arthritis (JIA) remains poorly understood. Racial disparities exist in JIA, including increased pain and joint damage among Black and Latinx children. Adverse childhood events (ACEs) have been associated with increased odds of childhood arthritis, suggesting an association with chronic stress exposure. However, studies on the impact of poverty and insurance status have yielded mixed results. Data suggests social risk may have a cumulative impact on health, with recent analyses using combined scoring systems to measure social determinants of health. Our aim was to calculate a cumulative social risk score (including income, race/ethnicity, education, and ACE data) and assess its association with arthritis in the National Survey of Children's Health (NSCH).

Methods: This is a cross-sectional analysis utilizing the 2017-2018 version of the NSCH, a federally administered survey focused on physical and emotional health of children 0-17 years of age in the US. Social risk score was generated, with a score of 1 given for each of the following domains: education (high school or less), income level (0-199% of Federal Poverty Level), insurance status (public or uninsured), and high ACE score (4). The cohort was dichotomized by the presence of currently reported arthritis and compared using descriptive statistics (Kruskal Wallis and Pearson's chi-squared or Fisher's exact tests, as appropriate). Univariate and multivariate logistic regression were used to measure the impact of social risk score on the odds of an arthritis diagnosis, controlling for age, sex, and race/ethnicity. An analogous method was used to investigate parent-reported severity of arthritis (moderate/severe versus mild) within the arthritis cohort.

Results: 146 children reported current arthritis, yielding a population estimate of 199,725 children using appropriate survey weights (Table 1). Families of children with arthritis reported lower income (40% vs 28%), lower education level (27% vs 15%), greater likelihood of having public insurance or being uninsured (40% vs 24%), and greater likelihood of having an ACE score ≥4 (16% vs 7%), as compared to children without arthritis (p-value < 0.001). In multivariate logistic regression, higher social risk score was predictive of an arthritis diagnosis (Table 2, p=0.009) with highest

odds among those with a score of 3 (adjusted OR 3.93, p=0.002). Among the arthritis cohort, social risk score predicted increased parent-reported arthritis severity (Table 3), though this was not statistically significant (p=0.2).

Conclusion: In this nationally representative sample, children with arthritis were more likely to come from households with lower income and education level and were more likely to have public insurance or be uninsured, yielding higher social risk scores than their peers without arthritis. In adjusted analysis, social risk factors predicted increased odds

Table 1. Demographic characteristics of the National Survey of Children's Health (NSCH) 2017-2018 by arthritis diagnosis

SESSION INFORMATION

Session Date: Sunday, November 7, 2021

Session Title: Abstracts: Pediatric Rheumatology – Clinical (0974–0979)

Session Type: Abstract Session

Session Time: 2:00PM–3:30PM

Background/Purpose: Health outcomes improve when people living with chronic conditions partner with their clinicians to coproduce care based on their values, preferences, goals, and the best scientific evidence. Patient-facing dashboards can be used to support coproduction by aggregating longitudinal data for review during clinical encounters, such as patient-reported outcomes (PROs), clinical data, and medications. We developed and implemented a point-of-care dashboard to enhance collaboration between families of children with juvenile idiopathic arthritis (JIA) and their clinicians and care teams.

Methods: The dashboard was developed through a co-design process including patients, parents, clinicians, and care team members. Delphi voting achieved consensus on dashboard data elements. The dashboard leveraged an Epic electronic health record (EHR) tool that was customized and integrated at four medical centers. The dashboard resides within each site's EHR and aggregates PROs and clinical data in real-time for review by the family and clinician together (Figure 1). A convenience sample of JIA patients and parents completed an anonymous 19-item feedback survey following their clinic visit to assess the utility and usability of the dashboard. A subset of patients and parents completed 30-minute interviews with the research team. Feedback from clinicians was collected during biweekly meetings, and via surveys and interviews. Data were collected between July 2020 and April 2021.

Results: During the development phase, end-users agreed that a dashboard needed to be easy to use and trend data over time. Data elements included: (1) PROs of pain interference, upper extremity function, mobility, patient questions/concerns, medication adherence, medication side effects; (2) clinical data including active joint count, disease activity score, and liver toxicity; and, (3) current and past medications (Table 1). There was some variability in implementation among sites due to factors such as programmer availability, workflow changes, and clinic staff. During the testing phase, 101 JIA families completed a post-visit feedback survey: 93% agree or strongly agree the dashboard was useful during discussions, 89% indicated that it helped to talk about what mattered most, and 81% reported that it helped to make healthcare decisions. The Net Promoter Score, which rated the likelihood of families to recommend the dashboard to a friend or peer, was a +68 (>50 = excellent). Families valued the ability to share questions/concerns in advance of the visit, insight into clinical assessment data used by clinicians, and visualization of data over time to inform shared treatment decisions with their clinicians.

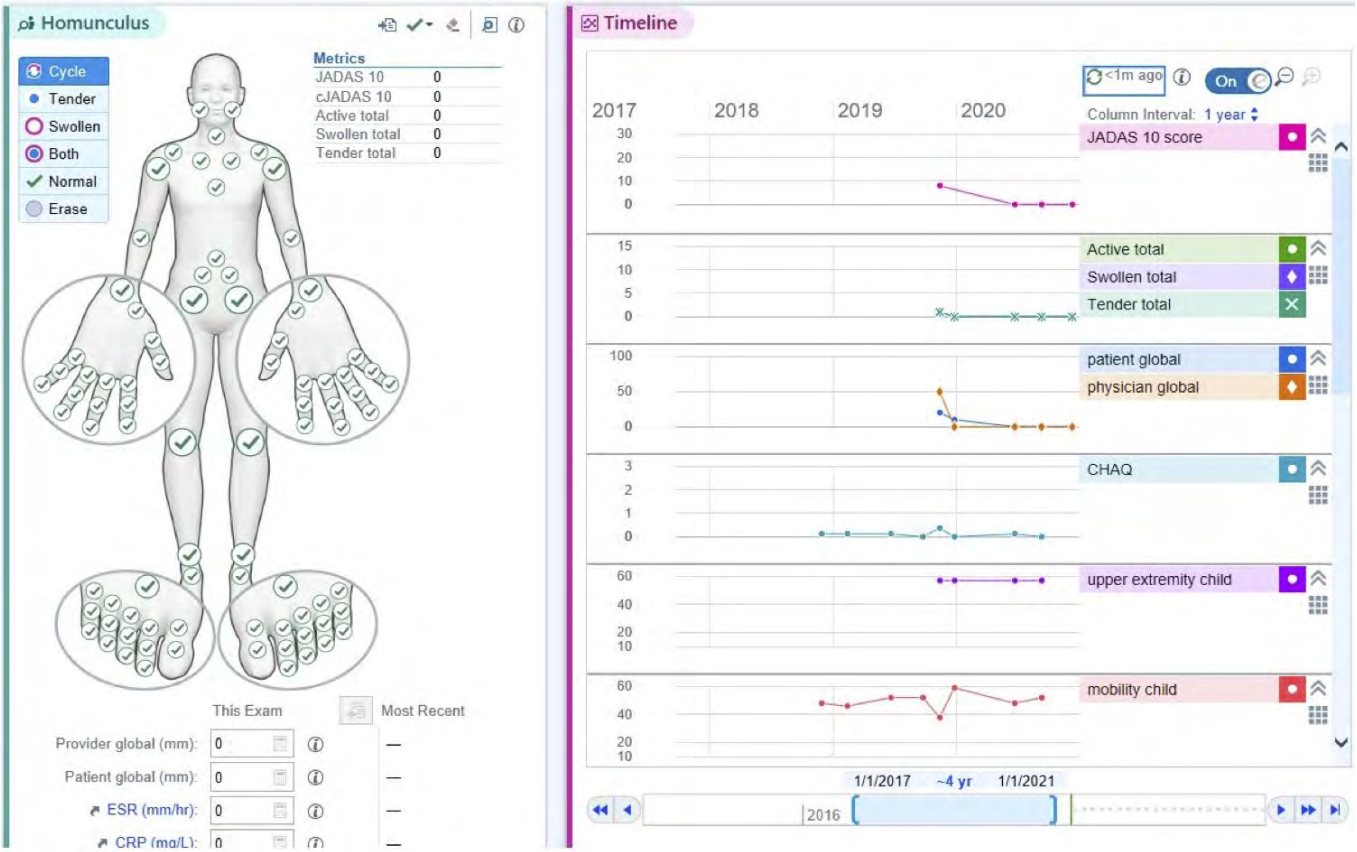

Figure 1. Pediatric Rheumatology Dashboard displaying longitudinal patient-reported and clinical data.

Table 1. Recommended Data Elements for inclusion in the JIA Dashboard

Domain	Data Element Description
Patient-Reported Outcomes	
Concerns, Questions	Free text patient and parent questions or concerns for discussion in the visit
Patient Global Assessment	Ordinal 0-10 scale, indicates patient's overall well-being
Medication Adherence	5-point Likert Scale, indicates how often medications are being taken as prescribed, includes option of "I am not currently taking any prescribed rheumatology medications"
Physical Function	PROMIS 1.0 Pediatric Upper Extremity short form raw summed score; PROMIS 1.0 Pediatric Mobility short form raw summed score
Medication Side Effects	List of symptoms from medications being taken
Pain, Pain Interference	Ordinal 0-10 current rating of pain; PROMIS 1.0 Pain Interference short form raw summed score
Clinical Data	
Joint Count	Total number of tender joints; total number of swollen joints
Provider Global Assessment	Ordinal 0-10 scale, provider's assessment of patient's overall disease activity
Disease Activity	0-30 composite score, incorporates patient global assessment, provider global assessment, joint count
Liver Toxicity	Alanine Aminotransferase (ALT)
Medications	
Medications	Medication name, dose, route, and frequency

Conclusion: Building upon basic Epic functionality, we implemented a JIA dashboard at four sites, informed by a human-centered design approach with a diverse group of stakeholders. Data demonstrated that the dashboard effectively facilitates shared decision making between JIA families and their clinicians. Additional efforts are ongoing to spread the dashboard use to other clinicians and to determine optimal use of the dashboard during telehealth visits.

Immunological and Clinical Features of Untreated Juvenile Dermatomyositis Patients with Elevated Neopterin

Amer Khojah[1], Gabrielle Morgan[2] and Lauren Pachman[3], [1]Ann & Robert H. Lurie Children's Hospital of Chicago, Chicago, IL, [2]Ann & Robert H. Lurie Children's Hospital of Chicago and Northwestern University Feinberg School of Medicine, Chicago, IL, [3]Northwestern's Feinberg School of Medicine. Ann and Robert H. Lurie Children's Hospital of Chicago; Stanley Manne Children's Research Institute of Chicago, Lake Forest, IL

SESSION INFORMATION
Session Date: Sunday, November 7, 2021
Session Title: Abstracts: Pediatric Rheumatology – Clinical (0974–0979)
Session Type: Abstract Session
Session Time: 2:00PM–3:30PM

Background/Purpose: Neopterin is a metabolic product of guanosine triphosphate, which is produced by macrophages upon stimulation with interferon-gamma from activated T helper cells. Despite the initial studies showing elevated neopterin in children with active Juvenile Dermatomyositis, the broad adoption of neopterin as biomarkers in clinical practice is still limited. We aim to study the immunological and clinical differences between newly diagnosed JDM patients with elevated and normal serum neopterin levels.

Methods: Children with JDM who had serum neopterin before initiating medical therapy were included. Elevated serum neopterin was defined by levels $\geq$ 10 nmol/l. We assessed T, B, and NK cell populations, Myositis-specific antibodies, Muscle enzymes and Disease Activity Score for skin (sDAS), muscle (mDAS), Total (tDAS). Student's t-test and chi-square to compare the baseline characteristics, disease activity markers, and among the two groups.

Results: 113 subjects (77% female, 77% white, 3.5 % black, 14.2 % Hispanic) were included in this study. 80% of untreated JDM patients had elevated serum neopterin. The mean age of onset was similar in the two groups however the duration of untreated disease was significantly shorter in the patients with elevated neopterin (7.7 months vs 14.1 months p = 0.007). Among the different MSAs group, anti-MJ group has the highest the mean neopterin at 26.7+/- 4.4 nmol/l and the Mi2 group has the lowest level at 14.2 +/- 6.0 nmol/l however the difference was not statistically significant . Also, the group with elevated neopterin had significantly more active disease with mean tDAS 11.7 vs 9.0 (p=0.0009), mDAS 5.7 vs 3.7 (p=0.005), sDAS 6.0 vs 5.4 (p =0.04), CK level 475.9 vs 274.1 IU/L (p= 0.006), Aldolase 21.0 vs 7.8 U/L (p=0.05) and ESR 19 vs 10.7 mm/hr (p=0.01). The flow cytometry showed reduced T cells (1517 vs 2348 /mm3 p < 0.001) and NK cells (144 vs 248 /mm3 p =0.002). TNFalpha-308AA/AG polymorphism was more common in subject with elevated neopterin than TNFalpha-308GG (chi-square p = 0.05). Of note, there was a positive correlation between the levels of serum neopterin and tDAS (R^2 = 0.14, p = < 0.001) and mDAS (R^2 = 0.17, p = < 0.001) but not sDAS.

Conclusion: Elevated serum neopterin is seen in 80 % of untreated JDM. JDM Patients with elevated have more muscle weakness and elevated muscle enzymes. Also, elevated neopterin is associated with an increased frequency of TNFalpha-308AA/AG polymorphism and decreased absolute NK, and T cells count.

Autoantibody Testing in Juvenile Localized Scleroderma and Systemic Sclerosis: Comparing Antibody Profiles and Clinical Correlations

Jonathan Li[1], Emily Mirizio[1], Katherine Buhler[2], May Choi[3], Haiyan Hou[2], Giffin Werner[1], Anwesha Sanyal[1], Kaila Schollaert-Fitch[1], Marvin Fritzler[2] and **Kathryn Torok**[1], [1]University of Pittsburgh, Pittsburgh, PA, [2]University of Calgary, Calgary, AB, Canada, [3]Brigham and Women's Hospital | University of Calgary, Calgary, AB, Canada

SESSION INFORMATION

Session Date: Sunday, November 7, 2021
Session Title: Abstracts: Pediatric Rheumatology – Clinical (0974–0979)
Session Type: Abstract Session
Session Time: 2:00PM–3:30PM

Background/Purpose: Pediatric scleroderma encompasses juvenile onset localized scleroderma (jLS) and juvenile onset systemic sclerosis (jSSc), both of which present with varied cutaneous fibrosis and systemic involvement. Autoantibodies (Aab) help serve as a prognostic tool for adult onset SSc disease manifestations; however, their clinical relevance for jSSc and jLS remains unclear. Development of commercially available Aab panels facilitates testing

Table 1: Comparison of Aab frequencies

EUROLINE	Healthy (n=42)	LS (n=143)	SSc (n=75)	FIDIS	Healthy (n=42)	LS (n=143)	SSc (n=75)

but requires clinical validation in pediatric cohorts. Using two of these panels, we sought to compare Aab profiles between jLS and jSSc, and investigate the association of Aabs in jLS with clinical characteristics.

Methods: Sera from 42 age-matched pediatric healthy controls (HC), 75 jSSc patients, and 143 jLS patients (IRB #STUDY19080297) underwent Aab phenotyping with the FIDIS™(F) Connective Profile addressable laser bead immunoassay (ALBIA) (TheraDiag, Paris, France) and the EUROLINE™(E) SSc Profile line immunoassay (LIA) (Euroimmun, Germany) comprising 26 distinct Aabs. Cutoffs were defined from HC and applied to jLS and jSSc samples to determine Aab positivity. Chi-square analysis was used to compare Aab profiles between cohorts and determine

Table 2: Clinical characteristics based on poly-positivity in localized scleroderma (LS)

Poly-positivity	NSITES	MLOSSI	LOSDI	PGAACT	PGADAMG	PGASEVER

PGASEVER	Physician global assessment of disease severity

significant ($p< 0.05$) relationships with clinical variables. For Aabs significantly higher in frequency than HC, poly-positivity profiles (3 or more Aab) were analyzed.

Results: Overall, Aab were positive in 80% of jSSc patients and 41% of jLS patients. Significant Aab elevation compared to HC, unique to jSSc, included Scl-70 (both), PM-Scl100 (E), PM-Scl (F), Sm (F), and Ro-52 (F) (Table 1). Whereas NOR90 (E) was unique to jLS compared to HC. Shared Aabs between jLS and jSSc, significantly elevated compared to HC, included CENP-A (E), CENP-B (E), Sm-RNP (F) and ribosomal P (Rib P) (F). Among jSSc, the most common Aabs were Scl70 (36%), Sm-RNP (35%), and Rib P (25%). Scl70 was the most common among single positive patients (41%), while combination of Sm-RNP, Sm, and Rib P were present among all polypositive jSSc patients. Most frequent Aabs in jLS were Sm-RNP (20%), CENP-B (17%), and Rib P (15%), with the combination of Sm-RNP/Rib P (53%) in polypositive patients. In jLS, those with 3+ Aabs had significantly elevated skin and global disease activity scores (Table 2). Rib P Aab positivity associated with jLS face/scalp involvement (OR 3.056, 95% CI: 1.16-10.55, p=0.026).

Conclusion: Using two scleroderma-targeted Aab panels, we observed that jLS patients have a lower frequency of Aab positivity compared to jSSc. This jSSc cohort had predominant Scl-70 positivity, as adult SSc, but differs in higher frequency of overlap Aab including PM-Scl and Sm-RNP. jLS patients share a number of Aabs with jSSc, namely Sm-RNP, Rib P, and anti-centromere (CENP-A, CENP-B) suggesting a degree of pathophysiologic overlap. Unique Aab patterns emerged based on the quantity of positive Aabs present and were associated with skin and global disease activity parameters. Rib P Aabs were associated with head involvement among jLS patients. Overall, our findings suggest that the jLS Aab profile is similar, but distinct from, jSSc and may be related to clinical disease characteristics.

Relationship Between Paraoxonase-1 Genotype, Activity, and Malignancies in Patients with RA Receiving Tofacitinib

Christina Charles-Schoeman[1], Craig Hyde[2], Shunjie Guan[3], Neil Parikh[1], Jennifer Wang[1], Ani Shahbazian[1], Lori Stockert[4] and John Andrews[4], [1]Department of Medicine, University of California, Los Angeles, Los Angeles, CA, [2]Pfizer Inc, Groton, CT, [3]Pfizer Inc, Cambridge, MA, [4]Pfizer Inc, Collegeville, PA

SESSION INFORMATION
Session Date: Sunday, November 7, 2021
Session Title: Abstracts: RA – Diagnosis, Manifestations, & Outcomes I: Bugs & Drugs (0980–0983)
Session Type: Abstract Session
Session Time: 2:00PM–3:00PM

Background/Purpose: Paraoxonase-1 (PON1) is a high-density lipoprotein-associated enzyme with paraoxonase, lactonase, and arylesterase activities.[1] PON1 gene polymorphisms at the Q192R allele (rs662) have been associated with a reduced risk of cancers, although larger samples are needed to confirm any prognostic role.[1,2] This post hoc analysis investigates the relationship between PON1 genotype/activity and risk of malignancies in the tofacitinib RA clinical program.

Methods: Data were pooled from patients (pts) enrolled in 9 Phase 2/3 studies of tofacitinib in RA (completed by March 31, 2015). Enzyme activities in pt plasma samples were measured at individual study baseline (BL), and at follow-up visits, using 3 substrates: paraoxon (paraoxonase activity), dihydrocoumarin (lactonase activity), and phenylacetate (arylesterase activity). The effect of the PON1 Q192R genotype (QQ, QR, or RR) on BL paraoxonase/lactonase/arylesterase activity was assessed using linear regression for each study, with age and sex as covariates; a fixed-effects meta-analysis assessed effects across studies. The risk of malignancies excluding non-melanoma skin cancer (NMSC), and NMSC events by enzyme activity, was determined using Cox proportional hazards regression, stratified by clinical studies. Univariate regression against BL enzyme activity and other risk factors, as well as both minimally and fully adjusted multivariable regressions against time-varying enzyme activity, are presented.

Results: The analysis included 1,969 pts with RA who received ≥ 1 dose of tofacitinib and had ≥ 1 PON1 activity measure available at BL; 53 pts had ≥ 1 malignancy event excluding NMSC, and 56 pts had ≥ 1 NMSC event. Compared with the QQ genotype, the RR genotype had a highly significant positive association with BL paraoxonase activity, and a highly significant negative association with BL lactonase and arylesterase activity (Figure 1). In the univariate analysis, age, RA duration, and smoking status ('ex-smoker/never smoked') were identified as risk factors for both malignancies excluding NMSC (Figure 2) and NMSC (data not shown). Time-varying models found a highly significant association of increased paraoxonase activity over time with lower risk of future malignancies excluding NMSC (Figure 3), but not with NMSC events (data not shown), even after controlling for risk factors including RA duration, age, and smoking status. No such trend was observed for lactonase and arylesterase for malignancies excluding NMSC or for NMSC events (data not shown).

Minimally adjusted model covariates: tofacitinib dose (10 mg/5 mg) and age
Fully adjusted model covariates: tofacitinib dose (10 mg/5 mg), age, RA duration, and smoking status
[a]All paraoxonase activities were standardized (mean = 0; SD = 1)
[b]All lipids analyzed were time-varying, log-transformed, and standardized (mean = 0; SD = 1)
[c]Analysis only conducted in European population
BL, baseline; CI, confidence interval; HDL, high-density lipoprotein; HR, hazard ratio; LDL, low-density lipoprotein; NMSC, non-melanoma skin cancer; pts, patients; SD, standard deviation

Conclusion: In this post hoc analysis, higher paraoxonase activity over time was associated with a significantly reduced risk of future malignancies excluding NMSC in pts with RA receiving tofacitinib, after controlling for risk factors such as RA duration, age, and smoking. Based on these findings, further investigation of PON1 as a novel functional lipid biomarker to assess malignancy risk in pts with RA is warranted.

SESSION INFORMATION
Session Date: Sunday, November 7, 2021
Session Title: Abstracts: RA – Diagnosis, Manifestations, & Outcomes I: Bugs & Drugs (0980–0983)
Session Type: Abstract Session
Session Time: 2:00PM–3:00PM

Background/Purpose: Inflammatory arthritis (IA) is an autoimmune disease targeting multiple joints and characterized by joint destruction caused by osteoclasts (OC), leading to physical disability. However, the precise cellular origins of OC are poorly understood. Myeloid lineage cells including OC and macrophages can derive from either hematopoietic stem cells (HSC) or erythro-myeloid progenitors (EMP). Previous studies in vitro suggest that in IA, HSC-derived monocytes differentiate into OC and others showed that macrophages can fuse to form OC under the influence of inflammatory cytokines. We hypothesized that in IA, embryonically derived Erythro-Myeloid Progenitor macrophages and Hematopoietic Stem Cell-derived progenitors can independently contribute to the formation of OC in vivo. These cell lineage tracing systems will allow to discriminate among distinct OC populations by their cell surface phenotype and selectively target them for therapeutic purpose.

Methods: To test this hypothesis, we used bone frozen sections and immunofluorescence, as well as flow cytometry (FACS) from cell lineage tracing systems, to discriminate among these progenitors. We used $Flt3^{Cre}$;$Rosa26^{LSL\text{-}YFP}$mice to label HSC and their progeny and both $Csf1r^{Mer\text{-}iCre\text{-}Mer}$;$Rosa26^{LSL\text{-}tdTomato}$ and $Cx_3cr_1^{CreERT2}$;$Rosa26^{LSL\text{-}tdTomato}$ mice, pulsed with 4-hydroxytamoxifen at E8.5 and E9.75 respectively, to label EMP-derived progenitors.

Results: Histology of ankle joints from healthy $Flt3^{Cre}$;$Rosa26^{LSL\text{-}YFP}$ embryos at E16.5, newborn at P0 and 8 week-old mice showed that ~7 % of synovial F4/80+ or CD68+ cells were of HSC origin, suggesting that EMPs are the major source of synovial macrophages. We confirmed, using both $Csf1r^{Mer\text{-}iCre\text{-}Mer}$;$Rosa26^{LSL\text{-}tdTomato}$ and $Cx_3cr_1^{CreERT2}$;$Rosa26^{LSL\text{-}tdTomato}$ mice, that ~40% of all F4/80+ synovial macrophages were TdTomato+, showing for the first time an EMP-origin. To test the HSC origin of OC in IA, adult $Flt3^{Cre}$;$Rosa26^{LSL\text{-}YFP}$ mice were treated with K/BxN arthritogenic serum and

Figure 1a. Study schematic for patients with RA and HZ

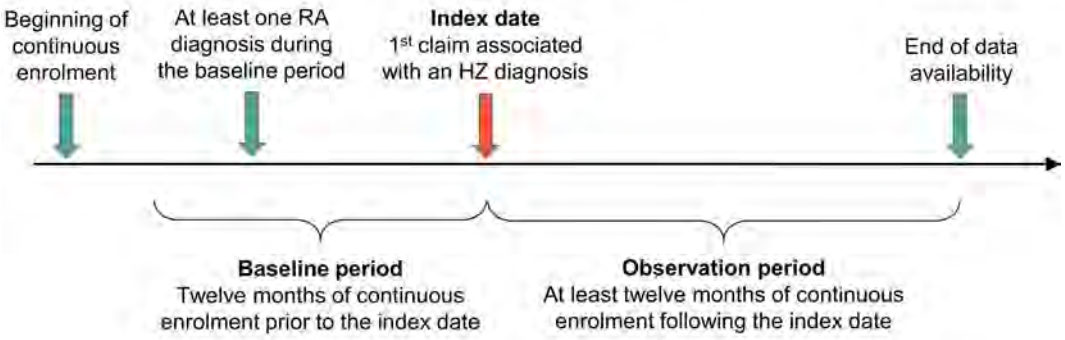

Figure 1b. Study schematic for patients with RA only

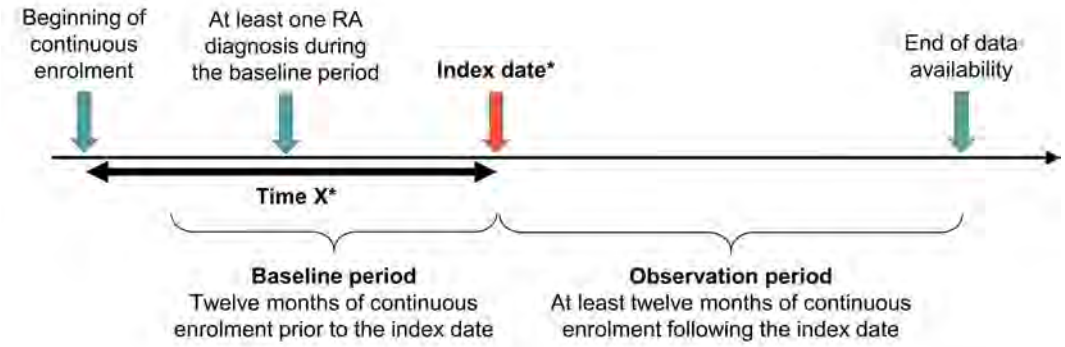

***The index date was randomly assigned based on the distribution of time from the start of continuous enrolment to index date in the RA and HZ cohort. Time X represents this distribution of time from the beginning of continuous enrolment to the assigned index date.**

HZ, herpes zoster.

ankle joints were harvested at day 10 (peak inflammation). Unexpectedly, we found that only 56% of OC were YFP-positive, indicating that a large proportion of synovial OC are not HSC-derived. Further, we identified CD68+TRAP+ cells localized to periosteal surfaces as candidate progenitors of synovial OC. Consistent with the dual origin of synovial OC, CD68+TRAP+ progenitors derive from both HSC (27%) and non-HSC (73%) lineages.

Conclusion: These data suggest that both HSC-derived and EMOP-derived osteoclast precursor cells independently contribute to OC formation in IA. These cell lineage tracing systems will help us to identify unique differences among OC of distinct origins. These differences will allow for differential targeting of OC via unique cell surface markers and for the development of new targets to inhibit OC formation and prevent bone and cartilage erosions in IA.

Table 1. Baseline demographic, clinical, and cost information for patients with RA and HZ and patients with RA only

	RA and HZ (n=1,866)	RA only (n=38,846)	Standardized difference[1]
Age, mean (SD)	68.3 (11.6)	66.2 (12.7)	17.1%
Female, n (%)[2]	1,489 (79.8)	29,521 (76.0)	9.2%
Geographic region, n (%)			
South	806 (43.2)	17,595 (45.3)	4.2%
West	461 (24.7)	8,943 (23.0)	3.9%
Midwest	421 (22.6)	8,633 (22.2)	0.8%
Northeast	178 (9.5)	3,655 (9.4)	0.4%
Unknown	0 (0.0)	20 (0.1)	3.2%
Index year, n (%)			
2016	167 (8.9)	2,430 (6.3)	10.2%
2017	745 (39.9)	15,285 (39.3)	1.2%
2018	825 (44.2)	18,533 (47.7)	7.0%
2019	129 (6.9)	2,598 (6.7)	0.9%
Insurance type n (%)			
Medicare advantage	1,338 (71.7)	26,166 (67.4)	9.4%
Commercial	528 (28.3)	12,680 (32.6)	9.4%
Modified Charlson-Quan comorbidity index, mean (SD)[3]	1.3 (1.7)	1.1 (1.6)	10.2%
Use of RA-related medications at index, n (%)			
NSAIDs	435 (23.3)	8,063 (20.8)	6.2%
Systemic steroids	731 (39.2)	11,013 (28.4)	22.9%
Conventional synthetic DMARDs	1,046 (75.3)	29,055 (74.8)	1.3%
Biologic DMARDs	555 (29.7)	11,382 (29.3)	1.0%
Targeted synthetic DMARDs (JAK inhibitors)	86 (4.6)	1,011 (2.6)	10.8%
Total costs, mean (SD)	$52,625 (67,774)	$46,332 (65,480)	9.4%

[1]For continuous variables, the standardized difference was calculated by dividing the absolute difference in means of cohorts RA+HZ vs RA only by the pooled SD of both groups. The pooled SD was the square root of the average of the squared SDs. For categorical variables with two levels, the standardized difference was calculated using the following equation where P_1 was the proportion of participants with an event in cohort RA+HZ, and P_2 was the proportion of participants with an event in cohort RA only: $(P_1-P_2)/\sqrt{p(1-p)}$, where $p = (P_1+P_2)/2$.
[2]One patient in cohort RA only had "unknown" gender and was imputed "female" gender.
[3]The Modified Charlson-Quan comorbidity index excluded rheumatologic disease.
Standardized differences of 20%, 50% and 80% can be interpreted to represent small, medium and large differences, respectively (Cohen J. Statistical Power Analysis for the Behavioral Sciences. 2nd edition: Lawrence Erlbaum Associates; 1988.).

HZ, herpes zoster; JAK, Janus kinase; n, number; NSAIDs, non-steroidal anti-inflammatory drugs; SD, standard deviation.

Table 2. Healthcare resource use and costs during 12 months after index date for patients with RA and HZ and patients with RA only

	RA and HZ (n=1,866)	RA only (n=38,846)	
HCRU, n (%) of patients			P-value (unadjusted, chi-square test)
Inpatient admissions	405 (21.7)	6,301 (16.2)	<0.001
ED visits	770 (41.3)	11,810 (30.4)	<0.001
Outpatient Visits	1,866 (100.0)	38,508 (99.1)	<0.001
HCRU, Incidence rate PPPY			Adjusted incidence rate ratio (95% CI)[2]
Inpatient admissions	0.33	0.24	1.16 (1.04, 1.30)
ED visits	1.03	0.77	1.34 (1.21, 1.47)
Outpatient visits	26.33	22.22	1.11 (1.08, 1.14)
Costs, mean (SD)[1]			Adjusted cost difference (95% CI)[3]
Total costs	$57,291 (75,481)	$50,562 (75,213)	$3,325 (-58, 7,345)
Medical costs	$40,033 (69,732)	$33,404 (68,319)	$3,428 (446, 6,781)
Inpatient	$19,511 (56,906)	$15,310 (56,037)	$1,953 (-17, 4,473)
ED	$2,870 (8,429)	$1,832 (5,501)	$705 (430, 1,003)
Outpatient	$16,790 (26,179)	$15,459 (28,775)	$168 (-798, 1,118)
Pharmacy costs	$17,258 (29,997)	$17,158 (31,295)	-$833 (-1,846, 386)

[1]All costs are presented in 2020 US Dollars.
[2]Adjusted incidence rate ratios are calculated using generalized linear model assuming a negative binomial distribution and log link, controlling for propensity score and key baseline measures. Propensity scores included variables selected based on expert review.
[3]Cost differences were estimated using the two-part modelling approach: (1) In the first part, the probability of observing a positive cost was modelled using logistic regression; (2) in the second part, a generalized linear model with a gamma distribution and log link was used to predict costs among patients with positive costs. Both models included the patients' propensity scores and relevant baseline characteristics. The 95% CI and approximate p-values were estimated from nonparametric bootstrap procedures with 499 replications.

CI, confidence interval; ED, emergency department; HCRU, healthcare resource use; HZ, herpes zoster; n, number; SD, standard deviation; PPPY, per patient per year; US, United States.

B Cells Repertoire Repartition Predicts Response to Methotrexate at 6 and 12 Months in Naïve RA: A Machine Learning Driven Approach

Aurelie Najm[1], Shrutii Sarda[2], Michelle Toro[3], Loni Pickle[3], Stephanie Ostresh[3], Fraser Morton[4], Geoffrey Lowman[3], Andrew Felton[5] and Carl Goodyear[4], [1]Institute of Infection, Immunity and Inflammation, College of Medical Veterinary and Life Sciences, University of Glasgow, Glasgow, United Kingdom, [2]Clinical Sequencing Division, Specialty Diagnostics Group, Thermo Fisher Scientific, South San Francisco-CA, United States, San Francisco, [3]Clinical Sequencing Division, Specialty Diagnostics Group, Thermo Fisher Scientific, Carlsbad, CA, [4]University of Glasgow, Glasgow, United Kingdom, [5]VP, Platforms, Research & Applied, Specialty Diagnostics Group, South San Francisco, CA

SESSION INFORMATION
Session Date: Sunday, November 7, 2021
Session Title: Abstracts: RA – Diagnosis, Manifestations, & Outcomes I: Bugs & Drugs (0980–0983)
Session Type: Abstract Session
Session Time: 2:00PM–3:00PM

Background/Purpose: The adaptive immune system plays a central role in Rheumatoid Arthritis (RA) pathogenesis. Moreover, the composition of the B cell repertoire and its perturbation are known to exist across disease phenotypes (i.e., ACPA positive versus ACPA negative). However, the influence of underlying B-cell repertoire changes in RA according to their response to treatment, and the ability of these to constitute as predictive biomarkers of response to Methotrexate (MTX) are not yet known. The objective of this analysis was to create a nomogram capable of predicting response to MTX at 6 and 12 months based on properties of the baseline B cell repertoire.

Methods: Peripheral blood leukocytes (PBL) from patients from the Scottish Early Rheumatoid Arthritis SERA cohort (1) were included in the analysis and classified into 3 categories according to their response to MTX measured by CDAI or DAS 28 at 6 and 12 months: responders (n=36), non-responders (n=35) and relapsing responders (n=28). BCR sequence repertoires were explored through IGH sequencing via the IGH-LR assay and the Gene Studio S5, sequencing to a target of 1.5M reads per sample. Data were analyzed via Ion Reporter 5.12 and 5.16. A gradient-boosting supervised learning method was used to build a prediction model of MTX response at 6 months and 1 year.

Results: 99 patients, with a mean age of 60.5 (SD 13.72) were included for analysis. Of interest, differences in class-switching and repartition of naïve B cells were observed across all groups. Notably, untreated patients displayed higher levels of IgA, IgE and IgG clones compared to after 12 months of MTX (p=0.003). At baseline, isotypes were more frequently switched towards IgA, IgE and IgG in non-responders than responders (p=0.008). Baseline levels of circulating IgD+ B cells clones were more frequent in responders compared to non-responders (p=0.004) while IgA1+ and IgA2+ clones tended to be more frequently represented in non-responders (p=0.069 and p=0.001 respectively). Over the course of the treatment with MTX, responders and non-responders tended to show an increased frequency of IgM+IgD+ clones whilst a depletion in IgG1+ clones was observed only in responders (p=0.034). In the relapsing responders' group, no significant depletion at both 6 and 12 months was observed. When analyzing somatic hypermutation (SHM) levels in the BCR variable regions, the levels of SHM were consistently lower in non-responders compared with responders, although the number of SHM tended to increase over time for most isotypes. The top

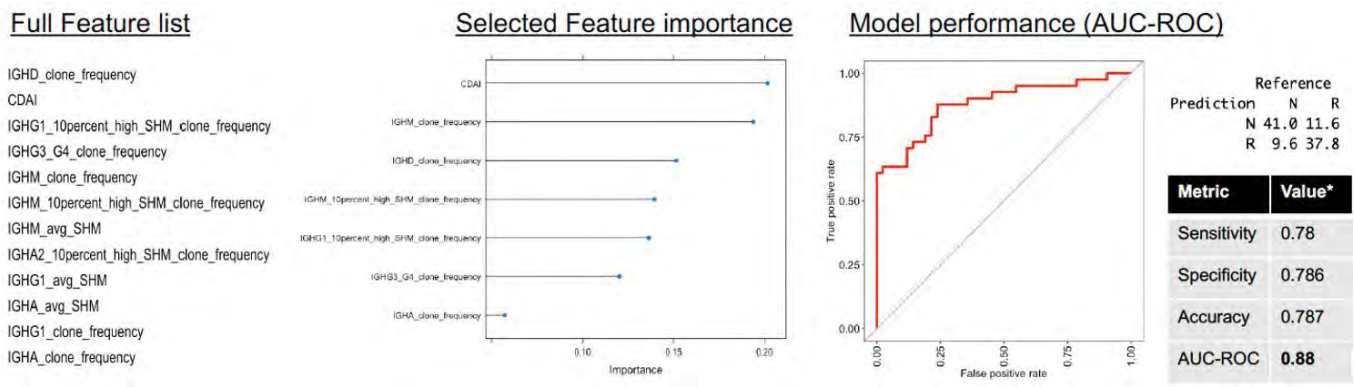

Figure 1. Final Prediction Model For Patient Response to Methotrexate. AUC: area under the curve; SHM: somatic hypermutations.

7 baseline features were selected from a preliminary random forest model: IgM, IgD, IgG3, IgG4 and IgA clone frequency, frequency of IgM and IgG clones with >10% SHM and CDAI. Additional training and optimization of a new gradient boosting model, revealed that the response to MTX in the cohort could be predicted with a sensitivity of 0.78, a specificity of 0.786 and an area under the curve of 0.88 (Figure 1).

Conclusion: This model, based on an innovative machine learning approach in conjunction with a cutting-edge B cell repertoire analysis in RA, constitute the first immunology-based prediction model for response to MTX to our knowledge. This could be further used for personalized therapy in RA.

available in patients on immunosuppressive therapy. The objective of this study is to analyse magnitude and kinetics of mRNA vaccine induced anti-S1 titers in patients with rheumatoid arthritis (RA) on DMARD therapy and healthy controls (HC).

Methods: 77 consecutive RA patients and 21 HC were eligible for vaccination according to federal guidelines and were enrolled in the prospective RECOVER trial (Rheumatoid>Covid-19 Vaccine Immune>Response) between 10th January and March 15th 2021. Vaccination itself was not part of the study. The anti-SARS-CoV-2 vaccines mRNA-1273 and BNT162b2 were applied according to the manufacturers` recommendations. All patients continued their DMARD therapy, patients on rituximab were excluded. Serum samples were obtained before the first vaccine, 3 weeks after

the first, 2 weeks after the second vaccine and after 12 weeks. Quantitative antibody testing was performed using the Roche Elecsys® Anti-SARS-CoV-2 S1 assay that measures antibodies to the S1 protein (range 0.4-2500 U/l) and nucleoprotein to exclude subclinical SARS-CoV-2 infection. A threshold level of anti-S1 that correlates to neutralization has been proposed at 133 U/l.[1] . More recently, even lower cut-off levels (>15 U/l) have been suggested.[2]

Results: Baseline characteristics are summarized in Tab. 1. Levels of anti-S1 antibodies after vaccination are presented in Table 2. 4/77 patients with antibodies to nucleoprotein at baseline were excluded from the analysis. At present, 43/73 patients reached the 12 week timepoint after the first vaccine dose. Median titers of anti-S1 antibodies were significantly lower in RA patients at all time points. 3 weeks after the first vaccine dose, 9/21 HC but only 1/73 RA patients developed anti-S1 titers exceeding 133 U/l (p = 0.0001) or 15 U/l (19/21 HC versus 11/73 RA patients). Two weeks after the second vaccine, the proportion of RA patients with anti-S1 titers exceeding 133 u/l was still significantly lower than in HC (75.3% versus 100%, p = 0.01). Of note, significantly fewer RA patients on abatacept (n=9) or JAK inhibitors (n = 19) achieved both threshold levels compared to patients on csDMARDs and/or anti-cytokine directed biologics.

Conclusion: The development of anti-S1 titers after vaccination with mRNA vaccines against SARS-CoV-2 in patients with RA is overall slower and results in lower antibody titers in comparison to healthy controls. Our data suggest that patients on abatacept or on JAK inhibitors have an increased risk of an impaired anti-S1 response compared to RA patients on csDMARDs or anti-cytokine directed biologics. Strategies need to be developed to optimize vaccine induced humoral immunity in patients with RA.

Abstract Number: 0984

Human Papillomavirus Infection Increases Risk of Primary Sjogren's Syndrome: A Population-based Cohort Study over a 15-year Follow-up

Kevin Sheng-Kai Ma, Center for Global Health, Perelman School of Medicine, University of Pennsylvania, Philidelphia, PA

SESSION INFORMATION
Session Date: Sunday, November 7, 2021
Session Title: Abstracts: Sjögren's Syndrome – Basic & Clinical Science (0984–0987)
Session Type: Abstract Session
Session Time: 3:30PM–4:30PM

Background/Purpose: Viral infection has been considered as an exogeneous risk factor for primary Sjogren's syndrome (pSS). We determined whether human papillomavirus (HPV) infection was associated with the risk of pSS in this population-based propensity score-matched cohort study.

Methods: In this cohort study, 47,300 patients with HPV infection and 189,200 propensity score-matched controls without HPV infection were enrolled. A Cox proportional hazard model was utilized to estimate the risk of pSS and survival analysis was adopted to assess the time-dependent effect of HPV infection on pSS. Subgroup analyses stratified by age, gender, and follow-up years were conducted to identify susceptible populations.

Results: Of all patients with HPV, 493 developed pSS (incidence rate=13.61 per 100,000 person-months, 95%CI=12.46-14.86). Patients with HPV infection were more likely to develop pSS than controls without HPV infection (incidence rate ratio=1.81, 95%CI=1.63-2.01; hazard ratio, HR =1.64, 95% CI =1.47–1.83, P < 0.0001), which persisted in the survival analysis (log-rank test P < 0.0001). The effect of HPV on pSS was significant in HPV-infected patients from both genders and all age subgroups, including male patients (HR=1.83, 95% CI = 1.47–2.28, P < 0.0001), female patients (HR=1.58, 95% CI = 1.40–1.79, P < 0.0001), patients aged between 16 and 45 (HR=1.60, 95% CI = 1.34–1.91, P < 0.0001), and patients older than 45 (HR=1.67, 95% CI = 1.46–1.91, P < 0.0001), all compared with respective matched controls without HPV infection.

Conclusion: This is the first longitudinal study that addresses the relationship between HPV infection and risk of pSS. Based on the observed relationship, regular follow-up in the rheumatology clinic is recommended for patients with HPV infection.

Sjögren's Symptom Burden Drives Immunomodulatory Therapies but Correlates Poorly with Disease Severity Markers

Sara McCoy[1], Miguel Woodham[1], Ian Saldanha[2], Esen Akpek[3], VATINEE BUNYA[4] and Alan Baer[5], [1]University of Wisconsin, Madison, WI, [2]Brown University School of Public Health, Providence, RI, [3]Wilmer Eye Institute, JHU, Baltimore, MD, [4]University of Pennsylvania, Penn Valley, PA, [5]Johns Hopkins University School of Medicine, Baltimore, MD

SESSION INFORMATION
Session Date: Sunday, November 7, 2021
Session Title: Abstracts: Sjögren's Syndrome – Basic & Clinical Science (0984–0987)
Session Type: Abstract Session
Session Time: 3:30PM–4:30PM

Background/Purpose: Sjögren's syndrome (SS) patients have lower quality of life driven by symptoms of pain, depression and fatigue. These symptoms often do not respond to traditional immunosuppressive therapy and may not be effectively addressed by physicians, driving a discordance between patient and provider expectations. Classification of SS patients into symptom-based categories has the potential to increase patient-provider harmony and impact therapeutic strategies. Our objective was to define relevant differences between clusters with respect to symptoms, treatment, disease activity, and laboratory profile.

Methods: We used the Sjögren's International Collaborative Clinical Alliance (SICCA) registry to analyze 1,541 adults fulfilling the 2016 ACR/EULAR criteria for SS. Unsupervised hierarchical clustering was applied to identify the optimal phenotypically similar clusters by: 1) dryness (a composite score derived from Vitali C et al. 2002 consensus criteria ranging 0-100), 2) fatigue (5-point Likert scale from "not at all" to "nearly every day"), and 3) pain (5-point Likert scale from "not at all" to "extremely"). We reported demographic features, symptoms, medication use, organ involvement and laboratory values within each cluster. We used ANOVA or Chi-square to identify cluster differences, controlling for recruitment site, age, sex, race, ethnicity and education.

Results: The analysis yielded 4 clusters among 1,454 participants with complete data on the 3 key symptoms (Figure 1). Clusters were characterized by low symptom (LS; 10% prevalence) and high symptom frequency/severity (HS; 37%) in all categories; high pain (HP; 23%) and low pain (LP; 30%). Depression, measured by mean PHQ9, was

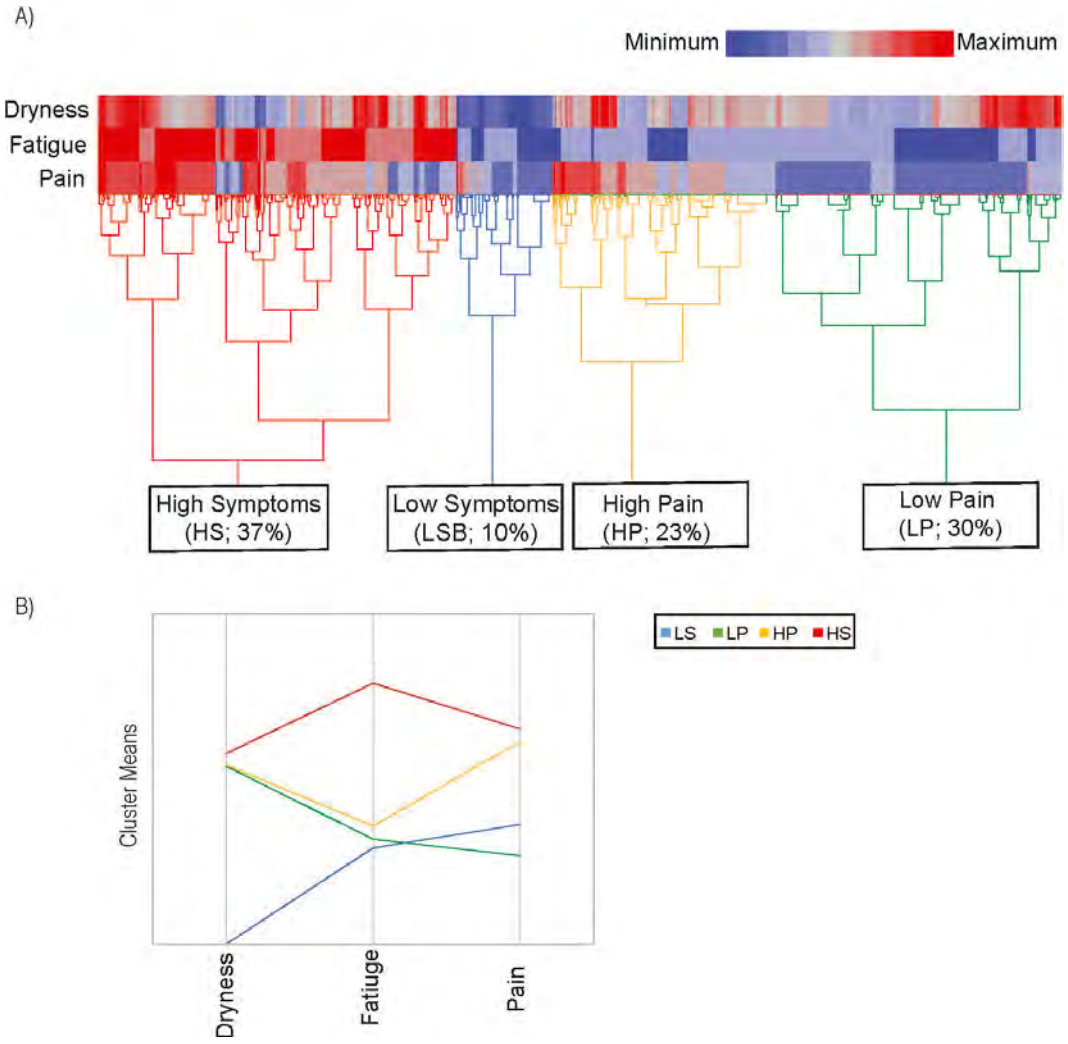

Figure 1. SS symptom-based hierarchical clusters. A) Clusters identified by Ward's method and generated on symptoms including dryness (a composite score of five questions: 1. presence of dry mouth, 2. need sips of liquid to swallow food, 3. presence of dry eye, 4. presence a gritty sensation in eyes, and 5. use of tear substitutes), fatigue (Likert from none of the time to all of the time) and pain (Likert from none of the time to all of the time); B) Cluster means for low symptoms (LS), low pain (LP), high pain (HP), and high symptoms (HS).

worse in the HS group (11.3) compared to the LS group (2.2) ($p< 0.0001$). Health related quality of life, measured by the short form (SF) 12 (6 questions related to physical health, 5 question to mental health, and 1 question to both), was best in the LS group (mental) and LP group (physical) (Figure 2). The HP group was treated with corticosteroids and DMARDs most (20% & 6%). Extraglandular manifestations occurred most often in the LP group, though not reaching significance due to low frequencies of these manifestations (Figure 3A). Interestingly, synovitis occurred most frequently in the HP group (11%). Both the LS and LP groups had higher IgG than the HS and HP groups (Figure 3 B&C). Rheumatoid factor and focus scores were highest in the LP group (Figure 3 D&E).

Conclusion: Here we identify four clusters of SS patients based on dryness, pain and fatigue severity and show that symptom burden does not correlate well with traditional disease markers of severity. Additionally, treatments differed by cluster. The HP group received DMARDs and steroids most often; however, the LP group had the most prominent organ involvement and laboratory abnormalities, yet received immune modulating medication less frequently than the

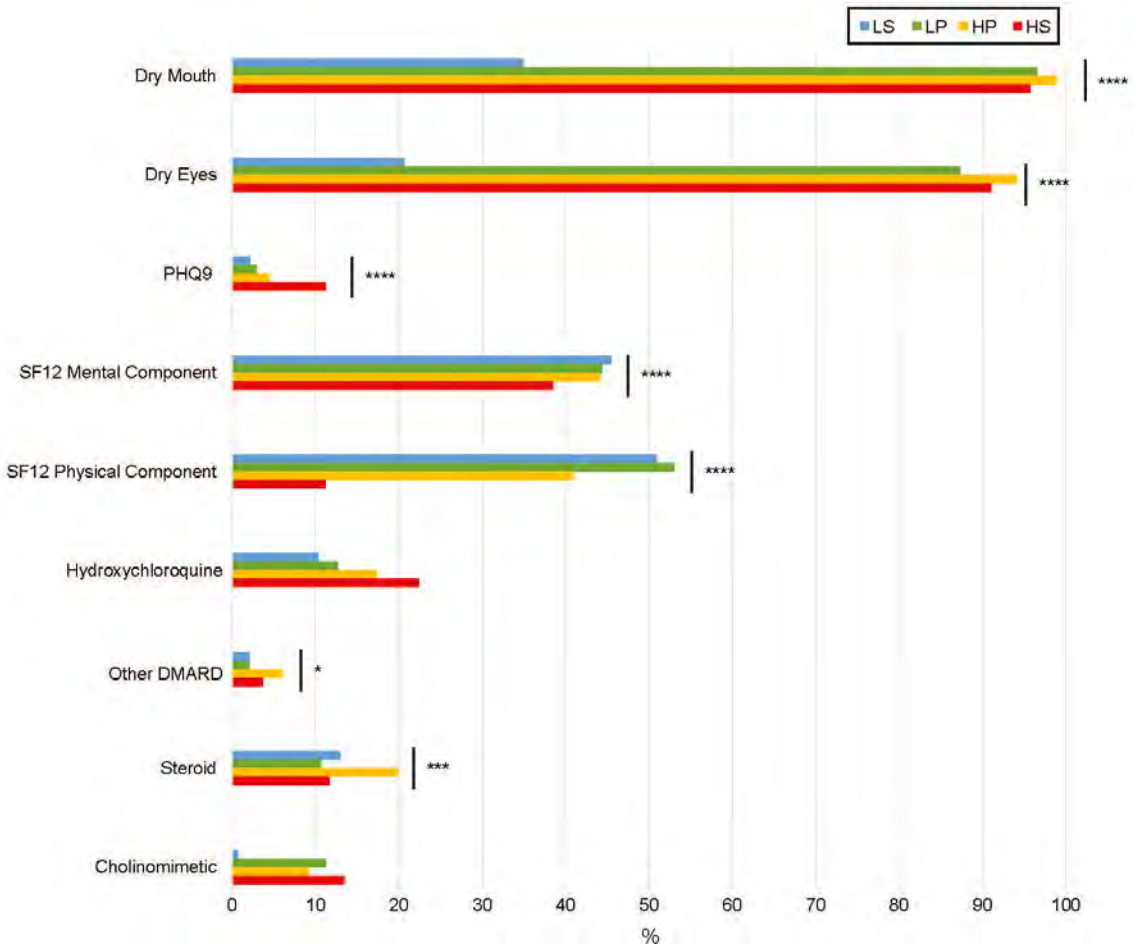

Figure 2. Frequency of patient experience and medication use within four symptom-based clusters. HS and HP groups. These findings highlight discordance between disease activity and treatments; symptoms drive therapies as opposed to disease activity. We propose future research defining these subsets to optimize treatment approaches in order to harmonize patient-provider expectations.

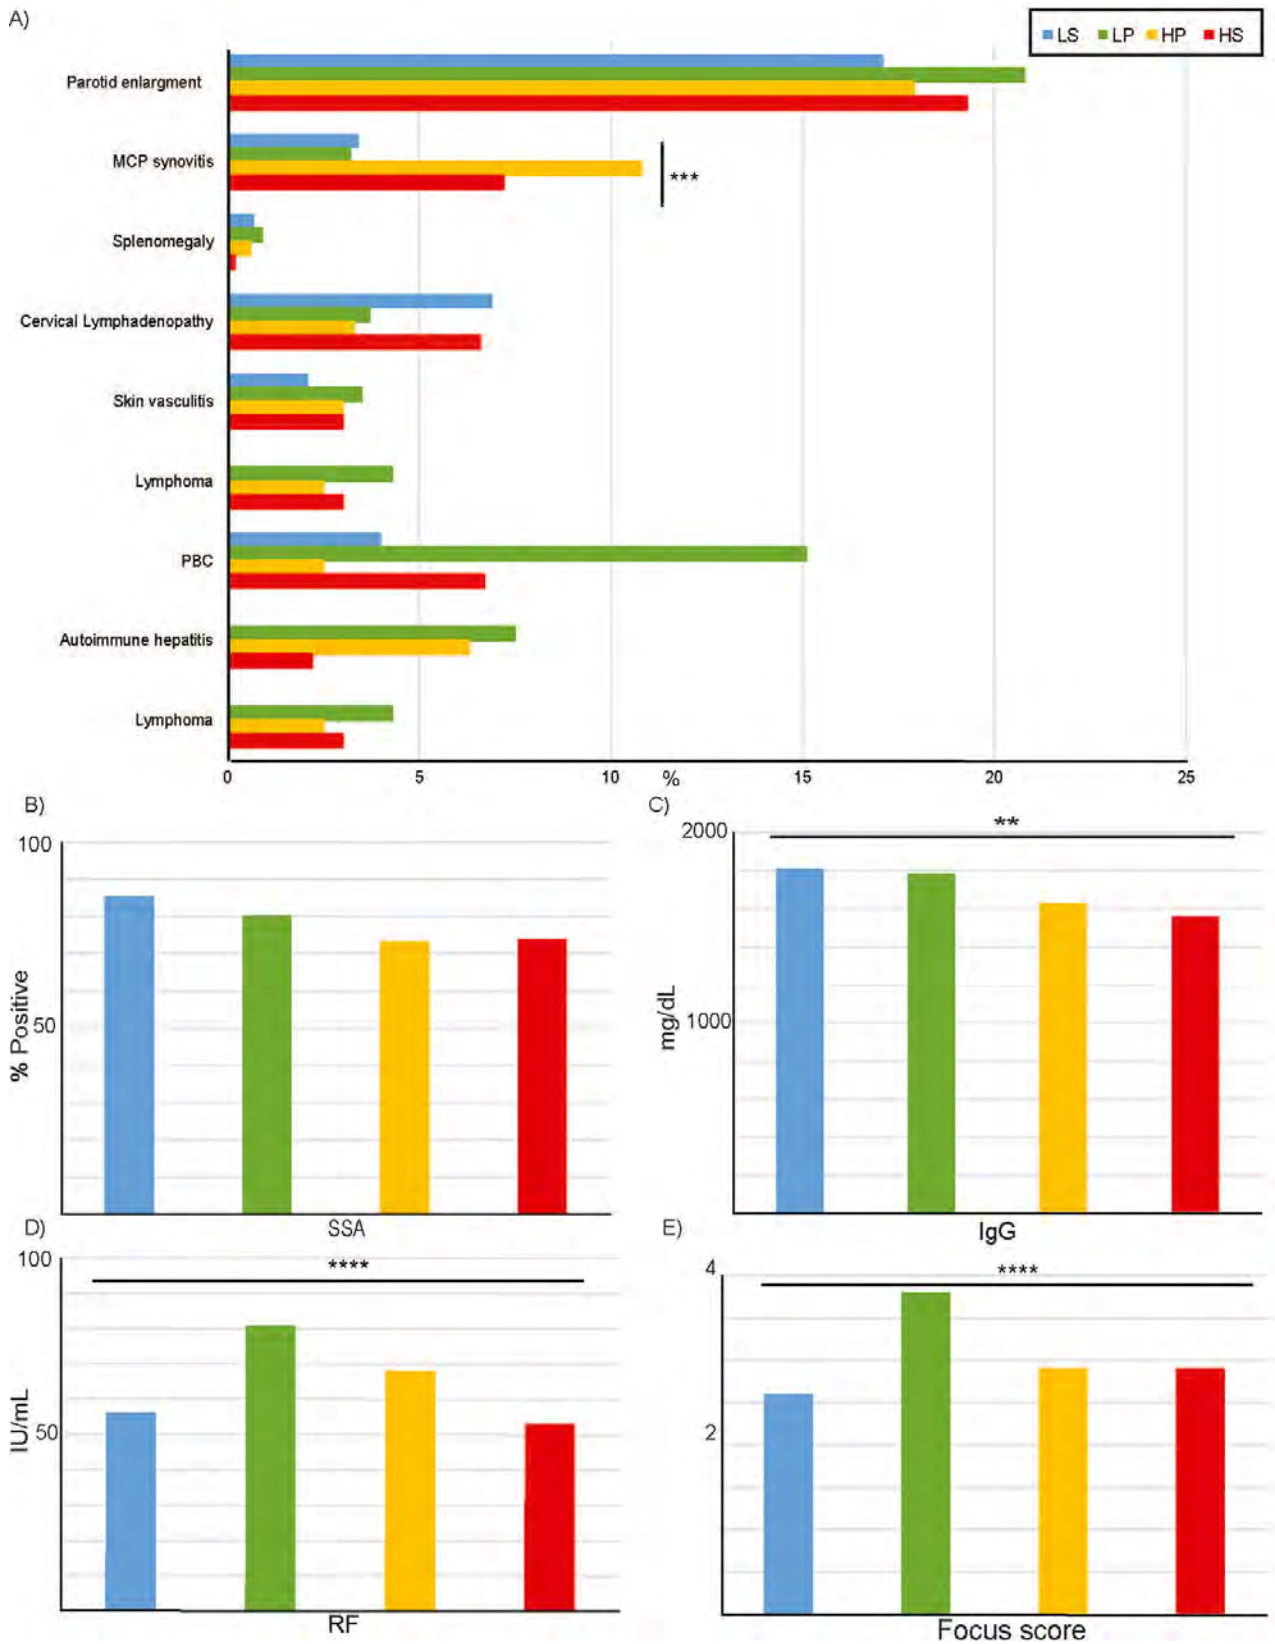

Figure 3. Organ involvement and laboratory findings within SS syptom-based clusters. A) Frequency of organ involvement among clusters; B) Frequency of anti-SSA antibody positivity; C) IgG levels; C) RF levels; D) Focus score. Figure. Summary of Efficacy data at Week 52 (Treatment Period from Wk 24 to Wk 52).

engineered for direct ADCC-mediated B-cell depletion. A Phase 2b study evaluated the dose-response of VAY736 vs placebo (PBO) in EULAR SS Disease Activity Index (ESSDAI) change from baseline (CHB) and other secondary endpoints. Primary results at Week (Wk) 24 were reported previously[1]. Here we report 52 Wks safety and efficacy from extended blinded treatment period 2 (TP2).

Methods: 190 patients were randomized equally to receive s.c. doses of VAY736 (5, 50, 300 mg) or PBO every 4 Wks (q4w). Eligible patients fulfilled American European Consensus Group (AECG) criteria, were anti-Ro/SSA+, had ESSDAI ≥6 and EULAR SS Patient Reported Index (ESSPRI) ≥5. At Wk 24, after completion of the first blinded TP (TP1), PBO-treated patients were switched to VAY736 150 mg, and patients on 300 mg were re-randomized to continue 300 mg or PBO for 28 Wks in TP2. Patients were followed post-treatment for ≥20 Wks. Safety was assessed for all periods. Due to lack of PBO-control in TP2, descriptive efficacy analysis was performed for ESSDAI, ESSPRI, Functional Assessment of Chronic Illness Therapy Fatigue (FACIT-F), Physician's (PhGA) and Patient's Global Assessments (PaGA), 36-Item Short Form Survey (SF-36), and SS symptom diary (SSSD).

Results: Overall, there was no dose dependency of treatment emergent adverse events (TEAEs) except for injection site reactions, which were mostly mild to moderate in severity. Lymphopenia and neutropenia were mostly grade (G)1 and G2, and none G4. Most common TEAEs were infections and infestations in exposure-adjusted analysis of incidence rates. Nasopharyngitis and upper respiratory tract infections were the most common TEAEs, with no dose response (**Table**). Tracheobronchitis and pneumonia, were mild to moderate severity, not associated with absolute neutrophil count G3, and none led to treatment withdrawal.

At Wk 52, efficacy was sustained for patients who continued 300 mg in TP2 (ESSDAI, ESSPRI, PaGA, PhGA CHB: –9.06, –1.91, –22.03, and –35.80, respectively). Efficacy was partially lost for patients who switched to PBO at Wk 24 (**Figure**). Improvement was noted for PBO patients who switched to 150 mg. Stimulated whole salivary flow at Wk 24 was improved for 300 mg (PBO-adjusted CHB 0.20 ml/min; P=0·037); last measurement at Wk 48 was 0.45 and 0.22 ml/min CHB in patients who continued 300 mg or PBO in TP2, respectively.

Conclusion: Ianalumab 300 mg was well tolerated up to 52 Wks. Exploratory efficacy measures showed that continuous dosing of 300 mg s.c. q4w provided sustained clinical benefit. PaGA was the outcome that showed the most prominent change following switch to PBO or VAY736.

SESSION INFORMATION
Session Date: Sunday, November 7, 2021
Session Title: Abstracts: Sjögren's Syndrome – Basic & Clinical Science (0984–0987)
Session Type: Abstract Session
Session Time: 3:30PM–4:30PM

Background/Purpose: The pathogenic role of B-cells in primary Sjögren's Syndrome (pSS) is well established and B cell abnormalities are hallmarks of the disease. Because of the substantial role of B-cells, rituximab (RTX), has been considered a potential biologic disease modifying drug in pSS. To date, the TRial for Anti-B-Cell Therapy In patients with pSS (TRACTISS) is the largest multi-centre, placebo-controlled trial with RTX. Despite the unmet primary end-points (30% reduction in fatigue or oral dryness, measured by visual analogue scale), RTX treated patients showed an improvement in unstimulated whole salivary flow. The study provides the first longitudinal transcriptomic and histological analysis at 3 time points over 48 weeks of labial salivary glands (SGs) of pSS patients treated with RTX, in comparison to placebo, from the TRACTISS cohort.

Methods: 26 pSS patients randomised to RTX or placebo arm consented for labial SG biopsies at baseline, weeks 16 and 48. Patients received two 1000mg cycles of RTX or placebo at baseline and week 24. The histological analysis was performed by digital imaging (QuPath software), RNA was extracted from matched labial SG lobules and sequenced with Illumina platform.

Results: Placebo-treated labial SGs showed a worsening of inflammation with an increment of B-cell density, development of new follicular-dendritic cell (FDC) networks, and a higher ectopic germinal centre (GC) prevalence at week 48, compared to RTX-treated patients. RTX downregulated genes involved in immune cell recruitment and inflammatory aggregate organisation (e.g. CCR7, CCL19, CD52, and PDCD1) and gene signature-based analysis of 64 immune cell types highlighted how RTX preferentially blocked class-switched- and memory-B-cells infiltration in SGs at week 48. Pathway analyses confirmed the downregulation of leukocyte migration, MHC class II antigen presentation, and T-cell co-stimulation immunological pathways, such as the CD40 receptor complex pathway. The analysis of placebo SGs transcriptomic at week 48 showed a higher expression of genes linked to ectopic GC organisation in female compared to male subjects. Gender was confirmed as a key co-variate responsible for most of the variation in the PrincipalComponentAnalysis, together with the SG focus score and the *foci* area fraction.

Conclusion: Treatment with RTX showed beneficial effects on labial SG inflammatory infiltration in pSS, by downregulating genes involved in immune cell recruitment, activation and organisation in ectopic GCs. Although a clear association with the clinical improvement in unstimulated salivary flow observed at week 48 in RTX-treated patients could not be established given the low number of patients consenting to 3 longitudinal biopsies it is conceivable that RTX is responsible for preserving exocrine function through the above-described mechanisms.
