description of the lesions, or a skin biopsy if available. In doubtful cases, medical records were reviewed by a dermatologist. Severity of psoriasis was defined based on the body surface area involved, sites involved, and requirement for phototherapy or systemic therapy. Incident psoriasis cases were age-, and sex-matched to subjects from the same population. Diagnosis codes (≥2 codes at least 30 days apart) within a five-year lookback period were used to determine the presence of comorbidities; at least one year of available medical history was required. Comorbidities were defined using 44 categories (England et al. Ann Rheum Dis. 2021). Standardized differences were calculated to examine differences between psoriasis and controls, and between mild and moderate to severe psoriasis subjects.

Results: There were 871 incident cases of psoriasis from 2000-2010. Excluding those with < 1 year of prior medical history, 817 psoriasis patients were analyzed, with a mean age of 45.7(SD=16.9) years and 52% females; severity of psoriasis ranking was available for 681 (83.4%). At incidence, 35.5, 20.2, 12.2, 7.1, 7.3, 15.9, and 1.7% of the psoriasis patients had 0, 1, 2, 3, 4, 5-9, and ≥10 England comorbidities. There was no substantial difference in the prevalence of the comorbidities between newly diagnosed psoriasis patients and controls (Table). Similarly, few comorbidities were meaningfully different (SMD >0.1) among subjects with mild psoriasis at diagnosis compared to those with moderate to severe psoriasis at diagnosis (Table).

Conclusion: In this population-based cohort of incident psoriasis, there were no substantial differences in the prevalence of comorbidities (including cardiometabolic) between newly diagnosed psoriasis and the general population. Comorbidities may develop over the course of psoriatic disease with no apparent differences at psoriasis diagnosis. Further studies to examine the trajectory of comorbidities in this incident psoriasis cohort are planned.

Session Date: Monday, November 8, 2021

Session Title: Spondyloarthritis Including PsA – Diagnosis, Manifestations, & Outcomes III: Comorbidities, Extra-muskuloskeletal Manifestations, & Related Conditions (1304–1328)

Session Type: Poster Session C

Session Time: 8:30AM–10:30AM

Background/Purpose: Obesity is associated with poor response to treatment in patients with psoriatic arthritis (PsA), however, available data are mostly focused on tumor necrosis factor inhibitor (TNFi) initiators with only a few studies that have examined this association with initiators of other therapies. There are even fewer studies with patient reported outcome (PRO) measures as the outcomes of interest in PsA treatment. The clinical Disease Activity Index for

Psoriatic Arthritis (cDAPSA) is a composite measure of disease activity in PsA and the, Routine Assessment of Patient Index Data 3 (RAPID3) and Psoriatic Arthritis Impact of Disease (PsAID) are PROs used in PsA. We examined the association of obesity with change in cDAPSA, RAPID3, PsAID among patients with PsA initiating TNFi, interleukin 17 inhibitors (IL17i) and oral small molecules (OSM).

Methods: Patients with PsA were enrolled in the Psoriatic Arthritis Research Consortium longitudinal cohort study in the US between 2016-2020, initiated therapy with either TNFi, IL17i or OSM and completed at least one follow up visit. Treatment response was assessed by change in cDAPSA, RAPID3, or PsAID. Patients were stratified based on body mass index category (normal weight = BMI 19 to < 25 kg/m^2, overweight = BMI 25 to < 30 kg/m^2, obese = BMI ≥ 30 kg/m^2). Baseline characteristics were reported descriptively. BMI category and its association with change in the outcomes of interest was examined in univariable and age-and-sex adjusted linear regression models.

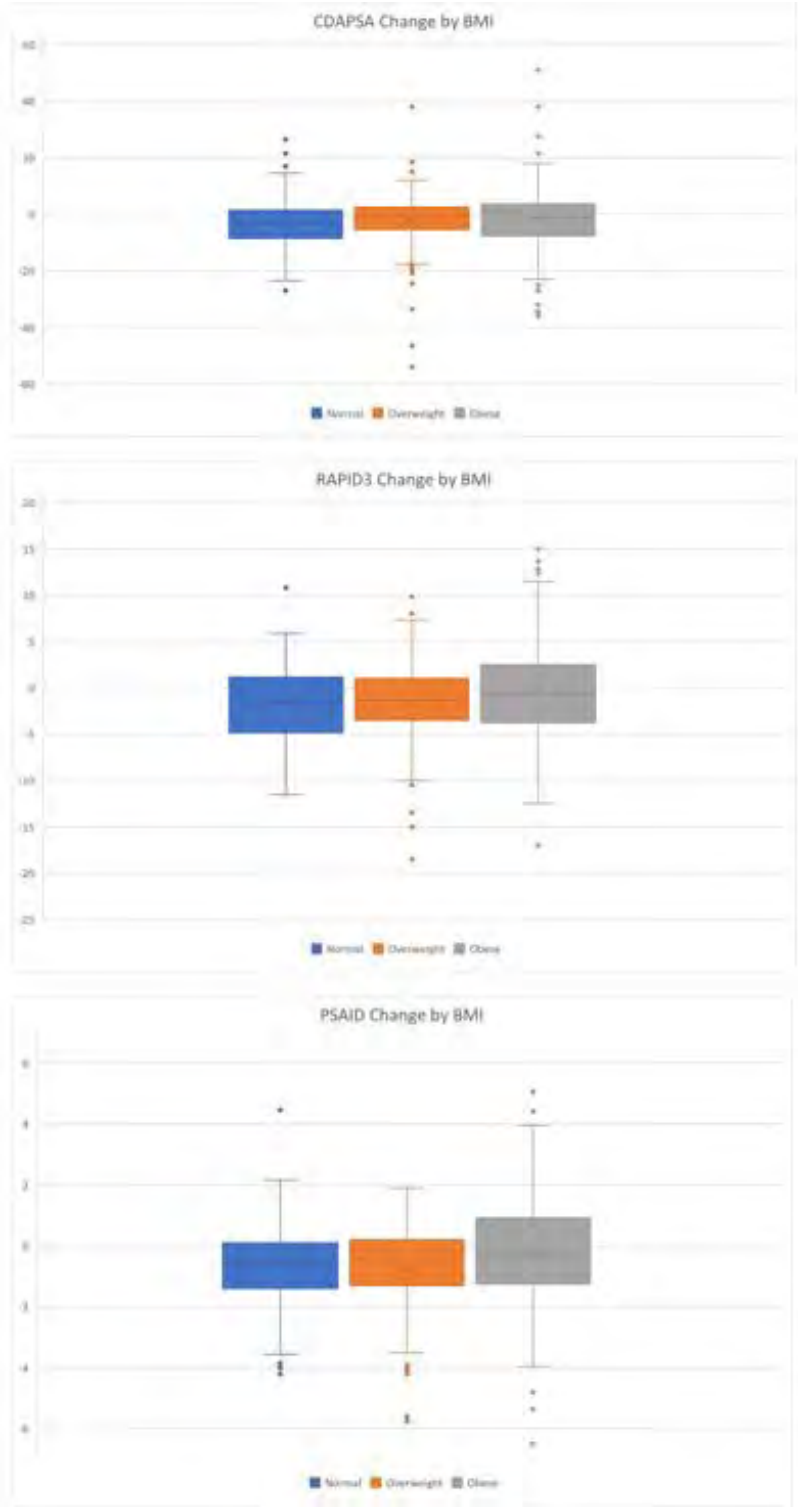

Figure 1. Change in Patient Reported Outcomes by BMI Category. The mean change in cDAPSA was lowest among obese patients (-2.91 (SD 9.56) in normal BMI, -2.29 (SD 11.48) in overweight BMI, and -1.42 (SD 12.33) in obese BMI, p value 0.38). The mean change in RAPID3 was lowest among obese patients (-1.53 (SD 4.50) in normal BMI, -1.69 (SD 4.47) in overweight BMI, and -0.26 (SD 5.46) in obese BMI, p value 0.12). The mean change in PsAID was lowest among obese patients (-0.58 (SD 1.48) in normal weight BMI, -0.72 (SD 1.47) in overweight BMI, and -0.17 (SD 1.98) in obese BMI, p value 0.24).

Table 2. Univariate and Age/Sex Adjusted Linear Regression Analysis. Beta-coefficients are interpreted as the difference in change in the outcome among the overweight group compared to the normal weight group and the obese group compared to the normal weight group. In other words, a beta-coefficient of 1.48 means that the obese group had 1.48 units less improvement than the normal BMI group (as the normal group was negative (improved), the obese group improved less). Abbreviations: TNFi = tumor necrosis factor inhibitor; IL17*i* = interleukin 17 inhibitor; OSM = oral small molecule

Treatment Category	BMI Category	CDAPSA		RAPID3		PSAID

	Overweight (n=16)	0.58 (-8.62-9.79)	1.36 (-8.63-11.34)	-0.10 (-3.34-3.14)	-0.52 (-4.01-2.96)	-0.46 (-1.58-0.67)	-0.54 (-1.77-0.69)
	Obese (n=27)	-1.81 (-10.17-6.55)	-0.64 (-9.95-8.67)	0.65 (-2.29-3.59)	0.35 (-2.90-3.60)	0.46 (-0.56-1.48)	0.39 (-0.76-1.53)
OSM	Normal (n=19)	Ref	Ref	Ref	Ref	Ref	Ref
	Overweight (n=40)	-4.28 (-11.04-2.49)	-4.10 (-10.96-2.76)	-1.74 (-4.21-0.72)	-1.54 (4.01-0.92)	-0.41 (-1.25-0.43)	-0.41 (-1.26-0.44)
	Obese (n=42)	-2.75 (-9.47-3.96)	-2.86 (-9.66-3.94)	-1.02 (-3.47-1.42)	-1.07 (-3.52-1.37)	0.12 (-0.71-0.96)	0.16 (-0.68-1.00)

Results: A total of 310 patients were included in the analysis. The mean age of patients was 52 and 56% were female. At baseline, the mean cDAPSA was 17.3 (SD 12.7), the mean PsAID was 3.6 (SD 2.2), the mean RAPID3 was 10.9 (SD 5.8). Baseline scores were overall similar when stratified by BMI category (**Table 1**). The mean change in cDAPSA was lowest among obese patients (-2.91 (SD 9.56) in normal BMI, -2.29 (SD 11.48) in overweight BMI, and -1.42 (SD 12.33) in obese BMI). The mean change in RAPID3 was lowest among obese patients (-1.53 (SD 4.50) in normal BMI, -1.69 (SD 4.47) in overweight BMI, and -0.26 (SD 5.46) in obese BMI). The mean change in PsAID was lowest among obese patients (-0.58 (SD 1.48) in normal weight BMI, -0.72 (SD 1.47) in overweight BMI, and -0.17 (SD 1.98) in obese BMI) (**Figure 1**). These differences were not statistically significant, potentially due to sample size. In unadjusted and age-and-sex adjusted analyses (**Table 2**), compared to the normal BMI category, obese patients had less improvement in cDAPSA, RAPID3 and PsAID. Similar numerical reduction in improvement was also found in the TNFi initiators although there was not a stepwise decrease in improvement with increasing BMI in IL17*i* nor OSM initiators.

Conclusion: The mean change in the selected outcome measures (cDAPSA, RAPID3, PsAID) was lowest among obese patients compared to the other BMI categories. Interestingly, this pattern was observed primarily among TNFi initiators as opposed to OSM or IL17i initiators.

Assessment of Microvascular Involvement in Psoriatic Arthritis by Nailfold Capillaroscopy

Roba Ghossan[1], Nour Chouman[2], krystel aouad[3], Mouin Jammal[4], Rafic Baddoura[1], Ouidade Aitisha[5], Jad Okais[1] and Fouad Fayad[1], [1]Rheumatology department, Saint-Joseph University, Beirut, Lebanon; Hotel-Dieu de France Hospital, Beirut, Lebanon, [2]Saint-Joseph University, Beirut, Lebanon, Beirut, Lebanon, [3]Sorbonne Université, INSERM, Institut Pierre Louis d'Epidémiologie et de Santé Publique, Paris, France, [4]Internal Medicine and Clinical Immunology department, Saint-Joseph University, Beirut, Lebanon; Hotel-Dieu de France Hospital, Beirut, Lebanon, [5]Rheumatology department, Bellevue Medical Center, Mansourieh, Lebanon

SESSION INFORMATION

Session Date: Monday, November 8, 2021

Session Title: Spondyloarthritis Including PsA – Diagnosis, Manifestations, & Outcomes III: Comorbidities, Extra-muskuloskeletal Manifestations, & Related Conditions (1304–1328)

Session Type: Poster Session C

Session Time: 8:30AM–10:30AM

Background/Purpose: Capillaroscopy has gained increasing importance in the microvascular assessment of rheumatic diseases (1). Increased cardiovascular risk has been observed in psoriatic arthritis (PsA) (2). Recent data suggest microvascular involvement (3). Few studies have analyzed capillaroscopic anomalies in PsA. No specific capillaroscopic pattern has yet been identified (4-6). Conditions that can affect the nail bed vasculature were not always excluded. The objective of this study was to determine capillaroscopic abnormalities in patients with PsA with no cardiovascular risk factors or other conditions that could interfere with nailfold capillaroscopy results.

Methods: We conducted a cross-sectional study on 13 patients diagnosed with PsA according to CASPAR Classification criteria. We excluded all patients with concomitant cardiovascular risk factors or conditions known to alter the nail bed capillaries including concomitant cardiovascular risk factors, coexistent connective tissue disorder, primary or secondary Raynaud's phenomenon, chronic kidney disease, current malignancy, pregnancy or lactation and vasoactive or anticoagulant therapies. Patient characteristics and disease activity score (DAPSA) were collected. Main outcome was the presence of any capillaroscopic abnormality on nailfold capillaroscopy performed by the same physician. Association with disease duration and activity was tested using Chi Square test for categorical variables and Mann-Whitney U test for continuous variables.

Results: Mean (+/-SD) age was 46 years +/- 13.5, mean disease duration 17 years +/- 15.2; 54.0% were men. None of the patients had distal interphalangeal joint involvement, mean DAPSA score was 23.36 +/- 19.5. 70,0% had cutaneous psoriasis and 54.0% had ungual involvement. All patients had capillaroscopic abnormalities (figure 1). The 3 most common findings were: tortuosity (84.6%, mean of 4 tortuous loops for a density of 8 loops/mm), reduced capillary density (50.0%, mean density of 8 +/- 1 loops/mm) and microhaemorrhages (38.5%). Less frequent findings were perivascular oedema (30.8%), ramifications (15.4%), dilated loops (15.4%), and visibility of subpapillary plexus (15.4%). We a small study population, we were unable to document statistical association between capillaroscopic findings and disease duration ($p < 0.4$) or DAPSA ($p < 0.42$).

Conclusion: PsA patients exhibit capillaroscopic abnormalities characterized by the presence of tortuosity, reduced capillary density and microhaemorrhages, independent from potential conditions that may alter the nailfold capillaries. Larger studies are needed to identify specific capillaroscopic patterns in PsA and to reflect on the prognostic value of our findings.

Week 100[a]	-1.9 (-2.1, -1.7)	-2.1 (-2.3, -1.8)	-2.1 (-2.3, -1.9)

[a]Results are LS Mean (95% confidence interval [CI]) change; LS mean change determined by ANCOVA; missing data was imputed as no change for pts who discontinued treatment and using multiple imputation for remaining missing data

patients (pts) with active PsA[1,2], with maintenance of response rates through 1 year.[3,4] Dactylitis and enthesitis, extra-articular manifestations of PsA, can be difficult to treat and cause significant disease burden.[5,6] Here, we evaluated the ability of GUS to provide long-term resolution of dactylitis and enthesitis in pts with PsA through 2 years of D-2.

Methods: D-2 biologic-naïve pts with active PsA were randomized 1:1:1 to GUS 100 mg every 4 weeks (Q4W); GUS 100 mg at W0, W4, Q8W; or placebo (PBO). At W24, PBO pts crossed over to GUS Q4W. Independent assessors evaluated dactylitis (total score: 0-60) and enthesitis (Leeds Enthesitis Index [LEI]; total score 0-6). These post-hoc analyses assessed baseline (BL) frequency and severity of enthesitis in pts with dactylitis and dactylitis frequency in pts with enthesitis. Post-baseline, changes in dactylitis and LEI scores over time (least squares [LS] mean changes; analysis of covariance [ANCOVA]) and rates of resolution of dactylitis and enthesitis (Chi square correlation test) were determined among pts with these manifestations at BL (missing data imputed as no change/response).

Results: At BL, more D-2 pts had enthesitis (68%) than dactylitis (45%). At BL 78% of pts with dactylitis vs 61% without dactylitis had enthesitis and 51% of pts with enthesitis vs 32% without enthesitis had dactylitis. Among pts with enthesitis at BL, a higher percentage of total pts with dactylitis had severe enthesitis with LEI score ≥3 (52%) versus pts without dactylitis (44%) (Table 1). Among those with the condition at BL, rates of resolution of dactylitis (57% [Q4W], 64% [Q8W]) and enthesitis (44% [Q4W], 54% [Q8W]) at W24 increased through W52 (dactylitis, 74% [Q4W], 78% [Q8W]; enthesitis, 57% [Q4W], 61% [Q8W]) and were maintained at W100 (dactylitis, 72% [Q4W], 83% [Q8W]; enthesitis, 62% [Q4W], 70% [Q8W]). Consistent results were observed when evaluating mean changes in dactylitis and LEI scores and also in pts who crossed over from PBO to GUS Q4W at W24 (Table 2). In pts with both dactylitis and enthesitis at BL, GUS-treated pts showed significant correlations between resolution of enthesitis and dactylitis at W24 ($p=0.004$), W52 ($p< 0.001$) and W100 ($p=0.039$), with nearly 90% of pts with enthesitis resolution also achieving dactylitis resolution at W52 and W100 (Figure).

Conclusion: Pts with PsA often present with concurrent enthesitis and dactylitis, both of which can be recalcitrant to treatment. GUS resolved enthesitis and dactylitis in substantial proportions of pts through W100. GUS-treated pts who achieved enthesitis resolution were more likely to achieve dactylitis resolution and vice versa.

SESSION INFORMATION

Session Date: Monday, November 8, 2021

Session Title: Spondyloarthritis Including PsA – Treatment Poster II: Psoriatic Arthritis I (1329–1363)

Session Type: Poster Session C

Session Time: 8:30AM–10:30AM

Background/Purpose: Guselkumab (GUS), a selective IL-23p19 inhibitor, resulted in greater mean improvements in BASDAI scores vs placebo (PBO) at W24 among patients (pts) with active PsA and investigator-confirmed sacroiliitis in pooled post hoc analyses of data from two phase 3 trials, DISCOVER-1&2. Improvements in these symptoms of axial involvement were maintained through 1 year.[1]We aimed to further assess maintenance of GUS effect on symptoms of axial involvement among biologic-naïve PsA pts with investigator-confirmed sacroiliitis through 2 years of DISCOVER-2.

Methods: In this phase 3, double-blind, PBO-controlled study, 739 bio-naïve pts with active PsA (≥5 swollen joints, ≥5 tender joints, CRP ≥0.6mg/dL despite standard therapies) were randomized 1:1:1 and treated with GUS 100 mg every 4 weeks (Q4W; n=245), GUS 100 mg at W0, W4, then Q8W (n=248), or PBO (n=246), with PBOàGUS 100 mg Q4W at W24. Pts identified by the investigator as having axial symptoms and sacroiliitis (prior X-ray or MRI, or pelvic X-ray at screening) were evaluated. Efficacy was assessed by change in BASDAI, modified BASDAI (mBASDAI, excluding Q3 [peripheral joint pain]), and BASDAI Q2 (Spinal Pain) scores and proportions of pts achieving BASDAI 50 response, Spinal Pain score ≤2, and AS Disease Activity Score (ASDAS) responses through W100. Through W24, pts who met treatment failure criteria or had missing data were considered nonresponders or to have no change from baseline. After W24, missing data were imputed as nonresponse for binary endpoints or no change from baseline for

continuous endpoints (nonresponder imputation [NRI]). Axial-related outcomes were also summarized by HLA-B27 status (+/-) among 149 pts with available data.

Results: 246 pts had sacroiliitis confirmed by the investigator. Baseline characteristics were similar across treatment groups (62% male; mean age 44.4 years); mean BASDAI scores ranged from 6.5-6.6. At W24, LSmean/mean changes in BASDAI (-2.4/-2.6) and ASDAS (-1.3/-1.5) scores were greater in GUS than PBO-treated pts. Mean changes from baseline were maintained through W100 in GUS-treated pts for BASDAI (-3.1), Spinal Pain (-3.1), mBASDAI (-3.1), and ASDAS (-1.7) scores. Similar response patterns were observed for BASDAI 50 response rates among GUS-treated pts (W24 38-40%; W100 49-54%). At W24, GUS-treated pts had higher response rates for achievement of ASDAS inactive disease, major improvement, and clinically important improvement vs. PBO; response rates (NRI) were maintained, or in some cases further increased, at 2 years. Consistent results were observed for achievement of ASDAS LDA and Spinal Pain score ≤2 (data not shown). GUS-related improvements in axial symptoms through W100 were generally consistent across pts who were HLA-B27+/- (data not shown).

Conclusion: In bio-naive pts with active PsA and investigator-confirmed sacroiliitis, GUS provided durable improvements in axial symptoms through W100, with substantial proportions of pts achieving and maintaining clinically meaningful improvements.

SESSION INFORMATION

Session Date: Monday, November 8, 2021

Session Title: Spondyloarthritis Including PsA – Treatment Poster II: Psoriatic Arthritis I (1329–1363)

Session Type: Poster Session C

Session Time: 8:30AM–10:30AM

Background/Purpose: Anemia related to systemic inflammation can be an important feature of psoriatic arthritis (PsA). Hemoglobin (Hgb) levels have been shown to be inversely related to disease activity in other rheumatic diseases.[1,2] This post hoc analysis assessed the effect of guselkumab (GUS), a selective IL-23p19 inhibitor, on anemia in the pooled Phase 3 DISCOVER-1 & -2 trials.

Methods: 1120 patients (pts) with active PsA, biologic naïve (except ~30% of DISCOVER-1 pts who had received 1-2 TNF inhibitors), were randomized and treated with SC GUS 100 mg every 4 weeks (Q4W); GUS 100 mg at W0, W4, Q8W; or placebo (PBO, with crossover to GUS 100 mg Q4W at W24). Treatment was given for 1 yr (DISCOVER-1) or 2 yrs (DISCOVER-2). Mean Hgb levels and number (%) of pts with anemia (Hgb < 13.5 g/dL males [M]; < 12.0 g/dL females [F]) were assessed by treatment group through 1 yr. A logistic regression model estimated odds ratios (ORs) and 95% CI for achieving anemia resolution (i.e., anemia at baseline [BL] but not W24). The binary endpoint was anemia responder status at W24 (Y/N); predictors examined included age, sex, swollen/tender joint count, and C-reactive protein (CRP).

Results: The analyses included 1074 pts (96% of pooled study population; 564 M and 510 F). At BL, ~24% of M (N=136) and F (N=120) pts were anemic. Pts with anemia at BL had, on average, more swollen & tender joints, systemic inflammation (CRP), and fatigue (assessed via Functional Assessment of Chronic Illness Therapy-Fatigue [FACIT-F] score) than pts without anemia (Table). For both GUS treatment groups, mean Hgb levels increased from BL through W52 for M and F, particularly among pts who were anemic at BL (Fig 1). For PBO pts, mean Hgb levels were unchanged from BL through W24; however, following PBO®GUS switch at W24, they increased to levels similar to GUS-randomized pts at W52 (Fig 1). Consistently, the proportions of M and F meeting criteria for anemia decreased over time (Fig 2), with M exhibiting a more rapid response (data not shown). Pts with anemia at BL but not at W24 (anemia resolution) comprised more M and had shorter duration of PsA and lower CRP levels at BL than pts with unresolved anemia at W24 (Table). Logistic regression analyses confirmed that F (OR [95% CI]: 0.37 [0.21, 0.65]) and pts with higher BL CRP levels (0.53 [0.41,0.69]) were significantly less likely to achieve anemia resolution at W24 than M and pts with lower BL CRP, respectively. Importantly, pts with anemia resolution (N=112) appeared to exhibit better outcomes at W24 than pts with unresolved anemia (N=136), with numerically fewer mean (SD) swollen (4.8 [6.76] vs 6.2 [8.01]) and tender (10.7 [11.07] vs 12.5 (11.89]) joints, less systemic inflammation (CRP 0.8 [0.92] vs 2.3 [2.73]), and less fatigue (FACIT-F 37.4 [10.60] vs 33.0 [10.45]).

Conclusion: In both M and F pts with active PsA, GUS treatment through 1 yr increased Hgb levels and lessened the prevalence of anemia. Anemia resolution with GUS use, which was more likely in M and pts with lower CRP levels at BL, was associated with improved clinical status relative to pts with persistent anemia.

Session Type: Poster Session C
Session Time: 8:30AM–10:30AM

Background/Purpose: It is important to assess symptoms of pain, fatigue, anxiety, depression, sleep disturbance, and impaired physical function in patients (pts) with psoriatic arthritis (PsA), as these symptoms are common and can negatively affect health-related quality of life (HRQoL).[1] The Patient-Reported Outcomes Measurement Information System-29 (PROMIS-29) Profile is a generic health outcomes instrument that is validated in several general and disease-specific populations[2] but not in PsA. Here we validate PROMIS-29 Profile psychometric properties using data from the global DISCOVER-1 Phase 3 study of guselkumab vs placebo in 381 pts with active PsA (≥3 swollen & ≥3 tender joints; C-reactive protein ≥0.3 mg/dL; 31% had prior TNF inhibitor exposure) and inadequate response to standard therapies.

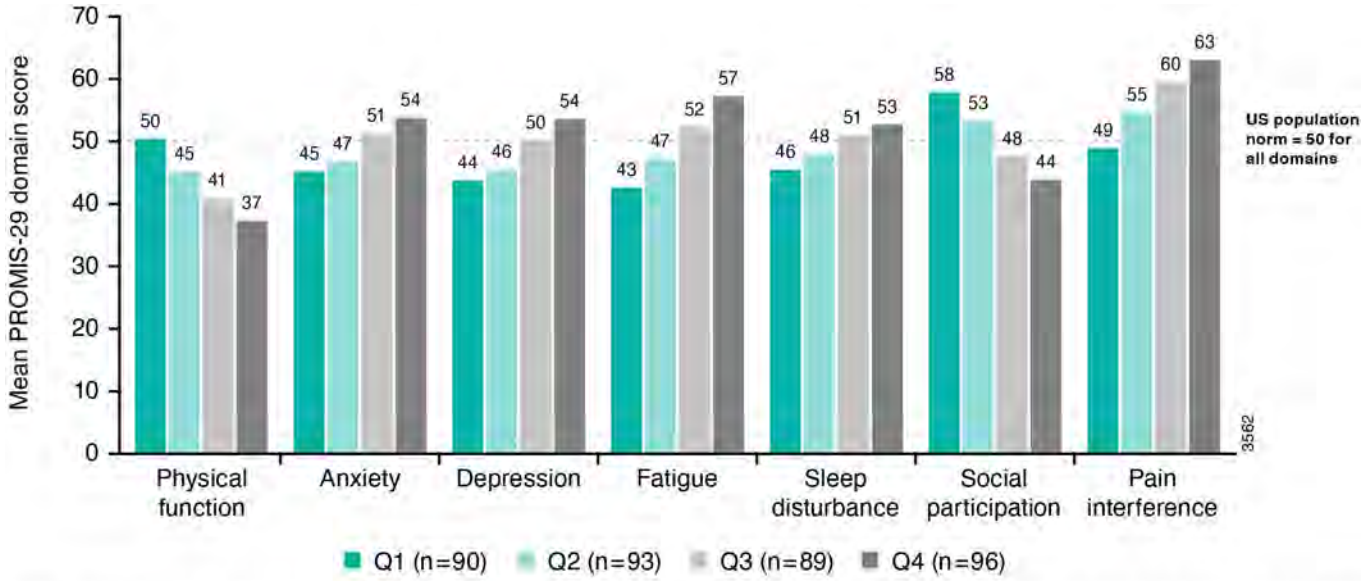
Methods: The PROMIS-29 Profile contains 4 items for each of 7 domains (physical function, anxiety, depression, fatigue, sleep disturbance, social participation, pain interference; 28 items scored on 5-point Likert scale) and 1 pain intensity item (0-10 visual analog scale). Raw scores are converted to standard T-scores, with norms based on a general US population mean=50 and SD=10; changes ≥5 points are considered clinically meaningful. PROMIS-29 validation assessments included convergent and discriminant analyses based on Spearman's correlation (r_s) with 36-item Short Form Health Survey (SF-36) domain scores (r_s < 0.4=weak, 0.4-< 0.6=moderate, 0.6-1.0=strong correlation); known-groups validity of mean T-scores by the anchor variable of Patient Global Assessment Disease (PGAD) quartile scores at Week (W) 24; and test-retest reliability based on intra-class correlation (ICC) between PROMIS-29 scores at baseline/W16/W24 in pts with stable (change within ±10) PGAD (ICC ≥0.7=acceptable). Analyses were conducted using observed data, combining pts across treatment groups.

Results: The strongest correlations (r_s >0.8) between PROMIS-29 and SF-36 domains were observed for concepts that are similar for both instruments (eg, pain interference and pain intensity vs bodily pain; physical function vs physical function; fatigue vs vitality); correlations were weak (r_s < 0.4) for dissimilar domains (Table 1). Mean T-scores across subgroups defined by PGAD quartiles at W24 were significantly different for all PROMIS-29 domains, indicating known-groups validity (Figure). ICCs of test-retest reliability in pts with stable (change within ±10) PGAD at W16

Table 1. Spearman's correlation between PROMIS-29 domains and SF-36 subdomains and component scores

	SF-36 subdomains†								Component scores†	
PROMIS-29 domains*,†	Physical function	Vitality	Bodily pain	Role-physical	Social function	Mental health	Role-emotional	General health	PCS	MCS
Physical function‡	**0.88**	0.66	0.77	0.78	0.67	0.46	0.48	0.55	**0.85**	0.39
Fatigue**	-0.62	**-0.83**	-0.67	-0.67	-0.75	-0.68	-0.57	-0.57	-0.60	-0.68
Pain interference**	-0.79	-0.73	**-0.86**	-0.80	-0.73	-0.55	-0.50	-0.59	**-0.83**	-0.49
Pain intensity**	-0.72	-0.65	**-0.85**	-0.69	-0.59	-0.46	-0.45	-0.55	-0.78	-0.39
Social participation‡	0.72	0.76	0.73	0.76	0.78	0.60	0.58	0.60	0.72	0.59
Anxiety**	-0.33	-0.52	-0.40	-0.40	-0.56	-0.71	-0.66	-0.40	-0.23	-0.72
Depression**	-0.40	-0.59	-0.48	-0.48	-0.62	-0.72	-0.66	-0.49	-0.33	-0.74
Sleep disturbance**	-0.39	-0.61	-0.43	-0.43	-0.47	-0.61	-0.47	-0.42	-0.34	-0.58

*p<0.0001 for all correlations.
†For SF-36, higher score represents better health. For PROMIS-29, higher scores in anxiety, depression, fatigue, sleep disturbance, and pain interference indicate more severe symptoms; higher physical function and social participation scores indicate better health outcomes.
‡Positive values indicate correlations between improvements in each SF-36 subdomain and improved physical function and social participation, respectively, on the PROMIS-29.
**Negative values indicate correlations between improvements in each SF-36 subdomain and less anxiety, depression, fatigue, sleep disturbance, pain interference, and pain intensity, respectively, on the PROMIS-29.
Green=strong correlations (r_s=0.6-1.0); yellow=moderate correlation (r_s=0.4-<0.6); red=weak correlation (r_s<0.4). **Bold**=strongest correlations (r_s=>0.8).
MCS=mental component summary; PCS=physical component summary.



p<0.0001 for all PROMIS-29 domains vs PGAD quartile, indicating lower PGAD scores were associated with better physical function and social participation, and less anxiety, depression, fatigue, sleep disturbance, and pain interference.
PROMIS-29: Lower scores in anxiety, depression, fatigue, pain interference, and sleep disturbance indicate less severe symptoms; higher scores in physical function and social participation indicate better health outcomes. Mean general US population norm score=50 for all domains.
PGAD: 0-100 mm VAS scored from left (excellent) to right (poor); Q1, 0 to ≤18; Q2, 19 to ≤39; Q3, 40 to ≤62; Q4, 63 to 100. Higher PGAD quartiles represent greater disease activity or a worse state of global health.

Figure. Mean PROMIS-29 Domain T-Scores by PGAD Quartile at W24.

Table 2. Test-retest reliability among pts with stable PGAD (change within ±10 points) over time

	Stable PGAD from baseline to W16 (n=108)			Stable PGAD from baseline to W24 (n=100)		
Mean (SD) PROMIS-29 T-scores	**Baseline**	**W16**	**ICC (95% CI)**	**Baseline**	**W24**	**ICC (95% CI)**
Physical function	39.9 (6.8)	39.8 (6.6)	0.85 (0.79, 0.89)	40.6 (7.2)	40.3 (7.5)	0.83 (0.75, 0.88)
Anxiety	50.7 (9.1)	50.4 (8.9)	0.66 (0.55, 0.76)	52.3 (9.8)	52.7 (10.4)	0.66 (0.54, 0.76)
Depression	49.7 (8.4)	50.1 (8.4)	0.73 (0.63, 0.81)	51.0 (9.0)	52.1 (9.6)	0.68 (0.56, 0.77)
Fatigue	53.3 (9.5)	52.3 (9.3)	0.79 (0.71, 0.85)	54.0 (9.9)	54.5 (11.1)	0.75 (0.65, 0.82)
Sleep disturbance	51.5 (6.9)	50.1 (7.8)	0.68 (0.58, 0.78)	53.6 (7.0)	52.2 (8.1)	0.70 (0.60, 0.79)
Social participation	47.1 (8.7)	47.6 (8.1)	0.62 (0.50, 0.73)	47.0 (8.3)	46.5 (8.3)	0.67 (0.55, 0.77)
Pain interference	60.8 (6.2)	59.9 (6.4)	0.83 (0.77, 0.88)	60.7 (6.8)	60.4 (7.1)	0.84 (0.78, 0.89)
Pain intensity (0-10 VAS)	6.17 (1.8)	6.01 (1.9)	0.79 (0.71, 0.85)	6.21 (1.9)	6.08 (2.0)	0.75 (0.66, 0.83)

Intra-class correlation ≥0.7=acceptable.
CI, confidence interval; VAS, visual analog scale.

and W24 were generally ≥0.7, indicating PROMIS-29 results are reproducible when no change has occurred (Table 2). Mean (SD) PROMIS-29 T-score changes from baseline to W24 were sensitive to PGAD changes in disease severity. In pts with PGAD improvements of 21-30 and 31-40 points, respectively, absolute mean changes across PROMIS-29 domains ranged from 2.7 (anxiety) to 5.4 (pain interference) and 3.1 (sleep disturbance) to 6.6 (pain interference), respectively, from baseline to W24.

Conclusion: This analysis confirms the reliability and validity of the PROMIS-29 Profile to assess HRQoL in pts with active PsA, as well as the responsiveness of this instrument for detecting change.

SESSION INFORMATION

Session Date: Monday, November 8, 2021

Session Title: Spondyloarthritis Including PsA – Treatment Poster II: Psoriatic Arthritis I (1329–1363)

Session Type: Poster Session C

Session Time: 8:30AM–10:30AM

Background/Purpose: Guselkumab (GUS), a targeted inhibitor of IL-23p19, demonstrated significant efficacy v placebo (PBO) in achieving ACR20 response at week (W) 24 in patients (pts) with active PsA in 2 Phase 3 trials, DISCOVER-1 & 2.[1,2] Pts with PsA report pain relief as a priority for treatment.[3] We conducted post hoc analyses to further assess GUS effect on pt-reported pain across outcome measures and maintenance of pain relief with up to 2 years (yr) of GUS.

Methods: DISCOVER-1 (1 yr) included 381 pts with active PsA despite standard therapies, including 1-2 TNF inhibitors in 31% of pts. DISCOVER-2 (2 yr) included 739 biologic-naïve pts with active PsA. In both studies, pts were randomized (1:1:1) to GUS 100 mg every 4 weeks (Q4W); GUS 100 mg at W0, W4, then Q8W; or PBO with crossover to GUS 100 mg Q4W at W24 (PBO→Q4W). Pts rated pain using a 0-10 VAS (Pt Pain) as part of ACR, Disease Activity in Psoriatic Arthritis, and Minimal Disease Activity response criteria and reported Bodily Pain intensity over the past 4 W via the 36-Item Short-Form Health Survey (SF-36) question 21 (0-5). Pts with spondylitis and peripheral arthritis at

ACR=American College of Rheumatology; BASDAI=Bath Ankylosing Spondylitis Disease Activity Index; DAPSA=Disease Activity in Psoriatic Arthritis; GUS=guselkumab; MDA=minimal disease activity; PBO=placebo; pt=patient; Q=question; QxW=every x weeks; SD=standard deviation; SF-36=36-Item Short-Form Survey; SJC=swollen joint count; TJC=tender joint count; VAS=visual analog scale; W=week

*ACR, DAPSA, MDA: VAS 0-10; †BASDAI: VAS 0-10

baseline (BL) rated their Spinal and Joint Pain (0-10) as part of BASDAI. Pain data were evaluated for observed mean change, percent improvement from BL, and proportion of pts achieving ≥20% or ≥50% improvement in Pt Pain (non-responder imputation [NRI]). Percent improvement from BL in tender (TJC; 0-68) and swollen (SJC; 0-66) joint counts, determined by independent assessors, was determined to evaluate consistency of improvements in pt-reported v physician-derived pain measures.

Results: In DISCOVER-2, mean BL Bodily Pain (range across groups: 4.4-4.5), Pt Pain (6.2-6.3), Spinal Pain (6.5-6.7), Joint Pain (6.3-6.8), SJC (11.7-12.9) & TJC (19.8-22.4) indicated moderate pain and disease activity at study outset. GUS-treated pts reported ~2x the improvement in Pt Pain, Spinal Pain, Joint Pain & Bodily Pain intensity at W24 v PBO; GUS improvements were maintained or further increased at W52 & W100. PBO→Q4W pts had similar improvements in pain as GUS-randomized pts (Table 1, Figure). Pt-reported pain appeared more sensitive to treatment effect, with larger differences in percent improvement v PBO, than physician-reported TJC/SJC at W24 (Figure); further research is warranted. While patterns were consistent, pain improved to a lesser degree than TJC/SJC, suggesting other causative factors. Consistent results were seen in DISCOVER-1 through 1 yr (data not shown). Among 748 GUS-treated pts across DISCOVER-1 & 2, substantial proportions achieved meaningful improvement in Pt Pain at early time points: 32% (W4) and 48% (W8) achieved ≥20% improvement; 28% (W12) and 33% (W16) achieved ≥50% improvement. At W24, 63% and 39% reported ≥20% and ≥50% pain improvement (Table 2).

Conclusion: GUS provided consistent and durable improvements in pt-reported pain across several measures. Pt-reported pain as an early and sensitive indicator of treatment effect in pts with active PsA and other factors underlying pain merit further evaluation.

SESSION INFORMATION

Session Date: Monday, November 8, 2021

Session Title: Spondyloarthritis Including PsA – Treatment Poster II: Psoriatic Arthritis I (1329–1363)

Session Type: Poster Session C

Session Time: 8:30AM–10:30AM

Background/Purpose: Gender disparities in PsA can affect natural course of disease, clinical presentation and response to medication[1]. The German non-interventional study AQUILA provides real-world data on the influence of gender of patients with psoriatic arthritis (PsA) on therapeutic effectiveness and retention rate under treatment with secukinumab, a fully human monoclonal antibody that selectively inhibits interleukin-17A.The aim of this interim analysis is to describe selected baseline (BL) demographics, to evaluate secukinumab treatment outcomes on disease activity, depressive mood and retention rate depending on the gender of PsA patients.

Methods: AQUILA is an ongoing, multi-center study including more than 3000 patients with active PsA or ankylosing spondylitis. Patients were observed from BL up to week (w) 52. Real-world data was assessed prospectively and analyzed as observed. Data was collected on impact of disease (Psoriatic Arthritis Impact of Disease - 12 items, PsAID-12 score), skin disease activity (Psoriasis Area and Severity Index, PASI), joint counts and severity of depressive mood (Beck´s Depression Inventory version II, BDI-II), in addition to patient´s global assessment (PGA). Moreo-

Table 1. Overview of baseline characteristics in PsA patients depending on gender

Age, years	51.9 (11.6)	53.1 (11.2)
BMI, kg/m²	29.1 (4.9)	29.0 (6.4)
BMI >25 to ≤30 kg/m², n (%)	219 (42.8)	211 (29.5)
BMI >30 kg/m², n (%)	188 (36.7)	285 (39.8)
Smoker, n (%)	103 (19.4)	196 (26.2)
PsAID-12	4.8 (2.2)	5.3 (2.2)
PGA	4.9 (2.6)	5.6 (2.4)
PASI	6.8 (9.8)	7.0 (11.1)
Tender joint counts	6.8 (7.9)	7.3 (7.4)
Swollen joint counts	3.7 (5.3)	3.7 (5.0)
BDI-II	10.2 (8.8)	13.0 (9.4)
Medication prior to secukinumab initiation, n (%):		
NSAID	290 (54.6)	467 (62.5)
csDMARD	460 (86.6)	678 (90.8)
b-bsDMARD	299 (56.3)	477 (63.9)
*variables given as mean (SD)		

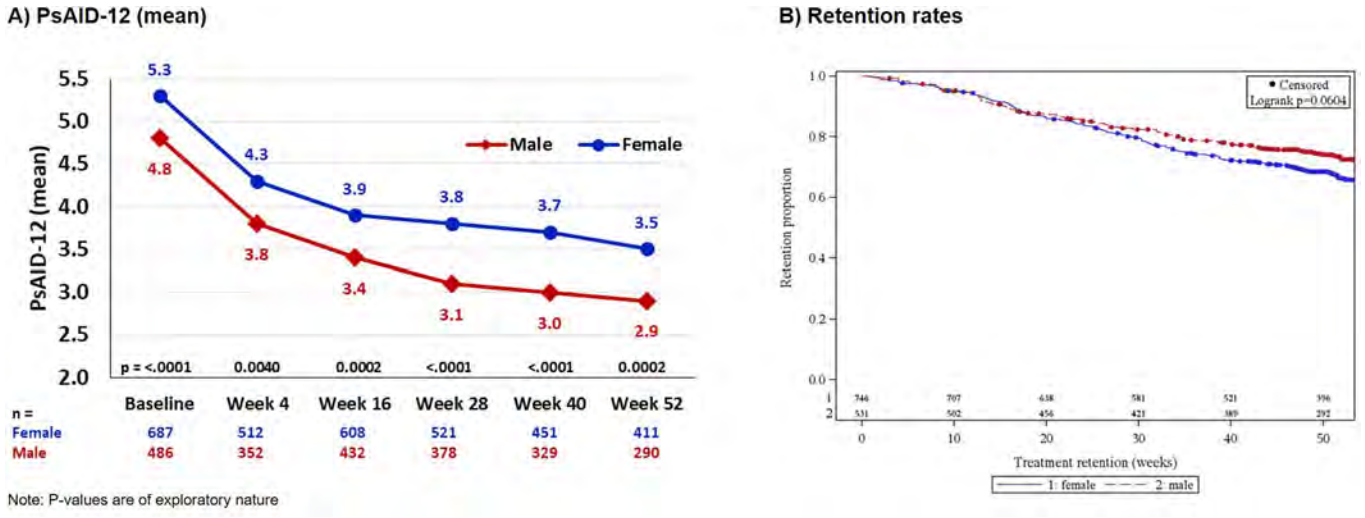

Figure 1. Impact of disease and treatment retention in PsA patients stratified by gender.

ver, retention rates (time from study inclusion until premature secukinumab treatment discontinuation) were assessed through Kaplan-Meier plots. This interim analysis focuses on the subgroups of male and female PsA patients.

Results: At BL, 1278 PsA patients were included: 41.5% (n=531) male and 58.5% (n=747) female. Demographic data (Table 1) of male and female PsA patients differed most obviously regarding proportion of overweight patients, smokers, pretreatment with nonsteroidal anti-inflammatory drugs (NSAIDs) and biologicals/biosimilars (b-bsDMARDs).

Mean PsAID-12 values over time were higher in women; nevertheless, PsAID-12 improved comparably for both genders from BL to week 52 (♂: 4.8 at BL to 2.9 at w52, ♀: 5.3 at BL to 3.5 at w52, Figure 1A). This was similar to the course of improvements for mean PGA across genders (♂: 4.9 at BL to 3.0 at w52, ♀: 5.6 at BL to 3.5 at w52). In terms of PASI scores, both BL mean values and improvements over time were similar across genders (♂: 6.8 at BL to 1.9 at w52, ♀: 7.0 at BL to 1.0 at w52). Mean joint counts (tender/swollen) also improved similarly (♂: 6.8/3.7 at BL to 3.1/0.9 at w52, ♀: 7.3/3.7 at BL to 2.8/0.9 at w52). Over time, male patients showed overall reduced BDI-II values;

nevertheless, BDI-II reductions were comparable across the genders (♂: 10.2 at BL to 8.1 at w52, ♀: 13.0 at BL to 10.6 at w52). Secukinumab treatment retention rate for men was (not significantly) higher than for women (Figure 1B).

Conclusion: In a real-world setting, secukinumab improved disease activity and depressive mood of PsA patients in both men and women. Women showed overall higher burden of disease. Altogether, this interim analysis shows that secukinumab is an effective treatment up to 52 weeks with high treatment retention rates in real-world setting, irrespective of gender.

SESSION INFORMATION

Session Date: Monday, November 8, 2021

Session Title: Spondyloarthritis Including PsA – Treatment Poster II: Psoriatic Arthritis I (1329–1363)

Session Type: Poster Session C

Session Time: 8:30AM–10:30AM

Background/Purpose: Guselkumab (GUS) is a human monoclonal antibody specific to the p19-subunit of interleukin-23. GUS significantly improved signs and symptoms of PsA through Week 24, and improvements were maintained through Week 52 in the phase 3 DISCOVER-1[1] and DISCOVER-2[2] studies. This study assessed GUS efficacy through Week 52 in DISCOVER-1&-2 using composite indices.

Methods: Adult patients enrolled had active PsA despite standard therapies. Patients in DISCOVER-1 had ≥3 swollen and ≥3 tender joints and C-reactive protein (CRP) ≥0.3 mg/dL; in DISCOVER-2, patients had ≥5 swollen and ≥5 tender joints and CRP ≥0.6 mg/dL. 31% of DISCOVER-1 patients received 1-2 prior tumor necrosis factor inhibitors; DISCOVER-2 patients were biologic-naïve. Patients were randomized 1:1:1 to GUS 100 mg every 4 weeks (Q4W); GUS 100 mg at Week 0, Week 4, then every 8 weeks (Q8W); or placebo (PBO); PBO patients crossed over to GUS 100 mg Q4W at Week 24. Composite endpoints pooled across the two studies were: Disease Activity Index for Pso-

Table. Pooled response rates for DISCOVER-1 and DISCOVER-2 randomized and treated patients.

	DISCOVER-1&2		
	GUS Q4W	GUS Q8W	PBO --> GUS Q4W[1]
Randomized and treated patients, n	373	375	372
PASDAS[2] LDA			
Wk 24	27.9%**	30.1%**	8.9%
Wk 52	45.3%	41.9%	36.8%
MDA[3]			
Wk 24	22.8%**	24.3%**	7.8%
Wk 52	35.9%	30.7%	28.2%
DAPSA[4] Remission			
Wk 24	10.2%**	8.3%**	2.2%
Wk 52	18.2%	17.6%	11.0%
VLDA[3]			
Wk 24	27.9%**	30.1%**	8.9%
Wk 52	45.3%	41.9%	36.8%

Data reported as proportions of patients, %. Unadjusted p values at Wk24 vs PBO: *p<0.05; **p<0.001.

[1] Patients randomized to PBO crossed over to GUS Q4W at Wk24.

[2] PASDAS is derived from Pt global assessment of arthritis and psoriasis (0-100), Physician global assessment (0-100), swollen joint count (0-66), tender joint count (0-68), CRP (mg/L), Leeds enthesitis index score, tender dactylitis count, and the 36-item Short-Form Health Survey Physical Component Summary score. PASDAS LDA ≤3.2.

[3] MDA is 5/7 criteria met; VLDA is 7/7 criteria met: tender joint count ≤1, swollen joint count ≤1, Psoriasis Activity and Severity Index ≤1, Pt assessment of pain ≤15 (0-100), Pt global assessment of disease activity ≤20 (0-100), Health Assessment Questionnaire-Disability Index score ≤0.5, Tender entheseal points ≤1.

[4] DAPSA Remission: score ≤4 (definition in figure legend).

CRP, C-reactive protein; DAPSA, Disease Activity Index for Psoriatic Arthritis; GUS, guselkumab; MDA, Minimal Disease Activity; PASDAS, Psoriatic Arthritis Disease Activity Score; PBO, placebo; Pt, patient; Q4W, every 4 weeks; Q8W, every 8 weeks; VLDA, Very Low Disease Activity; Wk, week.

riatic Arthritis (DAPSA), Psoriatic Arthritis Disease Activity Score (PASDAS), Minimal Disease Activity (MDA), and Very Low Disease Activity (VLDA). GUS versus PBO comparisons through Week 24 employed a Cochran-Mantel-Haenszel test with baseline stratification factors or Fisher's exact test; no treatment group comparisons were performed beyond Week 24. P-values were not adjusted for multiplicity. From Week 24 -Week 52, patients with missing data were considered nonresponders (>90% of patients completed study treatment through Week 52).

Results: In randomized and treated patients from DISCOVER-1 (N=381) and DISCOVER-2 (N=739), pooled baseline characteristics were generally well-balanced across treatment groups and reflected active disease. Differences in response rates between GUS Q4W or Q8W and PBO were seen as early as Week 8 and increased over time through Week 24. In patients continuing GUS Q4W or Q8W, respectively, post-Week 24 response rates associated with these composite indices continued to increase through Week 52, at which time they were 54.2% and 52.5% for DAPSA LDA, 45.3% and 41.9% for PASDAS LDA, 35.9% and 30.7% for MDA, 18.2% and 17.6% for DAPSA remission, and 13.1% and 14.4% for VLDA, with no discernable difference between the GUS Q4W and Q8W dosing regimens (Table and Fig). After PBO patients crossed over to GUS Q4W at Week 24, response rates increased through Week 52.

Conclusion: GUS 100 mg Q4W and Q8W provided robust and sustained benefits to patients with active PsA across multiple domains, indicating that GUS may provide an alternative treatment option for the diverse manifestations of PsA.

SESSION INFORMATION

Session Date: Monday, November 8, 2021

Session Title: Spondyloarthritis Including PsA – Treatment Poster II: Psoriatic Arthritis I (1329–1363)

Session Type: Poster Session C

Session Time: 8:30AM–10:30AM

Background/Purpose: Guselkumab (GUS), an anti-IL-23p19-subunit mAb dosed every 4 or 8 weeks (Q4W or Q8W), demonstrated efficacy for joint and skin symptoms, inhibition of structural damage progression (Q4W), and safety vs placebo (PBO) through Week (W) 24 of phase 3, double-blind, PBO-controlled trial in biologic-naïve patients with PsA (DISCOVER-2).[1] Favorable benefit-risk was also seen through 1 year.[2] This study assessed GUS efficacy and safety through 2 years.

Methods: Biologic-naïve adults with active PsA (≥5 swollen joint count [SJC] + ≥5 tender joint count [TJC]; CRP ≥0.6 mg/dL) were randomized (1:1:1) to GUS 100 mg Q4W; GUS 100 mg at W0, W4, Q8W; or PBO with crossover to GUS 100 mg Q4W (PBO→Q4W) at W24. Clinical efficacy (ACR/PASI/IGA/HAQ-DI) was assessed in the modified intention to treat (mITT) population through W100 with missing data imputation (nonresponse for categorical endpoints; no change/multiple imputation for continuous endpoints). Observed PsA-modified van der Heijde Sharp (vdH-S) scores derived from blinded radiographic images collected at W0, W24, W52, W100 (or at discontinuation [d/c]) and adverse events (AEs) through W112 were collected.

Table: Efficacy Through W100 (NRI)

Data are %	GUS Q4W			GUS Q8W			PBO→GUS Q4W

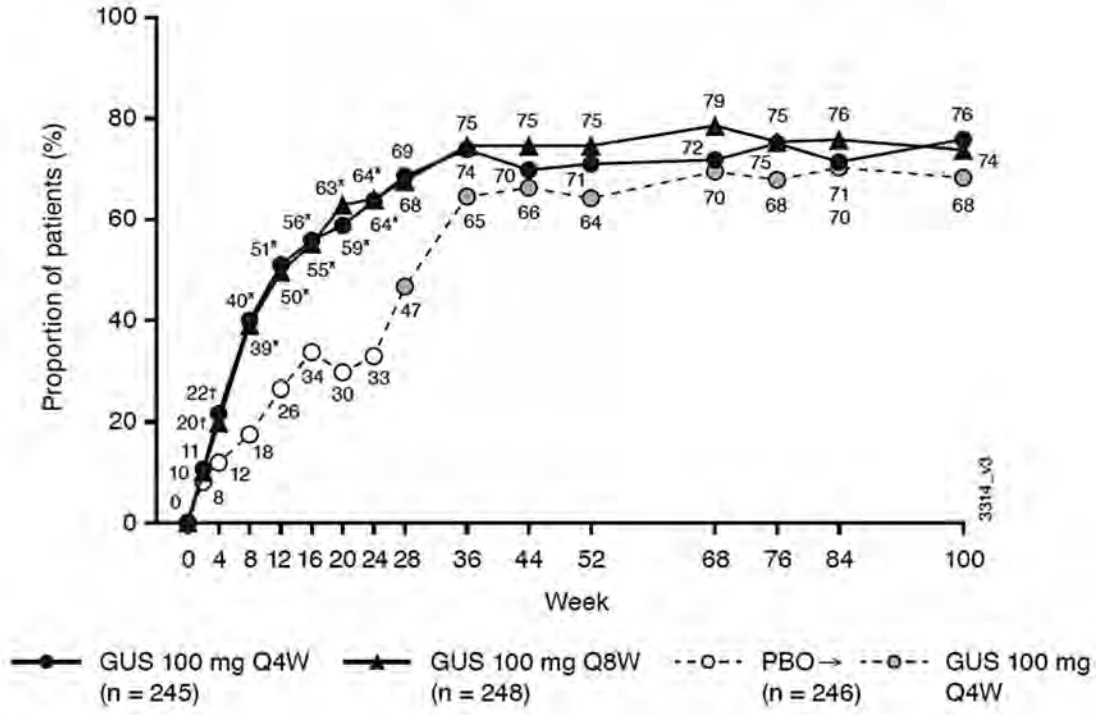
PASI100	45	58	59	46	53	53	3	52	61

[a]≥0.35 improvement among patients with HAQ-DI ≥0.35 at baseline

ACR, American College of Rheumatology; BL, Baseline; BSA, body surface area; GUS, guselkumab; HAQ-DI, Health Assessment Questionnaire Disability Index; IGA, Investigator Global Assessment; NRI, nonresponder imputation; PASI, Psoriasis Area and Severity Index; PBO, placebo; Q4W, every 4 weeks; Q8W, every 8 weeks; W, week.

Figure. ACR 20 Response Through W100 (NRI)
(Note: Patients randomized to PBO crossed over to GUS 100 mg Q4W at W24)



*p ≤ 0.001; †p < 0.05

ACR, American College of Rheumatology; GUS, guselkumab; NRI, nonresponder imputation; PBO, placebo; Q4W, every 4 weeks; Q8W, every 8 weeks; W, week.

Results: 712/739 (96%) randomized patients continued study agent at W24; 687/739 (93%) continued at W52; 652/739 (88%) completed W100. ACR20 response rates in the mITT population continued to increase after W24, and at W100 were 76% for Q4W and 74% for Q8W (Fig). Similar response patterns were seen for ACR50/70, HAQ-DI and PASI90/100 (Table), and IGA0/1 and PASI75 response rates were consistent through W100 in patients randomized to Q4W and Q8W; W100 data for PBO→Q4W patients were consistent with patients treated with Q4W and Q8W (Table). GUS improvements in SF-36 PCS/MCS at W52 also persisted through W100 (data not shown). Low rates of radiographic progression (as measured by PsA-modified vdH-S scores) were observed during W52-W100 for Q4W (n=227; 0.75) and Q8W (n=232; 0.46). In the PBO→Q4W group (n=228), radiographic progression was 1.12 during W0-W24 (while on PBO), 0.51 during W24-W100 (while on Q4W), and 0.13 during W52-W100. Through W112, the incidences of AEs, serious AEs (SAEs), AEs leading to d/c, infections, serious infections, and injection site reactions were generally consistent with the PBO-controlled period and through 1 year. Of the patients in Q4W (n=245), Q8W (n=248), and PBO→Q4W (n=238) groups, 9%, 9% and 7% had ≥1 SAE; 2%, 3% and 3% had ≥1 serious infection; 2 Q8W patients (fungal esophagitis, disseminated herpes zoster) and 1 PBO→Q4W patient (listeria meningitis) had opportunistic infections; 1 PBO→Q4W patient died (road traffic accident); 1 PBO-randomized patient had IBD; no patient had anaphylactic or serum sickness reaction, or active TB.

Conclusion: In biologic-naïve PsA patients, GUS improvements in joint and skin symptoms, physical function, and low rates of radiographic progression persisted through 2 years. GUS safety in PsA through 2 years was comparable with safety at 6 months and 1 year, similar between Q4W and Q8W, and consistent with GUS safety in psoriasis.

SESSION INFORMATION

Session Date: Monday, November 8, 2021
Session Title: Spondyloarthritis Including PsA – Treatment Poster II: Psoriatic Arthritis I (1329–1363)
Session Type: Poster Session C
Session Time: 8:30AM–10:30AM

Background/Purpose: Psoriasis and PsA are associated with multiple comorbidities such as cardiovascular disease and metabolic syndrome. These comorbidities may render patients prone to developing adverse events (AEs) during treatment. In contrast to randomized controlled trials (RCT), patients with comorbidities frequently receive biologic treatment in real life, and long-term safety profiles may differ from RCT findings. Here, we analyze the long-term safety of biologic treatments from the real-world PsABio study, including the influence of baseline comorbidities on treatment effects.

Methods: PsABio (NCT02627768) was a multinational, observational study in patients with PsA prescribed either ustekinumab (UST, an IL-12/23 inhibitor) or a TNF inhibitor (TNFi) as 1st, 2nd or 3rd line treatment. The safety set included all patients with baseline and any available follow-up data. The frequency of new AEs or aggravation of existing comorbidities was analyzed during 6-monthly follow-up periods until study end at a maximum of 3 years (36 ± 3 months) of follow-up. AEs were summarized for all treatments that started prior to the AE and included events that occurred within a 91-day period (risk window) after treatment stop. All neoplasm events, excluding the ones occurring within 12 months of treatment start, are included irrespective of when they occurred after treatment stop.

Results: Safety data exist for 494 patients treated with UST and 557 treated with TNFi during the 36-month study period (this includes patients who switched from one treatment to the other). Baseline characteristics, treatment data and comorbidities are presented in **Table 1**. The UST group were older, had more comorbidities (especially cardiometabolic disease) and later line of bDMARD treatment vs the TNFi group, who had higher MTX use. UST-treated patients were followed for a total of 991.3 patient-years (PY), and TNFi-treated patients for 1232.9 PY; the mean follow-up time per patient for the UST group was 2.0 (±1.0) years vs 2.2 (±0.9) years for the TNFi group. At least one

Table 1. Baseline demographics, treatment characteristics and comorbidities of patients with PsA treated with ustekinumab and TNFi

Third-line	95 (20.7%) [17.1 ; 24.7]	57 (12.0%) [9.2 ; 15.3]
Concurrent comorbidities, n (%)	308 (67.1) [62.6 ; 71.4]	272 (57.3) [52.7 ; 61.8]
Cardiometabolic disease and obesity*	75 (16.3) [13.1 ; 20.0]	64 (13.5) [10.5 ; 16.9]
Gastrointestinal disease	40 (8.7) [16.3 ; 11.7]	40 (8.4) [6.1 ; 11.3]
Depression	44 (9.6) [7.1 ; 12.7]	32 (6.7) [4.7 ; 9.4]
Anxiety or panic disorders	19 (4.1) [2.5 ; 6.4]	19 (4.0) [2.4 ; 6.2]
Neurological disease	6 (1.3) [0.5 ; 2.8]	2 (0.4) [0.1 ; 1.5]
Malignancies	9 (2.0) [0.9 ; 3.7]	8 (1.7) [0.7 ; 3.3]
Chronic hepatitis	10 (2.2) [1.0 ; 4.0]	1 (0.2) [0.0 ; 1.2]
Non-alcoholic fatty liver disease	21 (4.6) [2.9 ; 6.9]	14 (2.9) [1.6 ; 4.9]
Chronic obstructive pulmonary disease	10 (2.2) [1.0 ; 4.0]	11 (2.3) [1.2 ; 4.1]

35 patients in the UST group and 82 in the TNFi group received the drugs later over the course of the study.

*Hypertension, myocardial infarction, angina pectoris, congestive heart failure, stroke or transient ischemic attack, peripheral vascular disease, hyperlipidemia, type 1 or 2 diabetes plus BMI >30 kg/m².

BMI, body mass index; bDMARD, biologic DMARD; CI, confidence interval; SD, standard deviation; csDMARD, conventional synthetic DMARD; TNFi, TNF inhibitor; UST, ustekinumab.

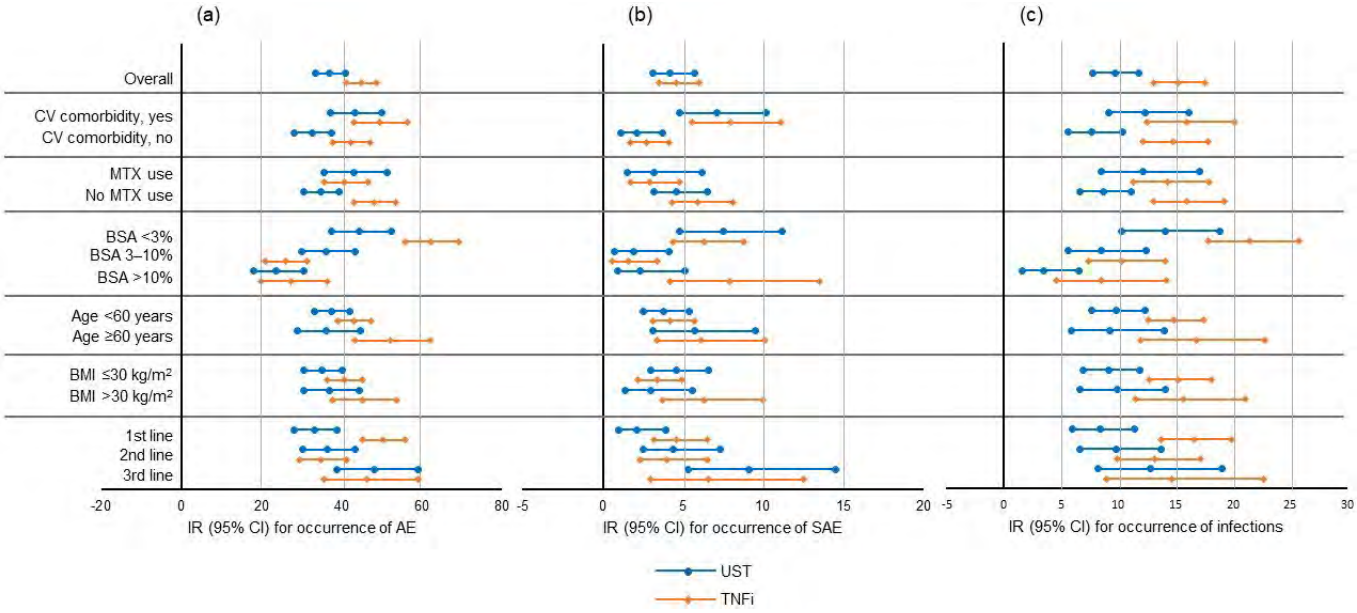

Figure 1. Exposure-adjusted incidence rate per 100 PY at risk (95% CI) for the occurrence of: (a) adverse events; (b) serious adverse events; and (c) infections in patients receiving UST and TNFi in the PsABio study. AE, adverse event; BMI, body mass index; BSA, body surface area; CI, confidence interval; CV, cardiovascular; IR, incidence rate; PY, patient-year; SAE, serious adverse event; TNFi, TNF inhibitor; UST, ustekinumab.

(non-neoplasm) AE was recorded in 34.6% of UST and 39.7% of TNFi-treated patients, with 6.3% and 7.2%, respectively, recording at least 1 serious AE (SAE). Malignancies were recorded in 3 (0.6%) UST (colon cancer, malignant neoplasm of eye, and prostate cancer) and 4 (0.7%) TNFi (bladder neoplasm, colon cancer, malignant urinary tract neoplasm, and squamous cell carcinoma of skin) patients. In the subgroup analysis by baseline characteristics and comorbidities, UST-treated patients generally tended to have a lower risk of clinically relevant AEs vs TNFi-treated patients in several subgroups (**Figure 1a**). The risk of infections was also lower with UST vs TNFi for the overall group and for several subgroups (**Figure 1c**). No clinically relevant differences were detected for SAEs (**Figure 1b**).

Conclusion: The PsABio study demonstrated an acceptable long-term safety profile of treatment with UST and TNFi in patients with PsA in a real-world setting.

SESSION INFORMATION

Session Date: Monday, November 8, 2021

Session Title: Spondyloarthritis Including PsA – Treatment Poster II: Psoriatic Arthritis I (1329–1363)

Session Type: Poster Session C

Session Time: 8:30AM–10:30AM

Background/Purpose: Bimekizumab (BKZ) is a monoclonal IgG1 antibody that selectively inhibits interleukin (IL)-17F and IL-17A, and has demonstrated clinical improvements in joint and skin outcomes up to 152 weeks (wks) and an acceptable safety profile in patients (pts) with active psoriatic arthritis (PsA).[1,2] We report the long-term efficacy and safety of BKZ treatment up to 3 years in the overall BKZ-treated population and TNFi-naïve (n) pts from a phase 2b dose-ranging study (BE ACTIVE; NCT02969525) and its open-label extension (OLE; NCT03347110).

Methods: BE ACTIVE and OLE study designs have been described previously.[1,2] Pts who completed 48 wks of BKZ treatment without meeting withdrawal criteria were eligible for OLE entry. All OLE pts received BKZ 160 mg every 4 wks after completing BKZ 160 mg or 320 mg in BE ACTIVE. Data are presented from Wk 48 to 152 for all BKZ-treated pts and the TNFi-n (defined as biologic DMARD-naïve) subgroup. Pre-planned subgroup analyses of efficacy outcomes are reported for the full analysis set (FAS; pts who received ≥1 dose BKZ with a valid primary efficacy variable measurement at baseline [BL]): ACR criteria 20/50/70; resolution of dactylitis (in pts with BL Leeds Dactylitis Index >0) or enthesitis (in pts with BL Maastricht Ankylosing Spondylitis Enthesitis Score >0); Psoriasis Area and Severity Index (PASI)100 (in pts with BL body surface area ≥3%); dual achievement of ACR50+PASI100; and minimal/very low disease activity (MDA/VLDA) in PsA. Treatment-emergent adverse events (TEAEs) are reported for the safety set (SS; pts who received ≥1 dose BKZ in BE ACTIVE).

Results: In BE ACTIVE, 206 pts were randomized at BL and 184 were enrolled in the OLE.[1,2] Of pts randomized at BL, 167 were TNFi-n. Over half of TNFi-n pts achieved ACR50 at Wks 48/152 (58.7/52.7% non-responder imputation [NRI]; 63.6/69.8% observed case [OC]; **Table 1; Figure 1**). At Wk 152, the majority of TNFi-n pts had resolution of dactylitis (70.2% NRI; 100.0% OC) and enthesitis (60.7% NRI; 80.6% OC). The proportion of TNFi-n pts with PASI100 at Wks 48/152 was high (63.3/58.7% NRI; 68.3/74.4% OC). At Wk 152, a large proportion of TNFi-n pts had dual achievement of ACR50+PASI100 (46.8% NRI; 60.0% OC). The proportions of TNFi-n pts achieving MDA/VLDA at Wk 152 were 52.1%/31.1% NRI, respectively; 69.0%/41.3% OC, respectively (**Table 1; Figure 1**).

Over 152 wks, the exposure-adjusted incidence rate per 100 pt-years for all BKZ-treated pts was 4.1 for serious TEAEs, 0.7 for serious infections and 4.6 for *Candida* infections (**Table 2**). One event was adjudicated by an independent committee as inflammatory bowel disease (microscopic colitis). All *Candida* infections were localized, mild/moderate

Table 1. Further efficacy outcomes up to 3 years

Efficacy (FAS)	Overall BKZ (N=206)		TNFi-n (N=167)	
	NRI n (%)	OC n/N (%)	NRI n (%)	OC n/N (%)

VLDA				
Wk 48	54 (26.2)	54/191 (28.3)	48 (28.7)	48/154 (31.2)
Wk 152	62 (30.1)	62/157 (39.5)	52 (31.1)	52/126 (41.3)

Full analysis set. All patients received BKZ 160 mg during the OLE (Wks 48–152) after completing BKZ 160 mg or 320 mg in BE ACTIVE. [a] in the subset of overall BKZ or TNFi-n patients with BL LDI >0, NRI: N=59 or 47, respectively; [b] in the subset of overall BKZ or TNFi-n patients with BL MASES >0, NRI: N=107 or 89, respectively; [c] in the subset of overall BKZ or TNFi-n patients with BL BSA ≥3%, NRI: N=137 or 109, respectively. BKZ: bimekizumab; BL: baseline; BSA: body surface area; DMARD: disease-modifying antirheumatic drugs; FAS: full analysis set; LDI: Leeds Dactylitis Index; MASES: Maastricht Ankylosing Spondylitis Enthesitis Score; MDA: minimal disease activity; NRI: non-responder imputation; OC: observed case; OLE: open-label extension; PASI: Psoriasis Area and Severity Index; TNFi-n: tumor necrosis factor inhibitor (biologic DMARD) naïve; VLDA: very low disease activity; wk: week.

and resolved with appropriate antifungal therapy (the majority were oral candidiasis). Overall, 17 pts (8.3%) discontinued study treatment due to TEAEs.

Conclusion: High thresholds of disease control were achieved by >50% of TNFi-n pts treated with BKZ up to 3 years, reflected in long-term improvements in joint and skin outcomes. The safety profile of BKZ up to 3 years in pts with PsA reflects previous observations.[1,2]

SESSION INFORMATION

Session Date: Monday, November 8, 2021

Session Title: Spondyloarthritis Including PsA – Treatment Poster II: Psoriatic Arthritis I (1329–1363)

Session Type: Poster Session C

Session Time: 8:30AM–10:30AM

Background/Purpose: Several options exist in the treatment of PsA, but data on long-term persistence are rare. Here, we assess long-term persistence with ustekinumab (UST) or TNF inhibitor (TNFi) in patients treated for PsA in the real world.

Methods: PsABio (NCT02627768) was a multinational, observational study in patients with PsA treated with 1st, 2nd, or 3rd line UST or a TNFi. Here we present drug persistence, one of the primary outcomes. All patients with baseline and post-baseline effectiveness data up to the complete study duration (3 years ± 3 months), including those who switched/stopped initial treatment, were analyzed. Persistence of UST and TNFi is presented as Kaplan-Meier (KM) curves and compared between cohorts using Cox regression analysis, including propensity score (PS) to adjust for baseline imbalanced covariates. Factors including concomitant MTX use and skin involvement were added to the Cox model to investigate their effect on the PS-adjusted treatment effect. Hazard ratios (HR) including 95% confidence intervals (CI) are presented.

Results: Baseline characteristics, treatment data, and comorbidities potentially influencing persistence showed imbalance between treatment groups, especially with treatment line (21% of patients in the UST group were on 3rd-line treatment vs 12% in the TNFi group) and comorbidities (67% in UST vs 57% in the TNFi group) (**Table 1**). Of 439 and 456 patients who started UST and TNFi, respectively, 42% and 41% stayed on their first treatment up to Month 36. Mean duration of initial treatment line was 24.7 (95% CI: 23.5 ; 25.8) months for UST and 24.1 (95% CI: 22.9 ; 25.3) months for TNFi-treated patients. Reasons for stopping/switching were related to safety and tolerability in 17% (UST) and 24% (TNFi) patients, and effectiveness in 83% (UST) and 76% (TNFi) patients.

Unadjusted KM graphs are shown in **Figure 1a–c**. Similar to findings from the 1-year persistence analysis (1), the estimates demonstrated similar drug persistence between UST and TNFi (**Figure 1a**). As expected, 1st-line biologic treatment was associated with longer treatment persistence than other lines. After PS adjustment for baseline imbalances, the risk of stopping/switching was similar for UST vs TNFi; HR 0.94 (0.75 ; 1.16). In patients with severe psoriasis (body surface area >10%), risk of stopping/switching was lower for UST vs TNFi; HR 0.55 (0.32 ; 0.98); a similar effect was seen for treatment with UST monotherapy vs TNFi monotherapy (without MTX); HR 0.75 (0.57 ; 0.98). This points to the importance of treatment persistence, next to concomitant therapy, when there is skin involvement.

Table 1. Baseline demographics, clinical characteristics and comorbidities of PsA patients treated with ustekinumab and TNFi

Mean [95% CI]	UST (n=439)	TNFi (n=456)
Age, years (SD)	51.1 (12.5) [49.9; 52.2]	48.5 (12.6) [47.3; 49.6]
Female, n (%)	247 (56.3%) [51.5; 61.0]	248 (54.4%) [49.7; 59.0]
BMI, kg/m² (SD)	28.6 (6.2) [27.9; 29.2]	27.8 (5.3) [27.2; 28.3]
Time since initial diagnosis, years (SD)	7.5 (8.1) [6.7; 8.3]	6.2 (6.6) [5.6; 6.9]
sDMARD exposure, n (%)		
Previous exposure	385 (87.7%) [84.3; 90.6]	422 (92.5%) [89.7; 94.8]
Ongoing exposure at baseline	175 (39.9%) [35.3; 44.6]	252 (55.3%) [50.6; 59.9]
Methotrexate exposure ongoing at baseline	132 (30.1%) [25.8; 34.6]	193 (42.3%) [37.7; 47.0]
Other treatment exposure ongoing at baseline, n (%)		
NSAIDs	240 (54.7%) [49.9; 54.9]	313 (68.6%) [64.2; 72.9]
Steroids	144 (32.8%) [28.4; 37.4]	156 (34.2%) [29.9; 38.8]
Line of bDMARD treatment, n (%)

*Hypertension, myocardial infarction, congestive heart failure, stroke or transient ischemic attack, peripheral vascular disease, hyperlipidemia, type 1 or 2 diabetes or angina pectoris.

BMI, body mass index; bDMARD, biologic DMARD; CI, confidence interval; SD, standard deviation; sDMARD, synthetic DMARD; TNFi, TNF inhibitor; UST, ustekinumab.

Conclusion: In the prospectively followed PsABio study across Europe, slightly more than 40% of PsA patients stayed on UST or TNFi for 3 years or more. After correction for baseline differences, the risk of stopping/switching treatment over 3 years was similar for UST and TNFi, with better persistence for UST vs TNFi in the subgroup of patients with severe psoriasis and in those receiving the biologic DMARD without MTX. Both drug classes offer interesting options for the treatment of PsA.

SESSION INFORMATION

Session Date: Monday, November 8, 2021

Session Title: Spondyloarthritis Including PsA – Treatment Poster II: Psoriatic Arthritis I (1329–1363)

Session Type: Poster Session C

Session Time: 8:30AM–10:30AM

Background/Purpose: Reaching control or improvement on enthesitis domain in psoriatic arthritis (PsA) is challenging, and it continues to be a priority for patients (pts) and rheumatologists. Upadacitinib (UPA) has demonstrated efficacy across key manifestations, including enthesitis, in pts with active PsA with inadequate response to non-biologic or biologic DMARDs from the SELECT-PsA Clinical trials program[1,2]. The objective of this analysis was to further estimate UPA 15 mg qd effects on enthesitis using different assessment tools through 56 weeks (W).

Methods: The SELECT-PsA 1 and 2 primary results were described elsewhere[1,2]. For the purpose of this analysis, the UPA 15 mg arms were pooled from the two studies to 56W (continuous UPA), the PBO arms to W24 and the PBO to UPA 15 arms from 24W to 56W.

Enthesitis resolution was assessed as proportion of pts achieving LEI =0 and/or SPARCC=0 at each timepoint for patients with LEI >0 or SPARCC > 0 at baseline (BL). Change from BL in LEI and SPARCC scores was also assessed at each timepoint. Residual enthesitis sites and maintenance of an enthesitis-free state were assessed through 56W. Non-responder imputation was used for binary endpoints and mixed-effect model repeated measures (MMRM) for continuous endpoints.

Results: Pooled population comprised 639 UPA 15 mg pts and 635 PBO pts. A significantly greater improvement in LEI and SPARCC scores (change from baseline) was observed with UPA 15 mg QD vs PBO as early as 12W to 24W, (nominal P< 0.0001; Figure 1) and results were either sustained or increased through 56W. A higher proportion of pts treated with UPA in comparison to PBO achieved complete resolution of enthesitis as assessed with LEI=0 or SPARCC=0 (nominal P<0.0001, **Figure 2)** and "LEI + SPARCC=0" (nominal p=0.0003 at 12W and p< 0.0001 at 16W / 24W). Resolution of enthesitis was sustained or increased through 56W, particularly in the continuous UPA 15 mg arm. Maintenance rate of an enthesitis-free state after LEI resolution at week 24 for UPA 15 mg continuous arm was: 84.2% at 36W, 80.2% at 56W, and with 72.3% remaining in remission at both 36W and 56W. Similarly, SPARCC assessment showed a 81.4% maintenance rate at 36W, 78.2% at 56 W, and 69.5% at both 36 W and 56W. For partial responders (pts experiencing a reduction in LEI or SPARCC but not achieving enthesitis resolution at 24W), UPA 15 mg still showed improvement over placebo for all components of LEI (or SPARCC) at 24W, with no specific refractory sites identified (Figure 3). For subjects with LEI=0 at baseline, Upa 15 mg also showed higher proportion of prevention of enthesitis versus placebo up to 24W, (between 12W and 24W the proportion of pts with LEI=0 for UPA ranged from 84.7% to 80.1% while for PBO ranged from 76% to 58.8%; nominal p< 0.05).

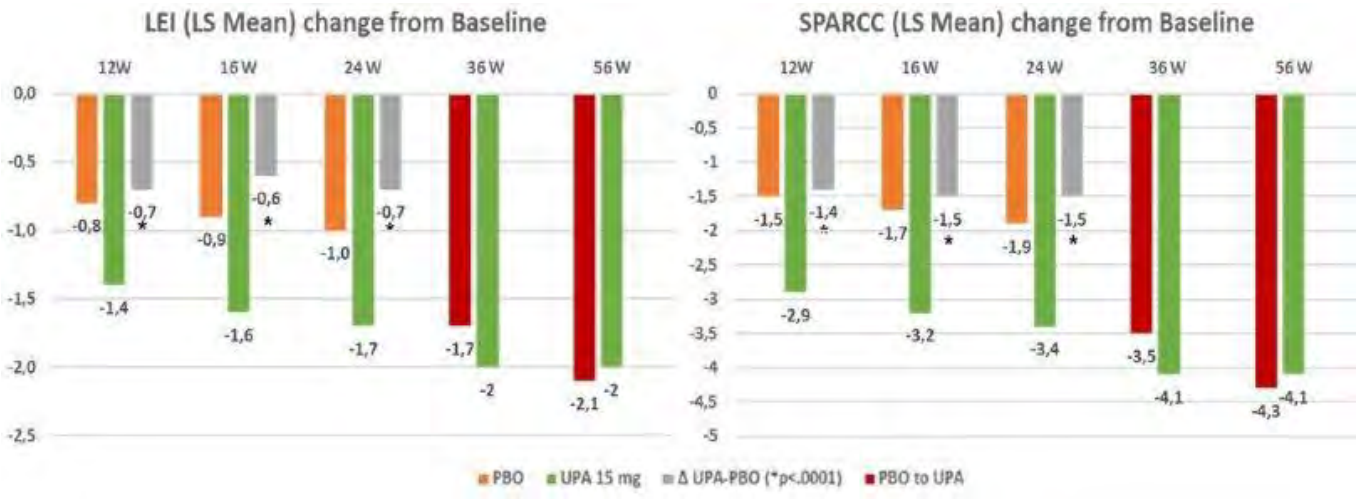

Figure 1. Change from BL in LEI/SPARCC by Visit and Treatment among subjects with BL values>0.

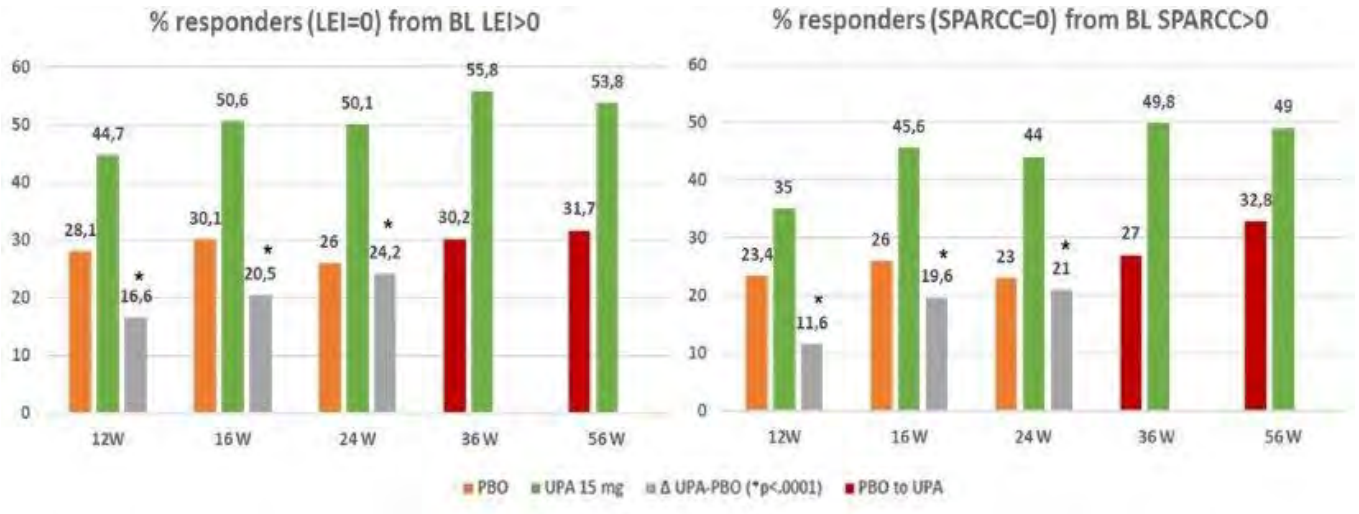

Figure 2. Proportion of Subjects Achieving Resolution of Enthesitis (LEI / SPARCC = 0) by Visit & Treatment among subjects with BL values>0.

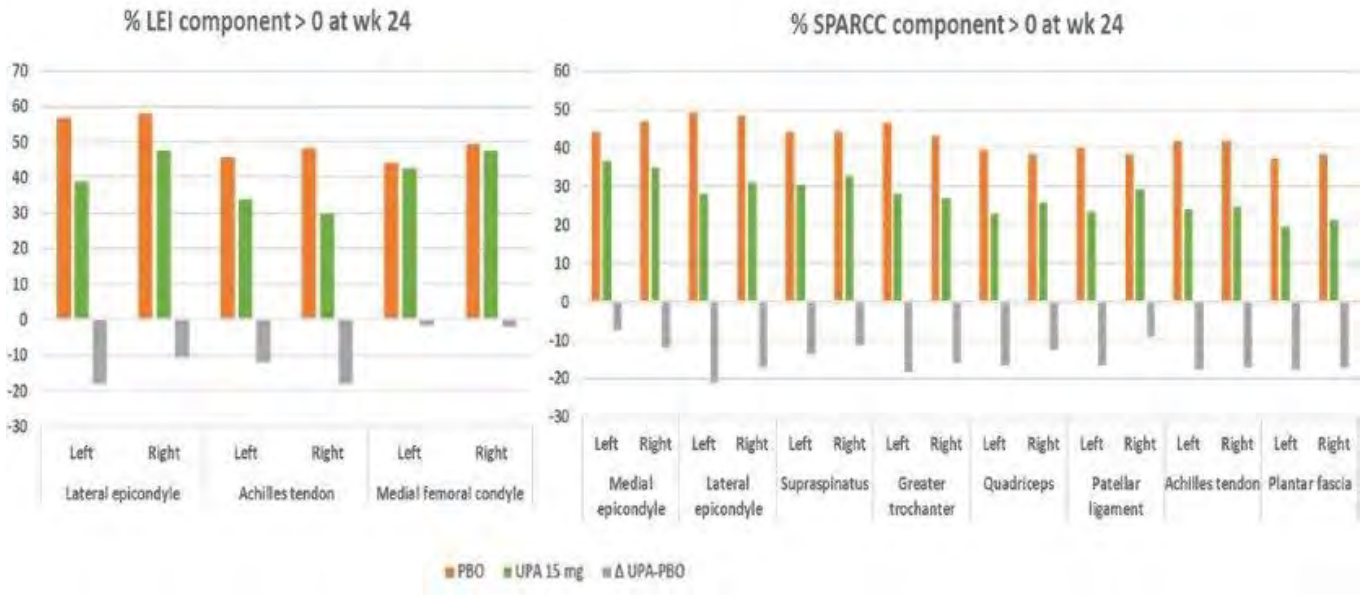

Figure 3. Residual Enthesitis sites at 24W among Subjects Not Achieving Full Resolution.

Conclusion: In pts with active PsA who had inadequate response to non-biologic or biologic DMARDs, UPA 15 mg achieved a rapid and comprehensive impact on enthesitis, across individual entheseal sites and with a high rate of maintenance of an enthesitic free state after resolution.

Ixekizumab Shows a Pattern of Pain Improvement in Patients with and Without Measurable Inflammation in Psoriatic Arthritis

Kurt de Vlam[1], Gaia Gallo[2], Philip Mease[3], Proton Rahman[4], Venkatesh Krishnan[2], David Sandoval[2], Chen Yen Lin[2], Danting Zhu[2], Rebecca Bolce[2] and Philip Conaghan[5], [1]University Hospitals Leuven, Leuven, Belgium, [2]Eli Lilly and Company, Indianapolis, IN, [3]Swedish Medical Center/Providence St. Joseph Health and University of Washington, Seattle, WA, [4]Department of Medicine, Eastern Health and Memorial University of Newfoundland, St John's, NL, Canada, [5]Leeds Institute of Rheumatic and Musculoskeletal Medicine, University of Leeds, Leeds, United Kingdom

SESSION INFORMATION

Session Date: Monday, November 8, 2021

Session Title: Spondyloarthritis Including PsA – Treatment Poster II: Psoriatic Arthritis I (1329–1363)

Session Type: Poster Session C

Session Time: 8:30AM–10:30AM

Background/Purpose: The efficacy of ixekizumab (IXE) and adalimumab (ADA) in patients with psoriatic arthritis (PsA) has been previously reported using ACR 50 and Psoriasis Area and Severity Index (PASI) 100 responses.[1,2] To minimize confounding effects, in this analysis we assessed the efficacy of either IXE or ADA monotherapy on reduction of pain beyond measurable inflammation in patients with active PsA and with low C-reactive protein (CRP) (< 5mg/L) at baseline.

Methods: SPIRIT-H2H (NCT03151551) was a 52 week (W), multicenter, randomized, open-label, parallel-group, assessor-blinded study evaluating the efficacy and safety of IXE vs ADA.[1] Participants were randomized (1:1) to approved-label dosing of IXE or ADA. This post-hoc analysis included only patients treated with IXE or ADA as monotherapy and with low CRP (< 5mg/L) at baseline. Changes in joint pain were measured using PsA Patient's Assessment of Pain Visual Analog Scale (VAS). We stratified patients into four categories by two measures of inflammation:

1. Sustained low inflammation either by
   a CRP < 5 mg/L during W4-24 or
   b ≥ 50% improvement in swollen joint count (SJC) during W8-24.
2. Fluctuating inflammation either by
   a CRP ≥ 5 mg/L at least once between W4-24 or
   b < 50% improvement in SJC at least once between W8-24.

Results: Ninety-five monotherapy patients with a CRP < 5mg/L at baseline were included in this analysis. Baseline characteristics were similar between both treatment arms. In patients with fluctuating inflammation as measured by CRP, IXE-treated patients demonstrated a numerically greater mean improvement in joint pain VAS vs ADA-treated

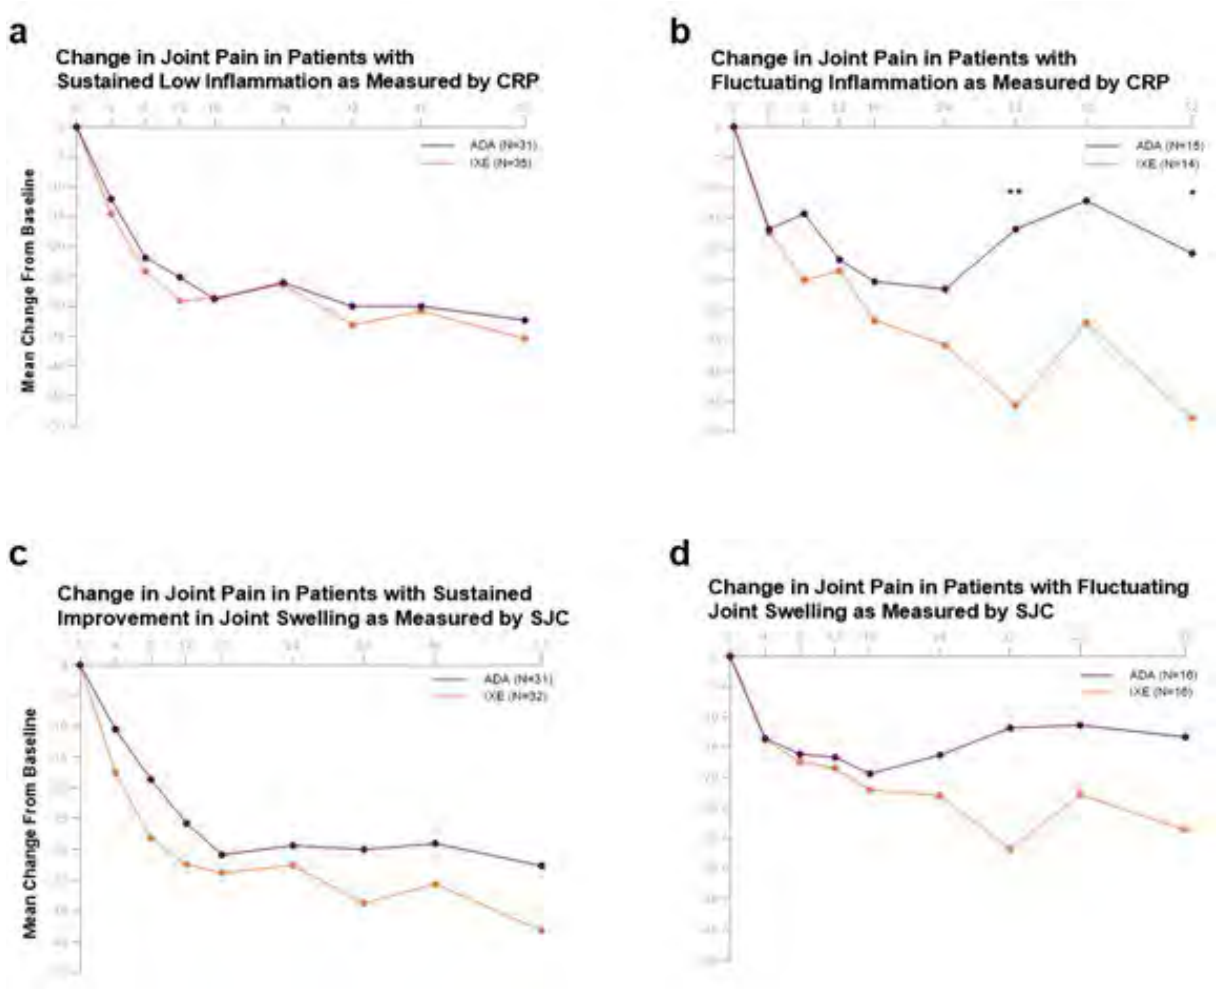

Figure 1. All patients had low baseline CRP (CRP < 5mg/L) and were treated with IXE or ADA as monotherapy. (a) Change in joint pain from baseline of patients with sustained low inflammation measured by CRP in IXE and ADA treatment groups. (b) Change in joint pain from baseline of patients with fluctuating inflammation measured by CRP in IXE and ADA treatment groups. (c) Change in joint pain from baseline of patients with sustained improvement in SJC in IXE and ADA treatment groups. (d) Change in joint pain from baseline of patients with fluctuating improvement in SJC in IXE and ADA treatment groups. *p value ≤ 0.05, **p value ≤ 0.01. Some patients were excluded from analysis due to missingness at visits.

patients at W16 (IXE: -31.64, ADA: -25.33, Figure 1b) that was sustained up to W52 (IXE: -47.69, ADA: -20.67, Figure 1b). There was significance in favor of IXE at W32 (p = 0.0045) and W52 (p = 0.0288, Figure 1b). In patients with sustained low inflammation as measured by CRP, there was no difference in improvement in joint pain between IXE and ADA-treated patients (Figure1a). In patients with sustained improvement in joint swelling as assessed by SJC, IXE-treated patients demonstrated a numerically greater mean improvement in joint pain VAS vs ADA-treated patients from W4 (IXE: -17.47, ADA: -10.42, Figure 1c) that was sustained through W52 (IXE: -43.16, ADA: -32.62, Figure 1c). In patients with fluctuating improvement in joint swelling as assessed by SJC, IXE-treated patients demonstrated a numerically greater mean improvement in joint pain VAS vs ADA-treated patients from W16 (IXE: -22.00, ADA: -19.31, Figure 1d) that was sustained through W52 (IXE: -28.57, ADA: -13.27, Figure 1d).

Conclusion: This analysis suggests a different pattern of pain improvement in patients with low baseline CRP treated with IXE or ADA monotherapy, with a favorable pain reduction outcome for IXE-treated patients, even when inflammation is fluctuating as measured by CRP or SJC improvement. This analysis supports the hypothesis that IXE improves joint pain in PsA patients with and without measurable inflammation.

SESSION INFORMATION

Session Date: Monday, November 8, 2021
Session Title: Spondyloarthritis Including PsA – Treatment Poster II: Psoriatic Arthritis I (1329–1363)
Session Type: Poster Session C
Session Time: 8:30AM–10:30AM

Background/Purpose: Guselkumab (GUS), an anti-interleukin (IL)-23p19-subunit mAb, demonstrated efficacy in VOYAGE (VOY) 1&2 patients (pts) with moderate to severe plaque psoriasis (PsO)[1,2] and in DISCOVER (DISC) 1&2 pts with active PsA.[3,4] IL-17 inhibitors used to treat PsO and PsA have been associated with exacerbation or new onset of IBD.[5] We evaluated the incidence of gastrointestinal (GI)-related and overall serious adverse events (SAEs) from pooled safety data through 1-year of GUS 100 mg treatment from the phase 3 VOY 1&2 and DISC 1&2 trials.

Methods: Using pooled safety data from VOY 1&2 PsO and DISC 1&2 PsA trials, GI-related SAEs were identified using the Medical Dictionary for Regulatory Activities (MedDRA) system-organ class "GI disorders". Pts with a previous history of IBD were not excluded; IBD history was collected at baseline in DISC 1&2. Rates of overall and GI-related SAEs were calculated as the number of SAEs per 100 pt-years (PY) of follow-up (95% confidence intervals). Data are presented for the placebo (PBO)-controlled period (VOY 1&2: Weeks [W] 0-16; DISC 1&2: W0-24) and through 1-year (VOY 1&2: through W48; DISC 1: through W60, DISC 2: through W52). Events of uveitis and opportunistic infections were also analyzed.

Results: Through the PBO-controlled period, the overall rates of GI-related SAEs per 100 PY for pooled VOY 1&2 were: PBO 0.78 (0.02, 4.34), GUS every (q) 8w 0; and for pooled DISC 1&2: PBO 0.58 (0.01, 3.23), GUS q8w 0.58 (0.01, 3.21), GUS q4w 0. The GI-related SAEs included: VOY 1&2, gastrointestinal hemorrhage (PBO; n=1); and DISC 1&2, IBD (PBO; n=1) and mechanical ileus (GUS q8w; n=1). Through 1-year, overall rates of GI-related SAEs for VOY 1&2 were: combined GUS group (GUS q8w + PBO→GUS) 0.51 (0.17, 1.20); and for DISC 1&2: GUS q8w 0.52 (0.06, 1.88), GUS q4w 0, combined GUS group (GUS q8w + GUS q4w + PBO→GUS) 0.21 (0.02, 0.74). The GI-related SAEs in the combined GUS group for pooled VOY 1&2 included: gastritis, hemorrhoids, inguinal hernia, pancreatitis, and umbilical hernia (0.10/100 PY [0.00, 0.57]; n=1 for each); and in the combined GUS group for pooled DISC 1&2: mechanical ileus and pancreatitis chronic (0.10/100 PY [0.00, 0.57]; n=1 for each). Overall, no cases of exacerbation or new onset of IBD were reported in GUS-treated pts, including 2 pts with a prior history of IBD in DISC 1&2 (total PY of follow-up for the combined GUS groups in VOY and DISC were 974 and 973, respectively). Through the PBO-controlled period, rates of overall SAEs for GUS-treated pts were comparable to PBO-pts and SAE rates remained low through 1-year of follow-up in VOY 1&2 and DISC 1&2. No cases of uveitis, opportunistic infections, or tuberculosis were reported in GUS-treated pts through 1-year.

Conclusion: Through 1-year of follow-up with GUS treatment in pooled VOY 1&2 and DISC 1&2, GI-related SAE rates were low. There were no reported cases of uveitis, opportunistic infections, or new onset/exacerbation of IBD in GUS-treated pts. No new safety concerns were identified through 1-year.

Guselkumab Treatment Modulates Core Psoriatic Arthritis Gene Expression in Two Phase 3 Clinical Trials (DISCOVER-1 and -2)

Stefan Siebert[1], Kristen Sweet[2], Christopher Ritchlin[3], Elizabeth Hsia[4], Alexa Kollmeier[5], Xie Xu[4], Qingxuan Song[2] and Michelle Miron[2], [1]University of Glasgow, Glasgow, United Kingdom, [2]Janssen Research & Development LLC, Spring House, PA, [3]Division of Allergy, Immunology, and Rheumatology, School of Medicine and Dentistry, University of Rochester Medical Center, Rochester, NY, [4]Janssen Research & Development, LLC, Spring House, PA, [5]Janssen Research & Development, LLC, La Jolla, CA

SESSION INFORMATION

Session Date: Monday, November 8, 2021

Session Title: Spondyloarthritis Including PsA – Treatment Poster II: Psoriatic Arthritis I (1329–1363)

Session Type: Poster Session C

Session Time: 8:30AM–10:30AM

Background/Purpose: Guselkumab (GUS), an anti-IL-23 p19-subunit monoclonal antibody, demonstrated efficacy vs placebo (PBO) in reducing signs and symptoms of PsA in the phase-3 DISCOVER-1 & -2 studies.[1,2] This study evaluated gene expression in the blood of PsA patients (pts) in DISCOVER-1 & -2 and the impact of GUS on the expression of these genes.

Table. Top DEGs derived from PsA vs healthy whole blood transcriptomes

Upregulated in PsA				Downregulated in PsA			
Gene	logFC	logCPM	FDR	Gene	logFC	logCPM	FDR
ADGRG7	**5.92**	-0.90	0.02101	AK8	-1.36	-1.06	1.61E-07

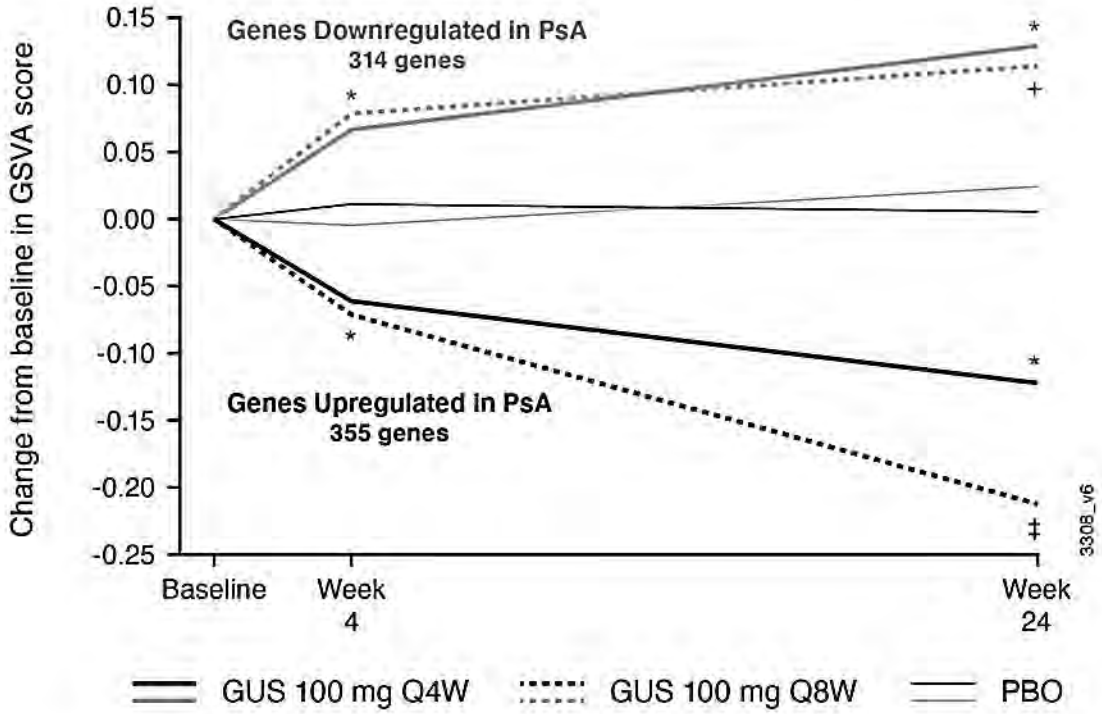
				BCAR1	-3.13	-2.58	6.24E-26

Bold indicates positive change.
CPM, counts per million; DEGs, differentially expressed genes; FC, fold change; FDR, false discovery rate.

Figure. Change from baseline in median GSVA scores for upregulated and downregulated genes in PsA for GUS and PBO treatment arms from DISCOVER-1 and 2.



*, +, ‡ $p \leq 0.05, 0.01, 0.001$, respectively. Wilcox test performed between GUS (Q4W, dashed line; Q8W, solid line) and PBO.

GSVA, gene set variation analysis; GUS, guselkumab; PBO, placebo; PsA, psoriatic arthritis; Q4W, every 4 weeks; Q8W, every 8 weeks.

Methods: Pts were treated with GUS 100 mg every 4 weeks (Q4W); GUS 100 mg at Week (W) 0, W4, then Q8W; or matching PBO. Whole transcriptome profiling by RNA-sequencing was performed using the Novaseq platform on blood samples obtained from a subset of 673 pts with PsA at baseline across the 2 DISCOVER studies, as well as from 21 demographically (age, sex, ethnicity) matched healthy controls procured independently of the clinical program. A subgroup (N=227), selected based on having baseline characteristics (demographics, disease activity, medication use) representative of the overall cross-study PsA population, also had serial blood samples (W0/W4/W24) evaluated. Significance of differentially expressed genes (DEGs) between PsA and healthy controls was defined by a false discovery rate < 0.05 based on a log-linear model using edgeR. Top genes were defined by significance and |logFC| >1. For cell type analysis, genes that changed with GUS treatment were tested for enrichment using Cibersort. Gene enrichment scores were calculated using Gene Set Variation Analysis.

Results: To define disease genes, we compared genes at baseline in pts with active PsA vs healthy control whole blood transcriptomes and detected 355 upregulated and 314 downregulated (top genes shown in Table), defined here as core disease genes. Upregulated genes were largely related to neutrophils, monocytes, macrophages, and extracellular matrix, whereas downregulated genes were related to T cells. The upregulated disease genes were significantly decreased and the downregulated disease genes were significantly increased by GUS treatment vs PBO at W4 and W24 (Figure). Upon stratification by ACR 20 response, changes in core disease gene expression from W0 were statistically significant among responders, but not in nonresponders, at W4 and W24 (data not shown). We then performed the second differential expression analysis comparing baseline to W4 and W24 for both PBO and GUS treatment arms to define genes that changed with treatment over time. At W4 and W24, we found many DEGs from baseline with GUS treatment and none with PBO. These included genes related to B-, T-, NK-, and plasma cells (increased by GUS) and neutrophils, monocytes, eosinophils, and macrophages (decreased by GUS), suggestive of a partial normalization of immune cell composition in whole blood.

Conclusion: Using whole transcriptome profiling, we detected DEGs in blood samples obtained from PsA pts vs healthy controls, suggesting a dysregulation of immune cell profiles in PsA. The majority of these disease-associated genes were modulated by GUS, with directionality toward a normalization of whole blood transcriptomic signatures.

Impact of Achieving Minimal Disease Activity on Patient-Reported Outcome Measures and Disease Activity Among Patients with Psoriatic Arthritis Treated with Biologic and Targeted Synthetic DMARDs

Alexis Ogdie[1], Robert McLean[2], Maya Marchese[2], Taylor Blachley[2], Laura Anatale-Tardiff[3], Christopher Saffore[4], Kevin Douglas[5], Danny Quach[5] and Philip Mease[6], [1]University of Pennsylvania, Philadelphia, PA, [2]CorEvitas, LLC, Waltham, MA, [3]CorEvitas, Waltham, MA, [4]AbbVie, North Chicago, IL, [5]AbbVie Inc., North Chicago, IL, [6]Swedish Medical Center/Providence St. Joseph Health and University of Washington, Seattle, WA

SESSION INFORMATION

Session Date: Monday, November 8, 2021

Session Title: Spondyloarthritis Including PsA – Treatment Poster II: Psoriatic Arthritis I (1329–1363)

Session Type: Poster Session C

Session Time: 8:30AM–10:30AM

Background/Purpose: Minimal disease activity (MDA) is a common goal for disease control when managing PsA. The aim of this study was to assess the association between MDA achievement and disease activity/patient-reported outcome measures (PROMs) after 6 months of biologic DMARD (bDMARD) or targeted synthetic DMARD (tsDMARD) therapy among PsA patients.

Methods: This study included patients with PsA enrolled in CorEvitas' prospective, multicenter, observational PsA/SpA Registry, who had not attained MDA, were initiating bDMARD or tsDMARD therapy at baseline, and had a 6-month follow-up visit (3/2013-3/2021). MDA was achieved at follow up if ≥5 of the following was met: tender joint count 68 ≤1, swollen joint count 66 ≤1, body surface area ≤3%, patient's assessment of pain ≤15 (0-100 VAS), patient's global assessment of disease activity ≤20 (0-100 VAS), HAQ-Disability Index ≤0.5, or Leeds Enthesitis Index ≤1. Baseline patient characteristics of MDA achievers and non-achievers were compared with t-tests and chi-square tests. Relative risk (RR) of achieving minimal clinically important difference (MCID) for PROMs and clinically meaningful improvements in disease activity components was estimated by Poisson generalized linear models adjusted for the baseline PROM or baseline disease activity component. RRs of maintaining or switching the initiated therapy by 6 months were calculated to determine the association with MDA achievement.

Results: MDA was achieved by 22.8% (285/1251) of patients 6 months after initiating bDMARD (n=987) or tsDMARD (n=264) therapy for PsA. Most baseline characteristics were similar between MDA achievers and non-achievers; however, those who achieved MDA tended to be younger with shorter duration of disease and were less likely to be female, obese, or have a history of depression (**Table 1**). DMARD therapy at initiation was similar between MDA achievers and non-achievers, except that more achievers were bDMARD-naïve at baseline (**Table 1**). Patients who achieved MDA were more likely to maintain the initiated bDMARD (RR =1.3, 95% CI 1.2-1.5) or tsDMARD (RR =1.4, 95% CI 1.1-1.8) therapy and less likely to switch from the initiated bDMARD (RR=0.5, 95% CI 0.3-0.7) and tsDMARD (RR=0.6, 95% CI 0.4-1.1) therapy (**Figure 1**). MDA achievement was associated with higher probability of achieving MDA components and MCID in PROMs at 6 months (**Figure 2**).

Conclusion: In this real-world study, MDA achievement was associated with a higher probability of achieving clinically meaningful improvements in disease activity and PROMs, suggesting MDA as a viable target endpoint for disease control. Patients who achieved MDA were also more likely to be persistent on b/tsDMARD therapy. This data underscores the importance of utilizing MDA in clinical practice in order to achieve optimal outcomes for patients.

Table 1. Baseline demographics and clinical characteristics among patients with PsA who initiated biologic or targeted synthetic DMARD treatment, by MDA achievement at 6 months follow-up

Demographic and health characteristics	MDA Status: Achievers N=285	MDA Status: Non-Achievers N=966	*P*-value[a]
Age, [years], mean ± SD	52.3 ± 13.2	53.9 ± 11.9	0.05
Female, n (%)	142 (50.0)	594 (61.6)	<0.001
White, n (%)	257 (90.2)	891 (92.2)	0.27
BMI category, n (%)			0.02
Underweight/normal weight	41 (14.5)	95 (10.1)	
Overweight	78 (27.7)	219 (23.2)	
Obese	163 (57.8)	628 (66.7)	
History of depression, n (%)	36 (12.6)	239 (24.7)	<0.001
Clinical characteristics			
Duration since PsA diagnosis [years], mean ± SD	5.9 ± 7.2	7.0 ± 7.8	0.04
Duration since PsA symptoms [years], mean ± SD	8.3 ± 9.0	10.9 ± 9.7	<0.001
BSA >3% affected, n (%)	106 (37.2)	383 (39.6)	0.46
Presence of enthesitis, n (%)	77 (27.0)	371 (38.4)	<0.001
Presence of dactylitis, n (%)	80 (28.1)	154 (15.9)	<0.001
DMARD treatment initiated at baseline[b]			
bDMARD, n (%)	231 (81)	756 (78)	0.31
Monotherapy	146 (63)	435 (58)	0.07
Naïve	129 (45)	289 (30)	<0.001
tsDMARD, n (%)	54 (19)	210 (22)	0.31
Monotherapy	26 (58)	121 (58)	0.12
Naïve	235 (83)	747 (77)	0.06

[a]*P*-values for differences between MDA groups were calculated using student t-test for estimated difference of means for continuous measures and chi-squared test for differences in distribution of categorical variables. [b]Monotherapy and naïve DMARD treatment groups are overlapping. bDMARD, biologic DMARD; BMI, body mass index; BSA, body surface area; CRP, C-reactive protein; MDA, minimal disease activity; SD, standard deviation; tsDMARD, targeted synthetic DMARD.

Figure 1. Treatment patterns and relative risk of switching or maintaining therapy in MDA achievers versus non-achievers at 6-month follow-up[a]

	Maintained initiated bDMARD	Maintained initiated tsDMARD	Switched from initiated bDMARD[a]	Switched from initiated tsDMARD[a]
RR[b] (95% CI)	1.3 (1.2, 1.5)	1.4 (1.1, 1.8)	0.5 (0.3, 0.7)	0.6 (0.4, 1.1)
P-value[c]	<0.001	0.005	<0.001	0.100

[a]Switching is defined as evidence of discontinuation of initiated therapy and initiation of a new therapy within the 6-month follow-up. [b]Relative risk estimates from the Poisson generalized linear model, with MDA non-achieving group as reference. [c]*P*-value is testing whether the relative risk of maintaining or switching from initiated therapy at six months for the MDA achievers is different from 1.0. bDMARD, biologic DMARD; MDA, minimal disease activity; tsDMARD, targeted synthetic DMARD.

Figure 2. Proportions of patients and relative risk of achieving MDA component threshold or MCID in PROMs among MDA achievers versus non-achievers at 6-month follow-up

	BSA ≤3%	HAQ-DI ≤0.5	TJC ≤1	SJC ≤1	Patient Pain ≤15[c]	Patient global ≤20[c]	LEI ≤1	HAQ-DI MCID: ≥0.35	BASDAI MCID: ≥1.1	Patient pain MCID: ≥10	Patient global MCID: ≥10	Fatigue MCID: ≥10	Morning stiffness MCID: ≥10	Overall Work Impairment[d,e] MCID: ≥15
RR[f] (95% CI)	1.9 (1.6, 2.2)	6.6 (5.1, 8.6)	3.9 (3.4, 4.6)	2.5 (2.2, 2.9)	19.5 (12.8, 29.7)	8.4 (6.5, 10.9)	1.5 (1.2, 1.8)	4.2 (3.6, 5.0)	3.3 (2.9, 3.7)	2.4 (2.1, 2.6)	2.5 (2.3, 2.9)	2.2 (1.9, 2.4)	1.7 (1.6, 2.0)	2.0 (1.6, 2.4)
P-value[g]	<0.001	<0.001	<0.001	<0.001	<0.001	<0.001	<0.001	<0.001	<0.001	<0.001	<0.001	<0.001	<0.001	<0.001

[a]Analysis was limited to patients who did not meet MDA criteria at baseline. [b]MCID values are the minimum point reductions from baseline that are considered clinically meaningful. [c]Measured using a 100-point visual analog scale. [d]MCID for overall work impairment is a percent increase from baseline. [e]Overall work impairment was only determined for those who reported employment at baseline. [f]Relative risk estimates determined from a Poisson generalized linear model, with MDA not-achieving group as reference. [g]*P*-value is testing whether the relative risk of maintaining or switching from initiated therapy at six months for the MDA achievers is different from 1.0. BASDAI, Bath Ankylosing Spondylitis Disease Activity Index; BSA, body surface area; HAQ-DI, The Health Assessment Questionnaire Disability Index; MCID, minimal clinically important difference; LEI, Leeds enthesitis index; MDA, minimal disease activity; PRO, patient-reported outcome; SJC, swollen joint count; TJC, tender joint count.

SESSION INFORMATION

Session Date: Monday, November 8, 2021

Session Title: Spondyloarthritis Including PsA – Treatment Poster II: Psoriatic Arthritis I (1329–1363)

Session Type: Poster Session C

Session Time: 8:30AM–10:30AM

Background/Purpose: In the SELECT-PsA 1 study, through 24 weeks (wks), once daily upadacitinib 15 mg (UPA15) and 30 mg (UPA30) showed improvements in musculoskeletal symptoms, psoriasis, physical function, pain, fatigue, and quality of life, as well as inhibition of radiographic progression in patients (pts) with psoriatic arthritis (PsA) and inadequate response or intolerance to ≥1 non-biologic disease-modifying antirheumatic drug (DMARD).[1] This analysis reports the efficacy and safety of UPA vs adalimumab (ADA) up to 56 wks from the ongoing long-term extension of SELECT-PsA 1.

Methods: Pts received UPA15 or UPA30, ADA 40mg every other wk for 56 wks, or PBO through wk 24 switched thereafter to either UPA15 or UPA30 until wk 56. Efficacy endpoints as listed and defined in the **Table** were analyzed at wk 56. Results for binary endpoints are based on non-responder imputation analysis; treatments were compared using the Cochran-Mantel-Haenszel test. Results for non-radiographic continuous endpoints are based on mixed model repeated measures model based on as observed data. Radiographic endpoints were analyzed based on linear extrapolation. Treatment-emergent adverse events (TEAEs) per 100 pt years (PY) were summarized for pts who received ≥1 dose of study drug.

Results: Of 1704 pts who received ≥1 dose of study drug, 1419 (83.2%) completed 56 wks of treatment on study drug. Across all treatment groups, the proportions of pts who had achieved ACR20/50/70, MDA, PASI75/90/100, resolution of enthesitis, and resolution of dactylitis were maintained or further improved from wk 24[1] through wk 56; these proportions were generally greater for pts originally randomized to UPA vs ADA (**Table**). At wk 56, mean change

Table. Efficacy Endpoints at Week 56

Endpoint	PBO → UPA15	PBO → UPA30	UPA15	UPA30	ADA
ACR20, %	73.0	74.1	74.4	74.7#	68.5
ACR50, %	54.5	60.4	59.7*	60.5#	51.3
ACR70, %	29.9	35.8	40.6*	43.7#	31.2

PASI90[a], %	41.7	53.7	49.1	49.5	46.9
PASI100[a], %	22.3	38.9	34.6	39.5	31.3
Resolution of enthesitis by Leeds Enthesitis Index[b], %	38.1	45.5	59.3	58.1	54.0
Resolution of dactylitis by Leeds Dactylitis Index[c], %	47.7	59.0	75.0	74.8	74.0
Δ from BL in Bath Ankylosing Spondylitis Disease Activity Index[d]	-3.1	-3.1	-3.3	-3.2	-2.8
Δ from BL in modified total Sharp/van der Heijde Score (mTSS)	0.44[e]		-0.05†	0.02‡	-0.06

* and †, p≤0.05; for UPA15 vs ADA and PBO, respectively; # and ‡, p≤0.05; for UPA30 vs ADA and PBO, respectively.

[a] for pts with psoriasis affecting ≥3% of body surface area at BL. [b] for pts with LEI >0 at BL. [c] for pts with LDI >0 at BL. [d] for pts with psoriatic spondylitis at BL. [e]pooled PBO.

ACR20/50/70, ≥20%/50%/70% improvement in American College of Rheumatology criteria; ADA, adalimumab; BL, baseline; PASI75/90/100, ≥75%/90%/100% improvement in Psoriasis Area and Severity Index; PBO, placebo; pts, patients; UPA, upadacitinib.

from BL in mTSS was similar with UPA15, UPA30, and ADA. Improvements in pts who switched from PBO to UPA were generally similar to those originally randomized to UPA at wk 56. Through wk 56, the rates of TEAEs and serious AEs, including serious infections, were similar in the UPA15 and ADA arms and higher with UPA30 (**Figure**). The rate of herpes zoster was higher with UPA vs ADA in a dose-dependent manner. Malignancies were reported at similar rates among all treatment groups. Adjudicated venous thromboembolic events and major adverse cardiovascular events were reported in all groups with comparable rates. Two deaths were reported with UPA15, 2 with UPA30, and 1 with ADA; 1 death was reported with PBO during the 24-wk PBO-controlled period.

Conclusion: Efficacy responses were maintained or further improved with UPA15 and UPA30 over 56 wks and were numerically higher for pts originally randomized to UPA vs ADA. The inhibition of radiographic progression was maintained at wk 56 and was similar with UPA and ADA. At wk 56, improvements in efficacy were observed in pts who switched from PBO to UPA. No new safety findings were observed with longer exposure to UPA.

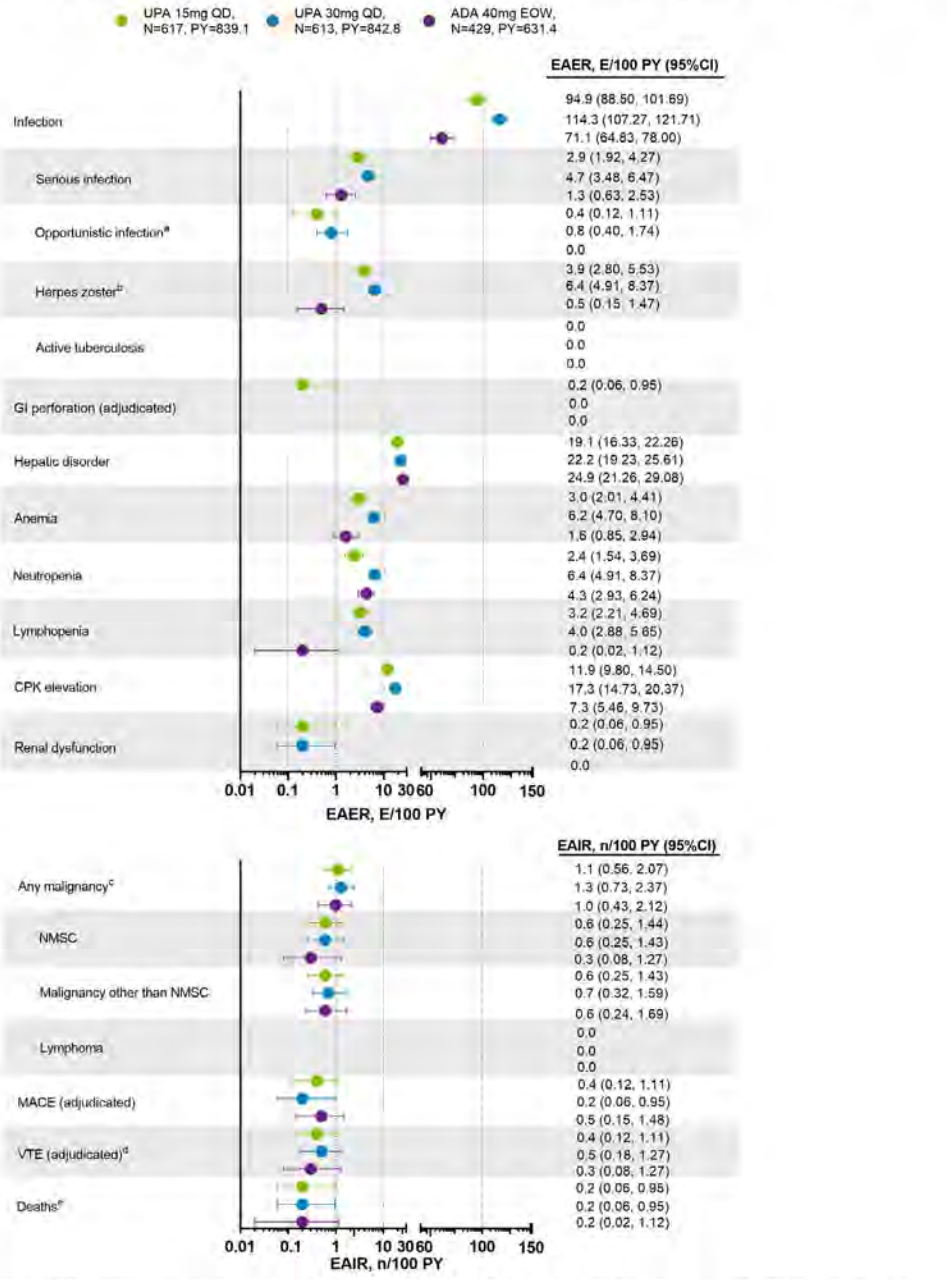
Figure. Exposure-adjusted Event and Incidence Rates of Treatment-emergent AEs Through Week 56



ADA, adalimumab; AE, adverse event; CI, confidence interval; CPK, creatine phosphokinase; EAER, exposure-adjusted event rate; EAIR, exposure-adjusted incidence rate; EOW, every other week; GI, gastrointestinal; MACE, major adverse cardiovascular events (defined as non-fatal myocardial infarction, non-fatal stroke, and cardiovascular death); NMSC, non-melanoma skin cancer; PY, patient years; QD, once daily; UPA, upadacitinib; VTE, venous thromboembolism (defined as deep vein thrombosis [DVT] and pulmonary embolism [PE]).

[a] Opportunistic infections excluding tuberculosis and herpes zoster. UPA15: one event each of candida urethritis, bronchopulmonary aspergillosis, and oral fungal infection; UPA30: one event each of cytomegalovirus infection, oropharyngeal candidiasis, and pneumocystis jirovecii pneumonia; and four events of oral fungal infection.

[b] Herpes zoster; most events were mild or moderate in severity, limited to 1-2 dermatomes, and did not lead to study drug discontinuation.

[c] UPA15: 4 basal cell carcinomas, 2 squamous cell carcinoma of skin, and 1 event each of endometrial adenocarcinoma, lung adenocarcinoma, lung cancer metastatic, malignant melanoma, and neuroendocrine carcinoma; UPA30: 2 basal cell carcinomas, 2 squamous cell carcinoma of skin, and 1 event each of adenocarcinoma of colon, Bowen's disease, breast cancer, clear cell renal cell carcinoma, invasive breast carcinoma, lung adenocarcinoma, and plasma cell myeloma); ADA: 2 basal cell carcinomas, and 1 event each of colon cancer metastatic, ovarian cancer, pancreatic carcinoma metastatic, and uterine cancer.

[d] 10 VTEs were reported in 9 patients. UPA15: 1 DVT, 1 PE, 1 pt had had concurrent DVT and PE; UPA30: 1 DVT, 3 PEs; ADA: 2 DVTs

[e] Deaths: UPA15: 1 due to metastatic lung cancer and 1 due to lower respiratory tract infection; UPA30: 1 due to corona virus infection and 1 due to interstitial lung disease; ADA: traffic accident. One death was reported in the placebo group during the 24-week placebo-controlled period in a patient who was driving and experienced an unspecified emergency.

Session Date: Monday, November 8, 2021

Session Title: Spondyloarthritis Including PsA – Treatment Poster II: Psoriatic Arthritis I (1329–1363)

Session Type: Poster Session C

Session Time: 8:30AM–10:30AM

Background/Purpose: DISCOVER 1&2 (PsA) and VOYAGE 1&2 (psoriasis [PsO]) are Phase 3 trials of guselkumab (GUS). Here we compared safety results through up to 1 year of GUS in PsA and PsO patients.

Methods: In DISCOVER 1&2, 1120 patients with active PsA despite standard therapy were treated. Most patients were biologic-naïve; ~30% in DISCOVER 1 had previous exposure to 1-2 TNFi. Concomitant MTX (57%), oral corticosteroids (17%), and NSAIDs (64%) were permitted. Patients were randomized to subcutaneous (SC) GUS 100 mg at week (W) 0, W4, then every 8 weeks (Q8W); GUS 100 mg Q4W; or placebo (PBO). At W24, PBO patients were switched to GUS 100 mg Q4W. In VOYAGE 1&2, in which concomitant MTX use was prohibited, 1245 patients with moderate to severe PsO were treated and randomized to SC GUS 100 mg at W0, W4, W12, then Q8W; or PBO at W0, W4, W12, with crossover to GUS at W16, W20, then Q8W. Adverse events (AEs) and laboratory parameters, analyzed by National Cancer Institute-Common Terminology Criteria for AEs [NCI-CTCAE] toxicity grades, were summarized through the PBO-controlled periods and 1 year.

Results: Safety profiles were generally consistent across the GUS PsO and PsA clinical programs (Table). Time-adjusted incidence rates for numbers of AEs, serious AEs, serious infections, malignancy, major adverse cardiovascular events and AEs leading to discontinuation were generally similar between PsO and PsA. No cases of anaphylaxis or opportunistic infections were reported. Proportions of patients with decreased neutrophil counts and

[b]For all patients who discontinued study treatment early with the last dose of PBO/GUS prior to W24 and who did not receive any PBO/GUS at or after Wk24, all data including the final safety follow-up visit collected through 1 year were included
[c]For patients in PBO group who switched to GUS due to cross-over or inadvertently, only data prior to first administration of GUS were included.
[d]CI based on an exact method assuming observed number of events follows a Poisson distribution
AE, adverse event; CI, confidence interval; GUS, guselkumab; MACE, major adverse cardiovascular events; PBO, placebo; pt, patient; Q4W, every 4 weeks; Q8W, every 8 weeks; SAE, serious adverse event; W, week; yrs, years

elevations in hepatic transaminases were slightly higher in PsA versus PsO. These abnormalities were mostly of NCI-CTCAE Grade 1 or 2 (< lower limit of normal-1000/mm^3 for neutrophils; < 5.0 x upper limit of normal for aspartate transaminase/alanine aminotransferase [AST/ALT]), generally transient, required no medical interventions, resolved spontaneously, and did not lead to interruption or discontinuation of treatment. Through 1 year, proportions of patients with ALT/AST elevations in PsA trials were slightly higher for GUS Q4W than Q8W and in patients with versus without baseline MTX use.

Conclusion: The GUS safety profile was generally consistent in PsA and PsO GUS-treated patients through 1 year of the DISCOVER and VOYAGE trials.

SESSION INFORMATION
Session Date: Monday, November 8, 2021
Session Title: Spondyloarthritis Including PsA – Treatment Poster II: Psoriatic Arthritis I (1329–1363)
Session Type: Poster Session C
Session Time: 8:30AM–10:30AM

Background/Purpose: Many patients with psoriatic arthritis (PsA) experience back pain and stiffness indicative of axial involvement [1]. The prevalence of axial involvement varies between 25-70% [2]. Ixekizumab (IXE), a monoclonal antibody with high affinity for IL17-A, has been studied in Phase 3 trials in patients with PsA (SPIRIT-P1 [Biologic-naïve; NCT01695239] and SPIRIT-P2 [Inadequate response or intolerant to 1 or 2 TNF inhibitors (TNFi); NCT02349295]) [3] [4]. The objective of this analysis was to determine the efficacy of IXE up to 52 weeks (Wks) in reducing axial symptoms and improving quality of life in patients with active PsA presenting with symptoms indicative of axial involvement.

Methods: This post-hoc analysis included data from two subpopulations of patients with PsA (pooled SPIRIT-P1 and -P2). Symptoms indicative of axial involvement were defined as Bath Ankylosing Spondylitis Disease Activity Index

Table. Baseline values and change from baseline (mBOCF) in the overall analysis population at Wks 16, 24 and 52 for BASDAI and ASDAS related endpoints in patients with PsA and axial pain. Data presented as mean (SD) unless otherwise specified. ‡p<0.001 vs PBO

	PBO (N=151)		IXE Q4W (N=162)		
Baseline values	**Wk 0**		**Wk 0**

Figure. Change from baseline (mBOCF) in BASDAI and ASDAS related endpoints in patients with PsA and axial pain in the overall analysis population. Data presented as mean (SD). ‡p<0.001 vs PBO.

(BASDAI) Q2 (back pain) ≥4, and an average of Q5 + Q6 (intensity and duration of morning stiffness in the spine) ≥4 at baseline. Patients included in the sensitivity analysis subgroup 1 were, in addition to the above-mentioned criteria, < 45 years of age, while patients included in sensitivity analysis subgroup 2 were aged < 45 but had also elevated C-reactive protein (CRP) (> 5 mg/l) at baseline. Efficacy of IXE was analysed using BASDAI questions, total BASDAI, mBASDAI (without Q3), and Ankylosing Spondylitis Disease Activity Score (ASDAS) change from baseline, as well as

BASDAI50 response and Short-Form-36 physical component summary (SF-36 PCS) improvement, at Wks 16, 24 and 52. Treatment comparison was done using logistic regression for BASDAI50, and analysis of covariance (ANCOVA) model for other endpoints. Missing data for binary and continuous endpoints were imputed by non-responder imputation and modified baseline carried forward (mBOCF), respectively.

Results: A total of 313 patients (placebo (PBO), N=151; IXE Q4W, N=162) met the overall analysis inclusion criteria. Baseline values for BASDAI and ASDAS related endpoints were balanced across treatment arms (Table). Improvement in axial symptoms were significantly greater in patients treated with IXE compared to PBO at Wks 16 and 24 (Figure). Improvement in quality of life (QoL) measures (SF-36 PCS) were also significantly greater in patients treated with IXE compared to PBO at Wks 16 and 24 (Table). Similar results were observed for patients < 45 years, and in patients < 45 years with CRP > 5 mg/l at baseline (sensitivity analysis, data not shown).

Conclusion: IXE is effective in reducing axial symptoms and improving QoL in patients with active PsA presenting with symptoms indicative of axial involvement.

Session Type: Poster Session C
Session Time: 8:30AM–10:30AM

Background/Purpose: Upadacitinib (UPA) 15 mg once daily (QD) has demonstrated efficacy and safety in patients with psoriatic arthritis (PsA) for up to 56 weeks in the Phase 3 SELECT-PsA 1 and 2 trials.[1,2] This post hoc analysis of these studies explored the association of baseline characteristics and short-term responses with achievement of minimal disease activity (MDA) and Disease Activity Index for Psoriatic Arthritis (DAPSA) low disease activity (LDA).

Methods: Data were pooled from patients with prior inadequate response or intolerance to ≥1 non-biologic (b) DMARDs (SELECT-PsA 1) or ≥1 bDMARDs (SELECT-PsA 2) originally randomized to UPA 15 mg QD. Logistic re-

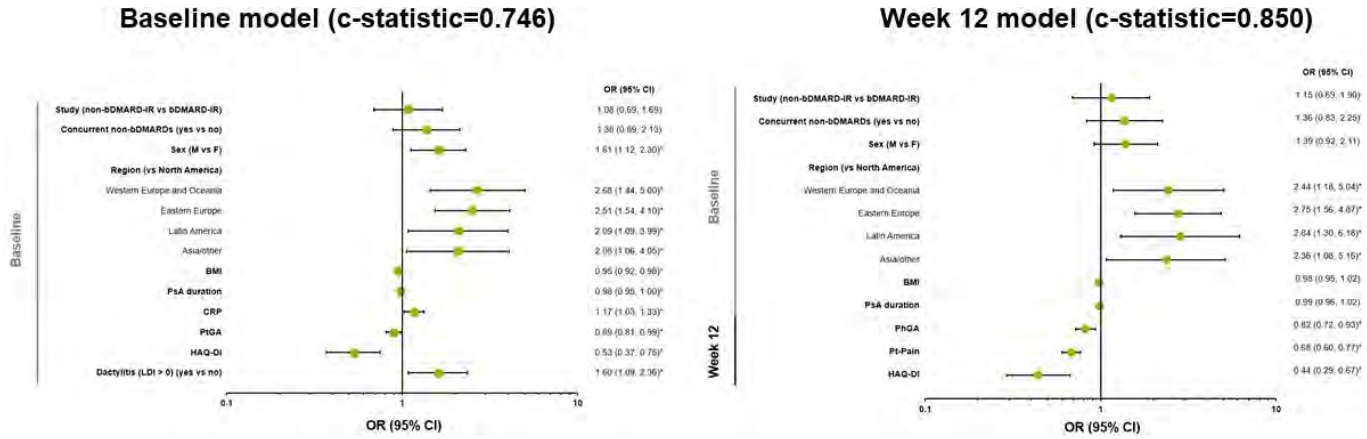

Figure 1. Predictors of Achievement of MDA at Week 56 with Upadacitinib 15 mg – Evaluated Simultaneously. *p<0.05. c-statistics: 0.6 indicates a fair model, 0.7 indicates a good model, and 0.8 indicates a strong model. Non-responder imputation was used for MDA at Week 56. bDMARD, biologic disease-modifying antirheumatic drug; BMI, body mass index; CI, confidence interval; CRP, C-reactive protein; F, female; HAQ-DI, Health Assessment Questionnaire-Disability Index; IR, inadequate responder; LDI, Leeds Dactylitis Index; M, male; MDA, minimal disease activity; OR, odds ratio; PhGA, Physician's Global Assessment; PsA, psoriatic arthritis; PtGA, Patient's Global Assessment; Pt-Pain, Patient's Assessment of Pain.

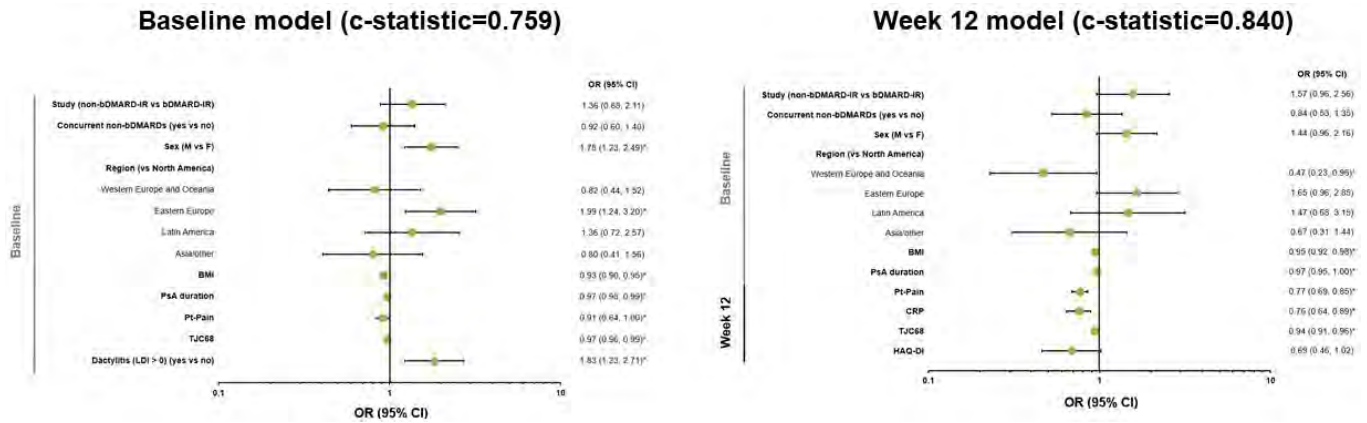

Figure 2. Predictors of Achievement of DAPSA LDA at Week 56 with Upadacitinib 15 mg – Evaluated Simultaneously. *p<0.05. c-statistics: 0.6 indicates a fair model, 0.7 indicates a good model, and 0.8 indicates a strong model. Non-responder imputation was used for DAPSA LDA at Week 56. bDMARD, biologic disease-modifying antirheumatic drug; BMI, body mass index; CI, confidence interval; CRP, C-reactive protein; DAPSA, Disease Activity Index for Psoriatic Arthritis; F, female; HAQ-DI, Health Assessment Questionnaire-Disability Index; IR, inadequate responder; LDA, low disease activity; LDI, Leeds Dactylitis Index; M, male; OR, odds ratio; PsA, psoriatic arthritis; Pt-Pain, Patient's Assessment of Pain; TJC68, tender joint count in 68 joints.

gression models were used to assess the association between baseline characteristics and short-term (Week 12) responses with achieving MDA or DAPSA LDA at 56 weeks, sustained MDA (MDA at Weeks 36 and 56), or sustained DAPSA LDA (DAPSA LDA at Weeks 36, 44, and 56). Each predictor was evaluated separately in an initial model that included effects for study and concurrent non-bDMARD use. Odds ratios and concordance (c-)statistics were used to determine the predictive accuracy. Statistically significant predictors were then evaluated simultaneously using stepwise logistic regression with the Akaike Information Criterion for model-building.

Results: Of 640 patients included in the analysis, 40% and 47% achieved MDA and DAPSA LDA, respectively, at 56 weeks. Evaluated separately, younger age, sex (male), geographic region, lower weight, lower body mass index, the presence of dactylitis or enthesitis, and lower scores of Patient's Assessment of Pain (Pt-Pain), Patient's Global Assessment (PtGA), tender joint count in 68 joints, and Health Assessment Questionnaire-Disability Index (HAQ-DI) were significant baseline predictors for achieving MDA and DAPSA LDA at Week 56. Lower Pt-Pain (Weeks 12–24) and PtGA (Weeks 16–24) scores were strongly predictive (c-statistics >0.8) of achieving MDA at Week 56, and both measures (from Week 8) were moderately predictive (c-statistics >0.7) of achieving DAPSA LDA. Evaluated simultaneously with several baseline characteristics, lower Pt-Pain and HAQ-DI scores at Week 12 were included in models strongly predictive of achieving MDA (c-statistic=0.850; **Figure 1**) and DAPSA LDA (c-statistic=0.840; **Figure 2**) at Week 56. For each 1-point increase in Pt-Pain or HAQ-DI scores at Week 12 (after adjusting for other effects in the model), patients were less likely to achieve MDA (by 32% or 56%, respectively) or DAPSA LDA (by 23% or 31%, respectively) at Week 56. Predictors for achieving sustained MDA and sustained DAPSA LDA were generally similar to those identified for achieving MDA and DAPSA LDA, respectively.

Conclusion: In patients with PsA receiving UPA 15 mg, baseline characteristics and early responses strongly predicted achievement of MDA or DAPSA LDA at Week 56. This may guide considerations of treatment targets in clinical trials and encourage physicians to further optimize treatment of their patients in clinical practice.

SESSION INFORMATION

Session Date: Monday, November 8, 2021

Session Title: Spondyloarthritis Including PsA – Treatment Poster II: Psoriatic Arthritis I (1329–1363)

Session Type: Poster Session C

Session Time: 8:30AM–10:30AM

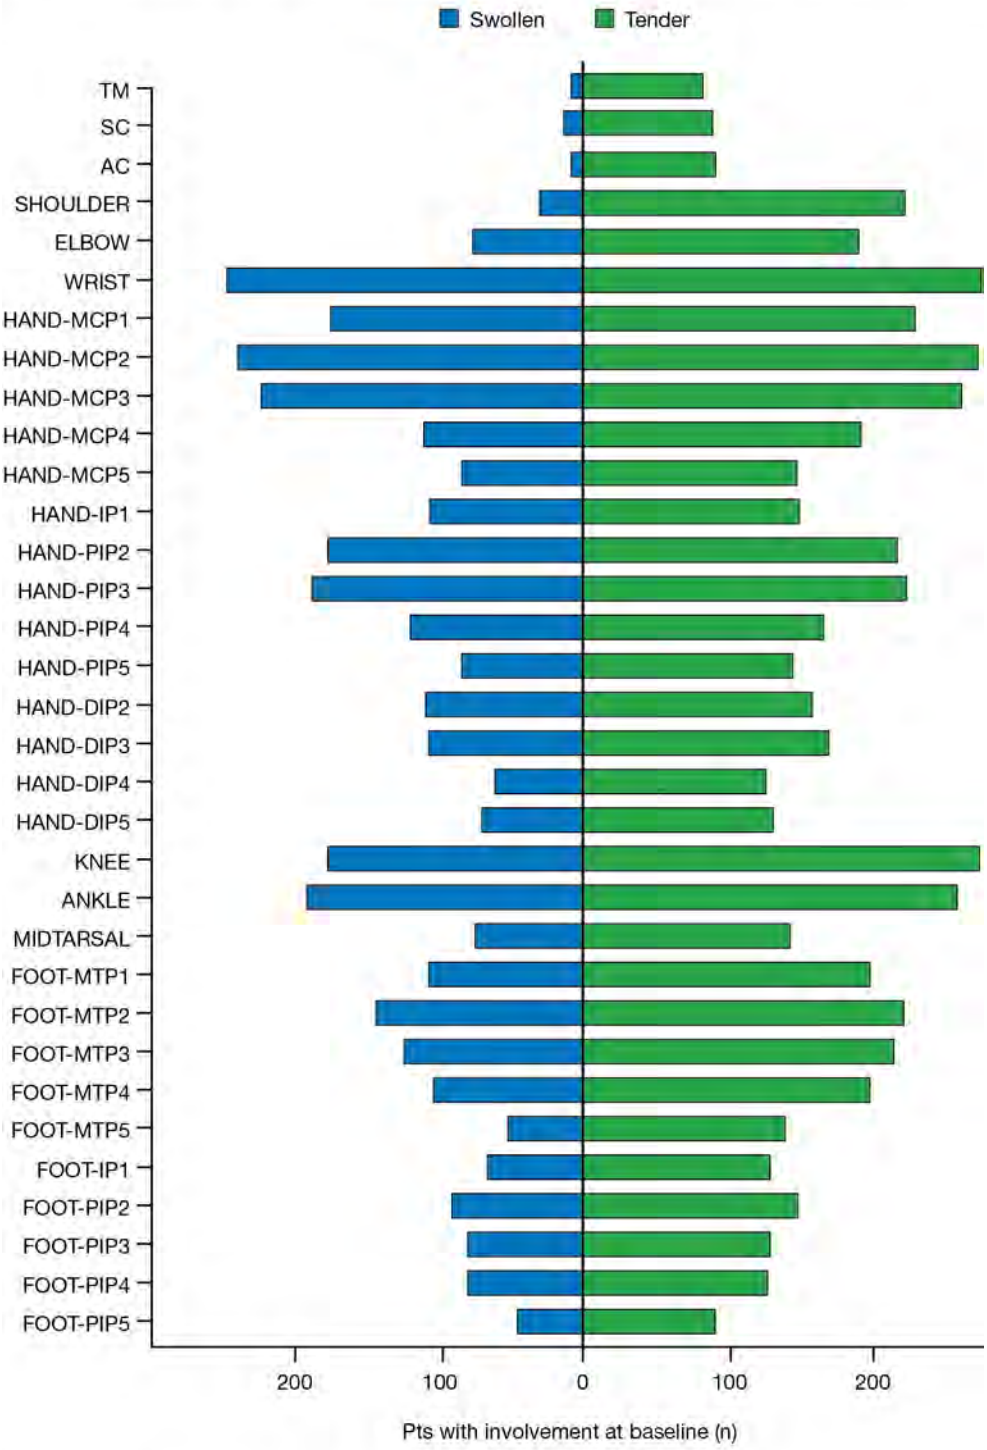
Background/Purpose: Peripheral joint involvement in PsA varies. In RA, varied joint involvement may reflect site-specific differences in stromal cell transcriptome, including Janus kinase-signal transducer and activator of transcription (JAK-STAT). Tofacitinib, an oral JAK inhibitor for the treatment of PsA, has been associated with improvements in peripheral arthritis.[1] Data on joint-specific responses in patients (pts) with PsA are sparse.[2] This analysis describes patterns of peripheral joint involvement and response to tofacitinib or adalimumab (ADA) treatment in pts with active PsA.

Methods: This post hoc analysis used data from OPAL Broaden (12 months; NCT01877668; N=422). Pts with PsA received tofacitinib 5 mg twice daily (BID), tofacitinib 10 mg BID, ADA 40 mg subcutaneous injection every 2 weeks, or placebo (PBO) switching to tofacitinib 5 or 10 mg BID at Month (M)3; all pts received a single background conventional synthetic DMARD (75–88% of pts received MTX).[1] OPAL Broaden was not designed to test non-inferiority/superiority between tofacitinib and ADA. Data at M3, 6, and 12 were included. A paired joint pathology score (PJPS), the sum of bilateral swollen/tender joint counts ranging from 0 (neither side swollen/tender) to 4 (both swollen and tender), was calculated. Percent change from baseline (%Δ) in PJPS for each joint and absolute differences in mean PJPS for each tofacitinib dose and PBO switch group at M3, 6, and 12 vs ADA were displayed as descriptive heat maps. Joint damage at M12 in the hand PIP, MCP, and wrist joints, and foot (IP and MTP joints), was assessed using components of the modified total Sharp score (mTSS). Statistical comparison of radiographic PJPS (rPJPS), derived from bilateral mTSS in each joint group, was performed using a mixed-effects model for repeated measurements.

Results: The baseline distribution of involved joints was typical for PsA (Fig 1).[2] At M3, %ΔPJPS (improvement) was greater in joints below the knee with PBO. At M12, greater reductions in PJPS were observed with tofacitinib or ADA in the wrist, radial MCPs, and hand PIPs vs other joints (Fig 2a). At M12, greater reductions in PJPS were observed with ADA vs tofacitinib in the hand DIPs, and in the hand PIPs and feet (especially PIPs) with tofacitinib vs ADA (Fig 2b). Despite no major numeric differences in %ΔrPJPS with tofacitinib vs ADA, greater radiographic progression in the feet was observed at M12 in pts switching from PBO to tofacitinib 10 mg BID at M3, vs ADA ($p < 0.05$) (Fig 2c). Various limitations preclude comparisons between tofacitinib and ADA.

Conclusion: We provide descriptive data on joint-level responses in pts with PsA receiving tofacitinib or ADA, and further evidence of a possible proximal/distal response gradient in MTX-treated arthritis.[3] No consistent joint response patterns were observed with tofacitinib or ADA. A 3-month delay in advanced therapy initiation may result in radiographic progression in the feet.

Figure 1. Total number of pts with specific joint involvement at baseline in OPAL Broaden (N=422)



N represents the number of pts with baseline PJPS > 0 for a given joint

AC, acromioclavicular; PJPS, paired joint pathology score; SC, sternoclavicular

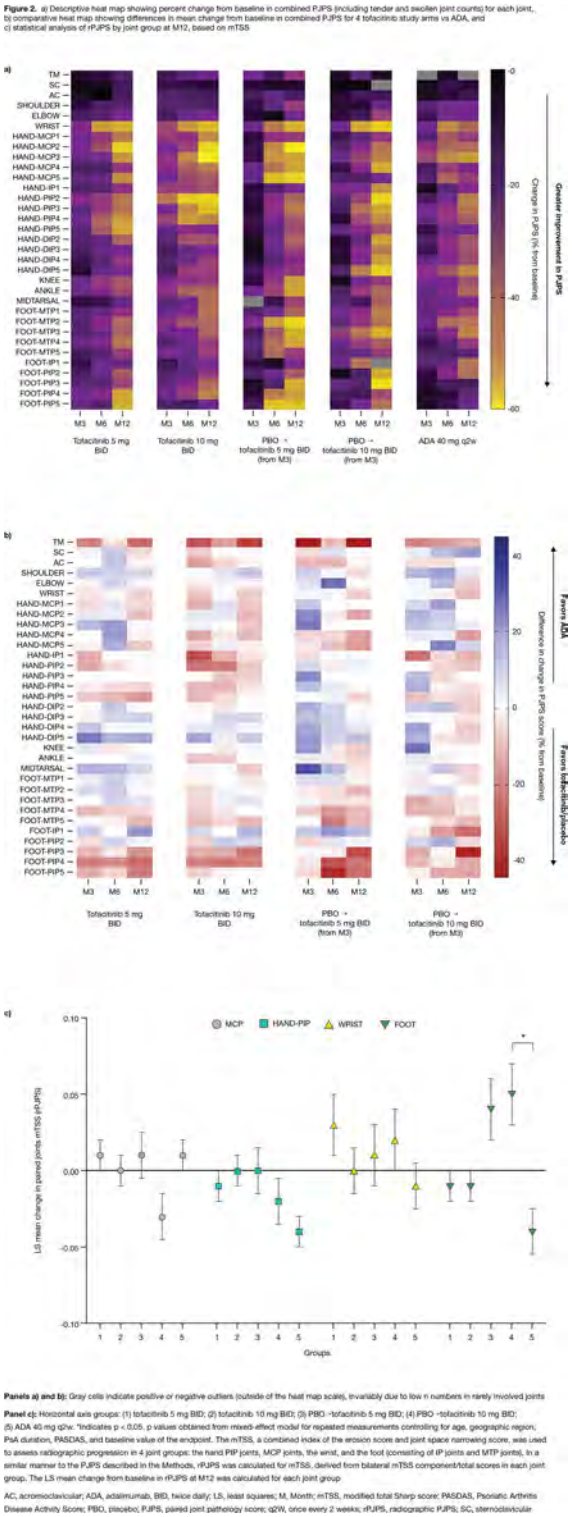

Figure 2. a) Descriptive heat map showing percent change from baseline in combined PJPS (including tender and swollen joint counts) for each joint, b) comparative heat map showing differences in mean change from baseline in combined PJPS for 4 tofacitinib study arms vs ADA, and c) statistical analysis of rPJPS by joint group at M12, based on mTSS

Panels a) and b): Gray cells indicate positive or negative outliers (outside of the heat map scale), invariably due to low n numbers in rarely involved joints

Panel c): Horizontal axis groups: (1) tofacitinib 5 mg BID; (2) tofacitinib 10 mg BID; (3) PBO →tofacitinib 5 mg BID; (4) PBO →tofacitinib 10 mg BID; (5) ADA 40 mg q2w. *Indicates $p < 0.05$. p values obtained from mixed-effect model for repeated measurements controlling for age, geographic region, PsA duration, PASDAS, and baseline value of the endpoint. The mTSS, a combined index of the erosion score and joint space narrowing score, was used to assess radiographic progression in 4 joint groups: the hand PIP joints, MCP joints, the wrist, and the foot (consisting of IP joints and MTP joints), in a similar manner to the PJPS described in the Methods. rPJPS was calculated for mTSS, derived from bilateral mTSS component/total scores in each joint group. The LS mean change from baseline in rPJPS at M12 was calculated for each joint group

AC, acromioclavicular; ADA, adalimumab, BID, twice daily; LS, least squares; M, Month; mTSS, modified total Sharp score; PASDAS, Psoriatic Arthritis Disease Activity Score; PBO, placebo; PJPS, paired joint pathology score; q2W, once every 2 weeks; rPJPS, radiographic PJPS; SC, sternoclavicular

SESSION INFORMATION

Session Date: Monday, November 8, 2021

Session Title: Spondyloarthritis Including PsA – Treatment Poster II: Psoriatic Arthritis I (1329–1363)

Session Type: Poster Session C

Session Time: 8:30AM–10:30AM

Background/Purpose: Bimekizumab (BKZ) is a monoclonal IgG1 antibody that selectively inhibits both interleukin (IL)-17F and IL-17A, and has demonstrated clinical improvements in joint and skin outcomes up to 152 weeks (wks) with an acceptable safety profile in patients (pts) with active psoriatic arthritis (PsA).[1,2] Achievement of low disease activity in pts with PsA has been associated with improvements in pt-reported health-related quality of life (HRQoL).[3] To report long-term impact of BKZ treatment, up to 3 years, on pt-reported outcome (PRO) measures from a phase 2b dose-ranging study (BE ACTIVE; NCT02969525) and its open-label extension (OLE; NCT03347110).

Methods: BE ACTIVE and OLE study designs have been described previously.[1,2] Pts who completed 48 wks of BKZ treatment without meeting withdrawal criteria were eligible for OLE entry. All OLE pts received BKZ 160 mg every 4 wks. Data are presented from BE ACTIVE baseline (BL) and at Wks 48 and 152. PROs reported (full analysis set [FAS]): 9-item Psoriatic Arthritis Impact of Disease (PsAID-9) individual domains (change from BL [CfB]) and Patient Acceptable Symptom State (PASS [score≤4]),[4] Health Assessment Questionnaire Disability Index (HAQ-DI) Minimal Clinically Important Difference (MCID; ≥0.35 decrease from BL), CfB in Short Form-36 (SF-36) individual domains, CfB in SF-36 Physical and Mental Component Summaries (PCS/MCS), and CfB in Patient's Assessment of Arthritis Pain (PtAAP) visual analogue scale (VAS). In addition to observed case (OC) data, we report results with non-responder imputation (NRI) or multiple imputation (MI; based on the missing at random assumption).

Results: Of 206 randomized pts at BL in BE ACTIVE, 66.5% had psoriasis body surface area ≥3%, 18.9% had prior tumor necrosis factor inhibitor exposure, and 63.6% received concomitant methotrexate. Mean BL PRO scores were

Baseline PRO scores, mean (SD)			
PsAID-9	4.5 (1.9)	4.9 (2.0)	4.6 (1.9)
HAQ-DI	1.0 (0.6)	1.0 (0.6)	1.0 (0.6)
SF-36 PCS	37.0 (9.1)	36.0 (9.0)	36.6 (9.1)
SF-36 MCS	56.0 (8.6)	55.4 (9.1)	55.8 (8.7)
PtAAP	50.8 (22.7)	54.3 (23.4)	52.2 (23.0)
Baseline PsAID-9 PASS, n (%)	45 (36.3)	26 (31.7)	71 (34.5)

comparable across dose groups in BE ACTIVE (**Table 1**). At Wks 48/152, the proportions of patients who achieved PsAID-9 PASS (NRI) were 74.2–76.8%/63.7–67.1%; the proportions of patients who achieved HAQ-DI MCID (NRI) were 47.6–53.7%/42.7–45.1% (**Figure 1A–D**). All PsAID-9 domains and the majority of the 8 SF-36 domains improved from BL to Wks 48 and 152, including measures of fatigue and bodily pain. SF-36 PCS improved from BL to Wks 48 and 152 and SF-36 MCS remained within the normal range from BL, as expected (**Figure 1E–F; Table 2**). Pts showed sustained improvements in pain by mean CfB in PtAAP VAS score at Wk 48 (between –26.8 and –34.7; MI) and Wk 152 (between –31.3 and –33.0; MI) (**Figure 1G**). There were no clear differences between pts who completed either BKZ 160 mg or BKZ 320 mg in BE ACTIVE prior to receiving BKZ 160 mg in the OLE.

Conclusion: BKZ treatment is associated with sustained improvements in PRO measures of disease impact up to 3 years, including in pain and fatigue. Furthermore, BKZ treatment is associated with substantial and durable improvements in measures of overall physical function and HRQoL up to 3 years.

The Impact of Skin Involvement and Depression on Patient Acceptable Symptom State in Patients with Psoriatic Arthritis and Psoriasis: Results from a Multinational Survey

Alexis Ogdie-Beatty[1], Joseph Merola[2], Pascal Richette[3], Sven Richter[4], Shauna Jardon[5], Lihua Tang[4] and William Tillett[6], [1]University of Pennsylvania, Philadelphia, PA, [2]Harvard Medical School, Brigham and Women's Hospital, Boston, MA, [3]Lariboisiere Hospital, Paris, France, [4]Amgen Inc., Thousand Oaks, CA, [5]Amgen Inc., Gilbert, AZ, [6]Royal National Hospital for Rheumatic Diseases, Bath, United Kingdom

SESSION INFORMATION

Session Date: Monday, November 8, 2021

Session Title: Spondyloarthritis Including PsA – Treatment Poster II: Psoriatic Arthritis I (1329–1363)

Session Type: Poster Session C

Session Time: 8:30AM–10:30AM

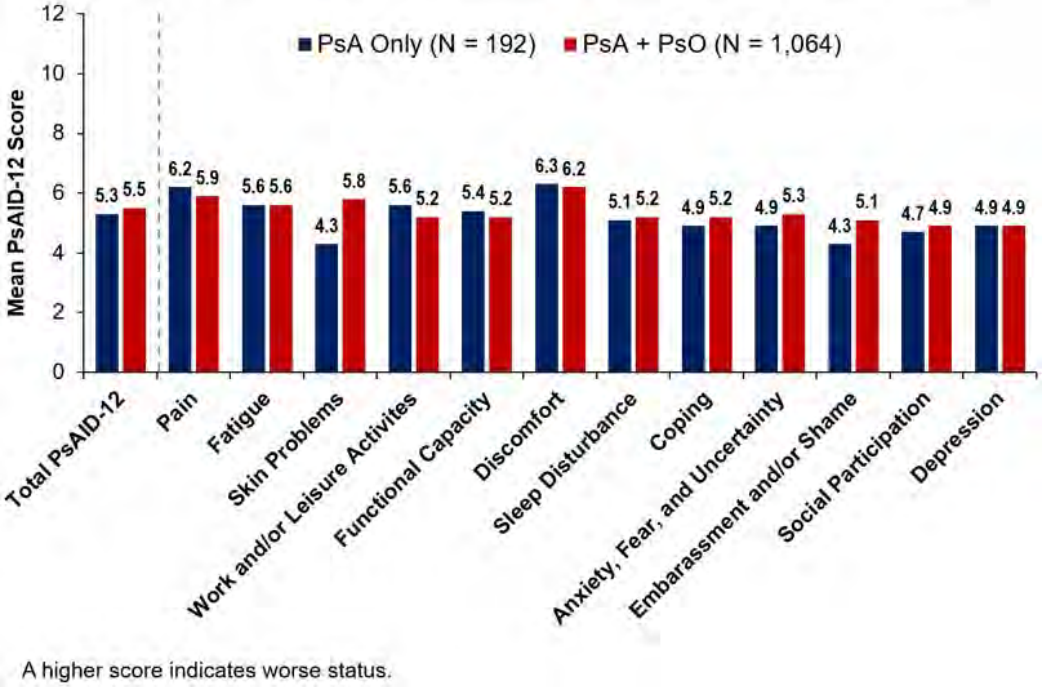
Background/Purpose: Depression, a common comorbidity in patients with psoriasis (PsO) and PsA, has been shown to be independently associated with Psoriatic Arthritis Impact of Disease (PsAID-12) scores. We investigated how

much active PsO and a positive 2-item Patient Health Questionnaire (PHQ-2) depression screen impacted PsAID-12 scores in patients with PsA in the Understanding Psoriatic Disease Leveraging Insights for Treatment (UPLIFT) survey.

Methods: UPLIFT was a multinational Web-based survey conducted in 2020 in adults who reported ever being diagnosed by a healthcare provider (HCP) with PsA and/or PsO. For patients with PsA, we report PsAID-12 total and domain scores and Patient Acceptable Symptom State (PASS) achievement (PsAID-12 ≤4) according to the presence of active PsO and depression status. A PHQ-2 score ≥3 indicates a positive screen for depression.

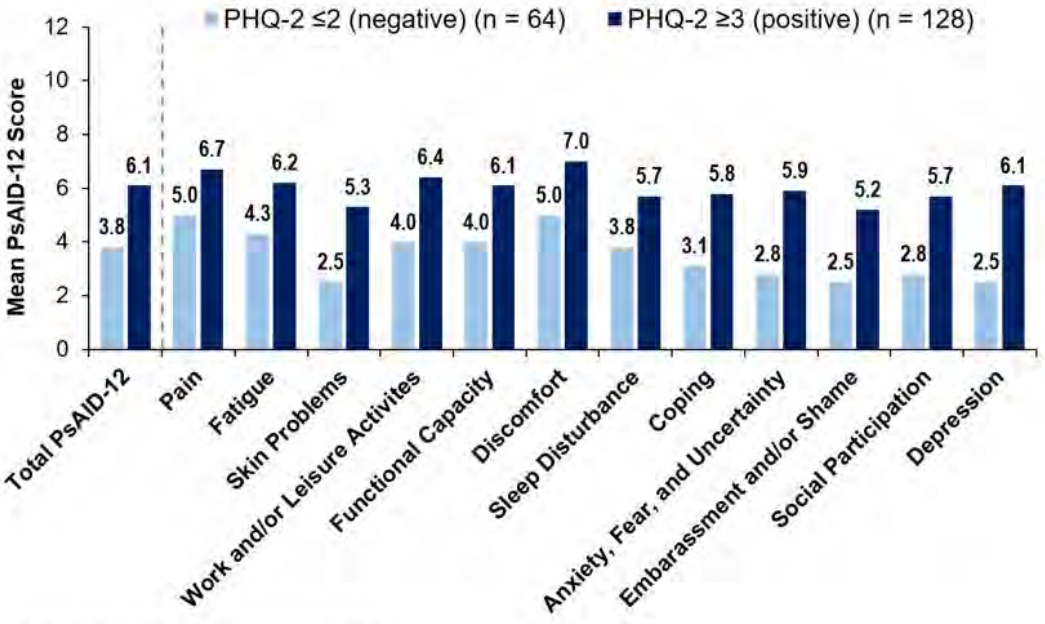
Results: Of the 3,806 patient survey respondents, 1,256 reported HCP-diagnosed PsA, of which 1,064 had HCP-diagnosed PsA + active PsO and 192 had PsA only. In patients with PsA + PsO, enthesitis (44.5%), dactylitis (47.0%), and polyarthritis (59.8%) were more prevalent than in patients with PsA without active PsO (37.5%, 37.5%, and 36.5%, respectively). More patients with PsA + PsO vs PsA only had a history of patient-reported HCP-diagnosed comorbidities, including depression (42.7% vs 26.6%), cancer (30.7% vs 21.4%), heart disease (23.1% vs 13.5%), hypertension (44.0% vs 33.3%), liver disease (21.0% vs 12.5%), and inflammatory bowel disease (25.5% vs 14.1%). Despite differences in comorbidity burden, mean total PsAID-12 scores (Figure 1) and rates of PASS achievement (25.0% vs 26.9%) were similar in patients with PsA only and PsA + PsO. Mean individual PsAID-12 domain scores were generally similar between groups; however, impact of "skin problems" and "embarrassment and/or shame" was more pronounced for the PsA + PsO group (Figure 1). A total of 67% of PsA only and 66% PsA + PsO patients had a PHQ-2 ≥3. Patients with PHQ-2 ≥3 had higher PsAID-12 scores, indicating worse health status, regardless of whether they had active PsO. Fewer patients with PHQ-2 ≥3 achieved PASS (PsA: 10.9%, PsA + PsO: 10.7%) compared with those who screened negative for depression (PsA: 53.1%, PsA + PsO 58.8%). Similarly, higher PsAID-12 domain scores were reported in patients with PsA with PHQ-2 ≥3 vs those with PHQ-2 ≤2 (Figure 2) and to a greater extent in those with PsA + PsO (Figure 3). The greatest differences between groups were observed in domains of "work and/or leisure activities," "coping," "anxiety, fear, and uncertainty," "embarrassment and/or shame," and "social participation."

Figure 1. Total PsAID-12 and Domain Scores in Patients With PsA and PsA + PsO



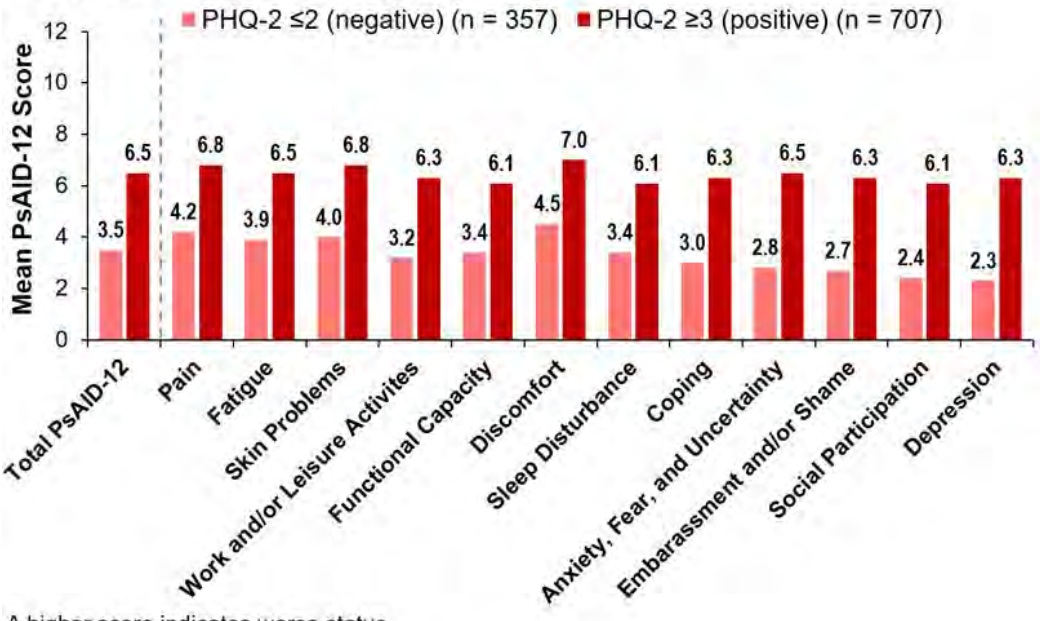
A higher score indicates worse status.

Figure 2. Total PsAID-12 and Domain Scores in Patients With PsA According to PHQ-2 Screening Status



A higher score indicates worse status.

Figure 3. Total PsAID-12 and Domain Scores in Patients With PsA + PsO According to PHQ-2 Screening Status



A higher score indicates worse status.

Conclusion: For patients with PsA in UPLIFT, active PsO was associated with generally more active disease and a higher prevalence of comorbidities, including depression. Having a positive PHQ-2 screen for depression was associated with overall disease impact as measured by PsAID.

Deucravacitinib Efficacy in Psoriatic Arthritis (PsA) by Baseline DMARD Use: Exploratory Analysis from a Phase 2 Study

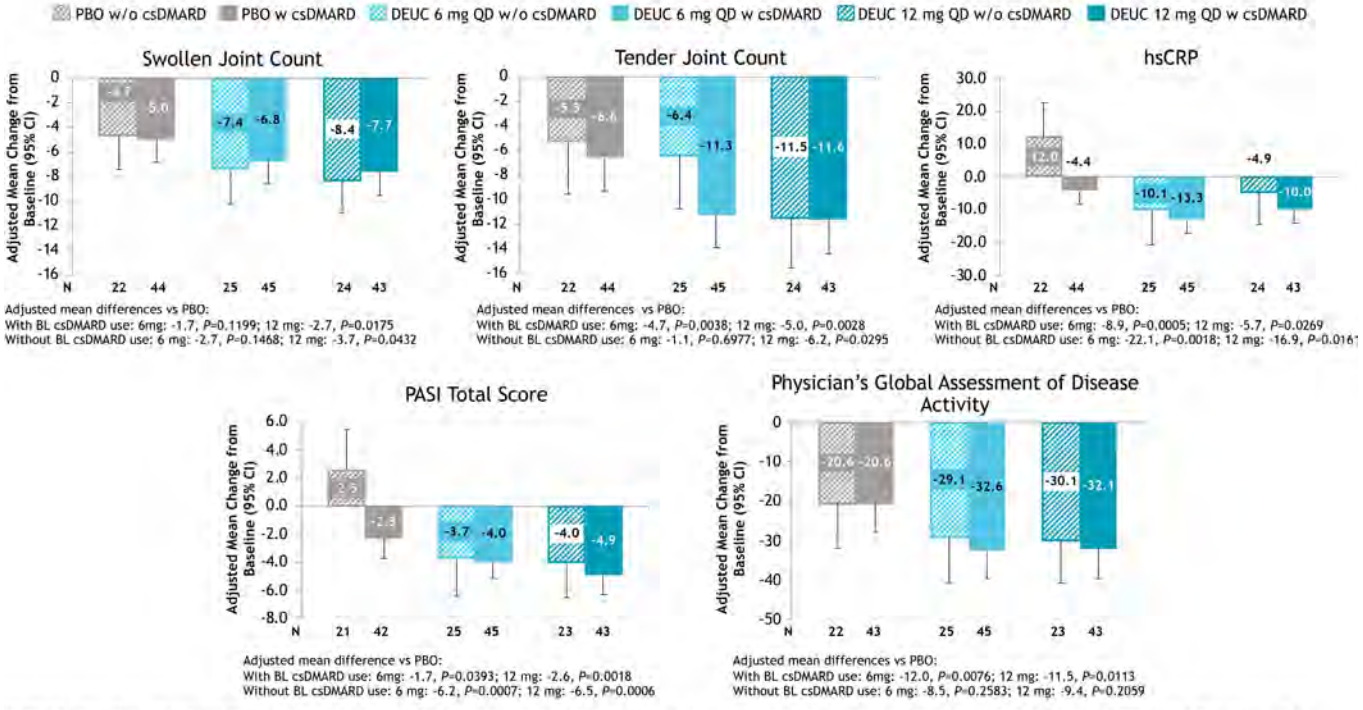
Atul Deodhar[1], Miroslawa Nowak[2], June Ye[2], Tom Lehman[2], Lan Wei[2], Subhashis Banerjee[2] and Philip Mease[3], [1]Oregon Health & Science University, Portland, OR, [2]Bristol Myers Squibb, Princeton, NJ, [3]Swedish Medical Center/ Providence St. Joseph Health and University of Washington, Seattle, WA

SESSION INFORMATION

Session Date: Monday, November 8, 2021
Session Title: Spondyloarthritis Including PsA – Treatment Poster II: Psoriatic Arthritis I (1329–1363)
Session Type: Poster Session C
Session Time: 8:30AM–10:30AM

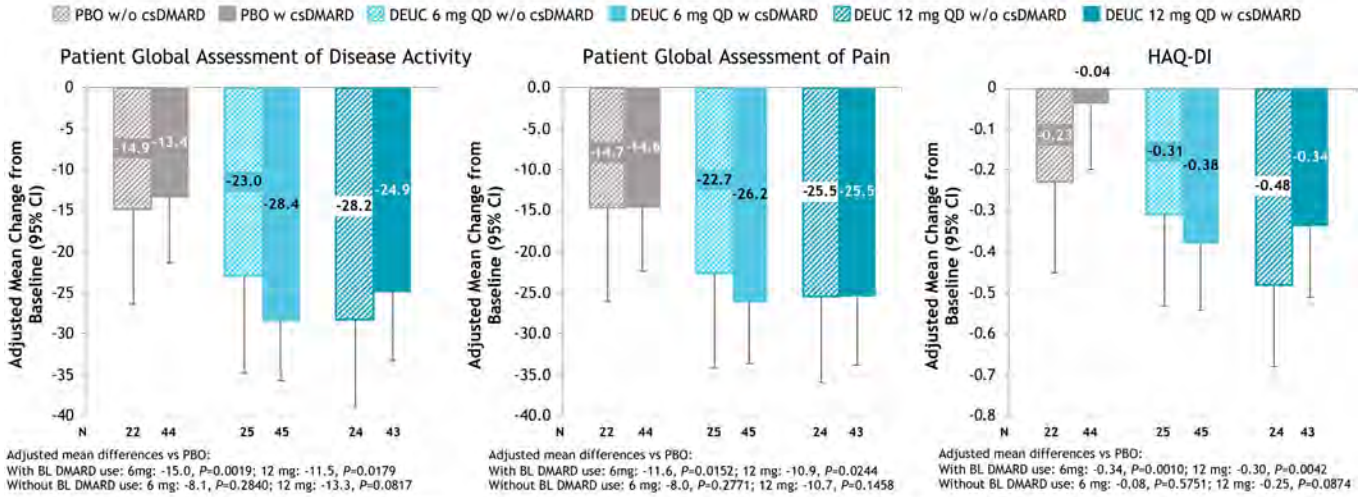
Background/Purpose: PsA presents with heterogeneous clinical manifestations including joint pain, enthesitis, dactylitis, and skin and nail lesions. Treatment guidelines recommend that PsA patients (pts) who do not adequately respond to conventional synthetic DMARDs (csDMARDs) can initiate treatment with targeted synthetic DMARDs with or without background use of csDMARDs. Deucravacitinib is a novel, oral, selective inhibitor of tyrosine kinase

Figure 1: Adjusted Mean Change from Baseline at Week 16 by csDMARD Use: Clinical Measures



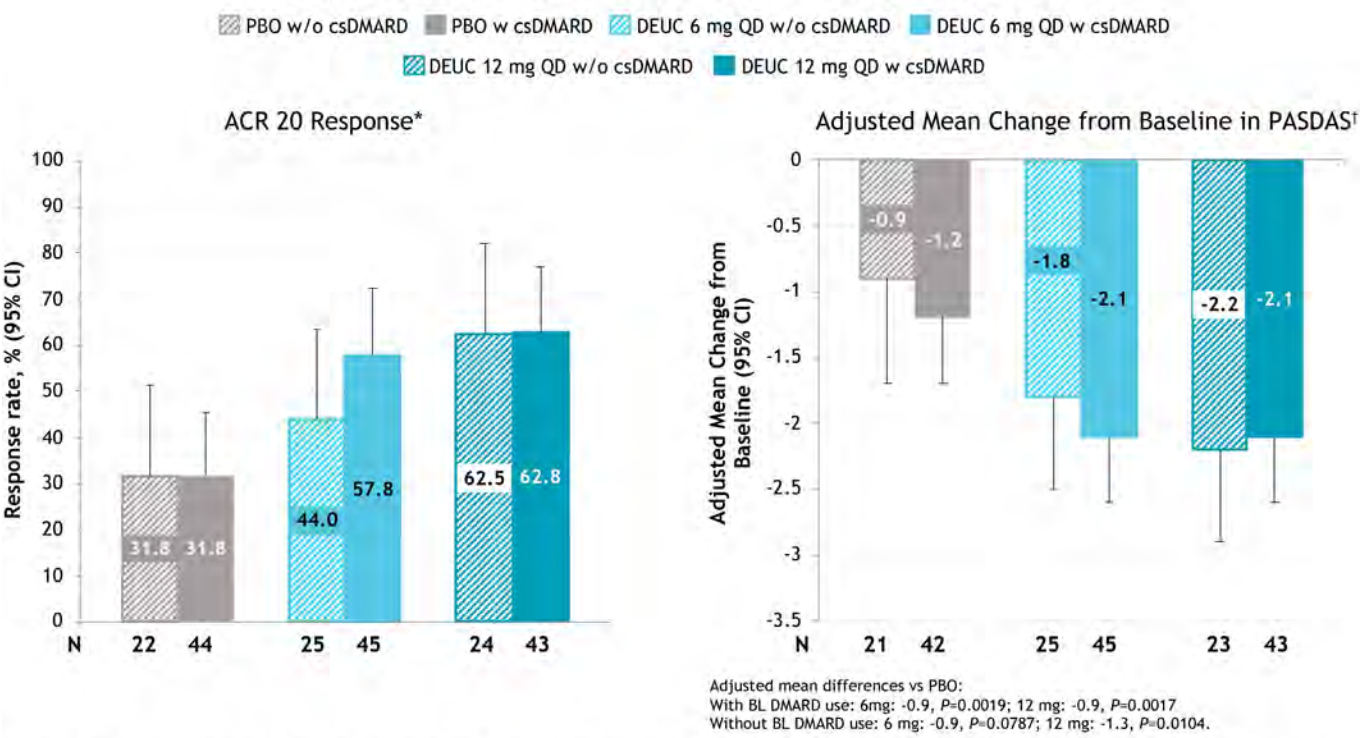
Modified baseline observation carried forward was used to impute missing data. Adjusted means, 95% CI, and p-values from an analysis of covariance model with factors for body weight and TNFi use and the baseline value as covariate. BL, baseline; csDMARD, conventional synthetic disease-modifying antirheumatic drug; DEUC, deucravacitinib; hsCRP, high-sensitivity C-reactive protein; PASI, Psoriasis Area Severity Index; PBO, placebo; QD, daily.

Figure 2: Adjusted Mean Change from Baseline at Week 16 by csDMARD Use: Patient-Reported Outcomes



Modified baseline observation carried forward was used to impute missing data. Adjusted means, 95% CI, and p-values from an analysis of covariance model with factors for body weight and TNFi use and the baseline value as covariate. BL, baseline; csDMARD, conventional synthetic disease-modifying antirheumatic drug; DEUC, deucravacitinib; HAQ-DI, Health Assessment Questionnaire Disability Index; PBO, placebo; QD, daily.

Figure 3: Composite Measures at Week 16 by csDMARD Use



*Analyses were performed using NRI for patients with missing data. †Modified baseline observation carried forward was used to impute missing data. Adjusted means, 95% CI, and p-values from an analysis of covariance model with factors for body weight and TNFi use and the baseline value as covariate. ACR, American College of Rheumatology; csDMARD, conventional synthetic disease-modifying antirheumatic drug; DEUC, deucravacitinib; NRI, non-responder imputation; PASDAS, Psoriatic Arthritis Disease Activity Score; PBO, placebo; QD, daily.

2 (TYK2) with a unique mechanism of action distinct from other kinase inhibitors. It binds to the TYK2 regulatory domain and allosterically inhibits the enzyme, thereby suppressing signaling of key cytokines (eg, IL-23) involved in the pathogenesis of PsA. In a Phase 2 trial in pts with active PsA, the primary endpoint, ACR 20 response at Week (Wk) 16, was met and the results showed that deucravacitinib was efficacious and well tolerated versus placebo (PBO).[1] This analysis further evaluated improvements with deucravacitinib in the Phase 2 trial in PsA pts treated with and without background csDMARDs.

Methods: This 1-year, randomized, double-blind, placebo-controlled, multicenter Phase 2 trial (NCT03881059) enrolled pts who had a PsA diagnosis for ≥6 months, fulfilled Classification Criteria for Psoriatic Arthritis (CASPAR) at screening, had active joint disease (≥3 tender and ≥3 swollen joints), a high-sensitivity CRP level of ≥3 mg/L, and ≥1 plaque psoriasis lesion (≥2 cm). Pts either failed or were intolerant to ≥1 NSAID, corticosteroid, csDMARD, and/or 1 TNF inhibitor (TNFi; up to 30%). Pts were randomized 1:1:1 to deucravacitinib 6 mg once daily (QD) or 12 mg QD, or PBO. A post hoc subgroup analysis in pts with and without background csDMARD use assessed improvements in select clinical outcomes (ACR 20 response, and change from baseline in ACR components, Psoriasis Area and Severity Index total score, and Psoriatic Arthritis Disease Activity Score) at Wk 16.

Results: Baseline demographics, clinical characteristics, and disease activity were generally similar among pts with and without background csDMARD use. At baseline, background csDMARD use was 64.3%, 64.2%, and 66.7% in the deucravacitinib 6 mg QD, 12 mg QD, and PBO groups, respectively. Among pts on csDMARDs at baseline, 77.8%, 86%, and 88.6%, respectively, were being treated with methotrexate. Pts with and without background csDMARD use showed similar improvements at Wk 16 with deucravacitinib treatment vs PBO on most clinical measures (**Figure 1**), pt-reported outcomes (**Figure 2**), and composite measures (**Figure 3**). No clinically relevant differences in adverse events (AEs) were observed in pts with or without background csDMARD use.

Conclusion: These analyses demonstrate that the efficacy of deucravacitinib for the treatment of PsA was similar in pts with and without background csDMARD use. The AE profile of deucravacitinib treatment with and without csDMARD use was consistent with findings from the overall Phase 2 PsA trial population.

SESSION INFORMATION

Session Date: Monday, November 8, 2021

Session Title: Spondyloarthritis Including PsA – Treatment Poster II: Psoriatic Arthritis I (1329–1363)

Session Type: Poster Session C

Session Time: 8:30AM–10:30AM

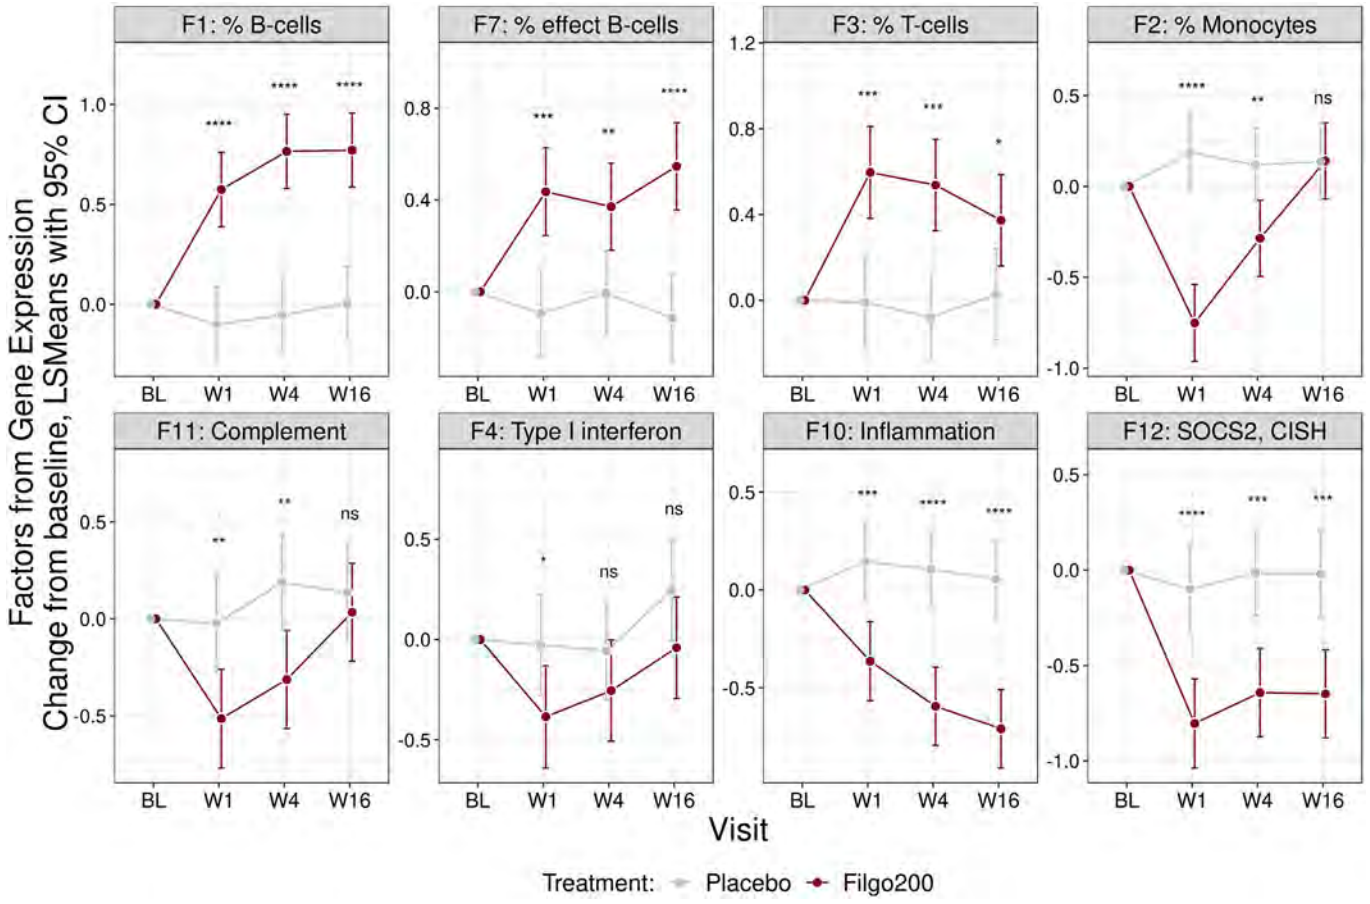

Figure 1. Pharmacodynamic gene expression changes observed during 16 weeks of treatment with FIL or PBO. Exploratory Factor Analysis was performed using the union of gene signatures (FIL vs PBO) at BL and Weeks 1, 4 and 16. Eight derived factors showed significant changes with FIL treatment as compared to PBO with FDR<0.05. Changes in circulating cell composition (Factor 1: % B cells, Factor 7: % Effector B cells, Factor 3: % T cells, Factor 2: % Monocytes) and changes in transcriptional pathways (Factor 11: Complement, Factor 4: Type I Interferon, Factor 10: Inflammation, Factor 12: SOCS2,CISH) were observed. * $p \leq 0.05$, ** $p \leq 0.01$, *** $p \leq 0.001$, **** $p \leq 0.0001$.

Background/Purpose: Psoriatic arthritis (PsA) is a chronic inflammatory autoimmune disease characterized by musculoskeletal and skin inflammation. Selective inhibition of Janus kinase 1 (JAK1) has the potential to simultaneously block multiple inflammatory pathways and alleviate pathology. In the recently completed EQUATOR study, filgotinib (FIL), a preferentially JAK1 selective inhibitor, showed significant improvements in clinical signs and symptoms of PsA versus placebo.[1] In this study, whole-blood RNA-Seq data analysis was performed to evaluate the impact of FIL on gene expression and biological pathways in the EQUATOR study.

Methods: EQUATOR (Clinicaltrials.gov identifier: NCT03101670) was a phase 2 double-blind, placebo (PBO)-controlled study in 131 patients with active moderate-to-severe PsA and insufficient response or intolerance to ≥1 conventional synthetic DMARD. Patients were randomized 1:1 to receive FIL 200 mg or PBO orally once daily for 16 weeks. Whole blood samples from patients were collected at baseline and weeks 1, 4 and 16. Illumina TruSeq Stranded mRNA was generated for 452 samples from 121 patients. Gene-level quantification of RNA-seq counts and transcripts/million was conducted using Salmon (v0.8.2, and gencode GRCh38.p7 v25). Pathway analysis was performed using single sample gene set enrichment analysis based on Hallmark 50 pathways (v7.0) from the MSigDB. Treatment effect was evaluated using differential expression analysis by limma. Twelve factors were extracted from the union of genes significantly affected by FIL treatment compared to PBO at either week 1, 4 or 16. An effect of FIL on Factor scores was evaluated with mixed effect linear models for repeated measures.

Results: At baseline, Spearman rank correlation analyses showed a number of inflammation-associated genes and immune related Hallmark 50 pathways significantly correlated with CRP, Disease Activity in Psoriatic Arthritis score (DAPSA) and patient reported pain. Several of these pathways were decreased with FIL treatment including IL6_JAK_STAT3 and Inflammatory Response. Differential gene expression analysis comparing PBO-corrected samples from FIL-treated patients revealed significant changes in individual gene expression across weeks 1, 4 and 16 such as downregulation of the CRP-associated gene FAM20A and the JAK-STAT pathway members SOCS2 and CISH.

The pharmacodynamic effects of FIL can be described by changes in 8 factors derived from latent variables resulting from Exploratory Factor Analysis (Figure 1). These factors are split into two distinct categories: changes in circulating cell composition (% total B cells, % effector B cells, % T cells, % monocytes) and changes in transcriptional pathways (Complement, Type I Interferon, Inflammation, SOCS2/CISH).

Conclusion: Treatment with FIL rapidly downregulates inflammatory and immune pathways associated with PsA disease activity as a result of changes in inflammatory gene expression and alterations in circulating cellular composition.

Differences in Real-World Patient Characteristics of 8921 Patients with Psoriasis with and Without Comorbid Psoriatic Arthritis Using the UK BADBIR Database

William Tillett[1], Alexis Ogdie[2], Patricia Gorecki[3] and Alun Passey[4], [1]Royal National Hospital for Rheumatic Diseases, Bath, United Kingdom, [2]University of Pennsylvania, Philadelphia, PA, [3]Janssen Medical Affairs, London, United Kingdom, [4]Janssen Real World Evidence, HEMAR EMEA, High Wycombe, United Kingdom

SESSION INFORMATION
Session Date: Monday, November 8, 2021
Session Title: Spondyloarthritis Including PsA – Treatment Poster II: Psoriatic Arthritis I (1329–1363)
Session Type: Poster Session C
Session Time: 8:30AM–10:30AM

Background/Purpose: Psoriatic arthritis (PsA) is a chronic inflammatory arthritis associated with psoriasis (PsO) and multiple comorbidities.[1] Approximately one-third of patients with PsO develop PsA during the course of their disease.[2] As patient cohorts included in randomized clinical trials are not necessarily representative of the real world, registry data can complement information gained on patient characteristics and disease outcomes.[1,3] The British Association of Dermatologists Biologic and Immunomodulators Register (BADBIR) is one such registry for patients

with plaque PsO, with PsA being one of the comorbidities recorded at patient enrollment. The primary objective of this study was to evaluate baseline characteristics and comorbidities in patients with PsO with and without a PsA diagnosis using the BADBIR database. The hypothesis was that patients with both diseases have a higher likelihood of being diagnosed with additional comorbid conditions vs. those with PsO alone.

Methods: This was a retrospective observational study using two cohorts of BADBIR data (i.e. adult patients with PsO either receiving ustekinumab [UST] as their biologic treatment or receiving conventional systemic anti-psoriatic medication [conventional systemic]). Comparisons were made between comorbid PsA and PsO alone patients in each cohort at baseline, additionally stratifying by biologic experience in the UST treatment group. Baseline characteristics of interest were evaluated, including body mass index, smoking, and employment status, as well as comorbidities (i.e. diabetes, hypertension, myocardial infarction, and depression). Strength of association between variables was measured by odds ratio, and 95% confidence intervals were generated; two-sided p-values were obtained by Fisher's exact test.

Results: Patient counts in each cohort were as follows: UST without PsA, n=2697; UST with PsA, n=590; conventional systemic without PsA, n=5105; conventional systemic with PsA, n=529. Patients with PsO and a PsA diagnosis had a higher prevalence of diabetes, obesity, and hypertension across both conventional systemic and UST cohorts vs. PsO alone (Table 1). Similarly, inability to work was notably higher in patients with PsO and comorbid PsA vs. PsO alone (Figure 1). Patients with PsO and comorbid PsA receiving UST were more likely to have a diagnosis of depression than those receiving conventional systemic treatment (Table 1).

Table 1. Prevalence odds ratio of baseline characteristics of patients with PsO treated with either UST or a conventional systemic agent. Odds ratios and 95% CIs are shown for the prevalence of each patient baseline characteristic in the PsO with comorbid PsA group vs. the prevalence in the PsO alone group. *Obesity is defined as a BMI ≥30 kg/m2. BMI, body mass index; CI, confidence interval; PsA, psoriatic arthritis; PsO, psoriasis; UST, ustekinumab

Baseline variable	Treatment cohort	Odds ratio	95% CI
Ability to work	UST	0.27	0.21–0.35
	Conventional systemic	0.49	0.37–0.65
Smoking	UST	0.94	0.76–1.17
	Conventional systemic	0.72	0.58–0.89
Depression	UST	1.54	1.25–1.88
	Conventional systemic	1.14	0.91–1.42

Hypertension	UST	1.54	1.26–1.87
	Conventional systemic	1.30	1.03–1.62
Myocardial infarction	UST	1.67	0.98–2.76
	Conventional systemic	1.17	0.56–2.21

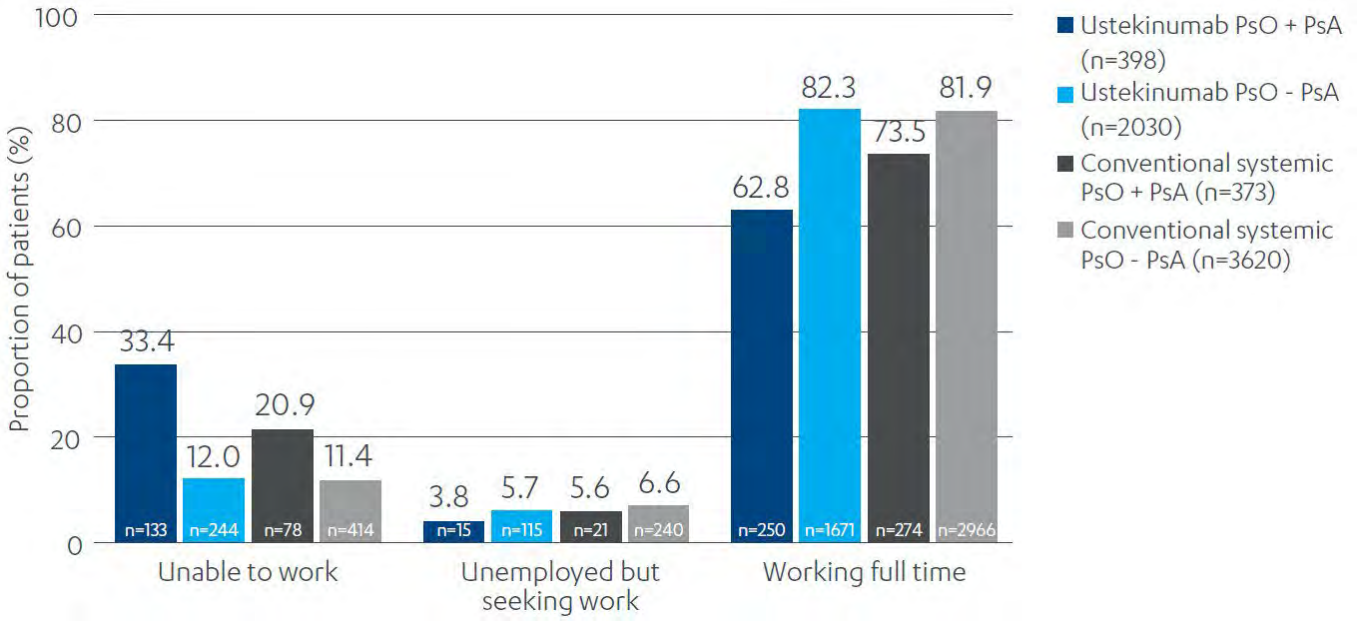

Figure 1. Employment status of patients with PsO by presence of comorbid PsA and treatment type. PsA, psoriatic arthritis; PsO, psoriasis.

Conclusion: These results indicate that the prevalence of obesity, diabetes, hypertension, and inability to work was higher in patients with PsO and comorbid PsA vs. PsO alone. Depression was also more prevalent in patients with PsO and comorbid PsA receiving biologic treatment vs. those receiving conventional systemics. These results potentially indicate a higher inflammatory and quality-of-life burden in patients with PsO and comorbid PsA, highlighting the need for adequate patient assessment and follow-up to ensure a best possible holistic patient management approach.

Psoriatic Arthritis Incidence Among Patients Receiving Biologic Medications for Psoriasis; A Nested Case Control Study

Iftach Sagy[1], Yael Shalev Rosenthal[2], Naama Schwartz[2] and Lev Pavlovsky[2], [1]Clinical Research Center, Soroka University Medical Center, Beer Sheva and Ben Gurion University of the Negev, DVIRA, Israel, [2]Rabin Medical Center, Petach Tikva, Israel

SESSION INFORMATION

Session Date: Monday, November 8, 2021

Session Title: Spondyloarthritis Including PsA – Treatment Poster II: Psoriatic Arthritis I (1329–1363)

Session Type: Poster Session C

Session Time: 8:30AM–10:30AM

Background/Purpose: The objective of this study was to investigate the effect of biological treatments for psoriasis on the incidence of psoriatic arthritis.

Methods: A retrospective cohort study using the electronic medical records of a large health maintenance organization. Patients who had received biological treatment for psoriasis and were not diagnosed with psoriatic arthritis before or at the time of biologic treatment initiation were included. Controls were matched by age at diagnosis, gender, time until treatment initiation, maximum BMI and smoking. The groups were different in most characteristics. Hence,

Table 1. comparisons between the study groups

	No biological treatment N=2278	Biological treatment N=687	P-value

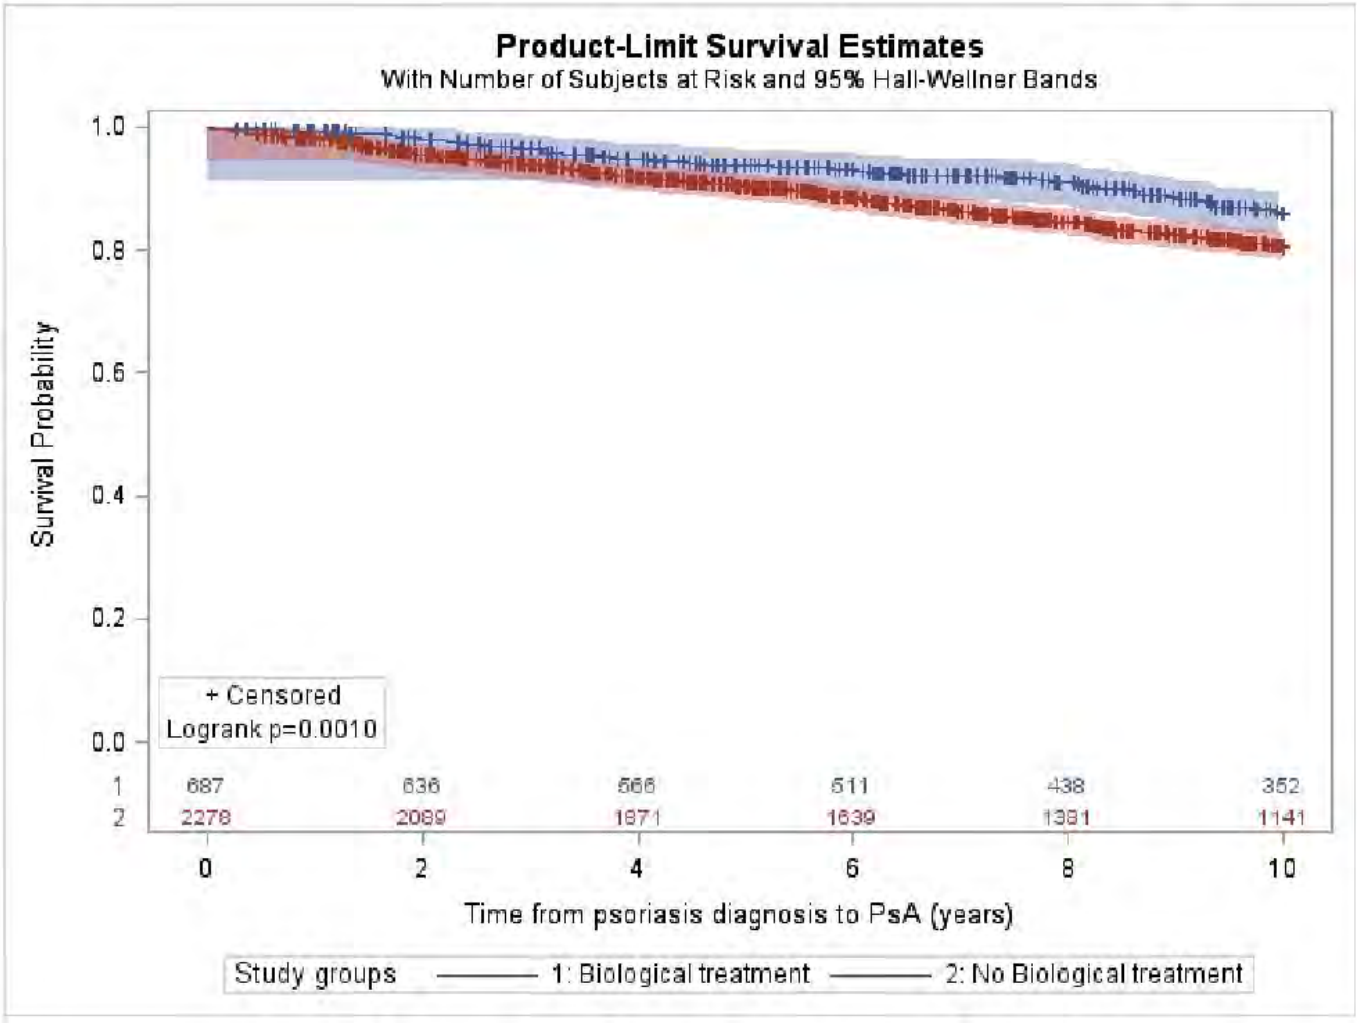
Continuous variables are presented with mean (standard deviation) [median, range].

Figure 1- Kaplan-Meier curve

Kaplan-Meier curves comparing PsA incidence in 10 years among patients with and without biological treatment.



a propensity score matching was implemented. The groups were compared via log rank test and a multivariable Cox regression.

Results: Overall, 1326 cases were included; 663 patients that had received biological treatment and 663 that had not. The Kaplan-Meier curve for the propensity score matched groups reflected a statistically significant increased risk for PsA among the control group compared to the biological treatment group. The results of the multivariable Cox regression showed that the control group had a significantly higher risk for PsA compared to the biological treatment group (adjusted HR=1.39; 95%CI: 1.03-1.87).

Conclusion: This study demonstrates a statistically and clinically significant lower risk for developing PsA among patients with psoriasis that receive biologic medications. The results suggest considering treatment with biologic medications in patients that present with significant risk factors for PsA at an earlier stage of treatment.

Effects of TNF-α versus Secukinumab on Active Ultrasound Confirmed Enthesitis in Psoriatic Arthritis

Ashley Elliott[1], Gary Wright[2], Adrian Pendleton[2] and Madeleine Rooney[1], [1]Centre for Experimental Medicine , School of Medicine, Dentistry and Biomedical Sciences, Queen's University Belfast, UK, Belfast, Northern Ireland, United Kingdom, [2]Belfast Health and Social Care Trust, Belfast, Northern Ireland, United Kingdom

SESSION INFORMATION

Session Date: Monday, November 8, 2021

Session Title: Spondyloarthritis Including PsA – Treatment Poster II: Psoriatic Arthritis I (1329–1363)

Session Type: Poster Session C

Session Time: 8:30AM–10:30AM

Background/Purpose: Enthesitis is an important aspect of disease in PsA and its clinical assessment has problems in terms of sensitivity and overlap with alternative co-morbid conditions. Imaging has emerged as the preferred option to assess enthesitis and research has demonstrated that those with persistent active US entheseal disease are at risk of progressive articular damage. There is limited data to help clinicians select the most appropriate biologic therapy for PsA patients. We wanted to assess the response on active US confirmed enthesitis to different forms of biologic therapy to study its utility in making more informed decisions and correlate clinical and imaging data.

Methods: The MAdrid Sonographic Enthesitis Index (MASEI) score assesses both chronic and active entheseal disease and is validated for use in SpA. The MASEI score was modified to count only the active elementary lesions (ActiveMASEI) which include hypoechogenicity, bursitis, tendon thickness and active power doppler signal at 12 entheses sites. This was a prospective observational study and to be included patients had to be aged ≥ 18 years, fulfil the classification criteria for PSA (CASPAR) and due to commence on their first biologic therapy. The trained

sonographer was blinded to all clinical findings and treatment choice prior to scanning. All patients were rescanned at 16 weeks of treatment as per their first review by the same investigator blinded to treatment and clinical outcomes.

Results: In total 80 patients were enrolled. All patients received the licensed dosing with 24 patients commenced on secukinumab (150mg n =18, 300mg n = 6) and 56 on TNFi (Adalimumab n = 50, certolizumab pegol n =4 and etanercept n = 2). 75 patients completed the study (Secukinumab n = 23 and TNFi n= 52). Baseline characteristics are as per Table 1 and were broadly similar for either class of biologic apart from the baseline DLQI (Skin questionnaire) score. The average age was 45.29 yrs (12.74) and 42 (52.5%) participants were female.

Table 2. Change in clinical outcomes from baseline after 16 weeks of treatment. Outcomes assessed with an independent t test apart from PsARC and MDA criteria which used a Chi square test

Outcome n = 75 unless stated	IL-17i (n = 23)	TNFi (n = 52)	P-value (< 0.05 in bold)
Tender Joint count	3.96 (8.01)	5.29 (7.19)	0.48
Swollen Joint count	2.61 (4.55)	2.65 (4.10)	0.97
PASI	3.44 (3.50)	1.03 (2.30)	**0.001**
Patients Global assessment of disease activity VAS mm	23.52 (26.91)	23.06 (28.89)	0.95
Patients Global assessment of pain VAS mm	22.39 (20.16)	23.73 (26.63)	0.83
LEI	0.61 (1.16)	0.27 (1.16)	0.25
SPARCC enthesitis index	1.39 (1.88)	1.11 (2.00)	0.58
BASDAI score	2.13 (2.18)	2.25 (2.19)	0.83
Dactylitis score /20	0.61 (1.37)	0.56 (1.16)	0.87
NAPSI fingernails /80 n = 60	8.74 (11.70) n=19	4.56 (7.46) n=41	0.10
HAQ-DI	0.30 (0.58)	0.32 (0.53)	0.90
DLQI	5.57 (7.52)	1.35 (4.18)	**0.005**
CRP mg/L n= 73	3.23 (11.46)	2.30 (13.88)	0.78
DAS-28 n = 73	0.98 (1.03)	1.01 (1.056)	0.89
DAPSA n =73	11.50 (13.30)	12.97 (12.93)	0.66
Achieved MDA (%)	10 (43.5)	21 (40.4)	0.81
PsARC response achieved (%)	16 (69.6)	41 (78.8)	0.40

The mean ActiveMASEI score reduction was 4.37 (5.31) with TNFi compared with 2.22 (3.01) for secukinumab which was significant (-2.148(-4.080, -0.216) p = 0.030). The Spondyloarthritis Research Consortium of Canada Enthesitis Index (SPARCC) correlated with the baseline ActiveMASEI score as per Spearman's Rank (rs = 0.23 p = 0.04) and a change in SPARCC significantly correlated with a change in ActiveMASEI (rs =0.30 p = 0.01). This was not seen with the Leeds Enthesitis Index (LEI) score at baseline or with change (rs= 0.07 p = 0.51 and rs =0.14 p = 0.23 respectively). Clinical outcomes are noted in table 2 and apart from a significant reduction in regards to the PASI and DLQI

score with Secukinumab versus TNFi (3.44 (3.50) vs 1.03 (2.30) p = 0.001 and 5.57 (7.52) vs 1.35 (4.18) p = 0.005 respectively) similar findings were seen for both classes of biologic therapy.

Conclusion: In this study we have compared the effect on active US confirmed enthesitis between different forms of biologic therapy for PsA. We have demonstrated superiority of TNFi versus secukinumab in regards to active entheseal disease. The SPARCC score correlated with baseline active entheseal US disease and with change in response to treatment highlighting it ability to capture active entheseal disease.

SESSION INFORMATION

Session Date: Monday, November 8, 2021

Session Title: Spondyloarthritis Including PsA – Treatment Poster II: Psoriatic Arthritis I (1329–1363)

Session Type: Poster Session C

Session Time: 8:30AM–10:30AM

Background/Purpose: 1) to evaluate clinical and subclinical markers of cardiovascular (CV) disease risk and its relationship with inflammation, disease activity and metabolic comorbidities in PsA patients and 2) to identify clinical and molecular profiles that could distinguish patients who may be benefit from the positive effects of PDE-4 inhibitor on CV risk.

Methods: Design: 1) Cross-sectional study including 100 PsA patients and 100 healthy donors (HDs) and 2) Longitudinal study including 45 patients treated with the PDE-4 inhibitor, Apremilast (n = 15), Methotrexate (MTX) (n = 15) alone or in combination (n = 15), evaluated at baseline and after 6 months of treatment. CV risk factors and clinical characteristics were recorded. Levels of 92 proteins mainly related to CV disease were evaluated in plasma by "Olink Proteomics" technology. The mRNA expression of CV-related proteins was analyzed in peripheral mononuclear cells (PBMCs). Cluster analyses were performed to identify specific clinical and molecular profiles of patients. ROC curve analyses were also performed to recognize biomarkers of disease activity, insulin resistance (IR) and therapeutic response.

Results: PsA patients showed a higher prevalence of metabolic alterations such as, obesity (30%) and IR (45%) compared to HDs. Metabolic complications were associated with disease activity and higher acute phase reactants. Specifically, IR state was related to a persistent inflammatory status (c-reactive protein) during the 5-years prior to

this study. Thirty-six CV-related proteins were altered in the plasma of PsA patients and associated with clinical parameters such as disease activity, acute phase reactants, body surface area affected by psoriasis and the presence of onychopathy. Biomarkers of IR (MMP-3, CD-163 and FABP-4) and disease activity (GAL-3 and FABP-4) were identified by ROC analyses. Two clusters of PsA patients were identified depend on the clinical and molecular profiles which showed different therapeutic responses to Apremilast and MTX. Thus, the cluster 2 which included patients with higher prevalence of CV risk factors and increased CV-related proteins in plasma showed a better response with Apremilast compared to MTX. In these patients, PDE-4 inhibitor reduced disease activity in parallel with body mass index and IR state. Likewise, biomarkers of therapeutic response to Apremilast were recognized (CD-163, LTBR and CNTN-1) with high sensitivity and specificity.

Conclusion: 1) Metabolic alterations in PsA are associated with disease activity and persistence of inflammatory profile; 2) Subclinical CV risk biomarkers in PsA is related to clinical characteristics where CD-163 could play an important role; 3) PsA patients with a specific clinical and molecular profile showed better response to therapy with Apremilast and 4) circulating plasma levels of CD-163, LTBR and CNTN-1 could be useful as biomarkers of therapeutic response to Apremilast.

GLOESS, Global EULAR-OMERACT synovitis score; HAQ-DI, Health Assessment Questionnaire-Disability Index; OMERACT, Outcome Measures in Rheumatology; SD, standard deviation; SPARCC, Spondyloarthritis Research Consortium of Canada Index; VAS, visual analogue scale.

Global OMERACT (PDUS) enthesitis score (definition 1) ranges from 0-48 and is the sum of the B-Mode (0 = absence, 1 = presence) and PD signal across 12 enthesitis sites.

(NCT02662985) was the first large, randomized, double-blind, placebo-controlled phase IIIb study in PsA, using the Global OMERACT EULAR Synovitis Score (GLOESS), an ultrasound score at patient level, to demonstrate that secukinumab (SEC) rapidly and significantly decreased synovitis.[2] However, little is known about the heterogeneity of PsA related to the distribution of ultrasound detected synovitis in PsA and its impact on treatment response. We report exploratory analyses to identify clusters of patients (pts) based on baseline ultrasound distribution and severity of synovitis [power doppler and greyscale alone and combined power doppler ultrasound (PDUS)] and their longitudinal treatment trajectory with SEC versus Placebo over 12 weeks.

Methods: ULTIMATE was a 52-week study with a 12-week double-blind, placebo-controlled period followed by 12-week open-label (OL) treatment and 6-month OL extension period. Factor analysis and clustering methods were applied post hoc to identify groups of PsA pts with similar baseline composite PDUS-detected synovitis characteristics. Aggregation of baseline demographics, clinical and ultrasound characteristics were explored through cluster analysis using descriptive statistics. Nonlinear mixed models for change in GLOESS (primary endpoint of the study) from baseline to Week 12 across clusters were used to explore the treatment difference between SEC and placebo up to Week 12.

Results: The baseline demographics, clinical and ultrasound characteristics have been reported previously.[3] One hundred and sixty-six pts could be categorized in 3 different clusters (N1=63, N2=49 and N3=54) at baseline. The heatmap in **Figure 1** shows the differences in the distribution of PDUS-detected synovitis at the joint level across the 3 clusters. The baseline ultrasound characteristics showed higher disease activity, more severe synovitis and enthesitis in clusters 3 and 1 vs. cluster 2 (**Table**). Cluster 3 showed a trend toward increased clinical activity (TJC, SJC, pain and PGA VAS). The longitudinal trajectories of the 3 clusters up to Week 12 showed a treatment difference in favor of SEC, compared with placebo, in clusters 3 and 1 but not in cluster 2 (**Figure 2**).

Conclusion: The cluster analysis in the ULTIMATE trial highlights the heterogeneity of PsA. Interestingly, only clusters 1 and 3, with evidence of higher amounts of PDUS-detected inflammation had disease activity that responded to secukinumab treatment. Ultrasound may help in identifying different levels of inflammation of synovitis and enthesitis at tissue level in patients with similar clinical phenotype and could support a more rigorous selection of patients with active disease in future clinical trials.

Session Date: Monday, November 8, 2021
Session Title: Spondyloarthritis Including PsA – Treatment Poster II: Psoriatic Arthritis I (1329–1363)
Session Type: Poster Session C
Session Time: 8:30AM–10:30AM

Background/Purpose: A variety of biologic and targeted synthetic disease modifying antirheumatic agents have been widely used among patients with psoriatic arthritis (PsA). Due to the lack of head-to-head comparison trials, the comparative risk of respiratory tract infections (RTIs) among these available agents remains unclear, however. Consequently, a network meta-analysis (NMA) was used to address this knowledge gap, and we sought to investigate the comparative risk of RTIs with different biologic and targeted synthetic disease modifying antirheumatic agents in PsA.

Methods: Medline, PubMed, Embase, Scopus, Cochrane Central, and clinicaltrials.gov were searched to identify phase 3 and 4 randomized clinical trials (RCTs) that reported safety outcomes of biologic and targeted synthetic disease modifying antirheumatic agents in PsA. Outcome of interest was occurrence of respiratory tract infection(s) within on-treatment or placebo-controlled duration. Mixed treatment comparisons were computed using NMA within

the frequentist framework. Fixed effect models were used due to sparse direct evidence and open network. Effect estimates were expressed as odds ratio (OR) with their 95% confidence intervals (CIs). P-scores were calculated to establish relative rankings of different treatment options. A sensitivity analysis was conducted using Bayesian NMA approach. All statistical analyses were conducted in R (v 4.0.2).

Results: A total of 33 RCTs were included in this systematic review. A total of 32 RCTs with 14,974 patients, and 17 unique treatment arms were included in the NMA and one RCT did not report any RTI events was excluded [see Figure 1.] Mixed treatment comparisons showed that abatacept (P-score 0.92) ranked as the best (lowest likelihood of RTIs) treatment compared to adalimumab (OR 0.49; 95% CI 0.24-0.99), apremilast (OR 0.36; 95% CI 0.17-0.74), certolizumab (OR 0.34; 95% CI 0.15-0.79), golimumab (OR 0.38; 95% CI 0.15-0.95), guselkumab (OR 0.42; 95% CI 0.19-0.92), tofacitinib (OR 0.36; 95% CI 0.16-0.83), and upadacitinib (OR 0.45; 95% CI 0.22-0.93). Apremilast ranked the lowest with increased likelihood of RTIs compared to infliximab (OR 2.00; 95% CI 1.09-3.67), and secukinumab (OR 1.58; 95% CI 1.11-2.25). However, no other significant differences were observed across different biologic and targeted synthetic disease modifying antirheumatic agents [Figure 2]. The results were consistent with Bayesian NMA.

Conclusion: Abatacept may have a lower risk of RTIs when used for treatment of PsA. Further analyses are warranted to assess the severity and type of RTIs associated with these treatments.

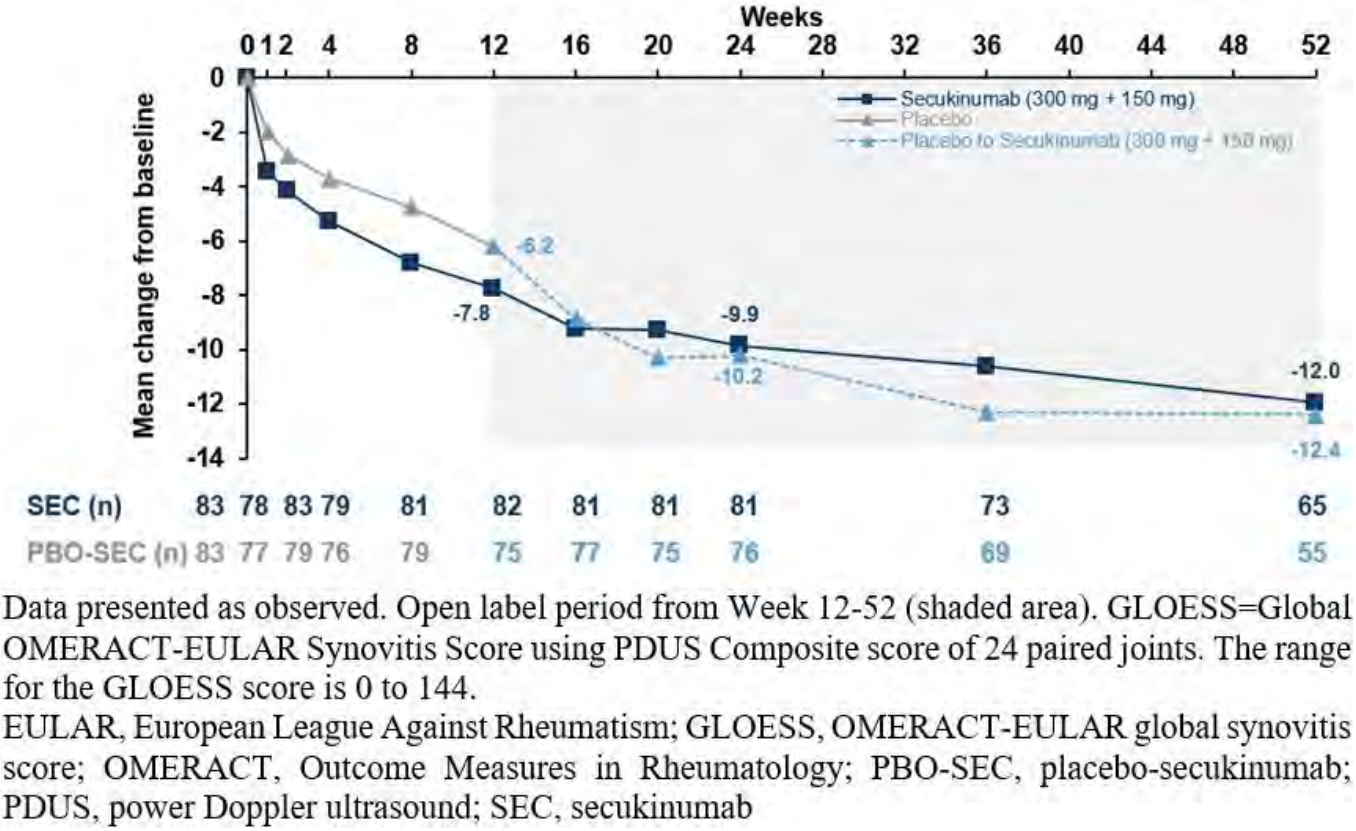
SESSION INFORMATION

Session Date: Monday, November 8, 2021

Session Title: Spondyloarthritis Including PsA – Treatment Poster II: Psoriatic Arthritis I (1329–1363)

Session Type: Poster Session C

Session Time: 8:30AM–10:30AM



Data presented as observed. Open label period from Week 12-52 (shaded area). GLOESS=Global OMERACT-EULAR Synovitis Score using PDUS Composite score of 24 paired joints. The range for the GLOESS score is 0 to 144.
EULAR, European League Against Rheumatism; GLOESS, OMERACT-EULAR global synovitis score; OMERACT, Outcome Measures in Rheumatology; PBO-SEC, placebo-secukinumab; PDUS, power Doppler ultrasound; SEC, secukinumab

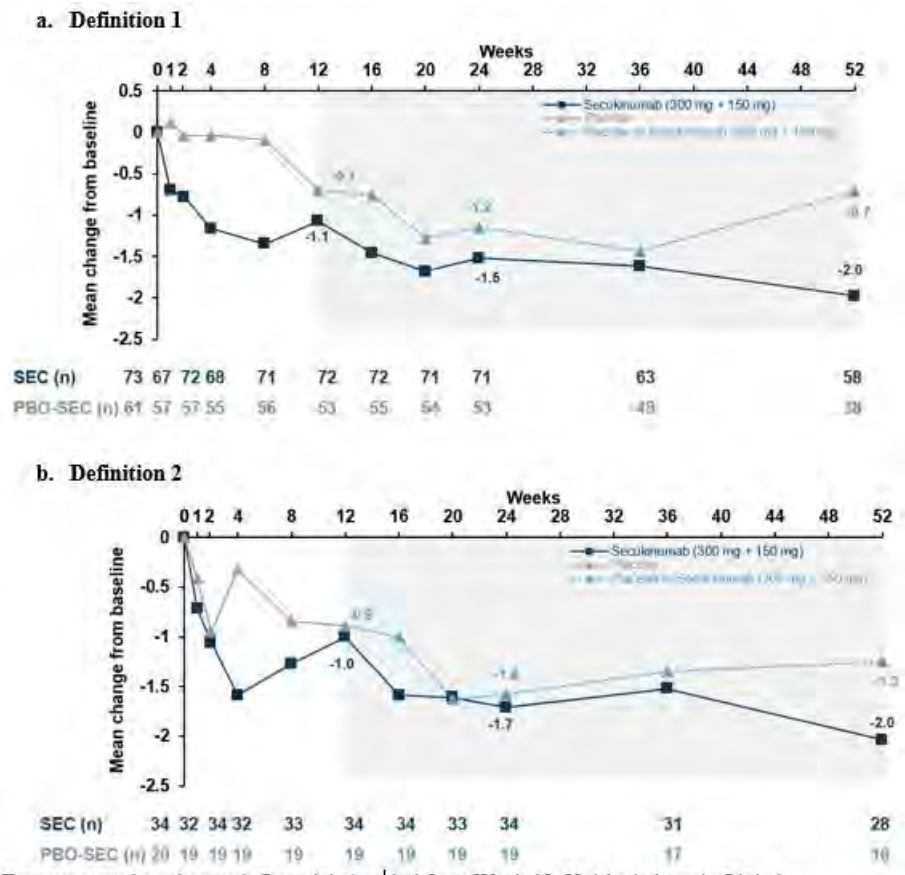
Figure 1. Mean change from baseline in GLOESS by treatment up to Week 52.

Background/Purpose: Power Doppler ultrasound (PDUS) is a sensitive non-invasive imaging tool to visualize a wide range of articular and periarticular inflammation in psoriatic arthritis (PsA).[1,2] ULTIMATE (NCT02662985) is the first large RCT that used ultrasound with Global OMERACT ultrasound synovitis score (GLOESS) as the primary endpoint, to demonstrate early benefits of secukinumab on synovitis in patients with PsA through 12 weeks.[3] Here we report the responsiveness of ultrasound on synovitis and enthesitis, clinical efficacy, and safety of secukinumab up to 52 weeks.

Methods: This was a 52-week study with a 12-week double-blind placebo-controlled treatment followed by 12-week open-label treatment and 6-month open-label extension treatment in all patients. Detailed study design and eligibility criteria have been reported previously.[3,4] Synovitis and ultrasound enthesitis response were measured by GLOESS and Global OMERACT enthesitis Score (Definitions 1 and 2)[4] at patient level, respectively. Other assessments across key PsA manifestations of joints (ACR responses), enthesitis, (SPARCC), skin (PASI responses), dactylitis (LDI) and physical function (HAQ-DI) were also evaluated. Data are presented as observed.

Results: A total of 166 patients were enrolled, of which 90% (75/83) of secukinumab and 83% (69/83) of placebo-secukinumab participants completed 52 weeks. A continued improvement in GLOESS was observed in both secukinumab and placebo-secukinumab group after switch to active therapy at Week 12 through Week 52 (**Figure 1**). A similar trend of improvement in Global OMERACT enthesitis score (Definition 1 and 2) was observed up to 52 weeks in both groups (**Figure 2**). Sustained clinical response rates were observed across multiple facets of disease and physical function up to 52 weeks in both secukinumab and placebo-secukinumab groups (**Table**). There were no new or unexpected safety findings.

Conclusion: ULTIMATE demonstrated the responsiveness of ultrasound on both synovitis and enthesitis outcomes in PsA supporting its use in clinical trials, and confirmed the rapid and continued benefits of secukinumab through 52



Data presented as observed. Open label period from Week 12-52 (shaded area). Global OMERACT (PDUS) enthesitis score Definition 1 ranges from 0-48 and is the sum of the B-Mode (0 = absence, 1 = presence) and PD signal across 12 enthesitis sites; Definition 2 ranges from 0-36 and is the sum of the PD signal across 12 sites. At each time point, only patients with a value at both baseline and that time point are included. Only patients with positive values (>0 at baseline) were included.
EULAR, European League Against Rheumatism; GLOESS, OMERACT-EULAR global synovitis score; N, total number of randomized patients; n, number of evaluable patients; OMERACT, Outcome Measures in Rheumatology; PBO-SEC, placebo-secukinumab; PDUS, power Doppler ultrasound; SEC, secukinumab

Figure 2. Mean change from baseline Global OMERACT enthesitis score up to Week 52.

weeks. Sustained efficacy was also observed across key clinical PsA manifestations with a safety profile consistent with previous reports.

SESSION INFORMATION

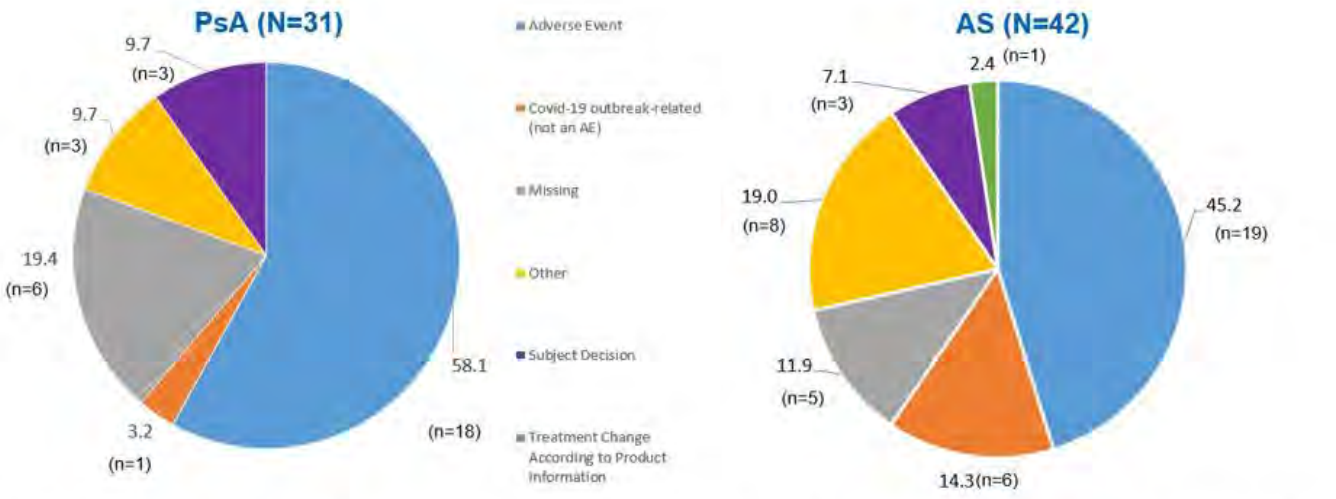
Session Date: Monday, November 8, 2021

Session Title: Spondyloarthritis Including PsA – Treatment Poster II: Psoriatic Arthritis I (1329–1363)

Session Type: Poster Session C

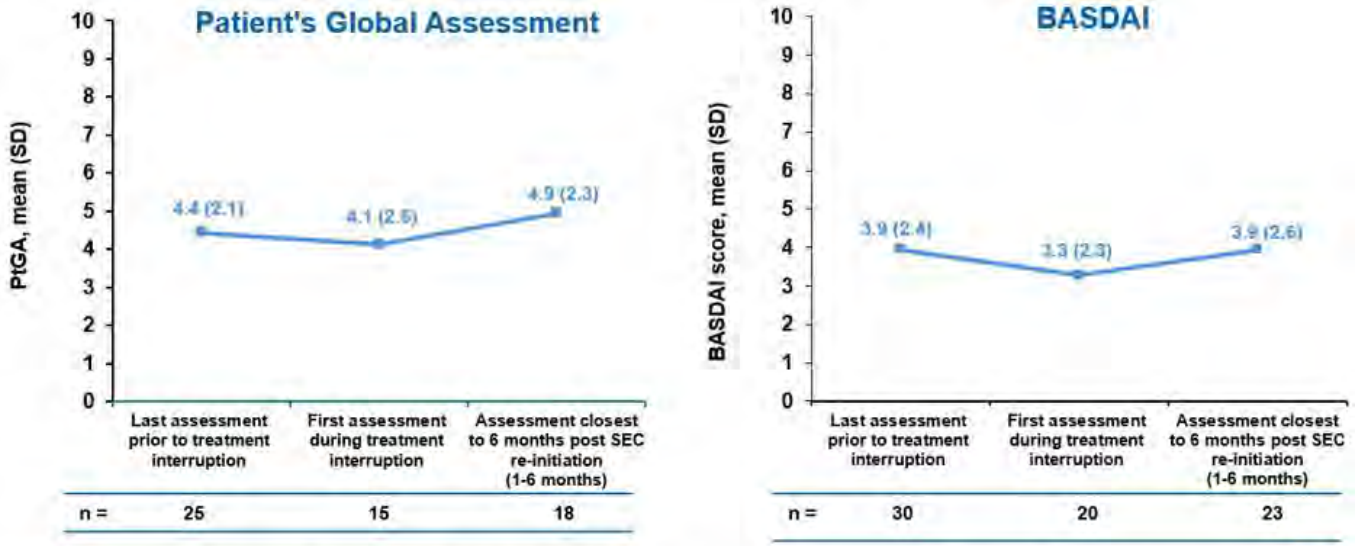
Session Time: 8:30AM–10:30AM

Background/Purpose: Secukinumab (SEC) has demonstrated long-lasting efficacy and a favorable safety profile in patients (pts) with psoriatic arthritis (PsA) and ankylosing spondylitis (AS) across Phase 3 trials.[1, 2] SERENA is an ongoing, longitudinal, observational study in more than 2900 pts with moderate to severe psoriasis, active PsA, and AS conducted at 438 sites across Europe with an expected duration of up to 5 years.[3] Here we report data on impact of intermediate treatment interruption on SEC effectiveness in pts with active PsA or AS from the SERENA study.



If a patient had more than one treatment interruption then the interruption with the longest duration was included.
AE, adverse event; AS, ankylosing spondylitis; PsA, psoriatic arthritis; n, number of patients with non-missing data; N, number of subjects with treatment interruption.

Figure 1. Reasons for a secukinumab treatment interruption in PsA and AS patients.



If a patient had more than one intermediate treatment interruption, then the interruption with 1. Assessments in all of the temporal periods (prior/during/post the intermediate treatment interruption) and 2. The longest duration, was included.
AS, ankylosing spondylitis; BASDAI, Bath Ankylosing Spondylitis Disease Activity Index; n, number of patients with non-missing data; PtGA, patient's global assessment; SD, standard deviation; SEC, secukinumab.

Figure 2. Patient's Global Assessment and BASDAI score before the treatment interruption, during the treatment interruption and post re-initiation in AS patients.

Methods: This interim analysis included data for 534 PsA and 470 AS pts enrolled in the study between Oct 2016 and Oct 2018 and followed up for at least 2 years. Pts (aged ≥18 years) with active PsA or AS were required to have received at least 16 weeks of SEC treatment before enrolment in the study. A treatment interruption was defined as interruption of SEC therapy for at least 3 months between the last injection and re-initiation. Effectiveness assessments included swollen and tender joint count in PsA pts, and Pt Global Assessment (PtGA) and BASDAI score in AS pts before and during treatment interruption and post SEC re-initiation. Pts with assessments in at least two of the time periods were included. The last assessment prior to the intermediate treatment interruption was used as baseline. The assessment closest to 6 months after re-initiation was considered as post SEC re-initiation assessment.

Results: A total of 31 PsA (5.8%) pts and 42 (8.9%) AS pts had an intermediate treatment interruption since initiation of SEC treatment. The mean (SD) duration of treatment interruption was 24.8 (16.4) and 26.4 (22.9) weeks for PsA and AS pts, respectively. The mean (SD) duration of SEC treatment before the treatment interruption was 86.8 (50.3) and 90.2 (46.9) weeks, and after the treatment interruption was 73.6 (44.4) and 63.2 (46.8) weeks. The most commonly reported reasons included adverse events (AEs) reported in 18 (58.1%) PsA and 19 (45.2%) AS pts, pt decision reported in 3 (9.7%) PsA and 3 (7.1%) AS pts, and COVID-19 outbreak-related reasons reported in 1 (3.2%) PsA and 6 (14.3%) AS pts (**Figure 1**). More than 80% of PsA pts and 76% of AS pts, reinitiated SEC without a loading phase after the treatment interruption. The swollen and tender joint count increased in PsA pts from the last assessment prior to the treatment interruption [1.3 (1.0) and 7.2 (11.4); n=6] to the first assessment during the treatment interruption [4.0 (1.4) and 16.5 (19.1); n=2], and gradually decreased post SEC re-initiation [0.4 (0.5) and 2.0 (0.7); n=5]. PtGA and BASDAI remained stable in AS pts from the last assessment prior to the treatment interruption to the first assessment during the treatment interruption and after SEC re-initiation (**Figure 2**).

Conclusion: SEC intermediate treatment interruption occurred due to a variety of reasons in the real-world setting mainly due to AEs and pt decision. The majority of pts re-initiated SEC treatment without a loading phase. No notable impact of the intermediate treatment interruption was observed on the effectiveness of SEC.

No Change in Bone Marrow Edema of the Sacroiliac Joints and Spine After High Intensity Interval Training in PsA

Ruth Stoklund Thomsen[1], Tom Nilsen[2], Mari Hoff[1], Glenn Haugeberg[3] and Arthur Kavanaugh[4], [1]Dept. of Rheumatology, University Hospital of Trondheim, Norway ; Norwegian University of Science and Technology, Trondheim, Norway, Trondheim, Norway, [2]Norwegian University of Science and Technology, Trondheim, Norway, Trondheim, Norway, [3]Dept. of Rheumatology, Hospital of Southern Norway Trust, Kristiansand, Norway; Norwegian University of Science and Technology, Trondheim, Norway, [4]University of California San Diego, La Jolla, CA

SESSION INFORMATION
Session Date: Monday, November 8, 2021
Session Title: Spondyloarthritis Including PsA – Treatment Poster II: Psoriatic Arthritis I (1329–1363)
Session Type: Poster Session C
Session Time: 8:30AM–10:30AM

Background/Purpose: Physical activity is recommended for patients with psoriatic arthritis (PsA) especially due to the high prevalence of overweight/obesity, and the risk of comorbidities such as CVD and metabolic syndrome. Further, physical exercise may be beneficial regarding disease activity in patients with arthritis. However, in PsA there is a potential risk of increased disease activity including worsening of enthesitis after physical exercise due to mechanical strain.

The primary aim of this study was to measure the effect of high intensity interval training (HIIT) on bone marrow edema (BME) in MRI of the sacroiliac joints (SIJ) and spine as an objective measure of inflammation. Secondly, we aimed to observe whether there was an association between BME and disease activity markers at baseline.

Methods: 41 PsA patients satisfying CASPAR criteria were recruited from clinics to a randomized clinical trial. The intervention group (N=21) performed HIIT, defined as 4 times 4 minutes training at 85-95% of maximum heart rate on a stationary bicycle 2-3 times a week for 11 weeks. The control group (N=20) was instructed not to change their pre-study physical exercise habits during the study. Patients underwent MRI of the SIJ and spine at baseline, and, at average 13 (range: 8 – 26) days after completion of the intervention. MRI was scored for BME according to the

Table 1. Baseline characteristics of the patients with psoriatic arthritis in the intervention and control groups

	Intervention (n= 21)	Control (n= 20)
Age, years mean (SD)	51.6 (9.1)	44.4 (12.9)
Female, n (%)	17 (81)	12 (60)

SIJ-BME-SPARCC, n		
<2	16	15
≥2	5	5
Spine-BME-SPARCC, median (IQR)	4 (39)	4 (36)
Spine-BME-SPARCC, n		
<2	8	7
≤2 – 10	7	9
>10	6	4

Hs-CRP = high-sensitivity C-reactive protein
IQR = interquartile range
DAPSA68 = Disease Activity index for Psoriatic Arthritis of 66/68 joints
DAPSA68 categories: 1. Remission (0-4) 2. Low (5-14) 3. Moderate (15-28) 4. High (>28)
PGA = patient's global assessment
ASDAS-CRP = Ankylosing Spondylitis Disease Activity Score using the CRP level.
SPARCC enthesitis index = Spondyloarthritis Research Consortium of Canada enthesitis index (0-16)
SIJ-BME-SPARCC = SPARCC index of sacroiliac joint bone marrow edema (0-72, remission<2)
Spine-BME- SPARCC = SPARCC index of spine bone marrow edema (0-108, remission<2)

Spondylarthritis Research Consortium of Canada (SPARCC). The minimal important change is 2,5 and 5 in SPARCC BME score for SIJ and spine, respectively. Logistic regression analysis was performed to calculate the odds ratio (OR) with 95% CI for worsening in SPARCC-BME for both SIJ and spine between HIIT and control groups. Disease activity markers like HS-CRP, Dapsa68, Pain, ASDAS-CRP and SPARCC enthesitis index assessed at baseline were compared with SPARCC BME scores for SIJ and spine using linear regression and Mann-Whitney test.

Results: The included patients had a low to moderate disease activity measured by Dapsa68 and ASDAS-CRP (table 1). There was no difference in change of SPARCC-BME in SIJ and spine between the two groups with an OR of 0.56 (95 % CI 0.05 to 6.81) and 1.19 (95 % CI 0.07 to 20.54) for SIJ and spine, respectively, for worsening comparing the HIIT with the control group. At baseline, there was an inverse association between SPARCC enthesitis index and SPARCC-BME of SIJ with a mean difference of -2.34 (95% CI -4.53 to -0.15). The results were confirmed by a Mann-Whitney test (p-value 0.02). There was no association between other disease activity markers and SPARCC-BME of SIJ and spine at baseline.

Conclusion: The risk of increased BME in SIJ and spine as an objective marker of inflammation after 11 weeks of HIIT was not higher in the HIIT group compared to controls in a cohort of PsA patients with low to moderate disease activity. Of interest, the degree of baseline BME in SIJ was inversely associated with the subjectively measured burden of enthesitis. The results support that physical exercise does not cause objective signs of increased disease activity in PsA.

Session Title: Spondyloarthritis Including PsA – Treatment Poster II: Psoriatic Arthritis I (1329–1363)

Session Type: Poster Session C

Session Time: 8:30AM–10:30AM

Background/Purpose: Psoriatic arthritis (PsA) is mainly described based on the individual domains or clinical components of the disease.[1,2] The aim of this *post hoc* analysis was to identify hypothesis-free clusters of phenotypes according to patients' clinical features and characteristics at baseline (BL) using data from the guselkumab Phase 3 DISCOVER-1 and -2 clinical trials of patients with PsA.

Figure 1. Examples of unsupervised machine learning-identified Clusters, 1 and 7.

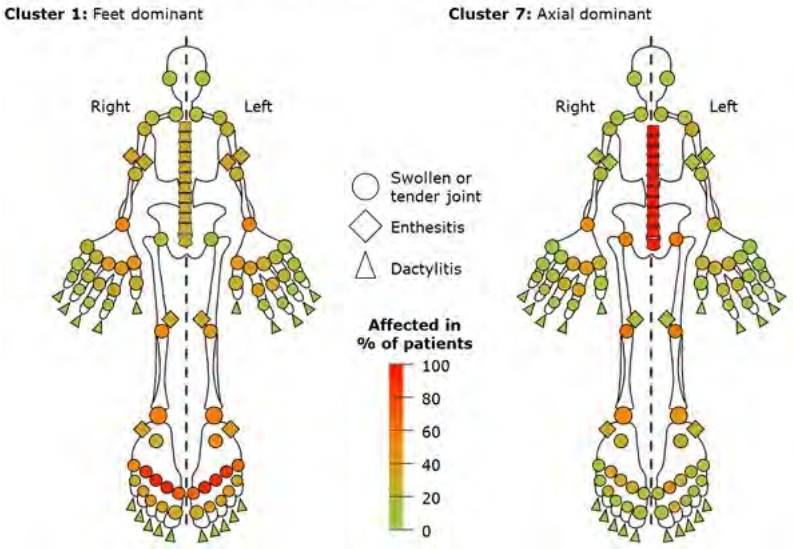

Table 1. Baseline characteristics of PsA phenotype clusters.

	Cluster 1 Feet dominant	Cluster 2 Male, skin, overweight	Cluster 3 Hand dominant	Cluster 4 Dactylitis dominant	Cluster 5 Enthesitis and large joints	Cluster 6 Enthesitis and small joints	Cluster 7 Axial dominant	Cluster 8 Obese, skin
Number of randomized and treated patients	79	125	95	38	57	60	83	124
Age, years	45.8 (10.4)	45.8 (13.2)	48.9 (11.8)	44.8 (12.3)	43.6 (13.3)	45.8 (11.6)	43.8 (10.4)	47.5 (11.1)
Female	54.4	20.0	60.0	26.3	64.9	41.7	36.1	61.3
BMI, kg/m²	29.3 (5.4)	27.4 (3.6)	29.3 (6.1)	26.9 (4.6)	28.6 (7.5)	29.0 (6.2)	28.4 (6.9)	32.1 (6.5)
CRP, mg/dL	1.7 (1.8)	1.7 (2.0)	1.4 (2.3)	2.5 (2.8)	1.7 (1.9)	1.7 (1.8)	2.2 (3.1)	1.5 (1.8)

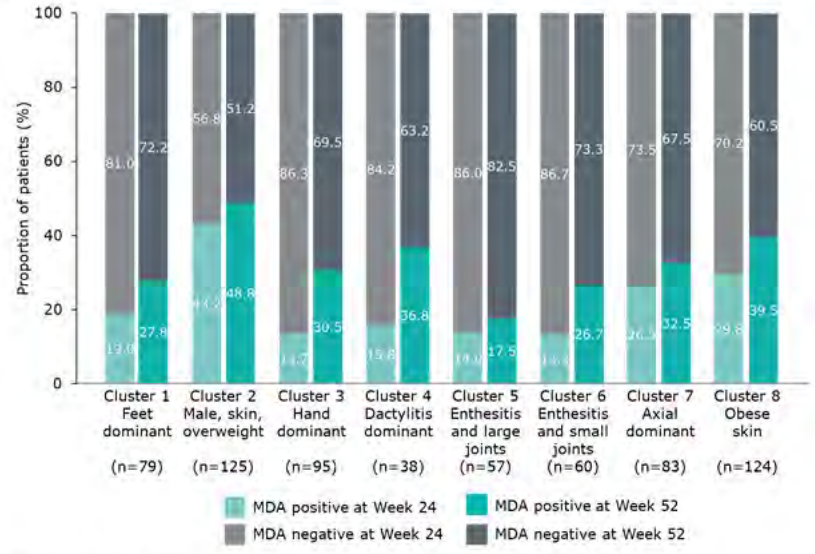
SJC, 0–66	13.2 (7.1)	8.2 (3.8)	15.0 (8.0)	18.0 (10.1)	10.1 (5.1)	17.5 (11.8)	9.0 (4.2)	8.8 (3.9)
TJC, 0–68	23.4 (10.1)	12.8 (5.9)	26.0 (12.0)	30.6 (15.3)	23.2 (12.6)	37.5 (18.6)	14.6 (6.5)	12.7 (5.2)
BSA, %	12.6 (19.4)	20.7 (19.8)	14.8 (19.5)	29.7 (26.4)	14.6 (21.6)	14.5 (18.4)	15.2 (19.4)	14.4 (15.7)
BSA >3%	63.3	86.4	76.6	100.0	61.4	72.9	81.9	90.3
BSA >10%	36.7	63.2	43.6	71.1	36.8	42.4	41.0	44.4
Dactylitis %	48.1	30.4	42.1	100.0	36.8	53.3	49.4	31.5
Dactylitis score	3.0 (4.8)	1.4 (3.2)	2.7 (4.8)	27.5 (12.3)	2.3 (5.2)	3.9 (6.8)	2.2 (2.9)	1.3 (2.5)
Enthesitis %	70.9	49.6	58.9	81.6	96.5	73.3	69.9	45.2
LEI score	2.0 (1.7)	1.0 (1.3)	1.7 (1.8)	2.9 (1.9)	4.2 (1.6)	2.7 (2.3)	1.3 (1.2)	1.0 (1.3)
Current smoker	16.5	23.2	13.7	18.4	12.3	23.3	13.3	21.8

Data shown are mean (SD) or %. White cells indicate differentiating features of individual clusters. BMI, body mass index; BSA, body surface area; CRP, C-reactive protein; LEI, Leeds Enthesitis Index; PsA, psoriatic arthritis; SD, standard deviation; SJC, swollen joint count; TJC, tender joint count.

Methods: Data from bio-naïve patients with active PsA treated with guselkumab 100 mg either every 4 or 8 weeks in DISCOVER-1 and -2 were retrospectively analyzed. Non-negative matrix factorization was applied as an unsupervised machine learning technique to identify clusters of PsA phenotypes, with BL characteristics and clinical observations as input features. Clusters are described here according to their characteristics and clinical features, including the relation to achievement of minimal disease activity (MDA) at Weeks 24 and 52 (W24; W52).

Results: Data from 661 bio-naïve patients were pooled. Eight distinct clusters of PsA phenotypes were identified. **Cluster 1** was characterized by a high frequency of lower limb involvement, notably foot/ankle, and the lowest rates of severe skin involvement (Figure 1). **Cluster 2** was characterized by high skin involvement, the lowest proportion of females, and the highest proportion of overweight patients (70% body mass index [BMI] 25–< 30). **Cluster 3** was

Figure 2. MDA response to guselkumab 100 mg (pooled Q4W and Q8W) at Week 24 and Week 52 by PsA phenotype clusters.



MDA, minimal disease activity; PsA, psoriatic arthritis; Q4W, every 4 weeks; Q8W, every 8 weeks.

characterized by a high burden of disease in the hands/wrists. **Cluster 4**, the smallest cluster, was distinguished by the highest degree of dactylitis involvement; second highest proportion of male patients; and the highest proportion of patients with ≥3% body surface area (BSA) psoriasis involvement. **Cluster 5** was differentiated based on the highest proportion of patients with enthesitis at BL. Large joint involvement was also common in this cluster. **Cluster 6** was characterized by a high level of involvement of small joints in the hands and feet, but a low mean dactylitis score. Presence of nail involvement (78%) and enthesitis at BL were also common in this cluster. **Cluster 7** was characterized by axial involvement at BL (100%); nearly one-half of patients with dactylitis, two thirds with enthesitis and the majority with BSA ≥3% at BL (Figure 1). **Cluster 8** was characterized by low rates of joint involvement, high rates of more extensive skin involvement, and the highest proportion of obese patients (67% with BMI >30; Table 1). MDA response rates at W24 and W52 were highest in **Cluster 2** and lowest in **Cluster 5**. **Clusters 3** and **4** were characterized by low MDA response rates at W24 that increased at W52 (Figure 2).

Conclusion: Unsupervised machine learning was able to identify 8 clusters of PsA phenotypes with significant differences in demographic and clinical features, including patterns of involvement of joint, skin/nail, dactylitis, and enthesitis manifestations as well as MDA responses. These clusters seem to differ in their initial vs. later responses to guselkumab. Further analysis will clarify which MDA domains play a role in this response kinetics.

SESSION INFORMATION

Session Date: Monday, November 8, 2021

Session Title: Systemic Sclerosis & Related Disorders – Clinical Poster II (1364–1390)

Session Type: Poster Session C

Session Time: 8:30AM–10:30AM

Background/Purpose: Autologous hematopoietic stem cell transplantation (AHSCT) is now established as a preferred standard of care treatment for patients with severe scleroderma with internal organ involvement (SSc). Two large randomized clinical trials of AHSCT vs. monthly cyclophosphamide (CYC) used CD34+ HSC enrichment to deplete immune cells from the autologous peripheral blood stem cell (PBSC) graft. One trial used total body irradiation (TBI)/CYC/anti-thymocyte globulin (ATG) conditioning regimen[1], the other used CYC/ATG (no TBI)[2]. After these trials, due to reporting issues, many SSc patients given HSCT received unmanipulated PBSC (no CD34+ enrichment). We sought to (1) update the outcomes of AHSCT for SSc in North America in a larger contemporary cohort and (2) examine the importance of patient factors and transplant regimens for overall survival (OS) and progression free survival (PFS).

Methods: A questionnaire for SSc-specific health status before and after AHSCT was created for patients reported to the Center for International Blood & Marrow Transplantation Research. Participating HSCT/rheumatology sites completed questionnaires for each SSc patient transplanted between 2000 to 2020, by conducting medical records review/ telephone interviews in early/mid-2021. Health status, physical function, toxicities, DMARD use and major medical events were recorded. Event endpoints included time to death, initiation of unplanned DMARD, organ failure/ transplant, supplemental oxygen, new diagnosis of pulmonary arterial hypertension, enteral feeding tube, total parenteral nutrition, or subsequent HSCT.

Results: 104 patients with SSc were reported to the registry and provided SSc-specific health data. All patients had skin involvement, 56% with lung, 29% lung with other organ, 3% with kidney/GI, and 13% with skin only SSc.

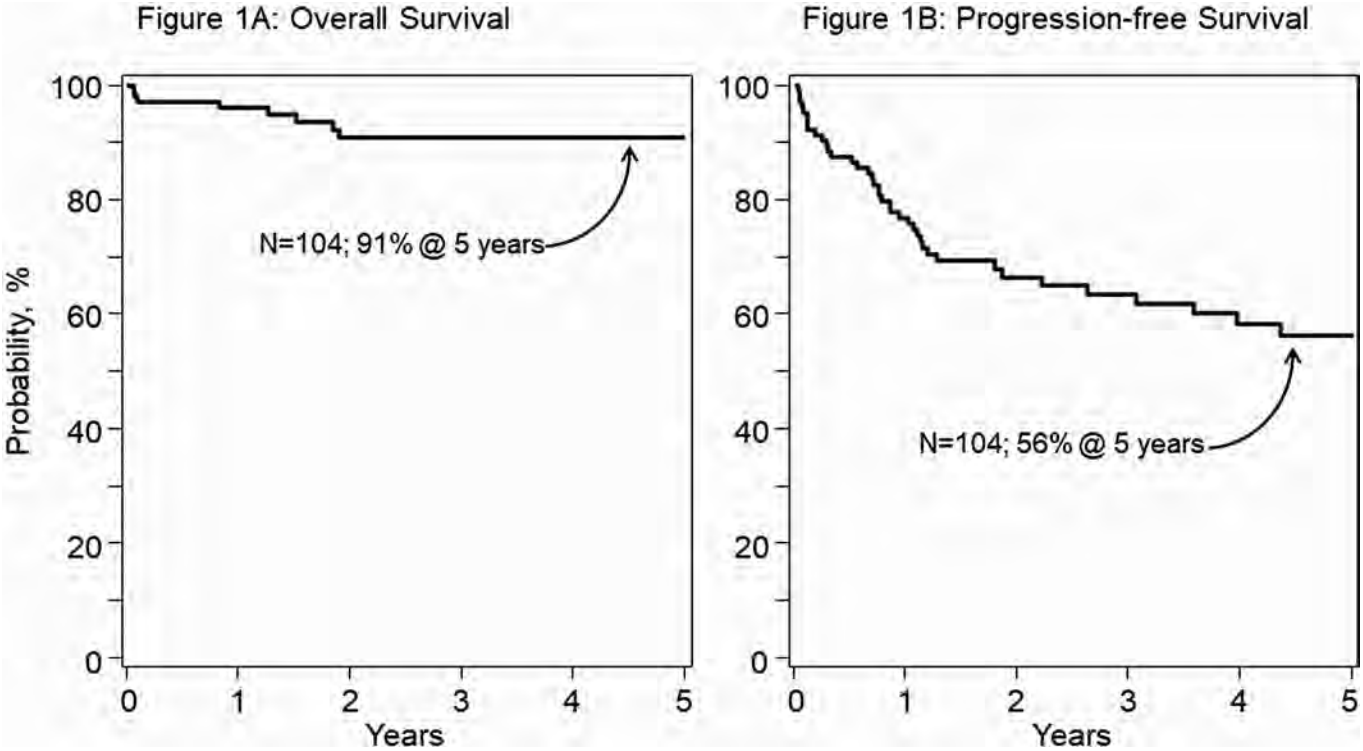

Figure 1. A. 5-year overall survival (OS) for 104 SSc registry patients with AHSCT between 2000 and 2020. B. Corresponding progression-free survival (PFS). Kaplan-Meier (KM) estimate.

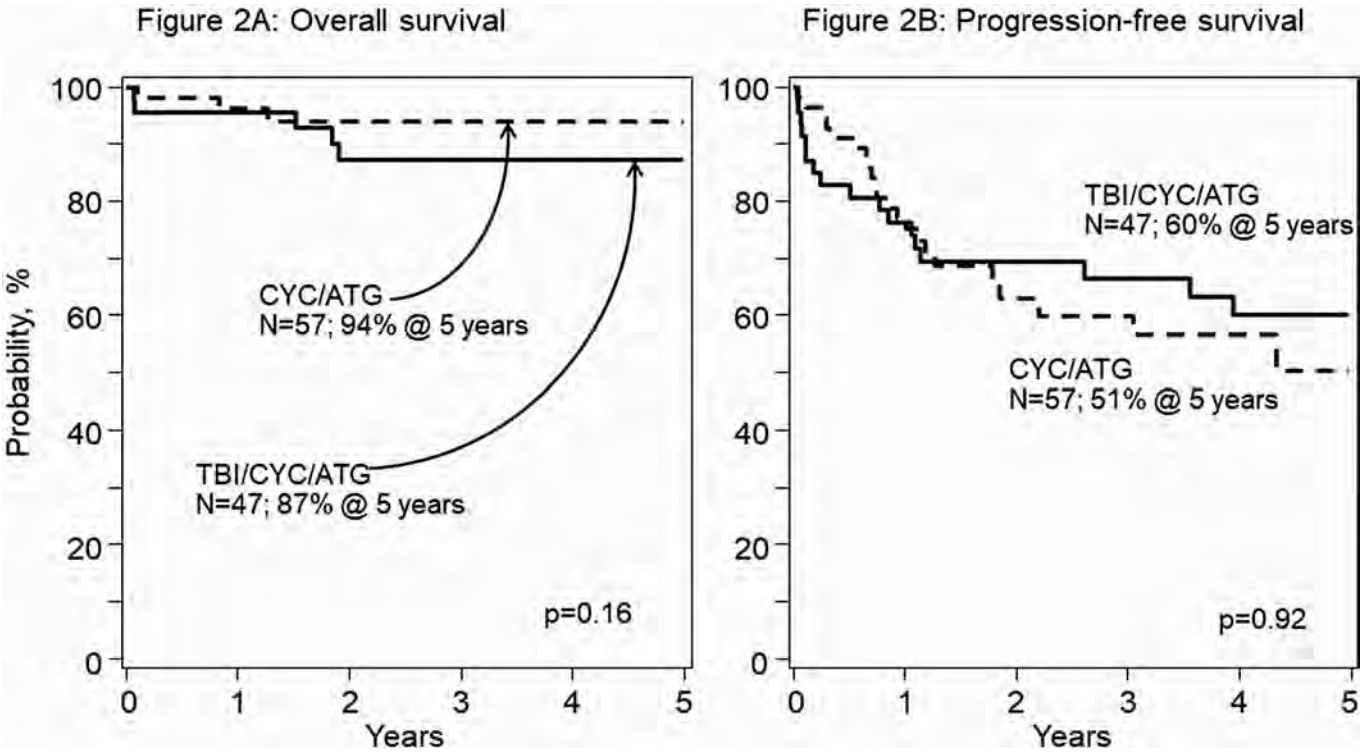

Figure 2. A. 5-yr. OS after AHSCT for SSc, non-randomized, registry patients conditioned with TBI/CYC/ATG vs. CYC/ATG, 87% and 94%, P= 0.16. B. Corresponding 5-yr. PFS, 60% and 51%, P=0.92, log-rank test.

Conditioning with TBI/CYC/ATG was in 45%, CYC/ATG was in 55%. CD34+ enrichment of PBSC was used in 39%, 61% without enrichment. 64% had AHSCT between 2015 to 2020. Median follow-up was 41 (range, 5-222) months.

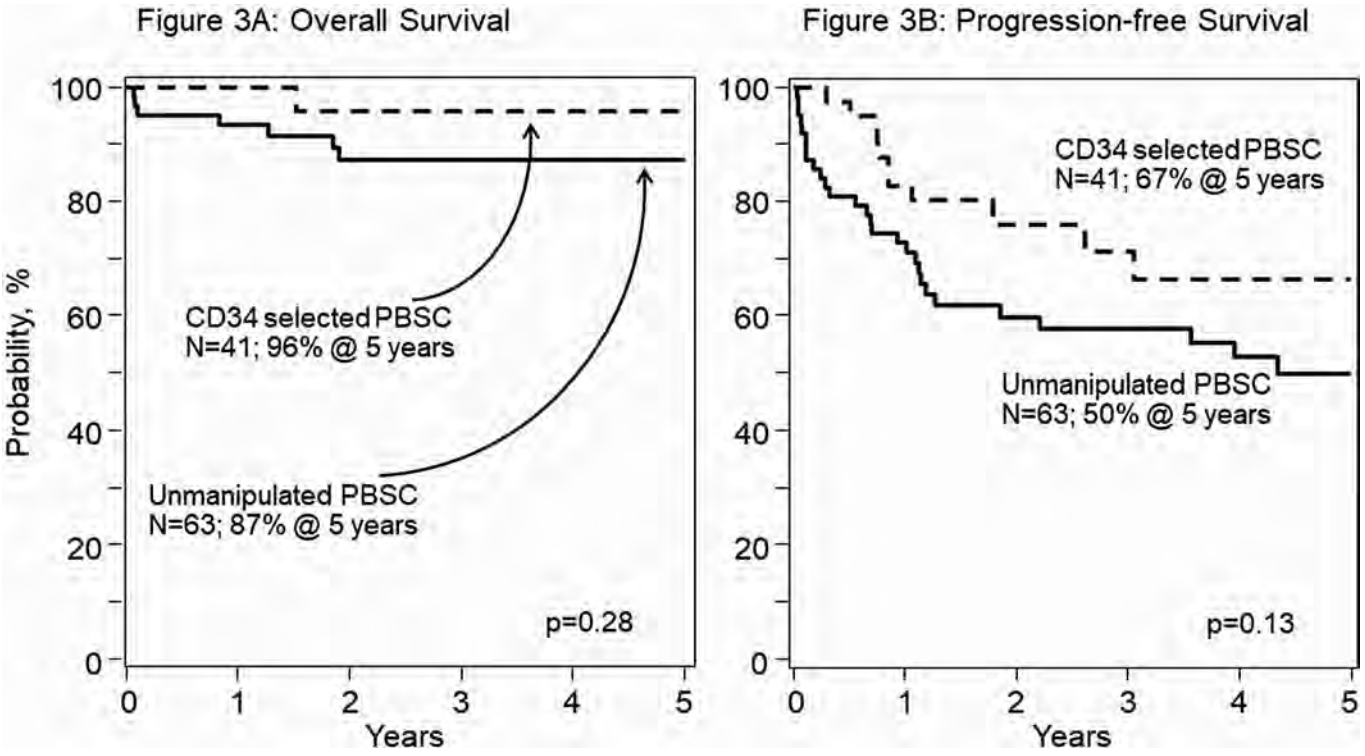

Figure 3. A. 5-yr. OS after AHSCT for SSc, non-randomized, registry patients with PBSC CD34+ enriched vs. unmanipulated, 96% and 87%, P=0.28. B. Corresponding 5- yr. PFS 67% and 50%, P=0.13, log-rank test.

Median age at AHSCT was 48 (range, 14-74) years (yr). For the entire cohort of 104 patients (Figure1), the 5-yr OS was 91%, (95% confidence interval, 84-95). The 5-yr PFS was 56% (45-67). Figure2, the 5-yr OS with TBI/CYC/ATG was 87% (75-96) and CYC/ATG 94% (86-99) (P-value = 0.16). The corresponding 5-yr PFS were 60% (45-75) and 51% (33-68) (P = 0.92). Figure3, the 5-yr. OS for the cohort given CD34+ enriched PBSC was 96% (85-100) and unmanipulated PBSC was 87% (77-95) (P = 0.28). The 5-yr. corresponding PFS were 67% (49-83) and 50% (36-64) (P = 0.13). ATG source (horse vs. rabbit) did not affect OS/PFS. Age, examined as a predictor for OS/PFS, was not significant. In multivariate analysis, no tested covariates were significant for OS or PFS.

Conclusion: The OS and PFS benefit of AHSCT for patients with severe SSc was confirmed in this 5-year retrospective, real-world, non-randomized analysis and was independent of the patient factors or transplant regimens analyzed. While the data suggested use of CD34+ enrichment of PBSC for AHSCT improved PFS for SSc patients, study of a larger cohort for a longer time is needed to evaluate significance.

Release of High-Mobility Group Box-1 After an Raynaud's Attack Potentially Leads to Fibroblast Activation and Interferon-γ Induced Protein-10 Production in Systemic Sclerosis

Isabella Atzeni[1], Yehya Al-Adwi[2], Berber Doornbos-van der Meer[2], Amel Eman Abdulle[2], Anniek Van Roon[2], Alja J. Stel[2], Harry Van Goor[2], Andries Smit[2], Johanna Westra[2] and Douwe J Mulder[2], [1]University of Groningen, University Medical Centre Groningen, Groningen, Groningen, Netherlands, [2]University of Groningen, University Medical Centre Groningen, Groningen, Netherlands

SESSION INFORMATION

Session Date: Monday, November 8, 2021

Session Title: Systemic Sclerosis & Related Disorders – Clinical Poster II (1364–1390)

Session Type: Poster Session C

Session Time: 8:30AM–10:30AM

Background/Purpose: Raynaud's Phenomenon (RP) leading to repetitive ischaemia and reperfusion (IR) stress, is the first recognisable sign of systemic sclerosis (SSc). Although RP has been linked to SSc aetiology, direct observations substantiating this are scarce. High-mobility group box-1 (HMGB1) is a nuclear factor released by necrotic cells, of which serum levels may rise quickly after IR injury in other diseases. IR injury promotes interferon (IFN) inducible

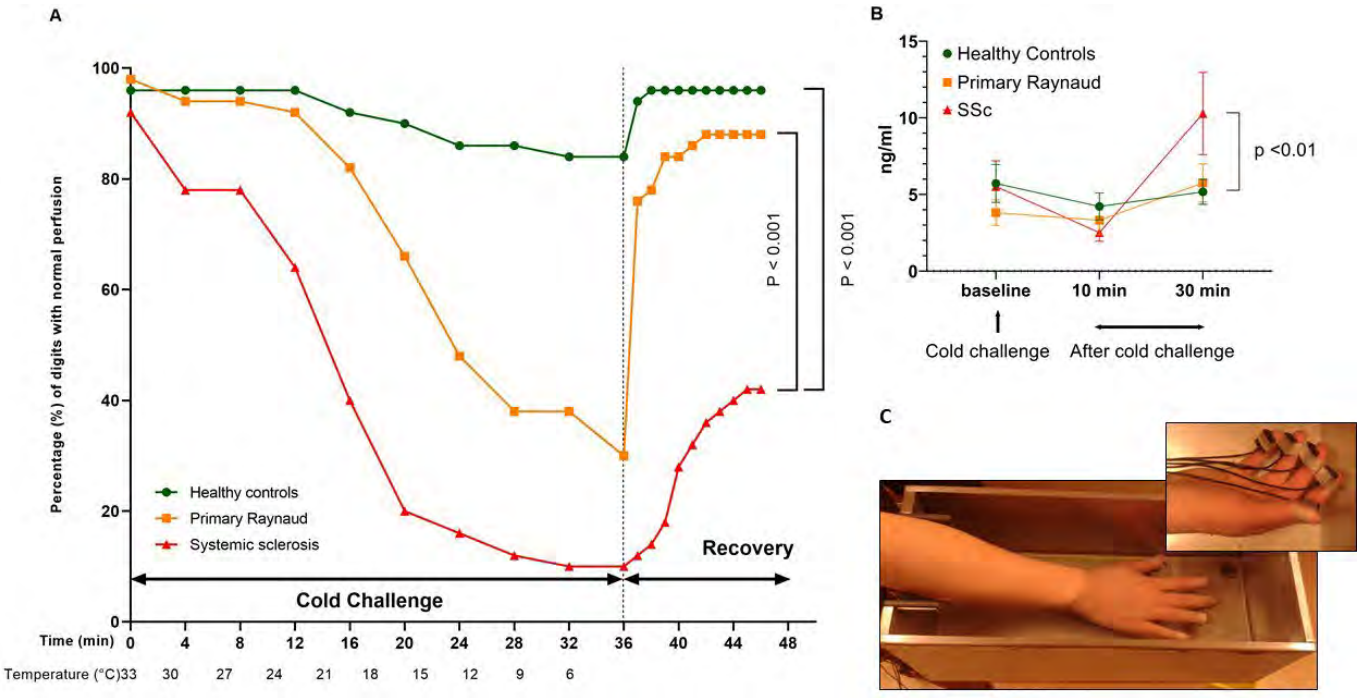

Figure 1. Cold challenge in patients with SSc, primary RP and healthy controls showing effects on fingers perfusion (Figure 1a). The hand is gradually cooled from 33 to 6 degrees Celsius within 36 minutes, and rewarmed at ambient temperature (22 degrees Celsius) to assesses recovery of perfusion. In Figure 1b the effect of the cold challenge is shown on levels of HMGB1. Figure 1c shows that hand is submerged in water to perform the cold challenge, and digital perfusion is measured by photoplethysmography.

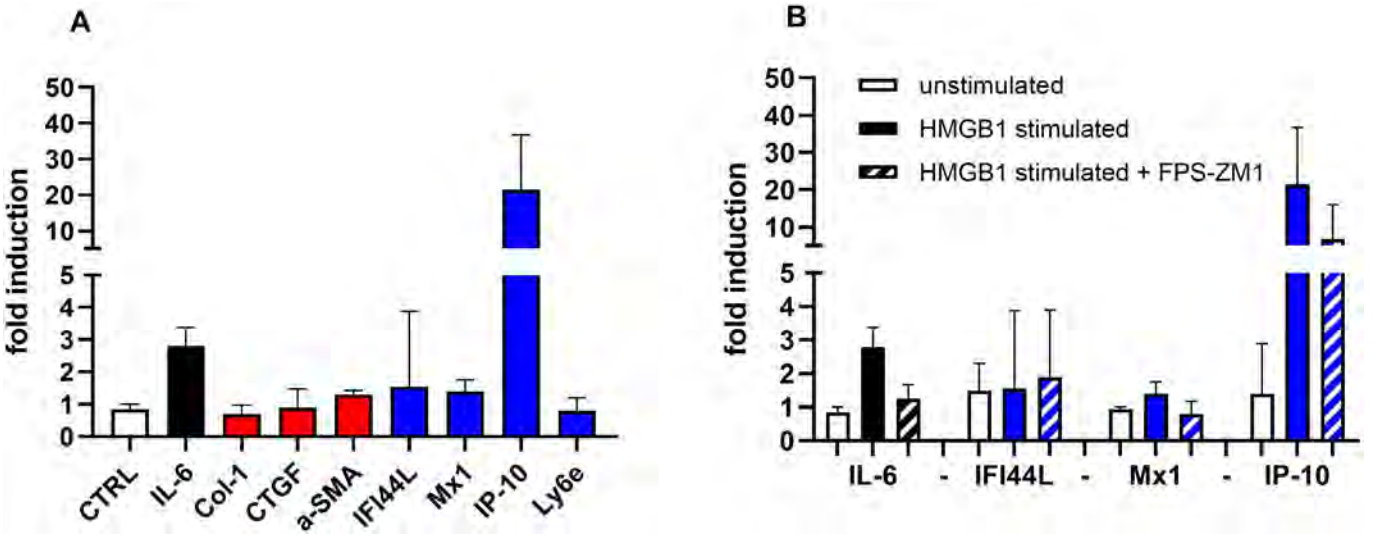

Figure 2. In vitro stimulation of dermal fibroblast with HMGB1. Figure 2a shows induction of inflammatory (black), profibrotic (red), and IFN genes (blue), and negative control (white). Fig 2b shows the RAGE inhibitor FPS-ZM1 on IL-6 (black) and IFN genes (blue).

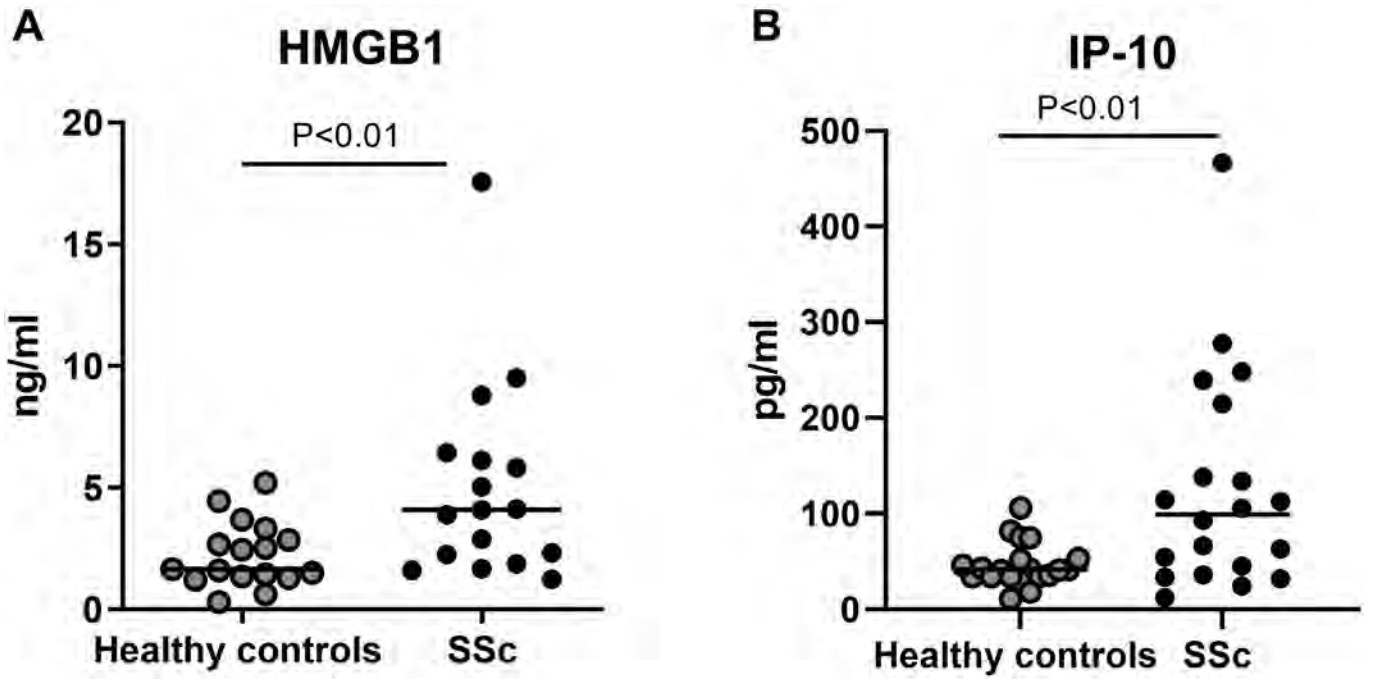

Figure 3. Serum levels of HMGB1 (Figure 3a) and IP-10 (Figure 3b) in patients with SSc compared with age and sex matched healthy controls.

genes, which have been implicated in SSc pathophysiology. Since HMGB1 can signal through the receptor for advanced glycation endproducts (RAGE), we investigated whether an RP attack promotes release of HMGB1, leading to fibroblast activation and upregulation of IFN- inducible genes in a translational study.

Methods: A cold challenge was performed to simulate an RP attack in patients with SSc (N=10, age 56.2 ± 11.5 years), primary RP (N=10, age 47.8 ± 16.2, 8), and healthy controls (N=10, age 29.9 ± 2.7). We measured levels of HMGB1 and IFN gamma-induced Protein 10 (IP-10) before, 10 and 30 min after cold challenge in blood drawn from ipsilateral forearm. Digital perfusion was assessed by photoplethysmography. For studying *in vitro* effects of HMGB1, healthy human dermal fibroblasts were stimulated with HMGB1 or TGF-β1 as control. Inflammatory (Interleukin-6 [IL-6]) genes, profibrotic (type 1 collagen [Col1], α-smooth muscle actin [α-SMA]), connective tissue growth factor

[CTGF]) genes, and IFN-inducible genes (IFN α-induced44L [IFI144L], Myxovirus resistance protein 1 [Mx1], Lymphocyte antigen 6 complex, locus E [LY6E];, and IP-10) were measured by RT-PCR. RAGE signalling was determined by preincubation with its inhibitor FPS-ZM1. Differentiation to myofibroblasts was assessed by staining of α-SMA. In an independent cohort, sera were obtained from 20 patients with SSc (age 50 (44–54) years, 13 female) and 20 age- and sex-matched healthy controls (53 (47–63), 13) to determine HMGB1 and IP-10 levels.

Results: During cold challenge, finger perfusion was reduced in SSc and recovered slower than in primary RP and healthy controls (Figure 1a). HMGB1 increased significantly 30 min after cold challenge in SSc compared to healthy controls, but not to primary RP (Figure 1b). IP-10 remained stable. I*n vitro* stimulation of fibroblasts with HMGB1 resulted in 20-fold increase in mRNA expression of IP-10, while IL-6 increased 3-fold. Col1, α-SMA, IFI144L, Mx1, and LY6E did not change (fig 2a). IP-10 expression was inhibited by 50% by preincubation with FPS-ZM1 (fig 2b). TGF-β1 stimulation promoted IL-6 and CTGF, without effects on IFN gene expression. HMGB1 stimulation induced myofibroblast differentiation and formation of α-SMA fibers. Both HMGB1 and IP-10 were significantly higher in patients with SSc compared to healthy controls (fig 3).

Conclusion: In this translational study, we show for the first time that an RP attack in patients with SSc leads to release of HMGB1. *In vitro*, HMGB1 induces IFN regulated gene expression in fibroblasts, especially interferon-γ inducible IP-10, at least in part in a RAGE dependent manner. This potentially links HMGB1 release following an RP attack to IFN inducible proteins as putative sequential steps leading to disease progression in SSc.

The Use of Lipid-Lowering Agents in Systemic Sclerosis: Is There a Relationship with Prevalence of Digital Ulcers and Overall Survival?

Olivia Sallis[1], Dylan Hansen[2], Kathleen Morrisroe[3], Wendy Stevens[3], Mandana Nikpour[4] and Susanna Proudman[5], [1]Royal Adelaide Hospital, Adelaide, Australia, [2]St. Vincent's Hospital Melbourne, Victoria, Australia, Adelaide, Australia, [3]St Vincent's Hospital, Melbourne, Australia, [4]University of Melbourne at St Vincent's Hospital, Melbourne, Australia, [5]University of Adelaide, Medindie, Australia

SESSION INFORMATION
Session Date: Monday, November 8, 2021
Session Title: Systemic Sclerosis & Related Disorders – Clinical Poster II (1364–1390)
Session Type: Poster Session C
Session Time: 8:30AM–10:30AM

Background/Purpose: Digital ulcers (DU) are common in systemic sclerosis (SSc). Vasodilator therapies have limited benefit in prevention and promoting healing. Lipid-lowering agents (LLAs) such as statins reduce endothelial damage, increase vasodilation, and in small studies prevent new DU. This study examined whether LLAs have an impact on the prevalence of DU and overall survival in patients with SSc.

Methods: Data collected prospectively from the Australian Scleroderma Cohort Study between 2008 and 2020 included patient demographics, the presence of DU, vasodilator therapies, SSc manifestations and other vascular comorbidities. LLA use was defined as use of a LLA on two consecutive annual reviews. Multivariate longitudinal logistic modelling was used to assess associations with DU and a Kaplan-Meier (K-M) curve and multivariate cox proportional hazard modelling were used to assess survival by LLA use.

Variable	Odds Ratio	p-value	95% CI
Ever had lipid lowering agents over 2 consecutive reviews	1.06	0.766	0.74 - 1.52
Diffuse disease Limited disease	3.40 1.00	<0.001	2.40 - 4.81
PAH	1.98	0.008	1.20 - 3.27
PVD	5.21	<0.001	2.46 - 11.02
CCA	2.62	<0.001	1.90 - 3.64
PDE-5 inhibitor	2.00	0.004	1.25 - 3.20
Iloprost	9.78	<0.001	5.28 - 18.11
IHD	0.80	0.369	0.49 - 1.31
Age at non-RP symptom onset	0.97	<0.001	0.96 - 0.98

Table 1. Multivariate logistic analysis of associations with digital ulcers

Results: Among 1485 patients, 323 patients (21.8%) had used a LLA. Patients in the LLA group were older at the onset of the first non-Raynaud's symptom than patients in the non-LLA group (51.6 years *vs* 44.8 years, p = 0.001) and were more likely to have the anti-centromere antibody, interstitial lung disease, pulmonary arterial hypertension (PAH) and to have used calcium channel blockers. In a multivariate analysis (Table 1), the odds of ever having a DU were increased in males, patients with the diffuse subtype of SSc, pulmonary arterial hypertension (PAH) and those who received calcium channel blockers and vasodilators for PAH. Patients with peripheral vascular disease (PVD) were much more likely to have DU with an OR 5.21 (p = < 0.001; CI 2.46-11.02). There was a protective effect of older age, likely explained by survivor bias. There was no association of DU with LLA or other cardiovascular disease. In a multivariate model, LLA use was associated with reduced all-cause mortality (HR 0.60, p < 0.002, 95% CI 0.44-0.83). Patients with disease duration of less than 4 years receiving LLAs had worse survival than those not taking LLAs, with a hazard ratio of 2.41 (p = 0.002, 95% CI 1.38 – 4.20) but not when adjusted for age and gender.

Conclusion: DU prevalence was not influenced by LLA use but was strongly associated with PVD. While DU are traditionally considered to be related to local vasoconstriction and microvascular disease, macrovascular disease may also be an aetiological factor. LLA use was associated with reduced all-cause mortality but did not improve survival in patients with incident SSc who have the highest mortality early in the disease.

Associations of Esophageal Dysmotility Patterns with Extra-intestinal Features in Patients with Systemic Sclerosis

Ana Tucker[1], Jamie Perin[2], Elizabeth Volkmann[3], Ami Shah[4], John Pandolfino[5] and Zsuzsanna McMahan[4], [1]Medical University of South Carolina, Charleston, SC, [2]Johns Hopkins University, Baltimore, MD, [3]Department of Medicine, Division of Rheumatology, University of California, David Geffen School of Medicine, Los Angeles, CA, [4]Johns Hopkins Rheumatology, Baltimore, MD, [5]Northwestern University, Chicago, IL

SESSION INFORMATION

Session Date: Monday, November 8, 2021

Session Title: Systemic Sclerosis & Related Disorders – Clinical Poster II (1364–1390)

Session Type: Poster Session C

Session Time: 8:30AM–10:30AM

Background/Purpose: The gastrointestinal (GI) tract is the most commonly affected internal organ in systemic sclerosis (SSc). SSc GI disease is heterogeneous, with some patients experiencing only mild acid reflux, while others progress to severe GI disease requiring total parenteral nutrition to sustain life.[1–3] As our understanding of disease pathogenesis is poor and risk stratification tools in SSc GI disease are limited, we sought to determine whether distinct types of esophageal dysfunction associate with specific clinical phenotypes and outcomes in SSc.

Methods: Patients in the Scleroderma Center Research Registry who had high resolution esophageal manometry (HRM) studies completed in our hospital system as part of their clinical care between 2011 and 2020 were identified through our Precision Medicine Analytics Platform. Data from the manometry reports were downloaded, abstracted, and merged with existing demographic, clinical and serologic data that had been collected longitudinally from 1991-2020 as part of our Center's Research Registry. Associations between esophageal abnormalities identified on manometry [absent contractility (AC), ineffective esophageal motility (IEM), hypotensive LES (hypoLES)] and patient demographics, clinical characteristics, and autoantibody profiles were examined.

Results: Ninety-five patients with SSc had HRM data. Of these patients, 67 patients (71%) had AC (44 patients with only AC, 23 patients with AC and a hypoLES), 17 patients (18%) had IEM (3 with a hypoLES), and 11 patients (12%) had normal studies. Median disease duration in patients with AC was 12 years (6-23) and in patients with IEM was 19 years (10-22). The presence of AC was significantly associated with diffuse cutaneous disease (36% vs. 14%; p=0.05), more severe cardiac involvement (Medsger score >1; 41% vs. 19%; p=0.04), and more severe Raynaud's phenomenon (Medsger score >1; 57% vs. 29%, p=0.01). AC was seen in 100% of the patients in the study that died (14/14, p< 0.01). Among patients with AC, 21% died, whereas none of the patients without AC died (p< 0.01). Interestingly, 93% (15/16) of Ro52 positive patients had AC (p=0.06). These findings were not seen in patients with IEM.

Conclusion: In patients with SSc who are referred for manometry, the presence of AC, but not IEM, is strongly associated with a severe clinical phenotype and a high risk of death. Further prospective studies are needed to assess the prevalence of AC in early disease, the timing of its onset relative to other end organ complications, and its rate of progression among patients with SSc.

AC: Absent contractility. IEM: Ineffective esophageal motility. LES: Lower esophageal sphincter. SD: Standard deviation. IQR: Interquartile range. SSc: Systemic sclerosis. RP: Raynaud's phenomenon. FVC: Forced vital capacity. DLCO: Diffusing capacity of lung for carbon monoxide. RVSP: Right ventricular systolic pressure. TTE: transthoracic echocardiogram. Scl-70: topoisomerase 1 antibody. Reduced FVC defined as <70% predicted. Reduced DLCO defined as <60% predicted. Elevated RVSP by TTE defined as >40 mm Hg. Severity of organ involvement was determined based on Medsger severity scores definitions.[3] Significance determined by Fisher's exact test if sample size =5 or chi-squared test if sample size >5.

Characterising Exercise Capacity in Systemic Sclerosis Using Cardiac Magnetic Resonance Imaging, Skeletal Muscle Imaging and Cardiopulmonary Exercise Testing

Laura Ross[1], Benedict Costello[2], Dylan Hansen[3], Anniina Lindqvist[2], Zoe Brown[4], Andrew Burns[4], David Prior[4], Wendy Stevens[4], Marcus Pianta[4], Warren Perera[4], Andre La Gerche[2] and Mandana Nikpour[1], [1]University of Melbourne at St Vincent's Hospital, Melbourne, Australia, [2]Baker Heart and Diabetes Institute, Melbourne, Australia, [3]St. Vincent's Hospital Melbourne, Victoria, Australia, Adelaide, Australia, [4]St Vincent's Hospital, Melbourne, Australia

SESSION INFORMATION

Session Date: Monday, November 8, 2021

Session Title: Systemic Sclerosis & Related Disorders – Clinical Poster II (1364–1390)

Session Type: Poster Session C

Session Time: 8:30AM–10:30AM

Background/Purpose: Impaired exercise capacity contributes to functional impairment, negatively impacting individuals' quality of life. Functional impairment is notable from early in the disease course of systemic sclerosis (SSc).[1] Routine investigations such as pulmonary function tests (PFT) and echocardiography (TTE) often fail to adequately

Table 1. Baseline demographics n=33

Age (years, mean, SD)	55.39 (7.60)	*Cardiopulmonary exercise test results (n=33)*	
Female (n, %)	24 (72.73%)	Peak VO_2 (L/min) (median, IQR)	1.18 (1.04-1.35)
Limited / Diffuse (n, %)	13 (39.39%) / 20 (60.61%)	Peak VO_2 (mL/kg/min) (mean, SD)	19.11 (5.01)
Disease duration (years, median, IQR)	10.17 (2.32-12.36)	Peak VO_2 <14.0 (n, %)	3 (9.09)
Disease onset < 4 years (n, %)	14 (42.42%)	Peak VO_2, % predicted (mean, SD)	70.18 (18.98)
Body Mass Index (kg/m^2, mean, SD)	25.04 (4.45)	VE/VCO_2 (median, IQR)	29.6 (26-35)
Current smoking (n, %)	2 (11.11%)	VE/VCO_2 >35 (n, %)	7 (21.21)
Hypertension (n, %)	3 (9.09%)	Peak workload (median, IQR)	96 (55-122)
Type II diabetes (n, %)	2 (6.06%)	RER >1.15 (n, %)	33 (100%)
Anti-centromere positive (n, %)	8 (24.24%)	Peak heart rate (mean, SD)	161 (14.1)
Scl70 positive (n, %)	12 (36.36%)	% predicted heart rate (mean, SD)*	111.45 (10.15)
RNA polymerase III positive (n, %)	5 (15.15%)	Heart rate recovery ≤12 beats at 1 min (n, %)	2 (6.06%)
Modified Rodnan skin score (median, IQR)	10 (3-19)	Peak systolic blood pressure (mmHg) (mean, SD)	184.27 (24.96)
Digital ulcers (n, %)	17 (51.52%)	*Cardiac MRI results (n=31)*	
Interstitial lung disease (n, %)	10 (30.30%)	LV ejection fraction (%) (mean, SD)	64.39 (6.37)
ILD currently requiring treatment	5 (15.15%)	LV end diastolic volume (mL) (median, IQR)	119 (106-147)
FVC (% predicted, median, IQR)	91 (79-98)	LV GLS (%) (mean, SD)	-16.68 (2.31)
DLCO (% predicted, median, IQR)	97.25 (72.32-106.50)	LV mass (median, IQR)	100 (86-115)
Inflammatory arthritis (n, %)	19 (57.58%)	RV ejection fraction (%) (mean, SD)	52.52 (5.74)
Myositis* (n, %)	2 (6.06%)	RV end diastolic volume (mL) (mean, SD)	139.26 (30.69)
Creatine kinase (median, IQR)	86 (69.5-110)	Native T1 time (ShMOLLI) (ms) (median, IQR)	1221.60 (1194.60-1252.90)
CRP (median, IQR)	5 (4-7)	ECV (ShMOLLi) (%) (mean, SD)	30.61 (2.55)
ESR (median, IQR)	15 (11-24.5)	Late gadolinium enhancement (n, %)	9 (30%)
Haemoglobin (g/L, mean, SD)	129.48 (11.71)	Native T2 time (FLASH) (ms) (mean, SD)	42.48 (3.74)
Transthoracic echocardiogram results (n=33)		*Skeletal muscle MRI results n=32*	
LV ejection fraction (%, mean, SD))	59.39 (4.47)	Muscle oedema (n, %)	12 (37.50%)
Average LV GLS (%, mean, SD)	-19.42 (2.48)	Fatty muscle infiltration (n, %)	5 (15.62%)
LV end diastolic volume (mL, mean, SD)	86.05 (17.26)	Muscle atrophy (n, %)	1 (3.13%)
LV end systolic volume (mL, median, IQR)	33 (29.2-37.2)		
LAVi (mL/m^2, mean, SD)	32.76 (7.45)		
Average E/e' (mean, SD)	7.96 (2.11)		
RVSP (mmHg, mean, SD)	27.92 (4.07)		

*Myositis previously diagnosed by muscle biopsy or typical MRI findings with elevated CK and/or ESR and CRP.

Abbreviations: CRP: C-reactive protein; DLCO: diffusing capacity of the lung for carbon monoxide, ESR: erythrocyte sedimentation rate; FLASH: fast angle low shot; GLS: global longitudinal strain; ILD: interstitial lung disease; IQR: interquartile range; LV: left ventricle; MRI: magnetic resonance imaging; ml: millilitre; ms: millisecond; RER: respiratory exchange ratio; RV: right ventricle; SASHA: saturated recovery single-shot acquisition; SBP: systolic blood pressure; Scl70: anti-topoisomerase antibody; SD: standard deviation; ShMOLLI: shortened modified look locker; VE/VCO_2: minute ventilation / carbon dioxide production slope; VO_2: oxygen consumption

Table 2. Regression analysis of clinical characteristics associated with peak oxygen consumption (% predicted)

Clinical variable	Coefficient	p value (95% CI)	Clinical variable	Coefficient	p value (95% CI)
Age	0.14	p=0.76 (-0.77-1.05)	*Transthoracic echocardiogram*

Abbreviations: CK: creatine kinase; CRP: C-reactive protein; DLCO: diffuse capacity for carbon monoxide; ESR: erythrocyte sedimentation rate; FVC: forced vital capacity; LAVi: left atrial volume index; LVEF: left ejection fraction; LV GLS: left ventricular global longitudinal strain; MRI: magnetic resonance imaging; mRSS: modified Rodnan Skin score; RVSP: right ventricular systolic pressure; ShMOLLI: shortened modified look locker

account for the symptom burden reported by patients.[2]Cardiopulmonary exercise testing (CPET) is the gold standard test for aerobic capacity. We sought to quantify the degree of exercise impairment in SSc using CPET and correlate disease manifestations, cardiac and pulmonary function and skeletal muscle abnormalities to peak VO_2. Our aim was to understand the disease specific features that contribute to impaired aerobic fitness in SSc.

Methods: Thirty four patients who all fulfilled 2013 ACR/EULAR criteria for SSc were recruited. Participants underwent PFT, TTE, cardiac MRI with mapping sequences, skeletal muscle MRI and CPET. No participant had a history of myocarditis, pulmonary arterial hypertension, ischaemic heart disease, valvular heart disease or renal impairment. Using logistic and linear regression analysis we analysed the SSc manifestations and imaging features associated with peak VO_2.

Results: Baseline characteristics of patients are listed in Table 1. We detected significant exercise impairment; mean % predicted peak VO_2 70.18 ± 18.98%. Diffuse myocardial fibrosis was a near universal finding with 30/31 patients having elevated native T1 times, including in those patients with early limited disease and no known SSc internal organ involvement. Nine (30%) patients had areas of late gadolinium enhancement. There was evidence of diffuse

myocardial oedema, with elevated T2 mapping times recorded. Skeletal muscle oedema was highly prevalent; 12 (37.50%) of participants had T2 hyperintensity on MRI. Skeletal muscle T2 hyperintensity was not associated with creatine kinase (p=0.94), ESR (p=0.79) or CRP (p=0.56).

Conclusion: Patients with SSc commonly have profoundly limited exercise capacity. This impairment is multifactorial; subclinical cardiac and skeletal muscle involvement and impaired lung function are significantly associated with reduced peak VO_2 in SSc. So-called subclinical organ involvement has negative physiological sequelae and contribute to global functional impairment. Future work is required to establish whether aerobic capacity in SSc can be improved by treatment of specific disease features or with exercise therapy.

Adipose Tissue-Derived Stromal Vascular Fraction Plus Fat Grafts for Hand Therapy in Patients with Systemic Sclerosis. a Randomized Controlled Clinical Trial

Martín Iglesias[1], Iván Torre-Villalvazo[1], Armando Tovar-Palacio[1], Alejandro Zentella-Dehesa[1], Patricia Butrón-Gandarillas[1], Marta Durand-Carbajal[1], Erik Torre-Anaya[2], Martha Guevara[2] and **Tatiana Rodriguez-Reyna**[2], [1]Instituto Nacional de Ciencias Médicas y Nutrición Salvador Zubirán, Mexico City, Mexico, [2]Instituto Nacional de Ciencias Medicas y Nutricion Salvador Zubiran, Mexico City, Mexico

SESSION INFORMATION
Session Date: Monday, November 8, 2021
Session Title: Systemic Sclerosis & Related Disorders – Clinical Poster II (1364–1390)
Session Type: Poster Session C
Session Time: 8:30AM–10:30AM

Background/Purpose: Adipose tissue-derived Stromal Vascular Fraction (ADSVF) has been proposed as regenerative treatment for hand deformities and digital ulcer healing in patients with Systemic Sclerosis (SSc). We aimed to evaluate its regenerative properties after local injection of autologous ADSVF in the hands of these patients.

Methods: This was an open-label, monocentric, randomized controlled study, approved by our local IRB and registered at clinicaltrials.gov (NCT04387825). Twenty patients diagnosed with SSc and moderate to severe hand contractures according to the Medsger's severity scale and/or digital tip ischemic ulcers (distal to PIP joints) with more than 30 days of evolution despite medical treatment, were enrolled and assigned to the experimental or control group. Both groups continued standard medical treatment. Autologous ADSVF was obtained by liposuction and then by enzymatic digestion in the experimental group. This group received ADSVF plus fat micrografts injection into the right hand. Digital oximetry, pain, Raynaud phenomenon (RP), digital ulcer healing (DUH) time, range of motion (ROM), vascular density of the nail bed, cell surface markers, hand function, and quality of life scores were evaluated in both

groups. The follow-up period was 168 days. Continuous variables were expressed as median with 95% confidence intervals. The differences between before and after the intervention were analyzed with the Wilcoxon range test, and the differences between the control and experimental groups at 0 and 168 days were analyzed with the Mann–Whitney U test. The range of total viable nucleated cells in the ADSVF was $167.5x10^6$, with viability of 82% or higher. Stem cell markers into the ADSVF were: CD34+ 4.72% , CD45+ 43.9%, CD44+ 36.3%, CD73+ 6.18 %, CD90+ 34.4 %, CD105+ 7.27%, HLA-DR 12.1%, Stromal cells 4.05%.

Results: At 168 days of follow-up there were significant improvements in pain level (p= 0.02) and DUH (p= 0.003) only in the experimental group. We also found increased active ROM of the MCP joints in the treated hand of the experimental group, while the non-treated hand MCP joint ROM decreased significantly. Raynaud phenomenon improved in both groups. There were no changes in disease activity or severity, nailfold capillaroscopy pattern, mobility or hand function between both treatment groups. One patient in the experimental group reported transient hand edema that solved within 7 days.

Conclusion: ADSVF local injection is safe and well tolerated in SSc patients. This therapeutic method may improve pain and time to digital ulcer healing in patients with severe joint contractures and refractory digital ulcers.

SESSION INFORMATION

Session Date: Monday, November 8, 2021

Session Title: Systemic Sclerosis & Related Disorders – Clinical Poster II (1364–1390)

Session Type: Poster Session C

Session Time: 8:30AM–10:30AM

Background/Purpose: Pulmonary arterial hypertension (PAH) is a severe vascular complication of systemic sclerosis (SSc) and a major cause of mortality. Despite significant advances in the treatment of PAH, the pathogenesis of SSc-PAH is not well understood. Our previous work has shown that serum levels of complement factor D (fD, adipsin), a critical regulator of complement alternative pathway (AP) activation and amplification loop engagement, is associated with limited cutaneous SSc and SSc-PAH. Here we assessed the levels of complement cascade proteins utilizing a well-characterized cohort of SSc-PAH to investigate the possible role of complement components as biomarkers for disease development and progression.

Table 1. Plasma levels of 11 complement components in SSc-PAH, SSc patients without PAH, healthy controls and patients with psoriatic arthritis are represented as mean and standard deviation (S.D.). Comparisons of all SSc-PAH (n= 156) vs all controls (n=100) and SSc-PAH vs SSc without PAH are shown with corresponding ANOVA p-value

Plasma Complement Component	SSc-PAH (n=156)		Healthy Control (n=40)		SSc no PAH (n=33)		Psoriatic Arthritis (n=27)		SSc-PAH vs all Controls	SSc-PAH vs SSc no PAH
	Mean	S.D.	Mean	S.D.	Mean	S.D.	Mean	S.D.	p-value	p-value
C1q	108.6	27.5	84.9	17.5	115.0	37.2	102.3	16.6	**0.012**	0.360

C4	133.9	32.3	141.8	28.8	120.6	28.6	190.6	58.0	**0.010**	**0.022**
C5	81.0	19.7	66.0	17	65.1	18.9	86.1	21.2	**0.0002**	**<0.0001**
Factor B	139.0	74.1	131.0	39.4	225.3	312.	171.4	29.2	0.085	0.130
Factor D	2.3	1.3	0.9	0.3	1.2	0.71	1.1	0.4	**<0.0001**	**<0.0001**
Factor H	195.5	31.6	203.2	40.1	182.6	47.1	282.6	83.1	**0.003**	0.140
Factor I	30.9	5.8	30.4	8.2	28.7	7.7	33.2	8.5	0.705	0.114
MBL	0.8	0.7	0.6	0.7	0.8	0.8	0.9	0.7	0.298	0.818
Properdin	17.7	3.7	19.2	4.7	17.7	5.2	24.6	4.5	**0.0002**	0.941

Methods: We evaluated 156 SSc-PAH patients from the PAH Biobank (www.pahbiobank.org), 33 SSc without PAH, 27 patients with psoriatic arthritis (PsA) and 40 healthy controls. Patients with interstitial lung disease were excluded from the SSc-PAH group. Plasma levels of complement components (C1q, C2, C3, C4, C5, fB, fD, fI, fH, Properdin and Mannose binding lectin) were assessed by Luminex at Exsera Biolabs, a CAP/CLIA certified laboratory. Associations between complement levels and clinical data in SSc-PAH (including NYHA functional status, 6-minute walk test, and hemodynamic data) were assessed and were corrected for age, sex, race, disease duration, obesity, smoking and scleroderma subtype. ANOVA was used to determine differences between serum complement levels across groups. Multiple logistic regression analysis was performed to characterize associations.

Results: Four out of 11 complement components (fD, C1q, C3, C5) were significantly dysregulated in SSc-PAH patients compared to healthy controls ($p< 0.0001$). Logistic regression analysis using these eleven markers revealed that C3, C5, fB and fH were able to distinguish SSc-PAH from all of the control groups. When comparing SSc-PAH to SSc without PAH, we found that fD, C2, C3, C4 and C5 were markedly and specifically elevated in SSc-PAH. Within the SSc-PAH cohort, a number of complement factors were significantly associated with markers of disease severity including VO2 (fH OR=1.03, p=0.02 and C3 OR=0.982, p=0.01), NYHA functional status (fB OR=1.063 $p< 0.001$, fH OR=0.964 p=0.03, fI OR=0.699 p=0.001, C2 OR=0.786 p=0.001), right atrial pressure (fD OR=0.320, p=0.001 and MBL OR=3.593, p=0.01), cardiac index (fH OR=1.048, p=0.008), cardiac output (fH OR=0.028, $p< 0.0001$) and mortality at follow-up (fH OR=0.975, p=0.014).

Conclusion: Factor D and other complement components are significantly altered in patients with SSc-PAH compared to controls. Factor H demonstrates potential utility as a marker of severity across multiple outcomes. These findings suggest that the alternative complement cascade plays a critical role in SSc-PAH pathogenesis and can potentially serve as a biomarker to inform diagnosis and prognosis.

Abstract Number: 1371

Symptom Management in Systemic Sclerosis: A Pilot Study of a Web-based Intervention Using Peer-Health Coaches

Susan Murphy[1], Yen Chen[2], Mary Alore[2], Sheri Hicks[2] and Dinesh Khanna[2], [1]University of Michigan, Grosse Ile, MI, [2]University of Michigan, Ann Arbor, MI

SESSION INFORMATION
Session Date: Monday, November 8, 2021
Session Title: Systemic Sclerosis & Related Disorders – Clinical Poster II (1364–1390)
Session Type: Poster Session C
Session Time: 8:30AM–10:30AM

Background/Purpose: People with systemic sclerosis (SSc) have a high burden of chronic symptoms that have dramatic effects on function and quality of life. Fatigue, along with pain, sleep disturbance, and physical limitations, affects the ability to fulfill life roles. Unfortunately, relevant interventions that can help people with SSc learn skills to manage fatigue and co-occurring symptoms and to improve wellbeing are not currently available in clinical care and are urgently needed. This pilot study examined feasibility and preliminary effects of a web-based intervention called the Resilience-Based Energy Management Program to Enhance Wellbeing (RENEW) intervention.

Methods: Participants with SSc and had access to a reliable, internet-connected device were enrolled. The study design was a one arm, pretest-posttest trial. The intervention involved 12 weeks of working on health goals based on online modules. Trained "peer" health coaches, who also had an SSc diagnosis, assisted in establishing goals and checking on progress during regular calls (10 over the study). We examined feasibility metrics (recruitment/retention rates, and coach call participation), symptom outcomes, patient global impression of change (PGIC), and end-of-program feedback. Outcomes were assessed at baseline, mid-treatment (6 weeks) and 12 weeks, including PROMIS29 and perceived self-efficacy to manage the condition. Participant characteristics and feasibility metrics were analyzed using descriptive statistics. One-way repeated-measures analysis of variance (ANOVA) was used to analyze changes in outcomes over time. SPSS 24.0 was used for analyses, and statistical significance was set at $p < 0.05$.

Results: Twenty-two participants consented, 21 completed baseline questionnaires; of these, 19 (90%) completed 12-week questionnaires. Participants had a mean age of 54 ± 11 years, (range 25 - 67), 64% were female, and 90% were White (Table 1). Of the 21 participants, 43% had diffuse SSc, 48% had limited SSc, and 9% had overlap. Mean health coach call participation was 9 calls ± 1.1. Among completers of the program, 13 (68.4%) rated overall quality of this program as excellent and 6 (31.6%) rated as good. 72% of participants reported moderate to great improvements on the PGIC. Over the 12 weeks, significant improvements were not shown in symptoms (Table 2), however, 50% of participants had improvements from baseline in sleep disturbance and 44% had improvements in anxiety, pain interference, and fatigue. A significant improvement was found in perceived self-efficacy in medications management ($p = 0.01$). Although perceived informational support increased, results did not reach statistical significance ($p = 0.08$). 95% of people (18/19) felt the program helped them stay positive; 89% said it improved their mood. Participants reported that health coaching was important to them and 63% said talking to someone with their condition was what they liked best.

Conclusion: A 12-week program addressing SSc symptom management with peer health coaches was feasible to deliver and was positively viewed by patients. Health coaching by trained peers was particularly valuable to patients.

Session Date: Monday, November 8, 2021
Session Title: Systemic Sclerosis & Related Disorders – Clinical Poster II (1364–1390)
Session Type: Poster Session C
Session Time: 8:30AM–10:30AM

Background/Purpose: Scleroderma is associated with underlying ILD. About 48% those with diffuse cutaneous SSc and 26% of those with limited cutaneous SSc were found to have ILD on HRCT based on prior literature. The most common cause of mortality in Scleroderma has shifted from renal crisis to pulmonary diagnoses. In our study, we aim to identify the risk factors and outcomes of acute respiratory failure in patients with underlying ILD and Scleroderma.

Methods: Data were abstracted from the National Inpatient Sample (NIS) Database. This database is the largest collection of inpatient admission data in the USA. It is a nationally representative sample of 20% of hospitalizations from approximately 1000 hospitals. The NIS was searched for hospitalizations in 2016, 2017 and 2018 containing ICD-10 for acute respiratory failure codes with J96 as principal diagnosis and underlying Scleroderma associated with ILD as secondary diagnoses with codes M34.81, J84 and J98.4. Using STATA software, the total number of discharges, age, race, length of stay (LOS), mortality and total hospital charges were recorded. A univariate logistic regression analysis was used to calculate unadjusted odds ratios (ORs) for a principal diagnosis of acute respiratory failure. All variables with p-values < 0.2 were included in a multivariate logistic regression model. P-values < 0.05 were considered significant in the multivariate analysis.

Results: A total number of 1,274 patients with underlying Scleroderma-ILD were hospitalized for acute respiratory failure in 2016, 2017 and 2018. Characteristics of patients with acute respiratory failure and underlying Scleroderma *vs* all other adult hospitalizations are displayed in table 1. When compared to the reference group, females were 81% *vs* 57%. Mean age was 61 yrs *vs* 57 yrs Caucasians formed 55% *vs* 67%, followed by African Americans 24% *vs* 15%. 125 (9%) patients underwent BAL *vs* 0.6%. Mean LOS was 7.25 days *vs* 4.74 days, mean total charge of hospitalization was $90,547 *vs* $53,572. Inpatient mortality was 14% *vs* 2%. The following were found to be significant risk factors for acute respiratory failure among scleroderma ILD patients in multivariate analysis: pneumonia OR 5.0, Heart failure OR 4.8, female sex OR 3.6, PE OR 2.6, white race OR 0.6, Quartile 1 of income status based on zip code OR 0.6 and smoking OR 0.3

Conclusion: This analysis represents the largest sample to-date to assess the incidence, mortality, and risk factors for development of acute respiratory failure among Scleroderma patients with ILD. Results show slightly higher mean

Table 1- Descriptive data of patients admitted with acute respiratory failure and underlying Scleroderma-ILD

Hospitalization characteristics	Acute Respiratory failure from SSc-ILD (n=1274)	Non-SSc ILD hospitalizations (n= 90,878,286)	P-value
Women, number (%)	1,045 (81%)	52468697 (57%)	<0.0001
Age, mean in years	61	57	<0.0001
Number (%) hospitalizations by age			
Age 18-40 years	65 (5%)	21950081 (24%)	<0.0001
Age 40-60 years	500 (39%)	21700952 (23%)	<0.0001
Age 60-80 years	610 (47%)	32359091 (35%)	<0.0001
Age > 80 years	100 (7%)	14868162 (16%)	<0.0001
Race (%)			
A) White	55%	67%	<0.0001
B) African American	24%	15%	<0.0001
C) Hispanic	12%	11%	0.518
D) Asian or Pacific Islander	2%	2%	0.4
E) Native American	1%	0.6%	0.251
F) Other	3%	3%	0.821
Bronchoscopy done, number (%)	125 (9%)	619515 (0.6%)	<0.0001
Length of stay, mean days	7.25	4.74	<0.0001
Total charges, mean	$90,547	$53,572	<0.0001
Inpatient mortality, number (%)	180 (14%)	2,020,154 (2%)	<0.0001

age in this group compared to the reference group. The cost of hospitalization and inpatient mortality are also noted to be significantly higher. Female sex, pneumonia, PE, and heart failure are risk factors for acute respiratory failure. This study emphasizes that Scleroderma-ILD patients have high inpatient mortality. Prompt recognition of respiratory distress and pro-active management of above risk factors should be studied as means to improve inpatient scleroderma outcomes.

Table 2 – Univariate screen of risk factors associated with acute respiratory failure in Scleroderma-ILD

Demographic variables	Odds ratio	P-value	95% CI	
Age	1.01	<0.001	1.00	1.01
Female sex	3.32	<0.001	2.40	4.60
Race: a) White	0.60	<0.001	0.46	0.77

SESSION INFORMATION

Session Date: Monday, November 8, 2021

Session Title: Systemic Sclerosis & Related Disorders – Clinical Poster II (1364–1390)

Session Type: Poster Session C

Session Time: 8:30AM–10:30AM

Background/Purpose: Our understanding of the pathogenesis of systemic sclerosis (SSc) continues to evolve. Oxidative stress has been implicated in the pathophysiology of disease, but minimal work has investigated specific markers and mechanisms for oxidative stress in SSc. Paraoxonase-1 is a major HDL-associated protein, which metabolizes pro-inflammatory, oxidized lipids. In the current work, we evaluated the paraoxonase (PON), lactonase

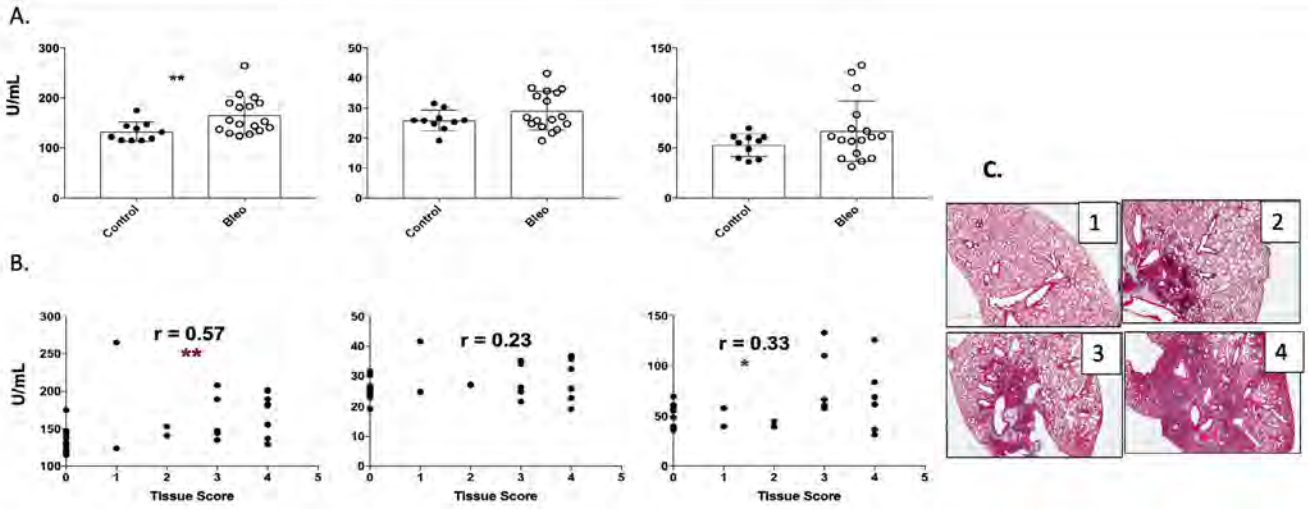

Figure-1: PON-1 activity in Bleo and PBS treated mice and correlation with lung tissue severity. A) Peripheral blood from 17 bleomycin-treated and 10 PBS -treated mice (CTRL) was evaluated for ARES, LAC and PON activity in U/ml. (B) Lung tissue were stained for Masson's Trichrome and assessed for fibrosis severity using a modified Ashcroft score, a numerical fibrosis scoring scale. A score of 0 indicates no fibrosis, 1 minimal, 2 mild, 3 moderate, and 4 severe fibrosis . Sample of lung tissue severity scoring is denoted in panel C. Each symbol represents data from an animal. *p<0.05, ** p<0.01, *** p <0.001.

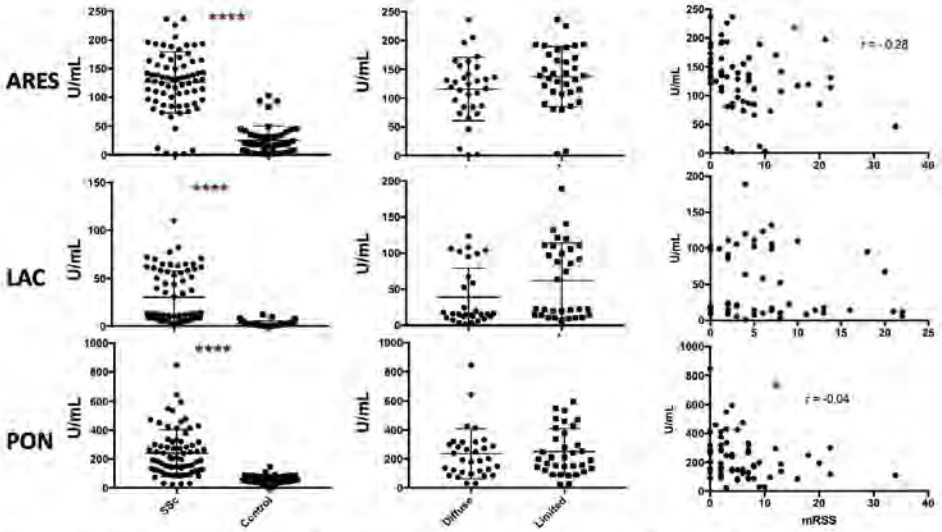

Figure-2: Detection of PON-1 activity in peripheral blood of controls and SSc patients and its correlation with disease type and skin severity score. Panel 1 -PON-1 activity (in U/ml) as denoted by ARES, LAC and PON in 50 controls as well as 72 SSc patients . Each symbol represents data from a patient. Panel 2- represent PON-1 activity in diffuse (dcSSc) as well as limited SSc (dcSSc). Panel 3- represents PON-1 activity in (U/ml)and its correlation with skin disease severity represented by modified Rodnan Skin Score, (ranging from 0-51). A score of 0 indicates no fibrosis, and 51 severe fibrosis . *p<0.05, ** p<0.01, *** p <0.001, **** p <0.0001.

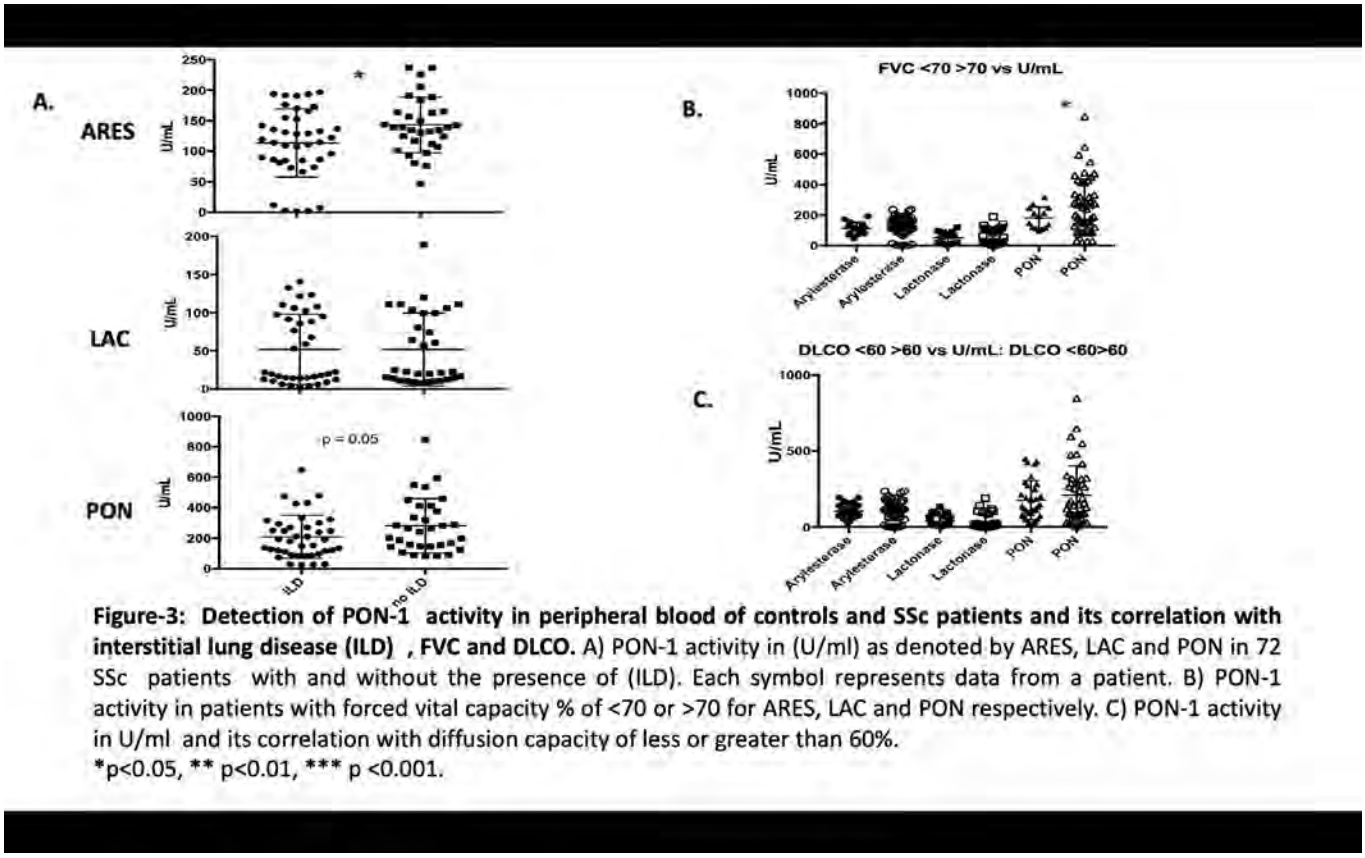

Figure-3: Detection of PON-1 activity in peripheral blood of controls and SSc patients and its correlation with interstitial lung disease (ILD) , FVC and DLCO. A) PON-1 activity in (U/ml) as denoted by ARES, LAC and PON in 72 SSc patients with and without the presence of (ILD). Each symbol represents data from a patient. B) PON-1 activity in patients with forced vital capacity % of <70 or >70 for ARES, LAC and PON respectively. C) PON-1 activity in U/ml and its correlation with diffusion capacity of less or greater than 60%.
*p<0.05, ** p<0.01, *** p <0.001.

(LAC), and arylesterase (ARES) activities of PON1 in both a murine model of SSc and human samples, assessing their correlation with the extent of SSc manifestations and severity.

Methods: We assessed PON, ARES and LAC activities in the murine model of SSc using Black 6 (B6) mice. To induce fibrosis, mice age 8-10 weeks were anesthetized with intraperitoneal ketamine (then treated via oropharyngeal installation with bleomycin (Bleo) or PBS. We assessed Masson's trichrome-stained lung sections using a modified Ashcroft score, a numerical fibrosis scoring scale. A score of 0 indicates no fibrosis, 1 minimal, 2 mild, 3 moderate, and 4 severe fibrosis. PON1 activities were also evaluated in serum samples from 72 SSc patients (pts) meeting the ACR/EULAR 2013 SSc criteria and 50 healthy controls (CTRL). We assessed associations of PON, ARES and LAC activities with disease manifestations including interstitial lung disease (ILD), in both humans and mice (histopathological), vascular disease (pulmonary arterial hypertension (PAH) as well as skin severity (modified Rodnan Skin Score (mRSS). PON1 activities were measured in mouse and human serum samples as described previously using paraoxon (PON), phenylacetate (ARES), and dihydrocoumarin (LAC) as substrates.

Results: Clinical patient characteristics include: 32 (44%) with diffuse SSc (dcSSc) , age (mean , range in years) (56 , 20-85) SSc and (48, 18-65) CTRL; gender,19.4% male (SSc) 18% male (CTRL); active skin ulcers 17 (25.7%); interstitial lung disease (ILD) 40 (55%) pts; (PAH) 23 (31%) pts.

In the murine model of SSc, serum PON1 activities were greater in bleo-treated mice when compared to PBS. Higher ARES , PON and LAC activities correlated with greater tissue severity scores (with r^2 of 0.57 ($p < 0.001$), 0.33 ($p < 0.05$) and 0.23 (p =ns) respectively) (Figure 1). In human data, mean ARES and LAC activities were higher in SSc compared to CTRL (66.43 ± 3.29 SSc patients vs 13.31 ± 1.91 CTRL) $p < 0.0001$. ARES and LAC activities were lower in patients with dcSSc compared to limited (lcSSc). No significant differences were noted in PON activity between dcSSc and lcSSc pts. Moreover, lower levels of ARES and PON significantly correlated with higher skin scores: mRSS correla-

tions: ARES (r^2= 0.08, $p < 0.05$) and PON (r^2= 0.06, $p < 0.04$), (Figure2. Interestingly, lower activities of ARES, LAC, and PON were noted in patients with ILD, (figure 3).

Conclusion: Markers of oxidative stress measured by PON1 activities associate with disease severity in both SSc patients and a murine model of SSc. Further work is warranted and ongoing to examine the role of PON1 as a disease marker and mechanism in the pathogenesis of SSc and SSc-associated ILD.

A Deep Neural Network Classifier to Identify Inflammatory Systemic Sclerosis Patients from Histological Images

Yiwei Yuan[1], Robert Lafyatis[2], Johann Gudjonsson[3], Dinesh Khanna[4] and Michael Whitfield[5], [1]Dartmouth College, Hanover, NH, [2]University of Pittsburgh, Pittsburgh, PA, [3]Department of Dermatology, University of Michigan, Ann Arbor, MI, [4]University of Michigan, Ann Arbor, MI, [5]Geisel School of Medicine, Lebanon, NH

SESSION INFORMATION
Session Date: Monday, November 8, 2021
Session Title: Systemic Sclerosis & Related Disorders – Clinical Poster II (1364–1390)
Session Type: Poster Session C
Session Time: 8:30AM–10:30AM

Background/Purpose: Systemic sclerosis (SSc) patients can be divided into four molecular subsets (inflammatory, fibroproliferative, limited and normal-like) identifiable with gene expression in skin and peripheral blood cells (PBCs). The inflammatory subset typically associated with the presence of inflammatory lymphocyte and innate immune cell infiltrates. SSc participants assigned to the inflammatory subset showed significant improvement in the Abatacept Systemic SclErosis Trial (ASSET). In order to provide a fast and more accessible inflammatory subset predictor, we trained a deep neural network to identify these participants using the images of immunohistochemically (IHC)-stained skin biopsies.

Methods: 164 whole-slide microscopy images were obtained from the ASSET clinical trial. Molecular-subset labels for each whole-slide image were obtained using a previously reported support vector machine (SVM) classifier applied to paired gene expression profiles from the same skin biopsy. A blinded rheumatologist (RL) scored the extent of inflammation and fibrosis in each biopsy. Images were split into training, validation, and test set (70%/15%/15%) with a focus on predicting the inflammatory subset. Small patches were generated using a sliding-window approach and used to train a convolutional neural network (CNN) to infer the subset of the given biopsy. Spearman correlations between predicted probabilities and clinical inflammation scores were examined to validate our model.

Results: A CNN was trained and validated on small patches generated from 140 whole-slide images. The model was evaluated using a hold-out test set of 24 whole-slide images. The final model identifies participants with inflammatory gene signature with 83.33% accuracy (F1-score of 0.75) when data sets are split-by-patient, and 91.30% accuracy (F1-score of 0.9) when data sets are split-by-biopsy. Visualization of patches and predicted decisive regions provided insights on important cell types contributing to the molecular subsets. Areas of the image important for inflammatory subset prediction were identified and visualized. The predicted inflammatory probabilities were significantly correlated with clinical inflammation scores, as assessed by RL.

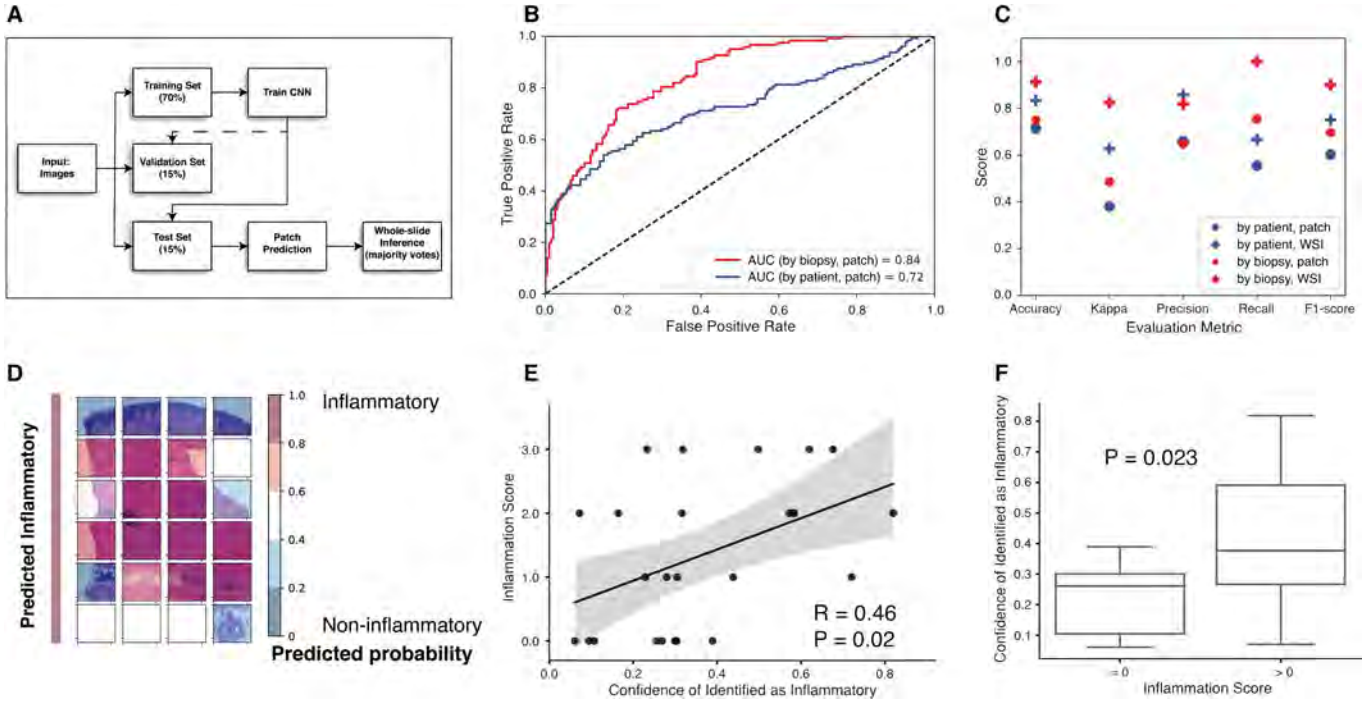

Figure 1. (A) Schematic depiction of the dataset partitioning. (B) Receiver operating characteristic (ROC) curves and their area under the curves (AUCs) on the test set. (C) Models' performance on the test set for models trained on splitting by patient or by biopsy datasets, patch-based and post aggregation whole-slide level. (D) Visualization of patches in a representative true inflammatory slide by overlapping a colored heatmap based on predicted probability. (E) Correlation of confidence scores for prediction as inflammatory subset and clinical inflammation scores. (F) Whole-slide images with inflammation showed significantly higher confidence scores for prediction as inflammatory subset.

Conclusion: We trained a CNN that classifies SSc patients into the inflammatory molecular subset using standard IHC images of skin biopsies. This provides a method that is less costly than genomic assays to identify these individuals and can be applied to evaluate retrospective data where genomic data were not collected but for paraffin embedded blocks or IHC-stained images are available.

SESSION INFORMATION

Session Date: Monday, November 8, 2021

Session Title: Systemic Sclerosis & Related Disorders – Clinical Poster II (1364–1390)

Session Type: Poster Session C

Session Time: 8:30AM–10:30AM

Background/Purpose: Systemic sclerosis (SSc) is a chronic disease characterized by vasculopathy, inflammation and fibrosis. Rheumatologists have limited options to effectively treat rapidly progressive disease. There is an important unmet medical need for disease modifying therapy for patients with SSc. Autologous hematopoietic stem cell transplantation (AHSCT) has been shown in randomized controlled trials and is well recognized to be an effective treatment for rapidly progressive SSc. However, there is a paucity of data pertaining to its performance as compared to real-world routine clinical practice. The objective of this study was to evaluate the effectiveness of AHSCT for SSc compared to conventional care used in routine clinical practice.

Methods: SSc patients from France who underwent AHSCT were compared to SSc patients who met criteria for AHSCT (as defined in the ASTIS trial[1]) but received conventional care in Canada. The primary outcome was overall survival. Secondary outcomes included modified Rodnan skin score (mRSS), forced vital capacity (FVC) and diffusion capacity for carbon monoxide (DLCO). Baseline characteristics were compared using descriptive statistics. Overall survival for both groups was estimated by constructing Kaplan-Meier survival curves based on time to death. Measures of mRSS, FVC and DLCO were compared using linear regression models. Analyses were adjusted for baseline scores and incorporated stabilized inverse probability of treatment weights to account for confounding by indication. Propensity scores were estimated using logistic regression.

Results: 41 SSc patients who underwent AHSCT and 85 patients treated with conventional care were compared. Baseline characteristics are delineated in Table 1. Mean mRSS was 25.0 (10.5) in the AHSCT group and 27.0 (8.0) in the conventional care group. Mean FVC and DLCO were 78.9 (17.5) and 55.2 (15.5) in the AHSCT group and 79.0 (20.2) and 62.0 (19.6) in the conventional care group, respectively. AHSCT was associated with improvement in overall survival (log-rank p=0.115; Figure 1). In follow-up, the mRSS was lower with AHSCT compared to conventional care: 7.25 point between group difference at 12 months (p=< 0.001), 6.41 points at 24 months (p=< 0.001) and 4.48 points at 36 months (p=< 0.001). There was no statistically significant difference in FVC between groups at 12 months but at 24 months, AHSCT was associated with a higher FVC (between group difference of 9.22 (p=< 0.001)) but a lower DLCO (between group difference of -3.43 (p=0.002)).

Conclusion: The present study provides crucial real-world long-term data pertaining to key clinical outcomes to support the use of AHSCT in patients with SSc.

Table 1: Baseline characteristics

	AHSCT *n / mean (SD)* (n=41)	Conventional Care *n / mean (SD)* (n=85)	Missing Data AHCST	Missing Data Conventional Care

Session Time: 8:30AM–10:30AM

Table 1. Domains and outcome instruments/measurements used in clinical research studying digital ulcers in systemic sclerosis

Domain	Outcome (number of studies)	Instrument or Measurement (number of studies)
DU Burden	Digital ulcer count/number (23)	Net ulcer burden/number of ulcers (17) Number of new ulcers (11)
	Digital ulcer improvement (20)	Ulcer healing (prevalence or number) (10) Ulcer measurement (7) All ulcers healed (6) Healing of cardinal ulcer (3) Time to healing of digital ulcer (2)
	Digital ulcer complications (7)	Ulcer infection (5) Gangrene (3) Need for hospitalization (3) Need for surgical intervention (2) New vasodilator therapy (2) Need for analgesia (2) Ulcer inflammation (2)
	Global digital ulcer assessment (2)	Clinician opinion (2) Patient opinion (1)
DU Impact	Function (10)	Scleroderma Health Assessment Questionnaire (7) Health Assessment Questionnaire Disability Index (6) Cochin hand function scale (4) McMaster-Toronto arthritis patient preference disability questionnaire (2) Hand mobility in scleroderma (1) Hand disability in systemic sclerosis-digital ulcers (1) Hand functional index (1) Scleroderma functional index (1) Kapandji score (1)
	Pain (6)	Visual analogue scale (6) Short-form McGill pain questionnaire (1)
	Health-related quality of life (4)	36-item short form survey (3) Hospital anxiety and depression scale (2) Pittsburgh sleep quality index (1)
Special tests	Microvascular assessment (4)	Laser speckle contrast analysis (2) Laser Doppler perfusion imaging (2)
	Histopathology (1)	Wound biopsies (with measurement of vascular endothelial growth factor and endothelin-1 type A receptor autoantibodies) (1)

Background/Purpose: Digital ulcers (DUs) are a major cause of pain and disability in patients with systemic sclerosis (SSc). Despite the availability of a range of treatment approaches including drug therapies, DUs are often slow to heal, and many patients experience recurrent digital ulceration. Assessment of DU burden is hugely challenging in both clinical practice and clinical trials resulting in a major barrier to the development of new and optimized treatment approaches for DUs. The aim of this scoping review of the literature was to evaluate the domains of illness studied, and the range of instruments and outcome measures used in clinical studies of DUs in patients with SSc.

Methods: Embase, MEDLINE and Cochrane Central Register of Controlled Trials were searched for all articles written in the English language relating to SSc-associated DUs. Two reviewers (MH & NM) independently screened the abstracts. A minimum of 15 participants for DU imaging-derived studies and 25 participants for questionnaire-based studies was required for inclusion. Basic laboratory and genetic studies, and studies of pediatric/juvenile SSc were excluded. There was no limitation by intervention, comparator, or study setting. All primary and secondary outcomes measured and instruments used in each study were recorded along with the study characteristics, including date of publication, sample size, interventions, and study types.

Results: A total of 4869 manuscripts was identified with 1126 duplicates excluded. Of the remaining 3743 abstracts, 123 were eligible for full-text review, and 40 were included in the final analysis. Most studies were either randomized controlled trials (n=13) or non-randomized prospective (n=12) or retrospective (n=8) studies. There was wide variation in the sample sizes of the intervention/actively studied (n=8 to 1439) and comparator (n=9 to 186) arms of the studies. Active interventions included oral/intravenous drugs therapies (n=25), topical/local treatments (n=4), and surgical interventions (n=2).

Domains and instruments/measurements used to study DUs in SSc are presented in **Table 1**. Half the studies assessed either the count/number of DUS (n=23) or improvement in DU (n=20). Functional impact of DUs was examined in 25% (n=10) of studies assessed. Other outcomes were related to complications of DU (n=7), pain (n=6), health-related quality of life (n=4), microvascular assessment/pathophysiology (n=4), or global DU assessment (n=2). For each outcome, there was significant heterogeneity regarding the types and number of instruments/measurements used within and between studies (**Table 1**).

Conclusion: This review identified a broad range of disease-related domains and associated outcome instruments/measurements used to study SSc-DUs, including in randomized clinical trials. There has been significant heterogeneity in outcomes used by investigators to study the impact of SSc-DUs.

These data will inform the ongoing work of the OMERACT Vascular Disease in Systemic Sclerosis Working Group to define a core set of disease domains to capture the burden of SSc-DUs.

Assessment of Autoantibodies and Clinical Associations in SSc Patients with ANA Positivity & Negative for Prototypic Autoantibodies

Karen Kruzer[1], Roberta G Marangoni[1], Ilana Heckler[2], Aya Elhage[2], Varga John[3], Monique Hinchcliff[4], Mary Carns[5], Kathleen Aren[5], Amy Wielgosz[1], Marc Nuzzo[6], Iswariya Venkataraman[2] and Benjamin Korman[1], [1]University of Rochester, Rochester, NY, [2]EUROIMMUN US, Mountain Lakes, NJ, [3]University of Michigan, Ann Arbor, MI, [4]Yale School of Medicine, Westport, CT, [5]Northwestern University Division of Rheumatology, Chicago, IL, [6]Division of Allergy, Immunology, and Rheumatology, School of Medicine and Dentistry, University of Rochester Medical Center, Rochester, NY

SESSION INFORMATION

Session Date: Monday, November 8, 2021
Session Title: Systemic Sclerosis & Related Disorders – Clinical Poster II (1364–1390)
Session Type: Poster Session C
Session Time: 8:30AM–10:30AM

Background/Purpose: Systemic sclerosis (SSc) is a clinically heterogenous disease typically characterized by a positive ANA (ANA+), and prototypical antibodies including anti-centromere, anti-topoisomerase, and anti-RNA polymerase III antibodies which each carry specific clinical associations. A subset of SSc patients, however, lack these prototypic SSc related autoantibodies (triple negative), and have been poorly characterized largely due to lack of clinical testing for additional autoantibodies. The purpose of this study was to identify the prevalence of autoantibodies present in ANA+ triple negative patients and assess their clinical correlations.

Methods: Patients with ANA+ and triple negative for prototypic SSc associated antibodies were selected from the scleroderma biorepositories at University of Rochester (UR) and Northwestern University (NU). Demographic and clinical data was obtained to identify specific disease outcomes and associations. Sera were screened for ANA by indirect immunofluorescence testing on HEp-20-10 slides with respect to the intensity, pattern, and titer through EUROPattern microscope. Autoantibody identification was performed using the EUROLINE SSc and Autoimmune Inflammatory Myopathies profiles (EUROIMMUN, Lubeck, Germany).

Results: Of the 280 SSc patient sera queried from UR and NU, 57 were identified as ANA+ and triple negative using clinical testing, and 40 were confirmed to have this status after EUROLINE testing. Of these 40 patients, 53% had limited cutaneous SSc, 83% of patients were female, 75% Caucasian, mean age 53 ± 14.5 years, with disease duration 9 ± 9.7 years. Patients had an average MRSS 7.6 ± 6.8, 19 (47.5%) patients had digital ulcers, 24 (60%) had interstitial lung disease (ILD) with an average FVC of 79 ± 20.6 percent predicted and DLCO 62 ± 19.5 percent predicted, and 6 (15%) had pulmonary hypertension. Of the ANA patterns, the majority of patients had mixed speckled/nucleolar patterns (42.5%) or speckled (30%). Of 29 autoantibodies tested, the most prevalent were Ro-52 (50%), Th/To (40%), MDA5 (35%), SAE1 (27.5%), PM-75 (25%), fibrillarin (25%) (Table 1). Ro-52 was associated with ILD (RR 2.67, 95% C.I. 1.51-5.29, p< 0.001) and elevated CK (RR 2.64, 95% C.I. 1.11-6.96, p< 0.05), PM-75 was associated with digital ulcers (RR 2.18, 95% C.I. 1.17-3.85, p< 0.05), and Mi-2b was associated with increased MRSS (RR 4.00, 95% C.I. 1.25-11.75. p< 0.05).

Conclusion: Patients defined as ANA+ triple negative have equal prevalence of lcSSc and dcSSc, and high prevalence of digital ulcers and ILD. These patients have a variety of autoantibodies which are not typically clinically assessed, and each has important clinical associations, particularly Ro-52 which is present in 50% of patients and strongly associated with ILD. ANA+ triple negative represents a unique and heterogenous patient population which should be further characterized in larger SSc cohorts.

Table 2. Antibody prevalence as measured by immunoblot. Prevalence of scleroderma and myositis specific antibodies in the ANA positive triple negative cohort, antibodies with a prevalence <10% are not shown. Associations with clinical variables (interstitial lung disease (ILD), pulmonary arterial hypertension (PAH), modified rodnan skin score (MRSS), creatine kinase (CK), and digital ulcers) were ascertained using a Fisher's exact test. Percentage prevalence of each clinical feature is calculated based on antibody prevalence. Statistically significant results (p<0.05) are highlighted

*Statistically significant, SD = Standard Deviation, IQR = Interquartile Range

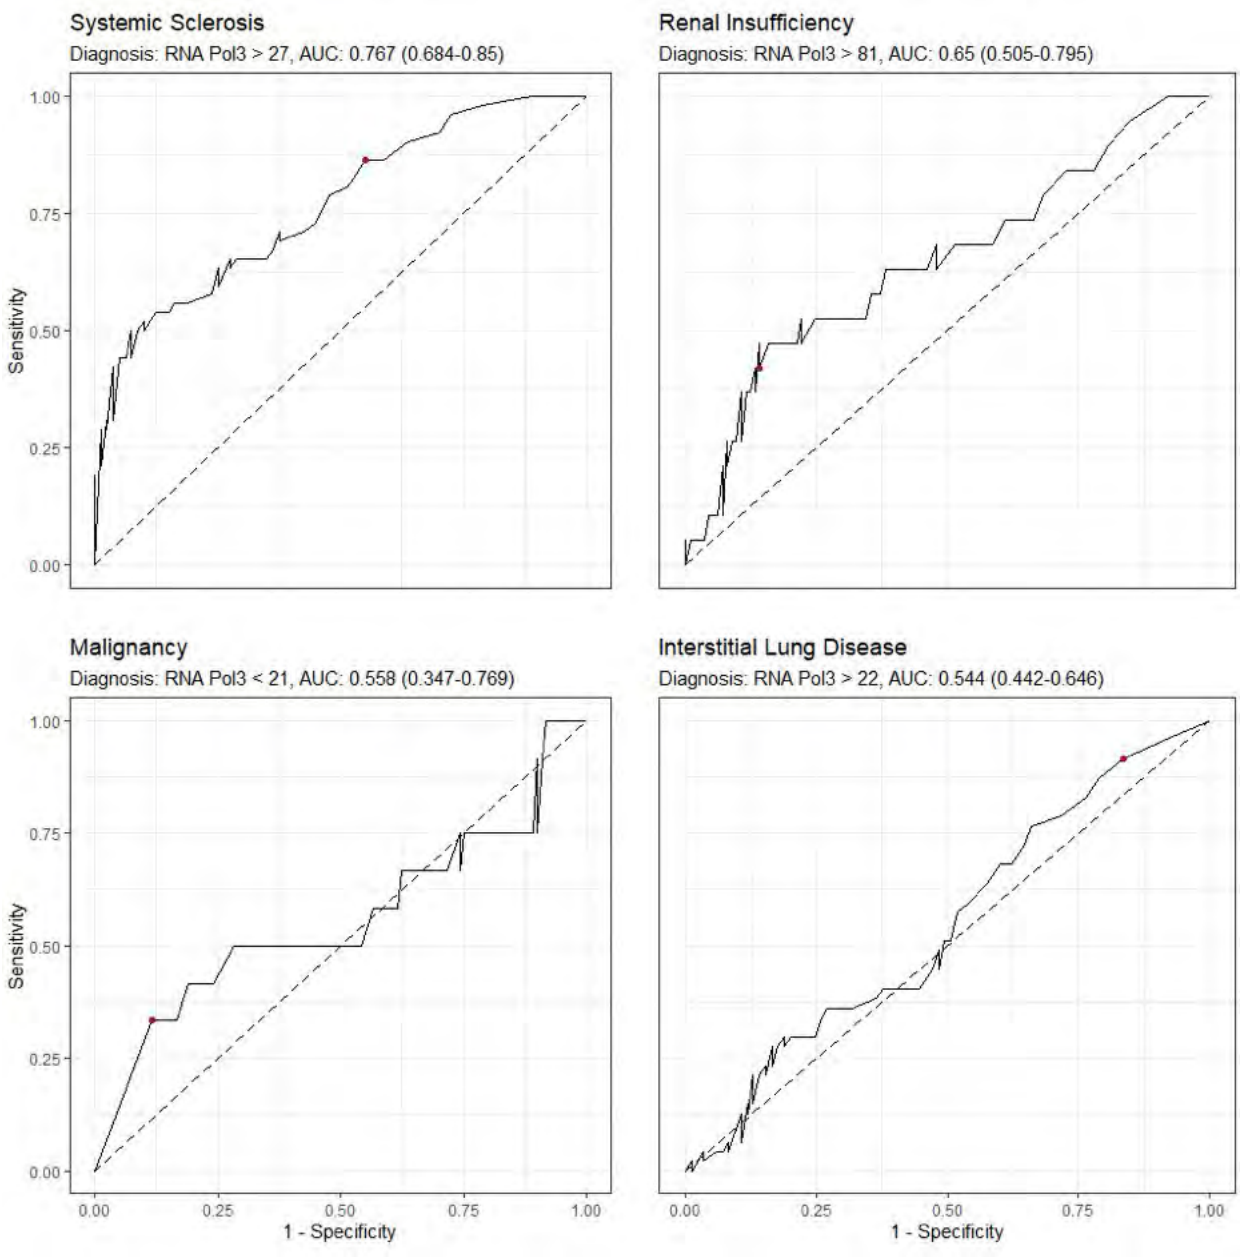

Figure 1. ROC curves and AUCs with 95% CIs (DeLong method). The red dots refer to the false positive rate (FPR) and true positive rate (TPR) of the optimal cutpoint.

Background/Purpose: Autoantibodies are included in the disease classification criteria for systemic sclerosis (SSc). Our group previously reported the level of topoisomerase autoantibody as an important factor for disease classification (Tebo, et al, J. Rheumatology, 46(4) 440-442, 2019). This project analyzed the level of anti-RNA polymerase 3 (RNApol3) antibodies in a cohort of patients assessed for autoimmune disease at a large academic institution.

Methods: 1555 patients were assessed for autoimmune disease under IRB #00029507. RNApol3 antibody positivity (≥20 units) was detected in 132 patients. Two investigators manually reviewed the clinical records for these patients and recorded age, sex, disease classification and disease features. The statistical hypothesis testing methods for age, gender, and RNApol3 are Student's t-test, Fisher's exact test and Wilcoxon rank-sum test, respectively.

Results: Among the 132 patients with a positive RNApol3 antibody, 80 did not meet classification criteria for SSc at the time of the assessment (Table 1). The 52 patients that did meet criteria for SSc had a higher level of RNApol3 antibody, with an optimal cut-off level of 27 units (Figure 1). Age and sex were not significantly different in the two groups of RNApol3 antibody positive patients with and without SSc. In the SSc patient population, age and RNApol3 level >81 units was significantly correlated with the presence of renal insufficiency (Figure 1). The presence of malignancy and ILD was significantly correlated to age but not level of RNApol3 antibody.

Conclusion: Our study supports that the level RNApol3 antibody may be important in classification criteria for SSc. Similarly, in the SSc cohort of patients with a positive RNApol3 antibody, the level may correlate with renal insufficiency. Our study did not find that the level of RNApol3 antibody correlated with ILD or malignancy.

Serum Levels of the Soluble Receptor for Advanced Glycation Endproducts Are Prospectively Associated with Pulmonary Arterial Hypertension in Systemic Sclerosis

Isabella Atzeni[1], Yehya Al-Adwi[2], Berber Doornbos-van der Meer[2], Anniek Van Roon[2], Caroline Roozendaal[1], Andries Smit[2], Alja J. Stel[2], Harry Van Goor[2], Tji-Joong Gan[1], Johanna Westra[2] and Douwe J Mulder[2], [1]University of Groningen, University Medical Centre Groningen, Groningen, Groningen, Netherlands, [2]University of Groningen, University Medical Centre Groningen, Groningen, Netherlands

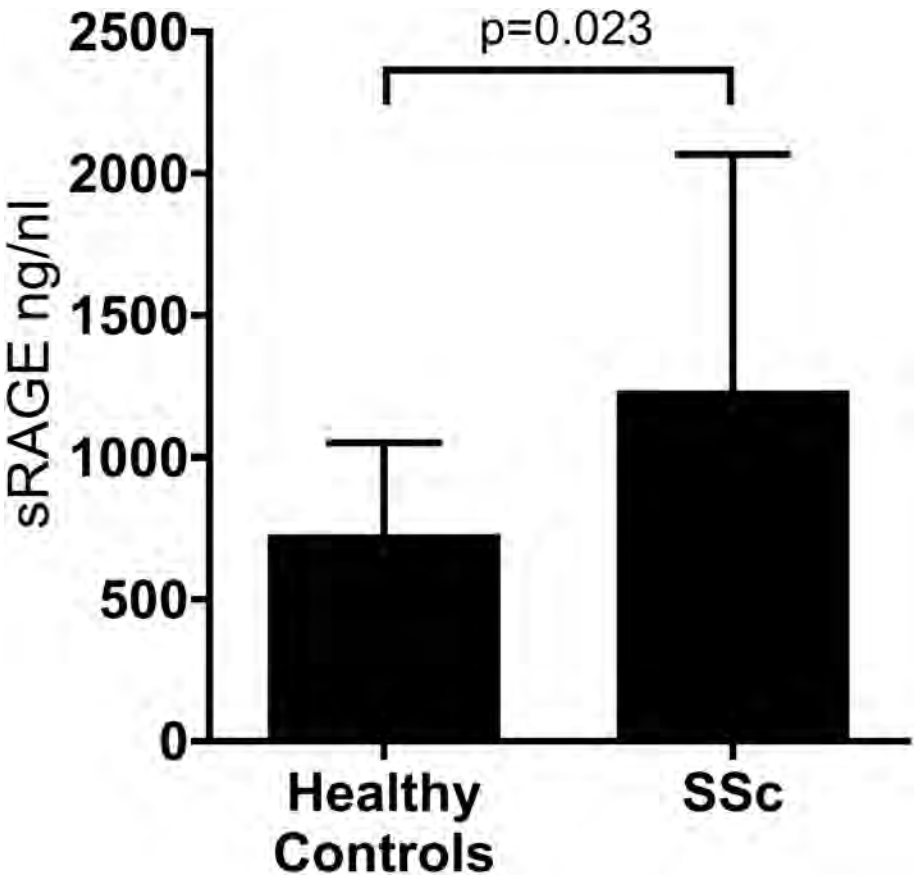

Figure 1. Serum sRAGE levels in patients with SSc compared with age- and sex matched healthy controls.

SESSION INFORMATION

Session Date: Monday, November 8, 2021
Session Title: Systemic Sclerosis & Related Disorders – Clinical Poster II (1364–1390)
Session Type: Poster Session C
Session Time: 8:30AM–10:30AM

Background/Purpose: Interstitial lung disease (ILD) and pulmonary arterial hypertension (PAH) are the leading causes of death in Systemic Sclerosis (SSc). Markers for early detection of these pulmonary complications are urgently needed. The receptor for advanced glycation endproducts (RAGE) is highly expressed in lung tissue. RAGE is involved in cell-matrix adhesion, proliferation and migration of alveolar epithelial cells, and remodeling of pulmonary vasculature. Therefore, we aimed to investigate soluble RAGE (sRAGE) in its association with current and future incidence of SSc-related pulmonary complications.

Methods: In a case-control study, sRAGE levels in 20 patient with SSc (age 51 (44-58) years, 13 female, disease duration since first non-RP 2 (1-8) years, 50% lung involvement, 40% gastrointestinal involvement) were compared with 20 age- and sex matched healthy controls (age 52 (45-62) years, 14 female). Subsequently, sRAGE was measured in an independent retrospective cohort of 188 patients with SSc (64 years (55-72), 145 female, 60% ACA positive, 89%

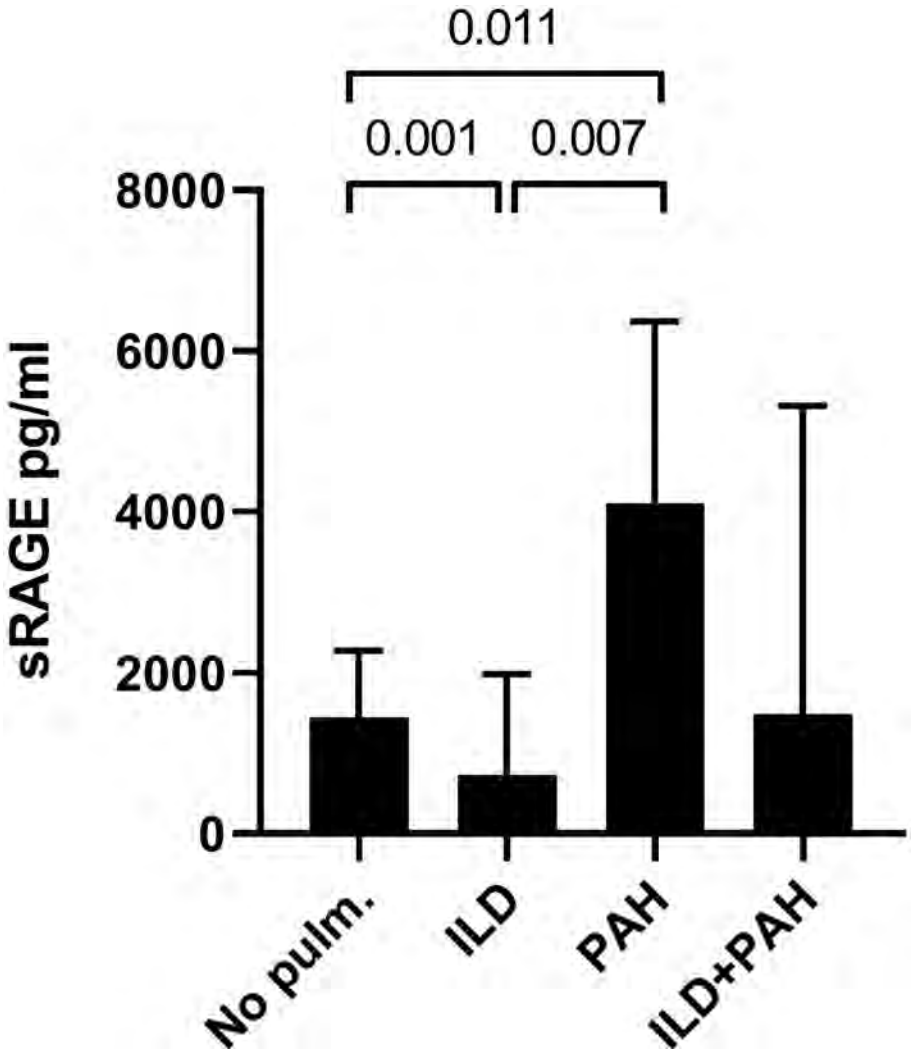

Figure 2. Serum sRAGE levels in patients with SSc in a retrospective cohort. Patients are divided into group of baseline presence of pulmonary complications. No pulm. indicates that ILD and PAH were not present clinically. ILD+PAH indicated that these patients had ILD as wel as PAH at baseline.

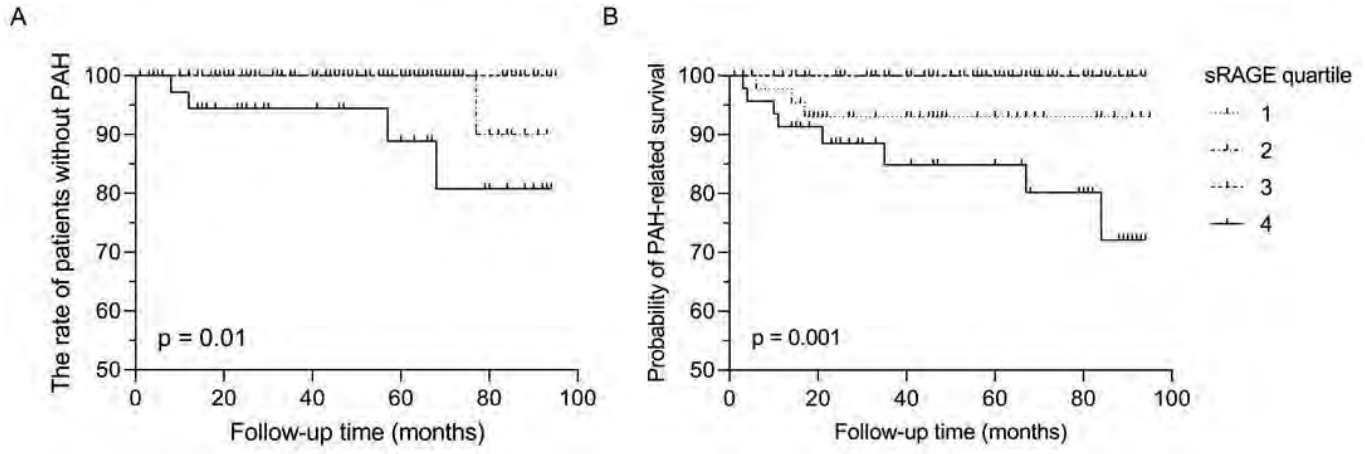

Figure 3. Kaplan-Meier survical curves of sRAGE quartiles. Fig 3a shows the association of sRAGE with the delepoment of SSc-PAH in those without pulmonary involvement at baseline. Fig 3b shows the association of sRAGE with mortality related to PAH. P value was calculated by log-rank test.

limited SSc, 83% sclerodactyly, 53% history of pitting scars or digital ulcers, 74% telangiectasia, 36% calcinosis cutis, 68% gastrointestinal involvement) who were followed for the long-term occurrence of pulmonary events and mortality. Levels of sRAGE were measured by an enzyme-linked immunosorbent assay in serum.

Results: Serum sRAGE levels were significantly higher in patients with SSc compared with controls (Figure 1). In the second cohort, levels of sRAGE were significantly lower (median 735.0 pg/ml [IQR 525.5-1988.5], p = 0.001) in SSc-ILD (n=41) and higher in SSc-PAH (n=12; 4099.0 pg/ml [936.3-6365.3], p = 0.011) compared to patients without pulmonary involvement at baseline (n=124; 1444.5 pg/ml [966.8-2276.0]). sRAGE levels in patients who had ILD as wel as PAH at baseline (n=11) did not differ significantly from those without pulmonary involvement (Figure 2). Regression analyses revealed that sRAGE levels were positively associated with the presence of SSc-PAH ($p < 0.001$), ACA serology ($p < 0.001$), and sclerodactyly ($p = 0.017$), independent of age, gender, ILD, COPD, use of vasodilators, or immunosuppression. Lung involvement developed in 13% (4% PAH after median time of 57 (10-73) months and 9% ILD after median time of 31 (15-57) months) of the patients without baseline lung involvement. sRAGE levels > 4th quartile were associated with the incidence of PAH (log-rank p = 0.01, Figure 3a) and PAH-related mortality (p = 0.001,Figure 3b). However, low sRAGE levels were not associated with ILD occurrence (p = 0.713) or ILD-specific mortality.

Conclusion: This is the first study to demonstrate that serum sRAGE levels are increased in patients with SSc, with significantly lower levels in SSc-ILD and higher levels in SSc-PAH. The association with PAH was independent of potential confounders. Importantly, high sRAGE levels in patients without baseline lung involvement were prospectively associated with the incidence of PAH and PAH-related mortality in SSc, potentially indicating it's role as a predictor for SSc-PAH and a putative future therapeutic target for early interventions.

Quality of Life in Patients with Scleroderma Associated Calcinosis Cutis: A Cross-Sectional Study

Aditi Patel[1], Mehnaj Grewal[2], Robert Butler[2] and Soumya Chatterjee[3], [1]Cleveland Clinic, Cleveland Heights, OH, [2]Cleveland Clinic, Cleveland, OH, [3]Cleveland Clinic, Richmond Heights, OH

SESSION INFORMATION
Session Date: Monday, November 8, 2021
Session Title: Systemic Sclerosis & Related Disorders – Clinical Poster II (1364–1390)
Session Type: Poster Session C
Session Time: 8:30AM–10:30AM

Background/Purpose: Calcinosis cutis (CC) can commonly affect patients with systemic sclerosis (SSc), which is often painful, resulting in functional impairment and morbidity. A radiographic scoring system called SCTC (Scleroderma Clinical Trials Consortium) hand score[1] was developed, which assesses the severity of hand calcinosis in patients with SSc. We aimed to use this scoring system and quality of life measures via patient-reported outcomes (PRO) to assess hand calcinosis in patients with SSc.

Methods: We screened 1104 adult patient charts for diagnosis of SSc and CC based on ICD-10 codes. Diagnosis of SSc was confirmed as per 2013 ACR/EULAR classification criteria, whereas the diagnosis of CC was established as per clinical diagnosis, radiographic evidence, or biopsy. Patients with an overlap syndrome were excluded. Data on patient demographics, serology, and clinical manifestations were collected. SCTC hand score was calculated on patients with available hand radiographs. Patients were invited to participate in a survey utilizing validated, SSc-specific PRO tools. The survey questionnaire included standardized tools such as pain visual analog scale, Scleroderma Health Assessment Questionnaire Disability Index (S-HAQ-DI), Mawdsley Calcinosis Questionnaire (MCQ), and Cochin Hand Function Scale (CHFS). Each survey computed a total score for each PRO tool.

Results: Our cohort included 19 patients with SSc and CC, of which 17 patients had CC in their fingers; 17 patients had hand radiographs available from which SCTC hand scores were calculated. Baseline demographics, disease manifestations, and serology are shown in Table 1. Means, medians, and standard deviations for total scores for each PRO tool were computed, and each total score was regressed against the patient's SCTC Hand Score, the statistical summary of which is shown in Table 2. In the case of each PRO tool, the total score for a single patient with an SCTC Hand Score of 755 was an extremely influential response. Regressions were run with and without this patient. There were no significant correlations ($P < .05$) between any of the total scores and SCTC Hand Scores using data from all patients. However, when the influential data point was removed, there was a significant correlation between SCTC Hand Scores and S-HAQ-DI and CHFS total scores. A significant correlation was also found between SCTC Hand Scores and the number of calcinotic digital ulcers. These correlations are shown in Figure 1.

Conclusion: Our study shows a significant correlation between SCTC hand scores and S-HAQ-DI, CHFS, and the number of calcinotic digital ulcers. A higher SCTC hand score may predict a higher likelihood of developing calcinotic ulcers. No significant correlation between SCTC hand scores and MCQ could relate to non-accountability for psychological aspects of CC in SCTC hand scores, highlighting the limitation of using SCTC hand scores alone to assess the quality of life in SSc patients with CC.

SESSION INFORMATION

Session Date: Monday, November 8, 2021

Session Title: Systemic Sclerosis & Related Disorders – Clinical Poster II (1364–1390)

Session Type: Poster Session C

Session Time: 8:30AM–10:30AM

Background/Purpose: Systemic sclerosis (SSc) carries high risk for progressive interstitial lung disease (ILD). Several anti-inflammatory therapies have been used to treat SSc-ILD and recently the first antifibrotic therapy has been approved. Personalized treatment strategies are largely missing to date and it is unclear, which patients to treat with which treatment approach. The two chemokines, CCL2 (MCP-1) and CCL17 (TARC) have been shown to be markers of inflammation and fibrosis, respectively. The aim of this study was to examine associations between ILD characteristics and serum levels of CCL2 and CCL17 in a large and unselected SSc cohort with complete data sets on pulmonary function and lung fibrosis extent on HRCT.

Methods: Sera from the prospective Oslo University Hospital SSc cohort (n=371) and healthy blood donor controls (HC; n=100) were analyzed for CCL2 and CCL17 by multiplex assays. CCL2 and CCL17 levels were defined as high or low using 95% CI in HC sera as cut-off values. Paired pulmonary function tests and HRCT images were obtained at baseline and follow-up. All patients in the SSc cohort met the 2013 ACR/EULAR classification criteria. ILD was diagnosed on HRCT and categorized by the extent of lung fibrosis as limited (1-10%) or extensive (>10%) ILD by semi-quantitative assessment. Descriptive statistics were applied.

Results: Of all 371 patients, 212 (57%) had available levels for circulating CCL2 and CCL17. These levels were significantly increased in SSc compared to HC (Figure). High levels of CCL17 (>700 pg/ml) and CCL2 (>1000pg/ml) were identified in 43/254 (17%) and 84/471 (18%) of the SSc patients, respectively (Table). High levels of both CCL17 and CCL2 were associated with lower FVC at baseline and a higher extent of lung fibrosis on HRCT (Table). Of those with high CCL2 and CCL17, 67% had extensive lung fibrosis on HRCT. Categorization of ILD into no ILD, limited or extensive ILD showed a numerical association between high CCL17 levels and the extent of fibrosis (Table).

Conclusion: In this explorative SSc cohort study, high levels of both CCL2 and CCL17 were associated with more severe ILD, potentially mirroring ongoing inflammatory and fibrotic processes, which may have an implication on treatment choices for SSc-ILD.

Table 1. Demographics and clinical findings in the SSc cohort stratified by level of CCL2 and CCL17

	All patients (N=371)	Low CCL2 and CCL17	High CCL17	High CCL2	High CCL2 and CCL17
SSc patients, n (%)	371	94 (44.3)	75 (35.4)	34 (16)	9 (4.2)

Survey on Treatment Practices in Subclinical Interstitial Lung Disease in Systemic Sclerosis

Sabrina Hoa[1], Murray Baron[2] and Marie Hudson[3], [1]Division of Rheumatology, Centre hospitalier de l'Université de Montréal; Department of Medicine, Université de Montréal, Montréal, QC, Canada, [2]Jewish General Hospital, Montréal, QC, Canada, [3]McGill University, Montréal, QC, Canada

SESSION INFORMATION
Session Date: Monday, November 8, 2021
Session Title: Systemic Sclerosis & Related Disorders – Clinical Poster II (1364–1390)
Session Type: Poster Session C
Session Time: 8:30AM–10:30AM

Background/Purpose: Interstitial lung disease (ILD) is a leading cause of mortality in systemic sclerosis (SSc). Early detection and treatment of SSc-ILD may lead to improved outcomes, however no formal recommendation exists to guide management in subclinical SSc-ILD. We undertook an international survey to understand current screening and treatment practices in subclinical SSc-ILD.

Methods: An electronic REDCap survey was distributed to 611 general rheumatologists, 348 national and international SSc experts, 285 respirologists and 15 experts in ILD.

Results: Up until April 8th, 2021, 178 participants responded to the survey, including 131 (76%) general rheumatologists and 32 (19%) respirologists. The estimated response rate was 23% among general rheumatologists, 25% among SSc experts, 8% among respirologists and 23% among ILD experts. The majority saw SSc-ILD patients at least monthly (79%) and had been in practice for at least 5 years (80%).

Overall, 59% of respondents reported routinely ordering HRCTs in all newly diagnosed SSc patients, whereas 40% ordered HRCTs only in the presence of symptoms, crackles or abnormal pulmonary function tests or chest X-ray (35%) and/or in the presence of risk factors for severe or progressive ILD (17%). There was significant regional heterogeneity in screening practices, with HRCTs being routinely ordered by 48% (40/84) in North America, 83% (29/35) in Europe, 70% (7/10) in Asia, 40% (2/5) in Australia and 100% (4/4) in Latin America.

Six-minute walk tests (6MWT) were ordered by 34% of respondents in the baseline evaluation of subclinical SSc-ILD, and more frequently by respirologists (72%) than general rheumatologists (24%). 6MWT were more rarely used in the routine follow-up of SSc-ILD (33%), with most (57%) respondents using 6MWT only if there was disease progression. Factors that influenced 6MWT use included access/availability, symptoms, pulmonary function tests and extent of ILD on CT, risk factors for progressive ILD, suspicion of hypoxemia on ambulation or concomitant pulmonary hypertension, and presence of other SSc manifestations that could affect test validity (including severe Raynaud, skin or musculoskeletal disease).

Nearly half (47%) of participants responded that they would not treat subclinical lung disease, 17% would treat and 36% responded that it would depend. Factors that would influence their decision included risk factors for progressive lung disease, other SSc manifestations requiring treatment (e.g. progressive/diffuse skin disease, myositis), disease trajectory over close follow-up, comorbidities/life expectancy, discussions with the treating respirologist, and shared decision-making with the patient regarding risks and benefits. The majority (75%) of respirologists would not treat subclinical lung disease.

Conclusion: There is considerable variability in screening and treatment practices in subclinical SSc-ILD. Further studies are required to define the impact of screening and treatment strategies on clinical outcomes in subclinical SSc-ILD, including controlled trials.

Session Title: Systemic Sclerosis & Related Disorders – Clinical Poster II (1364–1390)

Session Type: Poster Session C

Session Time: 8:30AM–10:30AM

Background/Purpose: Digital ulcers (DUs) affect half of the patients with systemic sclerosis (SSc) and can be complicated by gangrene and amputation. Platelets are known to be activated in SSc, therefore, platelet inhibitors might represent a therapeutic option in the management of DUs. However, until now, there is no clinical study to assess the importance of platelet inhibitors in the occurrence of DUs in patients with SSc. The aim of the study was to develop and validate a prediction model for the occurrence of DUs in patients with SSc based on platelet inhibitors and other parameters.

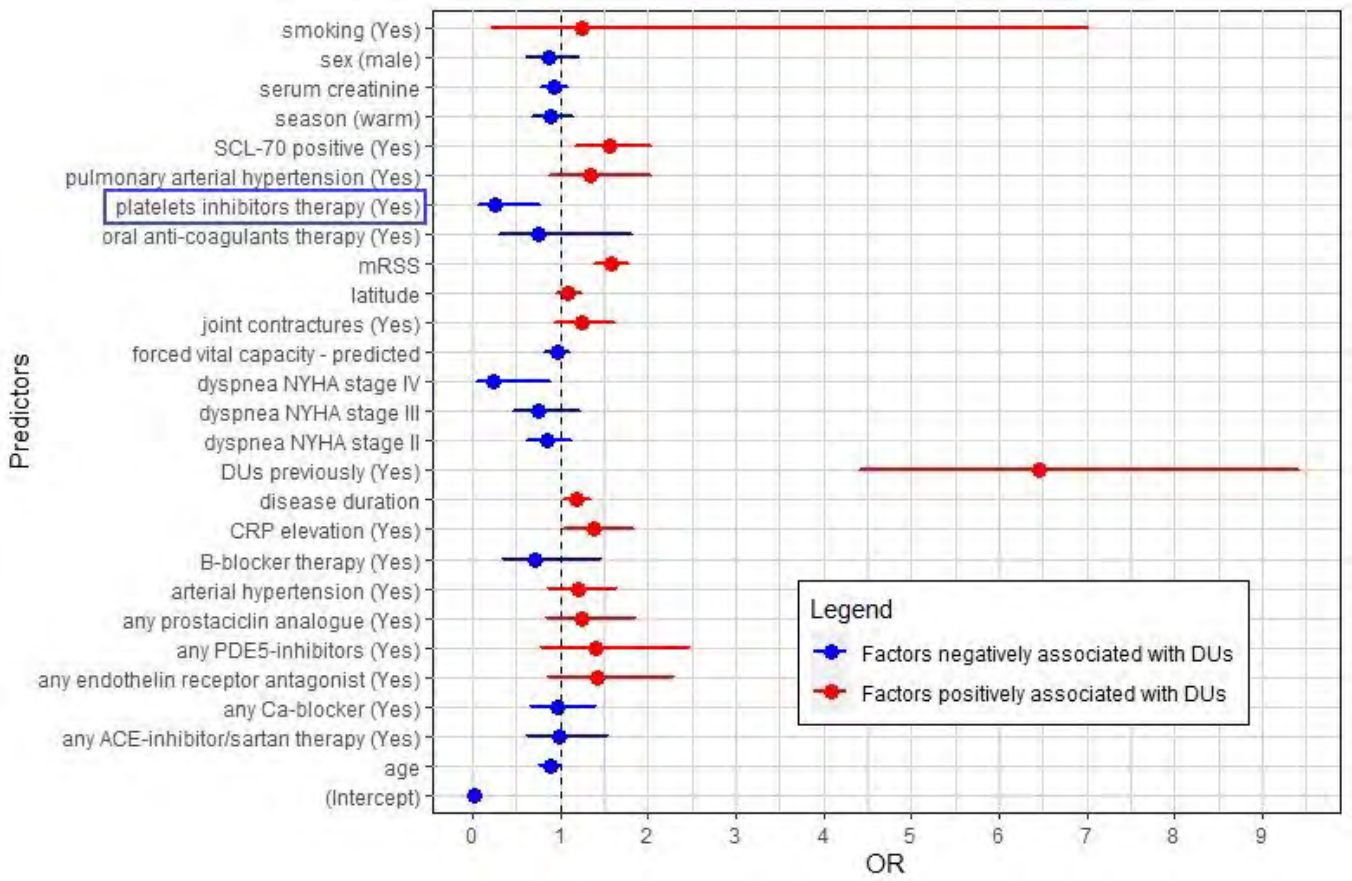

Figure 1. Forest plot displaying the OR of the logistic classification model.

Methods: This study used prospectively collected data from the European Scleroderma Trials and Research group (EUSTAR) registry. Patients fulfilling the 2013 ACR/EULAR SSc classification criteria with complete longitudinal data on the presence of DUs and platelet inhibitors were included in the analysis. Multiple imputation using a *random forest* algorithm was implemented to handle missing values.

The dataset, containing the information of the last follow-up visit of every patient, was split into a derivation cohort (patients recorded before 2017-01-01 in the EUSTAR registry) and validation cohort (patients recorded after 2017-01-01). To investigate the response for the binary dependent variable of DUs, binary logistic regression was implemented to develop a prediction in the derivation cohort and to validate it using ROC analysis and calibration plots to address discrimination and calibration, respectively.

Results: Of 3,710 patients (14.6% males, 67.8% limited cutaneous SSc, median age 56.97 years, median disease duration 8.94 years), 486 had current DUs at the baseline and 150 were exposed to platelet inhibitors. At the follow-up visit (median follow-up time 1.03 years) 487 had current DUs and 90 remained exposed to platelet inhibitors.

Factors associated with absence or presence of DUs at the next follow-up visit are shown in *figure 1*. This confirmed the risk factors for the presence of DUs identified by previous studies.

The discrimination ability of the model evaluated by ROC curve analysis showed an AUC = 80.8% (95% CI = [78.7% to 83.0%]) for the derivation cohort (2,827 patients) and AUC = 83.4% (95% CI = [80.0% to 86.8%]) for the validation cohort (883 patients), respectively, corresponding to an acceptable discrimination (*figure 2*). The calibration plots revealed an adequate calibration of the model (*figure 3*).

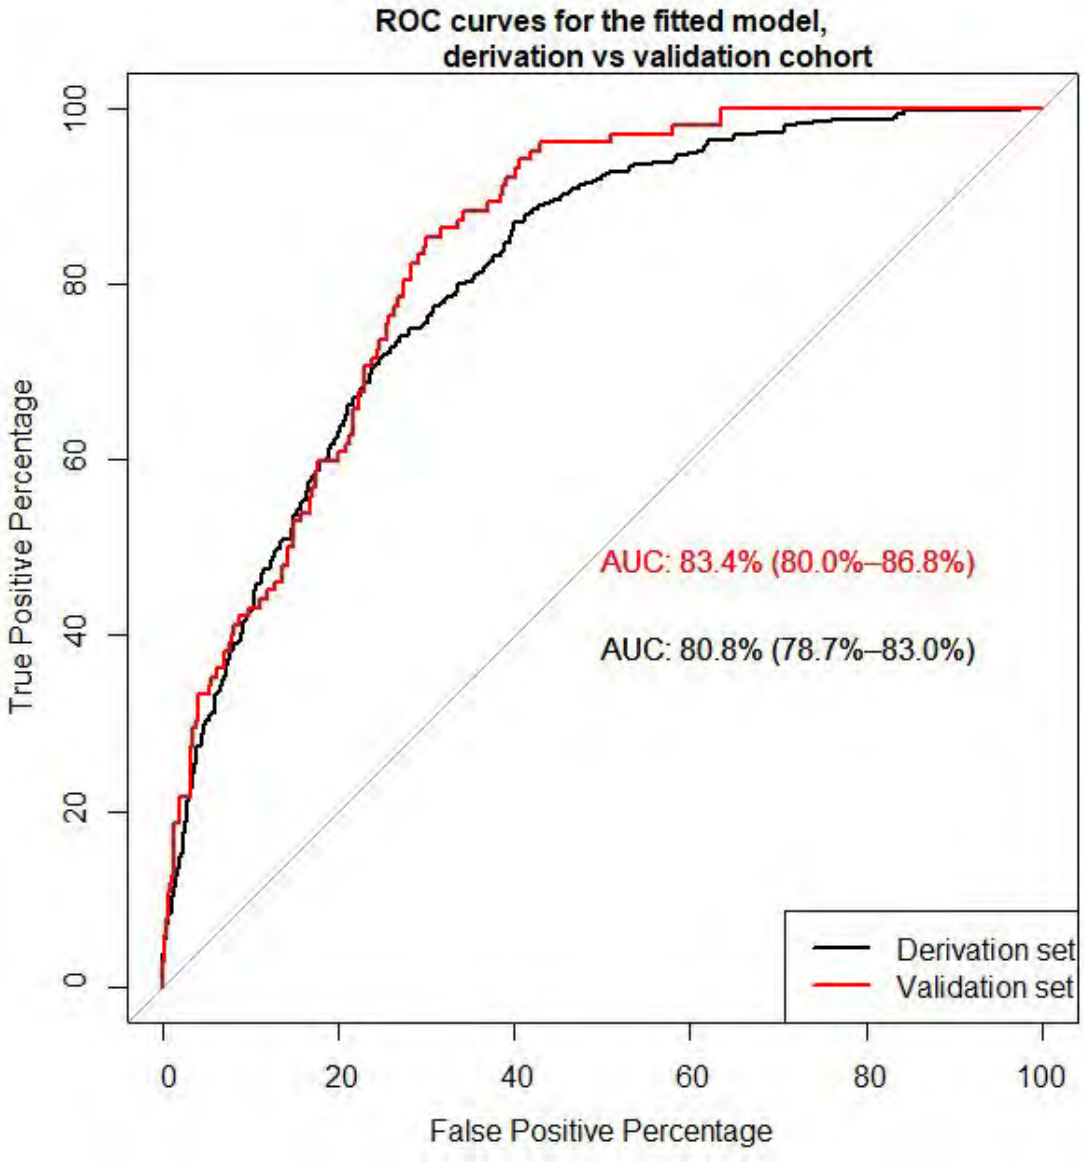

Figure 2. ROC curves displaying the discrimination ability of the fitted model in the derivation and validation cohort, respectively.

Amongst other predictive factors, our model revealed that exposure to platelet inhibitors is associated with a reduced odds ratio of DUs occurrence at the next follow up visit (OR = 0.25, 95%CI [0.07-0.77]).

Conclusion: Our model shows good discrimination and adequate calibration for the difficult task of predicting the occurrence of DUs at a one-year follow up visit. Use of platelet inhibitors was among the factors predicting lower probability of DUs occurrence at follow-up.

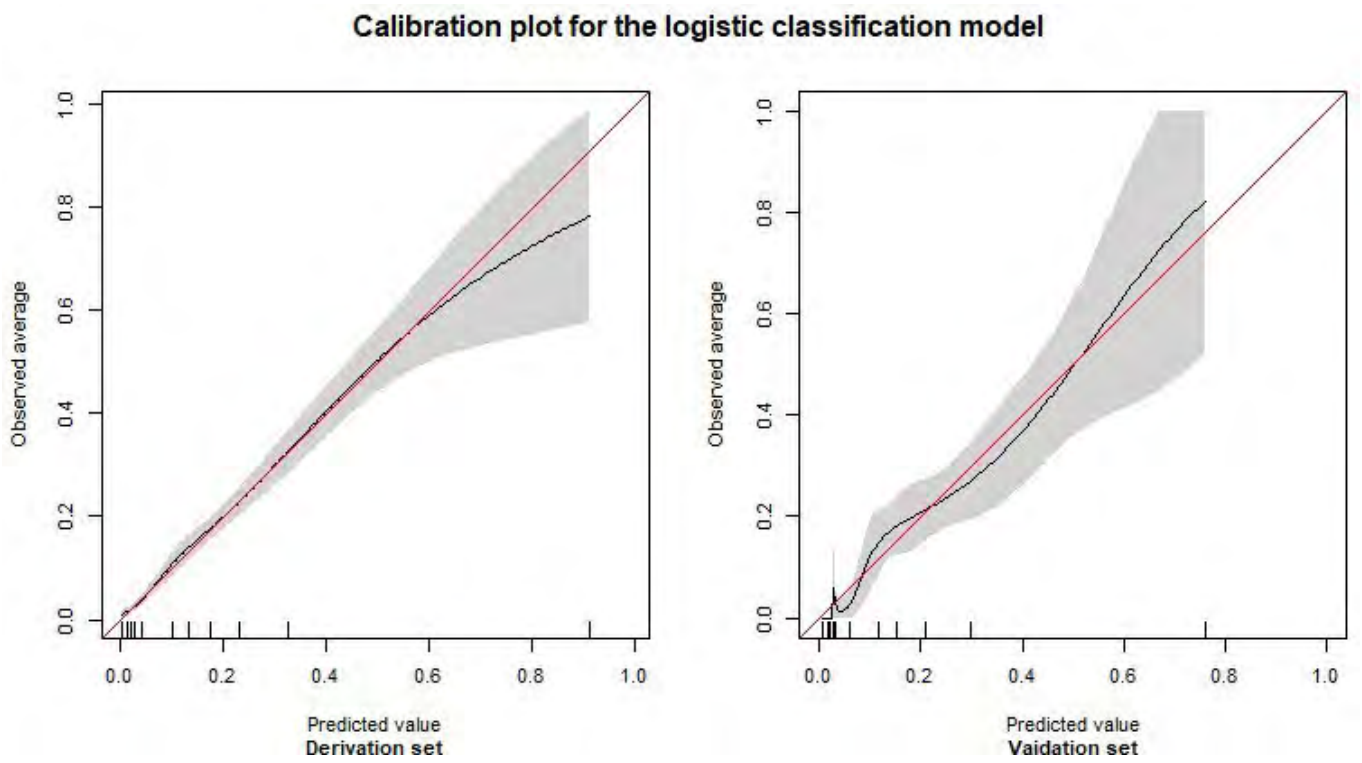

Figure 3. Calibration plots for the logistic classification model - the figure shows the calibration plot of the model in the derivation cohort (left side) and in the validation cohort (right). On the X-axis, the model's predicted probability of the occurrence of DUs is plotted against the observed risk of presence of DUs on the Y-axis (0 = absence of DUs, 1 = presence of DUs). The red line represents perfect prediction, meaning that the predicted risk is exactly the same as the observed risk across the whole range. Ideally, the lines obtained should lie exactly on top of the red line.

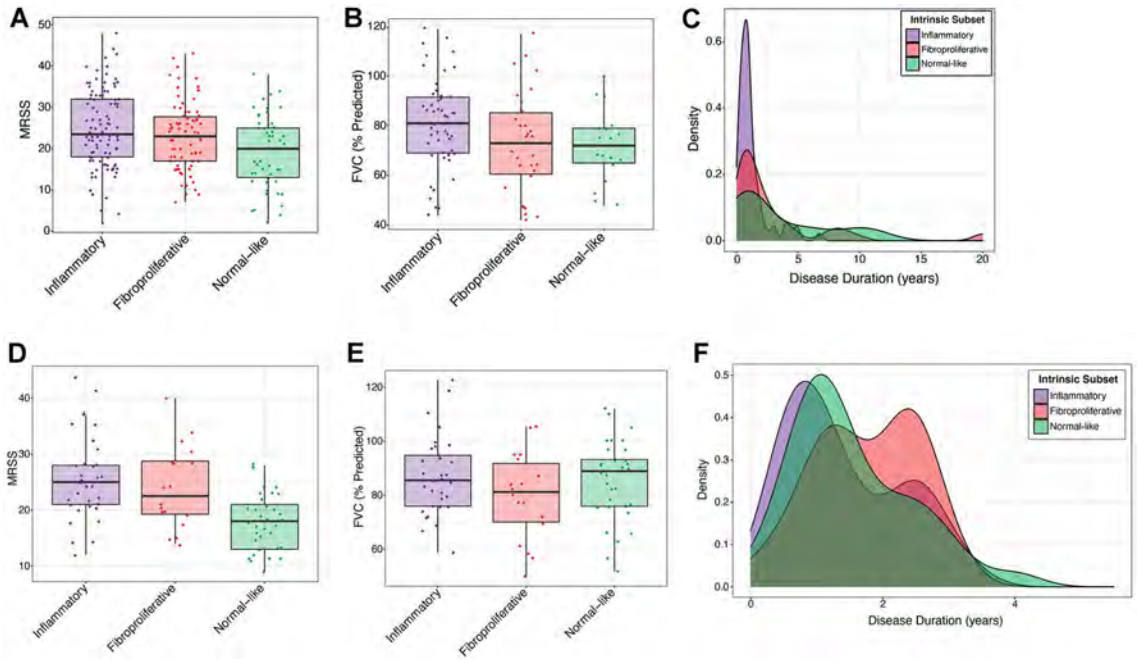

Figure 1. Measures of phenotypic severity in dcSSc patients of the discovery (A-C) and validation cohorts (D-F) stratified by intrinsic subset. Differences in MRSS (A, D), FVC (B, E) and disease duration (C, F) are shown.

investigated associations between baseline clinical demographics and intrinsic subsets in a meta-analysis of 14 gene expression datasets for 395 individuals with SSc.

Methods: Publicly available gene expression data measured in skin for 311 independent SSc patients were classified into the intrinsic molecular subsets using a previously trained machine learning classifier. Data from 84 independent participants from the ASSET trial was used as a validation cohort. Normalized RPKM values from skin were similarly classified into the intrinsic gene expression subsets. Patient clinical and demographic data were collected for each cohort from original publications or from individual investigators. Associations were tested using Fisher's Exact Test and Tukey's pairwise comparisons.

Results: The majority of the SSc patients in this analysis were white (50.74%), female (69.49%), and classified as dcSSc (70.96%). Males were 2.5 - 4x as likely to be fibroproliferative than females in discovery (p=0.0046) and validation cohorts (p=0.015). Females and males were equally likely to be classified as inflammatory, normal-like, or limited. SSc patients who identified as African-American/Black were 2.5x more likely to be classified as fibroproliferative compared to White/Caucasian patients in both discovery (p=0.0378) and validation cohorts (p=0.0062). SSc patients who identify as White or Caucasian were more likely to be classified as inflammatory or normal-like (p=0.0037). Patients sera positive for RNA pol I (p< 0.0001) and RNA pol III (p=0.0001) autoantibodies were enriched in the inflammatory subset, while Scl-70 was enriched in the fibroproliferative subset, but did not reach statistical significance. There were statistically significant differences in modified Rodnan skin score (mRSS). Inflammatory and fibroproliferative subsets had higher average mRSS relative to normal-like (p=0.0027). There was no difference between the average mRSS for inflammatory (avg=24.67) and fibroproliferative (avg=23.13) individuals. Patients in the fibroproliferative and normal-like subsets on average had a trend toward lower %FVC. We identified a statistically significant difference in average disease duration between the inflammatory, fibroproliferative, and normal-like intrinsic subsets (p=8.8E-4). Patients in the inflammatory subset had the shortest disease duration, which was lower than both the fibroproliferative subset (p=0.0073) and the normal-like subset (p=0.0042).

Conclusion: We found multiple significant associations between demographic and clinical variables with intrinsic subsets. By leveraging data from multiple studies, we increased statistical power and validated these associations. These findings identify may have clinical implications for identifying treatments more likely to work in certain SSc populations. This difference in temporal distributions may reflect chronological stages of fibrosis.

Overall Survival in Patients with Systemic Autoimmune Diseases Following Lung or Heart-Lung Transplantation at a Single High-Volume Academic Transplant Center: A Comparative Cohort Study

Jason Melehani[1], Shufeng Li[2], Joshua Mooney[3] and Lorinda Chung[2], [1]Stanford University, San Jose, CA, [2]Stanford University, Palo Alto, CA, [3]Stanford University, Stanford, CA

SESSION INFORMATION
Session Date: Monday, November 8, 2021
Session Title: Systemic Sclerosis & Related Disorders – Clinical Poster II (1364–1390)
Session Type: Poster Session C
Session Time: 8:30AM–10:30AM

Background/Purpose: Lung manifestations of systemic autoimmune diseases are a frequent cause of early death. For many patients, current treatments cannot arrest the inexorable progression to end-stage lung disease. Lung transplantation can be life-saving, but many transplant centers withhold this option from patients with systemic autoimmune diseases due to concerns that extrapulmonary manifestations and immune abnormalities could lead to additional post-transplant risks. Additional data on lung transplant experience in patients with systemic autoimmune diseases are needed to clarify risks and benefits in this population.

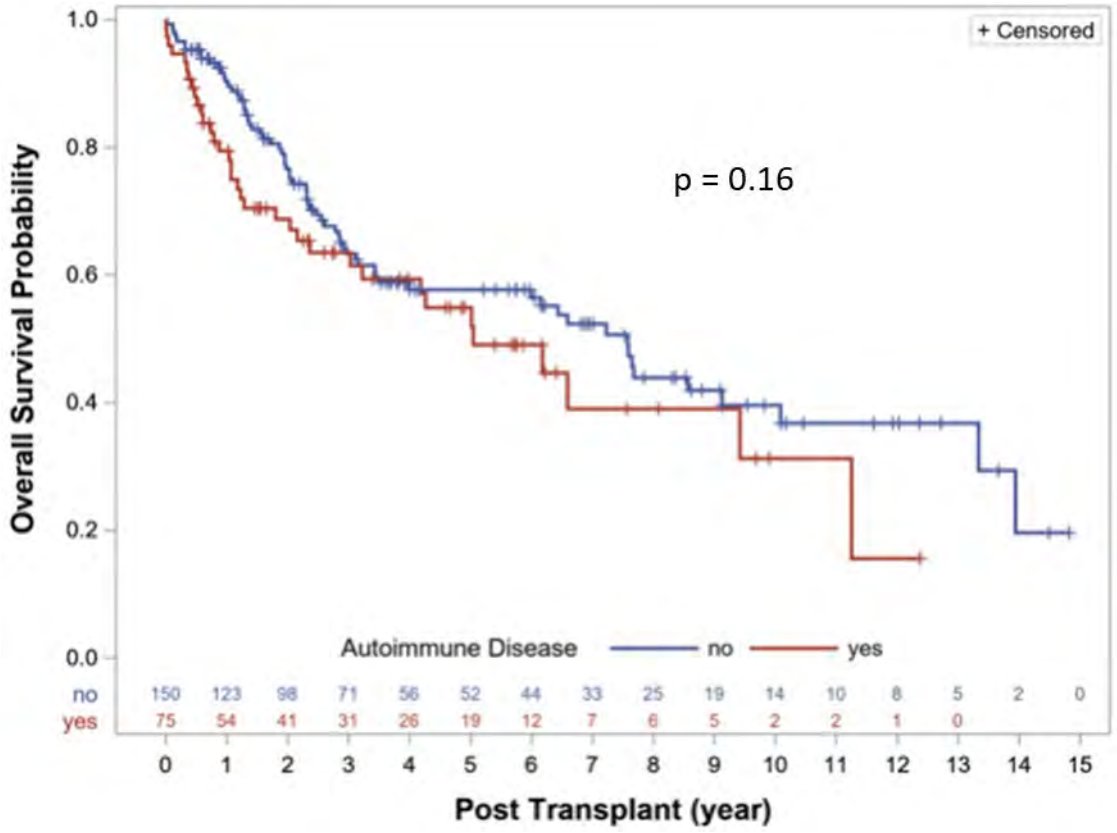
Methods: We conducted a retrospective cohort study of patients undergoing lung or heart-lung transplant at Stanford University between January 1, 2005 and January 1, 2020. Patients whose lung disease was attributed to a systemic autoimmune disease were identified from among this population based on ICD-9 or ICD-10 coding followed by verification that patients fulfilled classification criteria specific to their disease by medical record review. Patients were matched 1:2 to controls without autoimmune diseases according to their age, gender, year of transplantation, indication for transplantation (interstitial lung disease vs. pulmonary hypertension) and type of transplant procedure (single lung, double lung, heart-lung). We compared overall survival in those with and without autoimmune diseases using Kaplan-Meier curves by log-rank test. We used multivariable Cox proportional hazard regression to estimate the hazard ratios (HR) and 95% confidence intervals (CI) for overall survival following transplant accounting for the variables described above.

Population Characteristics	Autoimmune	Non-Autoimmune
Age (average)	55	55
Gender (% Female)	51%	61%
Autoimmune Disease (total)	75	--
Rheumatoid arthritis	17	--
Systemic sclerosis	16	--
Sarcoidosis	15	--
Idiopathic inflammatory myositis	14	--
Sjogren's syndrome	8	--
Mixed connective tissues disease	4	--
Systemic lupus erythematosus	1	--
Transplant Indication		
Interstitial lung disease	52	116
PAH / ILD-PH	23	36
Transplant Procedure		
Single lung transplant	6	14
Double lung transplant	64	134
Heart-lung transplant	5	4

Basic population characteristics of patients who underwent lung transplantation for end-stage lung disease due to their underlying systemic autoimmune disease compared to matching patients without systemic autoimmune diseases

Results: In total, 75 lung or heart-lung transplant patients with systemic autoimmune diseases were identified, including 17 with rheumatoid arthritis, 16 with systemic sclerosis, 15 with sarcoidosis, 14 with idiopathic inflammatory myositis, eight with Sjogren's syndrome, four with mixed connective tissue disease, and one with systemic lupus erythematosus. These patients were matched to 152 patients without autoimmune diseases. One-year and five-year survival was 79.4% and 54.9% in patients with autoimmune diseases and 90.3% and 57.7% in the matched cohort (p=0.16). The hazard ratio for overall survival following transplant favored patients without autoimmune diseases but was not significantly different from those with autoimmune diseases (unadjusted HR 1.29, 95% CI [0.80 – 2.08] p-value 0.31, adjusted HR 1.24, 95% CI [0.71 – 2.18] p=0.45).

Conclusion: Patients with systemic autoimmune disease fared as well after lung or heart-lung transplantation as patients without systemic causes of end-stage lung disease. These data continue to provide support for lung transplantation as a life-saving option for well-qualified patients with systemic autoimmune diseases.



Kaplan-Meier survival curves comparing post-lung transplant survival in patients with systemic autoimmune diseases (red) versus those without (blue)

Session Title: Systemic Sclerosis & Related Disorders – Clinical Poster II (1364–1390)

Session Type: Poster Session C

Session Time: 8:30AM–10:30AM

Background/Purpose: CTD is a disease with immune abnormalities which could alter normal cytokine profile. CTD-PH has a different pathogenesis from that of iPAH, and immunosuppressive therapy is effective. These facts suggest that the two PH conditions have different pathologies related to pulmonary artery inflammation. Various cytokine abnormalities have also been reported to be involved in the pathogenesis of CTD-PH. However, the relationship between these cytokine abnormalities and pulmonary artery pressure has not been fully elucidated.

To clarify the relationship between cytokines and mean pulmonary artery pressure by analysis of the cytokine profile in PH patients including CTD-PH. In addition, we will clarify the differences in cytokine profiles between CTD-PH and iPAH.

Methods: Patients who underwent RHC for PH diagnosis at our hospital from 2015 to 2020 years were included in the study. Right heart catheterization and left heart catheterization were tried, and pre- and post-pulmonary sera were collected to measure cytokines. The target cytokines were TIMP-1, MCP-1, IL-17 and IL-21, IL-12p70 and IL-6, which were measured by ELISA (ABCAM UK, Ella simple plex USA). The relationship between the measured cytokine profiles and hemodynamic parameters was compared.

Results: 21 CTD patients (SSc 12 cases, MCTD 7cases, SLE 2 cases) and 13 non-CTD patients were subjected to be analyzed cytokines in pulmonary vessels . As previously reported, there was a positive correlation between serum IL-6 level and mPAP (mean pulmonary arterial pressure) in all our patients, but not observed in CTD patients(Figure1.). Furthermore, serum TIMP-1 level showed a significant correlation with mPAP in all patients. Additionally, this correlation was observed more remarkable in CTD patients compared to non CTD patients (Figure 2.). In addition among CTD patients, serum MCP-1, IL-6, and TIMP-1 level in SSc-PH cases tend to be higher than those in those of non SSc CTD-PH. Serum IL-12p70 and IL-17 level were lower in SSc- PH compared that non SSc CTD-PH. In some CTD cases who were investigated before and after PH treatment, serum IL-17, IL-21, and TIMP-1 level were decreased along with improvement of pulmonary vascular hemodynamics.

Conclusion: The cytokine profile of pulmonary capillaries reflected hemodynamics, the significance of which was different in CTD-PH and iPAH. Measurement of IL-17, IL-21, and TIMP-1 in pulmonary vessels may be useful for diagnosis, monitoring, and evaluation of therapeutic effects in CTD-PH.

Macrovascular Dysfunction and Its Clinical Implication in Systemic Sclerosis

Devender Bairwa[1], Chengappa Kavadichanda[2], sanket Shah[3], Anoop Mathew[1], saikumar dunga[3], Aishwarya Gopal[3], Molly Mary Thabah[1] and VirSingh Negi[1], [1]Jawaharlal Institute of Postgraduate Medical Education and Research (JIPMER), Puducherry, India, [2]JIPMER, Pondicherry, India, [3]Jawaharlal Institute of Postgraduate Medical Education and Research, Puducherry, India

SESSION INFORMATION
Session Date: Monday, November 8, 2021
Session Title: Systemic Sclerosis & Related Disorders – Clinical Poster II (1364–1390)
Session Type: Poster Session C
Session Time: 8:30AM–10:30AM

Background/Purpose: Microvascular dysfunction is a key and determining feature of scleroderma (SSc). But contrary to earlier belief there is emerging evidence to suggest co-occurrence of macrovascular dysfunction. The clinical

implication of macrovascular dysfunction in SSc is unknown and its correlation with microvascular dysfunction is inconclusive. Therefore the objectives of this study were to assess the prevalence and clinical impact of macrovascular dysfunction in a cohort of SSc. To study the correlation between macrovascular dysfunction as assessed by percent change in flow mediated vasodilation (FMD) of brachial artery and microvascular dysfunction as assessed by nail fold capillaroscopy (NFC) findings in SSc.

Methods: Cross-sectional comparative study enrolled SSc patients (n=59) and age & gender matched healthy controls (n=64). FMD change was calculated using standard USG probe (6 MHz) in right brachial diameter from the average of 3 consecutive end diastolic frames. NFC was performed using portable nail fold capillary microscope at 800X magnification. Clinical features of SSc were compared between SSc patients with and without macrovascular dysfunction.

Results: SSc had significantly ($p < 0.001$) lower FMD change (median-4.54, IQR 3.13-8.82) compared to healthy controls (median – 10.30, IQR 8.33-13.16). Two out of every three SSc patients 43/59 (66.2%) had impaired FMD. We replicated significantly (p-value< 0.0001) lower capillary density (median – 3.19, IQR 2.38-3.94) in SSc compared to healthy controls (median – 7.56, IQR 7.06-8.0) (Table 01). Impairment in FMD was not associated with Raynaud's phenomenon, digital gangrene, digital ulcer, acro-osteolysis or pulmonary hypertension suggesting need for a prospective study to identify the implications (Table 02). Magnitude of NFC findings and FMD changes did not corelate with the impairment in FMD among SSc patients (Figure 01)

Table 1. Comparison of parameters between the SSc patients with healthy controls (*P value < 0.001)

Parameters	SSc patients (n=59)	Healthy controls (n=64)
	Frequency (percentage) / median (interquartile range)	
FMD changes		
FMD % change*	4.54 (3.13-8.82)	10.30 (8.33-13.16)
Impaired FMD (Δ FMD <8.33)	43/59 (66.2%)	-
NFC changes		
Number of capillaries *	51 (38-63)	121 (113-128)
Average capillary density *	3.19 (2.38-3.94)	7.56 (7.06-8)
Disorganized architecture (%) *	37.5 (12.5-37.5)	0
Abnormal (%) *	36.11 (14.03-55.26)	0
Enlarged (%) *	10.63 (2.94-23.68)	0
Giant (%) *	21.05 (0-45.45)	0
Microhemorrhages (%)*	6.25 (0-12.5)	0
Neoangiogenesis (%) *	3.85 (0-20)	0
Avascular area (%) *	50 (31.25- 75)	0

Table 2. comparison of macrovascular complication between SSc patients with or without impaired FMD

Parameters	SSc patients with impaired FMD (n=43)	SSc patients with normal FMD (n=16)	P value
Age in years (median, IQR)	37 (28-46)	40 (26-46.5)	0.595
Disease subtype			0/686
Diffuse SSc	21/43 (48.8%)	08/16 (50%)	
Limited SSc	14/43 (32.6%)	06/16 (37.5%)	
SSc sine scleroderma	07/43 (16.3%)	01/16 (6.3%)	
Overlap with myositis	01/43 (1.7%	01/16 (6.3%)	
Disease duration in years (median, IQR)	5 (03-10)	5 (03-8.5)	0.791
Scl-70 positivity	27/43 (62.7%)	13/16 (81.3%)	0.454
NFC pattern			0.254
Normal	01/43 (02.3%)	02/16 (12.5%)	
Early	07/43 (16.3%)	02/16 (12.5%)	
Active	19/43 (44.2%)	09/16 (56.3%)	
Late	16/43 (37.2%)	03/16 (18.8%)	
Raynaud's phenomenon	33/43 (76.7%)	12/16 (75%)	1.0
Digital pitting	20/43 (46.5%)	08/16 (50%)	1.0
Fingertip ulcer	03/43 (07%)	05/16 (31.3%)	0.028
Fingertip gangrene	01/43 (2.3%)	01/16 (6.3%)	0.472
Fingertip infection	01/43 (2.3%)	02/16 (12.5%)	0.176
Acro-osteolysis	04/43 (9.3%)	04/16 (25%)	0.194
Ulcer elsewhere	04/43 (9.3%)	00/16 (0%)	0.566
Pulmonary Hypertension	08/43 (18.6%)	05/16 (31.3%)	0.311

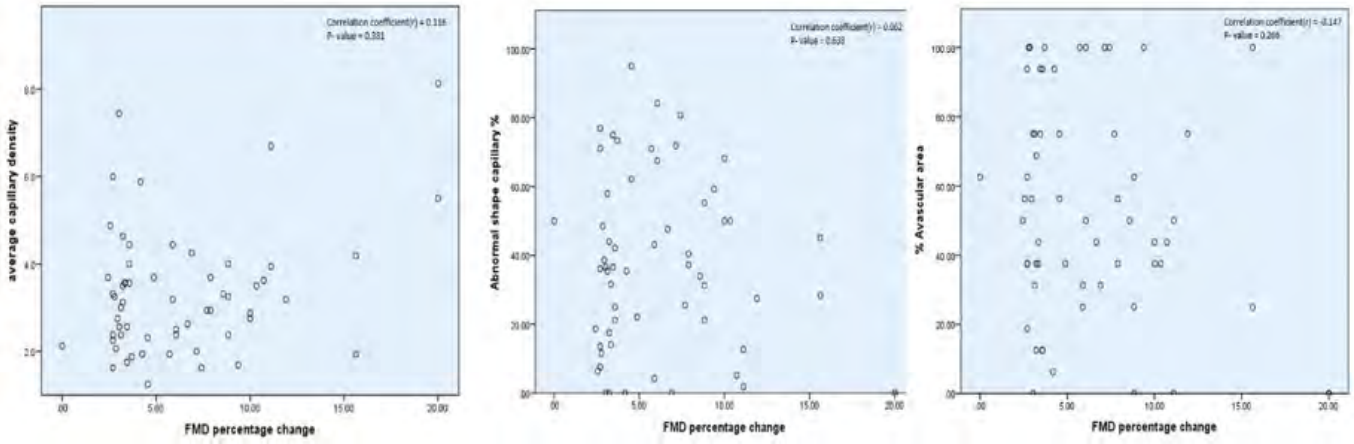

Figure 1. Correlation of FMD percent change with (a) average capillary density (b) abnormal capillaries and (c) % avascular area.

Conclusion: About 2/3rd of patients with SSc have macrovascular complications but their clinical implications may need long term prospective follow up. Macrovascular and microvascular dysfunction appears to be independent of each other in SSc.

Heterogeneity of Primary and Secondary Peristalsis in Systemic Sclerosis: A New Model of Scleroderma Esophagus

John Pandolfino[1], Harris Perlman[1], Monique Hinchcliff[2], Mary Carns[3], John Pandolfino[1], John Pandolfino[1], Chase Correia[1] and John Pandolfino[1], [1]Northwestern University, Chicago, IL, [2]Yale School of Medicine, Westport, CT, [3]Northwestern University Division of Rheumatology, Chicago, IL

SESSION INFORMATION
Session Date: Monday, November 8, 2021
Session Title: Systemic Sclerosis & Related Disorders – Clinical Poster II (1364–1390)
Session Type: Poster Session C
Session Time: 8:30AM–10:30AM

Background/Purpose: Although esophageal dysmotility is common in systemic sclerosis (SSc), little is known regarding the pathophysiology of the motor abnormalities driving reflux severity and dysphagia. This study aimed to assess primary and secondary peristalsis in SSc using a complementary approach focused on High-resolution manometry (HRM) and functional luminal imaging probe (FLIP) Panometry to provide a more comprehensive assessment of esophageal motility.

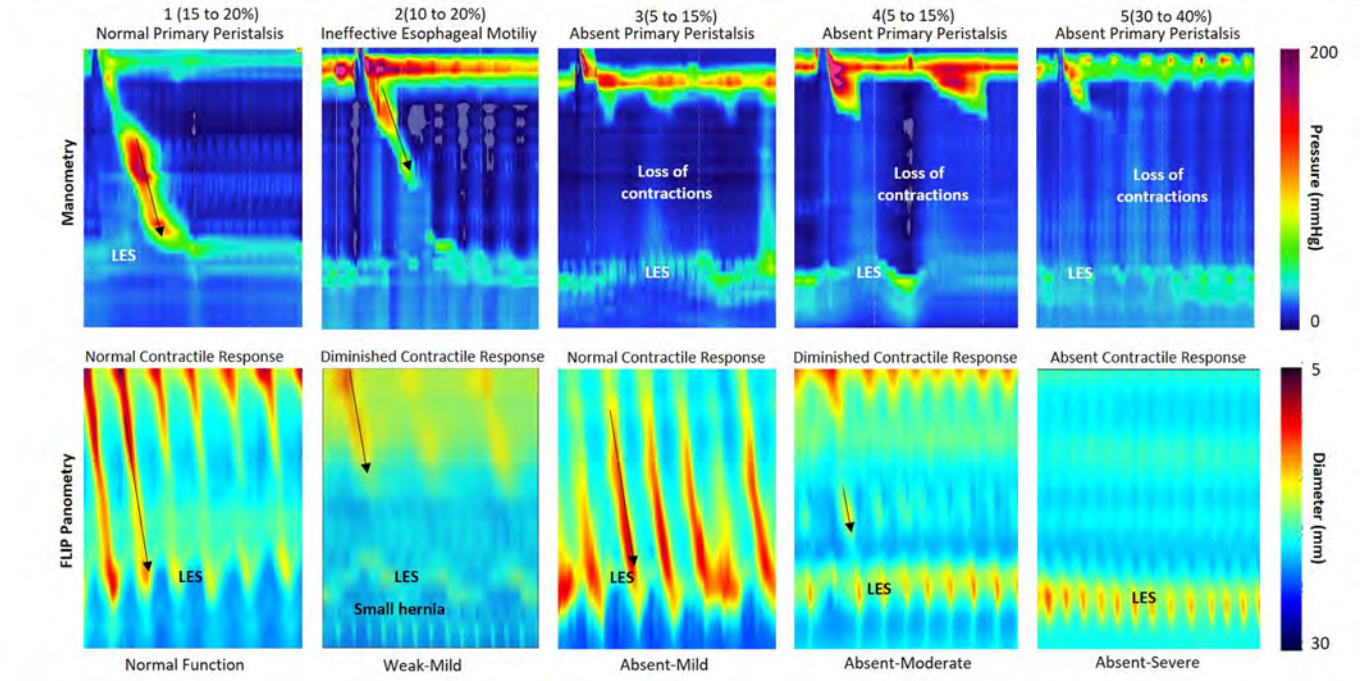
Methods: We performed simultaneous HRM and FLIP Panometry in 33 patients with SSc (28F, ages 38 to 77). Secondary peristalsis, i.e. contractile responses (CR), was classified on FLIP Panometry by presence and pattern of contractility as normal (NCR), borderline (BCR), impaired/disordered (IDCR), absent (ACR), or spastic-reactive (SRCR). Primary peristalsis on HRM was assessed according to the Chicago Classification. EGJ-distensibility index (EGJ-DI) was measured in all patients during FLIP-Panometry as a marker of LES function/opening.

Results: We were able to obtain complete data in 32 subjects as one patient had a sensor malfunction on FLIP. The manometric diagnoses were: Absent Contractility- 18 (56%); Ineffective Esophageal Motility- 7 (22%); Normal motility- 7 (22%). SSc patients also had heterogeneity in terms of secondary peristalsis with 38% (n=12) of patients having ACR, 38% (n=12) having IDCR, 19% (n=6) having BCR and 15% (n=5) having normal. The median (IQR) EGJ-DI was 5.8 mm^2/mmHg (4.8-10.1) mm^2/mmHg; 10/32 (31%) of the SSc patients had an EGJ-DI >8.0 mm^2/mmHg and all 32 patients had an EGJ-DI >2.0 mm^2/mmHg. Of the 18 patients that had absent contractility on HRIM; 11 (61%) patients had ACR, 5 (28%) had IDCR and 2 (11%) had BCR. Of the 7 patients with IEM, 1 patient had ACR, 1 patient had NCR and 5 had IDCR. All of the patients with Normal peristalsis had NCR or BCR. Based on these observations, a three tiered classification describing the relationship between findings on HRM and FLIP-Panometry is described in the Figure.

Conclusion: This was the first study to assess combined HRM and FLIP–Panometry in a cohort of SSc patients. Our results support heterogeneity in both primary and secondary peristalsis and a hierarchal classification scheme which can more accurately describe abnormalities of bolus transit.

Patients are defined by peristaltic function on manometry (top panels) and contractile response to volumetric distention (bottom panels). Each pair of Manometric and FLIP Panometric images can be combined to create specific subtypes [Normal, Weak, Absent] /stages [Mild, Moderate, Severe]. Examples are noted in the 5 panels: 1) SSc with Normal Esophageal Function, 2) SSc Esophagus with IEM and borderline or diminished function on FLIP, 3) Absent Contractility with Normal Contractile Response, 4) SSC esophagus with impaired contractile response and 5) SSc with aperistalsis on manometry and an absent contractile response to volumetric distention.

This model has the capacity to define disease progression along the neurogenic and myogenic pathway in extreme detail to provide a timeline for our translation assessment of molecular targets and biomarkers. Additionally, this assessment may uncover distinct phenotypes beyond the classic progression to aperistalsis and that may have varying levels of neurogenic dysfunction . LES- Lower esophageal sphincter



Subtypes of Esophageal Function in SSc defined by combined manometry/FLIP-panometry.

Extent of ILD% (SD)	0 (0)	2.3 (1.5)	19.3 (16.8)
ILD progression% (SD)	0.08 (1.0)	3.1 (6.2)	3.6 (9.9)
ILD progressors, n (%)	3 (2)	20 (38)	72 (51)

Background/Purpose: Based on the argument that symptoms-define-disease, physicians commonly apply the terms pre-clinical or sub-clinical disease to describe patients with disease-related findings, but no accompanying symptoms. For patients with connective tissue disease associated interstitial lung disease (CTD-ILD), the term sub-clinical applies frequently to patients with mild ILD changes on HRCT, within normal range functional capacity and no respiratory symptoms. Previous work in systemic sclerosis (SSc)-ILD did however show that patients with even minor extent of ILD at baseline often progressed and had increased mortality risk; indicating that it is not appropriate to define these patients as “subclinical”. The objective of this study was to to identify the prevalence of subclinical ILD across CTD diagnoses, and assess the rate of progression of lung fibrosis compared to CTD without ILD and with clinical ILD.

Methods: All CTD patients, including SSc, anti-syntethase syndrome (ASS) and mixed connective tissue disease (MCTD) from the Oslo University Hospital diagnosed before 2015 assessed for the presence of ILD by HRCT were included. 2015 was chosen to secure an observation time of at least 5 years from ILD diagnosis to study end on 01.01.2021 or time of death. All patients fulfilled the respective CTD classification criteria. Subclinical ILD was defined as an ILD extent < 5% by semi-quantitative assessment at baseline HRCT, preserved lung function with a forced vital capacity (FVC) >80%predicted and no respiratory symptoms. Clinical ILD was defined as >5% extent of ILD or < 5% extent of ILD on HRCT with respiratory symtoms or FVC< 80%. The outcome was progression of lung fibrosis assessed on HRCT at follow up. Vital status was available in all patients and mortality assessed. Descriptive statistical analyses were conducted and time to progressive event determined by Kaplan-Meier estimates.

Results: We identified 525 CTD patients, including 296 SSc, 135 MCTD and 94 ASS patients assessed for ILD. Of these, 227 (43%) had no ILD, 67 (13%) subclinical and 231 (44%) clinical ILD (Table). Of the 67 subclinical ILD patients, 45 (15%) had SSc, 13 (10%) MCTD and 9 (10%) ASS. Over a median time of 4.5 years between baseline and follow up HRCT, 95/395 (24%) showed lung fibrosis progression, including 72 (26%) SSc and 23 (19%) MCTD patients. Disease progression was frequently present in both subclinical ILD (38%) and clinical ILD (51%) patients (Figure). Age, gender, underlying CTD and baseline lung function were not predictive for lung fibrosis progression. The events were too low for multivariable regression analyses. After a median observational period of 12 years, 153 (29%) of the patients died. The 1-, 5- and 10-year survival rates in no ILD, subclinical and clinical ILD were 97%/97%/99%, 88%/91%/82% and 82%/85%/68% (p< 0.001), respectively.

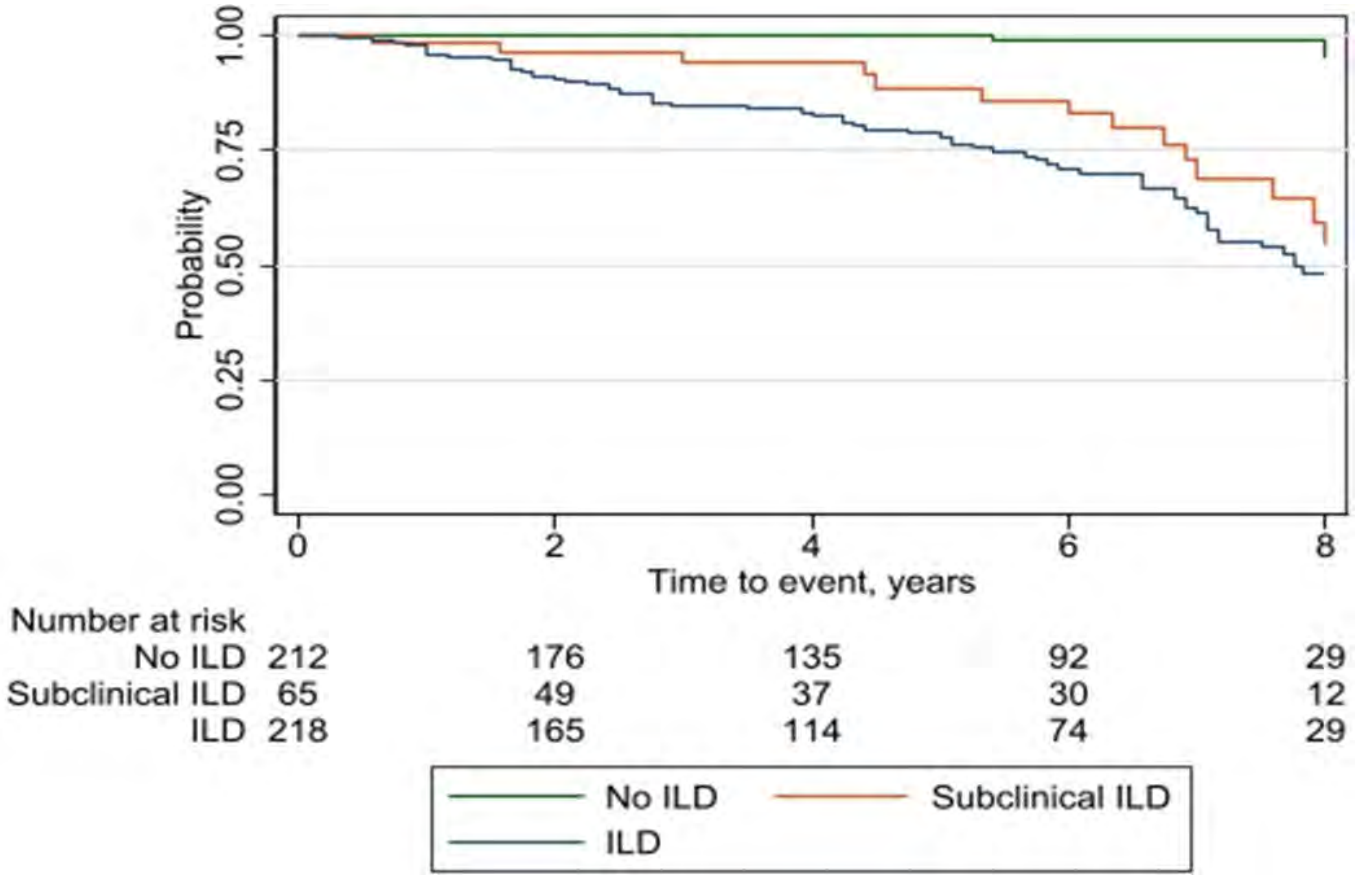

Figure 1. Time to progressive event.

Conclusion: Subclinical ILD is frequently present across CTDs and progresses over time in a substantial subgroup of patients, comparable to patients with clinical ILD. Our findings question the terms sub- and preclinical ILD, which may potentially lead to to a suboptimal "watchful waiting management strategy".

A 5% Increase in Interstitial Lung Disease at 1-Year Follow-up Is Associated with Long-Term ILD Progression in Systemic Sclerosis

Alicia Hinze[1], Shreyasee Amin[1], Ashima Makol[1], Robert Vassallo[1], Cynthia Crowson[2] and Brian Bartholmai[1], [1]Mayo Clinic, Rochester, MN, [2]Mayo Clinic, Eyota, MN

SESSION INFORMATION

Session Date: Monday, November 8, 2021
Session Title: Systemic Sclerosis & Related Disorders – Clinical Poster II (1364–1390)
Session Type: Poster Session C
Session Time: 8:30AM–10:30AM

Background/Purpose: The clinical course of interstitial lung disease (ILD) in systemic sclerosis (SSc) is highly variable. Some patients experience a progressive decline in lung function while others remain stable. SSc patients with ILD may be monitored for progression by high-resolution computed tomography (HRCT), pulmonary function studies (PFT), or both, to determine i) need for therapy, or ii) stability on therapy. However, the percent change in ILD over time that constitutes significant progression on HRCT remains unclear. Additionally, whether short-term change in ILD% is associated with an increased risk for long-term ILD progression (traditionally defined as a reduction in forced vital capacity (FVC) on PFT of ≥10% predicted from baseline) is unknown. Small increases in ILD% on short-term follow-up HRCT scans may not be easily recognized due to high interrater variability in grading of the severity and extent of ILD on serial HRCT. The purpose of this study is to evaluate whether rate of change in interstitial lung abnormalities measured by quantitative CT (QCT) associates with long-term ILD progression.

Methods: All patients meeting the 2013 ACR/EULAR Classification Criteria for SSc and seen between 2007 and 2019 at our institution were identified. Subjects were eligible for inclusion in this initial proof of concept study if they had a baseline HRCT ± 2 yrs of SSc diagnosis, a follow-up HRCT within 12 months ± 6 months of baseline HRCT, and had ≥5% total ILD on baseline HRCT. Additionally, subjects were required to have a baseline PFT ± 6 months of baseline HRCT, and at least one or more PFTs after the 12-month follow-up HRCT. Subjects were excluded if the eligible HRCT scans showed pulmonary edema secondary to heart failure, pleural effusions, malignancy, or infection. HRCTs were analyzed using CALIPER (Computed Aided Lung Informatics for Pathology Evaluation and Rating) QCT software, and all parenchymal (e.g. ground glass opacities (GGO), reticular densities (RD), honeycombing (HC)) and vascular features (pulmonary vascular related structures: PVRS) were quantified and normalized by total lung volume. Total ILD% is the summation of GGO%, RD%, and HC%. ILD progression was defined as a decline in FVC of ≥10% predicted from baseline PFT. The association between rate of change in quantitative parenchymal and vascular features and ILD progression was determined using Cox models.

Results: 36 subjects (75% female; mean age 60 yrs [SD 8.4]) were analyzed. Most had limited cutaneous SSc (75%) and had no current or prior history of smoking (69%). Median time under observation was 3.3 yrs (IQR 1.4, 4.6). A

Table 1. Univariable association between 12-month change in CALIPER parameters and ILD progression by PFT, adjusting for age, sex, and diffuse SSc.

CALIPER parameters	HR (95% CI)	p-value
GGO% per 5% increase	2.64 (0.99-7.03)	0.052
RD% per 1% increase	1.09 (0.58-2.04)	0.79
Honeycomb% per 0.001% increase	1.10 (0.99-1.24)	0.07
ILD% per 5% increase	2.53 (1.02-6.23)	0.044
PVRS% per 1% increase	5.49 (1.11-27.24)	0.037

Baseline HRCT to next follow-up HRCT (median 0.8 years; IQR 0.5-1.4 years)

total of 8/34 subjects (24%) met ILD progression endpoint. A 5% increase in total ILD conferred a 2.5-fold increase in risk of ILD progression (HR: 2.53, 95% CI 1.02-6.23) (Table 1). A 1% increase in PVRS was associated with a 5-fold increase in risk of ILD progression (HR: 5.49, 95% CI 1.11-27.24).

Conclusion: QCT detects changes in parenchymal and vascular features on 1-year follow-up HRCT that may otherwise be too small to consistently detect and characterize by visual assessment, yet are early radiomic biomarkers of long-term disease progression risk. The utility of QCT in the evaluation and follow-up of SSc-ILD warrants further study.

Rituximab Is Superior to Placebo in Polymyalgia Rheumatica Patients: A Double Blind Randomized Controlled Proof of Principle Trial

Diane Marsman[1], Nathan den Broeder[2], Frank van den Hoogen[3], Alfons den Broeder[1] and Aatke van der Maas[4], [1]Sint Maartenskliniek, Nijmegen, Gelderland, Netherlands, [2]Radboud University Medical Centre, Nijmegen, Gelderland, Netherlands, [3]Sint Maartenskliniek, Ubbergen, Gelderland, Netherlands, [4]St Maartenskliniek, Nijmegen, Gelderland, Netherlands

SESSION INFORMATION
Session Date: Monday, November 8, 2021
Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster I: Giant Cell Arteritis & Polymyalgia Rheumatica (1391–1419)
Session Type: Poster Session C
Session Time: 8:30AM–10:30AM

Background/Purpose: Corticosteroids remain the cornerstone of polymyalgia rheumatica treatment, but their use has several disadvantages such as long treatment duration and glucocorticoid-related adverse events.[1,2] Data on evidence based effective glucocorticoid-sparing agents are negative or absent.[2]

Because B-cells may be involved in the pathogenesis of polymyalgia rheumatica, we evaluated the efficacy of rituximab in polymyalgia rheumatica.

Methods: In a 21-week double-blind placebo controlled exploratory study, 47 polymyalgia rheumatica patients (recently diagnosed n=38 / relapsing on prednisolone ≥7.5mg/day n=9) fulfilling the 2012 EULAR/ACR criteria, were randomized 1:1 to intravenous rituximab 1 x 1000 mg (n=23) or placebo (n=24), with a 17-week long glucocorticoid co-treatment. Primary outcome was glucocorticoid-free remission at week 21. Secondary outcomes were glucocorticoid ≤5mg/day and adverse events. Several post-hoc analyses were done for robustness of results.

Results: Glucocorticoid-free remission was achieved in 48% (rituximab) versus 21% (placebo), one-sided 95%-CI 4% to 100%; p=0.049, and glucocorticoid ≤5mg/day in 100% versus 54% (one sided 95%-CI 20% to 100%; p=0.005). Post-hoc analysis showed efficacy mainly in recently diagnosed patients: glucocorticoid-free remission in 58% versus 21% (one-sided 95%-CI 10% to 100%; p=0.02); glucocorticoid ≤5mg/day in 100% versus 47% (one-sided 95%-CI 29 to 100%; p< 0.001). No significant differences were observed regarding other outcomes (table 1), except for less morning stiffness after rituximab.

Conclusion: Rituximab is superior to placebo in combination with 17-week glucocorticoid-treatment to achieve glucocorticoid free remission in polymyalgia rheumatica. The largest effect was seen in recently diagnosed polymyalgia rheumatica patients (funding: Sint Maartenskliniek; Dutch trial number NL7414).

Table 1. Outcomes at week 21*

	Rituximab (n=23)	Placebo (n=24)	Difference, one sided 95%-CI	One sided p-value

Assessment of a Patient Self-Report Frailty Tool in Patients with Polymyalgia Rheumatica

Sebastian Sattui, Deanna Jannat-Khah, Lindsay Lally, Sarah Lieber, Lisa Mandl and Robert Spiera, Hospital for Special Surgery, New York, NY

SESSION INFORMATION

Session Date: Monday, November 8, 2021

Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster I: Giant Cell Arteritis & Polymyalgia Rheumatica (1391–1419)

Session Type: Poster Session C

Session Time: 8:30AM–10:30AM

Background/Purpose: Frailty, a syndrome characterized by decreased physiologic reserve, is associated with chronic inflammation. We have shown a high prevalence of frailty in patients with polymyalgia rheumatica (PMR) using the Fried criteria (FC), the gold standard frailty phenotypic instrument[1]. However, the FC is not practical to use at point of care. The Frail scale (FS), an easy-to-use self-report frailty instrument, has not been evaluated in patients with PMR.

Table 1. Frequency of frailty components for each classification and categorization

FRAIL scale		Fried frailty criteria	
Component	**Participants (N = 41), %**	**Component**	**Participants (N = 41), %**
Fatigue	16 (39%)	Weight loss	10 (24%)
Resistance	11 (27%)	Exhaustion	17 (41%)
Ambulation	0 (0%)	Inactivity	6 (15%)
Illnesses	10 (24%)	Slowness	1 (2%)
Loss of Weight	9 (22%)	Weakness	21 (51%)
Overall			
Robust	14 (34%)	Robust (0 criteria)	10 (24%)
Pre-frail	22 (54%)	Pre-frail (1-2 criteria)	24 (59%)
Frail	5 (12%)	Frail (≥3 criteria)	7 (17%)

Table 2. Baseline characteristics by frailty classification as classified by FRAIL scale

Characteristic	Robust N = 14	Pre-fail N= 22	Frail N = 5	p-value
Age, years, median [IQR]	71.3 (65.2,74.9)	75.4 (67.1, 79.1)	75.8 (72.5, 78.5)	0.20
Sex, female, n (%)	7(50%)	8 (36%)	5 (100%)	0.04

Body mass index (BMI), kg/m^2, median [IQR]	25.8 (23.9, 27.3)	26.4 (23.9, 29.3)	28.3 (24.3, 30.1)	0.80

*Steroid sparing agents such as methotrexate, hydroxychloroquine, tocilizumab. PMR-AS = Polymyalgia Rheumatica Activity Score
†Prednisone equivalent in mg/day.

The objectives of this study were to evaluate the prevalence of frailty using the FS, to compare its performance with the FC, and to describe the association of frailty with health-related quality of life (HRQoL) in patients with PMR.

Methods: Patients with PMR who fulfilled 2012 EULAR/ACR Provisional Classification Criteria at time of diagnosis, ≤ 12 months from diagnosis and on active treatment with glucocorticoids were recruited from a single center. Disease activity was measured with the PMR-activity score. Comorbidity burden was measured by the Charlson Comorbidity Index (CCI). Frailty and pre-frailty were defined according to FC and the FS[2]. HRQoL was assessed using global Patient-Reported Outcomes Measurement Information System (PROMIS) computerized adaptive tests. Sarcopenia

Table 3. Health-related Quality of Life, Sarcopenia and Disability by frailty classification

	FRAIL scale				Fried frailty criteria

ADL = activities of daily living assessed by Katz Index; IADL = instrumental activities of daily living assed by Lawton scale

was assessed by DXA. Fisher's exact test, chi-square tests and Kruskal-Wallis tests were used to describe differences among groups as appropriate. Frailty according to FC and FS were compared using a Spearman correlation.

Results: 41 patients completed a baseline visit. 12% and 17% of patients were frail, and 54% and 59% were pre-frail according to the FS and FC, respectively (Table 1). There was a strong correlation between the FRAIL scale and the Fried frailty criteria ($r = 0.71$, $p < 0.05$). Based on the FS, there were significant differences in the sex and CCI among frail, pre-frail, and robust patients ($p = 0.03$) (Table 2). Although non-significant, frail patients had higher CRP at diagnosis and ESR at study visit. According to both definitions, frail patients had more pain behavior (FS: p=0.04; FC: p=0.01) and pain interference (FS: p=0.02; FC: p< 0.01) (Table 3). Additionally, according to FS, frail patients also had more fatigue (p=0.02) and anxiety (p=0.02), and worse physical function (p=0.01). Pre-frail patients, according to FS, had more sarcopenia (p=0.02). There were no differences in disability according to either definition.

Conclusion: There was a higher prevalence of frailty and pre-frailty in this cohort of patients with PMR. Despite similar disease duration, comorbidity burden, and dose of glucocorticoids, frail patients with PMR had statistically significant and clinically meaningful worse HRQoL. There was a strong correlation between self-reported frailty and a standard frailty measure suggesting the use of the FS as a simple frailty screening tool for patients with PMR in clinical practice.

All-cause Mortality in a Hospital Ascertained Cohort with Giant Cell Arteritis: A Longitudinal Population-level Data Linkage Cohort Study

Helen Keen[1], Warren Raymond[2], Susan Lester[3], David Preen[2], Charles Inderjeeth[4], Catherine Hill[5] and Johannes Nossent[2], [1]University of Western Australia, Daglish, Australia, [2]University of Western Australia, Perth, Australia, [3]Rheumatology Department, The Basil Hetzel Institute, The Queen Elizabeth Hospital, Adelaide, Australia, [4]University of Western Australia, Nedlands, Perth, Australia, [5]Queen Elizabeth Hospital, Woodville, Australia

SESSION INFORMATION

Session Date: Monday, November 8, 2021

Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster I: Giant Cell Arteritis & Polymyalgia Rheumatica (1391–1419)

Session Type: Poster Session C

Session Time: 8:30AM–10:30AM

Background/Purpose: Giant Cell Arteritis (GCA) is the most common primary vasculitis in high income countries and ischemic complications of GCA include blindness and stroke. The impact of GCA on mortality is unclear, with conflicting evidence as to whether mortality is increased. We utilized whole-population linked health data to investigate all-cause mortality and the contributing causes of death of hospitalised GCA patients compared to matched hospital controls.

Methods: All hospital presentations with GCA from 1980 to 2015 were identified. Each patient (n=1,802) was propensity score matched with hospital-based controls (n=3,945). Data from the from the Death Registrations database were used to determine all-cause and contributing causes of mortality. The association between GCA and mortality was assessed using Cox regression models. Standardized mortality ratios (SMR) were produced for the GCA cohort compared to the general population of Western Australia.

Results: GCA patients had increased unadjusted (HR 1.58, 95% CI 1.46, 1.71; P< 0.001), and multivariable-adjusted risk of mortality (aHR 1.13, 95%CI 1.04, 1.23; P< 0.001) compared to controls. GCA patients requiring hospital care had an increased likelihood of mortality compared to the general population for up to ten years, most pronounced in the first year (SMR 2.67, 95%CI 2.30, 3.10; p< 0.001). Adjusting for age, sex and IA status, people with GCA had an increased likelihood of 18-year deaths related to diseases of the musculoskeletal, connective tissue and subcutaneous system diseases (excluding GCA); diseases of the eye and adnexa; diseases of the blood and blood-forming organs and certain disorders involving the immune mechanism; diseases of the genitourinary system; certain infectious and parasitic diseases; diseases of the digestive system; endocrine, nutritional and metabolic diseases; diseases of the respiratory system; diseases of the circulatory system. Adjusting for age, sex and IA status, people with GCA had a decreased likelihood of 18-year deaths related to neoplasm and diseases of the central nervous system.

Conclusion: Western Australians presenting to hospital with GCA from 1980 to 2015 had increased mortality compared to matched controls. The increased risk of death is likely related to both the disease, and complications of steroid therapies; both more efficacious and less harmful therapies are required to reduce mortality in GCA.

Vascular Ultrasound for Giant Cell Arteritis: An Effective Diagnostic Modality for a Fast Track Clinic in the United States

Charlie Oshinsky[1], Alison Bays[1], Ingeborg Sacksen[2], Elizabeth Jernberg[3], Eugene zierler[1], Andreas Diamantopoulos[4] and Scott Pollock[1], [1]University of Washington, Seattle, WA, [2]University of Washington, Bellingham, WA, [3]Virginia Mason Medical Center, Seattle, WA, [4]Akerhus University Hospital, Brum, Norway

SESSION INFORMATION

Session Date: Monday, November 8, 2021

Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster I: Giant Cell Arteritis & Polymyalgia Rheumatica (1391–1419)

Session Type: Poster Session C

Session Time: 8:30AM–10:30AM

Background/Purpose: Giant cell arteritis (GCA) is the most common form of large vessel vasculitis. Prompt diagnosis and treatment of GCA is vital to prevent vision loss. The European League Against Rheumatism (EULAR) recommends ultrasound as the preferred imaging modality for GCA, and in subjects with positive imaging findings and a high clinical suspicion, diagnosis can be made without temporal artery biopsy (TAB). Fast track clinics (FTC) evolved in European countries to diagnose GCA through the use of ultrasound. However, the American College of Rheumatology (ACR) does not yet endorse the use of ultrasound for diagnosis, and FTCs in the United States are still relatively new. We present the results of the largest cohort of subjects reported to date referred to a United States FTC for the diagnosis of GCA.

Methods: Subjects referred to the FTC from November, 2017 – April 2021 were triaged by an attending rheumatologist who arranged for urgent rheumatology consultation and ultrasound and/or TAB. A protocolized ultrasound for the evaluation of GCA was performed by a trained vascular sonographer. The first 43 subjects referred to the FTC received both TAB and ultrasound. After demonstrating concordance between ultrasound and TAB, in subsequent referrals TAB was not performed in the setting of high clinical suspicion for GCA and positive ultrasound, or low suspicion for GCA and negative ultrasound. Ultrasound was considered positive for GCA if there was a halo sign with compression in the temporal arteries or if intima-media thickness (IMT) was increased in the large vessels.

Results: 209 subjects were referred to the FTC for ultrasound evaluation. 166 referrals were for evaluation of suspected new onset GCA, 16 were to evaluate for recurrent GCA, 18 were to evaluate concern for extracranial large vessel vasculitis, and 1 was to evaluate refractory PMR. The median time from referral to ultrasound was 1 day, with subjects on prednisone for 2 days prior to ultrasound. The time from referral to TAB was 7 days. 63 subjects were diagnosed with GCA. 209 subjects underwent ultrasound for GCA, and 51 were positive for GCA. Of the 51 positive ultrasounds, 25 had a positive halo sign and 35 had increased IMT of a large vessel. 69 subjects underwent TAB, and 9 were positive for GCA. Only one subject had a positive TAB and negative ultrasound, after IV methylprednisolone. Ultrasound identified evidence of vasculitis in 12 of 59 subjects with negative TAB. 10 subjects were diagnosed with GCA on clinical grounds alone despite negative TAB and/or ultrasound. 7 subjects diagnosed with GCA had permanent vision loss at the time of referral to the FTC. No subjects developed permanent vision loss following referral to the FTC. 3 subjects diagnosed with GCA died.

Table 1. describes baseline clinical characteristics and outcomes. Median (IQR) reported for continuous variables. Abbreviations: FTC, fast track clinic; GCA, giant cell arteritis; IQR, interquartile range; TAB, temporal artery biopsy

	Fast Track Ultrasound N=209 (IQR)
Clinical Characteristics Age, years	69 (23)
Female	146
ESR (mm/h)	40 (51)
CRP (mg/L)	18 (46)
Reasons for Ultrasound Suspected GCA	166
Recurrent/known GCA	16
Eval of LVV	18
Refractory PMR	1
Fast Track Clinic Outcomes Time from FTC referral to US, days	1 (2) N=159
Time from FTC activation to rheumatology evaluation, days	1 (2) N=131
Time on prednisone prior to ultrasound, days	2 (0) N=127
Time on prednisone prior to TAB, days	7 (5) N=59
Positive ultrasound (temporal arteries and large vessels)	51 N=209
Positive temporal artery biopsy	9 N=69
Clinical Outcomes Diagnosed as GCA	63 N=193
Transient visual complaints in subjects with GCA	43
Permanent visual loss in subjects with GCA	7
Death in subjects with GCA	3

Conclusion: This FTC in the United States used ultrasound to successfully facilitate the diagnosis of GCA. Subjects received ultrasound rapidly following referral to the FTC and received prednisone for a short duration prior to ultrasound. Ultrasound frequently identified evidence of vasculitis in subjects with negative TAB.

Session Date: Monday, November 8, 2021

Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster I: Giant Cell Arteritis & Polymyalgia Rheumatica (1391–1419)

Session Type: Poster Session C

Session Time: 8:30AM–10:30AM

Background/Purpose: The implementation of fast track clinics (FTC) has enabled quick diagnosis and reduced the blindness rate of giant cell arteritis (GCA). Recently, the Southend Pre Test Probability Score (SPTPS) has been proposed, which allows establishing a probability of having GCA and validating the results of imaging before deciding to perform other diagnostic tests. Since this score has only been tested in the cohort from which it originated, we believe that it should be validated in other populations. The objective is to evaluate the validity of the SPTPS and its usefulness in our population.

Methods: Demographic, clinical and laboratory data of the patients referred to the GCA-FTC of La Paz University Hospital (Madrid, Spain) between 2016 and 2020 were retrospectively collected. Those for which insufficient data were available were excluded. SPTPS was calculated in all included patients. All had undergone color Doppler ultrasound (CDUS) of the temporal arteries and large vessels (axillary, subclavian and carotid arteries). The definitive diagnosis was established according to the physician's criteria, based on clinical features, CDUS -and other imaging tests or biopsy according to physician criteria- and evolution, after a minimum follow-up of 6 months. The quartiles to stratify the risk of GCA, the ROC curve and the validity of the SPTPS in our cohort were calculated.

Results: A total of 297 patients were included, of which 97 (32.7%) were diagnosed with GCA. Their characteristics are shown in table 1. The mean value of SPTPS was 9.9 ± 3.6 and it area under the curve 0.787 (95% confidence interval: 0.731-0.843) (image 1). The mean SPTPS in the GCA group was 12.4 ± 3.6 and 8.7 ± 3.1 in the non-GCA group ($p < 0.005$). The SPTPS results showed a value of 10 at the 50th percentile and 12 at the 75th percentile. Therefore, we classified as low risk (LR) the value of SPTPS < 10, intermediate risk (IR) 10-12, and high risk (HR) > 12. The category of HR included 47 patients with GCA (48.5%) and only 20 non-GCA patients (10%), showing a specificity of 90%, sensitivity 48.4%, positive predictive value (PPV) 70% and negative predictive value (NPV) 78%. The IR category included 32 patients with GCA (33%) and 63 non-GCA (31.5%) (specificity 68.5-83%). And the LR category, 18 with GCA (18.5%) and 117 non-GCA (58.5%). A SPTPS ≥ 10 (that is, IR or RA), showed a sensitivity of 81.4%, specificity of 58.5% and NPV of 86.6%. The cut-off ≥7 (equivalent to p25) showed a sensitivity of 95% and a NPV of 90%, while the cut-off ≥14 had a specificity of 95.5% (table 2). There were 51 cases with a score < 7, of which 5 had GCA; the majority had a pattern of extracranial involvement (3 out of 5), which represented 20% of all cases with this pattern. Despite this trend, no statistically significant differences were observed in the SPTPS value between the different patterns of involvement (cranial, mixed, extracranial).

Table 1. Demographic, clinical and laboratory characteristics included in the SPTPS of the patients in our cohort

	TOTAL (n = 297)	GCA (n = 97)	Non-GCA (n = 200)
Age (years)	Mean: 75.4 ± 9.6 ≤ 49: 4 (1.3%) 50-60: 22 (7.4%) 61-65: 25 (8.4%) ≥ 66: 246 (82.8%)	Mean: 77.3 ± 7.9 ≤ 49: 0 (0%) 50-60: 2 (2.1%) 61-65: 7 (7.2%) ≥ 66: 88 (90.7%)	Mean: 74.4 ± 10.2 ≤ 49: 4 (2%) 50-60: 20 (10%) 61-65: 18 (9%) ≥ 66: 158 (79%)
Sex	Female: 205 (69%) Male: 92 (31%)	Female: 53 (54.6%) Male: 44 (45.4%)	Female: 152 (76%) Male: 48 (24%)

Alternative diagnosis	Infection: 31 (10.4%) Cancer: 23 (7.7%) Systemic rheumatic disease: 41 (13.8%) Head and neck pathology: 10 (3.4%) Other: 17 (5.7%) Total: 96 (32.3%)	Infection: 5 (5.2%) Cancer: 13 (13.4%) Systemic rheumatic disease: 9 (9.3%) Head and neck pathology: 1 (1%) Other: 3 (3.1%) Total: 19 (19.6%)	Infection: 26 (13%) Cancer: 10 (5%) Systemic rheumatic disease: 32 (16%) Head and neck pathology: 9 (4.5%) Other: 14 (7%) Total: 77 (38.5%)

Conclusion: The SPTPS is useful to stratify patients referred to GCA-FTC. A score ≥14 is associated with a very high probability of having GCA and a value < 7 with a very low probability. However, although there were no statistically significant differences, 20% of the patients with extracranial GCA had an SPTPS < 7, so this test may not be able to discriminate well this subtype of the disease.

Baricitinib in Relapsing Giant Cell Arteritis: A Prospective Open-Label Single-Institution Study

Matthew Koster[1], Cynthia Crowson[2], Rachel Giblon[1], Ali Duarte-Garcia[1], Jane Jaquith[1], Cornelia M. Weyand[1] and Kenneth Warrington[3], [1]Mayo Clinic, Rochester, MN, [2]Mayo Clinic, Eyota, MN, [3]Mayo Clinic, Rochester, Minnesota

SESSION INFORMATION

Session Date: Monday, November 8, 2021

Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster I: Giant Cell Arteritis & Polymyalgia Rheumatica (1391–1419)

Session Type: Poster Session C

Session Time: 8:30AM–10:30AM

Background/Purpose: Pre-clinical giant cell arteritis (GCA) mouse models have demonstrated effective suppression of arterial wall lesional T-cells through inhibition of Janus kinase 3 (JAK3) and JAK1. However, the use of JAK inhibition in patients with GCA has not been formerly investigated.

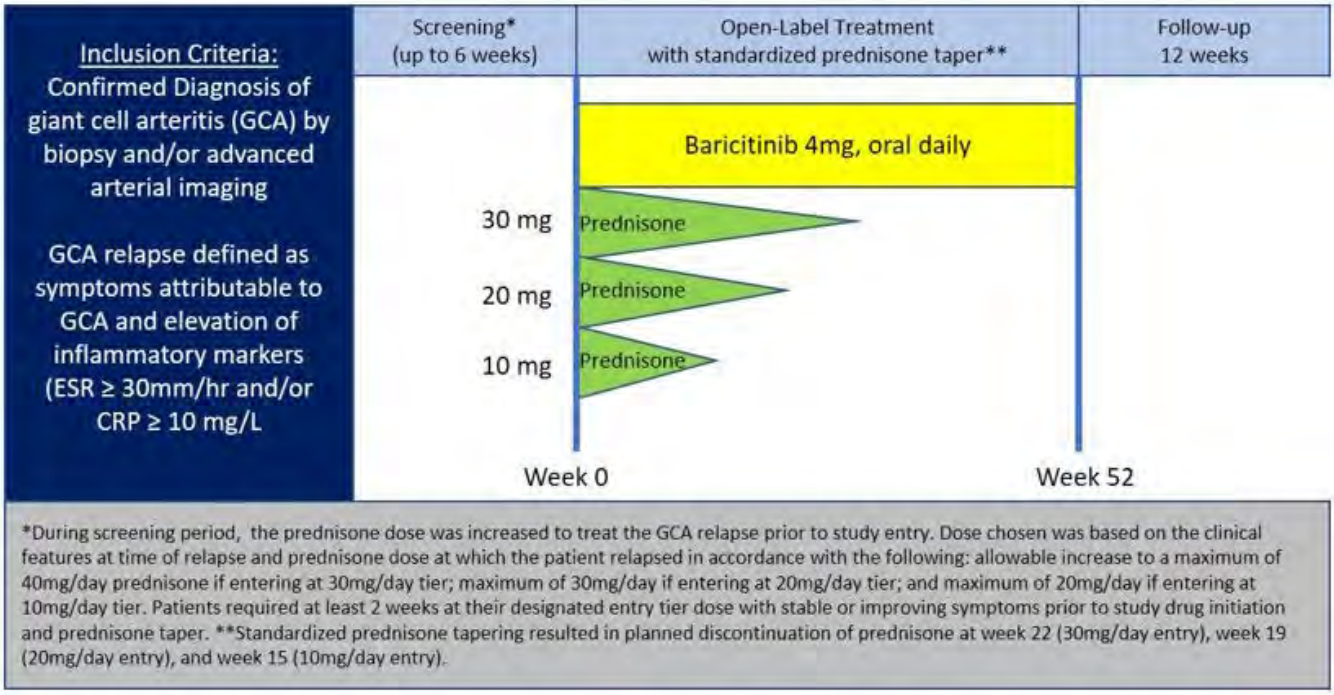

Figure 1. Study Schema.

Table 1. Characteristics at giant cell arteritis diagnosis and relapse prior to study entry

Characteristic	GCA diagnosis (N=15)	Relapse prior to study entry (N=15)
Headache	11 (73)	6 (40)
Scalp tenderness	10 (67)	3 (20)
Jaw claudication	7 (47)	1 (7)
Visual Ischemia	4 (27)	0 (0)
Limb claudication	1 (7)	0 (0)
Polymyalgia rheumatica	4 (47)	8 (53)
Constitutional symptoms	11 (73)	8 (53)
New or worse large vessel vasculitis on arterial imaging	5 (33)	4 (27)
Method of diagnosis		—
TAB (+) / Imaging (+)	5 (33)	
TAB (+) / Imaging (-) or ND	5 (33)	
TAB (-) or ND / Imaging (+)	5 (33)	
TAB, temporal artery biopsy; ND, not done		

Methods: We performed a prospective, open-label, pilot study of baricitinib (4mg/day) in patients with relapsing GCA. The primary outcome was the frequency of adverse events and serious adverse events at week 52. Secondary outcomes included relapse at week 24 and week 52, change in pre-enrollment erythrocyte sedimentation rate (ESR)

Table 2. Study Outcomes

Outcome	Pre-baricitinib relapse	Week 0	Week 24	P-value	Week 52	p-value
Prednisone dose, mg/day**	---	20 (10,30)	0 (0, 0)[γ]	<0.001[ε]	0 (0, 0)	<0.001[ε]
ESR, mm/h*	36.1 (19.3)	10.3 (7.6)	21.1 (29.2)	0.005[ψ]	18.4 (29.8)	0.04[ψ]
CRP mg/L*	22.8 (7.7)	5.2 (3.7)	7.2 (16.9)	0.006[ϕ]	4.0 (3.0)	<0.001[ϕ]

Patient global assessment*	---	22.4 (21.6)	8.6 (12.9)[γ]	0.04[ε]	7.1 (9.1)	<0.007[ε]
Stopped glucocorticoids	---	---	14/14 (100%)	---	13/14 (93%)	---
Relapse on study drug	---	---	1/14 (7%)	---	1/14 (7%)	---

*mean(SD), **median(IQR)
[ϕ]Comparison pre-baricitinib relapse value to week 24; [ψ]comparison pre-baricitinib relapse value to week 52
[γ]Comparison week 0 value to week 24; [ε]comparison week 0 value to week 52

and C-reactive protein (CRP) to week 24 and week 52, and comparison of glucocorticoid dose at enrollment to week 24 and week 52. The study schema is outlined in Figure 1.

Results: 15 patients were enrolled in the study (11, 73% female) with a mean(SD) age at entry 72.4(7.2) years, median (IQR) duration of GCA of 9 (7, 21) months, and median of 1 (1, 2) prior relapse. Treatments prior to study entry included: glucocorticoids (15, 100%); methotrexate (2, 13%); cyclophosphamide (1, 7%); sirukumab (1, 7%). Characteristics at GCA diagnosis and at relapse prior to study entry are listed in Table 1. Four (27%) patients entered the study on prednisone 30mg/day, 6 (40%) at 20 mg/day, and 5 (33%) at 10mg/day. One patient with baseline chronic kidney disease had a decline in renal function below study threshold for continuation and was withdrawn at week 8. The remaining 14 patients completed 52 weeks of baricitinib. At week 52, 14/15 (93%) patients had at least one adverse event recorded with the most frequent events including: infection not requiring antibiotics (n=8), infection requiring antibiotics (n=5), nausea (n=6), leg swelling (n=2), fatigue (n=2), diarrhea (n=1), abdominal pain (n=1). Two patients contracted COVID-19 during the study, both with mild symptoms, neither hospitalized. Only one patient had a serious adverse event during the study (transient thrombocytopenia attributed to concomitant use of antimicrobial therapy).

Study outcomes are highlighted in Table 2. ESR and CRP were significantly lower at week 24 and week 52 compared to pre-enrollment values. Patient global assessment at week 0 was also significantly improved at both week 24 and week 52. Only 1 of 14 (7%) patients relapsed during the study (same patient at week 24 and week 52) The remaining 13 patients achieved steroid discontinuation and remained in disease remission during the duration of the 52-week study. Among patients completing the study, 4/14 (29%) flared during the 12-week follow up period after baricitinib discontinuation.

Conclusion: In this proof of concept study, baricitinib at a dose of 4mg/day appeared both safe and effective in the management of patients with relapsing GCA. Larger randomized clinical trials are needed to determine the utility of JAK inhibition in GCA.

Session Date: Monday, November 8, 2021

Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster I: Giant Cell Arteritis & Polymyalgia Rheumatica (1391–1419)

Session Type: Poster Session C

Session Time: 8:30AM–10:30AM

Background/Purpose: Giant cell arteritis (GCA) is an inflammatory condition of medium- and large-sized arteries. Prospective clinical trials have demonstrated the efficacy of tocilizumab (TCZ) for treatment of patients with GCA.

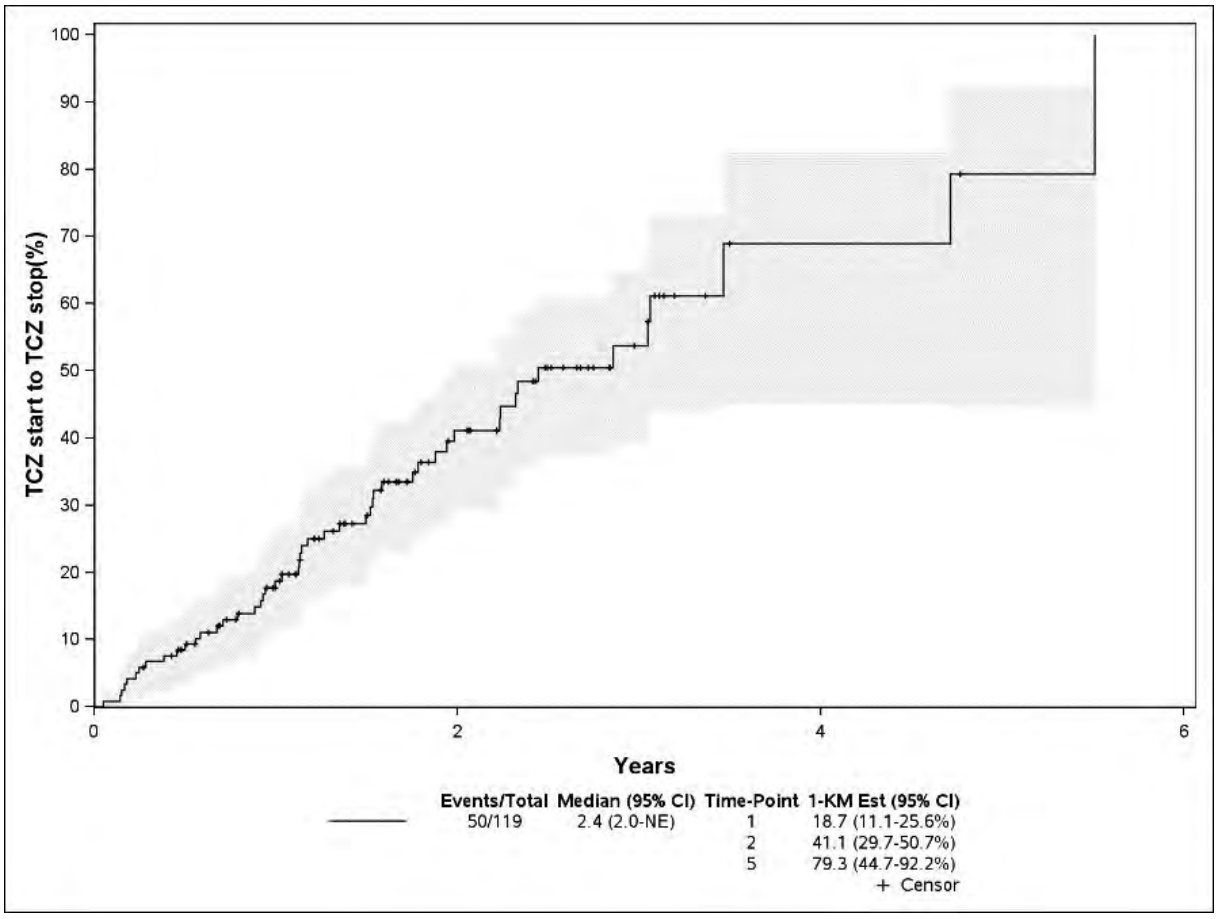

Image 1. Time from TCZ start to TCZ discontinuation.

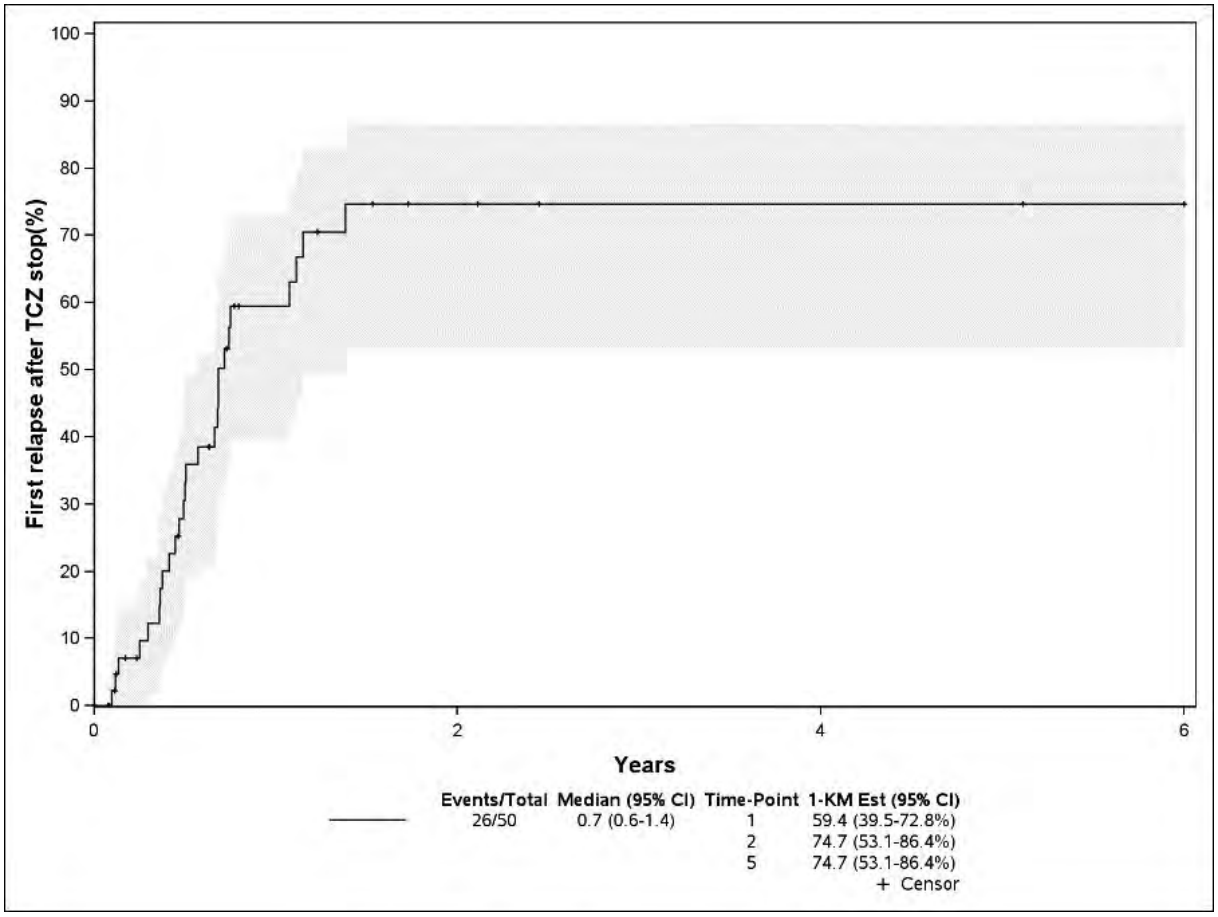

Figure 2. Time to first relapse after TCZ stop.

However, there is a limited data on the use of TCZ in routine clinical practice. The objective of the study was to evaluate the efficacy and safety of TCZ in a retrospective cohort study of patients with GCA treated with TCZ.

Methods: Patients with GCA treated with TCZ at 4 clinical centers of a single tertiary care institution (2000-2020) were identified. The diagnosis of GCA was confirmed by arterial biopsy, large vessel imaging, or clinical diagnosis meeting ACR classification criteria and physician diagnosis. Patient demographics, clinical presentation, laboratory studies, treatment course and adverse events were abstracted from the medical record; only patients with at least 6 months of follow-up after TCZ initiation were included. Kaplan-Meier methods were used to estimate time to TCZ discontinuation and first relapse after discontinuation. Poisson regression models were used to compare relapse rates before and after TCZ initiation.

Table 1. Main outcome variables

	At TCZ initiation	At TCZ discontinuation/last follow up visit
Prednisone dose, mean (SD) mg/day	31 (19)	3.8 (6.6)
ESR, mean (SD) mm/hour	22 (20)	5.9 (9.2)
CRP, mean (SD) mg/L	19.1 (25)	5.4 (16.6)
Relapse rate per year	0.77	0.44

Results: The study included 119 patients [61% female; mean(SD) age at GCA diagnosis 70.3(8.2) years]. The majority of patients (89%) had a biopsy-proven and/or imaging-based diagnosis of GCA, while 13(11%) had a clinical diagnosis of GCA. In addition to glucocorticoids, 40(34%) patients received other immunosuppressive agents prior to TCZ. The method of initial TCZ administration was subcutaneous (162mg/ml) weekly in 48(41%), subcutaneous every other week in 20(17%), monthly 4mg/kg infusions in 34(29%), monthly 8mg/kg infusions in 14(12%) and non-standard dosing in 3 remaining patients. The median(IQR) duration from GCA diagnosis to TCZ initiation was 4.8(1.2-22.0) months. The median(IQR) duration of TCZ treatment was 18(11-28) months. The mean(SD) dose of prednisone at TCZ initiation was 31(19) mg/day and was reduced to a mean(SD) dose of 3.8(6.6) mg/day at TCZ discontinuation/last follow-up visit. The relapse rate per year decreased 43% from 0.77 to 0.44 after the initiation of TCZ (RR=0.57; 95% CI: 0.44-0.75; p< 0.001). The mean(SD) ESR and CRP decreased from 22(20) mm/hour to 6(9.2) mm/hour and from 19.1(25) mg/L to 5.4(16.6) mg/L, respectively from TCZ initiation to TCZ discontinuation/last follow-up visit. At 2 years of follow-up, 67% of patients had discontinued glucocorticoids. At last follow up, 50 patients had discontinued TCZ, only 16 of which were due to adverse events. The median time to TCZ discontinuation was 2.4 years. The most common adverse events were infections and cytopenias. While on TCZ, 1 patient developed new onset vision loss related to GCA and 1 patient, without history of diverticulitis, had bowel perforation. Among those discontinuing TCZ, 61% had relapsed at least once by 1 year after discontinuation.

Conclusion: TCZ use significantly reduced relapse rate and prednisone dosage. Patients tolerated long-term use with only 13% discontinuing due to adverse events. However, the high relapse rate after discontinuation indicates that ongoing use may be required beyond two years to maintain remission.

Adrenal Insufficiency After Glucocorticoid Treatment of Giant Cell Arteritis

Alojzija Hocevar[1], Rok Jese[1], Jelka Kramaric[2], Matija Tomšič[3] and Ziga Rotar[3], [1]UKC Ljubjana, Ljubjana, Slovenia, [2]UKC Ljubjana, Ljubjana, [3]Department of Rheumatology, University Medical Centre Ljubljana, Ljubljana, Slovenia

SESSION INFORMATION

Session Date: Monday, November 8, 2021

Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster I: Giant Cell Arteritis & Polymyalgia Rheumatica (1391–1419)

Session Type: Poster Session C

Session Time: 8:30AM–10:30AM

Background/Purpose: Adrenal insufficiency is frequently neglected and underappreciated complication of systemic glucocorticoid therapy. We aimed to evaluate the prevalence of glucocorticoid induced adrenal insufficiency in giant cell arteritis (GCA).

Methods: We analysed adrenal function data in a cohort of GCA patients (51 (67.1%) females, median (IQR) age 72.9 (66.3-77.4) years) in whom a discontinuation of methylprednisolone therapy was planned. Adrenal function was tested by Corticotropin (Synacthen®) stimulation test (CST). To perform the CST, methylprednisolone was substituted with hydrocortisone (20mg qd in three divided doses) for one to four weeks before the test. Adrenal insufficiency was defined as cortisol level < 450 nmol/l measured 30 minutes after the corticotropin injection; additionally, the result of

the CST was defined as borderline when the cortisol level 30 minutes after corticotropin injection was between 450 nmol/l and 500 nmol/l.

Results: Adrenal function was tested in 76 GCA patients before definite methylprednisolone withdrawal (after a median 13.5 (12.9 – 24.6) months of glucocorticoid therapy). The mean (SD) methylprednisolone dose, prior to substitution with hydrocortisone and subsequent CST, was 3.7 (0.9) mg. Adrenal insufficiency was detected in 37/76 patients (48.7%); additionally, 10/76 patients (13.2%) had a borderline CST result. Twenty-two patients with either adrenal insufficiency or borderline CST result, had a repeated CST after a median (IQR) 11.6 (8.1; 13.3) months. Adrenal insufficiency persisted in 12/22 (54.5%) patients and was borderline in one patient (4.5%). In 9/22 (40.9%) patients adrenal function recovered meanwhile. A third CST was performed in 6/13 patients with abnormal second CST after median (IQR) 8.3 (6.9; 12.6) months. Adrenal function recovered in one patient, while insufficiency persisted in the remaining 5 patients.

Conclusion: Adrenal insufficiency is frequent and potentially long-lasting glucocorticoid induced adverse event in GCA patients.

Session Date: Monday, November 8, 2021
Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster I: Giant Cell Arteritis & Polymyalgia Rheumatica (1391–1419)
Session Type: Poster Session C
Session Time: 8:30AM–10:30AM

Background/Purpose: Giant cell arteritis (GCA) is the most common large vessel vasculitis. Failure to rapidly diagnose and treat patients with GCA can result in irreversible blindness. The American College of Rheumatology (ACR) developed classification criteria for GCA in 1990. However, these criteria are neither sensitive nor specific. Furthermore, these criteria do not provide a mechanism to quickly risk stratify referrals for GCA as the criteria rely in part on temporal artery biopsy (TAB) results, often not available at the time of referral. Triage, early treatment, and diagnosis would benefit from a GCA probability score. Laskou et al produced the GCA Probability Score (GCAPS) in 2019, which was subsequently used by Sebastian et al to successfully risk-stratify referrals to the Southend fast track clinic (FTC). However, this probability score requires further external validation. We report the results externally validating this probability score from our ultrasound-based FTC in the United States.

Methods: We included subjects referred to the FTC from November 2017 – December 2020. Only subjects with complete data to calculate the probability score were included. Subjects deemed very low risk were not offered an ultrasound for GCA and were not included in this study. All subjects evaluated by rheumatology received an ultrasound for GCA. Subjects received TAB at the discretion of the rheumatologist. A probability score was calculated as defined by Laskou et al, and compared to the low (< 9), intermediate (9-12), and high risk (>12) probability score thresholds as defined by Sebastian et al. Diagnosis of GCA was also compared to the ACR 1990 classification of GCA criteria. A subject was determined to have GCA if this was deemed the most likely diagnosis 6 months after initial presentation.

ACR>=3	51 (42.1%)
Ultrasound positive	27 (22.3%)
Diagnosed as GCA	42 (34.7%)

Clinical characteristics and outcomes of subjects evaluated by the fast track clinic for giant cell arteritis.

Results: 166 subjects were referred to the FTC for suspected GCA during the specified time period. 121 had complete data to calculate the probability score (Table 1). 42 subjects were diagnosed with GCA. The median (interquartile range) probability score in the group diagnosed with GCA was 15 (5.75), in those not diagnosed with GCA was 11 (5), and the difference in probability score between the two groups was statistically significant (p=< 0.001). 3/27 subjects with low risk probability score, 12/42 subjects with intermediate risk probability score, and 27/52 subjects with high risk probability score were diagnosed with GCA. The low risk probability threshold was 92.9% sensitive and 30.4% specific (Table 2) for GCA. Of the low risk subjects diagnosed with GCA, one had a negative ultrasound for GCA and other diagnoses are being considered, one subject had negative TAB and ultrasound and was diagnosed based on clinical suspicion, and one subject had evidence of extra-cranial large vessel vasculitis on ultrasound. The high risk probability threshold was 64.3 sensitive and 68.4 specific. The 1990 ACR Classification of GCA Criteria were 52.4% sensitivity and 63.3% specific. Ultrasound was 62.5% sensitive and 97.3% specific.

	Sensitivity	Specificity
ACR criteria	52.38%	63.29%
Vascular ultrasound	62.50%	97.26%
Low Risk probability score	92.86%	30.38%
High risk probability score	64.29%	68.36%

Sensitivity and specificity of diagnostic and screening modalities for GCA.

Conclusion: In our cohort, the low risk probability score was sensitive, but not 100% sensitive, for GCA, and may serve as a reasonable screening tool. The high risk probability score threshold was not specific.

Analyses of Plasma Inflammatory Proteins Reveal Biomarkers Predictive of Subsequent Development of Giant Cell Arteritis; A Nested Case-Control Study

Karin Wadström[1], Jan-Åke Nilsson[1], Aladdin Mohammad[2], Kenneth Warrington[3], Eric Matteson[4], Magnus Jakobsson[2], Lennart Jacobsson[5] and **Carl Turesson**[6], [1]Lund University, Malmö, Sweden, [2]Lund University, Lund, Sweden, [3]Mayo Clinic, Rochester, MN, [4]Mayo Clinic College of Medicine and Science, Rochester, MN, [5]University of Gothenburg, Gothenburg, Sweden, [6]Lund University, Malm, Sweden

SESSION INFORMATION

Session Date: Monday, November 8, 2021

Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster I: Giant Cell Arteritis & Polymyalgia Rheumatica (1391–1419)

Session Type: Poster Session C

Session Time: 8:30AM–10:30AM

Background/Purpose: Previous studies have demonstrated that metabolic factors may predispose to giant cell arteritis (GCA). The purpose of this study was to investigate the relation between biomarkers of inflammation in biobank samples and subsequent development of GCA.

Methods: Participants in a population-based cohort established in 1991-1996 who were subsequently diagnosed with GCA were identified through register linkage and validated in a structured process. GCA-free controls, matched for sex, year of birth, and year of inclusion, were selected from the study cohort. Plasma samples from cases and controls that had been obtained at inclusion were analyzed using the OLINK proteomics inflammation panel, which measures 92 inflammatory proteins, and provides arbitrary values based on log2 normalized quantification. Variables with a skewed distribution were log transformed, and Z-scores for all proteins were included in conditional logistic regression models with GCA case/control status as the dependent variable. Analyses were pre-designated as hypothesis-driven or hypothesis-generating. A priori hypotheses were formulated for 8 biomarkers. For these, Holm's correction of p-values was applied to account for multiple testing. In the hypothesis-generating part of the study, principal component analysis was used to identify groups of proteins that explain the variance in the pro-

teome. Within components selected based on Eigenvalues, proteins with a factor loading of >0.50 were investigated as potential predictors of GCA. All analyses were stratified by quartile of time from inclusion to GCA diagnosis among the cases.

Results: A total of 94 cases with a confirmed incident diagnosis of GCA (82 % female; 64 % biopsy positive, mean age at diagnosis 73.6 years) were identified and had preserved plasma samples. The median time from inclusion to diagnosis was 11.9 years (range 0.3-19.1). Among biomarkers with a priori hypotheses, IFN-g was positively associated with GCA (odds ratio (OR) 1.52; 95% confidence interval (CI) 1.00-2.30). However, none of the associations in this subset reached statistical significance after correction for multiple testing (Table 1). Of 37 biomarkers with factor loading >0.5 within 6 principal components with Eigenvalues >2.5, 8 were significantly associated with development of GCA (Table 2). Among these, higher levels of IFN-g (OR 2.37; 95% CI 1.14-4.92) and MCP3 (OR 4.27; 95% CI 1.26-14.53) were particularly associated with increased risk of GCA in the subset sampled < 8.5 years before diagnosis. Several other proteins known to be important for T cell function were also associated with GCA in these analyses, e.g. CXCL9, IL-2, CD40 and CCL25 (Table 2).

Odds ratios (OR) per standard deviation with 95 % confidence intervals (CI).

Conclusion: In this nested-case control study, elevated IFN-g levels were found years prior to diagnosis in cases who were subsequently diagnosed with GCA, although we cannot exclude that this finding is due to multiple testing. Principal component analysis revealed that several T cell related proteins that explain a major part of the variance in the proteome were associated with subsequent GCA, suggesting that T cell activation may precede the clinical onset of GCA.

SESSION INFORMATION

Session Date: Monday, November 8, 2021

Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster I: Giant Cell Arteritis & Polymyalgia Rheumatica (1391–1419)

Session Type: Poster Session C

Session Time: 8:30AM–10:30AM

Background/Purpose: Although giant cell arteritis (GCA) relapse is mostly defined by the recurrence of GCA signs/symptoms, in patients treated only with glucocorticoids, the C-reactive protein (CRP) and the erythrocyte sedimentation rate (ESR) help clinicians assess disease activity. Tocilizumab directly inhibits IL-6-driven acute-phase reactant synthesis in the liver rendering ESR and CRP unreliable for monitoring of disease relapse. Mavrilimumab (MAV), a GM-CSF receptor α inhibitor currently under study for GCA,[1] downregulates inflammation upstream of IL-6. Therefore, we hypothesized that MAV would not interfere with the utility of CRP and ESR in monitoring disease activity.

In this study we analyzed the relationship between CRP/ESR and clinical disease activity in GCA patients treated with MAV.

Methods: New-onset and relapsing GCA patients with active disease were recruited. Glucocorticoid-induced remission (no GCA symptoms and CRP < 1 mg/dL or ESR < 20 mm/hr) was required by baseline. Patients were randomized 3:2 to MAV 150 mg or placebo (PBO) subcutaneously every 2 weeks (wks) plus a protocol-defined 26-wk prednisone taper. The primary efficacy endpoint was time to relapse by Wk 26. Relapse (adjudicated) was defined as recurrent GCA signs/symptoms, and/or new/worsening vasculitis on imaging and concurrent CRP ≥1 mg/dL and/or ESR ≥30 mm/hr. CRP and ESR were measured periodically during the trial. This post hoc analysis assessed the CRP and ESR levels from randomization through Wk 26 in patients with and without relapse by treatment arm.

Results: A total of 70 patients were enrolled (MAV, N=42; PBO, N=28). Relapses occurred in 8 (19.1%) and 13 (46.4%) patients in the MAV and PBO groups, respectively. Unequivocal GCA symptoms were present in 20/21 patients with relapse. In the patient without unequivocal GCA symptoms, flare was determined based on worsening vasculitis by imaging. CRP or ESR were elevated at the time of relapse in all cases regardless of treatment arm (Table). Among 34 MAV recipients without relapse, 47.1% had at least one elevated ESR and 29.4% had at least one elevated CRP value. Among 15 PBO recipients without relapse, 66.7% had at least one elevated ESR and 73.3% had at least one

Table. CRP and ESR levels in patients with or without GCA relapse

Assessment§	Mavrilimumab + Pred-26 N=42	Placebo + Pred-26 N=28	Mavrilimumab + Pred-26 N=42	Placebo + Pred-26 N=28
	With Relapse		Without Relapse	
# of patients	19.1% (8)	46.4% (13)	81.0% (34)‡	53.6% (15)‖
Elevated CRP* or ESR†	**100.0% (8)**	**100.0% (13)**	**58.8% (20)**	**93.3% (14)**
Elevated CRP*	87.5% (7)	76.9% (10)	29.4% (10)	73.3% (11)
Median (interquartile range) mg/dL**	1.8 (1.4 – 6.3)	1.8 (1.2 – 2.8)	2.6 (1.8 – 3.0)	2.0 (1.5 – 3.4)
Elevated ESR†	75.0% (6)	69.2% (9)	47.1% (16)	66.7% (10)
Median (interquartile range) mm/hr**	40 (33 - 73)	49 (33 - 51)	42 (34 - 62)	54 (42 - 59)

§% (#), except where indicated otherwise.
*CRP ≥ 1 mg/dL. Any patient with at least one CRP ≥ 1 mg/dL at any visit from randomization to Wk 26 were included for this analysis.
†ESR ≥ 30 mm/hr. Any patient with at least one ESR ≥ 30 mm/hr at any visit from randomization to Wk 26 were included for this analysis.
‡Four mavrilimumab recipients had self-limited, equivocal symptomatology without concurrent CRP or ESR elevation; all 4 completed the prespecified prednisone taper by Wk 26 without need for rescue glucocorticoids, so relapse was not confirmed. Three of the four patients had asymptomatic CRP or ESR elevation at another timepoint during the study.
‖One placebo-treated patient developed chronic anemia, unexplained weight loss, and elevated ESR at Wk 24, which was assessed by the investigator as relapse but was not confirmed by adjudication because of the absence of unequivocal GCA symptoms or positive imaging. PET-CT showed increased vascular FDG uptake in this patient at Wk 30.
**For patients with relapse, CRP/ESR levels were those associated with the relapse. For patients without relapse, CRP/ESR levels were the maximum value measured from randomization to Wk 26. Local CRP/ESR measurements were used; if local CRP was not available, central measurements were used.
Pred-26 = 26-week prednisone taper

elevated CRP value. Overall, at least one elevated inflammatory marker (ESR or CRP) measurement was observed in 58.8% and 93.3% of patients receiving MAV and PBO, respectively (nominal p-values: 0.03 for ESR/CRP; < 0.01 for CRP; 0.32 for ESR).

Conclusion: The observed association of CRP and ESR elevation with recurrent GCA signs/symptoms supports the feasibility of a stringent definition of relapse (i.e., characteristic clinical manifestations plus increased inflammatory markers) in GCA clinical trials. The frequency and magnitude of CRP and ESR elevations at relapse were similar in both treatment groups, indicating that CRP and ESR retain their clinical value under GM-CSF blockade therapy. Transient CRP and ESR elevation without relapse, indicating possible subclinical activity, occurred more often in PBO recipients.

SESSION INFORMATION

Session Date: Monday, November 8, 2021

Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster I: Giant Cell Arteritis & Polymyalgia Rheumatica (1391–1419)

Session Type: Poster Session C

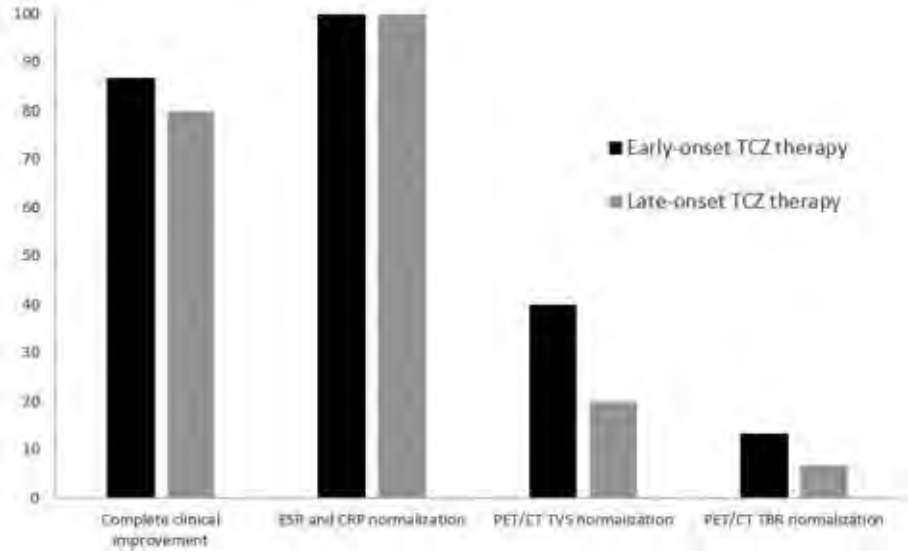
Session Time: 8:30AM–10:30AM

Background/Purpose: Tocilizumab (TCZ) has shown efficacy in large vessel vasculitis (LVV)-Giant Cell Arteritis (LVV-GCA) **(1-2)**. ^{18}F-fluodeoxyglucose positron emission tomography (^{18}F-FDG PET/CT) is useful to assess LVV disease activity **(3-5)**. It is unknown if early treatment with TCZ may have an influence on clinical, laboratory and imaging outcomes. Our aim was to assess clinical, laboratory and PET/CT activity improvement in LVV-GCA patients treated with TCZ according to the time from disease diagnosis to TCZ onset.

Methods: Comparative single-center study of 30 LVV-GCA patients treated with TCZ who were divided into 2 groups depending on the time of onset of TCZ: **a)** early onset (≤ 6 months; n=15) and **b)** late onset (> 6 months; n=15). All patients had a baseline and a follow-up PET/CT scan. Complete clinical improvement and normalization of laboratory markers (CRP ≤0.5mg/dL and/or ESR ≤ 20 mm/1st hour) was assessed. For imaging evaluation, normalization of total visual score (TVS) was considered when TVS = 0 and normalization of semiquantitative activity if the target to background ratio (TBR) at the thoracic aorta was < 1.34.

	Early-onset TCZ therapy (n= 15)	Late-onset TCZ therapy (n=15)	p
General features			
Age (years), mean ± SD	65.8 ± 9.9	65.5 ± 10.1	0.94
Sex (female), n (%)	11 (73.3)	13 (86.7)	0.65
GCA evolution before TCZ onset, median [IQR]	2.0 [1.0-5.0]	18.0 [9.0-34.0]	**< 0.01**
Laboratory			
ESR (mm/1st hour), mean ± SD	34.7 ± 26.3	30.8 ± 28.7	0.70
CRP (mg/dL), median [IQR]	1.1 [0.6-2.3]	0.8 [1.8 -2.5]	0.28
Prednisone dose (mg/day), mean ± SD	10.0 [5.9-15.0]	5.0 [5.0-7.5]	**0.01**
TCZ therapy			
Intravenous, n (%)	10 (66.7)	11(73.3)	0.99
Combined with MTX, n(%)	6 (40)	8 (53.3)	0.46
PET /CT activity			
TBR at thoracic aorta	1.86 ± 0.69	1.54 ± 0.18	0.09
TVS	7.0 [4.0-9.0]	3.0 [2.0-5.0]	**< 0.01**
Complete clinical improvement, n (%)	13 (86.7)	12 (80)	0.99
Normalization of ESR and CRP, n (%)	15 (100)	15 (100)	0.99
PET/CT improvement			
Complete TBR normalization	6 (40)	3 (20)	0.23
Complete TVS normalization	2 (13.3)	1 (6.7)	0.54

CRP: C-reactive protein; ESR: erythrocyte sedimentation rate; TBR: target-to-background ratio. * Normalization of TBR was considered when TBR < 1.34. ** Normalization of TVS was considered when TVS=0.



Results: 30 patients were included (24 women/6 men); mean age 65.7± 9.8 years. Patients in the TCZ early-onset group were receiving higher doses of prednisone (10.0[5.9-15.0] vs 5.0 [5.0-7.5] mg/day; p< 0.01) and had higher TVS scores (7.0 [4.0-9.0] vs 3.0 [2.0-5.0]; p< 0.01) at baseline (**Table**). Following TCZ initiation, after a mean of 10.8±3.7 months, most patients achieved complete clinical improvement and normalization of ESR and CRP in both groups. Uncoupling with imaging outcomes was observed in both groups. Although non-significant statistical differences were observed, complete TBR normalization (TBR < 1.34) and complete TVS normalization (TVS=0) tended to be more frequent in the group ofpatients who received early-onset TCZ therapy (**Figure**).

Conclusion: TCZ was effective in patients with LVV-GCA regardless the time from disease diagnosis to TCZ onset. However, complete normalization of vascular activity in PET/CT scans tended to occur more likely in patients who receive early-onset TCZ therapy within the first 6 months of the disease.

SESSION INFORMATION

Session Date: Monday, November 8, 2021

Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster I: Giant Cell Arteritis & Polymyalgia Rheumatica (1391–1419)

Session Type: Poster Session C

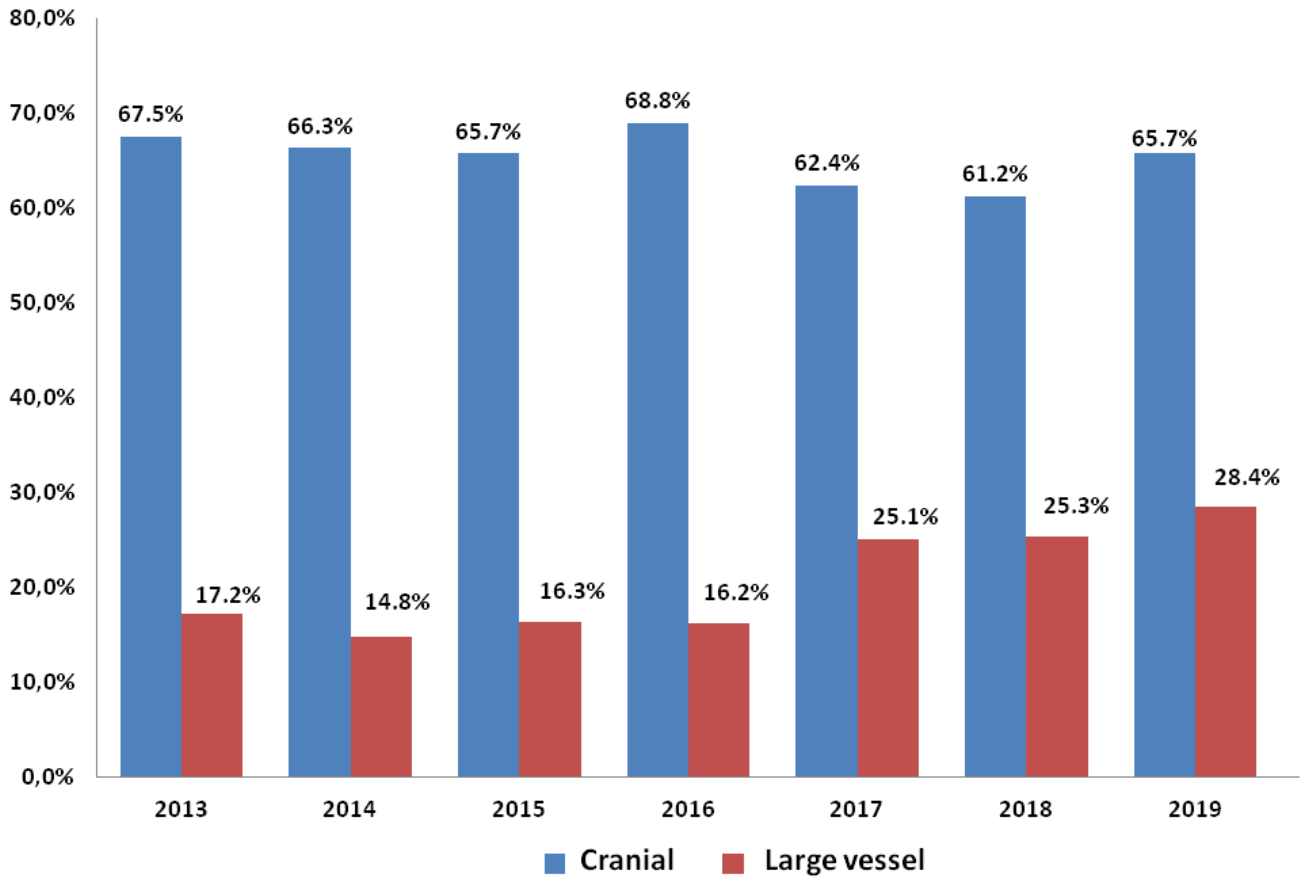
Session Time: 8:30AM–10:30AM

Background/Purpose: Giant cell arteritis (GCA) is the most common systemic vasculitis over 50 years of age. Classically, GCA was assimilated with the involvement of the temporal arteries and a biopsy of these arteries (TAB) was used for its diagnosis. Although the risk of developing aortic aneurysms and large vessel involvement in this disease was well known, the study of the large vessels was not included in the standard diagnosis process. Nowadays, with the incorporation of imaging techniques, the diagnosis of GCA extracranial forms is more and more frequent. The objective of this study was to determine the frequency of cranial and extracranial vessel involvement in our population with GCA.

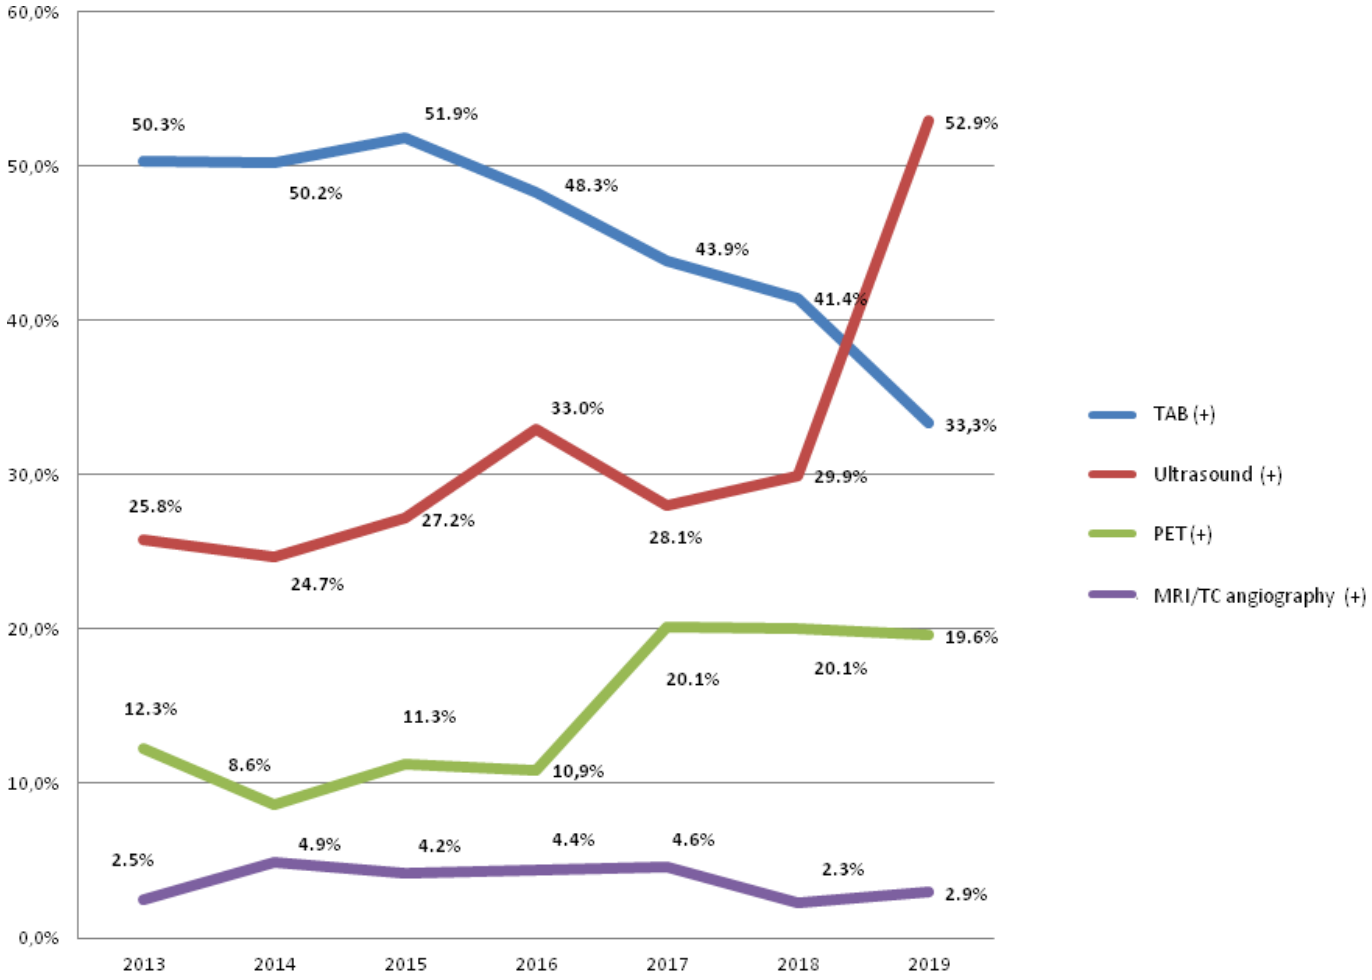
Methods: ARTESER is a multicenter observational retrospective study promoted by the Spanish Society of Rheumatology with 26 participating centers and in which patients diagnosed with GCA between June 1 2013 and March 29 2019 were included. The gold standard for the diagnosis of the disease was the opinion of the responsible physician according to the clinical, analytical, imaging and TAB data available. This analysis includes the data collected from TAB and imaging (ultrasound, PET, and MRI/CT-angiography) as support to classify the patient as having a cranial and/or extracranial GCA subtype.

Results: 1675 patients with GCA were included. Mean age ± SD was 76.9 ± 8.1 years and gender distribution was 1178 (70.3%) women and 497 (29.7%) men. From the data collected, it was found that 1091 patients had cranial involvement, 331 extracranial involvement and 170 patients had mixed involvement (cranial and extracranial). The Figure 1 shows how the frequency of extracranial involvement has increased in recent years, coinciding with the increase of the use of imaging tests in diagnosis. The Figure 2 shows how the ultrasound diagnosis increased from 25.8% in 2013 to 52.9% in 2019, and PET increased from 12.3% in 2013 to 19.6% in 2019. TAB was performed in the 46.3% of the patients and contributed to the diagnosis of cranial forms. Since imaging tests were not performed in all patients, and that the increase in their use is directly related with the increase in the diagnosis of forms with extracranial large vessel involvement, it is likely that the frequency of large vessel GCA increases by the next years. As a limitation, it should be noted that the subtype of vascular involvement was not detailed in 253 patients.

Conclusion: The forms with cranial involvement are the most frequent in GCA. The diagnosis of large vessel GCA has increased in recent years in direct relation to the increase in the diagnostic use of imaging tests. The diagnosis of extracranial vessel involvement it is likely to increase in the coming years.



Evolution of GCA subtypes cranial and extracranial along the time



GCA: Temporal evolution of diagnostic tests

Session Date: Monday, November 8, 2021

Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster I: Giant Cell Arteritis & Polymyalgia Rheumatica (1391–1419)

Session Type: Poster Session C

Session Time: 8:30AM–10:30AM

Background/Purpose: Advancing age, female sex and white race are well-known risk factors for development of giant cell arteritis (GCA). Recent studies suggest that certain metabolic features such as lower fasting blood glucose (FBG) may predispose to GCA. However, risk factors for development of GCA remain incompletely understood. We aimed to assess the frequency of comorbidities and metabolic risk factors at, and prior to, onset of GCA.

Methods: We conducted a retrospective case-control study of patients diagnosed with incident GCA in a geographically defined population from 01/01/2000 till 12/31/2019. Two age- and sex-matched controls were identified for every GCA case and assigned an index date corresponding to the incidence date of GCA. Twenty-five chronic conditions from either the Charlson, Elixhauser, or Rheumatic Disease Comorbidity Index were identified using ICD-9 diag-

nosis codes within a two-year lookback period; 2 or more codes ≥30 days apart were used to define a comorbidity. Prevalence of comorbidities, clinical and laboratory data among cases and controls were compared at incidence date and 5 years prior. Subjects with less than one year of diagnosis history were excluded from each analysis. Medical records of all subjects were manually abstracted for comorbidities and laboratory data at incidence date, at 5 years, and at 10 years prior to incidence date. Comparisons were performed using Chi square, Fisher exact, or t-tests.

Results: The cohort included 129 patients with GCA (74% female, mean age at diagnosis 77 years) and 253 controls (Table 1). At GCA incidence/index date, the prevalence of diabetes mellitus (DM) was lower in patients with GCA (5% vs 17%; p=0.001) while that of other comorbidities was similar in cases and controls. At 5 years prior to incidence/index date, cases had a lower prevalence of DM (2% vs 13%; p< 0.001) and hypertension (HTN) (27% vs 45%; p=0.002) as compared to controls. The mean number (SD) of comorbidities at 5 years prior to incidence/index date was lower [0.7 (1.0)] in cases than controls [1.3 (1.4)] (p< 0.001) (Table 1).

Moreover, at 5 years prior to incidence/index date, cases had a significantly lower median FBG (96 vs 104 mg/dL; p < 0.001) and body mass index (BMI) (25.8 vs 27.7 kg/m^2; p-value=0.019) as compared to controls. At 10 years prior to the incidence/index date, the median FBG among cases was also lower (93 vs 98 mg/dL; p=0.002), although BMI was not significantly different at this time point. On the other hand, total cholesterol (median 211 vs 201 mg/dL; p=0.036), low-density lipoprotein (123 vs 112 mg/dL; p=0.043), and high-density lipoprotein (62 vs 57 mg/dL; p=0.032) were higher among cases compared with controls at 5 years prior to incidence/index date, and no different at 10 years prior. (Table 2).

Conclusion: Development of GCA was associated with a lower prevalence of DM and HTN, and lower total number of comorbidities, at 5 years prior to incidence date. FBG and BMI were also lower among individuals who later developed GCA, suggesting that metabolic factors influence the risk of GCA. Future studies to elucidate the pathomechanisms underlying these observations are warranted.

SESSION INFORMATION

Session Date: Monday, November 8, 2021

Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster I: Giant Cell Arteritis & Polymyalgia Rheumatica (1391–1419)

Session Type: Poster Session C

Session Time: 8:30AM–10:30AM

Background/Purpose: Giant cell arteritis (GCA) may be divided into cranial, and extracranial GCA phenotypes. Tocilizumab (TCZ) has shown efficacy and safety in GCA.

Our aim was to compare the efficacy of TCZ in cranial and extracranial phenotypes of GCA.

Methods: Multicenter observational study of 471 patients with GCA treated with TCZ. Patients were divided into 3 groups: **a)** exclusively cranial involvement (cGCA), **b)** exclusively extracranial involvement (ecGCA) and **c)** mixed involvement (mixGCA). GCA was diagnosed by: **a)** ACR criteria and/or **b)** temporal artery biopsy and/or **c)** imaging

TABLE. Main features of the 471 GCA patients at TCZ onset.

	Overall (n=471)	cGCA (n=217)	ecGCA (n=80)	mixGCA (n=174)	Cranial vs Extracranial GCA p
Main features					
Age at TCZ onset, years, mean± SD	74±9	76±8	68±10	73±8	**0.000***
Sex, women/men, n (% women)	342/129 (73)	156/61 (72)	60/20 (75)	126/48 (72)	0.699
Time from diagnosis to TCZ onset (months, median [IQR]	6 [2-18]	5 [2-17]	5 [2-15.5]	9 [3-24]	0.699

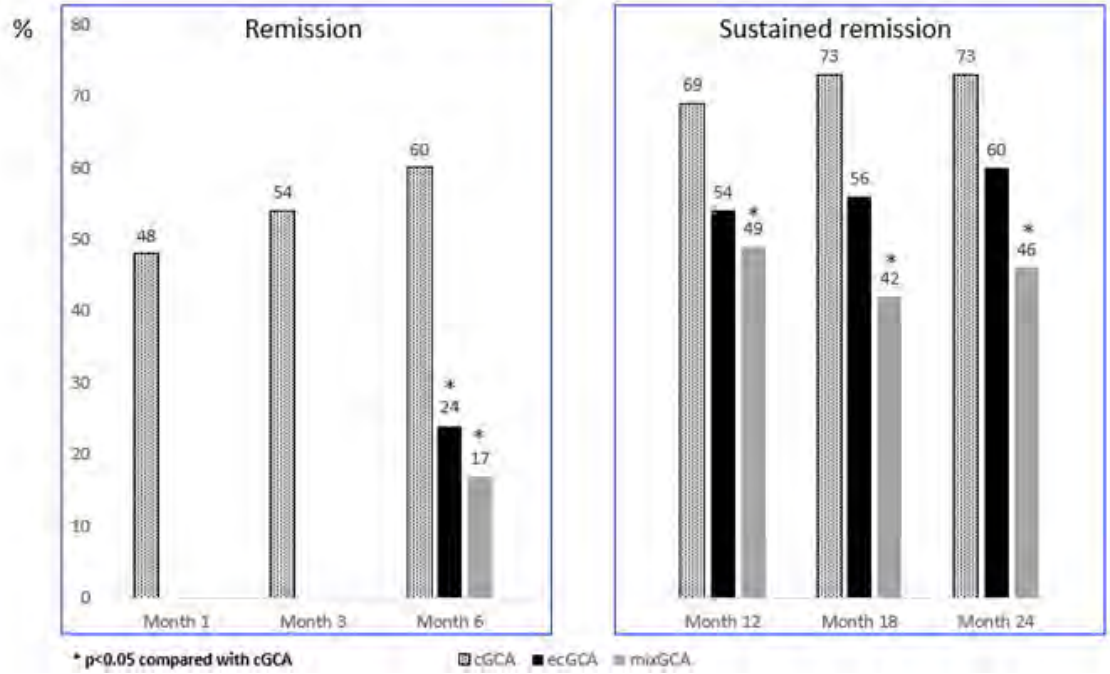
TCZmono/TCZcombo, n (% TCZ mono)	353/118 (75)	176/41 (81)	51/29 (64)	126/48 (72)	**0.003***
Follow-up (months), mean ± SD	25.3±21.7	24.5±19.6	26.4±21.4	25.8±24.2	0.613

Abbreviations: CRP: C-reactive protein; ESR: erythrocyte sedimentation rate, GCA: giant cell arteritis, IQR: interquartile range, PmR: polymyalgia rheumatica; SD: standard deviation, TCZcombo: tocilizumab in combination with synthetic immunosuppressants (besides corticosteroids), TCZmono: tocilizumab in monotherapy (besides corticosteroids)

FIGURE. Remission and sustained remission of ecGCA and mixGCA according to EULAR recommendations. In the first 3 months we only could assess cGCA because in most patients with ecGCA and mixGCA a control imaging test was not performed.



tests. Remission and sustained remission were defined according to EULAR definitions. In ecGCA and mixGCA we also assessed improvement (complete or partial) by imaging techniques.

Results: We studied 471 patients (342 women/129 men; mean age: 74±9 years). **TABLE** shows the main characteristics of the 3 groups. Remission at 6 months was observed in a higher number of patients with cGCA, as well as the sustained remission at 12, 18 and 24 months **(FIGURE)**. Partial/complete improvement by imaging techniques at 6, 12, 18 and 24 months was 67%/17%, 58%/19%, 63%/16% and 56%/33%, respectively in ecGCA, and 81%/12%, 57%/29%, 85%/11% and 73%/13% in mixGCA.

Conclusion: TCZ seems to be more effective in the cGCA phenotype. Improvement by imaging techniques was partial and rarely complete in ecGCA and mixGCA.

SESSION INFORMATION

Session Date: Monday, November 8, 2021

Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster I: Giant Cell Arteritis & Polymyalgia Rheumatica (1391–1419)

Session Type: Poster Session C

Session Time: 8:30AM–10:30AM

Background/Purpose: Epidemiological information on Giant Cell Arteritis (GCA) comes mainly from the Scandinavian countries of northern Europe, which show a higher incidence than the countries of southern Europe. GCA clinical manifestations can be divided into cranial, extracranial, and general syndrome.

In a large series of GCA from Spain, we studied **a)** the incidence of GCA, **b)** clinical manifestations, and **c)** comorbidities at the time of disease diagnosis.

Methods: ARTESER is a retrospective epidemiological observational study of GCA promoted by the Spanish Society of Rheumatology in which 26 hospitals participate. The inclusion criteria were: all new patients diagnosed with GCA by a) ACR criteria, b) positive diagnostic test (temporal artery biopsy, temporal artery ultrasound or other relevant imaging techniques) and/or c) investigator's clinical judgment. The patient recruitment period ranged from June 1, 2013 to March 29, 2019. The overall incidence of GCA per 100,000 people ≥50 years for the whole period and the mean annual incidence were evaluated. The clinical variables were collected by reviewing the patient's medical history.

Results: 1675 patients were included. The average annual incidence rate was 7.42 (95% CI: 6.57-8.27). All the cases were older than 50 years, and the age group with the highest incidence was that of 80 to 84 years, where it reached a value of 130.12 (95% CI: 126.71-133.54). The mean annual incidence is higher in women than in men 10.06 (95% CI: 8.7-11.5) vs 4.83 (95% CI 3.8- 5.9) (**Table 1**).

The description of the population is shown in **Table 2**, the mean age at diagnosis was 76.9±8.1 years, 1178 (70.3%) were women. ACR criteria were met by 1400 (83.6%) patients and an objective diagnostic test by 1258 (75.1%). The

Low-grade fever or fever, n (%)	113 (22.7)	254 (21.6)	367 (21.9)
Analysis at diagnosis			
Erythrocyte sedimentation rate mm/h, years, mean (SD)	72.3 (34.7)	77.4 (33.0)	75.9 (33.6)
Hemoglobin, g/dl, years, mean (SD);	12.3 (1.8)	11.6 (1.5)	11.9 (1.6)
Platelets, x 10^2/L, years, mean (SD)	302.3 (144.3)	337.0 (192.5)	326.6 (180.0)
Alkaline phosphatase, IU/L, years, mean (SD)	109.8 (92.6)	112.3 (97.3)	111.5 (95.9)
Alanine transaminase, IU/L, years, mean (SD)	24.6 (18.9)	21.4 (21.8)	22.4 (21.0)
Aspartate transaminase, IU/L, years, mean (SD)	23.0 (15.7)	21.5 (17.5)	21.9 (17.0)

more frequent comorbidity was arterial hypertension (n=1079; 64.6%), followed by dyslipidemia (n=801, 48%). The predominant cranial manifestation was headache, (n= 1337; 79.9%) and 605 patients experienced visual symptoms (36.1%). Polymyalgia rheumatica (n=699; 41.8%) and asthenia (n=837; 52.2%) were the most frequent extracranial and general syndrome manifestation, respectively. Regarding laboratory parameters, the most characteristic data was the increase of ESR (75.9±33.6 mm/1st h).

Conclusion: The mean annual incidence of GCA in Spain, 7.42 (95% CI: 6.57-8.27), is lower than that of the Scandinavian countries. It is higher in people older than 80 years. Cranial manifestations constituted the most clinical features. The most frequent clinical manifestations are cranial. Up to a third of patients had visual manifestations.

Characterization of Synovial Fluid T Cells in Polymyalgia Rheumatica: Implication of Th1 and Tc1 Effector Memory Profiles

Rosanne Reitsema[1], Lieske Wekema[2], Wayel Abdulahad[1], Peter Heeringa[3], Minke Huitema[1], Maria Sandovici[3], Annemieke Boots[3], Elisabeth Brouwer[3] and Kornelis van der Geest[3], [1]Department of Rheumatology and Clinical Immunology, University of Groningen, University Medical Center Groningen, Groningen, Netherlands, [2]Department of Pathology and Medical Biology, University of Groningen, University Medical Center Groningen, Groningen, Netherlands, [3]University Medical Center Groningen, Groningen, Netherlands

SESSION INFORMATION

Session Date: Monday, November 8, 2021

Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster I: Giant Cell Arteritis & Polymyalgia Rheumatica (1391–1419)

Session Type: Poster Session C

Session Time: 8:30AM–10:30AM

Background/Purpose: Polymyalgia Rheumatica (PMR) is a common rheumatic inflammatory disease in the elderly. PMR is characterized by synovial inflammation of (peri)articular structures in the shoulders and hips. Patients are treated with glucocorticoids. Targeted treatments are lacking since little is known about the synovial pathobiology of PMR. We aim to investigate the phenotype and function of various T cell subsets in blood and synovial fluid of patients with PMR.

Methods: Blood samples were obtained from 18 newly diagnosed PMR patients before treatment, and 36 age- and sex-matched healthy controls. In addition, paired blood and bursal synovial fluid (subacromial-subdeltoid bursa, subscapular bursa) or tenosynovial fluid (biceps long head) samples were collected from 9 patients with active PMR. The following T cell subsets were identified by flow cytometry: T naive (CD45RO-CCR7+), central memory (CD45RO+CCR7+), effector memory (CD45RO+CCR7-), effector memory re-expressing CD45RA (CD45RO-CCR7-) cells and CD28null senescent cells. Expression of intracellular cytokines (IL-17A, IFN-γ, IL-4) was determined at 4 hours after stimulation with PMA/calcium ionophore.

Results: The frequencies of all major T cell subsets were similar in the blood of patients with PMR and healthy controls. Synovial fluid of patients with PMR was enriched with effector memory CD4+ and CD8+ T cells, whereas the

percentage of CD28null senescent CD8+ T cells was lower in the synovial fluid than in blood. Synovial fluid T cells demonstrated a capacity to produce IFN-γ rather than IL-17 or IL-4.

Conclusion: Synovial fluid T cells in PMR show a non-senescent effector memory phenotype with the capacity to produce IFN-γ, a Th1/Tc1 type cytokine. Our study provides first insights into T cell populations at the site of inflammation in patients with PMR.

SESSION INFORMATION

Session Date: Monday, November 8, 2021

Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster I: Giant Cell Arteritis & Polymyalgia Rheumatica (1391–1419)

Session Type: Poster Session C

Session Time: 8:30AM–10:30AM

Background/Purpose: Glucocorticoids (GC) are the mainstay therapy in Giant Cell Arteritis (GCA), initially at high doses (40-60 mg/day) followed by gradual glucocorticoid tapering. This treatment, especially in older patients, is associated with numerous adverse effects (AE). In addition, there are frequent relapses. Therefore, conventional synthetic immunosuppressants such as methotrexate (MTX), leflunomide, azathioprine, cyclophosphamide or my-

cophenolate, have been used with controversial results. Studies with biological immunosuppressants, such as TNFi have been ineffective; in contrast, tocilizumab (TCZ) has obtained positive results and was approved for the treatment of GCA.

In the ARTESER study we describe **a)** treatment with GC, synthetic or biological immunosuppressants and concomitant treatments; **b)** AE of CG; and **c)** evolution.

Methods: ARTESER is a retrospective observational study sponsored by the Spanish Society of Rheumatology. 26 Spanish centers participated and all new patients diagnosed with GCA from June 1, 2013 to March 29, 2019 were included. Data on GC and immunosuppressants were collected at the beginning and during the follow-up of GCA patients. For the calculation of the cumulative dose of GC, an application was developed that, by including the periods of time, dose and type of GC received during follow-up, performs the automatic calculation in mg of prednisone.

Results: Of the 1675 patients included, GC treatment was adequately recorded in 1650 patients **(Table 1)**. All received oral treatment, being prednisone the most frequently drug used (N=1602, 97.09%). In addition, 426 (25.82%) patients received at least one iv pulse of methylprednisolone, being the 1000 mg regimen the most frequent (n=217; 50.9%). The total mean duration of GC treatment was 22.65 months. The mean cumulative dose per patient at the end of follow-up was 8514.98 mg of prednisone.

The most prescribed concomitant treatment at the time of diagnosis of GCA was calcium (n=1281, 76.9%), vitamin D (n=1258, 75.6%) and bisphosphonates (n=831, 50.1%). The most widely used immunosuppressant was MTX both at diagnosis (n=165; 9.9%) and during follow-up (n=532; 31.8%), followed by TCZ, at diagnosis (22; 1.3%) and at follow-up (153; 9.1%).

AE with GC were described in 393 patients (23.8%), highlighting serious infections (n=67; 10.03%) followed by diabetes mellitus (n=63; 9.43%), steroid myopathy (n=53; 7.9%), vertebral fractures (n=47; 7.04%), non-vertebral fractures (n=36; 5.39%), heart failure (n=36; 5.39%), arterial hypertension (n=34; 5.09%) and neuropsychiatric alterations (n=27; 4.04%).

During the follow-up, 334 (19.9%) patients had relapses, 532 (31.8%) were hospitalized on some occasion, and 142 patients (8.48%) died. The main cause of death were infections (n=44; 30.99%), neoplasms (n=23; 16.2%), cardiovascular (n=15; 10.56%), and cerebrovascular (n=10; 7.04%).

Table 1. Corticosteroid treatment

Table 1. Corticosteroid treatment	
Patients taking oral corticosteroid	1650
Prednisone, n (%)	1602 (97.09)
Methylprednisolone, n (%)	164 (9.94)
Deflazacort, n (%)	64 (3.88)
Patients receiving intravenous corticosteroid, n (%)	426 (25.82)
Patients receiving pulses n (%)	426
125 mg pulse	52 (12.2)
250 mg pulse	65 (15.3)
500 mg pulse	130 (30.5)
1000 mg pulse	217 (50.9)
Mean duration of steroid treatment, mean (SD)	22.65 (17.36)
Mean cumulative dose at the end of follow-up per patient, mg of prednisone, mean (SD)	8514.98 (6570.21)

Table 2. Immunosuppressant and concomitant treatments

Table 2. Patients with immunosuppressive treatment at diagnosis *(no more than 30 days have passed between the diagnosis of GCA and the start of treatment)*	
Methotrexate, n (%)	165 (9.9)
Leflunomide, n (%)	2 (0.1)
Azathioprine, n (%)	3 (0.2)
Cyclophosphamide, n (%)	7 (0.4)
Mycophenolate, n (%)	1 (0.1)
Tocilizumab, n (%)	22 (1.3)
Patients with immunosuppressive treatment during follow-up	
Methotrexate, n (%)	532 (31.8)
Leflunomide, n (%)	19 (1.2)
Azathioprine, n (%)	26 (1.5)
Cyclophosphamide, n (%)	10 (0.6)
Mycophenolate, n (%)	10 (0.6)
Tocilizumab, n (%)	153 (9.1)
Patients with treatments concomitant to diagnosis	
Aspirin prior to diagnosis, n (%)	313 (18.8)
Aspirin initiation after diagnosis, n (%)	585 (35.4)
Calcium initiation after diagnosis, n (%)	1281 (76.9)
Initiation of Vitamin D after diagnosis, n (%)	1258 (75.6)
Bisphosphonate initiation after diagnosis, n (%)	831 (50.1)

Conclusion: The main treatment for GCA was oral GC, which were required for almost two years on average, in a quarter of patients associated with IV pulses. The cumulative steroid dose was high as well as the side effects. MTX was the most widely used immunosuppressant and TCZ was prescribed in 10%. Relapses and admissions at the hospital were relatively frequent.

Clinical Features at Disease Onset of Different Subsets of Large-vessel-giant Cell Arteritis in a Monocentric Cohort of 100 Patients

Francesca Regola[1], Giovanni Bosio[2], Laura Andreoli[3], Franco Franceschini[1] and Paola Toniati[1], [1]Rheumatology and Clinical Immunology Unit, ASST Spedali Civili and University of Brescia, Brescia, Italy, [2]Nuclear Medicine Unit, ASST Spedali Civili of Brescia, Brescia, Italy, [3]University of Brescia, Brescia, Italy

SESSION INFORMATION

Session Date: Monday, November 8, 2021

Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster I: Giant Cell Arteritis & Polymyalgia Rheumatica (1391–1419)

Session Type: Poster Session C

Session Time: 8:30AM–10:30AM

Background/Purpose: Giant Cell Arteritis (GCA) is the most frequent systemic vasculitis in patients older than 50 years involving medium-sized and large arteries. Inflammation of the extracranial branches of the carotid artery gives rise to the classic symptoms of GCA. However, GCA involves also the aorta and its major branches in almost two-thirds of patients (1,2). Large vessel involvement leads to a different atypical clinical picture which can be challenging to diagnose (3). More information on clinical presentation and vessel involvement in large-vessel GCA are needed to better diagnose it. The aim of this study is to analyze a large cohort of GCA comparing patients with large-vessel involvement to patients with classical cranial disease.

Methods: 100 consecutive patients with a clinical diagnosis of GCA were enrolled in this retrospective study. All patients were older than 50 years of age, met the ACR criteria for GCA (4) or had a positive temporal artery biopsy or evidence of large vessel vasculitis at FDG-PET/CT scan.

Results: Based on vascular involvement, patients were classified into three group: 61 patients with only cranial arteritis (C-GCA), 16 patients with only extracranial large vessel vasculitis (LV-GCA) and 23 patients with both cranial and large vessel involvement (LV-C-GCA).

	GCA (n: 100)	C-GCA (n: 61)	LV-C-GCA (n: 23)	LV-GCA (n: 16)	*p*
Age: median (IQR)	76 (67-79)	75 (71-80)	74 (69-77)	63 (59-72)	0.001

New temporal headache	77 (77%)	58 (95%)	19 (83%)	0 (0%)	<0.001
Visual symptoms	39 (39%)	34 (56%)	5 (22%)	0 (0%)	<0.001
Jaw or tongue claudication	35 (35%)	27 (44%)	8 (35%)	0 (0%)	0.004
Fever	48 (48%)	23 (38%)	14 (61%)	11 (69%)	0.032
Fatigue	75 (75%)	40 (66%)	21 (91%)	14 (88%)	0.023
Weight loss	52 (52%)	28 (46%)	13 (57%)	11 (69%)	0.235
Polymyalgia rheumatica	43 (43%)	27 (44%)	13 (57%)	3 (19%)	0.061
Arm or leg claudication	5 (5%)	0 (0%)	4 (17%)	1 (6%)	0.005
CRP (C-reactive protein)	83 (45-127)	77 (39-115)	89 (50-134)	95 (20-124)	0.461
ESR (erythrocyte sedimentation rate)	72 (47-96)	70 (46-88)	75 (28-105)	66 (44-91)	0.711
Cranial arteries	84 (84%)	61 (100%)	23 (100%)	0 (0%)	<0.001
Carotid arteries	19 (19%)	0 (0%)	12 (52%)	7 (44%)	<0.001
Subclavian and upper limb arteries	21 (21%)	0 (0%)	10 (43%)	11 (69%)	<0.001
Thoracic aorta	29 (29%)	0 (0%)	15 (65%)	14 (88%)	<0.001
Abdominal aorta	21 (21%)	0 (0%)	10 (43%)	11 (69%)	<0.001
Iliac and inferior limb arteries	10 (10%)	0 (0%)	6 (26%)	4 (25%)	<0.001

Compared to C-GCA, patients with large vessel involvement (LV-GCA and LV-C-GCA) were younger and more frequently women, and the difference was further significant for patients with isolated LV-GCA. Patients with isolated LV-GCA had also the longer duration of symptoms at GCA diagnosis [LV-GCA 20(16-82) vs LV-C-GCA 12(4-16) vs C-GCA 4(3-12) weeks; p< 0.001]. Systemic symptoms, as fever and fatigue, were associated with large vessel involvement, both in LV-GCA and LV-C-GCA groups. Polymyalgia rheumatica was equally reported in all three groups and no significant differences were found in inflammatory markers levels according to vessel involvement. In patients with large vessels involvement (LV-GCA and LV-C-GCA) thoracic aorta, subclavian arteries and abdominal aorta were the most frequently involved arteries.

Conclusion: GCA is not a single entity but includes several patterns of disease. Female gender, younger age and systemic symptoms are associated with large vessel involvement, regardless the presence or absence of cranial symptoms. The different clinical manifestations of large vessel GCA lead to a longer time to diagnosis if compared to C-GCA. For these reasons, in patients with the aforementioned characteristics, a large vessel involvement should be considered in order to reduce the time to diagnosis.

Predictors of Relapse in Giant-Cell Arteritis: A Retrospective Single Center Analysis

Kathleena D'Anna[1], David Lim[2], Lorena Salto[1] and Mehrnaz Hojjati[1], [1]Loma Linda University Health, Loma Linda, CA, [2]Loma Linda University Health, Redlands, CA

SESSION INFORMATION
Session Date: Monday, November 8, 2021
Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster I: Giant Cell Arteritis & Polymyalgia Rheumatica (1391–1419)
Session Type: Poster Session C
Session Time: 8:30AM–10:30AM

Background/Purpose: Giant Cell Arteritis (GCA) is the most common systemic vasculitis in North America, typically affecting Caucasian female adults over 50 years of age. Flares and relapses requiring increased and prolonged steroidal medication remains a common trend in patients with GCA. The adverse effects of steroid therapy, and the morbidity and mortality associated with relapsing GCA, is well described however, predictors of relapse remains an understudied area.

Methods: A retrospective chart analysis was performed on 400 patients with an associated ICD10 code diagnosis of GCA seen at Loma Linda University Health from 2013 to 2020. 60 patients were identified with confirmed diagnosis of GCA based on either a positive temporal artery biopsy or meeting the ACR 1990 GCA classification criteria confirmed by a Rheumatologist. We used Pearson's chi-square to test for independence between demographic, clinical categorical variables, and relapse status. We then used logistic regression to model the relapse binary outcome regressed on permanent vision loss, new onset headache, fever, anterior ischemic optic neuritis, abnormal vascular ultrasound, and pulse steroid as predictor variables. We set alpha equal to 0.05 for statistical significance.

Table 1. Demographic and Comorbid Conditions

	All	Relapse, n=37	No Relapse, n=23	*p*-value[a]
Gender, % (*n*)				
Male	14	16.2% (6)	34.8% (8)	0.098
Female	46	83.8% (31)	65.2% (15)	
BMI, kg/m^2, mean ± SD	60	29.35 ± 7.37	27.19 ± 6.62	0.606
Age, years, mean ± SD	60	71.62 ± 10.32	71.35 ± 10.29	0.97
Ethnicity, % (*n*)				
Caucasian	31	59.5% (22)	39.1% (9)	
Asian	6	10.8% (4)	8.7% (2)	
African American/Black	5	8.1% (3)	8.7% (2)	
Hispanic/Latino	18	21.6% (8)	43.5% (10)	
Delay in treatment >3 months	4	8.1% (3)	4.3% (1)	0.57
Comorbid Conditions at Diagnosis				
Cerebrovascular Accident	7	85.7% (6)	14.3% (1)	0.154
Coronary Artery Disease	20	70% (14)	30% (6)	0.311
Hyperlipidemia	29	75.9% (22)	24.1% (7)	0.029
Diabetes Mellitus	29	75.9% (22)	24.1% (7)	0.029
Hypertension	44	63.6% (28)	36.4% (16)	0.603
Anticoagulation Use	8	62.5% (5)	37.5% (3)	0.989
History of Smoking	20	65%(13)	61.5% (24)	0.79
Obesity	21	71.4% (15)	28.6% (6)	0.25

Percentages are estimated across rows and may not add to one-hundred due to rounding.

[a]*p*-value based on the chi-square statistic for categorical variables. Data shown for rows displays only yes category values.

Results: A total of 60 patients were included, of which 46 were female, with an average age of 71 years old and BMI of 28. In our cohort, relapse was defined as an increase in prednisone dose by ≥10 mg for at least two weeks within the first 12 months of GCA diagnosis.

Overall, Caucasians had a higher rate of relapse when compared to other ethnicities, other demographic information was similar between the two groups (Table 1). We found that Hyperlipidemia (HLD), Diabetes Mellitus (DM), and the use of pulse steroids were not independent of relapse status. Those with HLD were more likely to relapse compared to those without HLD (p=0.029). The same outcomes were seen in DM (Table 1). We noted that a higher proportion of patients who relapsed were also those who did not receive pulse steroids (p=0.039) (Table 3). Furthermore, the use of pulse steroids at the time of diagnosis decreased the odds of relapse in this group of patients [OR 0.325 (95% CI 0.110, 0.961)].

Those in the relapse group also had a higher proportion of Cerebrovascular Accidents, Coronary Artery Disease, Hypertension, Obesity, elevated creatinine, and were on anticoagulation treatment at the time of diagnosis. A higher proportion of the relapse group presented with new onset headache, jaw claudication, scalp ischemia, facial pain/ trigeminal neuralgia, and fever (Table 1). In addition, this group were more likely to have been diagnosed via positive temporal artery biopsy (Table 3).

Table 2. Initial Presentation, Laboratory, and Imaging data

	All	Relapse, n=37	No Relapse, n=23	*p*-value[a]
Initial Presentation at Diagnosis				
New Onset headache	52	61.5% (32)	38.5% (20)	0.96
Abnormal Temporal Artery	19	57.9% (11)	42.1% (8)	0.682
Scalp Ischemia	9	77.8% (7)	22.2% (2)	0.26
Facial Pain/Trigeminal neuralgia	23	65.2% (15)	34.8% (8)	0.69
Jaw Claudication	22	63.6% (14)	36.4% (8)	0.811
PMR symptoms	39	56.4% (22)	43.6% (17)	0.254
Unintentional Weight Loss	13	61.5% (8)	38.5% (5)	0.96
Fever (T>100.4)	16	75% (12)	25% (4)	0.2
Anterior Ischemic Optic Neuritis	21	52.4% (11)	47.6% (10)	0.31
Permanent Vision Loss	22	59.1% (13)	40.9% (9)	0.75
Transient Vision Changes	20	65% (13)	35% (7)	0.71
Laboratory Data at Presentation				
Elevated ESR	50	58% (29)	42% (21)	0.361
Elevated CRP	51	56.9% (29)	43.1% (22)	0.099
Elevated Creatinine	6	83.3% (5)	16.7% (1)	0.25
Elevated IL6	12	58.3% (7)	41.7% (5)	0.831
Elevated Liver function tests	9	55.6% (5)	44.4% (4)	0.68
Elevated Alkaline Phosphatase	4	25% (1)	75% (3)	0.19
Anemia	11	36.4% (4)	63.6% (7)	0.06
Elevated Platelet count	5	60% (3)	40% (2)	0.94
Elevated WBC count	12	41.7% (5)	58.3% (7)	0.11
Imaging				
Main Aortic Branch Stenosis on CT	7	42.9% (3)	57.1% (4)	0.28
Temporal/Axillary Ultrasound				
Positive Halo Sign	6	50% (3)	50% (3)	0.54
Negative	54	63% (34)	37% (20)	

Percentages are estimated across rows and may not add to one-hundred due to rounding.
[a]*p*-value based on the chi-square statistic for categorical variables. Data shown for rows displays only yes category values not complete chi-square table.

Conclusion: In our cohort, we found patients with comorbidities such as HLD and DM, as well as patients who did not receive pulse steroids were more likely to relapse within the first 12 months of GCA diagnosis. A few clinical manifestations at the time of diagnosis were associated with higher rates of relapse. Our findings suggest certain clinical manifestations and patient comorbidities may provide meaningful insight in relapse prediction. Larger scale studies are required to replicate our findings.

Table 3. Modality of Diagnosis, Steroid use

	All	Relapse, n=37	No Relapse, n=23	*p*-value[a]
Modality of Diagnosis				
Clinical	39	56.4% (22)	43.6% (17)	0.25
Biopsy	21	71.4% (15)	28.6% (6)	
Pulse Steroids				
Yes	29	48.3% (14)	51.7% (15)	0.039
No	31	74.2% (23)	25.8% (8)	

Percentages are estimated across rows and may not add to one-hundred due to rounding.

[a]*p*-value based on the chi-square statistic for categorical variables.

Decreased Use of Ultrasound Fast-track Pathways of Giant Cell Arteritis Due to COVID-19 Pandemic: A Potential Risk for Permanent Visual Loss

Fernando Montero[1], Juan Molina[2], ISABEL CASTREJON[3], Julia Martínez Barrio[1], Juan Carlos Nieto[1] and Jose Maria Alvaro-Gracia[1], [1]Hospital General Universitario Gregorio Marañón, Madrid, Spain, [2]Hospital General Universitario Gregorio Maran, Madrid, Spain, [3]Pfizer Spain, Chicago

SESSION INFORMATION

Session Date: Monday, November 8, 2021

Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster I: Giant Cell Arteritis & Polymyalgia Rheumatica (1391–1419)

Session Type: Poster Session C

Session Time: 8:30AM–10:30AM

Background/Purpose: The implementation of ultrasound (US) fast-track pathways (FTP), aiming at an early diagnosis of giant cell arteritis (GCA), has led to a decrease in permanent vision loss. However, the COVID-19 pandemic lock-down has had a negative impact in GCA patients, leading to a decline in referral rates of patients accompanied by cases with delayed presentation and vision loss.

The aim of our analysis was to assess the rate of US examinations included in our FTP and the rate of permanent visual loss due to GCA since the COVID-19 pandemic.

Methods: Retrospective observational study including patients referred to our US FTP for evaluation of possible GCA over a 16-month period. Visual loss due to anterior ischemic optic neuropathy (AION) confirmed by ophthalmology evaluation was checked. The gold standard for GCA diagnosis was the clinical confirmation after 6-months of follow-up. We compared the 8-month pre- and post- COVID-19 outbreak periods (July 2019 to February 2020 and March 2020 to October 2020).

Results: Since the beginning of the COVID-19 pandemic, 31 patients were referred to the FTP compared with 50 patients in the previous 8-months (38% reduction), although the service was regularly operating. The number of newly GCA diagnosis during the COVID-19 pandemic remained similar, although the percentage over the total examinations was higher (45.2% vs 22%; p=0.028). We found no notable differences in clinical referral patterns. However, it is note-

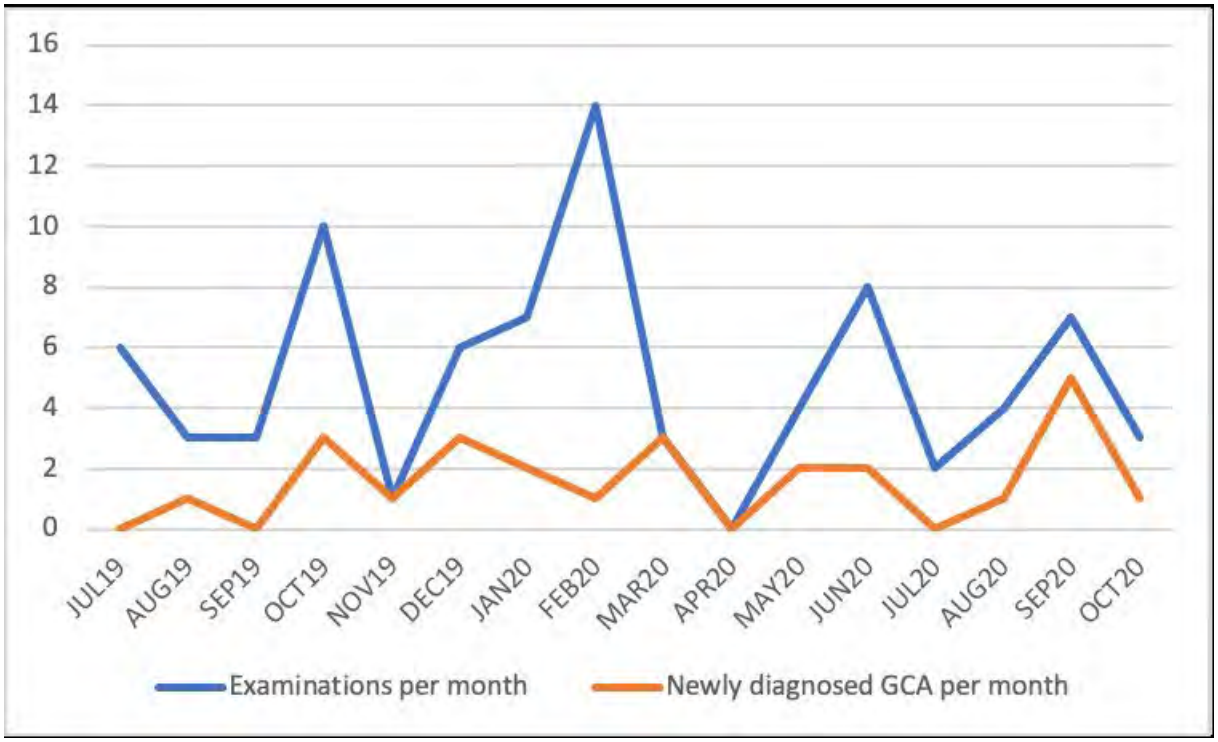

Figure 1. Number of patients evaluated in the fast-track pathway and number of newly GCA diagnosis over the study period.

worthy that 2 patients presented with AION during the COVID-19 pandemic, while noN AION in the previous period, although these differences were not statistically significant (p=0.14). During confinement, patients referred to the FTP presented higher C-reactive protein (7.6 vs 3.4 mg/dL; p=0.008), erythrocyte sedimentation rate (73.9 vs 45.7mm/h; p=0.02), platelets (342.1 vs 254.1 10^9/L; p=0.001) and lower hemoglobin levels (11.7 vs 12.8 g/dL; p=0.019). We found that the halo and compression sign were more frequently found during the COVID-19 pandemic (38.7 vs 16%; p=0.021 and 25.8 vs 10%; p=0.06, respectively). It is also worth highlighting a higher proportion of positive temporal artery biopsy during the COVID-19 pandemic (50% vs 33% p=0.049).

Conclusion: Our data shows a reduction in utilization of GCA FTP since the COVID-19 outbreak and an increase of possibly preventable AION. US FTP has demonstrated to be useful in the reduction of permanent vision loss (1,4), so an impaired use of this tool may lead to worse outcomes. Our results go in line and confirm previous work that noticed a reduction in the requests for FTP assessments by May 2020 (3) . Although a higher proportion of patients referred to the FTP had GCA, the number of newly diagnosed GCA remained similar before and after the COVID-19 outbreak, in contrast with other studies that observed an increased number of GCA after the COVID-19 outbreak(5,6).

Our study highlights the potential risks of COVID-19 lockdown in the reduced referral of suspected GCA patients, the occurrence of permanent visual loss, and the need for maintaining urgent access to FTP during the COVID-19 pandemic

Table 1. Clinical, laboratory and ultrasound findings of patients referred to the fast-track clinic for suspected GCA before and after lockdown.

	Total n=81	8 months period previous to lockdown (July 2019 – February 2020) n=50	8 months period after lockdown (March 2020 – October 2020) n=31	p
Age, mean (SD)	74.1 (11.2)	75 (10.8)	72.7 (11.8)	0.394

SESSION INFORMATION

Session Date: Monday, November 8, 2021

Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster I: Giant Cell Arteritis & Polymyalgia Rheumatica (1391–1419)

Session Type: Poster Session C

Session Time: 8:30AM–10:30AM

Background/Purpose: One of the most feared complications of giant cell arteritis (GCA) is visual affection. Tocilizumab (TCZ) has demonstrated efficacy and safety in GCA. However, data on visual affection with TCZ are scarce and sometimes contradictory.

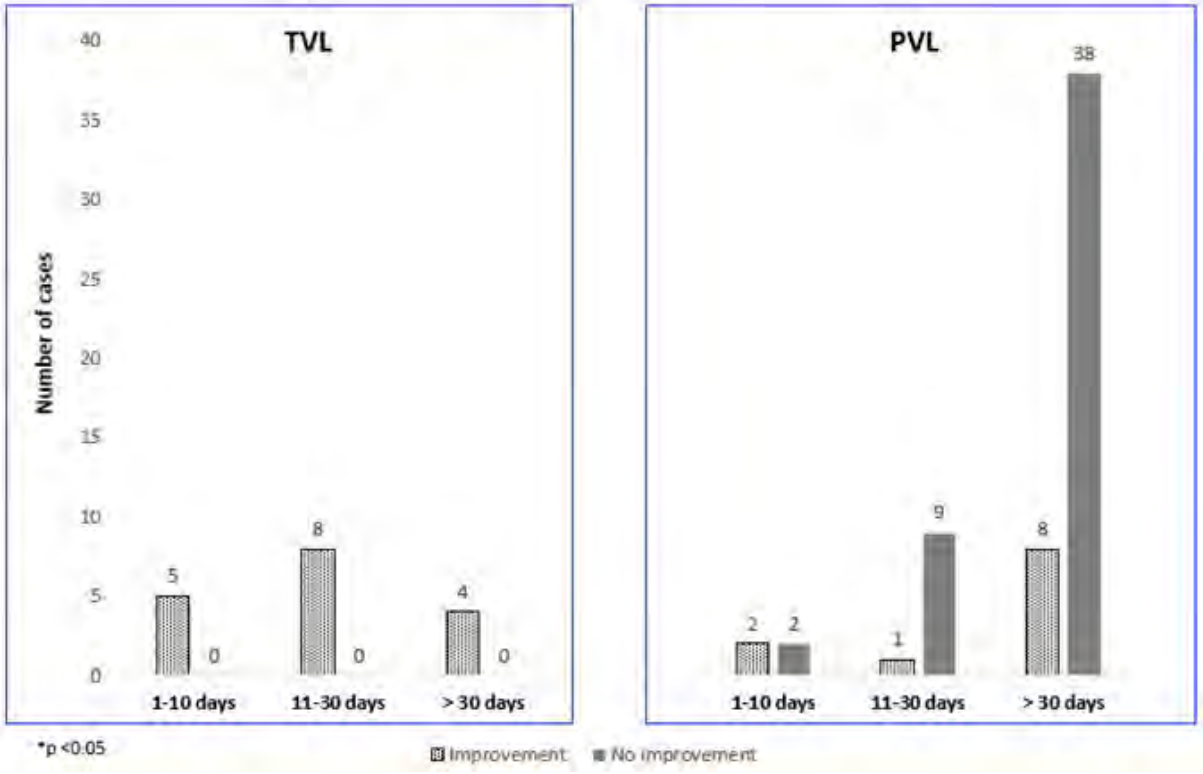
Our objectives were to evaluate the efficacy of TCZ in **a)**preventing the onset of new visual manifestations, and **b)**improving visual symptoms when present.

TABLE. Main features of 471 GCA patients at TCZ onset.

	Overall N= 471	GCA with visual involvement (n= 122)	GCA without visual involvement (n=349)	p
General features				
Age (mean±SD)	74±9	76±8	73±9	**0.000**
Women/Men (% of women)	342/129 (73)	77/45 (63)	265/84 (76)	**0.006**
Time from GCA diagnosis to TCZ onset (months), median [IQR]	6 [2-18]	5 [1-12]	7 [2-22]	0.088
Positive TAB, n (%)	201 (43)	55 (45)	146 (42)	0.53
Ischemic manifestations				
Visual involvement, n (%)	81 (17)	81 (66)	0 (0)	**0.000**
Headache, n (%)	259 (55)	92 (75)	167 (48)	**0.000**
Jaw claudication, n (%)	112 (24)	49 (40)	63 (18)	**0.000**
Systemic manifestations				
Fever, n (%)	57 (12)	10 (9)	47 (13)	0.12
Constitutional syndrome, n (%)	175 (37)	43 (35)	132 (38)	0.55
PmR, n (%)	284 (60)	66 (54)	218 (62)	0.094
Acute phase reactants				
ESR, mm/1 hour, median [ICR]	32 [12-57]	34 [15-67]	30 [11-54]	0.22
CRP (mg/dL), median [ICR]	1.5 [0.5-3.4]	1.5 [0.4-4.7]	1.4 [0.5-3.0]	**0.042**
Prednisone dose, mg/day, mean±SD	20 [10-40]	30 [15-45]	20 [10-30]	**0.000**

Abbreviations: GCA: giant cell arteritis, SD: standard deviation, TCZ: Tocilizumab, IQR: interquartile range, TAB: temporal artery biopsy, PmR: polymyalgia rheumatica, ESR: erythrocyte sedimentation rate, CRP: C-reactive protein.

FIGURE. Effectiveness of TCZ in GCA patients with TVL and PVL



Methods: Multicenter observational study of 471 patients with GCA treated with TCZ of clinical practice. Patients were diagnosed with GCA according to **a)**ACR criteria, and/or **b)**temporal artery biopsy, and/or **c)**imaging techniques.

Patients were divided into 2 groups: **a)**with visual involvement at some time during the disease, and **b)**without visual involvement. Visual manifestations were classified as: **a)**transient visual loss (TVL) (amaurosis fugax), **b)**permanent

visual loss (PVL) (more than 24 hours) (partial or complete; unilateral or bilateral), **c)**diplopia, and **d)**blurred vision. According to the duration between the onset of visual symptoms and the onset of TCZ we have considered **a)**1-10 days, **b)**11-30 days, and **c)**more than 30 days.

Results: We studied 471 (342 women/ 129 men; mean age: 74 ± 9 years). Visual manifestations at any time of the disease were observed in 122 (26%) patients. In 81 of them visual manifestations were present at TCZ onset, while the remaining 41 patients had had a complete recovery previously to TCZ. The main GCA features of patients with and without visual involvement are shown in **TABLE**. Patients with visual involvement were older, with other ischemic complications, and required higher doses of corticosteroids.

After starting TCZ, no patient developed new visual involvement. At TCZ onset, 81 patients had the following visual manifestations: PVL (n= 60; unilateral/bilateral: 48/12), TVL (n= 17; unilateral/bilateral: 11/6), diplopia (n=2) and blurred vision (n=2).

None of the patients with TVL had new episodes after initiation of TCZ, while 11 out of 60 patients with PVL experienced some improvement **(FIGURE)**. The two patients with diplopia and one of the two patients with blurred vision improved.

Conclusion: TCZ seems to prevent the appearance of new ocular manifestations. When they are present, TCZ may improve totally TVL and partially PVL.

Tocilizumab in Combination with 8 Weeks of Prednisone for Giant Cell Arteritis

Mark Matza[1], Adam Jarvie[2], Ana Fernandes[1], John Stone[3] and Sebastian Unizony[4], [1]Massachusetts General Hospital, Boston, MA, [2]Masssachusetts General Hospital, Boston, MA, [3]Massachusetts General Hospital Rheumatology Unit, Harvard Medical School, Boston, MA, [4]Massachusetts General Hospital, Winchester, MA

SESSION INFORMATION

Session Date: Monday, November 8, 2021

Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster I: Giant Cell Arteritis & Polymyalgia Rheumatica (1391–1419)

Session Type: Poster Session C

Session Time: 8:30AM–10:30AM

Background/Purpose: Even with the use of tocilizumab (TCZ), significant glucocorticoid exposure (usually ³ 6 months) continues to be an important problem in giant cell arteritis (GCA). Therefore, we evaluated the efficacy and safety of TCZ in combination with 2 months of prednisone in a group of patients with GCA.

Methods: We conducted a prospective, single arm, open-label study of TCZ in combination with 2 months of prednisone for new-onset and relapsing GCA patients with active disease. GCA diagnosis required confirmation by temporal artery biopsy or vascular imaging. Active disease was defined as presence of cranial or polymyalgia rheumatica symptoms needing treatment within 6 weeks of baseline. All patients received TCZ 162 mg subcutaneously every week for 12 months and an 8-week prednisone taper starting between 20 mg and 60 mg daily. The primary endpoint, sustained prednisone-free remission, was defined as absence of relapse from induction of remission up to week 52 while adhering to the prednisone taper. Relapse was defined as recurrence of symptoms of GCA requiring treatment intensification, regardless of erythrocyte sedimentation rate (ESR) and C-reactive protein (CRP) levels. Safety was also evaluated.

Results: Between 11/2018 and 11/2020 we enrolled 30 patients (mean age 74 years, 60% female, 97% Caucasian, 57% new-onset disease, 77% temporal artery biopsy-proven, 47% imaging-proven) (Table 1). The mean ESR and CRP at screening were 50.3 mm/hour and 53.2 mg/L, respectively. At this moment, 22 patients have completed the study treatment protocol and 8 patients have yet to reach week 52 (mean follow up 35 weeks). Here we report the outcomes of the 22 patients that have completed the study. The initial prednisone dose in this group was 60 mg (n

Table 1 shows patient baseline characteristics

	GCA patients (n = 30)
Age, years: mean (SD)	74 (8.0)
Female sex	18 (60.0)
White race	29 (96.7)
New onset disease	17 (56.7)
Biopsy-proven disease	23 (76.7)
Imaging-proven disease	14 (46.7)
Cranial signs or symptoms	26 (86.7)
PMR symptoms	19 (63.3)
ESR, mm/hour: mean (SD)	50.3 (21.9)
CRP, mg/L: mean (SD)	53.2 (45.8)

Values represent number and (%) unless otherwise specified.
SD, standard deviation; PMR, polymyalgia rheumatica;
ESR, erythrocyte sedimentation rate; CRP, C-reactive protein.

Table 2 shows outcomes for the 22 patients who have completed the treatment protocol to date

	GCA patients (n = 22)
Efficacy	
Sustained, prednisone-free remission by week 52	18 (81.8)
Cumulative prednisone dose (mg) at week 52, mean (SD)	1,037 (367)
Relapse	4 (18.2)
Time to relapse, weeks: mean (SD)	20.5 (15.9)
Clinical manifestations at relapse	
Headaches	2 out of 4 patients
Scalp tenderness	2 out of 4 patients
PMR symptoms	2 out of 4 patients
Safety	
Serious adverse events	4 (18.2)
Cellulitis	1 (4.5)
Cholecystitis	1 (4.5)
COVID-19	1 (4.5)
Fragility fracture	1 (4.5)

Values represent number and (%) unless otherwise specified. SD, standard deviation; PMR, polymyalgia rheumatica.

= 6), 40 mg (n = 7), 30 mg (n = 4), and 20 mg (n = 5). All patients entered remission within 4 weeks of baseline. The primary endpoint was achieved by 18 (82%) patients (Table 2). The mean (SD) cumulative prednisone dose in these 18 patients was 1,037 (367) mg. After a mean period of 20.5 weeks, 4 (18%) patients relapsed (Table 2). All relapses occurred after the completion of the prednisone taper. Overall, 4 (18%) participants developed a serious adverse event (Table 2). No cases of vision loss occurred during the study.

Conclusion: Pending the final analysis of this pilot study, the results presented here suggest that 12 months of TCZ in combination with 8 weeks of prednisone could be efficacious for maintaining disease remission in patients with GCA. Confirmation of these findings in a randomized controlled trial is required.

Abstract Number: 1414

The Current State of Expedited Referral Systems Incorporating Vasculitis Ultrasound for the Diagnosis of Giant Cell Arteritis in Rheumatology Practices in the United States

Mark Matza[1], Karina Torralba[2] and Minna Kohler[3], [1]Massachusetts General Hospital, Boston, MA, [2]Division of Rheumatology, Department of Medicine, Loma Linda University Healthcare, Loma Linda, CA, [3]Massachusetts General Hospital, Harvard Medical School, Boston, MA

SESSION INFORMATION

Session Date: Monday, November 8, 2021

Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster I: Giant Cell Arteritis & Polymyalgia Rheumatica (1391–1419)

Session Type: Poster Session C

Session Time: 8:30AM–10:30AM

Background/Purpose: Expedited referral systems or "fast-track" clinics incorporating vasculitis ultrasound (VUS) into the evaluation of patients with suspected giant cell arteritis (GCA) have shown reduced complications, such as blindness and inappropriate use of prednisone. EULAR guidelines recommend VUS as an initial diagnostic modality in GCA. The use of VUS for GCA diagnosis in the United States has been limited to date. We report the current state of fast-track clinics that include VUS in the diagnosis of GCA at several academic institutions and 1 large private practice in the United States, on behalf of USSONAR.

Methods: A 31-item survey questionnaire was sent via Qualtrics® to the lead clinic director of 6 practices using VUS in the diagnosis of GCA within an expedited referral system. The survey included 31 questions (Qs) with the following domains: 1) general identifying data (3 Qs), 2) clinical evaluation of GCA patients (3 Qs), 3) VUS utilization, acquisition, interpretation (8 Qs), 4) interdisciplinary collaboration (4 Qs), 5) systems-based effectiveness; support for GCA referral system (9 Qs), 6) utilization of other imaging modalities (4 Qs).

Results: Survey respondents included 5 academic institutions: Massachusetts General Hospital (MGH), University of Washington (UW), Brigham and Women's Hospital (BWH), Loma Linda University (LLU), and University of California-Los Angeles (UCLA); and 1 large private practice Arthritis and Rheumatism Associates PC, Wheaton MD (ARA). VUS acquisition and interpretation varied by institution. At 2 centers (MGH, UCLA), VUS images were obtained and interpreted by a vasculitis specialist. At 3 centers (MGH, LLU, ARA), a vasculitis specialist referred patients to a VUS-trained rheumatologist for acquisition and interpretation. At 2 centers (UW, BWH), vasculitis specialists referred patients to US technicians trained in VUS; images were interpreted by a vascular surgeon with verification by a VUS-trained rheumatologist (UW), or a vascular medicine specialist (BWH). VUS evaluation for GCA occurred within 48 hours at all centers. The majority of referred patients had clinically high suspicion of GCA; some referrals were deemed inappropriate, e.g. headache only. A multidisciplinary collaborative approach to the evaluation and management of LVV was employed by most centers; EM, ENT, neurology, and plastic, vascular and general surgery were the most common collaborators. Three institutions co-led the expedited referral system with primary care or one or more specialties. Most rheumatologists managed the cases post-diagnosis, except for one institution (LLU) where there was co-management with ophthalmology. Additional imaging was utilized in some cases despite a positive VUS to ascertain other non-cranial large-vessel involvement and possible inclusion in clinical research (MGH, ARA). A temporal artery biopsy was obtained if VUS was positive (UCLA, LLU), or negative/indeterminate based on clinical scenario (ARA, UW, BWH, MGH).

Conclusion: VUS in GCA is currently implemented in different ways in few institutions in the United States. There is a need for further training and systems-based changes to support the development of fast-track clinics in the United States.

Session Type: Poster Session C

Session Time: 8:30AM–10:30AM

Background/Purpose: Studies of giant cell arteritis (GCA) rely on classifying temporal artery biopsies (TABs), the gold-standard diagnostic test. However, these results exist as free text, rather than discrete classifications stored in databases or tables. Automated phenotyping using TAB reports in the electronic medical record (EMR) can streamline GCA studies.

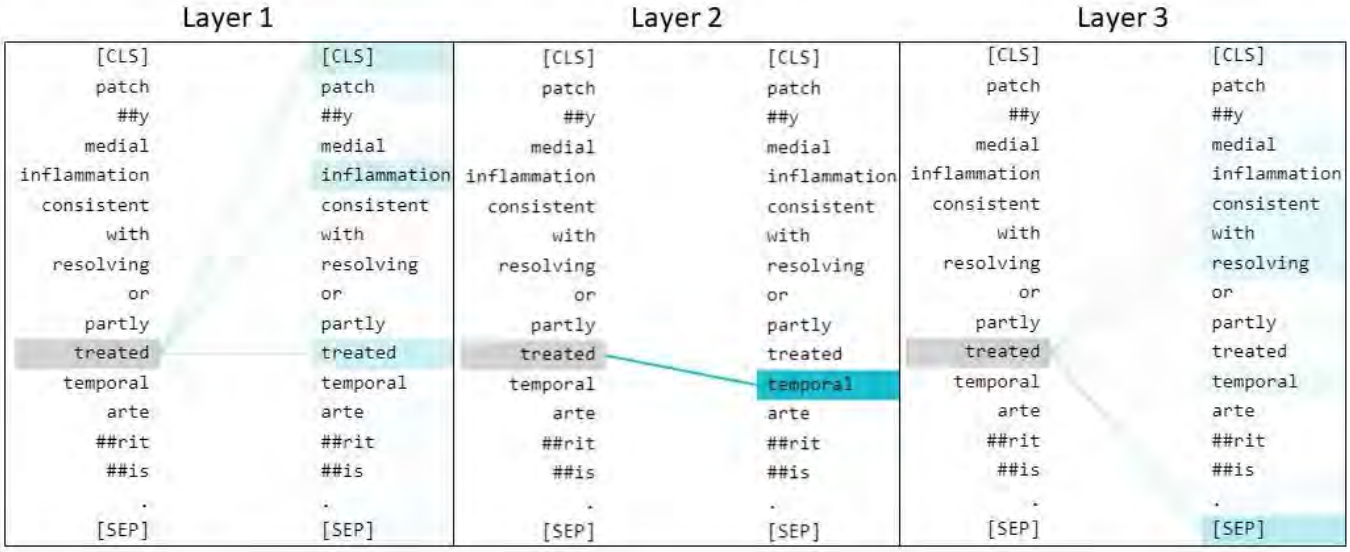
Methods: TAB reports from a single centre (Centre A) between January 2011 and November 2020 were manually classified according to the presence or absence of 4 features: intimal hyperplasia, adventitial inflammation, giant cells, and whether the TAB was diagnostic for GCA. The body of the biopsy reports was extracted using regular expressions, and the dataset was split into training (70%) and validation (30%) sets. All models were trained from a pre-trained DistilBERT (1) architecture, using the Transformers Python library (2) after text tokenization using a pre-trained tokenizer. This architecture is a light-weight neural network that uses multihead attention to learn word meaning from textual context (see figure 1). Summary statistics for Centre A are reported on the validation set, which was held out from model training. The models were then tested on an external cohort of TABs from another centre (Centre B), which were processed in an identical manner. Finally, the data from both centres was pooled, with the single centre method used to train and test a new model. Model performance was assessed with the area under the receiver operating characteristic (AUC).

Results: 161 TAB reports from Centre A were included in the study, comprising 41 patients with GCA. The most uncommon histopathological feature was adventitial inflammation, occurring in just 23 of 161 patients (14%). Within the validation dataset, the model had excellent discrimination of GCA cases (AUC 0.991), and of most histopathological features (table 1). Testing the same model on Centre B (220 TAB reports, 35 cases of GCA), there was a drop in discrimination of GCA cases (AUC 0.930), although performance on adventitial inflammation improved. The model

Table 1: Area under the receiver operating characteristic curve by biopsy feature, model and validation dataset

	Model Trained on Centre A (70% train set)		Model Trained on Centres A + B (70% train set)
	Centre A (30% validation set)	Centre B (full dataset)	Centres A + B (30% validation set)
GCA	0.991	0.930	0.995
Intimal hyperplasia	0.919	0.935	0.957
Adventitial inflammation	0.833	0.949	0.954
Giant cells	0.985	0.967	0.994

Figure 1: Model Attention Layers



Note: interrogating 3 layers of the attention maps shows the words and phrases that attend to the word "treated" in order to derive their meaning. "Inflammation", "temporal" and "consistent with resolving" all attend to the word "treated" in these layers.

trained on the pooled dataset had improved performance on all four tasks, with almost perfect accuracy for discriminating GCA cases (see figure 2).

Conclusion: Machine learning algorithms can accurately classify TAB reports according to histopathological features. These algorithms are robust to changes in language between centres, but performance is improved with larger datasets. In practice, this could streamline studies of GCA by reducing the need for manual review of biopsy reports.

Background/Purpose: Giant cell arteritis (GCA) is the large and medium vasculitis that affects elderly people GCA frequently overlaps with polymyalgia rheumatica (PMR). PMR is a common rheumatic disease and it affects the proximal large joints in the shoulders and hips. Long-term glucocorticoids (GCs) administration is the main treatment option for GCA and PMR patients. However, GCs lead to GC-related adverse events including hypercholesterolemia, hypertension, diabetes mellitus, cataract, and infections. Therefore, new treatment options is required. Previous studies suggest a negative association between metabolic features cholesterol, blood glucose) and a BMI in the development of GCA. However, data are limited. In this study, we aimed to investigate the metabolic features, BMI in two independent GCA/PMR cohorts and elaborate the prevalence of comorbidities in GCA/PMR patients at the time of diagnosis and during treatment to stratify patients.

Methods: This study included two independent cohorts from Aarhus and Groningen (GPS cohort). The GPS cohort included 50 GCA and 44 PMR patients. As a background population, 50-93 years old participant of Lifelines cohort study was included. In addition, 52 GCA and 25 PMR patients from the Aarhus cohort were included. Baseline characteristics of GCA/PMR patients from the GPS cohort were compared with general population and patients in the Aarhus cohort. Patients in the GPS cohort were prospectively followed with visits at 3 months, 1, 2, 3, 4 and 5 years. Laboratory measurements, comorbidities (diabetes mellitus, hypercholesterolemia, hypertension, obesity and cataract) were assessed at every visit.

Results: In contrast to previous literature, higher HbA1c and glucose levels and lower LDL, HDL and cholesterol were detected in GCA patients than in general population. This suggested a dysregulation in lipid and glucose metabolism in GCA patients. Aarhus cohort was comparable with GPS cohort. Next, association of comorbidities with acute-phase markers at the time of diagnosis was investigated. GCA patients with cataract had reduced CRP and ESR whereas higher ESR was observed in PMR patients with cataract compared to patients without cataract. Analysis of GC treatment effect on comorbidities revealed a significant increase in diabetes and cataract in GCA patients, mainly after 3 months and 5 years, respectively, compared to baseline. BMI significantly increased 1, 4 years and 5 years after GC treatment initiation. Additionally, frequency of obese patients increased after 5years of GC usage in GCA patients.

Conclusion: Here we show that a disturbance in glucose and lipid metabolism in newly-diagnosed GCA patients. GC treatment resulted in the development of comorbidities and BMI in GCA patients, emphasizing the need for improved GC-sparing treatment options.

Machine Learning Enhances the Identification of GCA from Its Mimics Based on Clinical Factors

Christopher McMaster[1], Victor Yang[1], Russell Buchanan[2] and David Liew[1], [1]Austin Health, Heidelberg, Australia, [2]Austin Health, Heidelberg, Melbourne, Australia

SESSION INFORMATION
Session Date: Monday, November 8, 2021
Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster I: Giant Cell Arteritis & Polymyalgia Rheumatica (1391–1419)
Session Type: Poster Session C
Session Time: 8:30AM–10:30AM

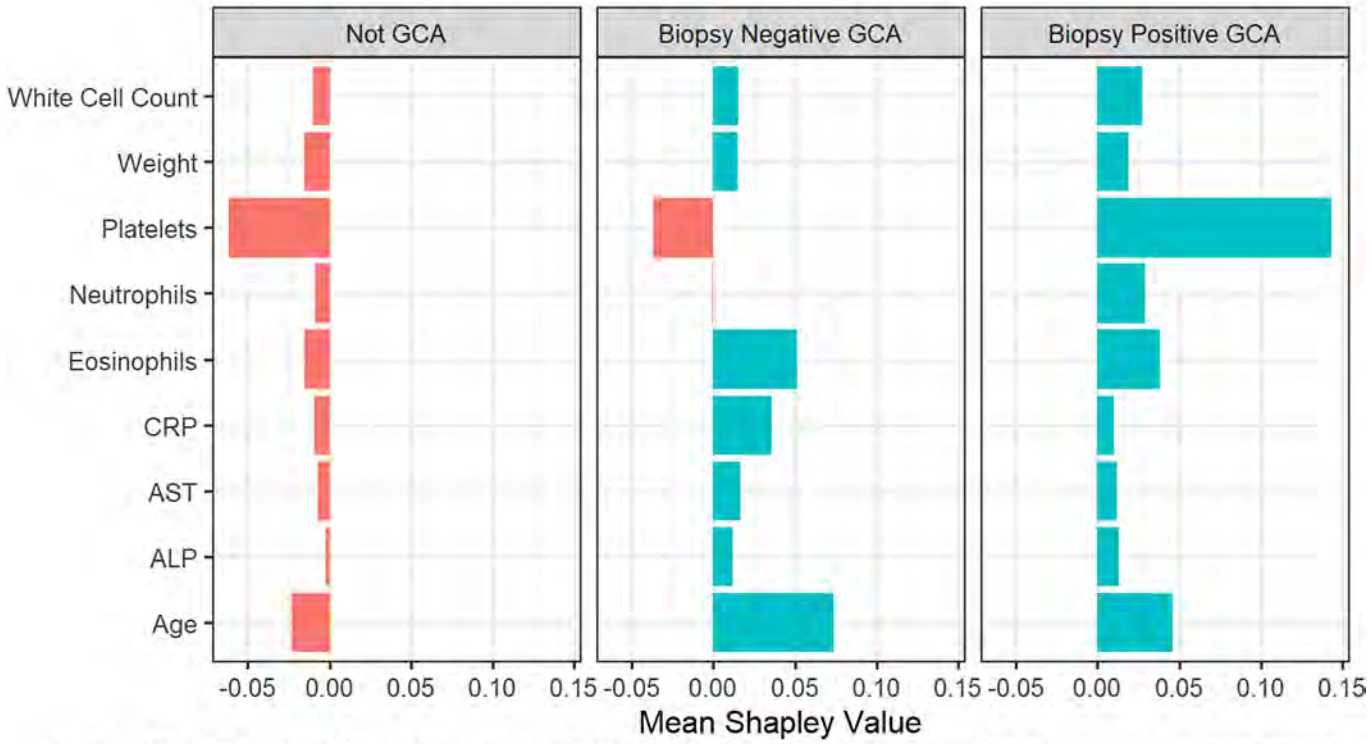
Background/Purpose: To determine whether an eventual diagnosis of giant cell arteritis in both temporal artery biopsy positive and negative patients can be identified using prospective clinical factors, either through direct identification or machine learning techniques.

Methods: All patients at a single center who underwent temporal artery biopsy between January 2011 and November 2020 with accessible progress notes were included. Final diagnosis was determined from the documented clinical disease course after a minimum of one year, and was ascertained from the medical record by two assessors, with arbitration by a third assessor for cases of disagreement. Models were trained to distinguish GCA from mimics, with further comparisons performed on the subgroups of biopsy-positive and biopsy-negative GCA. Variables considered included pathology, clinical and demographic features (Table 1). Missing variables were imputed using k-nearest neighbours and the minority class was upsampled using SMOTE(1). After hyperparameter tuning, random forest models were fitted to the data(2), using 50-repeated 5-fold cross-validation to determine the out-of-sample area under the receiver operating characteristic (AUC). To assess individual variable contribution to model predictions, Shapley scores were calculated and compared between the three groups(3).

Results: During the study period, 194 patients underwent temporal artery biopsy (130 not GCA, 19 biopsy-negative GCA, 45 biopsy-positive GCA). The mean AUC of the random forest classifier was 0.726 (95% CI 0.715 - 0.737), with an overall classification accuracy of 70.4%. The Shapley scores demonstrate that, whilst the platelet count strongly predicts biopsy-positive GCA, the model must rely on a variety of other variables to predict biopsy-negative GCA. In particular, the eosinophil count, patient age, and liver function tests were discriminators of biopsy-negative GCA (Figure 1). The presence of an elevated eosinophil count or elevated aspartate aminotransferase distinguishes GCA mimics from biopsy-negative GCA (Figure 2).

Conclusion: Platelets, eosinophils, age, and ALT assist in differentiating biopsy-negative GCA, but discriminating GCA from mimics is best performed by machine learning models. In particular, the more difficult cases of biopsy-negative GCA may be distinguishable using models that use both positive markers of GCA diagnosis and vari-

Figure 1: Top Ranking Model Variables



Note: variables with the highest Shapley scores were selected. The absolute value of the Shapley score represents its contribution to the model prediciton. Positive scores indicate variables that predict GCA. Negative scores indicate variables that predict not GCA.

Figure 2: Eosinophil Count and ALT by Diagnosis

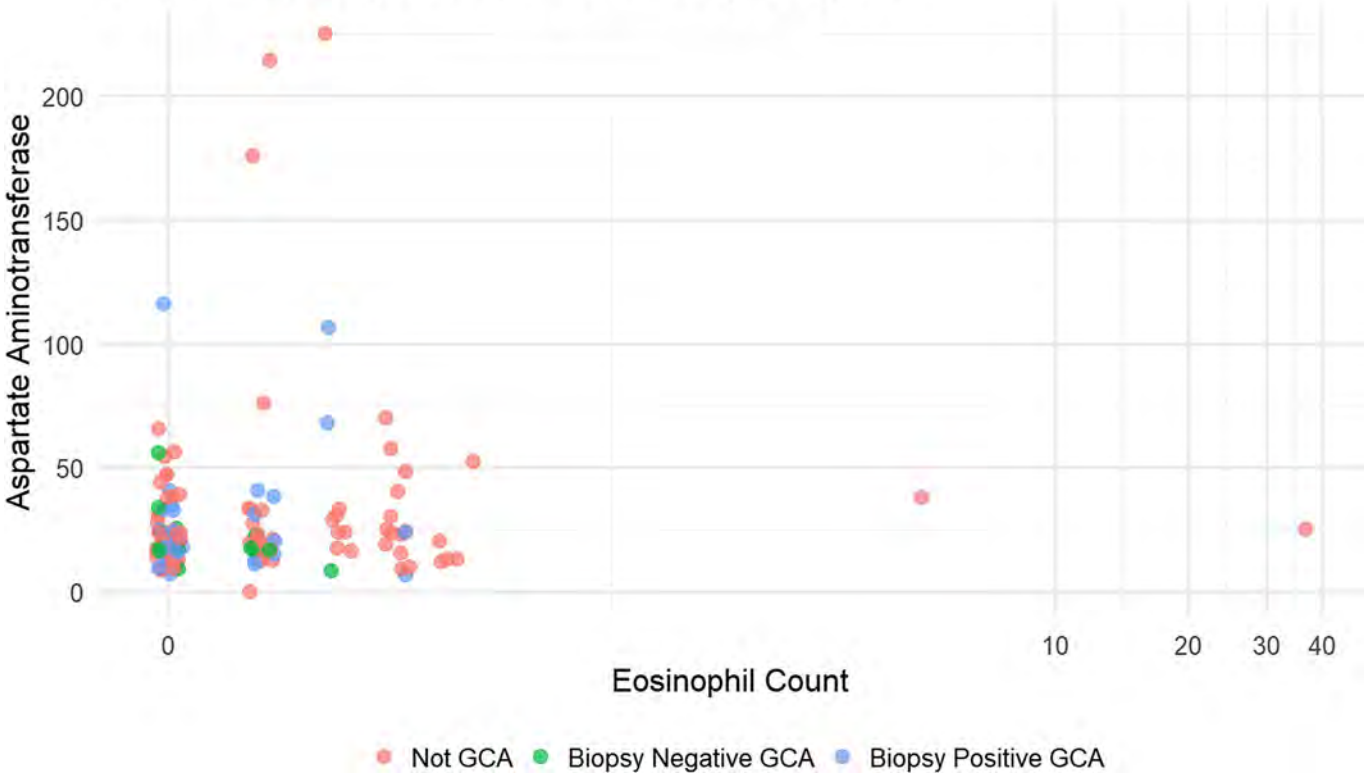


Table 1: Variables included in the machine learning model.

Age (years)	PMR (yes or no)

Patient Reported Outcomes on Quality of Life in Patients with Giant Cell Arteritis and Polymyalgia Rheumatica

Yannick van Sleen[1], Kornelis van der Geest[2], Annemieke Boots[2], Maria Sandovici[2] and Elisabeth Brouwer[2], [1]University of Groningen, Groningen, Netherlands, [2]University Medical Center Groningen, Groningen, Netherlands

SESSION INFORMATION

Session Date: Monday, November 8, 2021

Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster I: Giant Cell Arteritis & Polymyalgia Rheumatica (1391–1419)

Session Type: Poster Session C

Session Time: 8:30AM–10:30AM

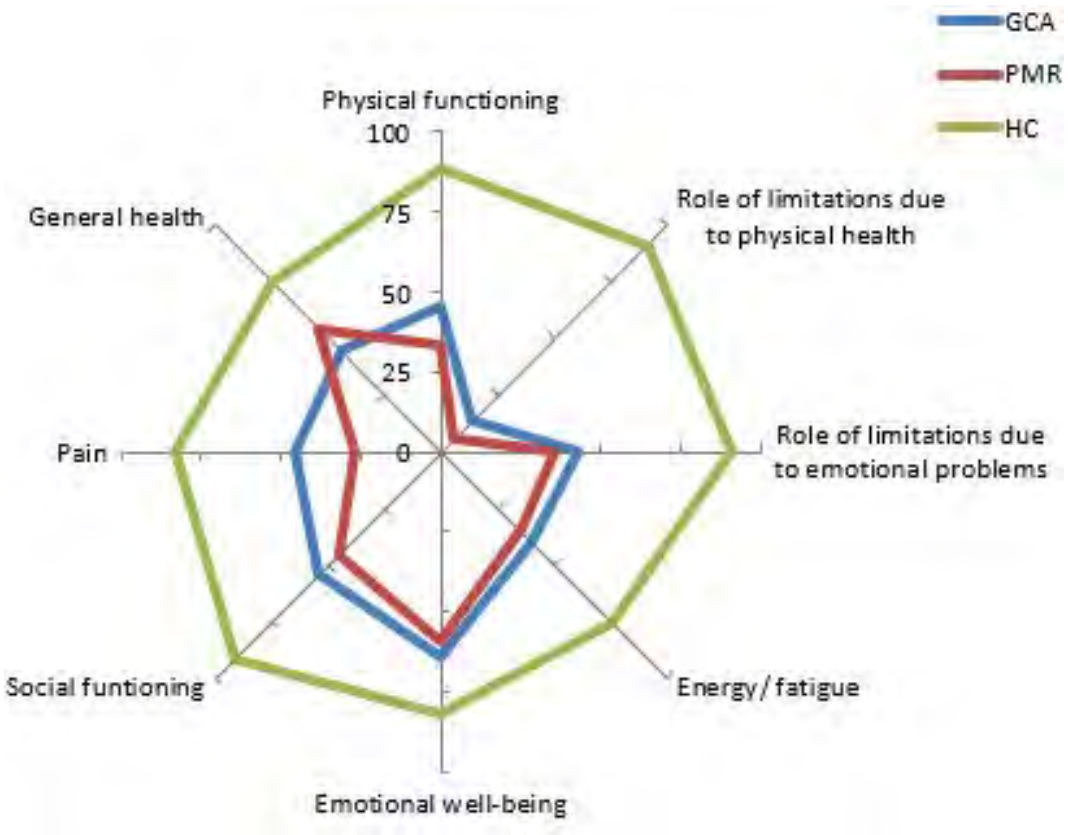

Figure 1. Scores of the eight domains of the SF-36 at baseline in GCA and PMR patients. Data are compared to age- and sex-matched HCs. Scores range from 0-100; a score of 100 indicates the most healthy outcome.

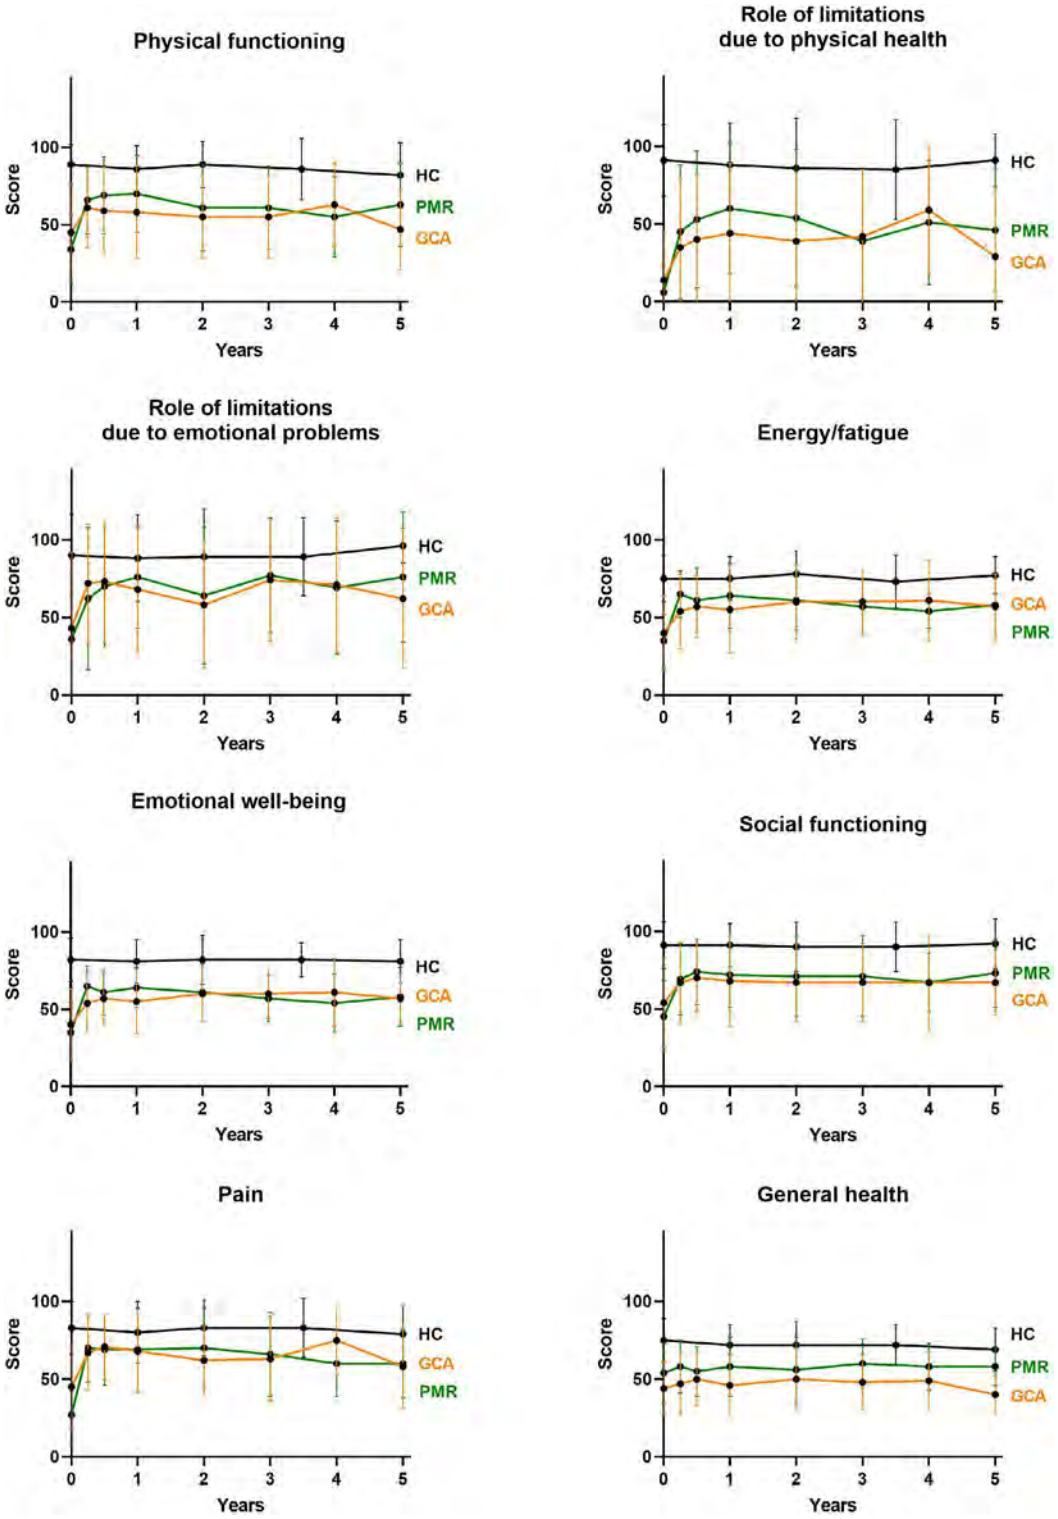

Figure 2. Scores of the eight domains of the SF-36 throughout the disease course in GCA and PMR patients. Data are compared to age- and sex-matched HCs.

Background/Purpose: Giant cell arteritis (GCA) and polymyalgia rheumatica (PMR) are often overlapping inflammatory diseases that occur in people older than 50 years. Both diseases can affect the quality of life, due to the burden of vascular inflammation and ischemia-related symptoms (GCA), joint symptoms (PMR) and systemic symptoms (GCA and PMR), in addition to the side-effects of long-term treatment with glucocorticoids. We hypothesized that

GCA and PMR have both short- and long-term impact on the quality of life. We therefore documented patient reported outcomes (PROs) on the quality of life in GCA and PMR patients for five years.

Methods: We followed treatment-naïve GCA (n=44) and PMR (n=40) patients since diagnosis for up to five years. At each visit, PROs were recorded by the Groningen Frailty Indicator (GFI), the Health Assessment Questionnaire-Disability Index (HAQ-DI) and the Short Form (SF)-36. Data were compared with age- and sex-matched healthy controls (HCs) that were also followed for up to five years.

Results: At diagnosis, both GCA and PMR patients reported significantly worse on each PRO compared to HCs. On each of the eight domains of the SF-36, patients scored substantially lower than HCs, with PMR patients scoring slightly worse than GCA patients (Figure 1). Initiation of GC treatment rapidly improved PROs, however, scores either never recovered to HC values (GFI, SF-36 (Figure 2)) or increased again after two years (HAQ-DI).

Conclusion: GCA and PMR patients experience both short-term and long-term impact on their quality of life, likely caused by both the disease and its treatment. Future studies should document whether a direct start of additional treatment such as methotrexate or tocilizumab substantially improve PROs in these patients.

Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster I: Giant Cell Arteritis & Polymyalgia Rheumatica (1391–1419)

Session Type: Poster Session C

Session Time: 8:30AM–10:30AM

Background/Purpose: Giant cell arteritis (GCA) causes inflammation of the blood vessels of the head and neck and can cause visual loss and large vessel vasculitis. Patients suffer severe headaches, pain around the scalp and jaw and musculoskeletal symptoms. Treatment includes high dose glucocorticoids, to control symptoms and protect sight.

The aim of this study was to produce a validated disease-specific PROM for patients with GCA, to capture the impact of GCA and its treatment on health-related quality of life

Methods: This was a large cross-sectional survey including patients with clinician-confirmed GCA (cranial, visual loss and large vessel vasculitis) from the UK. Participants with a diagnosis date within the last three years OR flare of disease within the last year were recruited, to enrich the sample of participants with active disease. An underpinning

Table 1. Fit statistics for each of the four domains GCA-PROM

Domain	Location	Standard error	Fit Residuals	Chi Square	DF	p-value
Acute symptoms (8 items)	0.270	0.017	2.807	3.346	6	0.764
Activities of daily living (7 items)	-0.047	0.010	-1.969	9.336	6	0.156
Psychological (7 items)	-0.208	0.013	-0.421	4.271	6	0.640
Participation (8 items)	-0.016	0.011	-1.828	8.267	6	0.219

Table 2. Convergent validity of the four domains with EQ5D-5L and CATPRO5

Correlation with EQ5D		
Domain	**Spearman's Correlation coefficient**	**p-value**
Acute symptoms	-0.631	<0.001
Activities of daily living	-0.729	<0.001
Psychological	-0.648	<0.001
Participation	-0.735	<0.001
Total score	-0.778	<0.001
Correlation with CAT-PRO5		
Acute symptoms	0.551	<0.001
Activities of daily living	0.557	<0.001
Psychological	0.442	<0.001
Participation	0.490	<0.001
Total score	0.556	<0.001

qualitative study and cognitive testing developed 40 candidate items each with a 5-point Likert scale [1]. Patients completed this 40-item draft GCA-PROM alongside EQ5D-5L, CAT-PRO5 and self-report disease activity and steroid usage.

The statistical analysis aimed at determining the construct validity with Rasch models and factor analysis performed iteratively. Items were fitted to the Rasch model to determine its construct validity, reliability, unidimensionality and statistical sufficiency of the total score from the scale. Factor analysis was used to establishing factor structure. Item reduction decisions were be based on clinical importance, lack of fit to the Rasch model, and redundancy.

Further evidence of validity was tested by comparing the scores of the newly validated GCA-PROM (i) in participants who self-identify as having 'active disease' versus patients 'in remission' (known groups validity) (ii) with scores derived from EQ5D-5L and CAT-PRO5 (convergent validity).

Results: The validation sample comprised 426 patients, with a mean (SD) age of 74.2 (7.2), 327 (76%) had cranial GCA and 285 (67%) were female.

The initial analysis of the 40 items, resulted in a lack of fit to the Rasch model and led to the deletion of 10 items. Of the remaining items, 22/30 displayed disordered thresholds necessitating collapsing two categories (very mild and mild) resulting into a 4-response category structure which improved the thresholds.

Four factors (domains) were identified: Acute symptoms (8 items), Activities of daily living (7 items), Psychological (7 items) and participation (8 items). The four domains were analysed as 'super-items' and shown to fit the Rasch model. Table 1 presents item parameters for each of the 4 domains (non-significant Chi-Square probabilities indicate fit to the Rasch model).

The overall scale had an adequate fit to the Rasch model: $X^2 = 25.219$, DF=24, p=0.394 including reliability PSI=0.828. The raw-to-linear transformation scale was calibrated to enable parametric analyses if desired.

Each domain was shown to have known-groups validity and correlation with EQ5D-5L and CAT-PRO5 (Rs) ranging between 0.4.42 and 0.778 (Table 2).

Conclusion: The final 30-item GCA-PROM with 4 domains is a robust measure of health-related quality of life in people with GCA. Further work will explore its use in clinical trials and practice.

SESSION INFORMATION

Session Date: Monday, November 8, 2021

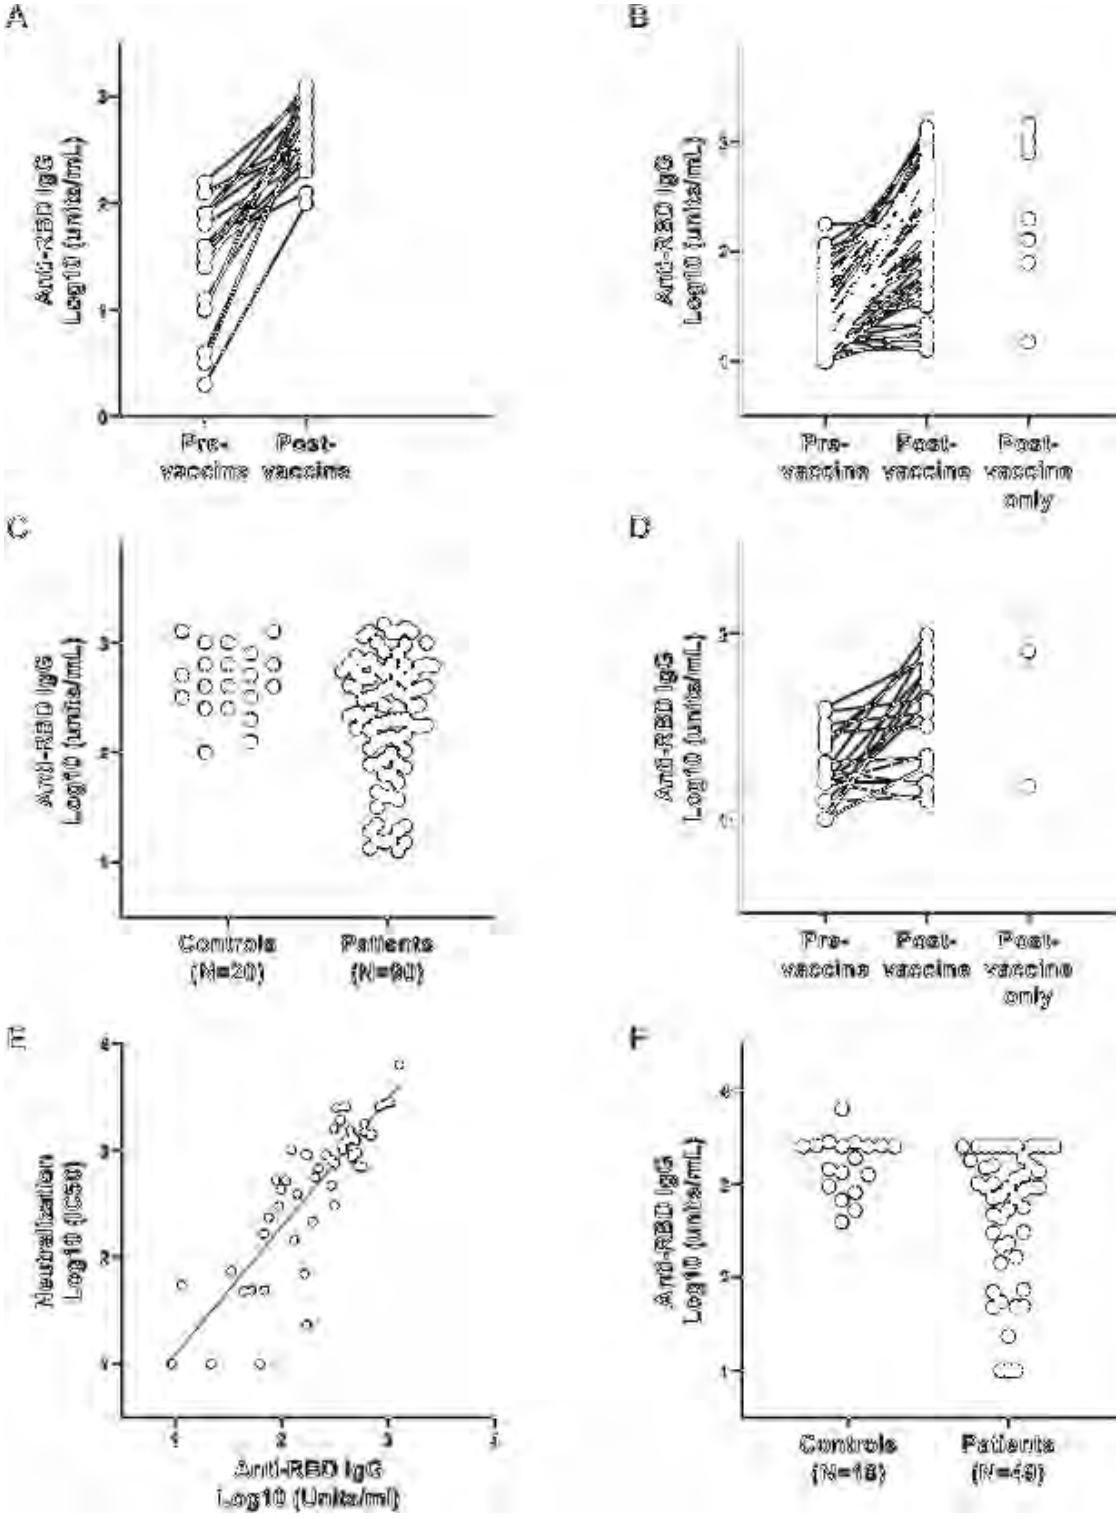
Session Title: Abstracts: SLE – Diagnosis, Manifestations, & Outcomes I: COVID-19 Vaccine Experience & Translational Science (1420–1423)

Session Type: Abstract Session

Session Time: 9:00AM–10:00AM

Background/Purpose: Since the Phase 3 clinical studies of all three COVID-19 vaccines excluded patients on immunosuppressants or immune-modifying drugs within 6 months of enrollment, data on SLE is virtually absent. Given the potential of disease flares following immunization, there has been hesitancy for vaccination in patients with rheumatic diseases, including those with SLE. Accordingly, this study was initiated to evaluate seroreactivity and disease flares after COVID-19 vaccination in a multi-ethnic/racial cohort of patients with SLE.

Methods: 90 patients from the NYU Lupus cohort and 20 healthy controls who received a complete COVID-19 vaccine schedule were included. IgG seroreactivity to the SARS-CoV-2 Spike receptor-binding domain (RBD) measured by ELISA and SARS-CoV-2 microneutralization assay were used to evaluate B cell responses, and IFN-γ production



to assess T cell responses as measured by ELISpot. Disease activity was measured by the hybrid SLE disease activity index (SLEDAI) and flares assigned by the SELENA/SLEDAI flare index.

Results: Overall, the mean titers of post-vaccine antibody levels were lower in SLE patients compared to controls (Figure 1). Specifically, 26 (29%) patients generated IgG antibody responses to the SARS-CoV-2 Spike RBD that fell below that of the lowest response obtained for the controls (≤100) (Table 1). Factors in the SLE patients which significantly associated with poor responses in bivariate analysis included prednisone use in combination with at least 1

immunosuppressant (p=0.049), a combination of two immunosuppressants (p=0.01), prednisone use (p=0.021), mycophenolate mofetil or mycophenolic acid use (p=0.001), receiving the Jansen/Johnson & Johnson vaccine (p=0.04) and a normal anti-dsDNA level prior to vaccination (p=0.03); only antimalarial use associated with a positive response (p< 0.0001). A logistic regression model of predictors of ELISA response >100 among SLE patients showed that taking antimalarials or no medications [OR 11.8 (95%CI 2.9, 48.5, p=0.0006)], and elevated anti-dsDNA prior to vaccination [OR 7.8 (95%CI 2.9, 48.5, p=0.0047)] are independent predictors of vaccine response. IgG seroreactivity to the SARS-CoV-2 Spike RBD strongly correlated with the SARS-CoV-2 microneutralization assay (R=0.81; p< 0.0001,

Table 2: Flares Post Vaccination

Flare Severity	Flare Type	Flare Details	Timing of Flare	Vaccine Type	Treatment
Mild/moderate	Pleuritis	Recurrent mild pleuritis	After first dose	Pfizer	No treatment
Mild/moderate	Arthritis	Recurrent mild joint pain and swelling	After second dose	Pfizer	No treatment
Mild/moderate	Renal	Recurrent proteinuria. Urine Protein/Creatinine Ratio increased from 0.8 to 1.4	After second dose	Pfizer	Rituximab/Tacrolimus changed to Voclosporin
Mild/moderate	Oral ulcers	Recurrent oral ulcers. Patient had been off of Benlysta for 3 months	After second dose	Moderna	No treatment
Mild/moderate	Pericarditis	New presumed pericarditis, EKG negative. Resolved with naproxen	After second dose (two weeks)	Pfizer	Naproxen
Severe	Arthritis	Recurrent arthritis	After second dose	Moderna	Methotrexate
Mild/moderate	Thrombocytopenia	Recurrent thrombocytopenia within patient's range	After second dose	Pfizer	No treatment
Mild/moderate	Arthritis	New mild joint pain and swelling	After second dose	Pfizer	No treatment
Mild/moderate*	Thrombocytopenia	Recurrent thrombocytopenia	After second dose	Pfizer	No treatment
Other Notables Events:					
Non-SLE related	COPD/Asthma Flare		After second dose	Pfizer	Treated in ER with steroids, then released

*Patient with SLE/APLS and ESRD was admitted 13 days after second dose of vaccine. The patient had her anticoagulation temporarily held for a procedure presented with shortness of breath found to have superior vena cava syndrome. The patient had a prolonged hospital course complicated by bleeding and sepsis and was transitioned to hospice care and died 50 days after second dose

Figure 1) and correlated with the ELISpot (R=0.57; p=0.0135). In a subset of patients with poor antibody responses, IFN-γ production was likewise diminished. In aggregate, there was no change in post-vaccination SLEDAI scores compared to those measured pre-vaccination. Only 11% of patients were considered to have post vaccination disease flares; 1% severe (further details in Table 2).

Conclusion: In a multi-ethnic/racial study of SLE patients nearly 30% had a low response to the COVID-19 vaccine. Having a normal anti-dsDNA and taking any medications other than antimalarials independently associated with a decreased vaccine response. Reassuringly, disease flares were rare. While minimal protective levels remain unknown, these data suggest protocol development to assess efficacy of booster vaccination.

Efficacy and Tolerance of Vaccination Against COVID-19 in Patients with Systemic Lupus Erythematosus: The International VACOLUP Study

Renaud Felten[1], Lou KAWKA[2], Maxime DUBOIS[2], Manuel Ugarte-Gil[3], Yurilis Fuentes-Silva[4], Matteo PIGA[5] and Laurent Arnaud[1], [1]Department of Rheumatology, French National Reference Center for Autoimmune Diseases (CRMR RESO), Strasbourg, France, [2]National Reference Center for Rare East South-West Autoimmune Systemic Diseases RESO, Strasbourg University Hospitals, Strasbourg, France, [3]Hospital Guillermo Almenara Irigoyen, Essalud/Universidad Científica del Sur, Lima, Peru, [4]Division of Rheumatology, Complejo Hospitalario Universitario Ruiz y Páez, Universidad de Oriente, Ciudad Bolívar, Centro Nacional de Enfermedades Reumáticas, Ciudad Bolívar, Venezuela, [5]Department of Medical Science and Public Health, University of Cagliari, Cagliary, Italy

SESSION INFORMATION

Session Date: Monday, November 8, 2021

Session Title: Abstracts: SLE – Diagnosis, Manifestations, & Outcomes I: COVID-19 Vaccine Experience & Translational Science (1420–1423)

Session Type: Abstract Session

Session Time: 9:00AM–10:00AM

Background/Purpose: Both efficacy and safety data regarding COVID vaccines in systemic lupus erythematosus (SLE) are lacking. We conducted the international Vaccination Against COvid in systemic LUPus study (VACOLUP) to evaluate the efficacy and tolerance of the vaccination against SARS-CoV-2 (COVID-19) in SLE. Our main objective was to describe the tolerance of SARS-CoV-2 vaccination in SLE patients, and to assess the risk of post-vaccination flare.

Methods: VACOLUP was designed as a cross-sectional study which consisted of 43 web-based questions. The study took place from March 22, 2021 to May 17, 2021. Main study outcomes included: demographical characteristics; history of COVID-19; history of vaccination against SARS-CoV-2 and tolerance. Self-reported side-effects, medically-confirmed lupus flare or COVID-19 after vaccination were analyzed.

Results: The study included 696 participants (669 [96.1%] women and 27 [3.9%] men), with a median age of 42 years [IQR: 34-51]), from 29 countries. Side-effects were reported by 316 patients (45.4%) after the first dose of COVID-19 vaccine and 181 (52.8%) of those who received a second dose of vaccine. There was no difference in the occurrence of side effects according to gender (p=0.11), age (p=0.08) or by mechanism of action (mRNA vaccines versus others, p=0.69). The type and intensity of side effects are shown in figure 1, being minor or moderate in intensity (i.e., with no consequence on the ability to perform daily tasks) in more than 80% of cases. Taking into account all vaccine doses together (n=1039), side effects required a medical consultation in 81 cases (7.8%), an emergency consultation in 14 cases (1.3%) and an hospitalization in 5 cases (0.5%), including 4 for the occurrence of a SLE flare. A total of 21 patients (3.0%) reported a medically-confirmed lupus flare, typically with predominant musculoskeletal symptoms

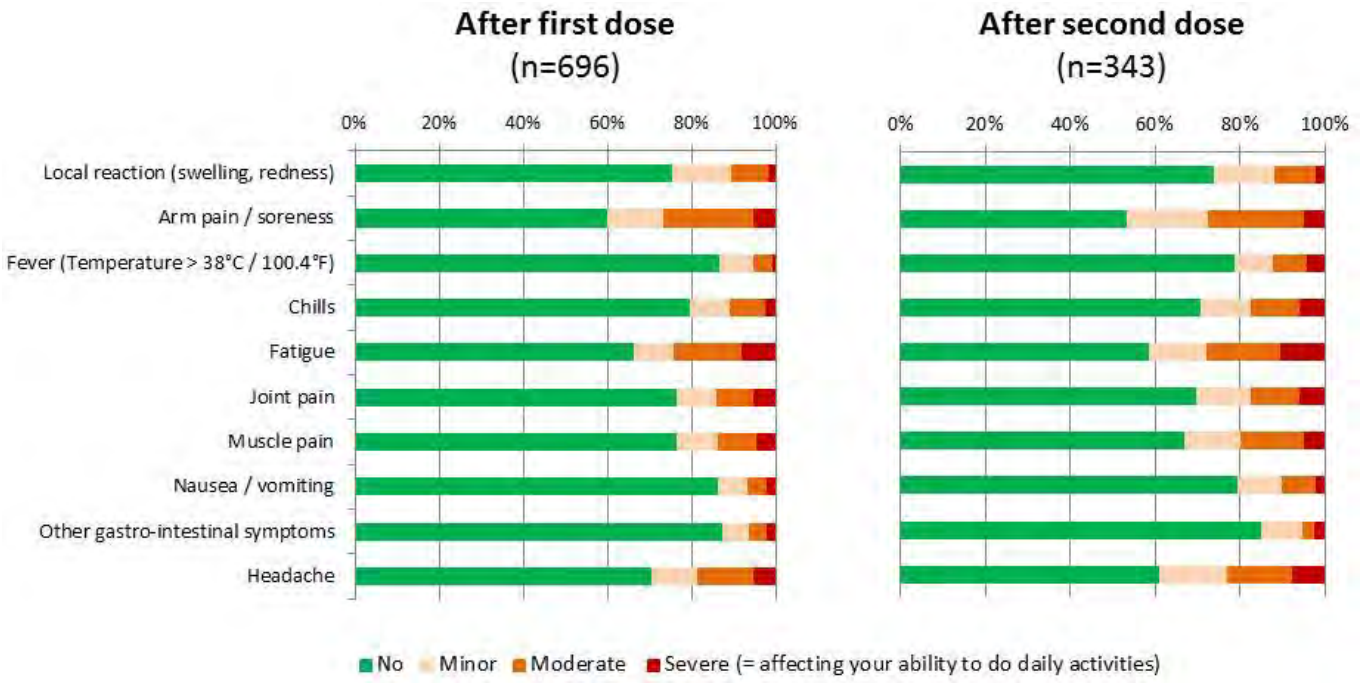

Figure 1. Type and intensity of side effects after COVID-19 vaccination Cumulative plot showing the proportion of minor, moderate and severe reaction for each adverse event (as self-reported by patients, with severe manifestations defined as affecting the ability to do daily activity).

(90.5%) and fatigue (85.7%). Of note these symptoms were reported to occur after a median delay of 3 days (IQR: 0-29) following COVID-19 vaccination. This led to a change in lupus treatment in 15/21 cases.

Conclusion: Side effects are common but minor or moderate in 80% of the cases. Only 21 (3.0%) self-reported a medically confirmed SLE flare. These flares were mainly represented by musculoskeletal symptoms (90.5%) and fatigue (85.7%) and occurred early after COVID-19 vaccination, suggesting it might be difficult to distinguish between lupus flares and common side-effects of vaccination in SLE patients. Disseminating these reassuring data should therefore help clinicians to increase vaccine coverage in SLE patients.

Urinary CD163 Predicts Proliferative Lupus Nephritis in SLE Patients with Proteinuria: A Practical Liquid Biopsy Approach

Andrea Fava[1], Jessica Li[1], Daniel Goldman[2], Jose Monroy-Trujillo[1], Mohamed G. Atta[1], Derek Fine[1], Jill Buyon[3], Joel Guthridge[4], Judith James[4], Michelle Petri[2] and Accelerating Medicines Partership (AMP) RA/SLE Network[5], [1]Johns Hopkins University, Baltimore, MD, [2]Johns Hopkins University School of Medicine, Baltimore, MD, [3]NYU School of Medicine, New York, NY, [4]Oklahoma Medical Research Foundation, Oklahoma City, OK, [5]Brigham and Women's Hospital, Everett, MA

SESSION INFORMATION

Session Date: Monday, November 8, 2021

Session Title: Abstracts: SLE – Diagnosis, Manifestations, & Outcomes I: COVID-19 Vaccine Experience & Translational Science (1420–1423)

Session Type: Abstract Session

Session Time: 9:00AM–10:00AM

Background/Purpose: Diagnosis of lupus nephritis (LN) relies on a kidney biopsy obtained in SLE with proteinuria. Delayed access to kidney biopsies may delay diagnosis and treatment, and can be limited by rapid access to biopsy, antithrombotic and anticoagulation treatments, thrombocytopenia, and in resource poor settings. Here, we employed urine proteomics to develop a non-invasive biomarker to predict proliferative LN.

Methods: We quantified 1200 biomarkers (Kiloplex, RayBiotech) in urine samples collected on the day of (73%) or within 3 weeks (27%) of kidney biopsy in SLE patients with proteinuria > 500mg/d and compared their abundance between patients with or without a subsequent biopsy with proliferative LN (ISN class III or IV ± V). Prospective urine proteomic profiles were obtained in patients with class III, IV, or V at baseline and week 12, 24, or 52.

Results: A total of 237 patients were included: 138 (58%) with proliferative LN, 57 (24%) pure membranous LN, 21 (9%) ISN class I or II LN, 9 (4%) ISN class VI, and 12 (5%) did not have LN. Forty urinary proteins were differentially abundant in patients with proliferative LN, topped by CD163 (**Figure 1**). Urinary CD163 (uCD163) was significantly elevated in proliferative LN compared to all other groups (**Figure 2**). Longitudinal analysis revealed that uCD163 selectively declined in patients that achieved renal response at 12 months (**Figure 3**).

Conclusion: Urinary CD163, a cleaved M2c macrophage receptor, can help to identify proliferative LN in SLE patients with proteinuria. Noninvasive monitoring of uCD163 may lead to early diagnosis and treatment of proliferative LN, thus reducing irreversible kidney damage.

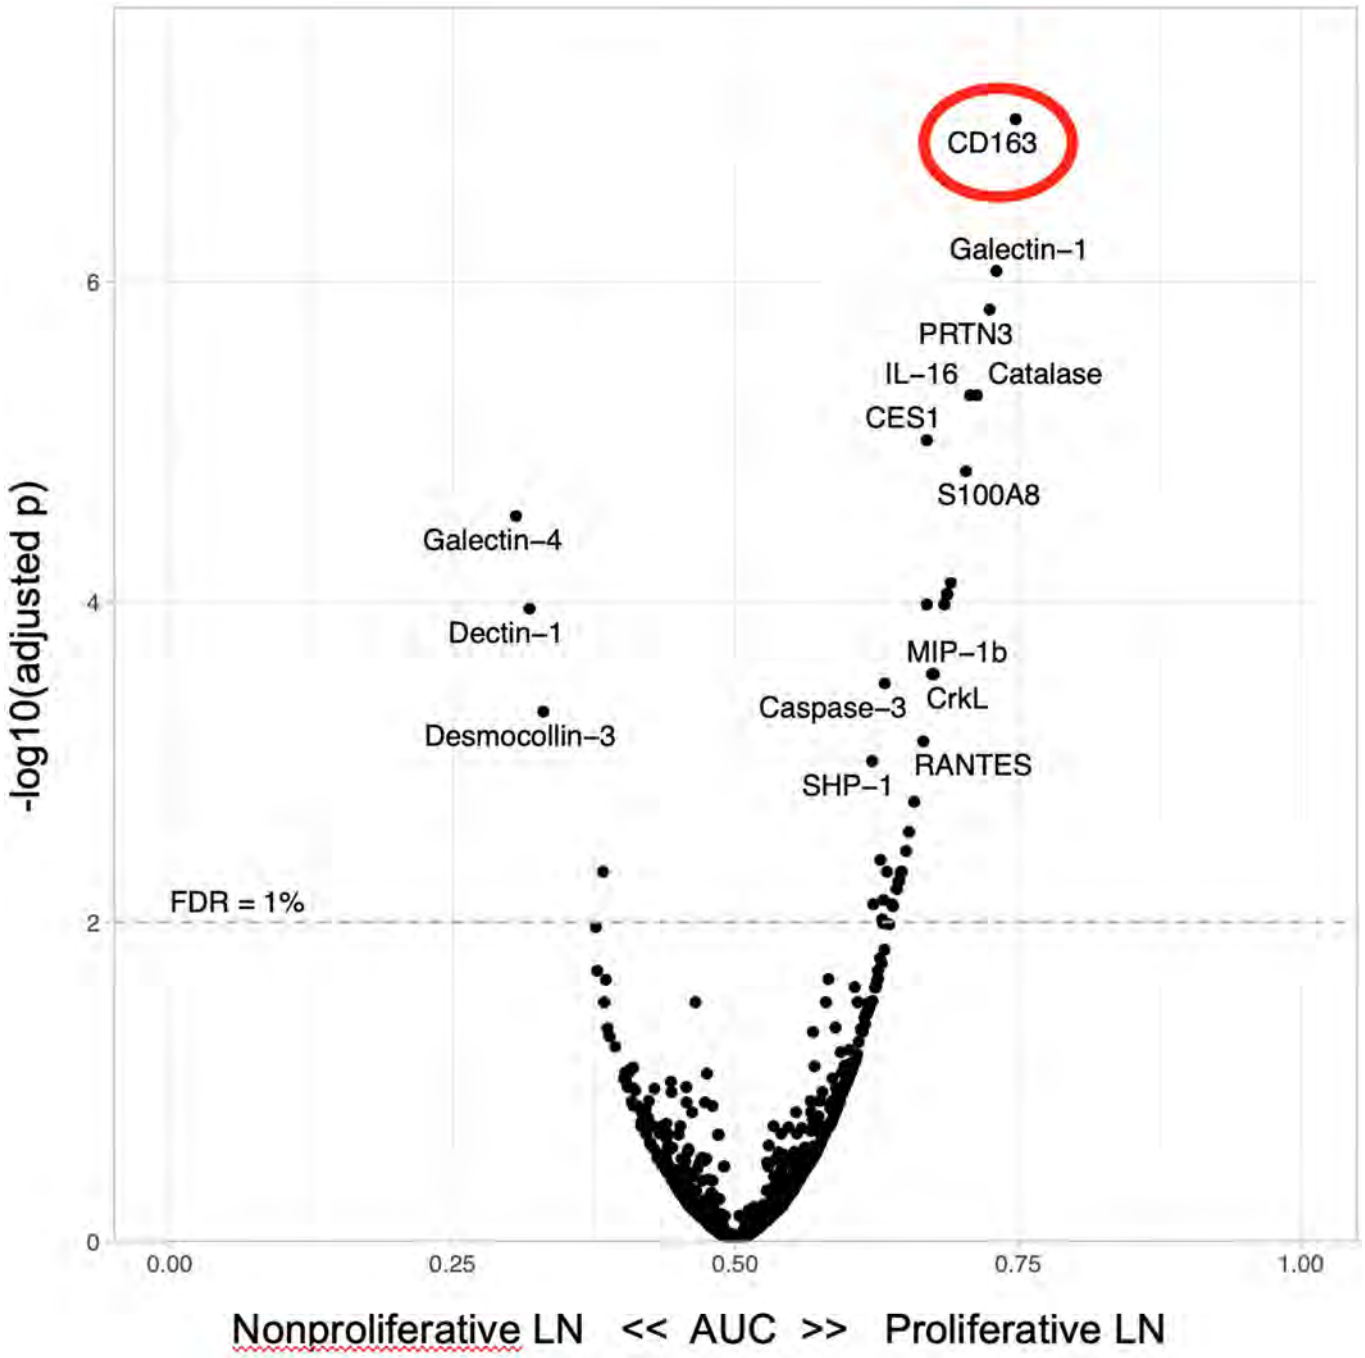

Figure 1. Urine proteomics to identify candidate biomarkers for proliferative LN. Volcano plot displaying the power of 1200 urinary proteins to discriminate proliferative from nonproliferative LN. Area under the curve (AUC), adjusted p values are shown, and a false discovery rate (FDR) of 1% threshold are shown.

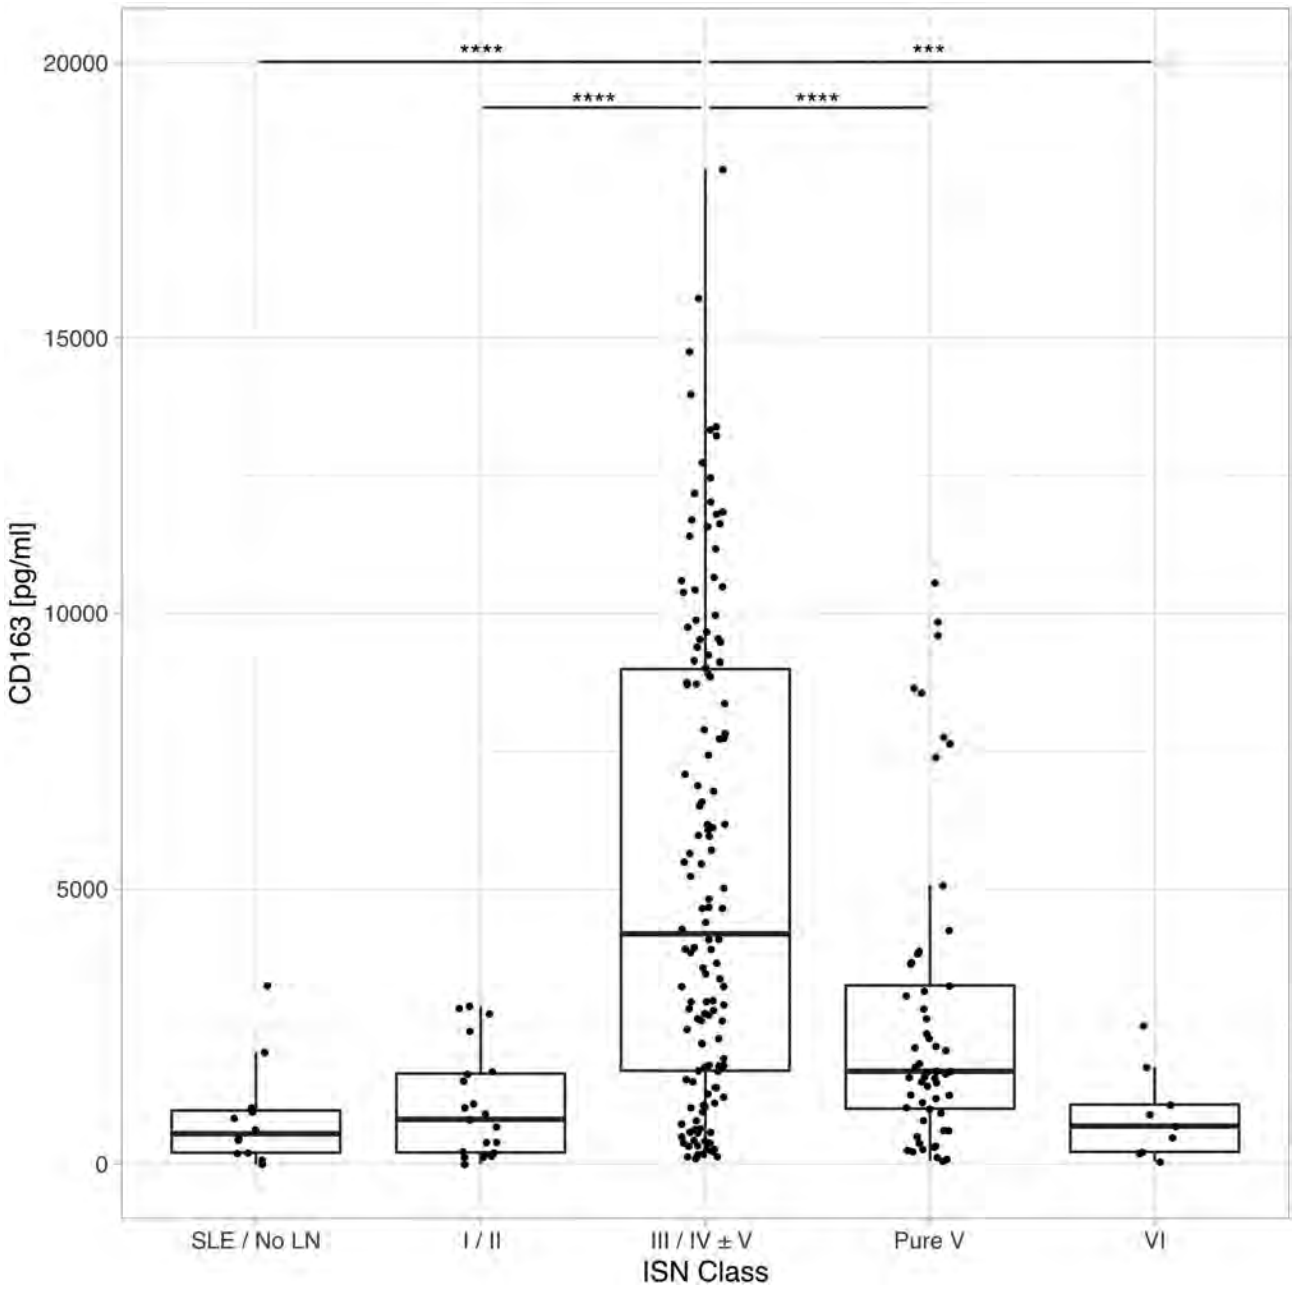

Figure 2. uCD163 is significantly elevated in proliferative LN. Scatter and boxplots displaying the concentration of uCD163 according to LN ISN class (n=237). ANOVA p<10-9; Tuckey post-hoc p values are reported (*** p<0.01, **** p<0.001).

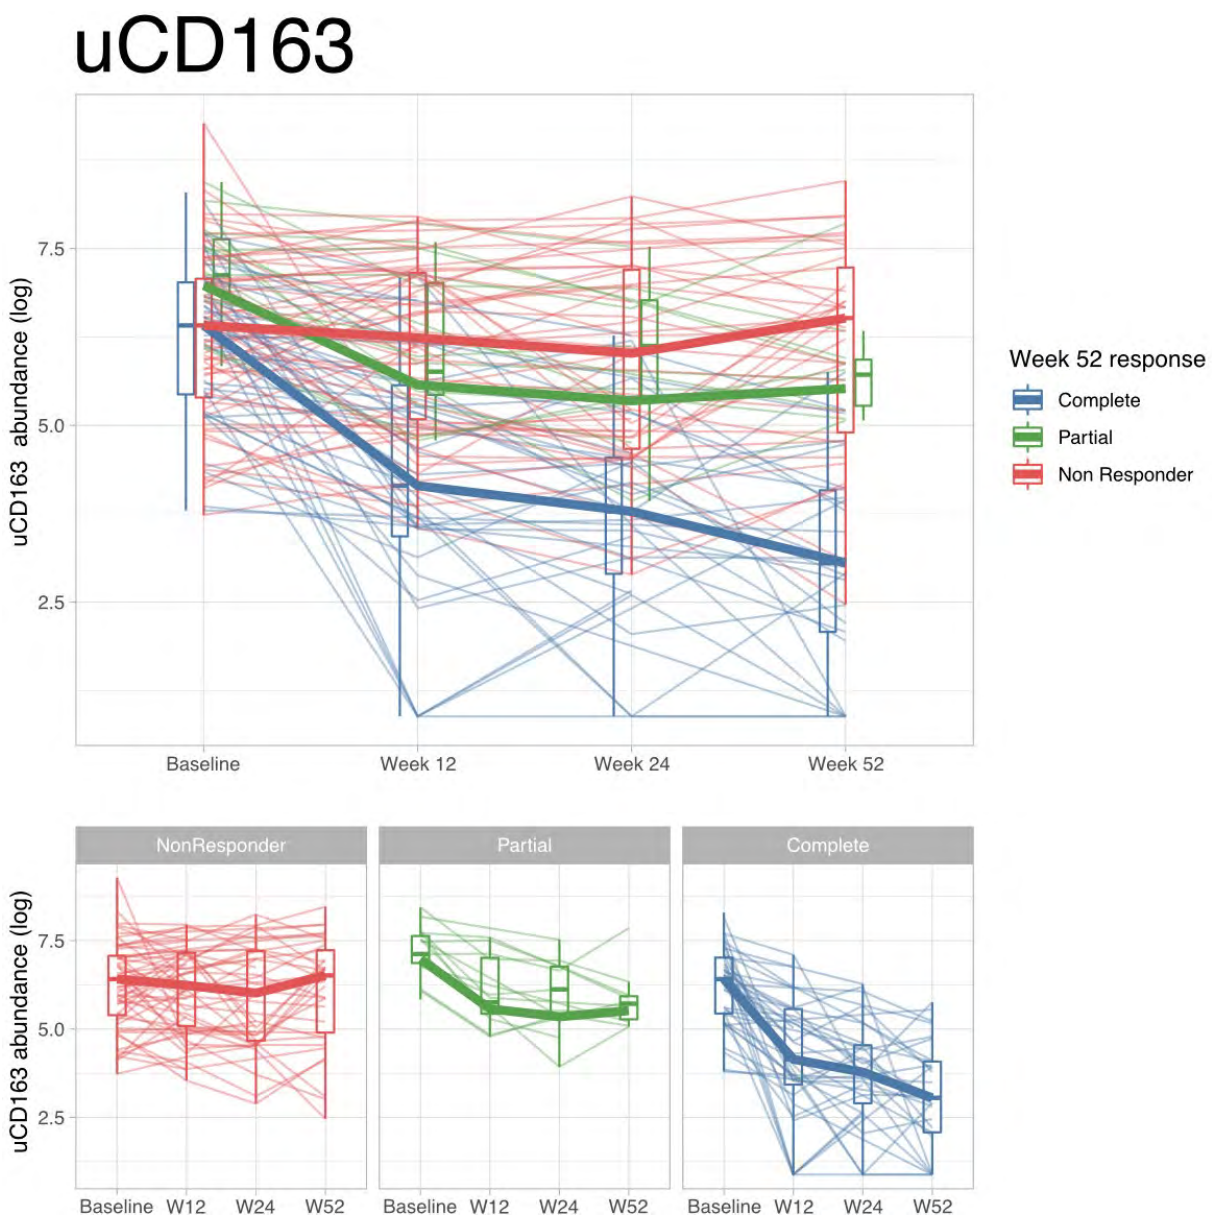

Figure 3. Urinary CD163 declined in treatment responders. Longitudinal trajectories of uCD163 in patients with class III, IV, or V LN (n=351) according to their response status. Thick lines connect the medians at each time point. Response was defined at 52 weeks from renal biopsy (Response was defined at 52 weeks from renal biopsy (Complete, urine pr/cr (UPCR) <0.5, serum creatinine <125% of baseline, prednisone < or equal to 10mg/day; Partial, UPCR < 50% from baseline but >0.5, same creatinine requirement but prednisone allowed to 15 mg; Non responder, not meeting previous definitions).

Ability of Soluble Immune Mediators and SLE-associated Autoantibody Specificities to Forecast Transition to Classified SLE and Inform a Lupus Classification Risk Immune Index

Melissa Munroe[1], Rufei Lu[2], Timothy Gross[1], George Tsokos[3], Michael Keith[4], John Harley[5] and Judith James[1], [1]Oklahoma Medical Research Foundation, Oklahoma City, OK, [2]Oklahoma Medical Research Foundation, OUHSC, Oklahoma City, OK, [3]BIDMC, Boston, MA, [4]Inova, Arlington, VA, [5]US Department of Veterans Affairs Medical Center, Cincinnati, OH

SESSION INFORMATION

Session Date: Monday, November 8, 2021

Session Title: Abstracts: SLE – Diagnosis, Manifestations, & Outcomes I: COVID-19 Vaccine Experience & Translational Science (1420–1423)

Session Type: Abstract Session

Session Time: 9:00AM–10:00AM

Background/Purpose: SLE is a chronic autoimmune disease driven by immune dysregulation. We have previously identified patterns of disordered immunity present prior to and concurrent with the accrual of SLE-associated autoantibodies (AutoAbs) and classification criteria (Munroe et al. Ann Rheum Dis. 2016; Lu et al. J. Autoimmun. 2016). This study seeks to determine the feasibility of an immune mediator-informed Lupus Classification Risk Immune Index (LCRII) to distinguish patients who transition to classified SLE.

Methods: Sera from 84 SLE cases with serial specimens spanning from time points prior to 1997 ACR classification criteria through SLE classification (≥ 4 criteria; average timespan= 6.0 years) and matched healthy individuals (Ctrl) were obtained from the Department of Defense Serum Repository. Demographic, therapeutic, and ACR classification criteria were extracted from medical records. A modified version of the recent SLE Risk Probability Index (SLERPI; C. Adamichou et al. Ann. Rheum. Dis. 2021) was adapted to the 1997 ACR classification criteria (excluding alopecia, complement, and interstitial lung disease components). Samples were tested for SLE-associated AutoAbs, including dsDNA, chromatin, Ro/SSA, La/SSB, Sm, SmRNP, and RNP, and 32 soluble immune mediators, including cytokines, chemokines, and soluble receptors. The LCRII is the sum of log-transformed, standardized immune mediators, weighted by the Spearman r correlation coefficient of mediator levels vs. the number of SLE-associated AutoAbs present and correlates with number ACR criteria present (Spearman r = 0.456, $p< 0.0001$) and mSLERPI (Spearman r = 0.463, $p< 0.0001$).

Results: Unlike ACR classification criteria and mSLERPI, future SLE patients could be identified in the absence of classification criteria (Pre-Criteria) using the LCRII informed by 32 immune mediators (LCRII-32, **Fig 1**). Of 32 mediators assessed, after correcting for multiple comparison (Bonferroni $p\leq 0.0016$), 9 were elevated during the Pre-Criteria phase compared to matched Ctrl, including adaptive mediators IL-12p70, IFN-γ, IL-4, IL-5, IL-17A, TGF-β, chemokines IP-10 and MCP-3, and plasminogen activator inhibitor-1 (PAI-1). Informing the LCRII with these 9 mediators (LCRII-9) did not reduce the ability of the LCRII to distinguish future SLE patients in the Pre-Criteria and AutoAb negative phases of SLE development (**Fig 1**). Overall, the LCRII-9 more clearly identified individuals by classification and AutoAb status (**Fig 2**). On average, future SLE patients met their first clinical criterion 6.4 months before reaching disease classification. In addition to the immunologic criterion, LCRII-32 and select informative mediator levels were altered in initial univariate analyses with select clinical features, including photosensitivity, serositis, and renal criteria (**Fig 3**). Neither hydroxychloriquine nor steroid use at/after SLE classification impacted the LCRII.

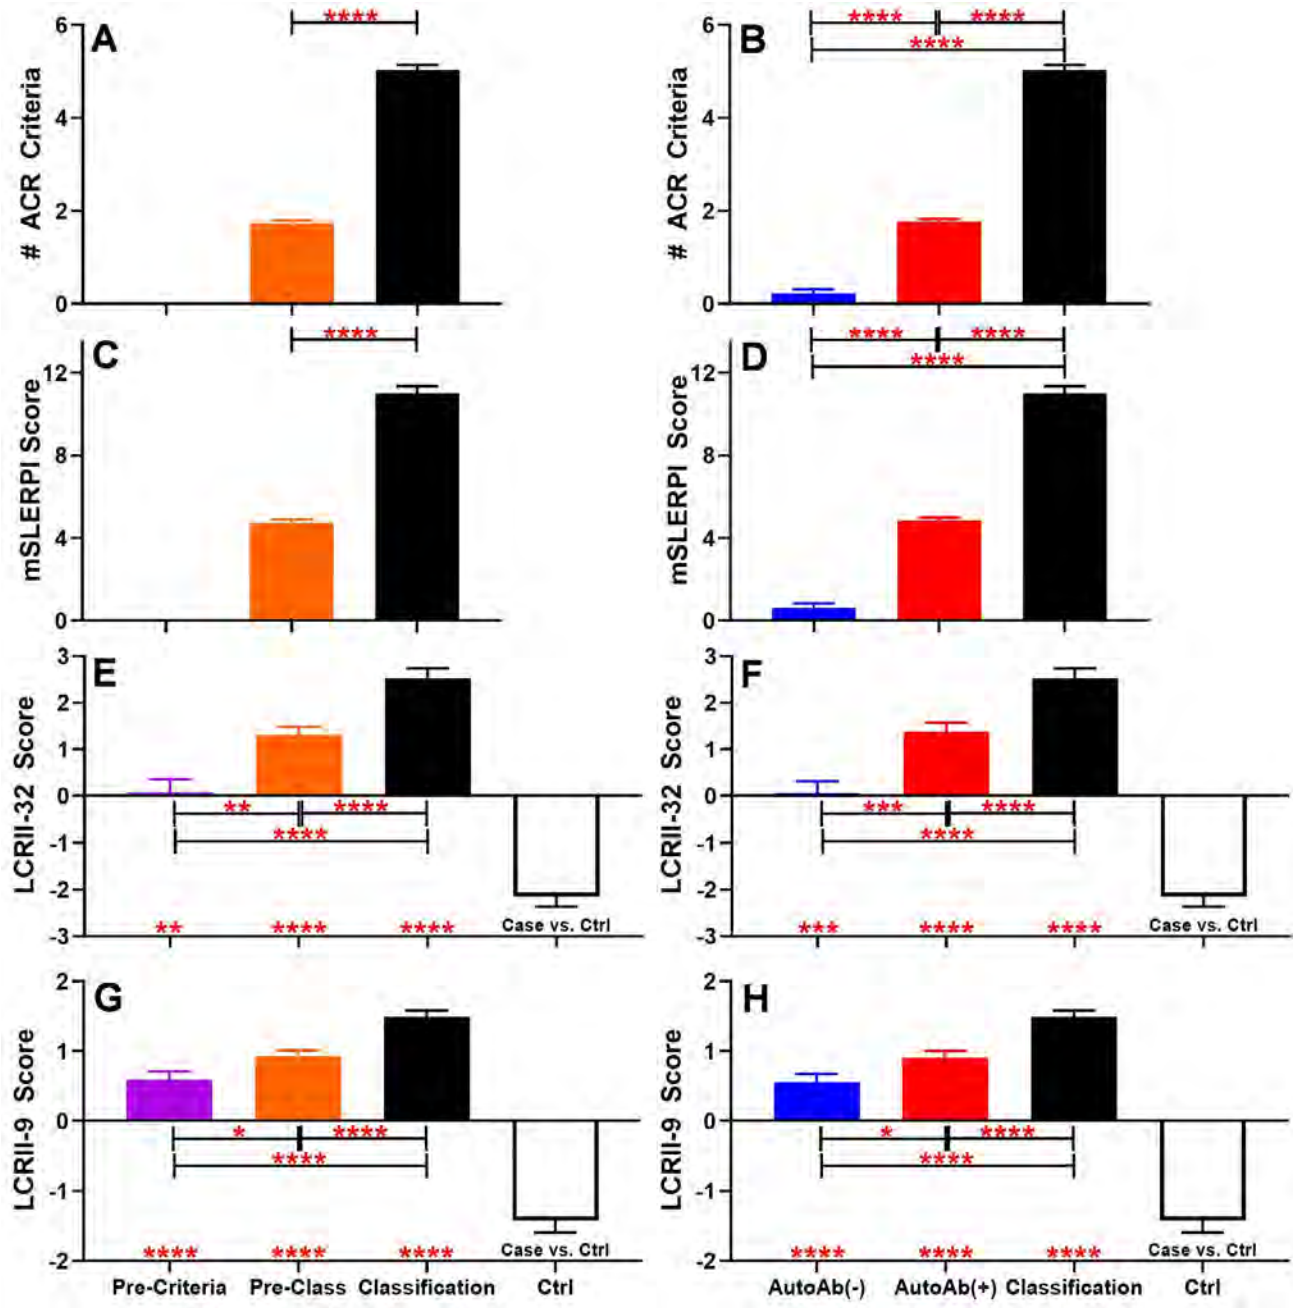

Fig. 1 Comparison of # of ACR criteria (**A-B**) vs. a modified SLE Risk Probability Index (mSLERPI, **C-D**) vs. a Lupus Classification Risk Immune Index (LCRII) informed by 32 (LCRII-32, **E-F**) or 9 (LCRII-9, **G-H**) mediators. Future SLE patients were compared by SLE classification status (prior to meeting ACR criteria [Pre-Criteria] vs. Pre-Classification vs. At/After Classification (Classification) in **A,C,E,G**) or by AutoAb status (absence (AutoAb[-]) vs. presence (AutoAb[+] of SLE-associated AutoAb specificities vs. Classification in **B, D, F, H**). LCRII-32 and LCRII-9 also contain SLE classification or AutoAb status comparisons to sex/race/age/time of sample procurement-matched healthy controls (Case vs. Ctrl comparisons along x-axis in **E-H**). Data are presented as mean ± SEM. *$p<0.05$, **$p<0.01$, ***$p<0.001$, **$p<0.0001$ Kruskal-Wallis test with Dunn's multiple comparison.

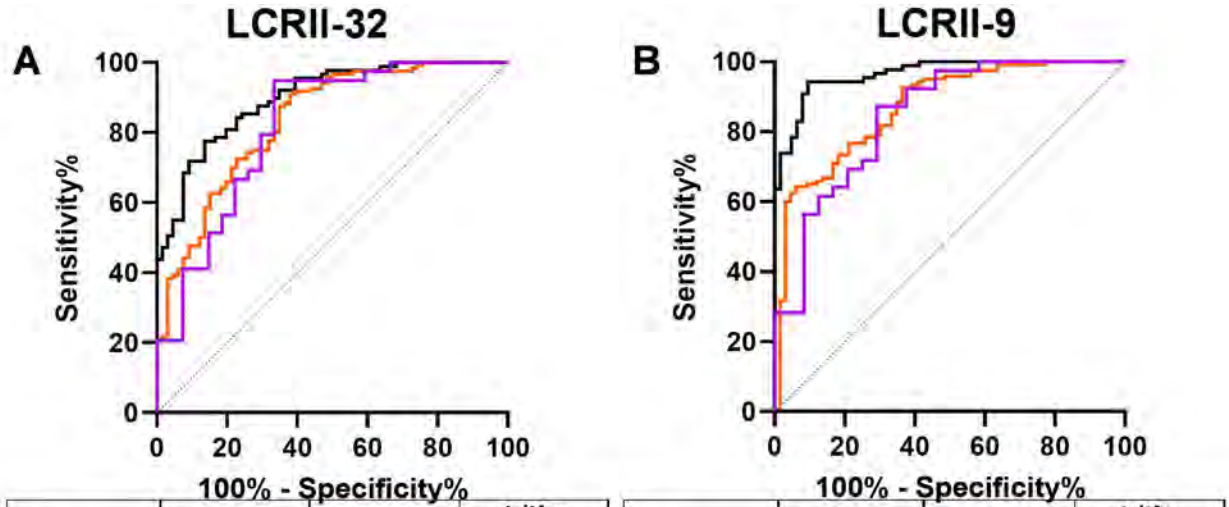
Conclusion: Clinically notable components of immunological profiles may help elucidate disease pathogenesis and help identify individuals at risk for developing SLE for clinical monitoring, early intervention, and enrollment in prevention trials.



LCRII-32	Pre-Criteria	Pre-Classification	At/After Classification
AUC (95% CI)	0.817 (0.708, 0.926)	0.835 (0.774, 0.895)	0.898 (0.852, 0.945)

SESSION INFORMATION

Session Date: Monday, November 8, 2021

Session Title: Plenary III (1424–1429)

Session Type: Plenary Session

Session Time: 10:30AM–12:00PM

Background/Purpose: Enthesitis-related arthritis (ERA) and juvenile psoriatic arthritis (JPsA) are two conditions that represent pediatric correlates of axial spondyloarthritis (axSpA) and adult psoriatic arthritis (PsA), respectively.[1,2] Secukinumab (SEC) has demonstrated efficacy and safety in adult patients (pts) with PsA, ankylosing spondylitis and non-radiographic axSpA.[3-5] This study evaluated efficacy and safety of SEC using a randomized double-blind placebo controlled flare prevention design in pts with active ERA and JPsA.

Methods: Pts (aged 2 to < 18 years) classified as ERA or JPsA according to ILAR criteria of ≥ 6 months duration with active disease were included. The 2-year study consisted of open-label (OL) s.c. SEC (75/150 mg in pts < 50/ ≥ 50 kg) treatment at baseline (BL), and at Weeks (Wk) 1, 2, 3, 4, 8 and 12 in treatment-period (TP) 1. Responders who achieved at least JIA ACR 30 response at Wk 12 were randomized into the double-blinded TP2 to continue SEC or placebo (PBO) every four wks until a disease flare, or up to Wk 100. The primary endpoint was the time to flare in TP2; key secondary endpoints included JIA ACR 30/50/70/90/100, inactive disease, juvenile arthritis disease activity score (JADAS), enthesitis and active joint counts, and safety. Analysis of time to flare in TP2 included the proportion of pts with disease flare, Kaplan-Meier estimate of median days for time to flare, hazard ratio estimate, and stratified log-rank test *P*-value. Intent-to-treat (ITT) analysis using non-responder imputation (NRI) and as observed analysis were performed for JIA ACR 30/50/70/90/100 responses and inactive disease.

Results: 86/97 (88.7%) screened pts were enrolled in TP1 (mean age, 13.1 years; female, 33.7%; ERA, n=52; JPsA, n=34) with a mean JADAS-27 score of 15.1 and enthesitis count of 2.6 at BL. At Wk 12, 75/83 (90.4%) pts achieved JIA ACR 30 and entered TP2. There were 21 flares in PBO treated and 10 flares in SEC treated pts during TP2. The primary endpoint was met as, compared to PBO, SEC treated pts had a significantly longer time to flare, resulting

Efficacy Outcomes, %	TP1 (Wk 12)	TP2			
	SEC (N=86)	SEC (N=37)	95% CI	PBO (N=38)	95% CI

Active joint count, mean change from BL (SD)	−6.3 (7.2)	−6.8 (5.3)	NA	−5.5 (3.3)	NA

[#]Inactive disease: Definition adapted from JIA ACR criteria of Wallace et al., 2011. N=36 for SEC at the end of TP2
NRI data (ITT population) for binary variables, and as observed data for continuous variables presented for TP1 and TP2
N, total number of patients in the treatment group; NA, not available

in a 72% reduced flare risk (HR: 0.28; 95% CI: 0.13–0.63; $P< 0.001$). JIA ACR responses, disease activity, enthesitis count and joints with active arthritis are reported in the **Table**. There were minor differences between the ITT and as observed analysis in JIA ACR responses and inactive disease in TP1. Improvement in the JADAS-27 score was observed in pts in both the ERA and JPsA categories (**Figure**). Rates of adverse events (AEs; 91.7% vs 92.1%) and serious AEs (14.6% vs 10.5%) in the SEC and PBO groups were comparable in the entire TP. No new safety signals were observed in pts receiving SEC (injection site reaction, n=1; overall pt-years =141.5).

Conclusion: In children and adolescents with ERA and JPsA, efficacy of SEC was demonstrated with a significantly longer time to flare vs PBO with sustained improvement of signs and symptoms up to Wk 104. Efficacy was observed in both ERA and JPsA pts along with a favorable safety profile.

Voclosporin for Lupus Nephritis: Interim Analysis of the AURORA 2 Extension Study

Amit Saxena[1], Christopher Mela[2] and Antonia Coeshall[3], [1]NYU School of Medicine, New York, NY, [2]Aurinia Pharmaceuticals Inc., Victoria, BC, Canada, [3]Aurinia Pharmaceuticals Inc., Rockville

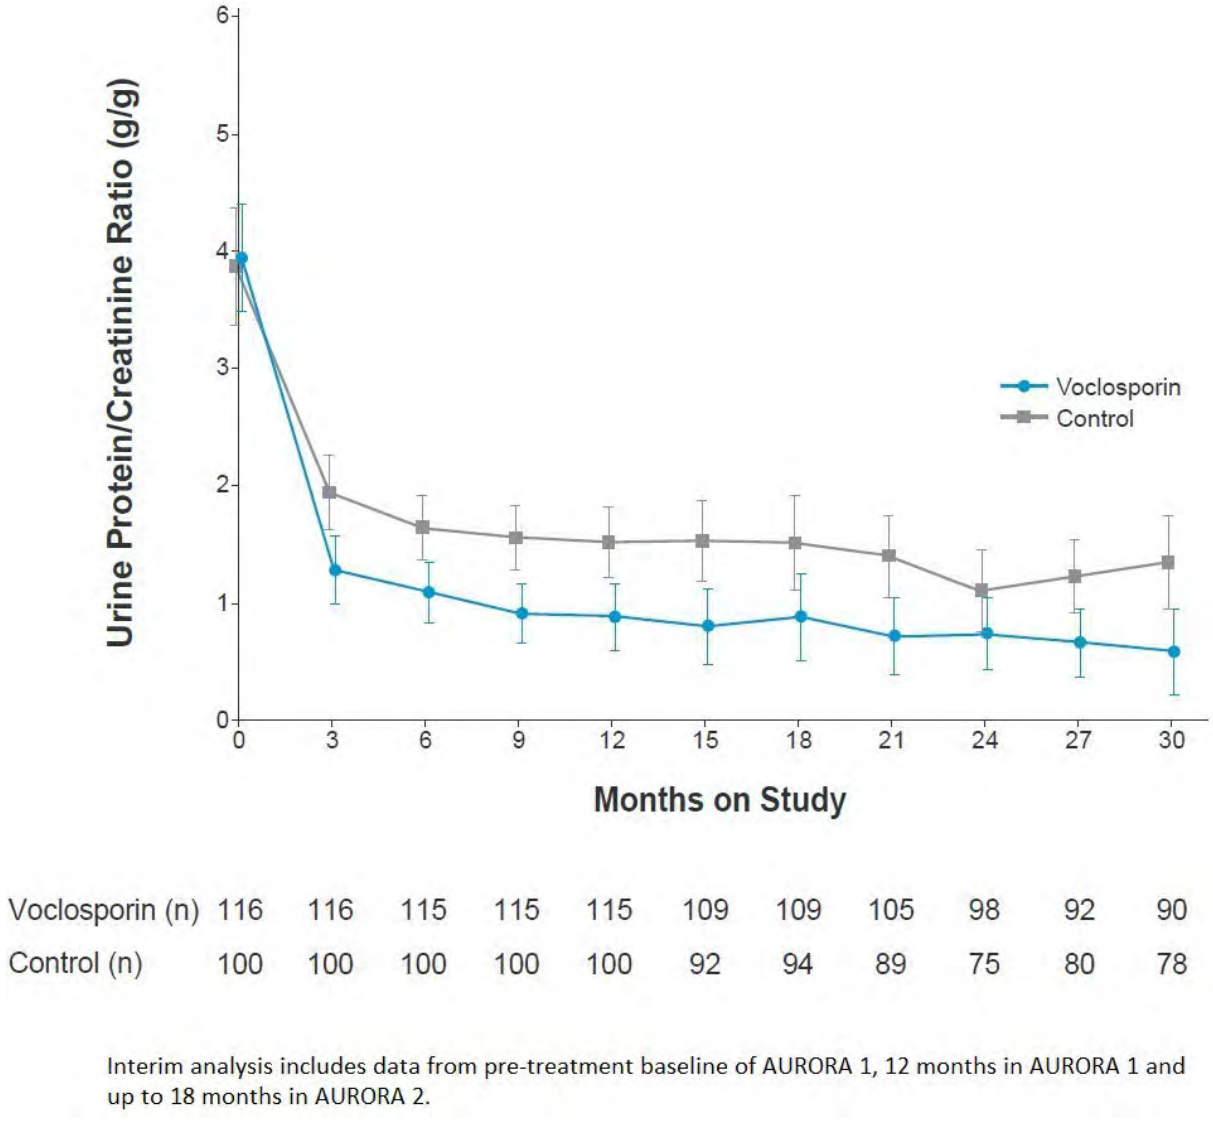

Figure 1. UPCR Over Time.

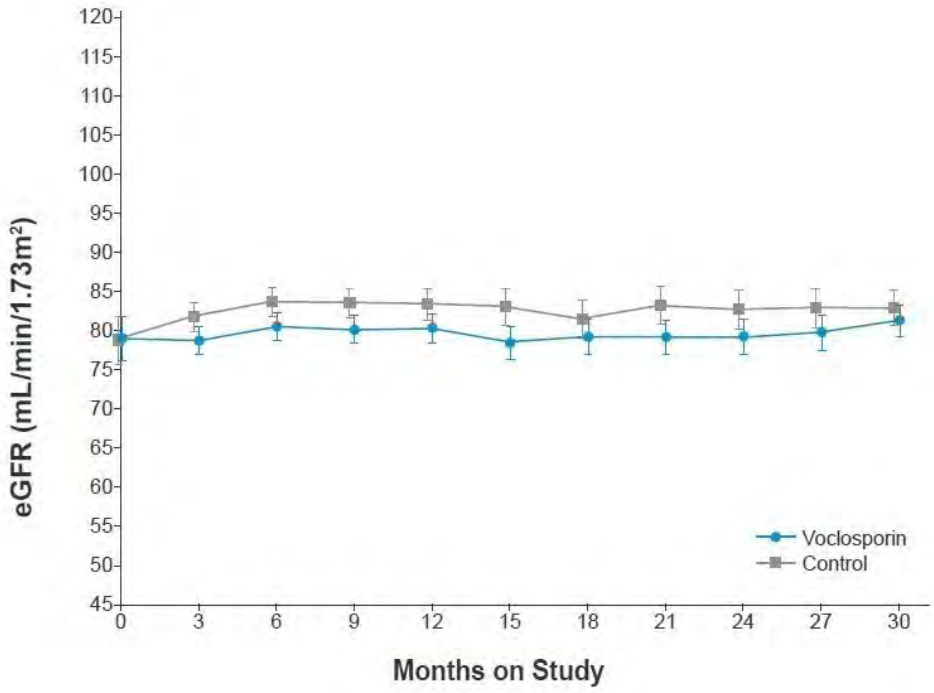
SESSION INFORMATION
Session Date: Monday, November 8, 2021
Session Title: Plenary III (1424–1429)
Session Type: Plenary Session
Session Time: 10:30AM–12:00PM

Background/Purpose: Voclosporin, a novel calcineurin inhibitor (CNI), has been tested successfully in 2 pivotal trials in adult patients with lupus nephritis (LN). Previously reported results from the Phase 3 AURORA 1 and Phase 2 AURA-LV studies showed that compared with mycophenolate mofetil (MMF) and low-dose steroids alone, the addition of voclosporin significantly increased the renal response rate and reduced proteinuria, as measured by urine protein creatinine ratio (UPCR), in patients with LN at 48 weeks in AURA-LV and 52 weeks in AURORA 1.

Methods: Here we report on the second interim analysis of the ongoing 2-year, blinded, controlled extension study, AURORA 2, with exposure up to 30 months (12 months from AURORA 1 and up to an additional 18 months in AURORA 2). All patients enrolled in AURORA 1 had a diagnosis of systemic lupus erythematosus according to the ACR



Voclosporin (n)	116	116	116	116	116	112	111	105	97	92	90
Control (n)	100	100	100	100	100	96	95	89	75	78	76

Renal function assessed with corrected eGFR (Chronic Kidney Disease Epidemiology Collaboration equation) using a prespecified ceiling of 90 mL/min/1.73 m². Interim analysis includes data from pre-treatment baseline of AURORA 1, 12 months in AURORA 1 and up to 18 months in AURORA 2.

Figure 2. eGFR Over Time.

criteria and biopsy-proven LN; patients completing AURORA 1 were eligible to continue in AURORA 2 with the same randomized treatment of voclosporin (23.7 mg BID) or placebo, in combination with MMF (1 g BID) and low-dose oral steroids. UPCR and estimated glomerular filtration rate (eGFR) were evaluated. In total, 116 patients in the voclosporin arm and 100 patients in the control arm enrolled in the extension study; 90 and 78 patients, respectively, had received 30 months of total treatment as of this interim analysis.

Results: Mean UPCR at pre-treatment (AURORA 1) baseline was 3.94 mg/mg in the voclosporin arm (n=116) and 3.87 mg/mg in the control arm (n=100). The LS mean change in UPCR from pre-treatment baseline to month 30 was -3.32 mg/mg for the voclosporin arm (n=90) and -2.55 mg/mg for the control arm (n=78; Figure 1). There was a small, expected and early decrease in mean eGFR in the voclosporin arm in the first 4 weeks of treatment in AURORA 1, after which eGFR remained stable through month 30 (Figure 2). There were no unexpected new adverse events reported in patients who continued voclosporin treatment compared to control-treated patients. A total of 6 and 10 patients in the voclosporin and control arms reported events of coronavirus (COVID-19) infection, with 2 and 6 patients, respectively, reporting serious coronavirus infections.

Conclusion: Patients in the voclosporin treatment arm maintained meaningful reductions in proteinuria with no change in mean eGFR at 30 months of treatment. Additional AURORA 2 efficacy and safety data will be provided at the conclusion of the study.

SESSION INFORMATION

Session Date: Monday, November 8, 2021

Session Title: Plenary III (1424–1429)

Session Type: Plenary Session

Session Time: 10:30AM–12:00PM

Background/Purpose: VEXAS (vacuoles, E1 enzyme, X-linked, autoinflammatory, somatic) syndrome is a newly defined disease cause by myeloid-restricted somatic mutations in blood. Missense mutations at codon 41 of *UBA1* comprise almost all cases of VEXAS and lead to amino acid substitutions of a methionine for either a threonine, valine, or leucine. Reduced translation of the UBA1b isoform and loss of cellular ubiquitylation contribute to severe inflammation. Median survival and predictors of mortality in VEXAS have not been defined and may be essential to guide management.

Methods: Patients referred to two centers for possible VEXAS were included if Sanger sequencing confirmed disease-associated variants in *UBA1*. Kaplan-Meier was used to estimate median survival. Difference in survival was compared by genotype using the logrank test. Cox proportional hazard regression was used to identify associations between clinical features of disease (age at disease onset, thromboembolic disease, pulmonary infiltrates), transfusion dependance, genotype, and mortality. In vitro expression systems were used to study associations between genetic variants and UBA1b isoform expression.

Results: 73 patients with genetically-confirmed VEXAS syndrome were included. Median age at disease onset was 66 years (range 40-85). All patients were male and white. All patients were treated with glucocorticoids.

Prior to genetic testing, the most common clinically assigned diagnosis was relapsing polychondritis (53%), myelodysplastic syndrome (35%), or Sweet syndrome (20%). The most common variants at methionine 41 were threonine

Figure 1 A

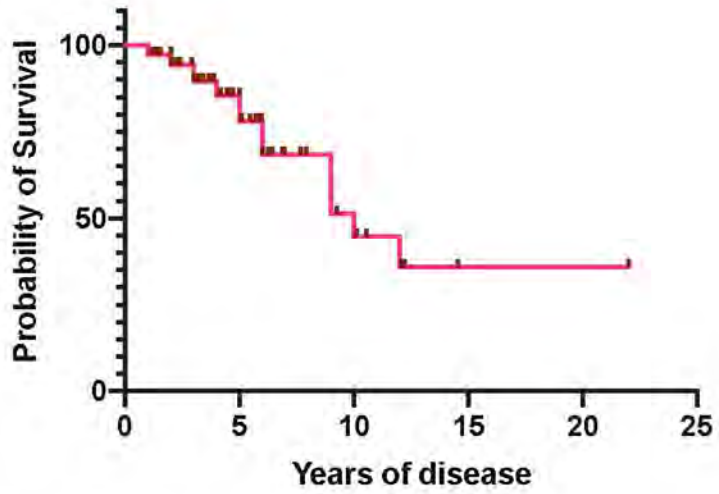

Figure 1 B

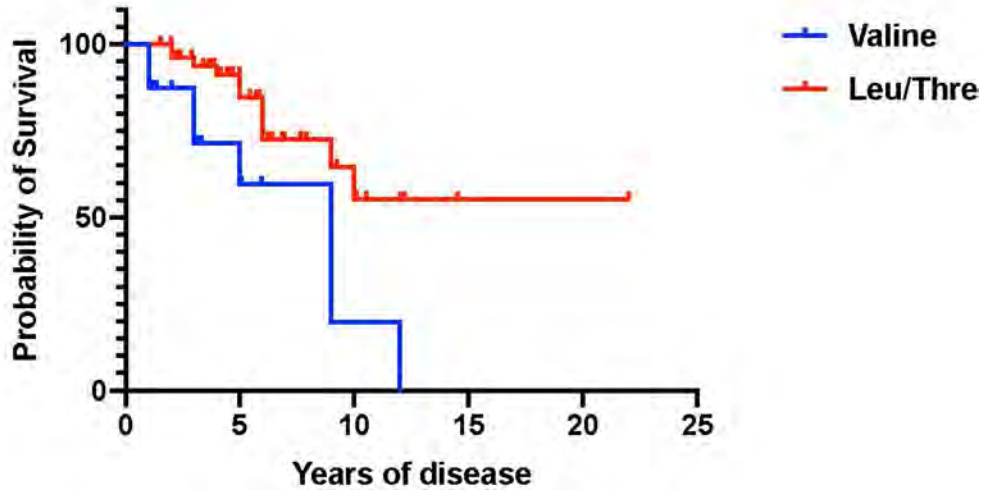

(p.Met41Thr) = 42, valine (p.Met41Val) = 16, and leucine (p.Met41Leu) = 11. Four patients had variants outside of codon 41 and were excluded from further analysis.

The overall mortality was 27%. Median survival from symptom onset was 10 years **(Figure 1A)**. Death was more common in patients with the valine variant (50%) compared to patients with leucine (18%) or threonine (22%). Median survival of patients with the valine variant was 9 years and was significantly shorter compared to patients with other variants ($p < 0.01$, **Figure 1B)**. In multivariable Cox regression, there were two independent predictors of mortality; patients with the valine variant and patients who became transfusion dependent had 3.84x (95% CI 1.50-9.81, $p=0.01$) and 3.48x (95%CI 1.28-9.49, $p < 0.005$) increased risk of death respectively. No other clinical features were associated with mortality. Translation of the UBA1b isoform was reduced in p.Met41Val compared to p.Met41Leu or p.Met41Thr.

Conclusion: A relationship between genotype, bone marrow failure, and survival is seen in patients with the VEXAS syndrome. While mortality rate is high in VEXAS, patients who become transfusion dependent and have a valine amino acid substitution at codon 41 have the highest risk for death. In vitro expression systems provide a mechanistic basis for the genotype specific mortality. Given the high mortality rate and lack of effective medical treatments,

patients with VEXAS should be considered for bone marrow transplantation, with particular focus on patients with risk factors for increased mortality.

Abstract Number: 1427

Reduction of Cardiovascular Disease and Mortality versus Risk of New Onset Diabetes with Statin Use in Patients with Rheumatoid Arthritis

Gulsen Ozen[1], Sophie Dell'Aniello[2], Sofia Pedro[3], Kaleb Michaud[4] and Samy Suissa[5], [1]University of Nebraska Medical Center, Bellevue, NE, [2]Center for Clinical Epidemiology, Lady Davis Research Institute - Jewish General Hospital, Montréal, QC, Canada, [3]Forward, The National Databank for Rheumatic Diseases, Wichita, KS, [4]University of Nebraska Medical Center, Omaha, NE, [5]Center for Clinical Epidemiology, Lady Davis Research Institute - Jewish General Hospital;Depts of Epidemiology and Biostatistics and of Medicine, McGill University, Montréal, QC, Canada

SESSION INFORMATION
Session Date: Monday, November 8, 2021
Session Title: Plenary III (1424–1429)
Session Type: Plenary Session
Session Time: 10:30AM–12:00PM

Background/Purpose: The risks of death and of type 2 diabetes mellitus (T2DM) are increased in RA mainly due to inflammation mediated accelerated cardiovascular disease (CVD) and insulin resistance. In the general population, statins reduce CVD and mortality with a slight increase in T2DM risk. We aimed to assess CVD and mortality benefits and T2DM risk with statins in RA patients.

Methods: We conducted a prevalent new-user cohort study within the UK Clinical Practice Research Datalink, the Hospital Episode Statistics [HES] and Office of National Statistics [ONS] databases. The cohort included individuals ≥18 years old who had a 1st diagnosis of RA and ≥1 DMARD use with no alternative diagnoses and ≥1 year baseline data between 1989 and 2018. Patients with prior DM and no HES/ONS linkage were excluded for T2DM and CVD/mortality cohorts, respectively. Statin initiators were matched with non-users (1:2) on the time-conditional propensity score (TCPS) that included age, sex, BMI, smoking, alcohol, joint surgeries, prior CVD, hypertension, rheumatic diseases comorbidity index, osteoporosis/fractures, cancer, thyroid, chronic liver, kidney, lung and other heart diseases, healthcare utilization, DMARDs, glucocorticoids, NSAIDs, and CVD medications (DM and ethnicity for CVD/mortality). The subjects were followed up for the outcomes of CVD (myocardial infarction, stroke, hospitalized heart failure, CVD death), all-cause mortality and T2DM (diagnostic codes or prescription of antidiabetics). The risk of outcomes was estimated using Cox proportional hazards with adjustment for deciles of TCPS and imbalanced patient characteristics after matching.

Results: The study included 1768 statin initiators and 3528 non-users for CVD/mortality; 3608 statin initiators and 7208 non-users for T2DM (*Figure*). Baseline characteristics of the statin initiators and non-users in the matched cohort were balanced except for DM, some medications and prior cerebrovascular disease (*Table 1*). Among 1768 statin initiators and 3528 non-users, 63 vs. 340 CVD (3.0/100 person-years [PY] vs. 2.7/100 PY) and 62 vs. 525 deaths (2.7/100 PY vs. 4.1/100 PY) occurred, respectively (*Table 2)*. Incident T2DM was noted in 128 of 3608 statin initiators (3.0/100 PY) and 518 of 7208 non-users (2.0/100 PY). Statin initiation was associated with 32% (HR=0.68, 95% CI

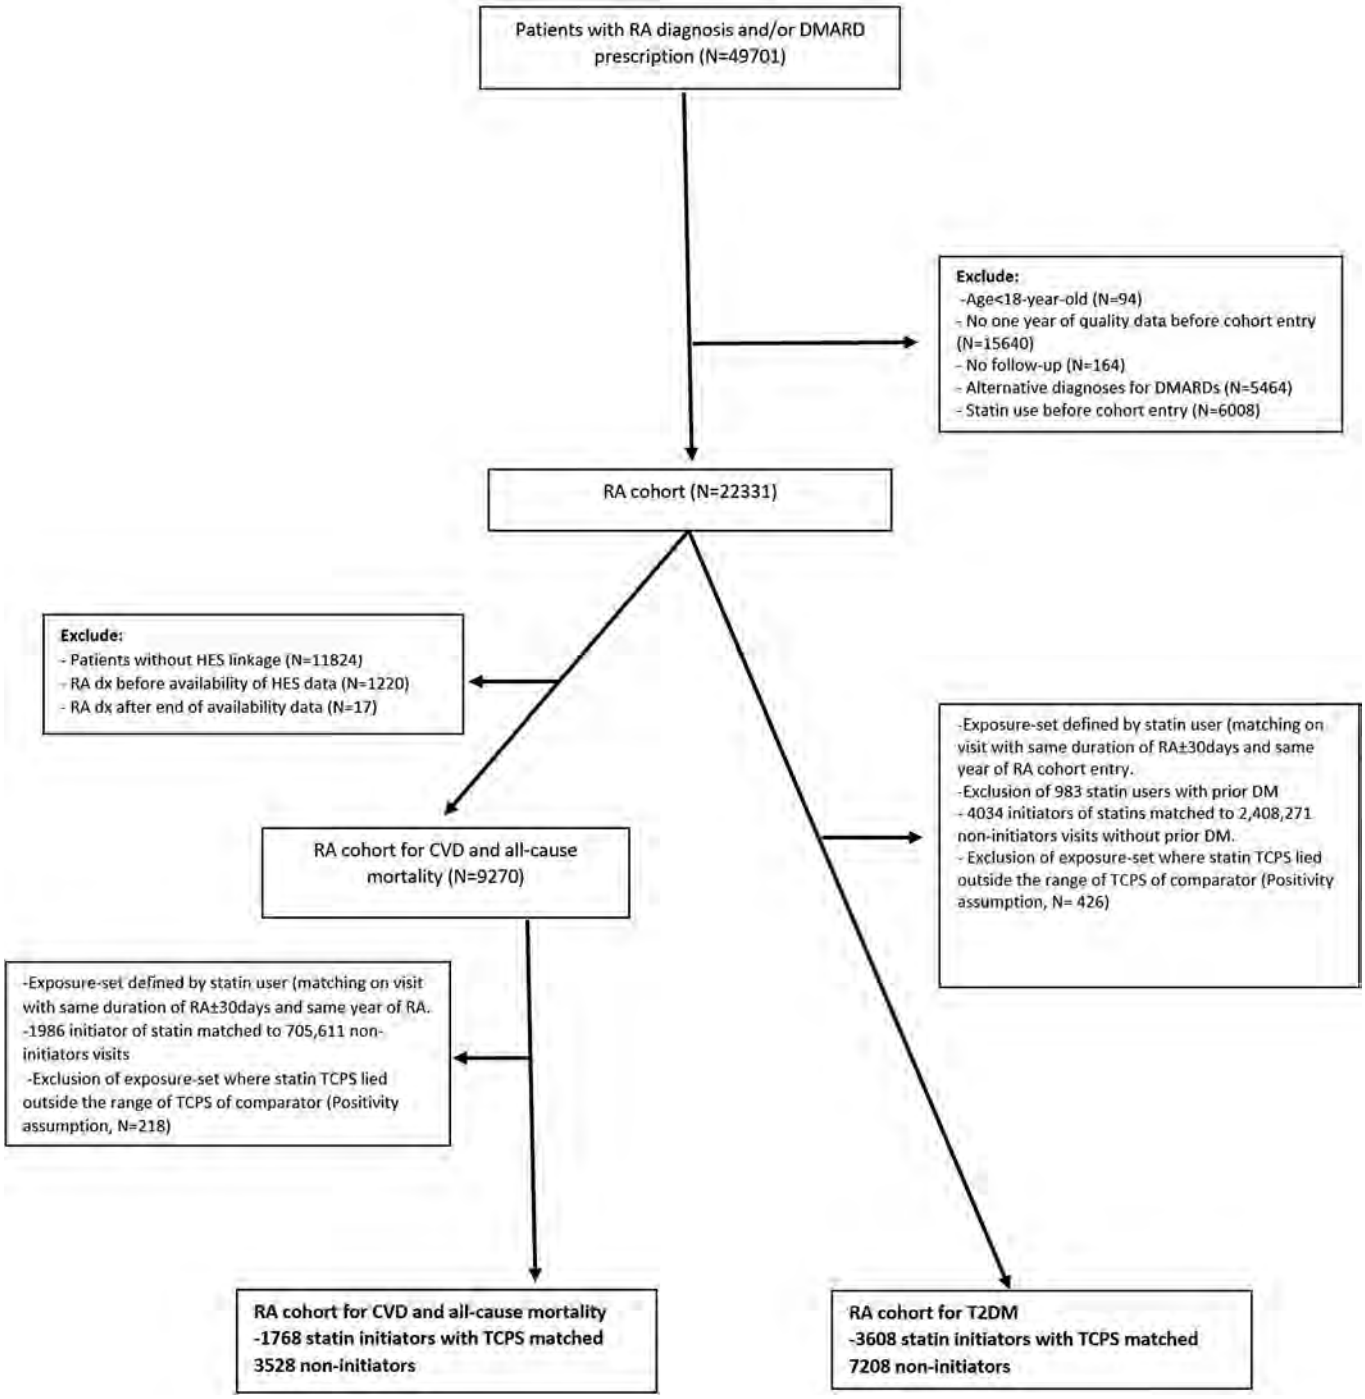

Figure. Overview of the study design and cohort creation for outcomes of cardiovascular disease (CVD), all-cause mortality and type 2 diabetes mellitus (T2DM).

0.51-0.90) reduction in CVD, 54% (HR=0.46, 95% CI 0.35-0.60) reduction in all-cause mortality, and 33% increase in T2DM (HR= 1.33, 95% CI 1.09-1.63) risks. Number needed to treat (NNT) to prevent a CVD and mortality in 1-year was 102 and 42, respectively. Number needed to harm (NNH) for a new T2DM was 127. Patients with and without prior CVD had similar CVD (36% vs. 34%) and mortality (62% vs. 54%) reduction with statins (*Table 2*).

Conclusion: Statins are associated with important reductions in CVD and mortality in both primary and secondary CVD prevention, with a modest increase in T2DM risk in RA patients. The resulting NNT/NNH suggest that CVD/mortality benefits of statins outweigh T2DM risk.

Abstract Number: 1428

Association Between Ongoing Glucocorticoid Use and Major Adverse Cardiovascular Events Among Veterans with Rheumatoid Arthritis

Beth Wallace[1], Yuqing Gao[2], Punyasha Roul[3], Shirley Cohen-Mekelberg[2], Bryant England[3], Ted Mikuls[3], Daniel Clauw[4], Wyndy Wiitala[2], Rodney Hayward[5], Jeremy Sussman[6] and Akbar Waljee[5], [1]Michigan Medicine, VA Ann Arbor Healthcare System, Ann Arbor, MI, [2]VA Ann Arbor Healthcare System, Center for Clinical Management Research, Ann Arbor, MI, [3]University of Nebraska Medical Center, Omaha, NE, [4]University of Michigan, Ann Arbor, MI, [5]University of Michigan, VA Ann Arbor Healthcare System, Center for Clinical Management Research, Ann Arbor, MI, [6]University of Michigan; VA Ann Arbor Healthcare System; Center for Clinical Management Research, Ann Arbor, MI

SESSION INFORMATION

Session Date: Monday, November 8, 2021

Session Title: Plenary III (1424–1429)

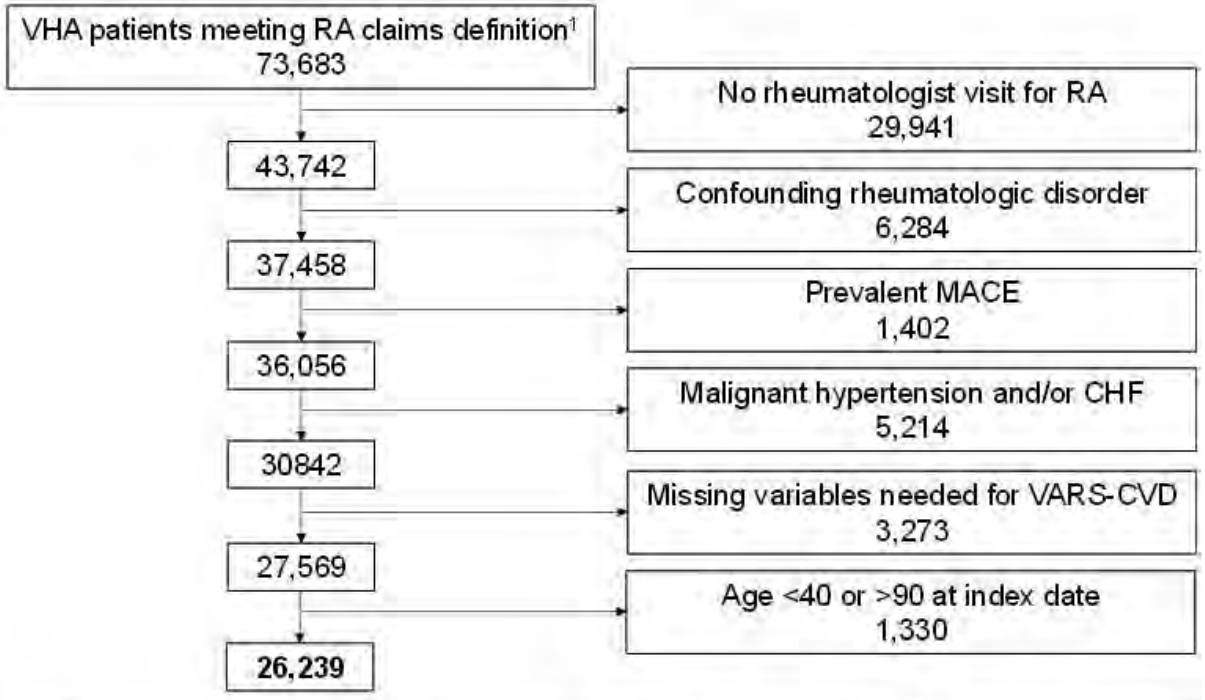
Session Type: Plenary Session

Session Time: 10:30AM–12:00PM

Background/Purpose: A third of RA patients use long-term glucocorticoids (GCs) despite a known dose-dependent association with major adverse cardiovascular (CV) events (MACE). Prior work suggests long-term GC use is common among RA patients with MACE risk factors. We know little about the incremental effect of ongoing GC use on MACE risk in RA patients.

Methods: In this retrospective cohort study, we used national VA administrative data to identify RA patients with ≥1 rheumatology visit during 2013-2018. We defined the index date as the first rheumatology visit in this period after

Figure 1: Data Attrition diagram



[1]Either 1) ≥2 RA outpatient diagnosis codes within >7 but <365 days and ≥1 DMARD dispensed within a year or 2) ≥1 outpatient rheumatologist visit for RA and ≥1 DMARD dispensed within a year

Table 1: Baseline characteristics by MACE risk

	Overall cohort 26,239	Low MACE risk* 5,504	Medium MACE risk* 14,751	High MACE risk* 5,984

RA status				
Methotrexate use/past year (y/n), N(%)	11395 (43%)	2300 (42%)	6530 (44%)	2565 (43%)
Biologic use/past year (y/n), N (%)	7331 (28%)	1410 (26%)	4347 (29%)	1574 (26%)
Rheumatology clinic visits/past year, median (IQR)	2 (1-3)	2 (0-3)	2 (1-3)	2 (0-3)
Glucocorticoid (GC) use				
90-days GC use, year prior to index date, N(%)	4590 (18%)	763 (14%)	2721 (19%)	1106 (19%)
90-days GC use, first year of study period, N(%)	6056 (23%)	1053 (19%)	3562 (24%)	1441 (24%)
GC duration (days), first year of study period, mean (SD)	60.7 (102.9)	49.8 (92.3)	63.8 (105.5)	63.3 (105.0)
MACE				
≥1 MACE during study period, N(%)	837 (3.2%)	65 (1.2%)	477 (3.2%)	295 (4.9%)

[1]Patients with any MACE event or congestive heart failure during the lookback period were excluded from the cohort
MACE: Major adverse cardiovascular events; HDL = high density lipoprotein
* Veterans' Affairs Risk Score for Cardiovascular Disease (VARS-CV) score <3%, 3-9%, and >9%, respectively
** Exclude RA, diabetes, hypertension, CHF

meeting RA diagnostic criteria. We excluded patients < 40 or >90 years and those with other rheumatologic disorders, prior MACE, or congestive heart failure during a lookback period of up to 5 years (Figure 1). We used pharmacy dispensing data to calculate days' supply of GC (exposure), and claims to identify incident MACE (outcome). We defined MACE as any of acute myocardial infarction, stroke, transient ischemic attack, cardiac arrest, or coronary revascularization. We used multilevel logistic regression to evaluate the association between days' supply of GC dispensed in a 6-month period, and the lagged outcome of incident MACE in the following 6-month period. Patients

Table 2: Multilevel logistic regression showing association between days' supply of GC over a 6-month period and incident MACE in the following 6 months

25,630 patients 217,093 observations	Unadjusted odds ratio OR	95% CI	P value
Days' supply GC (per 30 days increase)	**1.151**	**1.12-1.19**	**<0.0001**
VARS-CV score (per 5% increase)	**1.547**	**1.44-1.67**	**<0.0001**
	Model 1*		
Days' supply GC	**1.150**	**1.11-1.19**	**<0.0001**
VARS-CV score	**1.533**	**1.42-1.65**	**<0.0001**
	Model 2**		
Days' supply GC	**1.14**	**1.10-1.19**	**<0.0001**
VARS score	**1.55**	**1.38-1.71**	**<0.0001**

MTX = methotrexate
* Model 1 adjusted for VARS-CV score only
**Model 2 adjusted for 5 baseline covariates: VARS-CV score, sex, number of office visits in year prior to index date, modified Elixhauser count (excluding RA, diabetes, hypertension, and CHF] in year prior to index date, and use of >90 days of GC in the year prior to index date) and 2 time-varying covariates updated every 6 months: methotrexate use and biologic use

were censored after their first MACE event. We adjusted for baseline covariates including demographics, healthcare utilization, and long-term GC use (>90 days), and time-varying covariates including methotrexate and biologic use. We also adjusted for baseline MACE risk using the Veteran's Affairs Risk Score for CV Disease (VARS-CV), developed to recalibrate the ACC/AHA risk calculator for the Veteran population. The algorithm uses medical and pharmacy claims, vital signs, and lab results to calculate a continuous risk prediction estimate, but can also categorize 5-year MACE risk as low (< 3%), medium (3-9%) or high (>9%) using cut points from the ACC/AHA algorithm.

Results: Among 26,239 patients, median 5-year MACE risk by VARS-CV at baseline was 5.7% (IQR 3.4-8.7); 5,984 patients (23%) had high MACE risk (Table 1). Twenty-three percent of patients overall, and 24% with high MACE risk, received ≥90 days of GCs during Year 1 of followup. Incident MACE occurred in 3.2% of patients overall, and 4.9% of patients with high MACE risk. Median (IQR) time to incident MACE was 25 (12-44) months. After adjustment for the covariates above, ach additional 30 days of GC use in a 6-month period was associated with a 1.14 (95% CI 1.10-1.19) increase in odds of MACE in the following 6-month period (Table 2).

Conclusion: In this national RA cohort, 30 days of GC use in a 6-month period was associated with a 14% increase in odds of MACE over the subsequent 6 months. This association was independent of baseline CV, risk, prior long-term GC exposure, and claims-based markers of RA severity such as biologic use. Future work should be directed towards evaluating the effect of persistent GC use on rates of additional MACE events among those who have experienced prior MACE, and examining how baseline MACE risk impacts the relative effect of GC use on incident MACE.

Abstract Number: 1429

ALPN-303, an Enhanced, Potent Dual BAFF/APRIL Antagonist Engineered by Directed Evolution for the Treatment of Systemic Lupus Erythematosus (SLE) and Other B Cell-Related Diseases

Stacey Dillon, Lawrence Evans, Katherine Lewis, Jing Yang, Mark Rixon, Joe Kuijper, Daniel Demonte, Janhavi Bhandari, Steven Levin, Kayla Kleist, Sherri Mudri, Susan Bort, Daniel Ardourel, Michelle Seaberg, NinXin Wang, Chelsea Gudgeon, Russell Sanderson, Martin Wolfson, Jan Hillson, Pamela Holland and Stanford Peng, Alpine Immune Sciences, Seattle, WA

SESSION INFORMATION
Session Date: Monday, November 8, 2021
Session Title: Plenary III (1424–1429)
Session Type: Plenary Session
Session Time: 10:30AM–12:00PM

Background/Purpose: B cell activating factor (BAFF) and a proliferation inducing ligand (APRIL) are TNF superfamily members that bind TACI (transmembrane activator and CAML interactor), BCMA (B cell maturation antigen), and/or BAFF-R on B cells and together support B cell development, differentiation, and survival. Their co-neutralization dramatically reduces B cell survival and function, including antibody (Ab) production, whereas inhibition of either BAFF or APRIL alone mediates relatively modest effects. ALPN-303 is an Fc fusion protein of a human TACI variant TNFR domain engineered by directed evolution (**Figure 1**). It mediates significantly improved combined BAFF and

APRIL inhibition *in vitro* and enhanced pharmacokinetic (PK) and immunomodulatory properties *in vivo,* as compared to wild-type (WT) TACI-Fc molecules. B cell targeting therapies like the WT TACI-Fc fusions atacicept and telitacicept have demonstrated promising clinical potential in B cell-related diseases like SLE. ALPN-303, with enhanced inhibitory activity against BAFF & APRIL, may further improve clinical outcomes.

Methods: Variant TNFR domains (vTD) of TACI that exhibit enhanced affinity for BAFF and APRIL as compared to WT TACI were identified using our directed evolution platform (**Figure 1**). The most potent variant TACI domain identified was fused to a human IgG Fc to generate the therapeutic candidate ALPN-303. ALPN-303 was evaluated for functional activity: 1) *in vitro* in human lymphocyte assays and in a Jurkat/NF-κB reporter cell line transduced with TACI, 2) in mouse KLH immunization models, 3) in the mouse collagen-induced arthritis model, 4) in the bm12àBL/6

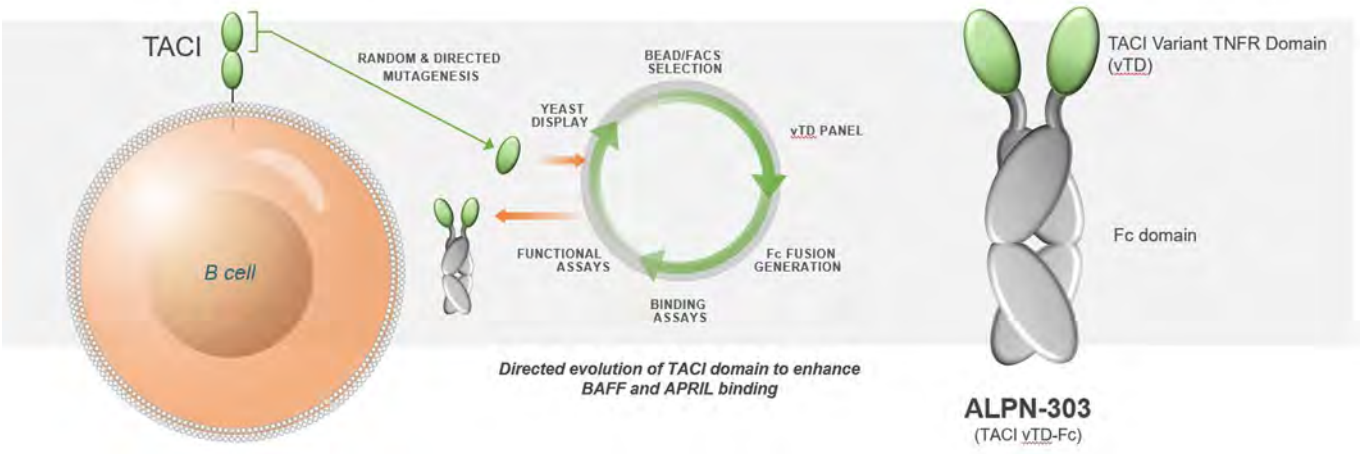

Figure 1. ALPN-303 is a modified TACI-Fc fusion protein generated via directed evolution that mediates enhanced BAFF and APRIL inhibition vs. WT TACI-Fc.

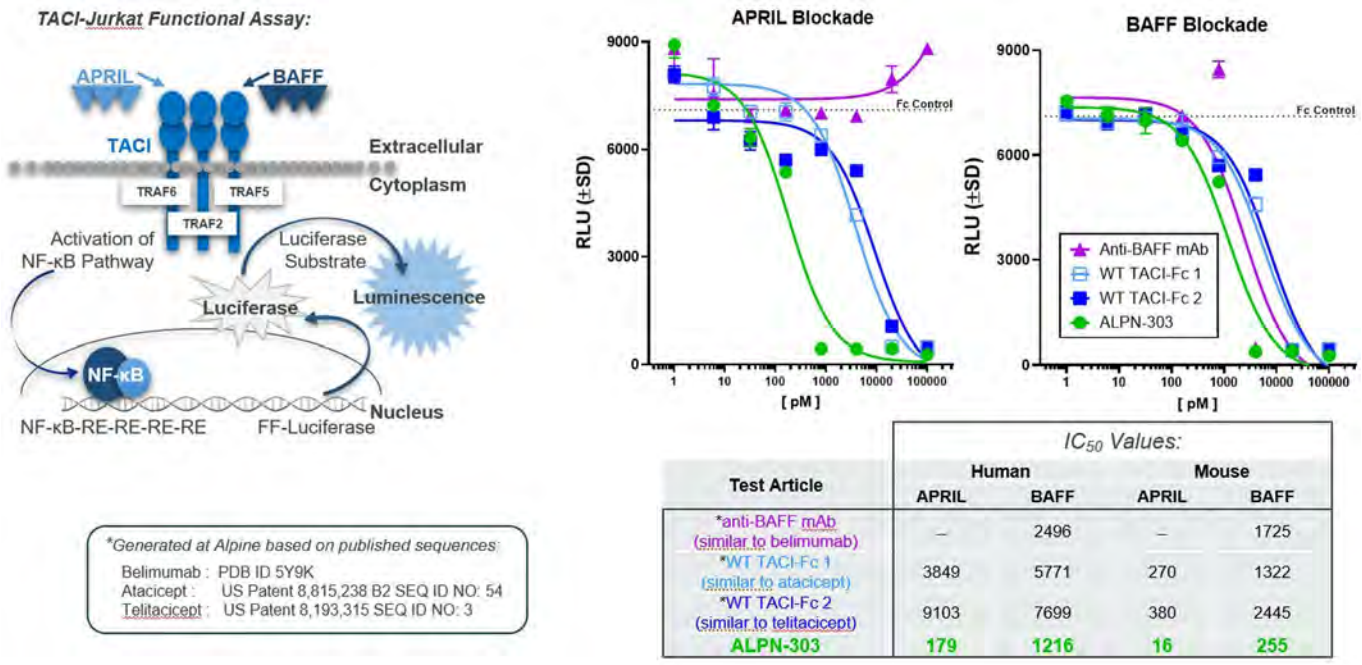

Test Article	IC_{50} Values: Human APRIL	Human BAFF	Mouse APRIL	Mouse BAFF
*anti-BAFF mAb (similar to belimumab)	–	2496	–	1725
*WT TACI-Fc 1 (similar to atacicept)	3849	5771	270	1322
*WT TACI-Fc 2 (similar to telitacicept)	9103	7699	380	2445
ALPN-303	**179**	**1216**	**16**	**255**

Figure 2. ALPN-303 neutralizes APRIL and BAFF activity more potently than WT TACI-Fc in a cell-based reporter assay.

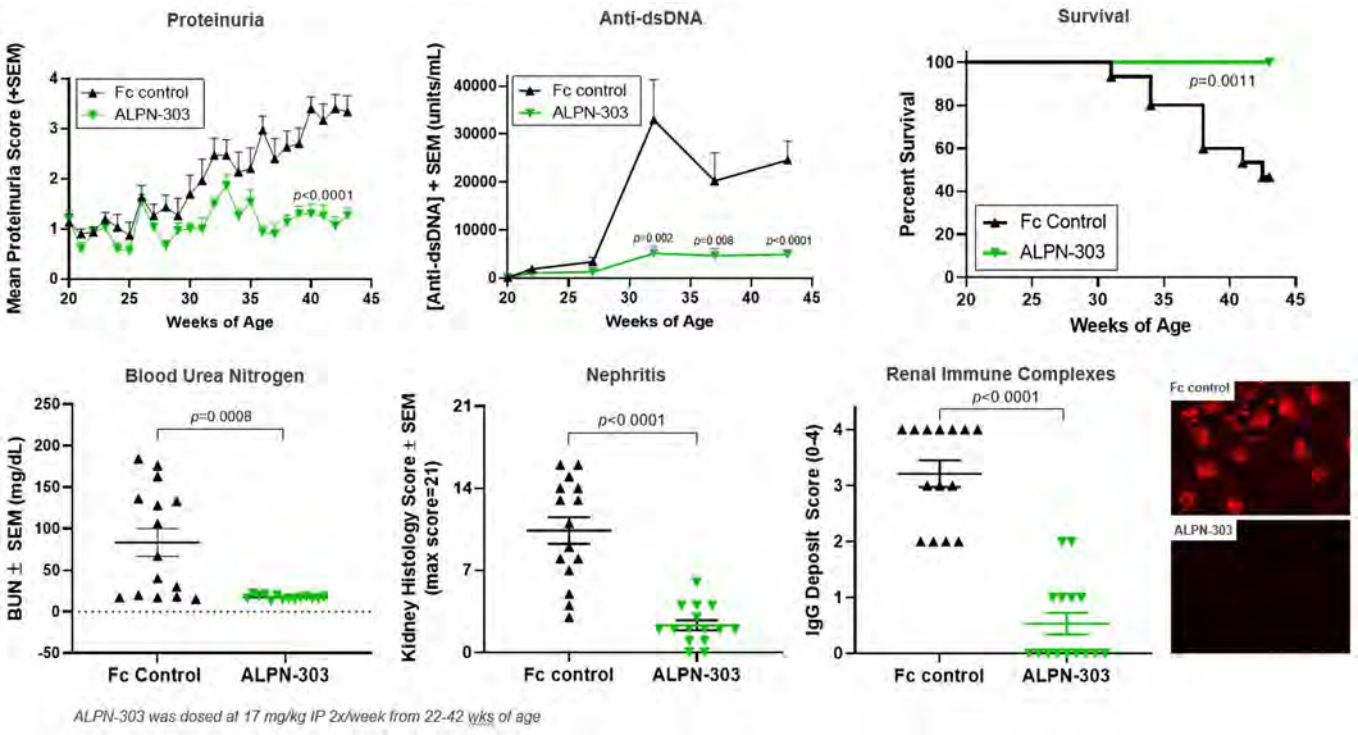

Figure 3. ALPN-303 suppresses disease in the (NZBxNZW)F1 spontaneous lupus model.

induced model of lupus, 5) in the (NZBxNZW)F_1 spontaneous mouse model of lupus, and 6) in preclinical PK/pharmacodynamic studies.

Results: ALPN-303 inhibited BAFF- and APRIL-mediated signaling *in vitro* in human lymphocyte and TACI$^+$ Jurkat assays (**Figure 2**), with significantly lower IC_{50} values than WT TACI-Fc and anti-BAFF Ab comparators. In all mouse models evaluated, administration of ALPN-303 rapidly and significantly reduced key lymphocyte subsets including plasma cells and follicular T helper cells. Furthermore, treatment with ALPN-303 significantly decreased titers of antigen-specific antibodies in immunized mice and in induced disease models, and potently suppressed anti-dsDNA autoAbs, blood urea nitrogen levels, proteinuria, glomerular IgG deposition, and nephritis in the spontaneous NZB/W lupus model (**Figure 3**). Following single dose administration to cynomolgus monkeys, ALPN-303 exhibited higher overall serum exposure and notably enhanced suppression of serum immunoglobulins IgA, IgM, and IgG as compared to WT TACI-Fc treatment.

Conclusion: Directed evolution of TNFR domains has successfully facilitated the development of the novel immunomodulator ALPN-303, a potent BAFF/APRIL antagonist that consistently demonstrates encouraging immunomodulatory activity and efficacy *in vitro* and *in vivo*, superior in preclinical studies to anti-BAFF Abs and WT TACI-Fc. ALPN-303 may thus be an attractive development candidate for the treatment of multiple autoimmune and inflammatory diseases. Preclinical development to enable clinical trials has been initiated.

Autoantibodies Stabilize Neutrophil Extracellular Traps in COVID-19

Yu Zuo[1], Srilakshmi Yalavarthi[1], Sherwin Navaz[1], Claire Hoy[1], Alyssa Harbaugh[1], Kelsey Gockman[1], Melanie Zuo[1], Jacqueline Madison[1], Hui Shi[1], Yogendra Kanthi[2] and Jason Knight[1], [1]University of Michigan, Ann Arbor, MI, [2]NHLBI, NIH, Bethesda, MD

SESSION INFORMATION
Session Date: Monday, November 8, 2021
Session Title: Abstracts: Innate Immunity (1430–1433)
Session Type: Abstract Session
Session Time: 10:30AM–11:30AM

Background/Purpose: The release of neutrophil extracellular traps (NETs) by hyperactive neutrophils is recognized to play an important role in the thromboinflammatory milieu inherent to severe presentations of COVID-19. At the same time, a variety of functional autoantibodies have been observed in individuals with severe COVID-19 where they likely contribute to immunopathology. Work by our group and others has found that many hospitalized COVID-19 patients develop antiphospholipid antibodies similar to those found in antiphospholipid syndrome (APS). Patients with APS (as well as lupus and ANCA-associated vasculitis) have also been reported to develop autoantibodies targeting NETs, which impair NET clearance and activate complement. Here, we aimed to determine the extent to which autoantibodies might target NETs in COVID-19 and, if detected, to elucidate their clinical associations and potential functions.

Methods: NETs were solubilized and coated onto ELISA plates. We then measured IgG and IgM global anti-NET activity in 328 individuals hospitalized with COVID-19 alongside 48 healthy controls. The ability of COVID sera and purified anti-NET antibodies to protect NETs from degradation was determined. We assessed complement deposition on NETs by immunofluorescence microscopy.

Results: We found elevated levels of anti-NET IgG and IgM in patients with COVID-19 as compared with healthy controls ($p< 0.0001$ for both IgG and IgM) (Figure 1A-B). Using a cutoff of 2 standard deviations above the control mean, 27% of patients were positive for anti-NET IgG and 60% for anti-NET IgM. There was a strong interrelationship between anti-NET IgG and anti-NET IgM ($r=0.4$, $p< 0.0001$). High anti-NET antibody levels associated with circulating markers of NETs. Specifically, anti-NET IgG and IgM levels were positively correlated with myeloperoxidase-DNA complexes (IgG $r=0.31$, $p< 0.0001$; IgM $r=0.41$, $p< 0.0001$) and calprotectin (IgG $r=0.33$, $p< 0.0001$; IgM $r=0.34$, $p< 0.0001$). Clinically, anti-NET antibodies tracked with impaired oxygenation efficiency defined as SpO_2/FiO_2 ratio (IgG $r=-0.17$, $p=0.018$; IgM $r=-0.30$, $p< 0.0001$) and elevated levels of circulating D-dimer (IgG $r=0.33$, $p< 0.0001$; IgM $r=0.19$, $p=0.0012$). Furthermore, patients who required mechanical ventilation had higher levels of anti-NET antibodies than those who did not require oxygen supplementation (IgG $p=0.0013$; IgM $p< 0.0001$). Mechanistically, levels of anti-NET IgG in particular demonstrated a negative correlation with the NET degradation potential of COVID sera (Figure 1C), while purified IgG from high anti-NET sera impaired the ability of DNases in healthy serum to degrade NETs (Figure 1D). As compared with low anti-NET COVID sera, high anti-NET sera also more efficiently deposited complement C3d on NETs (Figure 2).

Conclusion: In summary, these data reveal high levels of anti-NET antibodies in many individuals hospitalized with COVID-19, where they track with NETs themselves and also disease severity. It is likely that these antibodies impair

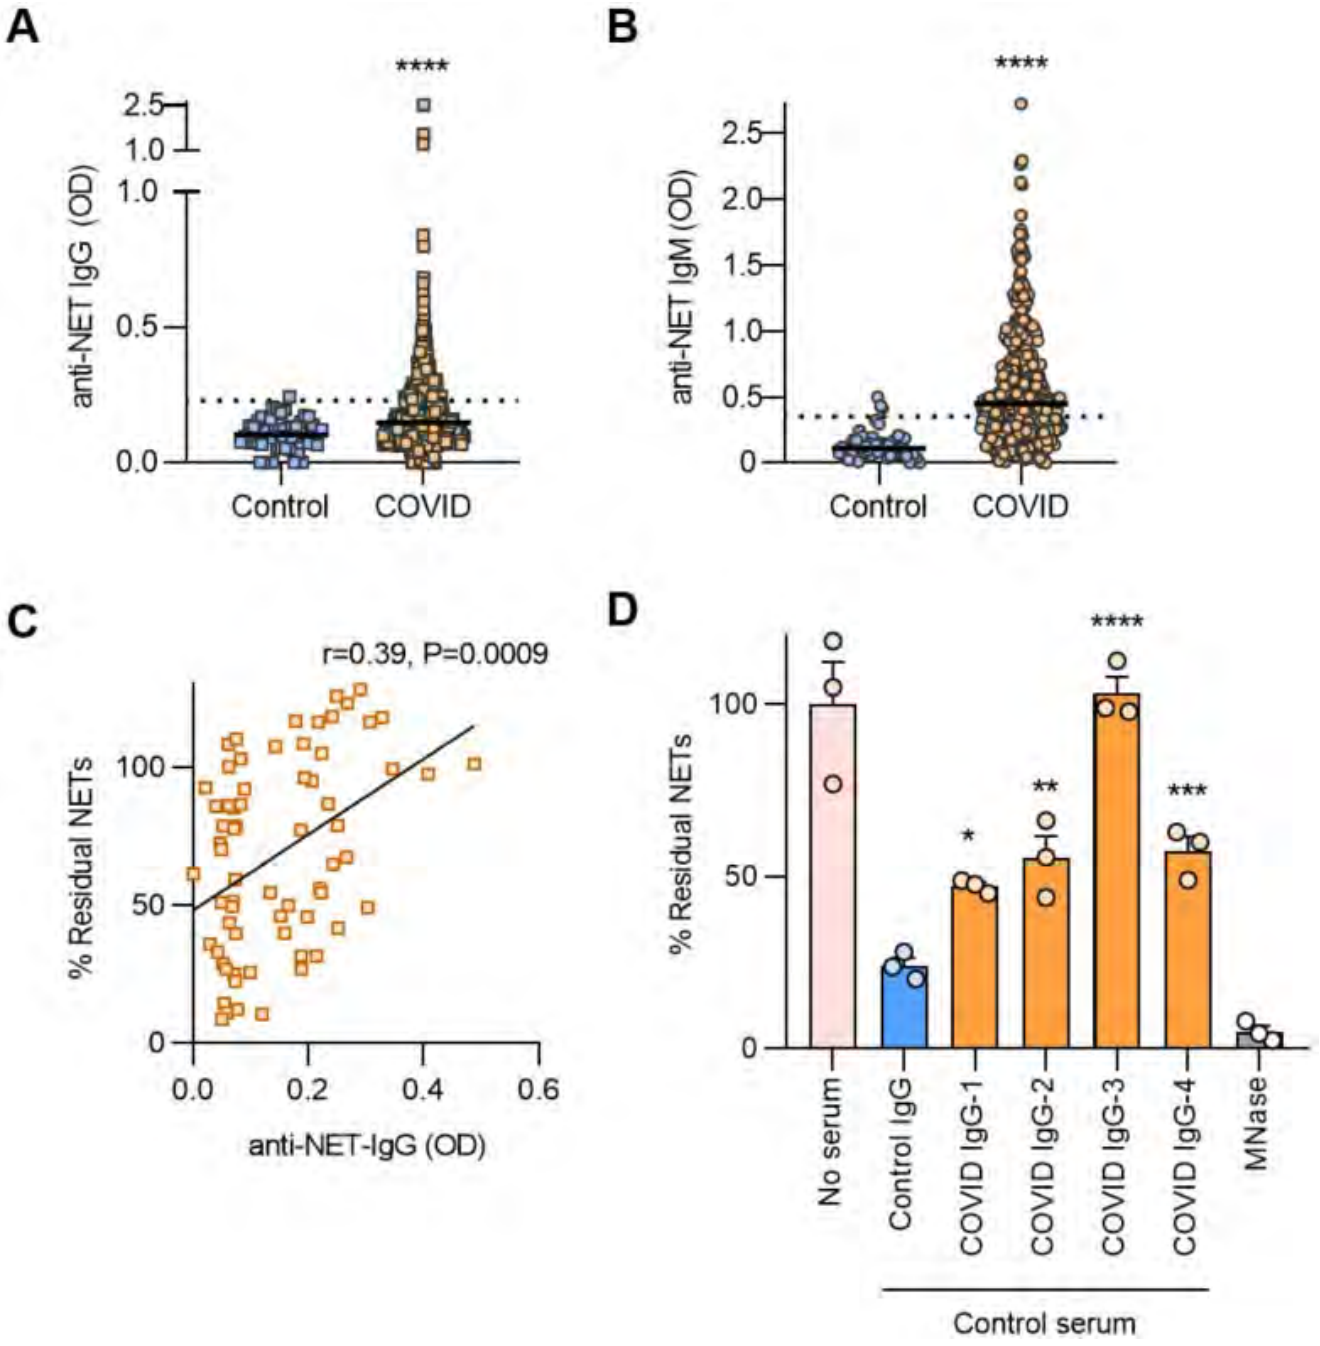

Figure 1. A-B, Anti-NET IgG/M levels were compared by Mann-Whitney test; ****p<0.0001. Dotted lines indicate positive threshold set at 2 standard deviations above the control mean. C, Freshly-induced NETs were incubated with sera from COVID-19 patients. After 90 minutes, percent residual NETs were determined. Correlation with anti-NET IgG was determined by Spearman's method. D, Freshly-induced NETs were incubated with control serum supplemented with either purified IgG from COVID patients or controls, and percent residual NETs were determined after 90 minutes. COVID IgG was compared to control by one-way ANOVA; *p<0.05, **p<0.01, ***p<0.001, and ****p<0.0001.

NET clearance and potentiate complement activation, which may together conspire to potentiate SARS-CoV-2-mediated thromboinflammation.

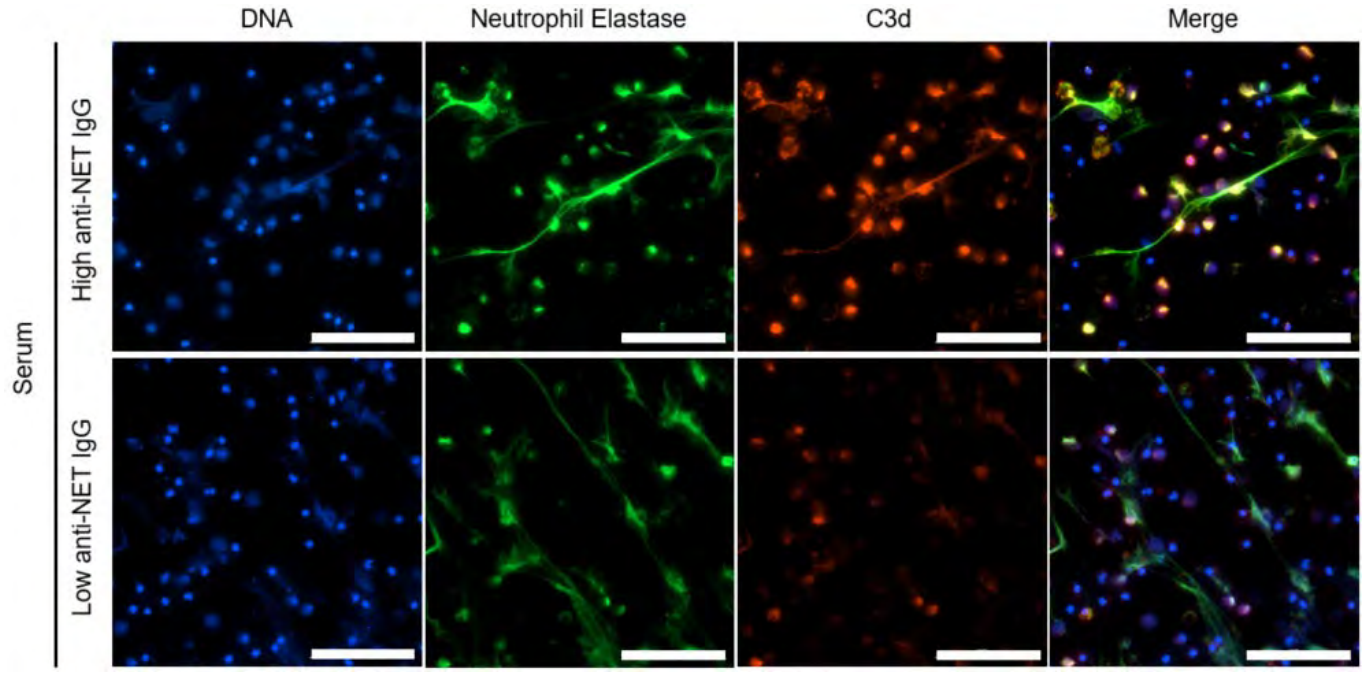

Figure 2. Control neutrophils were stimulated with PMA to generate NETs. After fixation with paraformaldehyde, NETs were incubated with sera from patients with high (top panels) or low (bottom panels) anti-NET IgG; scale bars=100 microns.

Human TLR8 Leads to Fatal Anemia Due to Ineffective Erythropoiesis in Bone Marrow Erythroblastic Islands in Murine SLE

Naomi Maria[1], Julien Papoin[1], Chirag Raparia[1], Zeguo Sun[2], Shani Martinez[1], Weijia Zhang[2], Lionel Blanc[1] and Anne Davidson[1], [1]Institute of Molecular Medicine, Feinstein Institutes for Medical Research, Manhasset, NY, [2]Division of Nephrology, Department of Medicine, Icahn School of Medicine at Mount Sinai, New York, NY

SESSION INFORMATION
Session Date: Monday, November 8, 2021
Session Title: Abstracts: Innate Immunity (1430–1433)
Session Type: Abstract Session
Session Time: 10:30AM–11:30AM

Background/Purpose: There are multiple causes of anemia in SLE including hemolysis, inflammation, renal insufficiency and, more rarely, microangiopathy, hemophagocytosis and bone marrow insufficiency. One cause of anemia in SLE is impaired bone marrow erythropoiesis, possibly mediated by inflammatory cytokines such as TNF or Type I interferon, or by autoantibodies. Because innate immune mechanisms are associated with anemia, here we studied the effect of TLR7 and TLR8 overexpression on SLE related anemia in an animal model in which we introduced human TLR8. Mouse and human TLR7 and human TLR8 recognize ssRNA but human TLR7 and TLR8 differ with respect to their cellular locations and the type of RNA they recognize.

Methods: Sle1.Yaa mice expressing 1-2 copies of huTLR8 as a BAC transgene (huTR8.tg) were generated and followed clinically. HuTLR8 DNA copy number and mRNA expression was confirmed by qDigital and qRT-PCR respec-

tively. Serum autoantibodies were assessed over time. Spleen weights were assessed and splenocytes, renal and bone marrow cells were characterized by flow cytometric analysis. Mammalian erythropoiesis occurs within anatomic niches, erythroblastic islands (EBIs), where erythroblast maturation occurs by close interaction with a central macrophage. EBIs from both bone marrow and spleen were characterized by multispectral imaging flow cytometry and isolated for single cell RNA sequencing (scRNAseq) analysis.

Results: HuTLR8.tg SLE1.Yaa males expressing 2 copies of huTLR8 showed accelerated mortality by 4 months of age compared with >9 months in Sle1.Yaa and homozygous huTLR8.tg C57BL/6.Yaa controls. Complete blood counts in male SLE1.Yaa.huTLR8 mice identified severe anemia as the cause of death. This phenotype first became evident at >12 weeks of age, required both the Sle1 and Yaa loci, as well as the huTLR8 transgene and was more common and severe in huTLR8tg homozygotes. Flow cytometric analyses revealed ineffective erythropoiesis with a block at the transition from the CFU-E to proerythroblast stage. Single cell RNASeq showed that this was associated with an inflammatory phenotype in erythroblastic island central macrophages with a downregulation in adhesion and phagocytic receptors. Compensatory stress erythropoiesis in the spleen was associated with vast expansion of red pulp macrophages with phagocytic properties and fatal anemia was associated with a decrease in red blood cell (RBC) half-life, suggesting that excessive RBC phagocytosis eventually exceeds the capability of stress erythropoiesis to replace the RBC mass.

Conclusion: These data implicate huTLR8 innate inflammatory signals and the presence of auto-antibodies in defective bone marrow hematopoiesis, resulting in an altered phenotype of bone marrow EBI-associated central macrophages consequently reducing erythroid output. Furthermore, loss of mature cells through increased phagocytosis of red cells results in a fatal anemia phenotype. Further elucidating how dysregulated TLR8 signaling disrupts homeostasis of the bone marrow niche is crucial to better understand the role of this TLR in autoimmunity and will facilitate more precise therapeutic targeting.

Modulation of Auto-Inflammation with a Novel Selective Cyclic GMP-AMP Synthase (cGAS) Inhibitor in a *Trex1*$^{-/-}$ Model

Kelly Pike[1], Alexandre Caron[1], Emilie Bérubé[1], Ramsay Beveridge[1], Marc-Oliver Boily[2], Jason Burch[1], Valerie Dumais[1], Nadine Fradet[1], Samuel Gaudreault[1], Daniel McKay[1], Marianne Raymond[1], Eleftheria Seliniotakis[1], Daniel Sietsema[3], Alexander Skeldon[1], Miguel St.-Onge[1], Li Wang[3] and Michael Crackower[4], [1]Ventus Therapeutics, Montréal, QC, Canada, [2]Ventus Therapeutics, Monreal, QC, Canada, [3]Ventus Therapeutics, Boston, MA, [4]Ventus Therapeutics, Boston, QC, Canada

SESSION INFORMATION
Session Date: Monday, November 8, 2021
Session Title: Abstracts: Innate Immunity (1430–1433)
Session Type: Abstract Session
Session Time: 10:30AM–11:30AM

Background/Purpose: Serum titers of anti-type II collagen (anti-CII) antibodies were reported to rise at the recurrence of relapsing polychondritis (RP). It remains to be identified whether anti-CII antibodies at the time of diagnosis are risk factors for relapse. The aim of this study is to investigate the association between anti-CII antibodies at diagnosis and relapse.

Methods: We conducted a retrospective study of patients diagnosed with RP in our hospital between April 2006 and June 2020. Relapse was defined as aggravation of manifestations or worsening of imaging findings which require intensified treatments. Anti-CII antibodies were assayed by a clinically certificated ELISA test.

Results: Eighteen patients were included in this study. The median age at diagnosis was 68.2 years (IQR 56.4-72.7 years), and 55.6% were females. The median period of observation was 40.9 months (IQR 20.7-57.1 months). Seven patients had relapses (38.9%). The median time to the first relapse was 161 days (IQR 135-394 days). The anti-CII antibodies were tested in 13 patients. Tracheobronchial involvement and nasal chondritis were more frequent in the relapse group compared to the non-relapse group (71.4% vs 18.2%, p = 0.049; 85.7% vs 9.1%, p = 0.002, respectively). The relapse group had higher levels of anti-CII antibodies at diagnosis [median (IQR) : 66.8 EU/mL(38.9-131.8 EU/mL) vs 14.5 EU/mL(10.7-18.7 EU/mL), p = 0.001] (**Figure 1**). Comparing for initial treatments, the relapse group tended to receive higher dose of prednisolone (median (IQR) 45.0mg (25.0-50.0 mg) vs 30.0mg (1.5-40.0 mg), p = 0.055). Immunosuppressive drugs and biologics were more often used in the relapse group (57.1% vs 0%, p = 0.011). Kaplan-Meier estimates of the relapse-free survival showed the anti-CII antibodies positive group was significantly more likely to relapse than the negative group (Log-rank p = 0.009; HR = 1.017, 95% CI 1.004-1.031) (**Figure 2**).

Conclusion: High titers of anti-CII antibodies at the time of diagnosis are the risk factors for relapse. This study shows that tracheobronchial involvement may also be a factor associated with relapse. We plan to measure anti-CII antibodies in consistent intervals and discuss whether routine anti-CII antibodies monitoring is useful for predicting future relapse.

Endothelium-protective, Histone-neutralizing Properties of the Polyanionic Agent Defibrotide

Hui Shi[1], Alex Gandhi[1], Stephanie Smith[1], Qiuyu Wang[1], Diane Chiang[1], Srilakshmi Yalavarthi[1], Ramadan Ali[2], Chao Liu[1], Gautam Sule[1], Eliza Pei-Suen Tsou[1], Yu Zuo[1], Yogendra Kanthi[3], Jiandie Lin[1], James Morrissey[1] and Jason Knight[1], [1]University of Michigan, Ann Arbor, MI, [2]University of Michigan, Ann Arobr, MI, [3]NHLBI, NIH, Bethesda, MD

SESSION INFORMATION
Session Date: Monday, November 8, 2021
Session Title: Abstracts: Innate Immunity (1430–1433)
Session Type: Abstract Session
Session Time: 10:30AM–11:30AM

Background/Purpose: Neutrophil-mediated activation of the endothelium plays a role in the pathogenesis of diverse disease states ranging from autoimmunity to cancer to COVID-19. Neutralization of cationic proteins (such as neutrophil extracellular trap/**NET**-derived histones) with polyanionic compounds has been suggested as a strategy for protecting the endothelium from such insults. Here, we investigated the role of the FDA-approved agent defibrotide (a pleotropic mixture of oligonucleotides) in engaging histones and blocking their pathological effects on endothelium.

Methods: Human umbilical vein endothelial cells (**HUVECs**) and human microvascular endothelial cells (**HMVECs**) were cultured with purified NETs or histone H4. Cell activation was determined by specific gene expression (e.g., E-selectin), neutrophil adhesion, enzymatic activity of tissue factor, and RNA sequencing. Cell viability was tested

by staining with crystal violet and annexin V. Surface plasmon resonance was used to verify molecular interactions. Thrombosis was modeled in mice via stenosis of the inferior vena cava.

Results: HUVECs and HMVECs were treated with NETs (1 μg DNA content/ml) in the presence or absence of defibrotide (10 μg/ml) for 4 hours. Defibrotide significantly ($p < 0.0001$) mitigated NET-mediated upregulation of E-selectin (30% reduction), ICAM-1 (70%), and VCAM-1 (60%). Calcein-AM-labeled neutrophils adhered 10-times more strongly to NET-activated endothelial cells, an effect that was reduced by 50% in the presence of defibrotide ($p < 0.01$). NET-mediated tissue factor upregulation was also significantly reduced by defibrotide, whether measured by gene expression or enzymatic activity. Network analysis of upregulated genes in NET-stimulated endothelial cells revealed an inflammatory signature highlighted by meta groups such as the TNF and NF-κB signaling pathways, which were downregulated by defibrotide. Narrowing the focus from polymolecular NETs to specific NET components, a strong interaction between histone H4 and defibrotide was confirmed by surface plasmon resonance (K_D 53.5 nM). Purified histone H4 (25 μg/ml) increased expression of E-selectin and ICAM-1 by endothelial cells, effects that were completely abolished by defibrotide. Furthermore, defibrotide markedly protected the viability of endothelial cells over a 24-hour period of exposure to histone H4 (100 μg/ml). Notably, histone H4-mediated cell death was on the spectrum of pyroptosis with increased IL-1β and cleavage of gasdermin D (both inhibited by defibrotide). Finally, in a mouse model of thrombosis, injection of histones (10 mg/kg) markedly increased thrombus accretion at 24 hours (mean thrombus weight 8 mg vs. 2 mg), with thrombus weight returned to baseline by infusion of 150 mg/kg defibrotide at the time of histone injection. Notably, soluble E-selectin tracked closely with thrombus accretion, as did infiltration of thrombus leukocytes.

Conclusion: These data provide insights into the potential role of polyanionic compounds in protecting the endothelium from thromboinflammation with potential implications for myriad NET- and histone-accelerated disease states.

Multiomic Study of Skin, Peripheral Blood and Serum: Is Serum Proteome a Reflection of Disease Process at the End-Organ Level in Systemic Sclerosis?

Victor Farutin[1], Elma Kurtagic[2], Joel Pradines[3], Ishan Capila[3], Maureen Mayes[4], Minghua Wu[5], Anthony Manning[3] and Shervin Assassi[6], [1]Janssen R&D, LLC, Watertown, MA, [2]Janssen R&D, LLC, Cambridge, [3]Momenta Pharmaceuticals, Inc., Cambridge, MA, [4]Division of Rheumatology and Clinical Immunogenetics, University of Texas McGovern Medical School, Houston, TX, [5]University of Texas Health Science Center at Houston, Houston, TX, [6]University of Texas McGovern Medical School at Houston, Houston, TX

SESSION INFORMATION

Session Date: Monday, November 8, 2021

Session Title: Abstracts: Systemic Sclerosis & Related Disorders – Basic Science (1434–1437)

Session Type: Abstract Session

Session Time: 10:30AM–11:30AM

Background/Purpose: Discovery of biomarkers in systemic sclerosis (SSc) represents an unmet clinical need. Samples from prominently affected fibrotic end-organs such as lung and skin are not readily available whereas serum proteins are assessed during routine clinical care. However, it is unclear to what extent serum proteins reflect the

molecular dysregulations of peripheral blood cells (PBCs) or affected end-organs. This study describes multiomic comparative analysis of SSc serum proteomic profile as well as gene expression analysis of PBC and skin biopsies in concurrently collected samples from SSc patients and healthy controls.

Methods: Global gene expression profiling on Illumina HumanHT-12 BeadChip was carried out in skin and PBC samples obtained from 49 patients and 25 unaffected controls. Levels of 911 proteins were determined in concurrently collected serum samples with Olink Proximity Extension Assay (PEA) technology.

Results: SSc serum profile revealed an upregulation of proteins involved in pro-fibrotic, homing and extravasation, as well as extracellular matrix components/modulators. Notably, several soluble receptor proteins such as EGFR, ERBB2, ERBB3, VEGFR2, TGFBR3, and PDGF-Rα were downregulated. Thirty-nine proteins correlated with severity of SSc skin disease as assessed by modified Rodnan Skin Score (mRSS) (FDR< 5%). There was a significant correlation between direction of differential expression of serum proteins in SSc vs. control comparison and their association with mRSS (ρ=0.59, permutation p< 0.0001) (Figure 1). Correlative analysis of differences between SSc patients and healthy controls among the three datasets demonstrated that:

1) The differential expression of serum protein in SSc vs. control comparison significantly correlated with the differential expression of corresponding transcripts in skin but not in PBCs (p=0.014 vs. p=0.24) (Fig 2A).

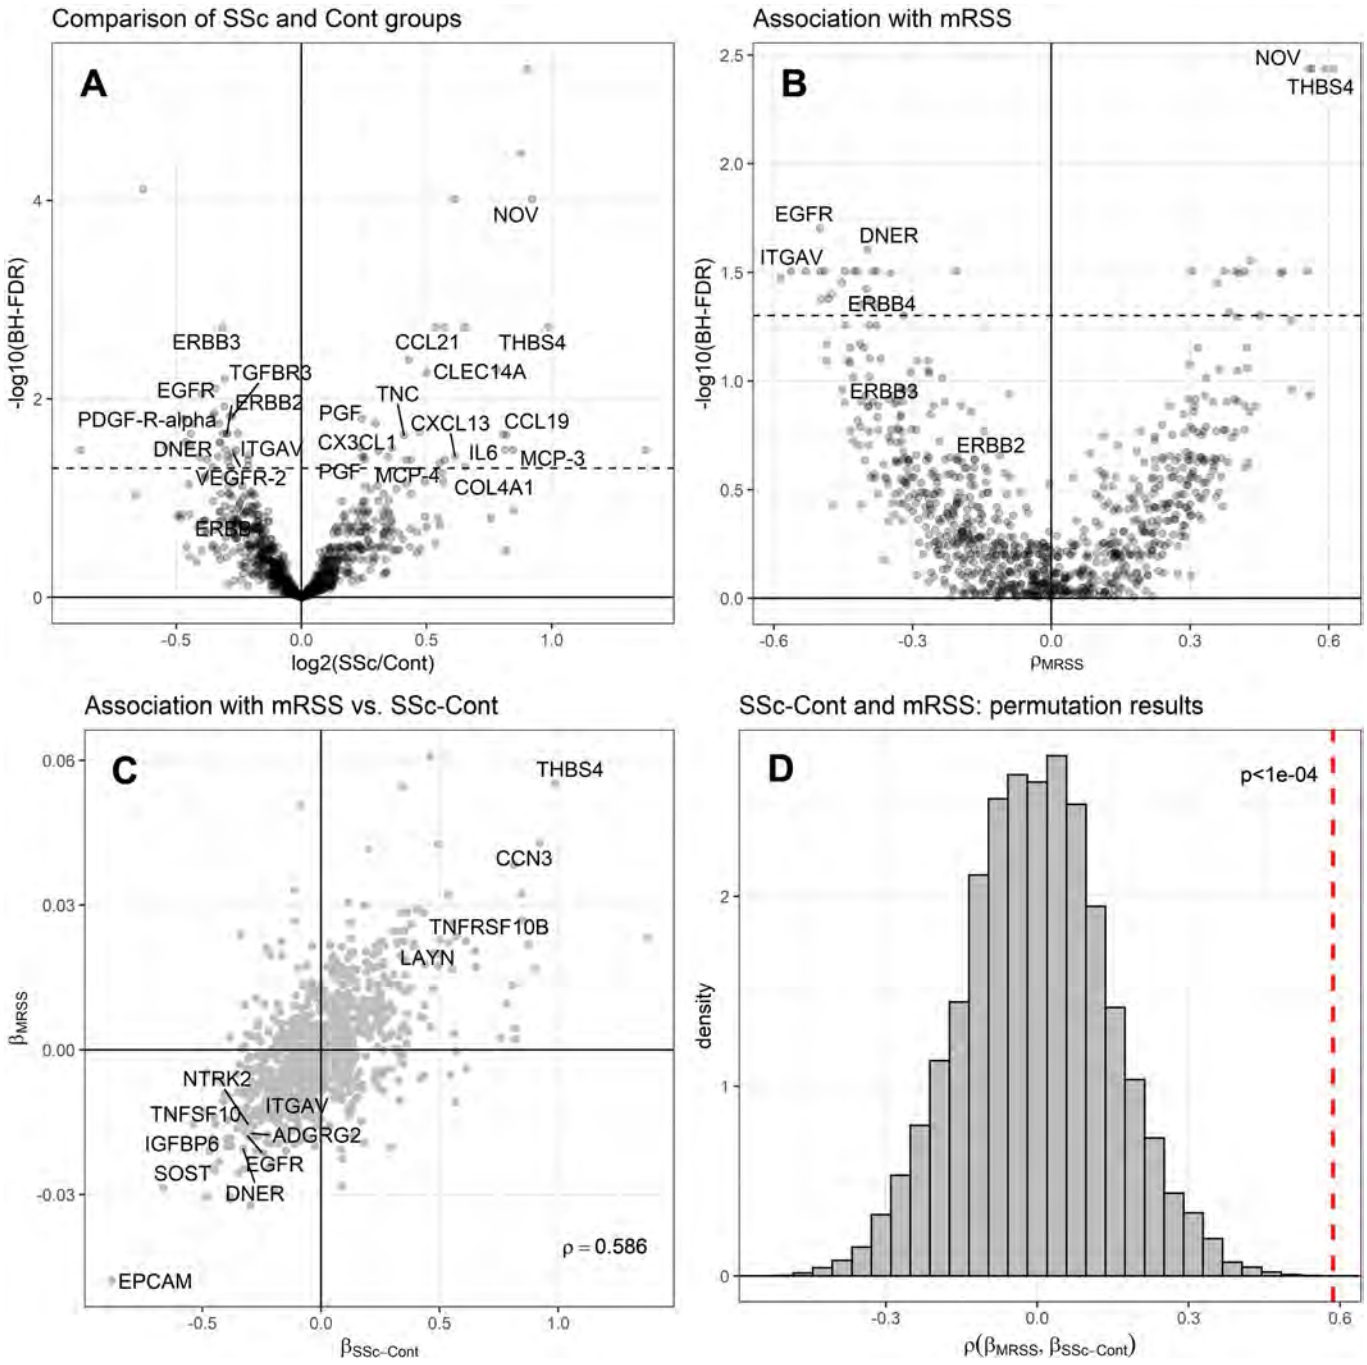
2) The differentially expressed serum proteins represented more significant Well-Associated-Proteins (WAP) (Pradines et al. PMC7046299) in the skin than in PBC gene expression dataset, as demonstrated by lower WAP scores in the skin tissue (Figure 2B).

3) The assessment of the concordance of between-sample similarities at the entire dataset level revealed that the molecular profile of serum proteins and skin gene expression data were significantly concordant in SSc patients but not in healthy controls. On the contrary, the concordance of similarities between serum protein and PBC gene expression profiles was most pronounced in healthy controls and notably reduced in patients, suggesting disruption of correlation between the serum proteome and PBC transcriptome in SSc patients, contrary to healthy controls due to spill-over effect from skin. (Fig 3).

Conclusion: In this first multiomic cross-comparison of SSc serum proteins, PBC transcriptome and skin transcriptome in concurrently collected samples, the serum protein profile correlated more closely with molecular dysregulations of skin than PBCs, supporting the notion that it might serve as a reflection of disease severity at the end-organ level.

Serum proteins associations with disease and mRSS: a) Volcano plot of SSc-Cont differences; b) Volcano plot of correlation with mRSS in SSc patients; c) Scatterplot of serum proteins associations with mRSS vs. SSc-Cont differences; d) Permutation-based significance of the correlation between serum protein associations with mRSS and SSc-Cont differences. Vertical red dashes in panel d) indicate observed correlation between mRSS and disease effects on serum proteome; histogram represents distribution of such correlations obtained for randomly permuted sample annotation. Text labels in panel c) indicate proteins associated at BH-FDR<5% both with mRSS and disease.

SSc-Cont differences for the serum proteins are significantly associated with SSc-Cont differences in skin: a) SSc-Cont differences are positively correlated between serum proteins and corresponding skin transcripts; b) WAP score ranks of differentially expressed serum proteins for SSc-Cont differences in skin and in PBC (lower values of rank represent more significant WAPs). The WAP ranking is generated based on prior knowledge in the form of protein-protein interaction networks.



Concordance of between samples similarities (as Spearman correlations) for each pairwise combination of the three datasets: serum proteins, PBC transcripts and skin transcripts. Top row displays results for healthy controls, bottom row – for SSc patients. Mantel test results (vertical red dashes represent the observed concordance of between sample similarities for the actual mapping of samples to subjects) are compared to their corresponding null distributions (obtained by randomly permuting assignment of samples to subjects in each dataset).

SESSION INFORMATION

Session Date: Monday, November 8, 2021

Session Title: Abstracts: Systemic Sclerosis & Related Disorders – Basic Science (1434–1437)

Session Type: Abstract Session

Session Time: 10:30AM–11:30AM

Background/Purpose: Systemic sclerosis (SSc) is a rare autoimmune disease characterized by skin and internal organ fibrosis, vascular abnormalities, and autoantibody formation. Single cell genomics studies have identified multiple fibroblasts populations in normal and fibrotic skin *in vivo*. Here we report a 3D skin-like tissue that reproduces multiple fibroblasts populations similar to those observed in human skin *in vivo*.

Methods: We have developed *in vitro* 3D skin-like tissues that reproduce phenotypic and molecular aspects of SSc. Two different types of 3D tissues were analyzed including a self-assembly (SA) tissue with only fibroblasts and a skin equivalent (saSE) tissue constructed with fibroblasts, keratinocytes, macrophages, and plasma isolated from donors. SA or saSE 3D skin-like tissues were seeded with either SSc-derived or control cells; the same cells were seeded into 2D culture in parallel. 3D skin-like tissues were dissociated into single cell suspensions and processed using the 10X genomics platform. Single cell RNA-sequencing (scRNA-seq) of the saSE tissues yielded expression profiles for 15,921 SSc and 31,632 control cells, the SA tissue model included expression profiles for 27,217 SSc and 26,415 control cells, 2D cells in cultures included 36,419 SSc and 26,991 control cells.

Results: scRNA-seq was performed to compare cells grown in 2D cultures to 3D SA, and saSE tissues. The most complex model, the saSE model, exhibited four distinct fibroblasts populations that parallel those observed in normal-human skin (Figure 1A). Analysis of fibroblasts grown in 2D culture showed the least diversity, consisting of only two fibroblast subsets. Fibroblast subsets in the more complex saSE tissue model were characterized by greater expression of mediators implicated in SSc pathogenesis. Fibroblast subpopulations were named by their top two differentially expressed genes and are referred to as “Fibroblast VEGFA, STC1”, “Fibroblast APOE, CDF”, “Fibroblast LUM, TPM1”, and “Fibroblast MMP2, PTGDS”. The “Fibroblast LUM, TPM1” cluster was marked by expression of collagen genes, notably COL1A1 and COL3A1, that are over-expressed in SSc (Figure 1B). Gene set enrichment analysis (GSEA) of each fibroblast subpopulation demonstrated upregulation of TGFβ signaling in clusters “Fibroblast LUM, TPM1” and “Fibroblast VEGFA, STC1”. IL2-STAT5 signaling, Hypoxia, and PI3K signaling were also reported as differentially-expressed pathways among these fibroblast subpopulations. Comparison to scRNA-seq data from human skin biopsies shows parallel populations of fibroblasts highly expressing APOE, PTGDS, and LUM.

Conclusion: We have used scRNA-seq to capture fibroblasts diversity in a fabricated 3D human skin model that recapitulates SSc dermal fibrosis. We identified four fibroblast subsets with potential roles in SSc. GSEA demonstrated that each of these populations is characterized by distinct signaling pathway activation. These fibroblast subsets likely make unique contributions to underlying SSc pathology and may represent targetable cell types for therapeutic intervention in 3D skin models that more closely approximate the human condition.

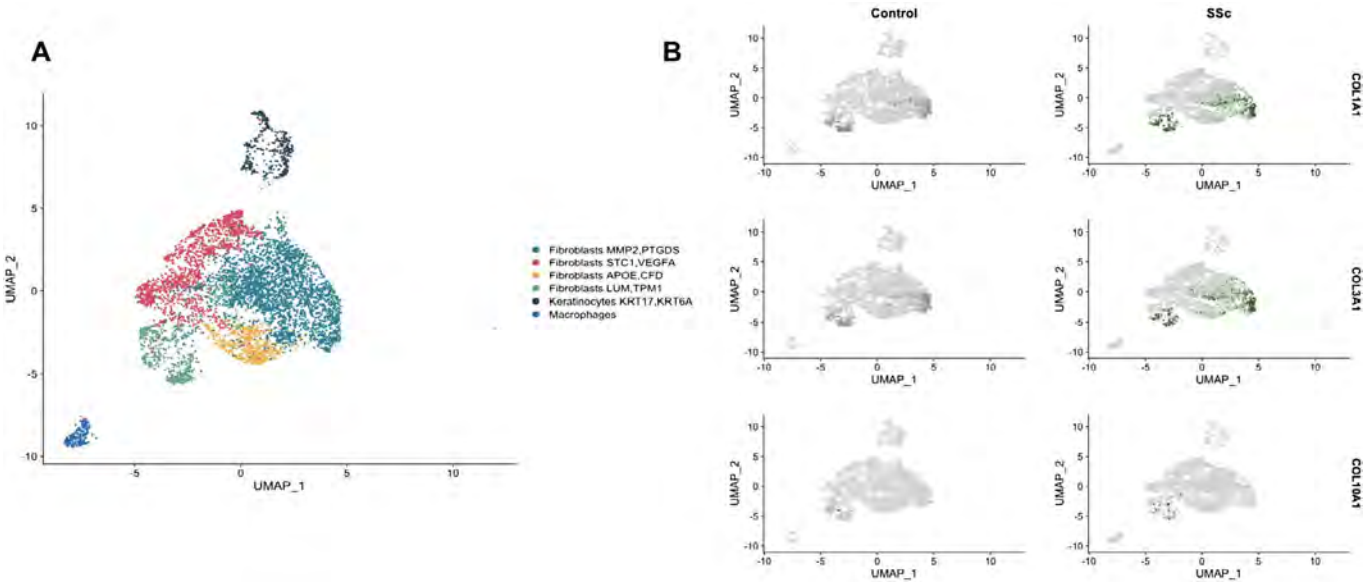

Figure 1. A. The saSE model system revealed four distinct fibroblast populations expressing biologically and pathologically relevant genes. We also identified a small populations of macrophages and keratinocytes. B. Differential gene expression between SSc and healthy control samples revealed upregulation of collagen genes COL1A1, COL3A1, and COL10A1 in SSc samples. This differential activation of fibroblasts is likely contributing to SSc pathogenesis.

Expanded PD-1^{hi} CXCR5^{-} HLA-DR^{+} T Cells Is Associated with Interstitial Lung Disease in Systemic Sclerosis

Mehreen Elahee[1], Alisa Mueller[2], Runci Wang[3], Ye Cao[2], Andrea Fava[4], Paul Dellaripa[2], Francesco Boin[5] and Deepak Rao[2], [1]Brigham and Women's Hospital, Natick, MA, [2]Brigham and Women's Hospital, Boston, MA, [3]Brigham and Women's Hospital, Boston, MA, [4]Johns Hopkins University, Baltimore, MD, [5]Cedars-Sinai Medical Center, West Hollywood, CA

SESSION INFORMATION

Session Date: Monday, November 8, 2021

Session Title: Abstracts: Systemic Sclerosis & Related Disorders – Basic Science (1434–1437)

Session Type: Abstract Session

Session Time: 10:30AM–11:30AM

Background/Purpose: Interstitial lung disease (ILD) is the major cause of morbidity and mortality in systemic sclerosis (SSc), yet there are few biomarkers to identify pathologic immune activation. T cells play a key role in initiating and promoting lung injury in SSc. Recent reports have indicated that circulating PD-1^{+} CXCR5^{+} T follicular helper cells (Tfh) and PD-1^{hi} CXCR5^{-} T peripheral helper cells (Tph) are expanded in SSc patients. Tfh and Tph cells are B cell-helper T cells that can display variable expression of ICOS and/or HLA-DR. Here we have evaluated both the frequency and phenotype of PD-1^{hi} cells in the peripheral blood of SSc patients, and assessed association with ILD.

Methods: We immunophenotyped blood T cells using a 39-marker mass cytometry panel. Peripheral blood mononuclear cells were collected from SSc patients (n=82) and age matched non-inflammatory controls (n=18). Patient samples were analyzed in barcoded batches with each one randomized to include both healthy controls and SSc

patients with varying lung disease. Data was analyzed by biaxial gating in FlowJo and by FlowSOM dimensional reduction and clustering. Comparisons between SSc patient samples and healthy controls were performed using Mann-Whitney *U* test with Bonferroni correction. Association between expanded cell population and lung disease metrics was assessed by Spearman correlation.

Results: In this cohort, the frequencies of Tph (PD-1^{hi} CXCR5^{-}) and Tfh (PD-1^{hi} CXCR5^{+}) CD4 T cells were not increased in SSc patients compared to healthy controls. However, tSNE visualization of PD-1hiCXCR5- cells revealed substantial heterogeneity in expression of ICOS and HLA-DR within this subset. A detailed cytometric analysis of expression of the markers in the cytometry panel on these cell subsets identified upregulation of HLA-DR and CD38 expression on PD-1^{hi} CXCR5^{-} cells from SSc patients compared to controls (Bonferroni adjusted p< 0.05) (Figure 1A). Biaxial gating confirmed the significant expansion of a specific CD4 T cell population with a PD-1^{hi} CXCR5^{-} ICOS^{-} HLA-DR^{+} phenotype, which was significantly increased in SSc patients compared to healthy controls (0.22% vs. 0.12%, p=0.003) (Figure 1B). This subset was also expanded in patients with SSc-ILD when compared with those

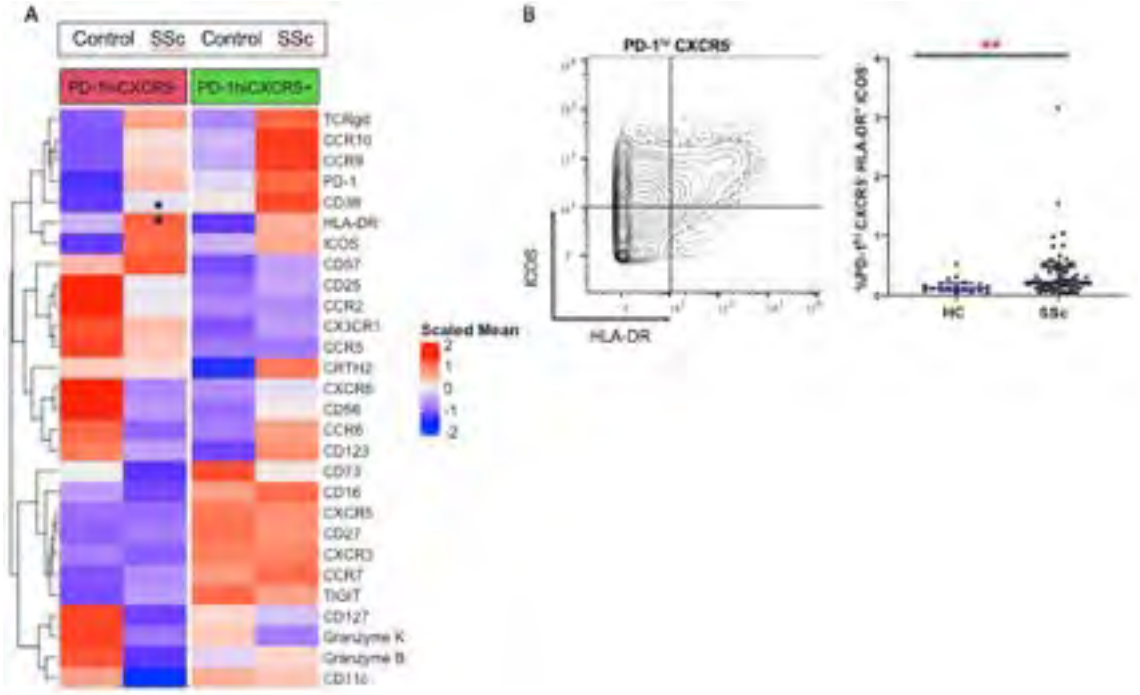

Figure 1. Altered cytometric phenotype of circulating PD-1hi CXCR5- cells in SSc patients. (A) Heatmap of row-normalized expression of cytometry markers on indicated subsets. * indicates markers (HLA-DR, CD38) that are significantly upregulated on PD-1hiCXCR5- cells in SSc compared to controls (Bonferroni adjusted p<0.05). (B) Biaxial gating of ICOS and HLA-DR expression on PD-1hi CXCR5- memory CD4 T cells. Frequency of PD-1hi CXCR5- HLA-DR+ ICOS- T cells was increased in SSc patients compared to controls (Mann-Whitney test p=.003).

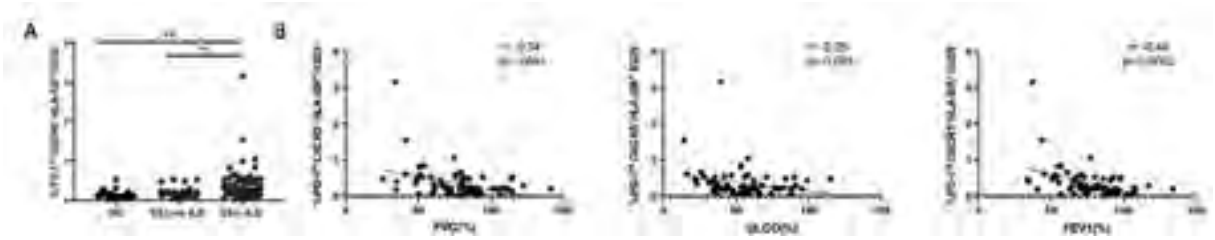

Figure 2. Association of CD4 T cell subset with ILD (A) Frequency of CD4+ T cells with PD-1hi CXCR5- HLA-DR+ ICOS- phenotype in SSc patients with ILD compared to controls and SSc patients without ILD (* p=0.017, ** p=0.001). (B) Correlation of PD-1hi CXCR5- HLA-DR+ ICOS- CD4+ T cells with FVCpp, DLCOpp and FEV1pp (pp=percent predicted). Spearman correlation statistics shown.

without ILD (p=0.02) and healthy controls (HC) (p=0.001) (Figure 2A). Further, the frequency of this CD4 T cells was increased in SSc subjects with more severe ILD (p= 0.017). Consistent with this observation, the frequency of PD-1^{hi} CXCR5^{-} ICOS^{-} HLA-DR^{+} CD4^{+} cells in SSc patients showed an inverse correlation with multiple metrics of pulmonary function, including forced vital capacity % predicted (FVCpp, r= -0.34, p=.0043), diffusing capacity for carbon monoxide (DLCO, r= -0.25, p=0.038) and forced expiratory volume 1 % predicted (FEV1pp, r=-0.44, p=0.0002) (Figure 2B).

Conclusion: High dimensional CyTOF analysis conducted in this cohort of SSc patients highlighted a specific expanded CD4+ T cell population (PD-1^{hi} CXCR5^{-} HLA-DR^{+} ICOS^{-}) that is significantly associated with presence and severity of lung disease. Further studies will evaluate whether this marker can predict the rate of decline of lung function in SSc-ILD, a critically needed tool in the care of patients with SSc.

Fat and Fibrosis: A Novel Developmental Gene in Systemic Sclerosis

Nancy Wareing[1], Brian Skaug[2], Minghua Wu[3], Scott Collum[1], Cory Wilson[1], Lucy Revercomb[4], Marka Lyons[5], Weizhen Bi[6], Tingting Mills[1], Julio Charles[5], Shervin Assassi[1] and Harry Karmouty-Quintana[1], [1]University of Texas McGovern Medical School at Houston, Houston, TX, [2]University of Texas McGovern Medical School Houston, Houston, TX, [3]University of Texas Health Science Center at Houston, Houston, TX, [4]Rice University, Houston, TX, [5]Division of Rheumatology, University of Texas McGovern Medical School at Houston, Houston, TX, [6]McGovern Medical School at UTHealth, Houston, TX

SESSION INFORMATION
Session Date: Monday, November 8, 2021
Session Title: Abstracts: Systemic Sclerosis & Related Disorders – Basic Science (1434–1437)
Session Type: Abstract Session
Session Time: 10:30AM–11:30AM

Background/Purpose: Early loss of skin-associated adipose tissue and concomitant replacement by extracellular matrix is a hallmark of systemic sclerosis (SSc). However, the contribution of adipose tissue to SSc pathogenesis remains poorly understood. In murine models of skin fibrosis, lipid-laden adipocytes acquire features of migratory myofibroblasts.[1] This adipocyte-to-myofibroblast transition offers up a promising suggests a mechanism for direct contribution of skin-associated adipose tissue to the early SSc skin phenotype. The developmental gene sine oculis homeobox homolog 1 (*SIX1*) is known to regulate cell fate and transdifferentiation in disease. We hypothesize that elevated *SIX1* promotes adipocyte-to-myofibroblast transition, thus contributing to loss of adipose tissue and progression of fibrosis in SSc.

Methods: Skin *SIX1* expression levels were identified by RNA sequencing and DNA microarray in the PRESS and GENISOS cohorts, respectively. All patients satisfied ACR classification criteria for SSc. Clinical correlations between *SIX1* were assessed by Spearman's rank-order and Pearson's correlation for continuous variables. Cellular localization of SIX1 was confirmed in patient and mouse skin samples by single molecule *in situ* hybridization. Ubiquitous genetic deletion of Six1 in eight-week-old mice was achieved using the tamoxifen-inducible Cre recombinase-loxp system. Immunofluorescent staining of collagen 6 (the primary collagen in fat tissue) was quantified as percent positive signal within the dermal adipose.

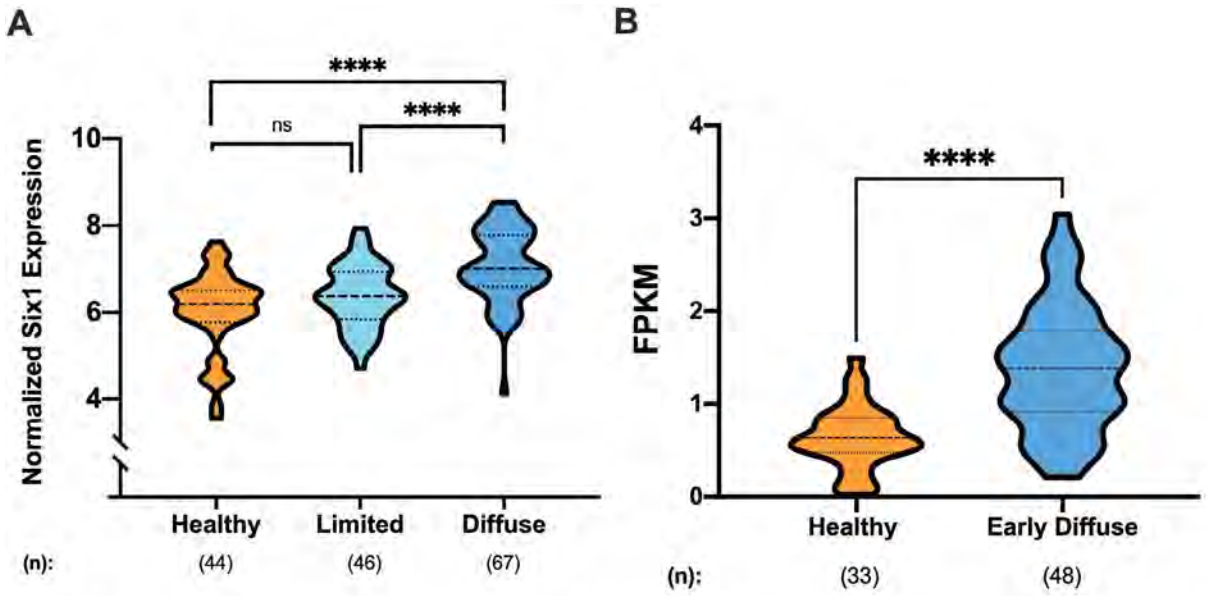

Figure 1. *SIX1* transcript is elevated in SSc versus healthy skin. *SIX1* expression in skin biopsies from SSc patients at the baseline visit, compared to age- sex- and race-matched controls. **A)** Gene expression by DNA microarray from patients in the Genetics Versus Environment in Scleroderma Outcome Studies (GENISOS) cohort. Statistics by non-parametric one-way ANOVA with multple comparisons. **B)** Expression profiling by RNA-sequencing in patients in the Prospective Registry for Early Systemic Sclerosis (PRESS) cohort. FPKM = fragments per kilobase million. Statistics by Welch's two-tailed t-test. ns = non- significant. ****p<0.0001.

Figure 1. SIX1 transcript is elevated in SSc versus healthy skin.

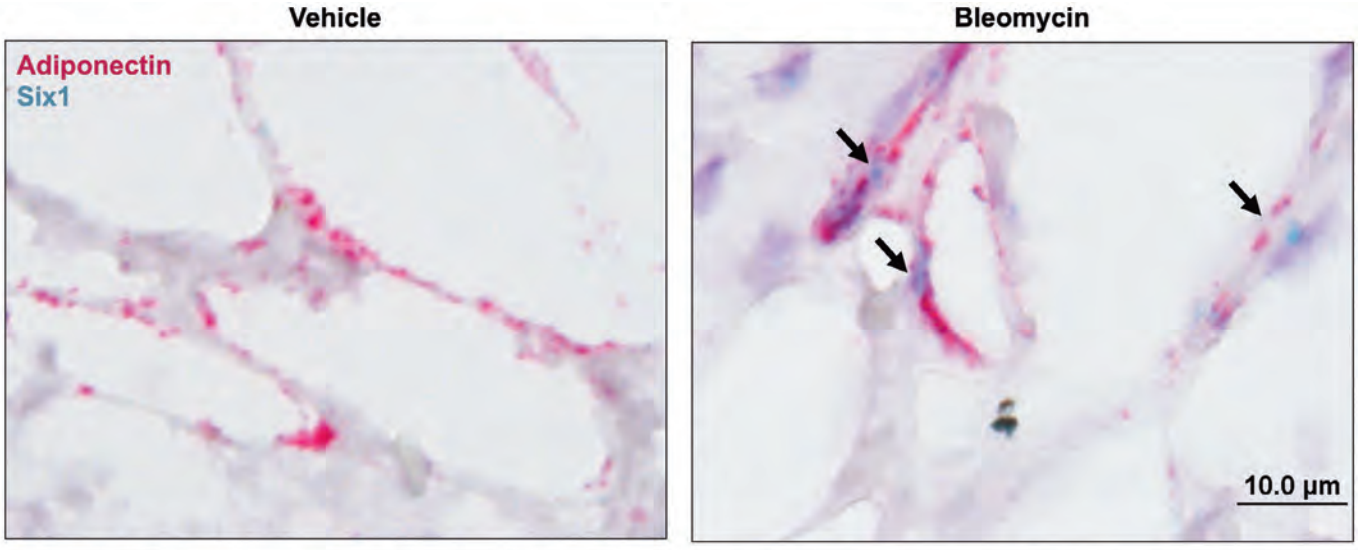

Figure 2. *Six1* is overexpressed in dermal adipocytes of bleomycin-treated mouse skin. *Six1* and *Adiponectin* mature transcript expression as detected by single molecule *in situ* hybridization after 7 days of subcutaneous bleomycin or vehicle (PBS). Arrows indicate double positive cells within the dermal adipose layer.

Figure 2. Six1 is overexpressed in dermal adipocytes of bleomycin-treated mouse skin.

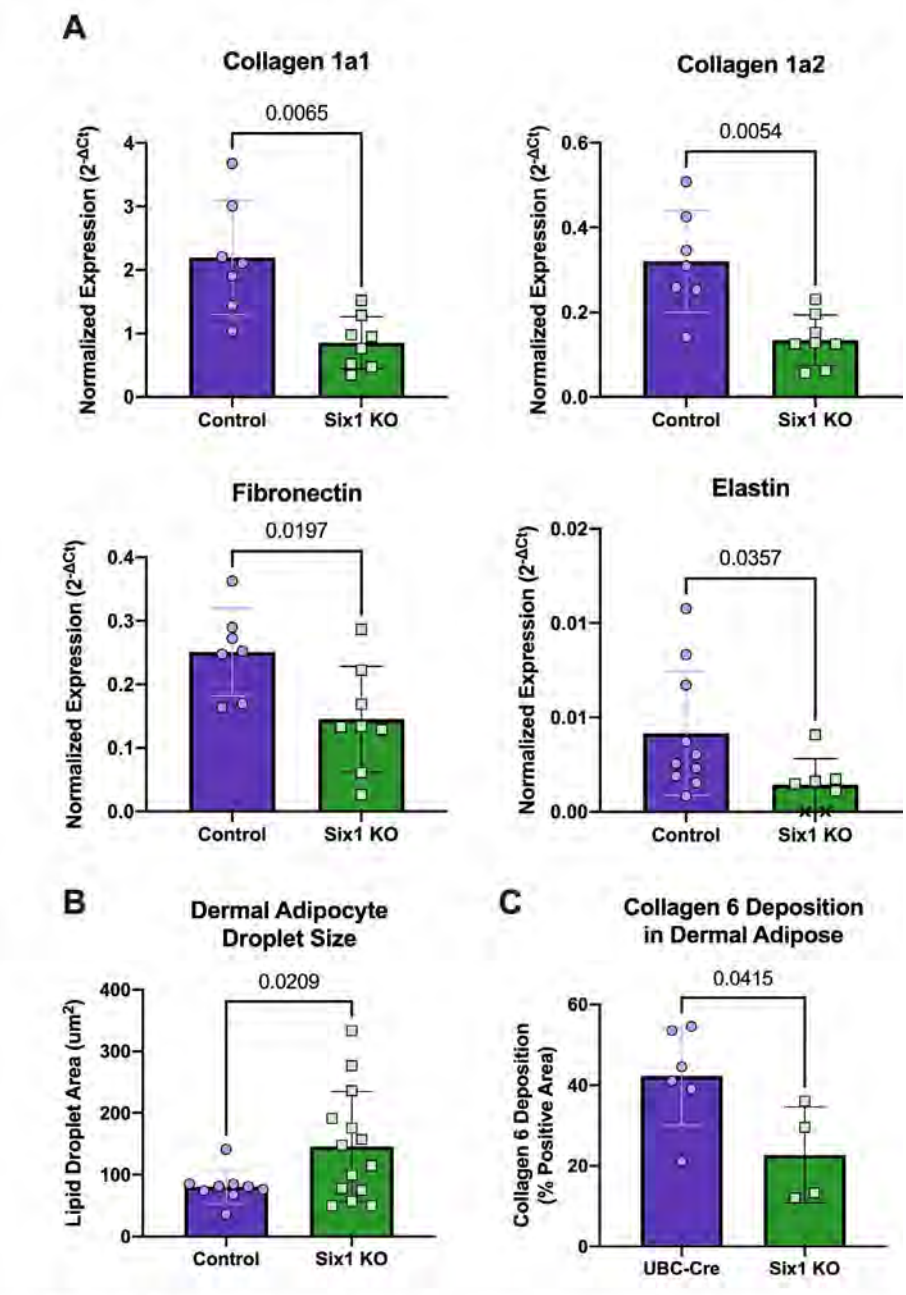

Figure 3. *Six1* depletion reduces fibrotic gene signature, lipoatrophy and dermal adipose collagen deposition in bleomycin-challenged mouse skin. A) Gene expression as measured by RT-qPCR. Raw Ct values were normalized to 18s rRNA. x = undetectable. **B)** Average droplet area of 100 dermal adipocytes per mouse. **C)** Percent of dermal adipose layer positive for collagen 6 staining by immunofluorescent staining.

Figure 3. Six1 depletion reduces fibrotic gene signature, lipoatrophy and dermal adipose collagen deposition in bleomycin-challenged mouse skin.

Results: *SIX1* was upregulated in the affected skin of patients in the GENISOS and PRESS cohorts (**Fig 1A & 1B, respectively**) at the time of enrollment. Baseline *SIX1* expression positively correlated with baseline modified Rodnan Skin Score ($r = 0.37$, $p < 0.0001$) and local skin score ($r = 0.38$, $p < 0.0001$). In dcSSc patients, *SIX1* negatively correlated with disease duration at the time of enrollment ($r = -0.28$, $p=0.022$). *SIX1* strongly correlated with a subcutaneous adipose gene expression signature in two independent cohorts and lipolysis-associated molecular pathways,

supporting a driving role of *SIX1* in adipocyte dysfunction. *Six1* was overexpressed early in dermal adipocytes of the subcutaneous bleomycin murine model of skin fibrosis (**Figure 2**). When challenged with bleomycin, inducible *Six1*-deficient mice (*Six1* KO) demonstrated lower fibrotic gene expression compared to control mice (**Figure 3A**). *Six1* KO mice were protected against lipoatrophy (**Figure 3B**) and collagen 6 deposition within the dermal fat (**Figure 3C**).

Conclusion: We concluded that *SIX1* is elevated in skin-associated fat of SSc patients, and enriched in early diffuse disease. Higher *SIX1* expression was associated with worsened skin fibrosis in baseline samples. Inhibiting *SIX1* can protect against atrophy of dermal fat and increased fibrotic responses in models of SSc-like skin fibrosis. Developmental genes that become activated during disease are ideal candidate targets for new therapeutics, as these genes are lowly expressed in healthy adult tissues, thus dramatically reducing the likelihood of off-target effects. Our findings support further investigation into *SIX1* as a feasible drug molecular target for SSc.

Development of a Computationally Designed, Hyperstable Dual Inhibitor of the IL-2 and IL-15 Receptors: A Novel Therapeutic Candidate for Inflammatory Conditions

Renan Vergara[1], Alex Chen[1], Jerry Chen[1], Marianne Riley[1], Luis Blancas-Mejia[1], Christie Mortales[1], Tania Berrocal[1], Tanu Priya[1], Marsha Mason[1], Kevin Yu[1], Olga Sharapova[1], Jorgen Nelson[1], Alfredo Quijano-Rubio[1], Thomas Linsky[1], **Ryan Swanson**[1] and Daniel-Adriano Silva[2], [1]Neoleukin Therapeutics, Inc., Seattle, WA, [2]Formerly of Neoleukin Therapeutics, Inc., Seattle, WA

SESSION INFORMATION
Session Date: Monday, November 8, 2021
Session Title: Abstracts: Cytokines & Cell Trafficking (1438–1441)
Session Type: Abstract Session
Session Time: 2:00PM–3:00PM

Background/Purpose: T cell mediated pathology is central to many forms of autoimmunity, and cytokines perform critical inflammatory functions during this process. IL-2 and IL-15 are well studied common gamma chain cytokine family members that sharply augment T and NK cell function. Antagonizing both pathways with a single molecule is an attractive therapeutic strategy, especially if the IL-2 function in suppressive Tregs can be spared. Using our computational design platform coupled with directed evolution, we created a de novo IL-2/IL-15 inhibitor that has high affinity for IL-2 receptor beta (IL2RB) with no detectable IL-2 receptor gamma (IL2RG) binding, resulting in an inhibitor that antagonizes both the IL-2 and IL-15 pathways. Further computational engineering strategies were performed to improve the inhibitor's thermodynamic stability in low pH environments and increase its resistance to proteases. The resulting therapeutic candidate has potential clinical applications that are differentiated from other related biological therapies, enabling local routes of administration and sparing Treg function.

Methods: Computationally derived binding profiles against IL2RB and IL2RG were determined via biolayer interferometry. Protein stability was addressed in the pH range 2.0-8.0 by thermal and/or chaotropic denaturation assays using spectroscopic techniques. Proteolytic resistance was separately assessed by mass spectrometry. Therapeutic candidates with high affinity for IL2RB and hyperstable biophysical properties were assessed for functional

	CD4+ cells	CD8+ cells	Tregs
IC_{50} (pM)	215	42	10,265

Figure 1. An IL-2/IL-15 dual inhibitor blocks human CD4+ and CD8+ T cell pSTAT5 signaling at concentrations where Tregs demonstrate 100% pSTAT5 signaling (best-fit values).

antagonism of IL-2 and IL-15 signaling via pSTAT5 flow cytometric analysis of human T and NK cell subsets. In vivo,biophysical properties were assessed by inhibitor quantification in the GI tract of orally dosed mice, and biological anti-inflammatory activity was assessed using a murine delayed-type hypersensitivity (DTH) model.

Results: We report development of a *de novo* IL-2/IL-15 inhibitor with higher affinity for IL2RB compared to wild type IL-2 (K_D < 1nM) and undetectable IL2RG binding via Octet biolayer interferometry. This molecule inhibits IL-2 pSTAT5 signaling in human pan T cells with single digit nM IC_{50} potency, while Treg cells are still able to utilize IL-2 through pSTAT5 signaling at those concentrations (Figure 1). In vitro, this therapeutic candidate shows better thermodynamic properties at pH 2 and > 10-fold increase in protease resistance compared to a parental agonist molecule. Systemically administered, the IL-2/IL-15 dual inhibitor blocked DTH swelling in mice with statistical significance; orally administered, it retained receptor binding activity in the intestines, demonstrating robust resistance to denaturation and degradation.

Conclusion: Computational design enabled development of a potent, hyperstable inhibitor of both the IL-2 and IL-15 pathways. These biophysical properties may enable novel therapeutic strategies for inflammatory and autoimmune diseases. Furthermore, these results demonstrate that de novo protein design can be readily applied to adjust receptor specificity and affinity to achieve the binding and functional therapeutic profile of interest.

Inhibitors of Endogenous Reverse Transcriptases Suppress *in Vitro* Type I Interferon Responses and *in Vivo* Antigen-specific T Cell Responses

Nafeeza Hafeez, Jimmy Zhong, Jared Steranka, Margit Hagel, Greg Bisacchi, Donna Romero, Rosana Kapeller, Dennis Zaller and **Wenyan Miao**, Rome Therapeutics, Cambridge, MA

SESSION INFORMATION
Session Date: Monday, November 8, 2021
Session Title: Abstracts: Cytokines & Cell Trafficking (1438–1441)
Session Type: Abstract Session
Session Time: 2:00PM–3:00PM

Background/Purpose: Transposable elements (TEs) are mobile DNA elements that can replicate and move from one position to another within the host genome. Through co-evolution, TEs in the human genome have developed complex relationships with the host to regulate a variety of cellular functions. TEs are largely silent in healthy adult cells but are reactivated and transcribed in certain disease states, such as cancer, autoimmunity, and neurodegeneration. Class I TEs are retrotransposons that have mobilized throughout the genome via reverse transcription of RNA intermediates. In humans, there are two Class I TEs that encode functional endogenous reverse transcriptases (RTs), LINE-1 and HERV-K. The DNA and RNA products from TE reactivation and reverse transcription are potential source of nucleic acid that are recognized by pattern recognition receptors, such as cGAS, that sense these nucleic acids and trigger proinflammatory responses during sterile inflammation. We tested inhibitors of these endogenous RTs for their ability to block immune responses.

Methods: We generated recombinant reverse transcriptases of LINE-1 and HERV-K and developed biochemical reverse transcriptase assays. We engineered a reporter cell line to measure LINE-1 retrotranposition in cells. Utilizing these assays, we discovered potent LINE-1 RT nucleoside reverse transcriptase inhibitors (NRTIs) with a range of potencies against HERV-K RT. These inhibitors were characterized *in vitro* for their impact on interferon responses in immune cells and *in vivo* on antigen-specific T cell responses in mice.

Results: Compound A is a potent inhibitor of LINE-1 RT and a weak inhibitor of HERV-K RT. In enzymatic assays, its active tri-phosphorylated form has an IC_{50} of 0.006 μM and 6.4 μM against LINE-1 and HERV-K RT, respectively. Compound A demonstrated excellent potency in the cell-based LINE-1 retrotransposition assay with IC_{50} of 0.12 μM. To characterize the impact of the NRTIs on immune responses, we used Decitabine to induce LINE-1 and HERV-K expression in TREX-1 knock out THP-1 cells, and subsequently measured the effect of NRTIs on TE-induced type I interferon responses. Compound A effectively inhibited this response with IC_{50} of 0.05 μM. We investigated the *in vivo* activity and mechanism of action of Compound A in a murine model of MOG peptide-induced T cell responses. Mice were immunized with MOG_{35-55}, 10 days later cells from draining lymph nodes were collected and cultured with

MOG_{35-55}. At 40 mg/kg oral dosing, Compound A suppressed antigen specific T cell proliferation and reduced IL-17A, TNFa and IFNg production.

Conclusion: We used biochemical and cell-based assays to identify potent endogenous RT inhibitors. These inhibitors suppressed *in vitro* repeat element-induced type I interferon responses in monocytic cells and attenuated *in vivo* antigen-specific T cell responses. These data demonstrate the potential of endogenous RT inhibitors to modulate host immune responses for therapeutic benefit in autoimmune/inflammatory diseases.

Targeting Endogenous Mesenchymal Stromal Cell Response to Interferong in Sjögren's Syndrome

Sara McCoy, Ilya Gurevic, Maxwell Parker and Jacques Galipeau, University of Wisconsin, Madison, WI

SESSION INFORMATION
Session Date: Monday, November 8, 2021
Session Title: Abstracts: Cytokines & Cell Trafficking (1438–1441)
Session Type: Abstract Session
Session Time: 2:00PM–3:00PM

Background/Purpose: Sjögren's syndrome (SS) is a systemic autoimmune disease that is associated with a lymphoma risk 14-fold that of the general population. Greater focal lymphocytic infiltrate of salivary glands (SGs) and high SG IFNg are associated with elevated lymphoma risk. Interestingly, IFNg is also biologically relevant to mesenchymal stromal cells (MSCs), a SG resident cell with unique regenerative and immunoregulatory capacity. In contrast to the role of IFNg in SS, IFNg is considered to promote a beneficial MSC immunomodulatory phenotype. The objective of this study is to define the immunobiology of IFNg-exposed SG MSCs with and without the JAK inhibitor ruxolitinib.

Methods: All SS subjects fulfilled ACR/EULAR criteria. Sicca-control subjects had symptoms of dryness but did not have diagnoses of autoimmune disease or laboratory abnormalities supportive of an autoimmune disease. SG MSCs were isolated from minor salivary gland tissue and frozen for storage. SS SG MSCs were treated with IFNg 10 ng/mL +/- various doses of ruxolitinib. Experimental methods included flow cytometry, RNA-Sequencing, chemokine array, ELISA, and transwell experiments.

Results: We found that the IFNg promoted expression of MSC immunomodulatory surface markers, and this expression was reversed by 1 μM ruxolitinib (Figure 1A-C). Accordingly, we performed RNA-Sequencing on MSCs pretreated with IFNg +/- 1 μM ruxolitinib. RNA-Sequencing of SS and control SG MSCs showed nearly identical responses IFNg inhibition with ruxolitinib (Figure 1D & E). Because several chemokines were highlighted in the RNA-Sequencing results, we performed a chemokine array on conditioned media from SG-MSCs treated with IFNg +/- ruxolitnib and identified candidate chemokines for further investigation (Figure 2A & B). We confirmed the differential expression of CXCL9, CXCL10, CXCL11, CCL2, and CCL7 using ELISA (Figure 2C). We then sought to define the effect of IFNg and ruxolitinib on MSC-induced PBMC migration (Figure 3A). MSCs promote migration alone, but PBMC migration is amplified by pre-treatment of SG-MSCs with IFNg (Figure 3B). Ruxolitinib reverses this increased migration, though not reaching statistical significance (Figure 3C). We determined $CD4^+$ T cells migrate significantly more with IFNg ($p=0.04$) and that neutralizing CXCL9, CXCL10, and CXCL11 attenuated IFNg-induced migration (Figure 3D).

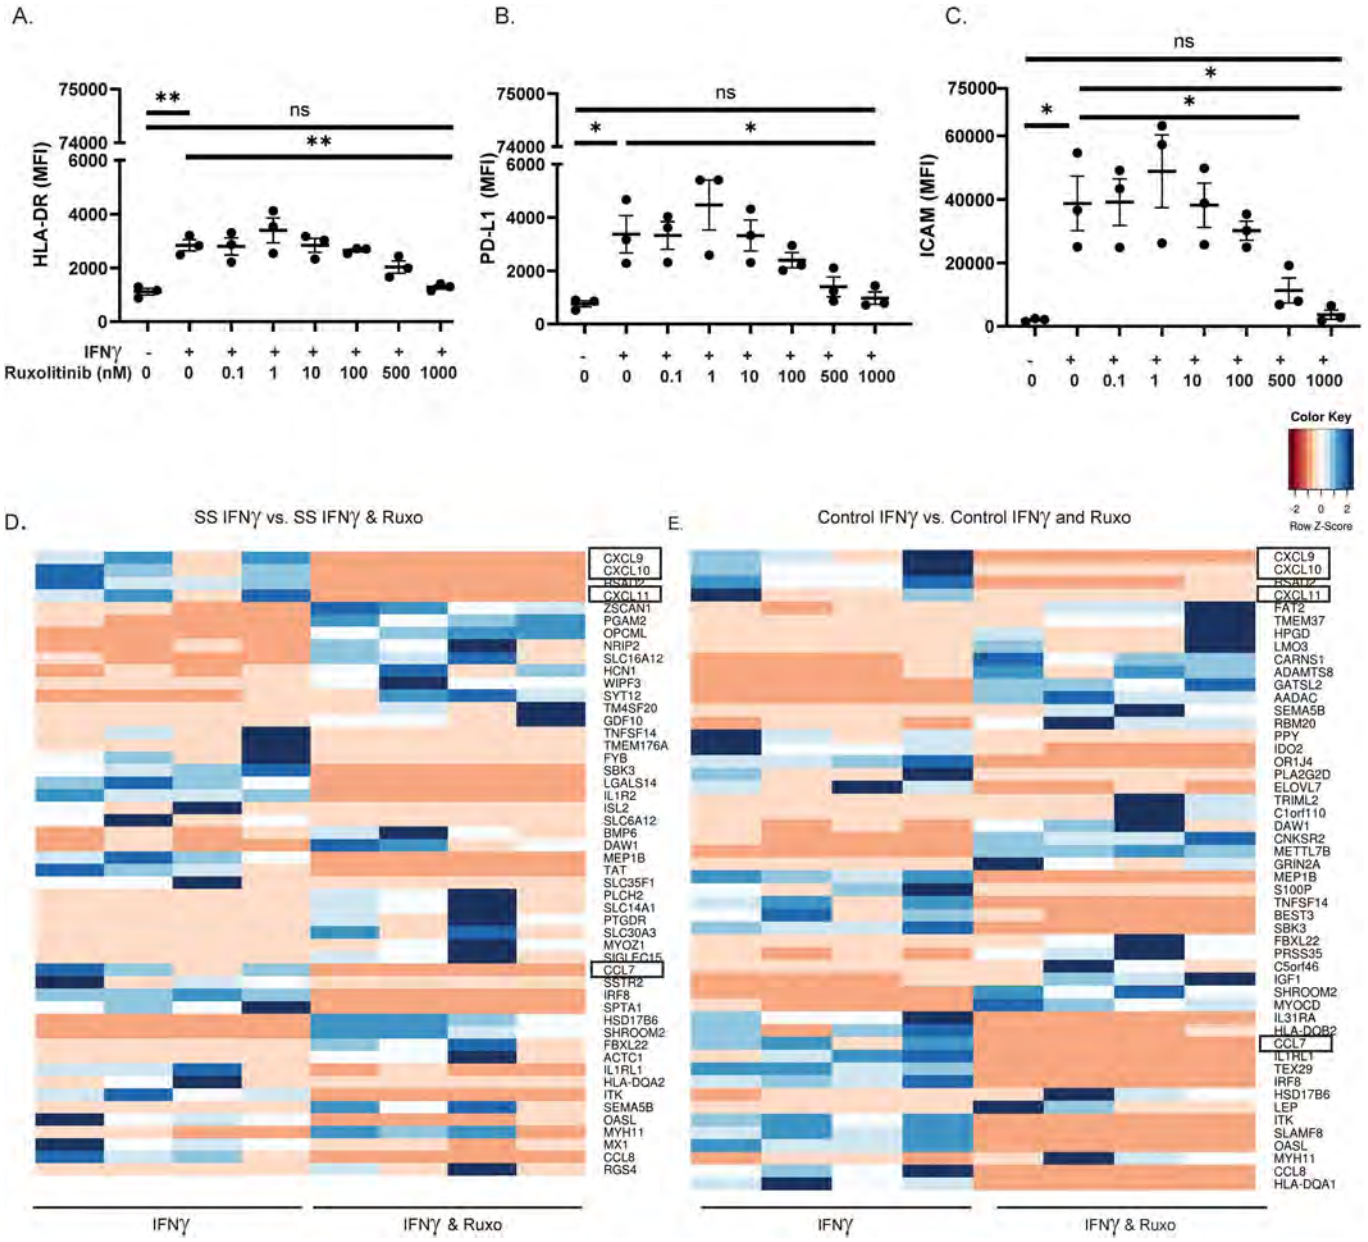

Figure 1. Ruxolitinib reverse IFN**γ**-induced SG-MSC immunomodulatory protein expression and transcript profile. SG-MSCs were treated +/- IFN**γ** for 48 hours +/- ruxolitinib. A-C) Median immunofluorescence intensity (MFI) of MSC immunomodulatory markers HLA-DR, PD-L1, and ICAM (n=3); D-E) Transcriptomic profiling of SS (n=4) and control (n=4) SG-MSCs. Heat maps display the top differentially regulated genes filtered for an adjusted p value of <0.05. Boxes highlight differentially expressed chemokines. .ns=not significant; *=p<.05; **=p<0.01.

Conclusion: These findings establish that ruxolitinib mitigates IFNg-induced expression of immunomodulatory surface markers and chemokines expressed by SG-MSC. Ruxolitinib also reverses IFNg-induced PBMC migration, likely through acting on CXCL9, 10, and 11 to reduce $CD4^+$ T cell migration. Because IFNg is higher in SS than control SGs, we have identified SG MSCs as a plausible pathogenic cell type in SS, promoting $CD4^+$ T cell chemotaxis within SS SGs. Further, we have shown ruxolitinib reverses the effect of IFNg on key chemokine expression, providing a possible therapeutic avenue. Future studies will confirm our findings with *ex vivo* and mouse model studies

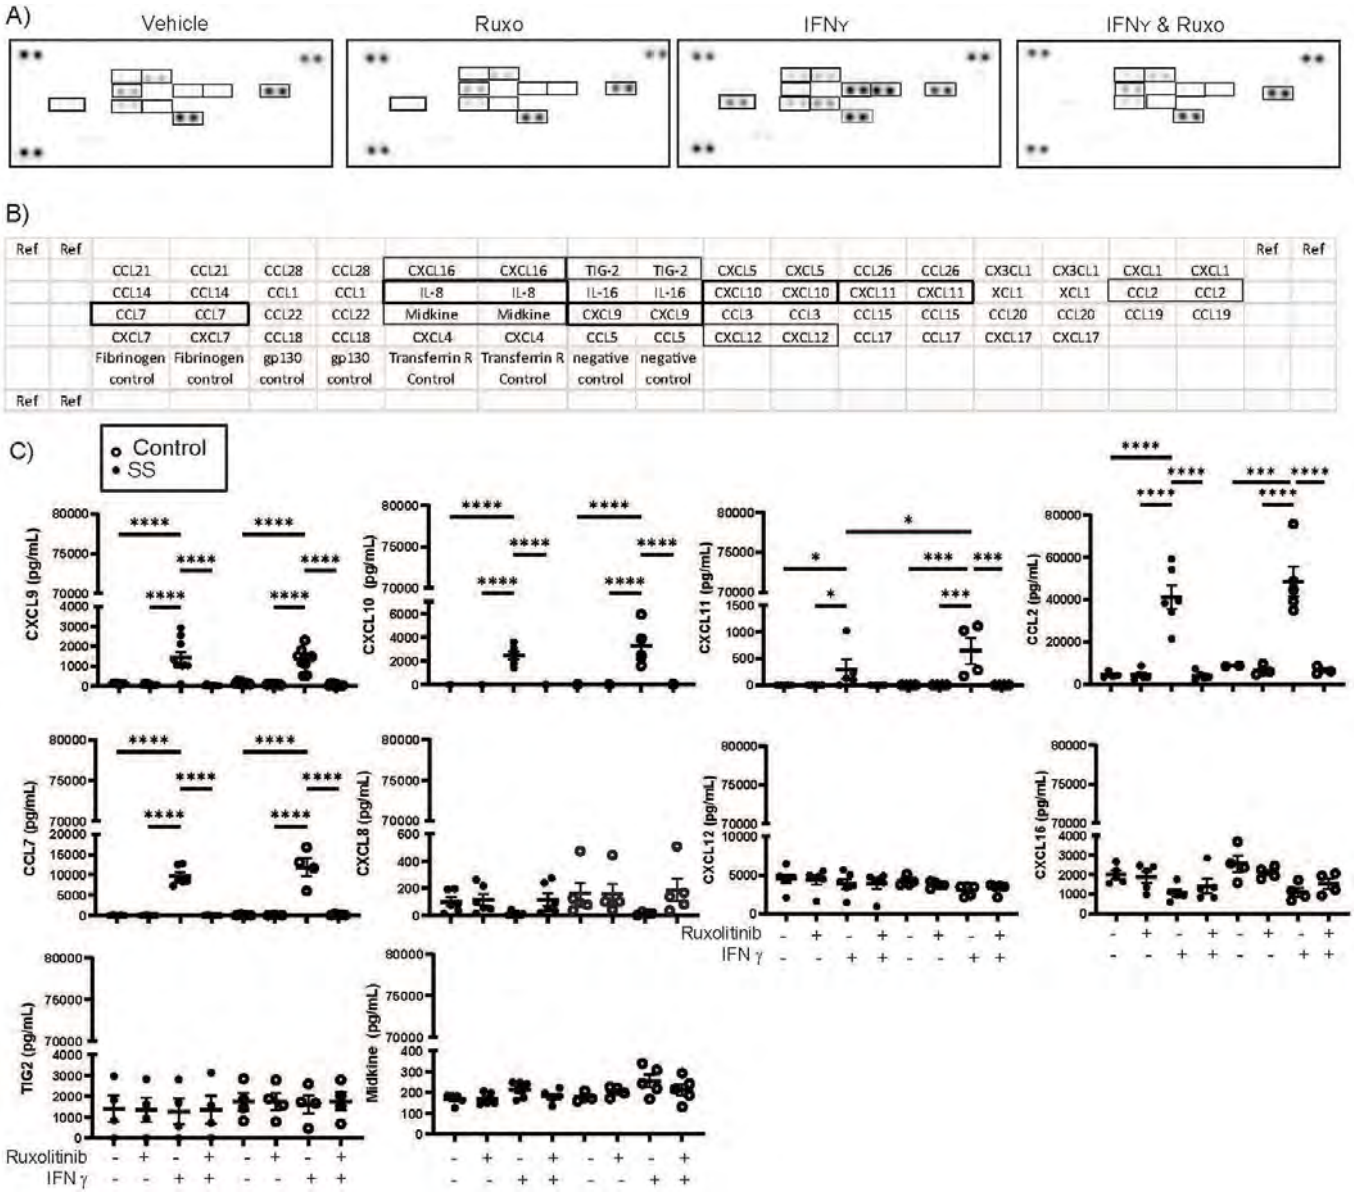

Figure 2. IFN**γ**-induced production of CXCL9, CXCL10, CXCL11, CCL2, & CCL7 in salivary gland MSCs is reversed by ruxolitinib. Salivary gland MSCs were culturedwith IFN**γ** +/- 1000 nM ruxolitinib or vehicle for 48 hours. After 48 hours, conditioned media was collected for further study. Conditioned media was applied to a chemokine array per the manufacturer's specifications. Quantitative analysis using densitometry was performed. ELISA was performed on the conditioned media for each chemokine identified as differentially expressed in the chemokine array per manufacturer's recommendations. A) Images of the chemokine membrane incubated with conditioned media derived from vehicle treated, IFN**γ** treated, ruxolitinib treated, or both IFN**γ** and ruxolitinib-treated salivary gland MSCs; B) Key identifying the layout of the chemokine array; C) Confirmation of the chemokine array was performed using the conditioned media ELISA including CXCL9, CXCL10, CXCL11, CCL2, CCL7, CXCL8, CXCL12, CXCL16, TIG2, and midkine. ELISAs were performed on control (n=5) and SS (n=6) subjects.*=p<0.05; **=p<0.01; ***=p<0.001; ****=p<0.0001.

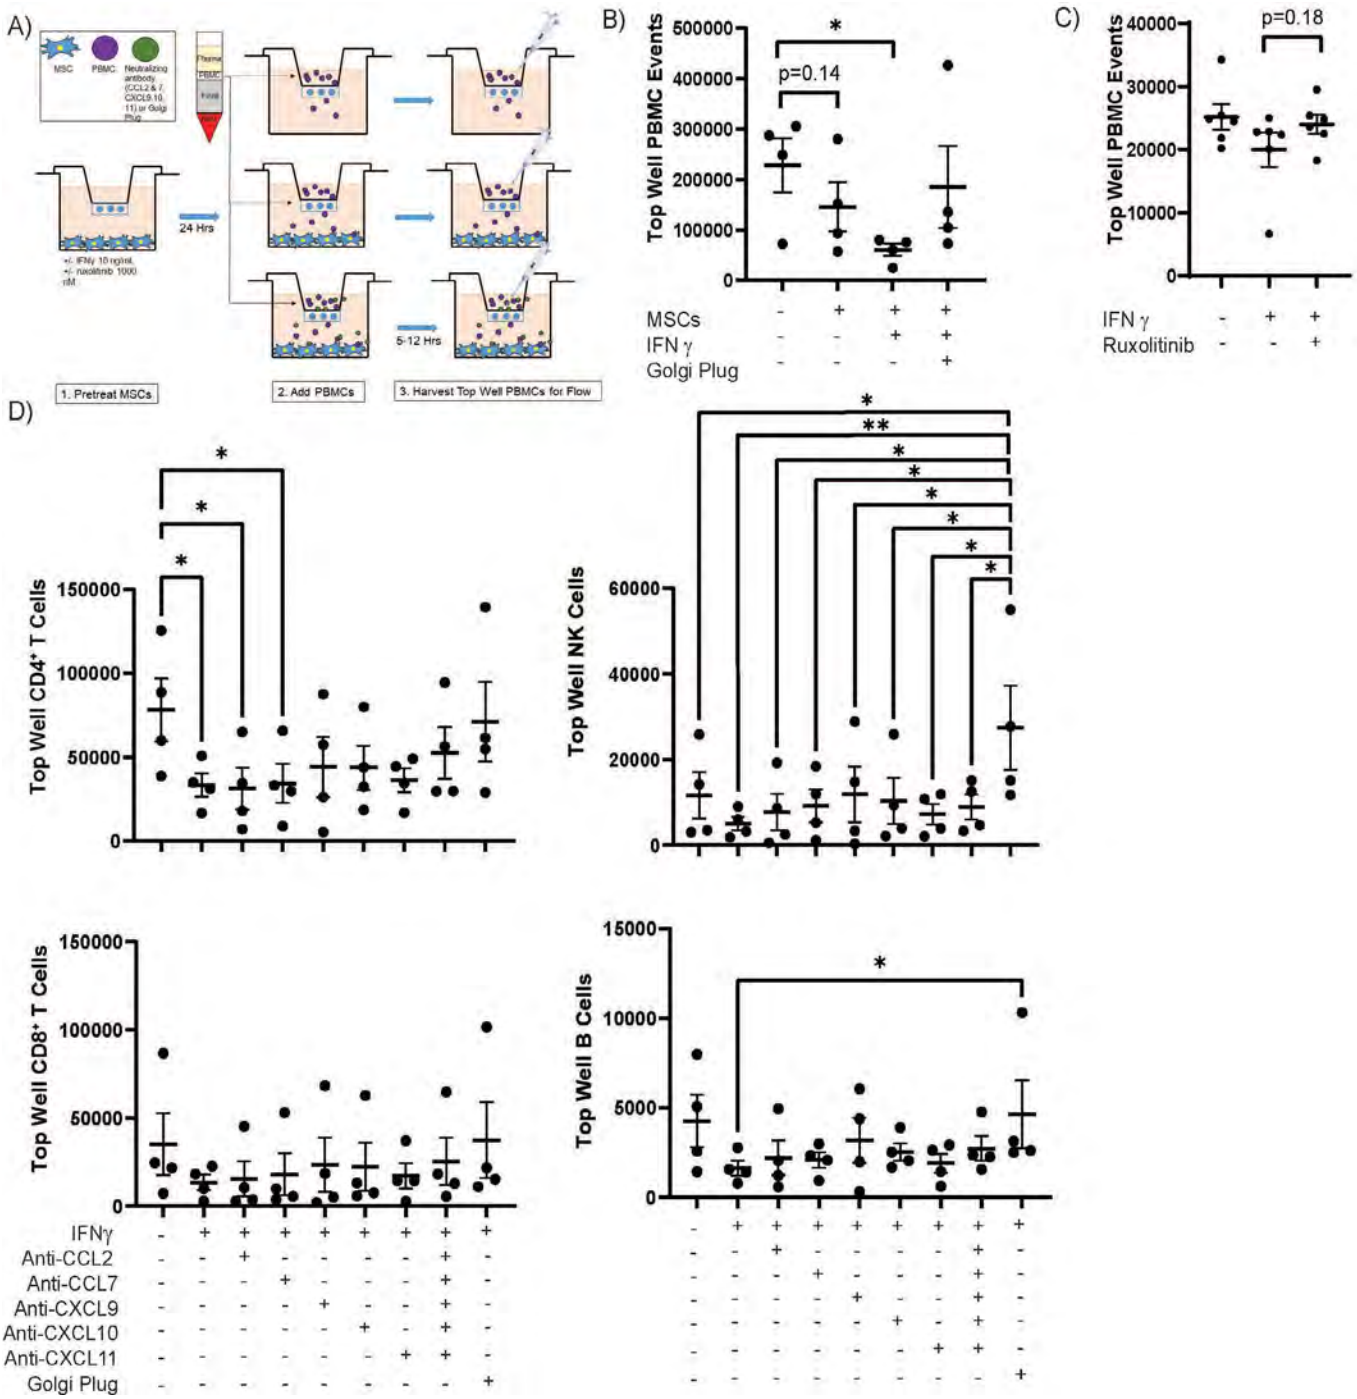

Figure 3. MSCs Promote PBMC Migration, an effect amplified by IFN**γ**. MSCs were plated onto the bottom of a transwell. MSCs were serum starved for 24 hours then treated +/- IFN**γ** or ruxolitinib for another 24 hours. The MSCs were washed well then PBMCs were added into the top well. After 5-12 hours, the cells remaining in the top well were collected, stained, and subjected to flow cytometry. A) Representative figure of the transwell experimental setup; B) MSCs (n=1)were treated with IFN**γ** 10 ng/mLfor 24 hours, washed, then PBMCs (n=4) were added into the top of a five micron transwell system for five hours. IFN**γ** increased PBMC migration across the transwell filter. C) MSCs (n=6) were treated with IFN**γ** 10 ng/mL +/- or 1000 nM ruxolitib for 24 hours, washed, then PBMCs (n=1) were added into the top of an eight micron transwell system for five hours. Ruxolitinib abrogates the pro-migratory effect of IFN**γ**. D) MSCs (n=1) were pre-treated with IFN**γ** then PBMCs (n=4) were added to the top well of a 5 micron transwell system in the presence of neutralizing antibodies or golgi plug. Data were presented as the number of lymphocytes from the top well (cells that did not migrate). CD4+ T cells migrated most robustly in the presence of IFN**γ** and neutralizing antibodies to CXCL9, 10, and 11 reduced migration. A similar less significant trend was seen in CD8+ T cells, B cells, and NK cells. *=p<0.05; **=p<0.01.

Pharmacological Characterization of GLPG3667, a Selective TYK2 Inhibitor for Treatment of Inflammatory Diseases

Roland Blanque[1], Kenji Shoji[1], Mia Jans[2], Florence Marsais[1], Laetitia Furio[1], Maikel Colli[2], Céline Cottereaux[1], Christelle David[1], Nicolas Houvenaghel[2], Isabelle Parent[1], An Van de Water[2], Laetitia Perret[1], Sofia Alves[1], David Amantini[1], Steven Van der Plas[3] and **René Galien**[4], [1]Galapagos SASU, Romainville, France, [2]Galapagos NV, Mechelen, Belgium, [3]Formally Galapagos NV, Mechelen, Belgium, [4]Galapagos NV, Romainvulle, France

SESSION INFORMATION
Session Date: Monday, November 8, 2021
Session Title: Abstracts: Cytokines & Cell Trafficking (1438–1441)
Session Type: Abstract Session
Session Time: 2:00PM–3:00PM

Background/Purpose: Tyrosine kinase 2 (TYK2) is an intracellular kinase that mediates the signaling from type 1 interferon (IFN), interleukin (IL)-12/IL-23 and the IL-10 family of cytokines. Genetic analyses have indicated an association between TYK2 variants and risk of inflammatory diseases. In addition, clinical data obtained with ustekinumab suggest that compounds that inhibit TYK2 could be potential treatments for inflammatory diseases, notably through inhibition of IL-12 and IL-23 signaling. We describe here GLPG3667, a potent and selective TYK2 inhibitor that is in development as a treatment for inflammatory and autoimmune diseases.

Methods: Potency and selectivity of GLPG3667 on TYK2 was addressed using radioactive and fluorescent biochemical assays. Peripheral blood mononuclear cells (PBMC) and human whole blood assays for various Janus kinase (JAK)-dependent pathways were performed to address GLPG3667 potency and selectivity, using flow cytometry or enzyme-linked immunosorbent assay. GLPG3667 pharmacological activity was demonstrated in a psoriasis mouse model driven by IL-23 (a cytokine that signals through JAK2/TYK2). In healthy human volunteers (HV), pharmacodynamic activity of GLPG3667 was demonstrated by measuring signal transducer and activator of transcription (STAT) phosphorylation using flow cytometry analysis on the IFNα pathway and selectivity described through analysis of IL-2 and granulocyte-macrophage colony-stimulating factor (GM-CSF) pathways. Biological effects of GLPG3667 in humans were assessed using transcriptomic analysis of blood cells after *in vivo* IFNα (1 million IU of IntronA) challenge in healthy HV.

Results: Biochemical assays showed that GLPG3667 displayed nanomolar potency on TYK2 with a selectivity over other JAK kinases >3-fold. In human PBMC, GLPG3667 showed comparable potency on the IFNα and IL-23 pathways (around 50 nM). Selectivity for TYK2 on the IFNα pathway was >14-fold and >19-fold toward the IL-2 and GM-CSF pathways in human PBMC and whole blood, respectively. Dermal ear inflammation in a mouse model of psoriasis driven by IL-23 was prevented by GLPG3667 with a minimal effective dose of 3 mg/kg given orally once daily. This effect was associated with a decrease in neutrophil infiltration and STAT3 phosphorylation at sites of inflammation. In healthy HV, GLPG3667 completely inhibited IFNα-induced STAT1 and STAT3 phosphorylation but did not impact IL-2- and GM-CSF-induced STAT5 phosphorylation. After *in vivo* IFNα challenge, GLPG3667 blocked the induced expression of IFN-response genes.

Conclusion: The TYK2 inhibitor GLPG3667 demonstrated selectivity toward the three other JAK family members in several biochemical, cellular and human whole blood assays *ex vivo* and *in vivo* during a Phase 1 study (NCT04097938)

in healthy HV. Pharmacological effects of GLPG3667 were demonstrated in a mouse model of psoriasis driven by IL-23 and in healthy HV challenged with IFNα. GLPG3667 is in development for the treatment of moderate to severe psoriasis.

SESSION INFORMATION

Session Date: Monday, November 8, 2021

Session Title: Abstracts: RA – Treatments II: New Findings in Established Therapies (1442–1445)

Session Type: Abstract Session

Session Time: 2:00PM–3:00PM

Background/Purpose: With the arrival of new Janus kinase inhibitors (JAKi), with different JAK inhibition profiles, there is the possibility of using a second JAKi in the event of failure to a first JAKi in patients with rheumatoid arthritis (RA). There are no data on the effectiveness of cycling JAKi compared to switching to biologic disease-modifying antirheumatic drug (bDMARD) in patients who have failed a first JAKi. The objective of this study is to compare the effectiveness of cycling JAKi vs switching to bDMARD in a real-world RA population.

Methods: Nested cohort study within an international collaboration of RA registries (data contributed from 14 national registries of the JAK-pot collaboration). We pooled prospectively collected data from RA patients who failed a first JAKi and were subsequently treated with either a second JAKi (JAKi cycling) or with a bDMARD (switching) in routine care. We compared the effectiveness of both strategies in terms of drug retention and in terms of disease activity (DAS28) evolution over 1 year after second treatment initiation. Differences in drug survival rates were assessed by Log Rank Test. DAS28 trajectories were predicted based on an age- and gender-adjusted linear mixed model with a quadratic trend over time.

Results: 708 patients who failed JAKi were included. 154 cycled to a second JAKi and 554 switched to a bDMARD (Table 1). Patients cycling JAKi were older, had longer disease duration, had received more bDMARDs and had longer exposure to first JAKi treatment than switchers to a bDMARD. Monotherapy was more prevalent and discontinuation of the first JAKi was more common for safety reasons than for lack of effectiveness. Cycling and switching strategies showed similar drug survival rates after two years of follow-up (Figure 1). Nevertheless, a non-significant trend emerged where discontinuation was more likely among patients cycling JAKi when reason for stopping the first JAKi was an adverse event, whereas discontinuation was less likely among patients cycling JAKi when reason for stopping the first JAKi was ineffectiveness. DAS28 over time evolved in a similar way between patients cycling JAKi and switching to a bDMARD, with improvements after one year of follow-up (Figure 2).

Conclusion: After failing a first JAKi, cycling JAKi versus switching to a bDMARD appears to have similar effectiveness despite a more difficult to treat patient profile for the patients cycling to JAKi.

Table 1. Baseline characteristics

	JAKi to JAKi (n=154)	JAKi to bDMARD (n=554)	P
Female (%)	135 (87.7)	448 (80.9)	ns
Age, mean (SD)	58.41 (12.43)	54.74 (12.74)	0.002
Disease duration in years, mean (SD)	13.95 (10.52)	11.37 (8.77)	0.002
Seropositive, RF or ACPA, n (%)	105 (74.5)	365 (75.1)	ns
N° of previous bDMARDs, median (IQR)	1.5 (1-3)	1 (0-2)	<0.001
First JAKi: tofacitinib (%)	117 (76.0)	441 (79.6)	ns
Stop reason of first JAKi, n (%)			0.003
Adverse event	42 (27.3)	99 (17.9)	
Lack of efficacy	94 (61.0)	360 (65.0)	
Other	18 (11.7)	95 (17.1)	
Treatment duration of first JAKi in years, mean (SD)	1.38 (1.31)	0.69 (0.72)	<0.001
Concomitant csDMARD (%)	69 (44.8)	349 (63)	<0.001
DAS28, mean (SD)	4.10 (0.98)	4.17 (0.85)	ns

SESSION INFORMATION

Session Date: Monday, November 8, 2021
Session Title: Abstracts: RA – Treatments II: New Findings in Established Therapies (1442–1445)
Session Type: Abstract Session
Session Time: 2:00PM–3:00PM

Background/Purpose: The optimal rituximab (RTX) dose for the treatment of rheumatoid arthritis remains unclear. RTX treatment of 1000mg per 6 months and 2000mg per 6 months were shown to be similarly efficacious (1). The REDO trial showed comparable 6-month efficacy of continued treatment with 500mg and 200mg compared to 1000mg, though formal non-inferiority could not be established (2). We followed trial participants for up to 4 years in this extension study to confirm effectiveness of ultra-low doses.

Methods: Patients from the REDO trial were invited to participate in this study. Treatment decisions were left at the discretion of the rheumatologist and patient. Disease activity (DAS28-CRP), and medication use (b/tsDMARD, csDMARD, gluccocorticoids [GC]) were collected from start of the trial to censoring in April 2021. The primary outcome was disease activity, secondary outcomes were RTX persistence, RTX doses and intervals, and use of comedication.

Disease activity was analyzed using a longitudinal mixed model with random intercepts to account for intra-patient correlations, in two ways: 1. By original randomization and stratification factors (RF/ACPA and csDMARD use). 2. By time-varying total RTX dose received in the year preceding each disease activity measurement, adjusted for current csDMARD or GC use, and RF/ACPA. The original DAS28-CRP non-inferiority (NI) margin of 0.6 was used.

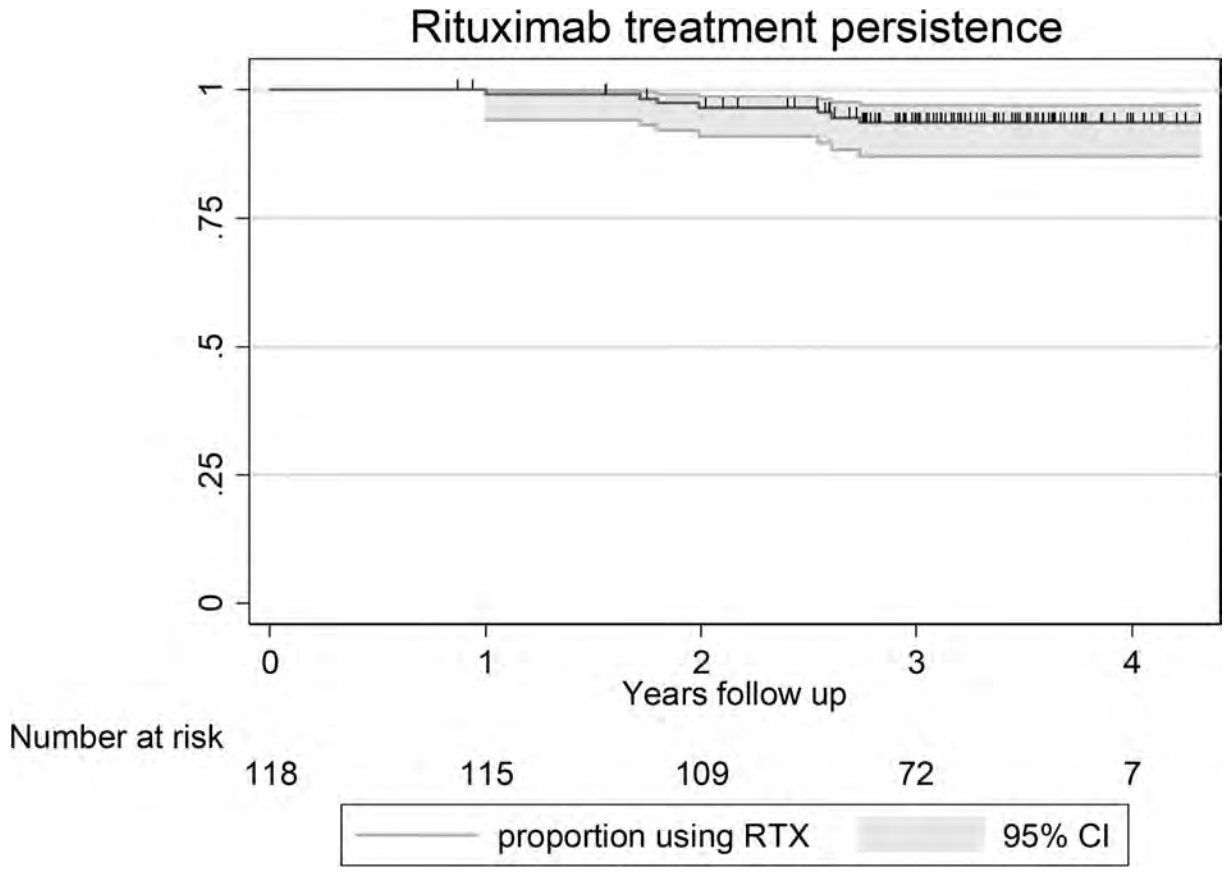

Figure 1. Rituximab treatment persistence during follow up.

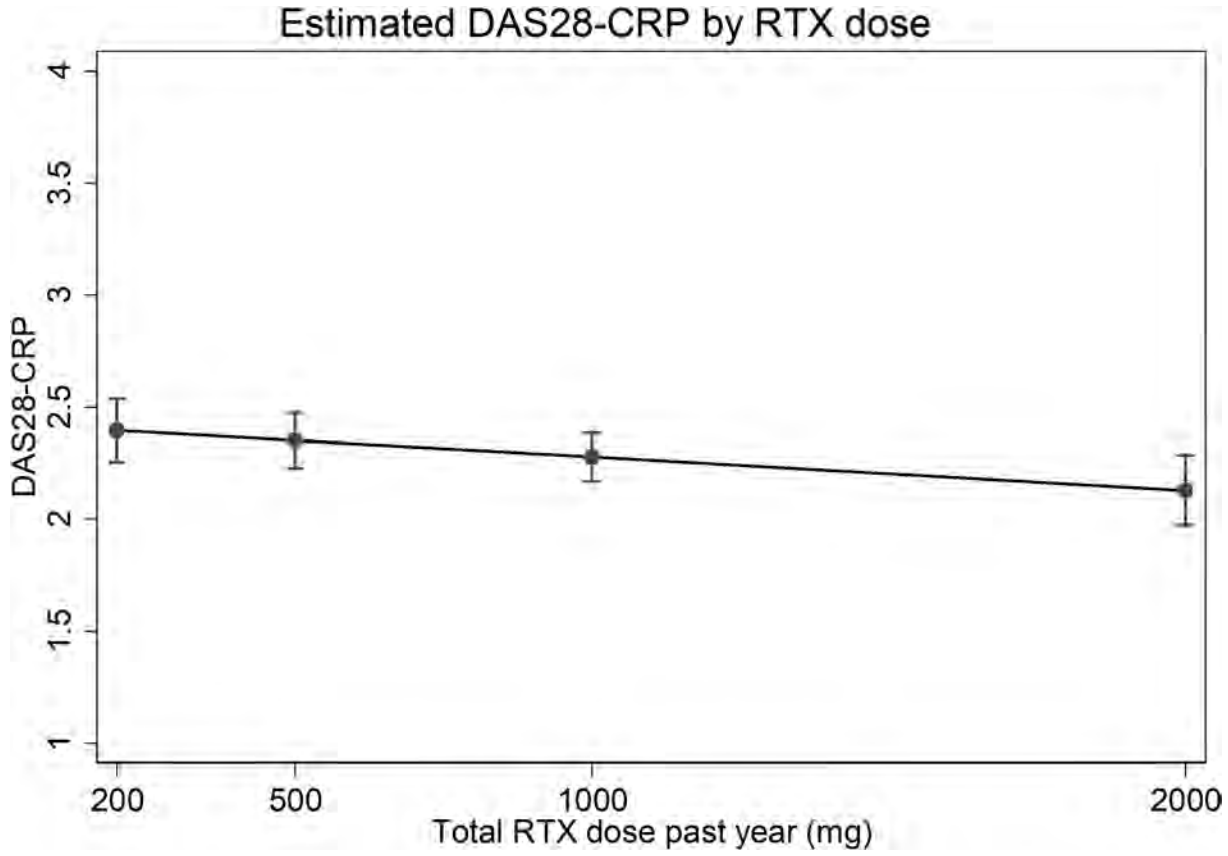

Figure 2. Estimated effect on disease activity of RTX dose in the year preceding disease activity measurement, corrected for RF/ACPA, csDMARD, oral and intramuscular glucocorticoid use.

Results: 118 out of 142 REDO patients were included in current analyses (table 1) Reasons for exclusion were: continuing treatment elsewhere (n=3), no informed consent (n=9) and data yet to be collected in 2 study centers (n=12). Mean follow up was 3.2 years (total of 377 patient-years), with 7 patients switching to another b/tsDMARD (Figure 1) upon which they were censored from disease activity analyses.

Disease activity in both ultra-low dose groups was non-inferior to the 1000mg group, with a mean DAS28-CRP (95% CI) during follow-up of 2.2 (2.0-2.4) in the 1000mg group, 2.2 (2.1-2.4) in the 500mg group and 2.3 (2.2-2.5) in the 200mg group.

Analyzed by received RTX dose, lower RTX dose was significantly associated with a higher DAS28-CRP: 0.15 (95% CI: 0.04-0.26) points higher per 1000mg more RTX (Figure 2). The upper limit for relevant RTX doses was below the prespecified NI margin, excluding a relevant effect of RTX dose on disease activity.

Median (IQR) yearly RTX dose was 978mg (704mg-1425mg). Final RTX dose per infusion was 200mg in 37 patients (31%), 500mg in 47 (40%) and 1000mg in 34 (29%), with a median (IQR) final interval between infusions of 6.0 (5.7-6.5), 6.2 (6.0-7.4) and 6.4 (6.0-9.6) months respectively. The rate of GC injections was 0.38 (95% CI: 0.32-0.44) per patient-year and initiation rate of oral GC was 0.05 (0.03-0.08) per patient-year.

Conclusion: A majority of patients treated with ultra-low dose RTX remained on ultra-low doses for up to 4 years, while disease activity remained low and did not relevantly differ between RTX doses, either according to original randomization or by received dose. Switching to other b/tsDMARDS or use of GC was rarely required.

Abstract Number: 1444

Baseline Factors Associated with the Development of Nausea and Alopecia over One Year in Patients Starting Methotrexate for Rheumatoid Arthritis

Ahmad Sherbini[1], James Gwinnutt[1], Kimme Hyrich[1] and Suzanne Verstappen[2], [1]University of Manchester, Manchester, United Kingdom, [2]School of Social Sciences, The University of Manchester, Manchester, United Kingdom

SESSION INFORMATION
Session Date: Monday, November 8, 2021
Session Title: Abstracts: RA – Treatments II: New Findings in Established Therapies (1442–1445)
Session Type: Abstract Session
Session Time: 2:00PM–3:00PM

Background/Purpose: Methotrexate (MTX) is the first-line treatment in the management of patients with rheumatoid arthritis (RA) due to its good efficacy. However, certain adverse events, such as nausea and alopecia, often create considerable concerns to patients starting the treatment, and could affect their quality of life. This may result in non-adherence to MTX or permanent discontinuation of treatment in the early period following the start of MTX. This study aimed to summarise the prevalence rates nausea and alopecia, and identify baseline factors associated with the development of these adverse events over the first year of MTX treatment.

Methods: The Rheumatoid Arthritis Medication Study (RAMS) is a multi-centre prospective cohort study of patients with RA commencing MTX for the first time. Relevant demographic, clinical and medication related data were collected at baseline (Table). Adverse events were reported at six- and twelve-month follow-ups. The prevalence rates of nausea and alopecia were calculated based on the proportions of patients who reported having an adverse event within one year of follow-up. Multivariable logistic regression analyses were performed to assess the associations between candidate baseline predictors and nausea or alopecia.

Results: A total of 1069 patients with early RA were included in this analysis. The mean age at the start of MTX was 59.2 (SD: 13.5) years, 65.3% were women, and the mean duration of symptom was 7.7 (SD: 5.6) months. Around one third of the patients (31.1%) reported nausea over the first year of treatment with MTX. Alopecia was reported by 83 patients (7.8%).

Women were more likely to report nausea and alopecia compared with men, odds ratios (ORs) were 2.22 (95%CI: 1.59 to 3.11) and 3.93 (95%CI: 2.01 to 7.70), respectively (Table). Older age was associated with decreased odds of reporting nausea, OR 0.97 (95%CI: 0.96 to 0.99). Alcohol consumption was associated with increased odds of

Table. Baseline factors associated with the development of nausea and alopecia

Baseline factors	Nausea (332 events)	Alopecia (83 events)
	Odds ratio (95% confidence interval)	
Demographic and lifestyles		
Age (years)	**0.97 (0.96, 0.99)**	1.00 (0.98, 1.02)

Medication related		
MTX starting dose> 15mg per week	0.92 (0.69, 1.22)	1.02 (0.63, 1.63)
Concomitant DMARDs, (yes vs no)	**0.72 (0.50, 1.02)**	**0.62 (0.34, 1.16)**
NSAIDs, (yes vs no)	1.11 (0.82, 1.50)	–

ACPA: Anti-citrullinated protein antibodies; BMI: body mass index; BMQ: Beliefs about Medicines Questionnaire; csDMARDs: conventional synthetic Disease-Modifying Antirheumatic Drugs; DAS28-CRP: disease activity score 28 joint counts; eGFR: estimated glomerular filtration rate; HAQ: health assessment questionnaire; MTX: methotrexate; NSAIDs: non-steroidal anti-inflammatory drugs; RF: rheumatoid factor; VAS: visual analogue scale

developing nausea and alopecia, ORs were 1.44 (95%CI: 1.04 to 1.97) and 1.98 (95%CI: 1.11 to 3.53), respectively. Higher Disease Activity Score and Belief about Medication Questionnaire – Concern scale at baseline were associated with increased odds of nausea. The use of concomitant csDAMRDs with MTX at baseline was associated with less reporting of nausea and alopecia.

Conclusion: Identifying factors associated with adverse event occurrence could help alleviate patients' concerns and improve adherence to MTX. Limiting alcohol consumption may influence the likelihood of developing MTX-related adverse events.

Abstract Number: 1445

Association Between Baseline Use of Rituximab and COVID-19 Outcomes in Patients with Rheumatoid Arthritis (RA)

Namrata Singh[1], Chen Hu[2], Vithal Madhira[2], Kate Fitzgerald[2], Timothy Bergquist[3], Kayte Anderson[2], Amy Olex[4], Rena Patel[5] and Jasvinder Singh[6], [1]University of Washington, Bellevue, WA, [2]Johns Hopkins, Baltimore, MD, [3]Sage Bionetworks, Seattle, WA, [4]Virginia Commonwealth University, Richmond, VA, [5]UW, Seattle, WA, [6]University of Alabama at Birmingham, Birmingham, AL

SESSION INFORMATION

Session Date: Monday, November 8, 2021
Session Title: Abstracts: RA – Treatments II: New Findings in Established Therapies (1442–1445)
Session Type: Abstract Session
Session Time: 2:00PM–3:00PM

Background/Purpose: Patients with Rheumatoid arthritis (RA) are at a potentially increased risk of SARS-CoV-2 infection, and immunosuppressive or biologic drugs used to treat RA might also be associated with a higher risk of infection or worse COVID-19 outcomes. Limited data to date suggest rituximab is associated with worse COVID-19 outcomes. The objective of our study was to evaluate the association between baseline use of rituximab and COVID-19 outcomes among patients with RA using a nationally representative sample of patients.

Methods: Our study sample included patients in the National COVID Cohort Collaborative (N3C), a centralized, harmonized, high-granularity electronic health record repository that is the largest, most representative U.S. cohort of COVID-19 cases and controls to date. N3C includes patient encounters from January 1, 2018 to provide information

Table 1. Baseline characteristics of the cohort

about pre-existing health conditions. We identified patients with RA who had two or more International Classification of Diseases (ICD)-10 codes for RA (M05.X or M06.X), and in sensitivity analyses we defined RA as having one or more than one RA-specific ICD-10 code (a more sensitive, less specific definition). We identified baseline use of DMARDs using the medication tables. Our primary outcomes were: SARS-CoV-2 infection, defined as COVID-19–positive polymerase chain reaction or antigen test, or an ICD-10-CM diagnostic code; and for those with COVID-19 diagnosis,

Table 2. Multivariable-adjusted association of Rituximab and no DMARD use with COVID-19 and COVID-19 outcomes

	SARS-Co-V-2 positivity	Hospitalized	Invasive ventilation	30-day mortality
	Odds ratio (95% Confidence Interval)			
Conventional synthetic DMARD (csDMARDs)	1.0	1.0	1.0	1.0
Rituximab use	0.89 (0.72-1.10)	**2.00 (1.32-3.04)**	**2.60 (1.13-5.70)**	1.98 (0.93-4.25)
No DMARD use	0.60 (0.58-0.64)	**1.60 (1.40-1.80)**	**1.40 (1.07-1.90)**	0.98 (0.78-1.22)
Adjusted for demographics (age, sex, race/ethnicity), Body mass index, US region, Deyo-Charlson comorbidity index [17 medical comorbidities], and smoking status				

hospitalization, invasive ventilation, and 30-day mortality. Multivariable logistic regression models assessed the association of rituximab use with the odds of COVID-19 and associated outcomes compared with the use of conventional synthetic DMARDs (csDMARDs) as the referent category. Analyses were adjusted for demographics, medical comorbidities, smoking status, US region, and body mass index (BMI).

Results: A total of 57,725 patients met our eligibility criteria of which 16,342 were SARS-CoV-2 positive during the study period. Mean (±SD) age of the cohort was 62 (±14.6) years, 75% females, 68% White and 76% were non-smokers (Table 1). 1477 (2.6%) patients were exposed to rituximab prior to their first positive COVID-19 test. Pulmonary disease was seen in 40% of the cohort. In multivariable-adjusted models, compared to the use of csDMARDs, baseline rituximab use was associated with increased odds of hospitalization among those who were diagnosed with COVID-19 (adjusted odds ratio, aOR 2.0, 95% CI 1.3-3), and invasive ventilation (aOR 2.6, 95% CI 1.13-5.7) (Table 2). No DMARD use was also associated with significantly higher odds of hospitalization among those who were diagnosed with COVID-19. Results were similar in sensitivity analyses where RA cohort was defined based on the presence of at least one ICD-10 code for RA (n=80,063).

Conclusion: We leveraged data from a large national repository to study the association between baseline use of DMARDs and various COVID-19 outcomes. Compared to csDMARD use, rituximab use in patients with RA was associated with higher odds of COVID-19 hospitalizations and invasive ventilation. These results stress the need of prioritizing COVID-19 vaccination for RA patients.

SESSION INFORMATION
Session Date: Monday, November 8, 2021
Session Title: Abstracts: Clinical Epidemiology (1446–1451)
Session Type: Abstract Session
Session Time: 2:00PM–3:30PM

Background/Purpose: Daily psychological stress and trauma exposure with or without symptoms of post-traumatic stress disorder have been linked to an increased risk of SLE onset.[1, 2] Adverse childhood experiences (ACEs) have been linked to worse patient-reported outcomes in SLE, but not to physician-assessed disease activity.[3] This analysis examines the association between experiences of trauma and disease flares in SLE.

Methods: Data are from the California Lupus Epidemiology Study (CLUES), a longitudinal cohort of individuals with rheumatologist-confirmed SLE. Data are collected annually through in-person research visits and structured interviews. The Brief Trauma Index (BTI) was administered to assess the experience of trauma as well as whether the respondent believed they were at risk for serious injury or death, and whether they were actually injured (Table 1). In contrast to ACEs, traumatic events could be in childhood or adulthood, although one question specifically addresses childhood events. The total number of traumatic events, events with perceived danger, and events with injury, as well as the experience of any of these were calculated. Lupus flares over the previous year were self-reported as any flare (FLARE) or whether the respondent visited the doctor or was hospitalized for the flare (DR-FLARE). Cross-sectional analyses examined whether trauma (number of events or any event) was associated with flares. Multivariable analyses examined the role of trauma on the occurrence of flares controlling for age, disease duration, sex, poverty, race/ethnicity, comorbidities, and obesity. Finally, analyses were repeated and stratified by whether the individual reported ACEs. For this analysis, the BTI item on childhood trauma was excluded.

Results: Among the 251 individuals who completed the BTI, mean age was 50 ± 13 years, disease duration 22 ± 11 years, 90% were female, 31% Asian, 23% Hispanic, 33% white non-Hispanic, and 10% African American. 106 (42%) reported FLARE in the past year; 62% of these (n=66) reported DR-FLARE. 83% reported any trauma; excluding the BTI item on serious illness, 77% reported any trauma (Table 1). 64% reported trauma with perceived danger, and 23% with injury. Among those with FLARE and DR-FLARE, the number of all types of events was higher (Table 2). In multivariate analyses, the associations remained significant (Table 3). The association between trauma in adulthood and flares appeared to be stronger among individuals who had previously experienced ACEs (e.g., 0-1 ACEs, odds of DR-FLARE per number of traumatic events = 1.2 [95% CI 0.9, 1.6)] vs. ≥2 ACES 1.7 [1.2, 2.5]).

Conclusion: Individuals with SLE who have experienced trauma during adulthood may be at increased risk for more frequent self-reported flares over time, and the experience of childhood trauma may magnify that risk. Given the high frequency of traumatic experiences, identifying both the mechanisms of these associations and interventions that may reduce the impact of trauma is critical.

Table 1. Frequency of responses to Brief Trauma Index (n=251)			
	Has this ever happened to you?	Did you think your life was in danger or you might be seriously injured?	Were you seriously injured?
	Yes →	Yes	Yes
1. Have you ever served in a war zone, or have you ever served in a noncombat job that exposed you to war-related casualties	2.0% (5)	1.2% (3)	0
2. Have you ever been in a serious car accident or a serious accident at work or somewhere else?	25.5% (64)	17.9% (45)	10.0% (25)
3. Have you ever been in a major natural or technological disaster, such as a fire, earthquake, tornado, hurricane, explosion, or chemical spill?	40.6% (102)	22.7% (57)	0.8% (2)
4. Have you ever had a life-threatening illness such as cancer, a heart attack, leukemia, AIDS, multiple sclerosis, etc.?	47.8% (120)	37.5% (94)	
5. Before age 18, were you ever physically punished or beaten by a parent, caretaker, or teacher so that: you were very frightened or thought you would be injured; or you received bruises, cuts, welts, lumps, or other injuries?	25.9% (65)	12.4% (31)	6.0% (15)
6. Besides what you just told me about, have you ever been attacked, beaten, or mugged by anyone, including friends, family members or strangers?	27.5% (69)	19.1% (48)	8.8% (22)
7. Has anyone ever made or pressured you into having some type of unwanted sexual contact?	32.3% (81)	13.6% (34)	10.0% (25)
8. Have you ever been in any other situation in which you were seriously injured, or have you ever been in any other situation in which you feared you might be seriously injured or killed?	21.1% (53)	7.6% (19)	
9. Has a close family member or friend died violently, for example, in a serious car crash, mugging, or attack?	23.5% (59)		
10. Other than the events you already told me about, have you ever witnessed a situation in which someone was seriously injured or killed, or have you ever witnessed a situation in which you feared someone else would be seriously injured or killed?	27.5% (69)

Long-Term Effect of Prescription Non-Steroidal Anti-Inflammatory Drug Regular Use on the Risk of a Knee Replacement

S. Reza Jafarzadeh[1], Tuhina Neogi[1] and David Felson[2], [1]Boston University School of Medicine, Boston, MA, [2]Boston University, Boston, MA

SESSION INFORMATION

Session Date: Monday, November 8, 2021
Session Title: Abstracts: Clinical Epidemiology (1446–1451)
Session Type: Abstract Session
Session Time: 2:00PM–3:30PM

Background/Purpose: Non-steroidal anti-inflammatory drugs (NSAIDs) are a primary treatment for osteoarthritis (OA). It is uncertain, however, whether regular use of NSAIDs affects the risk of structural progression and ultimately increase joint replacement risk. Reports suggest that users of analgesics including NSAIDs may experience more progressive structural deterioration than non-users. On the other hand, NSAIDs may reduce intra-articular inflammation sufficiently to minimize potential damage. Whereas regular use of prescription NSAIDs is common in persons with OA, the long-term effects of pain-relieving interventions on structural damage are not fully characterized. Previous studies focused on short-term effects and only compared always-users of NSAIDs with non-users and had limited ability to mitigate confounding by indication. We used a causal inference-based approach, and designed a hypothetical longitudinal trial from observational data to assess the risk of a knee replacement (KR) under various time-varying regimens of regular prescription NSAIDs use.

Methods: We included 8 years of data from the Osteoarthritis Initiative (OAI) cohort, including baseline, 12-, 24-, 36-, 48-, 72-, and 96-month OAI study visits. Study outcome was defined as a KR. Study exposure was defined as the regular use of any prescription NSAIDs, which was determined at every study visit. Study covariates included baseline and time-dependent confounders measured at all OAI visits that included knee pain characterized by the Western Ontario and McMaster Universities Osteoarthritis Index (WOMAC) pain subscale. We used targeted learning, a double-robust causal inference-based methodology, to compare the risk of a knee replacement under hypothetical intervention regimens that included comparing no NSAID use in persons with painful knees to a hypothetical regimen of regular NSAIDs use in the same persons and under the same conditions. We examined KR risk for hypothesized NSAIDs initiation at knee pain levels of 7, 10, and 15 on the 0-20 WOMAC scale, compared to no NSAID use at the same pain levels.

Results: Data included 528 KR events (in 9592 knees; 5.5%) in 4796 persons (58.5% female; baseline mean age = 61.2 [SD = 9.2]). The estimated reference risk of a KR event in OAI (i.e., the risk for the no intervention regimen), adjusted for loss to follow-up and death, was 5.9% (95% CI: 5.2%, 6.5%). KR risk increased by 232%, 51%, and 12% when NSAIDs initiation was triggered at WOMAC pain level of 7, 10, and 15, respectively, suggesting an increased risk of KR with NSAID use especially when prescription NSAIDs were initiated at lower knee pain levels. Examining WOMAC pain < 7 was not possible given the rarity of regular NSAID use at this threshold in OAI participants. To adjust for pain severity, we used WOMAC pain score at the annual exam prior to report of regular NSAID use and if pain worsened over the year, triggering NSAID use, our findings may overestimate NSAID risk.

Table 1. Estimated knee-level risk of a knee replacement in the Osteoarthritis Initiative cohort under dynamic intervention regimen of prescription NSAIDs initiation based on a knee pain level.

WOMAC pain score to trigger NSAIDs initiation	Average treatment effect risk ratio (95% CI)
7	2.32 (1.01, 5.35)
10	1.51 (1.25, 1.81)
15	1.12 (1.06, 1.19)

CI: Confidence interval; NSAIDs: Non-steroidal anti-inflammatory drugs; WOMAC: Western Ontario and McMaster Universities Osteoarthritis Index.

Conclusion: Our findings suggest that, for the same level of pain, prescription NSAIDs users may experience higher risk of a KR compared to non-users.

Confounders included demographics, body mass index, Kellgren and Lawrence grade, regular use of prescription opioids, WOMAC stiffness and function scores, objective functional performance measures of chair stand time, 20- and 400-meter walk tests, malalignment, Charlson comorbidity index, Center for Epidemiologic Studies Depression (CES-D) scale, Physical Activity Scale for the Elderly (PASE) score, a knee injury, hip pain or stiffness, and a family history of a knee or a hip replacement.

Session Title: Abstracts: Clinical Epidemiology (1446–1451)

Session Type: Abstract Session

Session Time: 2:00PM–3:30PM

Background/Purpose: TTT is the recommended paradigm for managing RA according to major rheumatology organizations, however the literature suggests that TTT has not been widely implemented in US rheumatology. In a prior randomized controlled trial, we found that a learning collaborative (LC) was effective for improving implementation of TTT. (1) During the current study, we worked with US rheumatology practices on implementing TTT during 2020-2021 when some visits were conducted face-to-face (F2F) and other visits virtually (VV). These analyses examine differences in adherence with TTT based on whether the visit was F2F or VV.

Figure 1: Adherence with Treat to Target Across All Sites, Comparing Face to Face with Virtual Visits

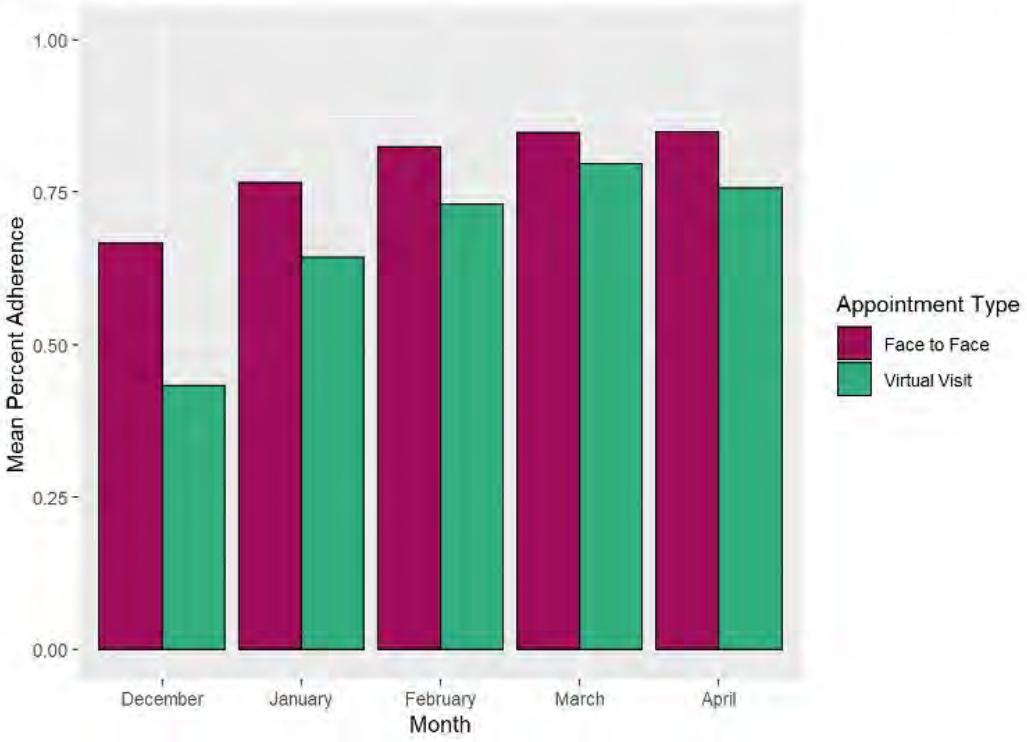

Table 1: Comparison of F2F versus VV and Adherence with Components of Treat to Target

Component of TTT	Face to face	Virtual visit	P-value
Disease activity measure	994 (87.4)	215 (67.8)	<0.0001
Target Noted	914 (80.4)	190 (59.9)	<0.0001
At Target	417 (36.7)	117 (36.9)	0.94
Not at target, change treatment	402 (35.4)	86 (27.1)	0.006
Shared decision making	702 (61.7)	204 (64.4)	0.40

Methods: During 2020-2021, we conducted a virtual Learning Collaborative (LC) for TTT in RA. 18 US-based rheumatology practices and 45 clinicians (MD, DO, NP, PA, RN) were engaged in the LC. The LC was 6 months in duration and each month the practices abstracted data from 20-25 visits with RA patients, focusing on adherence with TTT. Adherence was measured as a percentage of TTT component processes: 1) measure and document disease activity (any standard measure was acceptable), 2) determine a target disease activity, 3) make treatment changes if not at target, and 4) document shared decision-making. We then analyzed TTT adherence overall and by visit type, comparing F2F with VV. Further, VV visits were stratified as telephone or video.

Results: The 18 sites were distributed widely across the US, representing 10 states plus Washington DC, and their locations varied in COVID pandemic policies. During the 6 months, sites entered data on 1826 patient visits: 78% were F2F and 22% were VV. Overall adherence with TTT during the six months improved from a mean of 51% to 84%. Each component process of TTT was compared between F2F and VV visits (see **Table 1**). Over the full follow-up of the LC, there was greater adherence with TTT when visits were F2F (79% adherence) versus VV (65% adherence) ($p < 0.0001$). Documentation of a disease activity measure, a target, and change in treatment if not at target were all more common in the F2F versus VV visits (all $p < 0.05$). Documentation of shared decision making was similar across the

two types of visits. F2F adherence started at 67% whereas VV was 43% ($p < 0.0001$). However, by the last month, F2F was at 85% and VV at 76% ($p = 0.059$) (see **Figure 1**). Of the VV, 43% were conducted by telephone and 57% by video. Comparing overall adherence with TTT across these two types of VVs, there was not difference in overall adherence between video visits and telephone visits, 64.8% and 65.3%, respectively.

Conclusion: Implementing TTT for RA is a challenge, especially during the COVID pandemic. Among 18 US rheumatology practices engaged in implementing TTT, we found that adherence with TTT was slightly worse for VV compared with F2F. However, adherence with TTT improved for both types of patient visits, even during the COVID19 pandemic, and was similar after a six-month learning collaborative.

Is Repeat Serum Urate Testing Superior to a Single Test to Predict Incident Gout over Time?

Sarah Stewart[1], Amanda Phipps-Green[2], Gregory Gamble[1], Lisa Stamp[3], William Taylor[4], Tuhina Neogi[5], Tony Merriman[6] and Nicola Dalbeth[1], [1]University of Auckland, Auckland, New Zealand, [2]University of Otago Dunedin, Dunedin, New Zealand, [3]University of Otago, Christchurch, Christchurch, New Zealand, [4]University of Otago Wellington, Auckland, New Zealand, [5]Boston University School of Medicine, Boston, MA, [6]University of Alabama at Birmingham, Dunedin, New Zealand

SESSION INFORMATION
Session Date: Monday, November 8, 2021
Session Title: Abstracts: Clinical Epidemiology (1446–1451)
Session Type: Abstract Session
Session Time: 2:00PM–3:30PM

Background/Purpose: Elevated serum urate is the most important risk factor for developing gout. However, in longitudinal cohort studies, a small proportion of people with normal urate levels develop gout and the majority of those with high urate levels do not. These observations may be due to subsequent variations in serum urate over time. It is unclear whether repeated testing of serum urate improves the ability to accurately predict development of gout. This analysis aimed to examine whether single or repeat testing of serum urate more accurately predicts incident gout over time.

Methods: Individual participant data was included from three publicly available cohorts: Atherosclerosis Risk in Communities Study (ARIC), Coronary Artery Risk Development in Young Adults Study (CARDIA), and the original cohort of the Framingham Heart Study (FHS). Data from paired serum urate measures 3-5 years apart, followed by an assessment of gout incidence 5-6 years from the second urate measure were used to calculate the predictive ability of four models of serum urate measurement on incident gout: the first measure, the second measure, the average of the two measures, and the highest of the two measures. Participants with prevalent gout prior to the second measure were excluded. Receiver operator characteristic (ROC) curves and area under the curve (AUC) statistics were computed to compare the four models.

Results: A total of 16,017 participants were included across the three cohorts. Overall, 56% of participants were female, and 80% were European. The mean age of participants at baseline was 49 years. The mean follow-up from the first serum urate test was 9.3 years (range 8.9-10.1 years). Overall, there was a small increase in the mean serum urate between the first and second measures (5.42 mg/dL vs. 5.71 mg/dL, $P< 0.001$) which were a mean (SD) of 3.5 (0.9) years apart, but the first and second measures were highly correlated ($r = 0.81$, $P< 0.001$). No differences were observed in the predictive ability of incident gout between the four measures of serum urate measurement with ROC curve AUC statistics ranging between 0.81 (95% confidence intervals: 0.78-0.84) and 0.84 (95% confidence intervals: 0.81-0.87) (Table).

Conclusion: Repeat serum urate testing is not superior to a single measure of serum urate for prediction of incident gout over approximately one decade. These results may inform the design of longitudinal studies of incident gout, and clinical practice when providing advice to individuals about their risk of developing gout.

Unsupervised Machine Learning Methods to Cluster Comorbidities in a Population-based Cohort of Patients with Rheumatoid Arthritis

Elizabeth Atkinson[1], Tina Gunderson[1], John Davis[1], Elena Myasoedova[1], Vanessa Kronzer[1], Caitrin Coffey[1] and Cynthia Crowson[2], [1]Mayo Clinic, Rochester, MN, [2]Mayo Clinic, Eyota, MN

SESSION INFORMATION

Session Date: Monday, November 8, 2021
Session Title: Abstracts: Clinical Epidemiology (1446–1451)
Session Type: Abstract Session
Session Time: 2:00PM–3:30PM

Background/Purpose: Comorbidities are common in patients with rheumatoid arthritis (RA), and comorbidity patterns are of interest. We aimed to examine clusters of comorbidities and clusters of patients based on comorbidities using several methods.

Methods: In this retrospective, population-based study, residents of a geographically well-defined area with prevalent RA on 1-1-2015 were identified from a comprehensive medical record linkage system. Diagnostic codes were retrieved for a 5 year period prior to the prevalence date. Using 2 codes at least 30 days apart, the 44 comorbidities described by England et al (ARD 2020) were defined. Unsupervised machine learning methods of interest included ascendant hierarchical clustering, network analysis, partitioning around medoids and latent class analysis. Methodologic considerations include the research question of interest, whether the method is appropriate for categorical data, method assumptions (e.g., some methods assume equal sample size per cluster), the optimal number of clusters, internal validation, stability and biological plausibility.

Results: A total of 1409 patients with prevalent RA (72% female; 92% white; mean age 63.5 years) were studied. Comorbidities were present in 1187 (84%) of the subjects with 5+ comorbidities present in 749 (53%) subjects.

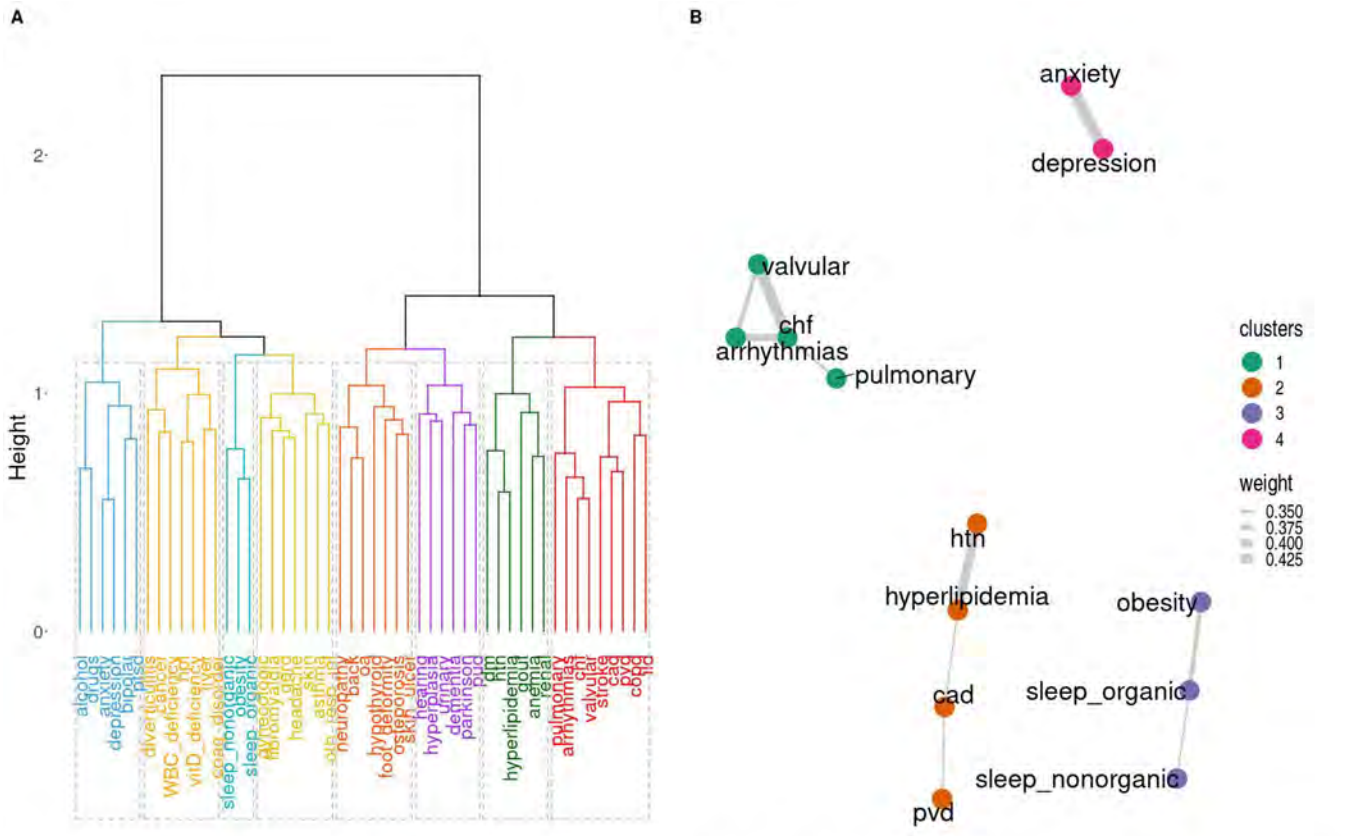

Figure 1. Panel A shows hierarchical clustering of comorbidities using the RA cohort; each color block represents a different cluster. Panel B shows network analysis using the same data. Thicker lines represent a higher correlation between the comorbidities and comorbidities not shown had smaller correlations with other comorbidities.

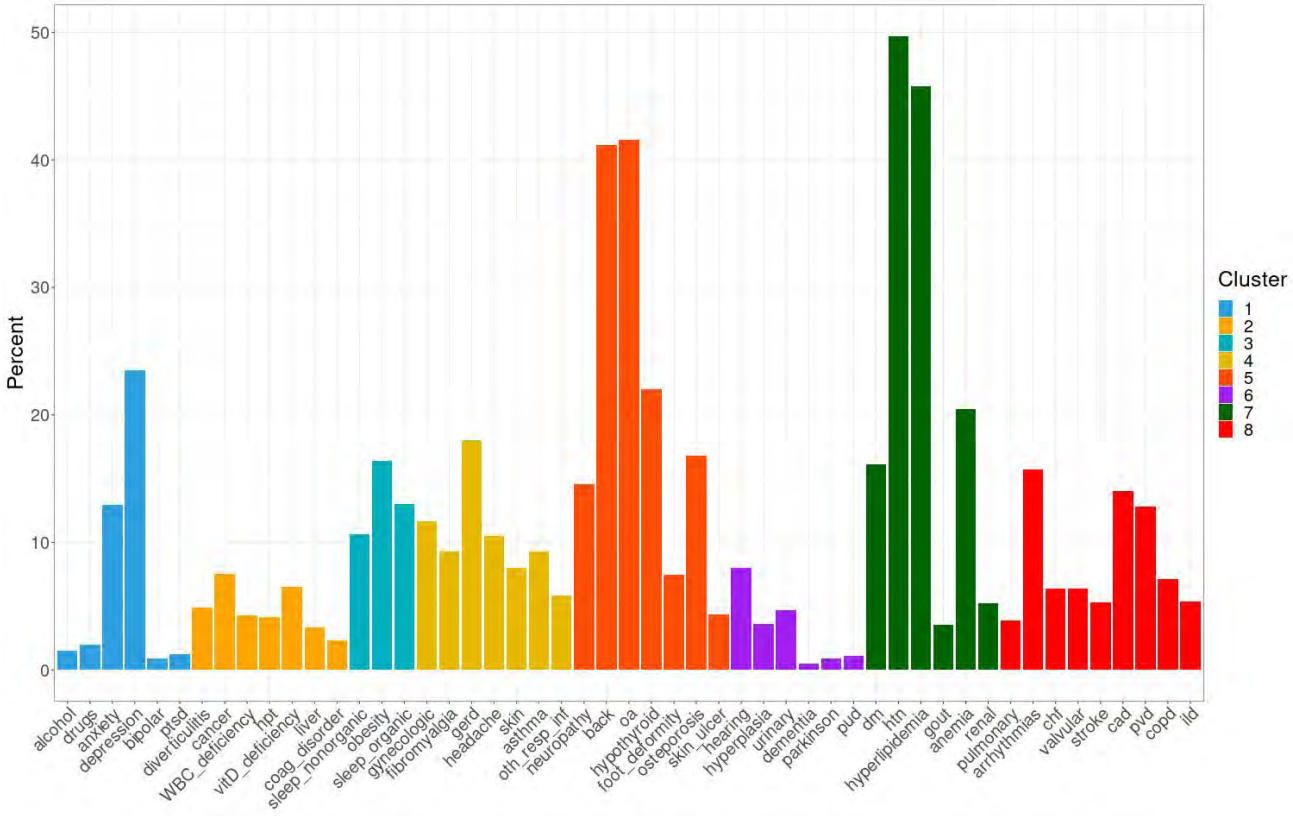

Figure 2: Frequency of comorbidities identified in the RA cohort within the past 5 years, grouped by the clusterd identified in Figure 1

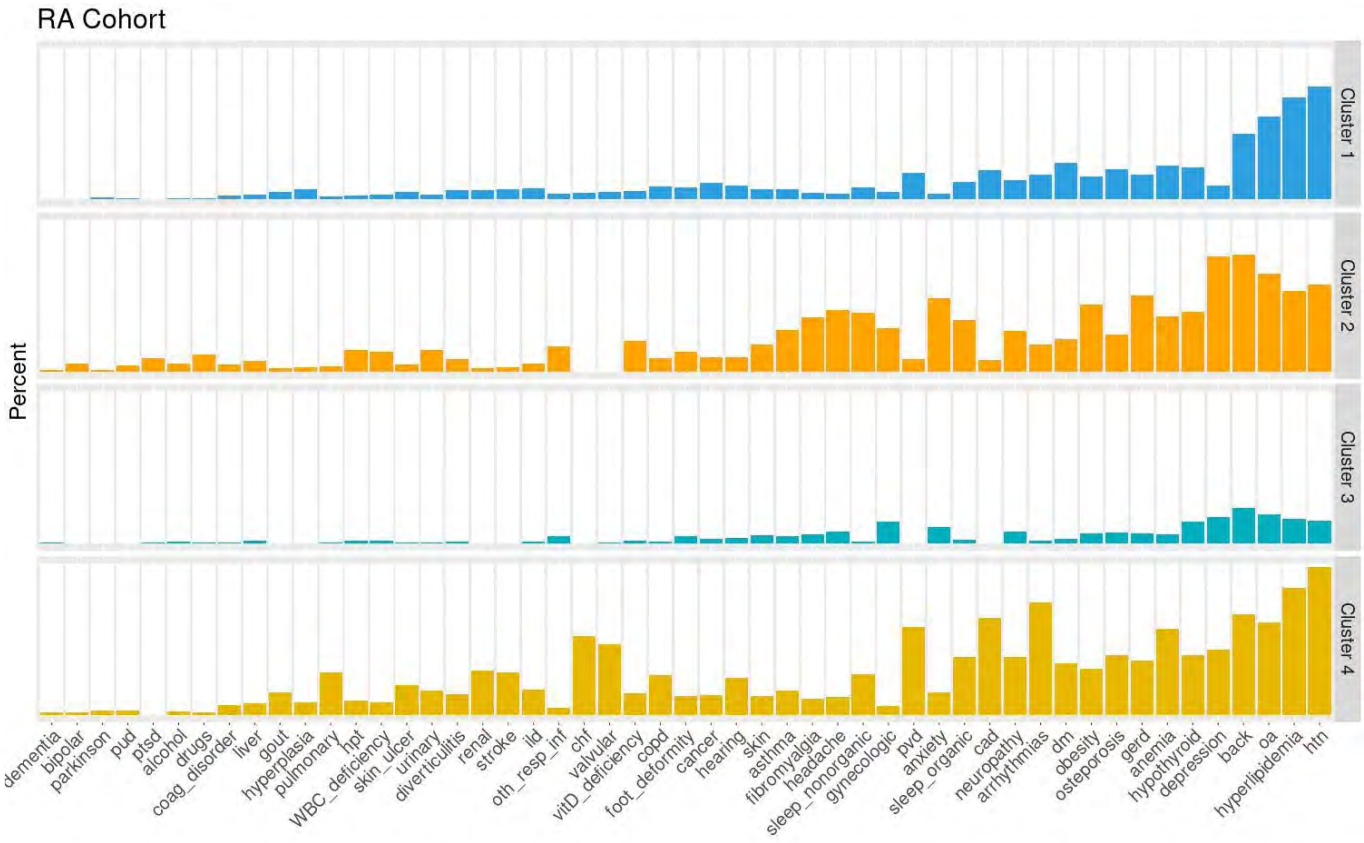

Figure 3: Latent class analysis using the RA cohort where each subject is in a cluster. The comorbidities listed along the horizontal axis are ordered by overall frequency in cohort. Cluster 3 includes subjects with few underlying comorbidities whereas cluster 4 includes subjects with multiple comorbidities.

Clustering of comorbidities using hierarchical clustering methods yielded 8 clusters (Figure 1a) while network analysis (Figure 1b) yielded 4 clusters. In both methods, the clusters were primarily organized around body systems (e.g., cardiovascular, respiratory, mental/behavioral comorbidities) with greater stability between methods for comorbidities with higher prevalence than those that were less common. Figure 2 illustrates the prevalence of each comorbidity within the cohort, grouped according to the clusters identified using the hierarchical approach.

Clustering of patients into subgroups based on comorbidity profiles using partitioning around medoids and latent class analysis yielded groups with no/few comorbidities, many comorbidities, and 2-3 intermediate groups with some comorbidities. Figure 3 shows the prevalence of each comorbidity within the 4 clusters identified using latent class analysis.

Conclusion: Clustering of comorbidities and clustering of patients can provide useful information about multimorbidity patterns in patients with RA. Clustering variables allows for easy application to other cohorts (e.g., non-RA). Clustering of RA subjects primarily created groups of subjects who had varying numbers of comorbidities. Various clustering methods are available, and these methods yield different results. It is important to understand the assumptions of these methods, as well as how to determine the optimal number of clusters for each method. Further research is needed to determine the best methods for identifying comorbidity patterns in RA.

Abstract Number: 1451

Improving Health Outcomes and Social Connectedness Through Virtual Exercise Programs in Community Members with Musculoskeletal Conditions

Titilayo Ologhobo[1], Bertilia Trieu[2], Claudia Zurlini[1], Bonnie McGrath[1], Linda Roberts[1], Vilma Briones[1], Pamela Sanchez-Villagomez[2], Robyn Wiesel[1], Sandra Goldsmith[1] and Laura Robbins[1], [1]Hospital for Special Surgery, New York, NY, [2]Hospital of Special Surgery, New York

SESSION INFORMATION
Session Date: Monday, November 8, 2021
Session Title: Abstracts: Clinical Epidemiology (1446–1451)
Session Type: Abstract Session
Session Time: 2:00PM–3:30PM

Background/Purpose: According to the 2020 American Health Ranking System, 26% of adults are physically inactive with a higher prevalence found in adults ages ≥65 years. Physical inactivity coupled with musculoskeletal conditions can result in poor health outcomes i.e., decreased pain tolerance, weak muscles, and stiff joints. These problems increase with age with nearly 75% of adults ages ≥65 years affected by musculoskeletal diseases. The COVID-19 pandemic resulted in significant disruption to daily living, social interaction, physical activity, and access to healthcare services. Under these conditions, physical inactivity was more prominent resulting to a potential decline of musculoskeletal function and health outcomes. To address these gaps, and ensure continued access to healthcare services, HSS pivoted from onsite to virtual exercise programming.

Methods: In March 2020, during the height of the pandemic, HSS shifted to 60-minute virtual exercise classes (Pilates, Yoga, and T'ai Chi) via Zoom. Our classes were targeted and structured to provide increased opportunity for

physical activity, social interaction with others, and access to programs. We introduced a variety of low-intensity exercises conducted safely at home, increased frequency of exercise classes, and promoted dialogue among participants before classes begin. Program effectiveness was measured using pre/post online surveys assessing sociodemographics, and self-reported health outcomes i.e., pain intensity, pain interference with seven aspects of daily living (ADL), physical functioning, stiffness, fatigue, physical activity, and self-efficacy. A longitudinal analysis was conducted using regression models.

Results: Our virtual exercise classes reached 5,030 community members. Of those assessed (n=287), 61 participants who self-reported having a musculoskeletal condition were mostly females (98%) ages ≥60 years (83%) and Caucasian (88%). Overall, these participants reported a 9% decrease in pain intensity ($p \leq 0.05$), 14% decrease in pain interference with relations with others ($p \leq 0.05$), and 9% decrease in stiffness ($p \leq 0.05$) with every 6-week virtual exercise session. In a sub-sample of participants with self-reported musculoskeletal conditions that participated in classes at least 2x/week (n=17), results revealed a 18% decrease in pain intensity ($p \leq 0.001$), 13% decrease in stiffness ($p \leq 0.001$), 14% decrease in stiffness ($p \leq 0.05$), and decreased pain interference with six ADL - general activity (18%; $p \leq 0.001$), mood (14%; $p \leq 0.05$), walking ability (17%; $p < 0.05$), normal work (16 %; $p \leq 0.01$), sleep (18%; $p \leq 0.05$), and enjoyment of life (18%; $p < 0.01$) with every 6-week virtual exercise session.

Conclusion: Our targeted approach in implementing safe low-intensity virtual exercises proved to be successful. Results indicate that virtual exercise classes were effective in improving health outcomes and fostering social connectedness in participants with musculoskeletal conditions. Amid uncertainties caused by the pandemic, shifting to virtual programming increased overall reach, reduced the negative impact of isolation, and enabled those with musculoskeletal conditions have increased access to effective health programs.

SESSION INFORMATION

Session Date: Monday, November 8, 2021

Session Title: Abstracts: Miscellaneous Rheumatic & Inflammatory Diseases: New Insights into Therapies & Mechanisms of Disease (1452–1457)

Session Type: Abstract Session

Session Time: 3:30PM–5:00PM

Background/Purpose: The impact of COVID-19 infection in patients with autoimmune/auto-inflammatory rheumatic diseases (AARD) under immunomodulatory treatment is not entirely clear and deeper knowledge is of paramount importance during the SARS-CoV-2 pandemic. Whether risk factors as in the general population or the immune dys-

regulation in the context of the underlying AARD per se and/or the immunomodulatory therapy used predispose to a more severe disease course and hospitalization, has to be elucidated.

Methods: In this observational study, demographic data, AARD related features and comorbidities, COVID-19 manifestations and outcome, as well as antibody responses to SARS-CoV-2 were recorded among 77 AARD patients infected by SARS-CoV-2. We next wished to identify risk factors for COVID-19 severity and subsequent hospitalization Analysis of data was performed using univariate and multivariate models.

Results: The majority of patients (68.8%) experienced a mild COVID-19 course. The predominant symptoms were upper respiratory tract symptoms (68.8%), fatigue (58.4%) and low grade fever (45.4%). One out of four patients required hospitalization (23.3%) and the mortality rate was 1.3%. Regarding COVID-19 severity, prior treatment with corticosteroids, mycophenolate mofetil or rituximab was more common in patients who developed a more serious disease course (60.0 vs 29.9%, p=0.003, 40.0 vs 7.5%, p=0.003, 10.0 vs 0.0%, p=0.009, respectively). Among COVID-19 related features, patients with shortness of breath and high-grade fever were more likely to get hospitalized (OR [95%]: 7.06 [1.36–36.57], 12.04 [2.96–48.86]), while anosmia was independently associated with lower hospitalization risk (OR [95%]: 0.09 [0.01–0.99]). When disease related features and comorbidities were considered in multivariate models, older age and lung disease in the context of the AARD were found to be independent predictive factors for hospitalization (OR [95%]: 1.09 [1.03–1.15] and 6.43 [1.11–37.19]).

Conclusion: Though the majority of AARD patients displayed a mild COVID-19 course, certain AARD related features and COVID-19 related manifestations should prompt alertness for the physician to identify patients with AARD at high risk for severe COVID-19 and need for hospitalization.

Lung Interleukin-33 Is Elevated in Rheumatoid Arthritis-Associated Lung Disease

Rohit Gaurav[1], Ted Mikuls[1], Geoffrey Thiele[1], Bryant England[1], Madison Wolfe[1], Kristina Bailey[1], Amy Nelson[1], Michael Duryee[1], Debra Romberger[1], Dana Ascherman[2] and Jill Poole[1], [1]University of Nebraska Medical Center, Omaha, NE, [2]University of Pittsburgh, Pittsburgh, PA

SESSION INFORMATION

Session Date: Monday, November 8, 2021

Session Title: Abstracts: Miscellaneous Rheumatic & Inflammatory Diseases: New Insights into Therapies & Mechanisms of Disease (1452–1457)

Session Type: Abstract Session

Session Time: 3:30PM–5:00PM

Background/Purpose: The alarmin interleukin (IL)-33 is a member of the IL-1 cytokine family that is rapidly released from the nucleus of a variety of lung cells upon cellular damage or xenobiotic (including airborne biohazard) exposures. IL-33 has been implicated in rheumatoid arthritis (RA), where increased levels in sera and synovial fluid correlate with disease activity. Moreover, elevated sera and lung IL-33 occur in idiopathic pulmonary fibrosis, a condition that resembles RA-interstitial lung disease. However, IL-33 levels and its role in the pathogenesis of RA-associated lung disease are not known.

Table 1. Characteristics of RA patients and corresponding lung tissue sample.

#	Sex	Age	Disease	Pathology Report
1	M	59	RA-ILD	Patchy and non-specific foci of subpleural fibrosis, chronic cellular bronchiolitis associated fibrosis and chronic interstitial pneumonitis suggestive of usual interstitial pneumonia
2	M	67	RA-ILD	Organizing diffuse alveolar damage, chronic interstitial pneumonia, and patchy foci of significant interstitial fibrosis with honeycomb change and areas of chronic pleuritis
3	F	62	RA-mild disease	Bronchial mucosa with mild chronic inflammation and eosinophils
4	F	49	RA-ILD	Patchy fibrosis with subpleural, paraseptal and peribronchiolar distribution, bronchiectasis, focal lymphoid aggregates
5	F	49	RA-ILD	Fibrovascular pleural adhesion, mild diffuse interstitial lymphoid hyperplasia, patchy non-specific chronic interstitial pneumonitis, chronic cellular bronchiolitis
6	F	60	RA-nodules	Nodules with diffuse interstitial deposition of eosinophilic extracellular materials with multinucleated giant cells on background of chronic inflammation of plasma cells and lymphocytes.
7	M	51	RA-ILD	Focal areas of pleural fibrosis with necrotizing granuloma with peripheral palisading histiocytes[1]
8	M	65	RA-nodules	Nodules of necrotizing granulomatous inflammation
9	F	42	RA-ILD	Mild ground-glass opacity, mild honeycombing, mild air trapping, features more consistent with usual interstitial pneumonia with fibrosis

[1]Evidence of both RA and RA-nodules.

Methods: Formalin-fixed, paraffin-embedded (FFPE) de-identified human lung sections from patients with RA-lung disease (N=9) and normal "control" (N=7) donors (deemed unsuitable for transplant) were obtained from the local institutional IRB-approved biobanks. An animal model combining the collagen-induced arthritis (CIA) and 5 weeks of repetitive inhalation of lipopolysaccharide (LPS, 100 ng) was utilized to obtain lung sections from 4 groups of DBA/1J mice (N=5/group): 1) Sham (saline injection/saline inhalations); 2) CIA (CIA injections/saline inhalations); 3) LPS (saline injections/LPS inhalations); and 4) CIA+LPS. Sections were stained for human or mouse anti-IL-33 and vimentin. Photographs (10 per lung section per patient/mouse) were taken using a Zeiss fluorescent microscope. Integrated densities (the product of area and mean gray value) of each protein were measured as a single color on black background with color thresholds determined by Image J.

Results: Characteristics of patients with RA-associated lung disease and corresponding lung tissue pathology are summarized in **Table 1**. Lung IL-33 expression was strikingly increased in the lung tissues of patients with RA-associated lung disease (5.7-fold), with lesser, but significant, increases in vimentin staining (1.9-fold) ($p=0.0002$ and $p=0.0033$, respectively) relative to control lung tissues (**Figure 1**). In sensitivity analyses excluding 2 subjects with RA-related pulmonary nodules and 1 subject with mild inflammation, IL-33 and vimentin expression remained significantly elevated ($p < 0.01$ for both). In murine modeling studies, lung IL-33 expression was increased with LPS alone (5.3-fold) and CIA+LPS (5.7-fold) vs. Sham ($p < 0.001$) and vs. CIA alone (3.1-fold and 3.4-fold, respectively, p<

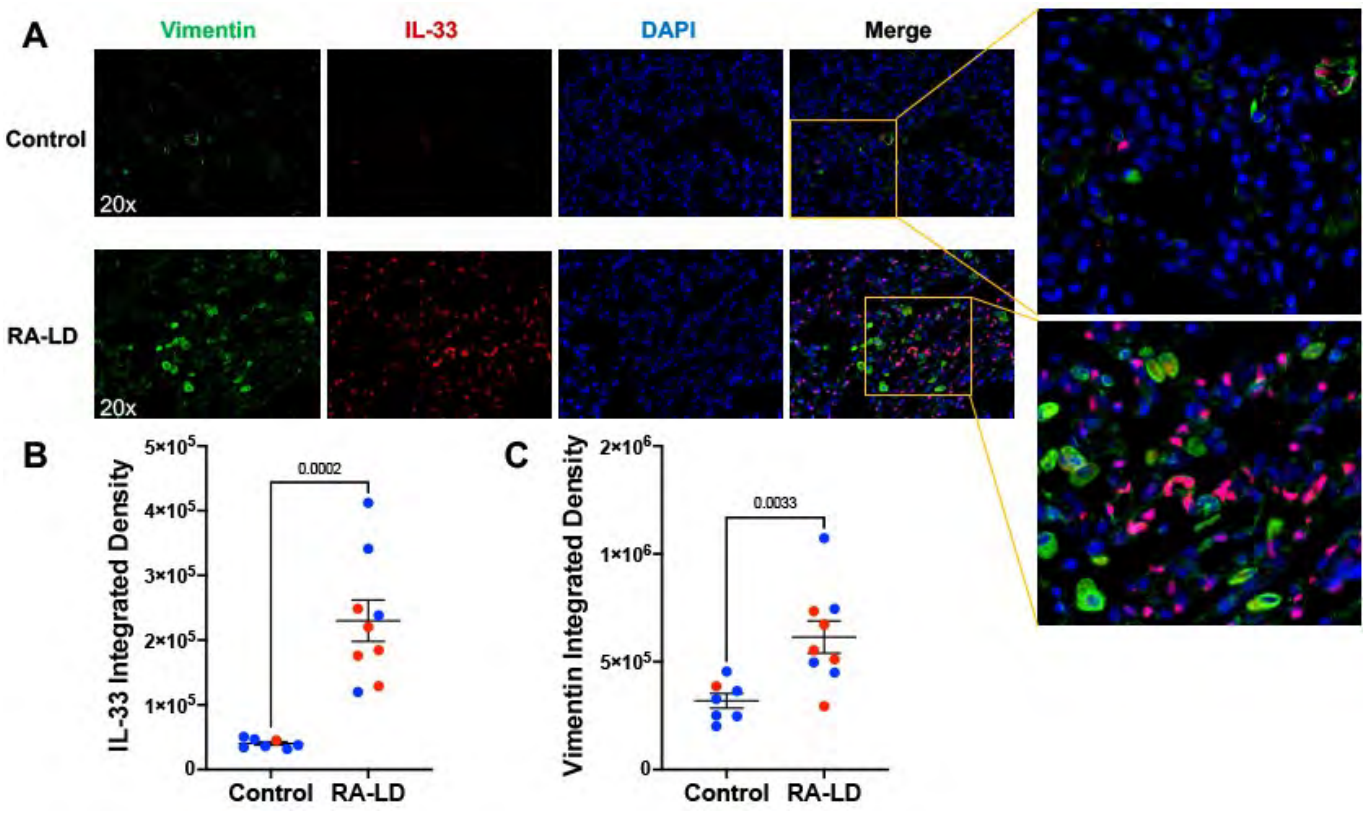

Figure 1. Lung IL-33 and vimentin expression in human tissue sections. Photomicrographs were taken of entire lung section using a Zeiss fluorescent microscope. (A) A representative image of individual and merged stains of IL-33 (red), vimentin (green) and DAPI (blue; nuclei), with a zoomed image of an area from a control subject and patient with RA-LD (RA-associated lung disease). Scatter plots with bar graph for IL-33 (B) and vimentin (C) with p values. Red dots denote females and blue dots denote males in each group.

0.001) with no significant difference between LPS and CIA+LPS (**Figure 2**). Vimentin expression was increased in CIA (2.6-fold, $p< 0.01$), LPS (2.8-fold, $p< 0.05$) and CIA+LPS (3.8-fold, $p< 0.01$) vs. Sham.

Conclusion: This study demonstrates that lung IL-33 expression is increased in patients with RA-associated lung disease. In the combined inhalant LPS+CIA animal modeling studies, lung IL-33 was also elevated, primarily driven by LPS exposure. As clinical studies are underway utilizing anti-IL-33/ST2 pathway antibodies in COPD, this approach could be explored in RA-associated lung disease. Alternatively, IL-33 warrants further investigation as a biomarker to identify patients with RA who are at risk of developing RA-associated lung disease.

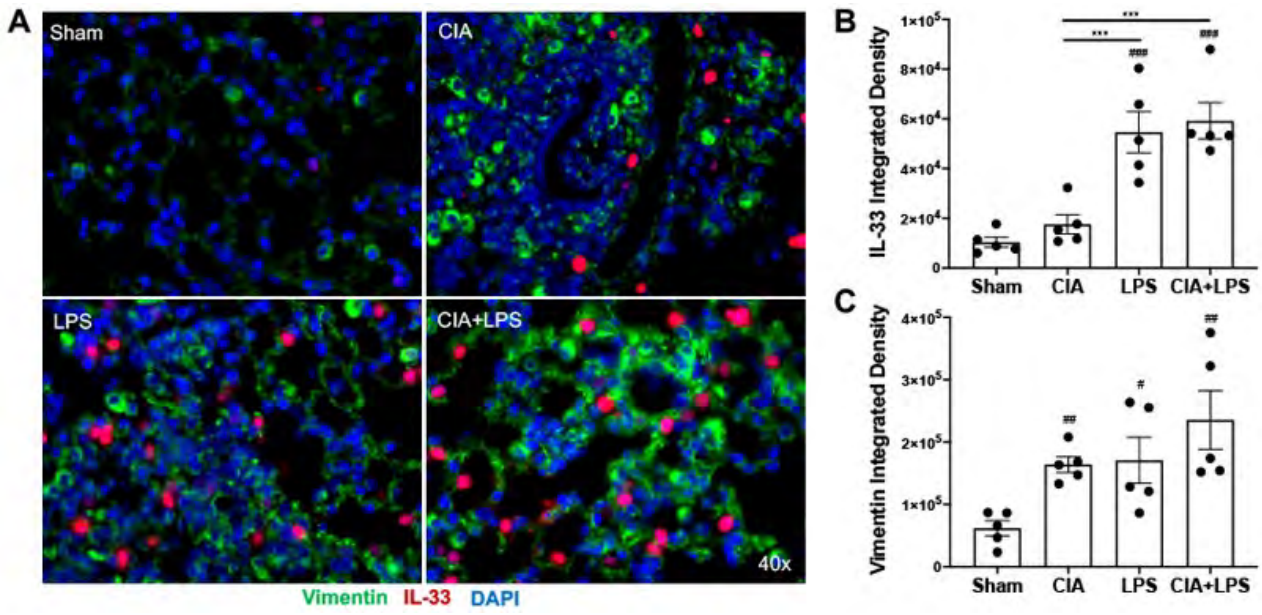

Figure 2. Combined modeling of repetitive lipopolysaccharide (LPS)-induced airway inflammation and collagen-induced arthritis (CIA) demonstrates increases in lung IL-33 expression. Photomicrographs were taken of entire lung section using a Zeiss fluorescent microscope. (A) A representative merged image of all three stains of IL-33 (red), vimentin (green) and DAPI (blue; nuclei) from each murine treatment group. N=5 mice/group. Scatter plots with bar graph for IL-33 (B) and vimentin (C). Statistical differences are shown for treatment groups versus sham (#p<0.05, ##p<0.01, ###p<0.001, ####p<0.0001) and between treatment groups (*p<0.05, **p<0.01, ***p<0.001, ****p<0.0001).

SESSION INFORMATION

Session Date: Monday, November 8, 2021

Session Title: Abstracts: Miscellaneous Rheumatic & Inflammatory Diseases: New Insights into Therapies & Mechanisms of Disease (1452–1457)

Session Type: Abstract Session

Session Time: 3:30PM–5:00PM

Background/Purpose: Recurrent pericarditis (RP) is an autoinflammatory disease with no FDA-approved therapies. RHAPSODY, a global Phase 3 study, evaluated rilonacept, a once-weekly IL-1α/IL-1β trap, in RP. RHAPSODY data helped support FDA approval of the first therapy for RP.

Methods: RHAPSODY was a randomized withdrawal (RW) trial: 86 patients (pts) with acute symptomatic RP, failing standard therapy (NSAIDs, colchicine, and/or corticosteroids [CS]), enrolled in a 12-week single-blind run-in (RI) period: rilonacept (320 mg SC load, 160 mg SC weekly) was administered while background pericarditis medications were discontinued. Clinical responders on rilonacept monotherapy were then randomized 1:1 to placebo or continued rilonacept in an event-driven double-blind RW period. Primary efficacy endpoint: time-to-first adjudicated pericarditis recurrence. Pts experiencing an eligible RP event during RW could receive open-label (OL) bailout rilonacept and remain on study.

Results: Etiology: idiopathic (85%), post-cardiac injury (15%).

Baseline characteristics (mean): disease duration was 2.4 years, with 4.7 lifetime episodes and 4.4 episodes/year.

Qualifying episode: pericarditis medications – NSAIDs (67%), colchicine (80%), and CS (49%). Mean pericarditis pain (11-point NRS scale) was 6.2, and mean C-reactive protein (CRP) was 6.18 mg/dL.

RI: 92% of pts completed RI; medians: time to NRS score ≤2 was 5 days; time to CRP normalization (≤0.5 mg/dL) was 7 days; time to Treatment Response was 5 days; time to monotherapy rilonacept was 7.9 weeks.

	Patients at Risk, n																									Number of Patients with Recurrence* n (%)	Number of Weeks to Recurrence* median (95% CI)
Week	0	2	4	6	8	10	12	14	16	18	20	22	24	26	28	30	32	34	36	38	40	42	44	46	48	50

Placebo	31	31	22	17	15	10	7	7	4	4	3	3	3	3	3	2	2	1	1	1	1						23 (74.2)	8.6 (4.0, 11.7)

CEC: Clinical Endpoint Committee; NE: not-estimable; HR: hazard ratio;
*First adjudicated pericarditis recurrence

Figure. Time to First CEC-Adjudicated Pericarditis Recurrence.

RW: 25 adjudicated events accrued in 61 randomized pts (Figure). Median time to event: placebo 8.6 wks, rilonacept Not-Estimable due to few events; HR 0.04 (96% risk reduction) ($p < 0.0001$). All 3 major secondary efficacy endpoints (Wk 16) were significant: maintained Clinical Response (rilonacept 81% vs. placebo 20% [p=0.0002]); absent/minimal pericarditis symptoms on 7-point Patient Global Impression of Pericarditis Severity scale (rilonacept 81% vs. placebo 25% [p=0.0006]); % of days with none/minimal pericarditis pain (rilonacept 98% vs. placebo 46% [$p < 0.0001$]).

No subsequent RP events were documented in pts on OL bailout rilonacept. 74 of 75 eligible pts continue OL rilonacept in a long-term extension up to 24 months.

Rilonacept was well-tolerated; 4 discontinuations in RI for AEs; SAEs: rilonacept (n=4), placebo (n=1), none drug-related; 1 withdrawn consent in RW.

Conclusion: Rilonacept (IL-1α/IL-1β trap) provided rapid and sustained reductions in pain and CRP as soon as after the first dose. Rilonacept monotherapy reduced RP event risk by 96% vs placebo. Rilonacept may provide a targeted therapeutic option for patients with RP.

IL1β mRNA Expressions in Peripheral Blood Mononuclear Cells Increase and May Associate with Cartilage Damage of the Respiratory Tract Probably Through Matrix metalloproteinase-3 Production in Patients with Relapsing Polychondritis

Jun Shimizu[1], Sueshige Wakisaka[1], Tomoko Suzuki[1] and Noboru Suzuki[2], [1]St. Marianna University School of Medicine, Kawasaki, Japan, [2]St. Marianna University School of Medicine, Kawasaki Kanagawa, Japan

SESSION INFORMATION

Session Date: Monday, November 8, 2021

Session Title: Abstracts: Miscellaneous Rheumatic & Inflammatory Diseases: New Insights into Therapies & Mechanisms of Disease (1452–1457)

Session Type: Abstract Session

Session Time: 3:30PM–5:00PM

Background/Purpose: Relapsing polychondritis (RP) is an inflammatory disorder that affects cartilage of ears, nose, joints, and respiratory tract. The inflammation often spreads to eyes, cardiovascular system, inner ears, skin, and CNS. Previous studies of RP disclosed that mononuclear cells migrated into the perichondral tissues and adjacent

chondrocytes produced matrix metalloproteinase (MMP)-3. We found that serum MMP3 concentrations were significantly higher in RP patients, especially in patients with respiratory involvement, than healthy individuals (HI). In the current study, we investigate whether serum MMP3 associate with inflammatory cytokine mRNA expressions of peripheral blood mononuclear cells (PBMC) in RP patients with a focus on the incidence and severity of the complications.

Methods: We obtained sera and PBMC from 30 RP patients and age and gender matched 14 HI. We divided the patients into two subgroups, that is, those with airway involvement (respiratory subgroup, 16 patients) and those without airway involvement (non-respiratory subgroup, 14 patients). We measured mRNA expressions of IL1β, IL6, TNFα, and MMP3, in freshly isolated, 6-hour-cultured, and 24-hour-cultured PBMC. We collected time series data of serum MMP3 and cytokine gene expressions from 6 RP patients (follow-up, mean ± sem., 34 ± 7.0 months) and 6 HI (45 ± 0.2 months).

Results: Inflammatory cytokine mRNA expressions of freshly isolated PBMC were significantly lower in RP patients than those in HI. IL1β and MMP3 mRNA expressions of 24-hour-cultured PBMC were significantly higher in RP patients than those in HI. Serum MMP3 increased significantly in respiratory subgroup compared with those in non-respiratory subgroup. Serum MMP3 and mRNA expressions of IL1β and IL6 showed positive linear correlations in 6-hour- and 24-hour-cultured PBMC of respiratory subgroup, but not those in non-respiratory subgroup. Linear correlations were found between serum MMP3 and PBMC MMP3 mRNA in both respiratory and non-respiratory subgroups. A linear correlation was observed between serum MMP3 and RPDAI in non-respiratory subgroup but not in respiratory subgroup. The time series study suggests that serum MMP3 and IL1β mRNA expressions of 6-hour-cultured PBMC were higher in RP patients than those in HI at least for several years (39 ± 3.7 months).

Conclusion: It is possible that IL1β has a potential to induce efficiently immune responses of RP cartilaginous tissues in the airway tract using MMP3. RPDAI may be more sensitive for the evaluation of disease status in non-respiratory subgroup than that in respiratory subgroup. RP PBMC may have a characteristic for persisting their dysregulated immune responses for a long time.

Cannabidiol Treatment in Hand Osteoarthritis and Psoriatic Arthritis - A Randomized, Double-blind Placebo-controlled Trial

Jonathan Vela[1], Salome Kristensen[2], Lene Dreyer[2], Kristian Kjær Petersen[3] and Lars Arendt Nielsen[3], [1]Dept. of Rheumatology Aalborg Denmark, Aalborg, Denmark, [2]Department of Rheumatology, Aalborg University Hospital, Aalborg, Denmark, [3]Aalborg University, Aalborg, Denmark

SESSION INFORMATION

Session Date: Monday, November 8, 2021

Session Title: Abstracts: Miscellaneous Rheumatic & Inflammatory Diseases: New Insights into Therapies & Mechanisms of Disease (1452–1457)

Session Type: Abstract Session

Session Time: 3:30PM–5:00PM

Background/Purpose: Medical cannabis is increasing in popularity yet the recent International Association for the Study of Pain presidential task force on cannabis and cannabinoid analgesia found a lack of trials examining canna-

bidiol (CBD) for pain management. We examined CBD as add on analgesic therapy in patients with hand osteoarthritis or psoriatic arthritis.

Methods: Our trial was randomized double-blind and placebo-controlled. Patients received synthetic CBD 20-30mg or placebo daily for 12 weeks. Primary outcome was pain intensity during the last 24 hours (0-100mm); safety outcomes were percentage of patients experiencing adverse events and a characterization of serious adverse events. Exploratory outcomes included change in Pittsburgh Sleep Quality Index (PSQI), Hospital Anxiety and Depression Scale (HADS), Pain Catastrophizing Scale (PCS) and Health Assessment Questionnaire (HAQ-DI)

Results: We recruited and randomized one hundred and thirty-six patients and 129 were included in the primary analysis. Between group difference in pain intensity at 12 weeks was 0.23mm (95%CI -9.41 to 9.90; p = 0.96). 22% patients receiving CBD and 21% receiving placebo experienced a reduction in pain intensity ≥ 30mm p=1. Between group difference for exploratory outcomes: HAQ-DI 0.03 (95%CI-0.11 to 0.18), PSQI -0.71 (95%CI -1.99 to 0.55), HADS depression -0.04 (95%CI -0.79 to 0.70), HADS anxiety -0.69 (95%CI -0.41 to 2.75) and PCS 1.07 (95%CI -1.73 to 3.88)

Conclusion: We found no statistically significant effect of CBD for clinical pain intensity in patients with hand osteoarthritis and psoriatic arthritis compared to placebo and no statistically significant effects regarding sleep quality, scores of depression, anxiety or pain catastrophizing.

Clinical Heterogeneity of the VEXAS Syndrome: A Case Series

Matthew Koster[1], Taxiarchis Kourelis[1], Kaaren Reichard[1], Tanaz Kermani[2], David Beck[3], Daniela Ospina Cardona[4], Matthew Samec[1], Abhishek Mangaonkar[1], Kebede Begna[1], Christopher Hook[1], Jennifer Oliveira[1], Samih Nasr[1], Benedict Tiong[5], Mrinal Patnaik[1], Michelle Burke[1], Clement Michet[1] and Kenneth Warrington[6], [1]Mayo Clinic, Rochester, MN, [2]University of California Los Angeles, West Hills, CA, [3]National Institutes of Health, Bethesda, MD, [4]National Institutes of Health, Germantown, MD, [5]University of California Los Angeles Medical Center, Culver City, CA, [6]Mayo Clinic, Rochester, Minnesota

SESSION INFORMATION

Session Date: Monday, November 8, 2021

Session Title: Abstracts: Miscellaneous Rheumatic & Inflammatory Diseases: New Insights into Therapies & Mechanisms of Disease (1452–1457)

Session Type: Abstract Session

Session Time: 3:30PM–5:00PM

Background/Purpose: VEXAS (vacuoles, E1 enzyme, X-linked, autoinflammatory, somatic) syndrome is a recently described myeloid-driven autoinflammatory condition caused by somatic mutations affecting methionine-41 (p.Met41) in the UBA1 gene which encodes the major E1 enzyme which initiates ubiquitylation.[1] The purpose of this study was to describe a series of cases highlighting the clinical features and outcomes of patients with this condition.

Methods: The divisions of rheumatology and hematology at Mayo Clinic, Rochester, Minnesota and the rheumatology division of the University of California, Los Angeles, (UCLA) identified all patients who underwent testing for UBA1 somatic mutations. The National Institutes of Health (NIH) performed testing for somatic mutations of the UBA1 gene, using methods previously described.[1] No patient included in this study was part of the original NIH cohort.[1] Demo-

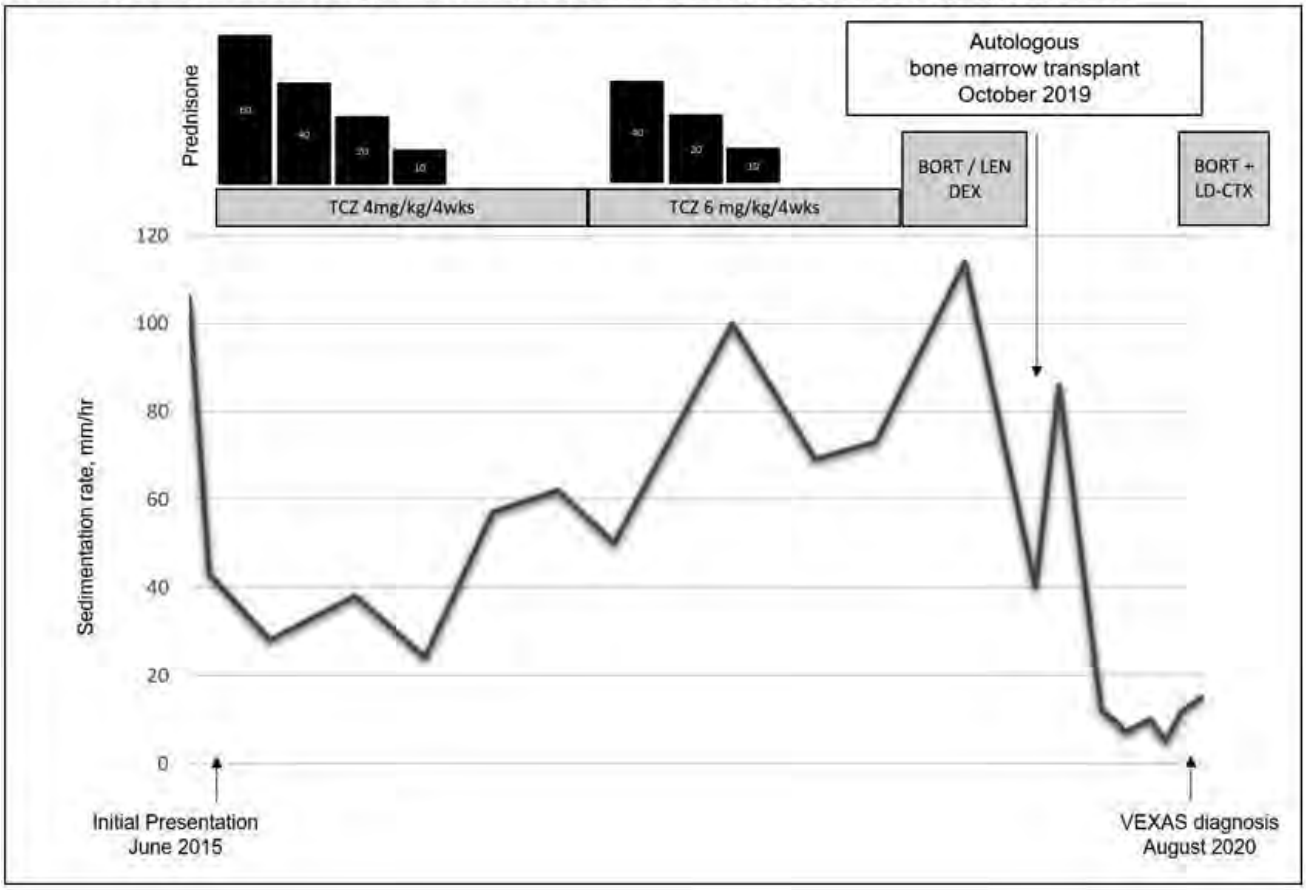
ADA, adalimumab; ANA, anakinra; ASCT, autologous stem cell transplant; AZA, azathioprine; BORT/LEN/DEX, combination treatment with bortezomib/lenalidomide/dexamethasone; Const. Sx, constitutional symptoms (fever, chills, night sweats, weight loss); CYC, cyclosporin; DAP, dapsone; DEC, decitabine; DEX, dexamethasone; DVT, deep vein thrombosis; Dx, diagnosis (VEXAS); GC, glucocorticoids; IFX, infliximab; LD-CTX, low-dose cyclophosphamide MMF, mycophenolate; MTX methotrexate; RTX, rituximab; Sx, symptom onset (VEXAS) TCZ, tocilizumab; TOFA, tofacitinib. *Vasculitis (cutaneous vasculitis patients 4, 7, 8, 9, large-vessel arterial occlusions in patient 9 and renal peritubular capillaritis with low titer positive proteinase 3 antibody in patient 4). **Uveitis (n=2), Episcleritis (n=2). Patient 7 declined bone marrow biopsy.
*Testing for VEXAS was performed in patient 2 following bone marrow transplant and in patient 4 while on hypomethylating agent resulting in lower mutational burden levels with reduced observed variant allele frequencies

Figure 1

Timing of inflammatory response and treatment in patient #2 with VEXAS syndrome undergoing autologous stem cell transplant. TCZ: tocilizumab; BORT, bortezomib; LEN, lenalidomide; DEX, dexamethasone; LD-CTX, low-dose cyclophosphamide.



Pre and Post transplant inflammatory response in patient #2.

graphic information, clinical characteristics, peripheral blood and bone marrow biopsy findings, treatment regimens and outcome were abstracted from direct medical chart review. Continuous data are presented as mean ± standard deviation (SD) or median [interquartile range (IQR) (25th percentile, 75th percentile)] and categorical variables as percentages.

Results: Nine men with somatic mutations in the *UBA1* gene were identified. Clinical features are noted in Table 1. The most frequent variant was p.Met41Thr (7/9, 78%). The median age at VEXAS diagnosis was 74 (67, 76.5) years, and patients had a median duration of symptoms for 4 years prior to diagnosis. Refractory constitutional symptoms (88%), ear/nose chondritis (55%) and inflammatory arthritis (55%) were common clinical features. Vasculitis was noted in four patients (44%). All four patients had cutaneous vasculitis, but additionally one (#4) had evidence of renal peri-tubular capillaritis, one (#8) had type III cryoglobulinemia with digital gangrene and one (#9) had large-vessel vasculitis. All patients had significantly elevated inflammatory markers and macrocytic anemia. Thrombocytopenia was present in 66% at VEXAS diagnosis. Eight patients had bone marrow biopsies performed. All bone marrows were hypercellular and there was vacuolization of the erythroid (100%) and/or myeloid precursors (75%). Glucocorticoids attenuated symptoms at doses ≥ 20 mg/day but no other immunosuppressive agent showed consistent long-term disease control. One patient with co-existing plasma cell myeloma received plasma cell directed therapy (bortezomib, lenalidomide, dexamethasone induction therapy) followed by autologous stem cell transplant resulting in improvement of the inflammatory response, which is a novel finding (Figure 1).

Conclusion: VEXAS syndrome is a clinically heterogenous, treatment-refractory inflammatory condition caused by somatic mutation of the *UBA1* gene. Patients present with overlapping rheumatologic manifestations and persistent hematologic abnormalities. Optimal treatment regimens remain to be defined. The utility of bone marrow transplantation requires further investigation.

SESSION INFORMATION

Session Date: Monday, November 8, 2021

Session Title: Abstracts: SLE – Treatment: New Agents, Old Agents (1458–1463)

Session Type: Abstract Session
Session Time: 3:30PM–5:00PM

Background/Purpose: We previously reported 24-wk results of a phase 2b trial of iberdomide, a high-affinity cereblon ligand that promotes proteasomal degradation of Ikaros (*IKZF1)* and Aiolos (*IKZF3*), 2 key transcription factors linked to SLE. The study (NCT03161483) met its primary endpoint at wk 24.[1] Results through wk 52 are reported here.

Methods: Adults (N=288) with autoantibody-positive SLE and SLEDAI 2K scores ≥6 were randomized (2:2:1:2) to oral iberdomide (0.45, 0.3, 0.15 mg) or placebo (PBO) daily, added to background lupus therapy. At wk 24, patients (pts) on PBO were re-randomized to iberdomide 0.3 or 0.45 mg, while pts on iberdomide continued their original regimens. Efficacy analyses were based on the intent-to-treat population, including all pts who were randomized at wk 0 and received ≥1 dose of study drug.

Results: 214 (87.0%) pts completed 52 wks. As previously reported, the primary endpoint, SRI-4 response at wk 24, was achieved by 54.3% of pts on iberdomide 0.45 mg vs. 34.9% on PBO (stratified difference, 19.4%; *P*=0.011). At wk 52, the proportions of SRI-4 responders were sustained or improved in all groups originally randomized to iberdomide: 0.45 mg (wk 24: 54.3% vs. wk 52: 51.9%), 0.3 mg (40.2% vs. 52.4%), and 0.15 mg (47.6% vs. 50.0%)

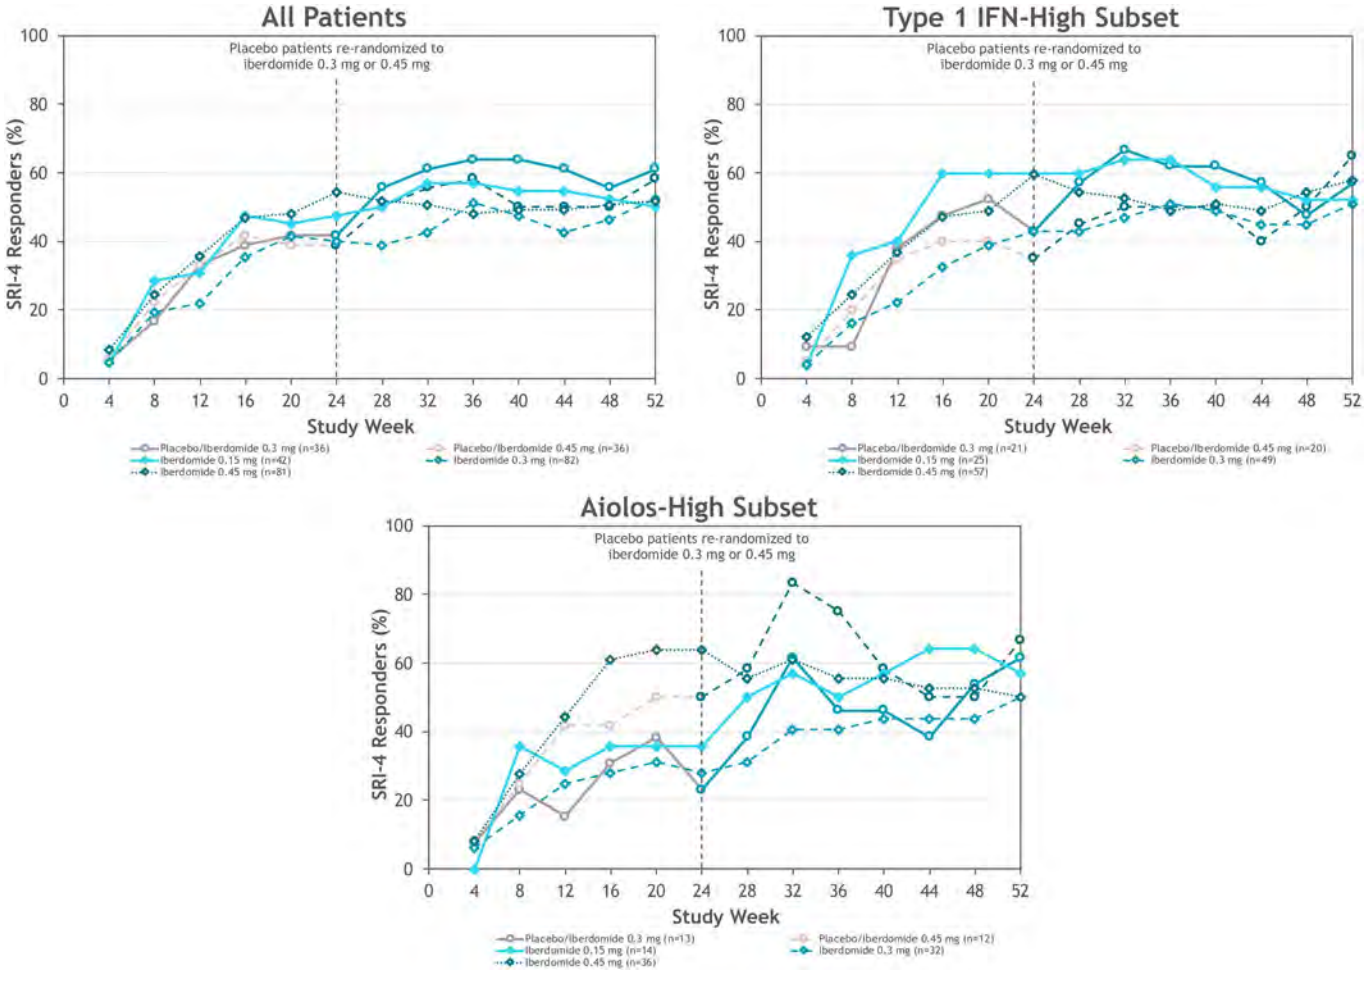
[a]EAIR per 100 person-years is 100 times the number of patients with the specific event divided by the total time (in years) at risk.
[b]1 patient on placebo had a pulmonary thromboembolism at week 8.
[c]1 patient on iberdomide 0.3 mg had a sudden cardiac death at week 44.
EAIR, exposure-adjusted incidence rate; QD, once daily; TEAE, treatment-emergent adverse event.



(**Figure**). Of wk 24 SRI-4 responders, response was maintained at ≥70% of the visits through wk 52 by 75.0%, 81.8%, and 70.0% in the 0.45-mg, 0.3-mg, and 0.15-mg groups. Increased proportions of pts attained SRI-4 response after switching from PBO to 0.3 mg (41.7% vs. 61.1%) or from PBO to 0.45 mg (38.9% vs. 58.3%) (**Figure**). In the iberdomide 0.3-mg group and the 2 PBO switching groups, improvements in the proportions meeting SRI-6 and ≥4-point decrease in SLEDAI-2K at wk 52 were observed (**Table 1**). In pts originally randomized to iberdomide, there were trends of increased BICLA responses and improved swollen/tender joint counts at wk 52 (**Table 1**). In the 0.3-mg and 0.45-mg groups, the enhanced SRI-4 responses at wk 24 in the prespecified subsets of pts with Type 1 IFN high signatures at baseline were similar or improved at wk 52 and also achieved by pts switching from PBO to iberdomide (**Figure** and **Table 1**). In Aiolos-high pts at baseline, enhanced responses were observed at wk 52 in the 0.15-mg and 0.3-mg groups and PBO switching groups, but response rates were not sustained in the 0.45-mg group. There were no increases in exposure-adjusted incidence of treatment-emergent adverse events (TEAEs), TEAEs leading to drug interruption or withdrawal, or serious AEs (SAEs) (**Table 2**). Most TEAEs were mild to moderate in severity, the most common being urinary tract infection (14.9%), upper respiratory tract infection (11.2%), and neutropenia (9.8%). Neutropenia was reversible and rarely led to discontinuation (1.4%). One pt on iberdomide (0.3 mg) had an SAE of varicella zoster pneumonia with full recovery.

Conclusion: Iberdomide treatment of pts with SLE was associated with sustained clinical benefits in multiple measures of disease activity up to wk 52. Enhanced clinical responses in pts with IFN-high and Aiolos-high signatures were also observed at 52 wks. Iberdomide was well tolerated with safety data consistent with that reported at wk 24.

Abstract Number: 1459

Attainment of the Lupus Low Disease Activity State in Response to Anifrolumab in 2 Phase 3 Trials

Eric Morand[1], Gabriel Abreu[2], Richard Furie[3] and Raj Tummala[4], [1]Monash University, Melbourne, Australia, [2]BioPharmaceuticals R&D, AstraZeneca, Gothenburg, Sweden, [3]Zucker School of Medicine at Hofstra/Northwell Health, Great Neck, NY, [4]BioPharmaceuticals R&D, AstraZeneca, Gaithersburg, MD

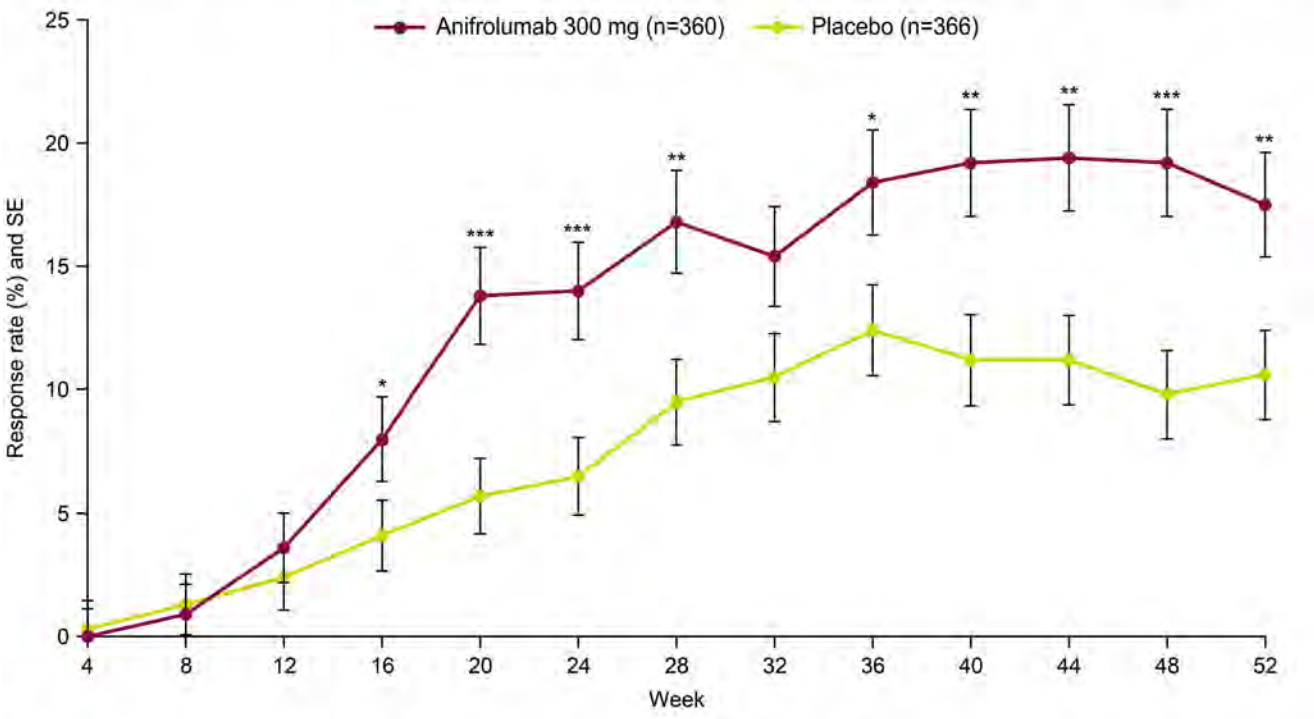
SESSION INFORMATION
Session Date: Monday, November 8, 2021
Session Title: Abstracts: SLE – Treatment: New Agents, Old Agents (1458–1463)
Session Type: Abstract Session
Session Time: 3:30PM–5:00PM

Background/Purpose: The Lupus Low Disease Activity State (LLDAS), a treat-to-target (T2T) endpoint for SLE, is prospectively validated as protective from flares and damage accrual.[1] LLDAS attainment is therefore an SLE treatment goal, and was achieved more frequently with active treatment than placebo in 2 SLE phase 2 trials.[2,3] In the TULIP-2 (NCT02446899) phase 3 trial, efficacy of anifrolumab, a type I IFN receptor mAb, was demonstrated using the BILAG–based Combined Lupus Assessment (BICLA) response, and these findings were supported in TULIP-1 (NCT02446912).[4,5] We investigated if anifrolumab treatment was associated with increased LLDAS attainment in pooled TULIP data.

Methods: TULIP-1/2 were randomized, placebo-controlled, 52-week trials of IV anifrolumab (Q4W, 48 weeks) in eligible patients meeting ACR 1997 criteria for SLE with moderate to severe SLE despite standard therapy. Pooled data for the anifrolumab 300 mg and placebo groups were analyzed by time point for LLDAS attainment (defined as all of the following: SLEDAI-2K ≤4 without major organ activity, no new disease activity, Physician's Global Assessment [0–3] ≤1, prednisone or equivalent ≤7.5 mg/day, and well-tolerated standard immunosuppressant dosing[6]). Time to first LLDAS attainment was compared between treatment groups using Cox regression, cumulative time in LLDAS was compared using a Cochran–Mantel–Haenszel approach, and responses were compared using logistic regression. All P-values are nominal.

Results: In an analysis agnostic to treatment group, 114 (13.9%) patients attained LLDAS at Week 52. Of these patients, 102 (89.5%) were also BICLA responders (analysis included the TULIP-1 anifrolumab 150 mg group). Among the 318 BICLA responders at Week 52, 102 (32.0%) attained LLDAS. LLDAS attainment increased across the 52-week trial and was attained earlier with anifrolumab 300 mg than placebo (Figure) (time to first LLDAS, HR 1.76, 95% CI 1.35–2.30, *P*< 0.001). At Week 52, 17.5% of anifrolumab-treated and 10.6% of placebo patients were in LLDAS (OR 1.8, 95% CI 1.2–2.8, P=0.008). More cumulative time (*P*< 0.001) and percentage of time (P < 0.001) was spent

Figure. LLDAS Response Rate by Randomized Treatment in Patients With SLE in the TULIP-1 and TULIP-2 Trials



CMH, Cochran–Mantel–Haenszel; LLDAS, Lupus Low Disease Activity State; SE, standard error.
Responder rates were calculated using a stratified CMH approach, with stratification factors of SLEDAI-2K at screening, Day 1 glucocorticoid dosage, type I IFN gene signature at screening, and study. Nominal *P*-values were calculated using logistic regression with the same factors as for the CMH approach.
*Nominal *P*<0.05; **nominal *P*<0.01; ***nominal *P*<0.001.

in LLDAS by patients receiving anifrolumab than placebo, and cumulative time in LLDAS thresholds of ≥20% (OR 1.8, 95% CI 1.2–2.7, *P*=0.004) and ≥50% (OR 1.9, 95% CI 1.0–3.4, P=0.035) also favored anifrolumab. Anifrolumab-treated patients were more likely to be in sustained LLDAS for ≥3 consecutive visits (18.6% vs 12.5%, OR 1.6, 95% CI 1.1–2.4, *P*=0.024), ≥5 consecutive visits (11.2% vs 7.7%, OR 1.5, 95% CI 0.9–2.6, *P*=0.106), or ≥7 consecutive visits (6.8% vs 2.7%, OR 2.6, 95% CI 1.2–5.6, *P*=0.014).

Conclusion: LLDAS is an attainable T2T endpoint in SLE clinical trials. LLDAS is more stringent than BICLA, but LLDAS attainment is highly coincident with BICLA response. Anifrolumab treatment was associated with earlier, more frequent, more prolonged, and more sustained LLDAS attainment.

Lupus Nephritis Renal Responses in Relation to Treatment and Demographics: Observations from a Multi-racial/ethnic Cohort of 159 Patients in the NYU Lupus Registry

Mayce Haj-Ali[1], Kristina Deonaraine[2], Alexis Engel[3], Yingzhi Qian[1], Amit Saxena[4], Peter Izmirly[2], Jill Buyon[4] and **H. Michael Belmont**[4], [1]NYU Grossman School of Medicine, New York, NY, [2]New York University School of Medicine, New York, NY, [3]NYU Langone Health, New Yok, NY, [4]NYU School of Medicine, New York, NY

SESSION INFORMATION
Session Date: Monday, November 8, 2021
Session Title: Abstracts: SLE – Treatment: New Agents, Old Agents (1458–1463)
Session Type: Abstract Session
Session Time: 3:30PM–5:00PM

Background/Purpose: Lupus nephritis (LN) disproportionately affects racial and ethnic populations. Contreras reported African-American (AA) and Hispanic patients had worse outcomes as compared to patients of European ancestry. ALMS highlighted different responses finding that AA and Hispanics had better response rates with MMF than with cyclophosphamide (CYC) (p=0.033). Reports from Asian nations describe high response rates especially with MMF regimens. The purpose of our study is to determine response rates in relation to treatment and demographics

Methods: Retrospective review of NYU Lupus registry. Patients met ACR/SLICC criteria for LN, had at least one episode of proteinuria (>500 mg spot or 24-hour uPCR), and LN flare after 2012 Epic implementation. Demographics, uPCR, Creatinine (Cr), albumin, C3, C4, anti-DNA levels collected at 0, 12, 24, 52, and 104 weeks for de novo epi-

Table 1. Demographics

TOTAL (N = 159)	Number of patients (%)
RACE	
African ancestry	51 (32%)
Asian ancestry	34 (21%)
European ancestry	74 (47%)
ETHNICITY	
Non-Hispanic	100 (63%)
Hispanic	59 (37%)
GENDER	
Female	138 (87%)
Male	21 (13%)

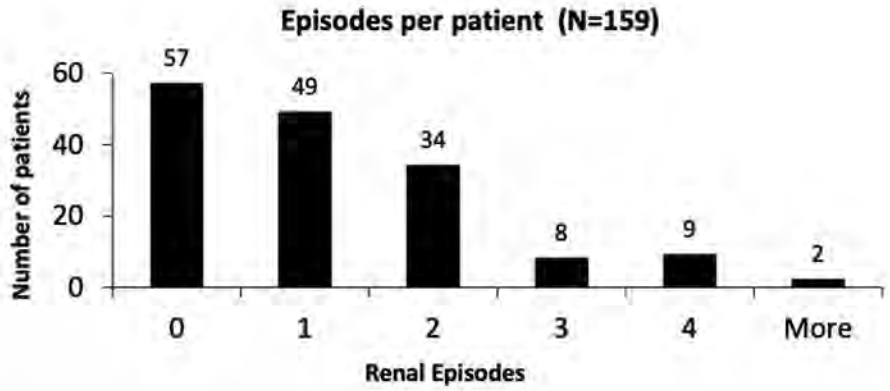

TABLE 1 describes the demographics of the patient population. The graph below is a histogram describing renal episodes per patient. Of the 159 patients, 57 patients only had a de novo episode labeled as 0 on the X-axis. 49 patients had 1 flare, 34 patients had 2 flares, 8 patients had 3 flares, 9 patients had 4 flares, 1 patient had 5 flares, and 1 patient had 6 flares.

sodes and renal flares. De novo episode defined as first episode leading to biopsy followed by change in medication or a clinical note documenting new onset LN accompanied by a change in medication. A renal flare was defined as a prior de novo episode and 1 of 3 conditions: biopsy, episode with change in proteinuria by at least 50%, or a note documenting a renal flare with each scenario required medication change. Responses are complete uPCR $\leq$ 0.5, satisfactory uPCR $\leq$ 0.7, or partial uPCR at least < 50% from baseline and in all 3 cases Cr unchanged or increased < 20%. No response uPCR more than 50% from baseline. Treatment regimens included MMF, CYC, MMF/tacrolimus, RTX, or other. Univariate analysis chi-squared test used to assess for differences in responses by treatment. Multivariable logistic regression (MR) analysis used to assess for differences in responses by gender, race, and ethnicity.

Results: 159 patients with de novo episodes, 188 flare episodes:138(87%) female, 74(47%) European, 51(32%) AA, 34(21%) Asian & Hispanic 59(37%) (Table 1A-B). There was a statistical difference (p= 0.003) in responses by treatment for de novo episodes at 104 weeks, favoring MMF or CYC as opposed to MMF/tacrolimus or RTX/CYC (Fig 1A).

FIGURE 1A. Statistically significant difference in renal response by treatment for 104 Week De Novo Episodes

	Total (N= 55)	Response (N = 44)	No Response (N = 11)	P value
TREATMENT				0.003

Other	19	19 (16.4%)	11 (15.9%)	

Figure 1D. No significant difference in renal responses by treatment for 104-week flares

	Total (N= 52)	Response (N = 92)	No Response (N = 40)	P value
TREATMENT				0.873
MMF	35	17(48.5%)	18 (51.5%)	
MMF/Tacrolimus	9	4 (44.4%)	5 (55.5%)	
CYC	14	6 (42.8%)	8 (57.2%)	
RTX/CYC	21	9 (42.8%)	12 (57.2%)	
Other	13	4 (30.8%)	9 (69.2%)	

There were no differences seen in responses by treatment for any flares occurring 24, 52, or 104 weeks (Fig1b-d). MR analysis demonstrated that patients who received "other" treatments had worse outcomes at 24 weeks as compared to MMF (p=0.004) (Fig2A). Patients who received RTX/CYC had worse outcomes when compared to MMF group at 52 and 104 weeks (p =0.013) (Fig2B-C). AA did not have worse responses when compared to Europeans. Asians had better outcomes when compared to Europeans at 52 and 104 weeks (Fig 2B-C).

CYC	0.56 [0.21, 1.56]	0.258
RTX/CYC	0.30 [0.11, 0.77]	0.013
Other	0.40 [0.15, 1.09]	0.071

Figure 2C.
Renal responses at 104 weeks adjusted for gender, race, and ethnicity

	OR [95% CI OR]	P (logistic)
Gender		
Female	1	Reference group
Male	0.51 [0.18, 1.41]	0.193
Race		
European ancestry	1	Reference group
African ancestry	0.75 [0.26, 2.19]	0.59
Asian ancestry	3.50 [1.09, 11.960]	0.039
Ethnicity		
Non-Hispanic	1	Reference group
Hispanic	1.89 [0.66, 5.63]	0.237
Treatment		
MMF	1	Reference group
MMF/Tacrolimus	0.57 [0.14, 2.21]	0.41
CYC	0.72 [0.25, 2.14]	0.547
RTX/CYC	0.37 [0.13, 1.01]	0.056
Other	0.43 [0.14, 1.30]	0.136

Conclusion: Renal responses for de novo episodes were superior with MMF or CYC at 104 weeks compared to MMF/tacrolimus or RTX/CYC explained by treatment resistance when first episode appeared on immunosuppression. There were no differences seen in responses by treatment for any flares. Our findings are inconsistent with previous studies demonstrating that AA and Hispanic patients have worse outcomes when compared to Europeans explained by reliance on MMF as first line therapy and use of rescue options including low dose CYC and RTX. Asian residents of NY metropolitan had better outcomes validating high response rates reported from Asian nations.

SESSION INFORMATION

Session Date: Monday, November 8, 2021

Session Title: Abstracts: SLE – Treatment: New Agents, Old Agents (1458–1463)

Session Type: Abstract Session

Session Time: 3:30PM–5:00PM

Background/Purpose: In the BLISS-LN trial (GSK Study BEL114054; NCT01639339), the administration of belimumab (BEL), a B-lymphocyte stimulator antagonist, resulted in improved renal outcomes in patients with active lupus nephritis (LN) compared with standard therapy alone.[1] The aim of this analysis was to evaluate the effects of BEL on renal outcomes in patients with or without intravenous (IV) steroid pulses during induction therapy for LN in the BLISS-LN trial.

Methods: This post hoc analysis assessed patients from the BLISS-LN trial, a Phase 3, randomized, double-blind, 104-week study of adults with active LN. Patients were administered with either IV BEL 10 mg/kg, or placebo (PBO), plus standard therapy that consisted of oral glucocorticoids and either cyclophosphamide (CYC) for induction followed by azathioprine (AZA) for maintenance, or mycophenolate mofetil (MMF) for both induction and maintenance. At the investigator's discretion, 1 to 3 IV pulses of methylprednisolone, 500 to 1000 mg each, could be administered during induction. The primary endpoint was Primary Efficacy Renal Response (PERR=urine protein:creatinine ratio [uPCR] ≤0.7; estimated glomerular filtration rate [eGFR] no more than 20% below preflare value or ≥60 ml/min/1.73 m^2; no rescue therapy) at Week 104. Other endpoints were Complete Renal Response (CRR=uPCR < 0.5; eGFR no more than 10% below preflare value or ≥90 ml/min/1.73 m^2; no rescue therapy) at Week 104, and time to a renal-related event (end-stage kidney disease, doubling of serum creatinine, increased proteinuria and/or impaired renal function, renal disease–related treatment failure) or death. The current analysis compared subgroups of patients who received BEL or PBO with and without IV steroid pulses at induction.

Results: In total, 76 (34.1%) of the 223 patients administered with BEL and 97 (43.5%) of the 223 patients administered with PBO received IV steroid pulses at induction. At Week 104, patients who received BEL, with or without IV steroid pulses at induction, had greater proportions of responders for both PERR and CRR compared with PBO (Table). A higher proportion of patients without, versus those with steroid pulses at induction, achieved PERR and CRR at Week 104, in both BEL and PBO groups. Risk of a renal-related event or death was lower at any time with BEL versus PBO, with or without IV steroid pulses at induction (Table).

Table. Renal outcomes (PERR, CRR, and time to renal-related event or death) at Week 104 by steroid pulse subgroups

	Steroid pulses		No steroid pulses	
	BEL (n=76)	**PBO (n=97)**	**BEL (n=147)**	**PBO (n=126)**
PERR at Week 104, n (%)	29 (38.2)	28 (28.9)	67 (45.6)	44 (34.9)
OR (95% CI) vs PBO	1.56 (0.79, 3.05)		1.59 (0.96, 2.66)	
p-value	0.1979		0.0743	
CRR at Week 104, n (%)	16 (21.1)	17 (17.5)	51 (34.7)	27 (21.4)
OR (95% CI) vs PBO	1.11 (0.50, 2.50)		2.19 (1.24, 3.89)	
p-value	0.7953		0.0071	
Time to renal-event or death, n (%)	12 (15.8)*	30 (30.9)*	23 (15.6)*	33 (26.2)*
HR (95% CI) vs PBO	0.42 (0.21, 0.83)		0.55 (0.32, 0.94)	
p-value	0.0122		0.0286	

OR, 95% CI and p-value are from a logistic regression model run within the subgroup level for the comparison between BEL and PBO with covariates: induction regimen (CYC vs MMF), race (Black vs non-Black), baseline uPCR, and baseline eGFR

HR, 95% CI and p-value are from a Cox proportional hazards model run within the subgroup level for the comparison between BEL and PBO adjusting for induction regimen (CYC vs MMF), race (Black vs non-Black), baseline uPCR, and baseline eGFR

*Number (percentage) of patients reporting the event

CI, confidence interval; HR, hazard ratio; OR, odds ratio

Conclusion: The addition of BEL to standard therapy for the treatment of active LN improved renal outcomes compared with PBO in patients with or without IV steroid pulses during induction therapy. Proportions of responders were generally higher in subgroups that did not receive steroid pulses at induction across both BEL and PBO groups. While one might postulate that those who received IV steroid pulses had more active kidney disease and might have been less responsive to therapy, additional analyses of steroid usage and correlates with LN class and severity are needed to address this question.

Hydroxychloroquine Dose and the Risk of Systemic Lupus Erythematosus Flares

April Jorge[1], Christian Mancini[1], Xiaoqing Fu[1], Gary Ho[2], Yuqing Zhang[3], Karen Costenbader[4] and Hyon K. Choi[5], [1]Massachusetts General Hospital, Boston, MA, [2]New York University, New York, NY, [3]Division of Rheumatology, Allergy, and Immunology, Mass General Hospital, Harvard Medical School, Boston, MA, [4]Brigham and Women's Hospital, Belmont, MA, [5]Massachusetts General Hospital, Lexington, MA

SESSION INFORMATION
Session Date: Monday, November 8, 2021
Session Title: Abstracts: SLE – Treatment: New Agents, Old Agents (1458–1463)
Session Type: Abstract Session
Session Time: 3:30PM–5:00PM

Background/Purpose: Hydroxychloroquine (HCQ) is an important treatment for systemic lupus erythematosus (SLE), known to reduce disease activity and flares. To minimize the risk of toxicity, recent guidelines recommend using HCQ dosages less than 5mg/kg/day, which is less than 400mg/day for many patients. However, the dose needed to prevent lupus flares is unknown. The aim of this study was to determine the association between HCQ dose and the risk of lupus flares.

Methods: We identified a cohort of patients with SLE taking HCQ who met 1997 ACR classification criteria and had at least two rheumatology visits between January 2016 and December 2020. We obtained demographics, anthropometrics, medications, SLE history and disease manifestations, and disease activity (e.g., clinical SLEDAI) assessed at each rheumatology visit. The outcome of interest was SLE flare defined by the revised SELENA-SLEDAI flare index (rSSFI). Among patients who had at least one SLE flare during the study period, we performed a case-crossover study. Each patient's follow up time was divided into case periods, defined by the 6-months prior to each flare, as well as control periods, defined as 6-month periods with no SLE flares (Figure 1). The exposure of interest was HCQ dose, categorized as high-dose (e.g. 400 mg/day) or low-dose (e.g., < 400 mg/day); low-dose was further categorized into < 300 and between 300 and < 400mg. The average HCQ dose was calculated for each case and control period. Conditional logistic regression was used to estimate the odds ratios (ORs) and 95% confidence intervals (CI) s for SLE flare associated with low-dose HCQ use compared with high-dose, and we stratified patients according to body weight. We adjusted for time-varying glucocorticoid use, SLE immunosuppressant use, and clinical SLEDAI score prior to each six-month observation period.

Results: Of 342 patients with SLE who used HCQ, mean age was 46 years, and 87% were female (Table 1). Body weight was below 80kg for 67% of patients, thus 400mg would exceed 5mg/kg/day. 74 patients (22%) received high-dose and low-dose HCQ during the study period, whereas 158 (46%) and 110 (32%) received only high-dose and only low-dose HCQ, respectively. There were 466 total rSSFI SLE flares over 2,176 visits during the study period, including 105 flares among those who received both high-dose and low-dose HCQ. The adjusted OR for SLE flare associated with low-dose HCQ was 2.38 (95% CI 1.24-4.56) (Table 2). For patients weighing less than 80kg/day, a

*Assessed at the initial visit during the study period. SLE, systemic lupus erythematosus

HCQ dose under 300mg/day was associated with an increased risk of SLE flares. For patients weighing at least 80kg, any HCQ dose under 400mg/day was associated with an increased risk of SLE flares.

Conclusion: Low-dose HCQ use was associated with an increased risk of SLE flares. The risks of toxicity and benefits for preventing SLE flares must be balanced in choosing the optimal HCQ dose.

Abstract Number: 1463

Use of Telemedicine for Follow-up of Lupus Nephritis in the COVID-19 Outbreak: The 6-month Results of a Randomized Controlled Trial

ho SO[1], Evelyn Chow[1], Isaac Cheng[1], Xerox Lau[1], Tena Li[1], Cheuk Chun Szeto[1] and Lai-Shan Tam[2], [1]The Chinese University of Hong Kong, Hong Kong, Hong Kong, [2]Department of Medicine & Therapeutics, The Prince of Wales Hospital, The Chinese University of Hong Kong, Hong Kong, China (People's Republic)

SESSION INFORMATION
Session Date: Monday, November 8, 2021
Session Title: Abstracts: SLE – Treatment: New Agents, Old Agents (1458–1463)
Session Type: Abstract Session
Session Time: 3:30PM–5:00PM

Background/Purpose: Telemedicine (TM) has been widely advocated and used to follow up patients with rheumatic diseases during the COVID-19 outbreak. However, there is no evidence supporting its use in systemic lupus erythematosus. We aimed to evaluate the short-term patient satisfaction, compliance, disease control and infection risk of TM compared with standard in-person follow-up (FU) for patients with lupus nephritis (LN) during the pandemic.

Methods: This was a single-center open-label randomized controlled study. Consecutive patients followed at the LN clinic were randomized to either TM or standard FU (SF) group in a 1:1 ratio. Patients in the TM group received FU via videoconferencing. SF group patients continued conventional in-person outpatient care. The 6-month data were compared and presented.

Results: From June to December 2020, 122 patients were randomized (TM: 60, SF: 62) and had at least 2 FUs. There were no baseline differences, including SLEDAI-2k and proportion of patients in lupus low disease activity state (LLDAS), between the 2 groups except a higher physician global assessment score (PGA) in the TM group (table). After a mean FU of 19.8±4.5 weeks, the overall patient satisfaction score was higher in the TM group with a significantly shorter waiting time from entering the clinic waiting room (virtual or real) to seeing a rheumatologist (figure). More patients in the TM group had hospitalization (15/60, 25.0% vs 7/62, 11.3%; p=0.049) with higher baseline PGA (OR=1.15, 95% CI 1.07-1.23) being the independent predictor. The proportions of patients remained in LLDAS were similar in the 2 groups (TM: 75.0% vs SF: 74.2%, p=0.919). None of the patients had COVID-19.

Conclusion: TM FU resulted in better patient satisfaction and similar short-term disease control in patients with LN compared to standard care. However, it was associated with more hospitalizations and might need to be complemented by in-person visits especially in patients with higher PGA.

Ambulatory Fetal Heart Rate Monitoring (FHRM) to Surveil Pregnancies at Risk for Congenital Heart Block

Mala Masson[1], Colin Phoon[1], Elena Sinkovskaya[2], Lisa Howley[3], Ruben Acherman[4], Majd Makhoul[5], Nelangi Pinto[6], Miao Chang[1], Robert Clancy[7], Bailey Drewes[8], Bettina Cuneo[9] and Jill Buyon[7], [1]NYU Langone Health, New York, NY, [2]East Virginia Medical School, Norfolk, [3]Children's Hospitals and Clinics of Minnesota, Minneapolis, MN, [4]Sunrise Children's Hospital, Las Vegas, NV, [5]UK Kentucky Children's Hospital, Lexington, KY, [6]University of Utah, Salt Lake City, UT, [7]NYU Grossman School of Medicine, New York, NY, [8]CU Anschutz Medical Campus, Aurora, [9]Children's Hospital Colorado, Aurora, CO

SESSION INFORMATION

Session Date: Monday, November 8, 2021

Session Title: Abstracts: Reproductive Issues in Rheumatic Disorders (1464–1467)

Session Type: Abstract Session

Session Time: 4:00PM–5:00PM

Background/Purpose: Congenital Heart Block (CHB) complicates 2% of anti-Ro/SSA antibody positive pregnancies and carries substantial perinatal morbidity and mortality. Almost all survivors require lifelong pacing. Data suggests the potential of anti-inflammatory treatment of 1° and 2° CHB in preventing progression to immutable complete block. However, the optimal surveillance strategy to detect rapidly transitioning and potentially reversible conduction disease is unknown. This study addresses the feasibility, acceptance and accuracy of the fetal heart rate and rhythm technique (FHRM) in high risk mothers.

Methods: Prospective data from the Surveillance To Prevent AV Block Likely to Occur Quickly (STOP BLOQ) study were leveraged. Mothers referred to the study all had commercially positive anti-Ro/SSA antibodies and were stratified into high and low titers of anti-Ro60 and Ro52 based on a research ELISA which used a threshold cutoff defined as the titer above or below that obtained for 50 mothers with a previous CHB offspring. Mothers with anti-Ro60 or 52 antibodies at or above 1,000 I.U or with a previous CHB offspring, were trained to perform FHRM with an educational video and personal instruction from a pediatric cardiologist. From 17- 25 weeks of gestation, FHRM was completed 3x/day in addition to weekly or biweekly fetal echocardiograms (echo). Mothers texted all FHRM sounds to the study's data coordinating center. For those FHRM deemed abnormal by the mothers, texts were immediately sent to an on call pediatric cardiologist who either reassured if FHRM was normal or referred for emergency fetal echo in < 6 hours if abnormal. Postnatal electrocardiograms were evaluated for CHB.

Results: Fifty-six mothers with commercial anti-Ro/SSA positivity were consented to the study. Of these, 37 (inclusive of 6 with previous CHB) performed FRHM since they had high titer anti-Ro60 (n=8) or 52 antibodies (n=7) or both (n=21), albeit one mother had unexpectedly low titer antibodies to both Ro60 and 52 and a child with incomplete CHB 4 yrs prior to enrollment. In total 3,360 FHRM audiotexts were received during the monitoring period. Of these, 39 recordings from 5 concerned mothers prompted an immediate call with the cardiologist. All but 2 recordings were deemed to be normal based on review of the audiotext alone; the cardiologist requested that the patient send repeat recordings after review as part of re-training and to provide additional reassurance. In the 2 cases an emergency echo was completed in < 6 hrs. In both there were premature atrial contractions which confirmed the mother's perception of the FHRM abnormality. However, there was no evidence of conduction disease. All surveillance echoes were normal. Thus, the overall rate of false positive recordings for the concern of a conduction defect perceived by the mothers was 1.1% (38/3360). There were no cases of CHB at birth.

Conclusion: These data support that FHRM is feasible and accurate. Mothers can be empowered to detect rhythm abnormalities with very few false perceptions thus supporting this technique to substantially enhance the management of anti-Ro/SSA pregnancies.

Trends in Adverse Pregnancy Outcomes Among Women with Systemic Sclerosis in the United States

Yumeko Kawano[1], Kathleen Kolstad[2], Shufeng Li[1], Julia Simard[3] and Lorinda Chung[1], [1]Stanford University, Palo Alto, CA, [2]University of California Los Angeles, Santa Barbara, CA, [3]Stanford School of Medicine, Stanford, CA

SESSION INFORMATION
Session Date: Monday, November 8, 2021
Session Title: Abstracts: Reproductive Issues in Rheumatic Disorders (1464–1467)
Session Type: Abstract Session
Session Time: 4:00PM–5:00PM

Background/Purpose: Autoimmune connective tissue diseases disproportionately affect women of childbearing age. Systemic sclerosis (SSc) is associated with increased risk of adverse pregnancy outcomes (APO). However, changes in obstetric practices may have improved SSc pregnancy outcomes in recent years, as seen for SLE. We sought to examine APO occurrences among women with and without SSc and determine whether APOs have declined over the past 18 years in a large nationwide sample.

Methods: The National Inpatient Sample (NIS) database for years 2000–2017 was used to derive national estimates of delivery-associated hospitalizations. SSc deliveries were identified using ICD codes, excluding those with concurrent SLE or RA. Each SSc hospitalization was matched by age, delivery year, and race to non-SSc hospitalizations from the NIS in a 1:100 ratio. APOs included fetal death, Cesarean delivery, hospital length of stay, preterm birth, intrauterine growth restriction, and hypertensive disorders of pregnancy (preeclampsia, eclampsia, gestational hypertension, and superimposed preeclampsia). All analyses accounted for the complex survey design and sampling weights were applied. Adjusted odds ratios for each APO for the entire study period were calculated from multivariable regression analyses using maternal age, race, diabetes mellitus, and preexisting hypertension as covariates. To compare differences in temporal trends in APOs between SSc and non-SSc deliveries, we pooled data into 6-year intervals and applied logistic or linear regression with an interaction term between SSc (yes vs. no) and year.

Results: From 2000 to 2017, there were 3,740 (95% CI 3,446–4,034) delivery-associated hospitalizations for women with SSc. Mean maternal age at delivery was 30 years. There were significant differences in comorbidities between the SSc and non-SSc groups including pre-existing hypertension, renal disease, and pulmonary hypertension (Table 1). The odds of all APOs during the entire study period were significantly higher in SSc vs. non-SSc deliveries (Table 2). Fetal deaths notably declined in SSc deliveries from 4,896 per 100,000 delivery-related admissions in 2000–2005 to 1,619 per 100,000 in 2012–2017. Difference in trend over time for fetal death was significant (p=0.043) between SSc and non-SSc deliveries, but trends in other APOs were not significantly different (Figure 1).

Table 1. Baseline demographics and clinical characteristics of SSc and non-SSc deliveries*

Variable	SSc (n = 3,740)	Non-SSc (n = 374,035)	P value
Mean age, years (SD)	30.2 (0.2)	30.2 (0.04)	0.8701

Smoker	211 (5.7)	16,721 (4.5)	0.1601

SSc, systemic sclerosis; SD, standard deviation.

*All values are weighted estimates.

† Includes preexisting and gestational diabetes.

‡ Includes chronic kidney disease and end stage renal disease.

Table 2. Adjusted odds ratios of adverse pregnancy outcomes in SSc and non-SSc deliveries

Pregnancy Outcome	SSc (n = 3,740)	Non-SSc (n= 374,035)	OR* (95% CI)
Fetal deaths per 100,000 admissions, n	2,888	704	**4.00 (2.55–6.27)**
Cesarean section, %	44.4	32	**1.66 (1.44–1.92)**
Preterm birth, %	21.9	9.4	**2.65 (2.23–3.14)**
Hypertensive disorders of pregnancy,† %	15.1	7.9	**1.97 (1.61–2.41)**
IUGR, %	5.5	2.2	**2.45 (1.74–3.45)**
Mean length of stay, days	4.1	2.7	**1.35 (0.98–1.71)‡**

SSc, systemic sclerosis; OR, odds ratio; CI, confidence interval; IUGR, intrauterine growth restriction.

% is given as % of deliveries.

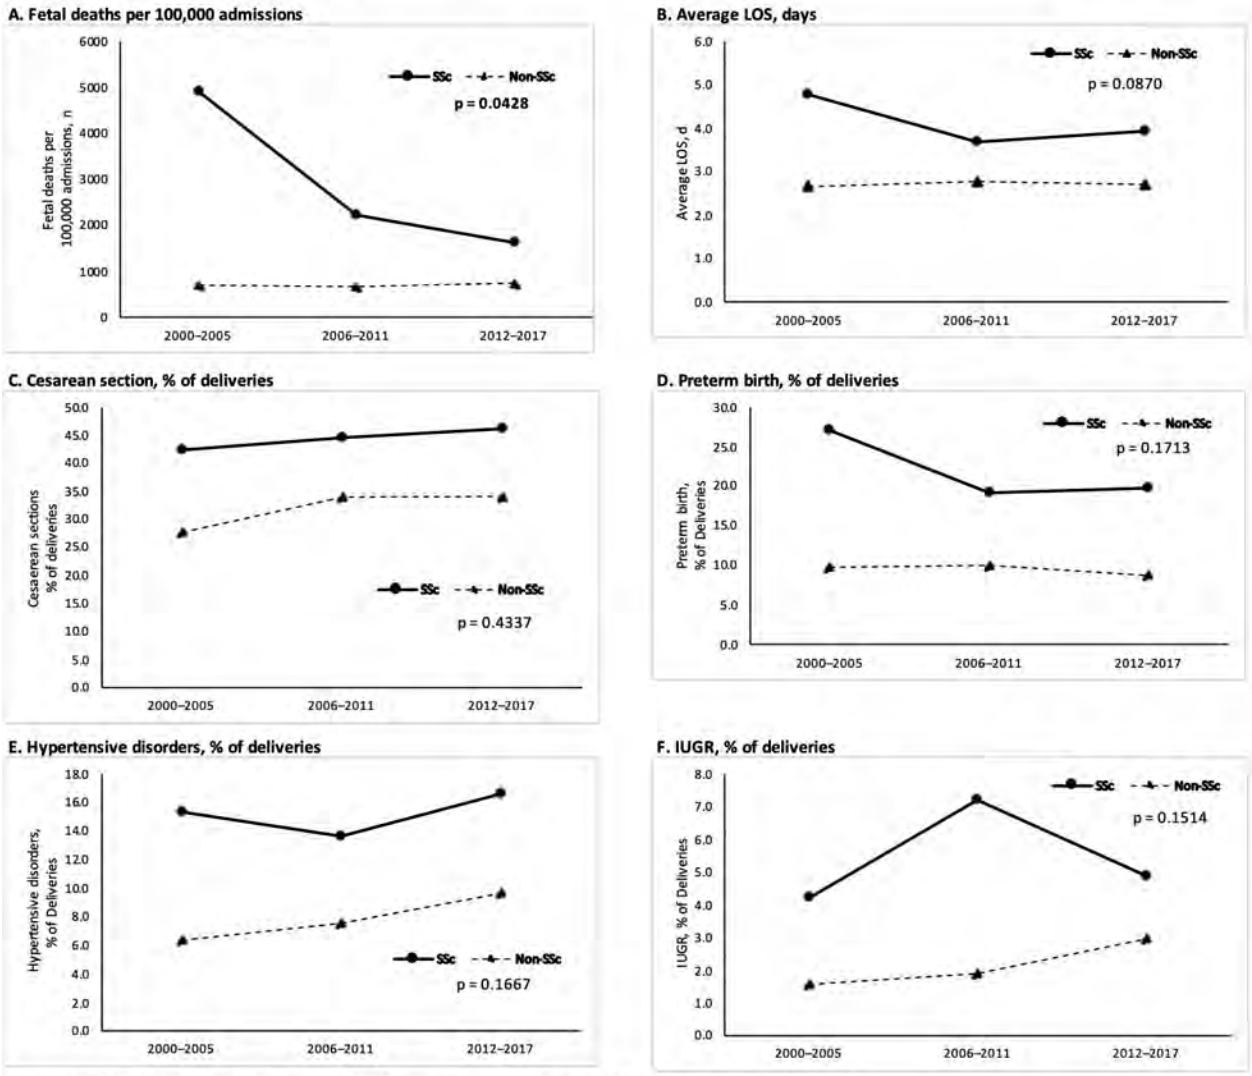
* OR expressed as adjusted odds ratios (95% CI) from multivariable logistic regression analyses except as noted. Covariates included maternal age, race, diabetes mellitus and preexisting hypertension.

† Includes gestational hypertension, preeclampsia, eclampsia, superimposed preeclampsia.

‡ Linear regression expressed as β coefficients (95% CI).

Conclusion: In this large nationwide sample, the risk of fetal death among women with SSc markedly improved over the past 18 years. We focused on delivery-associated hospitalizations rather than all obstetric hospitalizations; therefore, fetal death represents stillbirth, and captures neither miscarriages earlier in pregnancy nor neonatal death. The risk of other APOs remained high in SSc deliveries, and further studies are needed to determine what factors or therapeutics can improve these outcomes.

Figure 1. Temporal trends in adverse pregnancy outcomes in SSc and non-SSc deliveries



P value is for difference in trends. SSc, systemic sclerosis; LOS, length of stay; IUGR, intrauterine growth restriction.

A: Fetal deaths per 100,000 admissions declined among SSc deliveries from 2000–2005 to 2012–2017, with significant difference in trends between SSc and non-SSc deliveries (p=0.0428). **B–F**: There was no significant difference in trends between SSc and non-SSc deliveries for average LOS (**B**) or percentages of Cesarean section (**C**), preterm birth (**D**), hypertensive disorders of pregnancy (**E**), or IUGR (**F**).

Increased Adverse Maternal Postpartum Outcomes in Systemic Lupus Erythematosus Pregnancies Compared to Controls

April Barnado, Janie Hubbard, Sarah Green and Sarah Osmundson, Vanderbilt University Medical Center, Nashville, TN

SESSION INFORMATION

Session Date: Monday, November 8, 2021
Session Title: Abstracts: Reproductive Issues in Rheumatic Disorders (1464–1467)
Session Type: Abstract Session
Session Time: 4:00PM–5:00PM

Background/Purpose: Studies show increased risks of adverse pregnancy outcomes in SLE patients. Few studies have investigated postpartum outcomes in these patients. Using a large, de-identified electronic health record (EHR), we estimated rates of postpartum infection, blood transfusion, and hospital length of stay and compared them to rates in controls without autoimmune disease. We also assessed for postpartum flares in SLE mothers.

Methods: Using a large, de-identified EHR with over 3.2 million subjects, we identified deliveries to SLE mothers using a validated and published algorithm. This algorithm has a positive predictive value of 90% and uses ≥ 4 SLE ICD-9 or ICD-10-CM codes and ≥ 1 validated, delivery-related codes. We performed chart review to confirm SLE diagnosis by a rheumatologist and focused on SLE deliveries after SLE diagnosis. We assessed for SLE medication use at a postpartum visit between 6 weeks to 3 months after delivery. We identified control mothers without autoimmune disease ICD-9 or ICD-10-CM codes and the same delivery-related codes used to identify SLE deliveries. We then

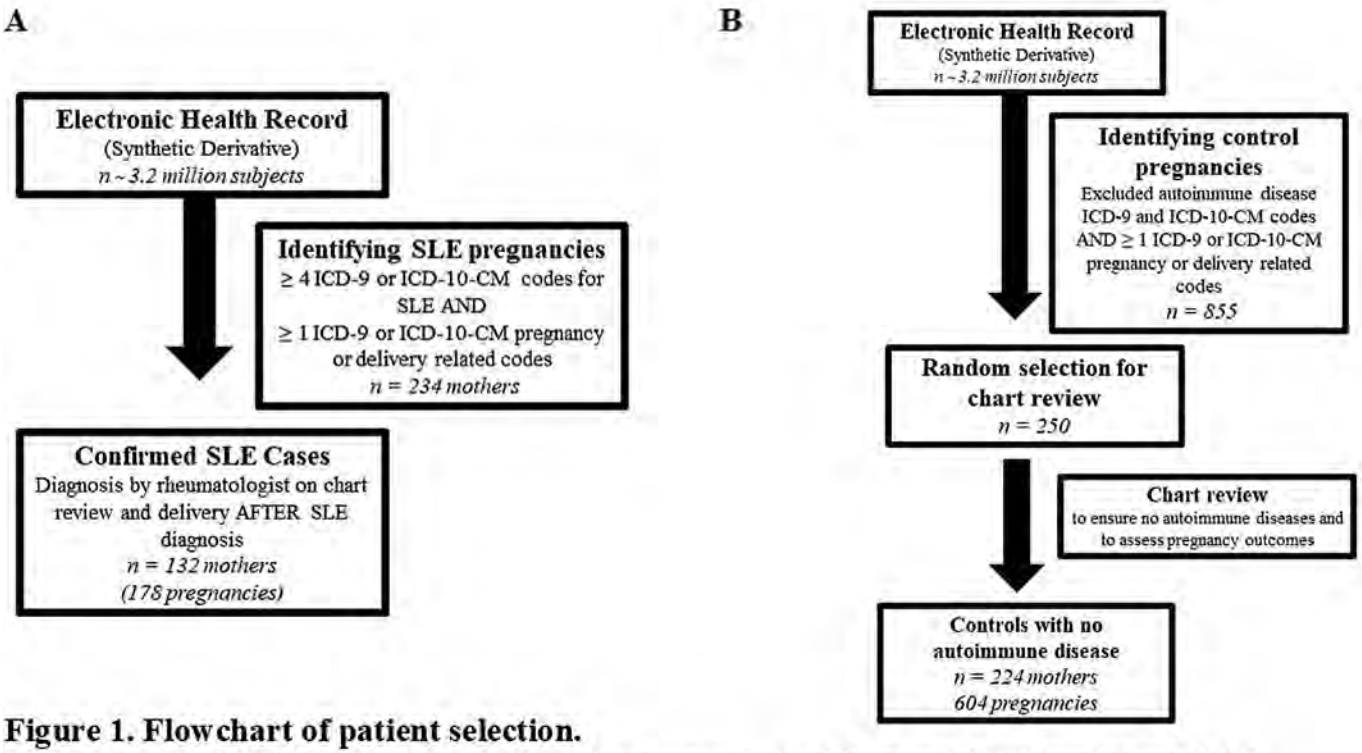

Figure 1. Flowchart of patient selection.
SLE pregnancies (A) were selected from the electronic health record (EHR) using = 4 SLE ICD-9 (710.0) or ICD-10-CM (M32.1 or M32.8 or M32.9) codes while also requiring = 1 ICD-9 or ICD-10-CM pregnancy or delivery related codes. We then required chart review to confirm SLE diagnosis by a rheumatologist and delivery after SLE diagnosis resulting in 132 SLE cases with 178 pregnancies. **Control pregnancies (B)** were selected from the EHR using the same pregnancy or delivery related codes used for the SLE pregnancies along with requiring that controls not have codes for autoimmune diseases. We then chart reviewed a random 250 controls to ensure no autoimmune disease and to assess pregnancy outcomes resulting in 224 mothers with 604 pregnancies.

Table 1. Demographics and postpartum outcomes in SLE cases compared to controls.

Characteristics	SLE deliveries (n = 178)*	Control deliveries (n = 604)*	p value
Mean age at delivery ± standard deviation	27.3 ± 6.0	27.0 ± 6.6	p = 0.67
Race (%)			
White	66%	59%	p = 0.11
Black	30%	38%	
Asian	2%	2%	
Other/Multi-race	2%	1%	
Ethnicity (%)			
Hispanic	5%	11%	p < 0.01
Duration in the EHR** (years) ± standard deviation	13.3 ± 8.3	12.0 ± 7.6	p = 0.18
Postpartum Outcomes			
Blood transfusion any (%)	23/143(16%)	6/350 (2%)	p < 0.001
Platelets	5/143 (4%)	0/350 (0%)	p = 0.01
Red blood cells	18/143 (13%)	6/350 (2%)	p < 0.001
Infection any (%)	30/122 (25%)	13/303 (4%)	p < 0.001
Urinary tract infection	10/122 (8%)	1/291 (0.3%)	p < 0.001

Cellulitis	1/121 (1%)	1/290 (0.3%)	p = 0.52
Length of stay (days) Mean ± standard deviation	4.7 ± 2.8	2.9 ± 1.8	p < 0.001

*n refers to deliveries.

**Duration in the EHR defined as time from first code to last code in the EHR.

randomly selected 250 control mothers for chart review to ensure they did not have autoimmune disease. A flowchart is shown in Figure 1. Postpartum infection was defined as infection documented by a physician from delivery to 6 weeks postpartum. Blood transfusions were assessed during the admission for delivery. SLE flares were defined as the rheumatologist documenting a flare or increase in disease activity in notes from delivery to 6 months postpartum. Length of stay was days from admission to discharge.

Results: We identified 178 pregnancies after SLE diagnosis to 132 SLE mothers and 604 pregnancies to 224 control mothers without autoimmune disease. Our SLE and control mothers had similar mean age at delivery (27.0 ± 6.6 vs. 27.3 ± 6.0, p = 0.67) and a similar racial/ethnic makeup that was predominantly White (66% vs. 59%, p = 0.11) (Table 1). Blood transfusion rates were significantly higher in SLE cases vs. controls (16% vs. 2%, p < 0.001) (Table 1). Postpartum infection rates for any infection were significantly higher in SLE cases vs. controls (25% vs. 4%, p < 0.001). Hospital length of stay was significantly longer in SLE cases vs. controls (4.7 ± 2.8 vs. 2.9 ±1.8, p < 0.001). For

Table 2. Comparison of SLE deliveries with flare vs. no flare postpartum.

SLE patient characteristics	SLE deliveries with a flare (n = 39)	SLE deliveries with NO flare (n = 63)	p value
Demographics			
Mean age at delivery ± standard deviation	28.3 ± 5.6	28.8 ± 5.5	p = 0.61
Race (%)			
White	55%	62%	p = 0.39
Black	42%	32%	
Asian	3%	5%	
Other	0%	1%	
Ethnicity (%)			
Hispanic	10%	8%	p = 0.75
Disease characteristics

Nephritis (%)	36%	37%	p = 0.90
Medication use* (%)**			
Corticosteroids	24/39 (62%)	41/63 (65%)	p = 0.72
Antimalarials	**17/39 (44%)**	**42/63 (67%)**	**p = 0.03**
DMARDs	10/39 (26%)	12/63 (19%)	p = 0.43
No medication	8/39 (21%)	10/63 (16%)	p = 0.55

*n refers to SLE deliveries.
**SLE disease duration defined as time from first SLE billing code in the EHR or date documented by a rheumatology note, whichever came first, to delivery date.
***Medication use was assessed at time of postpartum visit between 6 weeks and 3 months after delivery.

SLE cases, postpartum flare rate was 38%. We compared SLE deliveries with a disease flare vs. deliveries without a flare (Table 2). There were no significant differences in age, race, ethnicity, SLE nephritis, or SLE disease duration. For deliveries without a flare, mothers were more likely to be on antimalarials compared to deliveries with a flare (67% vs. 44%, p = 0.03). Flares were managed by adding or increasing corticosteroids (79%), adding an antimalarial (16%), adding or titrating a DMARD (11%), although 11% had no change to medications.

Conclusion: Our study demonstrates that SLE patients are at an increased risk for adverse postpartum outcomes compared to controls including infections, blood transfusions, and longer lengths of stay. We observed frequent flares postpartum with patients being more likely to flare if not prescribed antimalarials postpartum. This finding emphasizes the importance of antimalarials in the postpartum period to reduce flares.

Determinants of Cervical Cancer Screening Patterns Among Women with Systemic Lupus Erythematosus

Sarah Chung[1], Kimiko Oshima[1], **Jenna Thomason**[1], Michael Singleton[1] and Namrata Singh[2], [1]University of Washington, Seattle, WA, [2]University of Washington, Bellevue, WA

SESSION INFORMATION
Session Date: Monday, November 8, 2021
Session Title: Abstracts: Reproductive Issues in Rheumatic Disorders (1464–1467)
Session Type: Abstract Session
Session Time: 4:00PM–5:00PM

Background/Purpose: Women with systemic lupus erythematosus (SLE) are vulnerable to cervical dysplasia. This is due to the persistence of human papillomavirus (HPV) related to immunosuppression and also immune dysregulation inherent to the disease. Thus, routine screening for cervical cancer is important for SLE women. The United States Preventative Services Task Force (USPSTF), American College of Obstetricians and Gynecologists (ACOG), and the American Society of Colposcopy and Cervical Pathology (ASCCP) all provide different recommendations regarding screening intervals. The ASCCP provides the only SLE-specific guidelines, advising more frequent screening in this patient population. The purpose of this study was to investigate the prevalence of up-to-date cervical cancer screening per ASCCP guidelines among SLE women established in our institution's registry program. In addition to identify-

ing the organizational recommendations providers most frequently utilize, we aimed to identify SLE disease-specific determinants associated with overdue screening.

Methods: Inclusion criteria were women aged 21-65 years enrolled in our institution's SLE registry program. Data regarding cervical cancer screening status at the time of her last rheumatology clinic visit was obtained by retrospective chart review. Data regarding disease duration, 2019 ACR/EULAR SLE classification criteria, SLEDAI-2k score, SLE damage index (SDI) score, immunosuppressant exposure, and gynecologic history were collected. Descriptive

Table 2. Variables pertaining to healthcare factors, SLE disease characteristics, and medication exposure in patients up-to-date on cervical cancer screening per ASCCP guidelines (n=45), patients up-to-date on cervical cancer screening per ACOG guidelines (n=19), and patients overdue for cervical cancer screening per USTFPF, ACOG, or ASCCP guidelines (n=54) at time of rheumatology office visit. Categorical variables are represented as n (%) unless otherwise stated. Effect size for categorical variables is reported by Cramer's V where V=0.01 represents a small effect size, V=0.3 represents a medium effect size and V=0.5 represents a large effect size. Effect size for continuous variables is reported by η^2, where η^2=0.01 represents a small effect size, η^2=0.06 represents a medium effect size, and η^2>0.14 represents a large effect size.

statistics and univariable analyses were performed. Effect sizes were characterized by Cramer's V statistic for categorical variables and by eta squared for continuous variables.

Results: Our study included 130 women with SLE who met eligibility criteria. The mean age (±SD) was 38 (11.3) years, 46% self-reported her race as white (Table 1). 95% met 2019 ACR/EULAR criteria for SLE; mean SLEDAI-2k score (SD) was 5.5 (5.3). 94% had a primary care provider, but only 32% had established with a gynecologist. There were 12 women for whom screening status could not be determined, resulting in a sample size of N=118 for the univariable analysis of correlates of screening status. 45 women were up-to-date with screening per ASCCP guidelines, 19 women per ACOG guidelines, and 54 women were overdue for screening. Patients without a gynecologist were more likely to be overdue for screening. A higher proportion of women screened per ASCCP guidelines were on immunosuppressive medications compared to women screened per ACOG guidelines and those overdue. SLE disease characteristics were not associated with screening patterns (Table 2).

Conclusion: Only half of the women with SLE in our study cohort had guideline-congruent care for cervical cancer screening. A greater proportion of women screened per ASCCP guidelines were on immunosuppressive medications compared to those screened by ACOG guidelines. This study reveals the variety of practice patterns employed for cervical cancer screening in our SLE population and suggests the need for increased awareness among rheumatologists, primary care providers, and gynecologists regarding the ASCCP SLE-specific screening guideline schedules.

Abstract Number: 1468

Intra-articular (IA) Injection of Empty Large Multilamellar Vesicles Liposomes Reduces Cartilage Degeneration in Rat Osteoarthritis Model

Alison Bendele[1], Jacob Favret[1], Gadi Sarfati[2], Ronny Pinkus[2] and **Roni Wechsler**[2], [1]Bolder BioPATH Inc., Boulder, CO, [2]Moebius Medical LTD, Tel Aviv, Israel

SESSION INFORMATION
Session Date: Tuesday, November 9, 2021
Session Title: Osteoarthritis & Joint Biology – Basic Science Poster (1468–1479)
Session Type: Poster Session D
Session Time: 8:30AM–10:30AM

Background/Purpose: A suspension of **empty** large multilamellar vesicles (MLV) liposomes composed of dimyristoylphosphatidylcholine (DMPC) and dipalmitoylphosphatidylcholine (DPPC), is currently under clinical development for symptomatic knee osteoarthritis (OA). *In-vivo* bio-distribution studies and *ex-vivo* wear tests have shown that following IA injection, the MLV liposomes are retained on the cartilage surface, providing lubrication, and leading to a reduction in wear of the cartilage. In a first-in-man study, a single injection of the MLV liposomes was demonstrated to lower pain in knee OA patients for up to 3 months.

Given the lubricating properties, cartilage wear reduction, and pain-lowering effect of the MLV liposomes, we hypothesized that their IA administration may also reduce OA progression.

The purpose of the current study was to evaluate the effects of three consecutive weekly IA injections of the MLV liposomes on cartilage degeneration in a rat surgical model of osteoarthritis.

Methods: Male Lewis rats underwent a unilateral medial meniscal tear (MMT) on study day 0. The rats (n=15 per group) were treated by the IA route on study days 7, 14, and 21 with the liposomes (50ml/knee), a vehicle control or left untreated. At day 28, joints were processed for histological analysis following staining with toluidine blue. Scoring for cartilage degeneration was based on chondrocyte death/loss, proteoglycan (PG) loss, and collagen loss or fibrillation and was measured by ocular micrometer. Substantial Cartilage Degeneration was identified by chondrocyte and proteoglycan loss extending through greater than 50% of the cartilage thickness. Gait analysis was performed at day 24 to confirm expected animal mobility post-surgery.

Results: Weekly IA treatment with the MLV liposomes (5.35 mg/knee) resulted in significant beneficial effects on cartilage damage and collagen degeneration in the rat meniscal-tear–induced model of OA as determined by evaluation of knee histopathology including significant reductions in substantial cartilage degeneration widths (38% reduction), summed cartilage degeneration scores (33%), total joint scores (25-26%), and combined severe to mild collagen degeneration widths (32%) as compared to the vehicle control. The treatment also resulted in significant reductions in subchondral bone sclerosis (16%) and osteophyte scores (16%) as compared to vehicle control rats. Rats treated with the liposomes had a statistically significant increase in synovial inflammation as compared to the vehicle control group with all animals showing minimal to mild synovitis. Animal body weight gain and mobility post-surgery in rats treated with the liposomes did not differ statistically from the vehicle control group.

Conclusion: Weekly IA treatment with the MLV liposomes resulted in significant reduction in cartilage damage and collagen degeneration in a rat model of OA as determined by evaluation of knee histopathology. The minimal to mild synovitis associated with the injected liposomes is expected from IA-injected particulate agents that lodge in the

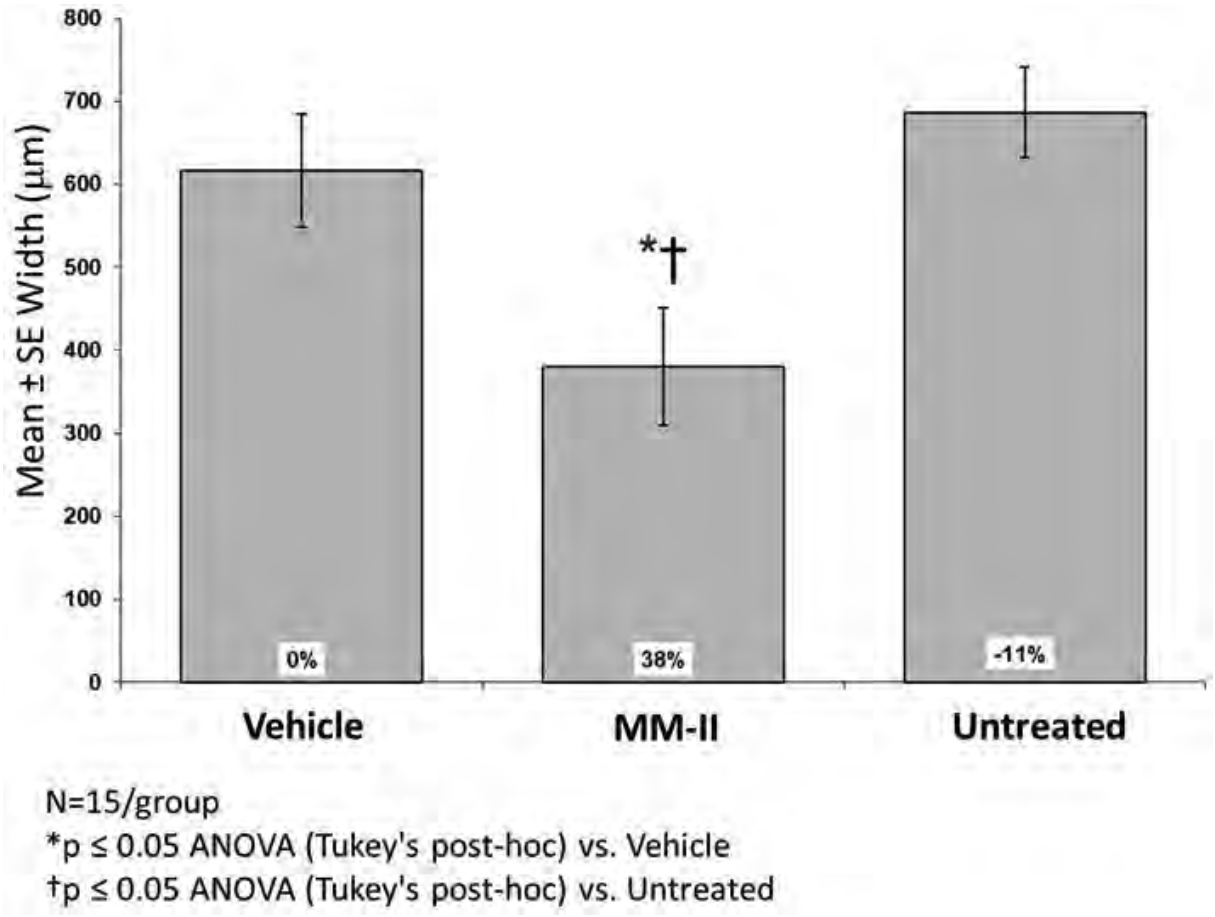

Figure 1. Substantial Tibial Cartilage Degeneration Width.

synovium. The above results indicate that treatment with large DPPC- and DMPC- based MLV liposomes has the potential to be a disease modifying OA therapy.

Lorecivivint (SM04690), an Intra-articular, Small-Molecule CLK/DYRK Inhibitor That Modulates the Wnt Pathway, as a Potential Treatment for Meniscal Injuries

Timothy Seo[1], **Vishal Deshmukh**[1] and Yusuf Yazici[2], [1]Biosplice Therapeutics, Inc., San Diego, CA, [2]New York University School of Medicine, La Jolla, CA

SESSION INFORMATION
Session Date: Tuesday, November 9, 2021
Session Title: Osteoarthritis & Joint Biology – Basic Science Poster (1468–1479)
Session Type: Poster Session D
Session Time: 8:30AM–10:30AM

Background/Purpose: Meniscal injuries are the most common pathology of the knee and are associated with pain, stiffness, and localized swelling. Meniscal damage is a frequent finding on MRI images of knee osteoarthritis (OA).[1] Efforts to repair meniscal damage have been largely unsuccessful and do not prevent the progression of degenerative changes that lead to knee OA.[2] The Wnt signaling pathway has been shown to be regulated during meniscal development,[3] suggesting that manipulation of this pathway may influence the regenerative capacity of the meniscus. Lorecivivint (LOR; SM04690) is an intra-articular (IA), small-molecule CLK/DYRK inhibitor that modulates the Wnt pathway.[4] LOR was evaluated in preclinical studies to determine its protective and anabolic effects in ex vivo explants and in a rat model of chemically induced inflammatory meniscal degeneration.

Methods: Effects of LOR (30 nM) on matrix metalloproteinase (MMP) expression in cultured rat menisci treated with IL-1b were measured by qRT-PCR. In vivo, LOR activity was evaluated in a rat model of monosodium iodoacetate

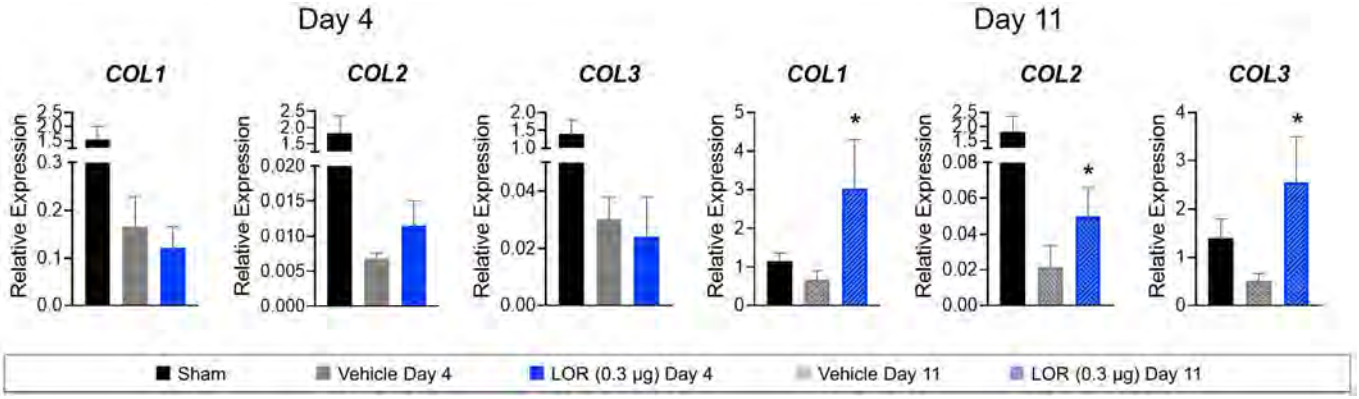

Figure 1. LOR increased collagen gene expression in vivo. A single IA injection of monosodium iodoacetate (MIA; 3 mg) was immediately followed by a single IA injection of LOR (0.3 µg) or vehicle at 10 weeks of age. Knees were harvested on Days 1, 4, and 11 after injection and menisci were isolated. Gene expression was measured by qRT-PCR. N=3, Mean ± SEM, *P<0.05, one-way ANOVA.

(MIA) injection-induced inflammatory meniscal degeneration. A single IA injection of MIA was immediately followed by a single IA injection of LOR (0.3 mg) or vehicle. Knees were harvested on Days 1, 4, and 11 and menisci were isolated. Anti-inflammatory effects were evaluated by qRT-PCR for *TNFA* and *IL6* expression. Meniscal protection was evaluated by qRT-PCR for MMPs and aggrecanase. Anabolic effects were evaluated by qRT-PCR for collagens.

Results: In ex vivo meniscal explants, LOR inhibited expression of *MMP1*, *MMP3*, and *MMP13* compared with DMSO ($P < 0.01$). In vivo, LOR significantly decreased expression of MMPs and aggrecanase ($P < 0.05$) and reduced expression of inflammatory cytokines *TNFA* and *IL6* compared with vehicle in the rat model of inflammatory meniscal degeneration at Day 4 after MIA injection. Additionally, LOR increased expression of collagen types I, II, and III at Day 11 after MIA injection (Figure 1).

Conclusion: LOR exhibited protective effects in the meniscus ex vivo and in vivo by reducing catabolic enzyme expression compared with control. Anti-inflammatory effects of LOR were demonstrated by inhibition of inflammatory cytokine expression. Compared with vehicle, LOR increased collagen expression in vivo, indicating potential meniscal anabolic effects. These data support further investigation of LOR as a potential structure-modifying treatment for meniscal injuries.

Cartilage Epigenetic Changes Induced by Microbial DNA Amplified from Human OA Samples

Vladislav Izda[1], Christopher Dunn[2], Cassandra Sturdy[1], Jake Martin[1], Cassandra Velasco[2], Paul Jacob[3] and Matlock Jeffries[1], [1]Oklahoma Medical Research Foundation, Oklahoma City, OK, [2]University of Oklahoma Health Sciences Center, Oklahoma City, OK, [3]Oklahoma Joint Reconstruction Institute, Oklahoma City, OK

SESSION INFORMATION
Session Date: Tuesday, November 9, 2021
Session Title: Osteoarthritis & Joint Biology – Basic Science Poster (1468–1479)
Session Type: Poster Session D
Session Time: 8:30AM–10:30AM

Background/Purpose: Strong links between epigenetic changes, particularly alterations in DNA methylation, have been linked with the onset and progression of knee osteoarthritis (OA); however, the environmental factors driving epigenetic changes within articular tissues have not yet been fully elucidated. We have previously demonstrated that the microbial DNA signatures within human cartilage and shown changes in microbial signatures correlate with primary knee OA progression. In this study, we hypothesized that alterations in microbial DNA may induce epigenetic changes within articular cartilage. To test this, we exposed chondrocyte cell lines *in vitro* to amplified microbial DNA from human OA patients and controls.

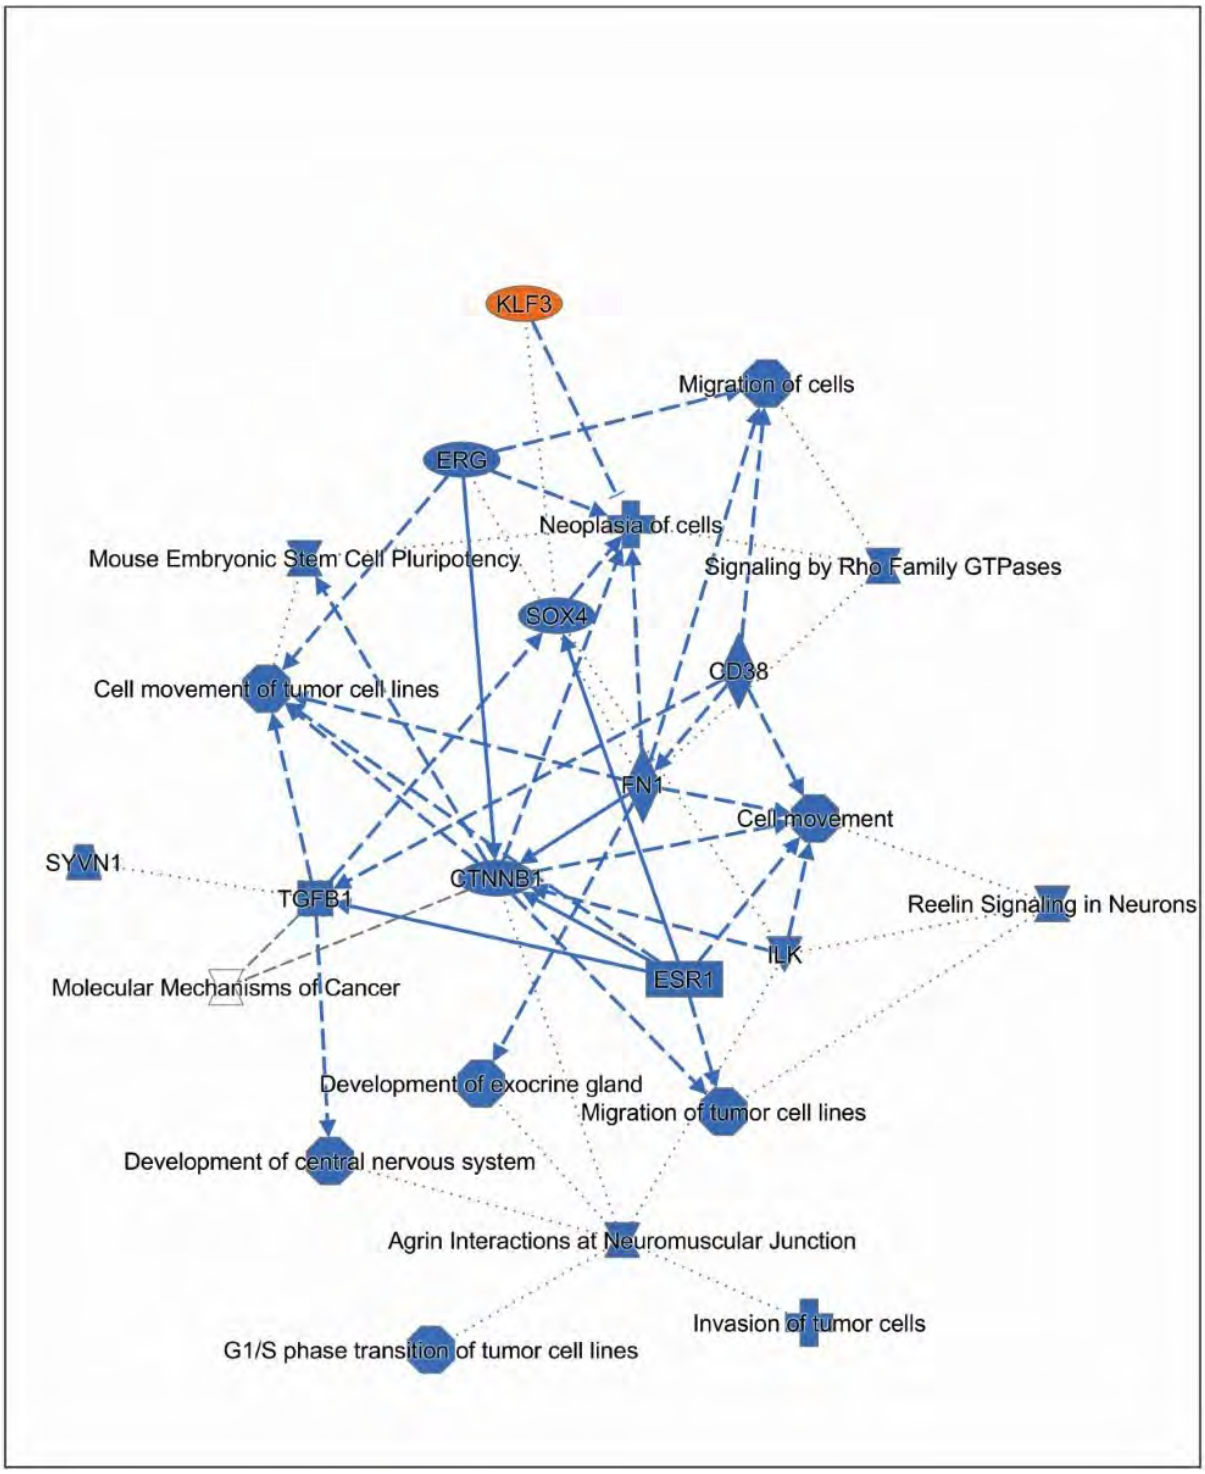

Figure 1. Graphical summary of top pathways and regulators associated with DNA methylation changes induced by exposure of chondrocytes in vitro to microbial DNA amplified from human OA patient cartilage samples.

Methods: Matched discarded cartilage samples from macroscopically eroded (n=4) and intact (n=4) OA specimens were obtained from patients undergoing total knee arthroplasty. Control cartilage samples were obtained from cadaveric control patients. Microbial DNA was isolated using an anti-MBD2 magnetic bead approach and microbial DNA subjected to whole-genome amplification. Twenty micrograms of amplified microbial DNA was added Tc28a2 cells in culture. After a 3-day incubation period, DNA was extracted, treated with sodium bisulfite, and loaded onto Illumina Infinium Methylation EPIC chips .DNA methylation beta values were extracted from raw chip imaging and

processed in R using the ChAMP package. Genes associated with differentially methylated CpG sites were evaluated ontologically using the Ingenuity Pathway Analysis (IPA) software package.

Results: Microbial DNA treatment induced substantial changes in DNA methylation levels. Comparing eroded-OA microbial DNA-treated cells with control microbial DNA-treated cells, we found 1638 differentially methylated CpG sites (DMPs), 1637 hypomethylated in the eroded group, corresponding to 1109 unique genes. No DNA methylation differences were induced when comparing non-OA with intact-OA microbial DNA-treated cells. Comparing eroded-OA to intact-OA, we identified 1275 DMPs, 1274 hypomethylated in the eroded group, corresponding to 881 unique genes. Ontology analysis of differentially methylated genes associated with eroded-OA vs. control microbial DNA treatment revealed numerous OA-related pathways and upstream regulators (**Figure 1**). These include axonal guidance signaling, Rho family GTPases, ERK/MAPK signaling, stem cell pluripotency, and ErbB signaling, among others. Upstream analysis included enrichment in ERG, miR-137 (which regulates ADAMTS5), miR-21 (which targets Gdf5), miR-16 (which targets Smad3), among others.

Conclusion: Herein, we demonstrate that exposure of human chondrocytes *in vitro* to microbial DNA is sufficient to induce widespread epigenetic changes. OA-related epigenetic modifications are identified when cells are treated with microbial DNA extracted from eroded-OA human cartilage samples. These data represent a novel potential mechanism of microbiome-epigenome interaction in the development of OA. Future work should focus on testing whether these findings are replicable *in vivo* and explore the mechanism(s) through which this epigenetic alteration is induced.

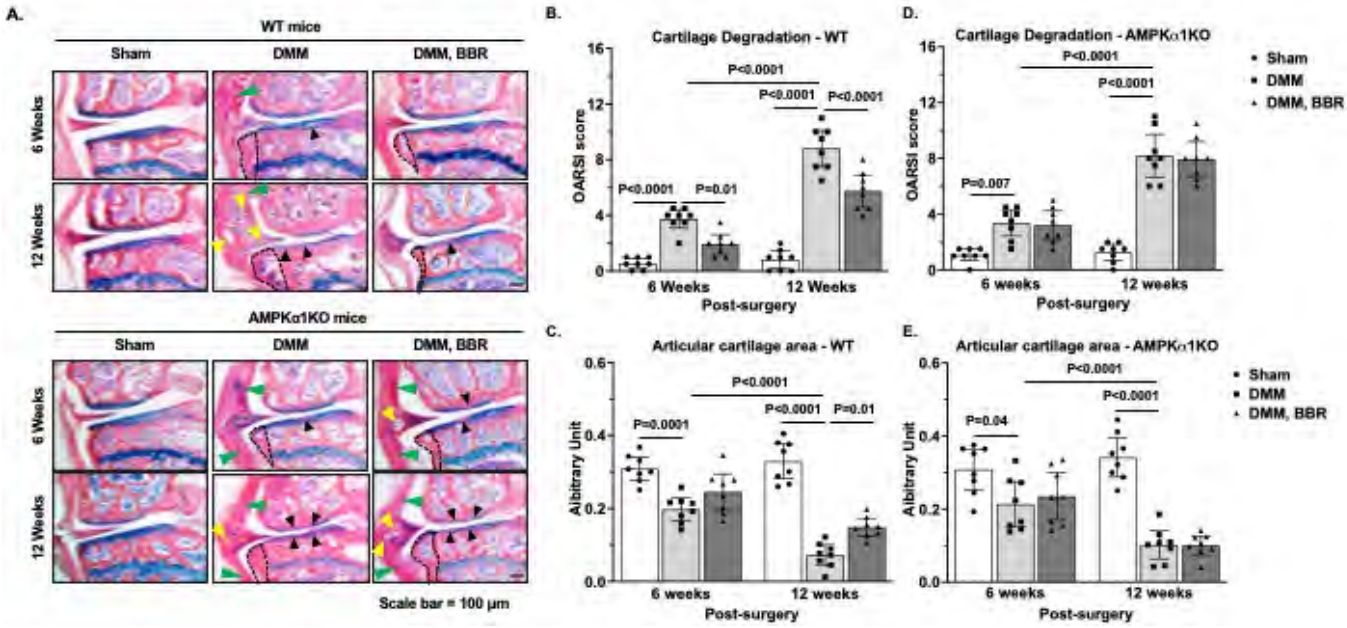
Oral Administration of Berberine Limits Post-traumatic Osteoarthritis Development and Associated Pain via AMP-activated Protein Kinase (AMPK) in Mice

Jun Li[1], Yun Wang[2], Di Chen[3] and **Ru Liu Bryan**[4], [1]Rush University Medical Center, Chicago, IL, [2]Valo Health, Lexington, MA, [3]Shenzhen Institutes of Advanced Technology, Chinese Academy of Sciences, Shenzhen, China (People's Republic), [4]University of California San Diego and VASDHS, San Diego, CA

SESSION INFORMATION
Session Date: Tuesday, November 9, 2021
Session Title: Osteoarthritis & Joint Biology – Basic Science Poster (1468–1479)
Session Type: Poster Session D
Session Time: 8:30AM–10:30AM

Background/Purpose: AMP-activated protein kinase (AMPK), a master regulator of energy balance and metabolism, is implicated to play an important role in cartilage homeostasis. Berberine is an isoquinoline alkaloid extracted from plants with low toxicity. It has anti-microbial, anti-inflammatory and anti-oxidant properties. The beneficial effect of berberine is mediated through multiple signaling pathways, and activation of AMPK is through to be one of the main actions of berberine. Although berberine exhibits chondroprotective effect, the underlying mechanism is not fully understood. In addition, whether berberine has ability to alleviate OA-associated pain remains unclear. Thus, in this study, we investigated the effect of berberine on OA development and associated pain in mice *in vivo*.

Figure 1. Berberine protected mice from cartilage damage in an AMPK-dependent manner in a post-traumatic OA model in mice.



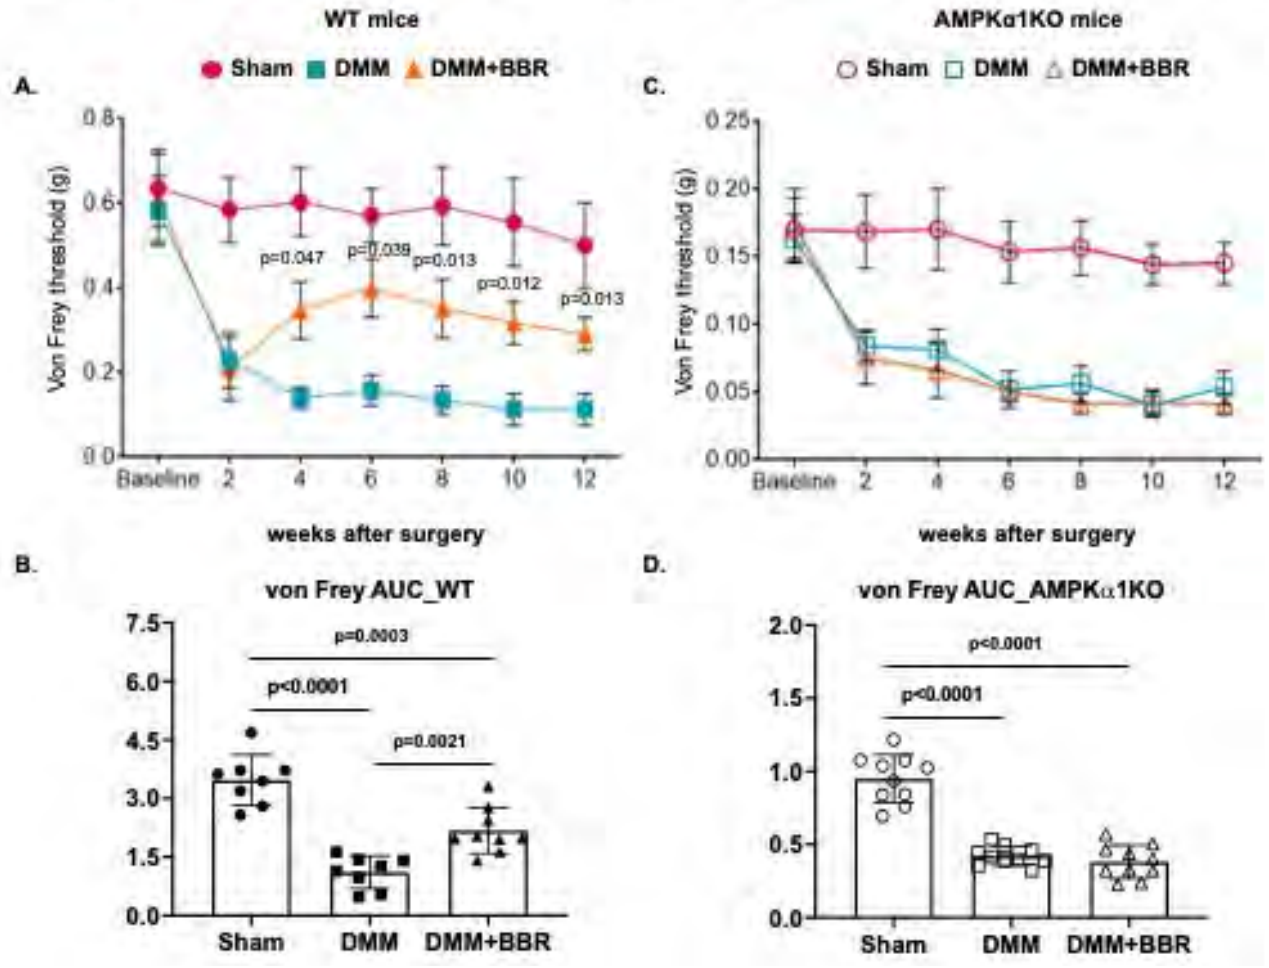
Methods: Human primary knee chondrocytes were included to investigate how AMPK is activated by berberine *in vitro*. Both global knockout (KO) of AMPKa1 and congenic wild type (WT) male mice were subjected to the post-traumatic OA through destabilization of medial meniscus (DMM) surgery. Two weeks after surgery, the mice were divided into two groups with one group receiving berberine chloride daily via drinking water. They were sacrificed at 6 and 12 weeks after surgery. OA severity was assessed by histological analyses of cartilage damage using the OARSI score system. Articular cartilage area of medial tibia plateau was quantified by tracing the Alcian blue-positive staining areas using the OsteoMeasure system. The osteophyte formation was evaluated semi-quantitatively based on both size and maturity of osteophytes. Immunohistochemistry (IHC) analyses were carried out to examine AMPK signaling. Pain behavior was evaluated by von Frey filament test to assess pain sensitivity. The Laboratory Animal Behavior Observation Registration and Analysis System was used to assess spontaneous pain behavior. GraphPad PRISM 8 was used for statistical analyses.

Results: Berberine induced phosphorylation of AMPKa (Thr172) via liver kinase B1 (LKB1), the major upstream kinase of AMPK, in chondrocytes *in vitro*. Both WT and AMPKa1KO exhibited OA phenotype such as cartilage damage, osteophyte formation and associated pain behavior, which progressed from mild to severe at 6 and 12 weeks post DMM surgery, respectively. Berberine treatment significantly reduced severity of OA and attenuated pain in WT but not AMPKa1KO mice, indicating the effect of berberine on chondroprotection and pain alleviation was AMPK-dependent. IHC analysis of WT mice revealed decreased phosphorylation of AMPKa (Thr172) and concomitantly reduced expression of SIRT1 and SIRT3 *in situ* in the DMM knee cartilage, which were significantly reversed by berberine. Stimulation human OA chondrocytes with berberine *in vitro* resulted in increased phosphorylation of AMPKa (Thr172), correlated with increased NAD^+/NADH ratio and expression of NAD^+-dependent SIRT1 and SIRT3, suggesting importance of activation of AMPK signaling in mediating beneficial effect of berberine.

Conclusion: Berberine acts through AMPK to reduce joint structural damage and alleviate pain associated with post-traumatic OA in mice *in vivo*, implicating its OA disease modifying potential.

Both WT and AMPKa1KO mice were subjected to the DMM surgery to induce OA development. Two weeks after the surgery, mice in the treatment group started to receive berberine chloride via drinking water. At 6 and 12 weeks after the DMM surgery, mice were sacrificed and histological analysis of mouse knee sections (A) and assessment of

Figure 2. AMPK mediated the effect of berberine on relieving pain through reduced pain sensitivity in post-traumatic OA.



cartilage damage including cartilage degradation (B and D) and cartilage area (C and E) were performed as described in the Methods. Two-way ANOVA with the post-hoc Tukey test was used for statistical analysis in B-E.

The von Frey test was performed to assess pain sensitivity biweekly after DMM surgery (n=8, each group) in WT and AMPKa1 KO mice with and without berberine treatment as described in the Methods. Statistical analysis was conducted using two-way ANOVA with the Tukey post-hoc test.

The LABORAS system was used to evaluate spontaneous pain biweekly after DMM surgery (n=4, each group) in WT and AMPKa1 KO mice with and without berberine treatment as described in the Methods, which included travel distance (A, B), average walking speed (C, D), rear frequency (E, F), and rearing duration (G, H). Statistical analysis was conducted using two-way ANOVA with the Tukey post-hoc test.

Figure 3. AMPK mediated the effect of berberine on relieving pain through improving spontaneous activities in post-traumatic OA.

SESSION INFORMATION

Session Date: Tuesday, November 9, 2021

Session Title: Osteoarthritis & Joint Biology – Basic Science Poster (1468–1479)

Session Type: Poster Session D

Session Time: 8:30AM–10:30AM

Background/Purpose: We have previously reported that stimulation of mouse bone marrow–derived macrophages with a combination of tumor necrosis factor α (TNFα) and interleukin-6 (IL-6) induces differentiation of osteoclast-like cells with bone resorption activity (Yokota K *et al*., Arthritis & Rheumatology 2014, 66:121-129). The present study aims to clarify the characterization and function of human TNFα and IL-6–induced osteoclasts using human peripheral blood cells collected from patients with rheumatoid arthritis (RA) or healthy donors. In addition, we also identify the differences in the molecular expression patterns between the novel TNFα and IL-6-induced osteoclasts and conventional RANKL-induced osteoclasts.

Methods: Human peripheral blood monocytes were cultured with a combination of TNFα and IL-6, TNFα alone, IL-6 alone, or RANKL, and their bone resorption ability were evaluated. Expression levels of nuclear factor of activated T cell (NFAT) c1, proinflammatory cytokines, matrix metalloproteinase-3 (MMP-3), and cathepsin K (CTSK) were analyzed. The effects of osteoprotegerin (OPG), NFAT inhibitor, and JAK inhibitor on these osteoclastogenesis were examined. Furthermore, we examined the relationship between the number of TNFα and IL-6–induced osteoclasts or RANKL-induced osteoclasts differentiated from peripheral blood mononuclear cells in patients with RA and the relationship, modified total Sharp score (mTSS) and whole-body bone mineral density (BMD).

Results: Peripheral blood monocytes stimulated with a combination of TNFα and IL-6 showed the ability to absorb bone matrix, which has been supposed to be the function of osteoclasts. The differentiation was not inhibited by the addition of OPG contrary to that of RANKL-induced ones. Stimulation with a combination of TNFα and IL-6 promoted NFATc1 expression, whereas the NFAT and JAK inhibitors prevented this TNFα and IL-6–induced osteoclast formation. Expression levels of *IL-1β*, *TNFα*, and *IL-12p40* were significantly increased in TNFα and IL-6–induced osteoclasts, but not in RANKL-induced osteoclasts. IL-1β up-regulated the differentiation of TNFα and IL-6–induced osteoclasts. The number of TNFα and IL-6–induced osteoclasts from patients with RA positively correlated with the mTSS, whereas RANKL-induced osteoclast numbers negatively correlated with the whole-body BMD of the same patients. The expression levels of *MMP-3* were significantly higher in TNFα and IL-6-induced osteoclasts than in RANKL-induced osteoclasts. Conversely, the expression levels of *CTSK* were significantly higher in RANKL-induced osteoclasts than in TNFα and IL-6-induced osteoclasts.

Conclusion: Our results demonstrate that TNFα and IL-6–induced osteoclasts differentiate via RANKL-independent pathways and may contribute to the joint destruction in the inflammatory arthritis, such as RA.

SESSION INFORMATION

Session Date: Tuesday, November 9, 2021

Session Title: Osteoarthritis & Joint Biology – Basic Science Poster (1468–1479)

Session Type: Poster Session D

Session Time: 8:30AM–10:30AM

Background/Purpose: In osteoarthritis (OA), defects in Autophagy are evident and precede joint damage. Therefore, identifying hallmarks associated with specific autophagy subtypes could shed light to fundamental mechanisms of joint disease.

Methods: A comparative analysis of 35 autophagy genes was performed from blood from the Prospective OA Cohort of A Coruña (PROCOAC). Non-OA subjects (n=18) and Knee OA subjects (n=18, OA III-IV) were profiled using an autophagy gene expression array. Confirmatory studies were performed in blood from Non-OA subjects (n=30) and Knee-OA subjects (n=30, OA III-IV).

The candidate gene was evaluated in human knee joint tissues (cartilage, meniscus, ligaments, synovium) with different KL grades (KL0, 2, 4) and in both spontaneous aging and surgically-induced OA in mice by IHC. The functional consequences were studied in primary human OA chondrocytes. Autophagy, Chaperone-mediated autophagy (CMA), inflammation, and cellular senescence were analyzing by gene and protein expression. Moreover, oxidative stress and cell death were evaluated by FACS. The contribution of CMA to chondrocyte homeostasis was evaluated by studying the capacity of CMA to restore proteostasis upon autophagy deficiency by siATG5.

Results: 15 autophagy-related genes were significantly downregulated in blood from knee OA patients compared to non-OA patients. No significant upregulation was found for any studied gene, although a trend towards upregulation was found in genes involved in the mTOR pathway. Interestingly, HSP90AA1 and HSPA8, CMA markers involved in stress response and protein folding, were downregulated. Confirmatory studies showed a significant downregulation of MAP1LC3B and HSP90AA1 in blood from knee OA patients. Remarkably, HSP90A was found reduced in femoral cartilage, meniscus and ACL, while in synovial membrane, the expression was found increased. This expression signature was dependent on OA severity. In addition, we observed a decrease of HSP90A with aging and OA in mice. The functional consequences of HSP90AA1 gene silencing are related to an increase in NFkB, MMP13, and p16 expression. Interestingly, LAMP2A, a key CMA marker, and MAP1LC3B expression were upregulated, which

might indicate an early response to maintain homeostasis. On the other hand, LAMP2A protein is decreased upon HSP90AA1 deficiency, while LC3II and p62 were increased, indicating a failure in the autophagy flux that leads to impaired lysosomal degradation. Moreover, p21, p16 and prbS6 were increased, besides increasing mitochondrial ROS production and apoptosis. ATG5 silencing blocks autophagy by reducing LC3II and increasing prbs6, p62, p16 and p21. Interestingly, LAMP2A and HSP90A were found increased, indicating a compensative activation of CMA in response to autophagy defects. These results support that HSP90A has an important role in chondrocyte homeostasis by participating in the cross-talk between CMA and autophagy.

Conclusion: Taking together, we identified HSP90A, a CMA regulator, as critical in chondrocyte homeostasis. These disease mechanisms are relevant in OA and constitute hallmarks potentially useful to prevent OA progression.

Automatic Detection of Bone Marrow Lesions from Knee MRI Data from the OAI Study

Shen Liu[1], **Xiaoxiao Sun**[1], Frank Roemer[2], Erin Ashbeck[3], Edward Bedrick[1], Zong-Ming Li[1], Ali Guermazi[4] and Kent Kwoh[1], [1]University of Arizona, Tucson, AZ, [2]Friedrich-Alexander University Erlangen-Nurnberg, Erlangen, Germany, [3]University of Arizona Arthritis Center, Tucson, AZ, [4]Boston University, Boston, MA

SESSION INFORMATION
Session Date: Tuesday, November 9, 2021
Session Title: Osteoarthritis & Joint Biology – Basic Science Poster (1468–1479)
Session Type: Poster Session D
Session Time: 8:30AM–10:30AM

Background/Purpose: Subchondral bone marrow lesions (BMLs) are associated with symptoms and structural progression of knee OA. BMLs are characterized by diffuse hyperintensity on fat suppressed T2-weighted images. BMLs are commonly assessed using semi-quantitative (SQ) scoring systems by expert readers or volume quantification. Automated detection of BMLs using machine learning approaches may help in screening potential participants in clinical trials enriched for fast structural progression.

Methods: The dataset consists of 1,899 knee MRI exams from three sub-studies of the Osteoarthritis Initiative (OAI) with available baseline SQ readings: Foundation for NIH (FNIH) OA biomarker, Pivotal OAI MRI Analysis (POMA) incident radiographic knee OA, and POMA knee replacement. We trained a deep learning model (modified MRNet) using the sagittal intermediate-weighted (IW) fat-suppressed (FS) images. We dichotomized the MOAKS (MRI Osteoarthritis Knee Score) grades into presence or absence categories. The split was done by categorizing grades > 0 as presence and grades = 0 as absence. The whole data were randomly split into a training set (1524 exams) to train the model, a validation set (182 exams) to select the best model, and a test set (193 exams) to evaluate prediction performance. After the deep learning models were trained, we obtained probabilities of the existence of BMLs from IW images on each of 15 subregions in the femur and tibia. The logistic regression model was trained to combine the probabilities of different regions for IW images to output a probability of BMLs status for each subject overall. We utilized the area under the receiver operating characteristic curve (AUC) to assess the model's performance and 95% confidence intervals of AUC to measure the variability of AUC. AUC values range from 0 to 1, with 1 indicating a 100% correct detection.

Table 1. AUC values for the test set

Subregions	AUC
femur medial anterior	0.51
femur lateral anterior	0.89
femur medial central	0.83
femur lateral central	0.86
femur medial posterior	0.59
femur lateral posterior	0.81
tibia sub- spinous	0.77
tibia medial anterior	0.81
tibia lateral anterior	0.83
tibia medial central	0.90
tibia lateral central	0.85
tibia medial posterior	0.83
tibia lateral posterior	0.69
patella medial	0.56
patella lateral	0.90

Results: The highest AUC value for IW images in the test set was 0.90 at two regions (tibia central medial and patella lateral). AUC values ranged from 0.51 to 0.89 in the test set for the other regions, see Table 1. At the subject level, the detection performance of the combined model achieved an AUC value of 0.87 with a 95% confidence interval of [0.82, 0.93].

Conclusion: We have developed and validated a fully automated deep learning framework to detect BMLs from MRI data. After the model had been trained, we applied the trained model to MRI data without MOAKS readings to predict the probability of BMLs status automatically. The prediction performance of detecting BMLs varied among different regions. Our method has some limitations, e.g., the prediction accuracy at the subject level is not as good as the accuracy for the individual subregions. In future studies, we will utilize images from other MRI sequences and additional MOAKS readings to improve our model's performance. Automated classification of diffuse vs cystic BMLs and severity grading will be important in addition.

Long Term Compressive Loading Modulates the Extracellular Matrix Response to Growth Factors in Bovine Cartilage Explants

Frederik Gillesberg[1], Amalie Engstrøm[1], Morten Karsdal[2], Anne-Christine Bay-Jensen[3] and Christian S Thudium[3], [1]University of Copenhagen, Herlev, Denmark, [2]Nordic Bioscience, Herlev, [3]Nordic Bioscience, Herlev, Denmark

SESSION INFORMATION

Session Date: Tuesday, November 9, 2021
Session Title: Osteoarthritis & Joint Biology – Basic Science Poster (1468–1479)
Session Type: Poster Session D
Session Time: 8:30AM–10:30AM

Background/Purpose: Mechanical loading of cartilage is an essential part of the function and maintenance of the joint. Despite the apparent importance of continuous mechanical loading, this factor is rarely considered in cell or tissue models potentially limiting their translatability. The majority of studies that have investigated the impact of mechanical loading on cartilage remodeling have done so in one sitting, investigating the effects of a single loading procedure,

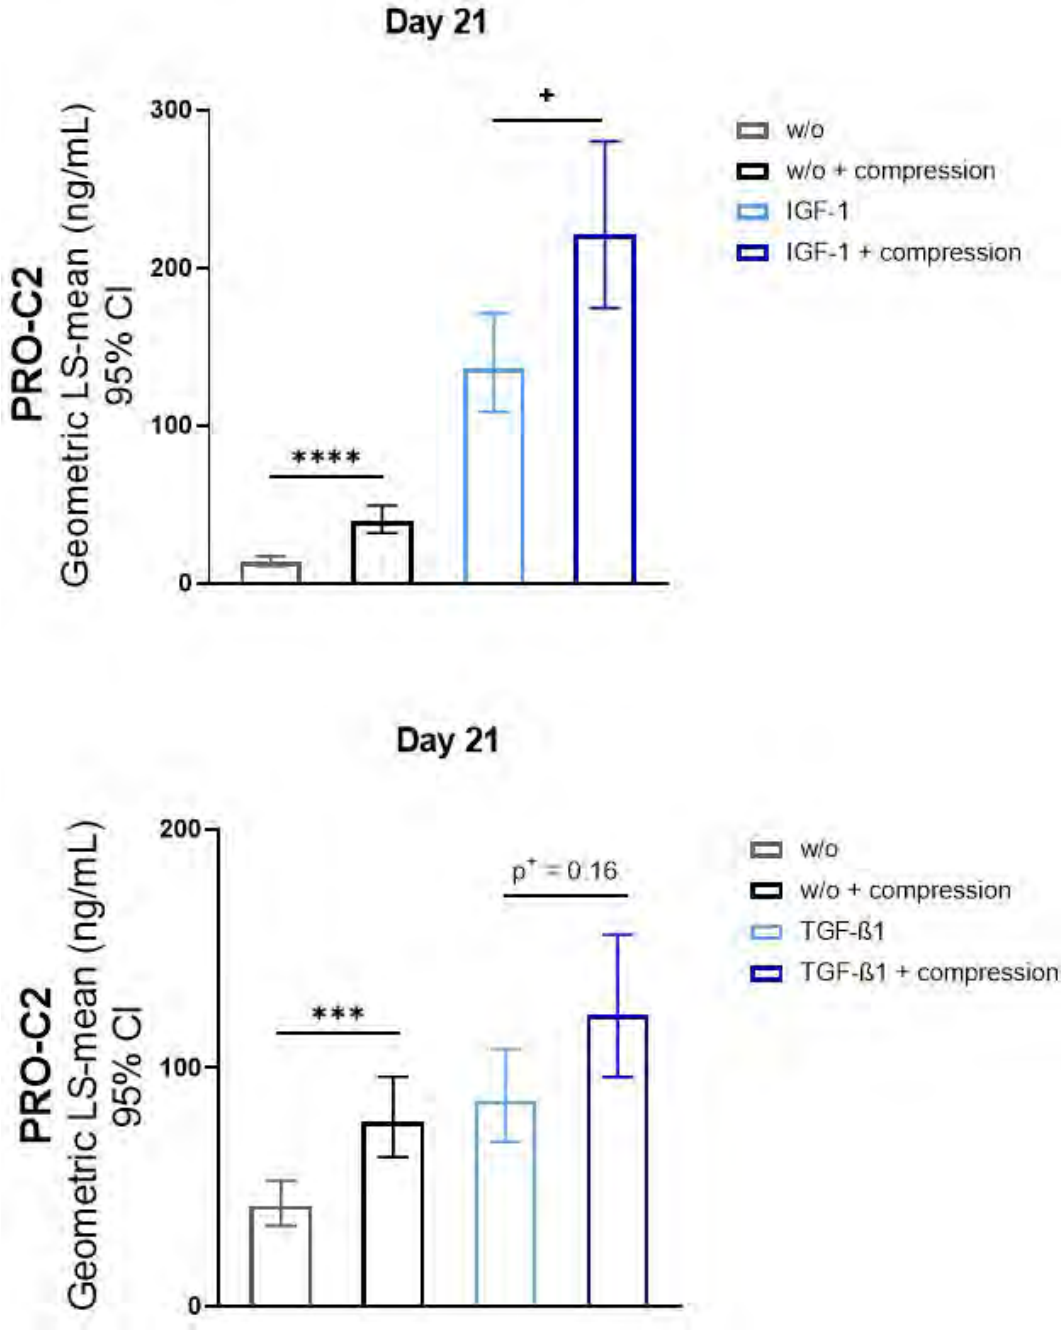

Figure 1. Effect of compression on IGF-1 and TGF-β1 induced cartilage formation.

typically lasting hours or days of duration. Cartilage remodeling has however been described to be augmented when loading procedures are repeated over several days, allowing creep recovery of cartilage to occur between loading procedures. The aim of this study was to elaborate on such regimens of repeated loading and investigate cartilage remodeling when dynamic compression was repeated daily for three weeks.

Methods: Bovine cartilage explants were isolated from the femoral condyles of 1–2-year-old calves. Explants were subjected to 20 minutes of 1 MPa dynamic compressive loading five times a week, with culturing lasting 21 days. The impact of dynamic compression on cartilage remodeling was investigated in presence of growth factors IGF-1 and TGF-β1, as well as SB525334, a TGF-β receptor 1-selective kinase inhibitor. Cartilage remodeling was determined at baseline and once every week by measuring biomarkers for type II collagen formation (PRO-C2) and fibronectin turnover (FBN-C) in the conditioned media from explants. Metabolic activity was likewise determined at baseline and once every week by alamarBlue™.

Results: Daily cyclic loading of bovine cartilage explants increased PRO-C2 and FBN-C levels at day 21 compared to unloaded explants. Treatment with IGF-1 increased PRO-C2, but not FBN-C levels, compared to vehicle, while daily cyclic loading increased both PRO-C2 and FBN-C compared to IGF-1 alone. TGF-β1 increased both PRO-C2 and FBN-C levels compared to vehicle, while no additional effect of daily cyclic loading was observed in explants treated with TGF-β1. Inhibition of SMAD2/3 signaling by SB525334 blocked PRO-C2 and FBN-C release in both naïve and dynamically compressed explants indicating inhibition of both regular and compression induced cartilage formation.

Conclusion: We here show that daily low-grade cyclic compression of cartilage explants increases type II collagen formation. We find that the growth factor IGF-1 work in addition to the anabolic response generated by compression, increasing the overall impact on cartilage formation. Further, TGF-β1 signaling was found to be important for mediating the anabolic effect of mechanical loading in bovine cartilage explants. These data suggest that mechanical loading is important to consider in translational models.

SESSION INFORMATION
Session Date: Tuesday, November 9, 2021
Session Title: Osteoarthritis & Joint Biology – Basic Science Poster (1468–1479)
Session Type: Poster Session D
Session Time: 8:30AM–10:30AM

Background/Purpose: Osteoarthritis (OA) is the most common degenerative joint disease worldwide, traditionally classified as non-inflammatory. Recently, attention has been drawn to the importance of synovitis in the pathogenesis

of OA. Fibroblast-like synoviocytes (FLS), which maintain structural and dynamic integrity of the joint under physiological conditions, have been proposed to be key factors in joint destruction during OA. Of these, pathogenic THY1- FLS of the synovial lining are assumed to destroy bone and cartilage, whereas THY1+ FLS of the sublining drive synovitis. The latter are classified as invasive proliferative cells characterized by a dominant glucose metabolism. In order to demonstrate inflammation-induced metabolic changes in FLS, we chose mesenchymal stromal cells (MSCs) as a phenotypically indistinguishable, non-activated fibroblast-like control. To identify novel targets for the diagnosis and treatment of OA, we compared human FLS isolated from tibial plateau samples collected during knee arthroplasty for OA with bone marrow-derived MSCs from patients with OA at the transcriptomic, proteomic, and metabolic levels.

Methods: We characterized FLS and MSCs for their multipotency, surface marker pattern, proliferation rate, expression of metabolic-related markers, and mitochondrial function using flow cytometry, immunofluorescence and Seahorse™ technology. Using qPCR and mass spectrometry, we analyzed selected gene and protein expression patterns.

Results: We observed a comparable phenotype of FLS and non-inflamed MSCs with respect to the minimal criteria defining the MSC phenotype. Mapping the distribution of subsets within expanded FLS, we observed >90% THY1+ FLS proliferating faster than non-inflamed MSCs. Global proteome comparison of FLS with MSCs revealed 592 differentially expressed proteins. In detail, we observed no differences between the two cell types with respect to the expression of classical fibroblast markers. When mitochondrial function was analyzed, FLS showed significantly lower basal respiration and ATP production rates but higher spare respiratory capacity and number of mitochondria compared with MSCs. In addition, we identified the pyruvate dehydrogenase kinase (PDK) 3 to be highly expressed in proliferative FLS compared with MSCs. Inhibition of PDKs by dichloroacetate (DCA) significantly increased basal respiration and ATP production rates in FLS but not in MSCs. Finally, DCA significantly reduced the proliferation of FLS compared with untreated FLS controls.

Conclusion: Our data suggest that, although the classical fibroblast markers do not distinguish between non-inflammatory MSCs and THY1+ FLS, the latter have significantly higher expression of PDK isoforms. PDK isoforms are known to inhibit the entry of pyruvate into the tricarboxylic acid cycle, thereby limiting the mitochondrial ATP production, and may play a critical role in the expansion of FLS during OA pathogenesis. Therefore, it is likely, that reprogramming FLS metabolism from glycolysis to mitochondrial respiration by inhibiting PDK isoforms might be a potential new approach to treat OA.

Circulating MicroRNAs in Hand Osteoarthritis

Aneta Pekacova[1], Jiri Baloun[1], Olga Sleglova[1], Jiri Vencovsky[1], Karel Pavelka[2], Ladislav Senolt[2] and Olga Ruzickova[1], [1]Institute of Rheumatology, Prague, Czech Republic, [2]Institute of Rheumatology, Department of Rheumatology, 1st Faculty of Medicine, Charles University, Prague, Czech Republic

SESSION INFORMATION
Session Date: Tuesday, November 9, 2021
Session Title: Osteoarthritis & Joint Biology – Basic Science Poster (1468–1479)
Session Type: Poster Session D
Session Time: 8:30AM–10:30AM

Background/Purpose: microRNAs (miRNAs) are small non-coding RNAs that can ignite the degradation of mRNAs or inhibit the protein translation and are therefore essential for several physiological and pathological functions. It is now clear that several miRNAs (e.g. miR-9, miR-140) regulating genes related to OA progression have a significantly different levels of expression in various tissues [1,2]. Under certain circumstances, miRNAs can be released into the body fluids and easily be detected in the blood samples.

The aim of this study was to evaluate circulating miRNAs in patients with hand osteoarthritis (HOA) and healthy individuals. Simultaneously, we studied specific miRNAs in order to differentiate between erosive and non-erosive subsets of the disease.

Methods: Eight patients with HOA (erosive: n=4, 3 females, mean age=63.7±7 yrs; non-erosive: n=4, 3 females, mean age= 62.4±6 yrs) and 4 healthy controls (3 females, mean age=63.5±7 yrs) were included in this study. Firstly, Advance TaqMan low-density assay (TLDA) was performed for the purpose of miRNA high-throughput screening. Differently expressed miRNAs were further verified by real-time qPCR on the validation cohort in 31 patients with hand OA (19 females, mean age=66.2±7 yrs, erosive: n=9, non-erosive: n=10, healthy controls: n=12).

Results: We identified 346 circulating miRNAs in plasma of HOA patients and healthy controls. Out of these, 40 circulating miRNAs were differently expressed in patients with HOA compared to healthy controls. We validated altered expression of 10 miRNAs in patients with HOA compared to healthy controls, e.g. miR-191-5p (3.4 fold), miR-151a-3p (3.4 fold) or miR-222-3p (2.4 fold). None of the miRNA could distinct erosive from a non-erosive subset of the disease.

Conclusion: Extensive profiling of circulating miRNAs revealed several miRNAs that can be associated with HOA and can help to better understand OA pathogenesis.

Session Date: Tuesday, November 9, 2021
Session Title: Osteoarthritis & Joint Biology – Basic Science Poster (1468–1479)
Session Type: Poster Session D
Session Time: 8:30AM–10:30AM

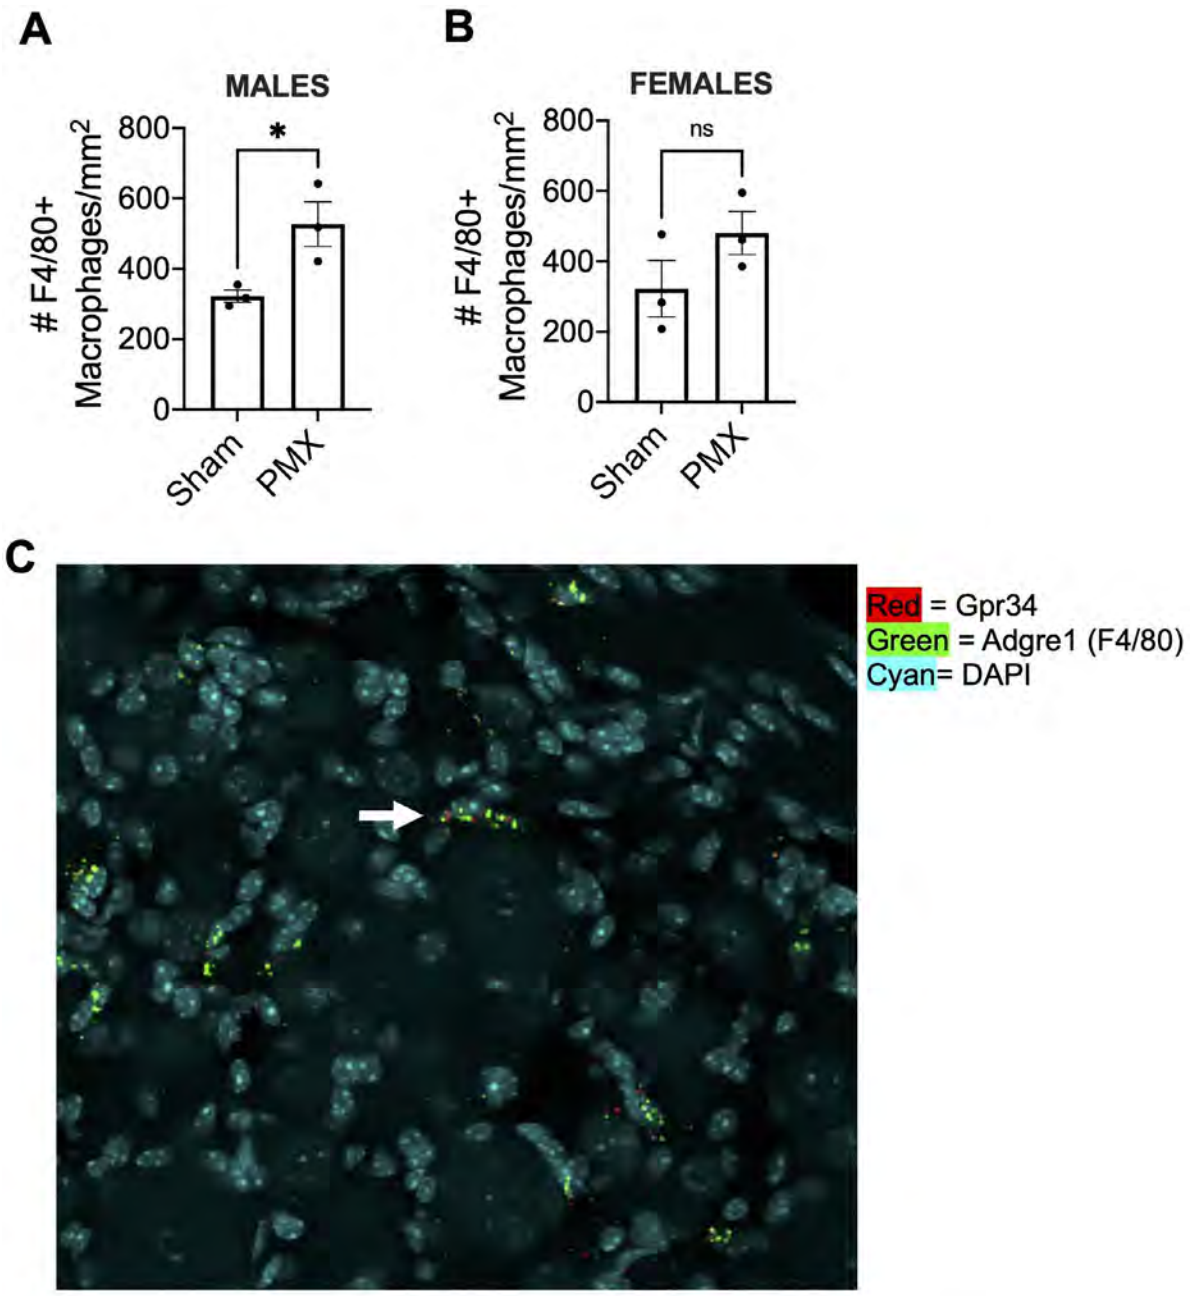

Figure 1. Macrophages (F4/80+Gpr34+) infiltrate the DRG in experimental OA. (A) F4/80+ cells quantified in the ipsilateral L4 mouse DRG of (A) male and (B) female mice 12 weeks after PMX or sham surgery (n=3). (C) RNAscope *in situ* hybridization of *Gpr34* or *Adgre1* (F4/80 gene name) co-stained with DAPI (nuclear stain) on a male PMX L4 DRG tissue sample (60X magnification). Arrow points to co-localization of *Gpr34* and *Adgre1* expression. Statistical analysis by Mann-Whitney t-test. *$p < 0.05$

Background/Purpose: Osteoarthritis (OA) is one of the leading causes of musculoskeletal pain and disability. Worldwide, an estimated 303 million patients have clinically diagnosed OA, with over 14 million new cases emerging annually. Yet, management of OA pain remains poor, and often relies on analgesics with limited efficacy. To identify new analgesic targets, we use molecular biology techniques to study the mechanisms underlying OA pain in mouse models. Single cell RNA-sequencing of mouse dorsal root ganglia (DRG) identified novel molecular targets, including several G-protein coupled receptor (GPCR) genes with specific expression patterns in populations of neuronal and non-neuronal DRG cells. In particular, we found that the rhodopsin class GPCR, *Gpr34*, is specifically expressed by macrophages in the DRG. Given that neuroimmune interactions have been implicated in the development of persistent pain, targets on immune cells infiltrating the DRG may be therapeutically useful. The objective of this study was to investigate expression of *Gpr34* by DRG macrophages in experimental OA, induced by partial meniscectomy (PMX). We have previously shown that both male and female mice develop joint damage and signs of pain behavior in this model by 12 weeks post surgery.

Methods: We performed PMX or sham surgery on 10-week-old male and female mice (n=3 per group). Ipsilateral L4 DRG were collected 12 weeks following surgery, fixed in 4% paraformaldehyde, transferred to 30% sucrose solution for cryoprotection and cryo-sectioned onto slides. RNAscope analysis was completed with probes for mouse Gpr34 and Adgre1 per ACD Bio-Techne Multiplex Fluorescent v2 Assay standard protocol. We evaluated macrophage presence in the DRG via immunofluorescence staining for F4/80, a pan-macrophage marker, as previously described. Final images were processed using a Fluoview FV10i confocal microscope, and quantification was completed via ImageJ software. Briefly, in ImageJ, regions of interest (ROIs) were automatically generated from a set intensity threshold and cell size parameters, and the number of positive cells in 30X image area were counted by a blinded observer.

Results: By immunofluorescence, we observed an increase in the total number of F4/80+ cells in DRGs 12 weeks post PMX compared to sham controls, in both male and female mice (n=3) (Figs. 1A+B). In addition, RNAscope in situ hybridization revealed overlap with *Gpr34* and *Adgre1* (gene name for F4/80) 12 weeks post PMX in male mice, supporting the single cell RNA sequencing data that these cells are indeed macrophages (n=3) (Figure 1C).

Conclusion: This study suggests that macrophages are increased in the DRGs of both male and female mice after PMX, during a time when the mice have developed both joint damage and persistent pain behaviors. Our lab has previously shown that macrophages numbers also increase in DRGs following destabilization of the medial meniscus (DMM), suggesting that these cells may contribute to the development of persistent pain. Moreover, a novel druggable receptor, *Gpr34* is expressed by these macrophages. Future work will examine the contribution of macrophages and *Gpr34* to OA pain, and GPR34 and macrophage gene expression in human DRGs.

CD14, a Toll-like Receptor Co-Factor, Influences Osteoclast Differentiation and Activity, but Does Not Alter Osteoblastic Potential of Bone-Marrow Precursors in Mice

Jerahme Martinez, Vu Nguyen, Cheng Zhou, George Dodge and Carla Scanzello, University of Pennsylvania, philadelphia, PA

SESSION INFORMATION

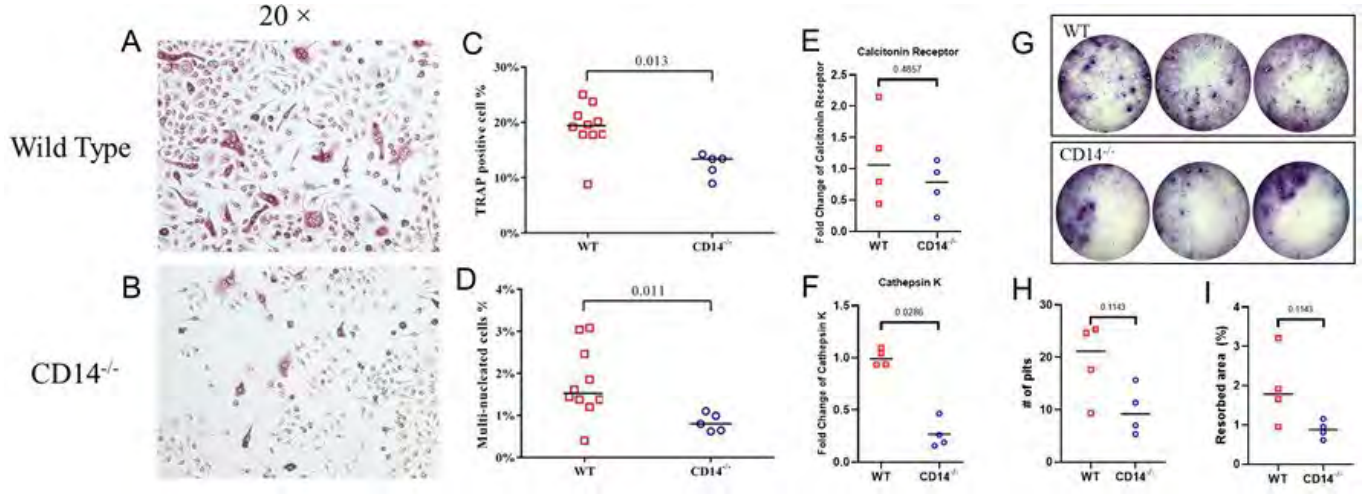
Session Date: Tuesday, November 9, 2021
Session Title: Osteoarthritis & Joint Biology – Basic Science Poster (1468–1479)
Session Type: Poster Session D
Session Time: 8:30AM–10:30AM

Background/Purpose: Changes in subchondral bone structure (SCB) occur in osteoarthritis (OA), and are visible by imaging as subchondral sclerosis on radiographs, and bone marrow lesions (BMLs) by MRI. These changes are the result of active bone remodeling that occurs in OA. BMLs are correlated with pain in OA patients. We previously demonstrated that bone remodeling was significantly reduced after joint injury in mice deficient in CD14. CD14 enhances Toll-like receptor (TLR) mediated inflammation by acting as a co-receptor for multiple TLRs, increasing TLR sensitivity to damage associated molecular patterns (DAMPS) to activate proinflammatory signaling pathways. Soluble CD14 (sCD14), TLRs, and DAMPs (TLR ligands) are all elevated in OA, and sCD14 has been implicated as a biomarker of symptom and structural severity in OA. Increasing evidence suggests TLR signaling influences bone remodeling as well, through activation of osteoclast precursor cells, but the specific role of CD14 on this process is unknown. Here, we investigate the potential mechanism by which CD14 influences bone remodeling through *in vitro* analysis of osteoclastogenic and osteoblastic potential.

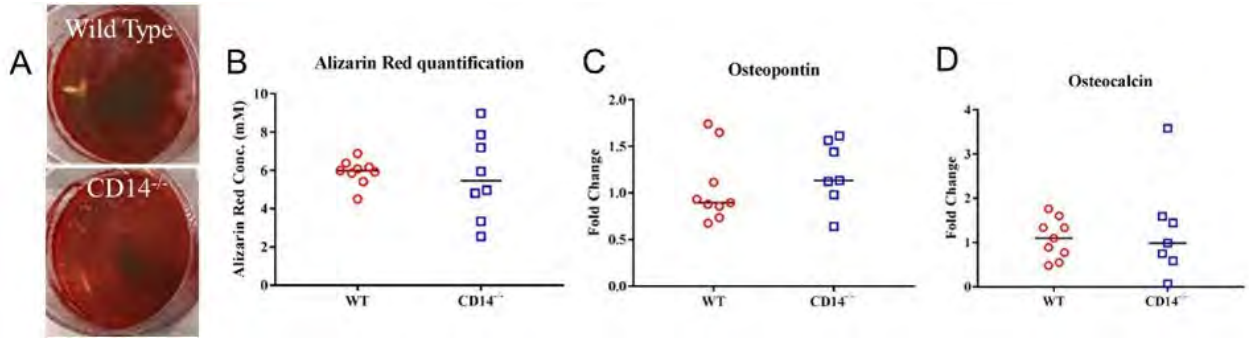
Methods: Bone marrow (BM) hematopoietic and mesenchymal precursors were isolated from long bones of male wild-type C57BL/6 (WT) and CD14-deficient ($CD14^{-/-}$) mice (12 weeks). BM cells flushed from long bones were cultured for 1 day to separate non-adherent from adherent population. Osteoclast differentiation (non-adherent cells) was stimulated by M-CSF and RANKL for 5 days. Osteoblastic cultures (adherent cells) were stimulated with β-glycerophosphate, ascorbic acid, and Dexamethasone for 19 days. Osteoclasts were identified as TRAP-positive multinucleated cells. Osteoclast activity was assessed by resorption assays on bone slices and toluidine blue staining. Osteoblast cultures were stained with Alizarin red to detect mineralization. RT-qPCR analysis was performed to detect mRNA levels of osteoclast (calcitonin receptor/CTR and cathepsin K/Ctsk) and osteoblast (osteopontin/OPN and osteocalcin/BLAP) differentiation markers.

Results: $CD14^{-/-}$ BM cells had reduced number of TRAP positive and multinucleated cells ($p = 0.01$; **Figure 1 A-D**) and reduced Ctsk mRNA ($p = 0.03$; **Figure 1 E&F**), compared to WT. $CD14^{-/-}$ cells showed a 50% reduction in resorption activity compared to WT (**Figure 1 G-I**). No significant differences were observed between strains in osteoblastic potential measured by mineralization and mRNA levels of osteoblastic markers (**Figure 2**).

Conclusion: $CD14^{-/-}$ BM precursor cells have reduced capacity to differentiate into osteoclasts, while osteoblastic potential is retained. This suggests that the reduced capacity of $CD14^{-/-}$ osteoclastic cells may impact bone remodeling in response to joint injury by disrupting the balance between resorption and formation. Future experiments will determine the influence of DAMPs relevant to OA pathogenesis on osteoclastogenesis, and the density of osteoclasts and precursors in SCB after injury. These experiments will lead to a better understanding CD14/ TLR signaling in SCB remodeling following joint injury and OA, and the potential for CD14 blockade to prevent pathologic bone remodeling in disease.



Representative TRAP staining from (A) wild type mice and (B) CD14-/- mice. (C) TRAP positive cells and (D) multinucleated cells quantitated by automated image analysis using ImageJ software. mRNA for CTR (E) and Ctsk (F) quantitated by qPCR. (G) Osteoclast activity was assayed by quantifying the (H) number of resorption pits and (I) resorption area on bone slices stained with toluidine blue.



(A&B) Alizarin Red staining of WT and CD14-/- BMMSCs after differentiation. No differences were observed between strains. This was confirmed by measuring mRNA levels of osteoblastic markers, (C) osteopontin and (D) osteocalcin.

LncRNA *XIST* Alters the Balance of Peripheral Blood Immune Cells in Systemic Lupus Erythematosus by Regulating the *miR-17-92/OFLM4* and *CEACAM8* Axis

Qi Cheng, Mo Chen, xin Chen, peiyu zhang, huaxiang wu and yan du, Second Affiliated Hospital of Zhejiang University School of Medicine, Hangzhou, China (People's Republic)

SESSION INFORMATION
Session Date: Tuesday, November 9, 2021
Session Title: SLE – Etiology & Pathogenesis Poster (1480–1506)
Session Type: Poster Session D
Session Time: 8:30AM–10:30AM

Background/Purpose: X-inactive-specific transcript (*XIST*) has been shown to silence linked genes on the X chromosome that may be related to the pathogenesis of systemic lupus erythematosus (SLE) in female patients. However, the function of XIST in SLE at other levels remains unclear. The present study aimed to clarify the correlations between *XIST* expression and SLE clinical features and the contribution of *XIST* to SLE pathogenesis at the transcriptome level.

Methods: Expression of *XIST* in 79 SLE patients and 23 healthy controls was detected by quantitative-polymerase chain reaction. Bioinformatics methods were used to explore the function and regulatory mechanism of *XIST*.

Results: Expression of XIST was significantly upregulated in SLE patients compared with healthy controls (Figure 1A, $p = 0.0043$), and had a high diagnostic value for SLE (Figure 1B, AUC = 0.762, 95% CI: 0.658 to 0.867, $p = 0.000136$). Compared with male patients and older patients, *XIST* was significantly upregulated in female patients (Figure 1C, $p = 0.0162$) and younger patients (Figure 1D, $p = 0.0429$). Moreover, *XIST* was highly expressed in patients with arthralgia (Figure 1E, $p = 0.0222$). Importantly, SLE patients with high expression of XIST tended to have elevated levels of total T cells and CD8+ T cells, but reduced levels of Treg cells and NK cells. Bioinformatics analyses suggested that XIST may regulate the expression of *OLFM4* and *CEACAM8* by acting as a spongy body for *miR-20a*, *miR-92a*, *miR-106a*, and *miR-449a* (Figure 2). Furthermore, *OLFM4* and *CEACAM8* are significantly upregulated in SLE patients and had significant positive correlations with expression of *XIST*.

Conclusion: We propose that *XIST* may alter the balance of peripheral blood immune cells in SLE by acting as a spongy body for the *miR-17-92* cluster and promoting the expression of *OLFM4* and *CEACAM8*, resulting in immune dysregulation and tissue damage in SLE.

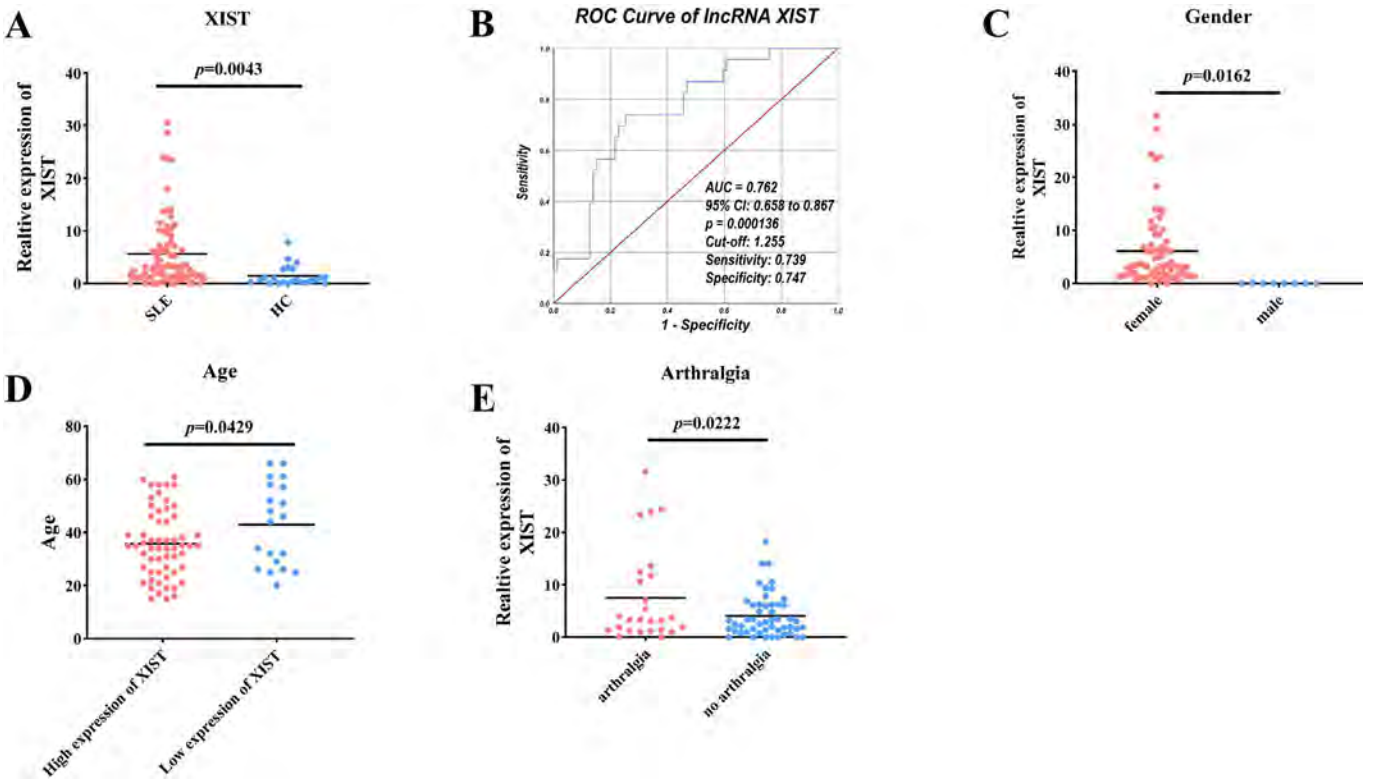

Figure 1. Expression of lncRNA XIST and its diagnostic value for SLE. A. Expression of XIST in SLE patients and healthy controls. B. ROC curves of XIST in the two groups. C and D. XIST is significantly upregulated in female (C) and young (D) patients. E. XIST is highly expressed in patients with arthralgia.

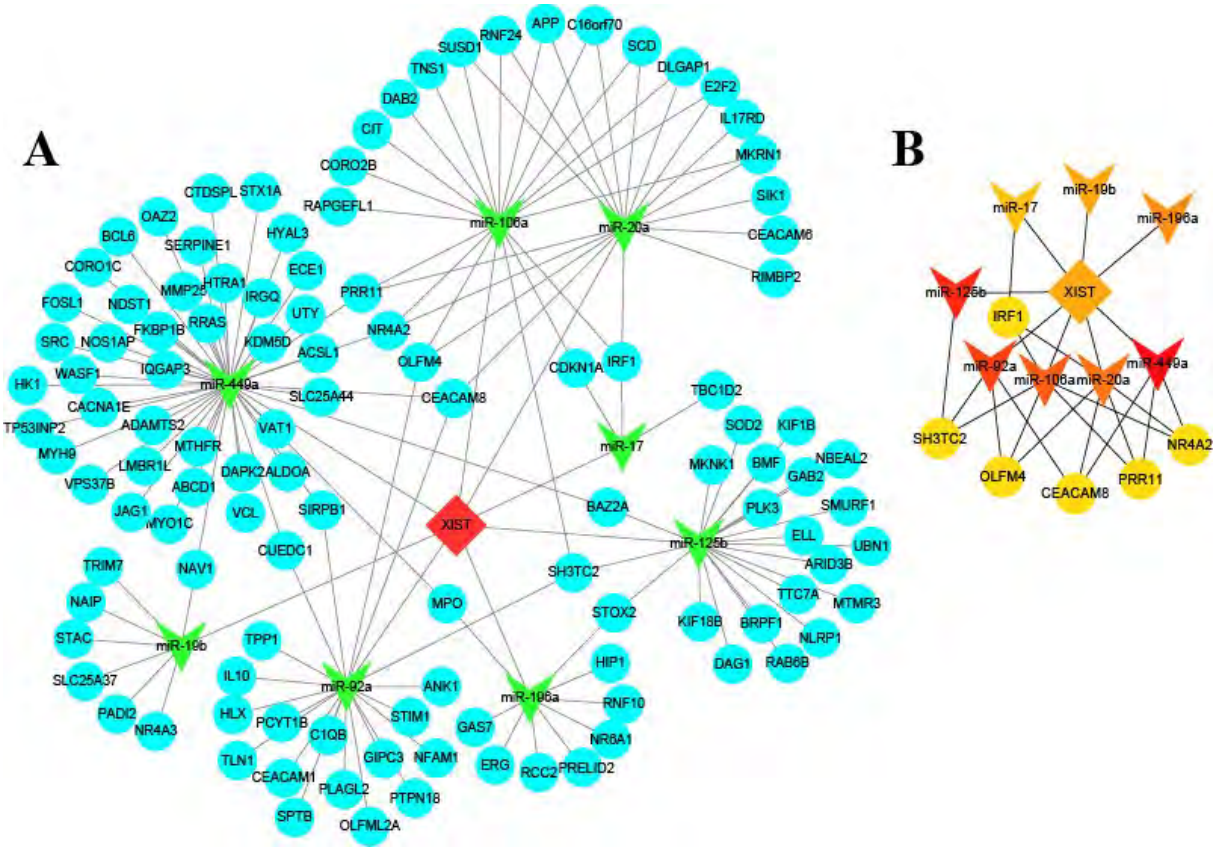

Figure 2. Function and regulatory mechanism of XIST at transcriptome level. A.The ceRNA network was composed of 1 lncRNA, 8 miRNAs, 115 mRNAs, and 150 edges. Each edge represents one interaction between two transcripts. Red diamond, lncRNA; green V, miRNA; sky-blue circle, mRNA. B. Subnetwork of hub transcripts constructed by Cytoscape and its plug-in Cytohubba.

Session Title: SLE – Etiology & Pathogenesis Poster (1480–1506)
Session Type: Poster Session D
Session Time: 8:30AM–10:30AM

Background/Purpose: Systemic lupus erythematosus (SLE) is a heterogenous autoimmune disease characterized by a global loss of self-tolerance. Although autoantibodies are an important hallmark of SLE, many autoantibodies are not specific for SLE or for a specific SLE manifestation. Post-translational modifications (PTMs), including citrullination and carbamylation, have been studied extensively in rheumatoid arthritis and antibodies against these PTMs are

Table 1. Prevalence of antibodies against specific post-translational modifications in patients with systemic lupus erythematosus (SLE) and healthy controls

	SLE patients (n = 349)		Healthy controls (n = 108)	
		n, % positive		*n, % positive*
Anti-MAA	35.2 [0 – 428]*	101 (29)	23.0 [0 – 54]	3 (3)
Anti-AGE	111.8 [0 – 1627]*	63 (18)	80.0 [0 – 436]	4 (4)
Anti-CarP	126.3 [0 – 1136]*	49 (14)	34.9 [0 – 1208]	5 (5)
Anti-Cit	3.2 [0 – 201]	22 (6)	3.3 [0 – 32]	3 (3)
Anti-AL	7.8 [0 – 615]	29 (8)	3.8 [0 – 243]	8 (7)
Anti-NT	44.0 [0 - 3510]	17 (5)	9.5 [0 – 3613]	8 (7)

Levels are presented as median [range] * $p \leq 0.0001$

MAA = malondialdehyde-acetaldehyde adduct; AGE = advanced glycation end-product; CarP = carbamylated protein; Cit = citrullinated protein; AL = acetylated protein; NT = nitrated protein.

associated with disease progression. While PTMs have also been detected in SLE patients, studies on the presence of anti-PTM antibodies and the relation to clinical aspects remain limited.

Methods: IgG antibody responses against six PTMs (malondialdehyde-acetaldehyde adducts (MAA), advanced glycation end-products (AGE), carbamylation (CarP), citrullination (Cit), acetylation (AL) and nitration (NT)) were tested using enzyme-linked immunosorbent assays in sera of SLE patients and compared to 108 healthy controls. Serum of SLE patients visiting the neuropsychiatric SLE (NPSLE) clinic of the Leiden University Medical Center between 2007-2019 was used. Levels and positivity of anti-PTM antibodies were correlated with clinical features and SLE manifestations.

Results: 349 patients with SLE were included in this study: 87% female and a mean age of 44 ± 13 years. Anti-MAA, -AGE and -CarP antibodies showed significantly higher positivity in SLE compared to controls, as shown in *Table 1* (all $p \leq 0.0001$). Anti-MAA and anti-AGE antibodies both correlated with clinical and serological measures associated with SLE, including complement consumption (low C3/C4) and Systemic Lupus Erythematosus Disease Activity Index (SLEDAI-2K). Patients with major NPSLE showed higher positivity of anti-MAA antibodies (39 vs 24%, $p = 0.007$) and anti-CarP antibodies (20 vs 11%, $p = 0.042$) compared to patients without NPSLE.

Conclusion: SLE patients have anti-PTM antibodies against MAA, AGE and CarP modified proteins. Interestingly, anti-MAA antibodies clearly associate with major NPSLE, a clinical condition for which virtually no biomarkers exist.

LN Urinary Proteomics Reveals Common Biological Pathways Identified by Distinct Disease Measures

Paul Newcombe[1], Madhu Ramaswamy[2], Dominic Sinibaldi[2], Catharina Lindholm[3], Frederick Jones[1], Ahmad Akhgar[2], Philip Brohawn[2], Raj Tummala[2] and Wendy White[2], [1]BioPharmaceuticals R&D, AstraZeneca, Cambridge, United Kingdom, [2]BioPharmaceuticals R&D, AstraZeneca, Gaithersburg, MD, [3]BioPharmaceuticals R&D, AstraZeneca, Gothenburg, Sweden

SESSION INFORMATION

Session Date: Tuesday, November 9, 2021

Session Title: SLE – Etiology & Pathogenesis Poster (1480–1506)

Session Type: Poster Session D

Session Time: 8:30AM–10:30AM

Background/Purpose: LN is a severe consequence of SLE and there is a huge unmet need for discovery of urine protein biomarkers that provide non-invasive surrogates of disease activity and response to therapy. The purpose of this study was to measure protein biomarkers in urine samples from a diverse cohort of LN patients and to assess their correlations with patient demographics and clinical characteristics including the renal measures of estimated glomerular filtration rate (eGFR), SLEDAI-renal (SLEDAI-R) and National Institutes of Health Activity (NIH-AI) and chronicity (NIH-CI) indices

Methods: The demographics and characteristics of the cohort of 112 patients is described in Table 1. All patients fulfilled the 1997 ACR criteria for SLE and all had biopsy-proven LN. Urine samples from patients and 16 healthy donors (HD) were analyzed for 192 proteins by Luminex and 5 by Simoa™. Protein concentrations were normalized to urinary creatinine levels. Log-concentrations of each protein was assessed for correlation with each clinical feature using linear regression adjusted for age, gender, ethnicity, disease duration, and treatment. eGFR was assessed using the cutoff of >60. The Benjamini-Hochberg procedure was used to calculate false discovery rates, with a cut-off of 0.1 used to determine significance. Statistical significance of intersections of protein lists was assessed via permutation. Pathway assessments were conducted using Ingenuity core analysis.

Results: Pre-filtering proteins for LN normalized mean concentrations to be greater than the HD mean + 1.5 SD yielded 97 distinct upregulated proteins. The largest numbers of protein-outcome associations were confounded by age (but not disease duration), gender, and MMF dose. After removing the influence of all confounders, numerous proteins showed statistically significant differential expression with respect to eGFR, SLEDAI-2K, SLEDAI-R, serum C3 and C4, NIH-AI, and NIH-CI. Conversely, no proteins were significantly correlated with LN class, race, or SDI (SLICC/ACR disease Index). The highest numbers of significant proteins were found for eGFR (55 proteins) followed by SLEDAI-R (36) and NIH-AI (20). There was a significant overlap of 11 proteins (Table 2) across these three lists (intersection $p=4.1 \times 10^{-5}$), indicating that these clinical renal measures share common biological processes. Pathway analysis of the 11 common proteins indicated enrichment for functions known to be associated with fatty acid/lipid metabolism, cardiovascular disease, cellular trafficking and immune cell infiltration

Conclusion: By analyzing LN urinary proteomics, we revealed that 3 clinical renal measures: eGFR, SLEDAI-R and NIH-AI are commonly associated with various proteins and pathways, most of which support the emerging importance of renal vascular pathology in LN.

Down-regulation of Hematopoietic Progenitor Kinase 1 by Aberrant Epigenetic Alterations in T Follicular Helper Cells Accounts for Excessive Immunity in Systemic Lupus Erythematosus

Qing Zhang[1], Huilin Zhang[2] and Yuming Xie[1], [1]Department of Dermatology, Second Xiangya Hospital, Central South University, Changsha, China (People's Republic), [2]Clinical Nursing Teaching and Research Section, Second Xiangya Hospital, Central South University, Changsha, China (People's Republic)

SESSION INFORMATION
Session Date: Tuesday, November 9, 2021
Session Title: SLE – Etiology & Pathogenesis Poster (1480–1506)
Session Type: Poster Session D
Session Time: 8:30AM–10:30AM

Background/Purpose: Recently, T follicular helper cells (Tfh cells) have been discovered to be the main $CD4^+$ T cells assisting B cells to produce antibody. Tfh cells are over activated in patients with systemic lupus erythematosus (SLE), consequently lead to excessive immunity. Hematopoietic progenitor kinase 1 (HPK1) negatively regulates T cell-mediated immune responses and TCR signal. This study aims to investigate the roles of HPK1 and the mechanisms that regulate HPK1 expression in SLE Tfh cells.

Methods: Naive $CD4^+$ T cells and B cells were isolated from 30 normal controls and 30 SLE patients. Subsequently naive $CD4^+$ T cells were induced to differentiate into Tfh cells by culturing with anti-CD3 antibody, anti-CD28 antibody, IL-6, IL-12, IL-21, and TGF-β. HPK1 mRNA and protein levels in Tfh cells were measured by quantitative PCR (qPCR) and western blot analysis respectively. The productions of IL-21, BAFF, IFNγ, IL-17A, IgM, IgG1, IgG2, and IgG3 were analyzed using ELISA. Tfh cells proliferation was evaluated with MTT assay. Numbers of histone H3 lysine 27 trimethylation (H3K27me3), H3K27 methyltransferase enhancer of zeste homolog 2 (EZH2), H3K27 demethylase jumonji domain containing 3 (JMJD3), and DNA methyltransferase 3a (DNMT3a) within the HPK1 promoter were determined by chromatin immunoprecipitation (ChIP) combined with qPCR. DNA methylation abundance at the HPK1 promoter was assessed by methylated DNA immunoprecipitation (MeDIP) combined with qPCR.

Results: HPK1 mRNA and protein levels were significantly reduced in SLE Tfh cells, and HPK1 mRNA level negatively correlated with SLE Disease Activity Index (SLEDAI). Knocking down HPK1 with siRNA in normal Tfh cells significantly elevated Tfh cells proliferation and secretions of IL-21, BAFF, IFNγ, IgG1, IgG2, and IgG3. There were no marked alters in IL-17A and IgM productions. The opposite effects were observed in SLE Tfh cells transfected with HPK1 overexpressing plasmid: Tfh cells proliferation and productions of IL-21, BAFF, IFNγ, IgG1, IgG2, and IgG3 were all alleviated. And there were no significant changes in IL-17A and IgM levels. H3K27me3, DNA methylation, and DNMT3a amounts sharply increased at the HPK1 promoter in SLE Tfh cells compared to controls. Moreover, a striking decrease was detected in JMJD3 enrichment, but no marked change in EZH2 number at the HPK1 promoter of Tfh cells from patients with SLE.

Conclusion: Our results suggest for the first time that at the HPK1 promote region of SLE Tfh cells, decreased JMJD3 binding up-regulates H3K27me3 amount, and increased DNMT3a enrichment elevates DNA methylation level. All these factors inhibit expression of HPK1 in SLE Tfh cells, leading to Tfh cells overactivation and B cells overstimulation, subsequently, the onset and progression of SLE.

Abstract Number: 1484

B Cell Intracellular IFNβ as a Unique Cellular Marker for the Development of Lupus Nephritis

Fatima Alduraibi[1], Huma Fatima[1], Winn Chatham[2], Hui-Chen Hsu[1] and John Mountz[1], [1]University of Alabama Birmingham, Birmingham, AL, [2]University of Alabama at Birmingham, Birmingham, AL

SESSION INFORMATION
Session Date: Tuesday, November 9, 2021
Session Title: SLE – Etiology & Pathogenesis Poster (1480–1506)
Session Type: Poster Session D
Session Time: 8:30AM–10:30AM

Background/Purpose: Our laboratory previously demonstrated a strong association of B cell intracellular interferon beta (IFNβ) with the development of anti-Smith/ribonuclear protein (Sm/RNP), anti-DNA, and lupus nephritis (LN) in African American (AA) systemic lupus erythematosus (SLE) patients. The objective of the present study is to determine if B cell IFNβ can be a unique SLE clinical prognostic marker and if specific histopathologic features of LN can be identified in patients with elevated B cell IFNβ.

Methods: All patients (N=80) met American College of Rheumatology (ACR) 1997 revised SLE criteria, ACR/EULAR classification criteria of SLE or Systemic Lupus International Collaborating Clinics (SLICC) classification criteria were recruited. Demographic, clinical data, and serologic manifestations included creatinine, urine protein/creatinine ratio, anti-DNA, anti-Sm, C3, and C4 were included. Intracellular IFNβ in naïve B cells was analyzed using high dimensional flow cytometry analysis. Isotype specific (IgG and IgM) anti-Sm/RNP and anti-DNA were measured using a standard ELISA method. LN class was defined based on the revised ISN/RPS (2004) criteria and included renal histopathology findings on light, electron microscopy, and immunofluorescence (IF) for IgM, IgG, IgA, C1q, and C3 staining (N=23).

Results: The most common manifestations were arthritis in 68% (n=54), photosensitivity rash in 47% (n=38), LN in 41% (n=33), and oral ulcer in 40% (n=32) of SLE patients. There was a significant positive correlation between naïve B cell IFNβ with race (AA > European American) and LN class (P=0.006, P< 0.0001, respectively). Naïve B cell IFNβ is negatively correlated with photosensitivity (P=0.0451) and oral/nasal ulcer (P=0.0031), and it did not correlate with other symptoms of SLE. Patients with elevated serum anti-Sm (P=0.032 by history; P=0.01 at the time enrollment) and anti-DNA (P=0.013 at the time enrollment) exhibited significantly higher naïve B cell IFNβ. Further, SLE patients with a higher percentage of intracellular IFNβ in naïve B cells also showed a higher serum C3 (P=0.005) and a lower circulating protein/creatinine ratio (P=0.065). Unsupervised ClustVis analysis was used to cluster histologic features associated with B cell intracellular IFNβ into two groups (Figure 1). LN group 1 (n=13) exhibited low activity (1.8±3.9, p=0.0018) and chronicity index (1.5±0.8, p=0.072) with a lower naïve B cell intracellular IFNβ (46±29%, p=0.0041) compere to LN group 2 (n=10) with high activity (5.9±3.8) and chronicity index (3.0±2.1) with a higher naïve B cell intracellular IFNβ (82±20%) (Figure 1). There was a lower incidence of wire loop lesions (p=0.0944), fibrocellular crescents (p=0.0005), fibrous crescents (p=0.0237), endocapillary hypercellularity (p=0.0449), and segmental scaring (p=0.0045) in LN group 1 compared to LN group 2 patients. Immunofluorescence did not show the significance for IgG, IgM, IgA, and C1q, and C3.

Conclusion: Our results suggest that B-cell intracellular IFNβ can be used in combination with other clinical diagnostic markers to identify patients at high risk of developing advanced LN. IFNβ blockade may be developed into individualized therapy for this subset of SLE patients.

Abstract Number: 1485

Glycosphingolipids: Potential Urine Biomarkers of Therapeutic Response in Lupus Nephritis

Tammy Nowling, Jessalyn Rodgers, Bethany Wolf, Brian Troyer and Jim Oates, Medical University of South Carolina, Charleston, SC

SESSION INFORMATION
Session Date: Tuesday, November 9, 2021
Session Title: SLE – Etiology & Pathogenesis Poster (1480–1506)
Session Type: Poster Session D
Session Time: 8:30AM–10:30AM

Background/Purpose: Lupus nephritis (LN) is a chronic, immune complex-mediated glomerulonephritis affecting up to 60% of patients with lupus. Progression of the most aggressive forms of LN (proliferative classes III and IV) to end-stage renal failure is ~20% and another ~40% develop chronic kidney disease despite aggressive treatment. Patients that fail to respond continue to accumulate organ damage. Thus, there is a critical need for noninvasive biomarkers

to predict therapeutic response. We previously demonstrated that the glycosphingolipid (GSL) lactosylceramide (LacCer) is elevated in the urine of lupus patients, and preliminary data suggests that GSLs in extracellular vesicles (EVs) in urine are higher prior to treatment in patients that do not respond to treatment. Thus, we compared levels of GSLs in urine EVs in longitudinal samples from LN patients that completely responded (CR) or did not respond (NR) to MMF treatment after one year of treatment.

Methods: EVs were isolated from longitudinal (baseline, and 3 or 12 months post-treatment) urine samples obtained from 59 LN patients (29 CR, 30 NR). All patients met ACR classification for SLE with biopsy-confirmed nephritis (93% with class III or IV LN). Criteria for CR included UPr:UCr < 0.5, normal sCr, inactive urine sediment, UPr:UCr reduced >75%, and eGFR increased >25%. NR criteria included persistent UPr:UCr >3, decreased UPr:UCr < 25%, eGFR decreased >25%, and failure to taper glucocorticoid therapy to < 10 mg/day. GSLs were quantified in the urine EV samples by SFC/MS/MS. Galectin-3 binding protein (G3BP) and gelsolin, identified in a small proteomics screen, were quantified in the urine EV samples or total urine using independent ELISAs. A panel of cytokines and chemokines were measured in total urine samples by a multiplex laser bead array.

Results: All chain lengths of Hexosylceramides (HexCers) were significantly higher ($p< 0.001$) in the baseline EV samples from NR patients (total HexCers, 48.6 ±56.9 pmol/ml/mg UCr) compared to CR patients (total HexCers, 11.7 ± 13.4 pmol/ml/mg UCr). All chain lengths of LacCers were significantly higher ($p< 0.001$) in the baseline EV samples from NR patients (total LacCers, 13.5 ± 10.9 pmol/ml/mg UCr) compared to CR patients (total LacCers, 3.5 ± 4.1 pmol/ml/mg UCr). Gelsolin levels in total urine, but not in urine EVs, were significantly different ($p=0.003$) between NR (574.8 ± 473.3 ng/mg UCr) and CR (178.1 ± 177.9 ng/mg UCr) at baseline. Total urine G3BP levels were significantly higher ($p=0.039$) in NR (282.4 ± 421.4 ng/mg UCr) compared to CR (115.2 ± 146.4 ng/mg UCr). Of the 23 cytokines/chemokines measured in total urine, 18 were detected and all 18 were significantly or showed a trends of higher levels in NR compared to CR.

Conclusion: These results suggest that in general, patients that failed to respond to therapy likely had worse disease prior to starting therapy. Urine EV levels of HexCers and LacCers, along with urinary levels of a panel of proinflammatory factors and clinical measures may be useful in identifying LN patients prior to beginning treatment that are unlikely to respond to conventional therapies.

A Novel Requirement for IFNβ1 Signaling for IFNκ Induction in Keratinocytes

Bin Xu[1], Yee Sun Tan[1], Jon Musai[1], William R Swindell[2], Mrinal Sakar[1], Johann Gudjonsson[1], J. Michelle Kahlenberg[1] and Grace Hile[1], [1]University of Michigan, Ann Arbor, MI, [2]Ohio University, Cincinnati, OH

SESSION INFORMATION
Session Date: Tuesday, November 9, 2021
Session Title: SLE – Etiology & Pathogenesis Poster (1480–1506)
Session Type: Poster Session D
Session Time: 8:30AM–10:30AM

Background/Purpose: Cutaneous lupus erythematosus (CLE) affects up to 70% of patients with systemic lupus erythematosus (SLE), and type I interferons (IFNs) are important promoters of SLE and CLE. Our previous work identified

IFN-kappa (IFNκ), a keratinocyte-produced type I IFN, as upregulated in non-lesional and lesional lupus skin and a critical regulator for enhanced UVB-mediated cell death in SLE keratinocytes. Importantly, the molecular mechanisms governing regulation of IFNκ expression have been relatively unexplored. Thus, this study sought to identify critical regulators of IFNκ and identified a novel role for IFN beta (IFNβ).

Methods: Human N/TERT keratinocytes were treated with the RNA mimic poly (I:C) or 50 mJ/cm^2 ultraviolet B (UVB), followed by mRNA expression quantification by RT-qPCR in the presence or absence of the JAK1 inhibitor baricitinib (BARI) or a neutralizing antibody to the type I IFN receptor (IFNAR). *IFNB, MYD88, IFNK, STAT1,* and *TMEM173* knockout (KO) keratinocytes were generated using CRISPR/Cas9.

Results: Time courses of poly-IC and UVB treatment revealed a differential expression of IFN genes: IFNβ was upregulated between 3-6 hours and IFNκ was upregulated 24 hours after stimulation. Intriguingly, while the upregulation of IFNβ and IFNκ was inhibited by baricitinib, only IFNκ expression was substantially abrogated by neutralizing antibodies to IFNAR, suggesting that only IFNκ upregulation required type I IFN signaling for induction. This was confirmed using *STAT1* KO keratinocytes which exhibited normal upregulation of *IFNB* but no upregulation of *IFNK* after poly-IC and UVB. The sequential nature of transcription, specifically *IFNB* followed by *IFNK* upregulation with both poly-IC and UVB treatment suggests that IFNβ1 may play a role in regulation of IFNk induction in KC. Indeed, *IFNB1* KO keratinocytes abrogated *IFNK* induction and the downstream IFN-stimulated gene MX1 expression in response to either PolyIC or UVB, suggesting that robust IFN-κ production is dependent on an initial upregulation of *IFNB*.

Conclusion: Collectively, our work describes a novel mechanistic paradigm in keratinocytes in which initial *IFNK* induction in response to PolyIC and UVB is IFNβ1-dependent. Loss of this regulatory dependence in SLE keratinocytes could be an explanation as to why IFNκ is increased in SLE skin. Further experiments to determine if this mechanism is intact or skewed in SLE keratinocytes are ongoing.

Type I Interferon Modulates Langerhans Cell ADAM17 in Lupus to Contribute to Photosensitivity

Thomas Li[1], Keila Veiga[2], Noa Schwartz[3], Jose Lora[4], Yong Liu[4], Ali Jabbari[5], William Shipman[1], Mehdi Rashighi[6], James Krueger[7], Niroshana Anandasabapathy[4], David Oliver[8], Yurii Chinenov[8], Carl Blobel[1] and Theresa Lu[1], [1]Hospital for Special Surgery, New York, NY, [2]New York Medical College, Hawthorne, NY, [3]Albert Einstein College of Medicine/Montefiore Medical Center, New York, NY, [4]Weill Cornell Medicine, New York, NY, [5]University of Iowa, Iowa City, IA, [6]University of Massachusetts Medical School, Worcester, MA, [7]Rockefeller University, New York, NY, [8]David Z. SESSION INFORMATION
Session Date: Tuesday, November 9, 2021
Session Title: SLE – Etiology & Pathogenesis Poster (1480–1506)
Session Type: Poster Session D
Session Time: 8:30AM–10:30AM

Background/Purpose: Photosensitivity is a common feature in the autoimmune disease lupus erythematosus (LE) where patients develop inflammatory skin lesions in response to ultraviolet radiation (UVR). In patients with the sys-

temic form of the disease (SLE), photosensitivity can also be associated with serious flares of systemic disease. As current treatments are limited, mechanistic understanding of photosensitivity can lead to better care and quality of life. We recently showed that Langerhans cells (LCs) limit UVR-induced keratinocyte apoptosis and skin injury via ADAM17-mediated EGFR ligand activation and that reduced LC ADAM17 activity in two lupus models contributed to their photosensitivity. However, what causes LC dysfunction in the lupus models is not known. Type I interferon (IFN-I) is elevated in SLE non-lesional skin, and anifrolumab (anti-IFNAR) showed efficacy in human cutaneous disease, suggesting a pathogenic role for IFN-I in SLE skin. This led us to assess a role for IFN-I in LC ADAM17 dysfunction.

Methods: To assess IFN-I gene signature, microarray of non-lesional skin from human cutaneous LE and RNA sequencing of whole skin from lupus mouse models were performed. To quantify LC ADAM17 activity and expression, flow cytometric-based assays were conducted using human and murine LCs. To evaluate photosensitivity, skin inflammation and cellular infiltrate were measured and characterized using *in vivo* lupus models.

Results: We show that non-lesional skin from human cutaneous LE and photosensitive MRL/lpr and B6.Sle1yaa mice have IFN-I signatures and that IFN-I is sufficient to reduce human and murine LC ADAM17 activity independently of surface ADAM17 levels. IFN-I-induced LC ADAM17 activity defects were abrogated with tofaticinib, a JAK kinase inhibitor approved for rheumatoid arthritis and other inflammatory diseases. We further show that anti-IFNAR1 treatment prior to UVR exposure in lupus models restores LC ADAM17 activity and limits photosensitivity.

Conclusion: Together, our results suggest that LC ADAM17 is dysregulated by the elevated IFN-I associated with disease and IFN-I contributes to LE skin disease, in part, by causing LC dysfunction.

Abstract Number: 1488

Metabolic Alterations of Systemic Lupus Erythematosus NK Cells Determine Response to Anti-CD38 and Anti-SLAMF7 Monoclonal Antibodies

Morgane Humbel, Natalia Fluder, Florence Bellanger, Alice Horisberger, Craig Fenwick, Camillo Ribi and Denis Comte, CHUV, Lausanne, Switzerland

SESSION INFORMATION
Session Date: Tuesday, November 9, 2021
Session Title: SLE – Etiology & Pathogenesis Poster (1480–1506)
Session Type: Poster Session D
Session Time: 8:30AM–10:30AM

Background/Purpose: Systemic lupus erythematosus (SLE) is a multisystem inflammatory condition of unknown pathogenesis. We have previously shown that SLE Natural killer (NK) cells are decreased in count and display a dysfunctional cytotoxicity. In addition, engagement of SLAMF7 with elotuzumab and CD38 with daratumumab restores the cytotoxic capacity of SLE NK cells. Furthermore, priming of SLE NK cells with daratumumab promotes the specific destruction of antibody-producing circulating plasma cells (cPC).

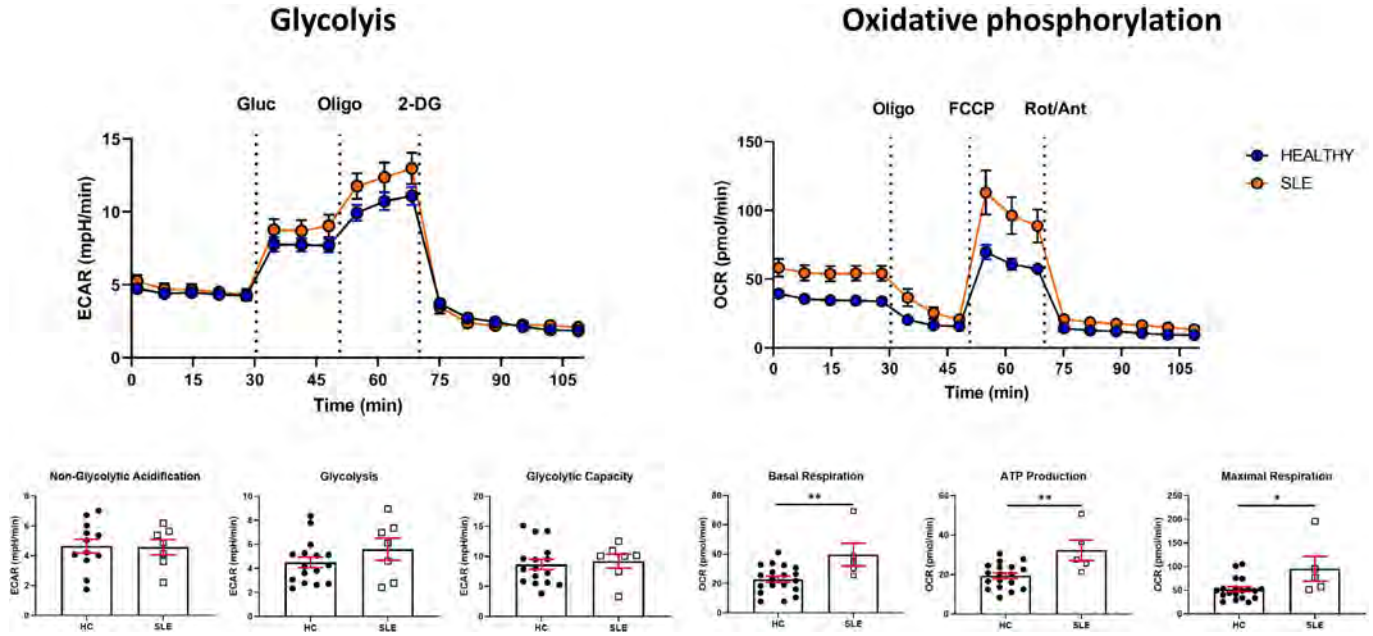

Figure 1. Oxidative phosphorylaation is increased in SLE NK cells. Glycolytic metabolism measured as extracellular acidification rate (ECAR) upon addition of glucose (Gluc), oligomycin (Oligo) and 2-Deoxy-glucose (2-DG) in NK cells of HC (n=13) and SLE (n=7) shows no statistical difference (Welch's T-test, points represent mean±SEM). Oxidative phosphorylation measured as oxygen consumption rate (OCR) upont addition of oligomycin (Oligo), FCCP, rotenone and antimycin-A (Rot/AA) in NK cells of HC (n=19) and SLE (n=9) shows a significatively higher basal respiration, ATP production and maximal respiration in SLE NK cells (Welch's T test, p*<0.003, **p<0.002, ***p<0.001).

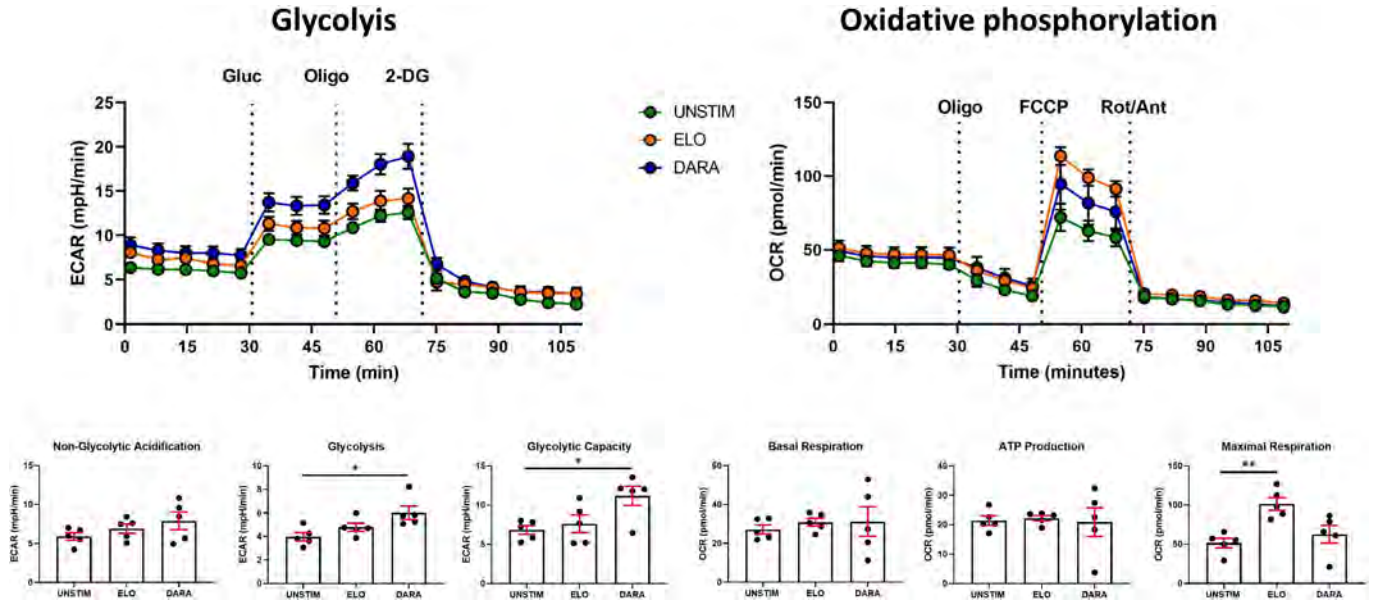

Figure 2. Daratumumab primarily promotes glycolysis and elotuzumab oxidative phosphorylation of NK cells. Stimulation of healthy NK cells with daratumumab significantly promotes glycolysis and glycolytic capacity compared to unstimulated condition (n=5,One-way ANOVA). Stimulation of healthy NK cells with elotuzumab significantly increases the maximal respiration (n=5, One-way ANOVA, p*<0.003, **p<0.002, ***p<0.001).

To deeper understand the alterations that characterize SLE NK cells and the contribution of CD38 and SLAMF7 in their dysfunction, we examined the cellular metabolism of SLE NK cell and how the ligation of daratumumab and elotuzumab influences the major metabolic pathways involved in NK cell activation.

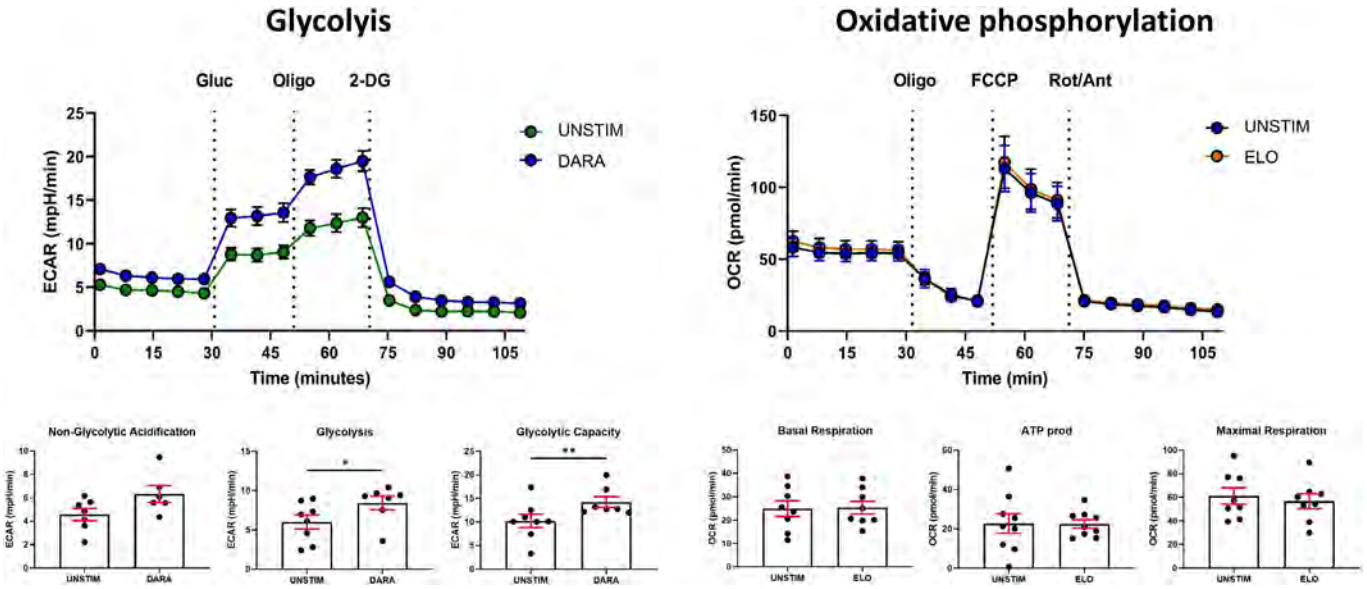

Figure 3. Daratumumab promotes glycolysis but elotuzumab has no effect on oxidative phosphorylation of SLE NK cells. Stimualtion of SLE NK cells with daratumumab significantly increases glycolysis and glycolytic capacity (n=7, Welch's T test), similarly to what was observed on healthy cells. Stimualtion of SLE NK cells with elotuzumab, contrarily to what was observed in healthy cells, has no impact on the oxidative phosphorylation (n=9, Welch's T test, p*<0.003, **p<0.002, ***p<0.001).

Methods: Cryopreserved PBMC from SLE patients and healthy controls were thawed to isolate NK cells by positive selection. Immunometabolism was assessed using XFe96 Seahorse. Analysis of glycolysis was measured by extracellular acidification rate (ECAR) and oxidative phosphorylation by oxidative consumption rate (OCR), after stimulations with mentioned conditions.

Results: We analyzed the cellular metabolic alterations of SLE NK cells. We showed that SLE NK cellular glycolysis is unaltered compared to healthy NK cells, whereas oxidative phosphorylation is increased (Figure1). In addition, the engagement of CD38 with daratumumab and SLAMF7 with elotuzumab activated different metabolic pathways in healthy NK cells: daratumumab primarily enhanced NK cell glycolysis, while elotuzumab increased oxidative phosphorylation (Figure 2). In SLE patients, daratumumab increased NK cell cellular glycolysis and had no significant effect on oxidative phosphorylation, while elotuzumab showed no significant effect on glycolysis or oxidative phosphorylation (Figure 3).

Conclusion: SLE NK cells exhibit abnormally high oxidative phosphorylation, while cellular glycolysis is normal.

Additionally, daratumumab and elotuzumab both enhance the degranulation of SLE NK cells, but only SLE NK cells activated with daratumumab have the ability to kill cPC, thus limiting the production of autoantibodies. This difference is likely explained by the fact that the two antibodies activate NK cells by enhancing two different metabolic pathways. Daratumumab primarily promotes glycolysis, while elotuzumab mainly increases oxidative phosphorylation, which is already abnormally high in SLE NK cells and cannot be increased further.

Session Title: SLE – Etiology & Pathogenesis Poster (1480–1506)

Session Type: Poster Session D

Session Time: 8:30AM–10:30AM

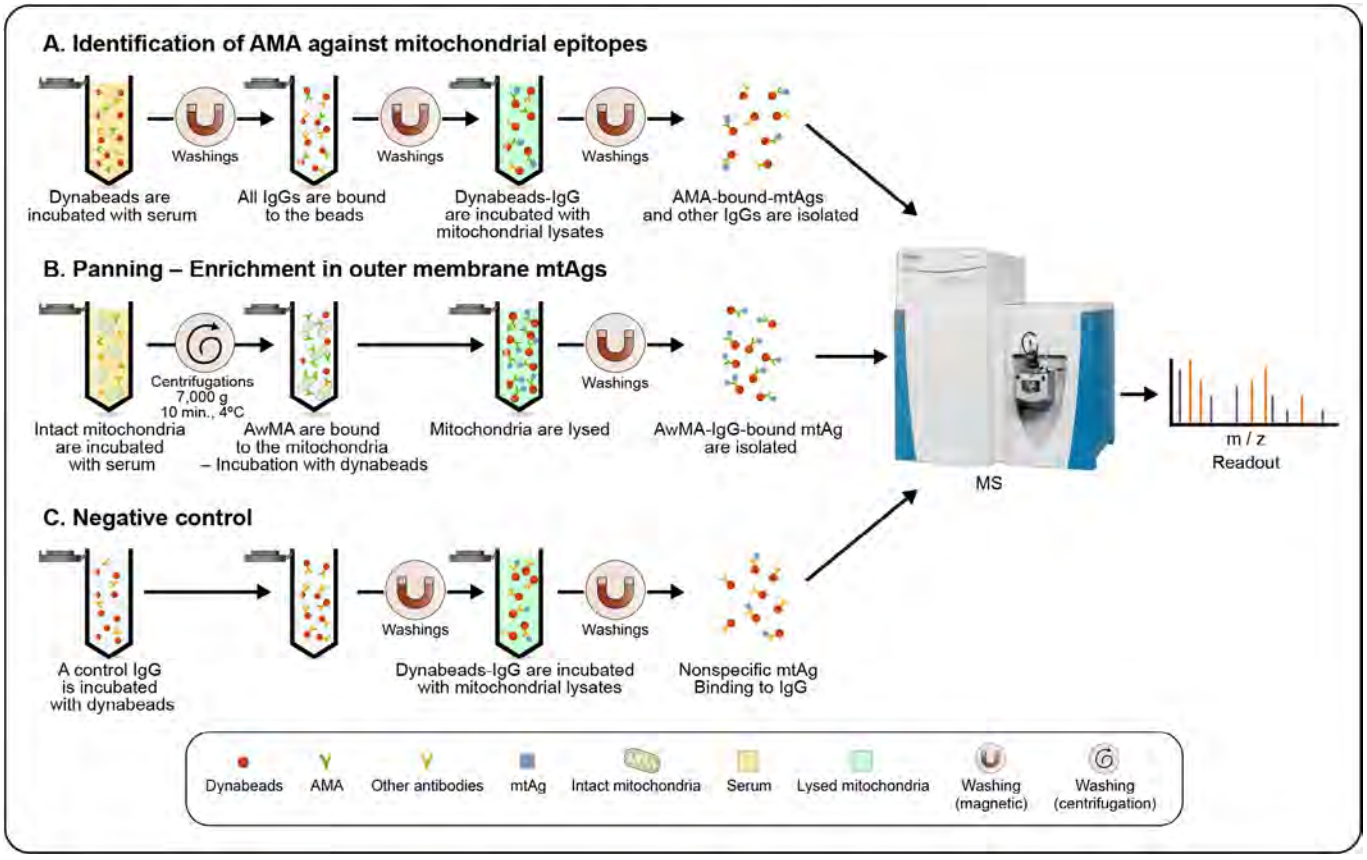

Figure 1. Workflow used for the detection of mitochondrial antigens targeted by anti mitochondrial antibodies in SLE. (a) Antibodies of the IgG subclass are isolated, using Dynabeads®-Protein G, from pooled sera from either 10 healthy donors or 10 SLE patients with high levels of anti-whole mitochondrial IgG (AwMA IgG). Dynabeads®-bound IgG were subsequently incubated with mitochondrial lysates, allowing the affinity purification of mitochondrial antigens (mtAgs) from all sub-localizations. (b) Freshly isolated intact mitochondria were incubated with pooled sera. Mitochondria incubated with AwMA were then lysed and AwMA-IgG isolated with Dynabeads™. (c) An irrelevant monoclonal IgG targeting FcγRIIa – a protein absent from mitochondria, is bound to Dynabeads™ and incubated with mitochondrial lysates in order to identify non-specific binding of mtAgs. For each approach, samples were acquired in triplicate and mtAgs were identified by mass-spectrometry (MS).

Background/Purpose: Mitochondria are organelles that possess several bacterial features such as a double-stranded genome with hypomethylated CpG islets, formylated proteins, and a double membrane composed of cardiolipin. In systemic lupus erythematosus (SLE), mitochondria and their inner components are released into the extracellular space, potentially eliciting a pro-inflammatory response by the immune system. While cardiolipin and mitochondrial DNA (mtDNA) and RNA (mtRNA) are confirmed targets of autoantibodies, antigenic mitochondrial proteins in SLE remain to be identified. Herein, we aim to characterize the antigenic protein repertoire recognized by anti-mitochondrial antibodies in SLE patients.

Methods: SLE (n=87) and healthy controls (n=30) agreed to participate to our systemic autoimmune rheumatic diseases biobank and database. Sociodemographic and disease characteristic variables [e.g., ACR classification criteria, SLEDAI-2K, SLICC/ACR damage index (SDI), comorbidities] as well as serum samples were collected at the time of the inclusion of the patients in the systemic autoimmune rheumatic disease biobank and data repository. The anti-dsDNA, IgGs against anticardiolipin or anti-β_2GPI (i.e., cut-offs of 40 UPL or above the 99th percentile of controls) were measured by ELISA. Lupus anticoagulant assay was performed, following international guidelines for this functional assay. Healthy controls were recruited under the conditions of having no known illnesses and infectious symptoms at the time of the blood draw. Autoantibodies against whole mitochondria (AwMA), mtDNA (AmtDNA) and mtRNA (AmtRNA) were previously assessed. Sera of either 10 healthy donors or 10 SLE patients with high titers of AwMA were pooled and incubated with sources of mitochondrial antigens (**Figure 1**) and IgG were isolated, using Dynabeads-protein G. Identification of mitochondrial proteins associated to IgGs were performed in triplicates by shotgun proteomic analysis. Immunoreactivities to C1qBP and Mfn1 were assessed by direct ELISA. Comparisons

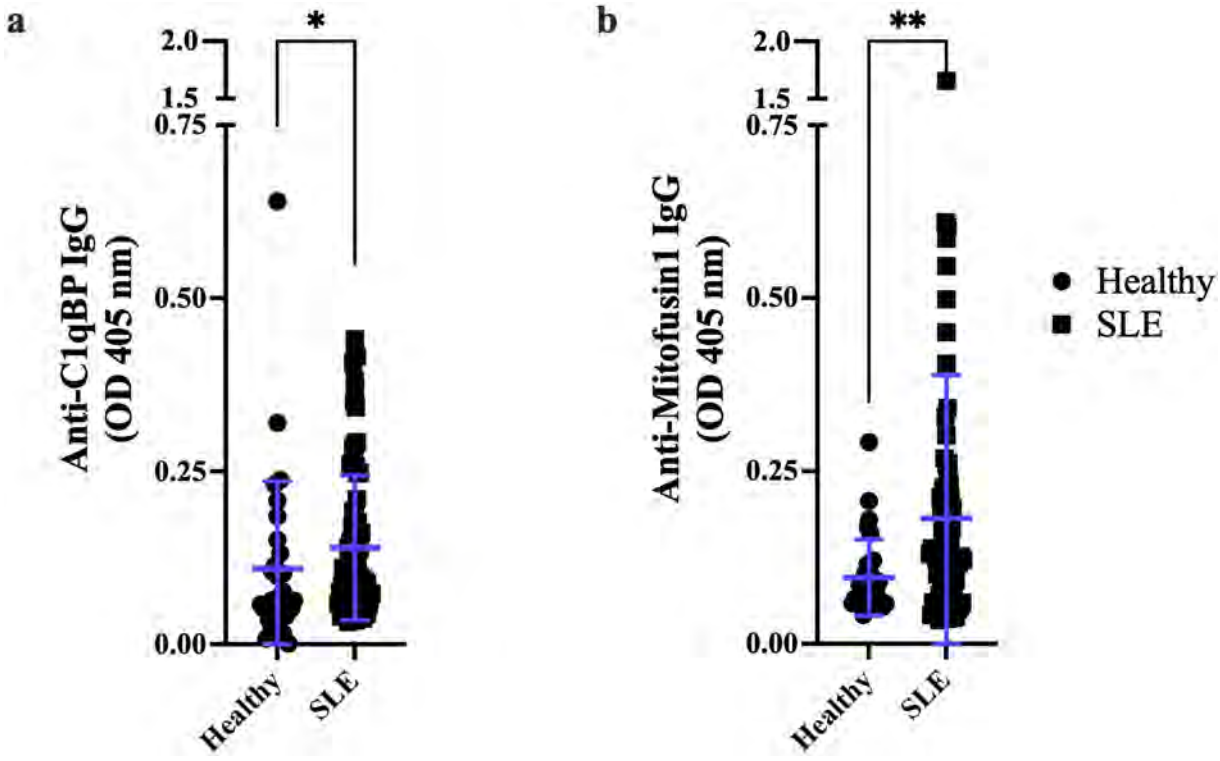

Figure 2. C1qBP and Mfn1 are two surface mtAgs with increased immunoreactivity in SLE. Immunoreactivity against mitochondrial proteins was assessed by direct ELISA. (a) The receptor for the complement component C1q (C1qBP) is a protein stored within the mitochondrion and subsequently dispatched to the cell surface and/or released into the extracellular space. SLE patients display increased levels of IgGs targeting C1qBP, compared with healthy individuals (p=0.0167). (b) Mitofusin 1 (Mfn1) is a protein expressed at the surface of the mitochondrion and is responsible for the fusion of mitochondrial outer membranes; anti Mfn 1 IgG are significantly increased in patients with SLE, compared with healthy donors (p=0.0022). Healthy: n=30, SLE: n=87. Data are mean optical densities read at 405 nm (OD405 nm) ± standard deviation. Wilcoxon-Mann-Whitney test. *: p≤0.05; **: p<0.01.

Table 1. Correlations between anti-C1qBP, anti-Mitofusin 1 and various continuous variables in SLE patients. Correlations presented, herein, for anticardiolipins or anti-β2-GPI were tested for IgGs

			Anti-C1qBP	Anti-Mitofusin 1
Clinical serology	Anticardiolipin antibodies (n = 80)		$r_s = 0.25$ $p = 0.02$	$r_s = 0.45$ $p < 0.0001$
	Anti-β_2 Glycoprotein I (n = 80)		$r_s = 0.12$ $p = 0.28$	$r_s = 0.26$ $p = 0.02$
	Anti-double-stranded DNA (n = 22)		$r_s = 0.11$ $p = 0.63$	$r_s = 0.44$ $p = 0.04$
Anti-mitochondrial antibodies	Anti whole mitochondria (AwMA)	IgG	$r_s = 0.32$ $p = 0.003$	$r_s = 0.65$ $p < 0.0001$
		IgM	$r_s = 0.08$ $p = 0.46$	$r_s = 0.31$ $p = 0.003$
	Anti-mitochondrial DNA (AmtDNA)	IgG	$r_s = 0.23$ $p = 0.03$	$r_s = 0.52$ $p < 0.0001$
		IgM	$r_s = 0.07$ $p = 0.50$	$r_s = 0.24$ $p = 0.03$
	Anti-mitochondrial RNA (AmtRNA)	IgG	$r_s = 0.03$ $p = 0.75$	$r_s = 0.27$ $p = 0.01$
		IgM	$r_s = 0.03$ $p = 0.82$	$r_s = 0.27$ $p = 0.01$

between groups were performed using the Wilcoxon-Mann-Whitney test. Spearman correlations were calculated to see associations between AMA and antibodies assessed in clinical laboratory.

Results: We identified 1345 proteins, 431 of which were associated with the mitochondrial proteome. Autoantibodies to two candidates, namely to the complement component 1 Q subcomponent-binding protein (C1qBP) and mitofusin 1 (Mfn1) were significantly increased in SLE patients compared to healthy individuals (anti-C1qBP: p=0.0167, anti-Mfn1: p=0.0022. **Figure 2**). Patients with positive lupus anticoagulant had increased anti-C1qBP (p=0.049), while anti-Mfn1 levels were increased in patients positive for antiphospholipids (p=0.011). Levels of Anti-Mfn1 were associated with those of IgGs to anticardiolipin (r_s=0.454; p< 0.0001), anti-β_2GPI (r_s=0.261; p=0.019) and anti-dsDNA (r_s=0.443; p=0.039) (**Table 1**).

Conclusion: These results suggest that autoantibodies to C1qBP and Mfn1 are comprised represented within the AMA repertoire in SLE and display different associations with serological criteria in the disease.

Myeloid and B Cell Transcriptional Phenotypes Reveal Race Dependent Differences in Early Autoimmunity

Aleksandra Bylinska, Samantha Slight-Webb, Kevin Thomas, Miles Smith, Susan Macwana, Nicolas Dominguez, Eliza Chakravarty, Joan Merrill, Judith James and Joel Guthridge, Oklahoma Medical Research Foundation, Oklahoma City, OK

SESSION INFORMATION
Session Date: Tuesday, November 9, 2021
Session Title: SLE – Etiology & Pathogenesis Poster (1480–1506)
Session Type: Poster Session D
Session Time: 8:30AM–10:30AM

Background/Purpose: Early immune events leading to clinical autoimmune disease are complex and the pathways involved remain incompletely defined. Anti-nuclear antibody (ANA) positivity is a feature of several autoimmune diseases; however, up to 20% of healthy women are ANA+, and most will never develop clinical autoimmune disease. We have previously evaluated T cells in healthy ANA+ individuals, and found differences by race. European American (EA) ANA+ subjects, at lower risk for transition to autoimmunity, had T cells with a decreased interferon (IFN) gene signature compared to ANA- healthy and EA SLE patients. T Cells of ANA+ African Americans (AA) had greater expression of IFN and activation markers. The current project evaluated the impact of race on gene expression in B Cells and myeloid cells of healthy ANA - and ANA+ individuals as well as SLE patients.

Methods: scRNA-seq and CITE-seq was performed on healthy EA and AA ANA- (n=12), and ANA+ (n=12) people, and SLE patients (n=12). CD2 depleted peripheral blood mononuclear cells were used to determine B cell and myeloid cell subset frequencies and identify differential gene signatures. Library preparation was done on a 10X Genomics® Chromium instrument and sequencing was completed on Illumina NextSeq. Analyses using Seurat package in R were used to identify and visualize distinct cell clusters, while clusterProfiler was used for gene enrichment and pathway analyses.

Results: Cells from all subjects clustered into 14 unique B cell populations and 6 distinctive myeloid cell populations. IgE+ B cells and several naïve B cell clusters frequencies were elevated in B cells of ANA+ healthy people compared to ANA- controls. Gene enrichment analyses revealed greater neutrophil activation and degranulation in AA ANA+ and SLE patients ($Q < 0.0025$), and greater expression of T cell stimulatory signals (CD52, HLA-Class I and II, ISG) ($Q < 0.00006$) in classical monocytes (CD14+CD16-) than EA subjects. Both EA and AA patients with SLE had gene enrichment in transcription initiation, viral transcription, and protein targeting to the endoplasmic reticulum ($Q < 0.0005$) with modest enrichment found in ANA+ healthy individuals ($Q < 0.01$). EA ANA+ healthy individuals also had enrichment of gene pathways involved in regulation of viral life cycle ($Q=0.01$), regulation of viral entry into the host cell ($Q=0.01$), and negative regulation of the viral process ($Q=0.01$). Expression of these pathways was reduced in SLE patients and not found in AA ANA+ healthy samples. S100 gene expression was increased with disease in both EA and AA SLE patients ($Q < 0.00007$); however, AA ANA+, AA SLE patients ($Q < 0.002$) and even AA ANA- controls ($Q < 0.0007$) had higher expression of genes in the S100 pro-inflammatory family than EA subjects.

Conclusion: In healthy ANA+ individuals, gene expression pathways in myeloid and B cell subsets are altered. Healthy ANA+ African Americans exhibit heightened gene expression in cellular activation pathways and decreases in certain viral regulatory networks, suggesting an ongoing struggle with viral-like stimuli which may enhance their risk for progression to clinical autoimmunity.

SESSION INFORMATION

Session Date: Tuesday, November 9, 2021

Session Title: SLE – Etiology & Pathogenesis Poster (1480–1506)

Session Type: Poster Session D

Session Time: 8:30AM–10:30AM

Background/Purpose: Cutaneous lupus erythematosus (CLE) is an incompletely understood autoimmune disease that can occur in isolation or in the context of SLE. CLE is often disfiguring, and no FDA-approved therapies exist. Further, evidence suggests skin inflammation in CLE can provoke systemic autoimmune disease, including precipitating nephritis. Thus, understanding CLE pathogenesis has great potential to alleviate lupus morbidity and even mortality.

Methods: We used single-cell RNA sequencing (scRNA-seq) to investigate cellular transcriptomes in lesional skin, sun-protected nonlesional skin, and peripheral blood mononuclear cell (PBMC) samples from 7 CLE patients. 6 of 7 patients met ACR criteria for SLE. Data were analyzed in combination with control skin biopsies taken from 14 healthy patients and PBMCs from 4 healthy donors using Seurat. Keratinocytes (KCs), melanocytes, eccrine gland

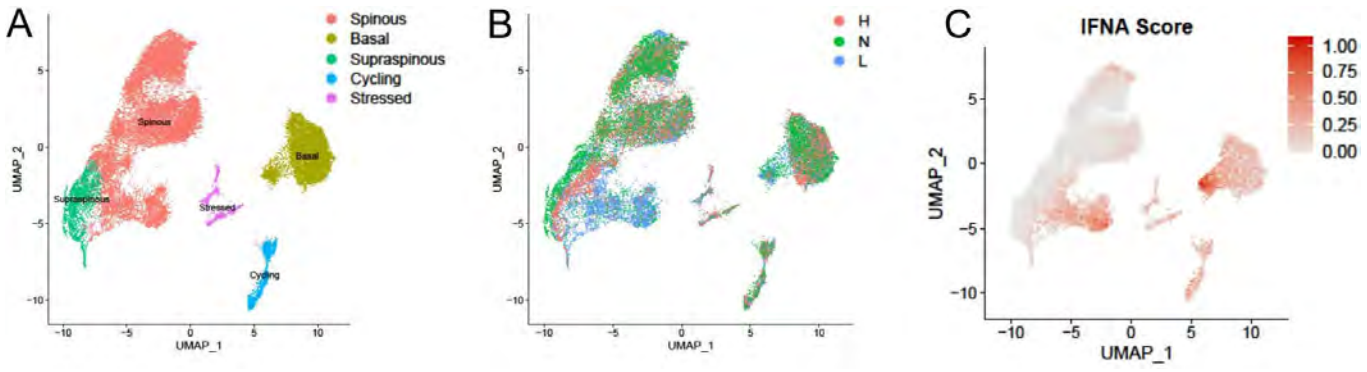

Figure 1. KC sub-clustering. A. KC subsets. B. KCs colored by origin; healthy (H), nonlesional lupus (N), lesional lupus (L) skin. C. KCs colored by IFNα cytokine module scores.

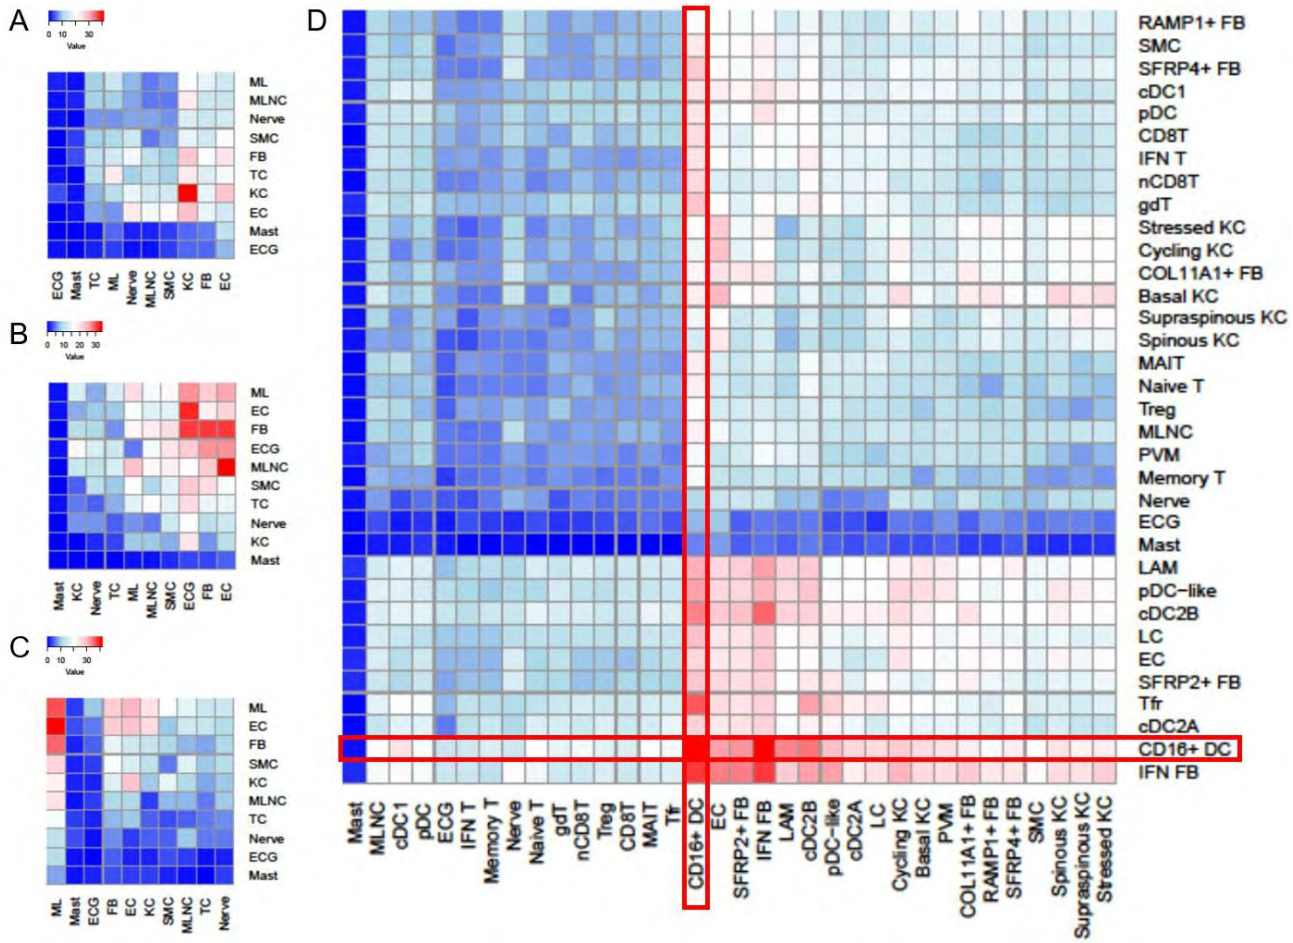

Figure 2. Number of predicted ligand-receptor interactions in skin. Red, more interactions. ML, myeloid cell. MLNC, melanocyte. SMC, smooth muscle cell. TC, T cell. EC, endothelial cell. ECG, eccrine gland. A. Control skin. B. Nonlesional lupus skin. C. Lesional lupus skin. D. Receptor-ligand interactions of detailed cell subsets in the skin.

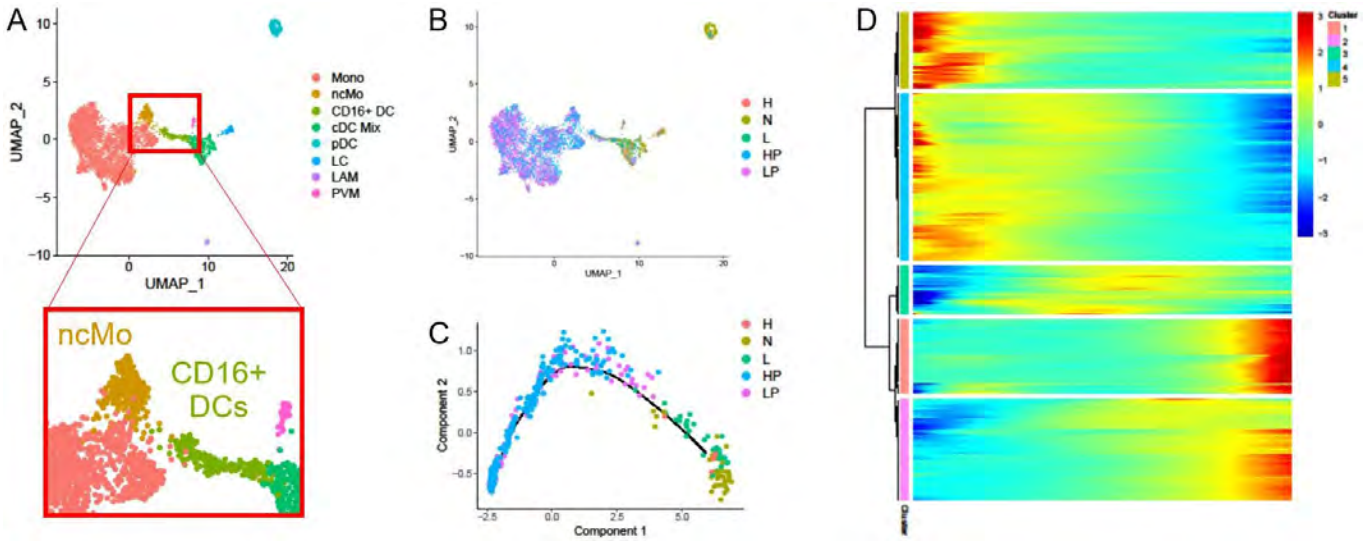

Figure 3. CD16+ DCs may arise from circulating non-classical monocytes (ncMo). A. Myeloid cells from paired skin and PBMC samples colored by subset. Mono, classical monocyte. B. Colored by origin. HP, healthy PBMC. LP, lupus PBMC. C. Pseudotime projection of the transition of ncMo to CD16+ DC. D. Gene markers cluster into five expression patterns across pseudotime.

cells, endothelial cells, fibroblasts (FBs), smooth muscle cells, nerve cells, T cells, myeloid cells, and mast cells were identified. KCs, FBs, T cells, and myeloid cells were sub-clustered and cell subsets annotated. Cytokine module scores were calculated for KCs and FBs using signature genes induced upon treatment of KCs and FBs with panels of cytokines. Cell-cell communication was examined using CellPhoneDB to perform ligand-receptor analysis for select cell subsets. To further investigate cellular interactions, spatial sequencing was performed, and cell signatures derived from scRNA-seq were used to identify the proximity of different cell types in lesional skin from a patient with DLE. Finally, pseudotime analysis was performed on cells bridging the connection between circulating and skin-resident myeloid cells.

Results: Both lesional and nonlesional SLE/CLE KCs showed very strong type I IFN signature scores (**Figure 1**). Lesional and nonlesional SLE/CLE skin exhibited dramatic shifts in cell-cell crosstalk (**Figure 2A-C**); CD16+ DCs were very enriched in CLE lesions relative to control and were among the most active communications both as expressers of ligands (horizontal) and receptors (vertical) even in nonlesional SLE/CLE skin (**Figure 2D**). Spatial transcriptomics demonstrated CD16+ DCs localizing most prominently in the superficial dermis, enabling interaction with KCs. Subclustering of paired circulating and skin myeloid cells revealed CD16+ DCs may arise from non-classical monocytes, with discrete shifts in myeloid cell transcriptional states, including a robust IFN education in the skin, detectable across this transition (**Figure 3**).

Conclusion: Nonlesional skin of patients with SLE and CLE exists in a type I IFN-rich, "prelesional" state. This affects gene transcription in all major cell types present in skin and dramatically alters cell-cell communication. Non-classical monocytes may infiltrate this environment to become CD16+ DCs that engage in crosstalk with diverse cell types as one of the earliest steps in the evolution of CLE lesions.

A Permissive Factor of Anti-Ro+ Mothers of Neonatal Lupus Children Is Linked to Overt SLE Associated with Immunity to a Gut Commensal

Robert Clancy[1], Miranda Marion[2], Hannah Ainsworth[2], Miao Chang[1], Timothy Howard[3], Peter Izmirly[4], Mala Masson[5], Jill Buyon[6] and Carl Langefeld[7], [1]NYU Grossman School of Medicine, New York, NY, [2]Wake Forest University, Winston-Salem, NC, [3]Wake Forest University, Quakertown, NC, [4]New York University School of Medicine, New York, NY, [5]NYU Grossman School Medicine, New York, NY, [6]NYU School of Medicine, New York, NY, [7]Wake Forest University, Winston Salem, NC

SESSION INFORMATION
Session Date: Tuesday, November 9, 2021
Session Title: SLE – Etiology & Pathogenesis Poster (1480–1506)
Session Type: Poster Session D
Session Time: 8:30AM–10:30AM

Background/Purpose: Unknown factors trigger the transition of anti-Ro+ mothers of neonatal lupus (NL) children from preclinical autoimmunity to clinical disease. One candidate may be the gut microbiome with specific taxa serving as environmental triggers contributing to clinical phenotype. We have previously reported differential abundances between anti-Ro+ mothers versus healthy controls (HC), noting a bloom in relative abundance of protective

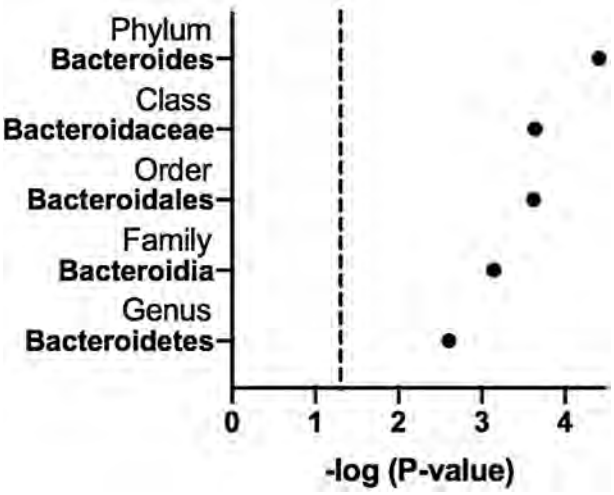

Figure 1. Analysis of the stool genus, Bacteroides, meeting statistical significance (FDR P-value<0.05) using the taxonomic stepdown method.

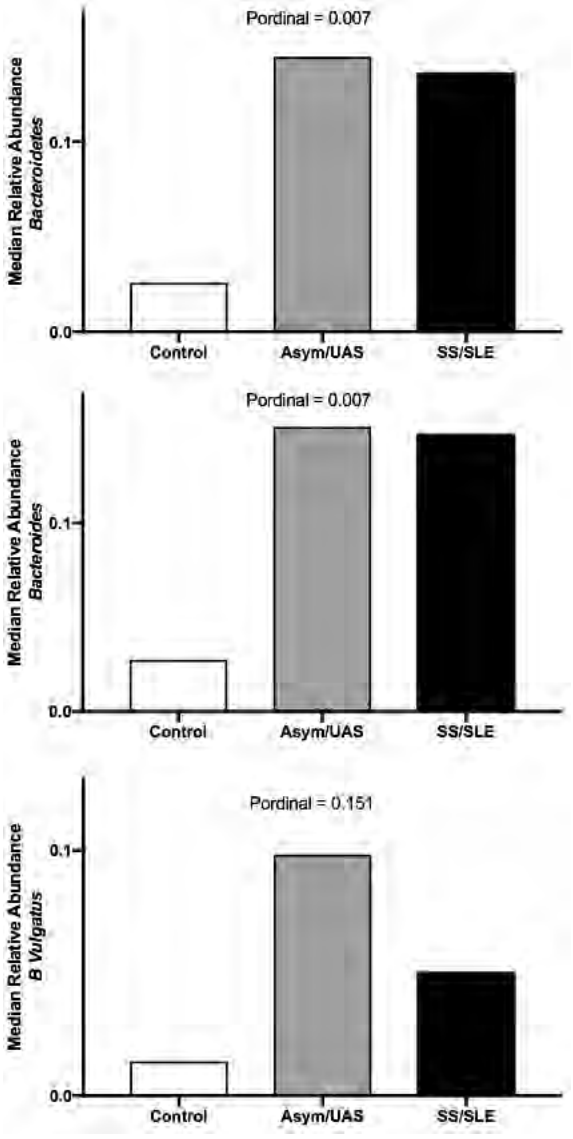

Figure 2. Species does not share ordinal significance, a feature that was evident at family and genus levels.

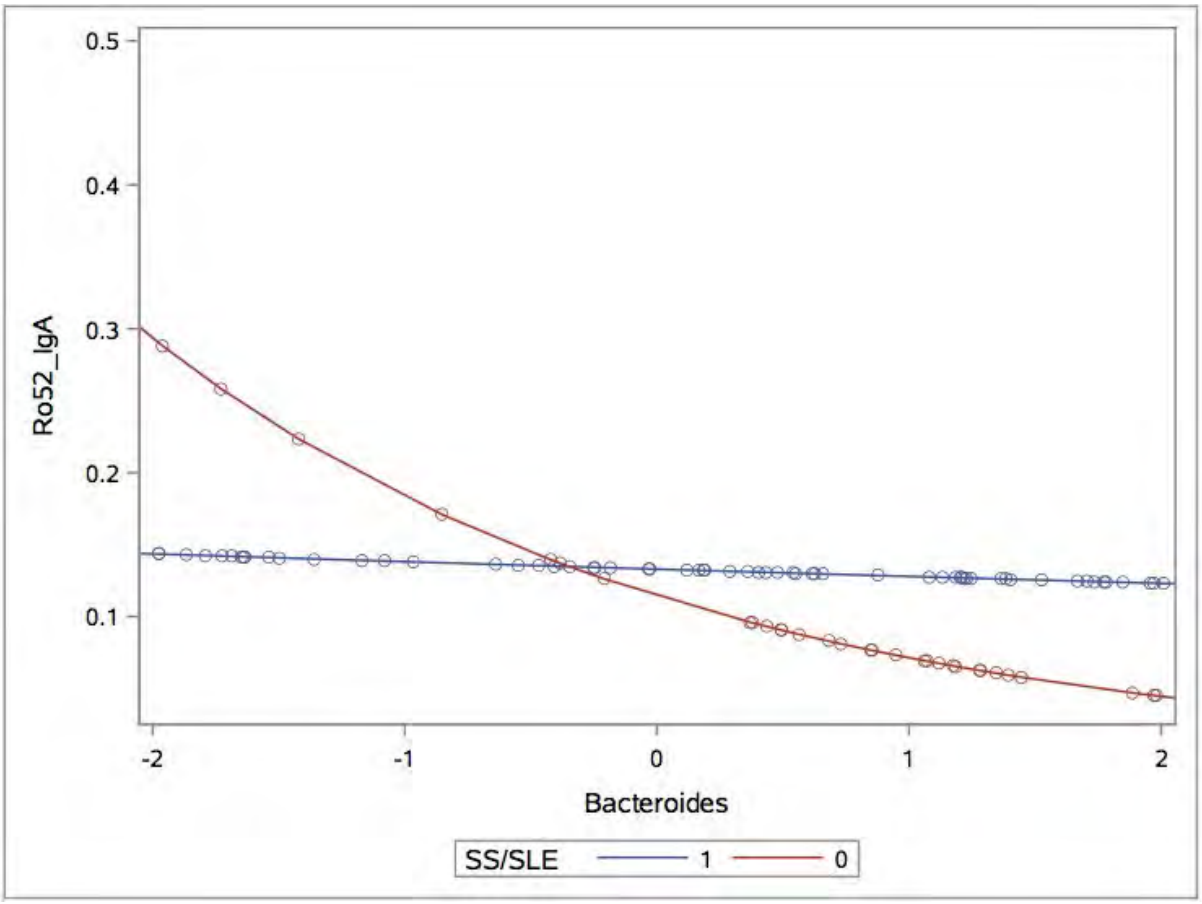

Figure 3. With anti-Ro52 IgA as an outcome, levels of autoantibody decreased with abundance in Asym/UAS subjects (P<0.005).

commensals including the genus *Bacteroides*. This taxon promotes tolerance at the interface of mucosal immunity. This study was initiated to test for associations of abundance of *Bacteroides*, and disease groups and for associations of anti-Ro titers.

Methods: Subjects included 125 RRNL mothers and 23 healthy controls. Stool microbiome of anti-Ro+ women in RRNL (asymptomatic and undifferentiated autoimmune syndrome (Asym/UAS), and SLE, SS, SS/SLE (SS/SLE)), and healthy controls (HC) were processed using 16S ribosomal RNA sequencing and use of a standard informatics pipeline. Tests for differential relative abundances of stool taxa applied compositional data analysis methods, linear models and adjustments for multiple comparisons. Assessments also included titers and specificities of anti-Ro using ELISA.

Results: The relative abundances varied as a function of clinical severity (HC < Asym/UAS < SS/SLE) shown across 13 genera (FDR < 0.05) including *Bacteroides*. Importantly, these ordered differences were maintained through the taxonomic hierarchy to *Bacteroides* (**Figure 1**) with the exception at species level *Bacteroides vulgatus* whereby relative median abundance reported at HC < SS/SLE < Asym/UAS (**Figure 2**), a finding that supported a focus on unique features of Asym/UAS that relate to *Bacteroides.* The initial analysis involved a comparison of Asym/UAS relative to HC. Applying multiple test correction, we observed an association of *Bacteroidetes* (P< 0.0001), as well as taxa at subsequent lower taxonomic levels including *Bacteroides* (P= 2.45 x 10-7), reflecting a higher relative abundance in Asym/UAS relative to HC. A subsequent analysis involved associations of *Bacteroides* relating to anti-Ro autoantibodies. While high titers of anti-Ro60 IgG and IgA as well as anti-Ro52 IgG and IgA titers were present in all NL mothers and absent in HC, there was an association between anti-Ro and *Bacteroides* relative abundance with an observed genus-by-disease interaction (P=0.0045; β=0.43 SE(β)=0.15) for Ro52 IgA levels. Specifically, with anti-Ro

as an outcome, levels were relatively constant for individuals diagnosed with SS/SLE but decreased with abundance in Asym/UAS (P< 0.005, **Figure 3**). These data suggest that the abundance of *Bacteroides* may influence features that are a distinction of SS/SLE such as high levels of autoantibody, which in this study was favored by low abundance of *Bacteroides*.

Conclusion: The data provide intriguing initial evidence that a permissive factor in NL anti-Ro+ mothers which links overt SLE immunity to a gut commensal, *Bacteroides vulgatus*.

SESSION INFORMATION
Session Date: Tuesday, November 9, 2021
Session Title: SLE – Etiology & Pathogenesis Poster (1480–1506)
Session Type: Poster Session D
Session Time: 8:30AM–10:30AM

Background/Purpose: Few reliable laboratory biomarkers exist to determine disease activity in SLE. The role of the soluble terminal complement complex, sC5b-9, in active SLE has yet to be elucidated. Its proinflammatory effects on a number of cell types, e.g. glomerular mesangial cells, have been reported.

The objective of the study was to correlate clinical activity according to the components of the SLEDAI and PROs with levels of soluble complement proteins and laboratory parameters of standard care. In completion of the preliminary analyses based on 2 consecutive patients' visits that suggested an association of sC5b-9 with haematuria und glomerular dysmorphic erythrocytes[1], we here present the analysis of all 4 visits during the 2-year time period of the study of 127 patients.

Methods:
Study population and design:
Patients fulfilling the ACR criteria were included into the Swiss SLE Cohort Study (SSCS, from the St. Gallen Centre) and were entered consecutively into a prospective observational, cross-sectional study (Oct. 2015 - Jan. 2021). The following parameters were determined at 2-4 clinical visits, at least 6 months apart, and compared with 48 healthy controls (age- and gender-matched):

- clinical disease activity (SELENA-SLEDAI, PGA), PROs (FACIT, SF-36) and SLICC-Damage
- sC5b-9 by ELISA
- a spectrum of routine laboratory of standard care

Statistics:
Independent associations of continuous variables were studied by analysis of covariance (ANCOVA) models, using the general linear model approach. Correlation analyses were performed calculating nonparametric Spearman rank correlation coefficients.

Results: Disease activity in our cross-sectional cohort was generally low (SELENA-SLEDAI 1.7 ± 2.6 (mean ± SD), SLEDAI of > 4 in 8.5% patients, 8.1 ± 3.3 (mean ± SD)). The median age was 48 [interquartile range (IQR) 38–54] years and disease duration 5.3 [IQR 3.8-8.8] years, respectively. Clinical manifestations were mainly hematologic 59%, musculoskeletal 56%, skin 41%, photosensitivity 41%, oral ulcers 37% and renal 15%.

A significant association in line with urinary signs of renal manifestations was found between:
- haematuria (F=2.501, p< 0.0001) and/or increase in glomerular dysmorphic erythrocytes
- (F=1.593, p= 0.039) and sC5b-9
- A significant correlation of proteinuria, albuminuria or pyuria with sC5b-9 could not be detected.

There were further correlations between sC5b-9 and:
- dsDNA antibodies (ab) (r=0.119, p= 0.014), IgG (r=0.181, p< 0.0001), soluble IL-2 receptor (r=0.100, p= 0.042), ESR (r=0.112, p= 0.017), CRP (r=0.223 p< 0.0001), C3a (r=0.317, p< 0.0001), C3 (r= 0.224, p< 0.0001)
- In addition, IgG (F=2.420, p= 0.004) and sIL-2 receptor (F=8.756, p< 0.0001) levels were associated with SELENA-SLEDAI in a multivariate model after adjustment for age, gender, CRP, ESR, levels of dsDNA ab, C3 and C4.

Conclusion: The study showed that sC5b-9 was associated with laboratory parameters of standard care and elevated in our cohort in line with urinary signs of renal manifestation. It may contribute to the pathogenesis of renal glomerular manifestation in SLE and serve as a new marker of active renal disease.

Functional Effects of a Lupus-associated *PRKG1* Variant on the RhoA-ROCK Pathway and Response to Type I Interferon

Ruth Fernandez Ruiz[1], Justine Shum[2], Kayla Van Buren[3] and Timothy Niewold[4], [1]NYU Grossman School of Medicine, New York, NY, [2]Marinhealth Medical Center, San Francisco, CA, [3]Mnemo Therapeutics, New York, NY, [4]Colton Center for Autoimmunity NYU School of Medicine, New York, NY

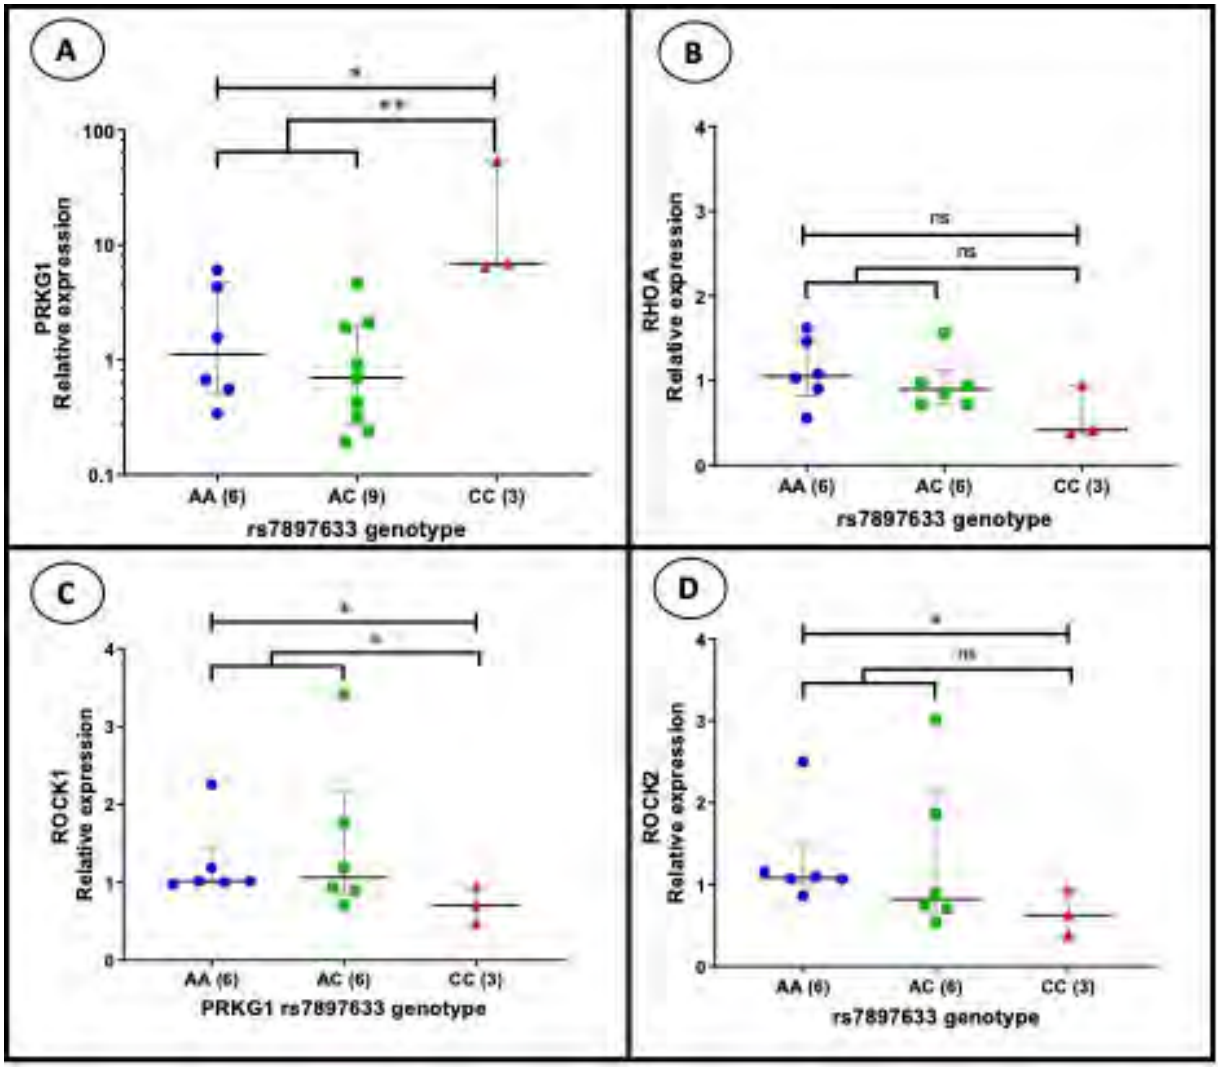

Figure 1. mRNA expression of PRKG1, RHOA, ROCK1 and ROCK2 in B lymphoblastoid cell lines according to the PRKG1 rs7897633 genotype category. (A) PRKG1, (B) RHOA, (C) ROCK1 and (D) ROCK2 mRNA levels are shown for B lymphoblastoid cell lines of different rs7897633 genotypes. Each symbol represents a cell line assessed in duplicate, n = 3 to 9. The median and interquartile ranges are shown. Mann-Whitney U was used to test significant differences for mRNA levels between genotype groups. *p<0.05; **p<0.01; ns=not significant.

SESSION INFORMATION

Session Date: Tuesday, November 9, 2021
Session Title: SLE – Etiology & Pathogenesis Poster (1480–1506)
Session Type: Poster Session D
Session Time: 8:30AM–10:30AM

Background/Purpose: Interferon (IFN)-α contributes to susceptibility and severe manifestations in systemic lupus erythematosus (SLE). The *PRKG1* rs7897633 variant has been previously identified as the top hit in European ancestry patients with SLE and high IFN-α compared to those with low circulating IFN activity. However, the mechanisms by which *PRKG1* polymorphisms impact the immune system remain unknown. *PRKG1* codes for the cGMP-dependent protein kinase I (PKGI). Activation of PKGI leads to VASP phosphorylation, and the inhibition of RhoA and Rho-associated kinases (ROCK). A subgroup of patients with SLE exhibit higher ROCK activity in circulating immune cells compared to healthy controls. ROCK inhibition decreases IFN-α production and ameliorates disease in murine

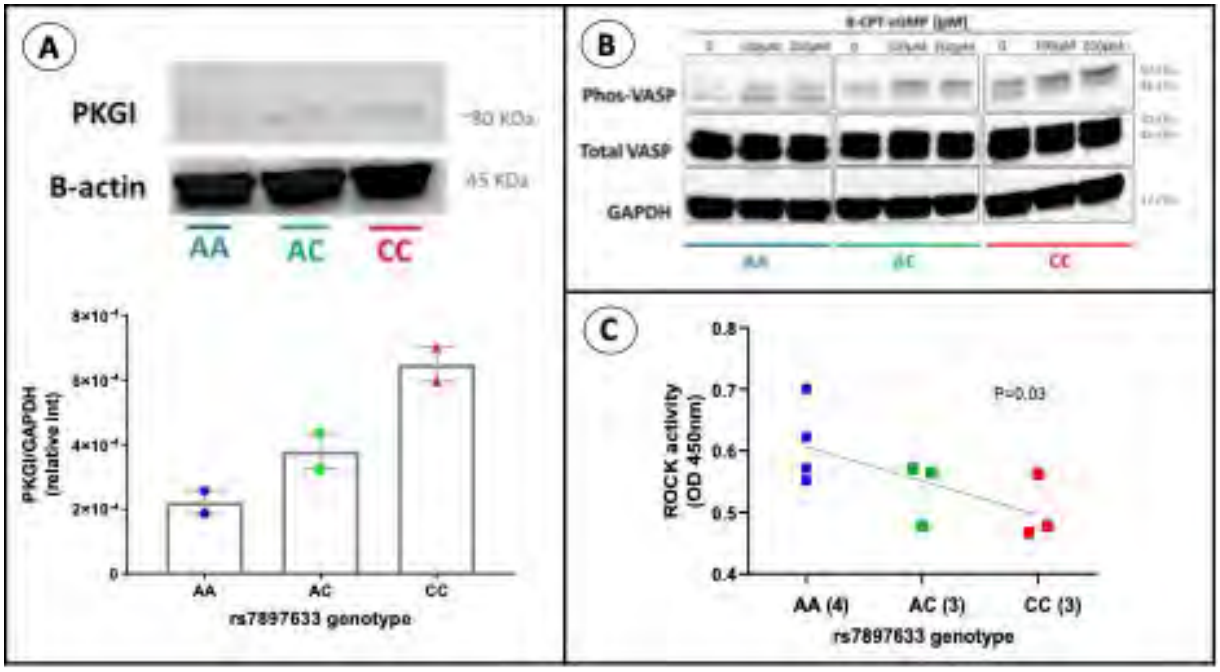

Figure 2. The rs7897633 AA variant is associated with lower PKGI abundance, decreased VASP phosphorylation, and greater baseline ROCK2 activity in B lymphoblastoid cell lines. (A) Representative Western blot analysis comparing PKGI (80 KDa) abundance, normalized for beta-actin (45 KDa), in different rs7897633 genotype categories. (B) Representative Western blot analysis comparing phosphorylated VASP and total VASP (46, 50 KDa) with increasing doses of 8-CPT-cGMP, a PKGI agonist, compared by rs7897633 genotype categories, n=2 (as a surrogate marker of PKGI activity). (C) Baseline ROCK2 activity in cells of different rs7897633 genotypes, with each symbol representing an individual cell line assessed in triplicate, and the P value reflecting the probability of the null hypothesis as compared to a regression line across genotype categories calculated using the sum-of-squares F test, n=3 to 4.

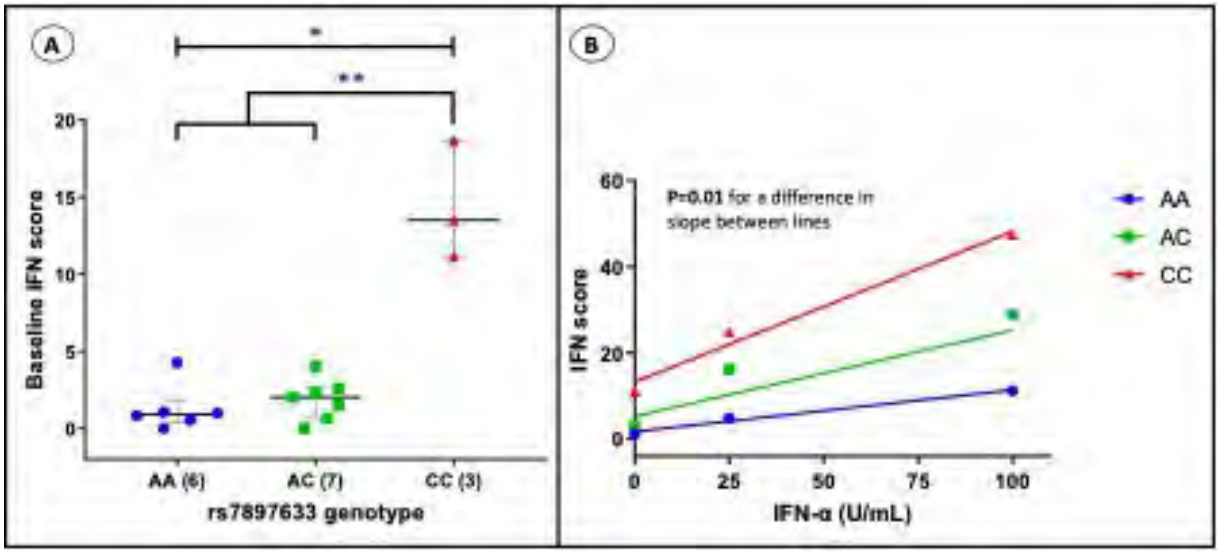

Figure 3. The rs7897633 CC genotype is associated with higher baseline and IFN-induced mRNA expression (as calculated by the interferon score) in B-lymphoblastoid cells. (A) Interferon (IFN) score (calculated from mRNA expression levels of the IFN-stimulated genes MX1, IFIT1, and PKR) at baseline in B-lymphoblastoid cells. Each symbol represents a cell line assessed in duplicate, n=3 to 7. The median and interquartile ranges are shown. Mann-Whitney U was used to test significant differences in IFN scores at baseline between genotype groups. *p<0.05; **p<0.01. (B) Association between rs7897633 genotypes and IFN score in B lymphoblastoid cells treated with increasing doses of IFN**α** (0, 25 U/mL, 100 U/mL). P value reflects the difference in slope between the regression lines of each genotype category, calculated using the sum-of-squares F test, n=2.

models of lupus. Accordingly, we aimed to assess whether the *PRKG1* gene variant was associated with decreased gene expression and activity of *PRKG1*, hyperactivation of the ROCK pathway, and altered response to type I IFN.

Methods: We used B lymphoblastoid cell lines (LCL) derived from healthy subjects of European ancestry (Coriell repositories) homozygous (AA or CC) and heterozygous (AC) at the rs7897633 SNP for all experiments. Gene expression of *PRKG1*, *RHOA*, and *ROCK* was assessed by RT-qPCR using gene-specific primers, normalized by GAPDH, and measured by the $2^{-\Delta\Delta CT}$ method. IFN score at baseline and after treatment of LCL with increasing doses of IFN-α was measured by quantifying 3 canonical IFN-stimulated genes (*IFIT1*, *MX1* and *PKR*) and summing to generate a score reflecting the degree of IFN-induced gene expression in the cells. Abundance of PKGI and VASP phosphorylation (as a surrogate of PKGI activity) were determined by Western blotting at baseline and after treatment with a PKGI agonist. ROCK2 enzymatic activity was performed by a colorimetric assay (Cell Biolabs). Unstimulated and stimulated cells were compared among PRKG1 genotype categories. Statistically significant differences were determined by Mann Whitney U test or sum-of-squares F test, as appropriate.

Results: *PRKG1* expression was lower in the homozygous AA genotype as compared with the homozygous CC genotype in LCL ($p< 0.05$). In contrast, ROCK expression was higher in LCL with the AA rs7897633 genotype ($p< 0.05$). Compared to LCL with the homozygous AA variant of rs7897633, homozygous CC LCL have greater abundance of PKGI, phosphorylated VASP/total VASP ratio in response to a PKGI agonist (indicating increased PKGI activity), and lower baseline ROCK activity (sum-of-squares F test, $p< 0.05$). The IFN score was significantly higher in the homozygous CC allele LCL, both at baseline and with increasing doses of IFN-α, suggesting increased sensitivity to type I IFN ($p< 0.05$).

Conclusion: *PRKG1* AA genotype associates with lower *PRKG1* and higher *ROCK* mRNA expression, decreased PKGI abundance and activity, and greater ROCK baseline activity. In contrast, the rs7897633 CC genotype is associated with increased response to IFNα. Overall, these findings suggest an important role of genetic variation at *PRKG1* in modulating the RhoA-ROCK pathway and regulating response to type I IFNs in LCL, which may have therapeutic implications in patients with SLE.

Session Title: SLE – Etiology & Pathogenesis Poster (1480–1506)

Session Type: Poster Session D

Session Time: 8:30AM–10:30AM

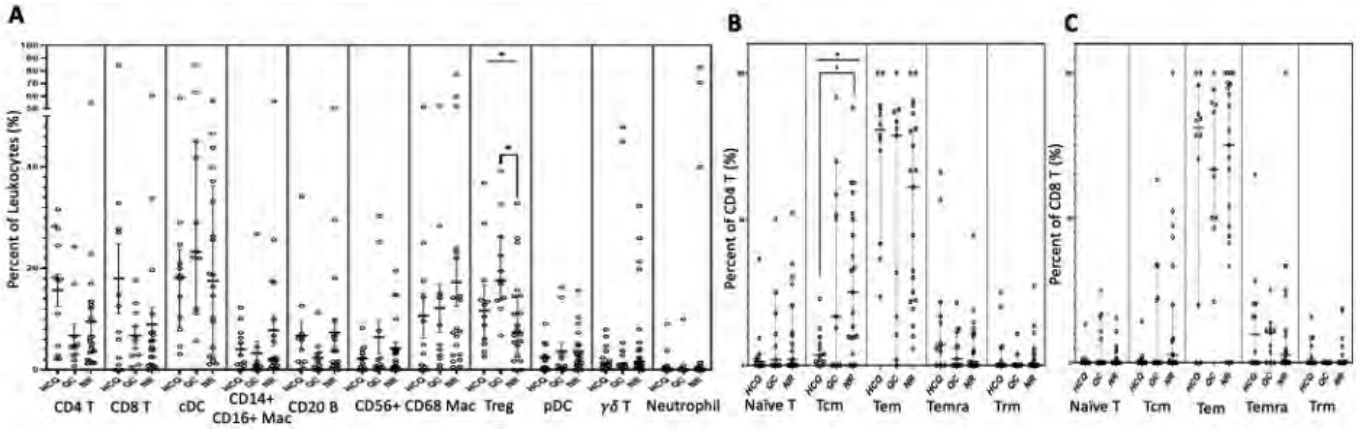

Figure 1. Cell types identified in cutaneous lupus stratified according to patient responses to antimalarials (A). CD4 (B) and CD8 (C) T cell subsets in cutaneous lupus stratified by patient responses to antimalarials.

Background/Purpose: Lupus erythematous (LE) is a systemic autoimmune disease with a variety of cutaneous manifestations. Antimalarials are first-line systemic therapy, yet not all patients respond to hydroxychloroquine (HCQ), quinacrine (QC), or either (NR). Our group has previously shown that QC responders demonstrate increased conventional dendritic cells (cDC) and TNF relative to HCQ responders.

Methods: Here, we investigated the differences between these patients using imaging mass cytometry (IMC), an unbiased multiplexed technique. 12 HCQ, 11 QC, and 20 NR treatment-naïve FFPE samples were stained with two panels consisting of 37 metal-conjugated antibodies and ablated on the Hyperion Imaging System (Fluidigm). Images were segmented using a nuclear staining based algorithm in Visiopharm and imported into histoCAT where single cell mean pixel intensity data was obtained to cluster cells using the Phenograph algorithm. RNA fluorescent *in situ* hybridization (ISH) using RNAscope was performed to confirm certain findings. Kruskal-Wallis, and post-hoc Dunn's tests were performed for cell percentages, and median with IQR are depicted. One-way ANOVA and post-hoc Tukey were performed for normally distributed intracellular markers with mean and SEM shown. Bivariate correlations were determined by Pearson's r.

Results: We identified 12 unique cell types. T cells were then manually gated on CCR7, CD69, and CD45RA to identify effector and memory subsets. NR patients were found to have a decreased percentage of Tregs compared to QC responders ($p< 0.05$) (Figure 1A). There was a significant increase in CD4+ central memory T cells in NR patients compared to HCQ patients ($p< 0.05$) (Figure 1B). We compared epidermal staining and found a significant difference is pNFκB staining between the treatment groups ($p< 0.05$) (Figure 2A). The post hoc test was not significant, but there was a trend towards decreased pNFκB in the QC group compared to both HCQ and NR. In the dermis, HCQ responders had significantly more pJAK3 staining than the QC group ($p< 0.05$) (Figure 2B). QC responders had a higher expression of pSTING and dermal cell IFNκ compared to HCQ responders ($p< 0.05$) (Figure 2A). The total expression of pSTING and IFNκ was found to positively correlate (Figure 3A) and colocalize in the dermis ($p< 0.0001$, $r=0.676$). We identified conventional dendritic cells (cDCs) as the major producers of IFNκ in CLE and found that their production of IFNκ and phosphorylation of STING was also elevated in the QC group compared to HCQ (Figure 3B). Since keratinocytes have been shown to be important producers of IFNκ in CLE, we compared the mean pixel intensity (MPI) of IFNκ in the epidermis to the cDCs and found a higher MPI in cDCs in all treatment groups. We then performed RNA ISH on QC responder biopsies and found CD11c mRNA (ITGAX) and IFNκ mRNA colocalized, suggesting cDCs are producers of IFNκ in CLE. CD14+CD16+/CD68+ macrophages and cDCs were the predominant cell types found to express pSTING and IFNκ.

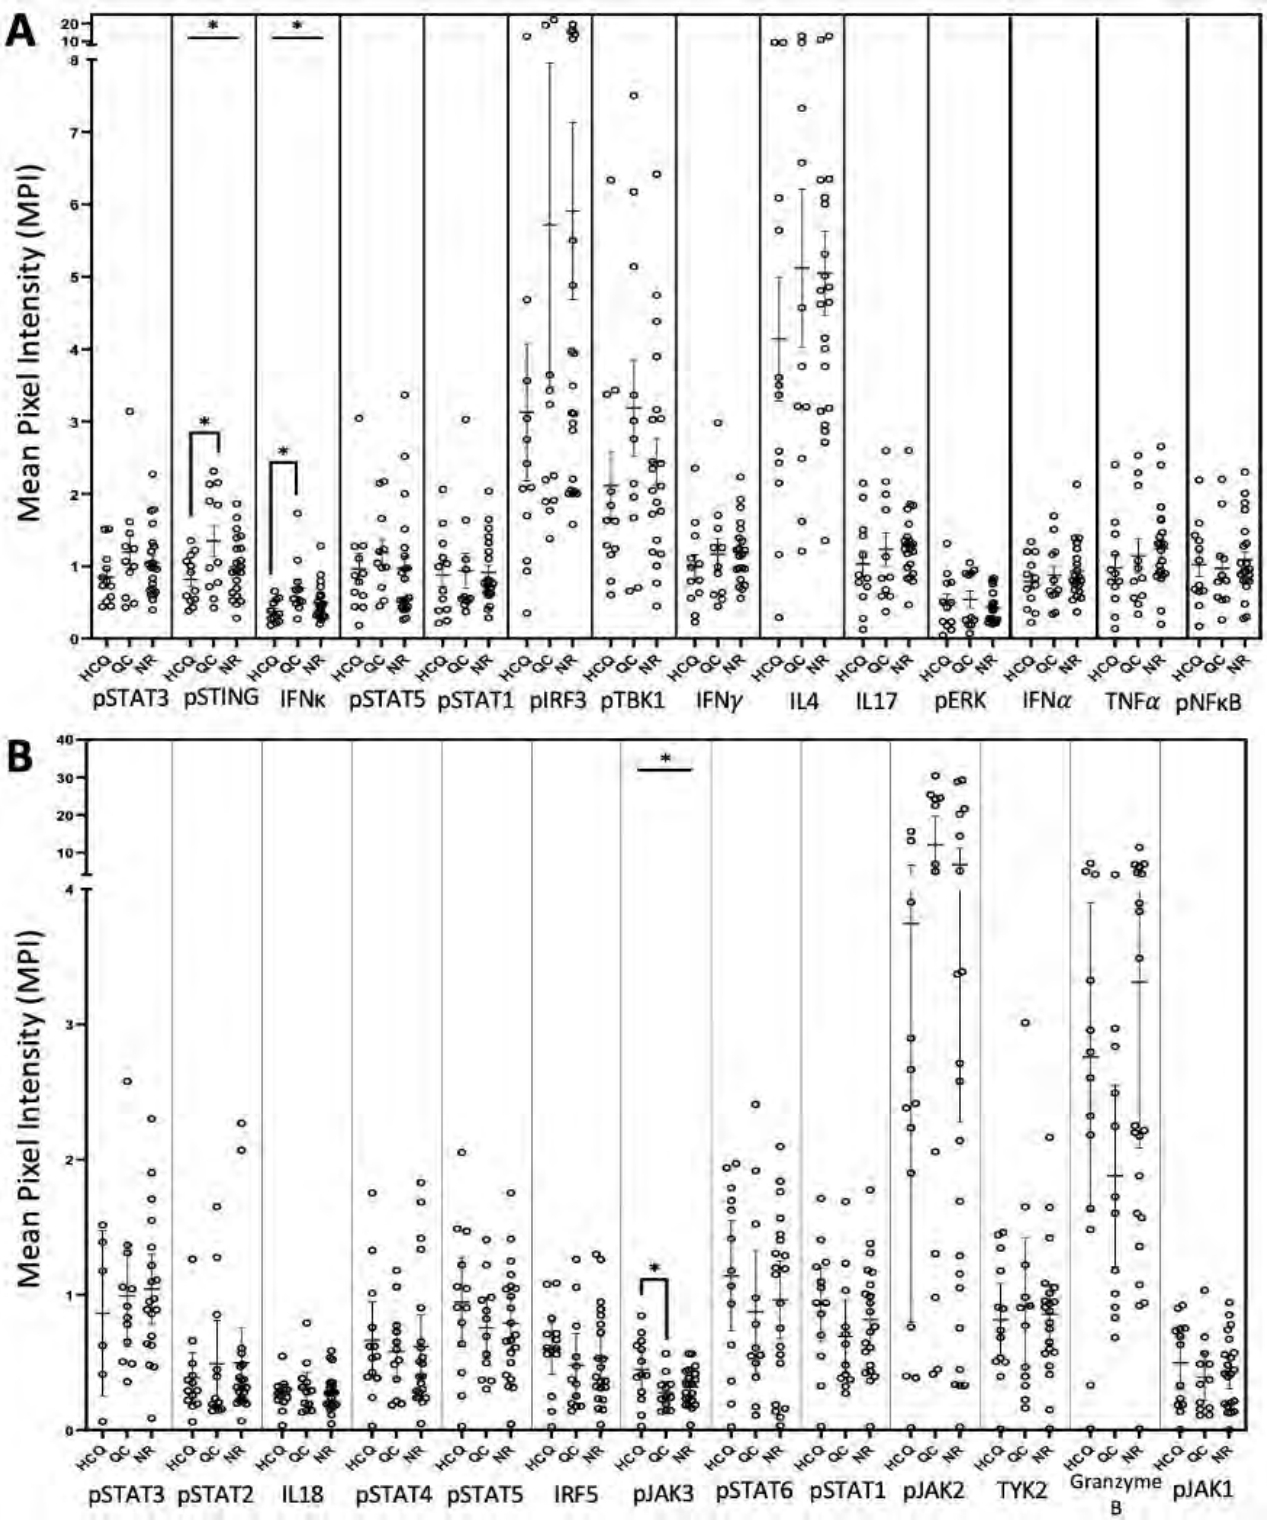

Figure 2. Mean pixel intensities of intracellular cytokines and activated cell signaling pathways in cutaneous lupus erythematosus.

Conclusion: This analysis on treatment naïve biopsies may lead to further discovery of biomarkers that may predict patient response to therapy and direct targeted treatment.

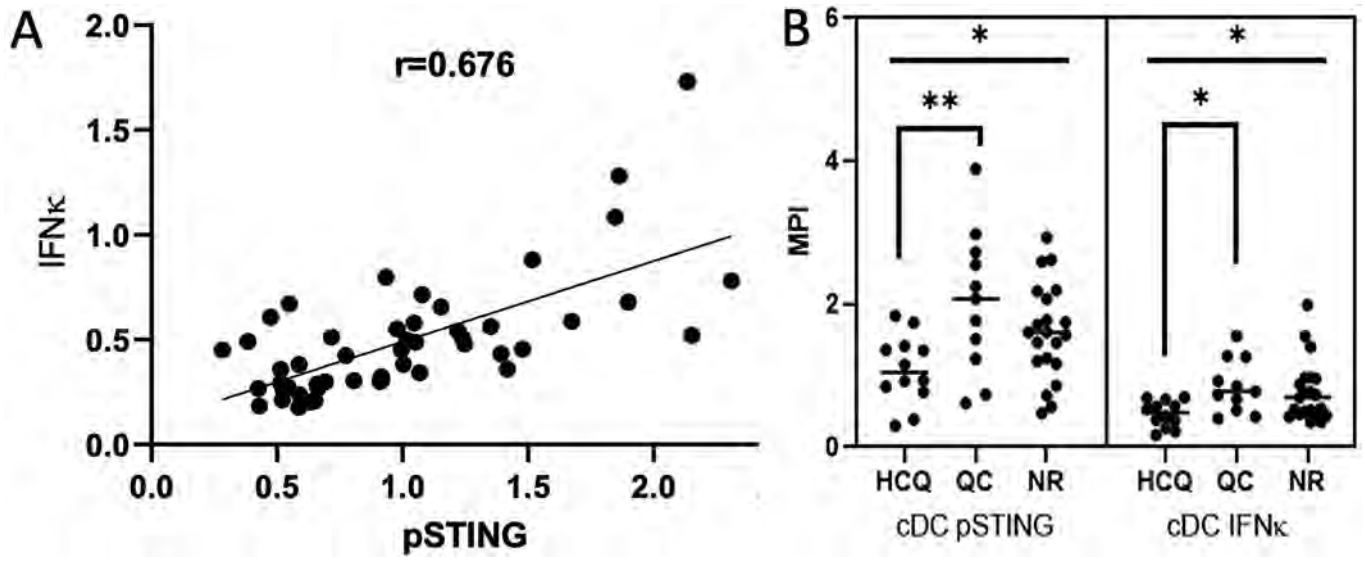

Figure 3. Phosphorylated-STING (pSTING) and interferon kappa are correlated in cutaneous lupus (r=0.676) (A). Conventional dendritic cells (cDCs) express more pSTING (p<0.01) and interferon kappa (p<0.05) in quinacrine (QC) responders (B).

Session Title: SLE – Etiology & Pathogenesis Poster (1480–1506)

Session Type: Poster Session D

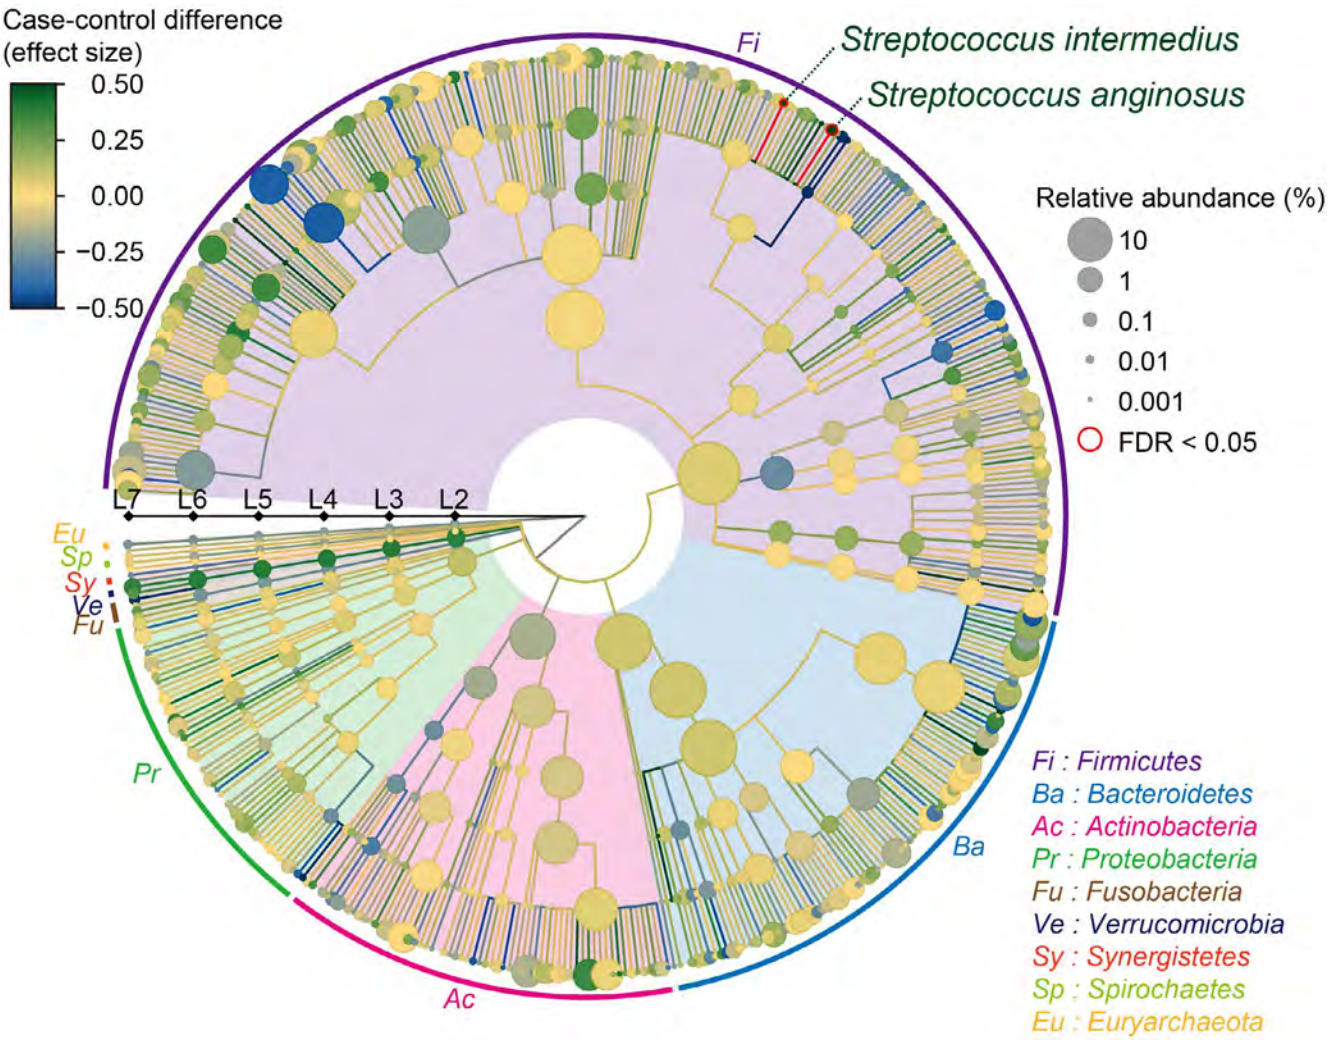
Session Time: 8:30AM–10:30AM

Background/Purpose: Alteration of the gut microbiome has been linked to the pathogenesis of systemic lupus erythematosus (SLE). However, a comprehensive view of the gut microbiome in SLE and its interaction with the host remains to be revealed. This study aimed to reveal SLE-associated changes in the gut microbiome and its interaction

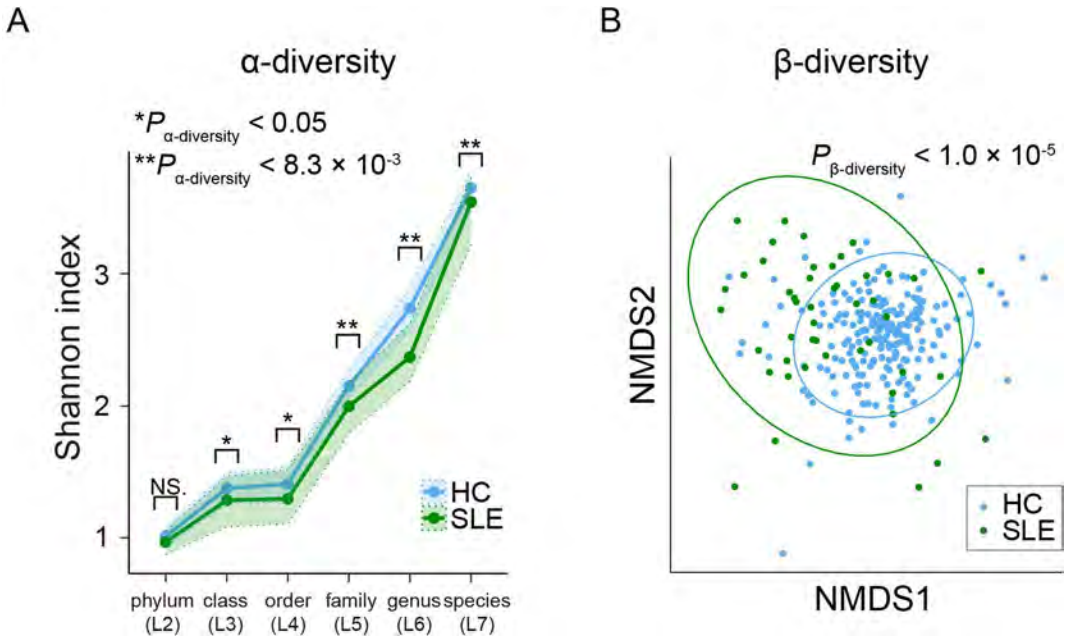
with the host by a comprehensive metagenome-wide association study (MWAS) based on shotgun sequencing followed by integrative analysis.

Methods: We performed a MWAS of SLE based on shotgun sequencing of the gut microbial DNA from Japanese individuals (N_{case} = 47, $N_{control}$ = 203). All of the 47 SLE patients were diagnosed according to the systemic lupus international collaborating clinics classification criteria (SLICC). Our MWAS consisted of three major bioinformatic analytic pipelines (phylogenetic analysis, functional gene analysis and pathway analysis). We integrated the result of the MWAS with the genome-wide association study (GWAS) data and plasma metabolite data.

Results: Via species level phylogenetic analysis, we identified and validated increases of *Streptococcus interdemius* and *Streptococcus anginosus* in the SLE patients (effect size = 0.617 and $P_{microbe} = 3.7 \times 10^{-5}$ for *Streptococcus anginosus*, effect size = 0.579 and $P_{microbe} = 7.5 \times 10^{-5}$ for *Streptococcus intermedius*; Figure 1). Microbial gene analysis revealed increases of the eight *Streptococcus* derived genes including one involved in redox reaction. Additionally, microbial pathways related to sulfur metabolism and flagella assembly were altered in the SLE patients. We identified a pathway level SLE-specific link between the metagenome and the germline genome by comparing the result of the



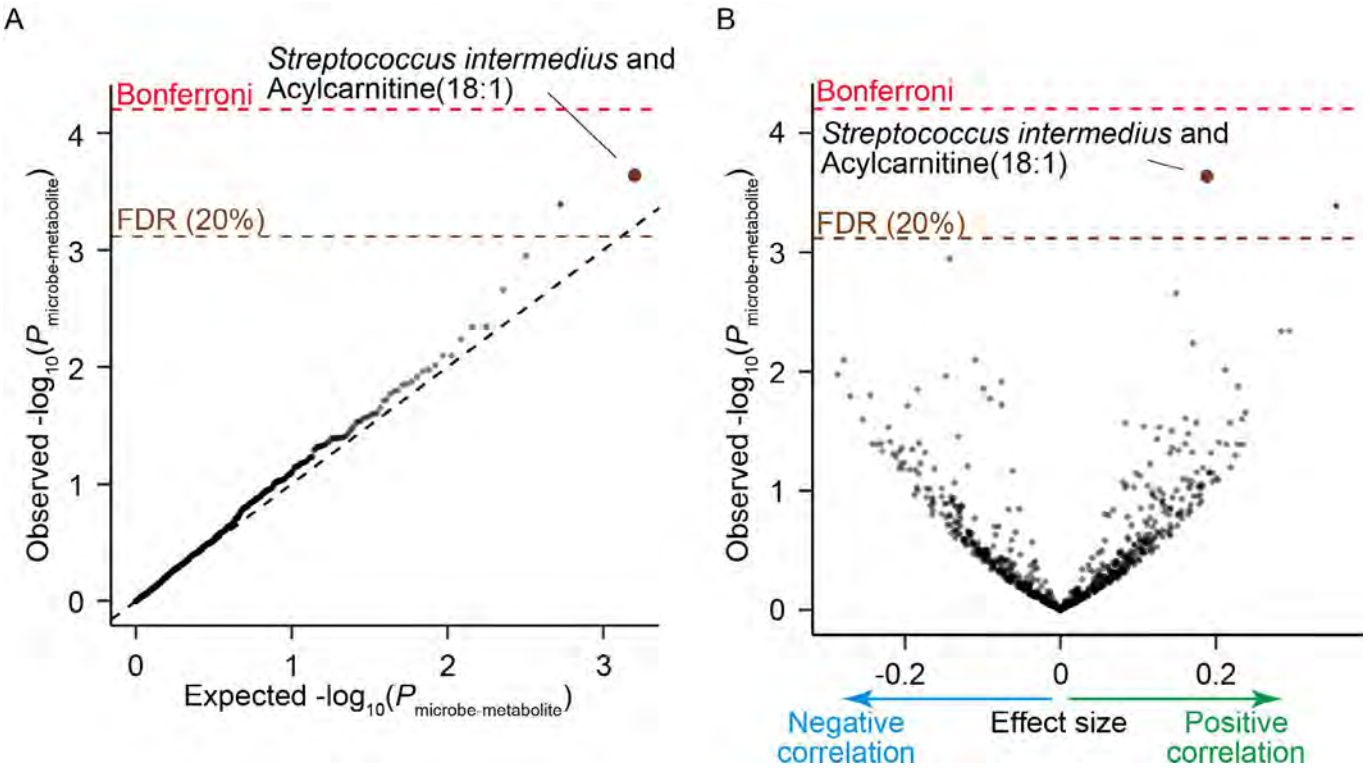
A phylogenetic tree. Levels L2-L7 are from the inside layer to the outside layer. The size and the color of nodes represent relative abundances and effect sizes, respectively. The two clades with significant case-control associations (FDR < 0.05) are outlined in red. FDR, false discovery ratio.



(A) A quantile-quantile plot of the p-values from the microbe-metabolite association analysis. The x-axis indicates log-transformed empirically estimated median P-value. The y-axis indicates observed -log10(P). The diagonal dashed line represents y = x, which corresponds to the null hypothesis. The horizontal red dashed line indicates the Bonferroni-corrected threshold (α = 0.05), and the brown dashed line indicates the FDR threshold (FDR = 0.20) calculated with Benjamini-Hochberg method. The microbe-metabolite pairs with FDR < 0.20 are plotted as brown dots, and the other microbe-metabolite pairs are plotted as black dots. (B) A volcano plot. The x-axis indicates effect sizes in linear regression. The y-axis, horizontal dashed lines and dot colors are the same as in (A). FDR, false discovery rate; HC, healthy control; SLE, systemic lupus erythematosus.

current MWAS and the GWAS of SLE (i.e., MWAS-GWAS interaction). α- and β-diversity analyses provided evidence of dysbiosis in the metagenome of the SLE patients (Figure 2). Microbiome-metabolome association analysis identified positive dosage correlation of acylcarnitine with *Streptococcus intermedius*, an SLE-associated taxon (Figure 3).

Conclusion: Our MWAS followed by integrative analysis revealed SLE-associated changes in the gut microbiome and its interaction with the host, which provided novel insights into the pathogenesis of SLE.



(A) α-diversities of the phylogenetic relative abundance data for the six taxonomic levels. Blue and green dots represent the median Shannon index of the HC and SLE subjects. Upper and lower dashed lines indicate the 1st and 3rd quantile of Shannon index for the HC and SLE subjects. (B) β-diversities of the phylogenetic relative abundance data at the species level. Result of NMDS based on Bray-Curtis distance is represented. Blue and green dots represent the HC and SLE subjects. HC, healthy control; IQR, interquartile range; NMDS, non-metric multidimensional scaling; SLE, systemic lupus erythematosus; *, $P < 0.05$; **, $P < 0.0083$.

SESSION INFORMATION
Session Date: Tuesday, November 9, 2021
Session Title: SLE – Etiology & Pathogenesis Poster (1480–1506)
Session Type: Poster Session D
Session Time: 8:30AM–10:30AM

Background/Purpose: The present study aimed at: 1- Identifying altered SLE monocytes transcriptomic signatures linked to the immune response and its association with clinical features. 2- Evaluating the involvement of those altered molecular profiles in lupus nephropathy. 3- Analyzing mechanistically the impact of spliceosome alterations in the SLE-monocytes activity.

Methods: Sixty SLE patients and forty healthy donors (HD) were included in the study. Infiltration rate of myeloid cells was analyzed in kidney biopsies by Immunohistochemistry. Circulating monocytes were purified from peripheral blood by immune-magnetic selection and both, transcriptome and spliceosome profiling were assessed, respectively, by Nanostring and a microfluidic qPCR array (Fluidigm). Extensive clinical/serological evaluations were also performed. *In vitro* studies involving over/down-expression of splicing machinery components were developed.

Results: Infiltration of CD68+ expressing cells was confirmed in kidney biopsies and associated with parameters of kidney failure (C3/C4, chronic index), highlighting the key role of the myeloid compartment in lupus nephropathy. Gene expression profiling recognized 156 genes differentially expressed in SLE monocytes *vs* HDs, most of them associated with the IFN response. In parallel, the altered expression of 27 components of the splicing machinery (SM) was revealed in SLE-monocytes. Correlation studies demonstrated that the aberrant expression of SM components was linked to both, the altered IFN signature and the plasma inflammatory profile. This altered molecular profile was associated with disease activity, anti-dsDNA positivity and C3/C4 levels. Interestingly, SLE patients with renal disease displayed a simultaneous alteration of both, the IFN and the SM signatures in monocytes, along with an enlarged pro-inflammatory profile in plasma. Logistic regression models integrating the concomitant alteration of SM components and IFNs genes identified lupus nephritis patients with high accuracy. In vitro SLE-serum promoted in DS-monocytes a concomitant deregulation of both, the IFN signature and several SM components. Besides, the over/down-expression of selected SM components in SLE-monocytes reduced the release of inflammatory cytokines and their adhesion capacity.

Conclusion: 1) Monocytes from SLE patients with renal involvement exhibit a remarkable alteration of genes associated with the IFN response, further linked with the aberrant expression of several SM components. 2) Serum SLE promoted the dysregulation in monocytes of both, the IFN and spliceosome signatures, along with an active release of proinflammatory mediators. 3) The modulation of key SM components in monocytes from SLE patients reduce their pro-inflammatory status and migration capacity.

Platelet Secreted LGALS3BP Induces a Pro-inflammatory Phenotype in Systemic Lupus Erythematosus

Hanane EL Bannoudi[1], MacIntosh Cornwell[2], Elliot Luttrell-Williams[2], Alexis Engel[3], Christina Rolling[1], Peter Izmirly[4], H. Michael Belmont[5], Kelly Ruggles[2], Robert Clancy[6], Jill Buyon[5] and Jeffrey Berger[2], [1]NYU Langone Health, New York, NY, [2]New York University, New York, NY, [3]NYU Langone Health, New Yok, NY, [4]New York University School of Medicine, New York, NY, [5]NYU School of Medicine, New York, NY, [6]NYU Grossman School of Medicine, New York, NY

SESSION INFORMATION

Session Date: Tuesday, November 9, 2021
Session Title: SLE – Etiology & Pathogenesis Poster (1480–1506)
Session Type: Poster Session D
Session Time: 8:30AM–10:30AM

Background/Purpose: Systemic Lupus Erythematosus (SLE) is a complex chronic heterogeneous autoimmune disease, which increases the risk of atherothrombosis. In addition to their well described role in thrombosis and hemostasis, platelets are key mediators of inflammation and have immune effector cell properties. This study was initiated to investigate the role of platelet associated Lectin Galactoside-binding Soluble 3 Binding Protein (LGALS3BP), which binds to macrophage-associated lectin Mac-2, as a mediator of inflammation in SLE and potential biomarker associated with clinical phenotypes.

Methods: RNA transcriptome analysis was performed on platelets isolated from 51 patients with SLE (not taking aspirin or anticoagulants) and 18 age, sex and race/ethnicity matched controls. LGALS3BP protein expression was determined in platelet releasates by ELISA and western blot analysis. Gene and protein expression of LGALS3BP in Megakaryocyte cell line (MEG-01) was investigated upon stimulation with IFN-α. Correlations between circulating serum LGALS3BP and LGALS3BP platelet mRNA and releasates were assessed. Subsequently, correlation analysis

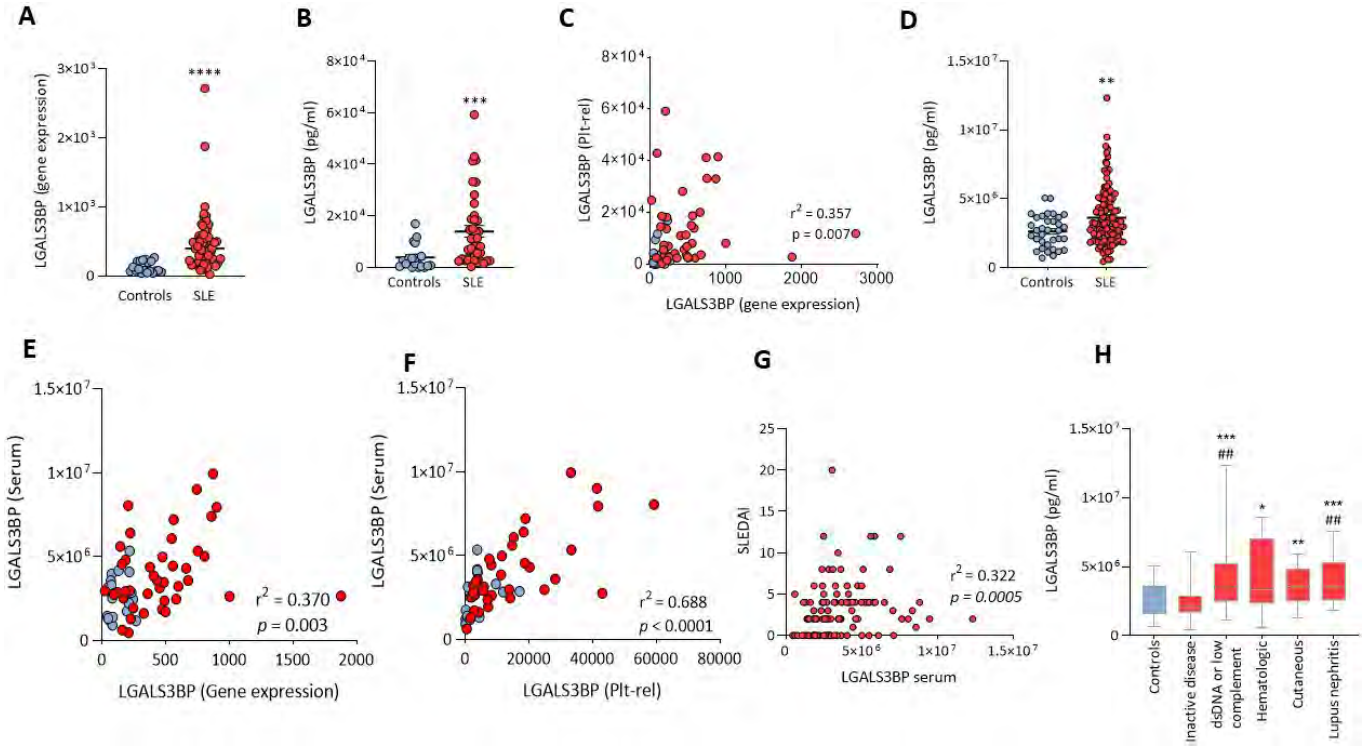

Figure 1. LGALS3BP is highly expressed in SLE and correlates with SELENA SLEDAI hybrid disease activity index A) LGALS3BP gene expression in platelets isolated from 51 patients with SLE and 18 age, sex and race/ethnicity matched controls, determined by RNA sequencing analysis. B) Levels of LGALS3BP measured by LGALS3BP specific ELISA in platelet releasates (plt-rel) of 40 patients with SLE and 20 healthy controls. C) Correlation between the levels of LGALS3BP measured in platelet releasates and platelet LGALS3BP gene expression D) LGALS3BP levels measured by LGALS3BP specific ELISA in serum of 115 patients with SLE and 34 healthy controls. E) Correlation between serum LGALS3BP and Platelet LGALS3BP gene expression F) Correlation between serum LGALS3BP and LGALS3BP in platelet releasates in 36 patients with SLE and 16 healthy controls G) Correlation between serum LGALS3BP levels and SELENA SLEDAI hybrid disease activity index in 115 patients with SLE H) Serum LGALS3BP levels stratified based on clinical phenotypes. Pounds indicate comparison to healthy controls and asterisks to inactive disease All data represent the mean ± s.e.m. and are analyzed by two-sided Student's t-test. *P < 0.05, **P < 0.01, ***P < 0.001, ****P < 0.0001.

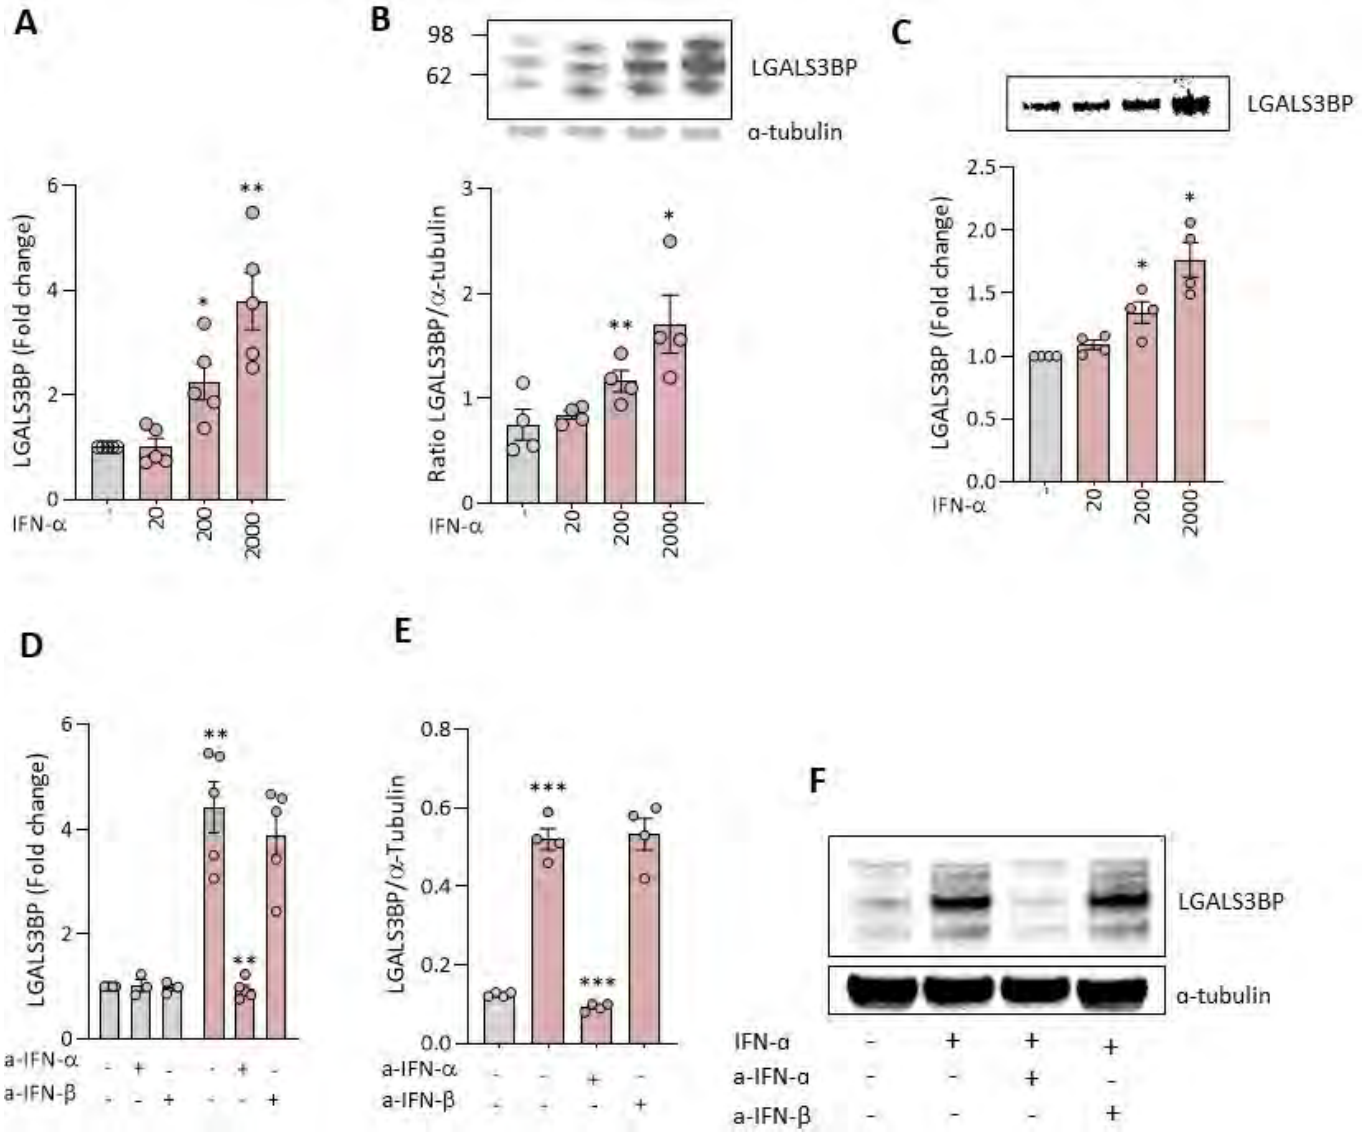

Figure 2. IFN-α induces the expression and the production of LGALS3BP in Megakaryocyte cell line (MEG-01) in a dose dependent manner MEG-01 cells were stimulated or not with 20, 200 and 2000 U/mL IFN-α. After 24h, LGALS3BP gene expression (A) and protein expression in the lysates and supernatants (B and C respectively) were determined by qPCR and western blot analysis. LGALS3BP gene (D) and protein (E and F) expression were quantified using qPCR and western blot in MEG-01 cell lysates after stimulation with 2000 U/mL IFN-α in the presence or absence of neutralizing antibodies against IFN-α and IFN-β All data represent the mean ± s.e.m. and are analyzed by two-sided Student's t-test. *P < 0.05, **P < 0.01, ***P < 0.001.

between clinical features of SLE and circulating serum LGLAS3BP was performed. Finally, the effects of platelets and LGALS3BP on macrophage inflammatory response were studied *in vitro*.

Results: Platelet transcriptome analysis revealed that LGALS3BP was one of the most differentially expressed transcripts in SLE versus matched-healthy controls (Fold change, 3.9, adjusted *P*-value = 2.5×10^{-11}) (**Figure1A**). Consistently, LGALS3BP in platelet releasates was significantly higher in 40 patients with SLE than 20 controls ($p = 0.002$) (**Figure1B**). Platelet LGALS3BP gene and protein expression were highly correlated with circulating LGALRS3BP in serum ($r^2 = 0.370$, $p = 0.003$ and $r^2 = 0.689$, $p < 0.0001$ respectively) (**Figure1E and F**). LGALS3BP measured in serum of 115 patients with SLE correlated with the SELENA SLEDAI hybrid disease activity index ($r^2 = 0.322$, $p = 0.0005$) (**Figure1G**). In particular, higher serum LGALS3BP levels were observed in SLE patients with lupus nephritis compared to those with SLE and inactive disease (P=0.0001) (**Figure1H**). In longitudinal analysis of 22 patients without

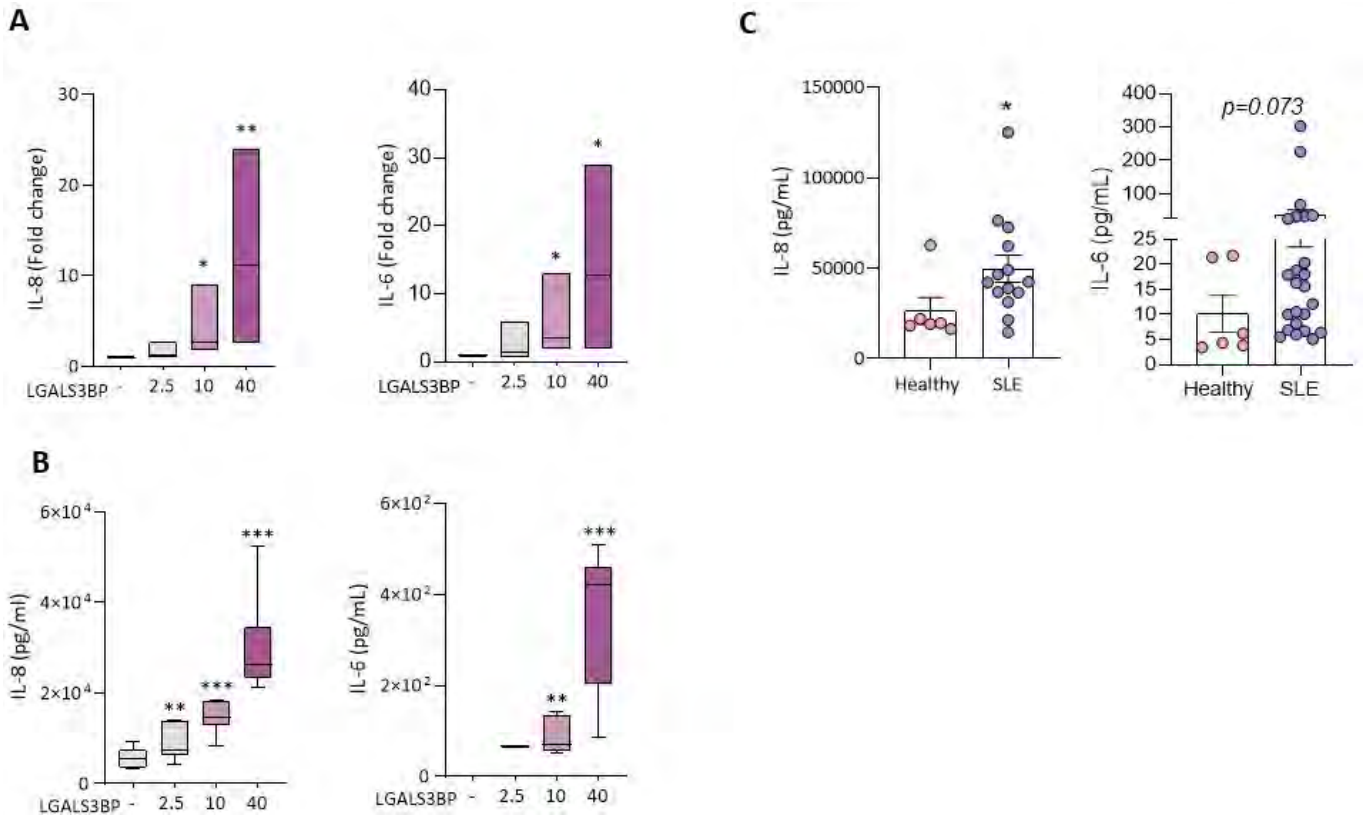

Figure 3. LGALS3BP and platelets from patients with SLE induce production of pro-inflammatory cytokines IL-8 and IL-6 in macrophages Monocytes derived macrophages were cultured for 7 days for differentiation in the presence of macrophage colony stimulating factor (MCSF) After differentiation, cells were either cultured without stimulation or stimulated with increasing concentrations of LGALS3BP (2.5, 10 and 40 μg/mL) for 6h and cytokine gene expression (A) and secretion (B) were determined by qPCR and multiplex beads-based assay respectively. Platelet releasates from patients with SLE or healthy controls were added to macrophages for 24h. IL-8 and IL-6 were measured in the supernatants using multiplex beads-based assay respectively. All data represent the mean ± s.e.m. and are analyzed by two-sided Student's t-test. *P < 0.05, **P < 0.01, ***P < 0.001.

proteinuria at baseline who went on to develop proteinuria over time, circulating plasma LGALS3BP tracked with flares of nephritis (p=0.06). *In vitro*, IFN-α induced the expression and production of LGALS3BP in MEG-01 cells in a dose dependent manner (**Figure2A, B and C**), which was completely inhibited by IFN-α neutralizing antibody (**Figure2D, E and F**). Recombinant LGALS3BP (**Figure 3A and B**) and Platelet releasates from SLE (**Figure 3C**) induced the production of pro-inflammatory cytokines such as IL-8 (p=0.04) and IL-6 (p=0.073) by macrophages.

Conclusion: These data show that platelets isolated from patients with SLE highly express and secrete LGALS3BP which induces a proinflammatory macrophage and is associated with SLE disease clinical phenotype. LGALS3BP may contribute to pathogenesis and serve as a novel biomarker of SLE disease activity.

SESSION INFORMATION

Session Date: Tuesday, November 9, 2021

Session Title: SLE – Etiology & Pathogenesis Poster (1480–1506)

Session Type: Poster Session D

Session Time: 8:30AM–10:30AM

Background/Purpose: Systemic Lupus Erythematosus (SLE) is a chronic autoimmune disease characterized by persistent inflammation and production of autoantibodies, which deposit within numerous tissues leading to systemic damage. Multiple studies have suggested a link between obesity, metabolic syndrome, and SLE. Our recent data has shown that fat-diet-induced obesity exacerbates lupus symptoms in lupus prone mice, suggesting a unique role of obesity in autoimmune pathogenesis. This study is to probe the role of follicular T helper (Tfh) cells and T regulatory (Treg) cells in fat-diet associated lupus development in MRL/lpr lupus prone mice.

Methods: Forty MRL/lpr mice were fed and grouped in a regular diet (RD, 10% calories from fat) or high fat diet (HFD, 60% calories from fat). Their body weights and skin lesions were recorded weekly. Urine protein was assessed weekly by Bradford assay. Blood was collected monthly for anti-dsDNA antibody and anti-nuclear antibody (ANA) detection. At week 14, mice were euthanized, their spleen were measured and weighed. Kidney and skin biopsy were embedded in paraffin and tissue sections for H&E and PAS staining to detect lupus histopathological lesions and quantified as kidney index and histological skin score. B cells ($CD19^+$), germinal center B cells (GC-B cell, $GL7^+CD19^+$), plasma cells ($CD20^-CD138^+$), Tfh cells ($CD4^+CXCR5^+ICOS^+$), and Treg cells ($CD4^+FoxP3^+$) were examined in splenocytes by flow cytometry and confirmed in the spleen slides using immunofluorescent staining.

Results: The HFD group demonstrated a significant increase in mouse body weight by week 3 and continued until week 14 compared to RD group ($p < 0.05$ to $p < 0.01$). SLE features, such as skin lesions on the dorsum of neck ($p < 0.05$), splenomegaly ($p < 0.05$), and proteinuria developed significantly earlier and more severe in HFD group than RD group. Increased of acute/chronic index of kidney and increased levels of anti-dsDNA antibody were also observed in HFD group. However, ANA level was comparable between HFD group and RD group. At week 14, the Immune cells such as the frequencies of GC-B cells and plasma cells were significantly higher in the spleens of HFD group than RD group ($p < 0.05$). There was no difference in the frequencies of $CD4^+$ and $CD8^+$ T cells in the spleens of HFD group and RD group. Significant increase of Tfh cells and enlarged germinal centers were observed in the spleen of HFD group ($p < 0.05$). The ratio of Tfh/Treg in the spleen of HFD mice was also significantly increased compared to the RD group ($p < 0.05$).

Conclusion: Our results show that high fat diet induced an accelerated and more severe form of lupus development and imbalance of Tfh/Treg cells in MRL/lpr mice. This indicates that HFD affects T cell homeostasis and exacerbates the autoimmunity in lupus development. Modulations of diet or restoring the balance between Tfh and Treg cells may improve both lupus symptoms and outcomes in genetically predisposed SLE patients.

Expression of Neuropilin-1 Is Significantly Increased in Dendritic Cells and CD4 + T Cells and It Correlates Disease Activity in the Patients with Systemic Lupus Erythematosus

Yunjung Choi[1], Eun-gyeong Lee[1], Yu-Mi Lee[2], Myeung-Su Lee[3], Chang-Hoon Lee[3], Chong Hyuk Chung[3] and **Wan-Hee yoo**[1], [1]Research Institute of Clinical Medicine of Jeonbuk national university-Biomedical Research Institute of Jeonbuk national university hospital, Jeonju, Republic of Korea, [2]Jeonbuk National University Hospital, Jeonju, Republic of Korea, [3]Wonkwang University Hospital, Iksan, Republic of Korea

SESSION INFORMATION
Session Date: Tuesday, November 9, 2021
Session Title: SLE – Etiology & Pathogenesis Poster (1480–1506)
Session Type: Poster Session D
Session Time: 8:30AM–10:30AM

Background/Purpose: Neuropilin-1 (NRP-1) is a transmembrane glycoprotein that acts as a receptor of class III/IV semaphorins which role in the pathogenesis of autoimmune diseases. The NRP-1 has been studied for its immunomodulatory activity in malignancy, but there have been limited studies on the role of autoimmune inflammatory rheumatic disease, including systemic lupus erythematosus (SLE). This study was aimed to investigate the expression and the clinical implication of NRP-1 in lupus mouse models and patients with SLE.

Methods: The expression of NRP-1 was measured in T cells in spleen and renal tissue and monocyte-induced dendritic cells from control mouse and TLR-7 agonist-induced lupus mouse by flow cytometry, PCR, and immunofluorescence. CD4+ T cells from human peripheral blood were isolated to investigate the expression of NRP-1 in healthy control and the patients with SLE (n=40). In vitro analysis, the activation of the JAK-STAT pathway was examined in monocyte-induced dendritic cells treated with TLR-7 agonists with or without NRP-1 receptor antagonists.

Results: The frequency of NRP-1 positivity in CD4+ T cells in spleen was significantly higher in lupus mouse group compared to vehicle mouse group. The quantitative analysis of NRP-1 fluorescence intensity in the kidney, and monocyte-derived dendritic cells isolated from bone marrow revealed an increased level in the lupus group compared to the control group.

The CD4+ T cells from peripheral blood mononuclear cells in the patients with lupus also showed significantly higher frequency of NRP-1 positive CD4+ T cells than those from healthy controls. Comparing the correlation of the expression of NRP-1 and disease activity with SLEDAI, C3, C4, and anti-DNA antibodies, the significant correlation between NRP-1 and disease activity markers were confirmed.

In vitro analysis of monocyte-derived dendritic cells, the phosphorylation of STAT and expression of NRP-1 were enhanced by treatment of TLR7 agonist and these expressions were decreased by co-treatment of EG00229, which is an NRP-1 receptor antagonist.

Conclusion: Our results show that NRP-1 is involved in the phosphorylation of STATs activated by TLR-7 agonists, and the expression of NRP-1 significantly correlates with the disease activity of patients with SLE.

These results indicate the significant contribution of NRP-1 in the pathogenesis of SLE and the potential of targeting NRP-1 for the treatment of SLE.

Molecular Modelling Predicts **Inhibition** of Functional Effects of Anti-thrombin III on Factor Xa Mediated Complement Activation by Anti-Factor Xa IgG in SLE and APS

Thomas McDonnell[1], Raj Amarnani[2], Valentina Spiteri[2], Carina Spicer[3], Charis Pericleous[4], Bahar Artim-Esen[5], Ian Mackie[1], Marina Botto[4], Anisur Rahman[1] and Ian Giles[1], [1]University College London, London, United Kingdom, [2]University College London, London, [3]Merck, Philadelphia, PA, [4]Imperial College London, London, United Kingdom, [5]Istanbul University School of Medicine, İstanbul, Turkey

SESSION INFORMATION

Session Date: Tuesday, November 9, 2021

Session Title: SLE – Etiology & Pathogenesis Poster (1480–1506)

Session Type: Poster Session D

Session Time: 8:30AM–10:30AM

Background/Purpose: The significance of antibodies directed against activated Factor (FXa) and thrombin (Thr) found in ~40% of patients with Systemic Lupus Erythematosus (SLE) and/or Antiphospholipid Syndrome (APS) has not been determined. FXa and Thr are both co-regulated by antithrombin (AT)III and increasingly implicated in alternative pathways of complement activation. Therefore, we studied the ability of anti-(a)FXa and/or anti-(a)Thr IgG to modulate complement activation in SLE and APS.

Methods: Patients with SLE +/- APS and known aThr and/or aFXa IgG positivity had serial measurements of complement C3 at clinic appointments at University College London Hospital from 2015-19. Affinity purification of aFXa and aThr IgG were performed by passage through heparin/FXa or heparin/Thr and then protein G column. The effect of this IgG upon FXa and Thr mediated C3 and C5 activation was measured by Western Blot. Structural analysis of FXa and Thr was performed by Scalable Molecular Dynamics (NAMD), Visual Molecular Dynamics (VMD) and Discotope

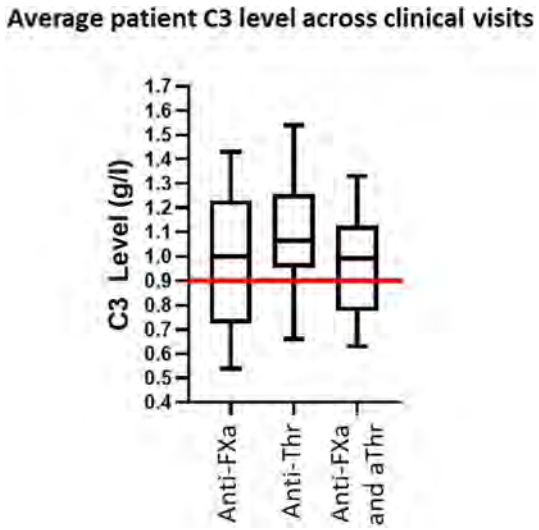

Figure 1. The average C3 level from SLE and APS patients (n=66) across their visits to clinic (2015-2019) demonstrate lower levels of C3 on average for FXa positive patients and double positive (aFXa and aThr) patients compared to aThr alone. The red line indicates clinical cutoff for low C3 levels. This implies the presence of aFXa antibodies may influence the C3 levels of SLE and APS patients.

(v1.1). Predicted sites were modelled onto high resolution crystal structures of the ATIII-FXa and ATIII-Thr complexes and compared with the in-vitro ability of ATIII to regulate aFXa-FXa and aThr-Thr mediated C3/C5 activation.

Results: Longitudinal analysis of 66 patients with SLE (n=5 with APS) from an average of 8.2 (range 1 to 10) visits across 5 years found that patients positive for anti(a)FXa alone (n=16) or in combination with anti(a)Thr IgG (n=26) had lower C3 levels than patients with aThr IgG alone (n=24) (Figure1). We affinity purified IgG from 15 of these patients. aThr IgG increased Thr mediated activation of C3 (x 1.8 fold) and C5 (x3 fold), whilst aFXa IgG increased (x 1.3 fold) C3 activation only. Using *in silico* epitope mapping we identified potential epitopes for binding of aFXa to FXa and aThr to Thr. These studies predicted steric hindrance of binding to ATIII at 2 of 4 potential aFXa IgG epitopes on FXa compared with only 1 of 6 aThr IgG epitopes on Thr. This increased likelihood of steric hinderance of aFXa compared to aThr was confirmed by in-vitro studies whereby ATIII inhibition of Thr-mediated C3 and C5 activation was not affected by aThr IgG, whilst ATIII inhibition of FXa-mediated C3 and C5 activation was abrogated by aFXa IgG.

Conclusion: We propose a novel method of complement regulation in SLE and APS patients whereby aFXa and aThr IgG increase complement activation. Furthermore, we demonstrate that natural inhibition by ATIII is less efficient on FXa-FXa IgG-mediated complement activation compared with the one mediated by Thr-aThr IgG due to proximity of the IgG epitope to the ATIII binding site in FXa but not Thr.

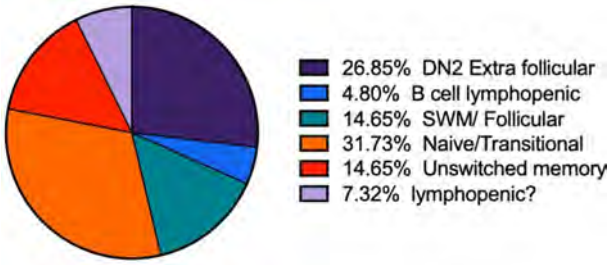
Longitudinal Changes in B Cell Subsets in Patients in the Mesenchymal Stromal Cell Trial in Lupus: Analysis of the First Cohort

Diane Kamen[1], S Sam Lim[2], Scott Jenks[3], Regina Bugrovosky[3], Aisha Hill[3], Chungwen Wei[3], Cristina Drenkard[3], Kenneth Kalunian[4], Ummara Shah[5], Mariko Ishimori[6], Rosalind Ramsey-Goldman[7], Saira Sheikh[8], Mary Alison Mahieu[7], Daniel Wallace[9], Ellen Goldmuntz[10] and **Gary Gilkeson**[1], [1]Medical University of South Carolina, Charleston, SC, [2]Department of Medicine, Division of Rheumatology, Emory University School of Medicine, Atlanta, GA, [3]Emory University, Atlanta, GA, [4]UC San Diego, La Jolla, CA, [5]University of Rochester, Rochester, NY, [6]Cedars-Sinai Health System, Los Angeles, CA, [7]Northwestern University, Chicago, IL, [8]University of North Carolina, Chapel Hill, NC, [9]Attune Health, Beverly Hills, CA, [10]National Institutes of Health, Bethesda, MD

SESSION INFORMATION
Session Date: Tuesday, November 9, 2021
Session Title: SLE – Etiology & Pathogenesis Poster (1480–1506)
Session Type: Poster Session D
Session Time: 8:30AM–10:30AM

Background/Purpose: Recent advances allow expanded identification of B cell subtypes of pathogenic potential in lupus. Of particular interest are IgD- CD27- double negative (DN2) B cells and activated naïve B cells (AN). These subsets are expanded in African American women with lupus and are progenitors of autoantibody producing cells. Less is known of these subsets in other ethnicities, their stability over time or their response to treatment. As part of the double-blind placebo controlled trial of mesenchymal stromal cells (MSCs) for treatment of refractory lupus, we assessed B cell phenotypes at week 0, week 4, week 8 and week 24 in patients in the first cohort of participants. To prevent unblinding, we did not determine associations between B cell phenotypes and clinical response during this low dose cohort of the trial.

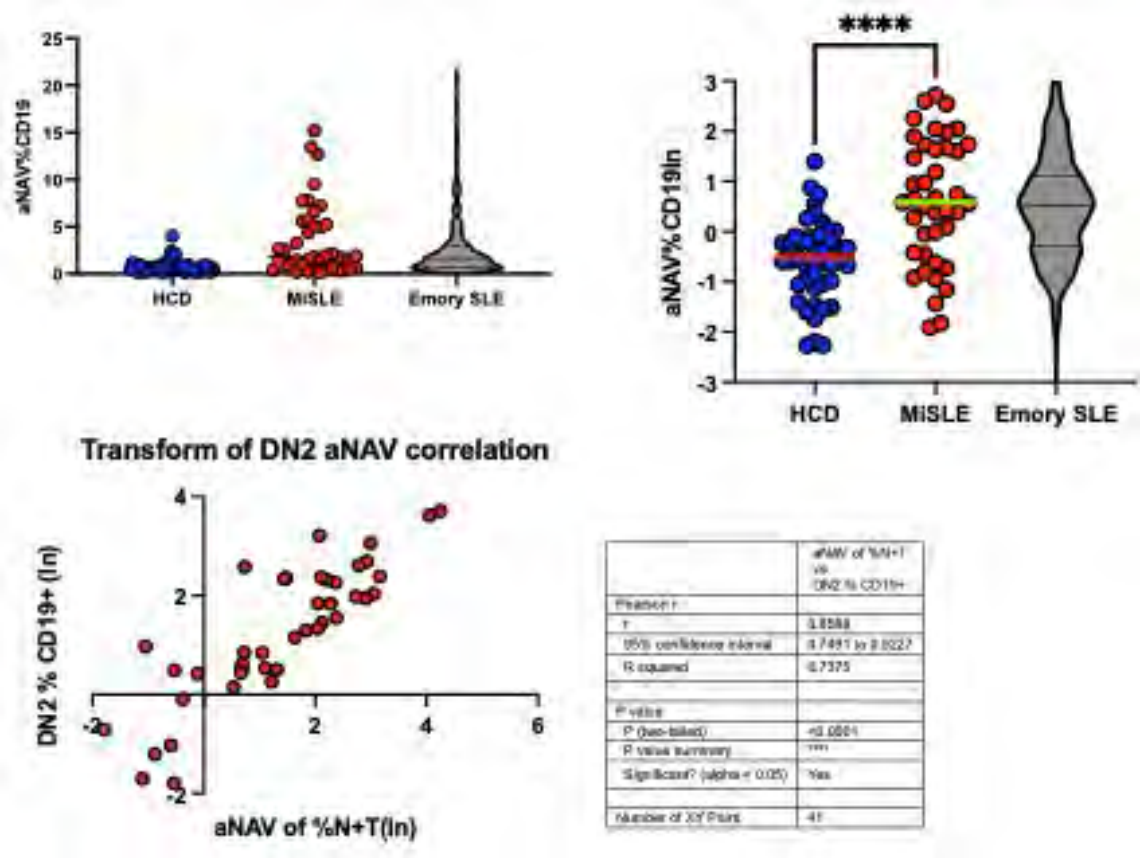
Methods: 41 lupus patients, primarily women (90%) and mixed ethnicities (49% Caucasian, 39% African American, 12% other) were enrolled. They were randomized to receive either $1x10^6$ umbilical cord derived MSCs/kg or placebo



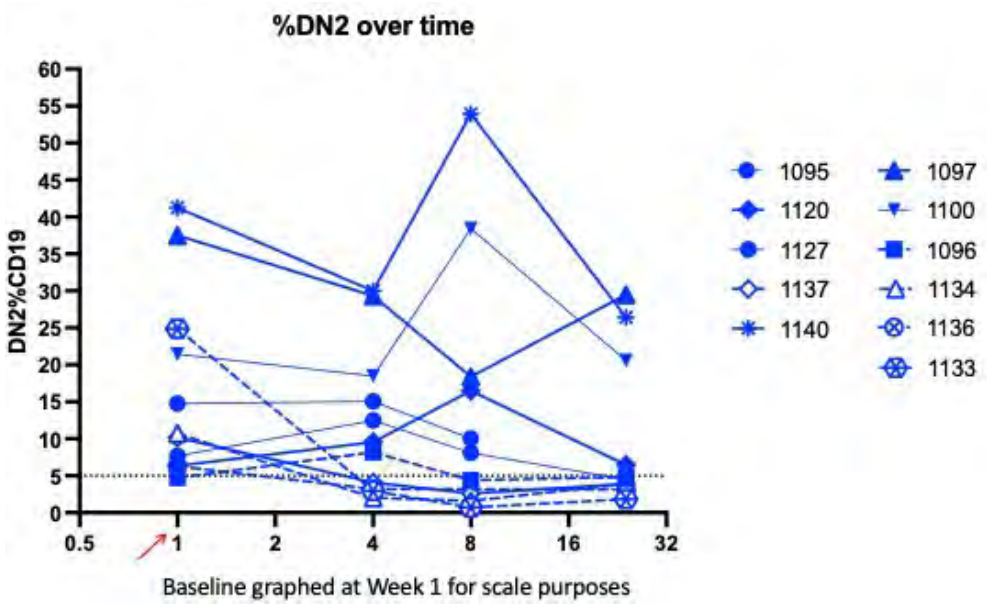
B cell phenotypes at baseline of the 41 patients enrolled into the MSCs in Lupus Erythematosus trial

at a 2/1 ratio. All patients met ACR criteria and had a SLEDAI >6 having failed immunosuppressive therapy. Patients with nephritis were included. Samples for B cell analysis were shipped to Emory for analysis via overnight delivery. Analyses were done by FLOW using 11 color flow. Comparative analyses were done with matched healthy controls and with previously analyzed samples in the Emory lupus cohort.

Results: As expected, there was significant heterogeneity of B cell phenotypes, as demonstrated in Figure 1. with 31.7% expressing a Naïve/Transitional phenotype and 26.9% having a DN2 extrafollicular phenotype. The B cell phenotype remained stable generally, but there were substantial shifts in some patients. Over 50% of lupus study patients had increased numbers of DN2 B cells compared to controls (Figure 2). There was a strong positive correlation between percent of DN2 B cells and AN B cells. Overtime, patients with a very high percentage of DN2 B cells retained this phenotype, where those with a moderate DN2 expansion at baseline, decreased significantly over



Activated naive B cells are expanded in patients with SLE. There is a strong correlation between percentage of activated naive and DN2 B cells in the patients in the trial.



Chronologic changes in DN2 B cells. Data presented is from patients whose baseline % of DN2 B cells was greater than 5%. As noted, patients with very high percentage of DN2 B cells tended to retain this phenotype while those with moderate increased percentage of DN2 B cells, the % DN2 cells trended down over the 24 weeks. Only 1/41 patients had an increased DN2 percentage during the trial period.

time. Patients with low DN2 B cells at baseline retained this phenotype. Unswitched memory B cells were low and remained low compared to controls. There was considerable heterogeneity in switched memory B cells, but no population level differences from controls. Overall naïve B cells were similar between patients and controls, but some patients had very low levels of naïve cells.

Conclusion: These results indicate mixed ethnicity patients from 7 sites in the US, participating in the MSC trial, exhibited considerable B cell phenotypic heterogeneity, though the majority had a B cell Naïve/Transitional or DN2 extrafollicular phenotype. Longitudinal analysis reveals stability of B cell phenotype in many patients, while others have significant changes in B cell phenotype, predominantly due to decreased frequency of DN2 and AN B cells. Further characterization will determine clinical correlates between baseline B cell phenotype and lupus disease phenotype and differences in response to therapy based on initial B cell phenotypes.

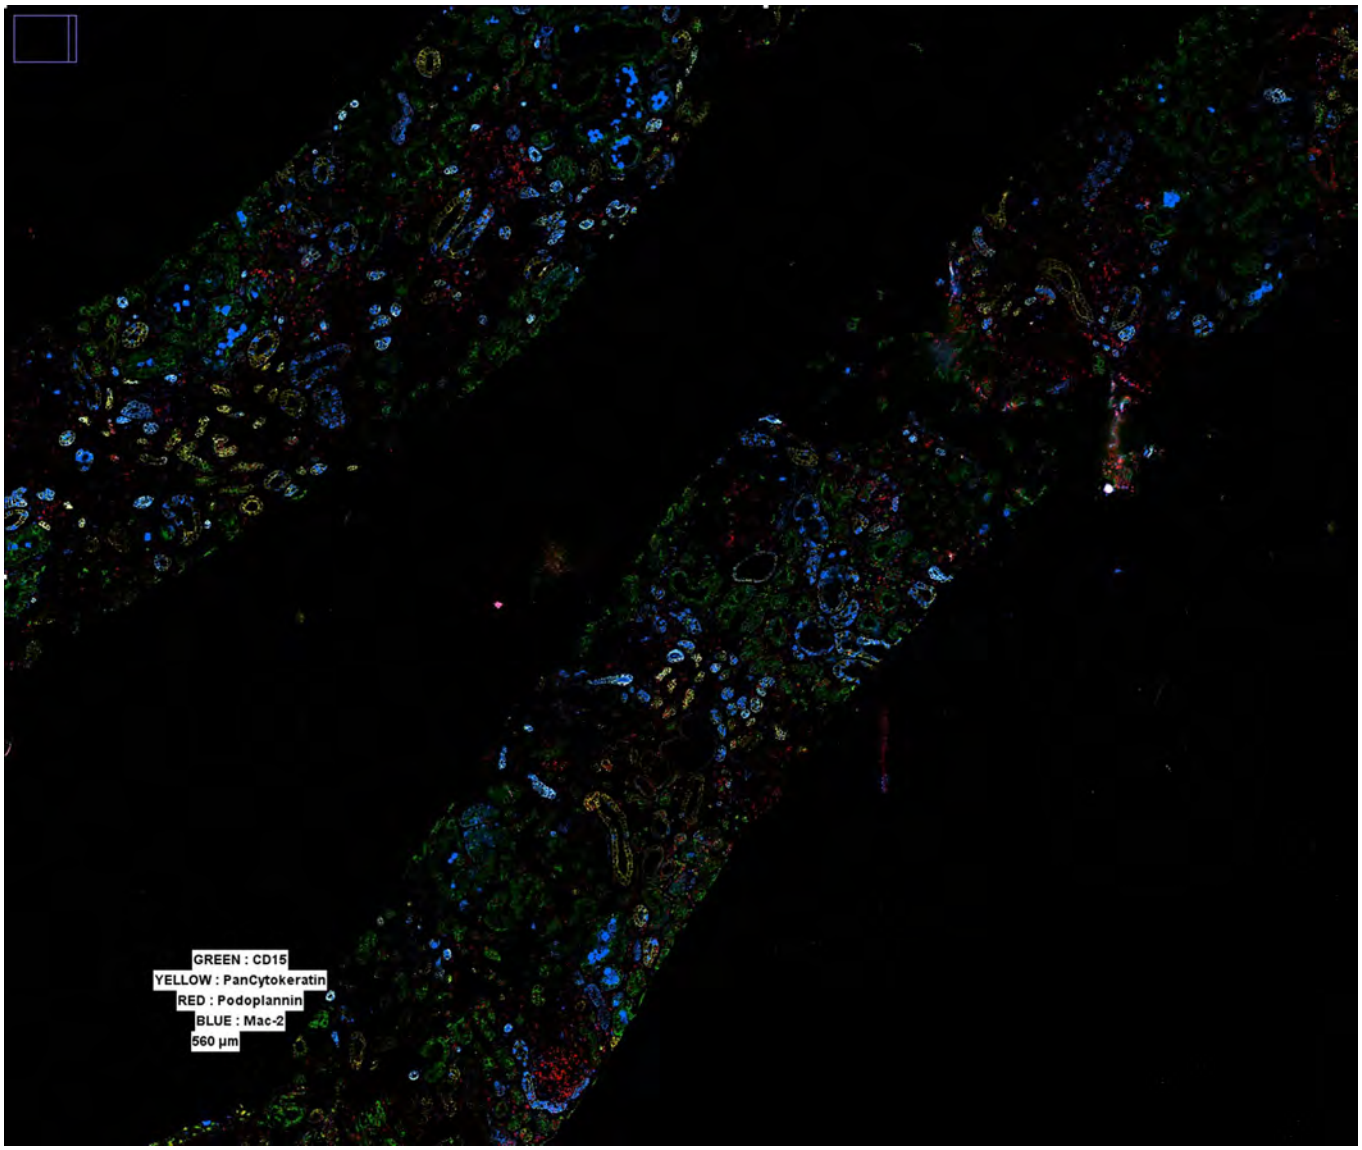
Putting the Pieces on the Board: Mapping SLE Nephritis Biopsies from the Accelerating Medicines Project Using High-Density Immunofluorescence Imaging

Craig Smuda[1], Anna Eichinger[2], Robert Clancy[2], Jill Buyon[3] and Boris Reizis[4], [1]NYU Grossman School of Medic ine, New York, NY, [2]NYU Grossman School of Medicine, New York, NY, [3]NYU School of Medicine, New York, NY, [4]New York University Grossman School of Medicine, New York, NY

SESSION INFORMATION
Session Date: Tuesday, November 9, 2021
Session Title: SLE – Etiology & Pathogenesis Poster (1480–1506)
Session Type: Poster Session D
Session Time: 8:30AM–10:30AM

Background/Purpose: The Accelerating Medicines Project (AMP) has enabled significant increases in understanding of SLE nephritis pathology, providing a profile of dozens of leukocyte subsets within affected kidneys by single-cell RNA sequencing of nephritis biopsies. While these results suggest a complex network of interactions between cell populations during nephritis, the spatial positioning of these cells is lost during the sequencing process. Inferred interactions between the diverse identified cell types would be greatly strengthened by detailed spatial information, placing these cells in context with each other and with the surrounding structures of the kidney.

Methods: In consultation with AMP, we have used CODEX, a multicycle imaging technology allowing for staining of up to 40 targets on a single tissue sample without tissue degradation, to capture preliminary images of the AMP

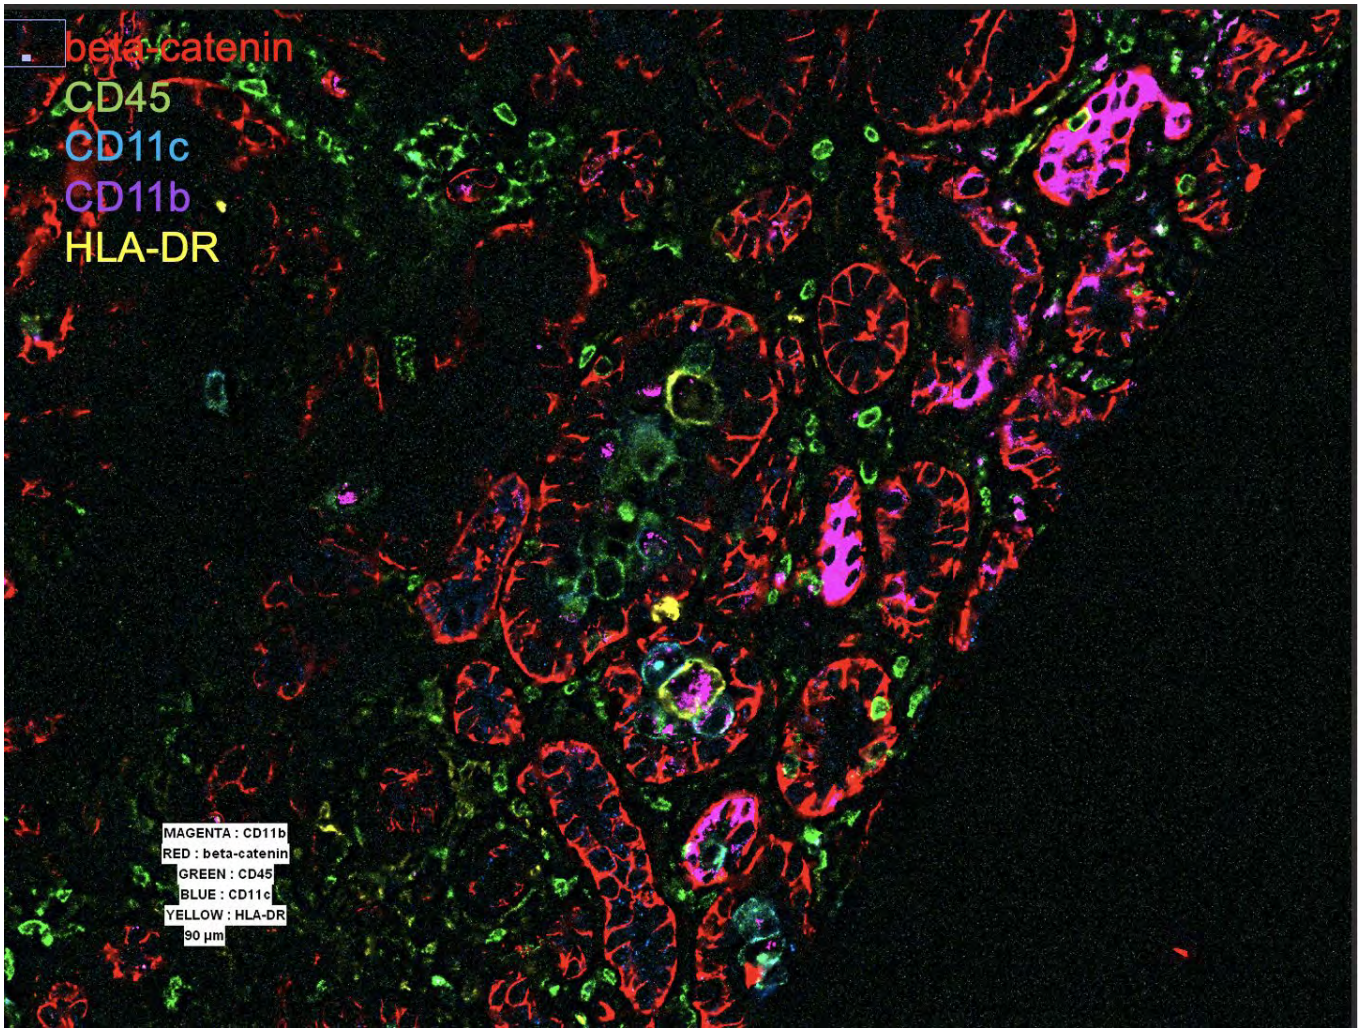


A wide view of a selected biopsy demonstrates ultrastructure via multiple structural markers. Multiple such regions can be captured, allowing for the entirety of a biopsy sample to be imaged. All images shown display only a subset of the overall stained markers due to visual limitations.

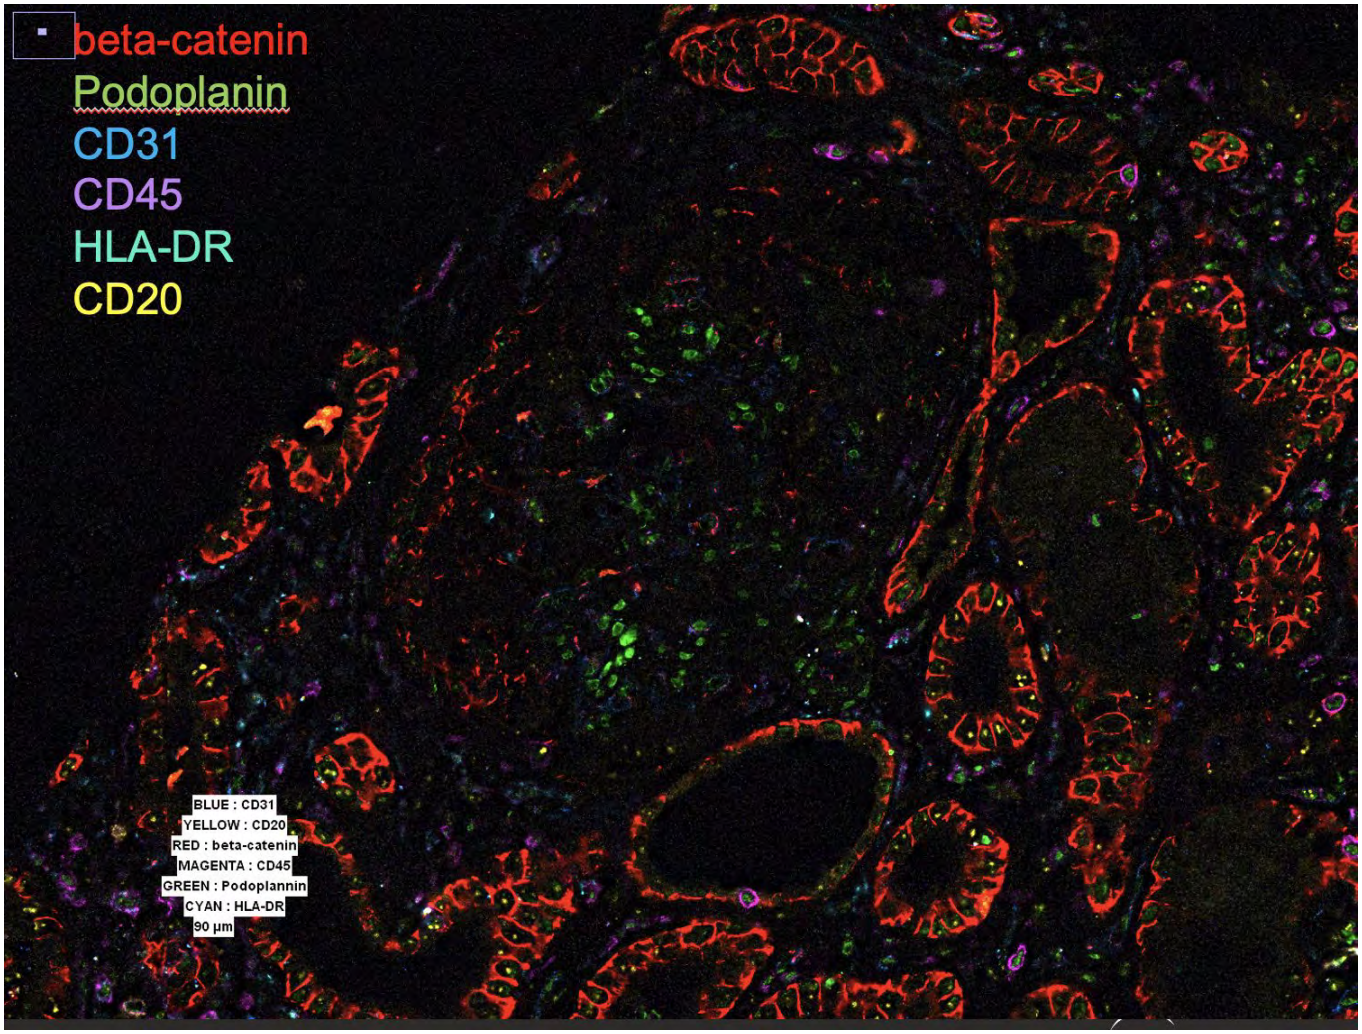
tissue biopsies available at New York University. Extensive antibody screening, sample preparation, optimization of antigen retrieval, and imaging steps are required, which remain under active optimization to allow for imaging the entirety of the AMP biopsy cohort available at the Grossman School of Medicine, which has been fully processed for future staining.

Results: At present we are able to image sixteen targets capturing dense interstitial T and B cell infiltrates, intratubular and interstitial myeloid populations, and sparser glomerular infiltrating cells in our demonstration cohort, with clear imaging of the glomeruli, tubules, and interstitial spaces. Further targets will be added as they are optimized, further allowing subsetting of T, B, and myeloid populations, with the goal of capturing the populations identified previously in single-cell sequencing.

Conclusion: CODEX imaging of renal biopsy samples provides spatial context for prior observations across a range of SLE nephritis samples, with complex interstitial populations found around glomeruli and tubules in active disease. Deeper profiling with expanded antigen targets to enable further sub-population phenotyping and activation states and imaging of the full cohort of biopsies available at NYU will provide a spatial atlas to SLE nephritis and further reveal underlying mechanisms of disease.



Close examination of a tubule reveals diverse infiltrating cells, including CD11c+, CD11b/c+, and sparse CD11b/c+ HLA-DR+ cells. Surrounding interstitial lymphocytes can be seen, which correspond to CD3+ CD4+ T cells (stains not shown).



Periglomerular infiltration, without significant glomerular cellular involvement, is seen in this image. CD20+ B cells and HLA-DR+ cells can be seen in the lower left.

Abstract Number: 1504

Association Between Anti-RNP Antibodies and Interferon Gene Expression but Not Complement Consumption in SLE

Erika Hubbard[1], David Pisetsky[2] and Peter Lipsky[1], [1]AMPEL BioSolutions, Charlottesville, VA, [2]Duke University Medical Center, Durham, NC

SESSION INFORMATION

Session Date: Tuesday, November 9, 2021
Session Title: SLE – Etiology & Pathogenesis Poster (1480–1506)
Session Type: Poster Session D
Session Time: 8:30AM–10:30AM

Background/Purpose: Anti-nuclear antibodies are important serologic features of SLE and facilitate diagnosis. Anti-double stranded DNA (dsDNA) antibodies are routinely monitored for disease prognosis and are related to complement consumption, with immune complex deposition in the kidneys causing tissue damage. Relatively less is known about autoantibodies against RNA binding proteins (RBP) and about the relationship between either autoantibody and expression of the interferon (IFN) stimulated gene (ISG) signature. Extensive laboratory measurements from 2 clinical trials of tabalumab in SLE (ILLUMINATE 1&2) allowed analysis of the relationships between autoantibody levels, ISG expression, and complement (C) C3 and C4 levels.

Methods: Microarray data from 1620 active (SLEDAI≥6), female SLE patients and accompanying laboratory measurements were analyzed (GSE88884). All patients satisfied ≥4 of the 1997 ACR classification criteria. Gene Set Variation Analysis (GSVA) was carried out to determine enrichment of the ISG signature in each patient. Linear regression analysis was used to determine relationships between ISG GSVA scores and C3 and/or C4 levels as well as autoantibody levels. Unbiased classification and regression trees (CART) were constructed to determine the highest predictors of ISG expression.

Results: Patients were stratified by autoantibody positivity. Comparison of GSVA scores of the core IFN signature, shared by type I and type II IFNs, demonstrated that SLE patients positive for anti-ribonucleoprotein (RNP) antibodies alone had greater enrichment of ISG than those positive for anti-dsDNA alone (Figure 1). Similar results were noted for gene signatures of type I IFN, IFNα2, IFNβ, and IFNγ. In contrast, the TNF gene signature was observed comparably in patients with anti-dsDNA or anti-RNP antibodies and the IL-1 signature was only observed in those with anti-dsDNA. By linear regression, IFN GSVA scores and C3 and C4 levels were significantly, inversely related in patients with anti-dsDNA antibodies but not those with anti-RNP antibodies. Antibody levels correlated with decreased C levels in dsDNA+ patients. Additionally, ISG GSVA scores were increased in anti-dsDNA+ patients with low C3 or C4 compared to anti-dsDNA+ patients with high/normal C, but there was no significant difference in ISG expression in anti-RNP+ patients with the same stratification. CART analysis identified anti-RNP status was the highest predictor of ISG GSVA score. Finally, 56.2% of SLE patients without an ISG signature exhibited autoantibodies, but only 13.7% of SLE patients negative for autoantibodies expressed the ISG signature (Figure 2).

Conclusion: Taken together, these data indicate that anti-RNP antibodies are associated with ISG expression more strongly than anti-dsDNA antibodies, but are not related to the depression of C3 or C4. Furthermore, ISG expression is not required for autoantibody production, but autoantibodies are likely directionally related to the ISG signature.

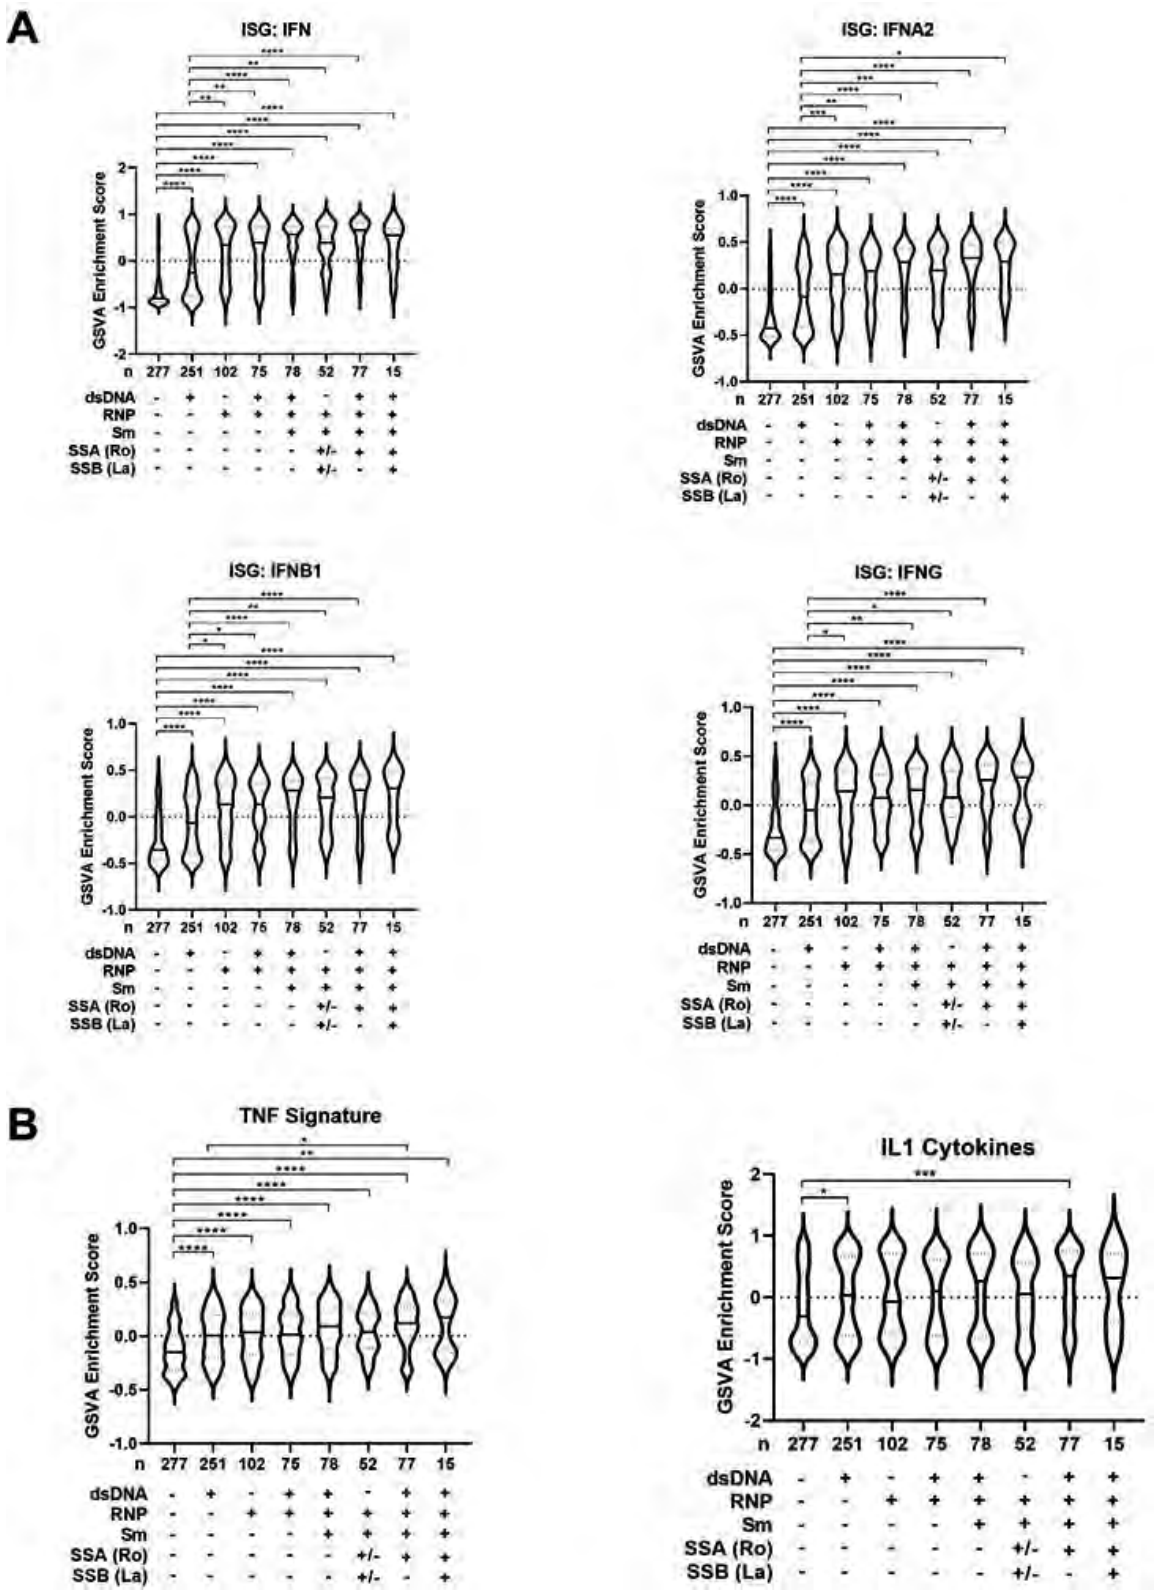

Figure 1. ISG (A) and other inflammatory cytokine (B) enrichment in SLE patients with various autoantibodies. Violin plots display median values of GSVA enrichment (solid lines) and upper and lower quartiles (dashed lines). *p<0.05; **p<0.01; ***p<0.001; ****p<0.0001 by Dunn's multiple comparisons test.

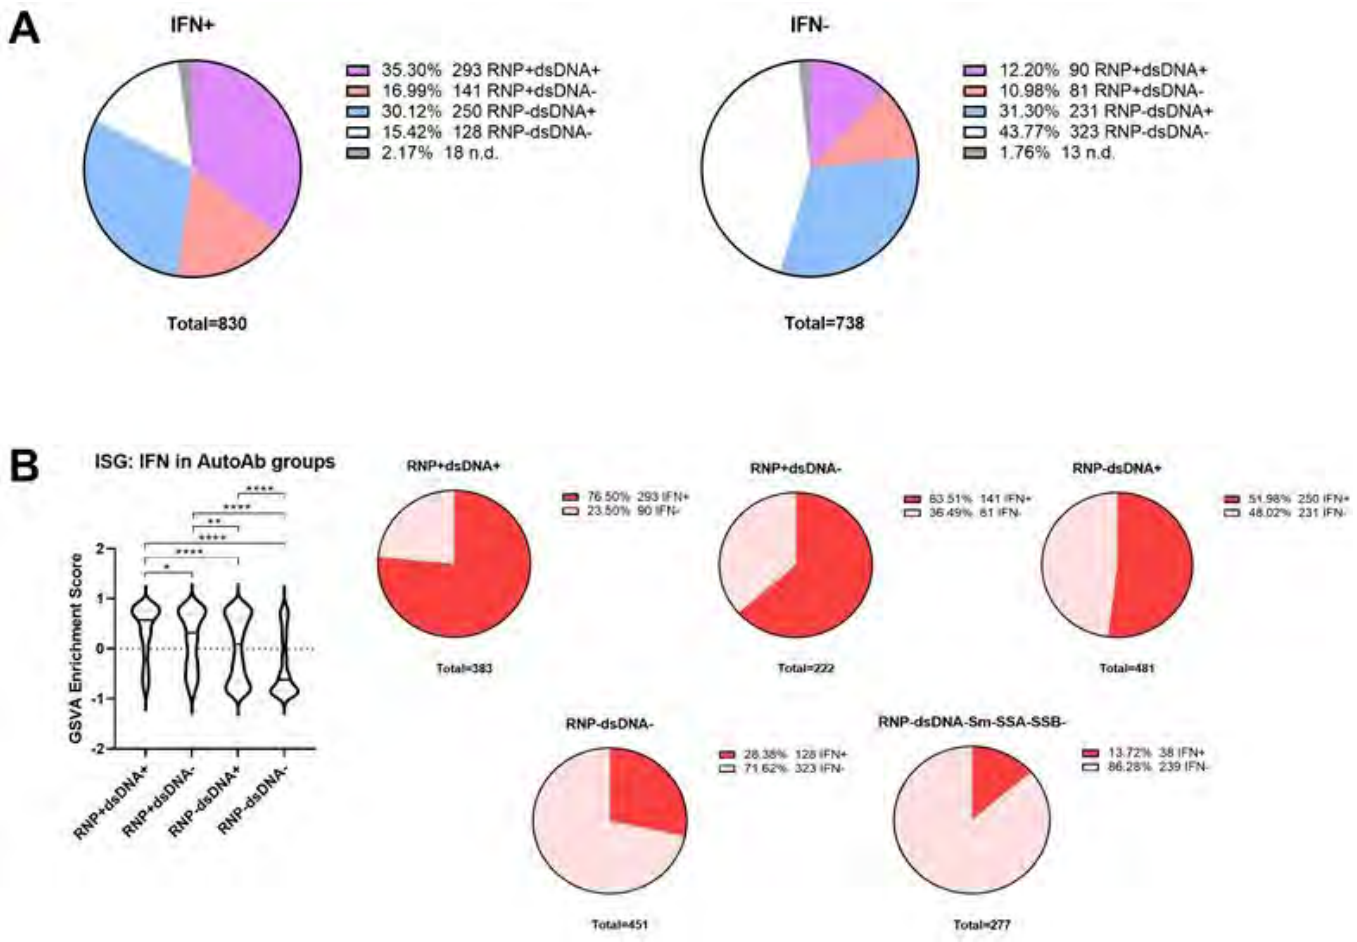

Figure 2. Autoantibody status was examined in IFN+ (GSVA enrichment score>0) and IFN- (GSVA enrichment score<0) SLE patients in (A) whereas IFN status was examined in autoantibody-stratified patients in (B). Dunn's multiple comparisons test determined significant differences in ISG enrichment among the groups displayed by violin plots. n.d.=no data. *p<0.05; **p<0.01; ***p<0.001; ****p<0.0001.

Inflammatory Dendritic Cell and Th17 Polarization in Mouse Model of Lupus Nephritis

Latha Prabha Ganesan[1], Noushin Saljoughian[1], James Turman[1], Murugesan Rajaram[1], Brad Rovin[2], Wael Jarjour[1] and Samir Parikh[2], [1]Ohio State University, Columbus, OH, [2]Ohio State University Wexner Medical Center, Columbus, OH

SESSION INFORMATION

Session Date: Tuesday, November 9, 2021
Session Title: SLE – Etiology & Pathogenesis Poster (1480–1506)
Session Type: Poster Session D
Session Time: 8:30AM–10:30AM

Background/Purpose: We have recently identified inflammatory dendritic cells (InfDC) in human lupus kidneys. These cells are over expressed in LN patients compared to healthy controls. Knowledge on how the infDC interact with intra-renal T cells and their role in pathogenesis of LN kidney is crucially needed

Methods: We examined infDC and T cells in the kidneys of NZM 2410 (NZM), from proteinuric (prot-NZM) mice (proteinuria ≥300mg/dl) and pre-proteinuric NZM (pre-prot-NZM) mice by Immunofluorescence (IF). To quantitatively assess infDC and various T cells, we analyzed single cell suspensions obtained by enzymatic digestion followed by gentle MACS dissociation from prot-NZM kidneys and pre-prot-NZM kidneys by multi-color flow cytometry using specific markers for infDC and T cells

Results: The immunofluorescence (IF) studies recapitulated the human LN robust infiltration of the infDC marked by FcRγ in the periglomerular and tubulointerstitium in prot-NZM compared to pre-prot-NZM. The infDC were also identified to be in close proximity to CD3+ T cells constant with an immunological synape. Further characterization by IF revealed infDC in mice LN were $FcR\gamma^{+}$, $MHCII^{+}$,$CD11c^{+}$,$CD163^{-}$,$CD11b^{+}$,$Ly6C^{+}$. Interestingly, 2 subtypes of infDC were identified in NZM mice, $FcR\gamma^{+}MHCII^{+}CD11c^{+}$,$CD11b^{+}$ and $FcR\gamma^{+}MHCII^{+}CD11c^{-}$,$CD11b^{+}$ and differentiated by the presence or absence of CD11c. Flow cytometry analysis of T helper cell phenotypes shows that Th17 expression, but not Th1 was upregulated significantly in prot-NZM compared to pre-prot-NZM in parallel to infDC.

Conclusion: 1) Similar to human LN, infDC are abundant in prot-NZM LN kidneys compared to respective pre-prot NZM and healthy control kidneys; 2) infDC synapse with CD3+ T cells in LN kidneys; and 3) Th17 cells, but not Th1 cells, correlate with infDC's expression in LN kidneys. These data suggests that infDC regulate the intra-renal Th17 cell response in LN and contribute to IL-17 mediated kidney injury. Ongoing studies will examine if these infDC are necessary or sufficient to cause LN.

Abstract Number: 1506

SLAMF6 Compartmentalization Regulates Autoimmune T Cell Responses

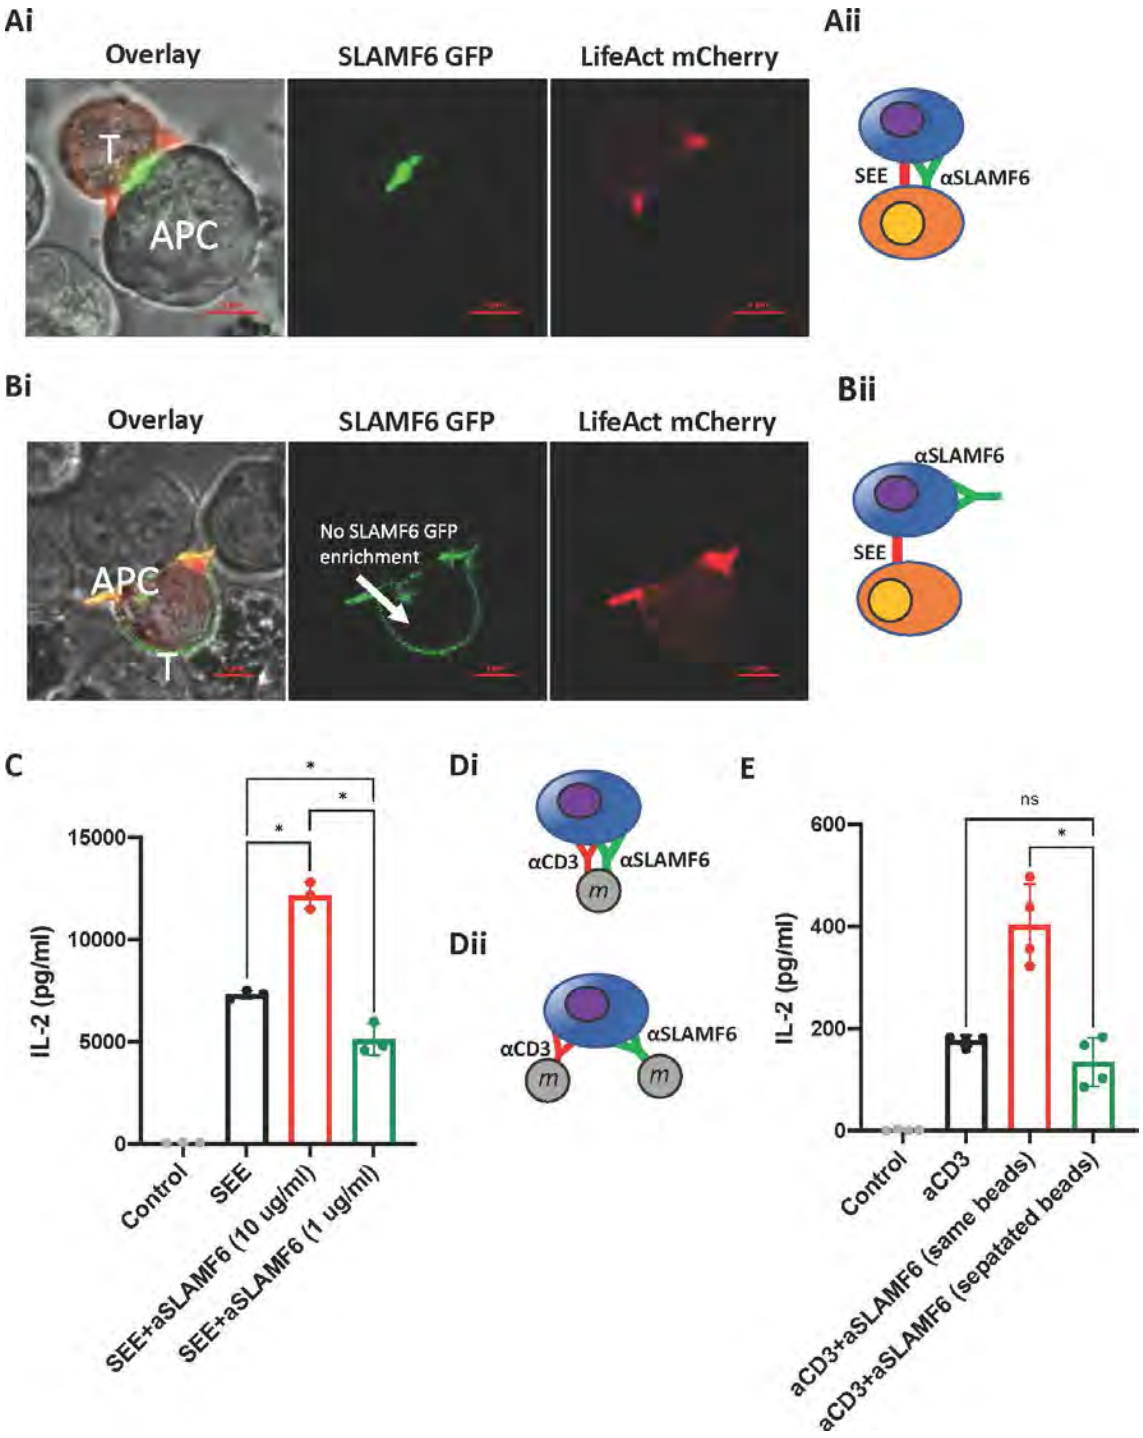
Yevgeniya Gartshteyn[1], Anca Askanase[2] and Adam Mor[3], [1]Columbia University Medical Center, Glen Rock, NJ, [2]Columbia University Medical Center, New York, NY, [3]CUIMC, New York, NY

SESSION INFORMATION
Session Date: Tuesday, November 9, 2021
Session Title: SLE – Etiology & Pathogenesis Poster (1480–1506)
Session Type: Poster Session D
Session Time: 8:30AM–10:30AM

Background/Purpose: T cell activation is initiated by engagement of the T cell receptor (TCR) complex and requires co-receptor signaling. SLAMF6 is a major T cell co-receptor and aberrant signaling downstream this receptor has have been implicated in the pathogenesis of systemic lupus erythematosus (SLE). Moreover, genome association studies in spontaneous murine lupus models of SLE associated SLAMF6 polymorphisms with loss of tolerance, autoantibody production, and susceptibility to SLE.

Accordingly, uncovering the mechanism of SLAMF6 signaling in autoimmune T cells could improve our understanding of the biology of SLE and could have translational therapeutic implications.

Methods: Activation of Jurkat T cells (ATCC) with 1) immobilized anti-CD3 and anti-SLAMF6 allowed for SLAMF6 clustering to the immunological synapse (IS) or 2) immobilized anti-CD3 and soluble anti-SLAMF6 resulted in exclusion of SLAMF6 from the IS. ELISA was used to measure cytokine secretion and CFSE assay to assess T cell proliferation. Co-immuno precipitation of SLAMF6 was performed using a SLAMF6 knock-out cell line that was transduced to express V5-tagged SLAMF6, results were analyzed using protein electrophoresis with immunoblotting and mass spectrometry.



SLAMF6 expression was evaluated in lymphocytes isolated from the peripheral blood of SLE patients with well characterized clinical phenotypes.

Results: Previously we discovered that SLAMF6 clustering is a requirement for its co-stimulatory functions. In the current work, we show that SLAMF6 recruitment to the immunological synapse (IS) is needed to support T cell proliferation and survival. Using confocal microscopy, we also show a direct correlation between SLAMF6 localization within the different compartments of the IS and the ability of this receptor to enhance secretion of multiple cytokines. Mechanistically, and through co-immunoprecipitation experiments, we reveal that SLAMF6 recruits several members of the Src family of kinases to IS, leading to enhance proximal phosphorylation of the TCR complex. Finally, taking

advantage of Tfh cell isolated from patients with active SLE, we show that specific pharmacological interventions that prevent SLAMF6 clustering inhibit TCR signaling and multiple effector functions.

Conclusion: This transitional study advances the understanding of how SLAMF6 contribute to SLE pathogenesis, linking known SLE susceptible genes to specific signaling pathway in autoimmune T cells. Means to manipulate SLAMF6 signaling are promising approaches for novel SLE therapeutics.

Role of CD4+ T Cells in the Pathogenesis of RA: Immunization with Citrullinated T Cell Epitopes Is Sufficient to Induce Immunological and Clinical Manifestations of Arthritis in DR4-Transgenic Mice

Elena Tonti[1], Bhargavi Duvvuri[2], Sudeshna Dhar[1], Derek Haaland[3], Maggie Larche[1] and Mark Larché[1], [1]McMaster University, Hamilton, ON, Canada, [2]University of Washington, Seattle, WA, [3]McMaster University, Hamilton, Ontario and The Waterside Clinic, Oro Medonte, ON, Canada

SESSION INFORMATION
Session Date: Tuesday, November 9, 2021
Session Title: T Cell Biology & Targets in Autoimmune & Inflammatory Disease Poster (1507–1515)
Session Type: Poster Session D
Session Time: 8:30AM–10:30AM

Background/Purpose: Although the etiology of rheumatoid arthritis (RA) remains unclear, existing research suggests a complex interplay of both genetic and environmental factors. Citrullinated proteins/peptides, and immune responses to them, may lead to the breaching of immunological tolerance, and subsequent disease. While most research to date has focused on the specificity of anti-citrullinated protein antibodies (ACPAs) in RA, the role of T cell responses to citrullinated peptides remains to be further investigated. The aim of this study is to better understand the involvement of T cells in the pathogenesis of the disease, with the ultimate vision of developing therapeutic interventions for RA.

Methods: HLA-DRA/DRB1*0401 transgenic mice were immunized with two subcutaneous injections of 10 citrullinated T-cell epitopes known to bind to DRB1*0401 and derived from proteins implicated in the development of RA. After 1 week, a second boost was performed, either with citrullinated human fibrinogen protein or with an additional dose of the 10 peptides. Two months after, the mice received an intra-articular (IA) boost in the right knee with a mixture containing 5 citrullinated peptides. All immunizations were performed in complete (for the priming injection, CFA) or incomplete (for the subsequent boosts, IFA) Freund's adjuvant.

Results: Within weeks of the initial subcutaneous immunizations, the mice developed T-cell responses that were specific for the citrullinated peptides and not for their native counterparts. Remarkably, the injection of citrullinated T cell epitopes was sufficient to induce the production of ACPA, detectable in the blood by ELISA. In addition, the IA boost led to the manifestation of clinical signs of arthritis: mice injected intra-articularly with citrullinated peptides and IFA showed prolonged articular swelling and systemic inflammation in comparison to the control groups. Such signs were even more pronounced in mice previously treated with the citrullinated human fibrinogen protein.

Conclusion: This study shows that immunization with shared epitope-binding citrullinated peptides is sufficient to induce immunological and clinical signs of RA, by triggering arthritogenic T cell responses. These results provide

direct evidence of the pathogenic contribution of particular peptides to arthritis and of the pivotal role of T cells in the pathogenesis of the disease. Furthermore, these findings also introduce the possibility of using peptide immunotherapy to re-establish immunological tolerance to RA autoantigens.

Session Title: T Cell Biology & Targets in Autoimmune & Inflammatory Disease Poster (1507–1515)

Session Type: Poster Session D

Session Time: 8:30AM–10:30AM

Background/Purpose: Interstitial lung disease (ILD) is one of the most significant complications of connective tissue diseases (CTD) leading to an increase of the morbidity and mortality in patients with CTD, mainly in those with systemic sclerosis (SSc) and rheumatoid arthritis (RA) [1]. A specific T cell subset termed angiogenic T cells (TAng), implicated in endothelial repair and revascularization, has been involved in the pathogenesis of CTD [2-4]. However, to the best of our knowledge, no information regarding the role of TAng in CTD-ILD$^+$ is available. Accordingly, we aimed to evaluate the role of TAng related to vascular damage in CTD-ILD$^+$.

Methods: This study included 40 patients with CTD-ILD$^+$: 20 RA-ILD$^+$ and 20 SSc-ILD$^+$. Furthermore, three comparative groups were included: 1) 43 patients with CTD-ILD$^-$: 24 RA-ILD$^-$and 19 SSc-ILD$^-$; 2) 21 patients with idiopathic pulmonary fibrosis (IPF); and 3) 20 healthy controls (HC). All subjects were recruited from the Rheumatology and Pneumology de-

partments of Hospital Universitario Marqués de Valdecilla, Santander, Spain. Quantification of TAng was performed from peripheral venous blood by flow cytometry. TAng were considered as triple-positive for CD3, CD31 and CXCR4.

Results: Patients with CTD-ILD$^+$ exhibited a significantly lower TAng frequency than CTD-ILD$^-$ patients ($p< 0.001$). Specifically, RA-ILD$^+$ patients and SSc-ILD$^+$ patients showed a lower frequency of TAng than RA-ILD$^-$ patients and SSc-ILD$^-$ patients, respectively ($p=0.006$ and $p=0.04$, in each case). A decreased TAng frequency was also found in CTD-ILD$^+$ patients when compared with HC ($p< 0.001$), whereas no difference was observed between CTD-ILD$^+$ patients and those with IPF. In addition, a significant increase of TAng frequency was shown in patients with CTD-ILD$^-$ in relation to IPF patients ($p< 0.001$), while no difference was observed between CTD-ILD$^-$ patients and HC.

Conclusion: Our study supports a role of TAng in the vascular damage in CTD-ILD$^+$. Furthermore, our results reveal a decrease of TAng frequency associated to the presence of ILD, both in CTD patients, in particular in those with RA and SSc, and in IPF patients.

Pharmacological Inhibition of MALT1 Reverses Activation-Induced Metabolic Reprogramming and Ameliorates Autoimmune Pathogenesis in Multiple Animal Models of Chronic Inflammation

Subhabrata Biswas, Mya Steadman, Ynes Helou, Katherine Sellers, Keng Soh, Aditi Chalishazar, Mehmet Badur, Joanna DiSpirito, Brian DeChristopher, John Monroe, Dania Rabah, Barbara Fox and Andy Long, Rheos Medicines, Inc, Cambridge, MA

SESSION INFORMATION
Session Date: Tuesday, November 9, 2021
Session Title: T Cell Biology & Targets in Autoimmune & Inflammatory Disease Poster (1507–1515)
Session Type: Poster Session D
Session Time: 8:30AM–10:30AM

Background/Purpose: Current therapies for autoimmune and inflammatory diseases generally target select disease nodes, often failing to produce durable clinical remission. Chronic inflammation is associated with alterations in immune cell metabolism, and it is possible that modulating metabolism may result in more durable responses. Mucosa-associated lymphoid tissue lymphoma translocation protein-1 (MALT1) is a component of the CBM (CARMA/CARD-Bcl10-MALT1) signaling complex that plays a critical role in effector functions of multiple immune cell subsets implicated in autoimmune diseases. While MALT1 is known to regulate NF-kB activation, its role in metabolic reprogramming of immune cells has remained relatively unexplored. We have used allosteric small molecule inhibitors

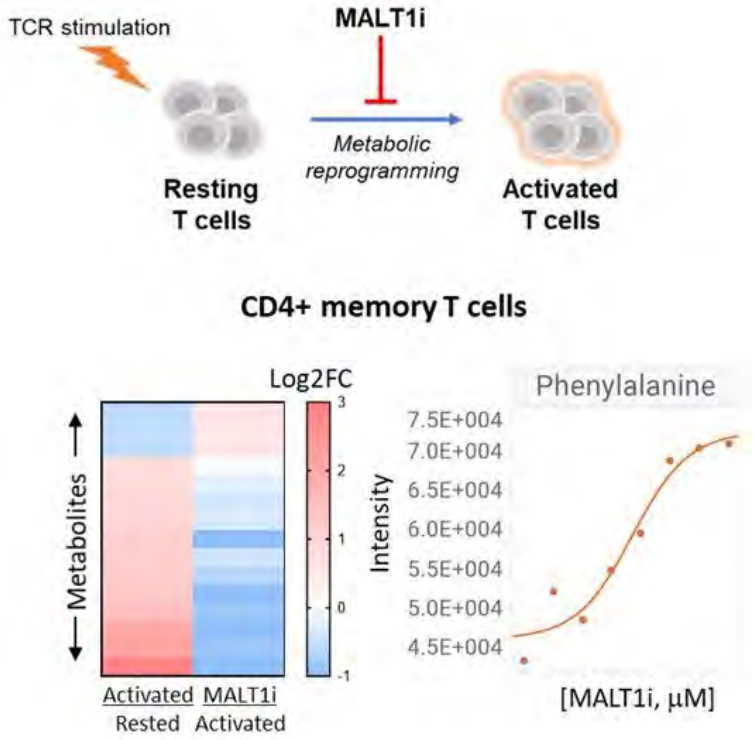

Figure. 1. Effect of MALT1 inhibition on metabolic reprogramming of T-cells. Metabolites were measured from human CD4+CD45RO+ cells 24 hours after stimulation with anti-CD3/CD28/CD2. MALT1 treated cells (MALTi) were preincubated with 5 uM REO-751 for 30 minutes. Dose-dependent effect (0-5 uM MALT1i) on essential amino acids (e.g., Phe) is shown.

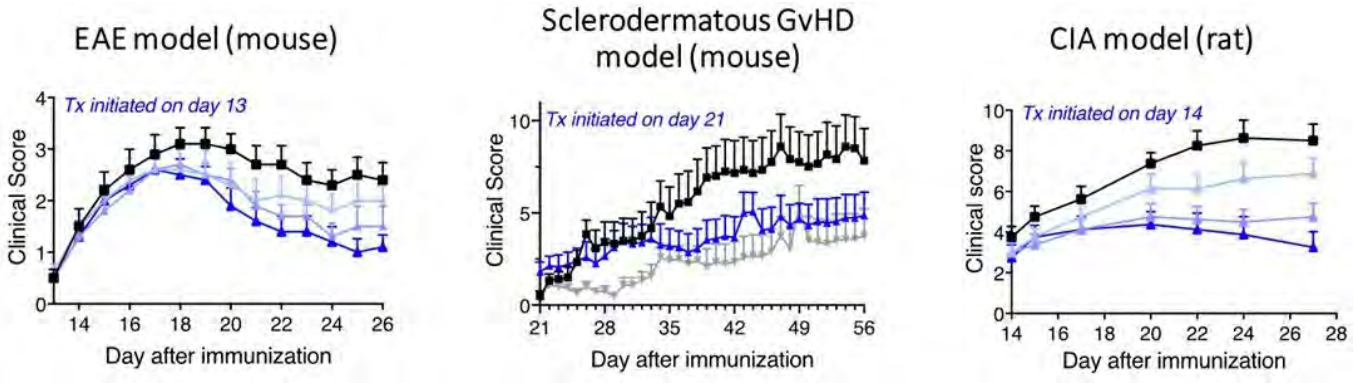

Figure 2. MALT1 inhibition is efficacious in multiple animal models of chronic inflammatory diseases. Black squares represent treatment with vehicle, blue triangles represent different doses (0.1 – 10 mg/kg; 100 mg/kg in scGVHD) of MALT1 inhibitor administered daily via oral route, gray inverted triangles represent Ruxolitinib, a JAK1/2 inhibitor as a comparator. n = 8-15 animals per group.

of MALT1 as tools to evaluate the relationship of MALT1 inhibition to activation-induced metabolic reprogramming with the goal of advancing MALT1 inhibitors as therapeutics for autoimmune disease.

Methods: Activated human memory T-cells, B-cells, macrophages, and whole blood were evaluated for the effect of MALT1 inhibitor on effector cell functions downstream of activation receptors. *In vivo* effects of MALT1 inhibition were evaluated in an anti-CD3 antibody treated mouse model of acute inflammation. Three rodent models of disease (EAE, chronic GVHD and CIA) were employed to evaluate effects of orally administered MALT1 inhibitors on disease activity and metabolite levels. Untargeted metabolomics was performed via LCMS in human memory T-cells and tissues from animal studies.

Results: We identified a common set of metabolite changes that are conserved across multiple immune cell subsets activated via immune tyrosine activated motif (ITAM) containing receptors. This metabolite-based 'activation

signature' was reversed by MALT1 inhibition *in vitro*. In parallel, MALT1 inhibition also decreased proinflammatory cytokine production from the same sets of cells: TCR-activated memory T-cells and immune-complex stimulated macrophages, as well as BCR-induced B-cell proliferation. The metabolic activation signature was also observed *in vivo* in isolated splenocytes from anti-CD3 challenged mice and again was associated with decreased cytokine production. Treatment with MALT1 inhibitors led to disease improvement in a mouse model of sclerodermatous cGVHD, to decrease in disease scores in a TH17-driven EAE model, and to reversal of joint pathology in a rat CIA model. We found that the effect of MALT1 inhibition on disease score coincided with alterations in metabolite levels at sites of inflammation. These data suggest that MALT1-dependent metabolic reprogramming is associated with immune cell activation and disease activity and opens up a new avenue for evaluating the activity of therapeutic agents.

Conclusion: Our results identify MALT1-dependent effects on immune cell metabolism downstream of immune activation and associate those changes with disease activity. Ongoing studies are exploring 1) the role these MALT1-dependent changes in metabolism play in directing the effector function of disease-relevant immune cells and 2) whether metabolic changes may help identify important new biomarkers for disease-associated effector cells.

Abstract Number: 1510

Joint CD8+ Tissue Resident Memory Cell Activation Produces Local Inflammatory Arthritis

Sahar Lotfi-Emran and David Masopust, University of Minnesota, Minneapolis, MN

SESSION INFORMATION
Session Date: Tuesday, November 9, 2021
Session Title: T Cell Biology & Targets in Autoimmune & Inflammatory Disease Poster (1507–1515)
Session Type: Poster Session D
Session Time: 8:30AM–10:30AM

Background/Purpose: Following infection, resident memory CD8+ T cells (T_{RM}) populate tissues as long lived sentinel cells. Their aberrant activation can trigger relapsing inflammation in autoimmune diseases with a strong site- and tissue-specific component such as inflammatory arthritis. Virus specific CD8+ T cells are a recognized component of synovial fluid and synovial biopsies from individuals with autoimmune arthritis. Here, we demonstrate vesicular stomatitis virus encoding ovalbumin (VSV-OVA) specific CD8+ T cells in the mouse knee following resolution of acute infection. With antigen exposure, joint T_{RM} proliferate and recruit additional immune cells preferentially to the site of activation.

Methods: OT1 lymphocytes express a transgenic TCR which recognizes the SIINFEKL peptide of ovalbumin. CD45.1+OT-1 cells are transferred intravascular (i.v.) to CD45.2+ C57BL/6 recipient mice. The next day, recipient mice received 10^6 PFU VSV-OVA i.v. Thirty days after infection, mice receive intra-articular (i.a.) SIINFEKL, PBS alone, or no injection. Knees are fixed, decalcified with EDTA, and frozen. Slides were stained with DAPI, anti-CD45.1, anti-collagen II, streptavidin-PE or streptavidin-C594, anti-B220, anti-Ly6G, and anti-CD4.

Results: Stimulation with SIINFEKL peptide induces proliferation of T_{RM} in target joint but not in opposite joint as demonstrated by both increased OT-1 numbers and their proportion to all cells as identified by DAPI staining

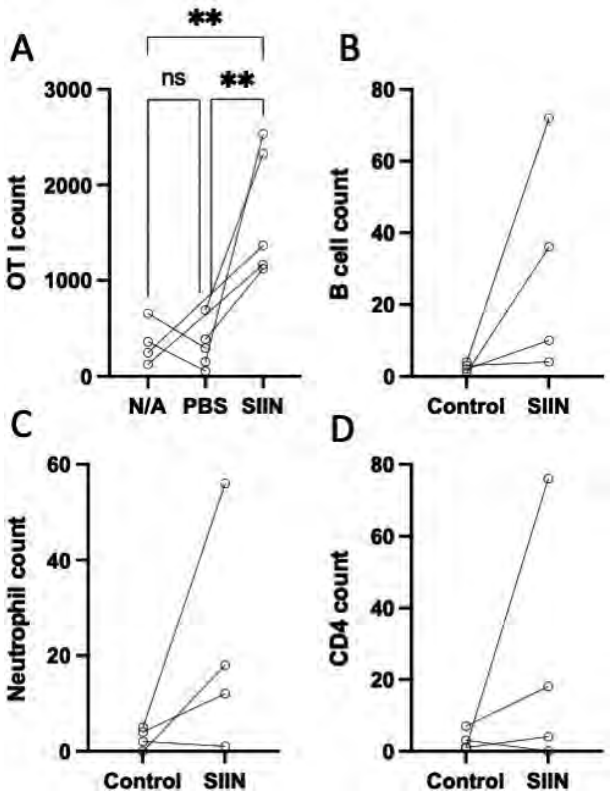

Figure 1. Intra-articular OT-1, B220, Ly6G, and CD4 enumeration. Connecting lines indicate paired knees from same indiivudal mouse. *,p<0.01, ANOVA followed by Tukey's multiple comparison.

(Figure 1A). Increased OT-1 numbers are accompanied by increased B cells, Neutrophils, and CD4 cells within the joint space. (Figure 1B-D).

Conclusion: Following acute infection with VSV-OVA, CD45.1+ donor OT-1 cells populate both joint synovium at a timepoint well past resolution of acute infection. As with T_{RM} at other sites, they proliferate in response to antigenic stimulation and recruit additional inflammatory cells to the joint space.

SESSION INFORMATION

Session Date: Tuesday, November 9, 2021

Session Title: T Cell Biology & Targets in Autoimmune & Inflammatory Disease Poster (1507–1515)

Session Type: Poster Session D

Session Time: 8:30AM–10:30AM

Background/Purpose: Idiopathic inflammatory myopathies (IIM) also known as myositis, are rare chronic autoimmune disorders represented by lesions in muscle, skin and lung. One of the most common autoantibodies in myositis, with a prevalence of 25-35%, is the anti Jo-1 autoantibodies, targeting the histidyl-transfer RNA synthetase (HisRS). The presence of autoantibodies in patients along with strong associations with the HLA-DRB1*03:01 genotype, which is responsible to present peptides to activate CD4+ T-cells, suggest the existence of autoantigens being recognized by autoreactive CD4+T-cells. Moreover, we have previously shown that upon stimulation of both peripheral blood mononuclear cells (PBMC) and bronchoalveolar lavage fluid cells (BALF) with HisRS protein and peptides, CD4+ T-cells were activated and produced inflammatory cytokines. Thus, presence of antigen specific autoreactive CD4+T-cells has not been established in myositis yet but there are clear indications about their existence.The main aim of this study is to investigate the HisRS specific CD4+T-cell population using HLA Class II tetramers. HLA Class II tetramer is an important tool for the characterization of specific CD4+T-cells and is being widely used in a large variety of diseases and vaccine studies. These cells are of specific interest to understand autoimmunity and to develop new therapies in autoimmune diseases.

Methods: HLA-DRB1*03/*01 monomers with selected tetanus and HisRS peptides were produced in-house in E.coli system. The peptides of interest were attached to the N-terminus of the HLA β-chain via a flexible peptide linker. HLA-tetramers were assembled using a commercial fluorescently labeled streptavidin. The efficacy of the peptide-HLA tetramers was validated by stimulating PBMC from HLA-matched healthy controls with tetanus peptide. The frequency of tetanus specific CD4+ T-cells were detected at different time points (6,13 and 21 days) from the cultures using tetanus peptide bound HLA-DRB1*03/*01 tetramers. The presence of tetanus specific T-cells was confirmed by the secretion of significantly higher IFNg levels upon re-stimulation of cells with tetanus peptide. HisRS specific CD4+ T-cells were investigated from PBMC of anti-Jo1+ and HLA-DRB1*03/*01 patients using tetramers and surface marker expressions.

Results: Our findings demonstrate the presence of HisRS+CD4+ T-cells in PBMC of Jo-1+ patients (n=4) using two HisRS tetramers with different fluorochromes and activation markers following stimulation with the respective peptide. We are now including more patient samples to confirm our findings, and further support our findings with functionality assays by flow cytometry and ELISA/fluorospot assays.

Conclusion: Myositis is a rare and chronic autoimmune disorder, with no currently available cure. Previous studies indicate the importance of T cells in this disease. However, the phenotype, functionality and role of these cells in the disease pathogenesis has not been fully established. Characterization of this autoreactive T-cell population will help us enhance our understanding of the disease pathogenesis and thus to develop better treatment options.

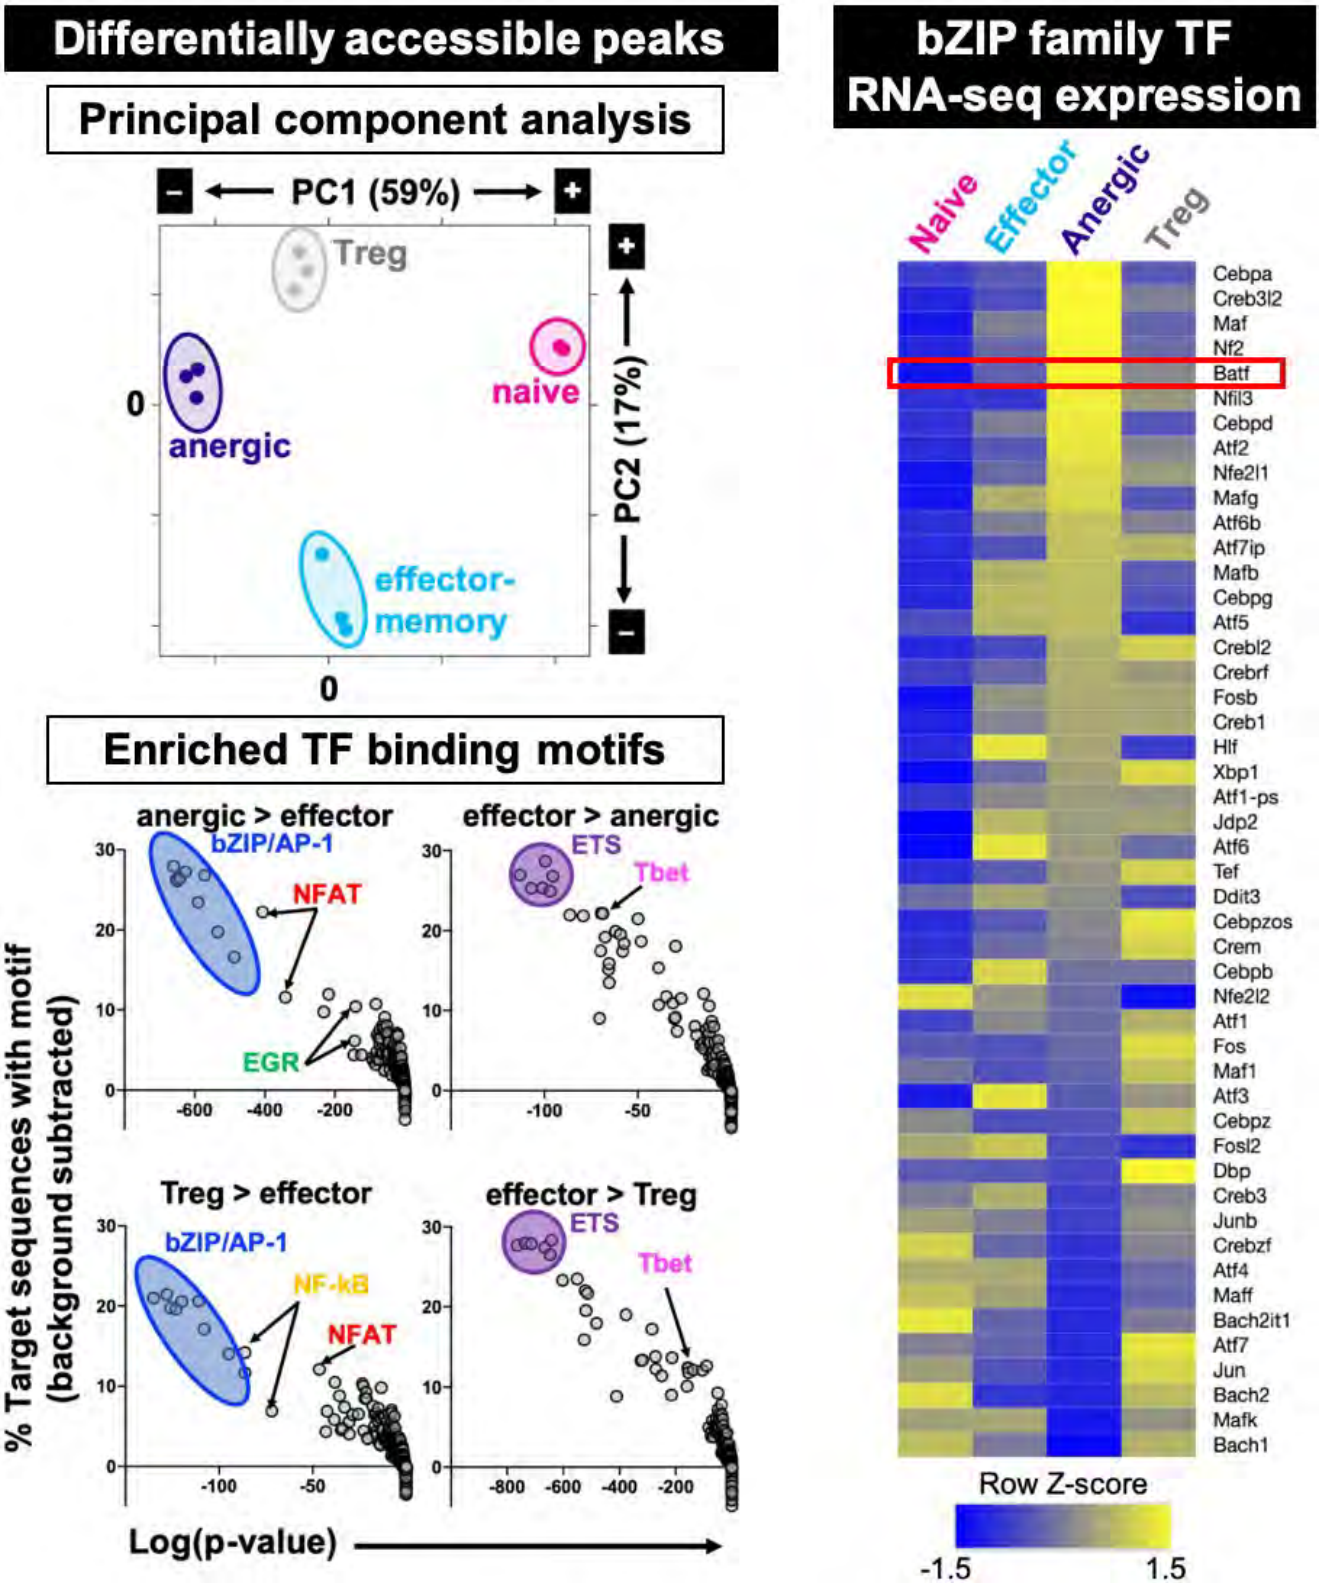
Epigenetic and Transcriptional Programs of CD4+ T Cell Anergy

Philip Titcombe, Milagros Silva Morales and Daniel Mueller, University of Minnesota, Minneapolis, MN

SESSION INFORMATION
Session Date: Tuesday, November 9, 2021
Session Title: T Cell Biology & Targets in Autoimmune & Inflammatory Disease Poster (1507–1515)
Session Type: Poster Session D
Session Time: 8:30AM–10:30AM

Background/Purpose: T cell tolerance is essential for preventing autoimmune diseases and resolving inflammation. To maintain tolerance, $CD4^+$ T cells recognizing self-antigens in the periphery can exert active suppression as regulatory T cells (Treg) or enter an inactive state known as anergy. Recent evidence suggests that anergy



Anergic T cells exhibit a distinct transcriptional program.

occurs naturally within a subpopulation of polyclonal CD4$^+$ T cells and can generate precursors to Foxp3-expressing Treg cells. We aimed to identify transcription factors (TFs) underlying T cell anergy induction and its potential plasticity.

Methods: Polyclonal CD4$^+$ T cell subsets from untreated C57BL/6 mice were sorted based on previously established markers for downstream sequencing-based interrogation. Anergic CD44^{high} Foxp3$^-$ CD73^{high} FR4^{high} Nrp1$^+$ T cells were compared to effector-memory (CD44^{high} Foxp3$^-$ CD73^{low} FR4^{low}), Treg (Foxp3$^+$ CD25$^+$), and naïve (CD44^{low}) T cell populations. Divided aliquots from the same samples were processed in parallel to generate corresponding bulk RNA-seq and accessible chromatin DNA information. Bioinformatic analyses were applied to identify unique transcriptional networks in the anergic T cell subpopulation. Anergy-enriched TFs were then investigated in an antigen-specific system of tolerization by repeated peptide infusions.

Results: Paired epigenome and transcriptome analysis revealed a unique anergy signature driven by bZIP family (*Batf*, *Cebpa, Nfil3, Maf*), NFAT family (*Nfatc1*), and EGR family (*Egr3*) transcription factors. In response to peptide tolerization, antigen-specific CD4$^+$ T cells from *Batf*-deficient mice demonstrated exaggerated expansion and minimal Foxp3$^+$ Treg cell differentiation.

Conclusion: Our data indicate that a unique transcription factor network, including BATF, generates and maintains peripheral CD4$^+$ T cell anergy

Control of T Cell Tolerance by the NR4A Family of Nuclear Receptors

Ryosuke Hiwa[1], **Hailyn Nielsen**[1], James Mueller[1] and Julie Zikherman[2], [1]University of California San Francisco, San Francisco, CA, [2]UCSF Medical Center, San Francisco, CA

SESSION INFORMATION
Session Date: Tuesday, November 9, 2021
Session Title: T Cell Biology & Targets in Autoimmune & Inflammatory Disease Poster (1507–1515)
Session Type: Poster Session D
Session Time: 8:30AM–10:30AM

Background/Purpose: Current therapies for autoimmune disease often lead to treatment-limiting immunosuppression. Selective manipulation of antigen (Ag)-specific immune responses could enhance our therapeutic approach. Targeting members of the NR4A family of nuclear receptors could achieve this as they mediate immune tolerance in Ag-activated lymphocytes. Thymic deletion of multiple – but not individual – NR4A genes (*Nr4a1* and *Nr4a3* > > *Nr4a2*, which is minimally expressed*)* results in deficiency of regulatory T cells (Treg) and a severe inflammatory disease (Fig. 1A-B). Thus, it has been challenging to unmask additional redundant functions of these druggable transcription factors (TFs) in conventional T cells (Tconv). We devised innovative conditional genetic and bone marrow chimera strategies to preserve Treg homeostasis and overcome this obstacle.

Methods: We created mixed radiation bone marrow (BM) chimeras reconstituted with congenically marked CD45.2 *Nr4a1*$^{-/-}$*Nr4a3*$^{-/-}$ (germline double knock-out or gDKO) and CD45.1 wild-type (WT) bone marrow. Control chimeras

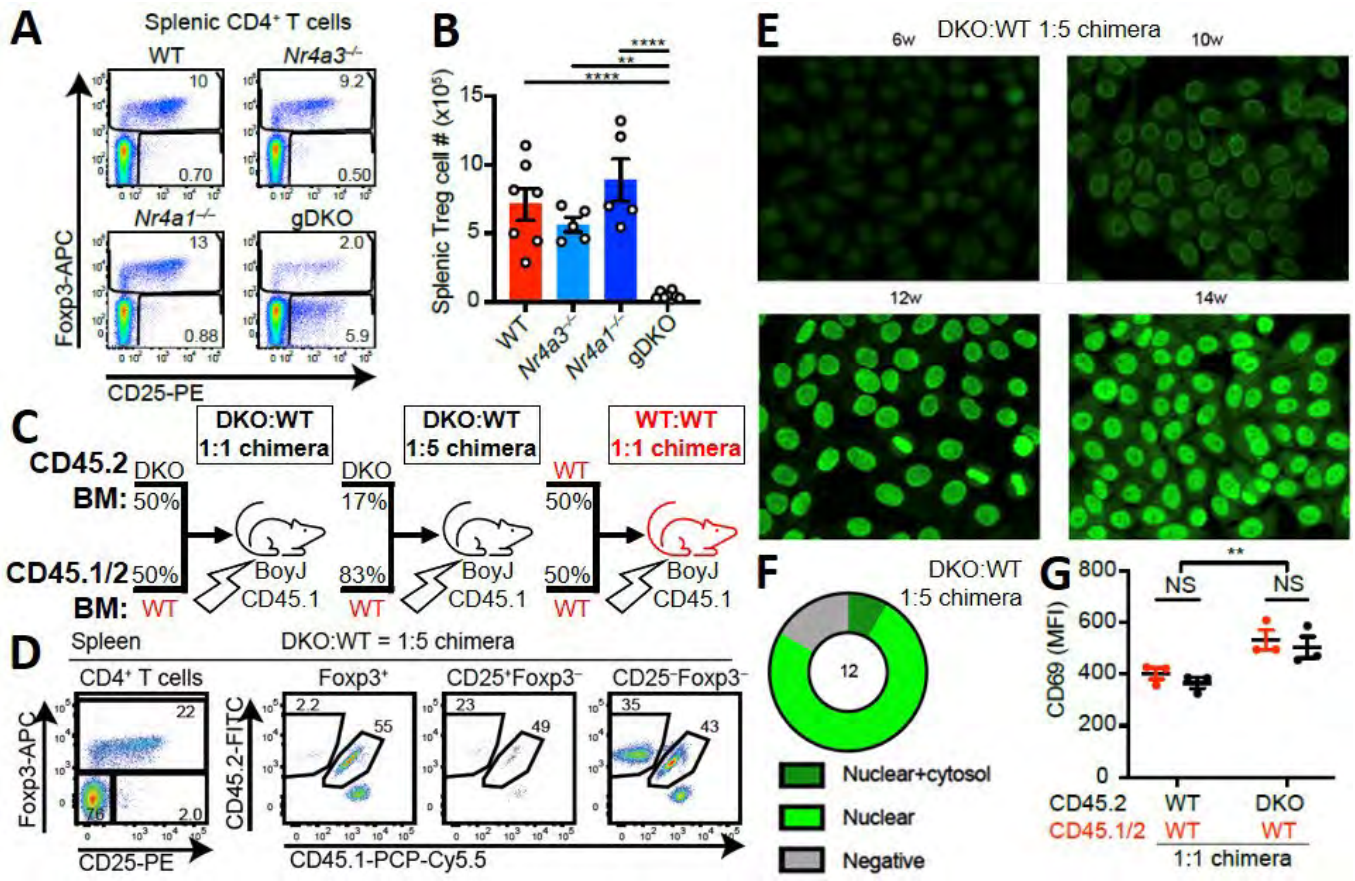

Figure 1. DKO:WT chimeras develop ANA and systemic autoimmunity despite restored Treg homeostasis. A) Representative plots showing loss of Foxp3+ Treg in germline DKO (gDKO) mice. B) Quantification of data from A. C) Schematic of mixed bone marrow chimera design. D) Representative plots from 1:5 DKO:WT chimeras showing reconstitution of Foxp3+ Treg compartment by WT donor cells. E) Representative immunofluorescence images on serum of 1:5 DKO:WT chimeras showing development of ANA in sera between 6-14 weeks post-reconstitution. F) Penetrance and staining pattern of ANA from 1:5 DKO:WT chimeras. G) Both DKO and WT B cells from DKO:WT but not WT:WT chimeras show increased CD69 expression.

were reconstituted with CD45.2 WT and CD45.1 WT BM. We evaluated Tconv and Treg homeostasis and thymic development with conventional methods.

Results: In DKO:WT chimeras, the Treg compartment was reconstituted from largely WT donor cells (Fig. 1D). Despite this, chimeras rapidly developed anti-nuclear autoantibodies (ANA) and evidence of cell-extrinsic polyclonal B cell activation (Fig. 1E-G). CD4 and CD8 single positive (SP) thymocytes accumulate in DKO but not control chimeras, suggesting a profound cell-intrinsic impairment of negative selection of DKO thymocytes (Fig 2A-D). Supporting this, activated caspase-3 expression was reduced in DKO double-positive (DP) thymocytes (Fg 2C-D). In addition, peripheral DKO CD8 T cells with a memory phenotype ($CD44^{hi}$) accumulate in DKO:WT chimeras (Fig 2E-G), but not in CD8-cre $Nr4a1^{fl/fl}$ $Nr4a3^{-/-}$ mice which delete NR4A genes only after thymic selection in the CD8 SP stage (Fig 2H-J). DKO CD4 Tconv cells expressing phenotypic markers of anergy (FR4hiCD73hi) accumulate in these DKO:WT chimeras (Fig. 3A-B), suggesting escape of self-reactive T cells into the periphery. Indeed, these cells indeed exhibit a dampened proximal signaling downstream of the T cell receptor (TCR) (Fig 3C-E). However, these self-reactive DKO CD4 Tconv also exhibit exaggerated IL-2 production (Fig 3F-G), suggesting that *functional* anergy is defective.

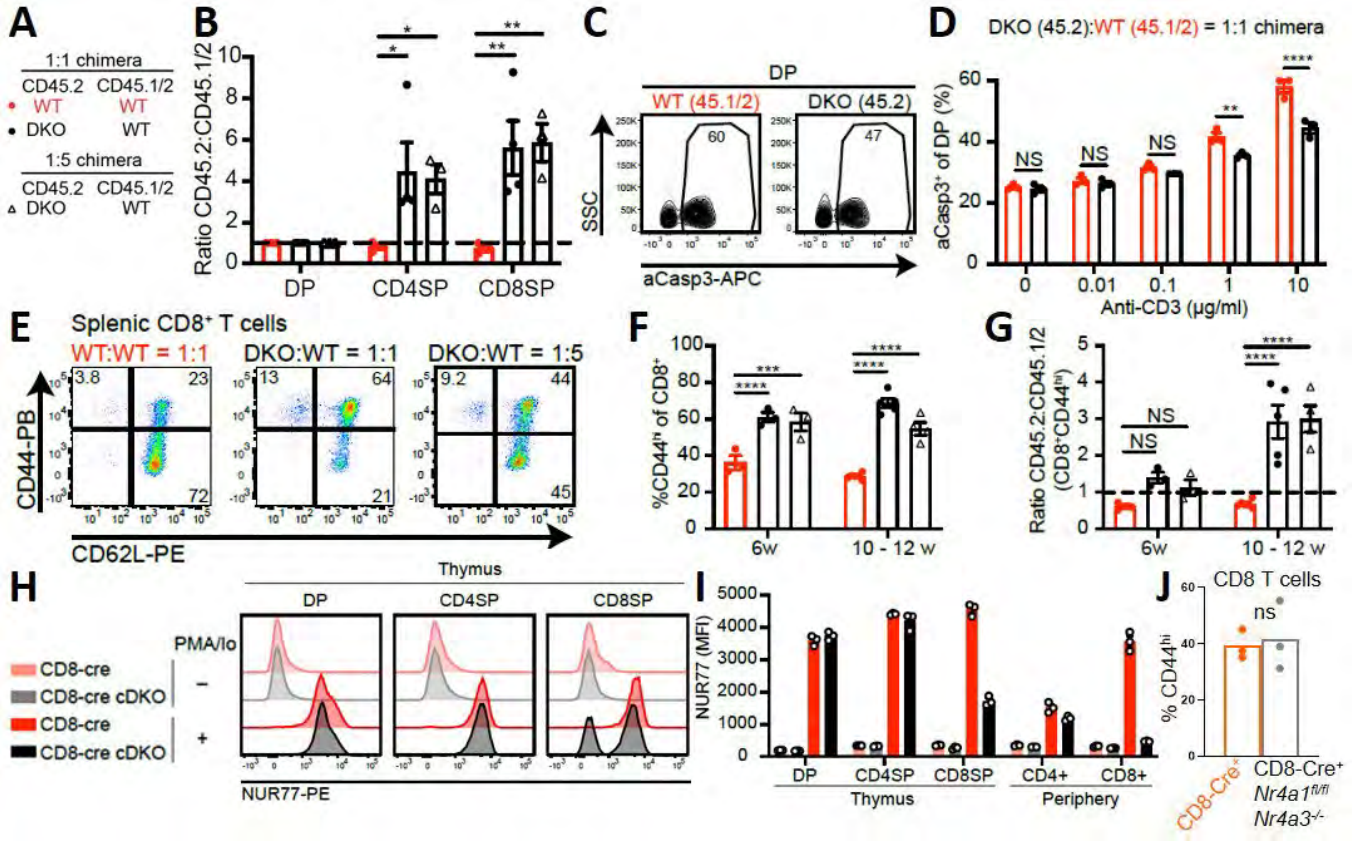

Figure 2. DKO thymocytes have a cell-intrinsic defect in negative selection. A) Key for graphs in B, F, and G. B) Ratio of CD45.2:CD45.1/2 cells among double positive (DP) and CD4 and CD8 single positive (SP) thymocytes normalized to DP. C) Representative plots showing reduced activated caspase-3 expression in DKO DP thymocytes from 1:1 DKO:WT chimeras upon ex vivo stimulation with anti-CD3. D) Quantification of data from C. E) Representative plots showing accumulation of CD44hi CD8 T cells from DKO chimeras. F) Quantification of data from E at 6 or 10-12 weeks post-reconstitution. G) Ratio of CD45.2:CD45.1/2 CD8+CD44hi cells. H) Representative plots showing Nur77 expression in thymocytes from CD8-cre and CD8-cre Nr4a1fl/fl Nr4a3-/- (CD8-cre cDKO) mice. I) Quantification of Nur77 expression in thymocytes (as in H) and splenocytes (key as in H). J) CD8+ CD44hi cells from CD8-cre and CD8-cre cDKO mice.

Conclusion: Together, these data support the unifying hypothesis that NR4A family members play cell-intrinsic, but redundant, roles in both central and peripheral CD4 T cell tolerance. These studies reveal roles for the NR4A family in multiple layered T cell tolerance mechanisms and demonstrate that each is essential to preserve immune homeostasis.

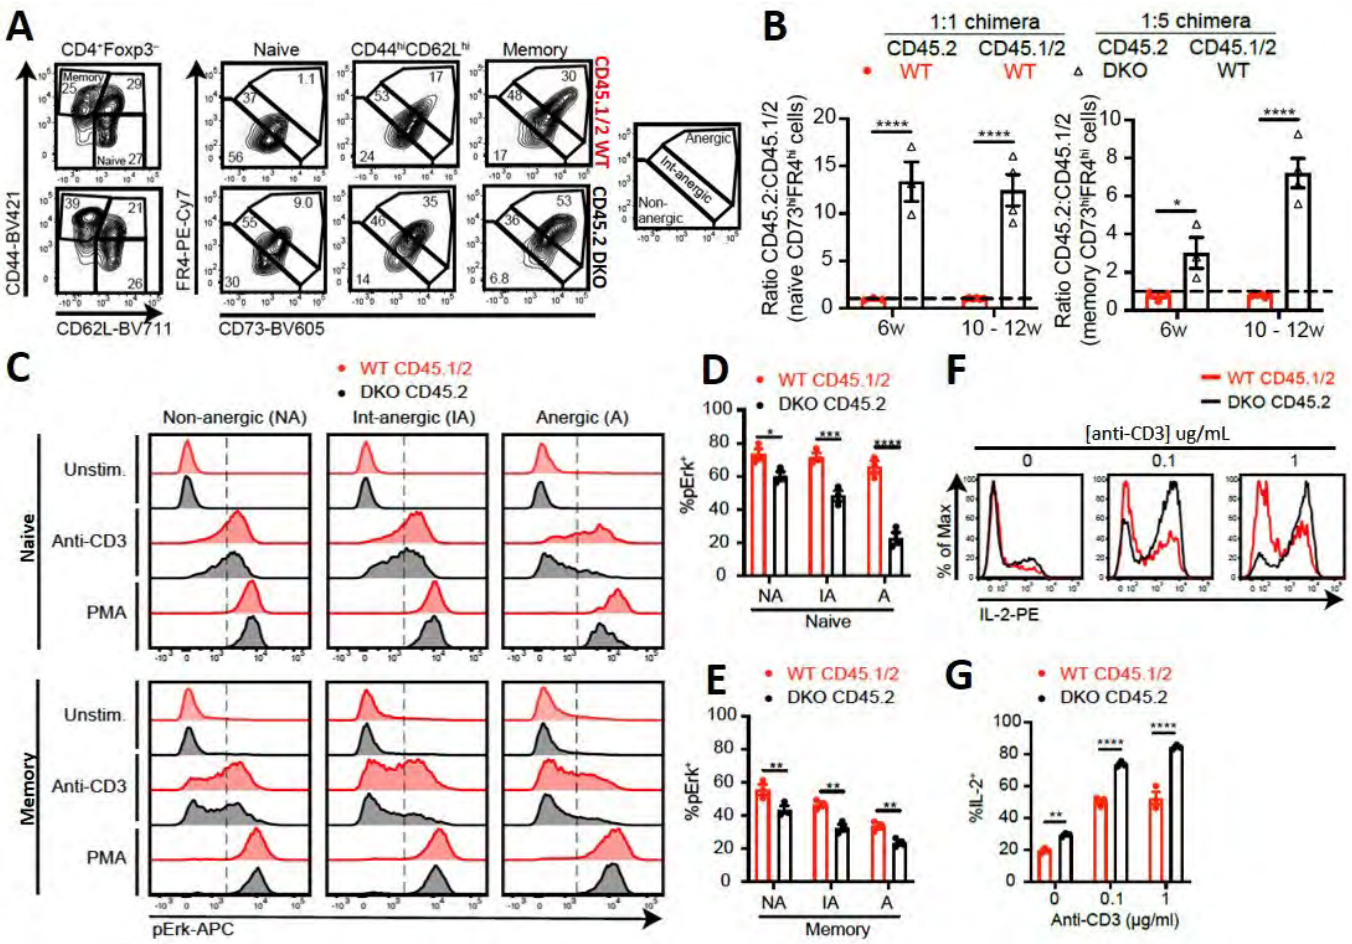

Figure 3. Conventional DKO CD4+ T cells have impaired peripheral tolerance. A) Representative plots from 1:5 DKO:WT chimeras showing gating strategy to identify FR4hiCD73hi anergic phenotype CD4 T cells among naïve and memory compartments. B) Ratio of CD45.2:CD45.1/2 FR4hiCD73hi cells from 1:5 DKO:WT chimeras in naïve (left) and memory (right) compartments 6-12 weeks post-reconstitution. C) Representative histograms showing intracellular phospho-Erk staining after ex vivo stimulation of non-anergic, intermediate anergic, and anergic phenotype cells from 1:5 DKO:WT chimeras in both naïve and memory compartments, gated as depicted in A. D-E) Quantification of data shown in C. F) Intracellular staining for IL-2 after ex vivo stimulation of splenocytes from 1:1 DKO:WT chimeras with anti-CD3 followed by PMA and ionomycin. G) Quantification of data shown in F.

Age-related Metabolic Reprogramming of Memory CD4+ T Cells Is Associated with Reactive Oxygen Species-induced Immune Cell Dysfunction

Yuling Chen[1], Pierre-Louis Krau[2], Pelle Löwe[3], Moritz Pfeiffenberger[4], Lisa Ehlers[3], Alexandra Damerau[4], Paula Hoff[3], Frank Buttgereit[5] and **Timo Gaber**[4], [1]Charité University Medicine Berlin, Berlin, Germany, [2]Charit Universittsmedizin Berlin, corporate member of Freie Universitt Berlin, Humboldt-Universitt zu Berlin, and Berlin Institute of Health, Department of Rheumatology and Clinical Immunology, Berlin, Germany, [3]Charité – Universitätsmedizin Berlin, corporate member of Freie Universität Berlin and Humboldt Universität zu Berlin, Department of Rheumatology and Clinical Immunology, Berlin, Germany, [4]Charité – Universitätsmedizin Berlin, corporate member of Freie Universität Berlin and Humboldt-Universität zu Berlin, Berlin, Germany, [5]Charité – Universitätsmedizin Berlin, Berlin, Germany

SESSION INFORMATION

Session Date: Tuesday, November 9, 2021
Session Title: T Cell Biology & Targets in Autoimmune & Inflammatory Disease Poster (1507–1515)
Session Type: Poster Session D
Session Time: 8:30AM–10:30AM

Background/Purpose: Inflamm-aging is a sterile, low-grade, chronic systemic inflammatory state characterized by an increase in proinflammatory cytokines involved in the development of most age-related diseases such as cancer, Alzheimer's disease, type 2 diabetes, stroke, cardiovascular disease, and rheumatoid arthritis (RA). Because cellular metabolism modulates T cell function, metabolic changes can be hypothesized to promote the reprogramming of memory CD4+ T cells into senescent CD4+ T cells and contribute to memory CD4+ T cell dysfunction during aging. Therefore, we hypothesized that metabolic reprogramming of CD4+ T cells may be a major factor promoting immune cell dysfunction during aging, contributing to the pathogenesis of age-related diseases such as RA.

Methods: To this end, we analyzed memory CD4+ T cells isolated from PBMCs from young donors (20-32 years) and old donors (52-67 years) using MACSTM technology. Ex vivo memory CD4+ T cells were analyzed using Seahorse™ technology to determine proton efflux rate (PER) as a measure of glycolysis (glycoPER) and oxygen consumption rate (OCR) as a measure of mitochondrial respiration (mitoOCR). Cytokine secretion was measured by flow cytometry and multiplex assay with and without mitotempo, an inhibitor of mitochondrial reactive oxygen species (ROS). Finally, TCR-stimulated proliferation of memory CD4+ T cells was determined by flow cytometry using CSFE and Ki-67 at 3 and 4 days. ROS and mitochondrial activity were analyzed by flow cytometry after 24 h using DCF-DA as well as CellROX Deep Red and Mitotracker.

Results: In a quiescent state, memory CD4+ T cells from elderly individuals demonstrated a decrease in basal glycolysis and compensatory glycolysis, and an increase in the ratio of basal mitoOCR to glycoPER while their mitochondrial profile was equivalent to that of young donors while the number of mitochondria was higher with no increase in steady-state ATP level. In this line and in comparison, to the younger reference group, memory CD4+ T cells from aged donors presented a greater spare respiratory capacity after TCR-activation and a marked increase in intracellular ROS production. Interestingly, we did not observe an impact of aging on memory CD4+ T cell proliferation as determined by CFSE and Ki-67. Although the capacity of intracellular cytokine expression did not differ between the compared groups, the levels of secreted IFN-γ, IP-10, IL-4, IL-6, IL-9, and MCAF were significantly higher in the supernatants of memory CD4+ T cells taken from aged donors but were sensitive to ROS inhibition.

Conclusion: These findings suggest that metabolic reprogramming in human memory CD4+ T cells during aging results in an increased expression of proinflammatory cytokines as a result of ROS production and mitochondrial dysfunction. This process may culminate in T cell dysfunction and thus contribute to the pathogenesis of inflamm-aging and the development of age-related diseases such as rheumatoid arthritis (RA).

Programmed Cell Death Protein 1 (PD-1)-Expressing CD4+ T Cells Are Expanded in Early Rheumatoid Arthritis and Correlate with Response to Treatment

Katie Williams[1], Annabelle Small[2], Qingxuan Song[3], Suzanne Cole[4], Ling-yang hao[5], William Murray-Brown[6], Susanna Proudman[7], Malcolm Smith[8], Sunil Nagpal[9] and Mihir Wechalekar[10], [1]Flinders University, Adelaide, Australia, [2]Flinders University, Bedford Park, Australia, [3]Janssen Research & Development LLC, Spring House, PA, [4]Janssen Research, Adelaide, Australia, [5]Janssen Research, Philadelphia, PA, [6]GlaxoSmithKline, Adelaide, Australia, [7]University of Adelaide, Medindie, Australia, [8]Flinders Medical Centre, Adelaide, Australia, [9]Janssen Research, Collegeville, PA, [10]Flinders Medical Centre, Bedford Park, Australia

SESSION INFORMATION

Session Date: Tuesday, November 9, 2021

Session Title: T Cell Biology & Targets in Autoimmune & Inflammatory Disease Poster (1507–1515)

Session Type: Poster Session D

Session Time: 8:30AM–10:30AM

Background/Purpose: Programmed death protein 1 (PD-1) expressing T cells, including T follicular and T peripheral helper cells, are expanded in the circulation of individuals with rheumatoid arthritis (RA). Despite this, the origins of these cells and their functional role in RA remain poorly understood. To address this, we sought to investigate the genetic profiles of PD-1-expressing lymphocytes of the peripheral blood and synovial infiltrate of patients with early RA, and to characterise these cells in disease.

Methods: Isolated peripheral blood mononuclear cells (PBMCs) from patients with established RA (n=5) were sorted into $CD4^+/CD8^+$ $PD\text{-}1^{+/-}$ populations by fluorescence activated cell sorting. mRNA was then isolated, converted into cDNA libraries, and subjected to total RNA sequencing using a NextSeq500. In conjunction with this, quantitative reverse-transcription PCR was used to support our findings. Finally, we assessed for alterations in $CD4^+PD\text{-}1^+$ and $CD8^+PD\text{-}1^+$ cell gene expression in synovial tissue (ST) biopsies (n=19) before and after six-month triple disease modifying anti-rheumatic drug (tDMARD) treatment.

Results: Proportions of $CD4^+$ and $CD8^+$ cells were expanded in the early RA synovial tissue (ST) compared with the peripheral blood. Comparisons of the gene signatures between $CD4^+PD\text{-}1^+$ vs. $PD\text{-}1^-$ cells from early RA PBMCs identified significant upregulation of genes involved in the inflammatory response including *IL21*, *CXCL13*, and *c-MAF*, and in pathways including T helper-1 pathways, neuroinflammation signalling, and pathways involved in crosstalk between dendritic cells and natural killer cells. No significant differences in gene signatures between $CD8^+$ $PD\text{-}1^+$ vs. $PD\text{-}1^-$ cells were observed. Additionally, analysis of gene signatures from early RA ST before and after six-month tDMARD treatment revealed down-regulation of the $CD4^+PD\text{-}1^+$ gene signatures (including genes such as *PDCD1*, *CXCL13*, and *CTLA4*) following treatment.

Conclusion: Our study suggests the pathogenic nature of $CD4^+$ PD-1-expressing T cells in RA, and also reveals a mechanism through which tDMARDs exert their effect through influencing T cell populations in the synovial compartment. Furthermore, we identify factors associated with B cell help that are enhanced in the RA ST compared with PBMCs, highlighting the importance of these molecules in driving inflammation within the synovium.

Clinical Phenotypes and Treatment of Rheumatic Immune-Related Adverse Events from Checkpoint Inhibitors: A Retrospective Cohort of 112 Patients

Tiphaine Lenfant[1], Yuxuan Jin[2], Elizabeth Kirchner[3], Pauline Funchain[2], Jung-Min Song[2], Moshe Ornstein[2], Laura Wood[2], Donald Eicher[2], Rula Hajj-Ali[4], Leonard Calabrese[2] and **Cassandra Calabrese**[5], [1]Institut Mutualiste Montsouris, Paris, France, [2]Cleveland Clinic, Cleveland, OH, [3]CCF, Cleveland, OH, [4]Cleveland Clinic, Hunting Valley, OH, [5]Cleveland Clinic Foundation, Cleveland Heights, OH

SESSION INFORMATION

Session Date: Tuesday, November 9, 2021

Session Title: Immunological Complications of Therapy Poster (1516–1529)

Session Type: Poster Session D

Session Time: 8:30AM–10:30AM

Background/Purpose: To describe a single center cohort of rheumatic immune related adverse events (irAEs) observed in patients treated with checkpoint inhibitor therapy (ICI) and to identify potential risk factors for persistent rheumatic disease activity.

Methods: Patients referred to the Cleveland Clinic Department of Rheumatic and Immunologic Diseases for rheumatic irAE were retrospectively included and assessed via chart review (2015-2020). Persistent rheumatic irAE was defined as still requiring treatment for rheumatic irAE at last follow-up.

Results: A total of 112 patients (median age 60 years) were identified. The most common irAE clinical phenotypes included inflammatory arthritis (IA, n=46), sicca syndrome (n=21), and polymyalgia rheumatica (n=19). In the entire cohort ICI therapy was held temporarily for rheumatic irAE in 15 patients (13%) for toxicity and permanently discontinued in 26 (23%). At last follow-up, rheumatic irAE had resolved in 41 patients (37%), whereas 71 patients still required treatment of rheumatic irAE (median follow-up 15 months, range 5-30 months). Among therapies administered for irAE, glucocorticoids (GC) were most commonly prescribed (n=78, 70%), followed by hydroxychloroquine (16%), methotrexate (14%), and anti-IL-6 agents (11%). Patients with persistent rheumatic irAE activity more frequently received GC (p=0.018) and had IA (p=0.02) compared to patients that had resolution of irAE. In multivariate analysis, IA patients were at higher risk of persistent rheumatic irAE (OR 3.5 [1.3-10], p=0.014). The overall mortality rate was 27% (n=30). Risk factors for mortality included tumor progression (OR 15.3 [4-65], p< 0.001) and continued treatment

	GC (PO)	GC (IV)	GC (IA)	Colchi	NSAID	MTX	HCQ	TNF-i	IL6-i	IVIg	RTX	Other
Cohort (n=112)	70%	7%	26%	7%	54%	14%	16%	6%	11%	4%	1%	33%
Infl. A (n=46)	83%	4%	35%	15%	63%	35%	22%	11%	17%	0%	2%	28%
PMR (n=19)	16%	0%	32%	0%	53%	0%	11%	5%	16%	0%	0%	11%
Myositis (n=7)	100%	86%	0%	0%	14%	0%	14%	0%	0%	57%	0%	14%

Figure 1. Treatment of rheumatic irAEs Colchi: colchicine; GC: glucocorticoids; HCQ: hydroxychloroquine; Infl. A: inflammatory arthritis; IA: intra-articular; IL6-i: interleukin 6 inhibitors; MTX: methotrexate; RTX: rituximab.

with GC at the last follow-up (OR 5.8 [1.5-29], p=0.016). In a survival analysis, continued GC at the end of follow-up was significantly associated with mortality (HR 4.0 [1.3-12], p=0.0001).

Conclusion: In this single-center retrospective cohort of rheumatic irAEs patients, the presence of ICI-related IA was associated with persistent rheumatic disease activity.

Abstract Number: 1517

Prevalence of Autoantibodies in Patients with Melanoma Who Develop Rheumatic Immune Related Adverse Events During Treatment with Immune Checkpoint Blockade

Sophia Weinmann[1], Amanda Eudy[2] and David Pisetsky[1], [1]Duke University Medical Center, Durham, NC, [2]Duke University, Durham, NC

SESSION INFORMATION
Session Date: Tuesday, November 9, 2021
Session Title: Immunological Complications of Therapy Poster (1516–1529)
Session Type: Poster Session D
Session Time: 8:30AM–10:30AM

Background/Purpose: Patients with malignancy who develop rheumatic immune related adverse events (IRAEs) during immune checkpoint blockade (ICB) are commonly autoantibody negative. The change from chemotherapy to ICB as first-line therapy in melanoma could be important since chemotherapy causes cell death of both malignant and healthy cells, potentially increasing exposure of self-antigen. This in turn could lead to autoantibody production against antigens that would not be exposed as frequently without chemotherapy. It is unknown whether the presence of autoantibodies in patients who develop rheumatic IRAEs varies based on prior exposure to chemotherapy. Our hypothesis in this pilot study is that patients with melanoma referred to rheumatology for rheumatic IRAEs from ICB who had prior chemotherapy would have a higher prevalence of autoantibodies compared to those who did not receive chemotherapy.

Methods: A total of 23 patients with melanoma who developed rheumatic IRAEs during treatment with ICB were seen at an academic medical center rheumatology clinic from September 1, 2017 to March 31, 2020. Demographic information, clinical characteristics/type of IRAEs, ICB treatments received including prior chemotherapy, and autoantibody profiles including ANA (indirect immunofluorescence using HEp-2 cell lines) were collected. An ANA titer of 1:40 was considered negative. Differences in ANA positivity between patients who did and did not receive chemotherapy were estimated by Fisher's exact test.

Results: There were 23 patients with melanoma who had a rheumatic IRAE, mean age of 61 years, 52% female and 2 non-white patients, who received single agent ICB (65%) versus combination ICB. Of the 23 total patients, 11 (48%) had 1 or more autoantibodies: 5 (22%) ANAs, 3 (13%) RFs, 2 (9%) Ro/SSA antibodies, 1 (4%) ACPA and 1 (4%) dsDNA. ANA was present in 3/5 patients (60%) who received chemotherapy prior to ICB compared to 2/18 patients (11%)

who did not (p=0.05). The most common rheumatic IRAE was inflammatory arthritis (70%) with 8/11 autoantibody positive, followed by myositis (13%) and PMR (9%).

Conclusion: About half of patients with melanoma who developed rheumatic IRAEs had one or more autoantibody. There was a higher prevalence of autoantibodies, specifically ANA, in patients who received chemotherapy prior to ICB. The majority of autoantibody positive patients developed inflammatory arthritis. Although this is a small pilot, the findings are consistent with the idea that prior chemotherapy, by exposing autoantigens, could influence the risk for autoantibody production and development of rheumatic IRAEs. Larger studies are needed to explore this idea and determine the importance of prior chemotherapy in risk stratification for rheumatic IRAEs.

SESSION INFORMATION

Session Date: Tuesday, November 9, 2021

Session Title: Immunological Complications of Therapy Poster (1516–1529)

Session Type: Poster Session D

Session Time: 8:30AM–10:30AM

Background/Purpose: Immune checkpoint inhibitors (ICIs) are a type of immunotherapy used for cancer management. ICI toxicities can challenge the ability to safely continue ICI therapy despite its notable clinical benefit. Immune-related inflammatory arthritis (ICI-IA) has been described in literature, but herewith we introduce and characterize post-ICI activated osteoarthritis (ICI-aOA), wherein there is exacerbation of a degenerative arthropathy after ICI initiation.

Methods: We conducted a multi-center, retrospective, observational study of patients with cancer treated with ICIs who experienced worsening of their osteoarthritis after ICI start. The ICI-aOA diagnosis was established by the treating rheumatologist and graded using the CTCAE (Common Terminology Criteria for Adverse Events) V6.0 rubric. RECIST (Response evaluation criteria in solid tumors) V.1.1 (v.4.03) guidelines determined tumor response. Chi-squared testing was used for tests of association and multivariate analysis was conducted using logistic regression analysis.

Results: Of the total 36 patients with ICI-aOA, mean age at time of rheumatology presentation was 66 years (51-81yrs). Most patients had metastatic melanoma (10/36, 28%) and had received a PD1/PDL1 inhibitor monotherapy (31/36, 86%) with 5/36 (14%) combination therapy. Large joint involvement (hip/knee) was noted in 53% (19/36), small joint (CMC, DIP, PIP) 25% (9/36), and spine 14% (5/36). Two-thirds (24/36) suffered multiple joint involvement. Three of 36 (8%) had CTCAE grade≥3, 14 (39%) grade 2 and 19 (53%) grade 1 manifestations. Symptom onset ranged from 6 days to 34 months with median of 5 months after ICI initiation; five patients suffered ICI-aOA after ICI cessation

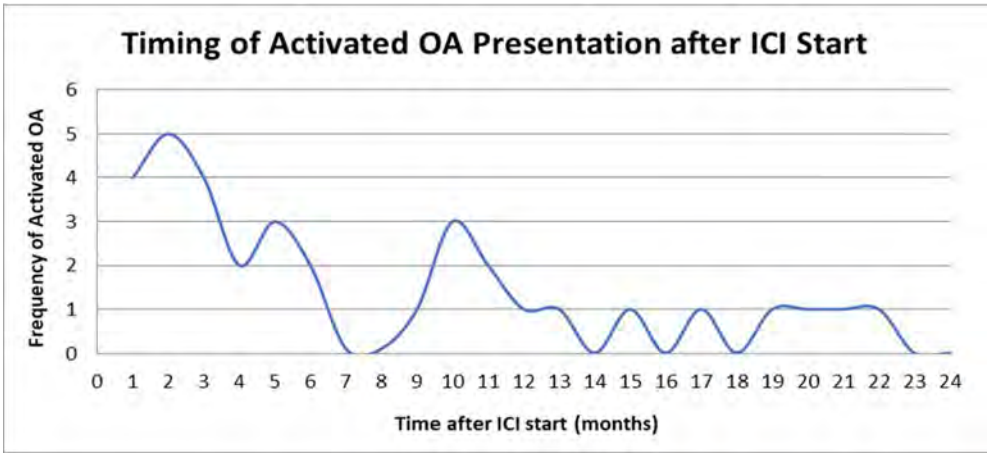

Figure 1. Median onset of ICI-aOA symptoms was 5 months with a wide range from about 6 days to 34 months. Five patients suffered ICI-aOA after ICI cessation (3, 15, 19, 32, 67 weeks after ICI cessation). ICI: Immune-checkpoint inhibitor; aOA: Activated osteoarthritis.

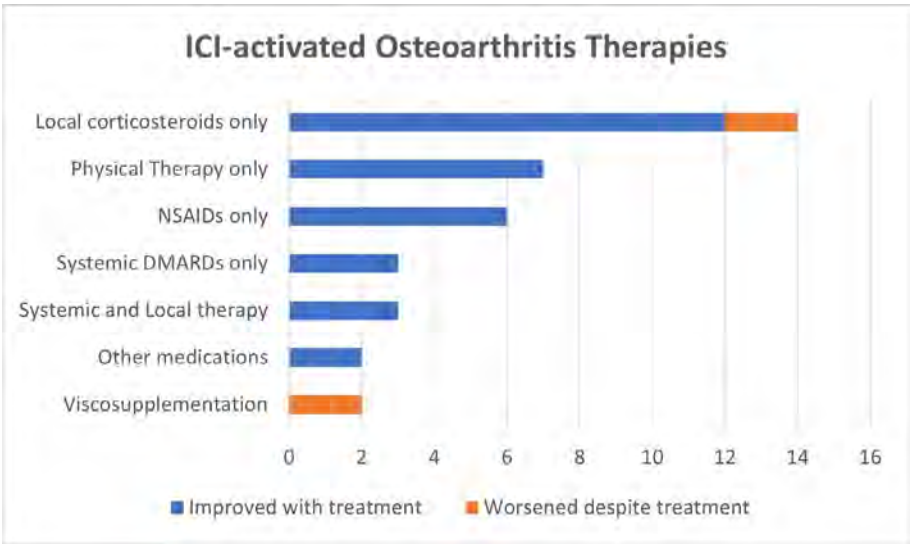

Figure 2. Local therapy was sufficient and successful for majority of the patients. Patients who failed their aOA therapy were all notably patients who had other immune-related adverse events. Systemic DMARDs used included prednisone and hydroxychloroquine. Other medications included acetaminophen and cyclobenzaprine. ICI: Immune-checkpoint inhibitor; NSAIDs: Non-steroidal anti-inflammatory drugs; DMARDs: Disease modifying anti-rheumatic drugs.

(3, 15, 19, 32, 67 weeks after ICI cessation). Most common form of therapy was local corticosteroid injections only (16/36, 44%) followed by NSAIDs only (7/36, 20%) or physical therapy only. Twenty patients (56%) experienced other irAEs, with rheumatic and dermatologic being the most common. All three patients with high-grade ICI-aOA also had another irAE diagnosis at some point after ICI initiation.

Conclusion: We present the first investigation of osteoarthritis exacerbation after cancer immunotherapy. Majority of ICI-aOA cases were low grade and manageable with local therapy or NSAIDs. This demonstrates the importance of early referral to a rheumatologist to facilitate the distinction between ICI-IA from ICI-aOA, the latter of which can be managed with local therapy that will not compromise ICI efficacy.

SESSION INFORMATION

Session Date: Tuesday, November 9, 2021

Session Title: Immunological Complications of Therapy Poster (1516–1529)

Session Type: Poster Session D

Session Time: 8:30AM–10:30AM

Background/Purpose: Treatment of irAEs is a balance of suppressing irAE-associated hyper-inflammation without inhibiting anti-tumoral effects of ICI. Treatment of grade 3/4 irAEs is most challenging and guidelines from multiple oncology groups recommend holding or permanently discontinuing ICIs and treating with escalating immunosuppression until resolved, followed by switch to conventional anti-cancer therapies. Such strategies are effective for mild and self-limiting irAEs and often allows resumption of ICI after resolution but can be highly problematic for rheumatic irAEs which are often chronic as well as more severe and refractory than non-rheumatic irAEs. For these patients a maintenance regimen of chronic targeted therapy followed by resumption of ICI therapy theoretically may allow ongoing irAE control while sparing the anti-tumoral potential of ICI with select immunomodulation. Unfortunately, the published experience of such combined therapies is extremely limited. We now report our experience of sustained targeted and ICI therapy in 9 patients.

Methods: All patients receiving concomitant biologic therapy and ongoing ICI seen in the Cleveland Clinic Department of Rheumatic and Immunologic Diseases and the Jewish General Hospital Department of Oncology at McGill University were included and retrospectively assessed for efficacy, tolerability, safety and effect on tumor progression.

Results: Nine patients received ICI concurrently with biologic therapy (6 melanoma, 1 gastric carcinoma, 2 renal cell). Three were treated with ipilimumab/nivolumab, 4 with nivolumab and 2 with pembrolizumab. Two of the nivolumab patients had previously received ipilimumab/nivolumab. Five patients had ICI-related inflammatory arthritis, 1 had pre-existing rheumatoid arthritis, and 3 had refractory ICI-related colitis. Three patients received concurrent treatment with adalimumab, 1 tocilizumab, 1 tofactinib and 4 infliximab. Prior to initiation of biologic, ICI was held for irAE in 8, all received systemic glucocorticoids and 3 methotrexate. The average duration of combined treatment with ICI and biologic was 4.5 months (range 1-11 months). irAEs were controlled (low disease activity) in 7/9 while 2/9 had moderate disease activity. Regarding tumor outcomes, 5 patients have stable disease, and 4 had disease progression. There were no adverse events, including serious or opportunistic infections known to be associated with biologic therapy.

Conclusion: This limited experience suggests that combining ongoing targeted therapies with ICI is possible with no clear serious adverse events noted to be directly associated with targeted therapies. The effect of combining such therapies on tumor response remains unclear and will require prospective clinical trials.

Abstract Number: 1520

Do Specific Rheumatic Autoantibodies Predict Severity or Time to Onset of Immune-related Adverse Events from Checkpoint Inhibitors?

Nilasha Ghosh[1], Deanna Jannat-Khah[2], Karmela Kim Chan[2], Michael Postow[3] and Anne Bass[4], [1]Hospital for Special Surgery, New York, NY, [2]Hospital for Special Surgery, New York, NY, [3]Memorial Sloane Kettering Cancer Center, New York, NY, [4]Hospital for Special Surgery, Weill Cornell Medicine, New York, NY

SESSION INFORMATION
Session Date: Tuesday, November 9, 2021
Session Title: Immunological Complications of Therapy Poster (1516–1529)
Session Type: Poster Session D
Session Time: 8:30AM–10:30AM

Background/Purpose: Immune checkpoint inhibitors (ICI) are a novel cancer therapeutic that have had a dramatic impact on treating advanced malignancies by enhancing the anti-tumor T cell response. However, the ongoing activation of T cells also cause autoimmune side effects, termed immune-related adverse events (irAE). Autoantibodies are present in many patients with irAE and, in lung cancer patients, autoantibodies have been associated with survival (Toi et al. JAMA Onc 2019). Given the similarity of some irAE to de novo rheumatic diseases, autoantibodies could also serve as biomarkers of organ specific irAE. In this study we asked whether prototypical rheumatological autoantibodies were associated with irAE organ specificity, severity, time or with patient survival.

Methods: This study utilized clinical data and plasma collected from 60 patients enrolled in a prospective phase II clinical trial of two doses of combination ICI (anti-CTLA4/anti-PD1) followed by anti-PD1 monotherapy for the treatment of advanced melanoma (PI Postow). IrAE severity was graded based on Common Terminology Criteria for Adverse Events (CTCAE) guidelines. Plasma was collected, frozen and stored at baseline and week six after treatment initiation, and later thawed and tested for anti-nuclear antibody (ANA), rheumatoid factor (RF) and anti-cyclic citrullinated peptide (CCP) using traditional methods. Characteristics were compared between seropositive and seronegative patients using Chi-square, t-tests and Wilcoxon rank-sum testing. The association of autoantibodies with timing of irAE was analyzed with Kaplan-Meier curves and log-rank testing, as was progression free and overall survival.

Results: **Table 1** highlights the 60 patients included in the study with the mean age (SD) of 60.4 (SD 13.3), 63% male and 85% with stage IV melanoma. Ninety-two percent of patients experienced at least one irAE, with 45% experiencing grade 1-2, or mild irAE, and 46.7% experiencing grade 3-5, or severe irAE. Timing of the first irAE was less than six weeks in 69% of patients, most of which were dermatologic or gastrointestinal. Twenty-eight percent of patients had a baseline antibody (ANA, RF or CCP). There were no significant differences between the seropositive and seronegative patients in severity of irAE or type of irAE, except for thyroid irAE which was more common in the seronegative group (**Table 2**). There were no differences between the two groups in time to first irAE or first severe irAE (**Figure 1**), nor in progression free survival and overall survival.

Conclusion: Our study of melanoma patients did not find any association between ANA, RF and CCP positivity and irAE development, time to first irAE, irAE severity or survival. Seronegative patients were more likely to experience thyroid irAE than seropositive patients. These specific autoantibodies do not appear to be reliable biomarkers for irAE, although other autoantibodies or autoantibody profiles may prove to be more informative.

SESSION INFORMATION

Session Date: Tuesday, November 9, 2021

Session Title: Immunological Complications of Therapy Poster (1516–1529)

Session Type: Poster Session D

Session Time: 8:30AM–10:30AM

Background/Purpose: Immune checkpoint inhibitors (ICI) are a novel cancer therapeutic that have had a dramatic impact on treating advanced malignancies by enhancing the anti-tumor T cell response. However, the ongoing activation of T cells also cause autoimmune side effects, termed immune-related adverse events (irAE). Given that some irAE draw comparisons to traditional autoimmune diseases, autoantibodies have been proposed as potential biomarkers to predict the occurrence of irAE.

Methods: This study utilized clinical data and plasma collected from 60 patients enrolled in prospective phase II oncologic clinical trial of two doses of combination ICI (anti-CTLA4/anti-PD1) followed by anti-PD1 monotherapy for the treatment of advanced melanoma (PI Postow). Plasma was collected, frozen and stored at baseline and week 6 after treatment initiation. Samples were later thawed and incubated with a 120-autoantigen microarray to identify IgM and IgG autoantibodies commonly associated with autoimmune diseases. Average signal intensities of autoantibodies both at baseline and fold changes between the baseline and week 6 timepoint were compared among patients with vs. without an organ-specific irAE. Student's t test was used to determine if there was a significant difference between average signal intensities for each antibody across toxicity groups, and $\log_2$ fold changes (FC) and p-values were recorded for each antibody. Statistically significant changes in differential expression are noted in the figures as green (negative FC) and red (positive FC) dots. Unsupervised clustering was also performed.

Results: The 60 patients had a mean age (SD) of 60.4 (SD 13.3), 63% male. Ninety-two percent experienced at least one irAE and 63% had their first irAE before 6 weeks. Patients who experienced an organ-specific irAE (e.g. colitis) tended to have fewer autoantibodies at baseline than patients who did not experience that irAE (Figure 1). Additionally, patients who experienced any irAE before 6 weeks had fewer autoantibodies at baseline than those with irAE only after 6 weeks (**Figure 1**). There were essentially no baseline autoantibodies whose presence predicted an organ-

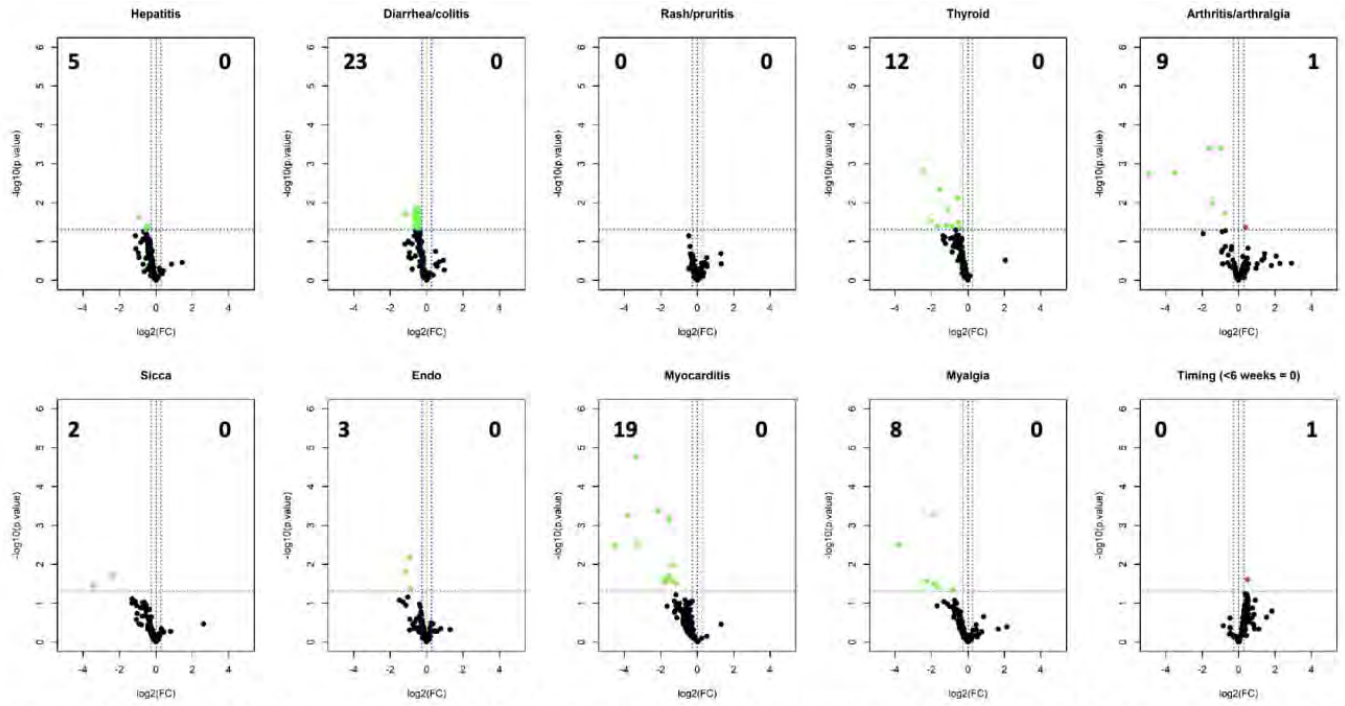

Figure 1. Differential expression of IgG based on organ specific irAE vs non-irAE groupings and late vs. early timing. Dots represent fold changes in autoantibody concentration between the groupings. Those on the left are lower in affected group, those on the right are higher. The dotted line represents a significant fold change with a p-value of 0.05. Black dots = non-significant fold changes, green = lower fold changes in event group, red = higher fold changes in event-group.

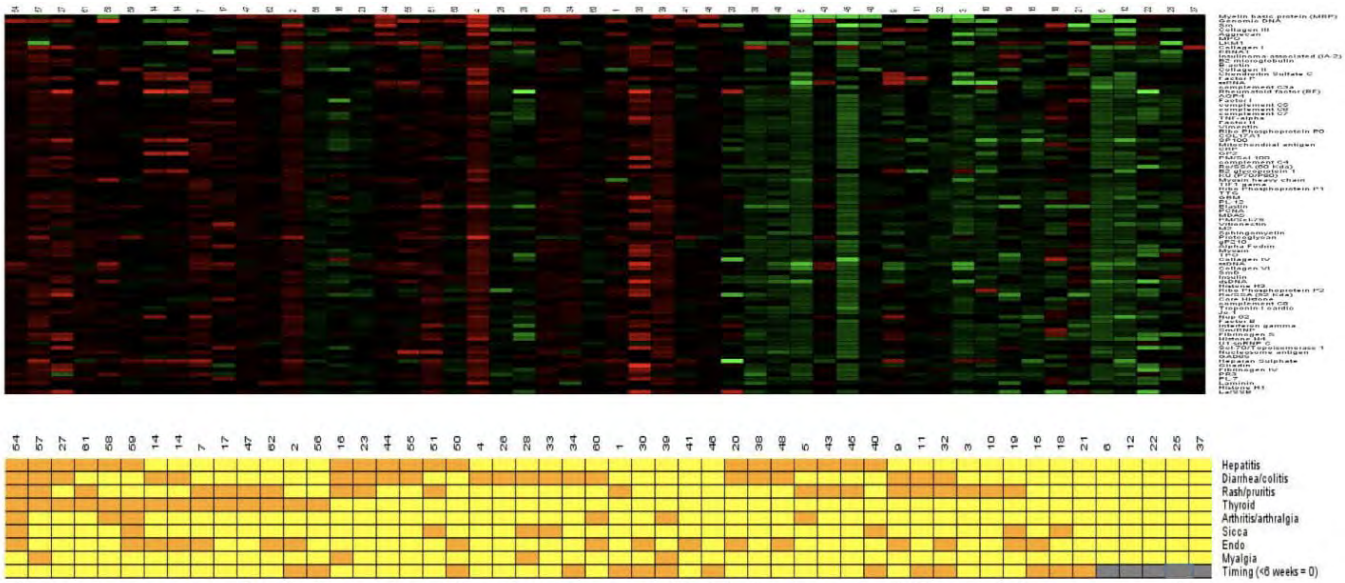

Figure 2. Unsupervised clustering of patient irAE and fold changes in differentially expressed IgM autoantibodies from baseline to 6 weeks (green = negative fold changes, red = positive fold changes)

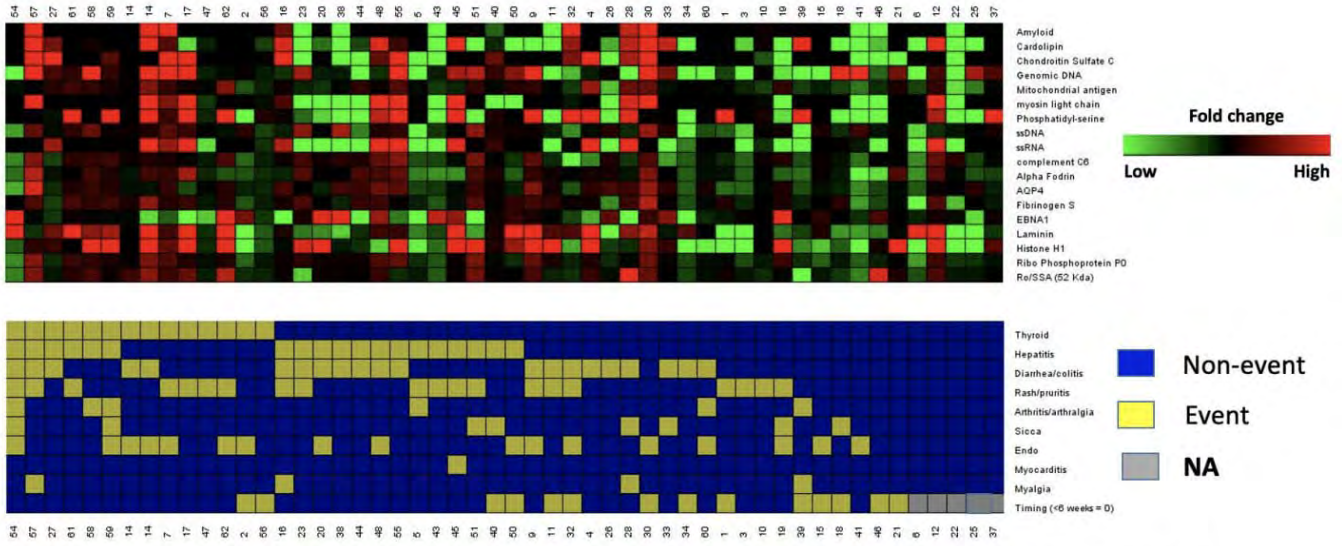

Figure 3. Unsupervised clustering of patient irAE and fold changes in differentially expressed IgG autoantibodies from baseline to 6 weeks

specific irAE. Unsupervised clustering suggested that patients with irAE had a greater fold change in IgM (Figure 2. and IgG (Figure 3. from baseline to 6 weeks than those without irAE, and the same was true for patients who experienced an irAE before compared to after 6 weeks.

Conclusion: A low level of baseline autoantibodies and an increase in autoantibodies after ICI treatment were associated with organ specific irAE. This finding may reflect a skewing toward cellular immunity in these patients prone to irAE rather than a humoral dispensation.

Potential Predictors of Persistence in Immune Check Point Inhibitor Induced Arthritis

Anu Desai[1], Lakshmi Priya Shadananan[1], Adam Croft[2], Lalit Pallan[1], Neil Steven[3] and Benjamin Fisher[4], [1]University of Birmingham, Birmingham, United Kingdom, [2]University of Birmingham, Halesowen, United Kingdom, [3]Institute of Immunology and Immunotherapy/University of Birmingham, Birmingham, United Kingdom, [4]Institute of Inflammation and Ageing, College of Medical and Dental Sciences, University of Birmingham; National Institute for Health Research (NIHR) Birmingham Biomedical Research Centre and Department of Rheumatology, University Hospitals Birmingham NHS Foundation Trust, Birmingham, United Kingdom

SESSION INFORMATION

Session Date: Tuesday, November 9, 2021

Session Title: Immunological Complications of Therapy Poster (1516–1529)

Session Type: Poster Session D

Session Time: 8:30AM–10:30AM

Background/Purpose: Immune Check Point Inhibitors (ICIs) are widely used in Oncology and are associated with multiple autoimmune and systemic inflammatory reactions called immune-related adverse events. We sought to investigate the long-term outcomes of patients who develop ICI induced inflammatory arthritis (IA) and identify potential risk factors associated with IA persistence.

Methods: We conducted a retrospective chart review of patients referred to the rheumatology department for IA associated with ICIs by medical oncology between December 2015 to March 2021 at the Queen Elizabeth Hospital, Birmingham. Information was obtained using clinical records at the baseline visit and 6, 12 and 18 month follow up visits. A qualitative analysis without formal statistical testing was conducted due to the small size of the cohort.

Results: 38 patients were identified. None had pre-existing IA. There was slight male predominance (55.3% Males vs 44.7% Females). Mean age at diagnosis was 65.2 years. Mean Duration of IA was 15.2 months. The knee was the most commonly involved joint (84.2%) at Baseline. Mean baseline CRP was 63.3 mg/L. All patients were ACPA negative, 2 had borderline RF positivity. Mean interval between the first immune checkpoint inhibitor infusion and the onset of the rheumatic adverse events was 6.4 months. ICIs were stopped in 11/38 (28.9%) and temporarily suspended in 5/38 (13.2%) due to IAs. 18/28 (47.3%) required DMARDs and 4/38 (10.5%) were initiated on tumour necrosis factor alpha inhibitors. Persistence at follow up was defined as the presence of clinically assessed synovial swelling and/or ongoing requirement for corticosteroid or DMARD treatment for IA. At 6, 12 and 18 months follow up, 27/34 (79.4%), 16/24 (66.7 %) and 13/23 (56.5%) of patients had persistent IA respectively. Persistence at 6 months follow up was associated with non-smoking status in 18/18 patients (100%), additive course (defined as patients who develop more inflamed joints in addition to the primarily affected joint) in 23/24 patients (95.8 %) and ANA positivity in 19/20 patients (95%). In comparison, all non-persistors had a history of smoking; only one patient had an additive course: 1/24 (4.2%) and only one patient had ANA positivity: 1/20 (5%) in this group. IA was more likely to persist in patients who presented with baseline characteristics such as insidious onset, polyarthritis, symmetrical pattern and, involvement of both small and large joints. Patients with persistent IA had more flares in first six months as compared to non-persistors. Non-persistors had a numerically slightly higher total corticosteroid exposure over the first three months as compared to persistors.

Conclusion: Our findings highlight that ICI-induced IA can become a long term complex disease necessitating management by rheumatology for immunosuppression. Large multicentre cohorts are required to confirm potential risk factors for persistence versus remission.

Data presented as median (range) or frequency (percentage). ICI: immune checkpoint inhibitor; SCC: squamous cell carcinoma; SCLC: small cell lung cancer; DLBCL: diffuse large B-cell lymphoma; PD1: programmed cell death 1; PDL1: programmed cell death ligand 1; CTLA4: cytotoxic T-lymphocyte-associated protein 4.

Background/Purpose: Since the introduction of the first immune checkpoint inhibitor (ICI) in 2011, they have become widely utilized in the treatment of malignancy. It is well established that patients with autoimmune disease, such as RA, are at risk for flares of their disease when treated with ICIs. However, there is little information available on patients with RA who receive ICIs. This study aims at evaluating RA disease characteristics, outcomes, and treatment in patients with RA who were treated with ICIs at Vanderbilt University Medical Center.

Methods: Patients with RA diagnosed at least one year prior to onset of malignancy receiving ICI therapy were included. Full medical record review was performed. Data collected includes type and stage of malignancy, ICI treatment regimen (anti-PD1, anti-PDL1, and/or anti-CTLA4 therapy), RA serologies, RA disease activity at time of cancer diagnosis and ICI start, RA treatment at the time of cancer diagnosis and ICI start, time on ICI therapy, treatment of RA while receiving ICI, treatment of RA flares, immune-mediated adverse events (IRAEs), and overall cancer survival.

Results: A total of 19 patients treated over the past 10 years were identified (Table 1). The most common cancer represented was melanoma (10 patients). Five patients were RF positive, 5 patients were anti-CCP antibody positive, 2 patients were seronegative, and serologies were unavailable for 10 patients. Only 1 patient had active RA by physician's assessment at time of cancer diagnosis. Fifteen patients were on a DMARD at the time of cancer diagnosis but only 7 remained on a DMARD at the time of ICI initiation. The most commonly continued DMARD was hydroxychloroquine (4) followed by methotrexate (3). Eleven patients had an RA flare (increase in joint pain and/or swelling) with median time to onset of flare of 25 days (range 1 to 185 days) (Table 2). Of the 7 patients on a DMARD at time of ICI start, 4 had RA flares and 3 required glucocorticoids. Ten patients received glucocorticoids for flare (prednisone 10 to 40 mg). Of the 6 seropositive patients, 4 had flares. One of the 2 seronegative patients had a flare and 6 of 11 patients with unknown serologies flared. Six patients had other IRAEs which included hepatitis (2), colitis (2), and pneumonitis (2). Median overall cancer survival was 12 months which includes 11 living patients, some of whom were undergoing active ICI treatment.

Conclusion: Most patients were on DMARDs for RA at the time of cancer diagnosis and all but one were well controlled. However, at the time of ICI start, most patients stopped their DMARDs. Patients with even well-controlled RA can have flares when treated with ICIs. Flares can happen at any time during treatment and risk of flare is not clearly associated with seropositivity. However, most patients stopped or decreased number/dose of immunosuppressive medications when starting ICI therapy which may have contributed to rate of flares. Most flares were treated with

COVID-19 Vaccination Rates and Adverse Events Among Patients on Immunosuppressive Therapy in the Rheumatology Clinic Caring for an Underserved Population

Suguni Gallappaththy[1], Sarah Ifteqar[2] and Amr Edrees[3], [1]University of Missouri Kansas City, Kansas City, KS, [2]UMKC, Kansas City, MO, [3]UMKC, Overland Park, KS

SESSION INFORMATION
Session Date: Tuesday, November 9, 2021
Session Title: Immunological Complications of Therapy Poster (1516–1529)
Session Type: Poster Session D
Session Time: 8:30AM–10:30AM

Background/Purpose: Patients with autoimmune inflammatory rheumatic disease (AIRD) are at a higher risk for serious infections due to a combination of disease related immune dysfunction and the use of immunosuppressive therapy[1]. With the advent of the COVID-19 vaccination, there is an opportunity to protect this vulnerable patient population. However, there is inadequate data regarding vaccination rates, efficacy and vaccine related adverse events in this unique patient population.

The primary aim of this study is to assess the vaccination rates and adverse events among patients who are on immunosuppressive therapy. The secondary aim was to assess disparities in vaccination rates based on gender, age and ethnicity in patients from an underserved population.

Methods: A retrospective cross-sectional study was conducted from 1st January 2021 to April 30th 2021. Patients aged 18 years and older, who were on immunosuppressive therapy (prednisone >=5mg, conventional and biologic DMARDs) presenting to the rheumatology clinic at an academic medical center, were included. Statistical analysis was done using Chi-square and a p-value of < 0.05 was considered statistically significant.

Results: 376 patients met inclusion criteria. 31.65% (119/376) received atleast one COVID-19 vaccine dose, of whom a majority 28.2% (96/376) were fully vaccinated. 69% patients received the Pfizer and 31% received the Moderna vaccine. Vaccine rates (for atleast 1dose) based on age were variable.18-24 years-41.6%; 25-44 years-16.9%, 45-64 years- 32.6% (58/178) and 65 years and above- 53.7% (36/67) ($p< 0.00001$). 31.7% (97/306) women and 31.4% (22/70) men receiving atleast one dose. Racial and ethnic differences in vaccinations did not reach statistical significance. 29.5% African Americans (47/159), 28.8% (39/135) Caucasians, 43.6% (17/39) Hispanics, 33.3% (3/9) Asians and 38.2% (13/34) Other received atleast one vaccine dose.

No major adverse events were reported (Table 1). Only 3 vaccinated patients (1.3%) presented to the ED with presumed post vaccination side effects. Complaints included rash, dizziness and headache. 4 vaccinated patients (1.7%) reported a mild exacerbation of their underlying rheumatologic disease. Only 2 vaccinated patients were diagnosed with COVID-19 infection with one patient having received only the 1st dose. The 2nd patient was found to be COVID-19 + within 3 weeks of receiving the 2nd vaccine.

Adverse events requiring hospital admission	Number of events observed
Anaphylaxis	0
Acute myocardial infraction	0
Stroke	0
Venous thromboembolism	0
Ischemic stroke	0
Hemorrhagic stroke	0
Immune thrombocytopenia	0
Transverse myelitis	0
Myocarditis/pericarditis	0
Encephalitis / myelitis / encephalomyelitis	0
Guillain-Barré syndrome	0
Bell's palsy	0
Multisystem inflammatory system in adults	0

Side effects of COVID vaccinations that required ED visits	Post 1 st dose/2 nd dose	Rheumatological diagnosis
Rash	2 nd dose	RA
Headache and Dizziness	1st dose	RA
Sore throat	1st dose	Sicca syndrome

Patients who reported an exacerbation of autoimmune disease post vaccination	Post 1st/2nd dose	Rheumatological diagnosis	Severity
	2nd dose	RA	Mild
	1st dose	RA	Mild
	1st dose	RA	Mild
	1st dose	Psoriatic arthritis	Mild

Conclusion: Vaccination rates observed in our patient population was comparable to rates in Missouri (MO)- 31.65% v/s 37.3%(MO) and 28.2% v/s 27.4% (MO) for the 1st and 2nd Covid vaccine doses respectively as of April 30th 2021. Severe adverse events were not seen and the vaccine was well tolerated by our patients. Statistically significant differences were not seen based on gender and ethnicity. Age differences were statistically significant with patients aged 65+ being more likely to get vaccinated, which is likely a reflection of preferential vaccine rollout in more vulnerable populations. Vaccine hesitancy or disparity in access was not seen in our patient population based on preliminary data. Our goal is to reassess the data again in 6 - 12 months to identify any vaccination disparities.

Session Date: Tuesday, November 9, 2021

Session Title: Immunological Complications of Therapy Poster (1516–1529)

Session Type: Poster Session D

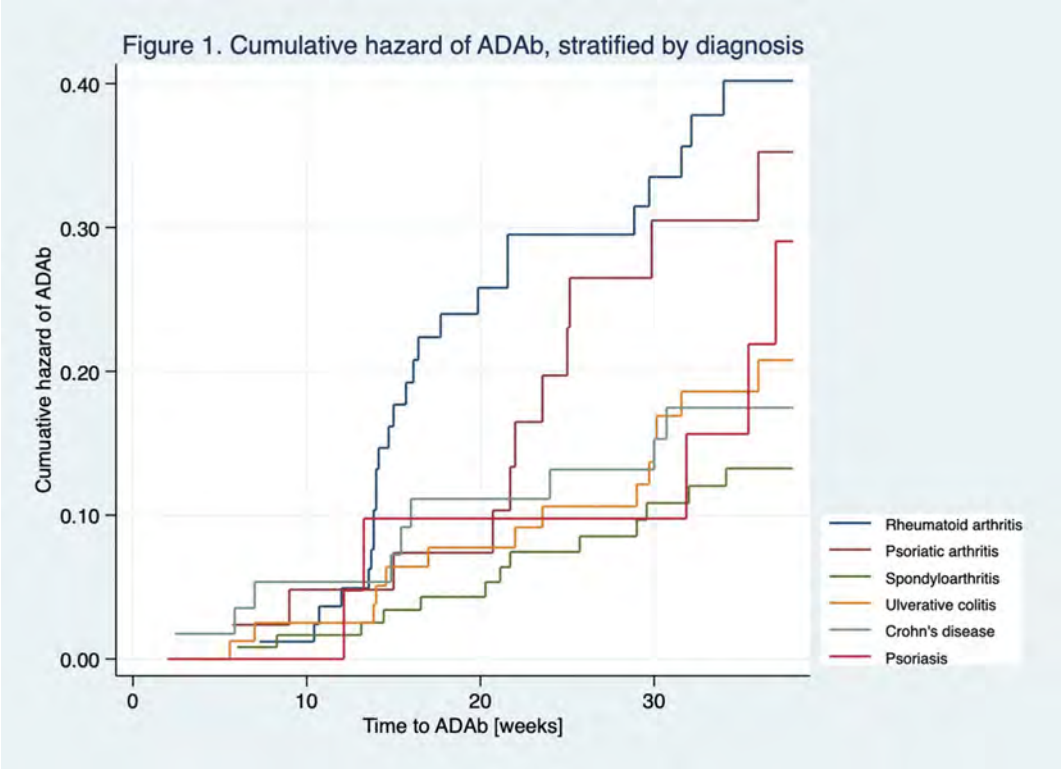
Session Time: 8:30AM–10:30AM

Background/Purpose: Immunogenicity is related to loss of efficacy and safety to TNFα inhibitors and is frequently observed early in the treatment course. The highest rate of anti-drug antibody (ADAb) formation has been reported for infliximab (IFX). Knowledge about risk factors for immunogenicity might contribute to better handling of this problem in clinical practice. The aim of this sub study of the NOR-DRUM A trial (main results recently published in JAMA[1]) was to identify risk factors for ADAb formation during the early phase of infliximab (IFX) treatment.

Table. Risk factors for ADAb formation. Results from logistic regression analyses

	Univariate analyses		Multivariate analyses (Adjusted for diagnosis- disease activity- age and gender)	
	OR	CI	OR	CI
RA	2.2**	1.3-3.8	2.1*	1.1-3.9
SpA	0.4**	0.2-0.8	0.5*	0.2-0.9
Concomitant immunosuppressive therapy*	0.9	0.5-1.4	0.4**	0.2-0.8
Current or former smoking	2.2**	1.3-3.8	1.8*	1.0-3.3
Mean sIFX	0.7***	0.6-0.8	0.7***	0.6-0.8
>11 weeks between infusions	3.9*	1.3-11.9	4.1*	1.2-13.8
IFX dose increment	0.5*	0.3-0.9	0.4**	0.3-0.8
Mean DAS28 (RA and PsA)	1.5*	1.0-2.1	1.5*	1.0-2.3
Mean ESR	1.1***	1.0-1.1	1.1***	1.0-1.1
Mean CRP	1.1**	1.0-1.1	1.1**	1.0-1.1

Results are presented as Odds ratios (OR) with 95% confidence intervals (CI). * p<0.05, ** p<0.01, *** p<0.001. All variables with a P-value <0.25 in univariate analyses were examined in multivariate analyses adjusting for potential confounders. Only variables with a p-value <0.05 are shown. Non-significant variables include other demographic variables and IFX dose. *Included in table despite an unadjusted P-value>0.25 because this variable vas significant in adjusted analysis.



Nelson-Aalen plot showing the cumulative hazard of ADAb for each diagnosis. Each step indicates a new event (ADAb). The slope of the curve indicates the hazard rate.

Methods: 411 patients with immune-mediated inflammatory diseases (84 rheumatoid arthritis (RA), 119 spondyloarthritis (SpA), 45 psoriatic arthritis, 83 ulcerative colitis, 58 Crohn's disease and 22 psoriasis) initiating IFX treatment were included in the 38-week NOR-DRUM A trial and randomised 1:1 to therapeutic drug monitoring or standard IFX therapy.[1] The primary endpoint was clinical remission at week 30. Serum (s) IFX levels and ADAb were measured at each infusion by in-house assays; time-resolved fluorometric assay for sIFX and inhibition assay for ADAb.[1] Possible risk factors for ADAb formation including demographic variables, diagnosis, comedication, disease activity, IFX dose, sIFX and drug holidays, were assessed using logistic regression. Variables with a p-value < 0.25 in univariate analyses were further examined in multivariate analyses adjusting for potential confounders (diagnosis, disease activity, age and gender).

Results: 410 patients with at least one available sIFX measurement were included in the present analyses. 76% were biologic-naive, and 45% (18% of RA patients) used IFX as monotherapy. Patients received a mean IFX dose of 3.2-5.9 mg/kg (RA 3.2 mg/kg). ADAb were detected in 78 (19%) patients. The Table shows variables with a significant association to ADAb formation. Analyses revealed an increased risk of ADAb development in patients with RA (Odds ratio (OR) 2.1, 95% confidence interval (CI) 1.1-3.9) ADAb formation, while SpA had a lower risk (OR 0.5, CI 0.2-0.9) compared to the other diagnoses. These findings were consistent in both univariate- and multivariate analyses. Figure 1 shows the cumulative hazard for ADAb formation according to diagnosis. Other risk factors for ADAb formation (Table) were smoking (OR 1.8, CI 1.0-3.3) and drug holidays of more than 11 weeks (OR 4.1, CI 1.2-13.8). Additionally, the risk of ADAb increased with higher disease activity (OR 1.5, CI 1.0-2.3) and lower sIFX levels (OR 0.7, CI 0.6-0.8). Patients using concomitant immunosuppressive medication (OR 0.4, CI 0.2-0.8), or having one or more IFX dose increments (OR 0.4, CI 0.3-0.8), had a reduced risk of immunogenicity.

Conclusion: This study identified smoking, drug holidays, high disease activity, IFX monotherapy and low sIFX levels as risk factors for ADAb development. Of particular interest, we found that RA patients had an increased risk of ADAb compared to the other immune-mediated inflammatory diseases. Whether this novel finding reflects different underlying disease mechanisms or the fact that RA patients receive a lower IFX dose, is not known and needs to be further explored.

Abstract Number: 1526

Development of Antinuclear Antibodies and Systemic Lupus Erythematosus in Patients on Tumor Necrosis Factor α Inhibitor Therapy

Chathura Wijewardena[1], Paramarajan Pirinavan[1], Sandy Nasr[1] and Andras Perl[2], [1]SUNY Upstate Medical University, Syracuse, NY, [2]State University of New York, Syracuse, NY

SESSION INFORMATION
Session Date: Tuesday, November 9, 2021
Session Title: Immunological Complications of Therapy Poster (1516–1529)
Session Type: Poster Session D
Session Time: 8:30AM–10:30AM

Background/Purpose: Tumor necrosis factor α (TNF-α) inhibitor therapy has been widely used worldwide as a potent immunosuppressant for a variety of rheumatological diseases. Induction of antinuclear antibodies (ANA) and systemic lupus erythematosus (SLE) in patients receiving anti-TNF-α therapy have been previously documented[1]. It is known that up to 15% of healthy individuals have a positive ANA test[2]. In this study we examined the frequency and safety outcomes of ANA and SLE induction following initiation of anti-TNF-α therapy.

Methods: Patients, age >18 years, from January 2012 – December 2020 who were newly prescribed the following TNF-α inhibitor were included in this study: golimumab, cetrolizumab, adalimumab, etanercept, infliximab and inflectra. They were categorized into two groups based on immune fluorescence ANA assay performed either before or after anti-TNF-α therapy was started. The ANA tested cohort was sub-categorized to ANA-positive and ANA-negative result. ANA positive patients were sub-categorized for ANA 'positivity before' or 'positivity after' TNF-α inhibitor start date. Fisher's exact two tailed test and two tailed chi-square was calculated on the GraphPad Prism 9.0 statistical software; two-tailed p values < 0.05 were considered significant.

Results: 2803 patients met inclusion criteria. 1120 were and 1683 were not tested for ANA. Of 1120, 742 had a positive test and 378 had a negative test result. From 742, 508 and 234 had a positive ANA test before and after the initiation of a TNF-α inhibitor, respectively. Percentage developing a positive ANA test following anti-TNF-α was 20.8%

Table 1. Effect of TNF-α inhibitors on the development of ANA and SLE in 2803 patients				
	Before TNF-α Inhibitor	After TNF-α Inhibitor	Chi-square	p value
ANA positive ANA negative	508 2295	742 2061	5.361	P<0.0001
SLE No SLE	83 2720	115 2688	56.38	0.0247

Table 2. Prevalence of ACR & SLICC SLE Criteria in 32 patients with TNF inhibitor-induced SLE	
SLE Criteria	Number (%)
ANA	32 (100)
Anti-dsDNA	2 (6.2)
Anti-Sm	3 (9.3)
Photosensitivity	2 (6.2)
Low complements	3 (9.3)
Alopecia	4 (12.5)
Synovitis	4 (12.5)
Non erosive arthritis	14(43.7)
Malar rash	7 (21.8)
Leukopenia	0 (0)
Thrombocytopenia	2 (6.2)
Acute cutaneous lupus	4 (12.5)
Chronic cutaneous lupus	0 (0)
APLA	5 (15.6)
Oral/nasal ulcers	2 (6.2)
Neurology	1 (3.1)
Lymphopenia	2 (6.2)
Discoid Rash	0 (0)
Serositis	0 (0)
Renal Involvement	0 (0)
Hemolytic Anemia	0 (0)
Direct Coombs Test	0 (0)

Table 3. Outcome of TNF-α inhibitor in 32 SLE induced patients	
Outcome (Number)	Reason (Number)
TNF-α inhibitor discontinued (22)	Subacute erythematous rash (4) Arthritis not improved (13) Diarrhea (1) Bronchitis (1) Injection site reaction (1) Depression (1) History of congestive heart failure (1)
TNF-α inhibitor continued (10)	SLE overlap syndrome (10)

(234/1120). 83 patients had SLE before and 32 developed clinician diagnosed SLE after TNF-α inhibitor. There was a statistically significant difference on the impact on ANA induction and development of SLE (Table 1).

32 patients met ACR or SLICC criteria for SLE (Table 2). Arthritis and synovitis had to be present before TNF-α inhibitor was started in these 32 patients. TNF-α was discontinued in 22 and continued in 10 (Table 3). No life-threatening SLE complications, hospitalizations, or death were noted in patients with TNF-α inhibitor-induced SLE.

Conclusion: The data from our cohort newly prescribed anti-TNF-α therapy demonstrate the autoimmunity which should be carefully monitored for adverse events attributable to the development of SLE. Timely discontinuation, less than a week from identification of TNF-α induced SLE, appears to have prevented serious SLE-related adverse events. Additionally, we show that compared to healthy persons that the prevalence of a positive ANA test is higher in TNF-α treated patients, 15% vs. 20.8%.

Effect of Rituximab on IgG Levels and Associated Infection Risk in Myositis

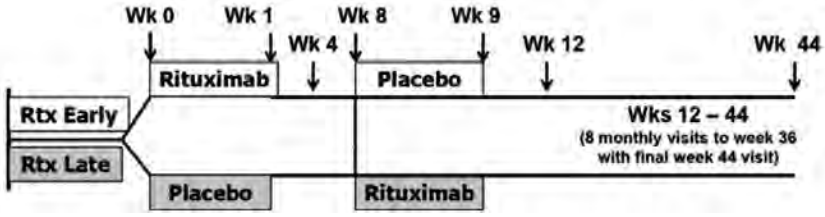
Michael Macklin[1], Chester Oddis[2], Siamak Moghadam-Kia[2], Dana Ascherman[2] and Rohit Aggarwal[2], [1]University of Pittsburgh, Pittsburgh, [2]University of Pittsburgh, Pittsburgh, PA

SESSION INFORMATION
Session Date: Tuesday, November 9, 2021
Session Title: Immunological Complications of Therapy Poster (1516–1529)
Session Type: Poster Session D
Session Time: 8:30AM–10:30AM

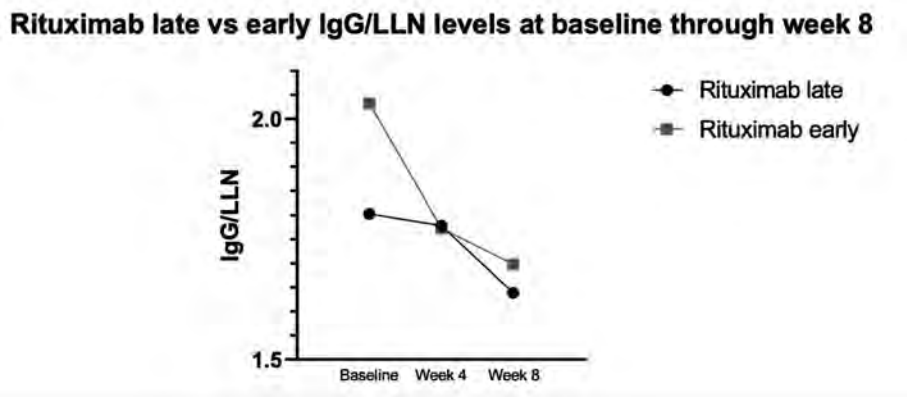
Background/Purpose: Rituximab is an anti-CD20 antibody with therapeutic use in myositis. However, given its B cell depleting mechanism, there is concern regarding its association with hypogammaglobinemia and consequent risk of infection in myositis. We therefore aimed to perform a comprehensive analysis of the effect of rituximab on IgG levels of DM/PM/JDM patients and the association of IgG levels with infections using the Rituximab in Myositis (RIM) study data.

Methods: We retrospectively analyzed data collected in the RIM Trial, which included a rituximab early (RE) and late (RL) group with rituximab administered at weeks 0/1 and at week 8/9, respectively (Figure 1). Serum IgG levels were measured as the ratio of absolute IgG level divided by the lower limit of normal (LLN) for the reference lab. Data were compared for the overall, RL, and RE groups, with/without stratification by disease states that included DM, PM and JDM. IgG levels were compared using a paired t-test. Frequency and duration of abnormally low IgG levels was also evaluated. Associations between the number of infections and IgG levels as well as baseline immunosuppressive drugs were determined using spearman correlation.

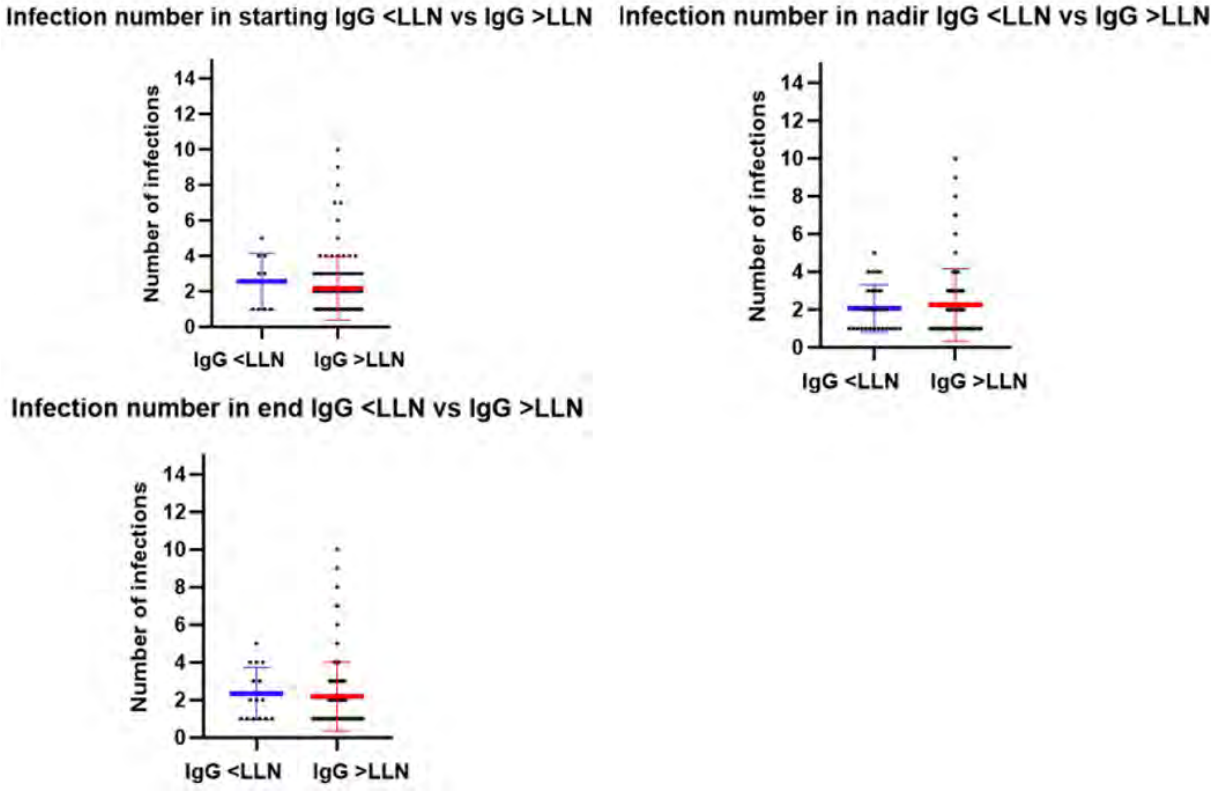
Results: A total of 194 patients (72 DM, 74 PM, 48 JDM) meeting Bohan & Peter criteria were included in this study; with mean age 41 years, 73% female and 71% Caucasian. There was a small, but significant decrease in mean IgG levels (1.9 vs 1.7 xLLN) seen from baseline to week 8, significant only in RE (Early: 2.0 vs. 1.7, p=0.005; Late: 1.8 vs. 1.6, p=0.10) (Figure 2). Nadir IgG levels showed a small but significant decline from baseline levels in both RE and RL; however, end of trial levels were significantly decreased only in RE. Similar trends were seen in subgroup analyses of



Study design of Rituximab in Myositis (RIM) study



Mean IgG/LLN levels for baseline through week 8 for rituximab late vs rituximab early



Infection number by LLN status at baseline, nadir and ending level. Note, plotted lines include mean in middle, SD at top/bottom

adult DM, PM, and JDM; except that end of trial levels were only significantly lower from baseline in DM ($p< 0.0001$), with a non-significant decline in PM ($p=0.110$ and JDM ($p=0.11$).

Despite the small decline in IgG levels, most patients (77%) had IgG levels that remained normal. Amongst 45 (23%) patients with IgG levels below LLN at any time, there were 3 trends: (a) patients with IgG levels below LLN at baseline (n=18); (b) patients with transient decline of IgG levels below LLN (n=14); (c) patients who developed long term decline of IgG levels below LLN (n=13).

Overall, 56.2% patients had infections during the study, with the average number of infections being 2.2 (Figure 3). There was no association between IgG level and number of infections anytime during the trial except in the DM subgroup, where more infections were seen in patients with IgG levels below LLN at baseline (median # infections: 4 vs 2, $p=0.027$). There was no correlation between number of immunosuppressant medications or baseline steroid dose and number of infections.

Conclusion: Rituximab led to a modest, but statistically significant decline in IgG in myositis patients of unclear clinical significance, without clear association between IgG levels and infection except in the DM subgroup with IgG levels below LLN at baseline. These data should provide additional evidence supporting the safety of rituximab in myositis, where most patients' IgG levels remained normal or declined only transiently.

Clinical Consequences of Hepatitis B Core Antibody Positivity After IVIG Administration

William West[1], Therese Posas-Mendoza[2], Jerald Zakem[3], William Davis[1] and Robert Quinet[4], [1]Ochsner Medical Center, New Orleans, LA, [2]Ochsner Clinic Foundation, New Orleans, LA, [3]Ochsner Health Systems, Metairie, LA, [4]Ochsner Health, River Ridge, LA

SESSION INFORMATION
Session Date: Tuesday, November 9, 2021
Session Title: Immunological Complications of Therapy Poster (1516–1529)
Session Type: Poster Session D
Session Time: 8:30AM–10:30AM

Background/Purpose: Intravenous immunoglobulin (IVIG) is a blood product created by pooling of donor plasma that is used for a wide range of indications. IVIG is commonly used in the fields of neurology, rheumatology, hematology, and transplant medicine. Previous studies have identified transient positivity of hepatitis B core antibody (HBcAb) after receiving IVIG. This phenomenon signifies a passive transference of HBcAb from IVIG as opposed to a previous exposure to HBV. This study examines the clinical consequences of this concept, including the inappropriate administration of antiviral therapy and the deferment of immunotherapy, such as anti-CD20 monoclonal antibodies, in fear of HBV reactivation.

Methods: Preliminary database search identified patients that were at least 18 years of age, tested HBcAb-positive, and received IVIG between January 2013 through January 2021. After exclusion criteria were applied, retrospective chart review was performed to determine the indication for IVIG, whether patients received antiviral therapy, and whether they received an anti-CD20 monoclonal antibody (rituximab, ocrelizumab, or ofatumumab).

Results: Preliminary search yielded 123 patients that met inclusion and exclusion criteria. Of these 123 patients, 37 (30.1%) tested HBcAb-negative before IVIG, tested HBcAb-positive after IVIG, and had undetectable HBV DNA levels (see Figure 1). Indications for IVIG included pathologies in hematology, immunology, neurology, rheumatology, and transplant medicine (see Figure 2). These patients represent confirmed false-positives for HBcAb. Of these 37 patients, 22 (42.3%) received antiviral therapy (either tenofovir or entecavir). 29 (78.4%) did and 8 (21.6%) did not receive anti-CD20 monoclonal antibody therapy.

Conclusion: This study demonstrates that a significant portion of patients receive unnecessary antiviral therapy due to the passive transfer of HBcAb with IVIG. This leads to an inappropriate utilization of resources and potential expo-

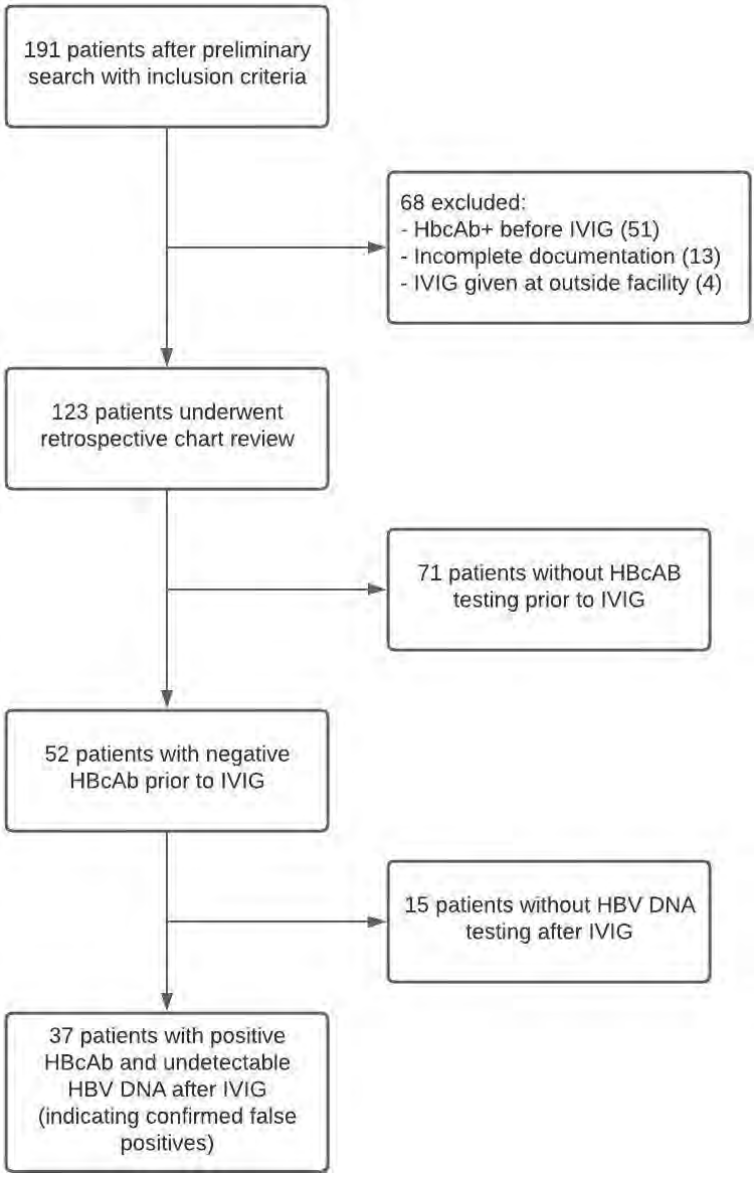

Figure 1. Flowchart of Retrospective Analysis.

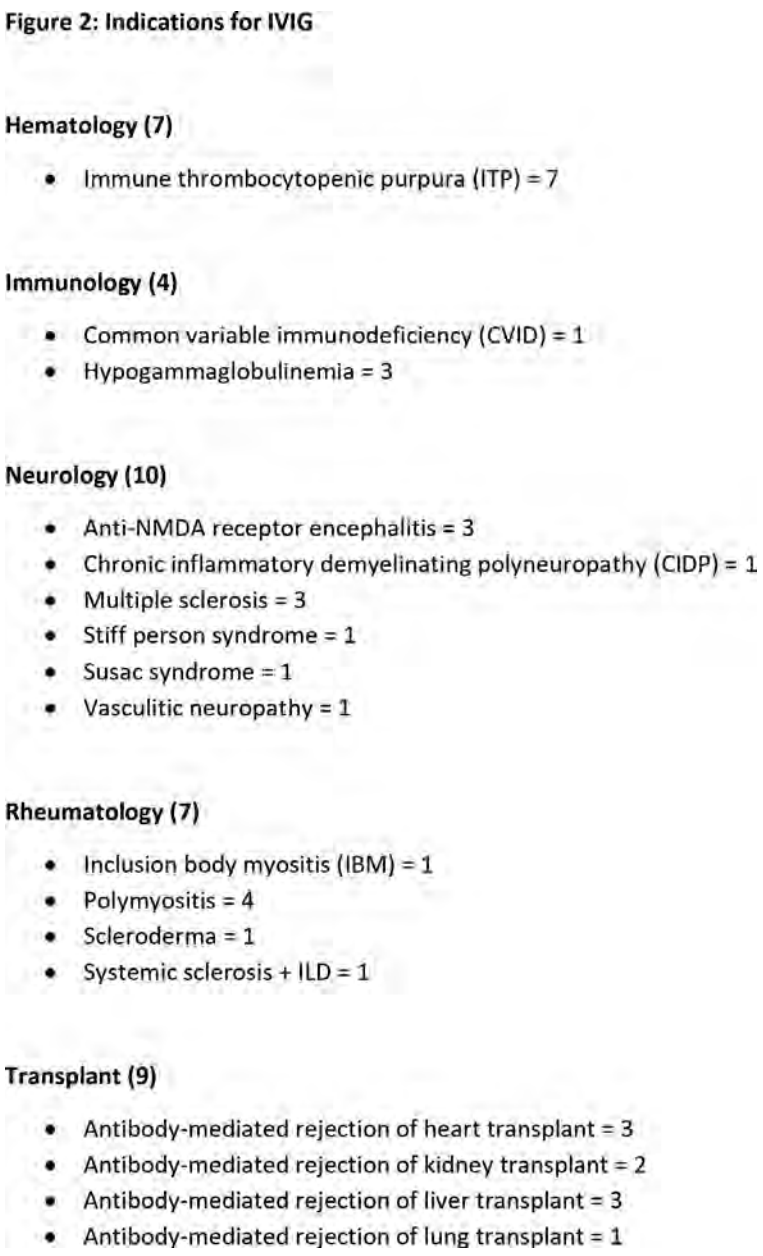

Figure 2. Indications for IVIG.

sure to side effects of the medication. This study also highlights a proportion of patients that do not receive anti-CD20 monoclonal antibody therapy, which may be related to HBcAb-positivity. As previous studies have suggested, HBV testing should be done prior to IVIG administration in order to establish an accurate HBV status for the patient. In doing so, patients may avoid unnecessary prescription of antiviral therapy. Furthermore, physicians would have a clear understanding of the actual risk of HBV reactivation when considering the use of anti-CD20 monoclonal antibodies.

Session Title: Immunological Complications of Therapy Poster (1516–1529)

Session Type: Poster Session D

Session Time: 8:30AM–10:30AM

Background/Purpose: Oral urate-lowering therapy (ULT) is one of the primary treatments for gout. Unfortunately, a proportion of patients with advanced gout are resistant to oral ULT or have severe tophaceous gout. For patients with uncontrolled gout, pegloticase, a recombinant pegylated uricase, is approved by the US Food and Drug Administration (FDA) and has proven efficacy. However, pegloticase use can be limited by immunogenicity as the development of anti-drug antibodies contributes to both loss of efficacy and a higher risk of infusion reactions. Small clinical trials (Khanna, 2021; Boston, 2021) have suggested that concomitant immunomodulatory (IMM) drugs (e.g. mycophenolate moefitil or methotrexate) reduce pegloticase immunogenicity and improve treatment persistence, but real-world evidence is still lacking. Therefore, we evaluated pegloticase persistence and adverse events associated with concomitant IMM drug use in patients with uncontrolled gout.

Methods: We conducted a retrospective cohort and selected patients with procedure code(s) for pegloticase (J2507) using ACR's Rheumatology Informatics System for Effectiveness (RISE) registry from 01/2016 through 06/2020. The first date of pegloticase was defined as the index date. Based on use of the concomitant IMM drug, we identified 2 exposure groups: 1) IMM users (defined as ≥ 1 IMM prescription within ±60days of index); 2) non-IMM users. We

Table 1: Demographic characteristics of the patients stratified by immunomodulatory (IMM) drug use given concomitant to pegloticase

		IMM users N=124	Non-users N=576	All N=700
Characteristics				
Age	Median (25%, 75%)	61.33 (51.46, 73.28)	61.68 (49.90, 72.32)	61.46 (50.22, 72.44)
Male		96 (77.4%)	449 (78.0%)	545 (77.9%)
Race	Asian	15 (12.1%)	29 (5.0%)	44 (6.3%)
	African American	11 (8.9%)	60 (10.4%)	71 (10.1%)
	White	74 (59.7%)	363 (63.0%)	437 (62.4%)
	Unknown	24 (19.4%)	122 (21.5%)	146 (20.9%)
Body Mass Index	Median (25%, 75%)	31.50 (27.30, 37.19)	31.67 (27.28, 36.26)	31.74 (27.28, 36.31)
Ever smoker	Yes	26 (21.0%)	108 (18.8%)	134 (19.1%)
RxRISK category count	Median (25%, 75%)	8.00 (6.00, 11.00)	8.00 (4.00, 11.00)	8.00 (4.00, 11.00)

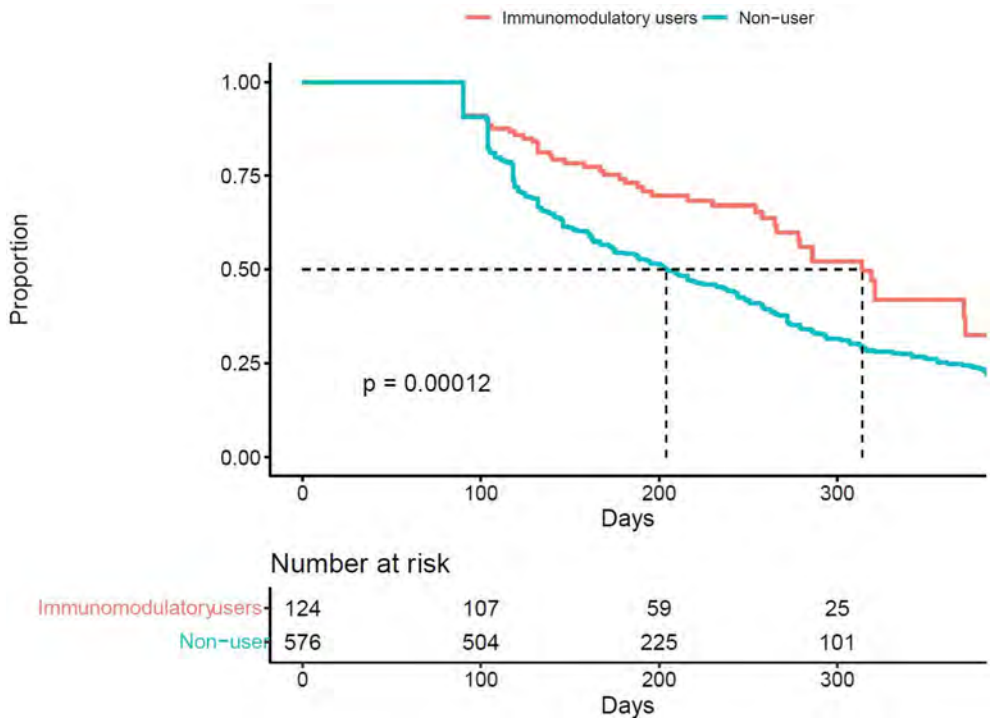

Figure 1. Kaplan-Meier plot for time to discontinuation stratified by immunomodulatory drug use given concomitant to pegloticase.

calculated the proportion of patients who ever achieved the serum urate (sUA) ≤ 6mg/dL and patients who had lab abnormalities (WBC < 3.4; platelets < 135,000; hematocrit [HCT] < 30; ALT or AST ≥1.5X ULN) within 180 days after the index date. Time to pegloticase discontinuation was analyzed using cox regression model controlling for potential confounders including age, sex, race, body mass index (BMI), national area deprivation index (ADI), concurrent medications (Rx), and number of RxRisk categories (a measure of comorbidity based on medications for specific diseases).

Results: We identified 700 pegloticase users with median follow-up of 14 months. Among these, 124 were IMM users and 576 non-users (**Table 1**). For IMM users, the most used IMM medications were methotrexate (79%), followed by azathioprine (12.1%). During follow-up, 90% of patients ever met sUA treatment target. The median number of pegloticase infusions were 7 for IMM drug users and 5 for non-users . Compared to non-users, IMM users were less likely to discontinue pegloticase (**Figure 1**). After adjustment, the hazard ratio of discontinuation of pegloticase associated with concomitant IMM therapy was 0.57 (95% CI: 0.43-0.78). Lab abnormalities were uncommon (< 5%) among pegloticase users, and were not higher in patients also on IMM therapy.

Conclusion: Consistent with small trials, results from this large observational registry suggest that concomitant immunomodulatory drug use improves pegloticase persistence. Rare lab abnormalities suggest no disproportionate toxicity resulting from this strategy.

Evaluation of the Possible Different Evolution of SARS-CoV-2 Infection with Tumor Necrosis Factor Inhibitors or with Rituximab in Rheumatic Patients

Simón Ángel Sánchez-Fernández[1], Luisa Marena Rojas Vargas[1], Leticia Del Olmo Pérez[2], Paula Virginia García Morales[1], Adela Alía Jiménez[1], José Antonio Carrasco Fernández[1] and Sandra Masegosa Casanova[3], [1]Hospital La Mancha Centro, Alcázar de San Juan, Spain, [2]Hospital Nuestra Señora del Prado, Talavera de la Reina, Spain, [3]Hospital General de Tomelloso, Tomelloso, Spain

SESSION INFORMATION

Session Date: Tuesday, November 9, 2021

Session Title: Infection-related Rheumatic Disease Poster (1530–1564)

Session Type: Poster Session D

Session Time: 8:30AM–10:30AM

Background/Purpose: To assess whether two different biological therapies (BT), tumor necrosis factor inhibitor (TNFi) and ritixumab (RTX), are related to a different course and severity of SARS-CoV-2 infection in patients with rheumatic diseases.

Methods: Observational and retrospective multicenter study that includes patients under follow-up by the rheumatology services of Hospital La Mancha Centro, Hospital Nª Sª del Prado and Hospital de Tomelloso, and who received some BT from at least 3 months prior to the beginning of the COVID19 pandemic until March 2021. Sociodemographic, clinical and treatment variables were collected through digital medical history, as well as the presence of confirmed SARS-CoV-2 infection (by nasopharyngeal RT-PCR, rapid antigen or antibodies IgG tests) and its posterior evolution. The development of pneumonia and the need for hospital admission, the need for ventilatory support, refractoriness to corticosteroids (CS), absence of development of IgG antibodies against the virus, higher WHO clinical progression scale and the exitus were considered worse evolution and greater severity. These evolution variables were compared between the patients who received TNFi versus others and also between who received RTX versus others.

Results: In the 3 hospitals, a total of 372 patients with rheumatic diseases received BT during follow-up, of which 68 patients (18.3%) had SARS-CoV-2 infection, with a mean age of 54.8±13.8 years (54.4% women and 45.6% men). The most frequent diagnoses were inflammatory spondyloarthropathy (39.7%), rheumatoid arthritis (32.3%) and pso-

Table 1. Patients with BT and SARS-CoV-2. Diagnoses and treatments (n = 68).

Diagnoses		Treatments	
SpA	27 (39.7%)	TNFα inhibitors	45 (66.2%)
RA	22 (32.3%)	Rituximab	9 (13.2%)
PsA	8 (11.8%)	IL17 inhibitors	4 (5.9%)
Vasculitis	5 (7.4%)	Ustekinumab	3 (4.4%)
Systemic Autoinmune disease	3 (4.4%)	JAK inhibitors	3 (4.4%)
Uveitis	2 (2.9%)	Abatacept	2 (2.9%)
Behçet disease	1 (1.5%)	IL6 inhibitors	1 (1.5%)
		Apremilast	1 (1.5%)

** Vasculitis: Granulomatosis withon polyangiitis (n=3), ANCA associated Vasculitis (n=1), Microscopic polyangiitis (n=1); Systemic autoinmune disease: Polymyositis (n=1), Sjögren´s Syndrome (n=1), Mixed connective tissue disease (n=1).*

Table 2. Evolution of SARS-CoV-2 patients; TNFi vs others BT.

IgG+ SARS-CoV2 development	**No** (n=9; 33.3%)	8 (100%)	1 (5.3%)	***p = 0.000***
	Yes (n=18; 66.7%)	0 (0%)	18 (94.7%)	

riatic arthritis (11.8%), and the BT administered were TNFi (66.2%), RTX (13.2%) and IL17 inhibitors (5.9%) (table 1). The mean time of BT administration was 54.9±46.4 months.

Of the patients infected with SARS-CoV-2, 21 (30.9%) developed pneumonia, 17 (25%) suffered hospital admission and 34 (50%) required some treatment (of which 9 (13.2%) were initially refractory to CS treatment and 6 (8.8%) required ventilatory support). The mean time of hospitalization was 25.1±30.5 days and the mean of the WHO clinical progression scale was 2.8±2.1, with 2 dead patients (2.9%). At the end of the follow-up, 9 patients (13.2%) had not developed IgG antibodies against the virus.

In the group TNFi compared to the others TB, there was a lower percentage of patients who developed pneumonia and hospitalization, had a lower score on the WHO clinical progresión scale and a shorter hospitalization time, with all patients developing SARS-CoV-2 IgG after infection. No patient in this group died (table 2).

In the RTX group there was a higher percentage of SARS-CoV-2 infection (37.5%) than in others (17%); also, the patients with RTX had a higher percentage of development of pneumonia and hospital admission and had a higher score on the WHO scale, with no developing of SARS-CoV-2 IgG during follow-up in any of them. One patient in this group died (table 3).

Conclusion: In our rheumatic patients under treatment with TB there has been a different evolution of the SARS-CoV-2 infection, having been better and less severe in patients with TNFi and worse and more severe in patients with RTX.

SESSION INFORMATION
Session Date: Tuesday, November 9, 2021
Session Title: Infection-related Rheumatic Disease Poster (1530–1564)
Session Type: Poster Session D
Session Time: 8:30AM–10:30AM

Background/Purpose: Coronavirus Disease 2019 (COVID-19), caused by Severe Acute Respiratory Syndrome Coronavirus-2 (SARS-CoV-2), is associated with a wide range of clinical manifestations, including autoimmune features and autoantibody production. Autoantibody production has been implicated in other acute viral infections; however, the extent and breadth of autoantibodies present during acute COVID-19 has been less characterized.

Methods: We developed three different protein arrays to measure hallmark IgG autoantibodies associated with Connective Tissue Diseases (CTDs), Anti-Cytokine Antibodies (ACA), and anti-viral antibody responses in 147 hospitalized COVID-19 patients in three different centers. The CTD autoantibody array included prominent antigens (Figure 1a, left to right) targeted in systemic sclerosis, myositis and overlap syndromes, systemic lupus erythematosus and Sjögren's syndrome, gastrointestinal and endocrine autoimmune disorders, chromatin-associated antigens, and mis-

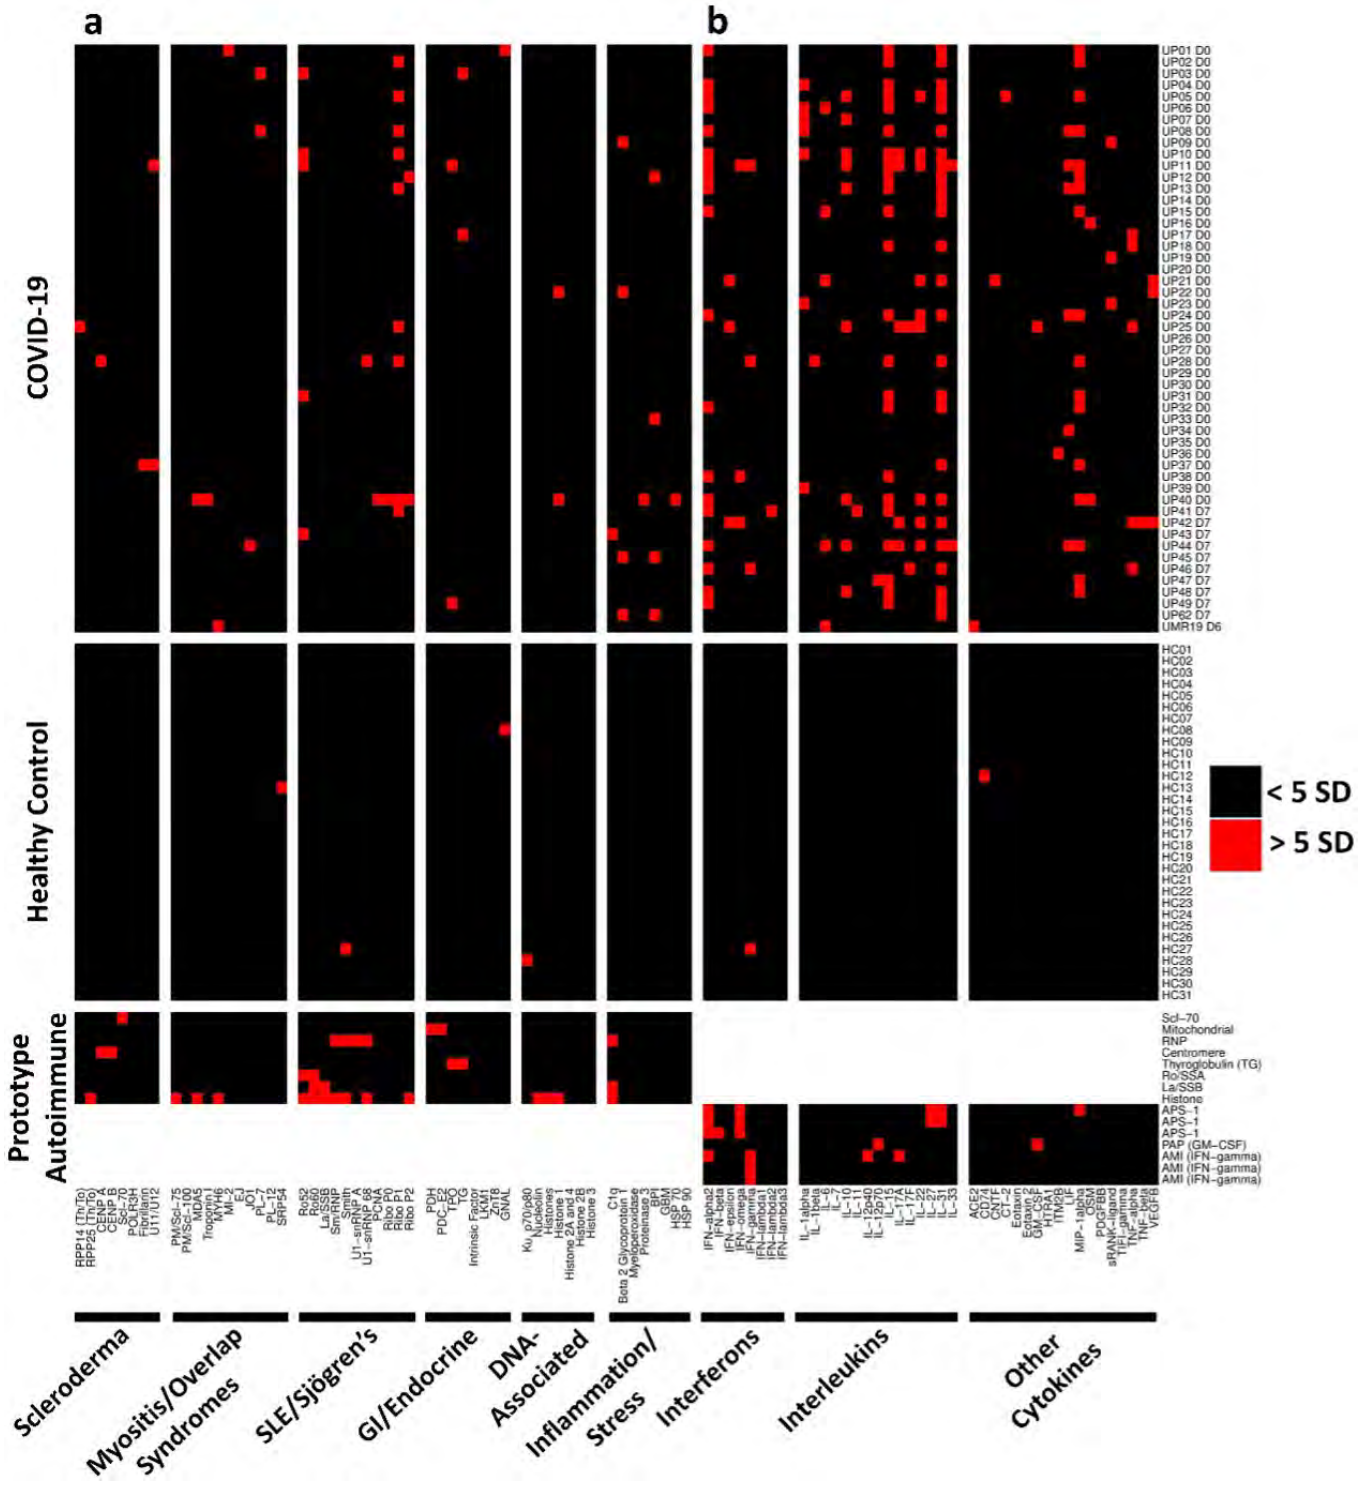

Figure 1.

cellaneous antigens, including proteins targeted in vasculitis. The ACA array included antigens represented within the interferon, interleukin or miscellaneous category (Figure 1b, left to right).

Results: Autoantibodies were identified in 49% of patients, but in < 15% of healthy controls. When present, autoantibodies largely targeted autoantigens associated with rare disorders such as myositis, systemic sclerosis and CTD overlap syndromes. Ribosomal P proteins (P0, P1, and P2) were most prominently targeted (10 of 50 patients, 20%), but were not found in any of the healthy controls. Patients with CTD autoantibodies tended to demonstrate one or a few specificities whereas ACA were more prevalent, and patients often had antibodies to multiple cytokines (Figure 1). Rare patients were identified with IgG antibodies against angiotensin converting enzyme-2 (ACE-2). Longitudinal analysis identified an expansion of autoantigen reactivity in a subset of patients at the second available time point (Figure 2). Focusing our analysis in patients early in their infection course based on spike/RBD antibody seroconversion between consecutive samples, we could identify a subset of CTD autoantibodies and ACAs that developed *de novo* following SARS-CoV-2 infection while others were transient (Figure 3. sequential samples in white boxes that demonstrated *de novo* development of CTD autoantibodies and ACAs). Autoantibodies tracked with longitudinal development of IgG antibodies that recognized SARS-CoV-2 structural proteins such as S1, S2, M, N and a subset of non-structural proteins, but not proteins from influenza, seasonal coronaviruses or other pathogenic viruses.

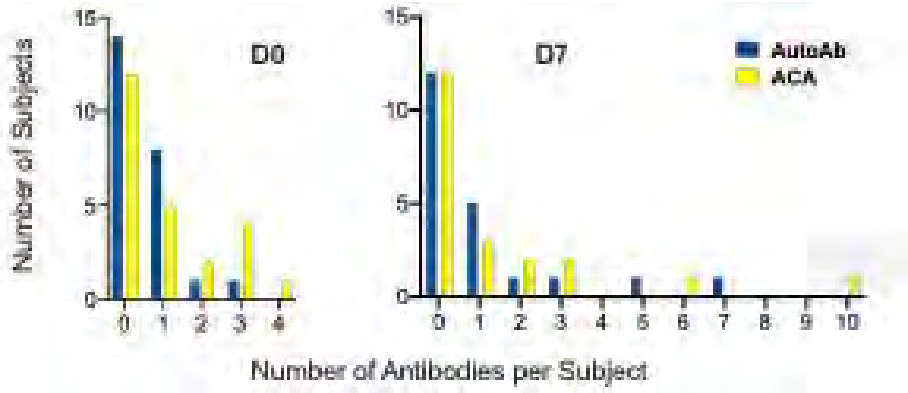

Figure 2.

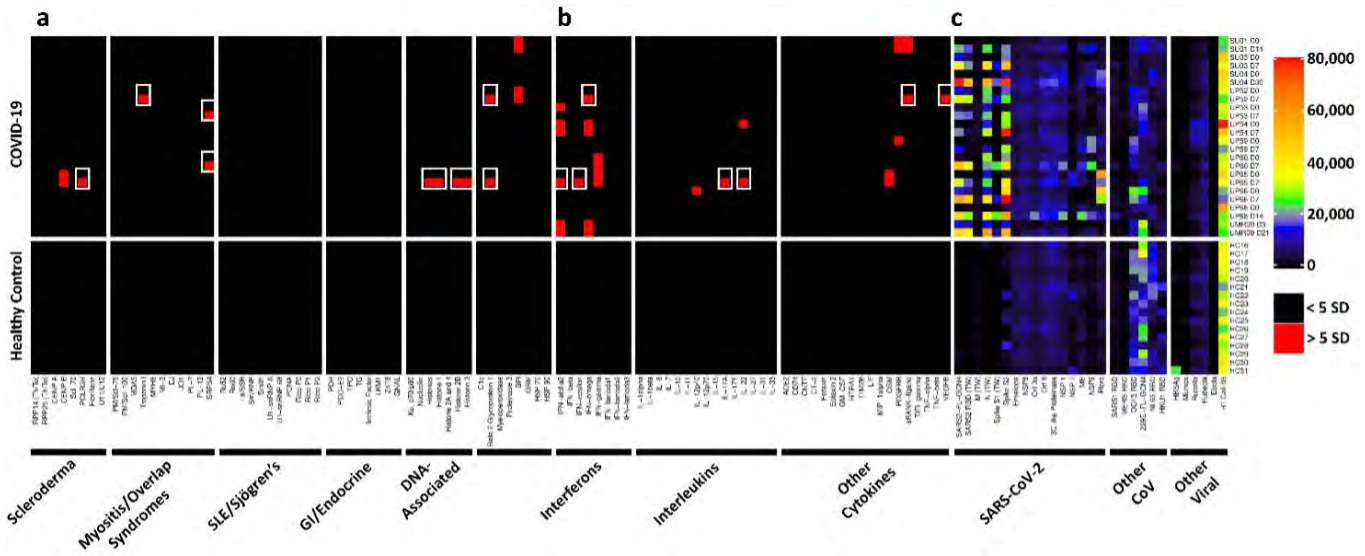

Figure 3.

Conclusion: We conclude that SARS-CoV-2 infection a) is accompanied by increased prevalence of CTD-related autoantibodies and ACAs, b) in a subset of patients causes development of new-onset IgG autoantibodies, and c) that autoantibody development is positively correlated with immune responses to SARS-CoV-2 proteins.

Session Title: Infection-related Rheumatic Disease Poster (1530–1564)

Session Type: Poster Session D

Session Time: 8:30AM–10:30AM

Background/Purpose: Patients with immune mediated inflammatory disorders (IMIDs) have an inherently heightened susceptibility to infection and may be considered high risk for developing COVID-19. While data regarding the COVID-19 vaccine's immunogenicity in an immunocompetent adult population is rapidly emerging, the ability of IMID patients to adequately respond to these vaccines is not known. Here, we investigate the humoral and cellular immune response to mRNA COVID-19 vaccines in patients with IMIDs on immunomodulatory treatment

Table 1. Baseline characteristics and spike-specific SARS-CoV-2 antibody titers in the New York Cohort.

Characteristic	Healthy (n = 27)	IMID No MTX* (n = 61)	IMID Yes MTX* (n = 64)	p-value
Age- mean (range, SD)	50.3 (28-78, 12.9)	49.1 (24-79, 14.7)	56.5 (22-81, 13.7)	0.011

*IMID denotes immune mediated inflammatory disease, MTX methotrexate.
*Vasculitis, dermatomyositis, adult onset stills disease, sarcoidosis, inflammatory bowel disease, and polymyalgia rheumatica.
#Adequate humoral response defined as greater than 5000 units.
^ Of note, three of the five patients who did not response in the IMID No MTX group were on rituximab.

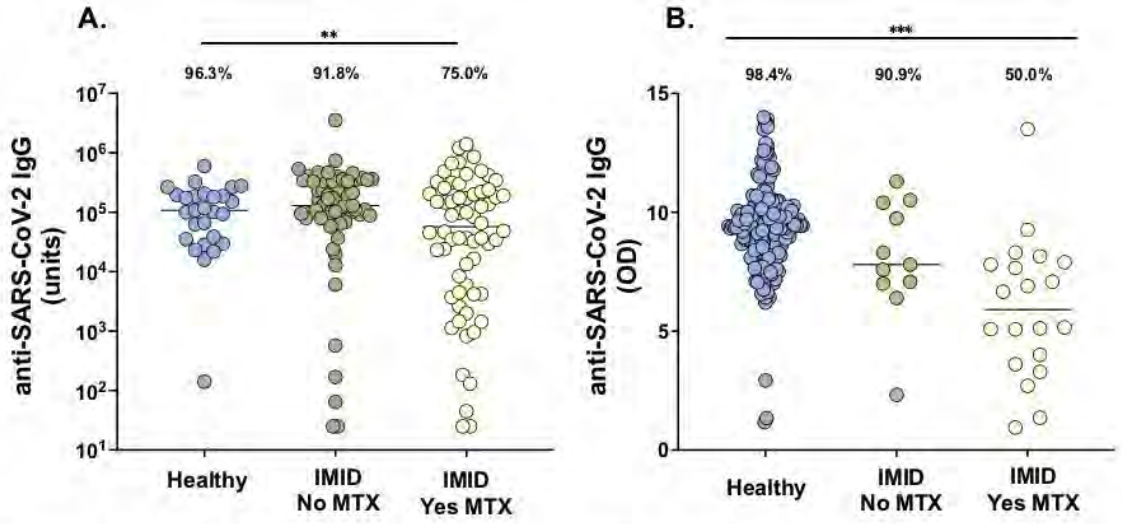

Figure 1. Anti-SARS-CoV-2 IgG levels in cohorts from New York City (A) and Erlangen (B) in healthy participants without immune-mediated inflammatory diseases (IMID; blue), IMID patients not receiving methotrexate (MTX; green), and IMID patients treated with MTX (yellow). Solid lines represent mean titer of each group. For the New York City cohort (A), adequate response is defined as greater than 5000 units and for the Erlangen cohort (B), adequate response is defined as greater than 5.7 (OD450nm), two standard deviations of the mean of controls. Percentages and group comparisons using chi squared test of independence reflect proportion of those achieving an adequate response within each group.
** $p < 0.01$
*** $p < .0001$

Methods: Patients with immune mediated inflammatory disorders (IMIDs) have an inherently heightened susceptibility to infection and may be considered high risk for developing COVID-19. While data regarding the COVID-19 vaccine's immunogenicity in an immunocompetent adult population is rapidly emerging, the ability of IMID patients to adequately respond to these vaccines is not known. Here, we investigate the humoral and cellular immune response to mRNA COVID-19 vaccines in patients with IMIDs on immunomodulatory treatment.

Results: The NY cohort baseline characteristics are found in Table 1. The Erlangen cohort consisted of 182 healthy subjects, 11 subjects with IMID receiving TNFi monotherapy, and 20 subjects with IMID on MTX monotherapy. In both cohorts, healthy individuals and those with IMID not on MTX were similar in age, while those IMID patients receiving MTX were generally older.

In the NY cohort, of the healthy participants, 96.3% demonstrated adequate humoral immune response. Patients with IMID not on MTX achieved a similar rate of high antibody response rate (91.8%), while those on MTX had a lower rate of adequate humoral response (75.0%) (Figure 1A). This remains true even after the exclusion of patients who had evidence of prior COVID-19 infection (*P*= 0.014). Of note, 3 out of the 4 IMID patients receiving rituximab did not produce an adequate response. Similarly, in the Erlangen validation cohort, 98.3% of healthy controls, 90.9% of patients with IMID receiving TNFi monotherapy, and 50.0% receiving MTX monotherapy achieved adequate immunogenicity (Figure 1B). These differences remain significant when combining the cohorts, using a stricter definition of adequate response, and in a subgroup analysis by age.

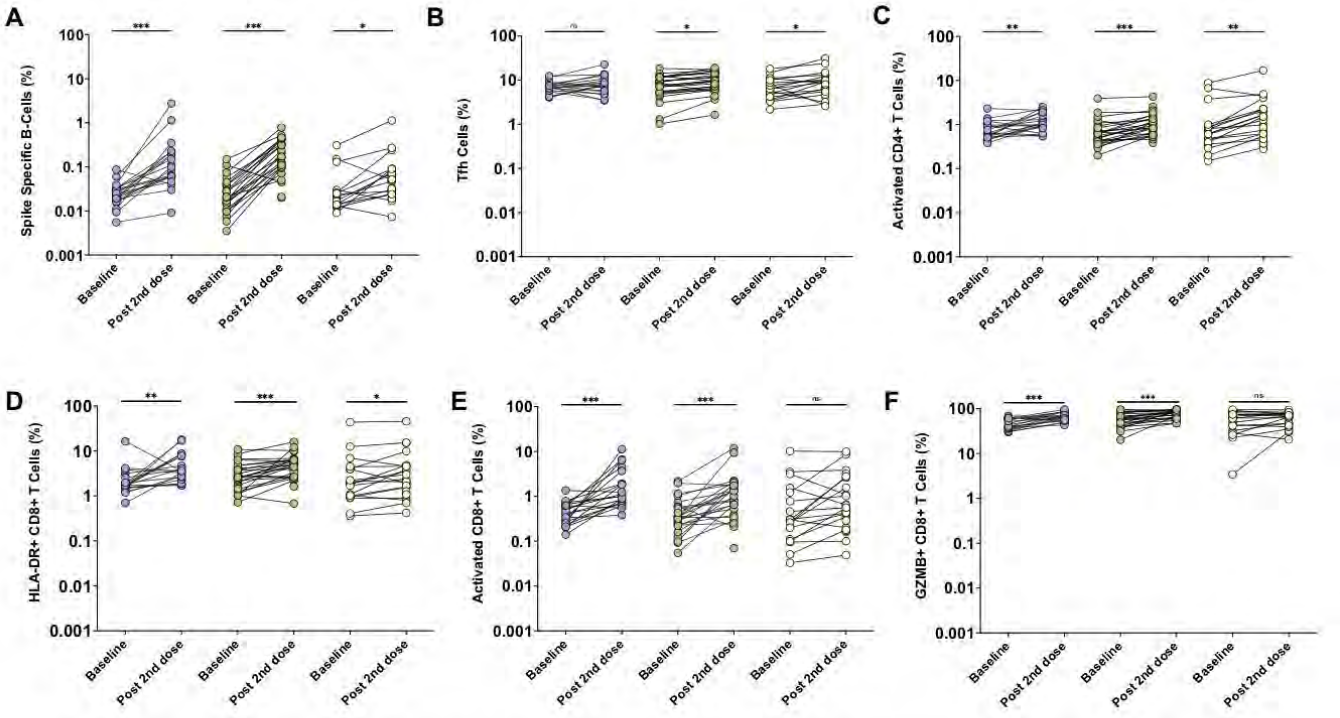

Figure 2. Immune cell populations from the New York City cohort by high-spectral flow in healthy controls (blue, n=20), patients with immune mediate inflammatory disease (IMID) not on methotrexate (MTX; green, n= 24), and patients with IMID on MTX (yellow, n=18), at baseline and post 2nd dose of BNT162b2 mRNA vaccine. Pre- and post- vaccination comparisons were performed using Wilcoxon Signed Rank tests. Y-axes presented as a logarithmic scale.
ns indicated no statistical significance
* p < .05
** p < .01
*** p< .0001

Cellular response was also analyzed in a subgroup of the NY cohort before and after second vaccination. Activated CD8+ T cells (CD8+ T cells expressing Ki67 and CD38) and the granzyme B-producing subset of these activated CD8+ T cells, were induced in immunocompetent adults and those with IMID not on MTX, but not induced in patients receiving MTX (Figure 2).

Conclusion: In two independent cohorts of IMID patients, MTX, a widely used immunomodulator for the treatment of several IMIDs, adversely affected humoral and cellular immune response to COVID-19 mRNA vaccines. Although precise cut offs for immunogenicity that correlate with vaccine efficacy are yet to be established, our findings suggest that different strategies may need to be explored in patients with IMID taking MTX to increase the chances of immunization efficacy against SARS-CoV-2, as has been demonstrated for other viral vaccines.

SESSION INFORMATION

Session Date: Tuesday, November 9, 2021

Session Title: Infection-related Rheumatic Disease Poster (1530–1564)

Session Type: Poster Session D

Session Time: 8:30AM–10:30AM

Background/Purpose: The COVID-19 pandemic has brought uncertainties to the rheumatological practice, and despite the large number of publications to date, many questions remain unanswered. One of the unmet needs is

related to the differential risk among the immune mediated rheumatic diseases (IMRD), mainly related to the severity COVID-19 outcomes.

The aim of this study was to compare COVID-19 outcomes among patients with Systemic Lupus Erythematosus (SLE), Rheumatoid Arthritis (RA) and Spondyloarthritis (SpA) in a cohort of Brazilian patients and the main risk factors associated.

Methods: We performed a cross-sectional analysis from the ReumaCoV-Brasil registry comparing the moderate/ severe forms, including hospitalization, intensive care unit (ICU) admission, mechanical ventilation (MV) and death, in patients with RA, SLE and SpA and COVID-19. COVID-19 diagnosis was defined as clinical symptoms and lab test confirmation (RT-PCR and/ or serology against SARS-CoV-2). Demographic and clinical data, as well as details on COVID-19 management and endpoints were collected on the REDCap database. Specific and international classification criteria were used to define each IMRD of this study. This study was registered at the Brazilian Registry of Clinical Trials—REBEC, RBR-33YTQC.

Results: From May 20th, 2020 to Jan 24th, 2021, a total of 751 patients were included, of whom 317 with SLE (42.2%), 269 with RA (35.8%) and 165 with SpA (22.0%). Most of patients were female (81.6%) with mean age was 46.7 (13.5) years. The main comorbidity was hypertension (36.6%). Regarding the symptoms of COVID-19, patients with RA reported a higher frequency of arthralgia than the other groups (35.3% vs. 23.0% and 21%; p=0.001, respectively) and longer symptoms duration (15.5±10.7 days vs. 12.1±8.8 days and 13.1±9.9 days, p< 0.001, respectively). The COVID-19 endpoints were quite similar among groups, including hospitalization, ICU admission, MV and mortality rate (Table 1). Analyzing the whole group, older age was significantly associated with all outcomes, as well current oral corticosteroids dosage above 10mg/day and cardiopathy. On the other hand, absence of any comorbidity played a protective role for all the outcomes. After multiple adjustments, the risk factors associated with death were age (OR=1.03; 95%CI 1.004-1.09, p=0.027) and have no kidney disease (OR = 0.150; 95%CI 0.04-0.45, p=0.0001) (Figure 1).

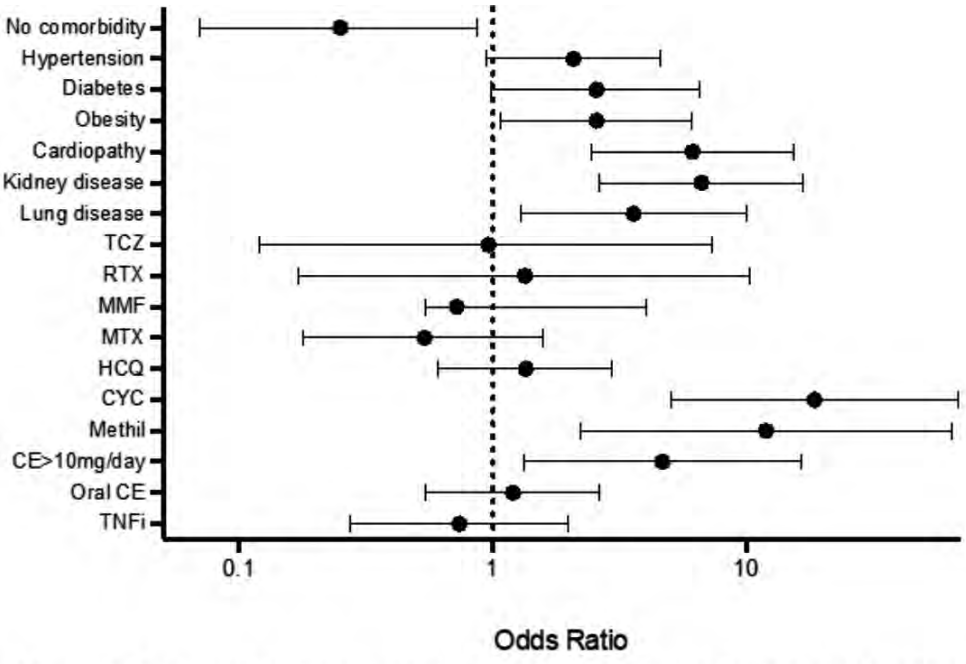

Figure 1: Odds ratio of death associated with comorbidities and medications used to treat rheumatic diseases

TNFi: Tumor necrosis factor inhibitor, TCZ: Tocilizumab, RTX: Rituximab, Methil: Methilprednisolone pulse therapy, CYC: Cyclophosphamide pulse therapy, MMF: Mycophenolate mofetil, MTX: Methotrexate, HCQ: hydroxychloroquine, CE: corticosteroid

Conclusion: Although no differences have been observed regarding COVID-19 outcomes among patients with SLE, RA and SpA, some risk factors associated with death, hospitalization, IUC admission and MV are directly related to DMARDs, particularly current corticosteroids. However, it is important to note that traditional risk factors are more related to unfavorable COVID-19 than underlying IMRD, especially older age and comorbidities.

SESSION INFORMATION

Session Date: Tuesday, November 9, 2021

Session Title: Infection-related Rheumatic Disease Poster (1530–1564)

Session Type: Poster Session D

Session Time: 8:30AM–10:30AM

Background/Purpose: Severity factors for COVID-19 have been widely studied in the general population. However, the severity factors and characteristics of COVID-19 in patients with rheumatic immune-mediated inflammatory diseases (R-IMID) remain unknown. Our aim was to analyze the severity factors of COVID-19 infection in R-IMID.

Methods: Cross-sectional study in a single University Hospital. We included all consecutive patients with a diagnosis of a R-IMID and a positive test for COVID-19 up to March 31st, 2021. Confirmed infection was defined if the patient had a positive nasopharyngeal swab for SARS-CoV-2. Medical records of 25,367 patients that suffered COVID-19 in our region, and 7,218 with R-IMID from our hospital were reviewed. COVID-19 severity was divided into mild, moderate, severe and critical according to the United States National Institute of Health (NIH) COVID-19 guidelines. Mild/moderate COVID19 was compared to critical.

Table. Clinical severity of 274 with R-IMID diagnosed with COVID-19 (analytical findings and Immunosuppressants are at COVID diagnosis)

	Overall N= 274	Mild/Moderate N= 245	Severe/Critical N= 29	Mild/moderate vs severe/critical p

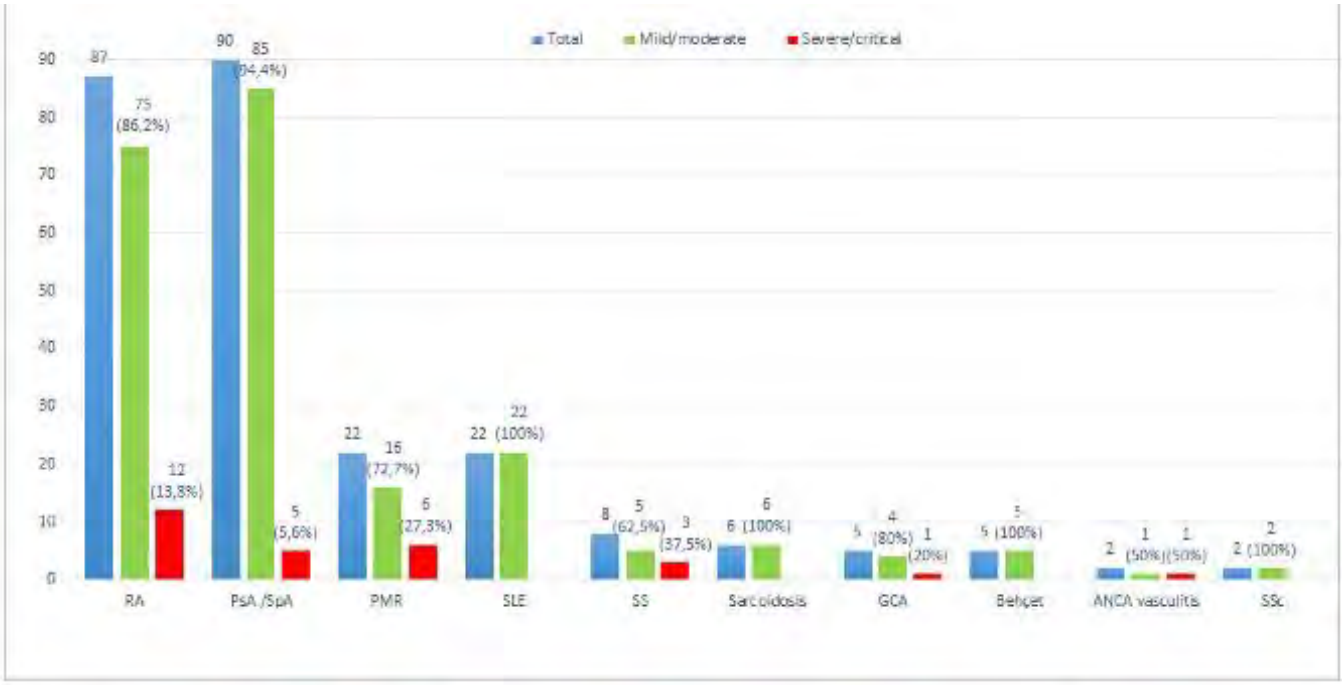
AZA: azathioprine, GC: Glucocorticoids, HCQ: Hydroxychloroquine, MM: mycophenolate mofetil. MTX: Methotrexate, RTX: Rituximab *P <0.05

Results: We included 274 patients (185 women/89 men), mean age 59.1±18 years. Most cases were mild to moderate (n=245). The remaining patients presented severe (n=8) or critical (n=21) disease. 17 (6.2%) presented a fatal outcome.

More frequent R-IMID were: Rheumatoid arthritis (RA) (n=87, 31.8%), Axial spondyloarthritis/ Psoriatic arthritis (SpA/PsA) (n=90, 32.8%), Polymyalgia Rheumatica (PMR) (n=22, 8%) and Systemic Lupus Erythematosus (SLE) (n=22, 8%) (**FIGURE**).



GCA: Giant cell arteritis, SLE: Systemic lupus erithematosus, SpA: Axial spondyloarthritis, SS: Sjögren's syndrome, SSc: Systemic scleroderma, PsA: Psoriatic arthritis, RA: Rheumatoid arthritis

Figure. Severity of COVID-19 according to R-IMID. Data between parentheses are the percentage of patients with mild/moderate or severe/critical disease.

Main comorbidities were hypertension (n=119, 43.4%), dyslipidemia (n=119, 43.4%), age higher than 65 years old (n=100, 36.5%), obesity (n=49, 17.9%), cardiovascular disease (n=45, 16.4%), diabetes mellitus (n=36, 13.1%), chronic pulmonary disease (n=29, 10.6%) and chronic kidney disease (n=27, 9.9%).

Comorbidities in R-IMID associated with severe to critical disease ($p< 0.05$) were hypertension, dyslipidemia, age higher than 65 years, previous cardiovascular, kidney or lung disease and PMR.

Rituximab was the only treatment associated with increased severity of COVID-19 ($p <0.05$). Severe/critical compared with mild/moderate disease showed significantly higher levels of serum creatinine, and lower levels of lymphocytes and received more frequently systemic glucocorticoids **(TABLE)**. Tocilizumab and Anakinra were used only in critical patients, 2 cases each.

Conclusion: Although most cases of COVID-19 are mild, it can be a life-threatening disease in patients with R-IMID. Hypertension, dyslipidemia, older age, previous cardiovascular, kidney or lung disease, the use of rituximab and PMR were associated with critical disease.

SESSION INFORMATION

Session Date: Tuesday, November 9, 2021

Session Title: Infection-related Rheumatic Disease Poster (1530–1564)

Session Type: Poster Session D

Session Time: 8:30AM–10:30AM

Background/Purpose: Recent studies have shown high rates of autoantibody production in patients hospitalized with COVID-19, including antinuclear antibodies (ANA) and antibodies associated with antiphospholipid syndrome. However, the long-term implications of these phenomena remain unknown. Similarly, whether vaccination against SARS-CoV-2 with novel mRNA constructs may lead to an increase in autoantibody production (or clinically evident autoimmunity) is yet to be elucidated. Here, we describe the incidence of ANA seroconversion in a cohort of patients with immune-mediated inflammatory diseases (IMID) after mRNA COVID-19 vaccination.

Methods: As part of the NYU Langone SAGA (Serologic Testing and Genomic Analysis of Autoimmune, Immune-mediated, and Rheumatic patients with COVID-19) cohort, 72 subjects (n=27 healthy controls and n=45 patients with IMID) were assessed for autoantibody production via serum ELISA. Time-points included pre/post COVID-19 infection as well as pre/post mRNA COVID-19 vaccination with time points up to 3 months post initial dose of mRNA vaccine. Spike IgG antibody titers were also assessed by in-house laboratory-based ELISA.

Results: In the SAGA cohort of healthy controls and IMID patients, 12 participants had documented prior COVID-19 infection. Of these, one patient with IMID converted from a negative to a positive ANA. Sixty participants, none of whom had previous COVID-19 infection, completed their 2-dose mRNA COVID-19 vaccination series. The overall incidence of *de novo* ANA positivity in these patients at 4-5 weeks post vaccination was 5% (3/60, 1 healthy control and 2 IMID). In the 3 participants who demonstrated ANA positivity, the healthy control was also Scl-70 positive on an extended autoantibody ELISA panel whereas the other 2 participants were negative for dsDNA, Smith, SS-A, SS-B, Scl-70, CENP, and Jo-1. Further, ANA antibodies were no longer present at the 3-month time point. Four patients (one of whom developed positive ANA) reported a flare of their disease after vaccination. No participant developed clinical manifestations of new autoimmune disease. There was no difference in the level of the SARS-CoV-2 spike IgG antibody response between those who transiently seroconverted after vaccination and those who did not ($p = 0.496$).

Conclusion: In a cohort of healthy controls and patients with IMID, the rate of ANA positivity after COVID-19 mRNA vaccination was low. In patients who developed a positive ANA, this finding was transient, resolving by the 3-month time point. While our findings are reassuring regarding the risk of developing autoimmunity after vaccination, the sample size is small and follow up is limited. Larger, long-term studies are critically needed to better characterize possible autoimmune manifestations after vaccination.

Abstract Number: 1536

Acceptability of Vaccines Against COVID-19 and Other Preventable Infections Among Patients with Rheumatic Disease

Sara Tedeschi[1], Jack Ellrodt[1], Jacklyn Stratton[1], Leah Santacroce[1], Paulette Chandler[1], Ellen Gravallese[2] and Daniel Solomon[3], [1]Brigham and Women's Hospital, Boston, MA, [2]Brigham and Women's Hospital, Harvard Medical School, Chestnut Hill, MA, [3]Brigham and Women's Hospital, Newton, MA

SESSION INFORMATION
Session Date: Tuesday, November 9, 2021
Session Title: Infection-related Rheumatic Disease Poster (1530–1564)
Session Type: Poster Session D
Session Time: 8:30AM–10:30AM

Background/Purpose: Vaccination against preventable infections is widely recommended for patients with systemic rheumatic disease. The COVID-19 pandemic has highlighted variability in attitudes toward vaccination, particularly with the use of novel vaccine platforms. We studied attitudes toward vaccination against COVID-19 and other preventable infections among patients with systemic rheumatic disease, and compared these against the general population.

Methods: We invited a convenience sample of patients treated for systemic rheumatic disease at an academic medical center in MA to complete a secure web-based survey or paper survey in English or Spanish, 12/2020-4/2021. The survey covered self-reported race and ethnicity, socioeconomic status, rheumatic disease diagnoses and treatments, comorbidities relevant to risk of severe COVID-19, prior infections, prior vaccination, COVID-19 infection, and vaccination against COVID-19. We included survey questions used in the nationwide Harris Poll (2/2021, n=2043 respondents), allowing comparison of responses to the general population. Response frequencies were summarized with descriptive statistics and compared using Chi square tests.

Results: Of 243 participants (25% response rate), mean age was 56 years, 82% were women, 67% White, 16% Asian, 10% Black; 13% identified as Latinx (Table 1). Rheumatoid arthritis (50%), systemic lupus erythematosus (28%), and psoriatic arthritis (13%) were the most common diagnoses. 88% were currently taking an immunomodulator. 30% had previously been hospitalized for any type of infection. 76% worried a lot or somewhat about contracting COVID-19. Attitudes toward vaccination were very favorable, with 92% having received a flu shot in the past year and 84% desiring a COVID-19 vaccine as soon as possible compared to 42% of Harris Poll respondents ($p< 0.001$). Intent to receive a COVID-19 vaccine (yes vs. no/not sure) did not differ by immunomodulator use ($p=0.99$), race ($p=0.16$), or Latinx ethnicity ($p=0.10$) (Table 2). Physician recommendation to receive a vaccine (90%) and desire to avoid infection (70%) were the most common reasons for previously receiving vaccines. Among the 11% of participants that had declined a vaccine in the past, reasons included concerns about possible flare of rheumatic disease, concerns about safety, not believing in getting vaccines, previous adverse reaction to vaccines, and allergy.

Table 1. Characteristics of 243 survey respondents	
Age in years	56.0 (14.5)

Abstract Number: 1537

Impact of COVID-19 Infection on Patient-Reported Outcomes in Rheumatic Disease Patients: A Cross Sectional Study

Elaine Husni[1], Cassandra Calabrese[2], Brittany Lapin[1], Elizabeth Kirchner[3] and Leonard Calabrese[1], [1]Cleveland Clinic, Cleveland, OH, [2]Cleveland Clinic Foundation, Cleveland Heights, OH, [3]CCF, Cleveland, OH

SESSION INFORMATION
Session Date: Tuesday, November 9, 2021
Session Title: Infection-related Rheumatic Disease Poster (1530–1564)
Session Type: Poster Session D
Session Time: 8:30AM–10:30AM

Background/Purpose: The persistence of symptoms following COVID 19 is an area of great interest yet remains poorly understood. Long COVID symptoms are dominated by fatigue (58%) and musculoskeletal pain (19%)1 and thus, of great interest, to know whether patients with rheumatic diseases will experience similar or worse outcomes than the general population. Prior analysis in the current COVID-19 literature lack pre-COVID infection data on these symptoms. This study provides a unique opportunity to examine the change in patient-reported outcomes (PROs) following COVID-19.

Methods: Rheumatic disease patients were evaluated for routine care and completed PROs in 2019 and following documented COVID-19 were included. Patients completed NIH's Patient Reported Outcomes Measurement Information System (PROMIS) Fatigue, Physical Function, Pain Interference, Global Health (mental and physical function), and PHQ-2 or 9 depression scale. Data on potential predictors of worsening PROs were collected including severity of COVID-19 infection, index diagnosis, concomitant therapies and associated high risk comorbidities. Change in PROs was evaluated with paired t-test. Predictors of patients who meaningfully worsened on PROs (≥5 T-score points) following COVID-19 were identified through multivariable logistic regression models.

Results: There were 264 rheumatic disease patients (57yrs (+/-12.9), 203 female (77%)) seen in the outpatient department with 222 (84.1%) patients had a diagnosis of immune mediated disease by a board certified rheumatologist and 42 (15.9%) patients had a non immune mediated disease. Regarding COVID-19 outcomes, 43 (16.3%) were

*p-value based on paired t-test for change; †Higher scores indicate worse symptoms and positive change indicates worsening; For the other domains, lower scores indicate worse symptoms and negative change indicates worsening; ‡Clinically meaningful worsening defined as 5+ T-score points; SD = standard deviation

hospitalized with 3(1.1%) requiring mechanical ventilation and 10 (3.8%) with pneumonia. Average length of stay was 6 (3,6) days and one patient died 1 (0.4%). PROs were completed a median of 6.5 months prior to COVID, and again median of 3 mo following COVID-19. Patient T-scores worsened on all PROs, but were only significantly worse on the domains of fatigue (mean±sd, 1.32±7.78) and pain interference (0.97±6.82). (Table 1) Meaningful worsening (≥5+ T-score) occurred for 25.4% of patients on PROMIS Fatigue, 23.5% on PROMIS Pain Interference, 17.2% on PROMS Physical Function, 18.2% on Global Mental Health, and 22.3% on Global Physical Health.

Eighty-seven patients completed the PHQ-2 or 9 prior to and following COVID-19. Eighteen patients (20.7%) had moderate/severe depressive symptoms and following COVID-19, depressive symptoms were indicated in only 10 (11.5%), p=.033. A reduction in Global Mental Health was experienced overall but was not significant. There were few predictors of worsening PROs and having better pre-COVID-19 PROs was the most predictive indicator of worsening.

Conclusion: Data from our rheumatology clinic where pre-infection PROs were available demonstrated a surprising modest effect of COVID including relevant domains of pain interference and fatigue compared to baseline. While further analysis is necessary including comparisons to non-rheumatic disease patients, these data suggest that in general patients with rheumatic disease make reasonable recovery following COVID-19 and may not have increased susceptibility to Long COVID-19 sequelae.

Adverse Events After SARS-CoV-2 Vaccination Among Rheumatology Outpatients in New York City

Medha Barbhaiya[1], Deanna Jannat-Khah[1], Jonah Levine[1], Huong Do[1], Lindsay Lally[1], Vivian Bykerk[2] and Lisa Mandl[1], [1]Hospital for Special Surgery, New York, NY, [2]Division of Rheumatology, Hospital for Special Surgery, New York City, NY

SESSION INFORMATION
Session Date: Tuesday, November 9, 2021
Session Title: Infection-related Rheumatic Disease Poster (1530–1564)
Session Type: Poster Session D
Session Time: 8:30AM–10:30AM

Background/Purpose: Vaccination against SARS-CoV-2 is important for patients with systemic rheumatic diseases (SRDs), who may be at increased risk of severe outcomes post-COVID-19 infection. However, as patients with SRDs were not included in vaccine trials, limited data exist on post-vaccine adverse events in the SRD population. We evaluated the prevalence of adverse events post- SARS-CoV-2 vaccination in rheumatology outpatients from New York City.

Methods: We emailed a secure web-based survey on March 5, 2021 to 7,505 patients aged ≥18 years evaluated at least once between 2018-2020 by a rheumatologist at a single Rheumatology Division in New York City. We included

individuals who received at least one vaccine dose. ICD-10-CM codes were used to identify SRD diagnoses. We collected data on sociodemographics, medical comorbidities, and medication use at time of vaccination. Patients were asked to report adverse events defined as "symptoms within 1 week" of receiving each vaccine dose. Patients were asked to report symptoms they did not attribute to an SRD flares, which were reported separately.

Results: As of May 17, 2021, 1852 respondents (24.7% response rate) had received at least one COVID-19 vaccine dose (53.9% Pfizer vaccine, 44.4% Moderna, 1.4% Janssen, 0.3% Astrazeneca). Mean age of respondents was 62.8 [14.2] years; 80% female; 88.6% White; 4.2% Hispanic/Latinx ethnicity). 1173 patients received two vaccine doses and 679 patients received only the first dose. 1076 patients (58.1%) met an ICD-10-CM algorithm for an SRD. Immunosuppressive or immunomodulatory medications were used by 47.6% of individuals at the time of vaccination. Adverse events at the first or second vaccine dose were reported by 1357 (73.3%) individuals, and most commonly included pain at injection site (45.3%), fatigue (38.8%), headache (26.2%), muscle aches (23.1%), sore shoulder (22.2%). 14.4% of respondents reported only local injection site reactions (i.e. pain, swelling, redness, rash) at either vaccine dose. Severe symptoms such as throat closing, wheezing, fainting, chest pain, difficulty breathing, bleeding, and swelling of the eyes, lips or other parts of body were reported by less than 1%. Medications to prevent vaccine side effects were used by 8.4% of patients (Table); after vaccination, only 2 patients (0.1%) required use

• Other	48 (2.6%)
• Missing	612 (33.0%)

of epinephrine and 21 patients (1.1%) used corticosteroids for symptom relief. 35 patients (1.9%) reported seeking medical attention (i.e. urgent care, ER or hospital) after any vaccination. Typical adverse event duration was 2-7 days (47.4%); 13% experienced symptoms < 1 day, and 13% experienced symptoms >1 week.

Conclusion: Interim data from our cohort demonstrate that 73.3% of rheumatology patients experienced a local or systemic adverse event post-SARS-CoV-2 vaccination, similar to estimates from Pfizer BioNTech vaccine clinical trial data. Symptoms were typically transient (< 7 days) and consisted predominantly of common side effects such as injection site pain, fatigue, headache, and myalgias. Less than 1% of patients experienced more serious post-vaccination events, which is reassuring and may help inform vaccine decision making for rheumatology patients.

Abstract Number: 1539

High Disease Activity, as Assessed by RAPID3, Increases Risk of Hospitalization and Predicts Lower Chance of Recovery from COVID-19 in a Cohort of Tertiary Care Rheumatology Patients

Matas Orentas[1], Sonali Khandelwal[2], Michael Grant[2], Yanyu Zhang[1], Najia Shakoor[2] and Sobia Hassan[1], [1]RUMC, Chicago, IL, [2]Rush University, Chicago, IL

SESSION INFORMATION
Session Date: Tuesday, November 9, 2021
Session Title: Infection-related Rheumatic Disease Poster (1530–1564)
Session Type: Poster Session D
Session Time: 8:30AM–10:30AM

Background/Purpose: There is a need to understand which patients with rheumatologic diseases may be at highest risk for poor COVID-19 related outcomes so that both physicians and patients can make informed decisions regarding disease management and pandemic-related precautions. Routine assessment of patient index data 3 (RAPID3) is a quick tool to assess disease activity that has been validated in numerous rheumatologic conditions. Here, we evaluate the association between RAPID3 and other comorbidities with COVID-19 related outcomes in a cohort of rheumatology patients treated at an urban academic medical center.

Methods: The department of rheumatology COVID-19 data repository is an IRB approved registry consisting of patients at an academic center with both a COVID-19 diagnosis and a rheumatologic condition. Data collected included demographics, comorbidities, and disease activity as measured by the RAPID3. Chi-square and paired t-tests and logistic regression models were used to analyze associations between demographics, comorbidities, disease activity and COVID-19 hospitalization rates and recovery.

Results: 169 patients with a laboratory confirmed diagnosis of COVID-19 were included. Demographics are summarized in Table 1. The majority of patients had high or moderate pre-COVID-19 RAPID3 scores. In our analysis, increased age, T2DM, HTN, chronic kidney disease (CKD), and high pre-COVID-19 RAPID3 score were associated with higher odds of COVID-19 infection requiring hospitalization (Table 2). High pre-COVID-19 RAPID3 scores were also associated with lower odds of full recovery (Table 3).

Table 1
Demographics of cohort of patients with rheumatologic condition and COVID-19 diagnosis

Rheumatologic Disease	N (% Total)
SLE	43 (24.4%)
RA	52 (30.9%)
Psoriasis	20 (11.9%)
Psoriatic arthritis	6 (3.6%)
Vasculitis	0 (0%)
Sjogren's	5 (3%)
JIA	3 (1.8%)
Other	41 (24.4%)
Sex	N (% Total)
Female	133 (78.7%)
Male	36 (21.3%)
Ethnicity	N (% Total)
Asian	2 (1.2%)
African American	60 (44.6%)
Hispanic	63 (36.7%)
Caucasian	29 (17.5%)
Native	0 (0%)
Other	2 (1.2%)
Refused	3 (1.8%)
BMI	N (% Total)
Underweight / Normal (<18.5 - 24.9)	34 (20.4%)
Overweight (25 - 29.9)	35 (20.9%)
Obese I (30 - 34.9)	31 (18.6%)
Obese II (35 - 39.9)	35 (20.9%)
Obese III (>= 40)	32 (19.2%)
Medical Comorbidities	N (% Total)
T2DM	28 (16.6%)
CHF	14 (8.3%)
HTN	77 (45.6%)
CAD	17 (10.1%)
COPD / asthma	31 (18.3%)
CKD	12 (7.1%)
Pre-COVID RAPID3 score	N (% Total)
High (> 12)	50 (54.9%)
Moderate (6.1 - 12)	19 (20.9%)
Low (3.1 - 6)	10 (11%)
Remission (<= 3)	12 (13.2%)
	N (Mean)
Age	169 (50.5)
BMI	167 (33)

HTN and CKD were associated with higher odds of intensive care (ICU) admission (HTN OR 5.8, CI 1.6-21.1, p 0.007; CKD OR 5.8, CI 1.5-22.1, p 0.02) and intubation (HTN OR 10.9, CI 1.3-89.3, p 0.01; CKD OR 7.8, CI 1.6-36.9, p 0.02). HTN was also associated with an increase in length of stay (14.9 days vs 6.6 days, p 0.01).

Table 2
Association between comorbidities and pre-COVID-19 RAPID3 scores and outpatient versus inpatient management

		Total (N=169)	Outpatient management (N=119)	Inpatient management (N=50)	Odds ratio (95%CI)	P-value
Variable		N (% Total)	N (% Total)	N (% Total)		
Pre-COVID-19 RAPID3	**High (>12)**	**50 (55%)**	**35 (49%)**	**15 (79%)**	**0.25 (0.08-0.83)**	**0.018**
	Other (<= 12)	41 (45%)	37 (51%)	4 (21%)		
T2DM	**Yes**	**28 (17%)**	**12 (10%)**	**16 (32%)**	**0.24 (0.1-0.55)**	**<0.001**
	No	141 (83%)	107 (90%)	34 (68%)		
HTN	**Yes**	**77 (46%)**	**45 (38%)**	**32 (64%)**	**0.34 (0.17-0.68)**	**0.002**
	No	92 (54%)	74 (62%)	18 (36%)		
CKD	**Yes**	**12 (7%)**	**5 (4%)**	**7 (14%)**	**0.27 (0.08-0.9)**	**0.043**
	No	157 (93%)	114 (96%)	43 (86%)		

Table 3
Association between pre-COVID-19 RAPID3 scores and likelihood of recovery

		Total (N=120)	Full Recovery (N=88)	No Full Recovery (N=32)	Odds ratio (95%CI)	P-value
Variable		N (% Total)	N (% Total)	N (% Total)		
Pre-COVID RAPID3 Group	**High (>12)**	**37 (53%)**	**23 (43%)**	**14 (82%)**	**6.09 (1.56-23.72)**	**0.009**
	Other (<=12)	33 (47%)	30 (57%)	3 (18%)		

Conclusion: In this cohort of rheumatology patients, high pre-COVID-19 disease activity, as assessed by RAPID3 scores, was associated with increased odds of COVID-19 infection requiring hospitalization and decreased odds of full recovery. To our knowledge, this is the first study to use an exclusively patient-reported outcome tool to demonstrate the relationship between disease activity and COVID-19 outcomes in patients with rheumatic disease.

Similar to other studies, age, HTN, T2DM, and CKD were associated with severe COVID-19 outcomes. In contrast to previously described cohorts, this group is younger, predominantly female, and consists of a high proportion of Hispanic and Black patients.

SESSION INFORMATION

Session Date: Tuesday, November 9, 2021

Session Title: Infection-related Rheumatic Disease Poster (1530–1564)

Session Type: Poster Session D

Session Time: 8:30AM–10:30AM

Background/Purpose: The development and duration of humoral immunity after SARS-CoV-2 natural infection remains of interest. For the general population, available data suggest a robust immune response, able to protect against reinfection for at least 6-8 months. As for the subgroup of patients with rheumatic and musculoskeletal diseases (RMDs), information is lacking. Considering that immunosuppression might preclude an adequate anti-viral response, we aimed to assess the rate of seroconversion after natural infection in patients with RMDs and to find factors that may influence antibody response.

Methods: Multicenter observational study of patients with RMDs prospectively-followed in the Rheumatic Diseases Portuguese Register – Reuma.pt –in the first 6 months of the pandemic in Portugal – March to September 2020. We included all patients with inflammatory and non-inflammatory RMDs with confirmed (PCR-positive) or suspected COVID-19. Patients were asked to collect a blood sample for antibody testing against SARS-CoV-2 at least 3 months after the resolution of infection. All samples were processed in a single center. IgG antibodies recognizing the SARS-CoV-2 receptor-binding domain (RBD) were quantified using ELISA. Seroconversion was assumed for any titer ≥1:50.

Results: Out of 179 included patients, 79 (44%) performed antibody testing. Of these, 65 (82%) had inflammatory RMDs and 14 (18%) had non-inflammatory RMDs – described in Table 1. Blood samples were collected between days 89 and 331 (median time 237, IQR 125 days) after symptom onset or positive PCR test (if asymptomatic). Seventy (89%) patients had positive IgG antibodies, with a geometric mean titer of 1/1508±4.075 (min 1/100- max 1/25600).

No differences were seen in the seroconversion rate between patients with and without inflammatory RMDs. Disease activity status at the time of the infection also did not influence seroconversion. Although DMARD therapy didn't influence seropositivity, the proportion of patients under TNF inhibitors (TNFi) was numerically higher in patients who did not develop IgG antibodies (33.3% vs 8.6%, p=0.062). Of note, all patients treated with corticosteroids (N=30) and rituximab (N=2) developed antibodies. There was no correlation between sample timing and RBD IgG titers. On multivariate analysis, treatment with TNFi (OR 0.13, 95%CI: 0.02-0.91, p=0.041), and symptomatic COVID-19 (OR 15.1, 95%CI 2.33-98.48; p=0.004) were the only variables independently associated with serological response (Table 2).

Conclusion: Most patients with rheumatic diseases developed IgG antibodies against SARS-CoV-2, with medium-to-high titers detected between 3 to 11 months after natural infection. In this population, treatment with TNFi decreased the odds of seroconversion while symptomatic COVID-19 was associated with a higher likelihood of developing a humoral immune response.

Table 1 – Demographic and clinical data of patients with inflammatory and non-inflammatory RMDs who performed serology

	Inflammatory arthritis[1] N, %	CTD/Vasculitis[2] N, %	Non-inflammatory diseases[3] N, %	Total N, %	p value

SESSION INFORMATION

Session Date: Tuesday, November 9, 2021

Session Title: Infection-related Rheumatic Disease Poster (1530–1564)

Session Type: Poster Session D

Session Time: 8:30AM–10:30AM

Background/Purpose: COVID-19 runs a severe disease associated with acute respiratory distress syndrome in a subset of patients, and a hyperinflammatory response developing in the second week contributes to the worse outcome. Inflammatory features are mostly compatible with macrophage activation syndrome (MAS) observed in other viral infections despite resulting in milder changes. Early detection and treatment of MAS may be associated with a better outcome. However, available criteria for MAS associated with other causes have not been helpful. To identify distinct features of MAS associated with COVID-19 using a large database enabling to assess of dynamic changes.

Methods: PCR-confirmed hospitalized COVID-19 patients followed between March and September 2020 constituted the discovery set. Patients considered to have findings of MAS by experienced physicians and given anakinra or tocilizumab were classified as the MAS group and the remaining patients as the non-MAS group. The MAS group was then re-grouped as the cases with exact-MAS and borderline-MAS cases by the study group. Clinical and laboratory data including the Ct values of the PCR test were obtained from the database, and dynamic changes were evaluated especially for the first 14 days of the hospitalization. The second set of 162 patients followed between September-December 2020 were used as the replication group to test the preliminary criteria. In the second set, hospitalization rules were changed, and all patients required oxygen support and received dexamethasone 6mg/day or equivalent glucocorticoids. Daily changes were calculated for the laboratory items in MAS, borderline, and non-MAS groups to see the days differentiating the groups, and ROC curves and lower and upper limits (10-90%) of the selected parameters were calculated to determine the cutoff values.

Results: A total of 769 PCR-confirmed hospitalized patients were analysed, and 77 of them were classified as MAS and 83 as borderline MAS patients. There was no statistically significant difference in the baseline viral loads of MAS patients compared to the non-MAS group according to the Ct values. Daily dynamic changes in the MAS group differed from the non- MAS group especially around the 6th day of hospitalization, and more than a twofold increase in ferritin and a 1.5-fold increase in D-dimer levels compared to the baseline values help to define the MAS group.

Table 1. Preliminary Criteria for Macrophage Activation Syndrome Associated with Coronavirus Disease-19

1. Fever (>37.0 °C)
2. Ferritin concentration > 550 ng/mL
3. More than 2 times increase of ferritin concentration within 7 days of disease onset
4. Neutrophil count > 6000 cell/mm3
5. Lymphopenia < 1000 cell/mm3
6. Neutrophil/lymphocyte ratio > 6
7. D-dimer concentration > 1000 ng/ml
8. More than 50% increase of D-dimer concentration within 7 days of disease onset
9. CRP concetration > 50 mg/L
10. LDH concentration > 300 U/L
11. ALT or AST concentration > 50 U/L
12. Procalcitonin concentration < 1.2

1 point for each positive item assessed on Days 5-7

Score calculation: Total points / 12 x 100

Possible MAS ≥45 and Definite MAS ≥60

Twelve items selected for the criteria are given in Table 1 below. The total score of 45 provided 79.6% sensitivity for the MAS (including borderline cases) and 81.3% specificity around days 5 and 6 in the discovery set, and a score of 60 increased the specificity to 94.9% despite a decrease in sensitivity to 40.8%. The same set provided a similar sensitivity (80.3%) in the replication, but a lower specificity (47.4-66% on days 6 to 9) due to a group of control patients with findings of MAS possibly masked by glucocorticoids.

Conclusion: This study defined a set of preliminary criteria using the most relevant items of MAS according to the dynamic changes in the parameters in a group of COVID-19 patients. A score of 45 would be helpful to define a possible MAS group with reasonable sensitivity and specificity to start necessary treatments as early as possible.

Does Adjustment to Dosing and Timing of Immunomodulatory Drugs Impact Immunogenicity of COVID19 Vaccines in Patients with Autoimmune and Inflammatory Rheumatic Disease (AIIRD)?

Andrew Laster[1], Gordon Lam[1], Sarah McCarter[1], Heather Gladue[2], Ahmad Kashif[1], Erin Siceloff[1], Victoria Lackey[2], Cheryl Robertson[2], Ashley Toci[1] and Leonard Calabrese[3], [1]Arthritis and Osteoporosis Consultants of the Carolinas, Charlotte, NC, [2]Arthritis & Osteoporosis Consultants of the Carolinas, Charlotte, NC, [3]Cleveland Clinic, Cleveland, OH

SESSION INFORMATION
Session Date: Tuesday, November 9, 2021
Session Title: Infection-related Rheumatic Disease Poster (1530–1564)
Session Type: Poster Session D
Session Time: 8:30AM–10:30AM

Background/Purpose: Clinical trials leading to approval of the COVID19 vaccines did not include immunocompromised individuals. Concerns have been raised that immunogenicity of the vaccines may be impaired in patients with

AIIRD on immunomodulatory drugs. The ACR COVID-19 Vaccine Clinical Guidance Task Force has suggested that the timing and dosing of certain drugs be modified to optimize vaccine response but acknowledged it was a "living document" that would likely change as additional studies were published. We sought to characterize antibody re-

Table 1. Recommendations regarding adjustment of dosing/timing. *AOCC: Arthritis & Osteoporosis Consultants of the Carolinas, Charlotte, NC 1https://www.rheumatology.org/Portals/0/Files/COVID-19-Vaccine-Clinical-Guidance-Rheumatic-Diseases-Summary.pdf

	ACR[1] (2/8/2021; modified 3/4/2021)	AOCC *(12/20/2020)
methotrexate	*"Hold for 1 week after each of the 2 mRNA vaccine doses, for those with well–controlled disease; no modifications to vaccination timing."*	Reduce dose to 7.5 mg for 2 weeks after each vaccine dose
JAK inhibitors	*"Hold JAKi for 1 week after each vaccine dose; no modifications to vaccination timing."*	Hold 2 days before and for 2 weeks after each vaccine dose
abatacet iv	*"Time vaccine administration so that the first vaccination will occur four weeks after abatacept infusion (i.e. the entire dosing interval) and postpone the subsequent abatacept infusion by one week (i.e. a 5 week gap in total); no medication adjustment for the second vaccine dose."*	Wait 4 weeks after abatacept infusion to receive the first vaccine dose; delay next infusion until 2 weeks after 2nd vaccine dose.
abatacept sc	*"Hold SQ abatacept both one week prior to and one week after the first COVID-19 vaccine dose (only); no interruption around the second vaccine dose."*	Hold abatacept sc 1 week prior and for 2 weeks after each vaccine dose.
rituximab	*"...schedule vaccination so that the vaccine series is initiated approximately 4 weeks prior to next scheduled rituximab cycle; after vaccination, delay RTX2-4 weeks after final vaccine dose, if disease activity allows."*	Wait 4 mos. (Moderna), 4.5 mos. (Pfizer) or 5 mos. (J&J) after last rituximab infusion for 1st vaccine dose; delay next rituximab infusion for 2 weeks after last vaccine dose.

sponses to the SARS COV-2 spike protein in patients with AIIRD both in those who adjusted and in those who failed to make adjustments to their drug therapy in a real world study.

Methods: We measured SARS CoV2 IgG antibody levels to the receptor-binding domain of the S1 spike antigen using a semi-quantitative assay (Siemens Atellica; QUEST) in patients with AIIRD followed in a single specialty community based practice of 13 providers (AOCC) in Charlotte NC from 3/17 – 5/14/2021. Patients with a prior self-reported history of COVID19 were excluded. All tests were performed by Day 14 or later following BNT162b2 (Pfizer), mRNA -1273 (Moderna) or Ad26COV2.S (Johnson & Johnson) vaccine. We compared the number of antibody positive (Ab+) vs. antibody negative(Ab-) and mean Ab levels in Ab+ patients for those who did or did not make adjustments to dosing/timing of methotrexate (MTX), JAK inhibitors (JAKi), rituximab (RTX) and/or abatacept (ABA). Associations were evaluated using Student's t-test. In 12/2020, our clinic recommended adjustments to the dosing/timing of these drugs that were similar but slightly more stringent than subsequent recommendations in 2/2021 from the ACR Task Force (Table 1).

Results: 198 patients with AIIRD were studied. Baseline characteristics including gender, age, vaccine type and diagnosis are presented in Table 2. Findings related to % of total patients on MTX, JAKi, RTX and ABA with absent antibody response and comparison of antibody response with or without adjustment in dosing and/or timing are presented in Table 3. Only 13% of all patients on RTX and 52 % of all patients on ABA were Ab+. In contrast, fully 91% of patients on JAKi were Ab+ whereas 80% of patients on methotrexate alone were Ab+. Adjustments to the dose of MTX or JAKi did not significantly alter the immunogenicity as measured by IgG antibodies to the S1 spike antigen.

Table 3. Adjustments to drug dosing/timing. IgG antibodies to SARS CoV-2 S1 RBD antigen were measured using a semi-quantitative chemiluminescent immunoassay (Siemens Atelllica IM/Siemens Atellica IM Analyzer; QUEST) in which negative/nonreactive was <1.0, and positive/reactive was reported from 1.00 to 20.00 or > 20.00. https://www.siemens-healthineers.com/en-us/laboratory-diagnostics/assays-by-diseases-conditions/infectious-disease-assays/sars-cov-2-igg-assay

				No adjust		Adjust				
Drug	N	Total without antibody response (Ab-)	Total with antibody response (Ab+)	Ab -	Ab +	Ab-	Ab+	No Adjust mean Ab+	Adjust mean Ab+	P value
methotrexate (all)	110	27 (25%)	83 (75%)	16 (27%)	44 (73%)	11 (22%)	39 (78%)	12.08	10.88	0.437
methotrexate (no bio)	51	10 (20%)	41 (80%)	6 (20%)	24 (80%)	4 (19%)	17 (81%)	12.92	8.79	0.087
JAK inhibitor	23	2 (9%)	21 (91%)	1 (8%)	11 (92%)	1 (9%)	10 (91%)	12.96	13.89	0.137
rituximab	38	33 (87%)	5 (13%)	17 (85%)	3 (15%)	16 (89%)	2 (11%)	5.07	11.28	0.427
abatacept	27	13 (48%)	14 (52%)	5 (45%)	6 (55%)	8 (50%)	8 (50%)	12.62	12.7	0.406
abatacept iv	20	11 (55%)	9 (45%)	4 (67%)	2 (33%)	7 (50%)	7 (50%)	5.4	12.74	0.317
abatacept sc	7	2 (29%)	5 (71%)	1 (25%)	4 (75%)	1 (50%)	1 (50%)	12.51	20.00	

IgG antibodies to SARS CoV-2 S1 RBD antigen were measured using a semi-quantitative chemiluminescent immunoassay (Siemens Atelllica IM/Siemens Atellica IM Analyzer; QUEST) in which negative/nonreactive was <1.0, and positive/reactive was reported from 1.00 to 20.00 or > 20.00 .
https://www.siemens-healthineers.com/en-us/laboratory-diagnostics/assays-by-diseases-conditions/infectious-disease-assays/sars-cov-2-igg-assay

Adjustments to the timing of vaccine in relationship to last RTX dose and last vaccine injection in relation to next RTX infusion failed to increase the likelihood of an antibody response. Adjustments to the timing of ABA (either iv or sc) did not significantly increase antibody response. Limitations to this real world study include a non-randomized design and not measuring potential residual confounders.

Conclusion: Holding JAKi, lowering the dose of MTX or altering the timing of the vaccine in relation to RTX or ABA administration did not alter immunogenicity as measured by SARS CoV2 Abs to the S1 spike antigen. Coupled with additional measure of humoral immune response and T cell function, these findings may provide further guidance for dosing and timing of immunomodulatory therapies in the setting of COVID19 vaccinations in patients with AIIRD.

SESSION INFORMATION

Session Date: Tuesday, November 9, 2021

Session Title: Infection-related Rheumatic Disease Poster (1530–1564)

Session Type: Poster Session D

Session Time: 8:30AM–10:30AM

Background/Purpose: As of May 2021, Canada had reached over 1.3 million confirmed cases of SARS-CoV-2 infection, and over 25,000 deaths. This study identified children in Canada hospitalized with paediatric multisystem inflammatory syndrome temporally associated with SARS-CoV-2 infection (PIMS), also known as multisystem inflammatory syndrome in children (MIS-C), and aimed to 1) Describe clinical and laboratory features at presentation, management, outcomes, and 2) Identify risk factors for intensive care unit (ICU) admission.

Methods: We conducted a national prospective study using the infrastructure of the Canadian Paediatric Surveillance Program (CPSP), a network of >2,800 paediatricians across Canada. Physicians reported cases of hospitalized children who met study criteria from March 2020-May 2021, through a weekly online questionnaire distributed via the CPSP network. Cases were categorized as confirmed MIS-C, presumed MIS-C, and/or confirmed PIMS defined in **Figure 1.** Modified Poisson regression analysis was used to compute adjusted risk ratios (aRR) for ICU risk factors associated with PIMS/MIS-C.

Results: A total of 506 cases of children hospitalized with PIMS/MIS-C were reported during the study period, of which 383 unique cases were included in the primary analysis (161 confirmed MIS-C, 202 presumed MIS-C, and/or 352 confirmed PIMS) with the majority of cases being reported from the provinces of Ontario (44.6%) and Quebec (39.7%). A total of 167/383 (43%) cases had a SARS-CoV-2 link (62.3% close contact, 58.1% positive PCR, 32.3% known positive serology). Of the 216 cases (56%) with no known link, 55/114 with serology results available were negative. Majority were preschool (1-5 years) or school aged (6-12 years), with slight male predominance (57.7%), and were previous healthy (60 (15.7%) with co-morbidities). Median duration of fever was 6 days; 283/383 (74%) had gastrointestinal involvement; more than half had mucocutaneous changes including rash (64.5%), bilateral non-exudative conjunctivitis (62.9%), and changes in lips/oral cavity (58.7%). Laboratory features indicated hyperinflammation (**Table 1**).

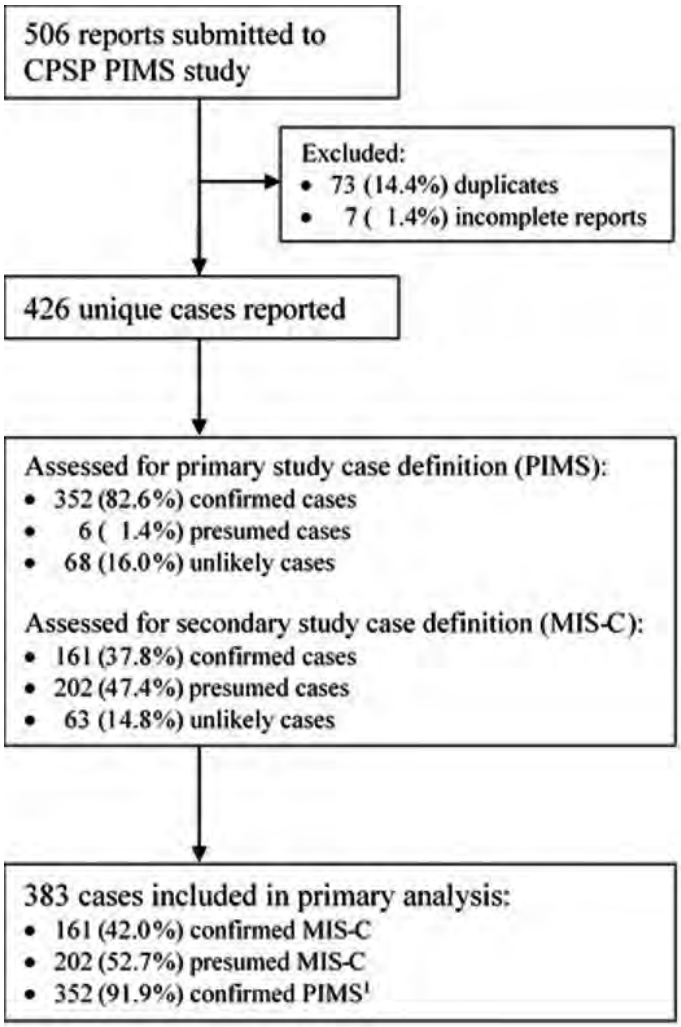

Figure 1. Flow chart of participants meeting the case definitions for MIS-C and PIMS. Confirmed MIS-C: meets MIS-C criteria (adapted by the World Health Organization (WHO))a AND no other cause identified AND SARS-COV-2 link present (defined as a history of positive PCR, rapid test, or serology or close contact with microbiologically confirmed SARS-CoV-2 infection); Presumed MIS-C: same as confirmed MIS-C except no known SARS-CoV-2 link; Confirmed PIMS: meets study criteria (1) fever ≥3 days (2) elevated inflammatory markers (C-reactive protein (CRP) ≥ 30 mg/L, Erythrocyte sedimentation rate (ESR) ≥ 40 mm/h OR Ferritin ≥ 500 µg/L) (3) one or both: features of Kawasaki disease or toxic shock syndrome AND (4) no other cause identified. a https://www.who.int/news-room/commentaries/detail/multisystem-inflammatory-syndrome-in-children-and-adolescents-with-covid-19 1Of confirmed PIMS cases, 150 also met criteria for confirmed MIS-C, 182 also met criteria for presumed MIS-C, while 20 did not meet criteria for MIS-C. Six cases met criteria for confirmed or presumed MIS-C but not confirmed PIMS.

Table 1. Clinical and laboratory features of children meeting case definitions for MIS-C and PIMS in Canada.

Characteristics	All Cases	SARS-CoV-2 Linkage		p-value[1]
		Absent/Unknown	Present

[1]Statistical tests are conducted between children with versus without a SARS-CoV-2 link

Shock/hypotension was reported in 125 (32.6%). There were no deaths. Cardiac involvement with abnormal echocardiograms was reported in 161/366 (44%) including decreased heart function (14.5%), coronary dilatation (9.1%) and aneurysms (13.1%). Almost one third (28.5%) required ICU admission, with 25.1% requiring respiratory/hemodynamic support. For treatment, 235 (61%) received both IVIG and corticosteroids, 111 (29%) received IVIG only, 7 (1.8%) received corticosteroids only, 30 (7.8%) received neither, and 18 (4.7%) received biologics. Risk factors for ICU admission included presence of SARS-CoV-2 link (aRR 2.79, 95% CI 1.79-4.35; $p < 0.001$) and older age groups: school aged (aRR 2.76, 95% CI 1.71-4.46; $p < 0.001$) and adolescents (13-17 years) (aRR 3.00, 95% CI 1.81-4.98; $p < 0.001$); while no association found with sex or comorbidity (**Table 2**).

Conclusion: This national prospective study reports on the largest series of children hospitalized with PIMS/MIS-C in Canada, providing insight on overall severity and at–risk groups that is essential for prompt recognition and management.

SESSION INFORMATION

Session Date: Tuesday, November 9, 2021

Session Title: Infection-related Rheumatic Disease Poster (1530–1564)

Session Type: Poster Session D

Session Time: 8:30AM–10:30AM

Background/Purpose: Since the beginning of the COVID-19 pandemic, some studies have addressed risk factors for severe forms of the disease in patients with rheumatic diseases. Higher prednisolone doses and rituximab (RTX) have been associated with an increased risk of severe COVID-19, although not consistently. Our main goal was to assess the clinical features and to identify risk factors for severe COVID-19 in patients with rheumatic diseases.

Table 1. Characteristics of patients with COVID-19 *Diagnosis with n≥3 are specified

Rheumatic diagnosis, N (%)	
Inflammatory arthropathies*	111 (62.0)
Rheumatoid arthritis	48 (26.8)

Osteoporosis	3 (1.7)
COVID-19 diagnosis, N (%)	
PCR confirmed	170 (95)
Positive Serology	4 (2.2)
Suspected	5 (2.8)
COVID-19 severity, N (%)	
Asymptomatic	17 (9.5)
Mild	29 (16.2)
Moderate	88 (49.2)
Severe	30 (16.8)
Critical	15 (8.4)
COVID-19 Hospitalization care, N (%)	
Hospitalization	45 (25.1)
Low flux oxygen therapy	34 (19.0)
Non-invasive ventilation/high flux oxygen therapy	12 (6.7)
Invasive ventilation	4 (2.2)
COVID-19 treatment, N (%)	
Corticosteroids	19 (10.6)
Hydroxychloroquine	28 (15.6)
Azithromycin	16 (8.9)
Other antibiotic	6 (3.4)
Lopinavir/ritonavir	6 (3.4)
Remdesivir	3 (1.7)
Tocilizumab	1 (0.6)
Intravenous immunoglobulin	1 (0.6)
DMARD modification during COVID-19	
Conventional synthetic DMARD suspension	35/124
Biologic DMARD suspension	21/38
JAK inhibitor suspension	2/2
COVID-19 complications	
Acute respiratory distress syndrome	13 (7.3)
Heart failure	1 (0.6)
Bacterial infection	16 (8.9)
Macrophage activation syndrome	2 (1.1)
Thromboembolic event	1 (0.6)
Acute kidney failure	8 (4.5)
COVID-19 outcome	
Cure	166 (92.7)
Death	10 (5.6)

Methods: Multicenter observational nationwide study of adult patients with rheumatic diseases and confirmed or suspected infection by SARS-CoV-2 prospectively-followed in the Rheumatic Diseases Portuguese Register – Reuma.pt – between march and september 2020. Mild COVID-19 was defined as symptomatic disease without pneumonia; moderate disease if clinical signs of pneumonia without hypoxemia; severe disease as hypoxemic pneumonia and/or need for hospitalization; and critical disease as requiring admission to intensive care unit or death. Clinical features and treatment of patients with mild/moderate vs. severe/critical COVID19 were compared using Pearson Chi-Square, exact Fisher and Mann-Whitney U tests, as adequate. Independent association between demographic, disease-related and treatment-related variables and COVID-19 severity was evaluated through multivariate logistic regression.

Results: We included 179 patients with confirmed (97.2%) or suspected (2.8%) COVID-19 (Table 1). Forty-five (25.1%) patients developed severe/critical disease, requiring hospitalization, and 10 (5.6%) patients died. In the same time frame, the national rate of hospitalization was 8.4% and mortality 2.6%. Most patients reported direct contact with a positive patient (65.9%). Major symptoms reported were cough, fever, malaise, fatigue, myalgia, headache and anosmia (Table 2). Lymphopenia and elevated CRP were the most frequent laboratory abnormalities. Patients with severe/critical disease were older (p< 0.001), had a higher prevalence of arterial hypertension (p=0.001), diabetes (p< 0.001), cardiovascular disease (p=0.007) and chronic kidney disease (p=0.036) (Table 3). Considering inflammatory arthritis as the reference category, patients with CTD/vasculitis (33.3% vs 26.9%, OR 1.69, 95CI 0.787-3.611) and non-inflammatory diseases (17.8% vs 6.7%, OR 3.60, 95CI 1.25-10.39) had a higher probability of severe/critical COVID-19. Regarding therapy, the proportion of patients under RTX was higher in severe/critical COVID-19 patients (11.1% vs 1.5%, OR 8.25, p=0.012). Treatment with TNF inhibitors was associated with less probability of severe/crit-

Table 2. Symptoms and laboratory data in COVID-19 patients

Symptoms, N (%)	
Cough	91 (50.8)
Fever	87 (48.6)
Malaise	81 (45.3)
Fatigue	67 (37.4)
Myalgia	61 (34.1)
Headache	55 (30.7)
Anosmia	55 (30.7)
Dysgeusia	52 (29.1)
Dyspnea	36 (20.1)
Diarrhea	36 (20.1)
Thoracic pain	32 (17.9)
Odynophagia	28 (15.6)
Arthralgia	27 (15.1)
Rhinorrhea	25 (14)
Abdominal pain	16 (8.9)
Vomiting	14 (7.8)
Laboratory abnormalities, n/total N	
Anemia	6/60
Leucopenia	19/60
Lymphopenia	36/60
Thrombocytopenia	6/60
Elevated transaminases	15/59
Elevated C-reactive protein	27/59
High D-dimers	26/38
Low fibrinogen	2/30
Ferritin>2000	4/28
High IL6	1/7

Table 3. Comparison of patients with severe/critical vs mild/moderate COVID-19 *At least 1 comorbidity among arterial hypertension, obesity, diabetes, cardiovascular disease, asthma, chronic obstructive pulmonary disease, chronic kidney disease

	Severe/critical COVID19 (n=45)	Mild/moderate COVID19 (n=134)	Univariate analysis p-value	Multivariate analysis OR (95%CI); p-value)

Ustekinumab	0 (0.0)	1 (0.7)	0,561	
Rituximab	5 (11.1)	2 (1.5)	**0.012**	**13.77 (2.23-85.17); p=0.005**
Belimumab	0 (0.0)	1 (0.7)	0,561	

ical COVID-19 (2.2% vs 17%, OR 0.11, p=0.033). Treatment with other DMARDs was not associated with COVID-19 severity. Age (OR 1.09, 95CI 1.06-1.13, p< 0.001) and treatment with RTX (OR 13.77, 95CI 2.23-85.17, p=0.005) were independently associated with severe/critical COVID-19 (Table 3).

Conclusion: Hospitalization and mortality in rheumatic patients was higher than the reported in the general national population for the same time frame, although a reporting bias must be considered. Older age and treatment with RTX were independent risk factors for severe/critical COVID-19 in patients with rheumatic diseases.

Abstract Number: 1545

Safety of JAK Inhibitor in Patients with Rheumatoid Arthritis Who Developed Reactivation of Herpes Zoster Virus After Receiving JAK Inhibitor

Wonho Choi[1], Soo Min Ahn[2], Yong Gil Kim[1], Chang-Keun Lee[1], Bin Yoo[2] and Seokchan Hong[1], [1]Asan Medical Center, Seoul, Republic of Korea, [2]ASAN MEDICAL CENTER, Seoul, South Korea

SESSION INFORMATION
Session Date: Tuesday, November 9, 2021
Session Title: Infection-related Rheumatic Disease Poster (1530–1564)
Session Type: Poster Session D
Session Time: 8:30AM–10:30AM

Background/Purpose: Janus kinase inhibitor (JAKi) increases the risk of the reactivation of herpes zoster (HZ) virus and may thus be temporarily discontinued in cases of HZ infection. However, the amount of information on the outcomes of JAKi use after an episode of HZ reactivation is insufficient. In this study, we sought to determine the safety of JAKi during or following an HZ reactivation.

Methods: Medical records of all patients (*n* = 417) who received JAKi at a tertiary referral center between August 2015 and May 2021 were retrospectively reviewed. Among them, data from patients who developed HZ reactivation were collected and the clinical outcomes were evaluated for those who continued or resumed JAKi after HZ reactivation.

Results: Of 417 patients who received JAKi, 33 (7.9%) developed HZ reactivation during JAKi treatment (tofacitinib, n = 22; baricitinib, n = 11). The median age of the patients (male, n = 2; female, n = 31) was 61 years (IQR, 53–69); 14 patients received glucocorticoids, and the mean dose of prednisone was 4.0 ± 2.3 mg. The median duration of JAKi administration before HZ reactivation was 11 months (IQR, 4–29). JAKi was continued in 24 (72.7%) patients during the HZ reactivation episode, and 5 (15.2%) patients temporarily discontinued the JAKi and then resumed it after episode of HZ. All patients with HZ reactivation had typical skin lesions, and 3 (9.1%) patients had acute complications such as encephalitis with HZ ophthalmicus. Four (12.1%) patients, including the three patients with complications, permanently discontinued JAKi. Of the 27 patients who were followed up for a median of 12 months (IQR, 5.5–22.5) after the HZ reactivation episode, HZ reactivation recurred in one (3.7%) patient; this patient maintained JAKi treatment for further 18 months, during which additional HZ recurrence was not observed. Two (6.1%) patients had postherpetic neuralgia.

Table 1. Clinical characteristics of the patients who were receiving JAKi at the time of diagnosis of HZ reactivation

	Patients ($n = 33$)
Age (yrs), median (IQR)	61 (53–69)
Female, *n* (%)	31 (93.9)

Ramsay Hunt syndrome (HZ oticus), *n*	1
Sustained neuritis, *n*	1
Postherpetic neuralgia, *n* (%)	2 (6.1)
Continued use of JAKi during HZ reactivation, *n* (%)	24 (72.7)
Resumed JAKi after HZ reactivation, *n* (%)	5 (15.2)
	Patients ($n = 27$)
Follow-up duration after JAKi use, (months), median (IQR)	12 (5.5–22.5)
HZ recurrence after JAKi use, *n* (%)	1 (3.7)

JAKi=Janus kinase inhibitor. HZ=herpes zoster.

Conclusion: JAKi was commonly continued or re-administered in patients with HZ reactivation, and the majority of patients did not experience significant complications or a recurrence of HZ reactivation. Thus, the use of JAKi after HZ reactivation episode may be generally safe and well-tolerated.

Abstract Number: 1546

Immune Responses to COVID-19 Vaccines in Patients Using Immunosuppressive Medication for Inflammatory Arthritis - An Observational Study of 1500 Patients

Ingrid Jyssum[1], Anne Therese Tveter[1], Fridtjof Lund-Johansen[2], Ludvig Munthe[2], Sella Provan[1], Kristin Jørgensen[3], Gunnveig Grødeland[2], Grete Kro[2], David Warren[2], Joseph Sexton[1], Tore Kvien[1], Siri Mjaaland[4], Espen Haavardsholm[1], John Torgils Vaage[2], Silje Watterdal Syversen[1] and Guro Goll[1], [1]Diakonhjemmet Hospital, OSLO, Norway, [2]Oslo University Hospital, Oslo, Norway, [3]Akershus University Hospital, Lørenskog, Norway, [4]Norwegian Institute of Public Health, Oslo, Norway

SESSION INFORMATION

Session Date: Tuesday, November 9, 2021

Session Title: Infection-related Rheumatic Disease Poster (1530–1564)

Session Type: Poster Session D

Session Time: 8:30AM–10:30AM

Background/Purpose: To assess the strength and duration of the immunological response to COVID-19 vaccines in patients treated with immunosuppressive medication for inflammatory arthritis.

Methods: Adult patients with a clinical diagnosis of rheumatoid arthritis (RA), spondyloartritis (SpA) or psoriatic arthritis (PsA) on treatment with any bDMARD, csDMARD, tsDMARD or prednisolone (> 7,5 mg/day) intending to receive a COVID-19 vaccine and without contraindications for vaccination were eligible for inclusion in this observational study. A cohort of healthy controls consisting of health care workers has also been established. All subjects receive vaccines according to the national corona vaccination program, independent of the current study.

Serum samples have been obtained from participants before the first vaccine dose. Vaccinations and collection of blood samples 2-4 weeks after the second vaccine dose is still ongoing. Further serum samples will be collected for assessment every 3-6 months during the study period of 5 years. Samples are consecutively analysed for antibodies to SARS-CoV-2 using Microsphere Affinity Proteomics (MAP) (1). In order to further elucidate the immune response to COVID-19 vaccines, the T cell response will also be evaluated in a subgroup of patients and controls. Data regarding demographics, immunosuppressive medication and adverse events related to vaccination are recorded. Information regarding vaccination status and potential COVID-19 disease is obtained from relevant national health registers.

Results: From February 15 until May 27 2021, 1713 patients have been enrolled in the study. At present, 1515 patients have received at least one vaccine dose and 130 participants have provided samples for T cell analyses. The distribution of diagnoses and medication in the 1515 patients with at least one vaccine dose is shown in Table 1. 651 patients have received a second vaccine dose and 80 patients have serum samples available for analysis 2-4 weeks after the second vaccine dose. Further analyses of serological and cellular responses are currently ongoing, with first results expected summer of 2021.

Conclusion: Long-term immunosuppressive medication may differentially impact the COVID 19 vaccine response in patients being treated for arthritic diseases. Determining how strong and how long lasting the immune response is in different treatment groups will be crucial in decision-making with regard to adjustments in medication and to assess a possible need for re-vaccination. Further results on serological and cellular responses are expected late summer 2021 and will be of urgent importance to patients, health care systems and decision makers.

Table1. Distribution of diagnoses and medication. Patients may have several diagnoses and use several medications.

SESSION INFORMATION

Session Date: Tuesday, November 9, 2021
Session Title: Infection-related Rheumatic Disease Poster (1530–1564)
Session Type: Poster Session D
Session Time: 8:30AM–10:30AM

Background/Purpose: Coronavirus Disease 2019 (COVID-19) runs a severe course in a subset of patients with acute respiratory distress syndrome and multiorgan failure, and a hyperinflammatory syndrome compatible with features of macrophage activation syndrome (MAS) contributes to this worse outcome. Glucocorticoids have become standard of care for those requiring oxygen support or mechanical ventilation. More targeted anti-inflammatory treatment with tocilizumab and anakinra have also been shown to be effective, however, more studies are being awaited to clarify the features of patients who would benefit more. We, therefore, investigated characteristics of the patients who received anakinra in a single tertiary referral center.

Methods: The records of hospitalized adult COVID-19 patients between March 2020 and May 2021 were retrospectively analyzed, and those patients diagnosed with MAS and who received anakinra treatment constituted the study group. Diagnosis of COVID-19 was confirmed by RT-PCR or typical findings on computed tomography. Diagnosis of MAS was based on expert opinion and the preliminary criteria developed by the investigators. All laboratory features and clinical findings were recorded using a standard form. Anakinra dose was determined according to the needs of the patients mainly determined by the inflammatory parameters, varying 100-300 mg/day SC to 400-800 mg/day IV.

Results: Out of 1080 COVID-19 patients, 218 (151 male, 67 female, mean age 60.6±15.2) who received anakinra were identified. Among them, 125 (57.3%) patients followed in the ward, 21(9.6%) did not need oxygen treatment during the hospitalization. Sixty-nine (31.6%) patients followed at ICU, 40 of them were intubated, 30 (13.7%) died in ICU. Despite similar baseline values with an exception of lower procalcitonin levels in survivors, dead patients had higher CRP, ferritin, D-dimer, and LDH levels at the anakinra initiation (Table 1). Died patients did not show a significant response in CRP, ferritin, and D-dimer values, and they had even higher ferritin and a 2-fold increase in D-dimer levels on the day of death. Laboratory follow-up studies also revealed an increase in procalcitonin, troponin, transaminase

Table 1. Characteristics of patients treated with anakinra

	Survivors			Died			
	Baseline	Anakinra initiation	Discharge	Baseline	Anakinra initiation	Death	P value

levels in dead patients indicating contribution of accompanying secondary infections. A similar pattern was observed when patients followed in the ward and ICU were analyzed separately (Table 2).

Conclusion: Laboratory parameters predicting the outcome of anti-cytokine treatments in the management of hyper-inflammatory response associated with COVID-19 are urgently needed. Analysis of this cohort of patients indicates that earlier use of anakinra treatment in hospitalized patients provides better results, and a decrease in CRP, ferritin, and D-dimer values, as well as an increase in lymphocyte count, are associated with favorable outcomes. Increasing values of D-dimer and troponin during the anakinra treatment were found to be associated with worse outcomes, possibly indicating cardiovascular and thrombotic pathologies not responding well to anakinra.

Abstract Number: 1548

Q Fever as a Mimicker of Rheumatologic Conditions: A Case Series from Two Tertiary Care Academic Centers in Southern California

Manushi Aggarwal and Marven Cabling, Loma Linda University Health, Redlands, CA

SESSION INFORMATION
Session Date: Tuesday, November 9, 2021
Session Title: Infection-related Rheumatic Disease Poster (1530–1564)
Session Type: Poster Session D
Session Time: 8:30AM–10:30AM

Background/Purpose: Q fever, an endemic disease in Southern California, is a zoonosis caused by Coxiella burnetii. The infection can present with multiple non-specific acute and chronic manifestations including fever, headache, fatigue, endocarditis, and hepatitis. Q fever is also associated with the presence of elevated inflammatory markers and autoimmune antibodies. This combination of the clinical picture and laboratory features may be misinterpreted for various rheumatologic conditions.

Methods: We evaluated records of patients who were newly diagnosed with Q-fever during an inpatient stay at 2 academic medical centers from 2013 to 2021. Data was collected for all Q fever cases in whom rheumatology was consulted, including demographics, symptoms on admission, comorbidities, labs, imaging, tissue sample obtained, and medical specialties consulted. Inpatient rheumatology consultation reports were reviewed. The reason for the consult, differential diagnosis, the time it took from admission to rheumatology consult, and rheumatology consult to Q fever diagnosis were analyzed.

Table 1. Patient demographics and presenting symptoms of patients diagnosed with Q fever patients who received Rheumatology inpatient consultation (n=8)

Age in years (range)	20-65
Gender	
Male	4 (50%)
Female	4 (50%)
Comorbidities	
Hypertension	4 (50%)
Diabetes	4 (50%)
Hyperlipidemia	3 (37.5%)
Vestibular migraines	1 (12.5%)
Recent COVID infection	1 (12.5%)
Graves' disease	1 (12.5%)
Obesity	1 (12.5%)
CAD, heart failure, Atrial fibrillation	1 (12.5%)
Timing of symptom onset	
Jan-March	5 (62.5%)
April- June	2 (25 %)
July-Sept	1 (12.5 %)
Oct- Dec	0
Animal exposure	
Dog	2 (25 %)
Cow	2 (25 %)
Rat	1 (12.5%)

Number of medical specialties consulted		3-6, average 4.6/patient
Abnormal labs/imaging		
Elevated ESR/CRP		8 (100%)
Transaminitis		5 (62.5%)
Splenic infarct		1 (12.5%)
Positive ANA		1 (12.5%)
Positive RF		1 (12.5%)
Positive EBV IgG, CMV IgG, Rubella IgG		1 (12.5%)

ANA– antinuclear antibody; APS- antiphospholipid antibodies; CCP- Cyclic Citrullinated Peptide; RF-rheumatoid factor

Results: From 2013-2021, 23 patients were diagnosed with Q fever during an inpatient stay. Eight patients (34.7%) received rheumatology consultation prior to their Q fever diagnosis. Majority of the patients (62.5%) had symptom onset during the first quarter of the year, 75% of patients had exposure to cattle, sheep, goat, or rats, 37.5% had do-

Table 3. Details on rheumatology consultation, differentials, and workup

	Reason for rheumatology referral	Rheumatology Differentials	Labs and/additional consults requested by rheumatology	Imaging requested by rheumatology	Admit to Q fever diagnosis (in days)	Rheum consults to Q fever diagnosis (in days)
Case 1	FUO, elevated inflammatory markers	Infection, malignancy, Vasculitis, Behcet's, AOSD, Sarcoidosis	ANA panel, C3, C4, MPO, PR3, Vasculitis panel, Cryoglobulins, RF, CCP	CTA chest	10	6
Case 2	FUO, elevated inflammatory markers	AOSD, autoimmune hepatitis	ANA, APS, Vasculitis panel, Cryoglobulin, ANCA, Immunoglobulins, Genetic testing for fever syndromes	none	10	5
Case 3	FUO, elevated inflammatory markers	Autoimmune/auto-inflammatory, infection, malignancy, AOSD	Ferritin, ESR, CRP daily, ANA-hep 2, C3, C4	CT chest	11	6
Case 4	GCA evaluation	GCA	Temporal artery biopsy, ENT, Ophthalmology consult	CTA chest, MRI orbit	6	7
Case 5	FUO, elevated inflammatory markers, positive RF	Infection vs malignancy vs sJIA	Consider GI eval for IBD	None	7	1
Case 6	FUO, positive ANA	Infection, malignancy, AOSD, autoinflammatory syndromes	Ferritin, SSA, SSB, RF, CCP, auto-inflammatory gene panel (MEFV, MVK, TNFRSF1A)	None	13	6
Case 7	FUO, headaches, hepatitis, positive ANA	Aortitis, Autoimmune hepatitis, AOSD	ANCA, ANA hep 2, IgG4, liver biopsy, Ferritin, ESR, CRP, Cryoglobins	CTA chest, XR hands	12	3
Case 8	Sarcoidosis evaluation	Neurosarcoidosis, Pulmonary sarcoid, Autoimmune hepatitis, CNS vasculitis	TB quantiferon, ACE, Lysozyme, Vit D, Lumbar puncture, ANCA	MRI brain, cardiac MRI	16	13

ACE – angiotensin converting enzyme; ANA – antinuclear antibody; ANCA- Antineutrophil Cytoplasmic Antibodies; AOSD – adult-onset still's disease; APS- antiphospholipid antibodies; CCP- Cyclic Citrullinated Peptide; FUO –fever of unknown origin; GCA- giant cell arteritis; MPO- myeloperoxidase; PR3-proteinase 3; RF – rheumatoid factor; sJIA- Systemic juvenile idiopathic arthritis

mestic pet exposure, and 1 patient did not report any known animal exposure. Almost all (87.5%) patients had fever and flu-like symptoms, with 63% having GI symptoms. All patients had extensive infectious workup done. All patients had elevated inflammatory markers, and 63% with abnormal liver enzymes. One patient had a low titer antinu-

clear antibody and another one had a positive rheumatoid factor. Two patients underwent liver biopsy showing ring granulomas and granulomatous hepatitis, findings characteristic but not pathognomonic of Q fever.

Fever of unknown origin (FUO) was the most common (75%) reason for consultation while one patient each was referred for evaluation for giant cell arteritis (GCA) and sarcoidosis. In 50% of cases, the rheumatology service thought a rheumatologic disease is less likely and thus recommended additional studies for infectious or oncologic etiology. Rheumatologic differentials included adult-onset Still's disease, Bechet's disease, sarcoidosis, and systemic vasculitis including GCA. An auto-inflammatory gene panel was done in 2 patients and temporal artery biopsy was done in 1 patient with results all negative. On average, Q fever was diagnosed approximately 10.6 days after admission and 5.8 days after rheumatology consultation.

Conclusion: The non-specific presentation of Q fever, accompanied by elevated inflammatory markers, and autoimmune antibodies can mimic various rheumatologic conditions including vasculitis, Still's disease, and sarcoidosis. Our case series demonstrates that Q-fever should be considered as a differential diagnosis especially for patients with FUO and residing in endemic regions.

Experience from a Diverse Rheumatology Cohort with COVID-19: Are We Doing Better Than We Expected?

Michael Grant[1], Matas Orentas[2], Sobia Hassan[1], Sonali Khandelwal[1], Donyea Moore[3] and Najia Shakoor[1], [1]Rush University, Chicago, IL, [2]RUMC, Chicago, IL, [3]Rush University Medical Center, Chicago, IL

SESSION INFORMATION
Session Date: Tuesday, November 9, 2021
Session Title: Infection-related Rheumatic Disease Poster (1530–1564)
Session Type: Poster Session D
Session Time: 8:30AM–10:30AM

Background/Purpose: The COVID-19 pandemic has been particularly concerning for patients with rheumatologic conditions because they are potentially predisposed to more severe outcomes. Studies have suggested that higher steroid dose, rituximab and certain DMARDs were associated with worse COVID-19 outcomes while TNF-inhibitors were associated with better outcomes. However, more studies are needed to confirm these trends particularly in more diverse patient populations. Here, we evaluate a predominantly Black and Hispanic cohort of rheumatology patients with COVID-19 compared to controls on their infection-related outcomes.

Methods: An urban academic medical center has a registry of patients with rheumatological conditions and laboratory confirmed COVID-19 as well as a separate repository of COVID-19 patients without rheumatic disease. Data collected included demographics, comorbidities, medications, hospitalization and hospital course. Chi-squared, independent samples t-test, and logistic regression were used for analyses.

Results: Results are summarized in Tables 1 and 2. 175 rheumatology patients (43 SLE, 52 RA, 26 psoriasis and psoriatic arthritis, 22 other connective tissue diseases, 32 other diagnoses including inflammatory arthritis and myositis) and 481 control patients were evaluated. Both groups had a substantial portion of Black patients while the rheumatology group also included a significant number of Hispanic patients. Prevalence of DM was higher in the control group.

Table 1: Rheumatology patients vs Controls

	No (n=113)	34 (30%)		1 (1%)	
Anti-TNF	Yes (n=22)	2 (9%)	**0.2 (0.0-.9)**	0 (0%)	1.0 (0.9-1.0)
	No (n=153)	49 (32%)		3 (2%)	
Rituximab	Yes (n=5)	4 (80%)	**10.5 (1.1-96.0)**	1 (20%)	**21.0 (1.6-282.0)**
	No (n=170)	47 (28%)		2 (1%)	

Patients with rheumatic disease had longer length of stay in the hospital (p=0.034), however, overall did not have increased odds of hospitalization, ICU admission, intubation, or death even after adjustment for confounders. GC and DMARD use were not associated with overall outcomes. There was decreased odds of hospitalization with use of TNF-inhibitors. Rituxan use was associated with increased odds of hospitalization and death.

Conclusion: This predominantly Black and Hispanic cohort of rheumatology patients with COVID-19 had very comparable outcomes overall to those without rhematic disease. TNF-inhibitor use was associated with decreased risk of hospitalization while rituximab use was associated with increased risk of hospitalization and death. These results are reassuring for our patients overall but suggest that we need to continue to evaluate subsets of our patients on

specific therapies for potentially better or worse outcomes. Continued sharing of data across the country and world will be invaluable in helping us provide appropriate guidance and management for our patients.

Abstract Number: 1550

Flares and Side Effects After COVID-19 Vaccination in Patients with Rheumatic Diseases

Anna Carbone, Gentiana Vukatana, Enrica Vandelli, Marica Trevisani, Elisa Rossi, Rita Mulè and Marco Fusconi, Rheumatology Unit, Azienda Ospedaliero-Universitaria Bologna, Bologna, Italy

SESSION INFORMATION
Session Date: Tuesday, November 9, 2021
Session Title: Infection-related Rheumatic Disease Poster (1530–1564)
Session Type: Poster Session D
Session Time: 8:30AM–10:30AM

Background/Purpose: There is increasing interest in the safety of COVID-19 vaccination in patients with underlying chronic conditions. We investigated the rates of side effects and/or disease flares in the short term after COVID-19 vaccination in patients with rheumatic diseases.

Methods: In this single-center observational study, we analyzed the proportion of self-reported systemic side effects and flares in patients with rheumatic diseases who received one of the approved COVID-19 vaccines in our country (BNT162b2, AZD1222, mRNA-1273 and JNJ-78436735) between Dec. 27, 2020 and May 28, 2021. Demographic data, type of rheumatic disease, activity of the disease determined by clinical scores when applicable, treatment, and previous SARS-CoV-2 infection were also collected.

Results: One-hundred and eighty patients (female=127) were included in the study. Median age was 70 years (range 23-92), due to the fact that our vaccination campaign began with older and fragile patients. Patient characteristics are summarized in Table 1.

Of the 180 patients, 146 received BNT162b2, 25 AZD1222, 8 mRNA-1273, and 1 patient received JNJ-78436735. Six patients reported SARS-CoV-2 infection prior to vaccination. Thirty-four patients (18.9%) reported systemic side effects after the first dose: BNT162b2 23/146 (15.7%); AZD1222 10/25 (40%); mRNA-1273 1/8 (12.5%); JNJ-78436735 0/1. A total of 118 patients had received the second dose of the BNT162b2 or mRNA-1273 vaccine at the time of data collection. Of these, 39 (33.1%) reported systemic side effects after the second dose: BNT162b2 38/112 (33.9%); mRNA-1273 1/6 (16.7%). The most frequent side effects were fever, headache, fatigue and arthromyalgia. All systemic side effects were mild and resolved spontaneously within a few days. Disease flare was reported in 1 out of the 180 patients (0.6%) who received the first dose, and in 4 out of the 118 patients (3.4%) who received the second dose. Two of these five patients had RA and three had PsA. All five had received BNT162b2. These results are illustrated in Table 2.

Conclusion: Preliminary results suggest that disease flares are possible but infrequent after COVID-19 vaccination in patients with rheumatic diseases. Rates of systemic side effects are comparable to the general population. Further

Generation of Autoantibodies and Their Association with Rheumatic Disease Flares in Adult Patients with Autoimmune Inflammatory Rheumatic Diseases and General Adult Population Following BNT162b2 mRNA Covid-19 Vaccination

Tal Gazitt[1], Joy Feld[2], Amir Haddad[3], Muna Elias[4], Nizar Hijazi[4], Nili Stein[4], Victoria Furer[5], Tali Eviatar[6], Hagit Peleg[7], Ori Elkayam[8] and Devy Zisman[4], [1]Carmel Hospital, Haifa, Israel, [2]Carmel and Zvulun Medical Centre, Haifa, Israel, [3]Carmel Medical Centre, Haifa, Israel, [4]Carmel Medical Center, Haifa, Israel, [5]Tel Aviv Sourasky Medical Center, Tel Aviv, Israel, [6]Tel Aviv Sourasky Medical Center, Givataim, Israel, [7]Hadassah Medical Center, Jerusalem, Israel, [8]Tel Aviv Medical Center, Tel Aviv, Israel

SESSION INFORMATION
Session Date: Tuesday, November 9, 2021
Session Title: Infection-related Rheumatic Disease Poster (1530–1564)
Session Type: Poster Session D
Session Time: 8:30AM–10:30AM

Background/Purpose: The rapid spread of the COVID-19 pandemic has created the need for mass vaccination of patients with autoimmune rheumatic disease (AIIRD) despite the lack of information on the effect of BNT162b2 mRNA vaccine on the underlying autoimmune disease and the possible generation of autoantibodies. Our objective was to investigate the generation of autoantibodies following BNT162b2 mRNA vaccine and its association with disease flares in AIIRD patients compared with the general population.

Methods: We investigated the generation of autoantibodies as a part of a prospective study aimed to monitor immunogenicity, efficacy, and safety of the two-dose regimen BNT162b2 mRNAvaccine in adult patients with AIIRD including immune-mediated arthritis, connective tissues diseases (CTD), systemic vasculitis, and idiopathic inflammatory myositis (IIM) compared to control subjects from the general population. Sera were taken prior to vaccination and 2-6 weeks following the second vaccine dose to examine titers of antinuclear antibodies (ANA) measured by immunofluorescence and multiplex, antiphospholipid antibodies (aPL) and rheumatoid factor (RF). Data on generation of autoantibodies was calculated for each type of autoantibody individually based on number of patients with available data. Post-vaccination seroconversion was defined as any first-time ANA, aPL, or RF seropositivity. Pre- and post-vaccination disease activity indices were assessed as appropriate for each disease, and any signs or symptoms of new-onset AIIRD were noted in controls.

Results: A total of 166 AIIRD patients and 59 controls participated in the study, 72.9% (n=121) female. AIIRD patients were significantly older than controls, mean age 58.0±14.6 vs 50.8 ±14.7, respectively (p=0.008). Disease representation in AIIRD group included RA (47.0%), PsA (20.5%), AS (12.0%), SLE (11.4%), vasculitis (5.4%), IIM (2.4%), Sjogren's (0.6%), IGG4-RD (0.6%). A total of 94.6% (n=157) AIIRD patients were treated with immunomodulatory medications. Immunoserologic data before and following vaccination was available for ANA serology in 137 (82.5%) AIIRD patients and 45 (76.3%) controls; aPL serology for 134 (80.7%) AIIRD patients and 51 (86.2%) controls, and RF serology for 138 (83.1%) AIIRD patients and 50 (84.7%) controls. The ANA seroconversion rate was 10.2% (n=14)

in patients with AIIRD compared to 6.7% (n=3) in controls (p=0.570); the aPL seroconversion rate was 1.5% (n=2) in AIIRD compared to 0% in controls (p >0.99). No cases of RF seroconversion were observed in AIIRD patients or controls. There was no statistically significant difference in age or sex among individuals who experienced seroconversion to those who did not, regardless of AIIRD status. Post-vaccination disease activity remained stable in patients who generated autoantibodies and no new signs of disease onset were seen in healthy controls who underwent seroconversion in the followup period.

Conclusion: Vaccination with the BNTb262 vaccine resulted in the generation of autoantibodies in a minority of AIIRD patients and controls. Autoantibody generation was not associated with disease flares or new-onset disease.

Systemic Autoimmune Conditions and Hospital Admissions in Covid-19 Infection

Inés Perez - Sancristobal[1], Leticia Lopez Pedraza[2], María Paula Álvarez Hernández[1], Jose Ignacio Colomer[3], Alfredo Madrid - Garcia[2], Benjamin Fernandez[4], Cristina Martínez - Prada[4], Luis Rodriguez Rodriguez[5], Arkaitz Mucientes[2], Leticia Leon - Mateos[2] and Lydia Abasolo[6], [1]Hospital Clínico San Carlos, Reumathology, Madrid, Spain, Madrid, Spain, [2]Instituto de Investigación Sanitaria del Hospital Clínico San Carlos, Reumathology, Madrid, Spain, [3]Fundación para la Investigación Biomedica, Reumathology, Madrid, Spain, [4]Hospital Clínico San Carlos, Reumathology, Madrid, Madrid, Spain, [5]Hospital Clinico San Carlos, Madrid, Spain, [6]Rheumatology Department, Hospital Clínico San Carlos, Madrid, Spain

SESSION INFORMATION
Session Date: Tuesday, November 9, 2021
Session Title: Infection-related Rheumatic Disease Poster (1530–1564)
Session Type: Poster Session D
Session Time: 8:30AM–10:30AM

Background/Purpose: The COVID-19 pandemic continues worldwide and has had a strong impact on public health. From the beginning of the pandemic, efforts were intensified to identify risk factors for development of the severe form of COVID-19.

In patients with rheumatic and musculoskeletal diseases (RMDs) and infected with COVID – 19, we aim to investigate the role of systemic autoimmune conditions compared to other type of RMDs in severity of COVID-19 in terms of hospital admissions.

Methods: An observational longitudinal study was conducted during the epidemic peak in Madrid (1stMar to 20thMay2020). All patients attended at the rheumatology outpatient clinic of a tertiary hospital with a diagnosis of RMDs and Covid-19 infection were included (according to a medical diagnosis or confirmed with a positive SARS-CoV-2 PCR diagnostic test). All patients were included since the time of COVID-19 diagnosis. The main outcome: hospital admissions related to COVID – 19 infection in patients with RMDs. Independent variable: Type of RMD including: autoimmune (systemic autoimmune conditions (SAC) and inflammatory join disease (IJD) and non - autoimmune diseases (mechanical diseases, and inflammatory diseases (mycrocrystaline arthritis and tendonitis)). Covariables: 1) Sociodemographic baseline characteristics. 2) Baseline comorbid conditions. 3) Treatment for the RMDs: a) Glucocorticoids, b) conventional syntethetic DMARDs (csDMARDs) and c) targeted syntethetic/biologic DMARDs

(ts/bDMARDs). Statistical análisis: description of the sociodemographic, clinical and treatment characteristics of the patients. A multivariate logistic regression adjusted by age, sex and comorbidities was used to evaluate the risk of the different types of RMDs in hospital admissions related to COVID – 19. The results were expressed as OR with its corresponding confidence Interval (95% CI).

Results: 405 patients were included with RMDs and COVID – 19 infection. 69, 14% were women with a mean age at diagnosis of 60 ± 15,26 years. The evolution time from the diagnosis of RMD was 8 ± 8,4 years. Of the 405 patients, 243 (60%) had non – autoimmune RMD and 162 (40%) ((106 (65,43%) IJD and 56 (34,56%) SAC) had autoimmune RMD. 36% of all patients were admitted (31% from non - autoimmune RMDs, 36% for autoimmune RMD (IJD) and 57% for autoimmune RMD (SAC) (p =0,001). After adjusting by confounders, the risk of hospital admission in non -autoimmune RMD compared to SAC (OR: 0.28 [0.13-0.59], p = 0.001) and autoimmune RMD IJD compared to SAC (OR IJD: 0.34 [0.15-0.78], p = 0.011) was lower. Advanced age (OR: 1.10 [1.07-1.12], p < 0.001), male (OR female sex (OR: 0.59 [0.34-1.03], p=0.067) and more number of comorbidities (OR: 1.38 [1.01-1.88] increased the risk of hospitalization related to COVID-19.

Conclusion: One third of the RMD patients infected with COVID-19 required hospital admission. This study shows that patients with autoimmune and specifically with systemic autoimmune conditions have a higher risk of hospitalization related to COVID-19. We also show that advanced age, male sex and a higher number of comorbidities can contribute to worsen the prognosis of the COVID-19 disease.

Abstract Number: 1553

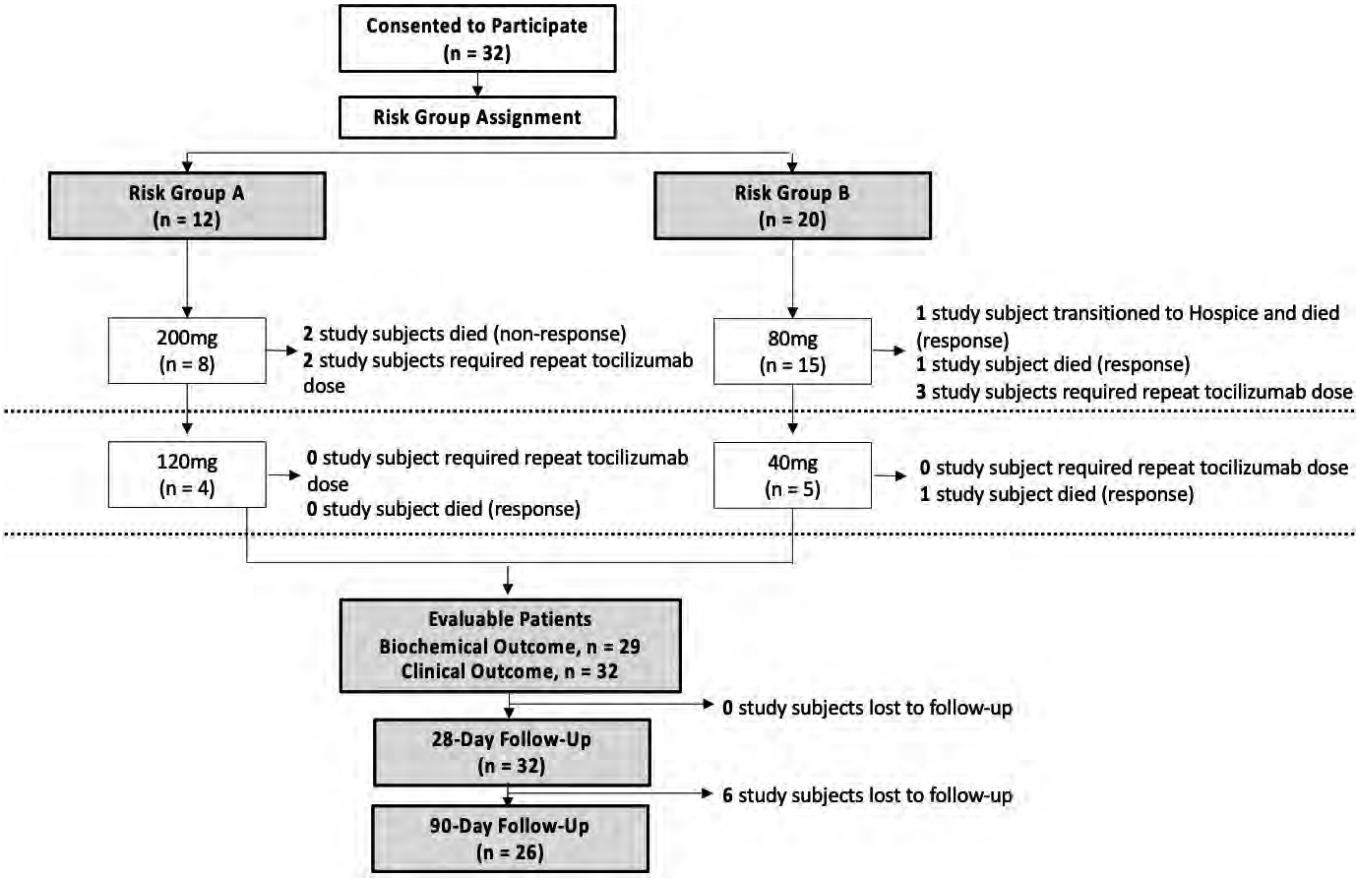
Low-dose Tocilizumab in the Treatment of COVID-19 Pneumonitis: 90-day Mortality Follow-up

Lauren He[1], Garth Strohbehn[2] and Pankti Reid[3], [1]University of Chicago, Chicago, IL, [2]VA Ann Arbor Center for Clinical Management and Research, Chicago, IL, [3]University of Chicago Medical Center, Chicago, IL

SESSION INFORMATION
Session Date: Tuesday, November 9, 2021
Session Title: Infection-related Rheumatic Disease Poster (1530–1564)
Session Type: Poster Session D
Session Time: 8:30AM–10:30AM

Background/Purpose: Tocilizumab (TCZ) for treatment of severe coronavirus disease 2019 (COVID-19) pneumonia decreases the probability of progression to invasive mechanical ventilation (CORIMUNO-TOCI) or death (REMAP-CAP, RECOVERY). Standard doses of 400-800 mg or 8 mg/kg of body weight have been used in previous studies; however, determining the optimal dose is critical given the possibility of increased rates of infection in higher doses and limited global supplies. The COVIDOSE study evaluated the pharmacodynamic and clinical efficacies, safety and dose response of low-dose TCZ in COVID-19.[1] With the emergence of "long COVID" sequelae, we present follow up to COVIDOSE with analysis of 90-day mortality.

Methods: This was an adaptive phase 2 study of low-dose TCZ in hospitalized, non-mechanically ventilated adult patients with COVID-19 pneumonitis, C-reactive protein (CRP) ≥ 40 mcg/mL, and at least 1 epidemiologic risk factor for increased risk of COVID-related death (e.g. underlying medical conditions). Dose cohorts were determined by a



Study design.

trial Operations Committee, with the initial doses of 80 or 200 mg. Doses were decreased to 40 mg and 120 mg after interim assessment. Pre-specified secondary objectives included 28-day mortality; 90-day mortality was a later addendum given the emergence of "long COVID."

Results: Thirty-two patients received low-dose TCZ (Figure 1). Within the 28-day follow up period, 5 (16%) patients died. Within the 90-day follow up period, 6 participants were lost to follow up, and 6 (23%) had died (including 5 who died within the 28-day period). Four out of 6 died during index COVID-19 hospitalization. Mean baseline CRP did not differ between patients who died versus those alive at 90 days (158 ± 96 mcg/mL vs 158 ± 83 mcg/mL). Mean CRP decrease in the 24 hours following first TCZ dose did not differ between patients who died vs those alive at 90 days (38 ± 11% vs 34 ± 15%).

Conclusion: Ninety-day mortality rate in this small phase 2 study was 23%, with 1 out of 26 patients dying between the 28-day and 90-day mark. Previously reported 90-day mortality rate of similar patients with elevated CRP receiving usual care has been reported at 35%.[2] These findings support our actively enrolling randomized controlled trial of low-dose tocilizumab versus standard of care in hospitalized, non-invasively ventilated patients with COVID-19 pneumonia, COVIDOSE2 (ClinicalTrials.gov NCT04479358). (ClinicalTrials.gov COVIDOSE Identifier: NCT04331795)

COVID-19 Vaccine Hesitancy Among Patients with Rheumatic and Other Diseases

Valeria Valerio[1], Emmanouil Rampakakis[2], Marie Hudson[3], Sasha Bernatsky[3], Elizabeth M. Hazel[3] and Ines Colmegna[4], [1]Research Institute of the McGill University Health Centre, Montréal, QC, Canada, [2]JSS Medical Research, Montréal, QC, Canada, [3]McGill University, Montréal, QC, Canada, [4]The Research Institute of the McGill University Health Centre, Montréal, QC, Canada

SESSION INFORMATION

Session Date: Tuesday, November 9, 2021
Session Title: Infection-related Rheumatic Disease Poster (1530–1564)
Session Type: Poster Session D
Session Time: 8:30AM–10:30AM

Background/Purpose: Vaccination is fundamental to reduce COVID-19 risk and its complications. Vaccine hesitancy is a threat to COVID-19 vaccination uptake. We assessed the frequency of COVID-19 vaccine hesitancy among RD and other patients.

Methods: Between Nov-Dec 2020 (prior to COVID-19 vaccine roll-out), a cross-sectional survey was completed by patients presenting to a Canadian university-affiliated hospital network for influenza immunization. Sociodemographics, comorbidities, concomitant medications, previous COVID-19 infection, and perceptions related to COVID-19 vaccination (e.g., likelihood of receiving a future COVID-19 vaccine, causes of vaccine hesitancy) were assessed. We defined 3 specific groups: (i) RD, (ii) non-RD immunosuppressed patients (HIV, cancer, transplant, inflammatory bowel disease), and (iii) other. According to self-reported likelihood to receive a future COVID-19 vaccine and the tertile distribution of the responses, patients were classified as significantly hesitant (scores 0-7); somewhat hesitant (scores 7.5-9.5), or non-hesitant (score 10). Logistic regression using backward stepwise variable selection was performed to evaluate determinants of vaccine hesitancy.

Results: Among 2491 people vaccinated, 1793 people completed the survey (72%). Of those, 820 were patients (45.7%), 542 physicians or nurses (30.2%), 228 patients' family members (12.7%), and 203 other (11.3%). Participants had a mean age (±SD) of 52.2±16.9 years, and 58.6% were females. Just over one-tenth (10.7%, n=191) had RD, 9.4% (n=169) were immunosuppressed non-RD patients, and the remaining were other participants. Concerning COVID-19 vaccination, most subjects were non-hesitant (n=1124, 62.7%), 315 were somewhat hesitant (17.6%), and 354 (19.7%) significantly hesitant. RD patients were significantly more hesitant than other groups (hesitant %: RD: 44.5 vs. non-RD immunosuppressed: 30.8 - OR:1.80, 95% CI: 1.17 - 2.78; RD: 44.5 vs. other: 37.1 - OR: 1.36, 95% CI: 1.00 - 1.84). Vaccine hesitancy was associated with the following: perception that COVID-19 vaccines should not be mandatory; having concerns about vaccine safety; and being uncertain if vaccine benefits overweight its risks. Table 1 for predictors of vaccine hesitancy.

Table 1. Factors associated with COVID-19 vaccine hesitancy among people receiving influenza vaccine (no hesitancy as a reference group); (a) HIV, transplant, cancer, and inflammatory bowel disease; (b) Distance to the vaccine provider, time needed to get to the vaccine provider, waiting time at the vaccine provider, cost/parking in getting to the vaccine provider, and efforts of traveling to the vaccine provider; (c) Participants that were not receiving immunosuppressant treatment or did not have a disease that affects the immune system

Conclusion: COVID-19 vaccine hesitancy was common among RD patients receiving influenza vaccination. Vaccine hesitancy in RD was higher than in other immunosuppressed patients and the general population. Factors associated with vaccine hesitancy are not unique to RD. Education about the benefits and safety of COVID-19 vaccines might enhance vaccine uptake among RD patients.

Abstract Number: 1555

Clinical Outcomes of Coronavirus Disease-2019 (COVID-19) in Hospitalized Patients with Rheumatic and Musculoskeletal Diseases (RMD)

Ikwinder Kaur[1], Mohsin Mughal[2], Abdul Asbeutah[3], Mili Kakadia[2], Reem Alhashemi[4], Hasan Mirza[5], Harjot Jagdey[6], Rasha Alhashimi[7], vishakha sirpal[2], Punit Jariwala[2] and Eugenio Capitle[8], [1]Monmouth Medical Center, an affiliate of Rutgers health system, Long Branch, NJ, [2]Monmouth Medical Center, Long Branch, NJ, [3]University of Tennessee Health Science Center, Memphis, TN, [4]Monmouth Medical Center, Long Branch, NJ, [5]Berkshire Medical Center, Pittsfield, MA, [6]BronxCare Hospital, Bronx, NY, [7]BIDMC, Havard, Boston, MA, [8]Rutgers New Jersey Medical School, New Brunswick, NJ

SESSION INFORMATION
Session Date: Tuesday, November 9, 2021
Session Title: Infection-related Rheumatic Disease Poster (1530–1564)
Session Type: Poster Session D
Session Time: 8:30AM–10:30AM

Background/Purpose: COVID-19 has been implicated in an exaggerated inflammatory response by activating both innate and adaptive immune responses. Rheumatic disease patients are a vulnerable population because of the underlying dysregulated immune system. The data regarding the impact of COVID-19 on rheumatic disease patients is limited. Data is heterogenous whether the patients on immunomodulatory therapy have lower mortality due to mitigation of immune response. Our study aimed to analyze the clinical characteristics of COVID-19 in hospitalized inflammatory rheumatic disease patients. And, compared the patients on chronic immunosuppression with those who weren't on immunosuppressive therapy.

Methods: This is a single-center study performed in a community hospital in the state of New Jersey. The adult patients with confirmed SARS-CoV-2 infection by nasopharyngeal RT-PCR who were hospitalized from March 2020 to January 2021 were screened for RMD. Data were manually extracted using the hospital's electronic medical record retrospectively after IRB approval. Categorical variables were compared by conducting a chi-square test while continuous ones were compared by conducting a median two-sample t-test. Statistical analysis was done with SAS software.

Results: A total of 600 patients were admitted under medicine service. Out of these, 19 patients (3.1 %) had documented RMD. These included Rheumatoid arthritis (n=4), SLE (n=1), systemic sclerosis (n=2), Sjogren syndrome(n=1), gout (n=8), sarcoidosis (n=1), familial Mediterranean fever (n=1), psoriatic arthritis (n=1), ANCA induced vasculitis (n=1) and polymyalgia rheumatica (n=1). The median age was 73 years, 57.9% were male (Table 1). The most common comorbidity was hypertension (n=13) followed by diabetes mellitus(n=6) and chronic kidney disease (n=5). Shortness of breath was the most common presenting symptom followed by fever. None had a rheumatic disease flare-up. In terms of treatment, 52.6% received steroids, 31.6% hydroxychloroquine, 31.6% remedesivir, 26.1% IL-6 inhibitor, and 10.5 % were treated with convalescent plasma. ICU level of care was required in 26.3% and 10.5%

Table 1. Baseline characteristics

Demography	All patients(n=19)	Cohort-1 (n=12) Patients not on chronic immunosuppression	Cohort-2 (n=7) Patients on chronic immunosuppression	p-value
Age -Median (IQR)	73.0 [63.0-83.0]	73.9 [67.75-91.0]	67.0 [63.0-78.0]	0.227
Male (n,%)	11 (57.9)	8 (66.7)	3 (42.9)	0.377
Caucasian (n,%)	6 (31.5)	2 (16.7)	4 (57.1)	0.129

Table 2. Inflammatory markers

Inflammatory markers (median, IQR)	All patients(n=19)	Cohort-1 (n=12) Patients not on chronic immunosuppression	Cohort-2 (n=7) Patients on chronic immunosuppression	p-value
CRP at admission (median, IQR)	122.0 [47.5-176.5]	122 [9.7-197]	107.7 [29.0-152.1]	0.884
Peak CRP (median, IQR)	146.0 [76.3-196.0]	142.7 [60.1-187.9]	146.0 [68.9-201.5]	1.00
Ferritin at admission (median, IQR)	584.0 [324.5-1096.5]	786.0 [298.8-1193.8]	1294.5 [558.5-1840.8]	0.315
Peak ferritin (median, IQR)	1251.5 [1082.3-1920.5]	1251.5 [1089.8-5161.5]	1501.0 [613.5-1920.5]	0.933
LDH at admission (median, IQR)	383.5 [278.5-583.3]	313.0 [261.0-528.5]	474.0 [434-657.0]	0.073
Peak LDH (median, IQR)	474.5 [307.3-626.5]	423.0 [272.0-624.5]	491.0 [434-695.5]	0.438
D-Dimer at admission (median, IQR)	1.68 [0.57-2.43]	1.82 [0.63-4.28]	0.65 [0.43-2.0]	0.181
Peak D-dimer (median, IQR)	1.82 [0.95-4.35]	2.25 [1.4-4.4]	1.16 [0.54-3.67]	0.368

were intubated. Overall, 84.2% were discharged from the hospital and 15.8% had a poor outcome and died. The patients were further divided into two cohorts. Cohort 2 included patients who were on chronic DMARDs or immunosuppression therapy (methotrexate, cyclosporine, hydroxychloroquine, and oral steroids). None of the patients were on biologic DMARDs. There was no statistically significant difference in inflammatory markers (CRP, LDH, D-dimer, ferritin) on admission and peak values during the hospitalization (Table 2). There was no significant difference in complication rate and final outcomes (ICU admission, intubation, discharged alive) between the two cohorts (Table 3).

Conclusion: Our study revealed that 3.1% of hospitalized COVID-19 patients had the RMD. There was no statistically significant difference in inflammatory markers, complication rate, and final outcomes among patients on chronic immunosuppressive therapy vs those who were not on any immunosuppressant. The limitation of our study is a small sample size and a single-center retrospective data.

Table 3. Complications and final outcomes

Complications (n,%)	**All patients(n=19)**	**Cohort-1 (n=12)** **Patients not on chronic immunosuppression**	**Cohort-2 (n=7)** **Patients on chronic immunosuppression**	**p-value**
Septic shock (n,%)	1 (5.3)	1 (8.3)	0 (0)	1.00
ARDS (n,%)	6 (31.6)	4 (33.3)	2 (28.6)	0.829
AKI (n,%)	1 (5.3)	1 (8.3)	0 (0)	1.00
New dialysis (n,%)	0	0	0	
Superinfection (n,%)	2 (10.5)	1 (8.3)	1 (14.3)	1.00
Thrombosis (n,%)	0	0	0	
Tachyarrhythmias (n,%)	1 (5.3)	1 (8.3)	0 (0)	1.00
None of above (n,%)	5 (26.2)	3 (25)	2 (28.6)	1.00
Final outcome(n,%)				
ICU level of care (n,%)	5(26.3%)	3 (25%)	2(28.6%)	0.509
Intubated (n,%)	2 (10.5)	2 (16.7)	0 (0)	0.509
Discharge alive (n,%)	16 (84.2)	9 (56.3)	7 (43.8)	0.149
Died in the hospital (n,%)	3(15.8)	3 (25)	0 (0)	0.149
Length of stay-days(median, IQR)	7.0 [4-12]	5.5 [4-11]	7 [3-18]	0.312

Mortality Rate Related to COVID-19 in Rheumatic and Musculoskeletal Diseases (RMDs)

Ines Perez - Sancristobal[1], Dalifer Freites[1], Leticia Lopez Pedraza[2], Maria Paula Alvarez Hernandez[1], Jose Ignacio Colomer[3], Alfredo Madrid - Garcia[2], Benjamin Fernandez[1], Cristina Vadillo[1], Luis Rodriguez Rodriguez[4], Arkaitz Mucientes[2], Leticia Leon - Mateos[2] and Lydia Abasolo[5], [1]Hospital Clínico San Carlos, Reumathology, Madrid, Madrid, Spain, [2]Instituto de Investigación Sanitaria del Hospital Clínico San Carlos, Reumathology, Madrid, Spain, [3]Fundación para la Investigación Biomedica, Reumathology, Madrid, Spain, [4]Hospital Clinico San Carlos, Madrid, Spain, [5]Rheumatology Department, Hospital Clínico San Carlos, Madrid, Spain

SESSION INFORMATION

Session Date: Tuesday, November 9, 2021

Session Title: Infection-related Rheumatic Disease Poster (1530–1564)

Session Type: Poster Session D

Session Time: 8:30AM–10:30AM

Background/Purpose: In patients with rheumatic and musculoskeletal diseases (RMDs) and infected with Covid – 19, a) we want to assess the mortality rate (MR) related to COVID-19; and b) to analyze the role of RMDs in mortality risk.

Methods: An observational longitudinal study was conducted during the epidemic peak in Madrid (1stMar to 20thMay2020). All patients attended at the rheumatology outpatient clinic of a tertiary hospital with a diagnosis of RMDs and SARS - CoV 2 infection were included (according to a medical diagnosis or confirmed with a positive SARS-CoV-2 PCR diagnostic test). **Main outcome:** death related to COVID-19 infection. **Independent variable:** type of RMDs including: autoimmune (systemic autoimmune conditions (SAC) and inflammatory joint disease (IJD)) and non–autoimmune (mechanical diseases and inflammatory diseases (microcrystalline arthritis and tendonitis)). **Covariates:** sociodemographic, comorbidities, treatment for the RMDs.

Survival techniques were used to estimate the MR related to COVID-19, given per 1,000 persons-month with a 95% confidence interval [CI]. The time of observation comprised the elapsed time between the date of COVID-19 diagnosis of infection until the date of patient's death, or end of study. Cox multiple regression analysis was run to examine the effect of autoimmune RMDs compared to non-autoimmune RMDs on mortality risk adjusted by sex, age and comorbidities. Results were expressed by Hazard Ratio (HR) and [CI].

Results: 405 patients were included with RMD and COVID – 19 infection with a total follow-up 642.57 patients-month. 69.14 % were women with a mean age at diagnosis of 59.37 ± 15.26 years. The evolution time from the diagnosis of rheumatic disease was 7.62 ± 8.39 years. Of the 405 patients, 243 (60%) had non-autoimmune RMD and 162 (39.9%) (106 (65.43%) IJD, 56 (34.56%) systemic condition) had autoimmune RMD. Of the 405 patients, 44 (11%) died during the follow-up, being 12± 14 days the mean time from infection to death (P50: 6[2-12] and a maximum of 60 days). MR was estimated in 68.48 [50.96-92.01] per 1,000 persons-month. CMR was higher for men (MR 105.45 [68.03-163.45]) than for women (MR 52.99 [35.52-79.06]) and in older people (MR < 60: 4.47, [0.67-31.70]; MR 60-75 years: 32.28 [13.44-77.55]; MR >75Years: 487.18 [354.49-669.53]). The HR of mortality in autoimmune RMDs compared to non-autoimmune RMDs did not achieved statistical significance (HR: 1.39 [0.77-2.5], p=0.27). After adjusting for confounders, we did not find higher risk of mortality among the different types of RMDs (HR autoimmune vs non-autoinmunes: HR: 1.12 [0.6-2.02], p=0.7; HR IJD vs SAC; 1.42 [0.58-3.48], p=0.441; HR non-autoimmune vs SAC: 1.19 [0.52-2.68], P=0.677). Age (HR: 1.13; [1.10-1.15], p< 0.001), and the presence of comorbidities (HR: 2.43; [1.16-4.15], p=0.015) increased the Mortality risk.

Conclusion: In patients with RMD and COVID-19 infection, we found a mortality rate of 68.5 per 1000 persons-month. This study shows that the mortality risk related to COVID-19 is similar between autoimmune and non-autoimmune diseases after adjusting by confounders. We also found that age and comorbidities are risk factors for mortality related to COVID-19 infection.

Abstract Number: 1557

Immunogenicity and Safety of an Inactivated Virus Vaccine Against SARS-CoV-2 in Patients with Autoimmune Rheumatic Diseases

Ana Medeiros-Ribeiro[1], Nadia Aikawa[1], Carla Gonçalves Schahin Saad[1], Emily Figueiredo Vieira Neves Yuki[1], Tatiana do Nascimento Pedrosa[1], Solange Fusco[1], Priscila Rojo[1], Rosa Pereira[1], Samuel Shinjo[1], Danieli Andrade[1], Percival Sampaio-Barros[1], Carolina Ribeiro[1], Giordano Deveza[1], Victor Adriano de Oliveira Martins[1], Clovis Artur Silva[1], Marta Lopes[1], Alberto Duarte[1], Leila Antonangelo[1], Ester Sabino[1], Esper Kallas[1], Sandra Gofinet Pasoto[2] and Eloisa Bonfá[1], [1]Hospital das Clinicas da Faculdade de Medicina da Universidade de São Paulo, São Paulo, Brazil, [2]Hospital das Clinicas de Medicina da Universidade de São Paulo, São Paulo, Brazil

SESSION INFORMATION

Session Date: Tuesday, November 9, 2021
Session Title: Infection-related Rheumatic Disease Poster (1530–1564)
Session Type: Poster Session D
Session Time: 8:30AM–10:30AM

Background/Purpose: Brazil is among the countries with the highest numbers of confirmed cases and deaths by COVID-19. CoronaVac (SARS-CoV-2 inactivated vaccine) has been largely used as the main available immunogen for COVID-19 in several countries and it is reported to have 50.7% efficacy. However, its immunogenicity in immunocompromised individuals has not been established. The objective is to evaluate the immunogenicity and safety of the inactivated virus vaccine against SARS-CoV-2 (CoronaVac) in autoimmune rheumatic diseases (ARD) patients.

Methods: This was a prospective controlled study of 910 adult ARD patients and 182 age- and sex-matched control group (CG) who received two doses of CoronaVac. Both groups had negative serology and neutralizing antibodies for COVID-19 at baseline. **Anti-SARS-CoV-2 IgG and neutralizing antibodies (NAb) were assessed prior to each vaccine shot (D0 and D28) and 6 weeks after the 2nd dose (D69).** Blood samples were collected from all participants for quantitative serological testing for IgG antibodies against SARS-CoV-2 S1/S2 proteins (DiaSorin) and NAb (GenScript). The primary outcome was immunogenicity (seroconversion rate of anti-SARS-CoV-2 IgG, and frequency of patients with NAb) at D69. Geometric mean titers (GMT) and factor increase in GMT (FI-GMT) of anti-SARS-CoV-2 IgG, and median (interquartile) percentage of neutralizing activity of NAb were also calculated. ARD patients and CG were vaccinated with standardized schedule (**28-days interval)** and evaluated using COVID-19 symptoms and adverse events **(AE)** diaries, three face-to-face visits, and 24-hs available phone, Whatsapp and e-mail contact.

Table 1 - Seroconversion (SC) rates and anti-SARS-CoV-2 S1/S2 IgG titers before and after the first and second doses of CoronaVac vaccination in autoimmune rheumatic diseases (ARD) and Control Group (CG)

	Before vaccine 1st dose	After vaccine 1st dose			After vaccine 2nd dose		
	GMT	SC	GMT	FI-GMT	SC	GMT	FI-GMT
CG, n= 179	2.3 (2.1-2.4)	62 (34.6)	10.3 (8.5-12.5)$^{\text{Ŧ}}$	4.6 (3.9-5.4)	171 (95.5)	67.0 (59.8-74.9)$^{\text{Ŧβ}}$	29.7 (26.3-33.5)
ARD, n= 859	2.2 (2.2-2.3)	161 (18.7)*	5.1 (4.7-5.5)*$^{\#}$	2.3 (2.1-2.5)*	605 (70.4)*	27.0 (24.7-29.5)*$^{\#\alpha}$	12.1 (11.0-13.2)*
CIA, n= 430	2.2 (2.1-2.2)	64 (14.9)*	4.4 (4.0-4.9)*	2.1 (1.9-2.3)*	304 (70.7)*	26.3 (23.3-29.8)*	12.2 (10.8-13.8)*
Other ARD, n= 429	2.3 (2.2-2.4)	97 (22.7)*	5.9 (5.3-6.6)*	2.5 (2.3-2.8)*	301 (70.2)*	27.7 (24.3-31.6)*	12.0 (10.5-13.7)*

Results are expressed in geometric mean (95%CI) and n (%). GMT – Geometric mean titers (AU/mL); SC – seroconversion (defined as post vaccination titer > 15 AU/mL - Indirect ELISA, LIAISON® SARS-CoV-2 S1/S2 IgG, DiaSorin, Italy); FI-GMT – factor increase of Geometric mean titers; ARD – autoimmune rheumatic diseases; CG – control group; CIA – chronic inflammatory arthritis (rheumatoid arthritis, axial spondyloarthritis and psoriatic arthritis); Other ARD– systemic lupus erythematosus, primary vasculitis, systemic sclerosis, primary Sjögren syndrome, idiopathic inflammatory myopathies and primary antiphospholipid syndrome; * - p<0.001 in comparison among ARD and CG at the same time points; # - p<0.001 for longitudinal comparisons of GMT in ARD at D28 and D69 vs. baseline; α - p<0.001 for longitudinal comparison of GMT in ARD at D69 vs. D28; Ŧ - p<0.001 for longitudinal comparison of GMT in CG at D28 and D69 vs. baseline; β - p<0.001 for longitudinal comparison of GMT in CG at D69 vs. D28.

Table 2 – Frequency of neutralizing antibodies (NAb) and median percentage of neutralizing activity in positive cases, after the first and second doses of CoronaVac vaccination in autoimmune rheumatic diseases (ARD) in comparison to control group (CG).

	After vaccine 1st dose		After vaccine 2nd dose	
	Subjects with positive NAb, N (%)	Neutralizing activity (%) Median (interquartile range)	Subjects with positive NAb, N (%)	Neutralizing activity (%) Median (interquartile range)
CG, n=179	65 (36.3)	45 (34 .5-71.1)	142 (79.3)	64.5 (48.4-81.4)

Biologic therapy	112 (44.1)	195 (32.2)	**<0.001**	155 (41.3)	152 (31.4)	**0.003**

Results are expressed in median (interquartile range) and n (%). ARD – autoimmune rheumatic disease; CIA – chronic inflammatory arthritis (rheumatoid arthritis, axial spondyloarthritis and psoriatic arthritis); Other ARD – systemic lupus erythematosus, primary vasculitis, systemic sclerosis, primary Sjögren syndrome, idiopathic inflammatory myopathies and primary antiphospholipid syndrome. SC – seroconversion defined as a positive serology (IgG titer > 15 AU/ml) for anti-SARS-CoV-2 S1/S2 IgG antibodies after vaccination (Indirect ELISA, LIAISON® SARS-CoV-2 S1/S2 IgG, DiaSorin, Italy). Positivity for Nabs defined as a neutralizing activity ≥ 30 % (cPass sVNT Kit, GenScript, Piscataway, USA).

Symptomatic cases were tested by RT-PCR for SARS-CoV-2 and a subgroup of positive samples were evaluated for the presence of variants of concern (P.1, B.1.1.7, and B.1.351 lineages).

Results: We observed significant lower anti-SARS-Cov-2 IgG seroconversion (70.4% vs. 95.5%,p< 0.001) and GMT [12.1(95%CI 11.0-13.2) vs. 29.7(95%CI 26.3-33.5),p< 0.001], frequency of NAb (56.3% vs. 79.3%),p< 0.001) and median (interquartile range) neutralization activity [58.7(43.1-77.2)% vs. 64.5(48.4-81.4)%,p=0.013] in ARD patients compared to CG. Vaccine safety analysis revealed similar AE between the groups, with no moderate/severe event. Thirty-nine incident symptomatic cases of COVID-19 confirmed by RT-PCR were observed among ARD patients and CG [36/910 (4%) vs. 3/182 (1.6%), p=0.186] throughout the study. Frequency of cases occurring from D0-D39 (up to 10 days after the second dose) was higher compared to D40-D79 [33/1092 (3.0%) vs. 6/1057 (0.6%), p< 0.0001]. Four ARD patients were hospitalized (up to 10 days after second dose) and none deceased due to COVID-19.

Conclusion: CoronaVac has an excellent safety profile and reasonable rates of seroconversion (70.4%) and adequate neutralization activity (56.3%) in ARD patients. The impact of this reduced immunogenicity in vaccine effectiveness warrants further evaluation.

Therapy Based Outcomes in Patients with Multisystem Inflammatory Syndrome in Children: A Single Center Study

Diana Villacis Nunez[1], Kaitlin Jones[2], Lucie Fan[3], Whitney Moore[2], Aysha Jabbar[2], Matthew Oster[4], Preeti Jaggi[1] and Sampath Prahalad[5], [1]Emory University School of Medicine - Children's Healthcare of Atlanta, Atlanta, GA, [2]Children's Healthcare of Atlanta, Atlanta, GA, [3]Emory University School of Medicine, Atlanta, GA, [4]Emory University School of Medicine - Sibley Heart Center/Children's Healthcare of Atlanta, Atlanta, GA, [5]Emory + Children's Pediatric Institute, Atlanta, GA

SESSION INFORMATION
Session Date: Tuesday, November 9, 2021
Session Title: Infection-related Rheumatic Disease Poster (1530–1564)
Session Type: Poster Session D
Session Time: 8:30AM–10:30AM

Background/Purpose: Management and outcomes of multisystem inflammatory syndrome in children (MIS-C) remain under investigation and vary by institution. This study aimed to describe the outcomes of MIS-C patients treated at our center, and compare these outcomes based on initial management.

Methods: A single center retrospective study was conducted; all patients with MIS-C diagnosis between March 2020 and February 2021 were eligible. Demographic and clinical variables were collected. Patients were divided into 3 groups, based on immunomodulation within the first 24 hours of treatment initiation for patients in the intensive care unit (ICU), or 48 hours for non-ICU patients. The primary outcome was failure of initial therapy defined as need to escalate immunosuppression due to fever, worsening laboratory parameters, and/or lack of improvement/worsening

cardiac or non-cardiac findings. Secondary outcomes included duration of fever and vasoactive support, coronary aneurysms/dilation, length of ICU stay, hospital length of stay, readmission, and number of emergency room (ER) visits up to 6 months after discharge. Groups were compared using Kruskal Wallis test for continuous variables and Fisher/Chi-square test for categorical variables, employing R software. P values of ≤0.05 were considered statistically significant.

Results: Two-hundred and thirty-one MIS-C patients were identified. Patients who did not receive immunomodulation (n=5), required biologics within the first 24 hours (n=3), received intravenous immunoglobulin (IVIG) at another center

Table 1: Demographic features and outcomes of MIS-C patients according to therapy group

Category	Group 1: IVIG+ Steroids (n=116)	Group 2: IVIG alone (n=31)	Group 3: Steroids alone (n=69)	P value

Infliximab	2 (1.7)	0 (0.0)	1 (1.4)
IVIG (first dose)	0 (0.0)	0 (0.0)	10 (14.5)
IVIG (second dose)	19 (16.4)	3 (9.7)	1 (1.4)
Steroids (not pulse dosing)	4* (3.4)	12 (38.7)	1* (1.4)
Tocilizumab	2 (1.7)	0 (0.0)	0 (0.0)

Variables are expressed as n (percentage).
Abbreviations: IV: Intravenous; IVIG: Intravenous Immunoglobulin. *Re-initiation of steroid therapy after recurrence of symptoms post-discontinuation.

(n=3), or received therapy escalation without meeting the definition of failure of initial therapy (n=4) were excluded. Of the remaining 216 subjects, 116 received IVIG + steroids (Group 1), 31 received IVIG alone (Group 2), and 69 received steroids alone (Group 3) as initial therapy. Maximum initial steroid dose was methylprednisolone/prednisone 2 mg/kg/day. The groups differed in age and racial distribution; patients in group 3 were older ($p = 0.02$) and less frequently of African American race ($p = 0.01$). ICU status at the start of therapy was less frequent in group 3 (33.3%) vs group 1 (65.5%) and 2 (71%) ($p < 0.001$). Rates of initial therapy failure were lowest in group 3 (18.8% vs 30.2% and 54.8% for groups 1 and 2, respectively; $p = 0.001$). Group 3 had shorter duration of fever (median 5 days vs 6 days in group 1 and 2; $p = 0.002$), ICU length of stay (median 0 days vs 3 and 5 days for group 1 and 2, respectively; $p < 0.001$), and total length of stay (median 4 days vs 6 days in groups 1 and 2; $p < 0.001$). Vasoactive support duration was longer for group 1 (median 1 day vs 0 days for groups 2 and 3; $p < 0.001$). Coronary outcomes, need for readmission and ER visits post-discharge were similar between groups. All patients survived.

Conclusion: A subgroup of MIS-C patients was successfully treated with steroid monotherapy. This group was older, less frequently African American, likely had milder disease (less frequent ICU status), had lower rates of treatment failure and favorable secondary outcomes. For a subset of MIS-C patients, steroid monotherapy could be a suitable alternative to IVIG. Multivariate analysis controlling for severity and prospective studies are needed to further explore these findings.

SESSION INFORMATION

Session Date: Tuesday, November 9, 2021
Session Title: Infection-related Rheumatic Disease Poster (1530–1564)
Session Type: Poster Session D
Session Time: 8:30AM–10:30AM

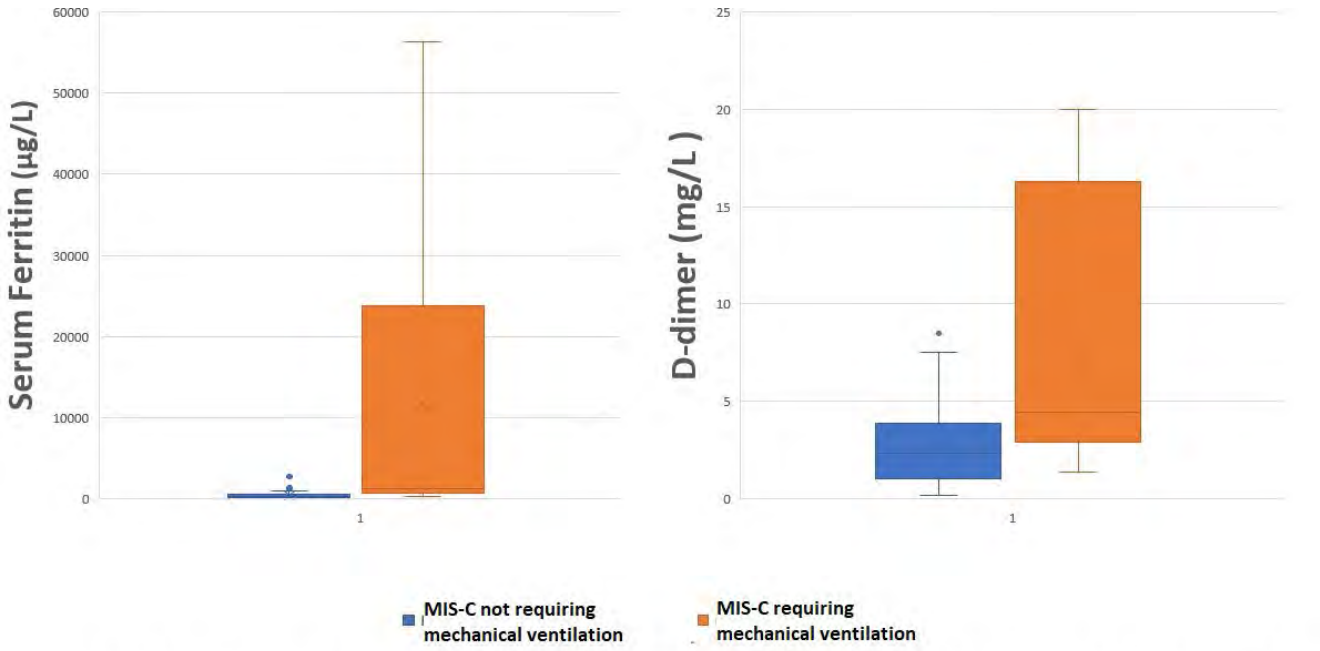
Background/Purpose: COVID-19 related multisystem inflammatory syndrome in children (MIS-C) has varied clinical presentation ranging from fever with mild gastrointestinal and/or mucocutaneous changes to life threatening multi-organ dysfunction. As it is a new disease and factors associated with development of severe MIS-C remain largely unknown. Hence, we planned this study to identify parameters associated with requirement of mechanical ventilation in diagnosed cases of MIS-C.

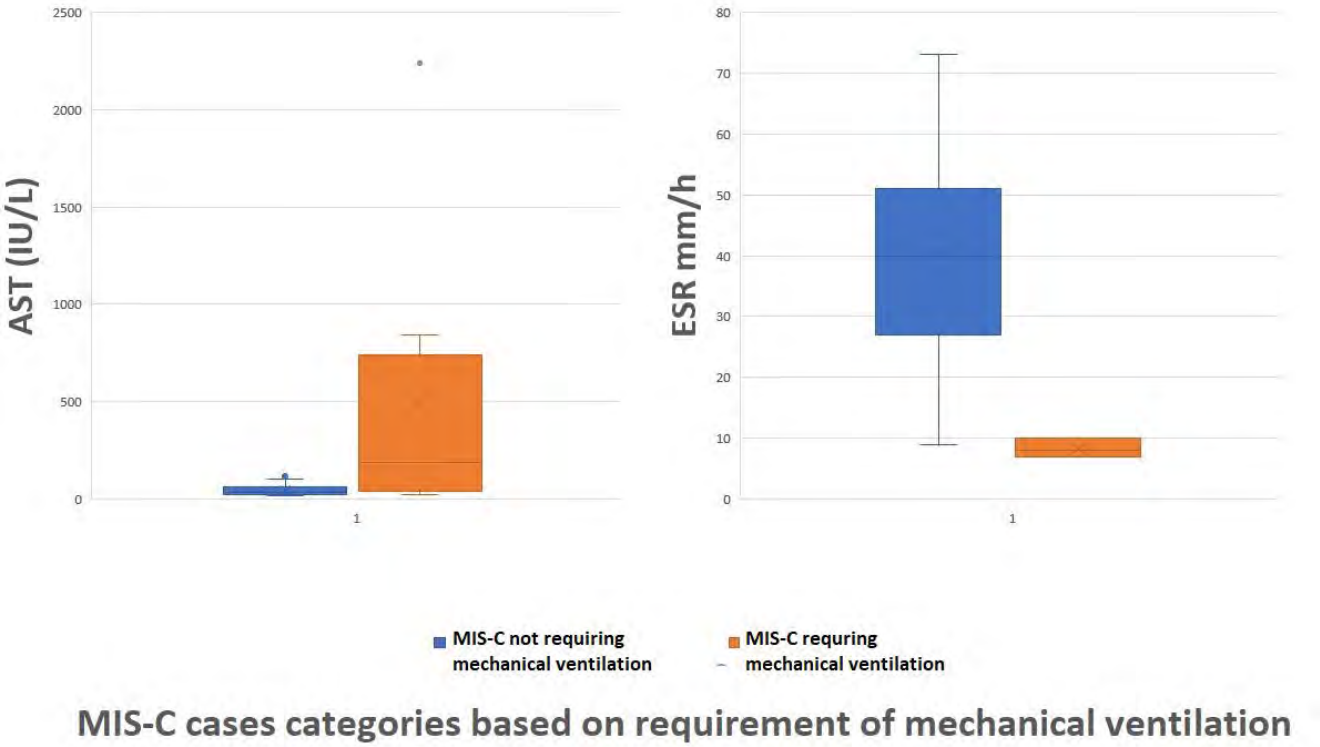
Bivariate Comparison of various clinical and laboratory parameters in MIS-C cases who required mechanical ventilation versus those who did not require mechanical ventilation *

Clinical and laboratory parameters of MIS-C cases	**Mechanical ventilation required (n = 8)**	**Mechanical ventilation not required (n = 33)**	**p-value** ‡
Presence of shock requiring inotropic agents-no.(%)	7 (88)	14 (42)	**0.045**
Median D-dimer mg/L (IQR)	4.5 (2.9-16.3)	2.3 (1.0-3.9)	**0.016**
Median serum ferritin µg/L (IQR)	1178.0 (717.0-23840.0)	266.0 (153.0-555.0)	**0.001**
Median ESR mm/h (IQR)	8.0 (7.0-10.0)	40 (27-51)	**0.016**
- no./total no. (%)	3/8 (38)	11/33 (33)	
Median serum AST IU/L (IQR)	188.0 (37.8-741.2)	33.0 (26.0-60.5)	**0.008**
Median serum procalcitonin µg/L (IQR)	5.4 (2.1-41.5)	11.1(1.6- 51.0)	0.716
- no./total no. (%)	4/8 (50)	12/33 (36)	
Median serum NT-proBNP pg/mL (IQR)	3533.5 (2141.5-46767.5)	1138.0 (349.0-6725.0)	0.096
- no./total no. (%)	6/8 (75)	13/33 (39)	
Median serum troponin ng/L (IQR)	55.2 (14.5-945.3)	15.0 (4.8-29.2)	0.143
- no./total no. (%)	4/8 (50)	26/33 (78)	
Median absolute lymphocyte count (IQR)	825 (521-2218)	1588 (895-3489)	0.061
Lymphopenia at admission -no. (%)§	7 (88)	19 (58)	0.220
Mean CRP mg/L ± SD	101.0 ± 85.3	123 ± 78.9	0.474
Median serum ALT IU/L (IQR)	141.0 (25.0-543.0)	29.0 (21.0-43.5)	0.113
Presence of coronary abnormalities - no. (%)	4 (50)	11 (33)	0.434
Presence of LV dysfunction - no. (%)	3 (38)	7 (21)	0.378

* Percentages may not total 100 because of rounding. IQR denotes interquartile range showing 25th and 75th centiles, ESR erythrocyte sedimentation rate, AST aspartate aminotransferase, NT-ProBNP N-terminal pro–B-type natriuretic peptide, CRP C-reactive protein, SD standard deviation, and ALT alanine aminotransferase.
‡ p-value was calculated by applying appropriate statistical tests according to the distribution of the data. Independent sample t-test or Mann-Whitney tests were applied to compare the potential markers of severity. A p-value of <0.05 was considered statistically significant.
§ Lymphopenia defined as <3000 lymphocytes/µL (<2 years age) , <1500 lymphocytes/µL (2-12 years age), and <1000 lymphocytes/µL (>12 years age).

Bivariate Comparison of various clinical and laboratory parameters in MIS-C cases who required mechanical ventilation versus those who did not require mechanical ventilation





Comparison of selected laboratory parameters in MIS-C cases who required mechanical ventilation versus those who did not

Methods: It was a cohort study conducted at two tertiary care centres in Kerala state of south India from March 2020 to April 2021. Cases diagnosed with MIS-C as per centres for disease control and prevention (CDC) case definitions were enrolled and studied for clinical profile. MIS-C cases were further categorised based on requirement of mechanical ventilation and these groups were compared for baseline clinical characteristics, laboratory parameters and echocardiographic changes in order to identify parameters associated with requirement of mechanical ventilation. Pearson Chi-Square test or Fisher's exact test to compare the categorical variables and the independent sample t-test or Mann-Whitney test were used to compare the continuous variables by age group and severity.

Results: A total of 41 (males-23) cases diagnosed of MIS-C were enrolled in the study. The mean age at onset of MIS-C was 6.16 (SD-4.0) years. Their clinical profile was studied in age categories of less than 5 years, 5-12 years, and more than 12 years. Cases were divided into syndrome clusters of dermatological or mucocutaneous changes, gastrointestinal symptoms, Incomplete or atypical Kawasaki disease. Shock, macrophage activation syndrome (MAS), neurological symptoms, and respiratory symptoms. The heat map of these syndrome clusters in different age groups is shown in figure 1.

MIS-C cases were categorised into two groups based on requirement of mechanical ventilation; 8 (20%) cases required mechanical ventilation whereas 33 (80%) cases did not require ventilatory support. These groups were compared for various clinical, laboratory and echocardiographic parameters shown in figure 2. Out of 8 patients who required mechanical ventilation, 7(88%) had presented in shock treated with ionotropic agents, whereas out of 33 cases who did not require mechanical ventilation 14 (42%) had presented in shock necessitating use of ionotropic agents; the difference was statistically significant ($p=0.045$). Serum D-dimer, serum ferritin, and aspartate aminotransferase (AST) were significantly high and erythrocyte sedimentation rate (ESR) was significantly low in patients of MIS-C requiring ventilatory support as compared to them who did not require it ($p < 0.05$), graphical representation of statistically significant parameters is shown in figure 3.

Conclusion: In our study we found that the presence of shock requiring inotropic agent, high ferritin, high D-dimer, high AST, and low ESR were associated with the requirement of mechanical ventilation in MISC cases ($p< 0.05$). The constellations of these parameters could reflect an ongoing process of Macrophage Activation Syndrome (MAS) in MIS-C cases requiring mechanical ventilation.

Abstract Number: 1560

A Multidisciplinary Timely Approach to Initiate Immunosuppressive Biologic Therapy and Improve COVID-19 Cytokine Storm Syndrome Outcome

Anand Kumthekar[1] and **Bibi Ayesha**[2], [1]Albert Einstein College of Medicine, Bronx, NY, [2]Montefiore Medical Center, Bronx, NY

SESSION INFORMATION
Session Date: Tuesday, November 9, 2021
Session Title: Infection-related Rheumatic Disease Poster (1530–1564)
Session Type: Poster Session D
Session Time: 8:30AM–10:30AM

Background/Purpose: Coronavirus disease (COVID-19) patients can progress to a state of unregulated inflammation called cytokine storm syndrome (CSS). A multi-disciplinary approach is needed to identify COVID-19 patients

at risk of CSS. Therapy with corticosteroids, anti-interleukin-1 (anti IL-1) and anti-interluekin-6 (anti-IL 6) reduce the systemic inflammatory response, which can prevent rapid progression of cytokine mediated diffuse alveolar damage. There is extremely limited literature on the safety and efficacy of biologic immunosuppressive therapy in COVID-19 patients. Till date there are no formal guidelines, as when to initiate immunosuppressive therapy in COVID-19 patients

Methods: Institutional experts from different sub-specialities formed a COVID-19 CSS task force at Montefiore Medical Center, Bronx, NY. Consensus recommendations regarding biologic therapy were made after daily multi-disciplinary virtual conference. This is a single center retrospective observational study, where we describe the baseline characteristics, clinical and laboratory parameters, and the outcome of our COVID-19 CSS consult cohort patients who received biologic immunosuppressive therapy either anti IL-1 and/or anti IL-6.

Results: Between April 4,2020 and May 7,2020, the CSS consult service evaluated a total of 288 patients for possible COVID-19 CSS, out of these 35 patients received biologic immunosuppressive therapy either anti IL-1 and/or anti IL-6. Among these 35 patients 4 patients received the biologic therapy on admission prior to COVID-19 CSS consult task force consultation and the 31 patients received the biologic therapy after the COVID-19 CSS task force consultation. Fifteen patients (83%) received anti IL-1 therapy, 18 patients (51%) received anti-IL6 therapy and 2 patients (6%) received both. Eleven patients (31%) receiving biologic immunosuppressive therapy survived. The patients who survived were younger with a median age of 42 years versus 55 years in the non-survivor group (p=0.04). A higher proportion of patients who survived, had earlier multidisciplinary CSS task force consultation on day 4 (IQR – 2-12 days) after admission as compared to day 6.5 (IQR- 3-11 days)in the non-survivor group.

Conclusion: We describe a unique approach from our institution where an earlier multi-disciplinary COVID-19 CSS task force consultation on the COVID-19 patients progressing towards CSS, could help alter the disease course by timely intervention with biologic therapy.

Abstract Number: 1561

Prevalence of SARS-CoV2 Infection in Diseases Inflammatory Rheumatology in the Rheumatology Service of the Hospital Docente Padre Billini, Dominican Republic

Jennifer Santana Peralta de Heyaime, Teresandris Polanco Mora, Angelo Cornelio Vasquez, Yamilet Cruz, Edral Rodriguez, Tirso Valdez Lorie, Roberto Munoz and Rafael Alba Feriz, Hospital Docente Padre Billini, Santo Domingo, Dominican Republic

SESSION INFORMATION
Session Date: Tuesday, November 9, 2021
Session Title: Infection-related Rheumatic Disease Poster (1530–1564)
Session Type: Poster Session D
Session Time: 8:30AM–10:30AM

Background/Purpose: SARS-CoV-2 infection is caused by a new coronavirus. The World Health Organization (WHO) had information about the existence of this new virus on December 31, 2019 in Wuhan, China. Common symptoms are fever, cough, dyspnea, and fatigue 1. There is a lack of data to understand the evolution of the disease in patients with inflammatory rheumatological diseases, especially in those undergoing treatment with immunosuppressants or biological therapy 2. It is unknown whether rheumatology patients are a vulnerable population. 3 Overall,

this population appears to have similar or only slightly worse outcomes compared to those without rheumatologic disease. 4,5,6

Methods: Observational, prospective, longitudinal study. Personal and telephone interviews were conducted with patients from the rheumatology service from June 2020 to February 2021. Inclusion criteria: 1) > 18 years of age, 2) History of SARS-CoV2 infection diagnosed by PCR and / or compatible CT, 3) Diagnosis of a rheumatological pathology based on classification criteria. Data were analyzed with SPSS V23.

Results: Of 4,416 consultations, 3,633 met the classification criteria for inflammatory rheumatological disease and 2,040 were in biological treatment. 44 patients met the inclusion criteria. Diagnosis by CoV-2 by PCR 38 and 6 by compatible chest CT. 35 female. The average age 55.3 +17.8 years. Mean time of illness was 7.9 +5.3 years. Rheumatological diagnoses: Rheumatoid arthritis 47.72% (21), Systemic lupus erythematosus 21.95% (9), Axial spondyloarthritis 12.19% (5), Psoriatic arthritis 9.75% (4), Reactive arthritis 5.88% (2), Juvenile idiopathic arthritis 2.94% (1), Adult Still's disease 2.94% (1), Sjögren's syndrome 2.94% (1). Biological treatment in 61.36% (27): Anti-TNF 40.74% (11), Tocilizumab 33.33% (9), anti-IL12 / 23 14.81% (4), Tofacitinib 7.40% (2), anti CD20 3.70% (1). Treatment with csDMARD 38.63% (17), glucocorticoids 9 with a mean dose of 5mg. Comorbidities: 29.54% (13) hypertensive, 15.9% (7) diabetic, 2.27% (1) interstitial lung disease, 2.27% (1) asthma, 6.81% (3) obese. There was one hospitalization and one death during the study period in a patient with systemic lupus erythematosus.

Conclusion: Our study showed that there is no increased risk of Sars-CoV2 infection or increased severity of the disease in patients with rheumatological inflammatory pathology compared to the general population.

B Cell Reconstitution Is Strongly Associated with COVID-19 Vaccine Responsiveness in Rheumatic Disease Patients Treated with Rituximab

Sarah Jinich, Deanna Jannat-Khah and Robert Spiera, Hospital for Special Surgery, New York, NY

SESSION INFORMATION
Session Date: Tuesday, November 9, 2021
Session Title: Infection-related Rheumatic Disease Poster (1530–1564)
Session Type: Poster Session D
Session Time: 8:30AM–10:30AM

Background/Purpose: Rituximab (RTX) has previously been shown to impair antibody response to vaccines such as influenza and streptococcus. Recently, diminished COVID-19 vaccine responsiveness in RTX treated patients has been reported. While COVID-19 vaccination guidelines have adopted time since last RTX infusion as a consideration for likelihood of vaccine responsiveness, a retrospective study suggested that B Cell reconstitution may be a more accurate predictor of vaccine response. Our hypothesis was that B Cell reconstitution would be associated with vaccine responsiveness.

Methods: A retrospective chart review was performed to assess patients that visited a rheumatology practice from 2/24-5/20, 2021. Analysis included patients who had received treatment with RTX and had completed COVID-19 vac-

cination. Demographics, diagnoses, concurrent therapies, vaccine type/dates, time from last RTX to first vaccination quantitative serological vaccine response, and % CD19 positive cells in the lymphocyte population were collected. COVID-19 serological response was the primary outcome. Descriptive statistics and bivariate comparisons were

Factor	Value	Negative for antibody response	Positive for antibody response	p-value*

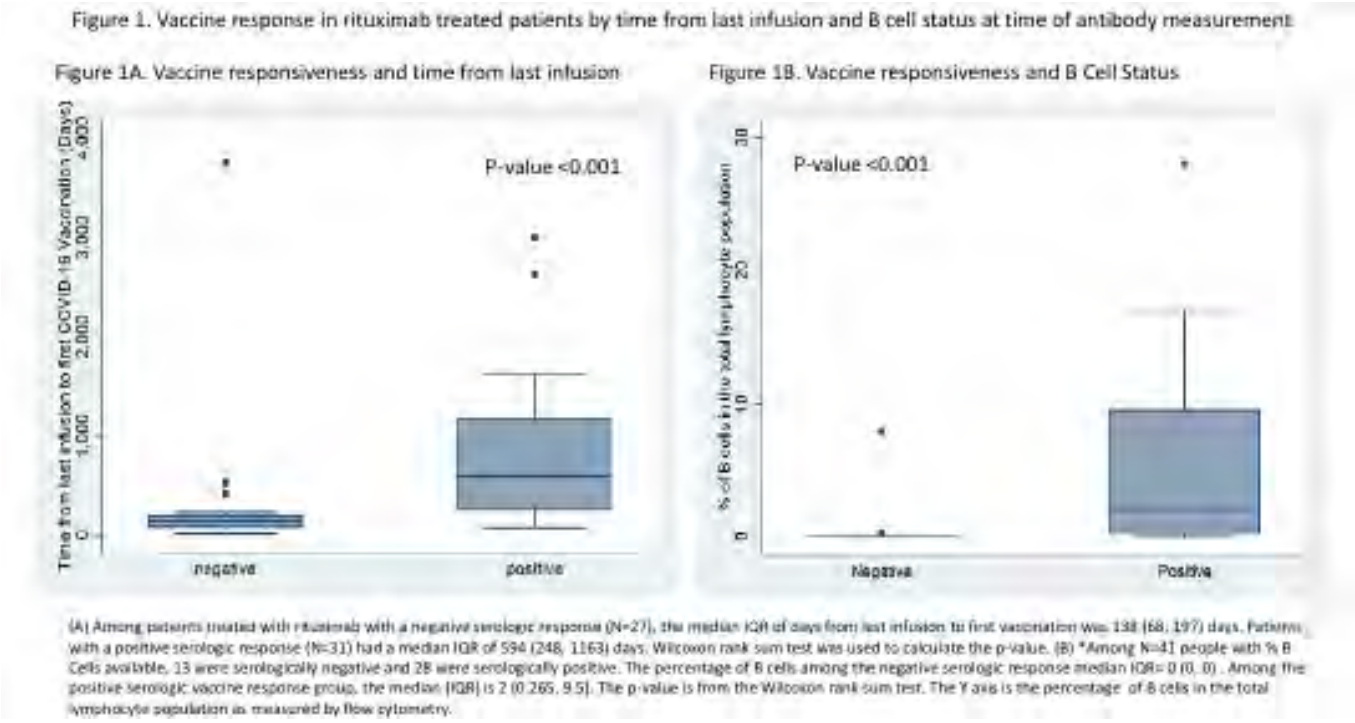
[a] N=54 (93%) had seropositivity measured by Roche Elecsys Anti-SARS-CoV-2, specificity 99.8% sensitivity 99.5%,, N=4 (7%) had seropositivity measured by Siemens Healthineers SARS-CoV-2 total (COV2T) Assay Atellica IM, specificity 99.82% sensitivity 100% or ADVIA Centaur XP/XPT, specificity 99.81% sensitivity 100%

performed. Negative and positive predictive value was calculated between COVID-19 serological response and B Cell reconstitution status.

Results: 58 patients were identified who met criteria for inclusion. The majority were female (40, 69%), white (52, 90%), and the mean age was 62.67 years (Table 1).

41 patients (71%) had B Cell status measured at time of antibody immunoassay. Time from last RTX was significantly longer in seropositive (median #days, IQR 594 (248, 1163) patients compared to seronegative patients

Figure 1. Vaccine response in rituximab treated patients by time from last infusion and B cell status at time of antibody measurement



(A) Among patients treated with rituximab with a negative serologic response (N=27), the median IQR of days from last infusion to first vaccination was 138 (68, 197) days. Patients with a positive serologic response (N=31) had a median IQR of 594 (248, 1163) days. Wilcoxon rank sum test was used to calculate the p-value. (B) *Among N=41 people with % B Cells available, 13 were serologically negative and 28 were serologically positive. The percentage of B cells among the negative serologic response median IQR= 0 (0, 0) . Among the positive serologic vaccine response group, the median (IQR) is 2 (0.265, 9.5). The p-value is from the Wilcoxon rank sum test. The Y axis is the percentage of B cells in the total lymphocyte population as measured by flow cytometry.

(median #days, IQR 138 (68, 197) days) (p-value < 0.001). There was a significant difference in B Cell reconstitution between patients who had positive antibody responses to vaccination (median, IQR 2 (0.265-9.5) % of total lymphocyte population) versus negative responses (median, IQR 0 (0-0) % (p< 0.001) (Table 2). Only 12% (3/25) of patients >12 months since last RTX did not demonstrate a serologic responses, whereas 24% of patients (9/37) > 6 months since last RTX and 50% (6/12) of those 6-12 months from last RTX did not have a serologic response to the vaccine (Figure 1. Table 2).

B Cell reconstitution and time from last RTX were both significant indicators of vaccine response. (Figure 1). Seropositivity was 76% among those >6 months from last RTX exposure, however that increases to 92% in those with detectable B Cells (p=0.006). In patients 6-12 months from RTX exposure, only 50% were seropositive, however that increases to 83.33% in those with detectable B Cells (p=0.190) The positive predictive value of B Cell reconstitution for COVID-19 serologic response was 92% (95%CI: 74%-99%) and the negative predictive value was 68.8% (95%CI: 41.3%-89%).

Conclusion: B Cell reconstitution and longer time from last RTX were associated with a positive serologic response to the COVID-19 vaccine. A substantial number of patients >6 months from last RTX did not have a serologic response, and B cell reconstitution increased the likelihood of a response. Strategies for maximizing vaccine responsiveness in RTX treated patients should incorporate B Cell reconstitution and time from last RTX.

SESSION INFORMATION

Session Date: Tuesday, November 9, 2021

Session Title: Infection-related Rheumatic Disease Poster (1530–1564)

Session Type: Poster Session D

Session Time: 8:30AM–10:30AM

Background/Purpose: Septic bursitis (SB) is a common medical problem. However, there are no current guidelines for managing the condition. The study aims to describe the clinical characteristics and management of olecranon and patellar septic bursitis in five French tertiary care centers.

Methods: We performed a retrospective multicenter study. Patients over the age of 18 years requiring hospitalization for olecranon or prepatellar SB from January 1, 2016 to December 31, 2018 were included. SB was diagnosed on the basis of positive cultures of bursal aspirate. In the absence of positive bursal fluid, the diagnosis came from typical clinical presentation, exclusion of other causes of bursitis, and favorable response to antibiotic therapy. The following characteristics were collected: age, gender, occupation, and comorbidities, date of diagnosis, presence of fever > 38.5°C, extensive cellulitis and skin lesion, and NSAIDs intake during the episode. Finally, the results of biological tests (CRP, bursal fluid and blood cultures), management (antibiotic type, route and duration of administration, surgical drainage) and outcomes were obtained from patients' charts. We considered the condition to be healed on the basis of data from follow-up consultations when the patient's symptoms had resolved (pain, fever, skin lesions) or if the patients did not need to be referred again by their general practitioner. For statistics, quantitative data were compared using a Mann-Whitney test, and a Chi square test (or Fisher's exact test for values < 5) was used for qualitative data. Values of $p < 0.05$ were considered significant.

Results: We included 272 patients (median age: 53, 85.3% male, manual occupation for 30.8% and 22.8% with at least one comorbidity). Fifty-one patients were taking NSAIDs to manage symptoms before diagnosis (18.3%). Fever was reported in 91 patients (33.4%) and a history of preceding knee/elbow injury or skin lesion was found in 161 patients (59.3 %). Median CRP level was 98.3 mg/L (range: 0-330). The bursal fluid was aspirated by puncture in 172 patients (63.2%) and collected during surgery in 51 patients (18.8%), while 49 patients (18%) were managed without bursal fluid analysis. A microorganism was identified in 80% of the samples (180/223). Bursal fluid analysis identified staphylococci in 73.4% and streptococci in 19%. Antibiotic treatment was initially administered intravenously (IV) in 41%, and this route was preferred in case of fever (p=0.003) or extensive cellulitis (p=0.002). When treatment was started IV, amoxicillin/clavulanate and oxa-/cloxacillin were most commonly given. When it was started orally, amoxicillin/clavulanate (44.7%) and pristinamycin (34%) were the most prescribed treatments. Twenty-six percent of patients (N=71) were treated surgically. A low failure rate was observed (N=16/272, 5.9%) and failures were more frequent when the antibiotic therapy lasted less than 14 days (p=0.02) in both surgically- and medically-treated patients.

Conclusion: Despite variable treatments, SB resolved in the majority of cases even when the treatment was exclusively medical. Antibiotic therapy shorter than 14 days was associated with more failures.

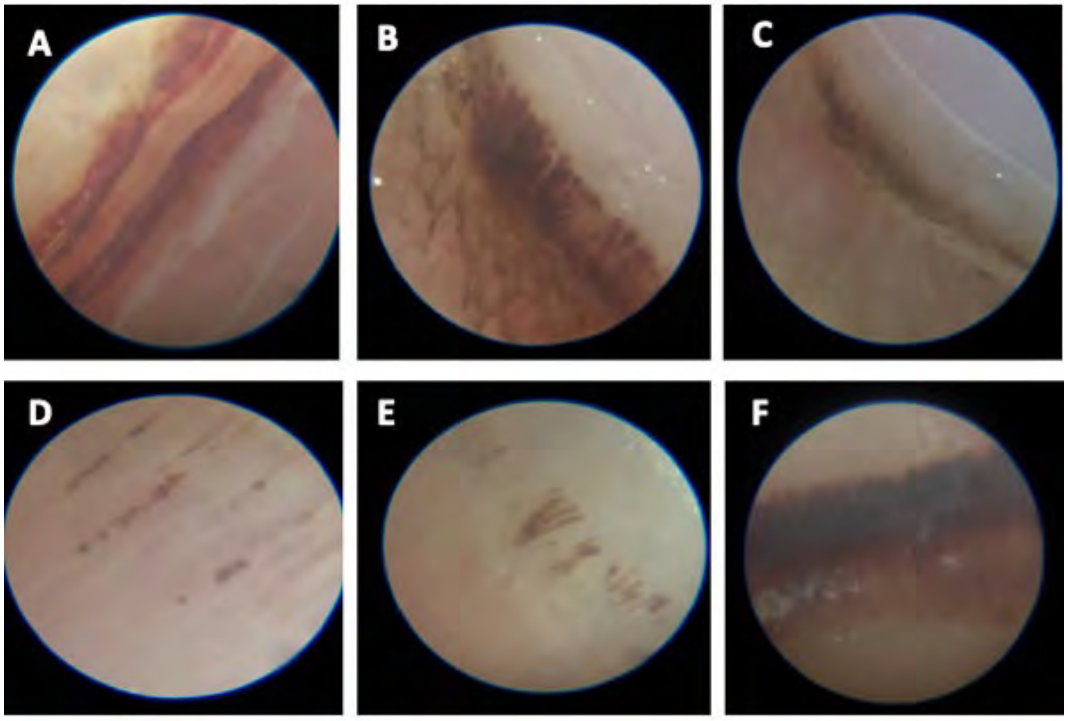
SESSION INFORMATION
Session Date: Tuesday, November 9, 2021
Session Title: Infection-related Rheumatic Disease Poster (1530–1564)
Session Type: Poster Session D
Session Time: 8:30AM–10:30AM

Background/Purpose: Nailfold capillaroscopy is a relatively easy-to-access, low-cost clinical tool that could help identify early coagulopathy in subjects with SARS-CoV-2, but specific findings vs. controls and its possible prognostic role has not been studied.

Methods: We designed a cross-sectional study, carried out in a single care center for critical patients with SARS-CoV-2 pneumonia at the ABC Medical Center, Mexico City, which included patients from an intensive care unit (ICU) and internal medicine ward from March to April 2020. Demographic, biochemical and clinical features were collected. All patients signed the informed consent and the study was approved by the hospital ethics committee. All patients underwent nail capillary imaging of the 3 central fingers of each hand with a portable microscope with 100x magnification coupled to a smartphone with 7 megapixel images in an immersion medium. Capillaroscopy was performed in patients who didn´t have fever or hypothermia, or need vasopressors at the time of evaluation. Control subjects are healthy subjects matched on age and sex from a database of healthy controls without rheumatic diseases. Image evaluation of COVID-19 patients was performed in a blinded way for their characteristics. Prior to the analysis, a pilot test was obtained with 4 rheumatologists in random cases, obtaining an acceptable global agreement in the visualization of capillaries and alterations. (Kappa=0.58, p=0.0019). Obtained data from capillaroscopies were used to be compared between severe and moderate cases of COVID-19. Additionally, we compared the findings against a healthy population in order to establish a reference.

Results: We included data from 27 patients and 32 controls with similar demographic features. Patients with COVID-19 patients had a mean age of 43 +/- 13.8 years, 63% female. Comorbidities were present in 44.4% with: type 2 Diabetes Mellitus 18.5%, systemic hypertension 18.5%, and rheumatoid arthritis 3.7%. The mean length of stay time was 13 +/- 7.1 days, 48.1% were admitted to the ICU, and 40.7% required invasive mechanical ventilation. In the capillaroscopic review remarkable findings of patients vs. controls were hemosiderin deposits (33 vs 12.5%, p=0.05), less frequently observable capillaries (77 vs 100%, p=0.005), any abnormality in capillaries (25.9 vs. 6.3%, p=0.03). Of notice, specific findings in COVID-19 patients were capillary tortuosities in 19%, dilatation 9.5%, serpentine pattern 4.8%, bush pattern 9.5% and decreased density in only 4.8% of the cases. Avascular areas or capillaries of ne-



Description: A. Extensive NB hemorrhage. B. Deposition of hemosiderin in multiple capillaries of the NB. C. Linear deposition of hemosiderin in the NB. D and E. Deposition of hemosiderin in some capillaries in the NB. F. Extensive hemorrhage accompanied by hemosiderin deposition in a large area of the NB.

oformation were not observed. The presence of hemosiderin was associated with worse presentation and risk factors for severe COVID-19: male sex 66.7 vs. 27.8%, (p = 0.024); Admission to ICU 77% vs 33% (p = 0.029); obesity 66.7 vs. 27.8% (p = 0.053). And risk for ICU admission OR = 7.0 (95% CI 1.098 - 44.6).

Conclusion: We present one of the first reports of nailfold capillaroscopic findings in COVID- 19 and the first to compare to healthy controls. Previous data suggests the presence of endothelial dysfunction and microvascular complications such as micro hemorrhage or micro thrombosis. Further studies may confirm these findings and prognostic value for worse outcomes in this illness.

Causal Mediation Analysis of the Relationship of Canakinumab's Protective Effect Against Gout Flares and High-sensitivity C-reactive Protein in the CANTOS Trial

Kazuki Yoshida[1], Robert J. Glynn[1], Hyon K. Choi[2], Brendan M. Everett[1], Yi Li[3], Jean G. MacFadyen[1], Paul M. Ridker[1] and DH Solomon[1], [1]Brigham and Women's Hospital, Boston, MA, [2]Massachusetts General Hospital, Lexington, MA, [3]Harvard T.H. Chan School of Public Health, Boston, MA

SESSION INFORMATION
Session Date: Tuesday, November 9, 2021
Session Title: Metabolic & Crystal Arthropathies – Basic & Clinical Science Poster II (1565–1583)
Session Type: Poster Session D
Session Time: 8:30AM–10:30AM

Background/Purpose: Previous analyses in the CANTOS trial demonstrated a benefit of canakinumab (CAN; IL-1β inhibitor) on gout flares. We aimed to quantify the mediating role of early inflammatory suppression of high sensitivity C-reactive protein (hsCRP) in explaining the protective role of CAN. If mediation is substantial, hsCRP may be a useful biomarker indicating treatment benefit.

Methods: We conducted a post-hoc analysis for gout flares in CANTOS, an RCT originally undertaken to examine the potential CV benefit of CAN compared to placebo. Our outcome of interest was time to first gout flare after hsCRP and other biomarkers, measured at 3 months. Based on previous analyses with similar gout benefits, we combined 3 different dosages of CAN.

We examined several biomarkers as mediators that may explain some proportion of the protective effect of CAN on future gout flares. hsCRP was the main biomarker of interest. We also analyzed serum urate (SU) as a "negative control mediator" (i.e., not expected to mediate CAN effect but known risk factor for gout flare). In approximately 50% of patients in the biomarker cohort, we also examined IL-6 (hypothesized to be like hsCRP) and IL-18 (not affected by CAN like SU).

We used the regression-based causal mediation analysis. The 3-month change in the log biomarker was the mediator and its relationship with CAN was examined in linear regression. We used Cox regression for the gout flare outcome modeling. We estimated the total effect (TE), natural direct effect (NDE; non-mediated part of TE), natural indirect effect (NIE; mediated part of TE), and proportion mediated (PM). On the hazard ratio (HR) scale, TE=NDE×NIE. We examined the cohort overall as well as stratified by prevalent gout at baseline.

Results: 9,221 patients without known prevalent gout at baseline and 747 with a known prevalent f gout were analyzed. Unadjusted analyses (Table 1) showed similar relative protective effects of CAN on future gout flares regardless of baseline gout. **Figure 1** shows that CAN is associated with early decreases of hsCRP and IL-6, but not SU or IL-18.

Table 2 summarizes the mediation results. As hypothesized, SU and IL-18 analyses consistently gave near-zero PM estimates. For the hsCRP analysis, the overall cohort result was HR 0.51=0.54×0.94, giving a PM of 6%. Mediation was inconsistent in the no prevalent gout cohort (HR 0.44=0.41×1.06). Upon closer examination, this unclear mediation was due to the poor prediction of future gout flare by the first 3-month change in hsCRP with CAN. In the gout

Table 1. Gout flare event rates in the study sample during the follow-up after 3-month biomarker measurement.

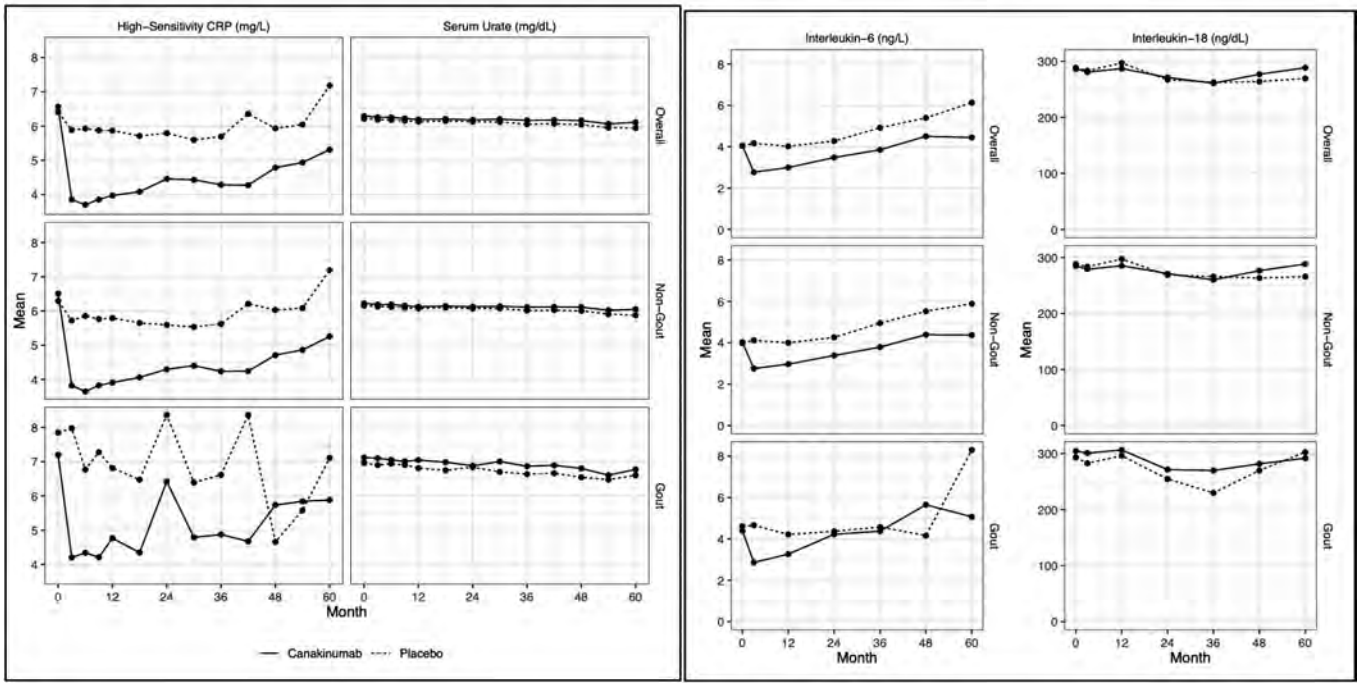
The TE HR represents the overall benefit of canakinumab compared to placebo on suppressing subsequent gout flare. It "decomposes" multiplicatively as follows: TE=NDE×NIE.

Abbreviations: Δ log hsCRP 3mo: difference of log high sensitivity C-reactive protein at 3 months and baseline; Δ log SU 3mo: difference of log serum urate at 3 months and baseline.

* A negative proportion mediated estimate can arise in cases where NDE and NIE estimates differ in the direction. These are not meaningfully interpretable but were presented for reference.

Figure 1. Mean biomarker values over time by study cohorts and treatment groups.



cohort, HR 0.61=0.74×0.82 (PM35%). This mediation was primarily driven by the interaction between be CAN and hsCRP reduction in the outcome model. That is, the first 3-month hsCRP reduction, when driven by CAN, is protective of gout flares. The overall cohort IL-6 analysis was similar although subgroup results did not concur.

Conclusion: The first 3-month reduction in hsCRP explained 6% of its protective effect on future gout flare suppression with a larger proportion mediated (35%) among prevalent gout patients. There may be a potential role of early hsCRP reduction under canakinumab therapy as a treatment benefit biomarker for future gout flares in addition to its role as a treatment benefit biomarker for future CVD.

Hyperuricemia Is Associated with Vascular Endothelial Dysfunction – the Impact of Hyperuricemia on Flow Mediated and Nitroglycerin Mediated Dilatation of the Brachial Artery

Rachael Flood, Colm Kirby, David Kane and Ronan Mullan, Tallaght University Hospital, Dublin, Ireland

SESSION INFORMATION
Session Date: Tuesday, November 9, 2021
Session Title: Metabolic & Crystal Arthropathies – Basic & Clinical Science Poster II (1565–1583)
Session Type: Poster Session D
Session Time: 8:30AM–10:30AM

Background/Purpose: Vascular endothelial cells line the entire circulatory system, these cells have very distinct and unique functions that are paramount to vascular biology. Hyperuricemia has been associated with vascular endothelial dysfunction (ED) in cardiovascular disease. Elevated serum urate (sUA) has been shown to directly impair vascular endothelial cell function through inhibition of nitric oxide. While direct measurement of impaired endothelial-dependent dilation during coronary angiography remains the historical "gold-standard", other approaches, including the measurement of brachial artery diameter via non-invasive ultrasound imaging, has been validated both as a sensitive predictor and surrogate endpoint in cardiovascular risk reduction interventional studies. Close concordance between these measurements with coronary artery endothelial-dependent vasodilation have been established. Our objective was to compare vascular endothelial cell function in hyperuricemic patients with normouricemic controls via flow mediated dilatation (FMD) and nitroglycerin mediated dilatation (NMD) of the brachial artery and the subsequent effect of treatment with urate lowering therapy (ULT).

Methods: Following informed consent hyperuricemic individuals (N = 34) underwent FMD and NMD studies of the brachial artery. Results were compared to age and sex matched normouricemic controls (N=16). Changes in brachial artery diameter were expressed as percentage change relative to the baseline vessel diameter. Those who met the criteria for commencement of ULT underwent repeat studies after a period of three months (N=28) treatment with febuxostat or allopurinol.

Results: 34 patients with hyperuricemia (sUA > 380umol/L) and 16 normouricemic controls were recruited and consented for the study. Mean sUA was 472 and 283 umol/L in the case versus control group respectively. There was no significant difference in mean age (Mean± SD) (50.35± 15.56 v 42.44±12.96) estimated glomerular filtration rate ml/min/1.73m^2 (91.82± 16.79 v 94.03±18.75) or total cholesterol (4.86± 1.25 v 4.73±0.72) between cases and controls respectively however there was a significantly greater (P< 0.05) BMI kg/m2 (33.45± 6.9 v 25.94±3.8) in cases. Cases had significantly impaired (P< 0.05) FMD (11.05± 8.71 v 17.26±8.42) and NMD (19.56± 9.15 v 34.16±9.26) when compared with controls. 28 cases underwent treatment with ULT and repeat FMD and NMD studies post 3 months of therapy, there was a trend toward improved of NMD (22.95 ±7.04) but this was not significant.

Parameter (Mean, SD)	Case (N = 34)	Control (N= 16)

IHD (N, %)	1 (3)	1 (6.3)
Malignancy (N, %)	1 (3)	0
BMI (kg/m2)	33.45 (6.96)*	25.94 (3.8)

Table 1: Case and Control Baseline Data.

SD – Standard Deviation. eGFR- Estimated Glomerular Filtration Rate. CRP- C Reactive Protein. ESR – Erythrocyte Sedimentation Rate. CKD – Chronic Kidney Disease. IHD – Ischaemic Heart Disease. BMI – Body Mass Index.

- * = P < 0.05.

Conclusion: These results suggest that hyperuricemia is associated with impaired vascular endothelial dysfunction which may contribute to the increased risk of cardiovascular disease in this cohort of patients.

Abstract Number: 1567

Pharmacokinetics and Pharmacodynamics of Anthocyanins After Oral Administration of Oral Tart Cherry Juice Concentrate to Gout Patients

Luigi Brunetti[1], Lujing Wang[2], Andrew Wassef[2], Anita Brinker[3], Brian T Buckley[4], Peter Lipsky[5], Ah-Ng Kong[2] and Naomi Schlesinger[6], [1]Rutgers The State University of New Jersey, Piscataway, NJ, [2]Department of Pharmaceutics, Ernest Mario School of Pharmacy, Rutgers, The State University of New Jersey, Piscataway, NJ, [3]Environmental and Occupational Health Sciences Institute, Rutgers, The State University of New Jersey,, Piscataway, NJ, [4]Environmental and Occupational Health Sciences Institute, Rutgers, The State University of New Jersey, Piscataway, NJ, [5]AMPEL BioSolutions, Charlottesville, VA, [6]Rutgers Robert Wood Johnson Medical School, New Brunswick, NJ

SESSION INFORMATION

Session Date: Tuesday, November 9, 2021

Session Title: Metabolic & Crystal Arthropathies – Basic & Clinical Science Poster II (1565–1583)

Session Type: Poster Session D

Session Time: 8:30AM–10:30AM

Background/Purpose: Tart cherries (TC) contain high levels of anthocyanins that exert potent antioxidant and anti-inflammatory effects. Approximately 50% of gout patients report using TC to help manage their gout, and preliminary data have demonstrated reduced gout flares in patients consuming TC. Our study aimed to characterize the major anthocyanins in Tart Cherry Juice Concentrate (TCJC) and identify the most prominently available anthocyanins in gout patients consuming TCJC.

Methods: Anthocyanins were determined using liquid chromatography-mass spectroscopy (LCMS). TCJC was diluted with deionized water and anthocyanins analyzed by LCMS using a Dionex UltiMate 3000 LC coupled with a Thermo Q Exactive HF, a Phenomenex Kinetex C18 column, and a gradient of 10% aqueous formic acid: acetonitrile. Cyanidin-3-arabinoside was used as an internal standard. anthocyaninswere identified by their fragmentation patterns and/or authentic standards. All available standards were purchased from Sigma Aldrich (St. Louis, MO), except for cyanidin-3-glucosylrutinoside, purchased from Diagnocine LLC (Hackensack, NJ). Individuals with gout (n=10) were administered either 60 or 120 mL of TCJC in a crossover design. Serial blood samples were drawn and used to characterize the pharmacokinetics and pharmacodynamics of anthocyanins in plasma.

Results: Cyanidin-3-glucosylrutinoside (C3GR) and cyanidin-3-rutinoside (C3R) were the main anthocyanins identified in the TCJC (Table 1). Various anthocyanins were bioavailable with C3GR and C3R achieving the highest plasma concentration in a dose-dependent manner.

Administration of oral TCJC resulted in a significant fold change in antioxidant mRNA gene expression NRF-2, HO-1, and NQO-1 (mean peak fold change 1.3, 1.6, and 1.4 versus baseline, $p< 0.05$; respectively) appreciated as early as 30 minutes after dose administration.

A significant reduction in iNOS and TNF-α mRNA gene expression (mean peak fold change 0.7 and 0.8 versus baseline, $p< 0.05$; respectively) was also observed and peaked at 2 hours post-dose. Only the high dose resulted in significant changes in gene expression. Pharmacokinetic analyses are ongoing.

Table 1. Quantitation of major anthocyanins identified in TCJC

Anthocyanin	Standard curve used	ng/μL
Cyanidin-3-glucosylrutinoside*	Cyanidin-3-glucosylrutinoside	343.3
Cyanidin-3-rutinoside*	Cyanidin-3-rutinoside	143.5
Petunidin deoxyhexose hexose	Cyanidin-3-rutinoside	37.8
Delphinidin deoxyhexose hexose	Cyanidin-3-rutinoside	33.4
Cyanidin-3-sophoroside*	Cyanidin-3-sophoroside	20.6
Delphinidin deoxyhexose hexose hexose	Cyanidin-3-rutinoside	19.2
Cyanidin pentose deoxyhexose hexose	Cyanidin-3-rutinoside	15.7
Peonidin-3-rutinoside*	Peonidin-3-rutinoside	15.5
Cyanidin deoxyhexose hexose	Cyanidin-3-rutinoside	10.0

Conclusion: The present study identifies the main anthocyanins present in the TCJC and patient plasma after oral administration of TCJC, as cyanidin 3-glucosylrutinoside and cyanidin 3-rutinoside. Since these anthocyanins are known to have anti-inflammatory and antioxidant effects, they may explain the benefit of TC in patients with gout.

Abstract Number: 1568

AR882, a Potent and Selective Uricosuric Agent, Showed Effectiveness in Patients with Various Degrees of Renal Impairment

zancong shen[1], Elizabeth Polvent[2], vijay hingorani[3], Rongzi Yan[4], Shunqi Yan[5] and **Litain Yeh**[6], [1]Arthrosi Therapeutics, Inc., San Diego, CA, [2]Arthrosi Therapeutics, Inc., Roseville, CA, [3]Vanguard Healthsciences, Inc., San Diego, CA, [4]Arthrosi Therapeutics, Inc, Irvine, CA, [5]Arthrosi Therapeutics, Inc., Laguna Hills, CA, [6]Arthrosi Therapeutics, Inc., Irvine, CA

SESSION INFORMATION
Session Date: Tuesday, November 9, 2021
Session Title: Metabolic & Crystal Arthropathies – Basic & Clinical Science Poster II (1565–1583)
Session Type: Poster Session D
Session Time: 8:30AM–10:30AM

Background/Purpose: AR882 is a novel, potent and selective uric acid transporter 1 (URAT1) inhibitor in Phase 2 development for the treatment of hyperuricemia and gout. In Phase 1 and Phase 2a studies AR882 exhibited good dose proportionality, long effective half-life and dose-dependent serum urate (sUA) lowering effect and was well tolerated in healthy subjects or gout patients.

Methods: AR882 had been evaluated in healthy subjects with normal renal function, mild or moderate impairment (estimated creatinine clearance ≥ 90, 60 to < 90, 30 to < 60 mL/min, respectively), or in gout patients with normal renal function or mild renal impairment. Subjects with severe renal impairment (15 to < 30 mL/min) are currently being enrolled for evaluation. AR882 was given as an oral capsule at 50 mg (multiple doses) or 100 mg (single dose). Serial blood and urine samples were collected for measurement of AR882 concentration and sUA levels for PK/PD assessment. Adverse events, laboratory safety tests, vital signs, and electrocardiograms were collected throughout the study.

Results: Following a single oral dose of AR882 at 100 mg, only mild increases in plasma exposure to AR882 was noted in subjects with mild (n=8) or moderate (n=8) impairment when compared to subjects with normal renal function (n=8). The sUA lowering effect of AR882 was not affected in subjects with mild or moderate impairment. Maximal reduction in sUA levels was approximately 50-60% in subjects with renal impairment, similar to those observed in subjects with normal renal function.

In 28 gout patients receiving 50 mg multiple doses for one week in a phase 2a study, similar AR882 plasma exposure was observed between patients with normal renal function (n=18) and those with mild renal impairment (n=10). At steady state, reduction of sUA levels was approximately 53% in both renal function groups. Response rate at target sUA levels were also similar.

Conclusion: AR882 sUA lowering effect is similar in subjects with mild or moderate renal impairment compared to subjects/patients with normal renal function. No clinically relevant serum creatinine elevation was observed in either the phase 2a gout patient study or the phase 1 renal impairment study.

Effect of Elevated Serum Urate on Kidney Function: Analysis of a Randomized Controlled Trial of Inosine Supplementation

Nicola Dalbeth[1], Borislav Mihov[1], Angela Stewart[1], Gregory Gamble[1], Tony Merriman[2], David Mount[3], Lisa Stamp[4], Ian Reid[1] and Anne Horne[1], [1]University of Auckland, Auckland, New Zealand, [2]University of Alabama at Birmingham, Dunedin, New Zealand, [3]Brigham and Women's Hospital, Boston, MA, [4]University of Otago, Christchurch, Christchurch, New Zealand

SESSION INFORMATION
Session Date: Tuesday, November 9, 2021
Session Title: Metabolic & Crystal Arthropathies – Basic & Clinical Science Poster II (1565–1583)
Session Type: Poster Session D
Session Time: 8:30AM–10:30AM

Background/Purpose: Observational studies have reported that serum urate associates with development and progression of kidney disease. However, it is uncertain whether elevated serum urate directly influences kidney function, with recent Mendelian randomization studies and clinical trials of urate-lowering therapy in CKD suggesting that elevated urate does not influence kidney disease. Inosine is a purine nucleoside that increases extra-renal urate production and thus, serum urate concentrations. We analyzed data from a 6-month randomized placebo-controlled trial of inosine supplementation to determine whether moderate hyperuricemia induced by inosine affects kidney function, as assessed by serum creatinine.

Methods: One hundred and twenty post-menopausal women were recruited into a six-month randomized, double-blind, placebo-controlled trial of inosine supplementation for bone health (*Arthritis Rheumatology* 2021, PMID: 33586367). Exclusion criteria included gout, kidney stones, eGFR≤60 ml/min/1.73m^2, and urine pH ≤5.0. Participants were randomized 1:1 to inosine supplements (doses adjusted to maintain serum urate below 8mg/dL), or placebo. Serum creatinine, serum urate, and fractional excretion of uric acid (FEUA) were pre-specified secondary endpoints. Data were analyzed on an intention to treat basis, using a mixed models approach to repeated measures, with false detection rate protected pairwise comparisons at each time point. For analysis of covariance of change from baseline (ANCOVA), baseline values were included in the models.

Results: Administration of inosine supplements led to a significant increase in serum urate and FEUA over the study period (Figure 1. and 1B respectively). The maximum difference between groups in both serum urate and FEUA was observed at week 6; at this time point, the mean (SD) serum urate was 7.3 (1.5) mg/dL in the inosine group, and 4.7 (1.0) mg/dL in the placebo group (P< 0.0001), and the mean (SD) FEUA was 10.1 (3.2)% in the inosine group and 7.7 (2.4)% in the placebo group (P< 0.0001). There was no between-group difference in serum creatinine values at any time point over the 26 week period (P>0.62 Figure 1C). Analysis of the change in serum creatinine from baseline

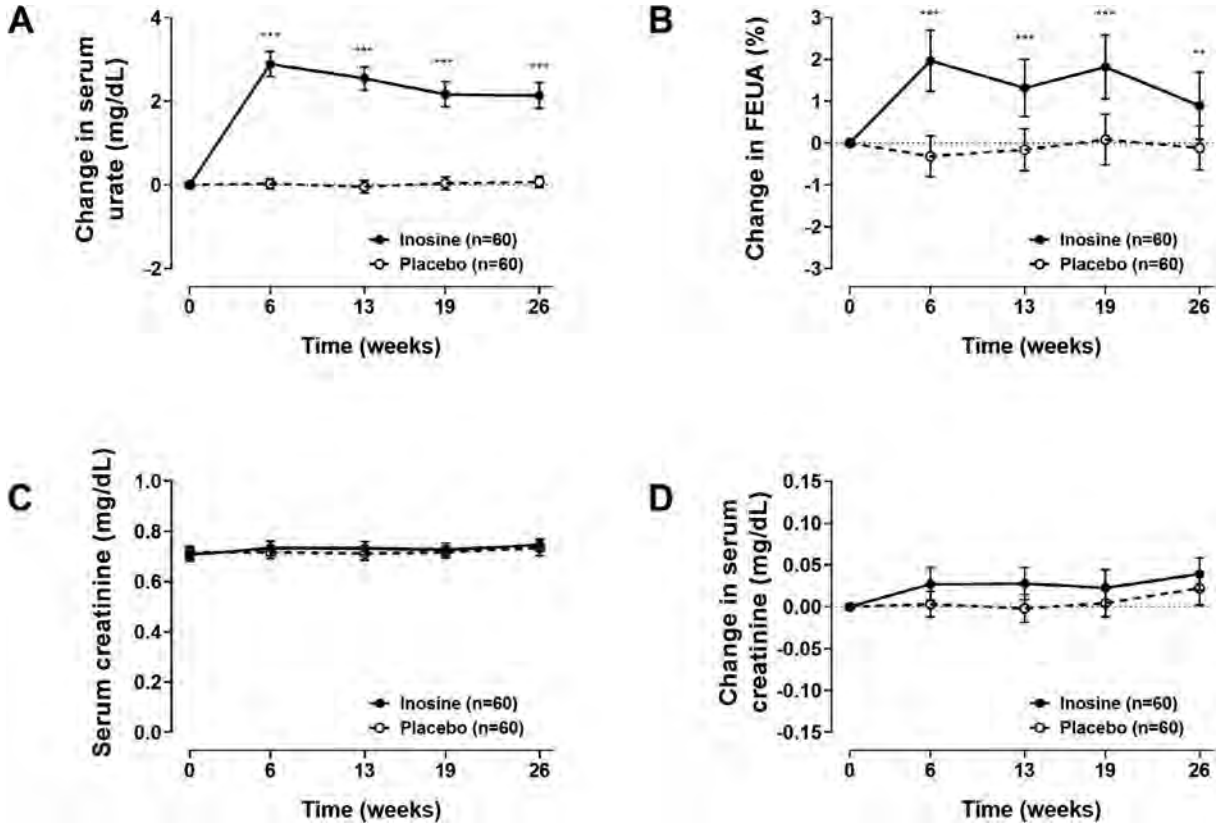

Figure 1. Study endpoints. A. Change in serum urate; B. Change in FEUA; C. Serum creatinine values; D. Change in serum creatinine; Data re presented as mean (95% CI). **false detection rate P<0.01, ***false detection rate P<0.001.

showed a maximal difference between groups at week 13 (with mean (95% CI) difference of +0.029 (-0.005, +0.055) mg/dL, P=0.059, Figure 1D). At all other time points, there was no between-group difference in the change in serum creatinine.

Conclusion: Elevated serum urate due to increased extra-renal urate production does not lead to kidney impairment over a six month period.

AR882, a Novel Uricosuric Agent, Exhibited Favorable Pharmacokinetic Profile and Balanced Excretion and Metabolic Pathways in a Human AME Study

Rongzi Yan[1], zancong shen[2], Elizabeth Polvent[3], vijay hingorani[4], Shunqi Yan[5] and **Litain Yeh**[6], [1]Arthrosi Therapeutics, Inc, Irvine, CA, [2]Arthrosi Therapeutics, Inc., San Diego, CA, [3]Arthrosi Therapeutics, Inc., Roseville, CA, [4]Vanguard Healthsciences, Inc., San Diego, CA, [5]Arthrosi Therapeutics, Inc., Laguna Hills, CA, [6]Arthrosi Therapeutics, Inc., Irvine, CA

SESSION INFORMATION
Session Date: Tuesday, November 9, 2021
Session Title: Metabolic & Crystal Arthropathies – Basic & Clinical Science Poster II (1565–1583)
Session Type: Poster Session D
Session Time: 8:30AM–10:30AM

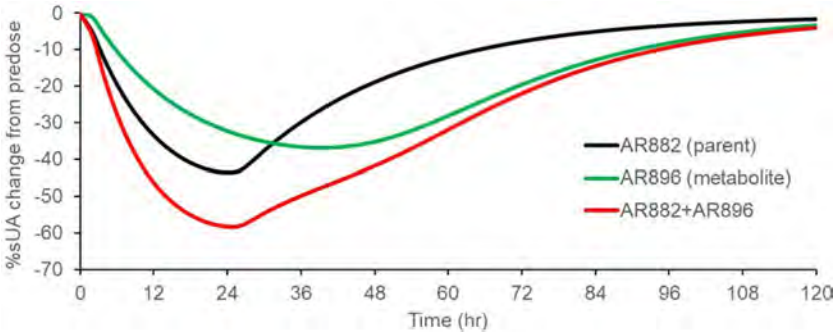
Background/Purpose: AR882, a novel uric acid transporter 1 (URAT1) inhibitor is being developed for the treatment of gout with hyperuricemia. In Phase 1 and Phase 2 studies, AR882 exhibited long lasting serum urate (sUA) lowering effect and good safety in healthy subjects and patients with gout. In a Phase 1 open-label, single-dose study with oral administration of [^{14}C] AR882, the absorption, metabolism, and excretion (AME) profile of AR882 was investigated in healthy subjects.

Methods: Six (6) healthy male subjects received a single oral dose of 100 mg (250 μCi) [^{14}C]AR882 under fasting conditions. Serial blood, urine, and fecal samples were collected up to 144 hours postdose, and then at 24-hour intervals thereafter until the subject was discharged (up to 288 hours). Total radioactivity in plasma, whole blood, urine, and fecal samples was measured using liquid scintillation counting methods. Concentration of AR882 and active metabolite, AR896, in plasma and urine was determined using validated liquid chromatography with tandem mass spectrometry (LC-MS/MS) methods. Metabolite profiling in each matrix and structure identification were performed using high resolution accurate mass LC-RAD-MS/MS with in-line fraction collection and off-line counting to obtain [^{14}C]- radiochromatographic profiles and provide information on the nature of the radioactive components present. In addition, the metabolite profile of AR882 comparison were made cross species.

Results: All 6 subjects completed the full study except one subject withdrew after 7 days due to personal reason. The overall total recovery was 89.2% (34% in urine and 55% in feces) of [^{14}C]AR882 administered and recovery was complete 10 days after dosing. Within 24 hours approximately 20% and 8% of dose was recovered in urine and feces, respectively. Both AR882 and total radioactivity were readily absorbed with terminal half-life of approximate 20 hours. AR882 was accounted for 88% of the circulating radioactivity followed by its active metabolite AR896 (8%).

The renal clearance was approximately 0.02 mL/min and 3.20 mL/min for AR882 and AR896, respectively. AR896 exhibited weak URAT1 inhibition and was identified to contribute to the sustained inhibition of URAT1 and sUA lowering effect of AR882 in a parent-metabolite pharmacokinetics/pharmacodynamic model (**Figure**). Metabolic pathway of AR882 included oxidation, sulfation, glucuronidation, and hydrolysis. There were no disproportional or unique human metabolites identified when compared to AME profiles in rats and monkeys. Based on the metabolic profile in feces and recovery of radioactivity in urine, at least 80% AR882 was absorbed.

Conclusion: The sustainable sUA lowering effect of AR882 observed in clinical studies is attributed to the pharmacological effects of parent drug and its active metabolite as well as its favorable PK properties and balanced metabolic and elimination pathways.



Simulated Serum Urate Lowering Effect of AR882 (Parent) and AR896 (Metabolite) following a Single Oral Dose of 100 mg AR882 based on PK/PD Model

Elevated Lactate, Procalcitonin Levels and SIRS (Systemic Inflammatory Response Syndrome) in a Subset of Patients with Gout

Christopher Podgorski[1], Paula Skarda[2] and Elie Gertner[3], [1]Department of Medicine, University of Minnesota Medical School, Saint Paul, MN, [2]Department of Medicine, Regions Hospital, University of Minnesota Medical School, Saint Paul, MN, [3]Section of Rheumatology, Regions Hospital and Division of Rheumatology, University of Minnesota Medical School, Minneapolis, MN

SESSION INFORMATION

Session Date: Tuesday, November 9, 2021

Session Title: Metabolic & Crystal Arthropathies – Basic & Clinical Science Poster II (1565–1583)

Session Type: Poster Session D

Session Time: 8:30AM–10:30AM

Background/Purpose: The intense inflammatory cascade of acute gouty inflammation makes it difficult to differentiate clinically between acute gouty inflammation and sepsis, particularly since they can occur together. A SIRS-like presentation attributed to acute gouty inflammation has been described sporadically [1-6]. In these cases, sepsis is usually considered first, and markers such as lactate and procalcitonin are used to confirm the diagnosis of sepsis. Gout is not even considered as a possibility. However, delayed diagnosis and treatment of gout when it is the cause of the presentation leads to unnecessary antibiotic use and prolonged hospitalization.

We describe a cohort of patients who presented with SIRS, elevated lactate (some markedly high) and/or elevated procalcitonin and even concerning NEWS2 (National Early Warning Scores) scores due to acute gout alone. While sepsis must always be ruled out, we describe those characteristics that may suggest that gout, rather than sepsis, is the presenting cause.

Methods: Retrospective chart review of patients with a gout related hospital encounter between 2014 and 2017 at Regions Hospital. Of 1,041 such episodes, 14 encounters had ≥2 SIRS criteria, elevated lactate/procalcitonin and were admitted for presumed sepsis. Demographics, clinical presentation, laboratory and imaging data are summarized in **Table 1**.

Results: There were 14 patient encounters including 11 patients with one episode and one with three separate similar presentations. All were male, mean age 58.6 years, mean time since gout diagnosis 11.2 years, 8 patients (66.6%) had tophi, and 10 patients (83.3%) had history of ≥5 gout flares. Mean **lactic acid** was elevated in 12/14 ranging from **2-12.2** mmol/L (normal 0.5-2.0 mmol/L), and **procalcitonin** was **0.23-2.79** ng/mL (< 0.24 ng/ml). Use of antibiotics beyond the first 24 hours of admission was seen in 7 presentations (58.3%). No infection was identified. While many patients were concurrently treated with antibiotics for presumed bacterial sepsis, the patient cohort showed rapid clinical improvement within 24-48 hours of starting appropriate gout therapy. Hospital courses are summarized in **Table 1**.

Conclusion: A **SIRS-like** presentation with **elevated lactate** and **procalcitonin** levels occurs in a subset of gout patients. A high index of suspicion for a gout flare is indicated if patients have a) **history of gout of >10 years duration** b) **tophi** c) ≥ **5 gouty flares**. Early recognition of gout as the cause of the marked inflammatory response can limit unnecessary antibiotic use and prolonged hospitalization. Hospitalists, emergency physicians and rheumatologists should be aware of this subset of gouty patients.

Table 1: Background Characteristics, Hospital Course of Gouty SIRS-like Presentation

Patient Case	Age (years)/ Sex	Years Since Gout Diagnosis	Number of Prior Gout Flares	Tophi Present	Peak Uric Acid Prior to Admission (mg/dL)	Presentation	SIRS Criteria Met	NEWS2 Score	Uric Acid (mg/dL)	Procalcitonin (ng/mL)	Lactic Acid (mmol/L)	Infectious Workup	Antibiotics Course (x total doses)	Acute Gout Treatment	Hospital Course
1	56/Male	4	>5	Yes	13.9	Acute polyarticular gout of bilateral knees, MCPs, wrist.	2	2	8.8	0.23	1.0	Negative blood cultures, UA, CXR	None	Oral steroids tapered over 1 week.	Improved within 48 hours of starting steroids
2	66/Male	10	>5	Yes, also urate stones	11.7	Acute polyarticular gout of bilateral hands, shoulder, feet, and ankles	2	3	6.2	-	1.1	Negative blood cultures, UA, CXR.	Aztreonam IV (x1) Vancomycin IV (x1)	Stress-dose IV steroids, then oral steroid taper over 2 weeks. Started on allopurinol, colchicine.	Improved within 48 hours of starting steroids
3	52/Male	15	>5	Yes	11.5	Acute gout of left shoulder	2	5	6.2	-	2.0	Negative blood cultures, UA, CXR, and *Clostridium difficile* stool antigen. CT without intraabdominal abscess	Metronidazole IV (x1) Linezolid IV (x3) Meropenem IV (x8) Zosyn IV (x3) Vancomycin IV (x2)	IV steroids, then oral steroid taper over 2 weeks. Started on allopurinol, colchicine.	Improved within 48 hours of starting steroids
4	37/Male	10	>5	No	-	Acute gout of right knee and hip	2	2	8.3	0.69	2.4	Negative blood cultures, UA, CXR, synovial fluid cultures.	Zosyn IV (x3) Vancomycin IV (x2)	IV then oral steroids	Improved within 24 hours of starting steroids
5a	49/Male	27	>5	Yes	-	ICU admission for shock.	3	11	7.2	-	3.4	Negative blood cultures, UA, *Strep. pneumoniae* and *Legionella* urine antigens.	Zosyn IV (x13) Vancomycin IV (x8) Ceftriaxone IV (x4)	IV stress-dose steroids and intra-articular steroids, then anakinra and oral steroid taper over 1 month. Started on allopurinol.	Gouty symptoms persisted through HD#10 in setting of renal failure
5b						Acute polyarticular gout flare after running out of prednisone and allopurinol after previous admission	3	5	14.8	-	3.5	Negative blood cultures, UA, CXR, HIV. CT without intraabdominal abscess.	None	IV then oral steroids with taper over 1 month. Started on allopurinol, colchicine.	Improved within 48 hours of starting steroids
5c						Acute polyarticular gout after failed medical follow-up from previous admission	3	4	12.1	1.01	2.9	Negative blood cultures, UA	Zosyn IV (x7) Vancomycin IV (x4)	IV then oral steroids. Started on allopurinol.	Improved within 48 hours of starting steroids
6	59/Male	8	>5	Yes	-	Acute polyarticular gout of right knee, right great toe, left elbow, left wrist	3	4	8.8	-	3.7	Negative blood cultures, UA, CXR	Ceftriaxone IV (x1)	Indomethacin	Improved within 72 hours
7	68/Male	1	2	No	12.3	Acute polyarticular gout of bilateral knees	3	3	4.5	0.61	2.9	Negative blood cultures, UA, CXR, synovial fluid cultures.	Zosyn IV 4.5g (x1) Ceftriaxone IV (x3) Vancomycin IV (x4)	Oral steroids. Started on allopurinol, colchicine	Improved within 48 hours of starting steroids
8	53/Male	4	5	Yes	9.7	Acute polyarticular gout or right knee, right elbow, and right wrist.	2	4	5.4	2.24	2.6	Negative blood cultures, UA, synovial fluid culture.	Vancomycin IV (x2)	Intra-articular, IV then oral steroids	Improved within 24 hours of starting steroids
9	53/Male	0	1	No	-	Acute left knee gout	3	4	-	-	3.4	Negative blood cultures, UA, CXR, synovial fluid cultures.	Ceftriaxone IV (x1)	Oral steroids with taper over 1 week.	Rapid improvement with next-day discharge
10	70/Male	15	>5	No	10.3	ICU admission for shock complicated by acute kidney injury	2	6	4.9	-	12.2	Negative blood cultures, UA, CXR, abdominal ultrasound	Zosyn IV (x8) Vancomycin IV (x4)	IV then oral steroids.	Improved within 48 hours of starting steroids
11	69/Male	10	>5	Yes	-	Acute polyarticular gout of bilateral MCPs, elbows, and right knee	3	4	21.4	2.79	2.8	Negative blood culture, UA. Negative synovial fluid cultures.	Zosyn IV 4.5g (x1) Cefepime IV (x2) Vancomycin IV (x1) Metronidazole IV (x3) Nafcillin IV (x1) Cefazolin IV (x3)	Anakinra and intra-articular steroids, then oral steroid taper over 1 month.	Improvement within 24 hours of starting anakinra
12	71/male	30	>5	Yes	-	Acute polyarticular gout of left elbow, left MCPs, bilateral MTPs	3	4	8.5	-	6.8	Negative blood cultures, CXR	Zosyn IV (x11) Vancomycin IV (x1) Augmentin PO (x7)	IV steroids and anakinra, then oral steroids with taper of 2 weeks. Started on colchicine.	Improvement within 24 hours of starting steroids and anakinra

Ultrasound Signs of Gout in a Population with Asymptomatic Hyperuricemia

Bilal Bengana[1], Aicha Ladjouze[2], Nabil Baramtane Raaf[3], Chaffa Aimeur[4], Soraya Ayoub[5], Abdenour Boukabous[6] and Salima Lefkir-Tafiani[7], [1]University Hospital of Beni Messous Algiers - Rheumatology Department, Algiers, Algeria, [2]Specialized hospital establishment of Benaknoune, Rheumatology, Algiers, Algeria, [3]Hospital of Bitraria, Biochemistry, El Biar, Algiers, Algeria, [4]University hospital of Mustapha Bacha, Radiology, Sidi Mhamed, Algiers, Algeria, [5]University hospital of Beni Messous, Internal Medicine, BeniMessous, Algiers, Algeria, [6]University Hospital of Beni Messous Algiers- Rheumatology Department, Algiers, Algeria, [7]University Hospital of Beni Messous Algiers - Rheumatology Department, Benimessous, Algeria

SESSION INFORMATION
Session Date: Tuesday, November 9, 2021
Session Title: Metabolic & Crystal Arthropathies – Basic & Clinical Science Poster II (1565–1583)
Session Type: Poster Session D
Session Time: 8:30AM–10:30AM

Background/Purpose: Hyperuricemia is a common biological abnormality, often clinically asymptomatic. However, it can announce a gout and be linked to many diseases such as metabolic syndrome, high blood pressure or kidney disease. In fact, the majority of learned societies do not recommend any urate lowering therapy (ULT) as long as the hyperuricemia remains asymptomatic. But it turns out that part of the population with asymptomatic hyperuricemia (AH) develops a gout after a few years particularly with genetic predisposition, but also on certain risk factors that need to be confirmed. By this way, musculoskeletal ultrasound (MUS) can detect "asymptomatic gout" by visualizing signs of urate deposits (UD) in subjects with AH.

Our main objective is already to estimate the prevalence of specific signs of gout in Algerian population with AH and assess the factors exposing to UD.

Methods: This is a descriptive cross-sectional study from January 2017 to February 2019, with the recruitment of subjects with AH and serum urate level > 360 µmol/l (6 mg/dl), who do not take any ULT and have not associated any chronic inflammatory rheumatism, where we performed a MUS of the knees, metatarsophalangeal joints MTP1, MTP2 and metacarpophalangeal joint MCP2 and MCP3 with the Achilles, patellar and quadricipital tendons.

Results: We retained 258 subjects with AH, 132 women and 126 men (sex ratio = 0.95), the mean age was 59 years, the mean body mass index (BMI) was 28.4 kg / m2, 42 patients were under diuretics, 37 patients reported being on low-dose of aspirin 100 mg daily. The mean rate of serum urate levels was 460 ± 6 µmol/l , the prevalence of UD found

at the MUS was 22% (n = 58), among them 36 % (21/58) had a sign of the double contour DC on the MTP1 and 29% (17/58) on the knee, 7% (4/58) had tophi on the MTP1 and 3% (2/58) had urate aggregates.

The factors reported to be linked to UD in the sample were: the male gender (p = 0.0016); the high uric acid level (p= 0.0355); BMI (p = 0.0427); taking diuretics for women (p= 0.0002).

Conclusion: Through this work, it is clear that elementary ultrasound lesions related to gout disease are common in a population with AH and concerned one fifth of subjects in our study with a higher risk in men and subjects with obesity and high uric acid level, but also in women taking diuretics. These results need to be enhanced with a randomized controlled study in order to better determine the predisposing factors for gout in any subject with AH.

Vascular Monosodium Urate Crystal Deposition in Gout: A Dual-energy CT and Microscopy Study of Cadaveric Donors

Nicola Dalbeth[1], Mariam Alhilali[1], Peter Riordan[1], Ravi Narang[1], Ashika Chhana[1], Sue McGlashan[1], Anthony Doyle[1] and MARIANO ANDRES[2], [1]University of Auckland, Auckland, New Zealand, [2]Hospital General Universitario de Alicante-ISABIAL, Alicante, Spain

SESSION INFORMATION
Session Date: Tuesday, November 9, 2021
Session Title: Metabolic & Crystal Arthropathies – Basic & Clinical Science Poster II (1565–1583)
Session Type: Poster Session D
Session Time: 8:30AM–10:30AM

Background/Purpose: Cardiovascular disease is a common comorbidity in people with gout. A hypothesized link between cardiovascular disease and gout is the deposition of monosodium urate (MSU) crystals in atherosclerotic plaque. Recent dual-energy CT (DECT) studies have reported that color-coded material consistent with MSU crystal deposition is present in calcified vessels of patients with gout. However, it is unclear whether these appearances represent true MSU crystal deposition or artifact during live imaging. The aim of this study was to examine whether MSU crystal deposition is present in the great vessels of cadaveric donors with gout by DECT or microscopic analysis.

Methods: Six cadaveric donors with a documented history of gout (two with visible tophi) were studied. Vascular tissue was dissected from the arch of the aorta through to the descending aorta at the level of the diaphragm, and included the proximal few centimeters of the brachiocephalic, common carotids, and subclavian arteries. Vascular tissue from each donor was scanned by DECT (SOMATOM Definition Flash, Siemens Medical, Erlangen, Germany) and analyzed for urate deposition on a Siemens workstation using proprietary gout software (syngo MMWP VE 36A 2009, Siemens Medical). After scanning, 100µl of phosphate buffered saline was injected into the vessel wall at ten standardized sites across each sample, and aspirated fluid was analyzed by polarizing light microscopy. Positive control tissue included the foot joints of cadaveric donors with tophaceous gout analyzed by DECT and microscopy using the same protocols, as well as synthesized MSU crystals as controls at the time of microscopic analysis.

Results: DECT scanning of the cadaveric vascular tissue showed calcification in all samples, but no evidence of MSU crystal deposition (Figure 1). In contrast, urate deposition was clearly evident in the positive control tophaceous joint tissue by DECT. Microscopic analysis demonstrated plate-like cholesterol crystals from vascular tissue from five of

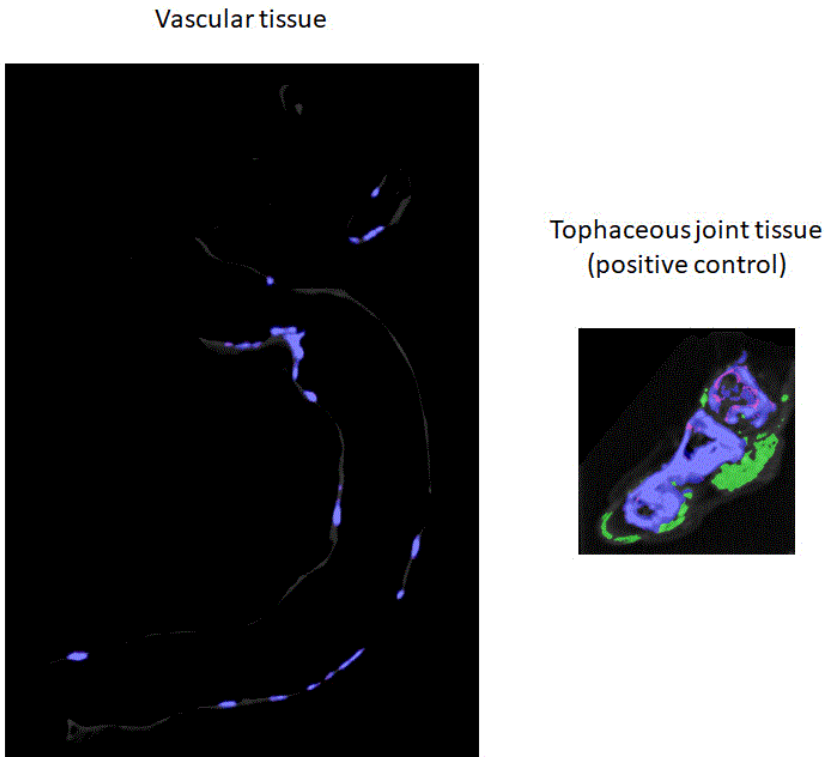

Figure 1. Dual energy CT. Left panel. Representative DECT image of cadaveric vascular tissue demonstrating vascular calcification in blue, but no urate deposition (color-coded green). Right panel. Representative DECT image of positive control cadaveric tophaceous joint tissue demonstrating urate deposition (color-coded green) within tophaceous deposits. Nail artifact is also evident.

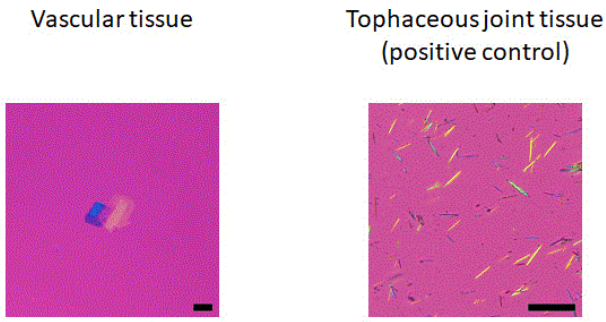

Figure 2. Polarizing light microscopy. Left panel. Representative polarizing microscopy image from cadaveric vascular tissue demonstrating plate-like cholesterol crystals, but no needle-shaped negatively birefringent crystals. Scale bar 10μm. Right panel. Representative polarizing microscopy image from positive control cadaveric tophaceous joint tissue demonstrating numerous needle-shaped negatively birefringent crystals. Scale bar 10μm.

the six donors (mean (SD) 3.2 (1.9) sites/donor, Figure 2). A single negatively birefringent needle shaped crystal was visualized from one of the 60 standardized sites analyzed, with no MSU crystals evident at any other site. In contrast, numerous negatively birefringent needle shaped crystals were present in aspirates from positive control tophaceous joint tissue.

Conclusion: This analysis has not demonstrated extensive MSU crystal deposition in vascular tissue of cadaveric donors with gout by DECT or polarizing light microscopy.

Comparison of Urate Quantification in Gout and Asymptomatic Hyperuricemia by Ultrasound and Dual Energy Computed Tomography

Rachael Flood[1], Aamir Saeed[2], Kate Harrington[1], Conor Shortt[1], Ronan Mullan[1] and David Kane[1], [1]Tallaght University Hospital, Dublin, Ireland, [2]Worcestershire Acute Hospitals NHS Trust., Worcester, United Kingdom

SESSION INFORMATION

Session Date: Tuesday, November 9, 2021

Session Title: Metabolic & Crystal Arthropathies – Basic & Clinical Science Poster II (1565–1583)

Session Type: Poster Session D

Session Time: 8:30AM–10:30AM

Background/Purpose: The diagnostic gold standard for gout remains aspiration and identification of monosodium urate (MSU) crystals under polarised light microscopy. Joint aspiration is invasive and in certain patients may not be possible. The 2015 gout classification criteria include imaging evidence of urate deposition in the diagnostic criteria. The imaging modalities with sufficient published data and investigator experience to support their utility in identifying urate deposition accurately were ultrasound (US) and dual energy computed tomography (DECT). Despite the fact that US and DECT are both candidates to quantify urate deposition and monitor urate depletion, it is still unknown whether these techniques provide similar quantification of the extent of urate deposition in a given patient.

The aim of the study was to compare the quantification of urate deposition by US and DECT in a group of patients with gout and asymptomatic hyperuricaemia (AH).

Methods: Patients with either AH or gout according to 2015 diagnostic criteria were prospectively recruited to undergo quantification of MSU deposition in the knees and feet using US and DECT. A urate quantification score for each imaging modality was calculated, for US images a semiquantitative composite scoring system (1= present, 0 = absent) was used to obtain a sum score for total elementary lesions of urate deposition (double contour, tophi, aggregate or erosion) across all four joints. Exact quantification of urate deposition was calculated using specific

Table 2: Ultrasound findings of OMERACT elementary lesions of urate deposition at the knees and feet.

MTP1 – Metatarsophalangeal Joint 1.

Results: A total of 62 patients (gout=25, AH=21, Control=16) were recruited. Mean (SD) age was 60 (13.11) years in gout, 58 (12.64) years in AH and 36 (8.9) years in control groups. Mean sUA umol/L levels at baseline in gout, AH and control were (398, 472 and 265) respectively.

For the gout cohort the mean (SD) US score at baseline was 3.64 (2.52) and on repeat US following 6 months of ULT this reduced to 2.68 (2.01). In the AH group the mean (SD) US score at baseline was 0.81 (0.98). There is a significant difference ($P < 0.01$) between the mean baseline US score in Gout and AH patients.

22 and 18 patients underwent baseline DECT imaging of the feet from the Gout and AH groups respectively. The Mean (SD) deposition urate score in the gout cohort at baseline was 0.104 (0.306.) Following 6 months of ULT the mean (SD) urate deposition score was 0.069 (0.246). The mean (SD) deposition urate score in the AH group was 0.782 (0.155).

In the gout cohort of patients there is a significant correlation between the sum US Score and the DECT deposition urate score (Spearman correlation coefficient .544).

Conclusion: US and DECT imaging modalities demonstrate correlation in urate quantification in patients with gout.

Session Date: Tuesday, November 9, 2021

Session Title: Metabolic & Crystal Arthropathies – Basic & Clinical Science Poster II (1565–1583)

Session Type: Poster Session D

Session Time: 8:30AM–10:30AM

Background/Purpose: Although metabolic reprograming and its regulation in macrophages after TLR activation is well established, little is known about the regulation and the role of metabolic changes after monosodium urate (MSU) crystal stimulation. Here, we evaluated the transcriptional and epigenetic changes, and its regulation, in macrophages after MSU stimulation.

Methods: RNA-Seq and ATAC-Seq of bone marrow derived macrophages (BMDM) or human monocyte-derived macrophages (mDM) after MSU (0.25 mg/ml) or LPS (100ng/ml) activation. ChIP-Seq for H3K27ac and H3K4me3 was also performed in BMDM. NMR was conducted on sera from patients with acute gout flare and in BMDM after MSU activation. Cytokine production was assessed by ELISA. Experiments with and without pretreatment of SP600125 (5uM), a JNK inhibitor, were also performed. For *in vivo* experiments, murine air pouch and intraarticular MSU injection models of acute gouty inflammation were performed to assess effects of inhibiting JNK (using SP600125, 15mg/kg) and glycolysis inhibition (using BAY-876, a GLUT1 inhibitor, 7.5mg/kg). Infiltrating leukocytes and cytokines from the lavage were quantified.

Results: RNA-seq results highlighted divergence of BMDM or mDM treated with MSU from those treated with LPS (Figure 1). Genes that were up-regulated only in MSU belonged to inflammatory -but not interferon activation- and

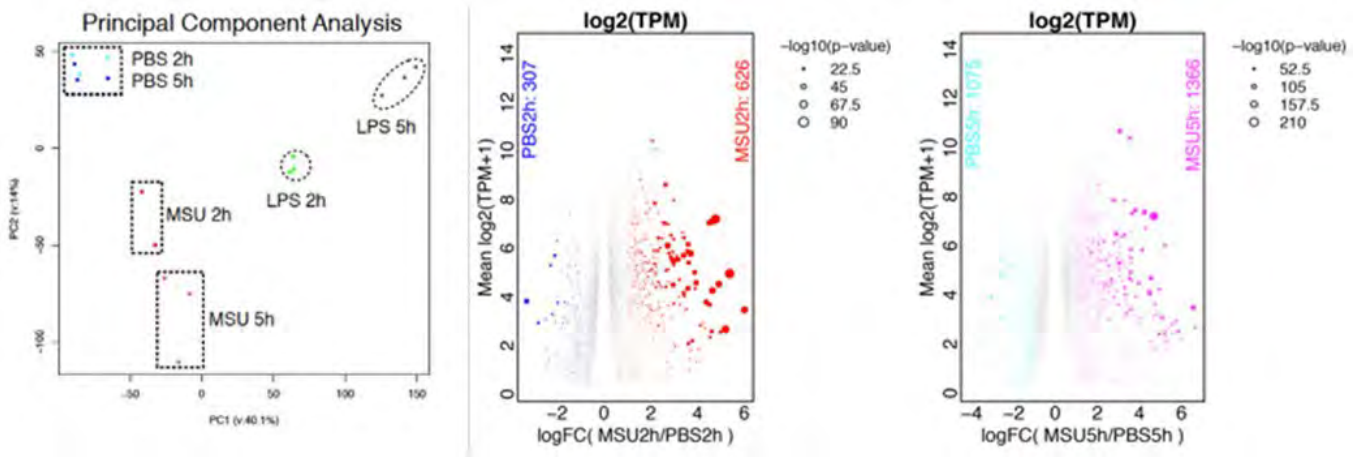

Figure 1. RNA sequencing (RNA-Seq) of bone marrow derived macrophages (BMDM) or human monocyte-derived macrophages (mDM) treated with MSU (0.25 mg/ml) or LPS (100ng/ml) for 2 and 5h. metabolic pathways, including glycolysis. NMR analysis showed low levels of glucose in sera from patients with acute attack, and an increase of glycolytic products in supernatants of BMDM after MSU activation. GSEA showed that whereas up-regulated genes in LPS with increased H3K27ac or H3K4me3 signal belong to inflammatory pathways, up-regulated genes in MSU with increased H3K27ac or H3K4me3 signal belong to inflammation and metabolic pathways, including metabolism of carbohydrates and transport of small molecules (Figure 2). Motif analysis showed that regions of H3K27ac or H3K4me3 up-regulated signal with up-regulated gene transcript in MSU are

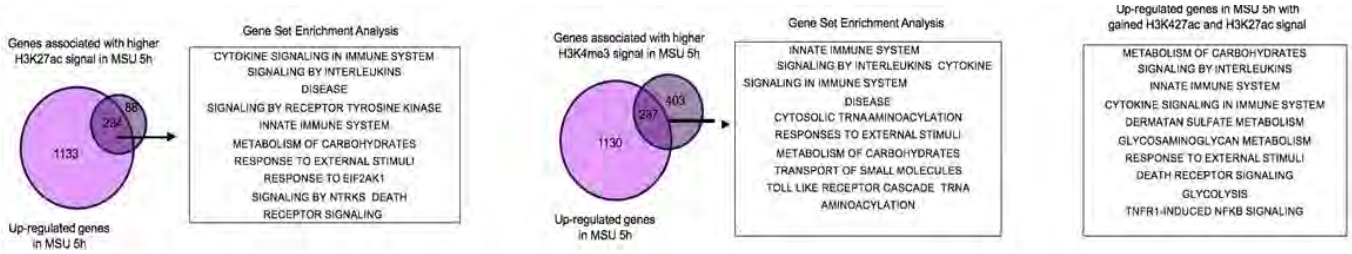

Figure 2. Chromatin immunoprecipitation (ChIP-Seq) for H3K27ac and H3K4me3 was performed to examine alteration in the activity of regions of open chromatin. Up-regulated genes in MSU with increased H3K27ac or H3K4me3 signal belong to inflammation and metabolic pathways, including metabolism of carbohydrates and transport of small molecules.

USF1	14.87	4.74	13

Figure 3. Motif analysis showed that regions of H3K27ac or H3K4me3 up-regulated signal with up-regulated gene transcript in MSU are majorly enriched in AP-1 motifs.

majorly enriched in AP-1 motifs (Figure 3). Treatment of BMDM with JNK inhibitor ameliorated the up-regulation of p-JUN^{Ser63} and reduced the of 88.8% of genes up-regulated by MSU, including inflammatory cytokines (*Ccl2*, *Ccl4, Tnf* and *Cxcl1),* metabolic genes (*Slc2a1*, *Eno2, Pfkfb3)* and AP-1 members (*Jun, Junb, Fosl1)*. This reduction in gene expression was accompanied by reduction on H3K27ac and H3K4me3 signal over regions of open chromatin. Finally, SP600125 significantly lowered numbers of infiltrating leukocytes in the air pouch gout flare model (1.34±0.45x10^6 vs 0.49±0.48x10^6, p< 0.01, in the MSU group after PBS or JNK inhibitor respectively) and amounts of CXCL1 and IL-1b. BAY-876 markedly reduced leukocyte infiltration after knee intraarticular injection of MSU (inflammation score: 1.5±0.9 vs 0.8±0.7, p< 0.03, in the MSU group after PBS or BAY-876 respectively).

Conclusion: These results indicated that up-regulation of JUN and p-JUN^{Ser63} via JNK is necessary for up-regulation of the transcriptional program and epigenetic changes induced by MSU in macrophages. Monocyte and macrophage JNK activation are novel targets for blunting metabolic-inflammatory response to MSU crystals in gout.

Development of a Plain Radiographic Scoring System for New Bone Formation in Gout

Chang-Nam Son[1], Ken Cai[2], John Ferrier[3], Yun-Jung Tsai[3], Thomas Bardin[4], Anthony Doyle[5] and Nicola Dalbeth[5], [1]Keimyung University School of Medicine, Daegu, Republic of Korea, [2]University of Auckland, Sydney, Australia, [3]Department of Radiology, Auckland District Health Board, Auckland, New Zealand, [4]Hôpital Lariboisiere, Paris, France, [5]University of Auckland, Auckland, New Zealand

SESSION INFORMATION

Session Date: Tuesday, November 9, 2021

Session Title: Metabolic & Crystal Arthropathies – Basic & Clinical Science Poster II (1565–1583)

Session Type: Poster Session D

Session Time: 8:30AM–10:30AM

Background/Purpose: Features of new bone formation (NBF) such as sclerosis and spurs are common on plain radiography in tophaceous gout. While a plain radiographic damage scoring system incorporating bone erosion and joint space narrowing has been developed, there are no published methods for scoring NBF in gout. The aim of this project was to develop a plain radiographic scoring system for NBF in patients with gout.

Methods: Following a systematic review of scoring systems for NBF in other bone and joint diseases, and a structured review of plain radiographs, a range of published scoring systems were tested in 80 individual joints (40 1st MTP joints and 40 5th MTP joints) from 20 patients with gout. Two readers scored the plain radiographs for sclerosis and spur using these scoring systems. Inter-reader reproducibility was assessed using intra-class correlation coefficients (ICC). In addition, construct validity was assessed by comparing plain radiography scores with gold standard computed tomography (CT) measurements of sclerosis and spur of the same joints. The best-performing scoring system was then tested in sets of hand and foot radiographs from an additional 25 patients with gout (n=52 sites/set, scores summed for each individual patient). Inter-reader ICCs were calculated, and NBF scores were correlated with plain radiographic erosion scores (using the gout-modified Sharp-van der Heijde system). All readers were blinded to each other's scores.

Results: A semi-quantitative scoring system for spur and sclerosis (**Table**) was found to have high feasibility and face validity. In the individual joint analysis, the inter-observer ICC (95% CI) using this system was 0.84 (0.76-0.89) for sclerosis and 0.81 (0.72-0.87) for spur. Plain radiographic sclerosis and spur scores correlated with CT measurements (r = 0.65-0.71, P < 0.001 for all analyses). For the hand and foot radiograph sets, the inter-observer ICC (95% CI) was 0.94 (0.90-0.97) for sclerosis score, 0.77 (0.62-0.86) for spur score, and 0.92 (0.86-0.95) for combined sclerosis and spur score. The sclerosis and spur scores correlated highly with plain radiographic erosion scores (r = 0.81-0.94, P < 0.001 for all analyses).

Conclusion: A semi-quantitative plain radiographic scoring method is feasible and reproducible for assessment of NBF in gout. This method may facilitate consistent measurement of NBF in gout.

Sclerosis	
Definition	Increased density of medullary or subcortical bone
Each bone is scored from 0 to 3 (joints with long bones are summed to a maximum score of 6)	0 = normal
	1 = mild (<1/3 bone)
	2 = moderate (1/3-2/3 bone)
	3 = severe (>2/3 bone)
Spur	
Definition	A sharp spicule of dense bone proliferation extending at an acute angle from the cortex
Each bone is scored from 0 to 3 (joints with long bones are summed to a maximum score of 6)	0 = no spur
	1 = mild (1 small spur)
	2 = moderate (≥ 2 small spurs and/or 1 moderate spur)
	3 = severe (≥ 2 moderate spurs and/or ≥ 1 large spur(s))

SESSION INFORMATION

Session Date: Tuesday, November 9, 2021

Session Title: Metabolic & Crystal Arthropathies – Basic & Clinical Science Poster II (1565–1583)

Session Type: Poster Session D

Session Time: 8:30AM–10:30AM

Background/Purpose: IL-37 is an anti-inflammatory cytokine, member of IL-1 family, related to inflammatory and autoimmune diseases. Here we aimed to investigate the association of genetic variants of IL-37 and IL-37 plasma levels in relation to hyperuricemia/gout.

Methods: The study involved normouricemic controls (n=50), primary hyperuricemia (n=100), primary gout (n=100), tophaceous gout (n=25) and acute gout flare (n=18). All patients met the ACR gout classification criteria (1). Levels of plasma IL-37 were analysed using Enzyme-Linked Immunosorbent Assay. All coding regions and intron-exon boundaries of IL-37, exon 1-5, were amplified and sequenced directly. Differences of measured levels of IL-37 between groups were compared using Wilcoxon test. Variant allele frequencies were compared using binomial test and Fisher exact test.

Results: IL-37 levels were fairly similar across groups except for patients with tophaceous gout that had IL-37 levels significantly increased in contrast to control subjects (p=0.019) and gout patients (p=0.036). We identified 12 IL-37 genetic variants: five intron (rs28947188, rs2466448, rs3811045, rs3811048, rs2708944), and seven non-synonymous allelic variants (rs3811046, rs3811047, rs2708943, rs2723183, rs2723187, rs2708947, rs27231927). Of those, rs28947188 showed a significant under-presentation in hyperuricemic and gout cohorts (no variant found among all 243 patients) compared to normouricemic control group (minor allele frequency: MAF = 0.05) and European population (MAF = 0.083).

Conclusion: Variant rs28947188 showed a significant under-presentation in hyperuricemic/gout cohorts compared to European population MAF/normouricemic cohort. Plasma IL-37 is significantly up-regulated in patients with tophaceous gout compared to other groups. This evidence highlights the role of IL-37 in the pathogenesis of gout.

synthesis. These findings need to be confirmed in vivo, as they may help explain the gout-related cardiovascular risk. This study aimed to assess the inflammasome pathway activation at human atheroma plaques regarding the uricemic status.

Methods: Consecutive patients with severe peripheral arterial disease candidates to lower limb amputation were prospectively enrolled. Clinical and laboratory variables were collected; hyperuricemia was established at median serum urate (SU) levels ≥7 mg/dL; other levels, as normouricemia (NU). Patients under colchicine were excluded. A 5cm artery segment of the amputated limb was sampled during the surgical procedure and fixed by 100º absolute alcohol. H-E staining was used to study the degree of calcification, the extension of lipid cores, and the type of plaque according to the AHA grading (I-VI). Macrophages (CD68) and neutrophils (elastase), and the expression of inflammasome components (NLRP3, ASC, caspase-1 and gasdermin-D), were marked using commercial antibodies (Merck) for immunohistochemistry (IHC). Two pathologists reviewed the samples simultaneously, blinded to clinical data. IHC staining was categorized as *absent/minor* (staining with negative or clusters with< 10 cell present) or *moderate/heavy* (cell clusters with >10 cells present or abundance of positive cells) [PMID 30629987]. Comparisons were performed using chi-2 and Fisher's exact tests.

Results: Out of 27 candidates, two were excluded (one for being on colchicine, the other for incomplete IHC process), so 25 participants were finally enrolled, median (IQR) aged 72.0 years (62.0-78.0), being 64.0% males. Ten patients (40%) were HU - two with gout - with a median SU of 7.6mg/dL (7.2-8.7), while 15 (60%) were NU, median SU of 4.4 (3.4-5.0). No patient was on urate-lowering drugs. Twenty-eight artery samples were available (16 from NU, 12 from HU), predominantly from popliteal arteries in both groups (50.0% in NU, 83.3% in HU). Type V (fibroatheroma) were the most common lesions seen in both cases (43.8% in NU, 50.0% in HU). The H-E and immunostaining findings and comparisons between study groups are shown in the **Table**. Similar calcification and lipid extension were seen. No differences were noted on macrophages distribution, while neutrophils were scarce in the samples. Interestingly, in regards to the inflammasome pathway, the plaque content of NLRP3 and gasdermin-D was significantly

larger in those with HU. ASC content was numerically larger in HU as well, while caspase-1 was scantly stained in both groups.

Conclusion: HU was revealed associated with a higher NLRP3 and gasdermin-D expression at human atheroma plaques in patients with peripheral artery disease. This finding needs further replication but may contribute to understanding the relationship between gout and atherosclerosis.

Phenome-Wide Association of Gout Risk Loci

Oleg Stens[1], Vivian Trang[2], Steven Cao[2], Robert Terkeltaub[1] and Rany Salem[2], [1]University of California San Diego School of Medicine, La Jolla, CA, [2]University of California San Diego School of Public Health, La Jolla, CA

SESSION INFORMATION
Session Date: Tuesday, November 9, 2021
Session Title: Metabolic & Crystal Arthropathies – Basic & Clinical Science Poster II (1565–1583)
Session Type: Poster Session D
Session Time: 8:30AM–10:30AM

Background/Purpose: Gout is a complex disease involving changes in urate biology and inflammatory responses, and is associated with comorbidities including metabolic syndrome and cardiorenal disease. Phenome-Wide Association Study (PheWAS) is a novel analytical technique where genetic variants are interrogated against a large set of phenotypic traits. PheWAS are a powerful tool to characterize the clinical significance of genetic variants and gain insights into their biological function.

We performed a PheWAS to define phenotypic traits associated with polygenetic risk of gout using 18 known gout risk loci.

Methods: Gout-associated loci were identified through literature review. Variants in linkage disequilibrium were removed, yielding a total of 18 loci which we analyzed in UK Biobank. The 18 loci were classified as urate-related or non-urate related based on association with serum urate ($p< 1 \times 10^{-5}$). Polygenetic risk scores (PRS) were calculated by summing gout risk increasing alleles weighted by published gout association beta estimates (natural log of odds ratios). PRS were then calculated for all loci, urate-associated loci, and non-urate associated loci, and PheWAS was performed using logistic regression on discrete phenotypic traits (e.g. ICD-10 codes) from the UK Biobank study. To limit ethnic/racial confounders, we performed analyses in unrelated European ancestry UK Biobank study participants (n=382,828).

Results: 10 of the 18 SNPs were urate-associated and 8 were not. The all-gout and urate-associated PRSs revealed phenome-wide significant associations with disorders of iron metabolism ($p=7.91 \times 10^{-29}$ PRS_all, $p=9.82 \times 10^{-31}$ PRS urate), celiac disease ($p=1.30 \times 10^{-10}$ PRS_all, $p= 2.42 \times 10^{-12}$ PRS_urate) and non-celiac disease intestinal malabsorption ($p= 1.97 \times 10^{-09}$ PRS_all, $p= 1.86 \times 10^{-10}$ PRS_urate). The non-urate gout PRS did not identify any phenome-wide significance associations. We determined the urate PRS associations were driven largely by rs1165176 on *SLC17A1* ($p= 4.2 \times 10^{-81}$ iron metabolism, $p= 5.0 \times 10^{-17}$ celiac disease). Adjustment for *HFE* SNP rs1800562 (263 kb away on chromosome 6) abrogated the association between rs1165176 and iron metabolism. However, the association of rs1165176 with celiac disease remained significant.

Figure 1. SNPs Utilized in PRS analyses and association With Gout and Urate in UKBB.

rs9952962	MIR302F	C	T	1.67×10^{-08}	2.36×10^{-01}
rs12980365	ZNF724	G	A	9.76×10^{-08}	8.24×10^{-01}
rs150414818	ALDH16A1	G	C	1.50×10^{-16}	2.73×10^{-27}

Conclusion: We performed a PheWAS analysis to interrogate the clinical manifestations of polygenetic risk of gout and identified relationships between gout, celiac disease, and intestinal malabsorption. This relationship was driven by genes associated with both gout and hyperuricemia, and not by genes that were associated with gout but not

with hyperuricemia. Though epidemiological correlation between gout and ferritin levels was previously described by Fatima et al, our results suggests that linkage between *SLC17A1* and *HFE* may underlie this observation.

Whole Blood Gene Expression and eQTL Analysis Implicate GGT7 and FADS2 in Gout Pathogenesis

Richard Reynolds[1], Riku Takei[1], Jeffrey Edberg[1], Nicholas Sumpter[1], Tony Merriman[2] and Megan Leask[1], [1]University of Alabama at Birmingham, Birmingham, AL, [2]University of Alabama at Birmingham, Dunedin, New Zealand

Session Date: Tuesday, November 9, 2021
Session Title: Metabolic & Crystal Arthropathies – Basic & Clinical Science Poster II (1565–1583)
Session Type: Poster Session D
Session Time: 8:30AM–10:30AM

Background/Purpose: Gene expression studies of whole blood represent a powerful approach for understanding the pathogenesis of gout because differentially expressed transcripts may reflect the activation and response of immune cells to relevant and gout-specific stimuli. We have previously reported results (ACR 2019 abstract # 1232) of 48 statistically significant differentially expressed genes between gout cases (N=13) and non-gout controls (N =6). If the pathogenic mechanism that generates the differential expression has a genetic basis then we expect, 1) genetic variants near these genes to be associated with gout or its causal factor serum urate, and 2) that these variants co-localize with genetic variants that themselves associate with gene expression; i.e. the variants are *cis*-eQTLs.

Methods: We compared the genes whose expression was at least nominally associated with gout with results from a previously published transancestral meta analysis of serum urate and a separate GWAS of gout (Tin et al. 2019). We then used the Genotype-Tissue Expression (GTEX) database and COLOC (Giambartolomei et al. 2013) to verify whether the identified variants were associated with gene expression and colocalized with the serum urate signal.

Results: Only two out of 48 of the differentially expressed genes (*GGT7* and *FADS2*) were found to harbor variants (*cis*-eQTLs-Figure 1), that co-localized with genome-wide significant loci for serum urate (but not with gout). These genes, *GGT7* = gamma-glutamyltransferase 7, involved in glutathionine metabolism, and *FADS2* = fatty acid desaturase 2, involved in fatty acid metabolism, were both underexpressed in gout cases relative to non-gout controls. These genes are therefore strong candidate genes for a causal pathogenic role in gout.

Conclusion: It may be the case that genetic variation for serum urate and gout that comprise eQTLs manifests as differentially expressed genes between gout cases and controls. However, the most frequent observation from our data is that no genetic signal was found that explained the differences. At least three factors may underly this observation: 1) It is possible that differentially expressed genes could be mediated through eQTLs acting in *trans*. 2) We lack statistical power to detect association of genetic variants and/or gene expression with gout. 3) Epigenetic regulation, and not genetic, may be the preeminent cause of the observed gene expression differences. As additional cell type-specific expression data and highly powered gout GWAS results become available we will continue to identify genetic loci that deserve attention as potentially pathogenetic features of hyperuricemia and gout.

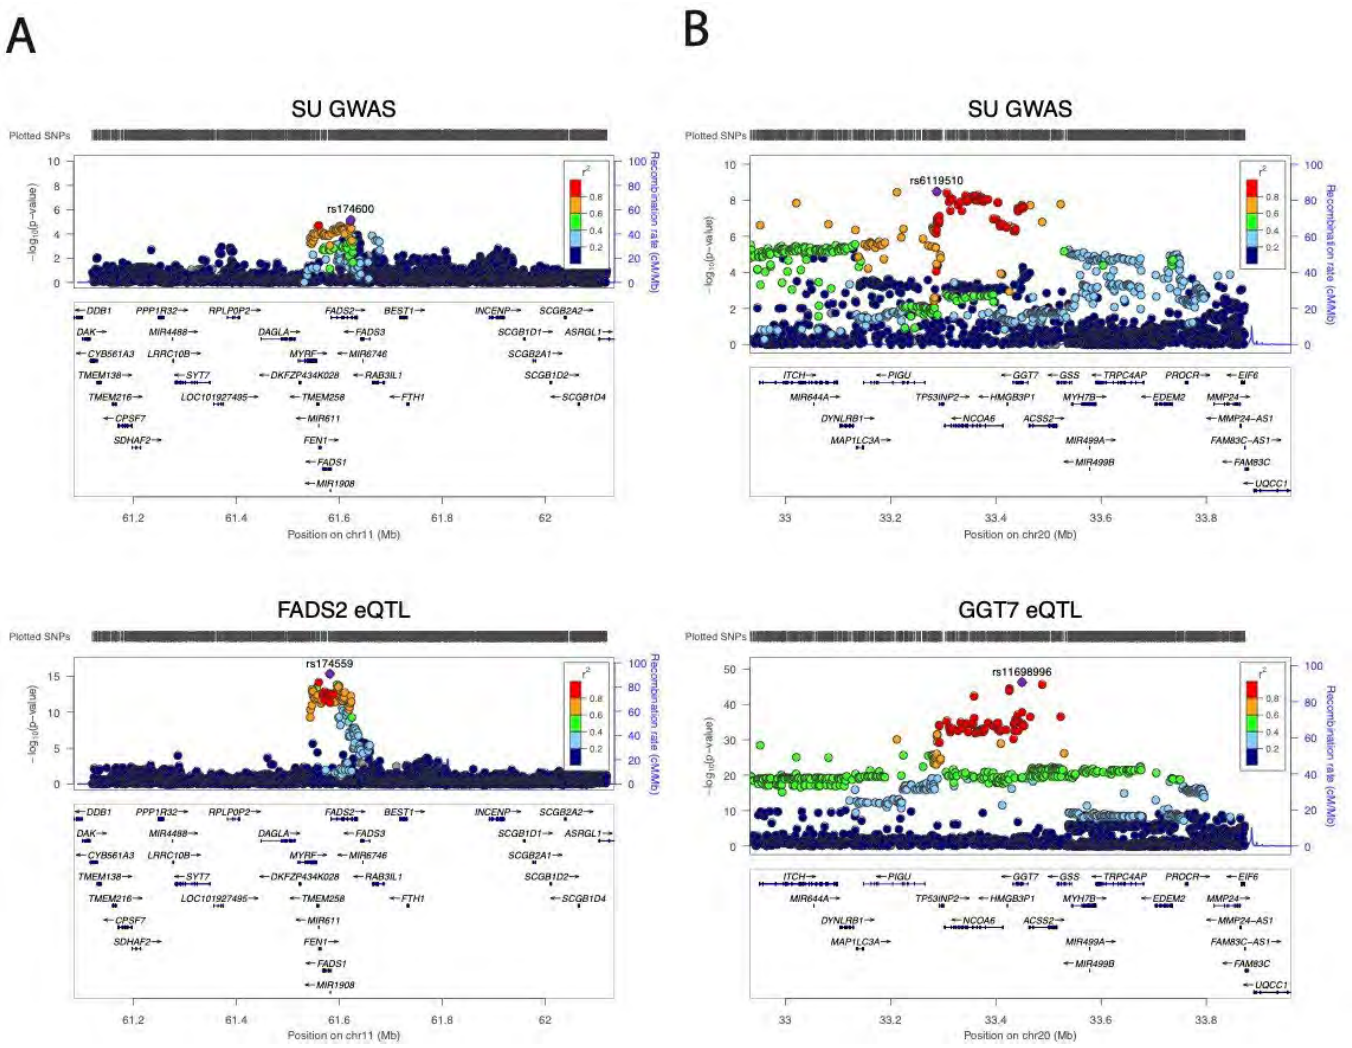

Figure 1. Colocalisation of eQTL and serum urate GWAS for FADS2 and GGT7. Regional association plots for serum urate (Tin et al. 2019) (EUR data) (top) and eQTL for (A) FADS2 (bottom left) and (B) GGT7 (bottom right). Dots indicate individual SNPs while position relative to the left y-axis indicates [-log10 (p-value)] of association. The blue line indicates the recombination rate across the locus. The lead serum urate and eQTL SNPs are indicated by a purple dot. The colouring of the surrounding SNPs indicates the strength of LD of the lead SNP according to the key on the left of each plot, measured as r2 found in the HapMap data for Europeans. The plot was generated using LocusZoom (Prium et al., 2010).

Genetic Effects on the Transition from Hyperuricemia to Gout

Nicholas Sumpter[1], Riku Takei[1], Richard Reynolds[1] and Tony Merriman[2], [1]University of Alabama at Birmingham, Birmingham, AL, [2]University of Alabama at Birmingham, Dunedin, New Zealand

SESSION INFORMATION

Session Date: Tuesday, November 9, 2021

Session Title: Metabolic & Crystal Arthropathies – Basic & Clinical Science Poster II (1565–1583)

Session Type: Poster Session D

Session Time: 8:30AM–10:30AM

Background/Purpose: There is clear evidence of genetic control of hyperuricemia resulting in increased gout risk, however genetic control of the transition from hyperuricemia to gout is unclear. Recent genome-wide association studies (GWAS) of this transition have used a serum urate threshold of 7 mg/dL to define hyperuricemic (HU) controls and tested for association of variants with gout under these conditions. Our goal was to investigate how modification of the serum urate threshold for HU controls influenced the estimated effects of these genetic variants on gout.

Methods: Using the UK Biobank European cohort (n > 330,000), we first performed a GWAS of HU to gout (using controls with serum urate > 7 mg/dL; gout case n = 7,131, control n = 27,018). We then took the resulting 7 common independent lead variants ($p < 5 \times 10^{-8}$; minor allele frequency > 0.01; independence established using PLINK LD clumping algorithm) and further investigated their association with gout when varying the definition of controls at 5 thresholds (no threshold, > 6, > 7, > 8, and > 9 mg/dL). Cases on urate lowering therapy (ULT) were not excluded as to emulate existing genetic studies of HU to gout. Additionally, we binned cases and controls based on their serum urate levels (after excluding cases on ULT; bins of 1 mg/dL ranging from 4 to > 9 mg/dL) and tested the variants for association with gout in these bins. The 7 variants were also combined into a polygenic risk score and the same models were run on this score. All models were adjusted for sex and age.

Results: We found that the effect size of each variant on gout decreased with increasing mean SU for controls (Figure 1), however, even at high control mean SU, most variants had a residual association with gout. This residual association was even more apparent when cases and controls were binned by SU level and association analysis done using individuals only in the specific bins (Figure 2).

Conclusion: The effect size of genetic variants associated with gout identified using HU controls (SU > 7 mg/dL) decreases as the serum urate threshold for defining controls increases. However, there are still residual effects on gout even at higher HU thresholds for controls. It is possible that these residual effects represent inflammatory genetic components of gout but given that all 7 variants tested have known strong effects on SU, other explanations may be more likely. One such explanation is that the observational study design (single measurements of serum urate) does not adequately capture the lifetime effects of these variants on serum urate and therefore gout, with residual gout associations perhaps indicating an effect of prolonged hyperuricemia due in part to these variants. Therefore, this

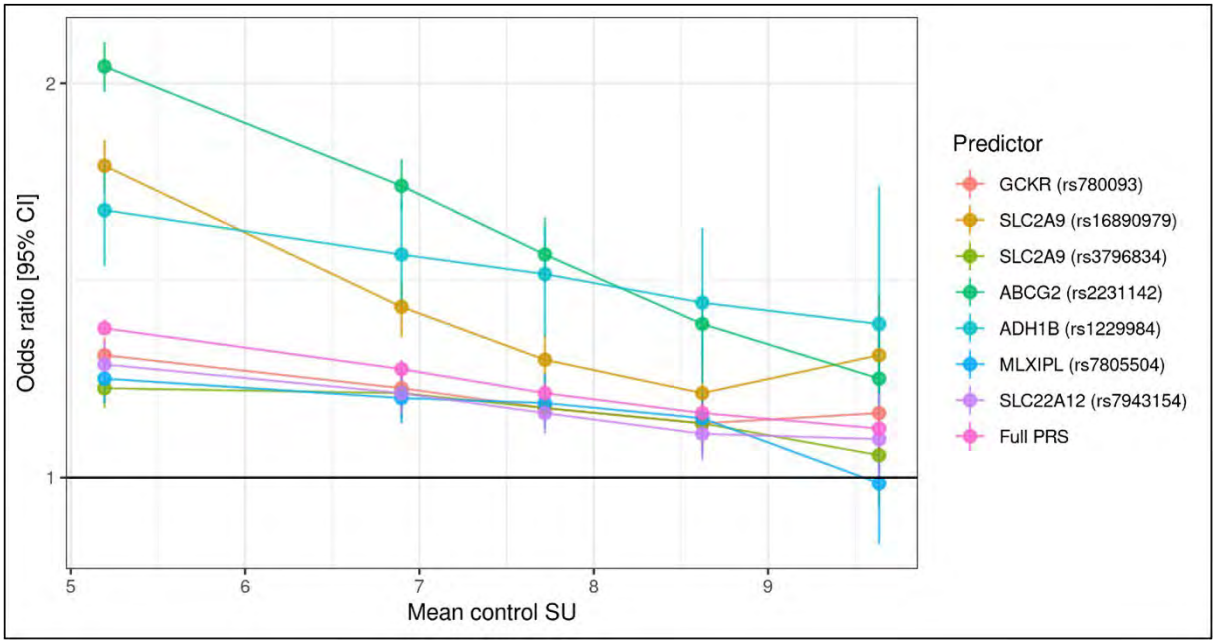

Figure 1. Effect of 7 HU to gout associated variants and their combined polygenic risk score (Full PRS) on gout with varied definitions of HU control. Y-axis shows odds ratio for gout ± 95% CI. X-axis shows mean control SU.

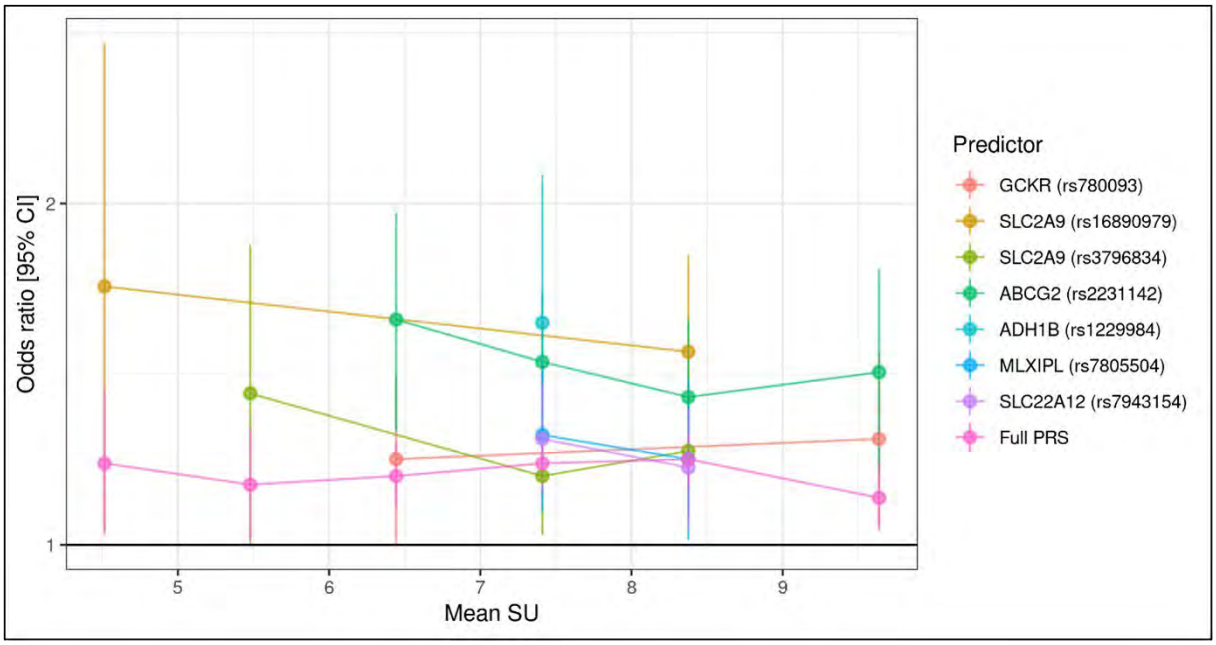

Figure 2. Significant ($p < 0.05$) binned effects of 7 HU to gout associated variants and their combined polygenic risk score (Full PRS) on gout with binned cases and controls (after exclusion of cases on urate lowering therapy). Y-axis shows odds ratio for gout ± 95% CI. X-axis shows mean SU of bin.

study indicates the need for genetic investigations of prolonged elevated serum urate on gout. Such investigations would focus on the lifetime burden of urate exposure, including urate crystal deposits.

SESSION INFORMATION

Session Date: Tuesday, November 9, 2021
Session Title: Metabolic & Crystal Arthropathies – Basic & Clinical Science Poster II (1565–1583)
Session Type: Poster Session D
Session Time: 8:30AM–10:30AM

Background/Purpose: Conventional Radiography (CR) has been widely used in Calcium Pyrophosphate Deposition Disease (CPPD) and is considered an important tool for the diagnosis. However, there are very few studies that examine the reliability and the diagnostic accuracy of CR. The aims of this study were to evaluate the diagnostic accuracy of knee CR in CPPD compared to histology and to assess the reliability of CR in CPPD.

Methods: This is an ancillary study of the Criterion Validity of Ultrasound in CPPD study. Consecutive patients with osteoarthritis (OA) awaiting total knee replacement were enrolled in 4 centres. All patients underwent CR of the knees taken maximum 6 months before surgery. DICOM files of the preoperative radiographs were read independently by two radiologists experienced in CPPD for the presence/absence of CPPD at the level of several knee structures. Each reader performed a second evaluation 3 weeks later to calculate the intra-reader agreement. In case of disagreement, for the assessment of accuracy, a consensus decision was taken. The new definitions of the ACR/EULAR taskforce for identification of CPPD in CR were used in this study [paper under submission]: CPPD in CR appears as "linear or punctate opacities in the region of fibro- or hyaline articular cartilage/synovial membrane or joint capsule/within tendons or entheses that are distinct from denser, nummular radio-opaque deposits due to basic calcium phosphate deposition". Menisci and the hyaline cartilage were analysed as described in the main study. Cohen's kappa was used to calculate the agreement between the two readers.

Results: 67 patients with OA were enrolled for the reliability study (65% F, mean age 71yo±8) and 51 for the accuracy study (63% F, mean age 74yo±8). For 16 patients not all specimens were retrieved during surgery, so they were excluded from the accuracy study. CR demonstrated to be a specific exam for identification of CPPD at the knee, but sensitivity remains low in all sites and in the overall evaluation (Table1). According to the results of the predictive

***Table 1**. reliability and accuracy of CR for identification of CPPD by using the new ACR/EULAR taskforce definitions*
Kappa values from 0.01–0.20 are considered as none to slight agreement, 0.21–0.40 as fair, 0.41– 0.60 as moderate, 0.61–0.80 as substantial, and 0.81–1.00 as almost perfect agreement.

	Medial meniscus	Lateral meniscus	Hyaline cartilage	Quadriceps tendon	Patellar tendon	Capsule/ synovia	Menisci + cartilage	Entire joint
RELIABILITY								
Inter-reader	0.62	0.56	0.57	0.38	NA	0.62	0.52	0.45
Intra-reader 1st assessor	0.78	0.85	0.83	0.49	0.66	0.66	0.69	0.68
Intra-reader 2nd assessor	1	0.83	0.96	1	1	0.94	0.97	1
ACCURACY								
Sensitivity	32%	40%	48%				54%	
Specificity	100%	96%	93%				92%	
PPV	100%	91%	87%				87%	
NPV	56%	62%	94%				67%	
AUC	0.66	0.68	0.70				0.73	
Accuracy	66%	68%	70%				73%	

values, the presence of typical deposition on CR allows a definite confirmation of the diagnosis, but a negative radiography does not exclude CPPD. The k values of the inter- and intra-reader agreement in the various structure are indicated in Table1. Inter-reader agreement was substantial at the level of both menisci but only moderate or fair at the other sites of assessment. On the other hand, intra-reader kappa values were substantial or higher in almost all sites.

Conclusion: The presence of typical CPPD calcifications on CR, according to the definitions of the ACR/EULAR task force, are highly specific but have low sensitivity for disease identification. The low sensitivity found in this study could be due to the advanced grade of OA in the cohort of patients. Furthermore, the difference of the intra-reader compared to the inter-reader kappa values, highlight a different application of the definitions for most of the sites, with the exception of the menisci. For that reason the assessment of calcium crystals at the menisci level should be used for identification of CPPD as other sites of the knee seem to present low reliability.

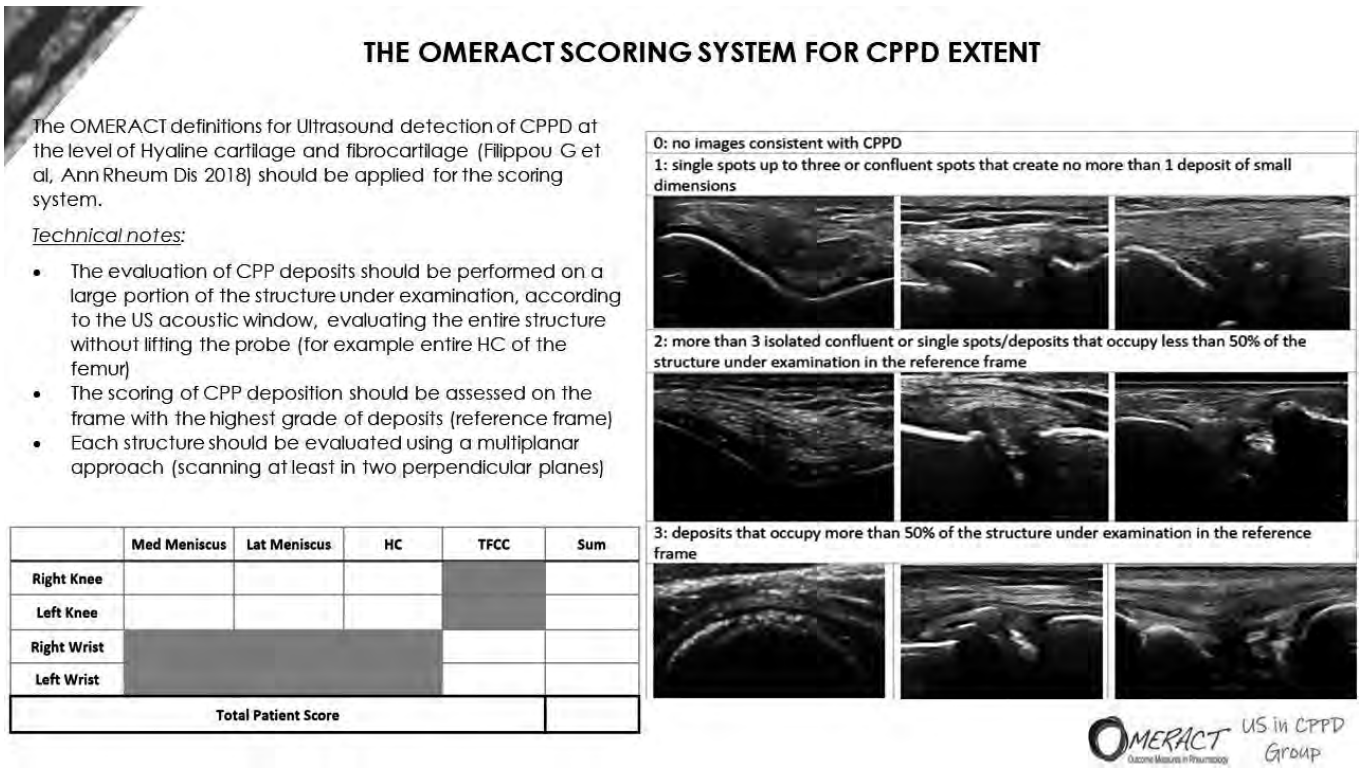
SESSION INFORMATION

Session Date: Tuesday, November 9, 2021
Session Title: Metabolic & Crystal Arthropathies – Basic & Clinical Science Poster II (1565–1583)
Session Type: Poster Session D
Session Time: 8:30AM–10:30AM

Background/Purpose: Ultrasound (US) has proven to be an excellent technique for detecting Calcium Pyrophosphate (CPP) deposits, however there are no grading systems that allow for a quantification and extent of deposition in patients. The only attempt was made on 2013 by Filippou *et al*. (Filippou G et al. *Ann Rheum Dis* 2013) but that score was never validated. The aim of this study is to create a scoring system for the quantification of CPP deposition at patient level according to the OMERACT framework.

Methods: According to the OMERACT methodology we performed a systematic literature review (SLR) aimed to estimate the prevalence of CPP deposition in peripheral joints by imaging in order to establish relevant joints for Calcium Pyrophosphate Deposition Disease (CPPD) monitoring [abstract submitted separately]. At the same time, a preliminary survey was circulated among the members of the OMERACT US – CPPD subgroup to collect their suggestions on the items to be included in the scoring system according to their personal experience. Subsequently, a Delphi survey was prepared and circulated between members of the OMERACT US – CPPD subgroup, including statements that reflected both the results of the SLR and of the preliminary survey. In total, 32 statements were created regarding the kind of scoring for single structures, the sites to be included, the final scoring at patient level, and the scanning technique. Participants were asked to reply on a Likert Scale and agreement was achieved when 4 and 5 grades reached 75% or more of concordance. In case of disagreement, new statements were proposed according to the members suggestions and proposed for voting in a consequent round.

Results: 3 Delphi rounds were needed in order to reach agreement on all items. 32 participants out of 41 members replied at the first round, 26/32 at the second and 25/26 at the third round. 20 statements were approved in the first round, 3 at the second and 3 at the third. Statements in some cases were grouped together (for example the scale



to use for the scoring) so once agreement was reached for one scoring the others were not proposed anymore. The experts decided to include only the knees (menisci and hyaline cartilage) and the triangular fibrocartilage of the wrists in the final score, using a four-grade scoring system (0-3). The final scoring with the definitions and the relative technical notes is represented in Figure 1.

Conclusion: This is the first attempt to create a scoring system for CPP crystals extent in patients affected by CPPD. In the next future the scoring will be assessed for reliability and hopefully released for use in clinical practice and research.

Relation of Depressive Symptoms to Alterations in Conditioned Pain Modulation in Knee Osteoarthritis: The Multicenter Osteoarthritis Study (MOST)

Kosaku Aoyagi[1], Lisa Carlesso[2], Laura Frey-Law[3], Gabriela Rabasa[4], Cora Lewis[5], Michael Nevitt[6] and Tuhina Neogi[7], [1]Boston University, Quincy, MA, [2]McMaster University, Hamilton, ON, Canada, [3]University of Iowa, Iowa City, IA, [4]Boston University, Boston, MA, [5]University of Alabama Birmingham, Birmingham, AL, [6]University of California San Francisco, Orinda, CA, [7]Boston University School of Medicine, Boston, MA

SESSION INFORMATION
Session Date: Tuesday, November 9, 2021
Session Title: Orthopedics, Low Back Pain, & Rehabilitation Poster (1584–1588)
Session Type: Poster Session D
Session Time: 8:30AM–10:30AM

Background/Purpose: Inefficiency of descending conditioned pain modulation (CPM) is present in 42-55% of individuals with knee osteoarthritis (OA), which can contribute to more pain and may result in poor response to current treatments. Depressive symptoms can induce increased activity in the forebrain region and limbic system that may influence the descending conditioned pain modulatory pathways. The extent to which depressive symptoms may be a risk factor for alterations in the descending pathways may be clinically important to identify new therapeutic targets for better pain management in people with knee OA. We therefore sought to examine the relation of depressive symptoms to presence and development of inefficient CPM over two years in people with or at risk of knee OA.

Methods: We used data from the Multicenter Osteoarthritis (MOST) Study, a NIH-funded longitudinal cohort of individuals with or at risk of knee OA. We defined depressive symptoms as a score of ≥16 on the Center for Epidemiologic Studies Depression Scale (CES-D). CPM was assessed with pressure pain threshold (PPT) at the wrist as the test stimulus and forearm ischemia as the conditioning stimulus. We calculated the ratio of post-conditioning stimulus PPT to the pre-conditioning stimulus PPT and defined inefficient CPM as a ratio < 1.12 of the post-conditioning

Table: Relation of Depressive Symptoms to Development of Inefficient CPM	
Relation of depressive symptoms at baseline to:	**Adjusted Effect Estimate (95% CI)**
Development of inefficient CPM over 2 years (N=1033)	OR 0.61 (0.40, 0.94)
Baseline inefficient CPM (N=2761)	OR 0.86 (0.68, 1.09)
Change in CPM over 2 years (N=2761)	Beta coefficient 0.03 (-0.02, 0.07)

stimulus PPT to pre-conditioning stimulus PPT based upon published data. For the main analysis, we limited our sample to those with efficient CPM at baseline to assess the relation of depressive symptoms to development of inefficient CPM over two years using logistic regression, adjusting for age, sex, and BMI. Because of concerns regarding potential collider bias given that depressive symptoms are often chronic and likely preceded our study baseline, we additionally performed 2 analyses using the whole study sample: 1) a cross-sectional analysis at baseline; 2) a longitudinal analysis evaluating change in CPM ratio over two years using linear regression; this analysis also aimed to account for potential misclassification of categorization of CPM status.

Results: 1033 participants were included in the main analysis (mean age 65±10.5 years, mean BMI 29.5±5.7 kg/m^2, 41% female). Of those, 13% had depressive symptoms at baseline and 45% developed inefficient CPM over two years. Compared to those without depressive symptoms at baseline, depressive symptoms were associated with 39% reduced odds of developing inefficient CPM (**Table**). When we included whole sample (N=2761) in the cross-sectional analysis, depressive symptoms were non-significantly associated with 14% reduced odds of being inefficient CPM. Depressive symptoms were not associated with change in CPM over two years.

Conclusion: In contrast to our hypothesis, we found that having depressive symptoms was protective of development of inefficient CPM in knee OA. These findings suggest that depressive symptoms may potentially contribute to strengthening or activation of the descending conditioned pain modulatory pathways, such as through enhanced central inhibitory neurotransmitter levels or other central mechanisms.

Abstract Number: 1585

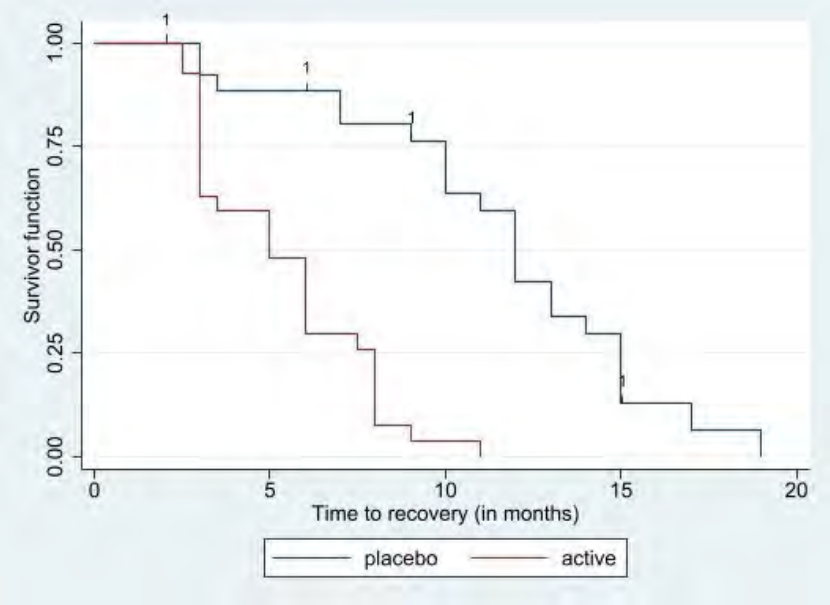
Suprascapular Nerve Block for the Treatment of Adhesive Capsulitis

Ernst Shanahan[1], Elizabeth Briggs[1], Tiffany Gill[2], Catherine Hill[3] and Tim Morris[4], [1]SA Health, Adelaide, Australia, [2]University of Adelaide, Adelaide, Australia, [3]Queen Elizabeth Hospital, Woodville, Australia, [4]Flinders University, Adelaide, Australia

SESSION INFORMATION
Session Date: Tuesday, November 9, 2021
Session Title: Orthopedics, Low Back Pain, & Rehabilitation Poster (1584–1588)
Session Type: Poster Session D
Session Time: 8:30AM–10:30AM

Background/Purpose: To investigate the value of suprascapular nerve block (SSNB) as a treatment option for adhesive capsulitis.

Methods: Patients with adhesive capsulitis confirmed by a rheumatologist were invited to participate in the study. A randomised, double blind placebo controlled trial of standard therapy plus placebo versus standard therapy plus



Survival analysis – Kaplan Meier curve, demonstrates the difference in time to resolution in the two groups.

SSNB was performed. Standard therapy comprised an intra-articular glenohumeral joint injection of 20 mg of triamcenolone at time zero, plus a physiotherapist supervised exercise program. Patients received either a SSNB (10 mls of 0.5% bupivacaine and 40 mg of depomedrol) or placebo (3 mls of subcutaneous normal saline) injection at time zero and then at 3 monthly intervals until resolution. Resolution was defined as a return to full range of movement and a reduction of pain scores to normal, or recovery to the satisfaction of the patient. Pain, disability, range of movement and patient perceived rate of recovery scores were measured at 12 weekly intervals in the two groups.

Results: 54 patients (19 male, 35 female, mean age 54 years (range 32-72) participated. 27 patients received standard therapy plus the SSNB and 27 patients received standard therapy plus a placebo. 4 patients withdrew during the course of the study (all in the placebo group). The mean time to resolution of the symptoms was 5,4 months (CI 4,4-6.3) in the active group versus 11.2 months (CI 9.3-13.0) in the placebo group. Pain, disability, patient perceived rate of recovery and range of movement scores were significantly better in the actively treated group compared with the placebo group at all time intervals. The was one presycopal episode in the actively treated group but no other significant complications.

Conclusion: SSNB is highly effective in reducing the duration of frozen shoulder. It reduces pain significantly and is associated with high levels of patient satisfaction with recovery. It is safe and can be recommended as a useful adjunct therapy.

Individuals with Pre-arthritic Hip Pain Walk with Hip Motion Alteration Common in Individuals with Hip OA

Cara Lewis[1], Anne Halverstadt[2], Kerri Graber[2], Zoe Perkins[2], Emily Keiser[2], Hadwin Belcher[2] and Anne Khuu[2], [1]Boston University, Brookline, MA, [2]Boston University, Boston, MA

SESSION INFORMATION

Session Date: Tuesday, November 9, 2021
Session Title: Orthopedics, Low Back Pain, & Rehabilitation Poster (1584–1588)
Session Type: Poster Session D
Session Time: 8:30AM–10:30AM

Background/Purpose: Individuals with hip osteoarthritis (OA) commonly walk with less hip extension compared to individuals without hip OA. This alteration is often attributed to walking speed, structural limitation, and/or hip pain. It is unclear if individuals with pre-arthritic hip disease (PAHD), such as dysplasia, femoroacetabular impingement syndrome, and acetabular labral tears, also walk with altered movement patterns. Thus, the objective of this study was to 1) determine if individuals with PAHD walk with less hip extension compared to individuals without pain, and 2) investigate potential reasons for this motion alteration.

Methods: Adolescent and adult individuals with PAHD and healthy controls without pain were recruited. Provocative hip tests (FABER, FADIR, and resisted straight leg raise) were used to confirm presence (PAHD group) or absence (Control group) of hip pain. Kinematic data were collected while walking on a treadmill at three speeds: preferred, fast (25% faster than preferred), and prescribed (1.25 m/s). Peak hip extension, peak hip flexion, and hip excursion were calculated at each walking speed. Linear regression analyses with GEE were used to examine the effects of group, sex, task, side, and their interactions.

Results: Hip angle data from 137 individuals with PAHD and 60 individuals without pain were included in the study (Table 1). The PAHD group was older than the Control group (p=.003). Individuals with PAHD had 2.9° less peak hip extension compared to individuals in the Control group (95% Confidence Interval (CI): 0.6, 5.1; p=.014) when walking at their preferred speed. At the prescribed speed, the PAHD group walked with 2.7° less hip extension than the Control group (95% CI: 0.4, 5.0; p=.022). Given the persistence of the finding despite walking at the same speed, the observed reduction in hip extension was not due to speed alone. When compared to the preferred speed, both groups increased their hip extension, hip flexion, and hip excursion by similar amounts at the fast speed, and no *group-by-task* interaction was noted (p=.206). This finding suggests that the PAHD group had the ability to walk with more hip extension at the preferred speed, and thus, the difference was not due to structural limitation. Within the PAHD group, individuals that reported pain during the walking task did not use different hip angles or excursion compared to individuals reporting no pain (p≥.185); thus, pain during walking was not the primary reason for reduced hip extension.

Conclusion: The results of this study indicate that the kinematic alteration common in individuals with hip OA exists early in the continuum of hip disease and was present in individuals with PAHD. The reduced hip extension during walking was not explained by preferred walking speed, structural limitation, or current pain; therefore, intervening on these factors alone is unlikely to address the habitual motion alteration.

Table 1. Mean (standard deviation or range) demographic data for individuals with pre-arthritic hip disease (PAHD) and individuals without pain (Control)

	PAHD		Control	
	Male (n=37)	Female (n=100)	Male (n=25)	Female (n=35)
Age, years	27.9 (9.5)	27.4 (8.6)	23.6 (5.6)	23.8 (5.4)
Height, meters	1.81 (0.07)	1.66 (0.07)	1.79 (0.07)	1.64 (0.07)
Mass, kg	80.7 (10.7)	66.6 (10.2)	77.5 (12.4)	61.3 (8.4)
BMI, kg/m^2	24.7 (3.1)	24.1 (3.4)	24.1 (2.9)	22.8 (2.5)
UCLA Activity Score (0-10)	8.3 (4-10)	7.8 (2-10)	8.6 (5-10)	8.4 (4-10)
Preferred Walking Speed, m/s	1.23 (0.17)	1.29 (0.18)	1.26 (0.19)	1.29 (0.16)
Modified Harris Hip Score	77.4 (11.1)	73.3 (13.3)	99.9 (0.9)	100 (0.2)

Abstract Number: 1587

Do Physical Therapists Use Recommended Treatments for Chronic Low Back Pain?

Debbie Feldman[1], Jonathan El-Khoury[2], Tatiana Orozco[1], François Desmeules[3], Maude Laliberté[1] and Kadija Perreault[4], [1]Université de Montréal, Montréal, QC, Canada, [2]Université de Sherbrooke, Sherbrooke, QC, Canada, [3]Research Centre of Hôpital Maisonneuve Rosemont, Montréal, QC, Canada, [4]Université Laval, Québec City, QC, Canada

SESSION INFORMATION
Session Date: Tuesday, November 9, 2021
Session Title: Orthopedics, Low Back Pain, & Rehabilitation Poster (1584–1588)
Session Type: Poster Session D
Session Time: 8:30AM–10:30AM

Background/Purpose: Chronic low back pain has been the subject of many studies in medicine and physical therapy for over half a century. Clinical practice guidelines based on evidence have not changed much in the past 30 years, recommending patient education and self-management, and generalized exercise programs. Other treatments such as orthotics, acupuncture, electrotherapies are not recommended, whereas manual therapy, psychological therapies are considered helpful in combination with patient education and exercise. Persons with chronic low back pain often consult a physical therapist. The purpose of our study was to determine whether physical therapists provide recommended treatments for a typical case of chronic low back pain. We also sought to identify factors associated with the use of some specific types of treatment, notably, electrotherapy (which is not recommended) and manual therapy (which can be recommended together with exercise).

Methods: We sent an online survey to physical therapists in the province of Quebec, Canada. The survey contained clinical vignettes of four different cases, one of which was chronic low back pain with sciatica. Participants were asked about what kind of treatment they would provide for this patient showing typical signs and symptoms of chronic low back pain with sciatica as well as whether they would refer the patient to another professional. Descriptive statistics were used to illustrate the proportions for each treatment chosen by physical therapists. We explored associations between choice of treatments with physical therapists' demographic and practice related factors, using inferential statistics and regression analyses.

Results: There were 176 physical therapists who responded, 41 who identified as male (23.3%) and the majority (63.6%) worked in private practice. The vast majority of physical therapists would provide education (93.8%) and exercise (81.8% mobility exercises, and 65.9% strengthening exercises). Nearly 73% would use manual therapy while 46% would use electrotherapy. The percentage who selected manual therapy together with any type of exercise was 72.7. Many thought it would be important to refer to another health professional such as a family physician (70.6%), a physical therapist who specializes in backs (62.1%), but not to a rheumatologist (0.4%). Regression analyses revealed certain factors associated with the selection of various treatments. Physical therapists with less experience were more likely to select manual therapy (p=0.01) while those working in rural areas were more likely to choose electrotherapy (p=0.03).

Conclusion: Physical therapists would treat a patient with chronic low back pain with the recommended treatments, i.e. education and exercise. Most would also use manual therapy, and for the majority, this was in conjunction with

both education and exercise. However, there is a need for improved knowledge translation/education since nearly half would still use the non-recommended electrotherapy treatment.

Abstract Number: 1588

Relation of Foot and Ankle Pain to Worsening Knee Pain: The MOST Study

Patrick Corrigan[1], David Felson[2], Tuhina Neogi[3], Cara Lewis[4], James Torner[5], Michael Nevitt[6], Cora Lewis[7] and Joshua Stefanik[1], [1]Northeastern University, Boston, MA, [2]Boston University, Boston, MA, [3]Boston University School of Medicine, Boston, MA, [4]Boston University, Brookline, MA, [5]University of Iowa, Iowa City, IA, [6]University of California San Francisco, Orinda, CA, [7]University of Alabama Birmingham, Birmingham, AL

SESSION INFORMATION
Session Date: Tuesday, November 9, 2021
Session Title: Orthopedics, Low Back Pain, & Rehabilitation Poster (1584–1588)
Session Type: Poster Session D
Session Time: 8:30AM–10:30AM

Background/Purpose: Foot and ankle pain may be a risk factor for worsening knee pain in those with or at risk for knee osteoarthritis (KOA). Foot and ankle pain is associated with biomechanical alterations that shift load from the foot and ankle to the knees. Since increased knee joint loading is a well-established risk factor for KOA, foot and ankle pain may play a key role in the onset and progression of knee pain. Previous work has shown that pain anywhere in the foot or ankle increases the odds of worsening knee pain in those with KOA. However, this work did not account for widespread pain (WSP), which could partially explain the effect of foot and ankle pain on worsening knee pain. We aimed to determine if foot or ankle pain is associated with worsening knee pain while accounting for WSP.

Methods: We used data from the 144- and 168-month visits of the Multicenter Osteoarthritis (MOST) Study, a cohort study of persons with or at risk for KOA. At 144-months, participants were asked "On most days, do you have pain, aching, or stiffness in any joints?" If the participant answered "yes," painful sites were marked on a homunculus. For the current study, our exposure was foot or ankle pain. For our outcome, worsening knee pain, we calculated the change in the Western Ontario and McMaster Universities Osteoarthritis Index – Pain (WOMAC-P) from 144- to 168-months for each knee, then defined "worsening" as an increase of ≥2 points. To determine the relation of foot or ankle pain to worsening pain of the ipsilateral and contralateral knees, we used logistic regression models with generalized estimating equations to account for bilateral data. Models were first adjusted for age, sex, BMI, race, depressive symptoms, and baseline WOMAC-P and Kellgren-Lawrence grade of the outcome knee. To account for WSP, analyses were then repeated adding the number of painful sites above the waist as a covariate. Those with knee replacement or missing data were excluded.

Results: 2201 participants were included (57% female; 81% white; mean (SD) age = 63.6 (10.1) years; mean (SD) BMI = 29.2 (5.6) kg/m^2). Of the 3892 limbs, 1271 (33%) had foot or ankle pain. Knee pain worsened in 758 knees (19.5%). Compared to limbs without foot or ankle pain, limbs with foot or ankle pain had 1.61 (1.30-1.99) and 1.50 (1.22-1.85) times the odds of worsening ipsilateral and contralateral knee pain, respectively (Figure 1). When accounting for the number of painful sites above the waist, limbs with foot or ankle pain had 1.29 (1.03-1.61) and 1.18 (0.95-1.48) times the odds of worsening ipsilateral and contralateral knee pain, respectively (Figure 1). The mean (SD; Min-Max) number of painful sites above the waist was 1.68 (1.77; 0-10), and for each additional painful site the odds of worsening ipsilateral and contralateral knee pain were increased by 1.22 (1.16-1.29) and 1.23 (1.16-1.30) times, respectively.

Conclusion: Foot or ankle pain is associated with increased odds of worsening ipsilateral knee pain, even after accounting for WSP. The odds of worsening contralateral knee pain, on the other hand, seems to be affected by WSP. Clinicians may need to pay attention to foot and ankle pain as well as consider WSP to optimize outcomes for patients with KOA.

Abstract Number: 1589

COVID-19 Vaccine Hesitancy in Rheumatology Patients

Rebecca Sadun[1], Amanda Eudy[1], Jennifer Rogers[1], Kai Sun[2], Lisa Criscione-Schreiber[2], Mithu Maheswaranathan[2], Jayanth Doss[1] and Megan Clowse[3], [1]Duke University, Durham, NC, [2]Duke University School of Medicine, Durham, NC, [3]Duke University, Chapel Hill, NC

SESSION INFORMATION

Session Date: Tuesday, November 9, 2021
Session Title: Patient Outcomes, Preferences, & Attitudes Poster IV: COVID-19 (1589–1613)
Session Type: Poster Session D
Session Time: 8:30AM–10:30AM

Background/Purpose: Patients with rheumatic diseases on certain immunosuppressant medications are known to be at higher risk for severe COVID-19. The ACR recommends COVID-19 vaccination for nearly all patients with rheumatic diseases. However, some individuals remain hesitant to receive a COVID-19 vaccine. This study assessed the basis for COVID-19 vaccine hesitancy in rheumatology patients. This study assessed the basis for COVID-19 vaccine hesitancy in rheumatology patients seen at a large academic medical center in the Southeastern United States.

Methods: A survey was distributed electronically during the last week of December 2020 and the first week of January 2021 (when in the US, COVID-19 vaccines were available only to health professionals) to rheumatology patients at a large academic center in the Southeastern United States. Patients completed a COVID-19 vaccine belief survey, adapted from the Vaccine Hesitancy Scale (VHS), along with a demographic survey. Patients were asked whether they would get a COVID-19 vaccine and responses were dichotomized as definitely/probably vs probably not/definitely not. Descriptive statistics and logistic regression models evaluated factors associated with vaccine hesitancy.

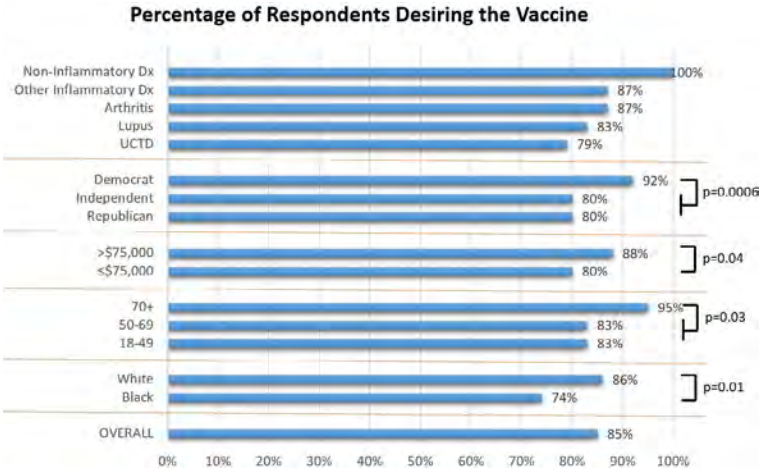

Figure 1. Vaccine hesitancy by rheumatic diagnosis, political affiliation, household income, age, and race.

Results: A total of 433 patients responded to the survey: 48% self-identified as having inflammatory arthritis, 83% as female, 4% as Hispanic, 10% as Black, and 50% as a member of the Democratic Party. Individuals who wanted the COVID-19 vaccine had less hesitancy on 3 survey subscales ($p< 0.001$). Of respondents who identified as White, 86% wanted to receive the vaccine, in comparison to 74% of respondents who identified as Black ($p=0.04$) (Figure 1). Patients over the age of 70, with income >$75,000, or identifying as Democrats were also more likely to desire COVID-19 vaccination. Backward regression models identified White race (OR: 4.43; 95% CI: 1.80, 10.98) and affiliation with the Democratic Party (OR: 4.20; 95% CI: 1.93, 9.20) to be independently associated with wanting the vaccine. The primary reasons cited

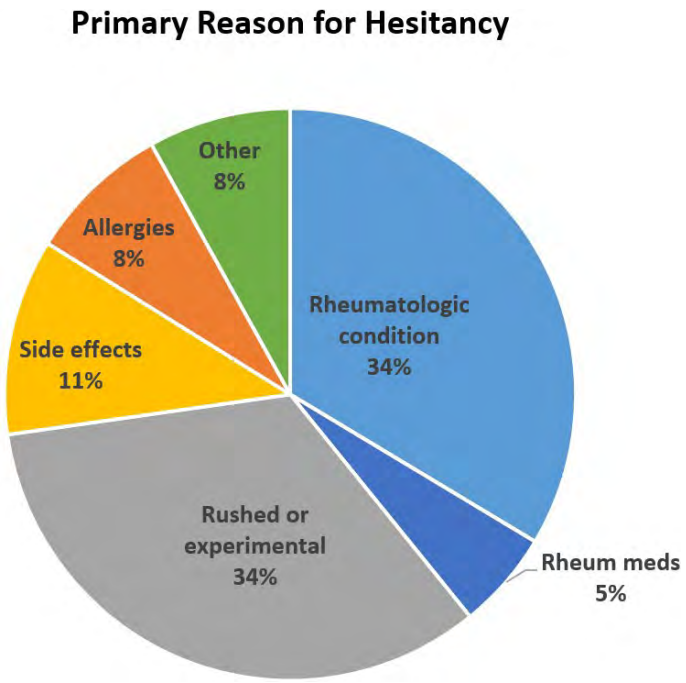

Figure 2. Patients' stated primary reason for COVID-19 vaccine hesitancy (free-response question with qualitative data coded by theme).

Figure 3. Factors rheumatology patients indicate would increase the likelihood of their opting to receive the COVID-19 vaccine in the future (multiple-choice, "select all that apply" question).

for hesitancy were: the vaccine being "rushed" or "experimental" (34%), safety of the vaccine in the context of patients' rheumatologic diagnoses (34%), side effects (11%), and concern for allergic reaction (8%) (Figure 2). Common reasons for vaccine-hesitant patients to consider getting the vaccine were: "evidence the vaccine is safe in patients with my rheumatic condition" (69%) and "the ACR recommends it for people with my condition" (57%) (Figure 3).

Conclusion: Rheumatology patients wanted to be vaccinated against COVID-19 at a rate that was higher than national surveys estimates (85% vs 60-69%) during the same time period. As in national surveys, White race and Democratic Party affiliation were strongly associated with rheumatology patients wanting the vaccine. More than one third of patients revealed factors related to their rheumatologic diagnosis as the primary reason for their hesitancy. Importantly, the majority of patients indicated that they would be more likely to get the COVID-19 vaccine based on recommendations from the ACR or their rheumatologist, or in the setting of evidence of vaccine safety in rheumatic conditions.

SESSION INFORMATION
Session Date: Tuesday, November 9, 2021
Session Title: Patient Outcomes, Preferences, & Attitudes Poster IV: COVID-19 (1589–1613)
Session Type: Poster Session D
Session Time: 8:30AM–10:30AM

Background/Purpose: As the COVID-19 pandemic unfolded, people across the world experienced a psychological burden with social confinement, concerns about health, potential infection, jobs, financial difficulty, and uncertainty about the future. Immunosuppressed patients with chronic inflammatory diseases (CID) may have experienced an additional burden with their immunocompromised status. The purpose of this study was to examine patient-reported outcomes over time in patients with CID undergoing SARS-CoV2 vaccination.

Methods: This is a prospective cohort of patients at two sites with CID undergoing SARS-CoV2 vaccination. Participants completed 3 study visits (baseline before vaccination (T1), after dose 1 (T2), and after dose 2 (T3)) where blood and clinical data were collected. Patient-reported outcomes were measured with the PROMIS-29, which includes 4-item scales for 7 domains (physical function, fatigue, anxiety, depression, sleep disturbance, social participation, pain interference) and a 1-item pain severity question. PROMIS-29 scales were summed and converted to T scores (population mean [SD] of 50 [10]). Mixed effects models were used to examine how the PROMIS scores compared to baseline after both vaccination doses, adjusting for age, gender and study site.

Results: The cohort was 72% female with a mean (± SD) age of 48.1±15.5 years (Table 1). In the overall cohort, sleep disturbance significantly improved after both doses of SARS-CoV2 vaccinations (T score -2.5, 95%CI -3.4, -1.6) (Ta-

bles 2). Anxiety improved after the second vaccine dose. Improvements in each were within the range of estimated minimally important differences (MID). Physical function worsened, although this did not meet the MID threshold (-1.0, 95% CI -1.6, -0.4). In an analysis stratified by levels of baseline anxiety (High anxiety: PROMIS Anxiety ≥55 vs < 55), improvement in anxiety at T3 was greater for the higher versus lower anxiety group (-5.4, 95% CI -7.2, -3.6 [T3 T1] vs. -3.7, 95%CI -5.6, -1.8). Improvements in fatigue (-2.1, 95% CI -3.6, -0.5) and social participation (2.3, 95% CI 0.5, 4.2) were also noted for the high-anxiety group (Table 2). Similar to the overall cohort, physical function worsened slightly for both groups and sleep disturbance improved significantly.

Conclusion: With the completion of the SARS-CoV2 vaccine series, sleep disturbance decreased in a significant and meaningful way in patients with CID. In patients with higher anxiety at baseline, not only did anxiety decrease, but so did fatigue and sleep disturbance in addition to an increase in social participation. Overall, this suggests vaccines may lead to improvements in mental health and wellbeing of patients with CID, particularly among those with greater anxiety.

Table 1. Demographic and Clinical Characteristics of Participants

Demographic Data	Overall cohort (n=310)	High Anxiety group (n=51)	Low Anxiety group (n=163)	p-value (High vs. Low Anxiety)

SESSION INFORMATION

Session Date: Tuesday, November 9, 2021
Session Title: Patient Outcomes, Preferences, & Attitudes Poster IV: COVID-19 (1589–1613)
Session Type: Poster Session D
Session Time: 8:30AM–10:30AM

Background/Purpose: The COVID-19 pandemic has impacted wellbeing of patients with Rheumatic and Musculoskeletal Diseases (RMDs). The aim is to assess wellbeing its associated factors in European RMD patients.

Methods: REUMAVID is an international collaboration led by the Health & Territory Research group at the University of Seville, together with a multidisciplinary team including patient organisations and rheumatologists. The study consists of an online survey gathering data from patients with a diagnosis of 15 RMDs in Cyprus, France, Greece, Italy, Portugal, Spain, and the United Kingdom. 1,800 participants were recruited by patient organisations. Data was collected between April and July 2020. Participants were divided into two groups: 1) Participants with poor wellbeing (World Health Organization-Five Wellbeing Index (WHO-5) ≤ 50), 2) Participants with good wellbeing (WHO-5 >50). The Mann-Whitney and $\chi 2$ tests were used to analyse possible relations between sociodemographic characteristics, lifestyle, and outdoor contact with wellbeing during the beginning of the COVID-19 pandemic. Univariate and multivariate binary logistic regression was used to determine the impact of the independent variables associated with poor wellbeing.

Results: 1,777 patients with 15 different RMDs were included. The mean age was 52.7, 80.2% female, 48.7% had a university degree, and 69.7% were married or in a relationship. The most frequent diagnoses were inflammatory arthritis (75.4%). 49.0% reported poor wellbeing. 57.7% of patients who belonged to a patient organisation reported good wellbeing (vs 46.3% who did not, p< 0.001). Compared to those patients who did not, those who did experienced poor wellbeing had higher disease activity (51.4% vs 41.3%, p< 0.001), a higher risk of anxiety (54.3% vs 41.7%, p< 0.001) and depression (57.0% vs 42.1%, p< 0.001), and poorer self-perceived health (53.0% vs 41.8%, p< 0.001). A higher proportion of those who engaged in physical activity presented good wellbeing (54.0% vs 46.5%, p=0.012). 57.4% of the patients who were unable to attend an appointment with their rheumatologist reported poor wellbeing, compared to 48.2% who did attend (p=0.027). Patients who did not walk outside (56.2%) or who lacked elements in their home to facilitate outside contact (63.3%) experienced poor wellbeing (p< 0.001). The factors associated with poor wellbeing were lack of elements in the home enabling contact with the outside world (OR=2.10), not belonging to a patient organisation (OR=1.51), risk of depression (OR=1.49), and not walking outside (OR=1.36) during the COVID-19 pandemic (Table 1).

Table 1. Logistic regression. Dependent variable: poor wellbeing (N=1,104)

	Univariate logistic analysis		Multivariate logistic analysis	
	OR	95% CI[1]	OR	95% CI[1]
Patient organization. Non-member	1.566	**1.295, 1.894**	1.505	**1.176, 1.925**
Disease activity (VAS ≥ 4)	1.502	**1.212, 1.863**	1.155	0.854, 1.561
Risk of anxiety (HADs, 0-21)	1.667	**1.378, 2.016**	1.203	0.916, 1.581
Risk of depression (HADs, 0-21)	1.828	**1.513, 2.209**	1.492	**1.117, 1.994**
Self-reported health. Fair to very bad	1.575	**1.295, 1.914**	1.256	0.939, 1.679
Change in health status. Worse	1.273	**1.056, 1.534**	1.047	0.797, 1.376
Physical activity. No	1.354	**1.069, 1.714**	1.076	0.829, 1.397
Talked with rheumatologist during COVID-19 pandemic. No	1.452	**1.041, 2.026**	1.044	0.678, 1.610
Walk outside during COVID-19 pandemic. No	1.474	**1.187, 1.830**	1.363	**1.024, 1.814**
Element in home with outdoor contact. No	1.930	**1.423, 2.618**	2.104	**1.408, 3.145**

[1]95% CI for test H_0: OR = 1

Conclusion: Almost half of the patients with RMDs reported poor wellbeing during the beginning of the COVID-19 pandemic. The lack of elements in the home that facilitate outdoor contact, not belonging to a patient organisation, the presence of anxiety, and not walking outside during the pandemic increase the probability of poor well-being. These results highlight the importance of environmental factors and the role of patient organisations in addressing the effects of the pandemic and its containment measures.

ACT for Lupus: Pilot Study of a Novel Acceptance and Commitment Therapy (ACT) Online Program to Support Patients with Lupus During the COVID-19 Pandemic

Tessa Englund[1], Saira Sheikh[2], Becki Cleveland[1], **Emily McCormick**[1], Crystal Schiller[3] and Teresa Dickson[1], [1]Thurston Arthritis Research Center, University of North Carolina at Chapel Hill School of Medicine, Chapel Hill, NC, [2]University of North Carolina Thurston Arthritis Research Center, and Department of Medicine, Division of Rheumatology, Allergy and Immunology, University of North Carolina at Chapel Hill School of Medicine, Chapel Hill, NC, [3]University of North Carolina at Chapel Hill, Chapel Hill, NC

SESSION INFORMATION

Session Date: Tuesday, November 9, 2021

Session Title: Patient Outcomes, Preferences, & Attitudes Poster IV: COVID-19 (1589–1613)

Session Type: Poster Session D

Session Time: 8:30AM–10:30AM

Background/Purpose: Systemic lupus erythematosus (SLE) is a chronic disease associated with significant symptom burden, including fatigue, anxiety, depression, pain, and negative impacts on health-related quality of life (HRQoL). The COVID-19 pandemic has resulted in additional stressors impacting the mental health and well-being of patients with SLE. Acceptance and Commitment Therapy (ACT) is a promising treatment approach that has shown efficacy in addressing many of the symptoms associated with SLE, such as such as depression, anxiety, and chronic pain. The goal of this pilot study was to develop and assess the feasibility and preliminary efficacy of ACT for Lupus, a novel online ACT-based virtual skills training program tailored for patients with lupus.

Methods: Participants with a diagnosis of SLE were primarily recruited through an academic healthcare system in North Carolina, as well as nationally in partnership with a large lupus advocacy organization. A total of 72 participants completed the baseline survey and were invited to attend two weekly one-hour webinar sessions in December 2020, which were delivered through a web-based platform. Educational content was tailored for patients with lupus and delivered by an experienced clinical psychologist who specializes in ACT. Topics and practice exercises encompassed ACT-principles of mindfulness, distress tolerance, self-care and advocacy, goal setting, and action planning. Patient-reported outcomes (PROs) including anxiety (General Anxiety Disorder-7; GAD-7), depression (Patient Health

Table 1. Participant characteristics (n=23)

Characteristics	Values
Age, years, mean ± SD	47.4 ± 13.1
Female, n (%)	20 (87.0)
Race/Ethnicity, n (%)	
White	16 (69.6)
Black/African American	3 (13.0)
Hispanic/Latino	2 (8.7)
Asian	2 (8.7)
Education, n (%)	
Some College, No Degree	3 (13.0)
Bachelor's Degree	12 (52.2)
Graduate Degree or Above	8 (34.8)
Employment Status, n (%)	
Full-Time	8 (34.8)
Part-Time	2 (8.7)
Unemployed	3 (13.0)
Retired	3 (13.0)
Medically Disabled/Unable to Work	6 (26.1)
Recruitment Source, n (%)	
North Carolina	19 (82.6)

Anxiety Medication Use (Past 30 days), n (%)	13 (56.5)

Questionnaire; PHQ-9), and disease-specific HRQoL (LupusQoL) were assessed at baseline and post-intervention. Additional questions in the follow-up survey assessed participant satisfaction with the program and suggestions/opportunities for refinement. Means and effect sizes (ES) with 95% confidence intervals (CIs) were computed for pre- and post- changes in PROs, adjusted for age, sex and baseline measurements (Table 2).

Results: Data was analyzed for a total of 23 individuals who participated in the program and submitted the end of study assessment survey. Most participants were women (86%), aged ≥ 28 years, and recruited through the North Carolina system (82.6%) (Table 1). In pre- post- analyses of the ACT for Lupus pilot data, we found modest improvements in LupusQoL fatigue scores (ES=0.25) and reduced symptoms of anxiety as indicated by GAD-7 scores (ES= -0.26). Feedback from participants highlighted unmet needs for mindfulness-based programs, tailored to the unique experiences of patients with lupus. Participant feedback included suggestions to inform growth and expansion of the program and added flexibility for participants to access the program at their own pace in a self-directed format.

Table 2. Means (SD) and effect sizes for changes in outcomes from baseline to end of study (n=23)

Outcome Measures	Baseline Mean (SD)	End of Study Mean (SD)	Effect Size
Anxiety GAD-7[a]	9.87 (6.01)	8.43 (4.77)	-0.26
Depression PHQ-9[b]	10.22 (5.55)	10.65 (6.12)	0.07
LupusQoL Domains[c]			
Pain	61.59 (27.38)	65.58 (21.51)	0.16
Physical Health	63.45 (27.61)	66.44 (19.34)	0.13
Planning	68.48 (29.19)	68.48 (23.70)	0.00
Intimate	69.57 (33.67)	73.37 (28.03)	0.12
Burden	56.16 (33.54)	59.06 (24.22)	0.10
Emotional Health	73.55 (18.28)	70.29 (18.00)	-0.18
Body Image	77.28 (20.26)	73.06 (22.54)	-0.20
Fatigue	50.00 (30.68)	56.52 (20.25)	0.25

[a]GAD-7 scores range from 0-21, higher scores represent worse symptoms
[b]PHQ-9 scores range from 0-27, higher scores represent worse symptoms
[c]LupusQoL domain scores range from 0-100, higher scores represent better HRQoL

Conclusion: Preliminary results suggest that an adapted ACT-based virtual skills training program has potential to improve psychological and QoL outcomes among patients with lupus, especially in the face of additional stressors.

Session Title: Patient Outcomes, Preferences, & Attitudes Poster IV: COVID-19 (1589–1613)
Session Type: Poster Session D
Session Time: 8:30AM–10:30AM

Background/Purpose: The COVID-19 pandemic has triggered nationwide disruptions that limit opportunities for physical activity (PA). Addressing suboptimal levels of PA is important for disease management and reducing risk of comorbidities in patients with rheumatologic conditions. The objective of this cross-sectional study was to

investigate the impact of the COVID-19 pandemic on PA levels of patients with rheumatologic disease and to examine characteristics associated with decreased PA that may inform future PA interventions.

Methods: A convenience sample of adult patients with rheumatologic disease (n=7,776) were identified through electronic medical records from an academic healthcare system in North Carolina. Eligible patients were invited to

participate in an online survey between July–September 2020. Rheumatologic and concurrent diagnoses as well as patient-reported outcomes during the COVID-19 pandemic were assessed, which included changes in PA, barriers to PA, psychological symptoms, and wellbeing. Descriptive statistics, age-adjusted odds ratios (OR), and 95% confidence intervals (CI) were computed to compare characteristics of those whose activity decreased versus those who did not (stayed the same or increased).

Results: A total of 1,133 participants completed the survey (17.2% response rate, mean age of sample: 57.6 ± 15.2 years, 75.4% female, 82.3% white and 14.1% African American). The most common primary diagnoses reported among participants include RA (25.6%), OA (14.6%), and SLE (12.6%). Over half of participants (55.5%) reported engaging in less PA since the start of the pandemic, followed by unchanged PA (26.6%) and increased PA (15.3%). Factors associated with engaging in less PA were male sex (OR 0.75, CI 0.57-0.99), lower income during the COVID-19 pandemic (OR 1.34, CI 1.01-1.79), and lower self-reported fair/poor health (OR 2.50, CI 1.91-3.27). Among rheumatologic diseases, a diagnosis of SLE was associated with lower self-reported PA (OR 1.59, CI 1.07-2.37). Comorbidities associated with decreased PA include chronic pain (OR 1.38, CI 1.04-1.82), depression (OR 1.48, CI 1.09-2.01), and hypertension (OR 1.44, CI 1.10-1.90). The most common reported barriers to PA include increased overall fear/anxiety (33.5%), lack of motivation (32.4%), and contracting coronavirus infection (32.1%). Most participants reported that they did not meet their exercise goals during the COVID-19 pandemic (67.2%).

Conclusion: The COVID-19 pandemic has further exacerbated barriers to PA in patients with rheumatologic diseases. There is a critical need to provide resources, support and multi-faceted to encourage PA in patients with rheumatologic diseases during the COVID-19 pandemic and beyond.

COVID-19 Pandemic-Related Changes in Health Routines and Self-Reported Physical Functioning Among Systemic Lupus Erythematosus Patients

Laura Plantinga[1], Courtney Hoge[1], C. Barrett Bowling[2], Charmayne Dunlop-Thomas[1], Brad Pearce[1], S Sam Lim[3] and Cristina Drenkard[1], [1]Emory University, Atlanta, GA, [2]Duke University, Durham, NC, [3]Department of Medicine, Division of Rheumatology, Emory University School of Medicine, Atlanta, GA

SESSION INFORMATION

Session Date: Tuesday, November 9, 2021

Session Title: Patient Outcomes, Preferences, & Attitudes Poster IV: COVID-19 (1589–1613)

Session Type: Poster Session D

Session Time: 8:30AM–10:30AM

Background/Purpose: The COVID-19 pandemic was disruptive to individual health routines. Changes in health routines may worsen disease management and reduce opportunities for physical activity, both of which may affect physical functioning. Leveraging on an ongoing ancillary cohort study [Approaches to Positive, Patient-centered Experiences of Aging in Lupus (APPEAL)], we examined whether pandemic-related changes in health routines were associated with self-reported physical functioning among individuals with systemic lupus erythematosus (SLE).

Methods: APPEAL subjects were recruited from Georgians Organized Against Lupus (GOAL), a population-based cohort of individuals with validated SLE in metropolitan Atlanta. A total of 153 participants (mean age, 48 years; 95% female, 76% Black) were consented (10/6/2020-5/4/2021) for a single visit during the period the COVID-19 survey was administered. Responses to items regarding pandemic-related changes in health habits (changes in activity, difficulty in obtaining food or medications and in obtaining routine medical care) were dichotomized as yes vs. no. Raw physical functioning scores were captured via the PROMIS Physical Functioning-Short Form 12a and converted to *t*-scores (50 = average score for a general adult population; differences of 10 = 1 SD; and higher scores = better physical functioning). Differences in scores were assessed via *t* tests and age-, gender-, and race-adjusted linear regression models.

Results: More than half of participants reported being less physically active, having more interrupted sleep, and more difficulty getting routine medical care as a result of the pandemic; nearly one-third reported having more trouble obtaining food, and nearly one-quarter reported difficulty in obtaining medications (Table). The overall mean physical

Change in health routine:	Yes, n/N (%)	Mean (SD) self-reported physical functioning score		*P*	Age-, gender-, and race-adjusted difference, (95% CI)
		Yes	No		
Less physically active	84/151 (55.6%)	41.1 (8.5)	46.1 (9.5)	*<0.001*	-4.6 (-7.6,-1.7)
More trouble obtaining food	47/153 (30.7%)	39.4 (8.8)	44.9 (8.9)	*<0.001*	-5.4 (-8.5,-2.4)
More interrupted sleep	81/153 (52.9%)	40.5 (9.1)	46.3 (8.4)	*<0.001*	-5.4 (-8.2,-2.6)
More difficulty getting routine medical care	87/153 (56.9%)	40.4 (8.4)	45.4 (9.3)	*0.001*	-5.1 (-7.8,-2.3)
More difficulty obtaining medications	34/153 (22.2%)	39.3 (9.2)	44.4 (9.0)	*0.005*	-4.4 (-7.9,-1.0)
More difficulty obtaining hydroxychloroquine	27/93 (29.0%)	41.6 (10.1)	44.8 (9.8)	*0.16*	-3.6 (-8.0,0.9)

functioning *t*-score (SD) was 43.2 (9.2). Scores were consistently lower (by ~0.5 SD) for those who reported declines in health routines, and the differences were statistically significant for all items except difficulty obtaining hydroxychloroquine; adjustment for age, gender, and race did not substantially change the associations (Table).

Conclusion: While the cross-sectional nature of the study precludes causal inference, our results suggest that experiencing pandemic-related disruptions in health routines was associated with meaningfully lower perceptions of physical functioning. Future studies should explore whether this association persists over time and whether lower perceived functioning is associated with long-term health outcomes.

Concern About the COVID-19 Pandemic and Community Mobility Among Systemic Lupus Erythematosus Patients

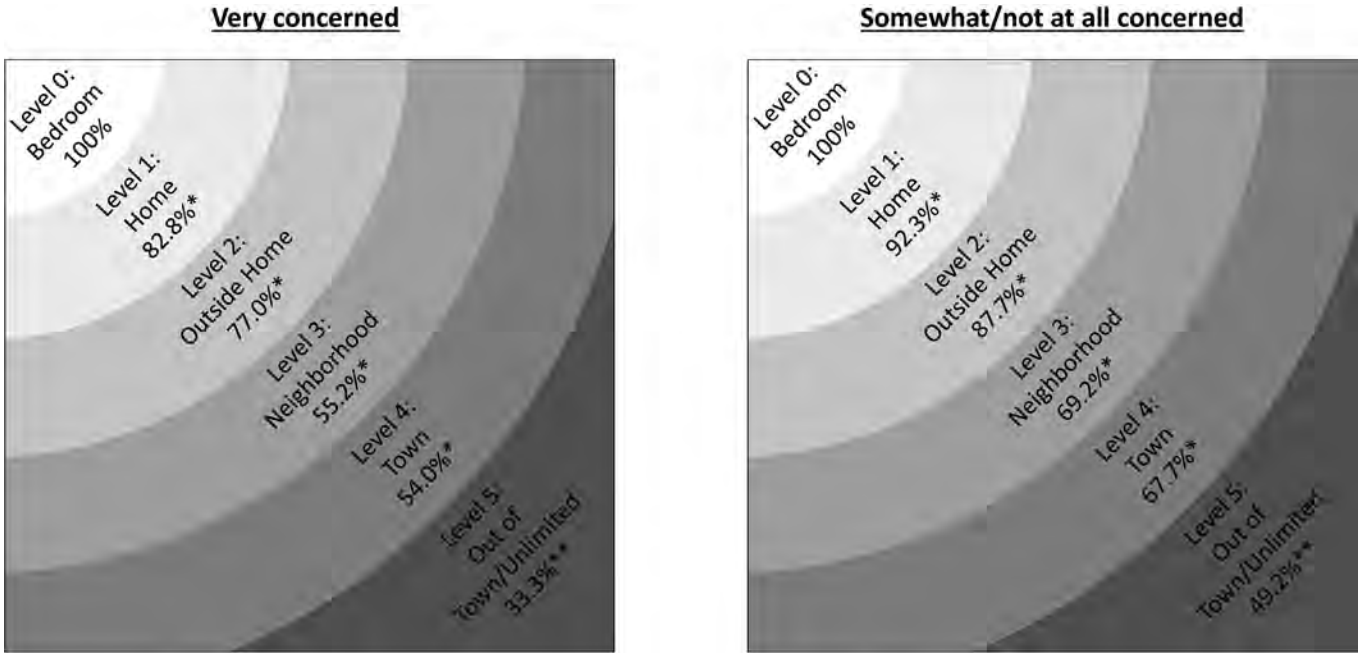
Laura Plantinga[1], Courtney Hoge[1], Cristina Drenkard[1], Charmayne Dunlop-Thomas[1], Brad Pearce[1], S Sam Lim[2] and C. Barrett Bowling[3], [1]Emory University, Atlanta, GA, [2]Department of Medicine, Division of Rheumatology, Emory University School of Medicine, Atlanta, GA, [3]Duke University, Durham, NC

SESSION INFORMATION
Session Date: Tuesday, November 9, 2021
Session Title: Patient Outcomes, Preferences, & Attitudes Poster IV: COVID-19 (1589–1613)
Session Type: Poster Session D
Session Time: 8:30AM–10:30AM

Background/Purpose: Opportunities for community mobility, which reflects both physical mobility and social participation, during the COVID-19 pandemic have been limited and may have been related to level of concern about the pandemic. We used data from an ancillary cohort study [Approaches to Positive, Patient-centered Experiences of Aging in Lupus (APPEAL)] to examine the association between level of concern about the pandemic and community mobility among individuals with systemic lupus erythematosus (SLE).

Methods: APPEAL subjects were recruited from the population-based Georgians Organized Against Lupus (GOAL) cohort of individuals with validated SLE. A total of 153 participants (mean age, 48 years; 95% female, 76% Black) were consented (10/6/2020-5/4/2021) for a single visit during the period the COVID-19 survey was administered. Responses to the item "How concerned are you about the COVID-19 pandemic?" (*N*=152) were dichotomized as very concerned vs. somewhat or not at all concerned. Community mobility was measured via the UAB Study of Aging Life-Space Assessment (score range, 0-120), with higher life-space scores representing greater community mobility (movement across greater distances from home, with greater frequency and less help). Scores were described overall and by level of concern [medians (interquartile ranges)], and Wilcoxon rank sum tests were used to obtain *p* values. The percentages of participants reaching each life-space level without personal assistance were calculated and compared by level of concern using chi-square tests. Finally, life-space scores were dichotomized as low (at or below the median, ≤48) vs. high (above the median, >48) in logistic models with concern as the exposure, adjusting for age, gender, and race.

Results: Life-space scores were lower among participants who were very vs. somewhat/not at all concerned about the pandemic [35 (16-72) vs. 58 (24-72); $p = 0.2$]. Overall, without personal assistance, 86.9% of participants reached



Percentages of SLE patients reaching life-space levels without personal assistance, by level of concern about the COVID-19 pandemic (very concerned vs. somewhat/not at all concerned). *p<0.1; **p<0.05.

the life-space level of home (excluding bedroom); 81.7%, outside the home; 61.4%, neighborhood; 60.1%, town; and 40.5% out of town/unlimited. Percentages of patients reaching each life-space level without personal assistance were lower among those who were very concerned about the pandemic, compared to those who were somewhat/not all concerned (Figure). Those who were very vs. somewhat/not at all concerned were 68% more likely to have a low vs. high life-space score [OR=1.68 (95% CI 0.79-3.21)]; adjustment for demographics slightly attenuated this association [OR=1.54 (95% CI 0.79-3.00)]. The associations were similar among older [≥50 years; OR=1.61 (95% CI 0.62-4.17)] and younger [< 50 years; OR=1.73 (95% CI 0.71-4.21); *p*-interaction=0.8] patients. Most of the differences and associations were not statistically significant.

Conclusion: In this cross-sectional study of individuals with SLE, we found that life-space scores were low overall and that these scores were even lower among those who expressed high level of concern about the COVID-19 pandemic. Future studies should explore whether these low levels of community mobility persist beyond the pandemic and whether they are associated with poor physical and/or mental health outcomes in SLE.

Changes in Patient-Reported Outcome (PRO) Scores During the COVID-19 Pandemic: Data from the ArthritisPower Research Registry

Kelly Gavigan[1], Esteban Rivera[1], Jeffrey Curtis[2], Shilpa Venkatachalam[1], Laura Stradford[3], David Curtis[1] and William Nowell[1], [1]Global Healthy Living Foundation, Upper Nyack, NY, [2]Division of Clinical Immunology and Rheumatology, Department of Medicine, Department of Epidemiology, University of Alabama at Birmingham, Birmingham, AL, [3]Global Healthy Living Foundation, Nyack, NY

SESSION INFORMATION

Session Date: Tuesday, November 9, 2021

Session Title: Patient Outcomes, Preferences, & Attitudes Poster IV: COVID-19 (1589–1613)

Session Type: Poster Session D

Session Time: 8:30AM–10:30AM

Background/Purpose: The COVID-19 pandemic caused particular concern among patients with autoimmune and rheumatic disease (ARD) due to increased risk of infection, and heightened sense of isolation due to social distancing.[1] We sought to determine whether mean patient-reported outcome scores for mental, social and physical health fluctuated during the COVID-19 pandemic.

Methods: Participants (pts) of ArthritisPower research registry completed PROMIS measures of physical health (Physical Function, Pain Interference, Fatigue, Sleep Disturbance), mental health (Anger, Anxiety, Depression) and social health (Social Isolation, Emotional Support) from January 2020 to April 2021. PROMIS measures are scored 0-100, with US general population mean of 50, and 10 as the standard deviation (SD) of the reference population. We tested the null hypothesis that there was no change in monthly average PROMIS scores across the 15-month pandemic period. Analysis of means (ANOM) compared assessment mean scores for each of the 15 months to overall mean score for each measure during the observed period. Pts with < 2 assessment time points and osteoarthritis with no ARD were excluded from analysis.

Results: A total of 41,547 PRO scores were contributed by 2,266 pts, with 4.5 (6.9) mean (SD) number of observations per pt. Among pts, 87.6% were female, 86.7% white, with mean age of 52.1 (12.7) years (Table 1). Rheumatoid arthritis (n=1,131, 49.9%) was the most common condition. The study sample was younger than the overall ArthritisPower population (55.0 [11.6]; p< 0.001). Most commonly reported measures were the default measures of Pain Interference, Fatigue, Sleep Disturbance and Physical Function; each had more than 9,000 total results. For all measures, PROMIS scores were worse than the US population mean during the observed period (Table 2). Over 15 months, mental health assessment scores varied significantly; mean (SD) overall study period scores were: Anger 61.6 (13.0), Anxiety 63.1 (10.7) and Depression 61.2 (9.5). In January and February 2020, Anger and Anxiety had

*Statistical significance ($p<0.05$) from ANOM to compare monthly assessment means to the overall assessment mean

significantly lower scores compared to the overall assessment mean. However, during the months of May and June 2020, mean scores were elevated by a standard deviation for Anger (May: 74.2 [14.1], $p< 0.001$; June: 76.4 [12.1], $p< 0.001$) and Anxiety (May: 72.0 [11.1], $p< 0.001$; June: 73.3 [12.3], < 0.001). Depression scores, while lowest in January, increased by half a standard deviation in May (66.6 [13.0], $p< 0.001$) and June 2020 (67.4 [11.1], $p< 0.001$). Among the social health assessments, Social Isolation peaked in June (66.0 [7.1]; overall mean 61.7 [9.9]) and Emotional Support dipped in December 2020 (36.7 [9.6]; overall mean 41.4 [9.7]) (Figure). Scores did not meaningfully vary from the overall mean for any of the physical health assessments across the 15 months.

Conclusion: Despite scores for mental health fluctuating significantly, particularly during the first US wave of the COVID-19 pandemic, scores for physical health remained relatively stable across the pandemic period.

Arthritis Patient Perspectives on Virtual Care for People Living with Arthritis During the COVID-19 Pandemic and for the Future

Maya Joshi[1], Anita Chan[1], Adriana Lima[2], Kelly Lendvoy[1], Eric Sayre[2] and Cheryl Koehn[1], [1]Arthritis Consumer Experts, Vancouver, BC, Canada, [2]Arthritis Research Canada, Richmond, BC, Canada

SESSION INFORMATION

Session Date: Tuesday, November 9, 2021

Session Title: Patient Outcomes, Preferences, & Attitudes Poster IV: COVID-19 (1589–1613)

Session Type: Poster Session D

Session Time: 8:30AM–10:30AM

Background/Purpose: Virtual Care (VC) is the delivery of health care services and information by electronic methods (video, smartphones, email, text) and may support arthritis patients in seeing their health care providers in a timely and convenient way. Arthritis Consumer Experts (ACE) conducted an online survey as little is known about arthritis patients' views and preferences on VC.

Methods: ACE conducted a 23-question online survey (Jan. 20-Feb. 9, 2021) of people with a physician-diagnosed arthritis in English and French. Respondents answered questions on their experiences with in-person and VC services from a health care provider pre-March 2020 and between March 2020-January 2021, their preferences and satisfaction with those services, and the importance of VC availability in the future. Data were analysed in aggregate (including incomplete survey responses). McNemar's test of agreement between time points was performed to com-

pare pre-COVID to during COVID to (anticipated) post-COVID. Chi-square tests (exact tests where possible) were used to test for associations.

Results: 253 responses were analyzed. **Demographics:** 79% were women; 50% had disease less than 10 yrs; 47% rheumatoid arthritis; 19% osteoarthritis; 13% lupus; 8% psoriatic arthritis; 4% ankylosing spondylitis; 66% lived in urban communities; 5.1% identified as Black, Indigenous or a person of colour (BIPOC). **Use of VC:** 59% of respondents reported accessing VC pre-pandemic increasing to 88% during the pandemic. 85% were satisfied with sharing health concerns and getting advice using VC. **Challenges accessing VC:** 32% of respondents reported they were unable to receive arthritis specific VC at a time they felt they needed it during the pandemic. 75% reported it was either very important, important or somewhat important to continue having access to VC when the pandemic ends. 16% faced certain difficulties using VC. **Inequities in VC:** 12% of respondents who identified as non-BIPOC versus

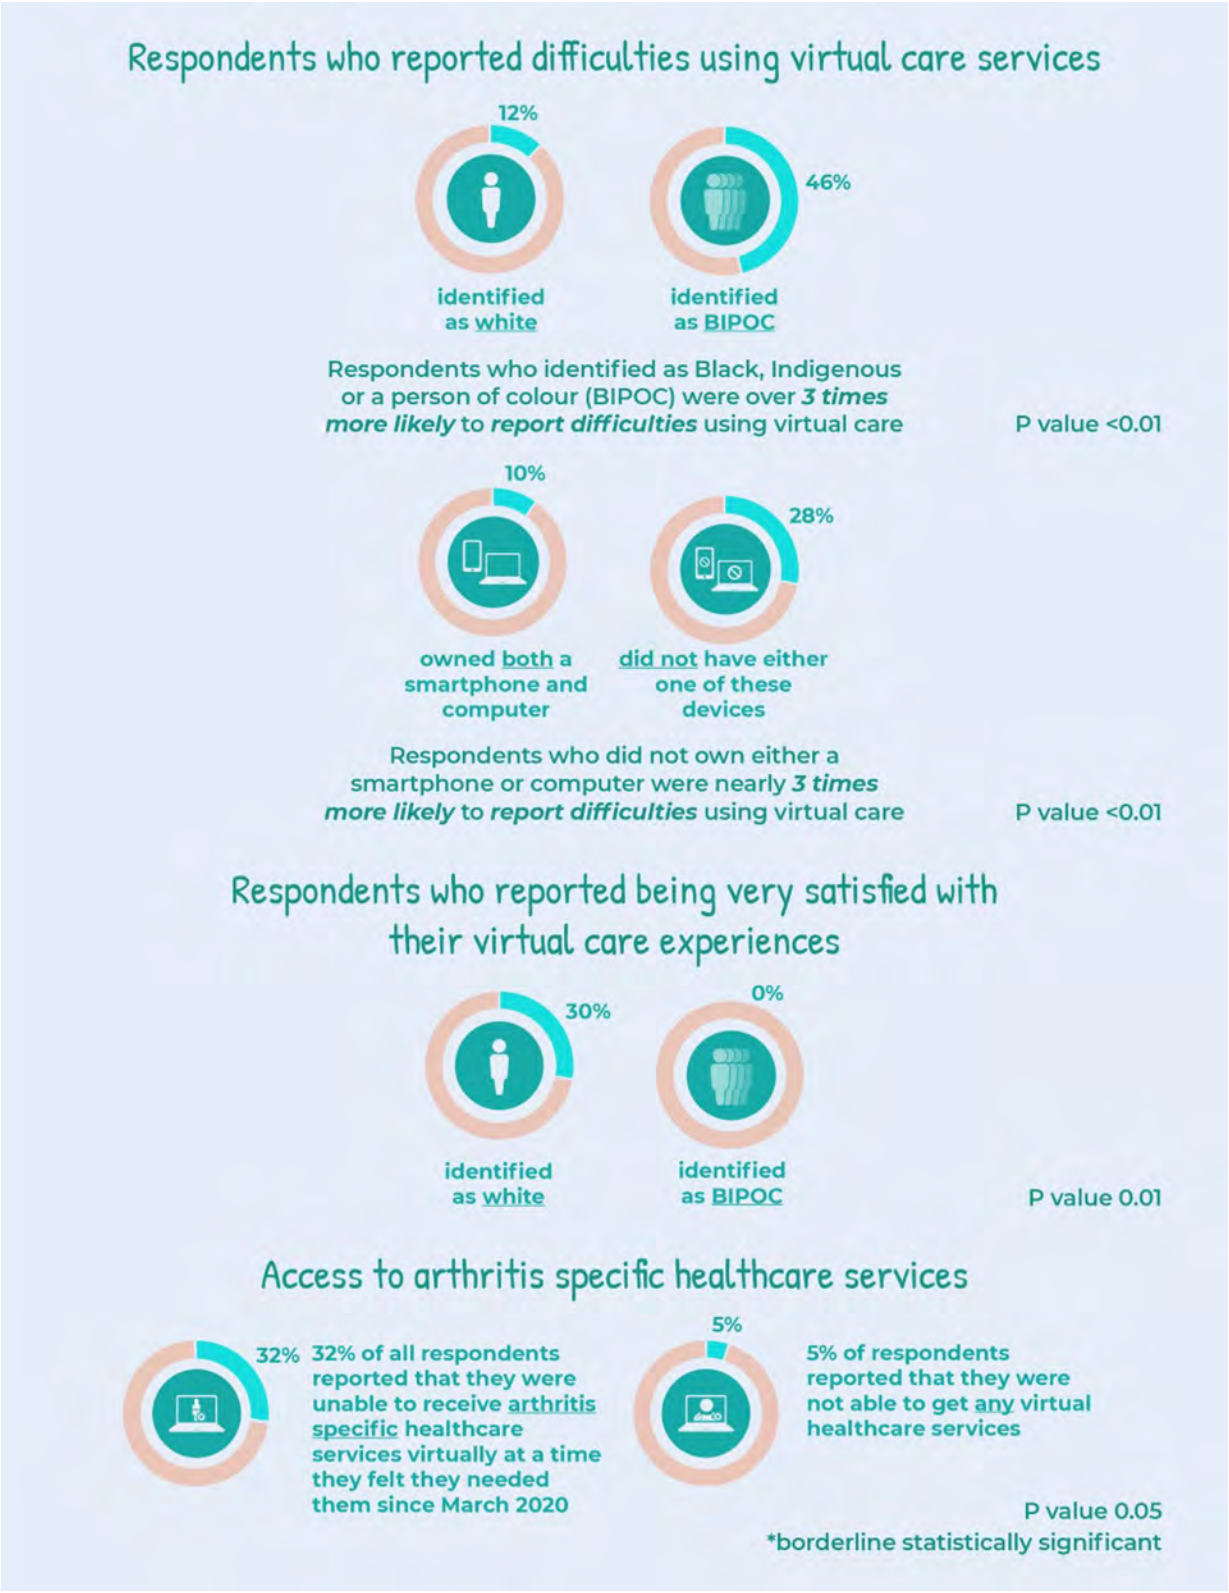
Table 1. Respondent demographics	
	Respondents (N = 253)
Gender identity	
Woman	79%
Man	20%
Gender diverse	<1%
Age group (years)	
<=30	4%%
31-50	17%%
51-70	56%%
71-90	23%%
91+	<1%%
Ethnicity	
white	94.9%
Indigenous	1.6%
People of colour	3.2%
Black	0.8%
Community	
Large urban centre (population of 100,000 or more)	66%
Small-medium sized population centre (population of 16,000 to 99,999)	21%
Rural/ remote community (population of 15,000 or less)	13%

Respondent Demographics

Table 2: Access to VC before, during, and after COVID-19, by type of care

Type of care	Period	Percent	P-value (vs. pre)
General	Pre-COVID	59% already using VC	
General	COVID	88% have accessed VC	<0.001
General	Post-COVID	66% would like continued VC option	<0.066
Rheumatologist	Pre-COVID	36% using some form of VC	
Rheumatologist	COVID	60% have accessed VC	<0.001
Rheumatologist	Post-COVID	49% would like continued VC option	<0.001
Family	Pre-COVID	44% already using VC	
Family	COVID	73% have accessed VC	<0.001
Family	Post-COVID	60% would like continued VC option	<0.001

Access to VC before, during and after COVID-19, by type of care



Difficulties, satisfaction and access inequities to VC

46% of respondents who identified as BIPOC reported difficulties using VC. 7% of white respondents compared to 39% of BIPOC respondents reported feeling uncomfortable or not knowing how to use the VC technology used by their health care provider. **Timeliness of VC:** 15% of respondents reported they were unable to get *any* arthritis

healthcare services in-person since March 2020 while 5% were not able to get *any* arthritis healthcare services virtually.

Conclusion: This community-led survey shows overall patient satisfaction with VC before and during the COVID-19 pandemic. 66% of respondents reported their preference for both in-person and VC services, with a preference of in-person for more complex examinations such as joint counts, and VC to augment care (between in-person visits or to support patient self-care). BIPOC with arthritis were more likely to experience factors that made it difficult to use VC and less likely to be very satisfied with their experiences. BIPOC were more likely to report "I don't feel comfortable" or "know how to use the VC technology being used by my health care provider (38.5% for BIPOC vs 6.7% for white patients; p value < 0.01)". The underrepresentation of BIPOC respondents in this survey suggests their lack of inclusion in arthritis patient organization networks.

Trends in Medication Interruptions and Associations with Disease Flares During a Public Health Crisis: Longitudinal Data from Patients with Autoimmune Rheumatic Diseases During the COVID-19 Pandemic

Tiffany Dharia[1], Michael George[2], Shilpa Venkatachalam[3], Shubhasree Banerjee[2], Joshua Baker[2], David Curtis[4], Maria I. Danila[5], Kelly Gavigan[4], Peter Merkel[2], Dianne Shaw[6], Jeffrey Curtis[7] and William Nowell[4], [1]Hospital of the University of Pennsylvania, Philadelphia, [2]University of Pennsylvania, Philadelphia, PA, [3]Global Healthy Living Foundation, New York, NY, [4]Global Healthy Living Foundation, Upper Nyack, NY, [5]University of Alabama at Birmingham, Birmingham, AL, [6]Vasculitis Foundation, Kansas City, MO, [7]Division of Clinical Immunology and Rheumatology, Department of Medicine, Department of Epidemiology, University of Alabama at Birmingham, Birmingham, AL

SESSION INFORMATION
Session Date: Tuesday, November 9, 2021
Session Title: Patient Outcomes, Preferences, & Attitudes Poster IV: COVID-19 (1589–1613)
Session Type: Poster Session D
Session Time: 8:30AM–10:30AM

Background/Purpose: The COVID-19 pandemic has had substantial impact on the care of patients with autoimmune rheumatic diseases (ARDs), resulting in frequent medication interruptions early in the pandemic. This study used longitudinal data to examine trends in medication interruptions and patients' feelings of anxiety throughout the pandemic and to evaluate whether medication interruptions were associated with an increased risk for disease flares.

Methods: Members of the ArthritisPower and Vasculitis Patient Powered Research Network online patient registries and other patient organizations were invited to complete a baseline survey (week 0) and then every 2 weeks until week 8, monthly until week 28, with a final survey at week 38. We analyzed patients with ARDs who completed baseline surveys between March 29 and June 30, 2020 and completed at least one follow-up survey, with follow-up captured through February 2021. Changes over time in PROMIS Anxiety T-scores and medication interruptions due to COVID-19 concerns (among patients receiving DMARDs) were assessed using generalized estimating equation (GEE) models to account for within-person correlations. GEE models were also used to assess associations between medication interruptions and self-reported disease flares at the next survey among patients on DMARDs who were not currently in a flare, adjusting for demographics, medication type, disease type, and calendar time.

Results: A total of 2,396 patients completed a median of 6 surveys (interquartile range 3-9). Mean age was 57 years, 87% were female, and the most common ARDs were rheumatoid arthritis, vasculitis, and psoriatic arthritis (Table 1). Average PROMIS-Anxiety T scores decreased significantly from 59.0 in April 2020 to 55.6 in

Table 1. Baseline Characteristics of Study Participants

	N = 2396
Age, years	56.8 (12.0)
Female	2074 (86.6%)
White	2175 (90.8%)

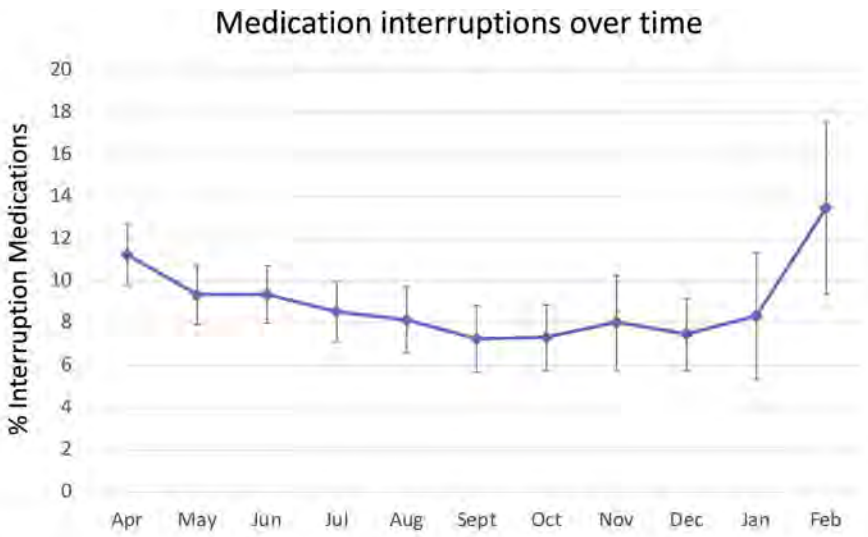
Glucocorticoids ≥10 mg/day	111 (4.6%)
PROMIS Anxiety, T-score**	58.9 (8.6)
Stopped a medication because of COVID-19 concerns***	188/1729 (10.9%)

Number (%) or mean (standard deviation) shown

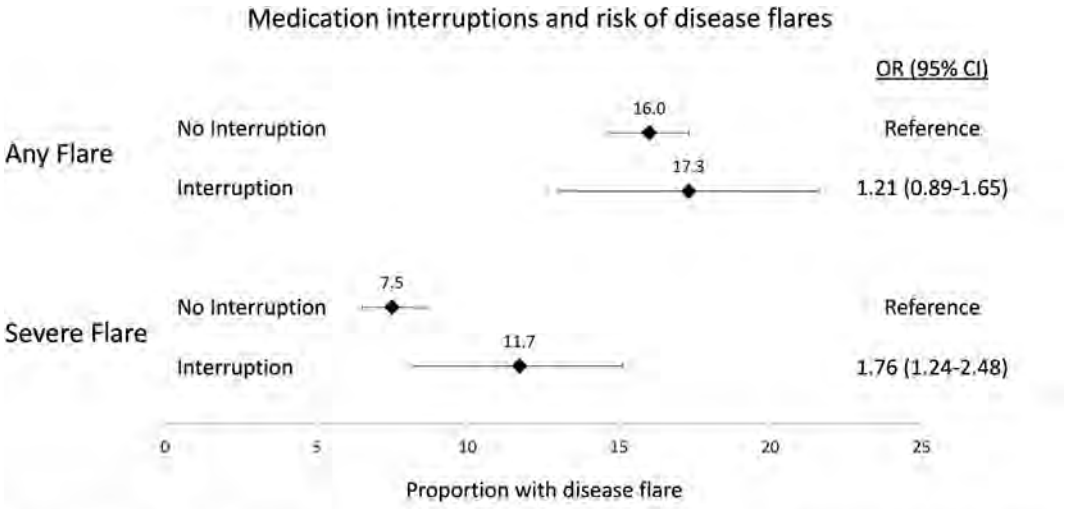
* Other includes patients with other autoimmune conditions (most commonly inflammatory bowel disease, Sjögren's syndrome, or psoriasis) or patients who reported a non-listed autoimmune condition.

** From PROMIS Anxiety short form with range of 1-100, U.S. adult population mean=50 and standard deviation=10.

*** Medication interruptions among patients receiving immune-modulatory medications who did not report a respiratory illness.



Evaluated among patients who were on an immunomodulatory medication and reported that they were not ill. Point estimates and 95% confidence intervals from a GEE model to account for patients contributing multiple observations. $p < 0.001$ for trends in medication interruptions from April to December and $p = 0.001$ for medication interruptions in February vs. December.



Results from GEE models assessing risk of any flare or of severe flares (rated ≥6/10) at the subsequent visit among patients receiving immunomodulatory medications who did not report a respiratory illness or COVID-19 and did not report currently having a flare. Models also included age, sex, race, autoimmune disease type, glucocorticoid use, DMARD type, and month.

February 2021 ($p < 0.001$ for trend) and medication interruptions also decreased significantly from April (11.2%) to December 2020 (7.5%) ($p < 0.001$ for trend) but increased to 13.5% in February 2021 ($p = 0.001$ vs. December) (Figure 1). Medication interruptions were more common in those with higher anxiety ($p < 0.001$), occurring in 10.5% with PROMIS-Anxiety T-score ≥60 vs. 7.8% with score < 60. 1,419 patients had at least one survey response during which they were on DMARDs and did not report a current flare (5,270 total responses). Among this population, 839 (15.9%) reported any flare and 459 (8.7%) a severe flare (≥6/10) at the next survey. Medication interruptions were associated with a significant increase in the risk of severe flare [11.7% vs. 7.5%; OR 1.76 (95% CI 1.24-2.48)] (Figure 2).

Conclusion: Patients with ARDs had high levels of anxiety and frequent medication interruptions at the start of the COVID-19 pandemic. Although anxiety and frequency of medication interruptions improved over time, interruptions increased in February of 2021, possibly related to vaccination efforts or the national surge in COVID-19. Medication interruptions were associated with an increased risk of severe disease flares, highlighting the importance of maintaining continuity of care and avoiding unnecessary medication interruptions during the pandemic and future public health crises.

SESSION INFORMATION

Session Date: Tuesday, November 9, 2021

Session Title: Patient Outcomes, Preferences, & Attitudes Poster IV: COVID-19 (1589–1613)

Session Type: Poster Session D

Session Time: 8:30AM–10:30AM

Background/Purpose: The purpose of this qualitative study was to understand the concerns, behaviors, and experiences of adults with autoimmune rheumatic conditions, and to evaluate the impact of the COVID-19 pandemic on their quality of life. Intentional efforts were made to amplify a diverse range of patient voices. Recruitment methods purposefully targeted persons who identify as Black, Indigenous, and People of Color (BIPOC) and/or part of underrepresented and underserved communities.

Methods: Between December 2020 - May 2021, 60-minute interviews were conducted with English- and Spanish-speaking adults, aged ≥ 18 years with self-reported diagnosis of autoimmune rheumatic condition, via phone or videoconference using a semi-structured interview guide. Participants were recruited through social media posts, word-of-mouth, or clinical referral. To ensure rigor while maintaining relevance in response to the changing nature of the COVID-19 pandemic, the research team met regularly to perform preliminary analysis and reflexivity (e.g., acknowledging researchers' pre-conceptions). Ongoing analysis combined methods of phenomenology and content analysis through three steps: 1. Summarizing interviews, 2. Discussing potential units of meaning based on iterative review of transcripts and literature, 3. Axial and selective coding to determine cross-cutting themes.

Results: Participants included 19 adults (40.3 ± 15.1 years old), most reporting a diagnosis of rheumatoid arthritis (52.6%). Demographics included race (52.6% BIPOC), ethnicity (31.6% Hispanic/Latinx), insurance (21.1% Medicare/Medicaid; 15.8% uninsured), employment (26.3% identified as disabled), and representation across U.S. geographic locations. Ongoing analysis produced four preliminary themes (Table 1).

- Theme 1: Based on their learned and experiential knowledge of rheumatic disease and its treatment, most participants perceived themselves to be at higher risk for COVID-19 than the general population.
- Theme 2: Participants vigilantly worked to balance COVID-19 risk, disease management, and mental health. Participants' decisions of whether, how, and when to engage in activities often centered around trust or distrust in their social circles, local geographic communities, and United States politics and public health response.
- Theme 3: Participants felt unsupported by all levels of the healthcare system, from direct interaction with providers to messages received from public health authorities.
- Theme 4: Combined, these factors led to a self-reported increase in autoimmune disease symptoms; relapse or exacerbation of established mental health conditions; and/or new symptoms of trauma, depression, and/or anxiety.

Table 1. Sample Quote(s) per Qualitative Theme

Preliminary Theme Topic	*Sample Quote(s) per Theme*
Theme 1: COVID-19 Risk Perception	*I actually thought I was going to die from it if I had gotten it, because we're told that if you're immuno-compromised, that your chances of getting COVID is higher and it's harder to battle the virus if you do have a pre-existing condition. Being fed all this information, it put me in a state where I felt that unstable feeling and being afraid of going out and making sure that I was doing everything I could to stay healthy. I was washing my hands every 20 minutes and I was like, 'I'm at home. Why am I doing this if I'm at home?'*
Theme 2: Balancing Act	*I can definitely see from the startup of COVID how strict we were [when deciding whether or not to do activities] versus now it's definitely on a scale. Little things started giving way and it was definitely more a mental health thing and less of 'I'm learning more about COVID.'... The type of person I am, I'm like 'Well, if there's any risk, I don't want to take it or you don't need to be doing that. It's unnecessary.' But it got to a point where I can definitely tell you it was necessary for my mental health, for my partner's mental health.*
Theme 3: Interaction with Healthcare System	*I think the misinformation in our community is playing a big role and the historical discrimination against the immigrant communities, in my case, and in the case of the communities [of Color] that I work with. And language barriers, again, the lack of accessibility to information for those families. It has played a major role in these disparities, for example, ... anyone [with or without documentation] can get a vaccine if they're eligible for it, but our community doesn't really know. I think there's this lack of understanding from the authorities that people right now are just focused on surviving the day-to-day basis, like having enough food on their table at the end of the day and paying for rent, not being homeless.*
Theme 4: Physical and Mental Health Symptoms	• *We were on a prayer and a wing, nothing. When the shutdown came, we weren't able to go to the doctor, see the doctor, or talk to the doctor...The shutdown really just took a toll on my body really because I hadn't had any issues with my hands and my fingers in a long time. My fingers were swollen, they were locking up. I mean, when I did have a chance to go to [the doctor], I got two injections in one day, one in each hand.* • *There was the mental toll of quarantine. And then not being able to see my family. Then the chances of getting COVID. Then definitely being Asian, being Chinese, added just a little bit more to that. Because if I wasn't, if I was White, that wouldn't be a thing. I mean I wouldn't be worried that someone would attribute the 'China-virus' to me and that I might get attacked... It added to the stress and anxiety of an already stressful situation.*

Conclusion: Participant interviews during the COVID-19 pandemic revealed critical patient needs for direct and timely communication as well as increased sensitivity to the psychosocial effects of the pandemic on disease symptoms. It is likely these needs will persist post-pandemic.

Has the COVID 19 Pandemic Impacted the Management of Chronic Musculoskeletal Pain?

Samon Oomen-Lochtefeld[1], Rochelle Tsemekhin[2], Lori Lyn Price[2], Chen Guang[3] and Chenchen Wang[2], [1]Tufts University, Boston, MA, [2]Tufts Medical Center, Boston, MA, [3]Harvard Medical School, Boston, MA

SESSION INFORMATION
Session Date: Tuesday, November 9, 2021
Session Title: Patient Outcomes, Preferences, & Attitudes Poster IV: COVID-19 (1589–1613)
Session Type: Poster Session D
Session Time: 8:30AM–10:30AM

Background/Purpose: The management of the patients with chronic conditions such as musculoskeletal pain can be affected by the COVID-19 pandemic. However, the impact of COVID-19 pandemic in the management of pain has not been clearly delineated. We conducted a descriptive review of the impact of the COVID-19 pandemic on chronic musculoskeletal pain management and healthcare system accessibility during 2020-2021 to better inform clinical decision-making.

Methods: We searched MEDLINE and the Cochrane Database from December 2019 to May 2021. We included studies of any design investigating the impact of COVID-19 pandemic on the management of patients with chronic musculoskeletal pain. Screening and data extraction were undertaken by two reviewers. We summarized the disease conditions, demographic information, study design types, duration of observation, treatment accessibility, outcomes measured, and main conclusions.

Results: We identified 114 abstracts and examined 8 published studies from 8 different countries during 2020-2021 on the impact of the COVID-19 pandemic on adults with chronic musculoskeletal pain conditions. **Table 1** summarizes the evidence reviewed according to types of conditions, including osteoarthritis, fibromyalgia, rheumatoid arthritis, chronic lower back pain and miscellaneous chronic musculoskeletal pain. There are 4 cohort and 4 cross-sectional studies with 1,724 participants. The mean age ranged from 36-62 years and data was collected for 1 to 6 months. 59-100% of patients in studies reported reduced treatment accessibility. Of 8 studies, 2 prospective cohort studies on osteoarthritis reported significant increases in pain and loss of function, with an average Visual Analog Score (VAS) increase of 0.7 pre- to post-quarantine. Similarly, higher pain intensity was reported among fibromyalgia and chronic lower back pain patients. Additionally, back pain point prevalence increased from 38.8 to 43.8% within the same sample. In a cross-sectional study, 68 rheumatoid arthritis patients reported increased VAS pain scores and lower quality of life since the onset of the pandemic. 2 other cross-sectional studies with 787 miscellaneous chronic pain patients reported conflicting results; while one study found an 8% average pain severity increase and a 6% average pain interference increase, the other one reported decreases in both average pain severity and pain interference as measured by the Brief *Pain* Inventory scale. Vulnerable patients reported high dependence on others, low ability to self-manage pain, and restricted access to healthcare. Notably, the study with the highest treatment accessibility reported some improvements in pain, depression and sleep quality.

Conclusion: Overall, the COVID-19 pandemic has adversely affected pain severity, physical function and quality of life in patients with chronic musculoskeletal pain. Despite the small number of studies available, our review suggests the pandemic had negative impacts on these patients and lowered treatment accessibility. Further consideration on patient wellbeing and healthcare accessibility for chronic pain management during the pandemic is recommended.

Table 1. summarizes the impacts of the COVID-19 pandemic on patients with chronic musculoskeletal pain

Reference	Condition	N* (F%)	Mean age / range, Race	Study design	Duration (months)	Reduced treatment access	Outcomes measured	Main conclusions
Endstrasser et al., 2020, Austria	94% OA 6% hip dysplasia	68 (44%)	62	Prospective cohort	2	100%	WOMAC, QOL	Significant impact on pain and physical function in patients with end-stage hip and knee OA.
Knebal et al., 2021, Germany	Arthroscopy (35% knee 40% hip) 24% other	77 (44%)	<30 - >80	Cohort	2	79%	Pain, depression	Cancellation of surgery resulted in significant pain levels and in psychosocial distress.
Aloush et al., 2021, Israel	Fibromyalgia	231 (91%)	17 - >61	Cohort	2	98%	Symptom severity, pain, depression, stress, QOL	Patients reported adverse mental and physical outcomes. Reduced treatment accessibility was correlated with higher symptom severity.
Cavalli et al., 2020, Italy	Fibromyalgia	32	ND	Cohort	6	ND	Fibromyalgia impact questionnaire	67% of patients experienced a worsening clinical status, and 33% reported improvement since the pandemic's onset.

SESSION INFORMATION

Session Date: Tuesday, November 9, 2021

Session Title: Patient Outcomes, Preferences, & Attitudes Poster IV: COVID-19 (1589–1613)

Session Type: Poster Session D

Session Time: 8:30AM–10:30AM

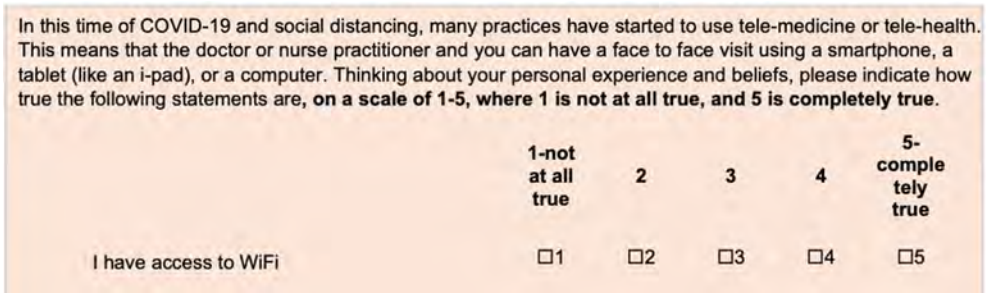
Background/Purpose: COVID-19 can lead to severe and life-threatening complications, which is particularly unnerving for patients with autoimmune disease (AID) on immunosuppressive therapy. Telemedicine has enabled these patients to receive healthcare while socially distant. We describe preliminary data regarding the capacity of telemedicine to meet the healthcare needs of patients with AID who are immunosuppressed.

Methods: This cross-sectional survey included immunosuppressed young adults with AID and parents of immunosuppressed children with AID. The validated Local Inventory of Needs and Knowledge (LINK) survey with a 5-point Likert scale (completely true to completely untrue) was used to assess met and unmet medical and non-medical needs. LINK was modified to address the impact of the pandemic on access to medical care, experience with telemedicine, and health-related behaviors in immunosuppressed AID patients. Consistent with LINK's intention, responses were dichotomized at the extremes, either completely true (5) versus all other responses, or not at all true (1) versus all other responses, depending upon the stem's framing. See figure 1 for a sample of a LINK survey question.

Results: The first 29 respondents were 17 young adults and 12 parents. Patient (7-24 years old) diagnoses included: lupus (n=7), multiple sclerosis (n=6), juvenile arthritis (n=2), uveitis (n=2), vasculitis (n=2), minimal change disease (n=2), neuromyelitis (n=2), nephrotic syndrome (n=1), Henoch-Schonlein purpura (n=1), dermatomyositis (n=1), focal segmental glomerular sclerosis (n=1), post renal transplant (n=1), and systemic sclerosis (n=1).

Within this sample, 24% worried about going to a doctor's office/hospital due to immunosuppressed status. Fear of getting COVID-19 prevented 17% from seeking in-person medical care (Fig 2). Almost all (97%) had access to Wi-Fi, 71% felt comfortable with the idea of seeing a doctor using telemedicine and 59% found it to be a convenient form of healthcare delivery. Many (69%) felt telemedicine was "easy to use" and 59% reported that telemedicine minimized "pandemic-associated stress." Most (72%) believed telemedicine saved time. While 68% of patients were comfortable with in-person appointments, 48% of patients felt "more comfortable with telemedicine appointments during the pandemic." Only 55% thought "all of [their] important healthcare needs were met (Fig 2)." Patients also reported non-medical issues such as difficulties with access to adequate food and housing (data analysis is underway). Responses from young adults and parents were similar.

Conclusion: In this sample of immunosuppressed patients with AID and their parents, a majority identified telemedicine as a convenient and effective alternative to in-person appointments during the pandemic. While respondents expressed satisfaction with telemedicine services that were delivered, nearly half (45%) reported that they remained with unmet needs, suggesting that satisfaction alone is insufficient to assess the adequacy of telemedicine in this population. Data collection is ongoing to understand the unmet needs and drawbacks of telemedicine.



In this time of COVID-19 and social distancing, many practices have started to use tele-medicine or tele-health. This means that the doctor or nurse practitioner and you can have a face to face visit using a smartphone, a tablet (like an i-pad), or a computer. Thinking about your personal experience and beliefs, please indicate how true the following statements are, **on a scale of 1-5, where 1 is not at all true, and 5 is completely true.**

	1-not at all true	2	3	4	5-completely true
I have access to WiFi	☐1	☐2	☐3	☐4	☐5

Sample of LINK survey question and response set (only 1 question out of several questions has been included)

Factors Associated with COVID-19 Vaccine Hesitancy in Rheumatology Outpatients in New York City

Medha Barbhaiya[1], Brandon Schneider[2], Jonah Levine[1], Huong Do[1], Caroline Siegel[1], Vivian Bykerk[3], Candace Feldman[4], Deanna Jannat-Khah[1] and Lisa Mandl[1], [1]Hospital for Special Surgery, New York, NY, [2]Hospital for Special Surgery, New York, [3]Division of Rheumatology, Hospital for Special Surgery, New York City, NY, [4]Brigham and Women's Hospital, Boston, MA

SESSION INFORMATION

Session Date: Tuesday, November 9, 2021

Session Title: Patient Outcomes, Preferences, & Attitudes Poster IV: COVID-19 (1589–1613)

Session Type: Poster Session D

Session Time: 8:30AM–10:30AM

Background/Purpose: COVID-19 vaccination is particularly important for patients with systemic rheumatic diseases (SRDs), who may be at increased risk of infection with SARS-CoV-2 and of worse COVID-19 outcomes. However, despite remarkable vaccine safety and efficacy data, some individuals remain hesitant to be vaccinated. We aimed to measure the degree of vaccine hesitancy in rheumatology outpatients from a U.S. COVID-19 "hotspot" and explore factors associated with hesitancy or refusal in this high-risk patient population.

Methods: We emailed a secure web-based survey on March 5, 2021 to 7,505 patients aged ≥18 years evaluated at least once by a rheumatologist between 2018-2020 at a large Rheumatology center in New York City and who previously agreed to participate in surveys on COVID-19. We included individuals who completed a modified vaccine hesitancy questionnaire (based on *Larson et al. Vaccine. 2015*), with questions specific to COVID-19 vaccination. We also collected data on sociodemographics, medical comorbidities, medication use, other immunizations during adulthood, and COVID-19 history. ICD-10-CM algorithms were used to identify SRD diagnoses. We evaluated patient

characteristics and vaccine hesitancy questionnaire responses by vaccination status (refusing vaccination, undecided, already received/willing). Categorical variables were calculated using chi-square/Fishers exact test. Continuous variables were tested with one factor ANOVA.

Results: Among 2,384 patients who completed the vaccine hesitancy questionnaire (31.8% response rate), 2,240 (94.0%) patients were willing/already received COVID-19 vaccination. 88 (3.7%) patients were 'undecided', and 56 (2.3%) reported vaccine refusal (Table 1). Compared to patients willing/already received vaccine, those refusing or undecided had lower mean ages (52.1y [SD 13.5] and 53.4 [SD 12.7] versus 61.4 [SD14.4]), higher percentage of Black, Hispanic/Latinx patients, patients with lower household income, and married/partnered patients; they had lower percentage with an advanced education degree (Table 1). Undecided patients were least likely to have received other immunizations during adulthood (Table 2), and those refusing the vaccine were most likely to have had a history of COVID-19 infection (33.9% versus 20.5% versus 9.1%, $p< 0.01$). SRD status differed between the groups, with SLE-like diseases being highest in those refusing the vaccine ($p< 0.01$). No differences in current use of immunosuppressive medications were observed. Vaccine questionnaire responses indicated that those refusing the vaccine were least likely to believe in the importance for health of vaccines in general, and in the safety or efficacy of the COVID-19 vaccine (Table 3). Patients refusing or undecided were most concerned about long-term vaccine side effects, lack of study in rheumatology patients, and the speed of vaccine development (Table 3).

Conclusion: Although vaccine hesitancy/refusal was only reported by 6% of respondents, our study provides useful insights into why rheumatology patients may refuse COVID-19 vaccination, including data that suggest the misperception that previous COVID-19 infection may mitigate the need for immunization.

rheumatoid arthritis flare. Noteworthy, the mRNA vaccines studies that were conducted excluded patients with rheumatic diseases who are on immunosuppressive therapy, therefore it is still unclear whether the mRNA covid vaccines might provoke flares of underlying rheumatologic diseases.

The purpose of our study is to assess whether rheumatoid arthritis patients who received the mRNA COVID-19 vaccine developed a flare of their disease.

Methods: We conducted a single-center retrospective study at the Louis Stokes Cleveland VA Medical Center. We included all patients with RA who are actively on immunosuppressive therapy and received the Pfizer vaccine. Those patients were contacted by phone and a survey questionnaire was used to collect data about their RA, immunosuppressive therapy, and development of symptoms post vaccinations. We included 60 patients in this abstract. Our primary end point was to calculate the percentage of any flare up of RA after COVID-19 vaccine. Secondary end points were to estimate the side effect profile from the vaccine among this population, to check if patients developed

a COVID infection after they received the vaccine, and to evaluate whether patients stopped their immunosuppressive medications around the time of the vaccine.

Results: Between 3/9/2021 and 5/27/2021, a total of 60 patients were contacted. One out of the sixty patients (1.67%) reported symptoms of RA flare up after taking the vaccine. Most common side effects in our patients were soreness over the injection site (26.27%), fatigue for one day (3.33%), headaches (3.33%) and arthralgias (3.33%), similar to what was reported in the general population. Most of the patients did not stop their immunosuppressive medications before or after the vaccine (90.91%). None of the patients developed COVID-19 infection following the vaccine up till the date of the phone call. Among our RA patients, one patient developed an RA exacerbation after the Pfizer COVID-19 vaccine administration. This patient had poor symptoms control before taking the vaccine however he had worsening of his symptoms following the second dose. Most of the patients had minimal side effects. The question remains as to whether COVID-19 vaccine would confer adequate immune protection in these patients with altered immune response either from underlying rheumatic disease or secondary to disease modifying agents. Some of the Limitations we faced were the small number of patients, and potential recall bias from phone surveys.

Conclusion: Rheumatoid arthritis patients receiving the COVID-19 Pfizer vaccine did not develop major symptoms, flares or side effects following the vaccine. The mRNA COVID vaccine was mostly safe and patients with RA are recommended to receive it. Further research with larger numbers of patients is needed to evaluate the safety and effectiveness of COVID-19 vaccine within patients with autoimmune rheumatic diseases.

Perceptions About COVID-19 Vaccination Among Patients with Rheumatic Diseases Enrolled in a National Patient Registry

Maria I. Danila[1], Kelly Gavigan[2], Esteban Rivera[2], Michael George[3], Jeffrey Curtis[4], William Nowell[2] and Shilpa Venkatachalam[2], [1]University of Alabama at Birmingham, Birmingham, AL, [2]Global Healthy Living Foundation, Upper Nyack, NY, [3]University of Pennsylvania, Philadelphia, PA, [4]Division of Clinical Immunology and Rheumatology, Department of Medicine, Department of Epidemiology, University of Alabama at Birmingham, Birmingham, AL

SESSION INFORMATION
Session Date: Tuesday, November 9, 2021
Session Title: Patient Outcomes, Preferences, & Attitudes Poster IV: COVID-19 (1589–1613)
Session Type: Poster Session D
Session Time: 8:30AM–10:30AM

Background/Purpose: COVID-19 vaccine confidence is key to promoting vaccination efforts to mitigate the spread of COVID-19 among people with rheumatic diseases. The goal of this study was to examine concerns and beliefs about COVID-19 vaccination among patients with rheumatic diseases enrolled in a national patient registry and to determine if education level is associated with COVID-19 vaccine confidence.

Methods: Members of the national ArthritisPower patient research registry were invited to complete an online survey. Vaccination confidence was evaluated using 1-item confidence scale from the validated 5C scale (range 1 = strongly disagree to 7 = strongly agree, higher values are better). Descriptive statistics summarized demographic characteristics, receipt of and concerns and beliefs about COVID-19 vaccination. Multiple regression assessed whether education is associated with vaccine confidence after adjusting for the effect of age, sex, and race and ethnicity (Model 1), age and sex (Model 2), and age (Model 3). Individuals who self-reported being Hispanic, non-Hispanic Black and non-Hispanic other race were grouped together as race and ethnic minority group.

Table 1. Characteristics of Survey Respondents Recruited from ArthritisPower Patient Registry

Frequencies and percentages are shown, unless otherwise noted.

Table 2. Receipt of COVID-19 Vaccine and Vaccine Concerns and Beliefs Among Survey Respondents Recruited from Arthritis Power Patient Registry

Variable	N= 1,345
Offered COVID-19 vaccine	728 (54.1%)
No COVID-19 vaccine receipt	781 (58.1%)
Very unlikely/unlikely to get vaccinated	138 (17.7%)
Reasons for not getting vaccinated among unvaccinated members	
Use of immunosuppressive medications	159 (51.5%)
Concerns of disease flares	157 (50.8%)
Fear of side effects	97 (31.4%)
Prior reactions to other vaccines	66 (21.4%)
Fear of vaccine modifying their DNA	49 (15.9%)
Key information needs during ongoing deliberation about COVID-19	
Long-term efficacy	196 (63.4%)
Side effects of the vaccine in "people like me"	194 (62.8%)
Efficacy among "people like me"	161 (52.1%)
Desire to talk to my doctor	79 (25.6%)
COVID-19 Vaccine beliefs, mean (SD)	
"I am completely confident that the COVID-19 vaccine is safe" (confidence)	5.2 (2.01)
"COVID-19 vaccination is unnecessary because COVID-19 is not common anymore" (complacency)	1.5 (1.1)
"COVID-19 is not so severe that I should get vaccinated" (complacency)	1.7 (1.5)
"Everyday stress prevents me from getting vaccinated with the covid-19 vaccine" (complacency)	1.5 (1.2)
"When I think about getting the COVID-19 vaccine, I weigh benefits and risks to make the best decision possible" (calculation)	6.2 (1.5)
"Getting the COVID-19 vaccine is important because I can help protect other people from getting infected" (collective responsibility)	6.0 (1.7)

Frequencies and percentages are shown, unless otherwise noted. Vaccine beliefs scales range from 1 (strongly disagree to 7 strongly agree); higher scores are better for confidence, calculation, and collective responsibility measures and lower scores are better for complacency and constraints measures.

Results: Between February 9 and March 24, 2021, we received 1345 responses. Mean (standard deviation) age was 59 (11.5) years, 86% were female, 87% were non-Hispanic white (**Table 1**). While 54% stated they had been offered a COVID-19 vaccine, only 42% had received at least one dose of the vaccine (**Table 2**). Among those unvaccinated,

Table 3. Multiple Regression Analysis for Association between Levels of Education and COVID-19 Vaccine Confidence Among Survey Respondents Recruited from ArthritisPower Patient Registry

	Model 1			Model 2			Model 3		
Variable	Estimate	95% CI	p	Estimate	95% CI	p	Estimate	95% CI	p

CI, confidence interval

almost 18% said they were unlikely to get vaccinated. The most common reasons for not getting the vaccine were use of immunosuppressive medications (52%), concerns of disease flare (51%), fear of side effects (31%), prior reactions to other vaccines (21%), fears about the vaccine modifying one's DNA (16%). While deliberating about vaccination, the following information was thought to be important: long-term efficacy of the vaccine (63%), side effects of the vaccine (63%) and its efficacy (52%) among people with the same health condition as the respondent. Compared to vaccinated people, unvaccinated persons had significantly lower scores on the confidence scales [6.3 (1.2) vs 4.5 (2.2), $p< 0.01$]. After controlling for age, sex, and race, lower level of education was associated with lower vaccine confidence (**Table 3**).

Conclusion: During the initial COVID-19 vaccine roll out, a substantial minority of patient members of a large national patient registry had received COVID-19 vaccination. Approximately 1 in 10 said they were unlikely to get vaccinated, even among this highly engaged and research-interested patient population. The main reasons for not getting the vaccine were use of immunosuppressive medications and concerns about a disease flare. Respondents felt they needed more information about the safety and efficacy of the COVID-19 vaccine among people with their conditions. Lower education level was associated with lower vaccine confidence. These findings highlight the need for developing COVID-19 vaccination campaigns that are tailored to different levels of education for people with rheumatic diseases.

Abstract Number: 1605

Health Related Quality of Life in Rheumatology Outpatients with COVID-19 from New York City over the Course of the Pandemic

Lisa Mandl[1], Jonah Levine[1], Vivian Bykerk[2] and Medha Barbhaiya[1], [1]Hospital for Special Surgery, New York, NY, [2]Division of Rheumatology, Hospital for Special Surgery, New York City, NY

SESSION INFORMATION
Session Date: Tuesday, November 9, 2021
Session Title: Patient Outcomes, Preferences, & Attitudes Poster IV: COVID-19 (1589–1613)
Session Type: Poster Session D
Session Time: 8:30AM–10:30AM

Background/Purpose: The impact of the COVID-19 pandemic on the mental and physical well-being of patients with systemic rheumatic diseases (SRDs) remains to be quantified. We assembled a cohort of Rheumatology outpatients with history of COVID-19 and compared HRQOL in patients with and without SRD over the course of the pandemic.

Methods: Between April 24, 2020 and May 26, 2020 we emailed a secure web-based survey to 26,045 patients ≥age 18 evaluated by a rheumatologist at a specialty hospital in New York City. A follow-up survey was sent in March 2021.SRD and non-SRD patients had relevant ICD-10-CM codes on ≥ 2 visits at least 7 days apart. Patients with an SRD code at only 1 visit were excluded. Non-SRD patients also had no SRD ICD-10-CM code. In this analysis, we included patients diagnosed with COVID-19 by a positive SARS-CoV-2 PCR or antigen test, or who were told by a medical provider they likely had COVID-19. The latter was included because in early 2020 SARS-CoV-2 tests were not readily available. Patients self-reported demographics on the first survey, and select PROMIS-29 domains at both time points. We used paired T-tests to compare within person change, and T-tests and Chi-Square to compare differences between groups.

Table 1. Baseline Characteristics of Rheumatology Outpatients with COVID-19, Stratified by Systemic Rheumatic Disease (SRD) Status

	All Patients with COVID-19 N=354	SRD With COVID-19 N=189	Non-SRD With COVID-19 N=105	p-values
Sociodemographic Factors				
Age (years), Mean (SD)	53.5 (14.8)	53.3 (13.8)	55.1 (16.0)	0.31
BMI kg/m², Mean (SD)	27.5 (13.1)	28.7 (16.9)	25.4 (5.1)	0.052

Table 2. PROMIS-29 Domains Measured in Rheumatology Outpatients with COVID-19 in April-May 2020, Overall and by SRD Status

PROMIS Score	All Patients with COVID-19 N=354	SRD With COVID-19 N=189	Non-SRD With COVID-19 N=105	p-values
Anxiety T-Score (SD)	58.5 (10.2)	58.8 (9.7)	57.9 (11.2)	0.49
Depression T-Score(SD)	52 (9.2)	52.5 (8.8)	51.8 (9.5)	0.53
Fatigue T-Score(SD)	54.5 (11.4)	55.6 (11)	52.9 (12.1)	0.06
Sleep T-Score(SD)	53.1 (7.2)	53.7 (6.9)	52.8 (7.1)	0.29
Pain T-Score(SD)	54.7 (10.6)	56.1 (10.3)	52.1 (10.4)	0.002
T-score: higher= more of the domain; 50 is the population mean				

Table 3. Mean Within-Person Differences in PROMIS T-Scores Between April/May 2020 and March 2021, Overall and by SRD Status

PROMIS Score	All Patients with COVID-19 N=100	SRD with COVID-19 N=57	Non-SRD with COVID-19 N=32	p-value
Anxiety T-Score(SD)	-2.7 (9.4)	0.7 (9.5)	-1.7 (7.7)	0.19
Depression T-Score(SD)	0.2 (8.9)	0.8 (2)	-0.7 (8.2)	0.32
Fatigue T-Score(SD)	2.5 (10.7)	4.6 (9)	0.4 (7.6)	**0.02**
Sleep T-Score(SD)	-0.7 (9.9)	4 (12.2)	-0.1 (10.5)	0.1
Pain T-Score(SD)	3.3 (8.8)	0.6 (0.9)	2.1 (8.6)	0.33

Results: Of 6584 (25.3%) patients responding to the PROMIS-29 on the first survey, 354 subjects reported having COVID-19; of those 189 met SRD and 105 met non-SRD criteria. SRD and non-SRD patients were of similar age (53.3 vs. 55.1 years), percent female (85.7% vs 80%), and body mass index (28.7 vs. 25.4). Patients with SRD were more likely to be White (76.2% vs. 81.9%; p=0.038) and be on chronic active corticosteroids (18% vs 2.9%; p< 0.0001). Overall, 17.5% went to an emergency room, though few were hospitalized (6.9% SRD vs. 4.8% non-SRD, p=0.47) . At baseline, SRD and non-SRD patients had similar PROMIS-29 T-scores except SRD had worse pain (Table 1). Of 100 subjects reporting PROMIS-29 at both time points, within-person changes for the fatigue domain indicated worsening only in SRD (T-score difference of 4.6; p= 0.02). 44% of SRD subjects compared with only 28% of non-SRD subjects reported clinically meaningful (T-score >=5) worse fatigue at follow up; p< 0.028). There was no significant association between clinically meaningfully worse fatigue at follow up and use of chronic active corticosteroids, going to the ER, or being hospitalized (data not shown).

Conclusion: Although all subjects with a history of COVID-19 had similar PROMIS-29 scores at baseline, subjects with SRD were 1.6 x more likely to report clinically meaningful worsening of fatigue nearly 1 year after COVID-19 diagnosis, compared to non-SRD patients followed at the same Rheumatology practice. Analysis is ongoing to identify predictors of poor HRQOL after COVD-19 in patients with SRD.

Telemedicine for Rheumatology Care During the COVID-19 Pandemic: Patient Perceptions and Preferences

Maria I. Danila[1], Kelly Gavigan[2], Esteban Rivera[2], William Nowell[2], Michael George[3], Jeffrey Curtis[4], Lisa Christopher-Stine[5], Shubhasree Banerjee[3], Peter Merkel[3], Kalen Young[6], Dianne Shaw[6], Jennifer Gordon[6] and Shilpa Venkatachalam[2], [1]University of Alabama at Birmingham, Birmingham, AL, [2]Global Healthy Living Foundation, Upper Nyack, NY, [3]University of Pennsylvania, Philadelphia, PA, [4]Division of Clinical Immunology and Rheumatology, Department of Medicine, Department of Epidemiology, University of Alabama at Birmingham, Birmingham, AL, [5]Johns Hopkins University, Baltimore, MD, [6]Vasculitis Foundation, Kansas City, MO

SESSION INFORMATION

Session Date: Tuesday, November 9, 2021

Session Title: Patient Outcomes, Preferences, & Attitudes Poster IV: COVID-19 (1589–1613)

Session Type: Poster Session D

Session Time: 8:30AM–10:30AM

Background/Purpose: The COVID-19 pandemic disrupted the delivery of medical care and resulted in a substantial uptake in telemedicine care for patients with chronic conditions, including autoimmune rheumatic diseases. The objective of this study was to assess perceptions and preferences about telemedicine among patients with autoimmune rheumatic diseases during the COVID-19 pandemic.

Methods: We conducted an online survey among members of ArthritisPower and Vasculitis Patient Powered Research Network online patient registries and members of the following patient organizations: Myositis Support and

Table 1. Respondents' demographic and clinical characteristics by type of telemedicine visit

Characteristic	All Participants	Video Telemedicine Visit	Phone Telemedicine Visit	No Telemedicine Visit	p-value (Telemedicine yes vs no)
	N=819	N = 303	N = 146	N=370

Number (%) and mean +/- standard deviation shown. Urban status shown among participants with available zip code. Statistically significant differences between characteristics of those who had a telemedicine visit vs those who did not are denoted in bold font. *Other rheumatic diseases include anti-phospholipid antibody syndrome, anti-glomerular basement membrane antibody disease, juvenile idiopathic arthritis, mixed connective tissue disease, psoriasis, sarcoidosis, scleroderma, Sjogren's syndrome; **Lung disease includes asthma, emphysema, chronic obstructive pulmonary disease, pulmonary hypertension, other chronic lung disease; *** PROMIS Anxiety short form with range of 1-100, U.S. adult population mean=50 and standard deviation=10. DMARD, disease modifying anti-rheumatic drug; NSAIDs, nonsteroidal anti-inflammatory drugs.

Understanding, Lupus and Allied Disease Association, American Bone Health, and International Foundation for Autoimmune & Autoinflammatory Arthritis. Attitudes about telemedicine (i.e., telemedicine acceptability) were evaluated using the validated telemedicine perception questionnaire (TMPQ). The TMPQ score (range 17 to 85) was calculated; higher scores show higher acceptability. Visit satisfaction was measured using the one question scale from the validated Agency for Healthcare Research and Quality Consumer Assessment of Healthcare Providers and Systems (CAHPS)® survey (0-10 scale, 0 represents worst possible visit, 10 represents best possible visit). T-tests and multivariable linear regression compared the satisfaction and TMPQ scores between respondents who reported participating in video and phone-only visits. Chi-square tests compared preferences for telemedicine visits for specific clinical scenarios between those who had telemedicine visit versus those who had not.

Results: Between June 18 and August 10, 2020, we received 819 responses. Participants had a mean (SD) age of 58.6 (11.6) years and were mostly white (n= 759, 92.7%) and female (n=702, 85.7%). Of 618 participants who said that telemedicine was available to them, 449 (72.7%) reported having a telemedicine visit, with 303 (67.5%) reporting at least one telemedicine video visit; the remainder had a phone-only visit (**Table 1**). On a 0-10 scale, the mean (standard deviation) visit satisfaction score for telemedicine visits was 7.3 (1.8) with 25.8% being very satisfied (score 9 or 10). The mean (SD) telemedicine acceptability as assessed by TMPQ score was 62.8 (10.7). Video visits and higher TMPQ score were associated with higher satisfaction (data not shown). Preference for a telemedicine visit varied

Figure 1. Preference for telemedicine versus in-office visits among all survey respondents by reason for visit (N=819).

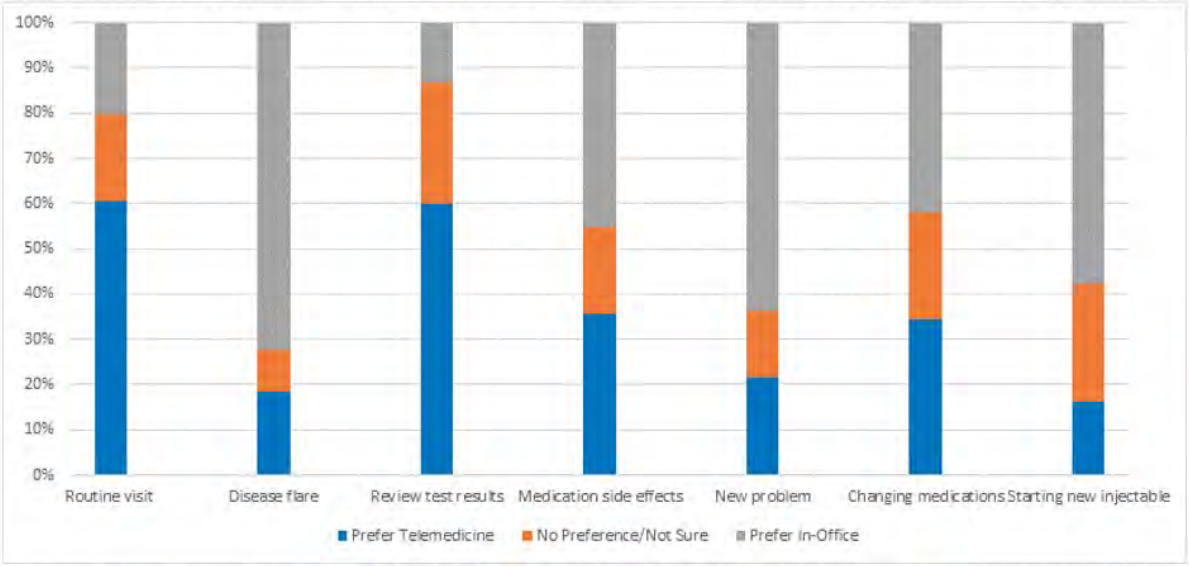

Table 2. Preference for telemedicine visit for different visit reasons by prior experience with telemedicine (N=819)

Reason for clinic visit	All (N=819)	Had a Telemedicine Visit (N=449)	Didn't have a Telemedicine Visit (N=370)	p-value*
Routine care	495 (60.4)	331 (73.7)	164 (44.3)	**<0.001**
Disease flare	150 (18.3)	79 (17.6)	71 (19.2)	0.56
Review of test results	490 (59.8)	291 (64.8)	199 (53.8)	**<0.001**
Medication side effects	293 (35.8)	169 (37.6)	124 (33.5)	0.22
New problem	176 (21.5)	101 (22.5)	75 (20.3)	0.44
Medication change	281 (34.3)	182 (40.5)	99 (26.8)	**<0.001**
Start a new injectable medication	132 (16.1)	85 (18.9)	47 (12.7)	**0.02**

*Statistically significant differences between characteristics of those who had a telemedicine visit vs those who did not are denoted in bold font.

substantially by reasons for the visit (**Figure 1**). Compared to those who had not yet had a telemedicine visit, patients who had experienced telemedicine were more likely to prefer telemedicine for routine visits (73.7% vs 44.3%, p< 0.001), reviewing test results (64.8% vs 53.8%, p< 0.001), when considering changing medications (40.5% vs. 26.8%; p< 0.001), and when starting a new injectable medication (18.9% vs. 12.7%; p=0.02) (**Table 2**).

Conclusion: During the COVID-19 pandemic, patients with autoimmune rheumatic diseases frequently had telemedicine visits, the majority via video, and were often satisfied with these visits. These results suggest that because such patients prefer telemedicine for certain types of visits, maximizing effective use of telemedicine should take into consideration specific clinical scenarios and patient preferences.

Abstract Number: 1607

The Impact of Health Literacy and Numeracy on COVID-19 Vaccine Hesitancy in SLE

Rebecca Sadun[1], Mithu Maheswaranathan[1], Megan Clowse[2], Kai Sun[1], Jennifer Rogers[1], Jayanth Doss[1], Lisa Criscione-Schreiber[3] and Amanda Eudy[1], [1]Duke University, Durham, NC, [2]Duke University, Chapel Hill, NC, [3]Duke University School of Medicine, Durham, NC

SESSION INFORMATION
Session Date: Tuesday, November 9, 2021
Session Title: Patient Outcomes, Preferences, & Attitudes Poster IV: COVID-19 (1589–1613)
Session Type: Poster Session D
Session Time: 8:30AM–10:30AM

Background/Purpose: The ACR has issued guidance recommending COVID-19 vaccine for all patients with rheumatic diseases. Vaccine hesitancy research prior to the COVID-19 pandemic has demonstrated associations between health literacy and vaccine hesitancy. In this study, we assessed the relationship between SLE patients' desire to receive a COVID-19 vaccine and their health literacy/numeracy.

Methods: Health literacy was assessed by the Newest Vital Sign (NVS); NVS < 4 denotes limited health literacy. Numeracy was assessed with the Subjective Numeracy Scale (SNS-3); SNS-3 ≤12 was considered to be low numeracy. The Vaccine Hesitancy Scale (VHS) was modified to assess adult vaccine beliefs, with additional questions specific to the COVID-19 vaccine and patients' self-assessed COVID-19 risk. The survey also asked whether patients would choose to get the COVID-19 vaccine if it were made available to them the following week (definitely/probably vs probably not/definitely not). The survey was distributed by email on 02/24/2021 to the 353 patients in the Duke Lupus Registry, all of whom met ACR or SLICC criteria for SLE. Linear regression models adjusted for education estimated the associations of health literacy and numeracy on the desire to receive the COVID-19 vaccine.

Table 1. Study population

	Overall	Adequate health literacy	Limited health literacy		Adequate numeracy	Limited numeracy	
	n=63	n=29	n=9	p	n=43	n=14	p

Results: A total of 63 patients who completed the COVID-19 vaccine had recently completed an assessment of health literacy or numeracy: 38 patients had completed the NVS, 57 had completed the SNS-3, and 32 had completed both. Overall, 98% of respondents were female, 56% White, and 68% college educated (Table 1). Patients with adequate health literacy were more likely to be college educated (p=0.04), and patients with limited health literacy were more likely to lack private health insurance (p=0.03); these associations were not seen for numeracy.

Importantly, 60 out of 63 SLE patients (95%) wanted to receive the COVID-19 vaccine as soon as possible. Adequate and limited literacy patients had similar VHS scores and were similar on most sub-scales, although there was a trend

Table 3. Associations between numeracy and vaccine beliefs

*adjusted for education

toward more hesitancy in the low literacy group for the Safety sub-scale (Table 2). Within this sub-scale, even after adjusting for education, limited literacy patients were more likely to express fear of vaccines causing autism (p=0.05), fear of getting COVID-19 from the vaccine (p=0.05), and fear that the COVID-19 vaccine was rushed (p=0.05). Limited numeracy patients were less likely to agree with having a family member who is high-risk for COVID-19, although their assessment of personal risk for severe COVID-19 was similar to adequate numeracy patients (Table 3).

Conclusion: The vast majority of SLE respondents wanted to receive the vaccine, regardless of health literacy and numeracy status. Patients with limited health literacy were more likely to believe vaccine falsehoods, including concerned that vaccines cause autism, that they could get COVID-19 from the vaccine, and that the COVID-19 vaccine was rushed; such patients may be more susceptible to vaccine conspiracy theories.

Session Date: Tuesday, November 9, 2021
Session Title: Patient Outcomes, Preferences, & Attitudes Poster IV: COVID-19 (1589–1613)
Session Type: Poster Session D
Session Time: 8:30AM–10:30AM

Background/Purpose: Patients with chronic inflammatory rheumatic diseases (CIRD) may be at increased risk of Corona Virus Disease 2019 (COVID-19).1 The quality of information obtained plays a crucial role for patients' decision to be vaccinated. Knowing patients' needs for information and which sources are used is important for the management of CIRD patients by rheumatologists and other physicians.

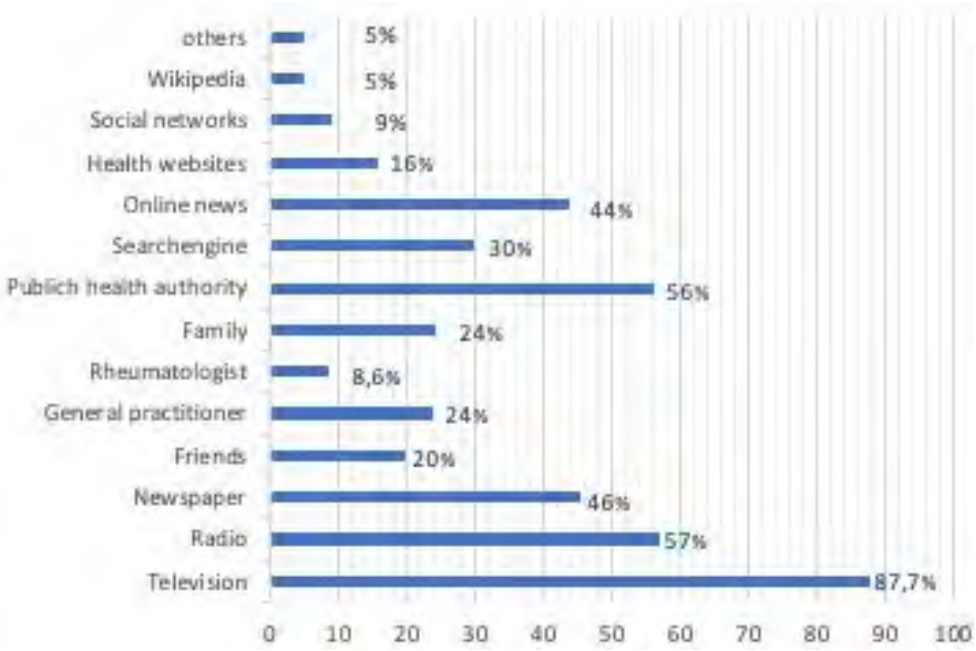

Figure 1. Sources of information of CIRD patients about SARS-CoV-2.

To identify main sources of information on SARS-CoV-2 used by patients with CIRD and to analyze their influence on opinions and willingness to be vaccinated.

Methods: CIRD patients presenting to our tertiary rheumatology hospital were, after informed consent, consecutively included in the study once the vaccination campaign in Germany had started, to fill out a questionnaire. Next to sociodemographic and disease-specific data, vaccination willingness and knowledge regarding SARS-CoV-2 were assessed. Furthermore, patients' sources of information and their concerns about accuracy of information were evaluated. A numerical rating scale (NRS) ranging from 0 (completely disagree) to 10 (completely agree) was used. Values between ³7 were taken as positive answer. Nonparametric tests and multivariate linear regression analyses were performed.

Results: In early 2021, a total of 514 patients were interviewed (table 1). The majority (63.9 %) reported to be well-informed (NRS ³7), whereas 18% had doubts regarding information on SARS-CoV-2. The most often used source of information was television, and only 8.6% reported to have been informed by a rheumatologist (figure 1). About 20% of patients were no longer interested in receiving any information on SARS-CoV-2 through media. Information from rheumatologists, general practitioners, public health authorities or health related web sites did not reach 30.5% of patients. Of interest, 16% of subjectively well-informed patients were hesitant towards vaccination. As many as 43.6% of patients with doubts regarding information about SARS-CoV-2 indicated that they were not willing to be vaccinated. No source of information showed a strong correlation with SARS-CoV-2 vaccination willingness or with knowledge on SARS-CoV-2. Weak positive correlations were found between age and education level on the one hand and information sources about SARS-CoV-2 on the other hand (table 2). A weak negative correlation was found between doubts about information and health authorities, whereas positive correlations were found with social networks, friends and family.

Conclusion: Most CIRD patients think that they are well-informed about SARS-CoV-2. However, their information rarely comes from expert-based sources and rarely from rheumatologists. Thus, there is an unmet need for CIRD patients to receive appropriate and comprehensive information about SARS-CoV-2, its influence on rheumatic diseases, and about vaccination of patients with CIRD.

Abstract Number: 1609

SARS-CoV-2 Vaccination Willingness and Its Predictors in Patients with Chronic Inflammatory Rheumatic Diseases (CIRD)

Iulia Roman, Ioana Andreica, Xenofon Baraliakos, Uta Kiltz and Juergen Braun, Rheumazentrum Ruhrgebiet Herne, Ruhr-Universität Bochum, Herne, Germany

SESSION INFORMATION
Session Date: Tuesday, November 9, 2021
Session Title: Patient Outcomes, Preferences, & Attitudes Poster IV: COVID-19 (1589–1613)
Session Type: Poster Session D
Session Time: 8:30AM–10:30AM

Background/Purpose: Whether patients with chronic rheumatic diseases (CIRD) are at increased risk of developing severe COVID 19 infections is not entirely clear. However, some DMARDs seem to be associated with worse outcomes. Out of this perspective vaccination protection should be sought for all CIRD patients. Recent surveys showed in CIRD patients an alarming degree of vaccine hesitancy[1]. Strategies should be developed to increase the vaccination rates in patients with CIRD.

To identify sociodemographic, patient and disease specific predictors of vaccine willingness in CIRD patients and to compare these with a control group.

Methods: Using a cross-sectional study design, a survey was conducted to assess vaccination willingness of consecutive CIRD patients and controls without CIRD presenting to our tertiary rheumatology hospital. In addition to sociodemographic data, patient and disease characteristics including comorbidities and therapy were recorded. A numerical rating scale was used to measure vaccination willingness (0: fully disagree; 10: fully agree). Definite willingness to be vaccinated was assumed if ³7 was selected. Nonparametric tests and multivariate linear regression were performed where appropriate.

Results: A total of 514 CIRD patients and 100 controls were prospectively included (table 1). No significant differences were found regarding the definite vaccination willingness (79.6% vs. 76%) in CIRD vs. control patients. In the CIRD group, the willingness to be vaccinated against SARS-CoV-2 showed a moderate positive correlation with the level of information on influenza and pneumococci as well as a history of travel vaccination (table 2); this was not the case in the control group.

Table 1. Patients and disease characteristics

**** Kendall´s tau-b correlation coefficient

Furthermore, a positive correlation was found in CIRD patients with age and an even stronger with educational level, but no correlation was seen with known risk factors for severe outcomes of COVID-19 disease except for hypertension. A status of “no comorbidity” was associated with a lower vaccine acceptancy in CIRD patients. Finally, neither the number nor the type of current immunosuppressive therapy correlated with vaccination willingness. CIRD patients, who did not think that they are at risk for a COVID 19 disease were less likely to accept a SARS-CoV-2 vaccination.

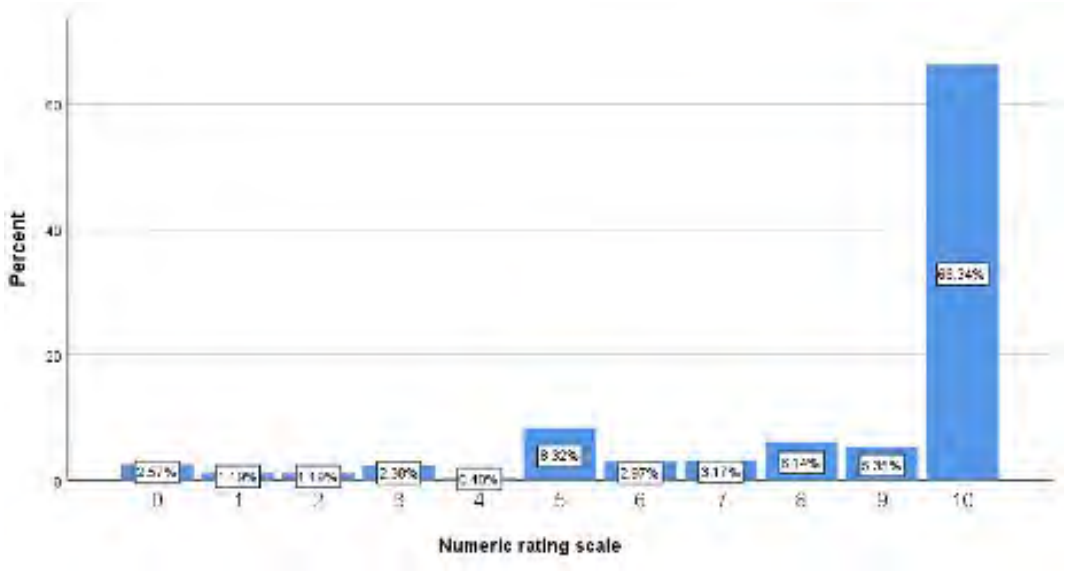

Figure 1. Vaccination willingness of CIRD patients.

Conclusion: The majority of CIRD patients was ready to be vaccinated against SARS-CoV-2. This was especially the case in older patients, those with a higher educational level and those who rated themselves as being at increased risk. Moreover, our survey highlights several factors that are relevant for vaccination willingness, including appropriate information about preventable infections and its relevance in general. The fact that known risk factors for a severe COVID-19 did not show an interference with vaccine acceptancy is alarming and indicates that more patient education is needed.

"You Can't Touch, You Can't Bond": COVID-19 and Telehealth Impacts on Communication, Goals, and Experience of Care for Persons with Rheumatoid Arthritis and Their Clinicians

Elizabeth Hulen[1], Christopher Larsen[2], Rachel Matsumoto[2], Patricia Katz[3] and **Jennifer Barton**[4], [1]VA Portland Health Care System, Portland, OR, [2]Center to Improve Veteran Involvement in Care/VA Portland Health Care System, Portland, OR, [3]University of California San Francisco, San Francisco, CA, [4]VA Portland Health Care System/OHSU, Portland, OR

SESSION INFORMATION

Session Date: Tuesday, November 9, 2021
Session Title: Patient Outcomes, Preferences, & Attitudes Poster IV: COVID-19 (1589–1613)
Session Type: Poster Session D
Session Time: 8:30AM–10:30AM

Background/Purpose: A rapid shift to telehealth visits has been a key part of health system response to the ongoing COVID-19 pandemic. This study explores the impacts of the pandemic and care delivery via telehealth on patient goals, patient-clinician goal communication, and management of rheumatoid arthritis (RA).

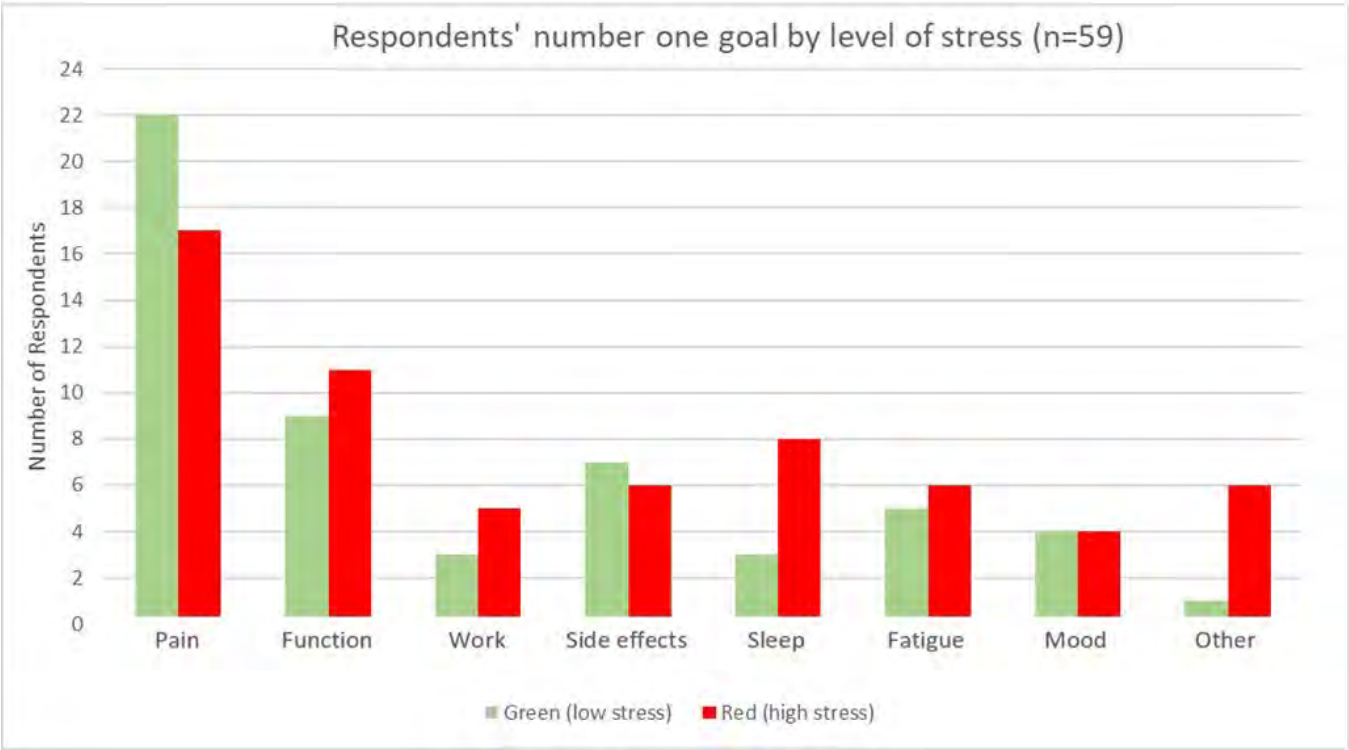
Methods: RA patients who had a telehealth visit between March 1 and July 31, 2020 (university and Veterans Affairs, VA) were invited to participate in a survey study via phone or mail. Survey questions included demographics, health status, COVID-19 impacts, treatment goals, stress, resiliency, and measures of decisional conflict, clinician empathy, communication, and optional-free-text comments. Descriptive and bivariate analyses were conducted on survey items and qualitative content analysis was conducted on free-text comments. Over the same study period, 6 clinicians from university and VA clinics participated in a 60-minute focus group to discuss impacts of telehealth and the COVID-19 pandemic on communication and goal discussions with patients. The focus group was audio-recorded, transcribed verbatim and analyzed using a framework matrix.

Results: Of the 159 eligible patients invited to participate, 59 (37%) completed the survey (28 by phone; 31 by mail). Average age was 69 (± 10.5) years, 71% male, 86% white, 22% with inadequate health literacy and 85% Veterans. Patients overwhelmingly ranked having less pain as their #1 goal (66%) followed by having fewer problems doing daily activities (34%) and avoiding side effects (22%). Over half (58%) reported ≥moderate stress from COVID-19. Compared with patients who reported lower stress, those with ≥ moderate stress reported increased decisional conflict, lower resiliency and clinician empathy (Table). Goals stratified by stress level reflect higher prioritization of function and sleep over less pain among those with ≥moderate stress (Figure). Analysis of free-text responses indicated that patient participants held concerns about medication changes and RA flares, social and relational stress as well as frustrations with government regulations and pandemic response. In the focus group, clinicians perceived that increased use of telehealth presented logistical and safety challenges that undermined development of high-quality relationships with patients due to the absence of physical co-location and change in visit formality.

Table. Measures of emotional support, resiliency, self-efficacy, decisional conflict, empathy and trust in physician by stress level from Covid-19 (moderate to high vs. none or a little) among 59 RA patients

Measure[a]	Total (n=59)	Mean, SD or N (%)	Moderate to high stress (n=34)	Low stress (n=25)	P-value
Emotional support (0-20)	59	17 (4.37)	16.15	18.16	0.075
Resilience scale (0-5)	57	3.76 (0.90)	3.50 (33)	4.10 (24)	0.012
Self-efficacy, mean SD (0-10)	59	6.44 (2.20)	6.00	7.04	0.095
SURE[b] (proportion with a score of 4 out of 4 indicating no decisional conflict)	57	49 (86%)	75% (32)	100%	0.003
CARE (0-50)	59	43.86 (8.33)	42.06	46.31	0.034
Trust in Physician, (0-50)	56	48.38 (6.83)	47.55 (31)	49.40	0.296

[a]Scoring: All scales with higher number indicating higher levels of concept being measured. Ranges: Emotional support (0-20), Resilience scale (0-5), Self-efficacy, (0-10), CARE (0-50), Trust in Physician, (0-50).
[b]SURE is a 4-item measure of decisional conflict (each item solicits dichotomous response, Yes/No). Score of 4 indicates no decisional conflict; score < 4 indicates some decisional conflict.



Conclusion: RA participants with higher pandemic-related stress reported greater decisional conflict, lower resilience and clinician empathy, and prioritized goals of better function and improved sleep over pain reduction, which in a prior study accounted for majority of patient-clinician goal concordance. Clinicians experienced difficulties implementing safe and effective virtual care, leaving little room to focus on fostering high-quality patient relationships. Considering increased patient stress levels and impediments to clinician-patient relationship-building, health systems must implement telehealth-specific supports to both patients and clinicians to ensure effective communication, goal discussion, and access to high-quality care.

Abstract Number: 1611

A Population-Based Evaluation of Telemedicine Use and Satisfaction in SLE Patients During the COVID-19 Pandemic in Atlanta, Georgia

Sarah Simmons[1], Cristina Drenkard[2], Gaobin Bao[2], Charmayne Dunlop-Thomas[2], Kim Schofield[2] and S Sam Lim[3], [1]Duke University, Durham, NC, [2]Emory University, Atlanta, GA, [3]Department of Medicine, Division of Rheumatology, Emory University School of Medicine, Atlanta, GA

SESSION INFORMATION

Session Date: Tuesday, November 9, 2021

Session Title: Patient Outcomes, Preferences, & Attitudes Poster IV: COVID-19 (1589–1613)

Session Type: Poster Session D

Session Time: 8:30AM–10:30AM

Background/Purpose: The COVID-19 pandemic resulted in the shift from in-person physician appointments to the development and proliferation of the use of telemedicine in an attempt to give comparable levels of care despite

social distancing and travel restrictions. It is unclear how patients with SLE, particularly from minority communities, used and perceived telemedicine during this time.

Methods: Georgians Organized Against Lupus (GOAL) is a population-based cohort of adult, validated SLE patients in Atlanta. GOAL participants were surveyed by internet, mail, and/or phone from January 19, 2021 through March 25, 2021. Survey questions covered sociodemographics and use and perceptions of telemedicine during the COVID-19 pandemic. Frequency of responses were reported overall and by sex, race, age group, and work status. Differences within groups were evaluated using t-tests and P-values. The 21-item Telemedicine Satisfaction and Usefulness Questionnaire (TSUQ) measures usefulness, effectiveness, ease of use, attitude, intention to use, and compares telemedicine to in-person visits. Each question uses a 5-point Likert scale that ranges from 1 (strongly disagree) to 5 (strongly agree). Being in agreement equated to a score of 4 or 5. Questions that showed significance in univariable analysis by race, age at survey, disease duration, sex, and poverty status were evaluated by multivariable logistic regression.

Results: A total of 732 participants had an average age of 51.4 years with a disease duration of 18.2 years (Table 1). Most were female (93.3%) and self-identified as Black (78.1%) with 26.8% living at or below the Federal poverty level. Although 40.3% were employed, 36.5% were unemployed and 23.3% were off the work force (disabled, retired, student, homemaker). Black participants were more frequently in poverty (32.1 vs. 8.3%) and less likely employed. The youngest age group (18-34) lived in poverty most frequently and the oldest (55+) was the least employed. A total of 74% of respondents had a telemedicine visit during the pandemic with 90% having an adequate internet connection (Table 2). Most connected from home. There were no differences by race, age group, and work status. Smartphones with cameras were used more often by Blacks and younger participants Laptops were also used more frequently by younger and employed individuals. There were no significant

Table 1. Sociodemographics of GOAL Participants

Category		Overall (n=732)	Sex			Race			Age Group				Work Status

Table 3. Multivariable Logistic Regression for Being In Agreement With Questions from the Telemedicine Satisfaction and Usefulness Questionnaire

Question	Effect	OR (95% CI)	P value
In general, I am satisfied with the telemedicine system.			
	Black Race	0.93 (0.60-1.44)	0.75
	Age at Survey (per 5 years ↑)	0.89 (0.82-0.96)	**0.0021**
	Disease Duration (per 5 years ↑)	1.03 (0.94-1.14)	0.53
	Male Sex	1.14 (0.55-2.36)	0.72
	Not in Poverty	1.98 (1.32-2.97)	**0.0009**
I am more involved in my care using the telemedicine system.			
	Black Race	3.83 (1.85-7.93)	**0.0003**
	Age at Survey (per 5 years ↑)	0.95 (0.86-1.04)	0.28
	Disease Duration (per 5 years ↑)	1.09 (0.97-1.23)	0.14
	Male Sex	1.37 (0.59-3.16)	0.46
	Not in Poverty	0.83 (0.52-1.32)	0.42
I follow my doctor's advice better since working with the telemedicine system.			
	Black Race	3.49 (1.74-7.01)	**0.0004**
	Age at Survey (per 5 years ↑)	0.95 (0.87-1.05)	0.31
	Disease Duration (per 5 years ↑)	1.07 (0.95-1.20)	0.27
	Male Sex	1.30 (0.56-3.02)	0.54
	Not in Poverty	0.55 (0.35-0.85)	**0.0079**
Talking to a nurse during a video visit is as satisfying as talking in person			
	Black Race	2.08 (1.34-3.21)	**0.001**
	Age at Survey (per 5 years ↑)	0.95 (0.89-1.03)	0.21
	Disease Duration (per 5 years ↑)	1.04 (0.95-1.14)	0.39
	Male Sex	1.16 (0.59-2.25)	0.67
	Not in Poverty	0.90 (0.62-1.32)	0.59
Video visits are a convenient form of healthcare delivery for me.			
	Black Race	0.69 (0.45-1.07)	0.1
	Age at Survey (per 5 years ↑)	0.91 (0.85-0.98)	0.012
	Disease Duration (per 5 years ↑)	1.07 (0.97-1.17)	0.17
	Male Sex	1.51 (0.74-3.08)	0.26
	Not in Poverty	2.05 (1.39-3.02)	**0.0003**

Each question is scored: 1: strongly disagree, 2: disagree, 3: neither agree nor disagree, 4: agree, 5: strongly agree. Being in agreement equated to a score of 4 or 5. OR=odds ratio; CI=confidence interval

differences between males and females in any category (Tables 1 and 2). Multivariable logistic regression (Table 3) showed that Blacks were more involved in their care, followed their doctor's advice better, and more satisfied with talking to a nurse. Not being in poverty was associated with being satisfied with telemedicine and finding video visits as convenient. However, those in poverty followed their doctor's advice better. Younger age was associated with higher satisfaction with telemedicine.

Conclusion: In this diverse SLE cohort, telemedicine was widely used during the pandemic. Blacks felt more involved in their care, and Blacks and those in poverty followed their doctor's advice better using telemedicine. Telemedicine may potentially offer an opportunity to mitigate health disparities through the pandemic and beyond.

Sought COVID-19 testing	46.3	41.1	39.2	46.9
Tested positive for COVID-19	3.3	7.3	5.6	11.7

Values are mean (SD) or %.

Vaccinated = received at least one vaccine dose at the time of the monthly questionnaire response.

Background/Purpose: COVID-19 vaccination efforts are ongoing and there is a need to understand factors associated with vaccine hesitancy. Individuals with rheumatic diseases have been uniquely impacted by the COVID-19 pandemic and little is known about vaccine acceptance rates in this population in the United States. The objective of this study was to identify reasons for vaccine hesitancy as well as associated risk factors in a US-based rheumatic disease population.

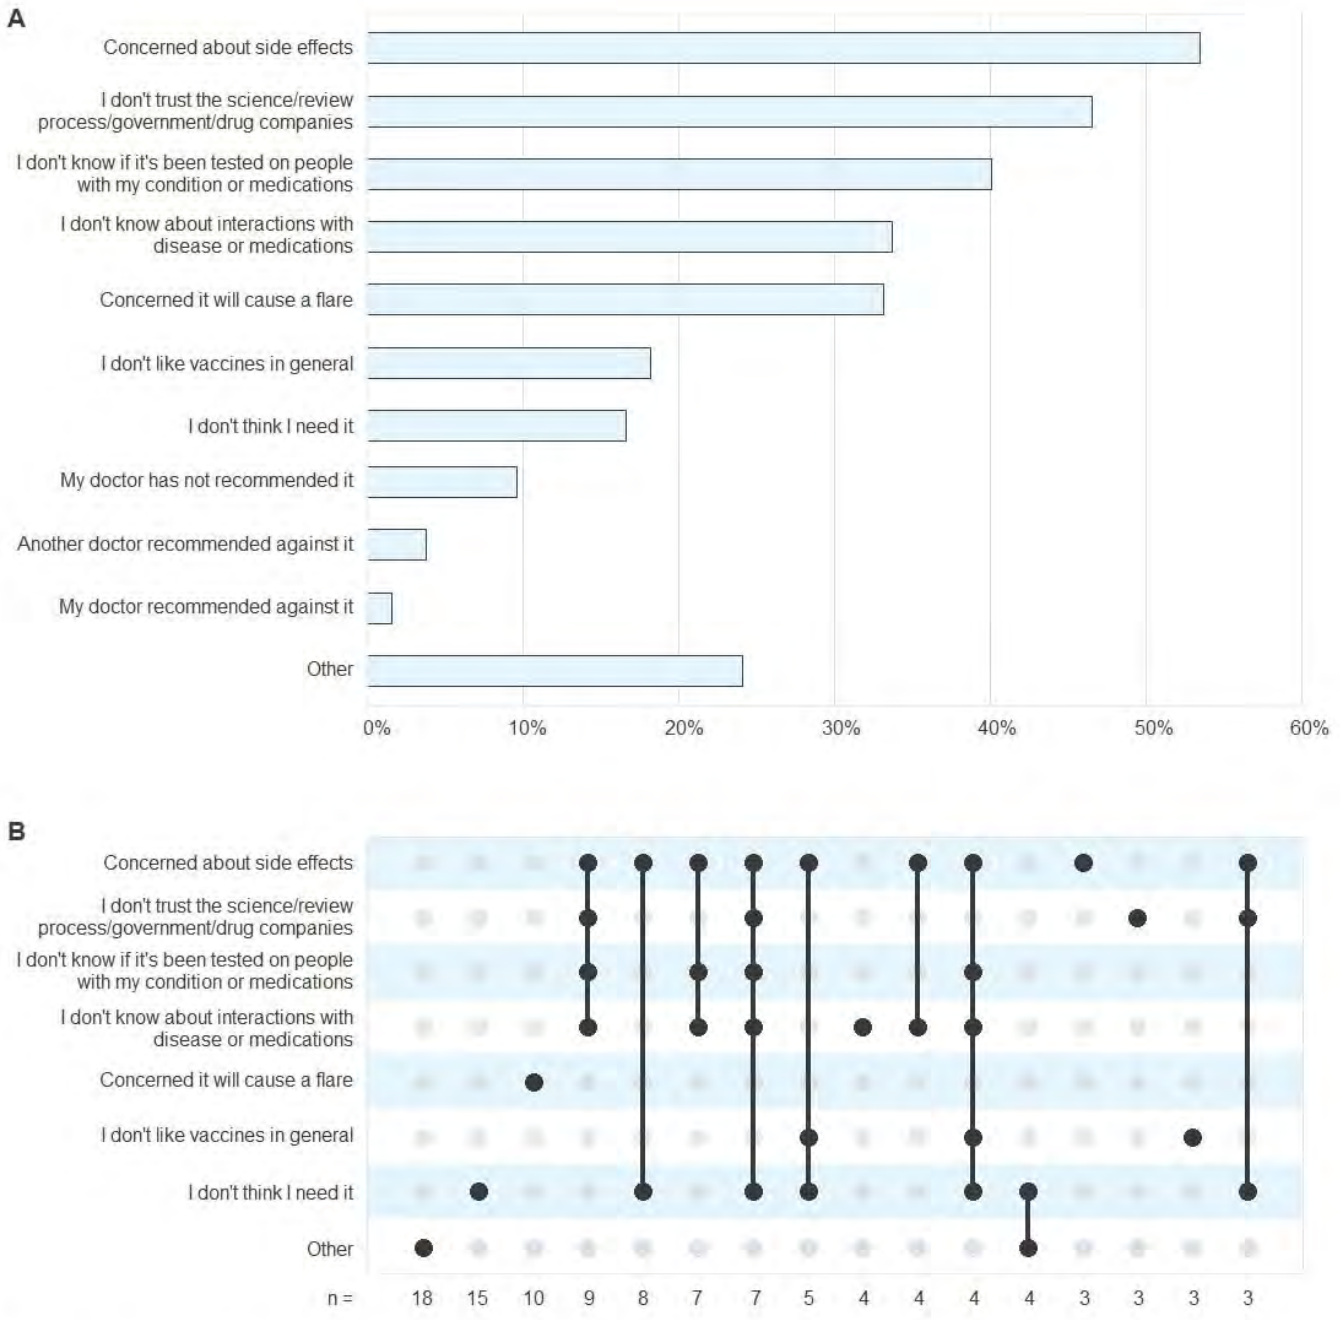

Figure 1. Frequency of reported reasons for vaccine hesitancy among unvaccinated individuals with a rheumatic disease diagnosis (n=187). (A) Percent of respondents reporting each reason for vaccine hesitancy. (B) UpSet plot displaying the most frequently reported individual or grouped reasons for vaccine hesitancy. Filled circles indicate that that reason was reported in conjunction with other filled circles in each column by the number of respondents indicated in the sample size on the x axis. Sets of reasons reported by at least three individuals were included.

Methods: Data were provided by adults enrolled in FORWARD, The National Databank for Rheumatic Diseases. Participants complete comprehensive semiannual questionnaires and were invited to answer supplemental questionnaires focused on COVID-19 vaccination in March and April 2021. Responses to the supplemental questionnaires were linked to each participant's most recently completed semiannual questionnaire for demographics, diagnosis, patient-reported outcome measures, medication use, and pandemic response variables. Respondents were compared by vaccination status, and (among those who were unvaccinated) by intention to be vaccinated. Reported reasons for vaccine hesitancy were described for those respondents who did not intend to be vaccinated, and risk factors associated with vaccine hesitancy were identified with logistic regression adjusted for age, sex, race, education, rural residency, BMI, physical function (HAQ-II), COVID-19-specific stress (Likert scale), and diagnosis (RA reference).

Results: Among the 2,579 unique respondents, 1,925 (75%) reported receiving at least one dose of a COVID-19 vaccine at the time of questionnaire completion. Of those who were not vaccinated, 456 (71%) reported an intention to be vaccinated in the future (Table 1). Of those who did not plan to receive a COVID-19 vaccine (n=187, 7% of respondents), the most frequently reported reason was concern about side effects (54%), followed by distrust (47%), and concern about sufficient testing on individuals with rheumatic diseases (40%; Figure 1A). Many respondents selected multiple reasons for vaccine hesitancy, and the most frequently reported groups of responses are ranked in Figure 1B. Respondents of non-white race were significantly more likely to be vaccine hesitant (OR [95% CI] = 6.7 [2.0, 22]; p=0.002), as were individuals with higher HAQ-II scores (1.8 [1.1, 2.9]; p=0.024; Figure 2). Respondents with a primary diagnosis of SLE were significantly more likely to be vaccine hesitant than were individuals with RA (2.7 [1.1, 7.1]; p=0.038). Individuals who reported higher levels of pandemic-related stress were significantly less likely to be vaccine hesitant (0.4 [0.3, 0.6]; p< 0.001).

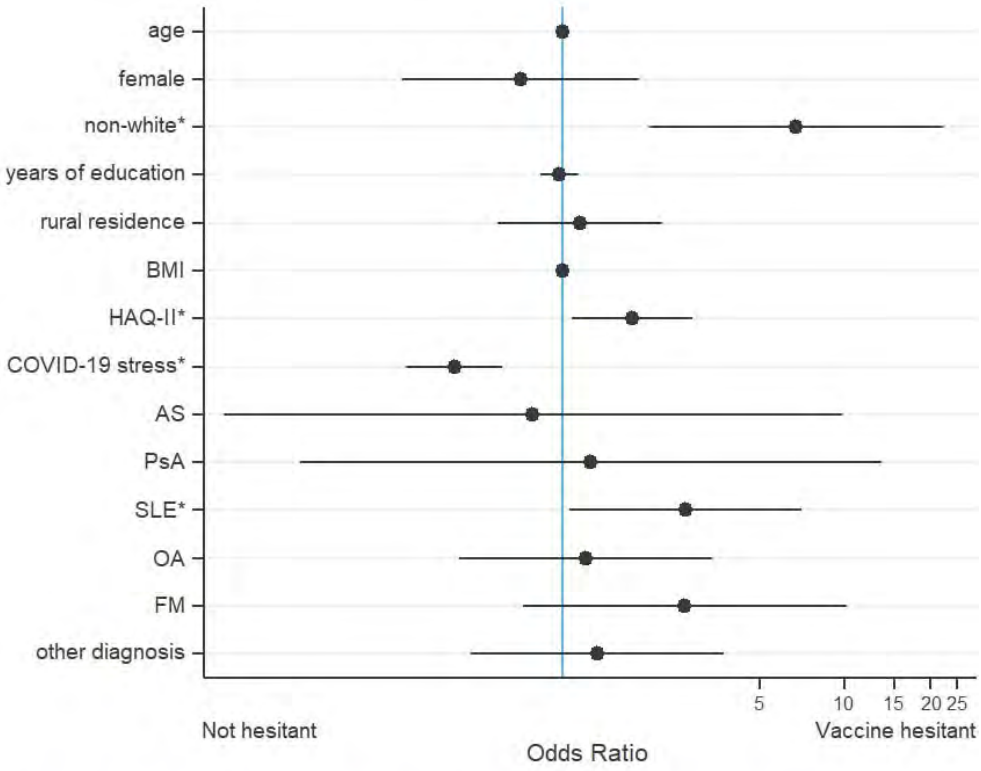

Figure 2. Odds ratios and 95% confidence intervals for factors associated with vaccine hesitancy among individuals with a rheumatic disease diagnosis. All individuals included in the model were unvaccinated at the time of questionnaire response and indicated whether they intended to be vaccinated in the future. RA was the comparator for the diagnosis variable. Statistical significance (p<0.05) is indicated by asterisks (*).

Conclusion: Most individuals in this cohort had already been vaccinated against COVID-19 or intended to be vaccinated. The difference in vaccine hesitancy by race is consistent with reports on vaccine hesitancy in populations not specific to individuals with rheumatic diseases. Most of the frequently reported reasons for vaccine hesitancy were related to concerns about possible physical responses to COVID-19 vaccines or to perceived lack of information/knowledge, both of which could potentially be addressed by education from a health care provider.

Pandemic and Patients: Examining Health-Related Behaviors of Patients with Systemic Sclerosis During the COVID-19 Pandemic

Nancy Dorr[1], Patricia Fennell[2] and Lee Shapiro[3], [1]The College of Saint Rose, Albany, NY, [2]Albany Health Management Associates, Inc. Steffens Scleroderma Foundation, Albany, NY, [3]Albany Medical College, Stillwater, NY

SESSION INFORMATION

Session Date: Tuesday, November 9, 2021
Session Title: Patient Outcomes, Preferences, & Attitudes Poster IV: COVID-19 (1589–1613)
Session Type: Poster Session D
Session Time: 8:30AM–10:30AM

Background/Purpose: Prior to COVID-19, few studies examined how patients with a chronic illness, such as systemic sclerosis (SSc), react to a pandemic. This study examined if fears of COVID are affecting health care for scleroderma patients, their mental and physical functioning, and if patients with SSc engage in COVID-19 risky behavior.

Methods: Participants were 60 people with SSc who had not had COVID-19 and had not yet been vaccinated for COVID. Participants had a mean age of 58 years (*SD* = 11.5) and were primarily female (92%) and white (87%). The ACR-Eular criteria for diagnosis of systemic sclerosis was met for 87% of participants and was unknown for the rest.

Participants completed an online survey after learning about it from a scleroderma organization newsletter or at their visit with a rheumatologist specializing in scleroderma. Data were collected August 2020 through March 2021. Participants completed measures assessing exercise, risk behaviors, vaccination intent, health-related appointments attendance, and PROMIS measures of anxiety, depression, fatigue, sleep disturbance, and physical function.

Results: Eighteen percent of the sample reported exercising less during the pandemic. For COVID-19 risk behaviors, 37% ate indoors at a restaurant, 28% went to an indoor gathering (e.g., wedding), and 58% went to a hair/nail salon. In terms of COVID-19 vaccination intent, 32% would be vaccinated as soon as eligible, 27% intended to wait, 12% might get vaccinated, 16% did not plan to get vaccinated, 8% were letting their physician decide, and 5% were not sure.

As can be seen in Table 1, 29% of respondents had health care appointments in-person, 32% had only telemedicine appointments, 24% had a combination of appointments, and 10% cancelled appointments due to COVID concerns. As can be seen in Table 2, of the respondents for whom pulmonary function tests were relevant, 40% cancelled or postponed these due to COVID concerns. Similarly, among respondents who normally had physical or occupational therapy, 46-50% of them cancelled due to COVID concerns. Patients cancelled 24% of dental appointments due to COVID concerns.

We compared respondents who cancelled one or more appointments due to COVID-19 concerns (N = 28) versus those who did not (N = 32). Participants who cancelled reported higher anxiety, $t(58) = 2.46$, p =.02, sleep disturbance, $t(56) = 3.31$, $p = .002$, and worse physical functioning, $t(56) = 2.00$, $p = .05$.

Many participants reported moderate or severe anxiety (36%), depression (22%), fatigue (32%), sleep disturbance (28%), and physical dysfunction (40%, see Table 3).

Conclusion: The results that a majority of participants were willing to get vaccinated for COVID-19 are encouraging. Less encouraging, almost one in five participants exercised less during the pandemic and half of them did not exercise to begin with. Additionally, almost half of participants cancelled one or more health appointments due to their COVID fears. This subgroup reported significantly higher anxiety, sleep disturbance, and worse physical functioning. Future research should examine the extent to which changes in health-related behavior during the pandemic have implications for disease progression in patients with SSc.

Response option	Percentage (N = 59)
Only attended in-person	29%
Only telemedicine appointments	32%
Combination of in-person and telemedicine appointments	24%
Provider cancelled	3%
Participant cancelled due to COVID concerns	10%
Participant cancelled due to other reasons	2%

Percentage of Respondents who Attended or Cancelled an Appointment with a Health Care Professional Since the Beginning of the COVID-19 Pandemic in the U.S.

Response option	Pulmonary Function Tests		Physical Therapy		Occupational or Hand Therapy		Dentist	
	N	%	N	%	N	%	N	%

Preliminary Results from a Pilot Feasibility and Acceptability Trial of Resilience Coaching for Adolescent Chronic Musculoskeletal Pain

Sabrina Gmuca[1], Pamela Weiss[1], Mackenzie McGill[1], Maitry Sonagra[2], David D. Sherry[1], Peter Cronholm[3], Jeffrey S. Gerber[1], Tonya M. Palermo[4], Jami F. Young[1] and Abby R. Rosenberg[4], [1]Children's Hospital of Philadelphia, Philadelphia, PA, [2]Children's Hospital of Philadelphia, Cherry Hill, NJ, [3]University of Pennsylvania, Philadelphia, PA, [4]Seattle Children's Hospital, Seattle, WA

SESSION INFORMATION

Session Date: Tuesday, November 9, 2021

Session Title: Pediatric Rheumatology – Clinical Poster III: Miscellaneous Rheumatic Disease (1614–1644)

Session Type: Poster Session D

Session Time: 8:30AM–10:30AM

Background/Purpose: Chronic musculoskeletal pain (CMP) affects up to 40% of youth and is associated with physical disability and psychological distress. Resilience coaching interventions, such as Promoting Resilience in Stress Management (PRISM), are well-established for reducing stress and building resilience in pediatric chronic illness. Our previous research demonstrated that self-perceived resilience is low among youth with CMP and resilience correlates with symptom severity. It is not known whether youth with CMP would participate in and benefit from resilience coaching. We therefore aimed to 1) assess the feasibility and acceptability of PRISM and 2) explore whether it results in improved clinical outcomes for adolescent CMP.

Methods: We conducted a single center pilot study of PRISM among youth with CMP. Eligible participants were English-speaking youth ages 12-17 years diagnosed with CMP seen for initial evaluation and one of their caregivers. Youth with inflammatory, neurologic or oncologic/hematologic diagnoses or cognitive impairments were ineligible. PRISM is a manualized, skills-based intervention consisting of four (~30 minute) required and one optional one-on-one sessions scheduled every 1-2 weeks. Participants chose mode of delivery: in-person, video chat, or telephone. Youth completed pre- and post- intervention surveys. Both patients and caregivers participated in semi-structured interviews upon study completion. Feasibility of intervention delivery was defined as ≥70% of subjects completing all 4 required sessions. The intervention was defined as acceptable if the mean satisfaction score for patients was ≥ 3 on a 5-point Likert scale (1=very dissatisfied and 5=very satisfied). We also administered the Acceptability of the Intervention Measure (AIM) (1=completely disagree and 5=completely agree) and defined acceptability as a mean AIM ≥ 3. All qualitative interviews were transcribed verbatim and qualitative analyses are ongoing.

Results: We approached 37 eligible patients and enrolled 19 (51%). High feasibility in intervention delivery was demonstrated with 84% (n=16) of youth having completed all study visits. One participant completed session 1 and one participant completed sessions 1 and 2 before early discontinuation; another never started PRISM. Video visit (69%) was the preferred mode of delivery, followed by telephone (25%). High overall satisfaction and acceptability were found. Mean participant satisfaction was 4.19 (SD 1.05) and the average satisfaction score for each session was >4 (Table 1). Similarly, the mean AIM was 4.25 (SD 0.99). Table 1 shows preliminary changes pre-post treatment in clinical outcomes demonstrating increased resilience and clinically relevant outcomes.

Conclusion: Resilience coaching is a feasible and acceptable adjunctive treatment for youth with CMP. Video visit was the preferred delivery format. Exploratory analyses suggest improvements in resilience and clinically relevant

outcomes. Given high feasibility and acceptability, we plan to move forward to conduct a future randomized controlled trial of PRISM using videoconferencing as a delivery platform for this vulnerable patient population.

Table 1. Satisfaction with PRISM among Youth with CMP (n=16)

PRISM Session	Skills	Satisfaction Score, mean (SD)
1: Managing Stress	Mindfulness, relaxation	4.3 (1.14)
2: Setting Goals	Setting specific and realistic goals, planning for roadblocks	4.1 (0.96)
3: Positive reframing	Recognizing and replacing negative self-talk	4.1 (1.12)
4: Making Meaning	Identifying benefits, gratitude, purpose and legacy	4.3 (0.93)
5: Coming Together (optional)	Discussion of what worked; option to include caregivers	4.1 (0.80)
	Average Overall	**4.2 (1.05)**

Legend. One subject did not rate session 5. In-between sessions, subjects had access to worksheets, and the PRISM app to practice and build on skills.

Table 2. Change in Patient-Reported Outcome Measures Pre- and Post- PRISM for Youth with CMP (N=16)

Domain	Measure	Pre-PRISM	Post-PRISM	Direction of Change	Reference Range
Overall HRQOL	PROMIS Pediatric Global Health 7	41.9 (13.1)	42.3 (12.1)	-	MCID= 3.0 T-score with mean as 50, and SD 10
Resilience	Connor-Davidson Resilience Scale 10-item (CD-RISC 10 [0-40])	26.5 [16.0, 32.0]	28.5 [23.5, 34.0]	↑	MCID = 3.0
Self-perceived energy	Self-perceived energy level (0-100)	60.0 [32.0,80.0]	71.5 [55.,80.0]	↑	-----
Functional disability	Functional disability inventory [FDI] (0-60)	21.5 [6.0, 29.5]	14.0 [8.0, 30.0]	↓	MCID = 8.0 0-12: no//minimal 13-20: mild 21-29: moderate ≥30: severe
Psychological Distress	Psychological Distress [K6 Total Score] (0-24)	8.0 [2.5, 13.0]	5.5[3.0, 9.0]	↓	MCID = 2.3 ≥7 = high distress ≥13 = debilitating distress
Pain Catastrophizing	Pain Catastrophizing [PCS-C Total] (0-52)	14.0 [4.5, 34.5]	11.5 [2.0, 24.5]	↓	0-14: low 15-25: moderate ≥26: high
Stress related to COVID-19	COVID PTSD [UCLA Brief COVID-19 Screen for Child/Adolescent PTSD] (0-44)	8.0 [1.5, 16.0)	4.5 [0.5, 10.5]	↓	1-10: minimal 11-20: mild ≥21: potential PTSD
Pain Intensity	PROMIS Pain Intensity (0-10)	6.0 [5.0, 7.0]	6.5 [4.5, 7.0]	-	MCID = 3.0
Pain Widespreadness	Widespreadness of pain [WPI] (0-19)	8.0 [2.5, 15.0]	7 [3.0, 16.5]	-	-----
Symptom severity	Symptom Severity [SSS] (0-12)	7.0 [3.0, 8.5]	5.5 [3.0, 8.0]	-	----

Legend. PRISM = Promoting Resilience in Stress Management. CMP = chronic musculoskeletal pain. MCID = Minimal clinically important difference. PROMIS PGH7=Patient Reported Outcome Measure Information System pediatric global health 7 (T-score with 50 as mean in reference population and 10 is SD). K6=Kessler-6 Psychological Distress Scale, with scores ≥7 consistent with high distress and those ≥ 13 meet criteria for serious or debilitating psychological distress. FDI=Functional disability inventory: No/minimal (0-12), Mild (13-20), Moderate (21-29), and severe (≥30). CD-RISC-10=Connor Davidson Resilience Scale 10 item (40) with higher scores indicating greater resilience. PCS-C=Pain Catastrophizing Scale for Children. PTSD=post-traumatic stress disorder. WPI=Widespread pain index and SSS=symptom severity scale as per the ACR criteria for fibromyalgia syndrome. UCLA=University of California Los Angeles.

Abstract Number: 1615

Responsiveness of Quality of Life and Function Assessment to Changes in Topical Eye Medications in Children with Uveitis

Virginia Miraldi Utz[1], Amy Cassedy[1], Theresa Hennard[1], Najima Mwase[2] and Sheila Angeles-Han[1], [1]Cincinnati Children's Hospital Medical Center, Cincinnati, OH, [2]University of Nevada, Las Vegas, Las Vegas, NV

SESSION INFORMATION

Session Date: Tuesday, November 9, 2021

Session Title: Pediatric Rheumatology – Clinical Poster III: Miscellaneous Rheumatic Disease (1614–1644)

Session Type: Poster Session D

Session Time: 8:30AM–10:30AM

Background/Purpose: Children with uveitis often require topical eye medications (eye drops) to control inflammation (glucocorticoids) and complications such as elevated intraocular pressure and synechiae (glaucoma or cycloplegic agents). Eye drops may sting when instilled and be given frequently during the day, which may impact quality of life (QOL) and function. The Effects of Youngsters' Eyesight on QOL (EYE-Q) is a valid pediatric uveitis-focused questionnaire that assesses vision-related QOL (VRQOL) and vision-related function (VRF). The Pediatric Quality of Life Inventory (PedsQL) questionnaire assesses health-related QOL (HRQOL). The purpose of this study was to assess the responsiveness of the EYE-Q and PedsQL to changes in topical medication regimen in children with non-infectious uveitis (NIU).

Methods: Pediatric patients from a tertiary medical care center with a diagnosis of NIU were enrolled. EYE-Q and PedsQL questionnaires were administered to both patients and parent-proxies at baseline and at the 6-month visit. Ophthalmologic examination findings and current treatments were collected. Two comparison groups were created to assess the sensitivity of the EYE-Q based on topical eye medication regimen: Group 1 patients had changes in either type of topical medication or in the frequency of drops between baseline and follow-up. Group 2 patients did not have any changes in topical eye medication regimen. Repeated-measures mixed-models was used to examine changes in scores for both groups. An alpha of $p < 0.05$ was considered statistically significant.

Results: Fifty-nine pediatric patients/parent-proxies participated in the study. Average patient age was 11.1 years (SD=3.4); most were White (85%) and female (70%). 59% had a diagnosis of JIA and uveitis, while 41% had uveitis-only; 18 patients had a change in their topical eye medication regimen (Group 1). Within Group 1, EYE-Q Total scores significantly increased from baseline to 6-month visit (patients, 79 vs. 84; parents 83 vs. 87, p=0.03) (Table 1). Group 1 patients also reported a significant improvement in VRF (81 vs. 87, p=0.02). The PedsQL Total and psychosocial summary scores also increased significantly for patients (81 v. 86, p=0.03; 81 v. 87, p=0.03) and parents (77 v. 84, p= 0.03; 76 v. 83, p=0.02) respectively (Table 1). There were no significant changes in EYE-Q or PedsQL score for Group 2. Despite improved VRQOL scores, Group 1 had significantly lower VRQOL compared to Group 2 (77 vs. 86, $p< 0.05$) at the 6-month visit.

Conclusion: The EYE-Q and PedsQL were sensitive to clinically meaningful differences in QOL in children with NIU who required changes in treatment regimen. A change in topical medications or the frequency of administration of eye drops led to improved QOL and function. Interestingly, children without changes in topical therapy had similar QOL and function at both time points. Improved scores from baseline to 6-month follow-up exam may be attributed

Table 1. Pre and post EYE-Q[a] and PedsQL[b] scores for patients and parent-proxies for children with (Group 1, n=18) and without (Group 2, n=41) a change in topical eye medication regimen including medication type and frequency of instillation

Questionnaire scores per group (0-100)		Parents/Proxies, n = 59			Patients, n = 59

Abstract Number: 1616

Acceptability of COVID-19 Vaccine Among Pediatric Rheumatology Patients in California's Central Valley

Sukesh Sukumaran[1], Reshma Patel[2] and Deepika Singh[3], [1]Valley Children's Healthcare, Madera, CA, [2]Valley Children's Hospital, Madera, CA, [3]Valley Children Healthcare, Madera, CA

SESSION INFORMATION

Session Date: Tuesday, November 9, 2021

Session Title: Pediatric Rheumatology – Clinical Poster III: Miscellaneous Rheumatic Disease (1614–1644)

Session Type: Poster Session D

Session Time: 8:30AM–10:30AM

Background/Purpose: The U.S. FDA has expanded the emergency use authorization of the COVID-19 vaccine to include children >12 years of age. Gaining an understanding of the acceptability of a COVID-19 vaccine among children with autoimmune diseases may help rheumatologists to develop resources and best practices for shared decision making when offering the COVID-19 vaccine to their patients.

The objective of this study is to evaluate the knowledge and perceptions regarding COVID-19 vaccination and determine the self-reported likelihood of receiving a hypothetical COVID-19 vaccine among children with rheumatic diseases.

Methods: We surveyed a convenience sample of 54 children seen in our pediatric rheumatology clinic in May 2021 to estimate the respondents' perceptions regarding the COVID-19 vaccine. Respondents were asked questions to assess their knowledge about COVID-19 and willingness to accept the COVID-19 vaccine.

Results: Of the 54 patients surveyed, the median age of the participants was 12.9 (range 5-18) years and 78% were females. Racial/ethnic minorities contributed about 52% among the respondents. Forty percent of the respondents had juvenile idiopathic arthritis.

Regarding knowledge about COVID-19 disease, 83% agreed with the statement that COVID-19 was caused by a virus but 20% "agreed" or "strongly agreed" with the statement that influenza and COVID-19 were caused by the same virus. Twenty-one percent of respondents perceived that COVID-19 patients were symptomatic, sick, and required hospitalization. Our respondents gathered information about the pandemic from social media (45%) and television (50%). Sixty-eight percent of patients discussed COVID-19 and its implications with their doctor.

Regarding perceptions about the vaccine, 82% of respondents "strongly agreed" or "agreed" with the statement, "There is misinformation regarding COVID-19 vaccine on the internet". Greater than 75% of our respondents practiced social distancing, hand hygiene and wore masks in public spaces. Although 55% of our respondent reported willingness to accept a COVID-19 vaccine, only 39% perceived that the vaccine would provide protection from the disease and 85% stated concerns about side effects. Respondents cited greater concerns about vaccine side effects when compared to disease complications (40%).

We found that the acceptability of the COVID-19 vaccine was higher among whites when compared to racial/ethnic minorities (84% vs. 58%). Similarly, concerns about side effects and was higher among racial/ethnic minorities. Willingness to pay for the vaccine was also lower among racial/ethnic minorities.

Conclusion: Our study identifies the specific knowledge gaps and incorrect perceptions about COVID-19 and the COVID-19 vaccine among children with rheumatic diseases. Concerns about the effectiveness of the vaccine and potential side effects were high. We found that self-reported likelihood of vaccine acceptability was lower among racial/ethnic minorities when compared to whites. The results of this survey study may help inform public health campaigns to address COVID-19 vaccine hesitancy among these special populations.

Abstract Number: 1617

Burden of Adverse Childhood Experiences in Pediatric Chronic Pain and Rheumatic Disease

Maitry Sonagra[1], Jeremy Jones[2], Mackenzie McGill[3] and Sabrina Gmuca[3], [1]Seattle Children's Hospital, Seattle, WA, [2]University of Pennsylvania, Philadelphia, PA, [3]Children's Hospital of Philadelphia, Philadelphia, PA

SESSION INFORMATION
Session Date: Tuesday, November 9, 2021
Session Title: Pediatric Rheumatology – Clinical Poster III: Miscellaneous Rheumatic Disease (1614–1644)
Session Type: Poster Session D
Session Time: 8:30AM–10:30AM

Background/Purpose: Adverse childhood experiences (ACEs) serve as stressors that can have negative, lasting effects on health and wellbeing. While there has been increasing evidence to suggest an etiologic role of ACEs in pediatric chronic pain and rheumatic disease, our understanding of how ACEs may shape a child's clinical presentation remains limited. We aimed to determine 1) the association between the presence of ACEs and clinical manifestations of pediatric chronic pain and 2) explore the interaction of ACEs and pediatric rheumatic disease among youth with chronic pain on health-related outcomes.

Methods: This was a retrospective cross-sectional cohort study of patients 3-18 years old with chronic pain seen in a pediatric rheumatology pain clinic between August 2018 and July 2020 and previously enrolled in a patient registry. Abstracted clinical data included demographics, past medical, psychological, and social histories, as well as patient reported outcome (PRO) measures including: functional disability inventory (FDI; 0-60), verbal pain report (0-10), symptom severity score (SSS; 0-12) and widespread pain index (WPI; 0-19). We stratified our sample into three groups: no ACEs, one ACE and ≥2 ACEs. We assessed clinical signs and symptoms associated with the presence of ACEs using Chi-square or Wilcoxon-rank tests. The association between ACEs and functional impairment was tested using simple and multivariable linear regression.

Results: A total of 412 patients were included in the study. More than 75% of patients reported at least one ACE. The most frequently reported ACEs included history of mental illness in a first degree relative (56%) and parental divorce or separation (20%). Those with ≥2 ACEs had more somatic symptoms, worse physical function, and a higher proportion of comorbid mental health conditions than those with no or one ACE (Table 1). Bivariate linear regression indicated positive linear association of patient physical disability (FDI) with WPI, SSS, and verbal pain (all $p < 0.05$; Table 2). Moreover, presence of mental health conditions and autonomic changes were associated with increased FDI scores in patients. Dose dependent interaction between ACEs and co-morbid rheumatologic conditions was found. As compared to the no ACE group, those with one or more than two ACEs were found to have an additional increase in FDI score by 8.5 and 11 points, respectively, for each additional rheumatologic condition. In multivariable regression (Table 3), higher verbal pain score, symptom severity score and presence of autonomic changes were independently associated with estimated average increase in FDI score by 1.05, 1.95 and 4.76 respectively (all $p < 0.01$). The interaction demonstrating worsened functional impairment from rheumatologic disease for those with ACEs was again observed.

Conclusion: Children with chronic pain and/or rheumatologic diseases who are exposed to ACEs are at increased risk of worse disability, greater symptom severity, and a higher burden of co-morbid mental health conditions. Our findings indicate an ongoing need for systemic evaluation of ACEs exposure in children with chronic pain and/or rheumatic disease and incorporation of trauma-based care.

SESSION INFORMATION

Session Date: Tuesday, November 9, 2021

Session Title: Pediatric Rheumatology – Clinical Poster III: Miscellaneous Rheumatic Disease (1614–1644)

Session Type: Poster Session D

Session Time: 8:30AM–10:30AM

Background/Purpose: Patients with chronic atypical neutrophilic dermatosis with lipodystrophy and elevated temperatures /proteasome-associated autoinflammatory syndrome (CANDLE/PRAAS) respond to treatment with baricitinib but require higher exposure than doses used to treat patients with rheumatoid arthritis (1, 2). After clinical observations of disease flares associated with baricitinib dose reductions due to a possible adverse event, we systematically assessed the effect of baricitinib dose reductions on the CANDLE/PRAAS disease activity and leveraged these observations for developing and validating "disease flare criteria" that can be used to quantify disease activity and in clinical study design.

Methods: Between October 2011 and August 2018, 10 genetically confirmed CANDLE patients were enrolled in an institutional review board approved open label expanded access program (NCT01724580) and treated with baricitinib. Patients or their parents provided written informed consent. We retrospectively identified all instances of dose reductions and assessed clinical symptoms recorded on a daily diary, laboratory markers of inflammation and an interferon (IFN) score. We observed and characterized clinical symptoms and laboratory changes during disease

Table 1.Definition of Clinical and Subclinical CANDLE/PRAAS Disease Flare

Definition	Laboratory Biomarkers*
Clinical Flare A worsening in DDS** by a minimum of 15% or the documentation of flare symptoms in the medical record *AND* changes in 2 or more laboratory biomarkers	• CRP, ESR, IFN score [≥ 20% increase] • WBC, platelets [≥ 20% **decrease**] • ALC and hemoglobin [≥ 15% **decrease**]
Subclinical Flare Less than 15% worsening in DDS** or on physician evaluation compared to the reference visit *AND* changes in 3 or more laboratory biomarkers	• CRP, ESR, IFN score [≥ 20% increase] • WBC, platelets [≥ 20% **decrease**] • ALC and hemoglobin [≥ 15% **decrease**]

*Acute change in laboratory biomarkers with disease flares compared to the reference visit (last visit with documented laboratory biomarkers prior to reduction period). For inclusion as flare criterion, the change of CRP, ESR and/or IFN score must result in a clinically abnormal value and an increase of greater or equal to 20% must occur.

**Mean DDS for 7 days (ranges from 3 days before and after the visit)

CANDLE/PRAAS, Chronic Atypical Neutrophilic Dermatosis with Lipodystrophy and Elevated temperature/Proteasome-associated Autoinflammatory Syndrome; DDS, daily diary score; CRP, C-reactive protein; ESR, erythrocyte sedimentation rate; WBC, white blood cell count; IFN, interferon; ALC, absolute lymphocyte count.

flare periods and developed “flare criteria” that captured clinically meaningful changes (table 1). Time to flare was evaluated using Kaplan-Meier analysis and the Cox proportional hazards model. To validate the flare criteria, we compared the baricitinib dose reduction associated flare rate during the flare period (post dose reduction) with the flare rate during a stable period (on optimal baricitinib dose) for patients who fulfilled flare criteria using a two-sided chi-squared test of homogeneity.

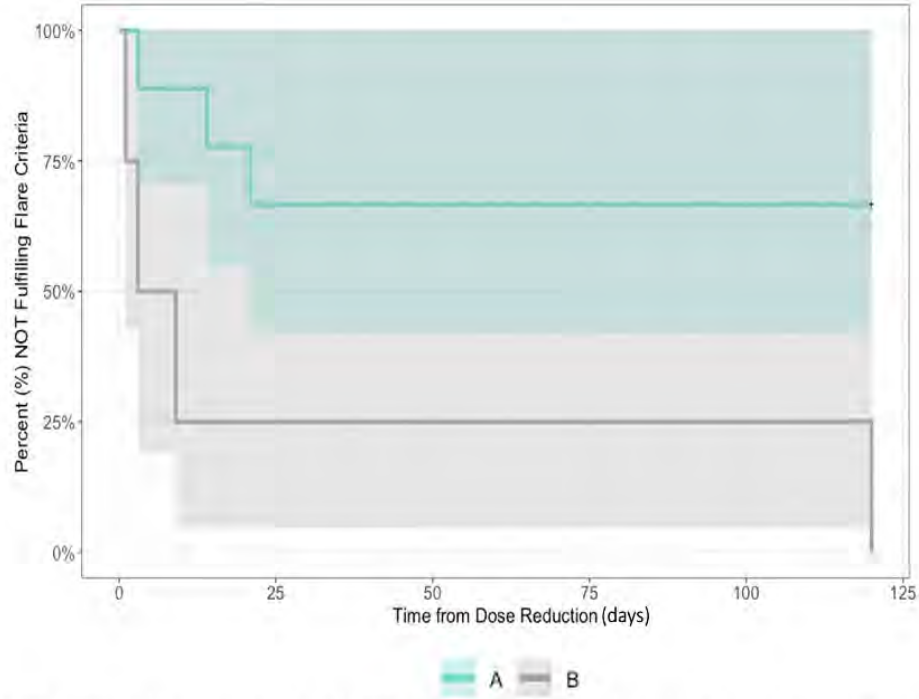

Figure 1. Kaplan-Meier curve depicts the rate of occurrence of baricitinib dose reduction associated disease flares (%) in CANDLE/PRAAS on y axis and time to flare (days) on x axis. Green line represents group A and gray represents group B. Group A is composed of occurrences of 25% or less baricitinib dose reductions (n=9) and group B is composed of occurrences of more than 25% of baricitinib dose reductions (n=4). All four dose reductions (100%) in group B resulted in a disease flare within 120 days whereas 3 out of 9 (33%) baricitinib dose reductions resulted in a disease flare in group A. The difference was significant using the Cox proportional hazards model (p=0.023). One dose reduction was excluded from this analysis and six dose reductions that did not result in a disease flare are censored at 120 days.

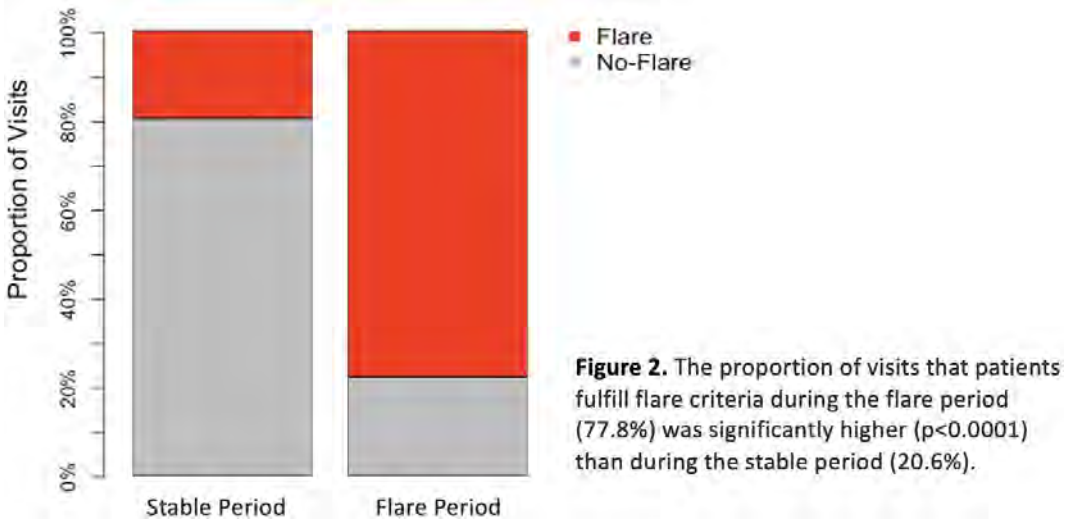

Figure 2. The proportion of visits that patients fulfill flare criteria during the flare period (77.8%) was significantly higher (p<0.0001) than during the stable period (20.6%).

Results: Fourteen baricitinib dose reductions in 9/10 patients occurred and 7/14 (50%) resulted in disease flares in 7/9 patients. A typical flare pattern with acute changes in clinical and/or laboratory biomarkers and cut offs used to define disease flares is outlined in table 1. Time to flare ranged between 1 to 120 days (mean 24 +/- 43 days). A dose reduction of greater than 25% triggered a flare in all patients (figure 1). In patients with baricitinib dose reduction-associated flares, the proportion of visits that patients fulfill flare criteria during the flare period is 77.8% compared to 20.6% during the stable period ($p < 0.0001$) (figure 2).

Conclusion: We observed significant rebound inflammation and disease flares with >25% dose reductions of baricitinib and propose flare criteria that may be used in quantifying diseases flares and in designing clinical studies in CANDLE/PRAAS. It is important to raise awareness of the development of rebound inflammation with baricitinib dose reductions and the need to closely monitor dose reductions.

Abstract Number: 1619

Where Do Multisystem Inflammatory Syndrome in Children (MIS-C) and Pediatric COVID-19 Fit Under the Cytokine Storm Syndrome Umbrella?

Randy Cron and **Daniel Reiff**, University of Alabama at Birmingham, Birmingham, AL

SESSION INFORMATION
Session Date: Tuesday, November 9, 2021
Session Title: Pediatric Rheumatology – Clinical Poster III: Miscellaneous Rheumatic Disease (1614–1644)
Session Type: Poster Session D
Session Time: 8:30AM–10:30AM

Background/Purpose: Although COVID-19 has been less severe in the pediatric population, with cases more likely to be mild or asymptomatic, there remains a proportion of pediatric cases with features of cytokine storm syndrome (CSS), leading to hyperinflammation, uncontrolled immune activation, respiratory disease, and end-organ failure. Additionally, multisystem inflammatory syndrome in children (MIS-C) has emerged as a relatively rare post-infectious sequela of COVID-19 with similar hyperinflammation, severe shock, and organ dysfunction. Prior to and during the COVID-19 pandemic, scoring systems have been developed and used to identify patients at risk for CSS. Our study explores the utility of existing CSS, macrophage activation syndrome (MAS), and hemophagocytic lymphohistiocytosis (HLH) scoring systems in identifying pediatric patients at risk for CSS in the setting of MIS-C and COVID-19.

Methods: Pediatric patients with MIS-C and active COVID-19 infection at a single institution were identified. Infectious data, clinical findings, and laboratory values were collected, and patients were stratified by disease severity

into mild MIS-C, severe MIS-C, and severe COVID-19, dependent on symptomology, positive COVID-19 polymerase chain reaction (PCR) or serology, and need for vasopressor and/or ventilatory support. Eight historically utile scoring systems for MAS, HLH, and CSS were used to examine the cohort of MIS-C and pediatric COVID-19 patients for features and diagnosis of cytokine storm.

Table 3. Maximum Cytokine Storm Score During Hospitalization				
	Mild MIS-C	Severe MIS-C	Total MIS-C	Severe COVID-19
HLH-2004	0/23 (0%)	1/18 (5.6%)	1/41 (2%)	0/12 (0%)
H-score > 169	0/23 (0%)	0/18 (0%)	0/41 (0%)	3/12 (25%)
H-score Median (IQR)	68 (49-68)	68 (52-100.25)	68 (49-79)	101 (55.75-142.5)
2016 sJIA/MAS	4/23 (17%)	6/18 (33.3%)	10/41 (24%)	6/12 (50%)
2019 sJIA MS Score > -2.1	16/23 (70%)	15/18 (83.3%)	31/41 (76%)	12/12 (100%)
2019 sJIA MS Score Median (IQR)	-1.4 (-2.08-(-0.78))	-0.56 (-1.84-0.69)	-0.91 (-1.97-0.47)	1.69 (0.59-2.43)
Ferritin/ESR ratio > 11.3	12/23 (52%)	11/18 (61.1%)	23/41 (56%)	10/11 (91%)
Ferritin/ESR ratio > 21.5	5/23 (22%)	7/18 (38.9%)	12/41 (29%)	9/11 (82%)
Ferritin/ESR ratio Median (IQR)	12.04 (7.42-17.78)	16.69 (12.48-34.48)	13.95 (7.92-30.44)	66.07 (33.57-102.89)
Caricchio COVID-CS Criteria	-	-	-	8/11 (73%)
COVID-19 cHIS Criteria Median (IQR)	4 (2.5-4.5)	4.5 (4-5)	4 (3-5)	4.5 (3-5)
COVID-19 CSS Quick Score	15/23 (65%)	12/17 (70.6%)	27/40 (68%)	10/12 (83%)

Results: 23 patients with mild MIS-C, 18 patients with severe MIS-C, and 12 patients with severe COVID-19 were identified. The HLH-2004 and HScore scoring systems did not identify any MIS-C or COVID-19 patients as having CSS on admission to the hospital, with only one MIS-C patient meeting HLH-2004 criteria and three patients meeting HScore criteria at peak disease severity during hospitalization. The 2016 sJIA/MAS criteria, ferritin/ESR ratio, and COVID-19 CSS Quick Score identified CSS in more patients and was more useful in distinguishing between COVID-19 and MIS-C hyperinflammation and severity. The 2019 MS Score and COVID-19 cHIS criteria were less helpful, as the MS score likely overestimated CSS due to use of headache as a feature of its criteria, and the cHIS resulted in similar scores across the board regardless of severity or disease. The Caricchio COVID-CS did well in identifying CSS in pediatric COVID-19, but was less useful in MIS-C due to its COVID-19 specific criteria.

Conclusion: MIS-C and pediatric COVID-19 result in relatively unique cytokine storm syndromes and patterns of inflammation. Existing scoring systems for cytokine storm syndromes likely do not capture the full breadth of this disease process in MIS-C and pediatric COVID-19.

SESSION INFORMATION

Session Date: Tuesday, November 9, 2021

Session Title: Pediatric Rheumatology – Clinical Poster III: Miscellaneous Rheumatic Disease (1614–1644)

Session Type: Poster Session D

Session Time: 8:30AM–10:30AM

Background/Purpose: Pediatric noninfectious uveitis is a major clinical challenge for Pediatric ophthalmologists and rheumatologists. The burden of disease is considerable and etiological diagnosis elusive in many cases. Uveitis outcomes have improved dramatically with antirheumatic drugs, especially anti TNFα agents.

Methods: A multicenter cross sectional and retrospective cohort study was conducted from october 2019 to march 2021. Multidisciplinary participation was mandatory for joining the study; to ensure homogeneity data of associated systemic disease and disease modifying antirheumatic drug (DMARD) therapy were provided by rheumatologist and ophthalmology related data were introduced by ophthalmologist, in a web based form. Only patients with uveitis onset before 16th birthday and complete data were included in the analysis. Three distinct groups were made for comparison: Juvenile Idiopathic Arthritis related uveitis (JIAu), Idiopathic childhood uveitis (ICU) and Pars Planitis (PP).

Results: A total of 501 patients from 22 centers were included in the analysis, 310 (61.9 %) with an associated immune disease, 91 (18.2%) with an ophthalmologically distinguishable uveitis and 100 (20%) idiopathic. JIAu accounted for 54.8 % (275), 259 (51.6%) non B27 related; 67 patients (13.3%) had PP. JIAu was significantly associated with female gender, younger age at uveitis onset, ANA positive, anterior location and insidious presentation, with less ocular complications, systemic corticoid use and ocular surgeries. DMARD exposure was more prolonged, started

earlier after uveitis onset and had less unilateral severe visual loss. ICU tended to present as panuveitis and was associated with male gender, older age at onset, ANA negative, acute presentation and acute clinical course. Ocular complications were higher, mainly synechiae at onset and cataracts. Exposure to DMARD was significantly lower for both synthetic and biologic agents. PP showed the highest complication rate within groups (71.6%), especially cataracts during follow up and greater tendency to present vitreoretinal complications (macular edema, epiretinal membrane and retinoschisis), requiring ocular surgery more frequently. PP patients also received more systemic steroids, showing no difference in regards to DMARD use.

Conclusion: We present a large cohort of childhood onset not infectious uveitis. Homogeneity of data was cared for with a multidisciplinary approach, but case selection bias may have occurred as participation and case selection was voluntary. Our data suggest that differences in outcome may correspond partially to differences in treatment

approach depending on the aetiology or diagnosis associated with the ocular inflammatory disease. Surprisingly, JIAu patients showed the best prognosis despite its chronicity in comparison with the other groups, traditionally considered mild self-limited diseases. Awareness of ophthalmologists and rheumatologists on these observations could ameliorate the burden of disease by inducing rheumatology referral for early treatment.

Self-reported Transition Readiness of Adolescent Patients with Rheumatologic Disease: Do the Parents Agree?

Christina Ma[1], Molly Dushnicky[1], Habeba Talaat[1], Steffy Thomas[1], Karen Beattie[1], Tania Cellucci[2], Stephanie Garner[1], Liane Heale[1], Mark Matsos[1] and Michelle Batthish[1], [1]McMaster University, Hamilton, ON, Canada, [2]McMaster Children's Hospital, Hamilton, ON, Canada

SESSION INFORMATION

Session Date: Tuesday, November 9, 2021

Session Title: Pediatric Rheumatology – Clinical Poster III: Miscellaneous Rheumatic Disease (1614–1644)

Session Type: Poster Session D

Session Time: 8:30AM–10:30AM

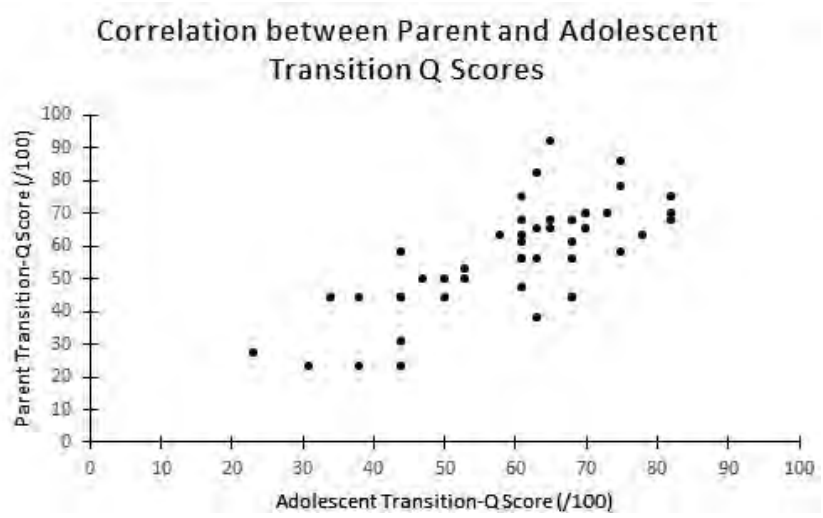

Figure 1. Correlation between parent and adolescent Transition-Q scores.

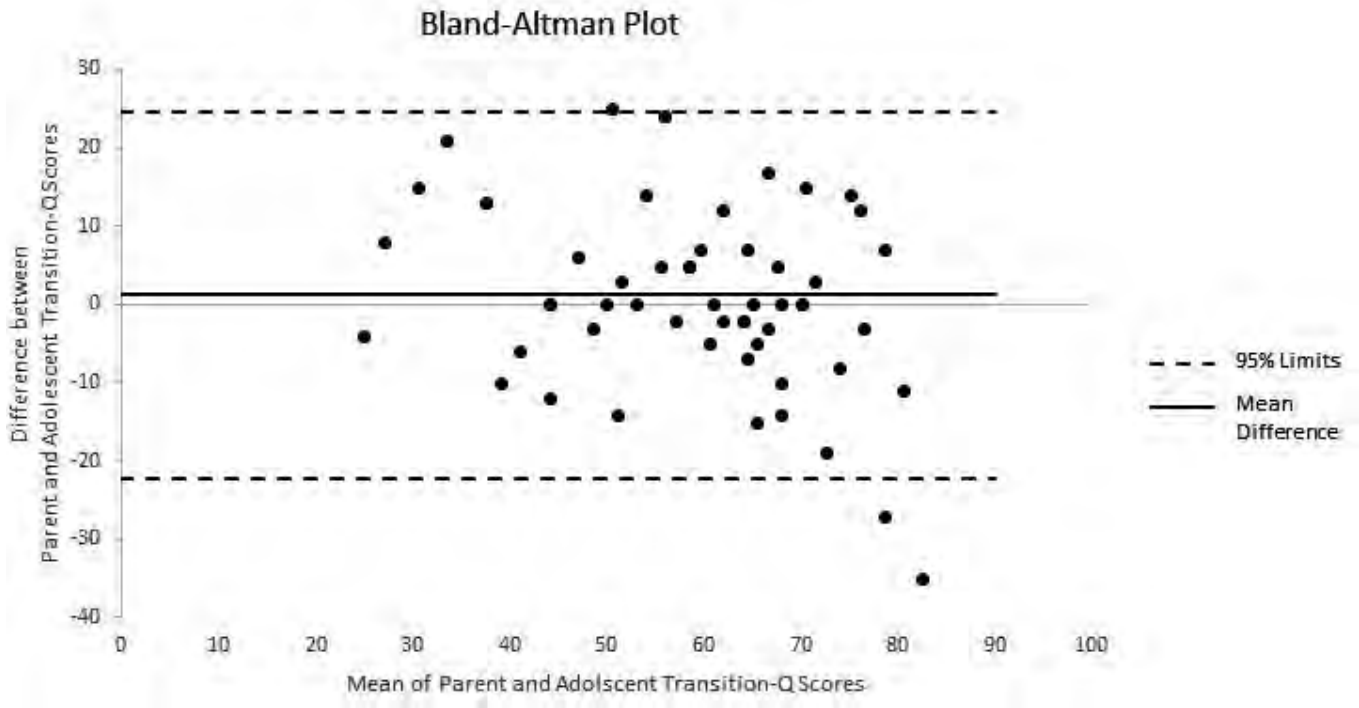

Figure 2. Agreement between parent and adolescent Transition-Q scores illustrated by Bland-Altman plot.

Background/Purpose: The transition from pediatric to adult rheumatology care is associated with increased disease activity and morbidity. The parent-child relationship is a significant relationship in the transition journey and parents play a key role in promoting self-management skills in adolescent patients. Assessing both adolescents' and parents' perception of the adolescent's independence and self-management skills are important to identifying discordant views and developing strategies to improve transition. Thus, we compared transition readiness assessment scales from both perspectives and analyzed their level of agreement.

Methods: Adolescents aged 14-18 years old with JIA or jSLE and their parents were recruited in our multidisciplinary rheumatology transition clinic. The patient and one parent both independently completed the TRANSITION-Q during clinic appointments. The TRANSITION-Q is a 14-item, validated, self-administered questionnaire assessing health-

care self-management skills where higher scores (max. 100) indicate greater transition readiness. Total scores and frequencies of responses to each question ("never", "sometimes" or "always") were recorded and the proportion of agreement between their responses were determined. Pearson correlation analyses determined the correlation between adolescent and parent total transition scores and agreement was analyzed using a Bland-Altman plot.

Results: Among 57 patient/parent dyads, the Pearson correlation coefficient between parents' and adolescents' total scores was 0.71 ($p< 0.001$). Bland-Altman analysis illustrated generally good agreement with a mean difference of 1.2 and no consistent bias between parent and adolescent scores. For each question, dyads agreed an average of 70% of the time. The majority of disagreement was mild (i.e. sometimes/always or sometimes/never). Most frequent disagreements pertained to adolescents' discussion with people about their health condition and asking questions regarding their health. Extreme disagreements (i.e. always/never) were rare and only occurred 7% of the time in relation to whether adolescents contact the doctor when they need to, and 9% of the time in relation to seeing the doctor/nurse on their own.

Conclusion: Adolescents and parents generally agree on the level of the adolescent's transition readiness, however there is occasional disagreement in specific domains. Identifying items more prone to disagreement can help identify areas to target future interventions to improve self-management skills in adolescent patients and successful transition to adult care.

Mind the Gap: The Experience of Adolescents in a Rheumatology Transition Clinic

Claire Fine[1], Karen Beattie[1], Tania Cellucci[2], Liane Heale[1], Mark Matsos[1], Stephanie Garner[1] and Michelle Batthish[1], [1]McMaster University, Hamilton, ON, Canada, [2]McMaster Children's Hospital, Hamilton, ON, Canada

SESSION INFORMATION
Session Date: Tuesday, November 9, 2021
Session Title: Pediatric Rheumatology – Clinical Poster III: Miscellaneous Rheumatic Disease (1614–1644)
Session Type: Poster Session D
Session Time: 8:30AM–10:30AM

Background/Purpose: The transition from pediatric to adult healthcare is a critical time for the wellbeing of patients with chronic illness including rheumatologic disease. Low patient engagement during transition has been associated with lower treatment adherence, poor clinic attendance, increased hospital admissions and adverse health outcomes. A supportive environment and a multidisciplinary approach to transition, including the presence of both an adult and paediatric rheumatologist, are key components to support youth as they prepare to transition. We aimed to assess the transition clinic experiences of rheumatology patients to identify potential areas for improvement.

Methods: The "Mind the Gap" validated questionnaire was administered to our Rheumatology Transition Clinic patients, with either JIA or jSLE, aged 14-18 years. The questionnaire assesses the transition clinic expectations and experiences and includes 22 questions covering 3 domains: management of environment, provider characteristics and process issues. Patients completed the questionnaire twice on a single occasion; first with respect to their "ide-

Table 1. Mean (min, max) gap scores by domain

Domain	Male (n=20)	Female (n=43)	Total (n=63)
Management of the Environment	0.0 (-1, 2.4)	0.4 (-3.8,5.4)	0.2 (-3.8,5.4)
Provider Characteristics	0.2 (-0.9, 1.5)	0.3 (-1.4,6.9)	0.2 (-1.4,6.9)
Process Issues	0.2 (-1.5, 2)	0.5 (-1.7,5.7)	0.3 (-1.7,5.7)

Table 2. Percentages of patients who recorded a gap score ≥1

	%
Management of Environment	
Provides opportunities for me to meet other young people with arthritis	43
Has a physical environment that caters to my age group	39
Provider Characteristics	
Has staff who understand the realities of being teenagers	34
Has staff I can talk to about sensitive or difficult issues	43
Has staff who know how to talk and listen to teenagers	34
Process Issues	
Let's other people know how arthritis affects me (e.g. school teachers)	45

Only percentages above 33% are reported

al" experience and second regarding their current clinic experience. Responses ranged from strongly disagree (1) to strongly agree (7). For each question, a "gap" score was calculated by subtracting the current from the ideal score. A score of 0 signifies that the current experience is ideal; positive scores suggest current care is less than ideal, and negative scores suggest current care exceeds the ideal experience. The greater the positive gap score, the lower the level of satisfaction. Similarly, the greater the negative gap score, the greater the satisfaction. Descriptive statistics summarized our patients' responses.

Results: Of 63 patients (43 female, 20 male) with a mean (SD) age of 16.4 (1.2), 86% had JIA and 14% had jSLE. For each domain, the mean gap score was between 0 and 1, indicating virtually no gap between current and ideal care (Table 1). Table 2 reveals areas where the gap score ≥1. The largest frequency of patients recording a gap score ≥ 1 was 45%, for the clinic's ability to communicate information to the patient's school teachers. When comparing gap scores for males and females, mean gap scores were similar for the environment and process issues. However, for provider characteristics, mean (SD) gap scores for females (0.41 (1.2)) appeared higher than males (0.0, (0.5)). Females were less satisfied with how well the staff knew them and the staff's "ability to understand the realities of being a teenager".

Conclusion: Although overall Transition Clinic experiences appear to be meeting the expectations of the majority of our rheumatology patients, there is room for improvement within all three domains. Future directions should include developing standardized interventions to address the identified gaps, such as communication with schools and the provider's abilities to discuss sensitive issues.

SESSION INFORMATION

Session Date: Tuesday, November 9, 2021

Session Title: Pediatric Rheumatology – Clinical Poster III: Miscellaneous Rheumatic Disease (1614–1644)

Session Type: Poster Session D

Session Time: 8:30AM–10:30AM

Background/Purpose: The COVID-19 pandemic has disrupted the delivery of routine healthcare and clinical research around the world. Several reports have shown an impact on rheumatology care. The U.K. reported that rheumatologists were averaging a 50% reduction in clinic function during the first six months of the pandemic. Higher rates of JIA disease flares presenting to hospital during the pandemic were reported by our Italian colleagues, perhaps due to delayed follow-up intervals. The aim of this study was to characterize COVID-related disruptions in JIA research and initial presentation of JIA to pediatric rheumatology (PR) care in Canada. We hypothesize that research disruption would be mostly reflected by a drop in study recruitment, while disruption of care would result in prolongation of time from symptom onset to first assessment and a greater severity at presentation.

Methods: Data was collected by the Canadian Alliance of Pediatric Rheumatology Investigators (CAPRI) National JIA Registry, a registry of children newly diagnosed with JIA that collects and shares longitudinal data on disease course, outcomes and adverse events. Data from the year pre-pandemic (March 11, 2019-March 10, 2020) was compared to data from the pandemic year (March 11, 2020-March 10, 2021). The number of patients enrolled in the Registry during the two periods was determined. To assess the pandemic's impact, we compared time from symptom onset to first PR appointment, disease activity at presentation, and parent/patient reported well-being at presentation. Descriptive analysis of the data was performed. Proportions were compared with chi square tests and medians with Mann-Whitney tests.

Results: A total of 225 patients were enrolled in the pre-pandemic year, and 111 in the pandemic year. Registry enrollment was notably decreased during the months of March to June 2020, at the start of the global pandemic (Figure 1). The median time from symptom onset to first assessment was 138 days (IQR 64-365 days) in the pre-pandemic year, and 146 days (IQR 83-359 days) in the pandemic year. The JIA categories of patients enrolled remained stable; predominantly oligoarthritis (44% pre-pandemic, 46.8% pandemic) with the next most common being enthesitis-related arthritis and RF-negative polyarthritis in both cohorts (Table 1). Clinical features and patient reported measures were very similar between the two cohorts. The Physician Global Assessment

Figure 1. Monthly recruitment in the CAPRI JIA Registry pre-pandemic and during pandemic.

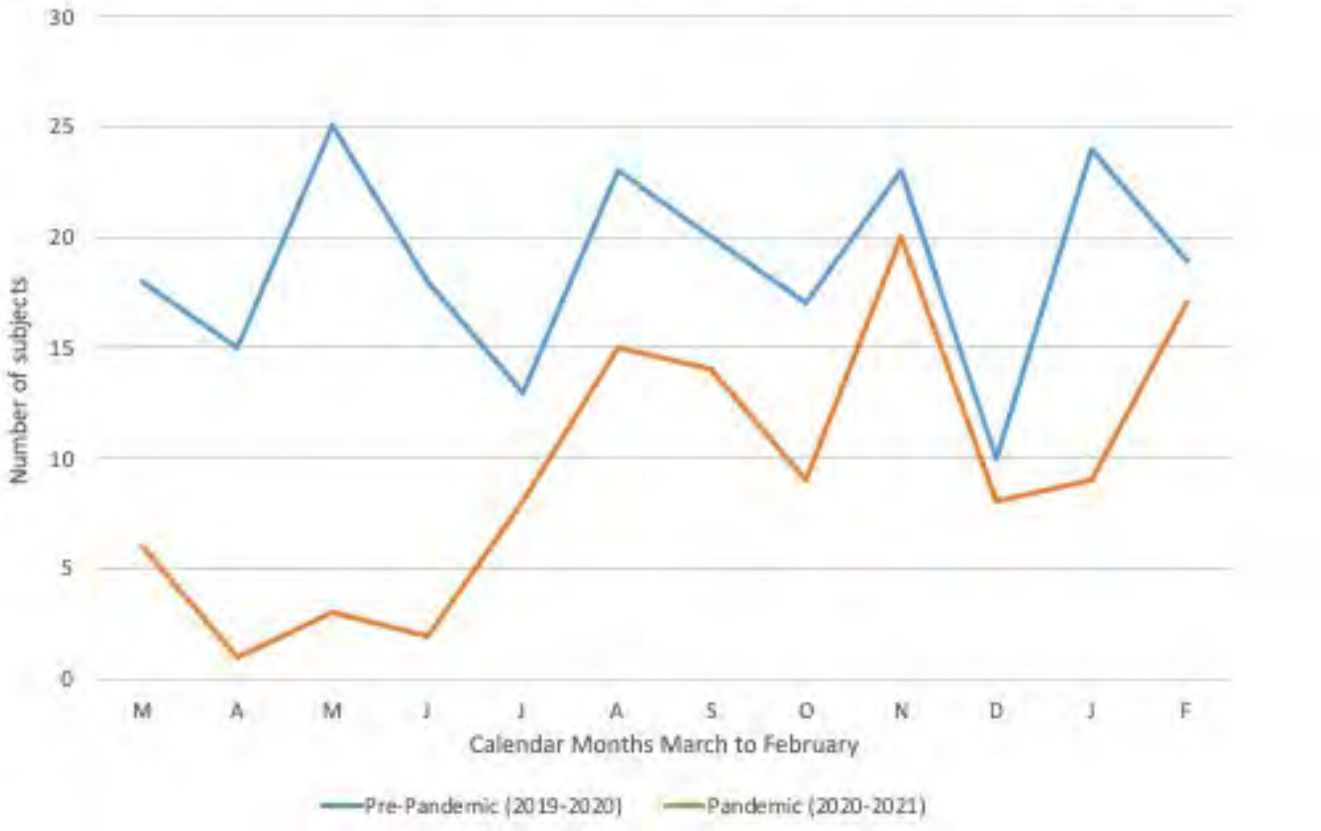

Table 1. JIA category of enrolled patients pre-pandemic and during pandemic.

	Pre-Pandemic Cohort (n=225)	Pandemic Cohort (n = 111)
JIA Category	# (%)	# (%)
Oligoarticular	70 (31.1%)	37 (33.3%)
Oligoarticular – persistent	29 (12.9%)	13 (11.7%)
Oligoarticular – extended	0	2 (1.8%)
Systemic	12 (5.3%)	1 (0.9%)
Polyarticular RF -ve	40 (17.8%)	18 (16.2%)
Polyarticular RF +ve	11 (4.9%)	2 (1.8%)
Psoriatic arthritis	14 (6.2%)	11 (9.9%)
Enthesitis-related arthritis	33 (14.7%)	19 (17.1%)
Undifferentiated	16 (7.1%)	8 (7.2%)

(PGA) of Disease Activity Score and Juvenile Arthritis Quality of Life Questionnaire (JAQQ) were virtually identical (Table 2).

Conclusion: The CAPRI National Registry has allowed us to describe the impact of the global COVID-19 pandemic on JIA presentation to PR care. Research disruption was associated with a 50% enrollment decrease in the pandemic year, most significantly from March to June 2020. It has since improved, consistent with a limit in non-essential research staff presence in hospitals early on. We did not observe the hypothesized delay in presentation and increased severity at presentation. This suggests that within Canada, PR care has adapted well to provide ongoing support and care to new patient consults and avoided significant negative impacts.

Submitted on behalf of the CAPRI Registry Investigators.

Table 2. Characteristics at presentation pre-pandemic and during pandemic.

	Pre-Pandemic Cohort (n=225)	Pandemic Cohort (n = 111)	
Clinical Features at Presentation			*p-value*
Median active joint count (IQR)	2.0 (1.0-5.0)	2.0 (1.0-4.0)	0.835
Median limited joint count (IQR)	1.0 (1.0-4.0)	1.0 (0.0-3.0)	0.257

Patient-Reported Care Utilization, Socioeconomic Status, and Health Status Among Young Adults with JIA

Emily Smitherman[1], Rouba Chahine[1], Nicole Bitencourt[2], AKM Rahman[1], Erica Lawson[3] and Joyce Chang[4], [1]University of Alabama at Birmingham, Birmingham, AL, [2]Loma Linda University Medical Center, Redlands, CA, [3]University of California San Francisco, San Francisco, CA, [4]Boston Children's Hospital, Brookline, MA

SESSION INFORMATION

Session Date: Tuesday, November 9, 2021

Session Title: Pediatric Rheumatology – Clinical Poster III: Miscellaneous Rheumatic Disease (1614–1644)

Session Type: Poster Session D

Session Time: 8:30AM–10:30AM

Background/Purpose: Young adulthood is a vulnerable period for individuals with childhood-onset rheumatic diseases, especially the transition from pediatric to adult care. Our objective was to determine patterns in patient-reported care utilization, socioeconomic status, and health status among young adults with juvenile idiopathic arthritis (JIA), including factors associated with completed transfer to adult rheumatology.

Methods: We analyzed prospectively collected observational data from the Childhood Arthritis and Rheumatology Research Alliance (CARRA) JIA Registry. Enrollment began in 2015, collecting clinical information from pediatric

Table 1. Patient-reported care utilization, socioeconomic status, and health status in patients with JIA ≥ 18 years at first CARRA Long-Term Follow-Up Call Registry visit

rheumatology centers every 6 months. After a 6-month period of Registry inactive status, patients are automatically enrolled in the Long-Term Follow-Up Call Registry which collects patient-reported information via phone surveys every 6 months. We included patients in the Call Registry with JIA who were ≥18 years old at their first Call visit. We

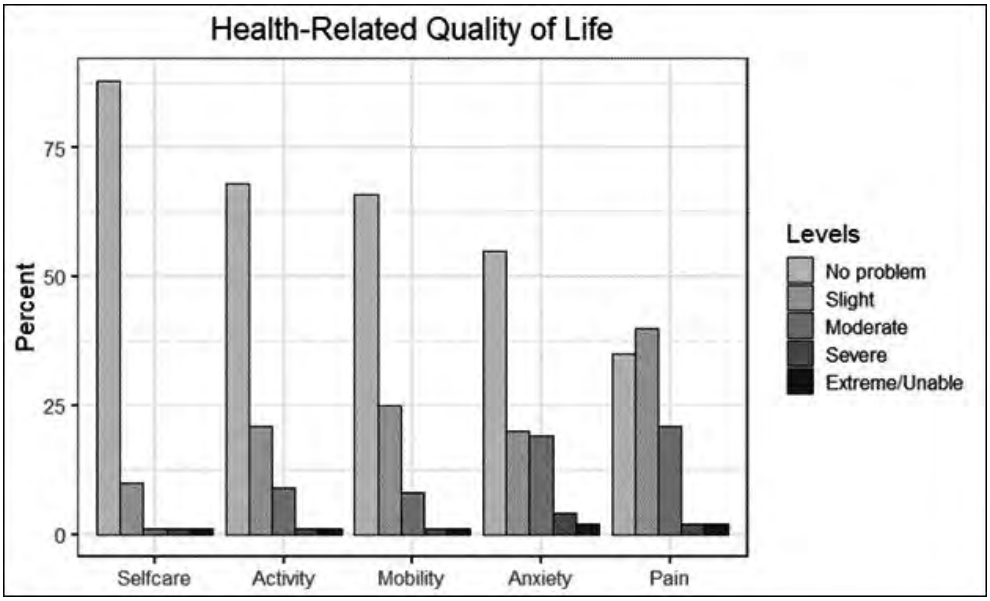

Figure 1. Reported problems in health-related quality of life (EQ-5D domains) among young adults with JIA in the CARRA Long-Term Follow-Up Call Registry.

extracted available demographic, care utilization, and socioeconomic and health status data from each patient's last CARRA Registry visit and first Call Registry visit. We compared characteristics of patients who completed transfer to adult rheumatology care to those who did not.

Results: Of 187 young adults in the Call Registry, 101 (54%) had completed transfer to an adult rheumatologist, 30 (16%) reported still being under the care of a pediatric rheumatologist, 9 (5%) were under the care of both an adult and pediatric rheumatologist, and 56 (30%) were not under the care of any rheumatologist. "Transition" was the most common reason for inactive CARRA Registry status and was more likely for those who completed transfer compared to those who did not, though there was no difference in reported transition preparedness between groups (Table 1). Transferred patients were more likely to have private insurance, have completed some college, be full-time students, and were older at first Call visit compared to those who had not completed transfer. JIA disease activity at the last CARRA Registry visit was not associated with transfer to adult care. Biologic medication use was high at both visits (Table 2) and did not differ by transfer status. However, 63% reported problems with pain/discomfort and 44% with anxiety/depression using the EQ-5D generic health status scale (Figure 1). Patients who completed transfer to adult rheumatology reported higher pain scores, higher self-assessed disease activity, and more morning stiffness compared to those who did complete transfer.

Conclusion: Young adult respondents with JIA commonly report problems in the pain and anxiety/depression domains of health-related quality of life. There was persistent high use of biologic medications, and those who completed transfer to adult rheumatology had higher pain and self-reported disease activity than those who did not, despite high levels of perceived transition preparedness. Additional work is needed to understand how best to address comorbid pain and anxiety/depression during the peri-transition period. Care of young adults with childhood-onset rheumatic disease entering adult care should include efforts to minimize the impact of these comorbidities.

Abstract Number: 1625

Clinical Characteristics of Multisystem Inflammatory Syndrome in Children: A Provincial Cohort

Herman Tam[1], Alison Lopez[2], Mona Patel[2], Jonathan Rayment[3], Lori Tucker[4] and Catherine Biggs[5], [1]Stollery Children's Hospital, University of Alberta, Edmonton, AB, Canada, [2]British Columbia Children's Hospital, University of British Columbia, Vancouver, BC, Canada, [3]British Columbia Children's Hospital, University of British Columbia, Vancouver, BC, Canada, [4]BC Children's Hospital, Vancouver, BC, Canada, [5]catherine.biggs@cw.bc.ca, Vancouver, BC, Canada

SESSION INFORMATION

Session Date: Tuesday, November 9, 2021

Session Title: Pediatric Rheumatology – Clinical Poster III: Miscellaneous Rheumatic Disease (1614–1644)

Session Type: Poster Session D

Session Time: 8:30AM–10:30AM

Background/Purpose: Multisystem Inflammatory Syndrome in Children (MIS-C) is a post-infectious complication of COVID-19 infection with overlapping features of Kawasaki Disease (KD) and Toxic Shock Syndrome (TSS). In April 2020, a provincial multidisciplinary working group was developed expeditiously in anticipation of emerging MIS-C cases following the first wave of COVID-19 infections. The clinical characteristics of children evaluated for MIS-C in British Columbia are presented.

Methods: We included all children evaluated for MIS-C at British Columbia Children's Hospital, a provincial quaternary care centre, from May 2020 to April 2021. We developed an evidence based guideline adopting the World Health Organization MIS-C case definition. We prospectively collected patient demographics, clinical and laboratory characteristics, treatment, and outcomes.

Results: Fifty-two children were included. Median age was 6.0 years (interquartile range [IQR] 2.0-12.5 years) and 53% were female. 11 were diagnosed as confirmed MIS-C cases and 41 were ruled out cases without evidence of an epidemiologic link.

10/11 (91%) MIS-C cases presented with shock and prominent gastrointestinal, conjunctivitis, and mucocutaneous involvement. Common laboratory features included elevated C-reactive protein (CRP), D-Dimer, Troponin, and Brain Natriuretic Peptide (BNP). On echocardiography, 4/11 (36%) had myocardial dysfunction and 3/11 (27%) had coronary artery abnormalities. All patients tested positive for SARS-CoV-2 serology, 7/11 (64%) tested positive for Polymerase Chase Reaction (PCR), and 3/11 (27%) had a PCR-confirmed infection 4-6 weeks prior to admission for MIS-C. 10/11 (91%) received IVIG and intravenous corticosteroids, 5/11 (45%) required inotropic support, and 3/11 (27%) were intubated and ventilated. Median hospital stay was 6 days (IQR 4-9 days) and 7/11 (64%) required ICU admission. There were no deaths.

Of the 41 ruled out cases, diagnoses included KD, TSS, viral infections, bacterial infections, and other new systemic inflammatory syndromes. When compared to ruled out cases, MIS-C patients were more likely to have shock (91% vs 37%, p = 0.002); require ICU admission (64% vs 15%, p = 0.003); have myocardial dysfunction (36% vs 6%, p=0.02); and have higher D-Dimer (3339 vs 2050 mcg FEU/L, p = 0.03), Troponin (0.05 vs 0.0004 mcg/L, p = 0.02), and BNP (384 vs 109 ng/L, p = 0.02). MIS-C cases were also more likely to be treated with IVIG (91% vs 56%; p = 0.02), and corticosteroids (91% vs 37%; p = 0.002).

Conclusion: Our provincial cohort of MIS-C patients were more likely to present with shock and cardiac dysfunction, require ICU admission, and be treated with corticosteroids compared to ruled out cases. Our working group's

evolving process ensured children with features of MIS-C were rapidly identified, had standardized evaluation, and received appropriate treatment in our province.

Use of Total Hip Arthroplasty in Patients Under 21 Years Old: A U.S. Population Analysis

J. Alex Gibbons[1], Cynthia Kahlenberg[1], Deanna Jannat-Khah[1], Susan Goodman[1], Lisa Mandl[1], Peter Sculco[1], Stuart Goodman[2], Mark Figgie[1] and **Bella Mehta**[3], [1]Hospital for Special Surgery, New York, NY, [2]Stanford University, Stanford, CA, [3]Hospital for Special Surgery, Weill Cornell Medicine, New York, NY

SESSION INFORMATION
Session Date: Tuesday, November 9, 2021
Session Title: Pediatric Rheumatology – Clinical Poster III: Miscellaneous Rheumatic Disease (1614–1644)
Session Type: Poster Session D
Session Time: 8:30AM–10:30AM

Background/Purpose: Total hip arthroplasty (THA) is a treatment option for young patients with severe hip pathology due to congenital, developmental, rheumatologic, traumatic, and other acquired conditions. However, the frequency with which THA is used to treat patients in this population in the United States is unknown. Knowledge of the epidemiology of use of THA in this population may help to guide health policy and future research into the indications, outcomes, and failure modes of THA in very young patients. Therefore, the purpose of this study was to evaluate the use of THA in patients under 21 years of age in the United States.

Methods: We retrospectively reviewed the Kids' Inpatient Database (KID), an inpatient US national database of hospital admissions in patients under 21 years of age from approximately 4,200 hospitals in 46 states. We queried the database using current procedural terminology (CPT) codes for elective and non-elective primary THA from 2000-2016. Descriptive statistics such as means and percentages, along with their 95% confidence intervals were calculated using the appropriate sample weights as recommend by the Agency for Healthcare Research and Quality (AHRQ) for use with the KID dataset. Discharge weights were used for nationwide estimates.

Results: The weighted total number of THAs performed in patients under 21 in the KID increased from 347 in 2000 to 551 in 2016, while the total pediatric population in the US remained stable (**Figure 1**). The mean age of patients under 21 undergoing THA was 17.1 years (95% confidence interval: [16.9, 17.4]) (**Table 1)**. The mean age remained consistent (between 17.0 and 17.4) throughout the course of the study. Most patients were white (55.3%) and had private insurance (56.5%). During the study period, 80% of THAs were performed in urban teaching hospitals, 17% were performed in urban non-teaching hospitals, and 2% were performed in rural hospitals. The most common diagnoses were osteonecrosis, osteoarthritis, and juvenile idiopathic arthritis (JIA)/inflammatory arthritis. During the study period (2000-2016), the frequency of THA for osteonecrosis increased from 24% to 38%, while the frequency of THA for JIA/inflammatory arthritis decreased from 27% to 4% (**Figure 2**).

Conclusion: The number of THAs in patients under 21 has increased over the past two decades and these procedures are increasingly performed in urban teaching hospitals. The decrease in THA for inflammatory arthritis in this

Abstract Number: 1627

Long Term Follow-Up of Patients with Childhood-Onset Lupus Nephritis After Transition to Adult Care

Dahima Cintrón[1], Suheiry Márquez[1] and Luis Vilá[2], [1]University of Puerto Rico Medical Sciences Campus, San Juan, PR, [2]University of Puerto Rico Medical Sciences Campus, San Juan, Puerto Rico

SESSION INFORMATION
Session Date: Tuesday, November 9, 2021
Session Title: Pediatric Rheumatology – Clinical Poster III: Miscellaneous Rheumatic Disease (1614–1644)
Session Type: Poster Session D
Session Time: 8:30AM–10:30AM

Background/Purpose: Approximately 20% of patients with systemic lupus erythematosus (SLE) are diagnosed before 18 years of age. Pediatric patients have a worse disease course when compared to adults, and nearly 50% present with renal involvement. Most studies on childhood-onset lupus nephritis (cLN) are limited to the pediatric period. Therefore, we sought to determine the long term clinical outcomes in patients with cLN after reaching adulthood.

Methods: A cohort of Hispanics from Puerto Rico with SLE (per 1997 American College of Rheumatology classification criteria) was studied. Lupus nephritis (LN) was defined as the presence of proteinuria >0.5 g per day, urinary cellular casts, and/or a renal biopsy consistent with LN. Demographic parameters, clinical manifestations, comorbidities, disease activity (per Systemic Lupus Erythematosus Disease Activity Index ([SLEDAI]), disease damage (per Systemic Lupus International Collaborating Clinics/American College of Rheumatology Damage Index [SDI]), pharmacologic therapy, renal response, and chronic kidney disease staging (per National Kidney Foundation) were gathered at LN onset (baseline) and at last visit. Data from patients with cLN were compared to those with adult-onset LN (aLN) using Chi-square test, Fisher's exact test, or Mann-Whitney test, as appropriate.

Results: In total, 142 SLE patients with LN were studied; 27 (19%) had cLN and 115 (81%) had aLN. Among cLN patients, 88% were female. The mean (standard deviation [SD]) age at SLE diagnosis and LN onset for cLN patients were 14.6 (3.2) and 16.1 (3.9) years, respectively. The mean (SD) LN duration and follow-up after reaching adulthood were 14.7 (7.8) and 13.4 (7.7) years, respectively. No significant differences were found at baseline and last visit for lupus manifestations, comorbidities, SLEDAI and SDI scores, and pharmacologic treatment (induction and maintenance therapeutic modalities) between patients with cLN and aLN. Renal outcomes are depicted in table1. No significant differences were found for renal outcomes between these groups.

Conclusion: In this cohort of Puerto Ricans with SLE, patients with cLN followed through adulthood for more than a decade had a favorable outcome. Most patients remained in chronic kidney disease stage 1 or 2 and few evolved into end-stage-renal disease. Furthermore, long term renal outcomes were similar to those with aLN. The results of this study differ from those from other ethnic populations that show poor clinical outcomes in patients with cLN.

Table 1. Renal outcomes of childhood-onset lupus nephritis (cLN) and adult-onset lupus nephritis (aLN) at last visit

	cLN n= 27 %	aLN n= 115 %	p value
Renal response			
Complete renal response	50.0	37.7	0.774
Partial renal response	0.0	13.2	
Chronic kidney disease stage			
1	58.3	44.6	0.223
2	16.7	22.3	0.539
3A	8.3	10.7	1.000
3B	8.3	6.3	0.659
4	0.0	6.3	0.353
5	0.0	1.8	---
End-stage renal disease	8.3	8.0	0.504
Mortality	11.1	9.0	0.728

Reproductive Health Knowledge Gaps, Needs, and Barriers Identified by Pediatric Rheumatology Providers

Kimberly Hays[1], Catherine Lavallee[2], **Brittany Huynh**[3], Tova Ronis[4], Barbara Edelheit[5], Kathryn Cook[6], Veronica Mruk[7] and Cuoghi Edens[8], [1]Penn State Health, Hershey, PA, [2]Virginia Tech Carilion School of Medicine, Roanoke, VA, [3]Riley Hospital for Children at Indiana University, Indianapolis, IN, [4]Children's National Hospital, Washington, MD, [5]CT Children's Medical Center, Hartford, CT, [6]Akron Childrens Hospital, Copley, OH, [7]Ohio State University / Nationwide Children's Hospital, Columbus, OH, [8]University of Chicago, Chicago, IL

SESSION INFORMATION

Session Date: Tuesday, November 9, 2021

Session Title: Pediatric Rheumatology – Clinical Poster III: Miscellaneous Rheumatic Disease (1614–1644)

Session Type: Poster Session D

Session Time: 8:30AM–10:30AM

Background/Purpose: Rheumatic diseases and their treatments present unique challenges to sexual and reproductive health (SRH) issues facing patients and clinicians. Despite this, literature in the adult population suggests SRH is often unaddressed by health care providers, and providers report gaps in knowledge in this area. We sought to understand pediatric rheumatology providers' knowledge, needs, and practices regarding the SRH care of their patients.

Methods: An electronic survey was distributed to the Childhood Arthritis and Rheumatology Research Alliance (CARRA) providers in the fall of 2020. 248 CARRA members completed the 37-item online survey about SRH issues facing pediatric rheumatology providers.

Results: Survey response rate was 82%. Participants were mostly pediatric rheumatologists, female, practicing in the United States and affiliated with an academic hospital (Table 1). Fifty percent of respondents were in fellowship

or less than 10 years out of training. Sixty-six percent reported more than 50% of their time devoted to clinical care. Over 90% surveyed felt it was within their scope to address SRH topics with their patients. Top three SRH concerns reported by clinicians: teratogenic medications, contraception, and long-term medication safety. Fertility and pregnancy were also of high importance, with 70% of respondents having at least one pregnant patient in their career, 4% having >15 pregnancies. Lack of time and knowledge were the most common reasons cited for not discussing SRH with patients. Only a minority of providers speak to patients alone or routinely address sexual activity.

The majority of those surveyed were able to identify key teratogens used in pediatric rheumatology, however some pregnancy-compatible medications were incorrectly identified as teratogenic (Figure 1). Estrogen-containing contraceptives were erroneously identified as inappropriate in those without antiphospholipid antibodies (APLs) (Table 2). Progestin-only methods were underrecognized as appropriate in those with positive APLs or thrombus history, with hormonal IUDs and implants the most improperly identified. Immunosuppression and nulliparity were appropriately not seen as barrier to long-acting reversible contraceptives. The effectiveness of various contraceptives was overestimated. Emergency contraception, an intervention with no disease restrictions, was not well-recognized as safe for those with SLE with negative or positive APLs (Table 2) Potential fertility sequelae plays a role in medication

Table 1. Survey Respondent Characteristics

Total CARRA members participating	248 (82%)
Country	
United States	232 (94%)
Canada	16 (6%)
Position	
Pediatric Rheumatologist	170 (68%)
Adult/Pediatric Rheumatologist	12 (5%)
Fellow in a pediatric rheumatology program	47 (19%)
Fellow in a combined adult and pediatric rheumatology program	10 (4%)
Rheumatology nurse practioners or physician assistant	9 (4%)
Current practice/training environment	
Academic setting	235 (95%)
Nonacademic setting	13 (5%)
Gender of participants	
Female	184 (74%)
Male	63 (25%)
Chose not to answer	1 (1%)
Percent clinical time	
0-10%	6 (2%)
11-20%	22 (9%)
21-30%	29 (12%)
31-40%	5 (2%)
41-50%	22 (9%)
51-60%	20 (8%)
61-70%	27 (11%)
71-80%	45 (18%)
81-90%	31 (12%)
91-100%	41 (17%)
Percentage of patients between 14-26 years old	
0-24%	14 (5%)
25-49%	121 (49%)
50-74%	104 (42%)
>75%	9 (4%)

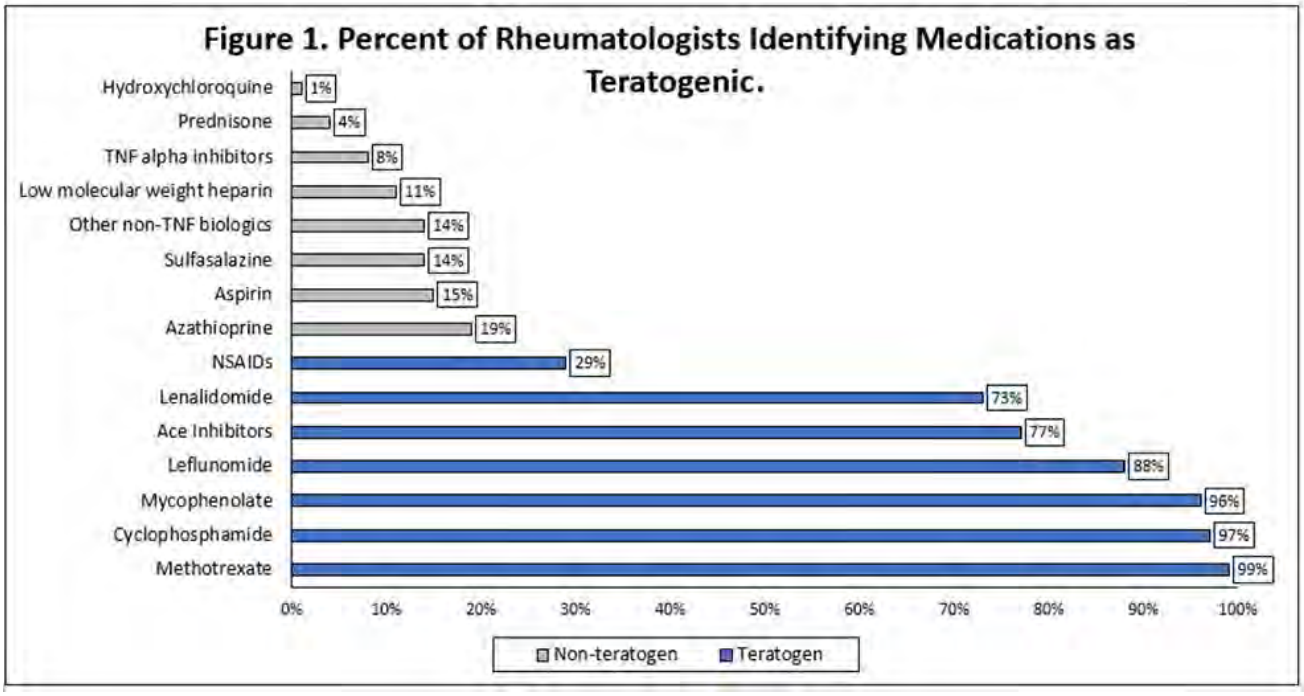

Table 2. Pediatric Rheumatologists Reporting Contraception Compatibility* in SLE patients with or without history of VTE/APLs

Contraception Type	-VTE/APLs	+VTE/APLs
Condoms	98%	95%
Combined Hormone OCP	64%	3%
Contraceptive Ring/Patch	66%	12%
Progesterone Only Pill	95%	85%
DMPA Injection	92%	71%
Hormonal Implant	87%	54%
Hormonal IUD	87%	54%
Copper IUD	94%	90%
Emergency Contraceptive Pill	82%	47%

Systemic lupus erythematosus = SLE; Venous thromboembolism = VTE; Anti-phospholipid antibodies = APLs; Oral Contraceptive Pill=OCP; Depot medroxyprogesterone acetate = DMPA; Intrauterine device = IUD

* Compatibility was adapted from the 2020 American College of Rheumatology Guideline for the Management of Reproductive Health in Rheumatic and Musculoskeletal Diseases (Arthritis & Rheumatology; Vol 72. No 4, April 2020, p531-532)

Dark green = Highly compatible; Light green = Likely compatible; Pink=Unlikely compatible; Red = Not compatible

decisions, however methotrexate and mycophenolate were incorrectly identified as affecting fertility. Fertility preservation was rarely pursued for males or females.

Conclusion: Sexual and reproductive health is an area pediatric rheumatology providers feel is within their clinical purview, barred by time and knowledge. Knowledge gaps recognizing pregnancy compatible medications, appropriate contraception based on disease characteristics, contraception effectiveness, and medications effecting fertility were identified. Emergency contraception safety awareness was lacking. This survey highlights future opportunities for provider education in pediatric rheumatology SRH.

SESSION INFORMATION

Session Date: Tuesday, November 9, 2021

Session Title: Pediatric Rheumatology – Clinical Poster III: Miscellaneous Rheumatic Disease (1614–1644)

Session Type: Poster Session D

Session Time: 8:30AM–10:30AM

Background/Purpose: Severe delayed hypersensitivity reactions (DHR) are under-recognized in inflammatory conditions, particularly drug reaction with eosinophilia and systemic symptoms (DRESS). Previous work has shown this reaction to occur implicating inhibitors of IL-1 and IL-6 during treatment of Stills disease.[1] The purpose of the present analysis of newly identified cases is to assess outcomes based on timeliness of recognizing drug reaction and withdrawal of the implicated medications.

Methods: This is a retrospective observational study of subjects with Stills disease who experienced a DRESS reaction implicating one or more of anakinra, canakinumab, tocilizumab or rilonacept. Classification as DHR required scoring as probable or definite using the validated scoring system RegiSCAR for DRESS.[2] Cases with and without diffuse parenchymal lung disease during treatment (DLD) were included. Variables included duration of drug exposure, development

Table. Drug duration and outcomes in Stills subjects with DRESS to inhibitors of IL-1 or IL-6

All DHR subjects (n= 59)				
	IL-1 and/or IL-6 inhibitor treatment < 6 months	IL-1 and/or IL-6 inhibitor treatment 6 months to 4.3 years[1]	*P* value	OR(95%CI)
DLD	8/59 (14%)	33/59 (56%)	2.1×10^{-6}	8.3 (3.3-20.0)
Deceased[2]	1/59 (2%)	11/59 (19%)	4.1×10^{-3}	13.3 (1.7-106.7)
DLD survivors with > 3 months of follow up (n= 25)				
	Permanently discontinued IL-1 and IL-6 inhibitors <3 months after DLD recognized		*P* value	OR(95%CI)
	Yes	No		
DLD improved	7/25 (28%)	0/25 (0%)	0.01	infinite

DHR, delayed hypersensitivity reaction; DLD, diffuse lung disease developing during treatment with IL-1 or IL-6 inhibitors; DLD improved, asymptomatic without supplemental oxygen plus improved CT and/or decreased or resolved clubbing

[1]Longest latency from inhibitor start to DLD was 4.3 years.

[2]Fatalities occurred only in subjects with DLD (41/59 DHR cases). Fatality rate is 29%(12/41) with median follow up from DLD to data close of 10 months (med(IQR),10 months (7,26)).

of diffuse lung disease, lung disease status at data close and death. Lung disease resolution was defined as absence of respiratory symptoms without supplemental oxygen, normal chest CT and resolution or absence of digital clubbing. DLD improvement differed from resolution by allowing improved chest CT or digital clubbing with neither worsening. Comparisons were made using Fishers exact test and odds ratios with 95% confidence intervals. 59 subjects met inclusion criteria for DHR implicating inhibitors of IL-1 and/or IL-6. Class II HLA associations were considered as available.

Results: Median age at Stills onset was 4 years (range 0.5-17.7 years), 69% (41/59) had DLD and 61% (36/59) were female. Fatalities occurred solely in subjects developing DLD (12/41,29%). Median latency from drug initiation to detection of DLD was 1.3 yrs (range 2 weeks-4.3 years). When biopsied, pathology in DLD was pulmonary alveolar proteinosis, as described.[1] Three cases resolved lung disease; all 3 had permanently discontinued IL-1 and IL-6 inhibitors within 6 weeks of DLD detection. DHR subjects without DLD who stopped IL-1 or IL-6 inhibitors did not develop DLD, during median follow-up of 1 year after drug stop (range 0.2-6.5 years). Drug withdrawal improved outcomes (table). HLA-DRB1*15 was present in 31/37(84%), strikingly exceeding population frequencies.[3]

Conclusion: Timely recognition of DRESS reactions and withdrawal of all IL-1 and IL-6 inhibitors improve outcomes in Stills disease, lessens risk of the often fatal drug-associated lung disease and may allow resolution of DLD. Mechanisms underlying cross reactions between these structurally different drugs are not known. Determination of HLA may limit the incidence of DHR.

Abstract Number: 1630

Multisystem Inflammatory Syndrome in Children: Clinical Characteristics and Predictors for Length of Hospitalization

Lauren Covert[1], Mara Becker[2], Rebecca Sadun[1] and Heather Van Mater[1], [1]Duke University, Durham, NC, [2]Duke University Medical Center/Duke Clinical Research Institute, Chapel Hill, NC

SESSION INFORMATION
Session Date: Tuesday, November 9, 2021
Session Title: Pediatric Rheumatology – Clinical Poster III: Miscellaneous Rheumatic Disease (1614–1644)
Session Type: Poster Session D
Session Time: 8:30AM–10:30AM

Background/Purpose: Multisystem Inflammatory Syndrome in Children (MIS-C) is a recently defined post-infectious phenomena associated with coronavirus disease 2019 (COVID-19). We assessed the demographics, clinical characteristics, hospital course, and short-term outcomes of patients admitted with MIS-C.

Methods: We performed a retrospective analysis of patients who met the World Health Organization definition of MIS-C and were admitted to Duke Children's Hospital from August 3, 2020 to March 25, 2021. Demographic and clinical data were collected from the electronic medical record. Associations between admission lab values and hospital length of stay (LOS) were examined using univariate and multivariate linear regression after log transformation for variables with skewed distribution.

Results: Twenty patients were included. The mean (±SD) age was 9.5 (5.4) years; 10 patients (50%) were male; 16 (80%) were Black. Twelve patients (60%) were previously healthy; the most common comorbidity was obesity in 8 (40%) children. All patients presented with fever, cardiovascular dysfunction, and coagulopathy. Other common manifestations were gastrointestinal distress (80%), acute kidney injury (60%), respiratory compromise (50%), and mucocutaneous symptoms (45%). Echocardiographic abnormalities were noted in 18 (90%) patients, with coronary artery changes in 14 (70%) and reduced systolic ejection fraction in 12 (60%) (Figure 1). Intensive care unit admission, ionotropic support, and mechanical ventilation were indicated in 80%, 70%, and 20% of patients, respectively. All patients were treated with intravenous immunoglobulin (IVIG), with 19 (95%) requiring additional treatment: 17 (85%) with 1-4 mg/kg/day intravenous glucocorticoids, 6 (30%) with pulse dose glucocorticoids, and 7 (35%) with anakinra (Figure 2). Treatment complications included IVIG-associated hemolytic anemia (10%) and steroid-related adverse effects such as hypertension, bradycardia, hyperglycemia, and delirium (35% collectively). All patients survived and were discharged home. Median (IQR) LOS was 8 (7, 11) days. All echocardiograms normalized in a median (IQR) of 16.5 (3, 41) days. Univariate analyses of admission lab values and LOS revealed a positive association between ferritin (p=.004) and a negative association between Hgb (p=.036) and albumin (p=.001). Controlling for all significant variables in a multivariate linear regression model, ferritin (adjusted p=.043) and albumin (adjusted p=.017) remained significantly associated with LOS (adjusted R^2=.59).

Clinical Presentation	Prevalence (n=20)
Fever	20 (100%)
Cardiovascular dysfunction	20 (100%)
Coagulopathy	20 (100%)
Gastrointestinal symptoms	16 (80%)
Acute kidney injury	12 (60%)
Respiratory symptoms	10 (50%)
Mucocutaneous symptoms	9 (45%)
Neurologic symptoms	6 (30%)

Cardiac Manifestations	Values (n=20)
Any coronary involvement	14 (70%)
Dilation only (z-score 2-2.5)	6/14 (43%)
Small aneurysm (z-score >2.5-5)	7/14 (50%)
Medium aneurysm (z-score >5-10)	1/14 (7%)
Large aneurysm (z-score >10)	0/14 (0%)
Reduced systolic ejection fraction	12 (60%)
Mild	4/12 (33%)
Moderate	6/12 (50%)
Severe	2/12 (17%)
Days to Normal Echocardiogram	
Average	27.4
Median	16.5

Figure 1. Clinical presentations and cardiac manifestations of MIS-C patients admitted to Duke Children's Hospital.

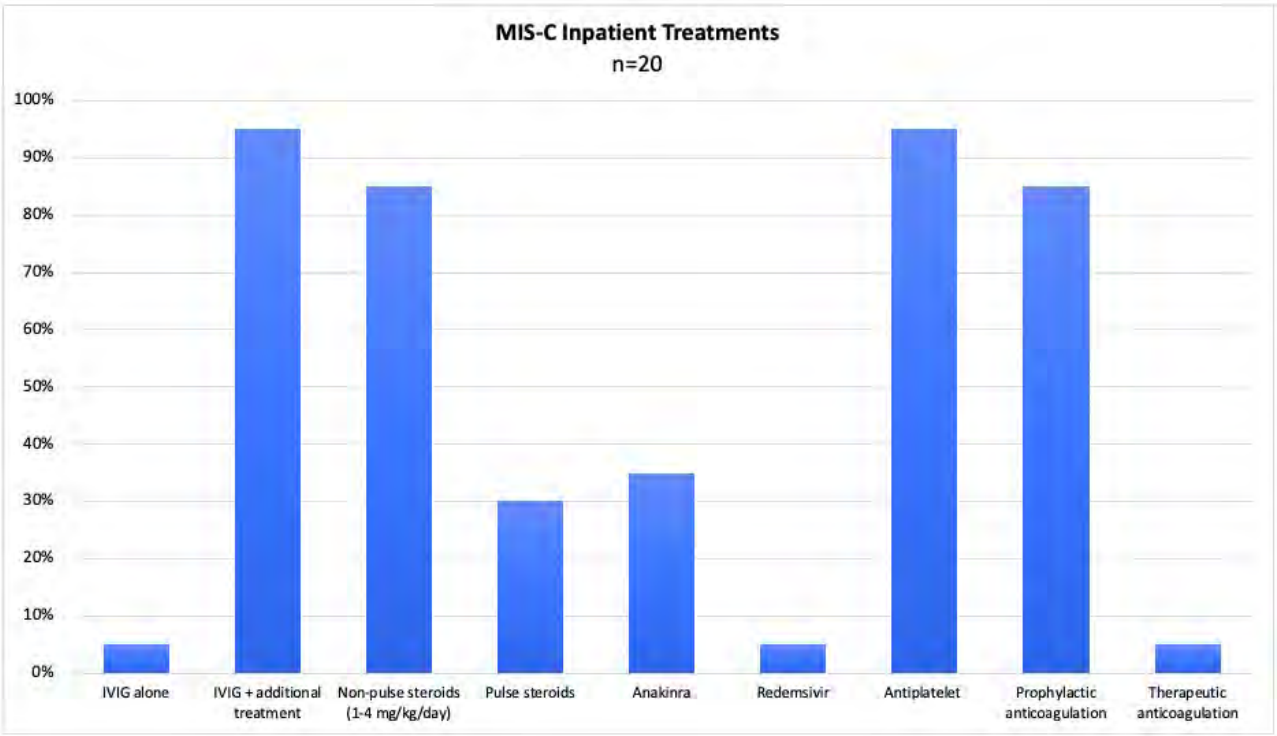

Figure 2. Therapies received by admitted MIS-C patients at Duke Children's Hospital.

Conclusion: MIS-C is a novel entity of high morbidity and low mortality in children previously infected with COVID-19. In this case series, children with MIS-C presented with fever and multiorgan failure, with cardiovascular compromise being most common. Higher baseline ferritin level and lower serum albumin were associated with longer LOS. Treatment with IVIG, glucocorticoids, and anakinra resulted in favorable short-term outcomes.

SESSION INFORMATION

Session Date: Tuesday, November 9, 2021

Session Title: Pediatric Rheumatology – Clinical Poster III: Miscellaneous Rheumatic Disease (1614–1644)

Session Type: Poster Session D

Session Time: 8:30AM–10:30AM

Background/Purpose: Uveitis is the main extraarticular complication of juvenile idiopathic arthritis (JIA) with still a significant impact on JIA morbidity, despite continuous improvement in systemic treatment. Although antinuclear antibody positivity and early onset of JIA have been associated with a high risk of uveitis onset, no clinical features have been widely recognized as predictive factors for JIA-associated uveitis (JIA-U) lack of response to treatment, so far. The aim of our study is to investigate clinical features associated with lack of response to systemic treatment in a long-term cohort of patients with JIA-U.

Methods: Clinical records of patients with JIA-U were retrospectively reviewed with regard to clinical features, therapeutic choices and outcome. The role of potential predictors for lack of response to treatment has been assessed at bivariate and multivariate levels. Furthermore, a multivariable logistic model has been applied in order to estimate the strength of association between predictors and outcome, adjusting for potential confounders.

Results: Data from 152 JIA-U patients were analysed (82.2% female), with a median follow up of 12.0 years (IQR 9.9) and a median age at uveitis onset of 4.8 (4.1) years. In 72 patients (43.4%) at least one biologic DMARD (bDMARDs) to control uveitis was required. Compared to patients responsive to a monotherapy with a DMARD (n=38), children requiring a bDMARDs for uveitis had a lower median age at uveitis onset, a longer disease duration and a greater frequency of bilateral uveitis at onset (**Table 1**). No difference was observed in uveitis activity grade at onset. Despite similar frequency of ocular damage at onset, patients not responsive to DMARDs showed a higher percentage of ocular damage at last visit (66.7% vs 39.5% p=0.011). Multivariable analysis confirmed younger age at disease onset as an independent factor for lack of response to DMARDs (p 0.018). Male gender is associated with higher frequency of ocular surgery (33.3% vs 12.4%, p=0.043), and, despite the inaccuracy of the estimate due to limited sample size, acts as an independent factor in multivariable analysis with an almost 9 times higher risk to lack of response to DMARDs (p=0.049).

	Monotherapy with DMARDs (n=38)	bDMARDs for uveitis (n=72)	p-value
Gender, %M (n)	7.9 (3)	25.0 (18)	0.055
Age at uveitis onset (yr), median (IQR)	6.0 (3.3)	4.1 (4.3)	0.008
Duration of disease (yr), median (IQR)	10.4 (8.0)	13.4 (10.7)	0.047
Oligoarthritis persistent course, % (n)	84.2 (32)	72.2 (52)	0.053
ANA positive, % (n)	89.5 (34)	94.4 (68)	0.444
Positive acute phase reactants at onset, % (n)	68.2 (15)	78.4 (29)	0.575
Active arthritis at uveitis onset, % (n)	57.6 (19)	72.7 (48)	0.197
Ocular damage at onset, % (n)	18.2 (6)	26.9 (18)	0.480
Bilateral uveitis at onset % (n)	50.0 (19)	77.8 (56)	0.006

Conclusion: Younger age at uveitis onset and male gender are predictors of a worse response to DMARDs, while the length of follow-up exerts a confounding effect on bilateral uveitis. Children resistant to conventional treatment need prompt recognition and additional strategies to improve long-term outcome.

Clinical Features and Colchicine Response in Patients with Undifferentiated Systemic Autoinflammatory Disease Carrying E148Q vs. Other *MEFV* Mutations

Bugra Egeli[1], Holly Wobma[1], Mariana Correia Marques[2], Jonathan Hausmann[3] and Fatma Dedeoglu[1], [1]Boston Children's Hospital, Boston, MA, [2]UPMC Children`s Hospital of Pittsburgh, Pittsburgh, PA, [3]Beth Israel Deaconess Medical Center, Boston, MA

SESSION INFORMATION

Session Date: Tuesday, November 9, 2021

Session Title: Pediatric Rheumatology – Clinical Poster III: Miscellaneous Rheumatic Disease (1614–1644)

Session Type: Poster Session D

Session Time: 8:30AM–10:30AM

Background/Purpose: Undifferentiated systemic autoinflammatory diseases (uSAID) are diverse syndromes characterized by acute flares of fever and inflammation, which do not meet clinical criteria for known disorders like Familial Mediterranean Fever (FMF). As part of the uSAID workup, many patients undergo genetic testing, sometimes revealing variants of uncertain significance in genes associated with autoinflammation. E148Q is a common polymorphism in exon 2 of the *MEFV* gene, which is not thought to be a disease-causing variant for FMF. The contribution of E148Q mutations in patients with uSAID is poorly understood, and it is unknown how it may respond to empiric treatment with colchicine, which is first line for FMF. To compare the clinical characteristics and colchicine response of children with uSAID identified to have E148Q vs non-E148Q mutations in the *MEFV* gene.

Methods: Children with uSAID ≤18 years old at initial evaluation seen at a single-center during 2000-2019 were included if they received ≥3 months of colchicine therapy and carried at least one *MEFV* mutation but did not meet clinical criteria for FMF (n = 25). Data on demographics, clinical features, laboratory/genetic studies, and treatment responses were collected.

Table 1. Characteristics of uSAID patients with heterozygous MEFV mutations

	E148Q group (n=8)	Non-E148Q group (n=17)	p value
Complete response, (%)	2 (25)	12 (70.6)	0.03
Mean episode duration (days), (SD)	8.3 (6.5)	3.7 (1.4)	0.009
Asian ancestry, (%)	3 (37.5)	0 (0)	0.04
GI symptom, (%)	5 (62.5)	8 (47.1)	0.47
MSK symptom, (%)	3 (37.5)	9 (52.9)	0.47
Pharyngitis, (%)	3 (37.5)	5 (29.4)	0.69
Rash, (%)	3 (37.5)	11 (64.7)	0.20

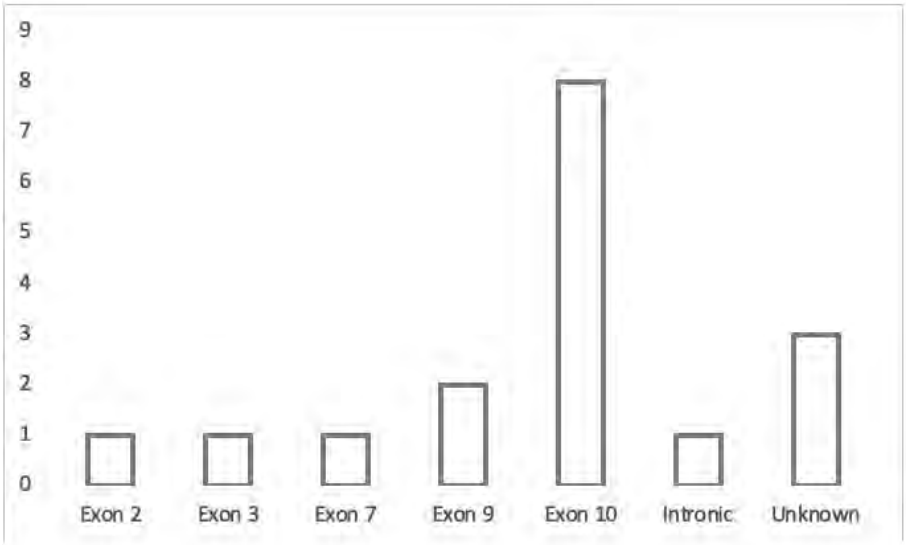

Figure 1. Location of non-E148Q MEFV mutations in uSAID patients (n=17).

Results: In our cohort of 25 children with uSAID and *MEFV* mutations, 8 (32%) were heterozygous for E148Q mutations. Half of these patients also carried another non- exon 10 *MEFV* mutation (2x 369S, 1x L110P, 1x I591T). Distribution of the remaining variants on *MEFV* gene is shown in Figure 1. Clinical features of children with E148Q vs. other *MEFV* mutations are shown in Table 1. Asian ancestry was seen in 3/8 (37%) children with E148Q mutations and in no child with other *MEFV* mutations. Children with E148Q mutations had longer length of febrile episodes (8.3±6.5 vs. 3.4±1.4 days; p=0.009) and were less likely to have a full response to colchicine (25% vs 70%; p = 0.03).

Conclusion: In our cohort of children with uSAID and *MEFV* mutations, E148Q was associated with longer duration of fever flares and a reduced colchicine response. Larger studies will be helpful in elucidating the unique role of these mutations in autoinflammation.

Epidemiology of Musculoskeletal Manifestations in Paediatric Inflammatory Bowel Disease: A Systematic Review

Aaisham Ali[1], Melanie Schmidt[2], David Piskin[2], Eileen Crowley[3] and Roberta Berard[4], [1]Schulich School of Medicine & Dentistry, London, ON, Canada, [2]Lawson Health Research Institute, London, ON, Canada, [3]Department of Paediatrics, Division of Paediatric Gastroenterology, Children's Hospital, London Health Sciences Centre, London, ON, Canada, [4]London Health Sciences Centre, London, ON, Canada

SESSION INFORMATION

Session Date: Tuesday, November 9, 2021

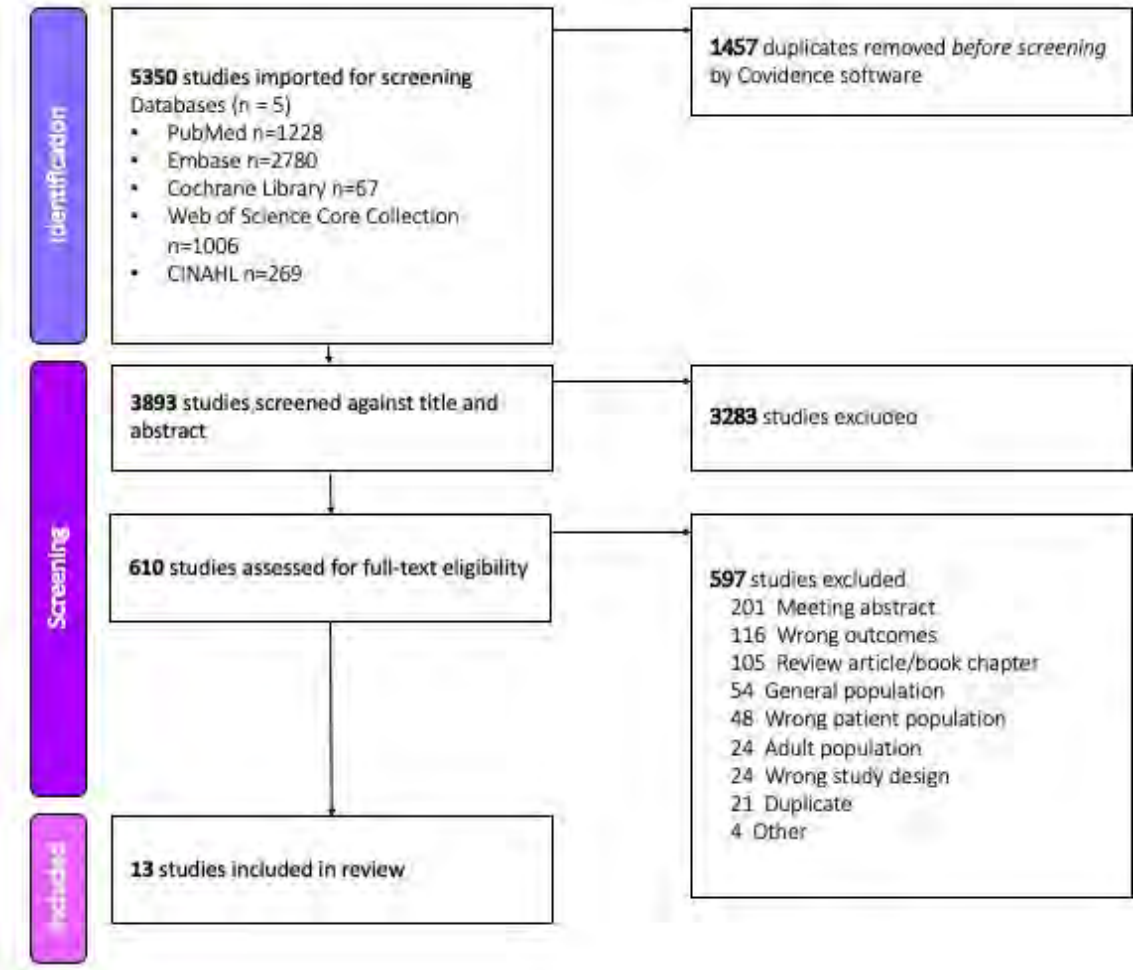
Session Title: Pediatric Rheumatology – Clinical Poster III: Miscellaneous Rheumatic Disease (1614–1644)

Session Type: Poster Session D

Session Time: 8:30AM–10:30AM

Background/Purpose: Paediatric inflammatory bowel disease (p-IBD) is a chronic and relapsing gastrointestinal disorder of childhood with associated long-term morbidity. Several extraintestinal manifestations (EIMs) are de-

Figure 1. PRISMA flowchart of the study search and selection for inclusion in the systematic review.



PRISMA flowchart for study inclusion.

scribed, the most common being joint pain and/or inflammation. In 1986, Passo et al. were the first to describe the association of arthritis in p-IBD patients. In this retrospective study, arthritis was described in 9% of children with ulcerative colitis (UC) and in 15.5% of children with Crohn's disease (CD). Arthralgia was more common than arthritis, occurring in 32% of patients with UC and 22% with CD. Data on the epidemiology, patient and disease factors associated with the development of, treatments required for, and outcomes of p-IBD associated musculoskeletal (MSK) disease is lacking. Our study aims to summarize the literature on the epidemiology of MSK EIMs in p-IBD in the era of biologics.

Methods: A systematic review of the literature was performed. PubMed, Embase, Cochrane Library, Web of Science Core Collection, and CINAHL databases were searched with relevant keywords. English studies published from January 1, 2000 to December 21, 2020 were included. In total, 3,893 papers were identified, and screening was

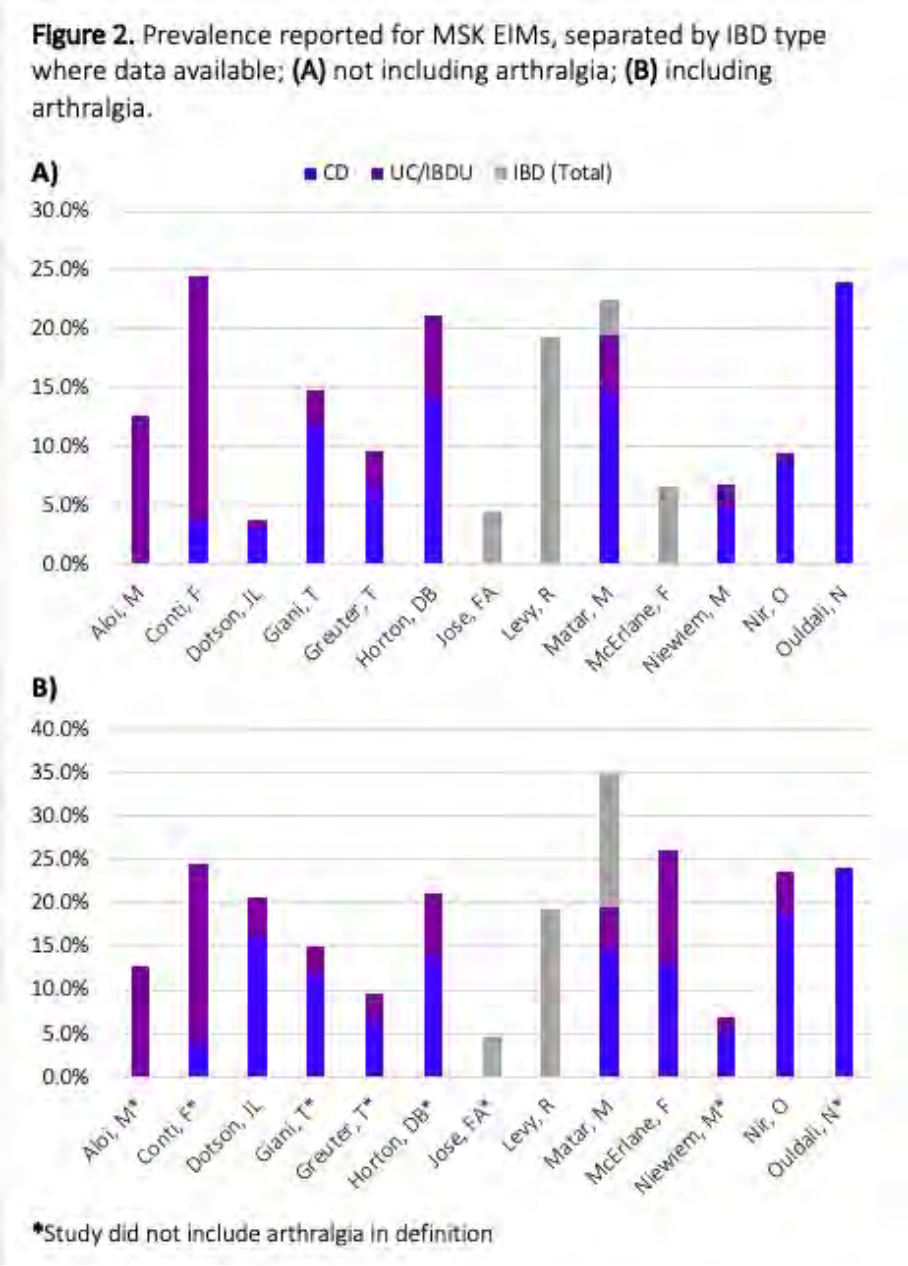


Figure 2. Prevalence reported for MSK EIMs, separated by IBD type where data available; **(A)** not including arthralgia; **(B)** including arthralgia.

MSK EIM reported prevalence rates.

performed by two independent reviewers (AA, MS; Figure 1). Conflicts were resolved by a third reviewer (EC or RB). Characteristics of the study such as research design, setting, and sample size, as well as phenotypic characteristics of the population were recorded. The primary outcomes of interest were MSK symptoms at presentation and course, method of diagnosis and definitions used for MSK EIMs. Risk of bias assessment was performed using the JBI Prevalence Study Critical Appraisal Tool.

Results: Thirteen studies were included for full review, which were primarily single-centre observational studies with retrospective or cross-sectional design. The method of diagnosis for MSK EIMs varied greatly across the studies, with only 4 studies stating the involvement of a rheumatologist in the diagnosis. The definitions used also varied, with MSK-related features such as peripheral arthritis, axial arthritis, enthesopathy, myalgia, and arthralgia included. Only 6 studies focused on MSK EIMs as their primary outcome, while the remainder reported on all p-IBD associated EIMs. There was a wide range in the prevalence of MSK EIMs from 3.7-34.8% (Figure 2a, 2b). Four studies reported on the therapeutic response of MSK EIMs to pharmacotherapy, and only 3 of those reported on biologic use. Risk of bias demonstrated heterogeneity in the quality of included studies.

Conclusion: This is the first systematic review of the literature for MSK EIMs in p-IBD. Analysis was limited due to variability in study design and data-reporting methods. Included studies reported prevalence of MSK EIMs, but the ascertainment of MSK EIMs, both method and definition varied with a clear lack in standardization. Our study demonstrates the need for research to capture the presentation, diagnosis, management, and morbidity associated with MSK EIMs in p-IBD.

Patient Activation and Health Literacy in the Pediatric to Adult Transition in Juvenile Systemic Lupus Erythematosus: Patient and Health Care Team Perspectives

Ashley Ciosek[1], Una Makris[2], Justin Kramer[3], Tracey Wright[4] and Nicole Bitencourt[5], [1]UT Southwestern Medical Center, Dallas, TX, [2]UT Southwestern Medical Center, Dallas Veterans Administration, Dallas, TX, [3]Texas A&M University, College Station, [4]UT Southwestern Medical Center, Children's Health, Texas Scottish Rite Hospital for Children, Plano, TX, [5]Loma Linda University Medical Center, Redlands, CA

SESSION INFORMATION

Session Date: Tuesday, November 9, 2021

Session Title: Pediatric Rheumatology – Clinical Poster III: Miscellaneous Rheumatic Disease (1614–1644)

Session Type: Poster Session D

Session Time: 8:30AM–10:30AM

Background/Purpose: Advances in treatment of juvenile-onset systemic lupus erythematosus have ensured increased survival such that long-term quality of life and disease management must be considered. Interventions to improve jSLE transition outcomes require an understanding of the challenges faced by patients and their health care teams during this time.

In this qualitative study, we had a unique opportunity to interview uninsured or publicly insured young adults with jSLE who recently transitioned to adult rheumatology care, along with health care professionals caring for pediatric and adult jSLE patients. Interviews identified influential factors affecting pediatric-to-adult rheumatology transition suc-

cess. A subset of influential factors are described herein, organized under the conceptual frameworks of patient activation and health literacy (HL). Recommendations to improve transition success were also elicited from each cohort.

Methods: Semi-structured in-depth interviews with patients and health care professionals were conducted from November 2019 - May 2020, until thematic saturation. Thirteen post-transfer adult participants diagnosed with jSLE (in concordance with 2019 EULAR/ACR classification) were recruited from a public safety-net hospital system or from private practice. Thirteen health care team members were recruited from two pediatric and four adult rheumatology clinical sites in the same metropolitan area. Interviews were recorded, transcribed, coded, and analyzed using thematic analysis.

Results: Our interviews suggest that patient activation is driven by internalization of the implications of jSLE diagnosis, capacity and willingness to engage in self-education, autonomy, introspection, and trustworthy doctor-patient relationships (Table 1). Patients and health professionals acknowledged numerous HL components as determinants of transition success, including: language fluency and baseline education, extent of SLE-specific knowledge, self-efficacy (ability to make appointments, fill prescriptions, and obtain and utilize insurance), and accurate knowledge of personal medical history (Table 2). When asked how to improve the transition process, patients valued access to their secure online electronic medical record and recommended multimodal SLE-specific educational materials and increased access to social work services (Table 3). Health care professionals stressed the importance of early preparation for transition, utilization of mobile medical applications, and endorsed interventions such as lupus camp and increased partnership with psychologists and social workers (Table 3).

Table 1. Patient & Health Care Professionals' Perspectives on Patient Activation

Understanding disease severity: P: You guys [the clinical team] can only do so much that you can. It's really up to us because we're the ones that are going through it…if we want to be able to get better, get well, be here with our families, we're gonna have to put everything else to the side and realize that this is very, very serious.

- HP: Pediatric lupus can present terribly, so the disease could be extremely severe…these patients [with jSLE] are pretty well informed, but as kids get older, they do tend to be a little bit more complacent about their disease.

Range of activation: HP: Some [patients] are very responsible, and they want to be well so they take charge, and they know about their symptoms, they're good about telling you how they feel, but others are just not that interested.

Engagement in self-education: P: Listen and read up about your condition…Just find out different stuff that you probably don't even know that your condition deals with or affect…and be able to sit there and ask the doctor questions and tell them what you're going through….

- P: Now [in adult care] I actually ask when I don't understand something. I'm more into the conversation than when I was at [the pediatric center].

Realized autonomy: P: When you take your medicine, you feel complete. You feel like I've done everything that I'm supposed to do. So if there was something that was to happen to me, I could say that- well, I done everything I'm supposed to do.

- HP: Around the age of…16 I try to have a private conversation with the patients and talk to them about taking control of their management, their medications…on being an advocate for themselves.

Physician-Patient Alliance: P: They wouldn't prescribe it to me if it wouldn't help me. Now if I have an issue when I'm taking a medication and it makes me feel some type of way, I let it be known... because I know I gotta stay healthy, and if they give me something to make me stay healthy, I'm gonna take it. I had to learn it though. I was one of those teenagers that wasn't taking it at first, so [when] I transitioned up to an adult and I changed up and got better with myself.

- HP: I usually empower [patients]. I want them to know about their health history without relying on the parents. So I tell them they're in control.

P = Patient, HP = Health care professional

Table 2. Patient & Health Care Professionals' Perspectives on Health Literacy

Functional Health Literacy

Language fluency: HP: If they're not Spanish or English [speaking]- I don't know how these families navigate…it is amazing to me that they are doing as well as they are.

Baseline level of education: P: I think people who are in college or people who have higher education I think that helps a lot…I have family members who are like immigrants and…I see how hard it is for them to go to doctors and understand what's being done and understand …I definitely think education plays a big part in being able to properly transition

Interactive Health Literacy

SLE-specific knowledge

Jargon: I: Did you understand- when the doctor, the nurse or whoever told you it looked like you had lupus, did you understand what lupus was? P: No…. I still have a hard time knowing what [is going on] I: …did you ask your doctor about what it is that lupus is or anything like that or have anyone explain to you what it is? P: They have, but since it's doctor's talk, I still don't get it that much.

- P: … my doctors never told me what my medications do and so- and I think that could be [helpful too]. I think if you understand [it] in layman's terms… [in a way] that makes sense.

Time constraints: HP: It's a little bit sad because our office visits we can only achieve so much. I do feel confident they know their medications and their dose and how they're gonna get the meds, but I feel less confident that they are able to fully explain their disease manifestations.

- HP: If you get a 17-year-old that you tell all of a sudden you have lupus, there's a lot of education that has to happen in a short period of time…They just haven't had a chance to absorb all that information and then take ownership of it [prior to transitioning].

Self-efficacy

Delayed self-efficacy: I: Do [patients] typically have a pretty good understanding of where they're at health wise? HP: Not necessarily, and I think it comes from the part that some of these kids have been sick since they were very young, and it's the parents who have been making all the decisions.

Transition of family involvement: P: It [the transition period] was just really confusing because, everything was completely different and my mom- she's also the one that handles most of my medical care stuff so I didn't know much of what that process was like.

Obtaining/utilizing insurance: P: [The pediatric hospital] never really- they never touched base on like- Hey, you're gonna have to have insurance once you transition. We never really talked about it. We just talked about like- You're not gonna see us no more. You're gonna get new doctors. You know, that's basically what it was…

- HP: Many patients come to me and think they're going to be able to keep Medicaid forever and so sometimes I've had to kind of break down that- Actually, no, it's gonna cutoff when you're 19.

Insurance literacy: P: As far as navigating insurance I feel like that's something that's really still confusing to me…I've tried to fill out applications for myself, and it's like a really confusing process.

Personal Medical History Knowledge

Information preparedness: P: [During my first adult rheumatology appointment] my nurse talked to me about what medications I was taking and I personally- I don't know literally every medication I'm taking name from name, and I remember that was like- you're an adult, you should know this, your mom can't answer for you no more…and to me it was like- this is my first appointment…you have to give me time.

- HP: I want to know that [patients] can independently identify their disease that they have, like an appropriate understanding of their disease, they know what the treatment for that is, they can accurately report on these are the medicines I'm taking, this is how much I'm taking, this is when I take them, these are the side effects to look out for.

P = Patient, HP = Health care professional, I = Interviewer

Patient & Health Care Professionals' Perspectives on Health Literacy.

Conclusion: Patient activation and HL are acknowledged by patients and health care teams as substantially influencing pediatric-to-adult transition success among an uninsured/publicly insured urban jSLE cohort. Further research is needed to evaluate whether improved patient activation and HL positively influence jSLE transition outcomes.

Table 3. Patient and Health Care Team Members' suggestions to improve jSLE transition

Multimodal education: P: I like people to talk to me, explain the paper to me, and maybe just like a few drawings like on the consequences like flareups or your muscles being icky or stuff like that.

- P: [On education about medications] I think another way either probably be a pamphlet and the doctors just kind of summarize it a little bit, but the pamphlet will be for the teenager to have and, you know, to read it on their own time, and I think a video's also helpful too

***Early preparation*:** HP: If you start coming up with your [transition] plan early then that is huge…for example, are you thinking about going to college in the middle of nowhere? Are you sure that they're going to have a rheumatologist somewhere in the middle of nowhere?...Can you give yourself your own injections?

Effect of lupus camp: HP: I've never been to Lupus Camp, but the patients that I've had that have come back from camp seem to have a better understanding, they feel, you know, a little more accepted, they have met some people that have lupus too. They don't feel like they're the only ones out there having to take medicines and dealing with stuff.

Engagement with Social Workers: P: There's places where they assign caseworkers to people who kinda check in with them and making sure that they're like taking their med, making sure that they're going to their appointments, and if they need anything, helping provide them with those resources… figure out how to navigate that issue.

- HP: The adult rheumatology team is more limited in terms of resources. We don't have a social worker. We don't have physical therapies. We don't have a psychologist or other things that I know that they have available [in pediatrics].

Mobile medical applications: P: [The patient-facing EMR] helps a lot, I mean you can have full communication with your nurses…so to me MyChart is like- it was a- it's a pretty big help…

- HP: [Patients] can actually access all of their labs and all their medications and things like that. So it is inherently all accessible to them. However, that clearly benefits a certain subsegment who will be able to understand and utilize that system and then it doesn't benefit people that are not as capable of navigating that type of system.

P = Patient, HP = Health care professional

Patient & Health Care Team Members' Suggestions to Improve jSLE Transition.

Nailfold Capillary Microscopy in Children with Raynaud's Phenomenon. Potential Predictive Value of Capillary Loss for Future Connective Tissue Disease?

Claudette Farenhorst[1], Anniek Van Roon[1], Anne van Gessel[1], Alja Stel[1], Hendrika Bootsma[2], Wineke Armbrust[1] and Douwe J Mulder[1], [1]University of Groningen, University Medical Centre Groningen, Groningen, Netherlands, [2]University Medical Center Groningen, Groningen, Netherlands

SESSION INFORMATION

Session Date: Tuesday, November 9, 2021

Session Title: Pediatric Rheumatology – Clinical Poster III: Miscellaneous Rheumatic Disease (1614–1644)

Session Type: Poster Session D

Session Time: 8:30AM–10:30AM

Background/Purpose: Nailfold capillary microscopy (NCM) is a cornerstone in the diagnosis of Systemic Sclerosis (SSc) in adulthood. Although Raynaud's phenomenon (RP) is common in childhood, studies on diagnostic methods to differentiate between primary RP (PRP) and secondary RP (SRP) at a young age are scarce. The aim of this study was to determine the value of NCM in differentiating between PRP and SRP in children and adolescents with RP.

Methods: In this nested case-control study, 83 patients diagnosed with RP and having undergone NCM in childhood were retrospectively included. Based on whether they were diagnosed with a connective tissue disease (CTD) during follow-up, patients were classified as PRP or SRP. Patients were considered to have SRP if they had received a CTD diagnosis based on current ACR/ EULAR classification criteria: SSc, Mixed CTD (MCTD) systemic lupus erythematosus (SLE), adult and juvenile idiopathic inflammatory myopathies (IIM), rheumatoid arthritis (RA) primary Sjögren's syndrome (SS). NCM was judged visually by a vascular technician. PRP and SRP patients were compared on demographics, NCM, and serology. Variables associated with SRP were included in a multivariate logistic regression model. Predictive values were calculated for NCM, ANA positivity, and the combination of NCM and ANA positivity.

Results: At the time of the NCM, the mean age of the RP patients was 15.4±2.3 years (Table 1). Of these patients, 78% were classified as PRP and 22% as SRP at mean follow-up of 6.4±3.20 years. Of the SRP patients, 22% had an

Serology				
Positive ANA screening, n (%)*	21 (26)	9 (14)	12 (67)	**<0.001**
Positive ENA screening, n (%)**	12 (22)	3 (8)	9 (50)	**<0.001**

Notes: *The last column shows p-value (in bold: p < 0.10) for comparison between PRP and SRP.*

**1 missing value (1.5%). **2 missing values (2.4%).*

Abbreviations: *ANA = Antinuclear antibodies; NCM = nailfold capillary microscopy; PRP = Primary Raynaud's phenomenon; SRP = Secondary Raynaud's phenomenon; SSc = Systemic sclerosis.*

undifferentiated CTD, 22% had a MCTD, 17% had SLE, 11% had IIM, 6% had SSc, 6% had SS, 6% had incomplete SLE, 6% had incomplete SSc and 6% had incomplete SS. In total, half of patients had dilated capillaries, 25% had giant capillaries, 22% had capillary los, 17% had hemorrhages. Giant capillaries were confined to patients with SSc (1 out of 1), MCTD (3 out of 4), and IIM (2 out of 2). An SSc-like NCM pattern was observed in only 25%, which did not differentiate between those who developed CTD and those who did not. Of the NCM parameters, only capillary loss was associated with SRP (p=0.01). In a multivariate logistic regression model, capillary loss was an independent predictor (OR=3.98, CI 95% 1.22-12.99) (Table 2). After including ANA in the model, capillary loss was not an independent predictor of SRP. Capillary loss had a sensitivity of 44% and a specificity of 84% for SRP. PRP was correctly predicted in 99%, while SRP was correctly predicted in 27% of the cases by using capillary loss. ANA combined with capillary loss had a sensitivity of 67% and a specificity of 86% (Table 3).

Conclusion: Of all NCM findings, only capillary loss was predictive of SRP in children presenting with RP. Using NCM in childhood should be done with caution since the majority of children developing future CTDs present without specific NCM abnormalities. However, if present, capillary loss on NCM has a high specificity for future CTD. Because of this, we believe NCM could be useful as a screening method to exclude SRP when combined with serology. Our study underlines that future research should determine the predictive value of NCM and its specific abnormalities for individual CTDs in children presenting with RP.

Table 2. Multivariate logistic regression model showing predictive value of baseline variables for SRP excluding ANA positivity

Independent variables	B(SE)	OR (95% CI)	p-value
Age at NCM	-0.23 (0.12)	0.79 (0.63-1.00)	**0.05**
Capillary loss (<18/3mm)	1.38 (0.60)	3.98 (1.22-12.99)	**0.02**

***Notes**: Variables associated with SRP in the univariate analysis (p<0.10) were considered for inclusion in the multivariate logistic regression model. Variables included in the model were: age at NCM and capillary loss. The number of capillaries was not included because of its correspondence to capillary loss.*
***Abbreviations:** CI = confidence interval; NCM = nailfold capillary microscopy; OR = odds ratio; SE = standard error.*

Table 3. Predictive value of logistic regression models comprising different independent variables for prediction of SRP

	Sensitivity (%)	Specificity (%)	PPV (%)	NPV (%)	% correctly classified
ANA screening	67	86	57	90	82
Capillary loss (<18/3mm)	44	84	44	84	76
ANA screening + Capillary loss (<18/3mm)	67	86	57	90	82

***Notes:** A classification cut-off of 0.44 was used for all models.*

Abstract Number: 1636

Pediatric Rheumatologists' Perspectives on Diagnosis, Treatment and Outcomes of Sjögren Syndrome in Children and Adolescents

Rachel Randell[1], Sara Stern[2], Heather Van Mater[1], Scott Lieberman[3] and Matthew Basiaga[4], [1]Duke University, Durham, NC, [2]University of Utah, Salt Lake City, UT, [3]University of Iowa, Iowa City, IA, [4]Mayo Clinic, Inver Grove Heights, MN

SESSION INFORMATION
Session Date: Tuesday, November 9, 2021
Session Title: Pediatric Rheumatology – Clinical Poster III: Miscellaneous Rheumatic Disease (1614–1644)
Session Type: Poster Session D
Session Time: 8:30AM–10:30AM

Background/Purpose: Sjögren syndrome in children and adolescents often presents differently from adult disease, with many pediatric patients failing to meet adult criteria. Additionally, treatment and outcomes in children and adolescents are not well defined. The objective of this study is to describe the current perspectives of pediatric rheumatologists on diagnosis, treatment and outcomes of pediatric Sjögren syndrome (pedSS).

Methods: A voluntary survey containing 17 questions was distributed via email to providers (pediatric rheumatologists, fellows, and advanced care providers) participating in the Childhood Arthritis and Rheumatology Research Alliance and/or the American College of Rheumatology Childhood Sjögren's Study Group at the 2020 Annual Meeting. Descriptive statistics were used to report the findings.

Results: Between September 21 and November 16, 2020, 152 providers participated in the survey. The majority were pediatric rheumatology attendings from the United States. Most (85%) saw five or fewer, half (51%) saw one to two, and 15% had not seen any patients with pedSS in the past year. About three quarters (73%) felt pedSS is a spectrum of adult disease, while one quarter (24%) felt that pedSS is a distinct entity from adult disease. To make the diagnosis of pedSS, most (77%) use clinical judgment and/or experience guided by adult criteria. Parotitis, dry eye and/or dry mouth, and constitutional symptoms were among the most specific and most commonly observed symptoms. Arthralgias were more common but less specific, and dental caries were less common but more specific. Serologic tests were routinely used by >70% of providers for diagnosis. Amongst diagnostic tests, minor salivary gland biopsy was "always" used by 8% and "often" used by 43% of providers for diagnosis; other diagnostic tests were utilized less frequently. The most commonly prescribed systemic medications were hydroxychloroquine (85%), corticosteroids (67%), methotrexate (60%), rituximab (37%), and mycophenolate mofetil (34%). Providers perceived fatigue to be the most frequent symptom affecting quality of life, although only 15% would initiate systemic medication for fatigue. Providers also reported dryness and parotitis frequently affected quality of life for patients. Seven providers had observed malignancy in a patient with pedSS, including one death.

Conclusion: Pediatric rheumatologists are diagnosing and treating pedSS, although most providers see only a few patients per year. Most providers rely on clinical judgment and serologic testing for diagnosis, and some recognize pedSS as a distinct entity from adult disease. The most frequently prescribed systemic medications are hydroxychloroquine and corticosteroids, but substantial experience is reported with disease-modifying antirheumatic agents including methotrexate, mycophenolate mofetil, and biologics. Malignancy is observed in pediatric patients. More studies are critically needed to understand the natural history of pedSS, prognostic factors, and the impact of systemic medications on disease course and outcomes over time.

Covid-19 Infection Among Pediatric Rheumatology Patients: A Single Center Experience

Eric Kok, Martha Curry, Andrea Ramirez, Eyal Muscal and Marietta DeGuzman, Baylor College of Medicine, Houston, TX

SESSION INFORMATION
Session Date: Tuesday, November 9, 2021
Session Title: Pediatric Rheumatology – Clinical Poster III: Miscellaneous Rheumatic Disease (1614–1644)
Session Type: Poster Session D
Session Time: 8:30AM–10:30AM

Background/Purpose: Infection with novel coronavirus (COVID-19) in children, unlike adults, is generally asymptomatic or causes mild disease although some may develop severe illness. In particular, pediatric rheumatology patients may be at higher risk due to their immunosuppression. There are few publications describing COVID-19 infection among children with rheumatologic diseases. The Southwest region has had multiple COVID-19 surges and less prominent mitigation than other parts of the country with perhaps greater risks to children with chronic illness. This study reports on COVID-19 infections, risk factors for morbidities, and outcomes in pediatric rheumatology patients cared for in a large urban tertiary pediatric health system.

Methods: With approval from the Institutional Review Board of Baylor College of Medicine, a retrospective review was conducted of pediatric rheumatology patients followed at Texas Children's Hospital (TCH) from March 10, 2020 to April 10, 2021. We abstracted charts for demographic data, rheumatologic diagnoses, immunomodulatory therapies, COVID-19 infection and hospital course if admitted. The SlicerDicer Epic tool (Madison, WI) was used to assess number of active patients seen during the study period. Analyses were performed with Stata v16.1. Categorical variables were compared using Fisher's Exact test.

Results: There were approximately 1593 pediatric rheumatology patients actively followed during the study, including 800 JIA patients and 204 lupus patients. During the study period, 43 had COVID-19 infection (43/1593, 2.7%), with an incidence of 2.1% in JIA patients and 5.9% in lupus patients. Table 1 summarizes demographic and clinical characteristics. Twenty-one held their rheumatologic therapy; of these, 5 patients (24%) had a flare of their condition. No patient developed MIS-C.

Eight patients were hospitalized, 3 (37.5%) whom required intensive care. The median length of stay was 6.5 days (1-81), and 8 days (2-42) for ICU patients. Majority were Hispanic (75%), and 6 (75%) were female. There was a statistically significant association between obesity with hospitalization as well as Steroid dose of ≥10 mg; all 3 ICU patients were taking ≥10 mg. No association was found between specific DMARD or biologic and hospitalization.

The characteristics and course of 3 ICU patients, 2 with SLE and 1 with a rare autoinflammatory syndrome, are presented in Table 2. All presented with fever ≥101°F (≥38.3°C), and 2 required supplemental O_2. One lupus patient required mechanical ventilation and passed away from respiratory failure.

Conclusion: In a county with a high COVID-19 prevalence, only a small percentage of pediatric rheumatology patients presented to medical care with confirmed infections. Most had mild courses that did not affect their underlying

Table 2. Characteristics and clinical course of 3 patients admitted to the ICU for COVID-19

Patient	Patient 1	Patient 2	Patient 3
Age at time of infection (years)	9.9	12.8	13.9
Gender	Female	Female	Female
Diagnosis	NEMO* , a rare autoinflammatory syndrome	SLE	SLE
Associated complications	Severe immunodeficiency, Long-term steroid use	Antiphospholipid antibody (+), hemolytic anemia	Hypogammaglobulinemia, Lupus Anticoagulant Hypo-prothrombinemia Syndrome, Hypertension
Current steroid dose (mg)	10	10	50 - additionally received recent steroid pulse
Immunomodulatory drugs	Anakinra, IVIG	Adalimumab, methotrexate, hydroxychloroquine	Rituximab (2 months prior to infection), Mycophenolate mofetil, Hydroxychlorquine
Presenting symptoms	Fever Tmax 101°F (38.3°C), loss of taste and smell, myalgias	Fever Tmax 101°F (38.3°C) , chest pain, shortness of breath	Fever Tmax 102.9°F (39.4°C), shortness of breath, septic shock
Maximum respiratory support	High flow nasal cannula 12 L	Room air	Intubation, mechanical ventilation, oscillator
Clinical course	Severe pneumonia, pancytopenia	Uneventful course, stable on RA. Nomal cardiopulmonary workup. Diagnosed with lupus flare.	Severe pneumonia, respiratory failure, complications including recurrent pulmonary hemorrhage, and decompensation
COVID-19 therapies	Dexamethasone, Remdisivir, Anakinra, convalescent plasma	Dexamethasone	Dexamethasone, Remdesivir, Convalescent Plasma, IVIG, Anakinra,Lovenox
Outcome	Recovered	Recovered	Passed away

*NEMO - Nuclear factor-kappa B Essential Modulator (NEMO) deficiency syndrome, a rare autinflammatory immunodeficiency

disease. As per adult experiences, obesity and higher steroid doses were observed in admitted patients. Children with SLE and from underrepresented minorities represented a large proportion of those affected, suggesting a significant role of socioeconomic factors with increased risk of exposures. The effect of vaccine protection on pediatric rheumatology patients will be studied during the upcoming year.

Abstract Number: 1638

Clinical Manifestations of COVID-19 and Its Impact on Pediatric Patients with Rheumatic Disease

Belina Yi, Sindhu Mohandas and Michal Cidon, Children's Hospital Los Angeles, Los Angeles, CA

SESSION INFORMATION
Session Date: Tuesday, November 9, 2021
Session Title: Pediatric Rheumatology – Clinical Poster III: Miscellaneous Rheumatic Disease (1614–1644)
Session Type: Poster Session D
Session Time: 8:30AM–10:30AM

Background/Purpose: Spread of SARS-COV-2 during the COVID-19 pandemic has raised concerns for patients with rheumatic disease. Rheumatology patients have an increased risk of developing infectious complications due to their underlying disease and chronic use of immunomodulating medications. Reports suggest children with rheumatic disease are not at an increased risk of developing severe symptoms from acute COVID-19; however, there are growing concerns that SARS-COV-2 may trigger their underlying disease, causing exacerbation or new diagnosis of diseases. We report clinical manifestations of SARS-COV-2 and its impact on underlying rheumatic disease activity on pediatric rheumatology patients at our tertiary care center.

Methods: Retrospective chart review of the Children's Hospital Los Angeles rheumatology clinic population from March 2020 to May 2021 identified pediatric rheumatology patients with reported positive SARS-COV-2 qualitative PCR test and/or positive SARS-COV-2 antibody test. Data including demographics, rheumatic disease diagnosis, medications, co-morbidities, acute symptoms of COVID-19, and rheumatic disease complications were collected. Acute COVID-19 manifestations and rheumatic disease complications (and/or exacerbations) were categorized into numeric scale of 0-3 (COVID-19 manifestations: 0 = No symptoms, 1 = Mild symptoms not requiring hospitalization, 2 = Respiratory distress requiring floor admission, 3 = Respiratory failure requiring intensive care unit (ICU) admission; Rheumatic disease complications: 0 = No flare, 1 = Flare with no escalation of treatment, 2 = Flare requiring escalation of treatment, 3 = Flare requiring hospitalization).

Results: A population of 82 patients of ages 0 to 21 were identified via chart review. Their demographics, diagnosis, medications are included in Table 1. The majority of patients were female (76%) and between ages of 16 to 21 (51%). Most had diagnosis of juvenile idiopathic arthritis (38%) and were taking methotrexate (22%). There were 14 patients with identified co-morbidities, and the most common co-morbidity was obesity (78%). Acute COVID-19 severity scores are demonstrated in Table 2. Most patients scored 1 (55%), followed by 0 (28%). Rheumatic disease complications scores are demonstrated in Table 3. Most patients scored 0 (77%), followed by 3 (13%).

Conclusion: Our findings were consistent with previous reports that many pediatric patients with rheumatic disease experience mild or no symptoms of acute COVID-19. Most patients did not have complications or exacerbations of their underlying disease after contracting SARS-COV-2, although there were cases that required

A Comparison of Cardiovascular Health Indicators in Children with Juvenile Idiopathic Arthritis Who Meet and Do Not Meet the Physical Activity Guidelines

Madelyn Byra[1], Nicole Proudfoot[2], Si Ru Chen[1], Maureen MacDonald[3], Tania Cellucci[4], Michelle Batthish[5], Brian Timmons[6] and Joyce Obeid[6], [1]Child Health & Exercise Medicine Program, McMaster University, Hamilton, ON, Canada, [2]Child Health & Exercise Medicine Program, McMaster University; Department of Kinesiology, McMaster University, Hamilton, ON, Canada, [3]Department of Kinesiology, McMaster University, Hamilton, ON, Canada, [4]McMaster Children's Hospital, Hamilton, ON, Canada, [5]McMaster University, Hamilton, ON, Canada, [6]Child Health & Exercise Medicine Program, McMaster University; Department of Pediatrics, McMaster University, Hamilton, ON, Canada

SESSION INFORMATION

Session Date: Tuesday, November 9, 2021

Session Title: Pediatric Rheumatology – Clinical Poster III: Miscellaneous Rheumatic Disease (1614–1644)

Session Type: Poster Session D

Session Time: 8:30AM–10:30AM

Background/Purpose: Children with juvenile idiopathic arthritis (JIA) engage in less physical activity than their healthy peers. The Canadian 24-h Movement Guidelines recommend children take part in at least 60 minutes of moderate-to-vigorous physical activity (MVPA) per day to help maintain optimal health. Meeting these physical activity guidelines may be even more important for children with JIA, as research suggests they may be at increased risk for accelerated cardiovascular disease. The aim of this study was to compare cardiovascular health indicators in children with JIA who meet and do not meet the MVPA guidelines.

Methods: Children with single diagnosis of JIA between 7 to 17 years of age were recruited from McMaster Children's Hospital and completed 2 study visits. During Visit #1, height, weight, and body fat were measured. Participants then wore an accelerometer for 7 consecutive days to estimate habitual levels of MVPA. During Visit #2, cardiovascular health indicators were assessed in a fasted state. Carotid artery b-stiffness and intima-media thickness (cIMT) were measured by ultrasound. Whole body arterial stiffness was assessed as carotid – foot pulse wave velocity (PWV). Endothelial function was measured using flow-mediated dilation (FMD) of the brachial artery. Participants were divided into two groups based on meeting (MET) or not meeting (NOT) guidelines of an average of ≥60-min MVPA per day. Participant characteristics, carotid artery b-stiffness and cIMT for MET and NOT were compared using independent sample t-tests, while PWV and FMD were assessed using analysis of covariance, with height or baseline artery diameter as a covariate, respectively.

Results: Twenty-one participants (12 girls) completed this study. Nine children (43%) were in the MET group and had a mean MVPA of 72.9±16.2 min/day, while 12 children (57%) were in the NOT group and engaged in 38.6±13.2 min/day. There were no between group differences in age, height, weight, or body fat (Table 1). There were no between group differences in cardiovascular health indicators including carotid b-stiffness, cIMT and relative FMD (Table 2). There was a trend towards MET having better PWV than NOT (4.8±0.42 m/s vs. 5.2±0.35 m/s, $F(1,18)=2.7$, $p=0.083$, partial $h^2 = 0.129$; Figure 1).

Conclusion: Over half of children with JIA in our sample did not meet physical activity guidelines. While we did not find any significant differences in cardiovascular health indicators between children who meet and did not meet the MVPA guidelines, these results, and particularly PWV, may be underpowered to detect differences. These findings highlight the need for further investigation of physical activity and cardiovascular health in JIA.

This study was funded by a Grant-in-Aid from the Heart and Stroke Foundation of Canada.

Table 1: Participant Characteristics

	MET	NOT	T (df)	p
N	9	12	-	-
Age (years)	11.9 ± 2.6	13.2 ± 3.1	1.32 (19)	0.873
Height (m)	1.50 ± 0.13	1.58 ± 0.14	1.038 (19)	0.572
Weight (kg)	48.9 ± 18.7	55.4 ± 18.2	0.806 (19)	0.883
Body fat (%)	25.2 ± 10.5	29.2 ± 8.6	0.954 (18)	0.505
MVPA (min/day)	72.9 ± 16.2	38.6 ± 13.2	-5.36 (19)	<0.001

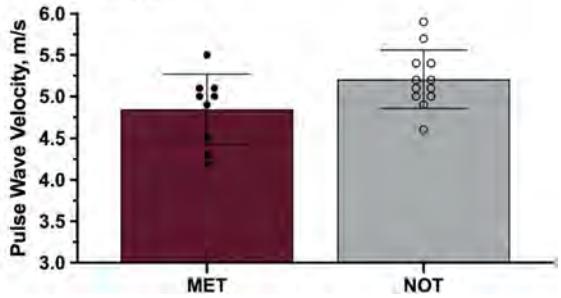
df = degrees of freedom; MVPA = moderate-to-vigorous physical activity. Data are presented as mean ± standard deviation.

Table 2: Cardiovascular Health Indicators

	MET	NOT	T or F (df)	p
N	9	12	-	-
Carotid artery β-stiffness (AU)	3.9±0.9	4.3±1.2	0.804 (19)^{T}	0.598
cIMT (mm)	0.38±0.03	0.39±0.04	0.416 (19)^{T}	0.349
Relative FMD (%)	8.3±2.2	7.3±1.7	0.194 (12)^{F}	0.732

cIMT = carotid intima media thickness; FMD = flow-mediated dilation. Data are presented as mean ± standard deviation. T = T statistic (degrees of freedom); F = F statistic (degrees of freedom).

Figure 1: PWV in MET vs. NOT



Data are presented as mean ± SD, with individual data displayed in closed circles for MET and open circles for NOT.

Multisystem Inflammatory Syndrome in Children at Two Tertiary Hospitals in Cape Town, South Africa: Clinical Phenotype and Distinguishing Features from Similar Acute Inflammatory Conditions

Claire Butters[1], Deepthi Abraham[2], Heidi Facey-Thomas[1], Debbie Abrahams[1], Ayodele Faleye[3], Helena Rabie[2], Christiaan Scott[4], Liesl Zühlke[5] and Kate Webb[6], [1]Paediatric Rheumatology, University of Cape Town, Cape Town, South Africa, [2]Tygerberg Hospital, Stellenbosch University, Cape Town, South Africa, [3]Lagos state university teaching hospital Ikeja, Lagos, Nigeria, [4]University of Cape Town, Faculty of Health Science, Cape Town, South Africa, [5]Paediatric Cardiology, University of Cape Town, Cape Town, South Africa, [6]University of Cape Town, Cape Town, South Africa

SESSION INFORMATION

Session Date: Tuesday, November 9, 2021

Session Title: Pediatric Rheumatology – Clinical Poster III: Miscellaneous Rheumatic Disease (1614–1644)

Session Type: Poster Session D

Session Time: 8:30AM–10:30AM

Background/Purpose: Distinguishing Multisystem Inflammatory Syndrome in Children (MIS-C) associated with Severe Acute Respiratory Syndrome Coronavirus 2 (SARS-CoV2) from acute, pyrexial childhood illness can be challenging. We present a case series from two tertiary hospitals and compare the clinical phenotype of MIS-C with mimicking systemic inflammatory disorders.

Methods: Children with MIS-C admitted to two tertiary hospitals in a province between 22 June 2020 and 5 March 2021 were recruited. At one of the two hospitals, children with suspected MIS-C with an ultimate alternate diagnosis (inflammatory controls) were also recruited. Clinical data were collected. Statistics were performed using SPSS V. 27.

Results: During the time period, 70 children had confirmed MIS-C and 27 suspected MIS-C cases had an alternate diagnosis including typhoid, tuberculosis, sepsis and appendicitis among others. Sixty five percent of children with MIS-C had no SARS-CoV2 contact but all had evidence of SARS-CoV2 exposure by antibody (90%) or PCR tests (14%). There was no difference in age, sex or ethnic distribution between children with MIS-C and inflammatory controls (Table 1). The most common presenting features of MIS-C were fever (100%), tachycardia (99%), rash (86%), conjunctivitis (79%), and abdominal pain (60%). Compared to inflammatory controls, the presence of tachycardia, abdominal pain and conjunctivitis resulted in 96%; 93% and 91% respectively increased odds of a diagnosis of MIS-C after controlling for all other presenting features. Compared to inflammatory controls, children with MIS-C had lower platelets, sodium and albumin and higher troponin-T and pro-brain natriuretic peptide (pro-BNP)(Table 1).

The median minimum ejection fraction in MIS-C was lower than inflammatory controls (52% vs 63%, p=0.048). Ninety four percent of MIS-C patients received at least one dose of intravenous immunoglobulin (IVIG), 63% required methylprednisolone and 6% received IL-6 inhibition. Children with MIS-C were more commonly admitted to the intensive care unit (ICU) compared to inflammatory controls (38% vs 12.5%, p=0.013) although there was no difference in mean hospital stay which was 8.2 days in MIS-C. There was no difference in requirement for inotropes (p=0.142) or ventilation (p=0.493). No children died.

Conclusion: Distinguishing MIS-C from acute infectious or inflammatory causes of childhood fever may be challenging. The presence of conjunctivitis, tachycardia or abdominal pain associates with higher odds of MIS-C in this pop-

Table 1

	MIS-C N=70	Inflammatory Controls N=27	p-value
Median age in years (IQR)	7.0 (2.4, 9.7)	5.3 (2.0, 9.5)	0.53
Sex: male (%)	36 (51.4)	16 (59.2)	0.506
Ethnicity: black African (%)	43 (61.4)	14 (51.8)	0.216
Minimum platelets ($x10^9$/L)	219.2	300.4 N=25	0.021*
Minimum sodium (mmol/L)	128.9	133.8 N=26	<0.001*
Minimum albumin (g/L)	27.6 N=65	32.1 N=16	0.015*

Long-term Cardiovascular Disease and Mortality Following Kawasaki Disease in Childhood: A Systematic Review

Francis Lao[1], Cal Robinson[2], Megan Schlorff[1], Jocelyne Ewusie[3], Karen Beattie[1] and Michelle Batthish[1], [1]McMaster University, Hamilton, ON, Canada, [2]The Hospital for Sick Children, Hamilton, ON, Canada, [3]St Joseph's Healthcare, Hamilton, ON, Canada

SESSION INFORMATION

Session Date: Tuesday, November 9, 2021

Session Title: Pediatric Rheumatology – Clinical Poster III: Miscellaneous Rheumatic Disease (1614–1644)

Session Type: Poster Session D

Session Time: 8:30AM–10:30AM

Background/Purpose: Kawasaki Disease (KD) is a common vasculitis of childhood, with an annual North American incidence of 20-26 per 100,000 children (< 5 years of age). Coronary artery aneurysms (CAAs) develop in 25% of

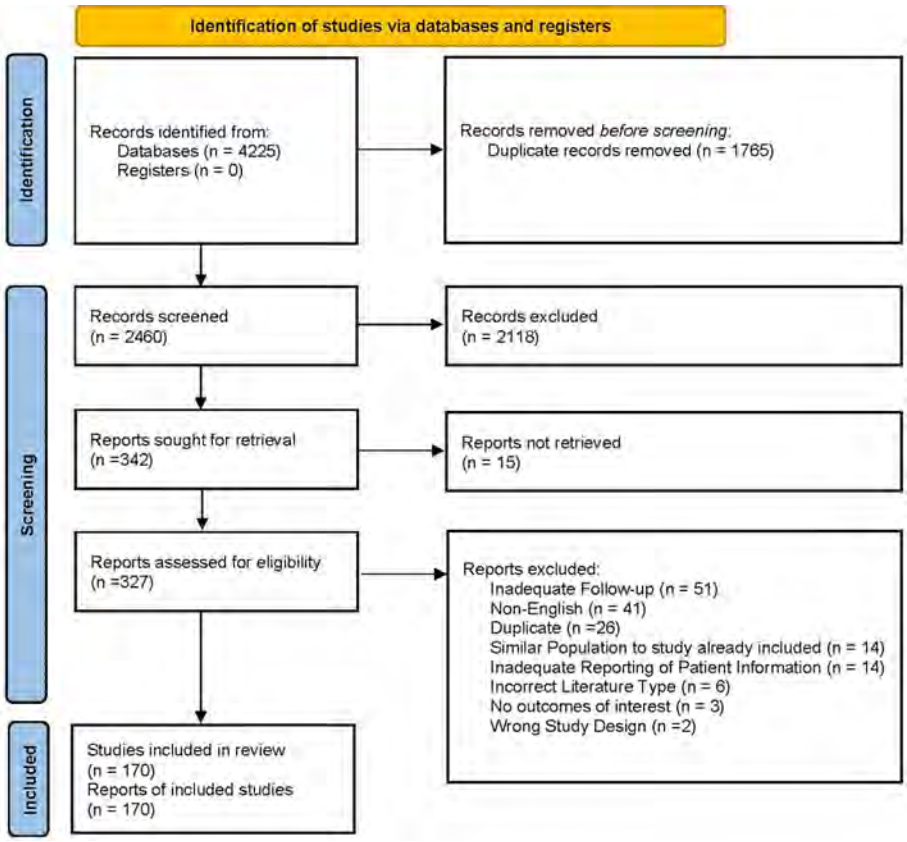

Figure 1. PRISMA flow diagram of study selection.

untreated KD patients. There are no precise estimates of the long-term cardiovascular (CV) events following childhood KD diagnosis. We aimed to determine the incidence of long-term CV events and mortality following KD diagnosis.

Methods: A systematic search of MEDLINE, EMBASE, CINAHL, Cochrane, and Web of Science databases was performed through 2019. Initial screening was performed by 2 independent reviewers. Inclusion criteria included English-only publications, patients 0-18 years at KD diagnosis, minimum follow-up >1 year, and ≥10 patients included in original clinical data. CV events (myocardial infarction (MI), heart failure (HF), cardiac arrest) and mortality were extracted and pooled for analysis. The Newcastle-Ottawa Scale assessed study quality focusing on participant selection, comparability, and measurement of outcome or ascertainment of exposure. This review was submitted to PROSPERO on November 23, 2019 and registered on April 28, 2020.

Results: Of 4225 articles identified, 170 were included in the review (Figure 1). The distribution of study designs was: 123 retrospective cohort studies, 54 prospective cohort studies, 2 case series, 13 cross-sectional studies, 1 case control study, and 4 interventional studies. A total of 167 articles had quality assessment scores ≥6 out of a maximum score of 9. The number of studies reporting coronary artery stenosis, coronary artery thrombosis, coronary artery occlusion, CV events and death are displayed in Table 1.

Among 86,812 KD patients across 110 studies, there were 1519 events of MI, HF, or cardiac arrest (1.8%). A subgroup analysis was performed, stratifying studies by CAA status of participants: no/few CAAs (≤ 10% of study participants), some CAAs (11-99% of study participants), all CAAs (100% of study participants). This was performed to determine the effect of CAAs on incidence of CV events and mortality. Composite CV events occurred in 457 of 29,393 (1.55%)

Table 1. Number of studies reporting at least one case of coronary artery stenosis/thrombosis/occlusion, CV events and death

	# studies reporting ≥1 case
Coronary artery stenosis	72
Coronary artery thrombosis	40
Coronary artery occlusion	58
Myocardial Infarction	99
Heart Failure	25
Cardiac Arrest	25
Death	70

Table 2. Incidence of cardiovascular events (myocardial infarction, heart failure, and cardiac arrest) and all-cause mortality

	Cardiovascular Events (MI, HF, Cardiac Arrest)				All-Cause Mortality			
Characteristic of Studies	# of studies	# of events	# of patients	Incidence	# of studies	# of deaths	# of patients	Incidence
All Studies	110	1519	86812	1.75%	99	1137	106497	1.07%
# of CAAs reported	99	1405	48412	2.90%	87	346	52092	0.66%
# of CAAs Not Reported	11	116	38495	0.30%	12	791	54405	1.45%
No/Few patients have CAA (≤ 10% of study participants))	9	457	29393	1.55%	10	75	33845	0.22%
Some patients have CAAs (11-99% of study participants)	49	502	15049	3.34%	41	157	14299	1.10%
All patients have CAAs (100% of study participants)	41	446	3970	11.23%	36	114	3948	2.89%

in no/few CAAs study participants, 502 of 15,049 (3.34%) some CAAs study participants, and 446 of 3970 (11.23%) all CAAs study participants (Table 2).

Across 99 studies, 1137 of 106,497 KD (1.07%) patients died. When stratified based on the proportion of patients in the study with CAAs: death occurred in 75 of 33,845 (0.22%) in no/few CAAs study participants, 157 of 14299 (1.10%) in some CAAs participants, and 114 of 3948 (2.89%) in all CAAs study participants (Table 2).

Conclusion: This study comprises the largest review of long-term cardiovascular outcomes of KD. Children with KD are at risk of developing long-term CV events, including MI, heart failure and cardiac arrest. Those with coronary artery aneurysms are especially at higher risk. Further studies are needed to better define these risks.

Baseline Body-mass-index and Risk for Obesity in Children with Rheumatic Disease on Moderate to High-dose Prednisone Therapy

Roberta Berard[1], Michael Rieder[2], Erkan Demirkaya[2], Michael Miller[3] and **Renee Pang**[2], [1]London Health Sciences Centre, London, ON, Canada, [2]University of Western Ontario, London, ON, Canada, [3]University of Western Ontario, Children's Research Institute, London, ON, Canada

SESSION INFORMATION
Session Date: Tuesday, November 9, 2021
Session Title: Pediatric Rheumatology – Clinical Poster III: Miscellaneous Rheumatic Disease (1614–1644)
Session Type: Poster Session D
Session Time: 8:30AM–10:30AM

Background/Purpose: Prednisone is a glucocorticoid (GC) medication commonly used in moderate (>7.5 mg per day) to high doses (≥ 1 mg/kg/day) for children with moderate to severe presentations of rheumatic disease. Adverse effects (AE) to GCs impose a significant burden on health and quality of life. We sought to evaluate a possible relationship between baseline patient body-mass-index (BMI) measure and development of select GC-mediated toxicity within the first 12 months of prednisone therapy. Secondary outcomes were to examine rates of GC-mediated hypertension, osteopenia, and osteoporosis.

Methods: We performed a retrospective chart review on children with rheumatic disease age 17 years and younger treated with moderate and high-dose prednisone therapy at a single Canadian academic hospital between January 1, 2010 and December 31, 2019. Demographic variables collected included diagnosis, age, sex, ethnicity. Clinical variables collected include weight, height, and body-mass-index (BMI), hepatitis (transaminases greater than two-fold upper normal limit), proteinuria (>0.1 g/L), and presence of hypoalbuminemia (< 38g/L) at baseline. We collected weight, height, and body-mass-index (BMI), at 6 and 12 months, the maximum BMI, and transformed them to z-scores according to the World Health Organization's Child Growth standards. Cumulative prednisone dose (mg/kg/12 months), total days on prednisone in the first 12 months of therapy were also obtained, in addition to bone-mineral-density scores after 12 months of prednisone therapy where available.

Baseline characteristics which were significant for the subsequent development of obesity during the first 12 months at the bivariate level ($p < 0.05$) were included as predictors of obesity in separate logistic regression analyses. In each regression analysis, we also adjusted for baseline BMI, and for confounding variables of hepatitis, hypoalbuminemia

(albumin less than 38 grams per litre), proteinuria and prednisone dose. All analyses were performed using SPSS v.26 (IBM Corp., Armonk, NY, USA), and p-values < 0.05 were considered statistically significant.

Results: Seventy-six charts were reviewed, and 73 patients met criteria for analysis. The diagnoses included 20 (26.3%) systemic JIA, 12 (15.8%) JIA, 24 (31.6%) SLE, and 8 (10.5%) JDM patients. Rates of adverse effects were as follows: obesity 27.6%, hypertension 34.2%, symptomatic vertebral fractures 2.2%, long-bone fractures 6.8%. Of 25 patients who had bone mineral density studies, 3 (12%) met criteria for pediatric osteoporosis. Greater BMI at baseline was associated with greater total weight gain (OR 3.358, 95% CI = [1.847-6.103, p< 0.001). Normal albumin (> 38 g/L was negatively associated with GC-related obesity (OR 0.349, 95% CI [0.132-0.921], p=0.035).

Conclusion: Greater baseline patient BMI was a predictor of GC-related obesity initiated with moderate to high-dose prednisone therapy in children with rheumatic disease. Further work is required to determine methods for individualized prednisone dosing and counseling and behavioral interventions to mitigate risk for weight gain.

Abstract Number: 1643

Increased Incidence of Pediatric SLE and Other Interferon Activated Diseases During COVID-19 Pandemic

Xinyu Dou[1], David Kaelber[2] and Hulya Bukulmez[1], [1]MetroHealth Medical Center, Case Western Reserve, Cleveland, OH, [2]The MetroHealth System Campus of Case Western Reserve University, Cleveland, OH

SESSION INFORMATION
Session Date: Tuesday, November 9, 2021
Session Title: Pediatric Rheumatology – Clinical Poster III: Miscellaneous Rheumatic Disease (1614–1644)
Session Type: Poster Session D
Session Time: 8:30AM–10:30AM

Background/Purpose: COVID-19, as a member of the Coronavirus family, has been described to trigger host immune response via type I interferon (IFN) signaling pathways with variable degrees. Some patients have mild IFN activation, while some develop hyperinflammation. In pediatric patient population COVID-19 has been a mild infection partially explained by the robust acute innate system activation early in the clinical phase of the infection. Etiopathogenesis of rheumatologic diseases like systemic lupus erythematosus (SLE) also involves IFN dysregulation and hyperinflammation as well, so do juvenile and adult dermatomyositis (JDM, DM), polymyositis (PM), systemic sclerosis (SSc) and scleroderma (SD). We hypothesized that COVID-19 infection may increase the incidence of autoimmune rheumatologic diseases that are known to have etiopathogenetic link with type I IFN-dysregulation.

Methods: Data were obtained from the COVID-19 Research Network of TriNetX, a real-world database collected from electronic health records in 61 health-care organizations globally. We created queries of patients who had been diagnosed with rheumatologic diseases (SLE, JDM, DM, PM, and SSc) one year before the pandemic (defined as March 1st, 2019 to February 29th, 2020) and during the pandemic (defined as March 1st, 2020 to February 28th, 2021). For patients diagnosed with SLE, two separate queries were created to divide patients into pediatric and adult population. We compared the incidence of these rheumatologic diseases during and before COVID-19 pandemic and their incidence in COVID-19 affected and unaffected population. We compared COVID-19 incidence in these rheumatologic diseases to those in regular population. We used chi square statistics for establishing significance.

Results: Incidence of pediatric SLE and JDM increased by 22% and 44% respectively during the pandemic as compared to before the pandemic. Incidence of adult SLE, PM, DM, SSc decreased by 8%, 20%, 10% and 15% accordingly (Table 1).

COVID-19 incidence in pediatric SLE patients (3.2%) is greater than COVID-19 incidence in regular pediatric population (1.2%). COVID-19 incidence in adult SLE (4.4%), PM (5.4%), DM (3.6%) and SSc (3.7%) patients is greater than COVID-19 incidence in general adult population (2.8%) (Table 2).

Incidence of pediatric and adult SLE in COVID-19 affected population were significantly higher when compared to COVID-19 unaffected population (pediatric SLE 0.027% vs 0.009%, p=0.00033; adult SLE 0.13% vs 0.077%, $p < 0.00001$) (Table 3).

Conclusion: Those pediatric rheumatologic diseases known to have dysregulation in type I interferon signaling showed increased incidence rate during COVID-19 pandemic. Our results indicate that COVID-19 infection may induce type I interferon activation in children and may result in particular autoimmune disease activity regulated with abnormal interferon pathway signaling. Further studies of pediatric patients affected by COVID-19 infection who

Storytelling of Young Adults with Chronic Rheumatologic Illnesses: A Pilot Study

Aviya Lanis[1], Emilee Tu[2], Malki Peskin[3], Maryann Melendez[1], Gabriel Tarshish[4], Alisha Akinsete[5], Alicia Hoffman[1], Kathleen Kenney-Riley[6], Tamar Rubinstein[7] and Dawn Wahezi[1], [1]Children's Hospital at Montefiore, Bronx, NY, [2]Albert Einstein School of Medicine, Bronx, NY, [3]Montefiore, Bronx, NY, [4]Children's Hospital at Montefiore, New York, NY, [5]Montefiore, Wayne, NJ, [6]Mercy College, Dobbs Ferry, NY, [7]Albert Einstein College of Medicine, White Plains, NY

SESSION INFORMATION

Session Date: Tuesday, November 9, 2021

Session Title: Pediatric Rheumatology – Clinical Poster III: Miscellaneous Rheumatic Disease (1614–1644)

Session Type: Poster Session D

Session Time: 8:30AM–10:30AM

Background/Purpose: Storytelling is a universal form of communication that allows expression of experiences. Narrative medicine can be described as a subset of storytelling in which patients reconstruct their medical experiences through written or oral portrayals of emotions and perspectives. By sharing these experiences, research has shown participants build experiential knowledge and a mutual depiction of illness while creating a sense of belonging. Currently, there are limited available group-sharing opportunities for pediatric patients with chronic rheumatologic illnesses, a population with a high prevalence of mental health symptoms and worse health-related quality of life. The current study aims to assess the feasibility of a storytelling intervention in this patient population. The primary hypothesis was that the study would be feasible, where 80% of all recruited participants were expected to complete all surveys as well as post-participation interviews.

Methods: This is a mixed methods study of English-speaking patients with chronic rheumatologic diseases, 13-21 years old, followed in the pediatric rheumatology clinic at the Children's Hospital of Montefiore in the Bronx, NY. Participants completed an hour-long interactive virtual creative writing session focused on patient experience with chronic disease. Pre- and post- questionnaires were completed to assess potential risks and benefits of storytelling, and post-participation video interviews were completed to assess personal experiences of participating in the storytelling session. Questionnaires included Peds Quality of Life Inventory (PedsQL), Pediatric Symptom Checklist-17 (PSC-17), Patient Health Questionnaire-9 (PHQ-9), and the Child Attitude Toward Illness Scale (CATIS). Post-participation interviews were reviewed by three independent researches using qualitative software (Dedoose) for coding and thematic analysis.

Results: Thirteen female patients, ages 14-21 years, were divided amongst four creative writing sessions, with groups ranging from two to six participants per session. Diseases included lupus, juvenile dermatomyositis, systemic sclerosis, juvenile idiopathic arthritis, polyarteritis nodosa, and amplified musculoskeletal pain syndrome. Twelve of the 13 patients completed pre-study questionnaires and 10 completed post-study questionnaires, with 100% completion of the post-participation interviews. PedsQL surveys showed a trend toward improvement in physical health, with pre-participation median 64.95 [IQR 56.25-79.95] and post-participation median 78.15 [IQR 62.5-93.8]. Preliminary analysis revealed no significant difference between pre- and post-scores for any of the questionnaires. Preliminary

post-participation interview analysis showed thematic domains of writing motivation, prior writing experience, illness experience, relating to others, relationship with providers, and support.

Conclusion: Creative writing is an intervention that is feasible and acceptable for youth with rheumatologic illnesses. Further evaluation is needed to understand if such interventions improve mental and physical symptoms, and children's attitude towards their illnesses.

SESSION INFORMATION

Session Date: Tuesday, November 9, 2021

Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster IV: Outcomes, Trajectory of Disease, & Epidemiology (1645–1673)

Session Type: Poster Session D

Session Time: 8:30AM–10:30AM

Background/Purpose: Adipokines are metabolic regulators and are associated with adverse outcomes in chronic conditions and among older adults. Elevations in one adipokine, adiponectin, have been associated with radiographic progression in rheumatoid arthritis (RA), suggesting an association with disease severity. We hypothesized that chronic inflammation leads to metabolic dysregulation and elevations in adipokines, which might serve as important

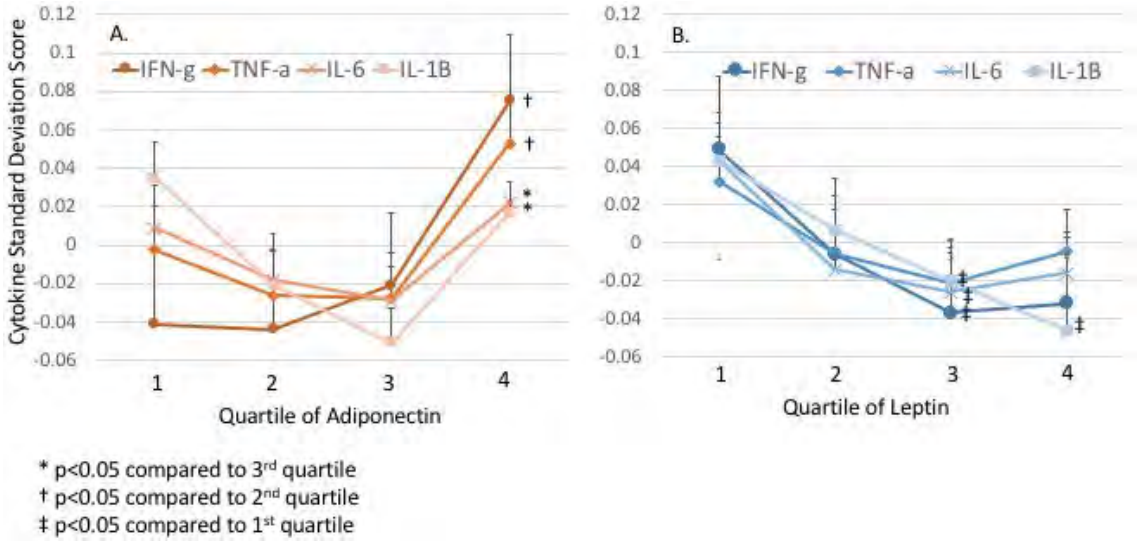

Figure 1. Line plots showing inflammatory cytokine levels by A) adiponectin quartile, and B) leptin quartile.

biomarkers and predict adverse outcomes. We assessed whether adiponectin and leptin were associated with higher overall and cause-specific mortality in RA independent of other known risk factors.

Methods: Participants were adults with physician-confirmed RA, enrolled in a Veteran's Affairs study, enrolled between 2003 and 2018. Adipokines and inflammatory cytokines (IFN-g, TNF, IL-6, IL-1b) were measured as part of a multi-analyte panel on banked serum from enrollment and were log-adjusted and standardized (per 1 SD). Dates of death and causes of death were derived from the Corporate Data Warehouse and the National Death Index. Covariates were derived from medical record databases, biorepository data, and registry databases. Levels of inflammatory cytokines were assessed over adipokine quartiles. Multivariable Cox proportional hazard models evaluated associations between clinical factors and all-cause and cause-specific mortality adjusting for demographics, comoribidity, and RA disease characteristics, including RA disease activity, at enrollment.

Results: A total of 2583 participants were included in this analysis with mean (SD) age of 71.9 (10.3). There were 960 deaths among 19,178 person-years of follow-up. The most common causes of death were cardiovascular (N=215), cancer (N=154), and respiratory (N=118). Higher adiponectin levels at enrollment were associated with older age, male sex, white race, lower BMI, higher rates of seropositivity, higher rates of radiographic damage, longer

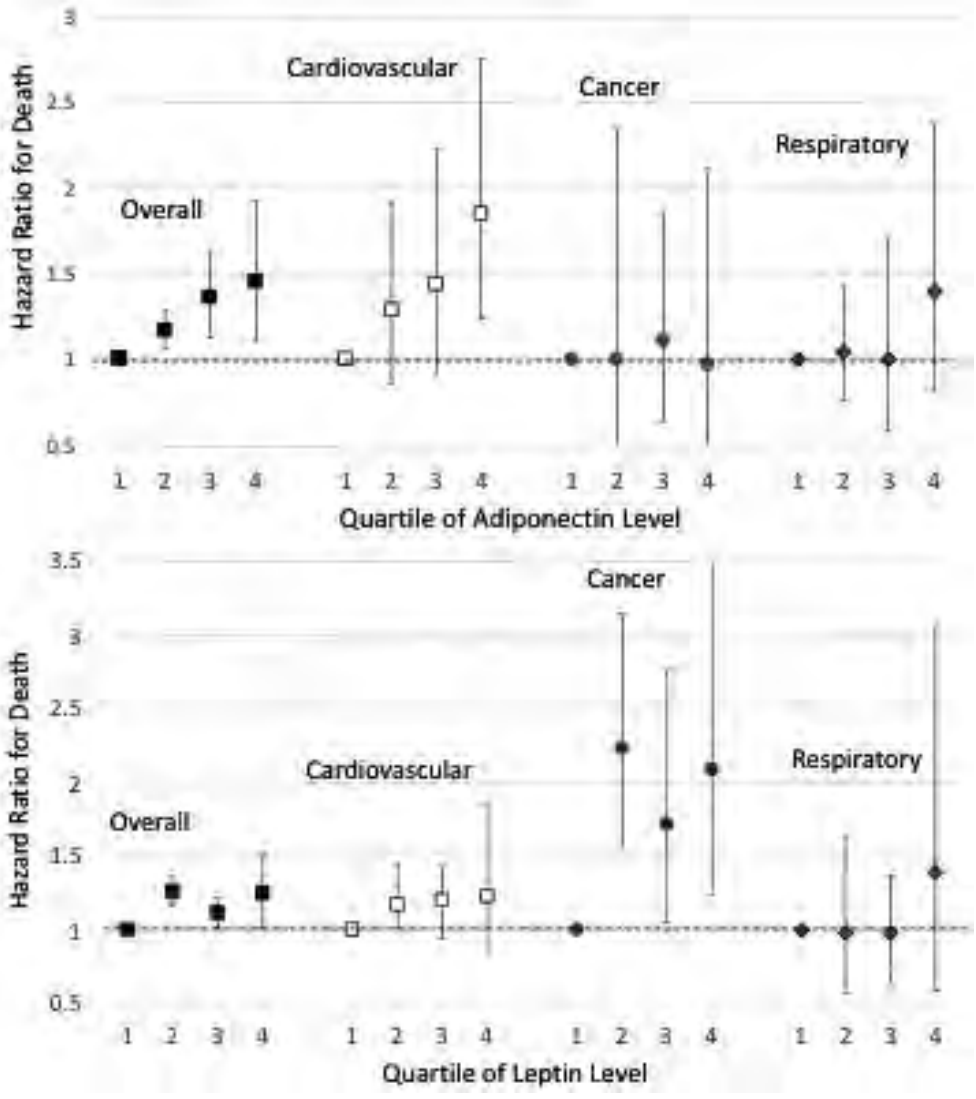

Figure 2. All-cause and cause-specific mortality in adjusted models by A) adiponectin quartile, and B) leptin quartile.

disease duration, use of prednisone, and higher rates of osteoporosis. High levels of adiponectin were also associated with higher levels of circulating inflammatory cytokines (**Figure 1.** but not with higher clinical disease activity (not shown). Leptin was primarily associated with greater BMI and obesity-related comorbidity as well as lower levels of inflammatory cytokines (particularly IL-1b). The highest quartile of adiponectin was independently associated with higher all-cause mortality [HR: 1.46 1.11, 1.93) p=0.009] which was largely driven by cardiovascular mortality [HR: 1.85 (1.24, 2.75) p=0.003] (**Figure 2**). Higher leptin levels were also independently associated with greater overall and cancer mortality.

Conclusion: Elevations in adipokine levels are associated with age, BMI, comorbidity, and seropositive and erosive RA and are independently predictive of early mortality. These observations suggest that adipokines may serve to identify patients with adverse metabolic profiles and may serve as important predictors of long-term risks. Associations noted between adiponectin and inflammatory cytokines support the hypothesis that chronic subclinical inflammation and metabolic changes, including elevations in adipokines, are interrelated.

Abnormal Cerebrovascular Biomarkers in Patients with Rheumatoid Arthritis: Results from a Prospective Study of Cognitive Aging

Maria Vassilaki[1], Cynthia Crowson[2], John Davis[1], Stephanie Duong[1], Aivi Nguyen[1], David Jones[1], Michelle Mielke[1], Vemuri Prashanthi[1] and Elena Myasoedova[1], [1]Mayo Clinic, Rochester, MN, [2]Mayo Clinic, Eyota, MN

SESSION INFORMATION
Session Date: Tuesday, November 9, 2021
Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster IV: Outcomes, Trajectory of Disease, & Epidemiology (1645–1673)
Session Type: Poster Session D
Session Time: 8:30AM–10:30AM

Background/Purpose: Patients with rheumatoid arthritis (RA) are at increased risk of cognitive impairment compared to the general population. This association might be due to chronic systemic inflammation and the associated cardiovascular risk factors (Sood A and Raji MA, 2021). Studies on RA and neuroimaging biomarkers associated with cognitive impairment are limited. The purpose of the study was to examine the associations between RA and dementia/vascular neuroimaging biomarkers in older adults.

Methods: The study included 34 RA cases and 101 participants without RA (≥50 years old) of a prospective study of cognitive aging in community-dwelling older adults, matched 1:3 for age, sex, education, cognitive status at baseline, and the availability of at least one MRI. All RA cases satisfied the 1987 ACR classification criteria. The outcomes of interest were the following neuroimaging biomarkers: global beta-amyloid (Aβ) using PiB-PET; neurodegeneration [glucose brain hypometabolism via FDG-PET, hippocampal volume and cortical thickness via structural MRI], and cerebrovascular pathology via FLAIR-MRI [white matter hyperintensity burden (WMH), subcortical, and cortical infarctions]. All participants had MRI; 47 (12 RA /35 non-RA) had Aβ PET, 45 (10 RA / 35 non-RA) had FDG PET, 55 (17 RA / 38 non-RA) were assessed for infarctions and 49 (14 RA / 35 non-RA) for WMH%TIV. We used Kruskal-Wallis rank-sum and Fisher's exact tests to compare the neuroimaging measures between the groups.

Table 1. Participants' baseline characteristics

Variables	With RA	Without RA	p-value*
Age (years) , mean (SD)	76.2 (7.9)	75.7 (7.9)	0.79
Male	13 (38)	37 (37)	1.00
Education (years) , mean (SD)	14.5 (2.5)	14.4 (2.4)	0.74
Apolipoprotein E ε4 carrier	6 (18)	26 (26)	0.49
Cognitively unimpaired	26 (76)	80 (79)	0.91
Mild cognitive impairment	7 (21)	18 (18)	
Dementia	1 (3)	3 (3)	
White matter hyperintensity volume % TIV, mean (SD)	1.12 (0.57)	0.76 (0.69)	0.01
Cortical infarctions, mean (SD)	0.24 (0.44)	0.05 (0.32)	0.02
Cortical thickness, mean (SD)	2.62 (0.16)	2.64 (0.15)	0.73
FDG SUVR, mean (SD)	1.51 (0.16)	1.59 (0.18)	0.46
Amyloid PET SUVR, mean (SD)	1.54 (0.40)	1.52 (0.33)	0.75
N (%) unless otherwise stated; SD=standard deviation; RA= Rheumatoid Arthritis; SUVR= standardized uptake value ratio; TIV= Total intracranial volume. *Kruskal-Wallis rank sum or Fisher's exact test.			

Results: Participants with vs. without RA did not differ in age, sex, years of education, Apolipoprotein E ε4 carrier status, or major comorbidities. No significant difference was observed between RA cases and non-cases in Aβ burden, and neurodegeneration measures. Although the sample size was small, we observed that RA participants (vs. without RA) had greater mean WMH volume relative to the total intracranial volume (TIV) (mean (SD) % : 1.12 (0.57) % vs 0.76 (0.69) % of TIV, p=0.01), were more likely to have cortical infarctions (4 vs. 1, p = 0.03), and had a higher mean (SD) number of cortical infarctions (0.24 (0.44) vs. 0.05 (0.32) (p=0.02) (Table 1). These associations persisted when the comparisons were limited to cognitively unimpaired individuals.

Conclusion: Patients with RA had more abnormalities in cerebrovascular imaging biomarker measures compared to individuals without RA, despite similar sociodemographics, Apolipoprotein E ε4 carrier status, markers of neurodegeneration, and similar proportion of cognitively impaired patients between the groups. Studies are ongoing to examine these associations further and understand their potential value for prognostication and prevention of cognitive decline and dementia in RA patients.

Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster IV: Outcomes, Trajectory of Disease, & Epidemiology (1645–1673)

Session Type: Poster Session D

Session Time: 8:30AM–10:30AM

Background/Purpose: In rheumatoid cachexia (RC), high resting energy expenditure (REE) has been associated with loss of muscle mass driven by proinflammatory cytokines. The objectives of this study were to evaluate alterations of REE, body composition, metabolic parameters and physical function in individuals with RA, and to investigate the interaction between systemic inflammation and modifiable risk factors for RC on REE.

Methods: A prospective, cross-sectional study was performed in RA individuals (n=35) and age/sex/race/BMI-matched healthy controls (n=11). Participants underwent measures for REE by indirect calorimetry, body composition by dual energy x-ray absorptiometry, in addition to anthropometric, biochemical and DAS-28 CRP measures.

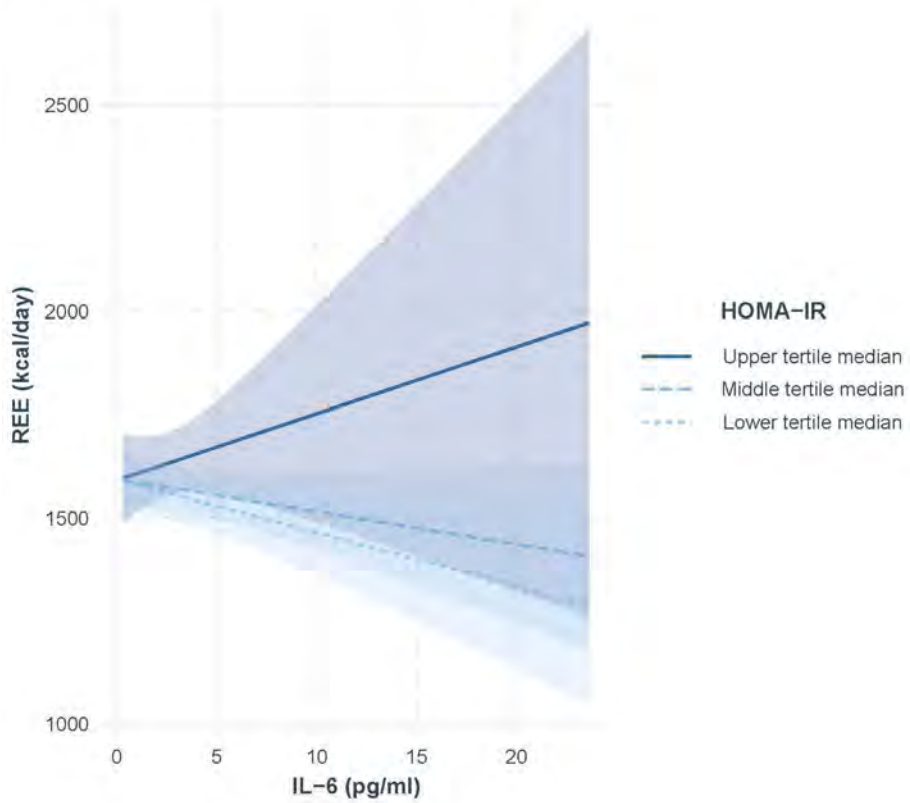
Physical activity			
METs	1.05 [1.02, 1.07]	1.08 [1.06, 1.16]	0.004
Total Activity Count (TAC/d)	900080.43 [678314.18, 1050311.02]	1068815.31 [882578.74, 1496606.76]	0.03
Step Counts	27096.50 [19861.50, 37523.75]	44354.00 [33033.50, 57268.50]	0.001

Physical activity (METs, total activity count/ day and step counts) and physical performance (5-repetition sit-to-stand, knee extensor MVIC and 5-repetition average power) data were also collected. Dietary intakes were estimated using consecutive four-day food records. Homeostasis model assessment for insulin resistance (HOMA-IR) and serum interleukin-6 (IL-6) were used as parameters of insulin resistance (IR) and systemic inflammation, respectively. Regression models tested association between REE and dependent variables, including pre-specified interaction tests involving HOMA-IR and IL-6 and dietary protein intake and IL-6.

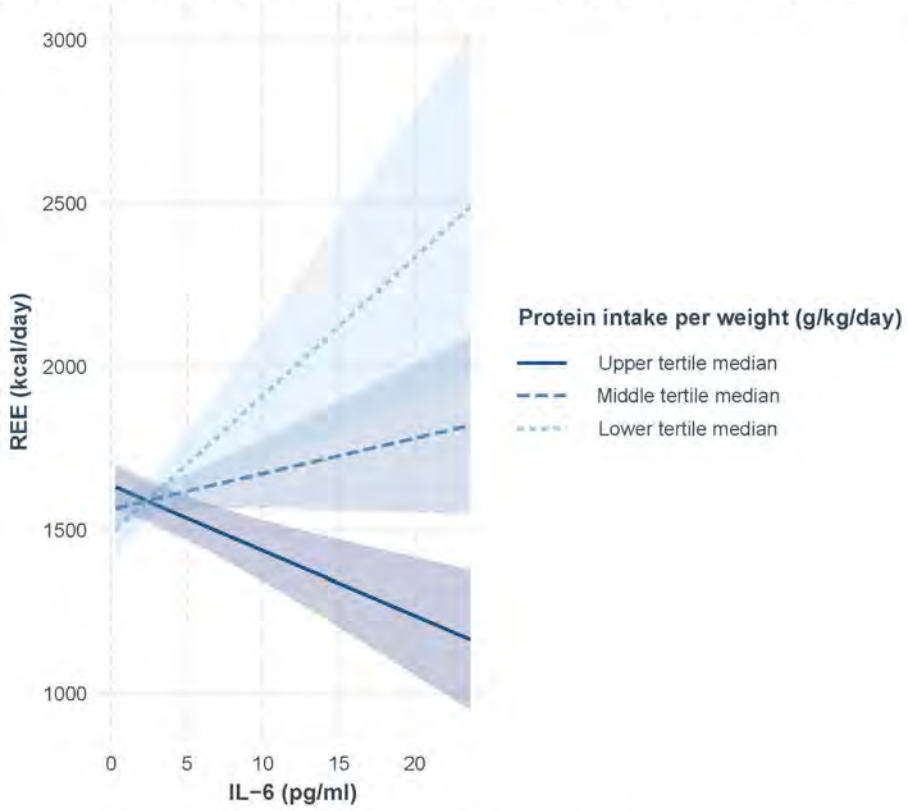
Results: RA subjects were mostly women (94%), with a median age of 54 years (50.5, 70), BMI of 30.5 kg/m^2 (26.1, 36.9), disease duration of 7.8 years (4.9, 18.1) and DAS-28 CRP of 1.77 (1.2; 2.8). Approximately two-thirds of RA subjects were either positive for rheumatoid factor on anti-CCP. Only 17% of RA subjects were on prednisone, at a median dose of 5.0 mg/ day (4.0, 5.0), and all RA subjects were on DMARD therapy. RA subjects demonstrated significantly lower levels of physical activity [METs (p= 0.004), total activity count/ day (p=0.03), step counts (p=0.001)], poorer physical performance [5-repetition sit-to-stand (p=0.002), knee extensor maximum voluntary isometric contraction (MVIC, p=0.03) and higher levels HOMA-IR (p=0.006)] compared to non-RA controls. Fat mass index [FMI] (p=0.06) and fat free mass index [FFMI] (p= 0.33) were not significantly different between RA and non-RA controls. Among RA subjects, HOMA-IR (β= 4.66; p=0.80), IL-6 (β=-9.45; p=0.24) and the interaction between HOMA-IR and IL-6 (β= 6.00; p=0.29) were not significantly associated with REE, after adjustment for age and FFMI. However, we observed a significant interaction effect between protein intake per weight (PPW) and serum IL-6 on REE among RA

Figure 1: Association between IL-6 and REE, stratified by HOMA-IR tertiles in RA subjects



Value of HOMA-IR	Estimate	S.E.	2.5%	97.5%	t value	*p*-value
1.09	-13.05	8.43	-30.28	4.19	-1.55	0.13
1.95	-7.89	8.11	-24.48	8.70	-0.97	0.34
5.96	16.17	25.60	-36.19	68.52	0.63	0.53

Figure 2: Association between IL-6 and REE, stratified by PPW tertiles in RA subjects



Value of PPW	Estimate	S.E.	2.5%	97.5%	t-value	*p*-value
0.53	42.24	18.48	4.25	80.23	2.29	0.03
0.79	10.89	9.65	-8.94	30.73	1.13	0.27
1.04	-19.97	7.51	-35.41	-4.54	-2.66	0.01

subjects in the multivariate model. The upper tertile of PPW demonstrated a significant negative correlation between REE and IL-6 (β=-19.97, 95% CI [-35.41, -4.54], p=0.01). The lower tertile of PPW demonstrated a significant positive correlation between REE and IL-6 (β=42.24, 95% CI [4.25, 80.23], p=0.03).

Conclusion: Inflammation is likely a common antecedent leading to both elevated REE and IR in patients with RA. While IR can lead to muscle catabolism, IR does not seem to be a major driver of REE in patients with RA. Higher dietary protein intake could attenuate the effect of systemic inflammation on REE in RA patients.

Increasing Rates of Positivity of Autoantibodies Indicates a Shorter Time-to-Diagnosis of Future Rheumatoid Arthritis

Dylan Bergstedt[1], Ryan Peterson[2], Marie Feser[1], LauraKay Moss[1], Geoffrey Thiele[3], Ted Mikuls[3], Jess Edison[4], V. Michael Holers[1] and Kevin Deane[5], [1]University of Colorado Denver, Aurora, CO, [2]Colorado School of Public Health, Aurora, CO, [3]University of Nebraska Medical Center, Omaha, NE, [4]Walter Reed National Military Medical Center, Bethesda, MD, [5]University of Colorado Denver, Denver, CO

SESSION INFORMATION

Session Date: Tuesday, November 9, 2021

Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster IV: Outcomes, Trajectory of Disease, & Epidemiology (1645–1673)

Session Type: Poster Session D

Session Time: 8:30AM–10:30AM

Background/Purpose: Rheumatoid arthritis (RA) has a 'pre-RA' period that can be defined by elevations in autoantibodies to citrullinated protein antigens (ACPA) and rheumatoid factor (RF) prior to clinically-apparent inflammatory arthritis. ACPA and RF elevations can be used to predict future RA; however, most models of prediction have only used autoantibody data from a single time point. To address this gap, we evaluated changing autoantibody positivity and timing of future RA in a sample set of pre- and post-RA samples from the Department of Defense Serum Repository.

Methods: We evaluated serial pre- and post-RA diagnosis serum samples from a cohort of 215 individuals with RA (213 with RA classified by 1987 criteria; 2 cases by diagnosis by a board-certified rheumatologist). All samples were tested for ACPA using the CCP3 assay (Inova, positivity based on manufacturer's recommendation) and RF-IgM, IgA and IgG (Inova, positivity based on level present in < 2% of healthy controls) We stratified cases by sex and utilized a Cox regression model that assumed a Markov renewal process to estimate the hazard of developing RA based on concurrent positivity of autoantibodies within individuals over time.

Results: Descriptive characteristics of the cases are presented in the **Table**. Overall, women were more likely than men to be positive for any RF pre- and post-RA diagnosis. Within cases stratified by gender, an increasing number of positive autoantibodies was associated with a shorter time to diagnosis of RA (**Figure**). In particular, positivity for CCP3 and any RF indicated a median time-to-diagnosis of RA of 1.52 years in men, and 1.08 years in women. Notably, if an individual's autoantibody positivity increased, their hazard of developing RA would increase (i.e. their time to diagnosis would update to a new estimate) (**Figure**).

Conclusion: In this pre-RA cohort, prevalence of positivity of a combination of CCP3 and RF occur closer to diagnosis. This suggests an expansion of autoimmunity across the development of RA where biologic processes influencing both ACPA and RF production culminate in the transition to clinically-apparent RA. Furthermore, while predictive ability herein is limited given the retrospective design of this project, prior work has established that autoantibody positivity, especially ACPA positivity, is predictive for future RA (reviewed in Deane Arthritis Rheum 2021). As such, if these findings are further validated, they could be applied in a 2-step fashion to identify an individual's overall risk for future RA, then evaluate the changing positivity of autoantibodies over time to estimate their evolving risk and

Median times from positivity of autoantibodies to time of diagnosis of RA, by gender. Overall, there is trend for increasing CCP3 and RF positivity as individuals move closer to a time of RA diagnosis. The shortest time between sample positivity and diagnosis seen in CCP3 and RF positive samples. Notably, using this approach (Cox regression with Markov renewal process) and with these case samples if an individual's autoantibody positivity increased, they would move to a different estimate of their time to diagnosis; for example, a women who had no positive antibodies would be in the group with a median time to diagnosis of ~6 years; however, if she developed positivity for CCP3 and any RF, she would move to the group with a median time of ~1 years to diagnosis. *Abbreviations: RA=rheumatoid arthritis; CCP3=cyclic citrullinated peptide-3; RF=rheumatoid factor.*

timing of future RA. Notably, the literature regarding the rate of autoantibody positivity in RA in men and women is conflicting, and issues such as diagnostic bias can influence these findings; however, the gender differences seen herein in the prevalence of autoantibody positivity and prediction of timing of future RA needs further investigation. Finally, while additional study is needed, these findings also suggest that in clinical trials for RA prevention altering the development of new autoantibodies may be a measure to understand success of an intervention.

SESSION INFORMATION

Session Date: Tuesday, November 9, 2021

Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster IV: Outcomes, Trajectory of Disease, & Epidemiology (1645–1673)

Session Type: Poster Session D

Session Time: 8:30AM–10:30AM

Background/Purpose: Methotrexate associated lymphoproliferative disorder (MTX-LPD) has various histological types from benign and malignant. Some MTX-LPDs spontaneously regress after discontinuation of MTX, even though

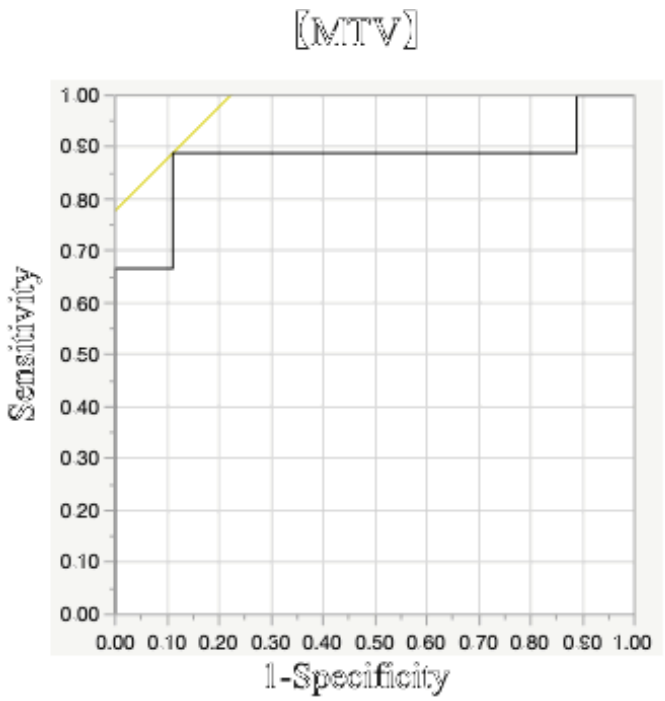
they have been diagnosed with malignant lymphoma. However it is difficult to predict spontaneous regression (SR) of MTX-LPD. On the other hand, FDG-PET/CT is used for diagnosis of malignant lymphoma.

We investigate the usefulness of FDG-PET/CT for predictive factor of SR in MTX-LPD.

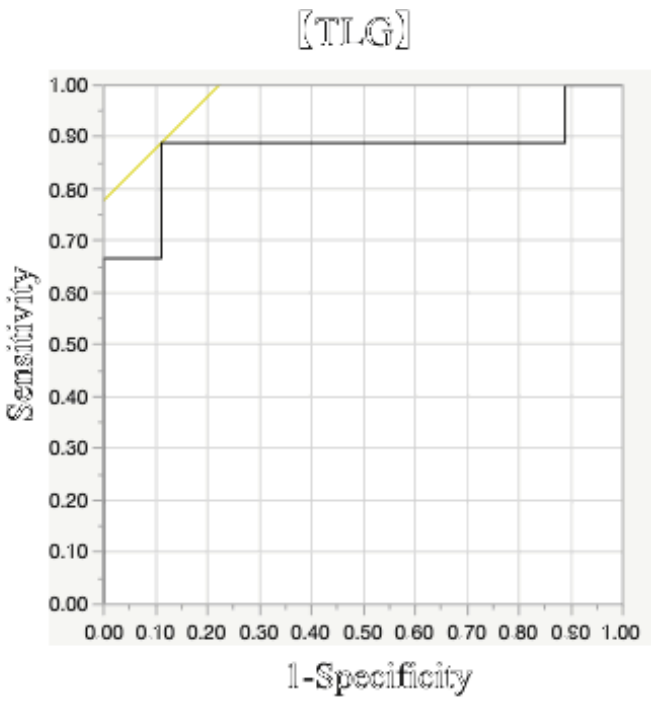
Methods: We enrolled 18 MTX-RA-LPD patients, which was histopathologically determined to be malignant and performed FDG-PET/CT from 2005 to 2019. We divided these cases into spontaneous regression cases (SR group; 9 cases) and cases that treated with chemotherapy after MTX discontinuation (CTx group; 9 cases), and compared the difference as follow subjects between two groups; biomarker (serum LDH and sIL-2R) at LPD onset, SUVmax to evaluate malignant tumor activity by FDG-PET/CT, metabolic tumor volume (MTV) and total lesion glycolysis (TLG) which refer to metabolically active volume of the tumor segmented FDG-PET/CT. In addition, we analyzed cut off levels, sensitivity and specificity using statistical software JMP.

Results: The level of sIL-2R was significantly lower in SR group. In addition, MTV and TLG by FDG-PET/CT was significantly lower in SR group, although SUVmax is no difference between two groups. Cut off levels of sIL-2R, MTV and TLG were1728 U/ml (sensitivity; 77.8%, specificity; 88.9%) 103.42 ml (sensitivity; 88.9%, specificity; 88.9%) and 361.75 ml (sensitivity; 88.9%, specificity; 88.9%), respectively.

Conclusion: We suggested that serum sIL-2R, MTV and TLG were useful for predict of SR in MTX-LPD.



Cut-off value	103.42ml.
Sensitivity	88.9%
Specificity	88.9%



Cut-off value	361.75ml.
Sensitivity	88.9%
Specificity	88.9%

SESSION INFORMATION

Session Date: Tuesday, November 9, 2021

Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster IV: Outcomes, Trajectory of Disease, & Epidemiology (1645–1673)

Session Type: Poster Session D

Session Time: 8:30AM–10:30AM

Background/Purpose: Rheumatoid arthritis (RA) has a 'pre-RA' period that can be defined by elevations of antibodies to citrullinated protein antibodies (ACPA), rheumatoid factor (RF), and other measures of inflammation prior to clinically-apparent inflammatory arthritis. Evaluating the evolution of these biomarkers in pre-RA may provide novel understanding of mechanisms of disease development. In addition, advanced analytic techniques may provide unique insights into biomarker evolution. As such, as a proof-of-concept, we evaluated ACPA and RF changes over time in pre-RA using artificial adaptive systems (AAS) in a sample set of pre- and post-RA samples from the Department of Defense Serum Repository.

Descriptive characteristics of RA cases and controls

	RA Cases(n=214)				Controls(n=210)*
	Time 1 Earliest Pre-RA diagnosis sample	Time 2 Intermediate Pre-RA diagnosis sample	Time 3 Immediate Pre-RA diagnosis sample	Time 4 Post-RA diagnosis sample	Time 4 Matched to RA case post-diagnosis sample
Time of sample from diagnosis of RA, mean (in years)	-11	-4	-1	+1	-
Age at diagnosis of RA, mean*	-	-	-	37	37
% Female	-	-	-	48%	48%
% Non-Hispanic white	-	-	-	58%	55%
% anti-CCP3.1 positive	17%	51%	74%	76%	4%
% any RF isotype positive	6%	28%	43%	60%	6%*

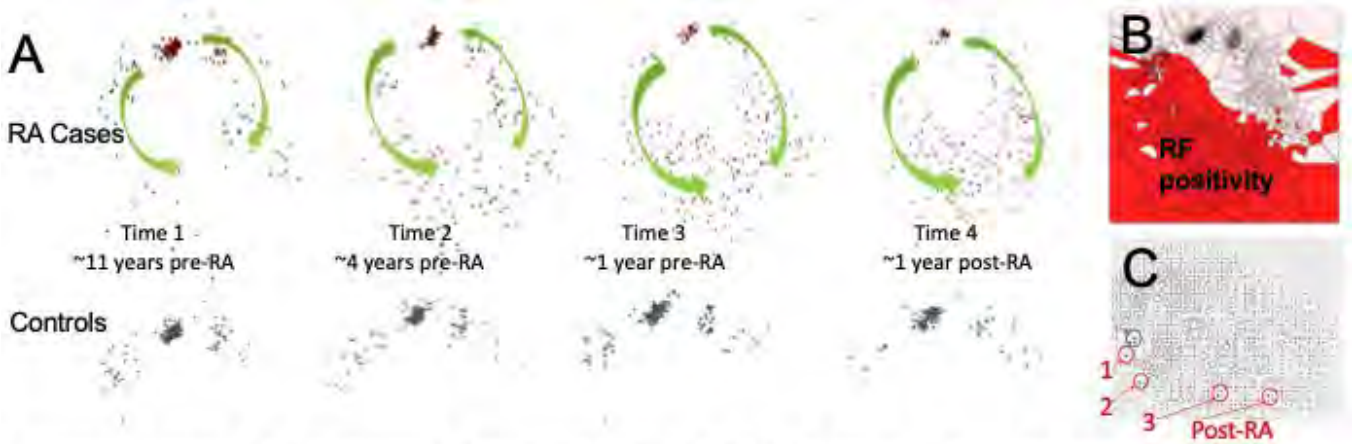
*For controls, only data from the last serum sample is presented; the age of controls is the mean age at time of index sample to their case.
**The positive levels for RF isotypes was determined in a subset of 156 Controls; as such, the % positive for any RF isotype was determined in the remainder of 54 controls.

Abbreviations: RA=rheumatoid arthritis; anti-CCP3.1=anti-cyclic citrullinated peptide antibody 3.1; RF=rheumatoid factor

Methods: We evaluated serial pre- and post-RA diagnosis serum samples obtained from a cohort of 215 individuals with RA (213 with RA classified by 1987 criteria; 2 cases by diagnosis by a board-certified rheumatologist) as well as serial samples from age, gender and race-matched controls. All samples were tested for ACPA using commercial assays for CCP2 (Axis-Shield), CCP3.1 (Inova) and RF-IgA, -IgM and -IgG (Inova). In addition, all samples were tested on a bead-based array containing citrullinated and non-citrullinated antigens. In total, there were 54 biomarkers. We analyzed these biomarkers using AAS and deep artificial neural networks (ANN's) that characterized biomarker abnormalities within individuals to a single point in time; then, the movement of that point was evaluated over time. Specifically, an Auto Contractive Map (Buscema 2018) was used to project weighted functional links among the biomarkers, an Auto Self Organizing Map (Massini 2021) was then applied to examine how the autoantibodies were clustered at the different temporal steps of the disease evolution, and a multi-dimensional scaling algorithm Population (Massini 2013) was used to understand how each individual summated biomarker profile 'moves' over time.

Results: The characteristics of the cases and controls are presented in the **Table**. At the earliest time point (mean 11 years pre-diagnosis), many RA cases were indistinguishable from controls; however, over time, most RA cases evolved over time to a distinct profile that was present prior to and post-RA diagnosis (Figure, Panel A). In addition, within RA cases, there were two distinct endotypes within cases, with one endotype characterized by RF positivity (Figure, Panel B). Furthermore, within the overall patterns of disease development, an individual RA case's trajectory could be identified with a clear separation from a control pattern (Figure, Panel C).

Conclusion: Testing for a panel of 54 autoantibodies and application of AAS identified the temporal evolution of RA cases from a state that was initially similar to controls, to a distinct state. Furthermore, within the evolution of RA, there were distinct endotypes of development that included RF-positivity. In addition, an individual's course could be plotted to estimate their specific time point in the course of disease evolution. Future studies utilizing these analytic approaches with additional biomarkers can be used to identify specific pathways of disease development as well as improve prediction models for future RA.



Evolution across the development rheumatoid arthritis (RA). In Panel A, each dot represents an artificial adaptive system-derived summation of 54 autoantibody biomarkers for each case and matched control at the specified time period. The cases (upper panels/red dots) demonstrate general movement from the upper left to lower right over time and in two 'pathways' (green arrows). This is distinct from controls who remain stable over time (lower panels/blue dots). Panel B demonstrates that within the lower pathway is weighted by an endotype of subjects with rheumatoid factor (RF) positivity (red regions). In additional analyses (Panel C), an individual RA case's (red circles and arrows) biomarker movement over the pre- and post-RA time periods was distinct from their matched control (blue arrow and circle).

Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster IV: Outcomes, Trajectory of Disease, & Epidemiology (1645–1673)

Session Type: Poster Session D

Session Time: 8:30AM–10:30AM

Background/Purpose: Rheumatoid arthritis (RA) has a 'pre-RA' period definable as elevations of antibodies to citrullinated protein antibodies (ACPA) before clinically-apparent inflammatory arthritis (IA). ACPA elevations can predict future IA; however, most prospective studies have studied symptomatic ACPA+ individuals. As such, it is unclear how ACPA may relate to future IA in asymptomatic individuals. Furthermore, there is limited understanding of the trajectory of symptoms prior to a transition to IA, or how individuals who are prospectively followed to IA may compare with individuals with new RA found through standard rheumatology referrals.

Abbreviations: CCP=cyclic citrullinated peptide antibody; SD=standard deviation; VAS=visual analog scale; DAS28CRP=Disease Activity Score 28 Joints C-Reactive Protein; RF=rheumatoid factor

Methods: Through clinics and screening of relatives of patients with RA and health fairs we identified 86 ACPA(+) individuals (CCP3, Inova) who had no history or examination evidence of IA. They were followed prospectively for IA development. We also evaluated 57 CCP3+ patients with EarlyRA from clinics with a baseline study visit < 30 days since confirmation of IA by a rheumatologist. Joint symptoms were captured by questionnaires capturing pain, stiffness and swelling in 68 joints. We evaluated trajectories of joint symptoms, physical examination and disease activity (DAS28CRP) through incident IA, and between individuals who transitioned to IA compared to patients with established EarlyRA.
