Results: Nineteen of 86 (22%) of anti-CCP3+ developed IA ('converters') at a median of 509 days of follow-up and 79% met 2010 ACR/EULAR criteria at time IA identification. At baseline, CCP3+ converters reported longer duration of morning stiffness, and a trend towards an increased prevalence of swollen joints compared to CCP3+ subjects who did not develop IA; in addition converters had higher levels of CCP3 and RFIgM (**Table 1**). In the converters there were 2 trajectories of symptoms prior to IA: 1) waxing and waning of joint symptoms and 2) period of minimal symptoms followed by steady worsening of symptoms over < 200 days prior to IA identification (these trajectories were not different than those who did not develop IA). In the 'converters', those without any joint symptoms at baseline (n=5) trended towards a longer duration to appearance of IA compared to those with baseline symptoms (median of 686 days vs 363 days, p~0.09). At the time of diagnosis of IA 'converters' had lower levels of symptoms, DAS28CRP and CCP3 than patients with EarlyRA (**Table 2**).

Conclusion: In this study, in CCP3+ individuals, self-reported morning stiffness and higher levels of CCP3 and RFIgM were associated with incident IA; in addition, there are 2 types of trajectories of joint symptoms in transition to IA, and a subset of CCP3+ individuals without symptoms developed IA. These findings can be considered in understanding the natural history of RA and building prediction models for future disease as well as to correlate biomarker changes with symptoms. Furthermore, the lower disease activity in 'converters' to IA compared to EarlyRA could indicate that prospective follow-up of ACPA+ individuals can identify IA at a time point where disease activity and CCP3 levels are less than in standard referral patterns, perhaps indicating a stage of disease more responsive to therapy.

Abstract Number: 1652

Symptom Burden in Anti-citrullinated Protein Antibody Positive Individuals At-risk for Rheumatoid Arthritis Is Changing over Time and Comparable to Patients with Early Rheumatoid Arthritis

Paul Studenic[1], Alexandra Circiumaru[2], Daniel Aletaha[3], Katerina Chatzidionysiou[4], Anca Catrina[5] and Aase Haj Hensvold[6], [1]Karolinska Institute; & Medical University of Vienna, Stockholm, Sweden, [2]Division for Rheumatology, Karolinska Institutet; Center for Rheumatology, Academic Specialist Center, Stockholm Region, Stockholm, Sweden, [3]Medical University Vienna, Vienna, Austria, [4]Karolinska Institute, Division of Rheumatology; & Karolinska University Hospital, Rheumatology Unit, Stockholm, Sweden, [5]Karolinska Institutet and Karolinska University Hospital, Stockholm, Sweden, [6]Karolinska Institutet, Division for Rheumatology; & Center for Rheumatology, Academic Specialist Center, Stockholm Region, Stockholm, Sweden

SESSION INFORMATION

Session Date: Tuesday, November 9, 2021

Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster IV: Outcomes, Trajectory of Disease, & Epidemiology (1645–1673)

Session Type: Poster Session D

Session Time: 8:30AM–10:30AM

Background/Purpose: Symptom burden in individuals at risk for developing rheumatoid arthritis (RA) - positive for anti-citrullinated peptide antibodies (ACPA) and musculoskeletal complaints - has not been explored. We aim to evaluate patient-reported symptoms in individuals in the risk phase for RA in comparison to patients with early seropositive RA (eRA).

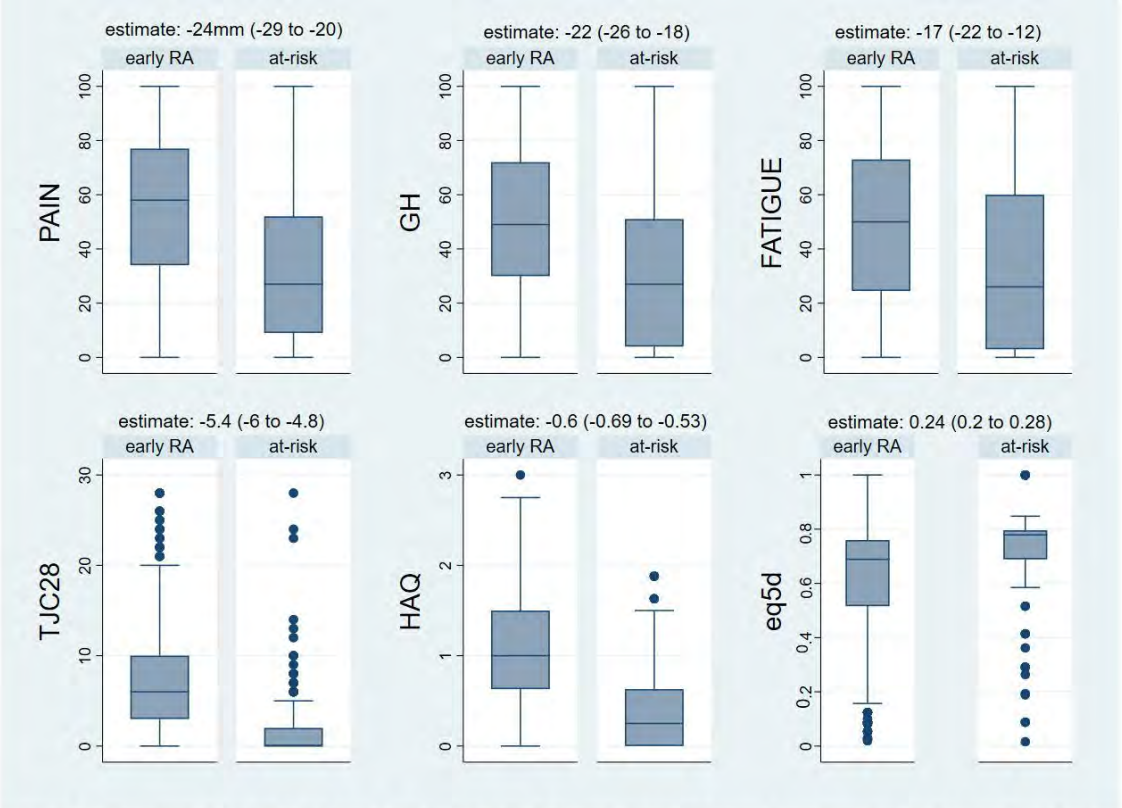

Figure 1: Boxplots of pain, global health, fatigue, TJC28, EQ5D and HAQ, separately displayed for people with early seropositive RA and individuals at-risk. Population effect estimates (all p<0.001) comparing at-risk at baseline to early RA are provided for every pair, with 95% confidence interval in brackets.

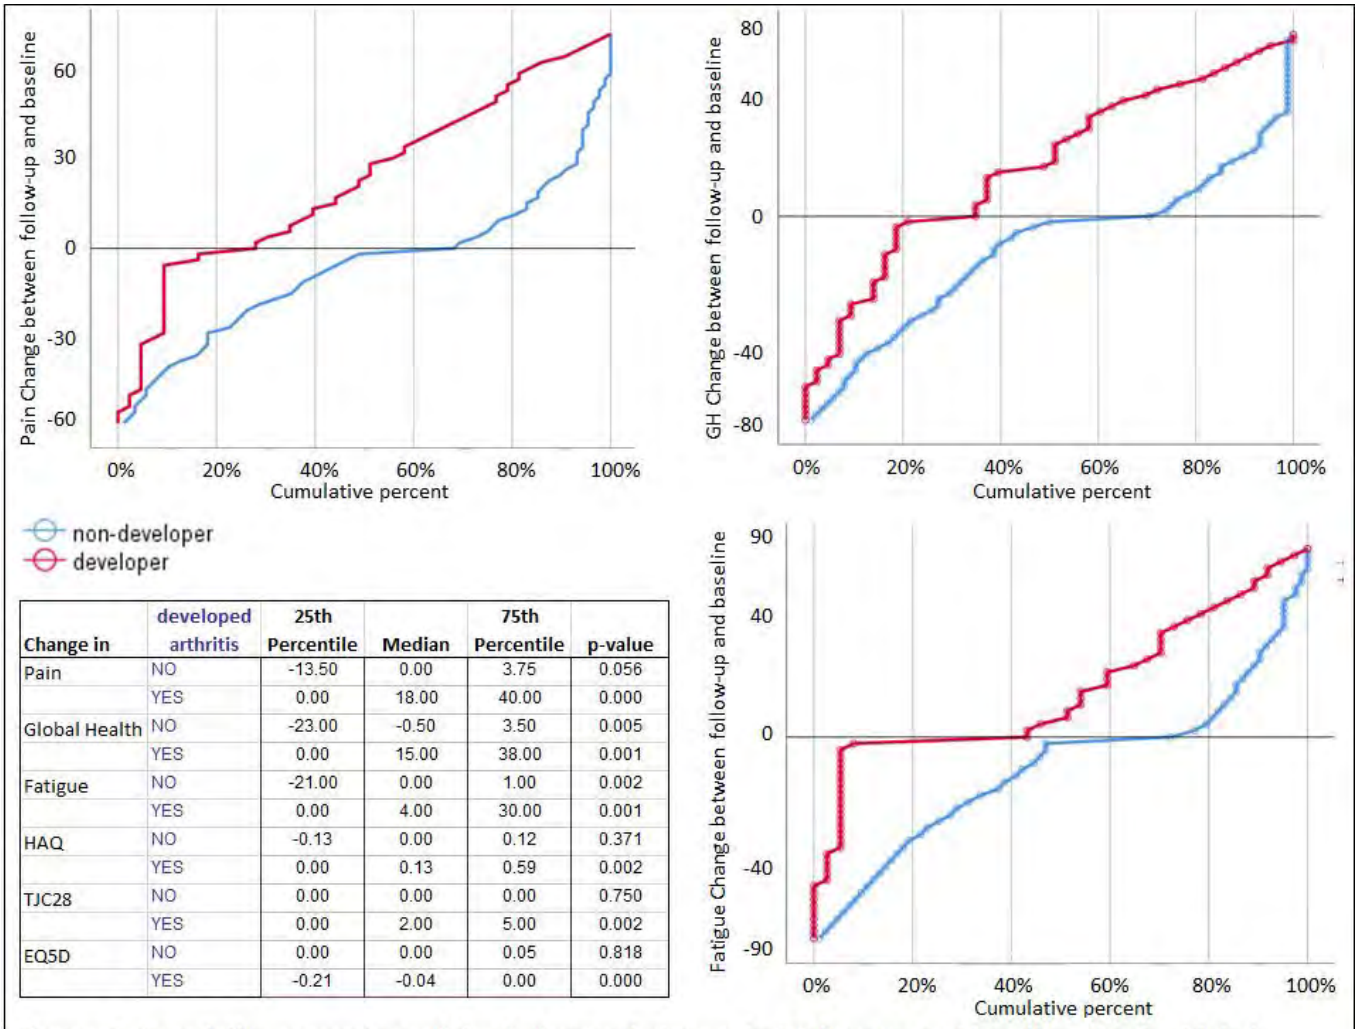

Change in	developed arthritis	25th Percentile	Median	75th Percentile	p-value
Pain	NO	-13.50	0.00	3.75	0.056
	YES	0.00	18.00	40.00	0.000
Global Health	NO	-23.00	-0.50	3.50	0.005
	YES	0.00	15.00	38.00	0.001
Fatigue	NO	-21.00	0.00	1.00	0.002
	YES	0.00	4.00	30.00	0.001
HAQ	NO	-0.13	0.00	0.12	0.371
	YES	0.00	0.13	0.59	0.002
TJC28	NO	0.00	0.00	0.00	0.750
	YES	0.00	2.00	5.00	0.002
EQ5D	NO	0.00	0.00	0.05	0.818
	YES	-0.21	-0.04	0.00	0.000

Figure 2: Cumulative percentage plots of changes between last follow-up and baseline of pain, Global Health (GH) and fatigue. Changes of HAQ TJC28 and EQ5D also outlined in integrated table (p-values provided concerning change in time in the respective outcome and group). Blue lines represent non-arthritis developers and red those that develop arthritis.

Methods: ACPA positive individuals with musculoskeletal complaints, but without clinical or ultrasound signs of joint inflammation were identified from the RISK RA Karolinska cohort. Data from baseline visit (BL) and the last follow-up visit (LF) in arthritis developers (A-D) and non-arthritis developers (n-A-D) were extracted. Additionally patients with early seropositive (ACPA and/or rheumatoid factor positive) RA (eRA) were identified as controls in the Swedish Rheumatology Quality Register. Data from the date of diagnosis were used. eRA and Risk-RA individuals were matched 1:3 by sex and age using the nearest neighbour method utilizing Mahalanobis distance, corrected for sample bias and exact matches on sex. Effect estimates for pain, patient global (GH), fatigue, health assessment questionnaire (HAQ), TJC28 and the EuroQol-5D (EQ5D; range: 0-1) were compared. Propensity score matching was used as sensitivity analyses. Via pairwise-comparisons changes between BL and LF were tested.

Results: In total 223 Risk-RA individuals were compared to 820 matched eRA patients. The distribution of symptoms and differences between Risk-RA at BL and eRA individuals are shown in Figure 1. Risk-RA individuals show 24mm of lower pain scores at BL than eRA ($p < 0.001$). This difference is less (-17mm, 95%CI: -24 to -11) when the estimate is additionally matched for the TJC. The TJC28 was on average 5.4 joints lower than in eRA. GH scores were 22mm lower (rate themselves better), fatigue scores 17mm lower and HAQ by 0.6 points lower in Risk-RA than eRA. Mean

EQ5D in Risk-RA was only 0.74 (95%CI: 0.71 to 0.77), which is 0.24 higher than in eRA. Sensitivity analyses revealed similar results.

Symptom burden in Risk-RA individuals developing and not developing arthritis: At BL no differences between future arthritis developers (A-D, n: 66) and non-developers (n-A-D, n: 157) were found. At LF differences between A-D and n-A-D were seen in all scores when comparing the visit at/or close to arthritis onset with the visit in individuals not progressing. When looking at changes between BL and FL in A-D and n-A-D separately, A-D showed increases in all variables, whereas n-A-D decreased in pain, fatigue and GH during follow-up (Figure 2).

Conclusion: The symptom burden in the Risk-RA phase is substantial, although less than in eRA. Initially the symptom burden in Risk-RA individuals developing arthritis is not different from those not developing arthritis in the future. By time the non-developers, take another path in the Risk-phase with decreasing of symptoms, potentially due to normalized immune and inflammatory processes, and as expected the arthritis developers worsen. This stresses the need for management strategies of Risk-RA individuals.

Positron Emission Tomography-Detected Uptake of ^{18}F-Fluorodeoxyglucose in Visceral and Subcutaneous Adipose Tissue Is Associated with Articular Disease Activity and Arterial Inflammation in Rheumatoid Arthritis

Jon Giles[1], Joan Bathon[2], Hadil Zureigat[3] and Ahmed Tawakol[4], [1]Columbia University Irving Medical Center, Division of Rheumatology, New York, NY, [2]Columbia University, New York, NY, [3]Harvard University, Boston, MA, [4]Harvard University/Massachusetts General Hospital, Boston, MA

SESSION INFORMATION

Session Date: Tuesday, November 9, 2021

Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster IV: Outcomes, Trajectory of Disease, & Epidemiology (1645–1673)

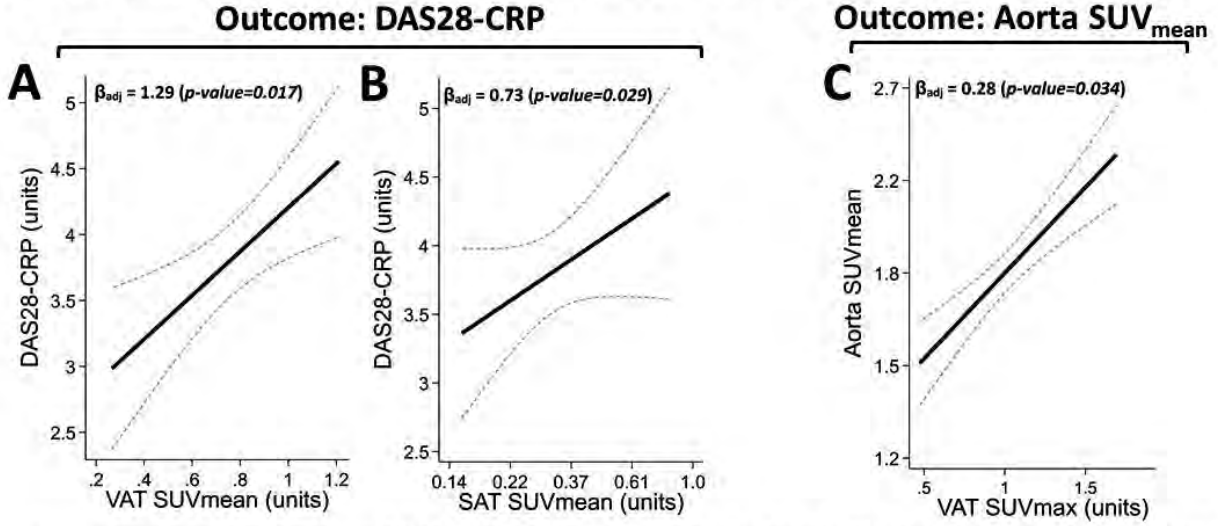
Session Type: Poster Session D

Session Time: 8:30AM–10:30AM

Background/Purpose: Subcutaneous adipose tissue (SAT) from people with RA contains more macrophages and expresses higher levels of cytokines, chemokines, and other inflammatory mediators compared with otherwise similar people without RA. Visceral adipose tissue (VAT), located within the thorax and surrounding mesenteric organs, tends to be more inflammatory than SAT and is more strongly associated with cardiometabolic outcomes, such as insulin resistance and atherosclerotic cardiovascular disease (CVD). However, due to its inaccessibility, little is known about the immunophenotype of VAT in RA and whether adipose inflammation is associated with other RA-specific features.

Methods: RA patients participating in a cohort study of CVD in RA underwent total body ^{18}F-fluorodeoxyglucose positron emission tomography/computed tomography (FDG PET/CT). VAT and SAT regions were manually traced and the mean and maximal standardized uptake values (SUV_{mean} and SUV_{max}) for FDG uptake were calculated for each adipose depot. Abdominal VAT and SAT volumes were measured at the L2/3 interspace. Mean and maximal uptake

Figure. Adjusted Associations of Visceral and Subcutaneous Adipose Uptake of ^{18}F-Fluorodeoxyglucose with Articular Disease Activity and Vascular Inflammation in RA



Least-squares estimates and 95% confidence intervals depicted. DAS28-CRP models adjusted for race, RA duration, anti-CCP seropositivity, current prednisone use. Aorta SUV model adjusted for age, diabetes, hypertension, and anti-CCP seropositivity. VAT and SAT covariates were modeled simultaneously.
SUV=standardized uptake value; VAT=visceral adipose tissue; SAT=subcutaneous adipose tissue

of FDG in the arterial wall of the ascending aorta was measured and reported for the entire vessel (SUV_{mean}) and for the most diseased segment (SUV_{MDS}). Generalized linear models were used to explore the associations of VAT and SAT volumes and SUV measures with RA features and aortic SUV.

Results: VAT and SAT FDG uptake was analyzed in 47 RA patients (81% women; mean age 55 years; median BMI=27.6 kg/m^2; median RA duration=6.7 years; mean DAS28-CRP=3.80; current methotrexate, biologics, and prednisone in 49%, 36%, and 32%, respectively). Average SUV_{mean} and SUV_{max} were higher in VAT than SAT [(SUV_{mean}: 0.76 vs. 0.34 SUV units, respectively; p< 0.001) (SUV_{max}: 1.02 vs. 0.52 units, respectively; p< 0.001). Both VAT and SAT SUV_{mean} were significantly and independently associated with DAS28-CRP, even after adjusting for pertinent confounders (Fig A & B). This association was driven by associations with swollen and tender joint counts, but not with CRP. VAT and SAT SUV_{mean} accounted for 20% of the explainable variability in DAS28-CRP (Model total R^2=0.58). Body mass index, VAT volume, and SAT volume were not associated with DAS28-CRP when comodeled with VAT and SAT SUV_{mean}. VAT SUV_{max} was significantly associated with all measures of aorta SUV (shown for Aorta SUV_{mean} in Fig C), even after confounder adjustment. SAT SUV was not associated with Aorta SUV.

Conclusion: Both visceral and subcutaneous adipose uptake of ^{18}F-FDG, representing increased metabolic activity and/or adipose inflammation, was highly associated with articular disease activity and aortic FDG uptake, representing atherosclerotic plaque inflammation. These findings suggest that adipose inflammation could be a contributor to articular and vascular inflammation in RA, and potentially a target for intervention.

Abstract Number: 1654

Comparative Characteristics of the Natural Course of Early Rheumatoid Arthritis with Onset at a Young Age (18-49 Years) and Older (50 Years and Older) Patients Who Did Not Take DMARDs, Biologics, Other Targeted Drugs, Corticoids According to the Russian Register of Arthritis OREL

Azamat Satybaldyev, Galina Gridneva, Anna Misiyuk, Natalia Demidova, Kamalia Kasumova and Evgeny Nasonov, V.A. Nasonova Reseach Institute of Rheumatology, Moscow, Russia

SESSION INFORMATION
Session Date: Tuesday, November 9, 2021
Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster IV: Outcomes, Trajectory of Disease, & Epidemiology (1645–1673)
Session Type: Poster Session D
Session Time: 8:30AM–10:30AM

Background/Purpose: Comparison of frequency of different clinical features of the natural course at the stage of early rheumatoid arthritis (RA) in patients with young and older age are not sufficiently covered in the literature.

Comparative study of early RA with onset at young (18-49 years) and older age (50 years and older) before start of DMARDs, biologics and other targeted therapy and glucocorticoids.

Methods: 292 patients with RA were included into the All-Russian register of patients with arthritis "OREL" in the period from January 01, 2012 to December 31, 2018 with research data at the time of the first visit. All patients did not receive DMARDs (synthetic, biological or other targeted drugs) and glucocorticoid systemic therapy before being entered into the registry and were investigated before prescribing DMARDs. 141/292 patients (25 men, 116 women, mean age 39.27 ± 7.97 years, mean duration of disease 5,7±2,75 months) had RA onset at a younger (18-49 years old) age – group 1, 151/292 (men - 41, women - 110, mean age 66.05 ± 7.34 years, mean duration of disease 4,3±3,6 months) had RA onset at senior age (50 years and older) – group 2. RA was diagnosed in accordance with 1987 ACR and 2010 ACR/EULAR criteria. Disease activity was assessed according to DAS-28 index, X-ray stage – according to Steinbrocker, modified stages, functional disorders – in accordance with functional class (FC).

Results: In the group 2, the male / female ratio was higher (1: 2.8) than in the group 1 (1: 4.6) (p=0,055), which indicates a tendency to equalization of the sex ratio with age. Following disorders developed more often in group 2 than group 1: restriction of mobility and morning stiffness (82% vs 59%) (p< 0.05), the frequency of damage to small joints of the hands (76% vs 65%) (p >0.05), wrists (65% vs 52%) (p< 0.05), elbow (33% vs 17%) (p< 0.05), knee (53% vs 36%) (p< 0.05), shoulder (44% vs 19%) (p< 0.05), the total number of affected joints also significantly prevailed in the group 2 (in total cases p< 0,05). Group 2 patients showed stronger and more frequently inflammatory process patients of group 2 comparatively with the Group 1 was (high inflammatory activity - 66% versus 35%, respectively) (p< 0.05), as well as destructive changes (erosive arthritis - 52% versus 29%; p< 0.05) in the joints and functional disorders (FC 3 - 68% versus 15%, respectively) (p< 0.05). Extra-articular manifestations in the form of rheumatoid nodules were more often recorded in the group 2 (10% versus 2%) (p< 0.05). At the same time, ACPAs was not significantly more often detected in group 1 (89% versus 78%) (p > 0.05) with the common frequency of RF detection (72% and 72%).

Conclusion: Comparative study of the clinical characteristics of the natural course of early RA with onset in young adult (18-49 years) and with onset in older (50 years and older) age according to the data of the All-Russian register of

patients with arthritis OREL showed that RA with onset in older age is characterized by stronger and more frequently inflammatory process, destructive and functional disorders in the joints than RA with onset at a younger age.

SESSION INFORMATION

Session Date: Tuesday, November 9, 2021

Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster IV: Outcomes, Trajectory of Disease, & Epidemiology (1645–1673)

Session Type: Poster Session D

Session Time: 8:30AM–10:30AM

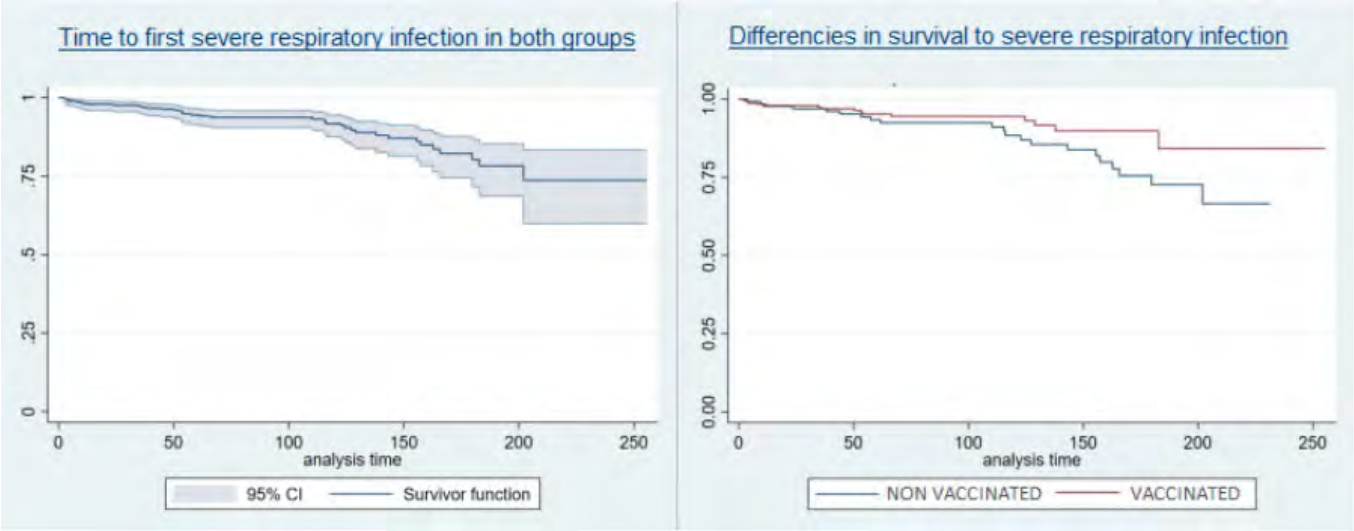
Background/Purpose: Rheumatoid arthritis (RA) patients are at increased risk of severe infections due to the disease itself, and the immunosuppressive treatment. Vaccination programs are designed to decrease the risk of infections.

Our aim was to assess **a)** the incidence of severe respiratory infections and **b)** to compare the risk between vaccinated and non vaccinated patients in patients with RA treated with biologic therapy (BT)

Methods: Observational study of 431 patients diagnosed with RA that iniciated BT. One group of patients participated in the vaccination program of the Preventive Medicina and Rheumatologúa departments of our hospital from

Table. Main general features at BT onset

	Group 1 Vaccination program N=299	Group 2 Non vaccination program N=132	p
Age (years) mean±SD	61.3±13	67.9±14.2	0.32
Women, n (%)	231 (77.3%)	105 (79.5%)	0.59
Duration of RA (months) mean±SD	73.2±10.4	112.6±60.2	
Positive RF/ Positive ACPA, n (%)	177(59.2)/172 (57.5%)	93(70.5%)98 (74.2%)	0.02
Erosive disease, n (%)	116 (38.8%)	70 (53%)	0.06
Vasculitis, n (%)	15 (5%)	2 (1.5%)	0.08
Interstitial lung disease n (%)	12 (4%)	7 (5.3%)	0.54
Subcutaneous nodules n (%)	16 (5.4%)	6 (4.5%)	0.72
Corticosteroids	299 (100%)	132 (100%)	1
Number of conventional DMARDs, mean±SD	1.6±0.9	2±1	0.3



October 2011 to October 2016 (*Group 1*). The other group was not included in the vaccination program (*Group 2*). The follow-up was made until June 2017 with a minimum follow-up period of 8 months and a maximum of 5.5 years.

Information on severe respiratory infections, defined as those that required hospitalization or at least one dose of intravenous antibiotic treatment at the emergency room, was retrieved from the hospital medical records.

Results: We studied 431 patients (335 women/96 men); mean age 63.4±13.7 years. In the vaccination program *(group 1)* were included 299 (69.4%) patients and in the *group 2;* 132 patients (30.6%). The main features of both groups are summarized in the **TABLE**.

During the follow-up, we registered 299 hospital admissions due to severe respiratory infections in both groups (incidence density 9,9 (95% CI: 6,9-13,6).

In group 1, vaccinated patients, this incidence density was reduced to 7,1 (95% CI: 4,1-11,6). **Figure**.

The vaccination program reduced the general incidence of severe respiratory infection in 44%.

Conclusion: RA patients with BT included in the vaccination program present a lower incidence of severe respiratory infections compared with non vaccinated patients.

Women with Rheumatoid Arthritis Have More Multimorbidity Than Men in a Large Nationwide US Study

Hayley Dykhoff[1], Elena Myasoedova[1], Madeline Peterson[1], John Davis[1], Vanessa Kronzer[1], Caitrin Coffey[1], Tina Gunderson[1] and Cynthia Crowson[2], [1]Mayo Clinic, Rochester, MN, [2]Mayo Clinic, Eyota, MN

SESSION INFORMATION
Session Date: Tuesday, November 9, 2021
Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster IV: Outcomes, Trajectory of Disease, & Epidemiology (1645–1673)
Session Type: Poster Session D
Session Time: 8:30AM–10:30AM

Background/Purpose: Patients with RA have an increased burden of multimorbidity. Although many comorbidities vary by sex, sex differences in multimorbidity among individuals with RA have not been examined. We aimed to compare multimorbidity between women and men with RA and comparators without RA.

Methods: We used a longitudinal, real-world database with de-identified administrative claims for commercial and Medicare Advantage enrollees to identify cases of RA and matched controls. Cases were defined as patients aged ≥18 years with ≥2 diagnoses of RA in January 1, 2010 - June 30, 2019 and ≥1 prescription fill for a DMARD any time after the first RA diagnosis. Controls were persons without RA matched 1:1 to RA cases on age, sex, census region, calendar year of index date (corresponding to the date of second diagnosis code for RA), and length of prior medical/pharmacy coverage. Race was classified as non-Hispanic White (White), non-Hispanic Black (Black), Asian, Hispanic, or other/unknown, based on self-report or derived rule sets. Multimorbidity (2 or more comorbidities, MM2+) and substantial multimorbidity (5 or more comorbidities, MM5+) were defined using 44 preidentified chronic comorbidities (England et al. ARD 2020) assessed during the year prior to index date. Logistic regression models were used to estimate odds ratios (OR) with 95% confidence intervals (CI).

Results: The study included 155,631 cases with RA and 155,631 matched non-RA comparators (mean age 59.6 years, 76.0% female for both cohorts). In both cohorts, women were slightly younger (mean age 60.0 vs. 62.0 years). Among RA patients, women were more racially/ethnically diverse than men, with 70% of women (76% men) being White, 11% (9%) Hispanic, 11% (7%) Black, 3% (2%) Asian, and 6% (6%) other/unknown. Racial/ethnic diversity was more similar among non-RA women and men with 72% women (74% men) being White, 9% (9%) Hispanic, 10% (8%) Black, 3% (4%) Asian, and 6% (6%) other/unknown. Overall, patients with RA had more MM2+ than non-RA subjects (69.9% vs 53.5%), and more MM5+ than non-RA subjects (30.5% vs 18.2%).

Observed rates of MM5+ were similar in women and men without RA (18.1% vs 18.5%, p=0.09), but among RA patients, women had higher observed rates of MM5+ than men (30.9% vs 29.0%, p< 0.0001). This pattern persisted following adjustment for age, race/ethnicity, and geographic region, showing increased rates of MM5+ among RA women versus men (OR: 1.18; 95% CI: 1.16-1.22) and similar rates among non-RA women and men (OR: 1.04; 95% CI: 1.00-1.08). Examination of individual comorbidities showed that women with RA had more depression, hypothyroidism, fibromyalgia, chronic back pain, asthma, gastroesophageal reflux disease, osteoarthritis, and osteoporosis compared to men with RA and women without RA.

Conclusion: This large nationwide study showed increased occurrence of multimorbidity in women with RA compared to men with RA, while women and men without RA had similar levels of multimorbidity, even after adjustment for age, race/ethnicity, and geographic region. The underlying mechanisms for these sex differences require further investigation.

Abstract Number: 1657

Comprehensive Assessment of Multimorbidity Burden in a Population-based Cohort of Patients with Rheumatoid Arthritis

Cynthia Crowson[1], Tina Gunderson[2], Elena Myasoedova[2], Elizabeth Atkinson[2], Vanessa Kronzer[2], Caitrin Coffey[2] and John Davis[2], [1]Mayo Clinic, Eyota, MN, [2]Mayo Clinic, Rochester, MN

SESSION INFORMATION
Session Date: Tuesday, November 9, 2021
Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster IV: Outcomes, Trajectory of Disease, & Epidemiology (1645–1673)
Session Type: Poster Session D
Session Time: 8:30AM–10:30AM

Background/Purpose: Multimorbidity is common in patients with rheumatoid arthritis (RA), and it is associated with poor outcomes. The literature on multimorbidity suffers from numerous definitions that make comparisons difficult. We aimed to use our population-based cohort to validate a list of morbidities proposed by England et al. (ARD 2020).

Methods: In this retrospective, population-based study, residents of a geographically well-defined area with prevalent RA on 1-1-2015 were identified from a comprehensive medical record linkage system. Age and sex-matched non-RA comparators were selected from the same underlying population. Diagnostic codes were retrieved for a 5-year period prior to the prevalence date. Using 2 codes at least 30 days apart, the 44 morbidities described by England were defined, as well as 78 Clinical Classification Software (CCS) categories with chronic disease flags that did not overlap with the 44 morbidities. Rheumatoid arthritis and categories likely representing diagnostic uncertainty with RA (e.g., lupus, polymyalgia rheumatica) were excluded from the morbidities for comparability between cohorts. False discovery rate methods were used to compare the prevalence of each morbidity in the RA vs non-RA cohorts adjusting for multiple comparisons.

Results: A total of 1409 patients with prevalent RA (72% female; 92% Caucasian; mean age 63.5 years) and 1409 non-RA (72% female; 90% Caucasian; mean age 63.4 years) were studied with 96% of RA and 90% of non-RA having at least 5 years of prior medical history. Multimorbidity (defined as 2+ morbidities) was present in 1187 (84%) of RA and 953 (68%) of non-RA subjects using the 44 morbidities with 5+ morbidities present in 749 (53%) of RA and 492 (35%) of non-RA ($p < .001$ for both). RA patients had significantly higher prevalence compared to non-RA of 20 of the 44 morbidities with 33 of 44 morbidities yielding OR >1.20 (Table). The modest sample size of this cohort may have reduced the number of significant findings compared to the original report on the 44 morbidities. Among the additional 78 CCS categories, 9 were significantly higher in RA than non-RA. The majority of these morbidities (i.e., embolism/thrombosis, organic sleep disorders, hyperparathyroidism, vitamin D deficiency, chronic skin ulcers, and foot deformities) are known to be more common in patients with RA. Some morbidities (i.e., thrombocytopenia, leukopenia, other upper respiratory infections) could reflect complications of RA therapy.

Conclusion: Patients with RA have a higher prevalence of multimorbidity compared to non-RA subjects. These results validate the previously published list of 44 morbidities, and only identify a small number of other morbidities to consider in patients with RA. Further research is needed to unify the list of morbidities used to study multimorbidity in patients with RA.

Table. Comparison of morbidity prevalence in patients with and without RA.

Morbidity	RA (%)	Non-RA (%)	Odds Ratio [95%CI] RA vs. Non-RA	Q-value
Multimorbidity (2+)	1187 (84.2)	953 (67.6)	2.92 [2.41-3.56]	<0.001
Multimorbidity (5+)	749 (53.2)	492 (34.9)	2.53 [2.13-3.01]	<0.001
Morbidities (England Categories)

Abstract Number: 1658

Risk of Other Autoimmune Conditions Among Relatives of Patients with Rheumatoid Arthritis

Katherine Liao[1], Thany Seyok[1] and Lisa Cannon-Albright[2], [1]Brigham and Women's Hospital, Boston, MA, [2]University of Utah School of Medicine, Salt Lake City, UT

SESSION INFORMATION
Session Date: Tuesday, November 9, 2021
Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster IV: Outcomes, Trajectory of Disease, & Epidemiology (1645–1673)
Session Type: Poster Session D
Session Time: 8:30AM–10:30AM

Background/Purpose: Autoimmune conditions appear to cluster in families, as may be expected by shared genetic risk factors in conditions such as rheumatoid arthritis (RA), autoimmune thyroiditis (AITD), celiac disease, and systemic lupus erythematosus (SLE). However, these conditions are polygenic, individual risk alleles have small effect sizes, and only a handful of alleles are shared across diseases. There are limited data on how to consider risk for autoimmune diseases among family members with RA. The objective of this study was to determine the risk of developing AITD, celiac, and SLE among first-, second-, and third- degree relatives (FDR, SDR, TDR) of RA patients.

Methods: This study was performed in the Utah Population Database (UPDB) containing genealogical data from the 1850s to modern day descendants. We analyzed UPDB genealogy data linked to in- and outpatient diagnosis code data from the University of Utah Health Sciences Center (UUHSC) electronic health record data from 1994-2020. International classification of diseases (ICD) 9th and 10th revision data were extracted on RA, AITD, celiac, inflammatory bowel disease (IBD), and SLE for RA patients and FDR, SDR and TDRs. Cases were defined using ≥1 diagnosis code. Odds ratios (OR) were estimated by comparing the number of autoimmune cases among relatives of RA patients to the expected cohort-matched population rates estimated using linked UUHSC EHR data. We calculated OR for RA among relatives of RA patients as a positive control; IBD served as a negative control.

Results: We studied 5,603 subjects with RA and 18,844 first-, 37,413 second-, and 78,169 third-degree relatives with linked UUHSC data. Among FDRs of RA subjects, we observed a significantly higher risk of AITD (OR 1.28, 95% CI 1.08. 1.50), celiac (OR 1.51, 95% CI 1.18, 1.92) and SLE (OR 1.34, 95% CI 1.11, 1.59) compared to population rates (**Figure**). Among the autoimmune conditions, only SLE had an increased risk among SDRs of RA patients. No

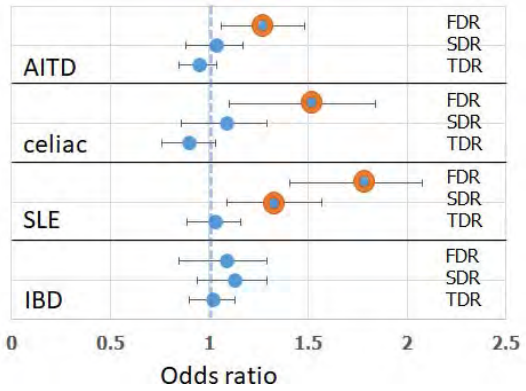

Figure. Risk of autoimmune thyroiditis (AITD), celiac, systemic lupus erythematosus (SLE), and inflammatory bowel disease (IBD) among first-, second-, and third-degree (FDR, SDR, TDR) among relatives of patients with rheumatoid arthritis (RA) compared to the population. [Orange circle, p<0.01].

significant increased risk for AITD, celiac or SLE was observed among TDRs compared to the overall population. The OR for FDRs of RA patients was 2.23 (95% CI 2.1-2.4), OR 1.37 (95% CI 1.3, 1.5) for SDRs, in line with prior studies. Rates of IBD among relatives of RA patients were similar to population rates.

Conclusion: Results from this unique dataset linking genealogy with phenotypic data in a large population suggest that a lower threshold for screening FDRs, i.e. the siblings, offspring, and parents of RA subjects, is warranted among relatives who exhibit signs or symptoms for AITD, celiac or SLE. Our data do not support a higher need to screen for these autoimmune conditions among TDRs, e.g. first cousins, of RA patients.

Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster IV: Outcomes, Trajectory of Disease, & Epidemiology (1645–1673)

Session Type: Poster Session D

Session Time: 8:30AM–10:30AM

Background/Purpose: Depression occurs with a prevalence of about 17% (95% confidence interval (CI): 10-24) in patients with RA (1) and both disorders may share common proinflammatory pathways affecting neural and extra-neural tissues (2). Recently, in an incident RA single center cohort, we have shown that the main indication for dispensing antidepressants is depression and the frequency of dispensing coincides with the occurrence of depression reported in the medical literature (3). In the present study, we used the first dispensing of antidepressants as proxy for clinical depression with the aim to describe the mortality risk associated with depression in patients with incident RA.

Methods: In DANBIO (4), we identified 18,085 patients diagnosed with RA (index date) from January 1, 2008 to September 30, 2018 by their unique personal registration numbers. We excluded patients with a recorded dispensing of MTX (Anatomic Therapeutic Chemical code L01BA01) and/or antidepressants (N06A) in the Danish National Prescription Register or recorded hospital contacts with RA (International Classification of Diseases (version 10) codes M05 or M06) in the Danish National Patient Register, 3 years prior to the index date. From the index date, we defined depression as first dispensing of antidepressants and collected death dates from the Danish Civil Registration System. The patients were followed until December 31, 2018 and all-cause mortality was estimated in two dynamic risk periods: the period from the index date until first dispensing of antidepressants (if it occurred) and the period after dispensing of antidepressants. We calculated hazard rate ratios (HRR) by modelling dispensing of antidepressants as time-varying exposure and adjusted for potential confounders: age, gender, comorbidity, cohabitation, employment status, highest attained education, and income.

Table 1. Baseline characteristics of RA patients by depression status defined as first dispensing of antidepressants (no missing observations unless otherwise stated)

	No antidepressants (n=10,076)	Antidepressants (n=1,111)
Age (years), %		
≤55	37	38
>55 to ≤70	38	33
>70	25	29
Female, %	65	72
Charlson comorbidity index, %		
0	76	69
1	13	17
≥2	10	14
Cohabitation, %		
Living alone	24	29
Together	74	69
Missing	1	2
Employment, %		
Employed	48	35
Unemployed	2	2
Not in labor market	43	46
Missing	7	17
Highest attained education, %		
Low	36	43
Medium	56	52
High	6	2
Missing	3	3
Yearly household income (5-year average before RA index date, USD), %		
Low (<33,000)	8	13
Medium low (33-49,999)	17	23
Medium high (50-66,000)	16	17
High (>66,000)	57	46
Missing	1	2

Table 2. Crude and adjusted HRR (95% CI) for death, comparing mortality in the risk period until and after dispensing of antidepressants

	No. deaths/person-years at risk		HRR	
Follow-up	Risk period until dispensing of antidepressants	Risk period after dispensing of antidepressants	Crude	Adjusted
0-2 years	93/20,125	15/437	3.67 (2.12-6.33)	3.53 (2.03-6.14)
0-11 years	511/54,084	162/3,862	3.36 (2.80-4.03)	3.23 (2.63-3.97)

Results: We included 11,187 incident RA patients of which 1,111 (10%) were initiators of antidepressants (Table 1). Initiation of antidepressants was a strong predictor of both 2-year mortality (adjusted HRR 3.53) and mortality during the total follow-up period (adjusted HRR 3.23) (Table 2).

Conclusion: Depression, defined as first dispensing of antidepressants, was associated with more than 3-fold increased mortality risk in patients with incident RA.

Relationship Between Risk of New Onset Diabetes Mellitus and Exposure to Individual Antirheumatic Drugs in Patients with Rheumatoid Arthritis: A Nationwide Population Study

So Hye Nam[1], Min-Ju Kim[2], Ye-Jee kim[2], Soo Min Ahn[2], Seokchan Hong[3], Chang-Keun Lee[2], Bin Yoo[3], Ji Seon Oh[4] and Yong-Gil Kim[2], [1]Uijeongbu Eulji Medical Center, Uijeongbu, Gyeonggi-do, Republic of Korea, [2]Asan Medical Center, Seoul, Republic of Korea, [3]Asan Medical Center, Seoul, South Korea, [4]Asan Medical Center, Ulsan, Republic of Korea

SESSION INFORMATION

Session Date: Tuesday, November 9, 2021

Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster IV: Outcomes, Trajectory of Disease, & Epidemiology (1645–1673)

Session Type: Poster Session D

Session Time: 8:30AM–10:30AM

Background/Purpose: Rheumatoid arthritis (RA) is a systemic inflammatory disease that affects glucose metabolism, mainly insulin resistance, which can lead to diabetes mellitus (DM). Although there have been reports that anti-inflammatory therapy can reduce the risk of diabetes in RA, the relationship between individual antirheumatic drugs and DM has not been sufficiently investigated. Therefore, we aimed to investigate the effect of disease-modifying antirheumatic drugs (DMARDs) on the incidence of DM in the RA population.

Methods: We conducted a nested case-control study in a cohort of 69 779 DM-naïve adult (≥ 18 years old) patients with RA from the Korean Health Insurance Review and Assessment Service claims data from 2011 to 2019. Cases with incident DM were identified and individually matched to randomly selected controls (RA cases without DM) by the age of RA diagnosis, sex, and disease duration (1:4 matched). Comorbidities including hypertension, chronic kidney disease, Charlson Comorbidity Index (CCI), and concomitant drug use were measured for one year prior to the event or index date. DMARDs use was stratified by duration of exposure. The association of each DMARD use with DM risk was estimated using conditional logistic regression adjusted for CCI and concomitant drug use.

Results: 3772 (5.4%) patients were diagnosed with DM (mean age, 62.3 ± 10.9 years; 77,6% women), and the mean duration between RA diagnosis and incident DM was 2.6 ± 2.1 years. A total of 146139 controls were matched, and DM risk was associated with corticosteroids use and cumulative dosage. 3515 of 3772 (93.2%) patients with DM have been treated with conventional DMARDs. The risk of incident DM was dependent on the type and the duration of exposure of DMARDs (Figure). In a multivariable-adjusted analysis, exposure of less than 90 days per year to hydroxychloroquine (HCQ), methotrexate (MTX), sulfasalazine, leflunomide, tacrolimus (TAC), or any targeted synthetic DMARDs (tsDMARDs) was associated with an increased risk of DM compared with no use. However, at exposure exceeding 270 days per year, HCQ (adjusted OR, 0.76; 95% CI, 0.69-0.84; $p < 0.001$) and MTX (adjusted OR, 0.81; 95% CI, 0.74-0.89; $p < 0.001$) were associated with a significant decrease in DM risk, and TAC (adjusted OR, 1.27; 95% CI, 1.07-1.51; $p = 0.006$) was associated with an increased risk. Among biologic DMARDs, use of TNF inhibitors or non-TNF inhibitors was not related to DM risk at exposure less than 90 days per year, but non-TNF inhibitors was associated with a significant decrease in DM risk at exposure more than 270 days per year (adjusted OR, 0.52; 95% CI, 0.29-0.93, $p = 0.026$).

Conclusion: This study suggested that long-term use of HCQ, MTX, or non-TNF inhibitors for periods more than 270 days per year was associated with a reduction in the incidence of DM. Thus, these regimens could be considered to control disease activity especially in patients with high risk of DM.

SESSION INFORMATION

Session Date: Tuesday, November 9, 2021

Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster IV: Outcomes, Trajectory of Disease, & Epidemiology (1645–1673)

Session Type: Poster Session D

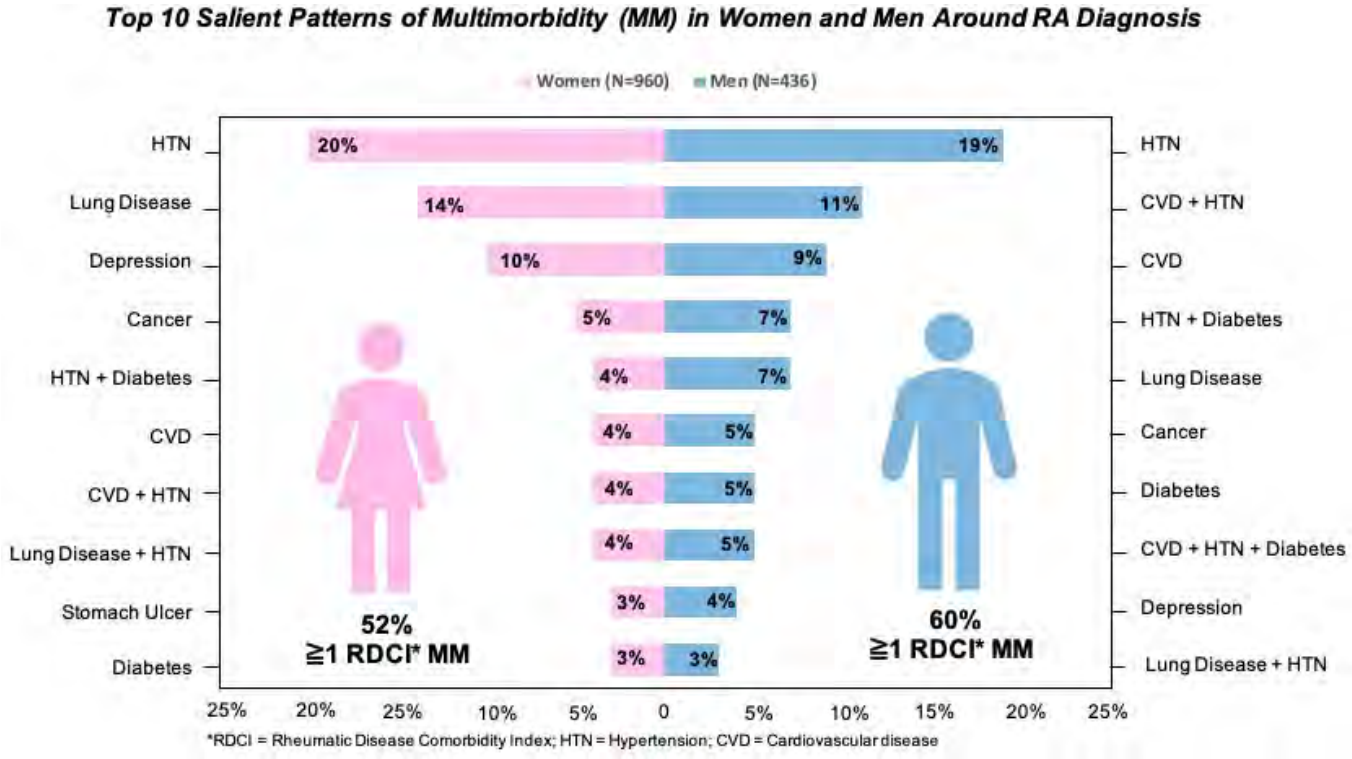
Session Time: 8:30AM–10:30AM

Background/Purpose: Chronic disease multimorbidity (MM) is prevalent in RA. As MM can vary in complexity and different combinations of chronic conditions may have different physical and psychological impacts on patients, there is an increasing need to identify which specific conditions may cluster around the time of RA onset. The objective of the present study was to identify the top 10 most prevalent MC patterns in women and men around RA diagnosis and estimate their associations with disability over the first year of follow up, in a large real-world incident RA cohort.

Methods: Data were from early RA patients (< 1-year of symptoms; 88% meeting RA classification criteria) diagnosed and treated in rheumatology clinics across Canada enrolled in CATCH (Canadian Early Arthritis Cohort) from Jan 2007 through March 2020. Participants were included in the present study if they completed the Rheumatic Disease Comorbidity Index (RDCI) at baseline and repeat assessments of disease activity (DAS28) and disability (MHAQ) every 3- months over 1 year follow up. The RDCI is a validated weighted comorbidity index (range 0-9) assessing the presence of 11 conditions selected based on associations with RD health outcomes (lung disease, CVD (MI, stroke, and other CV), HTN, fracture, depression, diabetes, cancer, ulcer or stomach problem). We identified the top 10 most prevalent MM patterns in women and men by first coding the presence/ absence of each condition for each participant and then ranking the prevalence of all possible reported combinations by sex. We estimated sex-stratified longitudinal associations between prevalent MM patterns and repeated measures of disability in the first year follow up with generalized estimating equations (GEE), adjusted for age, education, symptom duration, smoking, obesity and time-varying measures of DAS28 disease activity.

Results: The sample included 2,576 ERA patients, 1843 (72%) were female, with a mean(sd) age of 56 (15) years and 6 (3) months of symptoms. At baseline 2,449 (95%) were treated with csDMARDs (mostly methotrexate (74%)) and 40 (2%) with a biologic. More than half of patients (54%) reported >=1 MM. Prevalence, patterns and complexity of MM differed by sex. HTN, lung disease and depression were the most prevalent MM patterns reported in women and HTN, CVD, and CVD+HTN were the most prevalent patterns reported in men (Figure). More complex MM patterns involving multiple conditions were more prevalent in men (26%) than in women (12%) (Figure). In multivariable GEE models, depression (beta: 0.14, 95% CI: 0.04, 0.24) in women, and lung disease + HTN (beta: 0.22, 95% CI: 0.03, 0.42) in men, were significantly associated with higher disability over time.

Conclusion: Results from this large real-world incident cohort study suggest that multimorbidity is common around RA diagnosis and differs between men and women. MM patterns significantly associated with increased disability



over time included depression in women, and lung disease + HTN in men. Results suggest potential shared risk factors and pathways between identified MM patterns and highlight the need to screen for and treat MM conditions, particularly those which increase disability.

Unrecognised, Subclinical, Structural or Functional Lung Changes in Rheumatoid Arthritis Is Associated with a Higher Risk of Developing Serious Respiratory Tract Infection

Benjamin Worcester[1], Dorothy Wang[2], Susan Morton[3] and Michelle Leech[4], [1]Monash Health, Melbourne, Australia, [2]Melbourne Health, Clayton, Australia, [3]Monash Health, Clayton, Australia, [4]Monash Medical Centre, Australia, Australia

SESSION INFORMATION

Session Date: Tuesday, November 9, 2021

Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster IV: Outcomes, Trajectory of Disease, & Epidemiology (1645–1673)

Session Type: Poster Session D

Session Time: 8:30AM–10:30AM

Background/Purpose: The incidence of lung disease within the rheumatoid arthritis is well described and likely underestimated. Additionally, RA patients are at higher risk for developing significant infections (SI).

In our own cohort the most common infections recorded were respiratory tract infections (RTI) and this was most likely to lead to increased mortality. This accords with studies showing that hospitalisations from pneumonia are higher in RA cohort compared to matched cohorts.

To determine if pre-existing subclinical functional or structural lung disease had an association with an increased risk of respiratory tract infections, including viral pneumonias, as opposed to other infections.

Methods: All patients in our tertiary hospital RA cohort, in the last 3 years, who had any SI were included. The patient's medical history was examined to determine if they had evidence of functional or structural lung damage prior to the infection using imaging records and previous pulmonary function tests. Patients presenting to hospital, or their general practitioner, and their diagnosis on discharge was either community acquired pneumonia, viral respiratory tract infection or other lower respiratory tract infection were included. Patients with RTI were compared to a sample of patients with RA and any non-respiratory SI (Table 1).

A Chi-Square analysis was used to compare the groups. The two groups were matched for daily steroid use, smoking history and vaccination status, there was no statistical difference between these two groups.

Results: 142 patients were identified as having an SI in the past 3 years in our cohort. 48 patients developed RTI and 94 patients who developed other infections including Urinary traction infections, skin and soft tissue infections. Of the 48 who developed RTI, 32 had evidence of subclinical lung disease compared to 16 with no evidence of lung disease. Of the 94 who developed other SI, only 21 had evidence of subclinical lung disease compared to 73 with no evidence of subclinical lung disease (Table 2).

Table 1. Patient demographics and selected investigations (n =142)

	Patients with evidence of sub-clinical lung changes (n=55)	Patients with no evidence of sub-clinical lung changes (n=87)
Patient Age, mean ± SD, years	58.58 ± 14.1	57.24 ± 13.3
Gender, No. (% female)	42 (76.4)	65 (74.7)
Duration symptoms, mean ± SD, years	21.4 ± 5.6	22.7 ± 5.1
Known pre-existing lung disease	11 (7.7%)	N/A
No known pre-existing lung disease	50 (90.1%)	81 (93.1%)
Functional lung abnormality	21 (14.8%)	N/A
Radiological lung abnormality	34 (23.9%)	N/A
Average daily steroid dose, mean ± SD, mg/day	2.2 ± 0.6	2.1 ± 0.5
Smoking history, mean ± SD, pack years	12.3 ± 17.7	11.7 ± 15.4
Vaccinated against pneumococcal disease	34 (61.8 %)	54 (62.1%)

Table 2. Type of infections suffered and evidence of subclinical lung disease (n = 142)

	Respiratory Tract infections (RTI)	Other significant infections (SI)
No evidence of lung abnormality	16	71
Evidence of subclinical lung disease	32	23

A Chi-Square analysis of the data was performed

$X^2 = (1, N = 142) = 23.84, p < 0.001$

allowing us to consider that pre-existing lung disease may be involved in this subset of RA patients being more susceptible to LRTIs. Patients with known pre-existing lung disease where excluded from this analysis.

Conclusion: A greater number of patients within the RTI group had previous lung abnormality compared to patients in the non-pulmonary infection group. This supports evolving literature that even subclinical lung abnormality should be considered within the suite of risk factors for RTI risk in RA.

Given the current climate and fear surround viral pneumonias, screening this cohort will allow for better risk stratification and management of these patients. This may include early admission and intervention or, in the outpatient setting, highlight the need for discussion around vaccinations to reduce this risk.

Abstract Number: 1663

The Influence of Comorbidity on Mortality in Patients with Rheumatoid Arthritis 1980-2015: A Longitudinal Population-based Study in Western Australia

Khalid Almutairi[1], Johannes Nossent[1], David Preen[1], Helen Keen[2] and Charles Inderjeeth[3], [1]University of Western Australia, Perth, Australia, [2]University of Western Australia, Daglish, Australia, [3]University of Western Australia, Nedlands, Perth, Australia

SESSION INFORMATION

Session Date: Tuesday, November 9, 2021
Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster IV: Outcomes, Trajectory of Disease, & Epidemiology (1645–1673)
Session Type: Poster Session D
Session Time: 8:30AM–10:30AM

Background/Purpose: Rheumatoid arthritis (RA) contributes to excess morbidity and mortality in RA patients compared with the general population. In Australia, there is a paucity of published literature on the mortality and morbidity rates in RA patients, despite the significant morbidity and mortality burden on health care costs due to RA. Linked data is the preferred method to estimate morbidity and mortality outcomes as they provide the best case ascertainment. The aim of this study was to describe temporal changes in mortality rates for patients with Rheumatoid arthritis (RA) in relation to comorbidity accrual from 1980-2015 in Western Australia (WA).

Methods: Using population-level linked data from WA health administrative datasets (hospital morbidity, emergency department and death data), we followed 17,125 RA patients (ICD-10-AM M05.00–M06.99, ICD-9-CM 714) from 1980- 2015. Comorbidity was ascertained using the Charlson Comorbidity Index (CCI). Mortality rate ratios (MRR) were calculated per decade between the RA cohort and the WA general population by direct age standardisation

Table 1. Mortality rates observed among patients with rheumatoid arthritis, based on Charlson Comorbidity Index, per 1000 hospital separations, Western Australia hospitals (1980-2015)

Time period	1980-1990	1991-2000	2001-2010	2011-2015
Total number of hospital separations	82099	107731	185398	80410
Number of deaths	1620	2875	3183	1277
CCI score				
0	481 (29.7%)	1024 (35.6%)	1197 (37.6%)	565 (44.2%)
1	838 (51.7%)	1271 (44.2%)	1358 (42.6%)	467 (36.6%)
2	273 (16.8%)	518 (18%)	581 (18.3%)	232 (18.2%)
3	1 (0.1%)	4 (0.2%)	2 (0.1%)	0 (0%)
6	27 (1.7%)	58 (2%)	45 (1.4%)	13 (1%)
In-hospital RA mortality per 1000 hospital separation	19.7	26.7	17.2	15.9
Parentage of average annual change per annum in the period	0	3.8	-4.8	-2.6
Parentage of average annual change since 1980	0	1.5	-1.4	-0.2

CCI= Charlson Comorbidity Index.

method, while temporal trends of comorbidities and in-hospital mortality were estimated per 1000 hospital separations in three consecutive decades.

Results: During 356,069 patient-years, a total of 8955 (52%) deaths occurred in the RA cohort. The leading causes of deaths were cardiovascular diseases 2386 (26.6%), cancer 1511 (16.8%), rheumatic diseases 519 (5.8%), chronic pulmonary disease 491 (5.5%), dementia 269 (3.0%) and diabetes 235 (2.6%). The highest prevalence of comorbidity (688.6 per 1000 separations) was in the period 1991-2000 following a 1.3% average annual increase since 1980. In-hospital mortality rate was also highest (26.7 deaths per 1000 separations) in the same period. After 2001, both RA comorbidity and mortality rates decreased annually by -0.5% and -4.8%, respectively, with annual changes of -4.4% to -2% and from 2011- 2015, respectively. The overall mortality rate in RA patients after age adjustment was 2.5-times (95%CI: 2.52-2.65) higher than the general population between 1980- 2015 and 1.5-times (95%CI: 1.39-1.81) for the period 2011-2015.

Conclusion: The annual comorbidity prevalence and mortality rates in WA have decreased significantly since 2001, reflecting improvements in the management of RA and comorbidity. Nonetheless, the mortality rate in RA patients in WA remains 1.5-times higher than their community counterparts suggesting that there is room to achieve further improvements.

Changes in Physical Function Were Not Associated with Clinically Important Changes in Muscle Strength or Physical Performance over Time - A Cohort Study

Rafaela Espírito Santo[1], Joshua Baker[2], Jordana Silva[3], Lidiane Filippin[4], Juliana Portes[1], Claiton Brenol[1], Rafael Chakr[5] and Ricardo Xavier[6], [1]Hospital de Clínicas de Porto Alegre, Laboratório de Doenças Autoimunes, Serviço de Reumatologia, Porto Alegre, Brazil; Universidade Federal do Rio Grande do Sul, Faculdade de Medicina, Porto Alegre, Brazil, [2]University of Pennsylvania, Philadelphia, PA, [3]Institute of musculoskeletal medicine, University Hospital Munster, Munster, Germany, [4]Universidade La Salle, Canoas, Brazil, [5]Universidade Federal do Rio Grande do Sul, Porto Alegre, Brazil, [6]Departamento de Reumatologia, Hospital de Clínicas de Porto Alegre, Universidade Federal do Rio Grande do Sul, Porto Alegre, Brazil

SESSION INFORMATION

Session Date: Tuesday, November 9, 2021

Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster IV: Outcomes, Trajectory of Disease, & Epidemiology (1645–1673)

Session Type: Poster Session D

Session Time: 8:30AM–10:30AM

Background/Purpose: The Health Assessment Questionnaire Disability Index (HAQ) is negatively associated with muscle strength by handgrip test and positively associated with physical performance by timed up and go test (TUG test) in patients with rheumatoid arthritis (RA). Although the HAQ score may improve during treatment of inflammatory arthritis, the association between the self-reported HAQ scores and objective assessments of muscle strength or physical performance over time has not been clearly defined. We therefore aimed to evaluate the association between HAQ and clinical features, muscle strength and directly-assessed physical performance at baseline among patients with RA. Second, we aimed to determine the association between changes over time in self-reported physical function and disease activity, muscle strength, and physical performance.

Methods: In a prospective cohort design, two independent RA cohorts were retrospectively analyzed. Physical function was assessed by HAQ. Disease activity was assessed by the Disease Activity Score in 28 joint (DAS-28-CRP). Pain was assessed by The Visual Analog Scale for Pain (VAS Pain). Muscle strength was assessed by handgrip test and chair test. Physical performance was assessed by TUG test and The Short Physical Performance Battery (SPPB). T test for independent samples, Mann-Whitney U test of independent samples, Pearson's chi-squared test, Spearman correlation coefficients was performed.

Descriptive data of physical function, muscle strength and physical performance on the two cohorts at baseline.

	Combined cohorts	North American Cohort	Brazilian Cohort	P
HAQ-DI scores	0.8 (0.2 -1.5)	0.7 (0.2-1.3)	1.1 (0.3-1.9)	
Women	-	0.8 (0.1-1.4)	1,0 (0.2-1.8)	0.153[2]
Men	-	0.6 (0.2-1.1)	1.8(0.7-2.1)	0.00[2]
Handgrip test				
Women (kg), mean ± SD	16.9 ± 9.0	19.8 ± 9.2	14.7 ± 8.3	0.013[1]

p, values of the difference the American group and Brazilian group. 1 t test for independent samples; 2 Mann-Whitney U test of independent samples. HAQ-DI,by the Health Assessment Questionnaire Disability Index; TUG test, Timed up and go test; SPPB, The Short Physical Performance Battery.

Association among physical function (by HAQ-DI) and clinical features, muscle strength and physical performance.

	Combined cohorts	American cohorts	Brazilian Cohorts
DAS28-CRP	0.6 (0.000)	0.6 (0.000)	0.5 (0.000)
VAS pain scale	0.6 (0.000)	0.6 (0.000)	0.6 (0.000)
Muscle strength by Handgrip test	- 0.4 (0.000)	-0.5 (0.000)	-0.3 (0.001)
Muscle strength by Chair Test	0.5 (0.000)	0.5 (0.000)	0.5 (0.000)
Physical performance by TUG test	0.6 (0.000)	-	0.6 (0.000)
Physical performance by SPPB	-0.6 (0.000)	-0.6 (0.000)	-

*Spearman correlations; DAS-28–CRP, the Disease Activity Score-28 with C reactive protein; VAS pain, The Visual Analog Scale for Pain; HAQ-DI,by the Health Assessment Questionnaire Disability Index; TUG test, Timed up and go test; SPPB, The Short Physical Performance Battery.

Results: A total of 205 RA patients were studied [North American Cohort (N=115); Brazilian Cohort (N=90)]. At baseline, the mean age was 56.2 ± 10.5 years old in the combined cohort and not statistically different between the two cohorts (p=0.75). The majority of patients were in low disease activity and this was not statistically different between the two cohorts (p=0.92). Brazilian men had greater HAQ than North American men (p< 0.001), while HAQ was not statistically different among women (p=0.15). Brazilian women had lower muscle strength by handgrip test and chair test than North American women (p< 0.05), while Brazilian men showed less muscle strength by chair test than North American men (p< 0.05). In both cohorts the RA patients showed good physical performance. At baseline, HAQ was strongly associated with DAS28-CRP, VAS pain, muscle strength and physical performance (p< 0.05). Patients that experienced a change in HAQ as much as the minimal clinically important difference (0.22) (either improvement or worsening) were not more likely to experience a clinically important change in muscle strength or physical performance over time (p >0.05) in both cohorts. American patients that had a worsening of HAQ over time did show worsening on SPPB (p=0.022).

Conclusion: Poor physical function as measured by HAQ is closely associated with disease activity, pain, muscle strength, and physical performance among patients with RA. However, in this sample, the clinically important changes physical function were not associated with clinically important changes in muscle strength or physical performance over time. These observations highlight a disconnect between changes in self-report of disability over time in patients with RA compared to direct assessments of physical function.

Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster IV: Outcomes, Trajectory of Disease, & Epidemiology (1645–1673)

Session Type: Poster Session D

Session Time: 8:30AM–10:30AM

Background/Purpose: Prior studies show an independent association between greater physical activity and lower inflammatory markers among adults in the general population, but the impact of physical activity on systemic inflammation in people with rheumatoid arthritis (RA) is unknown. We aimed to determine whether physical activity associates with differential expression of inflammatory genes in RA.

Methods: Data derived from baseline assessments of a prospective observational cohort of RA patients. At each study visit, we obtained clinical data, collected peripheral whole blood for RNA sequencing, and provided

Table. Characteristics of Patients with Rheumatoid Arthritis by Physical Activity Category

Characteristics	Overall	Physical Activity** Status			P
		Active	Intermediate	Inactive	
	(N = 35)	(N = 13)	(N=14)	(N = 8)

*Values are percent unless otherwise indicated. P-values calculated using chi-squared tests for categorical measures and ANOVA for continuous measures.

**Physical activity was categorized by lower (inactive), middle (intermediate), and upper (active) tertiles for percentage of time spent in moderate or vigorous physical activity among all study participants.

RADAI - Rheumatoid Arthritis Disease Activity Index

TNFi - tumor necrosis factor inhibitor

DMARD - disease modifying antirheumatic drug

CVD - history of stroke, coronary artery disease, and/or myocardial infarction

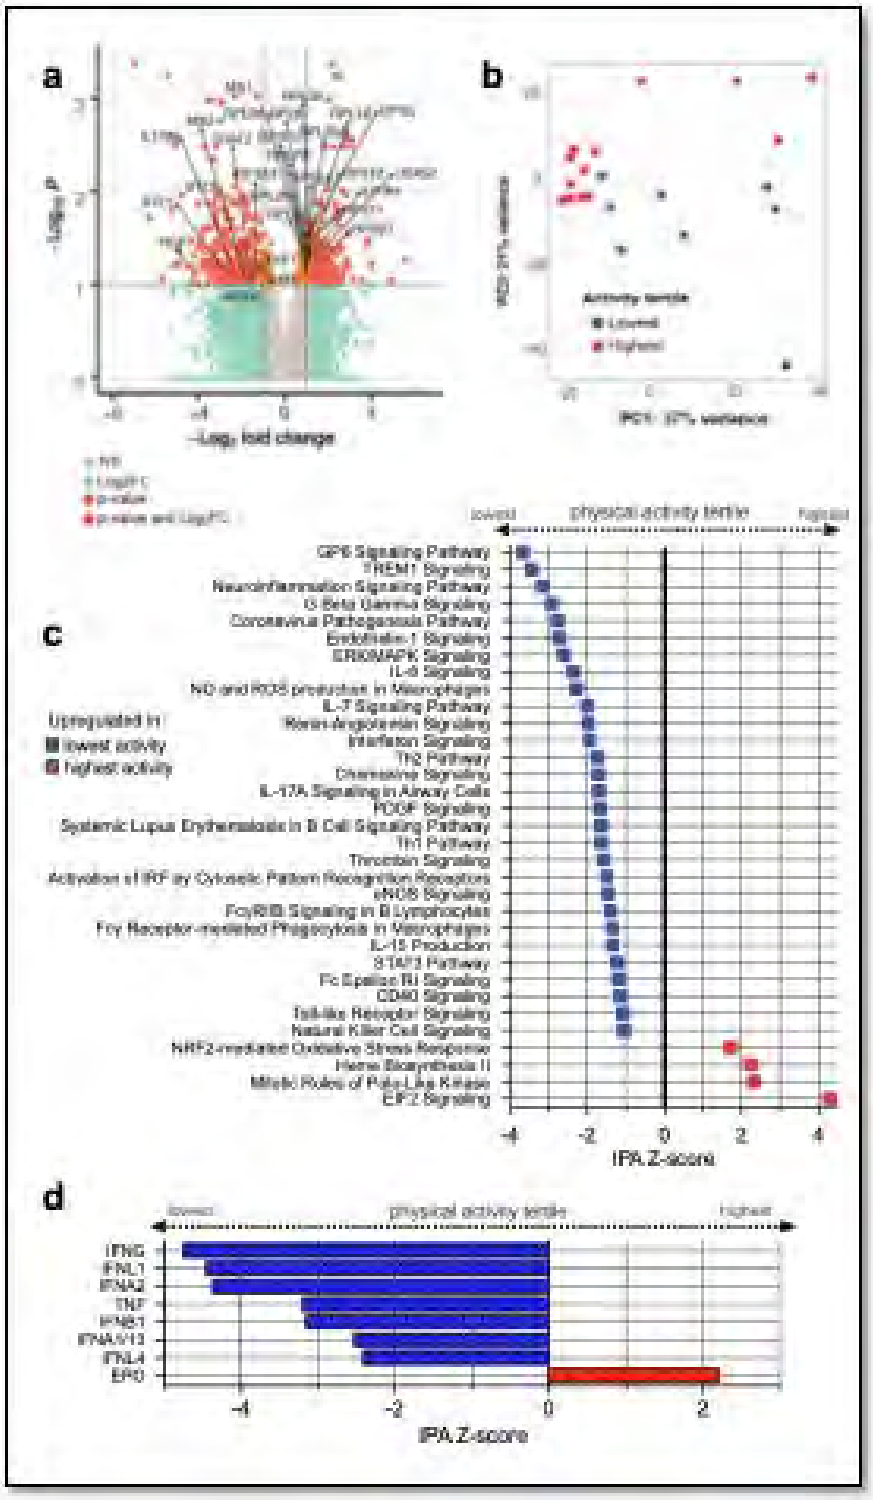

Figure 1. Differentially expressed (DE) genes and related signaling pathways identified from peripheral blood transcriptional profiling of RA patients with the highest versus lowest tertiles of physical activity. a) Volcano plot of DE genes depicting 365 genes up-regulated in the highest activity tertile and 402 down-regulated genes at an adjusted P-value < 0.1 with respect to the highest physical activity tertile. Genes related to immune signaling and translation are highlighted. b) Principal Component Analysis based on the DE genes demonstrates separation of patients based on tertile of physical activity. c) Ingenuity Pathway Analysis (IPA) based on differential gene expression analyses demonstrating expression of canonical signaling pathways. Significant IPA results were defined as those with a Z-score absolute value greater than 2 or an overlap P value < 0.05. Depicted are the top three up- and down-regulated canonical pathways based on Z-score, as well as all pathways related to immunity and inflammation with an |Z| > 1 and overlap P value < 0.05. d) Predicted activation state of upstream cytokines in the highest versus lowest physical activity tertiles. Cytokines with a |Z| > 2 and overlap P value < 0.05 plotted.

participants with actigraphs (GT9X ActiGraph Link device) to objectively measure physical activity for 7 consecutive 24-hour periods. Physical activity groups were defined by the highest and lowest tertiles for percentage of time spent in moderate/vigorous physical activity (metabolic equivalent level ≥2.00) across the sample. RNA extraction, library preparation, Illumina sequencing, and gene expression data processing were performed using established methods. Genes differentially expressed in the most versus least physically active groups were identified using DESeq2 with the Independent Hypothesis Weighting (IHW) multiple testing procedure. Sex, age, race and ethnicity were included as covariates in the linear model. Ingenuity Pathway Analysis (IPA) Canonical Pathway and Upstream Regulator Analyses were employed on differentially expressed genes with a $P < 0.1$ ranked by log2 fold change to identify biological pathways most affected by physical activity.

Results: 35 patients had complete clinical, actigraphy, and transcriptomic data available for analysis. Mean age was 56 years (SD 12.1), and 90% were female. Race/ethnicity was 32% white, 11% African American, 8% Asian, and 40% Hispanic (Table). Participants spent 48%, 41%, and 12% of time awake in sedentary, light, and moderate physical activity, respectively. None of the participants achieved vigorous activity. We identified 767 differentially expressed genes between the highest versus lowest physical activity tertiles at an adjusted P value < 0.1 (Figure 1a). IPA canonical pathway analysis revealed that the most physically active patients exhibited down regulation of diverse innate and adaptive immune signaling pathways (Figure 1c). Assessment of upstream cytokine activation states demonstrated inhibition of type I, II and III interferons and activation of EPO in the highest physical activity tertile patients (Figure 1d).

Conclusion: Among a racially and ethnically diverse RA cohort, participants who spent more time in moderately intense physical activity had down-regulation of genes involved in both innate and adaptive immune signaling compared to those who were more sedentary. These findings provide mechanistic evidence to support a disease-modifying effect of physical activity in RA.

Association of Objectively Measured Sleep Characteristics with Rheumatoid Arthritis Disease Activity

Patricia Katz[1], Sarah Patterson[2], Mary Nakamura[3], Aric Prather[1], Laura Trupin[4], Stephanie Rush[1] and Katie Stone[1], [1]University of California San Francisco, San Francisco, CA, [2]University of California San Francisco, Pacifica, CA, [3]UCSF/SFVAHCS, San Francisco, CA, [4]UC San Francisco, San Francisco, CA

SESSION INFORMATION
Session Date: Tuesday, November 9, 2021
Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster IV: Outcomes, Trajectory of Disease, & Epidemiology (1645–1673)
Session Type: Poster Session D
Session Time: 8:30AM–10:30AM

Background/Purpose: A large proportion of individuals with rheumatoid arthritis (RA), between 45%-70%, report sleep problems. Despite frequent reports of sleep problems, however, studies using objective measures of sleep in RA are rare, but are needed to provide greater accuracy than classifications based on self-report. Sleep disturbances may have unique causes and consequences in RA related to disruptions in the circadian rhythms of inflammatory and neuroendocrine biomarkers. We report objectively measured sleep characteristics among a cohort of individuals with RA and the associations with self-reported and physician-assessed disease activity.

Methods: Data are from the baseline assessment of an ongoing longitudinal study of sleep disturbances in RA, in which 111 participants completed at least 4 nights of sleep monitoring using an Actigraph GT9X. The following sleep parameters were examined and compared to age and sex reference values from polysomnography: total sleep time, sleep efficiency (minutes sleeping/minutes in bed), number of awakenings/night (measure of fragmented sleep), and duration of awakenings/night (WASO [wake after sleep onset], also a measure of fragmented sleep). Total time in bed was also examined. The RA Disease Activity Index (RADAI) was used as a patient-reported measure of disease activity. RADAI includes self-reports of pain, painful joint counts, morning stiffness time, and patient global assessments. Physician-assessed disease activity using the Clinical Disease Activity Index (CDAI) and the Disease Activity Score-28 joints (DAS28-CRP) was available for a subset of participants who had in-person research visits prior to the

	yes	3.6 ± 2.0	**(n=10) 26.5 ± 13.9**	**(n=9) 10.5 ± 3.8**
	p	.48	**.006**	**.0002**

onset of the pandemic. Analyses tabulated the frequency of poor sleep based on reference values and used t-tests to examine differences in RADAI, CDAI, and DAS28-CRP between those with poor vs. normal sleep.

Results: Participant characteristics are shown in Table 1. Sleep characteristics are shown in Table 2. Compared to age and sex references, 57.9% had short sleep time, 74.4% had poor sleep efficiency, 87.4% had high WASO, and 19.8% had a high number of awakenings. Poor sleep efficiency was associated with significantly worse patient-reported disease activity (Table 3). There were no significant associations between other sleep parameters and patient-reported disease activity. Short sleep time, a high number of nighttime awakenings, and long time in bed were each associated with significantly worse physician-assessed disease activity (Table 3). There were no significant associations between sleep efficiency or WASO and physician-assess disease activity.

Conclusion: In this sample of individuals with RA, a high proportion exhibited sleep disturbances compared to age and sex reference groups, and sleep disturbances were associated with both patient-reported and physician-assessed disease activity. It will be important in future studies to examine the causal directions of the relationships between poor sleep and disease activity.

Abstract Number: 1667

Efficacy of Plasma Phosphoethanolamine as a Biomarker for Rheumatoid Arthritis-associated Depression

Yusuke Miwa[1], Yoshiaki Ohashi[2], Hajime Tomatsu[3] and Yuko Mitamura[4], [1]Division of Rheumatology, Department of Medicine, School of Medicine, Showa University, Tokyo, Japan, [2]HMT Biomedical Inc., Yokohama, Japan, [3]HMT Biomedical Inc., Chuo, Japan, [4]Department of Nursing, Showa University School of Nursing and Rehabilitation Sciences, Shinagawa-ku, Japan

SESSION INFORMATION
Session Date: Tuesday, November 9, 2021
Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster IV: Outcomes, Trajectory of Disease, & Epidemiology (1645–1673)
Session Type: Poster Session D
Session Time: 8:30AM–10:30AM

Background/Purpose: The odds of patients with rheumatoid arthritis (RA) experiencing depression is 1.42 (95% CI: 1.3–1.5; approximately 15% of patients) compared with healthy individuals. Diagnosis of depression is based on an interview, which is subjective to both psychiatrist and patient, and auxiliary diagnoses such as a self-rating scale for depression are uncertainty. Phosphoethanolamine (PEA), a plasma biomarker, has been reported to be a useful diagnostic biomarker for depression. We examined the efficacy of PEA as a biomarker for RA-associated depression.

Methods: This study included 52 registered RA patients who were recruited between 2019 and 2020. Patients provided written informed consent to participate and the study was approved by the Institutional Ethics Committee of the Showa University. The following background factors were investigated: age, sex, and disease duration. RA disease activity was evaluated using the Simplified Disease Activity Index. The depression status was evaluated using the Patient Health Questionnaire (PHQ)-9 as a standard scale. Questionnaires for depression, anxiety, and ego were also performed. Items of these questionnaire were converted into Scale A (depression/anxiety scale) and Scale B (adaptation scale). Plasma PEA was measured in Human Metabolome Technologies Inc. Statistical analysis was performed using the chi-square test and one-way analysis of variance.

Results: Forty-nine RA patients with no missing data were included in the analysis. The PHQ-9 score, the gold standard, was used to stratify patients by disease severity—normal, 33; mild depression, 12; moderate depression, 3; and severe depression, 1. Each group was compared between groups.

①The patient visual analog scale (VAS) score was significantly high among patients with depression ($p = 0.00157$). The difference in VAS scores of patients and doctors was significantly high considering patients with depression ($p = 0.00409$).

②The Scale A score was significantly high among patients with depression ($p = 1.19 \times 10^{-10}$), and the ratio of Scale A score to PEA was significantly high ($p = 1.64 \times 10^{-7}$) among patients.

③A significant difference was noted between the groups for the plasma PEA concentration ($p = 0.0272$). The plasma PEA concentration was low in patients with mild and moderate depression and high in a patient with severe depression.

④The Scale B score tended to be higher among patients with depression compared with others, without significant difference.

Conclusion: Plasma PEA alone presents a weak performance as a diagnostic biomarker for depression in patients with RA. However, a composite measure for diagnosing depression, including questionnaires for depression, anxiety, and ego may be used as an auxiliary diagnosis.

Unmet Need in Early Rheumatoid Arthritis - Why Do Some Patients Do Badly Despite Modern Treat-to-target Strategies of Care? Results from the Scottish Early RA (SERA) Inception Cohort

Elizabeth Clarke[1], **Claire Wood**[1], Alistair Tindell[1], Kay Graham[1], Alasdair McIntosh[2], Fraser Morton[2] and Duncan Porter[3], [1]NHS Greater Glasgow and Clyde, Glasgow, United Kingdom, [2]University of Glasgow, Glasgow, United Kingdom, [3]University of Glasgow, Bearsden, United Kingdom

SESSION INFORMATION

Session Date: Tuesday, November 9, 2021

Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster IV: Outcomes, Trajectory of Disease, & Epidemiology (1645–1673)

Session Type: Poster Session D

Session Time: 8:30AM–10:30AM

Background/Purpose: 'Treat to target' strategies of care have significantly improved outcomes in people with early rheumatoid arthritis; nonetheless, a significant proportion of patients have impaired health related quality of life (HR-QOL). Identifying baseline predictors of poor HR-QOL could enable us to direct appropriate resources towards people at high risk for adverse outcomes.

Methods: The Scottish Early Rheumatoid Arthritis study (Dale et al, PMID:27829394) is an inception cohort of patients with newly diagnosed RA and undifferentiated arthritis recruited in Scotland between 2011 and 2015 and followed up prospectively. Data were collected on demographics (age, gender, body mass index [BMI], employment

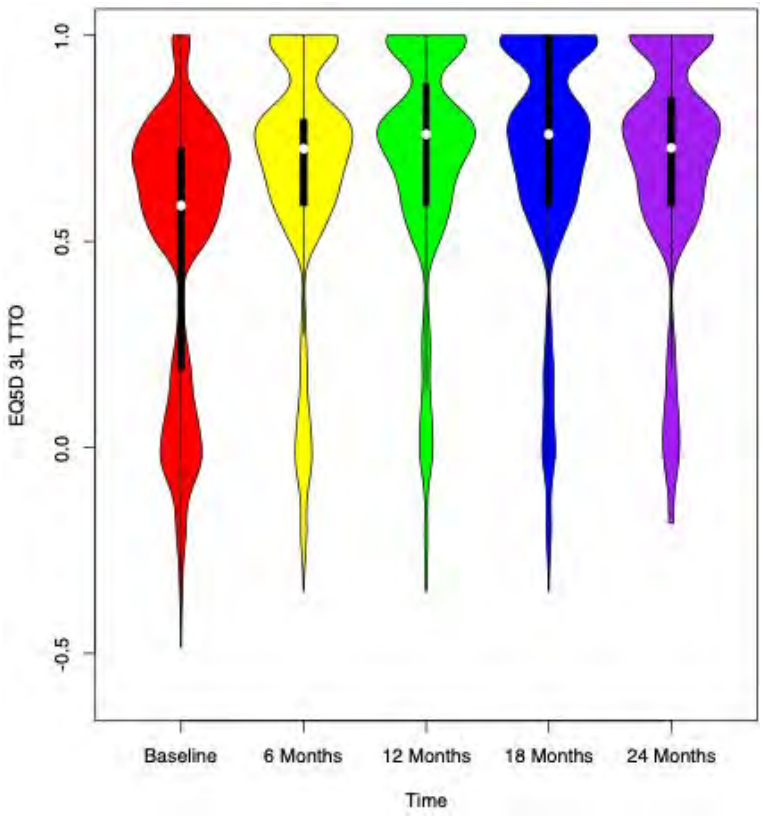

Figure 1. Violin Plot of EQ5D Time Trade Off (TTO) changes over 24 months.

status), serology, mood (Hospital Anxiety and Depression Score [HAD]), disease activity (SDAI), disability (Health Assessment Questionnaire [HAQ]) and socioeconomic status (Scottish Index of Multiple Deprivation [SIMD]). HR-QOL was measured using EQ5D; index scores calculated using the UK EQ5D-3L time trade off value set (Dolan et al, PMID:9366889). Univariate and multivariate models were developed to identify baseline predictors of HR-QOL at 12 months.

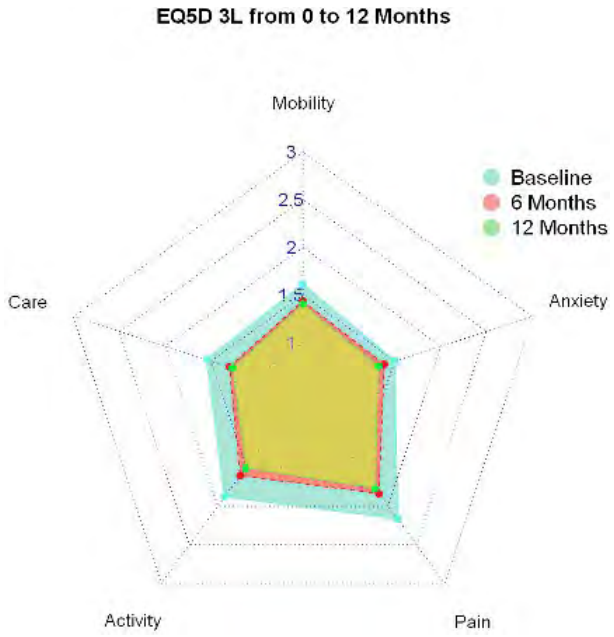

Figure 2. EQ5D 3L at baseline, 6 months, and 12 months.

Table 1. Model of EQ5D Time Trade Off (TTO) at 12 Months with Scottish Index of Multiple Deprivation

Variable	(95% CI)P-value
Model without interactions	
Intercept	56.818 (51.786 , 61.849) ; p<0.001
EQ5D at Baseline	0.204 (0.145 , 0.263) ; p<0.001
Gender Female (c.w. Male)	-0.804 (-3.981 , 2.373) ; p=0.620
Age (Decades)	0.405 (-0.746 , 1.556) ; p=0.491
SIMD 2nd quintile (c.w. most deprived)	3.711 (-1.058 , 8.479) ; p=0.128
SIMD 3rd quintile (c.w. most deprived)	5.511 (0.863 , 10.359) ; p=0.026
SIMD 4th quintile (c.w. most deprived)	6.565 (1.970 , 11.160) ; p=0.005
SIMD 5th quintile (c.w. most deprived)	8.708 (3.744 , 13.671) ; p<0.001
	AIC=4497.399 R^2=0.085

Results: HR-QOL over time shows a non-parametric distribution (fig 1). Improvement was seen in all EQ5D dimensions (Mobility, Self-Care, Usual Activities, Pain/Discomfort, Anxiety/Depression) at 6 and 12 months compared to baseline (fig 2), with most improvement within 6 months. Those in the lowest quartile of HR-QOL at 12 months (EQ5D TTO 0.32 v 0.82, p< 0.001) had substantial unmet need compared to those in the other quartiles: persistent disease activity (SDAI 20.1 v 7.6, p< 0.001), disability (HAQ 1.6 v 0.5, p< 0.001), anxiety (49% v 11%, p< 0.001) and depression (41% v 4%, p< 0.001). Univariate prediction models showed that baseline social deprivation, unemployment, disability (HAQ >1), and presence of anxiety or depression were significantly associated with lower HR-QOL at 12 months; age, gender, BMI and baseline disease activity were not predictive. Patients in the lowest quartile of HR-QOL at 12 months were more likely to live in the most socially deprived areas (SIMD lowest quintile: 36% v 14%, p< 0.001; see table 1), had higher baseline disability (HAQ 1.53 v 1.02, p< 0.001), were more likely to have anxiety (HAD-anxiety >8: 49% v 21%, p< 0.001) and depression (HAD-depression >8: 42% v 12%, p< 0.001) compared to those in other quartiles. Multivariate prediction models identified social deprivation, employment status, anxiety and depression as statistically significant independent predictors of HR-QOL at 12 months.

Conclusion: Social deprivation, employment status, depression, and anxiety are independent predictors of poor HR-QOL outcomes in patients with newly diagnosed RA/inflammatory arthritis. Psychological ill-health and the impact of social deprivation are potentially modifiable. Research is needed into the efficacy of strategies (such as psychological support) that aim to mitigate the negative impact of these factors on HR-QOL. "*Health inequalities and the social determinants of health are not a footnote to the determinants of health. They are the main issue.*" (Prof M Marmot) - our data support this assertion in patients with RA.

Abstract Number: 1669

Minimal Erosive Volume Needed for Radiographic Identification of Erosions in the Metacarpophalangeal Joints in Rheumatoid Arthritis. a Comparative Analysis of High Resolution Peripheral Quantitative Computed Tomography and Conventional Radiography

Rasmus Klose-Jensen, Josephine Therkildsen, Anne-Birgitte Garm Blavnsfeldt, Bente L. Langdahl, Anna Zejden, Jesper Thygensen, Kresten Krarup Keller and Ellen-Margrethe Hauge, Aarhus University Hospital, Aarhus, Denmark

SESSION INFORMATION
Session Date: Tuesday, November 9, 2021
Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster IV: Outcomes, Trajectory of Disease, & Epidemiology (1645–1673)
Session Type: Poster Session D
Session Time: 8:30AM–10:30AM

Background/Purpose: The purpose of this study was to estimate the minimal erosive volume identified by High-Resolution peripheral Quantitative Computed Tomography (HR-pQCT) needed in order to identify erosive damage by conventional radiography (CR) assessed by the Sharp/van der Heijde method in patients with rheumatoid arthritis (RA).

Methods: In this single-centre cross-sectional study with paired measurements, 353 patients with established RA (disease duration ≥ five years) had their second and third MCP joints of the dominant hand investigated by HR-pQCT and CR. Empirical estimation was used to find the optimal cutoff value for the number, and the total volume of erosions needed to be identified by CR assessed according to the Sharp/van der Heijde method.

Results: The second and third MCP joints from 353 patients were investigated. Erosive damage was identified in 157 of the 706 MCP joints by CR, whereas 464 of the 706 MCP joints had erosive damage by HR-pQCT. Patients with a total erosive volume in the second and third MCP joints by HR-pQCT below 48.9 mm3 (Sensitivity 79%, Specificity 0.85, area under the receiver operating characteristic curve (AUC) 0.82) were not consistently identified by CR. The empirical estimation of the optimal cutoff value for the number of erosions in the second and third MCP joints by HR-pQCT was 8.5 erosions (Sensitivity 73%, Specificity 0.90, AUC 0.81).

Conclusion: Conventional radiography could not consistently identify erosive damage in the second and third MCP joints in patients with a total erosive volume below approximately 48.9 mm3 and missed two-thirds of erosions identified by HR-pQCT; this suggests that HR-pQCT may be a valuable tool for earlier detection of erosion progression in RA allowing for earlier intervention.

Increased Prevalence of Gastroesophageal Disease Among Patients with Rheumatoid Arthritis: A Systematic Review and Meta-analysis

Patompong Ungprasert[1], Nipith Charoenngam[2], Ben Ponvilawan[3], Pitchaporn Yingchoncharoen[3] and Jerapas Thongpiya[4], [1]Cleveland Clinic, Cleveland Heights, OH, [2]Mount Auburn Hospital, Boston, MA, [3]Mahidol University, Bangkok, Thailand, [4]Mahdiol University, Bangkok, Thailand

SESSION INFORMATION

Session Date: Tuesday, November 9, 2021

Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster IV: Outcomes, Trajectory of Disease, & Epidemiology (1645–1673)

Session Type: Poster Session D

Session Time: 8:30AM–10:30AM

Background/Purpose: Recent experimental studies have suggested that systemic inflammatory response could lead to impairment of lower esophageal function, resulting in gastroesophageal reflux disease (GERD). Epidemiologic studies also support this association as increased prevalence of GERD has been observed in several systemic inflammatory disorders, including rheumatoid arthritis (RA), although the evidence is still quite limited. The current systematic review and meta-analysis is conducted with the aim to summarize data from all available studies.

Methods: Potentially eligible studies were identified from Medline and EMBASE databases from inception to April 2021 using search strategy that comprised terms for "gastroesophageal reflux disease " and " rheumatoid arthritis ". Eligible study must be cohort study that consists of one cohort of individuals with RA and another cohort of individuals without RA. Then, the study must report prevalence of GERD in each group or report odds ratio (OR) and 95% confidence interval (CI) comparing prevalence of GERD between the groups. OR of all included studies were combined together to calculate pooled OR using the generic inverse variance method of DerSimonian and Laird, which assigned weight of each study in reverse to its standard error. Funnel plot was used for assessment of publication bias.

Results: After two rounds of independent review by two investigators, a total of five eligible studies were identified. The meta-analysis found a significantly increased prevalence of GERD among patients with RA with the pooled OR

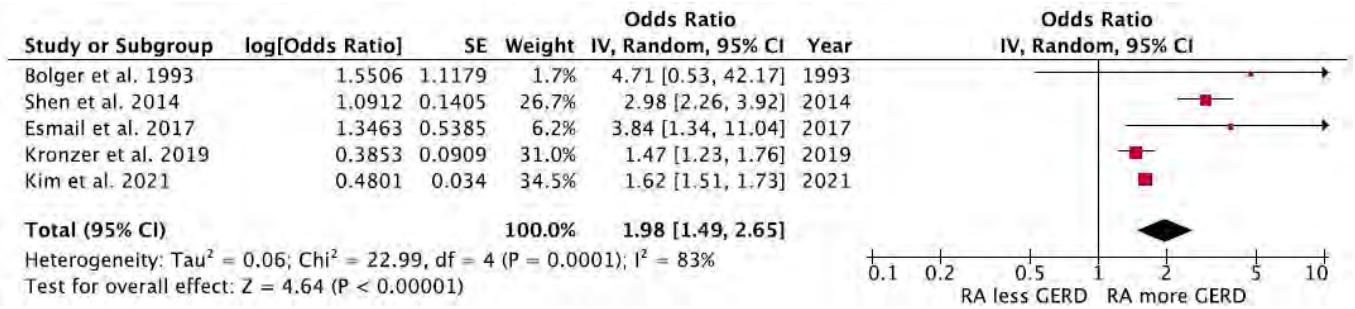

Figure 1. Forest plot of this meta-analysis.

of 1.98 (95% CI, 1.49 – 2.65; I^2 83%) compared with individual without RA (Figure 1). Funnel plot of this study was symmetric and was not suggestive of publication bias.

Conclusion: A significantly increased prevalence of GERD among patients with RA was observed in this study.

COVID-19 in Patients with Rheumatoid Arthritis Compared to Patients with Osteoarthritis During the Pandemic in New York City

Jonah Levine[1], Vivian Bykerk[2], Lindsay Lally[1], Lisa Mandl[1] and Medha Barbhaiya[1], [1]Hospital for Special Surgery, New York, NY, [2]Division of Rheumatology, Hospital for Special Surgery, New York City, NY

SESSION INFORMATION

Session Date: Tuesday, November 9, 2021

Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster IV: Outcomes, Trajectory of Disease, & Epidemiology (1645–1673)

Session Type: Poster Session D

Session Time: 8:30AM–10:30AM

Background/Purpose: COVID-19 in patients with rheumatoid arthritis (RA) is poorly understood. A recent study of mostly men with RA demonstrated increased COVID-19 risk in RA patients and more severe outcomes compared to matched non-RA patients; however, generalizability may be limited and findings need to be confirmed. We analyzed COVID-19 risk factors within RA patients overall and compared to those with osteoarthritis (OA) from our large musculoskeletal hospital during the initial wave of the pandemic in New York City.

Methods: We emailed a secure web-based survey to 26,045 patients ≥18 years old evaluated at least once by a rheumatologist between 2018-2020. Patients completed the survey between April 24, 2020-July 1, 2020. We collected data on demographics, COVID-19, medical history, and medication use. COVID-19 was suspected if the diagnosis was provided by a healthcare worker, and confirmed by a positive nasopharyngeal PCR antigen test. The former was included due to the lack of available testing early in the pandemic. ICD-10-CM algorithms were used to identify RA and OA. We used descriptive statistics as appropriate to compare patients with and without COVID-19 among RA and OA patients. We also compared RA versus OA subgroup of patients with COVID-19.

Results: Of the 6,583/26,045 (27.1%) patients who responded to our survey, 1,320 (20.1%) had RA and 675 (10.3%) had OA. Mean age of RA patients was 60.2 [14.4] years and 84.0% were female; mean age of OA patients was

69.7[12.1] years, and 75.2% were female. 5.7% of RA patients and 3.3% of OA patients self-reported COVID-19 (p=0.02). Compared to RA patients without COVID-19, RA patients with COVID-19 had higher BMI, were more likely to be Hispanic/Latinx and employed, and to have underlying asthma (Table 1). No difference in baseline steroid use or immunomodulatory medications were noted (Table 2). OA patients with COVID-19 were younger, more likely to

be male and Hispanic/Latinx, and had higher education compared to OA without COVID-19; no differences in race, income, employment or general medical history were noted (Table 1). RA patients with COVID-19 were younger (58.5[11.1] vs. 66.0[11.2] years), more likely to be female (81.3% vs. 63.6%) and employed (61.3% vs. 36.4%) than OA with COVID-19; no differences in general medical problems were noted. Although RA patients with COVID-19 had a non-significantly higher prevalence of abdominal pain, headaches, joint pain, vomiting, and fatigue, OA patients had significantly higher rhinorrhea (Table 3). ER visits and hospitalization were similar in RA versus OA patients with COVID-19 (Table 3).

Conclusion: In a cohort of rheumatology outpatients in New York City during the early pandemic surge, COVID-19 incidence was higher in RA versus OA patients, but there was no difference in ER or hospitalization. In RA patients COVID-19 was associated with higher BMI, Hispanic/Latinx ethnicity, being employed, and a history of asthma. In OA patients, COVID-19 was associated with younger age, Hispanic race/ethnicity, and lower education. These findings are hypothesis generating and will be evaluated prospectively using multivariable analyses to help identify predictors of COVID-19 in potentially high risk patients.

Abstract Number: 1672

Many Better, Many Worse: Mean PROMIS-29 Scores Mask Significant Shifts During COVID-19 in RA

Susan Bartlett[1], Dana DiRenzo[2], Michelle Jones[3] and Clifton Bingham[2], [1]McGill University, Montréal, QC, Canada, [2]Johns Hopkins University, Baltimore, MD, [3]Johns Hopkins Medicine, Baltimore, MD

SESSION INFORMATION

Session Date: Tuesday, November 9, 2021

Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster IV: Outcomes, Trajectory of Disease, & Epidemiology (1645–1673)

Session Type: Poster Session D

Session Time: 8:30AM–10:30AM

Background/Purpose: Rheumatic diseases (RD) are chronic conditions that require potent immunosuppressants to control systemic inflammation. Fears associated with increased vulnerability from being on immunosuppressants plus medications shortages (e.g., hydroxychloroquine) resulted in considerable stress for patients in the early months of the COVID-19 pandemic. We evaluated changes in HRQL in the initial months of the COVID-19 in adults with RD and hypothesized that multiple PROMIS-29 domains scores would be negatively impacted.

Methods: The sample included patients followed (virtually or in-person) in Rheumatic Disease clinics at Johns Hopkins 3/15/2020 to 6/30/2020. Patients complete the PROMIS-29 as part of routine care, and scores were compared with the most recent visit prior to 3/15. Anxiety was classified as worse (≥ 4.0 points), same (-3.9 to 3.9) or better (≤-4.0) at the second visit.

Results: Data were available for 151 patients with a mean (SD) age of 55 who were mostly white (81%) women (73%) with RA (50%), PSA (27%), AS/SPA (15%) or other RD (9%). Mean (SD) changes in PROMIS-29 scores ranged from -0.9 for Fatigue [7.6] and Depression [7.9] to 1.4 (9.7) for Anxiety. 45 (30%) patients were classified with worse anxiety, 40 (27%) with improved anxiety, and 66 (44%) the same. Change in anxiety was not associated with age, sex, race, or disease.

Table 1. PROMIS-29 scores in patients with rheumatic diseases before and during initial months of COVID-19 pandemic

PROMIS-29 Domain	Pre Pandemic	Pandemic	Mean Change	95% Lower CI	95% Upper CI	Sig
Anxiety	53.3 (10.7)	54.7 (9.4)	1.4	-0.1	3.0	0.072
Depression	50.9 (10.2)	49.9 (9.3)	-0.9	-2.2	0.4	0.156
Pain Interference	57.1 (9.6)	57.4 (8.4)	0.3	-0.8	1.4	0.59
Physical Function	42.2 (9.5)	42.8 (9.6)	0.6	-0.4	1.6	0.254
Fatigue	56.6 (11.2)	55.7 (10.5)	-0.9	-2.1	0.4	0.169
Sleep Disturbance	52.7 (8.6)	52.8 (9.5)	0.2	-1.2	1.6	0.807
Participation	47.9 (10.5)	48.2 (9.5)	0.3	-0.8	1.5	0.548

Table 2. Change in PROMIS in patients with improved, same or worsening anxiety during the initial months of COVID-19 pandemic

PROMIS Domain	Change in Anxiety During Pandemic					
	Improved (≤-4.0)		Same		Worse (≥4.0)	
	Mean	SD	Mean	SD	Mean	SD
Anxiety	-8.9_a	5.8	$.3_b$	2.3	12.3_c	8.0
Depression	-5.0_a	7.0	-1.2_b	6.9	3.2_c	8.0
Pain Interference	-2.5_a	7.9	$.4_b$	6.0	2.7_b	6.5
Physical Function	2.1_a	8.4	$.1_a$	4.7	$-.1_a$	5.4
Fatigue	-4.4_a	7.9	$-.3_b$	5.8	1.5_b	8.7
Sleep Disturvance	-3.4_a	8.5	$.1_b$	8.8	3.5_c	7.9
Participation	3.1_a	7.8	$.0_b$	6.6	-1.6_b	6.0

Note: Values in the same row not sharing the same subscript are significantly different at p< .05.

Table 3. Change in perceived rheumatic disease activity in patients with improved, same or worsening anxiety during the initial months of COVID-19 pandemic

Change in RD	Change in Anxiety During Pandemic					
	Improved (≤-4.0)		Same		Worse (≥4.0)	
	N	%	N	%	N	%
Lot worse	0	0%	6_a	50%	6_a	50%
Little worse	8_a	25%	12_a	38%	12_a	38%
Same	9_a	20%	20_a	43%	17_a	37%
Little Better	$7_{a,b}$	29%	14_a	58%	3_b	13%
Lot Better	6_a	43%	6_a	43%	2_a	14%

Note: Values in the same row not sharing the same subscript are significantly different at p< .05.

Among patients reporting worse anxiety (mean [SD] change +12.3 [9.0]), Depression was significantly worse (3.2 [8.0]) compared to patients with same (-1.2 [6.9] or improved anxiety (-5.0 [7.0]) (p's< .05). Among patients whose anxiety improved, Fatigue (-4.4 [7.9]) and Participation (3.1 [7.8] improved. Changes in anxiety were not associated with changes in physical function.

Patient Global Impression of Disease Change scores (N=128) indicated 34% of patient reported their disease was worse, 30% had improved, and 36% were the same. Most (88%) patients with worse anxiety reported worse (45%) or the same (43%) disease activity; 43% with improved anxiety had improved disease, 30% the same, and 27% were worse.

Conclusion: While the average within-person change in PROMIS-29 scores were trivial, a substantial proportion of patients experienced worsening or improved anxiety which also tracked with meaningful changes in several other PROMIS-29 domains.

Riding Multiple Waves of Uncertainty: Real World Canadian RA Patient Outcomes over 1 Year of COVID-19 Restrictions

Orit Schieir[1], **Susan Bartlett**[2], Marie-France Valois[2], Louis Bessette[3], Gilles Boire[4], Glen Hazlewood[5], Carol Hitchon[6], Edward Keystone[7], Janet Pope[8], Diane Tin[9], Carter Thorne[10], Vivian Bykerk[11] and CATCH Investigators[12], [1]Canadian Early Arthritis Cohort Study, Montréal, QC, Canada, [2]McGill University, Montréal, QC, Canada, [3]Centre de l'Ostoporose et de Rhumatologie de Qubec, Québec City, QC, Canada, [4]Universite de Sherbrooke, Sherbrooke, QC, Canada, [5]University of Calgary, Calgary, AB, Canada, [6]University of Manitoba, Winnipeg, MB, Canada, [7]Keystone Consulting Enterprises Inc., Toronto, ON, Canada, [8]University of Western Ontario, London, ON, Canada, [9]The Arthritis Program Research Group, Newmarket, ON, Canada, [10]Southlake Regional Health Centre, Newmarket, ON, Canada, [11]Hospital for Special Surgery, New York, NY, [12]Mt Sinai Hospital, Toronto, ON, Canada

SESSION INFORMATION

Session Date: Tuesday, November 9, 2021

Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster IV: Outcomes, Trajectory of Disease, & Epidemiology (1645–1673)

Session Type: Poster Session D

Session Time: 8:30AM–10:30AM

Background/Purpose: During the COVID-19 pandemic, Canadians adults with RA faced considerable uncertainty due to greater risk of infection, hospitalization, changing access to RA medications, and very limited access to in-person RA care due to stringent pandemic-related restrictions. We examined trends in perceived stress, physical, emotional, and social health, perceived disease activity and flares prior to and during the first two waves of COVID-19 in adults with RA.

Methods: Participants were enrolled in the Canadian Early Arthritis Cohort with available data. Descriptive statistics examined trends in Perceived Stress and PROMIS-29 from 6 months pre-pandemic (9/19-2/20) through Waves 1 (3/20-6/20) and Wave 2 (10/20-1/21). Disease activity was assessed using the RA-FQ, a validated PRO; scores ≥20 are consistent with inflammatory flares.

Results: A total of 858 visits were collected from 3/16/20 through 1/31/21 and compared with 956 pre-pandemic visits. Participants were mostly white (86%) women (72%) with a mean age of 55 years. Pre-pandemic mean PROMIS-29 scores were in the normal range. Monthly trends showed that pandemic impacts were greatest in April 2020 (Fig 1) where mean PROMIS-29 scores worsened for all domains except Participation (mean Δ -0.4); the largest changes were in Depression (Δ+4.8) and Anxiety (Δ+4.2)(p's< .01). Compared with pre-pandemic visits, by April higher proportions had moderate-severe Anxiety (12% vs 23%), Depression (11% vs 23%), Fatigue (18% vs 25%), Sleep Disturbance (10% vs 19%), Pain (23% vs 40%), Participation (15% vs 21%) and Disability (25% vs 34%) (all p's< 0.05). By July 2020, mean PROMIS-29 scores had improved for Depression (Δ -4.5), Anxiety (Δ -3.2), Fatigue (Δ -2.0) and Perceived Stress (Δ -0.7). The proportions of patients with moderate-severe symptoms (≥60) were similar to pre-pandemic for all domains except Pain, Function, Participation, and Sleep where 29%, 34%, 21% and 17%, respectively, continued to have moderate-severe impairments. Wave 2 scores were higher than pre-pandemic, but lower than Wave 1, with the largest changes in depression (p=.02) and anxiety (p=.06).

Mean RA-FQ increased from the pre-pandemic period, peaking in April 2020 and Dec 2020-Jan 2021 (Fig 2). More patients had RA-FQ scores consistent with disease flares in April (45%) and December (35%) than in the pre-pandemic period.

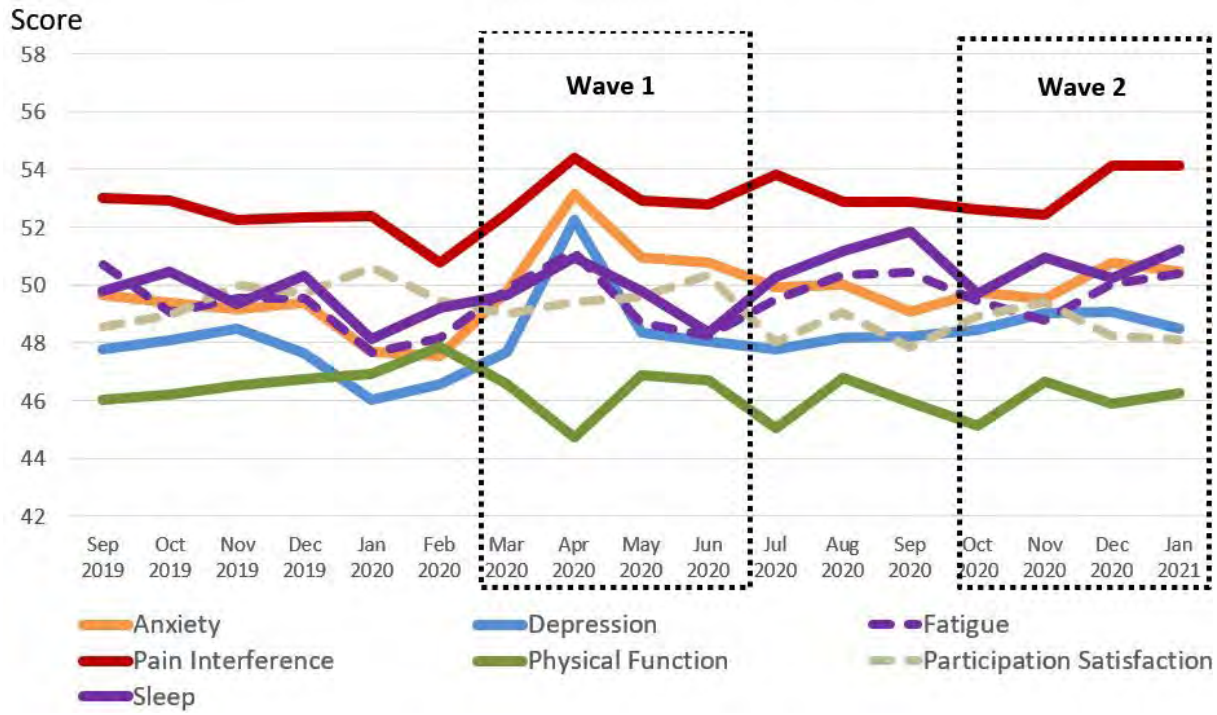

Figure 1. PROMIS-29 scores prior to and during the COVID-19 pandemic in Canadian RA patients.

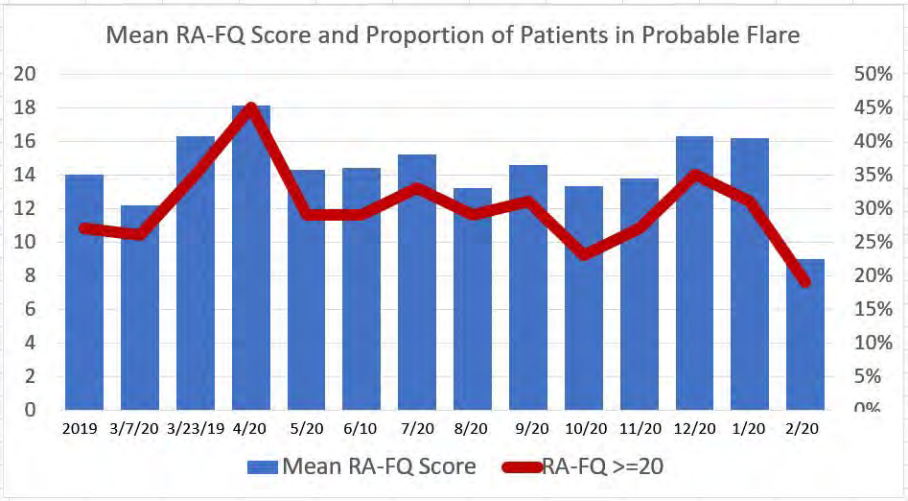

Conclusion: Stringent COVID-19 pandemic restrictions impacted care across Canada in Waves 1 and 2 resulting in considerable stress, higher perceived disease activity and flares, and meaningfully worse physical and emotional health. More than 1/3 experienced moderate-severe anxiety, depression, fatigue, sleep disturbance, pain, and disability.

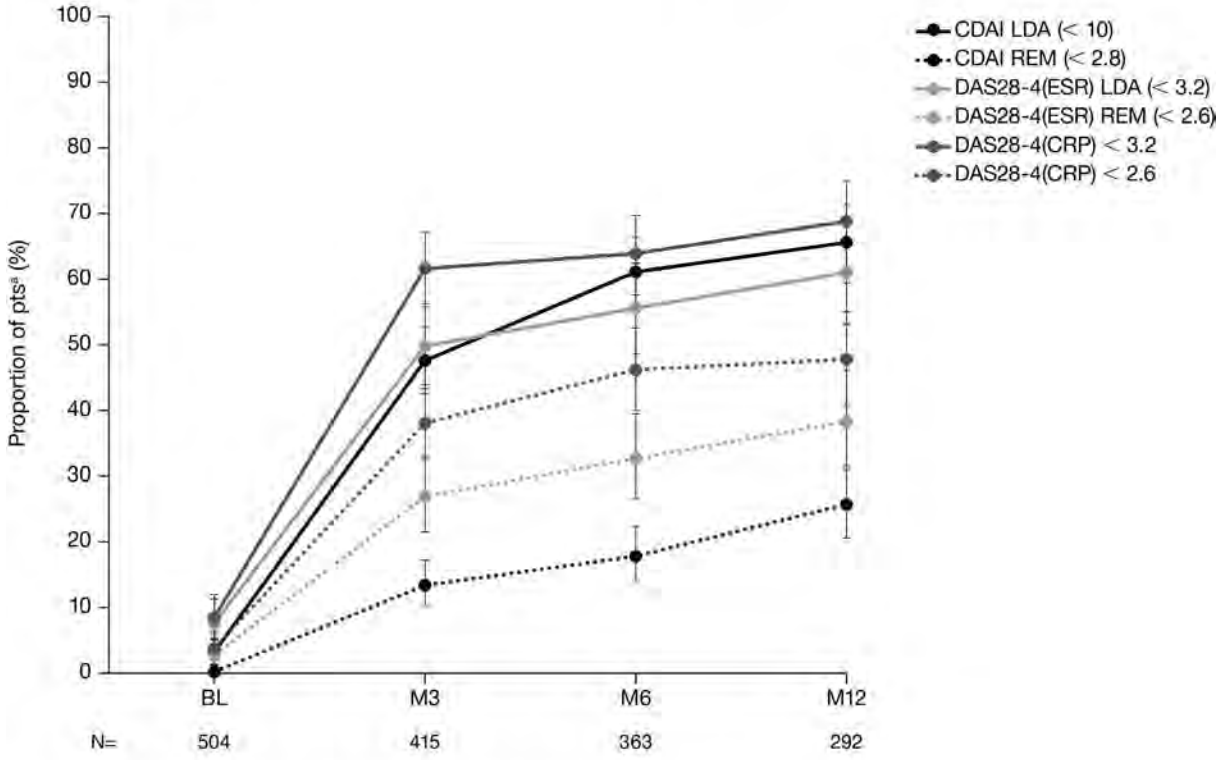
SESSION INFORMATION

Session Date: Tuesday, November 9, 2021
Session Title: RA – Treatments Poster III: RA Treatments & Their Safety (1674–1710)
Session Type: Poster Session D
Session Time: 8:30AM–10:30AM

Background/Purpose: Tofacitinib is an oral Janus kinase inhibitor (JAKi) for the treatment of RA. CANTORAL is the first large-scale, national, observational study assessing effectiveness and safety of a JAKi (tofacitinib) in Canadian patients (pts) with RA. Here we describe primary and key secondary effectiveness and safety endpoints from the CANTORAL study. Exploratory safety analyses were also conducted in pts with baseline (BL) cardiovascular (CV) risk factors.

Methods: Pts with moderate to severe active RA who initiated tofacitinib between Nov 2017–Jul 2020 were enrolled across 45 Canadian sites and managed per clinical standard of care. Effectiveness (up to Month [M]12) was assessed in enrolled pts (full analysis set), and safety (up to M36) was evaluated in pts with ≥ 1 post-BL visit (safety analysis set) as of Feb 26, 2021. An exploratory safety analysis was also conducted in pts aged ≥ 50 yrs with ≥ 1 CV risk factor (CV+ cohort), similar to ORAL Surveillance (NCT02092467) entry criteria. Co-primary endpoints included proportions of pts achieving CDAI low disease activity (LDA; < 10) and remission (REM; < 2.8) at M6. Secondary endpoints included proportions of pts achieving CDAI LDA and REM, DAS28-4(ESR) LDA (< 3.2) and REM (< 2.6), and DAS28-4(CRP) < 3.2 and < 2.6, over time; proportions of pts achieving improvements in HAQ-Disability Index (HAQ-DI) ≥ minimum

Figure. Proportions of pts who achieved CDAI and DAS28-4(ESR) LDA or REM, or DAS28-4(CRP) < 3.2 or < 2.6, over time (full analysis set)



[a]Proportions of pts were based on the total number of pts at each visit

Gastrointestinal perforation	0 (0.0) [0]	0 (0.0) [0]
HZ (non-serious/serious)[d]	8 (1.6) [1.4]	6 (2.2) [1.9]
Malignancies (excluding NMSC)	8 (1.6) [1.4]	7 (2.6) [2.3]
NMSC	4 (0.8) [0.8]	2 (0.7) [0.8]
Thrombosis[e]	1 (0.2)[f] [0.2]	1 (0.4)[f] [0.32]

[a]Pts with ≥ 1 post-BL visit

[b]Mean (SD) duration of follow-up: 14.3 (9.2) months (SAS); 14.8 (9.4) months (CV+)

[c]Renal failure and sepsis, n=1; salmonella bacteremia and sepsis, n=1; myocardial infarction, n=1

[d]One case of serious HZ

[e]Venous and arterial thrombotic events

[f]Non-occlusive thrombus in right posterior tibial vein

AE, adverse event; BL, baseline; CV+, cohort of pts aged ≥ 50 yrs with ≥ 1 cardiovascular risk factor; HZ, herpes zoster; IR, incidence rate; MACE, major adverse cardiovascular events; n, number of unique pts with an event; N, number of pts in each group; NMSC, non-melanoma skin cancer; pt, patient; PY, pt-yrs; SAE, serious adverse event; SAS, safety analysis set; SD, standard deviation; TEAE, treatment-emergent adverse event

clinically important difference (MCID; ≥ 0.22), HAQ-DI normative values (≤ 0.25), and ≥ 50% improvement in Pain (VAS) at M3; and least squares (LS) mean change from BL (ΔBL) in tender joint count (TJC), swollen joint count (SJC), HAQ-DI, and Pain, over time. Safety outcomes included treatment-emergent adverse events (TEAEs), serious AEs (SAEs), deaths, and AEs of special interest.

Results: 504 pts were eligible for analysis; most were female (77.8%), white (82.9%), with a mean age of 59.3 yrs and disease duration of 10.2 yrs. Most pts were biologic DMARD-naïve (66.5%), taking BL background conventional synthetic DMARDs (62.5%). At M6, 61.1% and 17.8% of pts achieved CDAI LDA and REM, respectively, with most also achieving outcomes at M3 (Figure); similar findings were seen for DAS28-4(ESR) and DAS28-4(CRP) (Figure). LS mean ΔBL at M3 ($p < 0.001$) in TJC, SJC, HAQ-DI, and Pain were -5.7, -5.1, -0.3, and -20.5, respectively, wherein improvements were continued/maintained to M12. At M3, HAQ-DI MCID and normative values were achieved by 53.7% and 19.9% of pts, respectively; ≥ 50% Pain improvement was achieved by 42.9% of pts. 54.0% (n=272) of pts met inclusion criteria for the CV+ cohort, of whom 25.4% were smokers and 8.1% had a history of coronary artery disease; hypertension, diabetes mellitus, and RA-associated extra-articular features were reported in 58.8%, 17.6%, and 26.8% of CV+ pts, respectively. Most TEAEs, SAEs, deaths, and AEs of special interest were reported in CV+ pts (Table).

Conclusion: Results of CANTORAL are consistent with tofacitinib efficacy and safety in the RA clinical program, including ORAL Surveillance, and Canadian observational studies of advanced therapies. AEs were more likely to occur in pts aged ≥ 50 yrs with CV risk factors.

Risk of Malignancy in Patients Treated with Tofacitinib: Results from the Safety of TofAcitinib in Routine Care Patients with Rheumatoid Arthritis (STAR-RA) Study

Farzin Khosrow-Khavar, Rishi Desai, Hemin Lee, Su Been Lee and Seoyoung Kim, Brigham and Women's Hospital, Boston, MA

SESSION INFORMATION

Session Date: Tuesday, November 9, 2021
Session Title: RA – Treatments Poster III: RA Treatments & Their Safety (1674–1710)
Session Type: Poster Session D
Session Time: 8:30AM–10:30AM

Background/Purpose: Initial reports from "ORAL Surveillance" post-marketing safety trial have suggested that tofacitinib, in comparison with tumor necrosis factor inhibitors (TNFI), may be associated with increased risk of malignancies in RA patients. We conducted a multi-database population-based study to further examine this safety concern in real-world settings.

Methods: The 'Optum' Clinformatics (2012-2020), IBM 'MarketScan' (2012-2018), and Medicare (parts A, B, and D, 2012-2017) claims databases were used to construct two cohorts of RA patients initiating treatment with tofacitinib and TNFI. The first cohort, "real-world evidence" (RWE), included a representative cohort of RA patients treated in routine practice. As a calibration exercise, we mimicked the inclusion and exclusion criteria of the ORAL Surveillance trial which consisted of patients minimum 50 years of age and with at least one cardiovascular risk factor, in the second cohort ("RCT-duplicate"). The primary endpoint, a composite cancer outcome, was defined using previously validated claims-based algorithms for any malignancy excluding non-melanoma skin cancer. In the primary as-treated analysis, patients were followed from treatment initiation until study outcomes, treatment discontinuation or switch, insurance disenrollment, death, or end of the study period, whichever occurred first. Cox proportional hazards models were used to generate hazard ratios (HR) and 95% confidence intervals (CI). Propensity score (PS)

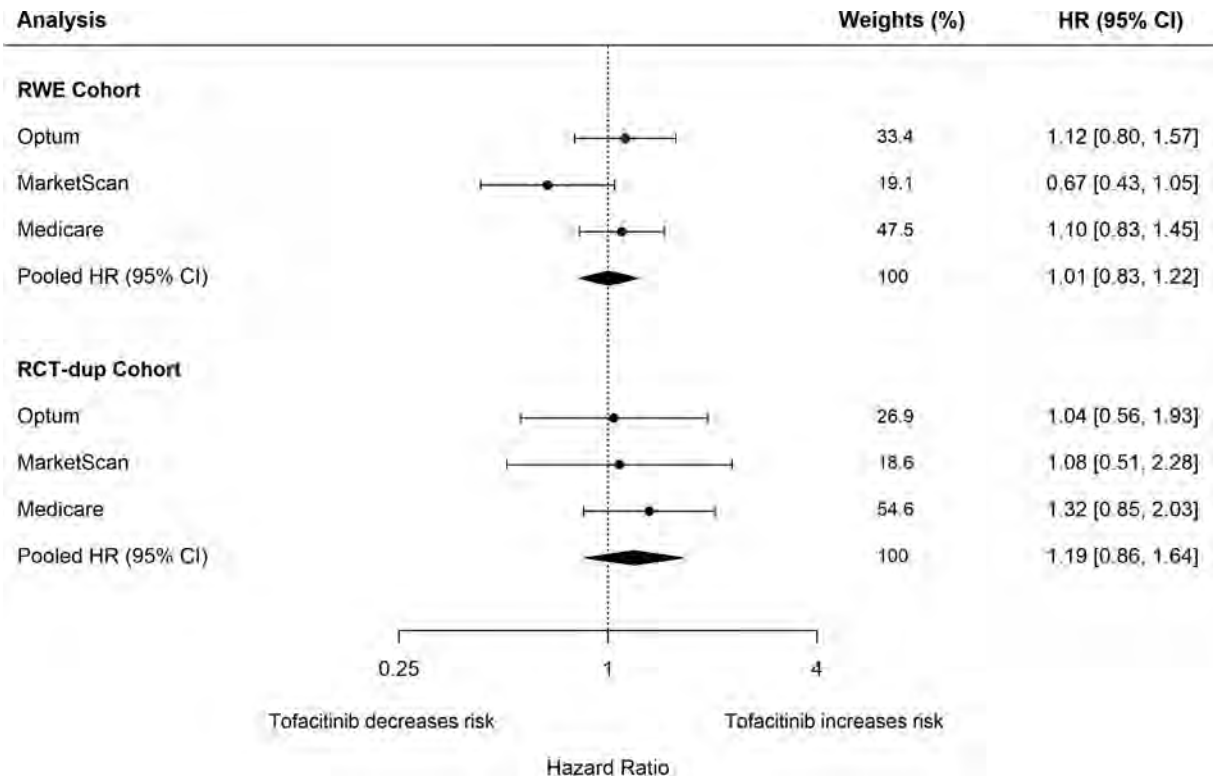

Figure. Risk of composite cancer outcomes when comparing tofacitinib with TNF inhibitors (reference) in patients with RA.

fine-stratification weighting accounted for over 60 potential confounders. Database-specific estimates were pooled using fixed effects models with inverse variance.

Results: The RWE cohort included 25,389 patients in Optum, 29,511 in MarketScan, and 28,374 in Medicare of whom 13.0%, 15.3%, and 9.5% initiated treatment on tofacitinib, respectively. The majority of RA patients were female across the three databases (77%-80%). The mean age was 54 and 52 in Optum and MarketScan and 71 in Medicare. The median follow-up time on treatment was 199-218 days. The crude incidence rates (95%CI) per 100 person-years of composite cancer endpoint comparing tofacitinib and TNFI users were 1.65 (1.21-2.19) and 1.36 (1.20-1.52) in Optum, 0.60 (0.39-0.90) and 0.84 (0.73-0.96) in MarketScan, and 2.70 (2.07-3.46) and 2.48 (2.28-2.70) in Medicare. The pooled PS-weighted HR (95%CI) for composite cancer outcome comparing tofacitinib with TNFI was 1.01 (0.83-1.22). The pooled PS-weighted HR (95%CI) was 1.19 (0.86-1.64) in RCT-duplicate cohort (versus Oral Surveillance trial, HR: 1.48, 95%CI: 1.04-2.09). Consistent results were observed in sensitivity analyses implementing a 90- day exposure lag for latency of treatment effect and a180-day grace period for persistence of effect after treatment cessation.

Conclusion: In this large population-based study, tofacitinib, in comparison with TNFI, was not associated with risk of malignancies in RA patients in the real-world setting. However, our results cannot rule out an elevated risk of cancer associated with tofacitinib among patients who were at least 50 years of age with one cardiovascular risk factor. Additional studies with long-term follow-up are required to corroborate these findings.

SESSION INFORMATION

Session Date: Tuesday, November 9, 2021

Session Title: RA – Treatments Poster III: RA Treatments & Their Safety (1674–1710)

Session Type: Poster Session D

Session Time: 8:30AM–10:30AM

Background/Purpose: An all-case post marketing surveillance (PMS) of baricitinib, that started in Sep 2017, collects safety and effectiveness for the first 24 weeks of treatment and continues to collect serious adverse events (SAEs) for 3 years. The objective of this analysis was to evaluate safety of baricitinib in RA patients in clinical practice.

Methods: We report patient baseline demographics and adverse events (AEs) up to 24 weeks for patients whose case report files for 24-week data were completed as of Jun 2020.

Results: Data from 3445 patients were analyzed (females=80%, mean age=64 years, mean RA duration=12 years). Baricitinib dose regimen was as follows: 4mg, 60%, 2mg, 27%, 4mgà2mg, 5%, 2mgà4mg, 5%, and others, 2%. Concomitant use of MTX and glucocorticoid was 65% and 48%, respectively. Overall, 74% continued treatment for 24 weeks. AE and SAE were recognized in 887 (26%) and 122 patients (4%), respectively. Six patients died of pneumonia, aspiration pneumonia, bacterial pneumonia, cerebral infarction/interstitial lung disease (ILD)/aspiration pneumonia, adenocarcinoma, and colorectal cancer. Major AEs were as follows: herpes zoster=3%, liver dysfunction=3%, serious infection=1%, anemia=1%, hyperlipidemia=1%, malignancy=0.3%, interstitial pneumonia=0.2%, major adverse cardiovascular event (MACE)=0.1%, and venous thromboembolism (VTE)=0.1%.

Conclusion: Data do not show new safety concerns and encourage guideline-compliant use of Baricitinib.

Effects of Biological-DMARDs on the Serum Low-density Lipoprotein (LDL) / High-density Lipoprotein (HDL) - Cholesterol Ratio in Patients with Rheumatoid Arthritis

Yusuke Miwa[1] and Yuko Mitamura[2], [1]Division of Rheumatology, Department of Medicine, School of Medicine, Showa University, Tokyo, Japan, [2]Department of Nursing, Showa University School of Nursing and Rehabilitation Sciences, Shinagawa-ku, Japan

SESSION INFORMATION
Session Date: Tuesday, November 9, 2021
Session Title: RA – Treatments Poster III: RA Treatments & Their Safety (1674–1710)
Session Type: Poster Session D
Session Time: 8:30AM–10:30AM

Background/Purpose: Rheumatoid arthritis (RA) and dyslipidemia are associated with inflammation. Although the low-density lipoprotein cholesterol (LDL-C) is normal range, the high-density lipoprotein cholesterol (HDL-C) is reduced in RA patients. We aimed to investigate the influence of biological disease-modifying antirheumatic drugs (bDMARDs) on the LDL-C / HDL-C ratio in patients with RA.

Methods: Patients with RA treated with bDMARDs from 2008 to 2018 were studied based on the All Showa University of RA (ASHURA) database. The association between LDL-C and HDL-C level reduction and treatment was evaluated. Of 629 patients treated with the bDMARDs, 346 patients with available LDL-C and HDL-C levels medical records were included. The following background factors were investigated: age; sex; type of bDMARDs; dosage of methotrexate (MTX) and prednisolone (PSL); usage of conventional synthetic DMARDs, dyslipidemia drugs and nonsteroidal anti-inflammatory drugs; body mass index (BMI); smoking history; HbA1c; presence or absence of hypertension and dyslipidemia; and serum creatinine, C-reactive protein, and matrix metalloproteinase-3 levels. We also used the simplified disease activity index (SDAI) to evaluate RA disease activity. The primary endpoint was LDL-C and HDL-C

levels before, and after 6 months and 1 year, which was determined using the repeated-measures analysis of variance (ANOVA).

Results: The LDL-C / HDL-C ratio were from 1.94 ± 0.76 to 1.88 ± 0.73 and 1.86 ± 0.74 before treatment and after 6 months and 1 year, respectively (p=0.328). Variation was within normal range (less than 2.0). The HDL-C levels increased from 61.8 ± 19.2 (mg/dL) to 64.8 ± 19.0 and 66.0 ± 19.2 before treatment and after 6 months and 1 year, respectively (p=0.013). Variation was within normal range (40-119). On the other hand, the LDL-C levels were not significant change from 110.2 ± 28.8 (mg/dL) to 112.3 ± 27.8 and 113.1 ± 28.1 before treatment and after 6 months and 1 year, respectively (p=0.372). Variation was within normal range (70-139).

Conclusion: Our study suggests that bDMARDs may affect increased HDL-C levels, not affect changes LDL-C levels and not affect LDL-C / HDL-C ratio in patients with RA.

SESSION INFORMATION

Session Date: Tuesday, November 9, 2021

Session Title: RA – Treatments Poster III: RA Treatments & Their Safety (1674–1710)

Session Type: Poster Session D

Session Time: 8:30AM–10:30AM

Background/Purpose: Low-dose glucocorticoid (GC) therapy is widely used in rheumatoid arthritis (RA) but the balance of benefit and harm is still unclear. We studied the effects of prednisolone (5 mg/day, 2 years) added to standard of care in patients aged≥65 with active RA (1988 or 2010 criteria).

Methods: Pragmatic double-blind placebo-controlled randomized trial; all co-treatments and changes therein were allowed during the trial except long-term open label GC; Ca/D supplementation was advised in all patients. Minimal exclusion criteria were tailored to seniors.

Benefit outcomes: disease activity (DAS28) and joint damage (Sharp/van der Heijde).

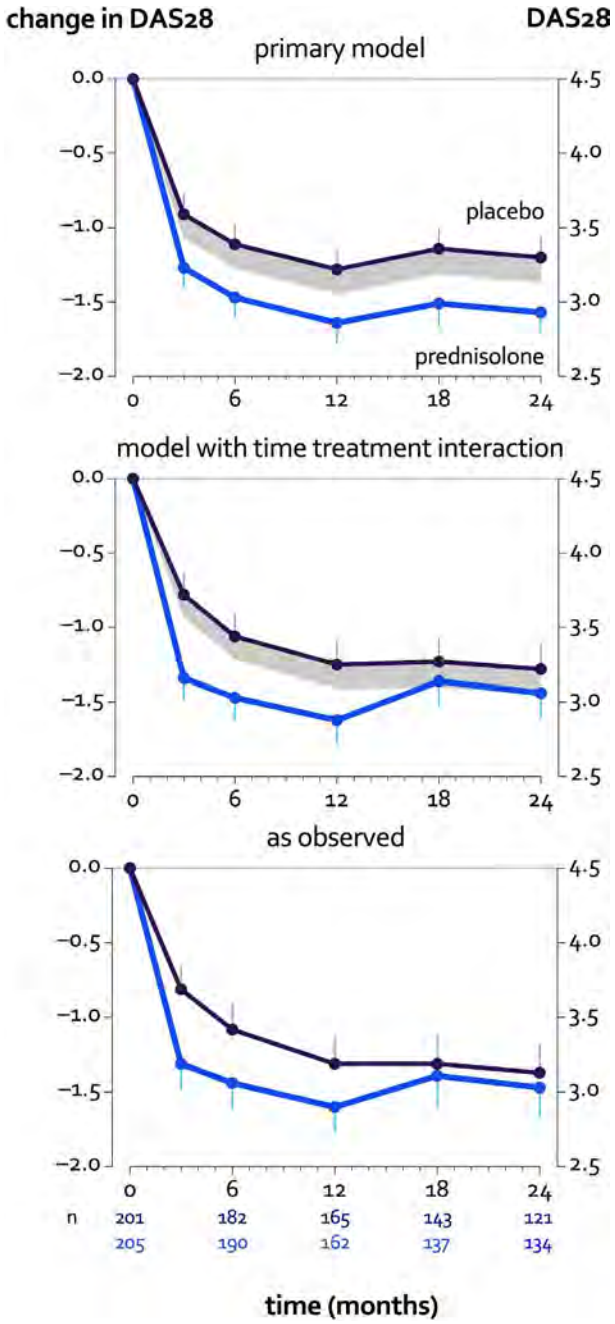

Figure 1. Change in DAS28 estimated in primary model, model with time-treatment interactions, and as observed, with numbers of patients. The grey area depicts the one-sided 95%confidence bound for the difference at each time point. Error bars depict one half of the two-sided 95%CI for the group means.

Harm outcome: proportion of patients with ≥1 adverse event (AE) of special interest: includes serious events, GC-specific events and those causing study discontinuation.

Analysis: longitudinal models, one-sided testing and 95% confidence limits (95%CL).

Results: We randomized 451 patients with established, impactful RA and mean 2.1 comorbidities: mean age 72 (max 88) years, 70% female, RA duration 11 years; 67% were RF+, 56% ACPA+, 96% had joint damage on radiographs; mean DAS28 4.5. 79% were on disease-modifying treatment, including 14% on biologics. 63% prednisolone vs 61%

Table 1. Important adverse events, per 100 patient-years.*

	SAE		other AESI	
	pred	placebo	pred	placebo
infection	7	4	35	26
ischemic cardiovascular	2.3	1.7	0.0	0.6
symptomatic fracture	0.6	1.1	3.1	1.7
new onset				
hypertension	0.3	0	1.1	2.0
diabetes mellitus	0	0	0.6	0.3
cataract	0	0.6	2.0	1.7
glaucoma	0	0	0.3	0.8
other	12	10	13	7
total	**23**	**18**	**55**	**39**

* SAE: Serious Adverse Events, mostly for hospitalization;
other AESI: other Adverse Events of Special Interest: mostly for treatment or study discontinuation

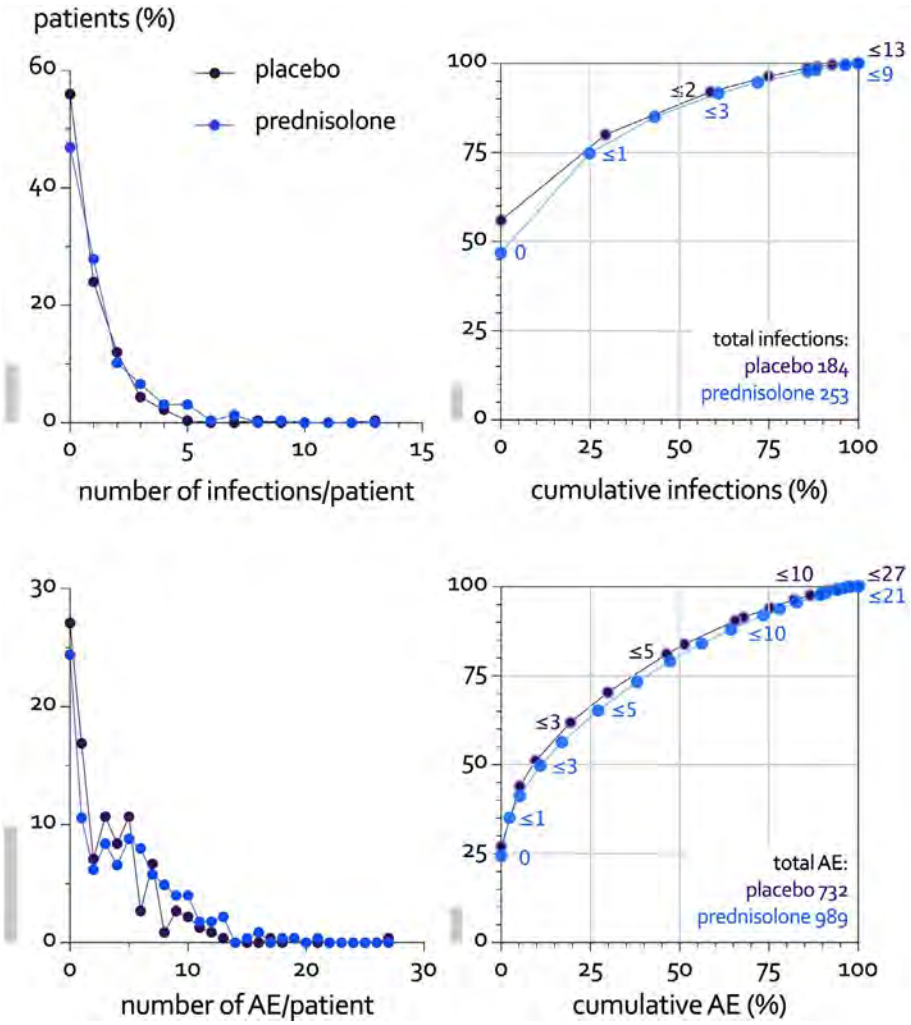

Figure 2. Patients with multiple adverse events (AE) have a major impact on the total number of events in both treatment groups: infection events in top panels, all AE in bottom panels. Left panels show the distribution of patients by number of events/patient. This shows most patients experience no or only a few events. Right panels plot bivariate cumulative distributions of patients by AE. The numbers next to the series indicate the maximum number of events of the population at that point. The right panels show the impact of multiple events: for example, 75% of patients (with 0 or 1 infection) contribute only 25% of all infections (top right panel); read in reverse, 50% of patients (with 2 resp. 3 or more events) contribute almost 90% of all AE (bottom right panel). To facilitate interpretation, grey vertical bars indicate 10% on the vertical scale.

placebo patients completed the trial. Discontinuations were for AE (14%), active disease (4%), and for other (incl. covid-related) reasons (20%) in both groups; mean time in study 19 months.

Prednisolone resulted in more benefit and harm than placebo. Disease activity rapidly declined in the first 3 months and stabilized after 1 year (Figure 1), and was lower in prednisolone patients (adjusted mean difference in DAS28 over 2 years: 0.37, 95%CL 0.23, p< 0.0001). In 331 patients adherent to protocol on stable treatment ('pure treatment comparison') the mean difference in DAS28 after 3 months was 0.62 (95%CL 0.44). Significant time-treatment interaction in secondary analyses suggested a decrease in contrast after the first year; this was most likely caused by significantly more changes in DMARD treatment favoring the placebo group. Joint damage progression over 2 years was 1.7 point lower in the prednisolone group (95%CL 0.7, p=0.003).

60% prednisolone vs 49% placebo patients experienced the harm outcome: 60 vs 49%, adjusted RR 1.24, 95%CL 1.04, p=0.02; largest contrast in (mostly non-severe) infections (Table 1). Other GC-specific events were rare. In both groups, AE clustered in a subgroup of patients (Figure 2).

Conclusion: Add-on low dose prednisolone has powerful long-term effects in established RA, with a tradeoff of 24% relative (11% absolute) increase in the number of patients with adverse events, mostly non-severe; this suggests a favorable balance of benefit and harm.

This trial was funded by the European Union's Horizon 2020 research and innovation program under grant agreement No. 634886.

Effectiveness and Safety of Tocilizumab SC Every 10 Days in Patients with Rheumatoid Arthritis Who Previously Used Tocilizumab EV During the COVID 19 Pandemic at the Hospital Docente Padre Billini, Dominican Republic

Teresandris Polanco Mora, Jennifer Santana Peralta de Heyaime, Angelo Cornelio Vasquez, Yamilet Cruz, Edral Rodriguez, Tirso Valdez Lorie, Roberto Munoz and Rafael Alba Feriz, Hospital Docente Padre Billini, Santo Domingo, Dominican Republic

SESSION INFORMATION

Session Date: Tuesday, November 9, 2021
Session Title: RA – Treatments Poster III: RA Treatments & Their Safety (1674–1710)
Session Type: Poster Session D
Session Time: 8:30AM–10:30AM

Background/Purpose: Rheumatoid arthritis (RA) is an autoimmune disease systemic, with a prevalence 0.5 - 1% of the population, with predilection for the female sex. (1) Tocilizumab (TCZ) is a humanized monoclonal antibody directed against the receptor Soluble and Membrane Interleukin-6, (2) Different Studies have demonstrated the non-inferiority of subcutaneous (sc) TCZ compared to intravenous (iv) TCZ. (3,4,5) Evidence of its efficacy in patients with sustained remission of 24 weeks or plus. 6 Following the COVID 19 pandemic and with initial results promising use of IV TCZ in these patients, the authorities of Our country considered it appropriate to change the administration of this drug in patients with RA who used it to TCZ sc every 10 days, from May 2020, with the aim of rationalizing and avoiding shortages and use IV TCZ in patients with COVID 19.

Methods: Observational, prospective, and longitudinal study, between May and October 2020, consultation patients with RA at weeks 0, 12 and 24 of rheumatology service of the Hospital Docente Padre Billini. CDAI, DAS 28, ESR, hemogram, TGO, TGP, Cholesterol, Triglycerides were measured. Inclusion criteria: > 18 years, diagnosis of RA according to the ACR / EULAR 2010 classification criteria, previous treatment with Tocilizumab EV in mono or therapy combined for more than 6 months of continuous use. The data is analyzed with SPSS V23.

Results: 119 met inclusion criteria. 93.2% (111) female, 78.15% (93) concomitant scDMARD, 21.8% (26) monotherapy, 12.6% (15) glucocorticoids. Baseline DAS28: 65.54% (78) low activity, 23.5% (28) remission, 9.2% (11) moderate activity, 1.6% (2) high activity. Baseline DAS28 mean: 2.75. CDAI baseline: 52.94% (63) remission, 44.53% (53) low activity, 2.52% (3) moderate activity, mean baseline CDAI: 2. 76.4% (91) ESR elevated. Week 12: DAS28: 62.1% (74) low activity, 26.8% (32) remission, 10.9% (13) moderate activity. CDAI week 12: 55.46% (66) remission, 31% (40) low activity, 10.92% (13) moderate activity. 73.1% (87) elevated ESR. Week 24: DAS 8: 58.8% (70) low activity, 16.8% (20) remission, 14.2% (17) moderate activity and 3.3% (4) high activity. CDAI week 24: 83.19% (99) remission, 10.92% (13) low activity, 2.52% (3) moderate activity, 2.52% (3) high activity. 76.4% (91) ESR elevated. Average DAS28: 2.9 and Average CDAI: 1 at week 24. Worsening at week 24 (DAS 28) 6.7% (8) from remission to low activity, 5.04% (7) low to moderate activity and 2.52% from moderate to high activity, CDAI showed improvement from low activity to remission of 22.6% and worsening from moderate to high activity 2.5%. ΔDAS 28: 0.15, CDAI: -1. Adverse events 1.6% (2) site reaction of injection, 2.52% (3) TGO and elevated TGP, were not reported hematologic events, dyslipidemia, or serious infections.

Conclusion: In our study, the change in the administration route and time of application of Tocilizumab did not demonstrate exacerbation, this option assessed circumstantially could be a possibility of dose optimization in patients with low clinical activity or remission for at least 6 months and good safety profile, which would reduce costs in the long term. We recommend a study with a longer period.

Impact of Race on the Efficacy and Safety of Tofacitinib in Patients with RA: A Post Hoc Analysis of Phase 2, 3, and 3b/4 Clinical Trials

Grace Wright[1], Eduardo Mysler[2], Yi-Hsing Chen[3], Cassandra Kinch[4], Arne Yndestad[5], Kenneth Kwok[6], Mary Jane Cadatal[7], Rebecca Germino[8] and Alexis Ogdie[9], [1]Grace C Wright MD PC, and Association of Women in Rheumatology, New York, NY, [2]Organización Médica de Investigación, Buenos Aires, Argentina, [3]Taichung Veterans General Hospital, Taichung, Taiwan (Republic of China), [4]Pfizer Canada ULC, Kirkland, QC, Canada, [5]Pfizer Inc, Oslo, Norway, [6]Pfizer Inc, New York, NY, [7]Pfizer Inc, Manila, Philippines, [8]Pfizer Inc, Groton, CT, [9]Perelman School of Medicine at the University of Pennsylvania, Philadelphia, PA

SESSION INFORMATION

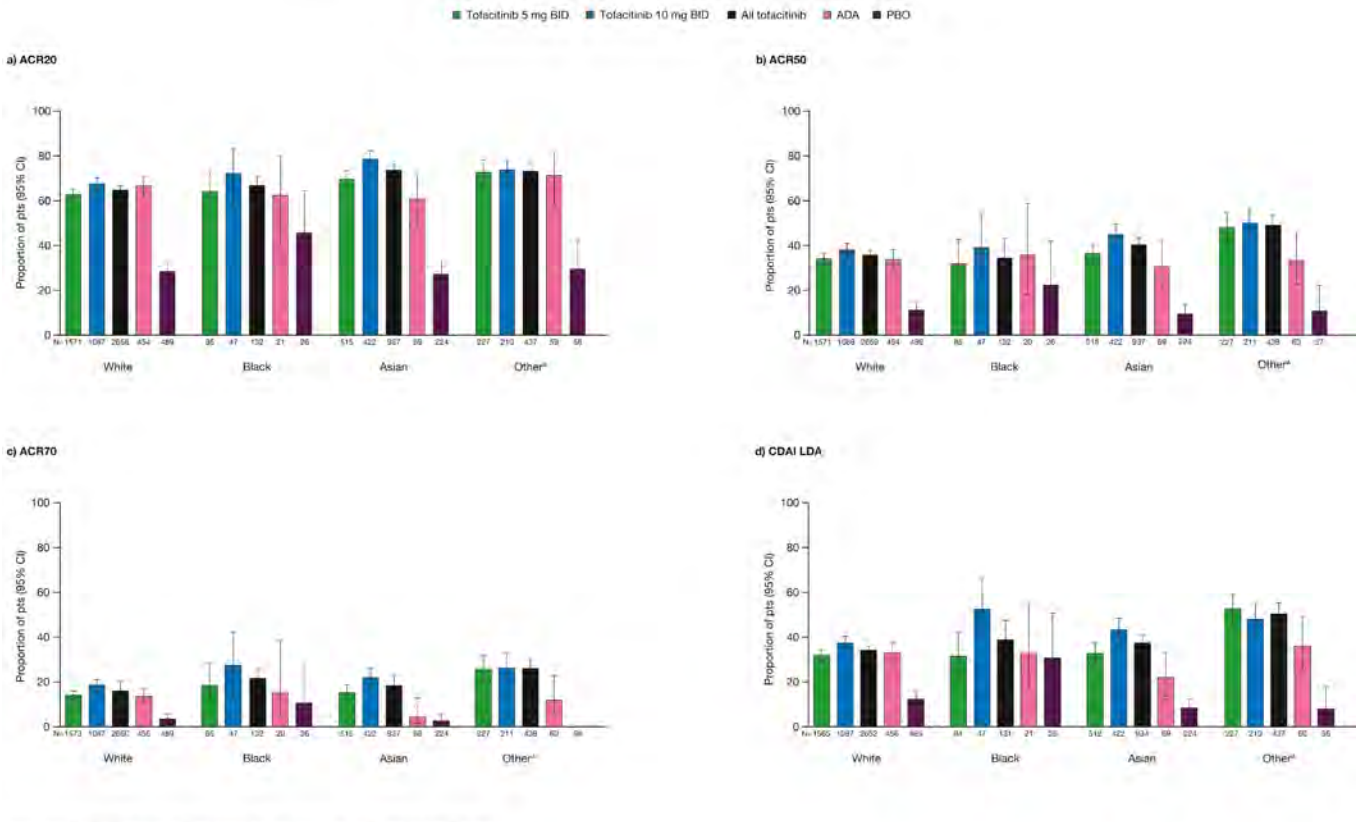
Session Date: Tuesday, November 9, 2021
Session Title: RA – Treatments Poster III: RA Treatments & Their Safety (1674–1710)
Session Type: Poster Session D
Session Time: 8:30AM–10:30AM

Background/Purpose: While racial disparities in clinical outcomes for RA patients (pts) receiving bDMARDs or csDMARDs have been described,[1] there remains a paucity of data on racial differences in response to advanced therapies. Here, we evaluate impact of race on tofacitinib efficacy and safety in RA pts.

Methods: This post hoc analysis used pooled data from 8 Phase (P)2, 6 P3, and 1 P3b/4 RCTs of pts treated with tofacitinib 5 or 10 mg BID, adalimumab (ADA; 40 mg Q2W), or placebo (PBO), stratified by self-reported pt race (White, Black, Asian, Other) at baseline (BL) visit. Efficacy outcomes at Month (M)3 were: ACR20/50/70 and CDAI/DAS28-4(ESR) LDA (scores ≤ 10 and ≤ 3.2, respectively) rates, and least squares (LS) mean change from BL (Δ) in DAS28(ESR) and HAQ-DI. Incidence rates (IRs; unique pts with events/100 pt-yrs) were estimated for adverse events (AEs), serious AEs, discontinuations due to AEs, and all-cause mortality.

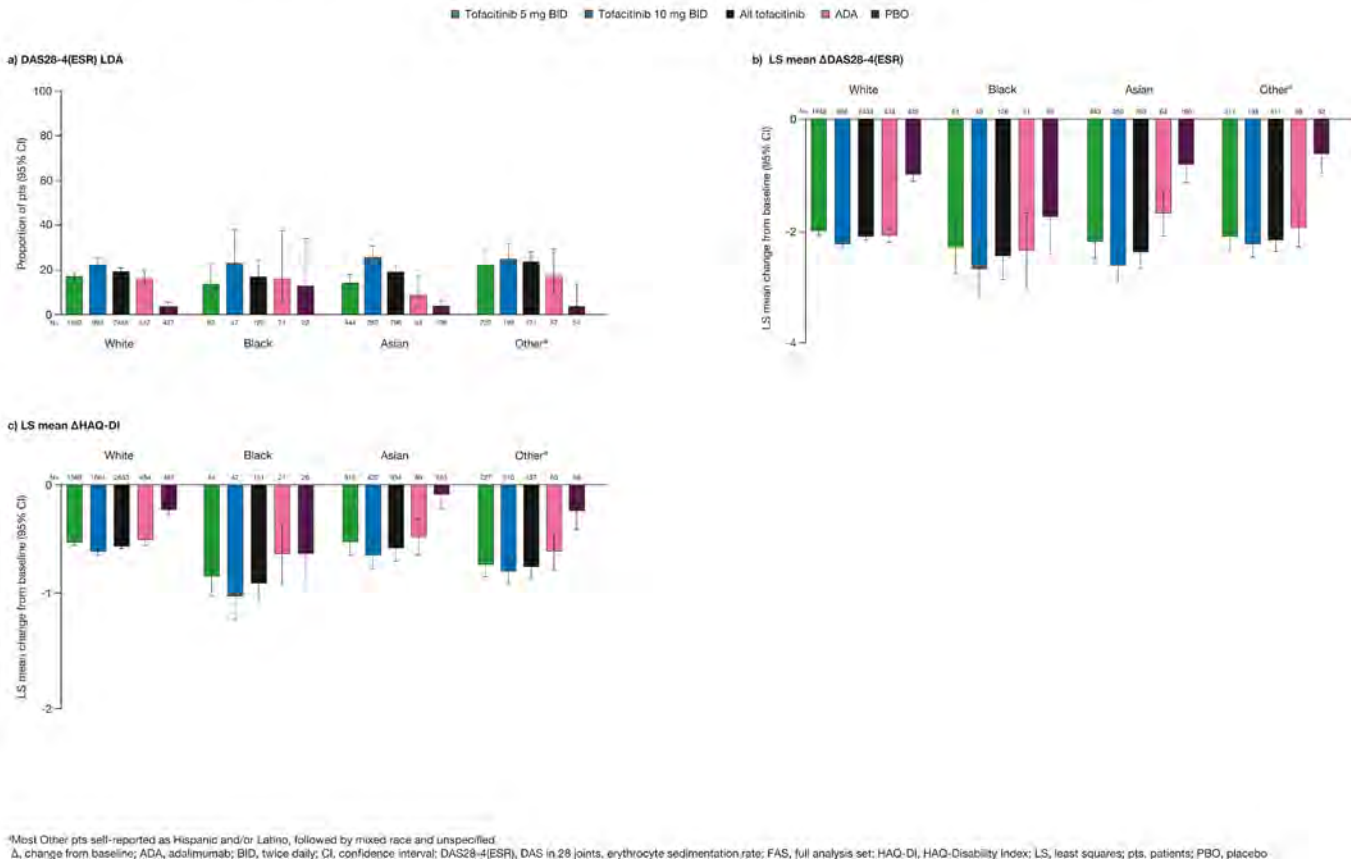
Results: 6,355 pts were included (White, n=4,145; Black, n=213; Asian, n=1,348; Other, n=649). BL characteristics were generally similar across treatment/racial groups, excepting higher rates of prior bDMARD exposure in White/Black vs Asian/Other pts. Across treatment arms, White, Black, Asian, and Other pts most commonly enrolled from Europe (40.9%), North America (68.1%), East/South Asia (97.9%), and Latin America (80.6%), respectively; most Other pts self-reported as Hispanic and/or Latino, followed by mixed race and unspecified. At M3, ACR20/50/70 and CDAI LDA rates were mostly higher in Other vs White pts with tofacitinib, similar across racial groups with ADA, and

Figure 1. Proportions of pts achieving a) ACR20, b) ACR50, and c) ACR70 responses, and d) CDAI LDA across treatment groups at Month 3, stratified by race (FAS)



[a]Most Other pts self-reported as Hispanic and/or Latino, followed by mixed race and unspecified
ACR20/50/70, ACR ≥20%, ≥50%, or ≥70% response criteria; ADA, adalimumab; BID, twice daily; CDAI, Clinical Disease Activity Index; CI, confidence interval; FAS, full analysis set; LDA, low disease activity; PBO, placebo; pts, patients

Figure 2. a) Proportions of pts achieving DAS28-4(ESR) LDA, and LS mean change from baseline in b) DAS28-4(ESR), and c) HAQ-DI across treatment groups at Month 3, stratified by race (FAS)



[a]Most Other pts self-reported as Hispanic and/or Latino, followed by mixed race and unspecified.
Δ, change from baseline; ADA, adalimumab; BID, twice daily; CI, confidence interval; DAS28-4(ESR), DAS in 28 joints, erythrocyte sedimentation rate; FAS, full analysis set; HAQ-DI, HAQ-Disability Index; LS, least squares; pts, patients; PBO, placebo

numerically higher in Black vs White/Asian/Other pts with PBO (Figure 1a–d). DAS28-4(ESR) LDA rates and LS mean ΔDAS28-4(ESR) were broadly similar across racial groups with active treatment, and numerically higher in Black vs White/Asian/Other pts with PBO (Figure 2a–b). Across active treatment arms, LS mean ΔHAQ-DI was generally comparable across racial groups with some numerical differences, and higher in Black vs White/Asian pts with PBO (Figure 2c). Safety outcomes were broadly similar across treatment arms, with some higher IRs for AEs seen with Black/Other vs White/Asian pts (Table).

Conclusion: Across racial groups, tofacitinib efficacy/safety was consistent with previous findings from the tofacitinib RA clinical program, although results should be interpreted with caution due to low pt numbers in some groups. Noting this limitation, some trends in efficacy outcomes were seen between racial groups; higher ACR20/50/70 and CDAI LDA rates in Other vs White pts with tofacitinib may be attributable to prior treatment history/regional practice norms. Numerically higher PBO responses in Black vs White/Asian/Other pts may reflect demographic differences, notably country of enrollment, across racial groups participating in RCTs. Safety findings were generally consistent across racial/treatment groups. Future analyses should focus on the impact of socio-economic, cultural, genetic, or practice-based differences that may underpin these results.

ATI-450, an Investigational MK2 Inhibitor, Is Well Tolerated and Demonstrated Clinical Activity in Patients with Mod/severe RA: A 12-week Phase 2a, Randomized, Investigator/patient-blind Study Investigating the Safety, Tolerability, PK and PD of ATI-450 + MTX vs PBO + MTX in MTX IR Patients

SESSION INFORMATION
Session Date: Tuesday, November 9, 2021
Session Title: RA – Treatments Poster III: RA Treatments & Their Safety (1674–1710)
Session Type: Poster Session D
Session Time: 8:30AM–10:30AM

Background/Purpose: p38 inhibition has been a focus of research in RA but efficacy in clinical studies was underwhelming, possibly because a large number of pro and anti-inflammatory pathways as well as negative feedback loops were modulated by this target. ATI-450 specifically blocks the downstream MK2-mediated inflammatory drive on the p38 pathway and may therefore avoid the tachyphylaxis associated with p38 inhibitors. Inhibition of ex vivo-stimulated IL1, IL6, TNFa and IL8 was seen in phase 1. This study explored whether MK2 inhibition was well tolerated and could deliver sustained anti-inflammatory effect leading to durable clinical activity in patients with RA.

Methods: A phase 2a, randomized, investigator/patient-blind, sponsor-unblinded, placebo (PBO) controlled study was conducted to investigate safety, tolerability, PK, and PD of ATI-450 versus PBO (both + MTX) in MTX inadequate responders with moderate to severe RA. Patients were randomized in a 3:1 ratio to receive oral ATI-450 (50 mg) or PBO, both BID. A 12-week treatment period was followed by a 4-week follow-up period. The primary endpoint was safety and tolerability. Secondary and exploratory endpoints included DAS28-CRP, ACR20/50/70, change from baseline in hsCRP and relevant endogenous cytokine levels in blood. MRI imaging will be reported elsewhere. The study was not powered to detect statistical significance on efficacy endpoints.

Results: Nineteen subjects were randomized (16:ATI-450, 3:PBO). Mean DAS28-CRP at baseline was 5.71 in the treatment arm and 5.77 in the PBO arm. Seventeen subjects (15 ATI-450, and 2 PBO) completed 12 weeks of treatment. One subject from each arm withdrew during the treatment period: the ATI-450 subject withdrew for an AE of elevated CPK.

ATI-450 was generally well tolerated. No serious adverse events were reported during the treatment period (1 unrelated SAE of COVID-19 pneumonia was reported off-treatment in the follow-up period in the ATI-450 arm). The most common adverse events (each reported in 2 subjects) were urinary tract infection and ventricular extrasystoles. All adverse events were mild to moderate.

In the per-protocol analysis (includes 15 ATI-450, 2 PBO who completed 12 weeks), the mean change from baseline in DAS28-CRP score at week 12 was -2.0 in the ATI-450 arm versus +0.35 in the PBO arm. 40% and 20% of ATI-450 subjects had a DAS28-CRP score ≤ 3.2 and < 2.6 at week 12, respectively, versus 0 PBO patients. ACR20/50/70 was observed at week 12 in 60%, 33% and 20% of 15 ATI-450 subjects versus 0% of 2 PBO subjects. The median reduction from baseline in hsCRP was >40% throughout the 12-week treatment period in the treatment arm; a sustained median reduction was not observed in the placebo arm. A marked and sustained inhibition of median endogenous plasma concentrations of TNFα, IL6, IL8, and MIP1β was observed in the treatment arm over the 12-week period.

Conclusion: ATI-450 was generally well tolerated and demonstrated durable clinical activity over 12 weeks in RA. This study is the first to demonstrate that MK2 inhibition can overcome key deficiencies associated with p38 inhibition. ATI-450 has potential to be an important new drug in RA and progression to phase 2b is supported.

SESSION INFORMATION

Session Date: Tuesday, November 9, 2021

Session Title: RA – Treatments Poster III: RA Treatments & Their Safety (1674–1710)

Session Type: Poster Session D

Session Time: 8:30AM–10:30AM

Background/Purpose: This systematic literature review and meta-analysis aimed to better estimate the effect of oral supplementation with polyunsaturated fatty acid (PUFA; omega (n)-3 and n-6) on inflammatory rheumatic disease (IRD) activity in terms of duration, dose, type and source.

Methods: The literature was searched in PubMed, EMBASE and Cochrane Library databases up to October 2020. Studies were reviewed in accordance with PRISMA guidelines. The effect of PUFA supplementation on disease ac-

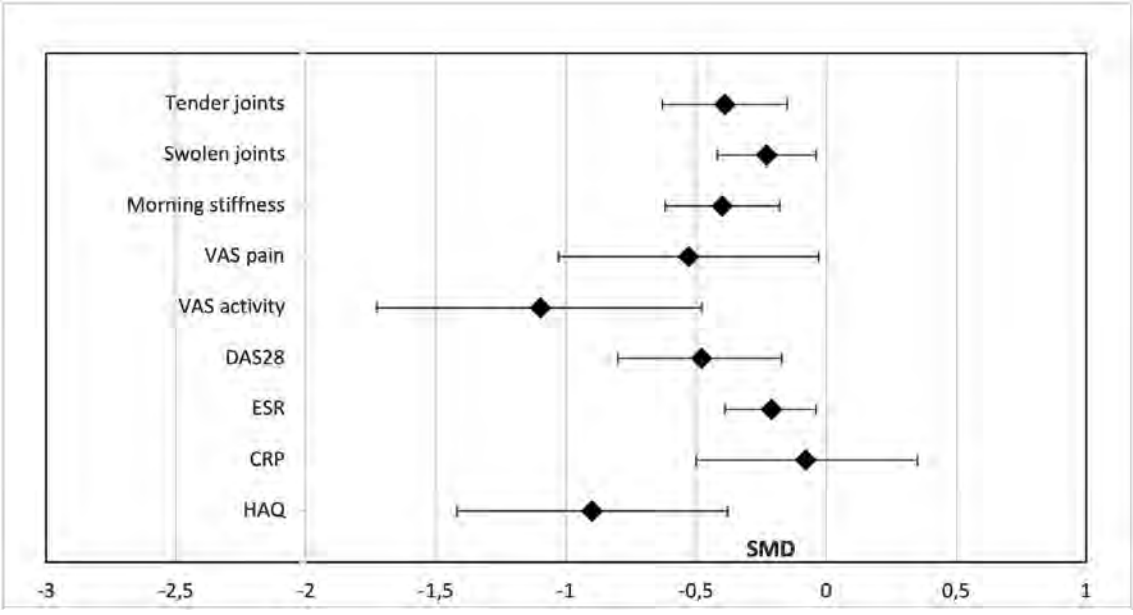

Figure 1. Overall effect of oral PUFA supplementation as compared with controls on parameters of rheumatoid arthritis (RA) Data are standardized mean difference (SMD) (95% confidence interval [CI]). VAS= visual analog scale; DAS28= Disease Activity Score in 28 joints; ESR= erythrocyte sedimentation rate; CRP= C-reactive protein; HAQ= Health Assessment Questionnaire.

tivity was expressed as the standardized mean difference. Metaregression and subgroup analyses involved type of IRD, Jadad score, PUFA source (animal or vegetable) and doses.

Results: We obtained 43 references; 31 randomized controlled studies compared the effects of PUFA and placebo on disease activity (732 IRD patients receiving PUFA supplementation and 732 receiving placebo, most with rheumatoid arthritis). We found a significant improvement in pain, swollen and tender joint count, Disease Activity Score in 28 joints, and Health Assessment Questionnaire score in IRD patients receiving PUFA supplementation as compared with controls, with a significant decrease in erythrocyte sedimentation rate but not C-reactive protein level. Although meta-regression revealed no difference by IRD type or source or dose of PUFA supplementation, subgroup analysis revealed more parameters significantly improved with animal- than vegetable-derived PUFAs and 3-to 6-month supplementation. Most studies examined high-dose supplementation (>2 g/day).

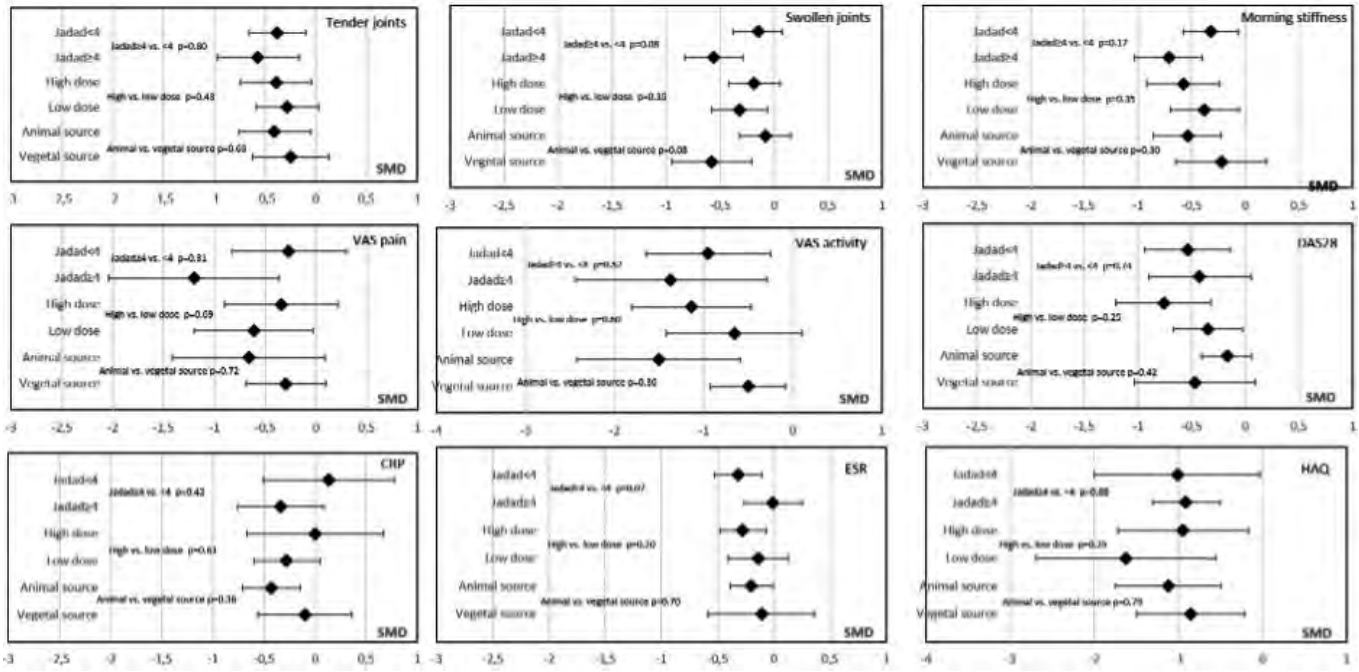

Figure 2. Meta-regression analysis of effect of oral PUFA supplementation as compared with controls on parameters of RA Data are standardized mean difference (SMD) (95% CI). VAS= visual analog scale; DAS28= Disease Activity Score in 28 joints; ESR= erythrocyte sedimentation rate; CRP= C-reactive protein; HAQ= Health Assessment Questionnaire.

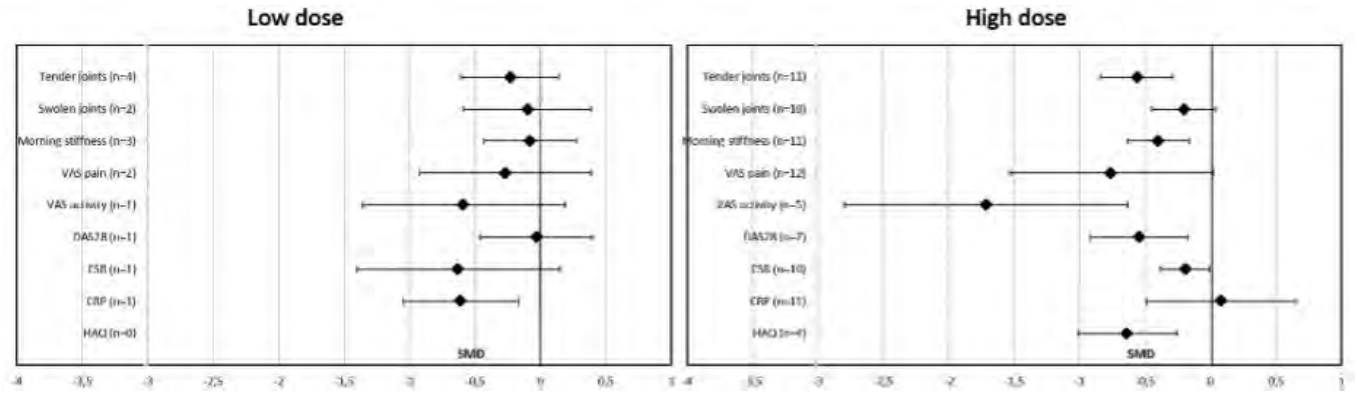

Figure 3. Effect of oral PUFA supplementation on RA disease activity by PUFA dosage (> or < 2 g/day). Data are standardized mean difference (SMD) (95% CI). VAS= visual analog scale; DAS28= Disease Activity Score in 28 joints; ESR= erythrocyte sedimentation rate; CRP= C-reactive protein; HAQ= Health Assessment Questionnaire.

Conclusion: PUFA consumption, especially omega-3 from animal source >2 g/day, may improve IRD activity and might be an adjuvant therapy in rheumatoid arthritis.

SESSION INFORMATION
Session Date: Tuesday, November 9, 2021
Session Title: RA – Treatments Poster III: RA Treatments & Their Safety (1674–1710)
Session Type: Poster Session D
Session Time: 8:30AM–10:30AM

Background/Purpose: Interstitial lung disease (ILD) is a severe complication of Rheumatoid Arthritis (RA). Usual interstitial pneumonia (UIP) is considered to be more frequent and severe in RA than non-specific interstitial pneumonia (NSIP). Abatacept (ABA) and Rituximab have demonstrated efficacy in RA-ILD [Fernández-Díaz C, et al. Semin Arthritis Rheum. 2018 Aug;48(1):22-27; Fernández-Díaz C, et al. Rheumatology (Oxford). 2020 Dec 1;59(12):3906-16; Atienza-Mateo B, et al. J Clin Med. 2020 Sep 23;9(10):3070]. Our aim was to compare the efficacy of ABA in RA-ILD patients according to radiological patterns of UIP or NSIP.

Methods: From an observational multicenter study of 263 RA-ILD patients treated with ABA, we selected those with UIP or NSIP. We analyzed in the 2 groups from baseline up to 24 months the following outcomes: **a)** Forced Vital Capacity (FVC), **b)** Carbon monoxide diffusing capacity (DLCO), **c)** Chest High Resolution Computed Tomography (HRCT), and **d)** dyspnea. Differences between final follow-up and basal visit were calculated as the average difference and 95% Confidence Interval (95% CI). Multivariable linear regression was used to assess the differences between the 2 groups.

Results: We studied 190 patients with UIP (n=106) and NSIP (n=84). Patients with UIP were older, had more positivity for rheumatoid factor and had received more sulfasalazine **(Table 1)**. ILD duration up to ABA initiation was relatively short in both groups, with a median [IQR] of 16 [4-50] and 11 [2-36] months in UIP and NSIP patterns, respectively. Mean baseline values of FVC and DLCO were > 80% and > 60%, respectively, in the 2 groups, with a lower FVC in

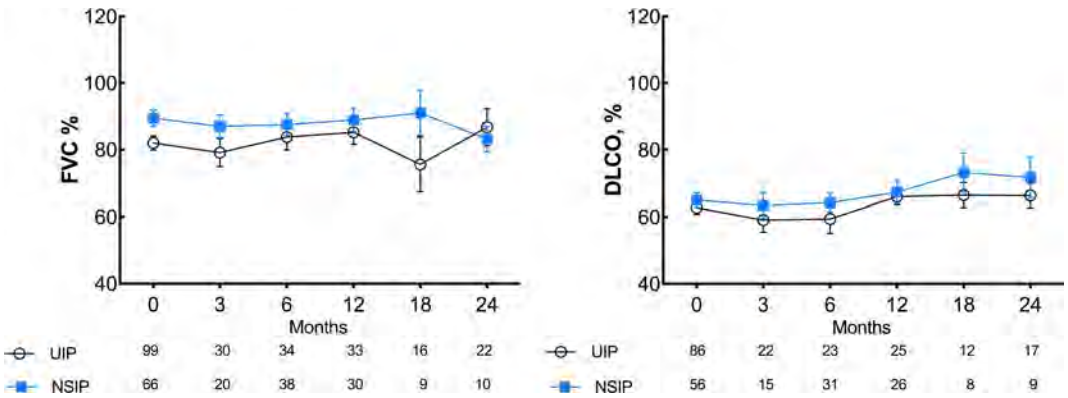

Figure 1. Evolution of pulmonary function tests in RA-ILD patients with UIP and NSIP patterns. FVC and DLCO are expressed as mean (95%CI) and compared between the 2 groups.

UIP (82% vs 89% in NSIP, p< 0.05). The evolution of FVC and DLCO is shown in **Figure 1.** Both parameters remained stable during 24 months of ABA therapy. Available chest HRCT images improved/ stabilized in 73.1% and 72.9% of UIP and NSIP patterns, respectively. With multivariable linear regression analysis, no differences were found in the changes of FVC, DLCO, or HRCT images. Stabilization or improvement of dyspnea was found in 91% and 95% of UIP and NSIP patterns, respectively.

Conclusion: ABA seems to be equally effective in stabilizing of DLCO, FVC and HRCT in UIP and NSIP in RA-ILD. Our results suggest that an early administration of ABA in ILD, before significant structural lung damage development, may be preferable to prevent interstitial progression, regardless of the radiological pattern.

Session Title: RA – Treatments Poster III: RA Treatments & Their Safety (1674–1710)

Session Type: Poster Session D

Session Time: 8:30AM–10:30AM

Background/Purpose: Previous clinical trial and real-world data suggest that risk of serious infection events (SIEs) and opportunistic infections (OIs) is similar with tofacitinib 5 mg twice daily (BID; recommended dosage for RA) vs

Table. Summary of infections and infestations in ORAL Surveillance

Pts with events, n (%)	Tofacitinib 5 mg BID (N=1,455)	Tofacitinib 10 mg BID[a] (N=1,456)	TNFi[b] (N=1,451)
Infections and infestations (System Organ Class)	1,036 (71.2)	1,055 (72.5)	930 (64.1)
Most frequently reported,[c] by Preferred Term			
Upper respiratory tract infection	308 (21.2)	312 (21.4)	255 (17.6)
Bronchitis	222 (15.3)	237 (16.3)	163 (11.2)
Urinary tract infection	186 (12.8)	221 (15.2)	184 (12.7)
HZ (non-serious/serious)[d]	180 (12.4)	178 (12.2)	58 (4.0)
Nasopharyngitis	164 (11.3)	165 (11.3)	158 (10.9)
Pneumonia	95 (6.5)	101 (6.9)	78 (5.4)
Sinusitis	92 (6.3)	79 (5.4)	91 (6.3)
Pharyngitis	86 (5.9)	79 (5.4)	75 (5.2)
Influenza	90 (6.2)	91 (6.3)	71 (4.9)
Latent tuberculosis	87 (6.0)	67 (4.6)	91 (6.3)
Gastroenteritis	64 (4.4)	79 (5.4)	53 (3.7)
Respiratory tract infection	43 (3.0)	43 (3.0)	31 (2.1)
Cellulitis	36 (2.5)	32 (2.2)	50 (3.4)

[a]The tofacitinib 10 mg BID group included pts who were switched from tofacitinib 10 to 5 mg BID as a result of a study modification in February 2019

[b]In the TNFi group, pts in North America (US, Canada, and Puerto Rico) received adalimumab 40 mg every other week, and pts in the rest of the world received etanercept 50 mg every week

[c]≥ 3% of pts with events in any treatment group

[d]Includes all HZ events from the clinical database and adjudicated events

The censoring time for the analyses was the 28-Day On-Treatment period, defined as the minimum of last contact date and last study treatment dose date +28 days. The last contact date was the maximum of event start date, event stop date, last study visit date, withdrawal date, and telephone contact date. If a pt died, the last contact date was the death date

BID, twice daily; HZ, herpes zoster; N, number of pts in treatment group; n, number of pts with events; pts, patients; TNFi, TNF inhibitors

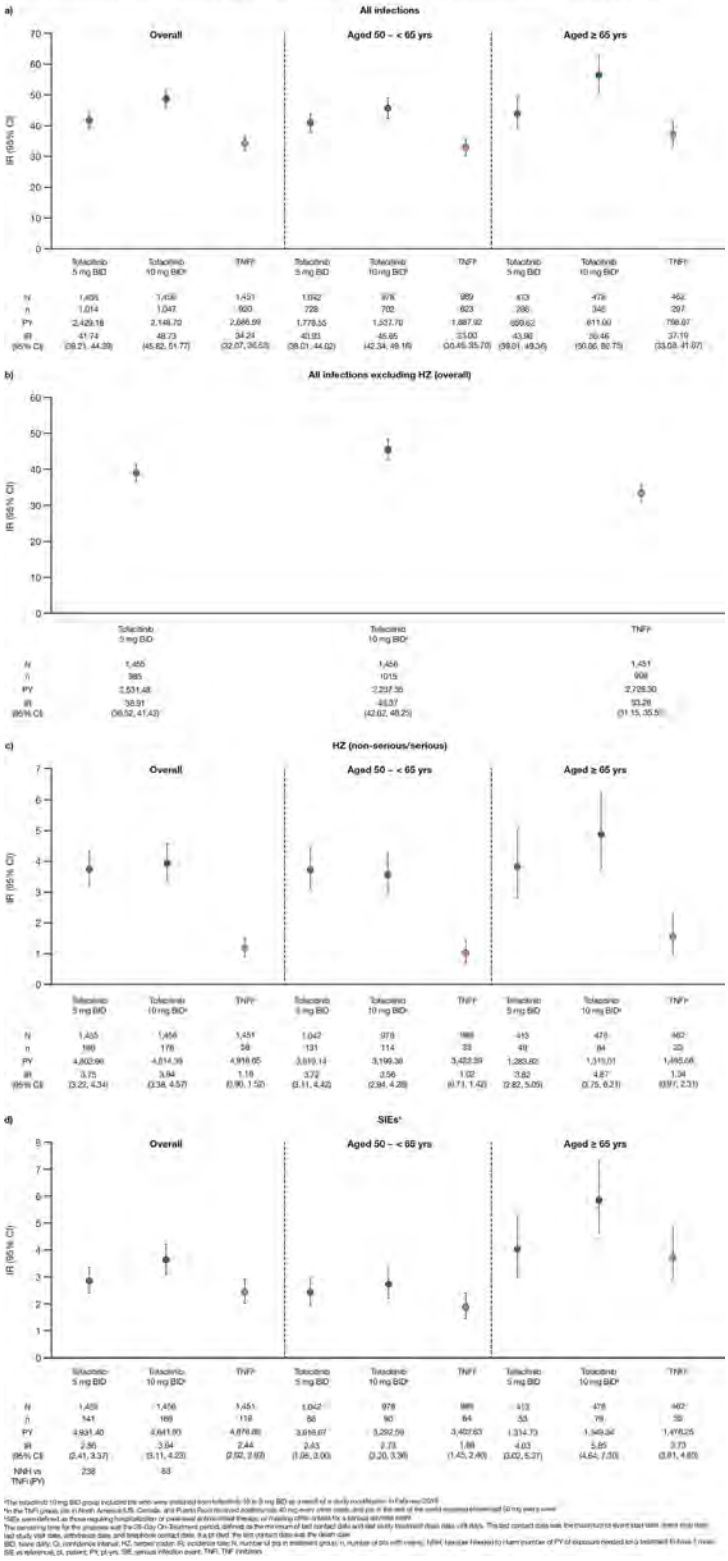

Figure 1. IRs (95% CI) in ORAL Surveillance for a) all infections (overall and stratified by age [50 – < 65 yrs vs ≥ 65 yrs]), b) all infections excluding HZ (overall), c) HZ (non-serious/serious; overall and stratified by age [50 – < 65 yrs vs ≥ 65 yrs]), and d) SIEs (overall and stratified by age [50 – < 65 yrs vs ≥ 65 yrs])

TNFi,[1,2] while herpes zoster (HZ) rates are higher with tofacitinib.[2] Here, we characterized infections in ORAL Surveillance (NCT02092467).

Methods: ORAL Surveillance was a long-term, randomized, open-label, non-inferiority, Phase 3b/4 safety endpoint study of tofacitinib vs TNFi in patients (pts) aged ≥ 50 yrs with active RA despite MTX treatment and ≥ 1 additional

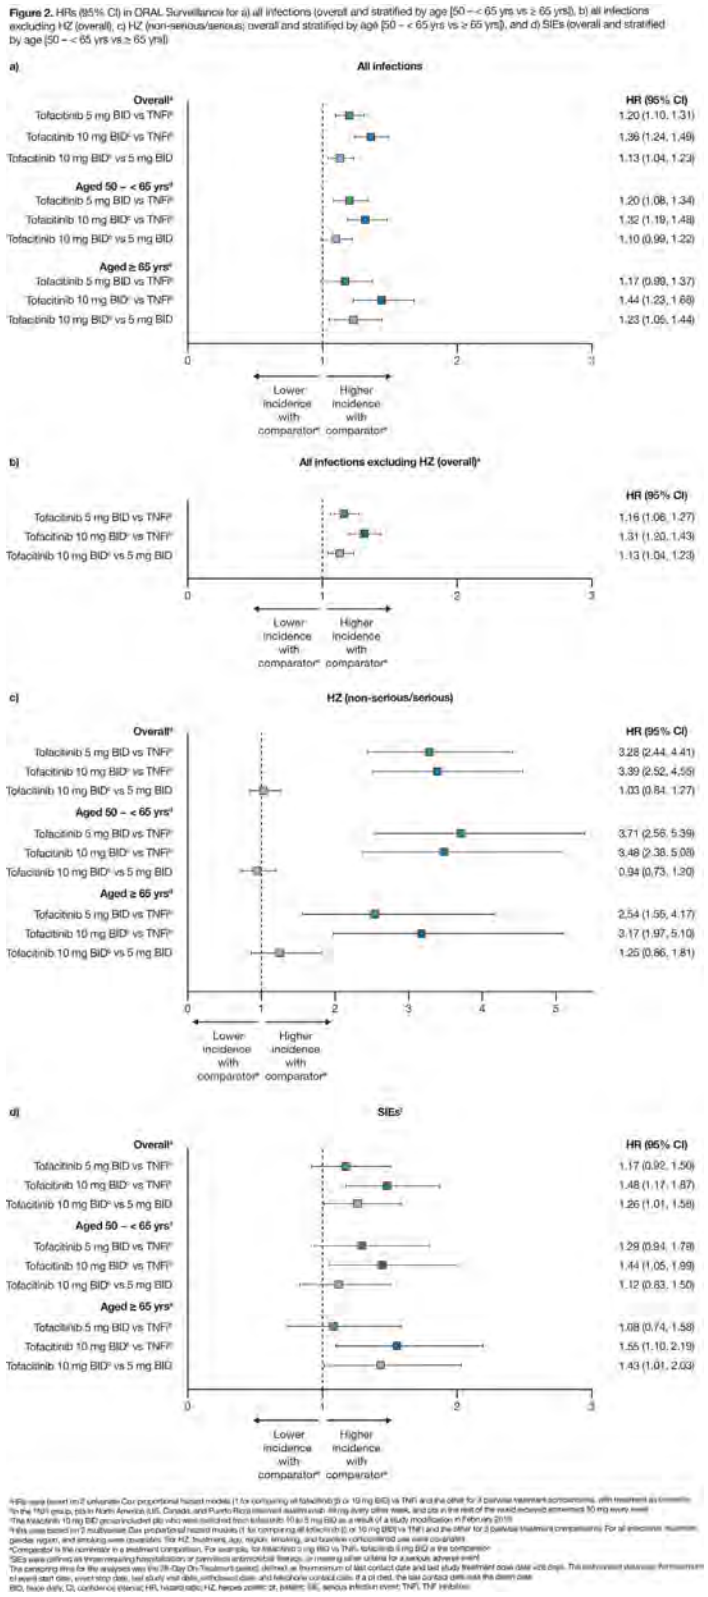

Figure 2. HRs (95% CI) in ORAL Surveillance for a) all infections (overall and stratified by age [50 – < 65 yrs vs ≥ 65 yrs]), b) all infections excluding HZ (overall), c) HZ (non-serious/serious; overall and stratified by age [50 – < 65 yrs vs ≥ 65 yrs]), and d) SIEs (overall and stratified by age [50 – < 65 yrs vs ≥ 65 yrs])

cardiovascular (CV) risk factor. Pts were randomized 1:1:1 to receive open-label tofacitinib 5 or 10 mg BID or a TNFi (adalimumab 40 mg every other week [North America]; etanercept 50 mg every week [rest of the world]) with stable background MTX. Incidence of all infections regardless of severity (any adverse event in the infections and infesta-

tions System Organ Class), HZ (non-serious/serious), and SIEs were analyzed overall and by age (50 – < 65 yrs; ≥ 65 yrs). Overall OI and tuberculosis (TB) incidence were also analyzed. Incidence rates (IRs; pts with events per 100 pt-yrs [PY]), hazard ratios (HRs), and Number Needed to Harm (NNH; number of PY of exposure needed for a treatment to have 1 more SIE vs reference) were calculated. First infection events occurring ≤ 28 days after the last dose or up to the last contact date were considered.

Results: Of 4,362 treated pts, 3,009 (69%) were aged 50 – < 65 yrs and 1,353 (31%) were aged ≥ 65 yrs. At baseline, mean age was 61.2 yrs, mean RA duration was 10.4 yrs, and pts had active disease (mean Clinical Disease Activity Index 39.8). Across treatment groups, 5.3–5.9% of pts were reported to have been vaccinated for HZ prior to or during the study. Respiratory infections, urinary tract infections, and HZ were the most common infections with tofacitinib (Table). Incidence of all infections was higher for tofacitinib vs TNFi, with notably higher HZ incidence for tofacitinib (Figure 1a–c, Figure 2a–c). Across treatments, > 90% of HZ cases were non-serious, and > 92% were mild/moderate in severity. IRs of all infections, HZ, and SIEs were generally higher in pts aged ≥ 65 vs 50 – < 65 yrs (Figure 1). For SIEs, IRs were numerically higher for tofacitinib vs TNFi (Figure 1d). HRs for SIEs were > 1 for tofacitinib 5 or 10 mg BID vs TNFi and tofacitinib 10 vs 5 mg BID; for tofacitinib 10 mg BID vs TNFi, 95% CIs were > 1 (Figure 2d). NNH for SIEs were 238 PY and 83 PY for tofacitinib 5 and 10 mg BID vs TNFi, respectively (Figure 1d). OI IRs were numerically higher for tofacitinib vs TNFi, due to HZ OI (adjudicated; data not shown). TB IRs were: tofacitinib 5 mg BID, 0.02; tofacitinib 10 mg BID, 0.10; TNFi, 0.10.

Conclusion: In pts aged ≥ 50 yrs with RA and ≥ 1 additional CV risk factor, overall incidence of infections was higher for tofacitinib vs TNFi, with notably higher HZ IRs. Incidence of SIEs was numerically higher for both tofacitinib doses vs TNFi and for tofacitinib 10 vs 5 mg BID; for tofacitinib 10 mg BID vs TNFi, 95% CIs for SIE HRs were > 1.

SESSION INFORMATION

Session Date: Tuesday, November 9, 2021

Session Title: RA – Treatments Poster III: RA Treatments & Their Safety (1674–1710)

Session Type: Poster Session D

Session Time: 8:30AM–10:30AM

Background/Purpose: Olokizumab (OKZ) is a humanized monoclonal antibody targeting IL-6 [1]. Here we present the results of a global phase III, head-to-head, randomized placebo (PBO) controlled clinical trial (RCT) in patients with active Rheumatoid Arthritis (RA) despite methotrexate (MTX) with a comparator arm of adalimumab (ADA).

Methods: This double-blind RCT (ClinicalTrials.gov Identifier NCT02760407, CREDO2) was conducted in the United States, European Union, Latin America, United Kingdom and Russia. Patients were randomized 2:2:2:1 to receive subcutaneous (SC) injections of OKZ 64 mg every 2 weeks (q2w), OKZ 64 mg once every 4 weeks (q4w), ADA 40mg q2w or PBO for 24 weeks, on background of MTX.

After week (Wk) 24, eligible patients could continue into an open-label study or enter a Safety Follow-Up Period of 20 weeks.

The primary endpoint was the percent of patients achieving an American College of Rheumatology 20 response (ACR20) at Wk 12.

Secondary endpoints at Wk 12 included the percentage of subjects achieving Disease Activity Score 28-joint count - C-reactive protein (DAS28-CRP) < 3.2 and improvement of physical ability from baseline to Wk 12 measured by the Health Assessment Questionnaire-Disability Index (HAQ-DI); at Wk 24, ACR50 response rate and percentage of sub-

Table 1. Demographic and Other Baseline Characteristics (intent-to-treat population). 1 - 100% patients were on MT; 2 - upper limit of normal 6 mg/L; TJC, tender joint count; SJC, swollen joint count

Metabolism and nutrition disorders	0	0	1(0.2%)	0
Psychiatric disorders	0	0	1(0.2%)	0
Reproductive system and breast disorders	0	1 (0.2%)	0	0
Surgical and medical procedures	0	1 (0.2%)	0	0

Both regimens of OKZ were statistically superior to PBO in all primary and secondary endpoints. Furthermore, non-inferiority to ADA was demonstrated for the pre-defined endpoints of ACR20 and DAS28-CRP< 3.2 for both OKZ treatment groups (Table 2).

The efficacy outcomes were maintained throughout the 24-week period of the study.

Overall incidence of treatment-emergent adverse events (TEAEs) was 70.0% in OKZ q2w arm; 70.9% in OKZ q4w arm, 65.4% in ADA arm and 63.4% in PBO, TEAEs leading to study treatment discontinuation were reported in 4.5%, 6.3%, 5.6% and 3.7% patients, respectively. The number of deaths were comparable among arms: 3 (0.6%; 2 infections, 1 cerebrovascular accident) in the OKZ q2w arm, 2 (0.4%; 1 infection, 1 myocardial ischemia) in OKZ q4w arm, 1 (0.2%; infection) in ADA arm and 1 (0.4%; sudden death) in PBO.

The most common treatment-emergent serious adverse events (TESAEs) were infections (Table 3).

Conclusion: Treatment with OKZ 64 mg q2w and OKZ 64 mg q4w plus MTX was associated with significant improvements in the signs, symptoms and physical function of RA compared to PBO plus MTX and non-inferior to ADA plus MTX over a 24-week period.

OKZ was generally well tolerated and no new safety signals have been observed.

Session Title: RA – Treatments Poster III: RA Treatments & Their Safety (1674–1710)

Session Type: Poster Session D

Session Time: 8:30AM–10:30AM

Background/Purpose: Olokizumab (OKZ), a humanized monoclonal antibody targeting IL-6, was studied in patients with active Rheumatoid Arthritis (RA) despite methotrexate (MTX) (NCT02760368, NCT02760407) [1]. Here we present the results of a global phase III; randomized placebo (PBO) controlled clinical trial (RCT) in patients with RA with an incomplete response to tumor necrosis factor inhibitors (TNFi).

Methods: Patients with active RA who had failed TNFi (NCT02760433) were enrolled in this double-blind RCT conducted in 11 countries including the USA. Patients were randomized in a 2:2:1 ratio to receive subcutaneous (SC) injections of OKZ 64 mg every 2 weeks (q2w), OKZ 64 mg once every 4 weeks (q4w) or PBO, plus MTX. At week (Wk) 16, all subjects in the PBO group were randomized in a 1:1 ratio to receive either OKZ regimens. After Wk 24, subjects could continue in an open-label study or entered a Safety Follow-Up Period for another 20 weeks.

The primary endpoint was the percent of patients achieving an American College of Rheumatology 20 response rate (ACR20) at Wk 12. Secondary endpoints at WK 12 included the percentage of subjects achieving a Disease Activity Score 28-joint count - C-reactive protein (DAS28-CRP) < 3.2, improvement of physical ability from baseline to Wk 12 measured by the Health Assessment Questionnaire-Disability Index (HAQ - DI), ACR50 response and percentage of subjects achieving a Clinical Disease Activity Index (CDAI) ≤2.8. Safety outcomes were assessed. A hierarchical statistical scheme was pre-defined to control for multiple comparisons.

Results: 368 subjects were randomized and 320 patients (87%) completed the 24-week treatment period. Baseline characteristics were comparable across arms (Table 1).

Both regimens of OKZ were statistically significantly better than PBO in achieving the primary endpoint (Table 2). The efficacy of OKZ was maintained to Wk 24.

Overall incidences of treatment-emergent adverse events (TEAEs) were 65.5% in OKZ q2w, 65.0% in OKZ q4w and 50.7% in PBO. Subsequent randomization of PBO arm to OKZ at Wk 16 did not substantially change the TEAE incidence rate per treatment group: 64.3% in any OKZ q2w and 59.7% in any OKZ q4w. The majority of TEAEs in all groups were of mild or moderate severity.

Incidence of treatment-emergent serious adverse events (TESAEs) were: 12 (7.0%) in subjects treated with OKZ q2w; 6 (3.2%) in subjects treated with OKZ q4w (Table 3).

The most frequently reported TESAEs across all treatment groups were infections and infestations: 2 (1.1%) in OKZ q4w group, 2 (1.2%) in OKZ q2w group.

Table 1. Demographic and Other Baseline Characteristics (intent-to-treat population). 1, 100% patients were on MTX; 2, upper limit of normal 6 mg/L; SD, standard deviation; BMI, body mass index; TJC, tender joint count; SJC, swollen joint count

Intervertebral disc protrusion	1(0.7%)	0	0
Musculoskeletal chest pain	1(0.7%)	0	0
Osteoarthritis	1(0.7%)	0	0
Injury, poisoning and procedural complications	1 (0.7%)	0	0
Hip fracture	1 (0.7%)	0	0
Ulna fracture	1 (0.7%)	0	0
Psychiatric disorders	1(0.7%)	0	0
Anxiety	1(0.7%)	0	0
Death	0	0	0

No serious opportunistic infections including active tuberculosis, major adverse cardiovascular events, gastrointestinal perforations or deaths were reported.

Conclusion: In this global Phase III trial in patients with active RA inadequately controlled by TNFi, treatment with OKZ 64 mg q2w and OKZ 64 mg q4w plus MTX was associated with significant improvements in the signs and symptoms of RA compared to PBO plus MTX over a 24-week period.

Treatment with OKZ q2w and q4w in this difficult to treat population was generally well tolerated and was similar with the established safety profile of IL-6 inhibitors.

SESSION INFORMATION
Session Date: Tuesday, November 9, 2021
Session Title: RA – Treatments Poster III: RA Treatments & Their Safety (1674–1710)
Session Type: Poster Session D
Session Time: 8:30AM–10:30AM

Background/Purpose: Upadacitinib (UPA) is an oral Janus kinase inhibitor approved for the treatment of rheumatoid arthritis (RA). The safety and efficacy of UPA has been evaluated across a spectrum of patients (pts) with RA in the Phase 3 SELECT clinical program.[1,2]

We describe long-term laboratory profiles (cut-off date: Jun 30, 2020) associated with exposure to UPA, adalimumab (ADA), and methotrexate (MTX) in pts with RA treated in the SELECT trials.

Methods: Data were analyzed from 6 randomized controlled UPA RA trials.[1,2] The proportions of pts experiencing potentially clinically significant laboratory changes at a single time point were summarized for the following groups: pooled UPA 15 mg once daily (QD; UPA15; 6 trials), pooled UPA 30 mg QD (UPA30; 4 trials), ADA 40 mg every other week (EOW; 1 trial), and MTX monotherapy (1 trial). Pts received UPA with/without background conventional synthetic disease-modifying antirheumatic drugs. Treatment-emergent adverse events are reported as exposure-adjusted

event rates (events/100 patient years [E/100 PY]). Toxicity was graded per OMERACT criteria, or NCI CTCAE for creatine phosphokinase (CPK) and creatinine.

Results: 4413 pts received ≥1 dose of UPA (UPA15 [n=3209]; UPA30 [n=1204]). Exposures were comparable between treatment groups (**Table**). Proportions of pts with Grade (Gr) 3 and 4 decreases in hemoglobin were highest with UPA30 and MTX (**Table**). Rates of anemia, as reported by the investigator, were comparable between UPA15, ADA, and MTX groups (**Figure**); the frequency of UPA-treated pts who discontinued due to anemia was uncommon in all arms. Gr 3 and 4 decreases in neutrophil and lymphocyte counts with UPA were dose-dependent and higher vs ADA or MTX. Discontinuations due to neutropenia and lymphopenia were rare (< 0.1%). Transaminase elevations were more frequent with UPA and MTX vs ADA; however, the proportion of pts who discontinued due to increases in alanine (ALT) or aspartate aminotransferase (AST) were comparable between UPA15 and ADA, and numerically higher with UPA30 and MTX. CPK elevations were more frequent with UPA (**Figure**). Most events were asymptomatic, and the 1 case of rhabdomyolysis in the UPA30 group was unrelated to study drug (which was attributed to influenza).

Conclusion: This long-term analysis of UPA-treated pts with RA showed dose-dependent relationships for several laboratory abnormalities. Incidences of these with UPA15 were similar to MTX but typically higher than with ADA. Treatment discontinuations due to laboratory abnormalities were infrequent and similar across all treatment groups.

Table. Pts with potentially clinically significant laboratory changes

Variable, n (%)	MTX monotherapy (N=314; 637.4 PY)	ADA 40 mg EOW (N=579; 1051.8 PY)	UPA 15 mg QD (N=3209; 7023.8 PY)	UPA 30 mg QD (N=1204; 3091.6 PY)

SESSION INFORMATION
Session Date: Tuesday, November 9, 2021
Session Title: RA – Treatments Poster III: RA Treatments & Their Safety (1674–1710)
Session Type: Poster Session D
Session Time: 8:30AM–10:30AM

Background/Purpose: Baricitinib (bari) is an oral selective Janus kinase (JAK)1/JAK 2 inhibitor approved for the treatment of adult patients with moderately to severely active rheumatoid arthritis (RA). The objective of this analysis was to report bari's safety profile with data up to 9.3 years of treatment.

Methods: Pooled data from 9 randomized (5 Phase 3, 3 Phase 2, 1 Phase 1b) and 1 long-term extension (LTE) study were assessed. Incidence rates (IR) per 100 patient-years at risk (PYR) were calculated for all patients treated with ≥1 dose of bari (All-bari-RA). Adverse events (AEs) of interest were assessed over time in 48-month intervals. Major adverse cardiovascular events (MACE) were adjudicated in 5 Phase 3 studies and the LTE. Incidence rates for MACE were also evaluated in subgroups of patients age ≥50 years and presenting with ≥1 cardiovascular risk factor (current smoker, hypertension, high-density lipoprotein cholesterol < 40 mg/dL, diabetes, or arteriosclerotic cardiovascular disease). To account for aging of the cohort, a standardized incidence ratio (SIR) for malignancy (excluding non-melanoma skin cancer [NMSC]) was estimated using the Surveillance, Epidemiology, and End Results 17 (SEER17), 2013-2017 US population cancer rates, and a standardized mortality ratio (SMR) was estimated using 2019 US population mortality calculated as compared to the general US population with the same age distribution. Exposure adjusted IRs (EAIRs) for deep vein thrombosis (DVT), pulmonary embolism (PE), and DVT and/or PE (DVT/PE) were also calculated for groups of patients while receiving bari 2-mg or bari 4-mg within All-bari-RA.

Results: A total of 3770 patients received bari for 14,744.4 PYE with a median exposure of 4.6 years and a maximum exposure of 9.3 years; 80.5% of PYE were bari 4-mg and 18.1% of PYE were bari 2-mg. Overall, EAIRs per 100 PYE for any treatment-emergent AE and serious AE (including death) were 22.6 and 7.4, respectively (Table). Overall IRs per 100 PYR were 2.58 for serious infections; 0.35 for DVT, 0.26 for PE, 0.49 for DVT/PE, 0.51 for MACE, and 0.92 for malignancy; IRs remained stable over time (Figure). The IR (95% CI) of MACE for patients age ≥50 years was 0.68 (0.52, 0.88). In patients age ≥50 with ≥1 of the cardiovascular risk factors, IR (95% CI) of MACE was 0.77 (0.56, 1.04). The SIR (95% CI) for malignancies excluding NMSC based on the SEER17 standard was 1.07 (0.90, 1.26); the SMR (95% CI) was 0.74 (0.59, 0.92) showing that the incidence of malignancy and death in patients treated with bari appear similar to the general US population. EAIRs (95% CI) for patients while receiving bari 2-mg (PYE=2678) and bari 4-g (PYE=11,872) were DVT 2-mg 0.41 (0.21, 0.73) and 4-mg 0.35 (0.25, 0.48); PE 2-mg 0.26 (0.11, 0.54) and 4-mg 0.27 (0.18, 0.38); and DVT/PE 2-mg 0.49 (0.26, 0.83) and 4-mg 0.51 (0.39, 0.66).

Safety summary among patients with RA treated with at least one dose of baricitinib (All-bari-RA analysis set)	
	n (EAIR per 100 patient years exposure)
Treatment emergent AE	3421 (22.63)
Serious AE (including death)	1117 (7.39)
Temporary d/c due to AE	1282 (8.48)
Permanent d/c due to AE	704 (4.66)
	N (IR per 100 patient years at risk)
Death	85 (0.56)
Serious infection	372 (2.58)
Opportunistic infection (excluding tuberculosis, including multidermatomal herpes zoster)	69 (0.46)
Herpes zoster	422 (2.98)
Tuberculosis	19 (0.13)
Major adverse cardiovascular events*	73 (0.51)
DVT	52 (0.35)
PE	39 (0.26)
DVT and/or PE	73 (0.49)
Malignancies excluding NMSC	139 (0.92)
NMSC	50 (0.33)
Lymphoma	9 (0.06)
Lung cancer	24 (0.16)
Gastrointestinal perforation	9 (0.06)

Note: Data are IR unless otherwise indicated.
IR is 100 times the number of patients experiencing the adverse event divided by the event-specific exposure to treatment (exposure time up to the event for patients with the event and exposure time up to the end of the period including follow up for patients without the event), in years.
EAIR is expressed as the number of patients experiencing an adverse event per 100 patient years of exposure and is 100 times the number of patients experiencing the adverse event divided by the sum of all patient exposure time (in years).
AE=adverse event; D/C= discontinuation; DVT=deep vein thrombosis; EAIR=exposure adjusted incidence rate; IR=incidence rate per 100 patient-years at risk; NMSC=non-melanoma skin cancer; PE=pulmonary embolism.

Table.

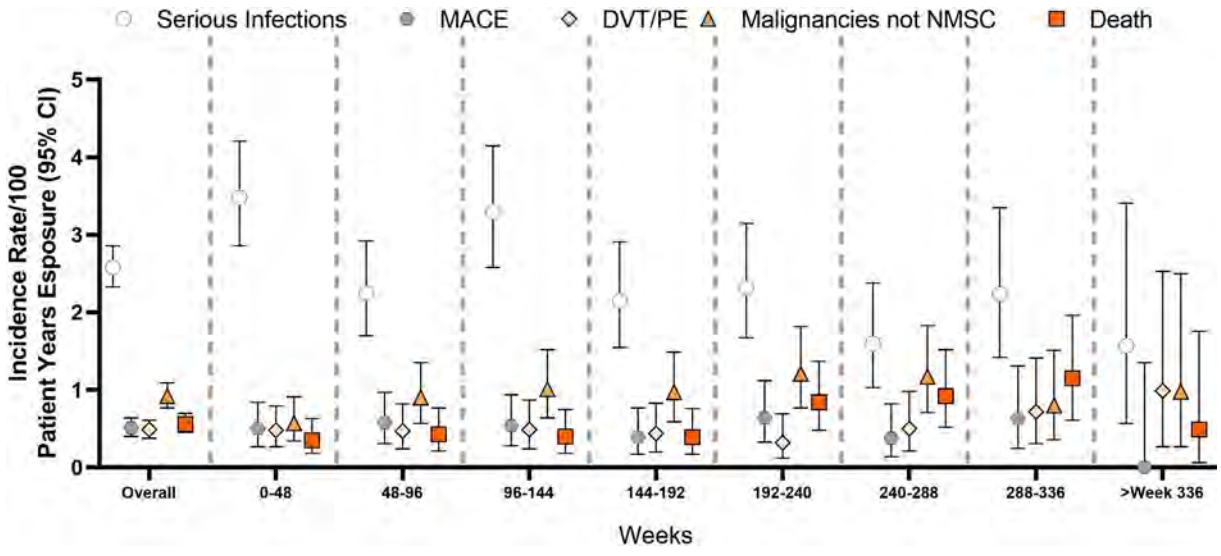

Figure. Incidence rates by 48-week exposure intervals.

Conclusion: In this report with 14,774 PYE, bari maintained a safety profile similar to that previously reported[1-3] with no increase of IRs across safety events through exposures up to 9.3 years.

Safety, Tolerability, Pharmacokinetics, Receptor Occupancy, and Suppression of T-cell-Dependent Antibody Response in a Phase 1 Study with KPL-404, an anti-CD40 Monoclonal Antibody

Manoj Samant[1], Alistair Wheeler[2], Guang-Liang Jiang[1], Moses Njenga[1], Madeline Spiers[1], Arian Pano[1] and John F Paolini[1], [1]Kiniksa Pharmaceuticals Corp., Lexington, MA, [2]Kiniksa Pharmaceuticals, Ltd., Hamilton, Bermuda

SESSION INFORMATION

Session Date: Tuesday, November 9, 2021
Session Title: RA – Treatments Poster III: RA Treatments & Their Safety (1674–1710)
Session Type: Poster Session D
Session Time: 8:30AM–10:30AM

Background/Purpose: T-cell priming and T-cell-dependent B-cell responses require an intact cluster of differentiation (CD)40/CD40L pathway. CD40 is expressed on the surface of B-cells, dendritic cells, antigen-presenting cells, and non-immune cell types; its ligand, CD40L (CD154), is expressed on the surface of activated T-cells, platelets, and other cell types. Blockade of CD40/CD40L interaction has been shown to ablate primary and secondary T-cell dependent antibody response (TDAR). We hypothesized that KPL-404, an anti-CD40 monoclonal antibody which inhibits interaction between CD40 and CD40L, would block T-cell dependent, B-cell-mediated autoimmunity in this Phase 1 study in healthy participants.

Methods: This randomized, double-blind, placebo-controlled, first-in-human study of KPL-404 in healthy participants was designed with two single-ascending-dose arms: single intravenous (IV) doses of 0.03 mg/kg, 0.3 mg/kg, 1 mg/kg, 3 mg/kg, or 10 mg/kg and single subcutaneous (SC) doses of 1 mg/kg or 5 mg/kg. The primary objective was safety and tolerability of KPL-404; secondary and exploratory objectives included pharmacokinetic (PK) parameters, TDAR

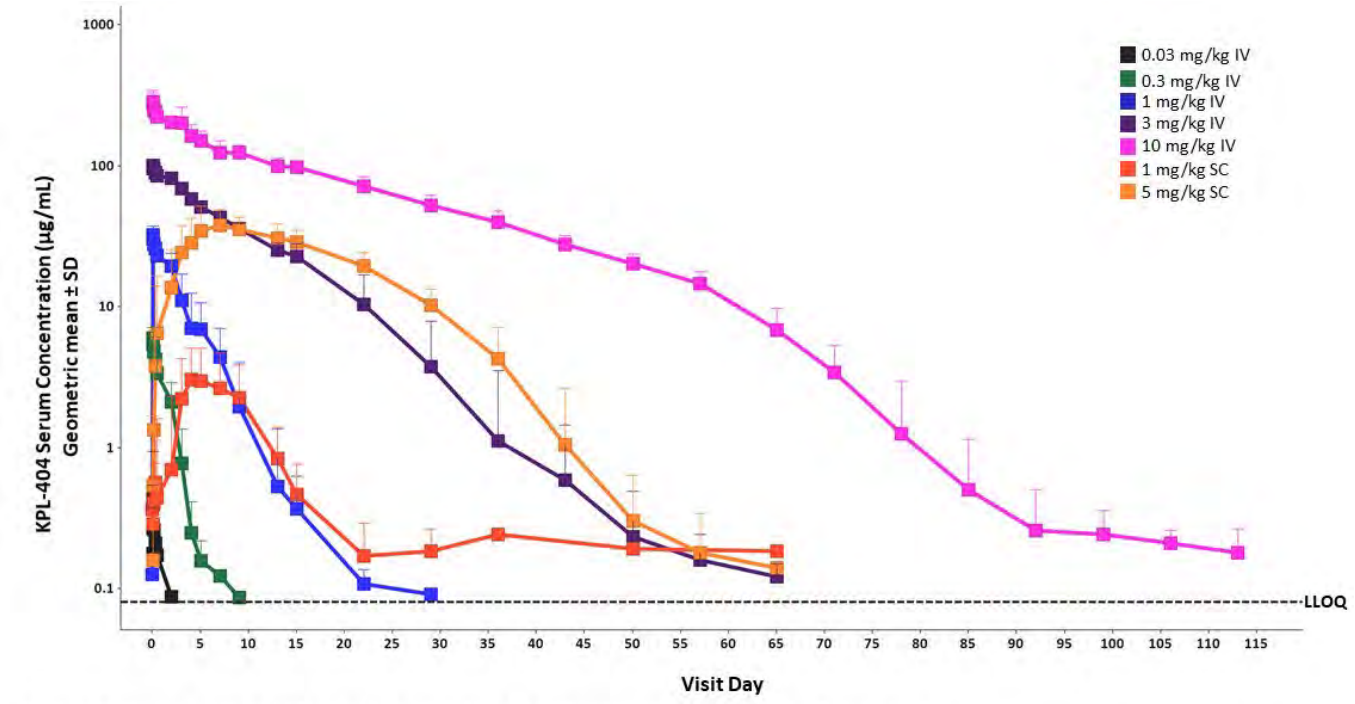

Figure 1. Pharmacokinetic profiles for KPL-404.

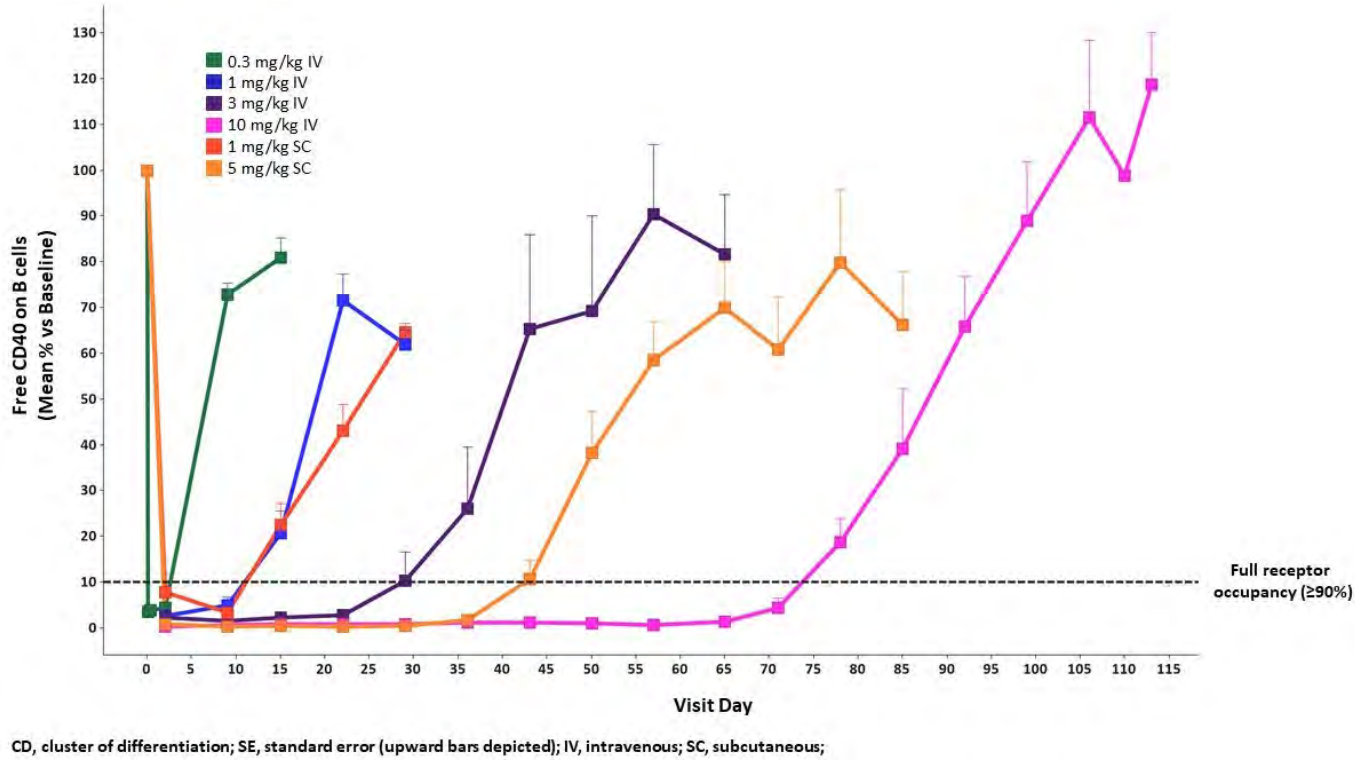

Figure 2. CD40 Receptor Occupancy (RO) on B cells (whole blood) as compared to baseline.

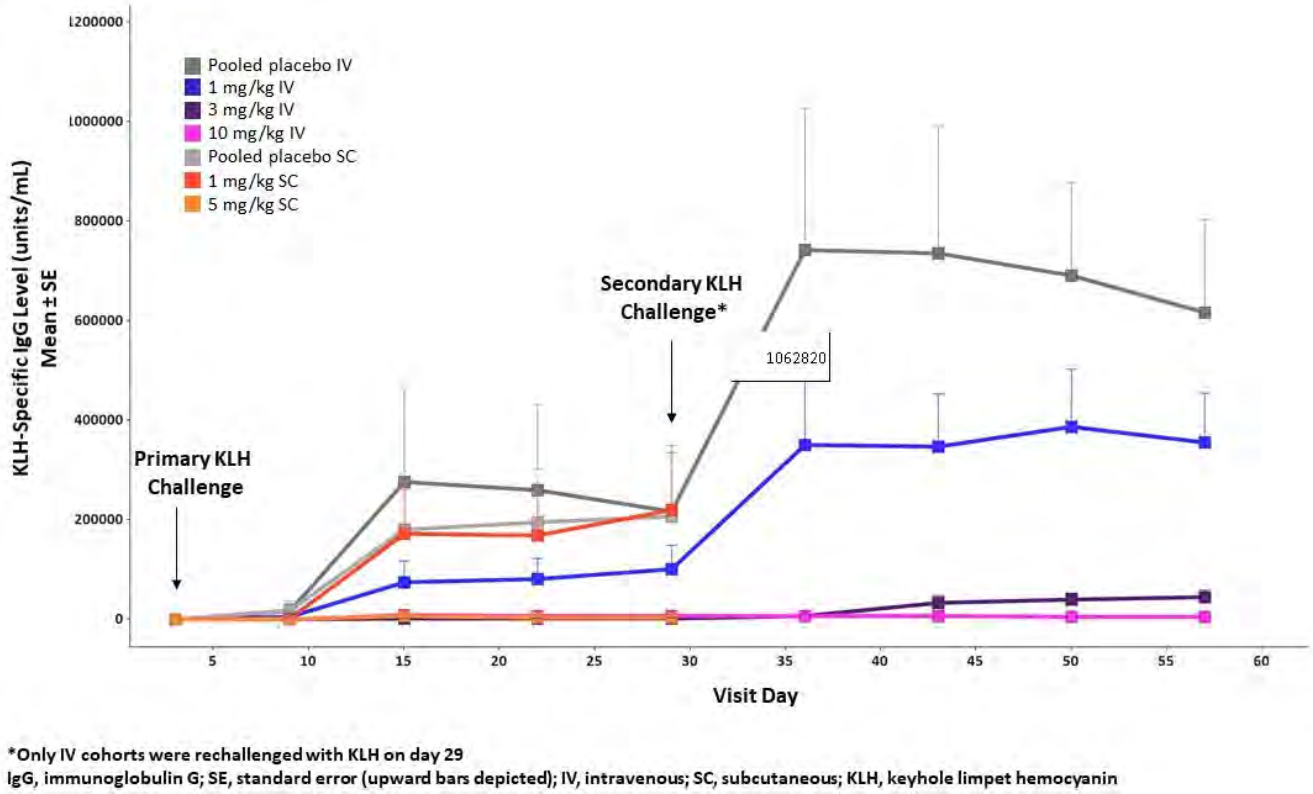

Figure 3. T-Cell Dependent Antibody Response (TDAR) to KLH antigen challenge.

inhibition, and receptor occupancy (RO). To evaluate TDAR inhibition, participants post-KPL-404 administration were immunized with 1 mg intramuscular injection of the test antigen Keyhole Limpet Hemocyanin (KLH) on day 4 and day 29 to elicit a primary and secondary Immunoglobulin (Ig) response, respectively. To evaluate RO, free and total CD40 receptor levels (percent change from baseline) on B-cells (whole blood) were measured using flow cytometry.

Results: There were no dose-limiting or dose-related safety findings in healthy participants after KPL-404 administration. One unrelated serious adverse event (patella fracture following a fall) occurred in the 10 mg/kg IV arm. The PK profile of KPL-404 in serum after IV or SC administration had low to moderate variability between individuals; elimination was dose-dependent and consistent with target-mediated drug disposition (TMDD) (Figure 1). For participants receiving 10 mg/kg IV, full receptor occupancy was observed through day 71 (Figure 2), complete TDAR suppression was observed through Day 57 (Figure 3), and anti-drug antibodies to KPL-404 were suppressed for at least 57 days; the suppression of antibody responses to the drug itself is an independent indicator of target engagement and pharmacodynamic effect. For participants receiving 5 mg/kg SC, full receptor occupancy was observed through day 43 (Figure 2), and complete TDAR suppression was observed through Day 29 (Figure 3). The TDAR response to KLH antigen correlated with the observed full RO.

Conclusion: The safety and tolerability data and the PK/PD profile of KPL-404 support further investigation of KPL-404 in a broad range of autoimmune diseases, including rheumatoid arthritis. These data support the optionality for studying chronic KPL-404 dosing in patients with subcutaneous and/or intravenous administration.

SESSION INFORMATION

Session Date: Tuesday, November 9, 2021

Session Title: RA – Treatments Poster III: RA Treatments & Their Safety (1674–1710)

Session Type: Poster Session D

Session Time: 8:30AM–10:30AM

Background/Purpose: In patients who experience intolerance or fail to respond to methotrexate, IL-6 receptor inhibitors (e.g. sarilumab) are one of the recommended options. The aim of this analysis was to assess the long-term safety and efficacy of sarilumab in patients with RA using data from two open-label studies: EXTEND (NCT01146652) and MONARCH (NCT02332590) open label extension (OLE).

Methods: EXTEND included patients from five trials which evaluated patients who were either inadequate responders to conventional synthetic DMARDs or biologic DMARDs. Patients enrolled in EXTEND received sarilumab 150 mg or 200 mg q2w (once every two weeks) based on their initial treatment for ≥264 weeks. MONARCH OLE included patients who completed the 24-week double blind (DB) period of the MONARCH study and opted to receive open label sarilumab 200 mg q2w for 276 weeks. Safety endpoints included treatment emergent adverse events (TEAEs), serious adverse events (SAEs), adverse events of special interest (AESI), and anti-drug antibody (ADA) positivity. Key efficacy endpoints were ACR 20/50/70 responses, mean change from baseline in DAS28-CRP, and clinical disease activity index for RA (CDAI). Safety and efficacy analyses in both open-label studies were descriptive.

Results: Total duration of sarilumab (N=111) and sarilumab+DMARD (N=1910) exposure was 453.8 patient years (PY) and 8552.7 PY in EXTEND and the cumulative duration of exposure to sarilumab (N=320) in MONARCH OLE was 1131.9 PY. Both studies had more females with a mean age of approximately 50 years. At least one TEAE was reported in 92.1% and 88.3% of patients in EXTEND and 86.9% of patients in MONARCH OLE; infections and infestations were the most common TEAEs in both studies. At least one SAE was reported in 32.3% and 24.3% of patients in EXTEND and 17.5% of patients in MONARCH OLE. In both studies, approximately 2.0% of patients died due to TEAEs. The number of patients who discontinued the treatment due to TEAEs were 26.0% and 13.5% in EXTEND and 13.1% in MONARCH OLE. Herpes Zoster was the most frequently reported opportunistic AESI in EXTEND (44/74 opportunistic infections) and MONARCH OLE (7/10 opportunistic infections). A detailed summary of adverse events reported in both studies is presented in **Table**. ADA positivity was low in both EXTEND and MONARCH OLE and was not associated with hypersensitivity reactions or discontinuations due to lack of efficacy. Clinical efficacy, measured as ACR 20/50/70 responses, mean changes from baseline in DAS28-CRP, and CDAI was maintained throughout the duration of both studies (**Figure 1 and Figure 2**).

Table. Summary of AESI and most common TEAEs, SAEs, and TEAEs leading to discontinuation in EXTEND and MONARCH OLE

	EXTEND (Safety population)			
	Sarilumab, (N=111)	Sarilumab, n_E (n_E/100 PY) (PY=464.3)	Sarilumab+DMARD, (N=1910)	Sarilumab+DMARD, n_E (n_E/100 PY) (PY=8758.5)
Any TEAE	98 (88.3%)	584 (125.8)	1760 (92.1%)	14839 (169.4)

SESSION INFORMATION

Session Date: Tuesday, November 9, 2021

Session Title: RA – Treatments Poster III: RA Treatments & Their Safety (1674–1710)

Session Type: Poster Session D

Session Time: 8:30AM–10:30AM

Background/Purpose: The efficacy and safety of the oral Janus kinase inhibitor, upadacitinib (UPA), has been evaluated for several rheumatic diseases. The objective of this analysis is to describe the long-term safety profile of UPA across rheumatoid arthritis (RA), psoriatic arthritis (PsA), and ankylosing spondylitis (AS) from the SELECT clinical program.

Methods: Safety data (cut-off: 30 June 2020) from the UPA SELECT clinical program were compiled for RA (6 trials[1]), PsA (2 trials[2]), and AS (1 trial[3]) for this analysis. Treatment-emergent adverse events (TEAEs; onset on or after first dose and ≤30 days after last dose for UPA and methotrexate [MTX] or ≤70 days for adalimumab [ADA]) were summarized for RA (pooled UPA 15 mg once daily [QD], ADA 40 mg every other week [EOW], and MTX), PsA (pooled UPA 15 mg QD and ADA 40 mg EOW), and AS (UPA 15 mg QD). TEAEs are reported as exposure-adjusted adverse event rates (EAERs; events/100 patient-years [E/100 PY]).

Table: TEAEs in Patients Treated with UPA, ADA, or MTX Across RA, PsA, and AS[†]

	RA			PsA		AS
	UPA 15 mg QD N=3209	ADA 40 mg EOW N=579	MTX N=314	UPA 15 mg QD N=907	ADA 40 mg EOW N=429	UPA 15 mg QD N=182

ADA, adalimumab; AE, adverse event; AS, ankylosing spondylitis; CI, confidence interval; CPK, creatine phosphokinase; E, event; EOW, every other week; GI, gastrointestinal; MACE, major adverse cardiovascular event; MTX, methotrexate; NMSC, non-melanoma skin cancer; PsA, psoriatic arthritis; PY, patient years; QD, once daily; RA, rheumatoid arthritis; TB, tuberculosis; TEAE, treatment-emergent adverse event; UPA, upadacitinib; VTE, venous thromboembolic event

[†]AEs defined using standardized MedDRA query or company MedDRA query search criteria

[‡]Includes non-treatment-emergent deaths

[§]Excluding TB and herpes zoster

[‖]MACE defined as cardiovascular death, non-fatal myocardial infarction, and non-fatal stroke

[¶]VTE includes deep vein thrombosis and pulmonary embolism

Results: In total, 4298 patients (RA, N=3209; PsA, N=907; AS, N=182) received ≥1 dose of UPA 15 mg, totaling 8562 PY of exposure, with the majority of exposure from RA studies (**Table**). AEs leading to discontinuation were generally similar across all treatment groups (UPA, ADA, and MTX) and patient populations (RA, PsA, and AS). The most common adverse events leading to discontinuation with UPA were pneumonia (RA), psoriatic arthropathy flare or worsening (PsA), and headache (AS). Rates of serious infection and opportunistic infection were generally similar across all treatment groups within each population and across RA, PsA, and AS. Pneumonia was both the most common serious infection and serious AE in RA and PsA. No serious infections were reported in patients with AS. Herpes zoster and increased CPK were reported more often with UPA compared to ADA or MTX, with UPA showing similar rates of herpes zoster across RA, PsA, and AS. Malignancies excluding NMSC were reported at similar rates across all treatment groups and populations. NMSC was not common, with numerically higher rates observed with UPA versus MTX and/or ADA in RA and PsA. Similar rates of adjudicated major adverse cardiovascular events (MACE) and adjudicated venous thromboembolic events (VTE) were observed across all treatment groups, with no events reported in patients with AS. Rates of death reported in these clinical studies were not higher than expected in the general populations. As anticipated for the patient populations, the most common cause of death observed was cardiovascular in nature.

Conclusion: With the exception of herpes zoster, exposure-adjusted adverse event rates were generally similar across UPA, ADA, and MTX in RA, as well as UPA and ADA in PsA. No new safety risks were identified with long-term

treatment in RA, PsA, or AS. UPA 15 mg demonstrated a consistent safety profile across RA, PsA, and AS populations in the SELECT clinical program.

SESSION INFORMATION

Session Date: Tuesday, November 9, 2021

Session Title: RA – Treatments Poster III: RA Treatments & Their Safety (1674–1710)

Session Type: Poster Session D

Session Time: 8:30AM–10:30AM

Background/Purpose: Upadacitinib (UPA), an oral Janus kinase inhibitor, demonstrated significant improvements in signs, symptoms, and structural inhibition as monotherapy (mono) vs methotrexate (MTX) in MTX-naïve patients (pts)

with rheumatoid arthritis (RA) through 48 weeks (wks).[1] The objective of this analysis was to report the efficacy and safety of UPA vs MTX mono up to 156 wks in pts with RA from the ongoing long-term extension (LTE) of the SELECT-EARLY trial.

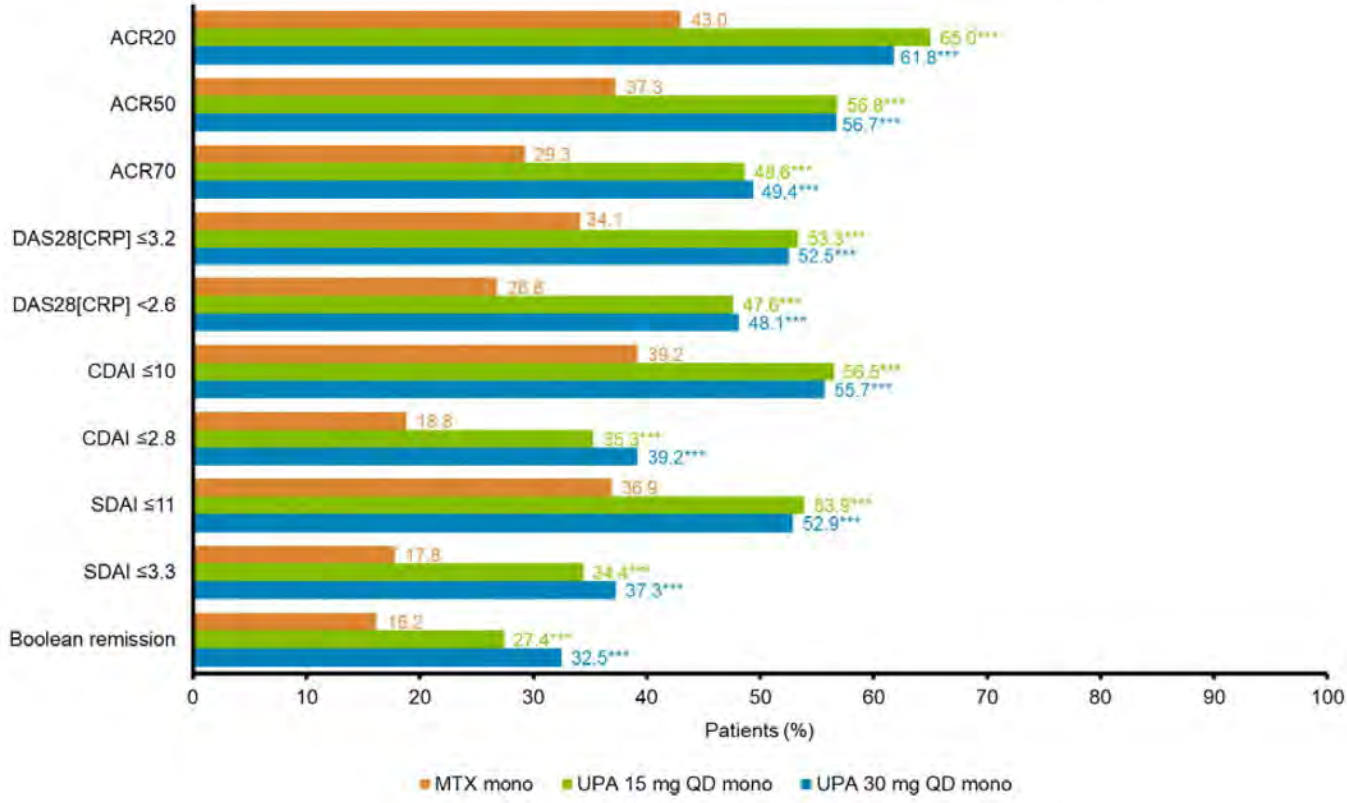
Methods: During the 48-wk double-blind study period, pts were randomized to UPA 15 or 30 mg once daily (QD) or MTX (titrated to 20 mg/wk by Wk 8). At Wk 26, pts who did not achieve Clinical Disease Activity Index (CDAI) remission (≤2.8) and had < 20% improvement from baseline in tender or swollen joint count received blinded rescue therapy (addition of MTX for UPA groups and UPA 15 or 30 mg for the MTX group). In the LTE, pts received open-label treatment once the last pt reached Wk 48. Efficacy assessments up to Wk 156 were summarized by randomized

Table. Safety overview

E/100PY (95% CI)	MTX mono (N=314; PY=601.9)	UPA 15 mg QD mono (N=317; PY=703.4)	UPA 30 mg QD mono (N=314; PY=687.6)
Any AE	240.2 (228.0, 252.9)	268.0 (256.0, 280.4)	292.5 (279.8, 305.5)
Any serious AE	10.8 (8.3, 13.8)	12.2 (9.8, 15.1)	16.3 (13.4, 19.6)
Any AE leading to discontinuation of study drug	6.5 (4.6, 8.9)	7.3 (5.4, 9.5)	7.7 (5.8, 10.1)
Any death[a]	0.7 (0.2, 1.7)	0.9 (0.3, 1.9)	1.0 (0.4, 2.1)
Serious infection	2.5 (1.4, 4.1)	3.3 (2.1, 4.9)	4.4 (2.9, 6.2)
Opportunistic infection excluding TB and HZ	0.2 (0.0, 0.9)	0.1 (0.0, 0.8)	0.3 (0.0, 1.1)
HZ	0.8 (0.3, 1.9)	4.5 (3.1, 6.4)	4.7 (3.2, 6.6)
Active TB	0	0.3 (0.0, 1.0)	0.3 (0.0, 1.1)
NMSC	0	0.4 (0.1, 1.2)	1.0 (0.4, 2.1)
Malignancy other than NMSC	1.0 (0.4, 2.2)	0.6 (0.2, 1.5)	1.2 (0.5, 2.3)
Hepatic disorder	14.1 (11.3, 17.5)	12.5 (10.0, 15.4)	15.0 (12.2, 18.2)
GI perforation (adjudicated)	0	0	0.4 (0.1, 1.3)
Neutropenia	2.2 (1.2, 3.7)	4.5 (3.1, 6.4)	5.7 (4.0, 7.8)
CPK elevation	1.8 (0.9, 3.3)	7.7 (5.8, 10.0)	15.4 (12.6, 18.6)
MACE (adjudicated)	0.3 (0.0, 1.2)	0.4 (0.1, 1.2)	0.6 (0.2, 1.5)
VTE (adjudicated)	0.3 (0.0, 1.2)	0.4 (0.1, 1.2)	0.6 (0.2, 1.5)

Data were censored at the time of MTX or UPA addition for rescued pts. [a]Includes treatment-emergent (≤30 days of the last dose of study drug) and non-treatment-emergent deaths

Figure. Efficacy endpoints up to Week 156 (non-responder imputation)



***Nominal p<0.001 vs MTX mono. CRP, C-reactive protein; DAS28, disease activity score for 28 joints; ESR, erythrocyte sedimentation rate; mono, monotherapy

group and included American College of Rheumatology (ACR) responses, remission and low disease activity (LDA) measures, and change in modified Total Sharp Score (mTSS; up to 96 wks). Treatment-emergent adverse events (AEs) per 100 pt-years (PY) for pts on continuous mono were summarized through 156 wks. Non-responder imputation was used for binary endpoints for missing data and when pts received rescue therapy or prematurely discontinued the study drug.

Results: Of 945 pts randomized and treated, 775 entered the LTE on study drug (including 57 rescued pts; MTX, 33; UPA 15 mg, 17; UPA 30 mg, 7). Overall, 161 (21%) pts discontinued during the LTE. At Wk 156, higher proportions of pts randomized to UPA achieved a 20/50/70% improvement in ACR response (ACR20/50/70), LDA, and remission vs MTX (Figure). Change from baseline in mTSS at Wk 96 favored UPA vs MTX (data not shown). Most AEs were numerically more frequent with UPA 30 mg. The overall rate of serious infection was numerically higher with UPA vs MTX (Table). Herpes zoster (HZ), neutropenia, non-melanoma skin cancer (NMSC), and creatine phosphokinase (CPK) elevation were more frequent with UPA vs MTX. Two active tuberculosis (TB) events were reported in each UPA arm; 3 adjudicated gastrointestinal (GI) perforation events were observed in the UPA 30 mg arm. Adjudicated major adverse cardiovascular event (MACE) or venous thromboembolism (VTE) were comparable across treatment arms.

Conclusion: UPA monotherapy showed sustained superior clinical responses including remission vs MTX through Wk 156 but higher rates of several AEs, including HZ, neutropenia, and CPK elevations; no new safety risks were observed compared with previous results.[1,2]

SESSION INFORMATION
Session Date: Tuesday, November 9, 2021
Session Title: RA – Treatments Poster III: RA Treatments & Their Safety (1674–1710)
Session Type: Poster Session D
Session Time: 8:30AM–10:30AM

Background/Purpose: To limit the risk of serious infections, guidelines recommend short term (< 3 months) or low-dose (≤10 mg/day) adjunct glucocorticoids (GCs) to control rheumatoid arthritis (RA) flares or high disease activity[1]. In the ICHIBAN study, which analysed the safety and effectiveness of tocilizumab (TCZ), similar proportions of patients with (61.2%) and without (62.5%) concomitant baseline (BL) GCs achieved DAS28-ESR remission[2]. Here, we examine the efficacy and safety of TCZ in subgroups according to BL concomitant GCs in detail.

Table 1. Adverse events (AEs) and serious adverse events (SAEs) in patients treated with tocilizumab in subgroups according the concomitant baseline glucocorticoids (GCs)

E (%) [rate/100 PY]	With concomitant GCs (n = 2550)	Without concomitant GCs (n = 607)
AEs	3546 (46.9) [112.9]	731 (45.8) [91.0]
Considered related	1203 (22.3) [38.3]	231 (21.3) [28.8]
SAEs	790 (15.2) [25.2]	153 (13.8) [19.1]
Considered related	200 (5.0) [6.4]	24 (3.1) [3.0]
AEs leading to withdrawal	301 (8.3) [9.6]	63 (9.1) [7.8]
Infections	965 (21.8) [30.7]	194 (19.8) [24.2]
SAEs	134 (3.8) [4.3]	19 (2.5) [2.4]

All patients with at least one dose of tocilizumab included in the analysis. AE; adverse event; PY, patient year; SAE, serious AE; SAF, safety analysis set. E, total number of events; % is the percent of patients with at least one event.

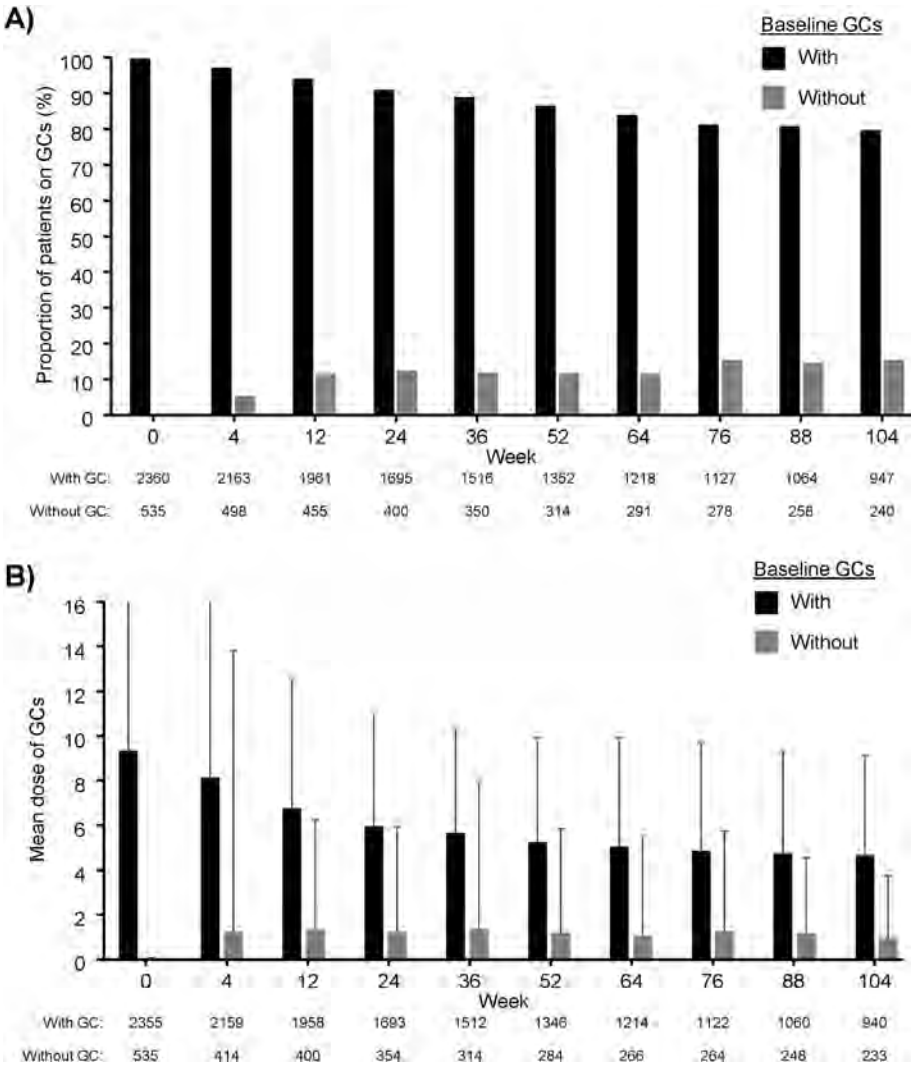

Figure 1. A) The proportion of patients treated with concomintant glucocorticoids (GCs) and B) mean GC dose throughout ICHIBAN by subgroup according to concomitant GCs at baseline. Analysis includes all patients treated with tocilizumab with no prior tocilizumab treatment. Means include patients with no GCs. Error bars represent standard deviation.

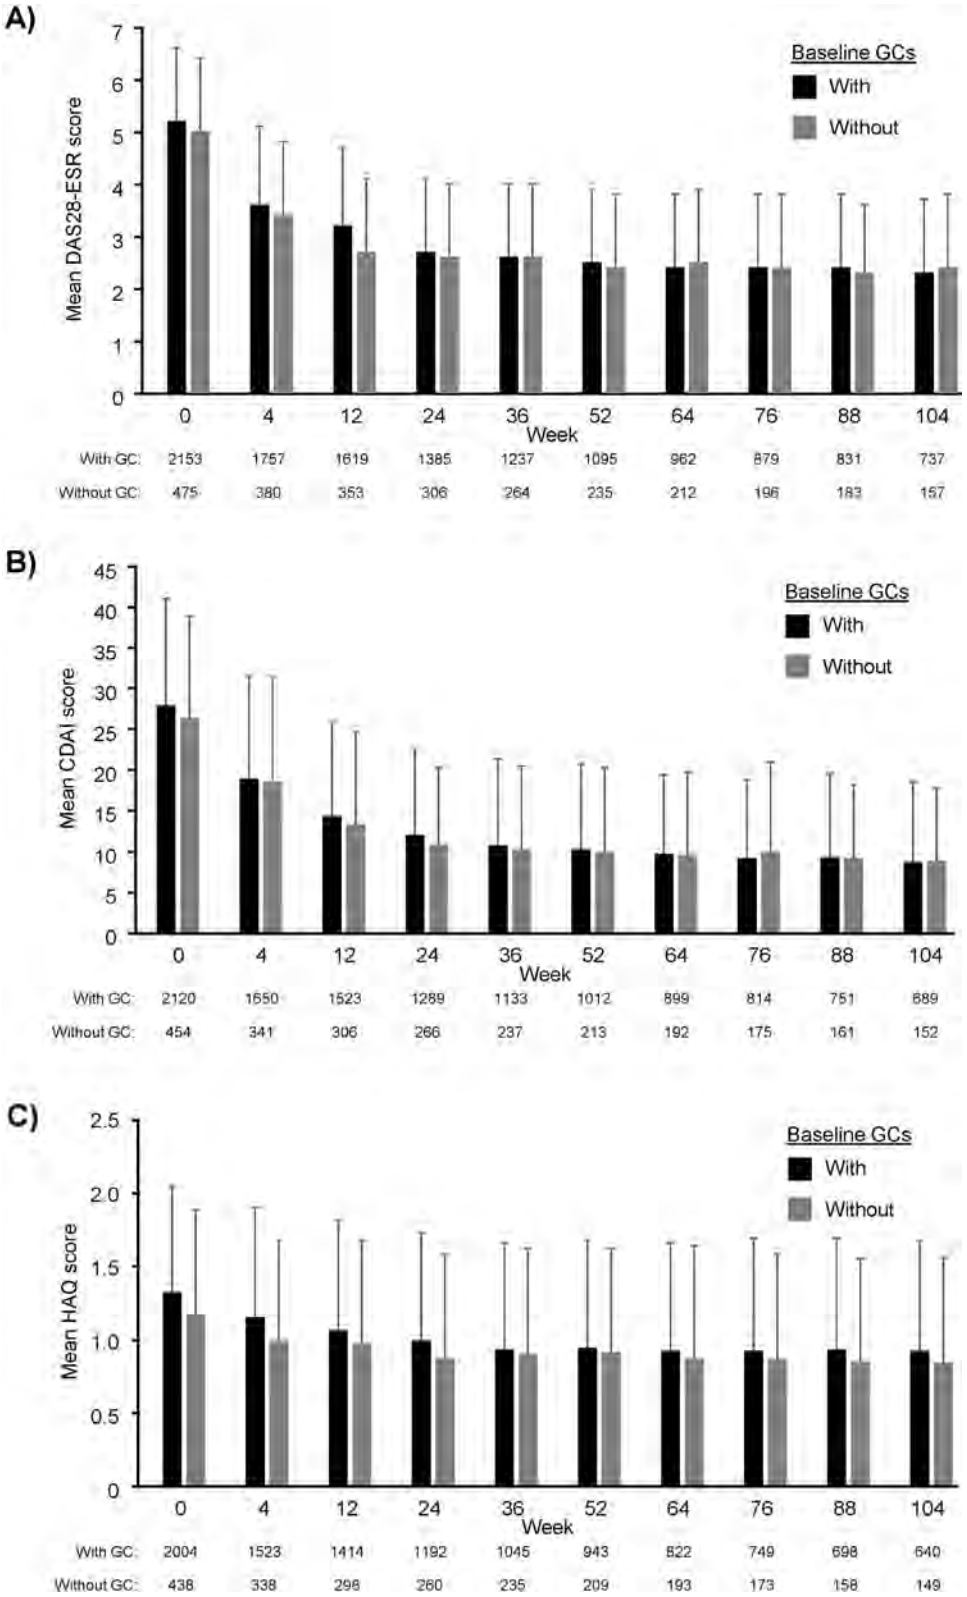

Figure 2. Mean disease activity of patients treated with tocilizumab with or without concomitant baseline glucocorticoids (GCs). A) Mean DAS28-ESR, B) CDAI and C) HAQ-DI scores throughout the ICHIBAN study. Analysis includes all patients treated with tocilizumab with no prior tocilizumab treatment. Error bars represent standard deviation. Missing data was not substituted; CDAI, Clinical Disease Activity Index; DAS28-ESR, Disease Activity Score (DAS) 28 -erythrocyte sedimentation rate, HAQ-DI, Health Assessment Questionnaire – Disability Index.

Methods: ICHIBAN was a prospective, multi-center, non-interventional study (NCT01194401; ML22928) that included adults with active, moderate-to-severe RA who received TCZ according to the local label in Germany. All patients who received ≥1 TCZ infusion were included in the safety population (SAF, n=3164). Effectiveness (DAS28-ESR and CDAI) and concomitant medication were analysed in all SAF patients with no prior TCZ (n=2902).

Results: In ICHIBAN, 2,550 (80.6%) patients received concomitant GCs, while 607 (19.2%) received no GCs (7 missing) at BL. Patients with or without GCs were of similar mean [SD] age (55.9 [13.0] vs 53.8 [13.6] years old). The proportion of female patients was numerically lower in the group with BL GCs (73.4%) than in those without GCs (80.9%). A numerically greater proportion of patients with BL GCs (73.1%) had comorbidities than those without (67.9%). Common comorbidities in patients with and without GCs were hypertension (37.4% vs 35.1%), degenerative joint disorder/spinal disease (20.4% vs 14.2%), and osteoporosis (19.1% vs 9.1%).

Throughout the study, patients with and without BL GCs had a similar mean exposure (SD) to TCZ (1.2 [0.85] vs 1.3 [0.87] years). Still, patients without BL GCs experienced lower rates (events/100 patient years) of adverse events (AEs) and serious AEs (SAEs) considered related to treatment, infections and serious infections (**Table 1**).

At week 104, 79.9% of the patients with baseline GCs and 15.4% of patients without BL GCs were receiving concomitant GC therapy (**Figure 1A**). The median GC dose changed by –2.5 mg/d in patient with and by 0.0 mg/d in patients without BL GCs (**Figure 1B**). Furthermore, the proportion of patients on csDMARDs decreased in both subgroups from BL to week 104 (with GC, 51.2–46.8%; without, GCs 48.4–37.5%).

Similar reductions in mean DAS28-ESR score were observed in patients with and without BL GCs (**Figure 2A**). CDAI also decreased in both subgroups (**Figure 2B**), with a mean (SD) reduction of 18.3 (13.3) in patients with and 16.6 (12.6) in those without BL GCs over 104 weeks. Similar reductions in HAQ-DI were also seen in both subgroups during ICHIBAN (**Figure 2C**).

Conclusion: Even though the majority had low dose GCs only, patients without BL GCs had numerically lower rates of AEs considered related to treatment and infections throughout the ICHIBAN study. Effectiveness endpoints were similar in both subgroups. In patients with BL GCs, the proportion of patients on and dose of GCs decreased throughout the study.

Sustainability of Response to Upadacitinib Among Patients with Active Rheumatoid Arthritis Refractory to Biological Disease-Modifying Anti-Rheumatic Drugs

Ronald van Vollenhoven[1], Stephen Hall[2], Alvin Wells[3], Sebastian Meerwein[4], Yanna Song[5], Jessica Subotícki[5] and Roy Fleischmann[6], [1]Department of Rheumatology and Clinical Immunology, Amsterdam University Medical Center, Amsterdam Rheumatology Center, Amsterdam, Netherlands, [2]Emeritus Research and Monash University, Melbourne, Australia, Melbourne, Australia, [3]Rheumatology and Immunotherapy Center, Franklin, WI, [4]AbbVie Deutschland GmbH & Co. KG, Ludwigshafen, Germany, [5]AbbVie Inc., North Chicago, IL, [6]Metroplex Clinical Research Center and University of Texas Southwestern Medical Center, Dallas, TX

SESSION INFORMATION

Session Date: Tuesday, November 9, 2021

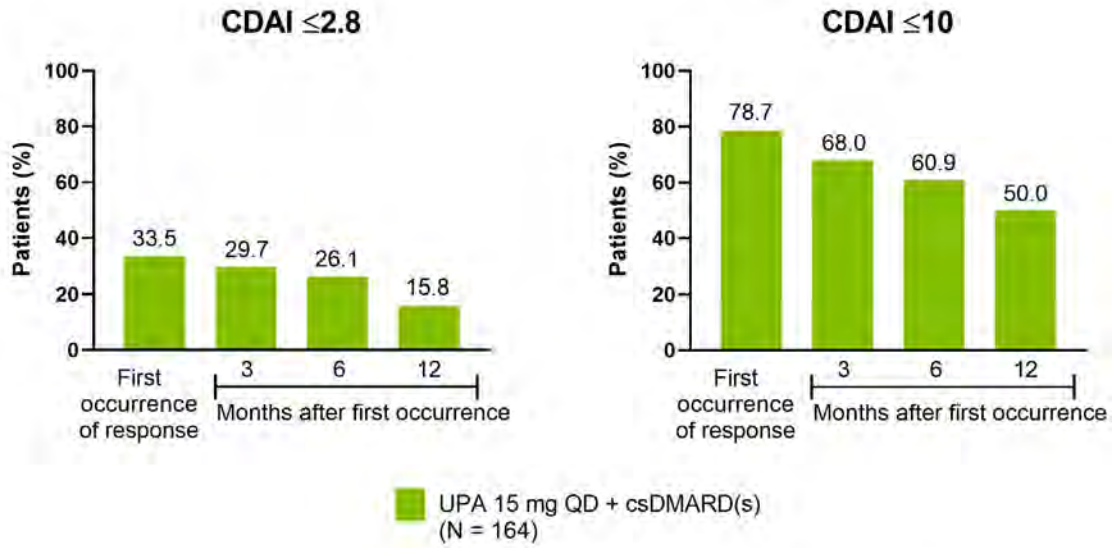
Session Title: RA – Treatments Poster III: RA Treatments & Their Safety (1674–1710)

Session Type: Poster Session D

Session Time: 8:30AM–10:30AM

Background/Purpose: Sustained clinical remission (REM) is the primary treatment goal for patients with rheumatoid arthritis (RA), with low disease activity (LDA) being an appropriate target for treatment-refractory patients.[1,2] This analysis evaluated the sustainability of response to the JAK inhibitor, upadacitinib (UPA) 15 mg once daily (QD), among patients with prior inadequate response or intolerance to biologic DMARDs.

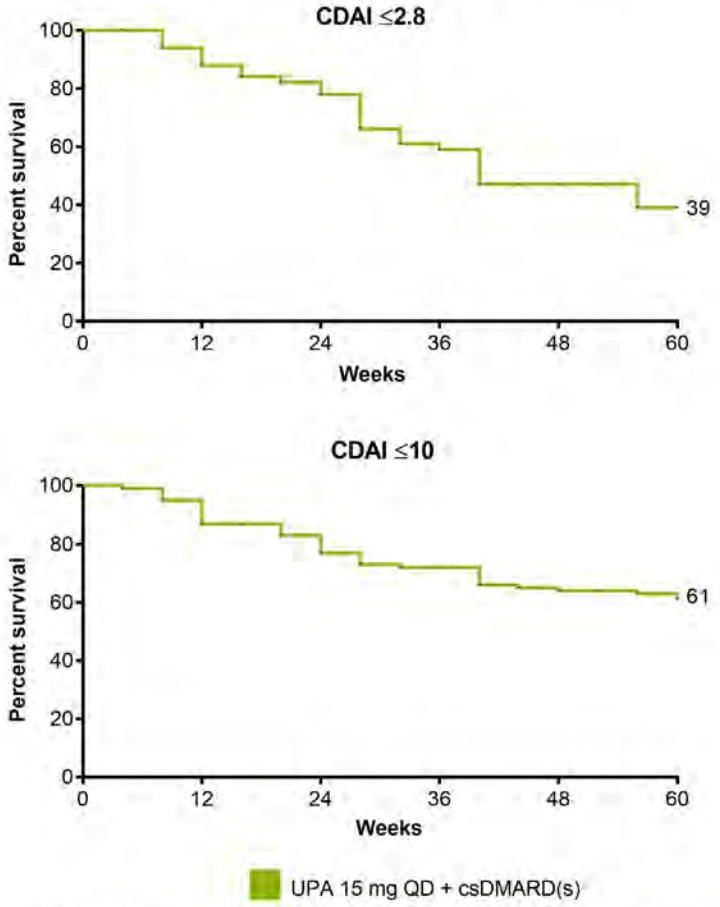
Figure 1. Proportion of Patients Sustaining CDAI Remission or Low Disease Activity at 3, 6, and 12 Months After Initial Occurrence of Response Among the Total Randomized Population



Treatment group is by initial randomization; non-responder imputation was used for missing data.

CDAI, Clinical Disease Activity Index; csDMARD, conventional synthetic disease-modifying antirheumatic drugs; QD, once daily; UPA, upadacitinib.

Figure 2. Kaplan-Meier Analysis of Time to Loss of CDAI Remission or Low Disease Activity After the First Occurrence of Response



Treatment groups are by initial randomization. Results are for patients who had achieved CDAI remission or low disease activity. UPA 15 mg QD + csDMARD(s): CDAI ≤10: n = 129; CDAI ≤2.8: n = 55.

Data were censored at the cut-off (16 April 2018, when all patients had reached the Week 60 visit; censored = stopped collecting data). Non-responder imputation was used for missing data. Week 0 indicates the first occurrence of response.
CDAI, Clinical Disease Activity Index; QD, once daily; UPA, upadacitinib.

Methods: Data come from the 12-week, phase 3 randomized, placebo (PBO)-controlled SELECT-BEYOND trial of UPA 15 mg or 30 mg QD in patients with moderate to severe RA on stable background conventional synthetic (cs) DMARDs. Initiation, change, or discontinuation of background RA medications, including ≤2 csDMARDs, was allowed starting at Week 24. Patients completing the 12-week trial were able to enter a long-term extension of up to 5 yrs with all PBO patients switching to UPA.[3] This post hoc analysis evaluated REM (CDAI ≤2.8; SDAI ≤3.3), LDA (CDAI≤10; SDAI≤11), and DAS28(CRP) < 2.6/≤3.2 at first occurrence of response before Week 60, as well as at 3, 6, and 12 months following initial response in patients randomized to UPA 15 mg. For those patients who achieved REM/LDA, Kaplan-Meier was used to define the time from when the response was first achieved to the earliest date at which the response was lost at two consecutive visits or discontinuation of study drug. The predictive ability of time to REM/LDA was evaluated using Harrell's concordance (c)-index (range: 0 to 1, where 0.5 indicates a model that is no better at predicting an outcome than random chance). The date of the last follow up was 16 April 2018, when all patients had reached the Week 60 visit. Non-responder imputation was used for missing data. Only data from the approved 15 mg dosage are reported here.

Results: In patients with active RA despite prior treatment with at least one bDMARD, 34% and 79% of those receiving UPA 15 mg + background csDMARD(s) achieved CDAI REM or LDA through Week 60, respectively. Sustained CDAI REM was attained by 30%, 26%, and 16% of patients randomized to UPA at 3, 6, and 12 months post initial

response, while CDAI LDA was achieved by 68%, 61%, and 50% of patients during the same time points (**Figure 1**). Time to initial clinical response weakly predicted sustained REM but did not predict sustained LDA, with a c-index (95% CI) of 0.62 (0.49, 0.74) and 0.52 (0.44, 0.61), respectively. Through the last follow-up visit at Week 60, 39/61% of patients on UPA remained in CDAI REM/LDA (**Figure 2**). Of those who lost CDAI REM, 58% remained in CDAI LDA, and 22% recaptured REM by the cut-off date; 18% of patients who lost CDAI LDA recaptured response. Similar results were observed for REM and LDA based on SDAI and for DAS28(CRP) < 2.6/≤3.2.

Conclusion: Among patients with inadequate response or intolerance to bDMARDs, over three-quarters on UPA 15 mg achieved CDAI LDA, a relevant therapeutic target for these treatment-refractory patients, and nearly two-thirds of those maintained this response through 60 weeks. Additionally, about one-third of UPA-treated patients attained CDAI REM and maintained that response over 60 weeks.

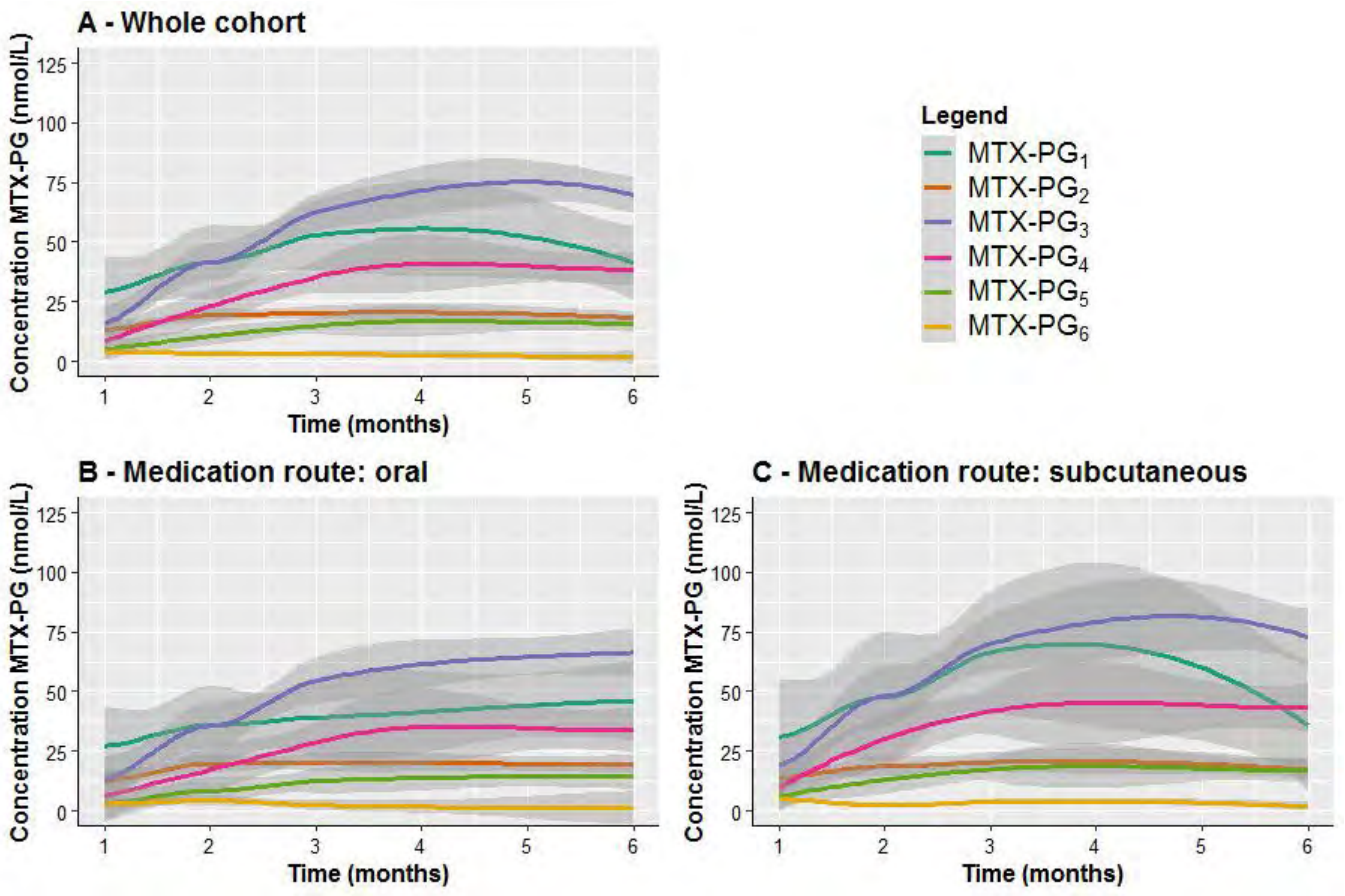

Figure 1. Erythrocyte individual MTX-PG accumulation in RA patients (A) during the first 6 months of oral (B) or subcutaneous (C) MTX administration. At 6 months, 18 patients using oral and 18 patients using subcutaneous MTX were still continuing MTX treatment. Means (colored lines) and standard errors (shaded areas) are depicted (Loess regression).

has been used as a tool to monitor clinical response of RA patients in the first 3-12 months of treatment and MTX-PG_{2-4} as well as total MTX-PGs were associated with lower DAS28 over 9 months. However, data per route of administration and from earlier time points, including MTX-PG_6 levels are lacking.

We investigated the pharmacokinetics and -dynamics of erythrocyte MTX-PG accumulation in RA patients receiving oral or subcutaneous MTX in the early phase (1, 2, 3 months) and later stage (6 months) of MTX treatment.

Methods: In a clinical prospective cohort study (MeMo study: NTR7149), newly diagnosed RA patients were treated with oral (n=24) or subcutaneous (n=22) MTX mostly according to the COBRA-light schedule (start 10 mg MTX, increased to 25 mg MTX in 8 weeks, with prednisolone). At 1, 2, 3 and 6 months after start of therapy, blood was collected and individual MTX-PGs (MTX-PG_1 – MTX-PG_6) were analyzed in erythrocytes using a validated UHPLC-MS/MS method with labeled internal standards. (De Rotte 2015) Dosing, concomitant treatments and DAS28-ESR assessments were in conformity with clinical practice. Adverse events were recorded. We used a linear mixed model analysis to assess the association between MTX-PG levels and DAS28-ESR (per group and total), with corrections for age, baseline DAS28, eGFR, MTX dose (1 month before sampling), smoking and BMI.

Results: 46 consecutive patients were included in this study of which 76% female, mean age was 57.8 years, BMI was 25.8, 20% were smokers, mean baseline DAS28-ESR was 3.5. MTX dose at baseline was 10.5 mg (SD: 1.5) for both groups, 15.4 (4.4) and 16.8 (1.8) at 1 month and 22.8 (3.9), 22.4 (5.2) at 2 months, 20.1 (6.3) and 20.8 (5.6) at 3 months and 19.0 (6.5) and 18.6 (8.6) at 5 months for oral and subcutaneous use, respectively. On average, patients starting subcutaneous MTX had significantly higher levels of long chain MTX-PGs (MTX-PG_{3-6}) in erythrocytes when compared to patients in the oral MTX group at 1 and 2 months (Figure 1. and 1C, Table 1). Similarly, erythrocyte MTX-PG_{1-6} and MTX-PG_3 concentrations were significantly higher in subcutaneous MTX-users at month 1 compared to the oral group (median 68.6 nmol/L (IQR:40.5) vs 51.9 (55.6) and 17.4 (11.1) vs 11.2 (15.6), respectively (Figure 1. and 1C, Table 1). This difference remained present at month 2. Erythrocyte MTX-PG accumulation reached a plateau after 3 months.

Apart from small positive and negative correlations, no (clinically) significant relation between MTX-PG concentrations and DAS28 was observed during the first 6 months of treatment; DAS28 decreased with 1.2 in the oral group and 1.6 in the subcutaneous group.

Side effects, mostly headache and dizziness were similar in both groups and not correlated with MTX-PG levels.

Conclusion: This study demonstrated significantly higher accumulation of long-chain and total MTX-PGs following subcutaneous versus oral MTX administration in the first 3 months. Early phase erythrocyte MTX-PG analyses may hold promise for optimization of individual patient MTX dose scheduling.

SESSION INFORMATION

Session Date: Tuesday, November 9, 2021
Session Title: RA – Treatments Poster III: RA Treatments & Their Safety (1674–1710)
Session Type: Poster Session D
Session Time: 8:30AM–10:30AM

Background/Purpose: The preferential Janus kinase-1 inhibitor filgotinib (FIL) is approved to treat RA in Europe and Japan. We assessed FIL efficacy and safety in patients (pts) with inadequate response (IR) to biologic DMARDs (bDMARDs) in a long-term extension trial (LTE; NCT03025308) enrolled from a Phase 3 parent study (PS; NCT02873936).[1]

Methods: bDMARD-IR pts received FIL 200 mg (FIL200), FIL 100 mg (FIL100), or placebo (PBO) all with stable conventional synthetic (cs)DMARDs up to 24 weeks (W). At W14 of the PS, pts with IR to FIL or PBO (< 20% improvement in swollen [66] and tender [68] joint counts) switched to standard of care (SOC; investigator's choice of appropriate treatment). Pts completing the PS on FIL, PBO, or SOC could enter the LTE. PS FIL pts were maintained, blinded, on their FIL dose; PS PBO and PS SOC pts were rerandomized, blinded, to FIL200 or FIL100. We report efficacy up to LTE W48 for ACR 20%, 50%, and 70% improvement (ACR20/50/70), DAS in 28 joints with CRP (DAS28[CRP]) ≤3.2 and < 2.6, and Clinical Disease Activity Index (CDAI) ≤10 and ≤2.8. Exposure-adjusted incidence rates (EAIR)/100 pt-years of exposure of treatment-emergent adverse events (TEAEs) and AEs of special interest (AESIs) are summarized up to data cutoff of June 1, 2020.

Results: The PS included 147, 153, and 148 pts on FIL200, FIL100, and PBO. Of the 121 pts who entered LTE from PS on FIL200, 80 (66%) continued study drug at June 1, 2020, as did 76/110 (69%) FIL100 pts. Pts still on LTE FIL from PBO were 35/47 (75%) FIL200 and 32/46 (70%) FIL100 pts; from SOC: 13/23 (57%) FIL200 and 13/22 (59%) FIL100 pts. LTE baseline (BL) characteristics were similar in FIL200 and FIL100 pts (mean RA duration: 13.2 and 12.8 years, DAS28[CRP]: 3.5 and 3.7). During LTE, PS FIL ACR20/50/70 response rates decreased modestly by W48 (**Table 1**). Among PS PBO pts, response rates were lower at LTE BL but reached similar levels as PS FIL pts by W48; rates increased up to W48 in PS SOC pts on either FIL dose but not to levels of other groups. Percentages of pts attaining DAS28(CRP) ≤3.2, DAS28(CRP) < 2.6, CDAI ≤10, and CDAI ≤2.8 were maintained up to W48 for FIL/FIL pts, while PBO/FIL and SOC/FIL pts showed similar patterns as for ACR responses (**Table 2**). At W48, DAS28 ≤3.2

Table 1. Proportions of patients achieving ACR20/50/70, NRI, FAS, up to LTE w48. ACR20/50/70 is calculated based on PS BL. and < 2.6 response rates were highest among PBO/FIL200 pts. By W12, more SOC/FIL200 pts attained DAS28 and CDAI activity scores versus SOC/FIL100, but rates were similar by W48 (except for CDAI ≤10). TEAE, serious AE, and serious infection EAIRs were higher in SOC/FIL pts vs FIL/FIL or PBO/FIL pts, with 2 nonmelanoma skin cancers on SOC/FIL200, but samples were small, and confidence intervals overlapped (**Table 3**). 5 pts died: FIL200/FIL200, n=3; PBO/FIL200, n=1; FIL100/FIL100, n=1. There were no opportunistic infections. EAIRs of major cardiovascular events were low, absent in PS SOC pts. Deep vein thrombosis and pulmonary embolism occurred in 2 FIL200/FIL200, 1 FIL100/FIL100, and 1 SOC/FIL200 pts.

Conclusion: Efficacy was mostly maintained in PS FIL pts up to W48. Response among PS PBO and SOC pts increased from BL to W48, but response in PS SOC pts continued to be lower than in other groups; these pts may represent a refractory population. FIL safety was largely consistent between PS and LTE.

inadequate response to MTX (MTX-IR) who completed a Phase 3 trial (NCT02889796)[1] and went on to enroll in a long-term extension (LTE; NCT03025308).

Methods: Pts who completed the parent study[1] (PS) on study drug were eligible to enter the LTE. LTE data cutoff was June 1, 2020, and safety data are reported to that date, with median exposure 2.2 years. Efficacy data to W48 are reported for 4 treatment groups (all with background MTX): pts who received FIL 200 mg (FIL200) or FIL 100 mg (FIL100) in the PS and continued their dose in LTE (FIL200/FIL200, FIL100/FIL100) and ADA pts who were rerandomized, double blind, to FIL200 or FIL100 for LTE (ADA/FIL200, ADA/FIL100). ACR 20%, 50%, and 70% response rates (ACR20/50/70), DAS in 28 joints with CRP (DAS28[CRP]) ≤3.2 and < 2.6, and Clinical Disease Activity Index (CDAI) ≤10 and ≤2.8 are reported. Exposure-adjusted incidence rates (EAIR)/100 pt-years of exposure of treatment-emergent adverse events (TEAEs) and AEs of special interest (AESIs) are summarized.

Results: As of June 1, 2020, 522/571 (91%) FIL200/FIL200, 502/570 (88%) FIL100/FIL100, 118/128 (92%) ADA/FIL200, and 115/130 (89%) ADA/FIL100 pts were still on study drug. LTE baseline (BL) disease characteristics were similar between groups: mean duration of RA was approximately 8.7 years; DAS28(CRP) was 2.55, and mean

concurrent MTX dosage was 15.0 mg/week. In general, proportions of pts achieving ACR20/50/70, DAS28(CRP) ≤3.2, < 2.6, and CDAI ≤10, ≤2.8 were maintained in all 4 LTE groups through W48 (**Tables 1, 2**). Numerically greater proportions of pts met response criteria at W48 in the FIL200 groups vs FIL100, regardless of PS treatment. TEAEs, serious AEs, and AEs Grade ≥3 were largely comparable between groups and lowest in ADA/FIL100 pts (**Table 3**). There were 3 deaths in each PS FIL group and 2 in each PS ADA group; EAIRs for deaths were lower for FIL/FIL groups compared with ADA/FIL groups. Opportunistic infections occurred only in FIL/FIL pts (2 in each group). Non-melanoma skin cancer (NMSC; n=5) occurred only in FIL/FIL groups, and malignancies excluding NMSC occurred in all groups except ADA/FIL100.

Conclusion: During the LTE through W48, response rates generally were maintained for FIL/FIL and ADA/FIL pts. Though there were differences between LTE groups, safety was largely comparable and consistent with that observed in the PS[1] and in previously reported results of safety data from 7 trials[2]: rates of AESIs were low, and all confidence intervals were overlapping. Limitation: the LTE was not formally randomized for comparison between FIL/FIL and ADA/FIL treatment groups, the groups were of unequal size, and the switch from ADA to FIL for LTE was by design, rather than based on disease activity.

SESSION INFORMATION

Session Date: Tuesday, November 9, 2021
Session Title: RA – Treatments Poster III: RA Treatments & Their Safety (1674–1710)
Session Type: Poster Session D
Session Time: 8:30AM–10:30AM

Background/Purpose: The preferential Janus kinase (JAK)-1 inhibitor filgotinib (FIL) significantly improved signs and symptoms of RA in Phase 2 and 3 trials,[1–5] and FIL is approved for treatment of moderately to severely active RA in Europe and Japan. Integrated safety analysis of FIL with patient data through 2019 was presented at the 2020 ACR virtual meeting.[6] This abstract reports updated, as-treated data with increased study-drug exposure (median, 2.2 years [y]; maximum, 6.8 y).

Methods: Data were integrated from 2 Phase 2 (NCT01668641, NCT01894516), 3 Phase 3 (NCT02889796, NCT02873936, NCT02886728), and 2 long-term extension (LTE) (NCT02065700, NCT03025308) trials. Phase 2 and 3 LTE data were through Nov 2020 and Jun 2020, respectively. The as-treated analysis set included all available data for patients receiving ≥1 dose FIL 200 (FIL200) or 100 mg (FIL100), including those rerandomized to filgotinib for LTE. Exposure-adjusted incidence rates (EAIR)/100 patient-years exposure (PYE) of treatment-emergent adverse events (TEAEs; onset after first dose and no later than 30 days after last dose or new drug first dose date –1 day) and TEAEs of special interest (AESIs)—including serious infections, opportunistic infections, herpes zoster, adjudicated major adverse cardiovascular events, adjudicated venous thromboembolism, atrial systemic thrombotic events, nonmelanoma skin cancer (NMSC), non-NMSC malignancies, and gastrointestinal perforations—are presented. EAIR and 95% CIs were estimated with Poisson models with treatment and study as covariates and natural log of exposure as offset, unless otherwise specified.

Results: 3691 patients received FIL200 or FIL100 for 8085.1 PYE (median 2.2, maximum 6.8 y). In the as-treated set, 61% of FIL200 and 45% of FIL100 patients received filgotinib for ≥2 years (**Table 1**). EAIR for TEAEs was higher with FIL100 than with FIL200; EAIRs for deaths were 0.5 and 0.3 for FIL200 and FIL100 (**Table 2**). Incidences of infections and serious infections were numerically greater for FIL100 vs FIL200, while EAIRs for other AESIs were comparable between doses (**Table 3**). EAIRs for AESIs tended to decrease since the previous update, except for VTE (total FIL 0.1 to 0.2) and non-NMSC malignancies (total FIL 0.5 to 0.6).

Table 1. Summary of exposure

	Long-term, as-treated		
	FIL 200 mg	**FIL 100 mg**	**Total FIL**
N	2267	1647	3691
Total PYE	5302.5	2782.6	8085.1
Treatment duration, median y (Q1, Q3)	2.3 (1.4, 2.8)	1.9 (0.5, 2.5)	2.2 (1.3, 2.7)
Exposed to study drug ≥ 1 y, n (%)	1909 (84.2)	1176 (71.4)	3093 (83.8)
Exposed to study drug ≥ 2 y, n (%)	1385 (61.1)	746 (45.3)	2145 (58.1)
Exposed to study drug ≥ 3 y, n (%)	419 (18.5)	79 (4.8)	505 (13.7)
Exposed to study drug ≥ 4.5 y, n (%)	256 (11.3)	8 (0.5)	272 (7.4)

PYE was defined as (last dose date – first dose date + 1)/365.25. Duration of exposure to study drug (years) = (last dosing date – first dosing date + 1)/365.25. A 7-day window was applied to the on-treatment Week 52 to match with the protocol-specified visit window. FIL, filgotinib; PYE, patient-years of exposure; Q, quartile; y, years.

Table 2. Overall summary of EAIRs of TEAEs, as-treated set

	FIL 200 mg N = 2267 PYE = 5302.5	FIL 100 mg N = 1647 PYE = 2782.6	Total FIL N = 3691 PYE = 8085.1
TEAE, n (%)	1881 (83.0)	1230 (74.7)	3048 (82.6)
EAIR (95% CI)	32.9 (31.2, 34.7)	54.4 (50.0, 59.1)	33.5 (32.0, 35.0)

Gastrointestinal perforations, n (%)	3 (0.1)	1 (<0.1)	4 (0.1)
EAIR (95% CI)	0.1 (0.0, 0.2)*	0.0 (0.0, 0.3)*	0.0 (0.0, 0.1)*

*Except when any study had 0 event within the treatment, the Poisson model was not adjusted by study. PYE was defined as (last dose date – first dose date + 1)/365.25. aPositively adjudicated. bAdjudicated as DVT or PE AE, adverse event; AESI, AE of special interest; ASTE, arterial systemic thrombotic event; CI, confidence interval; DVT, deep vein thrombosis; EAIR, exposure adjusted incidence rate per 100 PYE; FIL, filgotinib; MACE, major adverse cardiovascular events; NMSC, non-melanoma skin cancer; PE, pulmonary embolism; PYE, patient years of exposure; TB, tuberculosis; TE, treatment emergent; VTE, venous thromboembolism.

Conclusion: With 1 additional year of exposure since the 2020 report, FIL continues to be well tolerated with no new safety concerns emerging. EAIRs of TEAEs, including deaths, and AESIs remained stable or decreased since the 2020 report, except for slight increases in rates of NMSC and non-NMSC malignancies. In the context of demonstrated efficacy, both FIL doses had an acceptable risk/benefit profile.

SESSION INFORMATION

Session Date: Tuesday, November 9, 2021

Session Title: RA – Treatments Poster III: RA Treatments & Their Safety (1674–1710)

Session Type: Poster Session D

Session Time: 8:30AM–10:30AM

Background/Purpose: Fatigue is common symptom in rheumatoid arthritis (RA), associated with decreased quality of life and productivity. Fatigue mechanisms have not been well studied, hence, a poorly understanding of this symptom leads to a poor clinical management. Moreover, despite the high number of drugs available for RA, it can be a persistent symptom despite reaching a low/minimum disease activity.

Methods: We evaluated the effect of diet on fatigue in an open-label pilot trial which had as a main objective the evaluation of feasibility and efficacy of a 2-week anti-inflammatory diet (ITIS) in RA patients. 20 patients with active RA (at least 3 tender and 3 swollen joints) participated. Physical examination and collection of fecal and plasma samples for microbiome and metabolomics were performed, along with collection of data on fatigue on a visual analogue scale from 0 to 10 among other clinical outcomes. 16S rRNA gene amplicon profiling of the stools and untargeted mass spectrometry-based metabolomics in stool and plasma were performed.

Results: Patients had moderate disease activity (DAS28CRP 3.86 ± 0.73) and an average fatigue of 4.78 ± 2.71 (Table 1). Fatigue was more intense in patients with higher disease activity, suggested by the positive correlation between fatigue and DAS28CRP (r=0.5, p=0.02). Post-intervention, fatigue significantly improved from 4.78 ± 2.71 before vs 2.49 ± 2.37 after diet, $p < 0.01$. Of note, fatigue did not correlate with DAS28CRP after diet (r=0.04, p=0.85). Using a 50% improvement in fatigue, patients were categorized as responders (R, N=9) or non-responders (NR, N=11). At baseline, R microbiome was enriched in *Dialister* and *Anaerofilum*, with decreased fecal deoxycholic and chenodeoxycholic acid and increased plasma L-kynurenine, octadecadienoic and elaidic acid (Figure 1). No differences in alpha diversity (within subject) of fecal microbiome and metabolome, nor plasma metabolome, were observed between R and NR before or after the diet. Only plasma metabolome beta-diversity (between subjects) was different between R and NR after the diet (Figure 2A). Post intervention, R microbiome was enriched in *Tissierellaceae* family and *Gemmiger* and *Anaerofilum* genus, while *Bacteroides* genus was decreased (Figure 2B). R fecal metabolome was enriched in dypeptides (Val-Arg, Leu-Val), Guanine and Hirsutanone (plant derived), which has potential anti-inflammatory properties (Figure 2C). Fecal cis 8,5,11 eicosatrienoic acid and 8-oxo-OTrE, potentially pro-inflammatory, were decreased in R. R also had higher levels of glychochenodeoxycholate and omega-hydroxydecanoate, derivative of 10-hydroxydecanoc acid, a medium-chained fatty acid with potential anti-inflammatory properties (Figure 2D).

Conclusion: Fatigue significantly improved after the "ITIS" diet, however it didn't parallel the improvement in disease activity. This was associated with changes in fecal microbiome and anti-inflammatory compounds. Our results sug-

Log Fold Change of the differentially abundant fecal metabolites in R compared to NR at baseline. C. Log Fold Change of the differentially abundant plasma metabolites in R compared to NR at baseline. R – 50% improvement in fatigue; NR – less than 50% improvement in fatigue.

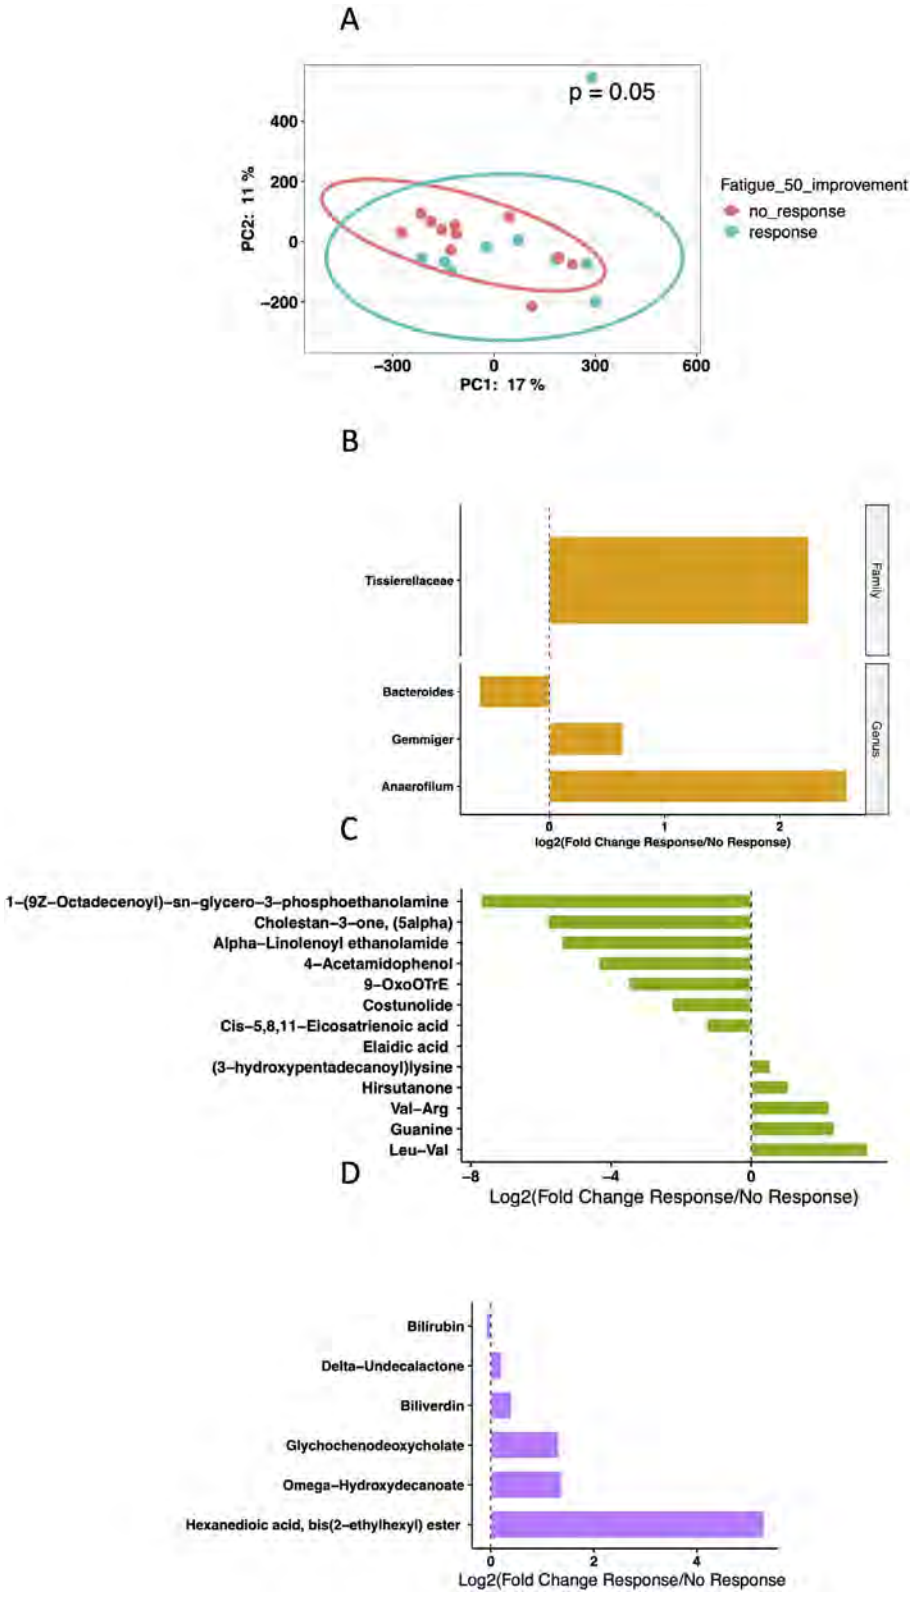

Figure 2. Characteristics of Fecal Microbiome and Plasma and Fecal Metabolome after Diet A. Principal Coordinate Analysis of the Unweighted UniFrac for the plasma metabolome after diet, in R and NR. B. Log Fold Change of differentially abundant microbes in R compared to NR on day +14. C. Log Fold Change of differentially abundant fecal metabolites in R compared to NR on day +14. D. Log Fold Change of differentially abundant plasma metabolites in R compared to NR on day +15. R – 50% improvement in fatigue; NR – less than 50% improvement in fatigue.

gest a potential role of diet in the management of fatigue in RA patients. Further studies are needed to establish the scientific basis for using diet to adjust the gut microbiome to improve fatigue management not only in RA patients, but perhaps in all rheumatic disease.

Session Title: RA – Treatments Poster III: RA Treatments & Their Safety (1674–1710)

Session Type: Poster Session D

Session Time: 8:30AM–10:30AM

Background/Purpose: Tofacitinib is an effective, yet costly, drug for treatment of RA and PsA. Tofacitinib is metabolized mainly by the cytochrome P450-enzyme CYP3A4, and the manufacturer recommends to halve the dose of tofacitinib when patients use concomitant medication that strongly inhibits CYP3A4. Therefore, we hypothesized that coadministration of cobicistat, an CYP3A4-inhibitor approved for boosting of antiretroviral drugs, next to half dose tofacitinib would lead to pharmacokinetics equivalent to standard doses tofacitinib. The aim of this study was thus

Table 1. Baseline characteristics. Either displayed as number (percentage), mean ± standard deviation or median (interquartile range). Percentages were calculated over the total number of participants unless indicated

to investigate the bioequivalence of tofacitinib 5 mg and cobicistat 150 mg once daily (QD) compared to tofacitinib 5 mg twice daily (BID) alone.

Methods: This open label, non-randomized, cross-over, bioequivalence study was performed between September 2019 and March 2021 in the Netherlands. Patients with RA or PsA, using tofacitinib and no other concomitant medication which could be significantly affected by cobicistat use, were included. After using tofacitinib 5 mg BID for at least 14 days, plasma samples of tofacitinib were collected pre-dose and 0.5, 1, 2, 3, 4, 6, 9 and 12 hours post-dose. After this first sampling day, patients switched treatment to tofacitinib 5 mg and cobicistat 150 mg QD. Two to six weeks after, plasma samples of both tofacitinib and cobicistat were collected at the same timepoints, with the addition of a sample at 24 hours post-dose. Bioequivalence of the average tofacitinib concentration (C_{avg}) was assessed of tofacitinib 5 mg with cobicistat 150 mg QD compared to tofacitinib 5 mg BID: the 90% confidence intervals of the geometric mean ratio of C_{avg} should be between 80% and 125% for bioequivalence. Secondary endpoints included efficacy (change in mean DAS28CRP measured at both sampling days), safety, and patient preference (7-point Likert Scale at study end).

Results: Twenty seven patients were included, of which five underwent adaptations to comedication prior to inclusion due to CYP3A4 interactions (Table 1). The geometric mean ratio for the C_{avg} was 84.8% (90% CI 75.1% - 95.6%), thus full bioequivalence could not be concluded. The change in mean DAS28CRP was 0.05, 95% CI -0.49 to 0.59. No serious adverse events occurred during the study. The majority of patients preferred the combination regime: 56% preferred combination therapy (score on Likert scale 5-7), 18% monotherapy (score 1-3) and 26% neutral (score 4), leading to a net promotor score of 38%.

Conclusion: Tofacitinib 5 mg with cobicistat 150 mg QD combination therapy was not bioequivalent to standard tofacitinib 5 mg BID. However, we think this combination treatment shows promise as a slightly reduced exposure is not expected to result in reduced efficacy, based on prior dose finding studies[1], combined with the fact that both drugs are registered and readily available. In addition, there was no difference in disease activity and a clear preference by patients. Further research should focus on safety and efficacy at longer use.

SESSION INFORMATION

Session Date: Tuesday, November 9, 2021

Session Title: RA – Treatments Poster III: RA Treatments & Their Safety (1674–1710)

Session Type: Poster Session D

Session Time: 8:30AM–10:30AM

Background/Purpose: Despite new therapeutic approaches in RA, the mortality gap between RA patients and the general population persists, and may even be increasing. Cardiovascular (CV) complications consist the leading cause of this increase in mortality. In this study, we tried to investigate the impact of biological agents (BA) on cardiovascular risk factors in RA patients.

Methods: Forty-nine, biologic-naïve RA patients, fulfilling the 2010 ACR/EULAR classification criteria with no previous history of CV disease were recruited in the study. We compared total cholesterol (TC), high-density lipoprotein cholesterol (HDL-c), low-density lipoprotein cholesterol (LDL-c), triglycerides (TGs), Apolipoprotein A1 (ApoA1), Apolipoprotein B (ApoB), Lipoprotein A (LpA), systolic blood pressure, inflammatory markers such as CRP and ESR between baseline and after 6 months of BA initiation. An ultrasonographic measurement of intima-media thickness (IMT) of carotids was performed by an experienced sonographer at baseline and after 6-month follow-up in order to determine the presence of subclinical atherosclerosis. The titer of autoantibodies against oxidised LDL (anti-oxLDL) was also estimated in a subgroup of 35 patients.

Table 1. Characteristics of patients included in the study

Total Number of Patients	49
Female N (%)	36 (73.5%)
Male N (%)	13 (26.5%)
Age (mean±SD) (years)	53.4±14.8
Smokers N (%)	11 (22.4%)
Disease Duration (mean±SD) (years)	4.5±1.3
Anti-TNF use N (%)	37 (75.5%)
RF (+) N (%)	32 (65.3%)
ACPA (+) N (%)	29 (59.18%)

Table 2. Results of CV risk parameters comparison between baseline and 6-month follow-up

CV RISK PARAMETERS	Baseline	6 months	P value
Systolic Blood Pressure[median (IQR)]	135 (125-147.5)	125 (120-132.5)	<0.001
Diastolic Blood Pressure [median (IQR)]	80 (75-85)	80 (75-85)	0.218
Heart Rates (mean ± SD)	78 ± 7	76 ± 9	0.060
DAS28 Score[median (IQR)]	3.39 (2.75-3.675)	2.89 (2.255-3.215)	<0.001
CRP [median (IQR)]	4 (2-7)	3 (2-4)	0.001
ESR [median (IQR)]	22 (12-38)	11 (6-22)	<0.001
TCHOL (mean ± SD)	209 ± 63	227 ± 48	0.030
TRG [median (IQR)]	107 (89.5-142.5)	101 (85-125)	0.622
HDL (mean ± SD)	58 ± 15	69 ± 17	<0.001
LDL (mean ± SD)	139 ± 39	135 ± 37	0.272
LpA [median (IQR)]	14.8 (5.6-27.05)	10.7 (4.8-27)	0.323
ApoA1 (mean ± SD)	162.4 ± 31.8	174.6 ± 32.9	<0.001
ApoB (mean ± SD)	95.6 ± 23.8	94.7 ± 26.2	0.696
IMT [median (IQR)]	0.9 (0.8-1)	0.7 (0.6-0.8)	<0.001
oxLDL (mean ± SD)	0.190 ± 0.056	0.132 ± 0.042	<0.001

Results: As regards the characteristics of patients, the mean (SD) age was 53.4 (14.8) years, 73.5% were women and 22.4% were smokers (Table 1). BA were administered in all patients and anti-TNF use was the most common (75.5% of patients). Six months after treatment initiation, patients presented with a significant increase in mean (SD) HDL [69 (17) vs 58 (15)] and ApoA1 [174 (33) vs 162 (32)] levels ($p< 0.001$) with a simultaneous significant reduction of mean (SD) systolic blood pressure [125 (12.5) vs 135 (22.5)] and the titer of anti-oxLDL [0.132 (0.042) vs 0.190 (0.056)]. IMT was also reduced after 6-month reassessment [0.7 (0.2)mm vs 0,9 (0.2)mm, ($p< 0.001$ for all comparisons)] (Table 2).

Conclusion: An improved lipid profile (increased HDL-c in combination with reduction of the anti-oxLDL titer) and a significant reduction of IMT were observed in a six-month period of BA administration. This study confirms that RA patients are prone to early atherosclerosis and BA initiation correlates strongly with more favorable values of CV risk parameters.

Abstract Number: 1702

Efficacy and Safety of Baricitinib in B/tsDMARDs Naive and B/tsDMARDs-IR Patients with Rheumatoid Arthritis

MASAOMI YAMASAKI, Shin-Yokohama Arthritis and Rheumatology Clinic, Yokohama, Japan

SESSION INFORMATION
Session Date: Tuesday, November 9, 2021
Session Title: RA – Treatments Poster III: RA Treatments & Their Safety (1674–1710)
Session Type: Poster Session D
Session Time: 8:30AM–10:30AM

Background/Purpose: Baricitinib, an oral selective inhibitor of Janus kinase (JAK) 1 and 2, improved signs and symptoms of rheumatoid arthritis(RA).We analyze efficacy and safety of baricitinib in real-world data.

Methods: Cases were recruited to SHin-yokohama Arthritis REgister (SHARE) between 2015 and 2020 (n=3,961). 154 Patients were diagnosed according to ACR/EULAR 2010 classification criteria and treated with baricitinib over 15 months. 32 cases fulfilled EULAR definition for difficult-to-treat RA (D2T-RA). In 154 (Male25, Female129 cases, RA duration 11.4+/-7.8years) cases, Clinical Disease Activity Index (CDAI), Health Assessment Questionnaire-Disability Index (HAQ-DI), anti-CCP2 and other clinical parameters were analyzed. They were arrayed based on previous treatments as b/tsDMARD-naïve and b/tsDMARD-insufficient responders (IR) after the failure or intolerance to bDMARDs. Tapering MTX dose was also analyzed in these two groups.

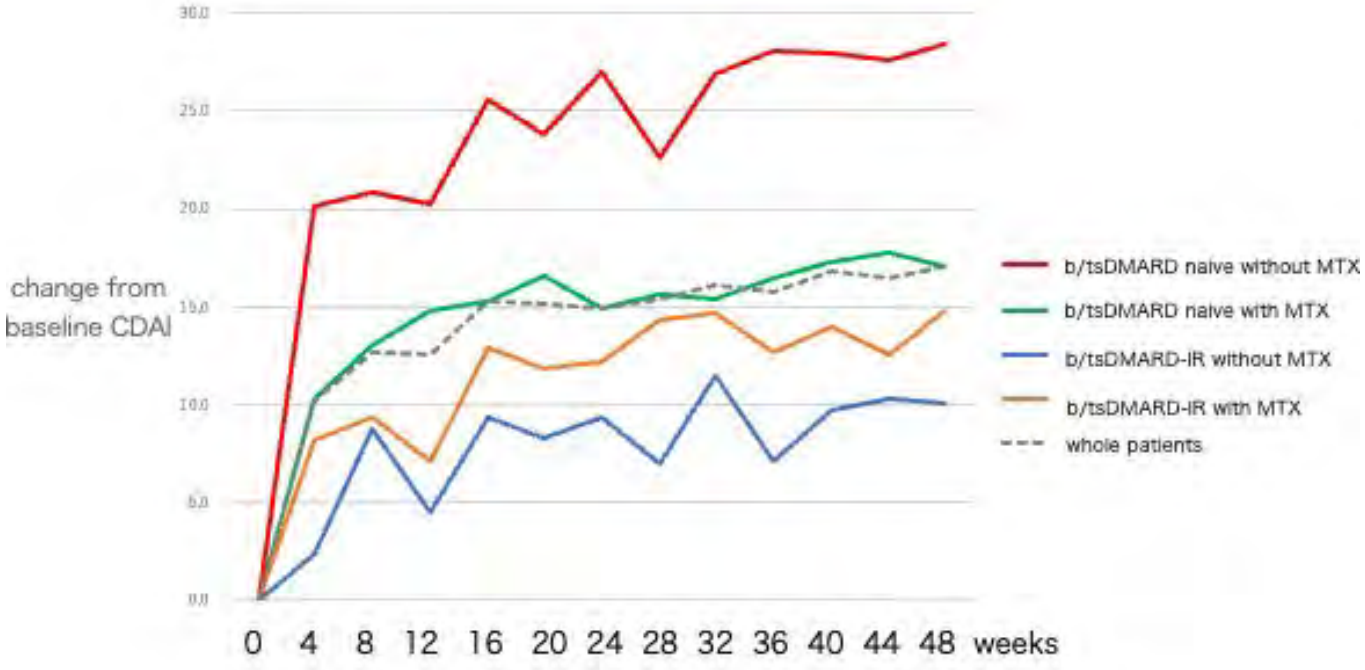

Fig. 1. Change from baseline CDAI

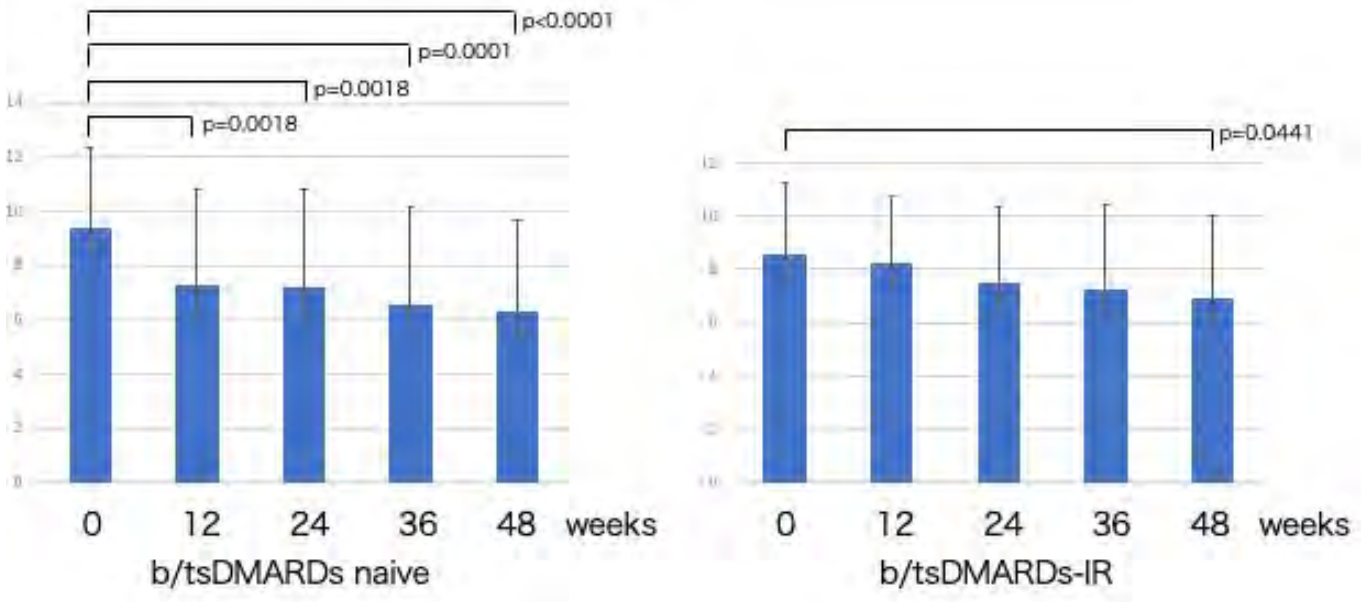

Fig. 2. MTX dose inn patients at 0, 12, 24, 36 and 48 weeks of treatment in baricitinib.

Table1. Predictors to detect patients who achieved LDA and/or REM in b/tsDMARDs group

	b/tsDMARD naive					
	CDAI≤10	10<CDAI		multivariate logistic regression		
n	n=65, 84.4%	n=12, 15.6%	p value	pvalue	OR	95%CI
M/F	13/52	1/11	0.336			
age	59.1+/-12.4	62.0+/-12.3	0.461			
RA duration	7.2+/-5.3	10.3+/-7.2	0.209			
ACPA	54.3+/-78.1	181.1+/-310.3	0.453			
PSL, cases, %	14, 21.5%	1, 9.1%	0.337			
PSL, dose	0.2+/-0.8	0.7+/-1.6	0.291			
MTX, cases, %	57, 87.7%	8, 66.7%	0.090			
MTX, dose	7.0+/-5.4	8.2+/-4.2	0.841			
CDAI at baricitinib 0W	20.6+/-11.1	33.4+/-11.1	0.023	0.0258	1.1	1.0075-1.1240
BARI 2/4mg, cases	55/10	3/9	<0.0001	0.0008	14.3	0.0145-0.3322

Results: 79 (51.3%) b/tsDMARDs naïve and 75(48.7%)b/tsDMARDs-IR patients were enrolled. There were no differences in RA duration time (11.4+/-7.8 vs. 12.9+/-8.3), anti-CCP2 positive(ave.242.6+/-158.9), and CDAI(20.2+/-12.4 vs. 17.8+/-11.3) at the beginning of baricitinib. Baricitinib withdrawal for inefficacy showed no difference between b/tsDMARDs naive and b/tsDMARDs-IR patients in RA with/without MTX (logrank p=0.8589). In b/tsDMARDs naïve group, 45(59.5%) patients were achieved LDA and 18 (22.8%) were acheived remission at 12 weeks. In b/tsDMARDs-IR group, 35(46.7%) patients were achieved LDA and 11(14.7%) patients were achieved remission. b/tsDMARDs naïve group showed more changes from baseline CDAI. In b/tsDMARDs group, predictors to detect patients who achieved LDA and/or remission were lower CDAI(20.6+/-11.1 vs. 33.4+/-11.1) and baricitinib 2mg/day in multivariate logistic regression(OR 1.1 and 14.3, 95%CI 1.0075-1.1240 and 0.0145-0.3322, p=0.023 and p< 0.0001, respectively). In A significant reduction in the dose of MTX was seen at 48 weeks in both b/tsDMARDs naïve group and b/tsDMARDs-IR group (p< 0.0001 vs. p=0.0441). 11(13.9%) parients were discontinued baricitinib due to herpes zoster (8.1/100PY). There were no thrombotic event in our cohort.

Conclusion: Our data confirm the efficacy and safety profiles of baricitinib in RA. It also showed baricitinib 2mg/day was effective in b/tsDMARD naïve patients.

AP1189: A Novel Oral Biased Melanocortin Agonist with Anti-inflammatory and Pro-resolving Effect for the Treatment of Rheumatoid Arthritis

Thomas Jonassen[1], Thierry Duvauchelle[1], Birgitte Telmer[2], Irene Sandholdt[2], Thomas Boesen[1] and Ellen-Margrethe Hauge[3], [1]SynAct Pharma, Holte, Denmark, [2]CroxxMed, Hørsholm, Denmark, [3]Aarhus University Hospital, Aarhus, Denmark

SESSION INFORMATION

Session Date: Tuesday, November 9, 2021

Session Title: RA – Treatments Poster III: RA Treatments & Their Safety (1674–1710)

Session Type: Poster Session D

Session Time: 8:30AM–10:30AM

Background/Purpose: Melanocortin (MC) type 1 and type 3 receptor stimulation is associated with anti-inflammation and promotion of inflammatory resolution. AP1189 is a biased MC type 1 and 3 receptor agonist aimed for oral administration currently in clinical development for treatment of active Rheumatoid Arthritis.

Methods: The pharmacokinetic profile of the compound has been evaluated in healthy male volunteers at three dose levels (N=27). Following once daily dosing with oral suspension for 14 days, PK analyses showed rapid absorption with tmax observed 1.5-2.5 hours post dosing. Elimination half-time between 19 (lowest dose) and 23 (highest dose) hrs (CV%: 13 and 21%). Approximately 10% of the compound was excreted unchanged in the urine. No drug accumulation was observed after steady state had been reached at day 7. Expose (based on AUC) was supra-proportional with a moderate increase of 2.25 when the dose was doubled. The most common side effects observed were nausea and headache with low to moderate intensity and observed in the time matched placebo controls too. Specifically, no sign of immunosuppression was observed. No, treatment related effect on vital signs were observed and telemetric CV safety evaluation did not reveal any QTcF prolongation nor other cardiac safety concerns.

The compound is currently tested in a double-blind placebo-controlled Phase 2a clinical trial in Europe with once daily dosing for four weeks as add on to Methotrexate (MTX) in previous MTX naïve patients with clinical disease activity (CDAI) above 22. The primary aim of the study is to evaluate safety and tolerability and potential treatment effects of the compound relative to placebo. The primary efficacy readout is defined as fraction of patients where disease activity goes for high (ie CDAI >22) to mediate or lower disease activity. The aim is to include a minimum of 105 subjects treated with either 50 mg AP1189, 100 mg AP1189 or placebo.

Results: An interim analysis of the first 26 patients showed the following:

16 women, 10 men, median age 57 (high/low: 79/27), median CDAI: 34 (high/low: 49/24) were treated with MTX according to the investigator's discretion (10-15 mg po once weekly increasing to 15-25 mg during the 4 weeks study period). 9 were treated with placebo, 9 with 50 mg AP1189 and 8 with 100 mg AP1189 as add on to the MTX treatment. There were no dropouts, and no serious adverse events were observed. The most common reported adverse events were nausea (9 cases disturbed equally between the three treatment groups) and 3 cases of headache. No signs of immunosuppression were observed. Median CDAI at end of treatment between groups were 18.5 (high/low: 46/4). 7 patients had low disease activity (CDAI 2.9-10); 9 had moderate disease activity (CDAI 10,1-22), 10 pts had high disease activity (CDAI >22). CDAI at end of treatment distributed between the three treatment groups: Placebo: 4 out of 9 (44%); 50 mg AP1189: 6 out of 9 (67%), 100 mg: 6 out of 8 (75%). To secure blinding of investigators and sponsor no further evaluation of group specific effects was made. Completion of the study is planned for third quarter 2021.

Conclusion: AP1189 is novel oral available compound with anti-inflammatory and pro-resolving effect with the potential to treat active RA

SESSION INFORMATION

Session Date: Tuesday, November 9, 2021

Session Title: RA – Treatments Poster III: RA Treatments & Their Safety (1674–1710)

Session Type: Poster Session D

Session Time: 8:30AM–10:30AM

Background/Purpose: to investigate the correlation between the rapid analgesic effect of tofacitinib and a decrease in RA activity after 3 and 6 months.

Methods: The study group consisted of 88 RA patients, age 53±11.5, 79.3% women, 89.8% RF "+", DAS28 5.2±1.2, who received DMARDs (59.5% methotrexate and 19.8% leflunomide), who had ineffectiveness or intolerance to biological therapy. All patients were prescribed tofacitinib 10 mg / day. The severity of pain was assessed using the Brief pain inventory (BPI) questionnaire, the presence of a neuropathic pain component (NPC) using the painDETECT questionnaire, and signs of central sensitization (CS) using the Central Sensitivity Inventory (CSI) questionnaire in the early stages after tofacitinib administration, and RA activity by DAS28 at 3 and 6 months.

Results: Pain intensity at baseline was 5.3±2.0 on the visual analog scale (VAS 0-10), 51.1% of patients had signs of central sensitization (CSI ≥ 40), 15.9% had NPC (painDETECT ≥18). 7 days after starting tofacitinib, there was a statistically significant decrease in pain intensity - to 4.1±1.8 ($p< 0.05$) and CS-CSI from 40.4±13.5 to 36.5±12.5 ($p=0.01$). After 28 days, the pain intensity (VAS) was 2.8±1.6 ($p=0.000$), painDETECT decreased from 11.8±5.6 to 6.8±3.1 ($p=0.000$), CSI to 31.6±13.9 ($p=0.000$). DAS28 after 3 and 6 months was 3.7±1.3 and 3.6±1.2. The number of patients with pain reduction ≥ 50% after 28 days of therapy was 59.9%. Low RA activity after 3 months (DAS28 ≤3.2) was achieved in 64.4% of patients. This was a clear correlation between the number of patients with significant pain reduction after 28 days and the number of patients who achieved low RA activity after 3 and 6 months ($rS=0.548$, $p=0.000$; $rS=0.790$, $p=0.000$). 6 patients dropped out of the study due to inefficiency or social reasons. No serious adverse reactions were observed.

Conclusion: Tofacitinib rapidly reduces the intensity of pain and signs of CS in RA. A quick response to this drug (pain reduction) makes it possible to predict a decrease in RA activity after 3 and 6 months of therapy.

SESSION INFORMATION

Session Date: Tuesday, November 9, 2021

Session Title: RA – Treatments Poster III: RA Treatments & Their Safety (1674–1710)

Session Type: Poster Session D

Session Time: 8:30AM–10:30AM

Background/Purpose: Hydroxychloroquine (HCQ) has been used safely for over 60 years in rheumatic patients. However, following its recent use in covid-19 disease, its safety has been questioned, following controversial reports of cardiac toxicity, possibly related to a prolongation of the QT interval. Furthermore, it was recently shown that concomitant administration of different drugs can affect QT interval in hydroxychloroquine chronic users.

Methods: 12-lead electrocardiograms were recorded in 355 ambulatory patients (SLE = 85, RA = 80, SSc = 71, UCTD = 68, other CTDs = 51). The analysis was performed on corrected QT intervals (QTc) calculated according to Framingham formula (QTc = QT+0.154 (1–RR)), with ULN = 449 ms in males, and 467 ms in females. Glomerular filtrate rate (eGFR) was calculated with the CKD-EPI equation. The influence on QTc values of demographic variables, chronic (≥3 months) HCQ treatment, and of the use of 23 comedications -including corticosteroids, immunosuppressants, biologics, statins, aspirin, angiotensin converting enzyme inhibitors, angiotensin receptor blockers, diuretics, betablockers, endothelin antagonists, duloxetine, selective serotonin reuptake inhibitors, gabapentinoids, proton-pump inhibitors (PPI), calcium channel blockers (CCBs) – were evaluated by parametric or non parametric statistical methods, as appropriate. All statistic analyses were performed with the IBM SPSS statistical package version 25.

Results: Demographic variables, and the use of comedications were not different in HCQ+ and HCQ- patients (Table 1). In the whole population, the QTc mean duration was 416.44 ± 19.53 ms, and was correlated with age (Fig. 1; $r = 0.211$, $p < 0.001$), but not with gender (F: 417.79±19.02 ms, M: 413.21±23.73 ms, $p = 0.303$), eGFR ($r = -0.83$, $p = 0.120$), BMI (-0.001, $p = 0.984$) or disease ($p = 0.139$). In only 4 patients (HCQ+: 3 (1.5%) – HCQ-: 1 (0.6%), $p = 0.629$) QTc duration was above ULN.

Table 1. Demographic and clinical variables in patients treated with HCQ (HCQ+) and in controls (HCQ-)

Tab. 1. Demographic and clinical variables in patients treated with HCQ (HCQ+) and in controls (HCQ-).									
	N	Age Yrs ±SD	Female N %	eGFR mL/min /1.73m² ±SD	BMI Mean ±SD	Hypo-thyroidism N %	VitD N %	PPI N %	CCB N %
All	355	57.74 ±14.25	320 90.1	87.00 19.44	24.65 4.70	52 14.6	237 66.8	202 57.1	53 14.9
HCQ+	194	57.56 ±14.40	177 91.2	86.35 20.10	24.24 4.49	26 13.4	138 71.1	112 58.0	30 15.5
HCQ-	161	57.96 ±14.10	143 88.8	87.79 18.63	25.17 4.91	26 16.1	99 61.5	90 55.9	23 14.3
p		0.069	0.280	0.476	0.074	0.548	0.070	0.384	0.438

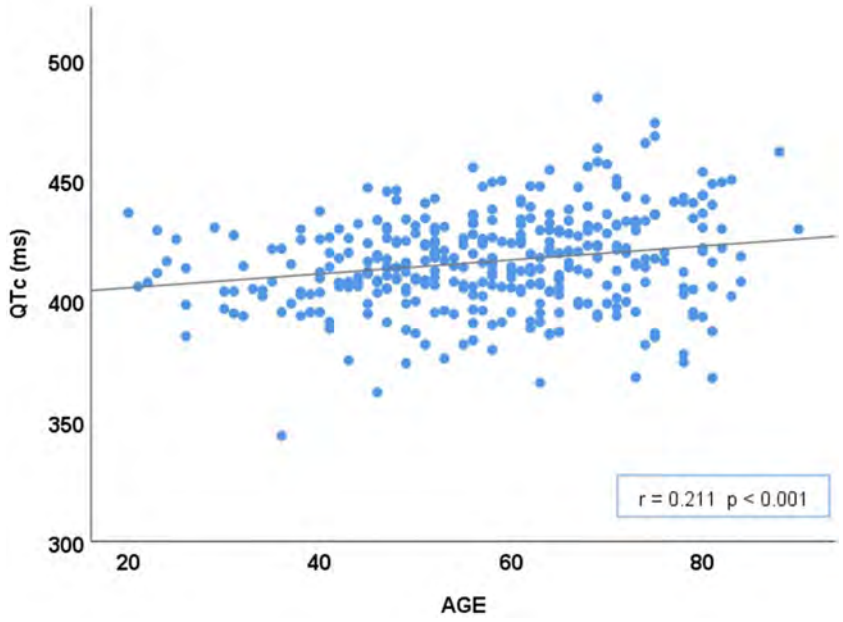

Figure 1. Correlstion between age and Qtc interval.

The patients were heavily cotreated, with 5.64 ± 3.47 concomitant medications on average (HCQ+ 5.58±3.47; HCQ- 5.59±3.33, p=0.804). Among the 23 cotreatments evaluated in univariate analyses, QTc duration was associated only with the assumption of vitamin D (418.95±19.56 ms vs 411.38±18.53 ms, p = 0.001), PPIs (419.14±20.00 ms vs 412.89±16.86 ms, p = 0.003), and CCBs (421.61±24.41 ms vs 415.53±18.44 ms, p = 0.036). In the analysis of covariance on age-adjusted data, only HCQ (p < 0.001) and Vitamin D (p =0.046) but not PPIs (p = 0.121) nor CCBs (p = 0.200) were still significantly correlated to QTc interval. Furthermore, as reported in Fig. 2, our data show a trend - albeit not statistically significant - towards an additive effect on QT prolongation of the association of Vitamin D, PPIs and CCBs with HCQ, even more evident in the case of association of the 3 drug classes.

Conclusion: In this study, the QTc interval duration was correlated to age and was significantly prolonged in patients treated with hydroxychloroquine as compared to controls, although significant prolongation was extremely infrequent. Furthermore, our data revealed signs of drug-drug interference, suggesting that regular monitoring of the electrocardiogram is advisable in these patients, often undergoing cotreatment with multiple drugs.

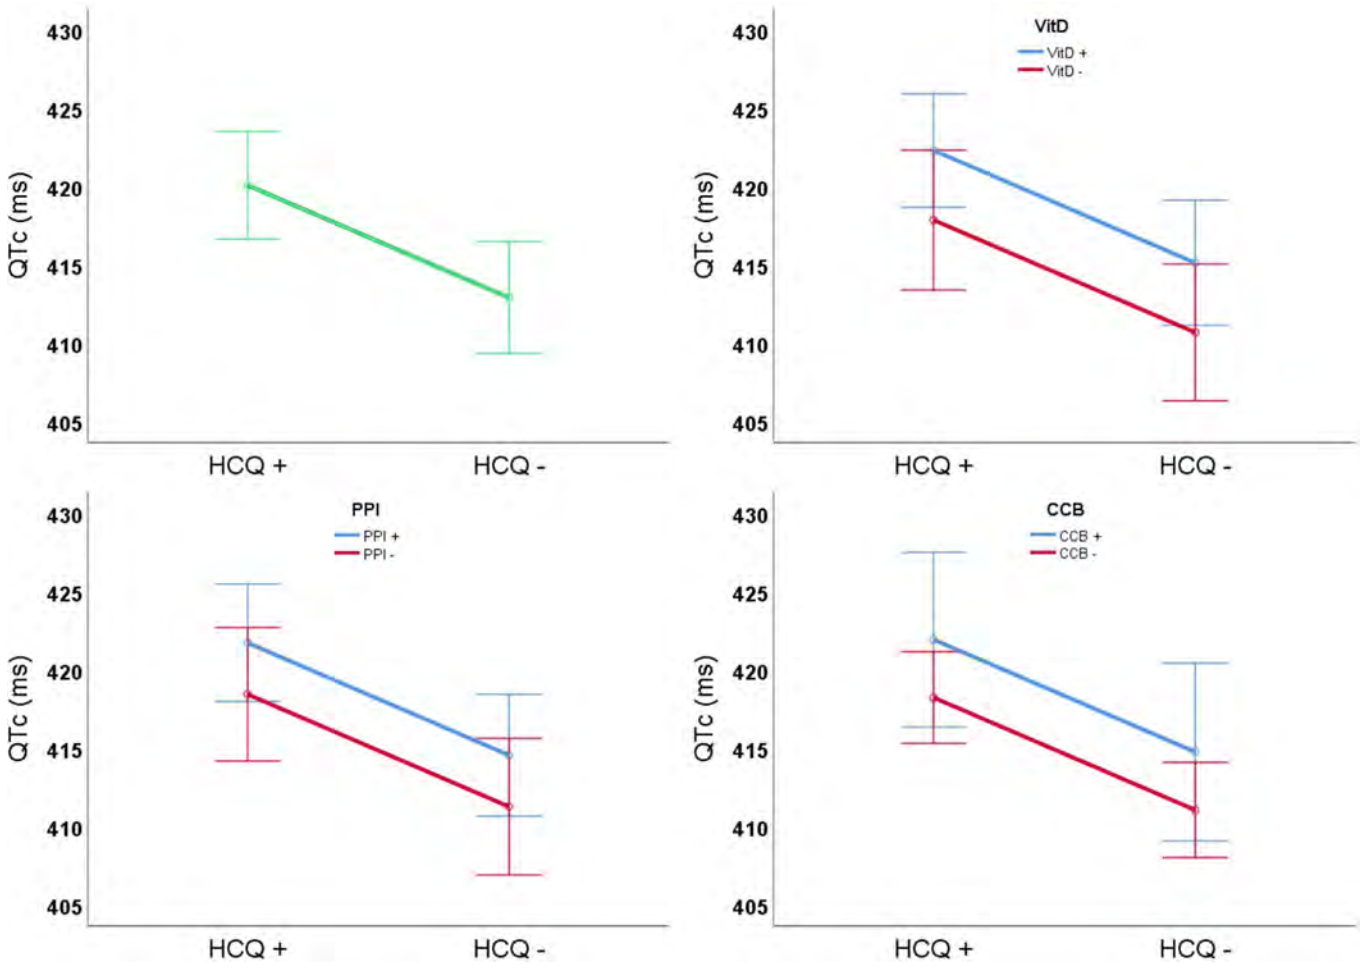

Figure 2. Influence of selected cotreatments in patients treated with HCQ and in controls.

SESSION INFORMATION

Session Date: Tuesday, November 9, 2021

Session Title: RA – Treatments Poster III: RA Treatments & Their Safety (1674–1710)

Session Type: Poster Session D

Session Time: 8:30AM–10:30AM

Background/Purpose: Vagus nerve stimulation (VNS) activates innate neuroimmune reflexes that have been shown to reduce pro-inflammatory cytokines and clinical disease activity in subjects with rheumatoid arthritis (RA) (Koopman PNAS 2016). We previously reported primary clinical outcomes from a first-in-human, double-blind study of a novel, implanted VNS device called a MicroRegulator (MR). That study showed 5/10 subjects with drug-refractory RA met or exceeded the minimal clinically important difference (MCID) in DAS28-CRP; 2 subjects achieved DAS28 remission (DAS28-CRP < 2.6); and pro-inflammatory cytokines were decreased by >30% following 12 weeks of VNS (Genovese et al. Lancet Rheum 2020). We now report 24-week efficacy and safety findings from this study.

Methods: The primary study was enrolled in 2 stages: Stage 1 (n=3) was open-label, and Stage 2 (n=11) was randomized and sham-controlled (Figure 1). Three weeks after MR implantation, the first 3 subjects were stimulated 1 min QD in Stage 1. Following safety review board approval, the remaining 11 patients were implanted with the MR and randomized to 1 min of sham, QD, or QID VNS in Stage 2. At Week 12, the blind was lifted, sham subjects were re-randomized to either QD or QID active VNS dosing, and all actively treated subjects remained on their dosing through Week 24. Safety and tolerability were assessed, and several secondary efficacy endpoints were evaluated measuring the change in disease activity from the start of VNS to Week 24.

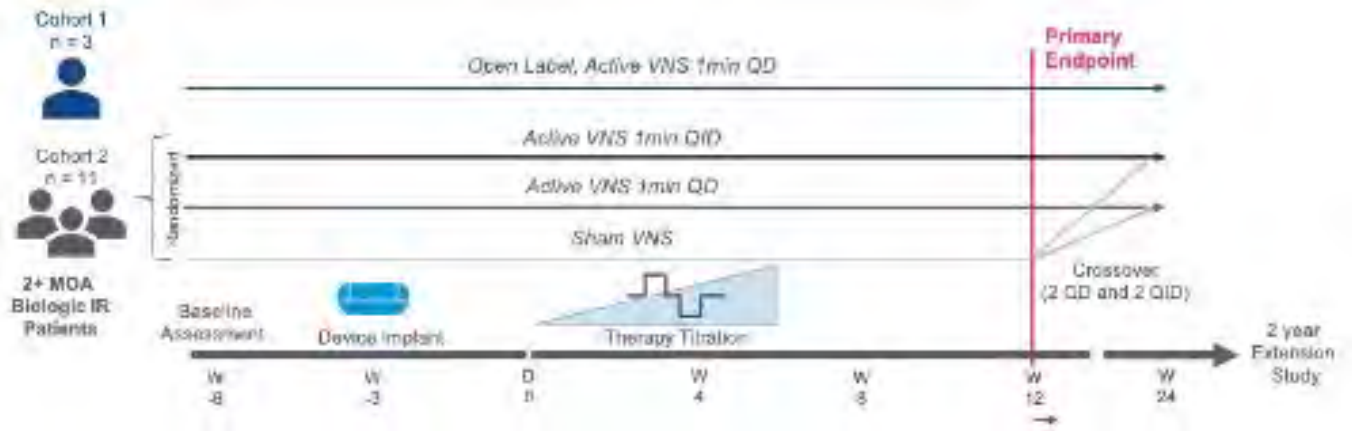

Figure 1. Study Schematic.

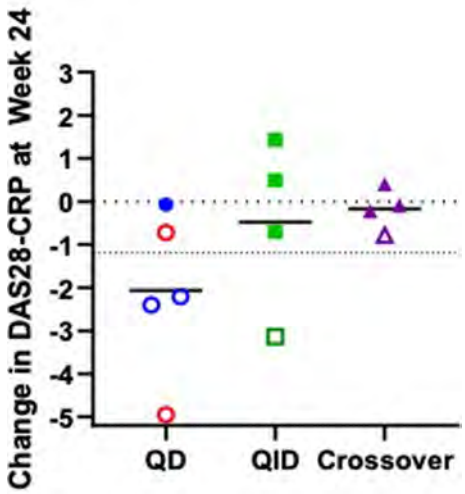

Figure 2. Change in DAS28-CRP at Week 24. Open shapes represent EULAR good and moderate responders. Red shapes represent subjects with a biologic added back as co-therapy with VNS.

Results: There were no device-related adverse events from Week 12 through Week 24. Improvement in clinical disease activity was sustained through Week 24: 5/9 patients within the original treatment groups met or exceeded EULAR response criteria for DAS28-CRP at Week 24 vs. 5/10 at Week 12 (one Week 12 responder was lost to follow-up). Similarly, 6/9 patients in the original treatment groups met or exceeded the MCID in CDAI at Week 24 vs. 5/10 at Week 12. In the long-term extension, 1/4 sham crossover patients had both EULAR and CDAI response after 12 weeks of VNS (1/2 QD, 0/2 QID). VECTRA composite scores and component analysis revealed an 18-point drop in median multi-analyte disease activity index in the QD group over 24 weeks of VNS with a decrease in serum levels of several analytes in key component categories (IL-6, serum amyloid A, and VCAM-1). Erosion progression by hand MRI was stabilized or decreased in all but 1 of the stimulated patients at Week 24.

Conclusion: Improvements in clinical disease activity, pro-inflammatory cytokine suppression, and joint preservation were maintained through 24 weeks of VNS treatment. Safety outcomes continue to support the risk/benefit profile of VNS as a treatment option for patients with RA with inadequate responses or intolerance to conventional DMARDS and biologic and targeted synthetic drugs.

A Bioengineered Probiotic for the Oral Delivery of an Immunomodulator in Rheumatoid Arthritis

Yuqing Wang[1], Duolong Zhu[1], Laura Ortiz-Velez[2], Jacob Perry[1], Michael Pennington[3], Joseph Hyser[1], Robert Britton[1] and Christine Beeton[1], [1]Baylor College of Medicine, Houston, TX, [2]TMC Innovation, Houton, [3]AmbioPharm Inc., North Augusta, SC

SESSION INFORMATION

Session Date: Tuesday, November 9, 2021

Session Title: RA – Treatments Poster III: RA Treatments & Their Safety (1674–1710)

Session Type: Poster Session D

Session Time: 8:30AM–10:30AM

Background/Purpose: CCR7– effector memory T (T_{EM}) lymphocytes are targets for immunomodulation for the treatment of rheumatoid arthritis (RA). Following activation, T_{EM} cells upregulate the expression of the potassium channel Kv1.3, and blocking this channel inhibits T_{EM} cell proliferation and secretion of pro-inflammatory cytokines with minimal effects of CCR7+ naïve and central memory T cells. Analogs of the small peptide ShK, engineered to enhance their selectivity for Kv1.3, are effective in reducing disease severity in animal models of RA and other autoimmune diseases and in patients with active plaque psoriasis. However, like most biologics, these peptides must be injected repeatedly. Here, we propose a novel approach for the delivery of the ShK analog ShK-235 by inducing its production and secretion by a probiotic bacterium, *Lactobacillus reuteri*, for oral delivery into the gastrointestinal tract.

Methods: We designed LrS235, a bioengineered *L. reuteri* that secretes the ShK-235 peptide and used a single-cell patch-clamp to quantify ShK-235 in the culture supernatant of LrS235 and in the circulation of healthy rats gavaged with LrS235. We used functional assays to define the effects of ShK-235 secreted by LrS235 on the proliferation of T_{EM} cells *in vitro*. We next tested the efficacy of LrS235 in two animal models, delayed-type hypersensitivity (DTH) and collagen-induced arthritis (CIA).

Results: Supernatants from LrS235 block Kv1.3 currents and inhibit human T_{EM} cells proliferation and IL-2 and IFN-g production *in vitro*. A single oral gavage of LrS235 in healthy rats results in sufficient levels of ShK-235 in the circulation to block Kv1.3 channels and reduces inflammation in the DTH model. The daily oral gavage of LrS235 is efficacious in reducing clinical signs of disease and joint inflammation in rats with CIA.

Conclusion: Our results demonstrate the potential of using the probiotic *L. reuteri* as a novel oral delivery system for ShK-235, and possibly other biologics, to treat RA.

The Efficacy and Safety of Piclidenoson vs Methotrexate in Early Rheumatoid Arthritis: Phase 3 Randomized, Double-blind, Placebo-controlled Study

Tatiana Reitblat[1], Alexandra Gurman- Balbir[2], Zivit Harpaz[3], Motti Farbstein[3], Michael Silverman[3], William Kerns[3] and **Pnina Fishman**[3], [1]Barzilai Medical Center, Ashkelon, Israel, [2]Rambam Medical Center, Haifa, Israel, [3]Can-Fite BioPharma, Petah Tikva, Israel

SESSION INFORMATION

Session Date: Tuesday, November 9, 2021
Session Title: RA – Treatments Poster III: RA Treatments & Their Safety (1674–1710)
Session Type: Poster Session D
Session Time: 8:30AM–10:30AM

Background/Purpose: Piclidenoson, a highly selective A3 adenosine receptor (A3AR) agonist, demonstrated safety and efficacy in phase 2 clinical studies in rheumatoid arthritis (RA) and psoriasis. Piclidenoson induces selective apoptosis of inflammatory cells via a molecular mechanism which entails de-regulation of the Wnt signaling pathway.

Methods: This randomized, double-blind, active- and placebo-controlled, parallel-group study enrolled patients with clinically active RA who were methotrexate (MTX)-naïve. Eligible patients were randomized to 4 groups in a 2:2:2:1 ratio: piclidenoson 1 mg; piclidenoson 2 mg; MTX; or matching placebo tablets/capsules. Piclidenoson or matching placebo tablets were administered every 12 h for up to 24 weeks of treatment. MTX or matching placebo capsules were administered once a week according to the dosing schedule. The primary endpoint was efficacy (noninferiority) of piclidenoson administered for 12 weeks relative to oral MTX, as assessed by the proportion of patients achieving a disease activity score (DAS) of low disease activity (LDA). Additional analyses of the primary efficacy parameter included comparison of each dose of piclidenoson to placebo at Week 12. Secondary endpoints included comparing response rates (ACR20, ACR50, and ACR70) between piclidenoson (each dose) and MTX or placebo. The study was designed to enroll 525 patients.

Results: Due to the SARS-CoV-2 pandemic, enrollment was paused and an interim analysis was performed after 50% of participants reached the Week 12 visit evaluation. The interim analysis included a total of 252 patients (72, 73, 73, and 34, in the piclidenoson 1 mg, piclidenoson 2 mg, MTX, and placebo groups, respectively). Patient demographics and baseline characteristics were overall similar between the groups. For the entire population included in the interim analysis, the median (range) age was 56 (18-75) years, and 197 (78%) were females. Piclidenoson was

ACR70	11 (16%)	6 (9%)	15 (21%)	5 (15%)	1 mg: 0.918 2 mg: 1.000	1 mg: 0.067 2 mg: 0.346

[a] *P*-value for comparison to placebo for superiority.
[b] *P*-value for comparison of each dose of piclidenoson to MTX for non-inferiority with margin of 15%.

safe and very well tolerated. The proportion of patients experiencing any treatment emergent adverse events (TEAEs) were similar for all groups (17%, 25%, 26%, and 29%, respectively) and the majority of TEAEs were mild. Although piclidenoson efficacy was significantly superior to placebo, the study did not meet the primary endpoint which was noninferiority vs MTX (Figure). At 12 and 24 Weeks, ACR20, ACR50 and ACR70 response rates were overall similar between the piclidenoson 1 mg (which was more effective than the 2 mg dose) and the MTX groups. The clinical benefits of piclidenoson 1 mg (as reflected in the ACR50 and ACR70 response rates) seemed more pronounced after 24 weeks (Table).

Conclusion: Piclidenoson was safe, but did not meet the primary endpoint in the current study; although it was superior to placebo in the DAS-LDA analysis. Since the primary endpoint was not met, the trial was discontinued by the sponsoring company.

Long-term Safety of a Single Infusion of Human Umbilical Cord Blood-derived Mesenchymal Stem Cell Therapy in Rheumatoid Arthritis: The 5-year Follow-up of the Phase I Clinical Trial

Min Jung Kim[1], Eun Hye Park[2] and Kichul Shin[3], [1]Seoul Metropolitan Government–Seoul National University Boramae Medical Center, Seoul, Republic of Korea, [2]Chung-Ang University Hospital, Seoul, Republic of Korea, [3]Seoul Metropolitan Government- Seoul National University Boramae Medical Center, Seoul, Republic of Korea

SESSION INFORMATION
Session Date: Tuesday, November 9, 2021
Session Title: RA – Treatments Poster III: RA Treatments & Their Safety (1674–1710)
Session Type: Poster Session D
Session Time: 8:30AM–10:30AM

Background/Purpose: Mesenchymal stem cell (MSC) therapy represents a promise for the treatment of autoimmune diseases due to its potent immunomodulatory effect. We investigated the long-term safety of a single treatment of human umbilical cord blood-derived (hUCB)-MSCs in patients with rheumatoid arthritis (RA).

Methods: Patients with RA who met the 2010 ACR/EULAR classification criteria and received a single intravenous infusion of hUCB-MSCs (3 groups; 2.5 x 10^7, 5.0 x 10^7, 1.0 x 10^8 cells) in a phase I trial (NCT02221258) entered this 5-year observational study. Safety assessments were carried out at 3, 6, and 12 months for the first year after the hUCB-MSC administration and annually thereafter for the remaining period. Key safety endpoints included overall adverse events (AEs), serious adverse events (SAEs) and AEs of special interest including infection, thromboembolism, and benign/malignant tumor. Physical examination, laboratory tests and electrocardiograms were also performed.

Results: A total of nine patients were treated after the phase I trial at a single center. The most frequent AEs (Table) over 5 years were osteoarthritis (66.7%), nasopharyngitis (44.4%), abdominal pain (33.3%), osteopenia or osteoporosis (33.3%), lumbar spinal stenosis (22.2%), and hypertension (22.2%). SAEs occurred in 5 patients (55.6%); a serious infection (cellulitis) happened in one patient in the 1.0 x 10^8 group that resolved after treatment. Three years after administration of MSCs, a benign ovarian tumor and a breast adenoma were reported in the 2.5 x 10^7 and 5.0 x

Table. Summary of AEs up to 5 years

	Total (N = 9)	2.5 x 10^7 (N = 3)	5.0 x 10^7 (N = 3)	1.0 x 10^8 (N = 3)
Events of any AE, N	97	37	30	30

Number of patients, N (%)	3 (33.3)	1 (33.3)	1 (33.3)	1 (33.3)
Number of events, N	7	5	1	1
Any SAE				
Number of patients, N (%)	5 (55.6)	3 (100)	1 (33.3)	1 (33.3)
Number of events, N	9	6	1	2
AEs reported in ≥3 of patients in any group, N (%)				
Musculoskeletal and connective tissue disorders	9 (100)	3 (100)	3 (100)	3 (100)
Infections and infestations	6 (66.7)	2 (66.7)	2 (66.7)	2 (66.7)
Gastrointestinal disorders	5 (55.6)	1 (33.3)	2 (66.7)	2 (66.7)
General disorders and administration site conditions	3 (33.3)	1 (33.3)	1 (33.3)	1 (33.3)
Injury, poisoning and procedural complications	3 (33.3)	1 (33.3)	1 (33.3)	1 (33.3)
Neoplasms benign, malignant and unspecified	3 (33.3)	1 (33.3)	2 (66.7)	0 (0)
AEs of special interest, N (%)				
Serious infections	1 (11.1)	0	0	1 (33.3)
Opportunistic infections	0	0	0	0
Thromboembolism	0	0	0	0
Malignancies	0	0	0	0
Benign tumor				
Benign ovarian tumor	1 (11.1)	1 (33.3)	0	0
Breast adenoma	1 (11.1)	0	1 (33.3)	0

10^7 groups, respectively. However, no death, thromboembolism or malignancy occurred during the follow up period. The incidence of AEs increased over time after administration of MSCs, but similar across the dose groups. There were no clinically significant laboratory finding, except for a case of hypertriglyceridemia and a case of anemia.

Conclusion: The long-term safety profile of a single dose of intravenous hUCB-MSC in patients with RA was reasonable and acceptable.

SESSION INFORMATION

Session Date: Tuesday, November 9, 2021

Session Title: RA – Treatments Poster III: RA Treatments & Their Safety (1674–1710)

Session Type: Poster Session D

Session Time: 8:30AM–10:30AM

Background/Purpose: The preferential Janus kinase (JAK)-1 inhibitor filgotinib (FIL) is approved for treatment of moderately to severely active RA in Europe and Japan. In this post hoc, exploratory analysis, we assessed efficacy and safety of long-term treatment with FIL (with or without MTX) in MTX-naïve patients (pts) treated with FIL or MTX in the Phase 3 parent study (PS; NCT02886728).[1]

Methods: Pts received FIL 200 mg (FIL200)+MTX, FIL 100 mg (FIL100)+MTX, FIL200 alone, or MTX alone up to 52 weeks (w) in the PS.[1] Those who completed the PS on study drug could enter the long-term extension (LTE; NCT03025308). MTX completers were rerandomized, blinded, to FIL200 or FIL100; pts who took FIL in the PS remained on the same dose in LTE. MTX was washed out for 4 w at LTE baseline (BL); pts could (re)start MTX and/or other csDMARDs ≥4 w after LTE first dosing.[1] We report proportions of pts who achieved ACR 20%, 50%, and 70% response (ACR20/50/70), DAS in 28 joints with CRP (DAS28[CRP]) ≤3.2 and < 2.6, and Clinical Disease Activity Index (CDAI) ≤10 and ≤2.8. Exposure-adjusted incidence rates (EAIR)/100 pt-years of exposure of treatment-emergent adverse events (TEAEs) and AEs of special interest (AESIs) are summarized, with data cutoff of June 1, 2020.

Results: As of June 1, 2020, 439 of 492 (89%) pts who entered LTE from the PS FIL200 groups and 144/169 (85%) from the PS FIL100 group were still on LTE study treatment; of those rerandomized from MTX, 131/148 (89%) FIL200 and 133/151 (88%) FIL100 pts were still on study treatment. LTE BL characteristics were similar between FIL200 and FIL100 groups: mean RA duration was 3.1 and 3.3 years; mean DAS28(CRP) was 2.5 and 2.7. After MTX washout, only 17% of FIL200 and 23% of FIL100 pts (re)started MTX (at clinical judgment). ACR20/50/70 response rates among pts from PS FIL arms decreased modestly from LTE BL to W12 then stabilized. Among pts who switched from PS MTX to LTE FIL, response rates remained stable or improved to approach those of PS FIL pts by W48 **(Table 1)**. Similar trends were seen in proportions of pts attaining DAS28(CRP) ≤3.2, DAS28(CRP) < 2.6, CDAI ≤10, and CDAI

[a]Positively adjudicated. bVTE adjudicated for DVT and PE. LTE FIL represents FIL dose with and without MTX. EAIR and 95% CIs were estimated using Poisson regression model including treatment group with an offset of natural log of exposure time. AE, adverse event; CI, confidence interval; DVT, deep vein thrombosis; EAIR, exposure-adjusted incidence rate; FIL, filgotinib; LTE, long-term extension; MACE, major adverse cardiovascular event; NMSC, nonmelanoma skin cancer; PBO, placebo; PE, pulmonary embolism; PYE, patient-years of exposure; TE, treatment-emergent; VTE, venous thromboembolism.

≤2.8 **(Table 2)**. TEAEs, Grade ≥3 AEs, serious AEs, and infections were largely comparable across groups and did not appear to increase after MTX to FIL switch **(Table 3)**. There were 6 deaths, all among PS FIL200 pts. There were 5 major cardiovascular events, 3 in PS FIL200+MTX and 2 in PS FIL200 monotherapy pts and 2 venous thromboembolisms, 1 each in PS FIL200+MTX and PS FIL200 monotherapy pts. EAIRs of herpes zoster were comparable across groups regardless of PS treatment. EAIRs for other AESIs were low.

Conclusion: Overall, response rates improved from LTE BL to W48 for pts switched from PS MTX to FIL and decreased modestly for PS FIL pts. In general, rates of AESIs were low and tended to be higher in pts maintained on FIL from PS. Safety findings in this subpopulation were comparable with the PS through W52[1] and with a 7-trial integrated safety analysis.[2] Limitations: the LTE was not formally randomized at BL, the groups were of unequal size, and the switch from MTX to FIL for LTE was by design, rather than based on disease activity.

Increasing Preeclampsia Knowledge in SLE with a Specific Educational Tool: Preliminary Results

Joo Young (Esther) Lee[1], Arielle Mendel[2], Isabelle Malhamé[2], Sasha Bernatsky[1] and Evelyne Vinet[3], [1]McGill University, Montréal, QC, Canada, [2]McGill University Health Centre, Montréal, QC, Canada, [3]McGill University Health Centre, Mont Royal, QC, Canada

SESSION INFORMATION

Session Date: Tuesday, November 9, 2021

Session Title: Reproductive Issues in Rheumatic Disorders Poster (1711–1731)

Session Type: Poster Session D

Session Time: 8:30AM–10:30AM

Background/Purpose: Pregnant women with systemic lupus erythematosus (SLE) are at high risk of preeclampsia, leading to substantial maternal and fetal morbidity. Aspirin reduces preeclampsia risk but recent studies suggest aspirin is used only in a minority of SLE pregnancies. There is an urgent need to improve preeclampsia counselling and management in this vulnerable population. Therefore, we are conducting the PREPARE (PREeclamPsia knowledge & Aspirin adheRence in lupus prEgnancies) trial, a randomized controlled trial (RCT) evaluating an educational tool on preeclampsia knowledge and aspirin adherence among pregnant women with SLE. We present preliminary analyses of the effect of this tool on preeclampsia knowledge.

Methods: We are recruiting consecutive pregnant SLE women (diagnosed according to the SLICC criteria) until the 16th gestational week at 5 Canadian SLICC centers (i.e. Montreal, Halifax, Quebec, Winnipeg, and Calgary) since May 2018. Participants are randomly assigned to receive either the specifically-designed educational tool (intervention group) or standard of care (control group). At baseline (i.e. first trimester) and second trimester visits, the participants complete self-administered preeclampsia knowledge questionnaires (scored out of 30 by the research team blinded to the intervention). We restricted the current analysis to participants enrolled at the coordinating center (accounting for nearly half of the total planned sample size). We performed a univariate linear regression analysis to assess the effect of the educational tool on preeclampsia knowledge (i.e. mean score difference between the two groups from baseline to second trimester visit).

Table 1. Baseline characteristics in the study population

	Intervention (n=16)	**Control (n=17)**
Age, mean years (SD)	32 (± 4.6)	34 (± 4.2)
Disease duration, mean years (SD)	10 (± 7.7)	10 (± 6.9)
Post-secondary education, n (%)		
No	3 (20%)	3 (20%)
Yes	12 (80%)	12 (80%)
Ethnicity, n (%)		
Caucasian	5 (31%)	12 (71%)
Native North American	1 (6%)	0
Hispanic	3 (19%)	0
Black	4 (25%)	3 (18%)
Asian	3 (19%)	1 (6%)
Other	0 (0%)	1 (6%)
Body mass index, mean kg/m^2 (SD)	24 (4.7)	24 (3.8)
Antiphospholipid syndrome, n (%)		
Any pregnancy morbidity & antiphospholipid antibodies (APA)	0	0
Vascular thrombosis & APA	1 (6%)	0
Any pregnancy morbidity & vascular thrombosis & APA	0	0
Prior eclampsia or preeclampsia, n (%)	1 (6%)	0
Prior or current lupus nephritis, n (%)	6 (38%)	3 (18%)
Heparin use, n (%)		
Prophylactic	1 (6%)	1 (6%)
Therapeutic	1 (6%)	1 (6%)

Results: Thirty-three pregnant SLE women were included in the study, among which 16 were exposed to the intervention and 17 were unexposed. Baseline characteristics were well-balanced between the two groups with similar mean maternal age between intervention group (32.2 years, standard deviation, SD, 4.6) and control group (34.1 years, SD 4.2) and identical proportion of participants with post-secondary education (i.e. 80%) (**Table 1**). The difference in mean preeclampsia knowledge scores between second trimester and baseline visits in the intervention group was 4.4 points (95% CI -0.1, 9.0) and in the control group was 1.5 points (95% CI -2.7, 5.7). The mean difference in knowledge scores (from baseline to second trimester) for those receiving the educational tool was 2.7 points higher (95% CI -1.5, 6.9) than those receiving standard of care.

Conclusion: Approximately midway into the trial, we observed a trend for improvement in preeclampsia knowledge from the baseline to the second trimester visit in pregnant women with SLE who received a specifically-designed educational tool compared to the control group, although the CIs included the null. Our RCT is well-poised to provide a new evidence-based approach to improve preeclampsia knowledge in pregnant women with SLE, which could help to optimize aspirin use and outcomes in this vulnerable population.

Adverse Outcomes and Rehospitalization After Delivery Among Women with Systemic Lupus Erythematosus or Rheumatoid Arthritis and Their Infants

Julianna Sabo[1], Namrata Singh[2], Deborah Crane[1], David Doody[3], Melissa Schiff[4] and Beth Mueller[5], [1]University of Washington, Seattle, WA, [2]University of Washington, Bellevue, WA, [3]Fred Hutchinson Cancer Research Center, Seattle, WA, [4]University of Washington, University of New Mexico, Seattle, WA, [5]Fred Hutchinson Cancer Research Center, University of Washington, Seattle, WA

SESSION INFORMATION
Session Date: Tuesday, November 9, 2021
Session Title: Reproductive Issues in Rheumatic Disorders Poster (1711–1731)
Session Type: Poster Session D
Session Time: 8:30AM–10:30AM

Background/Purpose: Women with rheumatoid arthritis (RA) or systemic lupus erythematosus (SLE) have greater risk of adverse obstetric and birth outcomes than women without these conditions. Infant outcomes are less well-studied. It is unknown whether re-hospitalization after delivery occurs more often for affected mothers and their infants.

Methods: This population-based cohort study used linked birth-hospital discharge data from Washington State for 1987-2014. International Classification of Disease 9th revision (ICD9) codes identified all women with RA (ICD9 714.X, 725.X) and SLE (ICD9 710, 710.0, 710.1) in the hospital discharge record at delivery, and a 10:1 comparison group of women without these codes. Analyses were restricted to singleton live births (1,223 RA; 1,354 SLE). Poisson regression with robust standard errors estimated relative risks (RR) and 95% confidence intervals (CI) for selected outcomes, accounting for delivery year, maternal age, and parity.

Results: Many adverse outcomes were more common among RA and SLE cases than among comparison women. Preeclampsia occurred more often during pregnancies of women with RA (RR 1.42, 95% CI 1.17-1.71) or SLE (RR 2.33, 95% CI 2.01-2.70), as did preterm rupture of membranes (PROM, RR 2.85, 95% CI 2.20-3.72 for RA; RR 3.28, 95% CI 2.54-4.23 for SLE). Cesarean deliveries were more common among nulliparous women in both groups (RR

1.32, 95% CI 1.18-1.48 for both conditions). Infants of women with RA or SLE were more likely to weigh < 2500 g (RR 2.08, 95% CI 1.72-2.52 for RA; RR 4.88, 95% CI 4.27-5.58 for SLE), be small for gestational age (RR 1.25, 95% CI 1.07-2.50; RR 2.30; 2.04-2.59, respectively), delivered at < 32 weeks gestation (RR 1.83, 95% CI 1.13-2.97; RR 5.13, 95% CI 3.75-7.01, respectively), and require neonatal intensive care unit admission (NICU, RR 1.89, 95% CI 1.56-2.30; RR 2.71, 95% CI 2.25-3.28, respectively). Infants of women with SLE were more likely to have a malformation (RR 1.46, 95% CI 1.21-1.75) or die within 2 years (RR 2.11, 95% CI 1.21-3.67). Rehospitalization levels among both women with RA (RR 2.22; 1.62-3.04) and SLE (RR 2.78, 95% CI 2.15-3.59) were greatest < 6 months of delivery and declined over time. Infants of women with SLE had increased rehospitalization < 6 months (RR 1.64, 95% CI 1.36-1.98).

Conclusion: Consistent with prior literature, we found women with RA or SLE experienced many adverse outcomes. In our data, these included preeclampsia, PROM, and cesarean deliveries, with increased risks more notable among women with SLE. Infants of women with either condition were more likely to weigh < 2500g, be < 32 weeks gestation, small for gestational age, and require NICU admission than infants of comparison women. Only infants of women with SLE had increased malformations. Maternal rehospitalization after delivery was more common in both groups; most marked at < 6 months. Infant rehospitalizations were increased in both cohorts to a lesser extent. Close follow-up during this time period is crucial to minimize adverse outcomes.

Abstract Number: 1713

Risk of Serious Infections in Offspring Exposed in Utero to Ustekinumab or Vedolizumab

Jonah Gorodensky[1], Sasha Bernatsky[1], Waqqas Afif[1], Yvan St-Pierre[2], Kristian Filion[1] and Evelyne Vinet[3], [1]McGill University, Montréal, QC, Canada, [2]Research Institute of the McGill University Health Centre, Montréal, QC, Canada, [3]McGill University Health Centre, Mont Royal, QC, Canada

SESSION INFORMATION
Session Date: Tuesday, November 9, 2021
Session Title: Reproductive Issues in Rheumatic Disorders Poster (1711–1731)
Session Type: Poster Session D
Session Time: 8:30AM–10:30AM

Background/Purpose: Ustekinumab, an IL-12/23 inhibitor, is indicated in adult patients with inflammatory bowel disease (IBD), psoriasis (PsO), and psoriatic arthritis (PsA) and vedolizumab, an $\alpha_4\beta_7$ receptor antagonist is indicated in IBD only. Both are monoclonal antibodies harbouring an Fc portion, which are actively transported across the placenta, often reaching higher fetal than maternal levels. As fetuses could be exposed to therapeutic or supra-therapeutic levels of these drugs, there are concerns that these agents could cause immunosuppression after birth. However, evidence is lacking.

We compared the risk of serious infections in offspring exposed to ustekinumab, vedolizumab, tumour necrosis factor inhibitors (TNFi), and non-biologic immunosupressives versus offspring unexposed during pregnancy among women with IBD, PsO and/or PsA.

Methods: We conducted a retrospective cohort study using the US MarketScan database, an employment insurance database. We included live births (01/2011-12/2018) among women with PsO, PsA, and/or IBD. Drug exposure was defined as ≥1 filled prescription or infusion procedure code during pregnancy. In offspring, we evaluated serious

infections within the first year of life as any single inpatient infection code. We performed multivariate analyses using logistic regression, adjusting for maternal age, co-morbidities, corticosteroid use, concomitant drug use, preterm birth and disease state.

Results: We included 16,115 offspring born to 7,612 women with PsO/PsA, 8,315 with IBD, and 188 with PsO/PsA and IBD. A total of 52 offspring were exposed to ustekinumab, 43 to vedolizumab (including 7 to both TNFi and vedolizumab),1,585 to TNFi, 1,857 to non-biologic immunosuppressives alone, and 12,585 unexposed to any drug. The percentage of serious infections in offspring exposed to ustekinumab was 3.8% (95% CI 0.4-13.9), versus 2.7% (95% CI 1.9-3.6) for TNFi, 2.3% (95% CI 0.4-12.0) for vedolizumab and 2.6 (95% CI 2.3-2.8) for those unexposed to any drug, though all estimates had wide, overlapping confidence intervals. Compared to children unexposed to any drug, there was a potential trend for increased risk with ustekinumab (OR 1.6, 0.4-6.8), but CIs were wide and included the null. For those exposed to vedolizumab (OR 0.9, 0.1-6.2) or TNFi (OR 1.0, 0.6-1.4) there was no clear excess risk.

Conclusion: In a large cohort, we did not detect a clear excess risk for offspring exposed in-utero to, vedolizumab or anti-TNF's, compared to unexposed patients; there was a signal for more events with ustekinumab, but confidence intervals were wide. Ongoing caution, as well as more research on short and long-term effects, is warranted for biologics actively transported across the placenta.

Abstract Number: 1714

Exploring the Sexual and Reproductive Health (SRH) Needs of Men with Rheumatic Diseases

Olivia Stransky[1], Nicole Hunt[2], John Richards[3] and **Mehret Birru Talabi**[1], [1]University of Pittsburgh, Pittsburgh, PA, [2]UPMC, Pittsburgh, PA, [3]Veterans Affairs Pittsburgh Healthcare System, Pittsburgh, PA

SESSION INFORMATION

Session Date: Tuesday, November 9, 2021
Session Title: Reproductive Issues in Rheumatic Disorders Poster (1711–1731)
Session Type: Poster Session D
Session Time: 8:30AM–10:30AM

Background/Purpose: Few studies have comprehensively evaluated the information needs and priorities that men with rheumatic diseases have about their sexual and reproductive health (SRH). This qualitative study sought to explore their SRH needs within the rheumatology context.

Methods: Men aged 18-45 years who were diagnosed with at least one rheumatic disease and used at least one disease-modifying anti-rheumatic drug or immunosuppressive medication were recruited from academic outpatient rheumatology clinics in western Pennsylvania. Research coordinators engaged participants in phone-based semi-structured qualitative interviews about their reproductive histories, parenting experience, perceptions of how their diseases and medications affected their SRH, and experiences of SRH-related clinical care. Interviews were audio-recorded and transcribed verbatim. Thematic saturation was reached after the twelfth interview, and additional interviews were conducted to verify that no new information emerged. Research coordinators developed a preliminary codebook based on the interview content. Using an inductive approach, two coders applied the codebook to the transcripts and adjudicated coding differences to full agreement. The finalized codebook was used to conduct a thematic analysis.

Results: The 18 participants ranged in age from 22 to 44 years old, and identified as Black (n=2), White (n=14), and Asian (n=2). The most common disease diagnoses were spondyloarthritis, systemic lupus erythematosus, and rheumatoid arthritis. Most men were married or in a heterosexual relationship; no men were in a same-sex relationship. Twelve men had at least one child, and six men had no children. Six participants were vasectomized— five of whom had the procedure prior to their disease diagnosis.

Four major themes were elicited from the interviews: 1) Men had family planning concerns, particularly related to the heritability of their diseases, their fertility, and potential effects of their medications on their offspring's health; 2) Men felt that fatigue, disability, and/or pain from their diseases either impaired or would impair their abilities to parent; 3) Men rarely discussed SRH with their rheumatologists, who they assumed would initiate the discussion if relevant to their health; 4) Men rarely discussed sexual dysfunction with their rheumatologists, even when they believed that it arose from their diseases or anti-rheumatic drugs.

Conclusion: In this study, men expressed a number of concerns related to their diseases, particularly the health and well-being of their children and physical challenges with parenting. Men rarely articulated these concerns to their rheumatologists, who, in turn, rarely initiated family planning conversations with them. Men who experienced sexual dysfunction generally implicated their diseases or medications as the cause but did not discuss this health issue with their rheumatologists. Our study found that some men's information needs are incompletely addressed in the current rheumatology clinical setting and suggests that rheumatologists may need to include SRH in their routine counseling and care of male patients.

Providing High Quality Family Care Planning for Women with Rheumatic Disease in Rheumatology Clinics: Perspectives of Rheumatology Clinicians

Daiva Mitchell[1], Leslie Lesoon[1], Cuoghi Edens[2], Traci Kazmerski[3], Olivia Stransky[4], Megan Clowse[5], Sonya Borrero[4] and Mehret Birru Talabi[4], [1]UPMC, Pittsburgh, PA, [2]University of Chicago, Chicago, IL, [3]Children's Hospital of Pittsburgh, Pittsburgh, PA, [4]University of Pittsburgh, Pittsburgh, PA, [5]Duke University, Chapel Hill, NC

SESSION INFORMATION
Session Date: Tuesday, November 9, 2021
Session Title: Reproductive Issues in Rheumatic Disorders Poster (1711–1731)
Session Type: Poster Session D
Session Time: 8:30AM–10:30AM

Background/Purpose: While rheumatologists in several descriptive studies have acknowledged the importance of family planning in their care of women with rheumatic diseases, they have also identified key barriers to this care, including time constraints, competing priorities, and inadequate communication with women's health providers. We conducted a series of focus groups composed of rheumatologists and rheumatology advanced practice providers (APPs) to synthesize their ideas for potential tools and solutions to overcome these barriers within the rheumatology clinical setting.

Methods: Semi-structured qualitative focus groups were conducted with rheumatologists (N=3 groups) and APPs (N=2 groups). Trained independent qualitative analysts conducted the focus groups via Zoom video conferencing. Discussions were transcribed and two trained research coordinators developed a content-based codebook. They

applied the codebook to transcripts, and discrepancies adjudicated to full agreement with the principal investigator. Differences in codes between the groups by provider type were also identified. The codes were synthesized and used to conduct a thematic analysis.

Results: A total of 22 clinicians participated in the study, most of whom were women (75%) working within academic practice settings (60%). Clinicians had practiced rheumatology for an average of six years (range 1-17 years). Four themes emerged from the focus groups: 1) Clinicians desired patient-directed tools and resources to educate and prepare patients to discuss reproductive health issues at the rheumatology visit; 2) Most clinicians were aware of existing reproductive health resources, but desired additional training or resources around contraception and medication safety; 3) Clinicians desired tools to facilitate contact with women's health providers to ensure early and uncomplicated access to reproductive health care (e.g., electronic consults); 4) Clinicians were less interested in using electronic health record (EHR) pop-up reminders or alerts to support family planning care, but more interested in using prepopulated text within the EHR to include in patient notes or educational information to add to patient visit summaries. Although similar ideas were generated between the APP and rheumatologist groups, the rheumatologists were generally more interested in additional training and education, whereas APPs were more interested in EHR prompts and tools.

Conclusion: In this study, rheumatologists and rheumatology APPs from primarily academic practice settings described tools and resources that could help them to provide more consistent and higher-quality family planning care to patients with childbearing potential. Future work should focus on the development of patient-facing tools and resources to prepare patients for family planning conversations with rheumatology clinicians. Additional educational resources are needed to address providers' knowledge gaps around contraception and medication safety in the context of pregnancy. Finally, individual health systems and practices need to prioritize the development of accessible pathways to reproductive health care for women with rheumatic disease.

Session Title: Reproductive Issues in Rheumatic Disorders Poster (1711–1731)

Session Type: Poster Session D

Session Time: 8:30AM–10:30AM

Background/Purpose: Systemic lupus erythematosus (SLE) primarily affects women of childbearing age, who have an increased risk of pregnancy complications such as preterm labor and preeclampsia, especially in the setting of active disease.[1] Contraception counseling is important in this population given the teratogenic nature of some med-

Table 1. Summary of characteristics of patients in the SLE cohort (N=478 women). Characteristics are divided into categories: demographics, counseling, immunosuppression, contraception, and pregnancy. Both number of women and percentages are reported. Unless otherwise specified, SD=standard deviation

ications used for treatment.[2] Our study describes the frequency of contraception counseling provided by multiple subspecialties to women with SLE, and investigates the associations between teratogenic medication use and receiving contraception counseling.

Methods: This was a retrospective cohort study following 478 women (aged 15-44) with an ICD diagnosis code of SLE over a 2-year period (6/2016-6/2018). Women were seen in outpatient subspecialty clinics in a large tertiary academic medical center. Those with a history of hysterectomy/bilateral oophorectomy were excluded. Demographic data was retrieved via the university-affiliated central data repository, and additional data, including documentation of contraception counseling, was obtained via manual chart abstraction. Univariable associations between categorical demographics or other clinical information and contraception counseling were assessed to produce unadjusted odds ratios and 95% confidence intervals (OR, 95% CI). T-tests were used to assess difference in age by contraception counseling.

Results: Data from 478 women (52% African American (AA), 25% Caucasian) with SLE were included **(Table 1)**. Rheumatology/immunology was the subspecialty to most frequently provide contraception counseling (57%). Nearly 80% of women received counseling from at least one subspecialty, 44% from at least two. Factors associated with receiving contraception counseling were younger age, AA race, and use of more than one immunosuppressive medication **(Table 2)**. Women on teratogenic medications (methotrexate (MTX), mycophenolate mofetil (MMF), or cyclophosphamide (CYC)) had higher odds of receiving contraception counseling from at least 1 subspecialty (OR, 2.01; 95% CI 1.23-3.26), from two or more subspecialties (OR, 2.18; 95% CI, 1.50-3.17), and from rheumatology/immunology (OR, 1.86; 95% CI, 1.27-2.73) **(Table 3)**.

Table 2. Description of odds ratios (OR) and 95% confidence intervals (95% CI) for the univariable associations of various factors (demographics, immunosuppression types and number of medications, APL antibody positivity, and contraception methods) and receiving contraception counseling. Overall counts and percentages provided. Unadjusted odds ratio with asymptotic confidence intervals are provided and shown in bold when the null effect is excluded at alpha= 0.05. For continuous age, mean +/- standard deviation (SD) are shown and t-test used to test the difference between the counseling groups using the pooled method assuming equal variances

OR>1 higher odds of contraception counseling defined; OR<1 lower odds of contraception counseling defined, compared to the reference (ref) group

Seventy-one women (15%) had a documented pregnancy outcome during the study period; of those, 25 (35%) had an adverse pregnancy outcome (spontaneous abortion, preterm delivery, or intra-uterine fetal demise).

Conclusion: In this study, women with SLE on teratogenic medications (MTX, MMF, CYC) had higher odds of receiving contraception counseling from their rheumatologist and from at least two subspecialties. Multidisciplinary approaches to enhance contraception counseling should be encouraged. Further investigation is needed to understand factors associated with adverse pregnancy outcomes in this high-risk patient population.

Abstract Number: 1717

One Year After the Publication of the American College of Rheumatology (ACR) Guidelines for Management of Reproductive Health in Rheumatic Diseases, Has Anything Changed? An Analysis of Rheumatology Practice at a Tertiary Care Medical Center

Yixuan Zhou[1] and Sobia Hassan[2], [1]Rush University Medical Center, Chicago, IL, [2]RUSH University, Chicago, IL

SESSION INFORMATION
Session Date: Tuesday, November 9, 2021
Session Title: Reproductive Issues in Rheumatic Disorders Poster (1711–1731)
Session Type: Poster Session D
Session Time: 8:30AM–10:30AM

Background/Purpose: Successful pregnancies in patients with rheumatic disease are possible when they are well-monitored, adequately treated, and planned during periods of disease quiescence. Previously, a lack of standardized guidelines and physician-patient discussions around reproductive health created risks for poorer outcomes. The ACR's reproductive guidelines include recommendations on contraception use, medication, and pregnancy with an emphasis on patients' inputs on pregnancy desires.[1] This study evaluates changes in rheumatologists' practice at an academic medical center following the publication of the ACR's reproductive guidelines.

Methods: Retrospective chart review was performed on reproductive age females (18 – 45 years) with ≥2 rheumatology office visits during the period of April 1st2019 to March 31st2021 and with the diagnoses of RA, SLE, and inflammatory arthritis (IA). The following data were collected: demographics, pre-pregnancy counseling, pregnancy wish, contraception usage via review of medication list or documentation, gynecology visit, and teratogenicity of medication. Generalized linear mixed models were used to evaluate for improvements in documentation regarding pre-pregnancy counseling/wish and contraception use, the year after the publication of the ACR guidelines (Period 2) compared to

Fetal Monitoring	14 (100.00)
Not Checked	11 (23.91)
Compliance with Rheumatology Visits (1 visit per Trimester)	14 (30.43)

** Routine assessment of patient index data 3 (RAPID3) is a patient reported outcome routinely used to assess disease activity and validated for use in multiple rheumatic conditions.

the year before (Period 1). For pregnant patients, additional data on aPL status, SSA/SSB, and pregnancy monitoring were collected and expressed as percentages depicting degree of compliance with the guidelines.

Results: Out of a total of 425 patients, 60 had undergone permanent birth control. Demographics for the remaining 319 non-pregnant women are shown in Table 1. There was a significant improvement in documentation related to pre-pregnancy counseling and discussion of pregnancy wish in Period 2 as compared to Period 1 as illustrated by the following odds ratios (OR): RA 3.33 [95% confidence interval (95% CI) 1.64-6.75], 3.27 [95% CI 1.62-6.61]; SLE 3.00 [95% CI 1.65-5.48], 2.34 [95% CI 1.29-4.26]; IA 3.53 [95% CI 1.39-8.95], 4.11 [95% CI 1.49-11.35], respectively. There were no improvements in areas of contraception use/documentation in all disease categories: patients on any contraceptive: 133 (51%) in Period 1 and 132 (55 %) in Period 2 (Table 2).

Of the 46 pregnant patients, all were followed by an obstetrician but only 14 (30 %) followed with their rheumatologist once per trimester. 15 patients (33%) presented to their rheumatology visit already pregnant and 16 (35%) conceived with high/moderate disease activity. Of the pregnant patients with positive SSA/SSB, all had adequate fetal monitoring but only half were on hydroxychloroquine (Table 3).

Conclusion: In the year following the publication of the ACR reproductive guidelines, there was improvement in documentation related to pre-pregnancy counseling and pregnancy wish. However, we identify ongoing practice gaps with regards to encouraging contraception use and aspects of pregnancy management.

Abstract Number: 1718

Use of Gonadotropin Releasing Hormone Agonist for Ovarian Preservation in SLE Patients on Cyclophosphamide

Jun Chu[1], Alice Fike[2], Michael Davis[3], Zerai Manna[4], Komal Ejaz[5], Yenealem Temesgen-Oyelakin[6], Elaine Poncio[7], Isabel Ochoa[7], Alan Decherney[4] and Sarfaraz Hasni[4], [1]National Institutes of Arthritis and Musculoskeletal and Skin Diseases (NIAMS), National Institutes of Health (NIH), Bethesda, MD, [2]National Institutes of Arthritis and Musculoskeletal and Skin Diseases (NIAMS), National Institutes of Health (NIH), Washington, DC, [3]NIAMS, Bethesda, MD, [4]National Institutes of Health, Bethesda, MD, [5]Sheikh Zayed Medical College, Scranton, PA, [6]National Institutes of Health (NIH), Bethesda, MD, [7]NIH/NIAMS, Bethesda, MD

SESSION INFORMATION

Session Date: Tuesday, November 9, 2021

Session Title: Reproductive Issues in Rheumatic Disorders Poster (1711–1731)

Session Type: Poster Session D

Session Time: 8:30AM–10:30AM

Background/Purpose: SLE is an autoimmune disease which predominantly affects women of childbearing age (age 20-40). Most of the medications used for treating SLE can adversely affect fertility, pregnancy, and fetal outcomes. Cyclophosphamide (CYC) is an immunosuppressive agent indicated for the treatment of severe SLE. The use of CYC cause ovarian insufficiency and lead to dormant primordial follicle activation and loss. Gonadotropin releasing hormone agonist (GnRHa) may preserve ovarian function by preventing early stage development of ovarian follicles from maturation. This may decrease the number of follicles that are vulnerable to chemotherapy.

There is conflicting data on whether GnRHa preserve ovarian function when given before cyclophosphamide. Furthermore, there are inconsistent guidelines from various professional societies regarding the administration of GnRHa for ovarian protection. We attempted to develop evidence-based practice guidelines for the use of GnRHa in SLE patients undergoing treatment with CYC.

Methods: We reviewed published literature on the use of GnRHa for ovarian protection by searching PubMed. The available evidence was discussed in multidisciplinary conferences for consensus building. The current guidelines

Table 1.

	2020 American College of Rheumatology Guideline for the Management of Reproductive Health in Rheumatic and Musculoskeletal Diseases	Fertility Preservation in Patients With Cancer: ASCO Clinical Practice Guideline Update
Year Released	2020	2018
Articles Reviewed	2 randomized double-blind trial, 1 case control study, 1 cross sectional study, 4 Retrospective review, 1 guideline	7 randomized controlled trials, 4 systematic review, 7 guidelines
Recommendation	To prevent inducing primary ovarian insufficiency in premenopausal women with RMD receiving monthly intravenous CYC, we conditionally recommend monthly gonadotropin-releasing hormone agonist co-therapy. This was based on evidence supporting benefits in early breast cancer, evidence more specific to rheumatic disease patients is less robust but positive.	It may be offered to patients in hope of reducing the likelihood of chemo induced ovarian insufficiency, but not be used in place of proven fertility preservation methods.

and alternate option for ovarian preservation were also reviewed. The final document for evidence-based practice guidelines will be developed in future.

Results: ACR guideline and American Society of Clinical Oncology (ASCO) conditionally recommends GnRHa to prevent ovarian insufficiency while on IV CYC (Table 1). Five research studies showed a protective effect of GnRHa on ovarian preservation (Table 2). An in vitro study using CYC showed no ovarian protection with GnRHa. The studies from use of GnRHa in patients with breast cancer showed conflicting results on its efficacy for ovarian preservation.

Conclusion: Most of the studies done in autoimmune diseases had a smaller cohort with no uniform criteria for defining ovarian insufficiency and preservation. Three studies were retrospective chart reviews which poses selection bias. The data from in-vitro study done with the removal of ovarian tissue was not replicated in clinical trials. In the breast cancer studies, patients were on several types of chemotherapy and the dose of CYC was much higher as compared to studies done in autoimmune diseases. Side effects of GnRHa mimic a hypo estrogen state. The alternate options for ovarian preservation involve surgical options with ovarian stimulation which could pose a risk of disease flare or thrombosis in SLE.

The evidence for the use of GnRHa for ovarian preservation while on CYC is not robust, but it is the least invasive procedure. A review of the evidence should be presented to the patient in a shared decision-making process and be evaluated by a multi-disciplinary team. The effectiveness and safety of GnRHa in SLE needs to be studied prospectively in a much larger population with well-defined outcome measures.

Abstract Number: 1719

Pandemic-Associated Complications in Pregnant Women with Rheumatic Diseases

Diana Johnson, Hiral Dave, Yunjun Luo and Christina Chambers, University of California San Diego, La Jolla, CA

SESSION INFORMATION
Session Date: Tuesday, November 9, 2021
Session Title: Reproductive Issues in Rheumatic Disorders Poster (1711–1731)
Session Type: Poster Session D
Session Time: 8:30AM–10:30AM

Background/Purpose: Pregnant women with rheumatic diseases may have been particularly vulnerable to the various consequences of the current pandemic, whether or not they were infected with SARS-CoV-2. Some of these consequences include increased stress, anxiety and depression, substance use, and reduced compliance with prenatal care, all of which could negatively impact pregnancy outcome. In addition, comorbidities may present increased risk of infection in women with underlying rheumatic diseases.

Methods: As part of the ongoing OTIS/MotherToBaby Autoimmune Diseases in Pregnancy Project, between February, 2017, and February, 2021, 382 pregnant women with rheumatic diseases were enrolled. The study assessed comorbidities, administered standardized measures of stress (PSS-10), anxiety (STAI state and trait) and depression (EPDS) mid-gestation or at enrollment if later than mid-gestation, captured maternal report of recreational substances used anytime in pregnancy, as well as compliance with routine prenatal care procedures such as ultrasound scans for

Table. Characteristics of pregnant women with rheumatic diseases before and during the SARS-CoV-2 pandemic

Measure	Rheumatic Diseases Pandemic Year COVID-19 Positive N = 25	Rheumatic Diseases Pandemic Year Not COVID-19 Positive N = 96	Rheumatic Diseases Pre-pandemic Period N = 261	p-value[a]
PSS-10 Stress Screen Positive Moderate to Severe (≥14)	75.0%	56.9%	50.0%	0.218
STAI Anxiety – State Screen Positive (>45)	33.3%	31.6%	14.8%	0.019
STAI Anxiety – Trait Screen Positive (>45)	25.0%	29.8%	14.8%	0.056
EPDS Depression Screen Positive (≥10)	41.7%	33.3%	21.8%	0.122
Ultrasound for Structure – Mid-Gestation	75.0%	75.6%	90.3%	0.001
Screening for Gestational Diabetes	77.7%	69.0%	88.5%	0.001
Any Alcohol Use in Pregnancy	60.0%	42.7%	44.1%	0.278
Comorbidities				
Asthma	28.0%	15.6%	13.0%	0.130
Pre-Pregnancy Body Mass Index ≥30	52.0%	27.1%	23.4%	0.005
Psychiatric Diagnosis	56.0%	36.5%	33.0%	0.068

[a]Chi-squared test for categorical variables or Fisher's Exact Test where expected cell number <5.

structure and screening for gestational diabetes. From the onset of the pandemic, COVID-19 test positive status at any time in pregnancy was assessed. Those enrolled in the pre-pandemic period (N = 261) were compared to those enrolled in the pandemic year (N = 121), stratified by COVID-19 test positivity in pregnancy.

Results: As shown in the Table, compared to the pre-pandemic period, pregnant women with rheumatic diseases were more likely to screen positive on state or trait anxiety. Screening positive on stress or depression was more common in those women who were infected compared to other groups, but not significantly so. Similarly, alcohol use was increased only among those with rheumatic diseases in the pandemic year who tested positive for COVID-19 in pregnancy. Pregnant women with rheumatic diseases who had a pre-pregnancy body mass index in the obese range (≥30) were significantly more likely to test positive for the virus in the pandemic year.

Conclusion: These data suggest that pregnant women with rheumatic diseases were particularly vulnerable during the pandemic year to complications that could influence pregnancy outcome.

Abstract Number: 1720

Cervical Dysplasia and HPV Infection in Women with Vasculitis

Taylor Koenig[1], Ambra Burrell[2], Hilary Kleppel[3], Ashlee Weaver[4], Veronica Mruk[5], Lynn Fussner[1], Salem Almaani[6] and Alexa Meara[1], [1]Ohio State University Wexner Medical Center, Columbus, OH, [2]Division of Rheumatology, The Ohio State University Wexner Medical Center, Columbus, OH, [3]Wright State University, Blacklick, OH, [4]Ohio State University College of Medicine, Columbus, OH, [5]Ohio State University / Nationwide Children's Hospital, Columbus, OH, [6]Ohio State University Medical Center, Columbus, OH

SESSION INFORMATION
Session Date: Tuesday, November 9, 2021
Session Title: Reproductive Issues in Rheumatic Disorders Poster (1711–1731)
Session Type: Poster Session D
Session Time: 8:30AM–10:30AM

Background/Purpose: The most common cause of cervical cancer is persistent human papillomavirus (HPV) infection in the cervical epithelium, causing precancerous cervical dysplasia and ultimately cervical cancer in a complex oncogenic pathway. HPV is commonly cleared by the immune system; however, an impaired immune system can facilitate the persistence of HPV infection in the cervix leading to increased risk of progression to cervical dysplasia and cancer. Women with autoimmune diseases have impaired immune systems through the presence of both rheumatic disease and immunosuppressive medications, and increased rates of cervical dysplasia have been reported in women with systemic lupus erythematous and rheumatoid arthritis. However, women with systemic vasculitis have not been included in these analyses. This study aims to fill this gap and evaluate the risk of cervical dysplasia in the female vasculitis population.

Methods: We performed a retrospective chart review of the women with vasculitis at The Ohio State University Wexner Medical Center. Criteria for inclusion included: female, diagnosis of vasculitis, documented Papanicolau (Pap) smear after date of vasculitis diagnosis and in years 2010-2019.

Results: We identified 119 patients for inclusion in this study. Of the 254 total Pap smears, 44 pap smears (17% of 254) in the 119 patients had abnormal results. Of the 254 Pap smears analyzed, 26 pap smears (10%) in 16 patients showed Atypical Squamous Cells of Undetermined Significance (ASC-US), 15 (6%) in 10 patients had Low-Grade Squamous Intraepithelial Lesion (LSIL), and 1 each resulted with Atypical Squamous Cells-Cannot Rule Out High Grade Squamous Intraepithelial Lesion, High-Grade Squamous Intraepithelial Lesion, and Squamous Cell Carcinoma. Additionally, 112 of the Pap smears were also tested for high-risk HPV, and nearly 20% (21 Pap smears in 85 patients) tested positive for this.

Conclusion: Out study show insights into the prevalence of cervical dysplasia and HPV infection in the female vasculitis population. The United States incidence of abnormal Pap smears is 4% with 2.8% resulting as ASC-US and 0.97% as LSIL; we found more than quadruple the rate of ASCUS and six-fold the rate of LSIL in our study population. We found a higher rate of high-risk HPV-positive pap smears in our vasculitis patient population compared to the 11% reports for SLE patients in prior studies. These elevated rates of cervical abnormalities should be considered for cervical cancer screening recommendations in this population.

Abstract Number: 1721

A Womb with Rheum: Women's Health Providers' Confidence and Educational Needs in the Care of Those with Rheumatic Diseases

Lauren He, Rachel Karani, Gabriel Arenas and Cuoghi Edens, University of Chicago, Chicago, IL

SESSION INFORMATION
Session Date: Tuesday, November 9, 2021
Session Title: Reproductive Issues in Rheumatic Disorders Poster (1711–1731)
Session Type: Poster Session D
Session Time: 8:30AM–10:30AM

Background/Purpose: Reproductive age women with rheumatic diseases are commonly cared for by non-rheumatologists who provide contraceptive counseling, preconception, pregnancy, and post-partum management. When women's health and rheumatology providers disagree, patients voice frustration and provider distrust. The education received by women's health providers pertaining to the recognition and management of rheumatic diseases in child-bearing age patients is not well-defined. This study aims to assess knowledge gaps, specify aspects of care with greatest uncertainty, and assess current resources used by women's health providers regarding their clinical management in those with rheumatic diseases.

Methods: An electronic survey was distributed nationally to physicians and allied health professionals who care for reproductive age women and are trained in Obstetrics and Gynecology (OBGYN), Internal Medicine, or Family Med-

Smartphone App	64 (61%)

icine. The survey consisted of three sections: 1) patients presenting with new rheumatic diseases, 2) contraception, and 3) preconception/antepartum medication management. Participants were also asked about resource utilization. Survey questions and scenarios were based on the ACR Guidelines for the Management of Reproductive Health in Rheumatic and Musculoskeletal Diseases and relevant American College of Obstetrics and Gynecology (ACOG) Committee Opinions. Responses and confidence ratings were captured using RedCap and analyzed using descriptive statistics.

Results: The survey was completed by 104 participants, majority being academic OBGYN generalists. (Table 1). Respondents performed the poorest in recognizing new rheumatic disease presentations including RA and SLE in patients presenting with post-partum joint pain or proteinuria and thrombocytopenia in pregnancy, respectively (Figure 1). The least confidence was reported when answering medication management questions. Contraception was the area of highest performance and confidence, although areas for contraceptive knowledge expansion exist. Most participants chose to discontinue medications in a pregnant patient with RA, despite these being deemed pregnancy-compatible by ACR guidelines and ACOG Committee Opinion. However, when counseling the same patient post-partum, 72% of respondents successfully chose the breastfeeding-compatible therapies.

Most respondents had no prior exposure to the reproductive health issues facing female patients with rheumatic diseases (Table 2), identified consultants as their main resource used in clinical practice, and would prefer more information to be provided as a website, published guidelines, or Smartphone App.

Conclusion: Women's health providers lack confidence, educational opportunities, and therefore knowledge across the spectrum of common clinical scenarios and management questions facing reproductive-aged women with rheumatic diseases. Recognizing new disease presentations and antepartum medication management have the largest educational needs. Collaborative resources created by women's health and rheumatology societies, including websites and smart phone apps, are most desired to fill educational needs and hopefully will improve patient care.

Session Date: Tuesday, November 9, 2021

Session Title: Reproductive Issues in Rheumatic Disorders Poster (1711–1731)

Session Type: Poster Session D

Session Time: 8:30AM–10:30AM

Background/Purpose: Pre-eclampsia is a pregnancy-related syndrome with potentially fatal outcomes. In RA, high disease activity has been associated to adverse pregnancy outcomes such as preterm birth and low birth weight. The risk of pre-eclampsia in relation to disease activity and anti-rheumatic treatment in women with chronic inflammatory arthritis has not been assessed. The objective of this study was to evaluate the overall risk of pre-eclampsia in pregnant women with RA, Axial (Ax)SpA, and PsA and to assess the impact of disease activity and anti-rheumatic treatment.

Table 1

Risk of preeclampsia in pregnant women with RA, AxSpA, and PsA overall and in relation to anti-rheumatic treatment strategy **pre-pregnancy**

Only singleton pregnancies. One woman may contribute with one or more pregnancies. ORs were estimated using logistic regression and generalized estimation-equation method. 1) Matched 1:10 on maternal age group, parity, and year, 2) DAS28-CRP was calculated including CRP and without Global Health-Visual Analog Scale (VAS) 3) No measurements of either DAS28-CRP, HAQ, or CRP 4)No measurements of neither HAQ, nor CRP, 5) Adjusted for maternal age, parity, year, country, BMI group, smoking, and educational level. Abbreviations: AxSpA, Axial SpA; BMI, Body Mass Index; CI, Confidence Interval; DAS28-CRP, 28-joint DAS, CRP adjusted; NA, Not Applicable; OR, Odds Ratio.

Methods: We conducted a register-based matched cohort study using data from Swedish and Danish nationwide clinical and health registers. We identified RA, AxSpA, and PsA singleton pregnancies (2006-2018) by linking medical birth registers (MBR) to rheumatology registers in Sweden (SRQ) and Denmark (DANBIO). Control pregnancies from the MBRs were matched 1:10 on age, birth year, and parity.

We obtained information on anti-rheumatic treatment nine months before (pre-pregnancy) and during pregnancy, and disease activity (DAS28-CRP/HAQ/CRP) during pregnancy. Information on pre-eclampsia was obtained from the National Patient Registers. The risk of pre-eclampsia was estimated using logistic regression and presented by odds ratios (aOR) with 95% confidence intervals (CI). Adjustments were made for maternal age, parity, year, country, BMI, smoking, and educational level.

Results: We identified 1739 RA, 819 AxSpA, and 489 PsA pregnancies. For RA and AxSpA pregnancies, there were no major differences in maternal characteristics compared to their control pregnancies. Pregnant women with PsA were more likely to be obese, smokers, and less educated compared to their controls.

We found an overall increased risk of pre-eclampsia in PsA pregnancies as compared to control pregnancies (aOR 1.85; 95% CI 1.10, 3.12), whereas the risk was not increased in RA or AxSpA (**Table 1**). Women with RA receiving pre-pregnancy combination therapy (conventional synthetic (cs)DMARD, biologic (b)DMARD, and CS in any combination of at least two) had a moderately increased risk compared to controls, whereas no treatment or monotherapy (csDMARD, bDMARD, or CS) did not increase the risk (**Table 1**). For PsA, pre-pregnancy monotherapy was associated with pre-eclampsia (**Table 1**). We observed no significantly increased risk of pre-eclampsia for any of the disease groups when stratifying on treatment during pregnancy.

Among RA exposed pregnancies with available information on disease activity during pregnancy (n=756, 43%), we observed a doubled risk of pre-eclampsia associated with high disease activity compared to control pregnancies (**Table 2**). In AxSpA and PsA, we found no such association, but numbers of events were low (**Table 2**).

Conclusion: Pregnant women with PsA, but not AxSpA, are at increased risk of pre-eclampsia overall. For RA pregnancies, our results indicate that severe disease, i.e. combination treatment before pregnancy and high disease activity during pregnancy, is a risk factor for pre-eclampsia.

Abstract Number: 1723

Factors Associated with Postpartum Flare in Women with Lupus

Anitha Ramu[1], Maedeh Veyseh[1], Brianna Lally[2], Shudan Wang[3] and Anna Broder[4], [1]Jacobi Medical Center/Albert Einstein College of Medicine, Bronx, NY, [2]Albert Einstein College of Medicine, Bronx, NY, [3]Albert Einstein College of Medicine/Montefiore Medical Center, New York, NY, [4]Albert Einstein College of Medicine/Montefiore Medical Center, Bronx, NY

SESSION INFORMATION

Session Date: Tuesday, November 9, 2021
Session Title: Reproductive Issues in Rheumatic Disorders Poster (1711–1731)
Session Type: Poster Session D
Session Time: 8:30AM–10:30AM

Background/Purpose: Several prior studies have assessed disease activity in the setting of pregnancy and have shown that certain factors such as thrombocytopenia, systemic lupus erythematosus (SLE) disease activity at pregnancy onset, lupus nephritis, hypertension, antiphospholipid syndrome, and history of preeclampsia are associated with higher rates of SLE flare in pregnancy (1). However, few have focused on the postpartum period and have shown varying results. While some studies showed an increase in flares in the postpartum period (2-4), others showed no flares in the postpartum period (5). The objective of this study was to identify factors associated with the occurrence

of SLE flares in the 6-month postpartum period. Identifying these factors is important for stratifying and monitoring lupus patients in the postpartum period.

Methods: Lupus pregnancies were retrospectively identified via chart review at a tertiary care center in New York from 2005 – 2020. Flares in the 6-month postpartum period were physician reported, as documented in the patient chart by the treating rheumatologist, or identified by an escalation in medication regimen.

Results: Of the 103 lupus pregnancies reviewed, 73 pregnancies had documented follow up in the 6-month postpartum period, of which 20 (27%) were identified to have had SLE flares. This sample was representative of the overall population of pregnant women at our center. The median (IQR) age of the patient population was 29 (24, 34) years old. Thirty-eight (52%) patients self-identified as Hispanic or Latina, 25 (34%) as Black or African American, 5 (7%) as Asian and 5 (7%) as Caucasian (Table). Patients with postpartum flare were more likely to have history of thrombosis (40% vs 14%, p=0.02), lupus nephritis (60%, vs 20%, p=0.001), and SLE flare in the 6 months prior to conception (40% vs 12%, p=0.007) when compared to those without flare. Women who experience postpartum flares were younger (median IQR) [25 (22, 30) years old vs 31 (25, 35) years old, p=0.003] and more likely to have fewer than 3 total pregnancies (80% vs 57%, p=0.07). The median (IQR) SLEPDAI score amongst those with postpartum flare was higher in comparison to those without [2 (0, 4) vs 0 (0, 2), respectively, (p=0.06)]. Pre-pregnancy flares were associated with postpartum flares

even after adjusting for SLEPDAI during pregnancy (OR 4.4, CI 1.15-16.81, p=0.03). Ethnicity, adverse pregnancy outcomes, pregnancy morbidity, and planned vs unplanned pregnancy were not associated with postpartum flare.

Conclusion: This study shows that younger women with fewer total pregnancies, history of thrombosis, lupus nephritis, and active disease prior to conception should be closely monitored for postpartum flare. Patients with these characteristics can be risk stratified and should be counseled appropriately to monitor for signs of flare in the postpartum period.

SESSION INFORMATION

Session Date: Tuesday, November 9, 2021

Session Title: Reproductive Issues in Rheumatic Disorders Poster (1711–1731)

Session Type: Poster Session D

Session Time: 8:30AM–10:30AM

Background/Purpose: Women with chronic rheumatic inflammatory diseases (CRID, i.e. rheumatoid arthritis (RA) or spondyloarthritis (SpA)) have been reported to have poorer pregnancy outcomes than the general population. The objective of this analysis was to describe the singleton pregnancy outcomes of women with CRID in France over the past decade.

Methods: This is a retrospective cohort study within the French Healthcare database (SNDS), which covers 97% of the French population. Adult women were included if they had RA or SpA according to CIM-10 codes, had started a singleton pregnancy between 2008 and 2017 (index date), and were continuously covered by this health insurance from 1-year before pregnancy onset to 1-year after end of the pregnancy or death (whichever came first). Both maternal and pregnancy outcomes were considered. Outcomes were identified either by ICM-10 codes or hospital discharge summaries between 2008 and 2018.

Results: Among the 35,737 adult women with a CRID (40.7% with RA and 59.3% with SpA) and a past history of DMARD reimbursement, 11,274 (41.7%) started a singleton pregnancy during the study period. Among them, 6,501 (57.7%) were exposed to at least one DMARD preconceptionally (6 months before last menstrual period) and during pregnancy.

Mean (SD) age of women at the start of pregnancy was 32 (5) years, and disease duration was 4 (4) years. Live-birth represented by far the most frequent pregnancy outcome (76.9%), but 56.6% patients presented at least one unfavorable outcome among those listed in the table.

Conclusion: More than 75% pregnancies in patients with CRID resulted in a live-birth, but half of patients presented at least an unfavorable pregnancy outcome. Prevalence of miscarriage was lower than reported in the literature, probably reflecting the fact that very early miscarriages often do not need hospitalization/ specific intervention, and thus are difficult to identify in claims databases. Maternal and infant outcomes seemed comparable to general population. Whether medications had an impact on such outcomes needs further evaluation.

	Unfavourable outcome	N(%)
Pregnancy outcomes	Miscarriage	590 (5.2%)
	Medical termination	97 (0.9%)
	Extra-uterine pregnancy	165 (1.5%)
	Other abortions*	48 (0.4%)
	Stillbirth	48 (0.4%)
	Intrauterine growth restriction	348 (3.1%)
	Low birth weight (<3th percentile)	135 (1.2%)
	Pre-term birth (<37 WG)	3366 (29.9%)
	Eclampsia/Pre-eclampsia	214 (1.9%)
	Perinatal death	2 (0.0%)
	Cesarean section	2304 (20.4%)
Maternal outcomes	Severe maternal infection	225 (2.0%)
	Maternal mortality	2 (0.0%)
	Gestational diabetes	853 (7.6%)
Infant outcomes	NCIU admission for more than 48h in infants born after 37 WG	95 (0.8%)
	Major congenital malformation	287 (2.5%)
	Severe infections during the first year of life	603 (5.3%)

Higher Prevalence of Aspirin Use with a Specific Educational Tool in SLE Pregnancies: Preliminary Results

Joo Young (Esther) Lee[1], Arielle Mendel[2], Isabelle Malhamé[2], Sasha Bernatsky[1] and Evelyne Vinet[3], [1]McGill University, Montréal, QC, Canada, [2]McGill University Health Centre, Montréal, QC, Canada, [3]McGill University Health Centre, Mont Royal, QC, Canada

SESSION INFORMATION
Session Date: Tuesday, November 9, 2021
Session Title: Reproductive Issues in Rheumatic Disorders Poster (1711–1731)
Session Type: Poster Session D
Session Time: 8:30AM–10:30AM

Background/Purpose: Pregnant women with SLE are at substantial risk of preeclampsia. Best international practice guidelines recommend aspirin (ASA) in this population, as it reduces preeclampsia risk by more than 50% in high-risk women. However, recent evidence suggests that only 25% of pregnant SLE women use ASA. It is therefore imperative to understand ASA use patterns in SLE pregnancies to promote ASA adherence. With this objective, we are conducting the PREPARE (PREeclamPsia knowledge & Aspirin adheRence in lupus prEgnancies) trial, a randomized controlled trial, evaluating a specifically-designed educational tool. In this analysis, we aimed to assess ASA use, adherence, and dosage at baseline and 2nd study visits according to the intervention status.

Methods: Since 2018, we are recruiting consecutive pregnant SLE women (diagnosed according to the SLICC criteria) until the 16th gestational week at 5 Canadian centers. Participants are randomly assigned to receive the educational tool (intervention) or standard of care (control). At baseline (i.e. 1st trimester) and 2nd visits (i.e. 2nd trimester, 20-24 weeks, for ongoing pregnancies or 4-8 weeks after end of pregnancy for women who miscarried), the participants complete self-reported ASA adherence questionnaires and the modified Adherence to Refills and Medications Scale (ARMS), scored out of 44 (lower score meaning better adherence). We defined the participants 'ASA users' if they were using ASA in ongoing pregnancies or if they had used ASA but had a miscarriage. Current analysis includes participants enrolled at the coordinating center (accounting for nearly half of the total planned sample size). We measured the proportion of ASA users, mean ARMS scores, and dosage at both visits. We estimated a 95% CI for difference in proportion of ASA users between the groups using the Wilson procedure and mean ARMS score difference between the groups using the Student's t test.

Results: Thirty-three participants were included, 16 exposed to the intervention and 17 controls. Baseline characteristics were well-balanced with mean age of 32.2 years (standard deviation, SD, 4.6) in the intervention and 34.1 years (SD, 4.2) in the control group, and an identical proportion of participants who had post-secondary education (i.e. 80%) (**Table 1**). Baseline mean gestational age was 61.6 days (SD, 19.4) and 61.2 days (SD, 21.4) and baseline ASA use prevalence was 56% and 41% in the intervention and control group, respectively. Proportion of ASA users at the 2nd visit was 100% in the intervention and 82% in the control group, with a difference of 18% (95% CI -5, 41). At the 2nd visit, mean ARMS score was not different in the intervention (12.4 points) and control (12.2 points) groups [difference of 0.3 points (95% CI -0.8, 1.3)]. Among ASA users at the 2nd visit, 6% and 14% used 80-81mg, and 75% and 71% used 160-162mg in the intervention and control group, respectively.

Conclusion: Halfway into the trial, we observed a trend for higher ASA use in pregnant SLE women who received a specifically-designed educational tool compared to those receiving standard of care. The PREPARE trial is on track to provide a new evidence-based approach to optimize aspirin use and potentially improve outcomes in this population.

Table 1. Baseline characteristics in the study population

	Intervention (n=16)	Control (n=17)

Session Date: Tuesday, November 9, 2021

Session Title: Reproductive Issues in Rheumatic Disorders Poster (1711–1731)

Session Type: Poster Session D

Session Time: 8:30AM–10:30AM

Background/Purpose: The safest pregnancies for women with SLE coincide with periods of disease quiescence maintained by pregnancy-compatible medications. In the US, Black women are more likely to experience unplanned pregnancy and experience higher rates of maternal and infant morbidity, possibly due to inequitable provider-patient planning discussions. The HOP-STEP Pregnancy Planning handout, which is aligned with the ACR Reproductive Health Guidelines, was created to facilitate pregnancy planning discussions between rheumatologists and their SLE patients. We have assessed the systematic ascertainment of pregnancy interest and pregnancy planning discussions in a lupus clinic to identify its impact on pregnancy planning quality and equitable care.

Methods: All women age 18-44 in a prospective registry who met ACR or SLICC criteria for SLE completed an intake form for each visit which included 1) whether she wanted to get pregnant in the next year and 2) contraceptive use. A woman was identified as 'not medically ready for pregnancy' if she was on a teratogen, had proteinuria ≥ 500 mg or a physician's global assessment (PGA) ≥ 1.5. Race was self-reported. We identified 10 Pregnancy-Planning Quality (PPQ) Measures, awarding one-point for each measure. If a woman interested in pregnancy was seen multiple times between 2/2018-12/2019, her score accounted for the accrual of points over subsequent visits.

Results: Pregnancy interest was reported by 26 of 152 (17%) women. Of those interested in pregnancy, the average age was 32.7 years (SD 5.5); 65% identified as Black and 15% as Hispanic. Fifteen patients (58%; 10 Black, 5 non-

Pregnancy Planning Quality Score (0-10) Mean (SD)	7.3 (1.6)	7.4 (1.4)	7.2 (1.8)	0.7

Footnote: Fifteen patients were not medically ready for pregnancy at any visit with 10 taking a teratogen. Two women on a teratogen were able to switch to pregnancy-compatible medications during this period making them ready for pregnancy.

[1] The HOP-STEP Pregnancy Planning handout is free to use and available at LupusPregnancy.org, created in an Independent Medical Education grant from GSK.

Black) were not medically ready for pregnancy across visits, with 10 taking a teratogen, 4 with proteinuria, and 7 with a PGA ≥ 1.5. Two women on teratogens were able to switch to pregnancy-compatible medications during this period.

There were no differences in PPQ Scores between Black (7.2) and non-Black (7.4) patients (Table 1). All but one visit included a discussion of pregnancy planning, and the majority of women were given instructions to continue their appropriate medications in pregnancy.

As of 4/2021, 10 women had 12 pregnancies in the follow-up period; 9 (75%) of these were planned and occurred when the patient was medically ready to conceive. One was unplanned and conceived in the midst of a severe cutaneous flare; two were conceived by the same woman when she was taking MMF. Five women had not conceived due to ongoing teratogen use or disease activity. Seven women no longer desired pregnancy due to personal, non-medical reasons.

Conclusion: This study demonstrates that systematic, patient-reported measures of pregnancy interest and proactive pregnancy planning are feasible in an academic specialty clinic. More than half of all women were not medically ready for a safe pregnancy. The risks of poor pregnancy outcomes can be mitigated by addressing plans for pregnancy. Within our study population the majority of pregnancies were planned. The non-pregnant patients cite social issues, medications, and ongoing disease as reasons to not pursue pregnancy. This method shows promise for improving current clinic protocols regarding pregnancy planning.

SESSION INFORMATION

Session Date: Tuesday, November 9, 2021

Session Title: Reproductive Issues in Rheumatic Disorders Poster (1711–1731)

Session Type: Poster Session D

Session Time: 8:30AM–10:30AM

Background/Purpose: Behcet's disease is a systemic inflammatory disease which commonly presents with episodes of acute inflammation, oral and genital ulcers, uveitis and skin lesions. It presents most commonly during the second and third decades of life, therefore frequently involves women during their reproductive years. The objective of our work was to determine the effect of Behcet's disease on pregnancy by evaluating the prevalence of fetal and maternal complications through systematic review and meta-analysis.

Methods: We performed a systematic review of the literature using Medline, Web of Science, and the Cochrane library from their inceptions until March 26, 2021. Studies were included if they presented the frequency of complications in

cohorts of pregnant patients with a diagnosis of Behcet's disease. Studies were selected by two independent reviewers and statistics were performed using REVMAN5.4.

Results: 6638 studies were identified of which 16 were included. Among patients' with Behcet's disease during pregnancy the prevalence of caesarean section was 23% (CI 10-36% , Figure 1), pre-term birth 11% (CI 8-15%, Figure 2), miscarriage 11% (CI 8-14%), pre-eclampsia 4% (CI 3-6%), intrauterine death 4% (CI 2-7%), new hypertension

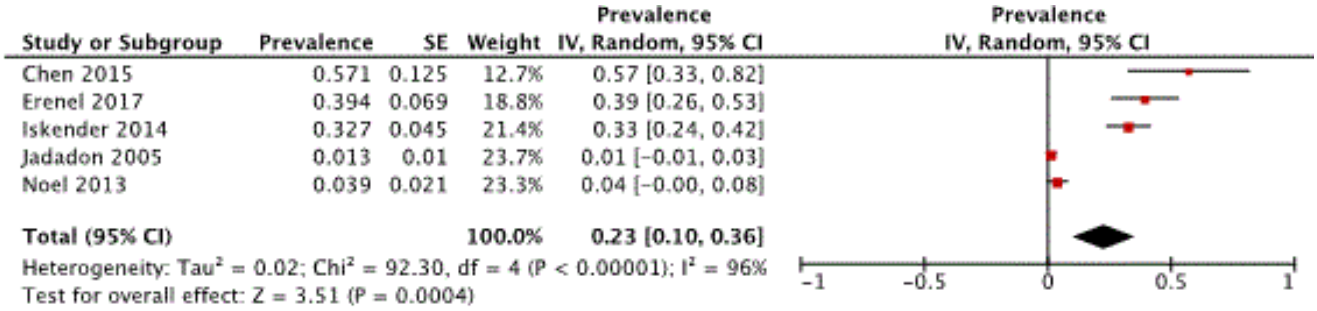

Figure 1. forest plot analysis of cesarian sections in patients with Behcet's disease

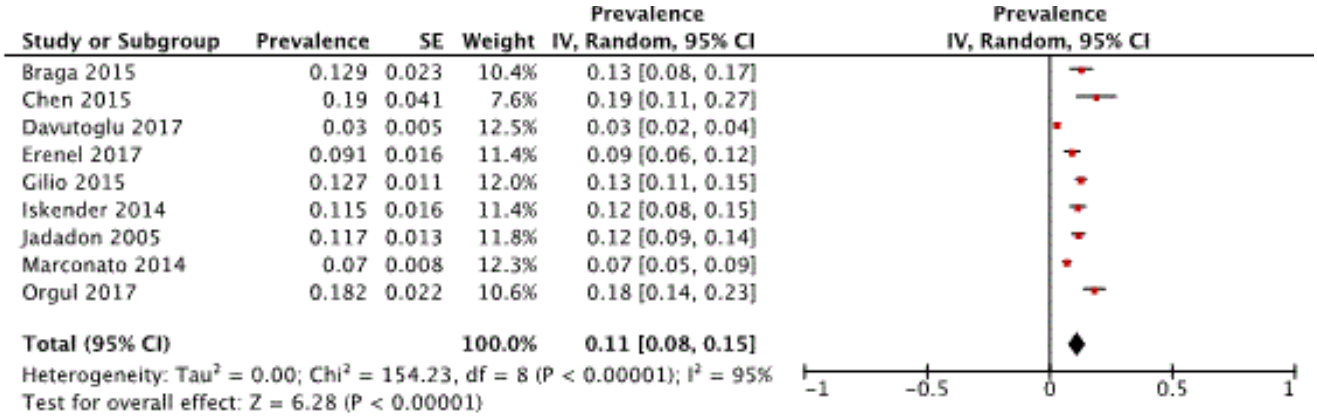

Figure 2. forest plot analysis of pre-term birth in patients with Behcet's disease

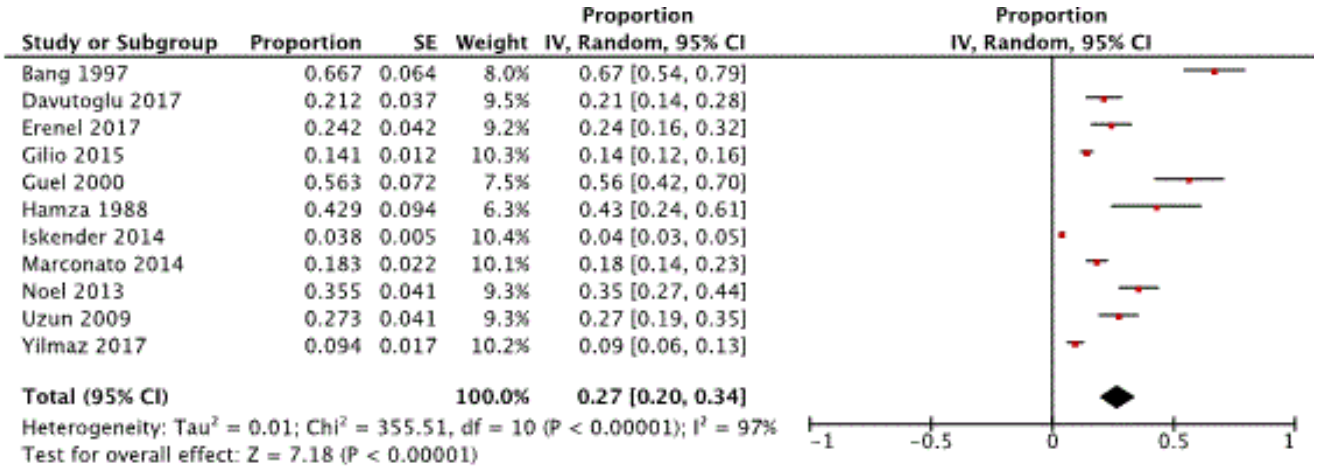

Figure 3. forest plot analysis of pre-term birth in patients with Behcet's disease

6% (2-10%) and 27% of women reported worsening of symptoms related to Behcet's disease during pregnancy (CI 20-34 , Figure 3).

Conclusion: Approximately one quarter of patients experienced worsening of symptoms related to Behcet's disease during pregnancy, 1 in 10 had a pre-term delivery and almost 1 in 4 delivered their baby by caesarean section. These results show the importance of close monitoring of patients with Behcet's disease during pregnancy – both for pregnancy complications and for worsening Behcet's symptoms.

SESSION INFORMATION

Session Date: Tuesday, November 9, 2021

Session Title: Reproductive Issues in Rheumatic Disorders Poster (1711–1731)

Session Type: Poster Session D

Session Time: 8:30AM–10:30AM

Background/Purpose: Takayasu's arteritis is a systemic autoimmune disease characterised by large vessel vasculitis. It usually affects women of childbearing age, with 90% of patients diagnosed < 30 years of age, and previous

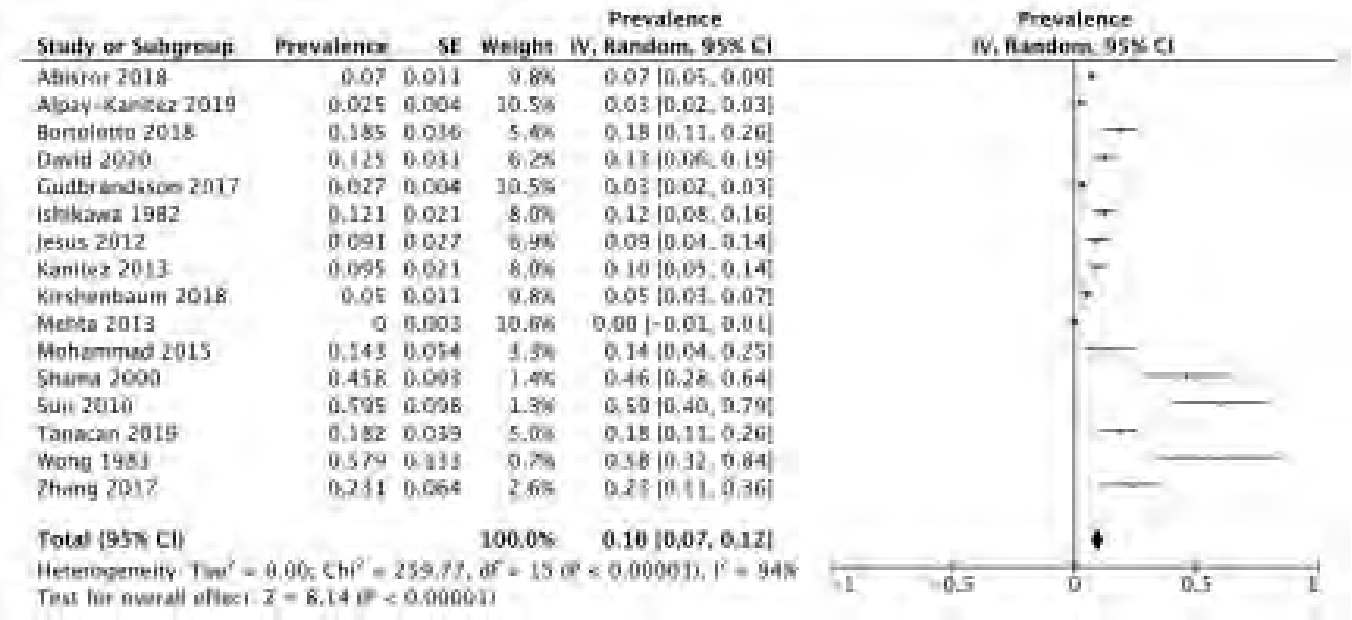

Figure 1. Prevalence of preeclampsia in Takayasu's arteritis patients.

studies suggest it is associated with adverse pregnancy outcomes. There is a vast discrepancy within the literature; some studies suggest preeclampsia occurring in 4.5% of patients, while others suggest a rate of 61%. The purpose of our work was to determine the prevalence of both maternal and fetal outcomes in patients with Takayasu's arteritis through a systematic review and meta-analysis.

Methods: We performed a systematic review of the literature using Medline, Web of Science, and the Cochrane library from their inceptions until March 26, 2021, to identify studies that reported pregnancy outcomes in patients with Takayasu's arteritis. Demographic information, maternal outcomes, foetal outcomes, prednisolone use, and information on disease activity were extracted from studies. Two authors independently selected the studies, extracted the data and assessed for risk of bias.

Results: Our systematic review identified 6638 abstracts, of which 23 articles were included. The miscarriage rate was 11 [7-16] % and an intrauterine death rate of 1[0-3] %. Preeclampsia was reported in 10[7-12] % of patients (Figure 1). Preterm delivery occurred in 15[12-19] %. New hypertension in pregnancy was reported in 12[8-16] %.

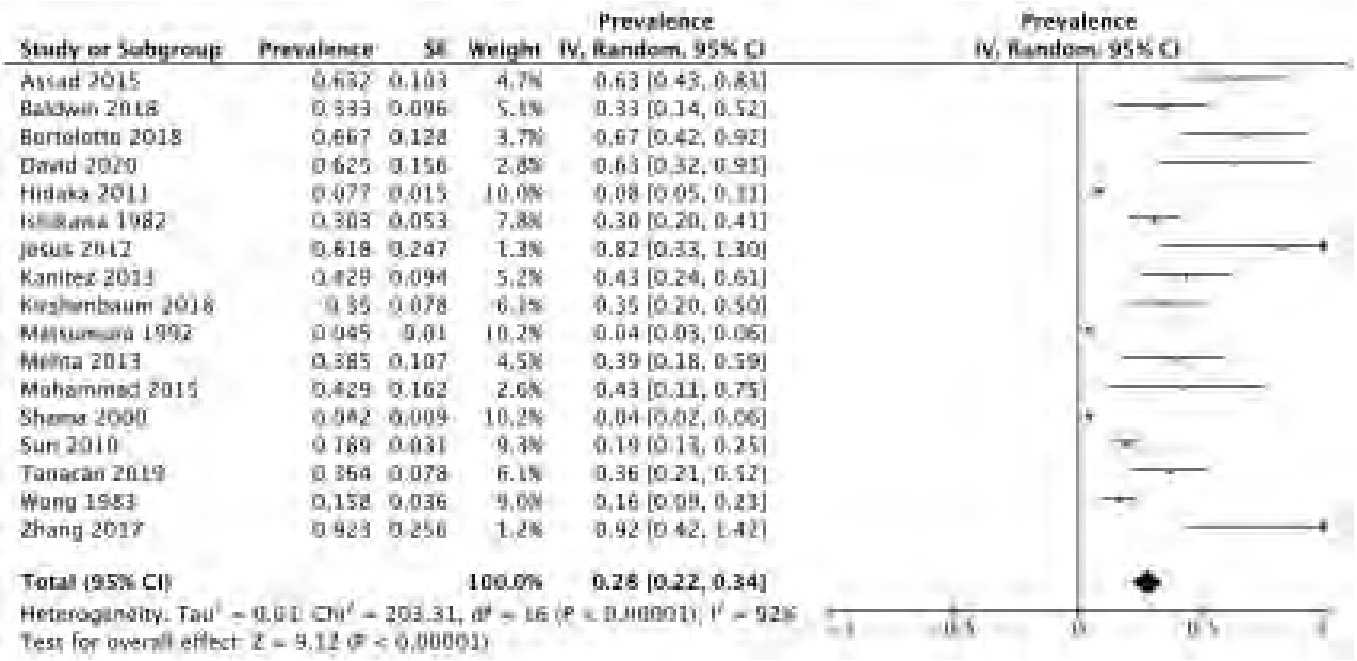

Figure 2. Prevalence of caesarean section in Takayasu patients.

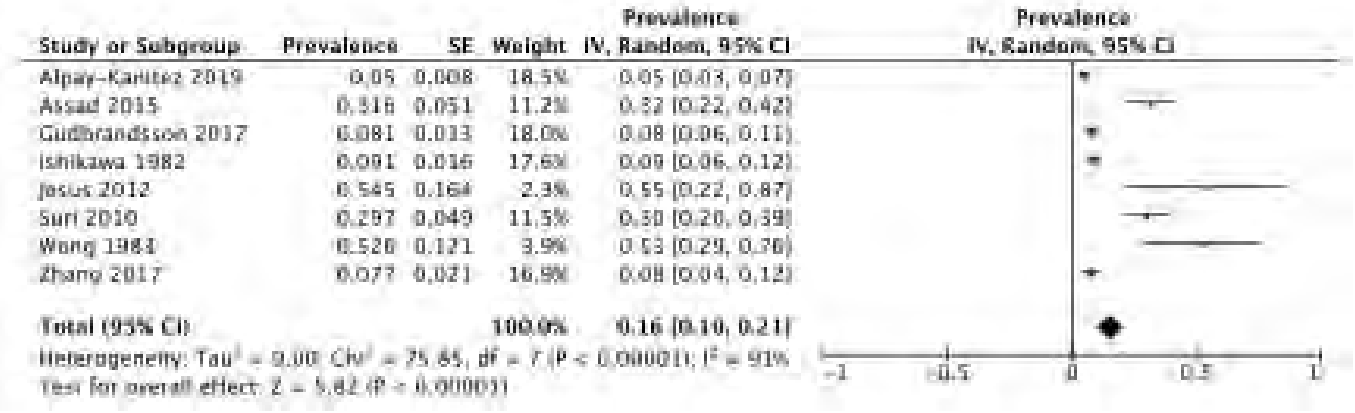

Figure 3. Prevalence of low birth weight among Takayasu patients.

Intrauterine growth restriction occurred in 16[10-21] % of pregnancies. The prevalence of caesarean sections among Takayasu patients was 28 [22-28] % (Figure 2). In terms of fetal outcomes, low birth weight was associated with 16[10-21] % of live births (Figure 3). Flares of vasculitis occurred in 11[8-15] % of patients.

Conclusion: There is a high prevalence of both maternal and fetal adverse outcomes in pregnant patients with Takayasu's arteritis, who require careful management by a multidisciplinary team during pregnancy.

Abstract Number: 1729

Predicting Adverse Pregnancy Outcomes in Women with Systemic Lupus Erythematosus (SLE) Using 2nd Trimester Estimated Glomerular Filtration Rate (eGFR)

Anika Lucas[1], Amanda Eudy[1], Michelle Petri[2], Rebecca Fischer-Betz[3], Abeer Nabil[4], Cecilia Nalli[5], Laura Andreoli[6], Angela Tincani[7], Yair Molad[8], Stephen Balevic[1] and Megan Clowse[9], [1]Duke University, Durham, NC, [2]Johns Hopkins University School of Medicine, Baltimore, MD, [3]Uniklinik Dsseldorf, Dsseldorf, Germany, [4]University of Cairo, Cairo, Egypt, [5]ASST SPEDALI CIVILI DI BRESCIA, Brescia, Italy, [6]University of Brescia, Brescia, Italy, [7]ASST Spedali Civili-University of Brescia, Gussago, Italy, [8]Rabin Medical Center, Beilinson Hospital, and Tel Aviv University, Petah-Tikva, Israel, [9]Duke University, Chapel Hill, NC

SESSION INFORMATION
Session Date: Tuesday, November 9, 2021
Session Title: Reproductive Issues in Rheumatic Disorders Poster (1711–1731)
Session Type: Poster Session D
Session Time: 8:30AM–10:30AM

Background/Purpose: Women with SLE are at increased risk for adverse maternal and fetal outcomes with increased odds of preeclampsia, hypertension, Cesarean and preterm deliveries, low birth weight, and congenital defects. Many markers of SLE disease activity fail to identify all women at risk for adverse pregnancy outcomes. Previous studies found a U-shaped relationship between 2nd trimester eGFR and adverse pregnancy outcomes. Both very low and high eGFR had a high risk for adverse pregnancy outcomes. The purpose of this study was to determine the relationship of 2nd trimester eGFR and adverse pregnancy outcomes in women with SLE.

Methods: This was an individual patient-level meta-analysis including 684 pregnant women with SLE who received rheumatology care at academic centers in North America and Europe from 1995 to 2017. Preeclampsia, preterm birth, fetal loss, and poor pregnancy outcome (composite outcome) were outcomes of interest. Polynomial and logistic regression models were used to evaluate the relationship between eGFR and adverse outcomes. Women with an eGFR 120-135 ml/min/1.73m^2 were in the reference group, based on previous studies demonstrating low adverse pregnancy outcome in this range. eGFR was stratified into groups based on established cut-offs from previous studies. Multivariable regression models adjusted for race, age, and SLE disease activity.

Results: Among 684 women, 52 women had very low eGFR (< 90ml/min/1.73m^2), 232 had low eGFR (90-120ml/min/1.73m^2), 336 had normal eGFR (121-135ml/1.73m^2), and 64 women had very high eGFR (>135ml/min/1.73m^2). Greater than a third of women had lupus nephritis and 22% of women were of Black race. A U-shaped relationship between 2nd trimester eGFR and adverse outcomes was observed. Women with very low eGFR had higher odds

of fetal loss, preterm birth, preeclampsia, and poor pregnancy outcome. Very high eGFR was associated with poor pregnancy outcome and preterm birth.

Conclusion: We demonstrate a U-shaped relationship between 2nd trimester eGFR and adverse pregnancy outcomes in women with SLE. Both women with very low eGFR defined as < 90ml/min/1.73m^2 and high eGFR, defined as >135ml/min/1.73m^2 had higher odds of adverse pregnancy outcomes. Measurement of kidney function with 2nd trimester GFR estimates may be an additional tool that can be utilized to predict adverse outcomes in pregnant women with SLE.

Table 1. Association of 2nd Trimester eGFR and Adverse Pregnancy Outcome

eGFR strata	Preterm Birth Unadjusted OR (95%CI)	Preeclampsia Unadjusted OR (95%CI)	Fetal Loss Unadjusted OR (95%CI)	Poor Pregnancy Outcome Unadjusted OR (95%CI)
Very Low eGFR<90	3.16 (1.63, 6.12)	2.91 (1.32, 6.37)	5.82 (2.28, 14.86)	3.79 (2.00, 7.19)

Disease Activity and Outcome in Pregnancies of Patients with SpA - Data from the German Pregnancy Register RHEKISS

Anja Weiß[1], Christina Bungartz[1], Jutta Richter[2], Susanna Späthling-Mestekemper[3], Xenofon Baraliakos[4], Peer Aries[5], Rebecca Fischer-Betz[6] and Anja Strangfeld[7], [1]DRFZ, Berlin, Germany, [2]Rheumatology and Hiller Research Unit, Heinrich-Heine-University Duesseldorf, Medical Faculty, Duesseldorf, Germany, [3]Rheumapraxis München, München, Germany, [4]Rheumazentrum Ruhrgebiet Herne, Ruhr-Universität Bochum, Herne, Germany, [5]Rheumatologie in Hamburg, Hamburg, Germany, [6]Uniklinik Dsseldorf, Dsseldorf, Germany, [7]Deutsches Rheuma-Forschungszentrum Berlin, Berlin, Germany

SESSION INFORMATION

Session Date: Tuesday, November 9, 2021

Session Title: Reproductive Issues in Rheumatic Disorders Poster (1711–1731)

Session Type: Poster Session D

Session Time: 8:30AM–10:30AM

Background/Purpose: SpA is a severe chronic inflammatory disease, which affects quality of life and functional status. It frequently occurs in women of childbearing age. Active disease and TNFi discontinuation at early pregnancy were found to be risk factors for flares during pregnancy (1). The aim of this study was to compare disease activity during pregnancy in patients with or without biological DMARD (bDMARD) exposure at conception and during pregnancy and to assess pregnancy outcomes.

Methods: RHEKISS is a prospective longitudinal cohort study including patients with confirmed diagnose of inflammatory rheumatic disease. Pregnant patients are eligible to be enrolled until the 20th week of gestation regardless of drug treatment. During observation, information on treatment, disease and pregnancy course, and outcome are collected from rheumatologists and patients. For this analysis, pregnancies of patients with SpA and a reported outcome since the beginning of the registry until June 8th 2020 were selected and stratified into three groups according to their exposure to bDMARDs.

Results: Of 140 SpA pregnancies included, 74 (53%) were not exposed to bDMARDs at conception (group 1), 38 (27%) were exposed to bDMARDs at conception, but not during pregnancy (group 2) and 28 (20%) were continuously exposed to bDMARDs at conception and during pregnancy (group 3). The bDMARDs prescribed were Certolizumab in 50%, Adalimumab in 21%, Etanercept in 12%, Infliximab in 9%, Golimumab in 2 patients, Sekukinumab and Ustekinumab in one patient each. Baseline characteristics according to treatment exposure are shown in table 1. Frequency of flares was highest in group 2: 21%, 38%, and 39% of patients flared during the 1st, 2nd, and 3rd trimester. These rates were 20%, 25%, and 21% in group 1 and 8%, 20%, and zero in group 3. The difference in flare rates was also mirrored in the course of mean physicians' assessed global disease activity (fig. 1). Whereas patients in group 1 seemed to have a quite stable disease activity during pregnancy, those who were in group 2 had an increasing activity

Table 1. Baseline characteristics; numbers are n (%) if not otherwise specified; * value at beginning of pregnancy: first 22 weeks after conception

Parameter	no bDMARD at conception (group 1) n=74	bDMARD at conception and discontinued during pregnancy (group 2) n=38	bDMARD at conception and continued during pregnancy (group 3) n=28	Total n=140

CRP in mg/l *, mean (SD)	6.6 (8.2)	5.4 (8.2)	5.2 (4.9)	6 (7.6)
CRP >5mg/l *	25 (41)	9 (30)	8 (35)	42 (37)
physician global* (NRS 0-10), mean (SD)	2.6 (2)	2.3 (2.5)	1.7 (1.4)	2.4 (2.1)
BASDAI* (0-10), mean (SD)	3.2 (2)	2.9 (2.3)	2.8 (1.5)	3.1 (2)
patient global* (NRS 0-10), mean (SD)	3.3 (2.7)	3 (2.8)	3 (2.3)	3.1 (2.6)

of disease during pregnancy with an even higher increase of disease activity after giving birth. Patients in group 3 had the lowest disease activity during the total observation period.

Of 137 singleton pregnancies, 130 (95%) ended in live birth. Two spontaneous abortions in group 1 occurred in the same patient in gestational week 10 and 7. The spontaneous abortions in group 2 and 3 occurred in different patients in gestational week 10 and 16 (group 2) and in week 9 and 11 (group 3). One pregnancy in group 1 was terminated in gestational week 22 due to suspected malformation. In one triple pregnancy, one baby was born alive and two aborted in week 13. All babies of the two twin pregnancies were born healthy.

Conclusion: SpA patients treated with bDMARDs at conception are not at higher risk for adverse pregnancy outcomes compared to those without bDMARD exposure. Furthermore, our results confirmed the findings of smaller studies that discontinuation of bDMARDs after conception is associated with increased disease activity during pregnancy and after birth and a higher risk of flares.

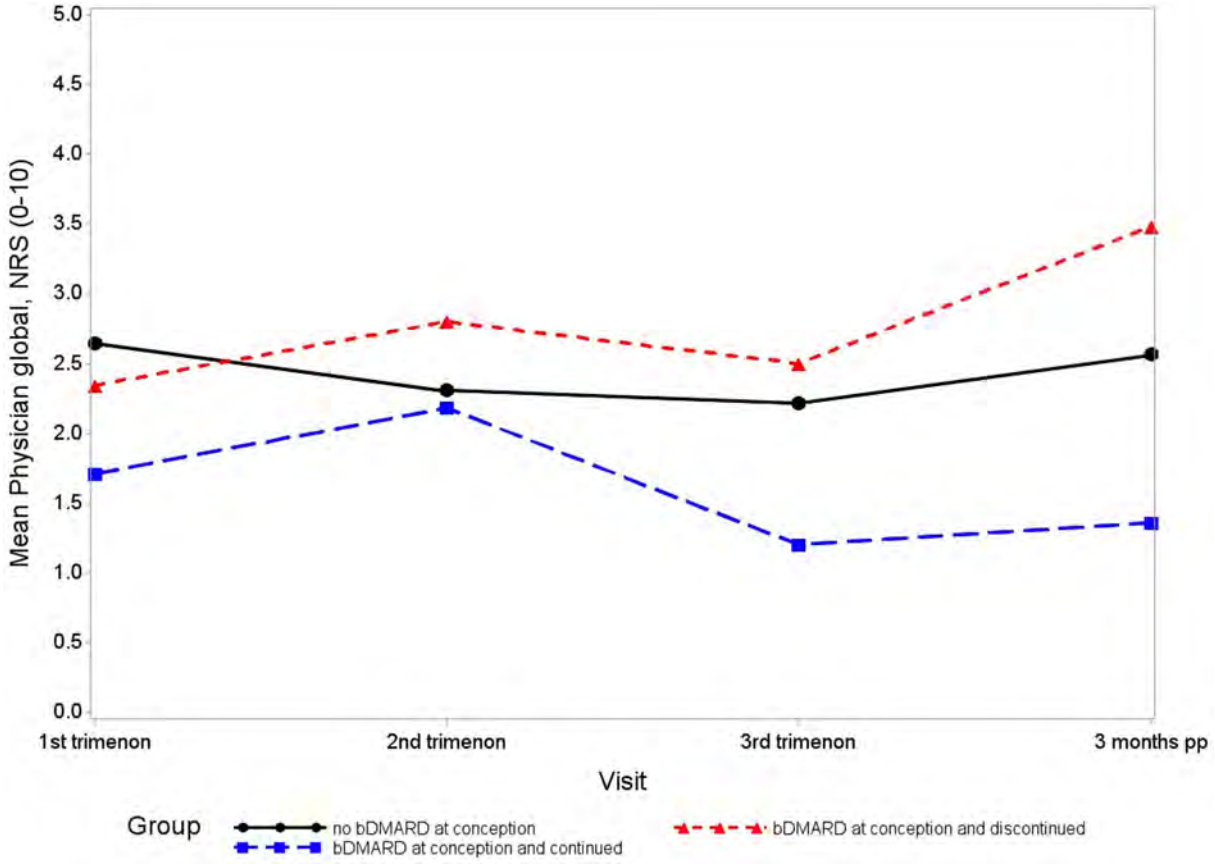

Figure 1. Mean course of physicians' assessed global disease activity.

SESSION INFORMATION

Session Date: Tuesday, November 9, 2021

Session Title: Reproductive Issues in Rheumatic Disorders Poster (1711–1731)

Session Type: Poster Session D

Session Time: 8:30AM–10:30AM

Background/Purpose: Autoimmune rheumatic diseases (ARDs) commonly affect women of childbearing age. Active maternal disease in the months prior to conception increases the risk of flares during pregnancy and adverse pregnancy outcomes. Therefore, maternal and fetal health can be optimized by planning conception when the disease is controlled so that a treatment regimen can be kept throughout the pregnancy.

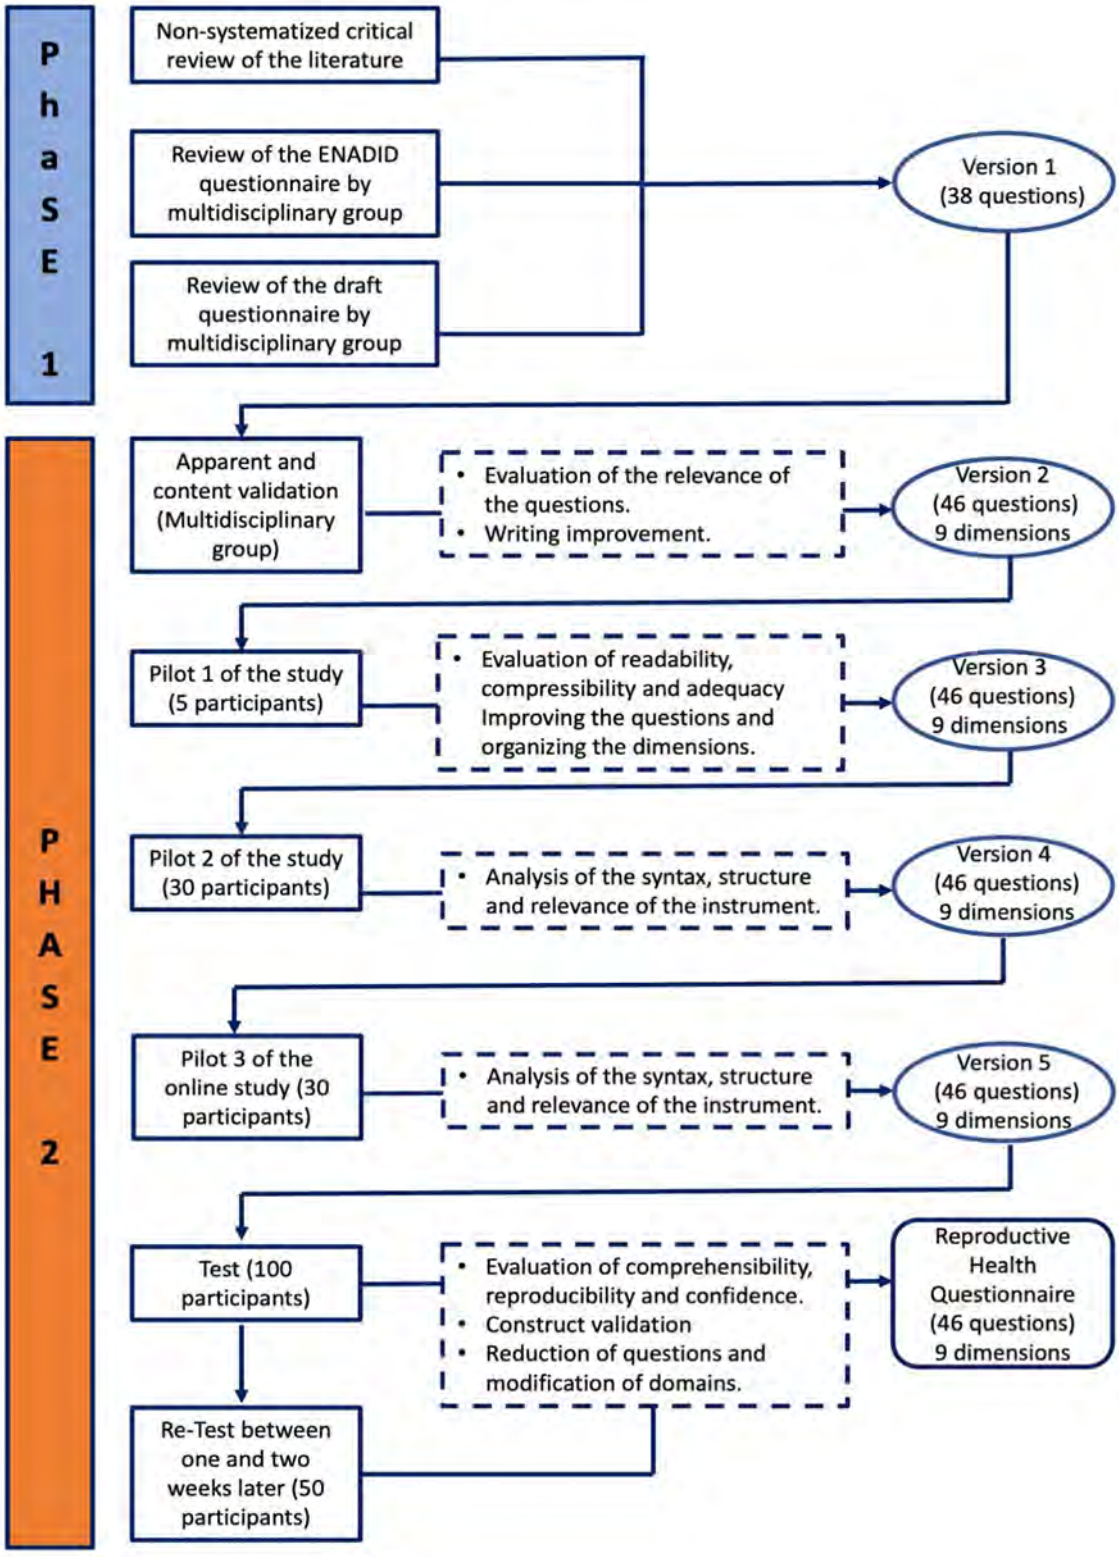

Figure 1. Phases.

This study aims to carry out the construction and validation of a Reproductive Health Questionnaire (RHQ) for patients with ARDs.

Methods: A validation and construction of a RHQ was carried out in women of reproductive age (18 to 50 years) with ARDs. The validation was realized in two phases. First phase: The National Demographic Dynamics Survey (2018) was used as the basis for obtaining the questions to form the draft questionnaire, as well as a previous non-validated questionnaire then a review of the literature and construction of the questionnaire was performed by a multidisciplinary team of experts, then the first version of the questionnaire was made. Second phase: During face and content validity, the multidisciplinary group met to assess the relevance of the written questions to create the second version of the questionnaire, following we carried out pilot tests to create versions 3, 4, and 5. Figure 1. A Cross-sectional study was conducted to complete the validation and estimate Cronbach's alpha based on tetrachoric correlation coefficients, correlation matrix, and Cohen's kappa coefficient test. The stability of the instrument was measured by comparing two measurements on the same study subject (re-test) with a time-lapse between them.

Results: A convenience sampling was carried out with a sample of 165 women, 65 women participated in the cross-cultural adaptation phase and 100 in the validation phase.

First phase: we developed an instrument of 38 questions; some drafting questions were modified because of the confusion or disconcerting they caused to some patients, furthermore more response options were added (Figure 1). In the second phase, version 5 of the RHQ was applied to 100 women with ARDs, the average age of the patients was 35 years. The most frequent disease was rheumatoid arthritis (54%). We founded a difference of 6 months between the onset of the symptoms of the disease and the diagnosis. The correlation matrices showed good to moderate correlations in dimensions 3, 5, 6, 7, 8, and 10 (0.53, 0.82, 0.84, 0.54, 0.35, and 0.45 respectively), we founded difficulties in two dimensions, therefore they were restructured. The test-retest analysis showed perfect correlations in 34 of the 41 items, moderate correlations in 6 items, and a negative correlation on one of the items due to a change in the reproductive status of one patient.

Conclusion: The RHQ is a useful and practice tool to assess reproductive health (fertility, reproductive preferences, contraception, preconception counseling, sexuality, and breastfeeding) in women with ARD, and could help with timely intervention on reproductive health issues, decreasing both fetal and maternal adverse outcomes.

Effects of B Cell Activating Factors/B Lymphocyte Stimulator Inhibitors Added to Standard of Care on Infection in Patients with Systemic Lupus Erythematosus: A Systematic Review and Meta-Analysis of Randomized Controlled Trials

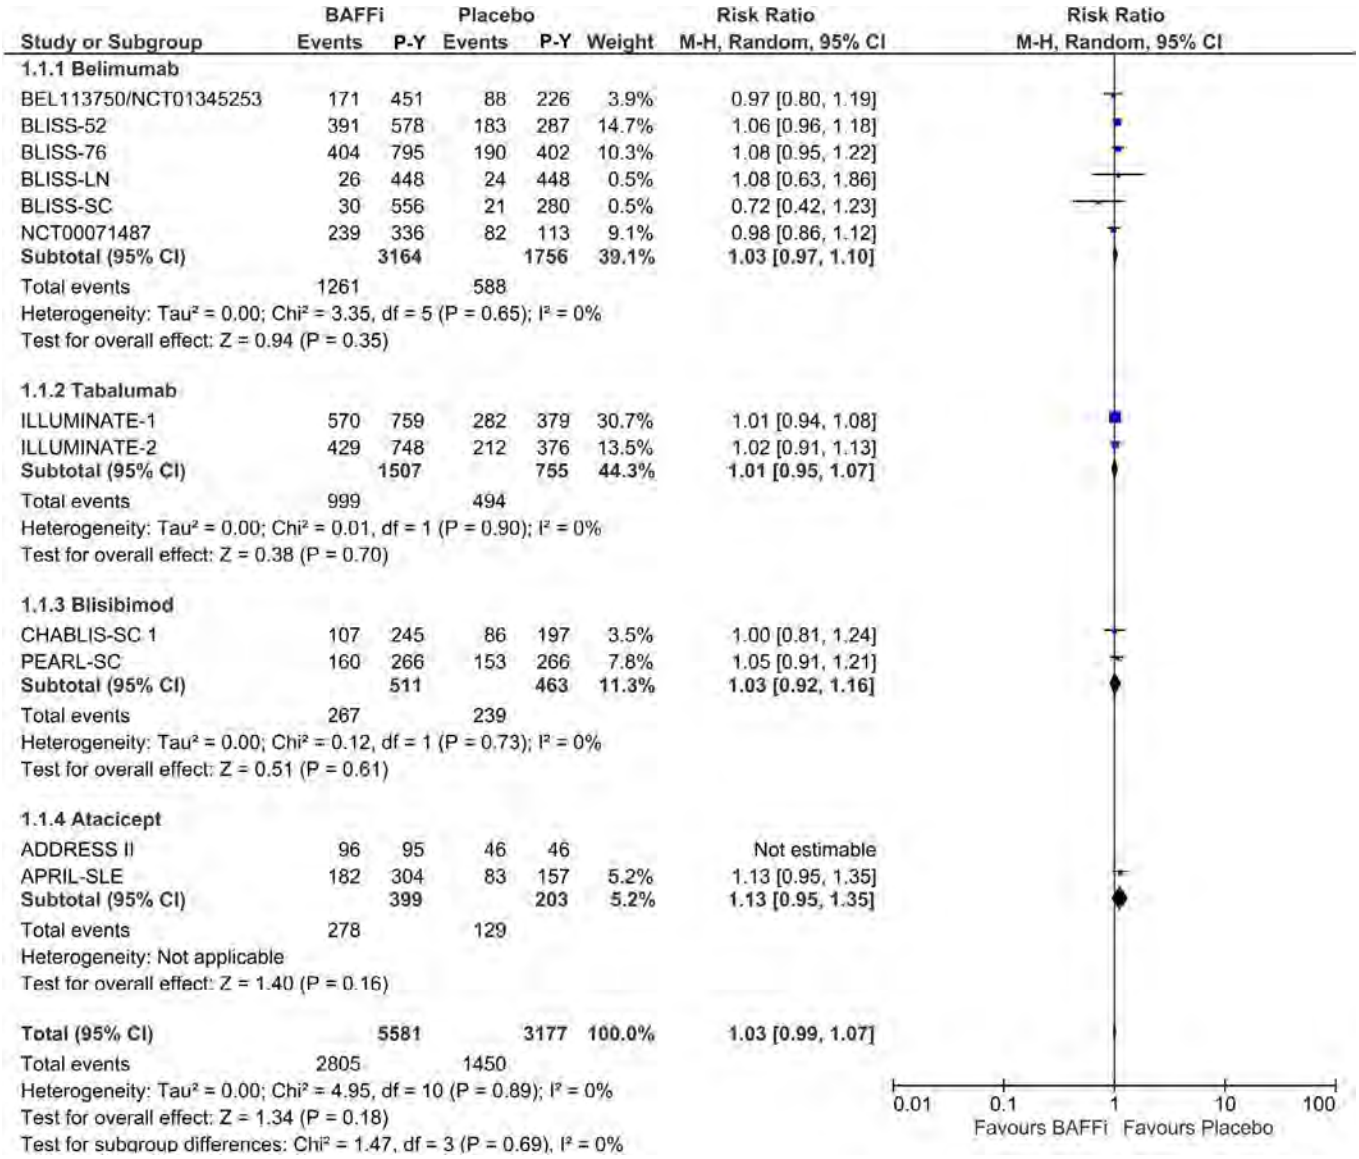
Ruoning Ni[1], Jiayi Zheng[2] and Ruru Guo[3], [1]Saint Agnes Healthcare, Baltimore, MD, [2]Department of Rheumatology, Renji Hospital, Shanghai Jiaotong University School of Medicine, Shanghai, China (People's Republic), [3]Renji Hospital, Shanghai, China (People's Republic)

SESSION INFORMATION

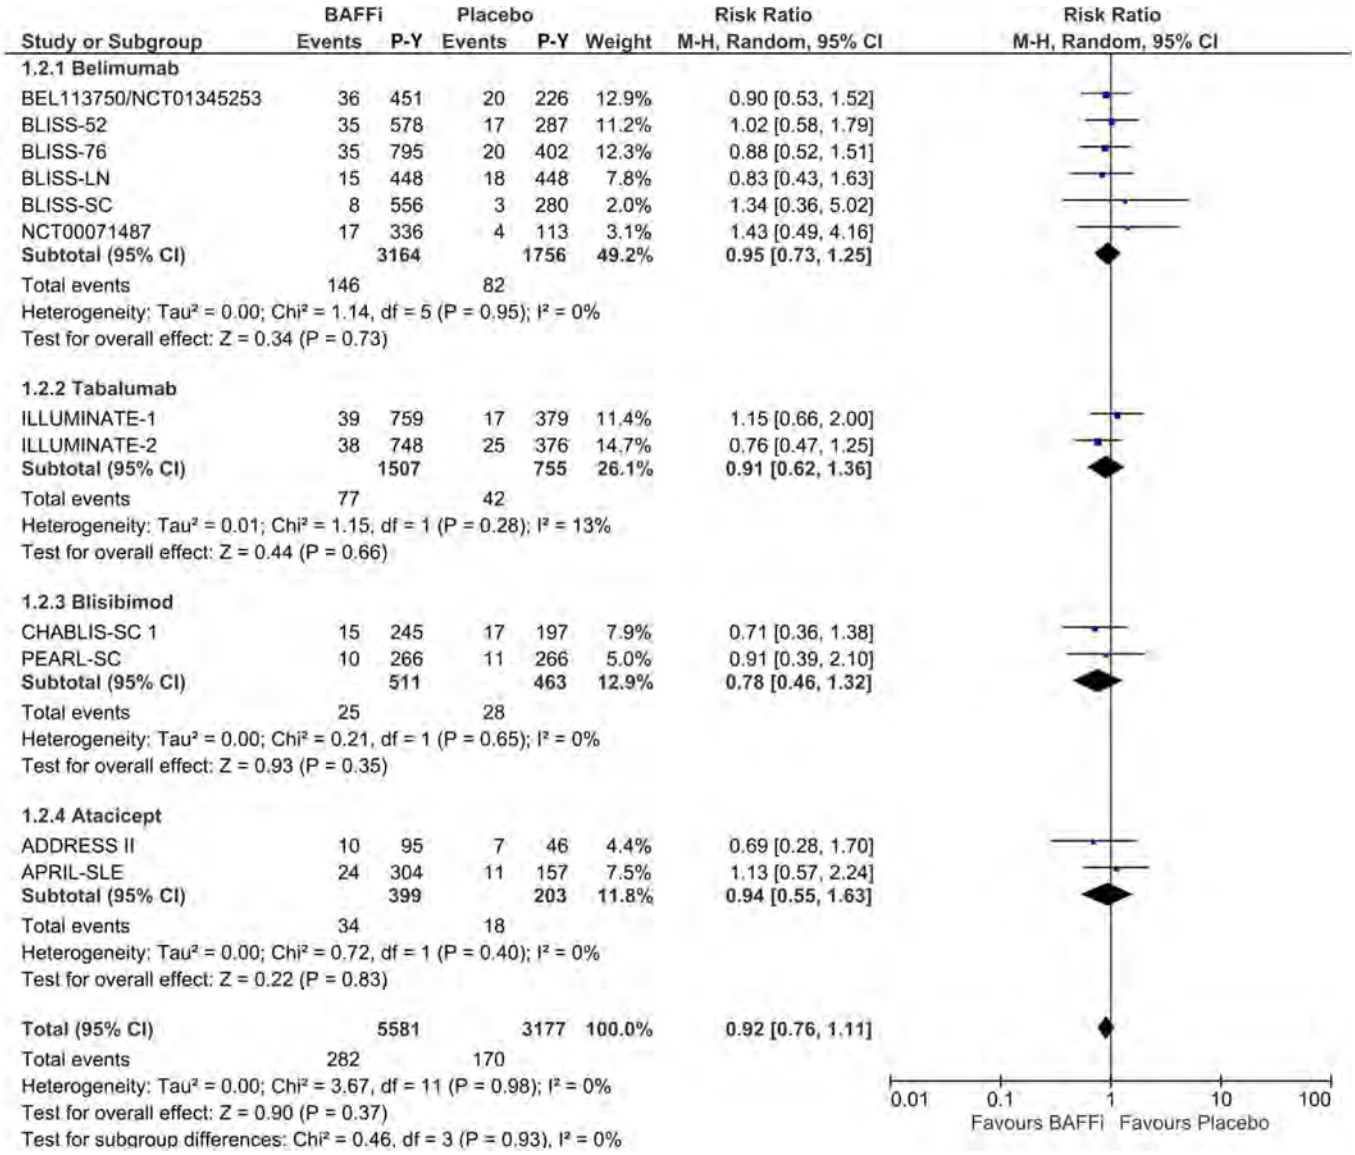
Session Date: Tuesday, November 9, 2021
Session Title: SLE – Treatment Poster (1732–1772)
Session Type: Poster Session D
Session Time: 8:30AM–10:30AM

Background/Purpose: The efficacy of B cell activator factor/B lymphocyte stimulator inhibitors (BAFFi/BLySi) for systemic lupus erythematosus (SLE) has been proven in clinical trials. However, it remains unclear whether the addition of BAFFi/BLySi to the Standard of Care (SoC) impacts infection risk in SLE. Therefore, the objective of this study was to determine the effects of BAFFi/BLySi on infection in patients with SLE via meta-analysis.

Methods: A systematic literature review was performed in PubMed, Embase, Cochrane Library databases from inception to Feb 2021 to identify randomized controlled trials (RCTs) of BAFFi/BLySi, including belimumab, tabalumab, blisibimod and atacicept. Relative risks (RR) and 95% confidence intervals (CIs) were calculated to compare infection



Relative Risks (RRs) of all infections in patients with systemic lupus erythematosus (SLE) treated with B cell activator factor/B lymphocyte stimulator inhibitors (BAFFi/BLySi) compared with placebo in addition to standard of care. P-Y, patient-year

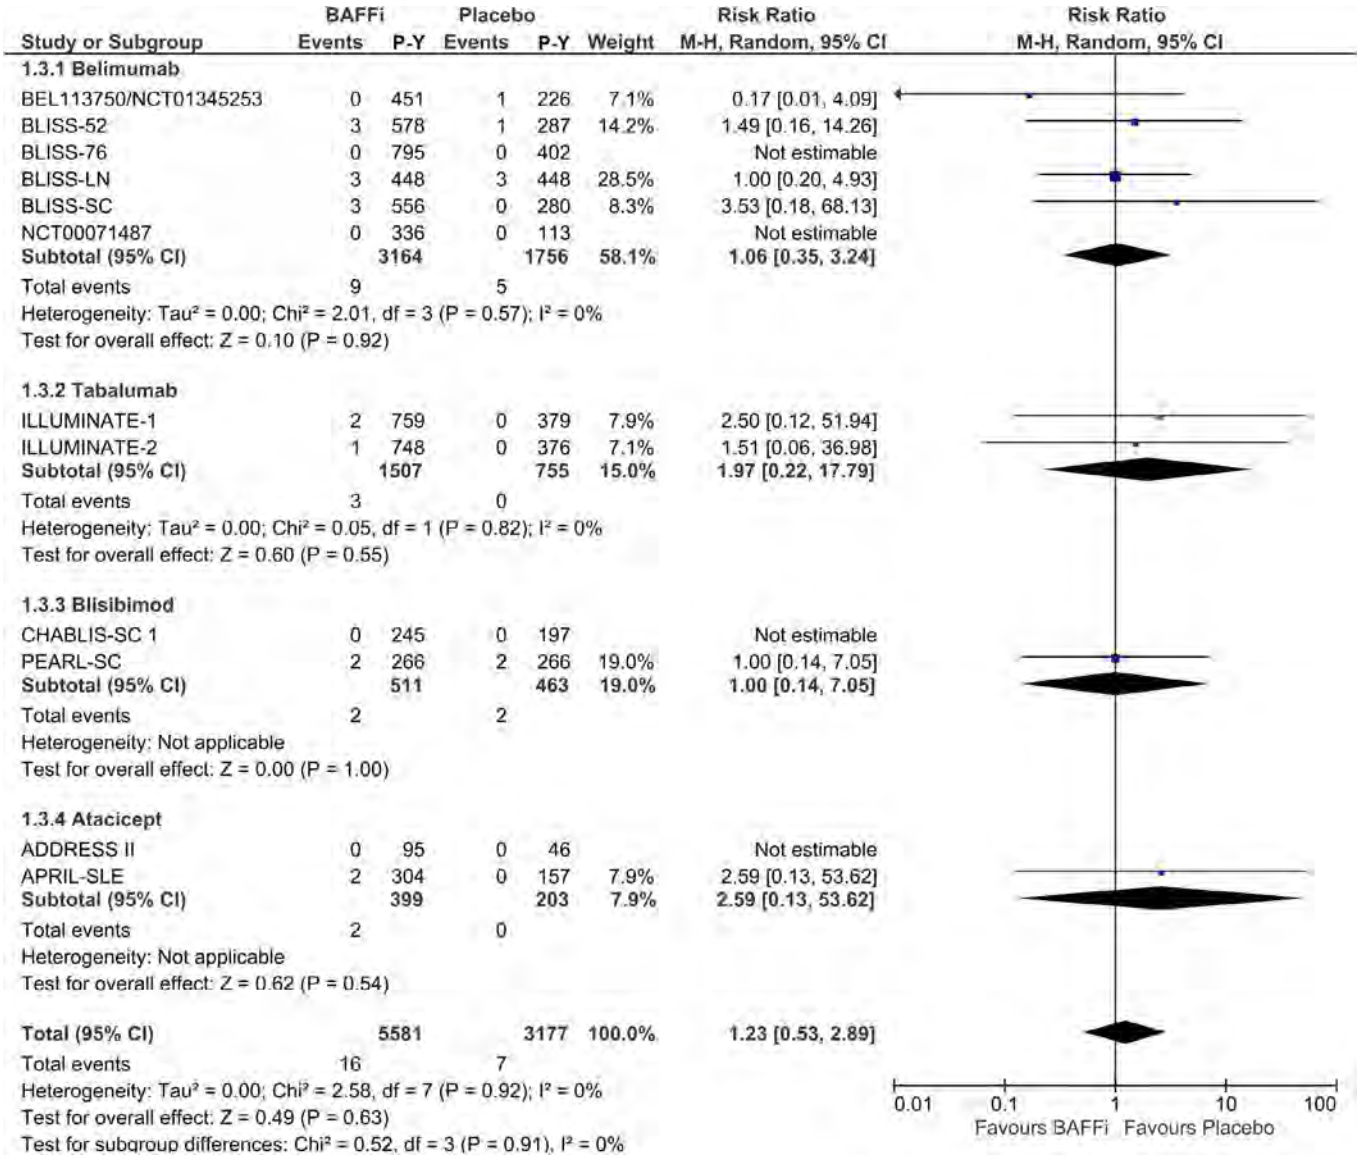


RRs of serious infections in patients with SLE treated with BAFFi/BLySi compared with placebo in addition to standard of care. P-Y, patient-year

events, serious infection events and mortality secondary to infection between BAFFi/BLySi and placebo in addition to SoC by using the Mantel-Haenszel random-effect method.

Results: A total of 443 articles were identified and 12 RCTs were included in the final analysis that comprised 8104 patients and 8387 patient-years. Forest plots of RR between BAFFi/BLySi and placebo for infections, serious infections and fatal infections are presented in *Figure 1.* *Figure 2* and *Figure 3.* respectively. There was no statistically significant difference between belimumab, tabalumab, blisibimod or atacicept and placebo in infection (RR=1.03; 95% CI (0.99,1.07)), neither serious infections (RR=0.92; 95% CI (0.76,1.11)) nor fatal infections (RR=1.23; 95% CI (0.53,2.89)). Dose-dependent effect of BAFFi/BLySi on the risk of infections was undetectable (RR=1.03; 95% CI (0.97,1.10)).

Conclusion: Adding BAFFi/BLySi to SoC in patients with SLE was not associated with increased risk of infection, serious infection, nor fatal infection.



RRs of fatal infections in patients with SLE treated with BAFFi/BLySi compared with placebo in addition to standard of care. P-Y, patient-year

Classification of Patients with Systemic Lupus Erythematosus Enrolled in 2 Phase 3 Trials by EULAR/ACR 2019 Criteria

Martin Aringer[1], Ian N. Bruce[2], Richard Furie[3], Eric Morand[4], Emmanuelle Maho[5], Catharina Lindholm[6] and Raj Tummala[7], [1]University Medical Center and Faculty of Medicine Carl Gustav Carus, TU Dresden, Dresden, Germany, [2]University of Manchester and NIHR Manchester Biomedical Research Centre, Manchester University Hospitals NHS Foundation Trust, Manchester Academic Health Science Centre, Manchester, United Kingdom, [3]Zucker School of Medicine at Hofstra/Northwell Health, Great Neck, NY, [4]Monash University, Melbourne, Australia, [5]BioPharmaceuticals R&D, AstraZeneca, Cambridge, United Kingdom, [6]BioPharmaceuticals R&D, AstraZeneca, Gothenburg, Sweden, [7]BioPharmaceuticals R&D, AstraZeneca, Gaithersburg, MD

SESSION INFORMATION

Session Date: Tuesday, November 9, 2021
Session Title: SLE – Treatment Poster (1732–1772)
Session Type: Poster Session D
Session Time: 8:30AM–10:30AM

Background/Purpose: The TULIP-1 and TULIP-2 trials of anifrolumab, an anti–type I IFN receptor mAb, enrolled autoantibody-positive (ANA, anti-dsDNA, and/or anti-Smith [anti-Sm]) patients, who fulfilled the ACR 1997 classification criteria for SLE.[1–3] The aim of this analysis was to assess how many patients who participated in the TULIP trials also met the updated EULAR/ACR 2019 criteria.[4]

Methods: TULIP-1 (NCT02446912) and TULIP-2 (NCT02446899) were randomized, placebo-controlled, 52-week trials of intravenously administered anifrolumab in patients with moderate to severe SLE despite standard therapy. Inclusion criteria included fulfilling at least 4 of the ACR 1997 criteria for SLE, positivity for ANA, anti-dsDNA, and/or anti-Sm antibodies, and moderate to severe SLE. Data for investigating classification using EULAR/ACR 2019 criteria were combined from the ACR criteria, BILAG-specific SLE history, and documented medical history.

Results: The TULIP-1 and TULIP-2 data pool included 726 patients with SLE. Of these, all but 2 (99.7%) met the ACR 1997 SLE criteria (**Table**). The EULAR/ACR 2019 classification criteria for SLE were met by 712/726 patients (98.1%). Thus, most patients (97.9% [711/726]) were concordant in meeting both the ACR 1997 and EULAR/ACR 2019 SLE classification criteria. Of the patients classified as having SLE using ACR 1997 criteria, 1.8% (13/726) did not meet the EULAR/ACR 2019 criteria. Of these 13 discordant patients, 8 were ANA negative but either anti-dsDNA or anti-Sm antibody positive, 5 were ANA positive and were discordant mainly due to photosensitivity not being included in the EULAR/ACR 2019 criteria. Two patients did not meet ACR 1997 criteria at baseline; one patient was not classified as having SLE using either ACR 1997 or EULAR/ACR 2019 criteria, and the other patient was classified as having SLE using EULAR/ACR 2019 criteria. This latter discordant patient did not meet ACR 1997 criteria, having just nonerosive arthritis and positive ANA, but met EULAR/ACR 2019 criteria with positive ANA, fever, nonscarring alopecia, and joint

Table. Classification According to ACR 1997 or EULAR/ACR 2019 in Patients Enrolled in the TULIP-1 and TULIP-2 Trials (Pooled Data)

Patients, n (%)	Placebo (n=366)	Anifrolumab 300 mg (n=360)	Total (n=726)
ACR 1997 classification			
Patients classified SLE	364 (99.5)	360 (100)	724 (99.7)
Patients not classified SLE	2 (0.5)	0	2 (0.3)
EULAR/ACR 2019 classification			
Patients classified SLE	361 (98.6)	351 (97.5)	712 (98.1)
Patients not classified SLE	5 (1.4)	9 (2.5)	14 (1.9)
Concordance	361 (98.6)	351 (97.5)	712 (98.1)
Patients classified SLE according to both classifications	360 (98.4)	351 (97.5)	711 (97.9)
Patients not classified SLE according to both classifications	1 (0.3)	0	1 (0.1)
Discordance	5 (1.4)	9 (2.5)	14 (1.9)
Not SLE using ACR 1997 but SLE using EULAR/ACR 2019	1 (0.3)	0	1 (0.1)
SLE using ACR 1997 but not SLE using EULAR/ACR 2019	4 (1.1)	9 (2.5)	13 (1.8)

involvement. At study baseline, positive ANA (97.2%) and nonerosive arthritis (97.5%) were the 2 most frequent ACR 1997 criteria among all patients.

Conclusion: Nearly all patients enrolled in the TULIP-1 and TULIP-2 trials were classifiable as having SLE using both the ACR 1997 criteria and the EULAR/ACR 2019 criteria. Of the patients not meeting the new criteria, most were ANA negative but had detectable autoantibodies against dsDNA and/or Sm.

Efavaleukin Alfa, a Novel IL-2 Mutein, Selectively Expands Regulatory T Cells in Patients with SLE: Interim Results of a Phase 1b Multiple Ascending Dose Study

Nadia Tchao[1], Hamid Amouzadeh[2], Nandita Sarkar[1], Vincent Chow[2], Xuguang Hu[1], Mark Kroenke[2], Hui Wang[2], Rong Zhang[2], Kevin Gorski[1], Richard Furie[3], Alan Kivitz[4] and Stanley Cohen[5], [1]Amgen Inc., South San Francisco, CA, [2]Amgen Inc., Thousand Oaks, CA, [3]Zucker School of Medicine at Hofstra/Northwell, Great Neck, NY, [4]Altoona Center for Clinical Research, Duncansville, PA, [5]Metroplex Clinical Research Center, Dallas, TX

SESSION INFORMATION
Session Date: Tuesday, November 9, 2021
Session Title: SLE – Treatment Poster (1732–1772)
Session Type: Poster Session D
Session Time: 8:30AM–10:30AM

Background/Purpose: Diminished IL-2 as well as both quantitative and qualitative abnormalities in regulatory T cells (Treg) are associated with autoimmune diseases including SLE. Efavaleukin alfa is a novel IL-2 mutein Fc fusion protein designed to selectively expand Treg. In healthy subjects, a single dose of efavaleukin alfa was well tolerated and demonstrated Treg selectivity with minimal changes in CD4+ conventional T cells (Tcon), CD8+ T cells, or NK cells (Tchao N *Blood* 2017). This interim analysis of an ongoing phase 1b study (NCT03451422) reports the safety, tolerability, pharmacokinetics (PK), and pharmacodynamic effects of multiple doses of efavaleukin alfa in patients with SLE.

Methods: Four of five ascending dosing cohorts are reported in this analysis. A total of 29 patients with SLE (age 18-70 years; 82.8% female; SLE diagnosed using SLICC or ACR criteria with ANA ≥1:80 and/or elevated anti-dsDNA antibodies) were randomized to receive efavaleukin alfa or placebo (5:2 ratio for cohorts 1–3; 3:1 ratio for cohort 4) subcutaneously every 2 weeks (Q2W; cohorts 1, 2, and 4) or every week (QW; cohort 3) in addition to standard of care

therapy for a total of 12 weeks, with 6 weeks of follow-up. Endpoints assessed in this analysis included treatment-emergent adverse events (TEAEs), serum PK profiles of efavaleukin alfa, changes in numbers of Treg, CD4+ Tcon, CD8+ T cells, and NK cells, and levels of cytokines in peripheral blood.

Figure 1: Fold change from baseline in number of Foxp3+ regulatory T cells following biweekly administration of efavaleukin alfa.

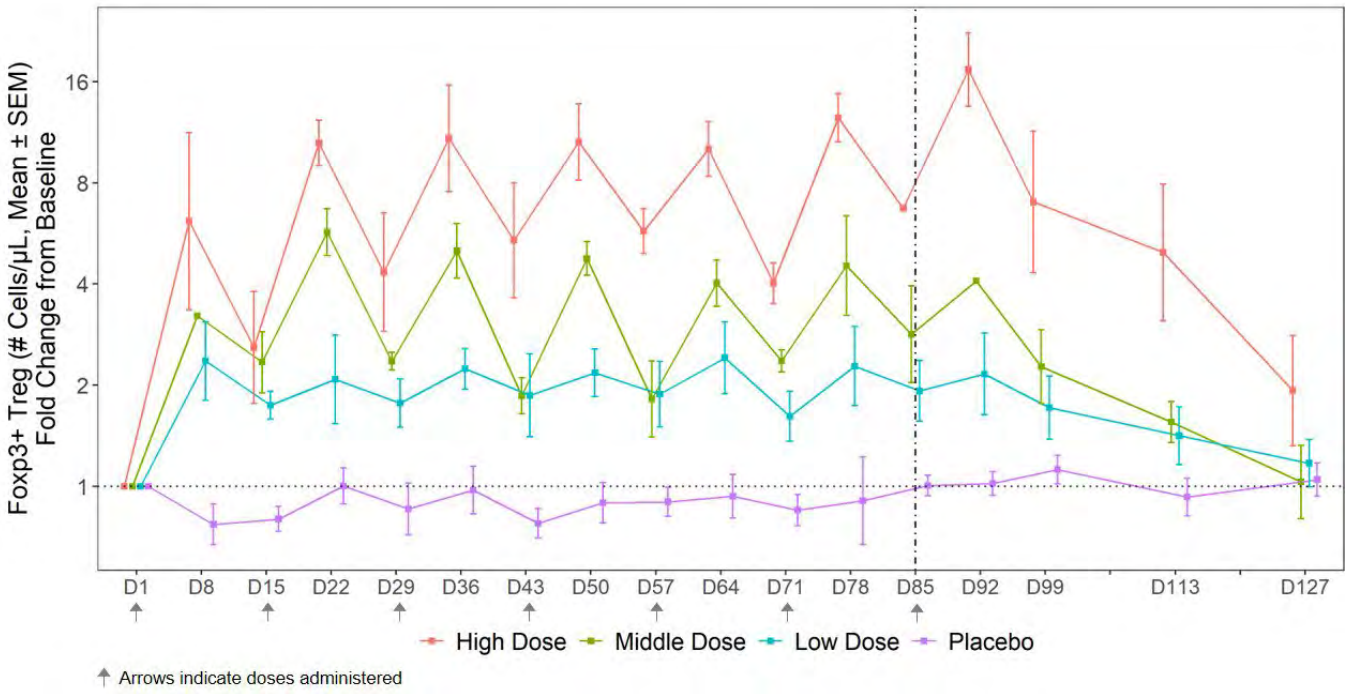

Figure 2: Fold change from baseline in number of $CD25^{bright}$ regulatory T cells following biweekly administration of efavaleukin alfa.

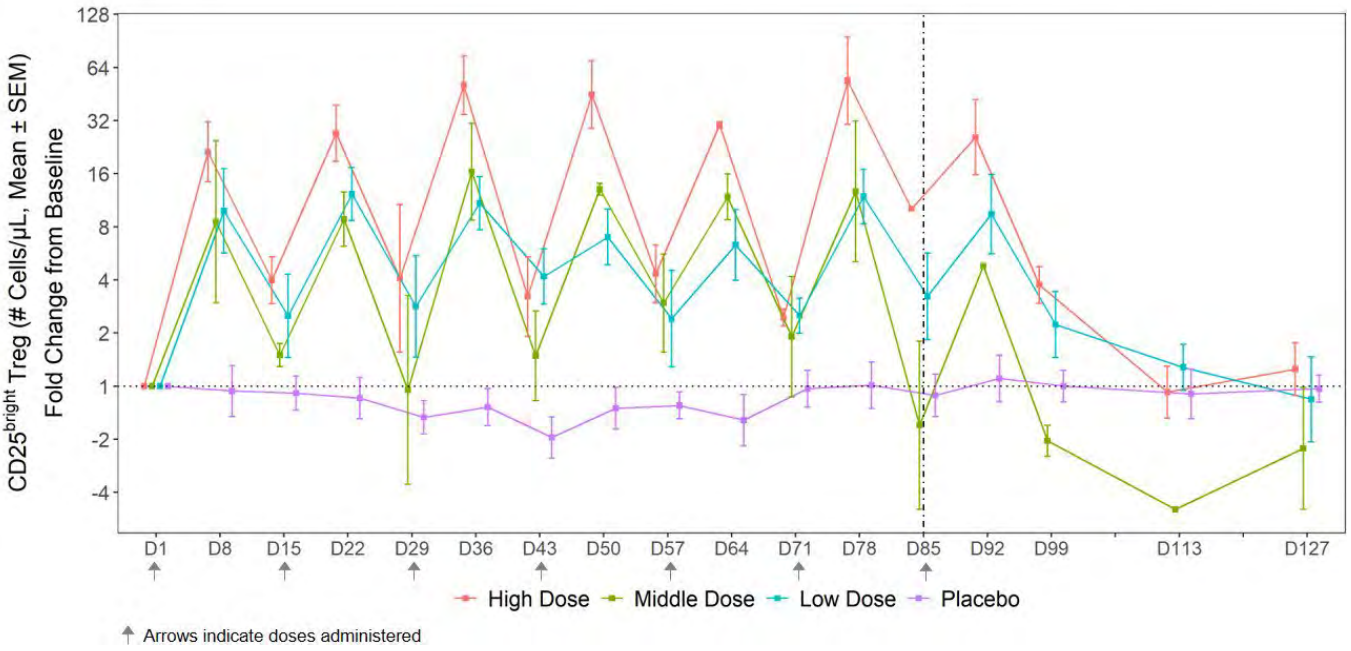

Results: The most commonly reported TEAEs (≥25% of all subjects) included non-serious, mild or moderate (grade 1–2) injection site reactions. No dose-limiting toxicities, treatment-related serious AEs, or deaths were reported. Efavaleukin alfa PK was generally linear and dose-proportional, with a terminal half-life ranging from 18 to 30 hours. Peak Foxp3+ Treg expansion was observed at 8 days post-dose, and the magnitude of the peaks was generally sustained after multiple QW or Q2W doses. Treg numbers remained above baseline for an average of 42 days after the last dose (**Figure 1**). The mean peak increases in Foxp3+ Treg were 17.4-, 5.7-, 2.4-, and 1.1-fold above baseline for the high, middle, and low Q2W efavaleukin alfa and placebo cohorts, respectively. At the highest dose, the mean peak increase in $CD25^{bright}$ Treg was 53.8-fold above baseline (**Figure 2**). Treatment with efavaleukin alfa expanded CD31+ recent thymic emigrant and naïve Treg populations; increases in these Treg subsets persisted longer than increases in memory Treg subsets. The majority of expanded Treg expressed markers associated with suppressive activity, including Helios, PD-1, ICOS, CD39, and GITR. There were no meaningful changes in numbers of CD4+ Tcon, CD8+ T cells, or NK cells or serum levels of pro-inflammatory cytokines with treatment.

Conclusion: Multiple doses of efavaleukin alfa were well tolerated in SLE patients. Treatment with efavaleukin alfa resulted in robust and prolonged dose-dependent Treg expansion, with minimal changes in other IL-2-responsive cells highlighting pharmacodynamic selectivity. These findings confirm and extend previous results in healthy subjects and support the ongoing phase 2b adaptive randomized controlled trial in patients with SLE.

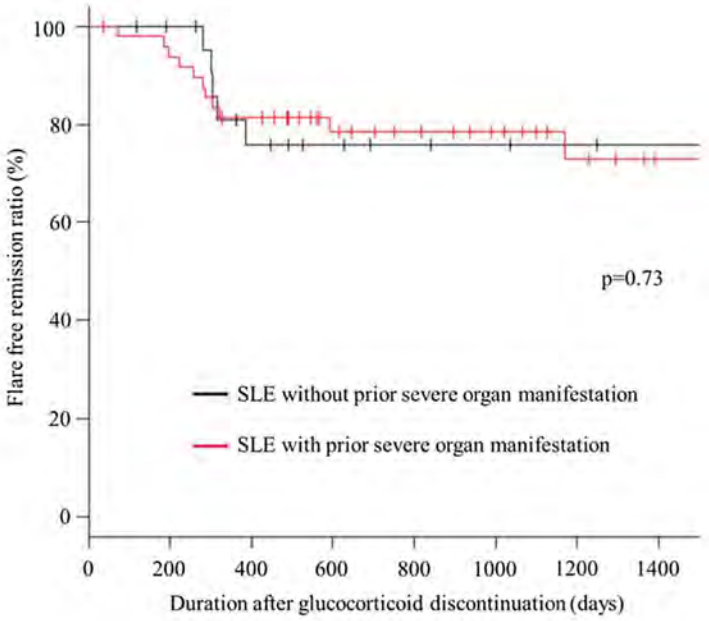
Session Date: Tuesday, November 9, 2021
Session Title: SLE – Treatment Poster (1732–1772)
Session Type: Poster Session D
Session Time: 8:30AM–10:30AM

Background/Purpose: Most long-term damage in systemic lupus erythematosus (SLE) has been attributed to continuous glucocorticoid use; however, glucocorticoid discontinuation is occasionally associated with disease flare-ups. Therefore, we evaluated the risk factors for disease flares and flare rates with gradual glucocorticoid tapering, especially in patients with prior severe organ manifestation.

Methods: Patients with SLE who had their glucocorticoid doses tapered off at our institute were retrospectively analyzed. We divided the patients according to the presence of prior severe organ manifestations and compared the 52-week flare rates after glucocorticoid discontinuation. Furthermore, risks/protective factors against flares after glucocorticoid cessation were investigated.



Number at risk								
SLE without prior severe organ manifestation	24	22	15	12	10	9	8	7
SLE with prior severe organ manifestation	49	45	38	29	24	20	13	9

Kaplan-Meier curve for flare free remission rate after glucocorticoid discontinuation

	Fisher's exact test			Cox proportional hazard model	
Factor	Flare (-) (n=54)	Flare (+) (n=19)	p value	Hazard ratio	p value (95% CI)
Prior severe organ manifestation	36 (66.7)	13 (68.4)	1	1.19	0.73 (0.44–3.17)
Renal manifestation	26 (48.1)	8 (42.1)	0.79	0.99	1.0 (0.39–2.53)

Anti-Smith antibody	4 (7.5)	6 (31.6)	0.02	3.5	0.01 (1.31–9.35)
Anti-Ro/SSA antibody	22 (42.3)	11 (57.9)	0.29	2.19	0.10 (0.87–5.55)
Anti-RNP antibody	7 (15.2)	11 (64.7)	<0.01	6.8	<0.01 (2.36–19.63)
HCQ use on the day of glucocorticoid discontinuation	29 (53.7)	7 (36.8)	0.29	0.75	0.56 (0.29–1.97)
Achievement of LLDAS on the day of glucocorticoid discontinuation	52 (96.3)	17 (89.5)	0.28	0.25	0.07 (0.06–1.1)

Risk factors for flares after glucocorticoid discontinuation

Results: In total, 309 patients with SLE were followed up; 298 had prednisolone tapered to less than 7.5 mg/day and 75 had glucocorticoids discontinued. Seventy-three patients met the inclusion criteria; 49 were classified as SLE with prior severe organ manifestation. No statistical differences were noted in the 52-week flare rate and time to first flare after glucocorticoid discontinuation between patients with and without prior severe organ manifestation (52-week flare rate: 16.7% vs. 18.2%, p=1.0; time to first flare: 322 [280, 1169] vs. 385 [304, 2345] days, p=0.33). A positive anti-Smith/anti-ribonucleoprotein antibody negatively influenced flare-free remission. Although this result was not statistically significant, the achievement of lupus low disease activity state (LLDAS) on the day of glucocorticoid discontinuation positively influenced flare-free remissions after glucocorticoid discontinuation.

Conclusion: Glucocorticoid discontinuation can be achieved in patients with SLE with prior severe organ manifestations. Achievement of LLADS is key for reaching flare-free remission after glucocorticoid discontinuation.

Treatment of Lupus Nephritis with Belimumab Is Associated with Reduction in Urinary CD23

Emma Weeding[1], Andrea Fava[2], Chandra Mohan[3], Daniel Goldman[4] and Michelle Petri[4], [1]Johns Hopkins Hospital, Baltimore, MD, [2]Johns Hopkins University, Baltimore, MD, [3]University of Houston, Houston, TX, [4]Johns Hopkins University School of Medicine, Baltimore, MD

SESSION INFORMATION
Session Date: Tuesday, November 9, 2021
Session Title: SLE – Treatment Poster (1732–1772)
Session Type: Poster Session D
Session Time: 8:30AM–10:30AM

Background/Purpose: Urine proteomic approaches have shown promise in identifying dynamic biological pathways in lupus nephritis (LN) which are not captured on renal histopathology or by measurement of proteinuria alone. We sought to investigate how the urine proteome changes with belimumab therapy and whether these changes might indicate any pathophysiologic explanations for the renal benefit of this drug.

Methods: Urine samples from 54 participants with biopsy-proven LN from the BLISS-LN trial (Furie *et al*., NEJM 2020) were collected at Week 0 (time of randomization), Week 24, and Week 52. A total of 1,000 urinary proteins were quantified using antibody microarrays (Raybiotech Kiloplex) at each time point and normalized using urine creatinine. The abundance of each urinary protein was compared in participants treated with belimumab (n = 28) versus standard of care (n = 26) at each time point using the Wilcoxon rank-sum test with Benjamini-Hochberg correction. Longitudinal fold change (e.g. fold change from Week 0 to 24) was also assessed for each protein in each treatment group.

Results: When comparing participants in the belimumab treatment group versus those in the standard of care group, there was no significant difference in the urine proteome at Week 0 per FDR threshold, as expected. At Week 24, five urinary proteins were found to be present at a significantly lower (CD23, Siglec-5) or higher (AIF, CRELD2, ROR2) level in those treated with belimumab (**Figure 1**). Numerically, lower CD23 and Siglec-5 (but not higher AIF, CRELD2,

or ROR2) in the belimumab group persisted into Week 52, though this was no longer significant per FDR threshold (CD23 p = 0.002, q = 0.69; Siglec-5 p = 0.004, q = 0.69). Belimumab therapy was particularly associated with a negative fold change in CD23 between Week 0 and 24 (**Figure 2**). Specifically, the median fold change was -6.02 (IQR

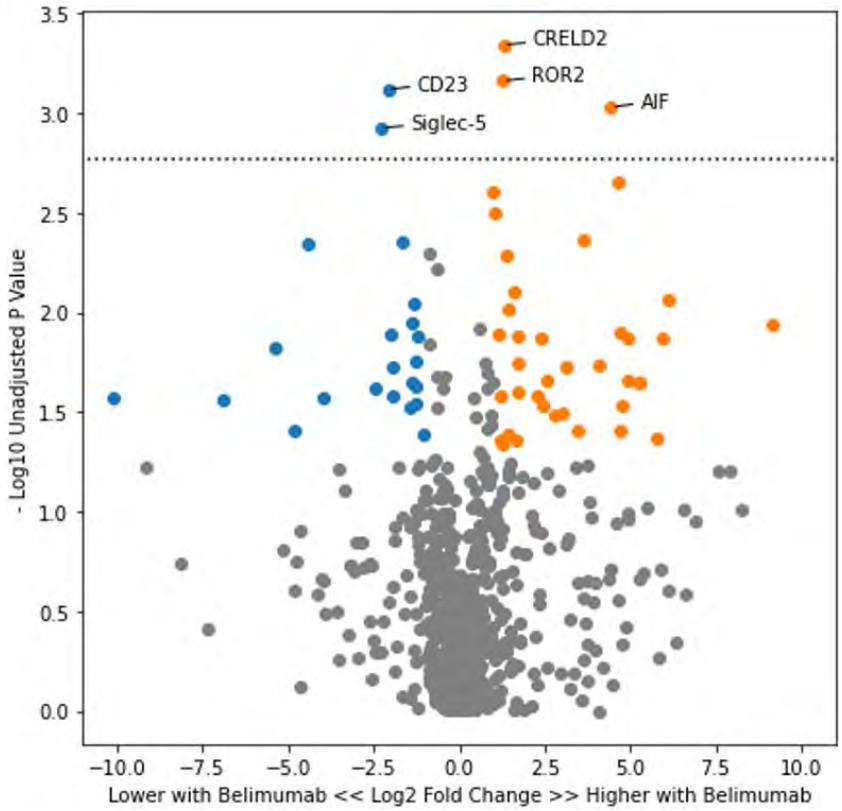

Figure 1. Volcano plot of urinary proteins at Week 24 in the belimumab versus standard of care treatment arms. Points in orange represent proteins which were higher in those treated with belimumab and had an unadjusted p value of < 0.05. Points in blue represent proteins which were lower in those treated with belimumab with an unadjusted p value of < 0.05. The dashed line is the p value threshold for a false discovery rate of 25% – this threshold was chosen given the relatively small sample size and exploratory nature of this work.

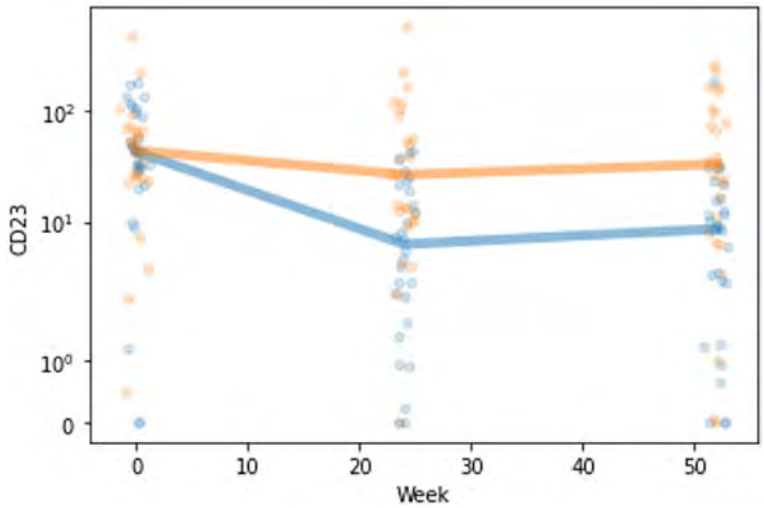

Figure 2. Abundance of CD23 over time in the belimumab (blue) and standard of care (orange) treatment groups. Each small circle represents one participant's CD23 value at the given time, and the thick lines represent the median CD23 value per group at each time point.

-14.42 to -3.82) in belimumab recipients versus -1.25 (IQR -2.60 to +1.56) in the standard of care arm (p = 0.0001, q = 0.12). With respect to longitudinal fold change, no other protein exhibited this behavior.

Conclusion: Significant reduction in urinary CD23 by Week 24 was most characteristic of belimumab therapy versus standard of care. CD23 is the low affinity receptor for IgE on B cells and also regulates IgE synthesis. CD23+ B cell-mediated antigen presentation of IgE-antigen complexes has been implicated in the enhancement of antibody and CD4+ T cell responses to said antigens. Anti-dsDNA IgE is common in SLE and is associated with active LN and worsened disease activity overall. Modulation of this CD23-mediated immune enhancement pathway might contribute to the added renal benefit of belimumab therapy versus standard of care alone. More generally, this work also provides evidence that treatment with specific medications can be detected in the urine proteome and could potentially be used for drug monitoring. We note that the full breadth of belimumab's effect on the urine proteome may not be captured here, given that participants in BLISS-LN were treated with mycophenolate mofetil or cyclophosphamide-azathioprine for up to two months prior to randomization, thereby potentially blunting pro-inflammatory urinary signals that can only be seen before immunosuppression is started.

Reduction in Urinary CD163 Is Associated with Treatment Response in the Belimumab Lupus Nephritis Trial

Emma Weeding[1], Andrea Fava[2], Chandra Mohan[3], Daniel Goldman[4] and Michelle Petri[4], [1]Johns Hopkins Hospital, Baltimore, MD, [2]Johns Hopkins University, Baltimore, MD, [3]University of Houston, Houston, TX, [4]Johns Hopkins University School of Medicine, Baltimore, MD

SESSION INFORMATION
Session Date: Tuesday, November 9, 2021
Session Title: SLE – Treatment Poster (1732–1772)
Session Type: Poster Session D
Session Time: 8:30AM–10:30AM

Background/Purpose: Urinary CD163 is a macrophage marker which correlates with histological activity index and response to treatment in lupus nephritis (LN), as evidenced by urine proteomic analyses in at least two independent cohorts. We investigated whether this finding could be confirmed in the BLISS-LN trial.

Methods: A total of 54 BLISS-LN (Furie *et al*., NEJM 2020) participants with biopsy-proven LN were included in this study. LN response status was determined at Week 52 based on proteinuria < 500 mg/mg, serum creatinine no greater than 1.25 times the Week 0 value, and prednisone dosage of no greater than 10 mg per day. Note that this response definition was specific to this series and differed from the BLISS-LN endpoints, which were not available. Urine samples were collected at Week 0 (time of randomization), Week 24, and Week 52, and 1,000 urinary proteins including CD163 were quantified using antibody microarrays (Raybiotech Kiloplex) at each time point and normalized using urine creatinine. The abundance of each urinary protein was compared in complete responders (n = 31) versus non-responders (n = 22) at each time point using the Wilcoxon rank-sum test with Benjamini-Hochberg correction for multiple comparisons with a false discovery rate (FDR) of 5%. One participant was excluded from analysis due to missing the clinical information required to determine response status.

Results: By Week 52, CD163 was the urine protein with the most significant difference in abundance between complete responders (median 1.8 pg/mg, IQR 0.8-2.6 pg/mg) versus non-responders (median 8.3 pg/mg, IQR 4.0-48.4 pg/mg) with a p value of 0.0004 after adjustment for multiple comparisons (**Figure 1**). This divergence in CD163 abundance was also observed at Week 24 though at a lower degree of significance between complete (median 3.5 pg/mg,

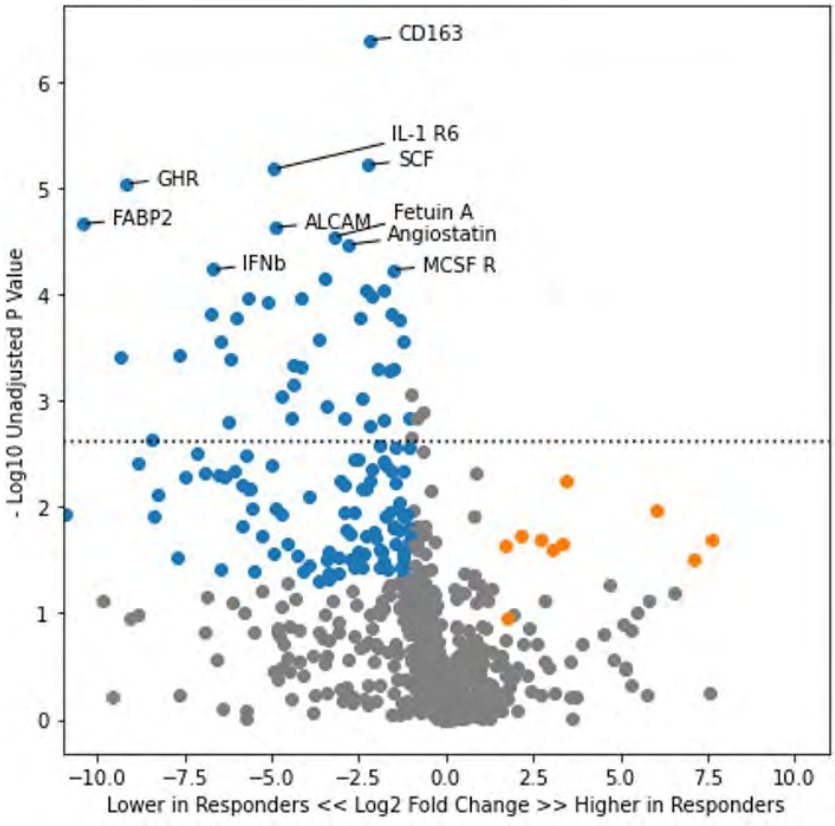

Figure 1. Volcano plot of urinary proteins at Week 52 in the complete responders versus non-responders. Points in blue represent proteins which were lower in the complete response group with an unadjusted p value of < 0.05. Points in orange represent proteins which were higher in the complete response group with an unadjusted p value of < 0.05. The dashed line is the p value threshold for a false discovery rate of 5%.

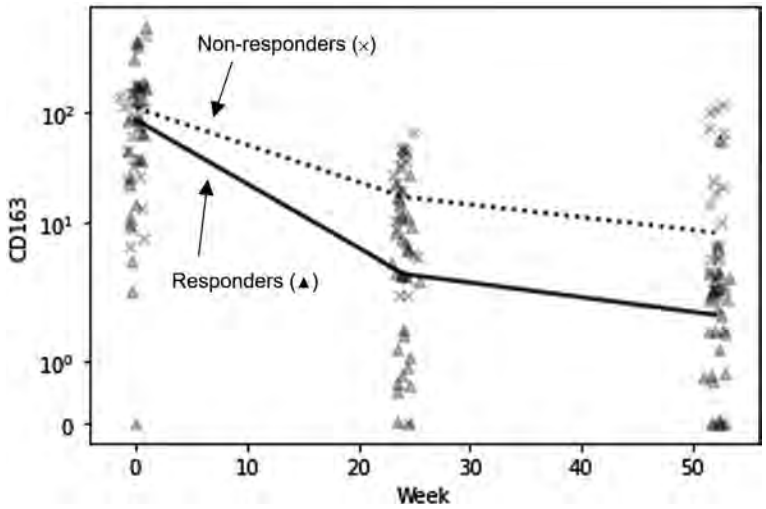

Figure 2. Abundance of CD163 over time in complete responders and non-responders. Each symbol represents one participant's CD163 value at the given time, and the lines represent the median CD163 value per response group at each time point.

IQR 1.1-10.4 pg/mg) and non-responders (median 17.4 pg/mg, IQR 6.2-36.1 pg/mg; adjusted p value = 0.07). CD163 versus time is shown in **Figure 2.** demonstrating a longitudinal reduction in both groups, but with a more robust reduction in CD163 in complete responders. All of the above findings were similarly found within both the belimumab and standard of care treatment subgroups (not shown).

Conclusion: Longitudinal reduction in urinary CD163 abundance was strongly associated with complete response (per the definition used in Methods) in the BLISS-LN trial. These results are consistent with our previous findings in the Accelerating Medicines Partnership SLE project and also those of Mejia-Vilet *et al*. (J Am Soc Nephrol, 2020), and support the potential use of specific urinary biomarkers such as CD163 as noninvasive measures of lupus nephritis response.

Uveitis Status in Patients with Ankylosing Spondylitis or Psoriatic Arthritis Under Secukinumab Treatment - Real World Data from a German Observational Study

Uta Kiltz[1], Jan Brandt-Jrgens[2], Peter Kästner[3], Elke Riechers[4], Daniel Peterlik[5], Annika Boas[6] and Hans-Peter Tony[7], [1]Rheumazentrum Ruhrgebiet Herne, Ruhr-Universität Bochum, Herne, Germany, [2]Rheumatologische Schwerpunktpraxis, Berlin, Germany, [3]Ambulantes Rheumazentrum Erfurt, Erfurt, Germany, [4]Department for Rheumatology and Immunology, Hannover Medical University, Hannover, [5]Novartis Pharma GmbH, Nürnberg, Germany, [6]Novartis Pharma GmbH, Nuernberg, Germany, [7]Universitätsklinikum Würzburg, Wuerzburg, Germany

SESSION INFORMATION
Session Date: Tuesday, November 9, 2021
Session Title: SLE – Treatment Poster (1732–1772)
Session Type: Poster Session D
Session Time: 8:30AM–10:30AM

Background/Purpose: Uveitis is a well-known non-musculoskeletal manifestation of spondyloarthropathies. Patients typically suffer from blurred vision, pain, and photophobia and have an increased risk of ocular complications. Prevalence varies greatly, as uveitis occurs in up to 50% of patients with ankylosing spondylitis (AS) and in approximately 7% of patients with psoriatic arthritis (PsA).[1] The German non-interventional study AQUILA provides real-world data on the development of uveitis in patients with AS or PsA under treatment with secukinumab, a fully human monoclonal antibody that selectively inhibits interleukin-17A. The aim of this interim analysis is to compare baseline (BL) characteristics depending on the presence of uveitis, as well as frequencies and course of uveitis during the study.

Methods: AQUILA is an ongoing, multi-center, non-interventional study including up to 3000 secukinumab treated patients with active AS or PsA. Patients were observed from BL up to week 52 according to clinical routine. Real-world data was assessed prospectively and analyzed as observed. Uveitis and its severity (mild, moderate, severe) was determined by the treating rheumatologist at BL and subsequent study visits. This interim analysis focuses on the subgroups of patients with or without uveitis at BL.

Results: At BL, 668 AS and 1216 PsA patients were included with information on uveitis status available: Prevalence of uveitis at BL was 6.3% (n=42) in AS and 1.7% (n=21) in PsA patients. Demographic data (Table 1) showed that the percentage of males was higher in AS patients with uveitis (78.6%) compared to those without (58.5%). PsA patients did not show this distribution as the percentage of males was lower in patients with uveitis (38.1% versus 41.7%). For both AS and PsA patients, the proportion of obesity (i.e. BMI >30 kg/m^2) was higher in patients with uveitis. One AS patient was included with a moderate uveitis which resolved and came back later with the same severity (uveitis status of this patient was considered as unchanged compared to BL; Figure 1). In all other cases, uveitis status improved or remained unchanged (Figure 1). Furthermore, most of the patients with uveitis remained on secukinumab treatment up to 52 weeks (AS: 61.9%, n=26; PsA: 81.0%, n=17). Both AS and PsA patients with uveitis, had a numerically higher percentage of pretreatment with bDMARDs (biological disease-modifying antirheumatic drugs). In addition, more patients with uveitis received concomitant corticosteroids compared to patients without uveitis throughout 52 weeks observational period (Table 1). Regarding patients without uveitis at BL, 3 patients (1 out of 626 with AS and 2 out of 1195 with PsA) developed new onset uveitis during the study.

Table 1. Overview of BL characteristics depending on the presence of uveitis

	AS		PsA	
Demographics*	**With uveitis at BL (N=42)**	**Without uveitis at BL (N=626)**	**With uveitis at BL (N=21)**	**Without uveitis at BL (N=1195)**
Male	33 (78.6)	366 (58.5)	8 (38.1)	498 (41.7)

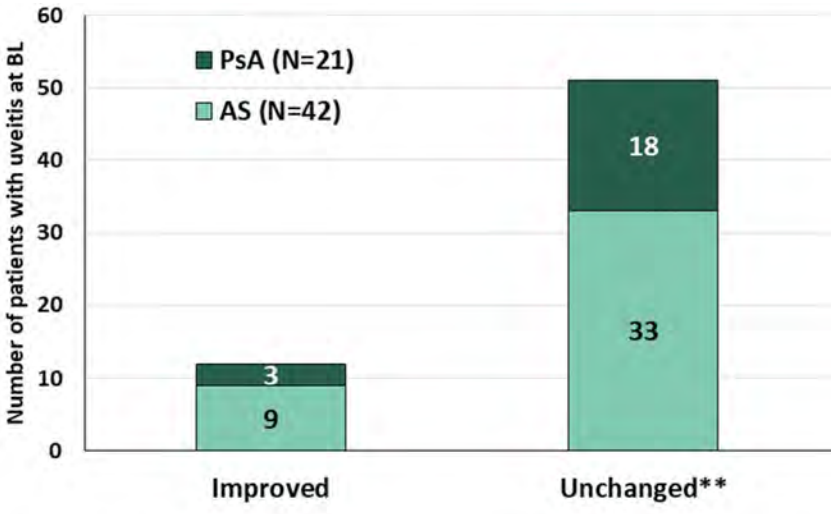
Concomitant medication, n (%):				
Corticosteroids	19 (45.2)	155 (24.8)	11 (52.4)	503 (42.1)
*variables given as mean (SD)				



*Change is defined as alteration of the severity grade (mild, moderate, severe) of uveitis.

**One AS patient started with a moderate uveitis which resolved and then came back later with moderate severity (uveitis status of this patient was considered as unchanged compared to BL)

Figure 1. Change of uveitis status* within 52 weeks of observational period.

Conclusion: In a real-world setting, the number of new onset uveitis under treatment with secukinumab was low. In most patients with uveitis at BL, uveitis status remained unchanged or even improved throughout 52 weeks observational period. Altogether, real-world data of this interim analysis are in line with those of Phase 3 studies and show that secukinumab did not increase the risk of uveitis.

SLE Treatment History and Anifrolumab Efficacy by Baseline Standard Therapies in Patients with SLE from 2 Phase 3 Trials

Susan Manzi[1], Richard Furie[2], Eric Morand[3], Yoshiya Tanaka[4], Gabriel Abreu[5], Catharina Lindholm[5] and Raj Tummala[6], [1]Allegheny Health Network, Pittsburgh, PA, [2]Zucker School of Medicine at Hofstra/Northwell Health, Great Neck, NY, [3]Monash University, Melbourne, Australia, [4]University of Occupational and Environmental Health, Kitakyushu, Japan, [5]BioPharmaceuticals R&D, AstraZeneca, Gothenburg, Sweden, [6]BioPharmaceuticals R&D, AstraZeneca, Gaithersburg, MD

SESSION INFORMATION
Session Date: Tuesday, November 9, 2021
Session Title: SLE – Treatment Poster (1732–1772)
Session Type: Poster Session D
Session Time: 8:30AM–10:30AM

Background/Purpose: In the phase 3 TULIP-1 and TULIP-2 trials, anifrolumab, a type I IFN receptor mAb, improved disease activity versus placebo in patients with moderate to severe SLE despite standard therapy with oral glucocorticoids (GCs), antimalarials, and/or immunosuppressants.[1,2] We investigated prior standard therapy use, and whether baseline standard therapy impacted anifrolumab efficacy in pooled data from TULIP-1 and TULIP-2.

Methods: TULIP-1 (NCT02446912) and TULIP-2 (NCT02446899) were 52-week trials of intravenous anifrolumab 300 mg or placebo every 4 weeks for 48 weeks, in which eligible patients fulfilled the ACR 1997 criteria for SLE. At screening, patients had moderate to severe SLE (SLEDAI-2K ≥6, ≥1 A or ≥2 B BILAG-2004 organ domain scores, Physician's Global Assessment ≥1) and were required to be receiving ≥1 of the following standard therapies: oral GCs, antimalarials, immunosuppressants (azathioprine, mizoribine, mycophenolate mofetil, mycophenolic acid, and/or methotrexate). Patients were divided into subgroups depending on which standard therapies they were receiving at baseline; BILAG–based Combined Lupus Assessment (BICLA) response at Week 52 was compared across subgroups using a stratified Cochran–Mantel–Haenszel approach.

Results: Overall, 726 patients received anifrolumab 300 mg (n=360) or placebo (n=366) in TULIP-1 and TULIP-2. Demographics and baseline disease characteristics were generally balanced between treatment groups. The median time from SLE diagnosis to randomization was 84.5 months, during which most patients had received GCs (89.5%), antimalarials (84.3%), and immunosuppressants (68.0%), and 100%, 34.3%, or 57.3% of patients had received ≥1, 2, or ≥3 SLE-related immunomodulatory therapies, respectively. At baseline, patients were re-

Table. Background Standard Therapy Regimens Prior to and at Baseline in TULIP-1 and TULIP-2

SLE standard therapies		Prior to baseline[a]		At baseline[b]	
		Anifrolumab 300 mg (n=360)	Placebo (n=366)	Anifrolumab 300 mg (n=360)	Placebo (n=366)
Any oral GC[c]		325 (90.3)	325 (88.8)	291 (80.8)	304 (83.1)
	Oral GC only	28 (7.8)	21 (5.7)	56 (15.6)	38 (10.4)
	Oral GC + antimalarial and/or immunosuppressant	297 (82.5)	304 (83.1)	235 (65.3)	266 (72.7)
Any antimalarials		299 (83.1)	313 (85.5)	243 (67.5)	267 (73.0)
	Antimalarial only	28 (7.8)	27 (7.4)	32 (8.9)	38 (10.4)
	Antimalarial + oral GC and/or immunosuppressant	271 (75.3)	286 (78.1)	211 (58.6)	229 (62.6)
Any immunosuppressants		248 (68.9)	246 (67.2)	173 (48.1)	177 (48.4)
	Azathioprine	121 (33.6)	113 (30.9)	62 (17.2)	61 (16.7)
	Cyclophosphamide	50 (13.9)	39 (10.7)	-	-
	Leflunomide	9 (2.5)	9 (2.5)	-	-
	Methotrexate	104 (28.9)	135 (36.9)	56 (15.6)	73 (19.9)
	Mizoribine	9 (2.5)	11 (3.0)	4 (1.1)	3 (0.8)
	Mycophenolate[d]	82 (22.8)	79 (21.6)	54 (15.0)	45 (12.3)
	Tacrolimus	18 (5.0)	23 (6.3)	-	-
	≥2 different immunosuppressants	103 (28.6)	102 (27.9)	3 (0.8)	5 (1.4)

GC, glucocorticoid

[a]Includes any standard therapy with SLE indication used since SLE diagnosis with start date prior to randomization; [b]Baseline is defined as the last measurement prior to randomization and investigational product dose administration on Day 1; [c]Prednisone or equivalent; [d]Mycophenolate or mycophenolic acid.

ceiving GCs (82.0%), antimalarials (70.2%), and/or immunosuppressants (48.2%), with most patients receiving combinations of the three (**Table**). Anifrolumab 300 mg was associated with higher BICLA response rates versus placebo across all evaluated baseline standard therapy subgroups (**Figure**); however, the impact of differing dosages of standard therapy on efficacy was not investigated. The positive treatment differences ranged from 6.9% (antimalarial + immunosuppressant) to 50.8% (immunosuppressant only), but these groups had small sample sizes (n=42 and n=15, respectively), which may limit interpretation of these treatment differences. Clear positive treatment differences favoring anifrolumab 300 mg vs placebo were observed in the 190 patients who were likely to have refractory or severe disease, as they were receiving GCs + antimalarials + immunosuppressants at baseline (53.6% vs 32.2%; Δ=21.4%; 95% CI: 7.4–35.4).

Conclusion: In 2 phase 3 trials, anifrolumab 300 mg was associated with consistently higher BICLA response rates than placebo, regardless of baseline standard therapy usage, including in patients with potentially more treatment-refractory SLE, requiring treatment with GCs, immunosuppressants, and antimalarials.

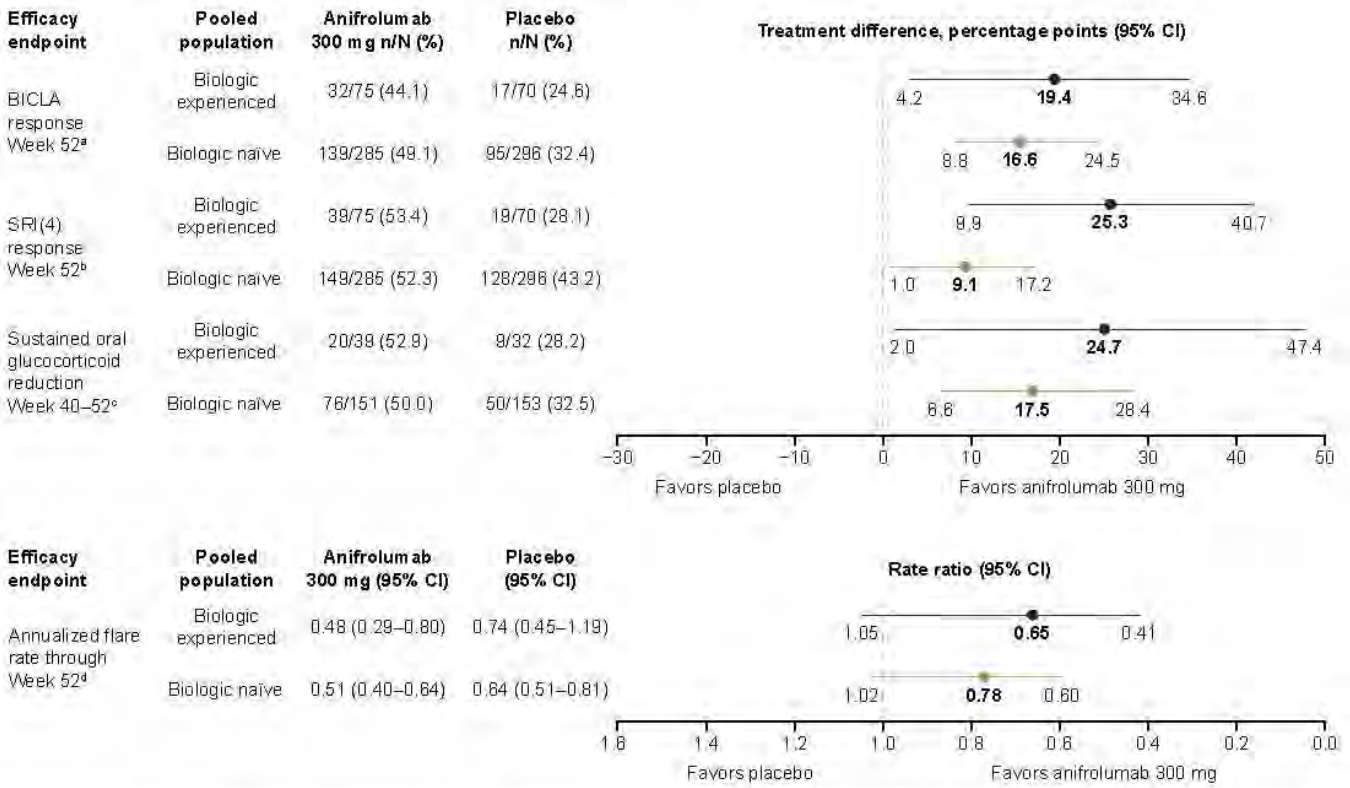
C3, complement 3; C4, complement 4; CLASI, Cutaneous Lupus Erythematosus Disease Area and Severity Index; GC, glucocorticoid; IFNGS, interferon gene signature; SDI, SLICC/ACR Damage Index.
Values are n (%) of patients unless otherwise specified.

[a]The other category includes patients with missing race data; [b]A score ≥1 is indicative of organ damage; [c]At screening rather than baseline; [d]Prednisone or equivalent; [e]Immunosuppressants include azathioprine, methotrexate, mycophenolate mofetil, mycophenolic acid, and mizoribine; [f]Mycophenolate or mycophenolic acid.

Methods: This analysis included patients who received intravenous anifrolumab 300 mg or placebo every 4 weeks for 48 weeks in the 52-week TULIP-1 (NCT02446912) and TULIP-2 (NCT02446899) trials, for which eligible patients met the ACR 1997 SLE criteria, had moderate to severe SLE, and were permitted prior biologic use with a 3–6 month washout period, regardless of the reason for cessation. Patients were split into biologic-experienced or biologic-naïve subgroups (≥1 or 0 previous biologic immunomodulators, respectively). Baseline SLE disease characteristics, efficacy, and safety were compared across subgroups. Efficacy measures included BILAG–based Combined Lupus Assessment (BICLA) response at Week (W) 52; SLE Responder Index of ≥4 (SRI[4]) response at W52; sustained oral glucocorticoid (GC) taper (≤7.5 mg/day prednisone equivalent, W40–52, if ≥10 mg/day at baseline); and annualized flare rate through W52. Binary endpoints and safety were analyzed with a Cochran–Mantel–Haenszel approach controlling for randomization stratification factors and study. Annualized flare rate was analyzed with a negative binomial regression model with treatment, randomization stratification factors, and study as covariates.

Results: There were 145 biologic-experienced patients (anifrolumab [n=75]; placebo [n=70]), and 581 biologic-naïve patients (anifrolumab [n=285]; placebo [n=296]). Most previous biologic use was with belimumab (n=70), epratuzumab (n=49), tabalumab (n=18), or rituximab (n=14). Baseline demographics, disease characteristics, and non-biologic SLE treatments were generally similar between groups. However, compared with biologic-naïve patients, biologic-

Figure. Forest Plot of Efficacy Endpoints in the Biologic-Experienced and Biologic-Naïve Patients With SLE in Data Pooled From the TULIP-1 and TULIP-2 Trials



BICLA, BILAG-based Composite Lupus Assessment; CI, confidence interval; IFNGS, interferon gene signature; n, number of responders; N, number of patients in the group; PGA, Physician's Global Assessment; SRI(4), SLE Responder Index ≥4.
The response rates, the differences in response rates, and associated 95% CIs were calculated using a stratified Cochran–Mantel–Haenszel method with stratification factors of SLEDAI-2K score at screening, baseline oral glucocorticoid dosage, IFNGS status, and study; therefore, percentages do not equal n/N*100. Annualized flare rate was analyzed with a negative binomial regression model.
[a]A BICLA response required: Reduction of all baseline BILAG-2004 A and B domain scores to B/C/D and C/D, respectively, and no worsening in other BILAG-2004 organ systems (worsening defined as ≥1 new BILAG-2004 A or ≥2 new BILAG-2004 B items), no increase in SLEDAI-2K score from baseline, no increase ≥0.3 points in PGA score from baseline, no use of restricted medications beyond protocol-allowed thresholds, and no discontinuation of investigational product; [b]An SRI(4) response required: ≥4-point reduction in SLEDAI-2K, <1 new BILAG-2004 A or <2 new BILAG-2004 B organ domain scores, <0.3-point increase in PGA from baseline; no use of restricted medications beyond protocol-allowed thresholds; and no discontinuation of investigational product; [c]Defined as oral glucocorticoid dosage reduction to ≤7.5 mg/day from Week 40 to 52 in patients with baseline dosage ≥10 mg/day prednisone or equivalent; [d]A flare is defined as either ≥1 new BILAG-2004 A or ≥2 new BILAG-2004 B items compared with the previous visit.

Table 2. Safety in Biologic-Experienced and Biologic-Naïve Patients With SLE in Data Pooled From the TULIP-1 and TULIP-2 Trials

AE category, n (%)	Biologic experienced		Biologic naïve	
	Anifrolumab 300 mg (n=75)	Placebo (n=69)	Anifrolumab 300 mg (n=285)	Placebo (n=296)
Any AE	68 (90.7)	61 (88.9)	250 (87.8)	234 (79.2)
Any SAE[a]	12 (15.7)	16 (23.3)	28 (9.9)	44 (14.9)
Any AE leading to discontinuation of investigational product	4 (5.4)	5 (7.4)	13 (4.6)	13 (4.5)
Any AESI	9 (12.8)	9 (13.3)	37 (13.0)	27 (9.2)
Non-opportunistic serious infections	3 (4.2)	7 (10.3)	13 (4.6)	15 (5.1)
Opportunistic infections	0	0	1 (0.4)	0
Anaphylaxis	0	0	0	0
Malignancy	0	1 (1.3)	3 (1.1)	2 (0.7)
Herpes zoster	4 (5.7)	1 (1.6)	19 (6.7)	4 (1.4)
Tuberculosis (including latent)	0	0	2 (0.7)	1 (0.3)
Influenza	1 (1.5)	1 (1.6)	5 (1.7)	7 (2.4)
Vasculitis (non-SLE)	0	0	0	0
Major adverse cardiovascular events	1 (1.5)	0	0	0

AE, adverse event; AESI, adverse event of special interest; SAE, serious adverse event.
Safety was analyzed in the safety population, which excluded 1 biologic-experienced patient who received placebo. The percentages were adjusted with a stratified Cochran–Mantel–Haenszel method with stratification factors of SLEDAI-2K score at screening, baseline oral glucocorticoid dosage, IFNGS status, and study; therefore, percentages do not equal n/N*100.
[a]Including events with outcome of death.

experienced patients had longer times from SLE diagnosis, were more likely to be from USA/Canada, have SLICC/ACR Damage Index score ≥1, anti-dsDNA antibodies, and IFN gene signatures, and less likely to have swollen/tender joints (**Table 1**). There were lower placebo responses (potentially more refractory disease) in biologic-experienced vs biologic-naïve patients (**Figure**). Anifrolumab was associated with comparable/greater treatment differences over placebo (Δ) in biologic-experienced vs biologic-naïve patients across endpoints, including BICLA (Δ=19.4 vs Δ=16.6), SRI(4) (Δ=25.3 vs Δ=9.1), and GC tapers (Δ=24.7 vs Δ=17.5). Incidence of serious adverse events was higher in biologic-experienced vs biologic-naïve patients with anifrolumab and placebo (**Table 2**). Herpes zoster incidence was higher with anifrolumab vs placebo in both biologic-experienced and biologic-naïve patients.

Conclusion: Regardless of whether patients with SLE had previously received biologics, anifrolumab 300 mg provided clinically meaningful benefit over placebo across efficacy endpoints and was generally well tolerated.

Anifrolumab Results in Favorable Responses Regardless of SLE Disease Duration: Post Hoc Analysis of Data from 2 Phase 3 Trials

Kenneth Kalunian[1], Maria Dall'Era[2], Richard Furie[3], Eric Morand[4], Konstantina Psachoulia[5], Emmanuelle Maho[6], Catharina Lindholm[7] and Raj Tummala[5], [1]University of California, La Jolla, CA, [2]University of California San Francisco, San Francisco, CA, [3]Zucker School of Medicine at Hofstra/Northwell Health, Great Neck, NY, [4]Monash University, Melbourne, Australia, [5]BioPharmaceuticals R&D, AstraZeneca, Gaithersburg, MD, [6]BioPharmaceuticals R&D, AstraZeneca, Cambridge, United Kingdom, [7]BioPharmaceuticals R&D, AstraZeneca, Gothenburg, Sweden

SESSION INFORMATION

Session Date: Tuesday, November 9, 2021
Session Title: SLE – Treatment Poster (1732–1772)
Session Type: Poster Session D
Session Time: 8:30AM–10:30AM

Background/Purpose: In 2 phase 3 trials, TULIP-1 and TULIP-2, anifrolumab, a type I IFN receptor mAb, improved disease activity in patients with SLE.[1,2] Here, we compared the efficacy of anifrolumab in patients with recent onset vs established SLE disease (defined by time since diagnosis), using pooled data from the TULIP trials.

Methods: TULIP-1 (NCT02446912) and TULIP-2 (NCT02446899) were randomized, placebo-controlled, 52-week trials of intravenous anifrolumab 300 mg every 4 weeks for 48 weeks in eligible patients who fulfilled the ACR 1997 criteria for SLE and had moderate to severe SLE despite standard therapy.[1,2] Baseline characteristics and BILAG–based Composite Lupus Assessment (BICLA)[3] response rates at Week 52 for anifrolumab 300 mg vs placebo were compared between patients who at the time of their baseline study visits were within 2 years of their SLE diagnosis (recent onset) and patients who were diagnosed beyond 2 years (established). Efficacy was analyzed with a stratified Cochran–Mantel–Haenszel approach controlling for randomization stratifications factors and study.

Results: Of the 726 patients included from TULIP-1 and TULIP-2 (anifrolumab, n=360; placebo, n=366), 594 had established disease (anifrolumab, n=301; placebo, n=293), and 132 had recent onset disease (anifrolumab, n=59; placebo, n=73) at baseline. In contrast to patients with recent onset disease, patients with established disease had a higher median age (43 vs 37 years), were more likely to be female (94.1% vs 87.1%), and less likely to be black (12.1% vs 16.7%). At baseline, patients with established disease were more likely to be IFN gene signature high (83.5% vs 78.8%), anti-dsDNA antibody-positive (45.6% vs 38.6%), have ≥1 BILAG-2004 A item (49.7% vs 43.9%), have a higher mean global SDI score (0.7 vs 0.1), and be receiving oral glucocorticoids (83.2% vs 76.5%), and immunosuppressants (49.8% vs 40.9%), but not anti-malarials (69.5% vs 78.0%) (**Table**). The numbers of BILAG-2004 A or B items across organ domains at baseline were comparable in patients with established or recent onset disease, excluding the renal domain, where a higher proportion of patients with established disease had more severe scores (A or B items; 8.9% vs 3.0%) (**Figure**). Treatment benefit of anifrolumab vs placebo, assessed by BICLA response at Week 52, was observed in patients with established (difference [95% CI] 17.1% [9.3–24.8], nominal $P<0.001$) and recent onset disease (difference [95% confidence intervals (CI)] 14.4% [–2.2–31.1], nominal $P=0.090$).

Table. Baseline Demographics, SLE Disease Characteristics, and Treatments in Data Pooled from TULIP-1 and TULIP-2 Trials

		Duration of disease					
		Recent onset (≤2 years)			Established (>2 years)

SESSION INFORMATION

Session Date: Tuesday, November 9, 2021

Session Title: SLE – Treatment Poster (1732–1772)

Session Type: Poster Session D

Session Time: 8:30AM–10:30AM

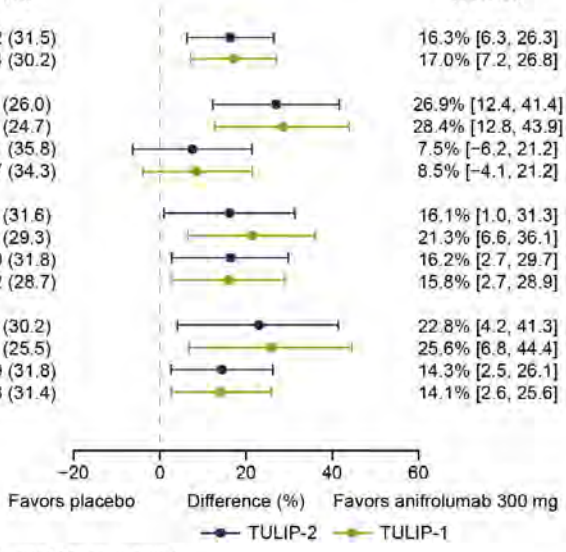
Background/Purpose: In the TULIP-2 and TULIP-1 trials of patients with SLE, the type I IFN receptor mAb anifrolumab resulted in higher BILAG–based Composite Lupus Assessment (BICLA) response rates vs placebo at Week 52.[1,2] Subgroup analyses revealed concordant BICLA response rates across clinically distinct SLE subgroups, including disease severity and SLE therapies.[3] Here, we compare BICLA response rates in serological subgroups (low complement, anti-dsDNA positivity, or both).

Methods: TULIP-2 (NCT02446899) and TULIP-1 (NCT02446912) were phase 3, randomized, placebo-controlled, 52-week trials of intravenous anifrolumab every 4 weeks for 48 weeks in eligible patients who fulfilled the ACR 1997 criteria for SLE and had moderate to severe SLE despite standard therapy.[1,2] BICLA response rates at Week 52 for anifrolumab vs placebo groups were compared across patient subgroups of baseline complement C3/C4 levels (low/normal) and anti-dsDNA antibody status (positive/negative).

Results: In TULIP-2 and TULIP-1, 180 patients in each trial received anifrolumab 300 mg, and 182 and 184 patients received placebo, respectively. BICLA response rates in the overall anifrolumab groups were similar in TULIP-2 (47.8%) and TULIP-1 (47.1%), with treatment differences (Δ) favoring anifrolumab over placebo (Δ=16.3% and 17.0%, respectively) (**Figure**). Anifrolumab response rates were generally higher in serologically abnormal vs normal subgroups in TULIP-2 (47.7%–52.9% vs 43.3%–47.9%) and TULIP-1 (50.6%–53.0% vs 42.8%–45.5%); the greatest anifrolumab response rate was seen in the low C3/C4 subgroup (TULIP-2: 52.9%; TULIP-1: 53.0%), while anifrolumab response rates were similar regardless of anti-dsDNA positivity. In contrast, placebo response rates were generally lower in serologically abnormal vs normal subgroups in TULIP-2 (26.0%–31.6% vs 31.8%–35.8%) and TULIP-1 (24.7%–29.3% vs 28.7%–34.3%), although placebo responses were similar regardless of anti-dsDNA positivity. Anifrolumab and placebo subgroup response rates did not vary by more than ±6% from the overall population. These variations in response rates led to greater treatment differences favoring anifrolumab in patients with low C3/C4, alone or in combination with anti-dsDNA positivity, vs the overall population; the largest difference was seen for patients with low C3/C4 (TULIP-2: Δ=26.9%; TULIP-1: Δ=28.4%). In the subgroups with normal serology, treatment

Figure. BICLA Response at Week 52 by Subgroup in the TULIP-2 and TULIP-1 Trials

	Anifrolumab 300 mg n/N (%)	Placebo n/N (%)	Treatment difference, percentage points (95% CI)
All patients	86/180 (47.8)	57/182 (31.5)	16.3% [6.3, 26.3]
	85/180 (47.1)	55/184 (30.2)	17.0% [7.2, 26.8]
Low complement (C3 or C4)	46/87 (52.9)	21/81 (26.0)	26.9% [12.4, 41.4]
	35/66 (53.0)	19/77 (24.7)	28.4% [12.8, 43.9]
No low complement (neither C3 nor C4)	40/93 (43.3)	36/101 (35.8)	7.5% [−6.2, 21.2]
	50/114 (42.8)	36/107 (34.3)	8.5% [−4.1, 21.2]
Anti-dsDNA positive	41/86 (47.7)	23/73 (31.6)	16.1% [1.0, 31.3]
	41/81 (50.6)	24/82 (29.3)	21.3% [6.6, 36.1]
Anti-dsDNA not positive	45/94 (47.9)	34/109 (31.8)	16.2% [2.7, 29.7]
	44/99 (44.5)	31/102 (28.7)	15.8% [2.7, 28.9]
Low complement (C3 or C4) and anti-dsDNA positive	27/51 (52.9)	16/53 (30.2)	22.8% [4.2, 41.3]
	24/47 (51.1)	13/51 (25.5)	25.6% [6.8, 44.4]
No (Low complement [C3 or C4] and anti-dsDNA positive)	59/129 (46.1)	41/129 (31.8)	14.3% [2.5, 26.1]
	61/133 (45.5)	42/133 (31.4)	14.1% [2.6, 25.6]



BICLA, BILAG–based Composite Lupus Assessment; C3, complement 3; C4, complement 4; CI, confidence interval; CMH, Cochran–Mantel–Haenszel; n, number of responders; N, number of patients in treatment subgroup.
The responder rates (percentages) and associated 95% CIs are weighted and are calculated using a stratified CMH approach, with stratification factors (SLEDAI-2K score at screening [<10 points vs ≥10 points], Week 0 oral glucocorticoid dose [<10 mg/day vs ≥10 mg/day prednisone or equivalent], and type I IFN gene signature test result at screening [high vs low]). Percentages are based upon all subjects in the full analysis set within subgroups. Baseline is defined as the last measurement prior to randomization and dose administration on Day 1.

differences ranged from 7.5%–16.2% in TULIP-2 and 8.5%–15.8% in TULIP-1; thus, treatment differences favored anifrolumab vs placebo in all evaluated serology subgroups.

Conclusion: BICLA response rates in clinically distinct subgroups of SLE were generally consistent with the overall TULIP-2 and TULIP-1 results.[3] Patients with low complement at baseline appeared to have a greater treatment effect than those with normal complement, while anti-dsDNA antibody status did not associate with response. The subgroup analyses indicate efficacy of anifrolumab 300 mg across all evaluated serological subgroups of SLE.

Whole Blood Hydroxychloroquine Levels Do Not Correlate with QTc Intervals in a Cohort of 84 SLE Patients: Evidence That Antimalarials Are Not Associated with Cardiac Conduction System Toxicity

Mayce Haj-Ali[1] and **H. Michael Belmont**[2], [1]NYU Grossman School of Medicine, New York, NY, [2]NYU School of Medicine, New York, NY

SESSION INFORMATION

Session Date: Tuesday, November 9, 2021
Session Title: SLE – Treatment Poster (1732–1772)
Session Type: Poster Session D
Session Time: 8:30AM–10:30AM

Background/Purpose: Hydroxychloroquine (HCQ) is an antimalarial drug used in the treatment of systemic lupus erythematous (SLE). There is limited data assessing cardiac toxicity as arrhythmias in association with HCQ exposure based on dose prescribed or pharmacy records and none relying on measured drug levels. Some of the risk factors associated with conduction abnormalities in the setting of hydroxychloroquine use include presence of chronic kidney disease, older age, underlying cardiomyopathy, and the use of concomitant prolonging QTc agents. In a retrospective study of 194 SLE patients on HCQ, the authors found that there was no significant difference in mean QTc based on HCQ use. Additionally, patients with CKD were more likely to have prolonged QTc when compared to those without CKD, but there was no significant difference in mean QTc based on HCQ use as well in this subset. Severe prolongation of QTc was rare in all groups and no episodes of serious tachyarrhythmia or Torsade de Pointes

were observed. The purpose of this study is to determine the relationship between whole blood HCQ levels and QTc intervals on simultaneous EKG performed during a routine visit.

Methods: This prospective study was IRB approved and all patients provided consent. At the time of data lock, 84 patients fulfilled ACR/SLICC criteria for SLE. These patients were on HCQ for at least 3 months at doses used for standard of care treatment. Whole blood levels were drawn and EKGs were obtained during a routine outpatient faculty practice visit for patients consecutively seen between February 5 and May 10, 2021 with senior author. Statistical analyses was performed using one way ANOVA, Pearson's correlation coefficient and t-test.

Results: 84 patients, 93% female, 47% European, 35% African, 15% Asian, and 25% Hispanic were included (Table 1). HCQ levels were higher in patients on 400 mg, lower after 10 years of exposure, and unrelated to eGFR (Table 2). There was no correlation between blood HCQ levels and QTc intervals in the 84 patients (r=-0.017; p=0.87) (Fig 1a).

Table 1. Demographics

Total (N=84)	Number of patients (%)
GENDER	
Female	78 (93%)
Male	6 (7%)
RACE	
African ancestry	29 (35%)
Asian ancestry	15 (18%)
European ancestry	40 (47%)
ETHNICITY	
Non-Hispanic	63 (75%)
Hispanic	21 (25%)

Table 2A: HCQ blood levels and different HCQ dosing

	HCQ 400 mg daily (n= 51)	HCQ 300 mg daily (n= 8)	HCQ 200 mg daily (n = 22)	HCQ 200 mg TIW (n = 5)
HCQ mean level (ng/mL)	1250 ± 678	776 ± 542	662 ± 392	378 ± 299

*p= 0.0001; f-ratio=7.637

Table 2B: HCQ blood levels by duration of exposure

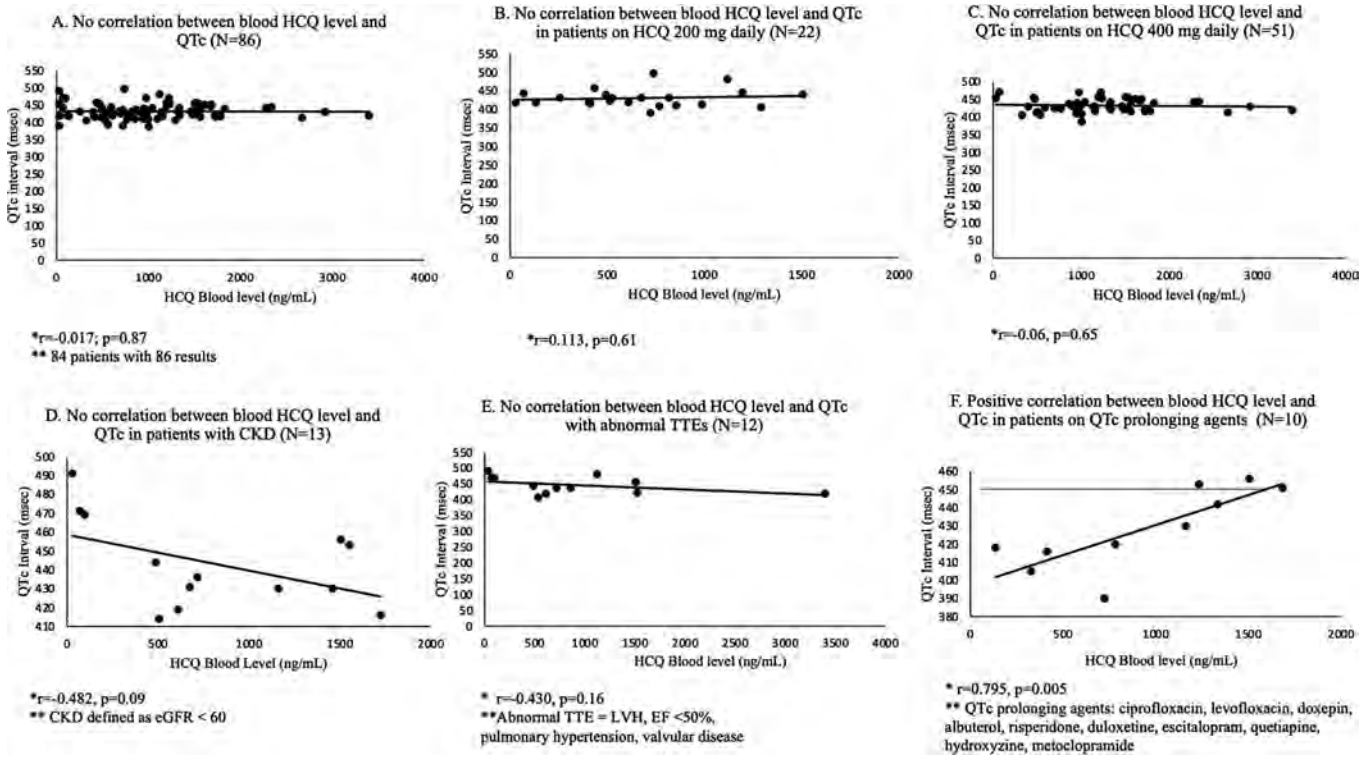
Duration of Exposure (years)	HCQ mean level, ng/mL (mean, +/- SD)
0-5	1385 ± 692
5-10	1099 ± 733
>10	769 ± 493

*p= 0.001; f-ratio=7.489

Table 2C: HCQ blood levels by eGFR

	eGFR <60 (n= 13)	eGFR >60 (n= 73)
HCQ mean level, ng/mL (mean, +/-SD)	815 ± 601	1038 ± 664

*p= 0.262



Additionally, there was no correlation between blood HCQ levels and QTc intervals in patients on 200 mg or 400 mg of HCQ (r=0.113, p=0.61; r=-0.06, p=0.65) (Fig 1b-c). There was no correlation between blood HCQ levels and QTc intervals in patients who had chronic kidney disease (defined as eGFR < 60), (r=-0.482, p=0.09) or those with underlying cardiac abnormalities noted on transthoracic echocardiogram (r=-0.430, p=0.16) (Fig 1d-e). However, there was a positive correlation between blood HCQ levels and QTc intervals in patients who were on concomitant QTc prolonging agents, (r=0.795, p=0.005). but none in excess of 456 msec (Fig 1f).

Conclusion: Our study provides reassurance that hydroxychloroquine is not associated with QTc prolongation in patients with SLE and across different subsets of patients irrespective of blood level, dose prescribed, CKD or underlying cardiac abnormalities. There was a positive correlation between blood HCQ levels and QTc intervals in patients on concomitant QTc prolonging agents, but none were severely prolonged (eg > 500 msec). This is the first study relying on measured blood levels demonstrating the absence of consequential increase in QTc levels in HCQ treated SLE patients.

Prior Chronic Steroid Use (%)	12/12 (100%)	9/61 (14.75%)
SLE related thrombocytopenia, anemia or leukopenia	7/12(58.3%)	9/61 (14.75%)

pro-inflammatory immune cell lineage specification in SLE (2). We herein, aim to define the safety, tolerance and selected renal and non-renal outcome measures in SLE patients who received sirolimus therapy in our institution over the past 21 years.

Table 2. Analysis of Selected Lupus outcome measures on nephritis and non-nephritis lupus cohort with sirolimus treatment. Data are presented as mean and SD for each patient subset. Effect of sirolimus was analyzed with two-tailed paired t-tests and chi-squared test, p values < 0.05 were considered significant (S*): Y, yes; N, no.

Outcome Measures	Nephritis Cohort				Non-Nephritis Cohort			
	Before sirolimus	After sirolimus	p value	S*	Before sirolimus	After Sirolimus	p value	S*
Urine Protein Creatinine ratio mg/mg	4.37 ± 4.48	1.59 ± 2.35	0.0287	Y	0.12 ± 0.07	0.11 ± 0.06	0.6251	N
Serum creatinine (mg/dL)	1.13 ± 0.63	0.93 ± 0.33	0.3330	N	0.85 ± 0.24	0.87 ± 0.34	0.1763	N
Hematuria or red cell cast (N/HPF)	12.6 ± 16.1	1.5 ± 3.1	0.0232	Y	2.1 ± 13.8	2.8 ± 20.0	0.4604	N
Change in sterile pyuria (N/HPF)	9.25 ± 25.5	1.0 ± 0.85	0.2808	N	0.8 ± 3.8	1.0 ± 6.7	0.5882	N
Anti-DNA antibody titers (IU)	244.4 ± 217	63.1 ± 74	0.0028	Y	158.4 ± 56	33.3 ± 45.9	0.0332	Y
C3 levels (mg/dL)	73.4 ± 17.2	104.1 ± 32.6	0.0070	Y	70.6 ± 16.8	94.9 ± 19.5	0.0021	Y
C4 levels (mg/dL)	11.2 ± 6.8	18.3 ± 9.5	0.0063	Y	10.7 ± 6.3	16.7 ± 9.1	0.0042	Y
CH 50 levels (U/ml)	61.2 ± 39	68.7 ± 34	0.4721	N	37 ± 5.5	41 ± 27.8	0.1112	N
Mean steroid dose (mg)	19.4 ± 12.4	2.8 ± 1.9	0.0200	Y	10.25 ± 7.3	2.43 ± 5.1	0.0163	Y
Change in Mycophenolate use	12/12 (100%)	7/12 (58.3%)	0.0593	N	N/A	N/A	N/A	N/A
Change in thrombocytopenia	3/12 (25%)	1/12 (8.3%)	0.2733	N	7/61	6/61 (9.83%)	0.7691	N
Change in leukopenia	2/12 (16.7%)	1/12 (8.3%)	0.5370	N	3/61	4/61 (6.56%)	0.6970	N
Change in SLE related anemia	6/12 (50%)	4/12 (8.3%)	0.4076	N	4/61	3/61 (4.92%)	0.6970	N

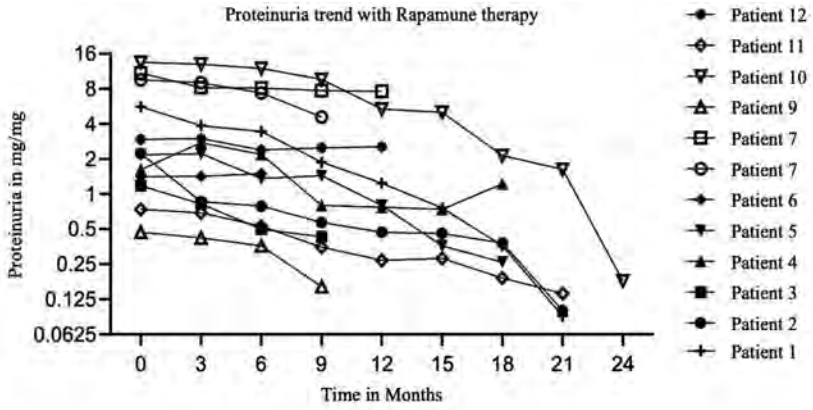

Figure 1. Longitudinal changes in proteinuria (urine protein/creatinine ratio - mg/mg) in twelve patients who received sirolimus therapy. The overall trend depicts the reduction of proteinuria over time.

Methods: We identified a total of 87 SLE patients in our institution who were on sirolimus therapy from March 2000 to March 2021 with the use of Epic EMR slicer-dicer. We included 73 patients, who met the SLE International Collaborating Clinics 2012 criteria and could tolerate sirolimus for at least 3 months (mean duration 38.8±34.9 months), and the rest were excluded. All patients received oral sirolimus with a starting dose of 2 mg daily, and further titrated based on their tolerance to maintain a therapeutic range of 6–15 ng/mL. We evaluated the influence of sirolimus on selected outcome measures. Continuous and categorical variables were analyzed by paired t-test and chi-squared test, respectively. Two-tailed p-value < 0.05 was considered significant.

Results: The details of the baseline demographic and clinical characteristics are summarized in Table 1. The mean age of the total population is 50.6 ± 14.1, consisting of 66/73 (90.4%) females and 7/73 (9.6%) males. The ethnic diversity of the total population consists of 63/73 86.3% whites, 9 (12.3%) African Americans, and (1/73)1.4% Asians. Treatment of active lupus nephritis with sirolimus resulted in a statistically significant reduction in proteinuria (Figure 1), and microscopic hematuria. (Table 2) In the lupus nephritis cohort 12 patients, the reduction was observed in urine protein creatinine ratio (p=0.0287), hematuria (p=0.0232), anti-DNA antibody levels (p=0.0028) and mean steroid dose (p=0.0200). In the non-renal cohort of 61 patients, anti-DNA antibody levels (p=0.0332) and mean steroid dosages were reduced (p=0.0163). Both in the renal and non-renal cohorts, increases of in complement levels C3 (renal p=0.0070; non-renal p=0.0021) and C4 were observed (renal p=0.0063; non-renal p=0.0042). Adverse effects of mouth sores (2/73), headaches (1/73), and gastrointestinal discomfort were noted in a minority of patients (6/73). Sirolimus was only discontinued in two of 73 patients due to headache and recurrent infections, respectively.

Conclusion: This study suggests that sirolimus is well tolerated and exerts long-term therapeutic efficacy in controlling renal and non-renal manifestations of SLE. Double-blind placebo-controlled trials are needed to further substantiate the significance of these findings.

Pre-pregnancy Switching from Mycophenolate to Azathioprine in Patients with Lupus Nephritis: A Retrospective Outcome Analysis

Saadia Ali[1], Shirish Sangle[2], Maha Al Falah[3] and David D'Cruz[4], [1]Guys and St Thomas' Hospital NHS Trust, Epsom, United Kingdom, [2]Guy's and St Thomas' Hospital NHS Trust, London, United Kingdom, [3]Guys and St Thomas' Hospital NHS Trust, Saudi Arabia, United Arab Emirates, [4]Guy's and St Thomas' NHS Foundation Trust, London, United Kingdom

SESSION INFORMATION
Session Date: Tuesday, November 9, 2021
Session Title: SLE – Treatment Poster (1732–1772)
Session Type: Poster Session D
Session Time: 8:30AM–10:30AM

Background/Purpose: Mycophenolate Mofetil is not recommended in pregnancy due to teratogenic effects. A previous small prospective study found that switching from MMF to AZA rarely led to renal flares. Our aim was to assess the impact of switching from MMF to AZA on renal flares and pregnancy outcomes in a lupus nephritis cohort.

Methods: A retrospective analysis of the records of patients attending the renal and antenatal clinics at St Thomas's Hospital in London who underwent pre-pregnancy counselling and switched from MMF to AZA was undertaken between January 2019 and December 2020. Inclusion criteria included a diagnosis of SLE based on the 2019 EULAR/ACR classification criteria for SLE and lupus nephritis assessed by a biopsy and classified according to the International Society of Nephrology/Renal Pathology Society 2003 classification. A flare was defined as rising urine PCR, decreasing serum albumin, decreasing serum complement and rising dsDNA antibodies and/or an increase in serum creatinine. Analyses included descriptive statistics [mean (standard deviation) and median (interquartile ranges) for continuous variables and frequency (percent) for categorical values].

Results: Twenty-seven patients were included in this study. 55% were of Afro-Caribbean or Asian background and remaining were Caucasian. The median age at SLE diagnosis was 22 (18-26) years. The average disease duration prior to treatment switch was 8 years. The median time between biopsy and switching was 32 months (17-69). 25.9% of patients had a diagnosis of APS. 48% were Ro positive, while 85.2% were positive for dsDNA antibodies. The median serum creatinine was 69 umol/L (58-84), median serum albumin was 42g/L (38-47) and median PCR was 26.5mg/mol (12-61) prior to switching. Our study showed that 9 patients (33.3%) flared after switching (Table 1). 5 patients (18.5%) flared during pregnancy. 10 (37%) patients went onto have successful pregnancies, 2 (7.4%) had miscarriages, 3 (11.1%) patients developed preeclampsia. 46% of patients with class III/IV Nephritis on biopsy developed complications in pregnancy. 36% of patients with dsDNA had poor pregnancy outcomes compared to 25% who were dsDNA negative. 42.2% of patients of Afro-Caribbean/Asian background flared during pregnancy compared to 25% of their Caucasian counterparts.

Table 1. Characteristics of SLE patients who flared

	No. of women	Flare*	No Flares
Total Number of women	27	9 (33.3%)	18 (66.6%)
Age			
<40	13	6 (46.1%)	7 (53.8%)
>40	14	7 (50%)	7 (50.0%)
Ethnicity			
Afro-Caribbean/Asian	14	4 (28.5%)	9 (64.2%)
Caucasian	12	5 (41.6%)	7 (58.3%)
Serum Albumin (g/L)			
<40	5	4 (80.0%)	1 (20.0%)
>40	19	5 (26.3%)	14 (73.6%)
Serum Creatinine (umol/L)			
<65	10	3 (30.0%)	7 (70.0%)
>65	16	7 (43.7%)	9 (56.2%)
Urine PCR (mg/mol)			
<50	17	5 (29.4%)	12 (70.5%)
>50	5	3 (60%)	2 (40%)
Hypocomplementemia	19	7 (36.8%)	12 (63.1%)
DsDNA positive	23	9 (39.1%)	14 (60.8%)
DsDNA negative	4	1 (25.0%)	3 (75.0%)

***refers to flare after switching and during pregnancy**

Conclusion: Although Azathioprine is an option in patients with lupus nephritis who are planning pregnancy, there is a need to identify patients at risk of a disease flare on switching from MMF. This study showed that patients with low serum albumin, creatinine >65, urine PCR >50 and positive dsDNA antibodies at the time of the switch were more likely to flare after switching and in pregnancy.

SESSION INFORMATION

Session Date: Tuesday, November 9, 2021

Session Title: SLE – Treatment Poster (1732–1772)

Session Type: Poster Session D

Session Time: 8:30AM–10:30AM

Background/Purpose: Baricitinib (BARI), an oral, selective Janus kinase (JAK)1 and JAK2 inhibitor, improved disease activity in adults with systemic lupus erythematosus (SLE) receiving standard background therapy in a phase 2 trial[1].

There were no meaningful reductions in least squares mean change from baseline (BL) in levels of serologic biomarkers for SLE with BARI treatment, including anti-double-stranded deoxyribonucleic acid (anti-dsDNA) antibodies and complement component (C)3 and C4[1]. The objective was to evaluate the median change from BL in serologic biomarkers in subgroups and the overall population of BARI-treated patients (pts) with SLE, in addition to the SLE Responder Index-4 (SRI-4) response by normalization of anti-dsDNA.

Methods: Data were assessed from the phase 2 trial JAHH (NCT02708095). All pts met ACR or SLICC classification criteria for SLE [2,3]. The median change from BL in anti-dsDNA, IgG, C3, C4, anti-Smith, Anti-cardiolipin IgM (aCL IgM), Anti-cardiolipin IgG (aCL IgG), Anti-cardiolipin IgA (aCL IgA), Anti-nuclear ribonucleoprotein (anti-RNP), Anti- Sjogren's-syndrome-related (SS) antigen-A (Ro/SSA) and Anti-SS antigen-B (Ro/SSB) were evaluated over time among the following populations at BL: anti-dsDNA positive (≥30 IU/mL), low C3 (< 90 mg/dL), low C4 (< 10 mg/dL), anti-Smith (≥30 IU/mL), aCL IgM (>12MPL), aCL IgG (>14 GPL), aCL IgA (>11 APL), anti-RNP (≥30 IU/mL), Ro/SSA and Ro/SSB (>20 IU/mL). Statistical tests were conducted for BARI 2-mg and 4-mg compared with placebo (PBO). Among pts who were anti-dsDNA positive at BL, SRI-4 responder rate was compared for those who stayed positive or achieved normal levels by Week (Wk) 24.

Results: Among pts who were anti-dsDNA positive at BL, significant decreases of anti-dsDNA antibodies were observed for BARI 2-mg and 4-mg compared to PBO beginning at Wks 2 and 4, respectively, and continuing through

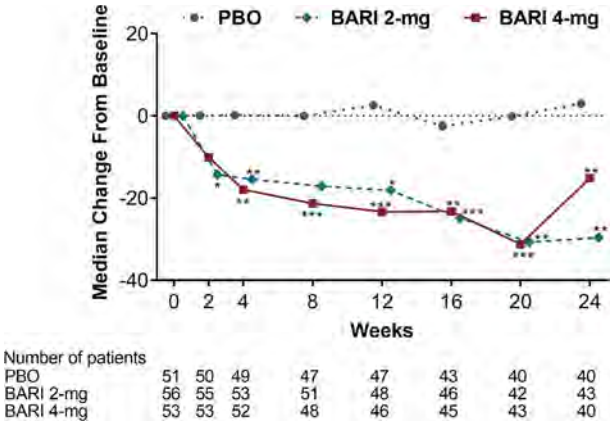

Figure 1. Median change from baseline in anti-dsDNA (IU/mL) (*p≤0.05, **p≤0.01 for BARI vs. PBO, BARI=baricitinib; Ig=immunoglobulin; PBO=placebo).

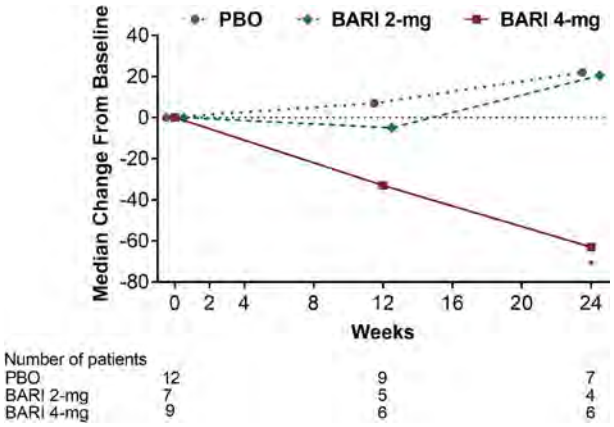

Figure 2. Median change from baseline in Anti-Smith (IU/mL) (*p≤0.05, **p≤0.01 for BARI vs. PBO, BARI=baricitinib; Ig=immunoglobulin; PBO=placebo).

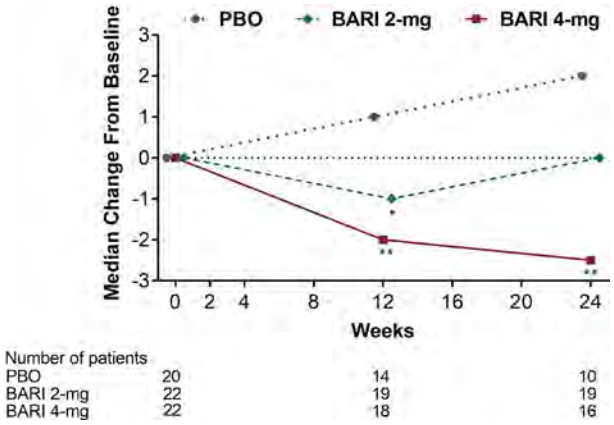

Figure 3. Median change from baseline in Anti-Cardiolipin IgM (IU/mL) (*p≤0.05, **p≤0.01 for BARI vs. PBO, BARI=baricitinib; Ig=immunoglobulin; PBO=placebo).

Wk 24 (Fig 1). Moreover, reductions of IgG levels were found for BARI-treated pts including significant decreases for BARI 4-mg compared to PBO at Wks 12 and 24. Among pts who had low levels of C3 and C4 at BL, no significant differences in median change from BL were observed over time with BARI compared to PBO. Among pts who had high levels of anti-Smith and aCL IgM at baseline, significant decreases in median levels were observed over time for BARI 4-mg compared with PBO (Fig 2 and 3). However, no significant changes in median values from BL were observed for aCL IgG, aCL IgA, anti-RNP, Ro/SSA and Ro/SSB autoantibodies. For pts who were anti-dsDNA positive at BL, no relationship in SRI-4 responder rate was observed for those who stayed positive or achieved normal levels by Wk 24, possibly due to the limited sample size.

Conclusion: BARI treatment resulted in a rapid and sustained significant decrease in anti-dsDNA antibodies compared to PBO among anti-dsDNA positive pts with SLE at BL. Treatment with BARI 4-mg also resulted in a statistically significant decrease in IgG and anti-cardiolipin IgM levels at Wks 12 and 24, and anti-Smith at Wk 24, compared to PBO. These data suggest that BARI may have an effect on B cell activity in SLE.

SESSION INFORMATION

Session Date: Tuesday, November 9, 2021

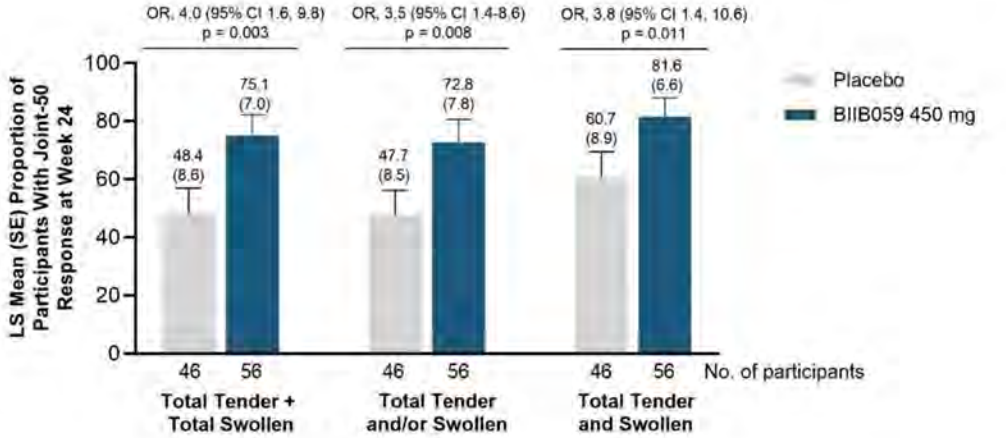
Session Title: SLE – Treatment Poster (1732–1772)

Session Type: Poster Session D

Session Time: 8:30AM–10:30AM

Background/Purpose: Joint involvement, a frequent manifestation of SLE, can be assessed using global lupus disease activity indices (SLEDAI-2K, BILAG-2004) and/or by assessing joint tenderness and swelling (28-joint count).[1] This post-hoc analysis evaluated changes in joint manifestations in the LILAC Part A trial of BIIB059 versus placebo (NCT02847598)[2] using various definitions.

Figure 1. Joint-50 Response at Week 24 With BIIB059 Versus Placebo in LILAC Part A Participants[a,b]



[a]Joint 50 response was defined as a ⩾50% decrease from baseline in joint count based on the following definitions: 1) sum of the tender joints plus the sum of the swollen joints (joints could be counted twice; primary endpoint definition); 2) sum of the joints that are either tender OR swollen (if a joint is both tender and swollen, it is only counted once); 3) sum of the joints that are both tender AND swollen. [b]Participants included in this analysis must have had ≥ 4 tender joints based on assessment of 28 joints. Participants must have had ≥ 4 swollen joints based on assessment of 28 joints, with ≥ 4 of the swollen joints occurring in the proximal interphalangeal, metacarpophalangeal, or wrist joints. Participants who were considered as treatment failures or discontinued treatment are considered as nonresponders at visits post treatment failure or treatment discontinuation. Participants who completed treatment but had a missing score at primary timepoint were classified as nonresponder for that timepoint. Based on generalized linear regression adjusted for treatment, baseline corticosteroid usage level (⩽10 mg, > 10 mg), and region (USA, Asia, Latin America, and Europe), Systemic Lupus Erythematosus Disease Activity Index 2000 at baseline, Physician Global Assessment Visual Analogue Scale at baseline, using a logit link function (logistic regression) for the odds ratios and p-values, and using an identity link function (linear probability model) for the LS means and LS mean differences.

Methods: The randomized, double-blind, placebo-controlled LILAC Part A study enrolled participants who fulfilled 4 of 11 revised ACR 1997 SLE classification criteria[3,4] and who had ≥4 tender and ≥4 swollen joints, active skin disease, and positive lupus antibodies (ANA and/or anti-dsDNA). "Joint-50" response was defined as a 50% reduction from baseline in active joint count at Week 24. Three definitions of total active joint count were used: (1) sum of total tender plus total swollen joints; (2) sum of joints that were tender and/or swollen; (3) sum of joints that were both tender and swollen. Arthritis scored on SLEDAI-2K and BILAG-2004 was also analyzed.

Results: The analysis included 56 and 46 participants treated with BIIB059 450mg and placebo, respectively. At Week 24, a greater proportion of BIIB059-treated participants achieved a Joint-50 response compared to placebo; findings were consistent across the 3 different definitions (Figure 1). The percentage of participants with resolution of arthritis by SLEDAI-2K was greater in BIIB059-treated participants (48.2%) versus placebo (21.7%); similar findings were seen with the BILAG-2004 arthritis (musculoskeletal domain) evaluation. Incidence and severity of adverse events were similar with BIIB059 versus placebo in LILAC Part A.

Conclusion: BIIB059 treatment was associated with improvement in SLE arthritis. More participants achieved a Joint-50 response with BIIB059 versus placebo, regardless of how active joint count was defined.

SESSION INFORMATION
Session Date: Tuesday, November 9, 2021
Session Title: SLE – Treatment Poster (1732–1772)
Session Type: Poster Session D
Session Time: 8:30AM–10:30AM

Background/Purpose: Premature cardiovascular events in SLE are associated with significant mortality and morbidity with no effective treatments described to date. Both immune dysregulation characteristics of SLE and metabolic disturbances appear to play a prominent role in the induction of vascular disease. In previous studies, the peroxisome proliferator-activated receptor (PPAR) agonist pioglitazone (PGZ) suppressed lupus phenotype, immune dysregulation, organ damage and vasculopathy in murine lupus. In human lupus peripheral blood mononuclear cells (PBMCs), in vitro PGZ modified T cell-specific responses and suppressed effector function. We hypothesized that PGZ could improve markers of vascular dysfunction and improve cardiometabolic parameters in SLE.

Methods: Eighty SLE subjects with mild to severe disease activity (SLEDAI 2K score between 4-20) were randomized to a sequence of PGZ (titrated up to 45 mg/day)followed by placebo for 3 months, or vice versa, in a 1:1 allocation ratio in a double-blind cross-over design with a 2 month wash out period. The primary endpoints were parameters of vascular endothelial function as measured by non-invasive multimodal vascular function studies. In a subset of patients, arterial inflammation was assessed by fluorodeoxyglucose positron emission tomography CT (FDG PET/CT). Additional outcome measures of disease activity, metabolic disturbances, adverse events (AEs), and gene expression studies were performed.

Results: A total of 72 subjects completed the study. The use of PGZ was associated with a decrease of 0.322±0.75 (mean±SD) in cardio ankle vascular index (CAVI) values compared to the placebo (0.02±0.65, p=0.005). Metabolic parameters also improved with PGZ, including the homeostasis model assessment of insulin resistance (HOMA2 IR) (p=0.0003), HDL-C (p=0.008), HDL particle size and number (p=< 0.0001; p=0.0009, respectively), and triglycerides (p=0.005). There were 249 predominantly mild adverse events (AE), 52.61% on PGZ and 47.39% on placebo. Most of the AEs experienced while on PGZ were related to fluid retention and mild transaminitis, which resolved with reduction in PGZ dose.

Conclusion: PGZ was well tolerated in SLE subjects with mild to severe disease activity. There was a significant improvement in vascular stiffness as well as improved cardiometabolic parameters. The results suggest that PGZ should be further explored as a modulator of cardiovascular disease risk in non-diabetic SLE patients.

SESSION INFORMATION

Session Date: Tuesday, November 9, 2021

Session Title: SLE – Treatment Poster (1732–1772)

Session Type: Poster Session D

Session Time: 8:30AM–10:30AM

Background/Purpose: Systemic lupus erythematosus (SLE) is a complex and heterogeneous autoimmune disease. Over the last decade, changes have occurred in the treatment of these patients, related to the inclusion of new agents, the strong recommendation to use lower doses of glucocorticoids and data favoring the use of antimalarials. The aim of this study is to describe lupus nephritis (LN) treatments in two Latin American cohorts over a 20-year period.

Methods: Two cohorts from the Latin American Lupus Study Group (GLADEL, *Grupo Latino Americano De Estudio del Lupus*) have been evaluated. The first, GLADEL 1.0, is an inception cohort started in 1997 that up to 2002 enrolled 1,480 patients; the second, GLADEL 2.0, is an observational prevalent and incident cohort initiated in 2019 that so far has enrolled 880 patients. In both cohorts, LN has been defined by kidney biopsy according to the International Society of Nephrology and Renal Pathology Society, and includes two groups: non-proliferative (class II/V) and proliferative (III/IV). The different therapeutic regimens used in both cohorts are described. In addition, the sociodemographic and serological variables and the histological characteristics are compared. Numeric variables are reported as medians (interquartile ranges) and compared using Mann-Whitney test; categorical variables are reported as frequencies (percentages) and compared using Chi-square or Fisher test, as appropriate.

Results: A total of 546 patients with LN diagnosis have been included; 362 from GLADEL 1.0 and 184 from GLADEL 2.0. One hundred and two and 35 patients form the respective cohorts were classified into LN-Class II/V; 260 and 149 patients were classified into LN-Class III/IV (Table1). LN patients from GLADEL 2.0 had longer disease duration, [months, median (Q1-Q3)] [73 (33-141) vs. 54 (32-75), p< 0.0001] compared to GLADEL 1.0. The comparison of the sociodemo-

Table 1. Comparison of the different treatments used in both GLADEL cohorts

Treatment	Class II/V		p value	Class III/IV		p-value
	GLADEL 1.0 (n=102)	GLADEL 2.0 (n=35)		GLADEL 1.0 (n=260)	GLADEL 2.0 (n=149)	
Oral Glucocorticoids; n(%)	91 (89.2)	31 (88.5)	0.999	230 (88.5)	135 (90.6)	0.501
Intravenous (IV) glucocorticoids; n(%)	26 (25.5)	8 (22.9)	0.756	103 (39.6)	46 (30.9)	0.077
Antimalarials; n(%)	55 (53.9)	31 (88.6)	0.003	87 (33.5)	123 (82.5)	<0.0001
Azathioprine; n(%)	19 (18.6)	0 (0.00)	0.004	35 (13.5)	11 (7.4)	0.061
Intravenous (IV) cyclophosphamide; n(%)	43 (42.2)	4 (11.4)	0.001	208 (80.0)	43 (28.9)	<0.0001
Intravenous (IV) immunoglobulin; n(%)	2 (1.9)	1 (2.9)	0.999	2 (0.8)	2 (1.3)	0.625
Cyclosporin; n(%)	0 (0.0)	1 (2.9)	0.256	2 (0.8)	0 (0.0)	0.536
Mycophenolate mofetil; n(%)	—	25 (71.4)	—	—	75 (50.3)	—
Tacrolimus; n(%)	—	4 (11.4)	—	—	13 (8.7)	—
Rituximab; n(%)	—	4 (11.4)	—	—	11 (7.4)	—
Belimumab; n(%)	—	0 (0.0)	—	—	0 (0.0)	—
Plasma exchange; n(%)	—	0 (0.0)	—	—	1 (0.7)	—

graphic variables showed that patients from GLADEL 2.0 have a higher proportion of Mestizos (71.2% vs. 44.4%), had a higher proportion of higher and middle socioeconomic status (19.6% vs. 5.5%, and 42.9% vs. 32.0%, respectively, p< 0.0001), and a higher level of formal education [years, median (Q1-Q3)] (13 (11-16) vs. 11 (7-139), p< 0.0001)]. In GLADEL 1.0, a higher number of patients with LN-Class III/IV had Hypocomplementemia (65.4% vs. 43.6%, p< 0.0001), and anti-dsDNA antibodies (58.1% vs 36.2), p< 0.0001) when compared with patients from GLADEL 2.0.

In GLADEL 2.0 a statistically significant increase in the use of antimalarials and decrease in the use of IV cyclophosphamide were observed. Azathioprine showed the same tendency as IV cyclophosphamide but no statistical significance was reached. As expected, new drugs were incorporated into the treatment scheme, mainly mycophenolate mofetil and less frequently tacrolimus and rituximab.

Conclusion: The management of LN in Latin America has changed over the last 20 years. New treatments have been included, there has been a trend towards a high use of mycophenolate mofetil and a decrease of cyclophosphamide. A higher use of antimalarials over time has also been observed.

(ALCAM), is expressed on antigen presenting cells, as well as epithelial and endothelial cells. Itolizumab (ITO) is a humanized IgG1 monoclonal antibody that binds CD6 and blocks ALCAM interaction to inhibit T cell activation and trafficking. ITO is being evaluated as a treatment for systemic lupus erythematosus (SLE) and lupus nephritis (LN).

Methods: EQUALISE is an open-label Phase 1b 2-part study that is evaluating the safety, pharmacokinetics (PK), pharmacodynamics (PD), and clinical activity of subcutaneous doses (SC) of ITO (0.4 to 3.2 mg/kg). Part A enrolled

adult patients with active or inactive SLE who had received ≥1 SLE treatment. Treated subjects received ITO SC Q2 weeks x 2. Part B of the study, which is evaluating ITO treatment of subjects with active proliferative Class III/IV LN for 24 weeks, is currently enrolling (NCT04128579).

Results: Part A enrolled 34 subjects in 5 cohorts: 0.4 mg/kg (n=6), 0.8 mg/kg (n=7), 1.6 mg/kg (n=7), 2.4 mg/kg (n=6), and 3.2 mg/kg (n=8). Similar baseline characteristics were noted across cohorts. The mean age was 51, with 94% female, 74% white (47% Hispanic) and ~11 years since SLE diagnosis (Table 1). The mean baseline SLEDAI-2K was 6.6.

SC dosing of cohorts 1-4 (0.4 mg/kg through 2.4 mg/kg (N=26)) was well tolerated (Table 2), with 3 subjects not receiving both doses, 1 due to a protocol eligibility deviation and 2 due to adverse events (AEs) (lymphopenia and urticaria). The most frequent AEs reported in these cohorts were mild to moderate injection site reactions. No serious adverse events (SAEs) were reported. For Cohort 5 (3.2 mg/kg), 8 subjects received at least 1 SC dose of ITO in at least 2 separate injection sites. In this cohort >85% of subjects reported an AE, the most common being injection site reactions, mainly moderate grade 2 reactions with erythema or pruritis. One subject (3.2 mg/kg) experienced 1 SAE (hypotension and syncope) that occurred in the follow-up period > 40 days after ITO. 4 subjects (50%) in Cohort 5 (3.2mg/kg) discontinued treatment after 1 dose. Across all cohorts, there were no notable changes in vital signs, ECGs, or safety lab parameters, with the exception of transient declines in absolute lymphocyte counts without clinical sequelae.

Preliminary PK results indicate dose-proportional increases in ITO exposure and rapid and dose-dependent decreases in CD4 cell surface expression of CD6, a PD marker of target engagement.

Conclusion: 2 SC doses of ITO up to 2.4 mg/kg in SLE subjects were well tolerated. There was reduced tolerability to the 3.2 mg/kg dose with 50% of patients discontinuing after the first dose. The PK, PD and safety data to date support continued evaluation of ITO in SLE/LN and other chronic autoimmune diseases. The ongoing EQUALISE Part B will assess ITO safety and efficacy in Class III/IV LN patients.

Voclosporin Is Effective in Achieving Complete Renal Response Across Lupus Nephritis Biopsy Classes: Pooled Data from the AURA-LV and AURORA 1 Trials

Anca Askanase[1], Simrat Randhawa[2], Laura Lisk[3] and Paola Mina-Osorio[4], [1]Columbia University Medical Center, New York, NY, [2]Aurinia Pharmaceuticals Inc., Seattle, WA, [3]Aurinia Pharmaceuticals Inc., Victoria, ON, Canada, [4]Aurinia Pharmaceuticals Inc., New York, NY

SESSION INFORMATION
Session Date: Tuesday, November 9, 2021
Session Title: SLE – Treatment Poster (1732–1772)
Session Type: Poster Session D
Session Time: 8:30AM–10:30AM

Background/Purpose: Voclosporin is a novel calcineurin inhibitor recently approved for the treatment of adult patients with active lupus nephritis in combination with background immunosuppressive therapy. Voclosporin has a favorable metabolic profile and a consistent dose-concentration relationship, eliminating the need for therapeutic drug monitoring. Pooled data from the similarly designed Phase 2 AURA-LV and the Phase 3 AURORA 1 trials demonstrated that compared with standard of care agents (mycophenolate mofetil [MMF] and low-dose steroids) alone, the addition of voclosporin resulted in higher complete renal response rates (CRR) at 24 weeks (31.7% vs 20.3%; odds ratio [OR] 2.01; p=0.0008) and one year (43.7% vs 23.3%; OR 2.76; p< 0.0001) of treatment in patients with lupus nephritis. This abstract reports CRR by biopsy class in the same pooled data.

Methods: AURA-LV and AURORA 1 enrolled patients with a diagnosis of systemic lupus erythematosus according to ACR criteria, biopsy-proven active lupus nephritis (Class III, IV, or V ± III/IV) and proteinuria of ≥1.5 mg/mg (≥2 mg/mg for Class V). Treatment randomization was stratified by biopsy class (Class V only vs Others) and by MMF use at screening. Pooled data included 268 patients in the voclosporin (23.7 mg BID) arm (89 from AURA-LV and 179 from AURORA 1) and 266 patients in the control arm (88 from AURA-LV and 178 from AURORA 1). All patients received MMF (1 g BID) and low-dose steroids (rapidly tapered to 2.5 mg/day at week 16). Though the trials were not powered to detect a significant difference between treatments groups by biopsy class, a post-hoc analysis of CRR by biopsy class subgroups was conducted.

Results: Demographic and clinical characteristics of the pooled population are shown in Table 1. The pooled analysis includes 79 (14.8%) patients with pure Class III, 253 (47.4%) with pure Class IV, 75 (14.0%) with pure Class V, and 127 (23.8%) with mixed Class V + III/IV lupus nephritis. The OR for CRR at one year in the voclosporin arm compared to control arm was 4.26 for pure Class III, 2.59 for pure Class IV, 1.50 for pure Class V, and 2.68 for mixed Class V + III/IV (Figure 1). Overall, 93.7% of patients in the voclosporin arm and 75.2% of patients in the control arm achieved ≥50% reduction from baseline in UPCR; the median time to ≥50% reduction in UPCR was 29 days for voclosporin arm and 58 days for the control arm (HR 1.96; log rank p< 0.0001; Figure 2). At 6 months, 83.2% of patients in the voclosporin arm and 85.0% of patients in the control arm were on ≤2.5 mg/day prednisone. At 12 months, 75.8% and 73.9% of patients in each arm, respectively, were on prednisone ≤2.5 mg/day.

Table 1. Baseline and Demographic Characteristics

	Control (n=266)	Voclosporin (n=268)

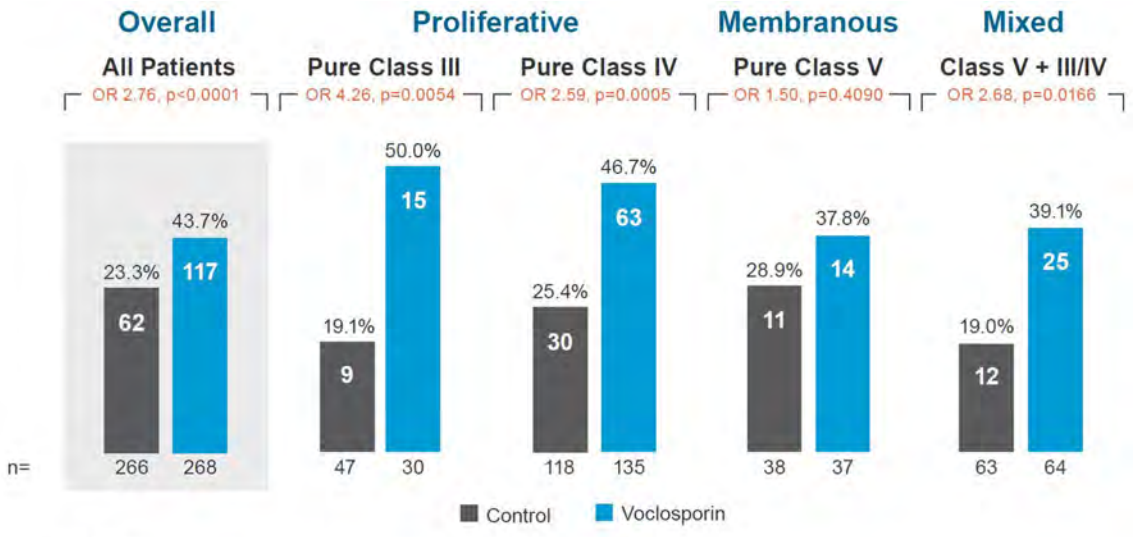
Biopsy Class, n (%)		
Pure Class III	47 (17.6)	32 (11.9)*
Pure Class IV	118 (44.4)	135 (50.4)
Pure Class V	38 (14.3)	37 (13.8)
Mixed Class V + III/IV	63 (23.7)	64 (23.9)

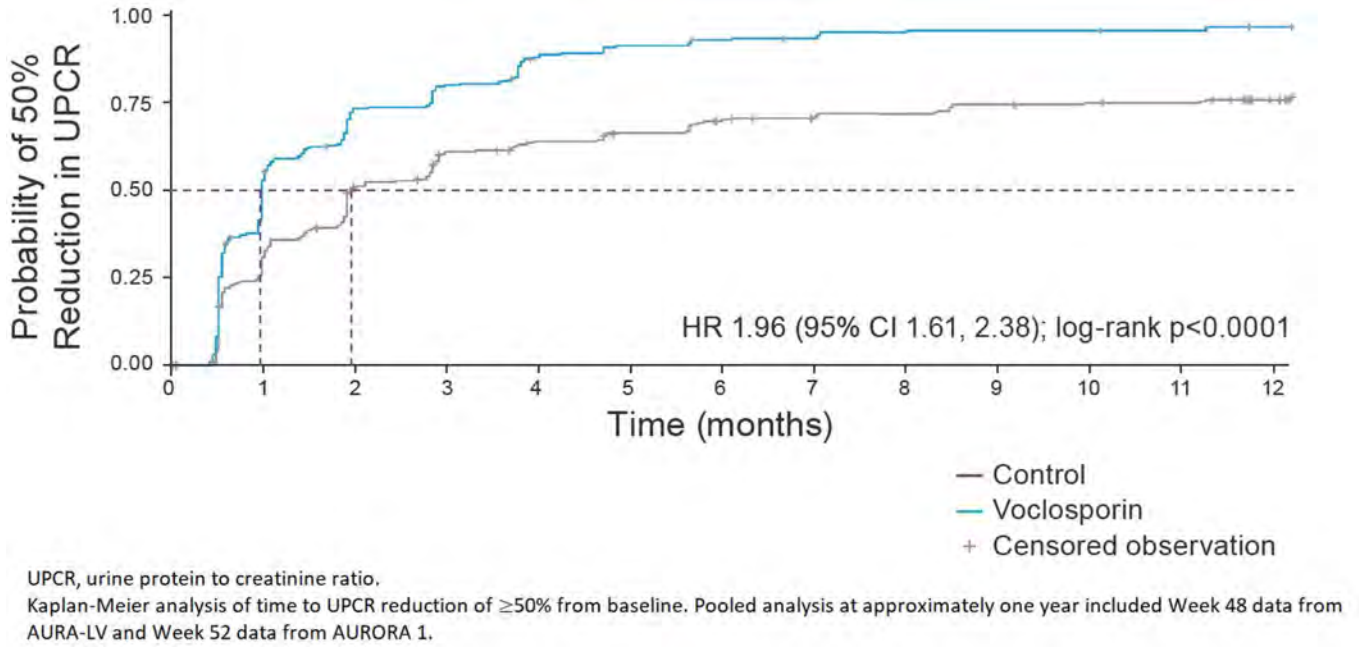
eGFR, estimated glomerular filtration rate; Max, maximum; Min, minimum; UPCR, urine protein to creatinine ratio.
*After the biopsy subgroup analysis was conducted, an additional two patients were identified to have pure Class III lupus nephritis that are not included in the subgroup analysis.

Conclusion: Patients with lupus nephritis treated with voclosporin in addition to MMF and low-dose steroids had improved CRR rates (OR >1) across all biopsy class subgroups compared to the control arm, with the highest OR seen in pure Class III. This analysis further supports the efficacy of voclosporin and the critical need to consider lower doses of steroids in the treatment of lupus nephritis.



OR, odds ratio.
Complete renal response defined as UPCR ≤0.5 mg/mg, stable renal function (eGFR ≥60 mL/min/1.73 m^2 or no decrease >20% from baseline), presence of sustained, low-dose steroids (in the 8 weeks prior to assessment) and no rescue medication. Pooled analysis at approximately one year included Week 48 data from AURA-LV and Week 52 data from AURORA 1.

Figure 1. Complete Renal Response by Biopsy Class at One Year.



UPCR, urine protein to creatinine ratio.
Kaplan-Meier analysis of time to UPCR reduction of ≥50% from baseline. Pooled analysis at approximately one year included Week 48 data from AURA-LV and Week 52 data from AURORA 1.

Figure 2. Time to UPCR Reduction of ≥50%.

Session Title: SLE – Treatment Poster (1732–1772)
Session Type: Poster Session D
Session Time: 8:30AM–10:30AM

Background/Purpose: Voclosporin is a novel calcineurin inhibitor recently approved for the treatment of adults with active lupus nephritis (LN) in combination with background immunosuppressive therapy. Voclosporin has a favorable metabolic profile and a consistent dose-concentration relationship eliminating the need for therapeutic drug monitoring.

Previously reported results from the Phase 3 AURORA 1 study and the Phase 2 AURA-LV study showed that compared with mycophenolate mofetil (MMF) and low-dose steroids, the addition of voclosporin significantly increased the complete renal response (CRR) rate and reduced proteinuria, as measured by urine protein-creatinine ratio (UPCR), in patients with LN at approximately one year of treatment (48 weeks in AURA-LV and 52 weeks in AURORA 1).

Table 1. Demographic and Baseline Characteristics

anti-dsDNA, anti-double stranded DNA; eGFR, estimated glomerular filtration rate; LN, lupus nephritis; SD, standard deviation; UPCR, urinary protein-creatinine ratio.

We describe here the results of a post-hoc analysis of AURORA 1 to assess whether patients with recent onset LN treated with voclosporin respond similarly to the overall population.

Methods: Patients with a diagnosis of systemic lupus erythematosus according to ACR criteria, biopsy-proven (Class III, IV, or V ± III/IV) LN and proteinuria of ≥1.5 mg/mg (≥2 mg/mg for pure Class V) were eligible to enroll in AURORA 1. Overall, 179 patients were randomized to the voclosporin (23.7 mg BID) arm and 178 patients were randomized to receive placebo treatment in the control arm. All patients received MMF (1 g BID) and low-dose oral steroids (tapered over 16 weeks to 2.5 mg/day).

In this post-hoc analysis, 45 patients in the voclosporin arm and 46 patients in the control arm were identified as having recent onset LN, defined as LN diagnosis within an estimated 6 months of study start based on reported year of diagnosis, study start date and date of biopsy. Disease duration and baseline clinical characteristics were evaluated and compared with the rest of the trial population to ensure the population was relevant to patients with recent onset disease seen in clinical practice (Table 1). Patients with biopsy pure class V LN (n=50) were excluded. Achievement of CRR (defined as UPCR ≤0.5 mg/mg with stable renal function in the presence of sustained, low-dose steroids and no rescue medication) was assessed at approximately one year of treatment.

Results: Patients with recent onset LN (n=91) had a mean (SD) LN disease duration of 0.2 (0.1) years compared to 5.4 (5.3) years for the rest of the population (n=216); baseline demographic and clinical characteristics were similar

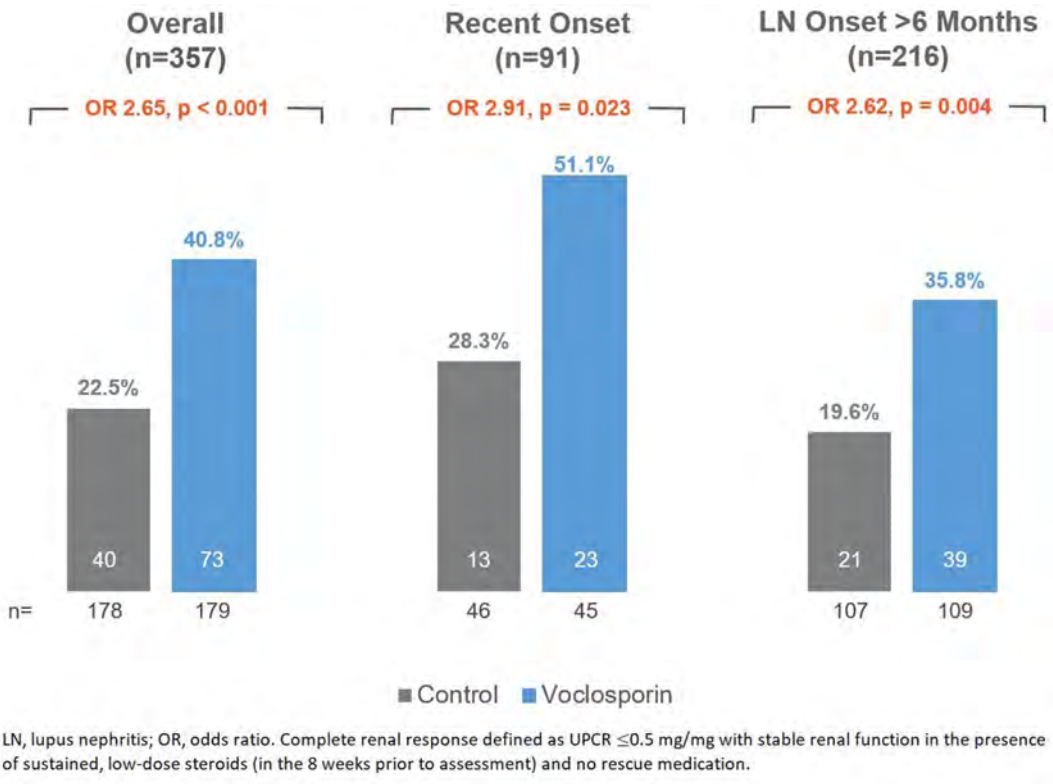

Figure 1. Complete Renal Response Rates at One Year in the Overall Patient Population, Recent Onset Disease, and Disease Onset >6 Months.

between the treatment arms (Table 1). Among recent onset patients, CRR was significantly increased in the voclosporin arm compared to the control arm (CRR of 51.1% vs 28.3%, respectively; OR 2.91; p=0.023) at one year of treatment (Figure 1).

Conclusion: Patients with recent onset LN treated with voclosporin in combination with MMF and low-dose steroids had clinically meaningful reductions in proteinuria and achieved significantly higher rates of CRR compared to patients treated with MMF and low-dose steroids alone. The efficacy benefit of voclosporin in recent onset LN patients is comparable with the efficacy in the overall population of patients participating in the Phase 3 AURORA 1 study. This post-hoc analysis also suggests significant efficacy benefit in the population with much longer duration of LN.

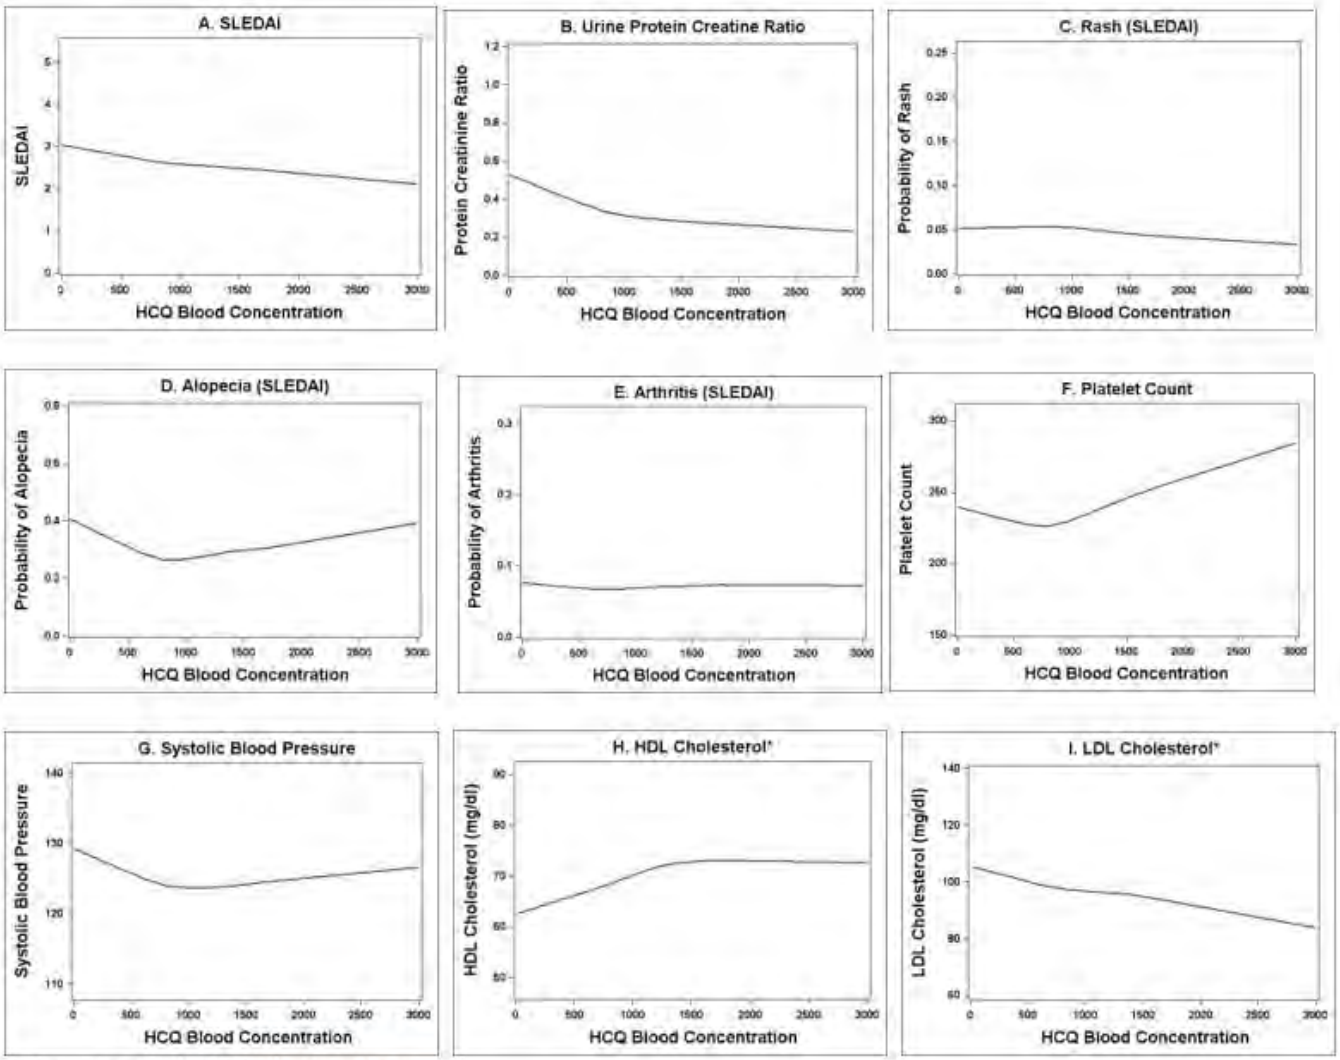
Hydroxychloroquine Blood Levels Are Associated with Reduced SLE Disease Activity and Improvements in Cardiovascular Risk Factors

Laurence Magder[1], Michelle Petri[2] and Daniel Goldman[2], [1]University of Maryland, Baltimore, Baltimore, MD, [2]Johns Hopkins University School of Medicine, Baltimore, MD

SESSION INFORMATION
Session Date: Tuesday, November 9, 2021
Session Title: SLE – Treatment Poster (1732–1772)
Session Type: Poster Session D
Session Time: 8:30AM–10:30AM

Background/Purpose: In SLE, treatment with hydroxychloroquine (HCQ) has been shown to be associated with reduced SLE flares and reduced risk of damage in several different organ systems. However, high HCQ blood levels

Figure 1. Estimated mean levels of various physiologic measures by blood concentration of HCQ (ng/ml)



* Based on only 323 observations

Table 1. Association between changes in HCQ blood levels and changes in various physiologic measures in consecutive visits.

Physiologic Measure	Changes in physiologic measures per 500 ng/ml change in HCQ levels			
	In the range of 0 to 1000	P-value	In the range of 1000-3000	P-value
SLEDAI	-0.11	0.059	-0.08	0.051
Urine Protein Creatinine Ratio	-0.038	0.0055	0.010	0.33
Probability of Rash	-0.005	0.27	0.000	0.97
Probability of Alopecia	0.014	0.079	0.008	0.15
Probability of Arthritis	-0.008	0.20	0.002	0.71
Platelet count (10^3 / mm^3)	2.63	0.0025	7.11	<0.0001
Systolic Blood Pressure (mmHg)	-1.24	<0.0001	-1.14	<0.0001
High Density Lipoprotein (mg/dl)	0.51	0.69	0.02	0.98
Low Density Lipoprotein (mg/dl)	-5.29	0.084	-0.99	0.67

over time are associated with retinopathy. To provide insight into the optimal treatment strategy, we determined the level of blood HCQ concentration needed for protection against several different manifestations of SLE disease.

Methods: The analysis was based on data from a large single-center clinical cohort of patients with SLE. Since 2013, whole blood levels of HCQ were measured at quarterly clinic visits among patients prescribed HCQ using liquid chromatography–tandem mass spectrometry. At each visit, numerous disease activity measures were performed (a visual analog scale for each organ and SLEDAI). Initially, we used loess to examine the shape of the cross-sectional relationship between blood levels of HCQ and average values of disease activity or cardiovascular risk factors. We then examined the association between changes in HCQ and concurrent changes in disease activity in consecutive visits from the same patient using a mixed effects model.

Results: The analysis was based on 10,370 clinic visits from 1095 different patients who were predominately Caucasian (46%) or African American (43%). Figure 1 shows the cross-sectional relationship between HCQ blood levels and various measures of SLE disease activity and other physiologic measures. Higher HCQ blood levels were associated with lower mean SLEDAI (Fig 1A), lower urine protein-creatine ratio (Fig 1B), lower systolic blood pressure (Fig 1G) and higher platelet counts (Fig 1F). For some measures, the relationship was strongest over HCQ concentrations in the range of 0 to 1000 ng/ml. Table 1 shows the association between changes in HCQ concentration between two consecutive visits and concurrent changes in physiologic measures. Within a patient, increases in HCQ concentration in the range of 0 to 1000 ng/ml were associated with decreases in urine protein-creatinine ratio, decreases in systolic blood pressure, and increases in platelets. Increases in the range of 1000 to 3000 ng/ml were associated with decreases in systolic blood pressure and increases in platelet counts. Surprisingly, changes in blood concentration were not significantly associated with changes in skin or joint manifestations of SLE.

Conclusion: We found that small but statistically significant improvements in physiologic measures are associated with increases in blood HCQ concentration. Interestingly, for most measures, the impact of increases in HCQ were seen primarily in the range of 0 to 1000 ng/ml, suggesting that 1000 ng/ml may be a good target to achieve protection without accruing a high risk of retinopathy.

SESSION INFORMATION

Session Date: Tuesday, November 9, 2021

Session Title: SLE – Treatment Poster (1732–1772)

Session Type: Poster Session D

Session Time: 8:30AM–10:30AM

Background/Purpose: Lupus nephritis (LN) is a complication affecting ~40% of patients with systemic lupus erythematosus (SLE). Belimumab (BEL), an anti–B-lymphocyte stimulator therapy, was approved in the USA and in the EU for active LN in adult patients. When given to patients without LN for 52 weeks, BEL reduced anti-double stranded DNA (anti-dsDNA) by 41% in patients with anti-dsDNA at baseline (BL; BLISS-52 & -76). The aim of this study was to evaluate changes in autoantibodies, complement, and B-cell subsets in response to BEL plus standard therapy versus placebo (PBO) plus standard therapy in patients with LN enrolled in BLISS-LN.

Methods: BLISS-LN was a Phase 3, 104-week study (GSK Study BEL114054; NCT01639339) in adult patients with active LN. Patients were randomized (1:1) to receive monthly BEL 10 mg/kg intravenous (IV) or PBO, plus standard therapy (high-dose corticosteroids plus either cyclophosphamide followed by azathioprine [CYC/AZA] or mycophenolate mofetil [MMF]). Changes from BL at Week 104 were determined for anti-dsDNA and anti-C1q antibodies (in patients with positive BL anti-dsDNA [≥30 IU/mL] or anti-C1q [≥22.2 IU/mL]), C3/C4, and B-cell subpopulations.

Results: Among patients with autoantibodies at BL, greater reductions in anti-dsDNA and anti-C1q levels were observed with BEL versus PBO in both standard therapy groups. There were notable increases in C3/C4 levels in favor of BEL in both standard therapy groups. BEL significantly reduced the total CD19+ and naïve B cells versus PBO, driven mainly by the MMF subgroup. However, the reduction in circulating memory B cells was numerically smaller with BEL versus PBO. BEL reduced plasmablasts versus PBO in both standard therapy groups (data in **Table**).

Conclusion: Treatment with BEL improved complement (numerically for C3) and anti-dsDNA and anti-C1q antibody levels in patients with LN to greater degrees than standard therapy alone, consistent with the mechanism of action of BEL. There were greater reductions in CD19+ B cells, naïve B cells and plasmablasts with BEL compared with PBO; however, there was a numerically smaller reduction in circulating memory B cells with BEL versus PBO.

Funding: GSK

[b]Includes homemaker (n = 4), unemployed, looking for work (n = 1), and student (n = 1)

Background/Purpose: Systemic lupus erythematosus disproportionately affects Black/African American (AA) and Latino/a populations.[1] Challenges to engage and include these populations in clinical trials (CTs) can be grouped into patient-side barriers to participation and provider-side barriers to referring patients.[1] Our aim was to address barriers in engaging with racial/ethnic populations and potential ways to ensure representation in lupus CTs.

Physicians with Medicare insured (> 50% of patients)	1 (5)
Physicians with mix (private and Govt insured, all < 50% of patients)	8 (40)

[a]Physician participants were recruited from a database of individuals who agreed to be contacted for research purposes. Interviews were conducted between December 2020 and February 2021.

Methods: In-depth qualitative interviews were conducted with lupus patients from underrepresented populations (Black/AA, Latino/a, Native American, Asian/Pacific Islander) and physicians (investigators or referring physicians in dermatology or rheumatology). Participants were screened to fulfill demographic quotas and assess conflicts of interest; those who qualified provided consent to be interviewed and were compensated for their participation. Interviews followed a semi-structured format in which participants were asked open-ended questions about CT awareness and motivating factors/barriers for CT participation.

Results: A total of 33 patients and 20 physicians participated in the study. Patient characteristics varied by age, region, education, employment status and type/severity of lupus (Table 1); physicians had varied practice settings and work experience (Table 2). The primary barrier to CT participation reported by patients was concern for investigational drug safety/efficacy (Figure 1). This included potential side effects, unknown efficacy and risk of missed benefit with placebo. Patients also reported impact of CT burden, such as time, transportation and financial impact of visits. Fewer patients reported mistrust of the healthcare system as a barrier; historical factors such as mistreatment of

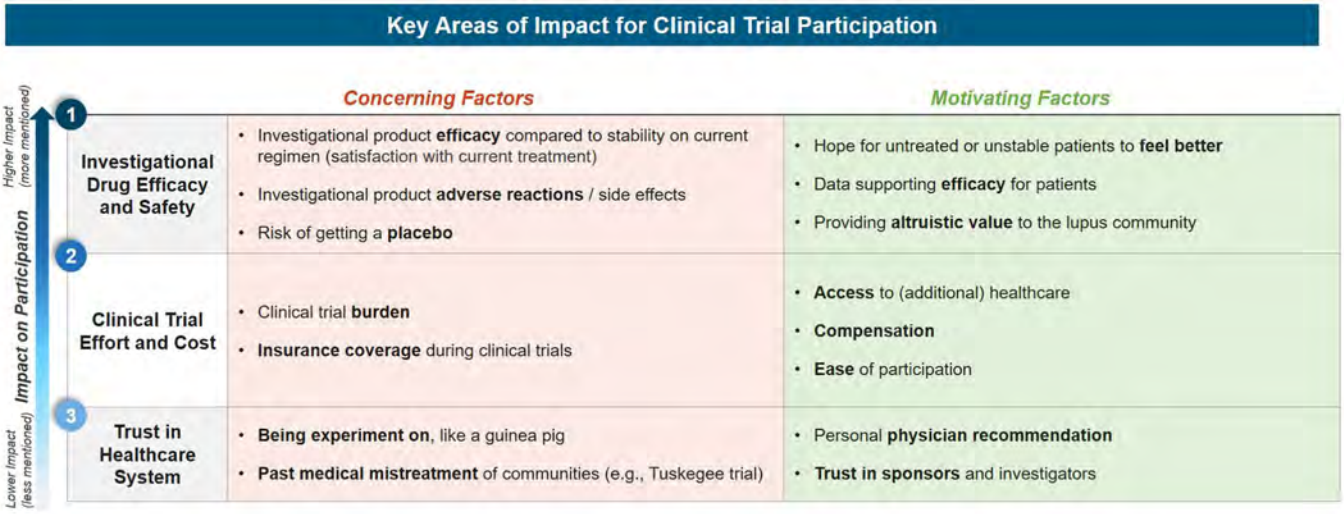

Figure 1. Patient-Reported Drivers and Barriers to Lupus Clinical Trial Participation Among Underrepresented Racial and Ethnic Groups.

underrepresented groups were less impactful than day-to-day challenges. Patients noted that participation could be improved by highlighting the value of CTs to individuals and their communities in a culturally competent way, minimizing trial burden and increasing trust through personal recommendation from treating physicians. From the physician perspective, < 50% were aware of ongoing CTs locally and some reported insufficient information for referring patients appropriately. Unconscious/implicit bias, such as assuming patients will not want to participate or be adherent, was also reported to influence physicians. Providing physicians with a centralized CT information source (website) and networking support, building patient awareness through trusted sources (churches, community centers) and including a broader mix of investigators from underrepresented communities may remove these perceived barriers.

Conclusion: Increasing participation of underrepresented racial/ethnic groups in lupus CTs is essential for assessing drug safety and efficacy, especially when these populations are most affected by the disease. Patient education, reduced CT burden, physician awareness of available CTs and strategies and educational efforts to address potential implicit bias should be critical components of health equity efforts.

Class V Systemic Lupus Erythematosus Nephritis Patients Are Undertreated and Face Similar Adverse Renal Outcomes as Class III/IV Patients

April Barnado and Alex Camai, Vanderbilt University Medical Center, Nashville, TN

SESSION INFORMATION
Session Date: Tuesday, November 9, 2021
Session Title: SLE – Treatment Poster (1732–1772)
Session Type: Poster Session D
Session Time: 8:30AM–10:30AM

Background/Purpose: Few studies have investigated treatment patterns and renal outcomes in class V systemic lupus erythematosus (SLE) nephritis patients compared to class III/IV patients. Prior findings are mainly from older clinical trial data. Using real-world, electronic health record (EHR) data, we compared prescribing patterns, laboratory data, and renal outcomes in class V compared to class III/IV SLE nephritis patients.

Methods: Using a large, de-identified EHR database called the Synthetic Derivative with over 3.2 million subjects, we identified incident SLE nephritis patients. We used previously published and validated SLE EHR algorithms with positive predictive values ranging from 86 to 95% and then searched for patients with keywords of "nephritis." We conducted chart review to ensure patients were incident SLE nephritis cases and had a diagnosis based on a renal biopsy. We also collected demographic and medication data prescribed at diagnosis (baseline), 6 months, and 12 months. We also assessed serum creatinine (mg/dL) and spot urine protein to creatinine ratios at baseline, 6-months, and 12-months. We examined for renal replacement therapy, defined as ever received dialysis or renal transplant. For

Table 1. Demographics and baseline data in Class III/IV vs. Class V SLE nephritis.

Patient Characteristics	Class III/IV SLE nephritis (n = 86)	Class V SLE nephritis (n = 43)	p value
Sex (%)			
Female	71 (83%)	36 (84%)	p = 0.87
Race (%)			
White	41 (48%)	13 (30%)	p = 0.06
Black	38 (44%)	26 (60%)	p = 0.08

Missing/Other	3 (3%)	0 (0%)	p = 0.72
Ethnicity (%)			
Hispanic	3 (3%)	0 (0%)	p = 0.72
Baseline medications (%)			
Antimalarials	60/80 (75%)	22/42 (52%)	**p = 0.01**
Immunosuppressants	74/85 (87%)	23/42 (55%)	**p < 0.001**
Corticosteroids	80/85 (94%)	32/42 (76%)	**p = 0.003**
Baseline laboratory values			
Serum creatinine mg/dL (± standard deviation)	1.90 ± 2.38	1.04 ± 0.88	**p = 0.002**
Spot urine protein/creatinine ratio (± standard deviation)	3.72 ± 3.18	3.44 ± 3.60	p = 0.50
Renal replacement therapy* (%)	24/86 (28%)	8/44 (18%)	p = 0.22
Deceased (%)	13 (15%)	5 (12%)	p = 0.59

*Renal replacement therapy defined as ever received dialysis or renal transplant.

Table 2. Six month and twelve-month data in Class III/IV vs. Class V SLE nephritis.

Patient Characteristics	Class III/IV SLE nephritis	Class V SLE nephritis	p value
6-month medications (%)			
Antimalarials	60/79 (76%)	25/39 (64%)	p = 0.18
Immunosuppressants	73/79 (92%)	27/37 (73%)	**p = 0.01**
Corticosteroids	69/79 (87%)	32/37 (86%)	p = 0.90
6-month laboratory values			
Serum creatinine mg/dL (± standard deviation)	2.09 ± 2.75	0.94 ± 0.49	**p = 0.01**
Spot urine protein to creatinine ratio (± standard deviation)	1.66 ± 2.92	2.26 ± 3.81	p = 0.17
12-month medications (%)			
Antimalarials	56/69 (81%)	28/40 (70%)	p = 0.18
Immunosuppressants	57/68 (84%)	24/36 (67%)	**p = 0.04**
Corticosteroids	58/70 (83%)	26/39 (67%)	**p = 0.05**
12-month laboratory values			
Serum creatinine mg/dL (± standard deviation)	1.83 ± 2.47	0.94 ± 0.47	p = 0.22
Spot urine protein to creatinine ratio (± standard deviation)	1.13 ± 1.59	0.98 ± 0.40	p = 0.58

SLE nephritis patients with multiple classes, we included patients with pure class V nephritis and patients with either class III, IV, or III + IV nephritis.

Results: We identified 43 incident class V and 86 incident class III/IV SLE nephritis patients. Sex, race, and ethnicity were all similar in class V vs. III/IV patients (Table 1). At baseline, class V SLE nephritis patients were less likely to be on antimalarials (52% vs. 75%, p = 0.01), immunosuppressants (55% vs. 87%, p < 0.001), and corticosteroids (76% vs. 94%, p = 0.003) compared to class III/IV patients. Class V SLE nephritis patients were also less likely to be prescribed immunosuppressants at 6 months (73% vs. 92%, p = 0.01) and 12 months (67% vs. 84%, p = 0.04) compared to class III/IV patients (Table 2). At 12 months, there were lower corticosteroid rates in class V vs. class III/IV (67% vs. 83%, p = 0.05). For baseline laboratory values, class V patients had similar spot urine protein to creatinine ratios but lower serum creatinine levels compared to class III/IV patients (1.04 mg/dL ± 0.87 vs. 1.90 mg/dL ± 2.38, p = 0.002). This lower serum creatinine trend for class V vs. class III/IV nephritis patients continued at 6 months (0.94 ± 0.49 vs. 2.09 ± 2.75, p = 0.01) with similar values at 12 months (Table 2). Class V patients had similar rates of renal replacement therapy (18% vs. 28%, p = 0.22) and death (12% vs. 15%, p = 0.59) compared to class III/IV SLE nephritis patients.

Conclusion: Our study demonstrated that class V patients were undertreated for their renal disease compared to class III/IV patients, particularly at time of diagnosis but also at 6 and 12 months after diagnosis. Class V patients may get undertreated for their renal disease, as it is generally thought that these patients will have a better prognosis compared to class III/IV patients. Our real-world, EHR data suggest that class V SLE nephritis patients are still at risk for adverse renal outcomes at similar rates to class III/IV patients and need appropriate treatment.

Abstract Number: 1757

Clinical Use of Belimumab for Systemic Lupus Erythematosus in the Setting of Advanced Chronic Kidney Disease and End-Stage Renal Disease on Dialysis: A Case Series

Matthew Snyder[1], Angel Chen[1], Sonali Narain[2] and Galina Marder[2], [1]Donald and Barbara Zucker School of Medicine at Hofstra/Northwell at Lenox Hill Hospital Program, New York, NY, [2]Northwell Health, Great Neck, NY

SESSION INFORMATION
Session Date: Tuesday, November 9, 2021
Session Title: SLE – Treatment Poster (1732–1772)
Session Type: Poster Session D
Session Time: 8:30AM–10:30AM

Background/Purpose: Belimumab is FDA approved for treatment of SLE and Lupus Nephritis. Patients with an eGFR < 30 ml/min/1.73m^2 were excluded from clinical trials, thus limiting data on its use in SLE patients with advanced chronic kidney disease (CKD) and end-stage renal disease (ESRD). We describe a case series on the safety and utility of belimumab in these patients.

Methods: We conducted a retrospective chart review of patients >18 years old, at Northwell Health, with SLE and CKD stage 4 or worse (sustained eGFR < 30) or ESRD on hemodialysis/peritoneal dialysis. Patients treated with both intravenous and subcutaneous belimumab from 2010 to 2020 were included. We excluded patients with a transient eGFR < 30. Clinical and laboratory data and concomitant immunosuppressive medications were collected in 3-month intervals from 12 months before belimumab initiation to the last time point of belimumab use. The primary

Table 1: Baseline Characteristics and Belimumab Information

	Age – year	Sex	Race/ Ethnicity	Type of dialysis	SLE duration (years)	LN duration (years)	Average prednisone dose before belimumab (mg/day)	Concomitant immunosuppressive medications	Belimumab dose (Route)	Duration of belimumab therapy (months)
Patient 1	30	Female	African American	Hemodialysis	14	14	8.39	None	200mg/week (SQ)	12
Patient 2	62	Female	African American	Hemodialysis	21	21	10.94	None	760mg/month (IV)	22
Patient 3	29	Female	African American	Hemodialysis	10	7	12.01	None	200mg/week (SQ)	10
Patient 4	25	Female	African American	Peritoneal	9	5	18.35	Thalidomide	760mg/month (IV)	10
Patient 5	33	Female	African American	Hemodialysis	4	2	16.96	Azathioprine	670mg/month (IV)	14*
Patient 6	36	Female	American Indian/Native Alaskan	None	20	11	0	Mycophenolate Mofetil	663mg/month (IV)	42*

*Denotes patient was still on Belimumab at time that chart review ended
SLE = Systemic Lupus Erythematous
LN =Lupus Nephritis
SQ = Subcutaneous
IV = Intravenous
IVIG = Intravenous Immunoglobulin

Table 2: Number and Type of Adverse Events Recorded while on Belimumab

	Infections		Allergic Reactions	
	Mild/Moderate	*Severe**	*Mild/Moderate*	*Severe**
Patient 1	0	0	0	0
Patient 2	2 URI	1 MSSA Bacteremia	0	0
Patient 3	0	0	0	0
Patient 4	0	1 Herpes zoster ophthalmicus / Varicella zoster meningitis	2 Rash	0
Patient 5	1 URI 1 Oral Herpes (Herpes Simplex)	0	0	0
Patient 6	0	0	0	0

*Severe adverse events defined as those requiring ED visit, hospitalization, change in dose/frequency of Belimumab, or discontinuation of Belimumab
MSSA= Methicillin-sensitive Staphylococcus aureus
URI= Upper Respiratory Infection

endpoint was safety defined by absence of events of interest, including allergic reactions, infections (viral, bacterial, and opportunistic), depression, suicide, and death. As secondary endpoints, we compared median SLEDAI change, serologic parameters, prednisone dose equivalent, and number of flares as determined by SLEDAI SELENA flare index for 12 months before belimumab use and while on belimumab. The only time points that had all data available were analyzed for efficacy.

Results: Of 353 patients, we identified six patients with sustained eGFR < 30 or requiring dialysis on belimumab therapy. Baseline demographic and clinical characteristics are recorded in **Table 1**. The average time of belimumab use in this group was 1.5 years (10-42 months). All patients were alive at the time of analysis. Belimumab was discontinued in 4 patients: 2 for renal transplant, 1 for infectious complications, and 1 for worsening of chronic heart failure. A total of 6 infections were recorded over 9 patient years with multiple events seen in 3 patients. Two infectious events were severe and 4 were mild/moderate. Belimumab was resumed after resolution in all but one patient with systemic H. zoster infection. All patients with infections were on concomitant prednisone (4-10mg/day), 1 patient was on thalidomide (100mg/day), and 1 patient was on azathioprine (150mg/day). No depression, suicide, leukopenia, hypogammaglobulinemia were identified **(Table 2)**. Median SLEDAI score decreased by 50% (from 8 to 4) after 6 months of belimumab use. During the same time frame, median dsDNA titers reduced by more than half (from 390 IU/mL to 167 IU/mL), but there was no change in median complement 4 level (from 18.5mg/dL to 21mg/dL). The cumulative prednisone dose decreased by a mean of 3.75 mg/day (from 13.33 mg/day to 9.58 mg/day) comparing time periods before and while on belimumab **(Figure 1)**. Arthralgia was recorded as improved in two-thirds of patients. There was no change in the median number of flares.

Conclusion: Belimumab is relatively safe in SLE patients with advanced CKD and ESRD on dialysis and may be helpful in reducing SLE activity and steroid use in these patients. However, it is important to be cognizant of the risk of infection, especially with concomitant use of other immunosuppressants.

SESSION INFORMATION

Session Date: Tuesday, November 9, 2021
Session Title: SLE – Treatment Poster (1732–1772)
Session Type: Poster Session D
Session Time: 8:30AM–10:30AM

Background/Purpose: Influenza A(H3N2) virus is the most important cause of seasonal influenza morbidity and mortality in the last 50 years surpassing the impact of H1N1. Data assessing immunogenicity and safety of this virus component is lacking in systemic lupus erythematosus (SLE) and restricted to small reports with other H3N2 strains.

Methods: 81 consecutive SLE patients and 81 age- and sex-matched healthy controls(HC) were vaccinated with influenza A/Singapore/INFIMH-16-0019/2016(H3N2)-like virus. Percentage of seroprotection(SP), seroconversion(SC), geometric mean titer(GMT), factor increase in geometric mean titer(FI-GMT) and adverse events were assessed before and 4 weeks post-vaccination. Disease activity and therapies were also evaluated.

Results: Before immunization, both groups had a high SP rate (89% vs. 77%,p=0.060) and elevated GMT titer with higher levels in SLE [129.1(104.1-154.1) vs. 54.8(45.0–64.6),p< 0.001]. Frequency of two previous years influenza vaccination was high and comparable in patients and HC(89% vs. 90%,p=1.000). Four weeks post-vaccination, median GMT increased for both groups and remained higher in SLE compared to HC [239.9(189.5-290.4) vs. 94.5(72.6-116.4),p< 0.0001] with a comparable FI-GMT [2.3(1.8-2.9) vs. 1.9(1.5-2.3),p=0.061]. Frequency of SC rates was low and comparable for both groups(16% vs. 11%,p=0.974,respectively). Disease activity scores remained stable throughout the study(p=1.000) and severe side effects were not identified.

Conclusion: Influenza A(H3N2)/Singapore vaccine has an adequate safety profile. The distinct immunogenicity pattern from other influenza A components characterized by a remarkably high pre- and post-vaccination SP rate and high GMT levels may be associated with previous influenza A vaccination. (www.clinicaltrials.gov, NCT03540823). (FAPESP #2018/16162-3)

An Analysis of Medication Responsiveness Based on Subtype and Race Within a Cohort of Cutaneous Lupus Erythematosus Patients

Emily Keyes[1], Anisha Jobanputra[2], Madison Grinnell[3], Rui Feng[4], Thomas Vazquez[5], DeAnna Diaz[6] and Victoria Werth[7], [1]Department of Dermatology, Perelman School of Medicine at the University of Pennsylvania and Philadelphia VAMC, Philadelphia, PA, [2]Department of Dermatology, Perelman School of Medicine at the University of Pennsylvania, Philadelphia, PA, [3]Department of Dermatology, Perelman School of Medicine at the University of Pennsylvania and Philadelphia VAMC, OMAHA, NE, [4]University of Pennsylvania Department of Biostatistics, Philadelphia, PA, [5]FIU Wertheim College of Medicine, Virginia Beach, VA, [6]Philadelphia College of Medicine, Philadelphia, PA, [7]Philadelphia VAMC, Philadelphia, PA, USA and Department of Dermatology, Perelman School of Medicine at the University of Pennsylvania, Philadelphia, PA

SESSION INFORMATION

Session Date: Tuesday, November 9, 2021

Session Title: SLE – Treatment Poster (1732–1772)

Session Type: Poster Session D

Session Time: 8:30AM–10:30AM

Background/Purpose: Cutaneous lupus erythematosus (CLE) can present in association with or without concomitant SLE, and with skin manifestations varying by subtype – acute CLE, subacute CLE (SCLE), and chronic CLE, of which the most common type is discoid (DLE). There is evidence of heterogeneity of response to therapy between subtypes, and surveys have shown that providers have preference for prescribing different medications based on subtype. Additionally, studies have shown that black patients are disproportionately affected by lupus, have a higher risk of damage, and have a higher incidence of CLE (specifically DLE) than white patients. However, there is a lack of evidence-based studies comparing medication response by subtype or race.

Methods: In this retrospective study of our longitudinal prospective database, we examined response rates to methotrexate (MTX), mycophenolate mofetil (MMF), and azathioprine (AZA), the most commonly used immunosuppressive medications in our cohort, by subtype and by race. Response or non-response was determined by 50% improvement or lack thereof in skin activity measured by the Cutaneous Lupus Erythematosus Disease Area and Severity

Table 1. Comparison of response rates for each medication between SCLE and DLE patients*

Medication	Response Type	SCLE	DLE	p-value from Fisher's exact test
MTX		n=18	n=13	0.262
	Responders	13 (72%)	6 (46%)	
	Non-responders	5 (27%)	7 (54%)	
MMF		n=7	n=27	>0.999
	Responders	5 (71%)	19 (70%)	
	Non-responders	2 (29%)	8 (30%)	
AZA		n=4	n=9	0.105
	Responders	0 (0%)	5 (56%)	
	Non-responders	4 (100%)	4 (44%)	

n=instances of medication use analyzed

*analysis excludes patients with ACLE, tumid LE, bullous LE, and patients with multiple subtypes

Table 2. Comparison of response rates for each medication between black and white patients*

Medication	Response Type	Black	White	p-value from Fisher's exact test
MTX		n=12	n=28	0.311
	Responders	6 (50%)	19 (68%)	
	Non-responders	6 (50%)	9 (32%)	
MMF		n=22	n=22	>0.999
	Responders	14 (64%)	14 (64%)	
	Non-responders	8 (36%)	8 (36%)	
AZA		n=7	n=8	0.0406*
	Responders	6 (86%)	2 (25%)	
	Non-responders	1 (14%)	6 (75%)	

n=instances of medication use analyzed
*analysis includes all subtypes, including patients excluded from Table 1 analysis

Index (CLASI) and/or chart abstraction, and analyzed using Fisher's exact test.[1] Discontinuations due to side effects were analyzed separately.

Results: Of the 191 patients with SCLE and DLE identified with sufficient longitudinal follow-up, 73 took at least one of these medications, including 34 with concomitant SLE by ACR 1997 criteria; the other subtypes were not powered for analysis and were excluded. Mean response rate was 52.6% (95% CI 30.3-74.9%). No statistically significant difference was found in rate of response to each medication when comparing SCLE vs DLE ($p > 0.05$). Results suggest that MMF may be more effective in DLE than MTX, but our sample was not powered to show this difference ($p=0.175$). Additionally, response rates were analyzed between black CLE patients and white CLE patients taking these medications. Of the 97 black CLE patients identified, 38 took at least one of these medications, including 19 with concomitant SLE by ACR 1997 criteria; of the 159 white, 53 did, including 21 with concomitant SLE by ACR 1997 criteria. Mean response rate was 59.3 (95% CI 43-75.6%). No statistically significant difference was found in rate of response to MTX or MMF in black vs white CLE patients ($p > 0.05$). Rate of response to AZA was higher in black patients than white patients ($p = 0.0406$).

Conclusion: These findings suggest that MTX and MMF appear equally efficacious between SCLE and DLE patients and between black and white patients, and AZA may work better in black patients than in white CLE patients. Further studies are needed to assess whether MMF may work better than MTX in DLE. Clinicians may then use other factors to guide medication choice, such as side effect profile and comorbid conditions.

Session Title: SLE – Treatment Poster (1732–1772)

Session Type: Poster Session D

Session Time: 8:30AM–10:30AM

Background/Purpose: Systemic lupus erythematosus (SLE) is a chronic condition that can be associated with both acute and chronic musculoskeletal pain as well as fibromyalgia. Opioids are rarely indicated for long-term management of chronic pain due to lack of efficacy and risk for dependency and developing medical comorbidities, such as osteoporosis and cardiovascular disease. By using a population-based cohort, we assessed the prevalence of opioid use among patients with and without SLE and examined potential risk factors for long-term opioid use among SLE patients.

Methods: By using an established population-based research infrastructure that links the medical records of all individuals in a geographically well-defined 27-county US population, we identified SLE cases meeting the 2019 ACR/EULAR classification criteria and living in the region on 1-1-2015. SLE patients were matched on age, sex, race/ethnicity and county to non-SLE comparators. Ambulatory opioid prescription data were used to define an episode of opioid use for patients using opioids on 1-1-2015. An episode was defined as contiguous prescriptions prior to 1-1-2015 with gaps < 30 days between prescriptions. Long-term users were defined following the Consortium to Study Opioid Risks and Trends (CONSORT) definition (opioid use episode that spans ≥ 90 days or ≥ 10 prescriptions). Data on SLE duration, presence of mood disorder (depression, dysthymia, bipolar disorder) and fibromyalgia diagnoses were abstracted, and area deprivation index (ADI) was obtained. Chi-square and rank sum tests were used to compare characteristics between the groups. Logistic regression was used to examine factors associated with long-term opioid use among patients with SLE.

Results: We identified 479 SLE patients and 479 non-SLE comparators. Mean age of SLE patients and the matched non-SLE comparators was 53.2 (SD 16.2) years, 82% were female and 85% were white. Mean SLE duration was 13.5 years (SD 11.6). On 1-1-2015, 13% of SLE patients used opioids compared to 3% of non-SLE comparators ($p< 0.001$), and 10% of SLE patients were long-term opioid users compared to 1% of comparators. 38% had a concurrent mood disorder diagnosis compared to 23% among comparators ($p< 0.001$), whereas, 14% had a concurrent fibromyalgia diagnosis compared to 5% among comparators ($p< 0.001$) (Table 1). Factors associated with long-term use among patients with SLE included age (odds ratio [OR]: 1.20 per 10 year increase; 95% CI: 1.00-1.46), SLE duration (OR: 1.34 per 10 years; 95% CI: 10.00-1.63), mood disorder (OR: 3.06; 95% CI: 1.64-5.71), and fibromyalgia (OR: 6.78; 95% CI: 3.44-13.39).

Table 1. SLE and Non-SLE Characteristics			
Characteristic	**SLE patients N=479**	**Non SLE Comparators N= 479**	**P-Value**
Age, years, Mean (SD)	53.2 (16.2)	53.2 (16.2)	0.99
Female sex, N (%)	394 (82)	394 (82)	1.00
Race/Ethnicity, N (%)			0.93
White	404 (85)	412 (86)	
Asian	15 (3)	17 (4)	
other/mixed	8 (2)	5 (1)	
Black	18 (4)	19 (4)	
American Indian	2 (0)	2 (0) 24 (5)	
Hispanic	29 (6)		
Opioid use, N (%)	63 (13)	13 (3)	<0.001
Long-term opioid use, N (%)	48 (10)	6 (1)	<0.001
SLE duration, years, Mean (SD)	13.5 (11.6)	--	--
Mood disorder, N (%)	182 (38)	112 (23)	<0.001
Fibromyalgia, N (%)	66 (14)	25 (5)	<0.001
Area Deprivation Index, Mean (SD)	94.4 (12.7)	94.5 (12.4)	0.99

Conclusion: In this study, 13% of SLE patients were opioids users compared to 3% among non-SLE comparators. Among SLE patients, 10% met the CONSORT definition for long-term opioid use. SLE duration and having a co-morbid mood disorder or fibromyalgia diagnosis were identified as significant risk factors for long-term opioid use.

Comparison of Belimumab and Standard of Care by Inverse Probability of Treatment Weighting Analyses Based on Propensity Score in Patients with Systemic Lupus Erythematosus in the Maintenance Phase

yusuke Miyazaki[1], Shingo Nakayamada[1], Shigeru Iwata[1], Kentaro Hanami[1], Shunsuke Fukuyo[1], Koshiro Sonomoto[1], Akio Kawabe[1], Yoshino Inoue[1], Naoaki Okubo[1] and Yoshiya Tanaka[2], [1]The First Department of Internal Medicine, School of Medicine, University of Occupational and Environmental Health, Japan, Kitakyusyu, Fukuoka, Japan, [2]University of Occupational and Environmental Health, Kitakyushu, Japan

SESSION INFORMATION

Session Date: Tuesday, November 9, 2021

Session Title: SLE – Treatment Poster (1732–1772)

Session Type: Poster Session D

Session Time: 8:30AM–10:30AM

Background/Purpose: Development of molecular-targeted agents is essential in treat-to-target treatment strategies for systemic lupus erythematosus (SLE). We analyzed the efficacy and safety of belimumab (BEL) in the clinical practice, focusing on SLE patients in the maintenance phase.

Methods: This study included the patients with SLE in the maintenance phase (SELENA-SLEDAI< 10, glucocorticoid (GC) dose ≤12.5 mg/day). The efficacy of BEL combined with standard-of-care (BEL+SoC group, n=100) was

compared with standard-of-care (SoC group including patients using either mycophenolate mofetil or hydroxychloroquine, n=103). Selection bias was reduced to a minimum using propensity score-based inverse probability of treatment weighting (IPTW). We analyzed the trajectories of changes in GC dosage in all patients in this study using growth mixture modeling (GMM). The observation period of the study was 52 weeks.

Results: No significant difference was observed in patient characteristics between the BEL+SoC and SoC groups after adjustment by propensity score-based IPTW. Only one case of BEL discontinuation (involving drug-induced eruption) was observed, and the 52-weeks retention rate was 99% (99/100). The BEL+SoC group had significantly lower GC doses at 52 weeks compared to the SoC group (BEL+SoC group, 2.2±2.7 vs. SoC group, 4.4±3.9 mg/day, respectively, p< 0.001), but no differences in SELENA-SLEDAI, 50% hemolytic complement, and anti-double stranded DNA antibodies was observed. The BEL+SoC group had a lower rate of relapse (defined as new appearance of BILAG A1 or B2 items) compared to the SoC group (BEL+SoC group, 0.9% vs. SoC group, 6.3%, respectively, p=0.031). The incidence of ≥ Grade 2 adverse events infections, as specified by the Common Terminology Criteria for Adverse Events, was significantly lower in the BEL+SoC group compared to the SoC group before adjustment by propensity score-based IPTW (BEL+SoC group, 4.0% vs. SoC group, 17.5%, respectively, p=0.003).

The trajectory of GC dose was divided into four groups by GMM; in a group (GC-free group), GC dosage could be reduced to 0 within 6 months, without any relapse. The majority of the GC-free group (87.5%) consisted of cases with concomitant BEL administration. When multivariable logistic regression analysis was performed for all patients, the factors contributing to belonging to GC-free group was onlyBEL use (odds ratio (OR) 8.86, 95% confidence interval (CI) 2.55-30.78, p< 0.001). Next, multivariable logistic regression analysis was performed for BEL+SoC group. The patients had lower the SELELNA-SLEDAI score (OR 0. 82, 95% CI 0. 68-0.98, p=0.03) and GC doses (OR 0. 75, 95% CI 0. 59-0.98, p=0.02) were more likely to belong to GC-free group.

Conclusion: In maintenance-phase SLE, administration of BEL was able to achieve reduction of GC dose while ensuring strict control of disease activity and suppression of flare-ups.

The present study suggests that among the patients who received BEL, those with low baseline SLEDAI and GC doses could discontinue GC without relapse.

Abstract Number: 1762

Hydroxychloroquine Alone Does Not Increase QTc in the Absence of Other QT-prolonging Medications

Haihui Wang, Upstate Medica University, Fayetteville, NY

SESSION INFORMATION
Session Date: Tuesday, November 9, 2021
Session Title: SLE – Treatment Poster (1732–1772)
Session Type: Poster Session D
Session Time: 8:30AM–10:30AM

Background/Purpose: Hydroxychloroquine (HCQ) is one of the widely used immunomodulator in rheumatology. Its temporary trendy use during the early phase of COVID pandemic stresses its short-term QT prolonging effect on COVID 19 patients. Many patients with autoimmune diseases have concurrent fibromyalgia or depression or psychiatric disorder that will require them to be on other chronic medication with potential QT prolongation effect. To clarify if HCQ or other medications is the culprit for prolonging QTc, we looked at the QTc prolongation effect in patients specifically not on other QT prolonging medications.

Methods: All adult patients, age >18 years, from Jan 2015 to Dec 2020 followed at SUNY Upstate Medical University who were prescribed HCQ were included in the study.

Results: 9484 patients were treated with HCQ, of which only 3917 were on HCQ without other QT prolonging medications (anti depression, antipsychotics, antiarrhythmics), among which 1036 patients had 1 EKG done, and 635 had 2 EKG done. Among the patients only on HCQ as potential QT prolong medications with 2 EKGs, only 68 patients had 1 EKG done before HCQ and 1 EKG done after HCQ initiation. Among these patients, 13 patients had prolonged QTc (>460ms) on their first EKG, and 7 remained to have prolonged QTc on repeat, 6 patients with initial long QTc had normal QTc on repeat; 16 patients had prolonged QTc on their 2nd EKG, 9 were new from normal QTc on initial EKG, shown as table below.

Number of patients on HCQ	9484
Number of patients on HCQ as only QT prolonging medication	3917
Number of patients on HCQ as only QT prolonging medication with 1 EKG	1036
Number of patients on HCQ as only QT prolonging medication with 2 EKG	635
Number of patients on HCQ as only QT prolonging medication with EKG done before and after initiation of HCQ	68

long QTc on 1st EKG	QTc remain long on 2ndEKG	QT normal on 2ndEKG
13	7	6
long QTc on 2nd EKG	QTc long on 1st EKG	QTc normal on 1stEKG
16	7	9

Conclusion: HCQ causing prolongation is a well-known drug effect, however routine EKG screening before starting HCQ is not done. This project showed that it is very common for patients on HCQ to be simultaneously on other QT prolonging medication chronically which may potentially have add-on effect. For those patients on HCQ only with EKG to compare before and after, this project was unable to show the QTc prolongation effect on HCQ, but this may be due to limited available samples.

Disclosure: H. Wang, None.

Baricitinib Reduces Proinflammatory Serum Cytokines in Patients with Systemic Lupus Erythematosus

Thomas Dörner[1], Yoshiya Tanaka[2], Daniel Wallace[3], Damiano Fantini[4], Alisa Koch[4], Maria Silk[5], Jorge Ross Terres[4], Jonathan Sims[4], Peter Fischer[6] and Michelle Petri[7], [1]Charite Universitätsmedizin Berlin and Deutsches Rheumaforschungszentrum (DRFZ), Berlin, Germany, [2]University of Occupational and Environmental Health, Kitakyushu, Japan, [3]Cedars-Sinai, Los Angeles, CA, [4]Eli Lilly and Company, Indianapolis, IN, [5]Eli Lilly and Company, Carmel, IN, [6]Eli Lilly and Company, North Easton, MA, [7]Johns Hopkins University School of Medicine, Baltimore, MD

SESSION INFORMATION
Session Date: Tuesday, November 9, 2021
Session Title: SLE – Treatment Poster (1732–1772)
Session Type: Poster Session D
Session Time: 8:30AM–10:30AM

Background/Purpose: Baricitinib, a Janus kinase (JAK)1/JAK2 inhibitor, improved disease activity in systemic lupus erythematosus (SLE) adults receiving standard background therapy in a phase 2 trial (NCT02708095).[1] The aim of this study was to elucidate the mechanism of action of baricitinib in SLE.

Methods: Patients with SLE were treated with baricitinib-2mg or -4mg in a phase 2, randomized, placebo-controlled study. Sera from 68 patients (baricitinib-2mg: n=29; baricitinib-4mg: n=25; placebo: n=14) were collected at baseline and Week 12 and analyzed for cytokines using a Proximity Extension Assay (PEA) with 87 detectable analytes (Target 96 Inflammation Panel (Olink)). Interferon (IFN) scores were determined using a Modaplex assay. Spearman correlations were computed. Analyte changes from baseline at Week 12 were compared between baricitinib-4mg and placebo groups by Wilcoxon rank-sum or t-tests. Adjusted $p< 0.05$ was considered significant.

Results: At baseline, CXCL10 (r=0.50), CXCL11 (r=0.38), and CCL19 (r=0.45) correlated with the IFN signature. Confirming previous findings using Quanterix assays[2], PEA analysis indicated that baricitinib-4mg, but not placebo, reduced IL-6 and IL-12p40 in SLE. Additionally, baricitinib-4mg significantly downregulated 1) serum cytokines that mediate lymphocyte and monocyte/macrophage recruitment (CCL19, TNFRSF9, TNF-β/Lymphotoxin-α), and 2) cytokines that induce bone turnover and augment joint pain (TRANCE/RANKL and Artemin).

Conclusion: These results suggest that downregulation of key cytokines that have proinflammatory and/or regulatory functions may play a role in the mechanism by which baricitinib acts to improve SLE disease activity.

Estimation of the Prevalence of Hydroxychloroquine-Induced Retinopathy in a Cohort of Hydroxychloroquine-Compliant Patients

Kelley Brady, Roberta Alexander, Rory Bloch, Mark Rudolph, Karina Baggiani, Deborah Stimson and Anja Kammensheidt, Exagen Inc., Vista, CA

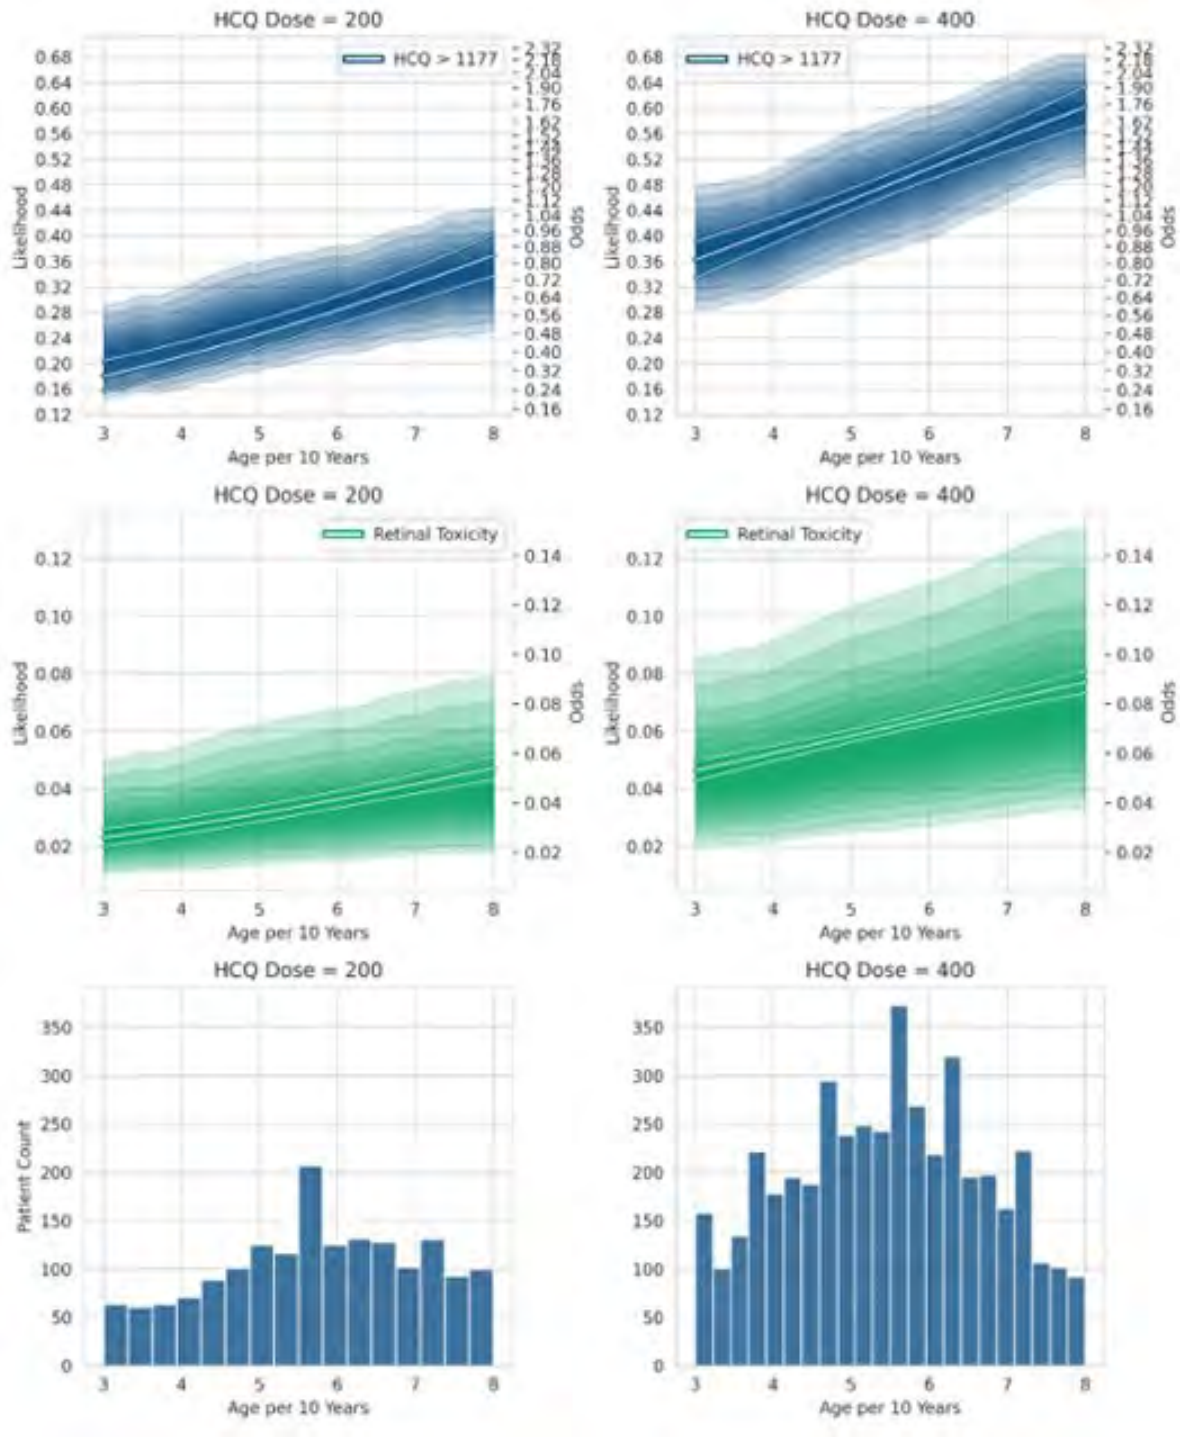
SESSION INFORMATION
Session Date: Tuesday, November 9, 2021
Session Title: SLE – Treatment Poster (1732–1772)
Session Type: Poster Session D
Session Time: 8:30AM–10:30AM

Background/Purpose: HCQ is an antimalarial drug effective in the treatment of rheumatologic conditions. High blood levels, advanced age, and extended treatment duration are associated with HCQ-induced retinopathy (R_{HCQ})(Petri et al. [Arthritis Rheum] 2020). We combined these insights with large amounts clinical therapeutic drug monitoring (TDM) data and deidentified patient information to develop interpretable linear models for the estimation of the overall prevalence of R_{HCQ} in a cohort of HCQ-therapy-compliant patients, and the odds of an individual patient presenting R_{HCQ} given HCQ dose and age.

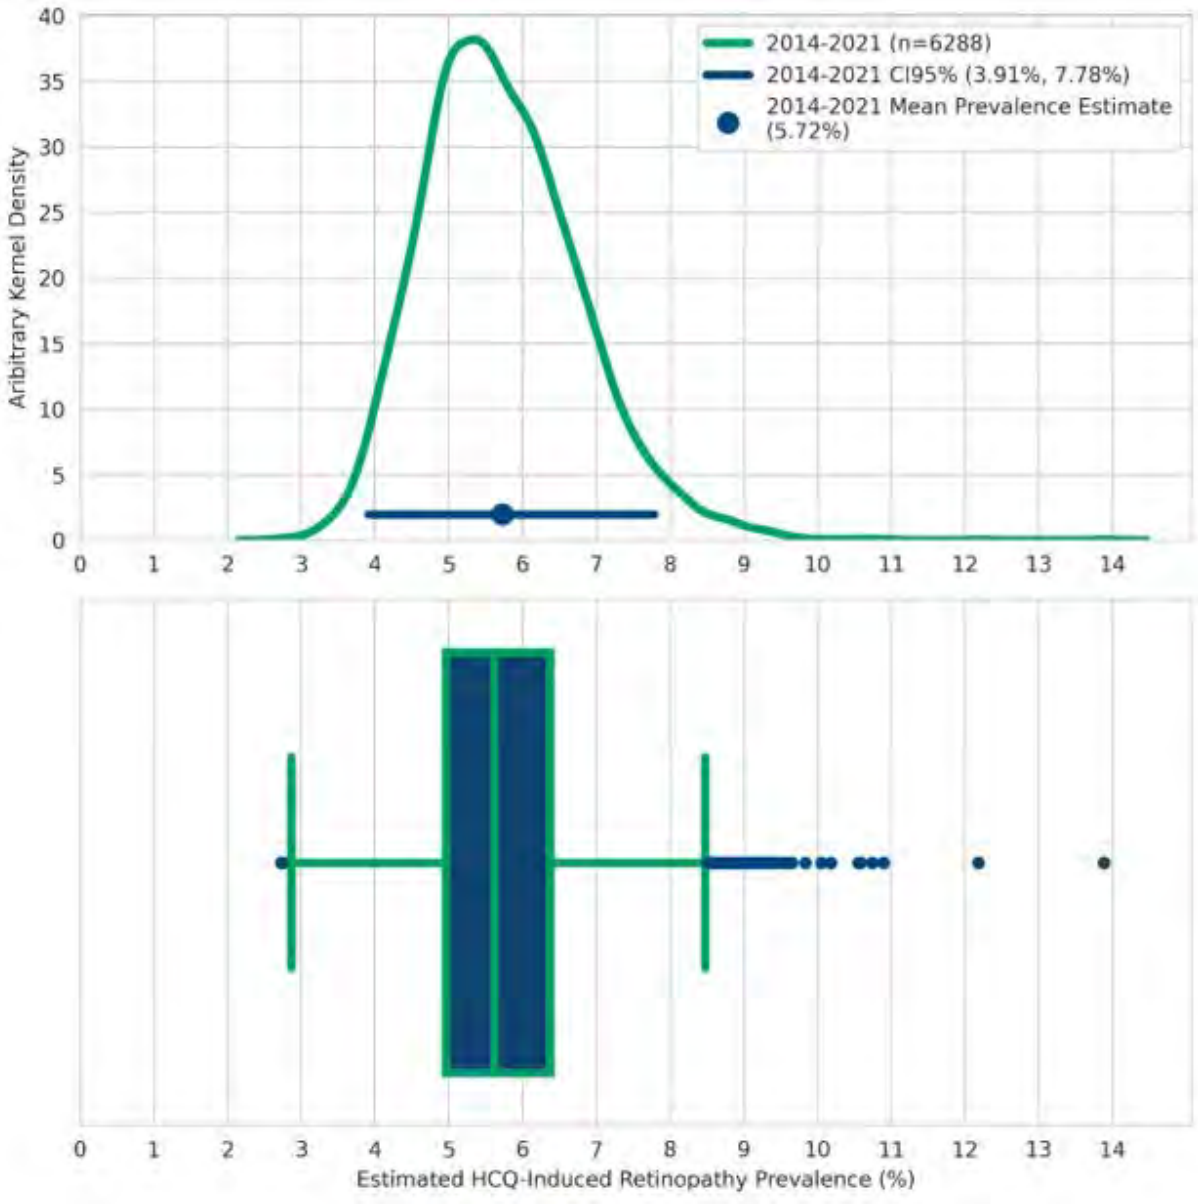
Methods: US ordering providers (n=986) submitted specimens collected from patients receiving therapy HCQ to Exagen Inc's CAP accredited clinical laboratory between December 2014 and April 2021 (Table 1). HCQ levels were measured in EDTA blood or capillary blood collected on micro-samplers using LC-MS/MS and reported to clinicians within 5 days of specimen receipt. Recommendation was made to collect specimens after 6 months therapy (steady state). The relationship between age per 10 years and HCQ dose per 200 mg qd with the likelihood of having HCQ levels greater than 1177 ng/mL was modeled using random intercept logistic regression. That estimated likelihood was combined with estimates of the sensitivity and positive predictive value of the cutoff HCQ ≥ 1177 ng/mL for the

Table 1. Patient Characteristics. 'Patients with HCQ Dose' refers to the subset of patients for whom HCQ monitoring was ordered, and the ordering provider opted to indicate dosing information at the time of test requisition submission. The subset 'Patients with HCQ Dose' was further filtered to include only patients with venous blood HCQ ≥ 500. 'All Patients with HCQ Order' refers to any patient for whom HCQ monitoring was ordered, including non-compliant patients and patients for whom HCQ dose was not indicated. Only the most recent visit per patient are included

	Patients with HCQ Dose (HCQ ≥ 500, Most Recent Visit)	All Patients with HCQ Order (Most Recent Visit)
Age (years)	55.3 ± 12.6	54.0 ± 12.8
% Female	90.40%	90.40%
n Unique Patients	6288	12979
n Unique NPI's	676	986
HCQ Dose (Mean mg/day)	349.0 ± 96.0	N/A
HCQ Dose (Median mg/day)	400	N/A
Mean Venous Blood HCQ (ng/mL)	1192.8 ± 504.2	945.3 ± 625.0
% Patients Having HCQ < 50 ng/mL	N/A	10.40%
% Patients Having HCQ < 200 ng/mL	N/A	14.50%
% Patients Having HCQ > 500 ng/mL	100%	75.20%
% Patients Having HCQ > 1177 ng/mL	43%	32.70%



Y-Axes are shared across each row; x-axes are conserved across all subplots. Top: Theoretical population mean estimates for the likelihood of achieving HCQ≥1177 ng/mL in a cohort of HCQ-therapy-compliant patients with prediction intervals describing the estimated likelihood of HCQ≥1177 ng/mL for individuals drawn from a population described by our cohort in increments of 10%, for 10%-90%, and 95%. Middle: Theoretical population mean estimates for the likelihood of R_HCQ in a cohort of HCQ-therapy-compliant patients with prediction intervals describing the estimated likelihood of R_HCQ for individuals drawn from a population described by our cohort in increments of 10%, for 10%-90%, and 95%. Bottom: Histograms describing the distribution patients by age allow an examination of the weight assigned to each vertical slice of likelihood in the middle plot when constructing the estimate of R_HCQ in Figure 3.



Top: Kernel density plot of estimated R_HCQ shows the uncertainty in the estimate of R_HCQ in a cohort of HCQ-therapy-compliant patients with CI95% and mean R_HCQ. Bottom: Box plot of the same distribution with outliers, minimum, 25th percentile, median, 75th percentile, and maximum.

prediction of the incidence of R_{HCQ}; thus allowing the estimation of the likelihood of R_{HCQ} given age and HCQ dose and the estimation of the overall rate of R_{HCQ}. Probabilistic modeling was performed with PyMC3 and compared to generalized estimating equations (GEE) implemented with StatsModels. Random intercept and GEE grouping was performed per ordering provider using only the most recent visit per patient. To ensure the analysis was performed using patients likely to be at least partially adherent to HCQ therapy, patients having HCQ < 500 ng/mL were excluded.

Results: Odds of having HCQ ≥ 1177 increased by 22% (CI95%Proba: [17%, 27%] | CI95%GEE: [15%, 26%]) per 10 years of age and 158% (CI95%Proba: [129%, 189%] | CI95%GEE: [102%, 206%]) per 200 mg HCQ prescribed qd. Figure 2 presents the theoretical population mean estimates (regression estimates with CI95%) and prediction intervals for individuals drawn from the cohort in increments of 10% from 10%-90%, and 95%. The estimated incidence of R_{HCQ} in the cohort of patients having HCQ ≥ 500 was 5.72% (CI95% = [3.91%, 7.78%], Figure 3).

Conclusion: The estimated CI95% ([3.91%,7.78%]) for the prevalence of R_{HCQ} in patients compliant to HCQ-therapy overlapped with estimates produced by previous studies. Model estimates for the population mean likelihoods agreed with individual prediction intervals, but the relatively wider prediction intervals emphasize the importance of appropriate utilization of HCQ TDM in patients chronically prescribed HCQ.

Abstract Number: 1765

Should SLE Patients Entering Clinical Trials Be Required to Have at Least One BILAG A and/or Two BILAG B Domain Scores?

Ewa Olech[1], Faizi Hussain[2] and Joan Merrill[3], [1]IQVIA, Las Vegas, NV, [2]IQVIA, Redding, United Kingdom, [3]Oklahoma Medical Research Foundation, Oklahoma City, OK

SESSION INFORMATION
Session Date: Tuesday, November 9, 2021
Session Title: SLE – Treatment Poster (1732–1772)
Session Type: Poster Session D
Session Time: 8:30AM–10:30AM

Background/Purpose: High placebo response rates have challenged interpretation of clinical trial results in SLE and may have contributed to failure of some effective treatments. One hypothesis to explain inflated placebo responses is that patients may not have sufficient disease activity at baseline. Most SLE study designs require a score of ≥6 on the SLE Responder Index (SLEDAI) at entry. Some have attempted to enrich for more active disease by adding an additional inclusion criterion for score A (severe) in ≥1 organ system and/or B (moderate) in ≥2 organ systems on the

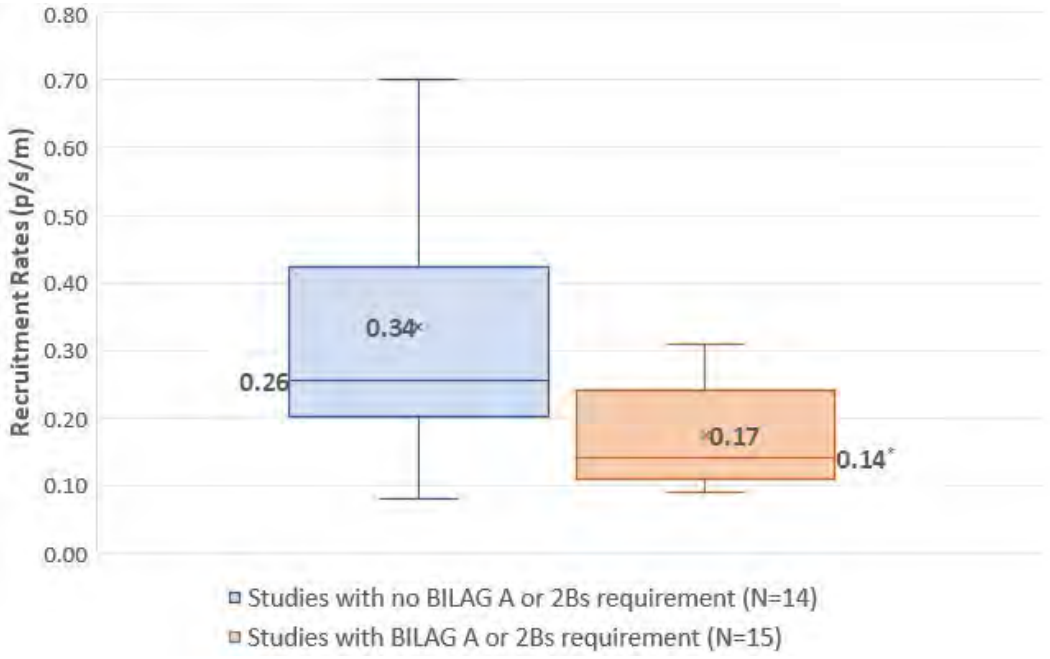

Figure 1. Impact of at least 1 BILAG A or 2 B scores requirement on recruitment rates: comparison of recruitment rates (patients/site/month) of trials that had this requirement with the ones that di not (*p<0.05, Mann-Whitney Rank Sum).

British Isles Lupus Assessment Group (BILAG) index (at least 1 BILAG A or 2 B). However, the impact of this requirement on enrollment and study outcomes, including placebo response has not been previously examined.

Methods: Data from completed Phase II and III SLE trials that enrolled ≥100 subjects and reported endpoints using SLEDAI and/or BILAG (SRI-4 and/or BICLA responses) were included in the analysis. In trials that did not require minimal BILAG scores, the proportions of patients who had at least 1 BILAG A or 2 B scores at baseline were examined. Trials that included the BILAG requirement were compared to those that did not for recruitment rates, meeting primary endpoint, and placebo SRI-4 and BICLA response rates.

Results: Thirty (16 Phase II and 14 Phase III) trials met the initial search criteria; one was excluded from the analysis because patients with BILAG A at screening were not allowed. Most of the studies (70%) required SLEDAI score ≥6 at entry; 15 (51.7%) trials required at least 1 BILAG A or 2 B scores and 14 (48.9%) did not. In studies with no BILAG requirement, the mean percent of patients with at least 1 BILAG A or 2 B scores was 61.1%.

Mean/median recruitment rates for all 29 studies combined were 0.25/0.21 patients/site/month (p/s/m). Trials with no BILAG requirement enrolled twice as fast as the ones that required at least 1 BILAG A or 2 B scores: mean/median recruitment rates 0.34/0.26 p/s/m versus 0.17/0.14 p/s/m ($p < 0.05$, Figure 1).

Eleven out of the 29 (39.7%) trials met the primary endpoint; average SRI-4 and BICLA placebo response rates were 44.4% and 34.8% respectively. More studies with no BILAG requirement met their primary endpoint and had lower means of placebo response for both SRI-4 and BICLA than the trials with at least 1 BILAG A or 2 B scores required (Figure 2).

Conclusion: It has been hypothesized that adding minimal BILAG requirement to the traditional SLEDAI criterion at entry will increase the probability of positive outcomes and decrease the inflated placebo response seen in trials of SLE. However, results from the completed studies suggest the opposite: at least 1 BILAG A or 2 B scores requirement at entry was associated with higher placebo response rates and lower likelihood of meeting the primary endpoint, and at the same time, significantly lower enrollment rates. This unexpected finding merits further investigation.

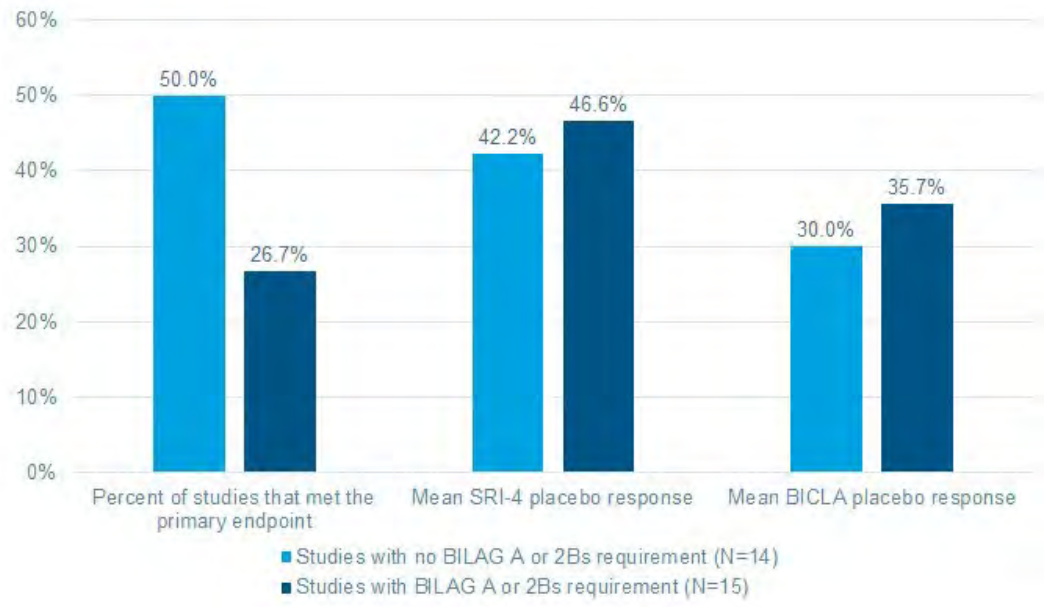

Figure 2. Impact of adding 1 BILAG A or 2 B scores requirement as inclusion on study outcomes: Percent of studies that met their primary endpoint and mean proportions of placebo patients achieving SRI-4 and BICLA responses.

Itolizumab-induced Modulation of Cell Surface CD6 Is a Pharmacodynamic Marker of Drug Activity in SLE Patients

Dalena Chu[1], Leslie Chinn[2], Jeanette Ampudia[1], Krishna Polu[1], Joel Rothman[1], Maple Fung[3], Dolca Thomas[4], Chaim Putterman[5], Cherie Ng[1] and Stephen Connelly[1], [1]Equillium, Inc., La Jolla, CA, [2]Equillium, Inc., South San Francisco, CA, [3]Equillium, Inc., San Diego, CA, [4]Equillium, Inc., Brooklyn, NY, [5]Albert Einstein College of Medicine, Bronx, NY

Session Date: Tuesday, November 9, 2021

Session Title: SLE – Treatment Poster (1732–1772)

Session Type: Poster Session D

Session Time: 8:30AM–10:30AM

Background/Purpose: Itolizumab (ITO) is a novel first-in-class monoclonal antibody (IgG1-k) specific for CD6, a co-stimulatory receptor that is highly expressed on T cells that plays an important role in their activity and trafficking.

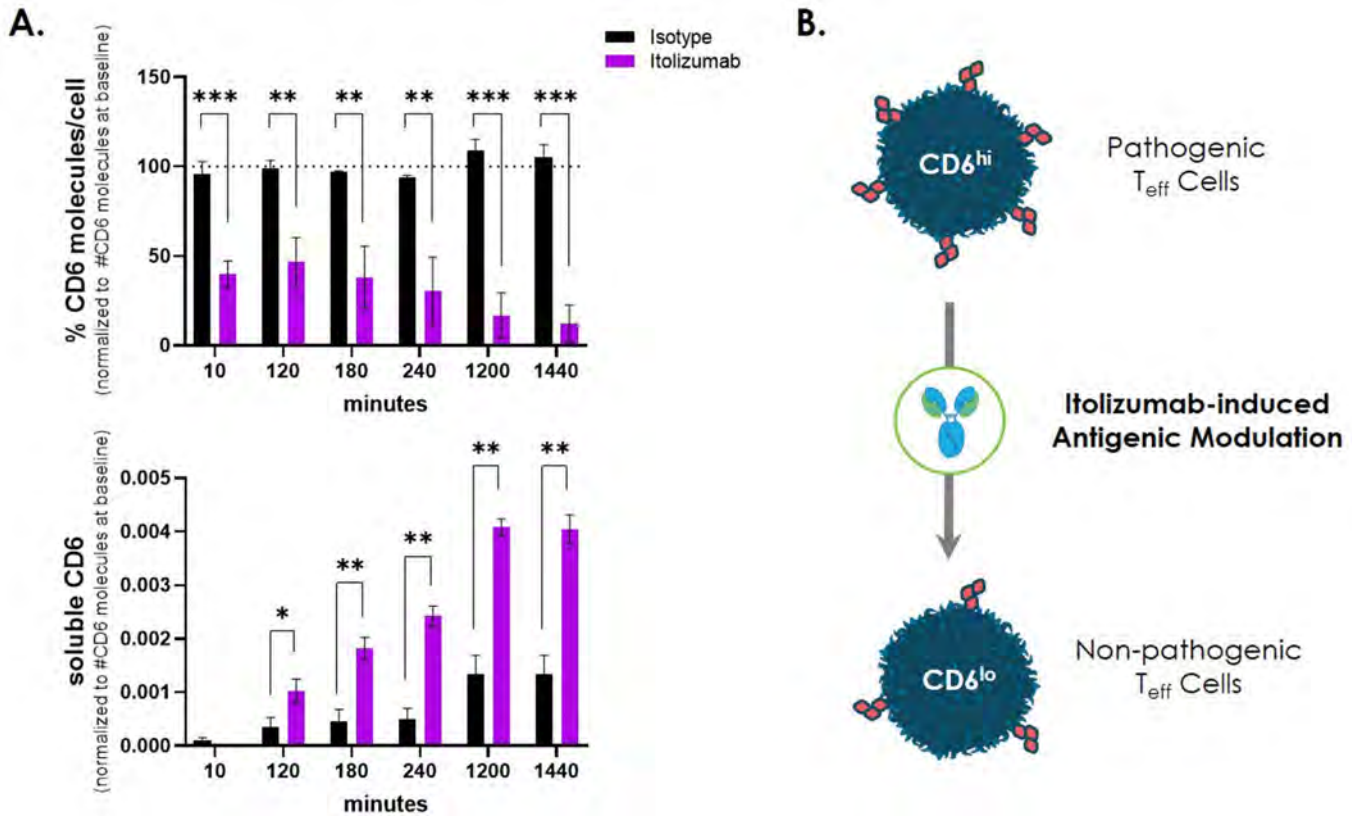

Figure 1. Itolizumab induces loss of CD6 from the T cell surface. (A) PBMCs from 3 different donors were incubated with 10ug/ml of itolizumab and cell surface expression of CD6 was assessed on CD4 T cells and soluble CD6 quantitated in the PBMC supernatant at the indicated timepoints. The calculated number of CD6 receptors on CD4 T cells at baseline as assessed by flow cytometry was used to normalize values across the 3 donors. (B) Schematic of how itolizumab-induced loss of CD6 (antigenic modulation) might affect T cell activity, transforming the cell to possess a less inflammatory phenotype. ***p<0.001, ** p<0.01, * p<0.05.

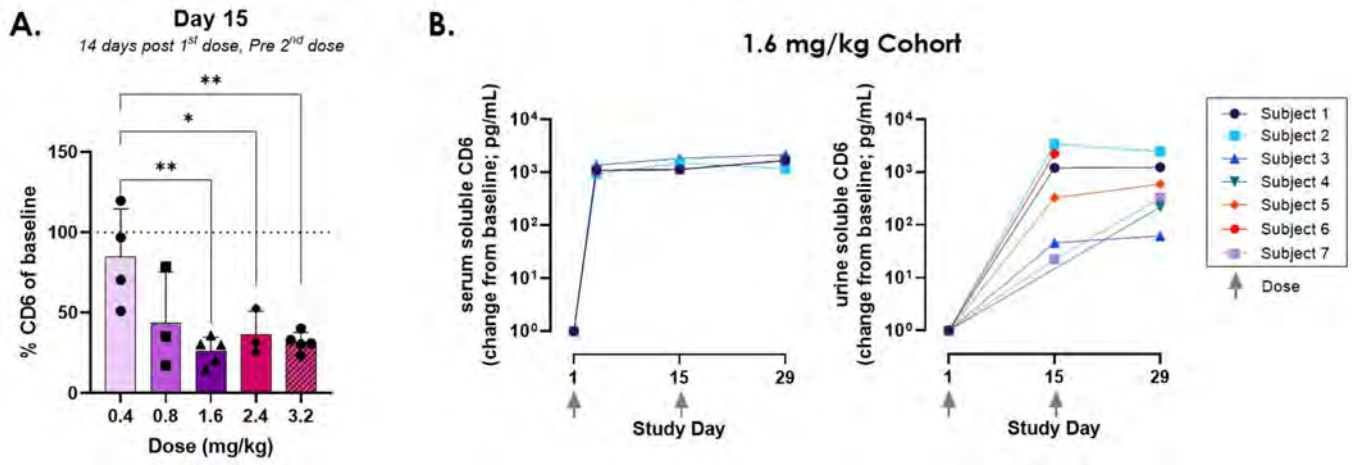

Figure 2. Changes in CD6 in EQUALISE subjects. (A) Cell surface CD6 expression on CD4 T cells decreases following first dose of itolizumab. Expression calculated as % of baseline (pre-drug) expression. (B) Levels of soluble CD6 in serum and urine increase after first dose of itolizumab. Data shown as change from baseline (pre-drug). ***p<0.001, ** p<0.01, * p<0.05.

Excessive activation through CD6 has been implicated in the pathogenesis of multiple autoimmune and inflammatory diseases, including systemic lupus erythematosus (SLE) and lupus nephritis (LN). Consequently, ITO is being evaluated as treatment for SLE and LN. Here, we demonstrate that ITO induces cleavage of cell surface CD6, leading to decreased T cell activity, and that the levels of cell and soluble CD6 in SLE patients dosed with ITO is a pharmacodynamic marker of drug activity.

Methods: Mechanistic experiments were carried out *ex vivo* using PBMCs from normal donors. Samples from patients dosed with ITO, including blood, serum and urine, were collected as part of the EQUALISE trial, an open label Phase 1b 2-part study evaluating the safety, tolerability, pharmacokinetics (PK), pharmacodynamics (PD), and clinical activity of subcutaneous doses of ITO (0.4 to 3.2 mg/kg on Day 1 and Day 15) in patients with SLE (NCT04128579). Cell surface CD6 was assessed by flow cytometry using an anti-CD6 antibody that does not compete with the binding of ITO, while soluble CD6 in cell supernatants, serum and urine was quantified by an electrochemiluminescent assay.

Results: When PBMCs were incubated with ITO (0.01-10ug/ml), CD4 and CD8 T cell populations exhibited loss of surface CD6 in a dose- and time-dependent manner. Cell surface loss was accompanied by a concomitant increase in soluble CD6 in the supernatant (Figure 1). The resulting $CD6^{low}$ T cells showed reduced T-cell activity (as indicated by activation markers and cytokine production), compared to isotype-treated $CD6^{high}$ cells, despite removal of ITO from the system. In samples from SLE patients dosed with ITO, significant loss of cell surface CD6 on T cells was observed after the first dose. Decreases in cell surface CD6 from baseline were most pronounced at doses ≥1.6 mg/kg and were accompanied by increases in soluble CD6 in the serum and urine (Figure 2). PK/PD analysis of the relationship between ITO concentrations and cell surface CD6 levels indicated that the data were described by an E_{max} model, which predicted a maximal decrease in CD6 expression of approximately 78%.

Conclusion: Cell surface CD6 regulates T cell activity and ITO-induced loss of CD6 leads to inhibition of T cell activity and can be used to monitor PD activity. SLE patients in the EQUALISE trial demonstrate dose-dependent loss of CD6 with maximal loss occurring at 1.6mg/kg, suggesting that higher doses are not necessary to achieve the greatest inhibition of T cell activity.

CXCL5 Dampens Inflammation in Murine Lupus by Orchestral Suppression of Effector Cell Proliferation and Leukocyte Extravasation

Xiubo Fan[1], Chin Teck Ng[1], Dianyang Guo[1], Frances Lim[1], Annie Law[2], Julian Thumboo[1], William Hwang[3] and Andrea Low[1], [1]Singapore General Hospital, Singapore, Singapore, [2]Singhealth, Singapore, Singapore, [3]National Cancer Centre Singapore, Singapore, Singapore

SESSION INFORMATION
Session Date: Tuesday, November 9, 2021
Session Title: SLE – Treatment Poster (1732–1772)
Session Type: Poster Session D
Session Time: 8:30AM–10:30AM

Background/Purpose: Systemic lupus erythematosus (SLE) is a potentially fatal autoimmune disease characterized by dysregulation of both innate and adaptive immunity. Current therapeutic options are limited, and 20-40% of patients are unresponsive to treatment. C-X-C motif chemokine ligand 5 (CXCL5) is known as a chemoattractant and activator of neutrophils. Our prior work identified CXCL5 as a key active factor secreted by mesenchymal stromal cells (MSCs) that was able to improve survival and reduce disease activity in a pre-clinical mouse model of graft versus host disease. However, whether CXCL5 could dampen inflammation and abrogate the pathological processes of SLE is unknown.

Methods: 16-week-old MLR/lpr (Fas^{lpr}) lupus-prone mice were treated with ten weekly intravenous doses of CXCL5 (3 μg/kg) and monitored for ten weeks. Immune and cytokine profiles were determined by flow cytometry and Luminex assays. Anti-DS DNA autoantibody levels were measured by ELISA. Proteinuria was evaluated by albumin creatinine ratio. Renal immune cell infiltration and complement 3 deposition were determined by Haematoxylin & Eosin and immunofluorescence staining. Potential molecular changes were identified by bulk RNA sequencing.

Results: Indeed, in MLR/lpr (Fas^{lpr}) lupus-prone mice, we found that intravenous treatment with CXCL5 significantly improved mouse survival with a concomitant reduction in anti-dsDNA levels, proteinuria, renal complement C3 deposition, leukocyte infiltration and neutrophil extracellular trap (NET) formation. Immune and molecular profiling and pharmacokinetic studies showed that CXCL5 treatment reduced inflammation via the orchestral suppression of effector cell (T_H17 cells, neutrophils and macrophages) proliferation mediated through T_H1 and T_H2 cells and leukocyte extravasation through restoration of the dysregulated CXCL5 blood-tissue chemokine gradient.

Conclusion: CXCL5 may represent a novel therapeutic option for SLE by restoring dysregulated innate and adaptive immune responses.

Session Title: SLE – Treatment Poster (1732–1772)

Session Type: Poster Session D

Session Time: 8:30AM–10:30AM

Background/Purpose: In systemic lupus erythematosus (SLE), atherosclerosis is strongly associated with vital prognosis. On the other hand, arteriosclerosis is strongly influenced by serum adipokines. The effect on serum adipokine by hydroxychloroquine (HCQ) therapy, which has a vital prognostic benefit in systemic lupus erythematosus, has not been fully investigated. The purpose of this study is to determine the effect of HCQ treatment on serum adipokines in SLE.

Table 1. Characteristics of SLE patients enrolled in this study Anti-dsDNA positive means anti ds-DNA titer increases over 12 IU/ml Low complement means any of C3, C4 and CH50 decreases to less 68mg/dl, less 12mg/dl, 30U/ml. APS: Anti-phospholipid antibody syndrome, NPSLE: neuropsychiatric SLE, LLDAS: lupus low disease activity state

Characteristics	n=41, no.(%)
Female, no(%)	37(90)
Age, years, mean±SD	41.3±13.2
Disease duration, years, mean±SD	14.9±11.3
Past involvement	
Renal involvement	18 (44)
NPSLE	3 (7)
Complication	
APS	8 (20)
Dyslipidemia	1 (2)
Diabetes	1(2)
Hypertension	8 (20)
Concomitant immunosuppressive treatments	
Prednisone No.(%) Median Dosage, mg/day (range)	 34 (83) 4.5 (1-10)
Disease activity	
SLENA-SLEDAI score, Median(range)	4.0 (0-8)
Current skin involvement	23 (56)
anti-dsDNA positive, no(%)	15 (37)
low complement, no(%)	20 (49)
LLDAS	25 (61)
Clinical remission on treatment	4 (10)

Methods: To determine the effect of HCQ treatment alone on serum adipokines, SLE patients with stable disease activity who had not previously received HCQ treatment were included in the study. Additional HCQ therapy was started in these patients from 2016 to 2020. Disease activity was assessed by SLEDAI, CLASI and LLDAS and serum complement titers, anti-ds-DNA antibodies. Serum adipokines (adiponectin, resistin and leptin) were analyzed using ELISA kit (Adiponectin/Acrp30 Quantikine ELISA Kit, R&D and Simple Plex, ProteinSimple) before and 3 months after starting additional HCQ treatment.

In addition, we measured serum cytokines (TNF-α, IL-6, IL-8, MCP-1, MIP-1a, IL-1ra, IL-2) reported to be associated with the pathogenesis of SLE using multiplex immunoassay (Luminex Assay, R&D) and analyzed the relationship with changes of serum adipokines.

Results: Forty-one patients (4 males, 37 females, mean age 41.3±13.2 years) without changing treatment regimens, including glucocorticoids and immunosuppressive drugs other than HCQ were included (Table 1).

Serum adiponectin levels were significantly increased and serum resistin levels were significantly decreased 3 months after additional HCQ administration compared to baseline. No significant changes were observed in serum leptin levels (Fig. 1).

Regarding the association between these adipokines and disease activity parameters, changes of these adipokines by HCQ treatment were not associated with those of hypocomplement. However, change of leptin alone were positively correlated with decreasing anti-dsDNA antibodies.

On the other hand, additional HCQ administration decreased serum TNF-α, IL-6, IL-1ra and IL-2 levels significantly 3 months after compared to baseline.

Regarding the association between these cytokines change and disease activity, the change of TNF-α levels were related to improvement of hypocomplementemia (C3 and C4). Furthermore, the reduction of IL-1ra by additional HCQ treatment was associated with the achievement of LLDAS .

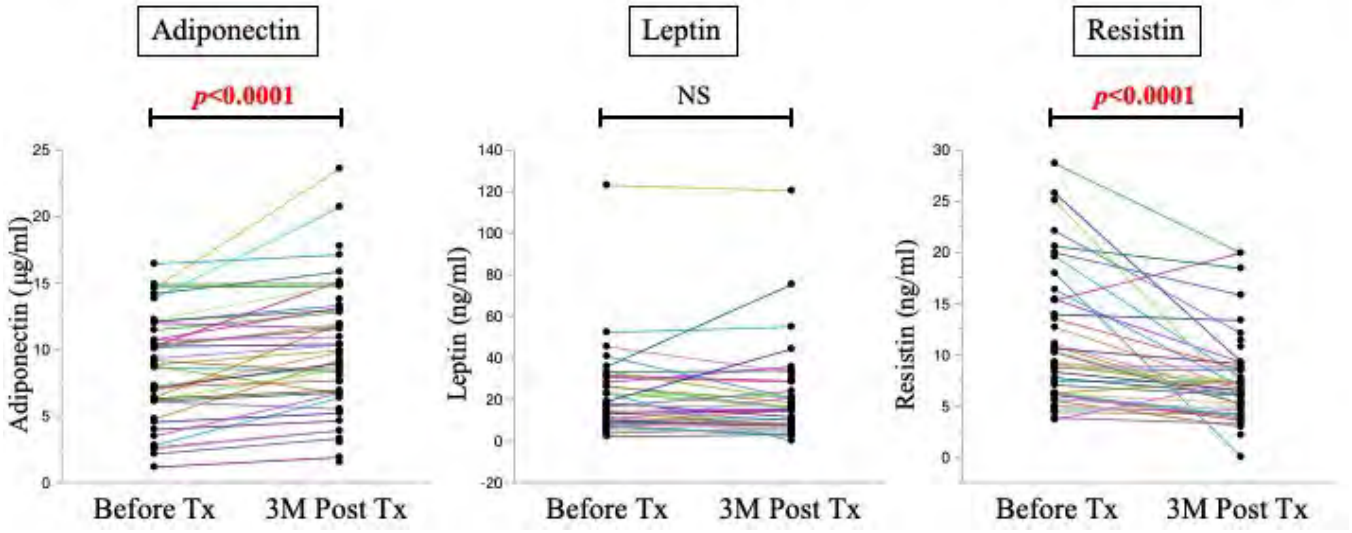

Figure 1. Serum adipockine levels before and after HCQ treatment. Serum levels of the indicated cytokines and factors were measured before or after 3 months (3M Post) treatment (Tx) with HCQ. Colored lines represent individual patients. NS: not significant. P values were determined by the Wilcoxon signed-rank test.

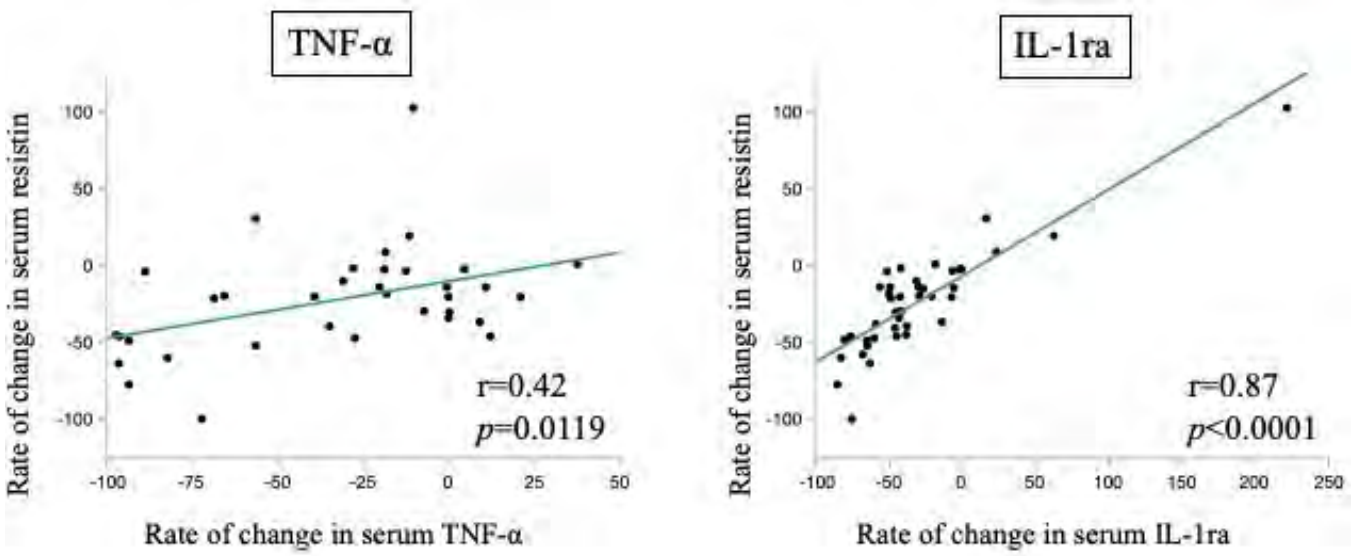

Figure 2. Association between changes in serum cytokines and resistin after HCQ treatment. Reduction of resistin was correlated with reduction of TNF-α or IL-1ra by HCQ therapy significantly. P values were determined by univariate analysis. r: correlation coefficient.

Among of these adipokines, change of resistin was correlated with reduction of TNF-α or IL-1ra by HCQ therapy significantly (Fig. 2). However, the increasing adiponectin was not correlated with change of these cytokines.

Conclusion: HCQ treatment could regulate serum adipocytokine in SLE patients. Resistin was modulated through the effect of HCQ on disease activity. However, the effect of HCQ on serum adiponectin was suggested to be independent on change of disease activity parameters or several cytokines associated with SLE disease activity.

BMS-986256, an Oral Novel Toll-like Receptor 7 and 8 (TLR7/8) Inhibitor, Does Not Affect the Pharmacokinetics of Mycophenolate Mofetil in Healthy Subjects

Manoj Chiney[1], Ihab Girgis[2], Melanie Harrison[1], Xiaoping Zhang[1], Yun Shen[3], Michelle Dawes[1], Lixian Dong[2], Diane Shevell[3], Urvi Aras[1] and Bindu Murthy[3], [1]Bristol Myers Squibb, Lawrenceville, NJ, [2]Bristol Myers Squibb, Princeton, NJ, [3]Bristol Myers Squibb, Lawrenceville

SESSION INFORMATION

Session Date: Tuesday, November 9, 2021
Session Title: SLE – Treatment Poster (1732–1772)
Session Type: Poster Session D
Session Time: 8:30AM–10:30AM

Background/Purpose: Toll like receptor (TLR) 7 and TLR8 are activated as part of the disease pathophysiology of systemic lupus erythematosus (SLE), including lupus nephritis (LN), and related autoimmune diseases, such as

Sjögren's Syndrome. BMS-986256, an orally administered, potent and selective inhibitor of TLR7/8, has demonstrated efficacy in animal models of lupus as well as favorable PK and acceptable safety profiles in healthy subjects. It is now in clinical development for the treatment of SLE. Mycophenolate mofetil (MMF) is an immunosuppressive agent that is widely used in immune-mediated diseases and is often used in the treatment of patients with more serious presentations of active SLE. MMF gets converted to its active metabolite mycophenolic acid (MPA) following oral administration. Therapeutic drug monitoring for MMF and MPA is recommended in certain cases, especially when used as a first-line therapy. Given that MMF is often used in the treatment of SLE, it is likely that BMS-986256 will be administered concomitantly with MMF in Phase 2 studies, and more importantly, in clinical practice. Thus, the effect of BMS-986256 on the exposures of the MMF active metabolite MPA and the phenolic glucuronide of MPA (MPAG) were evaluated.

Methods: This was an open label, single sequence crossover study in which 24 healthy participants received a single oral dose of MMF 1000 mg on Day 1. Starting on Day 5 through Day 28, participants received 30 mg BMS-986256 QD oral dose. On Day 26, subjects received a second oral dose of MMF 1000 mg (in addition to QD dose of BMS-986256). Blood samples were collected after each treatment for PK evaluation. Safety evaluations (adverse events (AEs)), physical and skin examinations, vital signs, electrocardiograms, laboratory tests) were performed during the course of the study.

Results: Co-administration of BMS-986256 with MMF resulted in no clinically meaningful increase in exposures of MPA with geometric mean maximum concentration (Cmax) and total exposure (area under the curve extrapolated to infinity AUC(INF)) increased by 27 % and 17.8%, respectively, compared with MMF alone. Exposures of the MPA metabolite, MPAG, were comparable in both treatment groups, indicating no impact on metabolism of MPA by BMS-986256. In addition, single oral dose MMF did not alter steady state BMS-986256 and BMT-271199 (metabolite) exposures. BMS-986256 was generally safe and well-tolerated with and without MMF. There were no concerning abnormal laboratory test results, including tests of hepatic function and no serious AEs, deaths, or AEs leading to discontinuation. All treatment-emergent AEs were mild and resolved spontaneously.

Table. Statistical Analysis of the Effect of Steady-State BMS-986256 on Single Dose of MMF for MPA and MPAG PK Parameters

	Geometric LS Mean					
	BMS-986256 with MMF Day 26 (Test)		MMF (1000 mg, single dose) Day 1 (Ref)		Geometric LS Mean Ratio (Test/Ref)	
Parameter	n	Result	n	Result	Estimate	90% CI
MPA						
Cmax (µg/mL)	22	23.4	24	18.5	1.270	(1.078, 1.495)
AUC(0-T) (h•µg/mL)	22	59.0	24	51.3	1.150	(1.073, 1.233)
AUC(INF) (h•µg/mL)	19	62.1	23	52.7	1.178	(1.092, 1.271)
MPAG						
Cmax (µg/mL)	22	37.9	24	34.6	1.095	(0.999, 1.200)
AUC(0-T) (h•µg/mL)	22	437.9	24	412.9	1.061	(1.010, 1.113)
AUC(INF) (h•µg/mL)	22	444.6	24	417.6	1.065	(1.015, 1.116)

AUC(INF) = area under the concentration-time curve from time of dosing extrapolated to infinity; AUC(0-T) = area under the concentration-time curve from time of dosing to the time of the last quantifiable concentration observed; CI = confidence interval; Cmax = maximum plasma concentration; LS = least squares; MMF = Mycophenolate mofetil; MPA = mycophenolic acid; MPAG = phenolic glucuronide of mycophenolic acid; N = number of participants; n = number of observations; PK = pharmacokinetics; Ref = reference

Conclusion: BMS-986256 at steady state had no clinically meaningful effect on the PK of a single dose of MMF. MMF alone or in combination with BMS986256 was safe and well tolerated in this study. Given the lack of clinically meaningful DDI, MMF can be co-administered with BMS-986256 without any dose adjustment.

Interim Analysis of Cohort 1 in the Mesenchymal Stromal Cell Trial in Systemic Lupus Erythematosis: Safety and Data Management During the Pandemic

Gary Gilkeson[1], Diane Kamen[1], S Sam Lim[2], Rosalind Ramsey-Goldman[3], Kenneth Kalunian[4], Saira Sheikh[5], Mariko Ishimori[6] and Daniel Wallace[7], [1]Medical University of South Carolina, Charleston, SC, [2]Department of Medicine, Division of Rheumatology, Emory University School of Medicine, Atlanta, GA, [3]Northwestern University, Chicago, IL, [4]UC San Diego, La Jolla, CA, [5]University of North Carolina Thurston Arthritis Research Center, and Department of Medicine, Division of Rheumatology, Allergy and Immunology, University of North Carolina at Chapel Hill School of Medicine, Chapel Hill, NC, [6]Cedars-Sinai Health System, Los Angeles, CA, [7]Attune Health, Beverly Hills, CA

SESSION INFORMATION
Session Date: Tuesday, November 9, 2021
Session Title: SLE – Treatment Poster (1732–1772)
Session Type: Poster Session D
Session Time: 8:30AM–10:30AM

Background/Purpose: There is heightened interest in the use of mesenchymal stromal cells (MSCs) for the treatment of autoimmune diseases. There are a number of reports of efficacy of MSCs with minimal safety concerns in lupus and rheumatoid arthritis. There are, however, only a very limited number of controlled trials to assess true efficacy and safety of MSCs in rheumatic diseases. There are no controlled trials of MSCs in lupus, while there are a number of uncontrolled trials, primarily from one center in China, reporting over 60% efficacy of MSCs in refractory lupus patients. The MSC in systemic lupus erythematosus trial (MiSLE) is the first double blind placebo controlled multi-center trial of MSCs as a treatment for refractory lupus.

Methods: The MiSLE trial is a two-cohort dose escalation trial at 9 centers in the United States. A total of 81 patients will be randomized. Cohort one is complete, consisting of 41 patients receiving either $1x10^6$ MSCs/kg or placebo in a 2/1 ratio. The MSCs are allogenic MSCs derived from umbilical cords of women undergoing elective C sections. They were prepared using standard ISCT protocols at our Clean Cell Facility. The blind is being maintained for cohort 1 through the completion of cohort 2. The second cohort of 40 patients, enrolling now, will receive $5x10^6$ MSCs/kg. Patients had a SLEDAI of 6 or greater at screening, had failed at least one immunosuppressant, and were on 0.5mg/kg prednisone or less. Clinical response was measured as a primary outcome using the SRI4 at 24 weeks post the single MSC infusion. Due to COVID, some of the followup visits were performed by Telehealth, using investigator judgement as to what parts of the SLEDAI and BILAG could be reliably scored.

Results: Forty-one patients were enrolled into cohort one of the MiSLE trial. Due to COVID, no new patients were enrolled from March 2020 through August 2020. The cohort consists of 90% women, 49% Caucasian, 39% African American and 12% other. Average age was 38. All 7 sites active in Cohort 1 enrolled patients. The organ systems

Table 1. Cumulative Adverse Events Summary

	Subjects N (%)[1][2]	Events N (events per subject)
Total subjects	41(100)	189(4.6)
Events Requiring 24 Hour Reporting		
BILAG A	8(19.5)	10(0.2)
Pregnancy	0(0)	0(0)
Serious Adverse Events	10(24.4)	15(0.4)
SAEs Related to:		
SLE	5(12.2)	5(0.1)
Study Intervention	0(0)	0(0)
Infection	3(7.3)	5(0.1)
Adverse Events	36(87.8)	189(4.6)
AEs Related to:		
SLE	25(61)	74(1.8)
Study Intervention	6(14.6)	7(0.2)
Infection	19(46.3)	41(1)
AEs By Severity		
Grade 1*	2(4.9)	3(0.1)
Grade 2	35(85.4)	154(3.8)
Grade 3	16(39)	30(0.7)
Grade 4**	2(4.9)	2(0)
Grade 5	0(0)	0(0)
Infusion Reaction	2(4.9)	2(0)
Deaths	0(0)	0(0)

Adverse events in Cohort 1 of the MiSLE trial

involved were 41.5% mucocutaneous, and 78.1% musculoskeletal. 14.6% had renal involvement. Mean SLEDAI score was 10.3 and 71% of patients were anti-dsDNA positive. 66% of patients were on prednisone. There were no deaths, no significant infusion reactions nor any SAEs attributed to the Investigational Product. Fifteen SAEs were reported in 10/41 participants. 10 BILAG A flares occurred in 5 patients. As expected, a number of the AEs and SAEs were infections, though MSCs are not believed to enhance infection risks. Notably a few patients contributed to most of the SAEs and lupus flares. The major issue arising due to the pandemic was delayed data entry and data inconsistency due to remote work and video visits.

Conclusion: The first cohort of patients in the MiSLE trial are infused and nearing completion of 52 weeks. There were a number of SAEs reported, but there was not a safety signal by DSMB review. Changes in data management and reporting are being instituted to improve prompt and accurate data entry. Overall, the safety data confirm that there are almost no infusion reactions with MSCs and the safety profile is sufficient to proceed to the higher dose cohort.

First-in-Human Safety, Pharmacokinetic and Pharmacodynamic Study of Escalating Single- and Multiple-Doses of BMS-986256, a Novel, Potent, Oral Inhibitor of TLR7 and TLR8

Melanie Harrison[1], Manoj Chiney[1], Diane Shevell[2], Lixian Dong[3], Michelle Dawes[1] and Ihab Girgis[3], [1]Bristol Myers Squibb, Lawrenceville, NJ, [2]Bristol Myers Squibb, Lawrenceville, [3]Bristol Myers Squibb, Princeton, NJ

SESSION INFORMATION
Session Date: Tuesday, November 9, 2021
Session Title: SLE – Treatment Poster (1732–1772)
Session Type: Poster Session D
Session Time: 8:30AM–10:30AM

Background/Purpose: Toll-like receptor (TLR)7 and TLR8 are endosomal receptors that are normally activated by pathogen-associated RNA. They are also activated by self-RNA as part of the pathophysiology of systemic lupus erythematosus (SLE) and related autoimmune diseases. Inhibition of TLR7 and TLR8 may be effective in the treatment of these diseases. BMS-986256 is an oral, potent and selective TLR7 and TLR8 inhibitor. It demonstrates robust pharmacodynamic (PD) activity and efficacy in multiple mouse models of lupus. The objective of this first-in-human, single ascending dose (SAD) and multiple ascending dose (MAD) study was to evaluate the safety, pharmacokinetics (PK) and pharmacodynamics (PD) of BMS-986256 in healthy volunteers (HV)

Methods: Each of the SAD and MAD parts of the study were randomized, double-blind, placebo-controlled trials in which HV were randomized 3:1 (BMS-986256:placebo) within each dose cohort. In the SAD part of the study, a total of 48 HV were enrolled across 6 dose cohorts (1mg through 120mg) of 8 participants each and followed for up to 28 days. In the first of two MAD parts of the study, 24 non-Japanese HV were enrolled across 4 dose cohorts (once daily 3mg through 60mg) for up to 21 days and followed for up to 42 days. A second MAD part (J-MAD) enrolled 24 Japanese HV across 3 dose cohorts, (once daily 10mg through 60mg) for up to 21 days and followed for up to 42 days. Safety, tolerability, PK and PD were assessed throughout the study and reviewed following each dose level prior to initiation of successive dose escalation cohorts.

Results: Across all cohorts, the frequency of treatment emergent adverse events (TEAEs) was low and the majority were unrelated to BMS-986256. There were no serious adverse events and all TEAEs were classified as mild except for 2 moderate TEAEs (viral upper respiratory infection and tooth fracture), both unrelated to BMS-986256. One participant in the J-MAD part of the study discontinued BMs-986256 for asymptomatic, elevated ALT, which then resolved. BMS-986256 has linear PK over the dose range evaluated in SAD and MAD parts. It has a long half-life of approximately 80 hours to support once daily dosing. BMS-986256 has low inter-individual variability in exposures and low level of single circulating metabolite (< 2 % of parent). An ex vivo assay that measured BMS-986256 inhibition of TLR7-agonist or TLR8-agonist induced IL-6 production showed rapid target engagement at all doses tested in the SAD and MAD parts. The effect was dose-dependent and durable, reaching >90% target engagement. BMS-986256 also exhibited dose dependent, robust effects in 2 other ex vivo assays that measured TLR7-agonist stimulation of CD69 expression on B cells and TLR8-agonist stimulated CD319 expression on monocytes, using flow cytometry.

Conclusion: BMS-986256 was generally safe and well-tolerated following single and multiple doses administered across the dose range studied. It has favorable PK properties. These findings along with its robust biomarker response support its further development as a treatment for SLE and related autoimmune diseases.

Autologous EBV-specific Cytotoxic T Cells in Systemic Lupus Erythematosus: An Innovative Phase I/IIa Clinical Trial

Antoine Enfrein[1], Beatrice Clemenceau[2], Soraya Saiagh[3], Céline Bressollette[4], Zahir Amoura[5], Henri Vie[2] and Mohamed Hamidou[1], [1]Médecine interne, CHU de Nantes, Nantes, France, [2]Inserm U1232, Université de Nantes, Nantes, France, [3]Unité de Thérapie Cellulaire et Génique, CHU de Nantes, Nantes, France, [4]Laboratoire de Virologie, CHU de Nantes, Nantes, France, [5]Médecine interne, Hôpital Pitié Salpêtrière, AP-HP, Paris, France

SESSION INFORMATION
Session Date: Tuesday, November 9, 2021
Session Title: SLE – Treatment Poster (1732–1772)
Session Type: Poster Session D
Session Time: 8:30AM–10:30AM

Background/Purpose: Epstein-Barr Virus (EBV) has been suggested as a potential environmental factor in systemic lupus erythematosus (SLE) onset and disease activity. Here, we report the results of a phase I/IIa clinical trial assessing the safety and the effects of anti-EBV CTL infusion in patients with non severe disease.

Methods: Nine patients meeting the American College of Rheumatology (ACR) criteria for SLE were included, and received a unique dose of 5.10^6/kg autologous CTL. They were then prospectively followed for one year. Clinical activity scores and main biologic parameters such as anti-DNA, C3 and C4 levels, lymphocytes, IFN-α plasmatic levels count were recorded. Humoral anti EBV responses were monitored with ELISA assays for anti VCA, EBNA, EA/D antibodies. We also assessed frequency of EBV-specific T-cell with IFN-γ ELISPOT assays and plasmatic EBV viral loads. Adverse events were collected according to Common Terminology Criteria for Adverse Events (CTCAE) guidelines.

Results: Average SLEDAI score at inclusion was 6,9, and three patients presented active EBV replication with positive PCR on blood (mean 3,17log ±0,65). Six patients were clinically stable during follow-up, one patient improved but with co-administration of other medications, two presented a flare requiring treatment intensification, but not immediately after injection.No critical adverse events related to the treatment were observed. We observed no significant changes in humoral and cellular anti-EBV responses after CTL infusion. Patients follow-up seems to show a relationship between IFN-α level and some serological parameters of the anti-EBV response, which needs to be confirmed in a larger group.

Conclusion: Although no serious adverse events were observed, and this treatment appears to be safe to use, none of the patients showed significant clinical improvement or changes in anti-EBV humoral or cellular responses. A larger demonstration of the relationship between IFN signature and EBV serological responses could justify pursuing this approach with adjustments in treatment.

Comparing Efficacy of Guselkumab versus Ustekinumab in Patients with Psoriatic Arthritis: An Adjusted Comparison Using Individual Patient Data from DISCOVER 1&2 and PSUMMIT Trials

Joris Diels[1], Pushpike Thilakarathne[2], Agata Schubert[3], Fareen Hassan[4], Steven Peterson[5] and Wim Noël[1], [1]Janssen Pharmaceutica, HEMAR Department, Beerse, Belgium, [2]JanssenCilag Ltd, HEMAR Department, Beerse, Belgium, [3]Janssen-Cilag Poland, HEMAR Department, Warsaw, Poland, [4]Janssen-Cilag Ltd, HEMAR Department, High Wycombe, United Kingdom, [5]Janssen Immunology Global Commercial Strategy Organization, Raritan, NJ

SESSION INFORMATION

Session Date: Tuesday, November 9, 2021

Session Title: Spondyloarthritis Including PsA – Diagnosis, Manifestations, & Outcomes Poster IV: Clinical Aspects of PsA & Peripheral SpA (1773–1800)

Session Type: Poster Session D

Session Time: 8:30AM–10:30AM

Background/Purpose: Guselkumab is an anti-interleukin (IL)-23 monoclonal antibody recently approved for the treatment of psoriatic arthritis (PsA). In two large Phase III trials of patients with PsA (DISCOVER 1&2), guselkumab has shown to be superior versus placebo. In this indication no direct comparison is available between guselkumab and ustekinumab, a monoclonal antibody targeting IL-12 and IL-23. Indirect comparisons based on relative treatment

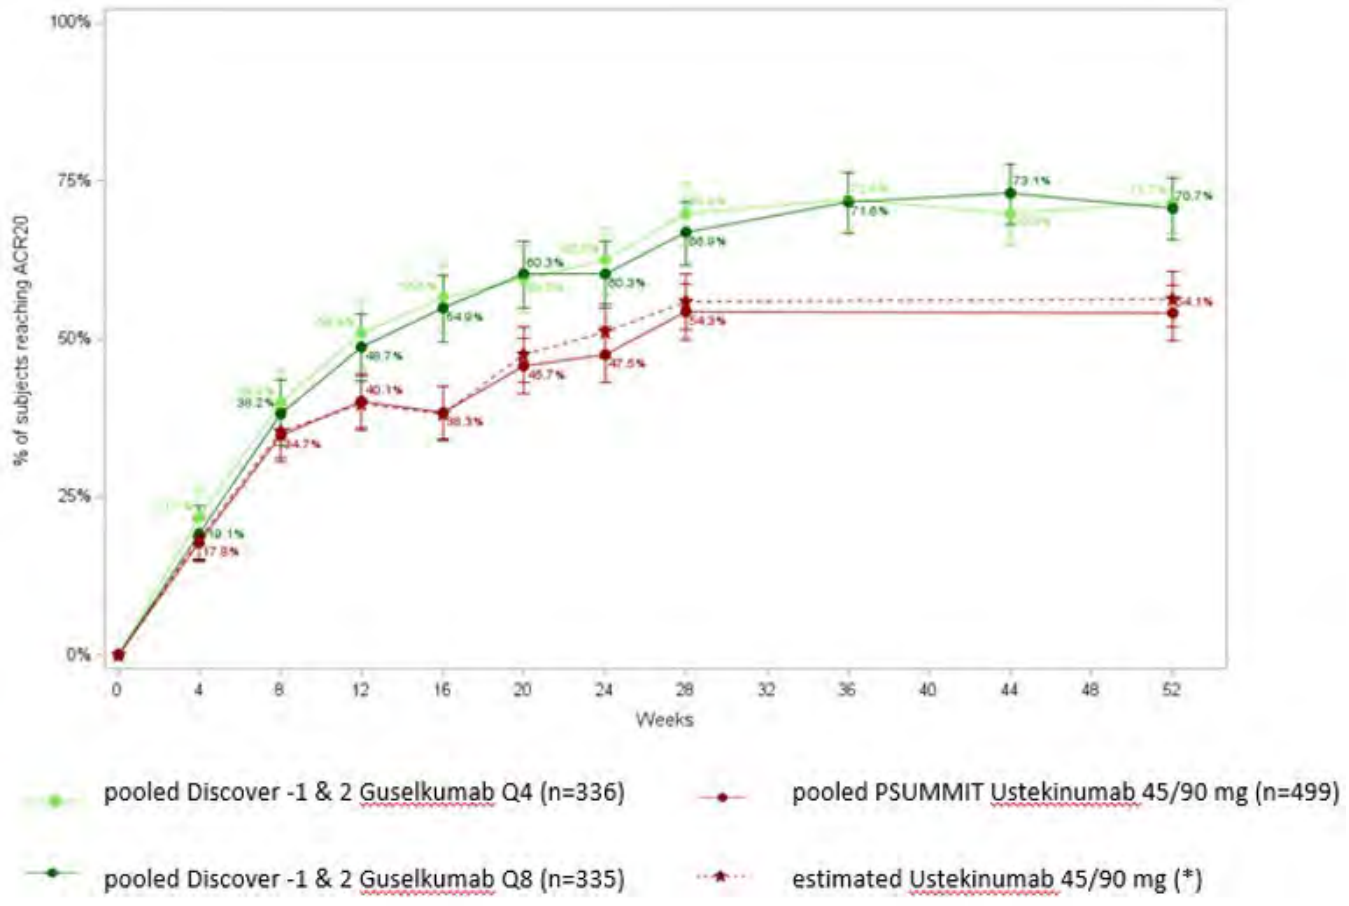

Figure 1. ACR 20 response for guselkumab vs ustekinumab in bio-naïve patients.

effects versus a common comparator (placebo) only allow for analyses up to week 24 due to cross-over to active arms in available PsA trials. The objective of this study was to indirectly compare joint and skin efficacy of guselkumab versus ustekinumab up to week 52, using pooled patient-level trial data from DISCOVER 1&2 and PSUMMIT 1&2, adjusting for cross-trial population differences.

Methods: Patient level data, including baseline characteristics and outcome data on ACR response and Psoriasis Area Severity Index (PASI) response from the guselkumab arms of DISCOVER 1&2 were pooled with the data from the ustekinumab trials PSUMMIT 1&2. Analyses were performed for bio-naïve and bio-experienced populations separately. Differences in patient characteristics across trial populations were adjusted for using multivariate logistic regression, including gender, age, body mass index, previous TNF use, disease duration, PASI level, number of swollen and tender joints. This method of indirect comparisons allows for analysis of comparative efficacy beyond controlled induction period. Odds ratios resulting from this model were translated into predicted response rates for ustekinumab, assuming same patient population, as enrolled in the guselkumab trial arms.

Results: Majority of baseline characteristics for patients on guselkumab (100mg q8w; 100mg q4w) were comparable to patients on ustekinumab 45/90mg, in both the bio-naïve and bio-experienced group of patients. The probability of reaching a ACR 20 in both the bio-naïve & bio-experienced population was significantly higher for guselkumab vs ustekinumab at weeks 52 for both dosing regimens of guselkumab (bio-naïve ACR 20: q8w OR= 1.88 [1.28;2.76]), q4w (OR= 1.92 [1.29;2.86]; bio experienced ACR20 q8w OR= 2.72[1.17;6.31], q4w OR=4.77 [1.95;11.63]). Similarly, guselkumab was superior to ustekinumab on PASI 90 outcome at week 52 in both bio-naïve & bio-experienced patients with BSA ≥3% at baseline (bio-naïve: q8w OR= 2.59 [1.68;3.99]), q4w OR= 3.19 [2.03;5.00], and bio-experienced q8w OR= 3.96[1.39,11.27], q4w OR=13.10[4.18,41.04]). Figure 1 represents unadjusted pooled DISCOVER 1&2 trial results and estimated proportions of ustekinumab treated patient group achieving ACR 20 in bio-naïve patient group up to week 52 using the method described above.

Conclusion: An adjusted comparison using patient level data from pivotal Phase III studies demonstrates both dosages of guselkumab to be significantly more effective versus ustekinumab in both skin and joint outcomes in both bio-naïve & bio experienced patients up to week 52.

Figure 1. Discrimination of PsA from Pso patients using a random forest classification model. (A) Schematic overview of the data analysis procedure. The significantly different cell subsets in PsA vs Pso were selected based on the univariate analysis as shown in Fig 1A and the highly correlated cell subsets were excluded. Randomly splitting for training X' (70%) and test Y' (30%) dataset was repeated 500 times. The RF classification model (containing 1000 forests) was built using the training dataset and the test dataset was shuffled to cross-validate the model. (B) Overview of the ROC curves derived from 500 RF classification models. The AUC value was shown as mean ± SD. (C) Top 10 most relevant-cell subsets contributing to the classifications of PsA and Pso. Cell subsets were ranked based on gini-score. Fold change is computed as the ratio of mean values of each cell subset's percentage in Pso vs PsA. Names of ICS in red indicate these cells are higher in PsA than in Pso.

Background/Purpose: Early detection of psoriatic arthritis (PsA) in psoriasis (Pso) patients is crucial for timely treatment and prevention of structural joint damage. We aimed to identify disease-specific immune profiles discriminating Pso from PsA patients, potentially facilitating adequate referral.

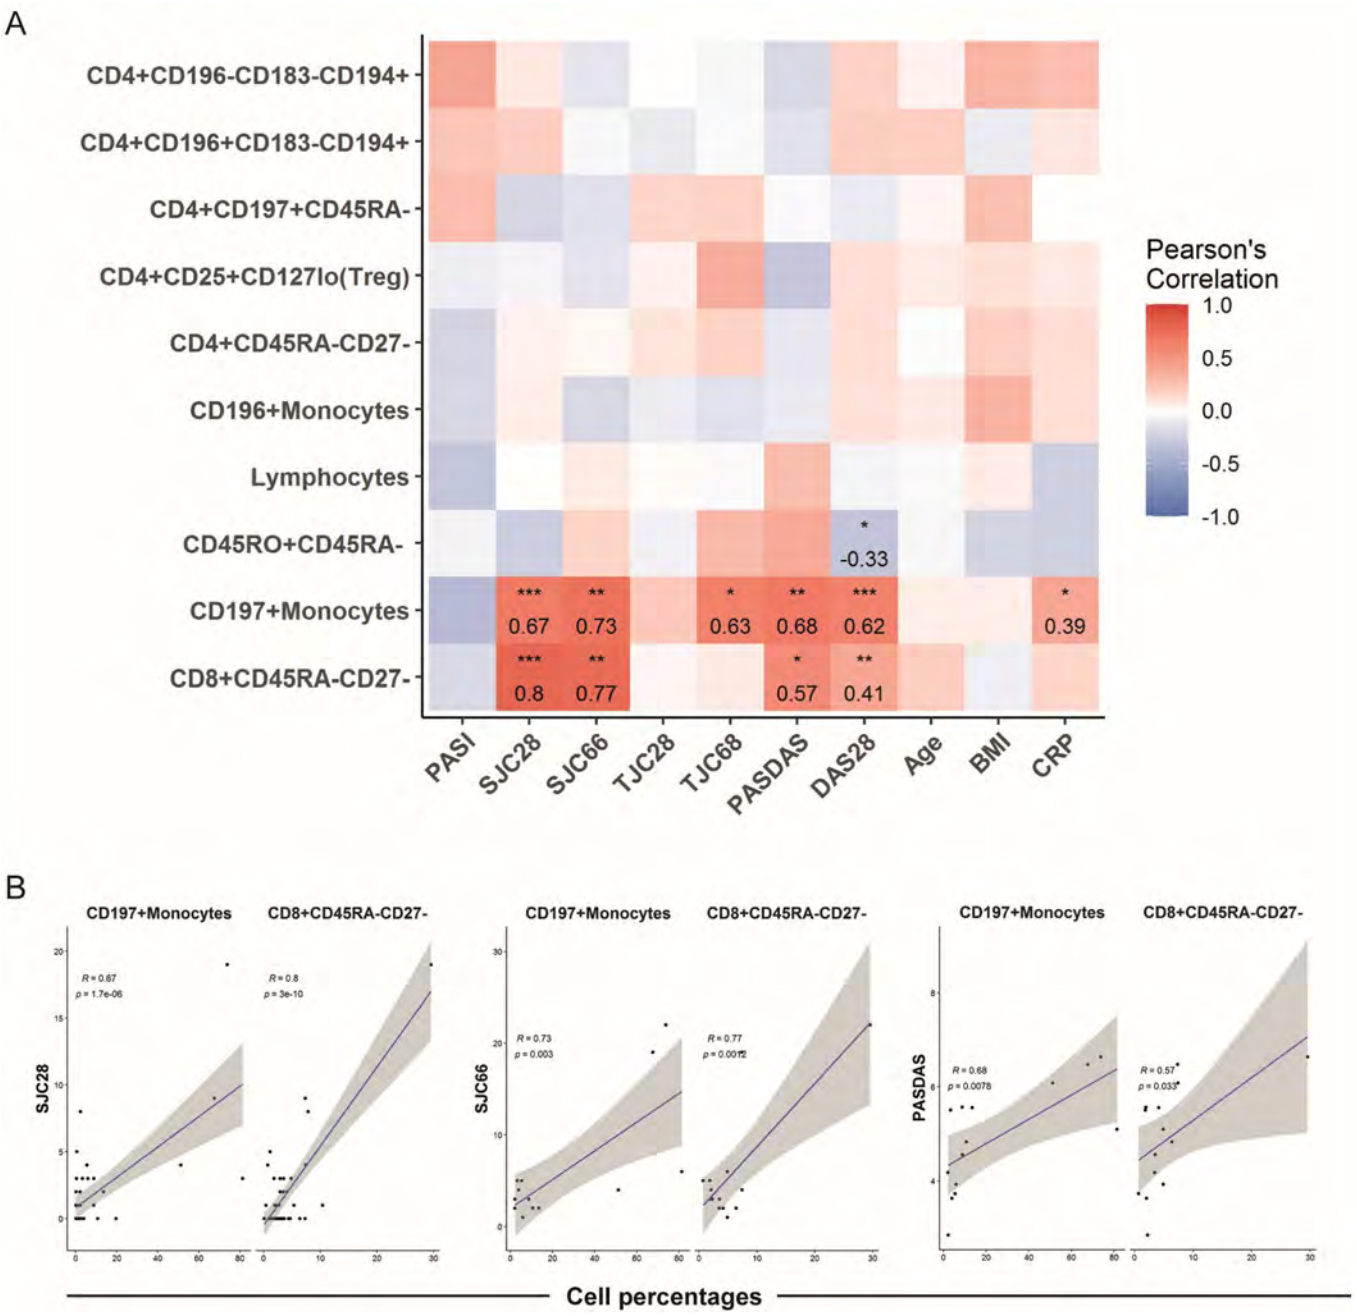

Figure 2. Correlation of clinical parameters with PsA-classifying immune cells. (A) Heatmap showing the pearson's correlation between percentages of cell subsets with clinical parameters in PsA. Numbers indicate the Pearson's correlation coefficient, * p<0.05; ** p<0.01; *** p<0.001. (B) Scatter plots showing the pearson's correlation of the percentages of CD197+ monocytes and CD8+CD45RA-CD27- memory T-cells with swollen joint count 28/66 and Psoriatic Arthritis Disease Activity Score (PASDAS).

Methods: The phenotype of PBMCs of consecutive Pso (N=45) and PsA (N=41) patients was determined using multi-color flowcytometry and univariate analysis to compare percentages of cell subsets between Pso and PsA. Disease-specific immune profiles were defined by machine learning using a random forest (RF) classification model. 1) The dataset was randomly split into a training (70%) and test-set (30%). 2) An RF model consisting of 1000 forests was built and optimized with internal cross-validation. 3) Step 1 and 2 were repeated 500 times. This procedure resulted in 500 RF-based models, each of which was evaluated by an Area under the Curve (AUC) analysis (Figure 1A/1B).

Results: In-depth immune phenotyping resulted in over one hundred different cell subsets for each blood sample being evaluated. A number of cell subsets was significantly different in Pso vs PsA. Key PsA identifying immune cell subsets selected by the RF classification model (AUC value of 0.95) included increased proportions of differentiated $CD4^+CD196^+CD183^-CD194^+$ and $CD4^+CD196^-CD183^-CD194^+$ T-cells and reduced proportions of $CD196^+$ and $CD197^+$ monocytes, memory CD4+ and CD8+ T-cells and CD4+ regulatory T-cells (Figure 1C shows top 10 PsA/Pso-classifying immune cell populations). Within PsA, joint scores showed a strong association with memory CD8+CD45RA-CCR7- effector T-cells and $CD197^+$ monocytes (Figure 2A/2B).

Conclusion: Through the integration of an extensive phenotyping of blood immune cell subsets and a machine learning approach, we identified an immune profile which discriminates PsA from Pso. This immune profile may facilitate timely diagnosis of PsA in Pso and it highlights the possibility of using a combination of selected immune cell subsets as a method for detecting PsA in Pso patients.

Session Title: Spondyloarthritis Including PsA – Diagnosis, Manifestations, & Outcomes Poster IV: Clinical Aspects of PsA & Peripheral SpA (1773–1800)

Session Type: Poster Session D

Session Time: 8:30AM–10:30AM

Background/Purpose: Isolated axial involvement exists in 2 to 5% of all psoriatic arthritis (PsA) patients. However, it is currently unknown whether patients with isolated axial disease are clinically different than those with concomitant peripheral disease. The primary objective of this study was to determine clinical features associated with isolated axial disease among PsA patients with axial disease irrespective of peripheral involvement. Furthermore, we evaluated predictors for the development of peripheral disease from isolated axial disease over time.

Methods: A longitudinal single center cohort was analyzed to identify PsA patients (all patients fulfilled CASPAR criteria) who had axial disease from January 1978 to October 2020 inclusive, as defined by ≥ grade 2 sacroiliitis bilaterally or ≥ grade 3 sacroiliitis unilaterally on sacroiliac joint radiographs, according to the modified New York criteria. Isolated axial disease was defined by the absence of active/damaged joints or dactylitis. Descriptive statistics determined the percentage of patients with isolated axial and axial with peripheral disease. A logistic regression model

SF-36 PCS	0.919	(0.817, 1.034)	0.161

[a]The sacroiliac joint with the highest grade was used preferentially for analysis
CI, confidence interval; PsA, psoriatic arthritis; ESR, erythrocyte sedimentation rate; HAQ, health assessment questionnaire; SF-36 PCS, short form health survey physical health

Results: Of the 1576 PsA patients evaluated, 495 (31.4%) had axial disease, of which 32 (2.0%) had isolated axial disease and 463 (29.4%) had concurrent peripheral disease (Table 1). Full protocol information was available for 237 patients for multivariate logistic analysis (Table 2). At initial presentation of axial disease, HLA-B*27 positivity (Odds ratio 25.00, p< 0.003) and lower Health Assessment Questionnaire (HAQ) scores (Odds ratio 0.004, p< 0.010) were associated with isolated axial disease. For the 32 patients with isolated axial disease, univariate cox proportional-hazards model adjusted for sex and age of PsA diagnosis did not reveal any significant predictors for the development of peripheral disease over clinic follow-up (Table 3).

Conclusion: In our PsA cohort, 2.0% patients had isolated axial disease at presentation. At presentation, PsA patients with isolated axial disease had a significantly higher chance of HLA-B*27 positivity. Moreover, those with isolated axial disease compared with concomitant peripheral disease also had lower HAQ scores at presentation,

Table 3. Time-dependent Univariate Cox Proportional Regression for the Development of Peripheral Disease amongst PsA patients who Presented with Isolated Axial disease, adjusted by Sex and Age at Diagnosis of PsA (N=32)

Variable	Hazard ratio	95% CI	*p*-value

HAQ	0.035	(0.001, 1.603)	0.086
NSAIDS	0.924	(0.322, 2.655)	0.884
DMARDS	1.454	(0.570, 3.710)	0.434
Biologics	1.086	(0.335, 3.515)	0.891

[a]The sacroiliac joint with the highest grade was used preferentially for analysis; CI, confidence interval; PsA, psoriatic arthritis; ESR, erythrocyte sedimentation rate; PASI, psoriasis area and severity index; HAQ, health assessment questionnaire; NSAID, nonsteroidal anti-inflammatory drug; DMARD, disease-modifying antirheumatic drug

suggesting better functional status. Lastly, there does not appear to be any predictors over time for the development of peripheral disease amongst patients who present with isolated axial disease, though analysis was limited by small sample size.

Session Title: Spondyloarthritis Including PsA – Diagnosis, Manifestations, & Outcomes Poster IV: Clinical Aspects of PsA & Peripheral SpA (1773–1800)

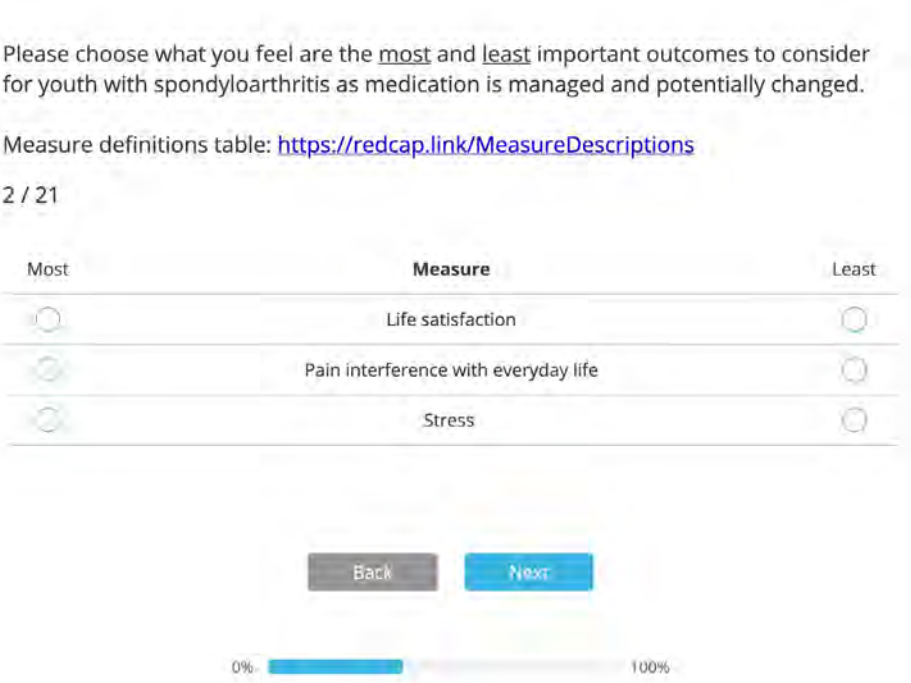
Session Type: Poster Session D

Session Time: 8:30AM–10:30AM

Background/Purpose: The BACK-OFF JSpA Study is a randomized pragmatic trial that will investigate different TNFi de-escalation strategies for children who have sustained asymptomatic disease. As part of the study design we aimed to identify the most important patient-reported outcomes (PRO) of interest to stakeholders that should be examined as part of the trial.

Methods: To identify the most important outcomes of interest to stakeholders we conducted a discrete choice experiment – a user-friendly, quantitative, choice-based approach to evaluate individuals' preferences regarding potential PROs (Sawtooth Software). With this software, stakeholders assessed a discrete list of 21 NIH Patient-Reported Outcome Measurement Information System (PROMIS) pediatric domains across four general categories of outcomes: physical health, mental health, social health and global health. PROMIS measures are self-reported instruments designed for use in the general population and chronic medical conditions. Rather than asking stakeholders to "rate" all items at once, only 3 domains were shown at a time. Within each set, stakeholders chose the outcomes they felt were "most" and "least" important to consider during TNFi therapy de-escalation. This process was repeated for 21 sets of unique outcome combinations, with each outcome being shown an equal number of times. Stakeholders were required to make choices instead of expressing the strength of a preference (as would be done with a Likert scale or Delphi rating process). Using this process left no opportunity for scale use bias, where respondents often rate the different attributes similarly.

Results: Fourteen caregivers, 12 patients (ages 9-22 years old), 16 rheumatologists and 3 payors completed the exercise, which took approximately 10 minutes. The discrete choice experiment resulted in an estimate of the relative



Sample question from the discrete choice experiment.

importance of each outcome and rank (Table). All stakeholder groups agreed that the primary PRO should be "Pain Interference", a measure that evaluates the effect of pain on a child's everyday activities, including impact upon social, emotional, mental, and physical health. Patients and caregivers were mostly aligned in their top priorities, with patients valuing physical health domains (50% of top 10) whereas caregivers were more interested in mental health domains (60% of top 10). Rheumatologists and payors were most interested in physical health domains, which were ranked as 80% and 60% of their top 10 PROs, respectively. Overall, the patients had the most diverse set of domains,

Table. Outcomes prioritization exercise

Family relationships	social	9	17	14	17	5.492	2.569	2.534	1.785	3.249

including at least one of each category in their top 10 rank order of importance. Patients were also the only stakeholders to prioritize an outcome from the "social" category.

Conclusion: The discrete choice experiment resulted in an estimate of the relative importance of each PRO and rank. Patients and caregivers were mostly aligned in their top priorities. The rank-order list directly informed the primary and secondary PROs for our upcoming trial.

Abstract Number: 1777

Association of Opioid Use and Opioid-Related Costs with Patient-Reported Outcomes in Patients with Psoriatic Arthritis or Ankylosing Spondylitis

Alexis Ogdie-Beatty[1], Mark Hwang[2], Phani Veeranki[3], Alexandria Portelli[3], Jason Shafrin[3], Sofia Pedro[4], Esther Yi[5], Steven Hass[6] and Kaleb Michaud[7], [1]University of Pennsylvania, Philadelphia, PA, [2]McGovern Medical School at the University of Texas Health Science Center at Houston, Houston, TX, [3]PRECISIONheor, Los Angeles, CA, [4]Forward, The National Databank for Rheumatic Diseases, Wichita, KS, [5]Novartis Pharmaceuticals Corporation, Weehawken, NJ, [6]H.E. Outcomes, LLC, Los Angeles, CA, [7]University of Nebraska Medical Center, Omaha, NE

SESSION INFORMATION

Session Date: Tuesday, November 9, 2021

Session Title: Spondyloarthritis Including PsA – Diagnosis, Manifestations, & Outcomes Poster IV: Clinical Aspects of PsA & Peripheral SpA (1773–1800)

Session Type: Poster Session D

Session Time: 8:30AM–10:30AM

Background/Purpose: Patients with psoriatic arthritis (PsA) or ankylosing spondylitis (AS) experience chronic pain due to inflammatory attributes of their disease. Nonsteroidal anti-inflammatory drugs and biologics are recommended to improve symptoms, and biologics are recommended to inhibit disease progression. Many patients with chronic pain syndromes may receive opioid therapies; however, opioids do not treat underlying inflammation and are associated with adverse events. Limited data exist on the relationship between disease burden and opioid use in patients with PsA or AS. This study evaluated the association of patient-reported outcome measures with opioid use and related costs in patients with PsA or AS from a national US registry.

Methods: This retrospective cohort study included adult participants enrolled in the FORWARD databank between July 2009 and June 2019. FORWARD is a longitudinal observational registry for rheumatic diseases that prospectively collects patient-reported data by questionnaires administered bi-annually. This sample included patients who completed ≥ 1 questionnaire from January 2010 to December 2019; patients had a physician-reported diagnosis of PsA or AS and responded to the Health Assessment Questionnaire Disability Index (HAQ-DI) or HAQ-DI and/or Bath Ankylosing Spondylitis Disease Activity Index (BASDAI; added in 2018), respectively. The primary outcomes were current opioid use and related costs at the time of the most recent questionnaire. The relationships between HAQ-DI or BASDAI and opioid use and related costs were assessed using logistic regression models for opioid use outcomes and generalized linear models with gamma distribution and log-link function for cost outcomes.

Results: This study included 828 patients with PsA and 334 patients with AS (**Table 1**). Overall, 177 patients with PsA (21.4%) and 91 with AS (27.3%) received opioids, with mean (SD) annualized related costs of $861 ($3669) and $1070 ($4617), respectively. There was a significant positive association (OR [95% CI]) between opioid use and HAQ-DI (1.99 [1.50-2.64] and 4.14 [2.59-6.63] in patients with PsA and AS, respectively; both $P < 0.01$) and BASDAI (1.22 [1.02-1.47] in patients with PsA; $P < 0.05$ and 1.94 [1.27-2.97] in patients with AS; $P < 0.01$). A 1-unit increase in HAQ-DI or BASDAI score was significantly associated (RR [95% CI]) with a 2.31 (1.40-3.81; $P < 0.01$) or 2.05 (1.09-3.86; $P < 0.05$) times increase, respectively, in opioid-related costs for patients with PsA, and a 17.82 (5.82-54.51; $P < 0.01$) or 8.20 (1.15-58.59; $P < 0.05$) times increase, respectively, in opioid-related costs for patients with AS (Figure 1).

Table 1. Demographics, Clinical Characteristics, and Disease Activity Measures in Patients With PsA or AS[a]

Characteristic	Patients with PsA (n = 828)	Patients with AS (n = 334)
Age, mean (SD), years	58.5 (13.5)	54.4 (14.3)
Female, n (%)	599 (72.3)	206 (61.7)
White, n (%)	697 (92.3)	282 (94.6)
Insurance status, n (%)		
Private	263 (31.8)	114 (34.1)
Medicare	362 (43.7)	135 (40.4)
Medicaid	68 (8.2)	30 (9.0)
Other	120 (14.5)	43 (12.9)
None	15 (1.8)	12 (3.6)
Disease duration, mean (SD), years [n]	17.5 (12.4) [759]	17.5 (12.4) [303]
Current treatment use, n (%)		
csDMARDs	360 (43.5)	78 (23.4)
b/tsDMARDs	407 (49.2)	153 (45.8)
General arthritis[b]	530 (64.0)	220 (65.9)
NSAIDs	298 (36.0)	160 (47.9)
Prednisone	93 (11.2)	33 (9.9)
Opioids[c]	177 (21.4)	91 (27.3)
Other drugs[d]	628 (75.9)	245 (73.4)
Any drug	751 (90.7)	298 (88.6)
Disease activity, mean (SD) [n]		
HAQ-DI	0.9 (0.7) [828]	0.9 (0.7) [333]
BASDAI	3.7 (2.4) [204]	3.7 (2.3) [81]
Current working status, n (%)	n = 801	n = 325
Unemployed	27 (3.4)	15 (4.6)
Employed	342 (42.7)	140 (43.1)
Retired	241 (30.1)	76 (23.4)
Disabled	126 (15.7)	69 (21.2)
Other	65 (8.1)	25 (7.7)

AS, ankylosing spondylitis; BASDAI, Bath Ankylosing Spondylitis Disease Activity Index; b/tsDMARD, biologic/targeted-synthetic disease-modifying antirheumatic drug; COX-2, cyclooxygenase-2; csDMARD, conventional synthetic disease-modifying antirheumatic drug; HAQ-DI, Health Assessment Questionnaire Disability Index; NSAIDs, nonsteroidal anti-inflammatory drugs.

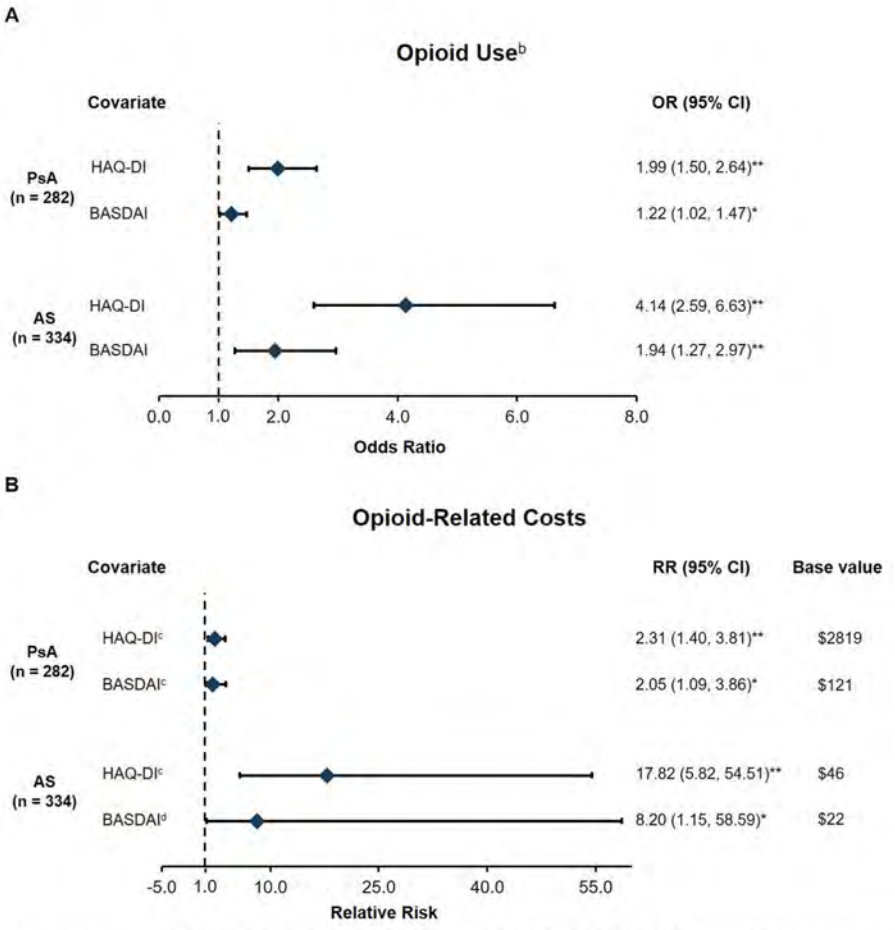
[a] Includes data for patients with PsA who responded to HAQ-DI and patients with AS who responded HAQ-DI and/or BASDAI.

[b] General arthritis: general arthritis drugs (glucosamine, hyaluronate, intra-articular injections, ketorolac, prednisone, topicals, and vitamins), NSAIDs, COX-2 inhibitors (celecoxib), analgesics, and acetaminophen.

[c] Opioids: mild opioids (codeine, hydrocodone, acetaminophen with codeine, acetaminophen with propoxyphene, acetaminophen with hydrocodone, acetaminophen with tramadol, and tramadol alone) and strong opioids (fentanyl, hydromorphone, methadone, morphine, narcotics, oxycodone, oxymorphone, and acetaminophen with oxycodone).

[d] Other drugs: Any medication for conditions other than PsA or AS.

Figure 1. Association of **(A)** Opioid Use and **(B)** Drug-Related Costs With HAQ-DI and BASDAI Among Patients With PsA or AS[a]

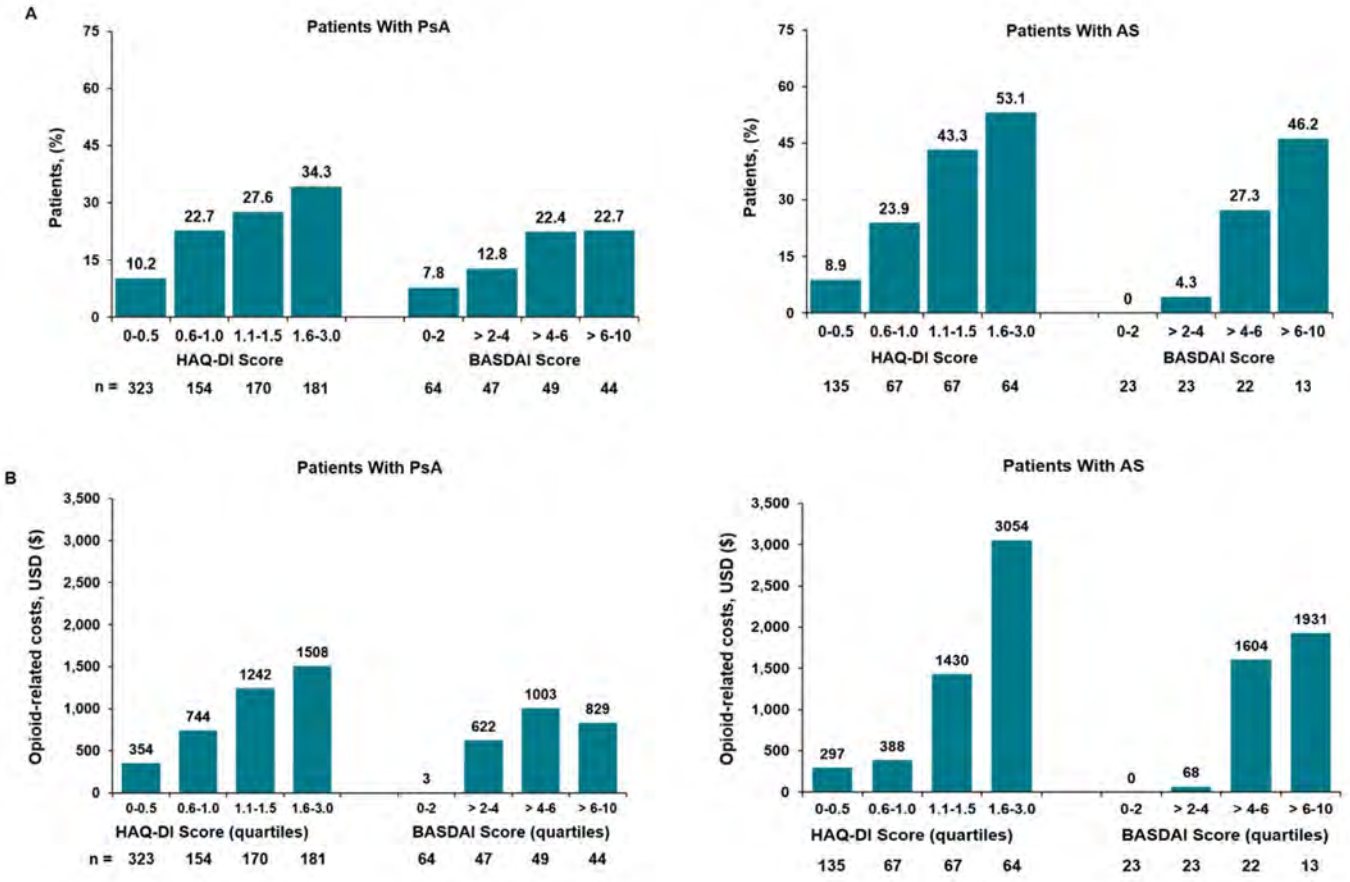


AS, ankylosing spondylitis; BASDAI, Bath Ankylosing Spondylitis Disease Activity Index; HAQ-DI, Health Assessment Questionnaire Disability Index; OR, odds ratio; PsA, psoriatic arthritis; RR, relative risk.
[a] HAQ-DI and BADSAI were modeled as continuous variables; includes data for patients with PsA who responded to HAQ-DI and patients with AS who responded HAQ-DI and/or BASDAI.
[b] Models adjusted for education level (PsA), smoking habits (PsA and AS), sex (PsA), rheumatic disease comorbidity index (PsA and AS), total income (AS), and physician-diagnosed disease (PsA and AS).
[c] Models adjusted for age (PsA and AS), education level (AS), and smoking habits (AS).
[d] Univariate model; covariates not significant.
* $P < 0.05$.
** $P < 0.01$.

Annualized average opioid use and costs increased with increasing HAQ-DI and BASDAI scores for patients in both cohorts (Figure 2).

Conclusion: Increased opioid use was associated with higher HAQ-DI and BASDAI scores among patients with PsA or AS. These findings suggest that, among patients with more severe disease, opioid use and related costs were numerically greater for patients with AS than patients with PsA.

Figure 2. Average Annualized Patient **(A)** Opioid Use and **(B)** Opioid-Related Costs Across HAQ-DI and BASDAI Scores for Patients With PsA or AS[a]



AS, ankylosing spondylitis; BASDAI, Bath Ankylosing Spondylitis Disease Activity Index; HAQ-DI, Health Assessment Questionnaire Disability Index; PsA, psoriatic arthritis.

[a] Includes data for patients with PsA who responded to HAQ-DI and patients with AS who responded HAQ-DI and/or BASDAI.

Abstract Number: 1778

The Role of Cathepsin G in Joint Destruction in Patients with Psoriatic Arthritis

Mariela Geneva-Popova[1], **Stanislava Popova**[1] and Anastas Batalov[2], [1]Medical University, Faculty of Medicine, Department of Propedeutic of Internal Diseases, Plovdiv, Bulgaria, [2]UMHAT KASPELA, Plovdiv, Bulgaria

SESSION INFORMATION
Session Date: Tuesday, November 9, 2021
Session Title: Spondyloarthritis Including PsA – Diagnosis, Manifestations, & Outcomes Poster IV: Clinical Aspects of PsA & Peripheral SpA (1773–1800)
Session Type: Poster Session D
Session Time: 8:30AM–10:30AM

Background/Purpose: Cathepsin G (CTSG) is a member of the serine protease family. It is stored in primary granules of myeloid cells, dendritic cells, plasma cells, and others, and when cells are stimulated by immune complexes, pharmacological agents, or phagocytosis, CTSG is released into the extracellular space or binds to the surface of those cells that have receptors for it. Cathepsin G plays an important role in the development of inflammation, as it promotes the migration of neutrophils, monocytes, and antigen-presenting cells by changing chemokines and converting prochemerin to chemerin, and by activating cell surface receptors.

The aim of the study was to examine the level of Cathepsin G in the synovial fluid of patients with psoriatic arthritis.

Methods: The level of CTSG in the synovial fluid of 156 patients with psoriatic arthritis was studied (56 of them with DAPSA≤14, 50 with DAPSA≥14.1≤28, and 50 with DAPSA≥ < 28.1). Control groups included 50 patients with activated gonarthrosis and 10 healthy volunteers. . The synovial fluid was taken by arthrocentesis by an experienced rheumatologist, after signing the informed consent of all persons examined and observing the principles of good clinical practice. The study was conducted in the Immunology Laboratory of the Bulgarian Academy of Sciences, Sofia through ELISA. Statistical processing includes descriptive and correlation analyzes, with statistical significance $p< 0.05$.

Results: The level of CTSG in the synovial fluid of patients with psoriatic arthritis and DAPSA≤14 is 0.113 ± 0.02 ng/ml, of those with DAPSA≥14.1≤28 - 0.152 ± 0.02 ng/ml, of those with DAPSA≥ < 28.1 - 0.179 ± 0.02 ng/ml). The level of CTSG in the synovial fluid of patients with gonarthrosis and effusion is 0.07 ± 0.01 ng/ml and in healthy controls 0.064 ± 0.01 ng/ml. The level of CTSG in the synovial fluid of patients with psoriatic arthritis was higher than that of patients with gonarthrosis and healthy controls ($p < 0.05$). The level of CTSG in the synovial fluid of patients with psoriatic arthritis correlated positively with the disease activity assessed by DAPSA ($R_{x,y}$= 0.89).

Conclusion: The level of CTSG in the synovial fluid of patients with psoriatic arthritis is significantly higher in patients with high disease activity, which is associated with more severe joint destruction.

Background/Purpose: To report the demographics, clinical characteristics, and differential impacts on quality of life measures among participants in the Psoriasis (PsO) and Psoriatic Arthritis (PsA) Registry (COPPAR).

Methods: The COPPAR registry is a prospective, longitudinal registry for patients ≥ 18 years of age who have a diagnosis of PsO or PsA and were enrolled from a dermatology-rheumatology combined clinic and an arthritis center at a large academic medical center. Descriptive characteristics and biospecimens were collected every six months. Patient data included demographics, clinical and patient-reported outcomes, comorbidities, and treatment history. Baseline demographics and disease characteristics at enrollment were summarized for each group and compared using univariate statistics. Quality of life outcomes were compared between PsO and PsA subjects in regression analyses adjusting for age and sex.

Results: As of April 30, 2021, 154 subjects were enrolled, including 28 PsO subjects and 126 PsA subjects. Demographic characteristics were mean age of 53.2 years, 55.2% female, 89% white, and 25.3% were overweight and 35.1% were obese (Table 1). The mean disease duration was 19.7 years [SD 11.1] for PsO and 13.3 years [SD 14.4] for PsA (p< .001) (Table 2). PsO subjects had a higher mean BSA compared with PsA subjects (4.4 % [SD 5.4] vs. 3.2% [SD 8.7], p< .001). Both PsO and PsA groups had a high percentage of biologic therapy (60.7 % for PsO and 78.5 % for PsA). The mean static physician's global assessment (sPGA) score was higher among PsO subjects (2.1

EQ-5D: European Quality of Life- 5 dimensions, SF-12: The 12-Item Short Form Health Survey, PHQ-8: The eight-item Patient Health Questionnaire depression scale, PROMIS: Patient-Reported Outcomes Measurement Information System, FACIT-F: Functional Assessment of Chronic IllnessTherapy – Fatigue, DLQI: Dermatology Life Quality Index, WPAI: Work Productivity and Activity Impairment, PtGA: Patient GlobalAssessment, VAS: Visual Analogue Scale, MHAQ: Modified Health Assessment Questionnaire

*Outcome comparisons adjusted for age and sex.

[SD 1.0] compared to PsA subjects (1.2 [SD 1.1], p< 0.001). The mean Psoriasis Area and Severity Index (PASI) was higher for PsO subjects (4.5 [SD 5.6] for PsO vs. 2.3 [SD 4.7] for PsA subjects(p< .001)). Multivariate comparisons of quality of life measures between PsO and PsA subjects indicated lower EuroQol- 5 Dimension (EQ-5D) scores in PsA subjects (PsA: mean 0.8 [SD 0.1] vs. PsO: mean 0.9 [SD 0.1], p< .001) and lower physical health status (SF-12 PCS) among PsA subjects (mean 43.7 [SD 11.6]) compared with PsO subjects (mean 49.2 [SD 11.3], p=0.04) (Table 3). There were no significant differences between the groups in PHQ-8, PROMIS anxiety, FACIT-fatigue, or Dermatology Life Quality Index (DLQI) scores. PsA subjects had slightly more daily work activity impairment (WPAI PsA: mean 16.7% [SD 22.8] vs. PsO: mean 6.0% [SD 14.5], p=0.08). There were no significant differences in patient global skin scores between PsO subjects (mean 7.4 [SD 2.1]) and PsA subjects (mean 5.9 [SD 5.7], p=0.4).

Conclusion: Subjects enrolled in a combined dermatology-rheumatology and arthritis center clinic at a tertiary academic medical center had mild to moderate disease activity with a high prevalence of biologic therapy. PsA subjects reported worse general physical health and lower quality of life than PsO subjects despite PsO subjects having worse overall psoriasis severity.

Session Title: Spondyloarthritis Including PsA – Diagnosis, Manifestations, & Outcomes Poster IV: Clinical Aspects of PsA & Peripheral SpA (1773–1800)

Session Type: Poster Session D

Session Time: 8:30AM–10:30AM

Background/Purpose: Racial heterogeneity of the US population makes it imperative to study the racial differences in clinical characteristics, medication use and co-morbidities of PsA patients to reduce the disparities in health care. We hypothesize that African-Americans (AA) with PsA have higher burden of co-morbidities then Caucasians in the US. We aimed to examine the racial differences in clinical characteristics, medication usage and co-morbidities in PsA patients.

Methods: We conducted a retrospective study using the IBM Explorys platform, a clinical research informatics tool that utilizes a health data gateway (HDG) server behind the firewall of 26 major integrated healthcare systems in the US from 1999, comprising of over 60 million patients in the participating healthcare organizations. The Explorys collects aggregated, standardized and normalized clinical data from different electronic health records, automatically updated in near real time (at least every 24 h), presented in a HIPAA and HITECH-compliant de-identified way from each participating healthcare organization and are passed into the Explorys data grid. Diagnosis, findings, and procedures are mapped into the systematized nomenclature of medicine (SONOMED-CT) hierarchy. Search criteria for PsA included the ICD diagnosis code of PsA and at least two visits with a rheumatologist, between 1999-2019. Cohorts were further stratified by adding the following variables to the search tool: race, gender, elevated ESR or CRP, smoker, peripheral arthritis, enthesopathy, dactylitis, uveitis, psoriasis, inflammatory bowel disease,TNF inhibitor or DMARD use) and co-morbidity (hypertension, diabetes, osteoporosis, fibromyalgia, heart disease and depression). Data sets were recorded as proportions and compared using chi-squared test ($p < 0.05$).

Results: A total of 26010 patients with PsA were identified. 95% of these patients were Caucasians whereas 5% were AA and 63% were females. 17% of PsA patients were smokers (n=4350) of which 4150 were Caucasians and 200 were AA, ($p < 0.05$). Comparisons of clinical features of PsA between racial groups can be found in Table 1. Treatment differences were also noted amongst racial groups. NSAIDs were used in 80% of Caucasians and 78% of AAs ($p < 0.0097$). TNFs were used in 51% of Caucasians and 41% of AAs ($p < 0.0001$). DMARDs were used in 72% of

Table 1.

	N	AA	Caucasian	P-value
Enthesopathy	6930	27%	25%	<0.0073
Dactylitis	30	0%	0.12%	<0.1971
Peripheral Arthritis	470	1%	18%	<0.0001
Axial Arthritis	470	2%	7%	<0.0001
Onycholysis	180	1%	2%	<0.0001
Elevated CRP	9870	37%	38%	<0.0195
Elevated ESR	8610	33%	34%	<0.0146

Table 2.

	N	AA	Caucasian	P-value
HTN	13730	59%	52%	<0.0001
DM	6080	31%	23%	<0.0001
Obesity	7940	37%	30%	<0.0001
Gout	2190	12%	8%	<0.0001
Uveitis	180	2%	0.6%	<0.0001
Malignancy	5200	16%	20%	<0.0002
Anxiety	7190	23%	28%	<0.0001
Osteoporosis	3600	12%	14%	<0.05

Caucasians and 98% of AAs (p< 0.0001). Significant difference in comorbidities between the 2 groups are shown in Table 2. Prevalence of other comorbidities including hyperlipidemia, coronary artery disease, depression and fibromyalgia were not significantly different among Caucasians and AA with PsA.

Conclusion: Our findings from a large US real world database revealed hypertension, diabetes, obesity, and gout were more prevalent in AA with PsA as compared to Caucasians. However, malignancy, osteoporosis and anxiety were more prevalent in Caucasians. The co-morbidities were significantly higher in AA patients with PsA and this warrants increased risk stratification. There was increased biologic use in Caucasians with PsA compared to AA who had a much higher use of DMARDs.

Abstract Number: 1781

A Direct-to-Patient PsA Screening Survey for Earlier Identification of At-Risk Psoriasis Patients and Reduction of Physician Burden

Megan Meier[1], Jessica Walsh[2] and Shaobo Pei[3], [1]University of Utah, Salt Lake City, UT, [2]Salt Lake City Veteran Affairs Medical Center (VAMC)/University of Utah Hospital, Salt Lake City, UT, [3]Salt Lake City Veteran Affairs and University of Utah Medical Centers, Salt Lake City, UT

SESSION INFORMATION

Session Date: Tuesday, November 9, 2021

Session Title: Spondyloarthritis Including PsA – Diagnosis, Manifestations, & Outcomes Poster IV: Clinical Aspects of PsA & Peripheral SpA (1773–1800)

Session Type: Poster Session D

Session Time: 8:30AM–10:30AM

Background/Purpose: Diagnostic delays are common with psoriatic arthritis (PsA) and contribute to unnecessary impairments in quality of life and function. Screening surveys for identifying at-risk patients are infrequently used in busy clinical practices. The goal was to develop a direct-to-patient screening approach that does not burden providers with PsA screening tasks. Objective 1 was to characterize patterns of rheumatology referrals and PsA diagnoses in psoriasis patients randomized to receive a screening survey (intervention group) vs. not receive a survey (control group). Objective 2 was to characterize referral and diagnostic patterns in subgroups of intervention group patients instructed to either contact study staff for a rheumatology appointment (direct access [DA] group) or discuss a rheumatology referral with their doctor (standard of care [SOC] group), if they screened positively for elevated PsA risk.

Methods: Patients with an International Classification of Diseases (ICD) code for psoriasis but not PsA in the electronic health record (EHR) were randomized to the control group vs. intervention groups (DA or SOC) (Figure 1). The Psoriasis Epidemiology Screening Tool Survey[1] was disseminated electronically and via postal mail beginning

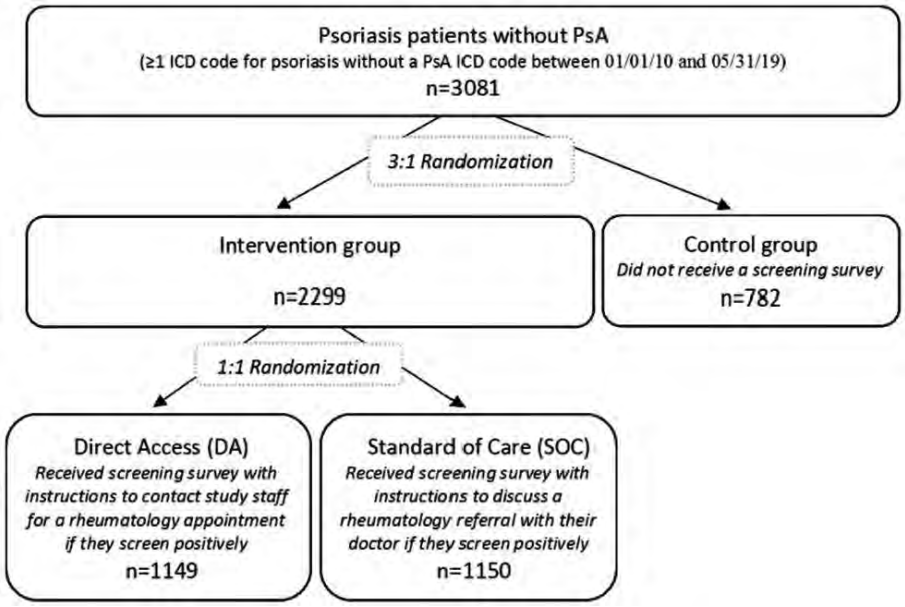

Figure 1. Attrition.

09/18/20 (index date). Referral and diagnostic outcomes were extracted from the EHR for preliminary analysis on 2/2/2021 and compared between DA, SOC, and control groups.

Results: The population included 3081 patients (Figure 1) with 51.5% females and a mean age of 50.1 years. 15.4% completed the online survey, of whom 29.3% screened positively. Among DA patients, 8.6% contacted study staff, of whom 32.5% screened positively, and 29.3% requested a rheumatology appointment. In EHR data, rheumatology appointments occurred with 1.4% DA, 0.7% SOC, and 0.1% control patients, and the mean times to a rheumatology appointment were 77.4, 60.6, and 133.0 days in DA, SOC, and control groups, respectively (Figure 2). PsA diagnosis occurred in 0.4% DA, 0.3% SOC, and 0 control patients, and mean times to PsA diagnosis were 66.0 days in DA and 77.0 days in SOC groups.

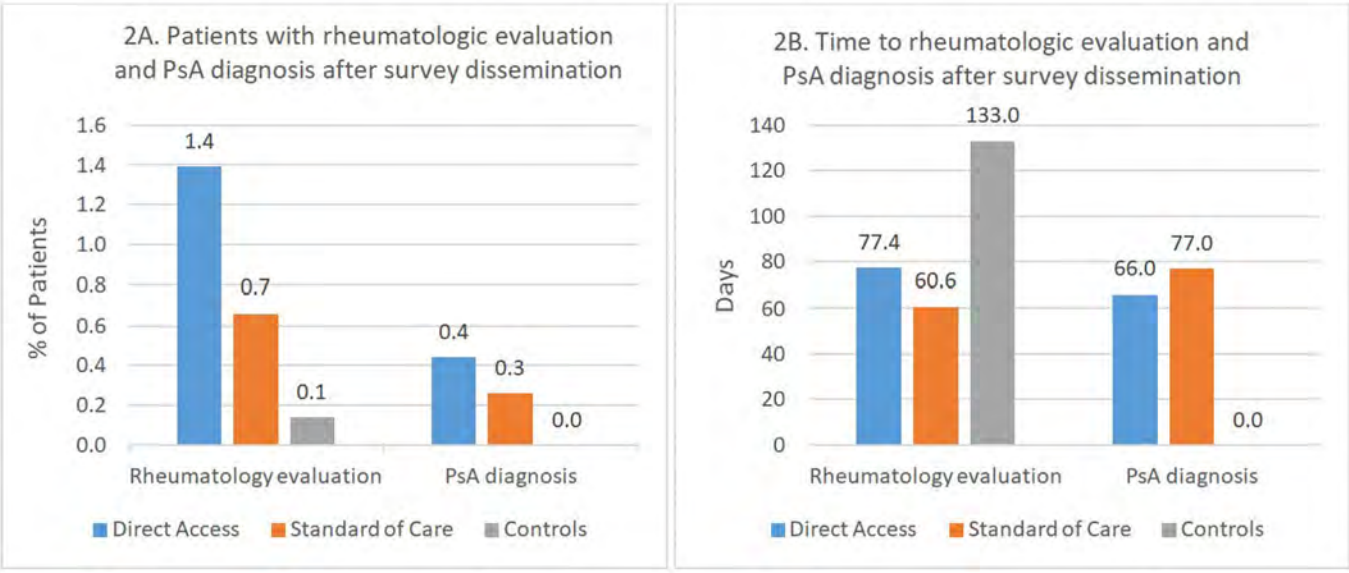

Figure 2. Referral and diagnostic patterns for PsA in patients with psoriasis.

Conclusion: Rheumatologic evaluations and PsA diagnoses were more frequent and earlier in patients exposed to a screening survey than unexposed patients. Rates of rheumatologic evaluations and PsA diagnosis were low, but patient engagement may improve with future study cohorts (n≈24,000 patients), as the impacts of the COVID-19 pandemic decline.

Disease Activity in Psoriatic Arthritis Patients with Enthesitis Across Different Therapies

Robert Chao[1], George Reed[2], Joel Kremer[3] and Arthur Kavanaugh[4], [1]Inova Health System, Fairfax, VA, [2]University of Massachusetts, Worcester, MA, [3]Department of Medicine, Center for Rheumatology, Albany Medical College, Albany, FL, [4]University of California San Diego, La Jolla, CA

SESSION INFORMATION

Session Date: Tuesday, November 9, 2021

Session Title: Spondyloarthritis Including PsA – Diagnosis, Manifestations, & Outcomes Poster IV: Clinical Aspects of PsA & Peripheral SpA (1773–1800)

Session Type: Poster Session D

Session Time: 8:30AM–10:30AM

Background/Purpose: Evidence on the treatment of enthesitis, a common feature of psoriatic arthritis (PsA), is limited. This post-hoc, cross-sectional study examined if prevalent treatment choices were related to enthesitis, or other prevalent characteristics of PsA patients.

Methods: Patients enrolled in the Corrona PsA database were included in this study if they had prevalent use of therapeutic drugs and indication of clinical enthesitis. Prevalent use was defined as drug initiation at least two months prior to visit. Enthesitis was defined as having at least one tender point of the 18 sites described by the validated enthesitis scoring index, spondyloarthritis research consortium of Canada (SPARCC) enthesitis index. Treatments groups included cDMARDs, TNF inhibitors (TNFi), and IL-17 inhibitors (IL-17i). The primary outcome was the association of enthesitis activity across different therapies. Secondary outcomes included differences between drug groups in the following disease domain measurements: CDAI, psoriasis body surface area (BSA) %, 68 tender joint count, 66 swollen joint count, health assessment questionnaire (HAQ) score, patient reported pain, patient reported fatigue score, patient global assessment, physician global assessment, and work productivity and activity impairment (WPAI) questionnaire. One-way analysis of variance was used to determine the association between SPARCC scores and prevalent drug use after adjusting for covariates at baseline. Logistic regression (unadjusted analysis) was used to find an association between disease activity and prevalent drug use. Principal component analysis (PCA) derived the primary dimensions of disease activity scores and examined for patterns of clustering among the different prevalent drug groups based on such scores.

Results: 394 PsA patients with enthesitis were identified with 151 patients taking a cDMARD, 167 patients taking a TNFi and 76 patients taking a IL-17i. Complete patient demographics are presented in Table 1. There was a trend of lower SPARCC scores in the IL-17i (3.09+2.54) and TNFi groups (3.28+2.62) as compared to the cDMARD group (3.87+3.28) but the global p-score was not statistically significant. Complete analysis of other disease domain scores

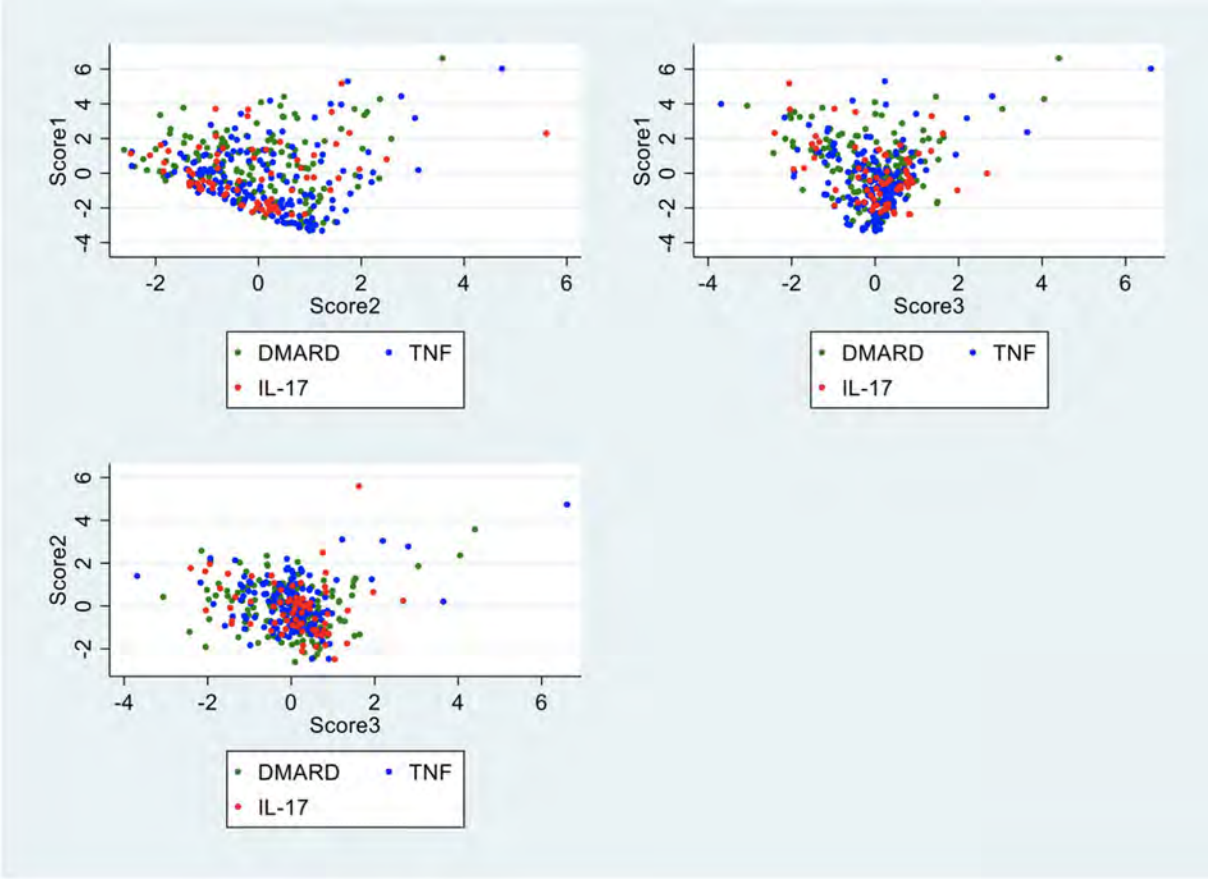

Figure 1. Principle component analysis of PsA disease activity measures across different therapies.

nor any disease activity measures were associated with prevalent use of TNFi compared to IL-17i. PCA resulted in three major dimensions representing 72% of the variation. Plots of the scores illustrated similar distributions of scores among the drug groups that mainly overlapped with no particular clustering (Figure 1).

Conclusion: Prevalent drug utilization was not related to enthesitis activity. Patients with prevalent use of cDMARDs were noted to have higher physician global assessment scores compared to TNFi and IL-17i use. In aggregate, there was no pattern of correlation in disease activity scores amongst the use of different prevalent PsA drug therapies.

National Trends in Hospitalizations for Serious Infections in People with Psoriatic Arthritis Using the National Inpatient Sample 2012 – 2017

Vagishwari Murugesan[1], Eleni Pilitsi[2], Gabriela Rabasa[3] and Maureen Dubreuil[4], [1]Boston University Medical Center, Boston, MA, [2]Boston Medical Center, Boston, MA, [3]Boston University, Boston, MA, [4]Boston University School of Medicine/ VA Boston, Boston, MA

SESSION INFORMATION

Session Date: Tuesday, November 9, 2021

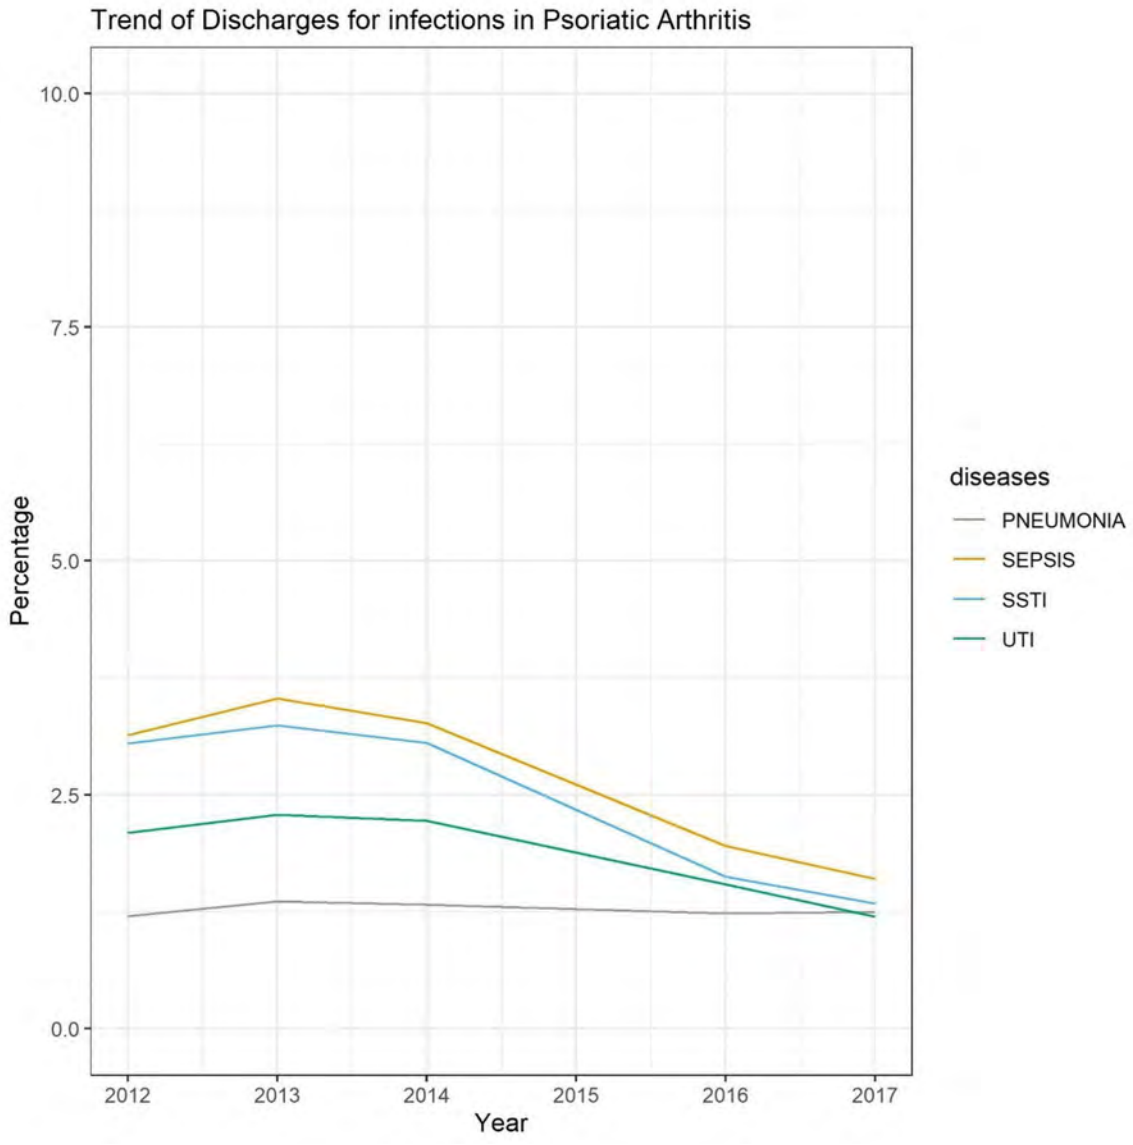
Session Title: Spondyloarthritis Including PsA – Diagnosis, Manifestations, & Outcomes Poster IV: Clinical Aspects of PsA & Peripheral SpA (1773–1800)

Session Type: Poster Session D

Session Time: 8:30AM–10:30AM

Background/Purpose: Given that uptake of biologic therapies has increased over recent years, we sought to investigate the national trends in serious infections in patients with psoriatic arthritis from the years 2012 – 2017 in the United States.

Methods: The NIS approximates a 20% stratified sample of all discharges from U.S. community hospitals, excluding rehabilitation and long-term acute care hospitals, with approximately 7 million discharge records. We examined data from 2012–2017 and identified any discharge diagnosis for PsA with a principal or secondary diagnosis of pneumonia, sepsis, urinary tract infection (UTI) and/or skin and soft tissue infections (SSTIs) using ICD-9 & ICD 10 codes. We standardized results for years 2012-2017 to match age distributions in the US population in the year 2012. We then



tested for a trend over years 2012-2017 using chi squared tests, evaluating for an increase in serious infections over the years.

Results: For the year 2012, the mean age of discharged patients overall was 59.5 ± 14.3 years. Females comprised 56% of discharged patients and Caucasians for 88.5%. The mean (SD) length of stay was 4.7 ± 4.7 days. For the year 2017, the mean age for discharged patients overall was 60.8 ± 14.1. Females accounted for 57.7% and Caucasians for 88.4 %. The mean (SD) length of stay was 4.9 ± 5.8 days.

In the year 2012, there were a total of 50,700 discharge diagnoses of PsA, of which 125 patients had a diagnosis of pneumonia, 230 patients with sepsis, 312 patients with a skin and soft tissue infection and 174 patients with a urinary tract infection (UTI). For comparison in 2017, there were a total of 179,400 discharge diagnoses of PsA, of which 344 patients had pneumonia, 374 patients had sepsis, 681 patients had SSTI and 348 patients had UTI.

From 2012 – 2017 there was a statistically significant decrease in discharges for sepsis, skin and soft tissue infections and UTI ($p < 0.001$ for all) over the years after standardizing for age. There was no statistical difference in the trend of pneumonia between the years ($p = 0.89$).

Conclusion: Our data shows statistically significant decrease in sepsis, skin and soft tissue infections and UTI in patients with PsA despite the increased use of biologics over the years. There was no statistical difference in pneumonia discharges after standardizing for age.

Session Title: Spondyloarthritis Including PsA – Diagnosis, Manifestations, & Outcomes Poster IV: Clinical Aspects of PsA & Peripheral SpA (1773–1800)

Session Type: Poster Session D

Session Time: 8:30AM–10:30AM

Background/Purpose: Patients (pts) with mild to moderate psoriasis (PsO) and musculoskeletal disease burden may be diagnosed with PsA upon referral to a rheumatologist. Early intervention in pts with PsA may result in improved joint, skin, and quality-of-life (QoL) outcomes. This analysis of CorEvitas' Psoriasis Registry sought to identify characteristics and musculoskeletal disease burden among pts naive to systemic treatment with mild to moderate psoriasis based on evidence of potential comorbid PsA.

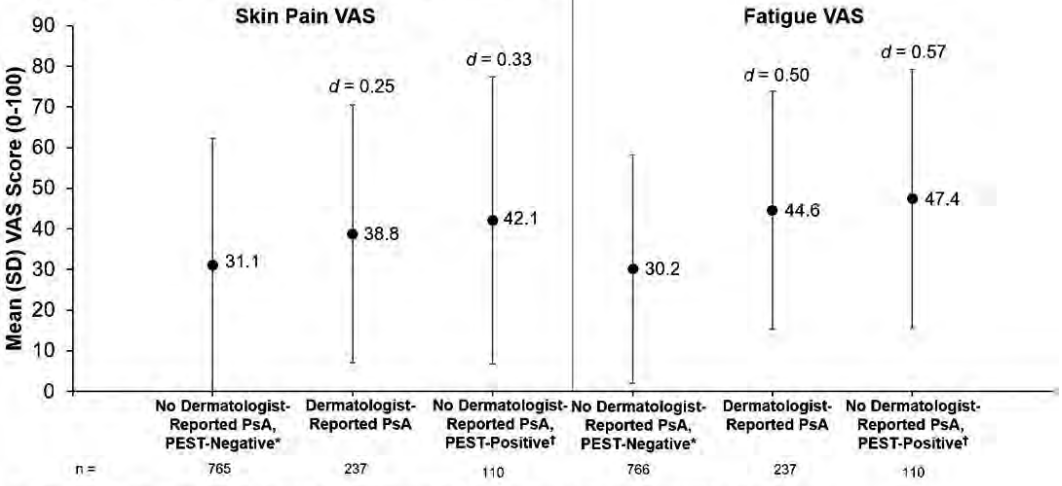
*No dermatologist-reported PsA and negative PEST screen (<3). †PEST screen ≥3 without dermatologist-reported PsA. ‡The *d* values (absolute value) vs group with No PsA, PEST-Negative group, respectively. §Tested for any difference across the 3 BMI levels. BMI = body mass index; GI = gastrointestinal; IBD = inflammatory bowel disease; NA = not applicable; WPAI = Work Productivity and Activity Impairment (questionnaire).

Methods: The prospective, observational CorEvitas' Psoriasis Registry enrolls adults with dermatologist-diagnosed PsO who initiated or switched to an eligible systemic treatment at enrollment or within 12 months before enrollment. Pts with mild to moderate PsO (Investigator Global Assessment: 2 or 3) initiating first systemic treatment at enrollment

Figure 1. Mean Skin Pain and Fatigue VAS Scores

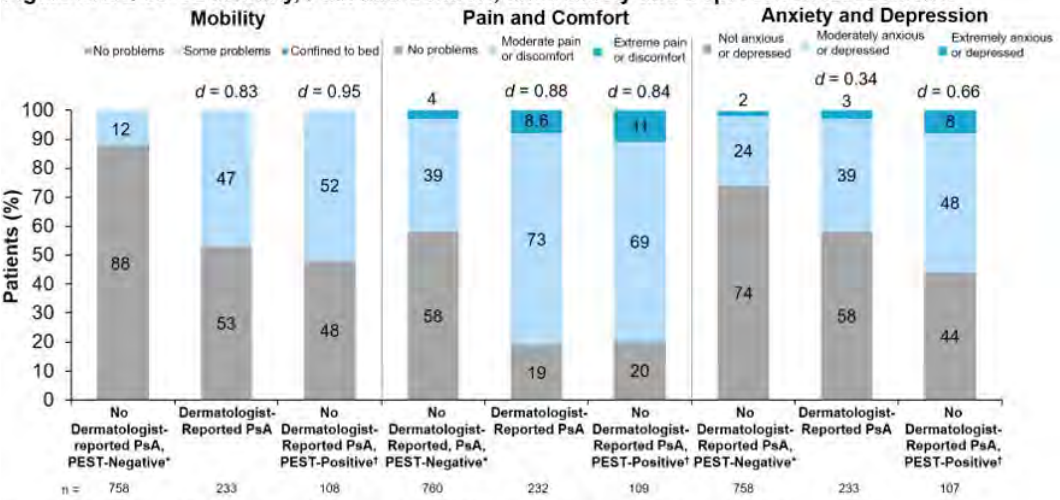


*No dermatologist-reported PsA and negative PEST screen (<3). †PEST screen ≥3 without dermatologist-reported PsA.
d values vs the No PsA, PEST-Negative group.

(April 2015−June 2020) were grouped by musculoskeletal disease burden. This descriptive analysis compares pts with no evidence of PsA (no dermatologist-reported PsA and negative Psoriasis Epidemiology Screening Tool [PEST] screen [< 3]) to pts with dermatologist-reported PsA and to pts without dermatologist-reported PsA but positive PEST (≥3). Standardized differences were calculated (potentially meaningful difference: $d > 0.1$; moderate difference: $d > 0.5$).

Results: Of the 1,113 pts enrolled, 766 (68.8%) had no evidence of PsA, 237 (21.3%) had dermatologist-reported PsA, and 110 (9.9%) had a positive PEST screen (PEST ≥3) without dermatologist-reported PsA. Concordance between dermatologist-reported PsA and positive PEST screen was 80%: 112 pts (10%) had dermatologist-reported PsA and negative PEST screen and 110 pts (10%) had positive PEST screen without dermatologist-reported PsA. For all groups, mean PsO duration was >9 years. For pts with dermatologist-reported PsA, mean PsA duration was 4 years (Table). Comorbidity histories were often higher in pts with dermatologist-reported PsA or positive PEST screen without dermatologist-reported PsA vs pts with no evidence of PsA (Table). Current employment was less prevalent among pts with dermatologist-reported PsA or positive PEST screen without dermatologist-reported PsA vs pts with

Figure 2. EQ-5D-3L Mobility, Pain and Comfort, and Anxiety and Depression Assessments



*No dermatologist-reported PsA and negative PEST screen (<3). †PEST screen ≥3 without dermatologist-reported PsA.
d values vs No PsA, PEST-Negative group.

no evidence of PsA (Table). Mean skin pain visual analog scale (VAS) and fatigue VAS scores were higher for pts with dermatologist-reported PsA or positive PEST screen without dermatologist-reported PsA vs no evidence of PsA (Figure 1). Also, EuroQol-5 Dimension 3 Level assessments indicated that pts with dermatologist-reported PsA or positive PEST screen without dermatologist-reported PsA had greater problems with mobility, pain and comfort, and anxiety and depression compared with pts with no evidence of PsA (Figure 2).

Conclusion: Pts naive to systemic treatment who have mild to moderate PsO and either PsA or musculoskeletal disease suggestive of comorbid PsA had greater comorbidity burden, symptom burden, and QoL impairment compared with pts with no evidence of PsA in this analysis from CorEvitas' Psoriasis Registry.

Session Date: Tuesday, November 9, 2021

Session Title: Spondyloarthritis Including PsA – Diagnosis, Manifestations, & Outcomes Poster IV: Clinical Aspects of PsA & Peripheral SpA (1773–1800)

Session Type: Poster Session D

Session Time: 8:30AM–10:30AM

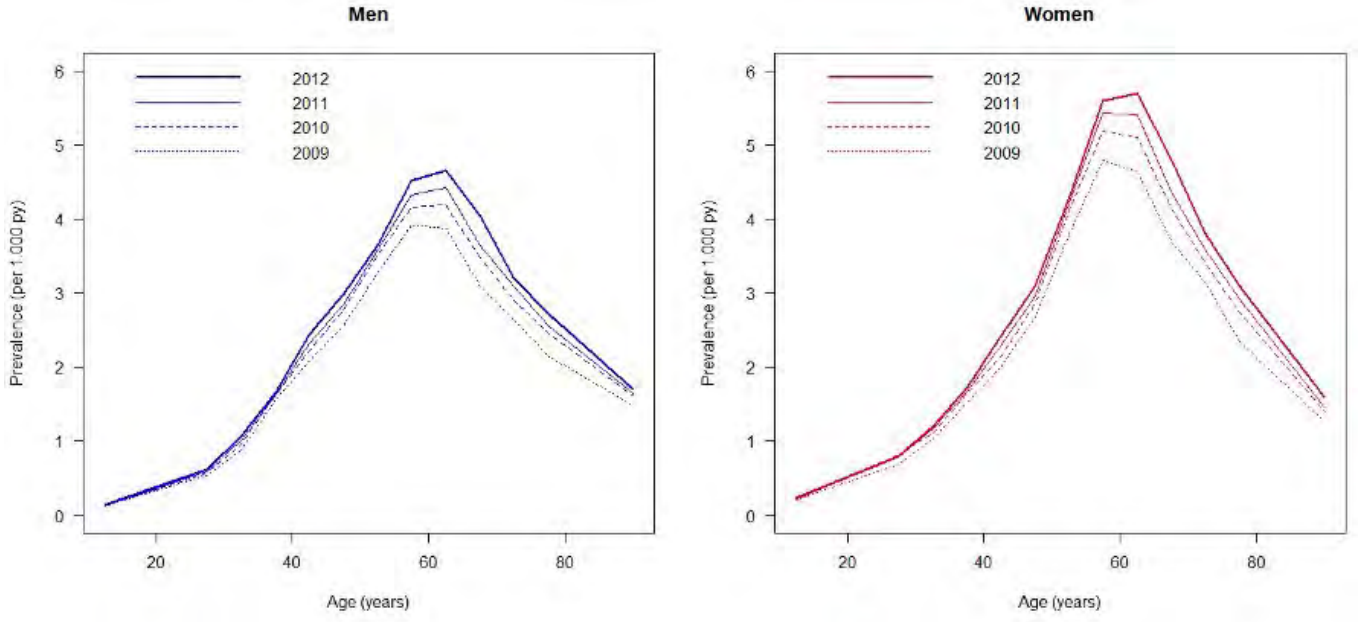

Figure 1. Age- and sex-specific prevalence of PsA in Germany (2009-2012).

Background/Purpose: Patients suffering from Psoriatic-Arthritis (PsA) can experience a substantial burden of disease, which may result in a significant reduction of their quality of life. Due to the relatively small sample size, the validity of previous cohort studies is partly reduced. Therefore, larger and more representative samples are urgently necessary to investigate prevalence and especially incidence in the real world. The present datasets enable a comprehensive examination of the epidemiology of the PsA in Germany.

Methods: The data was provided by the statutory health insurance as part of the morbidity-based risk adjustment. There, a cohort study collected the data of 65 million Germans with a statutory insurance from 2009 to 2012.

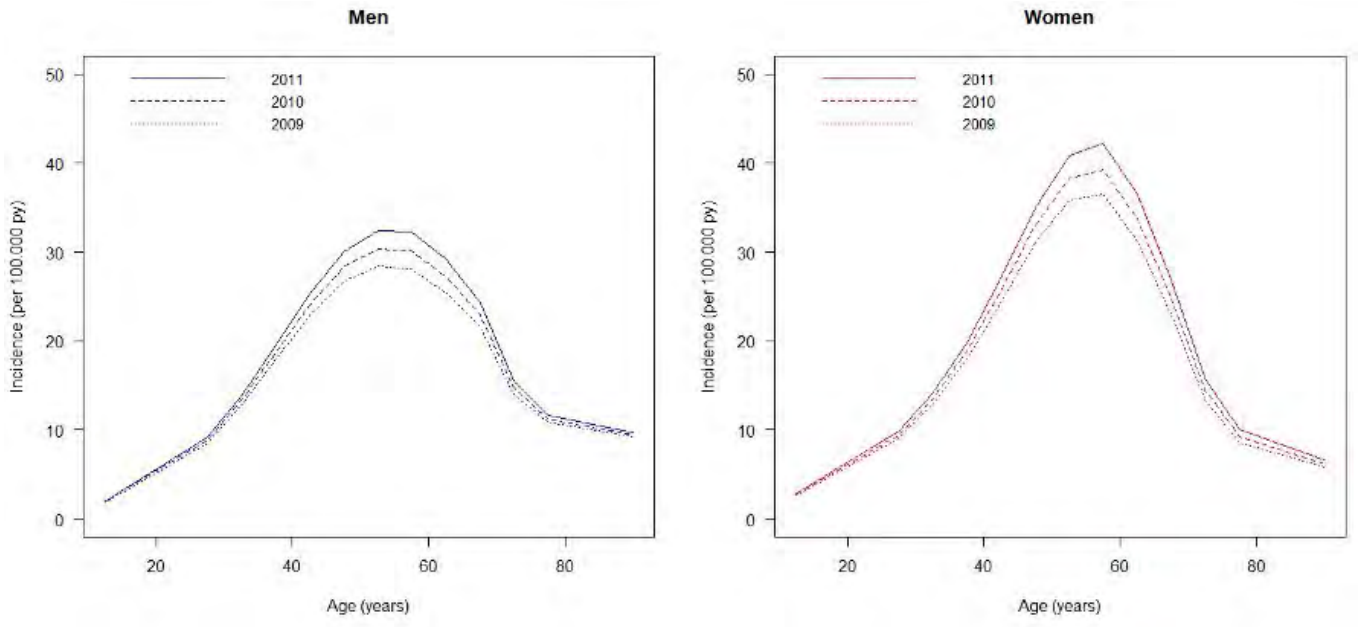

Figure 2. Age- and sex-specific incidence of PsA in Germany (2009-2011).

The main focus of this paper is to interpret the varying prevalence within the different age groups. Further, it aims to identify potential influences on this distribution. Especially the drastic decrease in the prevalence after the age of 60 remains in need of explanation.

A second step calculates the incidence values for PsA in Germany. For this purpose, we used a formula introduced by Brinks et. al., which requires the prevalence as well as the general mortality and the relative mortality associated with the disease (1, 2).

Results: The total number of persons suffering from PsA rose to approximately 127.000 in 2009 and 156.000 in 2012. A steady increase was observed for the age- and sex-specific prevalence over the lifetime of men and women, until it reached a plateau and declined thereafter. The prevalence plateaued at maximum of 5 per 1,000 py for men and 6 per 1,000 py for women. As previously mentioned, there is a sharp decrease in the prevalence in both sexes after the age of 60 (Fig. 1).

In contrast to the prevalence, the age- and sex-specific incidence peaks slightly earlier. The latter assumes a maximum value of 30 per 100,000 in men and 40 per 100,000 py in women. The subsequent decline of the incidence is less pronounced than for the prevalence (Fig. 2).

In general, an overall rise in the prevalence as well as the incidence can be observed during the study period.

Conclusion: In conclusion we demonstrated that there are considerable fluctuations in both the prevalence and incidence within the different age groups. A possible explanation for the change in the prevalence is the correlation between PsA and additional comorbidities, which coincide with an increased morbidity and mortality. Likewise, further influences such as an increased awareness for the diagnosis of PsA should be considered. Not only changed coding behavior of ICD codes but also the development of new therapeutic approaches has a significant impact on PsA prevalence and incidence.

SESSION INFORMATION

Session Date: Tuesday, November 9, 2021

Session Title: Spondyloarthritis Including PsA – Diagnosis, Manifestations, & Outcomes Poster IV: Clinical Aspects of PsA & Peripheral SpA (1773–1800)

Session Type: Poster Session D

Session Time: 8:30AM–10:30AM

Background/Purpose: PsA is an inflammatory rheumatic disease with manifestations including synovitis and enthesitis. During extensive study programs, IXE has shown a treatment effect across domains affected by PsA. Ixekizumab (IXE) is an IL17A inhibitor approved for the treatment of active PsA and axial SpA.

We sought to determine whether there is any association between the improvement of synovitis with that of enthesitis from baseline (BL) through week (wk) 52 in patients (pts) with PsA treated with IXE. Additionally, the association between the improvement of synovitis and enthesitis on health-related quality of life and patient-reported outcomes was investigated.

Methods: Data from SPIRIT-P1 (NCT01695239), SPIRIT-P2 (NCT02349295) and SPIRIT-H2H (NCT03151551) were analyzed. These were randomized, phase 3 trials involving pts with active PsA either biologic DMARD-naïve (P1, H2H); or who were TNF-inhibitor-experienced (P2).

We examined the patient population randomized to IXE-treatment (80 mg of ixekizumab every 4 weeks [IXEQ4W]), that had both synovitis and enthesitis at BL. For each study, a standardization procedure was applied to each study data in order to overcome the differences in score range between LEI and SJC. The Pearson correlation coefficient between improvement from BL in enthesitis and synovitis was calculated at each time point.

The mean improvement in the SF-36 Physical Component Summary score [PCS], the Patient's Global Assessment of Disease Activity [Pt GA], and the EuroQOL five dimensions [EQ5D]-visual analogue [VAS] score) was calculated over time for pts who reached or did not reach resolution of both enthesitis and synovitis at wk 52.

Missing data were imputed with modified Baseline Carried Out Forward (mBOCF) for continuous outcomes. Non-responder imputation was used for pts with missing resolution of enthesitis or synovitis.

Results: At BL, 68 (63% of patients treated with IXEQ4W in the ITT population), 68 (56%) and 159 (56%) pts from P1, P2 and H2H respectively, had both synovitis and enthesitis. In all 3 trials, the standardized mean change from baseline in synovitis and enthesitis showed a similar pattern over time (Figure 1). When statistically significant, Pearson correlation coefficient values ranged from 0.16 to 0.40 (Table), indicating a positive association between mean improvement in synovitis and enthesitis.

Pts were grouped according to whether they achieved resolution of both synovitis and enthesitis at wk 52, either or neither. We observed an improvement of SF-36 over the 52 wks regardless of the resolution of synovitis or enthesitis. The most pronounced improvement was shown by pts achieving resolution of both synovitis and enthesitis followed by the pts achieving one or the other (Figure 2). There was no difference in the trajectories for EQ5D and PtGAD in pts regardless of resolution of synovitis and/or enthesitis (data not shown).

Conclusion: Across the SPIRIT trials, treatment with IXE led to the significant improvement in synovitis and enthesitis with a positive association between the improvement of both. Furthermore, those pts that resolve both measures at wk 52, experienced an earlier and greater improvement in the SF-36 Physical Component Scale.

SESSION INFORMATION

Session Date: Tuesday, November 9, 2021

Session Title: Spondyloarthritis Including PsA – Diagnosis, Manifestations, & Outcomes Poster IV: Clinical Aspects of PsA & Peripheral SpA (1773–1800)

Session Type: Poster Session D

Session Time: 8:30AM–10:30AM

Background/Purpose: Peripheral spondyloarthritis (pSpA) shows features that overlap with psoriatic arthritis (PsA), axial spondyloarthritis (axSpA) and other forms of SpA and is unsatisfactorily defined despite the introduction of the

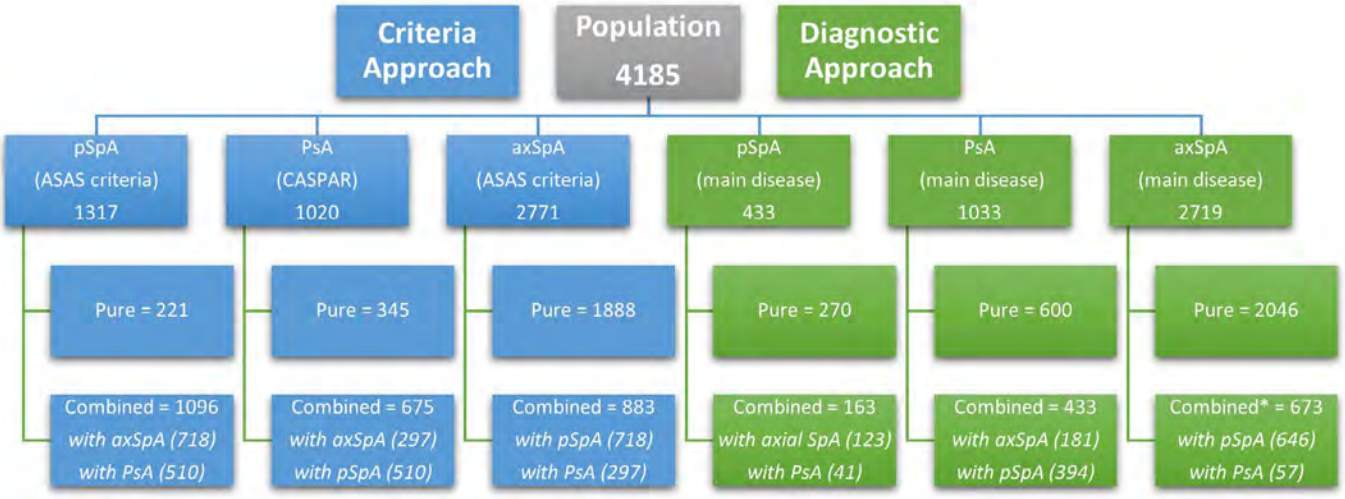

Figure 1. Prevalence of the pure and combined forms of spondyloarthritis (peripheral SpA (pSpA), psoriatic arthritis (PsA) and axial SpA (axSpA), using the criteria (ASAS and CASPAR) and to the diagnostic approach.

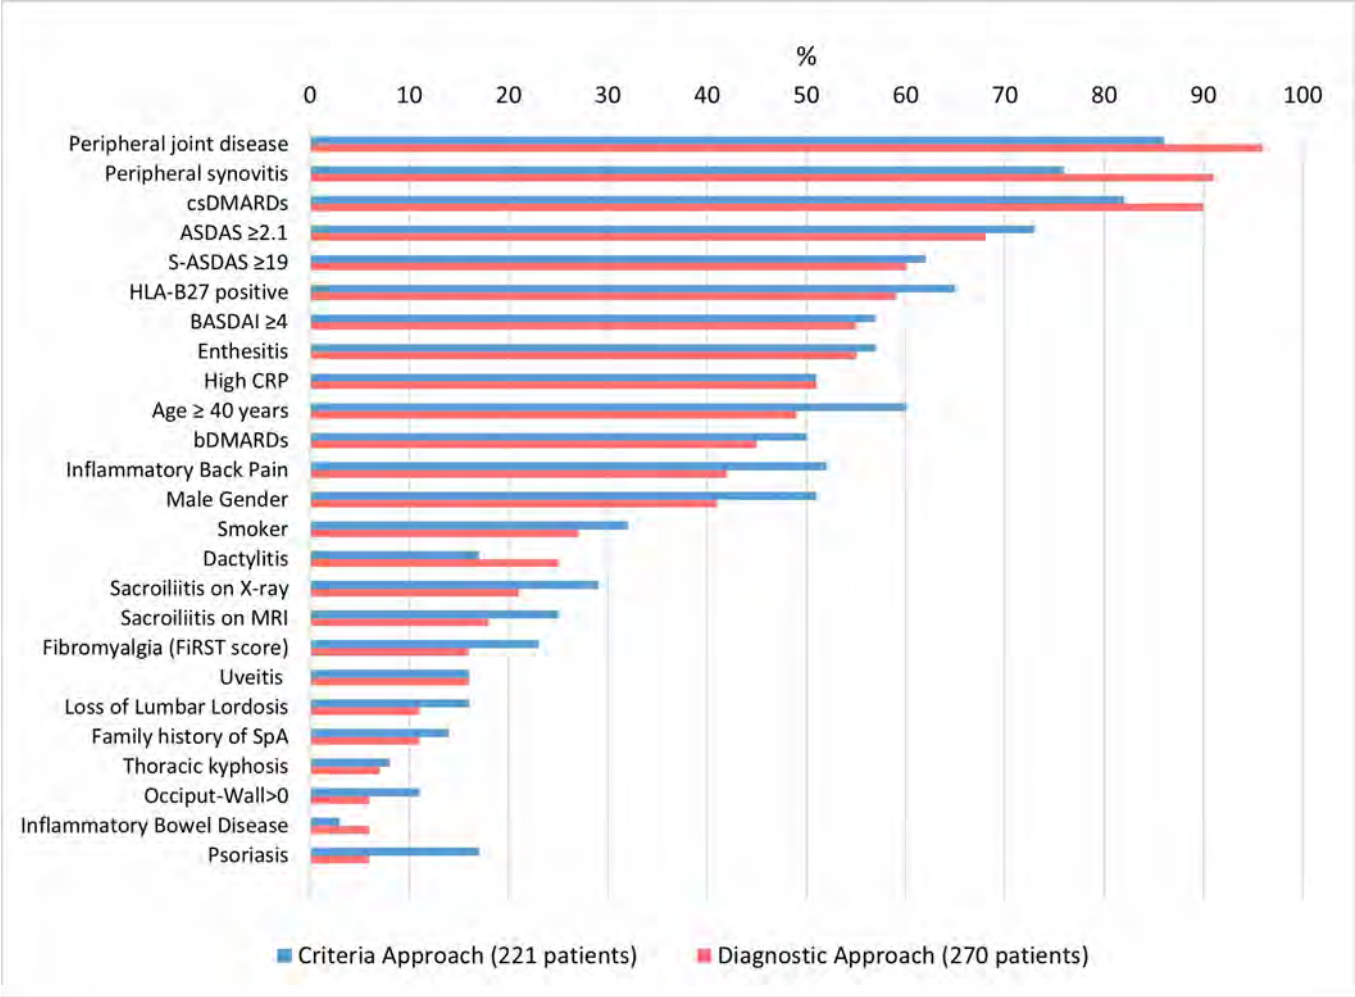

Figure 2. Phenotypic profile of patients with peripheral spondyloarthritis.

ASAS classification criteria in 2011. The objective of this study was to estimate the prevalence of pSpA among patients with SpA, to identify the phenotype and burden of patients with pure pSpA and to compare these findings with that of pure PsA, pure axSpA and combined forms of SpA.

Methods: This is a post hoc analysis of the ASAS-Peripheral involvement in SpA (PerSpA) study, based on 4,185 patients diagnosed by their rheumatologists with pSpA, PsA and axSpA. Two parallel approaches were used to define the disease subtypes (Fig.1). First, the criteria approach categorized the patients in 6 groups: pure disease (fulfilling either pSpA, or axSpA ASAS classification criteria, or CASPAR criteria) and combined disease (patients who fulfill more than one of the above-mentioned criteria). Second, the diagnostic approach categorized the patients in 6 groups as well: pure disease (diagnosed with pSpA, axSpA or PsA as the main SpA disease, exclusively) and combined disease (patients with overlapping features according to rheumatologists' judgement). Socio-demographic characteristics, clinical, biological, imaging phenotype, and disease burden were compared among patients with pure pSpA, PsA, axSpA and the combined forms of SpA (grouped together), using Chi-square, ANOVA and Kruskal-Wallis as appropriate.

Results: The prevalence of all pSpA was 31.5% using the criteria approach and 10% using the diagnostic approach (Fig.1). pSpA was pure in only 17% of pSpA using the criteria approach (compared to 34% pure PsA and 68% pure axSpA), and in 62% of pSpA using the diagnostic approach (compared to 58% pure PsA and 75% pure axSpA). Patients with pure pSpA had a socio-demographic profile and disease phenotype with "intermediate" features between PsA and axSpA

bDMARDs, N (%)	110 (49.8)	218 (63.2)	1146 (60.7)	1030 (59.5)	0.009

All percentages are presented in columns, except for world region, where they are presented in rows.

ASAS-HI: ASAS Health Index, ASDAS: Ankylosing Spondylitis Disease Activity Score, b-DMARDS: biological disease-modifying anti-rheumatic drugs, BASDAI: Bath Ankylosing Spondylitis Disease Activity Index, BASFI: Bath Ankylosing Spondylitis Functional Index, CRP: C-Reactive Protein, cs-DMARDs: conventional synthetic disease-modifying anti-rheumatic drugs, FiRST: Fibromyalgia Rapid Screening Tool, PGA: Patient Global Assessment of well-being S-ASDAS: Simplified ASDAS, SJC: Swollen Joint Count, SpA: Spondyloarthritis, TJC: Tender Joint Count, WPAI: Work Productivity Loss.

(Fig.2). Using criteria and diagnostic approach, respectively, pure pSpA patients had a high prevalence of peripheral joint disease (86 and 96%), synovitis (76 and 91%), and enthesitis (57 and 55%), a positive HLA-B27 in 65 and 59%, a high C-Reactive Protein level in 51% and inflammatory back pain in 52 and 42%. However, compared to pure PsA and pure axSpA, they had a significantly higher disease burden (BASDAI, ASDAS, ASAS-HI, BASFI, FiRST, WPAI and EQ-5D), with scores being in a similar range to that of the combined forms of SpA (Table 1), when using the criteria approach. This higher disease burden was confirmed in the diagnostic approach in comparison with axSpA only. Still, patients with pure pSpA had lower use of biological Disease-Modifying Drugs (b-DMARDs) using both approaches.

Conclusion: The prevalence of pSpA varies when using the classification criteria or the rheumatologist's diagnosis. It occurs in a pure form (i.e., associated with neither PsA nor axSpA) less frequently than PsA and axSpA. Pure pSpA has a distinct clinical phenotype with intermediate features between pure PsA and pure axSpA but with a higher disease burden compared to both diseases, and a lower use of b-DMRADs.

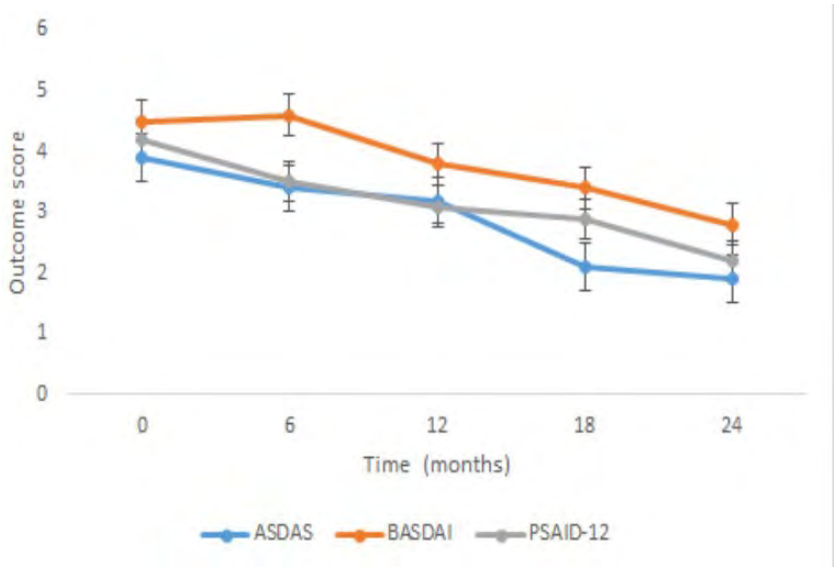
Improving Care and Capacity Through Capturing and Recording Patient Reported Outcomes with Digital Solutions in Spondyloarthritis

Antoni Chan[1], Kathryn Rigler[1] and Liz van Rossen[2], [1]Royal Berkshire NHS Foundation Trust, Reading, United Kingdom, [2]East Kent NHS Foundation Trust, Kent, United Kingdom

SESSION INFORMATION
Session Date: Tuesday, November 9, 2021
Session Title: Spondyloarthritis Including PsA – Diagnosis, Manifestations, & Outcomes Poster IV: Clinical Aspects of PsA & Peripheral SpA (1773–1800)
Session Type: Poster Session D
Session Time: 8:30AM–10:30AM

Background/Purpose: Patient-reported outcomes (PROs) have always been at the forefront for the assessment of spondyloarthritis (SpA) which includes axial Spa (axSpA) and psoriatic arthritis (PsA). With the increasing adoption of electronic health records (EHRs), collecting PROs electronically (ePRO) presents a great opportunity for advancing patient care in SpA. Electronic PROs are useful for guiding treatment decisions, with the aim of improving health outcomes through patient empowerment.

Methods: Electronic PROs were incorporated the in to routine clinical practice and the EHR at Royal Berkshire Hospital in Reading, UK since 2018. AxSpA patients meeting the ASAS criteria routinely completed the outcome measures BASDAI, BASFI, Spinal NPRS, and BASG. PsA patients meeting the CASPAR criteria completed patient assessed tender joint, swollen joint, global assessment, PSAID-12. Patients were sent reminders to complete the questionnaires through email or text messaging before each appointment and every 6 months routinely. The development of a clinician dashboard captures a range of multidimensional ePROs that was used proactively to support patient-centric appointment scheduling. Appointments were expedited or deferred depending on the clinical outcome scores. This enabled the clinical team to arrange non face to face / virtual follow-up appointments with some patients.



Outcome measure (ASDAS, BASDAI and PSAID-12) scores at baseline and 6 month interval for 24 months.

Results: There are 998 patients with AxSpA and PsA of which approximately 70% (n=692) completed the ePRO questionnaires. Over a 2.5 year period (2018-2021), a total of n=692 patients (n=470 axSpA and n=222 PsA patients) were recruited into the ePRO system. The mean (SD) age for axSpA patients were 44.7(13.3) and PsA 54 (9.9) years. n=308 (44%) patients were on biologics. At group level, there was a trend to the reduction in mean (SD) ASDAS at months 0, 6, 12, 18 and 24 (3.9±1.2, 3.4±1.1, 3.2±1.5, 2.1±0.9, 1.9±1.0) and BASDAI (4.5±2.7, 4.6±1.9, 3.8±2.4, 3.4±2.3, 2.8±1.2). In the PsA group, there was also a trend to the reduction in the mean (SD) PSAID-12 level (4.2±1.8, 3.5±0.8, 3.1±1.2, 2.9±1.1, 2.2±1.3). The reduction in ASDAS, BASDAI and PSAID-12 was most evident in patients on biologic treatments. In patients with an ASDAS of < 1.3 and PSAID-12 < 2, appointments were moved from routine 6 monthly to 12 monthly. In this group of patients, the appointments were also switched from face to face to video consultation. This resulted in a saving of 250 hours of clinical time. Over 90% of clinician and patient user rated the ePRO application as good or very good.

Conclusion: For this cohort of SpA patients, a trend based on questionnaire scores collated over a period was more informative, particularly when considered alongside interventions that were introduced into the clinics such as physiotherapy, psychological therapy and biologic treatment. In addition, by facilitating timely and effective use of ePROs, clinic workload has reduced allowing time for 'flare' slots and virtual clinics as well as the opportunity to stratify patients according to their disease activity e.g. mild/ moderate/severe. The system allows clinical encounters where needed, and more individualised treatment by identifying the patient perceptions of disease impact.

Prediction of Psoriatic Arthritis in Patients with Psoriasis Using DNA Methylation Profiles

Omar Cruz Correa[1], Remy Pollock[1], Rohan Machhar[2] and Dafna Gladman[3], [1]University Health Network, Toronto, ON, Canada, [2]Krembil Research Institute, University Health Network, Toronto, ON, Canada, [3]Schroeder Arthritis Institute, Krembil Research Institute, Toronto Western Hospital, Toronto, ON, Canada

SESSION INFORMATION
Session Date: Tuesday, November 9, 2021
Session Title: Spondyloarthritis Including PsA – Diagnosis, Manifestations, & Outcomes Poster IV: Clinical Aspects of PsA & Peripheral SpA (1773–1800)
Session Type: Poster Session D
Session Time: 8:30AM–10:30AM

Background/Purpose: Psoriatic arthritis (PsA) poses an immense clinical burden with significantly increased morbidity and mortality risk compared to psoriasis alone. PsA may develop in 30% of psoriasis patients, however, a large proportion of individuals with PsA remain undiagnosed due to several factors, including a lack of patient and clinical awareness, and a lack of means of predicting which psoriasis patients will develop PsA.

Regulation of gene expression through DNA methylation can be altered by stochastic events or environmental factors and can potentially trigger and maintain PsA pathophysiological processes. With this research, we hope to identify DNA methylation changes that can predict which psoriasis patients will develop PsA at an early stage of the disease, helping prevent permanent joint damage and disability.

Methods: We obtained blood samples from 60 psoriasis patients that developed arthritis (converters) and 60 psoriasis patients that did not (biologic naive, matched for age, sex, psoriasis duration, and duration of follow up). Genome-wide DNA methylation was assessed using Infinium Methylation EPIC BeadChips (Illumina, San Diego, CA, USA). Array data preprocessing, normalization, and correction for technical sources of variation were performed in the R programming environment as recommended in the ChAMP package pipeline. Methylation differences between converters and non-converters were identified by a multivariate linear regression model including clinical covariates (age, sex, BMI, smoking) and conversion status using the Limma package.

The predictive performance of methylation markers was assessed by developing machine learning classification models. Support vector machine models were trained using 75% of samples, keeping the other 25% as an independent set for evaluating the prediction of conversion or non-conversion. Prediction performance of differentially methylated markers was compared to that achieved by an unbiased model trained on the complete set of methylation markers.

Results: We identified 36 significantly differentially methylated positions (with FDR-adjusted p-values lower than 0.05 and a minimum change in methylation of 0.05). This set of 36 highly relevant methylation markers were found across 15 genes and several intergenic regions. Enrichment analysis of the 15 genes with highly relevant methylation markers showed no significantly enriched functional pathways.

The support vector machine classification model for the set of 36 significantly methylated markers achieved an accuracy of 93%, outperforming an unbiased classification model based on the complete set of methylation markers that showed 90% accuracy.

Conclusion: We identified a set of 36 highly significant methylation markers associated with the development of PsA in psoriasis patients. This work shows that DNA methylation patterns at an early stage of psoriatic disease can distinguish between psoriasis patients that will develop PsA from those that will not.

Session Title: Spondyloarthritis Including PsA – Diagnosis, Manifestations, & Outcomes Poster IV: Clinical Aspects of PsA & Peripheral SpA (1773–1800)

Session Type: Poster Session D

Session Time: 8:30AM–10:30AM

Background/Purpose: Psoriatic arthritis (PsA) shares genetic and clinical features with other forms of spondyloarthritis (SpA). However, no studies have evaluated regional differences regarding characteristics of PsA with axial involvement (axPsA). The aim of this study is to evaluate regional differences regarding clinical characteristics of axPsA patients.

Table 1. Prevalence of axial involvement among psoriatic arthritis across regions all over the world.

	Europe and North America	Latin America	Japan	Asia except for Japan	Middle East and North Africa
Total SpA patients (n)	1677	538	197	778	1275
PsA among total SpA patients (n, %)	489 (29.2)	176 (32.7)	90 (45.7)	75 (9.6)	203 (15.9)
Axial involvement among PsA (n, %)	164 (33.5)	56 (31.8)	37 (41.1)	32 (42.7)	78 (38.4)

Methods: Data from the ASAS-PerSpA study, a cross-sectional database recruiting SpA patients between July 2018 and February 2020 from 68 centers worldwide, was analyzed. For this analysis, PsA patients presenting at any time with axial involvement per physician judgement were defined as axPsA. AxPsA was further categorized by 5 regions (Europe and North America, Latin America, Japan, Asia (except for Japan) and Middle East and North Africa). Patient and disease characteristics, activities, and treatments were compared.

Table 2. Characteristics of patients who have psoriatic arthritis with axial involvement across regions.

	Europe and North America n=164	Latin America n=56	Japan n=37	Asia except for Japan n=32	Middle East and North Africa n=78	p-value
Sex (male)	83 (50.6)	32 (57.1)	24 (64.9)	24 (75.0)	33 (42.3)	0.013
Age	51.5 (12.7)	51.5 (12.0)	52.1 (13.6)	42.8 (12.6)	47.2 (11.6)	0.488

csDMARD	100 (61.0)	23 (41.1)	23 (62.2)	10 (31.3)	31 (39.7)	0.011
bDMARD	98 (59.8)	24 (42.9)	19 (51.4)	6 (18.8)	33 (42.3)	0.001

Values are expressed as n (%) or the mean ± standard deviation unless otherwise indicated.

Results: Of 4465 SpA patients from the study, 1033 (23.1%) had psoriatic arthritis (PsA). 367 AxPsA patients (35.5% of those with PsA) were compared by region. Percentage of axPsA patients among PsA by region were as follows: 164/489 (34%) from Europe and North America; 56/176 (32%) from Latin American; 37/90 (41%) from Japan; 32/75 (43%) from other Asian countries; and 78/203 (38%) from Middle East and North Africa (Table 1). At 12.4 years (SD 13.0), diagnostic delay in Japan was longer than those in other parts of the world (Table 2). Patients in Europe and North America had less AxSpA, with only 38% fulfilling ASAS AxSpA criteria. Disease activity was lower in Japan with mean ASDAS-CRP score of 2.2 (SD 1.0), despite less frequency of csDMARD (78%) and bDMARD (27%) use. In patients treated specifically for axial involvement, however, AxPsA patients in Japan demonstrated more frequent csDMARD (62%) and bDMARD (51%) use. Both Latin America and Asia showed higher disease activity with mean ASDAS-CRP of 3.2 (SDv1.2) and 3.2 (SD 1.5), respectively; both regions demonstrated less bDMARD use (43% and 19%, respectively) as a specific treatment for axial involvement.

Conclusion: This study suggests axPsA patients demonstrate differing disease manifestations, activities, and treatments by region.

SESSION INFORMATION

Session Date: Tuesday, November 9, 2021

Session Title: Spondyloarthritis Including PsA – Diagnosis, Manifestations, & Outcomes Poster IV: Clinical Aspects of PsA & Peripheral SpA (1773–1800)

Session Type: Poster Session D

Session Time: 8:30AM–10:30AM

Background/Purpose: To describe if the time of the onset of psoriasis (Pso) relative to the appearance of rheumatic symptoms in patients with spondyloarhtritis (SpA) is associated with a clinical phenotype, the rheumatologist's diagnosis and the evolution of the disease.

Methods: This was a cross-sectional study with data extracted from the REGISPONSER (Spondyloarhritis Registry of the Spanish Rheumatology Society) registry. Patients were classified in two groups to compare the clinical characteristics, disease activity, radiographic damage, functional ability and received treatment: "Pso as first symptom" and "Pso after rheumatic symptoms". Moreover, the rheumatologist's diagnosis was compared between the two groups. We use chi-square test and Student t-test to compare qualitative and quantitative variables in both groups, respectively. Multivariate analysis was performed in variables with significant differences.

Results: A total of 433/2367 (18.3%) patients included in the REGISPONSER database had Pso onset data available. Patients with Pso as first symptom had less body mass index [0.90 (95% CI 0.83 - 0.96)], shorter disease duration [0.94 (95% CI 0.91 – 0.97)], less prevalence of HLA-B27 antigen [0.22 (95% CI 0.11 – 0.44)] and higher prevalence of dactylitis [2.12 (95% CI 1.01 – 4.46)] with regard to patients with Pso after rheumatic symptoms. Furthermore, a higher prevalence of Psoriatic Arthritis (PsA) diagnosis [257/329 (78.1%) vs 57/101 (56.4%); p< 0.001)] and a lower prevalence of ankylosing spondylitis (AS) diagnosis [68/329 (20.7%) vs 38/101 (37.6%); p< 0.001] were found in patients with Pso as first symptom vs. Pso after rheumatic symptoms. Indeed, axial involvement was less frequent in patients with Pso as first symptom [29/330 (8.8%) vs 20/103 (19.4%); p=0.003], while peripheral involvement was more frequent [192/330 (58.2%) vs 39/103 (37.9%; p< 0.001]. The use of DMARDs was not statistically different between the two groups.

Conclusion: The moment of appearance of psoriasis influences significantly the clinical phenotypic of spondyloarthritis. Thus, the presence of psoriasis before the rheumatic symptoms could determine a more frequent diagnosis of PsA by Rheumatologist.

Abstract Number: 1792

Participation in Psoriatic Arthritis (PART2) – a Cross-sectional Study of Work Impairment in Psoriatic Arthritis Patients in the Netherlands

Tamara van Hal[1], Michelle Mulder[1], Mark Wenink[2] and Johanna Vriezekolk[1], [1]Sint Maartenskliniek, Nijmegen, Netherlands, [2]Sint Maartenskliniek, Malden, Netherlands

SESSION INFORMATION

Session Date: Tuesday, November 9, 2021

Session Title: Spondyloarthritis Including PsA – Diagnosis, Manifestations, & Outcomes Poster IV: Clinical Aspects of PsA & Peripheral SpA (1773–1800)

Session Type: Poster Session D

Session Time: 8:30AM–10:30AM

Background/Purpose: Psoriatic arthritis (PsA) can lead to pain, disability and a loss of quality of life [Rosen, Rheumatology 2012]. PsA can also lead to impairments in work and social activities, increasing societal costs. The magnitude and determinants of these impairments in Dutch PsA patients is insufficiently researched.

Methods: This cross-sectional study used sociodemographic and clinical data collected from the electronic patient files of PsA patients treated at the department of rheumatology of the Sint Maartenskliniek, Netherlands. All patients were treated according to Psoriatic Arthritis Disease Activity Score (PASDAS) driven treat-to-target, as described previously [Mulder, Rheumatology 2020]. Data about work and activity impairment were collected via the Work Productivity and Activity Impairment (WPAI) questionnaire. To compare our PsA-cohort with the Dutch general population (GP), we used age- and sex-matched data derived from the Central Bureau of Statistics. Regression analyses were performed to examine determinants of impairment.

Results: 246 patients were included in this study, of which 125 (48.8%) were male. Mean age was 55.7 years (SD=13.2). Over half of the patients had a paid job (work-for-pay, WFP, 53%). Compared to the age-and sex-matched Dutch GP, less patients with PsA had a paid job (Dutch GP 63% vs. PsA cohort 53%, $p < 0.001$). A lower age and a better physical function (Health Assessment Questionnaire-Disability Index (HAQ-DI)) were associated with WFP-status. Overall work impairment of those with a paid job was 10% (interquartile range, 10-40%). In this subgroup, higher disease activity score (PASDAS), worse physical function (HAQ-DI) and worse mental health-related quality of life (Mental Component Summary score – MCS-12) were associated with more work impairment ($p< =0.05$). Notably, age, sex and treatment modality were not associated with work impairment.

Conclusion: Our study indicates that Dutch patients with PsA were less likely to have a paid job compared to the Dutch general population. When working, they suffered an average productivity loss of 10%. Physical function seems to be a shared factor in the risk for work impairment as well as the risk for not having a paid job. Lower disease activity as measured by PASDAS seems to protect against work impairment, regardless of treatment modality. We suggest that by maintaining adequate disease control, patients can be protected from work impairment and future inability to work or loss of job.

Impact of Gender and Age on Psoriatic Arthritis Patient Profiles at Golimumab Initiation and 12-Month Outcomes

Arthur Karasik[1], Isabelle Fortin[2], Proton Rahman[3], Regan Arendse[4], Emmanouil Rampakakis[5], Odalis Asin-Milan[6], Allen Lehman[6], Francois Nantel[7] and Meagan Rachich[6], [1]Arthur Karasik Medicine Professional Corporation, Toronto, ON, Canada, [2]CREQ, Rimouski, QC, Canada, [3]Department of Medicine, Eastern Health and Memorial University of Newfoundland, St John's, NL, Canada, [4]University of Saskatchewan, Saskatoon, SK, Canada, [5]JSS Medical Research, Montréal, QC, Canada, [6]Janssen Inc., Toronto, ON, Canada, [7]., Montréal, QC, Canada

SESSION INFORMATION

Session Date: Tuesday, November 9, 2021

Session Title: Spondyloarthritis Including PsA – Diagnosis, Manifestations, & Outcomes Poster IV: Clinical Aspects of PsA & Peripheral SpA (1773–1800)

Session Type: Poster Session D

Session Time: 8:30AM–10:30AM

Background/Purpose: Gender and age have been previously identified as independent predictors of response to anti-TNFs. The aim of this analysis was to compare, between genders and age groups, the profile and outcomes of psoriatic arthritis (PsA) patients treated with golimumab during routine Canadian care.

Methods: This is a post-hoc analysis of data from the Biologic Treatment Registry Across Canada (BioTRAC). Patients with PsA who initiated treatment with subcutaneous golimumab were included. Patients were grouped into age tertiles: Young: 19.7–47.0 years; Middle: 47.1–59.3; Old: 59.4–85.4) and further stratified by gender. The impact of age and gender on outcomes and retention were assessed with multivariate logistic and cox regressions, respectively, adjusting for age tertile, gender, and respective outcome at baseline.

Results: 281 patients were included with a mean (SD) age of 52.8 (13.2) years and disease duration of 6.1 (7.7) years. Across age tertiles, significant differences ($p< 0.05$) were observed at baseline in disease duration, weight, employment status, insurance coverage, previous smoking status, previous/concomitant use of oral steroids, HAQ-DI, TJC28, and SJC28. Gender, RF status, anti-CPP status, family history, current smoking status, previous/concomitant use of DMARDs, NSAIDs, or MTX, number of previous DMARDs, experience with biologics, enthesitis, and dactylitis, and PASI were statistically comparable. Between genders, significant differences were observed in weight, employment status, number of previous DMARDs, concomitant NSAIDs, and baseline HAQ-DI, TJC28, and SJC28.

Based on multivariate regression, patients in Young age tertiles (OR [95% CI]: 9.44 [3.88–23.0]) and Middle (2.5 [1.05–5.95]), along with male patients (2.07 [1.03-4.18]), were more likely to achieve MDA-LDA at 6 months. Compared to Old age tertile, achievement of MDA-LDA at 12 months (3.40 [1.36–8.48]), VLDA at 6 (6.69 [2.09–21.4]) and 12 (6.59 [1.92–22.7]) months, and HAQ< 0.5 at 6 (7.68 [3.23–18.3]) and 12 (4.84 [1.98–11.82]) months were more likely among patients in Young age tertile. Male patients were less likely have enthesitis (0.37 [0.15–0.87]) at 6 months and dactylitis at both 6 (0.27 [0.08–0.97]) and 12 (0.17 [0.03–0.88]) months. There was no association between age tertile or gender and PASI75 achievement.

In terms of safety, notable differences were observed across genders and age tertiles in both adverse event incidence and profile. Furthermore, male gender (HR [95%]: 1.66 [1.14-2.44]), but not age tertile, was associated with higher odds of retention.

Conclusion: Significant variations in baseline characteristics, treatment outcomes, and safety profile exist across age groups and gender.

SESSION INFORMATION

Session Date: Tuesday, November 9, 2021

Session Title: Spondyloarthritis Including PsA – Diagnosis, Manifestations, & Outcomes Poster IV: Clinical Aspects of PsA & Peripheral SpA (1773–1800)

Session Type: Poster Session D

Session Time: 8:30AM–10:30AM

Background/Purpose: Previous analyses have identified enrolment year as an independent predictor of real-world retention on anti-TNF treatment whereby patients enrolled in later periods were more likely to be switched. The aim of this analysis was to compare between enrolment periods for psoriatic arthritis (PsA) treatment outcomes and frequency of treating to target, and to assess the impact of target type on long-term function.

Methods: This is a post-hoc analysis of data from the Biologic Treatment Registry Across Canada (BioTRAC). Patients were grouped into enrolment periods: 2005-2008, 2009-2012, 2013-2015, 2016-2017. Achievement of MDA (5/7 of: TJC28≤1, SJC28≤1, PASI≤1, pain≤15mm, PtGA≤20mm, HAQ≤0.5, tender entheseal points≤1), VLDA (7/7 criteria), and sustained MDA or VLDA (at 6 and 12 months) were compared between enrolment periods with the Chi-square test. The impact of achieving MDA or VLDA at 6 months, 12 months, or both (sustained) on HAQ-DI at 18 months was assessed with one-way ANOVA and generalized linear models.

Results: 392 PsA patients treated with anti-TNFs (IFX: n=111; GLM: n=281) were included. Across enrolment periods, a significant increase in baseline age (48.5 vs. 50.3 vs. 51.9 vs. 54.8 years; p=0.021) was observed. At 6 and 12 months, 44.2% and 45.6% achieved MDA, 18.4% and 19.9% achieved VLDA, while 36.8% and 13.2% achieved sustained MDA and VLDA, respectively, without significant differences across enrolment periods.

Among patients not achieving LDA at 6 and 12 months, an intervention was applied in 40-45% of patients, without significant differences between enrolment periods. Between 6 and 12 months, the most common intervention was anti-TNF discontinuation (71.2% of non-LDA achievers), followed by DMARD addition (12.1%), DMARD dose increase (7.6%) or NSAID addition (7.6%). Similar results were obtained post 12 months.

Patients achieving sustained MDA, followed by those achieving MDA either at 6 or 12 months had significantly lower HAQ at 18 months compared to patients not achieving MDA at either timepoint (0.2 vs. 0.6 vs. 1.2; p< 0.001). Similar results were observed when evaluating achievement of remission albeit with greater impact on HAQ at 18 months (0.1 vs. 0.2 vs. 0.9; p< 0.001). Adjustment for baseline HAQ did not impact the results.

Conclusion: Target achievement among PsA patients has remained stable over time with relatively infrequent regimen optimization prior to anti-TNF discontinuation. Achieving stricter targets was associated with greater benefits in terms of long-term patient function.

Session Title: Spondyloarthritis Including PsA – Diagnosis, Manifestations, & Outcomes Poster IV: Clinical Aspects of PsA & Peripheral SpA (1773–1800)

Session Type: Poster Session D

Session Time: 8:30AM–10:30AM

Table 1. Disease activity categories by Q-DAPSA vs. DAPSA

		Q-DAPSA (n = 104)			
		Remission (≤ 4)	Low Disease Activity (> 4 and ≤ 14)	High Disease Activity (> 14 and ≤ 28)	Very high Disease Activity (> 28)
DAPSA	Remission (≤ 4)	36 (34.6%)	1 (1.0%)		
	Low Disease Activity (> 4 and ≤ 14)		39 (37.5%)		
	High Disease Activity (> 14 and ≤ 28)			22 (21.2%)	
	Very high Disease Activity (> 28)				6 (5.8%)

The fields highlighted in red indicate that disease activity categories do not match.
DAPSA = Disease activity index for Psoriatic Arthritis, Q-DAPSA = DAPSA calculated based on a quick quantitative CRP

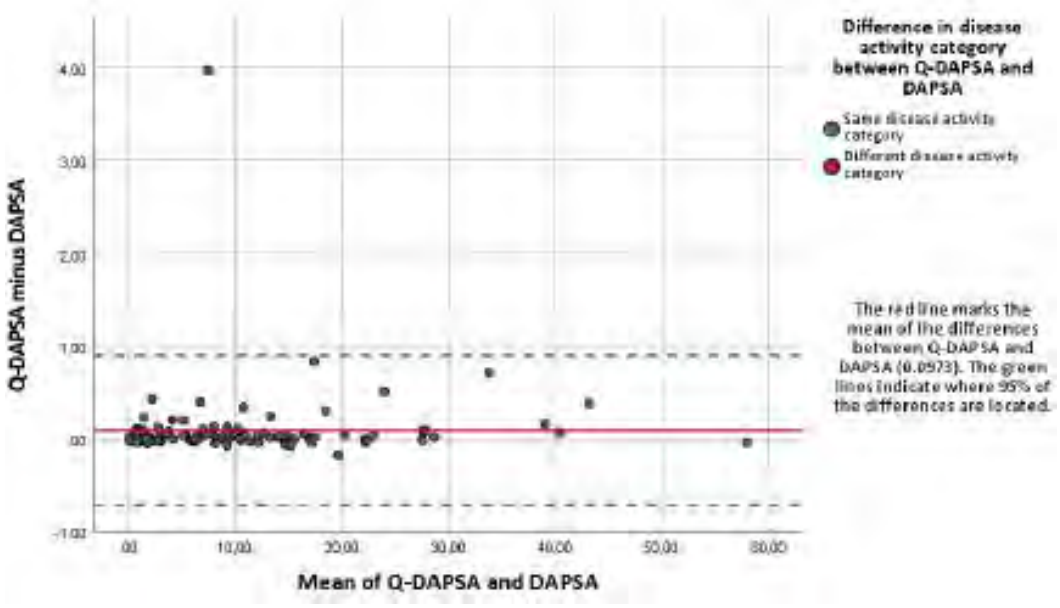

Figure 1. Bland-Altman plot for Q-DAPSA and DAPSA.

Background/Purpose: Psoriatic arthritis (PsA) is a heterogeneous disease with multiple musculoskeletal and dermatological manifestations. Due to this multifaceted clinical appearance, international guidelines do not provide a clear recommendation for one specific score to assess disease activity in PsA [1]. The Disease Activity Index for Psoriatic Arthritis (DAPSA), a validated, unidimensional score focusing on joint involvement, is one of the recommended options [1]. However, routine determination of C-reactive protein (CRP) to calculate DAPSA values takes hours to days. In contrast, quick quantitative CRP (qCRP) tests require only a few minutes and might facilitate regular assessment of the DAPSA (as Q-DAPSA) in clinical routine.

The objective of our study was to validate the Q-DAPSA in a prospective, multicenter study of PsA patients. Since the Disease Activity Score 28 (DAS28) is not only used in rheumatoid arthritis, but also in PsA patients, the study also investigated the performance of a qCRP based DAS28 (DAS28-qCRP) in a PsA cohort.

Methods: The study was conducted in five centers in Berlin, Germany. Consecutive adult (≥ 18 years) PsA patients were included. In addition to a rheumatological assessment, including patient reported outcomes (PROs), routine CRP and erythrocyte sedimentation rate (ESR) were measured in the local labs. Additionally, a qCRP testing with the „QuikRead go instrument“ (Aidian Oy, Finland) was performed locally at the study center (measurement range 0.5 - 200 mg/l for hematocrit concentrations of 40 – 45%). Statistical analysis included descriptive statistics, cross tabulation and weighted Cohen´s kappa comparing disease activity categories, Bland-Altman plots and intraclass correlation coefficient (ICC) for DAPSA, Q-DAPSA, DAS28- CRP and DAS28-qCRP.

Results: In this study 104 patients were included between January and October 2020 (mean age: 51.2 years, mean disease duration: 7.1 years, 49 patients (47.1%) were male). 53 patients (51.0%) were treated with a bDMARD and 37 patients (35.6%) with csDMARDs. CRP and qCRP showed mean values of 5.20 and 6.17 mg/l, respectively. With the Q-DAPSA, 103 patients (99.0%) were assigned to the same disease activity category when compared to DAPSA (Table 1). Weighted Cohen´s kappa was 0.990 (95%CI 0.970; 1.000). ICC for numerical values of DAPSA and Q-DAPSA was 1.000 (95%CI 0.999; 1.000). The agreement of Q-DAPSA and DAPSA is shown in a Bland-Altman plot (Figure 1). DAS28-CRP and - qCRP were available for 103 patients; 101 patients (98.1%) showed the same disease activity category in the DAS28-qCRP and weighted Cohen´s kappa was 0.951 (95%CI 0.886; 1.000).

Conclusion: The Q-DAPSA and DAPSA showed an almost perfect agreement on the assignment to disease activity categories (99%) with the important advantage of time. With Q-DAPSA, rheumatologists could base their clinical decision-making on a disease activity measurement by using a composite score immediately. Consequently, Q-DAPSA can be integrated in clinical routine and clinical trials and could be implemented into the treat-to-target concept in PsA patients. For rheumatologists who prefer DAS28-CRP for assessing disease activity in PsA patients, DAS28-qCRP may serve as a suitable alternative.

SESSION INFORMATION

Session Date: Tuesday, November 9, 2021

Session Title: Spondyloarthritis Including PsA – Diagnosis, Manifestations, & Outcomes Poster IV: Clinical Aspects of PsA & Peripheral SpA (1773–1800)

Session Type: Poster Session D

Session Time: 8:30AM–10:30AM

Background/Purpose: In the absence of reliable serological and/or imaging biomarkers for early psoriatic arthritis (PsA) and an existing diagnostic delay there is a need for screening tools for detection of early PsA. While different validated screening/referral tools focusing on peripheral manifestations of PsA exist[1], validated referral algorithms for PsA with axial involvement (axPsA) are missing. In this prospective, multicenter study we applied a dermatologist-centered screening tool to identify signs of axial involvement among patients with psoriasis (PsO) attending dermatology clinics.

Methods: Consecutive patients with PsO were screened by their dermatologist for eligibility for referral to a specialized rheumatology clinic. Eligible patients were ≥ 18 years with a confirmed diagnosis of PsO who reported having chronic back pain (≥ 3 months) with onset prior to 45 years of age and who had not been treated with any biologic or targeted synthetic DMARD in the 12 weeks prior to screening. For those patients who qualified for referral and attended the rheumatology clinic, a rheumatologic investigation including clinical, laboratory and genetic assessments as well as imaging with conventional radiography and MRI of sacroiliac joints and spine was performed. The primary outcome of the study was the proportion of patients diagnosed with axPsA among all referred PsO patients.

Table 1: Demographic and clinical characteristics of PsO patients with pPsA, axPsA and patients not diagnosed with PsA

Patient characteristics	Patients seen at rheumatology (N=100)	pPsA (N=5)	axPsA (N=14)	No PsA (N=81)	p-value[1]
Age (years) – Mean (SD)	45.6 (13.0)	42.6 (9.0)	46.2 (13.6)	45.7 (13.3)	0.883
Female – n (%)	56 (56.0)	2 (40.0)	9 (64.3)	45 (55.6)	0.543
BMI (kg/m2) – Mean (SD)	27.4 (5.5)	23.6 (1.2)	27.8 (6.6)	27.5 (5.4)	0.933
Positive family history of SpA – n (%)	48 (48.0)	3 (60.0)	7 (50.0)	39 (48.1)	0.511
Psoriasis, current – n (%)	100 (100.0)	5 (100.0)	14 (100.0)	81 (100.0)	
Psoriasis, duration (years) – Mean (SD)	19.2 (16.0)	16.6 (19.4)	13.6 (9.2)	20.3 (16.7)	0.291
PASI – Mean (SD)	4.0 (4.4)	3.3 (2.1)	4.3 (4.9)	4.0 (4.5)	0.971
Inflammatory back pain – n (%)	49 (49.0)	5 (100.0)	8 (57.1)	36 (44.4)	0.379
Duration of back pain (years) – Mean (SD)	17.3 (14.6)	10.8 (11.7)	12.2 (15.2)	18.8 (14.6)	0.058
HLA-B27 positive – n (%)	16 (16.0)	0	4 (28.6)	12 (14.8)	0.204
CRP (mg/L) – Mean (SD)	3.5 (6.1)	8.0 (15.4)	8.0 (10.8)	2.5 (3.1)	0.039
Elevated CRP (>5 mg/L) – n (%)	17 (17.0)	1 (20.0)	5 (35.7)	11 (13.6)	0.041
Peripheral arthritis, current – n (%)	11 (11.0)	5 (100.0)	3 (21.4)	3 (3.7)	0.012
Enthesitis, current – n (%)	8 (8.0)	0	0	8 (9.9)	0.219
Dactylitis, current – n (%)	1 (1.0)	0	1 (7.1)	0	0.016
Uveitis, ever – n (%)	1 (1.0)	1 (20.0)	0	0	
Sacroiliitis as per mNY criteria – n (%)	5 (5.0)	0	4 (28.6)	1 (1.2)	<0.001
Sacroiliitis >=grade 2 unilaterally – n (%)	9 (9.0)	0	5 (35.7)	4 (4.9)	<0.001
Active inflammation, sacroiliac joint (MRI) – n (%)	8 (8.0)	0	8 (57.1)	0	<0.001
Structural (post)inflammatory changes, sacroiliac joint (MRI) – n (%)	8 (8.0)	0	8 (57.1)	0	<0.001
Active inflammation, spine (MRI) – n (%)	13 (13.0)	0	13 (92.9)	0	<0.001
Structural (post)inflammatory changes, spine (MRI) – n (%)	8 (8.0)	0	8 (57.1)	0	<0.001
ASDAS (0-10) – Mean (SD)	2.4 (0.8)	3.1 (1.2)	2.9 (0.8)	2.3 (0.7)	0.017
BASDAI (0-10) – Mean (SD)	4.4 (1.7)	5.6 (2.1)	4.8 (1.5)	4.2 (1.7)	0.239
DAPSA – Mean (SD)	12.7 (9.5)	23.2 (14.2)	17.5 (14.3)	11.2 (7.4)	0.112
NSAIDs use, current – n (%)	42 (42.0)	3 (60.0)	8 (57.1)	31 (38.3)	0.185

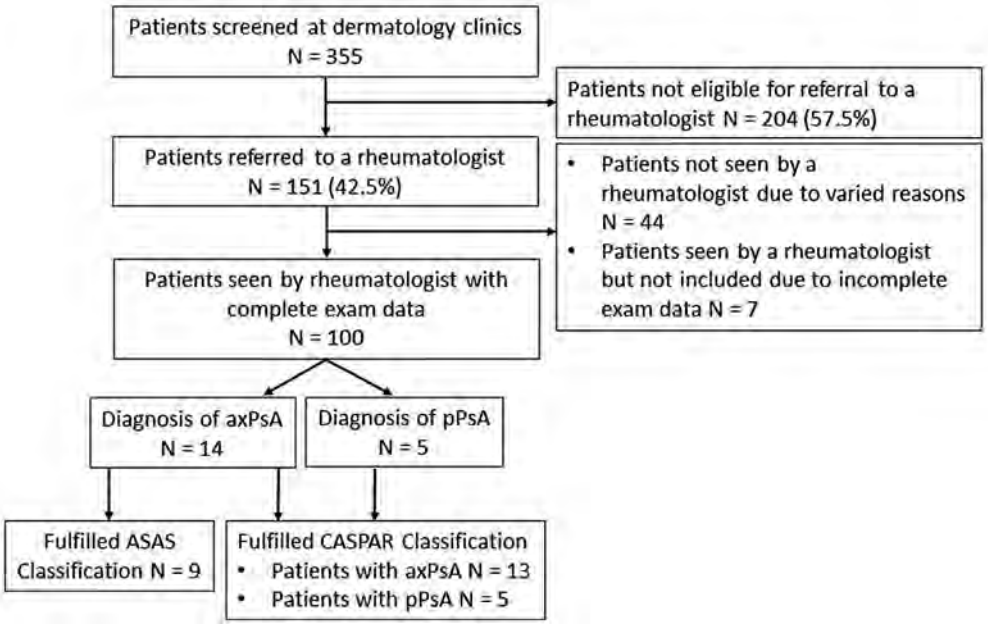
Abbreviation: ASDAS=ankylosing spondylitis disease activity, axPsA=axial psoriatic arthritis, BASDAI=Bath ankylosing spondylitis disease activity index, BMI=body mass index, CRP=C-reactive protein, DAPSA=disease activity in psoriatic arthritis, HLA-B27=human leucocyte antigen B27, MRI= magnetic resonance imaging, N=number, NSAIDs=non-steroidal anti-inflammatory drugs, PASI=psoriasis area and severity index, pPsA=peripheral psoriatic arthritis, SD=standard deviation, SpA=spondyloarthritis, UVB=ultraviolet B.
[1]Statistically significant differences between the axPsA and no PsA groups of patients were determined by using Mann–Whitney U test for continuous data and Chi-square test for categorical data.

Results: In total 355 patients were screened at 14 dermatology sites, of whom 151 (42.5%) qualified for referral to rheumatology clinic. Rheumatologists ultimately examined 100 (28.2%) patients (Figure 1). The diagnosis of axPsA was confirmed in 14 patients (14%) (3/14 with both, axial and peripheral involvement) and the diagnosis of peripheral PsA (pPsA) without axial involvement was made in five patients (5%). 81 (81%) patients were diagnosed with neither pPsA nor axPsA. Clinical, lab and imaging characteristics of the study population, as well as subgroups with and without axial involvement, are presented in Table 1. All patients diagnosed with axPsA had active inflammatory and/or structural (post) inflammatory changes in the sacroiliac joints and/or spine on imaging. In five (35.7%) patients, MRI changes indicative of axial involvement were found only in the spine. The Assessment of SpondyloArthritis international Society (ASAS) classification criteria for axSpA were fulfilled in nine (64.3%) of the patients diagnosed

Figure 1: Patient disposition, total number of patients screened, referred and seen by a rheumatologist



with axPsA. All but one patient diagnosed with PsA (13/14 with axPsA and 5/5 with pPsA) fulfilled the Classification Criteria for Psoriatic Arthritis (CASPAR) for PsA as illustrated in Figure 1.

Conclusion: Our study revealed that applying a dermatologist-centered screening tool is useful for the detection of axPsA and pPsA in PsO patients at-risk. These results provide valuable real-world insights into the possibility of

Figure 2: Imaging features of axial involvement in PsO patients diagnosed with axPsA

Session Title: Spondyloarthritis Including PsA – Diagnosis, Manifestations, & Outcomes Poster IV: Clinical Aspects of PsA & Peripheral SpA (1773–1800)

Session Type: Poster Session D

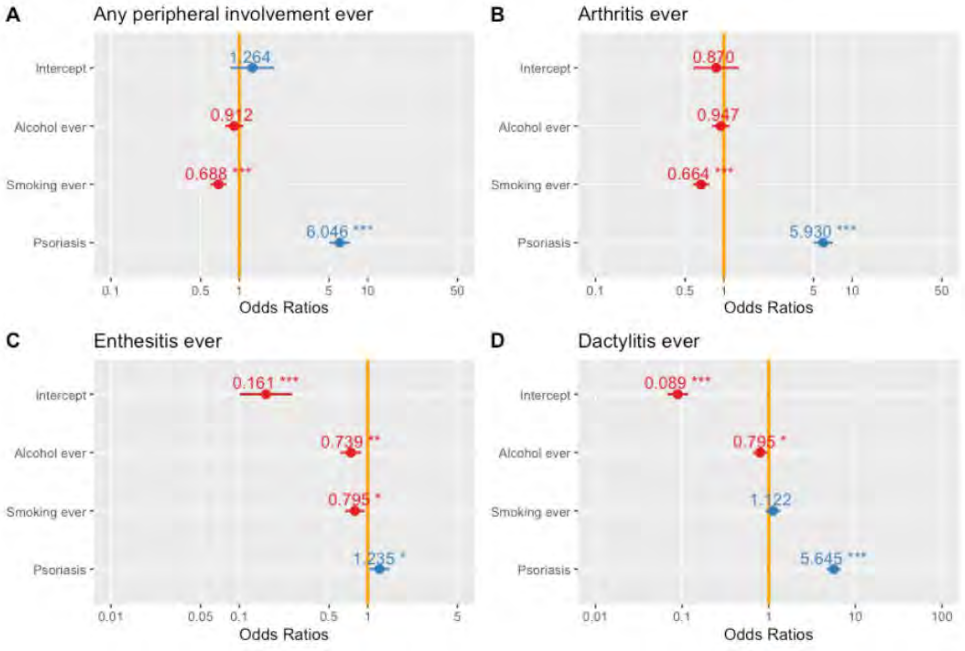
Session Time: 8:30AM–10:30AM

Background/Purpose: There are controversies around the role of smoking in manifestations of axial spondyloarthritis (axSpA) such as peripheral involvement. It has been observed an inverse association between alcohol consumption and disease activity and functional impairment, although it is still unclear its association with peripheral manifestations of SpA. Objectives: 1) To evaluate the association between smoking/alcohol intake and the prevalence of peripheral articular manifestations (i.e., arthritis, enthesitis or dactylitis); 2) to assess the association between smoking/alcohol intake and the specific location of such manifestations.

Table 1. Association between peripheral musculoskeletal manifestations and smoking and alcohol

Any peripheral manifestation ever				
	Yes = 2601	No = 1860	OR (95%CI) univariate	p-value
Alcohol ever	1057 (40.6%)	754 (40.5%)	1.00 (0.89 – 1.13)	0.945
Smoking ever	1034 (39.8%)	866 (46.6%)	0.76 (0.67 – 0.85)	<0.001
Psoriasis	1023 (39.4%)	187 (10.1%)	5.80 (4.91 – 6.90)	<0.001
Arthritis ever				
	Yes = 2292	No = 2169	OR (95%CI) univariate	p-value
Alcohol ever	929 (40.4%)	882 (40.7%)	0.99 (0.98 – 1.14)	0.929
Smoking ever	887 (38.7%)	1013 (46.7%)	0.72 (0.64 – 0.81)	<0.001
Psoriasis	949 (41.4%)	261 (12.0%)	5.17 (4.44 – 6.03)	<0.001
Enthesitis ever				
	Yes = 765	No = 3696	OR (95%CI) univariate	p-value
Alcohol ever	276 (36.1%)	1535 (41.5%)	0.79 (0.68 – 0.93)	0.005
Smoking ever	312 (40.8%)	1588 (43.0%)	0.91 (0.78 – 1.07)	0.267
Psoriasis	279 (36.5%)	931/3695 (25.2%)	1.70 (1.44 – 2.01)	<0.001
Dactylitis ever				
	Yes = 685	No = 3776	OR (95%CI) univariate	p-value
Alcohol ever	299 (43.6%)	1512 (40.0%)	1.16 (0.98 – 1.37)	0.077
Smoking ever	277 (40.4%)	1623 (43.0%)	0.90 (0.76 – 1.06)	0.216
Psoriasis	414 (60.4%)	796 (21.1%)	5.72 (4.82 – 6.80)	<0.001

Figure 1. Association between peripheral musculoskeletal manifestations and both alcohol and smoking, adjusting for the presence of psoriasis (multivariate analysis).



Methods: Patients from the cross-sectional ASAS-PerSpA study with available data for both the smoking status and alcohol intake were included. Mixed logistic regressions using the peripheral manifestation (or the location) as a dependent variable, the smoking status or alcohol intake and the presence of psoriasis as fixed effect and the country as random effect were used. The interaction between smoking and alcohol was tested.

Results: A total of 4451 patients with either axSpA, peripheral SpA or Psoriatic Arthritis were included in the analysis. 59.5% had smoked at any moment and 42.7% had been alcohol drinkers. Patients who have ever suffered arthritis showed a lower frequency of smoking habit (OR 0.72, 95%CI 0.63-0.82) and a lower alcohol consumption(OR 0.82, 95%CI 0.71-0.94) (table 1). In addition, among patients with arthritis, smoking was associated with a predominantly upper limbs involvement (OR 0.78, 95%CI 0.65-0.94), while alcohol was associated with a predominant mono/oligoarticular involvement (OR 1.13, 95%CI 0.94-1.36).

Patients who have ever suffered enthesitis also showed a lower frequency of smoking habit and alcohol intake (OR 0.75, 95%CI 0.63-0.89 and OR 0.69, 95%CI 0.57-0.83, respectively). No association was found with regard to the prevalence of dactylitis.

At the moment of the study visit, 20.4% patients were current smokers and 32.2% consumed alcohol. Current alcohol intake was associated with a lower prevalence of both current arthritis (26.9% vs. 33.6% (OR 0.76, 95%CI 0.64-0.91)) and current enthesitis (21.1% vs. 34.6% (OR 0.78, 95%CI 0.62-0.96)), while current smoking did not show significant differences.

No interaction was found in the association between alcohol and tobacco with regard to the prevalence of peripheral symptoms in the past. However, when assessing current arthritis, current smokers and no drinkers were found to be associated with arthritis in the lower limbs.

Conclusion: Taking into account the country and the presence of psoriasis, smoking and alcohol are associated with a lower prevalence of peripheral manifestations. Smoking seems to be associated with predominantly upper limbs arthritis while alcohol intake seems to be associated with a predominantly oligo/mono articular involvement. Future studies are required including the influence of psoriatic arthritis in the relationship between alcohol and smoking and its association with peripheral manifestations.

Background/Purpose: Psoriatic arthritis (PsA) occurs in up to 30% of patients with psoriasis (PsO), and usually follows the development of PsO by an average of 7-10 years. However, there is significant variability in the timing of transition from PsO to PsA which contributes to delays in diagnosis and high rates of undiagnosed PsA. In this study, we aim to identify clinical and demographic features associated with the time to transition from PsO to PsA.

Methods: In our longitudinal psoriatic disease cohort, we identified patients with PsO and PsA diagnoses. Time between PsO and PsA diagnoses was calculated as number of years between the 2 diagnoses dates, and were modeled as a continuous outcome variable using multivariable linear regression. Candidate predictors included: gender,

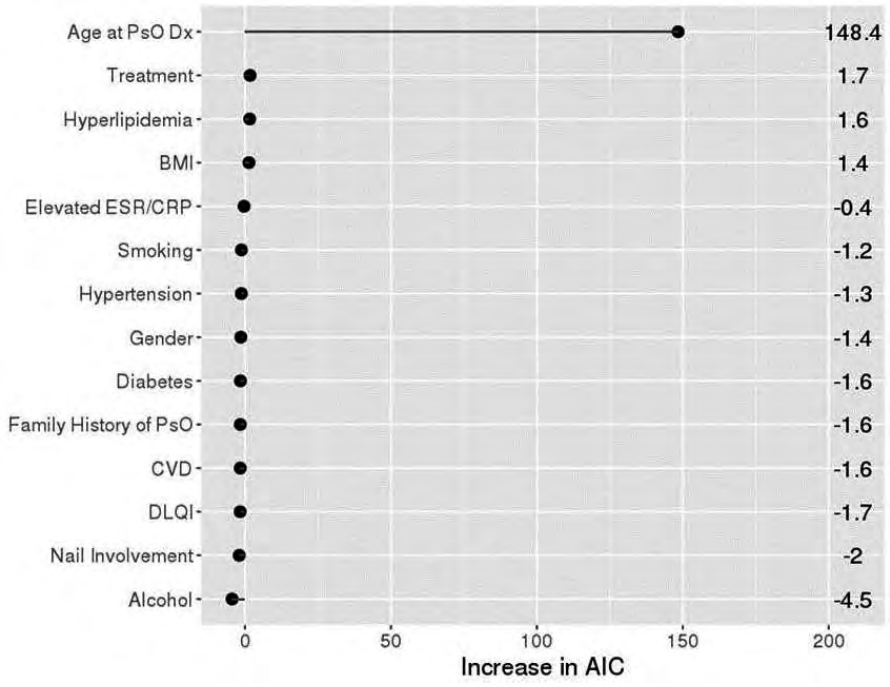

Figure 1. Ranking of Predictors for Time between PsO and PsA Diagnoses.

age at PsO diagnosis, family history of PsO, BMI, treatment, cardiovascular disease, hypertension, diabetes, dyslipidemia, nail involvement, DLQI, elevated ESR/CRP, alcohol and smoking. A subgroup model was built using patients with BSA data, and using a subset of predictors including age at PsO diagnosis, smoking, elevated ESR/CRP, BMI, family history of PsO and % body surface area (BSA). Model results were presented using coefficient estimates and respective 95% confidence intervals. Variables were ranked based on their relative contribution to the models, as assessed by AIC increase upon removal of the variable from the full model. All tests were two-sided, assuming an alpha level of 0.05.

Results: Our analysis cohort included 384 patients. The median age at PsO diagnosis was 30.4 years, and 52.2% of patients were female. Age at Diagnosis of PsO is statistically significantly associated with transition time from PsO to PsA. Patients aged 42.6 years (Q3) have on average around 12 years less between PsO to PsA compared to patients aged 18.9 years (Q1), after controlling for relevant variables in the model (-11.88 (-13.64, -10.12); $p < 0.001$). Patients on bDMARD have on average 4.5 years less between PsO to PsA compared to patients on NSAID only, after controlling for other variables in the model (-4.52 (-8.3, -0.74), $p = 0.02$). Although the use of bDMARDs appears to show a trend towards less years (4.5 yrs) compared to non bDMARDs, the overall effect of treatment was not statistically significant. Patients with BSA of 5% (Q3) have on average 1.1 years more (more number of years) from PsO to PsA compared to patients with BSA of 0.5% (Q1), after controlling for other variables in the model (1.11 (-0.44, 2.65), $p = 0.16$), though the overall effect of BSA is not significant. Age at PsO diagnosis contributed the most to the model according to the Akaike Information Criterion (AIC). AIC >= 2 justifies statistically improved model, which means it is beneficial to include age in the model.

Conclusion: Our study demonstrated that age of psoriasis onset is important predictor of time to transition from psoriasis to psoriatic arthritis. Patients diagnosed with PsO at an older age have a shorter interval before they develop PsA. The time difference is clinically significant; compared to younger patients (18.9 years, Q1), older patients (42.6 years, Q3) develop PsA on average 12 years sooner. These results suggest that older patients diagnosed with PsO may benefit from earlier screening for PsA.

Session Title: Spondyloarthritis Including PsA – Diagnosis, Manifestations, & Outcomes Poster IV: Clinical Aspects of PsA & Peripheral SpA (1773–1800)

Session Type: Poster Session D

Session Time: 8:30AM–10:30AM

Background/Purpose: Psoriatic arthritis (PsA) can affect differently women and men. Ultrasound (US) is an important tool in the evaluation of disease activity of PsA. To the best of our knowledge, there is no study that compared sonographic features of PsA between female and male patients.

The aim of this study is to investigate gender-based differences among PsA patients concomitantly evaluated by clinical examination and US.

Methods: The study population included prospectively recruited consecutive adult patients with PsA (CASPAR criteria). Patients' assessment included physical examination of joints (66/68 tender and swollen joint count, TJC/SJC), enthesitis (LEEDS and SPARCC), dactylitis, skin (PASI) and several patients reported outcome. All the patients underwent a detailed US evaluation (gray scale and Doppler), including 52 joints, 40 tendons and 14 points of entheses

(according to MASES index plus lateral epicondyles). The score of the US was based on the summation of a semi-quantitative score (0-3) for synovitis (EULAR-OMERACT definition), tenosynovitis, and enthesitis score. The US enthesitis score was categorized to inflammatory (hypoechogenicity, thickening, bursitis and Doppler) and to structural score (erosions and enthesophytes). All the evaluations occurred on the same day, and the sonographer was blinded to the clinical data. Patients were asked to stop NSAIDS 3 days before the evaluation.

The association between gender and US scores was assessed by multivariate ordinal logistic regression models adjusted for potential confounders (age, BMI, PsA duration, CRP, csDMARDS, and biologics).

Results: The study population included 159 PsA patients, 70 males and 89 females (table 1). The rate of employment was significantly higher in males compared to females (p=0.007). PASI and SJC were significantly higher in males compared to females (p=0.04). Disease duration, other indices of PsA activity, and treatment profile were similar in both genders.

The total US score and its subcategories, synovitis and tenosynovitis scores, were similar between the genders, whereas the total enthesitis score and its subcategory, inflammatory enthesitis score, were significantly higher in males vs females (23.33 ± 16.22 vs 17.55 ± 9.96 and 12.07±9.01 vs 8.74± 5.95, p=0.007, respectively) (table 2). In addition, male had significantly more prevalent hypoechogenicity, thickening, bursitis and enthesophytes compared to females (p< 0.001). Furthermore, there was a gender-based significant difference of US enthesitis total scores by anatomical sites: triceps to olecranon, quadriceps to patella, patellar tendon insertion to distal patella and to tibial tuberosity and Achilles tendon insertion which had a significantly higher US enthesitis score in males compared to females (table 3).

Finally, multivariate ordinal logistic regression models showed that male were prone to higher US inflammatory enthesitis score (OR 1.88, p=0.04).

Conclusion: The main gender-based sonographic difference in PsA patients was higher enthesitis score in males, in particular, higher inflammatory US enthesitis score, whereas these differences were not reflected by the standardized clinical enthesitis and disease activity scores.

Altered Metabolic Profiles in the Transition from Psoriasis to Psoriatic Arthritis: A Longitudinal Analysis

Ananta Paine[1], Paul Brookes[2], Dongmei Li[3], Somyaroop Bhattacharya[4], Maria de la Luz Garcia-Hernandez[1] and Christopher Ritchlin[1], [1]Division of Allergy, Immunology, and Rheumatology, School of Medicine and Dentistry, University of Rochester Medical Center, Rochester, NY, [2]Department of Pharmacology & Physiology, University of Rochester Medical Center, Rochester, NY, [3]Department of Clinical and Translational Research, University of Rochester Medical Center, Rochester, NY, [4]Division of Neonatology, Department of Pediatrics, University of Rochester, Rochester, NY

SESSION INFORMATION

Session Date: Tuesday, November 9, 2021

Session Title: Spondyloarthritis Including PsA – Diagnosis, Manifestations, & Outcomes Poster IV: Clinical Aspects of PsA & Peripheral SpA (1773–1800)

Session Type: Poster Session D

Session Time: 8:30AM–10:30AM

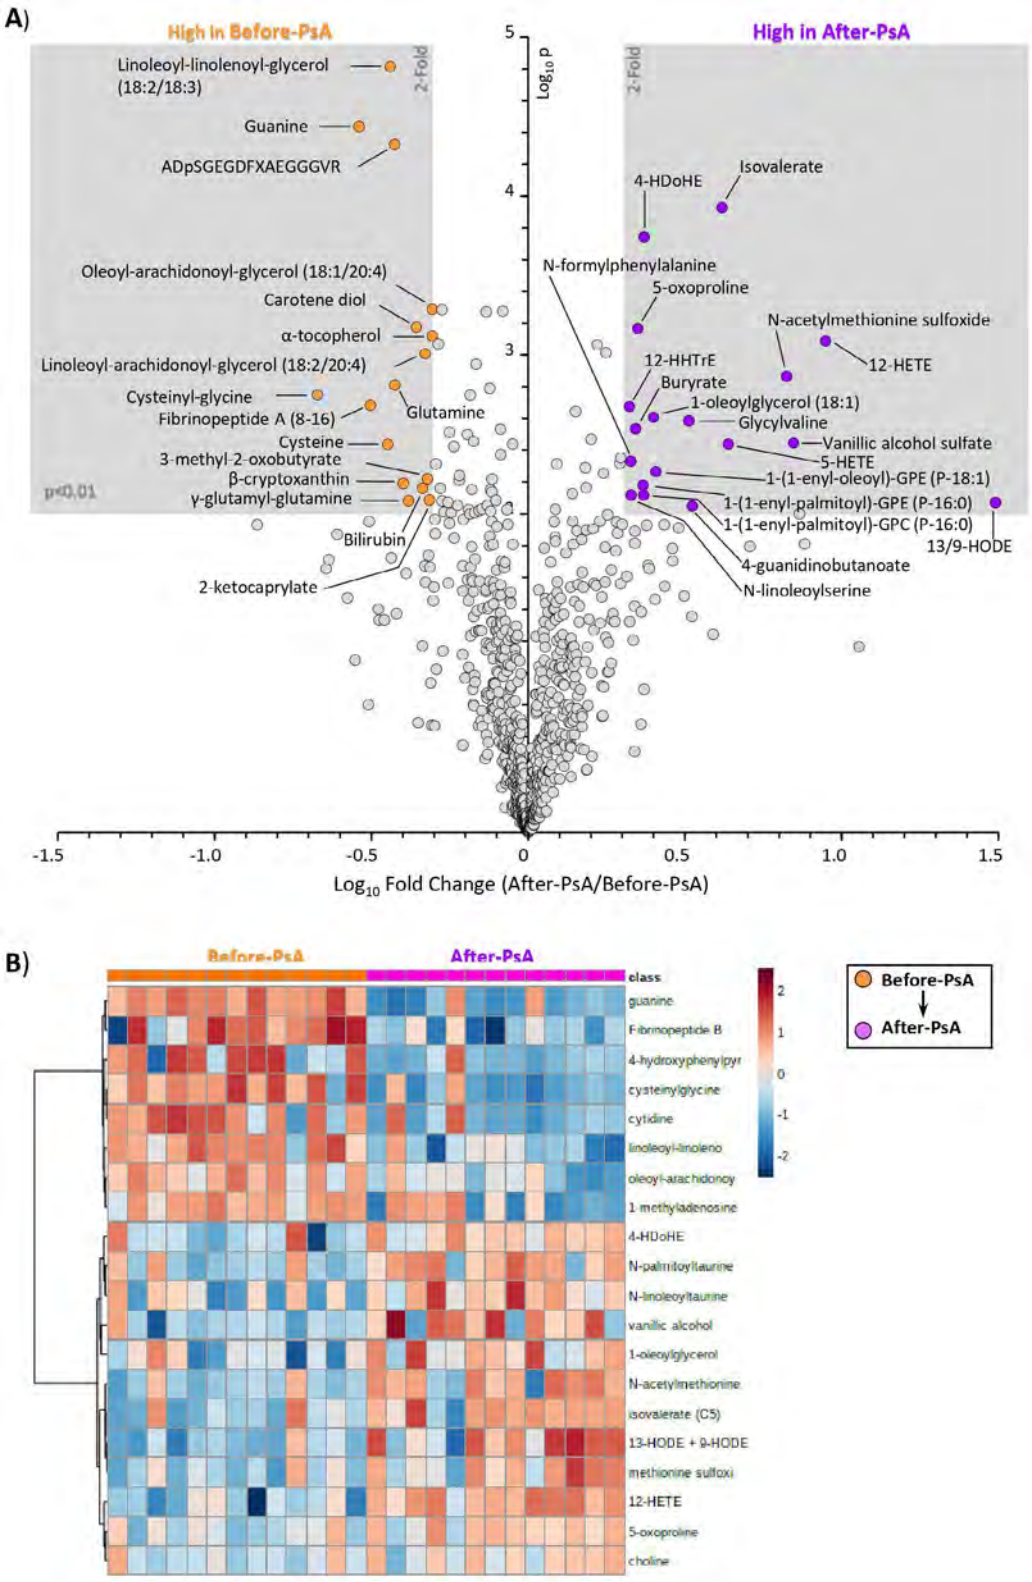

Figure 1. Metabolites different between before- and after the onset of PsA. (A) Volcano plot shows comparison between samples collected before (Before-PsA, orange) and after (After-PsA, purple) the onset of PsA (matched samples). X-axis shows Log10 of fold change. Y-axis shows –Log10 of p-value (pair-wise t-test). Metabolites achieving both statistical significance ($p<0.01$) and greater than 2-fold difference between groups, are shown inside the shaded gray areas, and identified with labels. Data are means from n = 13 individuals. (B) Heat Map showing metabolite abundance (top 25) in individual patients (n = 13).

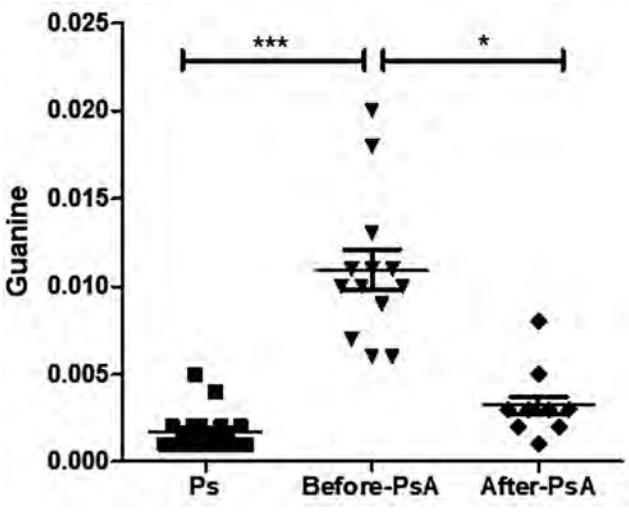

Figure 2. Guanine levels in converters (PsP) and non-converters (PsNP). Serum guanine levels were compared between samples from patients who did (PsP, n = 13) or did not covert (PsNP, n = 20) to PsA and normalized data presented as a dot plot. For the PsA-converters samples were collected before (Before-PsA), and after (After-PsA) the onset of PsA (matched samples). '***' indicates p-value less than 0.0001 and '*' indicates p-value less than 0.01.

Background/Purpose: The transition to psoriatic arthritis (PsA) occurs in 20-30% of psoriasis (Ps) patients, but the mechanisms underlying the emergence of musculoskeletal disease are not well understood. We compared serum metabolites of Ps and PsA patients to identify potential biomarkers of arthritis risk in Ps patients.

Methods: To identify differentially abundant metabolites in the sera of Ps patients, we analyzed serum samples for metabolites in cohorts of psoriasis patients who progressed (PsP) and did not progress (PsNP) to PsA. We performed unbiased metabolomic profiling using reverse-phase, and Hydrophilic Interaction Liquid Chromatography coupled to Q-Exactive Mass Spectrometry of the serum samples collected from PsNP (n=20), and PsP (n=13), and healthy controls (HC, n=18).

Results: We identified several key metabolites linked to diverse metabolic pathways that differed between patients who did or did not progress to PsA and healthy controls. Among the differentially abundant metabolites were those related to purine, pyrimidine, glutathione, and lipid metabolism (Figure 1). We also noted that guanine and linoleoyl-linolenoyl-glycerol were significantly decreased (more than 50%, $p < 0.001$), after the onset of arthritis. In contrast, multiple metabolites related to lipid metabolism (4-HDoHE, 12-HETE, 12-HHTrE, and 1-oleoylglycerol), were elevated (more than 2-fold, $p< 0.01$) and 5-oxoproline, a metabolite related to glutathione metabolism, was also elevated in the samples (more than 2-fold, $p< 0.001$) collected after the onset of arthritis (Figure 1). These changes were not noted in HCs. We also found that guanine levels were elevated in PsP compared to PsNP patients (Figure 2). Most intriguingly, we also noted that serum guanine levels significantly decreased after the onset of arthritis (Figure 2).

Conclusion: We identified a set of metabolites that were differentially abundant before and after the onset of arthritis in Ps patients. During the transition from psoriasis to PsA, we observed a changing pattern of purine, lipid and amino acid metabolites over time. The elevated guanine levels in Ps patients at risk for arthritis was particularly striking and may reflect altered proliferation of immune cells and enhanced cytokine expression. These metabolites represent potential biomarkers for PsA risk in Ps patients.

Abstract Number: 1801

The Effect of Ixekizumab versus Adalimumab on Individual Components of the ACR Composite Score, with and Without Concomitant Methotrexate or Other Conventional Synthetic DMARDs at 52 Weeks in Patients with Psoriatic Arthritis

Elaine Husni[1], Sona Kamat[2], Keri Stenger[3], Rebecca Bolce[3], Thorsten Holzkaemper[4], Cameron Helt[3], So Young Park[3], Jeffrey Lisse[5] and Luca Idolazzi[6], [1]Cleveland Clinic, Cleveland, OH, [2]St Louis University, Saint Louis, MO, [3]Eli Lilly and Company, Indianapolis, IN, [4]Eli Lilly and Company, Bad Homburg, Germany, [5]Eli Lilly and Company, Tucson, AZ, [6]University of Verona, Verona, Italy

SESSION INFORMATION

Session Date: Tuesday, November 9, 2021

Session Title: Spondyloarthritis Including PsA – Treatment Poster III: Psoriatic Arthritis II (1801–1835)

Session Type: Poster Session D

Session Time: 8:30AM–10:30AM

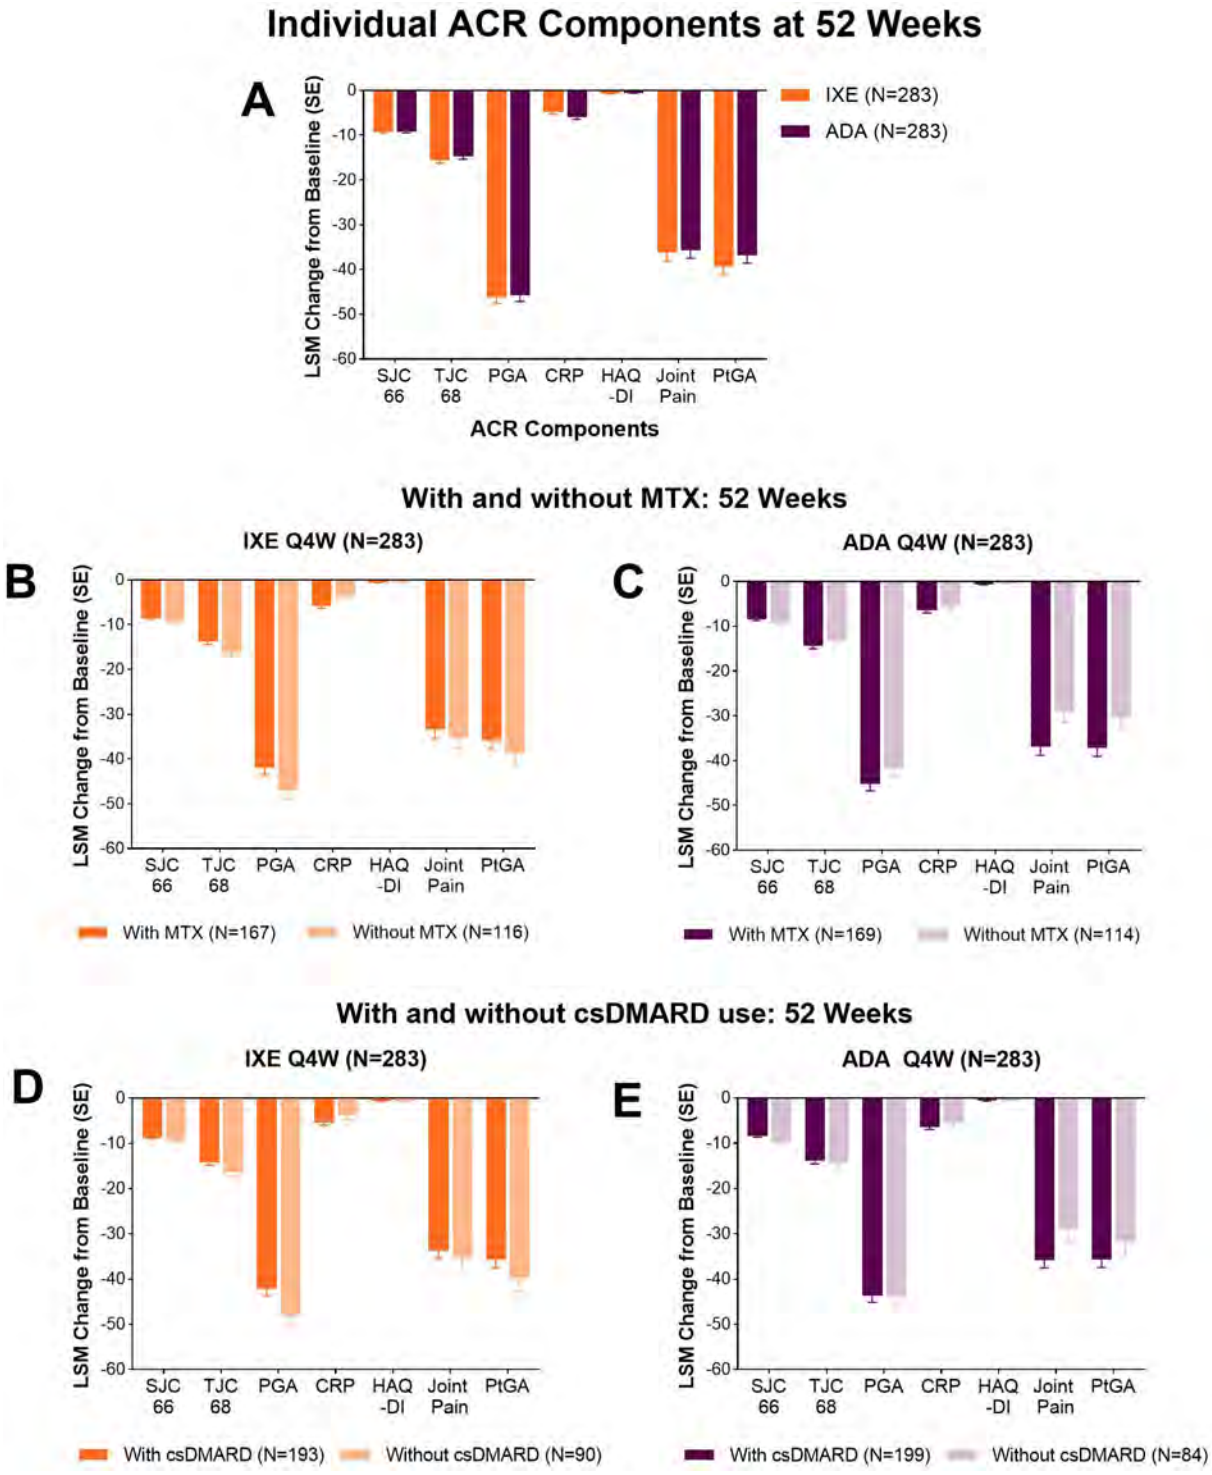
Background/Purpose: It is important to understand how to select among the multiple treatment options for active psoriatic arthritis (PsA). Since individual patient domains may influence treatment choice, it is useful to evaluate individual American College of Rheumatology (ACR) components in large trials. SPIRIT-H2H showed superiority of ixekizumab (IXE) over adalimumab (ADA) in patients with PsA and inadequate response (IR) to conventional synthetic disease modifying antirheumatic drugs (csDMARDs) [1]. This analysis describes the effect of IXE and ADA on individual ACR components at week (Wk) 52, with and without concomitant methotrexate (MTX) and csDMARDs.

Methods: Patients from SPIRIT-H2H (NCT03151551, 52 Wk randomized multicenter study) who met Classification Criteria for Psoriatic Arthritis (CASPAR) (N=566), were randomized (1:1, stratified by baseline concomitant csDMARDs

Table. Baseline demographics and disease characteristics for patients treated with IXE or ADA in the ITT population.

	ITT Population	
	IXE Q4W (N=283)	ADA Q2W (N=283)
Age (years)	47.5 (12.0)	48.3 (12.3)
Female, n (%)	121 (42.8)	133 (47.0)
Disease Duration (years)	5.9 (6.4)	6.6 (7.4)
SJC66	10.1 (7.5)	10.7 (8.1)
TJC68	19.1 (12.7)	21.3 (15.4)
PGA	58.9 (17.5)	59.4 (18.2)
CRP	9.8 (13.7)	10.5 (19.3)
HAQ-DI	1.2 (0.6)	1.3 (0.7)
Joint Pain	59.7 (21.9)	62.4 (21.1)
PtGA	62.4 (20.3)	65.2 (20.7)

Data presented as mean (SD) unless otherwise specified. Abbreviations: ADA, adalimumab; CRP, C-reactive protein; HAQ-DI, health assessment questionnaire disability index; ITT, intent-to-treat; IXE, ixekizumab; PGA, physicians' global assessment, PtGA, patients global assessment; Q2W, every two weeks; Q4W, every four weeks; SJC, swollen joint count; TJC, tender joint count.



Change from baseline in the individual components of the ACR composite score at week 52 in patients treated with IXE or ADA (A) in the ITT population, (B and C) with and without MTX use at baseline and (D and E) with and without csDMARD use at baseline. Data presented as least square mean (LSM) change from baseline (mBOCF) + SE. Abbreviations: ACR, American College of Rheumatology; ADA, adalimumab; CRP, C-reactive protein; csDMARD, conventional synthetic disease modifying antirheumatic drug; HAQ-DI, health assessment questionnaire disability index; ITT, intent-to-treat; IXE, ixekizumab; mBOCF, modified baseline observation carried forward; MTX, methotrexate; PGA, physicians global assessment, PtGA, patients global assessment; Q2W, every two weeks; Q4W, every four weeks; SJC, swollen joint count; TJC, tender joint count.

and moderate-to-severe PsO) to IXE or ADA on-label PsA or PsO dosing. Patients were bDMARD-naïve with IR to csDMARDs, active PsA (≥3 tender joints [TJC] and ≥3 swollen joints [SJC]) and had psoriasis (PsO) ≥3% BSA (body surface area). Patient's Global Assessment (PtGA) and Physicians Global Assessment (PGA), Health Assessment Questionnaire-Disability Index (HAQ-DI), and joint pain were assessed by visual analog scale, and TJC and SJC as well as C-reactive protein (CRP) were analyzed. All post-hoc analyses were performed on the intent-to-treat (ITT) population. Change from baseline (CFB) in individual ACR components was analyzed using an Analysis of Covariance (ANCOVA) model, for overall as well as with and without concomitant therapies (e.g., MTX or csDMARD). Least square mean (LSM) and standard error (SE) are presented. Missing data were imputed using modified baseline observation carried forward (mBOCF). Nine patients with active PsO and BSA ≥3% were assessed as Psoriasis Area and Severity Index (PASI)=0 at baseline, a medical inconsistency that was resolved using medical judgment. These patients were considered PASI100 responders if PASI=0 and BSA=0 at post baseline visits.

Results: A total of 566 patients received either IXE (N=283) or ADA (N=283). Baseline values for individual ACR components were balanced between IXE and ADA (Table). At Wk 52, IXE demonstrated efficacy across all individual ACR components in the ITT population, specifically in PGA, PtGA and Joint Pain; ADA also demonstrated numerical efficacy (Fig. A). Improvements from baseline for IXE were observed across ACR components, with or without MTX or csDMARD (Fig. B-E). The effect of MTX (with or without) was notably different between IXE and ADA in TJC68, PGA, Joint Pain, and PtGA.

Conclusion: In this analysis, there was improvement with IXE in all components of the ACR composite score at Wk 52, irrespective of MTX or csDMARD use (with or without). In the ITT population, IXE showed comparable efficacy to ADA at Wk 52 in all components of ACR, demonstrating improvement across musculoskeletal domains. These results may provide further confidence of the clinical benefits of ixekizumab across musculoskeletal domains in patients with PsA, regardless of MTX or csDMARD use.

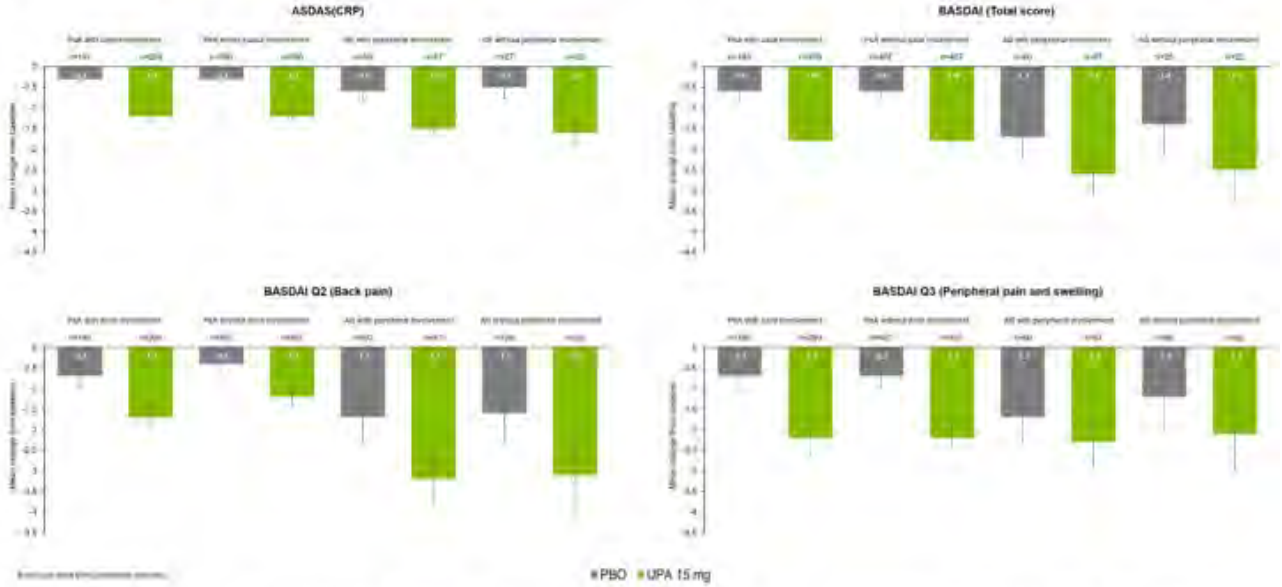
SESSION INFORMATION

Session Date: Tuesday, November 9, 2021
Session Title: Spondyloarthritis Including PsA – Treatment Poster III: Psoriatic Arthritis II (1801–1835)
Session Type: Poster Session D
Session Time: 8:30AM–10:30AM

Background/Purpose: Axial, peripheral, and other disease manifestations often overlap between psoriatic arthritis (PsA) and ankylosing spondylitis (AS). Upadacitinib (UPA) is an oral Janus kinase inhibitor under evaluation for the treatment of PsA and AS. The objective of this analysis was to describe and compare baseline characteristics and UPA efficacy across 4 subgroups of patients (pts) from clinical trials: active PsA (with/without axial involvement) and active AS (with/without peripheral involvement).

Methods: Baseline characteristics and efficacy of UPA in reducing axial and peripheral signs and symptoms were assessed via an integrated analysis across the 4 pt subgroups from the SELECT-PsA 1,[1] SELECT-PsA 2,[2] and SELECT-AXIS[3] studies. Analyses of baseline characteristics included pts in the UPA 15 mg once daily (QD), UPA 30 mg QD, and placebo (PBO) groups; efficacy analyses included pts in the UPA 15 mg QD group only. Axial involvement in PsA (axial PsA) was determined by investigator assessment. Peripheral involvement in AS was defined based on presence of tender or swollen joints (TJC68 >0 or SJC66 >0), or presence of enthesitis at baseline (Maastricht Ankylosing Spondylitis Enthesitis Score >0).

Figure Mean change from baseline (95% confidence interval) in ASDAS(CRP), BASDAI, back pain, and peripheral pain and swelling at Week 12, by patient subgroup (UPA 15 mg group)



AS, ankylosing spondylitis; ASDAS(CRP), Ankylosing Spondylitis Disease Activity Score with C-reactive protein; BASDAI, Bath Ankylosing Spondylitis Disease Activity Index; PBO, placebo; PsA, psoriatic arthritis; Q, question; UPA, upadacitinib

Results: 2102 pts (UPA 15 mg; UPA 30 mg; PBO) were evaluated across the 4 subgroups (PsA [with/without axial involvement]: 626/1289; AS [with/without peripheral involvement]: 135/52). 33% of pts with PsA had axial PsA; 72% of pts with AS had peripheral symptoms. Pts with axial PsA had higher peripheral joint (TJC68 and SJC66) and skin (psoriasis) burden than pts with AS with peripheral involvement ($p< 0.0001$). Pts with AS with peripheral involvement had significantly greater overall pain (pt's assessment of pain; $p=0.0002$) and back pain (BASDAI Q2; $p< 0.0001$) scores, and higher total BASDAI ($p=0.0076$) and ASDAS ($p=0.0351$) scores than pts with axial PsA; physician's global assessment of disease activity, and peripheral pain and tenderness (BASDAI Q3 and Q4) were numerically similar for these 2 subgroups (**Table**). The efficacy of UPA 15 mg (measured using ASDAS and BASDAI) was generally consistent across the 4 pt subgroups regardless of peripheral or axial involvement (**Figure**).

Conclusion: Pts with PsA with axial involvement and pts with active AS showed some differences in baseline characteristics but similar improvements versus placebo with UPA 15 mg QD.

Data presented as percentage (%) of pts. [a]Through W56 for Ph2, W60 for D-1, W112 for D-2; [b]For pts in the PBO group who crossed over to GUS, only data prior to the first administration of GUS are included. [c]For pts in PBO group who crossed over from PBO to GUS, only data on and after first administration of GUS were included; [d]Combined pts treated with GUS Q4W and Q8W (including pts who crossed over from PBO)

ALT, alanine aminotransferase; AST, aspartate aminotransferase; ULN, upper limit of normal

Background/Purpose: Guselkumab (GUS), a targeted IL-23 inhibitor, demonstrated significant improvements in signs and symptoms of psoriatic arthritis (PsA) and a favorable safety profile through week (W) 24 in one Phase (Ph)2[1] and two Ph3 (DISCOVER [D]-1&2)[2-4] randomized controlled trials (RCTs). In this study, we assessed GUS safety by pooling data across the 1-year (Y) Ph2, 1-Y D-1, and 2-Y D-2 RCTs.

Methods: Patients (Pts) with active PsA (≥3% BSA affected by psoriasis in Ph2; ≥3 tender/swollen joints and CRP ≥0.3 mg/dL in Ph2 and D-1; ≥5 tender/swollen joints and CRP ≥0.6 mg/dL in D-2), biologic naïve except 13/149 Ph2 and 118/381 D-1 pts who received prior 1-2 TNF inhibitors (TNFi), were randomized to subcutaneous GUS 100 mg at W0, W4, and every 8 weeks (Q8W) or placebo (PBO) in Ph2 or to GUS 100 mg every 4 weeks (Q4W); GUS 100 mg at W0, W4, Q8W; or PBO in D-1 & D-2. At W24, PBO pts switched to GUS 100 mg Q8W (Ph2) or Q4W (D-1 & D-2). In these pooled post-hoc analyses, adverse events (AEs; number standardized for 100 patient-years of follow-up [PY]),

laboratory investigations (abnormalities classified by National Cancer Institute Common Terminology Criteria for AEs [NCI-CTCAE] grade), and injection site reactions (ISRs) were reported through W56 for the Ph2 trial, W60 for D-1, and W112 for D-2.

Results: Across the 3 RCTs, 1,229 pts with active PsA received GUS 100 mg (725 Q4W, 504 Q8W) and were followed for an average of 1.5 Y, representing 1871 PY. Incidences of AEs, serious AEs, infections, serious infections, discontinuations due to an AE, malignancies, and major adverse cardiovascular events were similar between PBO and GUS through W24. No increased rates were seen with up to 2 Y of GUS, except for a somewhat higher rate of SAEs and serious infections in the GUS 100 mg Q8W group during long-term follow-up, although confidence intervals overlapped with those seen during the PBO-controlled period (Table 1). The majority of GUS-treated pts with elevated aminotransferases and blood bilirubin had NCI-CTCAE Grade 1/2, with very few Grade 3 and no Grade 4, elevations. The proportions of pts with elevated aminotransferases at W24 were somewhat higher in the GUS Q4W vs Q8W/PBO groups; no unexpected increase was observed with longer duration of treatment. Elevations were more common in pts with vs without methotrexate (MTX) use at baseline. The proportions of pts with Grade 1 elevated bilirubin were higher in GUS vs PBO groups; few Grade 2 and no Grade 3/4 elevations were seen (Table 2). ISRs occurred in similar proportions of GUS (1%) and PBO (0.5%) pts at W24, with no disproportional increase with up to 2 Y of GUS.

Conclusion: In pts with active PsA pooled across 3 RCTs, GUS demonstrated a favorable safety profile through up to 2 Y of treatment; the GUS safety profile in PsA was comparable to that observed through up to 5 Y of GUS in pts with moderate-to-severe psoriasis.[5]

ADA=Adalimumab; BSA=Body surface area; DMARD=Disease-modifying anti-rheumatic drug; NSAID=Non-steroidal anti-inflammatory drug; PASI=Psoriasis area and severity index; TNFi=Tumor necrosis factor inhibitor.

Background/Purpose: Guselkumab (GUS), a human monoclonal antibody that specifically binds to the p19 subunit of IL-23, demonstrated efficacy and a favorable safety profile in active PsA in the Phase (Ph) 2[1] and Ph3 DISCOVER-1&2 trials[2,3] and in moderate-to-severe plaque psoriasis (PsO) in the Ph3 VOYAGE-1&2 trials.[4,5]

Methods: Using pooled safety data through 2 years (yrs) from the PsA trials (N=1229; GUS 100 mg every 4 or 8 weeks [Q4W/Q8W])[1-3] and through 5 yrs from the PsO trials (N=1721; GUS 100 mg Q8W),[4,5] the incidences of serious adverse events (SAEs); gastrointestinal (GI)-related SAEs and other targeted AEs; including candidiasis, uveitis, and opportunistic infections (OIs; e.g., active tuberculosis [TB]) were evaluated. GI-related SAEs were identified using the Medical Dictionary for Regulatory Activities (MedDRA) system-organ class "GI disorders;" OIs, uveitis/iridocyclitis, and candidiasis were classified through medical review of preferred terms and/or a specified MedDRA search strategy. Patients (pts) with a history of IBD were not excluded in the PsA/PsO trials. Rates of overall SAEs, GI-related SAEs, and other targeted AEs were calculated as the number of events per 100 pt-yrs of follow-up (PY), along with 95% confidence intervals (CI). Pooled safety data are presented for the placebo (PBO)-controlled periods (W0-16: PsO trials; W0-24: PsA trials) and active treatment periods through 2 yrs in PsA trials (W56: Ph2; W60: DISCOVER-1; W112: DISCOVER-2) and through 5 yrs in PsO trials (W264: VOYAGE-1&2). Maximum duration of exposure was W100 for the PsA trials and W252 for the PsO trials.

Note: In PsA Ph2, data after early escape at W16 were excluded from analyses. AEs are coded using MedDRA Version 23.1.

[a]For pts in PBO group who changed treatment from PBO to GUS due to cross-over or inadvertently, only data on and after first administration of GUS were included in this group. Data prior to the first administration of GUS were not included in this group.

[b]PBO crossover pts were included in the GUS column after crossover to GUS.

[c]Events which occurred prior to GUS administration (ADA events) were excluded from the analyses. Only includes pts who were randomized to ADA at W0 and crossed over to receive GUS at or after W52 for PsO VOYAGE-1 & W28 for PsO VOYAGE-2.

[d]CIs based on exact method assuming that the observed number of events follows a Poisson distribution.

[e]For number of the said events, events are counted only once if events were started from same date with same MedDRA Preferred Terms.

[f]Search criteria: MedDRA SOC "GI Disorders."

[g]Herpes zoster disseminated, fungal oesophagitis, and meningitis listeria (1 report of each); search criteria: medical review for PsO VOYAGE-1 & VOYAGE-2, MedDRA SMQ for PsA DISCOVER-1 & DISCOVER-2.

[h]Candida Infections search criteria: MedDRA high level term "Candida infections."

[i]Non-pathogen specific fungal infections, suspicious for candida as defined by diagnosis and location; search criteria included MedDRA Preferred Terms of "fungal balanitis," "genital infection fungal," "vulvovaginal mycotic infection," "oral fungal infection," "tongue fungal infection," "oropharyngitis fungal," "fungal oesophagitis."

ADA=Adalimumab; SMQ=Standard MedDRA query; SOC=System organ class

Results: The PsA and PsO populations had comparable mean age and BMI. Prior or concomitant medication use reflected standard of care and study entry criteria (**Table 1**). Incidence rates of SAEs and GI-related SAEs were generally similar between GUS- and PBO-treated pts during the PBO-controlled periods, and between PsA pts receiving GUS Q4W or Q8W for up to 2 yrs and PsO pts receiving GUS Q8W for up to 5 yrs (**Tables 2,3**). Rates of other targeted AEs of interest were low in GUS-treated PsA/PsO pts. OIs did not occur in PsO pts and were infrequent in PsA pts (1 case each of herpes zoster disseminated, fungal oesophagitis, meningitis listeria). Candidal infections were reported infrequently and were non-serious (**Tables 2,3**). Iridocyclitis was reported in 1 PBO-treated PsA pt and 1 GUS Q8W-treated PsA pt. No cases of exacerbations or new onset of IBD were reported in GUS-treated PsA/PsO pts. No cases of active TB occurred in GUS-treated PsA/PsO pts.

Conclusion: Incidence rates of SAEs; GI-related SAEs; and AEs of interest including candidiasis, uveitis, and OIs were low, or no cases were reported. No new safety concerns were identified with GUS treatment through 2 yrs and 5 yrs of follow-up in the pooled PsA and PsO trials, respectively, supporting a durable and favorable GUS safety profile consistent between pts with active PsA and moderate-to-severe PsO.

Session Type: Poster Session D

Session Time: 8:30AM–10:30AM

Table. Observed erosion, joint space narrowing, and total PsA-modified vdH-S scores through W100 of DISCOVER-2

	GUS Q4W			GUS Q8W			PBO→GUS Q4W		
Baseline PsA-modified vdH-S score, n	221			228			215		
Erosion	14.2 (23.3)			12.0 (21.9)			12.1 (21.9)		
Joint space narrowing	13.8 (21.8)			11.9 (19.5)			13.5 (21.6)		
Total	28.0 (43.6)			23.9 (40.4)			25.6 (42.4)		
Mean (SD) change in PsA-modified vdH-S score	**W0-24 N=221**	**W24-52 N=221**	**W52-100 N=211**	**W0-24 N=228**	**W24-52 N=228**	**W52-100 N=216**	**W0-24 N=215**	**W24-52 N=213**	**W52-100 N=202**
Erosion	0.27 (1.91)	0.36 (1.77)	0.45 (2.90)	0.51 (1.96)	0.20 (1.24)	0.26 (1.75)	0.73 (2.20)	0.25 (1.85)	0.09 (1.98)
Joint space narrowing	0.21 (1.17)	0.21 (1.11)	0.30 (1.32)	0.17 (0.69)	0.12 (0.66)	0.20 (0.92)	0.39 (1.72)	0.09 (1.11)	0.04 (1.90)
Total	0.48 (2.70)	0.57 (2.66)	0.75 (4.02)	0.68 (2.36)	0.31 (1.57)	0.46 (2.42)	1.12 (3.80)	0.34 (2.79)	0.13 (3.74)

Data presented as mean (standard deviation).

Background/Purpose: Guselkumab (GUS), an IL-23p19-subunit inhibitor, is efficacious in treating patients (pts) with psoriasis and psoriatic arthritis (PsA). In the Phase 3, double-blind, placebo (PBO)-controlled DISCOVER-2 study, GUS 100mg given every 4 or 8 weeks (Q4W or Q8W) significantly improved joint and skin symptoms; GUS-treated pts had smaller mean changes in radiographic progression vs. placebo (PBO) at W24.[1] Clinical response rates and a favorable safety profile were durable through W100.[2, 3] We now report details of radiographic assessments comprising the third reading session through W100 of DISCOVER-2, including relationships between radiographic changes and measures of clinical outcomes.

Methods: Biologic-naïve adults with active PsA (≥5 swollen joint count + ≥5 tender joint count; CRP ≥0.6 mg/dL) were randomized (1:1:1) to GUS 100mg Q4W; GUS 100 mg at W0, W4, then Q8W; or PBO with crossover to GUS 100 mg Q4W (PBO→Q4W) at W24, all through W100. Radiographic Reading Session 3 included assessments at W0, W24, W52, and W100 (or at discontinuation after W52) from pts continuing study treatment at W52; readers were blinded to treatment group and timepoint. Observed mean changes in total PsA-modified van der Heijde-Sharp (vdH-S), joint space narrowing (JSN), and erosion scores are reported. Changes in total vdH-S scores from W0-100 were deter-

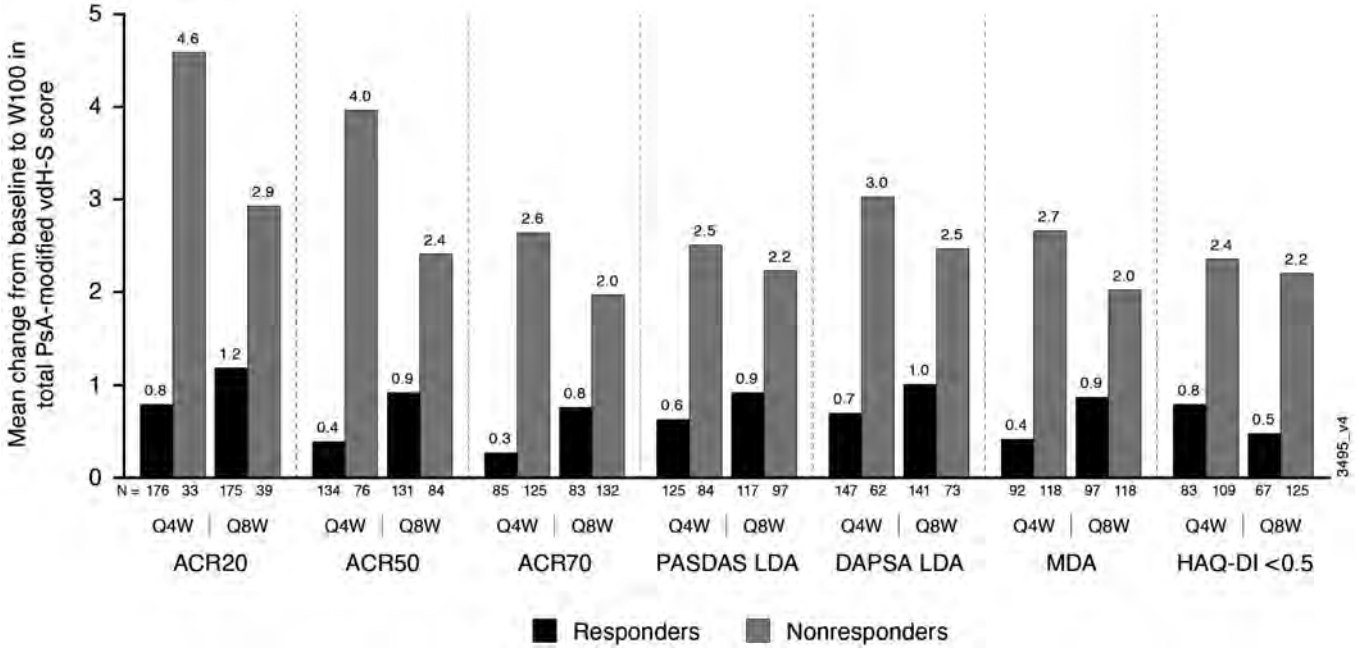

Figure. Mean changes in PsA-modified total vdH-S score from W0-100 for patients who did and did not achieve select clinical responses at W100.

mined in pts who did and did not achieve clinical response at W100, assessed by ACR20/50/70, low disease activity (LDA) based on Disease Activity in Psoriatic Arthritis score (DAPSA; ≤14) or Psoriatic Arthritis Disease Activity Score (PASDAS; ≤3.2), minimal disease activity (MDA), and normalized HAQ-DI score (< 0.5).

Results: Of 739 enrolled and treated pts, 664 had evaluable data from Reading Session 3; 629 pts had evaluable data from W52-100. Mean total baseline vdH-S scores were 28.0 (Q4W), 23.9 (Q8W), and 25.6 (PBOàQ4W). Mean progression of joint damage from W0-24 was numerically lower in GUS- than PBO-treated pts for erosion, JSN, and total vdH-S scores (Table), consistent with the results from Reading Session 1.[1] Mean changes in radiographic scores from W52-100 indicated low rates of radiographic progression across GUS groups. Among GUS-randomized pts, mean changes in vdH-S score from W0-100 were numerically lower for pts achieving clinical response assessed using a variety of outcome measures (ACR20/50/70, DAPSA LDA, PASDAS LDA, MDA, and HAQ-DI < 0.5) when compared with pts not achieving response at W100 (Figure).

Conclusion: In a population of biologic-naïve pts with active PsA enriched for greater risk of radiographic progression, GUS 100 mg (Q4W or Q8W) was associated with low rates of radiographic progression through 2 years. Pts achieving clinical response across several global measures of disease activity or normalized physical function at W100 had lower mean changes in total PsA-modified vdH-S scores compared with nonresponders.

SESSION INFORMATION

Session Date: Tuesday, November 9, 2021

Session Title: Spondyloarthritis Including PsA – Treatment Poster III: Psoriatic Arthritis II (1801–1835)

Session Type: Poster Session D

Session Time: 8:30AM–10:30AM

Background/Purpose: Tumor necrosis factor inhibitors (TNFi) are frequently chosen as the first biologic therapy for patients (pts) with PsA, though a sizeable proportion of pts have an inadequate response (IR), and some may also have intolerance. Guselkumab (GUS), a human mAb that targets the IL-23 p19 subunit, provides an alternative mechanism of action by which to treat PsA. In the Phase 3 (Ph3) DISCOVER-1 study of GUS in active PsA, GUS Q4W and Q8W clinical response rates were generally consistent between TNFi-naïve (263 pts) and TNFi-experienced (118 pts) cohorts. In the TNFi-experienced cohort and the limited number of DISCOVER-1 pts with IR to their prior TNFi (N=44), ACR 50% improvement (ACR50) and ACR70 response rates at W24 were numerically higher in GUS Q4W- than Q8W-treated pts.[1] Seeking to further investigate whether GUS Q4W could provide incremental benefit to some TNFi-IR PsA pts, we analyzed the existing DISCOVER-1 dataset to facilitate the design of a new clinical trial.

Table 1. Clinical efficacy at W24 among DISCOVER-1 TNFi-experienced pts

	Placebo	GUS Q8W	GUS Q4W
ACR20	17.9% (7/39)	56.1% (23/41)	57.9% (22/38)
ACR50	5.1% (2/39)	26.8% (11/41)	34.2% (13/38)
ACR70	2.6% (1/39)	2.4% (1/41)	21.1% (8/38)
MDA	2.6% (1/39)	17.1% (7/41)	26.3% (10/38)
IGA 0/1[a]	7.7% (2/26)	48.3% (14/29)	67.9% (19/28)

[a]IGA score of 0 (clear) or 1 (almost clear) among pts with ≥3% BSA of psoriatic involvement and an IGA score ≥2 (mild-to-severe psoriasis) at baseline.

Table 2. Power calculations for SOLSTICE primary endpoint (ACR20 response rate at W24)

Historical Trial Data	ACR20 response rate		Effect size	Power (α=0.05)[b]
	Placebo	GUS Q8W/Q4W		
DISCOVER-1[a]	22%	52% Q8W	30%	>99%
		59% Q4W	37%	>99%

[a]Based on the entirety of the DISCOVER-1 study population (N=381). [b]Based on N=150 per study group (1:1:1 randomization) and 2-sided significance of 0.05 utilizing a Chi-square test to compare treatments.

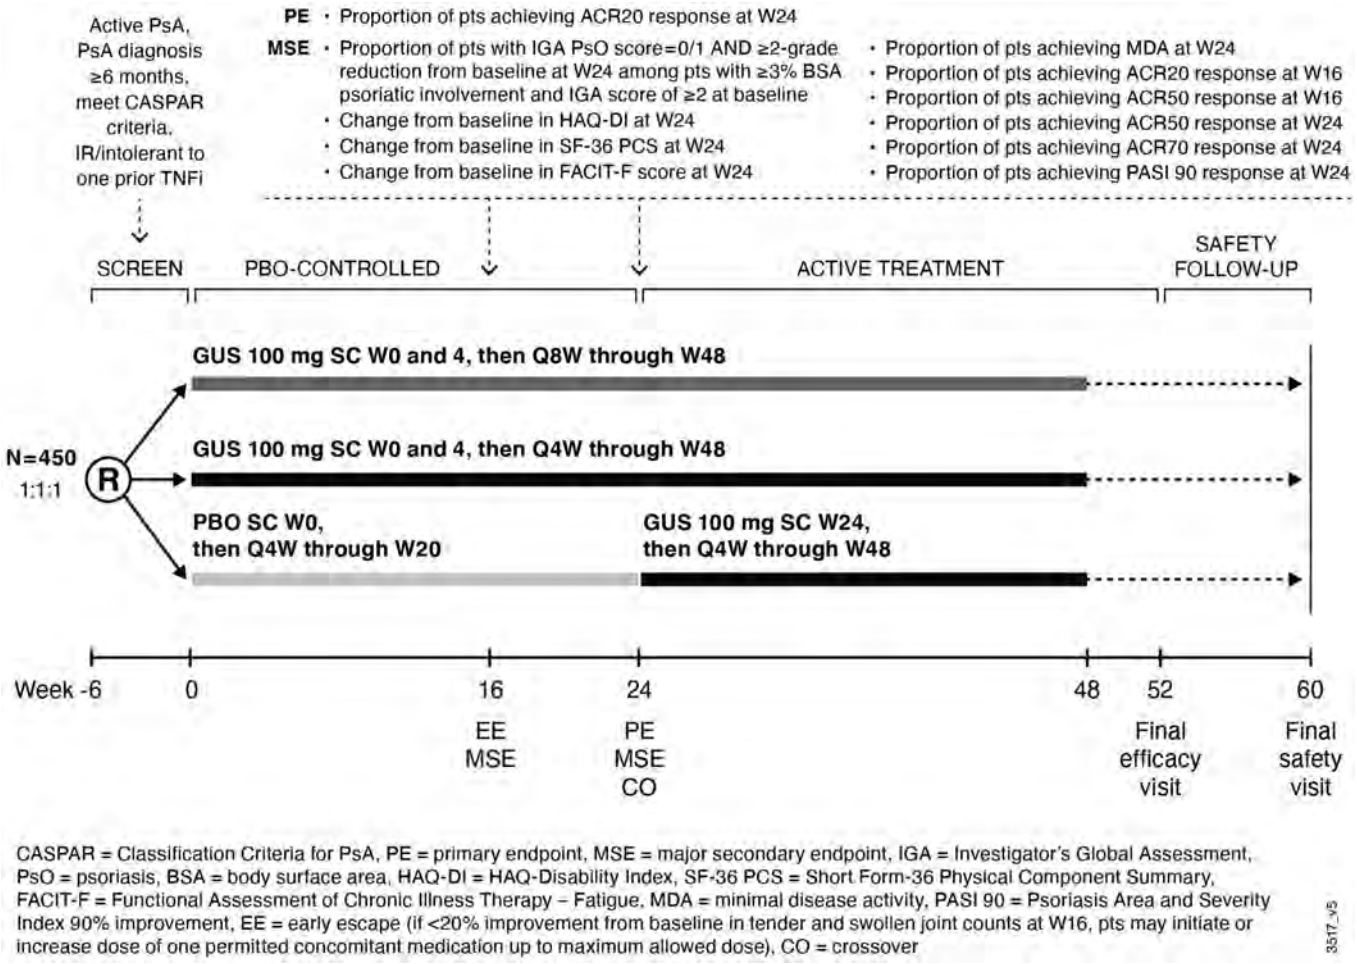

Figure. SOLSTICE study design.

Methods: Study feasibility assessments included comparison of key efficacy endpoints by treatment group at W24 among TNFi-experienced pts receiving GUS Q8W and Q4W in DISCOVER-1. Results from the DISCOVER-1 study also informed sample size power calculations for a primary endpoint of ACR20 response at W24 in a future trial in a TNFi-IR PsA pt population.

Results: Comparison of several efficacy endpoints (ACR70 response, minimal disease activity [MDA], Investigator's Global Assessment [IGA] of psoriasis 0/1 response) across treatment group in the TNFi-experienced DISCOVER-1 cohort supports a potential dose response, with more frequent GUS administration eliciting numerically higher response rates (Table 1). A similar trend was observed for ACR20/50/70 responses in the smaller TNFi-IR population[1], though these findings should be interpreted with caution due to limited sample size. ACR20 response rates at W24 of DISCOVER-1 were employed to estimate sample size requirements for a new study. Assuming comparable rates of GUS treatment effect seen in DISCOVER-1, a sample size of 150 randomized pts per group for PBO, GUS Q8W, and GUS Q4W would provide >90% power to detect a significant difference between each GUS group and PBO for ACR20 response at W24 (Table 2). Based on these findings, a new Ph3b, multicenter, randomized, double-blind, PBO-controlled study, SOLSTICE, was designed to further evaluate the efficacy and safety of GUS in approximately 450 pts with active PsA who had IR to one prior TNFi, and to investigate the effect of GUS dosing interval in this important cohort of pts with PsA (Fig).

Conclusion: PsA pts with TNFi-IR are typically difficult to treat. Overall data from the pivotal DISCOVER-1 trial of GUS in pts with active PsA showed consistent clinical response between doses and between TNFi-naïve and TNFi-

experienced pts. Analyses based on limited numbers of TNFi-experienced pts from DISCOVER-1 demonstrated potential incremental benefit for achievement of higher response criteria with more frequent dosing in some TNFi-IR pts. SOLSTICE, a Ph3b, randomized, placebo-controlled trial, will test this hypothesis.

SD=standard deviation
*Normal range: <0.3 mg/dL
†Determined by Pearson correlation coefficient; p-values derived from hypothesis tests of correlation ρ=0 (ie, no correlation)
¥p<0.0001 at each time point

Background/Purpose: Fatigue is a key patient (pt)-reported symptom of psoriatic arthritis (PsA).[1,2] Utilizing data from the Phase 3 DISCOVER-1 (D1) and -2 (D2) studies, these post hoc analyses explored: 1) correlation of fatigue with systemic inflammation (CRP) and hemoglobin (Hgb); 2) relationship between improvements in fatigue and clinical outcomes with guselkumab (GUS), a selective IL-23p19 inhibitor.

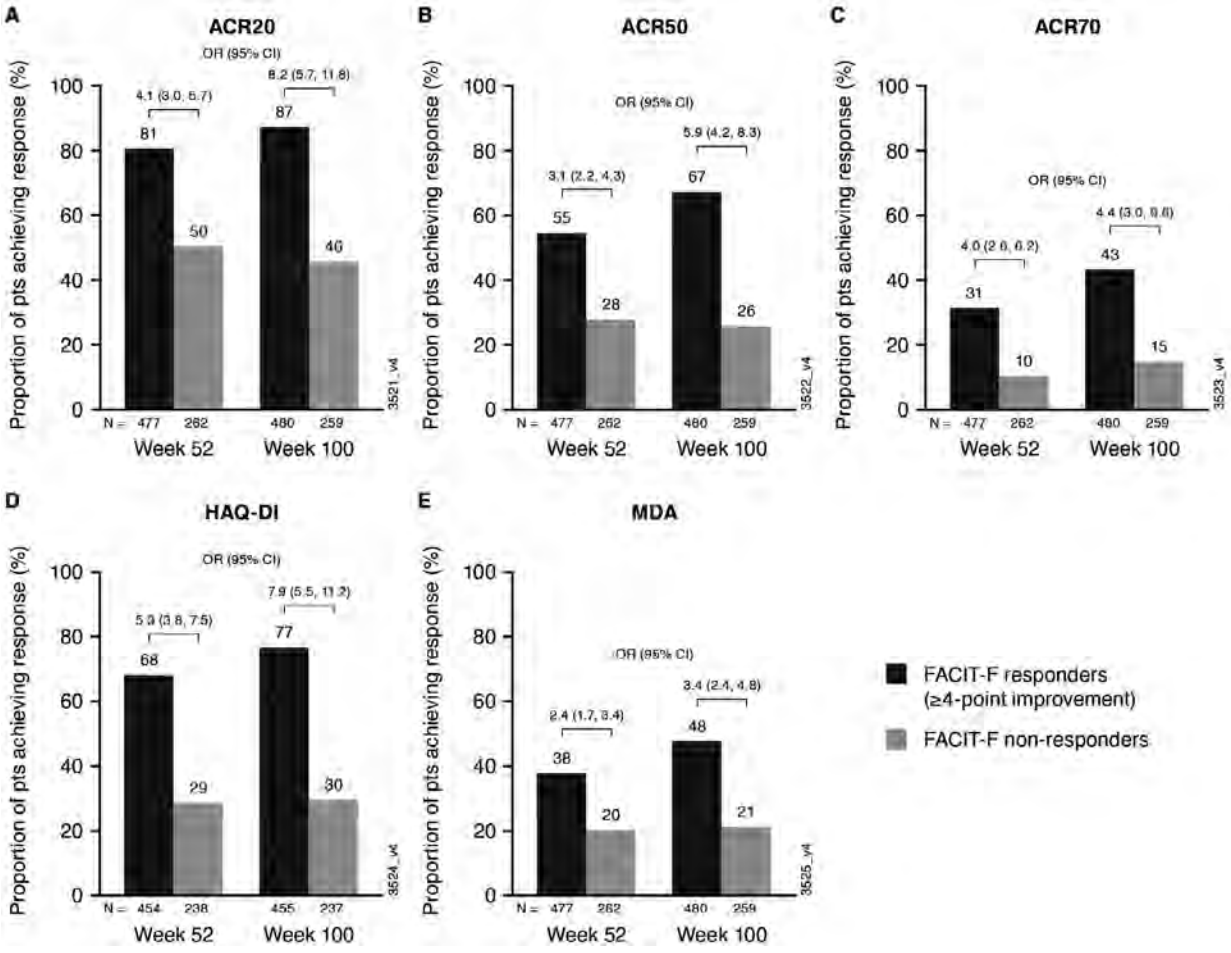

Figure. Achievement of ACR20/50/70, HAQ-DI, and MDA Responses by FACIT-F Response Status Among GUS-treated Patients at W52 and W100 of DISCOVER-2.

Methods: Pts with active PsA despite standard therapies in D1 (swollen joint count [SJC] ≥3, tender joint count [TJC] ≥3, CRP ≥0.3 mg/dL) and D2 (SJC ≥5, TJC ≥5, CRP ≥0.6 mg/dL) were randomized 1:1:1 to GUS 100 mg Q4W; GUS 100 mg at W0, W4, then Q8W; or placebo (PBO) with crossover to GUS 100 mg Q4W at W24 (PBOàQ4W). Fatigue was evaluated using the Functional Assessment of Chronic Illness Therapy Fatigue (FACIT-F) scale (0–52 [higher score=less fatigue]; clinically meaningful improvement ≥4 points). FACIT-F scores, as well as their correlation (Pearson) with CRP and Hgb were determined in pts with anemia (Hgb < 13.5 [males] or < 12 [females] g/dL) and without anemia through W24. Relationships between FACIT-F score (outcome) and CRP/Hgb (predictors, along with visit) were assessed via a mixed model for repeated measures (MMRM). Associations between FACIT-F response in GUS-treated pts (Q4W+Q8W+PBOàQ4W) and achievement of American College of Rheumatology (ACR) 20/50/70, Health Assessment Questionnaire Disability Index (HAQ-DI), and Minimal Disease Activity (MDA) responses were evaluated at W52 for D1/D2 and at W100 for D2 (nonresponder imputation).

Results: In pooled analyses (N=1120), mean baseline (BL) FACIT-F scores for 583 males (31.3) and 537 females (28.5) were [3]). Utilizing all pts pooled across treatment groups, significant correlations between FACIT-F scores and mean CRP/Hgb levels were seen at each visit (Table). Through W24, anemic pts had numerically lower FACIT-F scores (28.7-33.3) vs non-anemic pts (30.3-36.3). Among 112 pts with anemia at BL but not at W24, mean FACITF scores improved from 31 (W0) to 37 (W24). MMRM results showed that CRP and Hgb levels were statistically significant predictors of FACIT-F (each p< 0.0001; data not shown). GUS-treated pts achieving ≥4-point improvement in FACIT-F score at W52 (52-62% of 381 pts in D1 and 64-66% of 739 bio-naïve pts in D2) were more likely to also achieve ACR20/50/70, HAQ-DI, and MDA responses than FACIT-F nonresponders (D1 data not shown; D2 Figure). With continued GUS through W100, 65% of D2 pts with FACIT-F response showed an even stronger propensity than FACIT-F nonresponders for achieving ACR20 (odds ratio [OR]=8.2 [5.7, 11.8]), ACR50 (OR=5.9 [4.2, 8.3), ACR70 (OR=4.4 [3.0, 6.6]), HAQ-DI (OR=7.9 [5.5, 11.2]), and MDA (OR=3.4 [2.4, 4.8]) responses vs FACIT-F nonresponders (Figure).

Conclusion: In pts with active PsA, systemic inflammation and Hgb levels were key predictors of FACIT-F scores. FACIT-F responders were more likely to achieve favorable clinical outcomes through up to 2 years of GUS.

SESSION INFORMATION

Session Date: Tuesday, November 9, 2021

Session Title: Spondyloarthritis Including PsA – Treatment Poster III: Psoriatic Arthritis II (1801–1835)

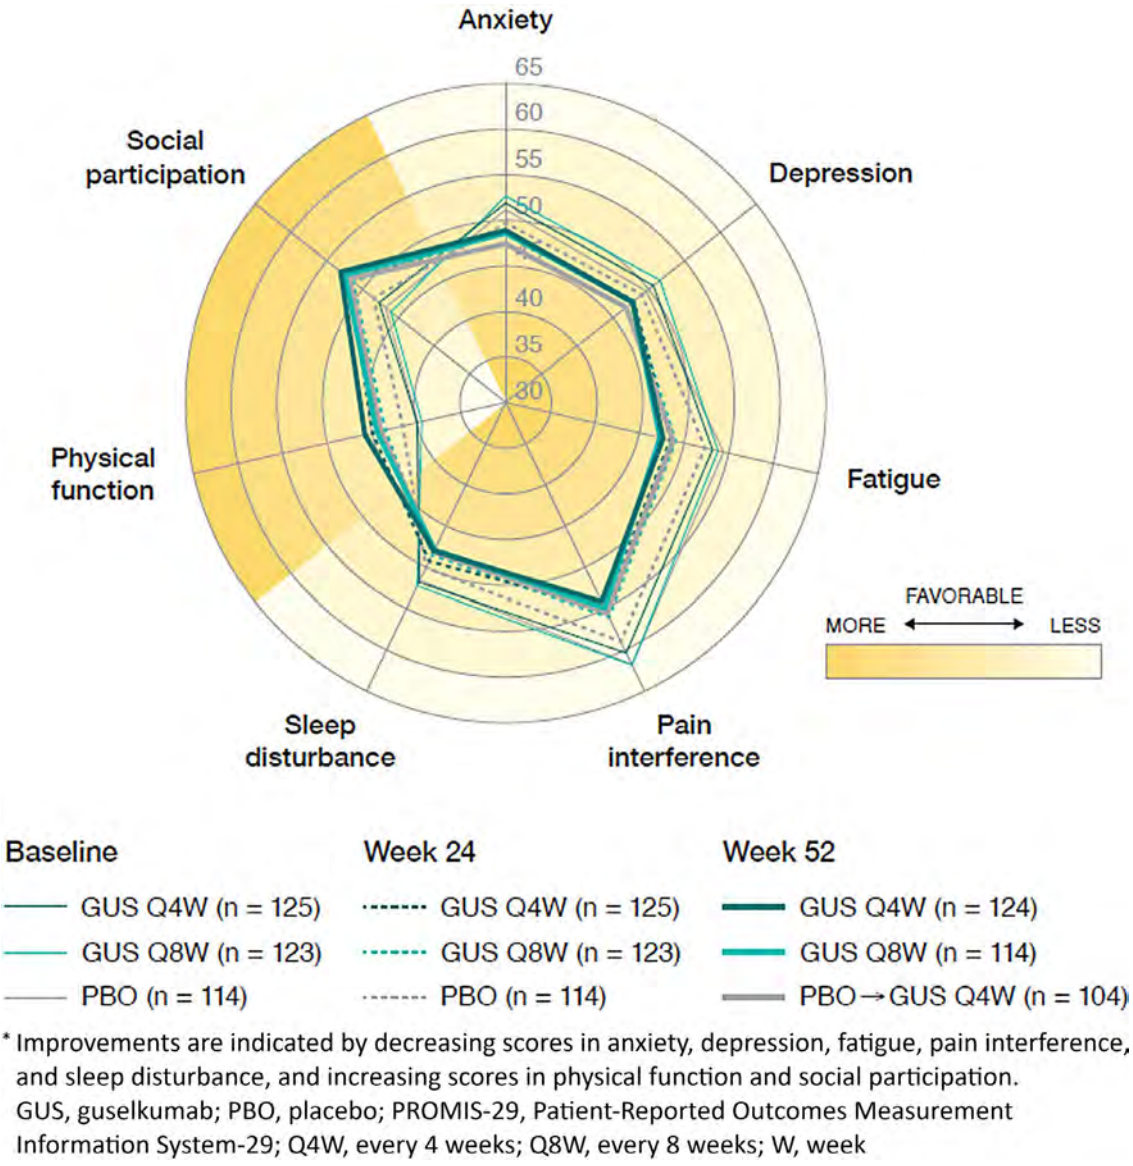
Session Type: Poster Session D

Session Time: 8:30AM–10:30AM

Background/Purpose: In the DISCOVER-1 study, the anti-interleukin-23p19-subunit monoclonal antibody guselkumab (GUS) demonstrated robust efficacy across joint and skin clinical manifestations of psoriatic arthritis (PsA).[1] Patients with PsA also experience a broad range of symptoms that negatively impact health-related quality of life (eg, pain, fatigue, anxiety, depression, sleep disturbance, poor physical function).[2] This study assessed the treatment effect of GUS on general health outcomes in patients with PsA in the DISCOVER-1 trial through Week (W) 52 using the Patient-Reported Outcomes Measurement Information System-29 (PROMIS-29) instrument.

Methods: Patients with active PsA (≥3 swollen + ≥3 tender joints; C-reactive protein ≥0.3 mg/dL) and inadequate response to standard conventional therapies were randomized 1:1:1 to GUS 100 mg every 4 weeks (Q4W); GUS 100 mg at W0, W4, then Q8W; or placebo (PBO). PBO patients switched to GUS 100 mg Q4W at W24. PROMIS-29 contains 4 items for each of 7 domains (anxiety, depression, fatigue, pain interference, physical function, sleep disturbance, social participation) and 1 pain intensity item; 28 items are scored on a 5-point Likert-type scale, and pain intensity is rated from 0 to 10. The raw score of each domain is converted to a standardized T-score, with norms based on a general population mean score=50 and a standard deviation (SD)=10. Higher scores in anxiety, depression, fatigue, pain interference, and sleep disturbance indicate more severe symptoms; higher physical function and social participation scores indicate better health outcomes. Changes ≥5 points (1/2 SD of T-score) are considered clinically meaningful. Analyses were performed using both observed (mean scores/changes, effect sizes) and imputed (clinically meaningful response, whereby change from baseline was set to 0 at W24/52 for patients who had missing data or at W24 for patients who met treatment failure criteria prior to W24).

Results: At baseline, mean PROMIS-29 T-scores for physical function, social participation, sleep disturbance, pain, and fatigue were worse in the 381 PsA patients enrolled in DISCOVER-1 than in the general US population. Across all 7 domains, observed mean PROMIS-29 T-scores showed improvements in GUS-treated patients from baseline to W24 and W52 (Figure). Observed mean changes from baseline to W24 and W52, with calculated effect size, are shown (Table). In all patients, including those with imputed data, significantly higher percentages of patients in both GUS treatment groups vs PBO had ≥5-point improvements in fatigue, pain interference, physical function, sleep



* Improvements are indicated by decreasing scores in anxiety, depression, fatigue, pain interference, and sleep disturbance, and increasing scores in physical function and social participation.
GUS, guselkumab; PBO, placebo; PROMIS-29, Patient-Reported Outcomes Measurement Information System-29; Q4W, every 4 weeks; Q8W, every 8 weeks; W, week

Figure. Mean PROMIS-29 T-scores at Baseline, W24, and W52 (Observed data)*.

disturbance, social participation, and pain intensity domains at W24 (all nominal $p< 0.05$). Mean improvements in PROMIS-29 domains were maintained through W52.

Conclusion: In patients with active PsA, PROMIS-29 results indicate that GUS treatment was associated with clinically meaningful reductions in fatigue and pain and improvement in physical function and social participation, which were maintained through 1 year.

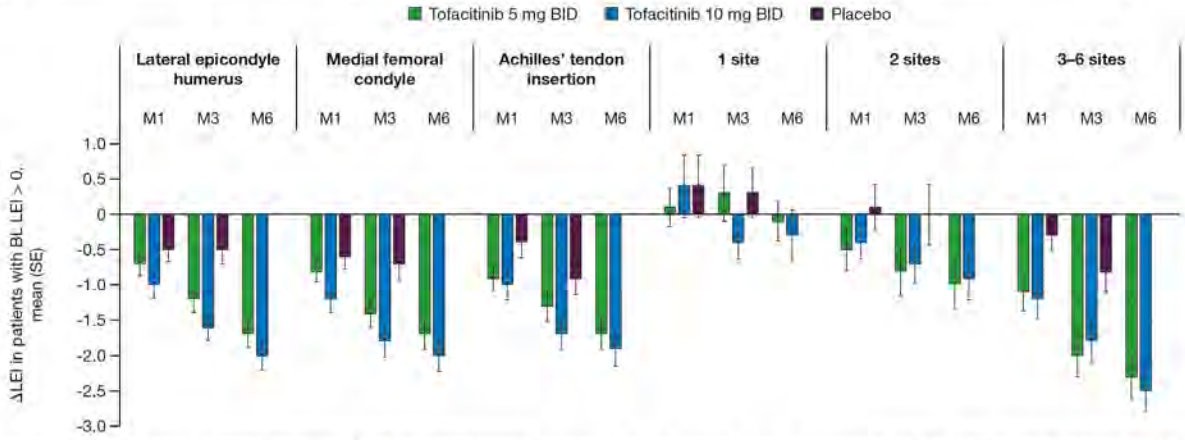
[a]For each site, both left and right sides were assessed and results were combined

[b]Pain was assessed in right and left lateral epicondyle humerus, medial femoral condyle, and Achilles' tendon insertion, and a score was assigned for each location dichotomously, where 0=no pain and 1=pain. LEI is calculated as the sum of those scores, ranging from 0–6, with a score of 6 being the highest enthesitis severity[5]

[c]N1, number of patients with non-missing data and BL LEI > 0

BID, twice daily; BL, baseline; LEI, Leeds Enthesitis Index; N, total number of patients with BL LEI > 0 in that particular location or number of affected sites; n, number of patients applicable for each category; SD, standard deviation

Figure 1. Change from baseline in LEI in patients with baseline LEI > 0, stratified by enthesitis location[a] and severity (pooled data from OPAL Broaden and OPAL Beyond)

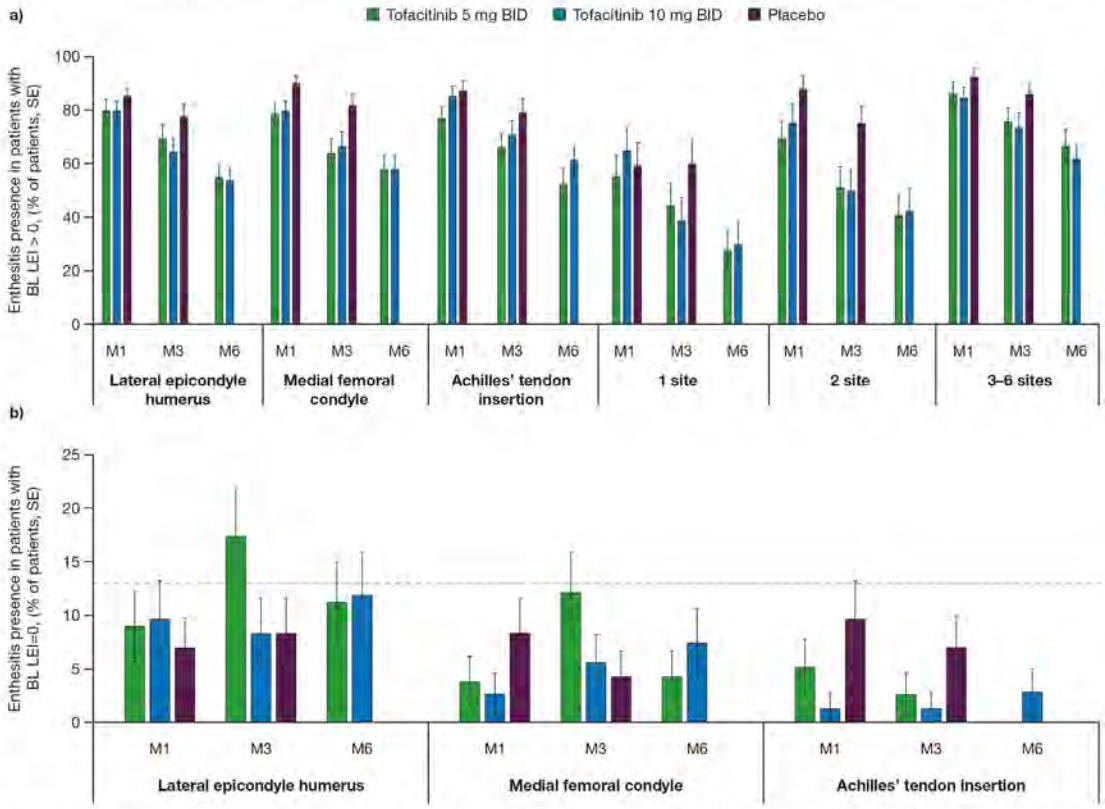


At M1, N ranged from: 99–114 for lateral epicondyle humerus; 88–98 for medial femoral condyle; 80–88 for Achilles' tendon insertion; 15–19 for 1 site; 21–24 for 2 sites; and 44–51 for 3–6 sites. At M3, N ranged from: 96–107 for lateral epicondyle humerus; 83–90 for medial femoral condyle; 71–82 for Achilles' tendon insertion; 15–19 for 1 site; 18–22 for 2 sites; and 41–46 for 3–6 sites. At M6, N ranged from: 95–106 for lateral epicondyle humerus; 88 for both groups for medial femoral condyle; 80 for both groups for Achilles' tendon insertion; 15–19 for 1 site; 19–23 for 2 sites; and 44–46 for 3–6 sites

[a]For each site, both left and right sides were assessed and results were combined

Δ, change from BL; BID, twice daily; BL, baseline; LEI, Leeds Enthesitis Index; M, Month; N, total number of patients with BL LEI > 0 in that particular location or number of affected sites at each visit; SE, standard error

Figure 2. Presence of enthesitis in patients with a) baseline LEI > 0, stratified by location[a] and severity, and b) baseline LEI = 0, by location[a] (pooled data from OPAL Broaden and OPAL Beyond)



Panel a: N is total number of patients with BL LEI > 0 in that particular location or number of affected sites at each visit. At M1, N ranged from: 100–114 for lateral epicondyle humerus; 89–98 for medial femoral condyle; 81–88 for Achilles' tendon insertion; 31–38 for 1 site; 36–46 for 2 sites; and 72–91 for 3–6 sites. At M3, N ranged from: 96–107 for lateral epicondyle humerus; 84–90 for medial femoral condyle; 72–82 for Achilles' tendon insertion; 31–36 for 1 site; 34–43 for 2 sites; and 70–84 for 3–6 sites. At M6, N ranged from: 96–106 for lateral epicondyle humerus; 88 for both groups for medial femoral condyle; 80–82 for Achilles' tendon insertion; 30–36 for 1 site; 31–44 for 2 sites; and 69–84 for 3–6 sites.

Panel b: N is total number of patients with BL LEI=0 at each visit. N ranged from: 72–77 at M1; 71–74 at M3; and 67–71 at M6 for all locations. The dashed line indicates < 13% of patients with BL LEI=0 who had developed enthesitis by M6

[a]For each site, both left and right sides were assessed and results were combined

BID, twice daily; BL, baseline; LEI, Leeds Enthesitis Index; M, Month; SE, standard error

treatment of PsA, has been associated with improvements in enthesitis.[3, 4] Here, we assessed the effects of tofacitinib on enthesitis by location and severity in pts with active PsA.

Methods: This post hoc analysis pooled data from 2 Phase 3 studies: OPAL Broaden (12 months; NCT01877668)[4] and OPAL Beyond (6 months; NCT01882439)[3], in pts with active PsA receiving tofacitinib 5 or 10 mg twice daily (BID) or placebo (up to Month [M]3); pts received a stable background dose of a single conventional synthetic DMARD. Enthesitis at baseline (BL) was defined as Leeds Enthesitis Index (LEI)[5] > 0 (no enthesitis: BL LEI=0); pts were stratified by BL enthesitis location (for each site, both left and right sides were assessed and results were combined) and severity (LEI site counts: 1/2/3–6 sites). Endpoints (assessed at M1/3/6) included change from BL in LEI score and presence of enthesitis. The proportion of pts without BL enthesitis (LEI=0) developing enthesitis at each location was also assessed.

Results: Data were pooled from 479 pts with LEI > 0 and 227 pts with LEI=0 at BL. For pts with BL LEI > 0, demographics and disease characteristics were generally similar across treatment groups (Table). BL LEI scores across all locations were higher in pts treated with tofacitinib 10 mg BID; BL CRP was higher in pts with 2 affected sites treated with tofacitinib 5 mg BID and in pts with 3–6 affected sites treated with tofacitinib 10 mg BID compared with other treatment groups (Table). Improvements in LEI with tofacitinib were observed as early as M1 and maintained up to M6 across all locations and in pts with greater BL enthesitis severity (≥ 2 sites affected; Figure 1). By M3, fewer pts treated with tofacitinib vs placebo had enthesitis, regardless of BL location or severity (Figure 2a). At M6, the proportion of pts with enthesitis at the specified locations was generally reduced by ~ 50%; similar results were reported for pts with lower BL severity (1 or 2 affected sites; Figure 2a). For pts with high BL disease severity (3–6 affected sites), while the proportion of pts with enthesitis decreased over time from BL, enthesitis was present at M6 in about 2/3 of pts (Figure 2a). By M6, < 13% of pts with BL LEI=0 in each treatment group had developed enthesitis (Figure 2b).

Conclusion: In pts with PsA, tofacitinib treatment resulted in improvements in enthesitis, regardless of location or severity. Therefore, tofacitinib is a treatment option for pts with PsA who have enthesitis.

Abstract Number: 1810

Current Medication Practices and Preferences Among Patients with Psoriatic Arthritis (PsA)

Monica Schwartzman[1], Zafir Abutalib[2] and Lisa Mandl[1], [1]Hospital for Special Surgery, New York, NY, [2]The Hospital For Special Surgery, New York, NY

SESSION INFORMATION
Session Date: Tuesday, November 9, 2021
Session Title: Spondyloarthritis Including PsA – Treatment Poster III: Psoriatic Arthritis II (1801–1835)
Session Type: Poster Session D
Session Time: 8:30AM–10:30AM

Background/Purpose: The advent of targeted synthetics and biologics has greatly broadened the options for effective treatment in PsA. Guidelines published in 2018 by the American College of Rheumatology/National Psoriasis Foundation (ACR/NPF) support the use of biologic agents, including as initial therapy. Despite clear directives, there is a paucity of data regarding medication use in real world clinical practice and patient medication preferences.

Methods: This is a cross-sectional survey of Classification Criteria for Psoriatic Arthritis (CASPAR) criteria defined PsA patients recruited from a single academic center PsA registry from June-September 2020. Preferences were ranked on a 5-point Likert scale ranging from 'not at all important' to 'extremely important.'

Results: One hundred thirty-seven(29%) PsA patients responded. Median age was 60 years (IQR 51-70). Median duration of PsA skin symptoms, joint symptoms and PsA diagnosis by a physician was 19 (IQR 10-34), 12 (IQR 8-21) and 8 (IQR 4-17) years, respectively.
Non-steroidal anti-inflammatory drugs were the first medication used for PsA in 62%. The most common initial immunomodulatory medications were anti-TNF-α (35%), followed by methotrexate (19%), anti-phosphodiesterase-4 (anti-PDE4) (12.4%), other conventional synthetic disease modifying anti-rheumatic medications (csDMARDs) (11.7%), anti-IL17 (5.1%), and anti-IL23 (2.9%). At survey administration, the most common immunomodulatory therapies were anti-TNF-α (30%), followed by anti-IL17 (20.4%), methotrexate (10.2%), anti-PDE4 (8.8%), other csDMARDs (8.0%), Janus kinase inhibitors (2.2%), and anti-cytotoxic T-lymphocyte-associated protein 4 (CTLA 4) (1.5%), while 28% of patients were not on any immunomodulatory therapy. After 2018, when updated guidelines from the ACR/NPF were published, a significantly higher percentage of patients' first medication was an anti-IL17 compared to 2018 or earlier (30% vs 3.5% $p< 0.001$); a pattern also seen with anti-PDE4 (40% vs 11.5% $p< 0.012$).
Medication preferences most ranked as "extremely" important were prevention of joint damage, (80%), ability to perform daily activities (71%), prevention of pain (70%), rheumatologist recommendation (63%) and medication side effects (62%).

Conclusion: The significant increase of anti-IL17 and anti-PDE4 medications as initial treatment after 2018 may reflect their inclusion as potential initial therapy in updated guidelines, along with the importance placed by patients on medication side effects. Surprisingly, over a quarter of patients were not on any immunomodulatory therapy. Given the expanding armamentarium of PsA medications, it is increasingly important to align patient preferences and therapeutic options to ensure durable use of effective therapy.

Session Title: Spondyloarthritis Including PsA – Treatment Poster III: Psoriatic Arthritis II (1801–1835)

Session Type: Poster Session D

Session Time: 8:30AM–10:30AM

Background/Purpose: Guselkumab (GUS), an anti-interleukin-23p19 subunit monoclonal antibody, is approved to treat psoriatic arthritis (PsA). Post hoc analyses of DISCOVER-1&2 suggested that GUS may be effective in improving symptoms of axial manifestation of PsA. This study evaluated the efficacy of GUS across components of the Bath Ankylosing Spondylitis Disease Activity Index (BASDAI) in improving symptoms of axial manifestations of active PsA patients using data from phase-3, randomized, placebo (PBO)-controlled studies.

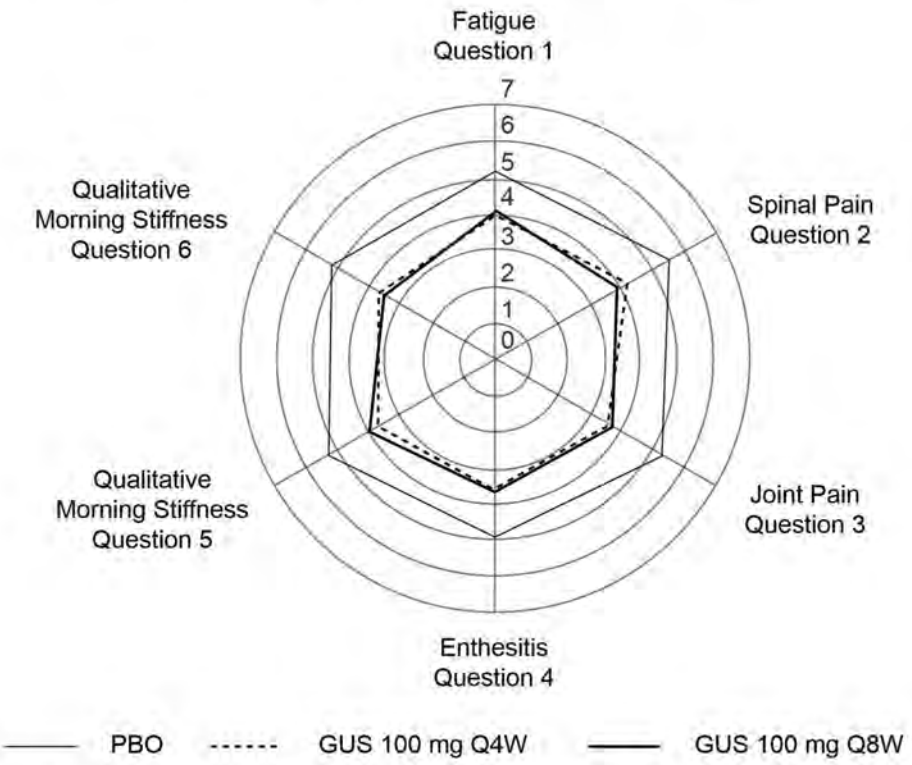
Methods: In DISCOVER-1&2, patients with active PsA were randomized to subcutaneous injections of GUS 100 mg every 4 weeks (Q4W) or at Week 0, 4, and Q8W, or PBO. These post hoc analyses included patients who were identified by the investigator as having axial symptoms and sacroiliitis (prior X-ray or MRI or screening X-ray). BASDAI scores were assessed at Weeks 0, 8, 16, 24, and 52. Mean BASDAI component scores through Week 52 are reported

Table: Baseline demographic and disease characteristics for patients who were identified by physicians as having symptoms consistent with spondylitis and had sacroiliitis confirmed via prior radiograph/MRI or screening radiograph

	GUS Q4W	GUS Q8W	Placebo
Patients, n	103	91	118
Male, n (%)	68 (66)	54 (59)	69 (59)
Age, years	44.9 ± 11.8	45.0 ± 10.7	45.3 ± 11.0
BASDAI			
Patients, n	95	84	110
Score	6.4 ± 1.7	6.5 ± 1.8	6.6 ± 1.5
BASDAI Components			
Fatigue	6.4 ± 2.0	6.7 ± 1.9	6.5 ± 1.9
Spinal pain	6.6 ± 2.1	6.5 ± 2.3	6.7 ± 2.0
Joint pain	6.3 ± 1.9	6.5 ± 2.2	6.8 ± 1.7
Enthesitis	6.3 ± 2.1	6.4 ± 2.2	6.3 ± 2.2
Qualitative morning stiffness	6.8 ± 2.1	6.7 ± 2.5	7.0 ± 2.0
Quantitative morning stiffness	6.2 ± 2.9	5.7 ± 2.9	6.1 ± 2.8

Data are mean ± standard deviation unless otherwise noted.
BASDAI, Bath Ankylosing Spondylitis Disease Activity Index; GUS, guselkumab; MRI, magnetic resonance imaging; Q4W, every 4 weeks; Q8W, every 8 weeks

Figure. Mean scores of BASDAI components at week 24, DISCOVER-1 and DISCOVER-2



BASDAI, Bath Ankylosing Spondylitis Disease Activity Index; GUS, guselkumab; PBO, placebo; Q4W, every 4 weeks; Q8W, every 8 weeks

by treatment group. Pooled data from the two studies are reported. Mean BASDAI component scores are reported using observed data; total BASDAI scores with missing components were set to missing. The proportion of patients achieving ≥50% improvement in BASDAI (BASDAI 50) was also determined; patients with missing data or who met the treatment failure criteria (discontinued study agent or used prohibited medications) were considered nonresponders at all subsequent timepoints.

Results: These analyses included 312 patients from DISCOVER-1&2 (103 GUS Q4W, 91 GUS Q8W, 118 PBO); mean total BASDAI scores at Week 0 were 6.4, 6.5, and 6.6, respectively. Demographics and mean baseline BASDAI component scores (ie, fatigue, spinal pain, joint pain, enthesitis, qualitative morning stiffness, and quantitative morning stiffness) were similar across treatment groups (Table). In comparison with the total study population, this subgroup of patients had a higher mean C-reactive protein level at baseline and a higher proportion of patients with enthesitis and included a slightly higher proportion of males. Mean scores for all six BASDAI components, including spinal pain, decreased through Week 24 in GUS-treated patients, with separation from PBO observed as early as Week 8; improvements were maintained at Week 52. At Week 24, BASDAI 50 response rates were higher in the Q4W and Q8W groups versus PBO (38% and 40% versus 19%).[1] At Week 52, mean BASDAI component scores for PBO patients who crossed over to GUS Q4W at Week 24 were similar to those for patients who were randomized to GUS.[2] A similar trend was observed for BASDAI 50 response.

Conclusion: Among PsA patients with axial symptoms and sacroiliitis (via investigator-confirmed imaging) in the DISCOVER-1&2 trials, GUS treatment resulted in lower mean scores for all six BASDAI components compared with PBO as early as Week 8 and through Week 24, with mean scores maintained at Week 52.

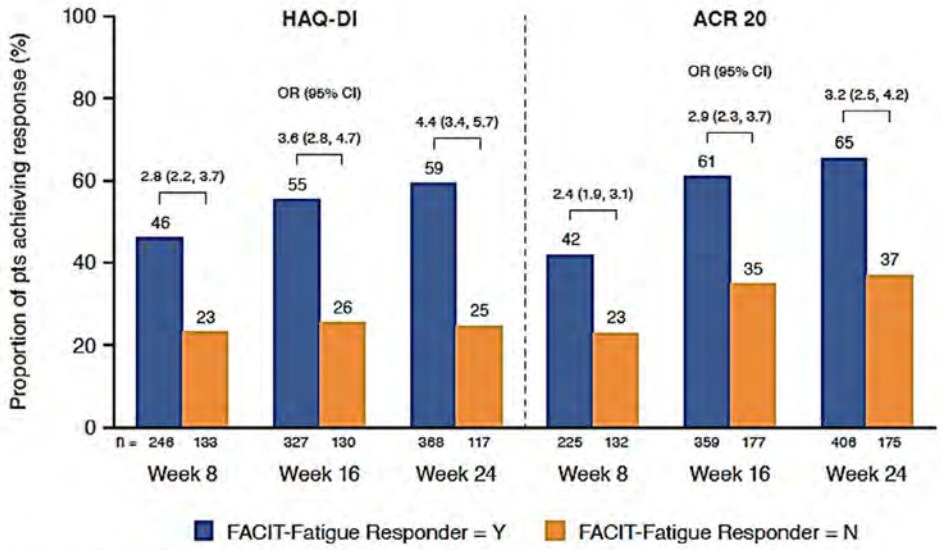
Table. Correlation* of FACIT-Fatigue and HAQ-DI

Visit	HAQ-DI and FACIT Fatigue Scores	Changes From Baseline in HAQ-DI and FACIT-Fatigue Scores
W8	−0.61 (p<0.0001)	−0.42 (p<0.0001)
W16	−0.60 (p<0.0001)	−0.47 (p<0.0001)
W24	−0.62 (p<0.0001)	−0.50 (p<0.0001)

*Determined by Pearson correlation coefficient; p-values derived from hypothesis tests of correlation ρ=0 (ie, no correlation).
FACIT, Functional Assessment of Chronic Illness Therapy; HAQ-DI, Health Assessment Questionnaire-Disability Index; W, week.

Figure. HAQ-DI and ACR 20 Responders by FACIT-Fatigue Responder Status (Y/N)



ACR 20, American College of Rheumatology 20% improvement; CI, confidence interval; FACIT, Functional Assessment of Chronic Illness Therapy; HAQ-DI, Health Assessment Questionnaire-Disability Index; OR, odds ratio; pts, patients.

Background/Purpose: In patients (pts) with PsA, fatigue is a major driver of perceived impact of disease and has been identified as an important domain to be assessed in clinical trials.[1,2] The association between fatigue and other PsA domains (eg, physical function) or clinical response is not well understood. Fatigue was measured with the Functional Assessment of Chronic Illness Therapy (FACIT)-Fatigue questionnaire in the pivotal DISCOVER-1 & -2 phase 3 studies of guselkumab (GUS) vs placebo (PBO). This post hoc analysis explores the correlation between FACIT-Fatigue and physical function and clinical response in the DISCOVER program.

Methods: This analysis used pooled data from pts (N=1120) treated with GUS or PBO. In DISCOVER-1 & -2, 381 pts with active PsA (swollen joint count [SJC] ≥3, tender joint count [TJC] ≥3, CRP ≥0.3 mg/dL) and 739 pts with active PsA (SJC ≥5, TJC ≥5, CRP ≥0.6 mg/dL) and inadequate response to standard therapies, respectively, were randomized 1:1:1 to GUS 100 mg every 4 weeks (Q4W); GUS 100 mg at Week (W) 0, W4, then Q8W; or PBO. PBO pts switched to GUS 100 mg Q4W at W24. The FACIT-Fatigue questionnaire has 13 items that assess self-reported fatigue/tiredness over the last 7 days. Items are scored from 0 (very much fatigued) to 4 (not at all fatigued). FACIT-Fatigue response was defined as an increase of ≥4 points from baseline. Physical function was evaluated with the Health Assessment Questionnaire-Disability Index (HAQ-DI). HAQ-DI response was defined as a decrease of ≥0.35 points from baseline. Clinical response was defined as achievement of ACR 20 criteria. Relationships between FACIT-Fatigue and HAQ-DI at W8/16/24 were assessed by Pearson correlation coefficients. Mean changes in HAQ-DI scores at W8/16/24 were summarized in FACIT-Fatigue responders and nonresponders. A logistic regression model was applied to estimate odds ratios (ORs) for achievement of HAQ-DI and ACR 20 response by FACIT-Fatigue response status at each visit. A multiple linear regression model was used to evaluate the association between FACIT-Fatigue and HAQ-DI at W24 after adjusting for SJC, TJC, CRP, and pt assessment of pain.

Results: FACIT-Fatigue and HAQ-DI scores and changes from baseline were negatively correlated at W8, W16, and W24 (Table). Mean changes in HAQ-DI were –0.31, –0.43, and –0.48 at W8, W16, and W24, respectively, in FACIT-Fatigue responders and –0.06, –0.07, and –0.09, respectively, in FACIT-Fatigue nonresponders. FACIT-Fatigue responders were significantly more likely than nonresponders to achieve HAQ-DI and ACR 20 response (OR [95% CI] at W8, 2.8 [2.2-3.7] and 2.4 [1.9-3.1]; at W16, 3.6 [2.8-4.7] and 2.9 [2.3-3.7]; and at W24, 4.4 [3.4-5.7] and 3.2 [2.5-

4.2], respectively; Figure). Correlations between FACIT-Fatigue and HAQ-DI remained significant after adjusting for SJC, TJC, CRP, and pt assessment of pain.

Conclusion: In pts with PsA, fatigue response is a clinically meaningful predictor of improvements in physical function and achievement of ACR 20 response, reinforcing the importance of assessing fatigue in PsA disease management.

CRP, C-reactive protein; FACIT-F, Functional Assessment of Chronic Illness Therapy-Fatigue; N, no; PASI, Psoriasis Area Severity Index; Pts, patients; SJC, swollen joint count; TJC, tender joint count; W, week; WPAI, Work Productivity & Activity Impairment; Y, yes

Background/Purpose: PsA, a chronic inflammatory disease characterized by peripheral arthritis, axial inflammation, dactylitis, enthesitis and skin/nail psoriasis, causes impaired physical function, disability, and loss of work productivity. We evaluated associations between PsA clinical characteristics and outcomes including fatigue and work productivity using Work Productivity & Activity Impairment Questionnaire: PsA (WPAI-PsA).

Methods: Phase 3 DISCOVER-2 trial assessed guselkumab (GUS), an anti-IL-23p19-subunit human mAb, in bio-naïve adults with active PsA (swollen joint count [SJC] ≥5, tender joint count [TJC] ≥5, CRP ≥0.6 mg/dL) despite standard therapies.[1] Patients (Pts) were randomized 1:1:1 to GUS 100 mg every 4 weeks (Q4W); GUS 100 mg at Week (W)0, W4, then Q8W; or placebo (PBO). WPAI-PsA assesses PsA-related work time missed (absenteeism), impairment while working (presenteeism), productivity loss (absenteeism+presenteeism), and daily activity during previous week. Spearman correlation testing evaluated relationships between pt demographics & PsA disease characteristics and WPAI domain scores based on observed values at baseline. Univariate linear regression assessed associations between WPAI, and these variables based on observed data at W0 and W24. Variables with $p< 0.10$ were included in a multivariate analysis employing a mixed-effects model for repeated measures, controlling for all other variables; resulting p-values < 0.05 were considered statistically significant.

Results: As reported,[2] least-squares mean % changes from baseline at W24 were -3.8/-19.5/-20.0/-20.5 for GUS Q4W, -3.1/-19.4/-19.7/-21.5 for GUS Q8W, and -3.5/-10.2/-10.9/-10.3 for PBO for absenteeism, presenteeism, absenteeism+presenteeism, and daily activity impairment, respectively. Among 738 pts, WPAI domain scores were moderately to strongly correlated (ie, ≥0.4) with pt-reported pain (0-10 visual analog scale), physical function (Health Assessment Questionnaire-Disability Index [HAQ-DI]), fatigue (Functional Assessment of Chronic Illness Therapy-Fatigue [FACIT-F] scale) and 36-Item Short Form Health Survey (SF-36) Physical Component Summary (PCS) score, but weakly correlated with other variables (Figure). Based on univariate analyses and evaluation of collinearity between variables, attributes included in multivariate models were age, BMI, gender, CRP, FACIT-F, pain, Psoriasis Area Severity Index (PASI), TJC, SJC, enthesitis and dactylitis. In final model, CRP, FACIT-F, and pain were statistically significantly associated with all WPAI domains (Table). Presence of enthesitis and higher PASI score were significantly associated with higher loss of work productivity and activity outside work.

Conclusion: In PsA pts, extra-articular symptoms, fatigue, pain, and elevated CRP were significantly associated with WPAI-assessed work and activity impairment. Treating all major clinical manifestations of PsA is needed to improve work and activity impairment. GUS effectively treats all major clinical manifestations[1] and improves work and activity impairment in PsA.[2]

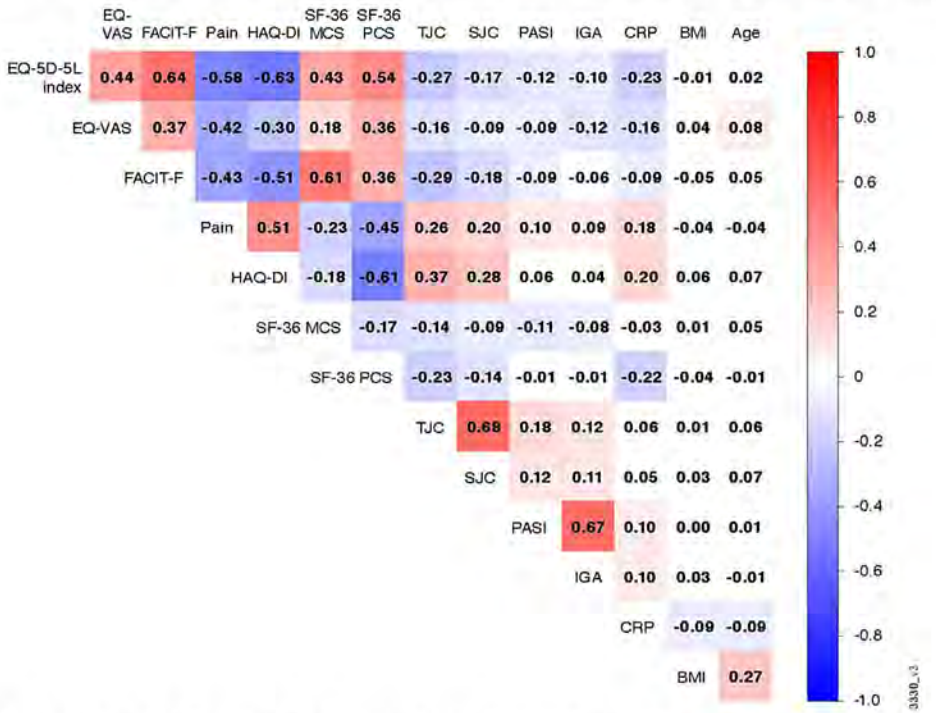
SESSION INFORMATION
Session Date: Tuesday, November 9, 2021
Session Title: Spondyloarthritis Including PsA – Treatment Poster III: Psoriatic Arthritis II (1801–1835)
Session Type: Poster Session D
Session Time: 8:30AM–10:30AM

Background/Purpose: PsA is a chronic inflammatory disease characterized by peripheral arthritis, axial inflammation, dactylitis, enthesitis, & skin/nail psoriasis. Patients (pts) with PsA often experience reduced health-related quality of life (HRQoL) due to these features. Using EuroQoL-5 dimension-5 level (EQ-5D-5L) questionnaire index & visual analog scale (EQ-VAS) scores, we assessed HRQoL in PsA pts & its association with pt characteristics & clinical features of PsA, including fatigue.

Methods: The phase 3 DISCOVER-2 trial evaluated guselkumab (GUS), an anti-IL-23p19-subunit mAb, in bio-naïve adults with active PsA (swollen joint count [SJC] ≥5, tender joint count [TJC] ≥5, CRP ≥0.6 mg/dL) despite standard therapies.[1] Pts were randomized 1:1:1 to GUS 100 mg every 4 weeks (Q4W); GUS 100 mg at Week (W) 0, W4, then Q8W; or placebo (PBO). EQ-5D-5L index assesses mobility, self-care, usual activities, pain/discomfort, & anxiety/depression. EQ-VAS assesses pt health state. Spearman correlation testing was used to evaluate relationships between baseline (BL) pt characteristics & PsA clinical features & BL EQ-5D-5L index & EQ-VAS scores (Fig). Employing absolute observed scores at W0 & W24, univariate linear regression was used to assess the association between EQ-5D-5L index & EQ-VAS scores & pt characteristics/PsA clinical features. Variables with $p < 0.20$ in the univariate analysis were included in a multivariate analysis employing mixed-effect model for repeated measures (MMRM), controlling for all other variables; $p < 0.05$ was considered statistically significant. Least-squares (LS) mean changes in EQ-5D-5L index & EQ-VAS were assessed at W24 using MMRM.

Results: Among 738 pts, BL EQ-5D-5L index & EQ-VAS scores were moderately to strongly correlated (≥0.4) with BL pt-reported pain (0-10 VAS), physical function (HAQ-Disability Index [DI]), fatigue (Functional Assessment of Chronic

Figure. Spearman correlations between BL pt characteristics/clinical features & BL EQ-5D-5L index & EQ-VAS scores at W0



BL, baseline; BMI, body mass index; CRP, C-reactive protein; EQ-5D-5L, EuroQoL-5 dimension-5 level questionnaire; EQ-VAS, EuroQoL-visual analog scale; FACIT-F, Functional Assessment of Chronic Illness Therapy-Fatigue; HAQ-DI, Health Assessment Questionnaire-Disability Index; IGA, Investigator's Global Assessment; MCS, mental component summary; PCS, physical component summary; PASI, Psoriasis Area & Severity Index; SF, Short Form Health Survey; W, week; SJC, swollen joint count; TJC, tender joint count

Illness Therapy-Fatigue [FACIT-F] scale), & 36-item Short Form Health Survey (SF-36) physical & mental component summary (PCS & MCS) scores; & weakly correlated with other variables (Fig). Based on univariate analyses ($p < 0.20$) & evaluation of collinearity between variables, attributes at W0 & W24 included in the multivariate models were age, sex, CRP, FACIT-F, pain, Psoriasis Area & Severity Index (PASI) score, TJC, SJC, enthesitis, & dactylitis. In the final model, CRP, FACIT-F, pain, PASI score, & the presence of dactylitis were significantly associated with EQ-5D-5L index & EQ-VAS scores. A higher TJC was significantly associated with a worse EQ-5D-5L index score. A higher SJC was significantly associated with a worse EQ-VAS score (Table). For reference, in the GUS Q4W (N=244), GUS Q8W

Table. Multivariate analysis of patient characteristics/clinical features & EQ-5D-5L index & EQ-VAS scores at Week 0 & Week 24

Parameter	EQ-5D-5L Index		EQ-VAS	
	Estimate	p value	Estimate	p value
Age (y)	-0.0001	0.69	0.06	0.12
Female	-0.003	0.53	1.11	0.20
CRP (mg/dL)	-0.005	**<0.001**	-0.51	**0.007**
FACIT-F (0-52)	0.007	**<0.001**	0.57	**<0.001**
Pain (0-10)	-0.02	**<0.001**	-3.47	**<0.001**
PASI (0-72)	-0.001	**0.03**	-0.17	**<0.001**
SJC (0-66)	-0.001	0.21	-0.17	**0.02**
TJC (0-68)	-0.001	**0.04**	-0.04	0.41
Dactylitis (Y/N)	0.01	**0.02**	1.74	0.49
Enthesitis (Y/N)	-0.004	0.33	-0.98	0.22

CRP, C-reactive protein; EQ-5D-5L, EuroQoL-5 dimension-5 level questionnaire; EQ-VAS, EuroQoL-visual analog scale; FACIT-F, Functional Assessment of Chronic Illness Therapy-Fatigue; PASI, Psoriasis Area & Severity Index; W, week; SJC, swollen joint count; TJC, tender joint count

(N=246), & PBO (N=244) groups, LS mean changes from BL at W24 were 0.12, 0.12, & 0.05, respectively, for EQ-5D-5L index & 18.1, 18.4, & 6.8, respectively, for EQ-VAS.

Conclusion: Joint & skin symptoms, dactylitis, fatigue, pain, & elevated CRP levels were significantly associated with reduced HRQoL (measured by EQ-5D-5L index & EQ-VAS) in bio-naïve pts with active PsA. Treatment of multiple PsA domains may help optimize HRQoL. Improvement across clinical domains[1] & in HRQoL was observed in GUS-treated PsA pts.

Randomised, Double-blind, Placebo-controlled Study of Iguratimod in the Treatment of Active Spondyloarthritis

yan li[1], Kunpeng Li[1], Zheng Zhao[1], yanyan wang[1], Jingyu Jin[1], jianglin zhang[1], Jian Zhu[1] and feng huang[2], [1]First Medical Center, General Hospital of Chinese People's Liberation Army, Beijing, China (People's Republic), [2]Chinese PLA General Hospital, Beijing, China (People's Republic)

SESSION INFORMATION
Session Date: Tuesday, November 9, 2021
Session Title: Spondyloarthritis Including PsA – Treatment Poster III: Psoriatic Arthritis II (1801–1835)
Session Type: Poster Session D
Session Time: 8:30AM–10:30AM

Background/Purpose: Iguratimod, also known as T-614, is a new type of small molecule compound with anti-inflammatory and immunomodulatory effects; It was listed in China(2011) and Japan(2012) for the treatment of rheumatoid arthritis;its safety and effectiveness have been verified in patients with rheumatoid arthritis. As Iguratimod could inhibit the production of inflammatory cytokines, such as IL-1 and TNF; block the IL-17 signalling pathway and inhibit cyclooxygenase, Iguratimod may be effective in the treatment of SPA/AS. However, no rigorous clinical research exists to confirm this speculation. Therefore, this study aimed to evaluate the efficacy and safety of Iguratimod in patients with active SpA.

Methods: Subjects with active SpA were enrolled and randomly divided into two groups at a ratio of 1:2 (placebo vs. Iguratimod). On the basis of non-steroidal anti-inflammatory drugs, combined treatment with Iguratimod or placebo, followed by follow-up every 4 weeks for 24 weeks. The primary efficacy endpoint was to evaluate the alleviation rate of ASAS20; the important improvement of ASDAS and the efficacy of spinal mobility, physical function and quality of life at the 24th week.

Results: A total of 48 cases in the Iguratimod group and 25 cases in the placebo group were included in the final analysis. On the 24th week, the percentage of responders to ASAS20 (80% vs. 44%) and ASAS40 (56% vs. 20%) treated with Iguratimod were significantly higher than that in the placebo group ($P < 0.05$). Twelve cases had gastrointestinal discomfort, of which eight were in the Iguratimod group (16.7%, one case withdrew from the study due to diarrhoea) and four were in the placebo group (16.0%). No significant difference was found between the two groups ($P < 0.05$). Three cases of elevated transaminase were observed in the Iguratimod group and none in the placebo group, with no significant difference ($P < 0.05$).

Conclusion: Iguratimod could significantly reduce the symptoms and signs of patients with active SpA. It could improve the physical function and quality of life of these patients and the overall safety and tolerance are good.

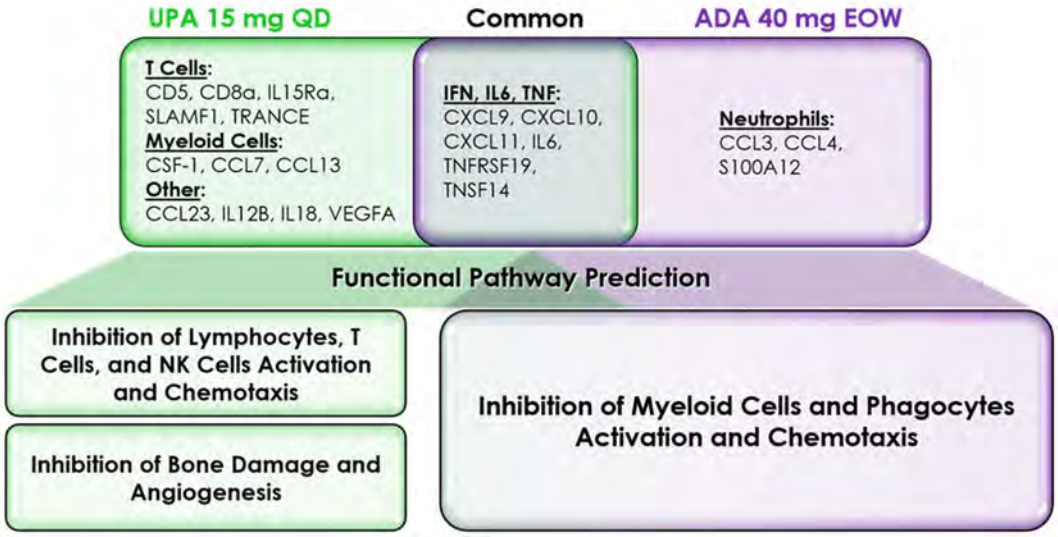
Session Title: Spondyloarthritis Including PsA – Treatment Poster III: Psoriatic Arthritis II (1801–1835)
Session Type: Poster Session D
Session Time: 8:30AM–10:30AM

Background/Purpose: Treatment of non-biologic-DMARD-IR (DMARD-IR) PsA patients with upadacitinib (UPA) at 15 mg QD, an oral JAK1 selective inhibitor, resulted in improvement in musculoskeletal symptoms, psoriasis, physical function, fatigue, quality of life, and inhibited radiographic progression; improvements were observed as early as Week 2 (ACR20 and ACR50). UPA 15 mg QD was non-inferior to ADA 40 mg EOW for ACR20.[1] The objective of this analysis was to determine the relative biological pathway modulation of UPA compared with ADA in patients with PsA via the evaluation of a pre-defined set of plasma proteins associated with inflammation.

Methods: Patients from the SELECT-PsA 1 study (DMARD-IR PsA patients) were randomly selected (PBO, n=100; UPA 15 mg QD, n=100; ADA 40 mg EOW, N = 100). The levels of 92 inflammation related protein biomarkers (pBM) were analyzed using the Olink® platform in plasma samples collected at baseline, week 2, and 12; change from baseline in protein levels were expressed as Log_2 Fold Change; a Repeated Measure Mixed Linear Model identified proteins modulated by UPA and ADA compared to Baseline. Functional pathway prediction was performed with Inge-



nuity® Pathway Analysis (Qiagen Inc.) where 52 significantly modulated pBM (mean $|Log_2 FC| \geq 0.1$ AND FDR ≤ 0.05) were selected; results were summarized based on 3 core biological groups: 1) adaptive immune system, 2) innate immune system, and 3) non-immune connective and vascular systems.

Results: At the single pBM-level, at the week 2 and 12 time points, treatment with UPA 15 mg QD resulted in distinct down modulation of T cell-associated (CD5, CD8a, IL15Ra, SLAMF1, TRANCE) and myeloid cell-associated pBM (CSF-1, CCL7, CCL13) that was not observed in the ADA treated group. Reciprocally, treatment with ADA 40 mg EOW resulted in a specific down modulation of a subset of neutrophil associated pBM (CCL3, CCL4, and S100A12). Both treatments resulted in the down modulation of IFN-, IL6-, and TNF-related pBM (CXCL9, CXCL10, CXCL11, IL6, TNFRSF19, and TNSF14) suggesting a common node of activity related to these pivotal cytokine-signaling pathways.

Functional pathway prediction based on the pBM data revealed that treatment with UPA is preferentially associated with the inhibition of T cells, but also NK cells and lymphocytes, compared to the predicted effects of treatment with ADA. Treatment with UPA also preferentially inhibited pathways related to bone damage and angiogenesis, as compared to the predicted effect of treatment with ADA. Finally, both treatments were predicted to inhibit multiple pathways associated with the activity of myeloid cells and phagocytes.

Conclusion: Consistent with previous observations in RA[2], UPA is predicted to inhibit multiple functional pathways associated the pathobiology of PsA belonging to the general categories of adaptive and innate immunity but also non-immune vascular and connective tissue biology. In contrast, treatment with ADA appears to affect more specifically functional pathways associated with the innate immune system.

SESSION INFORMATION

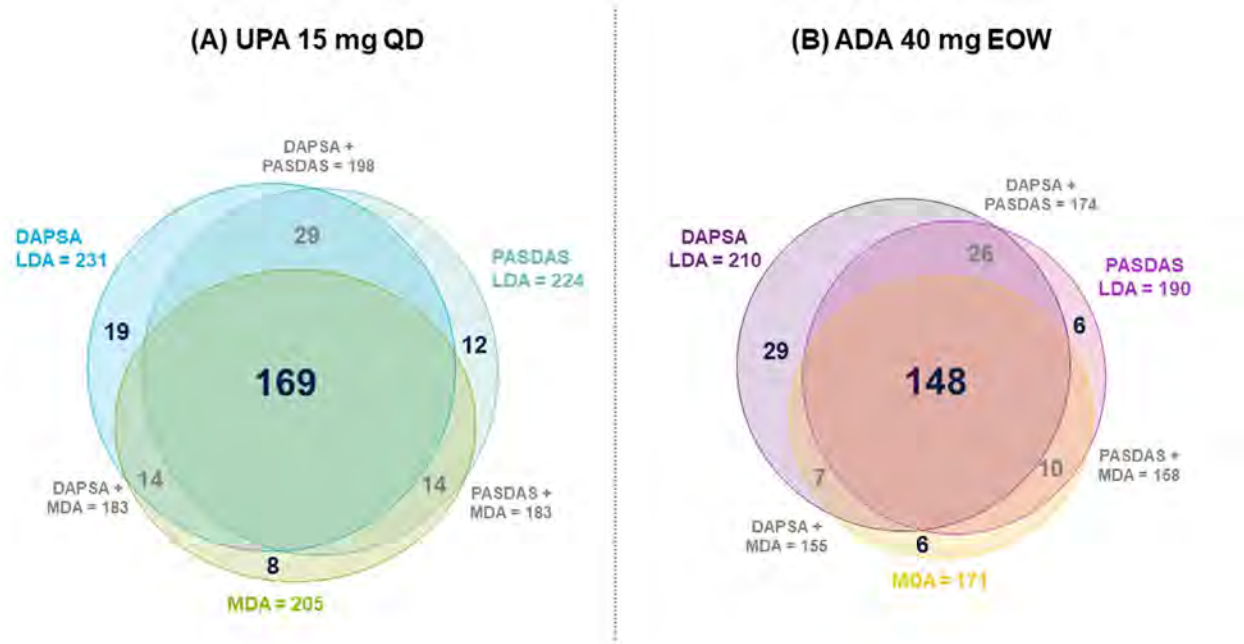
Session Date: Tuesday, November 9, 2021

Session Title: Spondyloarthritis Including PsA – Treatment Poster III: Psoriatic Arthritis II (1801–1835)

Session Type: Poster Session D

Session Time: 8:30AM–10:30AM

Figure 1: Number of PsA Patients Treated with UPA or ADA in LDA by MDA,† DAPSA,‡ and/or PASDAS§



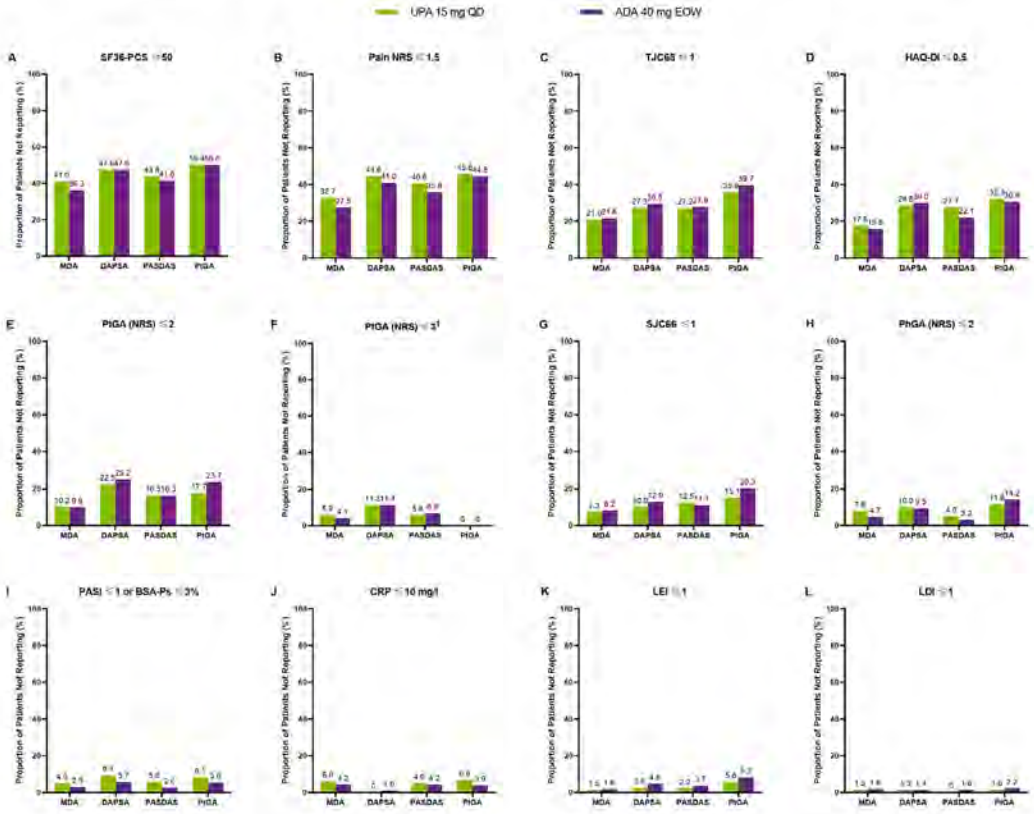
ADA, adalimumab; BSA-Ps, Body Surface Area with Psoriasis; DAPSA, Disease Activity in PsA; EOW, every other week; HAQ-DI, Health Assessment Questionnaire - Disability Index; LDA, Low Disease Activity; LEI, Leeds Enthesitis Index; MDA, Minimal Disease Activity; NRS, Numeric Rating Scale; PASDAS, PsA Disease Activity Score; PASI, Psoriasis Area Severity Index; PsA, psoriatic arthritis; PtGA, Patient Global Assessment of Disease Activity; Pain NRS, Patient Assessment of Pain; QD, once daily; SJC66, Swollen Joint Count 66; TJC68, Tender Joint Count 68; UPA, upadacitinib

†MDA defined as achieving 5/7 of the following criteria: TJC68 ≤1, SJC66 ≤1, PASI ≤1 or BSA-Ps ≤3%, Pain NRS ≤1.5 (0-10 scale), PtGA NRS ≤2.0 (0-10 scale), HAQ-DI ≤0.5, and LEI ≤1

‡LDA threshold for DAPSA: ≤14

§LDA threshold for PASDAS: ≤3.2

Figure 2: Proportion of PsA Patients Treated with UPA or ADA in LDA by MDA, DAPSA, PASDAS, or PtGA ≤3, but Not Reporting Meaningful Improvements in Individual Index Components



ADA, adalimumab; BSA-Ps, Body Surface Area with Psoriasis; DAPSA, Disease Activity in PsA; HAQ-DI, Health Assessment Questionnaire - Disability Index; CRP, C reactive protein; EOW, every other week; LDA, Low Disease Activity; LDI, Leeds Dactylitis Index; LEI, Leeds Enthesitis Index; MDA, Minimal Disease Activity; NRS, Numeric Rating Scale; PASDAS, PsA Disease Activity Score; PASI, Psoriasis Area Severity Index; PhGA, Physician's Global Assessment of disease activity; PsA, psoriatic arthritis; PtGA, Patient Global Assessment of disease activity; Pain NRS, Patient Assessment of Pain; QD, once daily; SF36-PCS, SF-36 Physical Component Summary; SJC66, Swollen Joint Count 66; TJC68, Tender Joint Count 68; UPA, upadacitinib

†LDA threshold for PtGA was defined as ≤ 3; therefore, due to the definition applied for this post-hoc analysis, all patients met this threshold (ie, 0% not achieving)

Background/Purpose: Achieving low disease activity (LDA) or remission is a main treatment target in PsA. Composite indices used to assess disease activity include Disease Activity index for PsA (DAPSA) and PsA Disease Activity Score (PASDAS), which both have cut points for the states of remission and LDA. In addition, LDA and remission can be assessed by the pure state instrument Minimal Disease Activity (MDA)/Very Low Disease Activity (VLDA). These analyses aim to identify overlap and differences between these composite indices in PsA patients treated with upadacitinib (UPA), a Janus kinase inhibitor, or adalimumab (ADA) in the phase 3 SELECT-PsA 1 trial.

Methods: In SELECT-PsA 1 (phase 3, randomized controlled trial, with long-term extension up to 5 years), patients with moderate to severely active PsA with prior inadequate response or intolerance to ≥1 non-biologic DMARD were randomized to oral UPA at doses of 15 mg or 30 mg (once daily), subcutaneous ADA 40 mg (every other week), or placebo.[1] LDA was assessed using MDA (threshold: 5/7 criteria), DAPSA (≤14), PASDAS (≤3.2), and Patient Global Assessment of Disease Activity (PtGA; ≤3).[2,3] These post-hoc descriptive analyses include 1-year (cut off: week 56) *as observed* data from UPA 15 mg and ADA.

Results: In total, 858 patients (UPA 15 mg: n=429; ADA: n=429) were included in these analyses. Patients receiving UPA and ADA were on average 52 years of age, 54% were female, with an average disease duration of approximately 6 years.[1] With both UPA and ADA, there was a high degree of overlap in the proportion of patients achieving LDA thresholds in MDA, DAPSA, and PASDAS (**Figure 1**), with reported PtGA improvements showing a similar trend. Defining LDA according to MDA or respective cut points for DAPSA, PASDAS, or PtGA, the proportion of "non-

responders" (ie, patients who did not reach such states) is shown in **Figure 2**. Of the individual components included in these indices, fewer patients reported low levels of SF-36 Physical Component Summary (SF36-PCS), Patient Assessment of Pain Numeric Rating Scale (Pain NRS), and Health Assessment Questionnaire - Disability Index (HAQ-DI) scores, as well as Tender Joint Count 68 (TJC68), with similar responses observed across all indices.

Conclusion: In this post-hoc analysis from the SELECT-PsA 1 trial, there was a high degree of overlap between patients in LDA across the composite indices, including MDA, DAPSA, and PASDAS, irrespective of treatment with UPA 15 mg or ADA and despite variability in inclusion of certain components in some indices but not others. Across all indices, fewer patients reported low levels of SF36-PCS, Pain NRS, and HAQ-DI scores, and TJC68. These data show that improvements in (subjective) "patient-driven" components were the most challenging to achieve. These data indicate a similar pattern of residual disease activity, or influence by residual damage or external factors, regardless of composite endpoint utilized.

ASDAS-CRP = Ankylosing Spondylitis Disease Activity Score-C-reactive protein; BASDAI = Bath Ankylosing Spondylitis Disease Activity Index; BSA = body surface area; cDAPSA = Clinical Disease Activity Index for Psoriatic Arthritis; HAQ-DI = Health Assessment Questionnaire-Disability Index; HAQ-S = Health Assessment Questionnaire for Spondyloarthropathies; MDA = minimal disease activity; PsA = psoriatic arthritis; PsO = psoriasis; SPARCC = Spondyloarthritis Research Consortium of Canada; TNFi = tumor necrosis factor inhibitor; VAS = visual analog scale.

Background/Purpose: The burden of PsA and its chronic symptoms may have considerable impact on patient function and quality of life. Real-world research is limited on treatment response in PsA patients with different manifestations of PsA who are treated with a biologic DMARD. The objective of this study was to describe patient characteristics and disease outcomes within different PsA domains for patients initiating treatment with a TNF inhibitor (TNFi).

Table 3. Time to Discontinuation and Proportion Persistent Over Time

Treatment Group	Median (95% CI) Time to Discontinuation (Months)	Proportion (95% CI) Persistent [$N_{at\ risk}$] at:		
		6 months	12 months	24 months
Overall TNFi	16 (14, 19)	0.75 (0.72, 0.79) [492]	0.57 (0.53, 0.61) [281]	0.39 (0.34, 0.43) [124]
Peripheral arthritis	16 (13, 19)	0.75 (0.71, 0.79) [413]	0.56 (0.51, 0.60) [235]	0.38 (0.33, 0.43) [103]
Any skin disease	18 (15, 21)	0.75 (0.71, 0.79) [398]	0.58 (0.53, 0.62) [234]	0.40 (0.35, 0.45) [104]
Nail psoriasis	16 (12, 19)	0.74 (0.69, 0.78) [270]	0.56 (0.50, 0.61) [160]	0.35 (0.30, 0.41) [73]
Moderate/high skin disease	19 (15, 24)	0.77 (0.72, 0.81) [254]	0.59 (0.53, 0.65) [146]	0.41 (0.34, 0.48) [68]
Enthesitis	12 (9, 16)	0.75 (0.68, 0.80) [162]	0.49 (0.42, 0.56) [89]	0.33 (0.26, 0.41) [37]
Oligoarthritis	20 (16, 36)	0.79 (0.73, 0.84) [165]	0.64 (0.56, 0.70) [94]	0.44 (0.35, 0.52) [43]
Dactylitis	16 (13, 21)	0.74 (0.67, 0.81) [114]	0.60 (0.51, 0.68) [72]	0.35 (0.26, 0.44) [28]
Axial PsA	13 (8, 19)	0.75 (0.65, 0.82) [96]	0.52 (0.42, 0.61) [48]	0.32 (0.22, 0.42) [24]

$N_{at\ risk}$ = number of patients at risk; PsA = psoriatic arthritis; TNFi = tumor necrosis factor inhibitor.

Methods: The CorEvitas PsA/Spondyloarthritis (SpA) Registry is a prospective, observational registry for patients with PsA or SpA under care of a rheumatologist. This study included adults with PsA who initiated treatment with a TNFi (adalimumab, etanercept, certolizumab pegol, infliximab, golimumab) from January 2013–January 2020. We present unadjusted change in disease activity and patient-reported measures from baseline to 6 months for each PsA domain (enthesitis, dactylitis, peripheral arthritis, oligoarthritis, axial PsA disease, nail psoriasis, any skin disease, and moderate/high skin disease). We examined median time to therapy discontinuation and proportions of patients persistent on TNFi at 6, 12, and 24 months.

Results: A total of 631 patients with PsA initiated TNFi treatment. Peripheral arthritis (85%), skin disease (81%), and nail psoriasis (56%) were the most common PsA manifestations (Table 1). Most patients were receiving first- or second-line therapy (73%) (Table 1). At 6 months, improvements were observed for the overall population of TNFi initiators and within the subgroups defined by PsA domains (Table 2). Mean change from baseline in scores for Physician Global Assessment of Disease Activity (100-point VAS) ranged from –11.2 in patients with oligoarthritis to –18.8 in patients with dactylitis (Table 2). Similar patterns of improvement were seen in a subanalysis of patients treated with etanercept.

Among the overall population of patients who were not in minimal disease activity (MDA) at baseline, 25.8% achieved MDA at 6 months. Among the subtypes, the proportion of patients achieving MDA ranged from 19.5% in patients with axial PsA to 34.1% in patients with dactylitis (Table 2). Persistency at 6, 12, and 24 months for patients treated with a TNFi was 0.75, 0.57, and 0.39, respectively, and was similar across subgroups of patients with PsA manifestations (Table 3). Time to discontinuation was shortest in patients with enthesitis and axial PsA (12 and 13 months, respectively) and longest in those with oligoarthritis (20 months) (Table 3).

Conclusion: This analysis highlights the heterogeneity in presentation of PsA domains. In this real-world population, improvement was seen across all PsA domains after initiation of TNFi treatment.

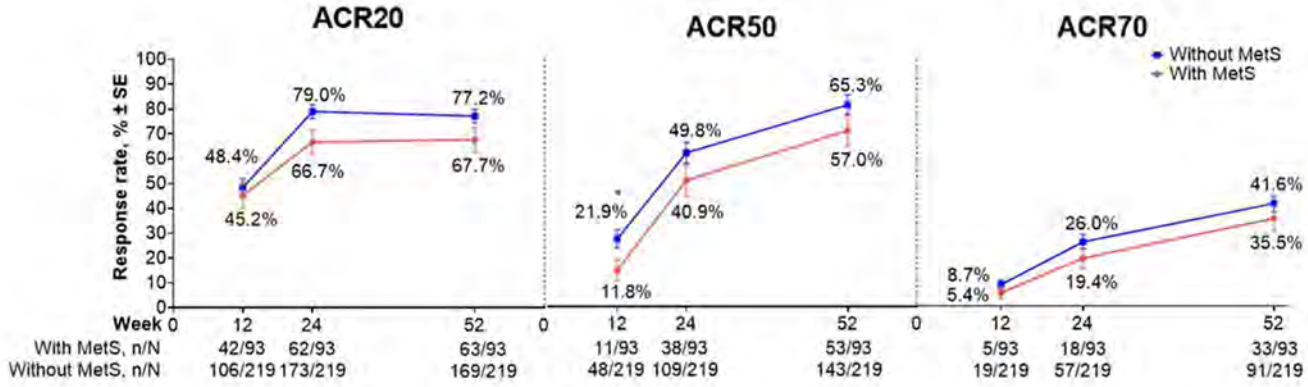
Session Title: Spondyloarthritis Including PsA – Treatment Poster III: Psoriatic Arthritis II (1801–1835)

Session Type: Poster Session D

Session Time: 8:30AM–10:30AM

Figure. ACR response rate by MetS status through Week 52.



ACR20/50/70 response, 20%/50%/70% improvement from baseline by American College of Rheumatology criteria; MetS, metabolic syndrome.

*P <0.05.

Table. Change from baseline in ACR core components at Week 24/52

	Week 24		Week 52	
	With MetS n = 93 [a]	Without MetS n = 219 [a]	With MetS n = 93 [a]	Without MetS n = 219 [a]
SJC	−6.8 ± 6.4	−7.4 ± 6.2	−6.8 ± 7.9	−7.1 ± 6.5
TJC	−11.4 ± 12.9	−11.5 ± 10.6	−11.2 ± 13.2	−12.2 ± 11.3
HAQ-DI	−0.2 ± 0.5	−0.3 ± 0.5	−0.4 ± 0.6	−0.4 ± 0.5
CRP	−1.4 ± 7.3	−3.6 ± 12.6	−1.8 ± 8.0	−4.6 ± 13.5
PtGA	−26.5 ± 25.3	−32.4 ± 23.2	−31.7 ± 28.3	−36.1 ± 26.3
PGA	−31.7 ± 21.6	−36.4 ± 19.1	−31.9 ± 24.7	−38.9 ± 22.3

Data presented as mean change from baseline ± SD.

[a]Number of tildrakizumab-treated patients in the full analysis set.

ACR, American College of Rheumatology; CRP, C-reactive protein; HAQ-DI, Health Assessment Questionnaire-Disability Index; MetS, metabolic syndrome; PGA, Physician Global Assessment; PtGA, Patient Global Assessment; SD, standard deviation; SJC, swollen joint count; TJC, tender joint count.

Background/Purpose: Metabolic syndrome (MetS) is a combination of specific risk factors for cardiovascular disease.[1] The prevalence of MetS in patients (pts) with PsA has been reported to range from 40%–60%; it has been associated with reduced efficacy of PsA treatment.[2,3] This study assessed whether MetS status affected efficacy and safety of tildrakizumab—a monoclonal IgG1-κ antibody targeting interleukin-23p19—in pts with PsA.[4]

Methods: This post-hoc subgroup analysis of a recently completed Phase 2b study (NCT02980692)[4] includes data from all pts who received any dose of tildrakizumab (200 mg every 4 weeks [Q4W], 200 mg Q12W, 100 mg Q12W, 20→200 mg Q12W) from baseline through W52, stratified by baseline MetS status.[4] Per modified National Cholesterol Education Program Adult Treatment Panel III criteria, MetS was defined by the presence of at least 3 of the following criteria: BMI >30 kg/m^2, blood pressure ≥130 mmHg (systolic) and/or 85 mmHg (diastolic), fasting triglycerides ≥150 mg/dL, fasting high-density lipoprotein cholesterol < 40 mg/dL (men) or < 50 mg/dL (women), and fasting glucose >110 mg/dL.[1] Efficacy endpoints included proportions of pts achieving 20%/50%/70% improvement from baseline by ACR criteria (ACR20/50/70 response) and change from baseline in swollen joint count, tender joint count, CRP, Patient Global Assessment (PtGA; 0–100 mm visual analog scale [VAS]), patient-reported pain VAS, and Physician Global Assessment (PGA; 0–100 mm VAS) at W24 and W52. Missing data were imputed as nonresponse. Incidence of adverse events (AEs), serious AEs (SAEs), and AEs of interest were evaluated at W24 and W52. Data are presented descriptively.

Results: Median baseline weight and BMI were substantially greater in pts with MetS (n = 93) vs those without MetS (n = 219). Tildrakizumab efficacy was generally lower for pts with vs without MetS but was well maintained through W52 in both subgroups (W52 ACR20 response rate [standard error], 67.7% [4.9%] vs 77.2% [2.8%] in pts with vs without MetS; **Figure**). The ACR50 and ACR70 response rates increased from W24 to W52 regardless of MetS status. Improvements from baseline in ACR response components were observed in both subgroups and maintained through W52. Improvements from baseline in CRP, PtGA, and PGA were numerically greater in pts without vs those with MetS (CRP, −4.6 ± 13.5 vs −1.8 ± 8.0; PtGA, −36.1 ± 26.3 vs −31.7 ± 28.3; PGA, −38.9 ± 22.3 vs −31.9 ± 24.7; **Table**). The incidence rate of SAEs in pts with vs without MetS was generally low (W0–W24, 4/93 [4.3%] vs 3/219 [1.4%]; W24–W52, 0/93 [0%] vs 3/219 [1.4%]).

Conclusion: In this Phase 2 trial, the efficacy of tildrakizumab in pts with active PsA tended to be lower among pts with comorbid MetS, with improvements from baseline across efficacy measures generally larger in pts without MetS vs those with MetS. Larger studies are necessary to investigate the long-term effects of MetS on tildrakizumab efficacy, safety, and drug survival in PsA.

Efficacy of Deucravacitinib, an Oral, Selective Tyrosine Kinase 2 Inhibitor, in Musculoskeletal Manifestations of Active PsA in a Phase 2, Randomized, Double-Blind, Placebo-Controlled Trial

Philip Mease[1], Atul Deodhar[2], Désirée van der Heijde[3], Frank Behrens[4], Alan Kivitz[5], Tom Lehman[6], Lan Wei[6], Marleen Nys[7], Subhashis Banerjee[6] and Miroslawa Nowak[6], [1]Swedish Medical Center/Providence St. Joseph Health and University of Washington, Seattle, WA, [2]Oregon Health & Science University, Portland, OR, [3]Department of Rheumatology, Leiden University Medical Center, Meerssen, Netherlands, [4]CIRI/Rheumatology and Fraunhofer Institute, Translational Medicine and Pharmacology ITMP, Goethe University, Frankfurt, Germany, [5]Altoona Center for Clinical Research, Duncansville, PA, [6]Bristol Myers Squibb, Princeton, NJ, [7]Bristol Myers Squibb, Braine-l'Alleud, Belgium

SESSION INFORMATION

Session Date: Tuesday, November 9, 2021

Session Title: Spondyloarthritis Including PsA – Treatment Poster III: Psoriatic Arthritis II (1801–1835)

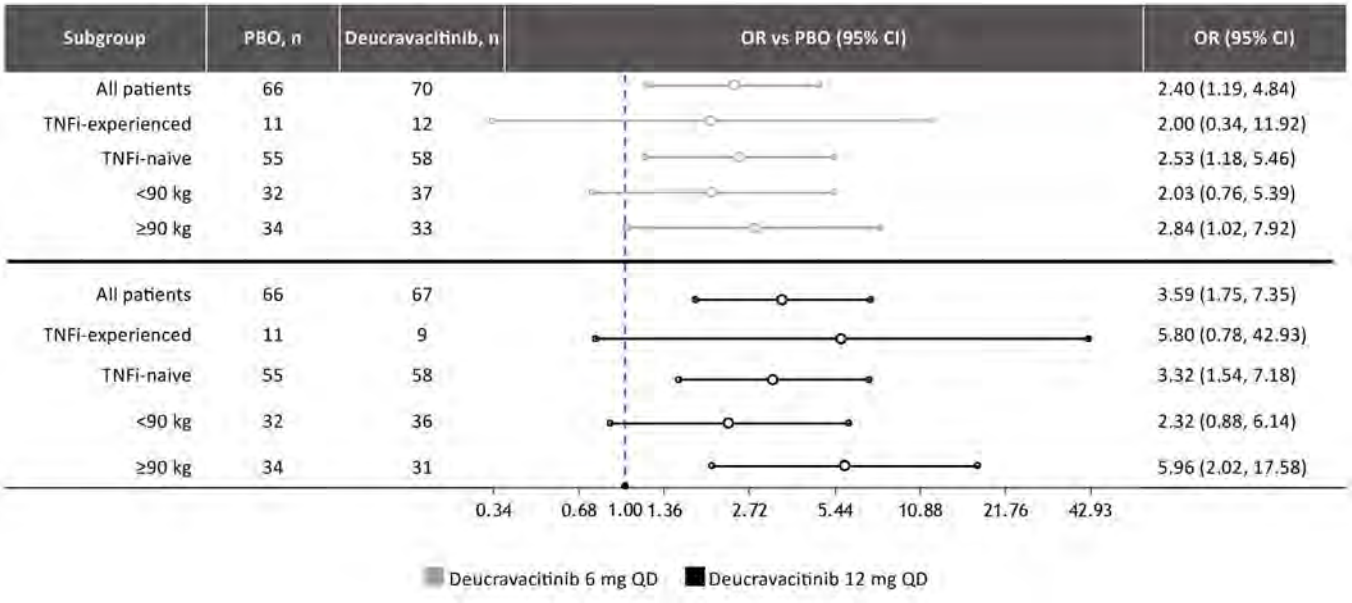
Session Type: Poster Session D

Session Time: 8:30AM–10:30AM

Background/Purpose: Tyrosine kinase 2 (TYK2) is an intracellular kinase that mediates IL-23, IL-12, and IFNα/β signaling. Deucravacitinib is a novel, oral selective inhibitor of TYK2 acting via the TYK2 regulatory domain. In a Phase 2 trial in patients with active PsA, the primary endpoint, ACR 20 response at Week (Wk) 16, was met and deucravacitinib was well tolerated versus placebo (PBO).[1] This analysis further evaluated improvements in musculoskeletal disease manifestations in patients in the Phase 2 PsA trial.

Methods: This Phase 2 trial (NCT03881059) enrolled patients who had a PsA diagnosis for ≥6 months, fulfilled Classification Criteria for Psoriatic Arthritis, had active disease (≥3 tender joints, ≥3 swollen joints, CRP ≥3 mg/L), and

Figure. ACR 20 subgroup analysis at Week 16



Comparative data for the TNFi-experienced groups should be interpreted with caution due to small sample sizes. OR and corresponding 95% CIs were obtained using the CMH test. Analyses were performed using NRI for patients with missing data.
ACR, American College of Rheumatology; CI, confidence interval; CMH, Cochran-Mantel-Haenszel; NRI, nonresponder imputation; OR, odds ratio; PBO, placebo; QD, once daily; TNFi, tumor necrosis factor inhibitor.

Table. Mean (SD) change from baseline for ACR components

	TJC	SJC	PtGA	Pain	PGA	HAQ-DI	hCRP
Baseline[a]							
PBO	16.9 (9.8)	10.5 (7.7)	66.2 (15.8)	64.9 (18.2)	63.8 (14.8)	1.3 (0.6)	20.4 (39.1)
DEUC 6	18.1 (10.3)	11.9 (7.0)	68.2 (16.8)	63.6 (21.7)	68.2 (14.7)	1.3 (0.6)	17.6 (23.6)
DEUC12	19.4 (11.8)	11.3 (9.0)	63.6 (15.6)	63.8 (15.9)	63.3 (16.1)	1.3 (0.6)	16.5 (21.7)
Week 16[b]							
PBO	-4.6 (9.7)	-4.3 (8.0)	-13.4 (23.5)	-13.8 (21.5)	-19.9 (21.8)	-0.1 (0.4)	-3.3 (22.6)
DEUC 6	-9.3 (9.7)	-7.7 (5.8)	-28.7 (23.1)	-25.3 (26.1)	-33.6 (23.0)	-0.4 (0.5)	-14.2 (24.5)
DEUC 12	-12.2 (10.2)	-8.5 (9.1)	-27.6 (25.8)	-27.5 (25.0)	-32.2 (25.0)	-0.4 (0.6)	-10.9 (22.8)

PBO, n/N=58/66; DEUC 6, n/N=63/70; DEUC 12, n/N=59/67; n/N=number of patients who completed treatment/number of patients randomized; the number of patients with data available for individual components at each time point may vary.

[a]Mean (SD). [b]Mean (SD) change from baseline.

ACR, American College of Rheumatology; DEUC 6, deucravacitinib 6 mg QD; DEUC 12, deucravacitinib 12 mg QD; HAQ-DI, Health Assessment Questionnaire-Disability Index total score; hCRP, high-sensitivity C-reactive protein; PBO, placebo; PGA, Physician's Global Assessment of psoriatic arthritis; PtGA, Patients' Global Assessment of disease activity; QD, once daily; SJC, swollen joint count; TJC, tender joint count.

had at least 1 active skin lesion. Patients either failed or were intolerant to ≥1 NSAID, corticosteroid, conventional synthetic DMARD, and/or 1 TNF inhibitor (TNFi; ≤30%). Patients were randomized 1:1:1 to deucravacitinib 6 mg QD or 12 mg QD or PBO, and stratified by TNFi status (experienced vs naive) and body weight (< 90 vs ≥90 kg). The current prespecified subgroup analysis assessed the likelihood of achieving ACR 20 response at Wk 16 based on study stratification factors. A post hoc analysis evaluated mean change from baseline (BL) to Wk 16 in ACR components (tender joint count, swollen joint count, Physician's Global Assessment of PsA, Patients' Global Assessment of disease activity, Patients' Global Assessment of pain, high-sensitivity CRP [hCRP], and HAQ-DI score). Analyses were descriptive using data as observed.

Results: Of 203 patients randomized, 180 (89%) completed 16 wks of treatment (deucravacitinib 6 mg QD, 63/70 [90%]; deucravacitinib 12 mg QD, 59/67 [88%]; PBO, 58/66 [88%]). Demographic and BL disease characteristics were similar across groups. Mean age was 49.8 years and median PsA duration since diagnosis was 4.5 years. Patients treated with deucravacitinib were numerically more likely to achieve ACR 20 response at Wk 16 compared with PBO-treated patients regardless of TNFi experience or body weight, although some of these groups were small (**Figure**). Improvements for deucravacitinib 6 mg and 12 mg QD versus PBO were observed in all ACR components (**Table**), with apparent separation occurring as early as Wk 4 on, for example, HAQ-DI (mean change from BL, -0.2 vs -0.2 vs -0.1, respectively) and hCRP (mean change from BL, -7.4 vs -5.2 vs 0.3, respectively), and maintained through Wk 16. No serious adverse events, including serious infections, herpes zoster infection, opportunistic infections, malignancies, or thromboembolic events, were reported in any deucravacitinib treatment group.

Conclusion: Analyses confirmed the efficacy of deucravacitinib versus PBO across TNFi and body weight subgroups. With deucravacitinib treatment, improvements were displayed in all ACR components.

SESSION INFORMATION

Session Date: Tuesday, November 9, 2021

Session Title: Spondyloarthritis Including PsA – Treatment Poster III: Psoriatic Arthritis II (1801–1835)

Session Type: Poster Session D

Session Time: 8:30AM–10:30AM

Background/Purpose: This study aimed to characterize the impact of pt advocacy group membership and its association with NPTM frequency and clinical parameters in axSpA pts. EULAR recently recommended the implementation of self-management strategies, such as participation in patient (pt) organizations to improve pt self-management and participation[1]. Non-pharmacological treatment modalities (NPTM)[2] are recommended in axial spondyloarthritis (axSpA) treatment guidelines[3], and are part of ASAS quality standards[4]. Evidence regarding improvements in pt participation in NPTM associated with membership in pt advocacy groups is limited.

Methods: Pts with a physician-judged axSpA diagnosis were enrolled in the multicenter, observational ATTENTUS-axSpA survey, conducted across Germany (11-2019 to 07-2020). Prescribed NPTM measures were assessed to study the effect of membership in pt advocacy groups. Demographics, clinical parameters and pt-related data were collected electronically.

Results: In total, 787 axSpA pts were enrolled in ATTENTUS; this analysis was conducted on the overall population (n=770) and working population (n=695), which was based on pre-defined criteria of working staus[5]. Overall, 12.2% (n=85) pts were members of a pt advocacy group and 87.8% (n=610) were not. Pt advocacy group members were older, had higher Bath Ankylosing Spondylitis Disease Activity Index (BASDAI) scores, increased functional impairment (BASFI, Bath Ankylosing Spondylitis Functional Index) and higher impact of axSpA on health (ASAS-HI, Assessment of SpondyloArthritis International Society-Health Index) (**Table 1**). Despite worse prognostic factors, there was no significant difference in Work Productivity and Activity Impairment (WPAI) score [40.6 (27.0) for pt advocacy group

	Table 1. Descriptive characteristics of the study population and impact of membership in pt advocacy group in working patient population			
Descriptive characteristics	**Pts member of patient advocacy group (n=85)**	**Pts not member of patient advocacy group (n=610)**	**Total (n=695)**	**p-value**
Age, years, mean (SD)	50.2 (7.7)	44.6 (11.1)	45.3 (10.9)	**< 0.001**

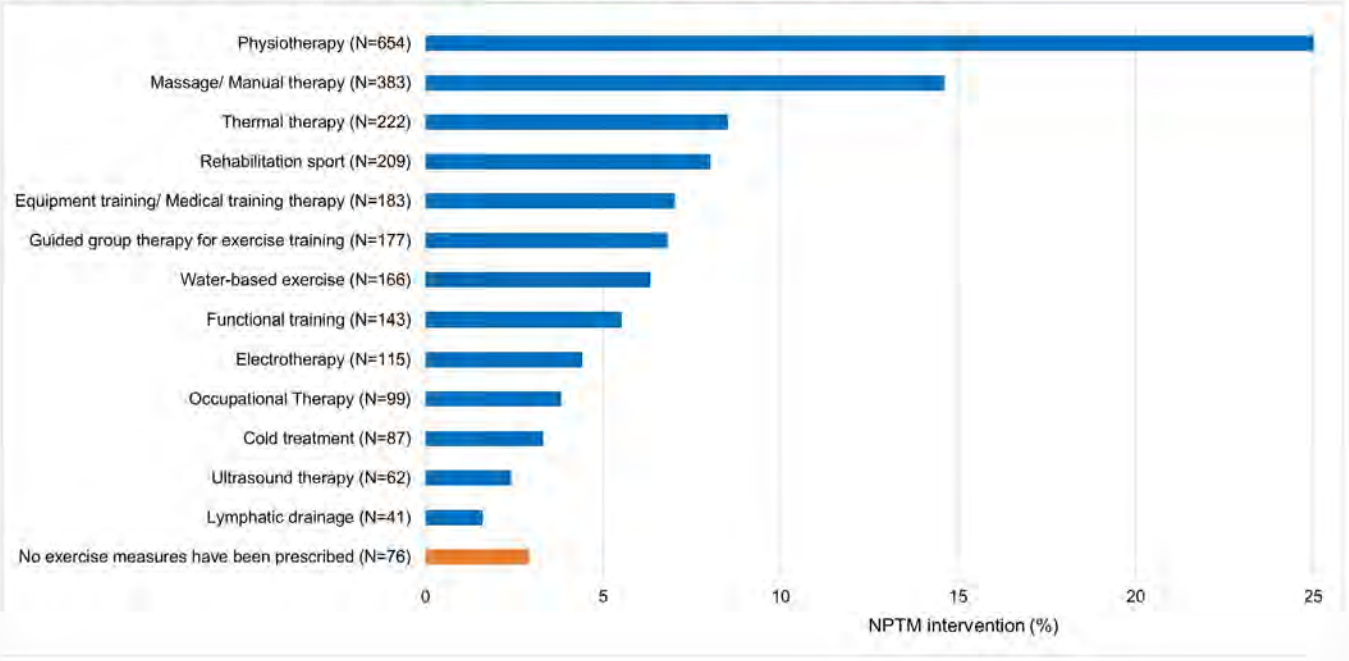
Overall work impairment score*	40.6 (27.0)	36.8 (29.9)	37.2 (29.6)	0.380
Activity impairment	46.7 (21.7)	40.5 (26.8)	41.3 (26.4)	0.058
Pts having ever received medicinal rehabilitation measurements, mean (SD)	67 (78.8)	328 (53.8)	395 (56.8)	**< 0.001**
Prescribed supervised group NPTM#, mean (SD)	49 (57.6)	210 (34.4)	259 (37.3)	**< 0.001**
Regular physical training†, mean (SD)	76 (89.4)	515 (84.4)	591 (85.0)	0.231

*Work-related questions of WPAI-score have been calculated for pts stated being employed (N=340); †Regular physical training in the context of their axSpA; #rehabilitation sport/functional training or both. ASAS-HI, Assessment of SpondyloArthritis International Society-Health Index; BASDAI, Bath Ankylosing Spondylitis Disease Activity Index; BASFI, Bath Ankylosing Spondylitis Functional Index; BMI, Body Mass Index; n, number of pts; pts, patients; SD, Standard Deviation; WPAI, Work Productivity and Activity Impairment; yrs, years.

members vs 36.8 (29.9) for non-members; p=0.380]. Importantly, membership in a pt advocacy group was associated with increased prescribed, supervised NPTM (57.6% [n=49] vs 34.4% [n=210]) and increased likelihood of having ever received medicinal rehabilitation (78.8% [n=67] vs 53.8% [n=328]) vs non-members. Pts reported to have ever received 2.6 rehabilitation measures in total, and ≥3.0 different rehabilitation NPTM measures. Cumulatively, 25.0% (N=654) of rehabilitation measures were physiotherapy, 8.0% (N=209) were rehabilitation sport and 5.5% (N=143) functional training (**Figure 1**). Importantly, there was no difference between self-applied regular physical training between groups (89.4% [n=76] vs 84.4% [n=515]).

Conclusion: Pt advocacy group membership was associated with increased prescribed NPTM in axSpA. Our data provide evidence for a significant role of patient organizations in the implementation of guideline-supported treat-

Figure 1. NPTM measures ever received in patients with axSpA (2617 answers from 770 pts)



Multiple answers were permitted. A total of 2617 answers were submitted from 770 patients. N, total number of pts. NPTM, non-pharmacological treatment modalities.

ments, as well as improvement of self-management strategies in pts with axSpA, which may have an influence on important health domains such as work participation.

SESSION INFORMATION

Session Date: Tuesday, November 9, 2021

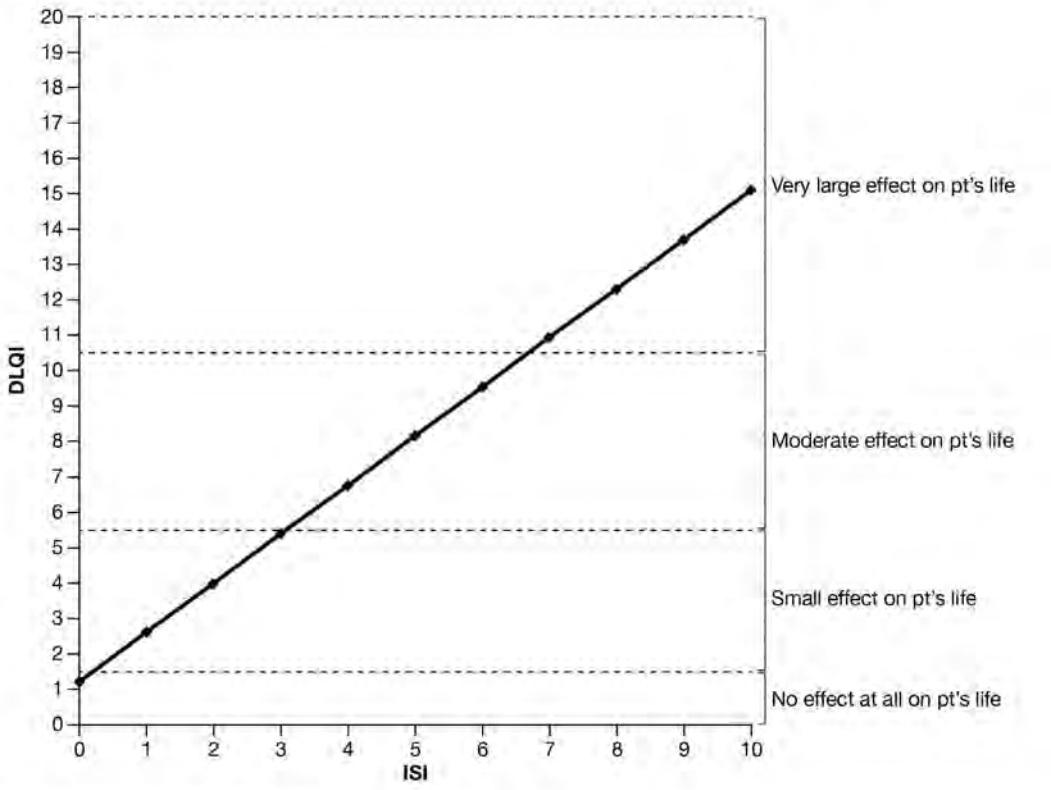
Session Title: Spondyloarthritis Including PsA – Treatment Poster III: Psoriatic Arthritis II (1801–1835)

Session Type: Poster Session D

Session Time: 8:30AM–10:30AM

Background/Purpose: Dermatologic symptoms of PsA can substantially impact patient (pt) health-related quality of life (HRQoL);[1] itch is the most commonly reported, and among the most bothersome of, symptoms.[2] In pts treated with tofacitinib, an oral Janus kinase inhibitor for the treatment of PsA,[3,4] improvements were observed in itch, Physician Global Assessment of Psoriasis (PGA-PsO), and HRQoL measures;[5] however, the relationships between these

Figure. Relationship between ISI and DLQI (pooled data from OPAL Broaden and OPAL Beyond)



ISI: 0 (no itching) to 10 (worst possible itching)

DLQI: score 0–1, no effect at all on pt's life; 2–5, small effect on pt's life; 6–10, moderate effect on pt's life; 11–20, very large effect on pt's life[6]

All available data from baseline to the end of the study were used. The mid points between adjacent severity categories were used as cut-offs for interpretation of the relationships of ISI and DLQI

DLQI, Dermatology Life Quality Index; ISI, Itch Severity Item; pt, patient

Table. Relationship between ISI, PGA-PsO, and PSA with DLQI and SF-36v2 domains (pooled data from OPAL Broaden and OPAL Beyond)

	SF-36v2 domains										DLQI
	PF	RP	BP	GH	VT	SF	RE	MH	PCS	MCS	
Responder-level CIC[a,b]	3.5	3.2	4.5	5.7	5.5	5.0	3.8	5.5	3.1	3.8	4.0
Dermatologic (anchor) assessment	**Improvements in SF-36v2 domains corresponding to 4-point/3-point/40-mm VAS improvements in ISI/PGA-PsO/PSA**										**DLQI improvements corresponding to 3-point/2-point/40-mm VAS improvements in ISI/PGA-PsO/PSA**
ISI	**3.8**	**3.9**	**4.7**	3.2	3.9	4.8	**4.4**	4.5	**3.5**	**4.3**	**4.2**
PGA-PsO	**4.8**	**4.6**	**6.2**	3.9	5.1	**5.9**	**5.1**	5.3	**4.5**	**4.9**	**4.1**
PSA	**4.0**	**4.1**	**5.5**	3.3	4.2	**5.0**	**4.7**	4.2	**3.9**	**4.2**	**4.4**

[a]Based on Optum's 1998 United States general population sample normative dataset[7]

[b]For general inflammatory skin conditions, a change in DLQI total score of at least 4 points is considered clinically important[8]

Bold numbers represent improvements larger than CIC

All available data from baseline to the end of the study were used

BP, bodily pain; CIC, clinically important change; DLQI, Dermatology Life Quality Index; GH, general health; HRQoL, health-related quality of life; ISI, Itch Severity Item; MCS, Mental Component Summary; MH, mental health; PCS, Physical Component Summary; PF, physical functioning; PGA-PsO, Physician Global Assessment of Psoriasis; PSA, Patient's Global Skin Assessment (assessed by 100 mm VAS); RE, role-emotional; RP, role-physical; SF, social functioning; SF-36v2, Short Form-36 Health Survey version 2; VAS, Visual Analog Scale; VT, vitality

outcomes have not been quantified. This post hoc analysis aimed to evaluate and quantify relationships between dermatologic symptoms and HRQoL in pts with PsA.

Methods: Data were pooled from 2 Phase 3 trials of pts with active PsA receiving tofacitinib 5 or 10 mg twice daily, or placebo (12-month OPAL Broaden [NCT01877668]; and 6-month OPAL Beyond [NCT01882439]).[3,4] A repeated measures longitudinal model assessed relationships between Itch Severity Item (ISI; numeric scale 0 [no itching]–10 [worst possible itching]), PGA-PsO (5-point severity scale defined by descriptors of erythema, induration, and scaling), and Patient's Global Skin Assessment (PSA; 100-mm Visual Analog Scale [VAS]) as predictors, and Dermatology Life Quality Index (DLQI; general dermatology questionnaire) and Short Form-36 Health Survey version 2 (SF-36v2) domains (physical functioning, role-physical, bodily pain, general health, vitality, social functioning, role-emotional, mental health, Physical Component Summary, Mental Component Summary) as outcomes. Each longitudinal model included one predictor and one outcome.

Results: An approximately linear relationship was observed between ISI, PGA-PsO, and PSA with total DLQI score, and each SF-36v2 domain. There was a direct relationship between itch severity (measured by ISI), severity of illness (measured by PGA-PsO), and pts' perception of disease (measured by PSA) and general dermatology QoL (measured by DLQI; Figure), as well as between ISI, PGA-PsO, and PSA and SF-36v2 domains. 3-point/2-point/40-mm VAS improvements from baseline (BL) in ISI/PGA-PsO/PSA, respectively, were associated with clinically meaningful improvements in DLQI (> 4 points; Table). 4-point/3-point/40-mm VAS improvements from BL in ISI/PGA-PsO/PSA were generally associated with clinically important improvements across SF-36v2 domains (Table). A 4-point ISI improvement was associated with a 4.7-point improvement in SF-36v2 bodily pain domain.

Conclusion: Substantial and quantifiable links exist between dermatologic symptoms and HRQoL in pts with PsA; physical and mental domains are ameliorated by tofacitinib. These findings help to inform pt care and pt-centered research.

Session Title: Spondyloarthritis Including PsA – Treatment Poster III: Psoriatic Arthritis II (1801–1835)
Session Type: Poster Session D
Session Time: 8:30AM–10:30AM

Background/Purpose: Although most patients with psoriatic arthritis (PsA) enrolled in clinical trials have polyarticular arthritis, patients in clinical practice may present with oligoarthritis. Data on the efficacy of Janus kinase inhibitors in patients with PsA with low joint counts are limited. The objective of this analysis was to evaluate the efficacy of upadacitinib (UPA) in subgroups of patients with PsA with a low (baseline swollen joint count [SJC] < 5) or high (SJC ≥5) SJC (LSJ or HSJ).

Methods: Data were pooled across the SELECT-PsA 1[1] (non-biologic disease-modifying antirheumatic drug [non-bDMARD] inadequate response [IR] or intolerance) and SELECT-PsA 2[2] (bDMARD IR or intolerance) trials, which both enrolled patients with ≥3 involved joints (SJC ≥3 and tender joint count [TJC] ≥3). Subgroup analysis was performed for patients with LSJ or HSJ treated with UPA 15 mg once daily (QD) or placebo (PBO). Efficacy endpoints included

minimal disease activity (MDA), very low disease activity (VLDA), Psoriatic Arthritis Disease Activity Score (PASDAS) low disease activity (LDA; ≤3.2), PASDAS remission (≤1.9), and 20/50/70% improvement in American College of Rheumatology (ACR) criteria (ACR20/50/70), all at Week 24, and Psoriasis Area Severity Index (PASI) 75 and static Investigator Global Assessment of Psoriasis (sIGA) 0/1 at Week 16.

Results: At baseline, patients with HSJ (n=1060) had similar demographic characteristics but tended to have higher overall disease activity than patients with LSJ across multiple disease domains (n=215; **Table**). UPA efficacy appeared comparable in patients with LSJ and HSJ, with similar proportions of patients achieving composite (MDA, VLDA, PASDAS LDA, and PASDAS remission) measures at Week 24, and skin endpoints (PASI 75 and sIGA 0/1) at Week 16 (**Figure**). At Week 24, 60.0/36.8/22.1% of patients with LSJ receiving UPA 15 mg achieved ACR20/50/70 vs 40.0/17.5/5.8% in the PBO group; rates were 70.3/49.7/26.2% (UPA 15 mg) and 36.1/15.3/3.3% (PBO) in those with HSJ.

Conclusion: UPA efficacy was generally similar in patients with PsA with LSJ or HSJ, with both patient groups showing improvements in composite clinical endpoints and skin responses vs PBO.

SESSION INFORMATION

Session Date: Tuesday, November 9, 2021

Session Title: Spondyloarthritis Including PsA – Treatment Poster III: Psoriatic Arthritis II (1801–1835)

Session Type: Poster Session D

Session Time: 8:30AM–10:30AM

Background/Purpose: Enthesitis is a key musculoskeletal manifestation of psoriatic arthritis (PsA). In the double-blind, head-to-head EXCEED study (NCT02745080), although the primary endpoint of superiority of ACR20 response for secukinumab (SEC) vs adalimumab (ADA) was not met, similar efficacy was observed across a range of musculoskeletal endpoints, including resolution of enthesitis at Week 52.[1] However, a detailed, site-level analysis of enthesitis was not conducted. Here, we report the baseline anatomical distribution of enthesitis, site-level entheseal response to SEC and ADA treatment through 52 weeks, and the dynamics of response based on the number of entheseal sites at baseline.

Methods: In this post hoc, descriptive analysis of patients in the EXCEED study who received SEC 300 mg or ADA 40 mg, enthesitis was assessed using the Spondyloarthritis Research Consortium of Canada Enthesitis Index (SPARCC). We reported the anatomical distribution of enthesitis at baseline based on the 16 sites targeted by SPARCC. Through descriptive efficacy analysis, we explored resolution of enthesitis at site level through Week 52 across the 2 treatment groups. Patients were further classified into subgroups of baseline enthesis severity as follows: mild (SPARCC < 3), moderate (SPARCC ≥ 3 to ≤ 6), or severe (SPARCC > 6 to ≤ 16). Resolution of enthesitis at Week 52 was assessed in patients stratified by baseline enthesitis severity. For enthesitis severity subgroups, resolution of enthesitis was assessed at Week 52, and time to resolution was estimated using Kaplan-Meier analysis with nonresponder imputation for missing data. Descriptive statistics are provided for each endpoint using an observed-case approach.

Results: Overall, 301 of 426 patients (70.7%) randomized to receive SEC and 331 of 427 patients (77.5%) randomized to ADA had enthesitis at baseline as determined by SPARCC. Baseline distribution of enthesitis sites was well balanced among patients across the 2 treatment groups (Figure 1). By Week 12, a high proportion of patients

Table. Proportion of Patients With Site-Level Resolution of SPARCC Enthesitis at Weeks 12, 24, and 52

Patients with enthesitis at site, n/M (%)	Secukinumab 300 mg (N = 426)	Adalimumab 40 mg (N = 427)
Achilles tendon insertion into calcaneum		
Week 12	229/286 (80.1)	246/311 (79.1)
Week 24	232/274 (84.7)	235/293 (80.2)

Greater trochanter		
Week 12	212/286 (74.1)	230/311 (74.0)
Week 24	225/274 (82.1)	234/293 (79.9)
Week 52	225/267 (84.3)	229/263 (87.1)
Lateral epicondyle		
Week 12	215/286 (75.2)	222/311 (71.4)
Week 24	216/274 (78.8)	227/293 (77.5)
Week 52	226/267 (84.6)	229/263 (87.1)
Medial epicondyle		
Week 12	226/286 (79.0)	232/311 (74.6)
Week 24	235/274 (85.8)	227/293 (77.5)
Week 52	232/267 (86.9)	229/263 (87.1)
Patellar ligament insertion into inferior pole of patella or tibial tubercle		
Week 12	234/286 (81.8)	242/311 (77.8)
Week 24	238/274 (86.9)	249/293 (85.0)
Week 52	242/267 (90.6)	237/263 (90.1)
Plantar fascia insertion into calcaneum		
Week 12	247/286 (86.4)	276/311 (88.7)
Week 24	243/274 (88.7)	255/293 (87.0)
Week 52	239/267 (89.5)	244/263 (92.8)
Quadriceps insertion into superior border of patella		
Week 12	236/286 (82.5)	263/311 (84.6)
Week 24	243/274 (88.7)	255/293 (87.0)
Week 52	242/267 (90.6)	238/263 (90.5)
Supraspinatus insertion into greater tuberosity of humerus		
Week 12	212/286 (74.1)	256/311 (82.3)
Week 24	227/274 (82.8)	244/293 (83.3)
Week 52	229/267 (85.8)	230/263 (87.5)

n, number of patients with enthesitis resolution at site; M, number of patients evaluated; SPARCC, Spondyloarthritis Research Consortium of Canada Enthesitis Index.

in both treatment groups achieved similar resolution of enthesitis at the level of individual entheses with sustained improvement through Week 52 (Table). Achievement of enthesitis resolution at Week 52 was similar between treatment groups irrespective of disease severity (Figure 2). Median (95% CI) number of days to resolution of enthesitis increased with increasing baseline enthesitis severity and was similar for SEC and ADA groups with mild (SEC: 29, 29-57; ADA: 31, 29-57), moderate (SEC: 100.5, 58-169; ADA: 113, 85-120), and severe (SEC: 372, 282-not estimable [NE]; ADA: 386, 281-NE) enthesitis.

Conclusion: The anatomical distribution of enthesitis at baseline was mostly balanced between the upper and lower extremities in both SEC and ADA groups in a pattern consistent with previous reports.[2] These analyses also highlight the early and sustained resolution of enthesitis through 52 weeks at site level with both drugs. SEC and ADA displayed similar dynamics of response on enthesitis irrespective of enthesitis severity at baseline.

Secukinumab Provides Clinical Improvements in Patients with Active Oligoarticular Psoriatic Arthritis: Results from a Pooled Analysis of 5 Phase 3 Studies

Alexis Ogdie[1], Dafna Gladman[2], Laura Coates[3], Effie Pournara[4], Xiangyi Meng[5], Bhumik Parikh[5] and Philip Mease[6], [1]University of Pennsylvania, Philadelphia, PA, [2]Schroeder Arthritis Institute, Krembil Research Institute, Toronto Western Hospital, Toronto, ON, Canada, [3]Nuffield Department of Orthopaedics, Rheumatology and Musculoskeletal Sciences, University of Oxford, Oxford, United Kingdom, [4]Novartis Pharma AG, Basel, Switzerland, [5]Novartis Pharmaceuticals Corporation, East Hanover, NJ, [6]Swedish Medical Center/Providence St. Joseph Health and University of Washington, Seattle, WA

SESSION INFORMATION
Session Date: Tuesday, November 9, 2021
Session Title: Spondyloarthritis Including PsA – Treatment Poster III: Psoriatic Arthritis II (1801–1835)
Session Type: Poster Session D
Session Time: 8:30AM–10:30AM

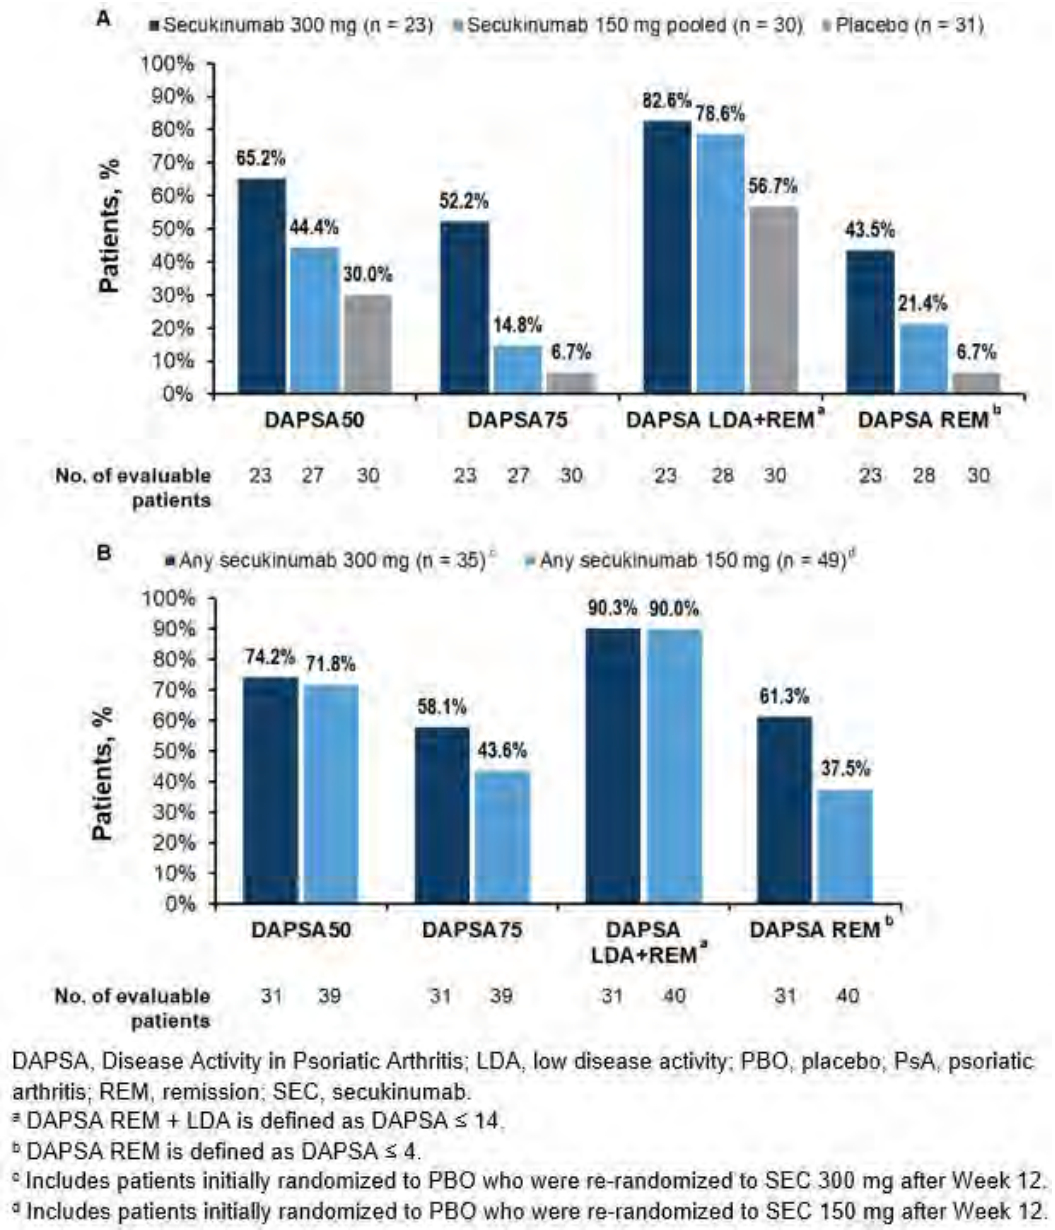
Background/Purpose: Oligoarticular psoriatic arthritis (PsA), defined as involvement of ≤ 4 joints, affects approximately 50% of the PsA population.[1,2] Disease burden is comparable for patients with oligoarticular or polyarticular disease, and most patients progress from oligoarticular to polyarticular PsA.[1,2] Evidence for the efficacy of biologics in patients with oligoarticular PsA is limited, as inclusion criteria for randomized controlled trials in PsA typically require ≥ 3 swollen and tender joints. We evaluated the efficacy of the interleukin 17 inhibitor secukinumab (SEC) in patients with oligoarticular PsA pooled from 5 phase 3 studies.

Methods: This post hoc analysis included patients with oligoarticular PsA from the FUTURE 2-5 and MAXIMISE trials (NCT01649375, NCT01989468, NCT02294227, NCT02404350, and NCT02721966). Oligoarticular PsA was defined as the presence of 1-4 tender joints and 1-4 swollen joints at baseline as measured by the tender joint count of 78 joints (TJC78) and the swollen joint count of 76 joints (SJC76), respectively. For this analysis, patients were pooled by treatment received at Week 12 and Week 52 according to the following groups: Week 12 (SEC 300 mg, SEC 150 mg

Table. Demographics and Baseline Disease Characteristics

Characteristic	SEC 300 mg (n = 23)	SEC 150 mg, pooled (n = 30)	PBO (n = 31)
Age, mean (SD), years	38.8 (13.3)	43.2 (12.1)	46.8 (14.3)
Male, n (%)	16 (69.6)	19 (63.3)	19 (61.3)
White, n (%)	22 (95.7)	29 (96.7)	31 (100)
BMI, mean (SD), kg/m^2	27.0 (5.8)	29.4 (6.0)	28.1 (4.3)
TJC78, mean (SD)	3.3 (0.9)	3.3 (1.0)	3.4 (0.7)
SJC76, mean (SD)	3.0 (1.1)	2.7 (1.1)	2.7 (1.0)
DAPSA, mean (SD)	18.0 (4.7)	16.7 (4.8)	17.6 (4.5)
HAQ-DI, mean (SD)	0.9 (0.5)	1.1 (0.7)	1.0 (0.7)
Time since PsA diagnosis, mean (SD), years	3.0 (3.5)	4.1 (6.4)	5.1 (5.8)

BMI, body mass index; DAPSA, Disease Activity in Psoriatic Arthritis; HAQ-DI, Health Assessment Questionnaire-Disability Index; PBO, placebo; SEC, secukinumab; SJC76, swollen joint count of 76 joints; TJC78, tender joint count of 78 joints.

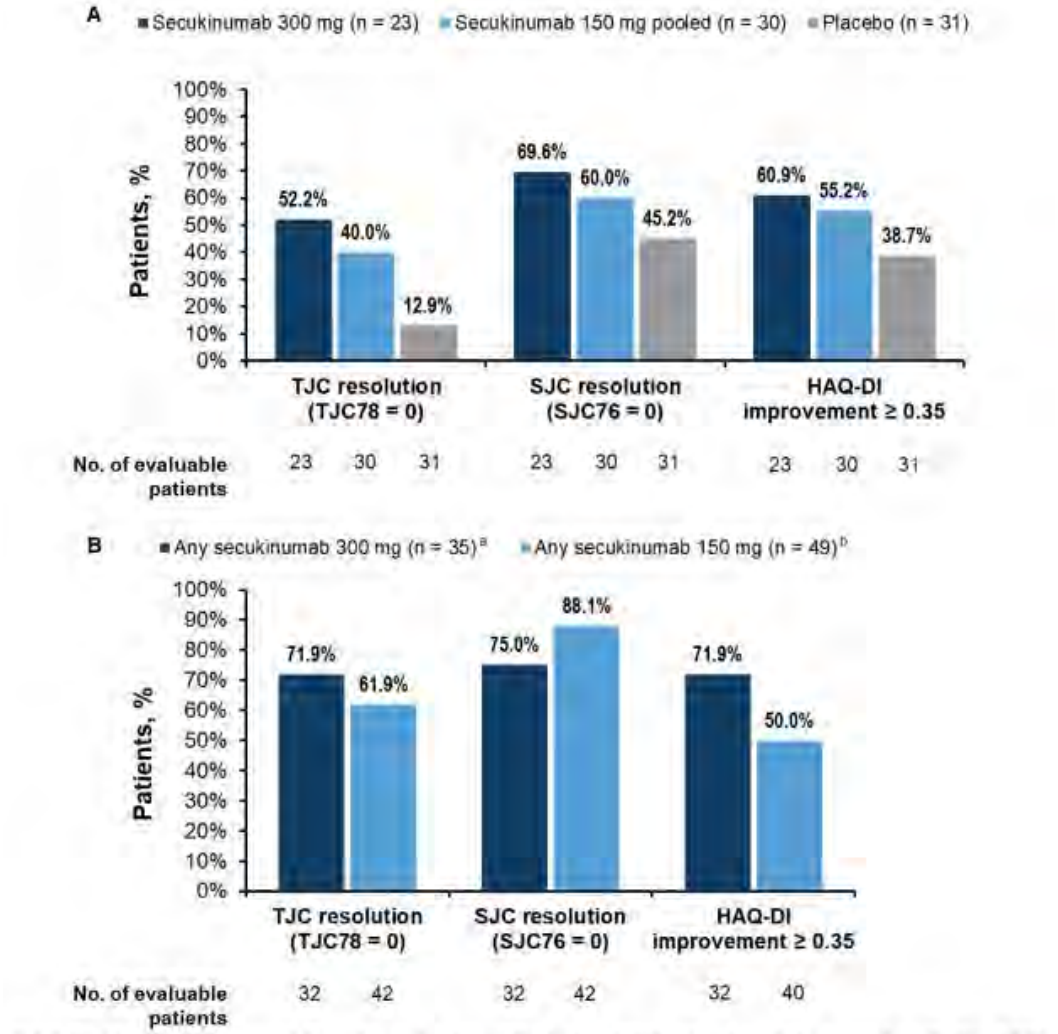


DAPSA, Disease Activity in Psoriatic Arthritis; LDA, low disease activity; PBO, placebo; PsA, psoriatic arthritis; REM, remission; SEC, secukinumab.
[a] DAPSA REM + LDA is defined as DAPSA ≤ 14.
[b] DAPSA REM is defined as DAPSA ≤ 4.
[c] Includes patients initially randomized to PBO who were re-randomized to SEC 300 mg after Week 12.
[d] Includes patients initially randomized to PBO who were re-randomized to SEC 150 mg after Week 12.

Figure 1. Proportion of Patients With Oligoarticular PsA Achieving DAPSA Responses at (A) Week 12 and (B) Week 52 (observed).

with or without loading dose [LD], or placebo [PBO]) and Week 52 (any SEC 300 mg or any SEC 150 mg). Efficacy was assessed by the proportion of patients achieving 50% improvement in Disease Activity in Psoriatic Arthritis (DAPSA50), DAPSA75, DAPSA-based low disease activity (LDA) and remission (REM), resolution of TJC78, resolution of SJC76, and a ≥ 0.35-point improvement in the Health Assessment Questionnaire-Disability Index score. Descriptive statistics are provided for each endpoint using an observed-case approach. Logistic regression analysis was used to identify potential predictors of DAPSA response at Weeks 12 and 52; multivariate logistic regression analyses were performed thereafter.

Results: In total, 84 patients were included in this analysis: 48 with active PsA from the FUTURE 2-5 trials and 36 with active PsA and axial manifestations from the MAXIMISE trial. Demographics and baseline disease characteristics



HAQ-DI, Health Assessment Questionnaire-Disability Index; PBO, placebo; PsA, psoriatic arthritis; SEC, secukinumab; SJC76, swollen joint count of 76 joints; TJC78, tender joint count of 78 joints.
[a] Includes patients initially randomized to PBO who were re-randomized to SEC 300 mg after Week 12.
[b] Includes patients initially randomized to PBO who were re-randomized to SEC 150 mg after Week 12.

Figure 2. Proportion of Patients With Oligoarticular PsA Achieving Resolution of TJC, Resolution of SJC, and a ≥ 0.35-Point HAQ-DI Score Improvement at (A) Week 12 and (B) Week 52 (observed).

are presented in the Table. At Week 12, notable improvements were observed for the SEC vs PBO groups across all the assessed outcome measures (Figures 1A, 2A). These improvements were sustained or increased further through Week 52 (Figures 1B, 2B). More than 90% of patients who received any SEC 300 mg or SEC 150 mg achieved LDA or REM at Week 52 (Figure 1B). At Week 52, a higher proportion of patients who received any SEC 300 mg vs any SEC 150 mg achieved higher hurdle endpoints of DAPSA 75 and DAPSA REM (Figure 1B). At Week 12, younger age was a predictor for the achievement of DAPSA LDA or REM and the achievement of DAPSA50, while lower baseline SJC was a predictor of the achievement of DAPSA REM ($P < .05$). No predictors were identified at Week 52.

Conclusion: SEC provides greater improvements vs PBO across a number of disease activity and physical function outcome measures in patients with oligoarticular PsA at Week 12, with sustained responses through Week 52.

Reduced Burden on Paid and Household Work Productivity with Stringent Thresholds of Disease Control: Further Results from Long-Term Certolizumab Pegol Treatment in Patients with Psoriatic Arthritis

William Tillett[1], Laura Coates[2], Sandeep Kiri[3], Vanessa Taieb[3] and Philip Mease[4], [1]Royal National Hospital for Rheumatic Diseases, Bath, United Kingdom, [2]Nuffield Department of Orthopaedics, Rheumatology and Musculoskeletal Sciences, University of Oxford, Oxford, United Kingdom, [3]UCB Pharma, Slough, United Kingdom, [4]Swedish Medical Center/Providence St. Joseph Health and University of Washington, Seattle, WA

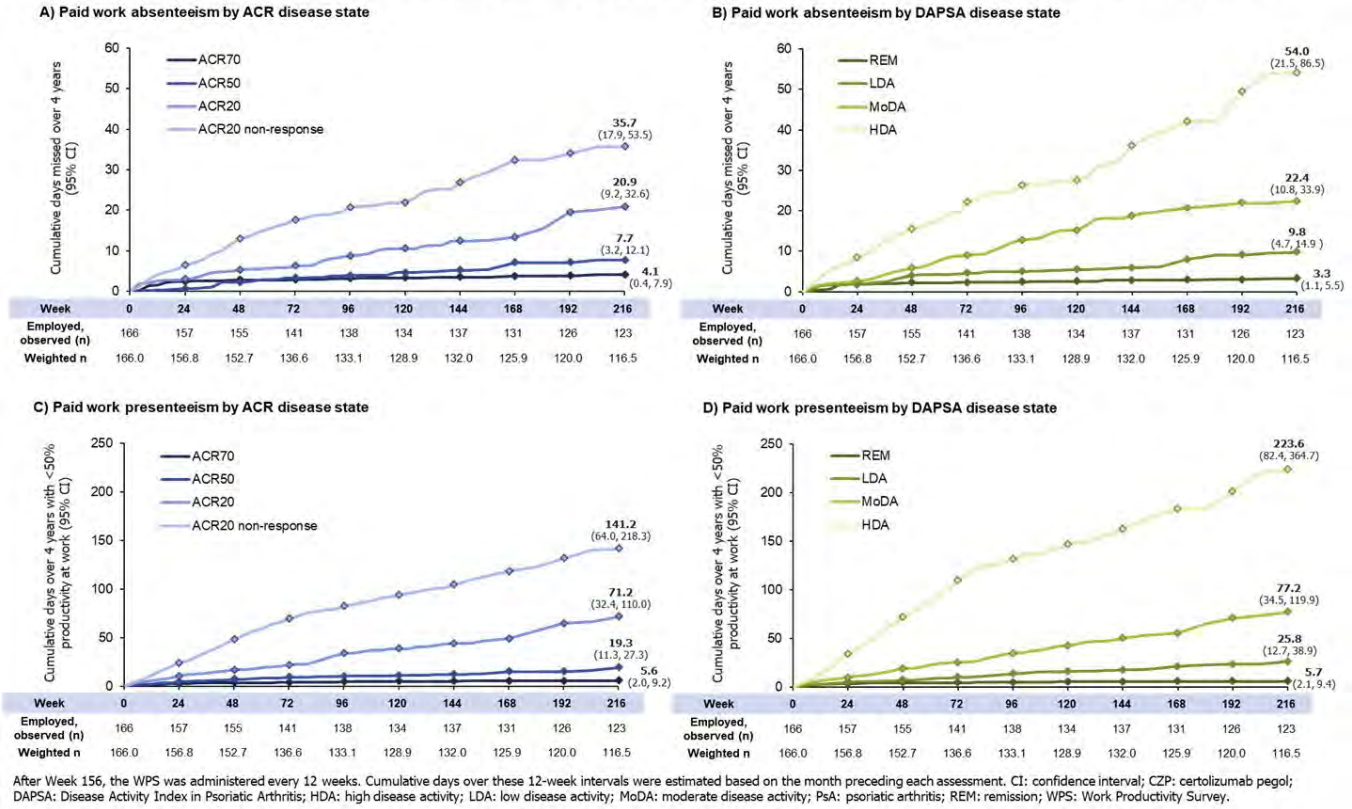
SESSION INFORMATION
Session Date: Tuesday, November 9, 2021
Session Title: Spondyloarthritis Including PsA – Treatment Poster III: Psoriatic Arthritis II (1801–1835)
Session Type: Poster Session D
Session Time: 8:30AM–10:30AM

Background/Purpose: Psoriatic arthritis (PsA) is associated with a reduction in workplace productivity,[1] which may extend into household productivity.[2] Certolizumab pegol (CZP) is a tumor necrosis factor inhibitor, clinically effective at improving disease activity outcomes for patients (pts) with PsA.[3] We have previously reported an association between stringent thresholds of disease control in pts with PsA, measured by ACR response criteria, and paid/household work productivity.[4] However, it is also important to assess the relationship between disease activity and paid/household work productivity using a measure more relevant to real-world practice, such as Disease Activity Index in PsA (DAPSA).

Our purpose was to evaluate the association between DAPSA disease states and burden on paid/household work productivity in pts with PsA during long-term treatment with CZP.

Methods: These analyses used data from pts originally randomized to CZP in RAPID-PsA (NCT01087788), a 216-week phase 3 study.[3] Pts were classified according to the ACR20/50/70 criteria and DAPSA disease states (high disease activity [HDA], moderate disease activity [MoDA], low disease activity [LDA] and remission [REM]). Paid/household work productivity, assessed with the arthritis-specific Work Productivity Survey, was compared for each threshold of disease control. An inverse probability weight model was used to account for predictors of dropout over

Figure 1. Paid work absenteeism and presenteeism by disease activity, assessed by (A, C) ACR 20/50/70 response criteria and (B, D) DAPSA disease states for CZP-randomized population



After Week 156, the WPS was administered every 12 weeks. Cumulative days over these 12-week intervals were estimated based on the month preceding each assessment. CI: confidence interval; CZP: certolizumab pegol; DAPSA: Disease Activity Index in Psoriatic Arthritis; HDA: high disease activity; LDA: low disease activity; MoDA: moderate disease activity; PsA: psoriatic arthritis; REM: remission; WPS: Work Productivity Survey.

216 weeks. Cumulative days affected since study baseline were estimated using a weighted generalized estimating equations model.

Results: 273 pts were randomized to CZP, 183 (67.0%) of these pts completed Week 216. At baseline, 60.8% of pts were employed outside the home. Through Week 216, fewer days of paid work absence (absenteeism) were reported by pts achieving ACR70 (4.1 [95% confidence interval: 0.4, 7.9]), DAPSA REM (3.3 [1.1, 5.5]) and the intermediate measures, than ACR20 non-responders (35.7 [17.9, 53.5]) and those with DAPSA HDA (54.0 [21.5, 86.5]; **Figure 1A**, **B**). These findings extended to household work absenteeism; again pts achieving ACR70 (8.5 [4.4, 12.5]) and DAPSA REM (6.7 [3.2, 10.2]) reported fewer absences than ACR20 non-responders (189.9 [129.1, 250.7] and those with DAPSA HDA (328.9 [220.5, 437.4]; **Figure 2A**, **B**).

Improved ACR and DAPSA outcomes also correlated with larger reductions in the number of days with < 50% productivity at work/home (presenteeism; **Figure 1C**, **D** & **Figure 2C**, **D**), compared with absenteeism.

Conclusion: Cumulative estimates of the number of work days affected by PsA, as correlated with DAPSA status, support earlier findings[4] that achievement of more stringent thresholds of disease control are associated with reduced burden on paid/household work productivity.

SESSION INFORMATION

Session Date: Tuesday, November 9, 2021

Session Title: Spondyloarthritis Including PsA – Treatment Poster III: Psoriatic Arthritis II (1801–1835)

Session Type: Poster Session D

Session Time: 8:30AM–10:30AM

Table 1. Baseline characteristics of patients with PsO treated with UST in the BADBIR (N=6302). BADBIR, British Association of Dermatologists Biologic and Immunomodulators Register; BMI, body mass index; PASI, Psoriasis Area and Severity Index; PsA, psoriatic arthritis; PsO, psoriasis; UST, ustekinumab

Baseline characteristic		Patients, n (%)
Comorbid PsA	No PsA	5353 (84.9)
	PsA	949 (15.1)
Biologic experience	No prior biologic	5206 (82.6)
	Prior biologic	1096 (17.4)
PASI (n=6281)	PASI ≤3	1125 (17.9)
	PASI >3–≤10	1723 (27.4)
	PASI >10–≤20	2643 (42.1)
	PASI >20	790 (12.6)
Sex	Female	2698 (42.8)
	Male	3604 (57.2)
Depression	No depression	4901 (77.8)
	Depression	1401 (22.2)
Obesity (BMI, kg/m^2) (n=5758)	<30	2979 (51.7)
	≥30	2779 (48.3)

Background/Purpose: Skin and joint symptoms both contribute to the burden of disease in psoriatic arthritis (PsA).[1] More severe skin symptoms in patients with both skin and joint involvement have been reported to be associated with poorer quality of life, higher disability and lower work productivity.[2] The objective of this study was hence to evaluate to what extent baseline (BL) factors, such as comorbid PsA and psoriasis (PsO) severity, are associated with ustekinumab (UST) persistence in patients with PsO enrolled in the British Association of Dermatologists Biologic and Immunomodulators Register (BADBIR).

Methods: This retrospective observational study used data from patients with PsO receiving UST in the BADBIR (first enrolled, 07/2009; data cut-off, 10/2020). Time to discontinuation (TTD) was defined as the time from treatment start date until treatment stop date, censoring for loss to follow-up where patients were lost to follow-up or active in the registry without a recorded treatment stop date. Hazard ratios (HRs), confidence intervals and p-values (Wald test) for the association between obesity, sex, PsA status, prior biologic exposure, depression, Psoriasis Area and Severity

Table 2. Cox regression model for time to discontinuation of UST in patients with PsO. *Indicates interaction between covariates. BMI, body mass index; HR, hazard ratio; PASI, Psoriasis Area and Severity Index; PsA, psoriatic arthritis; PsO, psoriasis; UST, ustekinumab

Covariate	Status	HR	p-value
Comorbid PsA	No PsA	Reference	–
	PsA	1.98	<0.0001
Biologic experience	No prior biologic	Reference	–
	Prior biologic	1.08	0.3
PASI	PASI ≤3	Reference	–
	PASI >3–≤10	1.35	0.002
	PASI >10–≤20	1.23	0.019
	PASI >20	1.77	<0.0001
Sex	Female	Reference	–
	Male	0.72	<0.0001
Depression	No depression	Reference	–
	Depression	1.21	0.0007
Obesity (BMI, kg/m^2)	<30	Reference	–
	≥30	1.08	0.15
PsA*prior biologic experience	PsA, no prior biologic	Reference	–
	PsA, prior biologic	2.35	0.005
PsA*PASI	PsA, PASI ≤3	Reference	–
	PsA, PASI >3–≤10	1.72	0.2
	PsA, PASI >10–≤20	1.35	0.0008
	PsA, PASI >20	1.37	0.004

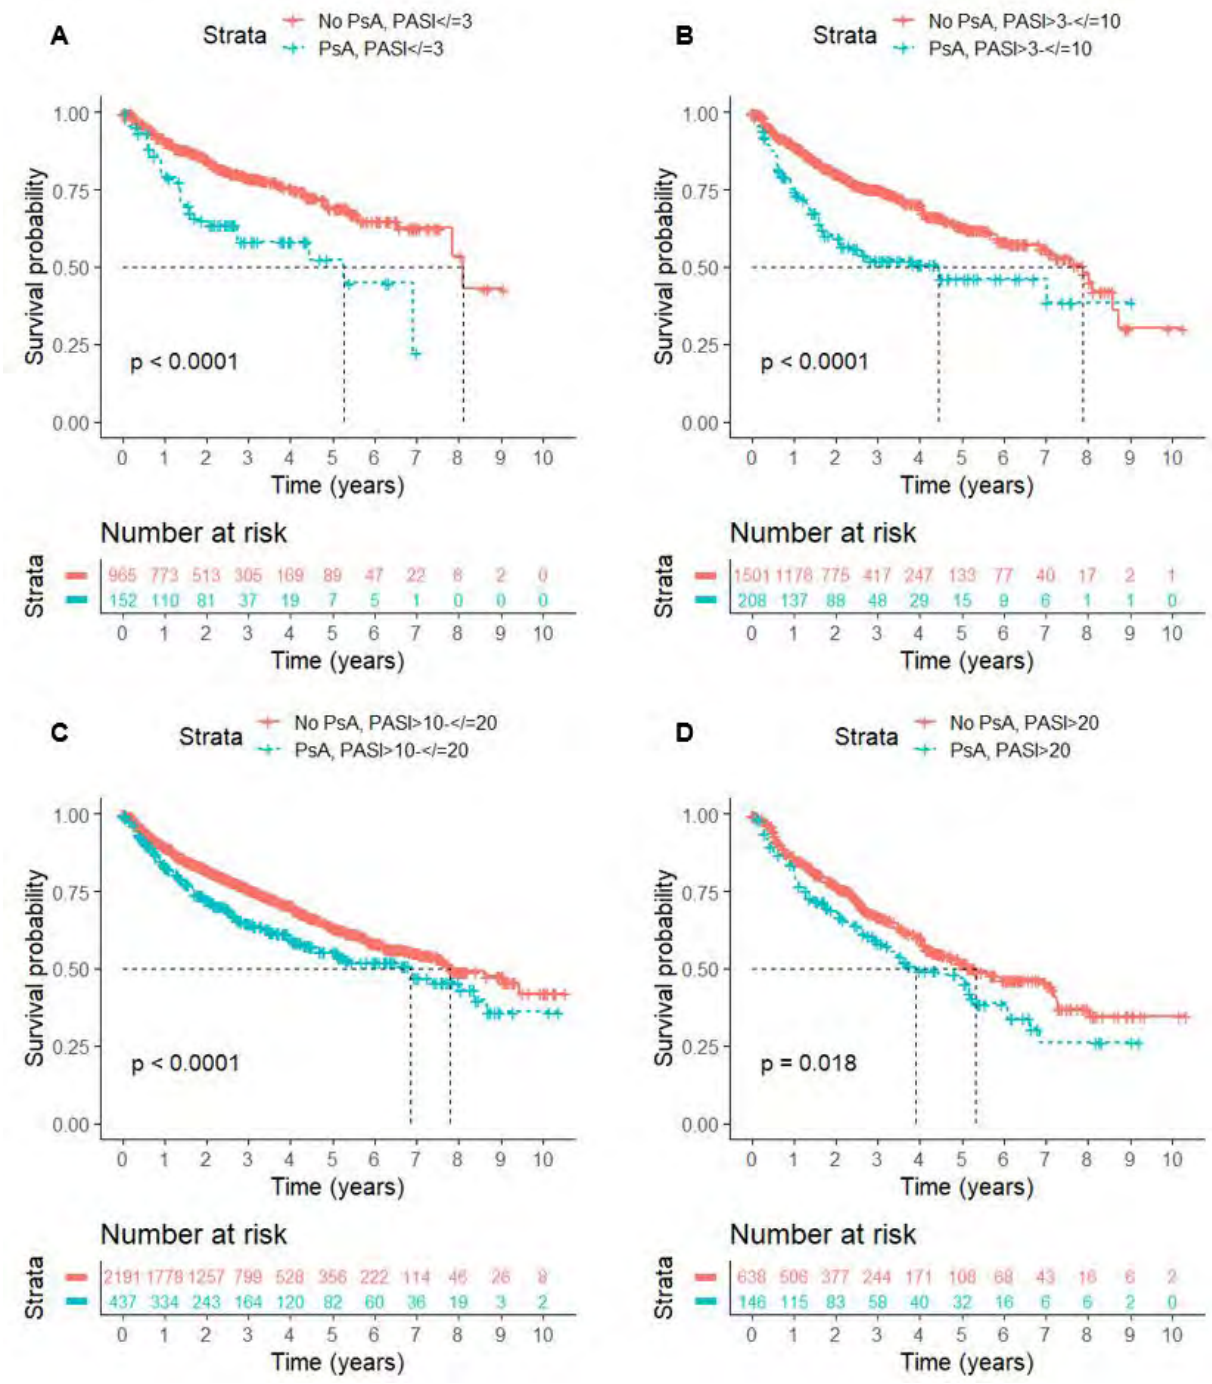

Figure 1. Drug survival in patients with PsO treated with UST, stratified by presence of comorbid PsA and according to PASI strata of (A) ≤3, (B) >3–≤10, (C) >10–≤20 and (D) >20. PASI, Psoriasis Area and Severity Index; PsA, psoriatic arthritis; PsO, psoriasis; UST, ustekinumab.

Index (PASI) strata, and interactions between covariates and TTD were generated using Cox proportional hazards regression. Kaplan–Meier analysis was used to estimate probability of TTD. Patients were stratified by PsA diagnosis at BL and PASI. The log-rank test was used to compare persistence among groups.

Results: Patient BL characteristics are listed in Table 1. Multivariable analysis (Table 2) found that median TTD was shorter for patients with comorbid PsA vs. PsO alone (HR 1.98; p< 0.0001). Median TTD was shorter in patients with depression vs. no depression (HR 1.21; p=0.0007). Men were at lower risk of discontinuation vs. women (HR 0.72; p<

0.0001). Prior biologic experience reduced TTD in patients with comorbid PsA vs. biologic-naïve patients with PsA (HR 2.35; p=0.005). PASI >3 at BL was associated with increased probability of discontinuation vs. PASI ≤3 (PASI >3–≤10, HR 1.35, p=0.002; PASI >10–≤20, HR 1.23, p=0.019; PASI >20, HR 1.77, p< 0.0001). In patients with comorbid PsA, higher skin severity at BL also led to a shorter TTD, with PsA seeming to have a greater impact on UST persistence in patients with lower skin severity at BL. Median TTD in patients with PsO alone and PASI ≤3 was 8.11 years vs. 5.27 years for patients with comorbid PsA (p< 0.0001). In patients with PASI >20, median TTD for patients with PsO alone was 5.33 years vs. 3.89 years for patients with comorbid PsA (p=0.018; Figure 1).

Conclusion: PsA, female sex and depression were associated with a shorter TTD of UST. More severe skin disease at BL had a higher association with discontinuation, irrespective of comorbid PsA, and comorbid PsA had a greater association with shorter TTD in patients with lower PASI scores. This suggests that patient-centric, multidisciplinary care needs to be considered to achieve the best possible outcomes in psoriatic disease.

Safety Profile of Ixekizumab for the Treatment of Psoriatic Arthritis and Axial Spondyloarthritis up to 3 Years: An Updated Integrated Safety Analysis

Sergio Schwartzman[1], Atul Deodhar[2], Bernard Combe[3], Ana Accioly[4], Andris Kronbergs[4], Boris Janos[5], Danting Zhu[4], David Sandoval Calderon[4], Proton Rahman[6] and Denis Poddubnyy[7], [1]Self Employed 72nd Street Medical Associates, Scarsdale, NY, [2]Oregon Health & Science University, Portland, OR, [3]CHU Montpellier Montpellier University, Montpellier, France, [4]Eli Lilly and Company, Indianapolis, IN, [5]Eli Lilly, Calgary, AB, Canada, [6]Department of Medicine, Eastern Health and Memorial University of Newfoundland, St John's, NL, Canada, [7]Department of Rheumatology, Charité – Universitätsmedizin, Berlin, Germany

SESSION INFORMATION
Session Date: Tuesday, November 9, 2021
Session Title: Spondyloarthritis Including PsA – Treatment Poster III: Psoriatic Arthritis II (1801–1835)
Session Type: Poster Session D
Session Time: 8:30AM–10:30AM

Background/Purpose: Ixekizumab (IXE) is a high-affinity monoclonal antibody that selectively targets IL-17A approved for the treatment of psoriasis, psoriatic arthritis (PsA), active ankylosing spondylitis (AS) and non-radiographic axial spondyloarthritis (nr-axSpA) with objective signs of inflammation. We report a summary of the safety outcomes with over 2000 patient-years (PY) of exposure up to 3 years in patients with PsA and axSpA.

Methods: Long-term safety of IXE was assessed from 8 randomized trials. Treatment-emergent adverse events (TEAEs) adjusted incidence rates (IRs) per 100 PY within 1-year time periods through 19 March 2021 were calculated for all patients treated with ≥1 dose of IXE. Safety outcomes included TEAEs, serious AEs (SAEs), discontinuations

Table. Safety Outcomes		
	Pooled PsA IXE (N=1401)	**Pooled axSpA IXE (N=932)**

axSpA, axial spondyloarthritis; IR, incidence rate; IXE, ixekizumab; MACE, major adverse cerebro-cardiovascular events; n, number of patients in each category; PsA, psoriatic arthritis; SAEs, serious adverse events; SMQ, Standardised MedDRA Queries; TEAEs, Treatment-emergent adverse events. Adverse event (AE) terms were derived from MedDRA v23.1. aThe 6 reported deaths in the PsA population were due to cardiovascular event (n=2), metastatic renal cell carcinoma (n=1), cerebrovascular accident (n=1), pneumonia (n=1), and drowning (n=1). In the axSpA population, the causes of deaths were suicide (n=1), sepsis (n=1), and murder (n=1). bOpportunistic infections included esophagus candidiasis, oral candidiasis, hepatitis B reactivation, and herpes zoster. cSome Candida infections cases were also considered as opportunistic infections. All cases of Candida infection were localized. In PsA program, most cases were mild (34/45, IR=1.5 per 100 patient-years) to moderate (10/45, IR=0.4 per 100 patient-years) in severity, except 1 case of esophagus candidiasis considered severe. The patient who reported severe esophagus candidiasis did not discontinue the study drug due to this AE. In axSpA program, all cases were mild (16/26, IR=0.8 per 100 patient-years) or moderate (10/26, IR=0.5 per 100 patient-years) in severity. Across indications, no cases of systemic candidiasis were reported. dNo cases of anaphylaxis were confirmed after medical reviews. eBroad, according to SMQ classification. fBased on neutrophils count lab results. Neutropenia grade ≥3, n (IR) [95%CI] PsA= 8 (0.4) [0.2, 0.7], axSpA= 4 (0.2) [0.1, 0.5]. gThe data represents events confirmed by adjudication. hBroad, according to SMQ or sub-SMQ classification. iThe data represents confirmed cases per external adjudication. In the PsA population, none of the patients with confirmed IBD per external adjudication had medical history of IBD. Three patients had events of IBD confirmed by adjudication. One patient had more than 1 event. In the axSpA population, of the 17 patients with adjudicated IBD, 5 patients had a history of IBD.

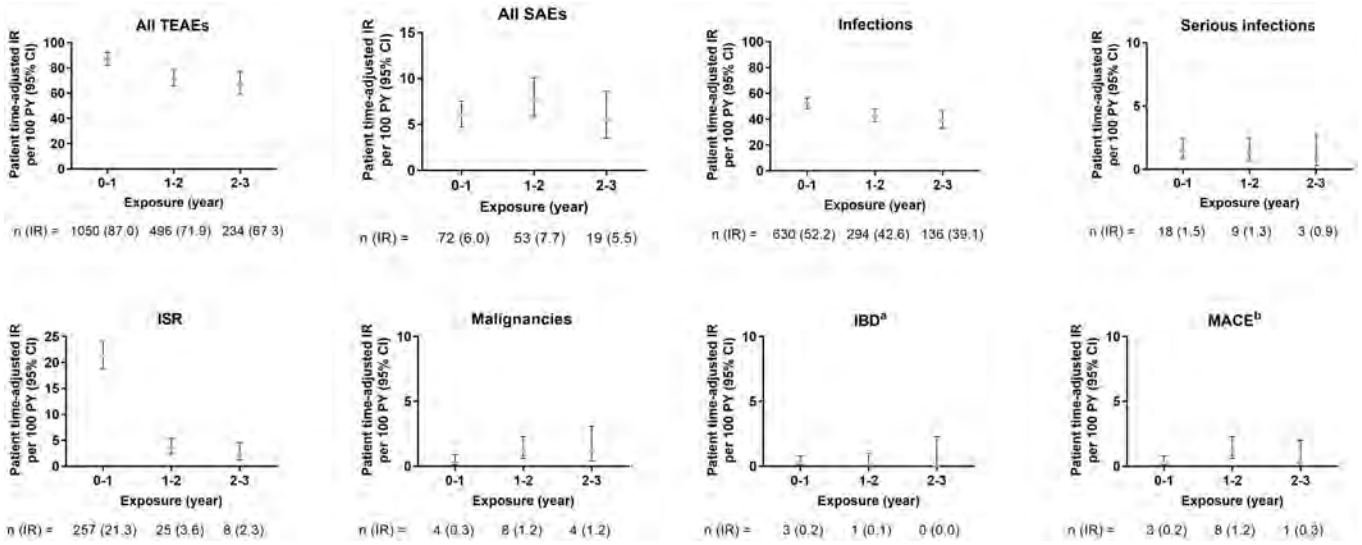

Figure 1. Exposure-adjusted incidence rate of TEAEs, SAEs, and selected AEs in PsA pooled population. The data points on the graph are the IR (95% CI)/100 patient-years at successive year intervals from year 0 to year 3. The CIs for the IRs are from likelihood ratio test of treatment effect from the Poisson regression model. aThe data represents confirmed cases per external adjudication. Three patients had events of IBD confirmed by adjudication. One patient had more than 1 event. bThe data represents events confirmed by adjudication. AEs, adverse events; CI, confidence interval; IBD, inflammatory bowel disease; IR, incidence rates; ISR, injection-site reactions; MACE, major adverse cerebro-cardiovascular events; PsA, psoriatic arthritis; SAE, serious adverse events; TEAEs, treatment-emergent adverse events.

due to AEs, deaths, and selected safety topics of interest. Major adverse cerebro-cardiovascular event (MACE) and inflammatory bowel disease (IBD) reported cases were adjudicated.

Results: A total of 1401 patients with PsA and 932 patients with axSpA with a cumulative IXE exposure of 2247.7 PY for PsA and 2096.2 PY for axSpA were included in this analysis (Table). The IRs per 100 PY for any TEAE were 50.3 for PsA and 38.1 for axSpA. Serious AEs were reported by 134 patients with PsA (IR=6.0), and 101 patients with axSpA (IR=4.8). A total of 9 deaths was reported, including 6 in PsA (IR= 0.3) and 3 in axSpA (IR=0.1). The IRs per 100 PY

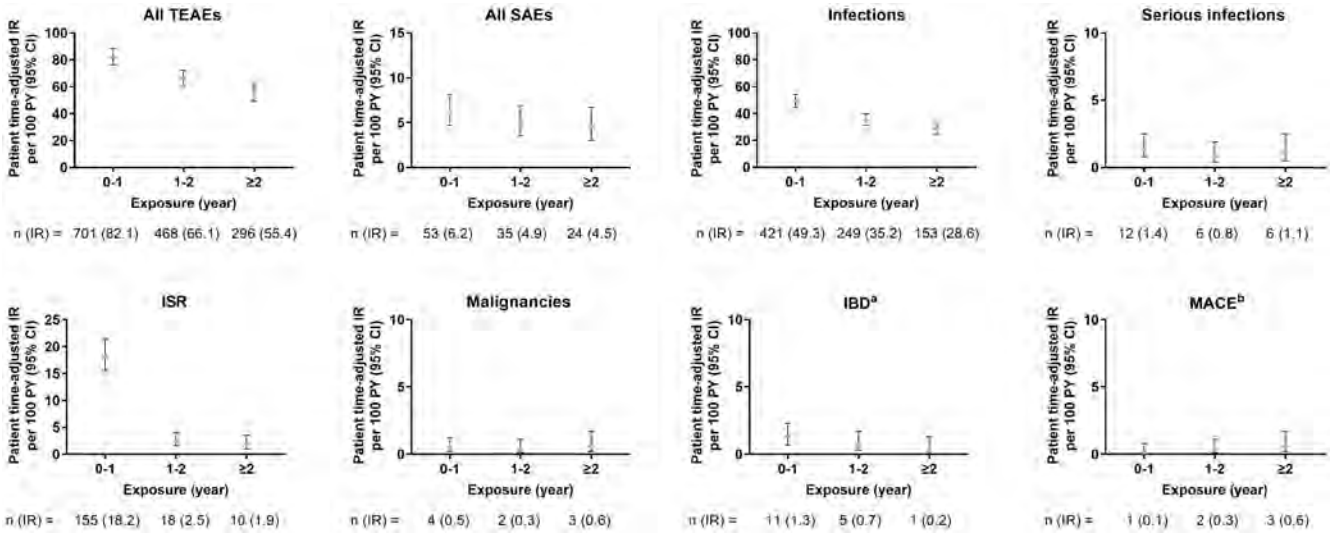

Figure 2. Exposure-adjusted incidence rate of TEAEs, SAEs, and selected AEs in axSpA pooled population. The data points on the graph are the IR (95% CI)/100 patient-years at successive year intervals from year 0 to ≥2 year. The CIs for the IRs are from likelihood ratio test of treatment effect from the Poisson regression model. aThe data represents confirmed cases per external adjudication. bThe data represents events confirmed by adjudication. AEs, adverse events; axSpA, axial spondyloarthritis; CI, confidence interval; IBD, inflammatory bowel disease; IR, incidence rates; ISR, injection-site reactions; MACE, major adverse cerebro-cardiovascular events; SAE, serious adverse events; TEAEs, treatment-emergent adverse events.

of discontinuation from the study drug due to AE were 5.1 (PsA) and 3.1 (axSpA). IRs of serious infections were low (PsA: IR= 1.2, axSpA: IR=1.1). IRs of opportunistic infections (PsA: IR= 1.8, axSpA: IR=0.8) and *Candida* infections (PsA: IR= 2.0, axSpA: IR=1.2) were low. There were no confirmed cases of reactivation of tuberculosis. Injection site reactions occurred with IRs of 11.6 (PsA) and 7.4 (axSpA). The IRs for allergic/hypersensitivity reactions were 4.5 (PsA) and 4.2 (axSpA). No confirmed events of anaphylaxis were reported. Across indications, IRs were low for cytopenia (≤2.5), malignancies (≤0.7), MACE (≤0.5), depression (≤1.6), and iridocyclitis (≤2.8). Per external adjudication, 20 patients had confirmed IBD (including 3 patients with PsA and 17 with axSpA) of which 1 was confirmed as ulcerative colitis for PsA (IR=0.0) and 10 for axSpA (IR=0.5); 2 events were confirmed as Crohn's disease for PsA (IR=0.1) and 7 for axSpA (IR=0.3). Across safety topics, IRs were decreased or remained constant over time (Figures 1 and 2).

Conclusion: In this updated analysis with 2247.7 PY for PsA and 2096.2 PY for axSpA, IXE maintained a safety profile consistent to that previously reported,[1-3] with no new or unexpected safety events through exposure up to 3 years.

Session Title: Spondyloarthritis Including PsA – Treatment Poster III: Psoriatic Arthritis II (1801–1835)
Session Type: Poster Session D
Session Time: 8:30AM–10:30AM

Background/Purpose: Enthesitis is a recognized as a hallmark of spondyloarthrtis (SpA), including psoriatic arthritis (PsA). However, it is an underestimated disease domain in both in clinical trials and clinical practice (1).

This systematic literature review (SLR) assessed the efficacy of the available pharmacological options for enthesitis.

Table.

Disease	Tested drug vs Reference	Superiority of the treatment arm against reference arm (p<0.05)	Reference

β-Open-label; PsA: Psoriatic arthritis; r-axSpA: Radiologic axial spondylarthritis; nr-axialSpA: non radiological axial spondylarthritis; PBO: Placebo; TNFi: Tumor necrosis factor inhibitors; ETN: Etanercept; IFX: Infliximab; ADA: Adalimumab; GOL: Golimumab; UST: Ustekinumab; CZP: Certolizmab; GUS: Guselkumab; SEC: Secukinumab; IXE: Ixekizumab; APR: Apremilast; TOF: Tofacitinib; MTX - Methotrexate

Methods: A SLR was conducted following the PRISMA reporting guidelines. Studies were sourced from PubMed and Embase databases, using the MeSH terms: enthesitis, entheses, treatment, spondylarthritis, ankylosing spondylitis and psoriatic arthritis. The search was limited to articles in English published between January 2000 and July 2020. Two independent reviewers screened the titles and abstracts.

Results: A total of 65 articles matched the research criteria. The included populations, the time to assessment of the primary endpoint and the chosen outcome for assessment of enthesitis was heterogeneous across studies. There were no studies assessing the effect of non-steroidal anti-inflammatory drugs, glucocorticoids, or csDMARDs. In PsA, all TNFis showed superiority in monotherapy against placebo (PBO). However, when combined with methotrexate (MTX), only some TNFi showed superiority against MTX monotherapy. In SpA, there was conflicting evidence

regarding the efficacy of TNFi in enthesitis. Regarding IL23i in PsA, Ustekinumab was superior to PBO, and to TNFis. Guselkumab was superior to PBO when given every 4 weeks. Regarding IL7i, Secukinumab (SEC) was superior to PBO, only for some dosing schemes. Ixekizumab (IXE) was superior to PBO for the treatment of enthesitis only in TNF-naïve patients. Studies comparing SEC and IXE to ADA, showed no difference. There was no reported data on IL17i for enthesitis in SpA. In PsA, Tofacitinib was superior to PBO in naïve patients, and Tofacitinib 10mg was superior to PBO in bioexperienced patients. Apresmilast 30mg showed superiority to PBO for enthesitis. All findings are summarized on Table.

Conclusion: This SLR emphasizes the current heterogeneity in the assessment and report of enthesitis. There is still an unmet need for further studies to improve our understanding about enthesopathy.

SESSION INFORMATION
Session Date: Tuesday, November 9, 2021
Session Title: Spondyloarthritis Including PsA – Treatment Poster III: Psoriatic Arthritis II (1801–1835)
Session Type: Poster Session D
Session Time: 8:30AM–10:30AM

Background/Purpose: Psoriatic arthritis (PsA) is a chronic inflammatory disease of the joints and skin that affects 1/1000 people in the US. Tumor necrosis factor-alpha (TNF-α) inhibitors are used when symptoms are severe. However, current research describing TNF-α inhibitors persistence rates, defined as time from initiation to discontinuation of the drug, is inconsistent and incomplete. This study examined characteristics associated with persistence of and response to TNF-α inhibitors, as well as reasons for discontinuation.

Methods: US veterans enrolled in the Program to Understand the Longterm Outcomes in Spondyloarthritis (PULSAR) database across 11 medical centers in the United States from 2007 – 2017 who 1) were diagnosed with PsA or psoriasis by a rheumatologist or dermatologist and 2) had been treated with a TNF-α inhibitor were included in the study. Length of treatment with a biologic was determined using VA prescription data. Drug discontinuation was defined as the length between the usual dose of the TNF-α inhibitor plus 90 days without treatment. Course was defined as the difference between the date the prescription was first filled and date of discontinuation without >90-day gap in treatment. Reasons for agent discontinuation were documented into PULSAR by a provider at rheumatology appointments. The following reasons for discontinuation were included: primary failure (no efficacy within 6 months

of treatment), secondary failure (loss of efficacy after 6 months of treatment), adverse event, concern for an adverse event, financial/access barrier, non-adherence, and other. Stata was used to conduct time-to-event and multivariate analyses.

Results: 321 individuals with 931 TNF-α inhibitor courses, including adalimumab (N = 381), certolizumab (N = 24), etanercept (N = 397), golimumab (N = 42), and infliximab (N = 87), were included in the study. The mean age was 55.4 years, and 252 of the 321 patients had a diagnosis of both PsA and psoriasis. 83.8% of the cohort continued at least one TNF-α inhibitor course at one year, and 64.8% continued at two years. On average, the probability of discontinuing a TNF-α inhibitor increased by 9.6% for each additional biologic trial (HR 1.096, p< 0.001). Former smoker (HR 0.827, p=0.037) and PsA duration in years (HR 0.991, p< 0.001) were also significantly correlated with discontinuation of a TNF-α inhibitor. On univariate and multivariate analyses, infliximab had a lower discontinuation rate than adalimumab (HR 2.114, p< 0.001), etanercept (HR 2.360, p< 0.001), and certolizumab (HR 3.048, p=0.001); however, the discontinuation rate of golimumab was lower than that of infliximab on univariate analysis only (HR 3.035, p< 0.001). The most commonly cited reason for discontinuing TNF-α inhibitor treatment was secondary failure (33%).

Conclusion: The majority of patients in this study continued at least one TNF-α inhibitor course at both 12 and 24 months. Secondary failure was the most prevalent reason for discontinuation, suggesting that further research should be conducted to examine reasons for loss of efficacy and immunogenicity of TNF-α inhibitors.

Predictors of Response, Adverse Events and Treatment Retention in Psoriatic Arthritis Patients Treated with Golimumab in a Prospective, Observational Registry

Proton Rahman[1], Isabelle Fortin[2], Regan Arendse[3], Derek Haaland[4], Arthur Karasik[5], Maqbool Sheriff[6], Emmanouil Rampakakis[7], Meagan Rachich[8], Francois Nantel[9], Allen Lehman[8] and Odalis Asin-Milan[8], [1]Department of Medicine, Eastern Health and Memorial University of Newfoundland, St John's, NL, Canada, [2]CREQ, Rimouski, QC, Canada, [3]University of Saskatchewan, Saskatoon, SK, Canada, [4]McMaster University, Hamilton, Ontario and The Waterside Clinic, Oro Medonte, ON, Canada, [5]Arthur Karasik Medicine Professional Corporation, Toronto, ON, Canada, [6]Nanaimo Regional Hospital, Nanaimo, BC, Canada, [7]JSS Medical Research, Montréal, QC, Canada, [8]Janssen Inc., Toronto, ON, Canada, [9]., Montréal, QC, Canada

SESSION INFORMATION

Session Date: Tuesday, November 9, 2021

Session Title: Spondyloarthritis Including PsA – Treatment Poster III: Psoriatic Arthritis II (1801–1835)

Session Type: Poster Session D

Session Time: 8:30AM–10:30AM

Background/Purpose: The Biologic Treatment Registry Across Canada (BioTRAC) was a prospective, observational registry that enrolled psoriatic arthritis (PsA) patients treated with subcutaneous golimumab (GLM) between 2010 and 2017.

Methods: Patient visits occurred at baseline and every 6 months thereafter. Multivariate logistic regression was used to identify independent predictors of achieving specific efficacy and safety endpoints and included the following covariates: age, gender, disease duration, enrolment period, concomitant medication, smoking and employment.

Results: A total of 281 patients were enrolled and followed for a mean duration of 1.9 years. The proportion of male gender was 46.3% and the mean disease duration at baseline was 6.1 years.

MDA was more likely to be achieved with lower baseline DAS28-CRP [OR (95% CI): 0.62 (0.45–0.84); p=0.002] and in patients who were employed [2.64 (1.22–5.71); p=0.014]. VLDA was more likely to be achieved with lower age [OR (95% CI): 0.96 (0.94–0.99); p=0.005], lower baseline DAS28-CRP [0.63 (0.44–0.89); p=0.009] and in patients who were employed [6.45 (2.30–18.27); p< 0.001], whereas VLDA was less likely to be achieved in patients who smoked [0.30 (0.10–0.92); p=0.035].

DAPSA LDA was more likely to be achieved with lower baseline DAPSA [OR (95% CI): 0.96 (0.94–0.98); p< 0.001]. DAPSA remission was more likely to be achieved with lower age [OR (95% CI): 0.98 (0.95–1.00); p=0.048] and lower baseline DAPSA [0.98 (0.96–1.00); p=0.043], while less likely to be achieved with later enrolment [2016-2017 vs. 2010–2012: 0.30 (0.11–0.78); p=0.014] and in patients who smoked [0.37 (0.15–0.93); p=0.035]. HAQ < 0.5 was more likely to be achieved in male vs. female gender [OR (95%): 2.03 (1.08–3.83); p=0.028] and in patients with lower baseline HAQ scores [0.19 (0.11–0.34); p< 0.001].

AEs were more likely to occur with baseline concomitant DMARD [1.97 (1.07–3.63); p=0.030] or NSAID use [1.88 (1.05–3.37); p=0.033], yet less likely in male vs. female [0.54 (0.30–0.98); p=0.043]. SAEs were more likely to occur with older age [1.04 (1.00–1.07); p=0.041], and less likely in patients enrolled later [2013–2015 vs. 2010–2012: 0.05 (0.01–0.18); p< 0.001 and 2016–2017 vs. 2010–2012: 0.03 (0.01–0.14); p< 0.001]. Being employed at baseline was a significant positive predictor of GLM retention [0.61 (0.38–0.97); p=0.035].

Conclusion: In PsA patients treated with golimumab, young age, employment and lower disease activity at baseline were associated with better treatment outcomes.

Session Title: Spondyloarthritis Including PsA – Treatment Poster III: Psoriatic Arthritis II (1801–1835)

Session Type: Poster Session D

Session Time: 8:30AM–10:30AM

Background/Purpose: Secukinumab has demonstrated to be efficacious for both psoriatic arthritis (PsA) and ankylosing spondylitis (AS): PASI, ACR and ASAS magnitudes of response have generally been higher in the anti-TNF-naïve population. However, real world data on effectiveness in quality of life (QoL) and function are missing.

To analyze the differences of secukinumab therapy (effectiveness in disease activity and QoL, persistence and safety profile) in biologic-naïve versus biologic-experienced patients.

Methods: Multicenter, observational study of PsA and AS patients using real world anonymous patient-level data from the Portuguese national register database - Reuma.pt. We analyzed data at baseline and after 3, 6 and 12

months after secukinumab initiation, between January 2017 and January 2021. We collected data on sociodemographic characteristics and safety (discontinuation and adverse events); effectiveness [ACR and ASAS response, patient global assessment (PtGA), physician global assessment (PhGA), C-reactive protein (CRP), erythrocyte sedimentation rate (ESR), BASDAI, ASDAS-CRP, DAPSA and DAS28 4 V]; function and QoL [ASQoL (Ankylosing Spondylitis QoL questionnaire), EQ-5D (Euro-QoL-5 dimensions), FACIT-F (Functional Assessment of Chronic Illness Therapy-Fatigue); HADS (Hospital Anxiety and Depression Scale); HAQ (Health Assessment Questionnaire); BASFI and SF-36 (Health Questionnaire Short-Form 36)].

Results: We included 334 patients (166 with PsA and 168 with AS), 68% were biologic-experienced. Differences between biologic naïve and biologic-experienced patients' clinical characteristics are shown in Table 1. When we analyzed disease activity, we found that PhGA (p=0.004) and ESR (p=0.002) were significantly lower in naïve patients and more naïve patients reached ACR50 response (p=0.045) at 3 months. At 6 months evaluation, in addition to PhGA (p=0.008) and ESR (p=0.008) that remained significantly lower in naïve patients, PtGA (p=0.009), ASDAS-PCR (p=0.008) and BASDAI (p=0.006) were also lower in naïve patients. In the last evaluation, at 12 months, besides the variables described, also DAS 28 4V was lower in naïve patients (p=0.048) (Table 2).

Regarding QoL and function, at 6 months, BASFI (p< 0.001), EQ5D-VAS (p=0.034), SF-36 scores, physical (p=0.013) and mental (p=0.023) domains and ASQoL (p=0.008) were significantly better in naïve patients. After a year of follow-up (12 months evaluation) naïve patients had a better health status (HAQ and ASQoL) (p=0.006 and p=0.003 respectively) and biologic-experienced patients had more anxiety (HADS, p=0.029) (Table 3).

Regarding, drug persistence, although not statistically significant, biologic-experienced patients were more prone to discontinue the drug (18.5% and 11.2%, respectively, p=0.091)

Regarding safety, there were no differences in the number or type of severe (naïve patients: 3/107 vs biologic-experienced: 9/227) or mild (naïve patients: 4/107 vs biologic-experienced: 7/227) adverse effects.

Conclusion: Secukinumab treatment showed a larger magnitude of response (disease activity, function and QoL) in the biologic-naïve population, both in PsA and AS patients. No differences on safety profile were found.

Risk of Major Adverse Cardiovascular Events (MACE) with Biologic and Targeted Synthetic Antirheumatic Agents in Psoriatic Arthritis: A Systematic Review and Network Meta-analysis

Muhammad Ajmal[1], Jawad Bilal[1], Syed Arsalan Ahmed Naqvi[2], Irbaz Bin Riaz[3], Zaina Shahid[4], Kaneez Zahra Rubab Khakwani[1], Yi-Shao Liu[5], Sandipan Bhattacharjee[5], Roxanne Bogucka[5], Noureen Asghar[6] and Kent Kwoh[1], [1]University of Arizona, Tucson, AZ, [2]Dow University of Health Sciences, Karachi, Pakistan, [3]Mayo Clinic, Phoenix, AZ, [4]Lehigh Valley Health Network, Allentown, PA, [5]University of Texas at Austin, Austin, TX, [6]Dow University of Health Sciences, Karachi

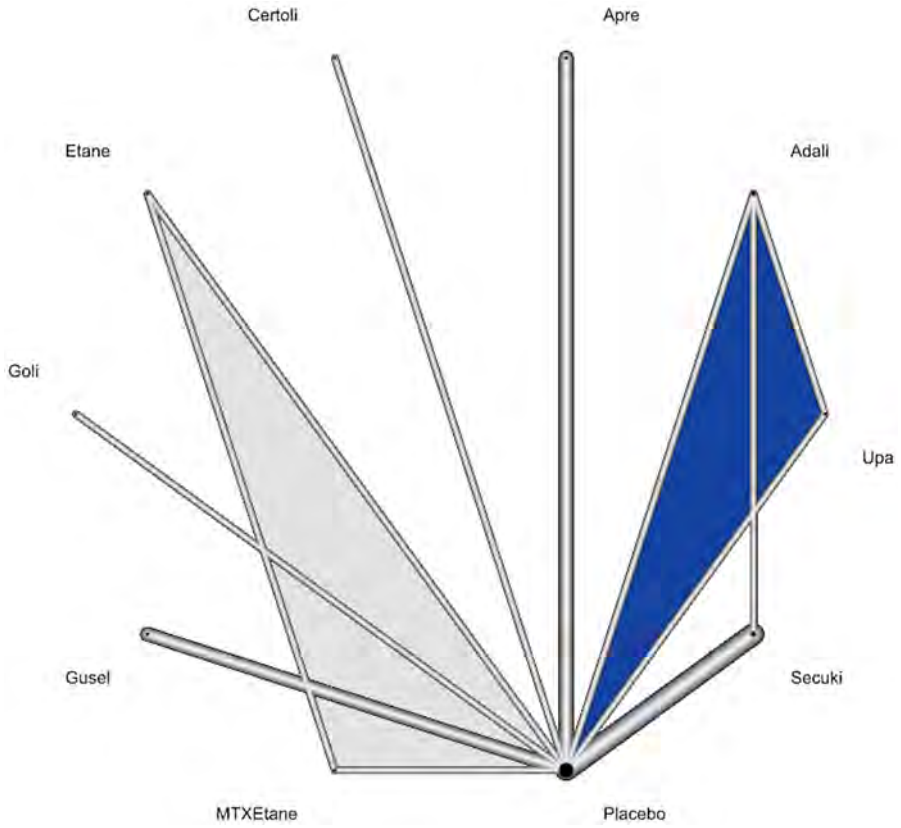
SESSION INFORMATION

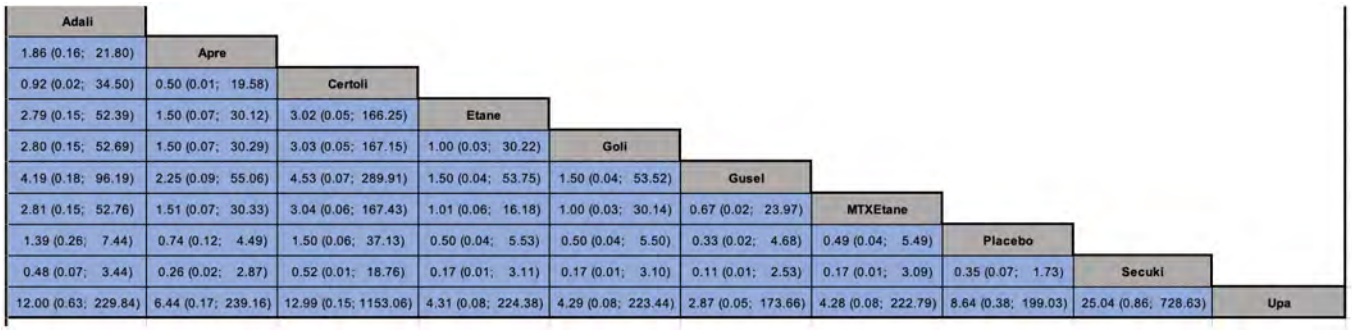
Session Date: Tuesday, November 9, 2021
Session Title: Spondyloarthritis Including PsA – Treatment Poster III: Psoriatic Arthritis II (1801–1835)
Session Type: Poster Session D
Session Time: 8:30AM–10:30AM

Background/Purpose: The efficacy of biologics and targeted synthetic disease modifying antirheumatic agents approved for treatment of psoriatic arthritis (PsA) is well documented, but cardiovascular safety profile of these agents is still a matter of debate. We examined risk of major adverse cardiovascular events (MACE) associated with use of biologics and targeted synthetic disease modifying antirheumatic agents in PsA.

Methods: Medline, PubMed, Embase, Scopus, Cochrane Central, and clinicaltrials.gov were searched to identify phase 3 and 4 randomized clinical trials (RCTs) reporting safety data of biologics and targeted synthetic disease modifying antirheumatic agents used in PsA. Outcome of interest was MACE within on-treatment or placebo-controlled duration. Mantel–Haenszel approach was used to pool data after continuity correction of zero events. Mixed treatment comparisons were computed using a fixed-effect NMA within frequentist framework. Effect estimates were expressed as odds ratio (OR) with 95% confidence intervals (CIs). P-scores were calculated to establish relative rankings of different treatment options. A sensitivity analysis was conducted using non-central hypergeometric (NCH) approach with Breslow approximation. All statistical analyses were conducted in R (v4.0.2).

Results: 33 trials met inclusion criteria; 12 RCTs [n=8501] with10 unique treatments and event(s) in at least one arm were included in network meta-analysis (Figure 1). Ten trials were excluded based on lack of reported data on MACE and 11 trials were excluded based on zero reported events in both or all arms (in case of multi-arm trials). A total of 27 (0.3%) MACE outcomes were observed among different treatments. Mixed treatment comparisons showed no statistically significant differences with upadacitinib (OR 0.12; 95% CI 0.01-2.66), guselkumab (OR 0.33; 95% CI





0.02-4.68,) methotrexate-etanercept (OR 0.49; 95% CI 0.04-5.49), golimumab (OR 0.50; 95% CI 0.04-5.50), etanercept (OR 0.50; 95% CI 0.04-5.53), apremilast (OR 0.74; 95% CI 0.12-4.49), adalimumab (OR 1.39, 95% CI 0.26-7.44), certolizumab (OR 1.50; 95% CI 0.06-37.13), and secukinumab (OR 2.85 95% CI 0.58-14.48) when compared to placebo. Similarly, no significant differences were observed among different biologics and targeted synthetic agents (Figure 2). Certainty of evidence was low due to very serious imprecision. The results were consistent with sensitivity analysis with NCH approach.

Limitations included study-level data with a relatively small number of studies and events of interest, sparse direct evidence, and open network.

Conclusion: During limited follow-up period in controlled clinical trials, composite MACE outcomes were not different among PsA patients treated with biologics and targeted synthetic disease modifying antirheumatic agents.

SESSION INFORMATION

Session Date: Tuesday, November 9, 2021

Session Title: Spondyloarthritis Including PsA – Treatment Poster III: Psoriatic Arthritis II (1801–1835)

Session Type: Poster Session D

Session Time: 8:30AM–10:30AM

Background/Purpose: Guselkumab (GUS), a human monoclonal antibody targeting the interleukin-23p19-subunit, has demonstrated efficacy across joint and skin endpoints at Week 24 (W24) in the Phase 3 DISCOVER-1 and -2 clinical trials of patients with active psoriatic arthritis (PsA).[1,2] The aim of this *post hoc* analysis was to identify clinical phenotypic predictors of minimal disease activity (MDA) response to GUS treatment at W24 in patients with active PsA.

Methods: Data from bio-naïve patients with active PsA who were treated with GUS 100 mg every 4 or 8 weeks (Q4W; Q8W) were pooled across DISCOVER-1 and -2. Patients in DISCOVER-1 were required to have ≥3 swollen and ≥3 tender joints and C-reactive protein (CRP) ≥0.3 mg/dL; patients in DISCOVER-2 were required to have ≥5 swollen and ≥5 tender joints and CRP ≥0.6 mg/dL. Logistic regression analysis was performed to identify potential predictors of MDA response to GUS at W24; odds ratios, 95% confidence intervals and p-values were calculated. Missing data for MDA at W24 were imputed as non-response; a few missing baseline (BL) values in 4 patients were imputed. Potential predictors of response were characterized by patients' baseline clinical features, including swollen and tender joint counts, affected joint location (including temporomandibular joint, hands, feet, wrist, elbow, shoulder, hip, and knee), BL dactylitis and enthesitis, Psoriasis Area Severity Index (PASI) score, and psoriasis (PsO) localization (including hands and feet, scalp, or nail involvement). Other selected BL characteristics are also described (Table 1).

Results: Clinical characteristics of 669 bionaïve, GUS-treated patients, which were generally consistent across DISCOVER-1 (n=176) and DISCOVER-2 (n=493), indicated substantial disease burden at BL. Patients had a mean tender and swollen joint count of 20.3 and 11.5, respectively, and a mean PASI score of 9.7; 63.5% had enthesitis, and 43.2% had dactylitis at BL (Table 1). At W24, MDA was achieved by 24.4% (163/669) of pooled GUS Q4W- and Q8W-treated patients. Lower body mass index (BMI) and tender joint count, CRP < 1 mg/dL, and higher PASI at BL (all $p < 0.05$) were significant predictors of MDA response at W24. Patients with presence of dactylitis at BL were significantly less likely than those without this manifestation to achieve MDA at W24 (Table 2; $p < 0.01$). The localization of PsO, affected joint location, or current tobacco use were not predictive of MDA response at W24 (Figure 1).

Table 1. Baseline characteristics of bio-naïve patients with psoriatic arthritis treated with guselkumab 100 mg Q4W or Q8W.

Baseline characteristics	Guselkumab 100 mg (Q4W and Q8W pooled)	IQR
Number of randomized and treated patients	699	–
Age, years	46.1 (11.8)	37.0–55.0
Female, n (%)	309 (46.2)	–
BMI, kg/m²	29.1 (6.1)	24.7–32.7
PsA duration, years	5.4 (5.8)	1.3–7.2
BSA with PsO, %	16.3 (19.7)	3.0–21.0
PASI score	9.7 (11.1)	2.4–12.6
CRP, mg/dL	1.7 (2.2)	0.5–2.1
Swollen joint count, 0–66	11.5 (7.4)	7.0–14.0
Tender joint count, 0–68	20.3 (13.1)	11.0–25.4
HAQ-DI	1.2 (0.6)	0.8–1.6
Patients with dactylitis at BL, n (%)	289 (43.2)	–
Dactylitis Severity Score (0–60)	3.6 (7.7)	0.0–4.0
Patients with enthesitis at BL, n (%)	425 (63.5)	–
LEI score	1.8 (1.8)	0.0–3.0

Data are mean (SD) or %. BL, baseline; BMI, body mass index; BSA, body surface area; CRP, C-reactive protein; HAQ-DI, Health Assessment Questionnaire Disability Index; IQR, interquartile range; LEI, Leeds Enthesitis Index; PASI, Psoriasis Area Severity Index; PsA, psoriatic arthritis; Q4W, every 4 weeks; Q8W, every 8 weeks; SD, standard deviation.

Table 2. Odds ratios and 95% confidence intervals for potential predictors of minimal disease activity response to guselkumab 100 mg Q4W or Q8W at Week 24 in patients with psoriatic arthritis.

Characteristic/clinical feature	Odds Ratio (95% CI)	p-value
Clinical features		
Swollen joint count, 0–66	0.99 (0.94–1.03)	0.51
Tender joint count, 0–68	0.97 (0.94–1.00)	0.04
Shoulder involvement	0.83 (0.60–1.16)	0.29
Elbow involvement	0.80 (0.60–1.07)	0.13
Knee involvement	0.99 (0.79–1.26)	0.90
Hip involvement	0.89 (0.71–1.11)	0.31
Foot joint involvement	0.85 (0.65–1.13)	0.24
Hand joint involvement	0.82 (0.60–1.11)	0.18
Wrist involvement	0.90 (0.72–1.13)	0.32
Temporomandibular joint involvement	1.44 (0.81–2.53)	0.20
Baseline dactylitis, Yes vs. No	0.54 (0.34–0.85)	<0.01
Baseline enthesitis, Yes vs. No	0.65 (0.43–1.00)	0.06
Baseline PASI	1.03 (1.01–1.05)	<0.01
Hand/foot PsO, Yes vs. No	1.45 (0.97–2.16)	0.07
Nail PsO, Yes vs. No	1.23 (0.80–1.88)	0.34
Scalp PsO, Yes vs. No	0.82 (0.49–1.37)	0.46
Baseline characteristics		
Age	0.98 (0.97–1.00)	0.05
Sex, Female vs. Male	0.75 (0.49–1.15)	0.18
BMI	0.96 (0.93–1.00)	0.03
PsA duration	1.00 (0.96–1.03)	0.91
CRP, <1 vs. ≥1 mg/dL	1.60 (1.06–2.41)	0.02
Current alcohol use, Yes vs. No	1.25 (0.83–1.87)	0.26
Current tobacco use, Yes vs. No	0.99 (0.60–1.64)	1.00

BMI, body mass index; BsA, body surface area; CI, confidence interval; CRP, C-reactive protein; PASI, Psoriasis Area Severity Index; PsO, psoriasis; Q4W, every 4 weeks; Q8W, every 8 weeks.

Conclusion: PsA phenotypes at BL are significant positive (lower tender joint count, higher PASI) or negative (presence of dactylitis) predictors of achieving the multidomain composite endpoint MDA at W24. BL BMI and CRP may also affect the prospect of reaching MDA. These data emphasize that all domains of PsA should be taken into account, and that more complex disease requires particular attention.

SESSION INFORMATION

Session Date: Tuesday, November 9, 2021
Session Title: Spondyloarthritis Including PsA – Treatment Poster III: Psoriatic Arthritis II (1801–1835)
Session Type: Poster Session D
Session Time: 8:30AM–10:30AM

Background/Purpose: Psoriasis (PsO), Psoriatic Arthritis (PsA) and Axial Spondyloarthritis (AxSpA) are chronic immune-mediated inflammatory diseases (IMIDs) requiring long-term treatment. Systemic inflammation in these IMIDs is associated with cardiovascular (CV) disease[1,2]. High sensitivity C-reactive protein (hsCRP) is an independent surrogate CV risk marker. Recently, high neutrophil-lymphocyte ratio (NLR) has emerged as a novel inflammatory biomarker predictive of CV disease and overall mortality[3]. Here, we report the effect of IL-17A inhibition with secukinumab on CV risk parameters in PsO, PsA and AxSpA patients over 1 year of treatment.

Methods: This is a post-hoc analysis of pooled Phase 3/4 secukinumab studies in PsO, PsA and AxSpA. CV-related exclusion criteria included uncontrolled hypertension and congestive heart failure. Traditional (body mass index [BMI], fasting glucose, blood pressure, cholesterol and lipids) and inflammatory CV risk parameters (hsCRP, absolute neutrophil count and NLR) were assessed. Exploratory statistical comparison of median change from baseline to Week 12 (PsO) or Week 16 (PsA/AxSpA) for secukinumab *vs* placebo was performed by Wilcoxon 2-sample test. Subgroup analyses were performed in high-risk patients (baseline hsCRP >10 mg/L in PsA/AxSPA and >4 mg/L in PsO).

Results: In total, 9,197 patients from 19 clinical trials (8 in PsO, n=4,742; 5 in PsA, n=2,475; 6 in AxSpA, n=1,980) were included. All traditional CV risk parameters remained stable in secukinumab-treated patients through 1 year (**Table 1**). Secukinumab administration rapidly reduced both hsCRP and the NLR, compared with placebo at Week 12 (PsO) or Week 16 (PsA/AxSPA) in the overall population and in high-risk patients defined by having high baseline hsCRP (all p< 0.01). This reduction was maintained for at least 1 year of secukinumab therapy in all indications (**Table**

Table 2. Traditional CV Risk Factors: Week 52

Systolic blood pressure (mmHg)	Baseline	128.0	127.0	126.0	128.0	127.5	124.0
	Week 52	127.0	126.0	126.0	126.5	124.0	122.0
Diastolic blood pressure (mmHg)	Baseline	80.0	80.0	80.0	80.0	80.0	78.0
	Week 52	80.0	80.0	78.0	80.0	79.0	77.0
Body Mass Index (Kg/m^2)	Baseline	27.9	28.4	28.1	29.1	25.6	27.2
	Week 52	28.0	28.6	28.3	29.3	27.9	25.7
Ratio of Total Cholesterol / HDL	Baseline	3.9	4.0	3.4	3.6	3.4	3.4
	Week 52	4.0	4.1	3.5	3.6	3.4	3.3
Triglycerides (mmol/L)	Baseline	1.3	1.4	1.3	1.3	1.0	1.1
	Week 52	1.4	1.6	1.4	1.4	1.1	1.2

Baseline is defined as the last observation, on the day of or before the first dose of study drug. Data are reported 'as observed' in patients with baseline value and at least one post-baseline value.

2). In some patients where available follow-up data allowed exploratory analysis through five years, secukinumab induced sustained reductions in hsCRP and NLR; traditional CV risk factors did not change.

Conclusion: Secukinumab rapidly reduced hsCRP and the NLR in patients with IMIDs with a high systemic inflammatory burden. Traditional CV risk factors remained stable for at least 1 year in patients with PsO, PsA and AxSpA.

SESSION INFORMATION
Session Date: Tuesday, November 9, 2021
Session Title: Systemic Sclerosis & Related Disorders – Clinical Poster III (1836–1861)
Session Type: Poster Session D
Session Time: 8:30AM–10:30AM

Background/Purpose: Autologous haematopoietic stem cell transplantation (SCT) has emerged as an effective treatment for patients with severe diffuse systemic sclerosis (dcSSc) based upon the results of two large clinical trials demonstrating long term benefit for survival, skin and lung involvement and quality of life. Over the past two decades routine management of dcSSc has improved and immunosuppressive drugs are increasingly administered in the early course of the disease. These developments may have improved survival of cases that would have been eligible for SCT trials compared with historically predicted outcomes. The aim of this study was to explore outcomes in a cohort of dcSSc patients fulfilling eligibility criteria for SCT studies but receiving contemporary standard treatment.

Methods: From a single-centre cohort dcSSc patients (n=636) were selected using the SCT trials' inclusion criteria (Table 1). Patients meeting the trials' exclusion criteria were excluded. Overall survival and event free survival (EFS)

* According to ARA-Classification Criteria Systemic Sclerosis
**According to 2013 ACR-EULAR classification criteria for diffuse cutaneous systemic sclerosis

In bold: criteria used to select patients for this study.

of patients eligible for one or more of the studies (ASTIS, SCOT or the ongoing UPSIDE trial) were assessed using Kaplan-Meier survival estimates. Hazard ratios (HR) were calculated using Cox proportional hazards regression analysis. EFS was defined as the time in years from eligibility until the occurrence of death due to any cause or development of major organ damage, defined as severe cardiac involvement or pulmonary fibrosis, scleroderma renal crisis (SRC) or pulmonary hypertension (PH).

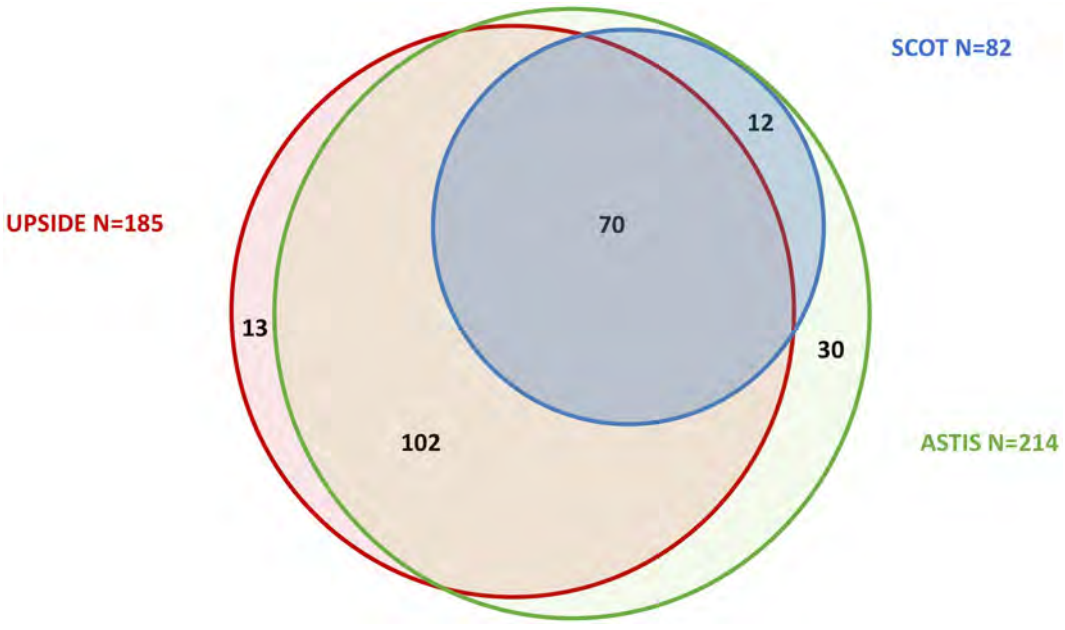

Figure 1. Venn diagram showing overlap of patients eligible for stem cell transplantation trials.

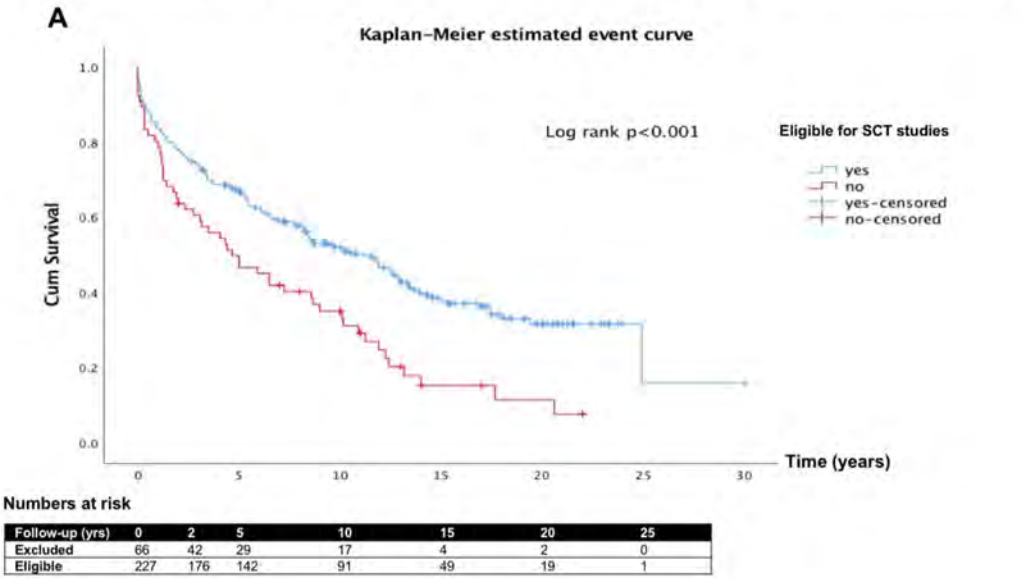
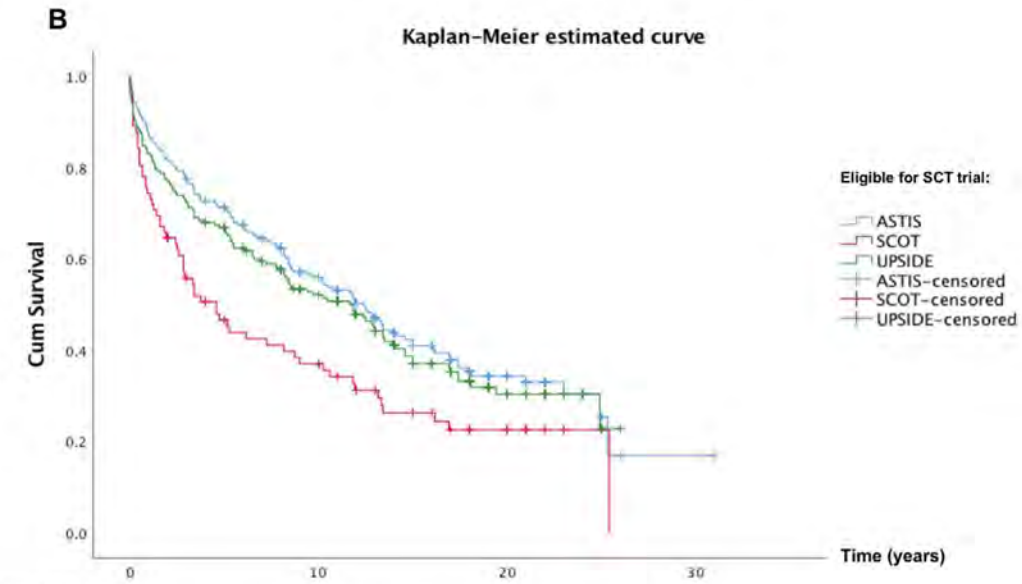
Figure 2. Event free survival
Comparison between patients eligible for SCT studies and patients excluded (A) and between SCT trials (B)



Numbers at risk

Follow-up (yrs)	0	2	5	10	15	20	25
Excluded	66	42	29	17	4	2	0
Eligible	227	176	142	91	49	19	1



Numbers at risk

Follow-up (yrs)	0	2	5	10	15	20	25
ASTIS	212	173	145	98	55	25	2
SCOT	82	50	33	25	14	5	0
UPSIDE	183	141	117	77	42	16	1

Results: Of the 227 eligible patients, 214 met the inclusion criteria for ASTIS, 82 for SCOT and 185 for the UPSIDE trial. 66 patients were excluded based on age > 65 years, low DLco, pulmonary hypertension or creatinine clearance < 40ml/min. There was overlap between eligible patient groups (Figure 1). The median follow-up time was 12 years (IQR 9). Among eligible patients, 103 (45.4%) died. Survival was 96% at 2-, 88% at 5-, 73% at 10- and 43% at 20 years. Compared to this 'SCT-eligible' cohort, those patients who would have been excluded from SCT trials had a worse long-term overall survival (97% at 2-, 77% at 5-, 52% at 10- and 15% at 20 years, log rank p< 0.001). Excluded

patients also had a significantly worse EFS (Figure 2A). Differences between the three different trials were observed as well (Figure 2B). Hazard of death was higher in patients with higher age at onset (HR 1.05, p< 0.001), higher ESR at onset (HR 1.01, p=0.025) and males (HR 2.12, p=0.008). Male sex was also an independent risk factors for a serious event (HR 1.97, 95% CI 1.34-2.88, p=0.001). Higher DLco at onset was associated with a lower hazard for an event (HR 0.98, 95% CI 0.97-0.99, p=0.001) in the multivariable Cox regression analysis.

Conclusion: This study demonstrates that SCT inclusion criteria identify patients with poor outcome despite current best practice treatment as long-term outcomes were unfavorable in our cohort compared to SCT in the trials. It shows that SCT trials have overlapping eligibility criteria but may recruit different populations which requires caution when comparing results. Our findings emphasize the need for better treatment strategies for the very poor outcome patients who are excluded from SCT.

KL-6, CXCL11 and CTGF Are Potential Biomarkers in Response to Treatment in CTD-ILD

Yu-Hsiang Chiu[1], Mareye Voortman[1], Eveline Delemarre[1], Stefan Nierkens[1], Pim de Jong[1], Firdaus Mohamed Hoesein[1], Jan Grutters[2], Jacob van Laar[1] and Julia Spierings[3], [1]University Medical Centre Utrecht, Utrecht, Netherlands, [2]St. Antonius Hospital, Nieuwegein, Netherlands, [3]University Medical Center Utrecht, Utrecht, Netherlands

SESSION INFORMATION
Session Date: Tuesday, November 9, 2021
Session Title: Systemic Sclerosis & Related Disorders – Clinical Poster III (1836–1861)
Session Type: Poster Session D
Session Time: 8:30AM–10:30AM

Background/Purpose: Connective tissue disease related interstitial lung disease (CTD-ILD) is common and an important cause of morbidity and mortality. We aimed to identify biomarkers in CTD-ILD correlating with radiographic characteristics and response to immunosuppressive therapy at one-year follow-up.

Methods: An exploratory set of 38 biomarkers were measured in serum of patients with CTD-ILD at baseline and one year of follow-up. The high resolution computed tomography (HRCT) patterns were classified according to the classification for idiopathic interstitial pneumonia and categorised into fibrotic or inflammatory. The predictivity of baseline biomarker, responsiveness of biomarkers to treatment, and correlations between the variation of biomarkers and pulmonary function test after one year of treatment were examined.

Results: Sixteen patients were included (12 females (75.0%), median age 51 years (IQR 45-62). The established CTD diagnoses, comorbidities, immunosuppressive therapies, and HRCT patterns were summarized in Table 1. Patients with inflammatory HRCT patterns showed less decline in forced vital capacity (FVC), 7.7% versus 33.3% in patients with fibrotic HRCT patterns. In patients with inflammatory HRCT patterns, CXCL11 reduced from a median 307.8 pg/ml to 253.8 pg/ml (p = 0.011), CTGF from 48.5 pg/ml to 9.5 pg/ml (p = 0.033) and KL-6 from 1221 U/ml to 543 U/ml (p = 0.040). (Figure 1) Additionally, an increase in levels of galectin-3 at one-year follow-up was associated with

Session Title: Systemic Sclerosis & Related Disorders – Clinical Poster III (1836–1861)

Session Type: Poster Session D

Session Time: 8:30AM–10:30AM

Background/Purpose: Evaluation of skin is central in clinical management of systemic sclerosis (SSc). Due to the COVID-19 pandemic remote consultations were widely implemented, which inevitably limited skin assessment using the modified Rodnan Skin Score (mRSS). In order to monitor skin during the pandemic, we developed and validated the PASTUL (Patient self-Assessment of Skin Thickness in Upper Limb) questionnaire. (Spierings J et al Ann Rheum Dis. 2021: https://doi.org/10.1136/annrheumdis-2020-219775. PMID: 33514506) We now explored utility of the PASTUL questionnaire in trials to translate the benefit of its use in clinical practice back into research in different subgroups of patients.

Methods: Patients included in the validation study were divided into subgroups: disease duration < 4 and > 4 years, males and females, diffuse cutaneous SSc (dcSSc) and limited cutaneous SSc (lcSSc), antibody profiles and age categories. The PASTUL questionnaire specifies a grading of skin (normal (0), mild (1), moderate (2), severely (3) thickening) at 8 sites corresponding to mRSS. To simplify the assessment, maximum score of an anatomical area was asked. Correlation between PASTUL, mRSS, Scleroderma Skin Patient reported Outcome (SSPRO) and Scleroderma Health Assessment (SHAQ) was assessed using Pearson's correlation coefficient (0-0.19 = negligible, 0.2-0.39 = weak, 0.4-0.59 = moderate, 0.6-0.79 = strong, 0.8-1.0 = very strong).

Results: Of the 104 patients included, 86% was female, 55 (53%) had lcSSc and 49 (47%) dcSSc, 75 (72%) had a disease duration > 4 years, 70 (67%) were older than 50 years. Mean age was 57 years (SD 12), mean disease du-

Table 2. Correlations (Pearson's correlation coefficient) of PASTUL with other outcome measures in different subgroups

ACA, anti-centromere antibodies; ARA, anti-polymerase III antibodies; ATA, anti-topoisomerase antibodies; DcSSc, diffuse cutaneous systemic sclerosis; lcSSc, limited cutaneous systemic sclerosis; mRSS, modified Rodnan Skin Score; SHAQ, Scleroderma Health Assessment Questionnaire; SSPRO, Scleroderma Skin Patient-Reported Outcome; yrs, years.

ration 11 years (SD 9), mean SHAQ 1.4 (SD 0.8) and mean SSPRO 48 (SD 27). MRSS was measured in 78 patients (75%), mean mRSS was 14 (SD 10). Table 1 shows characteristics of the different groups.

An overview of correlations between PASTUL and mRSS, SSPRO and SHAQ scores in the subgroups is provided in Table 2. Correlation between PASTUL and mRSS was very strong in ACA positive patients (r=0.82) and strong in females (r=0.61). Correlations between PASTUL and mRSS were stronger in lcSSc compared to dcSSc (r=0.53 vs 0.43), in females compared to males (r=0.61 vs 0.28), in patients with disease duration > 4 years (r=0.45 vs 0.59) and ACA positives compared to patients with ATA, ARA or other antibodies (r=0.82, 0.46, 0.13 and 0.45, respectively). PASTUL was moderately correlated with SHAQ in ACA positives (r=0.55) only. SSPRO and subdomains correlated weakly to moderately in this group, in contrast to other subgroups in which a stronger correlation between SSPRO and PASTUL was found.

Conclusion: Almost all subgroups showed moderate to strong correlations between PASTUL and mRSS and SSPRO. Correlations between PASTUL scores and mRSS were strongest in ACA positives and females, while ARA positive patients showed strongest PASTUL correlation with SSPRO. These correlations support potential utility of PASTUL as outcome measure and further validation in larger cohorts will define the role of PASTUL in future clinical trials.

Annual income > $29,999	0.66	0.45, 0.97	**0.037**

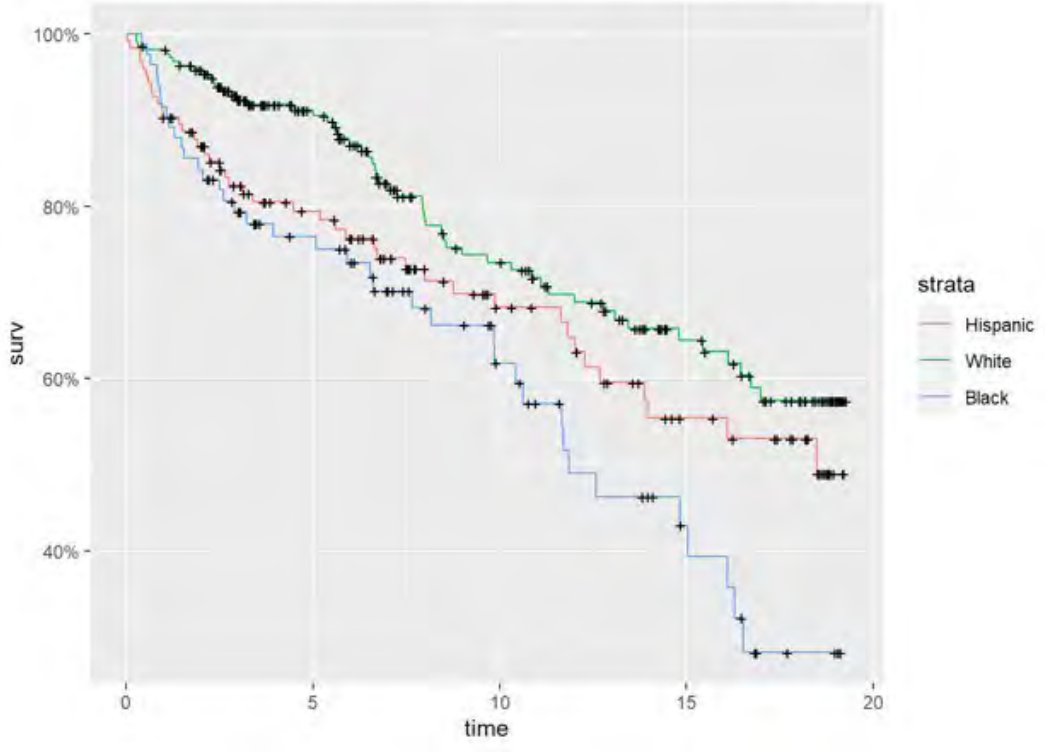
[1] HR = Hazard Ratio, CI = Confidence Interval; [2] Non-Hispanic White race is the reference group

scarce. Herein, we characterize SSc clinical features, antibody profile, and prognosis in Hispanic as compared to non-Hispanic White and African American (AA) patients.

Methods: Longitudinal clinical characteristics were collected prospectively in the Genetics versus Environment in Scleroderma Outcome Study (GENISOS) cohort. All patients fulfilled the ACR/EULAR Classification Criteria for SSc and had a disease duration less than five years at enrollment. Only patients with self-reported White, AA and Hispanic ethnicity were included in the present study. Mixed effect linear regression models were used to compare the longitudinal levels of modified Rodnan skin score (mRSS), Forced vital capacity % predicted (FVC%) and Health Assessment Questionnaire (HAQ) during the study period among three ethnic groups. Cox regression models were used for mortality analysis.

Results: A total of 427 patients, consisting of 124 Hispanic, 220 non-Hispanic White, and 83 non-Hispanic AA participants, were analyzed. The median follow-up time was 3.7 years. Table 1 shows the cross-sectional comparison

Figure. Kaplan-Meier survival estimates in systemic sclerosis based on ethnicity



of demographic and clinical characteristics of Hispanic patients to White and AA patients at the baseline visit. In comparison to Whites, Hispanic patients were significantly younger but had longer disease duration, had higher frequency of RNP positivity and an overlap disease with systemic lupus erythematosus (SLE), lower FVC%, and higher perceived functional disability (ie higher HAQ scores). Compared to AAs, Hispanic patients had more frequently limited cutaneous involvement and anti-centromere antibodies.

In the longitudinal analysis (FVC%: 1457, mRSS: 2239, and mHAQ: 1917 data points), Hispanic patients had significantly lower FVC% (point estimate=-9.3%, p< 0.001) than Whites but not AAs (p=0.6). Hispanic patients had similar serially obtained mRSS like Whites (p=0.9) but had lower longitudinal mRSS measurements than AA patients (point estimate = -3.2, p=0.029). Hispanic patients had significantly higher serially obtained perceived functional disability than White (point estimate=0.2, p < 0.001) but did not differ significantly from AA patients (p=0.6).

Hispanic patients had higher mortality than Whites (HR= 1.7, p= 0.011) after adjustment for age and gender but not in comparison to AAs (p=0.2) (also see Figure). As shown in Table 2, the higher mortality in Hispanic patients in comparison to Whites persisted even after adjustment for income and education levels.

Conclusion: SSc disease manifestations and prognosis differ in Hispanic American patients from other ethnic groups. Hispanic patients have higher likelihood of having RNP positivity and SLE overlap, lower lung volumes, as well as higher rate of mortality than White patients while they less frequently have diffuse cutaneous involvement and experience milder skin involvement than AA patients.

SESSION INFORMATION
Session Date: Tuesday, November 9, 2021
Session Title: Systemic Sclerosis & Related Disorders – Clinical Poster III (1836–1861)
Session Type: Poster Session D
Session Time: 8:30AM–10:30AM

Background/Purpose: Systemic sclerosis (SSc) is an autoimmune disorder that is characterized by a interplay of vascular abnormalities, immune system activation and an uncontrolled fibrotic response associated with interstitial lung disease affecting about 40% of patients. Identification of ILD relies on high-resolution CT that identify features suggestive of the histologic patterns of SSc(1). CT is used to determine pattern and extent of ILD and participates in

the prediction of ILD progression(2). All group of pulmonary hypertension (PH) may occur with an overall prevalence reported in up to one fifth of patient. Whereas extensive SSc-ILD can be responsible for PH, PH can also be seen as a consequence of myocardial abnormalities or as primarily affecting small pulmonary arteries and classified as pulmonary arterial hypertension. Dual-energy CT introduction offers perspectives in the evaluation of SSc-related pulmonary manifestations. While these are not strictly perfusion images, they have been reported as adequate surrogate markers of lung perfusion (3). In the field of PH, detection of perfusion defects highly concordant with V/Q scintigraphic findings has been reported in the diagnostic approach of CTEPH but also in the differential diagnosis between PAH and peripheral forms of CTEPH (4). Our objective is to investigate lung perfusion abnormalities in patients with SSc

Methods: The study population included 101 patients who underwent dual-energy CT (DECT) angiography in the follow-up of SSc. CT examinations were obtained on a 3rd-generation dual-source CT system with reconstruction of morphologic and perfusion images. All patients underwent pulmonary function tests within two months of the follow-up CT scan. Fifteen patients had right heart catheterization-proven PH.

Results: Our population included patients without SSc lung involvement (Group 1; n=37), patients with SSc-related ILD (Group 2; n=56) of variable extent (Group 2a: ≤10%: n=17; Group 2b: between 11-50%: n=31; Group 2c: >50%: n=8) and patients with PVOD/PCH (Group 3; n=8). Lung perfusion was abnormal in 8 patients in G 1 (21.6%), 14 patients in G 2 (25%) and 7 patients in G 3 (87.5%). Perfusion changes were mainly composed of bilateral perfusion defects, including patchy, PE-type perfusion defects and areas of hypoperfusion of variable size. In G 1 and G 2a (n=54): (a) patients with abnormal lung perfusion (n=14) had a significantly higher proportion of NYHA III/IV scores of dyspnea (p=0.031), a shorter mean walking distance at the 6MWT (p=0.042) and a trend towards lower mean DLCO% (p=0.055) when compared to patients with normal lung perfusion (n=40); (b) a negative albeit weak correlation was found between the iodine concentration in both lungs and the DLCO% (r=- 0.27; p=0.059) whereas no correlation was found with PAPs (r=0.16; p=0.29) and walking distance during the 6MWT (r=-0.029; p=0.84).

Conclusion: DECT lung perfusion provides complementary information to HRCT scans, depicting perfusion changes in SSc patients with normal or minimally infiltrated lung parenchyma.

Sensitivity, specificity and positive predictive value of anti-DSF70 autoantibody in different ANA titers (borderline patients excluded)

fine-speckled-70 antibody (anti-DSF70)[2]. This is detected less frequently in patients with connective tissue diseases (CTD) and is therefore often used as an exclusion criteria for CTD [2]. To date, however, it remains unclear how the presence of an anti-DSF70 reliably rules out CTD. We aimed to investigate the extent to which CTD can be excluded by the presence of anti-DFS70 and whether there are discrepancies between patients with CTD and negative anti-DSF70 and those with CTD and positive anti-DSF70.

Methods: We analyzed data of 460 patients who were tested for the presence of anti-DSF70 at the University Hospital Bonn, Germany. Patients were examined with regard to clinical symptoms and signs, type of rheumatic disease, type of CTD, fulfillment of the classification criteria for the particular CTD, presence of anti-DSF70, other systemic autoantibodies and ANA titers by indirect immunofluorescence (IIF) assays and immunoblots. Gold standard for presence of a CTD was the diagnosis of the treating rheumatologist.

Differences between anti-DSF70 positive patients with CTD and anti-DSF70 negative patients with CTD were examined.

In addition, specificity, sensitivity, and positive predictive value for different ANA titers were calculated.

Results: 182 out of 460 patients (79.8% female) had a CTD. 354 patients (77.0%) were anti-DSF70 negative, 81 (17.6%) anti-DSF70 positive and 25 (5.4%) had a borderline anti-DSF70 result.

21 patients with a positive anti-DSF70 were diagnosed with a CTD, which accounts for 25.9% of all anti-DSF70 positive patients. Concerning age, gender, symptoms, clinical signs and other disease-specific antibodies, no significant differences were found between anti-DSF70-positive patients with CTD and anti-DSF70 negative patients with CTD.

Of the 21 DSF70-positive patients with CTD, 12 (57.1%) were tested for the presence of disease-specific autoantibodies. Specific autoantibodies were detected in all of the tested patients with systemic lupus erythematosus, systemic sclerosis, Sjögren's syndrome and mixed connective tissue disease.

	All patients	Anti-DSF70 positive patients n=81	Anti-DSF70 negative patients n=354	Borderline anti-DSF70 patients n=25
Rheumatic disease	270 (100%)	36 (13.3%)	219 (81.1%)	15 (5.6%)
Connective tissue disease	182 (100%)	21 (11.5%)	151 (83.0%)	10 (5.5%)
Systemic lupus erythematosus	71 (100%)	5 (7.0%)	62 (87.3%)	4 (5.6%)
Systemic sclerosis	22 (100%)	3 (13.6%)	16 (72.7%)	3 (13.6%)
Sjögren's syndrome	32 (100%)	3 (9.4%)	28 (87.5%)	1 (3.1%)
Mixed CTD	21 (100%)	5 (23.8%)	16 (76.2%)	0
Myositis	11 (100%)	2 (18.2%)	8 (72.7%)	1 (9.1%)
Undifferentiated CTD	36 (100%)	3 (8.3%)	31 (86.1%)	2 (5.6%)
Other rheumatic diseases				
Rheumatoid arthritis	58 (100%)	9 (15.5%)	45 (77.6%)	4 (6.9%)
Spondylarthritis	8 (100%)	2 (25.0%)	6 (75.0%)	0
Psoriatic arthritis	14 (100%)	2 (14.3%)	11 (78.6%)	1 (7.1%)
Polymyalgia rheumatica	4 (100%)	0	4 (100%)	0
Reactive arthritis	2 (100%)	2 (100%)	0	0
Enteropathic arthritis	3 (100%)	0	3 (100%)	0
Undifferentiated arthritis	4 (100%)	0	4 (100%)	0
Small vessel vasculitis	2 (100%)	0	2 (100%)	0
Large vessel vasculitis	5 (100%)	0	5 (100%)	0

Occurrence of anti-DSF70 in different systemic autoimmune and rheumatic diseases

Anti-DSF70 had a specificity of 86.8%, a sensitivity of 26.9% and a positive predictive value of 68.2% at an ANA titer of ≥1:160, with respect to the absence of a connective tissue disease.

Conclusion: Autoantibodies to DSF70 often occur in CTD patients and are therefore not a valid exclusion criteria for a CTD. We observed no CTD in 68.2% of patients who were tested positive. Thus, the DSF70 test can be helpful in ambiguous situations. The additional exclusion of other autoantibodies may make CTD even less probable.

Background/Purpose: Response to immunosuppression is variable in systemic sclerosis (SSc) related interstitial lung disease (ILD). Contrary to pulmonary tissue, peripheral blood cell (PBC) RNA can be obtained during routine clinical care and can be used as easily accessible source for biomarker development. This study aims to examine the PBC gene expression changes ensuing from mycophenolate mofetil (MMF) or cyclophosphamide (CYC) treatment and to determine the predictive significance of baseline PBC transcript scores for response to immunosuppressive treatment in SSc-ILD.

Methods: All patients with an available baseline PBC RNA sample (stored in PAXgene tubes) enrolled in the Scleroderma Lung Study II (SLS II) were included. Baseline and 12-month samples corresponding to the active treatment period in both MMF and CYC arms were investigated by global RNA sequencing. A paired-end 150 bp sequencing strategy was used to generate an average of 99 million reads per sample. A modular analysis using 62 curated whole blood modules was pursued as previously described (Chaussabel et al. Nat Rev Immunol 2014). Each treatment arm was analyzed separately. First, a paired analysis comparing the 12-month to baseline samples was performed. Next, the predictive significance of baseline composite modular scores for the course of forced vital capacity (FVC) % predicted measurements from 3 to 12 months was investigated using a joint model (combines a mixed effects model

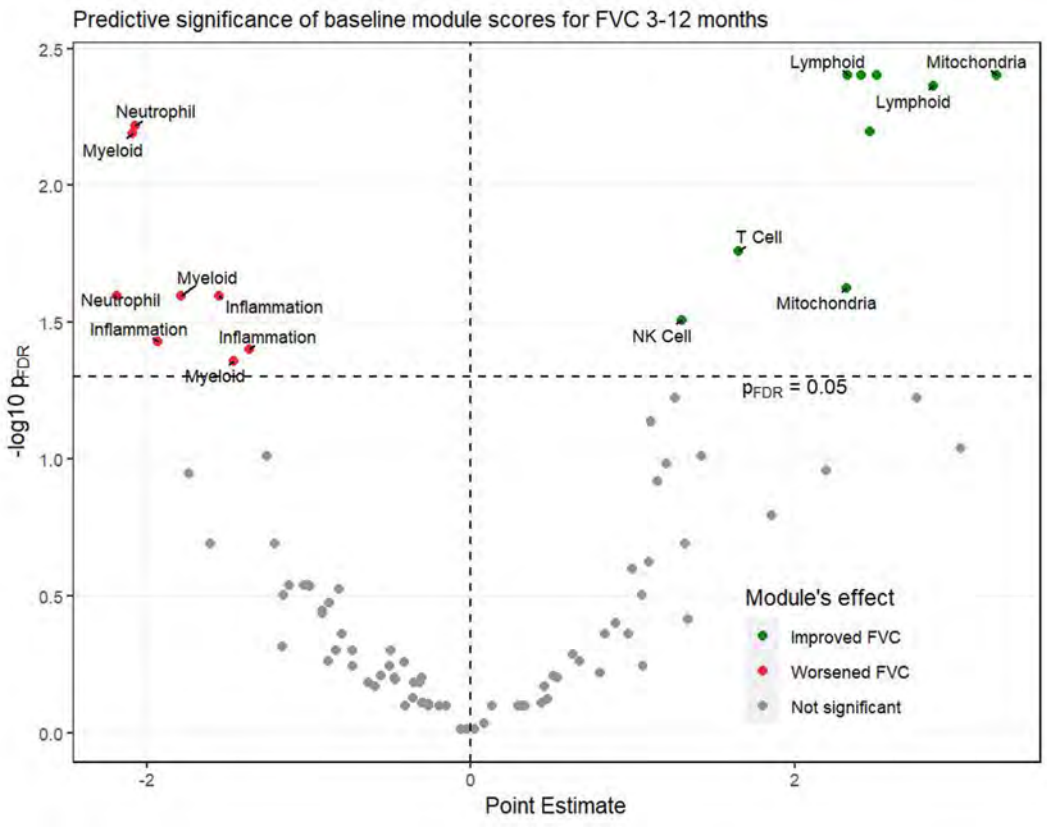

Figure 1. Predictive significance of baseline modular scores for FVC% during 3-12 month visits in the MMF arm. Higher T- and B-lymphocyte module scores predicted better ILD course while higher neutrophil/myeloid lineage module scores predicted worse ILD course. Of note, the modular analysis method can assign the same biological function to multiple modules.

for the longitudinally obtained FVC%s with a survival model to handle non-ignorable missing data). All analyses were corrected for multiple comparison by FDR method.

Results: A total of 134 patients with SSc-ILD (CYC=69 and MMF=65) enrolled in SLS II were investigated. The pairwise comparison of 12 month to baseline samples showed an upregulation of erythropoiesis, inflammation, and myeloid lineage related modules and a down-regulation of lymphoid lineage related modules in the CYC arm (Table 1). The modular changes resulting from MMF treatment were more modest. Plasma cell and cell cycle modules were downregulated after MMF treatment (Table 2).

In the longitudinal joint model, none of the baseline composite transcript module scores significantly predicted the course of FVC% in the CYC arm. In contrast, composite scores of certain transcript modules showed differential predictive significance in the MMF arm (Figure 1). Specifically, higher baseline Lymphoid Lineage (including T-cells and Cytotoxic/NK cells), and Mitochondrial Modules predicted better subsequent FVC% course, while higher baseline Myeloid Lineage (including Neutrophils / Granulocytes) and Inflammation modules predicted worse subsequent FVC% course in the MMF arm.

Conclusion: Oral CYC has a profound impact on the PBC gene expression profile in patients with SSc-ILD. MMF treatment leads to more modest gene expression changes including a decline in plasma cell modules. The predictive significance of immune related modules for response to MMF treatment varies as follows: Consistent with the primary mechanism of action of MMF on lymphocytes, patients with higher baseline lymphoid modules have a better response to MMF, while those with a higher myeloid cell lineage activation score have a poorer response.

Session Title: Systemic Sclerosis & Related Disorders – Clinical Poster III (1836–1861)

Session Type: Poster Session D

Session Time: 8:30AM–10:30AM

Background/Purpose: Hesitancy about COVID-19 vaccination exists among patients with rheumatic and musculoskeletal diseases, but previous studies have not assessed this specifically in patients with systemic sclerosis (SSc, or scleroderma). We surveyed patients enrolled in the Scleroderma Patient-centered Intervention Network (SPIN) Cohort regarding their willingness to be vaccinated as well as their perceptions and concerns about the vaccines.

Methods: Participants were adults with physician-verified SSc enrolled in the SPIN Cohort. SPIN includes 47 international centers and has approximately 1600 active participants. From April 9 to May 15, 2021, participants from the SPIN Cohort were invited by email and popups during regular SPIN Cohort assessments to participate in a COVID-19 vaccine survey, which was conducted in English and French. Participants were asked if they had received the vac-

Table 2. Perceptions of patients based on degree of hesitancy

	Received vaccine or plan to do so 842 (90.3%)		Unsure/Unlikely/Certainly will not get vaccine 90 (9.7%)		
	n (%) imp/very important	Likert rating Mean (SD)	n (%) imp/very important)	Likert rating Mean (SD)	mean difference (95% CI)
A. How important are each of the following considerations to you for getting the vaccine already or for considering getting it in the future?					
It reduces the chance of getting sick with COVID-19	809 (96%)	4.79 (0.54)	44 (49%)	3.14 (1.55)	1.64 (1.31, 1.97)
It protects others from getting COVID-19	788 (94%)	4.67 (.71)	48 (53%)	3.24 (1.49)	1.42 (1.10, 1.74)
It increases one's ability to socialize with friends and family	734 (87%)	4.50 (.88)	48 (53%)	3.21 (1.57)	1.28 (.95, 1.62)
It allows people to get back to or closer to normal life and routines.	762 (91%)	4.58 (.77)	47 (52%)	3.29 (1.51)	1.29 (.97, 1.61)
Proof of vaccination may be required in the future to travel or socialize	640 (76%)	4.09 (1.14)	37 (41%)	2.84 (1.63)	1.25 (.90, 1.59)
It is our duty to receive the COVID19 vaccine to set a good example to others	625 (74%)	4.07 (1.19)	12 (13%)	1.93 (1.26)	2.14 (1.86, 2.41)
We all need to work together to end this pandemic.	783 (93%)	4.66 (.74)	45 (50%)	3.33 (1.42)	1.33 (1.02, 1.63)
Someone close to me has been very sick with COVID-19	441 52%)	3.20 (1.68)	34 (38%)	2.79 (1.57)	.42 (.07, .76)
B. How important are the following to you in making a decision about getting a COVID-19 vaccine?					
The recommendation of the doctor who cares for my scleroderma	672 (80%)	4.23 (1.15)	45 (50%)	3.26 (1.45)	0.97 (0.66, 1.28)
The ability to obtain information and discuss any concerns with my doctor	626 (74%)	4.07 (1.17)	56 (62%)	3.64 (1.49)	.42 (.10, .75)
The opportunity to review publicly available data on vaccine effectiveness and safety	644 (77%)	4.09 (1.07)	58 (64%)	3.81 (1.45)	.28 (-.03, .59)
Information on whether or not my doctor received the vaccine	307 (37%)	2.77 (1.55)	37 (41%)	2.82 (1.64)	-.06 (-.41, .30)
The experiences of friends or family members who received the vaccine.	405 (48%)	3.24 (1.40)	40 (44%)	3.10 (1.47)	.14 (-.18, .46)
The experiences of other people with scleroderma who have received the vaccine	429 (51%)	3.33 (1.41)	58 (64%)	3.72 (1.52)	-.39 (-.72, -.06)
Guidelines for people with scleroderma and COVID-19 vaccination from trustworthy sources	597 (71%)	3.98 (1.24)	56 (62%)	3.74 (1.49)	.234 (-.09, .56)
Evidence that people with scleroderma have received the vaccine without major adverse reactions	553 (66%)	3.78 (1.31)	60 (67%)	3.8 (1.49)	-.06 (-.38, .27)
That enough time has passed for me to be comfortable that there are no long-term negative effects of the vaccines	500 (59.4%)	3.62 (1.36)	72 (80%)	4.36 (1.01)	-.74 (-.97, -.51)
The ability to have a vaccine appointment that is convenient for me	468 (55.6%)	3.46 (1.46)	25 (28%)	2.56 (1.55)	.91 (.57, 1.25)
Results are presented as the number (%) of patients who responded that a point was important or very important as well as the mean (SD) of the group's response on the Likert scale. The mean difference of these scores is presented with the 95% confidence interval. Results that cross zero are not significant.					

cine and if not, whether they planned to and their degree of certainty. All were asked to rate factors of importance in the decision to get vaccinated using a 5-point Likert scale (1 – not important, 2 – slightly important, 3 – somewhat important, 4 – important, 5 – very important). These questions were developed based on previous surveys by SPIN investigators in conjunction with patient partners. Responses of those who had or who planned to receive the vaccine were compared to those who were unsure, unlikely or certainly would not get the vaccine. Descriptive statistics and t-tests for mean item differences are presented.

Results: The demographic and clinical characteristics of the 932 responders are shown in Table 1. Of these, 699 (75%) had received at least one dose of COVID-19 vaccine, and 842 (90.3%) had either been vaccinated or planned

to do so. 90 participants (9.7%) reported feeling unsure [35 (3.8%)], unlikely [31 (3.4%)], or that they would certainly not [24 (2.6%)] get vaccinated.

Responses were compared based on hesitancy (table 2). Patients who received the vaccine or who planned to do so rated multiple considerations of higher importance than those who were hesitant. (2A) The highest mean differences were noted for the following factors: civic duty/setting an example, reducing risk of illness, protecting others. When asked about decision making about getting the vaccine, hesitant patients were more likely to rank as important or very important that enough time had passed to assess risk of long-term side effects and the experiences of other SSc patients. Compared to those who were hesitant, patients who had received the vaccine or who planned to were more likely to rank as important or highly important: their rheumatologist's recommendation, the ability to discuss concerns with their doctor, and convenience. (2B)

Conclusion: Approximately 1 in 10 participants reported vaccine hesitancy. These results identify factors associated with hesitancy in this group of SSc patients and highlight topics that may be emphasized in providing education which may be helpful for hesitant SSc patients.

SESSION INFORMATION

Session Date: Tuesday, November 9, 2021

Session Title: Systemic Sclerosis & Related Disorders – Clinical Poster III (1836–1861)

Session Type: Poster Session D

Session Time: 8:30AM–10:30AM

Background/Purpose: In the SENSCIS trial in patients with SSc-ILD, nintedanib reduced the rate of decline in forced vital capacity (FVC) vs placebo. Patients with SSc-ILD frequently have comorbidities that add to their functional impairment and complicate their care. We investigated the efficacy and safety of nintedanib in subgroups based on comorbidity burden.

Table 1. Baseline characteristics of subgroups of patients in the SENSCIS trial by number of comorbidities and CCI score.

	Number of comorbidities		CCI score	
	≤2 (n=371)	>2 (n=205)	≤1 (n=338)	>1 (n=238)
Female	273 (73.6)	160 (78.0)	258 (76.3)	175 (73.5)
Age, years	51.5 (12.5)	58.4 (10.3)	46.2 (9.2)	65.0 (5.8)
BMI, kg/m^2	25.4 (4.7)	26.7 (5.4)	25.7 (5.0)	26.2 (5.0)
Years since onset of first non-Raynaud symptom	3.5 (1.7)	3.5 (1.7)	3.6 (1.7)	3.3 (1.7)
Diffuse cutaneous SSc	199 (53.6)	100 (48.8)	198 (58.6)	101 (42.4)
ATA positive	243 (65.5)	107 (52.2)	225 (66.6)	125 (52.5)
Modified Rodnan skin score*	11.4 (8.8)	10.6 (9.3)	12.4 (9.4)	9.3 (8.1)
FVC % predicted	71.7 (16.5)	74.0 (16.9)	69.8 (16.2)	76.5 (16.5)
SGRQ total score†	38.4 (20.3)	43.1 (20.6)	40.4 (20.8)	39.7 (20.3)

Data are n (%) of patients or mean (SD). *2 patients had missing data. †11 patients had missing data. ATA, anti-topoisomerase I antibody; FVC, forced vital capacity; SGRQ, St George's Respiratory Questionnaire.

Methods: The SENSCIS trial enrolled patients with SSc-ILD with first non-Raynaud symptom in the last ≤7 years and an extent of fibrotic ILD on HRCT ≥10%. Patients with clinically significant pulmonary hypertension were excluded. Comorbidities at baseline were counted in categories based on organ group. In the Charlson Comorbidity Index (CCI), ages of 50–59 years, 60–69 years, 70–79 years and ≥80 years are assigned 1, 2, 3 and 4 points, respectively. The presence and severity of specific comorbidities are scored 1, 2, 3 or 6 points each. Patients with certain comorbidities used to calculate the CCI (e.g. metastatic solid tumor, AIDS) were not eligible for inclusion in the trial. SSc

Figure. Rate of decline in FVC (mL/year) over 52 weeks in the SENSCIS trial in subgroups by number of comorbidities and CCI score at baseline.

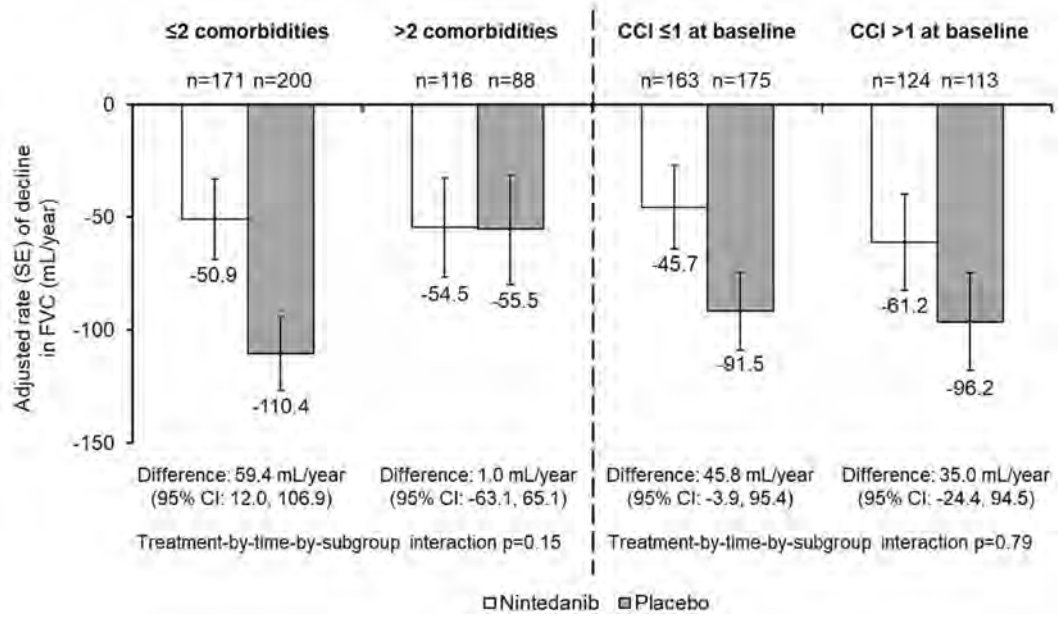

Table 2. Adverse events in subgroups of patients in the SENSCIS trial by number of comorbidities and CCI score at baseline.

Data are n (%) of patients with ≥1 such event reported on-treatment over 52 weeks (or until 28 days after last trial drug intake in patients who discontinued trial drug before week 52). *Adverse events, coded using the Medical Dictionary for Regulatory Activities (MedDRA), reported in >10% of patients in either treatment group in the overall trial population are shown.

was not counted as a comorbidity. We investigated the rate of decline in FVC (mL/year) and adverse events over 52 weeks in subgroups with ≤2 vs >2 comorbidities and CCI score ≤1 vs >1 at baseline.

Results: Among 576 patients treated in the SENSCIS trial, 205 (35.6%) had >2 comorbidities and 238 (41.3%) had a CCI score >1 at baseline. At baseline, compared with patients with ≤2 comorbidities, those with >2 comorbidities had a higher mean age, FVC % predicted, and St George's Respiratory Questionnaire total score, a greater proportion were female, and a smaller proportion had diffuse cutaneous SSc (dcSSc) (Table 1). Compared with patients with a CCI score ≤1, those with a CCI score >1 had a higher mean age and FVC % predicted and a smaller proportion had dcSSc (Table 1). In the placebo group, the rate of decline in FVC over 52 weeks was numerically greater in patients with ≤2 than >2 comorbidities, but similar between patients with CCI score ≤1 and >1. The effect of nintedanib versus placebo on reducing the rate of FVC decline was numerically greater in patients with ≤2 than >2 comorbidities and similar between patients with CCI score ≤1 and >1, but no heterogeneity in the treatment effect was detected (interaction p-values 0.15 and 0.79, respectively) (Figure). The adverse event profile of nintedanib was generally similar across the subgroups (Table 2). Adverse events leading to discontinuation were more frequent in patients treated with nintedanib than placebo and, in both treatment groups, were more frequent in patients with higher comorbidity burden.

Conclusion: In the SENSCIS trial in patients with SSc-ILD, patients with greater comorbidity burden had higher FVC at baseline. The rate of decline in FVC over 52 weeks in the placebo group, and the effect of nintedanib on the rate of FVC decline, were numerically greater in patients with ≤2 than >2 comorbidities, but no statistically significant heterogeneity was detected in the effect of nintedanib between the subgroups. Treatment discontinuation due to adverse events was more common in patients with greater comorbidity burden. Proactive management of adverse events is important to help patients stay on antifibrotic therapy.

Six-minute Walk Test as a Prognostic Marker in Systemic Sclerosis

Vinicius Verlangieri Soubihe, Juliana Zonzini Gaino, Alisson Pugliesi, Ana Paula Toledo Del Rio, Zoraida Sachetto, Marília Paula Souza Dos Santos and Luciana Campanatti Palhares, University of Campinas, Campinas, Brazil

SESSION INFORMATION
Session Date: Tuesday, November 9, 2021
Session Title: Systemic Sclerosis & Related Disorders – Clinical Poster III (1836–1861)
Session Type: Poster Session D
Session Time: 8:30AM–10:30AM

Background/Purpose: Pulmonary arterial hypertension (PAH) and interstitial lung disease (ILD) are the leading causes of mortality in systemic sclerosis (SSc). Although the six-minute walk test (6MWT) is generally used for evaluating physical functioning in PAH and ILD, its relevance in clinical practice is still uncertain. The purpose of this study was to evaluate which variables of 6MWT are correlated with demographic, clinical and serological data.

Methods: In this cross-sectional study, 75 SSc patients (all patients met the 2013 ACR-EULAR systemic sclerosis classification criteria) were evaluated regarding the following characteristics: demographic, clinical including diagnosis of SSc, disease duration, calcinosis, NYHA functional class, modified Rodnan skin score (MRSS), pulmonary function, ILD, c-reactive protein (CRP - mg/L) and immunological data (anti-topoisomerase-I, anticentromere and RNP antibodies) – table 1. Patients were submitted to 6MWT. A Kruskal-Wallis test followed by Dunn's multiple non-parametric pairwise tests was used to compare the categorical items with 6MWT variables (table 2). The numerical items were compared applying Spearman correlation coefficient (table 3). All the data were analyzed using 5% level of significance ($p < 0.05$).

Results: Total distance was negatively associated with age and advanced age at diagnosis. Predicted distance was positively related to age, disease duration, greater forced vital capacity (FVC) and lesser NYHA functional class (I >II; II >III/IV) class. Borg scale was positively related to higher NYHA functional class (I< II, II< III/IV). Drop of saturation was positively associated with worse FVC and anti-topoisomerase-I positivity. There were no associations between 6MWT variables and race, clinical classification of SSc (limited, diffuse or sine scleroderma), presence of calcinosis, MRSS, anti-centromere, anti-RNP, presence of ILD and CRP values.

Conclusion: The performance on 6MWT was well correlated with pulmonary function, anti-topoisomerase-I positivity, NYHA functional class, disease duration and age. 6MWT is a straightforward and inexpensive test, useful in identifying SSc patients with adverse outcomes in clinical practice. Prospective studies are necessary to confirm our findings.

Session Title: Systemic Sclerosis & Related Disorders – Clinical Poster III (1836–1861)

Session Type: Poster Session D

Session Time: 8:30AM–10:30AM

Figure 1. Rate of decline in FVC (mL/year) over 52 weeks in all patients and in patients with risk factors for rapid decline in FVC at baseline in the SENSCIS trial.

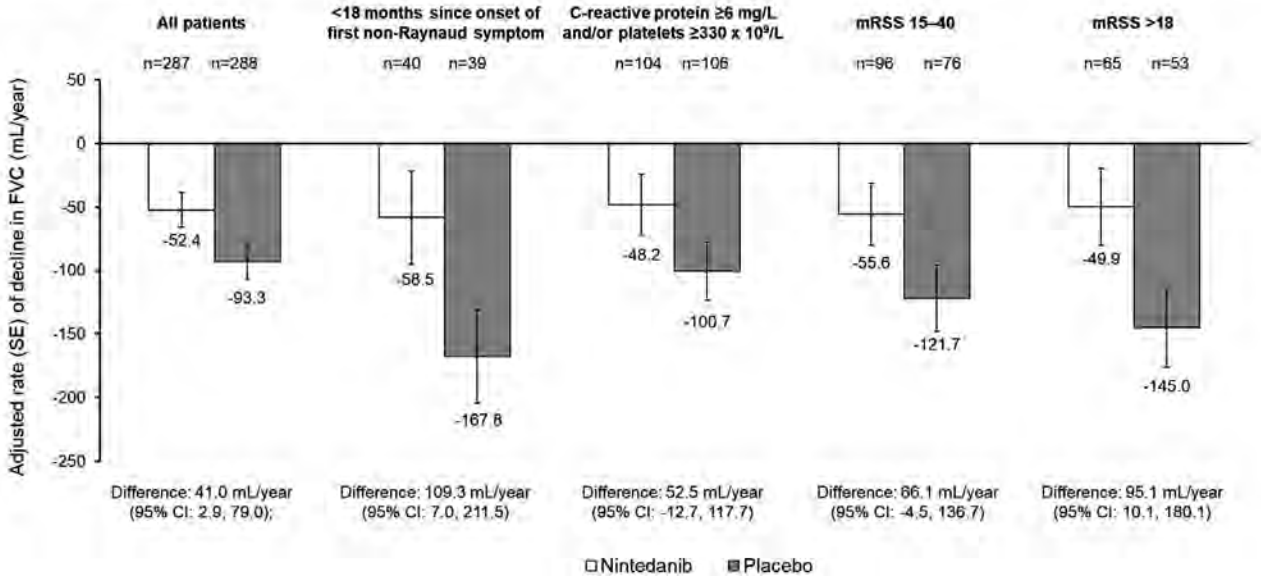

Figure 2. Rate of decline in FVC (mL/year) over 52 weeks in all patients and in patients with dcSSc and risk factors for rapid decline in FVC at baseline in the SENSCIS trial.

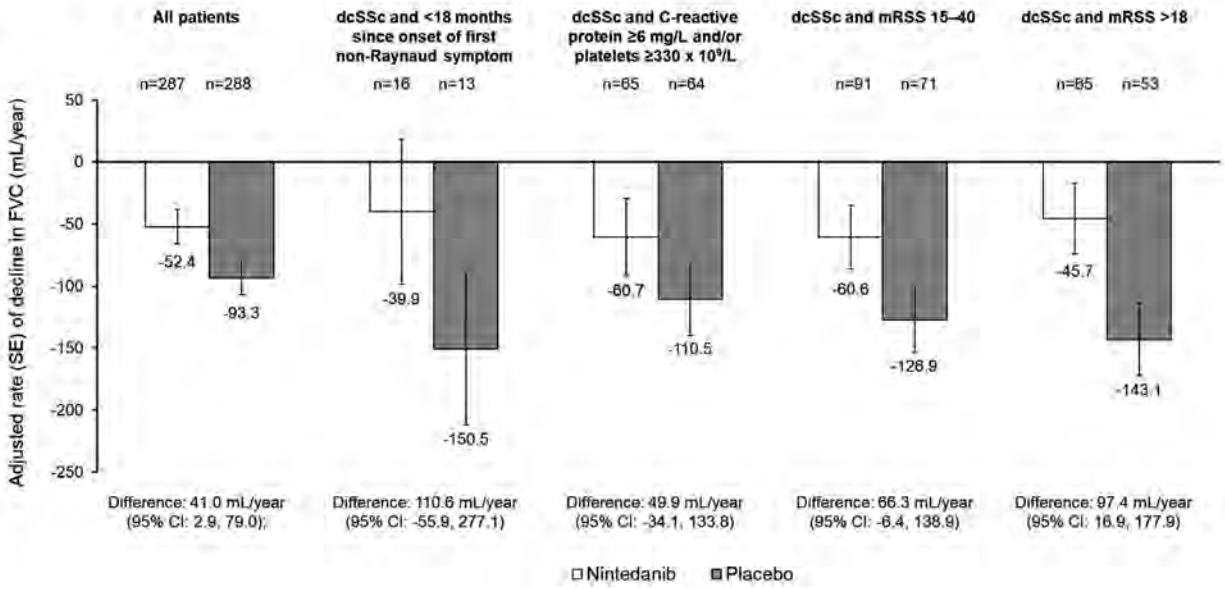

Background/Purpose: In the SENSCIS trial conducted in a population of subjects with systemic sclerosis-associated interstitial lung disease (SSc-ILD), with a mean time since onset of first non-Raynaud symptom of 3.5 years and 52% with diffuse cutaneous SSc (dcSSc), nintedanib reduced the rate of decline in FVC (mL/year) over 52 weeks by 44% versus placebo. Risk factors for a rapid decline in FVC in patients with SSc include early SSc, elevated inflammatory markers, significant skin involvement, and dcSSc. Patients with SSc with these risk factors for rapid progression of ILD are typically given immunosuppressants but not nintedanib. We analyzed the rate of decline in FVC and the effect of nintedanib on FVC decline in subjects with these risk factors in the SENSCIS trial.

Methods: In post-hoc analyses of data from the SENSCIS trial, we analyzed the rate of decline in FVC (mL/year) over 52 weeks in all subjects and in those with early SSc (< 18 months since onset of first non-Raynaud symptom), elevated inflammatory markers (C-reactive protein ≥6 mg/L and/or platelets ≥330 x 10^9/L), or significant skin fibrosis using two approaches (modified Rodnan skin score [mRSS] 15-40 or mRSS >18) at baseline. We also analyzed the rate of decline in FVC over 52 weeks in subjects with one of these risk factors and dcSSc.

Results: Of 575 subjects analyzed, 79 (13.7%) had < 18 months since onset of first non-Raynaud symptom, 210 (36.5%) had elevated inflammatory markers, 172 (29.9%) had mRSS 15-40 and 118 (20.5%) had mRSS >18. Of 299 subjects with dcSSc, 29 (9.7%) had < 18 months since onset of first non-Raynaud symptom, 129 (43.1%) had elevated inflammatory markers, 162 (54.2%) had mRSS 15-40 and 118 (39.5%) had mRSS >18. In the placebo group, the rate of decline in FVC over 52 weeks was numerically greater in subjects with these risk factors for rapid decline in FVC compared with all subjects. Across the subgroups, the rate of decline in FVC was numerically lower in subjects treated with nintedanib than placebo (Figures).

Conclusion: The SENSCIS trial included a broad range of subjects with a fibrotic ILD complicating SSc, including those with risk factors for a rapid decline in FVC. In the placebo group, subjects with these risk factors had a more rapid decline in FVC over 52 weeks compared with the overall trial population. By targeting fibrosis with nintedanib, the rate of decline in FVC in patients with risk factors for FVC decline was reduced in patients treated with nintedanib than placebo.

Severity of Gastroesophageal Reflux, but Not the Use of Proton Pump Inhibitors, Is Associated with Radiographic Progression of Interstitial Lung Disease in Systemic Sclerosis

Elizabeth Volkmann[1], Donald Tashkin[2], Mei Leng[2], Grace Kim[2], Jonathan Goldin[2] and Michael Roth[2], [1]Department of Medicine, Division of Rheumatology, University of California, David Geffen School of Medicine, Los Angeles, CA, [2]University of California Los Angeles, Los Angeles, CA

SESSION INFORMATION

Session Date: Tuesday, November 9, 2021

Session Title: Systemic Sclerosis & Related Disorders – Clinical Poster III (1836–1861)

Session Type: Poster Session D

Session Time: 8:30AM–10:30AM

Table 1. Severity of gastroesophageal reflux, but not PPI use, is associated with radiographic progression of fibrosis (QLF) in the whole lung in patients receiving treatment for SSc-ILD.

Covariate	Estimate	95% CI	P-value
Baseline QLF	-0.18	-0.30, -0.07	0.002
Treatment arm	-0.05	-1.67, 1.57	0.951
Baseline reflux score	2.19	0.69, 3.69	0.005
PPI use	-0.26	-2.33, 1.81	0.807

Table 2. Severity of gastroesophageal reflux, but not PPI use, is associated with radiographic progression of ILD (QILD) in the whole lung in patients receiving treatment for SSc-ILD.

Covariate	Estimate	95% CI	P-value
Baseline QILD	-0.23	-0.36, -0.09	0.001
Treatment arm	1.09	-2.45, 4.63	0.541
Baseline reflux score	3.45	0.18, 6.72	0.039
PPI use	0.53	-5.00, 3.95	0.815

Background/Purpose: Esophageal dysmotility is a common feature of systemic sclerosis (SSc) and aspiration of gastric contents may serve as an inciting and/or exacerbating factor in the pathogenesis of interstitial lung disease (ILD). The present study aimed to: (1) determine whether the severity of gastroesophageal reflux predicts progression of SSc-ILD and (2) evaluate whether proton pump inhibitors (PPI) moderate the relationship between reflux severity and ILD progression as defined both radiographically and physiologically.

Methods: The UCLA SCTC GIT 2.0 was used to assess the severity of reflux in participants of Scleroderma Lung Study (SLS) II (Tashkin et al. Lancet Resp Med 2016). SLS II compared 24 months of mycophenolate versus 12 months cyclophosphamide followed by 12 months of placebo in patients with active SSc-ILD. A multivariable linear regression analysis was used to evaluate the relationship between baseline reflux scores and change in quantitative extent of radiographic ILD (QILD) and fibrosis (QLF) in the whole lung at 24 months. A joint model was created to evaluate the relationship between baseline reflux scores and the course of the forced vital capacity (FVC)%-predicted

Table 3. Severity of gastroesophageal reflux is not associated with the course of the FVC%-predicted over 24 months in patients receiving treatment for SSc-ILD based on a joint model analysis.

Covariate	Estimate	95% CI	P-value
Baseline FVC	0.92	0.83, 1.02	<0.001
Time trend A (3-12 months)	0.28	0.17, 0.40	<0.001
Time trend B (12-21 months)	-0.13	-0.36, 0.11	0.295
Time trend C (21-24 months)	-0.41	-1.05, 0.16	0.168
Treatment arm	1.00	-1.09, 3.12	0.352
Baseline reflux score	-0.34	-2.08, 1.40	0.720
PPI use	0.56	-1.79, 2.91	0.625
Time trend A x Treatment arm	-0.10	-0.26, 0.06	0.231
Time trend B x Treatment arm	-0.01	-0.36, 0.32	0.991
Time trend C x Treatment arm	0.22	-0.63, 1.07	0.595

measured every 3 months over 24 months. All models controlled for treatment arm and baseline ILD severity, and tested whether PPI use was associated with ILD progression.

Results: 141 of the 142 SLS II participants had reflux scores at baseline and the mean score was 0.57, indicating moderate severity. There were no significant correlations between baseline reflux score and FVC%-predicted, QLF, QILD, disease duration, skin score, gender or the presence of diffuse cutaneous disease. Among participants with follow up HRCT scans (N=96), increased severity of reflux was significantly associated with increased QLF (Table 1) and QILD (Table 2) scores at 24 months. However, increased severity of reflux was not significantly associated with the course of the FVC%-predicted (N=130; Table 3). 112 (78.9%) of SLS II participants were taking a PPI at baseline; PPI users had higher reflux scores than non-users (P= < 0.0001). PPI use was not significantly associated with progression of ILD in any of the models.

Conclusion: Among patients receiving treatment for SSc-ILD, increased severity of gastroesophageal reflux symptoms was associated with ILD progression, based on worsening extent of radiographic fibrosis and total ILD, but not with the course of the FVC. PPI use was not associated with progression of ILD, suggesting that aspiration of non-acid gastric contents may play a role in perpetuating inflammation and fibrosis in SSc-ILD. Future studies are needed to assess whether other reflux treatments (e.g., pro-motility agents) moderate the relationship between reflux severity and ILD progression in SSc.

Abstract Number: 1848

Untangling the Gut: A Phenome-Wide Association Study of Drugs and Diseases with Gastrointestinal Dysfunction in Systemic Sclerosis

Rory Maclean[1], Fiza Ahmed[2], Voon Ong[3], Charles Murray[4] and Christopher Denton[5], [1]Royal Free Hospital & University College London, London, United Kingdom, [2]Royal Free Hospital, Ilford, United Kingdom, [3]University College London Medical School Royal Free Campus, London, United Kingdom, [4]Royal Free Hospital, London, United Kingdom, [5]University College London Division of Medicine, Centre for Rheumatology and Connective Tissue Diseases, London, United Kingdom

SESSION INFORMATION
Session Date: Tuesday, November 9, 2021
Session Title: Systemic Sclerosis & Related Disorders – Clinical Poster III (1836–1861)
Session Type: Poster Session D
Session Time: 8:30AM–10:30AM

Background/Purpose: Gastrointestinal dysfunction (SSc-GI) is a significant burden to patients with systemic sclerosis (SSc), particularly in those with longstanding disease. The management of SSc-GI is often challenging. Whilst hallmark mechanisms including vasculopathy, fibrosis, and inflammation underlie gut pathogenesis, reflected in autoantibody (ANA) associations, off-target effects of drugs used in SSc may contribute to GI dysfunction. We sought to discover and confirm associations with SSc-GI dysfunction in a Phenome-Wide Association Study (PheWAS).

Methods: Archived clinic letters (12,535 letters) of 2,058 consented patients at the Royal Free Hospital (UK) between 2002-2021 were parsed into a database. Patients with at least three letters were included. Two 'dictionaries', one of diagnoses (Disease Ontology project *CC0*, modified to included ANA) and another of drugs (DrugBank Open Data *CC0*) were used to label each patient. Using the PheWAS approach for six SSc-GI outcomes (constipation, diarrhoea,

Table 1. Study Cohort

PheWAS cohort	n	1546
Female	%	84
Limited	%	67
Disease onset (year)	range	1959 - 2019
ACA	%	26
ATA	%	24
ARA	%	11
PM-Scl	%	4.6
U1RNP	%	5.8
U3RNP	%	3.9
ThT0	%	0.5
Validation cohort (UCLA GIT 2.0)	n	516

dysmotility, incontinence, reflux, small intestinal bacterial overgrowth [SIBO]), we assessed every diagnosis and drug in univariate logistic regressions. P values were adjusted for false discovery rate (Benjamini-Hochberg). Significant PheWAS predictors ($p < 0.05$) were validated against the UCLA GIT 2.0 questionnaire score (UCLA GIT) in a second dataset of 516 patients including total GI, reflux, bloating, diarrhoea, soilage, constipation, social, and emotional scores.

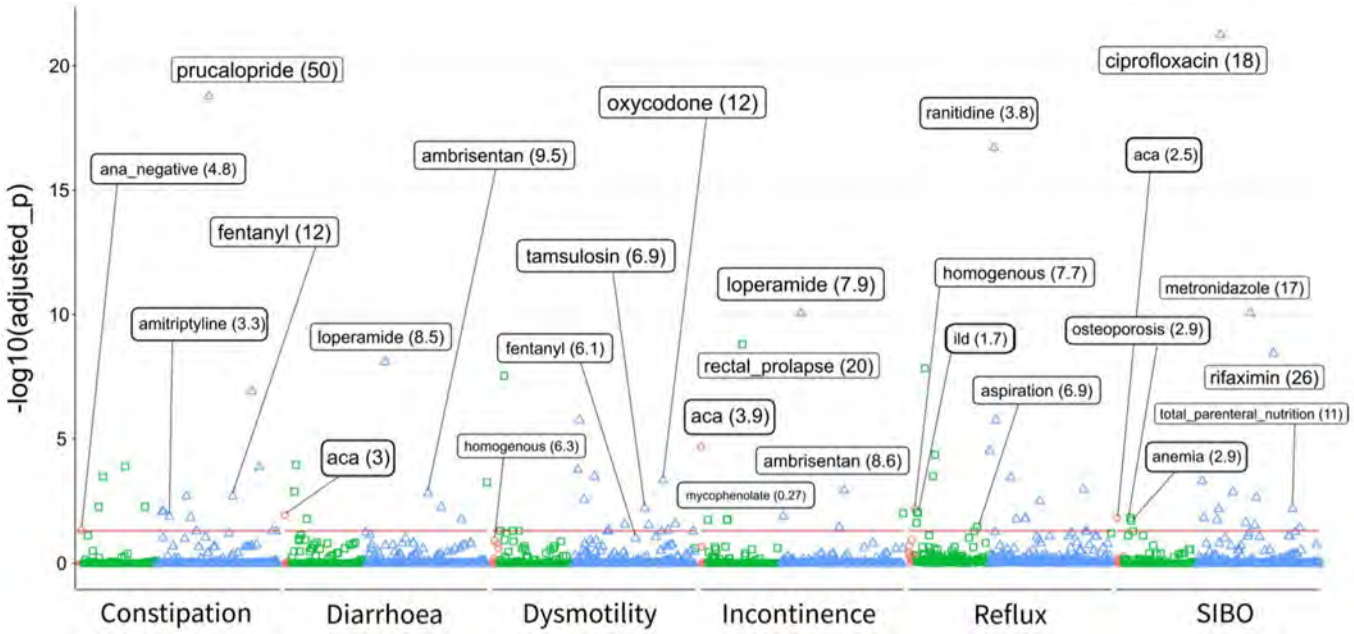

Figure 1. PheWAS analysis demonstrated significant associations between ANAs (red circles), diagnoses (green squares), and drugs (blue triangles) in six key SSc-GI areas. The red horizontal line indicates adjusted p values < 0.05. Key associations with named variables are presented; odds ratios in brackets.

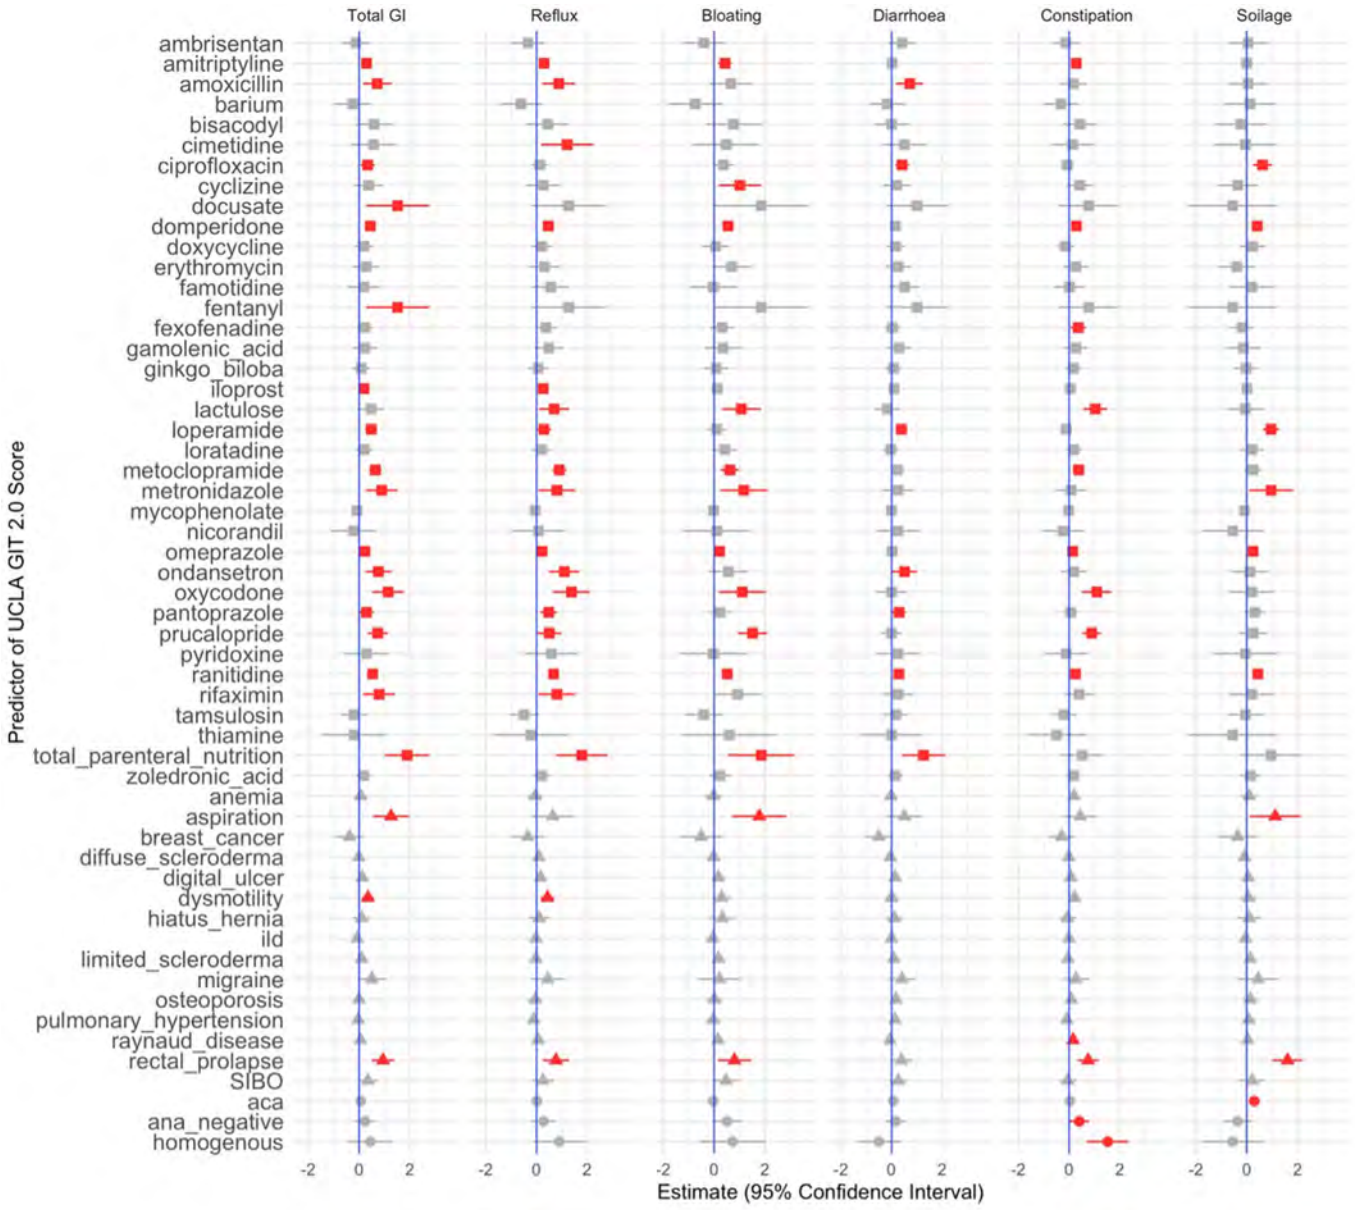

Figure 2. PheWAS hits were validated in a linear model against UCLA GIT 2.0 domain scores: total GI, reflux, bloating, diarrhoea, constipation, and soilage domains are shown. Estimates with 95% CIs are presented; red highlights $p < 0.05$. Square – drugs; triangle – diagnoses; circle – ANA.

Results: Table 1 presents cohort demographics. Using the diagnosis and drug dictionaries, we identified 673 diagnoses (including ANAs) and 634 drugs. Top drugs (prevalence): omeprazole 56%, losartan 49%, lansoprazole 42%, and mycophenolate mofetil (MMF) 40%; top diagnoses: limited SSc 65%, Raynaud's 50%, interstitial lung disease (ILD) 36%, and overlap 27%.

PheWAS analysis demonstrated significant associations across the six key SSc-GI outcomes (Fig. 1). Constipation was linked to fentanyl (OR = 12), amitriptyline (OR = 3.3), migraine (OR = 14), ANA negative (OR = 4.8), aspiration (OR = 15), and incontinence (OR = 5.3). Diarrhoea was linked to ambrisentan (OR = 9.5) and ACA (OR = 3). Dysmotility was linked to ANA homogenous (OR = 6.3), tamsulosin (OR = 6.9), fentanyl (OR = 6.1), and oxycodone (OR = 12). Incontinence was linked to ACA (OR = 3.9), ambrisentan (OR = 8.6), and inversely linked to MMF (OR = 0.27). Reflux was linked to ILD (OR = 1.7) and ANA homogenous (OR = 7.7). SIBO was linked to ACA (OR = 2.5), total parenteral nutrition (OR = 11), osteoporosis (OR = 2.9), and anemia (OR = 2.9).

Significant PheWAS associations were validated against UCLA GIT domain scores (Fig. 2). For the total GI score – 18 drugs and 3 diagnoses were validated; soilage – 6 drugs, 1 ANA, and 2 diagnoses; reflux – 17 drugs and 2 diagnoses; bloating – 11 drugs and 2 diagnoses; diarrhoea – 7 drugs; social – 19 drugs and 3 diagnoses; emotional – 17 drugs and 5 diagnoses; constipation – 2 ANA, 9 drugs, and 2 diagnoses.

Conclusion: Using a hypothesis-free PheWAS approach, we revealed potential contributors to SSc-GI dysfunction, including drugs such as opioids, anti-muscarinics, and endothelin receptor antagonists; and ANAs including ACA, ANA-homogenous and ANA-negative subtypes.

False Positive Anti-Topoisomerase I (Scl-70) Antibody Results: A Case Series from a Scleroderma Referral Center

Brian Lam[1], Rana Taherian[1], Julio Charles[1], Maureen Mayes[2], Shervin Assassi[3] and Brian Skaug[4], [1]Division of Rheumatology, University of Texas McGovern Medical School at Houston, Houston, TX, [2]Division of Rheumatology and Clinical Immunogenetics, University of Texas McGovern Medical School, Houston, TX, [3]University of Texas McGovern Medical School at Houston, Houston, TX, [4]University of Texas McGovern Medical School Houston, Houston, TX

SESSION INFORMATION
Session Date: Tuesday, November 9, 2021
Session Title: Systemic Sclerosis & Related Disorders – Clinical Poster III (1836–1861)
Session Type: Poster Session D
Session Time: 8:30AM–10:30AM

Background/Purpose: Systemic sclerosis (SSc) is a progressive autoimmune disease with high morbidity and mortality, making early diagnosis and management critical. Anti-Topoisomerase I antibody (anti-Topo I, also known as Scl-70) has important diagnostic and prognostic roles in SSc. Although positivity for anti-Topo I antibody is considered highly specific for SSc, the testing methods typically utilized in commercial laboratories have lower specificity than the immunodiffusion method. To highlight potential harms of a false-positive anti-Topo I antibody result, we describe a series of cases in which patients who tested positive for anti-Topo I antibody in a commercial laboratory were found to be negative for anti-Topo I antibody by the immunodiffusion method.

Methods: Patients seen in our clinic who had previously tested positive for anti-Topo I antibody performed by a commercial laboratory, but who lacked sufficient clinical criteria to be classified as SSc, were invited to undergo testing for anti-Topo I antibody by immunodiffusion in our research laboratory. Each patient's clinical features, commercial anti-Topo I antibody results, additional diagnostic testing, and clinical diagnosis at initial and follow up visits were recorded.

Results: Over a six-year period, 19 patients who fulfilled the above criteria underwent testing for anti-Topo I antibody by immunodiffusion (Table 1). 16 (84.2%) were found to be negative. 11 of the 19 patients (57.9%) had at least one follow up visit, typically 6-12 months after initial visit. Of those 11 patients with at least one follow up visit, all three patients who tested positive for anti-Topo I antibody by immunodiffusion, but none of the eight patients who tested

Table 1. Demographics, clinical features, and diagnostic testing

	Negative for anti-Topo I antibody by immunodiffusion (n = 16)	Positive for anti-Topo I antibody by immunodiffusion (n = 3)
Age in years, mean (SD)	44 (11.2)	40 (2)
Female, n (%)	16 (100)	2 (66.7)
History of Raynaud's prior to baseline visit, n (%)	5 (31.3)	2 (66.7)
Points in 2013 ACR/EULAR systemic sclerosis classification criteria at initial visit, median (min, max) *	2.5 (0, 7)	5 (4, 8)
Positive ANA by indirect immunofluorescence, n (%)^	10/14 (71.4)	3 (100)
Underwent chest CT, n (%)	7 (43.8)	2 (66.7)
Classifiable SSc at follow up visit, n (%)#	0/8 (0)	3 (100)

*Not including anti-Topo I antibody result from commercial laboratory

^of those tested by indirect immunofluorescence in a commercial laboratory

#of those who had at least one follow up visit

negative, developed sufficient criteria to be classified as SSc on follow up. One of the patients with a false-positive anti-Topo I antibody result was diagnosed with morphea, one with Sjogren's syndrome, one with antiphospholipid antibody syndrome, and two with undifferentiated connective tissue disease. The other 11 patients with false-positive anti-Topo I antibody results (68.8%) did not have a rheumatologic condition in the judgement of the treating physician. 7 of the 16 patients with false-positive anti-Topo I antibody (43.8%) had undergone chest CTs to screen for interstitial lung disease, one had been started on treatment with Mycophenolate Mofetil, and one had undergone pre-evaluation for autologous hematopoietic stem cell transplantation.

Conclusion: Our findings highlight the propensity of commercial laboratories to produce false-positive anti-Topo I antibody results. In the cases reported here, unnecessary referrals to a scleroderma specialty clinic, and in some cases unnecessary chest CTs, occurred after patients tested falsely positive for anti-Topo I antibody, demonstrating some of the potential negative impacts on patients and the healthcare system. While a thorough history and physical exam remain the mainstays of SSc evaluation, testing for anti-Topo I antibody using a more specific method such as immunodiffusion would likely help physicians and patients to avoid misdiagnoses, unnecessary referrals and diagnostic testing, and potentially risky treatments.

SESSION INFORMATION

Session Date: Tuesday, November 9, 2021

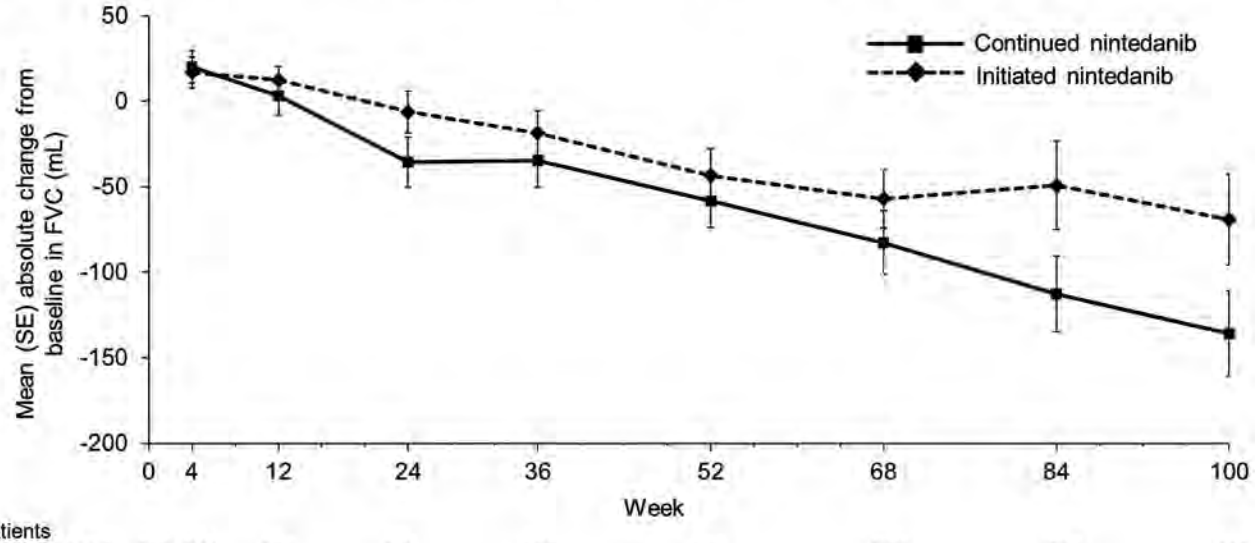
Session Title: Systemic Sclerosis & Related Disorders – Clinical Poster III (1836–1861)

Session Type: Poster Session D

Session Time: 8:30AM–10:30AM

Background/Purpose: In the SENSCIS trial in patients with SSc-ILD, nintedanib reduced the rate of decline in forced vital capacity (FVC) (mL/year) over 52 weeks by 44% compared with placebo, with adverse events that were manageable for most patients. The safety and efficacy of nintedanib over the longer term are being assessed in the open-label extension trial, SENSCIS-ON.

Figure. Change from baseline in FVC (mL) over 100 weeks in SENSCIS-ON



No. of patients									
Continued nintedanib	191	189	187	185	181	176	139	107	111
Initiated nintedanib	243	238	230	215	197	180	143	81	99

At week 84, 12.7% and 12.6% of patients in the continued and initiated nintedanib groups, respectively, completed a phone visit rather than a clinic visit, and so did not provide an FVC measurement; at week 100, 4.6% and 3.6% of patients in these groups, respectively, completed a phone visit.

Table. Adverse events reported over 100 weeks in SENSCIS-ON

	Continued nintedanib (n=197)	Initiated nintedanib (n=247)
Any adverse event(s)	193 (98.0)	245 (99.2)
Most frequent adverse events*		
Diarrhea	147 (74.6)	179 (72.5)
Nausea	37 (18.8)	68 (27.5)
Skin ulcer	45 (22.8)	48 (19.4)
Vomiting	35 (17.8)	56 (22.7)
Nasopharyngitis	29 (14.7)	38 (15.4)
Upper respiratory tract infection	36 (18.3)	29 (11.7)
Cough	34 (17.3)	27 (10.9)
Arthralgia	24 (12.2)	28 (11.3)
Weight decreased	19 (9.6)	30 (12.1)
Abdominal pain	9 (4.6)	36 (14.6)
Alanine aminotransferase increased	10 (5.1)	34 (13.8)
Aspartate aminotransferase increased	9 (4.6)	32 (13.0)
Liver test abnormalities†	26 (13.2)	56 (22.7)
Serious adverse event(s)‡	62 (31.5)	77 (31.2)
Adverse event(s) leading to treatment discontinuation	19 (9.6)	65 (26.3)

Data are n (%) of patients with ≥1 such event reported over 100 weeks (or until 7 days after last trial drug intake for patients who discontinued trial drug before week 100). *Events reported in >12% of patients in either group, coded according to preferred terms in the Medical Dictionary for Regulatory Activities (MedDRA). †Based on the standardized MedDRA query "liver related investigations, signs and symptoms" (broad definition). ‡Adverse events that resulted in death, were life-threatening, resulted in hospitalization or prolongation of hospitalization, resulted in persistent or clinically significant disability or incapacity, were a congenital anomaly or birth defect, or were deemed to be serious for any other reason.

Methods: In the SENSCIS trial, patients were randomized to receive nintedanib or placebo until the last patient reached week 52 but for ≤100 weeks. Patients with SSc-ILD who completed the SENSCIS trial or a drug–drug interaction (DDI) study of nintedanib and oral contraceptive (NCT03675581) were eligible to enter SENSCIS-ON. In descriptive analyses, we analyzed changes from baseline in FVC (mL) and adverse events over 100 weeks in patients who received nintedanib in SENSCIS and continued nintedanib in SENSCIS-ON (the "continued nintedanib" group) and in patients who received placebo in SENSCIS and initiated nintedanib in SENSCIS-ON or who received nintedanib for ≤28 days in the DDI study (the "initiated nintedanib" group). Analyses were based on observed FVC data available at the respective time-point.

Results: The continued nintedanib group comprised 197 patients and the initiated nintedanib group comprised 247 patients (231 from SENSCIS; 16 from the DDI study). In these groups, respectively, mean (SD) FVC at inclusion in SENSCIS-ON was 2379 (754) mL and 70.4 (18.1) % predicted and 2443 (814) mL and 70.8 (17.9) % predicted. In total, 148 (75.1%) and 145 (58.7%) patients in the continued nintedanib and initiated nintedanib groups, respectively, were receiving nintedanib at week 100 of SENSCIS-ON. Mean (SE) changes in FVC from baseline to week 100

of SENSCIS-ON were –135.7 (24.7) mL in patients who continued nintedanib in SENSCIS-ON, –69.2 (26.5) mL in patients who initiated nintedanib in SENSCIS-ON, and –104.3 (18.2) mL in all patients in SENSCIS-ON (Figure), similar to the change from baseline to week 100 in nintedanib-treated patients in the SENSCIS trial (–100.0 [36.7] mL) and lower than the change from baseline to week 100 in the placebo group of the SENSCIS trial (–164.4 [38.4] mL). Diarrhea was the most frequent adverse event (Table). Over 100 weeks, liver test abnormalities were reported in 26 patients (13.2%) in the continued nintedanib group and 56 patients (22.7%) in the initiated nintedanib group. Adverse events led to discontinuation of nintedanib in 19 (9.6%) patients in the continued nintedanib group and 65 (26.3%) patients in the initiated nintedanib group.

Conclusion: The safety profile of nintedanib over 100 weeks in SENSCIS-ON was consistent with that reported in the SENSCIS trial. The decline in FVC over 100 weeks in patients treated with nintedanib in SENSCIS-ON was consistent with the decline in FVC in patients treated with nintedanib over 100 weeks in the SENSCIS trial. These findings support a clinically meaningful benefit of nintedanib in slowing the progression of SSc-ILD.

Early Intervention with Immunomodulators Leads to Better Outcomes in Patients with Systemic Sclerosis

Keina Yomono[1] and Masataka Kuwana[2], [1]Nippon Medical School Graduate School of Medicine, Tokyo, Japan, [2]Department of Allergy and Rheumatology, Nippon Medical School Graduate School of Medicine, Tokyo, Japan

SESSION INFORMATION
Session Date: Tuesday, November 9, 2021
Session Title: Systemic Sclerosis & Related Disorders – Clinical Poster III (1836–1861)
Session Type: Poster Session D
Session Time: 8:30AM–10:30AM

Background/Purpose: Systemic sclerosis (SSc) is a complex disease characterized by microvascular abnormalities, immune dysregulation and chronic inflammation, and subsequent excessive fibrosis of the skin and internal organs. This leads to irreversible tissue remodeling and organ damage, resulting in increased morbidity and mortality. Recent accumulating evidence has shown that therapeutic disease modification is possible in SSc patients using immunomodulators. In rheumatoid arthritis, it has been shown that early disease is more susceptible to treatment, but we still don't know whether therapeutic "window of opportunity" exists in SSc patients.

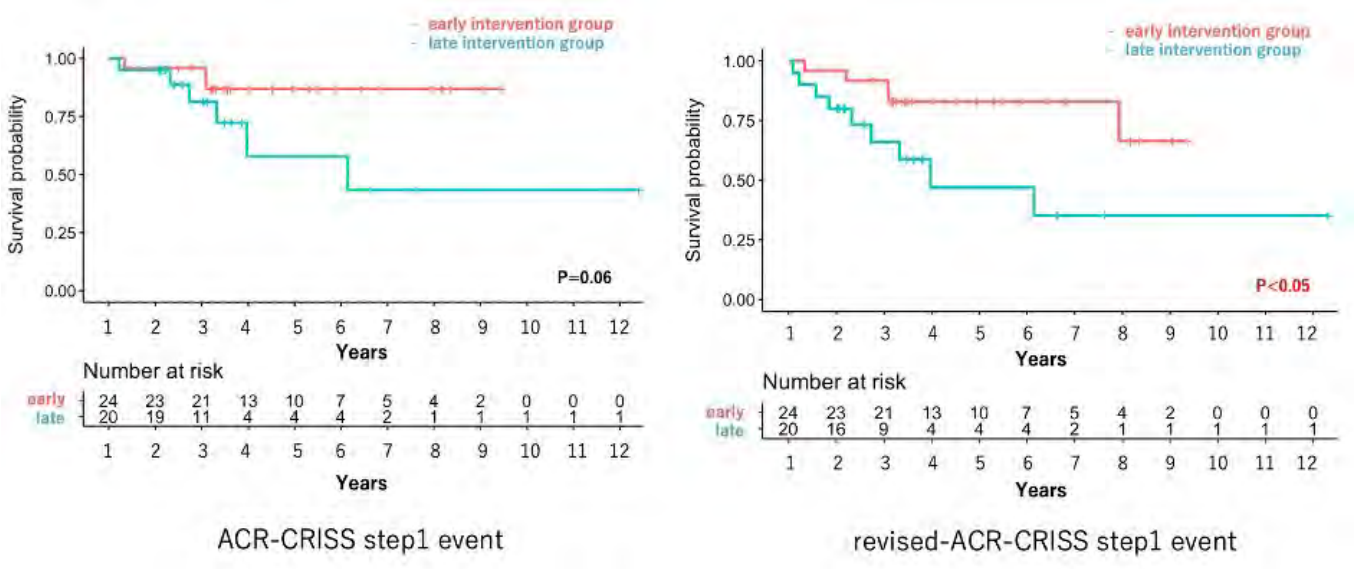

Figure 1. Time to clinical worsening defined by original and revised ACR-CRISS step 1 event.

Methods: This was a single-center, retrospective study enrolling SSc patients who received disease-modifying therapy for diffuse cutaneous SSc (dcSSc) or interstitial lung disease (ILD). Eligible patients were selected from our SSc database, and included those who i) fulfilled the 2013 ACR/EULAR classification criteria for SSc; ii) received treatment with cyclophosphamide, mycophenolate mofetil or tocilizumab for dcSSc or ILD within 6 years after onset of non-Raynaud's symptoms; and iii) had been on treatment for least one year. The patients were divided into early and late intervention groups based on the disease duration of ≤18 months or >18 months at treatment introduction. We evaluated changes of modified Rodnan total skin score (mRSS) and percent predicted forced vital capacity (ppFVC) from baseline to one year. Patients experiencing decrease of mRSS by ≥ 5 or relative increase of ppFVC by ≥10% were regarded as improvers. Clinical worsening was defined as development of at least one original or revised ACR-

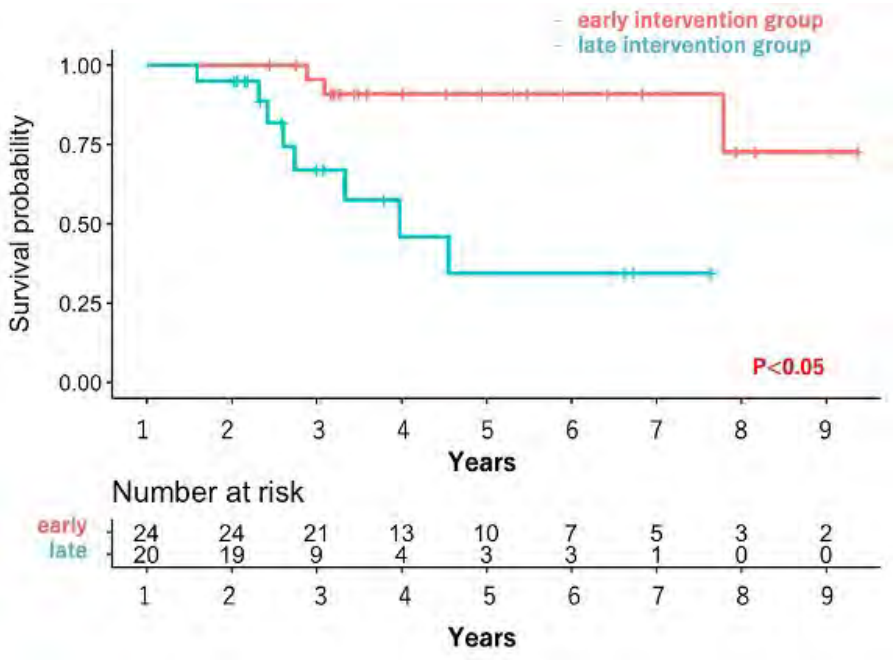

Figure 2. Time to clinical worsening defined by PF-ILD.

CRISS step 1 event or progressive fibrosing ILD (PF-ILD). Cumulative rates for clinical worsening were assessed using Kaplan-Meier analysis, and were compared between the groups with log-rank test.

Results: We enrolled 44 patients, including 24 in the early intervention group and 20 in the late intervention group. Disease duration at treatment introduction was 8.6 ± 4.2 and 34.3 ± 20.3 months in early and late intervention groups, respectively. Baseline characteristics were principally similar between the groups except ppFVC, which was significantly better in the early than late intervention group (93.2 ± 13.8 versus 80.4 ± 18.2; $P < 0.05$). There was no significant difference in changes of mRSS or ppFVC over one year between the two groups, but improvers tended to be more common in the early versus late intervention groups (37.5% versus 22.2% for mRSS, and 47.6% versus 16.7% for ppFVC). The Kaplan-Meier analysis revealed that the original and revised ACR-CRISS step 1 event tended to occur less frequently in the early than the late intervention group ($P = 0.06$ and $P < 0.05$, respectively; Figure 1). In addition, patients received early intervention developed PF-ILD less frequently, compared with those received late intervention ($P < 0.05$; Figure 2).

Conclusion: Our findings suggest that early intervention with immunomodulators in patients with dcSSc and/or SSc-ILD prevents clinical worsening, although further prospective study involving a larger number of patients is necessary to confirm the "window of opportunity" theory in the treatment of SSc.

Healthcare Utilization and Economic Burden in Systemic Sclerosis

Leonardo Martin Calderon[1], Mitali Chaudhary[1] and Janet Pope[2], [1]Western University, London, ON, Canada, [2]University of Western Ontario, London, ON, Canada

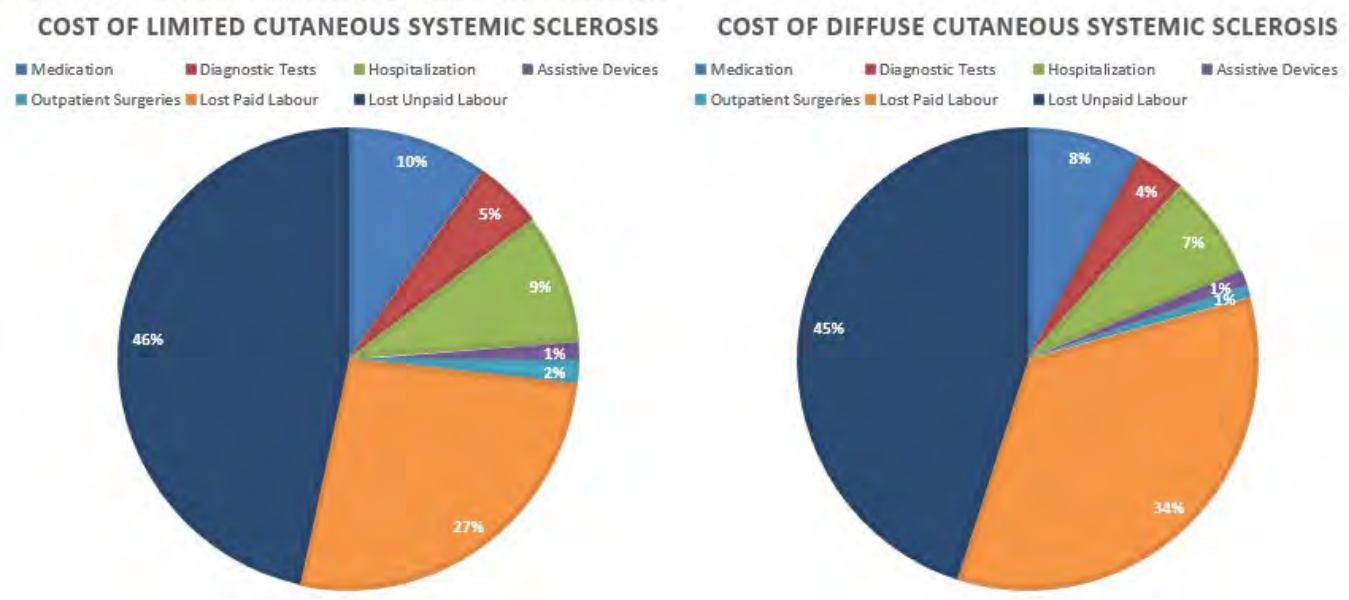
SESSION INFORMATION
Session Date: Tuesday, November 9, 2021
Session Title: Systemic Sclerosis & Related Disorders – Clinical Poster III (1836–1861)
Session Type: Poster Session D
Session Time: 8:30AM–10:30AM

Background/Purpose: Systemic Sclerosis (SSc) is a multi-system autoimmune disease, characterized by vasculopathy, fibrosis of the skin and internal organs, and autoimmunity with distinct antibodies. SSc associated complications include interstitial lung disease, pulmonary hypertension, and digital ulcers which lead to substantial morbidity and

Table 1. Overall Systemic Sclerosis Cost by Region

Region	Total cost	Direct cost	Indirect cost	Medication cost	Hospitalization cost
Canada (2)	$10,673-$18,453	$5,038	$13,415	$1,575	$1,448
USA (8)	$14,959-$23,268	$4,694-$16,269	$5,170-$10,228	$1,017-$5,746	$2,092-$6,502
Europe (5)	€4,607-€30,797	€1,215-€17,301	€10,526	€145-€4,258	€788-€7,951
Oceania (5)	$7,060-$11,607	-	-	$1,126-$3,617	$3,228-$4,730
Asia (1)	$1,005-1,440	-	-	$1,046-$1,143	-
South America (1)	-	-	-	-	R$14,180 (CAD $3,191)

Figure 1. Distribution of Annual Cost of Systemic Sclerosis Sub-types



disability for patients. Secondary to medical and functional limitations, patients with SSc may require considerable healthcare resources resulting in significant economic impact. The purpose of this systematic review is to provide a narrative summary of the economic impact and healthcare resource utilization associated with SSc.

Methods: MEDLINE and EMBASE were searched without language restriction from inception to January 20th, 2021. Studies were included if they provided information regarding overall SSc total, direct, and indirect medical costs including medication, diagnostic test, and assistive devices costs. The cost of SSc subtypes and associated complications was additionally collected. Included observational studies had risk of bias assessments through the Joanna Briggs Institute cross-sectional and case series checklists, and the Newcastle-Ottawa Cohort and Case-Control study scales.

Results: The search retrieved 1777 studies, of which 35 were included representing 20 cross-sectional, 11 cohort, and 4 case-control studies. Studies used various methods of calculating cost including prevalence-based cost-of-illness approach, bottom-up cost analysis, humanistic approach, and health resource units cost analysis. Overall SSc total annual medical cost ranged from USD $14,959-$23,268 in USA, CAD$10,673-$18,453 in Canada, €4,607-€30,797 in Europe, and AUD $7,060 to $11,607 in Oceania. Annual cost for SSc associated with interstitial lung disease and pulmonary arterial hypertension was USD $31,285-$55,446 and $44,454-$63,320, respectively.

Conclusion: Globally, SSc represents significant patient and systemic economic burden. SSc complications are associated with higher economic burden and are highly variable depending on geographical location and medical access. Governmental policies should emphasize prevention of SSc complications as a strategy to mitigate overall cost.

Abstract Number: 1853

Scleroderma Presentation in the Canadian Scleroderma Research Group Indigenous Population

Curtis Sobchak, Karen Beattie and Maggie Larche, McMaster University, Hamilton, ON, Canada

SESSION INFORMATION
Session Date: Tuesday, November 9, 2021
Session Title: Systemic Sclerosis & Related Disorders – Clinical Poster III (1836–1861)
Session Type: Poster Session D
Session Time: 8:30AM–10:30AM

Background/Purpose: Given the well-known burden of rheumatic disease in Canadian Indigenous populations, the Canadian Rheumatology Association (CRA) has highlighted Aboriginal Rheumatology as an area needing greater understanding, specifically on issues such as delays in care and access to specialists. Indigenous patients with rheumatoid arthritis (RA) often have worse disease than the general population yet are less likely to see specialized care. Indigenous populations appear to have earlier onset systemic sclerosis (SSc) than the general population. However, it is unclear if they experience delayed diagnosis (symptom onset to disease diagnosis), or more/less healthcare utilization during this time. We analyzed data from the Canadian Scleroderma Research Group (CSRG) registry to compare the length of time from symptom onset to disease diagnosis and healthcare utilization between North American Indigenous (NAI) and non-NAI populations. We also determined if these data were impacted by a person's rural or urban location.

Methods: Data was obtained from the CSRG, a national longitudinal registry of patients >18 years old with SSc. All patients were included irrespective of underlying comorbidities. Patients who self-identified as Métis, Inuit and First Nations were included as NAI. We characterized the study population at entry into the registry (sex, tobacco use, income, education, location comorbidities). Location was deemed urban or rural by Canada Post guidelines. Time from first symptom to SSc diagnosis was compared between those who were and were non-NAI. Healthcare utilization related to SSc presentation (visits to health practitioners including family doctors and rheumatologists, tests done, and hospitalizations) was compared between groups.

Results: Of 1561 patients, 79 self-identified as NAI. Age, gender and comorbidities were similar between the two groups, with NAI having a higher proportion of tobacco use and lower level of education and income (Table 1). Only

Table 1. Baseline demographics

Variable	NAI (n = 79)	Non-NAI (n=1482)
Age – mean (SD)	51.2 (11.9)	55.6 (12.2)
Female sex – no. (%)	68 (86.1)	1245 (86.4)
Education high school or greater – no. (%)	47 (59.4)	1108 (74.7)
Income $80,000 or greater – no. (%)	6 (7.5)	366 (24.7)
Current tobacco Use – no. (%)	21 (26.6)	187 (12.7)
Rural location – no. (%)	41 (51.9)	291 (19.6)
Diabetes Mellitus – no. (%)	8 (10.3)	86 (5.8)
Chronic Obstructive Pulmonary Disease – no. (%)	7 (8.9)	136 (9.2)
Rheumatoid Arthritis – no. (%)	22 (27.8)	255 (17.2)

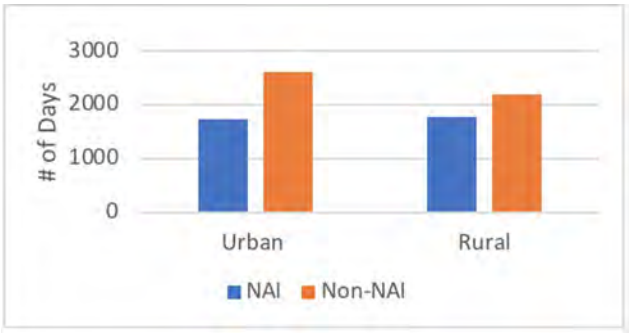

Figure 2. Number of Days from Raynaud's to systemic scleroderma diagnosis.

19.6% of non-NAI populations lived rurally compared to 51.9% of NAI patients. There was no significant difference in time from Raynaud's to diagnosis or 1st other symptom to diagnosis between NAI and non-NAI populations, regardless of location (Figure 2 and 3). There was also no difference in health care utilization, including visits to healthcare professionals, tests performed and hospitalizations.

Conclusion: This study suggests that, unlike other rheumatological conditions, SSc appears to be appropriately diagnosed without a time delay in those who are NAI compared to non-NAI patients. NAI SSc patients also access care at the same rate as non-NAI populations prior to SSc diagnosis.

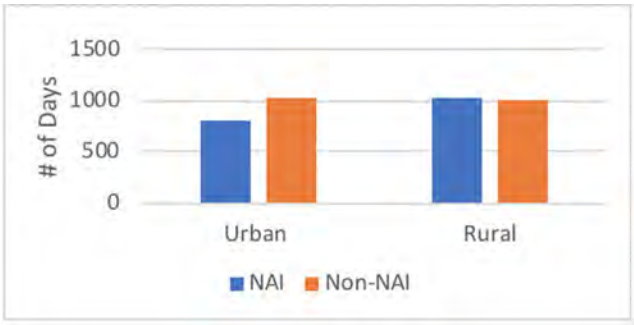

Figure 3. Number of Days from 1st other symptom to systemic scleroderma diagnosis.

Abstract Number: 1854

Disease Characteristics and Social Determinants in African Americans with Systemic Sclerosis: A Single Center Experience

Sarah Compton, DeAnna Baker Frost, Richard Silver and Diane Kamen, Medical University of South Carolina, Charleston, SC

SESSION INFORMATION
Session Date: Tuesday, November 9, 2021
Session Title: Systemic Sclerosis & Related Disorders – Clinical Poster III (1836–1861)
Session Type: Poster Session D
Session Time: 8:30AM–10:30AM

Background/Purpose: Systemic sclerosis (SSc) is a rare autoimmune disease categorized on the basis of skin involvement as either limited or diffuse cutaneous SSc, the latter of which manifests in more severe skin and internal organ involvement. SSc disproportionately affects women and, similar to other chronic diseases, health disparities have been noted in SSc with African American (AA) patients experiencing poor outcomes more frequently than patients from other ethnic/racial groups. We utilized a longitudinal cohort of well-characterized SSc patients to compare disease characteristics between AAs and non-AAs and look at gender and social determinants of health.

Methods: Data were collected as part of an ongoing IRB-approved longitudinal registry of SSc patients, including demographics, clinical disease manifestations and medical history. Patients were seen over a 16-year period at a single academic center. Retrospective chart review was performed to confirm age of onset, SSc disease type, and selected criteria for SSc to assess severity of disease. Pearson's chi-squared and Fisher's Exact testing for categorical measures, two-sample t-tests for continuous measures, and univariate logistic regression modeling was used.

Results: A total of 372 patients with SSc (79.6% female, 37.9% AA) were identified. AA patients developed SSc at a significantly younger age compared to the non-AA patient subset (41.8±14.3 yrs., 48.9±13.5yrs., respectively, p< 0.0001). Females developed SSc at a younger age than males (45.4±13.9 yrs., 50.2±11.3 yrs, p< 0.01) as shown in Figure 1. Comparing outcomes for diffuse cutaneous SSc, renal crisis, interstitial lung disease and restrictive lung disease were statistically significant in Figure 2A. Comparing AA to non-AA, there was statistically significant risk of all outcomes except renal crisis as shown in Figure 2B. Outcomes in AA versus non-AA and controlling for disease duration, mortality (p< 0.05), diffuse disease (p< 0.0001), pulmonary hypertension (p=0.01), and interstitial lung dis-

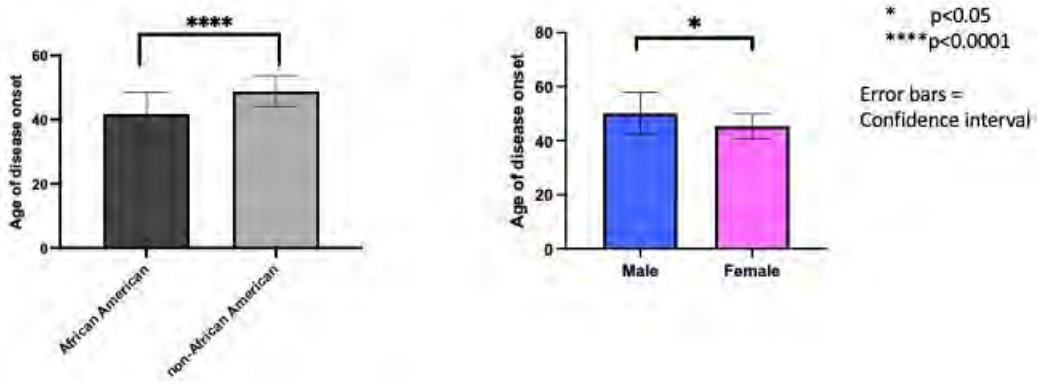

Figure 1. Age of SSc Disease Onset.

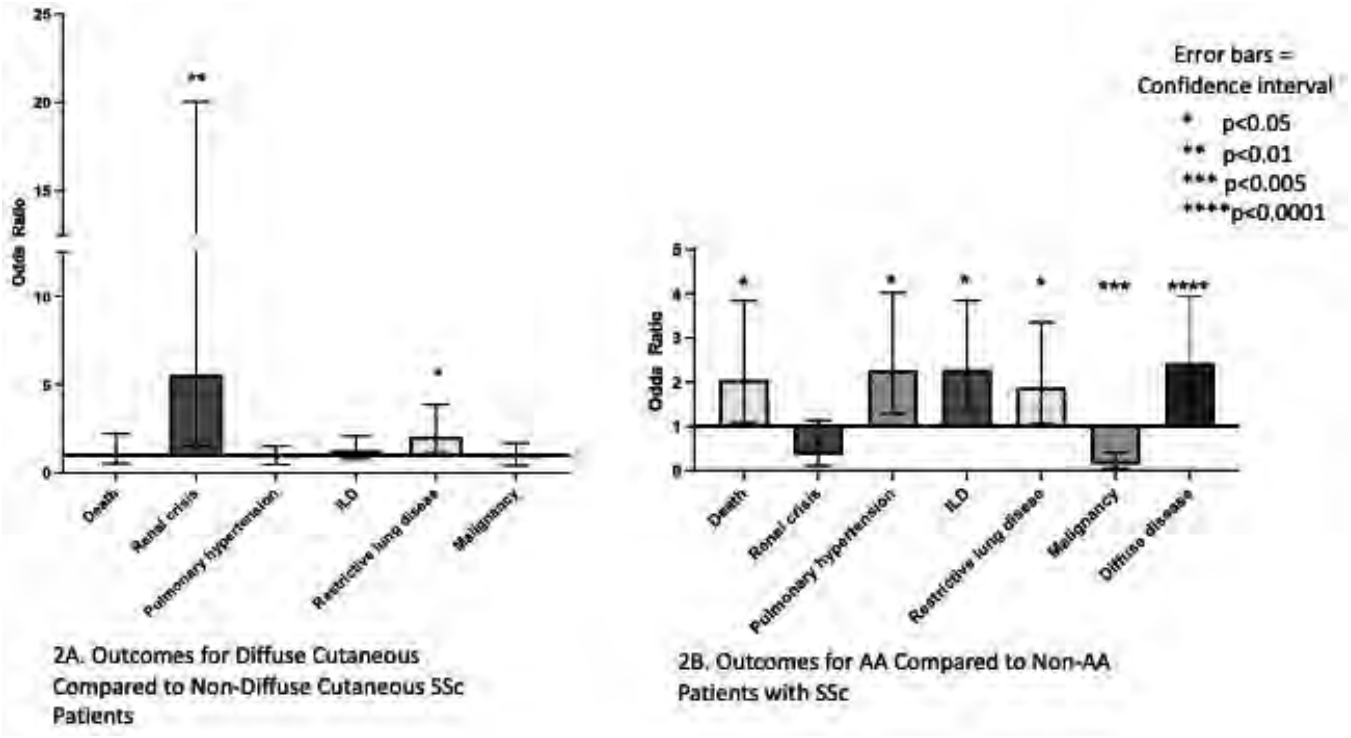

Figure 2. Outcomes.

ease (p=0.01) still remained statistically significant. We looked at two social determinants private insurance and high school graduate with no statistical difference in gender but a statistical significance in race (Table 1). 43.75% of AA had private insurance compared to 66.83% of non-AA (p< 0.0001). 96.39% of non-AA graduated high school compared to 89.72% of AA (p< 0.05). We found males had statistically significant higher percentages of diffuse disease (73.21%), dysphagia (24.59%), and restrictive lung disease (55.81%) compared to females.

Conclusion: We found that AA SSc patients were younger at disease onset and more likely to have diffuse cutaneous disease, compared to non-AA SSc patients. AAs compared to non-AAs with SSc had higher mortality and multiple poor prognostic features, with the exception of renal crisis which was more frequent among non-AAs. Two determinants, private insurance and high school graduate, may be associated with these outcomes. These data support the conclusion that AA have more severe disease with a more unfavorable SSc prognosis. Further investigation into the multifactorial causes for this disparity is needed in order to identify strategies to reduce them.

Table 1. Social Determinants

	Race/Sex	*Percentage*	*p-value*
Private insurance	African American	43.75	p<0.0001
	Non-African American	66.83	
	Female	58.08	ns
	Male	61.11	
High school graduate	African American	89.72	p<0.05
	Non-African American	96.39	
	Female	94.35	ns
	Male	92.45

Up-regulation of TNFα Gene in Peripheral Blood Is Useful for Predicting the Development of Exercise-induced Pulmonary Hypertension, Which Is Early Stage of Pulmonary Vascular Disease Associated with Systemic Sclerosis

Yoshinobu Koyama[1], Yoshiharu Sato[2], Tatsuma Shoji[2], Soichiro Fuke[1], Takatsune Umayahara[1] and Moe Sakamoto[1], [1]Japanese Red Cross Okayama Hospital, Okayama, Japan, [2]DNA Chip Research Inc, Tokyo, Japan

SESSION INFORMATION
Session Date: Tuesday, November 9, 2021
Session Title: Systemic Sclerosis & Related Disorders – Clinical Poster III (1836–1861)
Session Type: Poster Session D
Session Time: 8:30AM–10:30AM

Background/Purpose: Pulmonary hypertension (PH) is prominent as a vascular involvement of systemic sclerosis (SSc), which remains a leading cause of death in spite of current best treatments. The definition of PH was updated from mPAP≥25mmHg to mPAP >20mmHg and PVR≥3WU (G. Simonneau et al. Eur Respir J 2019, 53). Although it may enable to improve the prognosis of PH associated with SSc, it seems be still insufficient because more than 2/3 of the pulmonary circulation is already impaired before meeting the definition. Therefore, the ideal therapeutic intervention should be started at the subclinical stage of PH in SSc patients, but little is known about underlying pathological mechanisms. Recently, it was reported that TNFα drives PH by suppressing the BMP type-II receptor and altering NOTCH signalling (LA. Hurst et al., Nat Commun 2017. 13;8:14079). In this study, we try to detect the gene expressions in peripheral blood involved in the progression to exercise-induced PH (exPH), considered as subclinical PH, in the prospective registry of high-risk population for developing PH associated with SSc.

Methods: Total of 180 patients who had not met PH criteria with Raynaud phenomenon, skin sclerosis or SSc-related autoantibody was registered. To detect the early pulmonary vessel disease (PVD), exercise Doppler echocardiography (exDE) was carried out every 6 or 12 months for up to 6 years. The definition of exPH was maximum sPAP >40mmHg or increase in sPAP >20mmHg estimated by exDE during exercise (*R. Naeije et al., Am J resp and critical care med 2013, 187, 576-583*). For gene expression analysis, total RNAs from whole peripheral blood cells were extracted and then multiplex sequencing was done. To identify candidate genes involved in the progression to exPH, random forest machine learning method was employed. Volcano plots, a scatter plots to visualize fold-changes and p-values of differentially expressed genes (DEGs) between exPH and others (exN), were also used for seeking the important genes for disease progression.

Results: At the time of registration, 34.4% of patients met exPH criteria, and 15.6% of patients developed exPH during follow-up period (35.0±18.1 months). Expression of TNF gene was selected as the most useful genes to predict progression to exPH by random forest, and the accuracy of the model was about 87%. Volcano plots indicated that expressions of TMEM176A and TMEM176B were prominent (fold-change >2.4 and -log10 p-value >3.5) in exPH patients. The accuracy was improved to 90% if the expression of TNF and TMEMA/B were used for the prediction of progression to exPH. We found that the statistically significant increase in expression of TNF was eliminated at the time of fulfilling the exPH criteria, while the increase in expressions of TMEM A/B were still kept.

Conclusion: Our findings suggest that TNFα plays important role only in the period of pre-exPH. On the other hand, increase in expressions of TMEM A/B were observed through the period of pre-exPH to post-exPH. It suggests that there are multiple phases before developing PH associated with SSc. It is very important to understand the phases for the precise treatment to arrest the progression of PVD.

Serum IFN Score Predicts Long Term Outcome in Limited Cutaneous SSc

Ranjitha Karanth[1], Giuseppina Abignano[2], Vishal Kakkar[2], Rebecca Ross[2], Christopher Denton[3] and Francesco Del Galdo[2], [1]Leeds Institute of Rheumatic and Musculoskeletal Medicine, LTHT, Leeds, United Kingdom, [2]University of Leeds, Leeds, United Kingdom, [3]University College London Division of Medicine, Centre for Rheumatology and Connective Tissue Diseases, London, United Kingdom

SESSION INFORMATION
Session Date: Tuesday, November 9, 2021
Session Title: Systemic Sclerosis & Related Disorders – Clinical Poster III (1836–1861)
Session Type: Poster Session D
Session Time: 8:30AM–10:30AM

Background/Purpose: Limited cutaneous systemic sclerosis (lcSSc) carries a highly variable prognosis and to date there are no stratification tools to predict clinical outcomes. Evidence suggests that type-I Interferon (IFN) pathway is involved in progression of clinical manifestations of diffuse cutaneous SSc (dcSSc). However, the role of type-I IFNs in lcSSc has not yet been explored. Here we set out to determine in the context of an observational study the value of serum Type I IFN activation in stratifying for clinical outcome in lcSSc using a novel composite score developed for the MINIMISE clinical trial of mycophenolate mofetil in lcSSc (EudraCT: 2019-004139-21)

Methods: Consecutive patients with lcSSc (according to LeRoy) were selected within our observational cohort. Serum IFN score was measured as the average of the logged concentration of CCL2, CCL8, CCL19, CXCL9, CXCL10, and CXCL11, assessed by Luminex assay. 38 healthy volunteers were assayed as controls (HC). The composite morbi-mortality endpoint capturing "meaningful disease progression" included (i) New lung fibrosis on HRCT (FVC< 70%), (ii) Deterioration of established lung fibrosis, (iii) Significant progression of skin score, (iv) New major cardiac complication, (v) Scleroderma renal crisis, (vi) new RHC diagnosis of pulmonary hypertension, (vii) Severe SSc related GI disease, (viii) Severe digital vasculopathy and (ix) Mortality. Baseline observation serum from patients was assessed for IFN score. The statistical methodology employed included Pearson/Spearman correlation analysis and Fisher exact test as appropriate. Kaplan Meier curves compared event-free survival.

Results: HC had a mean IFN Score of 4.7 +/- 0.3 STDV. 66 lcSSC patients (64 F, mean age 65.5 years) were included in the analysis. Median(IQR) disease duration was 12 years (5 to 16), with 68 months median Follow up (33 to 88). 33 (50%) patients met the morbi-mortality endpoint within the follow-up period with a mean (STDV) time to event of 43 (26) months. Forty-two (63.63%) patients had anticentromere antibodies of which 35 had no other autoantibody detected. IFN score in lcSSC was not normally distributed. Median (IQR) IFN score of lcSSc patients was significantly higher than HC (5.2 (5,5.4), p< 0.0001). Within the patient cohort, median (IQR) IFN score of patients carrying only ACA was significantly lower than others (5.1 (4.9,5.3) vs 5.4 (5,5.7), p=0.003)). 49 (74%) patients had IFN score higher than Mean+ STDV of HC (IFN HI). 17 (35%) of the IFN HI patients met the morbi-mortality endpoint within 36 months

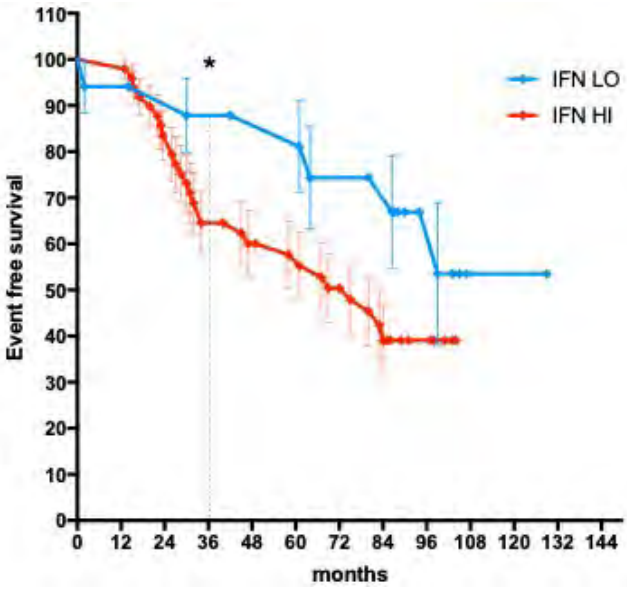

Figure 1. Kaplan Meier curves for event-free survival and difference at 36 months.

with a mean (STDV) time to endpoint of 40 (23) months, vs only 2 (12%) IFN LO patients (mean time to event 57 months (23))(One-Sided Chi-Square =0.036).

Conclusion: Within the limitations of retrospective analysis of observational cohort, our data suggest that patients with lcSSc do show evidence of Type I IFN dysregulation. Patients with HI Serum IFN scores tend to have worse outcomes than patients with normal or low IFN scores. Once confirmed in additional cohorts, IFN score could be a valuable tool for stratification of lcSSc and may help to better integrate clinical management of limited and diffuse subsets of SSc and facilitate timely implementation of organ-specific therapy across both subsets.

Ultra-High Frequency Ultrasound Compared to Durometry and Skin Score for Cutaneous Assessment in Systemic Sclerosis

Marco Di Battista[1], Saverio Vitali[2], Simone Barsotti[3], Alessandra Della Rossa[4], Valentina Dini[5], Marco Romanelli[5] and Marta Mosca[3], [1]Rheumatology Unit, University of Pisa, Pisa, Italy, [2]Radiology Unit - University of Pisa, Pisa, Italy, [3]Rheumatology Unit, Department of Clinical and Experimental Medicine, University of Pisa, Pisa, Italy, [4]Rheumatology Unit - University of Pisa, Pisa, Italy, [5]Dermatology Unit - University of Pisa, Pisa, Italy

SESSION INFORMATION

Session Date: Tuesday, November 9, 2021

Session Title: Systemic Sclerosis & Related Disorders – Clinical Poster III (1836–1861)

Session Type: Poster Session D

Session Time: 8:30AM–10:30AM

Background/Purpose: To assess skin involvement in a cohort of patients with systemic sclerosis (SSc) comparing results obtained from modified Rodnan skin score (mRSS), durometry and ultra-high frequency ultrasound (UHFUS). Additionally, correlations with clinical characteristics of the disease were analyzed.

Methods: SSc patients were enrolled along with healthy controls (HC), assessing disease-specific characteristics. Five regions of interest were investigated in the non-dominant upper limb: the central dorsal side of the distal, intermediate and proximal phalanx of the second finger, the dorsum of the hand and the volar side of the forearm. Each patient underwent rheumatological evaluation of the mRSS, measurement of skin thickness with durometer, and UHFUS assessment with a 70 MHz probe. Moreover, the mean grayscale value (MGV) of the dermal and epidermal layers in US images was collected.

Results: Forty-seven SSc patients (87% female, mean age 56.4 years, mean disease duration 10.8 years) and 15 HC were enrolled. Durometry showed a good correlation with mRSS (p=0.025, rho=0.34). When performing UHFUS, SSc patients had a significantly thicker epidermal layer (p< 0.001) and lower epidermal MGV (p=0.01) than HC in almost all the different regions of interest. Among the various SSc-characteristics, patients with interstitial lung disease and those with pulmonary arterial hypertension presented a significant lower MGV of both epidermal and dermal layers in several regions of interest. No correlations were found between UHFUS results either with mRSS or durometry.

Conclusion: UHFUS in SSc showed that skin thickness and echogenicity can be related to lung involvement. The lack of correlations between UHFUS and both mRSS and durometry suggests that these are not equivalent techniques, but indeed may represent complementary methods for a full skin evaluation in SSc.

SESSION INFORMATION

Session Date: Tuesday, November 9, 2021

Session Title: Systemic Sclerosis & Related Disorders – Clinical Poster III (1836–1861)

Session Type: Poster Session D

Session Time: 8:30AM–10:30AM

Background/Purpose: Several published studies have demonstrated activation of the interferon type 1 (IFN) pathway in sera from patients with systemic sclerosis (SSc). Specifically, levels of IFN activation correlate with severity of skin and lung fibrosis, cardiac involvement, quality of life, and measures of collagen turnover. Microarray and proteomic

studies have indicated that the serum concentrations of CCL2, CCL8, CCL19, CXCL9, CXCL10, and CXCL11 significantly correlate with the IFN-induced activation of peripheral blood mononuclear cells (PBMCs). The study goal was to determine the association between the serum IFN score at baseline and longitudinal outcomes at follow-up in the Prospective Registry of Early Systemic Sclerosis (PRESS) Cohort.

Methods: We performed a retrospective cohort study of patients enrolled in the PRESS Registry at eleven sites in the US between April 2012 and January 2019. Patients had early diffuse cutaneous (dc)SSc (disease duration < 2 years from the onset of the first non-Raynaud Phenomenon SSc symptom) and fulfilled the ACR/EULAR 2013 Classification Criteria for SSc. Serum from age- and sex- matched healthy controls obtained at one academic center as well as serum from SSc patients collected at the baseline visit was subjected to Luminex xMAP technology (Myriad-Ruled Based Medicine, Austin, TX). A serum IFN score was generated for each patient by averaging the natural logarithm of the concentrations of CCL2, CCL8, CCL19, CXCL9, CXCL10, and CXCL11. Dichotomization of scores were based on Mean + 2 standard deviations (SD) of healthy control, used as cut off for normal (or IFN Low vs IFN High). We compared baseline and follow-up clinical features of patients classified as IFN High or Low according to a score greater than (IFN High) or within two SD from mean of healthy controls (IFN Low).

Results: Sera from the baseline visit were available for 110 PRESS patients who were 69% female. Patients with IFN High Scores were older and had longer SSc disease duration compared to the IFN Low Score patients (Table 1). At baseline, IFN High versus Low patients had higher mRSS (mean [SD] 23.4 [9.6] vs. 20.7 [11.3], p-value 0.2037), and lower forced vital capacity (FVC) % predicted (76.0 [20.1] vs. 84.4 [18.1], p-value 0.0750) and lung diffusion for carbon monoxide (DLCO) % predicted (59.8 [21.1] vs. 80.6 [27.3], p-value 0.0023). The Health Assessment Questionnaire-

Last Follow-up	1.0 (0.8)	1.1 (0.8)	0.7 (0.6)	0.0789

NRP= Non-Raynaud Phenomenon, mRSS= modified Rodnan skin score, FVC= Forced Vital Capacity, DLCO = Lung Diffusion for Carbon Monoxide, HAQ-DI= Health Assessment Questionnaire-Disability Index

Disability Index (HAQ-DI) was also higher in the IFN High versus IFN Low patients. At last follow-up, IFN High patients maintained significantly higher mRSS and lower lung function parameters (Table 1).

Conclusion: Patients with early dcSSc enrolled in the PRESS Cohort with a IFN High Score at baseline had worse FVC and DLCO % predicted, worse mRSS and worse HAQ-DI, which they kept at last available follow up. While we could not measure treatment effects given the observational nature of this cohort, the data support the notion that serum interferon score may be a biomarker for active disease in patients with early dcSSc.

Bone Mineral Density in Patients Diagnosed with Giant Cell Arteritis Taking Glucocorticoids: A Case-control Study

Adam Geressu[1] and Marwan Bukhari[2], [1]Royal Lancaster Infirmary, Lancaster, United Kingdom, [2]British Society for Rheumatology, London, United Kingdom

SESSION INFORMATION
Session Date: Tuesday, November 9, 2021
Session Title: Systemic Sclerosis & Related Disorders – Clinical Poster III (1836–1861)
Session Type: Poster Session D
Session Time: 8:30AM–10:30AM

Background/Purpose: The standard treatment for Giant Cell Arteritis (GCA) is high dose glucocorticoid (GC). It is unknown whether steroids are more detrimental to the spine or the hip. The aim of this study was to examine bone mineral density (BMD) of the lumbar spine, left neck of femur, right neck of femur, left total hip and right total hip in patients diagnosed with GCA being treated with GC.

Methods: We collected data from patients with GCA who were referred to the rheumatology department at two hospitals in the North West of England between 2010 and 2019. Patient's details recorded at time of scan included age, gender, Body Mass Index (BMI), and drug treatment, specifically GC use. Dual X-Ray absorptiometry (DEXA) assessed BMD in the spine (mean of L1-L4 vertebrae), left femoral neck, right femoral neck, left total hip and right total hip. Two patient groups were identified, patients with GCA on current GC (cases) and matched 1:4 to those referred for a DEXA scan with no reason for scanning (controls). The prevalence of BMD in each group was compared by a two sample t-test. A comparison was made between the two groups using logistic regression adjusting for age and gender.

Results: A total of 309 patients were included. 61 of these patients were diagnosed with GCA and had a DEXA scan performed (48 females, 13 males). In comparison the control group had 248 patients (196 females, 52 males). Patients diagnosed with GCA had higher values of BMD than patients not diagnosed with GCA that were of the same age and gender. This gave an odds ratio (OR) of 0.68(95%CI 0.18; 2.64) at the lumbar spine, OR of 2.05(95%CI 0.22; 19.45) at the left femoral neck, OR of 3.27(95%CI 0.33; 32.73) at the right femoral neck, OR of 4.26(95%CI 0.27; 66.52) at the left total hip and OR of 8.01(95%CI 0.43; 147.91) at the right total hip. The numeric values of BMD at all sites were higher in the patients with GCA than in the controls.

Conclusion: The study has shown a surprising protective effect GCA has on BMD. Patients diagnosed with GCA receiving GC treatment have shown to have a higher BMD compared to patients without GCA of the same age and gender. Possible confounders include length of time on steroid when scanned or unmeasured confounders in the controls.

Three Distinct Transcriptional Profiles of Monocytes Correlate with Disease Activity in SSc Patients

Hadijat Makinde[1], Gaurav Gadhvi[1], Salina Dominguez[1], Miranda Gurra[1], Kathleen Aren[2], Mary Carns[2], Tracy Frech[3], Dinesh Khanna[4], Shervin Assassi[5], Lutfiyya Muhammad[6], Carla Cuda[1], Monique Hinchcliff[7], Deborah Winter[2] and Harris Perlman[1], [1]Northwestern University, Chicago, IL, [2]Northwestern University Division of Rheumatology, Chicago, IL, [3]University of Utah, Salt Lake City, UT, [4]University of Michigan, Ann Arbor, MI, [5]University of Texas McGovern Medical School at Houston, Houston, TX, [6]Northwestern University Feinberg School of Medicine, Chicago, IL, [7]Yale School of Medicine, Westport, CT

SESSION INFORMATION
Session Date: Tuesday, November 9, 2021
Session Title: Systemic Sclerosis & Related Disorders – Clinical Poster III (1836–1861)
Session Type: Poster Session D
Session Time: 8:30AM–10:30AM

Background/Purpose: Patients with SSc display a complex clinical phenotype.Our group has made important contributions to an emerging understanding of monocytes and macrophages as central to SSc pathogenesis. There are numerous studies that relate transcriptional signatures from PBMC or whole skin of SSc patients to disease activity. Like all whole tissue RNA-sequencing studies, these studies are subject to changes in cellular composition that can drive gene expression signatures and a loss of the ability to detect biologically important transcriptional changes within minority cell populations. Here, we focused circulating monocytes, which have been shown to exist as two central populations classical (CM) and non-classical (NCM).

Methods: SSc patients were recruited from four different sites that form PRESS: Northwestern University (Drs. Monique Hinchcliff and Chase Correia), University of Texas, University of Michigan and University of Utah. Comprehensive clinical data was collected for all patients. We isolated CM and NCM monocytes from these patients and age, sex, and race-matched healthy volunteers were used as controls. RNA-seq was performed on CM and NCM populations as well as on isolated bulk macrophages from skin.

Results: We first performed RNA-seq on CM, which are the predominant population in circulation. In order to capture the variability across the SSc cohort, we defined 1790 differentially expressed genes in each patient. We then used

these genes to cluster patients into 3 subgroups: Groups A-C. Group A exhibited the strongest interferon signature and innate immune pathways. Group B patients expressed genes in the same pathways but was also enriched for response to cAMP and corticosteroids. Both Group B and Group C exhibited upregulation of genes associated with vasculature development and blood vessel formation. Group C uniquely upregulated TGFB pathways. Next, we performed RNA-seq on NCM isolated from the same patients. When NCM were clustered based on the same 1790 genes as CM, we found that Groups A and C were recapitulated, while Group B was less cohesive. Our analysis stratified SSc patients based on their transcriptional profiles in monocytes but was agnostic to their clinical presentation. We found that Group B and C patients exhibited significantly worsened lung function at the time monocyte isolation than Group A patients. However, there were no significant differences in skin disease. We then isolated macrophages from skin biopsies of SSc patients and showed that the transcriptional profile of Group A and C in SSc patients was conserved. We also used gene expression data from another study on monocytes which stratified patients based on disease presentation. We found that Group A accurately distinguished dcSSc and ncSSc patients from controls, but not lcSSc.

Conclusion: We are the first to show that transcriptomic analysis of classical and non-classical circulating monocytes can unbiasly stratify SSc patients and correlate with disease activity outcome measures.

Session Date: Tuesday, November 9, 2021
Session Title: Systemic Sclerosis & Related Disorders – Clinical Poster III (1836–1861)
Session Type: Poster Session D
Session Time: 8:30AM–10:30AM

Background/Purpose: Systemic sclerosis (SSc) is a rare autoimmune disorder with chronic morbidity and high mortality. Disease pathogenesis involves microvascular damage, immune dysregulation, and fibrosis affecting skin and internal organs. There are no FDA approved antifibrotic treatments for skin disease. Tyrosine kinase inhibitors have demonstrated antifibrotic effects on SSc skin in clinical trials with variable efficacy and poor patient tolerance. Epidermal growth factor receptor (EGFR) is a receptor tyrosine kinase whose circulating ligands correlate with modified Rodnan skin score (mRSS) as part of a recently identified gene expression signature specific for SSc skin. EGFR

Characteristic Mean (Standard deviation), or as indicated	SSc N=7	HC N=14

activates multiple downstream signaling pathways, including PI3K/AKT (phosphatidylinositol 3-kinase, protein kinase B), MAPK (mitogen-activated protein kinase), and JAK/STAT (janus kinase/signal transducer and activator of transcription) pathways. The purpose of this project was to identify activation of EGFR and which of its downstream pathways occur in SSc patient skin.

Methods: Archived forearm skin biopsies from seven SSc patients who met the 2013 ACR/EULAR classification criteria and 14 matched healthy control participants (HC) were subjected to immunohistochemical (IHC) staining using antibodies to EGFR, phospho-EGFR (p-EGFR), and downstream transcription factors AKT, phospho-AKT (pAKT), ribosomal protein S6 (S6), phospho-S6 (pS6), signal transducer and activator of transcription 1 (STAT1), and phospho-STAT1 (pSTAT1). To focus on fibroblasts, non-vascular positively stained cells were enumerated by counting the number per high powered field (hpf) in the dermis. Outcomes measures also included correlation with mRSS for each SSc patient. Statistical analysis was done using based comparison around the two groups (SSc and HC), clustered at the patient level. Clustered spearman correlation was performed for IHC and mRSS.

Results: Baseline demographics and clinical characteristics of SSc patients and HCs are shown in Table 1. Among the skin biopsies, there was 1.3-fold higher staining for pEGFR ($p=0.008$), 1.41-fold higher S6 ($p< 0.00$), and 1.44-fold higher STAT1 ($p< 0.00$) in SSc dermis compared to HC biopsies. There were no statistically significant differences in staining for EGFR, AKT, pAKT, and pS6 (Table 2). We did not detect phosphorylation of STAT1 by IHC in the SSc samples. pEGFR staining showed an inverse correlation with mRSS.

Conclusion: The EGFR pathway appears activated in SSc patients compared to HCs as evidenced by increased staining of its phosphorylated protein. EGFR activation may reflect extent or stage of disease based on its inverse correlation with mRSS. More fibroblasts expressed STAT1 and S6 protein in SSc skin, which suggests a higher

Clonal Hematopoiesis Across the Age Spectrum in Patients with Systemic Vasculitis

Kristina Wells[1], Fernanda Gutierrez-Rodrigues[2], Bhavisha Patel[2], Kaitlin Quinn[3], Keith Sikora[1], Neal Young[4] and Peter Grayson[5], [1]National Institute of Arthritis, Musculoskeletal and Skin Diseases (NIAMS), National Institutes of Health (NIH), Bethesda, MD, [2]National Heart, Lung, and Blood Institute (NHLBI), National Institutes of Health (NIH), Bethesda, MD, [3]National Institute of Arthritis and Musculoskeletal and Skin Diseases (NIAMS), National Institutes of Health (NIH), Washington, DC, [4]National Heart, Lung, and Blood Institute (NHLBI), National Institues of Health, Bethesda, MD, [5]National Institutes of Arthritis and Musculoskeletal and Skin Diseases (NIAMS), National Institutes of Health (NIH), Bethesda, MD

SESSION INFORMATION

Session Date: Tuesday, November 9, 2021

Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster II (1862–1888)

Session Type: Poster Session D

Session Time: 8:30AM–10:30AM

Background/Purpose: Clonal hematopoiesis (CH) is a pre-malignant state characterized by somatic mutations in hematologic precursor cells in genes associated with myeloid malignancies. Incidence of CH increases exponentially with age in healthy people and is associated with an increased risk for all-cause mortality and cardiovascular disease. Small studies report increased prevalence of CH in various inflammatory diseases. To what extent age versus inflammation underlies these associations is unclear. In this study, vasculitis patients with giant cell arteritis (GCA), ANCA-associated vasculitis (AAV), or Takayasu's arteritis (TAK) were screened for CH to determine the relationship between CH and vasculitis in a cohort of patients with inflammatory disease across a wide age spectrum.

Methods: An error-correcting targeted sequencing panel was used to screen 137 vasculitis patients (GCA, AAV, TAK) and 30 healthy controls (HC) for somatic variants in peripheral blood in 40 genes related to CH. Variants were called if the variant allele fraction (VAF) > 0.5% and if the variants were predicted to impair protein function. Prevalence of CH in vasculitis was compared to controls using chi square test. Logistic regression was used to assess associations of age and vasculitis with CH. Relative contribution of predictor variables was assessed using standardized beta coefficients. Clinical features were compared using Fisher's exact test, Wilcoxon rank sum test, or logistic regression as appropriate. Correlation between clone size and clinical features was assessed by linear regression.

Results: The prevalence of CH in GCA, AAV and TAK was 54.1% (26/48), 36.1% (13/36), and 11.3% (6/53) respectively, compared to 6.7% (2/30) in HC (p= 0.0007). Median age for GCA, AAV, TAK, and HC was 71.5 (range: 50-88), 60 (range: 19-77), 32 (range: 3-57), and 47 (range: 14-71) years, respectively. In a logistic regression model, age and vasculitis were independently associated with CH (Age: *B*=0.05, standardized *b*=0.99, p< 0.0001; Vasculitis: *B*=0.77, standardized *b*=0.53, p=0.04). Median VAF was 1.3% (0.51-51.3%) and did not differ by diagnosis. Clones at VAF >10% were found in 7.3% (10/137) of patients. Of the somatic mutations identified, *DNMT3A* (48/71=67.6%) and *TET2*(12/71=16.9%) were the most frequently mutated genes. Patients with CHIP had lower percent lymphocytes (17.4% vs 25.5%, p=0.02) and higher absolute neutrophil count (6.1 vs 5.2 K/uL, p=0.04) than those without CH. Adjusting for daily prednisone dose, neutrophil to lymphocyte ratio was significantly associated with presence of CH (*B*=0.06, p=0.04). The VAF of somatic mutations was positively associated with age (*B*=0.01, p=0.01) and monocyte count (*B*=0.83, p=0.01).

Conclusion: There is a complex relationship between age, inflammation and CH. Age is 1.9x more strongly associated with CH than vasculitis, but each are independent contributors. CH is associated with skewing of peripheral blood counts towards myeloid lineages in patients with vasculitis. Still unanswered is to what extent CH directly contributes to inflammation in vasculitis, or conversely what role systemic inflammation plays in generation of mutations and clonal selection.

Consistent Efficacy with Apremilast in Men and Women to Treat Oral Ulcers Associated with Behçet's Syndrome: Results from Phase 3 Researching Oral Apremilast Safety and Efficacy in Behçet's Disease (RELIEF) Study

Gülen Hatemi[1], Alfred Mahr[2], Mitsuhiro Takeno[3], Doyoung Kim[4], Melike Melikoğlu[5], Sue Cheng[6], Sven Richter[6], Shauna Jardon[7], Maria Paris[6], Mindy Chen[6] and **Yusuf Yazici**[8], [1]Istanbul University−Cerrahpaşa, Cerrahpaşa Medical School and Behçet's Disease Research Center, İstanbul, Turkey, [2]Kantonsspital St. Gallen, St.Gallen, Switzerland, [3]Musashi Kosugi Hospital, Kawasaki, Japan, [4]Yonsei University College of Medicine and Severance Hospital, Seoul, Republic of Korea, [5]Istanbul University−Cerrahpaşa, İstanbul, Turkey, [6]Amgen Inc., Thousand Oaks, CA, [7]Amgen Inc., Gilbert, AZ, [8]New York University School of Medicine, New York, NY

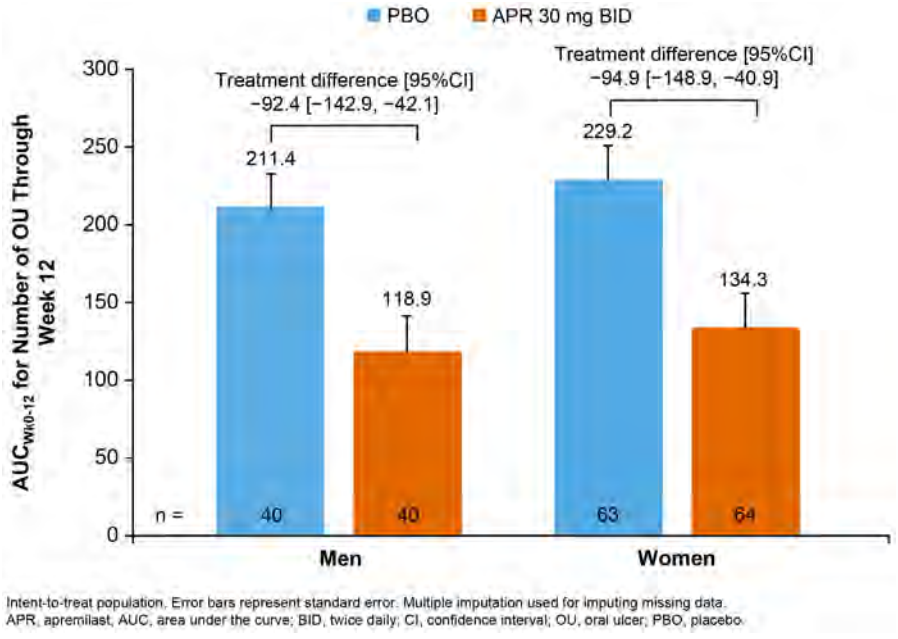
SESSION INFORMATION

Session Date: Tuesday, November 9, 2021
Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster II (1862–1888)
Session Type: Poster Session D
Session Time: 8:30AM–10:30AM

Background/Purpose: Painful, recurring oral ulcers (OU) associated with Behçet's syndrome negatively affect quality of life (QoL). Differences across sexes were reported in the frequency of disease manifestations, disease course, and response to colchicine. The phase 3, randomized, double-blind, placebo (PBO)-controlled RELIEF study showed overall efficacy of apremilast (APR) for OU associated with Behçet's syndrome, including improvements in OU pain, disease activity, and QoL. The objective of this subgroup analysis is to evaluate the consistency of efficacy with APR in men and women with Behçet's syndrome.

Methods: Adults with active Behçet's syndrome and ≥3 OU at randomization or ≥2 OU at screening and randomization, without active major organ involvement, were randomized to APR 30 mg BID or PBO during the 12-week PBO-controlled treatment phase. Randomization was stratified by sex. The primary endpoint was area under the curve for the number of OU through Week 12 (AUC_{Wk0-12}) to assess continued efficacy over the time period in a symptom that waxed and waned. Key secondary endpoints included OU pain, complete response (OU-free), maintenance of complete response, and QoL at Week 12. Disease activity was also assessed using Behçet's Syndrome Activity Score (BSAS) and Behçet's Disease Current Activity Index Form (BDCAF). QoL was assessed using Behçet's Disease QoL (BDQoL). Prespecified subgroup analyses in men and women were performed to assess treatment effect in primary and secondary endpoints.

Results: Eighty men and 127 women were randomized and received ≥1 dose of study medication. Mean age was 38.7 years (men) and 40.8 years (women). Mean (SD) OU count at baseline was 3.4 (1.4) (PBO) and 3.7 (1.5) (APR) for men and 4.3 (3.2) (PBO) and 4.5 (4.5) (APR) for women. Greater improvements in favor of APR vs PBO were observed in AUC_{Wk0-12} in men and women (Figure). Consistency in efficacy with APR was observed between men and women, with greater reduction in pain and achievement of OU complete response (OU-free) and maintenance of response at Week 12 vs PBO (Table). In men and women, consistent treatment effects in favor of APR vs PBO were observed for



Intent-to-treat population. Error bars represent standard error. Multiple imputation used for imputing missing data.

^{18}F-Fluorodeoxyglucose PET/MRI as an Alternative Hybrid Imaging Modality: Comparative Study in a Prospective, Longitudinal Cohort of Patients with Large-Vessel Vasculitis

Ertugrul Cagri bolek[1], Kaitlin Quinn[2], Hugh Alessi[3], Elaine Novakovich[4], Mark A. Ahlman[4] and Peter Grayson[5], [1]Vasculitis Translational Research Program, NIAMS, NIH, US, Lanham, MD, [2]National Institute of Arthritis and Musculoskeletal and Skin Diseases (NIAMS), National Institutes of Health (NIH), Washington, DC, [3]National Institutes of Health, Bethesda, Maryland, [4]National Institutes of Health, Bethesda, MD, [5]National Institutes of Arthritis and Musculoskeletal and Skin Diseases (NIAMS), National Institutes of Health (NIH), Bethesda, MD

SESSION INFORMATION

Session Date: Tuesday, November 9, 2021

Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster II (1862–1888)

Session Type: Poster Session D

Session Time: 8:30AM–10:30AM

Background/Purpose: Imaging modalities play an important role in the diagnosis and management of patients with large-vessel vasculitis (LVV). Use of 18F-fluorodeoxyglucose (FDG) positron emission tomography - computed tomography (PET/CT) to assess patients with LVV is well established; however, concerns about ionizing radiation exposure may limit its use, particularly in younger populations. PET coupled with magnetic resonance imaging (PET/MRI) offers potential for simultaneous acquisition of PET and angiography at substantially less radiation exposure than PET/CT. We aimed to investigate whether PET/MRI is a useful surrogate to PET/CT in LVV.

Methods: Participants who fulfilled the 1990 ACR Classification Criteria for Takayasu's arteritis (TAK) or modified 1990 ACR Criteria for giant cell arteritis (GCA), were prospectively recruited into an observational cohort. Following injection of one radiotracer dose, patients underwent a whole body PET/MR at 1-hour acquisition time and, when-

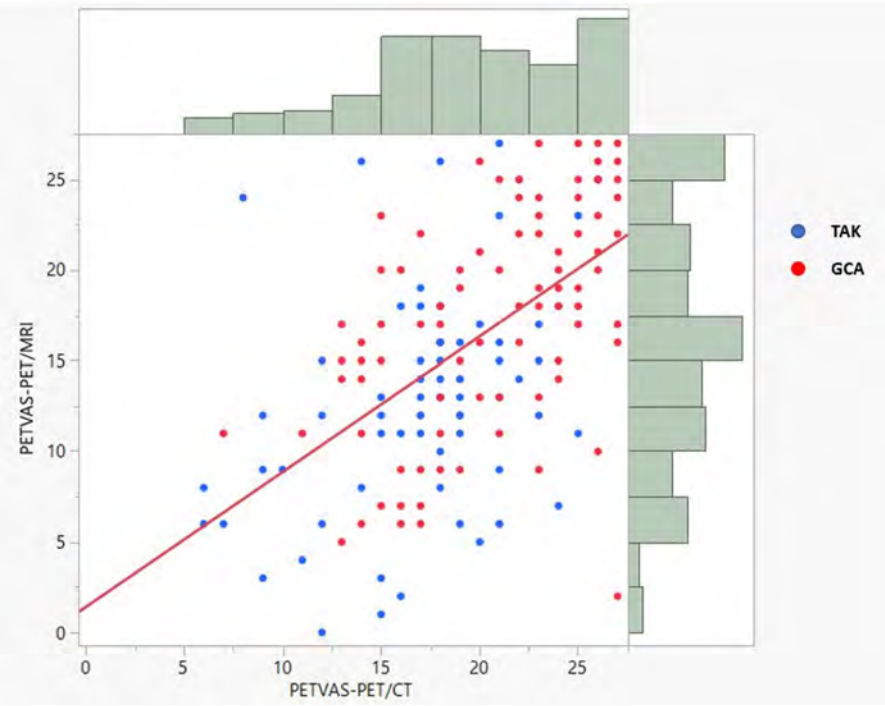

Figure 1. Distribution of PET/MRI-based and PET/CT-based PETVAS in patients with Takayasu's arteritis and giant cell arteritis.

ever possible, a PET/CT at 2-hour acquisition time. A single reader with vascular imaging expertise interpreted FDG uptake relative to liver uptake by visual assessment (scale 0-3) in 9 arterial territories. The PET Vascular Activity Score (PETVAS) was calculated for each study (scale 0-27)). MR angiography was obtained concurrently with the PET/MR study. Angiographic damage, defined as stenosis, occlusion, or aneurysm, was evaluated in 4 segments of the aorta and 13 branch arteries and compared to PET findings in the same territories. Patients could be studied repeatedly at ≥ 6-month intervals.

Results: PET/MR was obtained in 203 scans from 76 LVV patients (TAK: 93 scans in 36 patients and GCA: 110 scans in 40 patients). Eighteen scans were performed in 9 pediatric patients (< 18 years old). For 178 visits (87.8%), simultaneous PET/CT scans were obtained on the same day. PET/MRI-based PETVAS scores correlated with PET/CT based scores for both TAK and GCA (Spearman's correlation coefficient (r)= 0.59, CI95%: 0.48-0.67, p< 0.001; Figure-1). PET/CT scores were consistently higher than PET/MR scores (Median:19 and IQR: 8 vs Median:16 and IQR: 10.25) likely due to effects of delayed imaging acquisition (1 versus 2-hour uptake time). Out of 2041 arterial territories from 154 scans with both MRI angiography (MRA) and PET/MRI data; PET and MRA showed concordant abnormalities in 1446 territories (71%) and discordant finding in 595 territories (29%). No PET activity or damage was seen in 1254 territories (61%). PET activity with damage was seen in 192 territories (9%). PET activity without damage was seen in 238 territories (12%). Damage without PET activity was seen in 357 territories (17%). (Table-1 and Figure-2).

Conclusion: PET/MRI findings correlate with PET/CT findings in LVV. PET provides complimentary data to MRA that may better inform a clinician about vascular inflammation and damage. Given the need to minimize ionizing radiation

Incidence, Prevalence, and Mortality of Chronic Periaortitis: A Population-based Study

Umar Ghaffar[1], Kenneth Warrington[2], Stephanie Duong[1], Cynthia Crowson[3], Michelle Burke[1], Boyd Viers[1], Aaron Potretzke[1], Haraldur Bjarnason[1] and **Matthew Koster**[1], [1]Mayo Clinic, Rochester, MN, [2]Mayo Clinic, Rochester, Minnesota, [3]Mayo Clinic, Eyota, MN

SESSION INFORMATION

Session Date: Tuesday, November 9, 2021
Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster II (1862–1888)
Session Type: Poster Session D
Session Time: 8:30AM–10:30AM

Background/Purpose: Chronic periaortitis is an inflammatory condition that typically involves the infrarenal portion of the abdominal aorta. To date, no epidemiologic studies have been performed in North America. The purpose of this

study was to evaluate the epidemiology, presentation and outcomes of patients with chronic periaortitis from 1998 through 2018.

Methods: An inception cohort of patients with incident chronic periaortitis from January 1, 1998 through December 31, 2018, in Olmsted County, MN, USA, was identified based on comprehensive individual medical record review utilizing the Rochester Epidemiology Project medical record linkage system. Inclusion required radiographic and/or histologic confirmation of periarterial soft tissue thickening around at least part of the infra-renal abdominal aorta or the common iliac arteries. Data were collected on demographic characteristics, clinical presentation, renal and radiographic outcomes, and mortality. Incidence rates were age and sex adjusted to the 2010 United States white population.

Results: Eleven incident cases of chronic periaortitis were identified during the study period. Average age at diagnosis was 61.8±13.4 years. The cohort included 9 men (82%) and 2 women (18%). The most common presenting symptom was pain with 55% (6/11) reporting abdominopelvic-pelvic pain, 36% (4/11) back pain, and 18% (2/11) flank pain. Obstructive uropathy was present in 73% (8/11) subjects: 3 (27%) unilateral left, 1 (9%) unilateral right, and 4 (36%) bilateral. Mean±SD creatinine at presentation was 2.7±3.4 mg/dL. Ureteral stenting was required at diagnosis in seven patients, unilateral left in 2, unilateral right in 1 and bilateral in 4. All 11 patients received glucocorticoids with a median (IQR) dose of 40 (30, 60) mg/day. Additional non-glucocorticoid therapeutics were used in 10 patients.

Renal function stage at last follow up declined in 2 patients, remained the same in 3 patients and improved in 6 patients. Mean (±SD) creatinine at last follow-up was 1.2±0.2 mg/dL. Among the 7 patients requiring baseline indwelling ureteral stent placement only two required ongoing ureteral stenting at last follow up. None of the four patients without ureteral stenting at diagnosis progressed to require stenting during the follow-up period. No patient underwent ureterolysis surgery in this cohort. Periarterial soft tissue thickening at last follow up had increased in thickness in 1 (9%), was unchanged in 2 (18%), decreased in size but did not resolve in 6 (55%), and fully resolved in 18%.

Age- and sex-adjusted incidence rates per 100,000 population were 0.26 for females, 1.56 for males and 0.87 overall. Overall prevalence on January 1 , 2015 was 8.98 per 100,000 population. Median (IQR) length of follow-up was 10.1 (2.5, 13.8) years. Overall mortality was similar to the expected age, sex, and calendar estimates of the Minnesota population with standardized mortality ratio (95% CI) for the entire cohort 2.07 (0.67, 4.84).

Conclusion: This study reports the first epidemiologic data on chronic periaortitis in the United States. In this cohort of patients with chronic periaortitis, men were 4 times more commonly affected than women. Mortality was not increased compared to the general population.

Vasculitis in Patients with Sarcoidosis: A Single-Institution Case Series of 17 Patients

Bradly Kimbrough[1], Kenneth Warrington[2], Hannah Langenfeld[3], Cynthia Crowson[4], Eva Carmona[3], Andrew Virata[3] and Matthew Koster[3], [1]Mayo Clinic Rochester, Rochester, MN, [2]Mayo Clinic, Rochester, MN, [3]Mayo Clinic, Rochester, MN, [4]Mayo Clinic, Eyota, MN

SESSION INFORMATION

Session Date: Tuesday, November 9, 2021
Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster II (1862–1888)
Session Type: Poster Session D
Session Time: 8:30AM–10:30AM

Background/Purpose: Vasculitis in patients with sarcoidosis is rare and can affect blood vessels of any size. Limited information describing this association is available. The purpose of this study is to describe a large, single-institution case-series of patients with sarcoidosis and vasculitis.

Methods: A single-institution retrospective study was performed reviewing all patients with a diagnosis code for sarcoidosis and vasculitis between January 1, 1998 and December 31, 2019. Medical records were individually reviewed, and data regarding diagnosis, treatment, and outcomes were abstracted. Sarcoidosis was diagnosed based on histologic, radiographic, and clinical data with exclusion of alternative diagnoses. Diagnosis for small vessel vasculitis (SVV) required biopsy confirmation. Patients with large or medium-vessel vasculitis (L/MVV) required biopsy and/or arterial imaging. Comparison between patients presenting with L/MVV versus patients with only SVV was performed.

Table 1. Characteristics of vasculitis in patients with sarcoidosis

Case	Sex	Age Sarcoid / Vasculitis Dx, yr	WASOG Organ Involvement*	Vessel size	Arterial involvement on imaging†¥ or biopsy**

17	M	32/71	Lu	SVV	Skin

*WASOG Organ Involvement: B-J, bone-joint; BM, bone marrow; ET-LN, extra-thoracic lymph node; Li, liver; Lu, lung; NS, nervous system; Sk, skin; Sp, spleen. **Granulomatous vasculitis was observed in cases 7, 9, 10, 11, 14, 15, 16; leukocytoclastic vasculitis in cases 12, 13, 17)
† a, aneurysm; b, beaded irregularities; e, ectasia; en, enhancement; hm, hypermetabolism (on positive emission tomography); o, occlusion; pa, pseudoaneurysm; s, stenosis; wt, wall thickening
¥ AA, abdominal aorta; ACA, anterior cerebral artery; Ant Tib, anterior tibial; Ax, axial; Br, brachial; Ca, carotid; Ce, celiac; CF, common femoral; Hep, hepatic; I, iliac; ICA, internal carotid artery; IMA, inferior mesenteric artery; Innom, innominate; MCA, middle cerebral artery; Mes, mesenteric branch; PCA, posterior cerebral artery; Per, peroneal; Pop, popliteal; Re, renal; SF, superficial femoral; Sp, splenic; Sub, subclavian; TA, thoracic aorta; V, vertebral

Results: Seventeen patients were identified during the study period. Nine patients (56% female) had L/MVV and 8 (50% female) had SVV. Mean±SD age at sarcoidosis diagnosis was 53.2±17.8 and 51.9±11.4 years and mean±SD age at vasculitis diagnosis was 57.4±19.6 and 59.0±13.4 years in L/MVV and SVV groups, respectively. Number of organ systems involved by sarcoidosis was similar [median (IQR) 3 (1,4) L/MVV vs. 2.5 (1.75, 3.25) SVV]. Sarcoid organ involvement and vasculitis vessel distributions are noted in Table 1. Mean length of follow-up was 11.5±12.8 years in L/MVV and 13.1±14.3 years in SVV. All patients were treated with glucocorticoids for vasculitis. More patients with L/MVV were treated with at least one DMARD/biologic (8/9, 89%) compared to SVV (3/8, 38%, p=0.05). Complete response to therapy for vasculitis was observed in 8/9 L/MVV and 7/8 in SVV. Four patients in SVV group were able to stop all immunosuppression but only one patient with L/MVV was off all therapy at last follow-up.

Conclusion: Vasculitis in patients with sarcoidosis is uncommon. Variability exists in the vessels involved and the treatments utilized. Overall this series observed favorable outcomes with a high percentage achieving complete response, regardless of vessel size affected.

SESSION INFORMATION

Session Date: Tuesday, November 9, 2021
Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster II (1862–1888)
Session Type: Poster Session D
Session Time: 8:30AM–10:30AM

Background/Purpose: Deficiency of adenosine deaminase 2 (DADA2) leads to a broad phenotype that in some resembles polyarteritis nodosa with fever and rash, but in others is characterised by stroke or immunodeficiency. Small, medium and large vessel vasculitis has been reported. In contrast, plasma ADA2 activity is elevated in inflammatory conditions including systemic lupus erythematosus and systemic juvenile idiopathic arthritis with macrophage activation syndrome. The role of ADA2 and how its deficiency associates with the vasculitides is not yet understood. Using a well-characterised large vessel vasculitis cohort we sought to establish the potential role of ADA2 activity.

Methods: ADA2 activity was measured in adults with Takayasu arteritis (TA), large vessel giant cell arteritis (LV-GCA), intracranial vasculitis (IV) and healthy control (HC) subjects (Table 1), using a coupled spectrophotometric assay as previously described. Plasma from 11 patients with genotyped DADA2 and 10 patients heterozygous for pathogenic variants in ADA2 were used to define thresholds for deficiency and carrier status respectively (DADA2 activity 0 - 0.90 U/L, ADA2 carrier activity 2.02 - 10.62 U/L). Activity levels above the upper limit of normal (ULN) were defined as >99th

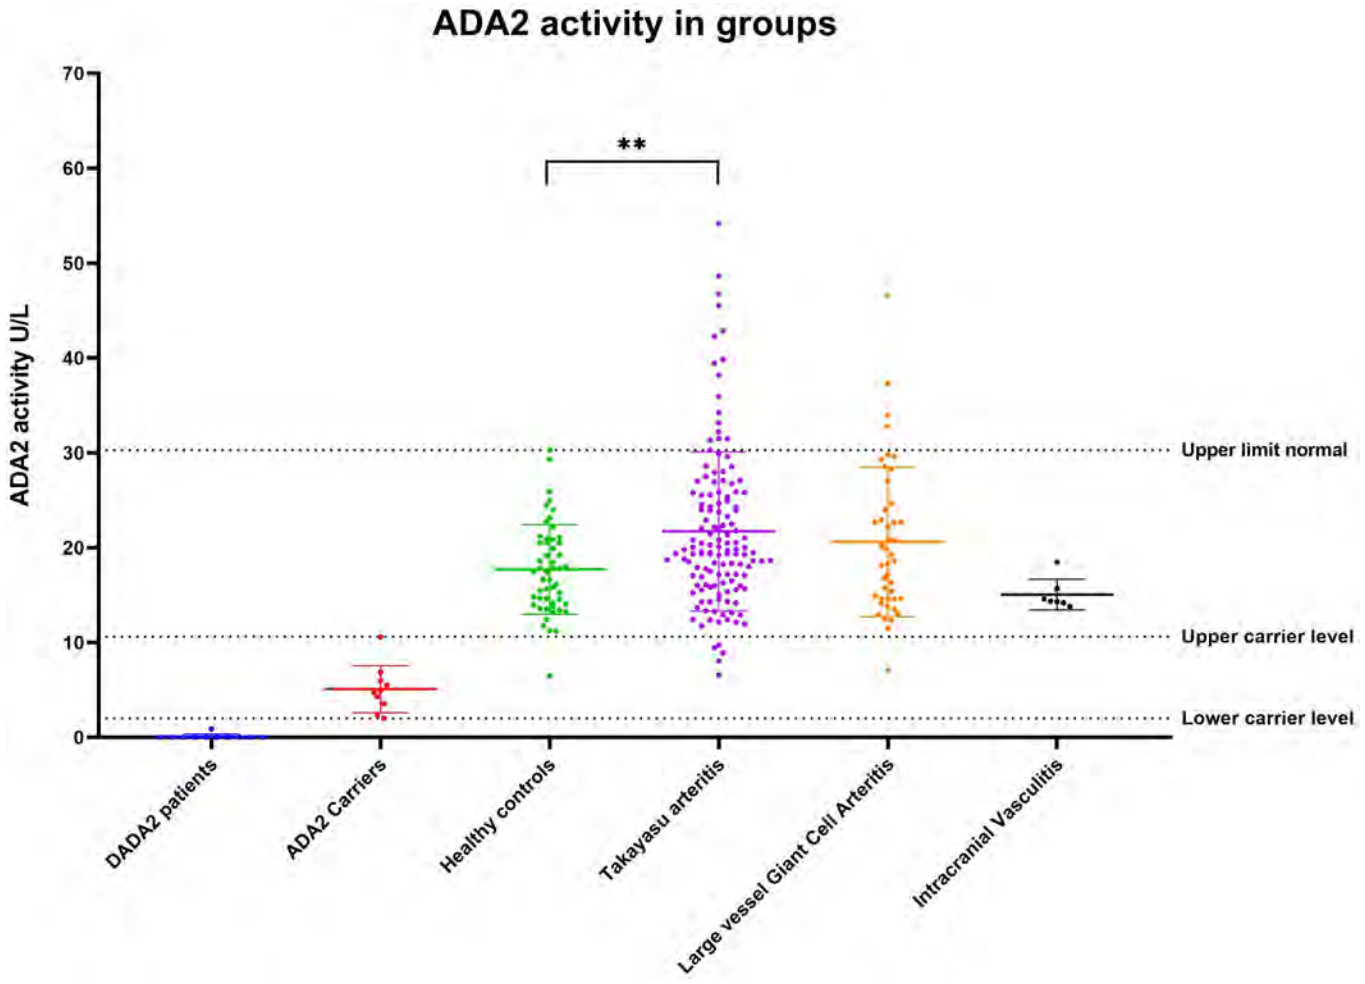

Figure 2. ADA2 activity in groups. Upper limit normal - defined as >99% percentile of HC activity (30.3U/L). Upper and lower carrier level (2.02-10.62U/L) - determined from 10 patients heterozygous for pathogenic variants in ADA2. ** p<0.01.

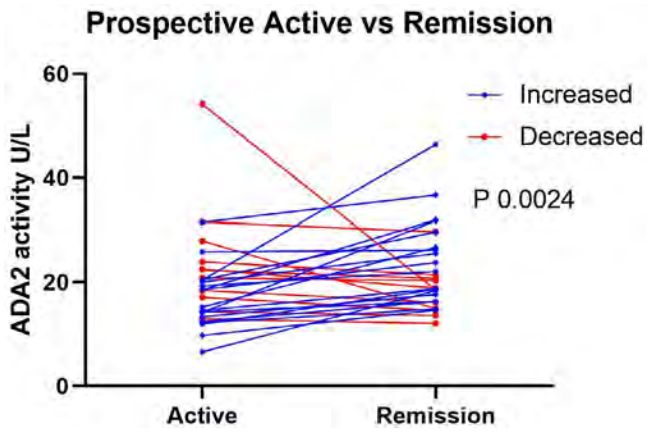

Figure 3. ADA2 activity in prospective active and remission samples. Increased - ADA2 activity higher in remission vs active. Decreased - ADA2 activity lower in remission vs active.

percentile of the HC activity (30.3 U/L). To assess potential associations with TA disease status, ADA2 was measured prospectively in matched active and remission samples.

TA disease activity was determined as active, grumbling or stable using clinical and radiological features, physician impression, CRP, ESR and Indian Takayasu clinical Activity Score (ITAS).

Median values are presented with differences between groups analysed using non-parametric tests, $P< 0.05$ was considered significant.

Results: No patients were found to have ADA2 deficiency while 7 subjects had activity within the carrier range (1 HC (1.9%), 5 TA (3.7%), 1 LV-GCA (2.3%)). Compared to HC levels (17.43 [14.11 – 20.78] U/L), activity in the TA group was significantly increased (TA 19.68U/L, p= 0.0061), while LV-GCA and IV were not significantly different (Figure 2). In 20 cases activity exceeded the upper limit of normal; 16 TA (11.9%, p=0.044; 4 active, 2 grumbling, 10 stable) and 4 LV-GCA (9.1%, ns). In TA, there was a positive correlation between ADA2 activity and ESR (Spearman R = 0.2863, p=0.0009) but not with CRP or ITAS score.

Subgroup analysis revealed that ADA2 activity was most prominently elevated in the stable group relative to HCs (TA stable 20.54 U/L [8.08 - 48.66], median +17.8%, p= 0.0006), but not with active or grumbling disease. Consistent with this, prospective analysis demonstrated a significant increase in ADA2 activity in remission vs active disease (p=0.024), with activity increasing in 18 (62%) patients achieving remission (Figure 3).

Conclusion: There were no cases of ADA2 deficiency in this cohort. Consistent with other inflammatory conditions, ADA2 activity was elevated in TA compared to HC subjects. Surprisingly, increased ADA2 activity was linked to stable TA in both cross-sectional and prospective analyses. This may suggest a potential role of ADA2 enzyme activity in vascular repair and regrowth – possibly tying in with known elevated levels of ADA2 activity in growing children

SESSION INFORMATION

Session Date: Tuesday, November 9, 2021

Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster II (1862–1888)

Session Type: Poster Session D

Session Time: 8:30AM–10:30AM

Background/Purpose: Neutrophil extracellular trap (NET) formation, the extrusion of chromatin and granular components from activated neutrophils, is essential in host defense. However, NET formation has also been linked to inflammation and autoimmunity, including in anti-neutrophil cytoplasmic autoantibody (ANCA)-associated vasculitis (AAV), a disease of small blood vessels. Neutrophil infiltration is seen in aortic specimens of patients with Takayasu's arteritis (TAK) and affected arteries of giant cell arteritis (GCA), two types of large-vessel vasculitis (LVV). Whether NET formation and autoimmunity against NET antigens such as extracellular histones, a common NET-related autoantigen in other autoimmune diseases including systemic lupus erythematosus and rheumatoid arthritis, occurs in LVV is not known. The purpose of this study was to compare levels of NET formation and anti-histone antibodies across different types of vasculitis.

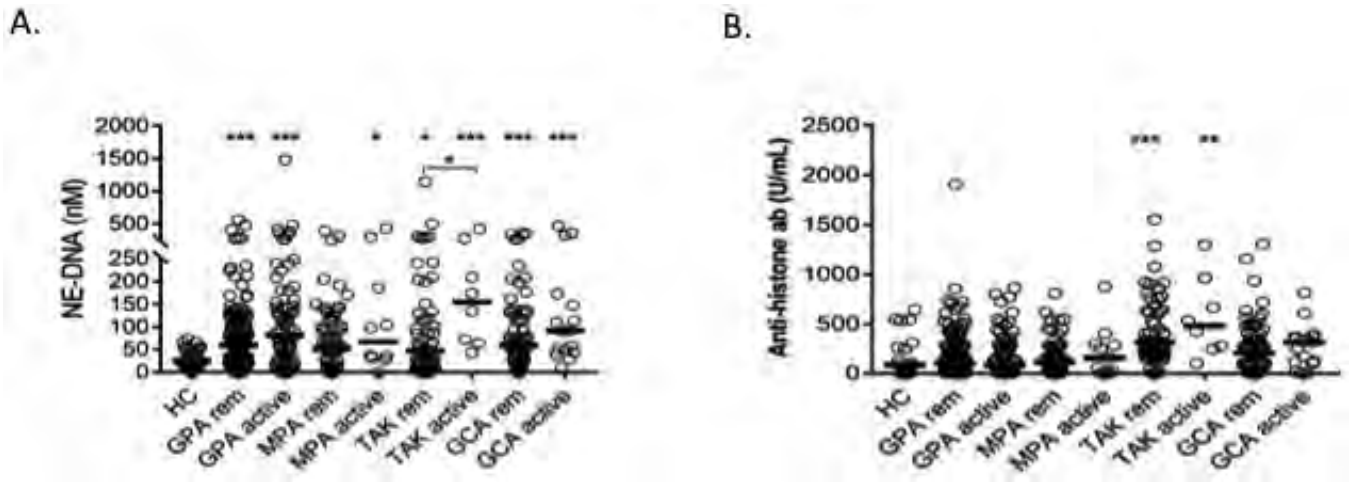

Figure 1. Levels of NE-DNA complexes and anti-histone antibodies in patients with vasculitis. Levels of A) NE-DNA complexes and B) anti-histone antibodies were analyzed in healthy controls (HC), and patients with vasculitis at times of remission (rem) and active disease. Statistical analyses were done by Mann-Whitney U test with *p<0.05, **p<0.01 and ***p<0.001. Unless otherwise indicated, all analyses are compared to healthy controls. Each circle represents an individual sample, with the bar representing the median of the group. GPA: granulomatosis with polyangiitis; MPA: microscopic polyangiitis; TAK: Takayasu's arteritis; GCA: giant cell arteritis.

Methods: Plasma levels of NETs (neutrophil elastase (NE)-DNA complexes) and anti-histone antibodies were analyzed in healthy controls (n=30), and patients with AAV (granulomatosis with polyangiitis (GPA, n=196), microscopic polyangiitis (MPA, n=74)), TAK (n=66), and GCA (n=82), at times of remission or flare. Disease activity was assessed using physician global assessments (PGA).

Results: Compared to healthy controls (HC) NE-DNA complexes were significantly elevated in all patients with vasculitis, both at flare and remission, except at remission for patients with MPA (Figure 1A). In patients with TAK, but none of the other conditions, elevated levels of NE-DNA complexes were seen at time of flare as compared to remission ($p< 0.05$), with NE-DNA levels correlating with PGA ($r=0.28$, $p< 0.05$). Levels of NETs did not correlate with C-reactive protein, a marker of general inflammation. Only patients with TAK had significantly higher levels of anti-histone antibodies in their circulation regardless of disease activity ($p< 0.01$) (Figure 1B). In patients with TAK, levels of anti-histone antibodies correlated with presence of NETs ($r=0.35$, $p< 0.01$).

Conclusion: NET formation, as assessed by NE-DNA complexes, is elevated in both small- and large-vessel vasculitis, suggesting a potential common disease link across vasculitides. The association of anti-histone antibodies with NETs in TAK suggests NETs may be a source of autoantigens in this disease. Further studies are needed to explore the role of NETs and anti-histone antibodies in the pathogenesis of vasculitis.

The Role of Faecal Calprotectin in IgA Vasculitis

Alojzija Hocevar[1], Matija Bajzelj[1], Matija Tomšič[2] and Katja Lakota[3], [1]UKC Ljubjana, Ljubjana, Slovenia, [2]Department of Rheumatology, University Medical Centre Ljubljana, Ljubljana, Slovenia, [3]Department of Rheumatology, University Medical Centre Ljubljana, Llubljana, Slovenia

SESSION INFORMATION

Session Date: Tuesday, November 9, 2021
Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster II (1862–1888)
Session Type: Poster Session D
Session Time: 8:30AM–10:30AM

Background/Purpose: Gastrointestinal involvement (GI) is associated with significant morbidity in acute IgA vasculitis (IgAV). Besides the abdominal pain, bowel ischemia could lead to bleeding, perforation, or ileus among others. Our aim was to investigate the role of faecal calprotectin measurement in patients with adult IgAV.

Table 1. Characteristics of IgA vasculitis patients with elevated vs. normal fecal calprotectin

Clinical characteristics	Elevated calprotectin (28)	Normal calprotectin (42)	P value
Male gender (%)	64.3	64.3	1.0
Age (years)*	67.9 (59.9; 75.9)	56.8 (39.1; 65.3)	0.003
Symptom duration (days)*	7 (5-21)	8 (5-14)	0.195
Constitutional symptoms (%)	17.9	7.1	0.252
Purpura above waistline (%)	60.7	40.5	0.143
Skin necroses (%)	57.1	35.7	0.091
Arthritis (%)	17.9	19.0	1.0
Renal involvement (%)	60.7	42.9	0.222
GI involvement (%)	28.6	21.4	0.574
ESR (mm/h) *	40 (28; 66)	27 (11; 52)	0.036
CRP (g/l) *	48 (12; 70)	19 (2; 44)	0.043
Elevated serum IgA (%)	46.4	54.8	0.626

Legend: * median and IQR; GI gastrointestinal;

Methods: Faecal calprotectin was determined at presentation in 70 patients with histologically proven adult IgAV diagnosed at our secondary/tertiary rheumatology center. Based on the calprotectin level, patients were stratified into two groups - those with elevated vs. normal level (the cut off >50 μg/g). Clinical features of patients with elevated vs. normal faecal calprotectin were compared. Logistic regression was used to determine factors associated with elevated faecal calprotectin in IgAV.

Results: Our cohort consisted of 45 males (64.3%) and 25 females (35.7%), median (IQR) age 63.9 (45.9; 69.2) years, with median (IQR) IgAV symptom duration time 7 (4; 21) days. Seventeen patients (24.3%) had GI involvement (abdominal pain, overt GI bleeding, occult GI bleeding, diarrhoea, ileus developed in 15, 4, 12, 6 and 1 patient, respectively). Twenty-eight out of 70 patients (40.0%) had elevated faecal calprotectin, with median (IQR) level of 86.3 (64.0; 192.8) μg/g, of them 8 had clinically GI involvement. We found no significant association between clinical GI involvement and elevated faecal calprotectin (p=0.574). Characteristics of IgAV patients with elevated vs. normal faecal calprotectin are presented in Table 1. Multivariate analysis showed that elevated calprotectin was associated with increasing patient age (OR 1.04 (95%CI 1.01-1.08); p=0.018), purpura above waistline (OR 3.37 (95%CI 1.07-10.58); p=0.037) and C-reactive protein (OR 1.02 (95%CI 1.00-1.03); p=0.017

Conclusion: Our result show that the role of faecal calprotectin measurements in evaluating GI involvement adult IgAV is rather limited.

SESSION INFORMATION

Session Date: Tuesday, November 9, 2021

Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster II (1862–1888)

Session Type: Poster Session D

Session Time: 8:30AM–10:30AM

Background/Purpose: Posterior segment involvement is the most serious affection of uveitis in Behçet's disease (BD), with cystoid macular edema (CME) being the leading cause of blindness. Anti-TNF, especially adalimumab (ADA) and infliximab (IFX), have demonstrated efficacy as first-line biologic agents in BD-related uveitis [Arthritis Rheumatol. 2019;71(12):2081-2089; Ophthalmology. 2018;125(9):1444-1451]. Moreover, the anti-IL6R tocilizumab (TCZ) has shown excellent results in highly refractory BD-uveitis and noninfectious uveitic CME [Rheumatology (Oxford). 2018;57(5):856-864; Am J Ophthalmol.2019;200:85-94; Clin Exp Rheumatol. 2014;32(4 Suppl 84): S54-7; Clin Exp Rheumatol. 2016;34(6 Suppl 102): S34-S40. Our aim was to compare the efficacy of ADA vs IFX vs TCZ in patients with refractory CME due to BD.

Methods: Observational multicenter study of patients with BD-associated CME refractory to conventional and/or biological immunosuppressive drugs. From a cohort of 177 patients treated with anti-TNF and 14 patients treated with TCZ, we selected those with CME at baseline. CME was defined as macular thickness > 300μm (measured by optic coherence tomography). We analyzed in the 3 groups of treatment (ADA, IFX, TCZ) from baseline up to 4 years the evolution of macular thickness (main outcome), best-corrected visual acuity (BCVA) and intraocular inflammation (Tyndall and vitritis). Differences between basal and final follow-up were evaluated. Multivariable linear regression was used to assess the differences between the 3 groups.

Table 1. Demographic and clinical characteristics of 49 patients with cystoid macular edema due to Behçet's disease receiving ADA, IFX or TCZ. Data are presented as mean ± SD or median (IQR) when data were not normally distributed. ADA, adalimumab; BCVA, best corrected visual acuity; CME, cystic macular edema; IFX, infliximab; TCZ, tocilizumab

	ADA (n=25)	IFX (n=15)	TCZ (n=9)	p
Number of eyes with CME, n	40	21	11	-
Age, years	41 ± 11	38 ± 9	43 ± 16	0.55
Sex, men/women	12/13	7/8	5/4	0.91
HLA–B51 positive, n (%)	19 (76)	10 (67)	6 (67)	0.75
Duration of uveitis before anti-TNF/ anti-IL6R, median [IQR] months	30 [12-82]	15 [8-60]	32 [24-144]	0.35
Ocular features at start of anti-TNF/anti-IL6R				
Macular thickness, mean ± SD µm	445 ± 130	484 ± 131	415 ± 104	0.30
BCVA, mean ± SD	0.40 ± 0.25	0.30 ± 0.25	0.20 ± 0.25	**0.015**
Anterior chamber inflammation grade (Tyndall), median [IQR]	2 [1-3]	1 [0-1]	1 [0.5-2]	**0.039**
Vitritis grade, median [IQR]	3 [1-3]	1 [0-2]	2 [1-2]	**0.033**
Treatment before start of anti-TNF/anti-IL6R, n (%)				
Oral glucocorticoids	18 (72)	4 (27)	7 (78)	0.27
Intravenous pulse methylprednisolone	13 (52)	9 (60)	8 (88)	0.15
Methotrexate	13 (52)	8 (53)	8 (88)	0.13
Cyclosporine A	22 (88)	13 (87)	6 (67)	0.31
Azathioprine	14 (56)	8 (54)	2 (22)	0.20
Adalimumab	0 (0)	0 (0)	7 (78)	-
Infliximab	0 (0)	0 (0)	3 (33)	-
Prednisone dosage at start of anti-TNF/anti-IL6R, median [IQR] mg/day	45 [30-60]	30 [20-60]	30 [30-30]	0.44
Combined treatment, n (%)				
Cyclosporine A	10 (40)	5 (33)	1 (11)	0.24
Azathioprine	10 (40)	5 (33)	1 (11)	0.25
Methotrexate	4 (16)	2 (13)	3 (33)	0.55
Duration of follow-up, median [IQR] months	24 [24-42]	24 [3-36]	13 [3-38]	0.26

Results: A total of 49 patients were included. ADA was used in 25 patients (40 eyes with CME), IFX in 15 (21 eyes with CME) and TCZ in 9 (11 eyes with CME). Thus, a sum of 72 affected eyes was analyzed. No statistically significant baseline differences were observed between the 3 groups **(Table 1)** except for a lower basal BCVA in patients treated with TCZ and a higher basal degree of intraocular inflammation in patients treated with ADA. Most patients from all groups had received several conventional immunosuppressive drugs. In addition, most patients in the group of TCZ had also received anti-TNF (5 patients received ADA, 1 received IFX and 2 received both ADA and IFX, in different times). Biological therapy was used in monotherapy or combined with azathioprine (n=10, 5 and 1 in ADA, IFX and TCZ group, respectively), cyclosporine A (n=10, 5 and 1) or methotrexate (n=4, 2 and 3). Macular thickness progressively decreased in the 3 groups, with no signs of CME after 1 year of treatment **(Figure 1)**. Similarly, BCVA improvement and inflammatory ocular remission was reached in all groups.

Conclusion: Refractory CME associated to BD's uveitis can be effectively treated with ADA, IFX or TCZ. Moreover, TCZ is effective in patients resistant to anti-TNF therapy.

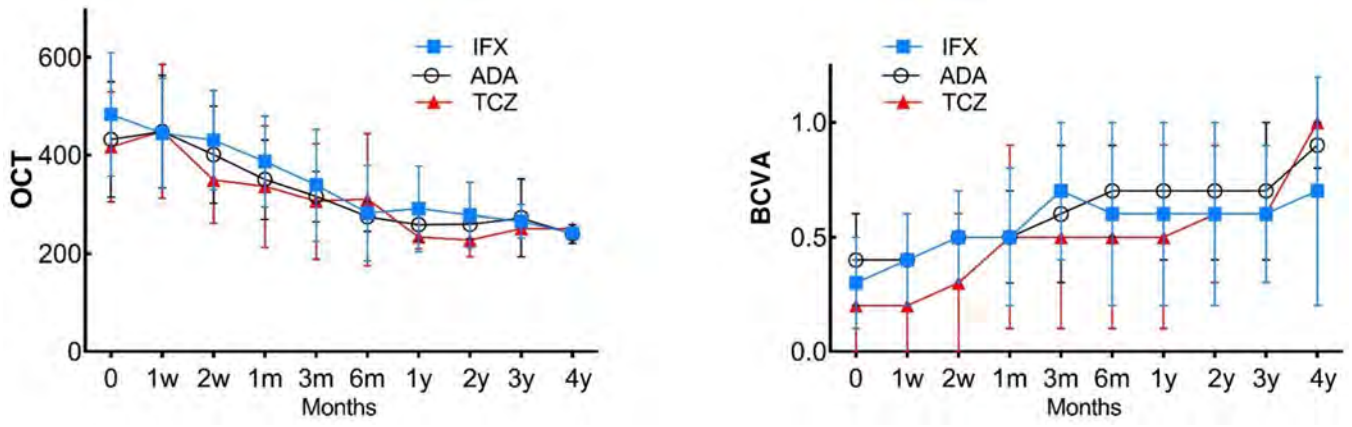

Figure 1. Evolution of ocular parameters in 49 patients with cystoid macular edema due to Behçet's disease receiving ADA, IFX or TCZ.

Characterization of Symptoms of Nasal Disease in Relapsing Polychondritis Using Patient-Reported Data

Shubhasree Banerjee[1], Nancy Linn[2], nathalie costedoat-Chalumeau[3], Guillaume Moulis[4], Peter Merkel[1], Peter Grayson[5] and Marcela Ferrada[6], [1]University of Pennsylvania, Philadelphia, PA, [2]Relapsing Polychondritis Foundation Inc., New York, NY, [3]Inserm DR Paris 5, Paris, France, [4]Toulouse University Hopital, Toulouse, France, [5]National Institutes of Arthritis and Musculoskeletal and Skin Diseases (NIAMS), National Institutes of Health (NIH), Bethesda, MD, [6]National Institutes of Health, Bethesda, MD

SESSION INFORMATION

Session Date: Tuesday, November 9, 2021

Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster II (1862–1888)

Session Type: Poster Session D

Session Time: 8:30AM–10:30AM

Background/Purpose: Nasal chondritis is a well-recognized manifestation of relapsing polychondritis (RP), occasionally leading to saddle nose deformity. Early symptoms of nasal chondritis such as nose pain are often overlooked. The objective of this study was to characterize nose pain and identify associated symptoms reported by patients with RP.

Methods: Patients with self-reported RP were invited to participate in an online survey. Participants were asked questions about nose pain such as location, onset, duration, frequency, quality, diurnal variation, aggravating and alleviat-

Table 1: Comparison of Clinical Manifestations among Patients with Relapsing Polychondritis Presenting with and without Nose Pain

	RP with nose pain n=430	RP without nose pain n= 215	P value
Eye inflammation n (%)	246 (57)	108 (50)	0.08
Saddle nose deformity n (%)	69 (16)	20 (9)	0.02
Ear pain, redness, swelling n (%)	397 (92)	189 (88)	0.05
Cauliflower ear n (%)	72 (17)	30 (14)	0.1
Hearing loss n (%)	134 (31)	54 (25)	0.2
Audio vestibular symptoms*n (%)	275 (64)	115 (53)	0.004
Airway damage** n (%)	108 (25)	62 (28)	0.5
Joint pain / swelling n (%)	369 (86)	165 (77)	0.01

*Audio vestibular symptoms: tinnitus, vertigo; **Airway damage: damage to trachea and/or bronchi

ing factors, associated symptoms, and saddle nose deformity. Participants with physician-diagnosed RP, aged ≥ 18 years, who meet McAdams diagnostic criteria were included in the study. Fisher's exact test was used to compare clinical characteristics between patients with and without nose pain.

Results: A total of 659 subjects were included, of which 484 (73%) were from the United States. The majority (n=548, 83%) identified themselves as Caucasians, and 574 (87%) were female. Mean age was 50 years (interquartile range = 41-58). Many patients (n=430, 65%) reported nose pain. RP diagnosis was commonly made by rheumatologists (n=313,73%) and otolaryngologists (101, 23%) in patients with nose pain. Compared to patients without nose pain, those with nose pain were more likely to report saddle nose deformity, audio vestibular symptoms, joint pain and swelling (Table 1). Treatment with prednisone was reported by 429 (99%) patients, of which 423 (99%) reported symptom relief with prednisone.

In patients with nose pain (n=430), pain was described as stabbing (n=147, 34%), sharp (n=73, 17%), dull (n=73, 17%), or burning (n=46, 10%); majority (n=313, 73%) reported at least two types of pain and (n=137, 32%) did not report a pain descriptor. Associated nasal pressure (n=150, 34%), tingling (n=119, 27%), or throbbing (n=61, 14%) was reported. Factors felt to aggravate nose pain were minimal trauma (n=240, 55%), stress (n=210, 48%), and cold exposure (n= 104, 24%); 50% reported more than one aggravating factor. Majority (n=322, 75%) reported the pain lasted for ≥1day. Frequency of reported nasal symptoms were daily (n=65, 15%), weekly (n=73, 17%), monthly (n=83, 19%), and few times/year (n=109, 25%). Onset of pain was mostly reported as variable (n=127, 30%) or gradual (n=138, 32%). The location of pain included bridge of the nose (n=252, 58%), sides (n=171, 39%), the base (n=146, 34%), or the tip (n=134, 31%) with 275 (64%) reporting pain in at least two locations. Many patients reported nose pain during the day (n=262, 60%), some reported nighttime pain (n=169, 39%) and pain during sleep (n=108, 25%). Most common associated symptoms were redness, swelling, and congestion, each reported by 50% of patients with nose pain.

Conclusion: Most patients with RP reported a wide range of symptoms of nasal disease. Commonest nasal complaints were stabbing pain with associated redness, swelling and congestion that lasts longer than a day, involves the bridge of the nose, and is aggravated by minor trauma. Detailed assessment of nasal manifestations could be helpful for clinicians for establishing a diagnosis and monitoring disease activity.

Differentiating Primary Central Nervous System Vasculitis from Non-inflammatory Intracranial Vasculopathy

Moein Amin[1], Takashi Shimoyama[2], Ken Uchino[1], Leonard Calabrese[1] and Rula Hajj-Ali[3], [1]Cleveland Clinic, Cleveland, OH, [2]Nippon Medical School, Tokyo, Japan, [3]Cleveland Clinic, Hunting Valley, OH

SESSION INFORMATION

Session Date: Tuesday, November 9, 2021

Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster II (1862–1888)

Session Type: Poster Session D

Session Time: 8:30AM–10:30AM

Background/Purpose: Establishing the diagnosis of Primary central nervous system vasculitis CNSV is challenging. In this study we aimed to investigate distinguishing primary CNSV compared to non-inflammatory intracranial vasculopathy using features in clinical presentation and blood and cerebrospinal fluid (CSF) markers.

Methods: We evaluated all cases enrolled in CNS vasculopathy registry (2012- present) which include patients with CNSV and other vasculopathies that mimics CNSV. Final diagnoses was verified with the last follow up. Final diagnosis of primary CNSV was based on criteria proposed by Calabrese and Mallek namely (1) the presence of an unexplained neurologic deficit after thorough clinical and laboratory evaluation, (2) documentation by cerebral angiography and/or tissue examination of an arteritic process within the central nervous system, and (3) no evidence of a systemic vasculitis or any other condition to which the angiographic or pathologic features could be secondary. In cases without evidence of histological confirmation, the diagnosis of CNSV was made according to the clinical pictures, MRI abnormalities, cerebral vascular imaging, and the presence of inflammatory CSF profiles and absolute certainty of the diagnosis that lead to therapeutic trial. Infectious vasculopathy, reversible cerebral vasoconstriction syndrome, systemic inflammatory disease, and cardio-embolic disease were excluded (Table 1). Clinical features on first presentation such as gender, ethnicity, clinical presentation, past medical history, and medications in addition to serum and CSF findings were investigated for their ability to predict the final diagnosis. CSF pleocytosis was defined as CSF white blood cell count ≥ 5 cells/μL and elevated CSF protein > 45 mg/dL.

Results: A total of 206 patients were identified with definite final diagnosis. 36 patients with CNSV and 26 with non-inflammatory vasculopathies (large vessel atherosclerotic disease, small vessel disease, intracranial dissection, and amyloid vasculopathy) were included. Demographics, clinical presentation, and comorbidities in two groups were not

Elevated protein, N (%)	24 (66.7)	11 (42.3)	0.056
Mean ± SD (mg/dL)	67.0 ± 31.4	47.3 ± 23.2	0.009*

Statistically significant results are highlighted with *. N=number. SD = standard deviation. CRP= C-reactive protein. ANA = antinuclear antibody.

significantly different with the exception higher prevalence of male gender and language deficits in CNSV group and higher prevalence of transient ischemic attack and hyperlipidemia in the past medical history of non-inflammatory vasculopathy group (Table 2). A logistic regression model was evaluated with the top 3 features identified in descending order included CSF pleocytosis (coefficient: 1.682), past medical history of hyperlipidemia (coefficient: -0.638), and seizure at presentation (coefficient: 0.478). The model predicted CNSV in validation cohort with sensitivity of 69% and specificity of 76%. This model was then cross-validated and was able to predict CNSV with AUC 0.81, sensitivity 69.44% and specificity 75.86%. The calibration plot for this model is demonstrated in Figure 1.

Conclusion: In this study, we demonstrated that differentiating inflammatory form non-inflammatory CNS vasculopathy can be enhanced using a simple logistic regression model based on patient's past medical history, clinical presentation, and CSF profile using a logistic regression model.

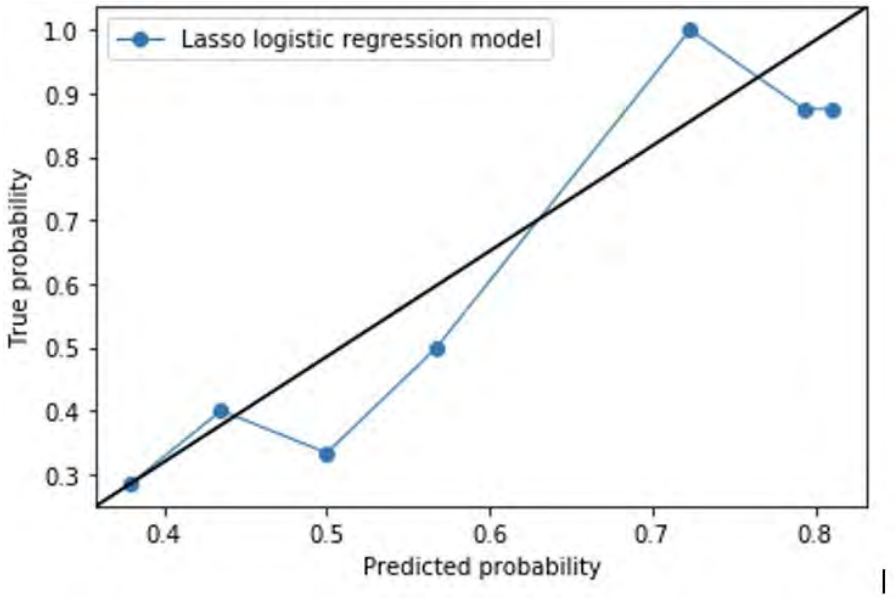

Figure 1. Logistic regression model.

The Importance of Lower Extremity Vein Wall Thickness in Patients with Behcet's Syndrome

Hasan Emre Kocabay[1], M. Enes Yayla[2], Evren Ustuner[1], **Emine Uslu yurteri**[3], Emine Aydemir Guloksuz[4], Serdar Sezer[2], Kinikli Gulay[4], Murat Turgay[4] and Askin Ates[4], [1]Ankara University, Ankara, Turkey, [2]Ankara Training and Research Hospital, Ankara, Turkey, [3]Hatay Training and Research Hospital, Hatay, Turkey, [4]Ankara University Faculty of Medicine, Department of Internal Medicine, Division of Rheumatology, Ankara, Turkey

SESSION INFORMATION
Session Date: Tuesday, November 9, 2021
Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster II (1862–1888)
Session Type: Poster Session D
Session Time: 8:30AM–10:30AM

Background/Purpose: Behçet's syndrome (BS) is a multisystemic chronic vasculitic disease that has mucocutaneous and joint involvement in addition to vascular, neurological and gastrointestinal involvement (1).

Earlier studies. showed that Behcet's Syndorme patients have increased vein wall thickness (2-3) .

We aimed to show that vein wall thickness may be an indicator of vascular involvement in Behcet's syndrome patients.

Methods: We enrolled 30 mucocutaneous BS, 30 vascular BS, 30 ankylosing spondylitis (AS) and 30 healthy controls (HC). Bilateral lower extremity vein wall thickness evaluated by B-mode ultrasonography by a blinded radiologist. The thickest part of vein wall was measured in milimeters.

Table 1-Demographic characteristics

	Helathy control	Ankylosing spndylitis	MC BS	Vasc BS	P
Age	49±9.4	44.4±9.7	43.7±9.5	43.7±12.1	0.033
Gender Male Female	 8 (26.7) 22(73.3)	 13((43.3) 17(56.7)	 10(33.3) 20(66.7)	 16(53.3) 20(66.7)	0.162

ESR (mm/h)	8 (8.3)	11.5 (19)	10 (13.3)	7 (12)	0.387
CRP (mg/L)	3.71.95(3.8)	3.3 (5.9)	2(4.8)	2.4(6.7)	0.137

(Abbreviation: BMI: Body mass index, MC BS: mucocutaneous Behcet's syndrome Vas BS:vascular Behcet's syndrome ESR:erythrocyte sedimentation rate, CRP: C-reactive protein)

Patients were compared between groups by measuring vein wall thickness with lower extremity vein doppler ultrasound.

Results: The demographic characteristics of the patient groups and the healthy group included in the study are given in Table 1.

While there was no differences between the four groups in terms of vascular wall thickness in the common femoral vein (CFV) and popliteal vein. Venous wall thickness in the vena saphena parva and magna, which are the superficial vein, was found to be significantly higher in patients with vascular BS patients compared to the other groups (table 2).

Table 2-Evaluation of venous venous wall thickness of healthy control and patient groups

	Healthy control (30)	Ankylosing spondylitis(n=30)	MC BS (30)	Vasc BS (30)	P
Right Common femoral vein	0.13±0.02	0.13±0.02	0.14±0.02	0.14±0.04	0.246

(Abbreviation:, MC BS: mucocutaneous Behcet's syndrome Vas BS:vascular Behcet's syndrome)

Table 3-Vessel wall thickness on the affected and unaffected side

	Limb on the effected side (n:12)	Limb on the non effected side n(12)	p
Common femoral vein	0.13±0.02	0.13±0.02	1
Femoral vein	0.18±0.11	0.18±0.10	0.772
Vena Saphena magna distalis	0.44±0.27	0.38±0.19	0.527
Vena saphena parva	0.43±0.26	0.36±0.17	0.470
Popliteal Verin	0.21±0.0.28	0.26±0.46	0.450

In 12 BS patients with unilateral deep vein thrombosis (DVT), ipsilateral affected vein and non-affected controlateral vein wall thicknesses were compared. No significant difference was found between the affected vein and the non-affected vein wall thickness (table 3).

Conclusion: In a study by Alibaz-Öner et al., CFV wall thickness was found to be significantly higher in BS patients (2). In a study conducted by Seyahi et al. in 2019, the wall thickness of the superficial and deep veins in vascular BS patients was found to be higher than those of BS patients without vascular involvement and healthy controls.(3). In our study, significant difference was found in all superficial veins,but not all deep veins.

In a study conducted with non-inflammatory DVT patients, it was shown that the venous wall vessel thickness with DVT was higher than the healthy side (4). However, when we look vascular BS patients an increase in affected and nonaffected vessels wall thickness was observed in our study.

In this context, measurement of vessel wall thickness in healthy veins in patients with unkown origin DVT may perhaps guide us in the diagnosis of Behçet's syndrome. The fact that our number of patients is only 12 limits our interpretation in this case.

The slower blood flow in superficial veins than in deep veins may prolong the exposure time of these vessels to inflammatory cytokines. This may cause a more pronounced increase in the superficial vein wall thickness.

In this study, we wanted to investigate a method to predict vascular involvement in BS patientes. We found a marked increase in the superficial venous wall thickness in patients with vascular BS. Measurement of superficial vein wall vessel thickness may be an effective way to predict vascular involvement in BS patients.

The fact that there is no other patient group with thrombosis and that the ultrasonography is performed by a single radiologist are important limitations of our study.

SESSION INFORMATION

Session Date: Tuesday, November 9, 2021

Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster II (1862–1888)

Session Type: Poster Session D

Session Time: 8:30AM–10:30AM

Background/Purpose: Disease activity assessment can be challenging in Takayasu's arteritis (TAK), which can lead to difficulty in determining eligibility for enrollment into randomized clinical trials (RCTs). FDG-PET can complement clinical assessment of disease activity. The study objective was to determine whether incorporation of PET data, in addition to clinical assessment, influences decisions about trial enrollment in TAK.

Methods: An online survey was completed by physicians with expertise in TAK. Participants were asked background questions, including personal experience with use of PET. Clinical vignettes of commonly-encountered clinical scenarios were presented, based on actual cases derived from a prospective, observational cohort. In part A of each vignette, clinical symptoms, examination findings, acute phase reactant (APR) levels, and angiographic data were presented. Participants were asked if there was sufficient evidence of active vasculitis to enroll into a RCT studying a new treatment agent and to rate level of confidence about their assessment (scale of 0-100). In part B, detailed information from the same patient's PET scan was presented and participants were again asked whether they would enroll

Table 1: Disease activity assessments from part A and part B of the clinical vignettes in the context of potential enrollment of the patient into a clinical trial for Takayasu's arteritis

	Clinical symptoms	Acute phase reactants	Part A: Enrolled (n, %)	Part A: Not Enrolled (n, %)	FDG-PET	Part B: Enrolled (n, %)	Part B: Not Enrolled (n, %)	Level of Confidence (Part A→Part B)
Case 1	Active symptoms (carotidynia, headache)	Elevated	54 (84%)	10 (16%)	Active	63 (98%)	1 (2%)	79%→93%
Case 2	Symptoms of damage (stable arm claudication)	Normal	1 (2%)	61 (98%)	Active	20 (33%)	41 (67%)	74%→69%
Case 3	Symptoms of damage (stable arm claudication)	Normal	0 (0%)	61 (100%)	Inactive	1 (2%)	60 (98%)	82%→91%
Case 4	Fatigue	Elevated	19 (31%)	42 (69%)	Active	54 (89%)	7 (11%)	62%→80%
Case 5	Fatigue	Elevated	16 (26%)	45 (74%)	Inactive	9 (15%)	52 (85%)	64%→75%
Case 6	Fatigue	Elevated	24 (39%)	37 (61%)	Active	55 (90%)	6 (10%)	65%→80%
Case 7	No symptoms	Normal	1 (2%)	60 (98%)	Active	21 (34%)	40 (66%)	83%→69%
Case 8	No symptoms	Normal	2 (3%)	59 (97%)	Inactive	3 (5%)	58 (95%)	83%→93%

FDG-PET: 18F-fluorodeoxyglucose Positron Emission Tomography

Table 2: Generalized linear mixed model to evaluate associations between PET activity, acute phase reactant levels, and enrollment decisions in part A and part B

	Predictor Variable*	Effects Estimate (95% confidence interval)	p-value
Part A	Elevated acute phase reactants (yes/no)	4.61 (2.68 - 6.55)	p<0.001
Part B	Elevated acute phase reactants (yes/no)	3.58 (2.77 - 4.39)	p<0.001
	PET activity (yes/no)	4.63 (3.62 - 5.65)	p<0.001

* All models adjusted for participant and case as random effects.

the patient into a RCT and level of confidence about their assessment. Generalized linear mixed models, adjusting for correlated data, were used to evaluate associations between PET activity, APR levels, and enrollment decisions.

Results: Sixty-eight vasculitis experts completed the survey. The majority of physicians were from Europe [n=45 (66%)] or North America [n=16 (24%)] and most were rheumatologists [n=54 (79%)]. Physicians had varying experience with managing patients with TAK: < 10 patients [n=15 (22%)], 10-40 patients [n=32 (47%)], and >40 patients [n=21 (31%)]. Most physicians reported using PET to diagnose TAK [n=56 (82%)] and to monitor disease activity [n=45 (66%)].

In part A of the vignettes, greater variability in trial enrollment decision was observed in cases of constitutional symptoms alone (e.g. fatigue) and elevated APR levels (Cases 4-6) **(TABLE 1)**.

In Part B, level of confidence improved when PET findings aligned with clinical assessment from Part A (Case 1,3,8). In cases where PET findings did not align with clinical assessment in part A (e.g. absent clinical symptoms with active PET scan, “subclinical inflammation”), the degree of variability about whether to enroll/not enroll increased in Part B and level of confidence worsened (Case 2, 7). In cases with the highest variability about enrollment in part A (Cases 4-6), PET activity drove the decision of whether to enroll in Part B and level of confidence improved. PET activity and APR levels independently contributed to trial enrollment decisions **(TABLE 2)**.

Conclusion: Physicians vary about which patients with TAK should be enrolled into RCTs. Incorporation of PET findings with clinical assessment influences trial enrollment decisions and improves physician confidence about disease activity assessment. Cases of subclinical inflammation pose unique challenges for trial enrollment. Future RCTs in TAK should consider incorporating PET findings into eligibility criteria.

Abstract Number: 1875

Hyoscine Butylbromide Inhibits Neutrophil Cell Death Induction by Cocaine-levamisole. a Proof of Concept for the Management of Vasculopathy Induced by Cocaine-Levamisole

Manuela Osorio[1], Tulio Lopera[1], Teresita Coneo[2], Isabel Velásquez-Giraldo[2], Ruben Vargas[2], Adriana Lucía Vanegas-García[3], Mauricio Rojas[2], **Gloria Vasquez**[4] and Carlos Muñoz-Vahos[5], [1]Universidad de Antioquia, Medellin, Colombia, [2]Universidad de Antioquia, Medellín, Colombia, [3]Division of rheumatology, Universidad de Antioquia – Hospital San Vicente Fundación, Medellín, Colombia, [4]Division of rheumatology, Universidad de Antioquia, Medellin, Colombia, [5]Hospital San Vicente Fundación, Medellín, Colombia

SESSION INFORMATION
Session Date: Tuesday, November 9, 2021
Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster II (1862–1888)
Session Type: Poster Session D
Session Time: 8:30AM–10:30AM

Background/Purpose: The Vasculopathy induced by Cocaine-Levamisole (VICOL) is a recently described vasculopathy characterized by the presence of tissue necrosis. One of the possible mechanisms associated with this disease is the presence of NETosis a type of cell neutrophil cell death. The content of Nets is involved in endothelial activation and could explain the clinical manifestations. The muscarinic receptors M3 could be activated by levamisole and induce Netosis, an event that triggers the inflammation associated with the disease.

Methods: Neutrophils from healthy controls were isolated on a density gradient Ficoll-Dextran 3%, and cell viability and purity were assessed by stain with PI, DIOC6, and CD45-PCy7 and CD33-PE, respectively. After that, the induction of NETosis was evaluated through treatment with 40μM of Cocaine and 20nM of Levamisole and a mix of two components (40μM and 20nM). Then, neutrophils were cultured in polystyrene test tubes for 6 hours. As a positive

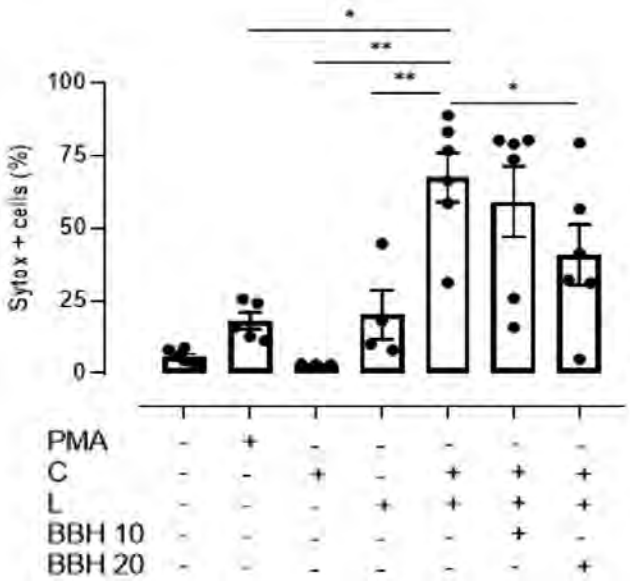

Figure 1. Hyoscine Butylbromide inhibits neutrophil cell death induction by cocaine-levamisole. Percentage of neutrophils cell death stimulated by PMA [10 nM], cocaine (C) [40 μM], levamisole (L) [20 nM] cocaine-levamisole (C-L) and non-stimulated cells (n=5). Inhibition of cell death by Hyoscine Butyl bromide (BBH) at 10nM and 20 nM induced by cocaine-levamisole (C-L+I) (n=5). ANOVA I and Bonferroni comparison of means was used to calculate the p-value. Error bars represent mean ± SEM. *p < 0.05, **p< 0.01, ***p<0.001.

control, 10 nM PMA was used. The presence of cell death was established by stains with 2μM Sytox and 1μg/μl Hoechst using cytometry. The double-positive cells indicate the presence of cell death. For the evaluation of inhibition, 10 nM and 20 nM of Hyoscine Butylbromide were added to the cultures before the stimulus, and the presence of cell death was also evaluated by cytometry. Flow cytometer data was analyzed using FlowJo, and statistical analysis was performed using GraphPad Prism V.8.

Results: The induction of neutrophil cell death was observed in the presence of cocaine and levamisole. A mean of 2.52% (range 0.443-3.35) and 20.28% (8.02-44.7) of neutrophils suffer cell death in the presence of cocaine and levamisole, respectively. The mix of Cocaine-Levamisole increases the median of cell death by 67.43% (31.3-88.8). The PMA was used as a control and induce cell death of 17.96% (11.3- 25.6). The cell death inhibition was assessed in neutrophils treated with Cocaine-Levamisole in the presence of 10nM and 20nM Hyoscine Butylbromide. The percentage of inhibition observed was 59.15% (15.9-80.3) with 10 nM of inhibitor and 40.95% (4.9-79.4) with 20 nM of inhibitor. As negative control not treated- neutrophils were evaluated and showed a cell death induction of 5,86% (3.5-8.9).

Conclusion: These results show that Levamisole induces a higher proportion of cell death than Cocaine, the mix of Cocaine-Levamisole enhanced the percentage of cell death. Hyoscine Butylbromide can inhibit the cell death induced by Cocaine-Levamisole. This is the first evidence of the capacity of Hyoscine Butylbromide to inhibit this phenomenon. In this study, we used flow cytometry as a tool for the evaluation of cell death that suggests NETosis. However, this strategy of flow cytometry should be assessed with antibodies against molecules involved in NETosis. The evidence of this study could suggest the potential use of this medicament to reduce the clinical manifestations of VICOL.

SESSION INFORMATION
Session Date: Tuesday, November 9, 2021
Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster II (1862–1888)
Session Type: Poster Session D
Session Time: 8:30AM–10:30AM

Background/Purpose: Mouth and genital ulcers with inflamed cartilage (MAGIC) syndrome is a rare and poorly understood entity with clinical features of both relapsing polychondritis (RP) and Behcet's disease (BD). This study characterized the clinical features of MAGIC syndrome and derived a disease definition for use in future studies.

Methods: Adult patients within an ongoing prospective, observational cohort study in RP were clinically assessed for MAGIC syndrome. A systematic review was conducted to identify additional cases of MAGIC syndrome. Clinical characteristics were compared between the pooled cases of MAGIC syndrome and cases of non-MAGIC RP. The performance characteristics of three different criteria to classify MAGIC syndrome were evaluated.

Results: Of the 96 patients with RP in the cohort study, 13 (14%) had MAGIC syndrome. The systematic review identified 27 additional MAGIC syndrome cases in literature. Patients reported in the literature were more likely to have ear chondritis (96% vs 54%, $p < 0.01$) and less likely to have nasal chondritis (63% vs 100%, $p = 0.02$), airway chondritis (19% vs 69%, $p < 0.01$), and costochondritis (7% vs 85%, $p < 0.01$) when compared with patients in the cohort study. When comparing clinical manifestations seen in BD, patients with MAGIC reported in the literature had a greater prevalence of BD-related cutaneous involvement (erythema nodosum, pseudofolliculitis or pathergy) than patients in the cohort study (48% vs 8 %, $p = 0.01$). Raynaud's phenomenon was reported in 54% patients in the cohort study but was not described in any cases of MAGIC syndrome reported in literature. Anti-collagen II antibodies were not reported in any MAGIC syndrome cases in literature.

Pooling the 40 cases together and comparing them with non-MAGIC RP, there was significantly higher prevalence of almost all BD-related features in patients with MAGIC syndrome, including BD-related ocular involvement (uveitis or retinal vasculitis (, 28% vs 4%, $p < 0.01$), BD-related cutaneous involvement (erythema nodosum, pseudofolliculitis or pathergy (, 35% vs 1%, $p < 0.01$), GI involvement (23% vs 4%, $p < 0.01$) and CNS involvement (8% vs 0, $p=0.04$). There was also a higher prevalence of aortitis (23% vs 1%, $p < 0.01$) and Raynaud's phenomenon (54% vs 11%, $p < 0.01$) and anti-collagen II antibodies (50% vs 9%, $p=0.04$) in MAGIC syndrome. Fulfillment of either McAdam's or Damiani's Criteria for RP plus the International Criteria for Behçet's Disease (ICBD) had excellent sensitivity (98%) to classify cases of MAGIC syndrome. Use of presence of oral and genital ulcers to define MAGIC syndrome had lower sensitivity (88%). In contrast, the International Study Group (ISG) criteria performed poorly for defining MAGIC syndrome with low sensitivity (43%).

Conclusion: MAGIC syndrome can be diagnosed in a substantial proportion of patients with RP. These patients have features of RP, BD, and other unique features such as aortitis, Raynaud's phenomenon and anti-collagen II antibodies. Fulfillment of McAdam's or Damiani's criteria for RP and the ICBD criteria for BD can be used to define MAGIC syndrome in future research studies.

Abstract Number: 1877

Takayasu Arteritis Patients with Tuberculosis Have Unique Clinical Characteristics

Yiming Luo[1], Kaitlin Quinn[2], Marcela Ferrada[1], Elaine Novakovich[1] and Peter Grayson[3], [1]National Institutes of Health, Bethesda, MD, [2]National Institute of Arthritis and Musculoskeletal and Skin Diseases (NIAMS), National Institutes of Health (NIH), Washington, DC, [3]National Institutes of Arthritis and Musculoskeletal and Skin Diseases (NIAMS), National Institutes of Health (NIH), Bethesda, MD

SESSION INFORMATION

Session Date: Tuesday, November 9, 2021

Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster II (1862–1888)

Session Type: Poster Session D

Session Time: 8:30AM–10:30AM

Background/Purpose: Takayasu's arteritis (TAK) is an idiopathic inflammatory disease primarily affecting the aorta and its major branches. *Mycobacterium tuberculosis* is prevalent in developing countries and can cause latent or active tuberculosis (TB) of the lung or other organs. Increased prevalence of TB has been reported in TAK but a causal relationship has not been established. The study objective was to determine if clinical characteristics differ among patients with TAK with known TB exposure.

Methods: Patients with TAK were recruited to a prospective observational cohort. All patients fulfilled the 1990 ACR Classification Criteria for TAK. TB was identified by medical history and/or Quantiferon-Gold screening. Categorical and continuous variables were compared using the Fisher's exact test and Mann-Whitney test, respectively. Vascular calcification was based on radiology report of high-density lesions consistent with calcium deposition in large- or medium-size arterial territories on CT scans. Relapse was defined as clinical assessment showing recurrence of active vasculitis requiring escalation of immunosuppressive therapy after a period of stable remission. Incidentally found was defined as receiving diagnostic work up for non-TAK non-TB related indications which leads to unexpected discovery of vascular pathology. Asymptomatic was defined as complete absence of any vascular or systemic symptoms.

Results: Among 80 patients with TAK, 10 patients had a history of TB. 8 patients had latent TB, 1 patient had TB endometritis, and 1 patient had TB lymphadenitis and erythema induratum. All patients with active TB completed anti-active TB treatment. 7 of out 8 patients with latent TB completed anti-latent treatment and 1 patent with latent TB was recommended to start treatment. The majority of the patients were female (9 (90%) in TB-TAK and 61 (87%) in non-TB TAK). Compared to those without TB, TAK patients with TB were older at diagnosis (35 vs 26 years, p=0.03) and less likely to be Caucasian (9 (10%) vs 51 (73%), p=0.002). TAK patients with TB had longer disease duration (17 vs 9 years, p=0.03), were more likely to be asymptomatic at diagnosis (2 (20%) vs 1 (1%), p=0.001) or diagnosed based on incidentally found vascular pathology (50% vs 6%, p=0.005). Patients with TB-TAK had distinct patterns of vascular disease, including increased thoracic aorta involvement (80% vs 40%, p=0.037), aortic aneurysms (5 (50%) vs 4 (16%), p=0.01), and vascular calcification (4 (40%) vs 9 (13%), p=0.05). In terms of treatment, patients with TAK-TB were less likely to have ever received treatment with glucocorticoids (5 (50%) vs 64 (91%), p=0.003), DMARDs (6 (60%) vs 65 (93%), p=0.012), or biologics (2 (20%) vs 43 (61%), p=0.018). Despite receiving less treatment, relapse was less frequent in patients with TB-TAK (3 (30%) vs 45 (66%), p=0.039).

Conclusion: Patient with TAK and TB have unique clinical characteristics. Compared to other patients, patients with TAK and TB are more likely to have clinically indolent disease, have more structural damage to the aorta, receive less

SESSION INFORMATION

Session Date: Tuesday, November 9, 2021

Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster II (1862–1888)

Session Type: Poster Session D

Session Time: 8:30AM–10:30AM

Background/Purpose: Tocilizumab (TCZ) has shown to be effective for large vessel vasculitis including Takayasu arteritis (TAK) **(1-3)**. Most evidence in TAK comes from Asian patients. However, white patients seem to have different clinical and prognostic features.

Our aims were to: **a)** assess the efficacy and safety of TCZ in white patients with refractory TAK, **b)** determine if clinical improvement correlates with imaging outcomes, **c)** compare TCZ in monotherapy (TCZ_{MONO}) vs combined with conventional immunosuppressive drugs (TCZ_{COMBO}).

Methods: Multicenter study of white patients with refractory TAK who received TCZ.Outcomes variables were remission, glucocorticoid-sparing effect, improvement in imaging techniques, and adverse events. A comparative study between patients who received TCZ_{MONO} and TCZ_{COMBO} was performed.

Table.

	Baseline n=54	**Month 1** N=54	**Month 3** N=49	**Month 6** N=44	**Month 12** N=36
Clinical remission, n (%)		12 (22.2)	19 (38.8)	23 (52.3)	27 (75.0)
Laboratory improvement					
CRP (*mg/dL*), median [IQR]	1.5 [0.5-3.5]	0.2 [0.1-0.7]*	0.2 [0.5-0.5]*	0.2 [0.1-0.5]*	0.1 [0.0-0.4]*
ESR (*mm/1st hour*), median [IQR]	30.5 [8.7-52.7]	7.0 [3.0-14.0]*	4.5 [2.0-8.0]*	5.0[2.0-6.0]*	4.0 [2.0-9.5]*
Hemoglobin (*g/dL*), mean ± SD	12.4 ±1.5	13.0 ±1.2*	13.0 ±1.4*	13.2 ±1.5*	12.9 ±1.6*
Prednisone dose, median [IQR]	30.0 [12.5-50.0]	20.0 [10.0-30.0]*	10.0 [5.0-20.0]*	5.0 [5.0-10.5]*	5.0 [0.0-5.6]*

CRP: C-Reactive Protein; **ESR**: Erythrocyte Sedimentation Rate; **IQR:** interquartile range; n: number. *p<0.01 vs baseline (Wilcoxon test).

Results: 54 patients (46 women/8 men; median age 42.0 [32.5-50.5] years). TCZ was started after 12.0 [3.0-31.5] months since TAK diagnosis. Remission was achieved in 12/54 (22.2%), 19/49 (38.8%), 23/44 (52.3%) and 27/36 (75%) at 1, 3, 6 and 12 months, respectively. Prednisone dose was reduced from 30.0 [12.5-50.0] to 5.0 [0.0-5.6] mg/day at 12 months (**Table**). 10 (26.3%) of the 38 patients in whom an imaging follow-up test was performed showed no radiographic improvement after a median of 9.0 [6.0-14.0] months. 4 of them were in clinical remission.23 (42.6%) patients were on TCZ_{MONO} and 31 (57.4%) on TCZ_{COMBO}: MTX (n=28), cyclosporine A (n=2), azathioprine (n=1). Patients on TCZ_{COMBO} were younger (38.0 [27.0-46.0] vs 45 [38.0-57.0] years; p= 0.048), with a trend to longer TAK duration (21.0 [6.0-38.0] vs 6.0 [1.0-23.0] months; p= 0.08) and higher C-reactive protein (2.4 [0.7-5.6] vs 1.3 [0.3-3.3] mg/dL; p=0.16). Despite these differences, similar outcomes were observed in both groups (log rank p=0.862) (**Figure**).

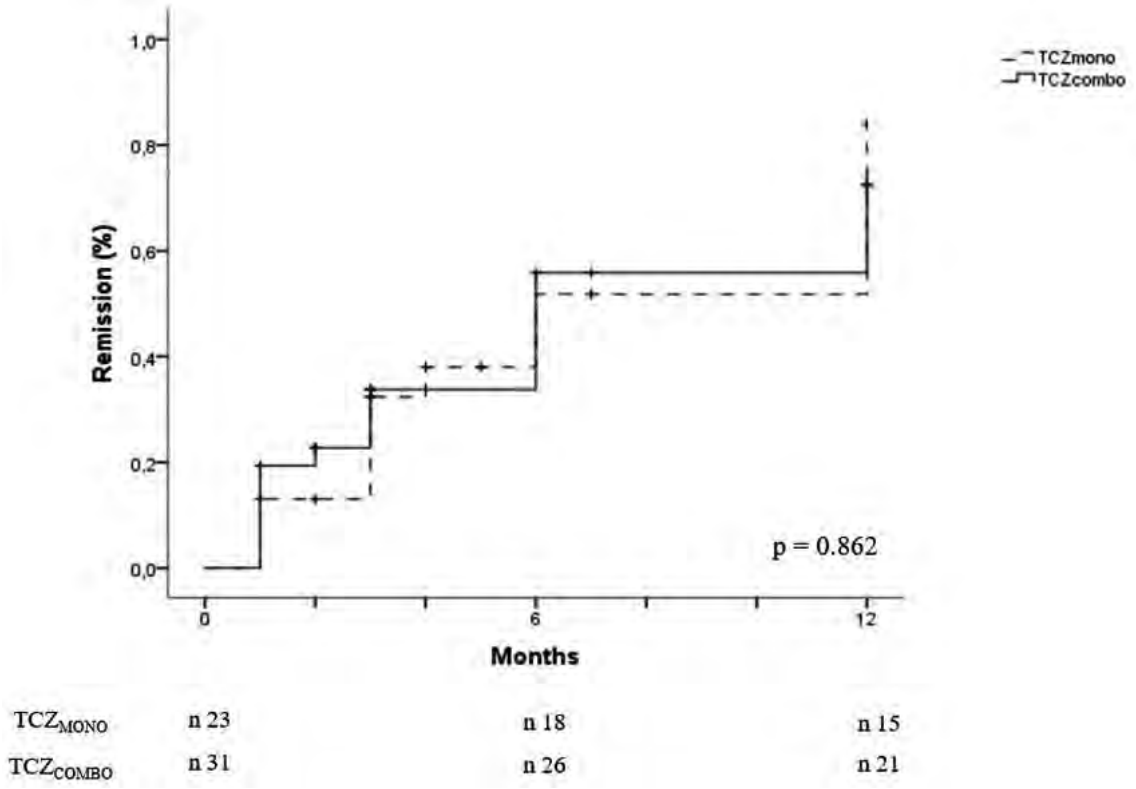

Figure.

Relevant adverse events were reported in 6 (11.1%) patients, but only 3 developed severe events that required TCZ withdrawal.

Conclusion: TCZ is effective and safe in white patients with refractory TAK. A discordance between clinical and imaging activity assessment may exist.

Delayed Diagnosis of IgG4 Related Disease Is Associated with Worse Outcome: A Retrospective, Real-life Observational Study

Elisheva Pokroy-Shapira[1], Iftach Sagy[2], Katya Meridor[3] and Yair Molad[4], [1]Institute of Rheumatology, Rabin Medical Center, Beilinson Hospital, and Tel Aviv University, Petach Tikva, Israel, [2]Clinical Research Center, Soroka University Medical Center, Beer Sheva and Ben Gurion University of the Negev, DVIRA, Israel, [3]Tel Aviv Sourasky Medical Center, Kfar Saba, Israel, [4]Rabin Medical Center, Beilinson Hospital, and Tel Aviv University, Petah-Tikva, Israel

SESSION INFORMATION

Session Date: Tuesday, November 9, 2021
Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster II (1862–1888)
Session Type: Poster Session D
Session Time: 8:30AM–10:30AM

Background/Purpose: The purpose of this study was to characterize clinical and pathological features as well as disease outcome of an Israeli incident cohort of patients with IgG4-related disease (IgG4-RD).

Methods: Retrospective, single-center study of incident patients with IgG4-RD diagnosed between 2010 and 2020. IgG4-RD was classified as 'definite', 'probable' or 'possible' according to international consensus guidelines and comprehensive diagnostic criteria for IgG4-RD or if patients fulfilled organ-specific criteria, as well as the 2019 ACR/EULAR classification criteria. Disease activity was determined by means of the IgG4-RD Responder Index (IgG4-RD RI). Disease features, as well as treatment and disease outcome were retrieved from the patients' electronic charts. Disease remission was defined as no clinical and imaging evidence of active disease.

Results: Thirty-six incident patients (30.6% female) with median age of 54.9 years were included in the study: 11 patients (30.56 %) - "definite", 10 patients (27.77%) - "possible", and 15 (41.67%)- "probable" IgG4RD, and 22 patients (61.1%) fulfilled the 2019 ACR/EULAR classification criteria. Nineteen patients (52.8%) had a single-organ disease, 8 patients (22.2%) had involvement of two organs, and 9 patients (25%) had 3 or more organs involved. The most involved organs were lymph nodes (36%), retroperitoneal fibrosis (25%), and pancreas (16.7%). Median follow-up was 28 months (IQR 13.2-40.7). Thirty-three patients (91.67%) had biopsies available for analysis. Lymphoplasmacytic infiltrate, fibrosis and obliterative phlebitis were found in 88.9%, 61.1%, and 11.1%, respectively. Thirty-four patients (94.4%) were treated with prednisone, 38.9% were treated with methotrexate, 27.8% with azathioprine, 5.6% with mycophenolate mofetil and 47.2% with rituximab. Median IgG4-RD RI at diagnosis and at last encounter was 6.0 (IQR 6.0-9.0) and 1.0 (IQR 0.0-2.0), respectively. Six patients died (16.7%) and malignancy was diagnosed in 8 patients (22.2%). At the time of charts review, 16 patients (44.4%) were in remission after a median time of 16 months (IQR 6.0-30.0). Only two patients (5.6%) relapsed. Disease remission was significantly associated with a shorter time from the first symptom to the time of diagnosis (median 3.5 months vs. 18.5 months, p=0.04), lower ACR/EULAR criteria index at diagnosis (p=0.01), and a trend toward lower number of organs involved and higher initial daily prednisone dose (p=0.06 for each parameter). Neither serum IgG4 level at diagnosis, nor type of organ involvement or type of immunosuppressive/biologic drugs used were associated with disease remission. Significantly higher rates of malignancy (p=0.01) and mortality (p=0.03) were demonstrated amongst patients who did not achieve remission

Conclusion: Our data suggest that remission is an achievable target in the management of IgG4-RD and that delayed diagnosis of IgG4-RD is negatively associated with remission.

Abstract Number: 1880

Description of an Internet-Based Cohort with a Self-Reported Diagnosis of Polyarteritis Nodosa

Jason Springer[1], Tanaz Kermani[2], Dianne Shaw[3], Kalen Young[3], Cristina Burroughs[4] and Peter Merkel[5], [1]Vanderbilt University Medical Center, Franklin, TN, [2]University of California Los Angeles, West Hills, CA, [3]Vasculitis Foundation, Kansas City, MO, [4]Health Informatics Institute, Tampa, FL, [5]University of Pennsylvania, Philadelphia, PA

SESSION INFORMATION
Session Date: Tuesday, November 9, 2021
Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster II (1862–1888)
Session Type: Poster Session D
Session Time: 8:30AM–10:30AM

Background/Purpose: Polyarteritis nodosa (PAN) is form of medium-vessel vasculitis with an estimated annual incidence of 1 per million. The rarity of the disease makes traditional center-based approaches to research in PAN challenging. The purpose of this study was to describe an internet-based cohort of participants with a self-reported diagnosis of PAN, and, to determine how many patients met established criteria for this disease.

Table 1. Means of diagnostic confirmation and manifestations of polyarteritis nodosa

Confirmation of diagnosis based on	Number (%)
Biopsy	60 (75)
Symptoms	41 (51)
Labs	37 (46)
General imaging	23 (29)
Angiogram	20 (25)
I don't know	1 (1)
Vasculitis-related manifestations	**Number/responses (%)**
Nerve damage	65/75 (87)
Muscle pain	62/72 (86)
Rash	59/78 (76)
Weight loss	47/78 (60)
Testicular pain (males)	18/34 (53)
Hypertension	27/74 (36)
Kidney problems	25/75 (33)

Methods: Participants with a self-reported diagnosis of PAN were included in a prospective, internet-based, longitudinal registry from November 2014 to May 2020. All patients completed standardized forms collecting data on disease manifestations, diagnostic testing, and treatment. Patients reporting a history of a positive test for ANCA (n=19) were excluded.

Results: 80 participants (58% female) self-reported a diagnosis of PAN without a history of ANCA. Two participants reported a history of hepatitis B viral infection. Race/ethnicity distribution: 87% Caucasian/White, 9% Asian, 8% His-

Table 2. Treating physicians and reported medications at enrollment

Specialty of physician treating the vasculitis	Number (%)
Rheumatology	66 (83)
Primary care	24 (30)
Nephrologist	9 (11)
Dermatologist	5 (6)
Neurologist	3 (4)
Pulmonologist	3 (4)
ENT	1 (1)
Cumulative use of medications	**Number (%)**
Glucocorticoids	69 (86)
Azathioprine	36 (45)
Cyclophosphamide	39 (49)
oral	*20 (25)*
intravenous	*19 (24)*
Methotrexate	28 (35)
Mycophenolate mofetile	16 (20)
Aspirin	12 (15)
Sulfamethoxazole/Trimethoprim	9 (11)
Colchicine	7 (9)
Dapsone	7 (9)

panic/Latino, 5% African American/Black, and 1% Native American. Enrollment included participants from across the world including North America (57), Europe (8), Australia (3), Asia (2), and South America (1). The mean age of onset of symptoms and diagnosis was 42.7 (SD 0.28) and 44.1 (SD 0.30) years. Only 13 participants (16%) were > 65 years old at the time of registration. Four participants were < 18 years old at the onset of symptoms.

Patients reported that the diagnosis was made based on biopsy (75%), symptoms (51%), laboratory studies (46%), or angiogram (25%) (**Table 1**). The most common manifestations of vasculitis included: nerve damage (87%), muscle pain (86%), skin involvement (76%), weight loss (60%), and testicular pain (53% of males) (**Table 1**). Blood clots were reported in 18%. 6 participants reported only skin involvement. The majority (83%) of patients reported that a rheumatologist was their treating physician (**Table 2**). The most common drug exposures included glucocorticoids (86%), cyclophosphamide (49%), and azathioprine (45%) (**Table 2**). 95% of participants met the 1990 American College of Rheumatology Classification Criteria for PAN. 95% of participants met the 2012 Chapel Hill Consensus Conference Definition of PAN.

Conclusion: In an internet platform based on self-reported patient information, the majority of patients met well-established criteria for PAN and reported disease manifestations in similar frequencies to published data from physician-reported cohorts. These results support the use of online patient cohorts to conduct research in PAN.

Session Type: Poster Session D
Session Time: 8:30AM–10:30AM

Background/Purpose: Behcet's disease (BD) is characterized by hyper-inflammatory response to trauma, which is called the pathergy phenomenon. Therefore, there are concerns about post-operative complications when the affected patients undergo surgical procedures. Here, we comprehensively investigated the incidences of postoperative complications after surgical procedures.

Methods: We retrospectively reviewed all the patients with BD who underwent surgeries at Seoul National University Hospital between January 2003 to December 2019. Diagnosis of BD was based on the International Study Group criteria or revised diagnostic criteria for the Behcet's Disease Research Committee of Japan (Japanese criteria). The incidence of surgical complications and the associated factors of surgical wound complications were analyzed.

Results: The patients were composed of 270 patients (49.1 ± 13.6 years at operation, 107 men) and they underwent 356 surgeries. A total of 38 cases (10.7 %) of postoperative complications were found, of which 32 (9 %) were sur-

Table. The incidence of surgical wound complications, reoperations due to surgical wound problems, and death

Type of surgery (N=356)	Surgical wound complications (%)	Reoperations (%)*	Death (%)†

total	32	16	4

CABG: coronary artery bypass surgery, ENT: ear, nose and throat, HBP: hepatobiliary and pancreatic

* Reoperations due to surgical wound problems

† Death due to current operations

gical wound complications including 16 wound dehiscences (50 %), 11 bleedings (34.4 %), 6 anastomotic dehiscences (18.8 %), 3 wound infections (9.4 %), 2 graft occlusions (6.3 %), and 1 fistula formation (3.1 %) with median time interval 10 days from the operation date (interquartile range (IQR) 5 to 19 days). Sixteen cases (4.5 %) required reoperations due to wound problems, and there were four operation-related deaths (1.1 %). Seventeen cases of long-term surgical recurrences were identified within the median follow-up of 21.5 months (IQR 16.8 to 52.5 months). Most postoperative wound complications occurred after cardiac (33.3 %), vascular (26 %), and gastrointestinal (12.5 %) surgeries, while those rarely occurred after orthopedic, thoracic, endocrinologic, and breast surgeries.

Conclusion: Incidences of postoperative complications vary among different surgeries in BD. The incidences of surgical wound complications are higher in cardiac, vascular, and gastrointestinal surgeries in patients with BD. Special perioperative care is recommended for these surgeries in BD patients.

Abstract Number: 1882

Clinical Characteristics and Reliability of a Self-Reported Diagnosis of Large-Vessel Vasculitis

Tannaz Kermani[1], Jason Springer[2], Dianne Shaw[3], Kalen Young[4], Cristina Burroughs[5] and Peter Merkel[6], [1]University of California Los Angeles, Los Angeles, CA, [2]Vanderbilt University Medical Center, Franklin, TN, [3]Vasculitis Foundation, Chapel Hill, NC, [4]Vasculitis Foundation, Kansas City, MO, [5]Health Informatics Institute, Tampa, FL, [6]University of Pennsylvania, Philadelphia, PA

SESSION INFORMATION

Session Date: Tuesday, November 9, 2021

Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster II (1862–1888)

Session Type: Poster Session D

Session Time: 8:30AM–10:30AM

Background/Purpose: To compare the clinical characteristics and determine the reliability of a self-reported diagnosis of giant cell arteritis (GCA) or Takayasu's arteritis (TAK) from an international, internet-based cohort.

Methods: Patients with GCA and TAK enrolled in an internet-based registry were included. Data provided by patients were collected through standardized forms, including type of vasculitis, symptoms, results of diagnostic testing, and medication use. The percentage of patients who met the 1990 American College of Rheumatology (ACR) classification criteria were calculated. For the 2012 Chapel Hill Consensus Conference (CHCC) definitions, age >50 years and report of a positive biopsy or imaging were used as surrogates for a diagnosis of GCA, and age < 50 years with diagnosis on imaging were used as surrogates for a diagnosis of TAK.

Results: The study included 250 patients with self-reported diagnoses (126 GCA and 124 TAK).

GCA cohort: The cohort was 80% female, mean (±SD) age 65 (±11.9) years. Mean (±SD) age at diagnosis of GCA was 62 (± 13.5) years. One patient aged 16 years was excluded. 9 patients (7%) reported age < 50 years old at the time of diagnosis (range 31 to 48 years). Of these, 2 patients had a temporal artery biopsy with 1 reported as positive in a 48 year-old. 93 patients (74%) reported having a temporal artery biopsy which was positive in 59 patients (63%). Abnormal imaging was reported in 39 patients (31%), 27 of whom also reported symptoms of limb claudication. The self-reported clinical symptoms of GCA are in Table 1. 87% met ACR classification criteria and 60% met the CHCC definition for GCA (93% met either, 87% met both).

TAK cohort: The cohort was 94% female, mean (±SD) age 42 (±15) years. Mean (±SD) age at diagnosis of TAK was 35 (±14.3) years. Twenty-six (21%) patients with TAK were ≥50 years at diagnosis, 15 patients (12%) with symptom onset at age ≥50 years. 97/112 patients (87%) reported blood pressure discrepancy in the upper extremities. Abnormal imaging was reported in 115 patients (93%). The self-reported clinical symptoms of TAK are outlined in Table 1.The subset of 26 patients ≥50 years old reported similar manifestations as the other patients with TAK, including abnormal angiogram (92%), limb claudication (77%), upper extremity blood pressure discrepancy (77%), bruits (77%). 95% of patients met ACR classification criteria. 75% met the CHCC definition for TAK; the majority who failed to meet the definition criteria did so on account of age. 96% patients met either ACR classification criteria or CHCC definition with 74% meeting both.

Conclusion: Patients with a self-reported diagnosis of GCA or TAK were able to reliably provide information about their symptoms and diagnosis. Clinical symptoms and treatments reported were consistent with what would be expected. The majority in both cohorts met ACR classification criteria or CHCC definitions. The high proportion of patients ≥50 years diagnosed as TAK likely reflects the uncertainty in clinical practice in this age group and classifi-

Table 1: Clinical manifestations in patients with a self-reported diagnosis of giant cell arteritis and Takayasu's arteritis

Clinical Manifestation	GCA* N=126	TAK* N=124
Weight loss >10 pounds	48/74 (65%)	65/118 (55%)
Fever >100.4°F	38/98 (39%)	41/89 (46%)
Myalgia	79/113 (70%)	96/116 (83%)
Headache	102/117 (87%)	70/104 (67%)
Scalp tenderness	93/121 (77%)	29/104 (28%)
Tenderness of temples	98/122 (80%)	36/107 (34%)
Vision loss	33/121 (27%)	28/115 (24%)
Pain/morning stiffness >30 minutes	89/115 (77%)	81/114 (71%)
Dizziness, syncope	60/106 (57%)	74/118 (63%)
Stroke	3/119 (3%)	17/115 (15%)
Chest pain or heart attack	21/119 (18%)	39/109 (36%)
Rash (including livedo, nodules)	34/109 (34%)	34/114 (30%)
Renal problems	15/119 (13%)	21/120 (18%)
Absent/weak pulse	25/91 (28%)	103/118 (87%)
Limb claudication	70/111 (63%)	82/116 (71%)
Bruit, neck/upper chest	9/111 (8%)	81/114 (71%)
Bruit, abdomen	5/111 (5%)	41/108 (38%)
Elevated blood pressure	41/103 (40%)	69/109 (63%)
Abnormal angiogram	31/117 (26%)	104/119 (87%)
Temporal artery biopsy	93/126 (73%)	9/117 (8%)
Abnormal ESR or CRP	106/119 (89%)	100/114 (88%)
Medication use for vasculitis		
Prednisone	121/124 (98%)	115/121 (95%)
Methotrexate	41/124 (33%)	81/121 (67%)
Azathioprine	0	35/121 (29%)
Mycophenolate mofetil	3/124 (3%)	31/121 (26%)
Anti-TNF therapy	2/124 (2%)	43/121 (36%)
Tocilizumab	18/124 (15%)	7/121 (6%)

* Numerator is the number of patients with this manifestation or treatment use; denominator is number of patients who responded Yes/No (response of "I don't know" excluded), data presented as number.

GCA=giant cell arteritis, TAK=Takayasu's arteritis, N=number, ESR=erythrocyte sedimentation rate, CRP=c-reactive protein

cation by phenotype. These results provide support for the feasibility of conducting some types of research in these rare diseases through online registries.

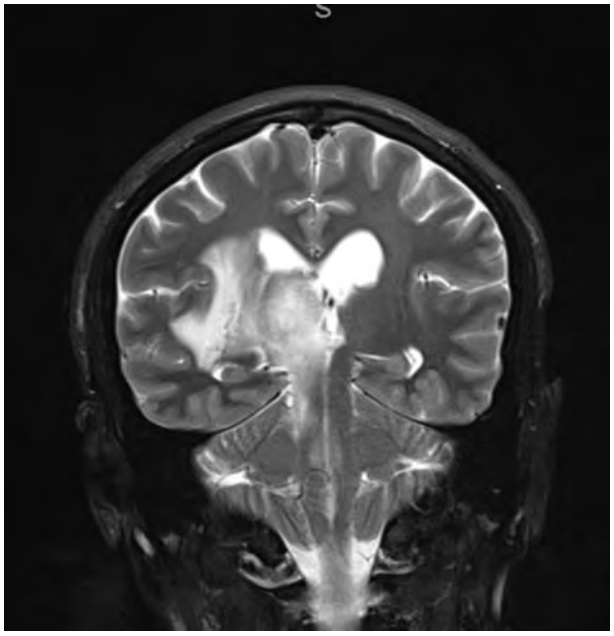
Neuro-Behcet's Disease: 20 Years Single Center Experience of Cyclophosphamide for Induction of Remission

Pablo Vinicius da Fonseca, Henrique Ayres Mayrink Giardini, Célio Roberto Gonçalves and Leandro Lara do Prado, Faculdade de Medicina da Universidade de São Paulo, São Paulo, Brazil

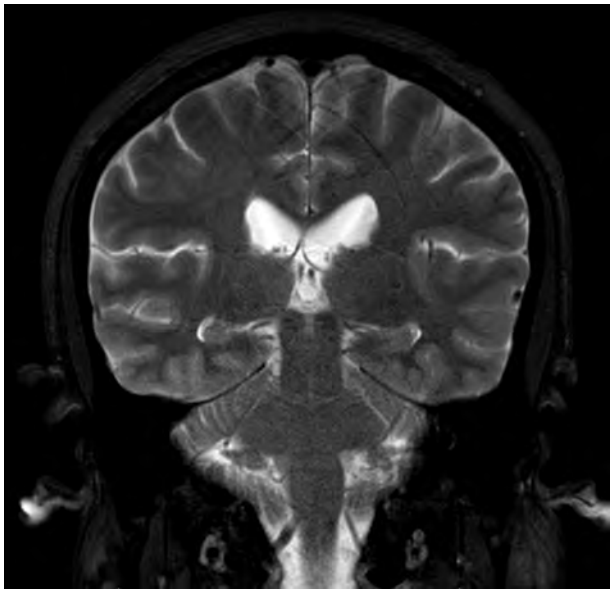
SESSION INFORMATION
Session Date: Tuesday, November 9, 2021
Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster II (1862–1888)
Session Type: Poster Session D
Session Time: 8:30AM–10:30AM

Background/Purpose: Behçet's disease (BD) is a systemic vasculitis. Neurological involvement, also known as Neuro-Behçet's disease (NBD), leads to great morbimortality. Diagnosis is challenging, since clinical presentation fluctuate greatly and systemic findings may be scarce, even after 2014 Classification Criteria included neurological manifestations. Treatment is based on corticosteroids and immunosuppressants, with azathioprine being widely used and tumor necrosis factor inhibitors (TNFi) as an option in refractory cases. Since access to TNFi is difficult, cyclophosphamide (CYC) may be used in severe NBD cases. However, strong evidence to corroborate its indications and treatment regimens are lacking. Our objective isto describe NBD patients' features, as well as safety and efficacy data of twenty years' experience of CYC use at a tertiary rheumatology center.

Methods: Retrospective cohort with data collected from electronic medical record, from January 2000 to December 2020, using keywords determinants. Treatment regimens allowed were methylprednisolone 1g for 3 to 5 days, followed by CYC 0.5 - 1g/m2 monthly for at least three months and compared to other immunosuppressant regimens (azathioprine, mycophenolate, TNFi). Subjects were divided in CYC and non-CYC groups and chi-square was used for statistical analysis.



Acute stage rhomboencephalitis.



After three months of treatment.

Results: Fifty-nine patients were included, 27 in the non-CYC group (55,55% women) and 32 in the CYC group (56,25% women). Mean age at BD diagnosis was 32.48 years in the non-CYC group and 29.75 years in the CYC group (p >0.05). Mean time from BD diagnosis to NBD was 26.85±9 months in the non-CYC group and 22.96±9,8 months in the CYC group (p >0.05). Mean follow-up months were 139.14 ±88 months in the non-cycle group and 78.78 ±43 months in the CFF group. Relapse rate was 14.8% in non-CYC versus 37.5% in CYC group (p >0.05), however relapse rate at 12-months follow-up was 50% at non-CYC group versus 12,5% at CYC group (p >0.05). Mean time for relapse was 30.5 versus 57.9 months at non-CYC and CYC groups, respectively (p >0.05). Mean cumulative CYC dose was 12.09g with an average of 10 infusions. There were 3 serious adverse events in each group (p >0.05).

Conclusion: Lower relapse rate at 12-months follow-up was a tendency in CYC patients in addition to sustained remission for a longer time, compared to other immunosuppressants. CYC use for NBD induction of remission presented a good safety profile, with few adverse effects and acceptable mean cumulative dose. Our study could not reach statistical significance due to small sample analysis and prospective studies are necessary to confirm relapse rates and establish the best CYC therapeutic schemes.

SESSION INFORMATION

Session Date: Tuesday, November 9, 2021
Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster II (1862–1888)
Session Type: Poster Session D
Session Time: 8:30AM–10:30AM

Background/Purpose: Deficiency of adenosine deaminase 2 enzyme (DADA2) is an autosomal recessive autoinflammatory disorder associated with ADA2 mutations. ADA2 works as a growth factor and its deficiency causes derangements in vascular integrity, increases in the proinflammatory type of macrophages, and results in tumor necrosis

Table 1. Demographic and clinical characteristics of patients

Patient ID	Current age, years/ Gender	Age at symptom onset, years	Age at diagnosis, years	Diagnosis date	All the treatments used	Initial organ involvement	Exitus

factor (TNF) mediated vascular inflammation. Given the importance of TNF in the pathophysiology, our aim was to understand the real-life outcomes of Anti-TNF treatment in patients with DADA2.

Methods: All DADA2 Adult or Pediatric patients among our Vasculitis Research Centre prospective database were included in this descriptive assessment. Demographics, clinical characteristics, and treatment details were recorded. From the overall cohort, patients who were initiated an anti-TNF agent were further assessed for the duration, dosage, indication of the treatment, and the outcome of the patients. Treatment response was evaluated according to physicians' reports (full-response, partial response-no response). A full response was defined as the symptom-free status of patients with normal acute phase reactants (AFRs)

Results: Totally 26 patients (Adult/Childhood age: 16/10) were analyzed. Mean (SD) current age was 25.6 (8.7) years in adults and 9.5 (2.5) years in children. The mean diagnosis age was 15.65 (9.2) years. The G47R mutation was homozygote in 19/21(90.5%) and heterozygote in 2/21 (9.5 %) of the patients. During a median (IQR) 48.5 (24-72)

Table 2. The details of the Anti-TNF treatment and the outcomes of the patients

Patient ID	Anti-TNF start date	Dosage	Still on Anti-TNF	Anti-TNF duration, months	Anti-TNF indication	Anti-TNF response
ID-2	September 2015	50 mg/ week ETN	Yes	69	Neurologic (central) involvement	Full
ID-3	N/A	40 mg/biweekly ADA	No	N/A	Constitutional symptoms	N/A
ID-4	March 2021	50 mg/ week, ETN	Yes	3	Neurologic involvement (peripheral)	Partial
ID-5	June 2020	50 mg/ week, ETN	Yes	12	Digital necrosis	Partial

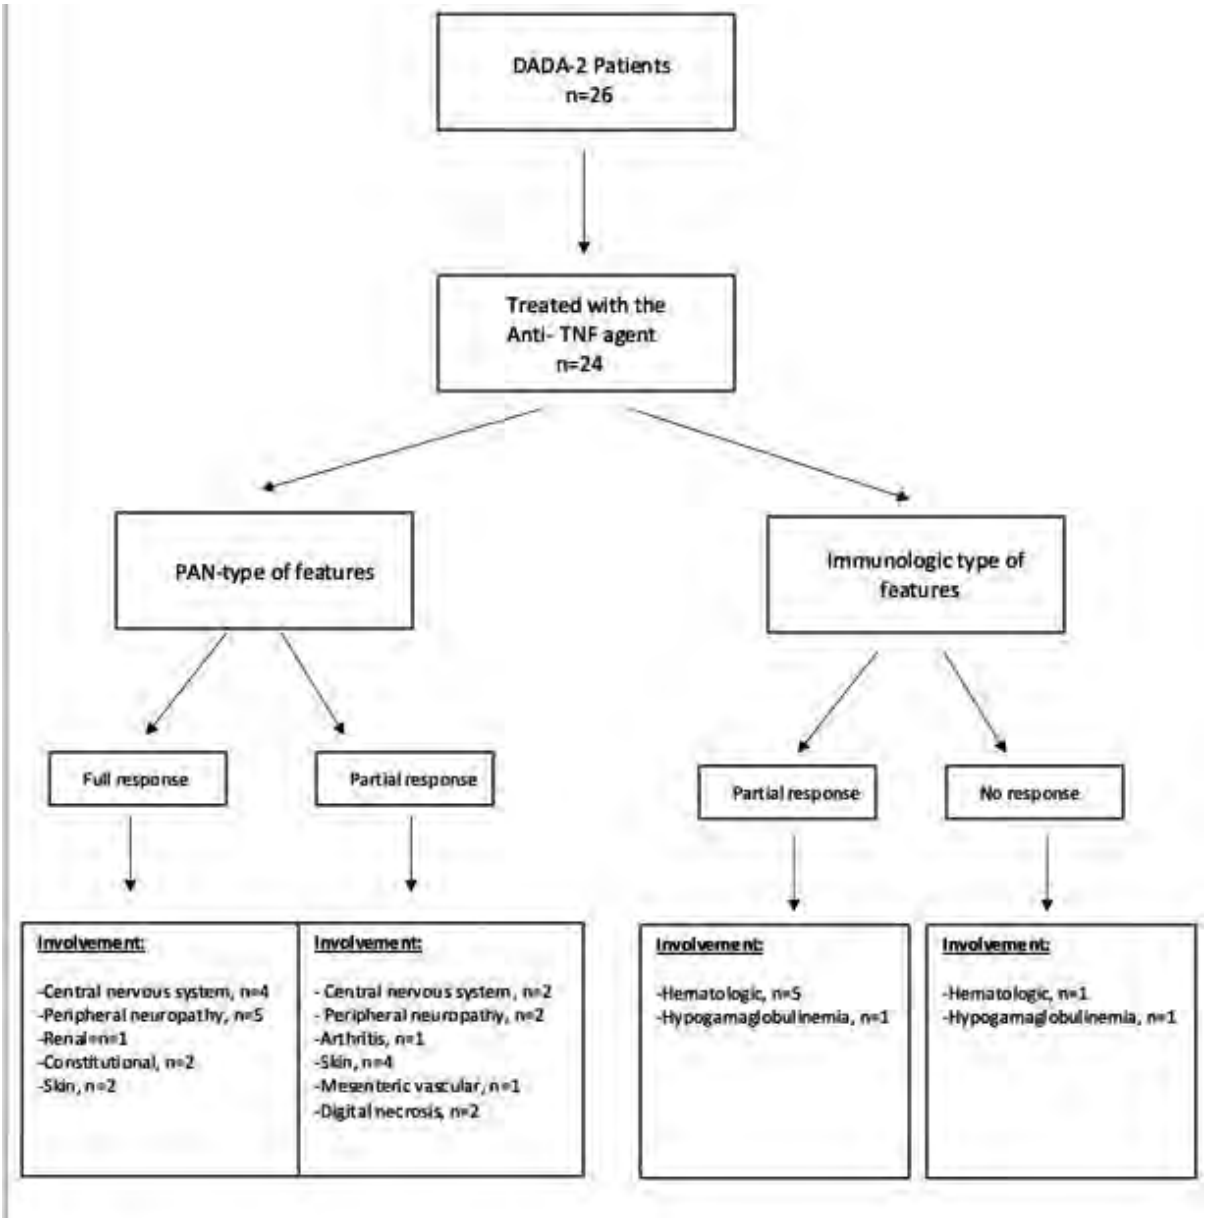
Anti-TNF: Anti-Tumor necrosis factor; ETN: Etanercept: ADA: Adalimumab
*Anti-TNF agent was stopped because of dilated cardiomyopathy



Flowchart of the patient outcomes.

months of follow-up, anti-TNF agents (Etanercept, n=22; Adalimumab, n= 2) were prescribed to 24 of the patients. Throughout median (IQR) 36 (11.5-64) months of follow-up on anti-TNF treatment, none of the patients with hematologic involvement (n=6) showed a full response. Overall, 9 (37.5%) of the patients showed a full response. Patients with full response had received anti-TNF agents for predominant nervous system involvement (central, n=4; peripheral, n=5), renal involvement (n=1), constitutional symptoms (n=2), or skin involvement (n=2).

Regarding the patients with partial responses (50%), the predominant manifestations were: nervous system involvement (central, n=2; peripheral, n=2), renal involvement (n=1), skin involvement (n=4), digital necrosis (n=2), mesenteric vascular involvement (n=1), arthritis (n=1), hematologic involvement (n=5) and hypogammaglobulinemia (n=1) (Figure).

Two of three deceased patients were on TNFi: One patient with hematologic involvement had no response to anti-TNF and the patient died after bone marrow transplantation. The other patient died after 3 months of treatment in 2015. In one patient Anti-TNF agent was discontinued because of cardiomyopathy (Table-2).

Conclusion: Anti-TNF treatment enables full recovery for the vasculitic and inflammatory lesions (including neurologic involvement) in 40% of the patients and partial response in the others. However, we once again confirm that hematologic involvement does not have a satisfactory response to anti-TNF; bone marrow transplantation or new modalities of treatment are indicated for this group of patients

SESSION INFORMATION

Session Date: Tuesday, November 9, 2021

Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster II (1862–1888)

Session Type: Poster Session D

Session Time: 8:30AM–10:30AM

Background/Purpose: Neurobehçet's disease (NBD) is a severe complication of Behcet's disease (BD). Despite well-established therapies, with glucocorticoids and conventional immunosuppressants (cIS) a significant proportion of patients are refractory. The aim of this study is to assess efficacy and safety of biologic therapy (BT) in NBD refractory to glucocorticoids and at least one cIS.

Methods: Open-label multicenter study of refractory NBD from 22 different referral Spanish Hospitals. The main outcome variables were safety and clinical response measured at baseline, 6, 12 and 24 months. Other outcome variables were improvement in analytical parameters and corticosteroid-sparing effect of biological therapy.

Table. Underlying neurologic manifestation of 41 patients with refractory neurobehçet's disease treated with biologic therapy

Parenchymal subtype, n (%)	**34 (81.0)**
- Hemiparesis	8 (19.0)
- Polineuropathy	8 (19.0)
- Encephalopathy	6 (14.3)
- Cognitive impairments	4 (9.5)
- Optic neuropathy	4 (9.5)
- Ophtalmoparesis	4 (9.5)
- Other cranial nerve involvement	3 (7.1)
- Hemihypoesthesia	3 (7.1)
- Cerebellar dysarthria	1 (2.4)
- Cerebellar involvement	1 (2.4)
- Non-esteroidal psicosis	1 (2.4)
Non-parenchymal subtype, n (%)	**17 (40.5)**
- Aseptic meningitis	12(28.6)
- Thrombosis	4 (9.5)
- Intracranial hypertension	1 (2.4)

Results: We studied 42 patients (21 women/21 men; mean age 40.4±10.8 years). HLA B51 was positive in 15 (40.5%) out of 37 patients tested. Non-neurological manifestations were oral ulcers (n=41, 97.6%), genital ulcers (n=31, 73.8%), skin lesions (n=28, 66.7%), arthralgia (n=27, 64.3%), uveitis (n=21, 50.0%), arthritis (n=9, 21.4%), venous thrombosis (n=9, 21.4%) and arterial thrombosis (n=4, 9.5%). The underlying neurologic manifestation were parenchymal (n=34, 81 %) and non-parenchymal (n=17, 40.5%) involvement **(TABLE)**. The first BT used was infliximab (n=20), adalimumab (n=13), golimumab (n=3), tocilizumab (n=3) and etanercept (n=2).

After 58.2±51.4 months since initiation of BT, neurological response was complete (n=27; 64.3%), or partial (11, 26.1%). Only 4 (9.5%) patients did not respond **(FIGURE)**. After 6 months of BT, ESR improved from.31.5±25.6 to 15.3±11.9 mg/L (p=0.005) and CRP from 1.4 [0.2-12.8] to 0.3 [0.1-3] mg/L (p= 0.002). Likewise, a decrease in oral prednisone dose was also achieved from 45.6±17.3 mg/day at baseline to 5.17±2.85 mg/day after 24 months (p< 0.0001).

Primary failure was observed in 16 (38.1%) patients due to inefficacy (n=11, 68.8%) or adverse effects (n=5, 31.3%). Similarly, secondary failure was detected in 6 (14.3%) patients due to inefficacy (n=5, 83.3%) or adverse effects (n=1, 16.7%). No serious adverse effects were observed.

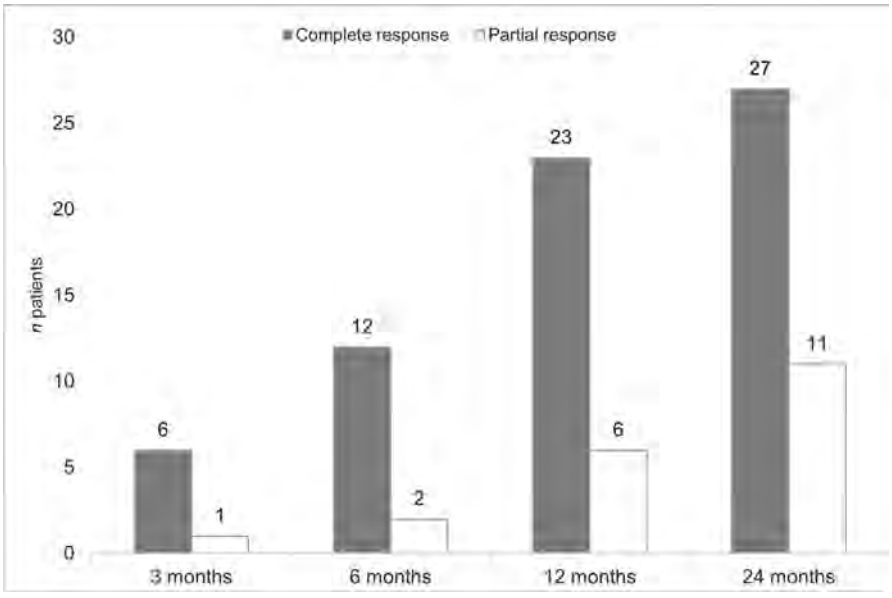

Figure. Neurological response after initiation of biological therapy.

Conclusion: BT, especially monoclonal anti-TNF drugs, seems effective and safe in patients with refractory NBD.

Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster II (1862–1888)

Session Type: Poster Session D

Session Time: 8:30AM–10:30AM

Background/Purpose: Previous studies using computer-driven methods have identified subsets of patients with Takayasu's arteritis based on angiographic patterns of disease. These subsets were consistent between independent cohorts in North America and India, however, the prevalence of each subset differed between continent. The objective of this current study was to validate in an independent cohort from Turkey angiographic patterns of disease in Takayasu's arteritis and determine if the prevalence of these patterns is more similar to cohorts from India, North America, or neither.

Methods: Angiograph data were derived from records of patients with Takayasu's arteritis from 12 tertiary rheumatology centers in Turkey. All patients underwent whole-body angiography of the aorta and branch vessels, with cat-

Table 1. Arterial distribution in clusters for a Turkish cohort of patients with Takayasu's arteritis. A heatmap of arterial distribution, where the darker the red indicates that more patients within that cluster had involvement of the territory. Displayed in each cell is the number and percent of patients in the cluster that had involvement of the territory

	Cluster One n = 90	Cluster Two n = 148	Cluster Three n = 183
Ascending aorta	18 (20%)	39 (26%)	32 (17%)
Aortic arch	14 (16%)	18 (12%)	24 (13%)
Thoracic aorta	29 (32%)	40 (27%)	35 (19%)
Abdominal aorta	44 (49%)	30 (20%)	51 (28%)
Left subclavian	63 (70%)	107 (72%)	112 (61%)
Right subclavian	34 (38%)	104 (70%)	45 (25%)
Innominate	5 (6%)	38 (26%)	14 (8%)
Left axillary	8 (9%)	18 (12%)	19 (10%)
Right axillary	6 (7%)	19 (13%)	12 (7%)
Left carotid	43 (48%)	129 (87%)	50 (27%)
Right carotid	33 (37%)	125 (84%)	9 (5%)
Left vertebral	17 (19%)	14 (09%)	19 (10%)
Right vertebral	10 (11%)	16 (11%)	6 (3%)
Left renal	77 (86%)	7 (5%)	9 (5%)
Right renal	67 (74%)	8 (5%)	10 (5%)
Mesenteric	65 (72%)	26 (18%)	31 (17%)
Left iliac	9 (10%)	4 (3%)	11 (6%)
Right iliac	10 (11%)	3 (2%)	13 (7%)
Left femoral	3 (3%)	2 (1%)	0 (0%)
Right femoral	0 (0%)	3 (2%)	2 (1%)

egorization of involvement (stenosis, occlusion, or aneurysm) in 13 arterial territories. K-means cluster analysis was performed to identify subgroups of patients based on pattern of angiographic involvement.

Results: Data from 421 patients in the cohort in Turkey were available for analysis. Using K-means clustering, three distinct clusters were identified for the Turkish cohort; these three clusters were identical to those previously identified in the Indian and North American cohorts (**Table 1**). Patients in Cluster 1 have significantly more disease in the abdominal aorta, renal, and mesenteric arteries ($p < 0.01$). Patients in Cluster 2 have significantly more bilateral disease in the carotid and subclavian arteries ($p < 0.01$). Compared to patients in Clusters 1 and 2, patients in Cluster 3 have asymmetric disease with fewer involved territories ($p < 0.01$).

The prevalence in each of the three clusters for patients from Turkey (current analysis) compared to the prevalences for patients from India and North America (previously published data) is outlined in **Table 2**. The distribution of pa-

Table 2. Distribution of patients with Takayasu's arteritis in angiographically-defined clusters among patients in India, North America, and Turkey

	India (n = 581)	North America (n = 225)	Turkey[1,2] (n = 421)
Cluster One	236 (40.6%)	53 (23.6%)	90 (21.4%)
Cluster Two	159 (27.4%)	79 (35.1%)	148 (35.2%)
Cluster Three	186 (32.0%)	93 (41.3%)	183 (43.5%)

[1]$p < 0.01$ vs. India; [2]$p = 0.79$ vs. North America; displayed in each cell is the number and percent of patients in each cohort that are assigned to each cluster

tients among the three clusters was quite similar among patients from Turkey and North America (p = 0.79), but these two cohorts differed in this respect from patients from India.

Conclusion: This study provides strong, independent confirmation that there are distinct subsets of Takayasu's arteritis based on angiographic disease. These patterns are consistent between continents; however, the prevalence of each pattern differs. Genetic and/or environmental factors may contribute to patterns of angiographic disease in patients with Takayasu's arteritis.

Evidence-Based Behçet's Disease Activity Scale (EBDA) – A New Instrument with Improved Acuity for Major Organ Disease Activity and Remission Depth Assessment

Maria Caterina Lagdameo[1], Hyungrok Do[2] and **Johannes Nowatzky**[1], [1]Division of Rheumatology, New York University School of Medicine, New York, NY, [2]Department of Population Health, NYU School of Medicine, New York

SESSION INFORMATION
Session Date: Tuesday, November 9, 2021
Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster II (1862–1888)
Session Type: Poster Session D
Session Time: 8:30AM–10:30AM

Background/Purpose: Most current Behçet's disease (BD) activity assessment tools are strongly based on patient-reported symptoms and findings allowing a wide range of observer-dependent interpretations and do not always differentially weigh organ-threatening vs non-organ-threatening disease activity or degrees of remission depth. Here we aimed to develop and test a BD-specific disease activity instrument that is focused to a high extent on objective findings, dissects the impact of organ-threatening from non-organ-threatening disease, and classifies remission depth.

Methods: We generated an instrument that requires the verification of reported symptoms through findings on physical exam and diagnostic studies and incorporates results of screening and follow-up studies in four minor system categories, including "mucosal", "cutaneous", "cutaneous pathergy", "articular", and four major system categories, including "ocular", "vascular", "CNS", "GI". Evidence of one or more phenotypically eligible findings in any category triggered scoring with major categories receiving a 3-fold weighed score over minor ones. EBDA and Behçet's Disease Current Activity Form (BDCAF, the current standard) scoring was applied to 59 BD patient encounters compris-

ing a wide range of degrees of BD severity and prototypical manifestations. Scores were analyzed using Pearson's, Spearman's, Kendall's correlation coefficients, and Lin's concordance correction.

Results: There was moderate positive correlation between EBDA and BDCAF across all scores (Pearson's 0.5817, $p< 0.0001$; Kendall's 0.5568, Spearman's 0.6328, $p< 0.000001$) without a linear relationship (Lin's 0.1019, 99.9% confidence). On analysis of categorized scores for lower (EBDA < 12, which excludes major organ involvement) vs higher activity (EBDA ≥ 12, which includes major organ involvement) there was evidence for moderate positive correlation with BDCAF for lower (Kendall's 0.4123, $p< 0.001$; Spearman's 0.4031, $p< 0.01$), but not for higher activity scores (Kendall's 0.2965, p=0.2546; Spearman's 0.3045, p=0.2698). BDCAF appeared to underestimate organ-threatening (mostly ocular and major vascular) disease in >70% and missed it completely in 13% of cases.

Conclusion: EBDA is a new instrument for the finding-based assessment of BD activity which may exhibit improved performance in moderate-severe and severe, potentially organ-threatening BD. In addition, the instrument allows estimates of disease remission depth. Given its strong focus on objectively verifiable findings directly relevant to the time point of assessment, EBDA may be especially suitable in research-intense settings such as for the classification of study subjects for analysis of presumably disease activity-dependent molecular or cellular responses and immune phenotypes.

Usefulness of 2019 ACR/EULAR Classification Criteria (AECC) for IgG4-Related Disease Differs Between Clinical Phenotypes of IgG4-RD

Gözde Kübra Yardımcı[1], Bayram Farisogulları[2], Gizem Ayan[1], Levent Kilic[1], Sule Apraş Bilgen[1] and **Omer Karadag**[3], [1]Hacettepe University, Faculty of Medicine, Department of Internal Medicine, Division of Rheumatology, Ankara, Turkey, [2]Division of Rheumatology, Department of Internal Medicine Faculty of Medicine, Hacettepe University, Ankara, Turkey, [3]Hacettepe University, Division of Rheumatology, Department of Internal Medicine, Faculty of Medicine, Ankara, Turkey

SESSION INFORMATION
Session Date: Tuesday, November 9, 2021
Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster II (1862–1888)
Session Type: Poster Session D
Session Time: 8:30AM–10:30AM

Background/Purpose: ACR/EULAR Classification criteria for IgG4-related disease (IgG4-RD) newly published [1]. On the other hand, four distinctive phenotypes of IgG4-RD have been described [2]. We aimed to identify clinical phenotypes of IgG4-RD and the evaluate usefulness of 2019 ACR/EULAR classification criteria (AECC) for clinical phenotypes in our cohort.

Methods: In the prospective database of the Hacettepe University Vasculitis Research Centre (HUVAC) 92 IgG4-RD patients meeting the 2011 comprehensive diagnostic criteria for IgG4-RD were registered by the end of the May 2021. We reviewed the medical records and determined the following clinical factors: Age, gender, serum levels of IgG4, presence of ANCA or other specific autoantibodies, histopathologies with immunostaining (if available) and distributions of organ involvement. An AECC score was calculated for all cohort.

Table. Clinical Phenotypes of IgG4-related disease

	Retroperitoneal and aorta (n=37)	Head and neck (n=22)	Mikulicz and systemic (n=15)	Pancreato-hepato-biliary (n=10)	Undefined phenotype (n=8)	P value
Sex, male, n (%)	67.6	31.8	46.7	50.0	37.5	0.091
Age, median (IQR) (years)	60 (50-67)	56 (33-66)	61 (31-69)	48 (41-70)	45 (32-55)	0.129
IgG4 level, median (IQR) (mg/dl)	202 (132-370)	119 (61-299)	335 (66-660)	210 (86-625)	144 (77-264)	0.628
AECC points, median (IQR)	23 (12-31)	18 (15-25)	23 (19-36)	24 (8-29)	15 (4-20)	0.037*
2019 AECC, n (%)	57	45	73	60	25	0.474

Results: We included 92 patients (M/F:47/45) with IgG4-RD. 61% of the patients had multiorgan involvement, median (IQR) organ involvement was 2 (1-3) and median (IQR) IgG4 level was 179 mg/dL (89-368). Majority of the patients had retroperitoneal fibrosis/periaortitis (Table). Retroperitoneal and aorta (RPF-Aortitis) accounted for 40% of the phenotypes, followed by head and neck (24%), Mikulicz and systemic (16%), and pancreato-hepato-biliary (PHB) (11%). Nine per cent had an undefined phenotype. Head and neck group had female predominance whereas RPF/aortitis group had male predominance. Mikulicz and systemic group had the highest IgG4 levels.

All of the patients fulfilled the entry criteria for AECC for IgG4-RD. Of the 42 false-negative cases, 7 met one exclusion criteria whereas 35 did not achieve sufficient inclusion criteria scores. 49 (53%) patients got a score ≥20 points, with a mean score of 29.3 points (SD.7.3). MS, PHB and RPF/Aortitis phenotypes met 2019 AECC at a higher rate, although the differences were not statistically significant.

Conclusion: Phenotype results of our cohort are concordant with Asian and American cohorts. RPF-Aortitis phenotype was more prevalent, while PHB and MS were less frequent. The 2019 AECC was met over half of the patients.

Arthritogenic T Cells Harbor a Transcriptional Program of T Cell Activation and a Repertoire Pruned by Endogenous Superantigen

JUDITH F ASHOURI, Elizabeth McCarthy, Steven Yu, Noah Perlmutter, Charles Lin, Chun Jimmie Yu and Arthur Weiss, University of California San Francisco, San Francisco, CA

SESSION INFORMATION
Session Date: Tuesday, November 9, 2021
Session Title: Abstracts: RA – Animal Models (1889–1892)
Session Type: Abstract Session
Session Time: 9:00AM–10:00AM

Background/Purpose: It is widely accepted that activation of specific CD4 T cells through their TCRs by self-antigen (Ag) is necessary for rheumatoid arthritis (RA) onset. Yet, the transcriptional profiles and TCR identities of the disease-causing pathogenic CD4 T cells remain unknown. SKG is an ideal platform to study questions relevant to RA since this model not only captures many of the important features of human RA, but also recapitulates the paradoxical ability of CD4 T cells to differentiate into pathogenic effector cells despite their impaired response to TCR engage-

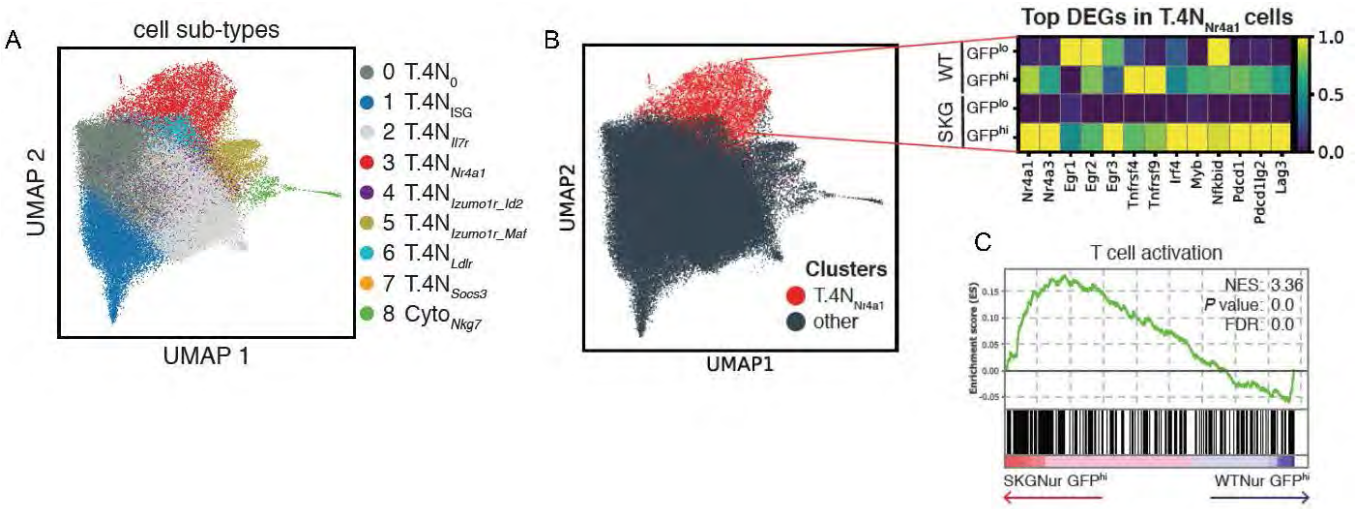

Figure 1. Arthritogenic SKG T cells upregulate a transcriptional TCR signaling program. (A) UMAP of 99,074 naïve T cells derived from 8 samples (2 replicates from each WT and SKG GFPlo and GFPhi subset); cells colored according to annotated leiden clusters. (B) Heatmap shows average expression of top DEGs (abs value(log2(FC)) > 2.8, adj P value < 0.05) of cells in T.4N_Nr4a1 (Nr4a1 high) cluster vs other cells by subgroup normalized by standard scale by column. (C) Enrichment plot of T cell activation pathway from GSEA analysis for ranked genes in T.4N_Nr4a1 cells from SKG GFPhi v. WT GFPhi differential expression analysis. FDR, false discovery rate. NES, normalized enrichment score.

ment. We combined SKG mice with a fluorescent reporter tethered to the regulatory region of *Nr4a1* (Nur77—which is rapidly and selectively upregulated in response to Ag, but not inflammatory stimuli) to read out the relative strength of TCR signaling (termed by us SKGNur mice). Using these mice we previously identified a CD4 T cell subpopulation that is greatly enriched for their arthritogenic potential (in the GFP^{hi} fraction). In this study, we examine the T cell repertoire and signaling networks invoked by endogenous Ag encounter in pre-arthritogenic T cells to study the evolution of autoimmune arthritis.

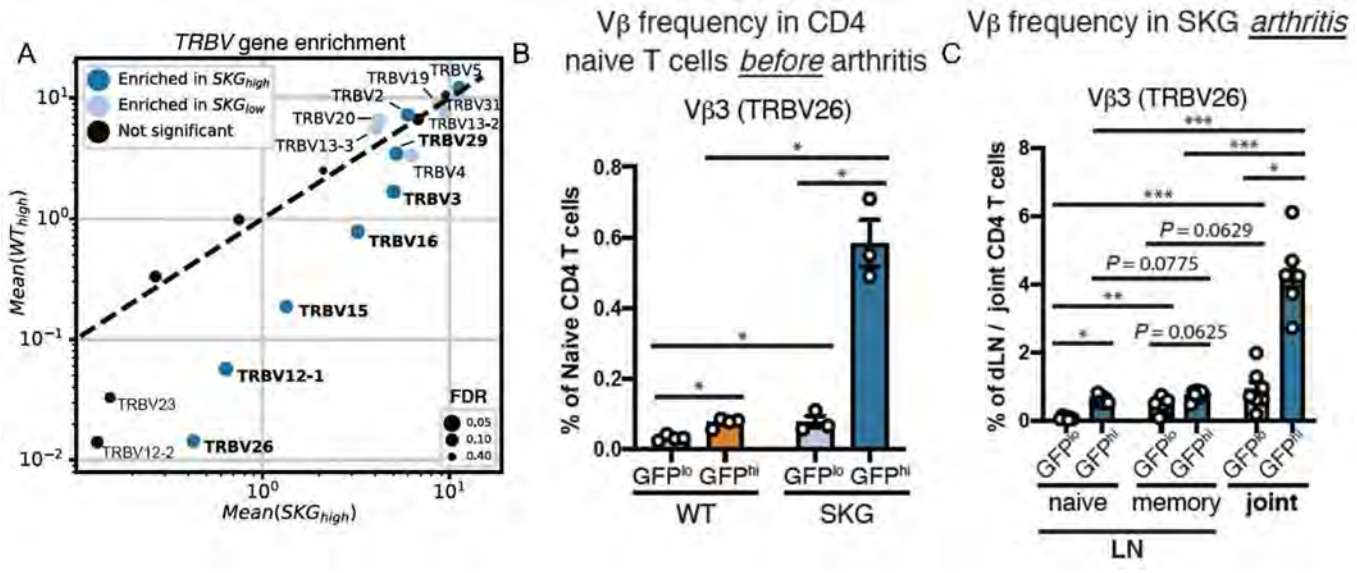

Figure 2. SKG T cells harbor a biased TCR Vb repertoire likely pruned by endogenous superantigen(s). (A) Scatterplot of mean frequency of cells expressing each TCR variable beta gene (TRBV) gene for SKGNur vs WTNur GFPhi. Dots for each TRBV gene are sized according to FDR from one-sided paired t-test comparing frequency in SKG GFPhi vs SKG GFPlo. Dots colored as either significantly enriched (FDR < 0.1) in SKG GFPhi (dark blue), SKG GFPlo (light blue), or not significantly enriched in either subgroup (black). Labels for TRBV genes significantly enriched in SKG GFPhi and more highly expressed in SKG GFPhi vs WT GFPhi samples are bolded. (B-C) Mean frequency (± SEM) of indicated CD4 T cell subset with TCR Vb3 protein usage determined by flow cytometry in GFPlo and GFPhi T cells from lymph nodes (LN) prior to arthritis induction (B) or LN and joints 2.5 weeks after arthritis (C), repeated > 2 times.

Methods: We used bulk and paired single-cell RNA and TCR-sequencing (scRNAseq and TCRseq) to simultaneously profile the transcriptome and TCR repertoire of self-reactive pathogenic T cells before arthritis onset in SKGNur mice. Analysis was performed on sorted naïve SKG and BALB/c (WT) CD4 T cells based on their Nur77-eGFP levels (GFP^{hi} and GFP^{lo}) using Q^2 Solutions and the 5' 10X platform respectively. After filtering of the latter, there were 99,074 cells with a mean of 12,384 cells per condition. We examined our datasets for differentially expressed genes (DEG) and TCR variable genes enriched in the arthritogenic SKGNur GFP^{hi} T cells. Flow cytometry was used to validate genes that were found to be up or down-regulated in arthritogenic T cells.

Results: In our bulk RNAseq dataset >990 DEGs were identified and clustered into 6 gene modules that capture the transcriptional differences between the SKGNur and WTNur GFP^{hi} and GFP^{lo} subgroups. Gene set enrichment analysis revealed a T cell activation signature in the naïve SKGNur GFP^{hi} CD4 T cells. Our scRNAseq dataset revealed significant heterogeneity within the unperturbed naïve CD4 T cell compartment with 8 distinct clusters further refining our bulk RNAseq results. We found that T cells expressing the highest levels of *Nr4a1 (red cluster in* **Fig 1***)* upregulate TCR signaling gene modules, which are enhanced in SKG mice despite their hypomorphic mutation in ZAP70, a tyrosine kinase critical for proximal TCR signaling. In simultaneous investigation of their TCR sequences, we uncovered a previously unknown biased TCR Vb usage in the SKG repertoire (**Fig 2**, DNS). The Vb genes whose expression is uniquely enriched in the SKGNur GFP^{hi} subset are well known to recognize endogenous mouse mammary tumor virus superantigen. We detect still further enrichment of these Vb's in the SKG arthritic joint (**Fig 2,** DNS).

Conclusion: Our results suggest both transcriptional activation and repertoire selection driven by endogenous viral superantigen(s) act as inter-related mechanisms that prime arthritogenic SKG T cells prior to disease onset.

Cellular Origin and Functions of Osteoclasts in Inflammatory Arthritis

Hannah Nelson[1], Ellen Gravallese[2], Julia Charles[1] and **Christian Jacome-Galarza**[1], [1]Brigham and Women's Hospital, Harvard Medical School, Boston, MA, [2]Brigham and Women's Hospital, Harvard Medical School, Chestnut Hill, MA

SESSION INFORMATION
Session Date: Tuesday, November 9, 2021
Session Title: Abstracts: RA – Animal Models (1889–1892)
Session Type: Abstract Session
Session Time: 9:00AM–10:00AM

Background/Purpose: Inflammatory arthritis (IA) is an autoimmune disease targeting multiple joints and characterized by joint destruction caused by osteoclasts (OC), leading to physical disability. However, the precise cellular origins of OC are poorly understood. Myeloid lineage cells including OC and macrophages can derive from either hematopoietic stem cells (HSC) or erythro-myeloid progenitors (EMP). Previous studies *in vitro* suggest that in IA, HSC-derived monocytes differentiate into OC and others showed that macrophages can fuse to form OC under the influence of inflammatory cytokines. We hypothesized that in IA, embryonically derived Erythro-Myeloid Progenitor macrophages and Hematopoietic Stem Cell-derived progenitors can independently contribute to the formation of OC in vivo. These cell lineage tracing systems will allow to discriminate among distinct OC populations by their cell surface phenotype and selectively target them for therapeutic purpose.

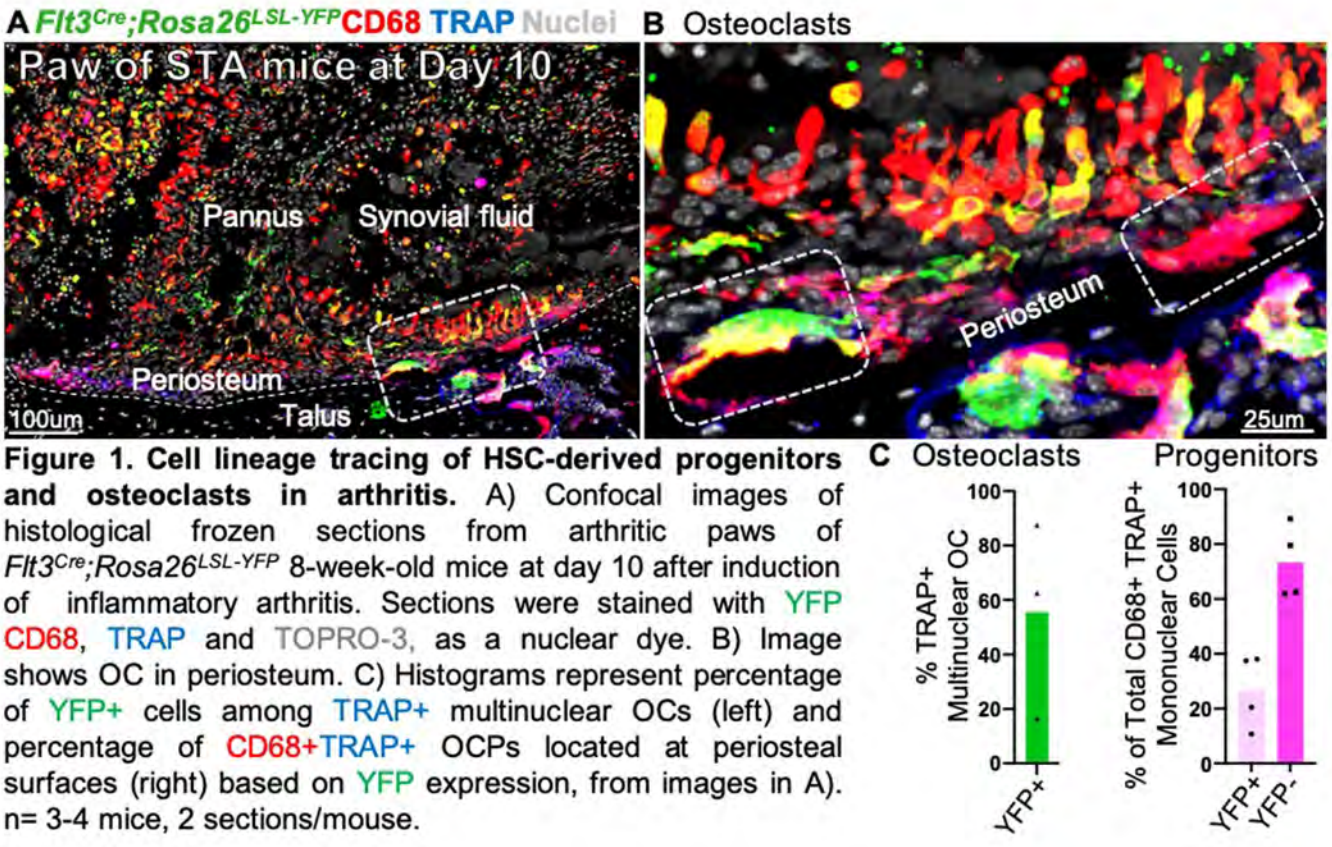

Figure 1. Cell lineage tracing of HSC-derived progenitors and osteoclasts in arthritis. A) Confocal images of histological frozen sections from arthritic paws of *Flt3*^{Cre}*;Rosa26*$^{LSL\text{-}YFP}$ 8-week-old mice at day 10 after induction of inflammatory arthritis. Sections were stained with YFP CD68, TRAP and TOPRO-3, as a nuclear dye. B) Image shows OC in periosteum. C) Histograms represent percentage of YFP+ cells among TRAP+ multinuclear OCs (left) and percentage of CD68+TRAP+ OCPs located at periosteal surfaces (right) based on YFP expression, from images in A). n= 3-4 mice, 2 sections/mouse.

Methods: To test this hypothesis, we used bone frozen sections and immunofluorescence, as well as flow cytometry (FACS) from cell lineage tracing systems, to discriminate among these progenitors. We used *Flt3*^{Cre}*;Rosa26*$^{LSL\text{-}YFP}$ mice to label HSC and their progeny and both *Csf1r*$^{Mer\text{-}iCre\text{-}Mer}$*;Rosa26*$^{LSL\text{-}tdTomato}$ and *Cx*$_3$*cr*$_1^{CreERT2}$*;Rosa26*$^{LSL\text{-}tdTomato}$ mice, pulsed with 4-hydroxytamoxifen at E8.5 and E9.75 respectively, to label EMP-derived progenitors.

Results: Histology of ankle joints from healthy *Flt3*^{Cre}*;Rosa26*$^{LSL\text{-}YFP}$ embryos at E16.5, newborn at P0 and 8 week-old mice showed that ~7 % of synovial F4/80+ or CD68+ cells were of HSC origin, suggesting that EMPs are the major source of synovial macrophages. We confirmed, using both *Csf1r*$^{Mer\text{-}iCre\text{-}Mer}$*;Rosa26*$^{LSL\text{-}tdTomato}$ and *Cx*$_3$*cr*$_1^{CreERT2}$*;Rosa26*$^{LSL\text{-}tdTomato}$ mice, that ~40% of all F4/80+ synovial macrophages were TdTomato+, showing for the first time an EMP-origin. To test the HSC origin of OC in IA, adult *Flt3*^{Cre}*;Rosa26*$^{LSL\text{-}YFP}$ mice were treated with K/BxN arthritogenic serum and ankle joints were harvested at day 10 (peak inflammation). Unexpectedly, we found that only 56% of OC were YFP-positive, indicating that a large proportion of synovial OC are not HSC-derived. Further, we identified CD68+TRAP+ cells localized to periosteal surfaces as candidate progenitors of synovial OC. Consistent with the dual origin of synovial OC, CD68+TRAP+ progenitors derive from both HSC (27%) and non-HSC (73%) lineages.

Conclusion: These data suggest that both HSC-derived and EMOP-derived osteoclast precursor cells independently contribute to OC formation in IA. These cell lineage tracing systems will help us to identify unique differences among OC of distinct origins. These differences will allow for differential targeting of OC via unique cell surface markers and for the development of new targets to inhibit OC formation and prevent bone and cartilage erosions in IA.

Variable Effects of Testosterone on Male versus Female Derived Macrophages in Inflammatory Arthritis

Kiana Chen[1], Xi Lin[1], Lianping Xing[2], H. Mark Kenney[3], Richard Bell[4], Edward Schwarz[5] and Homaira Rahimi[5], [1]University of Rochester School of Medicine and Dentistry, Rochester, NY, [2]University of Rochester Medical Center, Webster, NY, [3]University of Rochester Medical Center, Rochester, NY, [4]Hospital for Special Surgery, New York, NY, [5]University of Rochester, Rochester, NY

SESSION INFORMATION
Session Date: Tuesday, November 9, 2021
Session Title: Abstracts: RA – Animal Models (1889–1892)
Session Type: Abstract Session
Session Time: 9:00AM–10:00AM

Background/Purpose: Rheumatoid arthritis (RA) is a chronic inflammatory joint disease that is female predominant. The TNF-transgenic (TNF-Tg) mouse model of RA also develops a sexually dimorphic inflammatory arthritis with earlier disease appearing in female mice (1). While the mechanism of the sexual dimorphism is unknown, studies suggest androgens can provide a protective effect against inflammatory disease progression (2,3). We hypothesize that androgens' anti-inflammatory effects on myeloid cells in the joint may mediate inflammatory arthritis progression.

Methods: Orchiectomy and sham control procedures were performed on 4-week old male TNF-Tg mice (n=3 mice/group). Mice were sacrificed at 3-months old for serum and tissue collection. Testosterone and TNFα levels were compared between groups, and knee joints sections were H&E and TRAP stained for histological scoring. Bone marrow-derived macrophages (BMDMs), plated from 3-month old male and female TNF-Tg mice (n=3 mice/group), were treated with 0.1μM, 0.5μM, and 1μM of testosterone propionate (T), followed by murine IFNɣ and LPS stimulation. After 48 hours, supernatant was assayed in an ELISA for murine TNFα. Groups were analyzed using unpaired t-tests for orchiectomy studies and two-way ANOVA for in vitro studies. Values are reported as the mean ± standard deviation.

Results: Orchiectomized (Orch) mice joints had significantly higher (i.e. worse) histology scores than sham controls for synovial inflammatory infiltrate, pannus invasion, and TRAP+ area (2 Orch vs 1 Sham, 1.6 Orch vs 0.7 Sham, 1.4 Orch vs 0.3 Sham, $p< 0.05$). Orchiectomized TNF-Tg mice were confirmed to have low testosterone levels (0.078 ng/mL (0.054-0.12) ng/mL, normal=1.3 ± 0.4 ng/mL). Serum human (h) and mouse (m)TNFα levels remained unchanged between orchiectomized and sham TNF-Tg mice (827 pg/mL, range 271-1400 pg/mL Orch vs 841 pg/mL, range 613-1011 pg/mL Sham hTNF and 8.5 pg/mL, range 7-10 pg/mL Orch vs 8.8 pg/mL, range 8-9.8 pg/mL Sham mTNF). Male derived BMDMs did not have a significant change in TNFα expression when treated with T at any concentration compared to untreated cells (74.84 ± 101.9 pg/mL T 0.1μM, 107.1 ± 97.05 pg/mL T 0.5μM, 71.92 ± 64.55 pg/mL T 1μM vs 73.56 ± 72.48 pg/mL Untreated, $p >0.05$). Remarkably, female derived BMDMs had increased TNFα expression at a concentration of 0.1μM compared to untreated cells (544.06 ± 363.6 pg/mL T 0.1μM vs. 21.50 ± 22.48 pg/mL Untreated, $p< 0.01$) (Fig 1).

Conclusion: Here we show that reduced levels of testosterone from orchiectomies is associated with increased synovial inflammation in TNF-Tg males, yet does not affect systemic TNFα levels. In vitro studies of BMDMs indicate that macrophages from TNF-Tg mice have sex and testosterone concentration specific release of TNFα, suggesting a sexual dimorphism at the cellular level. Further trials of in vivo and in vitro T administration to both sexes is necessary to clarify local versus systemic immune responses in TNF-Tg mice.

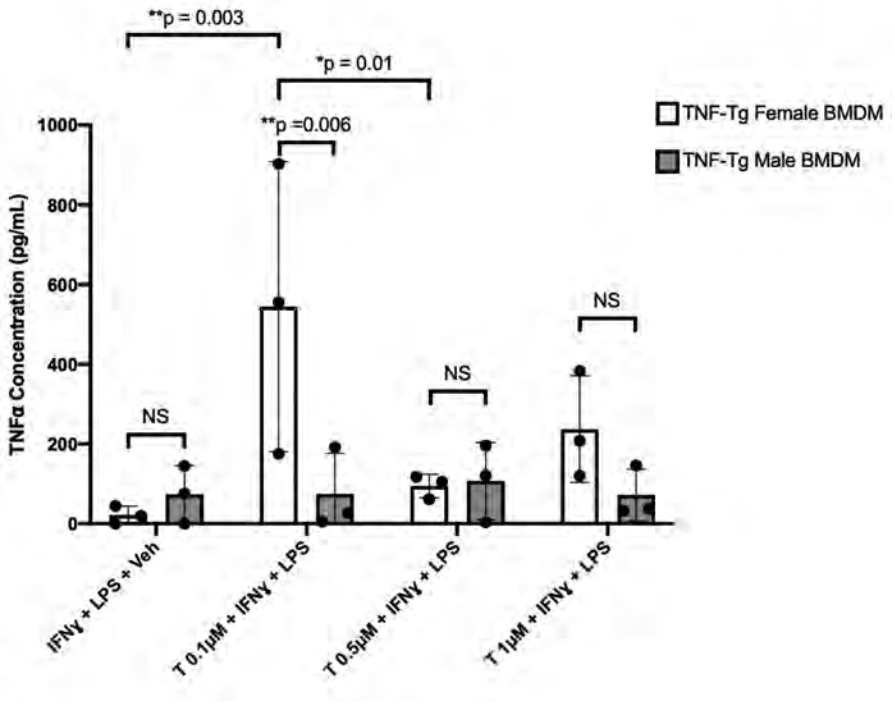

Figure 1. Female versus male TNF-Tg murine TNFα concentrations of stimulated bone marrow derived (BMDM) treated with testosterone propionate (T). TNF-Tg BMDMs from 3-month-old females (n = 3) and males (n = 3) were plated and treated with a T concentration of 0.1μM, 0.5μM, or 1μM or vehicle as control. BMDMs were then stimulated with 50ng/mL of murine IFNɣ and 50ng/mL of LPS. Murine TNFα ELISA of supernatant revealed a significant increase in TNFα concentration in the female derived T 0.1μM-treated cells compared to female vehicle control cells and compared to male derived treated cells. Male derived treated cells did not have a significant change in TNFα concentration compared to the vehicle control cells. NS = not significant (p>0.05).

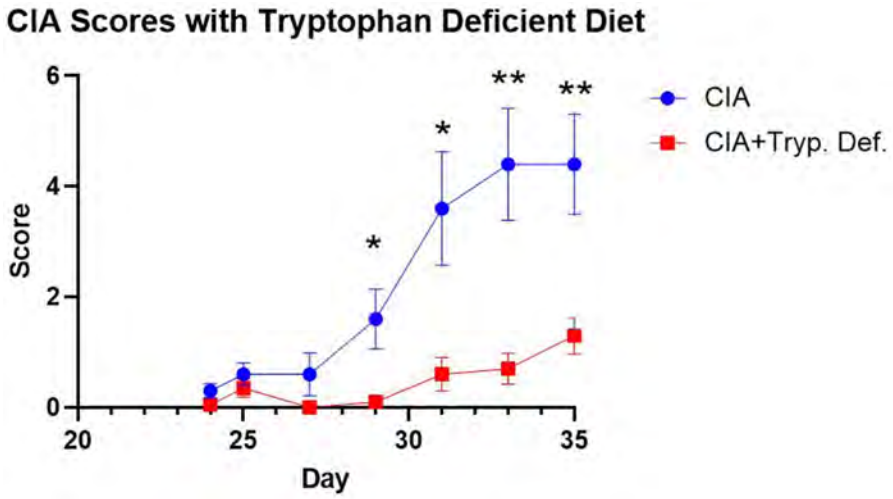
Promotion of Autoimmune Arthritis via Tryptophan Metabolism and Production of the Bacterial-Derived Tryptophan Metabolite Indole

Brandon Trent[1], Meagan Chriswell[2], Widian Jubair[1] and Kristine Kuhn[1], [1]University of Colorado Anschutz Medical Campus, Aurora, CO, [2]UC Denver SOM, Denver, CO

SESSION INFORMATION
Session Date: Tuesday, November 9, 2021
Session Title: Abstracts: RA – Animal Models (1889–1892)
Session Type: Abstract Session
Session Time: 9:00AM–10:00AM

Background/Purpose: Significant changes in gut bacterial richness and diversity occur during the development of inflammatory arthritis, in both murine models and human patients; however, the mechanisms by which dysbiosis

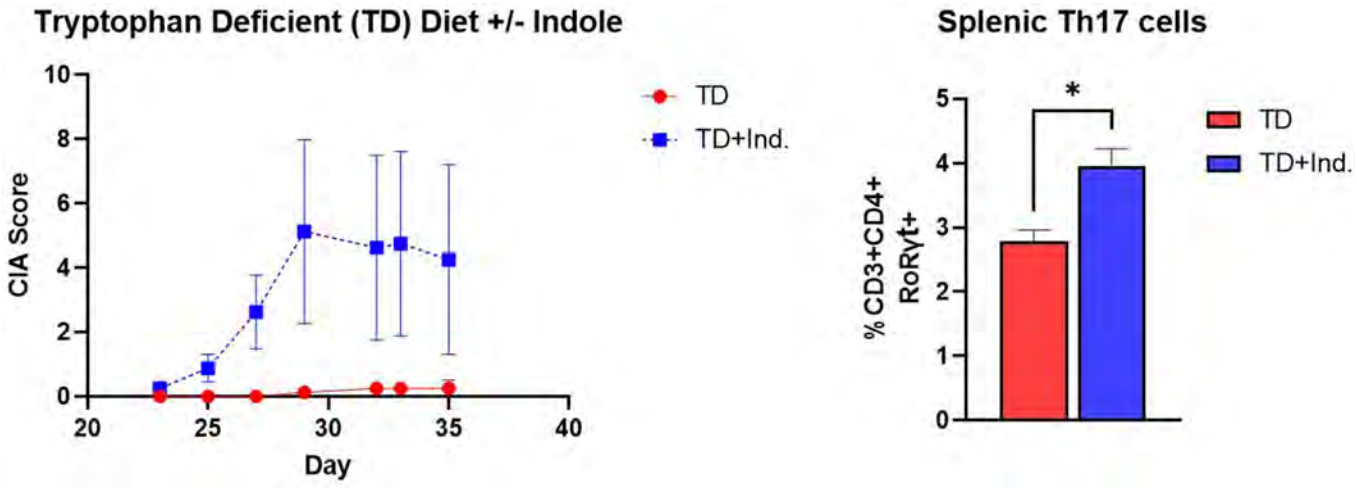


Amelioration of CIA in mice given a tryptophan deficient diet.

promotes disease pathogenesis remain unclear. Because microbiota can shape host physiology through catabolism and production of metabolites, we hypothesized that an altered microbiome during inflammatory arthritis leads to an altered metabalome, which impacts the development of autoimmune B and T cells.

Methods: Cecal metabolites were screened by LC-MS during CIA with antibiotic vs control treatment. CIA was induced by immunization of male 6–8-week-old DBA/1 mice with bovine type II collagen emulsified in complete Freund's adjuvant at days 0 and 21. To assess how the altered metabolites affected CIA, mice were provided a tryptophan deficient or control amino acid diet starting at day -1 and throughout CIA (with amino acid diet provided on the weekend to compensate weight loss). To supplement indole, 10mM of indole was provided in the drinking water or by oral gavage every other day. To perform the 4-Hydroxy-3-nitrophenylacetyl – chicken gamma globulin (NP-CGG) immunization, NP-CGG was given intraperitoneally (50µg) with 50µg alum adjuvant at days 0 and 10. Finally, to assess direct effects of indole on adaptive immune cells, splenic B cells were evaluated ex vivo after stimulation with LPS and/or anti-IgM for naïve B cells or type II collagen for memory B cell responses.

Results: Products of bacterial catabolism of dietary tryptophan were found to be significantly altered in the cecum of mice. Therefore, mice were given a tryptophan-free diet and found to have significantly decreased CIA associat-



Restoration of a CIA disease phenotype in mice administered the tryptophan bacterial metabolite, indole, during a tryptophan deficient diet.

ed with an increase in splenic regulatory T cells (Treg). One specific bacterial-derived tryptophan metabolite indole strongly correlated with CIA severity, and direct administration of indole during CIA with antibiotic treatment promoted disease and led to increases in T follicular cell (Tfh) and B cell populations in the Peyer's patches and mesenteric lymph nodes. Additionally, administration of indole to CIA mice fed a tryptophan deficient diet resulted in greater CIA incidence and splenic Th17 cell frequency. Indole administration was also found to increase splenic activated T cell (CD69+), Tfh, and plama cell numbers in an NP-CGG immunization model. Finally, *ex vivo* stimulation of B cells was conducted to understand the direct effect of indole, which resulted in significantly increased IgG production and a ≈10% increase in the frequency of CD23+ B cells.

Conclusion: Our results suggest that gut dysbiosis due to CIA results in altered tryptophan metabolism and indole production, promoting CIA pathogenesis via activation of T and B cell populations and antibody production. We hypothesize that the ability of indole to promote Th17 and plasma cell differentiation drives increased CIA development. Precise understanding of which indole metabolites are involved and how they engage cellular receptors will help elucidate the role of intestinal dysbiosis in autoimmunity.

"From Where I Stand": Using Multiple Anchors Yields Different Benchmarks for Meaningful Improvement and Worsening in the Rheumatoid Arthritis Flare Questionnaire (RA-FQ)

Susan Bartlett[1], Vivian Bykerk[2], Orit Schieir[3], Marie-France Valois[1], Louis Bessette[4], Gilles Boire[5], Glen Hazlewood[6], Carol Hitchon[7], Edward Keystone[8], Janet Pope[9], Diane Tin[10], Carter Thorne[11], Clifton Bingham[12] and CATCH Investigators[13], [1]McGill University, Montréal, QC, Canada, [2]Hospital for Special Surgery, New York, NY, [3]Canadian Early Arthritis Cohort Study, Montréal, QC, Canada, [4]Centre de l'Ostoporose et de Rhumatologie de Qubec, Québec City, QC, Canada, [5]Universite de Sherbrooke, Sherbrooke, QC, Canada, [6]University of Calgary, Calgary, AB, Canada, [7]University of Manitoba, Winnipeg, MB, Canada, [8]Keystone Consulting Enterprises Inc., Toronto, ON, Canada, [9]University of Western Ontario, London, ON, Canada, [10]The Arthritis Program Research Group, Newmarket, ON, Canada, [11]Southlake Regional Health Centre, Newmarket, ON, Canada, [12]Johns Hopkins University, Baltimore, MD, [13]Canadian Early Arthritis Cohort Investigators, Toronto, ON, Canada

SESSION INFORMATION
Session Date: Tuesday, November 9, 2021
Session Title: Abstracts: Measures & Measurement of Healthcare Quality (1893–1896)
Session Type: Abstract Session
Session Time: 10:30AM–11:30AM

Background/Purpose: The RA-FQ is a patient-reported measure of current disease activity in RA that can be used to identify disease flares. The RA-FQ queries pain, physical function, fatigue, stiffness, and participation and yields a score from 0-50. We previously reported on reliability, validity, and responsiveness. Our goal was to compare changes in the RA-FQ that represent minimal and meaningful improvement or worsening from the perspective of people living with RA, treating rheumatologists, and in relation to disease activity indices.

Methods: We used data from adults with early RA (symptoms < 1 year) enrolled in the CATCH (Canadian Early Arthritis Cohort), a prospective study of real-world patients treated across Canada. Participants completed the RA-FQ, Patient Global, and RA Global Change Impression item (a little vs. a lot better or worse or same) at 3- and 6-month

Domain	A Lot Better (N=346; 43%)			A Little Better (N=132; 16%)			The Same (N=174; 21%)			A Little Worse (N=94; 12%)			A Lot Worse (N=62; 8%)		
	Δ	95% CI	SD	Δ	95% CI	SD	Δ	95% CI	SD	Δ	95% CI	SD	Δ	95% CI	SD

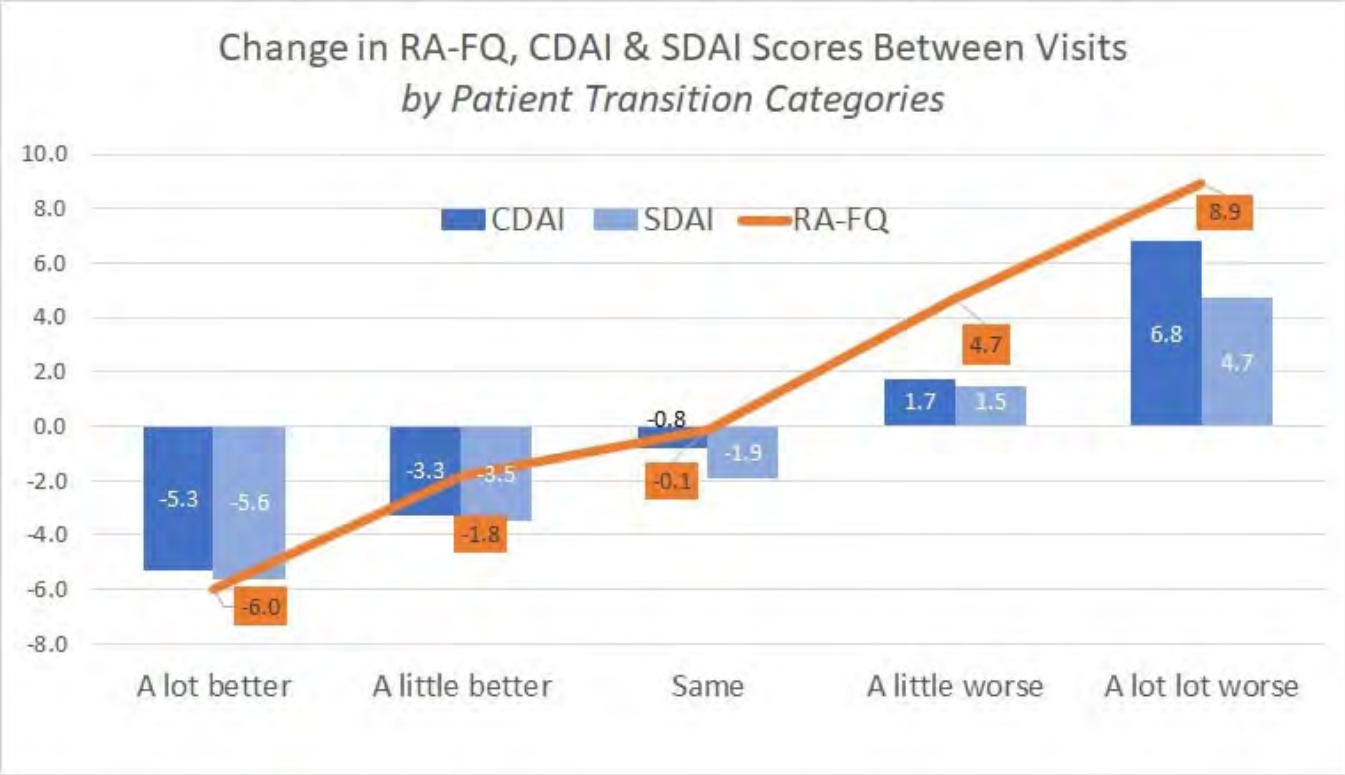
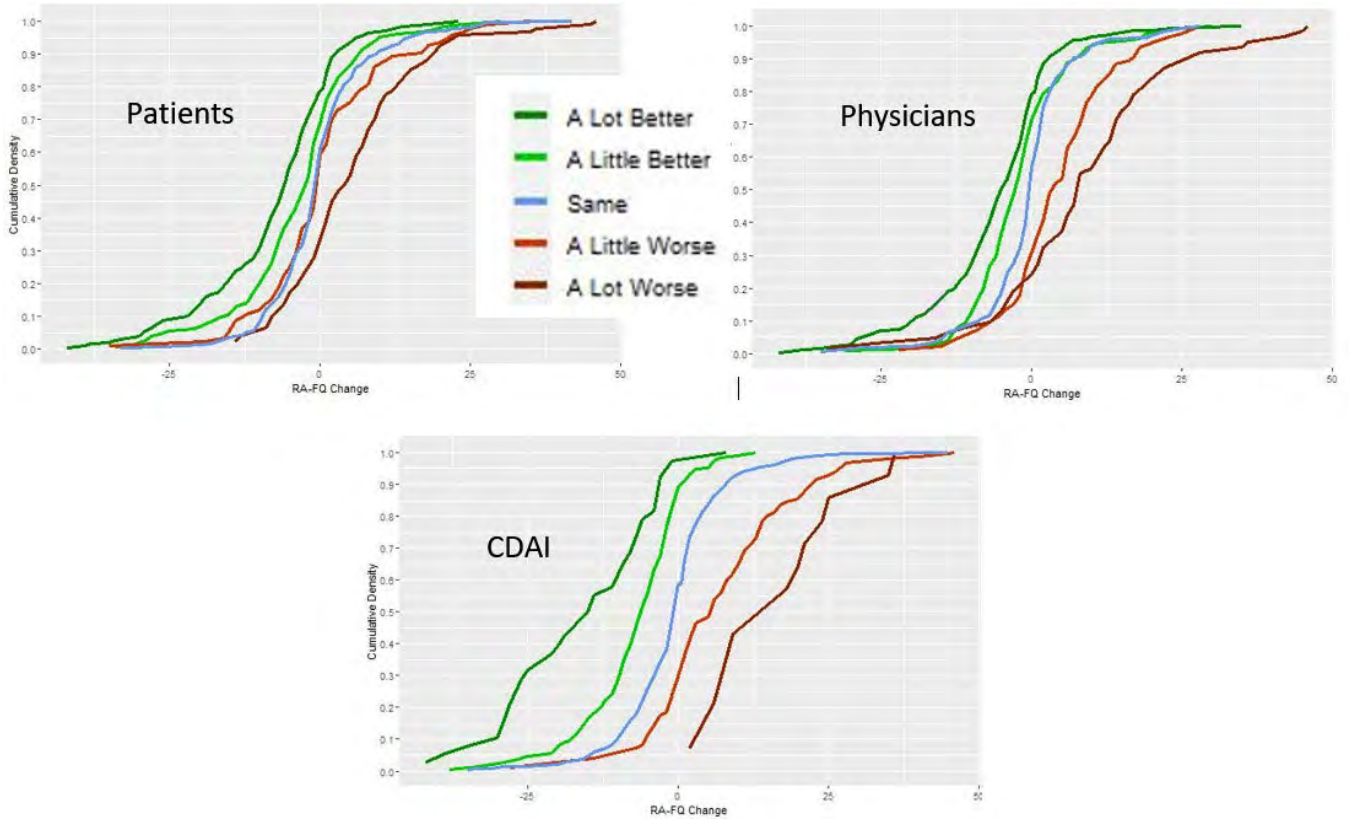
Change in RA-FQ scores between visits by patient ratings of RA status.

visits. Rheumatologists recorded joint counts and MD Global. We compared mean change across categories of improvement and worsening disease activity using patient, physician and CDAI anchors and created cumulative distribution function curves to visually examine separation among categories.





Cumulative distribution function curves for patient, physician and CDAI anchors.

Results: The 808 adults were mostly white (84%) women (71%) with a mean (SD) age of 55 (15) and moderate-high disease activity (85%) at enrollment. At the second visit, 79% of patients reported that their RA had changed; 59% were better and 20% worse. Patients who were *a lot worse* had a mean increase of 8.9 points whereas those who rated themselves as *a lot better* had a -6.0 decrease on the RA-FQ (Figure). Minimal worsening and improvement were associated with 4.7 and -1.8 change on the RA-FQ, respectively, while patients who rated their RA unchanged had stable RA-FQ scores (Table). Physicians and CDAI classified more patients as worse than patients, and minimal and meaningful RA-FQ thresholds differed by group. Similar changes were evident in CDAI, SDAI, and DAS indices (Table). Larger differences were observed with patient vs. physician global scores and tender vs. swollen joints. Across measures, the change associated with worsening was greater than for improvement. Results supported all prespecified hypotheses.

Conclusion: In this large cohort of adults with ERA, the RA-FQ was responsive to change and generally distinguished between minimal and meaningful improvement and worsening. These data add to growing evidence demonstrating robust psychometric properties of the RA-FQ and offer initial guidance about the amount of change associated with improvement or worsening, supporting its use in RA care, research and decision-making.

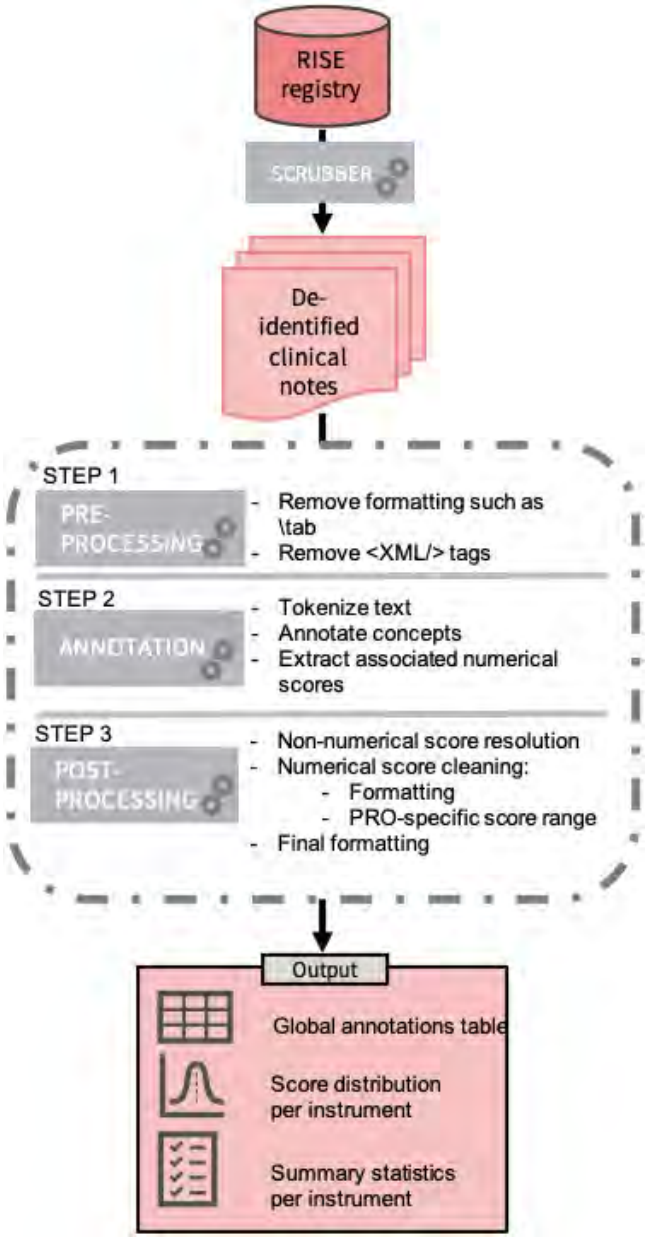
Session Title: Abstracts: Measures & Measurement of Healthcare Quality (1893–1896)
Session Type: Abstract Session
Session Time: 10:30AM–11:30AM

Background/Purpose: Patient reported outcomes (PROs) are increasingly used to track disease activity and facilitate shared decision making in patients with RA. Assessments of disease activity (DA) and functional status (FS) PROs during routine clinical care are recommended in national RA guidelines. However, many rheumatologists do not have support from health IT to reconfigure their EHR systems to collect PROs as structured data. We developed and evaluated a natural language processing (NLP) pipeline for extracting DA and FS scores from clinical notes within the ACR's Rheumatology Informatics System for Effectiveness (RISE) registry.

Methods: We examined de-identified notes and structured electronic health record (EHR) data from all patients with a confirmed diagnosis of RA (2 ICD codes at least 30 days apart), from January 1, 2015, to December 30, 2018 in the RISE registry. The NLP tool was developed in a stepwise approach to extract scores corresponding to Clinical Disease Activity Index (CDAI), Routine Assessment of Patient Index Data 3 (RAPID3), Multidimensional Health Assessment Questionnaire (MDHAQ), and HAQ (Figure 1). First, in a text pre-processing step, we harmonized the notes' format. Next, the concepts of interest (PRO instruments and scores) were annotated. A post-processing step involved formatting and score resolution. The performance of the NLP pipeline was evaluated against a gold standard of human chart review of 100 PRO mentions within 48 randomly-selected notes. We calculated an inter-rater agreement between the NLP-extracted scores and structured scores where available. Agreement was calculated according to (1) "exact" matching based on the numerical scores and (2) for DA scores, "fuzzy" matching, based on score categories (remission, low, etc).

Results: Over 34 million notes from 854,628 patients, from 158 practices, and 24 EHR systems were processed through the NLP pipeline. The majority of practices (n=134) had structured data available for comparison. Overall, our system achieved good fidelity for PRO instrument and score extraction, resulting in a sensitivity of 93.2%, specificity of 80.5% and positive predictive value of 87.3%. DA measures (CDAI and RAPID3) showed substantial agreement between notes and structured data; FS measures (MDHAQ and HAQ) showed almost perfect agreement (Table 1).



NLP pipeline.

Conclusion: The developed NLP pipeline demonstrated good performance, was able to extract PROs from clinical notes of practices in the absence of structured data and can potentially facilitate reporting of quality and performance measures for outpatient rheumatology practices. Further studies are needed to evaluate the potential generalizability of the NLP pipeline to other types of PRO instruments, and to determine whether NLP performance varies by EHR, practice or note type.

		Number of scores compared	Exact matching based on numerical scores	"Fuzzy" matching based on score categories
CDAI		234,400	0.43	0.87
RAPID3		140,680	0.68	0.69
	RAPID3(0-10)	6,218	0.91	0.94
	RAPID3(0-30)	134,462	0.66	0.68
MDHAQ		37,874	0.98	n/a
HAQ		1,313	0.86	n/a

Inter-rater agreement scores between the NLP extractions and the structured data obtained from RISE.

Abstract Number: 1895

Achievement of Target Serum Uric Acid Among Gout Patients Treated with Long-term Urate Lowering Therapy in the ACR's Rheumatology Informatics System for Effectiveness (RISE) Registry

Nevin Hammam, Jing Li, Julia L Kay, Jinoos Yazdany and Gabriela Schmajuk, University of California San Francisco, San Francisco, CA

SESSION INFORMATION

Session Date: Tuesday, November 9, 2021
Session Title: Abstracts: Measures & Measurement of Healthcare Quality (1893–1896)
Session Type: Abstract Session
Session Time: 10:30AM–11:30AM

Background/Purpose: The American College of Rheumatology's (ACR) 2012 guidelines for the management of gout recommend using a treat-to-target (T2T) approach to lower serum uric acid (SUA). However, few studies report the frequency of achieving a target of SUA < 6 mg/dL for treated gout patients at a population level. Using the ACR's RISE registry, we examined the proportion of patients with gout receiving long-term urate-lowering therapy (ULT) who achieved an SUA level < 6.0 mg/dL.

Methods: Included patients were required to have at least 1 ICD9/10 diagnosis for gout (ICD9: 274.*; ICD10: M10.*, M1A.*), at least 2 visits with a rheumatology provider prior to December 31, 2019, and continuous use of a ULT (Allopurinol, Febuxostat, Lesinurad, Probenecid, Pegloticase) for a minimum of 12 months. Continuous use was defined as having a prescription or reported use of any ULT medication with an allowable gap of < 90 days for oral medications or < 60 days IV infusions. The primary outcome was the proportion of patients who achieved SUA < 6.0 mg/dL (0.36 mmol/l) while still receiving ULT, during the measurement year (2019), consistent with the ACR's quality measure assessing T2T for patients with gout. Patient characteristics including sociodemographic, comorbidities, and treatment information were extracted from the RISE database. Bivariate analyses were performed across patient characteristics using independent t-tests or chi-square tests, as appropriate. We examined practice-level performance on this measure among practices with > 20 patients in the denominator.

Table 1. Basic characteristics of all patients.

Characteristics		Total patients (N=8,981)	Patients who achieved SUA target (N=3,308)	Patients who did not achieve SUA target (N=5,673)	P value
Age (years); mean (SD)		67.2 (12.7)	67.3 (12.3)	67.1 (13.0)	0.4761

SUA: serum uric acid, CCI: Charlson comorbidity index, and IQR: interquartile range. Other race= AMERICAN INDIAN OR ALASKA, NATIVE HAWAIIAN, Hispanic or Latino, and Multi-racial. †SUA results were for 1,319 patients. §For privacy protections, we reported no cell sizes < 10.

Results: Overall, 8,981 patients were included. The mean (SD) age was 67.2 (12.7) years, 74.6% were males, and 67.3% were White (Table 1). Most patients were using allopurinol (79.7%) or febuxostat (16.6%). Among patients tested (N=4,627), the median (IQR) SUA level in 2019 was 5.2 (4.3, 6.1) mg/dL. 36.8% of patients reached an SUA < 6.0 mg/dL, while 14.6% had an SUA ≥ 6.0 mg/dL, and 48.4% did not have an SUA recorded during the measurement

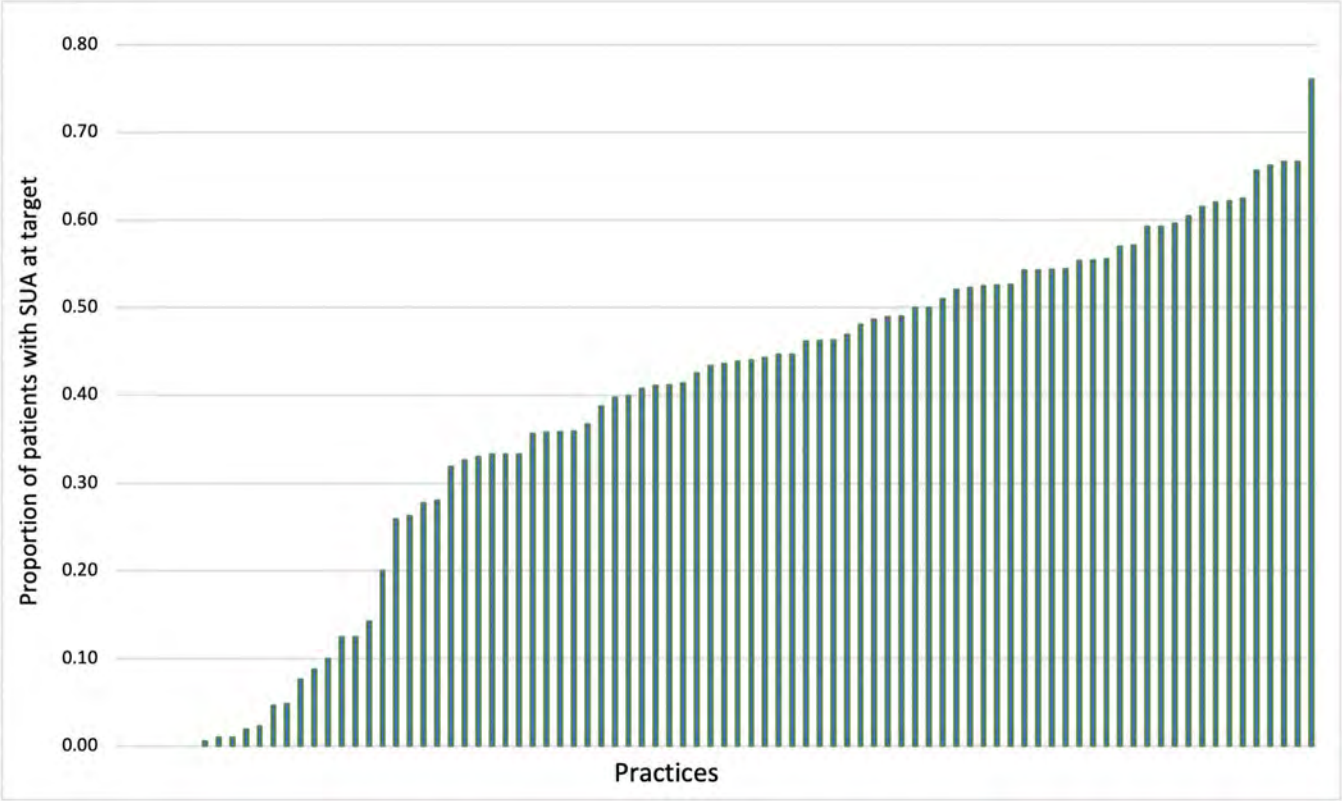

Figure 1. Practice-level performance on quality measure assessing serum uric acid for patients with gout among practices with at least 20 patients eligible (N practices = 88).

year. In bivariate analyses, patients who did not achieve the target SUA were more likely to be Black and have more comorbidities (see Table 1).

Among practices with at least 20 patients in the denominator, median practice-level performance on this quality measure was 43.5 (27.0, 53.5) (see Figure 1). In the 19 practices with the lowest performance (< 20.0% proportion of patients at target), more than 90% of patients did not have SUA assessed during the measurement year.

Conclusion: Among gout patients followed longitudinally by rheumatologists who were receiving long-term ULT, only one third had a documented SUA at the target level, suggesting that there is significant room for improvement in the management of gout. Quality improvement initiatives should focus on improving the documentation of SUA and optimizing ULT among patient groups less likely to be at target. Routine measurement of serum uric acid to monitor the achievement of a T2T strategy is a first step toward improving quality of care for patients with gout.

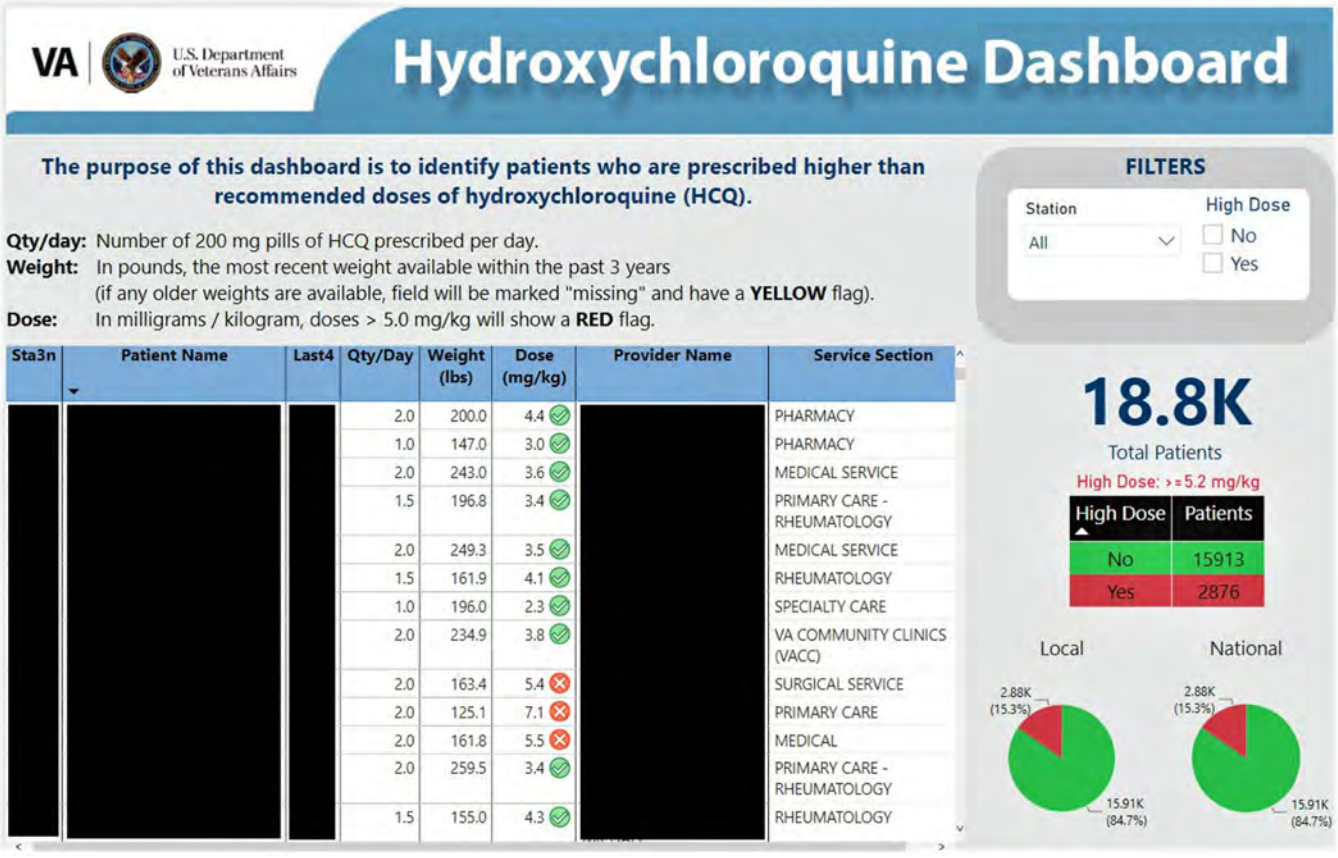
Session Title: Abstracts: Measures & Measurement of Healthcare Quality (1893–1896)

Session Type: Abstract Session

Session Time: 10:30AM–11:30AM

Background/Purpose: Hydroxychloroquine (HCQ) is a commonly used medication for patients with lupus erythematosus, rheumatoid arthritis, and other autoimmune conditions. However, HCQ daily doses of ≥ 5 mg/kg/day can cause retinal toxicity with long-term use. We developed and piloted a medication safety dashboard to improve safe prescribing of HCQ.



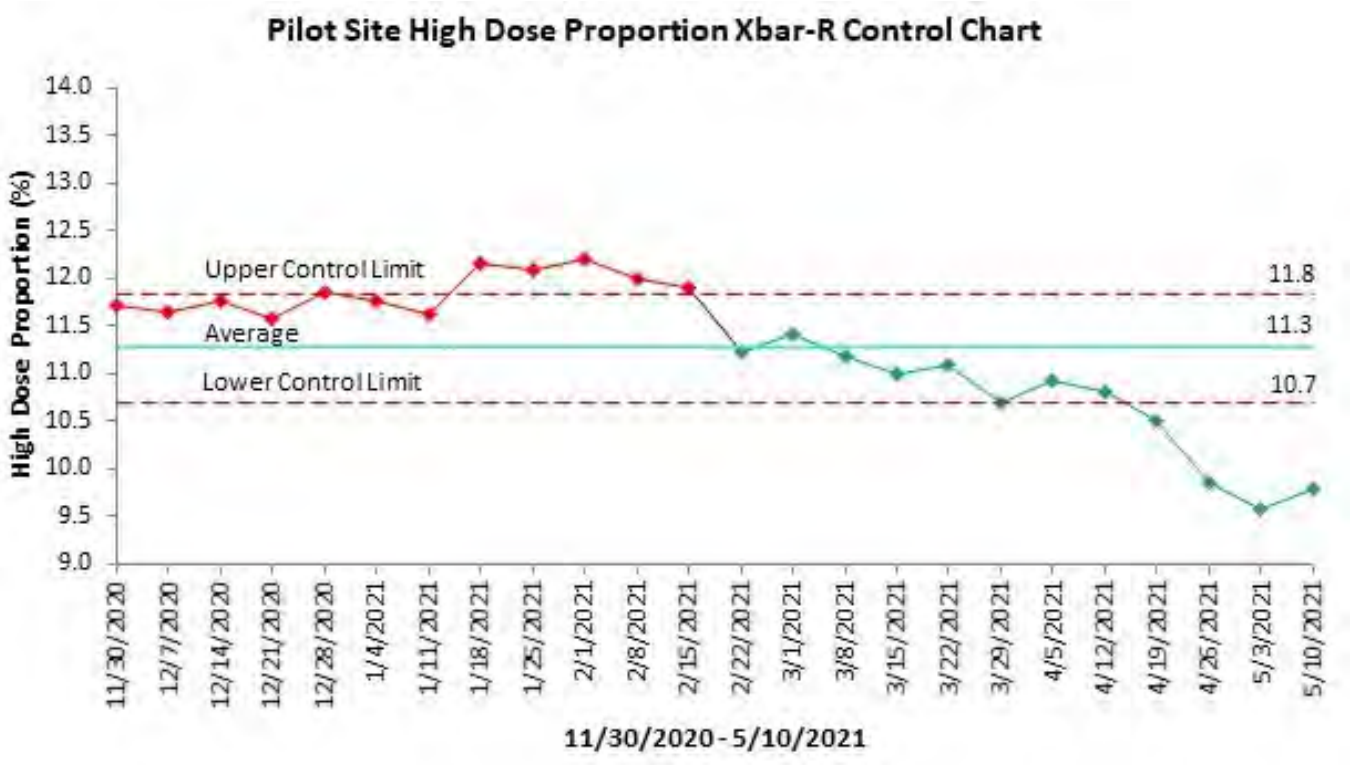
Hydroxychloroquine Dashboard (PHI removed).

Methods: The dashboard was created using Power BI (Microsoft), a data management software package available within the Veterans Health Administration (VHA) for approved users with secure access to EHR data. We extracted values for patients' most recently prescribed HCQ dose and body weight to calculate HCQ dose in mg/kg/day. The dashboard displayed patient identifiers, HCQ dose with a flag if ≥ 5.2 mg/kg/day, and prescriber name and service. It also displayed national-, facility-, and prescriber-level performance (proportion of patients with inappropriate HCQ doses/total number of patients receiving HCQ) for benchmarking (Figure 1).

We enlisted providers from 6 VHA pilot sites to test the dashboard based on their willingness to participate and sub-optimal facility-level performance on HCQ dosing (< 75th percentile nationally). We used Xbar-R control charts to assess the proportion of patients with inappropriate HCQ doses over 7 months. Pilot site leaders (N=7) were asked to provide qualitative feedback on the dashboard's usability, features, and the likelihood of recommending it to others via an online survey (Survey Monkey).

Results: There were 18,635 users of HCQ nationwide across the VHA. 80% of HCQ users had a rheumatology visit within the past 5 years. 1,365 were included at the 6 pilot sites. Pilot site performance improved from 11.7% to 9.8% by May 2021. The Xbar-R control chart showed a significant improvement in the proportion of patients with inappropriate HCQ doses over this 6-month period (Figure 2). Non-participating sites' performance was stable within the chart's control limits from November 2020 to May 2021 (16.0-15.8%).

6 leaders from 5 pilot sites completed the user feedback survey. 5 out of 6 reported the dashboard to be easy to use and would recommend the dashboard to a trainee or colleague. Respondents reported using the dashboard for quality improvement projects and as part of local pay-for-performance programs.



Bar-R Control Chart showing mean proportion of patients receiving inappropriate HCQ doses (≥ 5.2 mg/kg/day) across six pilot sites. X-axis shows 2-week time segments during the study period; y-axis shows proportion of patients with an active prescription for HCQ who were receiving inappropriate doses. Turquoise and red-dotted lines show the average and upper and lower control limits. Red and green dots represent performance at baseline and after a change in a stability trend, respectively.

Conclusion: Use of a medication safety dashboard to improve safe prescribing of HCQ resulted in significant improvement across 6 pilot sites over a 6-month period. With continued feedback from pilot sites, we plan to disseminate the dashboard to VHA clinics nationwide and evaluate performance on safe HCQ dosing over time. Rapid deployment of EHR-based dashboards can facilitate quality improvement by providing key measures and actionable reports directly to clinicians.

SESSION INFORMATION
Session Date: Tuesday, November 9, 2021
Session Title: Abstracts: Metabolic & Crystal Arthropathies – Basic & Clinical Science (1897–1900)
Session Type: Abstract Session
Session Time: 10:30AM–11:30AM

Background/Purpose: Bone erosion is a common consequence of tophaceous gout, and leads to joint deformity and disability. In small case series, intensive urate-lowering with intravenous pegylated uricase improved erosion scores in gout. However, the optimal strategy for management of erosive gout with oral urate-lowering therapy (ULT) is currently unknown. The aim of this randomized controlled trial was to determine whether intensive lowering of serum urate to a target to below 0.20mmol/L (3.3mg/dL) results in improved bone erosion scores, compared to the standard serum urate target to below 0.30mmol/L (5mg/L) in patients with erosive gout on oral ULT.

Methods: Two-year, randomized controlled trial of 104 participants with erosive gout on oral ULT and serum urate ≥ 0.30mmol/L. Participants were randomly assigned to serum urate target 0.10-0.19 mmol/L (intensive group) or 0.20-0.29 mmol/L (standard group). Both participants and study staff who had contact with participants were blinded to the serum urate target and serum urate results throughout the trial, and oral ULT was titrated using a standardized protocol until the target was reached (with allopurinol to 900mg daily, probenecid to 2g daily, febuxostat to 120mg daily, and benzbromarone to 100mg daily). The primary endpoint was total CT erosion score, and key secondary endpoint was the gout-modified Sharp-van der Heijde plain radiographic damage score. The OMERACT gout core outcome domains were also secondary endpoints.

Results: Over the study period, the serum urate was significantly lower in the intensive group compared to the standard group (P=0.002). However, fewer participants in the intensive group achieved the randomized serum urate target (at week 52, 53% vs 83%, P< 0.01, and at week 104, 62% vs 83%, P< 0.05). In the intensive group, allopurinol doses were higher (mean (SD) 746 (210) mg/day vs 496 (185) mg/day, P< 0.001), and more combination therapy was used (P=0.0004). Small increases in CT erosion scores were observed in both groups over two years, with no between-group difference (P=0.29), Figure. Similar findings were observed for the plain radiographic damage score (P=0.58), Figure. Other OMERACT gout core outcome domains (gout flares, tophus, pain, patient global assessment, health related quality of life, and activity limitation) improved in both groups over the two-year study period, with no between-group differences. Adverse event and serious adverse event rates were similar between groups.

Conclusion: Intensive serum urate lowering below 0.20mmol/L is difficult to achieve with oral ULT, leads to high medication burden, and does not improve bone erosion scores in patients with erosive gout. When using oral ULT, a serum urate target below 0.30mmol/L is sufficient to achieve clinical benefit in this patient group.

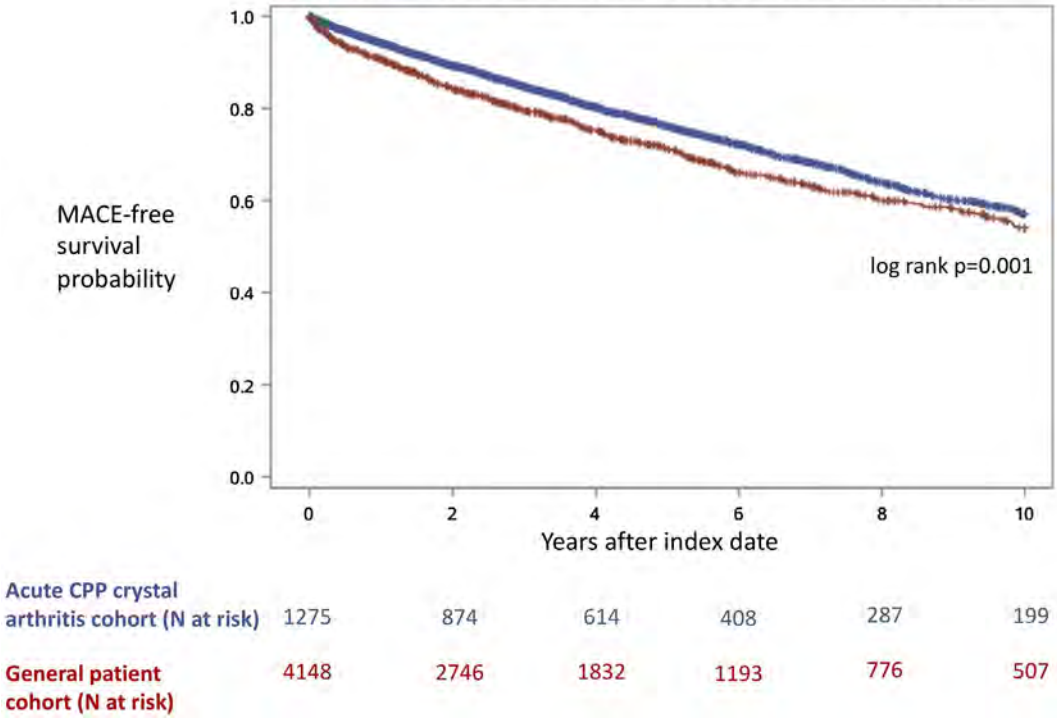
EHR: electronic health record

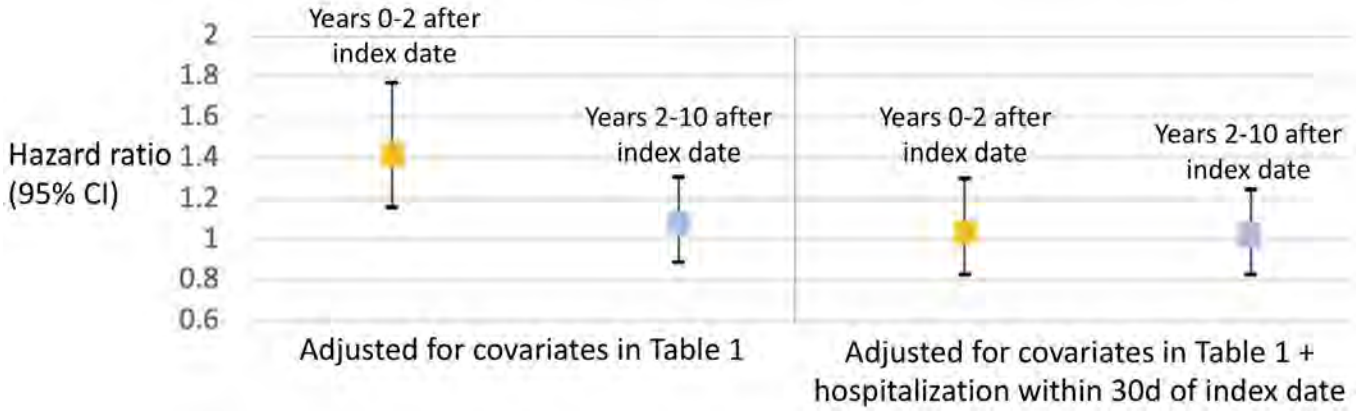
Figure 1. Unadjusted Kaplan-Meier curves for MACE-free survival



Background/Purpose: Acute calcium pyrophosphate (CPP) crystal arthritis, also known as pseudogout, causes an acute inflammatory arthritis that shares clinical similarities with gout. We investigated the risk of incident cardiovascular events in patients with acute CPP crystal arthritis.

Methods: We performed a matched cohort study using electronic health record (EHR) data at an academic medical center, 1990-2017. Major adverse cardiovascular event (MACE), defined as myocardial infarction, re-vascularization, stroke or death, was identified using inpatient diagnosis codes, inpatient/outpatient procedure codes, and vital status. We applied an EHR-based algorithm with a positive predictive value of 81% for acute CPP crystal arthritis to identify the exposed cohort, which we matched to an unexposed general patient cohort on year of EHR entry and index date. Follow-up began at index date (1st mention of "pseudogout" in notes or 1st positive synovial fluid CPP crystal result, or a matched encounter date for the general patient cohort) and ended at MACE or the last encounter before/at 10 years of follow-up. We required age ≥50, ≥180d enrollment before index date and ≥2 encounters dur-

Figure 2. Hazard ratios for MACE stratified by time after index date, comparing the acute CPP crystal arthritis cohort to the general patient cohort (reference)



ing that window for both cohorts. Subjects with MACE occurring from 1st EHR encounter through index date were excluded. Incidence rates (IR) and IR ratios (IRR) were estimated. A Kaplan-Meier curve and log-rank test compared MACE-free survival between the cohorts. Cox proportional hazards models estimated risk of MACE, adjusting for baseline traditional cardiovascular risk factors and healthcare utilization, and allowed for differential effects of acute CPP crystal arthritis over time.

Results: The acute CPP crystal arthritis cohort included 1,275 patients (mean age 72.9 years, 54.4% female) that were matched to 4,148 general patients (mean age 72.9 years, 59.0% female) with 23,144 total person-years follow-up. Cardiovascular comorbidities including hypertension, hyperlipidemia, and diabetes were more common in the acute CPP crystal arthritis cohort, as were prescriptions for NSAIDs and glucocorticoids (Table). MACE IR was highest in the first year after index date in each cohort: 10.1 per 100 person-years in the acute CPP crystal arthritis cohort and 6.2 per 100 person-years in the general cohort (IRR 1.64, 95% CI 1.31, 2.05). Acute CPP crystal arthritis was associated with significantly greater risk for MACE compared to the general cohort in the first two years after index date (HR 1.43, 95% CI 1.16, 1.77), but not in later years (Figures). Additional adjustment for hospitalization within 30 days of index date attenuated the HR during the first two years after index date (HR 1.04, 95% CI 0.83, 1.30).

Conclusion: Patients with acute CPP crystal arthritis were at increased risk for MACE in the first two years after index date, but not in subsequent years. Diagnosis of this acute, episodic crystalline arthritis in the inpatient setting confounds this association and partially explains the observed increased risk.

Mortality in Patients with Sub-Optimally Treated Gout in the Veteran's Health Administration: A National Retrospective Cohort Study

Lindsay Helget[1], Bryant England[1], Punyasha Roul[1], Harlan Sayles[1], Alison Petro[1], Tuhina Neogi[2] and Ted Mikuls[1], [1]University of Nebraska Medical Center, Omaha, NE, [2]Boston University School of Medicine, Boston, MA

SESSION INFORMATION
Session Date: Tuesday, November 9, 2021
Session Title: Abstracts: Metabolic & Crystal Arthropathies – Basic & Clinical Science (1897–1900)
Session Type: Abstract Session
Session Time: 10:30AM–11:30AM

Background/Purpose: Patients with gout have an increased risk of mortality. Current ACR guidelines for the treatment of gout recommend a treat-to-target approach with titration of urate lowering therapy (ULT) based on serum urate (SU) concentrations. However, it remains to be determined whether this treat-to-target approach improves long-term outcomes in gout. Therefore, the goal of this study was to examine whether ULT administration and SU values concordant with a treat-to-target approach are associated with all-cause mortality.

Methods: We performed a retrospective cohort study, identifying patients with gout using national Veteran's Health Administrative (VHA) data from 1/1999-9/2015 based on the presence of ≥2 ICD-9 codes for gout (274.X) (Helget LN et al. Arthritis Care Res 2020). Patients' gout treatment status was categorized in a time-varying manner as either "well-treated" or "sub-optimally treated" during each 365 days of follow-up. Gout patients were considered "well-treated" if during the preceding 365-day period had: 1) ≥2 fills of ≥90 days duration for ULT and 2) a mean SU < 6 mg/

Table 1. Study patients, follow-up, mortality rate and risk of death associated with treatment status

Number of Gout Patients	506,981	
Number of Deaths	176,591	
Patient Years of Follow Up	3,004,816	
Overall Mortality Rate	58.8 deaths / 1,000 PY	
Characteristic	**Unadjusted HR (95% CI)**	**Adjusted HR (95% CI)**
Gout Treatment Status		
Well Treated	Referent	Referent
Sub-Optimally Treated	1.24 (1.23-1.26)	1.22 (1.21-1.24)

dL, using VHA pharmacy and laboratory data. Gout patients who did not meet these criteria were classified as "sub-optimally treated". Patients were followed from the index date (date fulfilling gout algorithm) until death (identified through linkage with the National Death Index) or censoring due to end of study period (12/2015). We assessed the association of time-varying gout treatment status with all-cause mortality using multivariable Cox regression models adjusting for demographics and comorbidities obtained from VHA administrative data.

Results: We identified 506,981 gout patients in the VHA during our study period. Patients were predominantly male (99%) and had a mean (SD) age of 66.6 (11.6) years. During follow-up, 61.3% received at least one ULT prescription and >78% had at least one SU measurement. Over 3,004,816 patient-years of follow-up, there were 176,591 deaths. Kaplan-Meier survival curves demonstrated reduced survival in gout patients who were "sub-optimally treated" (log-rank p-value < 0.0001) (**Figure 1**). In unadjusted models, patients with gout who were "sub-optimally treated" had

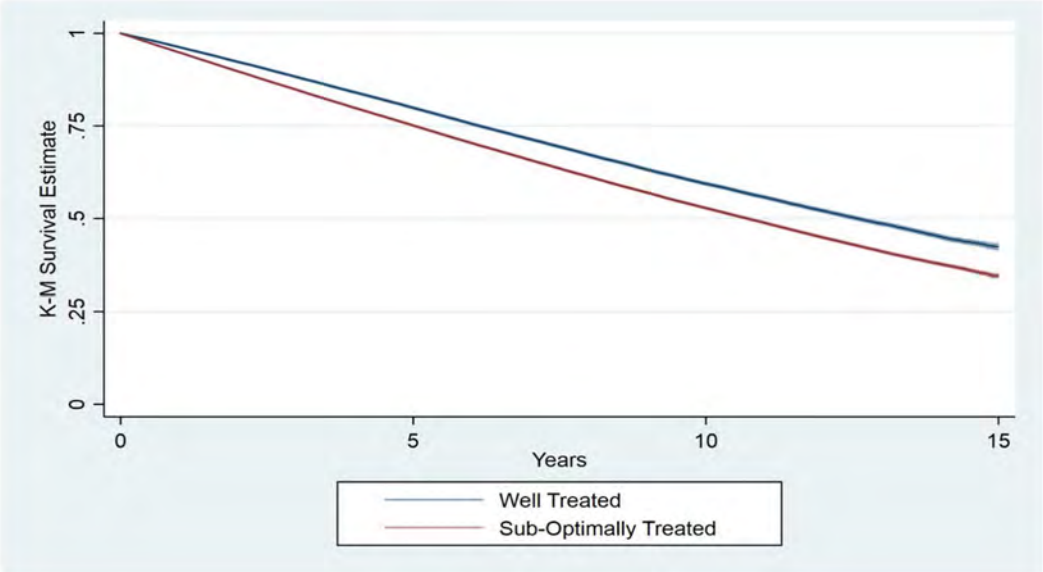

Figure 1. Kaplan-Meier survival estimates demonstrating increased all-cause mortality among sub-optimally treated gout patients (red line) compared to well-treated patients with gout (blue line); log-rank test p-value <0.0001.

a 24% higher risk of all-cause mortality (aHR 1.24 [95% CI 1.23-1.26]). These results were not changed following multivariable adjustment (**Table 1**).

Conclusion: Using data from the largest integrated health system in the U.S., we found that patients with gout receiving suboptimal gout management based on ULT administration and SU measurements demonstrated an approximately 22% higher rate of all-cause mortality. These findings illustrate the long-term consequences of suboptimal treatment and support current ACR guidelines recommending a treat-to-target approach in the management of chronic gout. Additional research is needed to better understand factors mediating the relationship between optimal management and survival, as this information will be essential in informing future strategies aimed at improving long-term outcomes in gout.

SESSION INFORMATION
Session Date: Tuesday, November 9, 2021
Session Title: Abstracts: Metabolic & Crystal Arthropathies – Basic & Clinical Science (1897–1900)
Session Type: Abstract Session
Session Time: 10:30AM–11:30AM

Background/Purpose: Urate lowering therapy (ULT) is a cornerstone treatment in the management of gout. A paucity of data exists about the relative efficacy and safety of the two major oral ULTs, allopurinol and febuxostat, when administered as part of a treat-to-target approach as recommended by ACR and EULAR. Evidence regarding the comparative efficacy and safety of these agents is particularly needed in the context of chronic kidney disease (CKD), a common comorbid condition among gout patients. This multicenter, randomized, double-blind, non-inferiority trial was designed to examine the comparative efficacy and safety of these ULTs in gout management.

Methods: Patients with gout and a serum urate (SU) concentration ≥ 6.8 mg/dl were randomized 1:1 between 2017-2019 to receive appropriately titrated allopurinol or febuxostat in this non-inferiority 72-week trial. Patients with persistent hyperuricemia, despite treatment with allopurinol (≤ 300 mg/dl), were eligible and the protocol specified that ≥ 1/3 would have CKD stage 3. The trial had 3 phases: 1) ULT titration (weeks 0-24), 2) Maintenance (weeks 25-48), and 3) Observation, with continued stable ULT (weeks 49-72). Allopurinol and febuxostat were initiated in daily doses of 100 mg and 40 mg with maximum titration to 800 mg and 120 mg (reduced to 80 mg in 2019 per FDA's request), respectively. Patients received anti-inflammatory prophylaxis chosen by site investigator according to 2012 ACR guidelines until the beginning of phase 3. The primary endpoint was the proportion of patients experiencing ≥ 1

Table 1. Baseline Characteristics of Patients with Gout

Demographics	Allopurinol (N=468)	Febuxostat (N=472)	Total (N=940)
Demographics			
Age, years; mean (SD)	62.9 (11.8)	61.3 (12.9)	62.1 (12.4)

Race/ethnicity, %			
White	66.7	68.2	67.5
Black/African American	22.0	21.6	21.8
Comorbidity			
Chronic kidney disease (stage 3), %	38.7	36.0	37.3
Serum creatinine, mg/dl; mean (SD)	1.2 (0.3)	1.2 (0.3)	1.2 (0.3)
Hypertension, %	78.0	74.8	76.4
Diabetes, %	35.0	31.6	33.3
Cardiovascular disease, %	30.1	23.5	26.8
Body mass index, (SD)	33.6 (6.6)	33.7 (6.6)	33.7 (6.6)
Gout Related Factors			
Serum urate, mg/dl; mean (SD)	8.6 (1.4)	8.5 (1.3)	8.5 (1.4)
Serum urate ≥ 9 mg/dl, %	34.2	31.4	32.8
Allopurinol use (300 mg/d or less), %	38.0	35.4	36.7
Gout duration, years; mean (SD)	9.7 (10.6)	10.2 (11.4)	10.0 (11.0)
Presence of Tophi, %	17.3	15.0	16.2
C-reactive protein, mg/L; mean (SD)	9.6 (18.7)	8.2 (15.4)	8.9 (17.1)

Values shown as mean (standard deviation) or %; Cardiovascular disease = history of coronary artery disease, myocardial infarction, or heart failure, Stage 3 chronic kidney disease defined by estimated glomerular filtration rate (eGFR) of 30-60 ml/min at enrollment; patients excluded if prior febuxostat use or eGFR <30 ml/min

flare during phase 3 with a pre-specified margin of < 8% difference indicative of non-inferiority. Secondary endpoints included: efficacy/tolerability in CKD stage 3, proportion achieving SU < 6 mg/dl at the end of phase 2, and serious adverse events (SAE).

Results: : Characteristics of the 940 patients with gout (n=21 sites) receiving at least 1 dose of study medication are shown in **Table 1**. Overall, 20% withdrew prior to completion with similar proportions by treatment arm. During phase 3, 35% of patients treated with allopurinol had ≥ 1 flare compared to 42% of participants treated with febuxostat ($p < 0.001$ for non-inferiority) (**Table 2**). Overall, 80% of patients achieved SU < 6.0 mg/dl (92% achieved SU < 6.8 mg/dl) during phase 2 with no difference according to ULT treatment. Likewise, there were no treatment differences in SAEs (including percent of patients with cardiovascular events) in those with or without CKD. Additional secondary outcomes are shown in **Table 2**.

Conclusion: This large, randomized double-blind trial demonstrates that allopurinol, when dosed appropriately as part of a treat-to-target strategy, is non-inferior to febuxostat in the treatment of gout. Both ULTs were highly efficacious in this context with 80% of patients achieving and maintaining SU goals after 1 year and more than 90% achieving SU < 6.8 mg/dl. There was no evidence of increased cardiovascular toxicity with febuxostat compared to

Table 2. Results

	Allopurinol	Febuxostat	Total	P Value
Primary Endpoint[1]				
≥ 1 Gout flare in Phase 3, %	34.7	42.2	38.5	< 0.001
Secondary Endpoints[1]				
All study Participants				
Serum Urate < 6.0 mg/dl in phase 2[2], %	81.1	78.4	79.8	0.34
Serious Adverse Event, %	26.7	26.1	26.4	0.60
Cardiovascular event[3], %	8.1	6.8	7.5	0.82
Early study termination, %	20.5	19.7	20.1	0.82

Severe Foot Symptoms Are Associated with Mortality: The Johnston County Osteoarthritis Project

Yvonne Golightly[1], Carolina Alvarez[1], Marian Hannan[2], Lucy Gates[3], Becki Cleveland[4], Amanda Nelson[1] and Leigh Callahan[5], [1]University of North Carolina at Chapel Hill, Chapel Hill, NC, [2]Marcus Institute for Aging Research, Hebrew SeniorLife, Milton, MA, [3]University of Southampton, Southampton, United Kingdom, [4]Thurston Arthritis Research Center, University of North Carolina at Chapel Hill School of Medicine, Chapel Hill, NC, [5]University of North Carolina Thurston Arthritis Research Center, Chapel Hill, NC

SESSION INFORMATION

Session Date: Tuesday, November 9, 2021

Session Title: Abstracts: Orthopedics, Low Back Pain, & Rehabilitation (1901–1904)

Session Type: Abstract Session

Session Time: 10:30AM–11:30AM

Background/Purpose: Foot symptoms (i.e., pain, aching, and stiffness [PAS]) are common in middle-aged to older adults and are linked to restricted physical activity, poorer physical function and balance, disability, and falls. Their contribution to mortality is not known. This longitudinal analysis examined whether presence and severity of foot symptoms were associated with mortality in a large prospective community-based cohort of Black and White men and women 45+ years old.

Methods: Data were from three study visits (baseline [1999-2004], 1st follow-up [2006-2010], and 2nd follow-up [2013-2015]) of the Johnston County Osteoarthritis Project (JoCoOA). Presence of foot PAS (yes/no) was assessed by the question: "On most days, do you have pain, aching or stiffness in your left/right foot?" Foot PAS severity was recorded as none (referent=0), mild=1, moderate=2, or severe=3. Foot PAS Severity Count summed severity across both feet (0 [none] to 6 [severe in both feet]). All-cause mortality was determined for participants at each follow-up study visit using data from the National Death Index to determine date and cause of death through December 31, 2015. Static covariates (did not change or changed at same rate for all participants over time) were enrollment cohort (original [1991-1997] or enrichment [2003-2004]), birth cohort, age, sex, race, and education level. Time-varying

No foot PAS	ref	ref	ref	ref	ref	ref	ref
Mild foot PAS severity	0.90 (0.71, 1.15)	0.85 (0.63, 1.13)	1.05 (0.69, 1.60)	0.94 (0.69, 1.28)	0.86 (0.59, 1.26)	0.82 (0.61, 1.10)	1.16 (0.75, 1.78)
Moderate foot PAS severity	1.20 (0.98, 1.47)	1.25 (0.98, 1.58)	1.08 (0.75, 1.56)	1.25 (0.95, 1.65)	1.16 (0.87, 1.55)	1.26 (1.00, 1.59)	1.06 (0.72, 1.56)
Severe foot PAS severity	**1.59 (1.23, 2.04)**	**1.54 (1.14, 2.10)**	**1.66 (1.12, 2.47)**	1.41 (0.97, 2.05)	**1.72 (1.24, 2.38)**	**1.46 (1.07, 1.99)**	**1.85 (1.25, 2.74)**
PAS severity count for both feet (1 unit increase)	**1.07 (1.03, 1.12)**	**1.07 (1.03, 1.13)**	1.07 (1.00, 1.14)	**1.06 (1.01, 1.12)**	**1.08 (1.02, 1.14)**	**1.06 (1.01, 1.11)**	**1.09 (1.02, 1.16)**

Adjusted enrollment cohort (original 1991-1997 or enrichment 2003-2004), age, sex, race, education level, body mass index, smoking, alcohol use, minutes/week of moderate/vigorous physical activity, non-steroidal anti-inflammatory drug use, diabetes, count of 5 comorbidities (hypertension, cardiovascular disease, diabetes, depressive symptoms, liver disease), knee PAS, hip PAS
All models stratified by decade birth cohort (before 1920, 1920-<1930, 1930-<1940, 1940-<1950, 1950-<1960) to account for calendar effects, as recommended for longitudinal analyses of healthy people and when the calendar effect is likely to affect the outcome (e.g., mortality) and other risk factors.
Cox proportional hazard modeling time to death to provide adjusted HR and 95% confidence intervals that are **bold** when significant at alpha=0.05
An interaction term is used to provide adjusted HR by race, obesity, and diabetes respectively; *=interaction is significant at p-value<0.1
Multiple imputation model including all baseline variables was used to impute missing covariate values (5.8%); 10 multiple imputed datasets were analyzed.

covariates were body mass index (BMI), smoking, alcohol use, minutes/week of moderate/vigorous physical activity, non-steroidal anti-inflammatory drug use, hypertension, cardiovascular disease, diabetes, depressive symptoms, liver disease, knee PAS, and hip PAS. For each foot symptom measure (PAS, PAS severity, PAS Severity Count), separate Cox proportional hazards regression models with covariates were used to estimate adjusted hazard ratios (aHR) and 95% confidence intervals (CI) for the total sample and stratified by sex, race, obesity (BMI< 30 vs. ≥30 kg/m^2), and diabetes (test for interaction significant at p< 0.1).

Results: At baseline, mean age was 63 years, 2/3 were women, 1/3 were Black, mean BMI was 31 kg/m^2, and 37% had foot PAS (Table 1). Mean follow-up time was 11.8 years, and there were 818 deaths. In adjusted models (Table 2), foot PAS was related to a 16% greater hazard of all-cause mortality (aHR 1.16, 95%CI 0.99, 1.35). Compared to no foot PAS, severe foot PAS was associated with a 59% greater hazard of excess mortality (aHR 1.59, 95% CI 1.23, 2.04). Every 1-unit increase in PAS Severity Count was associated with a 7% greater hazard of all-cause mortality (aHR 1.07, 95% CI 1.03, 1.12). There were no statistically significant differences by sex, race, obesity, or diabetes.

Conclusion: In the JoCoOA, individuals who had greater severity of foot symptoms had increased mortality, independent of confounders. Although mechanisms for this relationship are not yet understood, foot symptoms may contribute to less physical activity and loss of physical function, which over time leads to factors that impact mortality, such as comorbid conditions from increasing BMI or falls from muscle weakness/impaired balance. Strategies to prevent and treat more severe foot pain may be needed to reduce mortality.

SESSION INFORMATION
Session Date: Tuesday, November 9, 2021
Session Title: Abstracts: Orthopedics, Low Back Pain, & Rehabilitation (1901–1904)
Session Type: Abstract Session
Session Time: 10:30AM–11:30AM

Background/Purpose: Altered gait is related to structural worsening of knee osteoarthritis (OA). However, it is not known if altered gait is associated with increased risk of pain worsening over time. We applied machine learning approaches to gait data collected in a large epidemiological cohort to identify markers of gait alterations in people with worsening knee pain over 2 years.

Methods: The MultiCenter Osteoarthritis (**MOST**) study includes participants age 45-90 with, or at risk for, knee OA. Participants were categorized by presence of worsening knee pain over 2-years, defined as MCID increase in WOMAC pain (2+ points on 0-20 point scale). Gait was assessed at the 144 month visit using inertial sensors (OPAL, APDM, Portland, OR) worn on the trunk and both ankles during a 20-meter walk test in which participants walked at a self-selected pace.

We used an ensemble machine learning technique ("super learning") that uses multiple algorithms (Table 1 footnote) to improve outcome classification. All gait variables (both legs, Table 1 footnote), presence of pain during walking and K-L grade of each knee, age, BMI, depressive symptoms (CES-D), and sex were included as predictors. Data

Table 1. Variables contributing to prediction of worsening knee pain over 2 years (Frequency % across 100 test iterations from an ensemble prediction model[a])

The top ten variables selected during 100 iterations (n= frequency %)

- CES-D[b] (100)
- Gait speed (90)
- BMI[b] (82)
- Phase Coordination Index (72) : a measure of the bilateral coordination of gait
- Stride Time coefficient of variation (61) : quantifies magnitude of stride-to-stride variability in stride time
- Gait Asymmetry (51) : a measure of temporal left-right asymmetry of swing time
- Phase Difference (51) : % of the absolute difference from 180 degrees; a higher value indicates increased asymmetry
- Walking pain at 144 months, for designated knee (47)
- Stride Time (47): time measure of the average gait cycle
- Step Length (40)

Notes a.Algorithms included: Bayesian adaptive regression trees (BART), extreme gradient boosting, generalized linear models with convex penalties (that consisted least absolute shrinkage and selection operator [LASSO], ridge regression, and elastic net), logistic regression, random forest, and support vector machine.
b. BMI: Body Mass Index; CES-D: Center for Epidemiologic Studies Depression Scale; KL: Kellgren and Lawrence Grading System.
c. Gait parameters extracted include those describing spatiotemporal features (e.g., step length, velocity, cadence, stride time, double stance time, swing time), gait symmetry (e.g., step acceleration symmetry, phase coordination index, swing time symmetry), and gait variability (e.g., step regularity, entropy).

Table 2. GEE regression model: association of worsening knee pain over 24 months with predictors chosen by ensemble ML methods. Adjusted odds ratio (95% confidence intervals) are presented.

Parameters[c]	All knees, Total=4375, Cases=851	No walking pain at baseline Total=2699, Cases=471	Walking pain at baseline Total=1296, Cases=380

Notes
a. Continuous variables are standardized: PCI, Gait Asymmetry, Stride Mean Time, Average Step Length, Stride Time CV, age, BMI, CES_D, Gait Speed
b. K-L: Kellgren and Lawrence Grading System
c. Phase Difference variable was dropped from the GEE model due to collinearity concerns.

were randomly split into 70% training and 30% test sets; the data split and model training and testing were repeated 100 times. We used a variable importance measure (VIM) statistic to identify the top 10 variables that most frequently contributed to the prediction of worsening knee pain. A Generalized Estimating Equation (GEE) model accounting for correlated outcomes (2 knees/person) was used to evaluate the association of "important" variables with worsening knee pain over 2 years. Potential confounders age, BMI, sex, baseline walking pain and K-L status were included. Analyses stratified by baseline walking pain are also presented.

Results: Our sample included 4464 knees for 2232 participants (mean age 63.6 [SD: 10.5] years, 57% female). 19.5% of knees had worsening pain over 2 years. Top contributing variables from ensemble machine learning process (AUC=0.69) are shown in **Table 1**.

In a GEE model (**Table 2**), longer step length was associated with increased likelihood of worsening pain over 2 years. However, when stratified by baseline pain, the association of step length and pain worsening was only significant in people without pain at baseline.

Conclusion: Our results suggest higher step length was associated with worsening knee pain over 2 years in individuals with or at risk of knee OA who do not have pain during walking at baseline. Walking with longer step length is associated with greater knee joint loading and shortening step length has been recommended as a gait intervention to reduce knee joint loading in people with knee OA. Our findings, using gait data from a large cohort and using machine learning to agnostically identify important gait variables, provide further support for this recommendation.

Abstract Number: 1903

Does Limited Stair Climbing Lead to Poor Future Health? The Relationship Between Short-term Trajectories of Stair Climbing Frequency and Incident Slow Gait Speed over 1 and 2 Years in Adults with Knee Osteoarthritis

Jason Jakiela[1], Yuqing Zhang[2], Dana Voinier[1], Thomas Bye[1], Jennifer Copson[1] and Daniel White[1], [1]University of Delaware, Newark, DE, [2]Massachusetts General Hospital, Quincy, MA

SESSION INFORMATION
Session Date: Tuesday, November 9, 2021
Session Title: Abstracts: Orthopedics, Low Back Pain, & Rehabilitation (1901–1904)
Session Type: Abstract Session
Session Time: 10:30AM–11:30AM

Background/Purpose: Knee osteoarthritis (OA) is a common cause of functional limitation in older adults, and difficulty with climbing stairs is one of the first limitations to be reported. As such, reducing the frequency of stair climbing may serve as an early warning sign of future poor health outcomes. Little is known, however, about how stair use may fluctuate over time and if such fluctuations are related to future health – particularly slow gait speed given its strong relationship with poor health outcomes (e.g., hospitalization, early mortality). Therefore, the purpose of this study was to identify and describe trajectories of stair climbing frequency over 2 years in adults with or at high risk for knee OA and to determine the association between said trajectories and incident slow gait speed at 1- and 2-years.

Methods: Using data from the Osteoarthritis Initiative (OAI), stair climbing frequency was assessed by asking "How often do you climb up a total of 10 or more flights of stairs during a typical week, in the past 30 days?". Choices included None, 1-2 days per week, 2-3 days per week, 4-5 days per week, & nearly every day or every day. Responses were collected at baseline and at the 1- and 2-year clinic visits. Our study outcome was slow gait speed, defined as walking < 1.22 m/s over 20 meters, which is the pace needed for a timed crosswalk. We measured incident slow gait

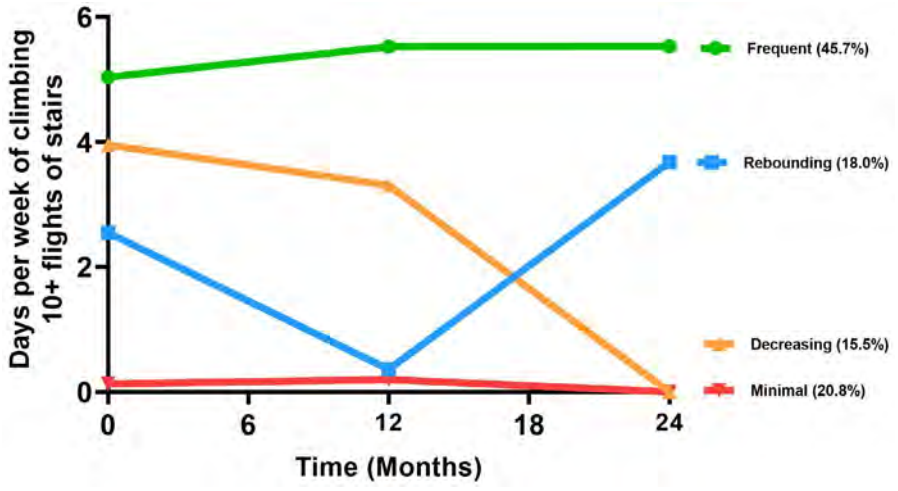

Figure 1. Short-term trajectories of stair climbing frequency over 2 years.

Table 1. Descriptive characteristics of the overall sample and each stair climbing frequency trajectory group at analytic baseline

	Overall Sample (n=2748)	Frequent (n=1232, 45.7%)	Rebounding (n=446, 18.0%)	Decreasing (n=480, 15.5%)	Minimal (n=590, 20.8%)
Age, years	61.8 ± 8.7	61.6 ± 8.5	62.0 ± 8.8	61.2 ± 9.0	62.7 ± 9.0
Sex, % female	53.7%	51.1%	52.2%	57.3%	57.5%
BMI, kg/m²	27.9 ± 4.6	27.3 ± 4.5	28.1 ± 4.6	28.3 ± 4.6	28.7 ± 4.7
Race, % non-white	12.9%	14.4%	12.1%	14.6%	9.2%
Education, % college degree	69.3%	73.5%	65.8%	67.6%	64.3%
Comorbidities, % ≥1	21.5%	18.5%	23.9%	22.7%	24.9%
Knee pain, % >3/10 VAS	51.9%	49.4%	54.0%	52.5%	55.1%
Radiographic knee OA, %	54.9%	53.7%	59.3%	51.5%	56.9%
Gait speed, m/s	1.42 ± 0.15	1.43 ± 0.15	1.42 ± 0.15	1.42 ± 0.14	1.40 ± 0.14
Posterior probabilities, %	---	96.9%	90.3%	83.4%	93.2%

Note: knee pain severity of 3/10 is the Patient Acceptable Symptom State; radiographic knee OA was determined using the Kellgren-Lawrence (KL) grading criteria (KL grade ≥ 2 = ROA present); posterior probabilities are the average probability of each individual trajectory fitting in their respective trajectory group

speed at the 3-year and 4-year clinic visits (i.e., 1- and 2-years of follow-up) in separate analyses. Our analytic dataset included those without slow gait speed at the 2-year clinic visit. Trajectories of stair climbing frequency over 2 years were identified using group-based modeling. Posterior probabilities of individual trajectories into the larger groups were used to describe model fit. Subject characteristics for trajectory groups were described using descriptive statistics. To determine the association of trajectory group membership with incident slow gait speed, we used binomial regression models to calculate relative risks (RR) and 95% confidence intervals (95% CI), adjusted for potential confounders at the 2-year clinic visit, i.e., our analytic baseline.

Results: Four distinct trajectory groups were generated (Fig 1): Frequent (45.7%), Rebounding (18.0%), Decreasing (15.5%), Minimal (20.8%), and descriptive characteristics are listed in Table 1. Compared to the Frequent stair climbing group, risk for incident slow gait speed was 45%, 68%, and 59% greater for the Rebounding, Decreasing, and Minimal Frequency groups, respectively, after 1 year (Table 2). We found similar findings for incident slow gait speed after 2 years (Table 2).

Conclusion: Compared to those who engaged in frequent stair climbing (at least 5 days per week), adults with knee OA who either seldom used the stairs, decreased their stair climbing over 2 years, or had a fluctuating pattern of stair climbing all were at greater risk for developing a slow gait speed by both subsequent years of follow-up. Given that stair climbing is a high-demand functional task, the stark increased risk in worsening function (via slow gait speed) over a short period of time is of concern. Adults with knee OA who report decreased stair climbing are prime targets for early intervention to prevent future loss of general function.

Table 2. RRs & 95% CIs for the association between stair climbing frequency trajectories and incident slow gait speed at 1 and 2 years

	% w/ GS <1.22 m/s at 1yr	Incident Slow GS at 1yr Adjusted RR [95% CI]	% w/ GS <1.22 m/s at 2yrs	Incident Slow GS at 2yrs Adjusted RR [95% CI]
Frequent Stair Climbing Frequency	134/1183 (11.3%)	1.0 [REF]	193/1182 (16.3%)	1.0 [REF]
Rebounding Stair Climbing Frequency	71/432 (16.4%)	1.45 [1.11, 1.89]*	96/431 (22.3%)	1.36 [1.10, 1.70]*
Decreasing Stair Climbing Frequency	89/468 (19.0%)	1.68 [1.31, 2.15]*	114/467 (24.4%)	1.50 [1.22, 1.84]*
Minimal Stair Climbing Frequency	71/432 (18.0%)	1.59 [1.26, 2.01]*	140/569 (24.6%)	1.51 [1.24, 1.83]*

Note: asterisk (*) indicates statistical significance; each model was adjusted for age, sex (female vs male), BMI, race (non-white vs white), education (college degree vs no college degree), knee pain severity, presence of radiographic knee OA (KL grade ≥2 vs KL grade <2), presence of comorbidities (1+ vs none), presence of depressive symptoms (≥16 on CESD vs <16 on CESD), physical activity level (PASE)

"Why Does My Knee Hurt After I Got My Knee Replaced?": Evaluation of Neuropathic-like Symptoms and Objective Signs of Neuropathy Post-Knee Replacement in Patients with Knee Osteoarthritis

Devin Driscoll[1], Priyanka Ballal[1], Na Wang[2], Laura Frey-Law[3], Cora Lewis[4], Michael Nevitt[5] and Tuhina Neogi[1], [1]Boston University School of Medicine, Boston, MA, [2]Boston University, Boston, MA, [3]University of Iowa, Iowa City, IA, [4]University of Alabama Birmingham, Birmingham, AL, [5]University of California San Francisco, Orinda, CA

SESSION INFORMATION
Session Date: Tuesday, November 9, 2021
Session Title: Abstracts: Orthopedics, Low Back Pain, & Rehabilitation (1901–1904)
Session Type: Abstract Session
Session Time: 10:30AM–11:30AM

Background/Purpose: Some people with knee osteoarthritis (OA) have persistent pain post-knee replacement, but why this occurs is not fully understood. One possibility is post-surgical neuropathy. We aimed to examine presence of neuropathy with objective clinical assessments and neuropathic-like pain evaluated with the self-reported PainDETECT questionnaire (PDQ) as potential contributors to persistent pain post-knee replacement. We also evaluated the association between objective neuropathy assessments and PDQ.

Methods: We used data from the Multicenter Osteoarthritis (MOST) Study, a NIH-funded longitudinal cohort of individuals with or at risk of knee OA. Participants in the study who had a knee replacement were invited for a study visit ~1 year post-surgery. We obtained clinical assessments for neuropathy (von Frey 2g and 26g monofilaments (allodynia and hypoesthesia) and pin prick (hyperalgesia and hypoesthesia)) at the replaced knee. Each test was assessed 4 times, and considered abnormal if there was no response on ≥3 of the 4 trials (hypoesthesia) or if there was pain on ≥3 of the 4 trials (allodynia for the monofilaments, hyperalgesia for the pin prick). We also obtained the PDQ (0-38) and WOMAC pain (0-20). We defined the patient acceptable symptom state (PASS) based upon published thresholds for WOMAC as ≤5/20 for knee replacement samples. A PDQ score of ≥12 was considered neuropathic-like pain. We evaluated the relation of the clinical neuropathy assessments and the PDQ to achievement of the PASS post-knee replacement, using logistic regression, adjusting for potential confounders (age, sex, BMI, diabetes, depressive symptoms).

Table: Relation of clinical assessments of neuropathy and of PainDETECT to likelihood of not achieving the Patient Acceptable Symptom State post-knee replacement

Assessment of 'neuropathy':	Adjusted† OR (95% CI) for not achieving the WOMAC PASS post-knee replacement
PainDetect score per SD unit increase	2.09 (1.38-3.14)
PainDetect score ≥12 ("neuropathic-like pain")	3.95 (1.15-13.5)
Any abnormality on clinical assessments of neuropathy*	1.43 (0.50-4.12)

*defined as either: pain response in ≥3/4 trials OR no response in ≥3/4 trials to any one of the clinical assessments (von Frey monofilaments (2g, 26g) or pinprick)
†adjusted for age, sex, BMI, depressive symptoms, diabetes

Results: We evaluated 171 participants ~1 year post-knee replacement (mean age 69, 62% female, mean BMI 32.6). Overall, 57% had an abnormality on the clinical neuropathy assessment at the replaced knee, with 51% exhibiting hypoesthesia, and 10% exhibiting allodynia or hyperalgesia. The mean post-knee replacement PDQ score was 4.4 (SD 4.7) and 9% had PDQ ≥12, reflecting neuropathic-like pain. The presence of any abnormality on any of the clinical assessments was not associated with achieving the PASS (Table). Similar results were obtained when we analyzed each individual clinical assessment. In contrast, higher PDQ scores and PDQ score ≥12 were significantly associated with higher likelihood of not achieving the PASS (Table). There was no association between having any abnormality on the clinical assessments of neuropathy and PDQ score (OR 1.13, 95% CI 0.75-1.72) or PDQ score ≥12 (OR 0.68 (95% CI 0.17-2.72).

Conclusion: Objective clinical assessments of neuropathy were not associated with worse pain status post-knee replacement, defined as not achieving the PASS for WOMAC. However, higher PDQ scores and having a PDQ score in the 'neuropathic-like pain' range were associated with worse pain post-knee replacement. Thus, clinically evident neuropathy does not appear to explain persistent pain post-knee replacement. The PDQ, including in the 'neuropathic-like pain' range, does not appear to correlate with clinical assessments of neuropathy. It is possible that the PDQ is reflective of pain severity in general, and potentially nociplastic, rather than neuropathic-like, pain.

CD11c+ Expression Associates with IFN-λ Responsiveness in Human B Cells with Clinical Implications for SLE

Jennifer Barnas[1], Jennifer Barnard[2], Cameron Baker[2], Nida Meednu[2], Andrew McDavid[1], R. John Looney[1] and Jennifer Anolik[2], [1]University of Rochester, Rochester, NY, [2]University of Rochester Medical Center, Rochester, NY

SESSION INFORMATION
Session Date: Tuesday, November 9, 2021
Session Title: Abstracts: B Cell Biology & Targets in Autoimmune & Inflammatory Disease (1905–1908)
Session Type: Abstract Session
Session Time: 2:00PM–3:00PM

Background/Purpose: Type I interferon (IFN), namely IFN- α, and B cell aberrations are long recognized in systemic lupus erythematosus (SLE) pathogenesis. Type I IFN receptor blockade has undergone clinical trials in SLE with varying degrees of success. Type III IFN (IFN-λ) produce a gene signature currently indistinguishable from that of type I in responsive cell types. IFN-λ are not blocked by type I IFN receptor blockade as they utilize a unique receptor (IFNLR1). Type III IFN are appreciated to have an important role in viral infection at epithelial barriers where IFNLR1 is strongly expressed. The effects of IFN-λ on immune cells remain understudied and are different between human and murine models. We have previously shown that human B cells can transcribe type I IFN genes after IFN-λ treatment including those associated with SLE. We have found that IFN-λ is detected in the serum of human SLE patients and correlates with IgD- CD27- CD21- CD24- (DN2) B cells, a compartment which contains CD11c+ age/autoimmunity B cells (ABC). ABC are a target of interest as recent studies suggest they are poised for plasma cell differentiation and enriched in autoreactivity and thus have the potential to contribute to SLE pathogenesis.

Methods: Patients meeting 1997 ACR systemic lupus erythematosus classification criteria (n = 8) and healthy donors (HD, n = 5) had blood drawn under IRB-approved protocol. The transcriptome of sorted IgD+ CD27- naïve and

IgD- CD27- (DN) B cells was measured by bulk RNA sequencing for differential expression and gene set enrichment analysis. Cell phenotype and STAT1 phosphorylation (pSTAT1) in IFN-α2 and IFN-λ1 treated PBMC was measured by flow cytometry (n =10).

Results: Naïve and DN cells display a prominent type I IFN gene expression profile in SLE. Transcript for type I, type II, and type III IFN receptors (IFNAR1, IFNAR2, IFNGR1, IFNGR2, IFNLR1, and IL10RB) are detected in HD and SLE B cells. CD11c+ CD21- frequency increased in DN compared to naïve B cells for SLE and HD (both $p< 0.001$). The mean and range of CD11c+ CD21- frequency was higher in SLE DN (30.7± 9.5%, mean±SEM; range 4.8-74.7%) compared to HD DN (7.6%±1.0%,3.6-9.4%). Increased IFNLR1 transcript correlated with CD11c+ CD21- B cell expansion (r^2=0.922, $p< 0.0001$). Increased pSTAT1 after IFN-α2 treatment is found in monocytes, T cells, and B cells but only in the B cells after IFN-λ1 treatment. Naïve, DN, switched, and unswitched memory HD B cells are responsive to type I and type III IFN, but demonstrated a higher pSTAT1 fold change with type I IFN treatment compared to type III IFN. In all B cell subsets, CD11c+ cells had a higher pSTAT1 fold change after IFN-λ1 stimulation than did CD11c- B cells. In HD with well-defined populations of CD11c+ CD21- DN cells, pSTAT1 fold change for IFN-λ approached that of IFN-α2.

Conclusion: All human B cell subsets defined by CD27 and IgD respond to IFN-α and IFN-λ, but those expressing CD11c+ have increased responsiveness to IFN-λ. CD11c+ cells expand in SLE and associate with autoreactive plasma cell development. Thus, the role of IFN-λ may take on increased clinical significance in the setting type I IFN receptor blockade. These results suggest IFN-λ is an underappreciated driver of the IFN signature and B cell aberrations in SLE.

IL-13Ra1-Mediated Signaling Regulates Age-Associated/Autoimmune B-Cell Expansion and Lupus Pathogenesis

SESSION INFORMATION

Session Date: Tuesday, November 9, 2021

Session Title: Abstracts: B Cell Biology & Targets in Autoimmune & Inflammatory Disease (1905–1908)

Session Type: Abstract Session

Session Time: 2:00PM–3:00PM

Background/Purpose: Age-associated B cells (ABCs) are an emerging B cell subset that aberrantly expand in SLE. ABC generation and differentiation exhibit marked sexual dimorphism and TLR7 engagement is a key contributor to these sex differences. ABC generation is also controlled by IL-21 and its interplay with IFNg and IL-4. Here we

investigated whether IL-13Ra1, an X-linked receptor that transmits IL-4/IL-13 signals, can regulate ABCs and lupus pathogenesis.

Methods: Mice lacking DEF6 and SWAP-70 (Double-Knock-out=DKO) that develop lupus preferentially in females were crossed with IL-13Ra1ko mice. IL-13Ra1 kos were also crossed to Yaa-DKO males, which develop severe disease due to TLR7 overexpression. ABCs were assessed by FACS and RNA-seq and lupus pathogenesis was evaluated by serologic and histological analyses.

Results: ABCs express higher levels of IL-13Ra1 than follicular B cells. Absence of IL-13Ra1 in either DKO females or Yaa-DKO males decreased the accumulation of ABCs, their differentiation into plasmablasts, and autoantibody production. Lack of IL-13Ra1 also prolonged survival and delayed the development of tissue inflammation. IL-13Ra1 deficiency diminished the *in vitro* generation of ABCs, an effect that, surprisingly, could be observed in response to IL-21 alone. RNAseq revealed that ABCs lacking IL-13Ra1 downregulated BCR signaling pathways but upregulated myeloid markers and proinflammatory mediators.

Conclusion: These studies uncover a novel role for IL-13Ra1 in the control of ABC generation and differentiation and suggest that IL-13Ra1 contributes to these effects by regulating a subset of IL-21-mediated signaling events. These studies also suggest that X-linked genes in addition to TLR7 participate in the regulation of the ABC compartment in lupus.

SESSION INFORMATION
Session Date: Tuesday, November 9, 2021
Session Title: Abstracts: B Cell Biology & Targets in Autoimmune & Inflammatory Disease (1905–1908)
Session Type: Abstract Session
Session Time: 2:00PM–3:00PM

Background/Purpose: Juvenile Dermatomyositis (JDM) is a rare pediatric inflammatory myopathy with a complex pathophysiology. Previously our group showed a significant increase in Otoferlin mRNA expression in JDM patients' PBMCs and muscle compared to healthy controls. Otoferlin is a member of the dysferlin family, which plays an essential role in regulating calcium-sensitive exocytosis in inner ears sensory hair cells. To understand the role of this novel aspect of JDM disease pathophysiology, we next identified the cell expressing of Otoferlin and its association with disease activity in untreated children with JDM.

Methods: This IRB approved study was conducted at the Ann & Robert H. Lurie Children's Hospital of Chicago. Otoferlin expression was determined by qRT-PCR in peripheral blood mononuclear cells from untreated children with JDM and age, race, sex matched controls. The arm to freezer time was held at 2 hours or less. Clinical and laboratory variables, including age, gender, duration of untreated disease (DUD) and Disease Activity Scores (DAS skin, muscle, total), MSA, neopterin, and the status of the TNFα 308 allele were obtained from the Lurie Children's Juvenile Myositis Registry REDCap database. To identify cells expressing otoferlin, the cells were first stained with live dead stain to exclude dead cell. The following surface markers were determined (CD45, CD3, CD19, CD16, CD56, CD14 and CD11b) to characterize the otoferlin positive cells. We fixed and permeabilized the cells and then stained for cytoplasmic otoferlin expression. The otoferlin positive cells were primarily B cells; more detailed flow cytometry was performed with the following markers (CD19, IgM, IgD, IgG, CD27, CD21, CD24 and CD38) to characterize these B cells further.

Results: 30 untreated JDM (87% female, 90 % white, 43% P155/140+ve, 13% MJ+ve. 13% Mi-2+ve ,7% MDA+ve) and 15 healthy controls were included in this study. With the live dead stain (trypan blue) the cells were >90% viable. There was a significant increase in otoferlin expression in JDM children compared to controls (Median 47.6 vs. 2.1; p=0.002). There was a positive correlation between mRNA otoferlin expression and disease activity markers: neopterin (R^2=0.33, p=0.003), DAS-total (R^2=0.23 p=0.008), DAS-Muscle (R^2=0.18, p=0.024). Of note, otoferlin expression was not associated with DAS-Skin. Otoferlin expression was assessed by flowcytometry in 8 JDM patients and 3 controls which showed an increased percentage of otoferlin positive lymphocyte (Median 1.9% vs. 0.2% p= 0.03). The majority of the otoferlin positive cells were B cells (63% - 99.4%). Detailed B cell phenotyping in two samples showed that these B cells were IgD+, IgM+ CD27- naive B cell with 65-75% of them expressing plasmablast markers (CD19+, IgM+, CD38 hi, CD24-).

Conclusion: In this pilot study, we found that otoferlin expression by qRT-PCR was associated with muscle weakness, suggesting its possible utility as a biomarker of disease activity. Furthermore, we identified B cells and plasmablasts as the primary cells expressing otoferlin. Further investigation is required to identify the role of otoferlin in both B cell activation and its contribution to JDM pathophysiology.

Interferon (IFN)-Stimulated Gene 15: A Novel Biomarker for Lymphoma Development in Sjögren's Syndrome

Ilir i. Cinoku[1], Kleio-Maria Verrou[1], Evangelia Piperi[1], Michael Voulgarelis[2], Haralampos Moutsopoulos[3] and **Clio Mavragani**[1], [1]National and Kapodistrian University of Athens, Athens, Greece, [2]Department of Pathophysiology, School of Medicine, National and Kapodistrian University of Athens, Athens, Greece, [3]Athens Academy of Athens, Chair Medical Sciences/Immunology, Athens, Greece

SESSION INFORMATION
Session Date: Tuesday, November 9, 2021
Session Title: Abstracts: B Cell Biology & Targets in Autoimmune & Inflammatory Disease (1905–1908)
Session Type: Abstract Session
Session Time: 2:00PM–3:00PM

Background/Purpose: Primary Sjögren's syndrome (SS), an autoimmune exocrinopathy, is expressed either as a local disease or as a systemic illness with an enhanced risk for the development of lymphoma. Several clinical, laboratory, histopathological and molecular markers have been identified, but the pathogenetic pathway of lymphoma

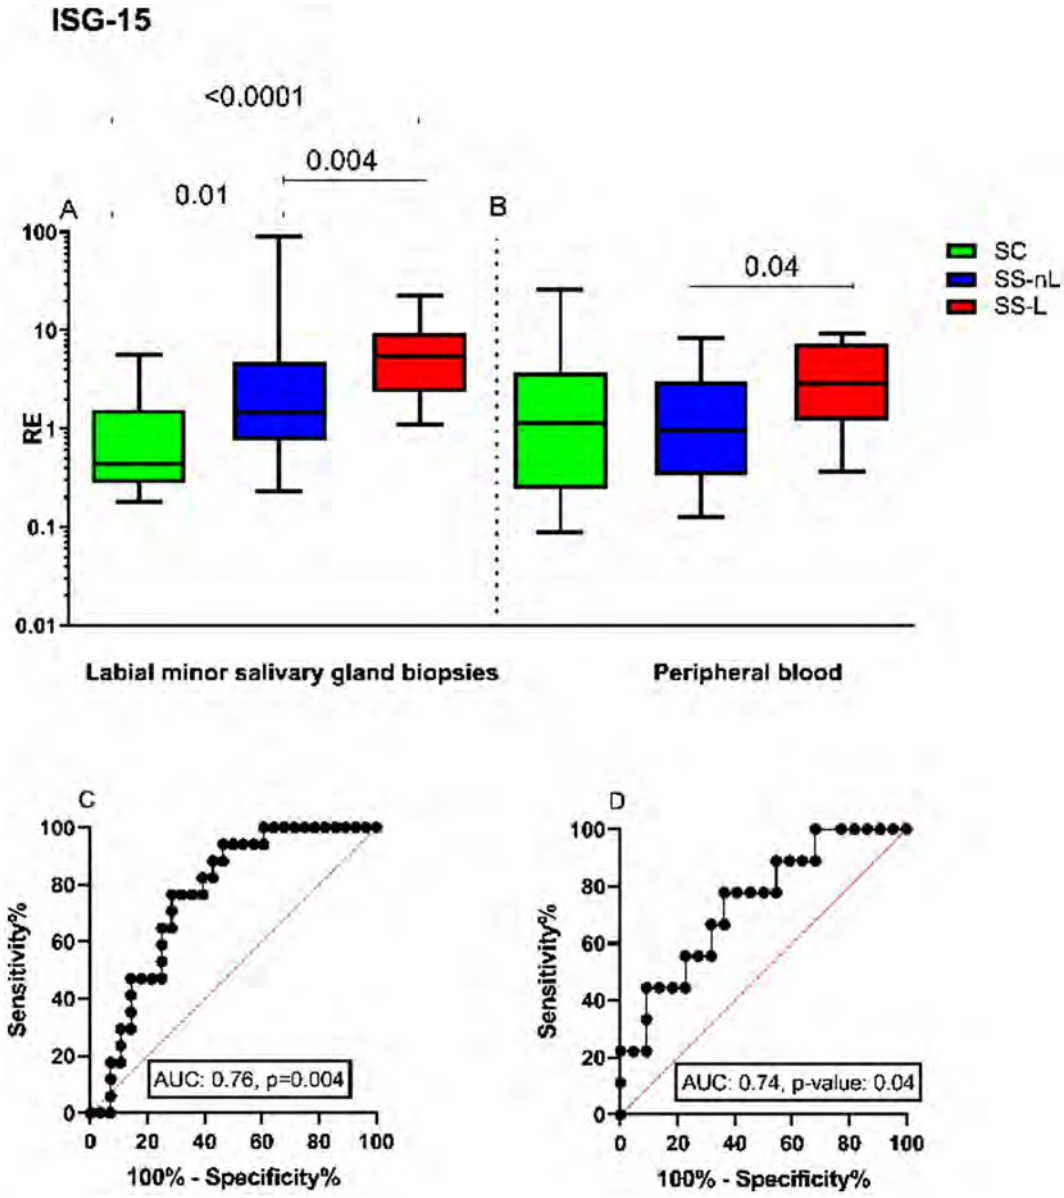

Figure 1. Relative expression of ISG-15 in 45 labial LMSG samples and 31 PB samples of SS patients and in 15 SC both in LMSG biopsies and PB samples.

development remains to a large extent unknown. We investigated whether interferon (IFN) induced genes could serve as biomarkers for the detection of lymphoma development among patients with SS.

Methods: Total RNA was extracted from 98 labial minor salivary glands (LMSG) biopsies of SS patients [61 not complicated by lymphoma (SS-nL) and 37 complicated by NHL (SS-L)] and from 67 matched to LMSG biopsies peripheral blood (PB) samples. Additionally, 30 LMSG biopsies and 17 matched PB of patients presenting with subjective dry eyes and/or dry mouth symptoms without fulfilling SS classification criteria (sicca controls, SC) were implemented. RNA sequencing was performed in total RNA extracted from 6 LMSG biopsies of 5 SS patients (2 at high risk and 3 at low risk for lymphoma development) and one SC. Expression analysis of type I (MX-1, IFIT-1, IFI44 and ISG-15) and type II IFN induced (CXCL9/MIG-1, GBP-1) genes was performed by real time PCR.

Results: Genes preferentially induced by type I IFNs including MX-1, IFIT-1 and IFI44 as well as ISG-15 and the type II IFN induced CXCL9/MIG-1 gene were up-regulated in “high risk” SS patients by next-generation sequencing (NGS).

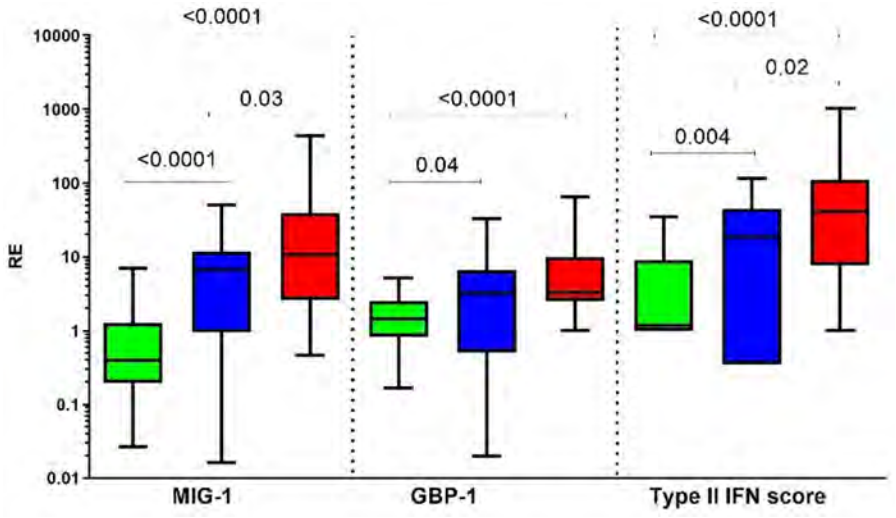

Figure 2. Relative expression of type II IFN inducible genes in LMSG tissues samples of SS patients and SC.

ISG-15 transcript levels measured by quantitative real time PCR were also higher in SS patients complicated by lymphoma (SS-L), compared to SS patients without lymphoma (SS-nL) in both LMSG tissues and PB specimens (mean ± SD: 6.6 ± 5.4 vs 6.3 ± 17.1, p = 0.004 and 4.2 ± 3.4 vs 1.9 ± 2.2, p = 0.04 respectively). ROC analysis revealed that both LMSG and PB ISG-15 gene expression has the potential to distinguish between SS-L and SS-nL patients (MSGB: AUC= 0.76, CI (95%): 0.62–0.90, p-value: 0.004 and PB: AUC= 0.74, CI (95%): 0.56–0.93, p-value: 0.04).

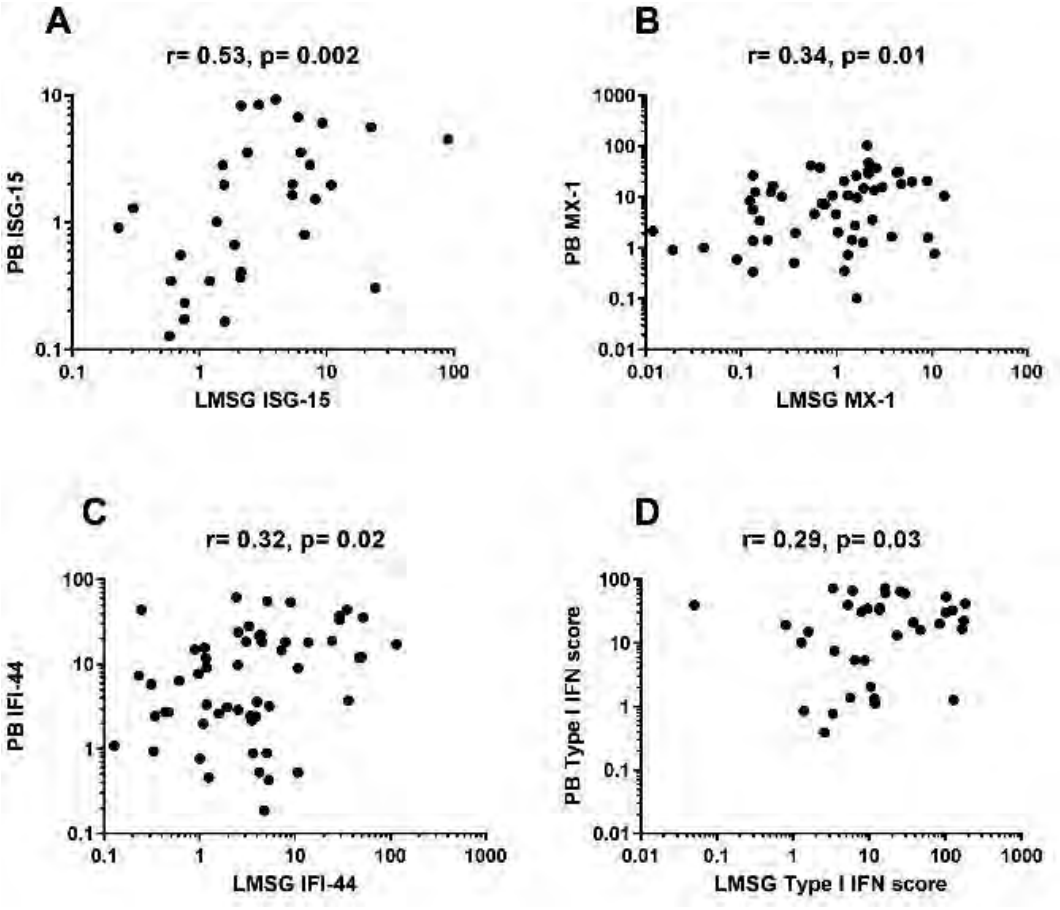

Figure 3. Correlation of relative gene expression in LMSG tissues and PB samples of type I and type II IFN induced genes.

(Figure 1) Only relative expression of MIG-1 and type II IFN score in LMSG tissues but not in peripheral blood were higher in SS-L patients compared to SS-nL patients (42.74 ± 93.18 vs 8.51 ± 9.95, p = 0.03 and 102.8 ± 205.2 vs 26.69 ± 30.27, p = 0.02, respectively) (Figure 2). Three of the genes preferentially induced by type I IFNs in LMSGs, ISG-15, MX-1 and IFI44, as well as type I IFN score in LMSG tissues were correlated with the corresponding values in PB (Spearman r = 0.53, p = 0.002, Spearman r = 0.34, p = 0.01, Spearman r = 0.33, p = 0.02 and Spearman r = 0.29, p = 0.03) (Figure 3). No other type I or II IFN inducible genes tested either at PB or LMSG level was predictive for lymphoma development in SS patients.

Conclusion: ISG-15 gene expression was able to distinguish SS-nL and SS-L at both periphery and tissue level and therefore could represent a novel biomarker for lymphoma development among SS patients. PB and LSMG seem to share a common transcriptional profile of type I IFN pathway.

Impact of Antimalarial Adherence on Cardiovascular Mortality Among Patients with Newly Diagnosed Rheumatoid Arthritis and Systemic Lupus Erythematosus: A Population-based Study

Md Rashedul Hoque[1], J. Antonio Avina-Zubieta[2], Diane Lacaille[2], Mary De Vera[3], Yi Qian[3], John Esdaile[4] and Hui Xie[5], [1]Simon Fraser University, Vancouver, BC, Canada, [2]Arthritis Research Canada, Richmond, BC, Canada, [3]University of British Columbia, Vancouver, BC, Canada, [4]Arthritis Research Canada, Vancouver, BC, Canada, [5]Simon Fraser University, Burnaby, BC, Canada

SESSION INFORMATION
Session Date: Tuesday, November 9, 2021
Session Title: Abstracts: Patient Outcomes, Preferences, & Attitudes (1909–1914)
Session Type: Abstract Session
Session Time: 2:00PM–3:30PM

Background/Purpose: Literature has shown poor adherence to antimalarial (AM) medications in rheumatoid arthritis (RA) and systemic lupus erythematosus (SLE) patients, with the percentage of adherers ranging from 25% to 57%. However, the impact of AM adherence on cardiovascular (CVD) mortality has not been extensively studied. Our objective is to examine the association between AM adherence and CVD mortality among newly diagnosed incident RA and SLE patients.

Methods: We used administrative databases from British Columbia (BC), Canada, to conduct a retrospective study of population-based incident RA and SLE cohorts with incident AM use. The incident RA and SLE cases first met previously published RA, and SLE, criteria using administrative data between January 1997 and March 2015. Follow-up started on the first day of receiving AM and meeting either RA or SLE criteria. Subjects were followed until they died, left BC, or March 2015, whichever occurred first. The outcomes were mortality for the following CVD causes: myocardial infarction (MI), stroke, or venous thromboembolism (VTE). We used marginal structural models (MSM) to estimate the effect of AM adherence on CVD mortality, accounting for potential confounders and competing events due to death unrelated to CVD. In the analysis, follow-up time was divided into 90-days windows. For each window, the proportion of days covered (PDC), representing the proportion of time when medications were taken as prescribed, was calculated and categorized as adherent (PDC≥0.90), non-adherent (0< PDC< 0.90), and discontinued (PDC=0). The analyses were controlled for baseline demographics and the indicator of having RA or SLE, as well as

Table 1. Overall risk of CVD mortality in incident RA and SLE patients during follow-up

Adherence Levels	Number of Deaths	Total Person-years	IR per 1000 person-years	IR Ratios (95% CI)	MSM aHRs (95% CI)
Discontinuation [Reference]	602	106,476	5.65	1.00	1.00
Non-adherence	165	35,272	4.68	0.82 (0.70-0.98)	1.08 (0.91-1.31)
Adherence	133	42,910	3.10	0.55 (0.45-0.66)	**0.51 (0.42-0.62)**
Contrast: Adherence vs. Non-adherence				0.66 (0.53-0.83)	**0.47 (0.37-0.60)**

Discontinuation: PDC=0, Non-adherence: 0<PDC<0.90, Adherence: PDC≥0.90. Abbreviations: **IR**, incidence rate; **aHR**, adjusted hazard ratio; **MSM**, marginal structural model; **CI**, confidence interval; **PDC**, proportion of days covered.

The multivariable models were adjusted for baseline covariates including demographic variables (age, sex, location of residence, neighborhood income quintile), indicator of having RA or SLE, health resource utilization (hospital visits, physician and specialist visits including rheumatologist, nephrologist, and psychiatrist visits), medication usage (statins, other cardiovascular drugs, hormone replacement therapy, glucocorticoids, anticoagulant therapy, Cox-2 inhibitors, immunosuppressive drugs), comorbidities (hypertension, chronic obstructive pulmonary disease, angina), and the Romano adaptation of the Charlson comorbidity index for administrative data. Also, the time-varying variables of health resource utilization, medication usage, Charlson comorbidity index, and comorbidities were used to calculate weights in marginal structural model.

the following sets of baseline and time-varying covariates: medication usage, health resource utilization, comorbidities, and Romano adaptation of Charlson comorbidity index (see footnote of Table 1). The MSM analysis produces valid estimates in the presence of time-varying confounding and competing events by balancing the distributions of time-varying confounders among the three adherence groups through inverse probability weighting.

Results: We identified 21,114 individuals with incident RA or SLE (mean age 55.8 years, 75.9% were women) who had filled at least one AM prescription. Over the mean follow-up of 8.6 years, 900 (4.3%) patients died due to a CVD cause: MI, stroke, or VTE. The incidence rate (IR) of CVD mortality when patients were adherent, non-adherent, and discontinued AM were 3.10, 4.68, and 5.65 per 1000 person-years. Using MSM, the adjusted CVD mortality hazard ratios (HRs) obtained for AM non-adherence and adherence in RA or SLE patients were 1.08 (95% CI: 0.91-1.31) and 0.51 (95% CI: 0.42-0.62), respectively, relative to discontinuation (**Table 1**). Also, the adjusted HR for adherence compared to non-adherence was 0.47 (95% CI: 0.37-0.60). Similar findings were obtained for each cause of CVD mortality individually except VTE (**Table 2**).

Conclusion: When RA and SLE patients adhere to AM therapy, they have a 49% lower risk of CVD mortality than when patients discontinue AM. Also, the protective effect of AM was not observed when patients were taking less than 90% of the prescribed AM dose.

Table 2. Overall risk of death caused by MI, stroke, and VTE in incident RA and SLE patients during follow-up

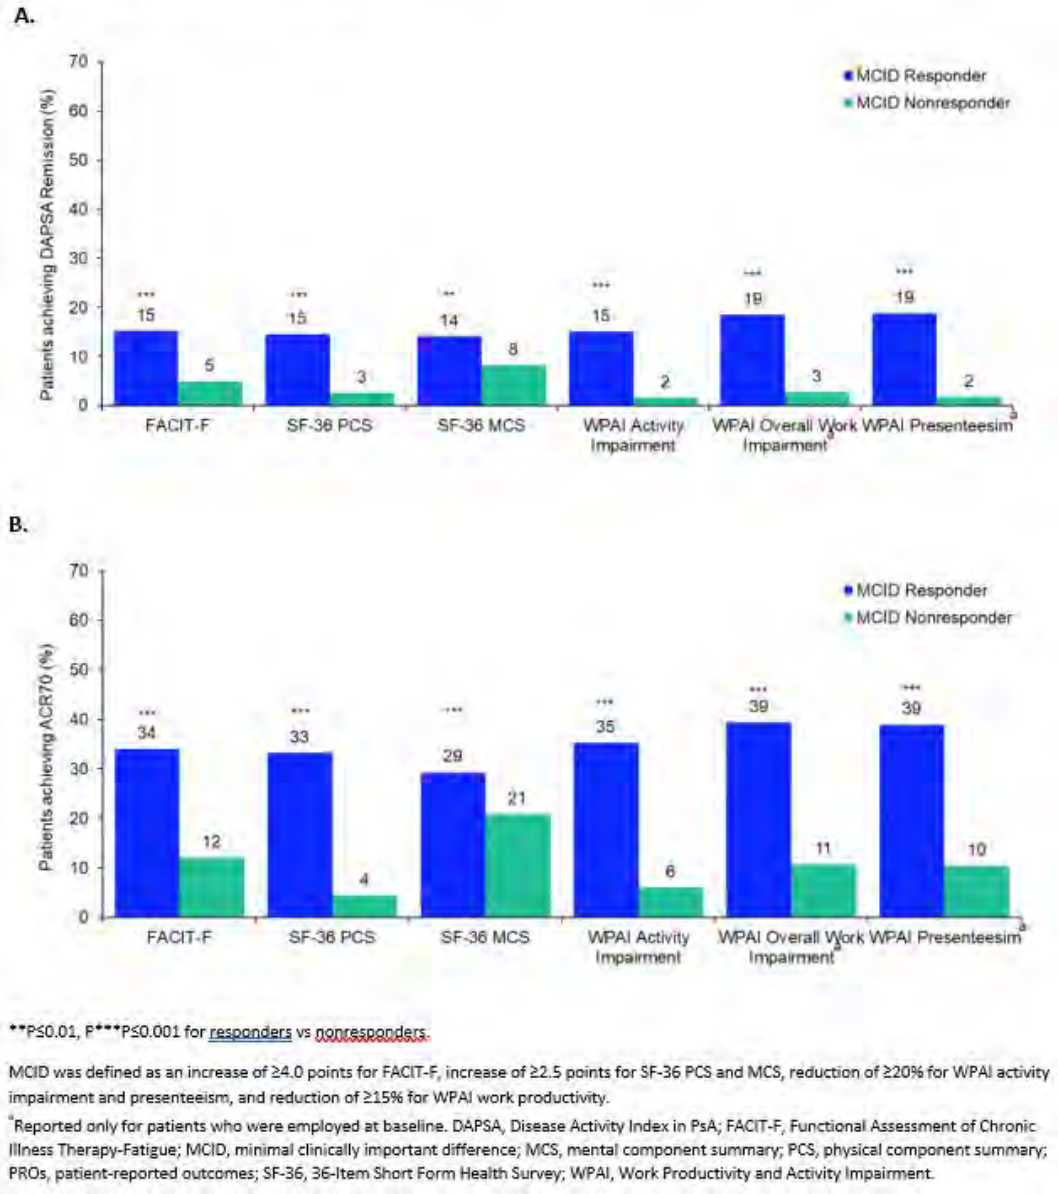
Session Date: Tuesday, November 9, 2021

Session Title: Abstracts: Patient Outcomes, Preferences, & Attitudes (1909–1914)

Session Type: Abstract Session

Session Time: 2:00PM–3:30PM

Figure 1. Proportions of Patients Achieving (A) DAPSA Remission or (B) ACR70 as a Function of PRO Improvements ≥MCID at Week 24



P≤0.01, P*P≤0.001 for responders vs nonresponders.

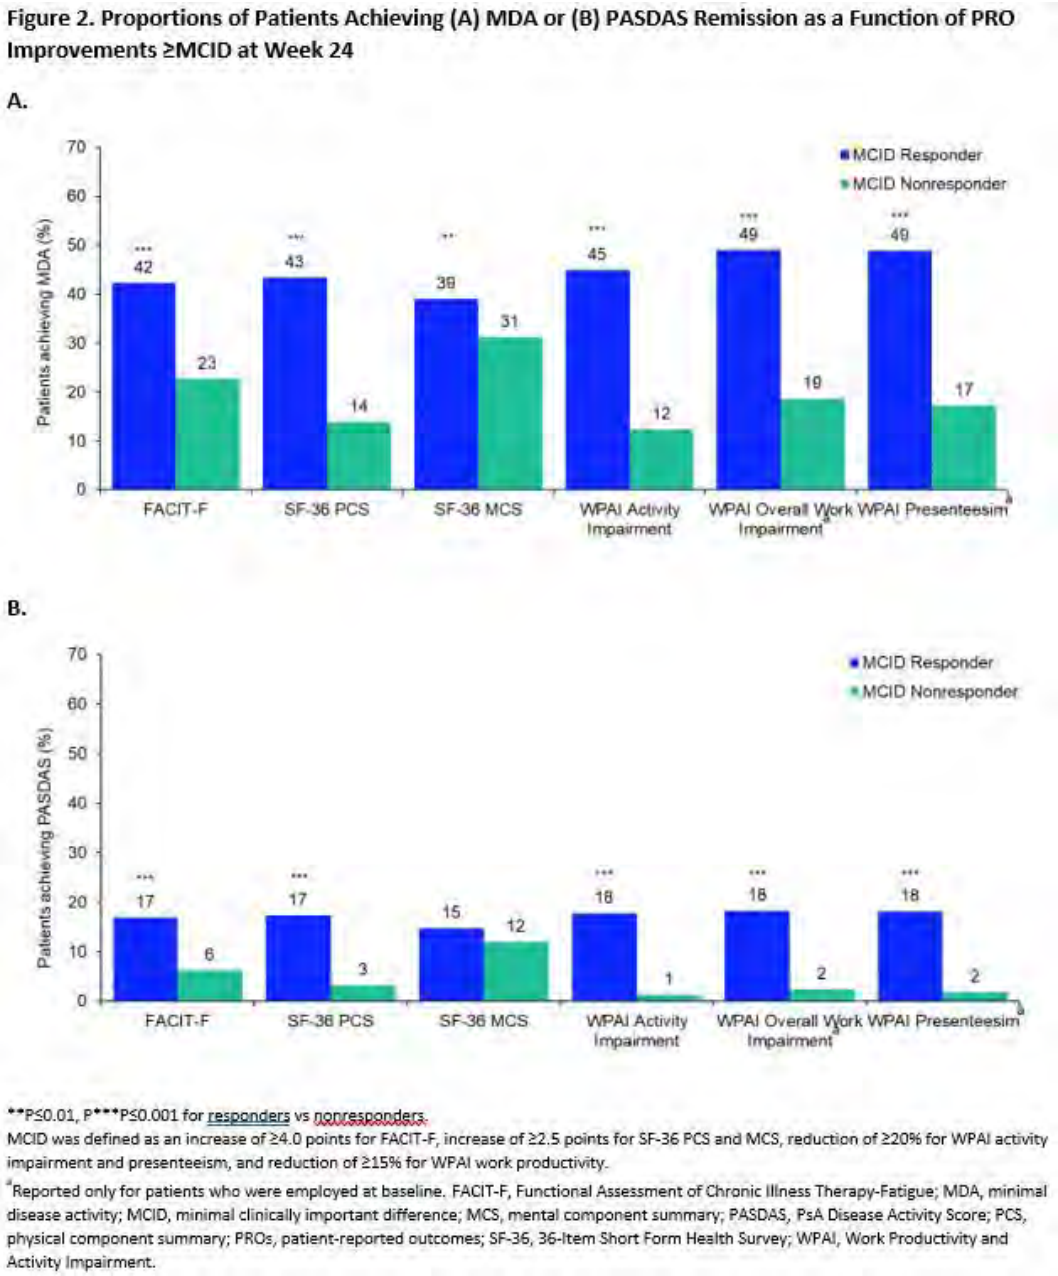
MCID was defined as an increase of ≥4.0 points for FACIT-F, increase of ≥2.5 points for SF-36 PCS and MCS, reduction of ≥20% for WPAI activity impairment and presenteeism, and reduction of ≥15% for WPAI work productivity.

[a]Reported only for patients who were employed at baseline. DAPSA, Disease Activity Index in PsA; FACIT-F, Functional Assessment of Chronic Illness Therapy-Fatigue; MCID, minimal clinically important difference; MCS, mental component summary; PCS, physical component summary; PROs, patient-reported outcomes; SF-36, 36-Item Short Form Health Survey; WPAI, Work Productivity and Activity Impairment.

Background/Purpose: The achievement of disease control has been shown to be associated with improved prognosis in PsA, though no single measure of low disease activity or remission is currently universally accepted. Patient-reported outcomes (PROs) have been well-established in PsA and are important indicators of patient improvement while on treatment. To date, the association between PROs and disease control in PsA has not been fully characterized. We examined the association between clinically meaningful improvement in PROs and stringent measures of disease control among patients with PsA enrolled in the Phase 3 SELECT-PsA 1 trial.

Methods: Patients with active PsA and an inadequate response to ≥1 non-biologic DMARDs were randomized to receive upadacitinib (UPA) 15 mg once daily (QD), UPA 30 mg QD, adalimumab (ADA) 40 mg every other week, or PBO for 24 weeks. PROs included: Functional Assessment of Chronic Illness Therapy-Fatigue (FACIT-F), 36-Item Short-Form Health Survey (SF-36), and Work Productivity and Activity Impairment (WPAI). Measures of stringent disease control included achievement of minimal disease activity (MDA), ACR70 response, and remission based on Disease Activity Index in PsA (DAPSA ≤4.0) or PsA Disease Activity Score (PASDAS ≤1.9). The percentage of patients

Figure 2. Proportions of Patients Achieving (A) MDA or (B) PASDAS Remission as a Function of PRO Improvements ≥MCID at Week 24



P≤0.01, P*P≤0.001 for responders vs nonresponders.
MCID was defined as an increase of ≥4.0 points for FACIT-F, increase of ≥2.5 points for SF-36 PCS and MCS, reduction of ≥20% for WPAI activity impairment and presenteeism, and reduction of ≥15% for WPAI work productivity.
[a]Reported only for patients who were employed at baseline. FACIT-F, Functional Assessment of Chronic Illness Therapy-Fatigue; MDA, minimal disease activity; MCID, minimal clinically important difference; MCS, mental component summary; PASDAS, PsA Disease Activity Score; PCS, physical component summary; PROs, patient-reported outcomes; SF-36, 36-Item Short Form Health Survey; WPAI, Work Productivity and Activity Impairment.

achieving stringent disease control was determined among patients reporting vs not reporting PRO improvements ≥ minimal clinically important differences (MCID) in the combined active treatment and PBO group at Week 24.

Results: A total of 1704 patients were included in the SELECT PsA 1 trial, of whom 59.2%, 72.4%, 51.3%, 62.3%, 64.6%, and 63.9% reported improvements ≥ MCID (MCID responders) in FACIT-F, SF-36 physical component summary score, SF-36 mental component summary (MCS) score, WPAI activity impairment, WPAI overall work impairment, and WPAI presenteeism, respectively, at week 24. The percentage of patients achieving MDA, ACR70 or DAPSA remission at week 24 was significantly higher (nominal $P \leq 0.01$) among patients who reported improvements ≥ MCID for all PROs vs those who did not (Figures 1,2). Similar results were seen in patients achieving PASDAS remission except for SF-36 MCS score (Figure 2). Among patients reporting improvements ≥ MCID across all PROs, more patients achieved ACR70 and MDA responses (29%-49%) with fewer patients achieving DAPSA or PASDAS remission (14%-19%).

Conclusion: PsA patients who reported clinically meaningful improvements in key PROs: fatigue, quality of life, and work productivity were more likely to achieve stringent measures of disease control. These results suggest a close association between meaningful improvements in patient-centric outcomes and achievement of stringent disease control.

Patient's and Rheumatologist's Perspectives on the Burden of Adverse Drug Reactions Attributed to Biologics: A Qualitative Study

Henrike Westerink[1], Leanne Kosse[2], Naomi Jessurun[2], Astrid van Tubergen[3], Harald Vonkeman[4], Mike Nurmohamed[5], Bart van den Bemt[6] and Marieke de Vries[7], [1]Netherlands Pharmacovigilance Centre Lareb, Nijmegen, Netherlands, [2]Netherlands Pharmacovigilance Centre Lareb, 's-Hertogenbosch, Netherlands, [3]Maastricht UMC+, Maastricht, Netherlands, [4]Medisch Spectrum Twente; University of Twente, Enschede, Netherlands, [5]Reade; Amsterdam Rheumatology & Immunology Center, Amsterdam, Netherlands, [6]Sint Maartenskliniek; Radboud University Medical Center, Ubbergen, Netherlands, [7]Radboud University Medical Centre, Nijmegen, Netherlands

SESSION INFORMATION

Session Date: Tuesday, November 9, 2021

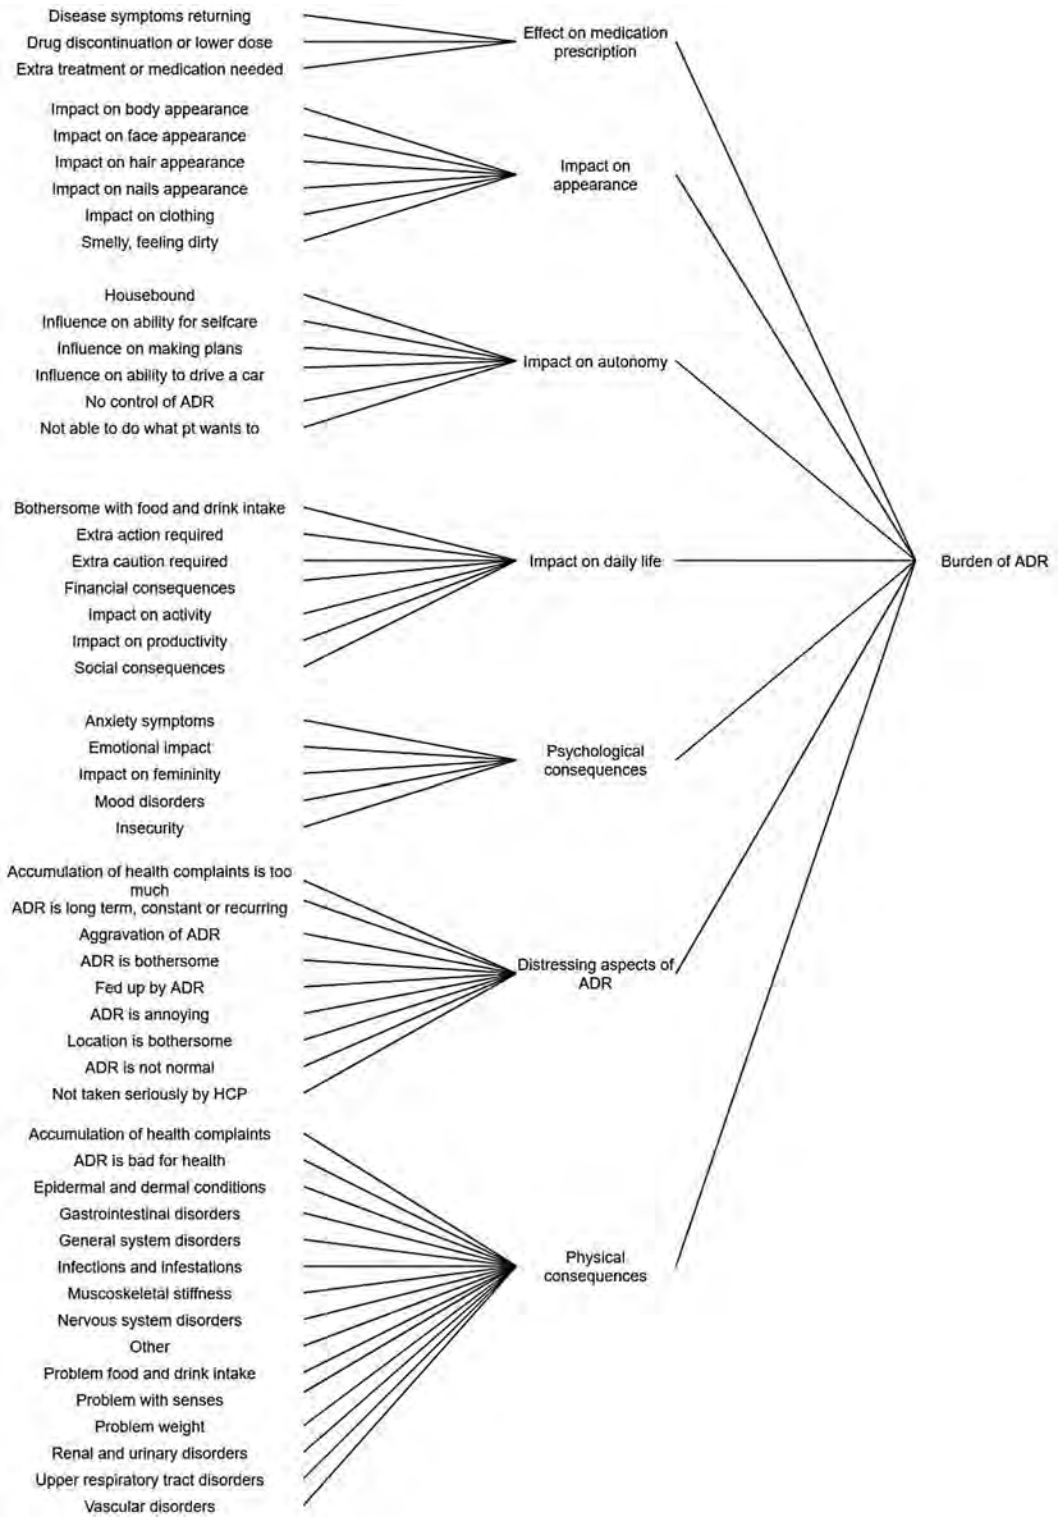
Session Title: Abstracts: Patient Outcomes, Preferences, & Attitudes (1909–1914)

Session Type: Abstract Session

Session Time: 2:00PM–3:30PM

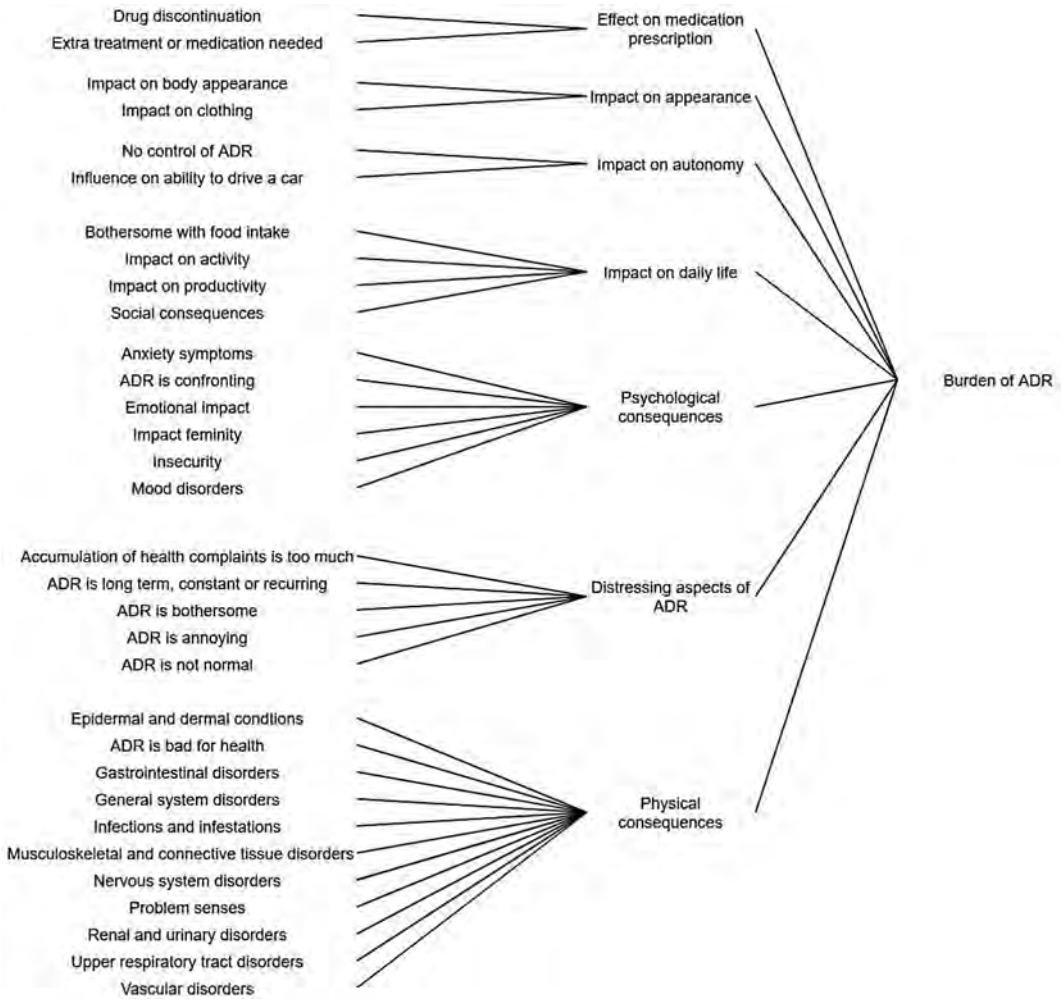
Background/Purpose: Previous studies showed a discrepancy between patient's and HealthCare Professional (HCP) perspective on the burden of Adverse Drug Reactions (ADRs), where HCPs often underestimate the burden. However, it is unknown which factors determine whether a patient perceives an ADR as burdensome. This study aimed to provide more insight into the burden of ADRs reported by patients with inflammatory rheumatic diseases that are attributed to the use of biologics, by identifying the factors that determine patient-perceived burden. Furthermore, this study aimed to compare both patient's and rheumatologist's perspective on these factors, to give more insight in the discrepancy between their perspectives.

Methods: Qualitative data from the Dutch Biologic Monitor (DBM) was used to assess the patient's perspective on the burden of ADRs. In the DBM, immune-mediated inflammatory disease patients were asked to fill out a bimonthly questionnaire on experienced ADRs attributed to the biologic, start and stop date, course, and the burden of the ADR using a five-point Likert-type scale ranging from 1 (no burden) to 5 (very high burden). Inclusion criteria for this substudy were: patients with inflammatory rheumatic diseases (i.e. rheumatoid arthritis, psoriatic arthritis and spondyloarthritis), reporting an ADR, and elaboration on the burden in an open text-field. Answers of the patients in open-text fields on the burden of the experienced ADR was analysed with a thematic analysis to develop a conceptual framework. Semi-structured interviews with 13 rheumatologists were performed and used to develop a conceptual framework on their perspective on the burden of ADRs. The two frameworks were compared to each other to highlight differences in perspectives.



Conceptual framework of ADR burden attributed to biologics from the patient's perspective. Participants were inflammatory rheumatic disease patients (n=440). ADR = Adverse Drug Reaction. HCP = HealthCare Professional. Medical Dictionary for Regulatory Activities (MedDRA®) terminology (version 21.0) was used for various subthemes in psychical consequences.

Results: A total of 440 unique patients were included in this study. Seven themes were identified that lead to the burden of ADRs according to patients. These were: effect on medication prescription, impact on appearance, impact on autonomy, impact on daily life, psychological consequences, distressing aspects of ADRs, and physical conse-



Conceptual framework of ADR burden attributed to biologics from the rheumatologist's perspective. Themes emerged from interviews with rheumatologists (n=11) and rheumatologists in training (n=2). ADR = Adverse Drug Reaction. HCP = HealthCare Professional. Medical Dictionary for Regulatory Activities (MedDRA®) terminology (version 21.0) was used for various subthemes in psychical consequences.

quences. Each theme consisted of several subthemes, shown in Figure 1. Most of these themes were also mentioned by the rheumatologists, but some subthemes were missing, e.g. influence on making plans (Fig. 2). Conversely, one subtheme was only mentioned by the rheumatologists, i.e. 'ADR is confronting', where the ADR would confront them with being ill or dependent on medication. In comparison to the patient's perspective, the rheumatologists paid less attention to the impact on the patient's autonomy and daily life, and more attention to the psychological aspects.

Conclusion: Overall, the patient perspective and the rheumatologist perspective on burden of ADRs were broadly comparable, but rheumatologists likely underestimated practical aspects that lead to burden of ADRs, and overestimated the psychological burden. The insights of this study facilitate the development of a Patient-Reported Outcome Measure on the burden of ADRs and create more awareness among rheumatologists.

SESSION INFORMATION

Session Date: Tuesday, November 9, 2021

Session Title: Abstracts: Patient Outcomes, Preferences, & Attitudes (1909–1914)

Session Type: Abstract Session

Session Time: 2:00PM–3:30PM

Background/Purpose: The notion that weather conditions may influence the symptoms and course of rheumatic and musculoskeletal diseases goes back to ancient times. We aimed to evaluate whether meteorological variables influence disease activity in patients with rheumatoid arthritis (RA).

Methods: We assessed the correlation between individual meteorological variables: temperature, effective temperature, saturation vapor pressure, absolute humidity, relative humidity, dew point, precipitation and clinical measures of disease activity: simplified disease activity index (SDAI), self-reported pain, patient's global assessment (PGA), 28 tender joint count (TJC) and 28 swollen joint count (SJC). Assessments documented in the Care for RA database were matched with weather variables on a daily basis for a period of 12 years between 2005 and 2017, and analyzed using generalized estimating equations (longitudinal data analysis). Patients with < 5 visits in the study period, those with < 1 visit/quarter or with pain=0 in ≥3 consecutive visits and those living outside of the catchment area were excluded.

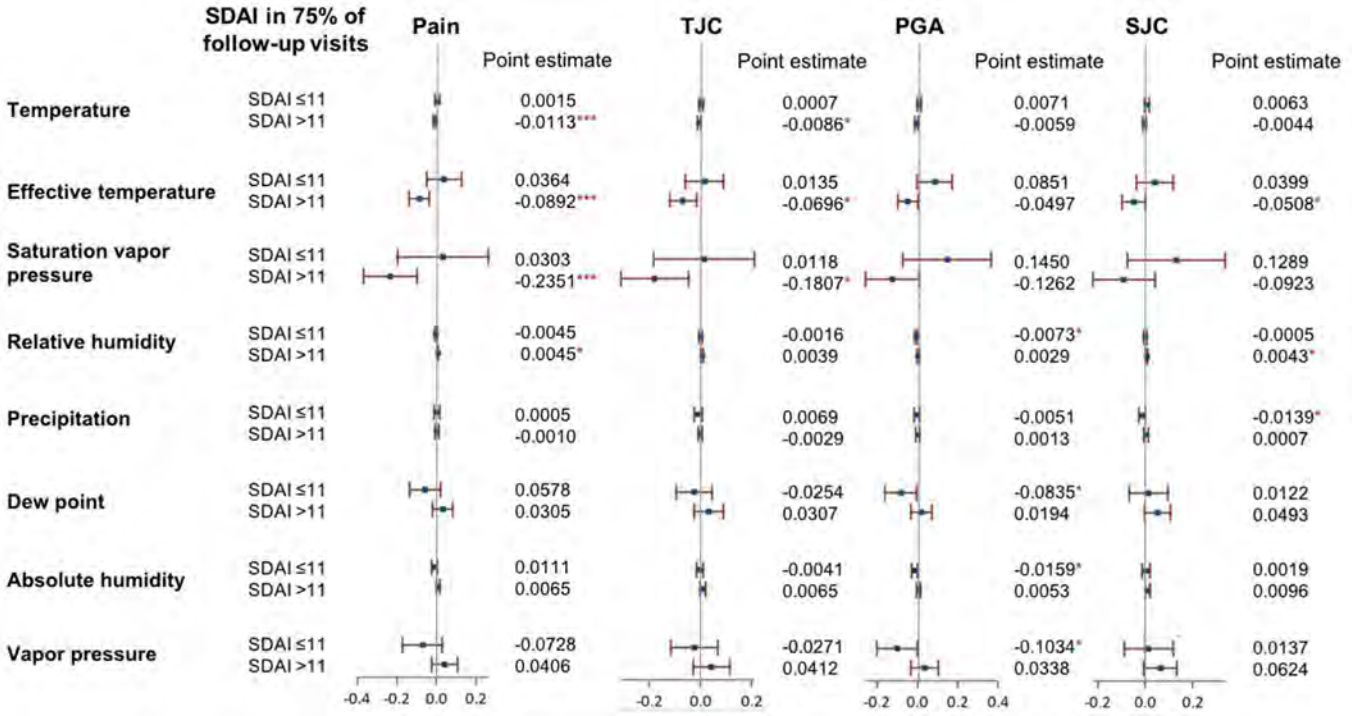

Figure 1. Association of meteorological variables and clinical measures of disease activity. PGA: patient's global assessment; SDAI: simplified disease activity index; SJC: swollen joint count; TJC: tender joint count; * p≤ 0.05, ** p≤ 0.01, *** p≤ 0.001.

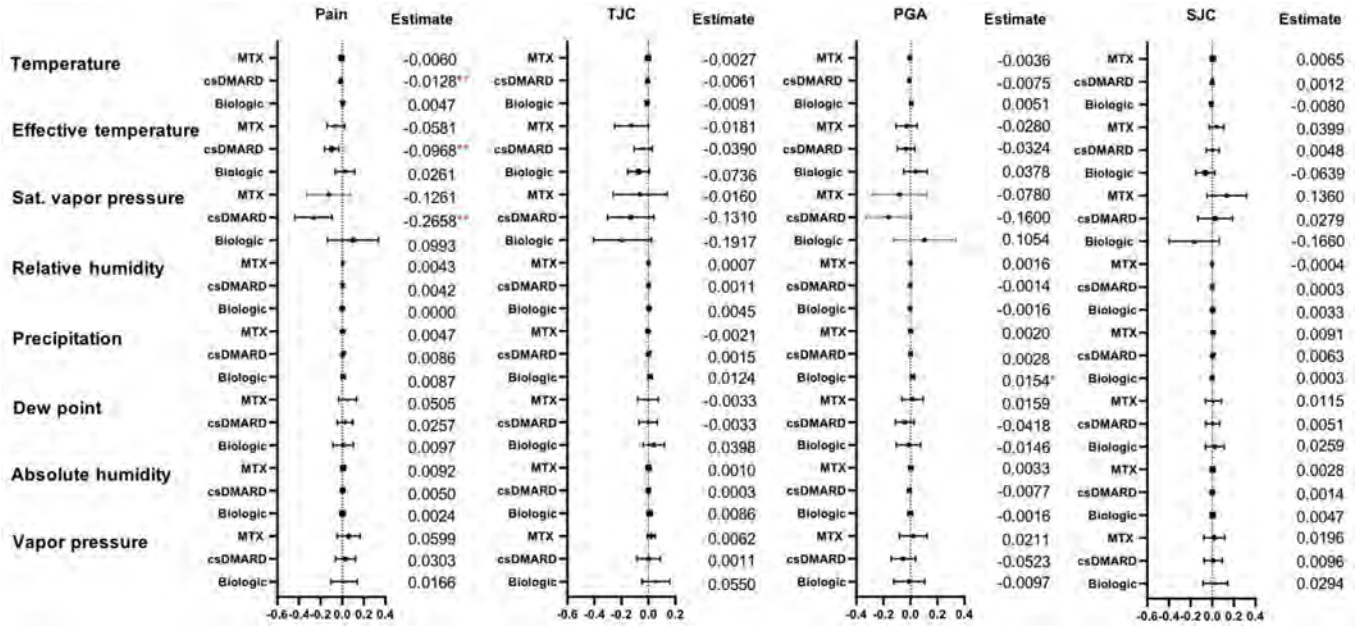

Figure 2. Association of meteorological variables and clinical measures of disease activity in stable therapy periods. csDMARD: conventional synthetic disease modifying anti-rheumatic drug; MTX: methotrexate; PGA: patient's global assessment; SDAI: simplified disease activity index; SJC: swollen joint count; TJC: tender joint count; * p≤ 0.05, ** p≤ 0.01, *** p≤ 0.001.

Patients were grouped into low (≤11) vs. moderate/high (>11) disease activity based on SDAI, and additionally considering only subsequent outpatient visits (>3 visits) where the therapy was stable (>6 months). On this basis three treatment groups were established: patients taking (1) methotrexate, (2) csDMARD or (3) bDMARD in mono- or combination therapy respectively.

Results: A total of 461 patients with an average disease duration at first visit of 5.7±7.4 years, age of 55.3±14.5 years, mean SDAI: 22.1±12.7 were analyzed. Among patients with moderate/high disease activity, higher temperature/effective temperature and saturation vapor pressure were associated with lower pain and TJC. On the contrary, higher relative humidity was associated with higher pain and higher SJC. Among patients with low disease activity higher relative humidity, absolute humidity, vapor pressure or dew point were associated with lower PGA. Higher precipitation was associated with lower SJC in the low disease activity group (Figure 1). When analysed according to stable treatment period, patients treated with csDMARD in mono- or combination therapy showed the same association between higher average daily temperature/effective temperature or saturation vapor pressure and lower pain as seen in patients with moderate/high disease activity (Figure 2).

Conclusion: In this largest association study of meteorological parameters with RA, both temperature and humidity were shown to have significant effects on pain, TJC and SJC, while PGA was mostly influenced by humidity. Weather had different effects depending on RA disease activity.

SESSION INFORMATION

Session Date: Tuesday, November 9, 2021

Session Title: Abstracts: Patient Outcomes, Preferences, & Attitudes (1909–1914)

Session Type: Abstract Session

Session Time: 2:00PM–3:30PM

Background/Purpose: During the COVID-19 pandemic, healthcare systems rapidly expanded telemedicine to ensure continued access to care. Few studies have explored patient perceptions of the telemedicine experience during the COVID-19 pandemic. The aim of this study was to better understand patient perspectives related to telemedicine use, including effectiveness and barriers of telemedicine use.

Methods: The COVID-19 Global Rheumatology Alliance (C19-GRA) Patient Telemedicine Survey was an anonymous, cross-sectional online survey of participants with rheumatic and musculoskeletal diseases (RMD) from December 2020 to May 2021. Information on diagnoses, demographics, socioeconomic status, and respondents' perspectives on benefits and limitations of telemedicine use were collected. Data were summarized with descriptive statistics. Multivariable regression models adjusted for age, sex, country, disease type, and education level to perform relative risk estimates for dichotomous outcomes.

Results: The cohort included 596 respondents, of which 87% (514) were female, 47% (281) were 41-60 years of age. Race and ethnicity data were only collected for U.S respondents in which 81% (211) were white (Table 1). Common diagnoses were SLE (33%, 196) and RA (21%, 125). Most respondents were from the USA (44%, 262) or the United Kingdom (32%, 190). 79% (468) had completed a college or university degree or higher.

Of the 78% (467) respondents who used telemedicine during the pandemic, 65% (305) used audio (telephone) and 52% (242) used video (Table 2); about 70% (323) reported no problems when using video for telemedicine visits. 61% (283) found telemedicine effective compared to in-person visit and 40% (186) reported it would be important after the COVID-19 pandemic.

After adjusting for age, sex, country, disease type, and education level, UK respondents were more likely to report lower satisfaction with telemedicine care by their rheumatologists during the COVID-19 pandemic compared to US respondents. Those in high school were more likely to report lower satisfaction with telemedicine care compared to college graduates. Groups that rated telemedicine as less effective in their rheumatologic care included people over 60, respondents from the UK, Canada and Australia/New Zealand, as well as participants with graduate level education. Groups that reported post-pandemic telemedicine use as less important in their care included people over age 60 and respondents from the UK and Norway (Table 3).

Table 1: Demographics of Respondents.

Demographic Variable	Summary Values (%) N=596
Age	
Under 20	61 (10.2)
21- 40	131 (22.0)

Medications without any reported usage at the time of vaccination: Chloroquine, Cyclosporine, Tacrolimus, Rilonacept, Cyclophosphamide.
Percentages are reported as column percentages.

Background/Purpose: Due to concerns about underlying immune dysregulation and immunosuppression, patients with systemic rheumatic diseases (SRD) may have modified their medications at the time of COVID-19 vaccination to optimize their immune response. Although the American College of Rheumatology COVID-19 Vaccine Clinical Guidance Task Force issued management guidelines on February 8, 2021, it is unclear how rapidly these guidelines were disseminated. Our study evaluated real-world medication modification at the time of COVID-19 vaccination by Rheumatology patients at a single center in New York City.

Methods: We emailed a secure web-based survey to 7,505 patients aged ≥18 years evaluated at least once by a rheumatologist between April 1, 2018-April 21, 2020 at a large Rheumatology center in New York City. A follow-up survey was sent between March 5, 2021 and March 25, 2021. In the current analysis, we included individuals who indicated receiving at least the 1st vaccine dose. We collected data on immunomodulatory and immunosuppressive medication usage and modifications at the time of COVID-19 vaccination. We also collected the source responsible for the medication modifications (i.e. rheumatologist, other physician, patient).

Results: 1852/7505 (24.7%) patients responded to vaccination and medication modification questions (mean age: 63±13.2 years, 79.6% female, 87.4% white, 4.8% Hispanic/Latinx). 1852 patients received at least 1COVID-19 vaccine dose (53.9% Pfizer, 44.3% Moderna, 1.4%% Janssen, 0.38% Other) and 1173 reported having two doses. At 1st dose, there were 1373 individual reports of immunomodulatory or corticosteroid use (27.7% hydroxychloroquine, 26.5% biologics, 27.7% conventional DMARDs, 12.7% corticosteroids, 4.7% small molecules, 0.9% other DMARDs). Before the 1st vaccine dose, 204 medications (15.7%) were modified; of these, 19% were taken earlier than scheduled, and 81% were delayed/skipped. At 2nd dose, out of 899 individual medication reports, 251 medica-

tions (27.9%) were modified. Of these, 105 medications (41.8%) were delayed/skipped between the 1st and 2nd dose, 41 (16.3%) were taken earlier than scheduled and 105 (41.8%) were delayed/skipped after the 2nd vaccine dose. Biologics, typically anti-TNF inhibitors, and conventional DMARDs, typically methotrexate, accounted for most of the medications modified before or after the vaccine doses **(Table 1)**. Patients modified their own medications >50% of the time before the 1st vaccine dose, and opted to take medication early >70% of the time before the 2nd vaccine dose **(Table 2)**. Over half of the medications that were delayed/skipped after the 2nd vaccine were recommended by a rheumatologist **(Table 2)**.

Conclusion: Up to 28% of immunomodulatory or immunosuppressive medications were modified around the time of COVID-19 vaccination, and patients were responsible for up to 73% of modifications. The wide variety of medication modification provides insight into patient behavior and underscores the need for increased usage of evidence-based guidelines to inform patient and physician guidelines. Future studies will assess the implications of these medication modifications on SRD activity and flares post-vaccination.

SESSION INFORMATION
Session Date: Tuesday, November 9, 2021
Session Title: Abstracts: RA – Diagnosis, Manifestations, & Outcomes II: Heart & Lung (1915–1918)
Session Type: Abstract Session
Session Time: 2:00PM–3:30PM

Background/Purpose: Many guidelines recommend limiting glucocorticoids to short-term use in patients with rheumatoid arthritis (RA), but up to 40% of patients remain on glucocorticoids long-term. In this study we evaluated the cardiovascular risk of long-term, low-dose glucocorticoid use by studying patients on stable DMARD treatments.

Methods: Using Medicare claims and Optum's deidentified Clinformatics Data Mart from 2006 to 2015, we identified patients with RA (2 diagnosis codes ≥7 days apart) who remained on stable DMARD therapy for >180 days (no gaps >90 days and no new DMARDs), excluding patients with previous myocardial infarction (MI), stroke, coronary artery bypass grafting, or percutaneous coronary intervention using all available data during or prior to the baseline period. The 180 days before DMARD initiation and the first 180 days of stable DMARD course comprised the baseline period. Average glucocorticoid dose was assessed during the final 90 days of the baseline period and categorized as none, ≤5mg, 5-10mg, or >10mg/day. Inverse probability weights for the likelihood of being prescribed each glucocorticoid dose category were constructed using multinomial logistic regression. Cause-specific proportional hazards models with inverse probability weights and clustering to account for patients with multiple treatment periods were used

Values are in the format: mean (standard deviation), n (%), or median [interquartile-range]

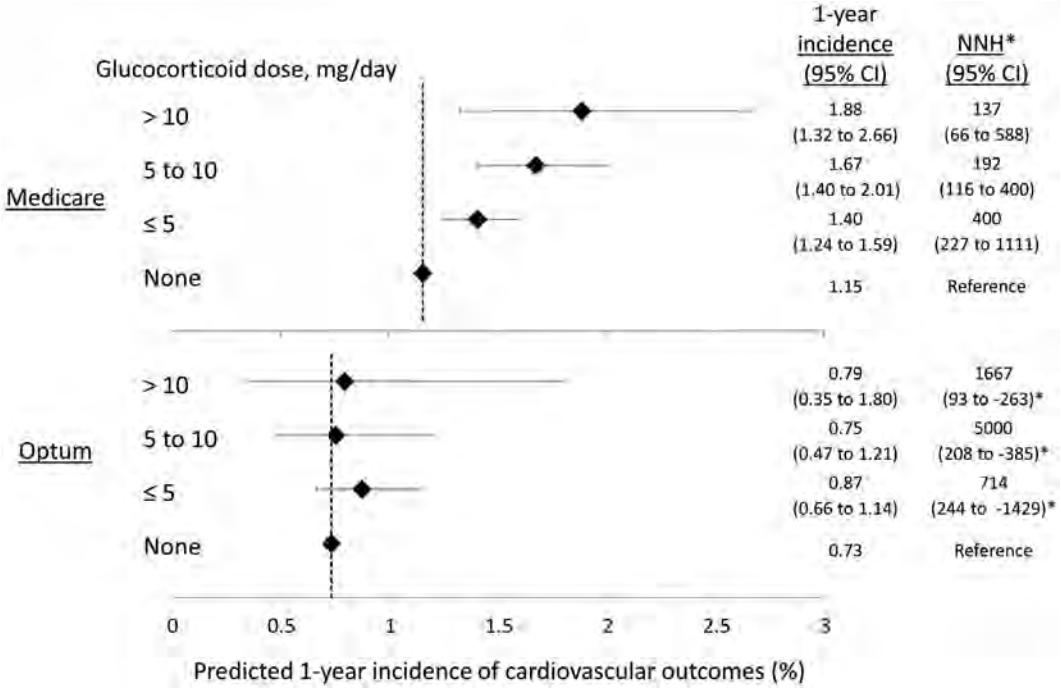
to estimate the effect of glucocorticoid use on composite cardiovascular outcomes (stroke or MI). Patients were censored at the end of the stable DMARD course, end of enrollment, 9/30/2015, death in Medicare data, or 90 days after a change in glucocorticoid dose category (the completion of a treatment period). Predicted 1-year incidence of events was calculated from the weighted models to estimate risk by glucocorticoid dose while controlling for confounding factors.

Table 2. Association of Average Daily Glucocorticoid Dose with Composite Cardiovascular Outcomes

Glucocorticoid dose, mg/day	Observations, n	Person-years	Outcome (incidence*)	Unadjusted HR (95% CI)	IPWS HR (95% CI)
Medicare					
None	101,624	106,945	1242 (1.2)	Reference	Reference
≤ 5	57,800	39,267	601 (1.5)	1.35 (1.23-1.49)	1.22 (1.10-1.35)
5 to 10	23,413	10,309	180 (1.7)	1.60 (1.36-1.87)	1.46 (1.23-1.74)
≥ 10	6,103	2,318	44 (1.9)	1.75 (1.29-2.37)	1.64 (1.16-2.32)
Optum					
None	31,457	27,610	207 (0.7)	Reference	Reference
≤ 5	13,438	6,970	75 (1.1)	1.48 (1.13-1.94)	1.19 (0.90-1.58)
5 to 10	5,039	1,868	23 (1.2)	1.73 (1.11-2.69)	1.06 (0.66-1.69)
≥ 10	1,361	428	8 (1.9)	2.65 (1.29-5.46)	1.24 (0.58-2.65)

Hazard ratios (HR) and confidence intervals (CI) are from unadjusted cause-specific proportional hazard models and from propensity adjusted models using stabilized inverse probability weights (IPWS). * Incidence per 100 person-years

Results: There were 188,940 treatment periods among 135,583 patients in Medicare and 51,295 treatment periods among 39,272 patients in Optum (Table 1). Medicare patients had 158,839 years at risk with 2,067 composite cardiovascular outcomes and Optum patients had 36,876 years at risk with 313 outcomes corresponding to an incidence of 1.3 and 0.8 per 100 person-years, respectively. In Medicare, glucocorticoids were associated with a dose-dependent increase in cardiovascular risk in weighted models (Table 2) with predicted 1-year incidence of 1.4% (95% CI 1.2-1.6) for ≤5mg, 1.7% (1.4-2.0) for 5-10mg, and 1.9% (1.3-2.7) for >10mg versus 1.1% for no glucocorticoids (Figure 1). Unadjusted results were similar in the younger Optum population, but adjusted results were not significant with predicted 1-year incidence of 0.9% (95% CI 0.7-1.1), 0.8% (0.5-1.2), and 0.8% (0.4-1.8), respectively, versus 0.7% with no glucocorticoids.



Predicted 1-year incidence of myocardial infarction or stroke calculated from inverse probability weighted cause-specific hazards models. Hazard ratios for these models are shown in Table 2. * NNH = number needed to harm. The NNH 95% confidence intervals (CI) for each glucocorticoid dose category in the Optum dataset overlaps with the reference estimate for no glucocorticoids. Negative estimates can be interpreted as the number needed to treat to avoid a composite cardiovascular outcome.

Conclusion: Among older RA patients on stable DMARD therapy, long-term use of low-dose glucocorticoid was associated with increased risk for stroke or MI. Higher doses of glucocorticoids were associated with even greater risk. The absolute risk in the younger Optum cohort was lower and research with larger patient populations will be needed to determine if risks exist among younger patients with lower baseline cardiovascular risk.

Values are hazard ratios (95% confidence intervals) per 1 standard deviation change in antibody concentration

Each antibody tested in separate Cox models adjusting for age, sex, race, smoking status, anti-CCP antibody positivity, and DAS28.

Abbreviations: CI, confidence interval; HR, hazard ratio; MAA, malondialdehyde-acetaldehyde

Background/Purpose: Because interstitial lung disease (ILD) causes substantial morbidity and mortality in rheumatoid arthritis (RA), there is a need for methods to facilitate early identification and diagnosis. Peripheral biomarkers including RA-autoantibodies, inflammatory cytokines/chemokines, and tissue remodeling proteins identify patients with established RA-ILD. Less is known, however, whether peripheral biomarkers predict incident RA-ILD. This is particularly relevant as the RA-related autoantibodies, anti-CCP and RF, are not highly predictive of future ILD risk (Natalini JG. *Ann Am Thorac Soc* 2021). Previously, antibodies to malondialdehyde-acetaldehyde adducts (anti-MAA), a

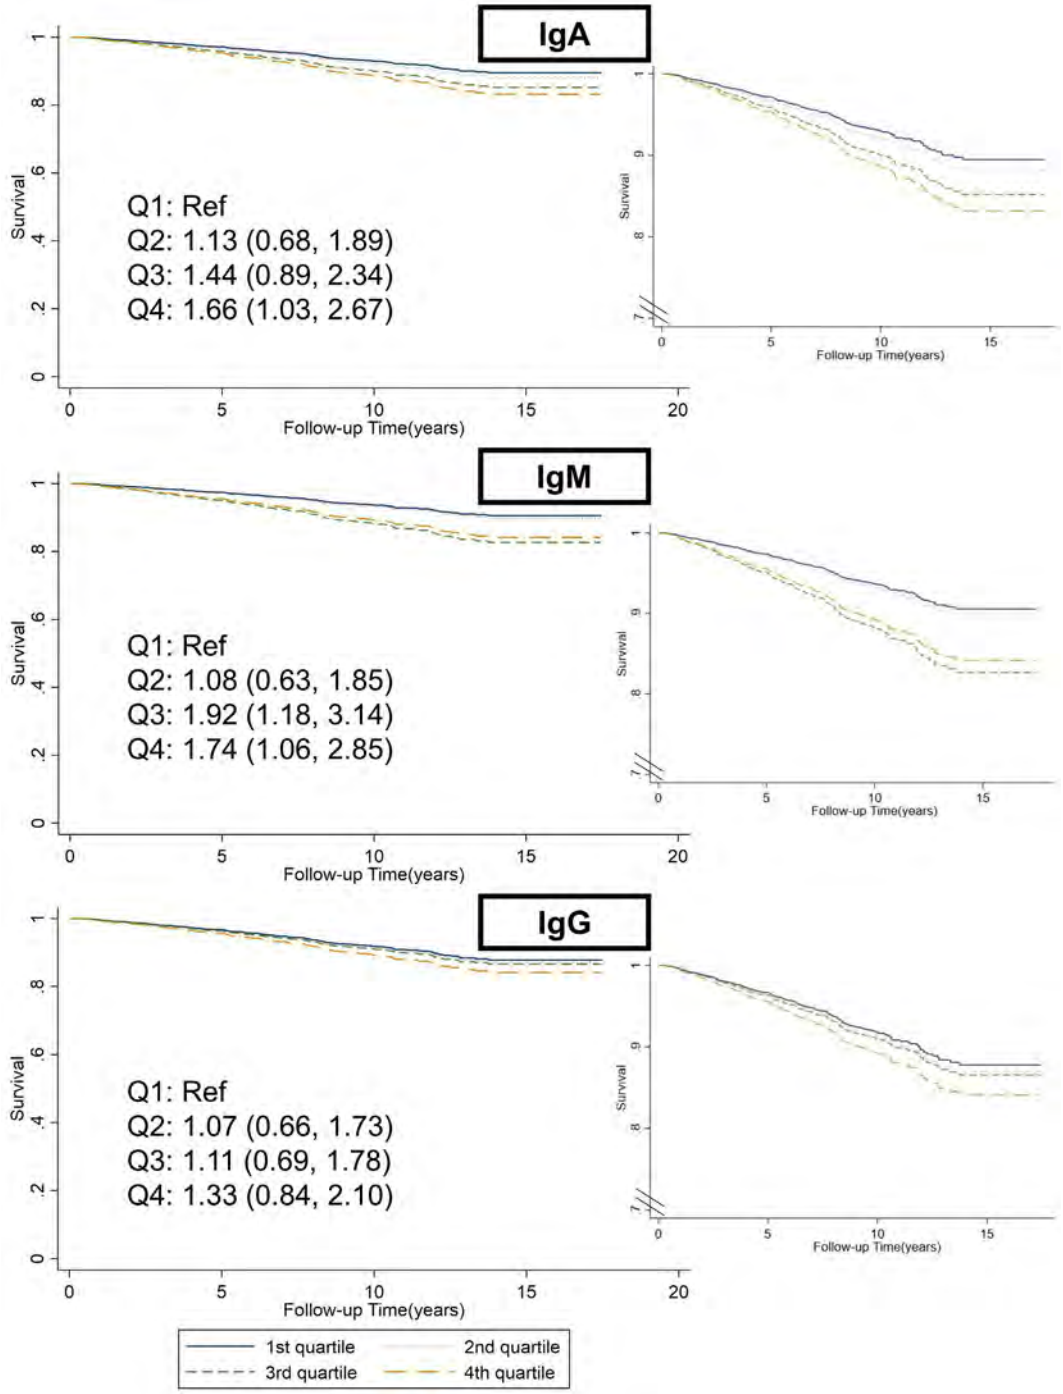

Figure 1. RA-ILD free survival by quartiles of anti-MAA-albumin antibodies. Values hazards ratios (95% confidence intervals) from Cox regression models adjusted for age, sex, race, smoking status, anti-CCP antibody positivity, and DAS28.

RA-related autoantibody, were found to be closely associated with prevalent RA-ILD (England BR. *Arthritis Rheumatol* 2019). In this study, we aimed to determine if anti-MAA antibodies were associated with risk of incident RA-ILD.

Methods: We studied participants in the Veterans Affairs Rheumatoid Arthritis registry, a prospective cohort of U.S. Veterans with RA. Patients with RA-ILD at the time of enrollment were excluded. Demographics, smoking status, and RA measures were collected from the registry. We measured anti-MAA antibody concentrations (IgA, IgM, and IgG) by ELISA on banked serum from registry enrollment for both MAA-modified albumin and MAA-modified collagen. Anti-MAA antibody values were log-transformed, standardized, and categorized into quartiles. Incident ILD consisted of ILD diagnoses occurring after registry enrollment, determined through a previously validated approach that included systematic review of medical records for clinical diagnoses, imaging findings, and biopsy reports. In sensitivity analyses, we excluded ILD cases developing ILD within 1 year of enrollment. Multivariable Cox regression models assessed associations of anti-MAA antibody with incident ILD adjusting for age, sex, race, smoking status, anti-CCP antibody positivity, and enrollment DAS28.

Results: Among 2,317 RA patients, 190 developed ILD over 18,044 patient-years of follow-up. Patients were male predominant (90%), with a mean age of 64 years, and had frequent smoking history (79%) and anti-CCP antibody positivity (77%). Higher IgA and IgM anti-MAA-albumin antibody concentrations were associated with an increased risk of incident RA-ILD (Table 1). Effect sizes were smaller for IgG and were not statistically significant. Those with the highest quartiles of IgA and IgM anti-MAA-albumin antibodies had a higher risk of incident ILD (Q4 vs Q1 HR: IgA 1.66 [1.03, 2.67], IgM 1.74 [1.06, 2.85]; Figure 1). In contrast, anti-MAA-collagen antibodies were not significantly associated with incident RA-ILD risk (Table 1). Results were consistent in sensitivity analysis excluding ILD cases occurring in the first year after registry enrollment (Table 1).

Conclusion: Serum anti-MAA-albumin antibodies are associated with a higher risk of developing ILD among RA patients. These findings highlight the role novel autoantibodies may serve in the pathogenesis of RA-ILD as well as support the development of risk models to predict ILD onset.

Background/Purpose: Increased levels of transforming growth factor β1 (TGF-β1) in the lung have been implicated in the pathogenesis of several fibrotic lung diseases, but their role in the lung in rheumatoid arthritis-associated interstitial lung disease (RA-ILD) has not been well studied. Evidence suggests that increased TGF-β1 production in the

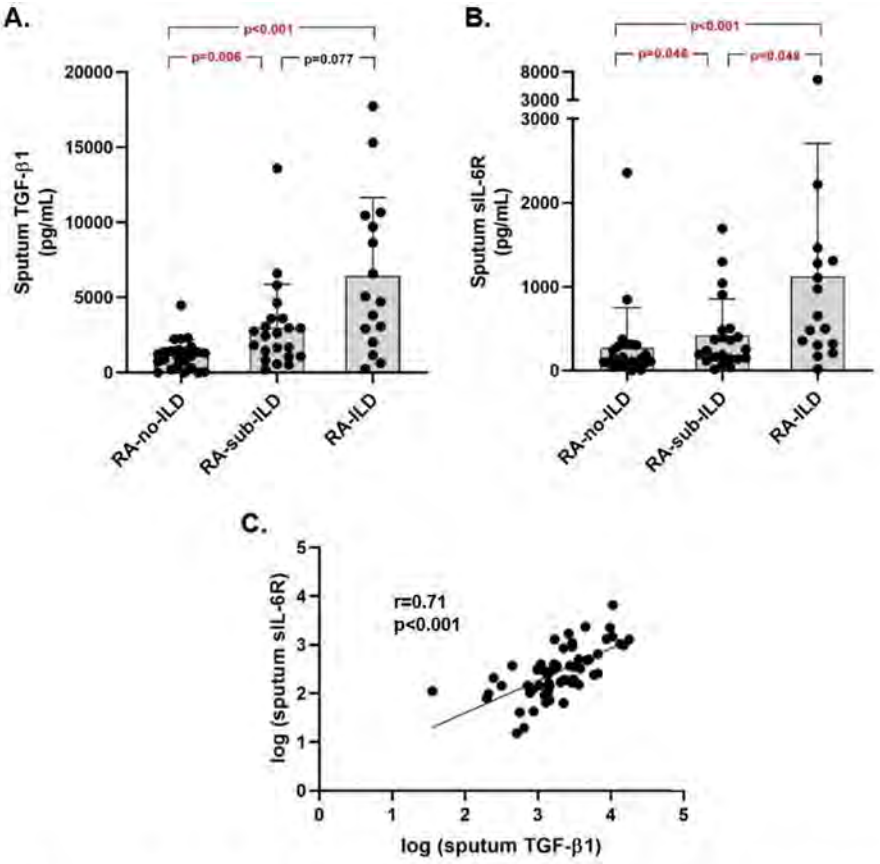

Figure 1. Sputum TGF-β1 and sIL-6R levels. (Panel A-B) Mean sputum supernatant levels + SD for TGF-β1 and sIL-6R in RA-no-ILD (n=24), RA-sub-ILD (n=22), and RA-ILD (n=16). P-values based on Wilcoxon rank-sum test. (Panel C) Log transformed sIL-6R levels correlated with log transformed TGF-β1 and IL-6 levels. Correlations calculated using Spearman's correlation coefficient (r-value).

lung can be driven by IL-6 trans-signaling, which requires soluble IL-6 receptor (sIL-6R) complexed with IL-6 binding to membrane-bound gp130; this is in contrast to IL-6 classical-signaling that requires IL-6 binding to membrane-bound IL-6R (mIL-6R). Importantly, gp130, and not mIL-6R, is present on lung fibroblasts which play a key role in lung fibrosis. Also, mIL-6R is present on neutrophils and can be released to form sIL-6R during neutrophil extracellular trap (NET) formation. In this study, we sought to evaluate the relationships between TGF-β1, sIL-6R, NETs and the presence of ILD across a spectrum of patients with RA.

Methods: We included 16 RA patients with clinically significant ILD (RA-ILD), 22 RA patients with subclinical ILD defined as having parenchymal changes on lung high resolution computed tomography (HRCT) (i.e. fibrosis, traction bronchiectasis, reticulation and/or ground glass opacities) but no clinical diagnosis of ILD and normal pulmonary physiology (RA-sub-ILD), and 24 RA patients without ILD on HRCT (RA-no-ILD). All subjects underwent pulmonary function testing (PFT) and induced sputum was collected using hypertonic saline. Sputum was tested for TGF-β1 (Meso Scale Diagnostics) and sIL-6R (R&D Systems). Sputum IL-6 was measured in a subset of 8 RA-ILD, 4 RA-sub-ILD and 3 RA-no-ILD (Luminex) and sputum NET remnants in a subset of 11 RA-ILD and 3 RA-sub-ILD patients (sandwich ELISA for DNA-neutrophil elastase (NE) and DNA-citrullinated histone H3 (DNA-citH3)).

Results: Patient demographics are summarized in Table 1. Sputum TGF-β1 and sIL-6R levels were significantly higher in RA-sub-ILD and RA-ILD compared to RA-no-ILD (Figure 1A and 1B). In regression analyses adjusting for age and smoking, TGF-β1 and sIL-6R levels remained significantly associated with RA-sub-ILD and RA-ILD. Sputum TGF-β1 correlated with sIL-6R levels (Figure 1C) while there was no correlation between TGF-β1 and IL-6. In a subset of RA-sub-ILD and RA-ILD subjects, sputum NET remnants positively correlated with sputum sIL-6R levels (Figure 2A and 2B) but not TGF-β1 levels ($p > 0.20$).

Conclusion: We found for the first time that sputum TGF-β1 and sIL-6R levels are increased in subclinical and clinically significant RA-ILD. The strong correlation between sputum TGF-β1 and sIL-6R along with the correlation between sputum sIL-6R and NET remnants suggest that increased TGF-β1 in the lung may be due to NET-associated increases in sIL-6R and subsequent IL-6 trans-signaling of lung fibroblasts. Future studies are needed to better understand the use of sputum TGF-β1 and sIL-6R as prognostic biomarkers in RA-ILD as well as mechanisms by which TGF-β1 production and IL-6 trans-signaling in the lung may contribute to RA-ILD.

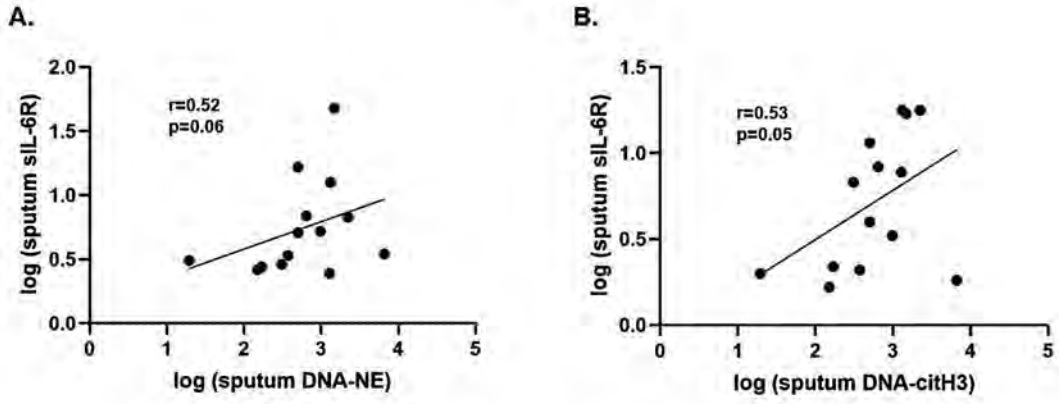

Figure 2. Correlation of sputum sIL-6R and NET remnant levels. Log transformed sIL-6R levels correlated with log transformed DNA-NE (Panel A) and DNA-citH3 (Panel B) levels in RA-ILD (n=11) and RA-sub-ILD (n=3). Correlations calculated using Spearman's correlation coefficient (r-value).

SESSION INFORMATION

Session Date: Tuesday, November 9, 2021
Session Title: Abstracts: RA – Diagnosis, Manifestations, & Outcomes II: Heart & Lung (1915–1918)
Session Type: Abstract Session
Session Time: 2:00PM–3:30PM

Background/Purpose: Long-term outcomes following a diagnosis of rheumatoid arthritis associated interstitial lung disease (RA-ILD) are poor, with a median survival estimated between 3 to 8 years. Despite the profound impact on survival, relatively few prognostic factors are known in RA-ILD. More severe pulmonary disease is associated with reduced survival, but little is understood regarding the contribution of RA disease activity to long-term outcomes in RA-ILD. We aimed to determine whether RA disease activity and functional status, as measured by DAS28-ESR and MDHAQ, were independently associated with survival in RA-ILD.

Methods: We performed a cohort study of patients with RA-ILD nested within a multicenter, prospective RA cohort (Veteran Affairs Rheumatoid Arthritis Registry) that contained patient data from 2003-2019. RA was diagnosed by a rheumatologist and fulfilled ACR criteria while ILD diagnoses were validated through detailed medical record confirmation (clinical diagnoses and corresponding dates, imaging findings, lung biopsy and pulmonary function [FVC and DLCO %-predicted] results). Demographics, seropositivity, RA disease duration, and RA medications were collected from the registry and linked administrative data. RA disease activity (DAS28-ESR) and functional status (MDHAQ) were collected longitudinally through routine care. Death was ascertained through linkage with administrative records and the National Death Index. Multivariable Cox regression models assessed the independent associations of RA disease activity and ILD severity with survival adjusting for age, sex, smoking status, and DMARDs.

Results: Patients with RA-ILD (n=227) had mean (SD) age of 69 (9) years, were 93% male, 75% white, frequently had a smoking history (85%), and a mean DAS28-ESR of 4.0 (1.3), MDHAQ of 1.0 (0.6), FVC % predicted of 77.2 (17.9), and DLCO % predicted of 60.2 (21.9). After RA-ILD diagnosis, the median survival was 8.5 years. Over 1,073 person-years of follow-up, 108 deaths occurred with respiratory disease being the leading cause of death (28% of deaths). When examined in separate models, DAS28-ESR, MDHAQ, and pulmonary (FVC and DLCO % predicted) measures of severity were independently associated with survival (Figure 1A-D). The association between DAS28-ESR (per 1-

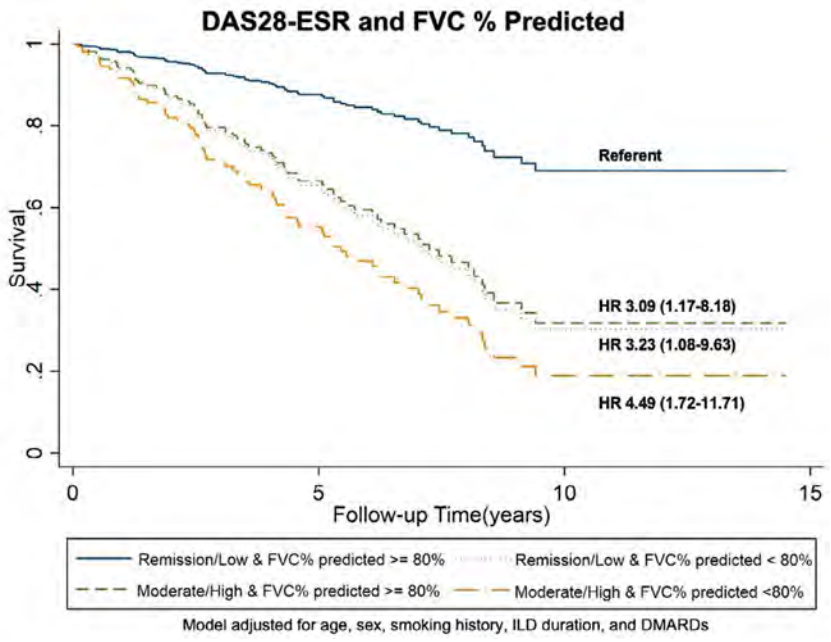

Figure 2. Survival in RA-ILD by Combined Disease Activity and Forced Vital Capacity Classification.

unit HR 1.22 [95% CI 1.04-1.43]) and MDHAQ (per 1-unit HR 1.89 [95% CI 1.33-2.69]) with mortality persisted after adjusting for FVC % predicted. When assessing RA disease activity and pulmonary severity together, moderate/high RA disease activity or impaired FVC (< 80% predicted) alone were associated with >3-fold higher risk of death compared to those with remission/low disease activity and normal FVC (Figure 2). The combination of moderate/high disease activity and impaired FVC carried the highest risk of death (HR 4.49 [95% CI 1.72-11.71];Figure 2).

Conclusion: Among patients with RA-ILD, more severe RA disease activity and impaired functional status were associated with poorer survival independent of ILD severity. To optimize long-term outcomes in RA-ILD, treatment should be targeted at both controlling the disease activity in RA and pulmonary disease manifestations.

Detection of Radiographic Sacroiliitis with an Artificial Neural Network in Patients with Suspicion of Axial Spondyloarthritis

Denis Poddubnyy[1], Fabian Proft[2], Kay-Geert Hermann[3], Laura Spiller[3], Stefan Niehues[3], Lisa Adams[3], Mikhail Protopopov[3], Valeria Rios Rodriguez[3], Burkhard Muche[3], Judith Rademacher[3], Murat Torgutalp[3], Keno Bressem[3] and Janis Vahldiek[3], [1]Department of Rheumatology, Charité – Universitätsmedizin, Berlin, Germany, [2]Department of Gastroenterology, Infectiology and Rheumatology (including Nutrition Medicine), Charité – Universitätsmedizin Berlin, corporate member of Freie Universität Berlin and Humboldt-Universität zu Berlin, Berlin, Germany, [3]Charité University Medicine Berlin, Berlin, Germany

SESSION INFORMATION
Session Date: Tuesday, November 9, 2021
Session Title: Abstracts: Spondyloarthritis Including PsA – Diagnosis, Manifestations, & Outcomes II (1919–1922)
Session Type: Abstract Session
Session Time: 2:00PM–3:30PM

Background/Purpose: Conventional radiography of the sacroiliac joints is still recommended as the first imaging method for the diagnosis of axial spondyloarthritis (axial SpA). In many clinical settings around the world, this is the only widely available imaging method to diagnose axial SpA. A high specificity of radiographic detection in the diagnostic setting is required to avoid improper diagnosis of axial SpA. We have recently developed a deep convolutional neural network (CNN) that was able to detect radiographic sacroiliitis with expert-like accuracy in two cohorts of patients with axial SpA, i.e., performing classification as radiographic or non-radiographic (Bressem KK, et al. Arthritis Res Ther 2021;23:106). The aim of the present study was to evaluate the performance of this CNN in detecting definite radiographic sacroiliitis in a diagnostic setting.

Methods: We evaluated sacroiliac radiographs of patients with chronic back pain who presented to a rheumatologist with a suspicion of axial SpA within the OptiRef study (Proft F, et al. Semin Arthritis Rheum 2020;50:1015-21). A total of 361 patients received a structured rheumatologic diagnostic work-up that resulted in the final diagnosis of axial SpA/no axial SpA. Radiographs of sacroiliac joints were evaluated according to the modified New York criteria; the consensus judgement of rheumatologist and radiologist on the presence of definite radiographic sacroiliitis (>=grade 2 bilaterally or >=grade 3 unilaterally) was used as a reference. The predictions of the deep CNN's inference on all available pelvic radiographs was compared to this reference judgement.

Table 1. Convolutional neural network predictions of the presence of definite radiographic sacroiliitis in patients with suspected axial SpA according to the final diagnosis by rheumatologist in OptiRef (N=340).

	CNN's prediction	
Clinical diagnosis	**Radiographic sacroiliitis present**	**Radiographic sacroiliitis absent**
Radiographic axial SpA	48/61 (78.7%)	13/61 (21.3%)
Non-radiographic axial SpA	4/49 (8.2%)	45/49 (91.8%)
No axial SpA	14/230 (6.1%)	216/230 (93.9%)

CNN=convolutional neural network, SpA=spondyloarthritis.

Results: Pelvic radiographs of 340 out of 361 patients (110 diagnosed with axial SpA including 61 patient with radiographic and 49 with non-radiographic axial SpA, and 230 without SpA) were available for the CNN evaluation. We used a balanced cutoff of 0.724 for the predictions of the model that was derived from the training and validation step previously. The deep CNN achieved a sensitivity of 79% for the diagnosis of radiographic axial SpA. The specificity of

Figure 1. Inference of the proposed CNN on a pelvic radiograph from the OptiRef study.

This exemplary class activation map shows that our CNN almost exclusively and correctly focusses on the sacroiliac joints to predict whether definite radiographic sacroiliitis is present or not. In this case, no definite radiographic sacroiliitis was detected.

radiographic sacroiliitis detection was 94% (table 1). The area under the receiver operating characteristics curve for the prediction of the presence of definite radiographic sacroiliitis was 88%. The absolute agreement on the classification as radiographic or non-radiographic axial SpA between the CNN and the reference was 85%. Figure 1 shows an exemplary class activation map of our CNN.

Conclusion: The artificial neural network showed good generalizability and a high specificity with acceptable sensitivity in the detection of radiographic sacroiliitis when applied in the diagnostic setting of patients with chronic back pain and suspicion of axial SpA. Thus, the trained CNN can therefore be used by non-specialized centers as an assistant tool for interpretation of sacroiliac radiographs as a part of the diagnostic approach.

Session Date: Tuesday, November 9, 2021
Session Title: Abstracts: Spondyloarthritis Including PsA – Diagnosis, Manifestations, & Outcomes II (1919–1922)
Session Type: Abstract Session
Session Time: 2:00PM–3:30PM

Background/Purpose: Psoriatic arthritis (PsA) is associated with accelerated atherosclerosis due to underlying inflammation. Whether inflammatory burden and drugs used to suppress inflammation over time are associated with cardiovascular (CV) events remained unclear. This study aims to examine the time-varying effect of C-reactive protein (CRP) levels and the use of drugs including non-steroidal anti-inflammatory drugs (NSAIDs) on the risk of CV events independent of traditional CV risk factors in PsA patients.

Methods: A retrospective cohort analysis was performed in patients with PsA who were recruited from 2008 to 2015 and followed till the end of 2019. The outcome was occurrence of a first CV event. Framingham risk score (FRS) was used to quantify the traditional CV risk. Cox proportional hazard models with time-varying CRP levels and drugs used were analyzed to identify the risk factors for CV events in PsA patients. Kaplan-Meier survival curve and log-rank test was used to illustrate CV event free survival distribution.

Results: 200 patients with PsA (median age: 47.5[40.0 – 56.0]; male: 119 [59.5%]) were recruited (Table 1). After a mean follow-up of 8.8±3.8 years, 30 (15%) patients developed a first CV event. The Kaplan-Meier survival curve and the log-rank test indicated a significant difference in the CV event-free survival between patients with and without CRP level >3 mg/L (Figure 1A) and an inverse relationship between time-varying NSAIDs exposure and CV event-free

survival (Figure 1B). The multivariable Cox regression model showed that time-varying CRP level (HR 1.02, 95% CI 1.00 to 1.04) and NSAIDs exposure (HR 0.30, 95% CI 0.15 to 0.95) were significantly associated with CV events after adjusting for baseline FRS (HR 5.04, 95% CI 1.83 to 13.85).

Conclusion: Increased inflammatory burden as reflected by elevated CRP level was associated with increased risk of CV events, while the risk was significantly reduced with NSAIDs use in PsA patients.

Session Title: Abstracts: Spondyloarthritis Including PsA – Diagnosis, Manifestations, & Outcomes II (1919–1922)

Session Type: Abstract Session

Session Time: 2:00PM–3:30PM

Background/Purpose: Psoriatic Arthritis (PsA) typically affects peripheral joints, but in some patients the disease can involve the spine. While magnetic resonance imaging (MRI) is an important diagnostic tool for spondyloarthritis, especially in early phases, there is minimal information about MRI features of axial PsA.

The purpose of the study was to describe the prevalence of inflammatory and structural lesions by whole-spine MRI in patients with psoriatic disease, and assess the correlation of MRI-defined spondyloarthritis (MRI-SpA) with clinical and laboratory features and with classification criteria for axial spondyloarthritis (axSpA).

Methods: In this retrospective analysis we included 93 patients selected from 2 populations: 1) 41 patients with active PsA, who were referred for a whole-spine MRI irrespective of whether they had axial symptoms, and 2) 52 pa-

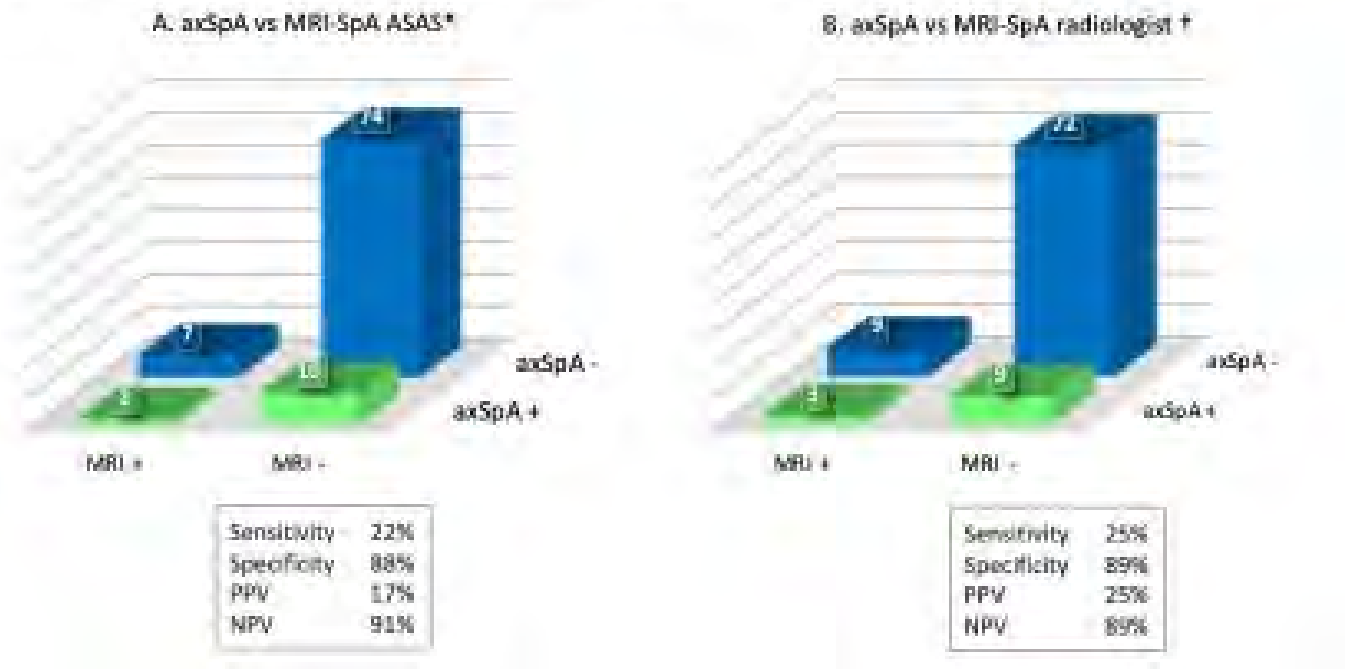
Fig. 1- Correlation between the ASAS classification criteria for axSpA and MRI-defined Spondyloarthritis (MRI-SpA) according to ASAS consensus* (A) and according to radiologist impression (B)†



*Spondylitis and/or sacroiliitis according to ASAS/OMERACT definitions (Spondylitis: anterior/posterior BME in ≥ 3 sites / fatty lesions at several sites. Sacroiliitis: ≥ 2 BME lesions on a single SIJ slice and/or ≥ 1 BME lesion on 2 consecutive slice). † Spondylitis and/or sacroiliitis according to radiologist impression (considering inflammatory and structural lesions).

MRI scans of the sacroiliac joints and whole-spine (T1W and STIR) were assessed by a musculoskeletal radiologist blinded to the clinical and radiographic data. MRI-SpA was defined as: 1) ASAS consensus for active spondylitis/sacroiliitis, and 2) the radiologist impression (considering inflammatory and structural lesions).

The agreement between MRI-SpA as a gold standard, and the ASAS classification criteria for axSpA and different definitions of IBP was assessed. Logistic regression evaluated the association between MRI-SpA and clinical, demographic and laboratory factors.

Results: 93 patients were analyzed (mean age 43.3 ±13, 52.7% women, Table 1). The prevalence of HLA-B*27 was 10.9%. Axial symptoms were present in 81.7%, being defined as IBP in 36.6%/36.6%/57% according to Berlin, ASAS and rheumatologist criteria, respectively. MRI-SpA was found in only 9 (9.7%) patients by ASAS definition and 12 (12.9%) by radiologist impression.

Overall, low agreement was found between the three IBP definitions and MRI-SpA (Table 2). IBP by rheumatologist impression was the most sensitive (50-56%) and ASAS and Berlin criteria for IBP were most specific (62-63%). Poor sensitivity was found for the ASAS criteria for axSpA and MRI-Spondylitis (ASAS definition 22.2%; radiologist impression 25%, Fig. 1). Onset of axial pain after the age of 40 and absence of axial pain accounted for most patients with MRI-SpA not meeting the ASAS axSpA criteria or IBP criteria. Male sex was associated with MRI-Spondylitis (OR 6.9; 95% CI 1.4, 33.6) in multivariable regression analysis.

Conclusion: The overall prevalence of axial inflammatory and structural spondylitis by whole-spine MRI was low despite the high prevalence of axial symptoms. Poor correlation was found between imaging and clinical findings highlighting the need for further research of the underlying mechanisms of axial involvement in PsA.

Early and Accurate Diagnosis of Patient with Axial Spondyloarthritis Using Machine Learning: A Predictive Analysis from Electronic Health Records in United Kingdom

Raj Sengupta[1], Shruti Narasimham[2], Borja Mato[3], Matic Meglic[3], Chiara Perella[3], Paula Pamies[4] and Paul Emery[5], [1]The Royal National Hospital for Rheumatic Diseases, Bath, United Kingdom, [2]Novartis Ireland Ltd, Dublin, Ireland, Dublin, Ireland, [3]Novartis Pharma AG, Basel, Switzerland, [4]Novartis Pharmaceuticals UK Ltd, London, UK, London, United Kingdom, [5]Leeds Institute of Rheumatic and Musculoskeletal Medicine, University of Leeds and Leeds NIHR Biomedical Research Centre, Leeds, United Kingdom

SESSION INFORMATION

Session Date: Tuesday, November 9, 2021

Session Title: Abstracts: Spondyloarthritis Including PsA – Diagnosis, Manifestations, & Outcomes II (1919–1922)

Session Type: Abstract Session

Session Time: 2:00PM–3:30PM

Background/Purpose: On an average, there is a delay of 6.7 years between symptom onset and diagnosis of axial spondyloarthritis (axSpA)[1]. Since traditional approaches to improving early axSpA identification have had limited success, predictive automated analyses on patient records may help alleviate the burden on healthcare providers[2-5].

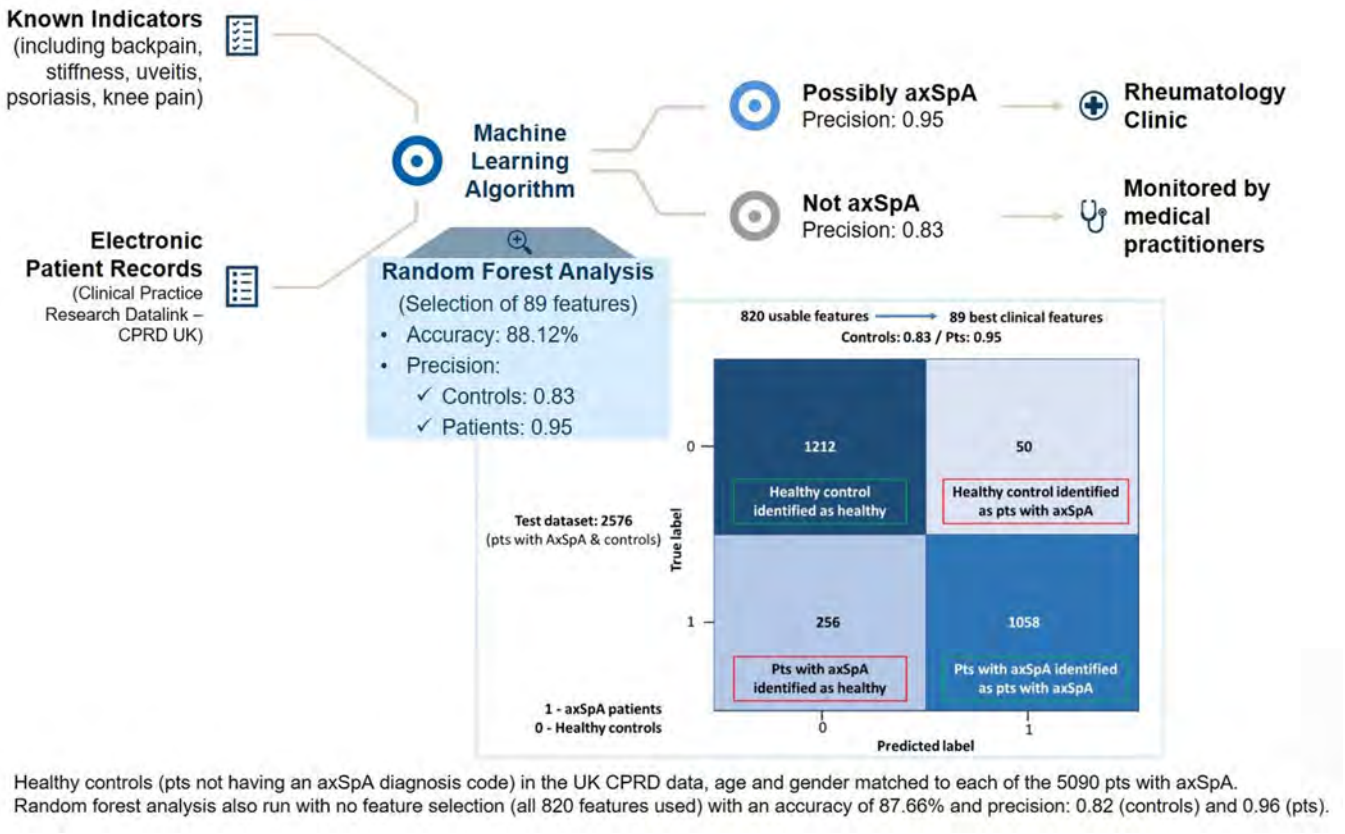

Figure. Automated axSpA diagnosis/rheumatology referral via pattern recognition in electronic patient data using ML.

Here, we report the results from a machine learning (ML) algorithm developed with UK electronic health records (EHRs) Clinical Practice Research Datalink (CPRD) data, to estimate the probability or likelihood of a pt being diagnosed with axSpA based on prior clinical indicators and pt history.

Methods: Primary care UK EHR data - CPRD GOLD was used to identify pts with axSpA and healthy controls (HC) (**Figure**). Pts aged ≥18 years, with first diagnosis date of axSpA within the identification period (01-Jan-2005 to 31-Dec-2018) and fulfilling CPRD research acceptability criteria were included in the study. Data pertaining to clinical presentation, consultation, referral, test, and therapy history were extracted for individual pt prior to diagnosis of axSpA. A total of 5090 pts with axSpA satisfied the acceptability criteria. HC were randomly sampled to create a subset of one unique HC matched to each pt with axSpA, resulting in 5089 HC. ML usable features derived from the total population (pts with axSpA and HC) numbered 820. After using a further exclusion criterion for the pts with axSpA and HC who had ≥1 out of 820 usable features, the final dataset included 7813 pts (3902 pts with axSpA and 3911 HC). This combined dataset was randomly split (67:33) into a train (N=5237) and a test (N=2576) dataset. A Random Forest (RF) model was trained on the train dataset. Cross-validation was performed for hyper-parameter tuning of the RF classifier. Once the model was trained, accuracy, precision, and F-1 scores were obtained with the test dataset.

Results: The RF based algorithm resulted in a high level of accuracy (88.12%), with precision of 0.95 for pts with axSpA and 0.83 for HC (**Figure**). RF algorithm identified 89 best clinical predictors (out of 820 used as inputs) that differentiated between pt and HC such as: total number of tests, total number of referrals, first age of consultation, first symptom age, number of low back pain symptoms. The sensitivity of the model was 75.04% and positive predictive value was 80.88%. The specificity of the model was 0.96 and negative predictive value was 82.56%.

Conclusion: The ML algorithm demonstrated a high level of accuracy and precision in the identification of possible cases of axSpA, which may be useful in reducing the delay in diagnosis. Previous studies have successfully demonstrated automated cohort identification of axSpA in large datasets, with only a few using ML based approaches for diagnosis from patient medical history. While the model supports previous work in axSpA[2-5], it needs further validation in routine clinical practice and this exploration is ongoing.

Antonio Avina-Zubieta[1], John Esdaile[2] and Hui Xie[1], [1]Arthritis Research Canada, Richmond, BC, Canada, [2]Arthritis Research Canada, Vancouver, BC, Canada, [3]University of British Columbia, Richmond, BC, Canada, [4]University of British Columbia, Vancouver, BC, Canada

SESSION INFORMATION

Session Date: Tuesday, November 9, 2021

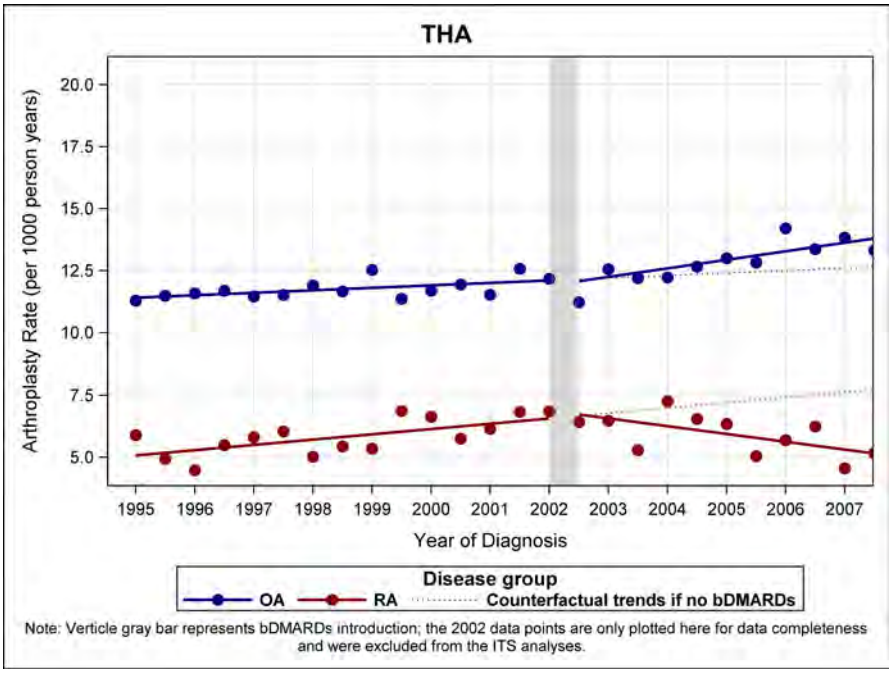
Session Title: Abstracts: Epidemiology & Public Health II: Inflammatory Arthritis (1923–1926)

Session Type: Abstract Session

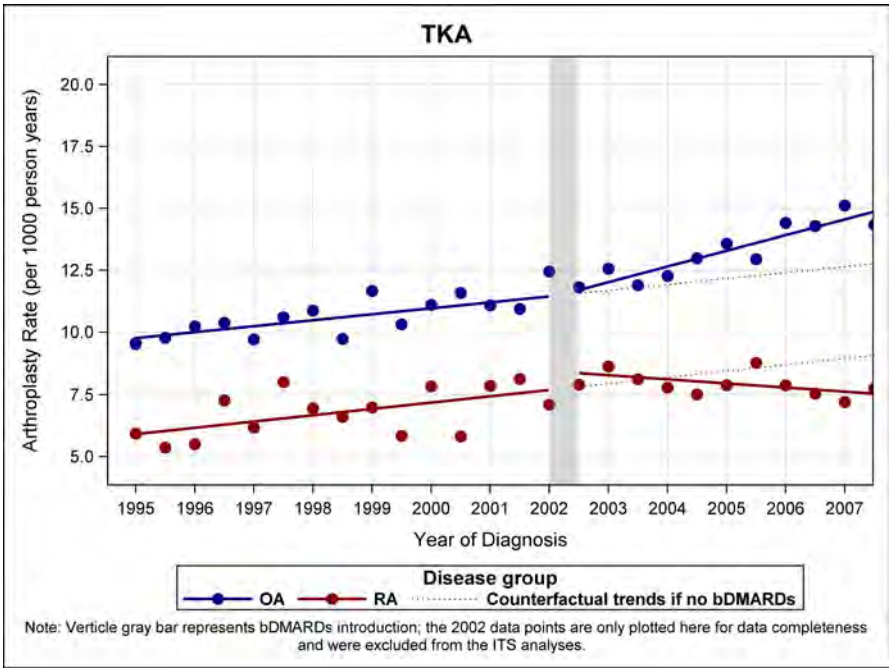
Session Time: 3:30PM–4:30PM

Background/Purpose: Total joint arthroplasty (TJA) is an undesirable long-term outcome of rheumatoid arthritis (RA) due to joint damage from uncontrolled inflammation. Although biological disease-modifying anti-rheumatic drugs (bDMARDs) would be expected to reduce the need for TJA due to better control of inflammation, evidence is conflicting. We aim to investigate whether the introduction of bDMARDs was associated with reduced incidences of total hip and knee arthroplasty (THA/TKA) among patients with RA compared with osteoarthritis (OA).

Methods: Using a population-based cohort in British Columbia, Canada, RA and OA patients diagnosed between 1995–2007 were divided into semi-annual cohorts according to diagnosis date. For each cohort, we calculated 8-year incidence rates of THA and TKA. We compared levels and trends of THA and TKA incidence in people with RA/OA diagnosis during pre-bDMARDs (1995–2001) and post-bDMARDs (2003–2007) periods using interrupted time-series analysis, adjusting for baseline characteristics



8-year incidence rate (per 1000 person years) of total hip arthroplasty (THA) among RA patients compared with OA patients. Abbreviations – bDMARDs: biological disease-modifying anti-rheumatic drugs; ITS: interrupted time-series.



8-year incidence rate (per 1000 person years) of total knee arthroplasty (TKA) among RA patients compared with OA patients. Abbreviations – bDMARDs: biological disease-modifying anti-rheumatic drugs; ITS: interrupted time-series.

Results: We identified 60,227 RA and 288,260 OA incident cases. For cohorts diagnosed pre-bDMARDs, 8-year incidence rates of THA and TKA increased over time in both RA and OA. For cohorts diagnosed post-bDMARDs, these rates decreased over time in RA but continued to increase for OA. For RA, differences between the post- and pre-bDMARDs secular trends in incidence rates were -0.49 (p=0.002) for THA and -0.36 (p=0.003) for TKA, compared to +0.40 (p=0.006) and +0.54 (p< 0.001), respectively, for OA. For cohorts with RA diagnosis five years after bDMARDs became available, 8-year incidence rates were 26.9% and 12.6% lower for THA and TKA, respectively, than expected rates based on extrapolation of pre-bDMARDs trends. In contrast, corresponding rates in OA were higher by 11.7%, and 16.6%, respectively.

Table Results of ITS analysis of eight-year incidence rates of surgery outcomes, adjusting for gender, age, comorbidities, and medication use

Patient Clustering Based on Multimorbidity Patterns Predicts Healthcare Utilization and Mortality in Rheumatoid Arthritis Within Independent Real-World Datasets

Bryant England[1], Yangyuna Yang[1], Punyasha Roul[1], Christian Haas[2], Harlan Sayles[1], Fang Yu[1], Brian Sauer[3], Joshua Baker[4], Kaleb Michaud[1], Jeffrey Curtis[5] and Ted Mikuls[1], [1]University of Nebraska Medical Center, Omaha, NE, [2]University of Nebraska Omaha, Omaha, NE, [3]University of Utah, Salt Lake City, UT, [4]University of Pennsylvania, Philadelphia, PA, [5]Division of Clinical Immunology and Rheumatology, Department of Medicine, Department of Epidemiology, University of Alabama at Birmingham, Birmingham, AL

SESSION INFORMATION

Session Date: Tuesday, November 9, 2021

Session Title: Abstracts: Epidemiology & Public Health II: Inflammatory Arthritis (1923–1926)

Session Type: Abstract Session

Session Time: 3:30PM–4:30PM

Background/Purpose: Rheumatoid arthritis (RA) leads to substantial healthcare utilization and premature mortality. Prior work has demonstrated that the overlapping presence of comorbid chronic conditions, termed multimorbidity, is a primary driver of these long-term outcomes. However, optimal methods to assess multimorbidity in RA in the clinical setting are not established. For example, traditional comorbidity indices (e.g. Charlson Comorbidity Index, Rheumatic Disease Comorbidity Index [RDCI]) have little clinical utility. Therefore, we aimed to derive informative multimorbidity clusters that could be readily applied in the day-to-day care of patients with RA.

Methods: We constructed RA cohorts within a large commercial insurance database (MarketScan) and the Veterans Health Administration (VA) between 2006 and 2015 using validated administrative algorithms for RA. Pre-selected chronic conditions (n=42) were identified using diagnosis codes from outpatient and inpatient encounters. We performed k-means clustering of factor analysis scores (reflecting morbidity patterns) that were generated from the aforementioned chronic conditions independently in both datasets. Associations of unique cluster assignment with healthcare utilization (number of inpatient, emergency room [ER], and outpatient encounters) over up to 5 years was evaluated separately in both datasets using generalized estimating equations models adjusting for age and sex. In the VA, we also used multivariable Cox regression models to compare survival between clusters adjusting for age, sex, race, smoking status, and calendar year.

Results: From the multimorbidity patterns, we identified 4 distinct patient clusters in MarketScan (n=113,425) and 3 clusters in the VA (n=32,640) based on cubic clustering criterion (**Figure 1**). Based on the frequency of chronic conditions present, we identified “low”, “moderate”, and “severe” multimorbidity clusters. Patients in the “moderate/severe” multimorbidity clusters were older, more frequently male, and had higher RDCI and Charlson scores (**Table 1**). A cluster characterized by mental health and chronic pain diseases was also identified in both datasets. Referent to the “low” multimorbidity cluster, patients in the other clusters had significantly higher rates of inpatient, ER, and outpatient encounters (**Table 2**). In VA survival analyses, 9,415 deaths occurred over 228,534 patient-years

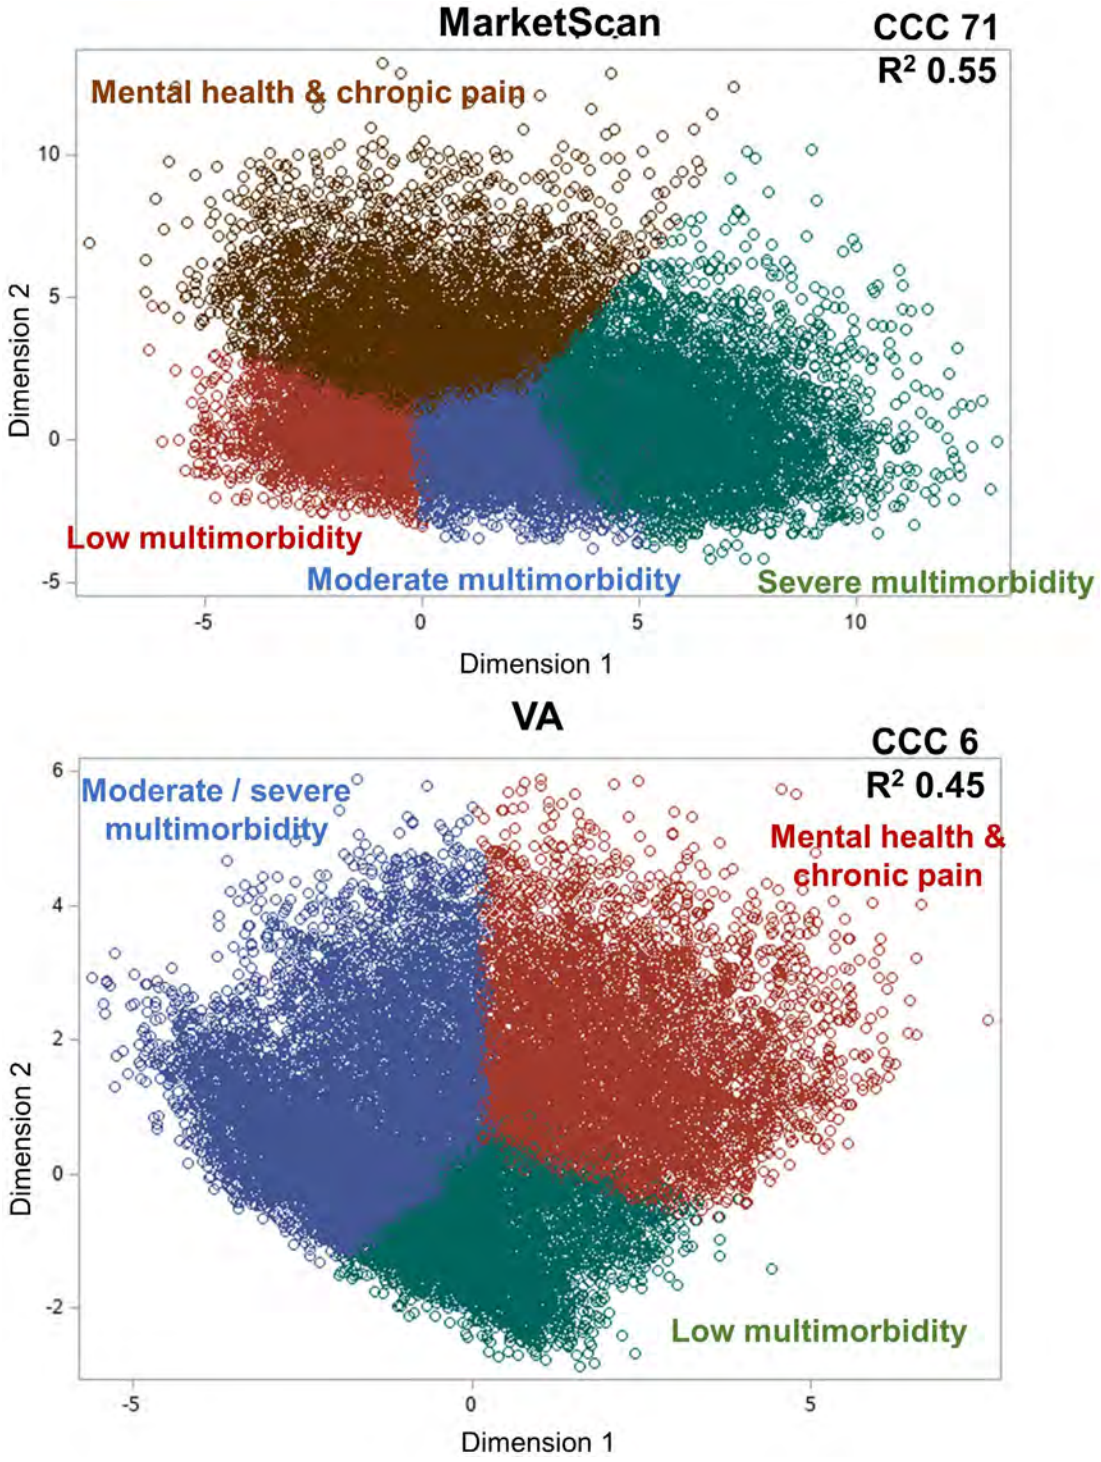

Figure 1. Clusters of RA patients based on multimorbidity patterns in MarketScan and the VA. Clustering of RA patients in both datasets performed using k-means clustering of factor analysis scores derived from the presence of 42 chronic conditions. Abbreviations: CCC, cubic clustering criterion.

of follow-up. Crude mortality rates were higher in both multimorbid clusters, but after multivariable adjustment, only the mental health and chronic pain cluster was significantly associated with higher mortality (HR 1.11 [95% CI 1.04, 1.18]).

Table 1. Characteristics of patients within each multimorbidity cluster

Cluster description *	N	Age	Female (%)	RDCI score	Charlson score
MarketScan					
Low multimorbidity	60,626	53 (14)	78	0.3 (0.9)	0.2 (0.5)
Moderate multimorbidity	28,486	60 (12)	72	1.3 (1.0)	0.5 (0.8)
Severe multimorbidity	14,153	62 (11)	71	2.0 (1.1)	1.0 (1.1)
Mental health & chronic pain	10,160	53 (12)	88	1.1 (1.2)	0.4 (0.7)
VA					
Low multimorbidity	14,203	62 (13)	14	0.4 (0.9)	1.4 (0.8)
Moderate / severe multimorbidity	11,630	67 (10)	7	1.0 (1.4)	2.3 (1.4)
Mental health & chronic pain	6,807	58 (11)	22	0.7 (1.2)	1.8 (1.1)

Values mean (SD) unless otherwise indicated.

*Cluster description based on RDCI score, Charlson score, and frequency of 42 chronic conditions (not shown)

Abbreviations: RDCI, Rheumatic Disease Comorbidity Index

Conclusion: Machine-learning approaches identified meaningful multimorbidity clusters among RA patients in two independent real-world datasets. Our approach highlights mental health and chronic pain multimorbidity, a pattern not accounted for in some widely used comorbidity indices, as a key determinant of long-term outcomes in RA. By retaining the ability to predict health outcomes with the simplicity of a cluster group assignment, this approach represents a crucial step forward in assessing multimorbidity at the point of care in clinical settings.

Table 2. Healthcare utilization over up to 5 years of follow-up by multimorbidity clusters

	Hospitalizations per year	Emergency room visits per year	Outpatient visits per year

SESSION INFORMATION

Session Date: Tuesday, November 9, 2021

Session Title: Abstracts: Epidemiology & Public Health II: Inflammatory Arthritis (1923–1926)

Session Type: Abstract Session

Session Time: 3:30PM–4:30PM

Background/Purpose: Individuals with inflammatory diseases (ID) have an increased risk of cardiovascular disease, frequently compared to that of diabetes mellitus (DM). However, the magnitude of risk for heart failure (HF) and potential etiologies of HF in ID have not been well described. We aimed to evaluate the risk of incident HF as well as its etiology in patients with ID compared to the general population with and without DM.

Methods: We linked multiple population-based health to construct a cohort of adults living in Ontario, Canada on January 1, 2011 and followed to December 2019. Patients diagnosed with rheumatoid arthritis (RA), ankylosing spondylitis (AS), psoriatic arthritis (PsA) and psoriasis (PsO) were identified using validated case definitions and matched by age, sex and geographic region with individuals without ID. We excluded all patients with a prior history of HF. The primary study outcome was incident HF defined as a first hospitalization for HF after January 1, 2011. Incidence rates of HF, per 1000 person-years (PY) for each exposure group were calculated. Hazard ratios (HRs, 95% confidence interval) for HF were calculated using Cox proportional hazard models, adjusting for demographics, cardiac risk factors and other comorbidities. The etiology of HF was descriptively classified in hierarchical order to mutually exclusive groups based on comorbidities prior to and at the time of HF hospitalization: 1) ischemic heart disease; 2) valvular disease; 3) atrial fibrillation; 4) hypertension/DM; 5) other.

Results: A total of 243,061 subjects had ID (35% RA, 8% AS, 3% PsA, 54% PsO) and 13% had co-morbid DM associated with their ID. There were 9,270,512 non-ID comparators, of which 8.3% had DM. The crude incidence rate for HF in ID was 2.70 per 1000/PY, with the highest rate in RA (3.93 per 1000/PY) and lowest in AS (1.80 per 1000/PY). All individual ID groups had significantly higher rates compared to the general population (0.84 per 1000/PY), but significantly lower HF incidence compared to subjects with DM alone (5.01 per 1000/PY, $p< 0.001$) (Figure 1).

In multivariable analyses, ID remained independently associated with an elevated risk of HF compared to non-ID subjects (HR 1.34, 95% CI 1.30, 1.38; Table 1); this relative risk was highest among subjects with RA and lowest in PsO. When stratified by DM, the risk of HF in ID was attenuated but remained increased (HR 1.11, 95% CI 1.06, 1.16). The leading cause of HF in all ID groups was ischemic heart disease (33%), followed by atrial fibrillation (27%), hypertension (23%), and valvular heart disease (12%) (Figure 2). The distribution of HF etiology was similar among non-ID comparators.

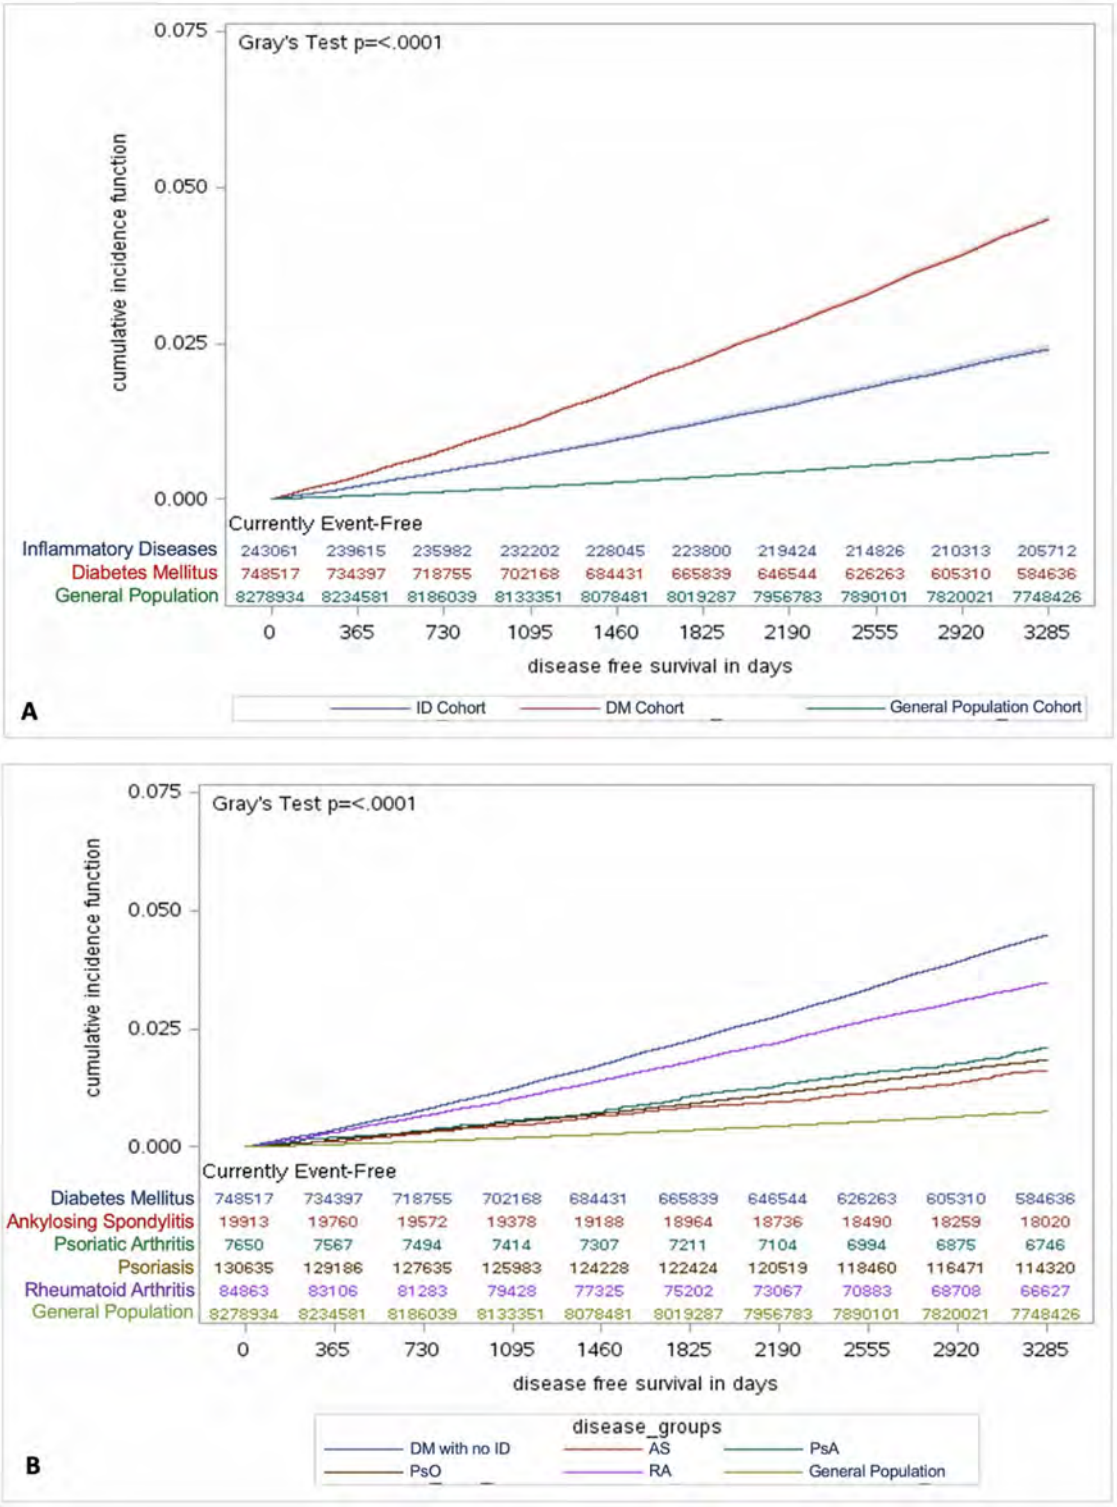

Figure 1. (A) Cumulative incidence of HF hospitalization in combined inflammatory diseases, diabetes, and general population comparators. (B) Cumulative incidence HF hospitalization in the individual inflammatory diseases, diabetes, and general population comparators.

Table 1. Multivariable Cox Proportion Hazards Models for HF hospitalization risk among all patients with inflammatory disease vs. non-inflammatory disease comparators, stratified by the presence of diabetes mellitus

	All ID (N=243,061) HR (95% CI)	RA (N=84,863) HR (95% CI)	AS (N=19,913) HR (95% CI)	PsA (N=7,650) HR (95% CI)	PsO (N=130,635) HR (95% CI)
Total number of HF events	**5836**	**2951**	**321**	**160**	**2404**
All patients with inflammatory disease					
With DM	1.11 (1.06, 1.16)	1.13 (1.06, 1.21)	1.24 (1.04, 1.47)	1.13 (0.88, 1.45)	1.08 (1.01, 1.15)
Without DM	1.34 (1.30, 1.38)	1.61 (1.54, 1.68)	1.19 (1.03, 1.37)	1.34 (1.10, 1.63)	1.09 (1.03, 1.15)
Males with inflammatory disease					
With DM	1.07 (1.00, 1.15)	1.05 (0.94, 1.18)	1.29 (1.04, 1.61)	0.88 (0.62, 1.26)	1.07 (0.98, 1.17)
Without DM	1.24 (1.18, 1.31)	1.55 (1.43, 1.68)	1.38 (1.16, 1.64)	1.19 (0.89, 1.59)	1.04 (0.97, 1.12)
Females with inflammatory disease					
With DM	1.14 (1.07, 1.22)	1.16 (1.06, 1.26)	1.20 (0.91, 1.58)	1.66 (1.18, 2.35)	1.09 (0.99, 1.20)
Without DM	1.42 (1.36, 1.48)	1.64 (1.56, 1.73)	0.92 (0.72, 1.19)	1.52 (1.15, 1.99)	1.14 (1.06, 1.23)

All models adjusted for age, sex, rural residence, ethnicity, hypertension, history of MI, PCI, CABG, COPD, Asthma, atrial fibrillation, CKD, and type of inflammatory disease

CI, confidence interval; CABG, coronary artery bypass graft surgery; CKD, chronic kidney disease; COPD, chronic obstructive pulmonary disease; DM, diabetes mellitus; HF, heart failure; HR, hazard ratio; MI, myocardial infarction; PCI, percutaneous coronary intervention

Conclusion: The risk of HF hospitalization is increased in patients with ID compared to the general population, but lower than in DM. Ischemic heart disease and atrial fibrillation are leading causes of HF hospitalization in ID. The effect of inflammation underlying ID on HF risk may be independent of traditional risk factors, such as DM.

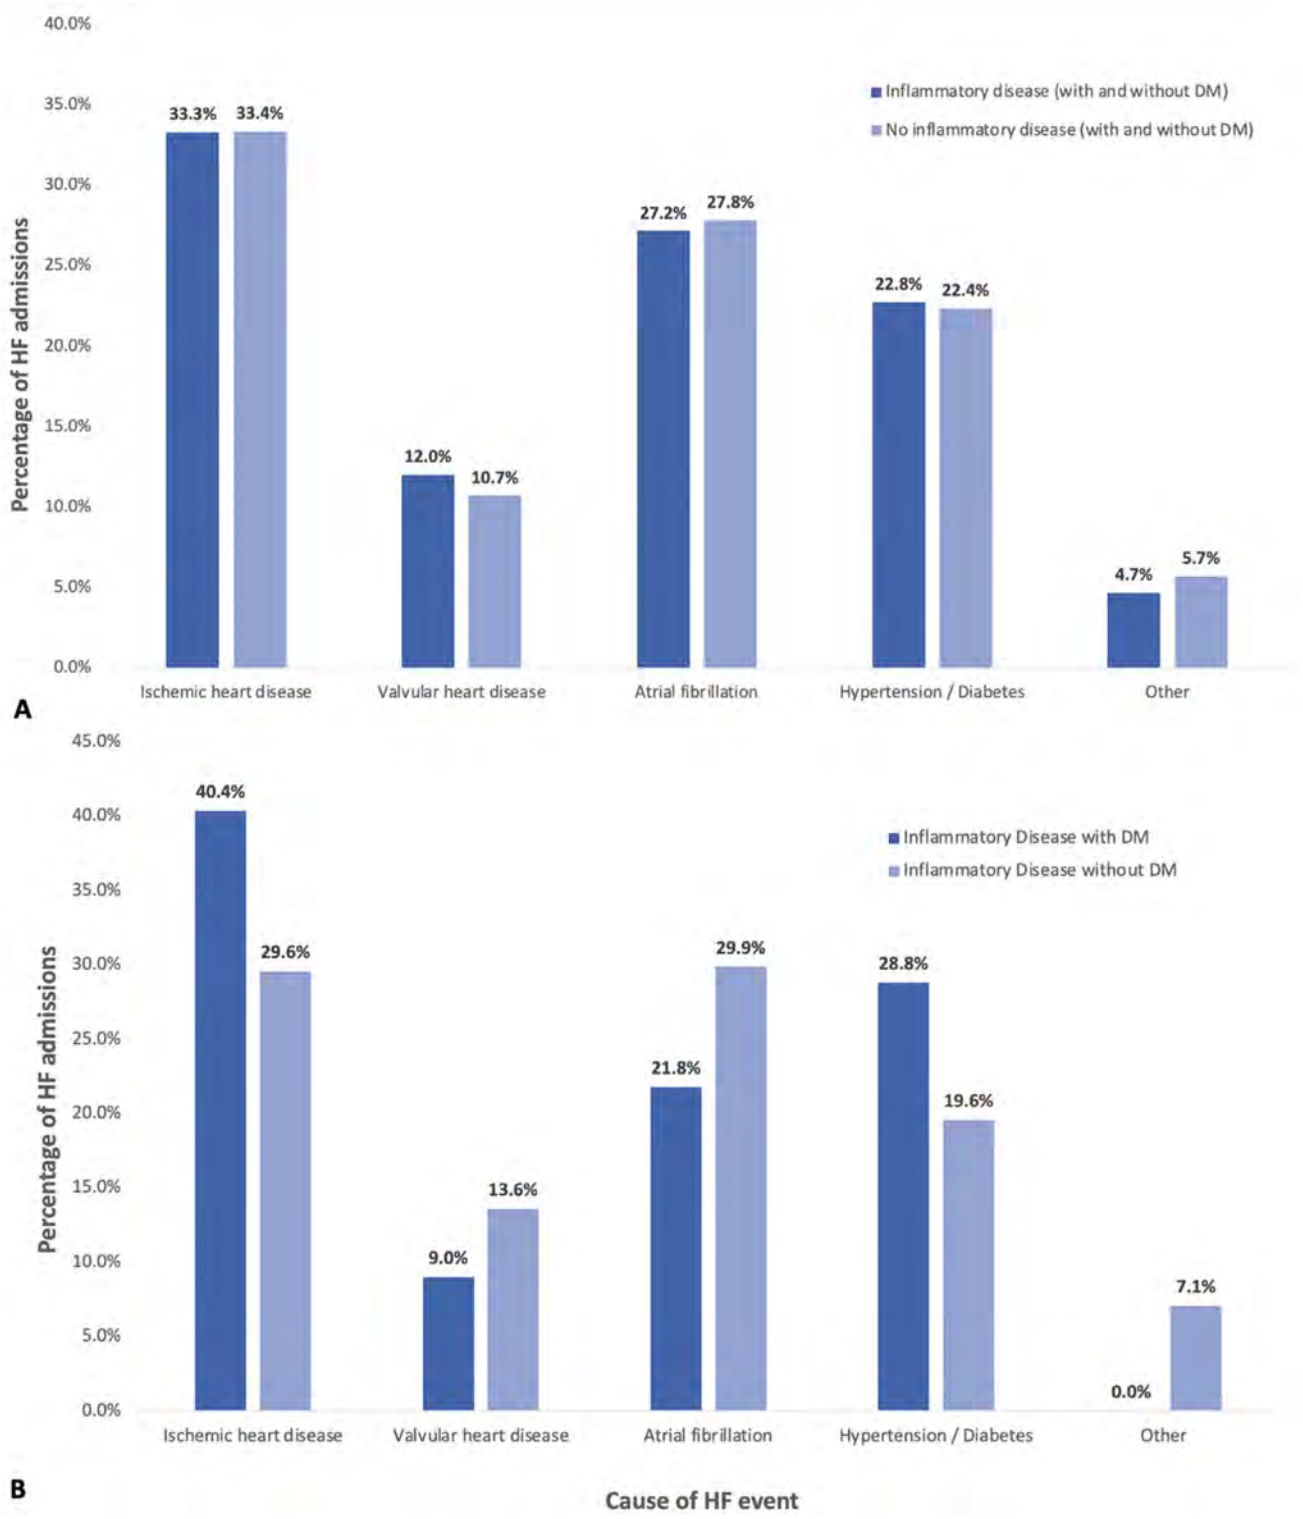

Figure 2. (A) Incident HF hospitalization by underlying etiology in patients with and without inflammatory disease. (B) Incident HF hospitalization by underlying etiology in all patients with inflammatory diseases.

Effectiveness of the Making It Work™ Program at Improving Absenteeism in Workers with Inflammatory Arthritis – Results of a Randomized Controlled Trial

Andre Luquini[1], Yufei Zheng[2], Hui Xie[2], Catherine L. Backman[3], Pamela Rogers[4], Alex Kwok[4], Astrid Knight[4], Monique Gignac[5], Dianne Mosher[6], Linda Li[3], John Esdaile[7], Carter Thorne[8] and Diane Lacaille[2], [1]University of British Columbia / Arthritis Research Canada, Fort Saint John, BC, Canada, [2]Arthritis Research Canada, Richmond, BC, Canada, [3]University of British Columbia, Vancouver, BC, Canada, [4]Arthritis Research Canada / UBC, Vancouver, BC, Canada, [5]Institute for Work & Health, Toronto, ON, Canada, [6]University of Calgary, Calgary, AB, Canada, [7]Arthritis Research Canada, Vancouver, BC, Canada, [8]Southlake Regional Health Centre, Newmarket, ON, Canada

SESSION INFORMATION

Session Date: Tuesday, November 9, 2021

Session Title: Abstracts: Epidemiology & Public Health II: Inflammatory Arthritis (1923–1926)

Session Type: Abstract Session

Session Time: 3:30PM–4:30PM

Background/Purpose: Despite advances in treatment, absenteeism remains a major problem for workers living with inflammatory arthritis (IA), leading to reduced income and quality of life. Yet, health services addressing employment needs of people with arthritis are lacking. We evaluated the effectiveness of the Making-it-Work™ (MIW), an online program developed to help people with IA deal with employment issues, at preventing days missed from work and work interruptions.

Methods: A multi-center RCT evaluated the effectiveness of MIW at improving absenteeism over two years. Participants were recruited from rheumatologist practices, consumer organizations and arthritis programs, in three provinces. Eligibility criteria included: diagnosis of IA, being employed, age 18-59, and concerned about ability to work.

Table 1. Baseline Characteristics

Variable	Control	Intervention
n	282	282
Age, median (IQR)	49.19 (13.65)	47.79 (15.19)
Sex, Female, n (%)	217 (77.0)	222 (78.7)
Ethnicity, Caucasian, n (%)	224 (80.6)	231 (83.1)
Completed Post Secondary Education, n (%)	209 (74.1)	220 (78.3)
Job Type, n (%)		
management, science, health and education	210 (74.7)	222 (78.7)
sales, services, arts and sports	54 (19.2)	42 (14.9)
transportation, trades	17 (6.0)	18 (6.4)
Arthritis Duration, Years, mean (SD)	10.62 (9.73)	9.31 (9.15)
Self Employed, n (%)	52 (18.5)	47 (16.7)
Joint Pain, NRS, mean (SD)	3.89 (2.38)	4.06 (2.71)
Disease Activity, RADAI, mean (SD)	3.66 (1.85)	3.70 (2.03)
Physical Function, HAQII, mean (SD)	0.72 (0.50)	0.74 (0.48)
Fatigue, NRS, mean (SD)	5.11 (2.53)	5.27 (2.70)

Table 2. Beta binomial logistic regression model estimating the effect of the intervention on absenteeism

	Univariate Model (N=532)		Multivariable Model (N=525)	
Outcomes	**Odds Ratio (95%CI)**	**P values**	**Odds Ratio (95%CI)**	**P values**
Sick Days per 100 workable days	0.79 (0.63, 0.97)	0.028	0.76 (0.61, 0.95)	0.014
Work Interruptions > 2 months per 100 days of follow-up	0.70 (0.47, 1.02)	0.064	0.7 (0.46, 1.06)	0.09
Combined per 100 days of follow-up	0.74 (0.6, 0.91)	0.004	0.73 (0.59, 0.91)	0.005

Participants were randomized 1:1 to MIW or usual care plus printed material on workplace tips. MIW consists of five online self-learning modules and group meetings, and individual vocational counselling and ergonomic assessments. Questionnaires were administered every 6 months. Outcomes were 1) number of sick days (occasional days missed from work and sick leaves shorter than 2 months duration), calculated as a rate per 100 workable days; 2) work interruptions greater than 2 months duration, calculated per 100 days of follow-up, and 3) the combined outcome (sum of sick days taken and work interruptions of any duration, calculated per 100 days of follow-up. Intention-to-treat analysis using Beta-binomial logistic regression models were used to evaluate the intervention effects on the three absenteeism outcomes, in separate analyses, accounting for the potential overdispersion in binomial outcomes. Odds ratios (OR) representing the intervention's effect on the daily risk of each absenteeism outcome, adjusting for baseline characteristics [age, sex, education, ethnicity, job type, RA duration, pain, disease activity (RADAI), fatigue, and physical function (HAQII)], 95% confidence intervals and Wald-tests were computed using robust standard errors accounting for potential model mis-specifications. Analyses were conducted using STATA 16.

Results: A total of 564 participants were recruited, with 85% completing 2-year follow-up. Baseline characteristics were similar between groups (Table 1). Mean (SD) number of sick days were 2.7 (4.6) and 2.3 (4.3) per 100 workable days, for controls and MIW, respectively; and mean (SD) number of days of work interruptions were 10.5 (22) and 8.8 (21.2) per 100 days of follow-up, respectively. The intervention group had a 21% lower odds of taking sick days from work (p=0.028), a 30% lower odds of work interruptions (p=0.064), and a 26% lower odds of the combined outcome (sick days and work interruptions) (p=0.004) (Table 2).

Conclusion: Results of the RCT reveal that the program was effective at improving absenteeism by decreasing the odds of sick days, and work interruptions, although the latter was of borderline statistical significance. Effectiveness at preventing long-term work disability will be assessed at 5 years. This program fills one of the most important unmet needs for people with inflammatory arthritis.

Heterogeneity of Juvenile Idiopathic Arthritis Synovial Fibroblasts Correlates to Disease Progression and Provides Compelling Diagnostic Data

Megan Simonds[1], Kathleen Sullivan[2], Carlos Rose[3] and **AnneMarie Brescia**[4], [1]Nemours, Wilmington, DE, [2]The Children's Hospital of Philadelphia, Philadelphia, PA, [3]Thomas Jefferson University/duPont Hospital for Children, Wilmington, DE, [4]Nemours/A.I.duPont Hospital for Children, Wilmington, DE

SESSION INFORMATION

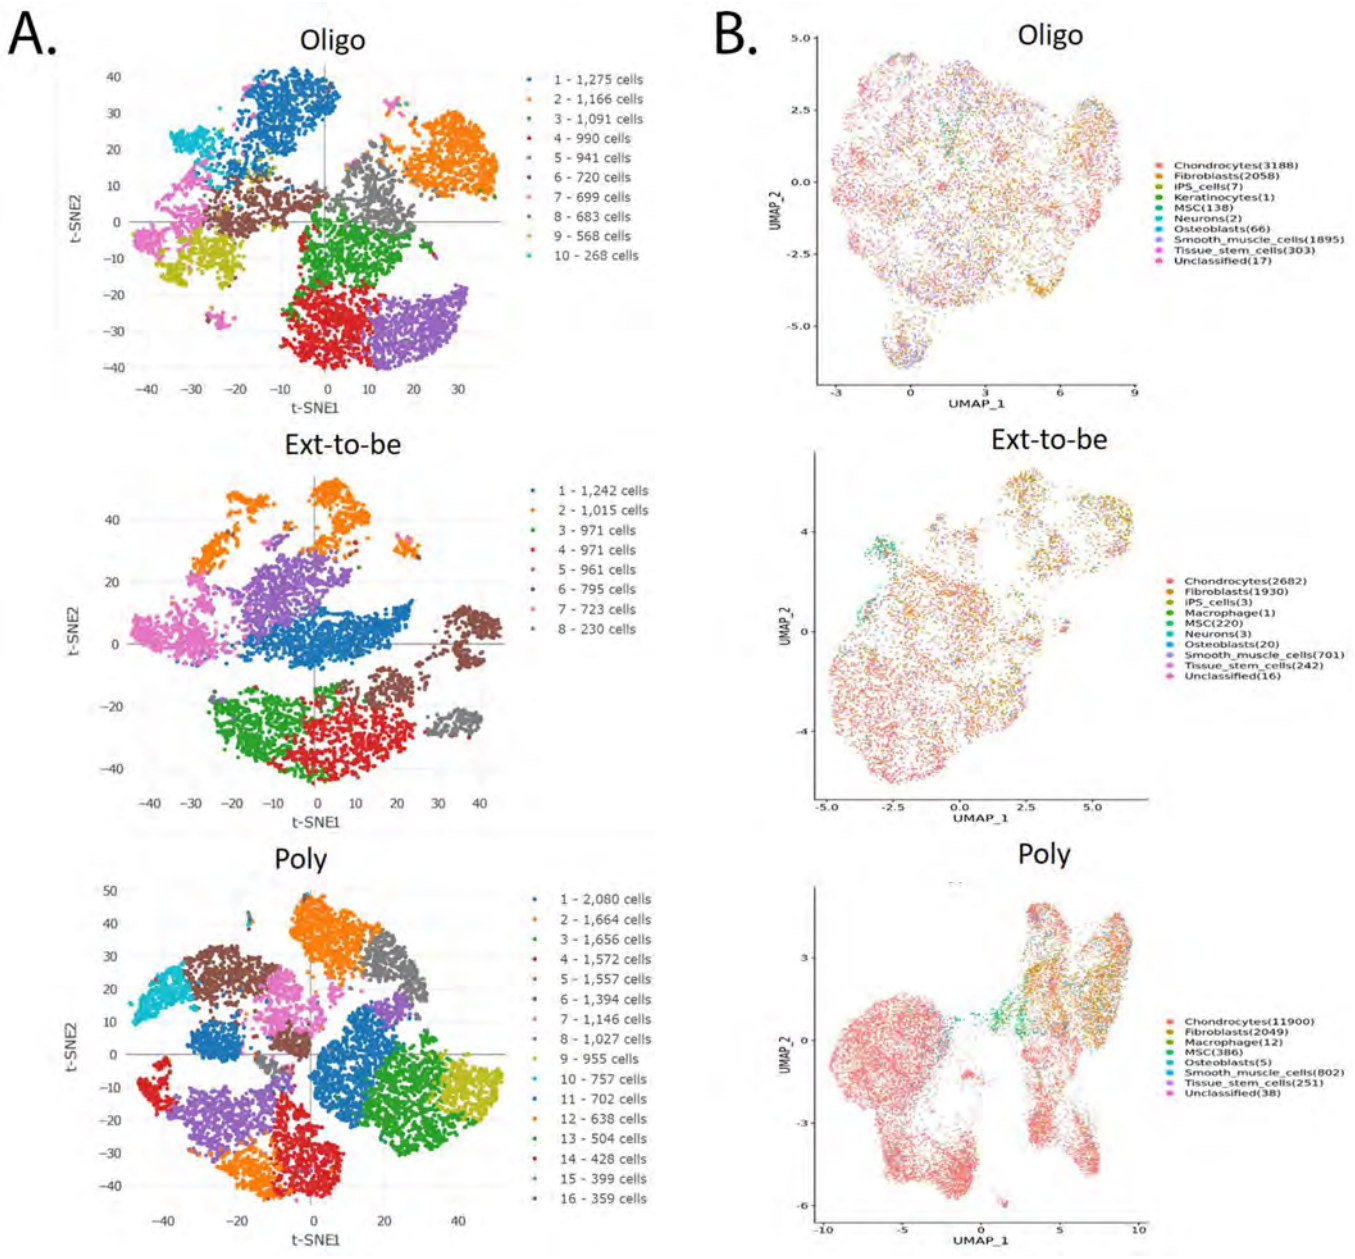
Session Date: Tuesday, November 9, 2021

Session Title: Abstracts: Pediatric Rheumatology – Basic Science (1927–1930)

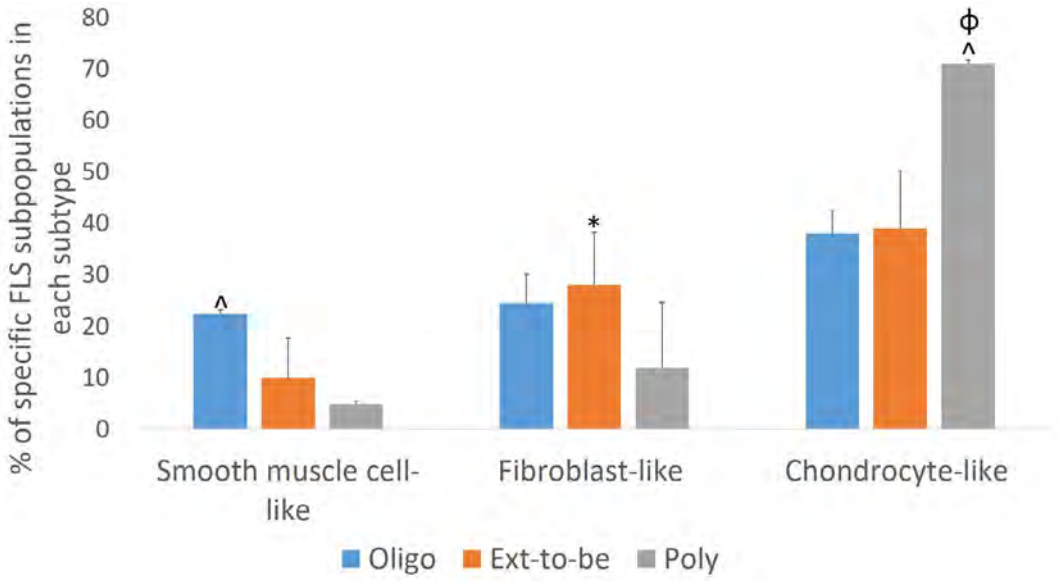
Session Type: Abstract Session

Session Time: 3:30PM–4:30PM

Background/Purpose: Juvenile Idiopathic Arthritis (JIA) induces growth disturbances in affected joints. Fibroblast-like synoviocytes (FLS) play a crucial role in JIA pathogenesis; however, the mechanisms by which they contribute to disease progression is not well described. Previous studies demonstrated that rheumatoid arthritis (RA) FLS are heterogeneous, and subpopulations with transformed, aggressive phenotypes cause invasive and destructive dis-



t-SNE (A) and UMAP (B) of FLS from patients with oligoarticular JIA who stayed persistent course (top row) or went on to an extended course (ETB, middle row) or with polyarticular JIA.

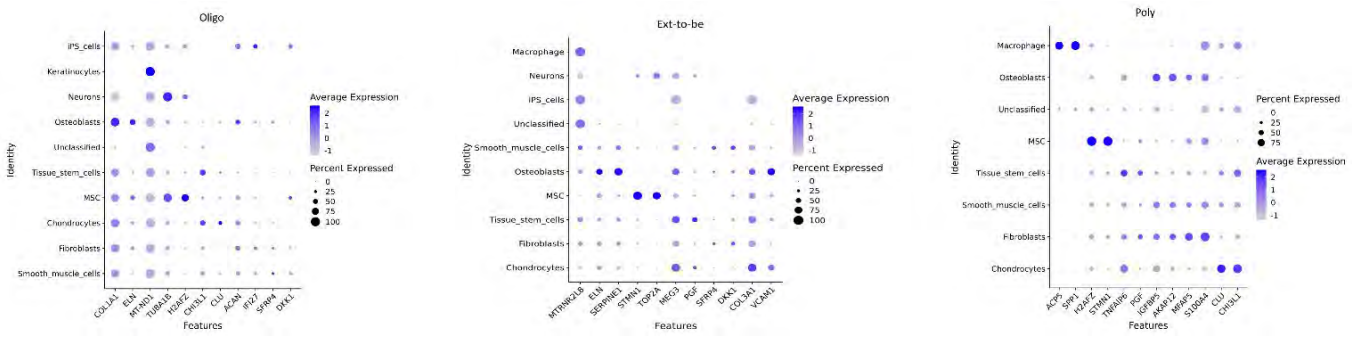


Percentage of FLS subpopulations in cultured FLS from patients with oligoarticular (Oligo), ETB, and polyarticular (Poly) JIA. Smooth muscle-like cells decrease in more severe subtypes of JIA. Percentage of fibroblast-like cells significantly increases in ETB compared to Oligo.

ease activity (1). Here, we employ single-cell RNA sequencing (scRNA-seq) to investigate JIA FLS heterogeneity and its' influence on disease extension.

Methods: JIA FLS cell lines from oligoarticular (oligo), extended-to-be (ETB), and polyarticular (poly) types were cultured. scRNA-seq was performed by Genewiz according to 10x Genomics Chromium protocols. Cell ranger software aggregated data from each patient to compare single-cell gene expressions within each JIA type. SeuratR package was used for QC, analysis, and exploration of data.

Results: Using t-Distributed Stochastic Neighbor Embedding (t-SNE), distinct clusters within each JIA FLS type illustrated heterogeneity (Figure 1A). Cells with similar expression patterns cluster together as indicated by a single color. Clusters in close proximity have similar gene expression profiles. Seurat performed Uniform Manifold Approximation and Projection (UMAP) dimensionality reduction, and the clusters co-localized. Majority of clusters within each type co-localize with greater distance between clusters within ETB and poly (Figure 1B). Cells were annotated based on similarity to a reference dataset of cells with known labels (Human Primary Cell Atlas Data) using SingleR data package. Subpopulation percentages were calculated from cell counts (Figure 2). Smooth muscle cell-like cells decreased in more severe JIA types ($p < 0.05$ in oligo v poly). Fibroblast-like cell percentage was higher in ETB than oligo ($p < 0.05$). Chondrocyte-like cells percentage increased in poly compared to oligo and ETB ($p < 0.05$). Differen-



Seurat single analysis identified the top features or genes of each projected cell type for each subtype. The dot plot shows the average expression of each feature in each cell type and the percent of cells that express that feature.

tially expressed genes were revealed within cell-type subpopulations between subtypes of JIA (Table 1). Specifically, ETB downregulate COL1A1 and ACAN and upregulate IFI27 and SERPINE1 in FLS-like cells when compared to oligo ($p< 0.00$). COL3A1 and VCAM were upregulated in chondrocyte-like cells in ETB when compared to oligo ($p< 0.00$).

Conclusion: Heterogeneity of FLS from JIA patients could present a novel JIA diagnostic tool. While single cells still co-localize by UMAP, known cell types were identified including: smooth muscle cell-like, fibroblast-like, and chondrocyte-like subpopulations. Differences in subpopulations composition in conjunction with differentially expressed genes within a subpopulation can contribute to distinguishing between subtypes of JIA. Specifically, predicting whether a patient will extend will allow clinicians to better determine therapeutic intervention.

Background/Purpose: Cytokine storm syndromes (CSS) are frequently fatal complications of a variety of oncologic, rheumatic, and infectious diseases. Many patients with CSS possess heterozygous missense mutations in genes related to the familial CSS, hemophagocytic lymphohistiocytosis (HLH). We recently identified missense mutations in a potentially novel CSS gene, *DOCK8*, among CSS patients. During the pandemic, we screened SARS-CoV-2 CSS patients (COVID-19 & MIS-C) for *DOCK8* mutations, and studied the role of *DOCK8* as a CSS gene using a murine model of HLH.

Methods: To date, 20 adult patients enrolled in a COVID-19 CSS clinical trial at UAB had whole genome sequencing. Four (20%) had rare heterozygous *DOCK8* mutations (3 missense, 1 intronic) (Table). *DOCK8* missense mutations were also identified in 6 children (UAB & Northwell) hospitalized with MIS-C (Table). *DOCK8* mutations, or wild-type (WT) sequence controls, were introduced into human NK-92 cells by FOAMY virus transduction. WT and mutant *DOCK8*-expressing NK-92 cells were incubated with K562 target cells and compared for cytolysis and degranulation (CD107a) by flow cytometry. *DOCK8* knock-out (KO) mice were compared to WT mice using an LCMV viral model of familial HLH (Jordan MB et al. *Blood* 2004;104:735). Following infection, mice were tracked for weight and changes in peripheral blood cell counts and cytokines as previously described (Rood JE et al. *Blood* 2016;127:426). After 8 days of infection, mice were euthanized and quantified for splenomegaly (weight) and liver pathology (scored by microscopy). Appropriate statistical approaches were employed for comparing nominal and ordinal data sets, respectively.

Results: Introduction of all *DOCK8* missense mutations (from COVID-19 adults and children with MIS-C) into NK-92 cells resulted in diminished NK cell cytolysis and degranulation (Figure 1). In comparison to WT mice, *DOCK8* KO mice displayed increased splenomegaly and prolonged weight loss (Figure 2). In addition, thrombocytopenia was statistically significantly pronounced in the *DOCK8* KO mice, as was increased serum interferon-gamma (Figure 2). Histopathology revealed statistically significant liver endothelial cell activation in the *DOCK8* KO mice (Figure 2).

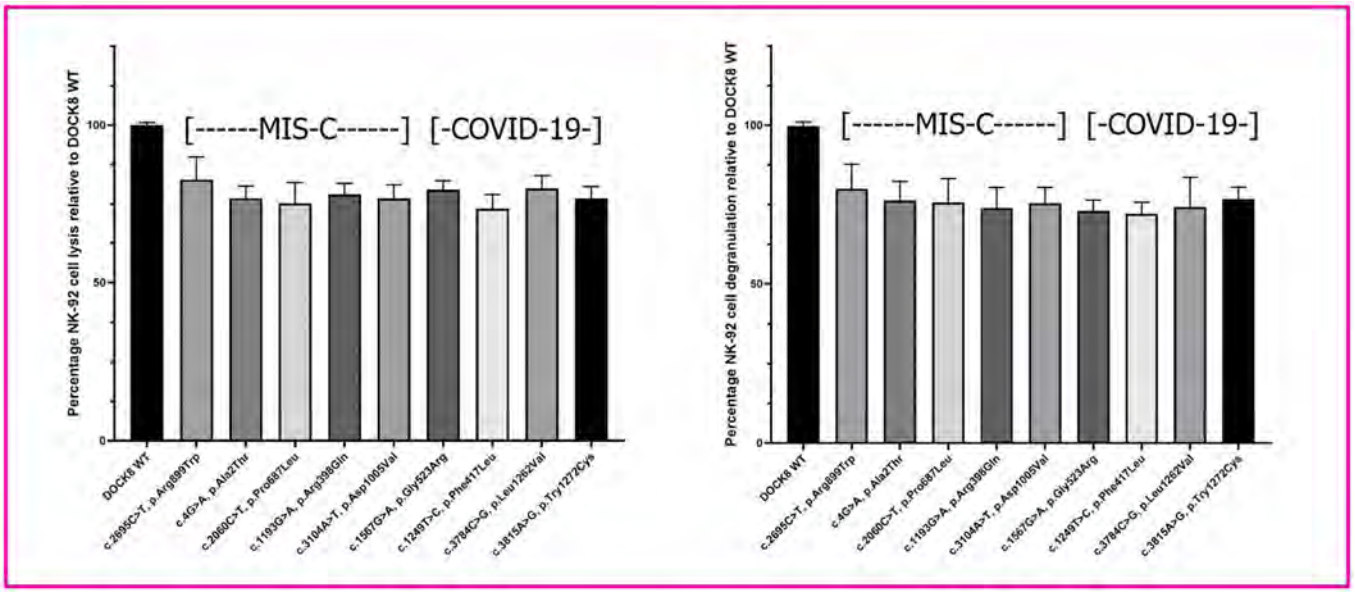

Figure 1. Functional analyses of DOCK8 patient mutations. Human NK-92 natural killer cells were infected with FOAMY viruses expressing DOCK8 wild-type (WT) or patient missense mutations. NK-92 cells were sorted by flow cytometry based on co-expression of green fluorescent protein. LEFT: NK-92 cell lytic activity versus K562 target cells was assessed for each patient DOCK8 missense mutation and compared to control (WT). Mean percentages +/- SEM are presented relative to WT (n=3). RIGHT: Degranulation of NK-92 cells stimulated by incubation with K562 target cells was assessed for each patient DOCK8 missense mutation by detection of cell surface CD107a by flow cytometry in comparison to WT control. Mean percentages +/- SEM are presented relative to WT (n=3). Studies were conducted as previously detailed (Zhang M et al. J. Immunol. 2016;196:2492).

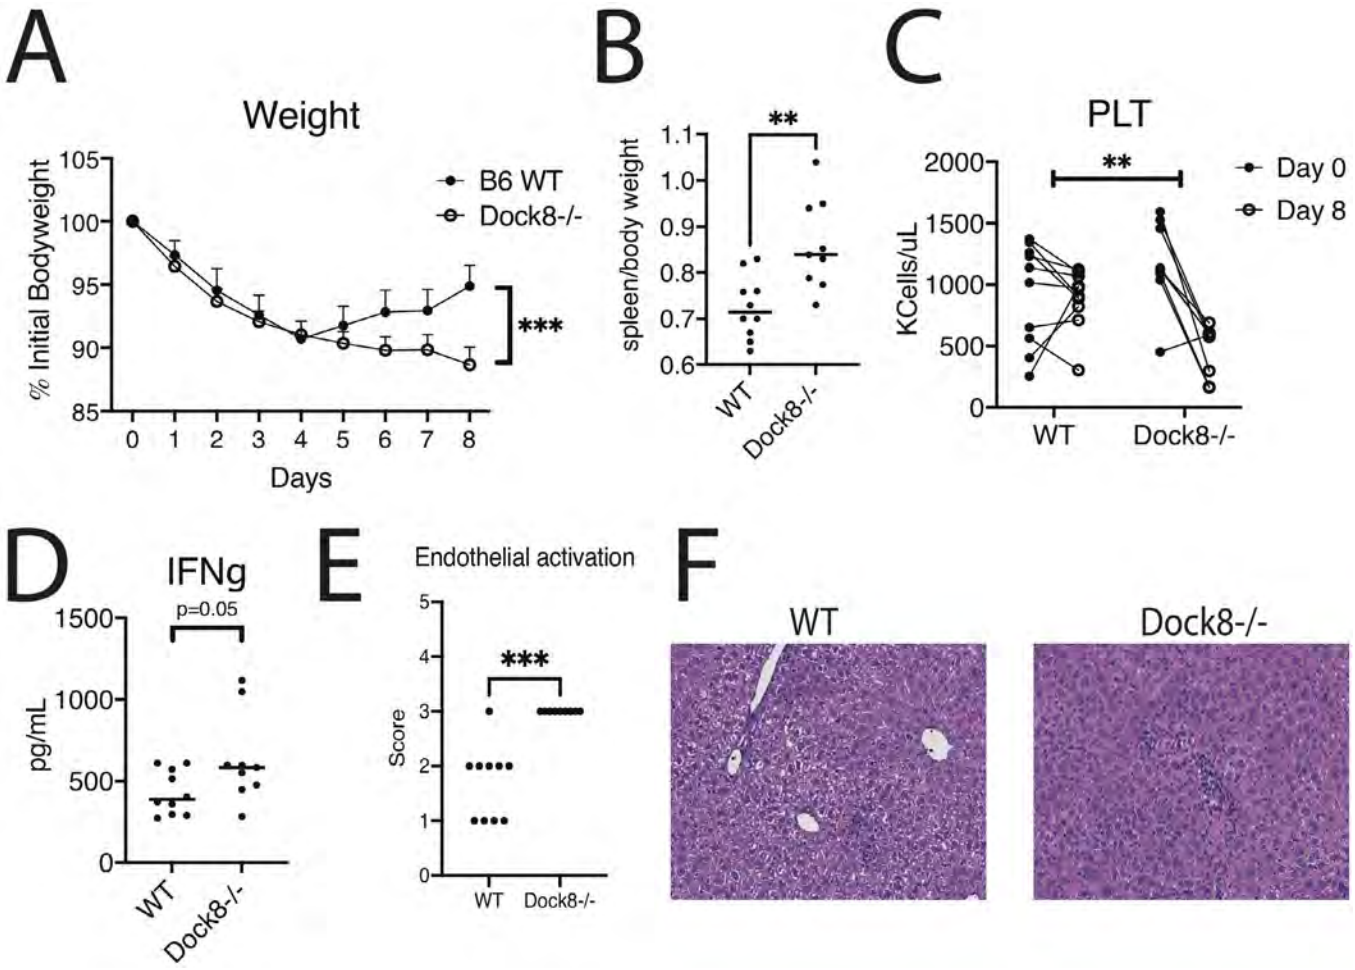

Figure 2. LCMV infection model of cytokine storm syndrome in DOCK8 deficient mice. Wild-type (WT) or DOCK8-/- mice were infected with LCMV as described (Rood JE et al. Blood 2016;127:426). A. Daily body weight as a percentage of initial body weight is graphed for B6 WT (closed circles) and DOCK8-/- (open circles) with means + SEM (n=9 per group). B. Splenomegaly was assessed by spleen weight after euthanization 8 days post-infection (n=9 per group). C. Platelet counts were assessed prior to (closed circles) and 8 days post-infection (open circles) for WT (left) and DOCK8-/- mice (right) (n=8 per group). D. Serum interferon-gamma levels were assessed at day 8 post-infection for WT and DOCK8-/- animals (n=10 per group). E. Endothelial cell activation was assessed by a pathology based scoring system for WT and DOCK8-/- mice (n=10 per group). F. Representative H&E stains of liver pathologic specimens for WT (left) and DOCK8-/- (right) mice 8 days after infection.

Conclusion: *DOCK8* partial dominant-negative missense mutations are present in CSS patients with COVID-19 and MIS-C and likely are risk factors for CSS development. A murine familial HLH model demonstrates a requirement for the presence of *DOCK8* to prevent a hyper-inflammatory CSS-like disease state.

Metabolomics Identifies Early Mechanisms of Atherogenic Dyslipidaemia in Juvenile-SLE Patients Associated with Inflammation

George Robinson[1], Kirsty Waddington[1], Junjie Peng[1], Anna Radziszewska[1], David Isenberg[2], Yiannis Ioannou[1], Ines Pineda-Torra[1], Coziana Ciurtin[1] and Elizabeth Jury[1], [1]University College London, London, United Kingdom, [2]Centre for Rheumatology, University College London, London, United Kingdom

SESSION INFORMATION
Session Date: Tuesday, November 9, 2021
Session Title: Abstracts: Pediatric Rheumatology – Basic Science (1927–1930)
Session Type: Abstract Session
Session Time: 3:30PM–4:30PM

Background/Purpose: Cardiovascular disease (CVD) is a leading cause of mortality in patients with juvenile-onset systemic lupus erythematosus (JSLE) through atherosclerosis, the build-up of lipids and inflammation in the sub-endothelial intimal layer of medium-sized to large arteries. Our findings in adult-onset SLE link immune cell dysregulation with dyslipidaemia, however, little is known about the immune profile or whether dyslipidaemia contributes to inflammation and atherosclerosis in JSLE.

Methods: Serum NMR metabolomics (130 lipid measures), proteomics (Proximity Extension Assay) and anti-high density lipoprotein(HDL) antibody (ELISA) analysis was performed on a cohort of JSLE patients (n=65, median age 19, 22 active, 43 inactive by SLE Disease Activity Index, SLEDAI) and healthy controls (HCs, n=32, median age=19). Data was analysed using balanced random forest (BRF) machine learning with 10-fold cross-validation and logistic regression (adjusted for demographic characteristics) and linear regression analysis correlating features with measures of disease activity. Flow cytometry evaluated the activation (CD69 and HLA-DR) and inflammatory lipid profile (lipid raft signalling platforms enriched in glycosphingolipids and cholesterol) of immune subsets.

Results: The BRF machine learning model could predict JSLE patients from HCs with a 76% accuracy based on all 130 serum lipid measures with the most important variables being a lower expression of atheroprotective small and medium HDL subsets in JSLE compared to HCs. In support, linear and logistic regression analysis of serum lipids identified atherogenic dyslipidaemia in JSLE patients compared to HCs exacerbated by active disease and altered liver function. Specifically, patients with active disease had significantly increased atherogenic very-low, intermediate and low density lipoproteins (VLDL, IDL and LDL) and decreased atheroprotective HDL compared to patients with low disease activity and HC's. Strikingly, HDL levels correlated negatively with anti-HDL antibodies ($r=-0.49$, $p=0.012$) and atherogenic lipoproteins correlated positively with T-cell and B-cell lipid rafts and activation markers. In addition, lymphocyte culture with serum isolated from JSLE patients with active disease induced a significant increase in cellular cholesterol and activation markers compared to serum isolated from patients with low disease activity and HC's. Finally, JSLE patients had increased serum levels of ICAM1 ($p=0.013$), VCAM1 ($p=0.007$) and lipoprotein lipase ($p=0.028$) compared to HCs, suggesting increased vascular inflammatory cell recruitment and atherogenic lipoprotein conversion in JSLE respectively.

Conclusion: Multi-omic analysis identified potential early mechanisms of dyslipidaemia in JSLE patients associated with inflammation and atherosclerosis. This could help to inform early lipid targeted therapies in JSLE to improve cardiovascular outcomes and quality of life for patients.

Single-Cell Genomics Reveals a Shared Monocyte Interferon Program in a Subset of Patients with Systemic Juvenile Idiopathic Arthritis, Macrophage Activation Syndrome and Lung Disease

Emely Verweyen[1], Kairavee Thakkar[2], Kashish Chetal[2], Sanjeev Dhakal[3], Alexei Grom[2], Nathan Salomonis[2] and Grant Schulert[2], [1]Cincinnati Children's Hospital, Cincinnati, OH, [2]Cincinnati Children's Hospital Medical Center, Cincinnati, OH, [3]Cincinnati Children hospital, Cincinnati, OH

SESSION INFORMATION
Session Date: Tuesday, November 9, 2021
Session Title: Abstracts: Pediatric Rheumatology – Basic Science (1927–1930)
Session Type: Abstract Session
Session Time: 3:30PM–4:30PM

Background/Purpose: Systemic juvenile idiopathic arthritis (SJIA) is a clinically heterogenous disease and can be complicated by macrophage activation syndrome (MAS) and lung disease (LD) thought to be driven by interferon signaling, though the contributing cell populations and distinctions between IFNγ and IFNα/β are undefined. To identify novel prognostic transcripts and potential patient subtypes, we aimed to characterize single-cell heterogeneity and patient-specific transcriptomics responses from the peripheral blood of children with SJIA, MAS and LD.

Methods: 10x Genomics single-cell RNA Sequencing (scRNA-Seq) was performed on PBMCs from 7 active SJIA and 5 inactive SJIA patients, 2 SJIA-MAS and 6 SJIA-LD patients and 5 healthy controls. Integration analyses were performed with the software Seurat 3 to identify discrete cell populations while correcting for donor and disease-level differences. To identify subsets of patients with cell-type specific signatures, we developed a new hybrid supervised/unsupervised computational pipeline in the software AltAnalyze, called cellHarmony 2.0, designed specifically for large cohort single-cell genomic studies.

Results: scRNA-Seq analysis was performed on a total of 234,128 individual cells (ranging from 6,662-12,647 cells/patient), with a mean number of 21,637 genes detected per sample. To assess cell-population level differences, we identified and annotated based on marker genes 34 discrete cell populations across all submitted samples. This indicated a consistent increase in Natural Killer (NK) cells and decrease in naïve and regulatory T cells in SJIA-LD, with the distribution of cells from inactive SJIA patients similar to that of controls. To exploit anticipated heterogeneity within this cohort, we applied our new cell-type aware patient subtype discovery algorithm cellHarmony 2.0. We computed an aggregate cell signature for all cell populations or pseudo-bulks (n=34) for each patient and their associated fold differences relative to matched control cell clusters, and performed unsupervised clustering of the pseudo-bulks to identify patient subtypes associated within one or more cell types. This analysis uncovered 11 pseudo-clusters of cell type gene expression differences, both shared and unique across the patients. Specifically, pseudo-cluster 4 was defined by IL-2 mediated signaling genes, composed of mostly NK cells from all SJIA subtypes except MAS. SJIA-MAS PBMCs were almost exclusively represented in three separate pseudo-clusters that contained genes mediating T-cell receptor activation, immune response and interferon signaling. Finally, pseudo-cluster 8 was composed of mainly monocytes/macrophages with specific upregulation of IFNα/β induced genes IFITM3, IFI6 and ISG15, only in active SJIA, SJIA-MAS and SJIA-LD.

Conclusion: Unsupervised single-cell cohort analysis provides new opportunities to uncover novel disease molecular programs and pathways in clinically heterogenous patient groups. Here, we found active SJIA, SJIA-MAS and SJIA-

LD PBMCs have distinct monocytic responses characterized by upregulation of interferon-induced genes, highlighting the role for both IFNγ and IFNα/β in driving disease pathogenesis.

The Burden of Thirty-day Readmission and Independent Predictors of Readmission in Patients with Systemic Lupus Erythematosus: A Nationwide Analysis

Ashu Acharya[1], Saffa Iftikhar[1], Yasmin Khader[1], Sachit Sharma[1], Joan N Gekonde[1], Rawish Fatima[1], Cameron J Burmeister[1] and Nezam Altorok[2], [1]University of Toledo Medical Center, Toledo, OH, [2]University of Toledo, Toledo, OH

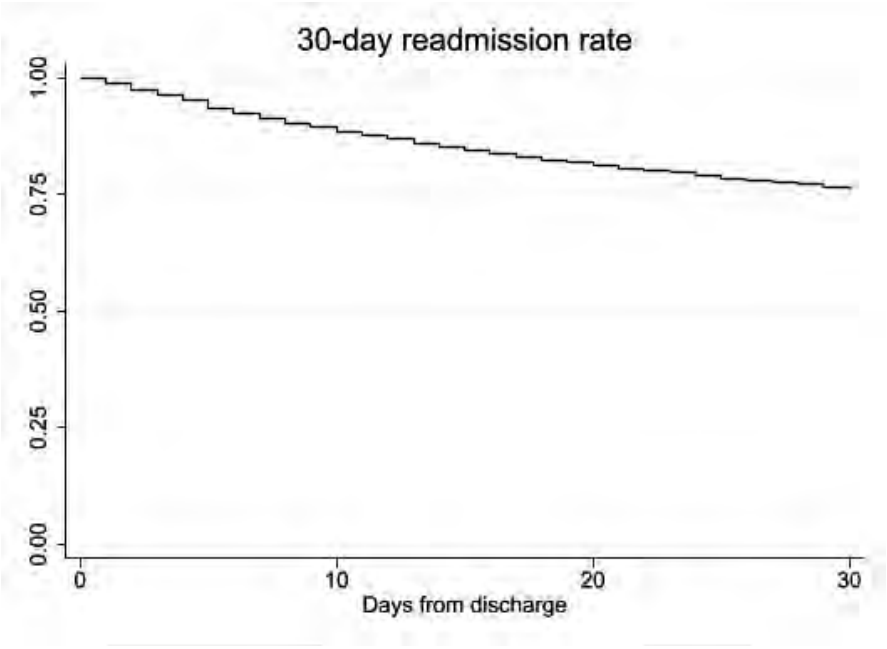
SESSION INFORMATION
Session Date: Tuesday, November 9, 2021
Session Title: Abstracts: SLE – Diagnosis, Manifestations, & Outcomes II: Predictors & Longitudinal Outcomes (1931–1934)
Session Type: Abstract Session
Session Time: 3:30PM–4:30PM

Background/Purpose: Systemic Lupus Erythematosus (SLE) is a chronic immune-mediated disease with 20-25% patients needing hospital admission annually. Early readmissions add to the clinical and economic burden on the healthcare system. Strategies to reduce readmission are now a crucial aspect of management. Therefore, we conducted this study to investigate the outcomes and predictors of 30-day readmission in patients with SLE.

Methods: We queried the 2017 Nationwide Readmission Database (NRD) using ICD-10-CM diagnosis codes to identify all patients admitted with a primary diagnosis of SLE. Outcomes assessed were 30-day readmission rates, mortality, length of stay (LOS) and hospitalization costs. A multivariate cox regression was done to obtain Hazard Ratio (HR) and identify independent predictors of readmission. Statistical analysis was performed using STATA software.

Results: A total of 8,664 adult patients were admitted with a primary diagnosis of SLE in 2017, with in-hospital mortality rate of 0.87%. Of the patients discharged, 23.72% patients were readmitted within 30-days. The most common primary diagnosis at readmission was “Systemic lupus erythematosus, unspecified” (12.99%). When compared to index admission, readmitted patients had higher in-hospital mortality (3.16% vs 0.87%, $p< 0.01$), longer mean LOS (7.05 days vs 6.4 days, $p< 0.05$) and higher mean hospitalization charges ($76,055 vs $68,087, $p< 0.01$). Readmissions added 14,427 inpatient days and $36 million in hospitalization cost to the healthcare burden. Higher Charlson comorbidity score (HR 1.08, $p< 0.01$), CHF (HR 1.36, $p< 0.01$), AKI (HR 1.24, $p< 0.01$), CKD (HR 1.32, $p< 0.01$), ESRD (HR 1.29, $p< 0.01$), and discharge other than home discharge (HR 1.36, $p< 0.01$) were independently associated with increased likelihood of 30-day readmission.

Conclusion: We performed a comprehensive assessment of patients admitted with SLE with the national inpatient data using the newer specific ICD-10 codes. In the US, about 1 in 4 patients with SLE are readmitted within 30-days of discharge. Readmission is associated with significantly increased in-hospital mortality, LOS, and hospitalization costs. 30-day readmissions resulted in an increased burden to healthcare resource utilization, adding considerable in-patient stay days and hospitalization costs. Patients with AKI, CHF, CKD, ESRD, discharge other than home discharge and higher comorbidity burden were significantly more likely to be readmitted within 30-days. Further



KM graph of 30-day readmission.

prospective studies are needed to assess the high-risk populations to reduce early readmission and improve value-based care.

Session Title: Abstracts: SLE – Diagnosis, Manifestations, & Outcomes II: Predictors & Longitudinal Outcomes (1931–1934)

Session Type: Abstract Session

Session Time: 3:30PM–4:30PM

Background/Purpose: Prior studies of SLE clusters based on autoantibodies have utilized cross-sectional data from single centers. We applied clustering techniques to longitudinal and comprehensive autoantibody data from a large multinational, multi-ethnic inception cohort of well characterized SLE patients to identify clusters associated with disease outcomes.

Table 1. Demographic and clinical characteristics that were statistically significant[1] at baseline and five-year follow-up between the four SLE longitudinal autoantibody clusters

1.Comparison between cluster groups using one-way ANOVA test and a Benjamini-Hochberg correction with false discovery rate (FDR) alpha = 0.05
2.Lupus nephritis was diagnosed by renal biopsy or fulfillment of the renal item on the ACR classification criteria.
3.The total score of SLEDAI-2K is the sum of all 24 descriptor scores. The total SLEDAI-2K score falls between 0 and 105, with higher scores representing higher disease activity.
4.A measurement of lupus disease activity over time determined by the calculation of the area under the curve of SLEDAI-2K over time by adding the area of each of the blocks of visit interval and then dividing by the length of time for the whole period.
Abbreviations: BMI, body mass index; SD, standard deviation; SLEDAI-2K, Systemic Lupus Erythematosus Disease Activity Index 2000; SLICC, Systemic Lupus International Collaborating Clinics; yrs, years.

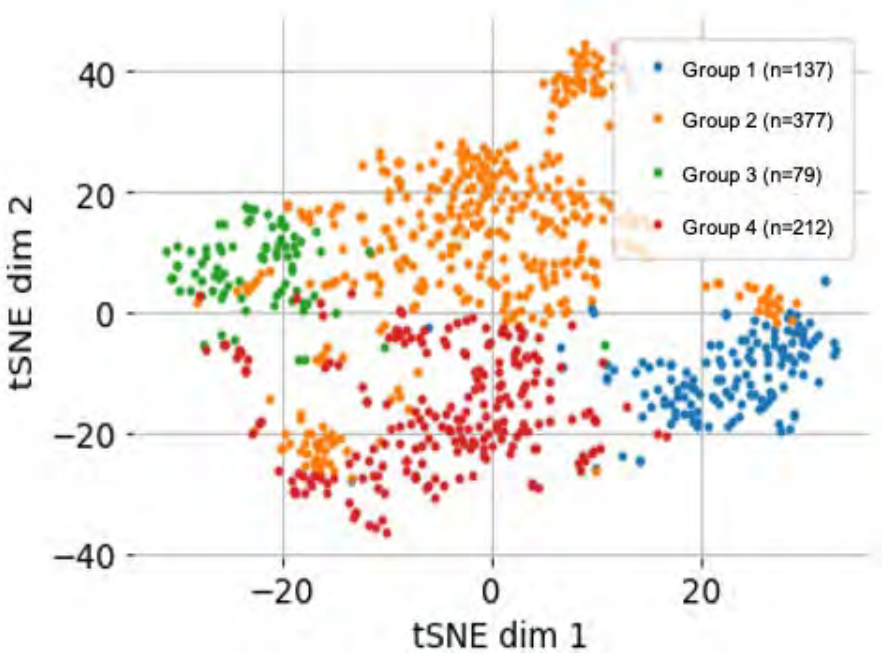

Figure 1. Four autoantibody cluster groups identified among 805 SLE patients followed from enrolment through years 3 and 5. Latent space visualized using a t-distributed stochastic neighbor embedding (t-SNE) with colors based on cluster labels.

Methods: We used demographic, clinical, and serological data at enrolment and follow-up visits years 3 and 5 from 805 patients who fulfilled the 1997 Updated ACR SLE Classification Criteria and were enrolled within 15 months of diagnosis. For each visit, ANA (HEp-2 indirect immunofluorescence assay), dsDNA, Sm, U1-RNP, SSA/Ro60, SSB/La, Ro52/TRIM21, histones, ribosomal P, Jo-1, centromere B, PCNA, antiphospholipid antibodies (IgG and IgM for anticardiolipin, anti–β2GP1, and aPS/PT, lupus anticoagulant (LAC), and IgG anti-β2GP1 D1), and anti-dense-fine speckled 70 were performed at a single lab (except LAC). K-means clustering algorithm on principal component analysis (10 dimensions) transformed longitudinal ANA and autoantibody profiles was used. We compared cluster demographic and clinical outcomes, including longitudinal disease activity (total and adjusted mean SLEDAI-2K [AMS]), SLICC/ACR damage index and organ-specific domains, SLE therapies and survival, using one-way ANOVA test and a Benjamini-Hochberg correction with false discovery rate alpha = 0.05. Results were visualized using t-distributed stochastic neighbor embedding (t-SNE).

Results: Four unique patient clusters were identified (**Table 1, Figure 1**). Cluster 1 (n=137), characterized by high frequency of anti-Sm and anti-RNP antibodies over time, was the youngest group at disease onset with a high proportion of subjects of Asian and African ancestry. At year 5, they had the highest disease activity (total SLEDAI-2K 4.3 [4.5] and AMS 4.3 [3.1]), were more likely to have active hematologic and mucocutaneous involvement, and to be on/exposed to immunosuppressants/biologics. Cluster 2 (n=377), the largest cluster, had low frequency of anti-dsDNA, were oldest at disease onset, and at year 5, had the lowest disease activity (total SLEDAI-2K 2.3 [3.3] and AMS 2.9 [2.5]), and were less likely to have nephritis and be on/exposed to immunosuppressants/biologics. Cluster 3 (n=79) had the highest frequency of antiphospholipid antibodies over time (**Figure 2**), were more likely to be of European ancestry, have an elevated body mass index, be former smokers, and by year 5, to have nephritis, neuropsychiatric involvement, including strokes and seizures (SLICC/ACR damage index). Cluster 4 (n=212) was characterized by anti-SSA/Ro60, SSB/La, Ro52/TRIM21, and histone antibodies, and active immunologic involvement (low complements) at year 5. Overall, survival of the 805 subjects was 94% at 5 years, and none of the clusters predicted survival.

Conclusion: Four SLE patient clusters associated with disease activity, organ involvement, and treatment were identified in this analysis of longitudinal ANA and autoantibody profiles in relation to SLE outcomes, suggesting these

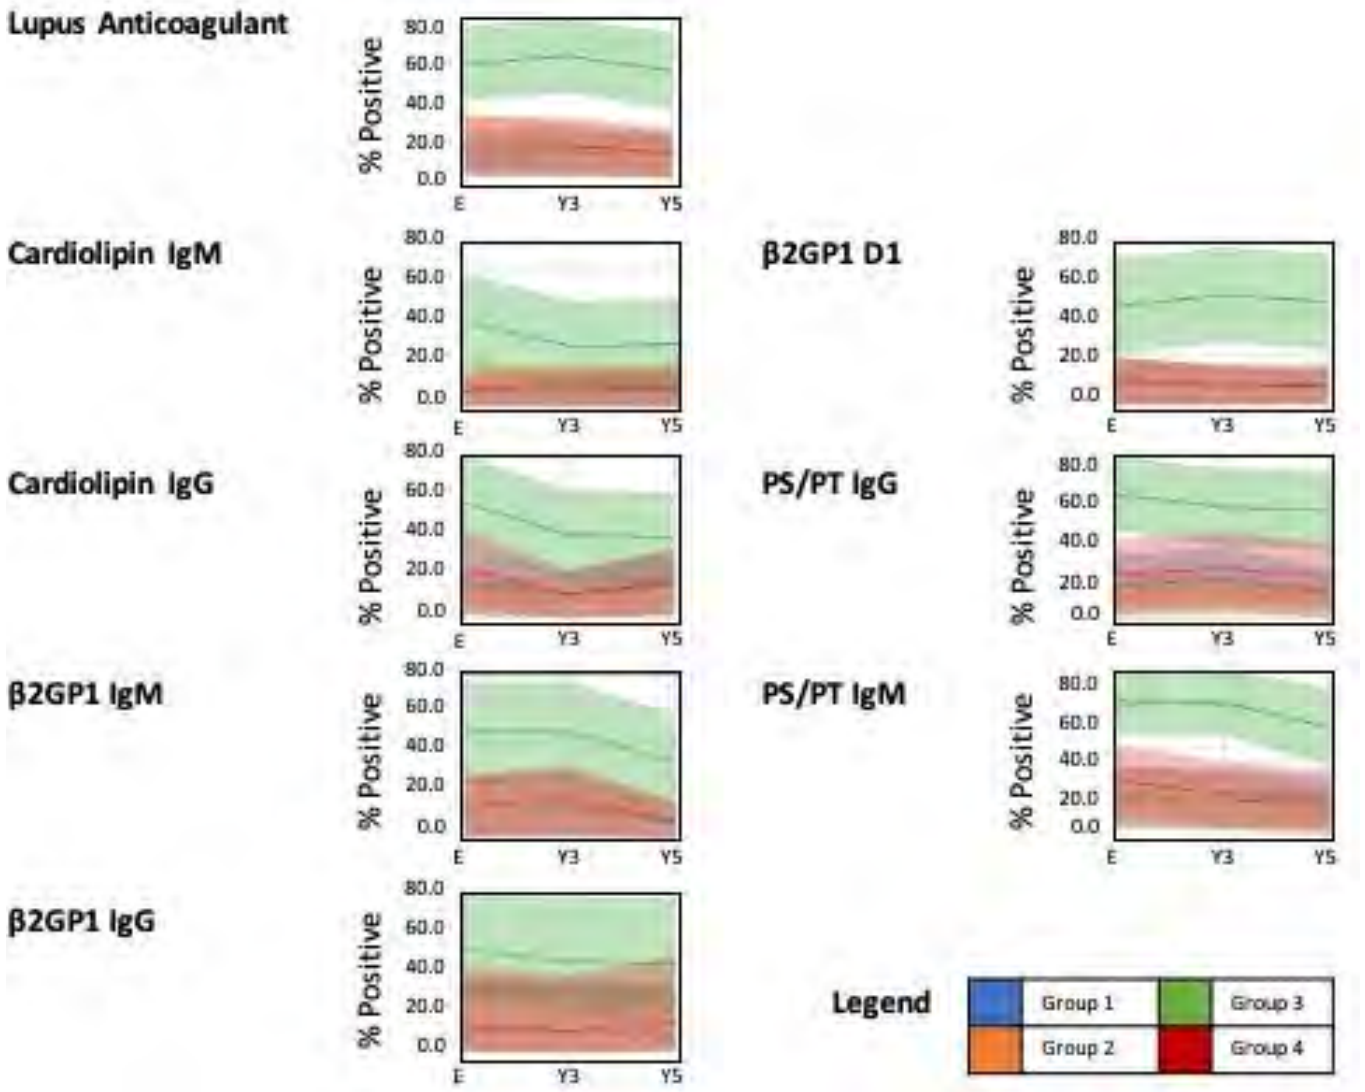

Figure 2. Antiphospholipid antibodies of the four cluster groups over time (E=enrolment, Y3=year 3, Y5=year 5). Group 3 had the highest frequency of antiphospholipid antibodies, including lupus anticoagulant, IgG and IgM anticardiolipin, IgG and IgM anti–β2-glycoprotein-1 (β2GP1), IgG anti-β2GP1 Domain 1 (D1), IgG and IgM antiphosphatidylserine/prothrombin (aPS/PT), over time compared to the other three clusters. Other connective tissue disease autoantibodies not shown. Line indicates the mean, shading indicates the standard deviation.

SLE subsets might be identifiable based on extended autoantibody profiles early in the disease and carry prognostic information.

IS: immunosuppressive; b/ts: biologics/target synthetic; OR: Odd ratio; CI: confidence interval

*The ordinal outcomes was: 1 not hospitalized, 2 hospitalized without supplementary oxygen or with non-invasive ventilation, 3 hospitalized with mechanical ventilation/extracorporeal membrane oxygenation and 4 death. This assumed that the relationship between each pair of outcome groups is of the same direction and magnitude.

Background/Purpose: Hispanic and African American race/ethnicities have been associated with poor COVID-19 outcomes in the general population and in rheumatic disease patients within the COVID-19 Global Rheumatology Alliance (GRA); however, such associations within SLE patients have not been evaluated. The aim of this study is to determine the association between race/ethnicity and COVID-19 outcomes in SLE patients from the US.

Methods: US SLE patients from the COVID-19 GRA enrolled between March 24th 2020 and April 12th 2021 were studied. Variables included were age, gender, race/ethnicity (White, African American, Hispanic and others), comorbidities (chronic renal disease, cardiovascular disease, and the number of other comorbidities), disease activity (remission, low, moderate, high), time period, glucocorticoid dose, antimalarials and immunosuppressive (IS) drug use. Drugs were categorized into five groups: antimalarials only (reference), no SLE therapy, classic IS drugs monotherapy, biologics/target synthetic IS drugs, and combination therapy. The ordinal outcome categories were: 1. hospitalized without supplementary oxygen and/or not hospitalized, 2. hospitalized with non-invasive ventilation, 3. hospitalized with mechanical ventilation/extracorporeal membrane oxygenation and 4. death. We constructed ordinal logistic regression models evaluating the relationship between COVID-19 severity and race/ethnicity, adjusting for possible confounders.

Results: Five-hundred and four patients were included; 458 (90.9%) were women and the median age was 46.8 (SD: 13.9) years. Four hundred and three (80.0%) patients were not hospitalized; 36 (7.1%) patients were hospitalized without oxygen or with non-invasive ventilation, 49 (9.7%) patients were hospitalized with mechanical ventilation/extracorporeal membrane oxygenation and 16 (3.2%) died. In a multivariable model, African American [OR=2.18 (1.07-4.31)] and Hispanic [OR=2.14 (1.07-4.31)] race/ethnicities were associated with poorer outcomes. Additionally, prednisone-equivalent doses between 5-10 mg/d [OR=7.33 (1.96-27.40)] and >10 mg/d [OR=2.61 (1.33-5.13)], IS drugs (combinations) [OR =2.25 (1.02, 4.99)] and chronic renal disease [OR =2.61 (1.35, 5.04)] were associated with more severe COVID-19 outcomes. COVID-19 diagnosis between October and April 2021 vs. earlier time periods [OR=0.39 (0.21-0.72)] was associated with less severe COVID-19 outcomes (Table 1).

Conclusion: African American and Hispanic individuals with SLE experienced more severe COVID-19 outcomes, which is consistent with findings in the US general population. These results likely reflect socioeconomic and health disparities and suggest that more aggressive efforts are needed to prevent infection in this population.

Intra-Individual Change in Cognitive Function Among Adults with Systemic Lupus Erythematosus: A Markov Analysis over 7 Years

Stefan Perera[1], Richard Cook[2], Ker-Ai Lee[2], Patricia Katz[3] and Zahi Touma[4], [1]Division of General Internal Medicine, University of Toronto, Toronto, ON, Canada, [2]Department of Statistics and Actuarial Sciences, University of Waterloo, Waterloo, ON, Canada, [3]University of California San Francisco, San Francisco, CA, [4]University of Toronto, Mississauga, ON, Canada

SESSION INFORMATION

Session Date: Tuesday, November 9, 2021

Session Title: Abstracts: SLE – Diagnosis, Manifestations, & Outcomes II: Predictors & Longitudinal Outcomes (1931–1934)

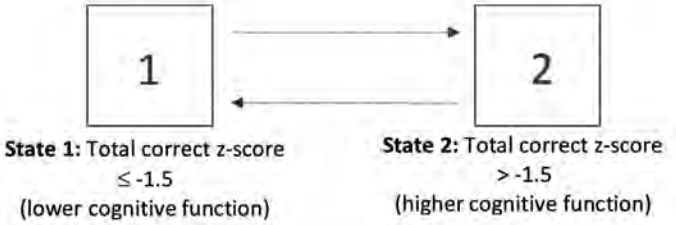
Session Type: Abstract Session

Session Time: 3:30PM–4:30PM

Background/Purpose: Cognitive impairment is a prevalent neuropsychiatric manifestation of SLE. Studies have primarily focused on the prevalence of cognitive impairment cross-sectionally; however, there remain gaps in understanding how SLE affects patients' cognition longitudinally and more importantly at the intra-individual level. We studied if and how cognitive function changes in SLE on repeated assessments (intra-individual change) and examined what factors influence cognitive change.

Methods: Data was drawn from a single centre longitudinal study that followed 1281 patients with SLE using annual telephone interviews. The Hopkins Verbal Learning Test-Revised (HVTL-R-verbal learning and memory) and the Controlled Oral Word Association Test (COWAT-verbal fluency) were the measures of cognition. The Systemic Lupus Activity Questionnaire (SLAQ) and Center of Epidemiologic Studies Depression Scale (CES-D) were used to assess disease severity and depressive symptoms respectively. A two-state Markov Analysis was used to model probabilities of transition between cognitive states: lower cognitive function [Z score ≤ -1.5] and higher cognitive function [Z score > -1.5] (**Figure 1**). Logistic regression analyses were used to examine what factors were associated with cognitive change.

Results: Most SLE patients demonstrated stability in cognition overtime. However, among those with change as assessed by the COWAT, individuals with SLE were 18 times more likely to improve in cognition than to experience cognitive decline over time (Improvement Intensity of 0.91 vs. Decline Intensity of 0.05). Higher levels of depressive



Transition To		State 1	State 2
Transition From	State 1	No Change	Cognitive Improvement
	State 2	Cognitive Decline	No Change

Figure 1. Two-state reversible Markov model for HVLT-R & COWAT to model the probabilities of transition between cognitive states.

Table 1. Multi-state regression model with COWAT

	Multivariate Regression Analysis Using COWAT Z-scores			
Cognitive Transition States	Covariate	RR	95% CI	*p*
1→2 (improvement in cognition)	Age: Per 1 Year	0.99	(0.98, 1.01)	0.52
	Education: Level 3-6 vs. Level 1-2	1.55	(0.94, 2.57)	0.09
	Steroids IV: Yes vs. No	0.95	(0.53, 1.68)	0.85
	SLAQ Score: Per 1 unit	1.01	(0.98, 1.04)	0.52
	CESD Score: Per 1 Unit	0.98	(0.96, 0.99)	0.02*
2→1 (decrease in cognition	Age: Per 1 Year	0.99	(0.97, 1.01)	0.54
	Education: Level 3-6 vs. Level 1-2	0.65	(0.36, 1.87)	0.15
	Steroids IV: Yes vs. No	1.24	(0.60, 2.55)	0.56
	SLAQ Score: Per 1 unit	1.05	(1.02, 1.09)	0.01*
	CESD Score: Per 1 Unit	1.00	(0.97, 1.02)	0.81

All models were adjusted for age; included assessments had complete covariates (number of patients = 911; total number of patient assessments = 3,097)

symptoms by CES-D were associated with less likelihood of experiencing improvement in cognition (RR 0.98; 95% CI 0.96-0.99); and greater disease severity by SLAQ was associated with an increased risk of cognitive decline (RR 1.05; 95% CI 1.02-1.09) (**Table 1**). As assessed by the HVLT-R, individuals were 3 times as likely to improve in cognition than to experience cognitive decline over time (Improvement Intensity of 0.20 vs. Decline Intensity of 0.07). Increasing age (RR 1.02; 95% CI 1.01-1.03) and higher education level (RR 1.82; 95% CI 1.29-2.58) were associated with a greater likelihood of improving cognition assessed by HVLT-R. Higher disease severity by SLAQ (RR 1.05; 95% CI 1.03-1.07) and depressive symptoms by CES-D (RR 1.02; 95% CI 1.01-1.03) were also associated with an increased risk of worsening cognition (**Table 2**).

Table 2. Multi-state regression model with HVLT-R

	Multivariate Regression Analysis Using HVLT-R Z-scores			
Cognitive Transition States	Covariate	RR	95% CI	*p*
1→2 (improvement in cognition)	Age: Per 1 Year	1.02	(1.01, 1.03)	0.00*
	Education: Level 3-6 vs. Level 1-2	1.82	(1.29, 2.58)	0.00*
	Steroids IV: Yes vs. No	1.18	(0.74, 1.88)	0.50
	SLAQ Score: Per 1 unit	1.02	(1.00, 1.04)	0.13
	CESD Score: Per 1 Unit	0.99	(0.98, 1.00)	0.14
2→1 (decrease in cognition	Age: Per 1 Year	1.00	(0.99, 1.01)	0.80
	Education: Level 3-6 vs. Level 1-2	0.71	(0.50, 1.00)	0.05
	Steroids IV: Yes vs. No	1.32	(0.81, 2.17)	0.27
	SLAQ Score: Per 1 unit	1.05	(1.03, 1.07)	0.00*
	CESD Score: Per 1 Unit	1.02	(1.01, 1.03)	0.00*

All models were adjusted for age; included assessments had complete covariates (number of patients = 1,023; total number of patient assessments = 5,283)

Conclusion: This study demonstrates that the majority of individuals with SLE experience stability in cognitive function over time. However, among those SLE patients that do experience change in cognition, improvement in cognition was more common than decline. Cognitive improvement over time was more noticeable in the verbal fluency domain (COWAT) than in the learning and memory domain (HVLT-R). Increasing age and higher education levels were associated with a greater chance of cognitive improvement. Self-reported higher levels of SLE disease severity and depressive symptoms were barriers to experiencing cognitive improvement and were risk factors for experiencing cognitive decline in both assessments.

Skewed Escape from X-inactivation: Insights into the Female Bias of Sjögren's Syndrome

Teressa Shaw[1], Wei Zhang[2], Sara McCoy[3], Xueer Qiu[1], Adam Pagenkopf[1], Robert Hal Scofield[4], Jacques Galipeau[3] and **Yun Liang**[1], [1]University of Wisconsin-Madison, Madison, WI, [2]University of California San Diego, La Jolla, CA, [3]University of Wisconsin, Madison, WI, [4]Oklahoma Medical Research Foundation, Oklahoma City, OK

SESSION INFORMATION

Session Date: Tuesday, November 9, 2021

Session Title: Abstracts: Genetics, Genomics & Proteomics (1935–1938)

Session Type: Abstract Session

Session Time: 4:00PM–5:00PM

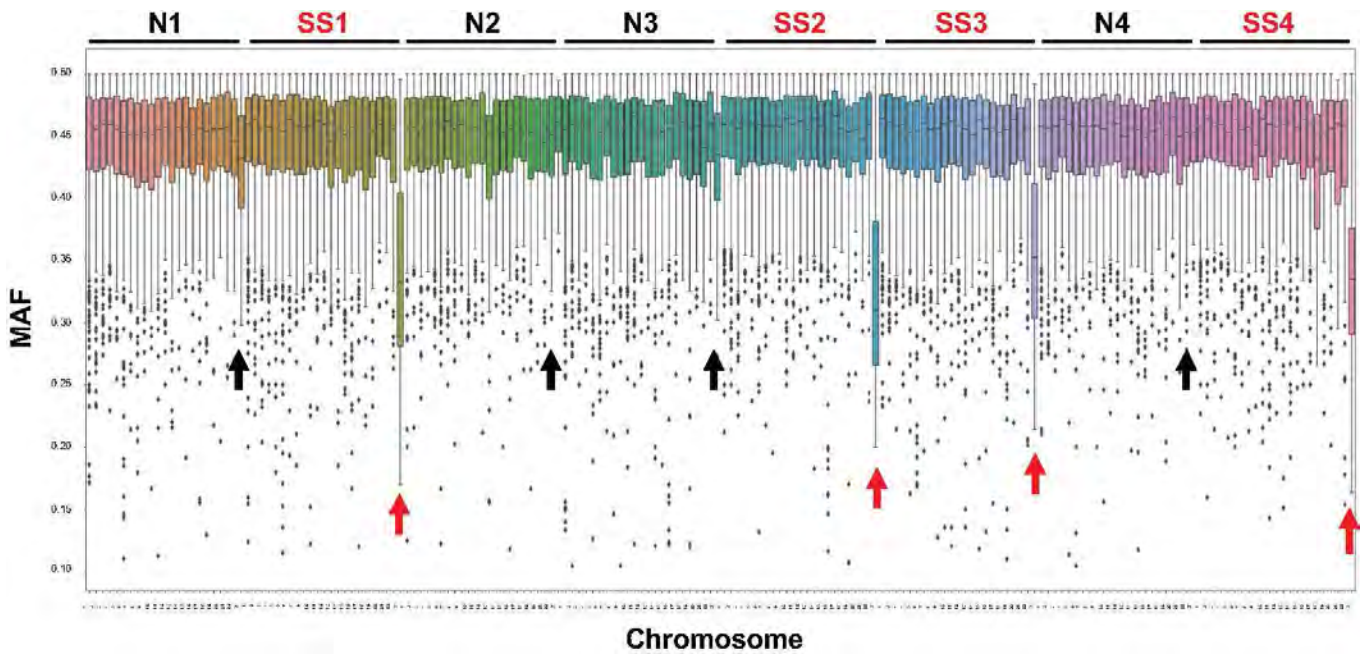

Figure 1. pSS MSCs demonstrate marked X skewing. Allele-specific transcriptomic profiling of control (N1 - N4) and pSS (SS1 – SS4) female MSCs, showing MAF (minor allele frequency) of heterozygous common SNPs on each chromosome. MAF of ~0.5 suggests equal contribution from maternal and paternal alleles, while MAF < 0.4 suggests skewing. For each sample, MAFs are shown for each chromosome (chromosomes 1-22, X; from left to right), with arrows pointing to MAFs on chromosome X (black for control, red for pSS).

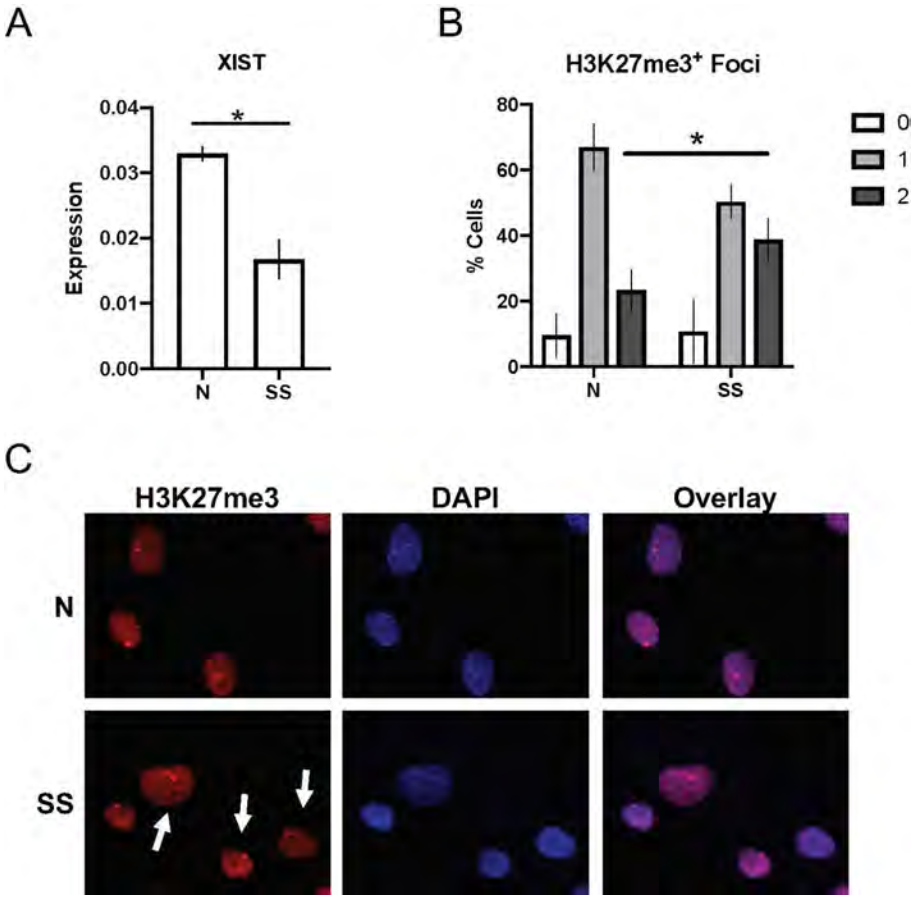

Figure 2. pSS MSCs exhibit XCI defects. A, qRT-PCR of XIST expression levels in control (N) and pSS (SS) MSCs. B, quantification of cells with 0, 1, and 2 H3K27me3+ nuclear foci in control (N) and pSS (SS) MSCs. C, immunofluorescence images of H3K27me3 and DAPI staining of control (N) and pSS (SS) MSCs, with arrows pointing to pSS cells with ectopic H3K27me3+ foci. Mean ± sem, * $P < 0.05$, two-tailed Student's t-test.

Background/Purpose: Many autoimmune diseases feature increased prevalence in females, with primary Sjögren's syndrome (pSS) being the most female-predominant autoimmune disease with a female-to-male ratio of 14:1. Recent evidence suggests that the presence of two X chromosomes may underlie the female bias in pSS. However, the exact X chromosomal alterations on a single-gene level in pSS and their contribution to the female bias in pSS remain elusive. The objective of this study is to define the contribution of X-linked gene expression to pSS pathogenesis, focusing on minor salivary gland-derived mesenchymal stromal cells (MSCs) which are critical players maintaining salivary gland homeostasis.

Methods: Genome-wide, allele-specific expression profiling was performed using MSCs derived from female pSS subjects meeting 2016 ACR/EULAR criteria (n=4) and female control subjects with sicca symptoms but without clinical or laboratory features of autoimmunity (n=4). qRT-PCR of *XIST* (X-inactive-specific transcript) and quantitative immunostaining of H3K27me3 were performed to assess status of X-chromosome inactivation (XCI) in pSS and control MSCs. Protein localization was analyzed by quantitative immunofluorescence in pSS and control MSCs. Expression levels of IL4 were measured by qRT-PCR before and after MSC adipogenesis to assess the immunomodulatory properties of MSCs. Student's t-test (two-sample, unequal variances) was used to compare experiment versus control groups for statistical significance.

Results: All pSS MSCs analyzed demonstrated marked skewing of X-linked genes that escape XCI (i.e. escapees), while all control MSCs exhibited balanced escapee expression (Fig. 1). Concomitantly, pSS MSCs showed decrease

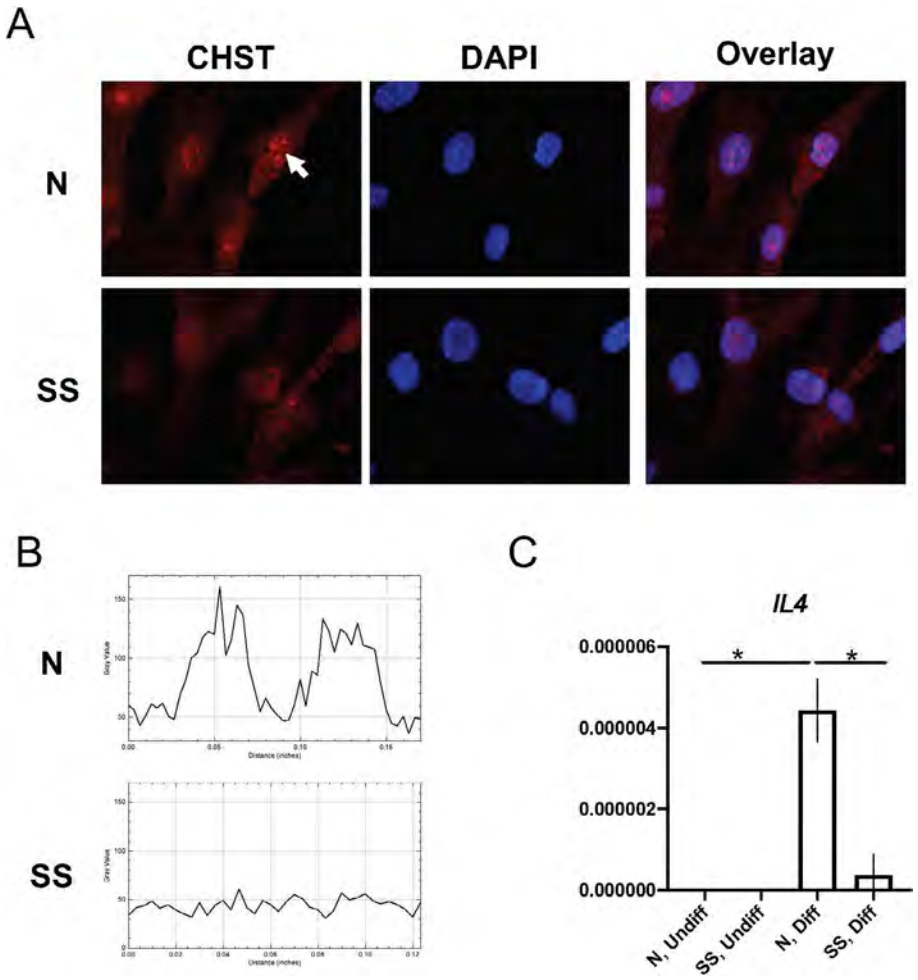

Figure 3. Escapee skewing in pSS MSCs is accompanied by escapee protein mislocalization and MSC inflammatory differentiation. A, immunostaining of a representative escapee, CHST, in control (N) and pSS (SS) MSCs. Arrow points to CHST+ nuclear foci that are absent in pSS MSCs. B, quantitative nuclear foci analysis in control (N) and pSS (SS) MSCs. C, qRT-PCR of IL4 in undifferentiated (Undiff) and differentiated (Diff) control (N) and pSS (SS) MSCs. Mean ± sem, * $P < 0.05$, two-tailed Student's t-test.

in *XIST* expression levels ($P < 0.05$) and reorganization of heterochromatic, silencing foci in the nucleus ($P < 0.05$), suggesting a global disruption in XCI maintenance (Fig. 2). The skewing in X-inactivation escape in pSS MSCs was accompanied by mislocalization of protein products encoded by the escapees as well as inflammatory differentiation of MSCs ($P < 0.05$), consistent with the hallmark features of inflammation and fibrosis in pSS salivary glands (Fig. 3).

Conclusion: We discovered global skewing of X-linked genes in pSS but not control MSCs, and identified escapee skewing as a new mechanism underlying pSS pathogenesis. Given that XCI is a female-specific process, our data suggests that dysregulation of XCI escape contributes to the female bias in pSS.

A Neutrophil Degranulation Signature Identifies Proliferative Lupus Nephritis

Andrea Fava[1], Jessica Li[1], Daniel Goldman[2], Brendan Antiochos[1], Jose Monroy-Trujillo[1], Derek Fine[1], Mohamed G. Atta[1], Jill Buyon[3], Joel Guthridge[4], Judith James[4], Michelle Petri[2] and Accelerating Medicines Partership (AMP) RA/SLE Network[5], [1]Johns Hopkins University, Baltimore, MD, [2]Johns Hopkins University School of Medicine, Baltimore, MD, [3]NYU School of Medicine, New York, NY, [4]Oklahoma Medical Research Foundation, Oklahoma City, OK, [5]Brigham and Women's Hospital, Everett, MA

SESSION INFORMATION

Session Date: Tuesday, November 9, 2021

Session Title: Abstracts: Genetics, Genomics & Proteomics (1935–1938)

Session Type: Abstract Session

Session Time: 4:00PM–5:00PM

Background/Purpose: The identification of intrarenal pathological processes is key to develop better diagnostic and treatment strategies in lupus nephritis (LN). But the direct comprehensive study of renal tissue can be limited by tissue degradation, availability, and cell survival. We employed urine proteomics to define the molecular pathways involved in proliferative LN

Methods: We quantified 1200 biomarkers (Kiloplex, RayBiotech) in urine samples collected on the day of (73%) or within 3 weeks (27%) of kidney biopsy in SLE patients with urine protein to creatinine ratio on random or 24 hr collection of > .5. Urine proteomic profiles were analyzed with respect to lupus nephritis histological features.

Results: A total of 195 patients were included: 138 (71%) had a proliferative histological class (III or IV +/- V), 57 (29%) pure membranous (V). There were 21 (FDR 1%) differentially abundant urinary proteins in proliferative compared to pure membranous LN (Figure 1A). These included several neutrophil granule proteins (Figure 1B) in addition to previously reported biomarkers such as IL-16 and CD163. Unsupervised clustering based on the proliferative LN signature identified 3 groups characterized by low, medium or high protein abundance (Figure 2). Higher proliferative signature

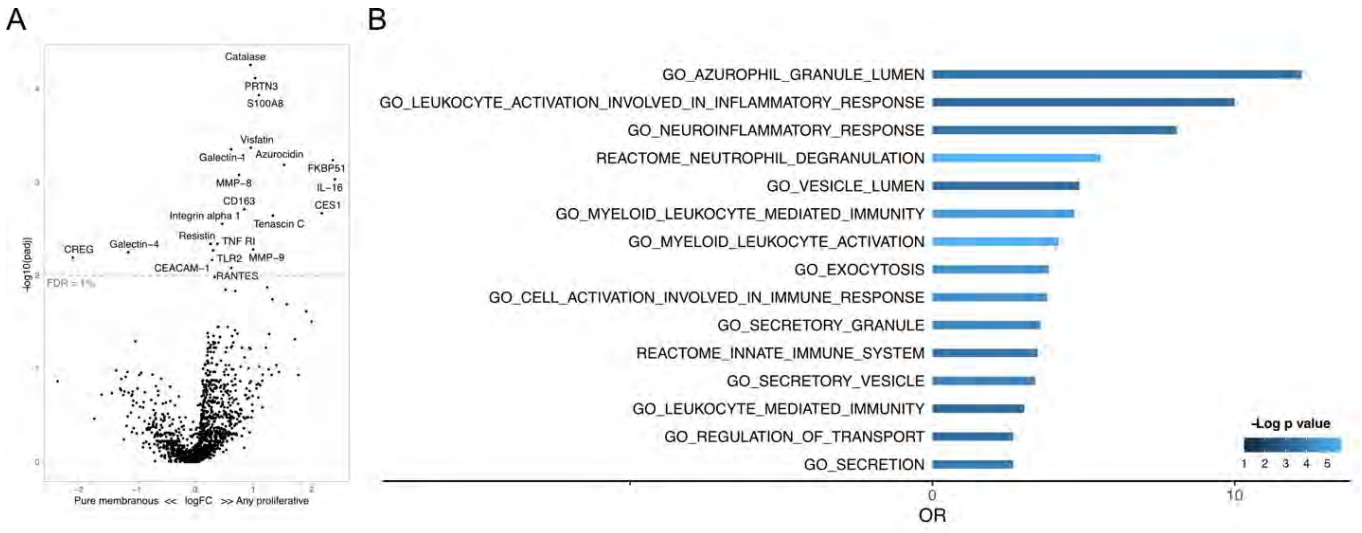

Figure 1. Urine proteomic profile of proliferative LN. (A) Volcano plot displaying the log fold change (FC) and adjusted p values of the differential abundance of 1200 urinary proteins. (B) Pathway enrichment analysis (Gene Ontology and Reactome) of the proteins enriched (FDR <1%) in proliferative LN. Odds ratios based on the hypergeometric test are displayed.

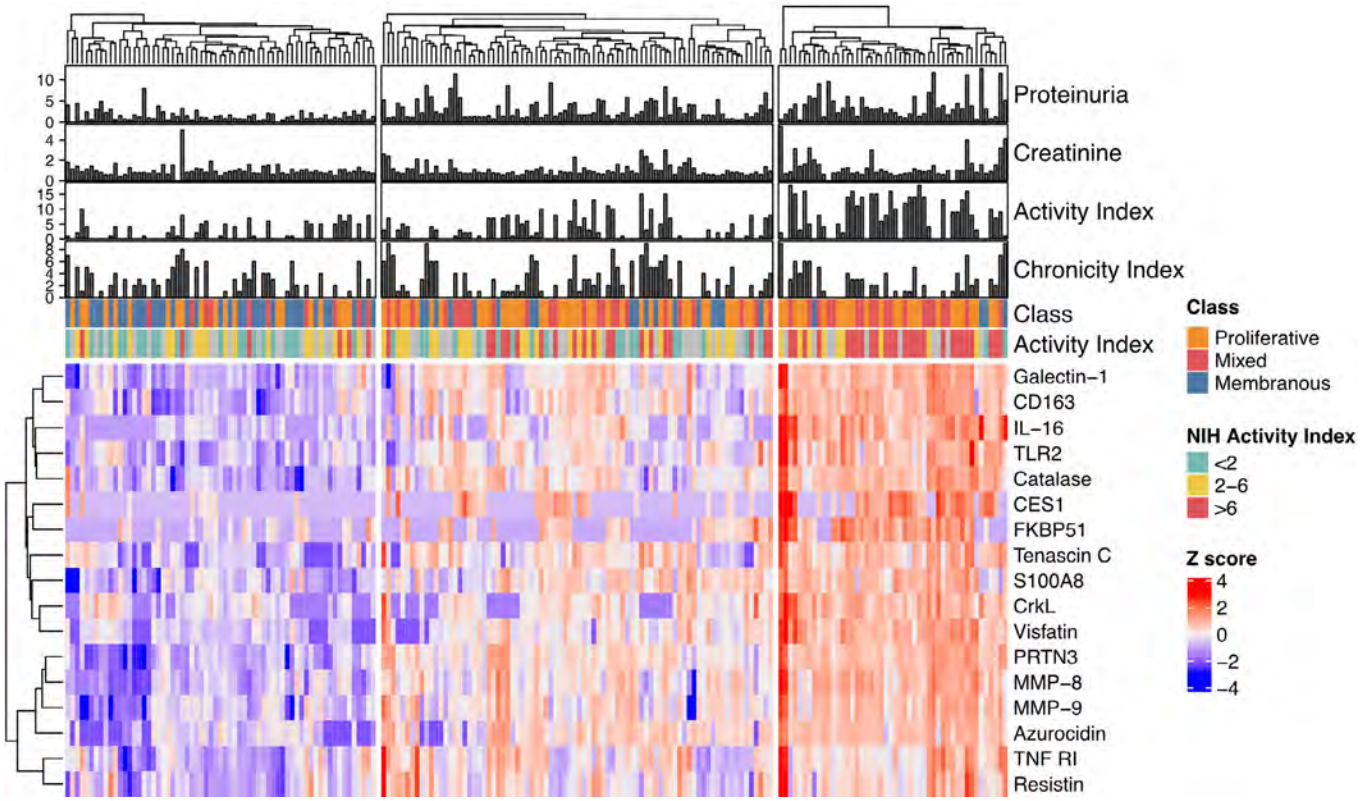

Figure 2. Higher urinary neutrophil signature is associated with higher lupus nephritis activity. Heatmap of the urinary protein differentially abundant in proliferative LN. Hierarchical clustering based on protein abundance identified 3 groups. Proteinuria in mg protein/mg creatinine.

abundance (right cluster) was associated with higher histological activity (NIH Activity Index). Immunofluorescence revealed an abundant MPO+ neutrophil infiltrate in proliferative LN (Figure 3).

Conclusion: Proliferative LN was associated with a urinary neutrophil degranulation signature, especially in patients with higher histological activity. Neutrophil activity could be non-invasively monitored to assist with the diagnosis of proliferative LN. These findings implicate neutrophils in LN activity and pathogenesis, nominate urinary neutrophil signatures as noninvasive biomarkers, and support the study of treatment targeted to neutrophils.

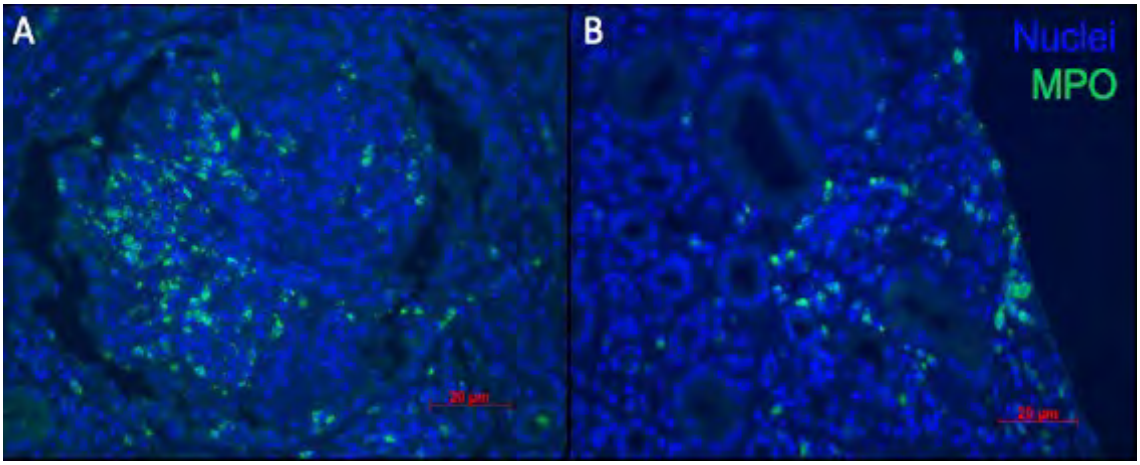

Figure 3. Neutrophil infiltrate in proliferative lupus nephritis. Immunofluorescence imaging of glomerular (A) and tubulointerstitial (B) neutrophil infiltration in a patient with class IV lupus nephritis. Myeloperoxydase (MPO) in green and DAPI in blue.

SESSION INFORMATION

Session Date: Tuesday, November 9, 2021

Session Title: Abstracts: Genetics, Genomics & Proteomics (1935–1938)

Session Type: Abstract Session

Session Time: 4:00PM–5:00PM

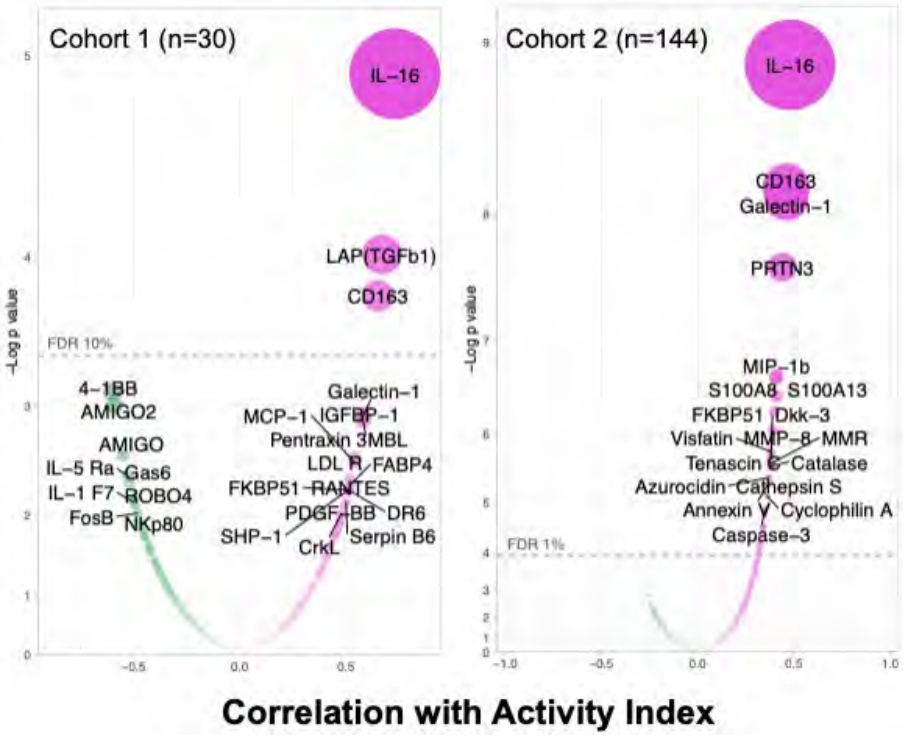

Figure 1. Urinary biomarkers associated with the LN NIH Activity Index. Volcano plots displaying Spearman correlation coefficient for 1000 (left) and 1200 (right) urinary biomarkers with LN histological activity. FDR = false discovery rate.

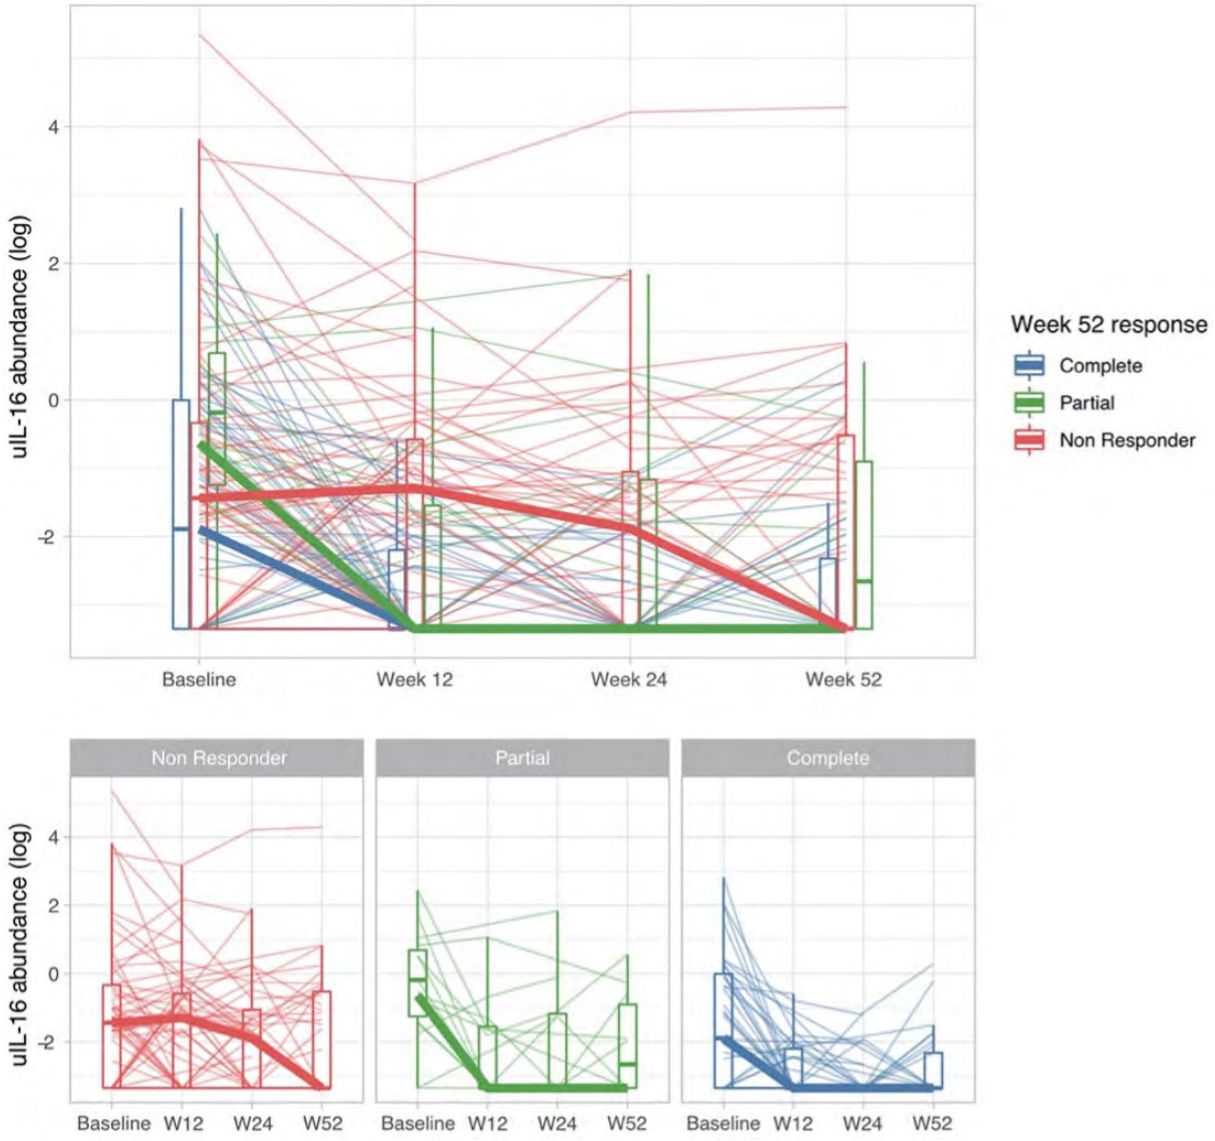

Figure 2. Urinary IL-16 declined early in treatment responders. Longitudinal trajectories of urinary IL-16 in patients with class III, IV, or V LN (n=351) according to their response status. Thick lines connect the medians at each time point. Response was defined at 52 weeks from renal biopsy (Complete, urine pr/cr (UPCR) <0.5, serum creatinine <125% of baseline, prednisone <10mg/day; Partial, UPCR < 50% from baseline but >0.5, same creatinine and prednisone requirements; Non responder, not meeting previous definitions).

Background/Purpose: There is a pressing need to identify novel therapeutic targets in lupus nephritis. Multiomic approaches hold great potential for discovery. We integrated urine proteomics and kidney single cell transcriptomics to discover biological processes and biomarkers associated with histologically active LN.

Methods: Urinary proteins (up to 1200) were quantified (RayBiotech Kiloplex) in urine samples from two independent cohorts of SLE patients with lupus nephritis (n=30 and n=144). Samples were collected on the day of (73%) or within 3 weeks (27%) of kidney biopsy in SLE patients with proteinuria > 500mg/d. The NIH Activity Index was determined by a renal pathologist at each site. Intrarenal expression of candidate biomarkers was evaluated using single cell transcriptomics of renal biopsies from patients with active lupus nephritis (n=24).

Results: A total of 174 patients were included: 127 (73%) had a proliferative histological class (III or IV +/- V), 47 (27%) pure membranous (V). Urinary IL-16 showed the strongest positive correlation with histological activity (NIH

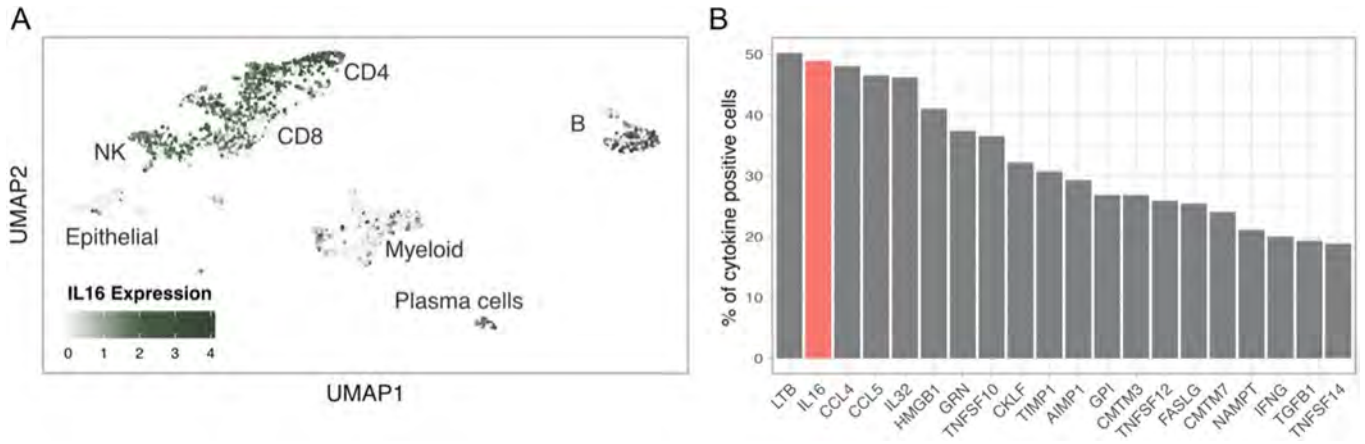

Figure 3. Intrarenal expression of IL16 based on single cell RNA sequencing of lupus nephritis kidney biopsies. (A) UMAP plot showing IL16 expression by all kidney infiltrating immune cells. (B) Percentage of cytokine positive cells across all kidney infiltrating immune cells. The bar plot shows the top 25 cytokines out of a comprehensive list of 236 obtained from the "Cytokine Registry" (Immport) and the Gene Ontology database.

Activity Index) in two independent cohorts (r=0.69, p=9·10^{-5}; r=0.49, p=3·10^{-10}; **Figure 1)**. Response to treatment was paralleled by an early reduction of urinary IL-16 (**Figure 2**). Single cell RNA sequencing independently demonstrated that IL16 is the second most widely expressed cytokine by most infiltrating immune cells in lupus nephritis kidneys (**Figure 3**).

Conclusion: Urine proteomics can profoundly change the diagnosis and management of lupus nephritis by noninvasively monitor active intrarenal biological pathways. These findings implicate IL-16, a proinflammatory chemokine, in lupus nephritis pathogenesis designating it as a potentially treatable target and biomarker.

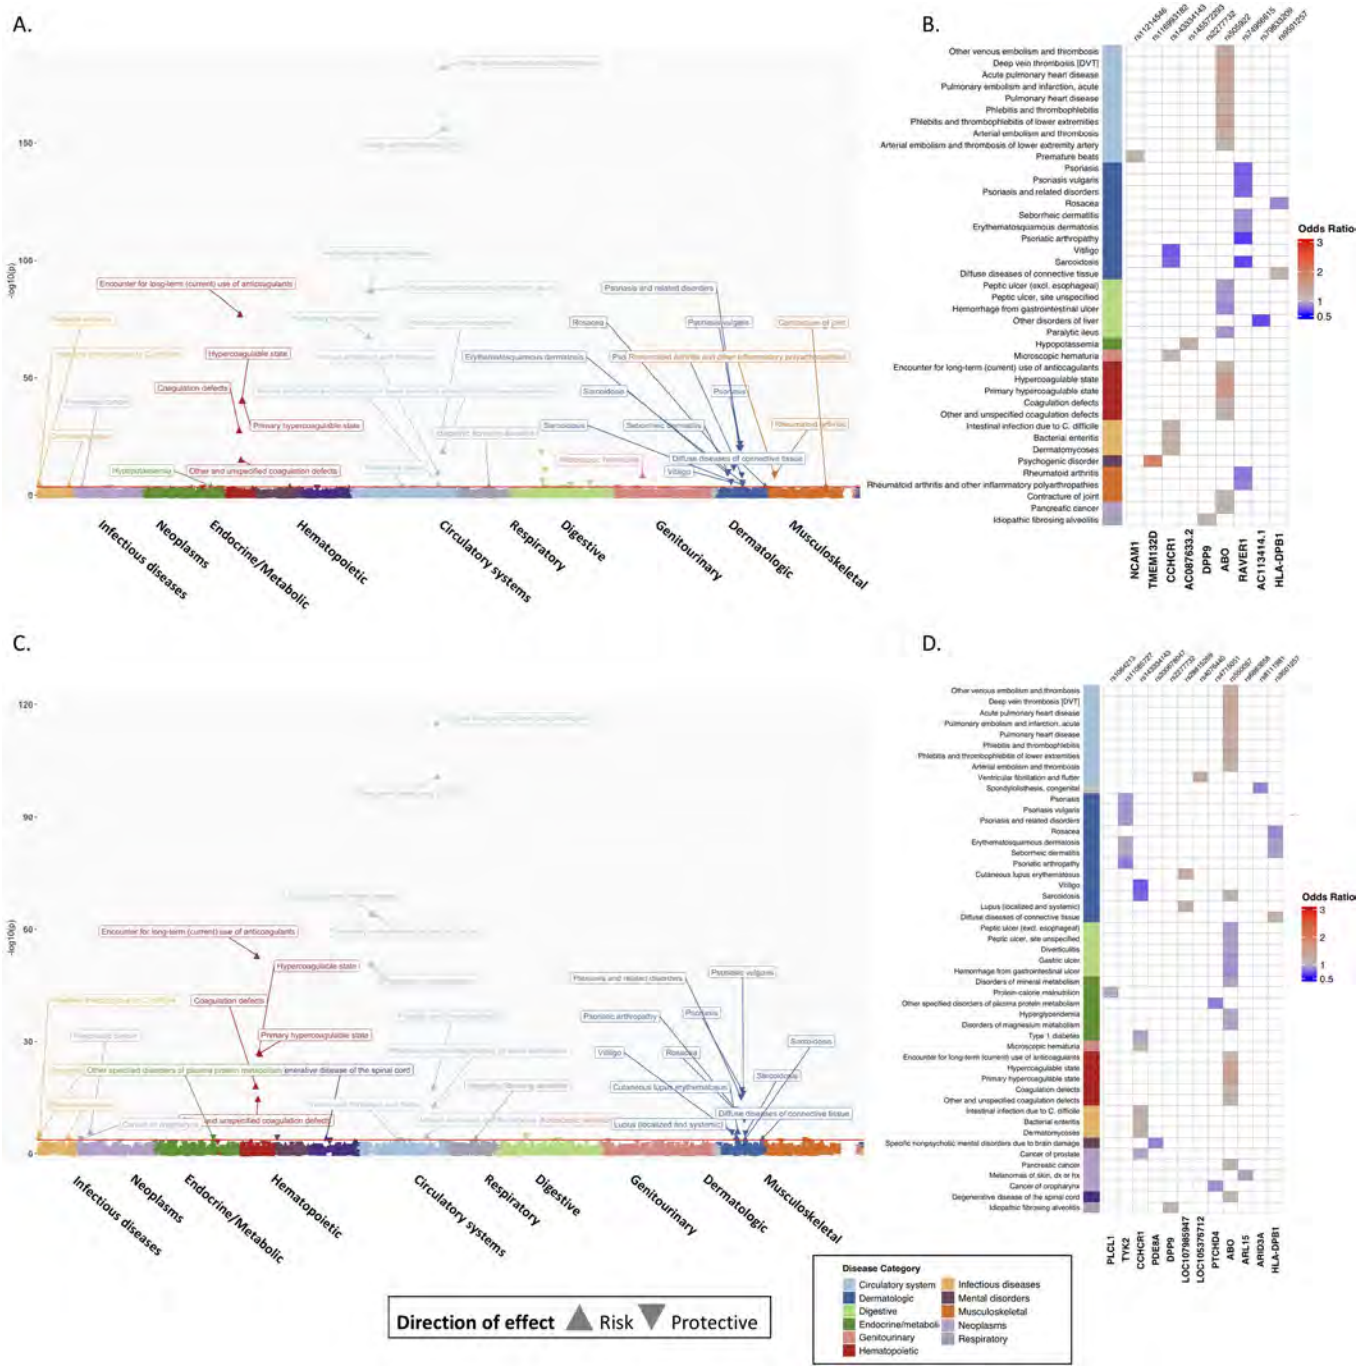
Session Time: 4:00PM–5:00PM

Background/Purpose: Severe coronavirus disease 2019 (COVID-19) is associated with a broad range of clinical conditions. International efforts have led to the identification of risk alleles associated with severe COVID-19. The objective of this study was to apply the Phenome-Wide Association Study (PheWAS) approach to study conditions sharing risk alleles with severe COVID-19 to inform potential shared pathways across conditions.

Methods: We performed the PheWAS in two mega-biobanks with linked clinical and genomic data: 1) Veteran Affairs (VA) Million Veteran Program (MVP), discovery cohort, 2) United Kingdom Biobank (UKBB), replication cohort. Genetic variants associated with a critical illness (n=48) or hospitalization (n=39) due to COVID-19 were selected from COVID-19 Host Genetics Initiative genome-wide association studies. Phenotypes were defined using a published PheWAS approach using International Classification of Diseases (ICD) codes mapped to clinically relevant groups. Data were extracted on subjects before 2019/pre-COVID-19 to avoid potential confounding. Logistic regression was applied to examine each SNP and phenotypes association and adjusted for sex, age, and the 1st 20 principal components. Ancestry-specific PheWAS was first performed across European (EUR), African (AFR), Hispanic, Asian ancestries and then meta-analyzed using an inverse-variance weighted fixed-effects model.

Results: We studied 455,683 US Veterans from MVP, mean age 68 years, 89% male; 68% EUR, and 19% AFR ancestry. Variants associated with severe COVID-19 were tested for association across 1,559 phenotypes. Genetic variants at the *ABO* locus (rs550057, rs505922) were associated with the largest number of phenotypes ($n_{rs55057}$= 53 and $n_{rs505922}$=61); strongest association with venous embolism (odds ratio $(OR)_{rs550057}$ 1.27, p=5.28 x 10^{-116}), and thrombosis ($OR_{rs505922}$=1.31, p=3.5 x10^{-183}). Among 67 respiratory conditions tested, only idiopathic pulmonary fibrosis, ($OR_{rs2277732}$ 1.17, p=1.3410^{-05}), and asthma ($OR_{rs143334143}$ 0.94, p=2.31 x10^{-04}), shared variants with severe COVID-19 (Figure). The *RAVER1* locus (rs74956615) associated with reduced risk for autoimmune conditions, e.g. psoriasis (OR 0.71, p= 1.53 x10^{-22}), rheumatoid arthritis (OR 0.78, p=1.04 x 10^{-09}) with findings replicating in UKBB (Table). A known functional missense variant (rs34536443, TYK2) in the region had the highest linkage disequilibrium with rs74956615, suggesting the signal stemmed from *TYK2*. MVP PheWAS results stratified by genetic ancestry did not demonstrate a significant difference in associations across ancestry.

Conclusion: We observed a shared genetic architecture between severe COVID-19 with thrombosis and asthma; this same genetic architecture was also associated with reduced risk of rheumatic conditions, e.g., RA. This divergent association may in part be explained by a *TYK2* variant known to impair type 1 interferon signaling, reducing risk for autoimmunity and simultaneously impairing viral host defense. Consideration is needed when targeting pathways that may balance immune tolerance and immunodeficiency to treat COVID-19.



PheWAS results of candidate SNPs from GWAS of critically ill and hospitalized COVID-19. Significant associations between 48 SNPs from critical ill COVID GWAS (A) and 39 SNPs from hospitalized COVID (C) and EHR-derived phenotypes in the Million Veteran Program. The phenotypes are represented on the x-axis and ordered by broader disease categories. The red line denotes the significance threshold using a false discovery rate of 10% using the Benjamini-Hochberg procedure. The description of phenotypes is highlighted for the associations with FDR < 0.1 and

odds ratio < 0.90 or odds ratio > 1.10. B) and D) A heatmap plot of SNPs with at least one significant association (FDR < 0.1). The odds ratio represents the direction of effect disease risk. A red color indicates increased risk, and blue color indicated reduced risk. The results with odds ratio < 0.90 or odds ratio > 1.10 are shown.

Phenotype	OR (95% CI)	p-value	Gene (SNP)	SNP (MAF)	COVID-severity
Psoriasis	0.72 [0.67 - 0.77]	1.5×10^{-22}	RAVER1	rs74956615-A (0.02)	Both
	0.88 [0.86 – 0.91]	1.35×10^{-17}	TYK2	rs11085727-T (0.3)	Critical

Risk of Cardiovascular Outcomes in Patients Treated with Tofacitinib: First Results from the Safety of TofAcitinib in Routine Care Patients with Rheumatoid Arthritis (STAR-RA) Study

Farzin Khosrow-Khavar, Seoyoung Kim, Hemin Lee, Su Been Lee and Rishi Desai, Brigham and Women's Hospital, Boston, MA

SESSION INFORMATION
Session Date: Tuesday, November 9, 2021
Session Title: Abstracts: RA – Treatments I: Safety & Harms (1939–1942)
Session Type: Abstract Session
Session Time: 4:00PM–5:00PM

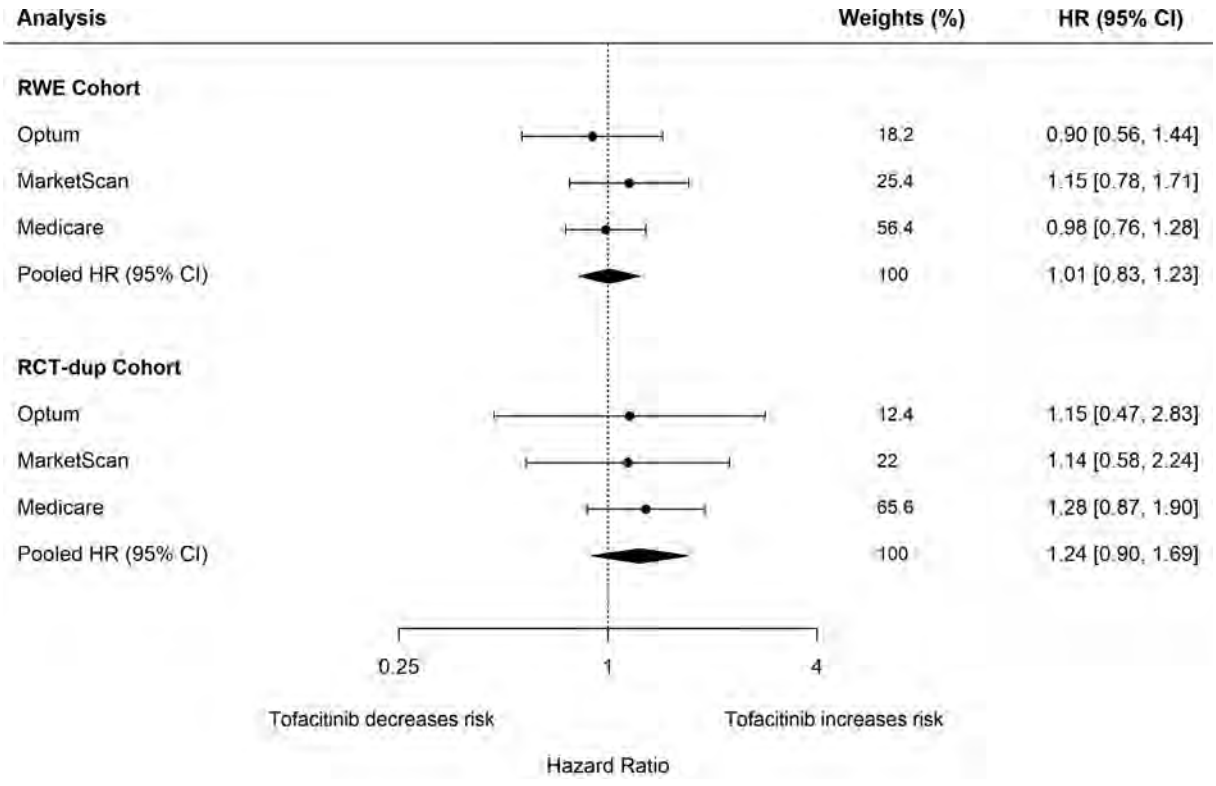

Figure. Risk of composite CV outcomes when comparing tofacitinib with TNF inhibitors (reference) in patients with RA.

Background/Purpose: Recent reports from a post-marketing safety trial, "ORAL Surveillance", indicated an increased risk of cardiovascular (CV) outcomes in RA patients treated with tofacitinib. Thus, the aim of this study was to examine the risk of CV outcomes associated with tofacitinib, compared with tumor necrosis factor inhibitors (TNFI), in patients with RA.

Methods: Using U.S. claims data from 'Optum' Clinformatics (2012-2020), IBM 'MarketScan' (2012-2018), and Medicare (parts A, B, and D, 2012-2017) databases, we created two study cohorts of RA patients initiating treatment with tofacitinib or TNFI: 1) A restrictive "RCT-duplicate cohort" mimicking inclusion/exclusion criteria of the ORAL Surveillance trial to calibrate our findings against trial results, 2) a broader "real-world evidence (RWE) cohort" including representative population from routine care. Patients were followed from treatment initiation for study outcomes until treatment discontinuation or switch, insurance disenrollment, death, or end of the study period. The primary composite CV outcome, was defined using inpatient claims for myocardial infarction or stroke. Cox proportional hazards models with propensity score fine-stratification weighting were used to generate hazard ratios (HR) and 95% confidence intervals (CI) and accounted for over 60 potential confounders in each of the datasets. Fixed effects models with inverse variance were used to pool database-specific effect estimates. Secondary analysis was conducted by baseline cardiovascular disease (RWE cohorts only).

Results: In RWE study population, 28,568, 34,083, and 39,612 patients were identified from Optum, MarketScan, and Medicare, respectively, of whom 13.2%, 15.6%, and 9.5% initiated treatment on tofacitinib. The mean age was 55, 53, and 72 years in Optum, MarketScan, and Medicare, respectively. In RWE cohort, 13% of patients in Optum, 10% in MarketScan, and 31% in Medicare had a history of cardiovascular disease. The crude incidence rates of the primary CV endpoint per 100 person-years (95% CI) for tofacitinib and TNFI users were 0.73 (0.47-1.09) and 0.61 (0.51-0.72) in Optum; 0.75 (0.52-1.05) and 0.52 (0.44-0.61) in MarketScan; and 2.14 (1.66-2.70) and 1.86 (1.71-2.02) in Medicare. Overall, in the RWE cohort, the pooled HR (95% CI) for CV outcomes comparing tofacitinib with TNFI was 1.01 (0.83-1.23). Results from the RCT-duplicate cohort were in alignment with reports from the ORAL Surveillance trial (pooled HR: 1.24, 95% CI: 0.90-1.69 vs trial: 1.33, 95% CI: 0.91-1.94). Among RWE patients with baseline cardiovascular disease, the pooled HR (95% CI) was 1.27 (0.95-1.70). Consistent results were observed across other secondary and sensitivity analyses.

Conclusion: This multi-database large population-based study did not find evidence for an increased risk of CV outcomes with tofacitinib, in comparison with TNFI, in the overall RA patient population treated in the real-world setting. However, similar to the reported results from ORAL Surveillance trial, tofacitinib, in comparison with TNFI, was associated with an increased, but statistically non-significant, risk of CV outcomes in RA patients with CV risk factors or a history of cardiovascular disease.

For all malignancies excluding NMSC and cancer subtypes of interest, total time was the censoring time, and was defined as the time from the first study dose to the last contact date. For NMSC and skin cancer subtypes of interest, the 28-day on-treatment period was the censoring time (time from the first study dose until the last study dose + 28 days or to the last contact date, whichever was earlier). The last contact date was the maximum of: AE start date, AE stop date, last study visit date, withdrawal date, or telephone contact date. If a pt died, the last contact date was the death date

PY includes time to first event for pts with events; pts with no events were censored at the end of the risk period

[a]The tofacitinib 10 mg BID arm included pts who were switched from tofacitinib 10 to 5 mg BID as a result of a study modification in February 2019

[b]Female only: tofacitinib 5 mg BID, N=1,169; tofacitinib 10 mg BID, N=1,124; all tofacitinib, N=2,293; TNFi, N=1,117

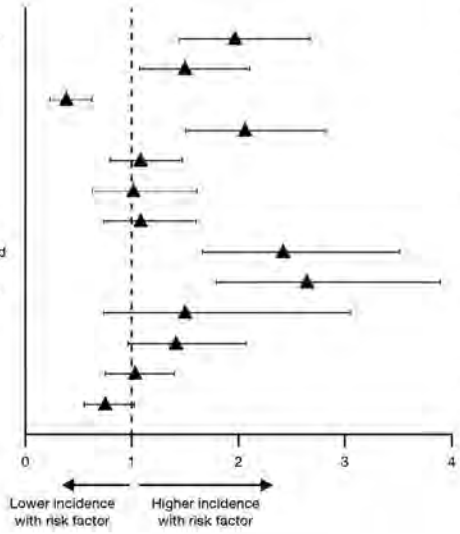
[c]Male only: tofacitinib 5 mg BID, N=286; tofacitinib 10 mg BID, N=332; all tofacitinib, N=618; TNFi, N=334

AE, adverse event; BID, twice daily; CI, confidence interval; IR, incidence rate (pts with events per 100 PY); N, pts in safety analysis set; n, pts with events; NMSC, non-melanoma skin cancer; pt, patient; PY, pt-yrs; TNFi, TNF inhibitors

Figure 1. Risk factors at baseline for all malignancies excluding NMSC in ORAL Surveillance: a) univariate analysis of potential risk factors and their interaction with treatment[a]; b) multivariate analysis of potential independent overall risk[b]

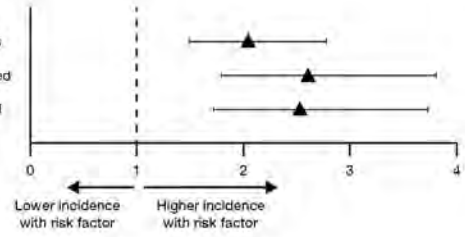
a)

Risk factor (at baseline)	Comparison	HR of risk factor HR (95% CI)	p value	Treatment-by-risk-factor interaction p value
Age ≥ 65 yrs	Age ≥ 65 yrs vs 50 – < 65 yrs	1.97 (1.44, 2.67)	< 0.0001	0.7649
Male	Male vs female	1.50 (1.07, 2.10)	0.0194	0.7394
Non-white	Non-white vs white	0.38 (0.23, 0.62)	0.0001	0.0572
Geographic region (by TNF use), North America[c]	North America vs RoW	2.06 (1.51, 2.81)	< 0.0001	0.4833
BMI ≥ 30 kg/m² (yes)	Yes vs No	1.08 (0.79, 1.47)	0.6219	0.3402
CRP > 2.87 mg/L (yes)	Yes vs No	1.01 (0.63, 1.61)	0.9772	0.3689
History of diabetes (yes)	Yes vs No	1.08 (0.73, 1.60)	0.7071	0.9694
Current smoker	Current smoker vs never smoked	2.42 (1.66, 3.51)	< 0.0001	0.2524
Past smoker	Past smoker vs never smoked	2.64 (1.79, 3.89)	< 0.0001	
Oral contraceptive or HRT use (yes)	Yes vs No	1.50 (0.73, 3.05)	0.2668	0.6619
Aspirin use (yes)	Yes vs No	1.41 (0.96, 2.07)	0.0776	0.8108
Corticosteroid use (yes)	Yes vs No	1.03 (0.75, 1.40)	0.8609	0.3399
Cox-1 or Cox-2 inhibitor use (without aspirin use) (yes)	Yes vs No	0.75 (0.55, 1.02)	0.0639	0.1713



b)

Risk factor (at baseline)	Comparison	HR (95% CI)	p value
Age ≥ 65 yrs	Age ≥ 65 yrs vs 50 – < 65 yrs	2.04 (1.49, 2.78)	< 0.0001
Current smoker	Current smoker vs never smoked	2.61 (1.79, 3.81)	< 0.0001
Past smoker	Past smoker vs never smoked	2.53 (1.72, 3.73)	< 0.0001



Total time was the censoring time and was defined as the time from the first study dose to the last contact date. The last contact date was the maximum of: AE start date, AE stop date, last study visit date, withdrawal date, or telephone contact date. If a pt died, the last contact date was the death date

[a]HR of risk factor based on a Cox model (separate model for each risk factor) with treatment and risk factor as covariates. Treatment-by-risk-factor interaction based on a Cox model (separate model for each risk factor) with treatment, risk factor, and treatment-by-risk-factor as covariates

[b]A backward model selection algorithm was used on a multivariate Cox model with effects of treatment and a pre-selected set of overall risk factors, where $p < 0.1$ for each risk factor and $p \neq 0.2$ for treatment-by-risk-factor interaction in the univariate Cox analyses. This set of overall risk factors were subject to model selection ($p < 0.1$ to stay in model), except for treatment, which was mandatorily included. Geographic region was not considered in the multivariate Cox analyses

[c]United States, Puerto Rico, and Canada. At baseline, there were higher percentages of pts with alcohol use, oral contraceptives or HRT use, aspirin use, anticoagulant use, antidepressant use, prior depression, history of DVT or PE, prior coronary heart disease, diabetes, hypertension, MI, history of CA procedures, and a family history of coronary heart disease in first-degree relatives in those from North America vs those from the RoW. Pts from North America were older and had a higher BMI, and a higher proportion were male vs pts from the RoW. Geographic differences at baseline were generally consistent across treatment arms

AE, adverse event; BMI, body mass index; CA, coronary artery; CI, confidence interval; CRP, C-reactive protein; DVT, deep vein thrombosis; HR, hazard ratio; HRT, hormone replacement therapy; MI, myocardial infarction; NMSC, non-melanoma skin cancer; PE, pulmonary embolism; pt, patient; RoW, rest of world; TNFi, TNF inhibitors

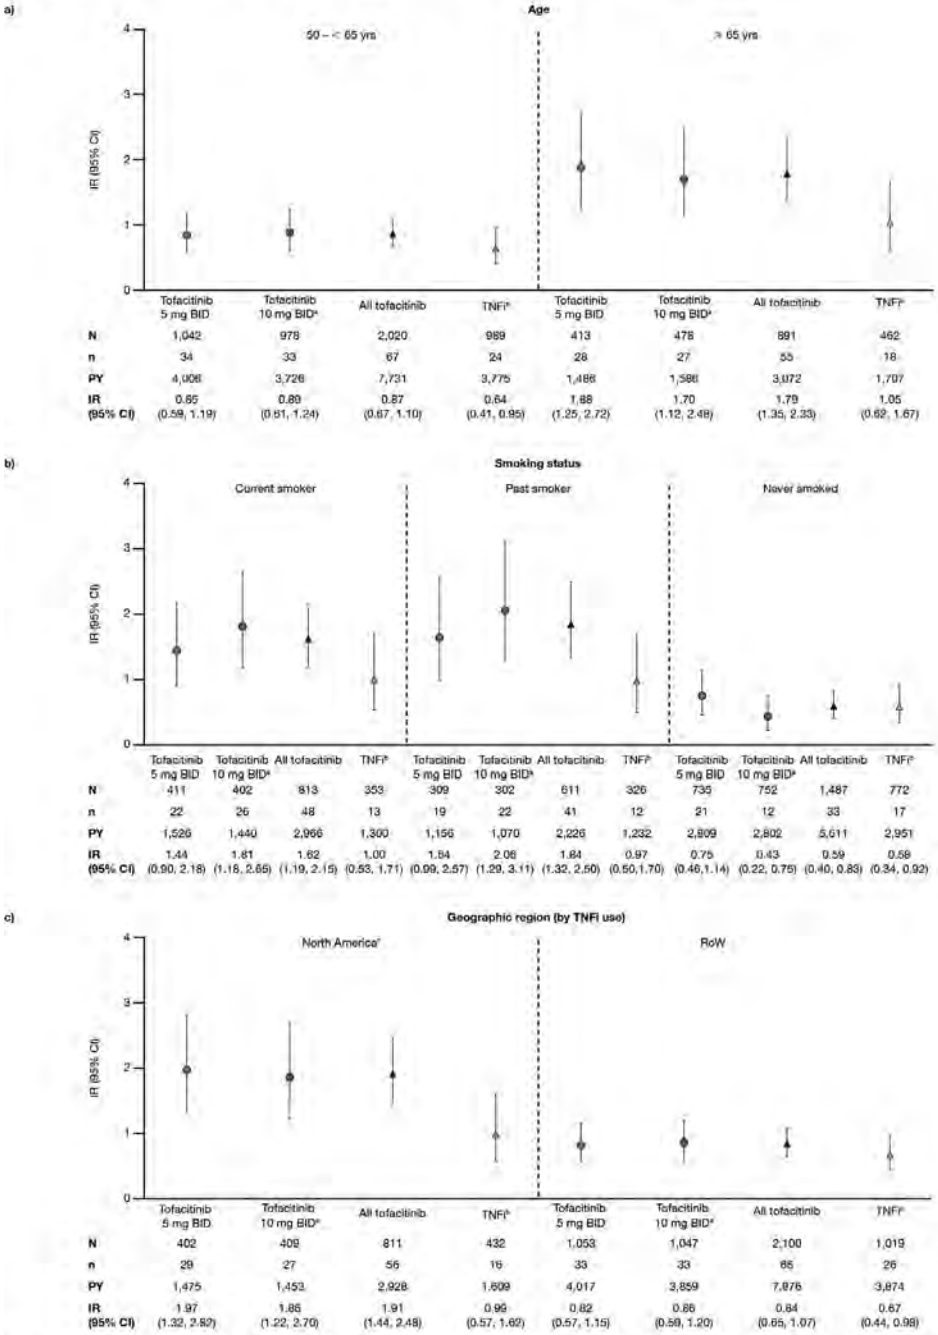
SESSION INFORMATION

Session Date: Tuesday, November 9, 2021
Session Title: Abstracts: RA – Treatments I: Safety & Harms (1939–1942)
Session Type: Abstract Session
Session Time: 4:00PM–5:00PM

Background/Purpose: ORAL Surveillance (NCT02092467) was a post-authorization safety study to assess the relative risk of tofacitinib vs TNF inhibitors (TNFi), based on observed increases in lipids and malignancies in patients (pts) with RA following tofacitinib treatment in the Phase 3 development program. Here, we characterized malignancies in ORAL Surveillance.

Methods: ORAL Surveillance was a long-term, randomized, open-label, non-inferiority, Phase 3b/4 safety study of tofacitinib vs TNFi in pts with RA aged ≥ 50 yrs, with ≥ 1 additional cardiovascular risk factor and an inadequate

Figure 2. IRs (95% CI, pts with events per 100 PY) for all malignancies excluding NMSC in ORAL Surveillance, stratified by a) age (50 – < 65 or ≥ 65 yrs), b) smoking status (current smoker, past smoker, or never smoked), and c) geographic region (proxy for TNFi use)



Total time was the censoring time and was defined as the time from the first study dose to the last contact date. The last contact date was the maximum of: AE start date, AE stop date, last study visit date, withdrawal date, or telephone contact date. If a pt died, the last contact date was the death date.

[a]The tofacitinib 10 mg BID arm included pts who were switched from tofacitinib 10 to 5 mg BID as a result of a study modification in February 2019.

[b]In the TNFi group, pts in North America received adalimumab 40 mg every other week, and pts in the RoW received etanercept 50 mg every week.

[c]United States, Puerto Rico, and Canada. At baseline, there were higher percentages of pts with alcohol use, oral contraceptives or HRT use, aspirin use, anticoagulant use, antidepressant use, prior depression, history of DVT or PE, prior coronary heart disease, diabetes, hypertension, MI, history of CA procedures, and a family history of coronary heart disease in first-degree relatives in those from North America vs those from the RoW. Pts from North America were older and had a higher BMI, and a higher proportion were male vs pts from the RoW. Geographic differences at baseline were generally consistent across treatment arms.

AE, adverse event; BID, twice daily; CA, coronary artery; CI, confidence interval; DVT, deep vein thrombosis; IR, incidence rate (pts with events per 100 PY); MI, myocardial infarction; N, number of evaluable pts; n, number of pts with events; NMSC, non-melanoma skin cancer; PE, pulmonary embolism; pt, patient; PY, pt-yrs; RoW, rest of world; TNFi, TNF inhibitors.

response to MTX. Pts were randomized 1:1:1 to receive open-label tofacitinib 5 or 10 mg twice daily (BID) or a TNFi (adalimumab 40 mg every two weeks [North America; NA] or etanercept 50 mg once weekly [rest of world; RoW]) while on stable background MTX doses. Incidence rates (IRs; pts with events/100 pt-yrs [PY]) of all malignancies excluding non-melanoma skin cancer (NMSC), NMSC, and cancer subtypes of interest were determined for each

treatment arm. Number Needed to Harm (NNH; PY of treatment exposure needed for 1 more pt to report an event vs reference) was evaluated post hoc for all malignancies excluding NMSC. Potential risk factors for all malignancies excluding NMSC were analyzed via univariate/multivariate Cox models (post hoc). IRs of all malignancies excluding NMSC were analyzed post hoc by baseline (BL) characteristics (eg age, smoking status, and geographic region [proxy for TNFi use]).

Results: In 4,362 treated pts (tofacitinib 5 mg BID, N=1,455; tofacitinib 10 mg BID, N=1,456; TNFi, N=1,451), mean age was 61.0 yrs, 78% were female, and 49% were current/past smokers. Differences in BL demographics were seen in pts from NA vs RoW (described in Figure 1 and 2 footnotes). IRs for all malignancies excluding NMSC, and for NMSC, were numerically higher with both tofacitinib doses vs TNFi (Table); hazard ratio (tofacitinib vs TNFi) for all malignancies excluding NMSC: 1.48 (95% CI 1.04, 2.09). Excluding NMSC, the most frequently reported cancer subtypes of interest (greatest number of pts with events) were lung cancer (tofacitinib) and breast cancer (TNFi) (Table). There were 10 pts with lymphoma in the tofacitinib arm (both doses) and 1 in the TNFi arm (Table). The NNH for all malignancies excluding NMSC was 276 PY for tofacitinib 5 mg BID vs TNFi, and 275 PY for tofacitinib 10 mg BID vs TNFi. Univariate and multivariate Cox analyses identified age (≥ 65 vs 50 – < 65 yrs) and smoking status (current/past smoker vs never smoked) as independent overall risk factors across treatment arms for all malignancies excluding NMSC (Figure 1a, b). Across treatment arms, IRs for all malignancies excluding NMSC were numerically higher in pts aged ≥ 65 vs 50 – < 65 yrs (Figure 2a), current/past smokers vs pts who had never smoked (Figure 2b), and pts in NA vs RoW (Figure 2c).

Conclusion: In pts with RA in ORAL Surveillance, IRs for malignancies were numerically higher with tofacitinib vs TNFi. Older age (≥ 65 vs 50 – < 65 yrs) and current/past smoking (vs never smoking) were independent risk factors for increasing malignancy rate across treatments.

SESSION INFORMATION
Session Date: Tuesday, November 9, 2021
Session Title: Abstracts: RA – Treatments I: Safety & Harms (1939–1942)
Session Type: Abstract Session
Session Time: 4:00PM–5:00PM

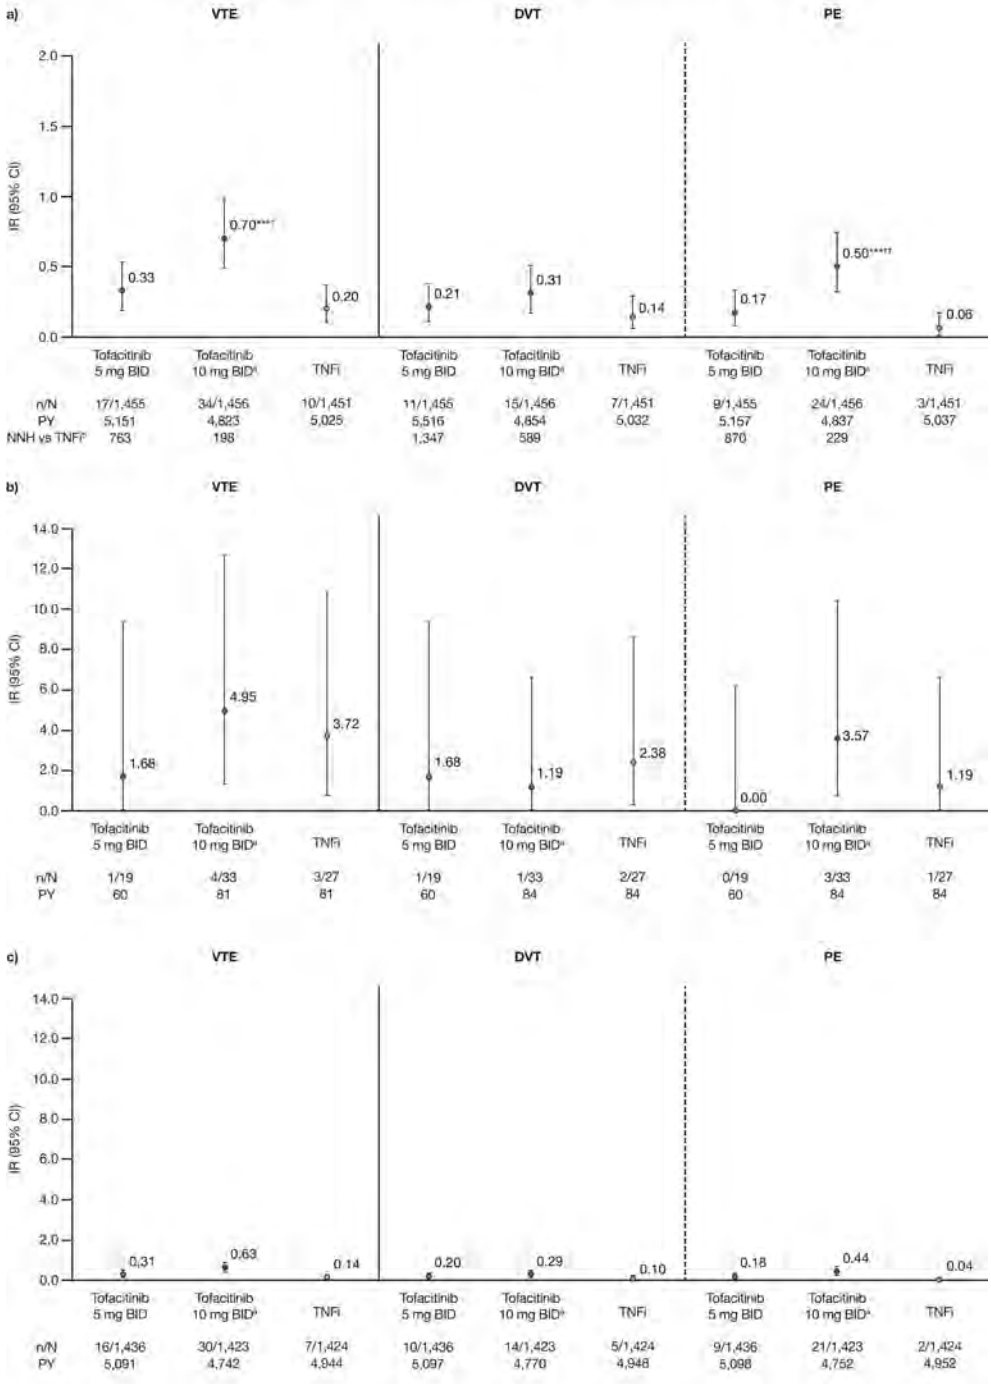
Background/Purpose: ORAL Surveillance (NCT02092467) was a randomized, open-label, non-inferiority, Phase 3b/4 study that assessed the relative risk of major adverse cardiovascular (CV) events (MACE) and malignancies with tofacitinib 5 and 10 mg twice daily (BID) vs TNF inhibitors (TNFi) in patients (pts) with active, moderate to severe RA, who had an inadequate response to MTX and a high risk of MACE (age ≥ 50 yrs; ≥ 1 additional CV risk factor). This analysis assessed the risk of venous thromboembolic events (VTE; including deep vein thrombosis [DVT] and pulmonary embolism [PE]) in ORAL Surveillance.

Methods: Pts were randomized 1:1:1 to receive tofacitinib 5 or 10 mg BID or a TNFi (etanercept 50 mg every week or adalimumab 40 mg every 2 weeks) with background MTX. A 2019 review by the Tofacitinib Rheumatology Data Safety Monitoring Board observed a statistically and clinically important difference in the occurrence of PE within the tofacitinib 10 mg BID treatment arm, compared with the TNFi control arm, resulting in a dose switch from tofacitinib 10 to 5 mg BID for the rest of the trial. All data are reported per randomized treatment. Incidence rates (IRs; pts with events/100 pt-yrs [PY]) were reported for adjudicated VTEs, DVT, and PE, and nominal p values comparing treatment arms were generated post hoc. The probability of not having an adjudicated event was assessed by Kaplan-Meier plots. Numbers Needed to Harm (NNH) were calculated post hoc. Multivariate Cox regression models were used post hoc to identify overall independent baseline (BL) risk factors for PE using backward model selection.

Results: This analysis included 1,455, 1,456, and 1,451 pts receiving tofacitinib 5 mg BID, 10 mg BID, and TNFi, respectively; BL pt characteristics were similar across treatment groups, with high mean disease activity (Clinical Disease Activity Index score, 39.7–39.9) and mean/median age of 61.2/60.0 yrs. In pts with VTE (n=66), mean age was 62.9–66.5 yrs across treatment groups. IRs for VTE, DVT, and PE were < 1.0 across treatment groups (Figure 1a); VTE, DVT, and PE IRs and probability of event were higher with tofacitinib 10 vs 5 mg BID, and higher for both tofacitinib doses vs TNFi (Figure 1a, Figure 2). NNH for tofacitinib 5 and 10 mg BID, respectively, vs TNFi were 763 and 198 PY for VTE, 1,347 and 589 PY for DVT, and 870 and 229 PY for PE. Across treatment groups, VTE, DVT, and PE IRs were higher in pts with vs without a history of VTEs (Figure 1b–c). Identified overall independent risk factors for PE across treatment groups included history of VTE; BL use of oral contraceptives or HRT; BL BMI ≥ 30 kg/m^2; age ≥ 65 yrs; and history of hypertension (Figure 3).

Conclusion: VTE, DVT, and PE IRs were higher for tofacitinib (10 > 5 mg BID) vs TNFi, and were < 1.0 across treatment groups. IRs were generally consistent with ranges reported for tofacitinib and biologic DMARDs among pts at

Figure 1. IRs (95% CI) for adjudicated VTE, DVT, and PE in a) all pts, b) pts with a history of VTE, and c) pts without a history of VTE



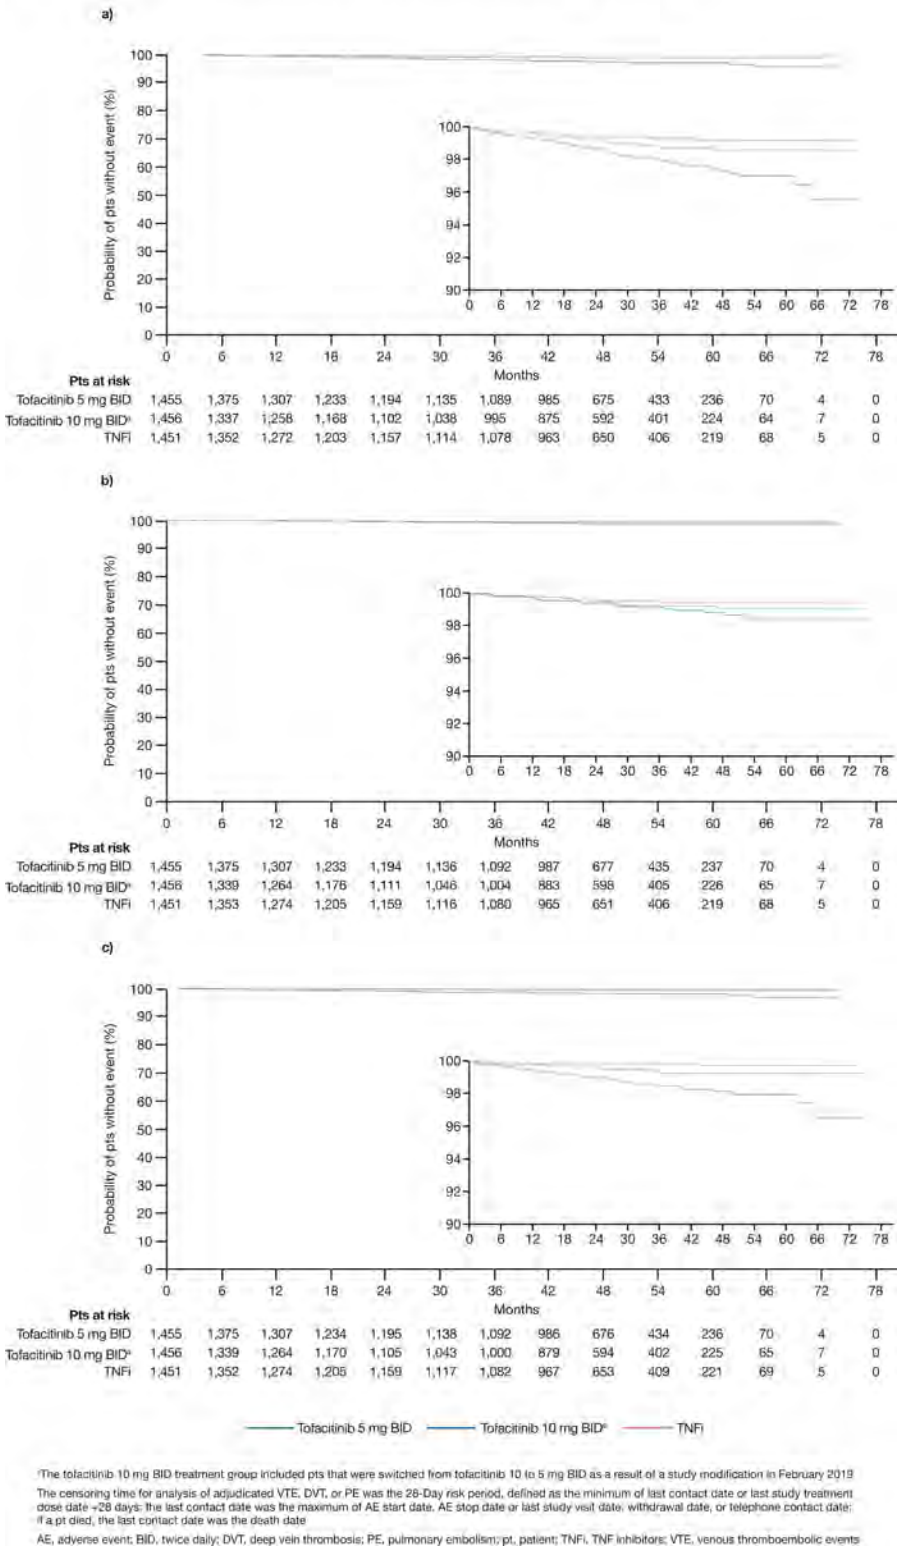
‡The tofacitinib 10 mg BID treatment group included pts that were switched from tofacitinib 10 to 5 mg BID as a result of a study modification in February 2019; §NNH was defined as the number of PY of exposure needed for 1 more pt to report an event with tofacitinib vs TNFi

***Nominal p < 0.001, for tofacitinib vs TNFi; †nominal p ≤ 0.05; ††nominal p < 0.01, for tofacitinib 10 vs 5 mg BID

Nominal p values (for descriptive purpose and hypothesis generating only) were based on a univariate Cox proportional hazard model, with treatment as a covariate; the censoring time for analysis of adjudicated VTE, DVT, or PE was the 28-Day risk period, defined as the minimum of last contact date or last study treatment dose date +28 days; the last contact date was the maximum of AE start date, AE stop date, last study visit date, withdrawal date, or telephone contact date; if a pt died, the last contact date was the death date

AE, adverse event; BID, twice daily; CI, confidence interval; DVT, deep vein thrombosis; IR, incidence rate (pts with events per 100 PY); N, number of pts in a treatment group; n, number of pts with an event; PE, pulmonary embolism; pt, patient; PY, pt-yrs; TNFi, TNF inhibitors; VTE, venous thromboembolic events

Figure 2. Kaplan-Meier plots of probability of not having an adjudicated event of a) VTE, b) DVT, and c) PE



[a]The tofacitinib 10 mg BID treatment group included pts that were switched from tofacitinib 10 to 5 mg BID as a result of a study modification in February 2019

The censoring time for analysis of adjudicated VTE, DVT, or PE was the 28-Day risk period, defined as the minimum of last contact date or last study treatment dose date +28 days; the last contact date was the maximum of AE start date, AE stop date or last study visit date, withdrawal date, or telephone contact date; if a pt died, the last contact date was the death date

AE, adverse event; BID, twice daily; DVT, deep vein thrombosis; PE, pulmonary embolism; pt, patient; TNFi, TNF inhibitors; VTE, venous thromboembolic events

a high risk of a CV event;[1] PE IR with tofacitinib 10 mg BID in ORAL Surveillance was higher than those reported in tofacitinib or biologic DMARD clinical trial or registry data.[1]

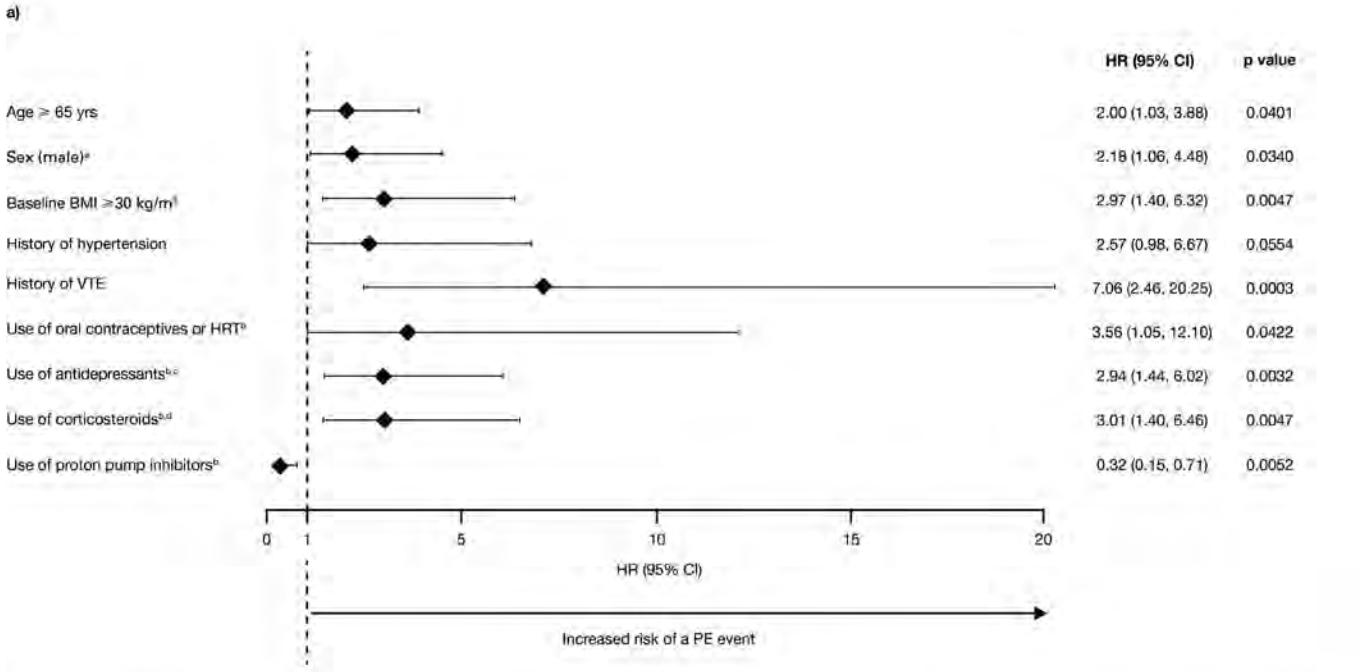
Figure 3. Multivariate Cox regression analyses for identifying overall independent risk factors across treatment groups for PE



[a]HR for sex (male) demonstrated a statistically significant HR in previous univariate analyses (HR 1.80 [95% CI 0.90, 3.61]), but HRs in this analysis were inconsistent between the tofacitinib 5 and 10 mg BID groups (HRs 0.52 and 2.43, respectively), and the overall HR for combined tofacitinib doses was similar to TNFi, therefore the impact of sex on PE risk was considered inconclusive; [b]Use at baseline; [c]Baseline antidepressant use was an indicator of an underlying condition of depression, and subgroup analysis did not identify any difference in HRs for depression across treatment groups; [d]Baseline corticosteroid use was a proxy for elevated baseline disease activity; HRs for baseline corticosteroid use were similar between all tofacitinib doses combined and TNFi

Multivariate Cox regression model using backward selection included effects of treatment (ie tofacitinib 5 and 10 mg BID, and TNFi; not subject to model selection) and overall potential independent risk factors (ie those affecting PE IRs equally across all 3 treatment groups; subject to model selection) identified from a prior set of Cox regression analyses (which included treatment and a single candidate risk factor in each model fitting, cycling through a predetermined set of risk factors); the cut-off for a risk factor to stay in the model was $p < 0.10$

The censoring time for analysis of adjudicated PE was the 28-Day risk period, defined as the minimum of last contact date or last study treatment dose date +28 days; the last contact date was the maximum of AE start date, AE stop date, last study visit date, withdrawal date, or telephone contact date; if a pt died, the last contact date was the death date

AE, adverse event; BID, twice daily; CI, confidence interval; HR, hazard ratio; IR, incidence rate (pts with events per 100 PY); PE, pulmonary embolism; pt, patient; PY, pt-yrs; TNFi, TNF inhibitors; VTE, venous thromboembolic events

SESSION INFORMATION

Session Date: Tuesday, November 9, 2021

Session Title: Abstracts: RA – Treatments I: Safety & Harms (1939–1942)

Session Type: Abstract Session

Session Time: 4:00PM–5:00PM

Background/Purpose: Squamous and basal cell carcinomas are the most common malignancies of the skin; they are subsumed under non-melanoma skin cancer (NMSC). The risk of NMSC is increased with sun exposure. Whether treatment with certain DMARDs influences their occurrence is not clear. A study of Swedish registry data reported an increased risk of NMSC in patients with rheumatoid arthritis (RA) treated with abatacept, calling for replication (1). Using data from the German RABBIT registry, we studied the risk of NMSC under different DMARD therapies.

Methods: Data from patients with RA who were enrolled in RABBIT with the start of a biologic (b), conventional synthetic (cs) or targeted synthetic (ts) DMARD treatment were analyzed. Patients enrolled between January 2007 and October 2020 with at least one follow-up visit were included. Crude incidence rates of NMSC under different treatments using an induction period of 3 months were determined. Adjusted hazard ratios (HRs) of NMSC were calculated using Cox regression. Further adjustment for factors influencing treatment decision ("confounding by indication") was performed using inverse probability weighting (IPW).

Results: A total of 13,870 patients were included in the analysis. There were 17 squamous cell carcinomas (0.12%) and 120 basal cell carcinomas (0.85% of patients) reported. Clear differences in patient characteristics at the start of each treatment (table 1) were seen between the classic first-line bDMARDs (tumour necrosis factor (TNF) inhibitors) and the second-line bDMARDs, with longer disease duration, significantly more severe functional limitations, higher number of prior treatment failures and more comorbidities. A comparison of crude incidence rates of NMSC under different DMARD treatments showed that the occurrence of NMSC was significantly more frequent under abatacept than under TNF inhibitors (figure).

In the adjusted Cox regression, a significantly increased risk of NMSC was observed with abatacept treatment (HR: 2.00 [95% confidence interval, CI: 1.28-3.11]) compared to csDMARD treatment. Furthermore, increasing age and number of comorbidities were significantly associated with a higher risk of NMSC occurrence (table 2). In the analysis performed with IPW, the effect for abatacept was amplified (HR: 2.18 [95% CI: 1.30-3.65]), with age and number of comorbidities also remaining significantly associated with a higher risk of NMSC (table 2).

Conclusion: This analysis of a prospective cohort study investigated the incidence rates and risk of NMSC in RA patients treated with different modes of action. Basal cell and squamous cell carcinomas were most commonly reported with abatacept treatment. Even after adjusting for differences in patient characteristics, there was a significantly increased risk of NMSC in patients treated with abatacept. It should be noted that patients initiated abatacept therapy

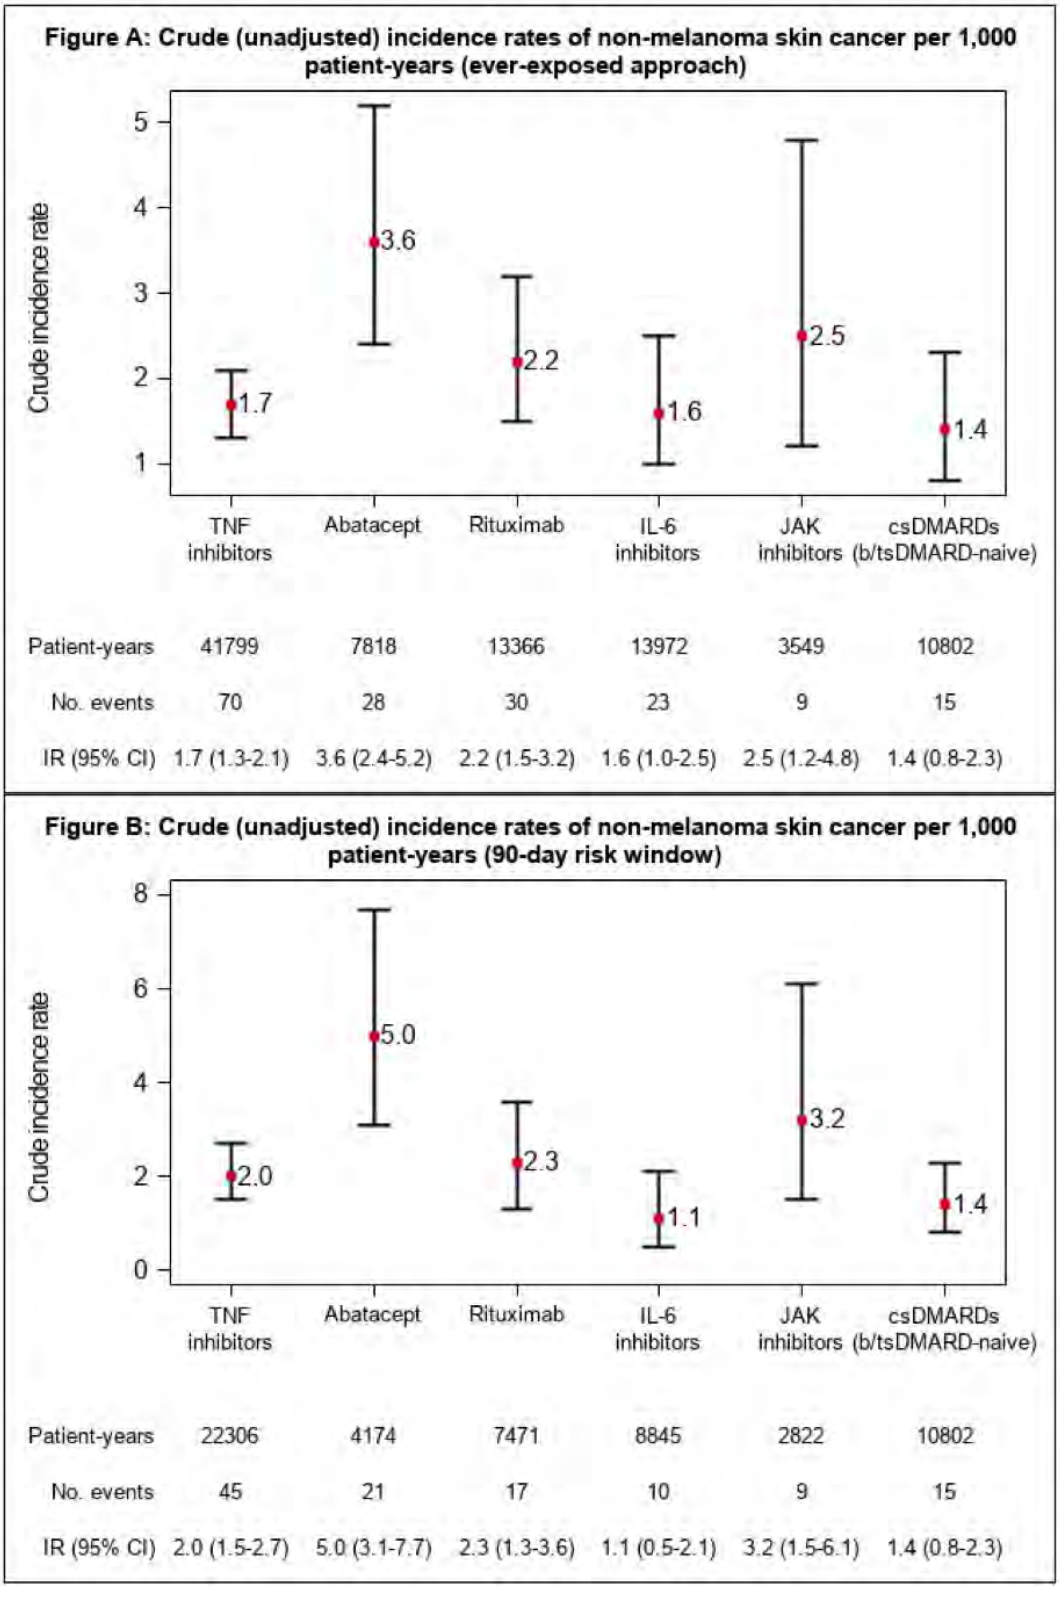

Figure 1. Crude incidence rates of non-melanoma skin cancer under different DMARD treatments.

had higher burden of comorbidity and considerable differences compared to all other treatment options. The higher risk of NMSC may be attributed to residual and unmeasured confounding due to higher burden of comorbidity or cumulative effect of therapies when used as a second or third line bDMARD.

Table 1. Characteristics of patients (N=13,870) at the beginning of a therapy episode

SESSION INFORMATION

Session Date: Tuesday, November 9, 2021

Session Title: Abstracts: Spondyloarthritis Including PsA – Treatment II: Biologic Therapies (1943–1946)

Session Type: Abstract Session

Session Time: 4:00PM–5:00PM

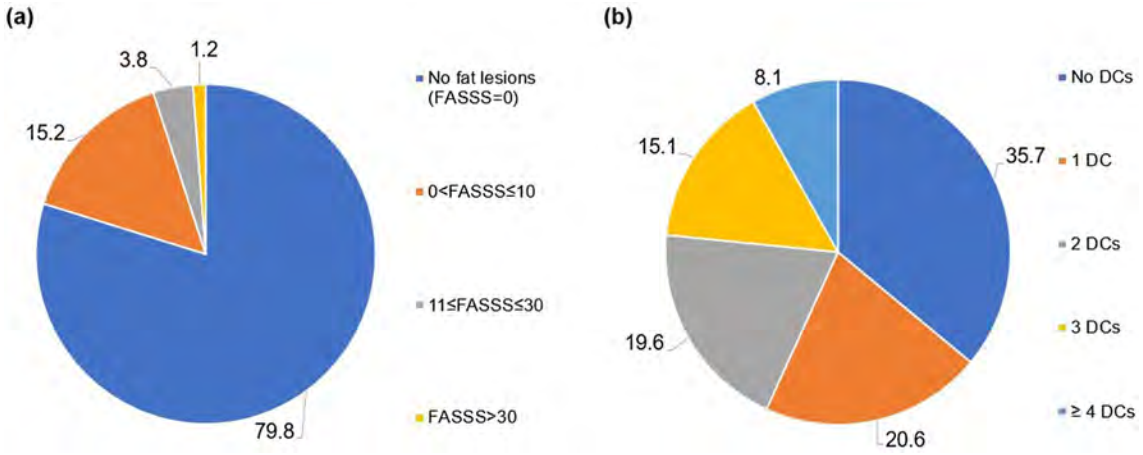

Figure 1. (a) Prevalence of FASSS categories (b) Prevalence of degenerative changes DC, degenerative change; FASSS, FAt Spondyloarthritis Spine Score.

Background/Purpose: Axial psoriatic arthritis (PsA) is the only one of the PsA manifestations, still not clearly defined, with no currently available universally acceptable clinical and imaging criteria.[1] MAXIMISE, the first RCT which has proven efficacy of a bDMARD in the management of axial manifestations of PsA, provides a dataset of MRIs in a population of PsA patients (pts) with a clinical diagnosis of axial disease and may address the gap in determining the role of MRI in diagnosis and classification of axial PsA.[2] So far, structural lesions such as fat lesions, which were shown to follow resolution of inflammation in the spine of pts with axial spondyloarthritis (axSpA) [3] or the presence of degenerative changes (DCs) which may delay or confound the diagnosis of axial PsA have not been assessed in any PsA cohort with axial involvement. This post-hoc exploratory analysis of baseline MRIs from the MAXIMISE trial[2] investigated: (1) the post-inflammatory changes by FAt Spondyloarthritis Spine Score (FASSS) [4], (2) the inflammatory changes in the posterior spinal elements (spinal process) and (3) the prevalence of DCs. [5]

Table 1: Specific degenerative changes (combined locations) by whole spine and spinal sub-locations (overall population)

Variable, n (%)	Whole spine	Cervical	Thoraic	Lumbar
Modic	107 (22.1)	26 (5.4)	10 (2.1)	88 (18.1)
Schmorl's Node with or without BME	57 (11.8)	2 (0.4)	44 (9.1)	22 (4.5)
Disc herniation/high intensity zone	178 (36.7)	102 (21.0)	29 (6.0)	116 (23.9)
Erosion	33 (6.8)	2 (0.4)	10 (2.1)	26 (5.4)
Sclerosis	1 (0.2)	0	1 (0.2)	0
Pfirrmann grade ≥3	248 (51.1)	80 (16.5)	39 (8.0)	203 (41.9)

The following changes such that a score of 1 on either denotes an overall score of 1, were combined as follows: Modic 1 and Modic 2; Schmorl's node with BME and Schmorl's node without BME; disc herniation and high intensity zone. Pfirrmann grade was dichotimized at each DVU: a score of 1 or 2 = 0; a score of 3 or greater = 1. BME, Bone marrow edema; DVU, disco-vertebral unit; n, number of patients with at least one DVU showing as 'present' for the associated spinal degenerative change variable in the whole spine

Methods: The baseline spinal-MRIs (T1 and STIR) for pts from the MAXIMISE trial fulfilling the pre-defined clinical criteria for active axial disease (BASDAI ≥4, spinal pain (VAS) ≥40 and inadequate response to ≤ 2 NSAIDs, N=485) were re-read. FASSS is a scoring method which addresses the spectrum of fat lesions according to anatomical localization and phenotypic diversity with a sum score ranging from 0 to 456 for the 23 disco-vertebral units (DVUs) [4]. Spinal process inflammation (SPi) was documented. The degenerative changes i.e., Modic 1, Modic 2, Schmorl's node with or without bone marrow oedema (BME), disc degeneration (herniation or marginally located high intensity zone), erosion, sclerosis, Pfirrmann changes, were also included in the reading protocol.[3, 5]

Results: For approximately 80% of the pts, no fat lesions were identified **(Figure 1a)**. The mean (SD) FASSS at baseline for the overall population was 1.8 (5.7), 0.2 (1.2), 1.0 (3.6) and 0.6 (1.9) for the whole spine, cervical, thoracic, and lumbar regions, respectively. SPi were documented for 11.1% of the patients. Approximately 63% of the pts had at least one type of DC **(Figure 1b)**. The most prevalent DCs for the overall population were: Pfirrmann changes (grade ≥3), 51.1%; disc degeneration, 36.7%; Modic 1 or Modic 2, 22.1%; Schmorl's node with or without BME, 11.8 %. The proportion of pts with specific changes in the spinal sub-locations are presented in **Table 1**.

Conclusion: Re-reading the baseline MRIs from the MAXIMISE trial, the largest cohort of PsA pts with active axial disease diagnosed by clinical criteria, revealed fat lesions and DCs for approximately 20% and 63% of the pts, respectively, while SPi occurred much less frequently. These data shed light into the imaging characteristics of patients with PsA and axial manifestations.

SESSION INFORMATION

Session Date: Tuesday, November 9, 2021

Session Title: Abstracts: Spondyloarthritis Including PsA – Treatment II: Biologic Therapies (1943–1946)

Session Type: Abstract Session

Session Time: 4:00PM–5:00PM

Background/Purpose: Among treatment options for PsA, IL-23/12 inhibition with ustekinumab (UST) was the first new biologic after TNF inhibitors (TNFi). Few data compare long-term effectiveness between UST and TNFi. Here we present the final 3-year analysis from the real-world PsABio study, focusing on the achievement of minimal disease

Table 1. Observed baseline characteristics of overall patients (n=895) and remainers (n=374)

Mean (95% CI)	UST (overall)	TNFi (overall)	UST (remainers)	TNFi (remainers)
N	439	456	186	188
Age, years	**51.1 (49.9 ; 52.2)**	**48.5 (47.3 ; 49.6)**	**51.5 (49.6 ; 53.4)**	**46.4 (44.6 ; 48.3)**
Male, %	43.7 (39.0 ; 48.5)	45.6 (41.0 ; 50.3)	46.2 (38.9 ; 53.7)	58.0 (50.6 ; 65.1)
BMI, kg/m^2	28.6 (28.0 ; 29.2)	27.8 (27.2 ; 28.3)	29.0 (28.0 ; 30.0)	27.3 (26.6 ; 28.1)
Time since initial diagnosis, years	7.5 (6.7 ; 8.3)	6.2 (5.6 ; 6.9)	7.7 (6.5 ; 8.9)	6.74 (5.8 ; 7.7)
Cardiometabolic disease, %	41.9 (37.3 ; 46.7)	35.5 (31.1 ; 40.1)	44.6 (37.3 ; 52.1)	33.0 (26.3 ; 40.2)
Dactylitis at baseline, %	18.1 (14.5 ; 22.2)	22.6 (18.6 ; 27.0)	20.2 (14.7 ; 26.8)	28.4 (22.0 ; 35.5)
Enthesitis at baseline, %	47.8 (42.8 ; 52.8)	50.9 (45.9 ; 55.9)	48.9 (41.5 ; 56.4)	50.3 (42.9 ; 57.6)
Line of bDMARD treatment, %				
First line	**45.1 (40.4 ; 49.9)**	**55.0 (50.3 ; 59.7)**	47.8 (40.5 ; 55.3)	58.0 (50.6 ; 65.1)

*Denotes physician-confirmed isolated axial PsA.

bDMARD, biologic DMARD; BMI, body mass index; BSA, body surface area; cDAPSA, clinical Disease Activity in Psoriatic Arthritis; CI, confidence interval; CRP, C-reactive protein; N/A, not available; PsAID, Psoriatic Arthritis Impact of Disease; TNFi, TNF inhibitor; UST, ustekinumab.

activity (MDA)/very low disease activity (VLDA) and low disease activity (LDA) or remission, as measured by clinical disease activity in psoriatic arthritis (cDAPSA).

Methods: The PsABio study (NCT02627768) evaluated effectiveness, tolerability and persistence of 1st, 2nd, or 3rd-line UST or TNFi in patients (pts) with PsA. Here we present proportion of pts reaching MDA/VLDA and cDAPSA LDA or remission up to 3 years (assessments for pts under the initial treatment at 3 years). Descriptive statistics included the last observation carried forward (LOCF) endpoint created in case of missing 3-year effectiveness data; for example, due to COVID-19. Cohort comparison was done among pts who stayed on their initial UST or TNFi treatment for the full 3 years (remainer analysis), and among those who switched/stopped their original treatment, imputed as non-responders (overall analysis). Logistic regression analysis presenting odds ratios (ORs) and 95% confidence intervals (CIs), including propensity score (PS), stratified on quintiles (inverse probability of treatment weighting as sensitivity analysis) to adjust for imbalanced baseline (BL) covariates.

Results: The overall analysis (n=895) included 439 UST and 456 TNFi-treated pts who had evaluable BL and follow-up data up to 3 years. The remainer analysis included 186 (42.4%) UST and 188 (41.2%) TNFi-treated pts staying on their initial treatment up to 36 ± 3 months. In both the overall and remainer analyses, UST and TNFi groups had significant BL differences in age and psoriasis skin involvement (body surface area >10%); in the overall analysis, significant difference was seen for 1st and 3rd bDMARD line of treatment (**Table 1**).

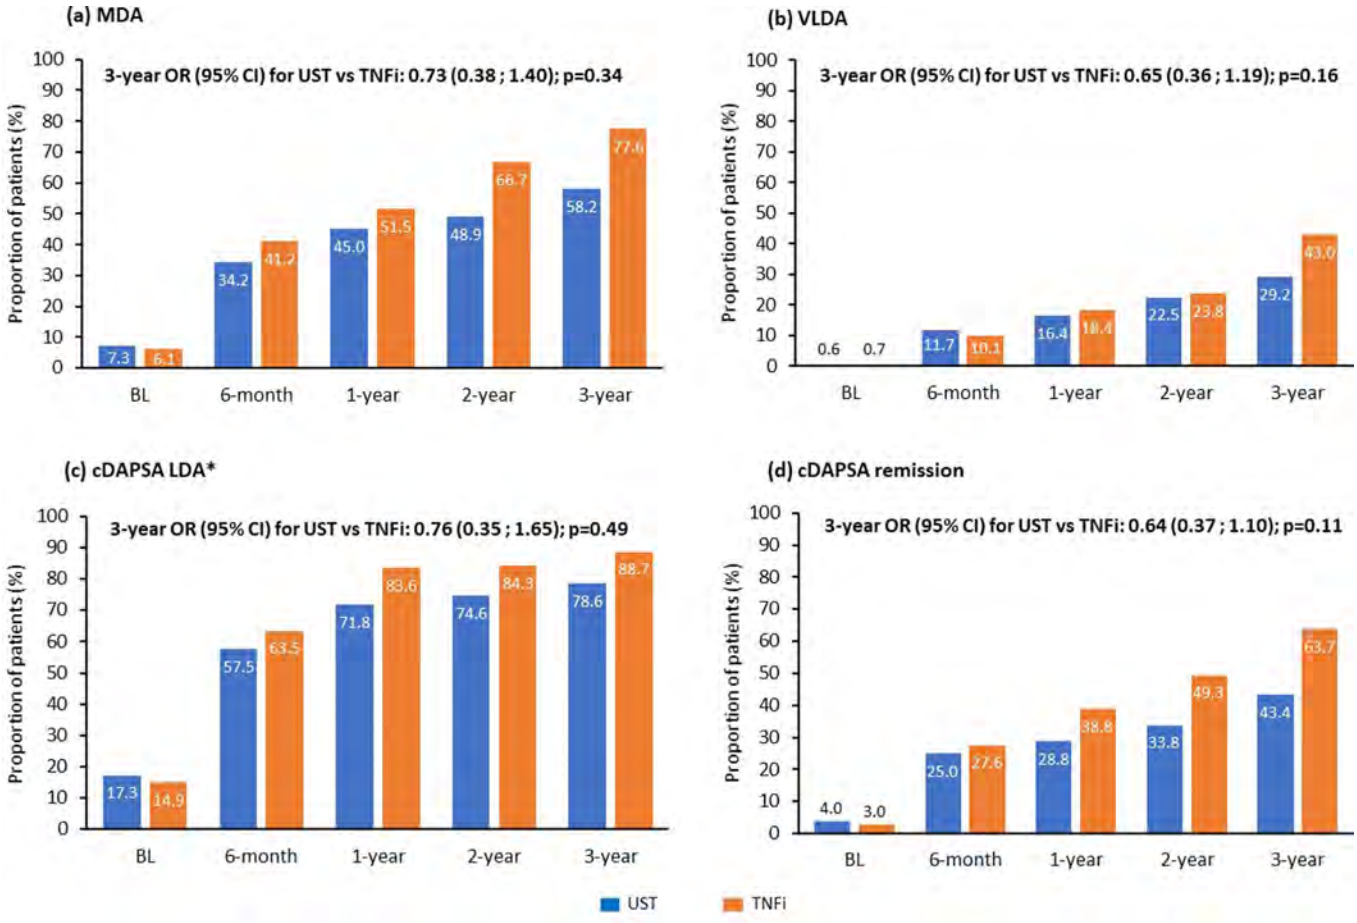

Figure 1. Observed proportions of patients and PS-adjusted ORs (95% CI) achieving: (a) MDA; (b) VLDA; (c) cDAPSA LDA; and (d) cDAPSA remission with UST or TNFi up to 3 years (remainer analysis). Results reflect 3-year LOCF data from assessments for patients still under initial treatment at 3 years. *Includes remission. BL, baseline; CI, confidence interval; LOCF, last observation carried forward; LDA, low disease activity; MDA; minimal disease activity; OR, odds ratio; PS, propensity score; TNFi, TNF inhibitor; UST, ustekinumab; VLDA, very low disease activity.

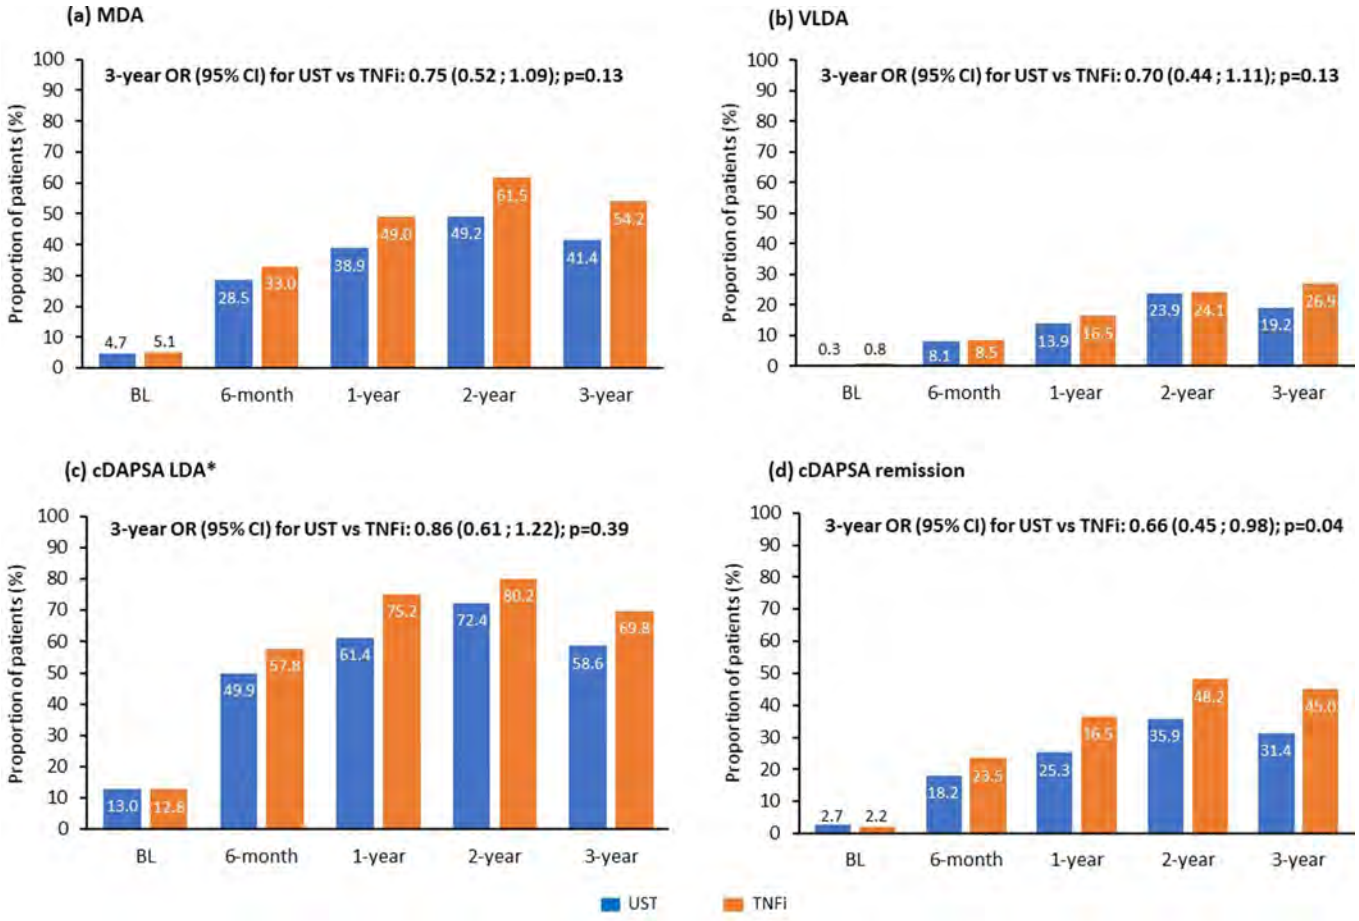

Figure 2. Observed proportions of patients and PS-adjusted ORs (95% CI) achieving: (a) MDA; (b) VLDA; (c) cDAPSA LDA; and (d) cDAPSA remission with UST or TNFi up to 3 years (overall analysis). The overall analysis included patients switching/stopping their original treatment during the 3-year observation period. The PS-adjusted ORs resulting from the overall analysis included non-response imputation in case of stop/switch initial treatment. *Includes remission. BL, baseline; CI, confidence interval; LOCF, last observation carried forward; LDA, low disease activity; MDA; minimal disease activity; OR, odds ratio; PS, propensity score; TNFi, TNF inhibitors; UST, ustekinumab; VLDA, very low disease activity.

In the remainer analysis, both UST and TNFi treatments led to a significant proportion of pts achieving MDA (up to 78%; **Figure 1a**), VLDA (up to 43%; **Figure 1b**), cDAPSA LDA (up to 89%; **Figure 1c**), and cDAPSA remission (up to 64%; **Figure 1d**). The PS-adjusted ORs (95% CI) indicated a similar response in both cohorts (**Figure 1a–d**). The overall analysis, which included pts switching/stopping initial treatment during the 3-year period, showed similar results (**Figure 2a–d**).

Conclusion: In the prospectively followed PsABio study across Europe, slightly more than 40% of pts with PsA stayed on UST or TNFi for 3 years or more. This long-term treatment, when used as 1st-, 2nd-, or 3rd-line bDMARD in a routine care setting, provided sustained improvement of disease signs and symptoms, enabling achievement of MDA, VLDA, cDAPSA LDA, or cDAPSA remission. While numerically more TNFi-treated pts achieved LDA or remission states, UST was used in more treatment-resistant patients and there was no statistical difference between the treatment groups; the improvements were maintained over the 3-year period. The findings demonstrate that remission/LDA are feasible when using targeted drugs in PsA.

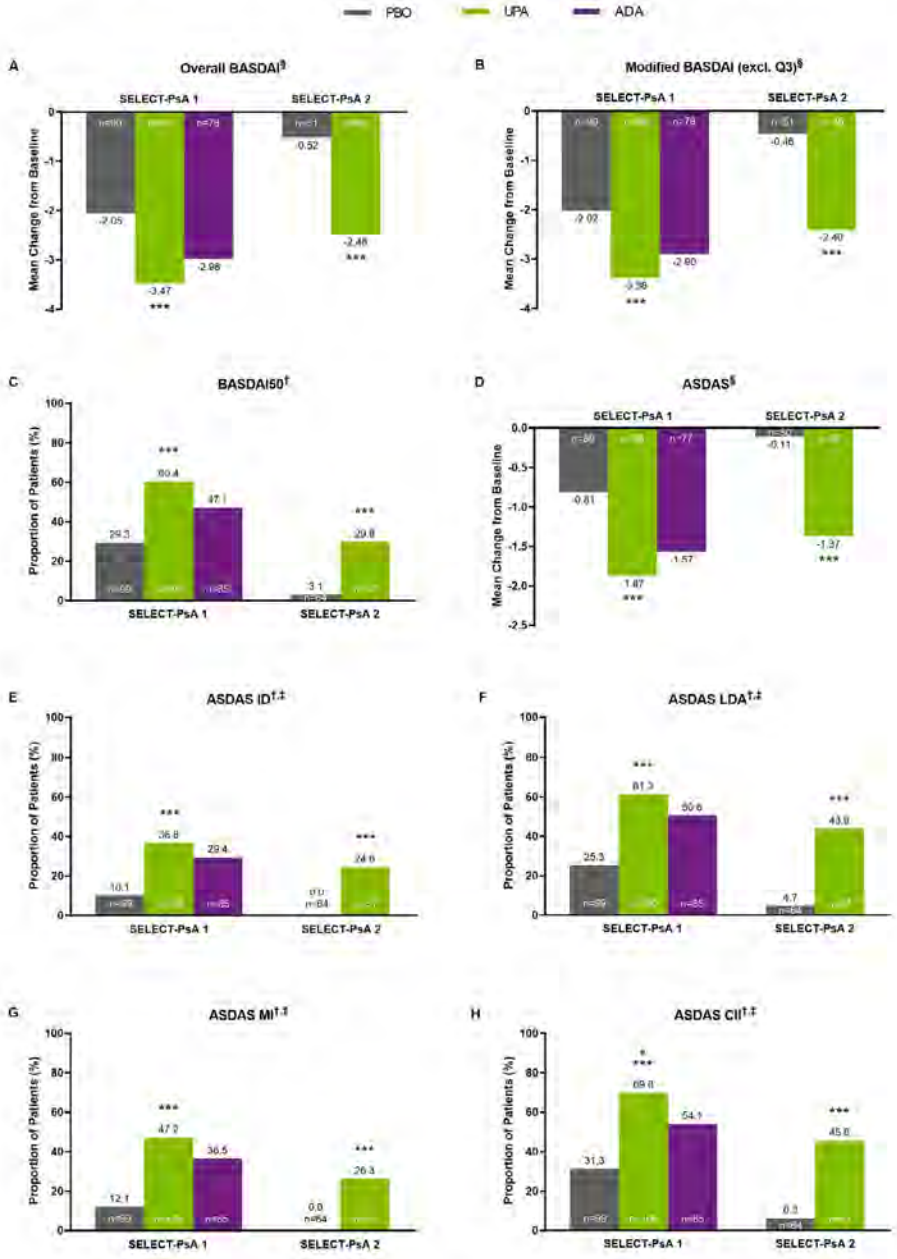
SESSION INFORMATION
Session Date: Tuesday, November 9, 2021
Session Title: Abstracts: Spondyloarthritis Including PsA – Treatment II: Biologic Therapies (1943–1946)
Session Type: Abstract Session
Session Time: 4:00PM–5:00PM

Background/Purpose: Patients with PsA and axial involvement have higher disease activity and greater reductions in quality of life;[1] however, there are no accepted criteria for identifying axial involvement in PsA. The objective of this post-hoc analysis is to assess the efficacy of upadacitinib (UPA), a Janus kinase inhibitor, on axial symptoms in patients with active PsA and axial involvement defined by investigator assessment and PRO-based criteria from two phase 3 SELECT trials.[2,3]

Methods: Patients with active PsA (≥3 swollen joints and ≥3 tender joints) and prior inadequate response or intolerance to ≥1 non-biologic (SELECT-PsA 1) or ≥1 biologic (SELECT-PsA 2) DMARD were randomly assigned to once daily oral UPA 15 mg or 30 mg, placebo (PBO), or every other week subcutaneous adalimumab (ADA) 40 mg (SELECT-PsA 1 only).[2,3] At baseline, axial involvement in PsA was determined by investigator assessment based on the totality of clinical information, such as duration and character of back pain, age of onset, and previous imaging. In addition to investigator assessment, PRO-based criteria for axial involvement (BASDAI ≥4 and BASDAI Question 2 ≥4 at baseline) were applied for this analysis to identify patients with active disease. Efficacy in the sub-group of pa-

Figure: Clinical Responses in Patients with Axial Involvement Defined by Investigator Assessment and PRO-Based Criteria at Week 24 from SELECT-PsA 1 and SELECT-PsA 2



ADA, adalimumab; ASDAS, Ankylosing Spondylitis Disease Activity Score; BASDAI, Bath Ankylosing Spondylitis Disease Activity Index; CII, clinically important improvement; EOW, every other week; ID, inactive disease; LDA, low disease activity; MI, major improvement; MMRM, mixed-effect model repeated measures; NRI, non-responder imputation; PBO, placebo; QD, once daily; UPA, upadacitinib

***P<0.001, UPA 15 mg vs. PBO; *P<0.05, UPA 15mg vs. ADA; nominal P-values are presented and were not adjusted for multiple comparisons
†NRI analysis constructed using Cochran-Mantel-Haenszel test adjusting for the main stratification factor of current DMARD use (yes/no) was used for binary endpoints
‡ASDAS thresholds: ID <1.3; LDA <2.1; MI change from baseline ≥2; CII change from baseline ≥1.1
§MMRM analysis with unstructured variance-covariance matrix, including treatment, visit, treatment-by-visit interaction, the stratification factor current DMARD use (yes/no) as fixed factors and the continuous fixed covariate of baseline measurement was used for continuous endpoints

tients defined using both investigator assessment and PRO-based criteria was evaluated at week 24 for UPA 15 mg vs PBO and ADA (SELECT-PsA 1 only). Data were analyzed using mixed-effect model repeated measures (MMRM) or non-responder imputation (NRI), with nominal *P*-values shown.

Results: Based on investigator assessment alone, 31.3% (n=534/1704) of patients in SELECT-PsA 1 and 34.2% (n=219/641) in SELECT-PsA 2 were defined as having axial involvement. When both investigator assessment and PRO-based criteria were applied, 23.1% (n=393/1704) of patients in SELECT-PsA 1, or 73.6% (n=393/534) of those defined using investigator assessment alone, and 27.5% (n=176/641) in SELECT-PsA 2, or 80.4% (n=176/219) using investigator assessment alone, met the combined criteria for axial involvement. In both studies, UPA 15 mg showed significantly greater clinical responses vs PBO at week 24 across all endpoints assessed (**Figure**). In SELECT-PsA 1, UPA showed numerically greater responses than ADA at week 24 across all BASDAI and Ankylosing Spondylitis Disease Activity Score (ASDAS) endpoints. The proportion of patients achieving ASDAS clinically important improvement (CII) at week 24 was significantly greater with UPA vs ADA based on nominal *P*-value.

Conclusion: Patients with active PsA and axial involvement defined by both investigator assessment and PRO-based criteria demonstrated statistically greater clinical responses related to their axial involvement with UPA 15 mg compared to PBO, and consistently numerically higher responses compared to ADA, at week 24 in the SELECT-PsA trials. Findings from this post-hoc analysis are consistent with previous data based on investigator assessment alone.[4]

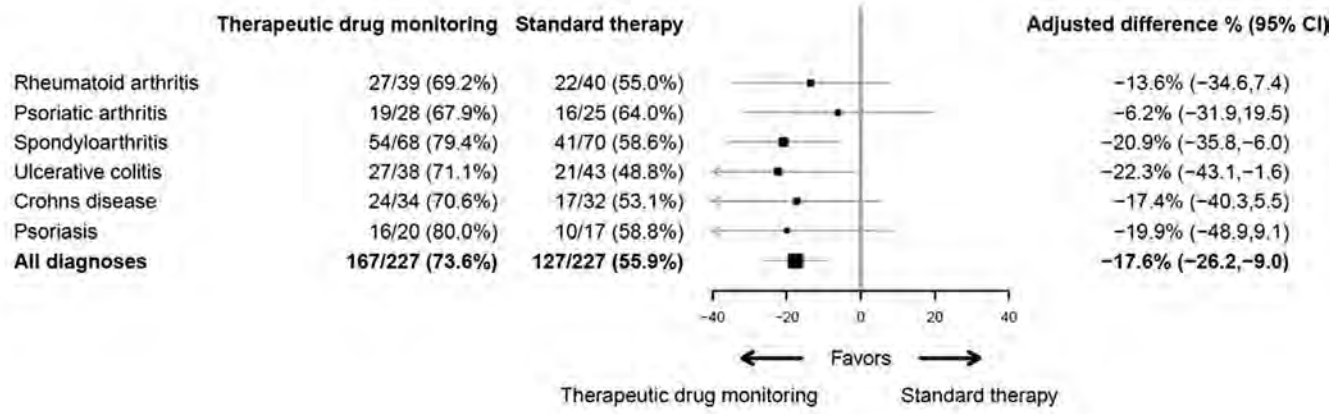
Session Title: Abstracts: Spondyloarthritis Including PsA – Treatment II: Biologic Therapies (1943–1946)

Session Type: Abstract Session

Session Time: 4:00PM–5:00PM

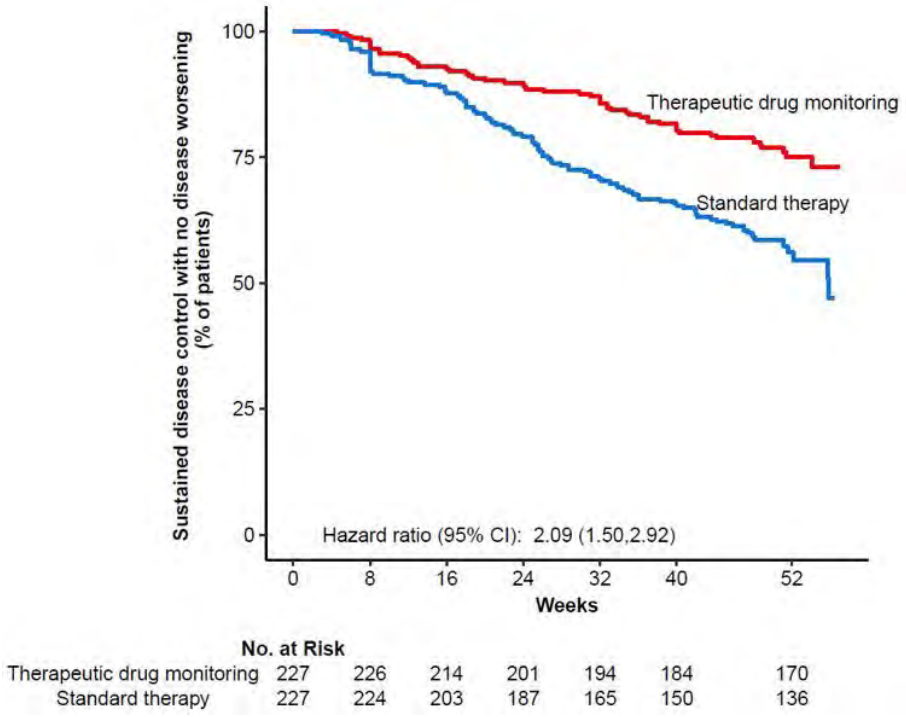
Background/Purpose: Proactive therapeutic drug monitoring (TDM), a treatment strategy based on scheduled assessments of serum drug levels, has been proposed to optimize efficacy and safety of infliximab and other TNF inhibitors. It is still unclear whether proactive TDM improves clinical outcomes. The NOR-DRUM trials (A and B) are the first randomized trials to assess the impact of proactive TDM of infliximab in a range of immune-mediated inflammatory diseases. The NOR-DRUM A trial focused on the induction phase of infliximab.[1] The aim of the present trial, NOR-DRUM B, was to assess effectiveness of TDM during maintenance infliximab therapy.

Figure 1. Sustained Disease Control with no Disease Worsening (Primary Endpoint)



Forest plot depicting the adjusted difference in the rate of sustained disease control without disease worsening during 52-weeks follow-up (95% confidence interval) overall (the primary endpoint) and by disease subgroup.

Figure 2 Kaplan-Meier Curve of Time to Disease Worsening



Methods: In this 52-week randomized, open-label, multicentre trial, adult patients with rheumatoid arthritis (n=79), spondyloarthritis (n=138), psoriatic arthritis (n=53), ulcerative colitis (n=81), Crohns disease (n=66) or psoriasis (n=37) on infliximab therapy for a minimum of 30 weeks were randomly assigned 1:1 to infliximab based on TDM or standard therapy. In the TDM group, infliximab doses- and intervals were adjusted according to an algorithm to maintain serum infliximab levels within the prespecified therapeutic range 3-8 mg/L. In the standard therapy group, administration of infliximab was based on clinical judgement. The primary endpoint was sustained disease control without disease worsening. Disease worsening was defined by disease specific composite scores or a consensus on disease worsening between investigator and patient leading to major change in treatment. The primary analysis was performed by mixed effect logistic regression.

Results: Between June 7, 2017, and December 12, 2019, 458 patients were randomized and 454 received the allocated strategy and were included in the primary analyses. During the 52-week follow-up, the primary endpoint of sustained disease control without disease worsening was achieved in 167 (73.6 %) patients in the TDM group compared to 127 (55.9%) patients in the standard therapy group. The estimated adjusted difference was -17.6% (95% confidence interval -26.2 to -9.0, p=< 0.001). (Figure 1) Results were consistent in sensitivity analyses. The two groups were balanced regarding baseline characteristics (Table 1). Time to disease worsening was different in the two groups, hazard ratio (95% CI) 2.1 (1.5-2.9) (Figure 2). Secondary endpoints comparing disease activity and patient reported outcomes at week 52 did not show significant differences between the groups. Mean infliximab dose received during the trial was 4.8 mg/kg in both groups. Twenty-one (9.2%) in the TDM group and 27 (15.0 %) in the control group developed clinically significant levels of anti-drug antibodies. Adverse events were reported in 137 (60%) and 142 (63%) patients in the TDM and standard therapy groups, respectively.

Conclusion: Proactive TDM proved more effective than standard therapy in sustaining disease control without disease worsening. These results support implementation of proactive TDM as a general strategy during maintenance therapy with infliximab and have the potential to change clinical practice across specialities.

Table 1 Characteristics of the Patients at Baseline

	Therapeutic Drug Monitoring (n=227)	Standard Therapy (n=227)
Demographics		
Age – yr	45.1±14.2	44.6±14.3
Female sex – no. (%)	117 (51.5)	99 (43.6)
Disease duration (range) – yr	6.2 (2.0-15.1)	5.3 (2.1-12.8)
Diagnoses		
Rheumatoid arthritis – no. (%)	39 (17)	40 (18)
Spondyloarthritis – no. (%)	68 (30)	70 (31)
Psoriatic arthritis – no. (%)	28 (12)	25 (11)
Ulcerative colitis – no. (%)	38 (17)	43 (19)
Crohn's disease – no. (%)	34 (15)	32 (14)
Psoriasis – no. (%)	20 (9)	17 (8)
Therapy		
Infliximab treatment duration (range) – weeks	40.0 (37.9-61.0)	39.9 (37.9-61.0)
Concomitant immunosuppressive therapy* – no. (%)	123 (54.2)	130 (57.3)
Concomitant use of glucocorticoids – no. (%)	15 (6.6)	13 (5.7)
Use of biologic therapy# prior to infliximab – no. (%)	62 (27.3)	63 (27.8)
Disease activity at baseline		
Erythrocyte sedimentation rate (range) – mm/h	7.0 (3.0-12.0)	5.0 (2.0-11.0)
C-reactive protein (range) – mg/L	1.0 (1.0-3.0)	1.0 (1.0-3.0)
Patient's global assessment of disease activity	25.8±21.6	22.5±19.1
Physician's global assessment of disease activity	13.8±15.8	11.2±12.6
Disease specific baseline characteristics		
Rheumatoid arthritis		
Disease activity score in 28 joints$^{\Delta}$	2.4±1.0	2.3±1.2
Spondyloarthritis		
Ankylosing spondylitis disease activity score¶	1.6±0.8	1.5±0.8
Psoriatic arthritis		
Disease activity score in 28 joints$^{\Delta}$	2.1±1.1	1.6±1.0

*Plus–minus values are means ±SD, range denotes interquartile range, TDM therapeutic drug monitoring, TNF tumor necrosis factor

*Concomitant immunosuppressive medication includes: Methotrexate, leflunomide, sulfasalazine, and azathioprine.

#Biologic therapy includes: Etanercept, adalimumab, certolizumab pegol, golimumab, abatacept, efalizumab, rituximab, secukinumab, tocilizumab, ustekinumab and vedolizumab.

Patient Perspectives

Abstract Number: PP01

Unicycling for a Cure: My UNIque Physical Activity Intervention for Rheumatoid Arthritis During the COVID19 Pandemic

Dana Guglielmo, San Diego, CA

SESSION INFORMATION
Session Date: Sunday, November 7, 2021
Session Title: Patient Perspectives Poster (PP01–PP09)
Session Type: Poster Session B
Session Time: 8:30AM–10:30AM

Background/Purpose: I was diagnosed with rheumatoid arthritis at age 17. In my 20s, I joined Racing For A Cure of the Arthritis National Research Foundation, a community platform for athletes thriving with rheumatic disease. Being an athlete and physical activity researcher have taught me that physical activity can reduce anxiety and fatigue, which are my most prominent symptoms. However, the COVID19 pandemic amplified both symptoms, and I felt exhausted and unmotivated to exercise. With each trip outside increasing my risk of COVID19, I became disheartened that most days it felt easier to stay inside.

Intervention: I troubleshooted my multifaceted problem and identified my barriers to physical activity: 1) Routine, repetitive exercise left me disengaged with my external surroundings and led to my mind getting consumed by internal anxiety; and 2) I felt unmotivated to exercise given my low energy levels and the risk of COVID19. Next, I identified my exercise needs: 1) low-impact and arthritis-friendly; 2) challenging enough to distract me from my anxiety; and 3) the most important: FUN! I thought back to my favorite childhood sport (Figure 1), and realized this same sport would meet these criteria with flying colors: unicycling!

Maintenance: I have improved my fitness, flexibility, strength, balance, and coordination, all of which allow me to safely ride my unicycle with rheumatoid arthritis. To maintain fitness, I engage in activities like plyometric drills, juggling, lifting weights, balance training, and stretching (Figure 2). I ride my unicycle 1-2x per week, and incorporate my love of adventure by finding cool new places to ride (Figure 3). To stay motivated and accountable, I communicate with other athletes with arthritis, many of whom are on social media (e.g., Athletes Beating Rheumatoid Arthritis Facebook group). The camaraderie of those who have successfully overcome their own exercise challenges helps keep me motivated, and I love sharing my own experiences to encourage others.

Quality of Life: A fun childhood sport took on new meaning in adulthood, as it became an activity I could look forward to during a traumatic year. My UNIque physical activity intervention led to subjectively improved fitness, physical functioning, mindfulness, self-efficacy, and quality-of-life, and reduced anxiety and fatigue. People with rheumatic conditions can utilize the same process I did to identify their own personal needs. Having social support is critical to sustaining physical activity. Joining a community of athletes with arthritis including Racing For A Cure can provide an avenue for social connection, peer support, and the ability to troubleshoot and overcome exercise barriers. When I ride my unicycle, I feel strong and capable. It makes all of the challenges, hardships, dedication, and perseverance feel worth it. My advice to others living with chronic disease is to choose fun over fear, and always be UNIque!

Figure 1. Where it all began: Dana unicycling as a child in New Jersey.

Figure 2. Behind the scenes: strength and balance training.

Figure 3. Dana unicycling at Ballona Creek Bike Path in Marina Del Rey, California.

Abstract Number: PP02

Leveraging Digital Health Tracking to Improve Arthritis Management

Katie Roberts, Annapolis, MD

SESSION INFORMATION
Session Date: Sunday, November 7, 2021
Session Title: Patient Perspectives Poster (PP01–PP09)
Session Type: Poster Session B
Session Time: 8:30AM–10:30AM

Background/Purpose: I was diagnosed with psoriasis when I was age 10 in 1986. At that time, my treatment plan consisted of regular application of Eucerin lotion, tar-based ointments, tanning beds, & frequent baths. Later I added

corticosteroids into my treatment plan. By the early 90's, novel treatments became available like steroid injections, PUVA, and methotrexate. When I turned 17, my diagnosis was amended to psoriatic arthritis. I cycled through many treatments for my condition, including up to 150 mg of methotrexate three times a week, steroid & gold injections, and eventually Remicade when it became available in the late nineties.

In 2003 I started taking Enbrel and have been taking it ever since. In addition to my biologic, I manage my arthritis with topical corticosteroids, steroid injections, and ibuprofen along with alternative medicine like massage therapy, acupuncture, a strict nutritional plan, herbal supplements, and heat therapy. All of these interventions allow me to live an active lifestyle, I frequently exercise and enjoy weight training, cardio, walking, pilates, yoga, and standup paddleboarding.

Intervention: Digital health tools like my Garmin Fenix 6 smartwatch, the TrainingPeaks training program, and the Arthritis Foundation's pain management app, Vim, inform my exercise regimen and care plan with patient reported data. With the support of my watch, I am able to track my pain & log my activity to identify the best exercise regimen for my care through an app called TrainingPeaks. A personal exercise coach reviews my data and builds exercise rec-

ommendations to meet my unique needs, and as I progress through my workout plans, I log notes about the impact of the activity on my joints. This log is even imported into my pain management app, Vim. When I meet with my rheumatologist, I am able to export the notes about my experience and discuss the data with them at my appointment. This in turn, informs my care plan.

Maintenance: I have been actively using my smart watch and exercise tracking tools for more than 3 years. Every day, my watch provides haptic feedback that reminds me to continue to track my progress and health. Weekly, my training coach at TrainingPeaks reviews the data and provides a recommended exercise plan for the upcoming week. After each workout, I diligently track how I'm feeling, what worked well during my exercise and what I feel I need more support on. Trends from the data are used to inform future workout plans, and I download the reports to use in talking with my rheumatologist. Bringing data into my doctor's office helps my doctor and I engage in shared decision making about my care, and it is much easier to report back to them how I've been doing with the support of consistently reported health data.

Quality of Life: Since incorporating digital health tracking tools into my routine, I have been able to stay active and keep my joints moving. The more I move the less I flare. This approach has helped me manage my disease activity. With tracking, I am more perceptive to my pain signals and have been able to detect early signs of a flare more easily – helping me be more proactive about my energy and effort conservation and self-care treatments. I am thankful that since adding digital health tracking into my care, I have had less disease activity.

Disclosure: K. **Roberts**, None.

Abstract Number: PP03

Navigating Maintenance of a Rare Autoimmune Rheumatic Disease in the Context of the COVID-19 Pandemic

Ida Hakkarinen, Greenbelt, MD

SESSION INFORMATION
Session Date: Sunday, November 7, 2021
Session Title: Patient Perspectives Poster (PP01–PP09)
Session Type: Poster Session B
Session Time: 8:30AM–10:30AM

Background/Purpose: On March 13th, 2020, the President of the United States issued a proclamation declaring that the outbreak of coronavirus disease 2019 (COVID-19) was a risk to the public health and safety of the Nation. Three days later, my workplace instituted mandatory telework. In a prescient tweet at the end of the month, Tseng (2020) shared a conceptual framework (Fig. 1) of four waves of the COVID-19 pandemic and potential impacts upon health care. Since my initial diagnosis of Granulomatosis with Polyangiitis (GPA) in January 2012 and two relapses, closely monitoring my health became an ongoing part of life. Navigating maintenance care for GPA brought challenges in the era of COVID-19.

Intervention: My medical team pivoted to telehealth in lieu of in-person appointments and established a secure collaboration tool for visits. Dao (2020) offered appointment tips for rheumatologists much like what I experienced with other doctors. Being able to see and speak with my physicians virtually lessened the isolation I felt in my single person household with no pets. Laboratory results showed my GPA remained quiescent. My pharmacy provided free medication delivery during the initial lockdown period.

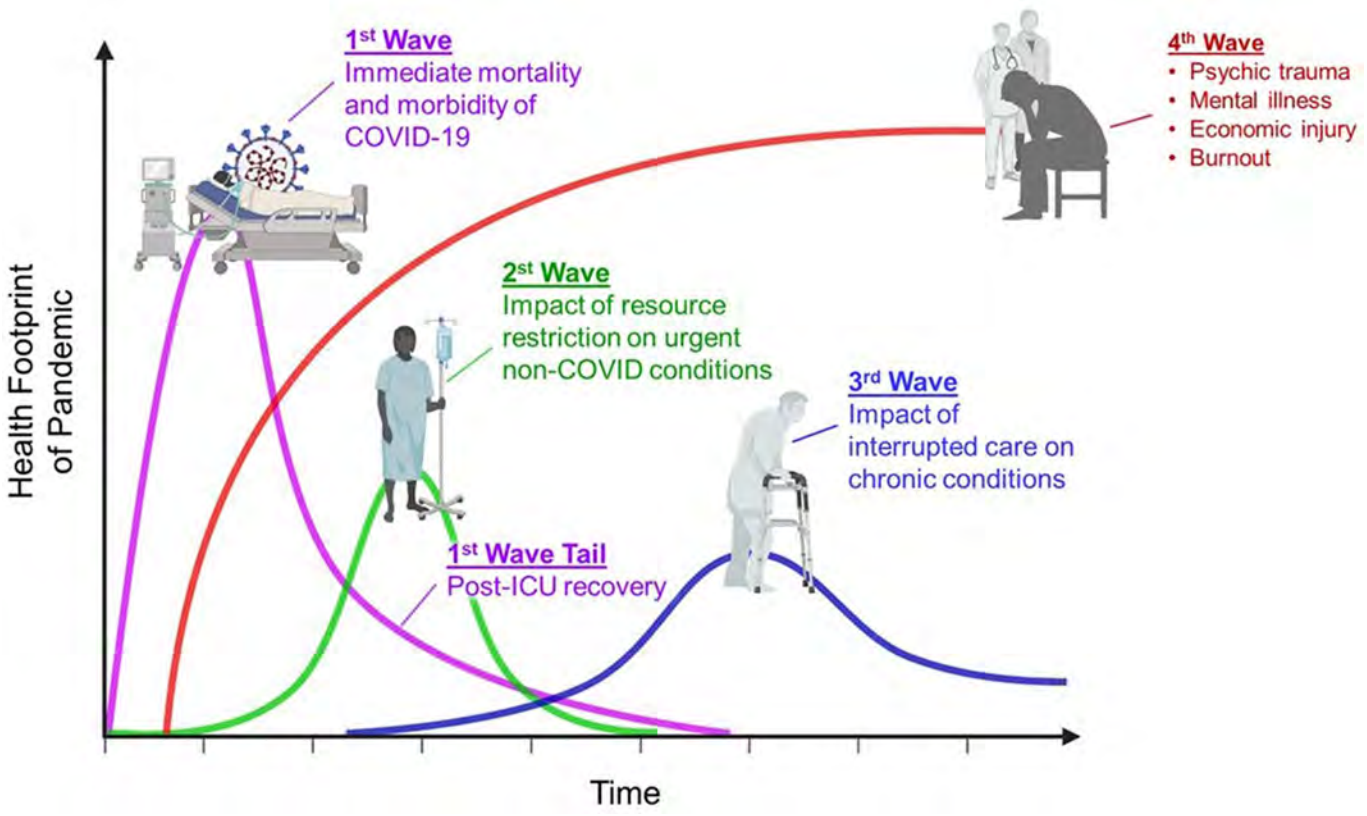

Figure 1. Conceptual model of the four waves of the COVID-19 pandemic (Tseng, 2020).

Maintenance: Gathering information from reputable sources enabled me to gain perspectives on the risks of COVID-19 infection and the benefits of early treatments and vaccines. Thoughtful comments from physician-scientists and clinicians helped me filter out "noise" found on social media. The Vasculitis Foundation hosted webinars where rheumatologists shared the latest data and information about COVID-19 and its potential impacts upon patients. The American College of Rheumatology also hosted webinars about patients with rheumatic diseases.

The global rheumatology community came together in a grass-roots collaborative effort to form the COVID-19 Global Rheumatology Alliance to collect, analyze and disseminate information about COVID-19 and rheumatology to patients, physicians and others. The group developed a patient experience survey that received over 14,000 responses in a year. With the advent of COVID-19 vaccines, it launched a patient experience vaccine survey (Fig. 2) to learn how people with rheumatic disease make decisions regarding the vaccines.

Quality of Life: Shortly before receiving my first dose of the Moderna vaccine (Fig. 3), I was able to enroll in an observational prospective study at the National Institutes of Health about the effects of COVID-19 infection and/or vaccination on patients with autoimmune diseases. Being able to contribute to scientific research has been very meaningful in the midst of these chaotic times.

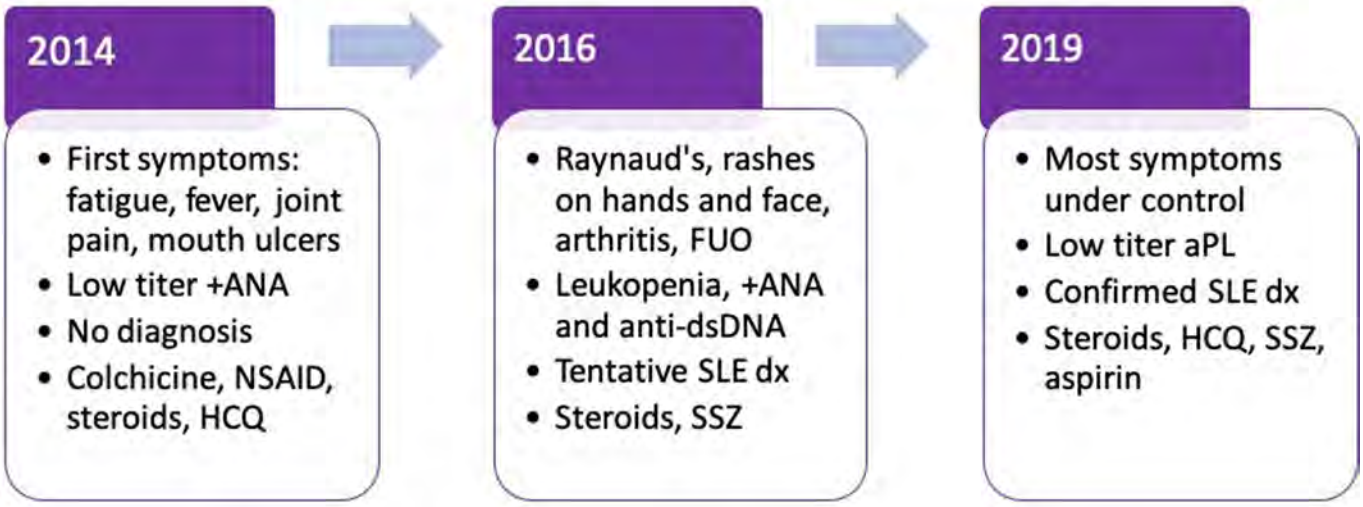
Abstract Number: PP04

Dual Roles: Thriving with SLE as a Medical Student

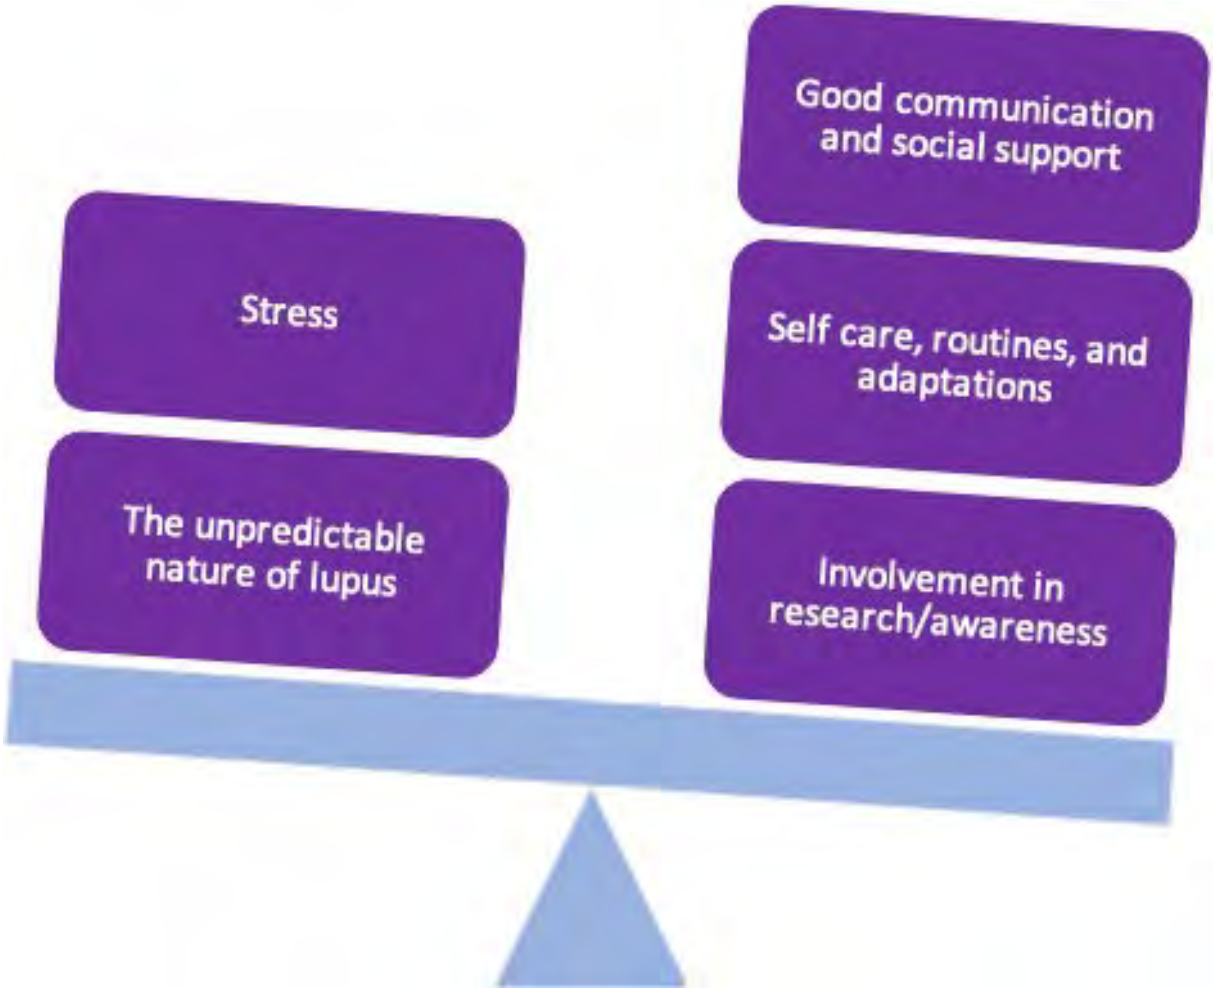
Chieh Lo[1] and Song-Chou Hsieh[2], [1]School of Medicine, I-Shou Univerity, Kaohsiung, Taiwan (Republic of China), [2]Division of Immunology, Allergy and Rheumatology, Department of Medicine, National Taiwan University Hospital, Taipei, Taiwan (Republic of China)

SESSION INFORMATION
Session Date: Sunday, November 7, 2021
Session Title: Patient Perspectives Poster (PP01–PP09)
Session Type: Poster Session B
Session Time: 8:30AM–10:30AM

Background/Purpose: A few days after my 18th birthday, I walked into a rheumatology clinic for the first time. I had ulcers in my mouth, felt extremely tired, and my knees were swollen and painful. In just a few years, I went from competing in triathlons to limping around. Leaving the clinic with a prescription of NSAIDs and colchicine, I thought these symptoms would disappear once I was done with stressful college entrance exams. But I had no idea of the journey that lay ahead.



The diagnosis process.



Factors that affect quality of life with lupus.

The author's first ICU clinical rotation.

I ran a low-grade fever for 2 years straight. Sometimes, I felt so sick I couldn't get out of bed. My white blood cell count was often low. Steroids made my face swell, and I felt tempted to stop my medications. At one point, even my own parents accused me of feigning illness-but I didn't have a diagnosis to prove them wrong! Despite all this, I was accepted to medical school. Shortly afterwards, I received a formal diagnosis of SLE. After years of rheumatology appointments, this news did not come as a surprise to me. But as a medical student, I now had to juggle 2 roles: patient and physician-to-be.

Intervention: My illness introduced me to the world of rheumatology. I was fascinated by all the research that was going on in the field, and I wanted to experience the thrill of creating knowledge that will directly help patients like myself. Previously, I was part of an international patient advisory board for lupus research. Currently, I am involved

in several projects ranging from translating an international vaccine survey for people living with rheumatic diseases, to researching HCV clearance and autoimmunity. With help from the rheumatologist who diagnosed me, I am now drafting my first original research article!

Another thing that has inspired me to become more engaged in healthcare is connecting with fellow patients through online groups. As a medical student, I sometimes provide information about lupus, help anxious people who have just been diagnosed, and explain the importance of adhering to treatment. But when things get tough for me, it is also very helpful to talk to people who have been through similar situations. This reciprocal relationship builds a strong sense of support and community.

Maintenance: Stress is a major part of medical school. Sometimes it can be easy to neglect my own health. Forgetting to take steroids in the morning, for example, can lead to an inconvenient bout of arthritis while studying or shadowing in the evening. Prolonged stress and sleep deprivation may also lead to disabling flares. Therefore, I must keep an eye on my mental and physical health, and manage it like any other obligation. This is easier said than done, so I rely on planners and pillboxes to hold myself accountable. Sometimes, I also experience "brain fog" and forgetfulness, so I use digital tools such as phone apps to keep me on track.

Quality of Life: My lupus has now been stable for more than a year. I've become better at recognizing signs of an impending flare and taking action to stop it. With my improved health, I am able to dedicate more of my energy towards academics, research, and having fun. Though I still occasionally worry about what the future holds for me as a physician living with lupus, I remain confident that scientific breakthroughs and advocacy will continue to improve the lives of patients all around the world.

Abstract Number: PP05

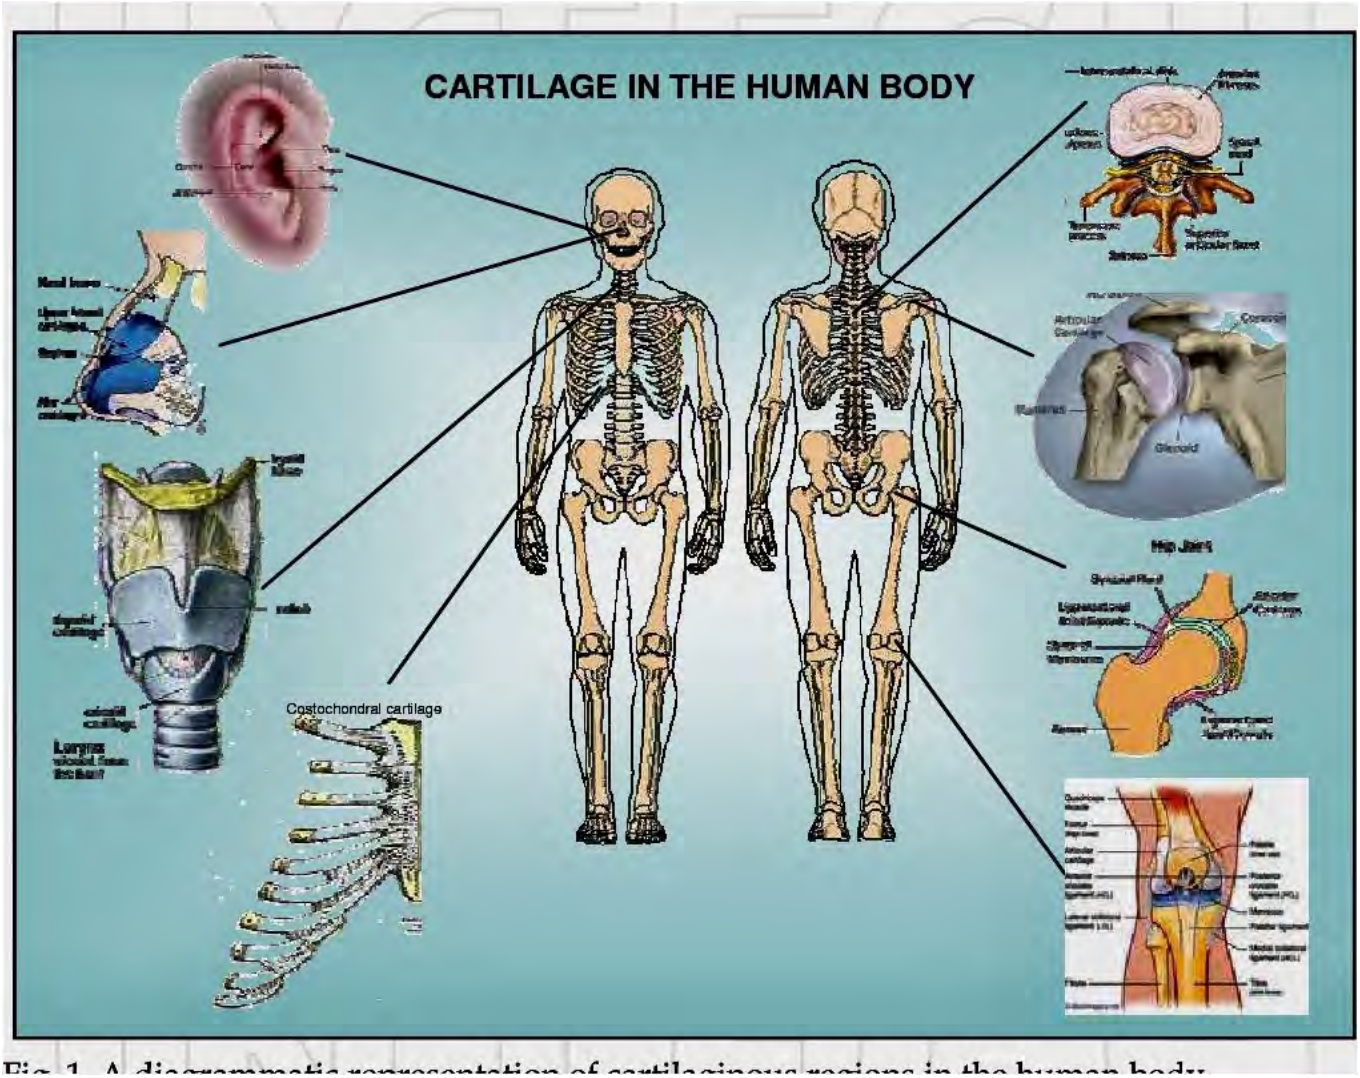
Fighting Health-Related Misinformation Using Social Media / How Creating an Online Group for Patients with Relapsing Polychondritis — and Moderating It with Health Professionals — Helps Spread Reliable and Empowering Information

Michael Linn[1], Spenser Mestel[2] and **Susie Ratledge**[3], [1]Relapsing Polychondritis Foundation, New York, NY, [2]New York, NY, [3]Relapsing Polychondritis: Secular Science and Support group, Chattanooga, TN

SESSION INFORMATION
Session Date: Sunday, November 7, 2021
Session Title: Patient Perspectives Poster (PP01–PP09)
Session Type: Poster Session B
Session Time: 8:30AM–10:30AM

Background/Purpose: Before I became ill in 2017, I was a registered nurse with a degree in health science who'd often educate patients about how they could better live with their disease by understanding it. In my career, I served as a Health Education Coordinator, for the benefit of patients and communities, and was certified in diabetes education. So, when I was diagnosed with relapsing polychondritis ("RP") in 2018, I began to do my own research.

Unfortunately, RP is a rare disease, and though my rheumatologist was relatively well informed about it, many doctors are unaware of the the case studies and (albeit few) larger population studies. In this vacuum of knowledge, patients



Relapsing Polychondritis: Secular Science and Support Group.

often seek out and fall prey to misinformation. For example, one doctor (commonly found on the internet) touts a diet that "cures" RP. While I certainly encourage others to eat healthy and exercise regularly, there can be significant danger in forgoing legitimate medical treatment in order to pursue unproven cures. Likewise, even well-meaning patients often present their own experiences as if they're proof of the success of a medication or lifestyle change.

Intervention: Troubled by the lack of peer-reviewed science and anecdotal evidence in some other online support groups, I created an online community for RP patients. Along with five other moderators, including two health professionals, we vet the information provided. First and foremost, we ensure that it's coming from a reputable source, and that it's accessible to laypeople. I'll listen to dozens of lectures and comb through pages of results from online archives of biomedical and life science journal literature before I post something to the group.

To provide consistent and practical information, we also do "Monday Meds," where we discuss the different medications for autoimmune disease, and "Favorite Things Friday," where we list what we're grateful for, like pillows with a hole in the center, which helps to relieve the pressure on our ears when sleeping.

However, it's not just about the quality of the information. Given all of us have spent years interacting with fellow RP patients, we've established trust and rapport within the community, allowing us to both highlight reputable sources and to gently discourage misinformation.

Susie Ratledge, Presenting Author.

Maintenance: Through this group, we've been able to equip patients with knowledge to bring to their doctors, empowering them to positively influence their own care. Similarly, we're able to prevent them from getting their hopes up about untested treatments. We offer an evidence-based, community-minded approach that has improved the quality of life for our members and for me.

Quality of Life: By offering both current scientific research and emotional support, our online group addresses the emotional and health-related needs of our community, which would otherwise go unmet for most of us.

Relapsing Polychondritis Foundation.

Abstract Number: PP06

Collaborative Advocacy Helps Me and Other Patients With Relapsing Polychondritis (“RP”) / My life improved by helping the RP Foundation and Race for RP facilitate awareness, education, and research to improve the quality of life for patients with RP and advance a cure for this disease

Michael Linn[1] and **Dan Smith**[2], [1]Relapsing Polychondritis Foundation, New York, NY, [2]Relapsing Polychondritis Foundation, Canton, MI

SESSION INFORMATION

Session Date: Sunday, November 7, 2021
Session Title: Patient Perspectives Poster (PP01–PP09)
Session Type: Poster Session B
Session Time: 8:30AM–10:30AM

Background/Purpose: In March 2020, I was diagnosed as having relapsing polychondritis ("RP"), an understudied, underdiagnosed, and undertreated debilitating autoimmune disease that can be fatal if left untreated. The disease affects multiple organ, particularly cartilaginous structures such as the ears, nose, airways, joints, as well as the eyes, skin, heart valves, and brain. The cause of RP remains unknown, and consequently, there is not a diagnostic test or targeted treatment options for patients with RP.

Dan & Debbie Smith with Race for RP car.

Race for RP.

Intervention: Since the early stages of my diagnosis, the RP Foundation (www.polychondritis.org) has continued to be a tremendous resource. Soon after my diagnosis, they provided educational materials and introductions to RP experts and an online RP support group. The RP Foundation also connected me to Race for RP (www.RaceForRP.org), which supports research, awareness programs, and care for those who are affected by RP.

From these connections, the importance of working as a team became particularly clear. Celebrating the successes and supporting teammates through the losses applies to sports, managing patient care, conducting research programs, and educating others about autoimmune diseases.

Maintenance: While fighting RP, I was inspired by the RP advocates that I met. So, I volunteered to be the primary liaison between the leading RP social media platforms (including the RP Foundation and Race for RP) and a large, private online support group.

Quality of Life: My life has been significantly improved by being part of a successful team whose purpose is to facilitate awareness, education, and research to improve the quality of life for patients with RP and advance a cure for this disease. It provides me with the opportunity to help others and be excited about the extraordinary advances in patient care and cutting-edge research. I enjoy being an active and helpful member of a successful team.

Relapsing Polychondritis Foundation.

Abstract Number: PP07

How Online Spanish-Language Resources Got Me and My RA Through the COVID-19 Pandemic

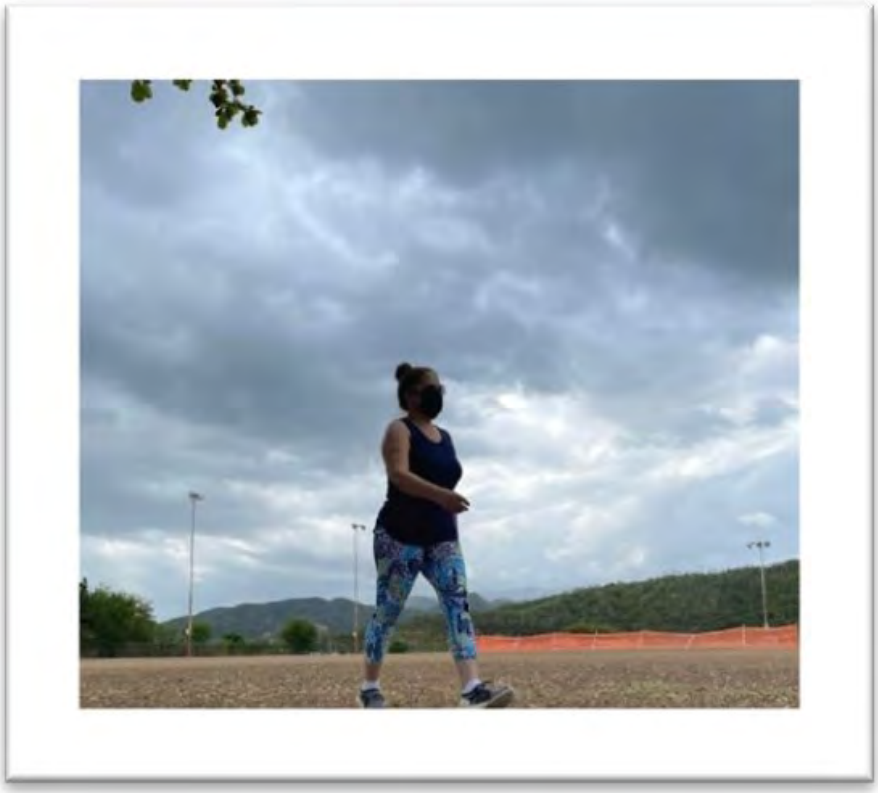
Wigna Cruz, Puerto Rico

SESSION INFORMATION
Session Date: Sunday, November 7, 2021
Session Title: Patient Perspectives Poster (PP01–PP09)
Session Type: Poster Session B
Session Time: 8:30AM–10:30AM

Background/Purpose: I was experiencing joint pain especially in my wrists, which led me to see my physician for testing. Initially I was misdiagnosed with lupus. After a few months of seeing my physician and not feeling like I was being heard, I got a second opinion. This led to further testing, and I was then diagnosed with rheumatoid arthritis (RA) in 2014. After attempting a few DMARDs, I was put on a DMARD treatment that works for me. Although I ended up getting the correct treatment for myself, the prior experience of being misdiagnosed and not feeling heard made me feel uncertain of who to trust. During the COVID-19 pandemic, I felt the same uncertainty and fear about who to trust, especially as I was getting so many different suggestions online from different news channels and from peers about what to do to keep safe as an RA patient. For example, was it safer to stop my RA treatment?

Intervention: Interacting with online articles from CreakyJoints Español, and the support I received from other CreakyJoints Español members, made me feel less anxious and more comfortable using the internet. This was es-

Figure 1. Easy-to-Understand COVID-19 Guidance for Patients at CreakyJoints Español.



Taking my daily walk.

pecially true in the beginning of the COVID-19 pandemic when I was getting contradictory information from news outlets and on social media. Luckily, the information I received through CreakyJoints Español was factual and helped me make decisions about my healthcare, including RA treatment decisions, with my doctor (Figure1). It made me feel less anxious and gave me confidence to get outside and walk regularly. Two Spanish-language articles that helped me during this time of uncertainty were:

- ACR guideline updates for patients
- Infographic and information on receiving care during the pandemic

Maintenance: I received COVID-19 information provided by CreakyJoints Español on their webpage and social media channels, and I was able to keep up to date on the ACR's recommendations, including COVID-19 vaccination and treating my RA during the pandemic. CreakyJoints Español gave me a better understanding of how to take into account the CDC COVID-19 guidance while considering trustworthy information that was specific to people with RA. I am continuing to stay informed about any new developments that affect patients like me through CreakyJoints Español.

Quality of Life: I stay physically active for overall health and make sure to attend my telehealth appointments and in-person infusions. I learned the importance of staying healthy physically and mentally and I am comfortable knowing that I can reach out to CreakyJoints Español with questions and for social support. It's important for me to stay informed about things that can affect RA and my quality of life throughout this pandemic and beyond. Having a trusted source of information has proved invaluable during this uncertain time.

Disclosure: W. Cruz, None.

Abstract Number: PP08

Should I Get the COVID-19 Vaccine With My RA? Using Evidence-Based Resources for Decision-Making

Aberdeen Allen, Colgate Palmolive, Parlin, NJ

SESSION INFORMATION
Session Date: Sunday, November 7, 2021
Session Title: Patient Perspectives Poster (PP01–PP09)
Session Type: Poster Session B
Session Time: 8:30AM–10:30AM

Background/Purpose: Patients with autoimmune rheumatic diseases have concerns about getting the COVID-19 vaccine. As vaccines began to receive emergency use authorization, individuals with conditions like rheumatoid arthritis (RA), looked for information to help make informed decisions. As a patient living with RA for 15 years, and on immunomodulating therapy for it, I was hesitant about getting the COVID-19 vaccine and needed to weigh the risks and benefits to feel confident getting a shot.

Intervention: People living with autoimmune diseases have nearly twice the risk of acquiring severe, vaccine-preventable infections. I was looking for reliable information about the new vaccine's safety and efficacy, and information that would be specific to my needs and experience with RA. I knew that there wasn't much information available on these vaccines that was specific to people with conditions like RA, so I was unsure of whether or when to get vaccinated. My questions were about whether to pause my RA medication, when to do so, and for how long. I wanted to know about possible side effects, like RA flare, and to learn if one of the three available vaccines was best suited for me. I searched online for resources to help me make a decision and gain confidence about my choice.

Given the rapidly changing information about COVID-19, I was anxious to know what was and wasn't evidence-based at every step (Figure 1). In my search, I came across the COVID-19 Patient Support Program offered by the Global Healthy Living Foundation (GHLF). The program shared up-to-date reliable information about COVID-19 through webinars, articles, and a newsletter circulated approximately weekly. Part of keeping up with the rapidly changing informational landscape involved accessing an online collection of fact-checked articles for patients called "COVID-19 Vaccine Information for Immunocompromised Patients" curated by GHLF and informed by medical experts. I learned through an informational webinar organized by GHLF about the American College of Rheumatology (ACR) guidance on COVID-19 vaccination for patients with autoimmune rheumatic diseases that it is important to know what questions to ask, especially when the evidence is changing or incomplete. In addition, after reading a Patient Support Program article called *7 Questions to Ask Your Rheumatologist If You're Nervous About Getting the COVID-19 Vaccine*, I was able to bring questions to with my doctor to help me reach a decision. Ultimately, I decided to get the COVID-19 vaccine (Figure 1).

Maintenance: I continue to have ongoing discussions with my rheumatologist about my concerns despite being fully vaccinated. This means I must stay updated by seeking out information on what experts are learning about COVID-19 as new evidence emerges.

Quality of Life: Being part of an online community like GHLF/CreakyJoints allowed me to voice my concerns and anxieties and to easily find information to address them. This allowed for more meaningful conversations between me and my doctor and helped me make an important decision: whether to get the COVID-19 vaccine. Now that I am fully vaccinated, I feel safer. I am enjoying life outside and socializing after being home for more than a year.

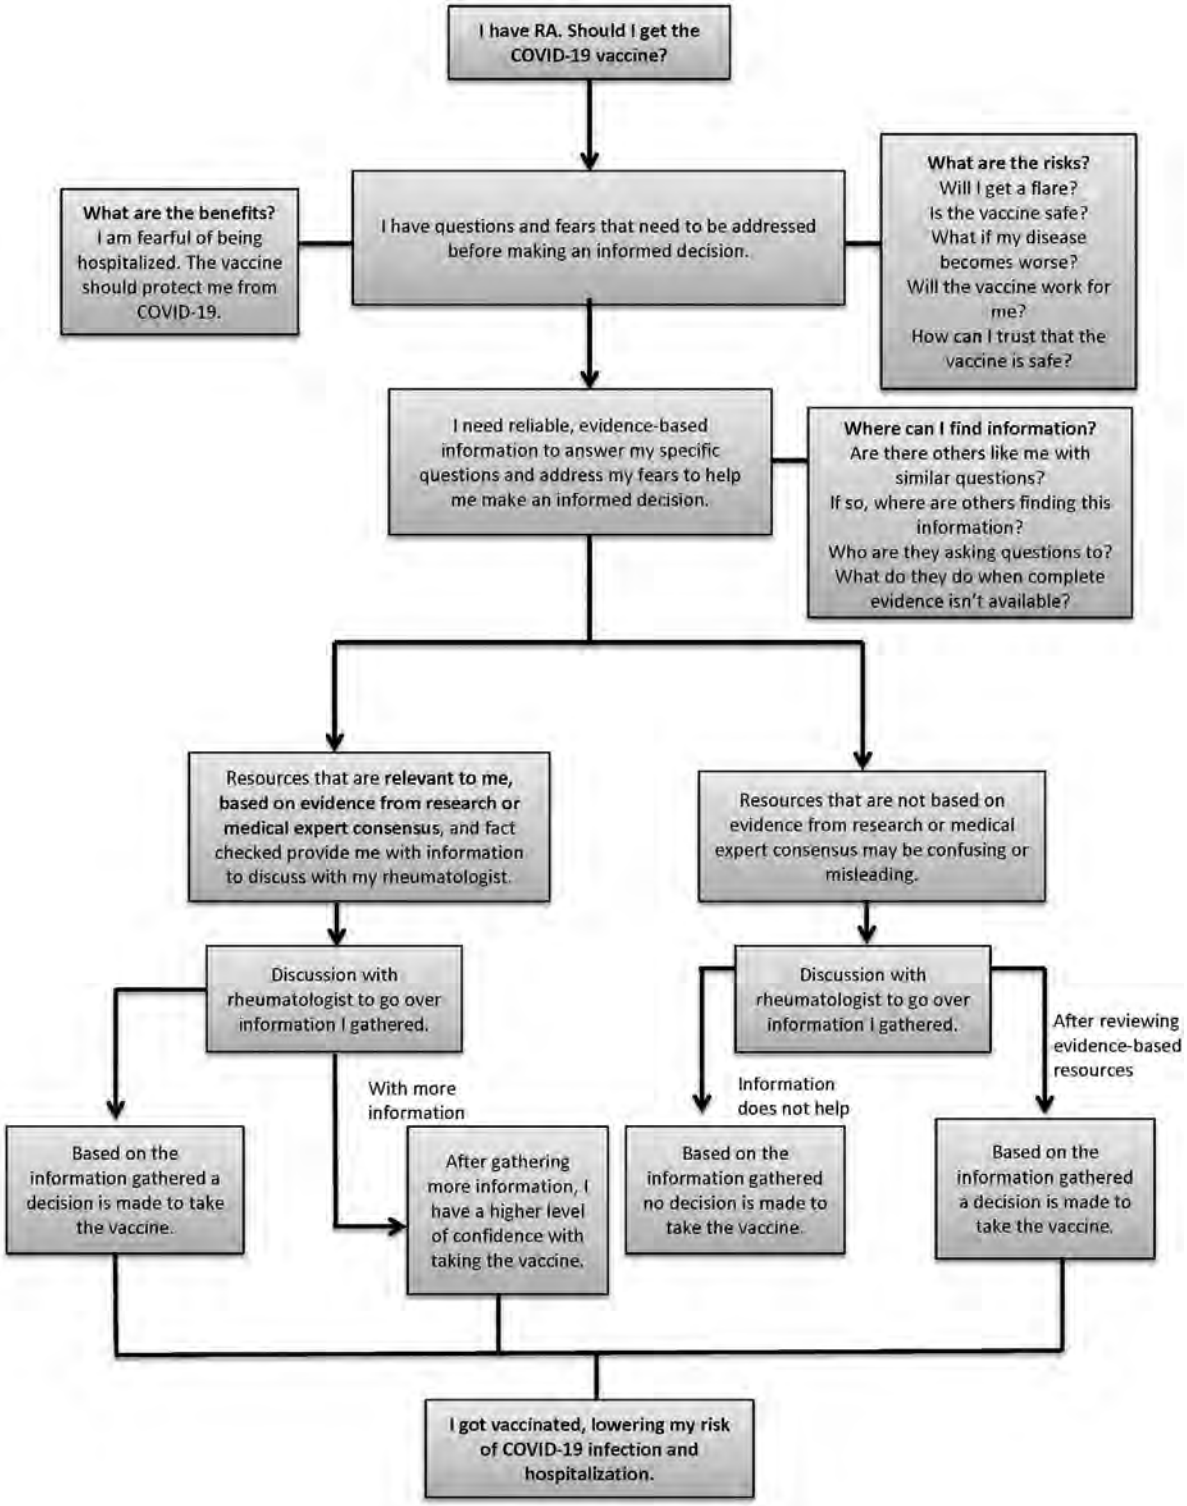


Figure 1. My steps to arrive at an informed decision about the COVID-19 vaccine.

Family Planning while Living with Rheumatoid Arthritis

Shannan O'Hara-Levi, Monroe, NY

SESSION INFORMATION
Session Date: Sunday, November 7, 2021
Session Title: Patient Perspectives Poster (PP01–PP09)
Session Type: Poster Session B
Session Time: 8:30AM–10:30AM

Background/Purpose: Over the course of my 30+ years living with Polyarticular Juvenile Rheumatoid Arthritis, I have never had long term success on any one biologic treatment, and disease progression continued eventually resulting in a need for a bilateral shoulder replacement surgery which I had in 2018. My husband and I have been hoping to start a family for years but have had to accommodate our plans due to my arthritis. We began seeing a fertility specialist years ago and while my initial fertility lab results were within a normal range, but a major flare prevented us from moving forward with treatments. We are finally in a place now where our family planning conversations can begin again. After an insurance battle early this year, I am now on a biologic that has some data indicating safety and efficacy for women who are pregnant or trying to become pregnant. With the guidance of my fertility specialist, we have added in vitro fertilization (IVF) medications and various supplements, changed my nutritional plan, and incorporated acupuncture into my care plan. Additionally, this May we had our first frozen embryo transfer that we hope to will result in a successful pregnancy.

Intervention: A care plan that empowers me to have a successful pregnancy is my primary focus and goal. In order to do that, careful family planning is essential for my partner and I with my rheumatologist and fertility specialist. Unfortunately, there is not enough data to suggest an ideal care plan for a person like me: someone that grew up with juvenile rheumatoid arthritis and is now of reproductive age hoping to start a family. Neither my fertility doctor nor my rheumatologist has all the answers. I am charged with finding the answers I need, carefully organizing my health information, and coordinating my care between providers.

Maintenance: The onus is on me to explain my arthritis to my fertility specialist and hope that they are able to make informed care plans based on their experience with others in a similar position. Similarly, communicating with my rheumatologist about my family planning is a responsibility that rests on my shoulders. In order to be an effective communicator, I have to organize my life around these two parts of the healthcare world and find ways to bring them together. Being a planner is critical to my care so that I can ensure all aspects of my healthcare team are coordinating to accomplish my care goal: a successful pregnancy while managing my arthritis. Support from other patients like me is essential, and I have found community through social media channels that keep me connected with others in a similar situation.

Quality of Life: We have been working for years to get my arthritis under control to a point where I would be healthy enough to effectively plan our family. I am thankful that we are finally at a point where we can move toward that future based on my medication plan, my successful bilateral shoulder replacements, and my care plan with my fertility specialist. While my juvenile rheumatoid arthritis symptoms are still present, they are maintained, allowing for better function as I pursue IVF treatment and family planning. The peace of mind that we are now able to work toward my ultimate care goal of starting a family has certainly improved my quality of life.

Discovering 'I' Through Interaction with Support Group Members: A Place of Empathy That Transcends the Limitations of Words

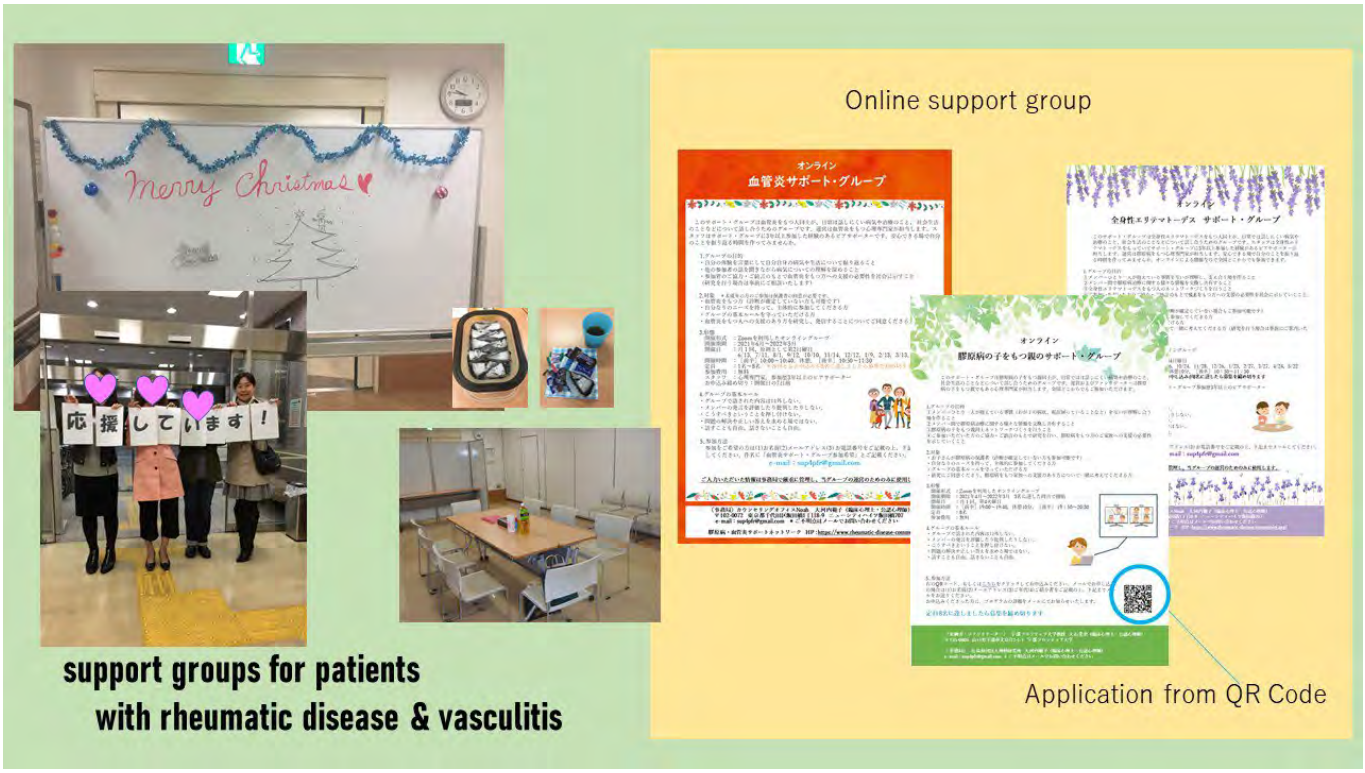
Noriko Okochi[1], Eiji Oishi[2] and Mika Ishiguro[1], [1]Rheumatic Disease and Vasculitis Support Network Japan, Tokyo, Japan, [2]Rheumatic Disease and Vasculitis Support Network Japan, Yamaguchi, Japan

SESSION INFORMATION
Session Date: Sunday, November 7, 2021
Session Title: Patient Perspectives (PP10–PP13)
Session Type: Patient Perspectives
Session Time: 3:30PM–4:30PM

Background/Purpose: Since 5-year-old, I have had unexplained symptoms. At the age of 13, my whole body became inflamed. The pain was so intense that I could move just one finger. I could not drink or speak. I found a way to keep from crying because it hurt so much that my parents would pat me on the head. I imagined myself as a log and stopped moving. My world was in my brain. Fortunately, Dr. Tomisaku Kawasaki and other experts in immune diseases helped me to live. I was diagnosed with polyarteritis nodosa around 2000, at the age of 26.

The impact on my personality of living through adolescence without knowing the true nature of my symptoms was immeasurable. Because I felt so close to death, I felt emotionally distant from others. My mind was a mixture of isolation, sadness, confusion, anger, and guilt for having that anger. I found it difficult to understand what was going on inside, even with my family and friends. I became interested in the human mind and became a psychologist. While

Information dissemination via website.



Support groups based on illness and living environment.

practicing psychotherapy in psychiatric, school, and pediatric settings, I was confronted with my habit of suppressing emotions and my tendency to deny my symptoms. I tried to sort out my internal issues through the "language" used by psychologists. However, the more I learned about the language used by psychologists, the more I realized that there were limits to explaining the mind through words.

Intervention: Yalom(1980) says, "Denial is a powerful and ubiquitous defense". For me, living with symptoms, coping with denial, repression, and dissociation was not something that needed to be "treated" but something that was "necessary". In Japan, there are very few opportunities to talk about one's disease. However, I was convinced that the most useful psychological support for a patient with rheumatic disease was the help of fellow patients.

Maintenance: In 2013, I started a support group for patients with rheumatic disease. The purpose of the group was to share experiences and exchange information, to better understand the disease, and to think about facilitating social life. After the corona outbreak, the group moved online and continued. The members who participated in the meeting gradually became staff members to support the participants. Currently, in addition to "the Rheumatic Disease Support Group", "the SLE Support Group", "Vasculitis Support Group", and "Support Group for Parents of Children with Rheumatic Disease" are conducted by these staff members.

Quality of Life: The members are gaining more control over their treatment. Knowing about the prognosis of the disease has led to mental stability. Some members who had lost their sense of self are reaffirming their own value and moving toward self-actualization. A member who lost her eyesight due to the effects of steroids became a swimmer. Some of the members who are inspired by these powerful people turn their introverted viewpoints outward and open themselves up to the hope of self-realization.

Japan is a country where harmony is valued and cooperative behavior is praised, so it is difficult to focus on individual suffering. The fact that members of a support group for people with invisible illnesses have shared their difficulties with the public has caused a stir in the support of people with other kinds of difficulties in Japan.

"Our Arthritis May Be Chronic but We Are Definitely Iconic" - Two Teens Created a National Podcast for Youth with Rheumatic Diseases

Trishtha Peters[1] and **Natasha Trehan**[2], [1]University of Ontario, Toronto, ON, Canada, [2]University of Ottawa, Toronto, ON, Canada

SESSION INFORMATION
Session Date: Sunday, November 7, 2021
Session Title: Patient Perspectives (PP10–PP13)
Session Type: Patient Perspectives
Session Time: 3:30PM–4:30PM

Background/Purpose: Trish Peters was diagnosed with JIA at 11. She has been on Methotrexate to lessen disease activity for her knees and hands. She does competitive swimming, running and rugby. It has taken her a long time to understand and accept that she is different from other people in how her body heals, but she has learned to appreciate it as a part of who she is. At 13, Natasha had inflamed fingers, wrists, ankles and feet in which an MRI showed extensive damage due to JIA. She started Prednisone and then switched to Methotrexate. However, six months in, there was no change to her swelling or pain. Natasha took Humira, then Actemra, then Tocilizumab, all of which failed to reduce her disease activity. Finally, ten corticosteroid injections in her joints and triple therapy - a combination of Methotrexate, Sulfasalazine and Plaquenil brought her blood and her inflammation under control. She believes that her healthy eating habits, her regular dance routine, and daily meditation along with the medications have provided her with a pain-free, happy and manageable lifestyle.

Intervention: Our friendship evolved in January 2020, when we both became leaders at Cassie and Friends. While organizing events for youth together we discussed our stories and realized that we shared similar experiences. We both had struggled to find support and talk to people our age about how we felt. We decided to create a platform to make sure that young patients who are initially diagnosed with any type of rheumatic disease do not go through the same rough journey we did. We co-founded and launched a podcast called Take a Pain Check (TAPC) in March of 2021. It is available on Spotify, YouTube, Apple podcast, and Anchor. Every week, TAPC features a new guest who shares their unique lived experience of rheumatic disease, offering listeners different perspectives to learn from.

Maintenance: TAPC has received amazing feedback from numerous guests - with and without arthritis as well as from hospitals and rheumatology clinics across Canada who have mentioned how youth need the support, moments of laughter, and fun related to their condition. Many guest speakers wished a platform like this existed when they were diagnosed as youth.

Quality of Life: TAPC is currently changing the lives of youth impacted with rheumatic diseases by modelling a wide variety of perspectives and experiences. This is especially important for youth who, like us, may feel too shy or lack the resources to advocate for themselves or meet others. Through TAPC, we have been able to spread the word about research being done. We want to ensure that people don't have to search endlessly for support. We want to actually make a difference in the lives of young people and inspire them to make the best out of this disease.

The accessibility of our podcast. We are available on multiple social media platforms in order to support our audience.

Abstract Number: PP12

Fighting for the Care We Deserve: My Experience as a Latina Patient-Researcher During the COVID-19 Pandemic

Guadalupe Torres[1], Courtney Wells[2] and Kristine Carandang[3], [1], [2]University of Wisconsin-River Falls, School of Social Work, St. Paul, MN, [3]Global Healthy Living Foundation, CreakyJoints, San Diego, CA

SESSION INFORMATION
Session Date: Sunday, November 7, 2021
Session Title: Patient Perspectives (PP10–PP13)
Session Type: Patient Perspectives
Session Time: 3:30PM–4:30PM

Background/Purpose: I am a 23-year-old first generation Latina with rheumatoid arthritis (RA). Despite being disproportionately affected by rheumatic conditions, the perspectives of Latinx remain poorly understood by rheumatology professionals and as such, we are more likely to experience negative health outcomes. I have spent years disengaged with my healthcare, without health insurance or a rheumatology provider. Western medicine and my culture's beliefs are often in conflict. Because I was poorly educated about my disease, I tried so many medications that I was diagnosed with fatty liver disease in 2017. I have felt isolated, without community or support since being diagnosed at 16.

Intervention: In 2020, I was approached by a team of researchers, who also have arthritis, to work as a patient-researcher on a qualitative research project about people's experiences living with rheumatic conditions during the COVID-19 pandemic. This project purposefully recruited Black, Indigenous, People of Color (BIPOC) and others from underrepresented communities. I was excited to bring my unique perspective and expertise and to ensure that Spanish-speaking populations were included. From the news and personal experience, I knew that BIPOC, specifically Latinx, were being hit the hardest by COVID-19 because many were classified as essential workers. Serving as a critical research team member allowed me to practice patient advocacy in the planning, recruitment, data collection, analysis, and dissemination of this project.

Maintenance: Collaborating in this research has helped me build connections with other rheumatology patients, increase my health knowledge, and better manage my mental health during the pandemic. During analysis with the research team, for the first time, I processed my own illness story including the opportunities and barriers that I have faced. In interactions with study participants, I listened to how others were coping and decreasing their risk to COVID-19, which lessened my anxiety as an essential worker and a Person of Color with RA. I also reflected on my own education and personal and professional skills, and felt empowered to help members of my community who continue to lack key health information. These experiences culminated in me fighting to obtain the care I deserve; although it's been years since I last saw my rheumatologist, I am in the process of obtaining health insurance and follow-up care.

Quality of Life: Before this project, I was not an activated patient, nor did I know what I wanted to do after graduating college. Being part of a team of patient-researchers has allowed me to talk about my illness story-in-progress for the first time. I am now actively reflecting on what my role is as a young advocate. This project has shown me how multiple factors (e.g. government response, medical response and cultural/linguistic response) are not in favor of BIPOC and how it affects our financial wellness and physical, mental/emotional, and social health. These lessons have led me to change career paths and work for a Latinx non-profit, and I am reinvigorated to utilize my expertise as a first-generation Latina with a rheumatic condition to fight for my own health as well as for health equity in my community.

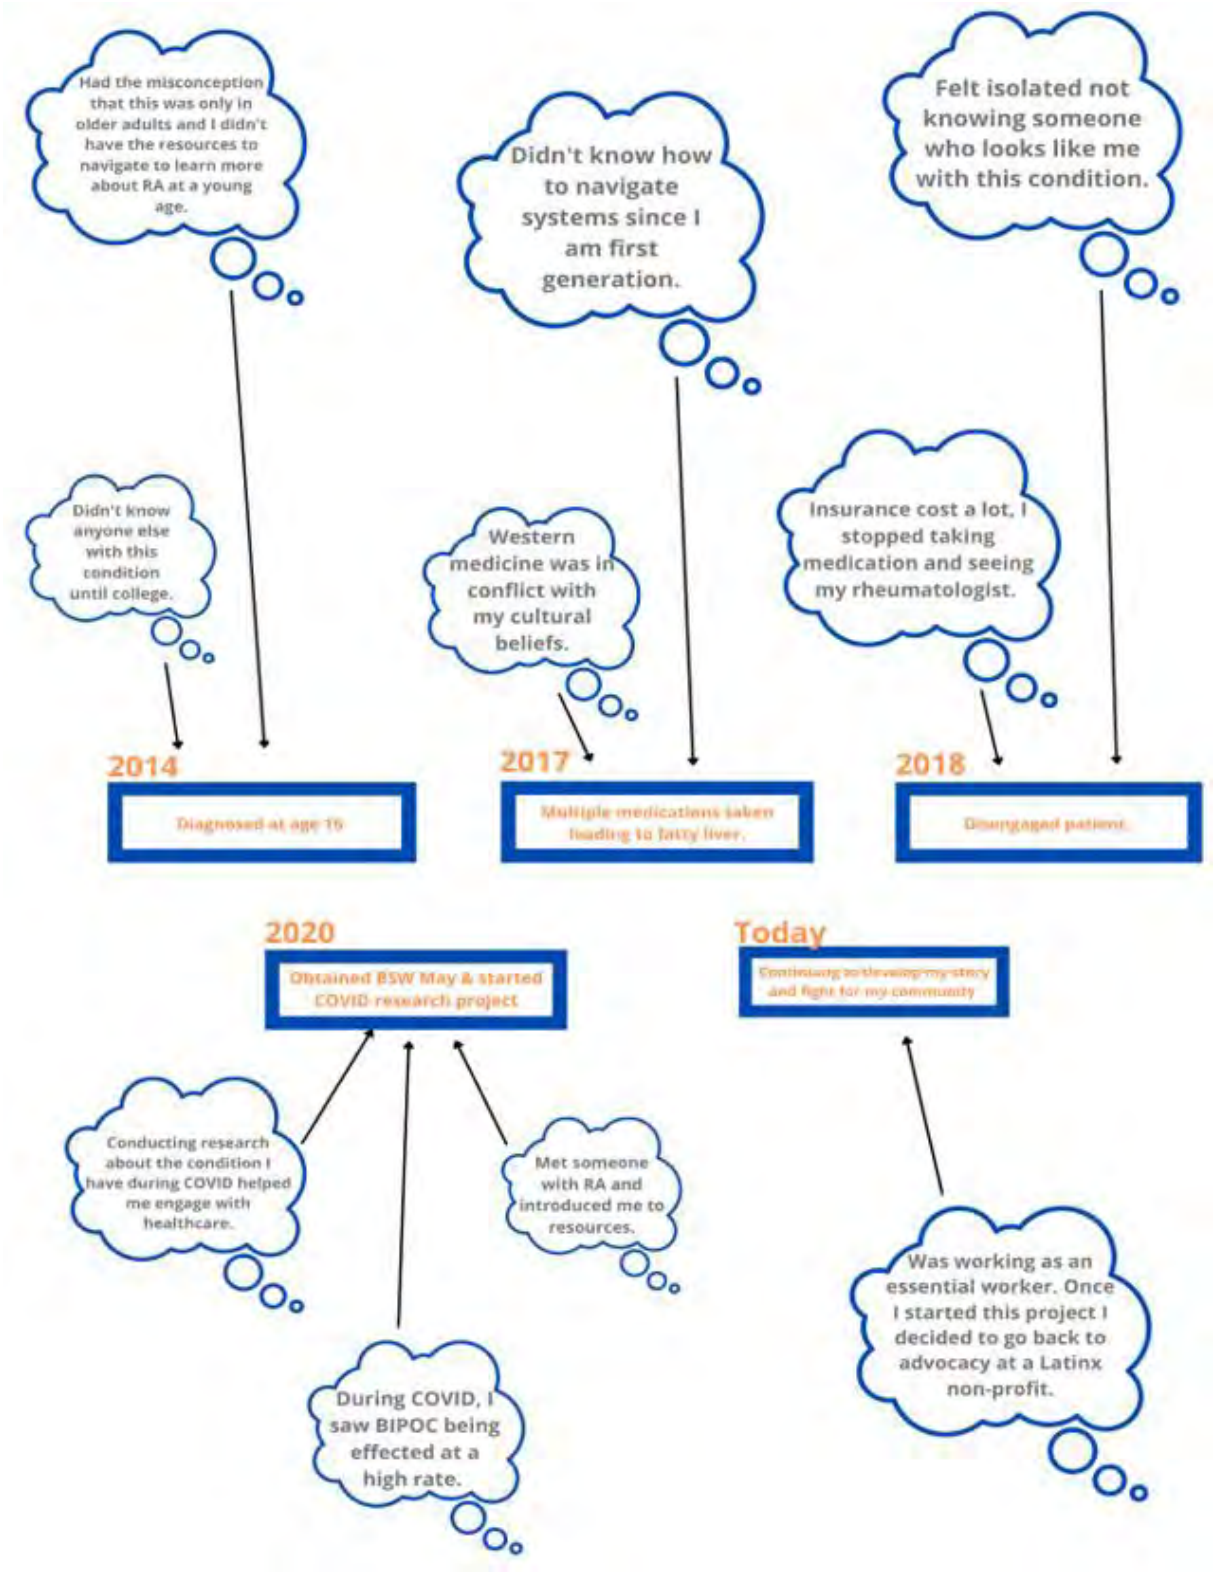

Figure 1. Patient timeline from pediatric diagnosis to adult re-engagement.

CreakyKitchen: How the Online Cooking Show I Started is Building Community and Encouraging Better Food Choices for Me and Others Living with Rheumatic and Chronic Disease

Chantelle Marcial, Boston, MA

SESSION INFORMATION
Session Date: Sunday, November 7, 2021
Session Title: Patient Perspectives (PP10–PP13)
Session Type: Patient Perspectives
Session Time: 3:30PM–4:30PM

Background/Purpose: At 19, I was mis-diagnosed with Lupus as it was a common condition in my family. My treatment at that time was mainly DMARDs, with little to no results. Approximately six years later, I was connected with my current rheumatologist who did a new panel of testing and accurately diagnosed me with rheumatoid arthritis (RA). I have participated in clinical trials and am currently well-controlled on biologic monotherapy.

Table 1 CreakyKitchen Events, 2020-2021

Recipe	Cooking/Nutrition Tip	Comments from Attendee
Stuffed Mushrooms Topped with Breadcrumbs and Parmesan	To keep your mushrooms fresh, store them in a cool place in their original packaging or a paper bag that breathes; try to use within 3 days.	"This is like being in the studio of a Food Network Show." – Patient living with HIV/AIDS
AppleBerry Slump with Drop Dumplings	Use kitchen tools like dycem to help open jars and make cooking easier.	"Celebrating the Holiday season during the pandemic was definitely isolating, but participating in the CreakyKitchen event allowed me to connect to others and feel excited about little adaptations that make cooking with arthritis easier." – Guest Occupational Therapist
Salad with Herbed Salmon	Look for "snack upgrades" to make healthier choices. Switch chips to whole grain rice cakes, switch salty pretzels to salty kale chips.	"CreakyKitchen Allows members of the community to feel normal, create positive associations with their conditions and have fun along the way." – Guest Registered Dietitian
Berry Chia Jam	Chia seeds are a great way to feed gut bacteria and keep our microbiome healthy.	"CreakyKitchen is such an important tool to have right now. It is giving us tools and bringing us together." – Patient living with Rheumatoid Arthritis
Vegetable Soup	Soups are a great way to use leftover vegetables in the fridge that are close to going bad.	"Having CreakyKitchen and learning new ways to navigate cooking, while chronically ill, is invaluable to the arthritis community because food is medicine for the body and soul." – Guest Body-Centered Psychotherapist and Certified Massage Therapist
Pasta Primavera	If you hate the smell of garlic on your hands, rub them with lemon juice when you're done cutting the garlic.	"Listen to your body, take plenty of breaks, don't push." – Patient living with Psoriatic Arthritis

Figure 1. Graphic created to announce CreakyKitchen events via emails and on social media posts. This graphic depicts a woman cooking with arthritis in her wrists.

Intervention: In 2020 during the COVID-19 pandemic, I was communicating with staff at the Global Healthy Living Foundation, CreakyJoints. During an exchange, I mentioned how a cooking show could be a fun idea to build a sense of community and to share cooking tips and tricks with other patients, and to introduce people to new recipes that are easy, healthy, and delicious. People with chronic disease often go through a trial-and-error process to figure out what foods help them feel good. In collaboration with the Global Healthy Living Foundation, CreakyKitchen was born in November 2020 as a way to come together as a community in a fun and stress-free environment to share strength and experience through cooking and nutrition. We send out email invitations, make announcements on social media using a graphic created to announce CreakyKitchen events (Figure 1), and then come together virtually as a community each month. I share a recipe while people cook and follow along from the comfort of their homes. We are joined by experts and guests in our community who share information about nutrition, along with tips for navigating the kitchen and cooking with arthritis (Table 1).

Maintenance: Our CreakyKitchen community has grown with each monthly streaming event, and now more than 100 people regularly attend in real-time. Being able to connect with members of my CreakyKitchen community has been a huge boost for my mental health. Also, I spend time each month researching healthier recipes to share, which has made an impact on my own meals at home, outside of the show. I have started re-thinking and changing my own go-to recipes and finding ways to alter them to keep the flavors as good as they were, but with a healthier twist. In doing so, I have already shed a few pounds, which is a great relief for my back, knees, and ankles.

Quality of Life: CreakyKitchen gives me a fun, interactive monthly event to look forward to, which has been especially important during the COVID-19 pandemic. I get to connect, share a few laughs and a great recipe (or two) with

other people who are living with rheumatic conditions around the world. Plus I always learn something new about cooking and nutrition thanks to our CreakyKitchen guest co-hosts. I have been able to take information from their segments and apply it in everyday life. From kitchen hacks, to remembering to rest, to finally planning my own herb garden, these have all been great learning moments. Rest has been especially helpful in that I usually push myself to exhaustion and have a hard time getting back to baseline. The reminders to stay mindful of my symptoms and follow their cues has been helpful in better managing my RA.
