Association of Mycophenolate and Azathioprine Use with Cognitive Function in Systemic Lupus Using a Bayesian Longitudinal Item-response Theory Model

Chrisanna Dobrowolski[1], Juan Pablo Diaz Martinez[2], Michelle Barraclough[3], Roberta Kretzmann[4], Sherief Marzouk[4], Kathleen Bingham[3], Lesley Ruttan[5], Dorcas Beaton[6], Joan Wither[3], Carmela Tartaglia[7], Patti Katz[8], Mahta Kakvan[9], Nicole Anderson[10], Dennisse Bonilla[3] and Zahi Touma[4], [1]Icahn School of Medicine at Mount Sinai Hospital, New York, NY, [2]Schroeder Arthritis Institute, University Health Network, Toronto, ON, Canada, [3]University Health Network, Toronto, ON, Canada, [4]University of Toronto, Toronto, ON, Canada, [5]University Health Network, Toronto Rehabilitation Institute, Toronto, ON, Canada, [6]Institute for Work & Health, Toronto, ON, Canada, [7]Krembil Brain Institute, University Health Network, University of Toronto, Toronto, ON, Canada, [8]University of California San Francisco, San Rafael, CA, [9]University Health Network, University of Toronto, Toronto, ON, Canada, [10]Schroeder Arthritis Institute, Krembil Research Institute, University Health Network and University of Toronto, Toronto, ON, Canada

SESSION INFORMATION

Session Date: Tuesday, November 14, 2023
Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster III
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Cognitive dysfunction (CD) is a common and often deleterious manifestation of systemic lupus erythematosus (SLE). CD is usually operationalized on the American College of Rheumatology Neuropsychological Battery (ACR-NB) as any z-score of ≤-1.5 on ≥2 domains or z ≤-2 in ≥1 domain; this approach necessarily omits information regarding affected cognitive domains. Using each individual ACR-NB z-scores, the aim of this study was to assess in further detail the association of azathioprine (AZA) and mycophenolate (MMF) use with performance in specific cognitive domains given that these medications have demonstrated overall neuroprotective qualities in prior studies.

Methods: Consecutive, adult SLE patients presenting to a single tertiary care center were considered for participation, providing demographic, clinical and psychiatric data, at multiple visits (0, 6, 12 months). Bayesian longitudinal item response theory (IRT) modelling using the cumulative dose of AZA and MMF, demographic and clinical variables as fixed effects and tests/domains and time/participant as random effects were undertaken to assess ACR-NB z-scores over time. Model One was fitted with an easiness parameter that was estimated for each domain and for each test nested within each domain (higher values represent a higher mean z-scores which represents better cognition). Model Two used the same structure as Model One but added a random slope for the cumulative dose of AZA to vary amongst domain and tests. Finally, leave-one-out cross-validation (loo-cv) was used to determine the best statistical model for our data.

Results: Three hundred participants representing 676 patient visits completed the study. The mean overall z-score with all covariates set to zero (ie. intercept) was -0.84 (95% CrI -1.73, 0.04). Cumulative AZA dose (decigrams/kg) was associated with a z-score increase of 0.34 (95% CrI -0.08, 0.61) on average (Figure 1). Time was also associated with a z-score increase, meaning that on average, z-scores improved as time passed. MMF use was not associated with a protective effect against CD (Figure 1). The easiness parameters for visual-spatial construction domain had the lowest estimate (Figure 2). On average, this domain decreased the z-score by -0.69 (95% CrI -1.77, 0.11). Of note, we found that simple attention and processing speed had a null effect on the mean z-score (Figure 2) but when examining each test within this domain we found

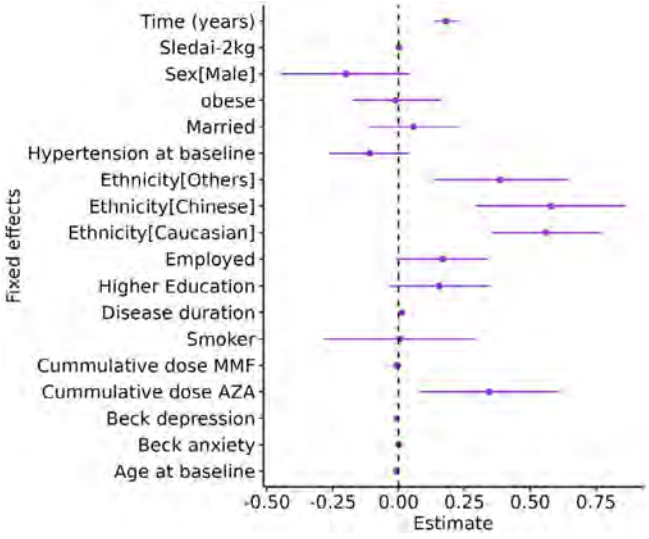

Figure 1. Posterior uncertainty intervals for the fixed effects in our model. X axis represents the distribution of the beta coefficients. Y axis represents the parameters where inference is made. The dark shaded region represents the point estimate from a frequentist point of view and the light shaded region represents the 95% uncertainty interval (CrI), i.e., with 95% of probability the estimate would lie in that region.

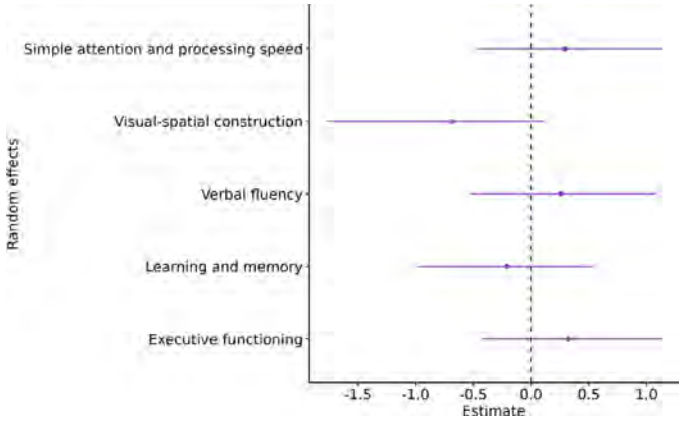

Figure 2. Posterior uncertainty intervals for the ACR Neuropsychiatric Battery domains (as random effects). X axis represents the mean z-score change and Y axis represents the parameters where inference is made. The dot on the graph represents the point estimate and the line represents the 95% CrI.

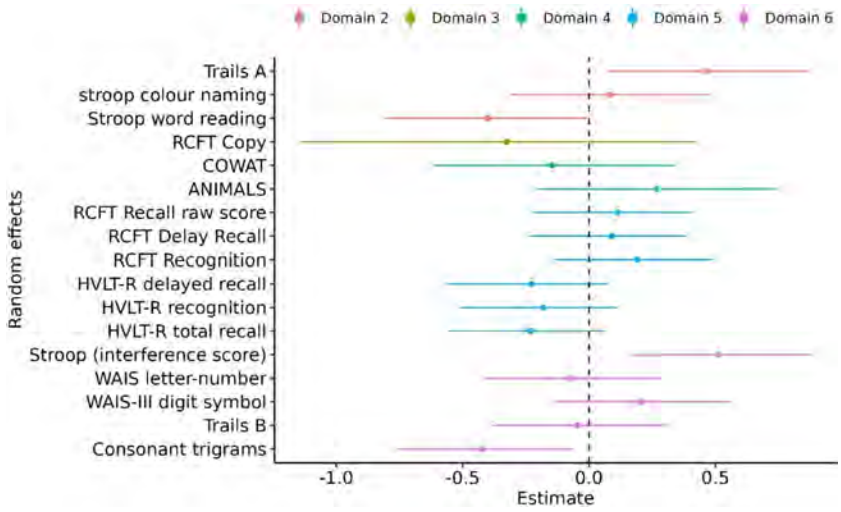

Figure 3. Posterior uncertainty intervals for the ACR Neuropsychiatric Battery tests (as random effects). X axis represents the estimated mean z-score change over time and Y axis represents the cognitive test parameters where an inference is made. Each color represents the cognitive domain where the test is nested. The dot on the graph represents the point estimate and the line represents the 95% CrI.

that Trails A had a positive effect while STROOP word reading decreased the mean z-score (Figure 3). Loo-cv showed Model One (without adding cumulative AZA dose as a random slope) to be the best fit for our data.

Conclusion: This analysis demonstrated that cognition may improve over time in patients with SLE. It also highlighted which cognitive domains and tests on the ACR-NB are more likely to be affected. Similar to our prior study, increasing cumulative AZA dose was associated with a protective effect against CD, while MMF use was not. This is the first longitudinal IRT model that examines trajectories of individual ACR-NB z-scores and relationship with immunosuppressant use. Additional studies are warranted to further investigate visual-spatial function in SLE, as well as the relationship of AZA and SLE-CD.

Therapeutic Drug Monitoring (TDM) of Hydroxychloroquine in Whole Blood: Analysis of over 10,000 Patient Results Using Lab Developed Liquid Chromatography Tandem Mass Spectrometry

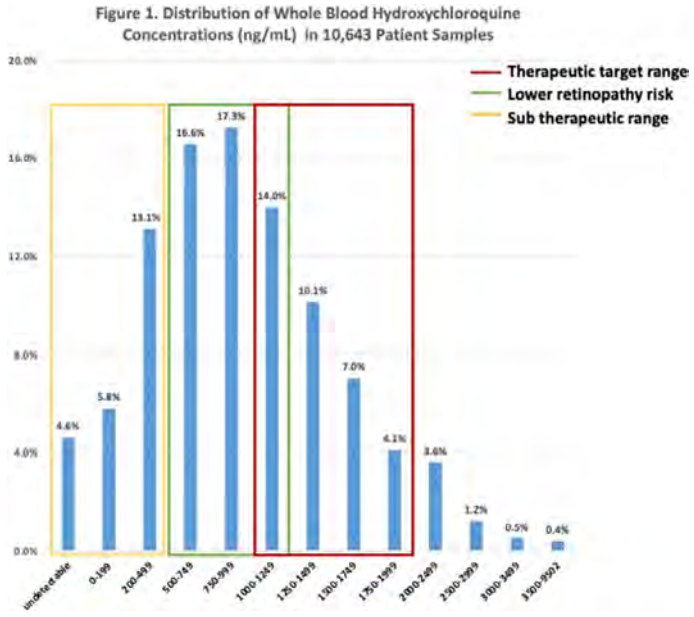
Jane Yang, Brett Holmquist, Rubio Punzalan and Kelly Chun, Labcorp, Calabasas, CA

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster III
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

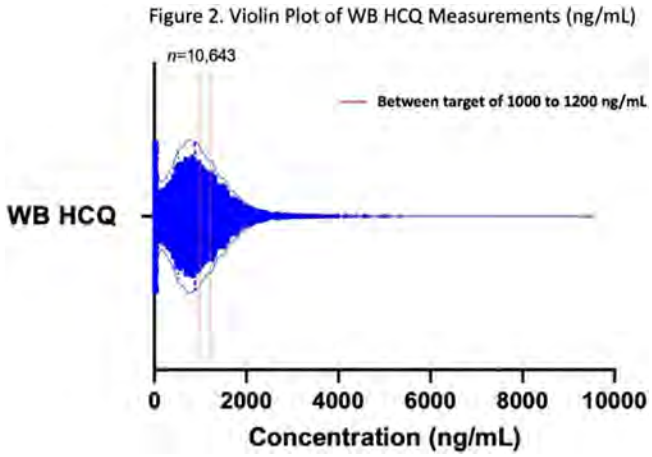
Background/Purpose: Hydroxychloroquine (HCQ), a mainstay SLE therapy, improves survival and reduces flares. Therapeutic drug monitoring (TDM) may be useful in 1) identifying and improving adherence issues, 2) titrating daily dose to achieve therapeutic benefits associated with whole blood HCQ >1000 ng/mL while 3) minimizing cumulative exposure by keeping levels < 2000 ng/mL.[1,2]*Whole blood* (WB) is the correct specimen because WB HCQ levels are higher than serum or plasma levels, more stable and reflective of the last month of HCQ ingestion, and are better correlated to efficacy and retinopathy risk.[2] Here, we report WB HCQ of 10,463 clinical patient samples and their distribution according to therapeutic targets.

Methods: HCQ in whole blood is quantitated by liquid chromatography tandem mass spectrometry (LC-MS/MS). Recommended sample collection is ~ 3 - 6 months into regular stable dosing to reach steady state and correlate with clinical efficacy.

Results: Distribution of WB HCQ in 10,463 patient samples showed more than one-third (3752, 35.9%) were within the target range of > 1000 and < 2000 ng/mL (Figure 1); About one-quarter (2568, 24.5%) were within a tighter therapeutic target window of 1000 to 1500 ng/mL. The vast majority (9852, 94.2%,) of all WB HCQ were < 2000 ng/mL with a small



Distribution of Whole Blood Hydroxychloroquine Concentrations in over 10,000 patients



Violin Plot Showing WB HCQ Concentrations over a Wide Range

percentage >2000 ng/mL (611, 5.8% between 2000 – 9502 ng/mL). About one-third (31.3%) were higher than 1177 ng/mL which corresponds to the upper tertile with higher retinopathy risk described by Petri *et al*.[1] Adherence issues were evident in 10.5% (1102) with undetectable (483, 4.6%) and very low (< 200 ng/mL) drug (619, 5.9%) . Depending upon the target threshold, levels < 500 ng/mL or < 1000 ng/mL may be considered subtherapeutic as seen in 2498 (23.9%) and 4263 (40.7%) samples, respectively.

Conclusion: Due to wide pharmacokinetic variability and adherence issues, a given prescribed dose of HCQ does not correspond to WB HCQ, e.g. following 4, 5 or 6 mg/kg/day, levels are known to vary widely from subtherapeutic < 500 to >2000 ng/mL.[2] Here, our clinical database reiterates this wide range in WB HCQ levels from undetectable (< 25) to 9502 ng/mL in 10,463 patient samples. One-quarter or one-third were within the therapeutic target range of 1000-1500 or 1000-200 ng/mL where >1000 has been associated with better disease control and survival. At the same time, levels less than 1177 avoid higher retinopathy risk (seen in green on Figure 1).1 A small percentage of samples, 5.8%, were higher than 2000 ng/mL, suggesting usefulness of TDM to fine tune daily dose. In 10%, there was evidence of poor adherence, with very low or nil drug, and one-quarter to 40% were subtherapeutic (< 500 or < 1000). The potential benefits of HCQ are many and include reduced flares and improved lupus nephritis, thrombosis risk, and long-term survival. At the same time, prescribed dose does not predict therapeutic levels. TDM-based counseling and dose adjustment may be instrumental in optimizing HCQ benefits while minimizing retinopathy risk.[1,2] In conclusion, our analysis demonstrates the growing use of HCQ TDM to facilitate dose titration to safe and most effective target levels.

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster III
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

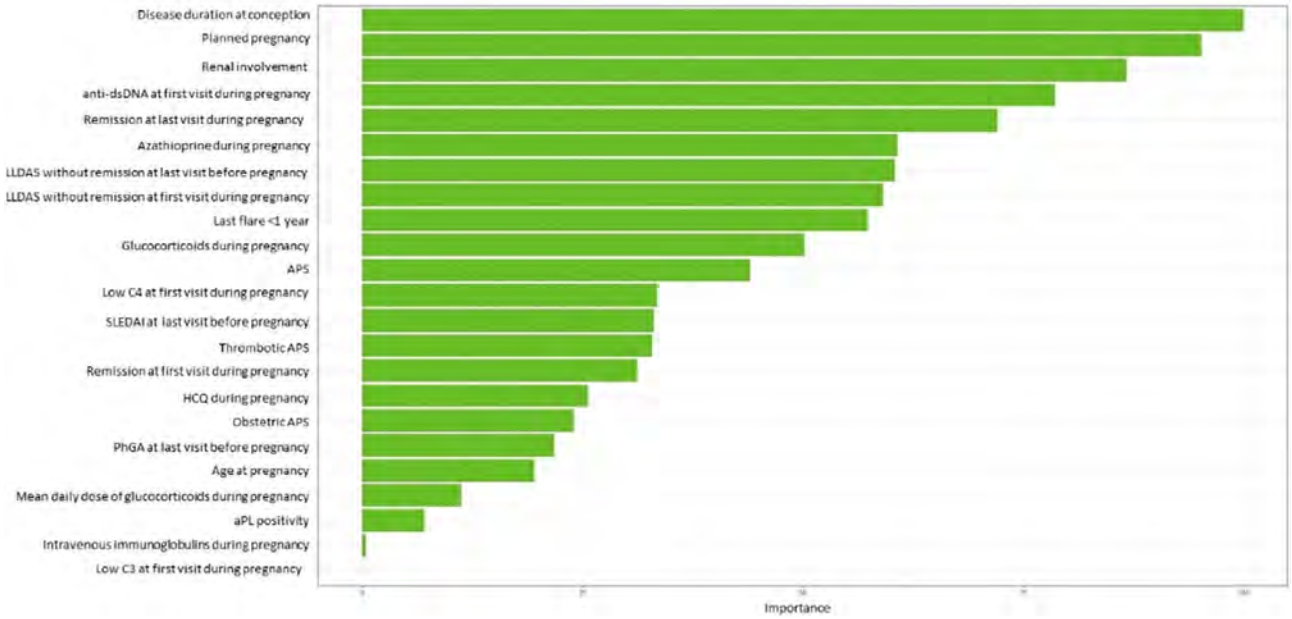
Background/Purpose: Systemic Lupus Erythematosus (SLE) patients are at risk of disease flare during pregnancy; risk stratification is crucial for personalized treatment and monitoring. Our hypothesis is that a machine learning (ML) approach could improve the flare prediction accuracy, enabling early identification of high-risk pregnancies. In this study, we aimed to build a ML model capable of predicting disease flares based on clinical and serological data obtained early in pregnancy.

Methods: 105 pregnancies in 84 SLE patients were prospectively followed at 4-week intervals during pregnancy and puerperium. At the first visit during pregnancy, demographic and clinical data, treatments as well as disease state at the last visit before pregnancy were gathered. At each visit, disease activity was assessed by means of the Systemic Lupus Erythematosus Disease Activity Index (SLEDAI) and Physician Global Assessment (PhGA). Disease state was defined according to the LLDAS and DORIS definitions. Flares were defined as the emergence or worsening of symptoms requiring therapeutic adjustments or hospitalization. Classical inferential statistics by means of multivariate logistic regression were paralleled by a ML approach to predict the risk of flare based on baseline variables. After missing data imputation and variable filtering, the dataset was subdivided into training and test set, with 70-30% split. A Generalized Linear Model (GLM) with repeated cross-validation was then fitted on the training set, with the aim of predicting "the emergence of flares".

Table 1: characteristics of the cohort

	Overall	Patients with flare during pregnancy (N=25)	Patients without flare during pregnancy (N=80)	P value
Age at conception (years, mean±SD)	32.5±4.6	31.6±4.7	32.7±4.6	ns
Disease duration at conception (years, mean±SD)	10.1±5.9	6.8±4.0	11.2±6.0	0.001
Planned pregnancy (%)	65 (61.9)	32%	70%	<0.01
Time between last flare and pregnancy (year, mean±SD)	4.6±3.8	3.9±3.1	4.8±4.0	ns
aPL (%)	51 (48.6)	52%	46.8%	ns
APS (%)	13 (12.4)	16%	10.1%	ns
Patient characteristics at last visit before pregnancy				
SLEDAI (mean±SD)	2 ± 2.1	2.6±2.8	1.8±1.7	ns
Remission (%)	74 (70.5)	52.3%	87.5%	<0.01
LLDAS but not remission (%)	13 (12.4)	27.3%	9.7%	0.045
Patient characteristics at first pregnancy visit				
SLEDAI (mean ± DS)	1.8±2.5	3.1±1.5	1.3±3.1	0.003
Remission (%)	84 (80)	56.5%	91%	<0.01
LLDAS but not remission (%)	9 (8.6)	26%	3.8%	<0.01
Physician global assessment (mean±SD)	0.1 ± 0.5	0.34±0.7	0.04±0.2	<0.01
C3 hypocomplementemia (%)	46 (43.8)	66.6%	47.7%	ns
C4 hypocomplementemia (%)	28 (26.7)	47.6%	26.8%	0.07
Anti-dsDNA positivity (%)	22 (20.9)	42.8%	19.1%	0.03

Figure 1



Results: 25 flares occurred among the 105 pregnancies examined (26.25%). Patients' demographic and clinical data are shown in Table 1. At univariate analysis, the variables significantly associated with flare were LLDAS without remission at last evaluation (p=0.045) and at first visit during pregnancy (p< 0.01), shorter disease duration (p< 0.01), anti-dsDNA positivity (p=0.03), higher SLEDAI (p=0.02) and higher PGA (p=0.02) at first visit during pregnancy. Remission status at both last (p< 0.01) and first visit during pregnancy (p< 0.01) and planned pregnancy (p< 0.01) were protective. In the multivariate analysis, planned pregnancy and disease duration remained significant (OR 0.84 CI 0.72 to 0.98 p=0.02 and OR 0.18 CI 0.45 to 0.78 p=0.02, respectively). The ML model achieves a high accuracy of 96.3% in predicting the target, unlocking the possibility to enact prevention measures on fragile subjects. Additionally, the model identifies key parameters for patient information collection. The model's optimization gives different weights and statistical importance to each variable (Figure 1), confirming the importance of the two previously recognized predictors, including renal involvement, among others.

Conclusion: The constructed ML model has demonstrated remarkable accuracy in identifying flare occurrences during pregnancy based on baseline data. It is worth noting that both the statistical analysis and the ML model emphasized parameters such as proper pregnancy planning and disease duration at conception as the most influential in predicting the likelihood of a flare during gestation.

Recurrent Intracellular Infections Cluster Together in Patients of SLE with Lymphopenia and Active Disease

Rudrarpan Chatterjee[1], Sarit Pattanaik[2], Durga P Misra[1], Vikas Agarwal[1], Able Lawrence[1], Ramnath Misra[3] and Amita Aggarwal[1], [1]Sanjay Gandhi Postgraduate Institute of Medical Sciences (SGPGIMS), Lucknow, India, [2]SCB Medical College and Hospital, Cuttack, Odisha, Cuttack, India, [3]Kalinga Institute of Medical Sciences, KIIT University, Lucknow, India

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster III
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

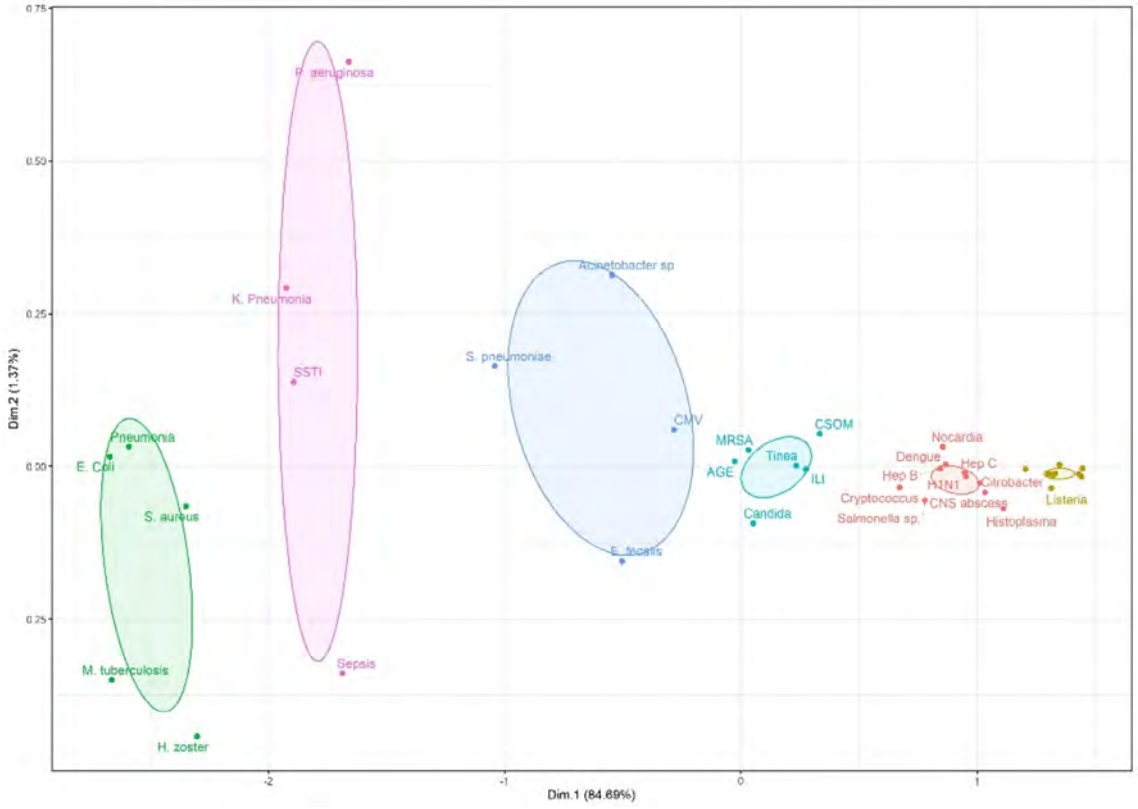
Background/Purpose: Infections are a major cause of morbidity and mortality in systemic lupus erythematosus (SLE). We studied whether infections cluster together and which patients are susceptible to recurrent infections.

Methods: Adult and juvenile SLE (ACR 1997 criteria) from 2000-2020 were reviewed retrospectively for minor and serious infections. Clusters were determined by principal coordinate analysis of a distance matrix from a random forest model.

Results: Of 1576 patients(1452 Female, mean age 27.98±10.53 years) with 8281.34 person-years of follow-up, 663 infections occurred in 490 individuals. Gram-negative bacteria were the most common, followed by mycobacteria (Table 1).

We identified 3 major and 3 minor clusters(Figure 1). Cluster 1 included predominantly intracellular infections: M. tuberculosis, S.aureus, H.zoster, E.coli, and pneumonia(microbiologically unconfirmed). Cluster 2 included bacterial infections: P.aeruginosa, K.pneumoniae, soft tissue infection, and sepsis(microbiologically unconfirmed). Cluster 3 included S.pneumoniae, E.fecalis, Acinetobacter, and Cytomegalovirus.

Cluster 1 was associated with fever(OR 1.95,1.39-2.73), nephritis(OR 1.6,1.23-2.06), myositis and serositis(OR 1.51,1.10-2.06), higher SLE disease activity index (SLEDAI) (14 vs 10), anti dsDNA(192 vs 150), low absolute lymphocyte counts(1296 vs 1512/cumm), C3(52.5 vs 61.8 mg/dl) and albumin(3 vs 3.5 g/dl). Cluster 2 was associated with



The plot shows principal coordinate analysis with the identification of 3 major and 3 minor clusters. The ellipses represent the 95% confidence interval for the centroid of the respective clusters.

Table 1. Prevalence of infections in the cohort.

Infection	Number (prevalence)		Number (prevalence)
Bacterial infections		Viral infections	
Escherichia coli	101 (6.4%)	*Herpes zoster*	44 (2.79%)
Pseudomonas aeruginosa	29 (1.84%)	*CMV*	13 (0.82)
Klebsiella pneumoniae	32 (2.03%)	*Parvovirus*	1 (0.06%)
Proteus mirabilis	2 (0.12%)	*Hepatitis B*	3 (0.19%)
Acinetobacter	12 (0.76%)	*Hepatitis C*	3 (0.19%)
Citrobacter	3 (0.19%)	*H1N1 influenza*	3 (0.19%)
Helicobacter pylori	1 (0.06%)	*Dengue*	4 (0.25%)
Staphylococcus aureus	53 (3.36%)	*Influenza like illness*	9 (0.57%)
MRSA	9 (0.57%)		
Streptococcus pneumoniae	20 (1.26%)	Fungal infections	
Listeria monocytogenes	1 (0.06%)	*Candida*	9 (0.57%)
Enterococcus	15 (0.95%)	*Cryptococcus*	5 (0.31%)
Nocardia	4 (0.25%)	*Histoplasma*	2 (0.12%)
Mycobacterium tuberculosis	93 (5.9%)	*Aspergillus*	1 (0.06%)
		Tinea	10 (0.63%)
Not microbiologically confirmed			
Acute gastroenteritis	9 (0.57%)	Parasitic infections	
Skin/soft tissue infection	36 (2.28%)	*Toxoplasma gondii*	1 (0.06%)
ENT infections	9 (0.57%)	*Neurocysticercosis*	1 (0.06%)
Pneumonia	66 (4.18%)	*Giardia lamblia*	1 (0.06%)
Sepsis	28 (1.77%)	*Plasmodium falciparum*	1 (0.06%)
CNS abscess	3 (0.19%)		

MRSA: methicillin resistant Staphylococcus aureus, ENT: ear, nose and throat. CMV: cytomegalovirus.

nephritis(OR 2.02, 1.33-3.06), gastrointestinal manifestations(OR 2.76, 1.13-6.75) and antiphospholipid syndrome(OR 1.87, 1.03-3.39), higher SLEDAI(14 vs 11), higher anti dsDNA antibodies(200 vs 150), low total leukocyte counts(5750 vs 6400) with similar absolute lymphocyte counts(1368 vs 1476), low C3(51.8 vs 61) and albumin(3.1 vs 3.5 g/dl). Cluster 3 was associated with low total leucocyte count(5100 vs 6400) and similar lymphocyte counts(1181 vs 1470), low C3(43.5 vs 60 mg/dl), and albumin(2.8 vs 3.4 g/dl).

Conclusion: A subset of patients prone to intracellular infections have lower lymphocytes. Patients prone to bacterial infections have lower total leukocyte counts with similar lymphocytes suggesting neutrophil deficiency. We hypothesize that functional assay of these cell lines in may predict future infection risk.

Organ Damage Progression in Systemic Lupus Erythematosus: An Analysis of the SLE Prospective Observational Cohort Study (SPOCS)

Richard Furie[1], Eric Morand[2], Christine Peschken[3], Martin Aringer[4], Laurent Arnaud[5], Barnabas Desta[6], Tina Grünfeld Eén[7], Alessandro Sorrentino[8], Stephanie Chen[9] and Bo Ding[7], [1]Northwell Health, Manhasset, NY, [2]Monash University, Centre for Inflammatory Diseases, Melbourne, Australia, [3]University of Manitoba, Winnipeg, MB, Canada, [4]Carl Gustav Carus, Dresden, Germany, [5]University Hospitals of Strasbourg, Strasbourg, France, [6]BioPharmaceuticals R&D, AstraZeneca, Gaithersburg, MD, [7]BioPharmaceuticals Medical, AstraZeneca, Gothenburg, Sweden, [8]Medical Affairs, AstraZeneca, Cambridge, United Kingdom, [9]BioPharmaceuticals Medical, AstraZeneca, Gaithersburg, MD

SESSION INFORMATION

Session Date: Tuesday, November 14, 2023
Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster III
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: The SLE Prospective Observational Cohort Study (SPOCS) is an international, multicenter study collecting data on patients with SLE, including in relation to oral corticosteroid (OCS) use and type 1 interferon gene signature (IFNGS) status. Here, we report SLICC/ACR Damage Index (DI) progression over 3 years in the overall population, as well as by baseline IFNGS category and average daily OCS use.

Methods: Eligible patients (aged ≥18 years) had physician-confirmed moderate-to-severe SLE (ACR or SLICC classification), a ≥6-month treatment duration with systemic SLE treatment beyond non-steroidal anti-inflammatory drugs and analgesics, and ≥1 lifetime positive serology of ANA or dsDNA. Disease organ damage burden was assessed using the SLICC/ACR DI score. IFNGS tests were performed in a central laboratory. The chi-square test was used to compare score categories and the proportions of patients with ≥1 new damage observation since the prior visit; the Kruskal–Wallis test was used for comparisons of the mean (standard deviation [SD]).

Results: Among 826 patients overall, 70.8% (n = 531) and 29.2% (n = 219) of patients had high and low IFNGS statuses, respectively; IFNGS status was missing for 76 patients. At baseline, 52.0% (n = 426) of patients grouped by high or low IFNGS status and 52.1% (n = 400) of patients grouped by OCS use had organ damage (DI score ≥1). The mean (SD) SLICC/ACR DI score was higher in patients with a low IFNGS than those with a high IFNGS; this trend continued throughout follow-up (**Table 1**). Average DI scores and percentages of patients with ≥1 new organ damage increased from baseline to 36 months in each category. Among patients stratified by daily OCS use (n = 768), 40.5% (n = 311), 44.0% (n = 338), and 15.5% (n = 119) of patients had no OCS use, low OCS use (0 – ≤7.5 mg/day), and high OCS use (>7.5 mg/day) at baseline, respectively. Baseline mean (SD) DI scores were also similar in the overall, no OCS use, and low OCS use categories and higher in the high OCS use category (P = 0.209 for the no OCS use, low OCS use, and high OCS use categories; **Table 2**). The proportion of patients with ≥1 new organ damage increased from baseline to 12 months in each category (P = 0.611 for no OCS use, low OCS use, and high OCS use); a greater percentage of patients had ≥1 new organ

[a]Average >0 – ≤7.5 mg/day OCS use.
[b]Average >7.5 mg/day OCS use.
[c]Comparison of the mean (SD) between no OCS, low OCS dose, and high OCS dose using the Kruskal–Wallis test.
[d]Comparison by score category between no OCS, low OCS dose, and high OCS dose using the chi-square test.
[e]Comparison of proportions of patients with ≥1 new damage since prior visit between no OCS, low OCS dose, and high OCS dose using the chi-square test.

damage in the high OCS category compared to the no or low OCS categories. Moreover, the mean (SD) DI score was higher in the high OCS category compared to the no OCS and low OCS categories after 12 months.

Conclusion: Results from the SPOCS study will enhance our understanding of the progression of SLE organ damage and will help improve clinical outcomes for patients with moderate-to-severe SLE. Nearly 20% of patients had new organ damage after 12 months. Patients with low IFNGS had greater organ damage than those with high IFNGS, and compared to no OCS or low daily average OCS use, organ damage is higher in patients with high average daily OCS use. Together, these indicate an unmet need for new treatment options for all patients with SLE, especially steroid-sparing treatments.

Abstract Number: 2295

Predictors of Adherence to Cervical Cancer Screening Guidelines Among Patients with Systemic Lupus Erythematosus

Lindsay Cho and Alexandra Legge, Dalhousie University, Halifax, NS, Canada

SESSION INFORMATION

Session Date: Tuesday, November 14, 2023
Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster III
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Women with systemic lupus erythematous (SLE) are at increased risk for cervical dysplasia and cervical cancer. In our jurisdiction, current guidelines recommend that average-risk women aged 25-69 years should undergo Pap tests for cervical cancer screening once every 3 years. Lifelong annual screening is recommended for immunocompromised women, including those with a history of HIV infection or prior organ transplant. Recent Canadian guidelines have suggested that women with SLE should be considered as part of this high-risk group. However, the uptake of these recommendations in clinical practice is unclear.

In this study, we evaluated the provision of cervical cancer screening in a Canadian cohort of women with SLE. Specifically, we measured adherence with current guidelines for the frequency of cervical cancer screening. We also sought to identify SLE-specific predictors of adherence to cervical cancer screening guidelines.

Methods: This was a longitudinal study of women aged 25-69 years followed in the Lupus clinic at a single academic medical centre in Canada between January 2014 and December 2019. All participants met the 1997 revised ACR classification criteria for SLE. Women were excluded from the analysis if they were not eligible for routine cervical cancer screening due to prior total hysterectomy, HIV infection, organ transplant, or history of cervical dysplasia/cancer. During the study period, participants underwent standardized clinical and laboratory assessments on an annual basis. Information regarding cervical cancer screening practices was obtained retrospectively through electronic chart review. We measured adherence with general population guidelines (i.e., Pap test once every 3 years) and SLE-specific guidelines (i.e., Pap test once annually)

Table 1. Sample characteristics of SLE patients

	One-year time periods	Three-year time periods
Number of eligibility periods	557	154
Number of SLE patients	131	98
Age (years), mean (SD)	47.6 (11.7)	46.4 (11.2)
White race (%)	88.6%	91.6%
Marital status		
Married/Common-Law (%)	76.7%	76.0%
Single/Divorced/Widowed (%)	23.3%	24.0%
Education level		
Did not complete high school (%)	10.0%	5.2%
Completed high school (%)	24.4%	29.2%
Post-secondary education (%)	65.6%	65.6%
Cigarette smoking		
Current or past smoker (%)	40.6%	38.3%
SLE disease duration (years), mean (SD)	15.4 (9.4)	14.3 (9.0)
SLE disease activity (SLEDAI-2K)		
Median (IQR) score	2 (0 – 4)	2 (0 – 4)
SLICC/ACR Damage Index (SDI)		
Median (IQR) score	0 (0 – 2)	0 (0 – 2)
Score ≥ 1 (%)	42.5%	40.1%
SLE Organ Manifestations		
Renal disease (%)	29.3%	30.5%
Neuropsychiatric disease (%)	4.6%	3.1%
SLE Medications		
Antimalarial use (%)	68.8%	70.1%
Corticosteroid use (%)	10.2%	10.4%
Immunosuppressive use (%)	59.4%	50.7%

SD = standard deviation; IQR = interquartile range; SLE = Systemic Lupus Erythematosus; SLEDAI-2K = Systemic Lupus Erythematosus Disease Activity Index 2000; SLICC = Systemic Lupus International Collaborating Clinics; ACR = American College of Rheumatology.

Table 2. Univariable generalized estimating equation (GEE) models for the association of demographic and clinical characteristics with adherence to cervical cancer screening guidelines among women with systemic lupus erythematosus (SLE)

	SLE-specific guidelines (1-year time periods) Odds ratio, 95% CI	General population guidelines (3-year time periods) Odds ratio, 95% CI
Number of eligibility periods	557	154
Number of SLE patients	131	98
Age, per 1-year increase	**0.97 (0.95 – 0.99)**	**0.96 (0.93 – 0.99)**
SLE disease duration, per 1-year increase	**0.97 (0.94 – 1.00)**	**0.96 (0.92 – 1.00)**
Marital status		
Single/Divorced/Widowed	Reference	Reference
Married/Common-Law	1.19 (0.65 – 2.15)	1.85 (0.81 – 4.21)
Education level		
Did not complete high school	Reference	Reference
Completed high school (%)	0.92 (0.31 – 2.77)	2.25 (0.35 – 14.3)
Post-secondary education (%)	1.80 (0.66 – 4.87)	3.76 (0.63 – 22.4)
Cigarette smoking		
Never smoker	Reference	Reference
Current or past smoker (%)	**0.59 (0.35 – 0.99)**	0.63 (0.31 – 1.31)
SLE disease activity (SLEDAI-2K), per 1-unit increase	1.00 (0.92 – 1.10)	1.01 (0.90 – 1.14)
SLICC/ACR Damage Index (SDI), per 1-unit increase	0.88 (0.73 – 1.05)	0.83 (0.65 – 1.05)
SLE Organ Manifestations		
Renal disease	**1.64 (1.00 – 2.80)**	1.41 (0.64 – 3.12)
Neuropsychiatric disease	0.78 (0.20 – 3.01)	0.66 (0.07 – 6.04)
SLE Medications		
Antimalarial use	1.43 (0.83 – 2.46)	2.00 (0.93 – 4.27)
Corticosteroid use	0.87 (0.41 – 1.85)	0.75 (0.26 – 2.16)
Immunosuppressive use	1.24 (0.75 – 2.03)	1.39 (0.69 – 2.80)

Bolded values indicated statistically significant associations ($p < 0.05$).

CI = confidence interval; SLE = Systemic Lupus Erythematosus; SLEDAI-2K = Systemic Lupus Erythematosus Disease Activity Index 2000; SLICC = Systemic Lupus International Collaborating Clinics; ACR = American College of Rheumatology.

for the frequency of cervical cancer screening. To achieve this, two separate analyses were conducted, whereby follow-up was divided into 1) one-year eligibility periods; and 2) three-year eligibility periods. For each analysis, adherence was defined as the proportion of time periods where ≥ 1 Pap test was performed. Pre-specified demographic and clinical variables were evaluated as predictors of adherence to screening guidelines using generalized estimating equation (GEE) models.

Results: There were 557 one-year eligibility periods contributed by 131 SLE patients; and 154 three-year eligibility periods contributed by 98 SLE patients. Participant characteristics are summarized in **Table 1**. Pap tests were performed in 125/557 (22.4%) of 1-year eligibility periods and in 79/154 (51.3%) of 3-year eligibility periods. Mean adherence rates were 49.5% for general population screening guidelines and 23% for SLE-specific guidelines.

Predictors of adherence to general population screening guidelines included age and SLE disease duration, while predictors of adherence to annual screening included the above variables, as well as cigarette smoking status and history of lupus nephritis **(Table 2)**.

Conclusion: Adherence to cervical cancer screening guidelines was suboptimal in SLE patients. Future work should aim to identify barriers to routine cervical cancer screening in this population.

Association Between EQ-5D-5L and SLEDAI Scores in Patients with Systemic Lupus Erythematosus in the United States and Europe: A Real-world Survey

Ebuwa Igho-Osagie[1], Rezaul Khandker[1], Jack Milligan[2], Emily Goddard[2] and Sophie Barlow[2], [1]Merck & Co. Inc., Rahway, NJ, [2]Adelphi Real World, Bollington, United Kingdom

SESSION INFORMATION

Session Date: Tuesday, November 14, 2023

Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster III

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: The EQ-5D-5L is validated for estimating health related quality of life (HRQoL) across a variety of different disease areas, including rheumatic diseases. However, its ability to effectively capture HRQoL in patients with complex conditions such as systemic lupus erythematosus (SLE) is debated. While disease-specific instruments may more robustly quantify HRQoL and disease burden in these patients, they cannot be used for cross-disease comparisons. Divergence of results between disease-specific instruments and the EQ-5D-5L may indicate an inability of the latter to completely capture the impact of disease manifestation in patients with SLE. In this study, we measured the correlation between the EQ-5D-5L and the SLE Disease Activity Index (SLEDAI) – a disease-specific instrument used to quantify SLE disease activity and severity.

Methods: Data were drawn from the 2021 Adelphi Real World Lupus Disease Specific Programme (DSP)™, a cross-sectional survey with retrospective data collection. Rheumatologists in France, Germany, Italy, Spain, the United Kingdom and the United States provided demographic and clinical information for their next 5-6 consecutively consulting patients with SLE. SLEDAI scores were derived from physicians' clinical assessment of their SLE patients. The same patients were then invited to complete a questionnaire that included an EQ-5D-5L form. We assessed the correlation between EQ-5D-5L and SLEDAI scores, and EQ-5D-5L subdomains and SLEDAI scores using Pearson's and Spearman's correlations, respectively.

Table 1: Patient demographics, clinical characteristics and treatment (n=211)	
Demographics	
Age, mean (SD)	42.9 (13.4)
Sex, female, n (%)	188 (89.1)
Ethnicity, White, n (%)	168 (79.6)
Years since SLE diagnosis (n=203), mean (SD)	5.6 (5.1)
Charlson Comorbidity Index, mean (SD)	0.3 (0.8)
Clinical Characteristics	
Physician-perceived current severity, n (%)	
Mild	134 (63.5)
Moderate/Severe	77 (36.5)
Physician-perceived flaring status, n (%)	
Currently flaring	19 (9.0)
Not currently flaring	192 (91.0)
Number of flares in the last 12 months, mean (SD)	0.7 (1.1)
Current number of symptoms, mean (SD)	3.7 (3.1)
Total SLEDAI Score	
Mean (SD)	10.4 (10.3)
≥6, n (%)	99 (46.9)
<6, n (%)	112 (53.1)
Current Treatments, n (%)	
Advanced therapy: (including biologics and JAK inhibitors)	69 (32.7)
Corticosteroids	145 (68.7)

Abbreviations: standard deviation (SD); systemic lupus erythematosus (SLE); SLE Disease Activity Index (SLEDAI); janus kinase (JAK).

Table 2: EQ-5D-5L correlations with SLEDAI (n=211)		
Total EQ-5D-5L and SLEDAI		
	Pearson's Rho (correlation)	**p-value**
Total EQ-5D-5L	-0.3637	<0.001
EQ-5D-5L subdomains and SLEDAI		
	Spearman's Rho (correlation)	**p-value**
Mobility	0.2031	0.003
Self-care	0.3076	<0.001
Usual activities	0.2532	<0.001
Pain/discomfort	0.1968	0.004
Anxiety/depression	0.3092	<0.001
Higher total EQ-5D-5L scores equate to higher quality of life; Higher scores on EQ-5D-5L subdomains equate to lower quality of life. EQ-5D-5L US tariff was used for the total utility score. Abbreviations: SLE Disease Activity Index (SLEDAI)		

Results: A total of 211 patients were included in this analysis. Mean (SD) age was 42.9 (13.4) years, 89% of patients were female and 80% were White. The mean (SD) SLEDAI score was 10.4 (10.3) and mean (SD) EQ-5D-5L score was 0.75 (0.24). Pearson's Rho correlation between SLEDAI scores and total EQ-5D-5L was r=-0.3637 (p< 0.001) while Spearman's Rho correlations between SLEDAI scores and each EQ-5D domain were: Mobility r=0.2031 (p=0.003); Self-care r=0.3076 (p< 0.001); Usual activities r=0.2532 (p< 0.001); Pain/discomfort r=0.1968 (p=0.004); Anxiety/depression r=0.3092 (p< 0.001).

Conclusion: Weak correlations were observed between SLEDAI and EQ-5D-5L and between SLEDAI and the EQ-5D-5L subdomains, suggesting a patient's clinical status may not be fully reflected in the EQ-5D-5L. More sensitive disease-specific instruments or HRQoL estimation tools may be required to fully capture the burden of disease in patients with SLE.

Abstract Number: 2297

Interferon-α as a Biomarker to Predict Flares in Lupus Nephritis

Laura Patricia Whittall Garcia[1], Dafna Gladman[2], Murray Urowitz[3], Zahi Touma[4] and Joan Wither[1], [1]University Health Network, Toronto, ON, Canada, [2]Schroeder Arthritis Institute, Krembil Research Institute, Toronto Western Hospital, Department of Medicine, University of Toronto, Toronto, ON, Canada, [3]Schroeder Arthritis Institute, Krembil Research Institute; University of Toronto Lupus Clinic; Division of Rheumatology, Toronto, ON, Canada, [4]University of Toronto, Toronto, ON, Canada

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster III
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Type I Interferons (IFN-I) play a role in SLE and Lupus Nephritis (LN) pathogenesis. We have recently shown that IFN-I gene expression predicts the risk of SLE flares and a more severe disease course in SLE patients. Furthermore, recently it has been suggested that patients with higher IFN-I gene expression in their renal tubular cells are less likely to respond to conventional therapy.

The aim of this study was to determine if the amount of IFN-α in serum at the time of an LN flare predicts response to therapy, subsequent LN flares, and decline in kidney function.

Table 1. Logistic Regression analysis and Multivariable Cox Regression analysis*. IFN-α predicts renal outcomes (N=95)

Table 1. Logistic Regression analysis and Multivariable Cox Regression analysis*. IFN-α predicts renal outcomes (N=95)		
Outcomes		
Failure to achieve a complete response		
	Odds Ratio (95% CI)	P value
Failure to achieve a CR at 1 year	1.14 (0.94-1.42)	0.16
Failure to achieve a CR at 2 years	1.25 (1.02-1.54)	0.03
LN Flares [a]		
	Hazard Ratio (95% CI)	P value
Time to first LN flare	1.12 (0.96-1.29)	0.14
Time to second LN flare	1.35 (1.07-1.71)	0.01
Decline in eGFR		
	Hazard Ratio (95% CI)	P value
Stage 3A CKD (eGFR ≤59)	1.23 (1.08-1.40)	0.001
Stage 3B CKD (eGFR ≤44)	1.22 (1.07-1.39)	0.003
Stage 4 CKD (eGFR ≤29)	1.27 (1.09-1.48)	0.001
Stage 5 CKD (eGFR <15)	1.17 (1.03-1.34)	0.01
[a] Development of end-stage renal disease (eGFR≤15) and death were used as competing risks for this analysis.		
[*] Logistic Regression analysis and Cox regression analysis were adjusted for ethnicity, adherence to treatment, history of a prior LN flare, serum creatinine at the time of the LN flare and the time in months from the sample collection to the IFN-α quantification.		

Methods: Patients with active LN were included in this study. All patients had 1) active LN, defined as a 24H urine protein >500mg/day with a subsequent modification in therapy by the treating physician, 2) stored serum sample ±3 months from the renal flare and 3) baseline estimated glomerular filtration rate (eGFR) ≥60ml/min (3 months prior to the flare).

The following outcomes were ascertained: 1) Complete Response (CR), defined as proteinuria < 500 mg/day and a serum creatinine within 15% of the baseline at 1 and 2 years after the flare, 2) number of LN flares during follow-up (defined by an increase in proteinuria of at least 1000 mg/d if the baseline was < 500 mg/d or doubling of proteinuria in baseline was ≥500 mg/d and a change in therapy by the treating physician, and 3) decline in eGFR to ≤59ml/min, ≤44ml/min,≤29ml/min and < 15ml/min during follow-up.

Serum IFN-α was measured by Simoa®

Table 2. Logistic Regression analysis and Multivariable Cox Regression analysis*. IFN-α cut-offs predicts renal outcomes (N=95)

Table 2. Logistic Regression analysis and Multivariable Cox Regression analysis*. IFN-α cut-offs predicts renal outcomes (N=95)		
Outcomes		
Failure to achieve a complete response		
IFN-α levels ≥0.6	Odds Ratio (95% CI)	P value
Failure to achieve a CR at 1 year	1.53 (0.60-3.94)	0.37
Failure to achieve a CR at 2 years	2.86 (1.05-7.00)	0.03
LN Flares [a]		
IFN-α levels ≥0.6	Hazard Ratio (95% CI)	P value
Time to first LN flare	1.12 (1.05-3.99)	0.03
Time to second LN flare	1.35 (1.12-8.03)	0.03
Decline in eGFR		
IFN-α levels ≥1.3	Hazard Ratio (95% CI)	P value
Stage 3A CKD (eGFR ≤59)	2.13 (1.06-4.02)	0.03
Stage 3B CKD (eGFR ≤44)	2.21 (1.04-4.67)	0.03
Stage 4 CKD (eGFR ≤29)	2.62 (1.10-6.00)	0.02
Stage 5 CKD (eGFR <15)	2.57 (1.02-6.04)	0.04
[a] Development of end-stage renal disease (eGFR≤15) and death were used as competing risks for this analysis.		
[*] Logistic Regression analysis and Cox regression analysis were adjusted for ethnicity, adherence to treatment, history of a prior LN flare, serum creatinine at the time of the LN flare and the time in months from the sample collection to the IFN-α quantification.		

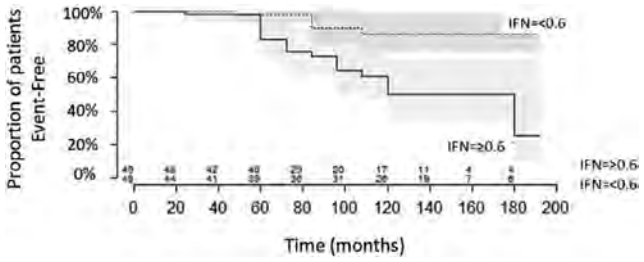

Figure 2. Time to ≥2 LN flares or end-stage renal disease (eGFR ≤15). Kaplan-Meier survival curves stratified by IFN-α levels ≥ 0.6 and <0.6, P=0.04.

Results: A total of 95 patients with active LN were included in the study. The median (IQR) age of the patients was 29 (23-41) years, 79 (83.7%) were women, and the disease duration was 6.0 (0.2-10.0) years. Forty (42.1%) were Caucasian, 21 (22.1%) were Afro-Caribbean, and 22 (23.1.%) were Asian. The baseline eGFR was 112 (98.7-127) ml/min, and the median (IQR) follow-up was 132 (96-156) months.76.8% had a kidney biopsy at the time of the LN flare, of whom 54.7% had a proliferative or mixed class, 17.8% class V, and 4.2% class I or II. The median (IQR) of prednisone was 40mg (30-38mg), 89 (93%) received antimalarial and all patients received immunosuppressive therapy.

The serum baseline levels of IFN-α predicted CR at 2 years from the LN flare. Furthermore, patients with higher baseline levels of IFN-α had a greater risk of having 2 or more subsequent renal flares. Every increase in 1 unit of IFN-α increased the risk of having 2 or more flares by 35%, and the risk of having a decline in kidney function during follow-up (**Table 1**).

Using ROC analysis, two IFN-α cut-offs were identified, 0.6 and 1.3 for predicting ≥2 LN flares and progression to eGFR ≤15, respectively. Even though the areas under the curve suggested that IFN-α is only a weak predictor (AUC=0.62 (0.51-0.74) and 0.60 (0.47-0.73) for ≥2 LN flares and progression to eGFR ≤15, respectively), these cutoffs continued to predict renal outcomes on Cox regression analysis, as seen in **Figure 2** and **Table 2.**

Conclusion: IFN-α serum levels predicted failure to respond to treatment at year 2 after the renal flare, the development of ≥2 LN flares, and decline in kidney function during follow-up.

SLE Patients Are at High Risk for Tuberculosis Infection: Data from a Lupus Center of an Endemic Country

Victor Leda[1], Andreia Sousa[1], **Fernanda Lopes**[1], Emily Neves[1], Sandra Pasoto[2], Danieli Andrade[2], Michelle Ugolini[1], Eloisa Bonfa[2], Eduardo Borba[1], Adriana Tonacio[1] and Luciana Seguro[1], [1]Hospital das Clinicas HCFMUSP, University of São Paulo, São Paulo, Brazil, [2]University of São Paulo, São Paulo, Brazil

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster III
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: SLE patients are at high risk for tuberculosis (TB) infection especially in endemic countries. Despite the importance of this infection condition, there are still some uncertainties regarding a better characterization of this subgroup of SLE patients which variesamong different series. Screening for TB is routinely performed before immunobiological therapy but this procedure is not always considered for SLE patients starting glucocorticoid or immunosuppressive therapies, and is still under discussion. The aim of the present study was to evaluate clinical and epidemiological characteristics of SLE patients that developed TB after SLE onset.

Methods: SLE patients (2012 SLICC criteria) regularly followed in a single tertiary Lupus center in Brazil who were diagnosed with TB after SLE onset between 2000-2023 were included. Data of SLE patients were obtained from a direct interview and physical examination, and also confirmed in our ongoing prospective electronic chart database established in 2000 that consisted of an extensive clinical and laboratorial evaluation of each patient, including variables of this study, at one to six months intervals.

Results: Sixty-seven (5.3%) SLE patients with TB were identified in a total of 1,254. These SLE patients had a mean age of 48 (**±13.6)** years. Median time between SLE onset and TB diagnosis was 10 (±7.42) years. Regarding infection site, 33 patients (49.3%) had pulmonary tuberculosis and 34 (50.7%) with extrapulmonary tuberculosis (EPTB). Twelve patients (18%) were diagnosed with disseminated infection. The most frequent EPTB sites were lymph nodes (10.4%) and osteoarticular (8.9%), followed by similar rates of gastrointestinal tract (3%), pleural (3 %), skin and soft tissue (3%) and central nervoussystem (3%). At time of TB diagnosis, 51 patients (76%) were in use of glucocorticoid therapy with a median dose of prednisone of 7.5 mg/day (min. 0 mg/day - max. 60 mg/day). The most common DMARD agents used at TB onset were hydroxychloroquine (55%), azathioprine (31%), mycophenolate mofetil (25%), and methotrexate (12%). Adverse events to TB therapy occurred in 22 patients (32%), with most frequently reported side effects being hepatotoxicity and gastrointestinal intolerance.

Conclusion: Our results demonstrated that SLE patients have a high prevalence of tuberculosis, especially extrapulmonary tuberculosis.The use of glucocorticoid therapy was frequently observed at time of TB diagnosis but other immunossupressive drugs could also contribute to increase the risk of this infection.Further studies should be performed in order to define the role of screening of latent TB in SLE patients living in endemic areas.

Medication-related Hospitalizations in Systemic Lupus Erythematosus

Michele Stanciu[1], Evelyne Vinet[2], Emily Gibson McDonald[3], Gregory Clark[3], Christian Pineau[2], Fares Kalache[4], Louis-Pierre Grenier[5], Sasha Bernatsky[6] and Arielle Mendel[3], [1]McGill University, Montreal, QC, Canada, [2]McGill University Health Centre, Montréal, QC, Canada, [3]McGill University Health Centre, Montreal, QC, Canada, [4]McGill University Health Centre, Carignan, AB, Canada, [5]Montreal General Hospital, Montréal, QC, Canada, [6]Research Institute of the McGill University Health Centre, Montreal, QC, Canada

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster III
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Adverse drug events (ADEs; harm from use of a drug) cause a significant burden to the healthcare system, with an estimated 5% of hospitalizations being drug-related. Up to 80% of ADEs may be preventable; and up to 20% of medication-related events may be related to non-adherence or drug omissions (including non-use of an indicated medication, i.e. prophylactic therapies). People with systemic lupus erythematosus (SLE) take multiple medications, increasing risk of ADEs and other medication-related adverse events. Within the McGill University Health Centre (MUHC) SLE cohort, we estimated the frequency and preventability of hospitalizations related to ADEs and medical omissions.

Methods: All patients in the SLE cohort satisfy the 1997 American College of Rheumatology (ACR) classification criteria and were enrolled after diagnosis. We identified consecutive MUHC admissions among SLE cohort participants between 2015-2020. For each hospitalization, we recorded home medications, admission diagnosis, and outcomes of ADEs and drug omissions. Two adjudicators independently evaluated each hospitalization using the Leape and Bates method, to rank confidence that an ADE or drug omission contributed to the admission (1=little/no confidence; 6=virtually certain). We computed a kappa statistic to assess inter-rater reliability. A third adjudicator helped resolve 7 unclear cases. Medication-related events were then classified as potentially preventable or ameliorable, or not, and potentially modifiable factors were identified.

Results: Among 481 SLE cohort members followed between 2015-2020 (2303 person-years), 67 hospitalizations occurred (3 hospitalizations/100 person-years) among 45 participants. At first admission, median age was 38 years (interquartile range, IQR 27-53), median disease duration was 12 years (IQR 6-20), and participants' home medications numbered a median of 8 (IQR 4-11). Forty one (91%) were female, and >50% were non-Caucasian. Over a quarter (n=19, 28%) of hospitalizations were likely due to one or more ADE (Leape and Bates scores 4-6). Initial unweighted kappa for adjudication was 0.7. ADEs (n=22) included infections (n=13, 59%), cutaneous hypersensitivity reactions (n=2, 9%), adrenal insufficiency (n=1, 5%), drug toxicity (n=4, 18%), and thrombosis (n=2, 9%). Prednisone (n=10, 45%) and/or other immunosuppressants

Table 1. Characteristics of all participants and study population subgroups according to presence/absence of medication-related event

Blood products (IVIg)	0	1 (8)
Antibiotics[a]	1 (10)	1 (8)

[a]Dapsone, trimethoprim-sulfamethoxazole

(n=18, 82%) were commonly involved. Eight (12%) hospitalizations related to drug omissions, of which 7 (10%) were flares due to non-adherence. Excluding these flares, 11 medication-related events (48%) were potentially preventable/ameliorable. Modifiable factors included timely glucocorticoid tapering (n=3, 25%), promptly acting on laboratory results (n=4, 33%), and preventative strategies (thromboprophylaxis, vaccination, infection screening; n=3, 25%).

Conclusion: In our SLE cohort, 40% of hospitalizations were medication-related, most often due to ADEs. At least half of medication-related hospitalizations were potentially preventable or ameliorable. Infection prevention should be a priority in this group.

Outcomes of COVID-19 Before and During the Omicron Variant Period in Patients with Systemic Lupus Erythematosus: A Global Multicenter Cohort Study Using the TriNetX Network

Wen-Nan Huang[1] and Hsin-Hua Chen[2], [1]Division of Allergy, Immunology, and Rheumatology, Department of Internal Medicine, Veterans General Hospital, College of Medicine National Chung Hsing University, Department of Business Administration, Ling-Tung University, Taichung, Taiwan; School of Medicine, National Yang Ming Chiao Tung University, Taipei, Taiwan, [2]Taichung Veterans General Hospital, Taichung, Taiwan

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster III
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: The global dominance of the SARS-CoV-2 Omicron variant ensued shortly after its initial identification in South Africa on November 24, 2021. The outcomes of COVID-19 Omicron variant period had been found to be better than those of COVID-19 before the Omicron variant period. Patients with systemic lupus erythematosus (SLE) have been

found to have a worse COVID-19 outcomes. However, whether the short outcomes of COVID-19 during the Omicron variant period are different from those before the Omicron period is still unclear. Utilizing the TriNetX Network, a worldwide federated health research network that leverages electronic medical records (EMR) from multiple centers, the study aimed to compare COVID-19 outcomes prior to and following the emergence of the Omicron variant in patients with SLE.

Methods: Using the EMR from the Global Collaborative Network database of TriNetX with 101 large health care organizations (HCOs) , we identified 22,782 and 20,668 COVID-19 patients with SLE aged 20–89 years before (between January 1, 2020 and October 31, 2021) and during (between January 1, 2022 and April 29, 2023) the Omicron variant dominance period predominance, respectively. The diagnoses of SLE and comorbidities were based on International Classification of Diseases tenth revision (ICD-10), while the diagnosis of COVID-19 was based on ICD-10, Current Procedural Terminology (CPT) Codes, or Logical Observation Identifiers Names and Codes (LOINC). The two groups of COVID-19 infected SLE patients were matched for age, sex, ethnicity, tobacco use, diabetes mellitus, chronic kidney disease, hypertensive diseases, chronic lower respiratory diseases, ischemic heart diseases, heart failure, neoplasms, anxiety, dissociate, stress-related somatoform and other nonpsychotic mental disorders, mood disorders, mental and behavioral disorders due to psychoactive substance use, and use of immune suppressants. We performed Cox regression analyses to compare the incidences of various COVID-19 outcomes within 30 days after COVID-19 diagnosis date in the pre-Omicron period group compared with those in the Omicron period group, shown as hazard ratios (HRs) with 95% confidence intervals (CIs).

Results: We finally included 20,155 matched SLE patients in both groups. The mean ± standard deviation (SD) age was 52 ± 16 years, and 89% of study subjects were females. Patients of SLE who got COVID-19 before the Omicron period had a higher risks of hospitalization (HR, 1.43; 95% CI, 1.26–1.64), ICU admission (HR, 1.37; 95% CI, 1.21–1.55), sepsis (HR, 1.33; 95% CI, 1.16–1.53), use of mechanical ventilation (HR, 1.64; 95% CI, 1.33–2.03), mental illness (HR, 1.59; 95% CI, 1.26–2.00), hemodialysis (HR, 1.54; 95% CI, 1.17–2.02), atrial fibrillation (HR, 1.44; 95% CI, 1.000–2.085; p = 0.049), acute kidney injury (HR, 1.16; 95% CI, 1.04–1.29), and death (HR, 1.56; 95% CI, 1.30–1.89). However, the risks of stroke and venous thromboembolism/pulmonary embolism were not significantly different between both groups.

Conclusion: This global multicenter cohort study revealed that most short-term (30-day) COVID-19 outcomes were better during the Omicron period than before the Omicron period in patients with SLE.

Relapse in Japanese Patients with Newly Diagnosed SLE and Its Clinical Characteristics in Daily Clinical Practice: A Single Center Experience in Recent 10 Years

Shuzo Sato[1], Shuhei Yoshida[1], Yuya Sumichika[1], Kenji Saito[1], Haruki Matsumoto[1], Jumpei Temmoku[1], Yuya Fujita[1], Naoki Matsuoka[1], Tomoyuki Asano[1] and KIYOSHI MIGITA[2], [1]Fukushima Medical University, Fukushima, Japan, [2]Department of Rheumatology Fukushima Medical University School of Medicine, Fukushima, Japan

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster III
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: SLE patients often experience relapse in the course of treatment, in spite of the progress of therapeutic strategy in SLE. The purpose of this study is to elucidate clinical features, outcome, and risk factors of relapse in patients with SLE who were newly diagnosed and treated at our hospital in recent 10 years.

Methods: This study is a retrospective cohort study. Newly diagnosed SLE patients who were treated in the department of Rheumatology, Fukushima Medical University hospital between 2011 and 2022 were collected. Patients who experienced relapse during observation period were regarded as Relapse-group (relapse was defined as BILAG grade B flare or more), and its clinical features including age, sex, disease duration, SLE symptoms, laboratory data and treatment such as the use of hydroxychloroquine (HCQ) and immunosuppressants (ISs), were compared with non-relapse SLE group. Cumulative relapse free survival in certain clinical items were also compared between the 2 groups using Kaplan-Meier curves.

Results: Among 382 SLE patients who received treatment in our department from 2011 to 2022, 83 newly diagnosed SLE patients were included. The mean age was 37.9 years old, and 75 patients were female (90.4%). The mean SLEDAI scores were 17.8. In 83 patients, 29 patients experienced relapse during the study period. The comparison of clinical characteristics between Relapse group (29 patients) and Non-relapse group (54 patients) were shown in Figure 1. General characteristics were similar between the 2 groups including age, sex, SLE symptoms and serology tests except for observation period ($p< 0.01$) and anti-SS-A antibody positive (P=0.01). In therapy, significantly increased frequency of HCQ intake and combination immunosuppressive therapy (steroids and HCQ plus IS, or more than 2 ISs) were observed (P=0.024 and 0.049, respectively) in non-relapse group. Kaplan-Meier analysis showed significantly higher cumulative relapse-free survival in anti-SS-A negative group and combination immunosuppressive therapy group (P=0.012 and 0.045, respectively) (Figure 2).

Figure 1

Clinical items mean SD, (%)	Relapse (n=29)	Non-relapse (N=54)	P

SESSION INFORMATION

Session Date: Tuesday, November 14, 2023
Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster III
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Previous studies in childhood-onset systemic lupus erythematosus (cSLE) have suggested that cSLE patients have more severe disease, compared to those with adult-onset disease (aSLE). These reported associations are mostly based on cross-sectional observational studies. We compared longitudinal disease characteristics, medication use, and outcomes in cSLE versus aSLE patients in adulthood.

Methods: We followed adult patients who fulfilled ACR or SLICC classification criteria for SLE, enrolled in the Australian Lupus Registry and Biobank (ALRB), a multicentre observational cohort, between 2007 and 2022. Patients who were aged < 18 at diagnosis were grouped as cSLE, and patients aged ≥18years were grouped as aSLE. Patients' disease activity assessed using SLEDAI-2K, SFI and PGA, and medication details were captured at each routine visit while organ damage (using SDI) and HRQoL (using SF36v2) were captured annually. Lupus low disease activity state (LLDAS) and high disease activity status (HDAS, ever SLEDAI-2K score ≥10) are derived as previously published. Triple therapy is defined as concurrent use of immunosuppressant, hydroxychloroquine and corticosteroid. Comparisons were made using appropriate bivariate tests.

Results: The cohort consisted of 519 patients from 9 ALRB centres, with a median age of diagnosis of 29 [IQR: 22,42] years. 68 patients (13%) had cSLE. Despite their younger age at enrolment (25 vs 41 years, p< 0.001), a higher proportion of patients with cSLE already had damage present (SDI≥1) at enrolment (53% vs 40%, p=0.05) consistent with their longer disease duration (median length of disease for cSLE 13.2 vs aSLE 4.2, p< 0.001). cSLE patients had more renal involvement at enrolment (62% cSLE vs 37% aSLE, p< 0.001). The median (IQR) observation period was 4.8 (2.6, 9.3) years. Disease activity, as measured by enrolment SLEDAI-2K (median (IQR) of 8 (4,12) vs 4 (2,8), p=0.013) and time-adjusted mean SLEDAI (AMS) (median (IQR) of 5.0 (3.0, 6.4) cSLE vs 3.6 (1.9,5.1) aSLE, p< 0.001) were significantly higher in cSLE patients, and the difference persisted in each year of observation (Table 1). A higher proportion of cSLE patients had AMS >4, or had HDAS. Only 36% cSLE vs 51% aSLE (p=0.03) spent ³50% time in LLDAS. The domains of disease activity and visit frequency were similar between the two groups. A high proportion of cSLE patients had been treated with triple therapy at enrolment (50% vs 35.5%, p=0.021), and have used mycophenolate (58.8% vs 38.8%, p=0.002). Exposure to Rituximab was seen in 14.7% cSLE vs 8.7% aSLE (p=0.111) whereas exposure to cyclophosphamide was seen in 8.8% cSLE vs 6.0% aSLE (p=0.371).

Table 1. Pattern of visit frequency, disease activity, and medication use in each year of followup between cSLE vs aSLE patients.

AMS = Time-adjusted mean SLEDAI-2K score, aSLE = adult-onset Systemic Lupus Erythematosus, cSLE = childhood-onset Systemic Lupus Erythematosus, LLDAS = Lupus Low Disease
*Defined as concurrent treatment with hydroxychloroquine, prednisolone and an immunosuppressant (including Azathioprine, Cyclosporin, Cyclophosphamide, Leflunomide, Methotrexate,

Conclusion: cSLE patients had severe disease that was discernible at enrolment and persisted during follow-up. This difference was not due to fewer review visits, disproportionate involvement of certain organ domains, or undertreatment with conventional immunosuppressants. These findings should raise awareness amongst clinicians to consider early aggressive control of disease, including earlier consideration of biologic therapy.

Abstract Number: 2303

Are Neuropsychiatric Symptoms in Systemic Lupus Erythematosus (NPSLE) Associated with More Frequent Hospitalizations or Exposure to a Greater Number of Immunosuppressive Medications?

Jaime Vondenberg[1], Chao Zhang[1] and Emily Littlejohn[2], [1]Cleveland Clinic Foundation, Cleveland, OH, [2]Cleveland Clinic, Cleveland, OH

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster III
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Neuropsychiatric (NP) symptoms occur in >50% of patients with systemic lupus erythematosus (SLE). A major barrier to research includes the non-specific nature of neuropsychiatric syndromes and the uncertainty of attribution to SLE activity. Unmet needs in NPSLE research include recognizing neuropsychiatric symptoms in lupus, diagnostic biomarkers, diagnostic imaging, prognostication, and novel therapies.

Methods: Charts of patients at a large academic center registry were reviewed to record the prevalence of the 19 NP symptoms described by the ACR in 1999. Patient demographics (gender, age, race, disease phenotype, disease duration), SLEDAI 2k score, autoantibody status, C3/C4 levels, and proteinuria >0.5 mg/mmol were collected from chart review. The number of hospitalizations, number and type of current and past immunosuppressive therapies as well as non-immunosuppressive therapies for patients with NP symptoms were compared to those without. Subgroup analysis was performed for those patients with seizure/cerebrovascular disease/polyneuropathy.

Results: 334 charts were reviewed, 327 were included in statistical analysis. 89% of patients were female, 11% male. By race, 65.9% White, 30.6% African American, 2.19% Asian, and 1.25% Hispanic/Latino. NP symptoms were present in 86.5% of the cohort, the most common were: headache (59.3%), anxiety (55.1%), mood disorder (49.8%), cognitive dysfunction (42.5%), polyneuropathy (20.3%), seizure (9.2%), and cerebrovascular disease (8%). There was no statistically significant difference in hospitalizations or immunosuppressive therapies utilized in patients with NP symptoms compared to

those without. However, patients with NP symptoms were more often hospitalized between 2-10 times compared to those without NP symptoms (not statistically significant). Patients with NP symptoms were more often on current steroid therapy and less often on current azathioprine, mycophenolate, or anifrolumab, and less often received *past* azathioprine or mycophenolate therapy (not statistically significant). Patients with NP symptoms were statistically more likely to be on antiepileptics (p=0.002), antidepressants (p< 0.001), or benzodiazepines (p=0.007). In subgroup analysis, patients with seizure/cerebrovascular disease/polyneuropathy were less likely to have low C3 (p=0.005) or proteinuria >0.5 (p=0.070) but were more likely to have leukopenia (p=0.011), be hospitalized (p=0.318), receive IVIG (p=0.04), antiepileptics (p< 0.001), antipsychotics (p=0.034), antidepressants (p< 0.001), and benzodiazepines (p=0.003).

Results

Table1 Descriptive table for demographics and neuropsychiatric events

Table1 Summarizes the demographics and neuropsychiatric events. 282 patients had NP symptoms, the prevalence rate for NP symptoms is 86.5%. 271 (84.7%) of the study cohort had ANA by IFA.

Table 1. Descriptive table for demographics and NP events

Variable	Level	All (n=327)	N
Sex	Male	36 (11.0%)	327
	Female	291 (89.0%)	
Race	African-American	98 (30.6%)	320
	Asian	7 (2.19%)	
	Hispanic/Latino	4 (1.25%)	
	White	211 (65.9%)	
Disease Duration	<1 Year	2 (0.62%)	322
	>=1 Year	320 (99.4%)	
Baseline SLEDAI 2K Score		2.00 [0.25;6.00]	274
NP Symptom		282 (86.5%)	326
NP Manifestation	Cognitive Dysfunction	139 (42.5%)	327
	Mood Disorder	162 (49.8%)	325
	Anxiety	179 (55.1%)	325
	Headache	192 (59.3%)	324
	Seizure	30 (9.20%)	326
	Cerebrovascular Disease	26 (8.00%)	325
	Psychosis	15 (4.62%)	325
	Acute Confusional State	3 (0.92%)	327
	Mononeuropathy	7 (2.15%)	326

Conclusion: There was no statistical difference in hospitalizations or immunosuppression between patients with NP symptoms versus those without. However, patients with NP symptoms were more often hospitalized between 2-10 times compared to patients without NP symptoms and were more often on current steroid therapy, and statistically more often on an antiepileptic, antidepressant, or benzodiazepine therapy. Patients with seizure/cerebrovascular disease/polyneuropathy were statistically less likely to have low C3 (p=0.005) but were more likely to have leukopenia (p=0.011).

Table 6. Subgroup Analysis for Seizure/Cerebrovascular/Polyneuropathy vs without any NP Symptoms

Variable	Level	All (n=151)	No Symptom (n=44)	Seizure/Cerebrovascular/ Polyneuropathy (n=107)	P-value	N

Disparity in Healthcare in Systemic Lupus Erythematosus: A Single-Center Study

Joshua Reed, **Anam Nazir**, Khalid Alghamdi and Catherine Ivory, The Ottawa Hospital Research Institute, Ottawa, ON, Canada

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster III
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Systemic lupus erythematosus (SLE) is variable in clinical presentation and has fluctuating disease severity. Health outcomes in SLE have been linked to both genetic and social factors related to differences in gender, ethnicity, education, income, and occupation. This cross-sectional study aims to evaluate the relationship between the access to primary care, social determinants of health (SDH), and disease outcome a single Canadian tertiary center.

Methods: Patients with 2019 EULAR/ACR SLE diagnosis were recruited consecutively and informed consent obtained after ethics board approval. Information on patient demographics, SDH and quality of life (Lupus QoL) was collected through a Patient Questionnaire. A chart review was conducted to document disease activity by SLE-Disease Activity Index (SLEDAi-2k) at the consenting visit, emergency department visits, ACR damage index and adverse outcomes.

Results: 93 patients with a confirmed diagnosis of SLE have been recruited and analyzed at this interim stage. 87.1% (n=81) had access to a General Practionner (GP group) and 12.9% (n=12) did not have access to a GP (Non-GP group). The Non-GP group had a mean SLEDAI-2K score of 4.2 ± 4.9 compared to 2.6 ± 3.6 in the GP group (p=0.21). The SLICC/ACR Damage Index score was 0.7 ± 1.2in Non-GP group and 1.2± 1.6 in GP group (p=0.21). Lupus QoL was similar with 61.2 ±20.5 compared to 64.8±19.5 (p=0.49) for the Non-GP group compared to GP group respectively. History of lupus related pregnancy complications were more frequent in non-Caucasian participants (32.4% vs 9.4%, p=0.010) compared to Caucasians and with a trend to occur more frequently in the Non-GP group (33.3% vs 15.8%). Compared to Caucasians, more

oral corticosteroids use was seen in the non-Caucasian group (51.4% vs 22.6% p=0.010), but similar rates of cardiovascular events and major infections.There is a trend, but not statistically significant, towards more osteoporosis in the non-Caucasian group (13.5% vs 1.9%) and a trend towards more fractures in that group (8.1% vs 0%). Equal rates of employment, education, smoking and emergency visits were recorded between GP an non-GP groups as well as between non-Caucasian and Caucasians.

Conclusion: Our interim results suggests that there remain discrepancies in health outcomes in our SLE cohort, despite our universal health care system. Preliminary results suggest SLE patients without access to primary care and non-Caucasians may have an increased risk of pregnancy complications, increased corticosteroid use and more osteoporosis. The sample size is small, and the study is ongoing. Further multivariate analysis is planned to elaborate on health determinants.

Infection Vulnerability in Pregnant Women with and Without Systemic Lupus Erythematosus

Dr Hiba Khogali[1], Ghada Al-Bluwi[2], Virgie Guy[2] and Ali Al Dhanhani[3], [1]Tawam Hospital, Al Ain, United Arab Emirates, [2]College of Medicine, UAE University, Al Ain, United Arab Emirates, [3]UAE University, Al Ain, United Arab Emirates

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster III
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Systemic Lupus Erythematosus (SLE) is a chronic autoimmune disease that predominantly affects women of childbearing age. Pregnant women with SLE have higher rates of adverse maternal and fetal outcomes than the general population. There is limited research on the risk of infection during pregnancy among women with SLE. This study aims to contribute to a better understanding of the incidence of infection in this population, the factors associated with increased infection risk, and compare the risk of infection among pregnant women with and without SLE.

Methods: Medical records from Tawam Hospital were reviewed retrospectively to identify patients with SLE (diagnosed based on ACR criteria) and pregnancy history. We collected data on demographics, clinical variables, and maternal (including infection). We randomly selected a one-to-one age-matched healthy control group and collected their pregnancy history. In cases of infection, we recorded the number and type of infection. We compared the infection odds ratios between pregnant women with and without SLE. Using multivariate analysis, we examined factors associated with infection in pregnant women with SLE.

Results: The outcomes of 78 pregnancies in 39 women with SLE and 107 pregnancies in 39 without SLE were analyzed. The mean age of both groups was similar (*P*=0.5). Infection episodes occurred in 55.8% of SLE pregnancies and 27% of non-SLE pregnancies (odds ratio 3.2, 95%CI 1.7-5.9). Among SLE pregnancies, we have a total of 98 infection episodes. In 51% of the SLE infections, patients received antibiotics. Most common infection was respiratory infection (43.9%), genitourinary (31.6%), skin and soft-tissue (9.2%), gastrointestinal (9.2%), and others (6.1%). In multivariate analysis, we

examined demographic, SLE disease activity, and symptoms for association with increased risk of infection. We found no factors to increase the risk of infection among SLE pregnancies. However, hydroxychloroquine was protective against infection (table 1).

Conclusion: Pregnant women with SLE have a significantly higher risk of infection compared to their non-SLE counterparts. The most common infection in SLE pregnancies was respiratory. No particular factors were identified to increase the infection risk among the SLE pregnancies. Interestingly, hydroxychloroquine use during pregnancy was found to be protective against infection. This finding highlights the importance of medication management in mitigating infection risks for pregnant women with SLE. However, further research is warranted to investigate the mechanisms involved in the increased risk of infection in pregnancies among women with SLE.

Changes in Rheumatology Disease Measures After Initiation of Belimumab Treatment in Patients with Systemic Lupus Erythematosus

Karen Worley[1], Christopher Bell[2], **Bernard Rubin**[3], Guillaume Germain[4], François Laliberté[4], Sean MacKnight[4], Ana Urosevic[4] and Mei Sheng Duh[5], [1]GlaxoSmithKline, US Value Evidence and Outcomes, Cincinnati, OH, [2]GlaxoSmithKline, US Value Evidence and Outcomes, Durham, NC, [3]GlaxoSmithKline, US Medical Affairs and Immuno-inflammation, Durham, NC, [4]Groupe d'analyse, Ltée, Montreal, QC, Canada, [5]Analysis Group, Boston, MA

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster III
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Real-world benefits of belimumab (BL) in patients with SLE have been shown using SLE-specific measures.[1,2] As SLE disease activity measurement is challenging,[3] assessment of treatment effectiveness using other measures is important. Routine Assessment of Patient Index Data 3 (RAPID3) questionnaire assesses SLE in patients with RA and is a valid measure of SLE disease[4]. This study used real-world data from United Rheumatology Normalized Integrated Community Evidence (UR-NICE) to assess intravenous (IV) BL in improving outcomes.

Methods: Adults with SLE in UR-NICE database who initiated IV BL between January 1, 2012–December 3, 2019, and had ≥5 subsequent BL infusions were included. Patients had SLE clinical activity recorded in the database for ≥12 months before and ≥24 months after first IV BL. Primary objective was time to minimally important difference (MID) from 12 months before index to 24 months post index, measured by Patient Pain Index (PPI), RAPID3, Tender Joint Count (TJC), Swollen Joint Count (SJC), Complement (C)3, C4, and anti-dsDNA. Outcomes were assessed in patients with ≥1 record of that measure during baseline/follow-up. MID was 0.5x the standard deviation of mean baseline values for each disease measure.[5] Kaplan–Meier rates of time to first decrease below/increase above MID were reported during follow-up (3, 6, 12, 18, and 24 months).

Variable	B	Odds ratio	*P*-value
Hydroxychloroquine during pregnancy	-1.73	.18	.05
Pulse steroids during pregnancy	1.32	3.73	.3
Conception at≥ 35 years	1.52	4.59	.09

Results: Of the 495 patients, >50% were in the PPI, C3, and C4 subgroups, ∼30% in the TJC, SJC, and anti-dsDNA subgroups, and 21% in the RAPID3 subgroup.

Improvements in PPI were observed early and continued; 42.6% reached decrease below MID at 3 months, 55.0% at 6 months, and 76.4% at 24 months. For RAPID3 scores, decreases below MID were achieved by 36.5% at 3 months and 61.5% at 24 months. Decrease below MID in TJC was 16.7% at 3 months, which more than doubled to 35.4% at 12 months, and improved through 24 months. Decrease below MID in SJC almost doubled between 3 and 24 months (11.5% to 21.6%), although swollen joints were not as prevalent as tender joints at baseline.

Increase above MID for C3 and C4 levels, respectively, was 8.7% and 8.8% ≤3 months of treatment, increasing to 55.2% and 46.4% at 24 months. Anti-dsDNA levels improved after treatment initiation, with decrease below MID doubling between 3 and 6 months (7.8% to 15.6%).

Conclusion: Among patients initiating IV BL therapy, meaningful improvement in outcomes assessed with multiple rheumatology disease measures, including RAPID3, can be seen as early as 3 months, incrementally increasing over time. While laboratory measures are used to show the rapid effect of BL treatment, this study demonstrated symptomatic improvement in patient pain, physical function, and tender/swollen joints among BL-treated patients with SLE.

Comparing Social Vulnerability Index to Area Deprivation Index to Patient Outcomes in SLE and Glucocorticoid Utilization

Avira Som[1], Lily McMorrow[1], Ling Chen[1], Deepali Sen[2], Elizabeth Baker[3] and Alfred Kim[4], [1]Washington University School of Medicine in St. Louis, St. Louis, MO, [2]Washington University in St. Louis, St. Louis, MO, [3]Saint Louis University, St. Louis, MO, [4]Washington University School of Medicine, St. Louis, MO

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster III
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: As shown in previous studies, outcomes in SLE are affected by social determinants of health which influence health care disparities. Evaluating health disparities through the lens of spatial context is an evolving field. Various indices have been developed to categorize the vulnerability of an area. Two such measures are the Center for Disease Control Social Vulnerability Index (SVI) and the Area Deprivation Index (ADI) by the University of Wisconsin-Madison. SVI was created with the intention of identifying vulnerable areas in times of disaster, while ADI was specifically created to inform healthcare delivery in disadvantaged neighborhoods. In addition, SVI is reported by census tract, versus ADI which is reported by census block (subdivision of census tract). Given the difference in intention behind each index and difference in area studied, we sought to understand whether SVI and ADI would have consistent associations with SLE disease activity and prednisone utilization. We also hypothesized that prednisone overutilization is prevalent across vulnerability indices, and that differences in prednisone use will be seen even between neighborhoods.

Methods: Patients from the Washington University Lupus Center who met either ACR or SLICC classification criteria for SLE were longitudinally assessed from April 2014 to August 2020. The patient's census tract and census block were determined using the address listed for each patient's index visit. Only patients with available SVI, ADI, disease activity assessments (SLEDAI 2000 Responder Index-50, S2K RI-50), and prednisone dose data were included. Census tracts corresponded to SVI from the CDC database, and census blocks corresponded to ADI from the Neighborhood Atlas. SVI ranges from 0 to 1, with 1 being most socially vulnerable, while ADI ranges from 0 to 100 with the 100th percentile being most disadvantaged. Any patient living in an area above the mean of 0.5 or 50th percentile can be seen as living in a socially vulnerable or disadvantaged area. SLE disease activity was assessed using the S2K RI-50, where scores > 4 correlated with active SLE. Prednisone prescribed at the index visit was divided into 4 categories (none, 0-7.5 mg, 8-20 mg, >20 mg).

American Indian or Alaska Native	2
Asian	3
Multiple Race	1

Table 2. Patients prescribed prednisone

Prednisone dosing	Number of Patients
None	135
>0-7.5 mg	20
>7.5-20 mg	40
>20 mg	10

Table 3. Number of patients in each quartile of SVI and ADI

SVI	Number of Patients
0-0.25	58
0.26-0.5	55
0.5-0.75	55
0.75-1	52
ADI	
0-25	13
26-50	64
51-75	54
76-100	89

Results: 220 patients were analyzed. There was no significant correlation between cumulative SVI and disease activity (OR 1.09, 95% CI=0.607-1.975, p=0.7635). Patients living in more disadvantaged areas per ADI were more significantly likely to have active disease (OR 1.65, 95% CI=0.864-3.161, p=0.129), although this was not statistically significant. Both those with vulnerable cumulative SVI (OR 2.23, 95% CI=1.24-3.99, p=0.006) and disadvantaged ADI were also more likely to be prescribed higher doses of prednisone (OR 3.57, 95% CI=1.73-7.36, p=0.0002).

Conclusion: Patients living in vulnerable areas determined by either SVI or ADI are likely to be prescribed higher doses of prednisone, despite having no statistically significant correlation with disease activity. This strongly suggests that those in more vulnerable or disadvantageous areas leverage prednisone utilization to control disease activity, which we hypothesize worsens long-term outcomes for this population.

Abstract Number: 2308

The Association Between Poverty and SLE Disease Burden: Experiences from a Saint Lucian Cohort

Amanda King[1], Catherine Brown[2], Cleopatra Altenor[1], Timothy Niewold[3] and Ashira Blazer[3], [1]Bay Medical Centre, Castries, Saint Lucia, [2]The University of the West Indies, Bridgetown, Barbados, [3]Hospital for Special Surgery, New York, NY

SESSION INFORMATION

Session Date: Tuesday, November 14, 2023

Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster III

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: Poverty increases non-communicable disease risk, however its influence on systemic lupus erythematosus (SLE) burden is poorly understood. Non-White racial/ethnic groups, particularly of African origin, disproportionately suffer both from SLE and poverty, making disentangling racial/ethnic vs socioeconomic influences on SLE outcomes a challenge. Saint Lucia is a Caribbean island with a predominantly African ancestry population and variable socioeconomic dynamics. We therefore tested the association between poverty and SLE severity in a unique African ancestry SLE cohort.

Methods: A 143-patient SLE cohort seeking care with the single practicing rheumatologist in Saint Lucia were included. All participants were at least 18 years old and met SLE classification criteria. Given that all rheumatology care is performed at this center, the cohort is expected to represent near-enumeration of SLE for the island population. Clinical data, demographics, and socioeconomic factors were obtained via chart review. Addresses identified district of residence, and area level poverty percentages in 2016 were obtained from the Saint Lucia National Report of Living Conditions. Incidence rates were calculated as the number of cases per 100,000 person-years of observation. The primary outcome was the Lupus Severity Index (LSI); calculated as a summation of ACR 1997 criteria multiplied by validated regression coefficients. Covariates that associated with LSI were identified by simple linear regression. Multiple regression was used to test the association between key covariates and LSI.

Results: The 2015-2018 incidence of SLE was 8 per 100,000 person-years (95% CI: 5.1-11.9). Incidence by district is shown in Figure 1. Of the 143 participants, 47 were below and 96 were above the poverty threshold. Impoverished patients were diagnosed 10 years earlier than non-impoverished patients, had lower BMIs, were more likely to live in impoverished districts, to take glucocorticoids at higher doses, and had higher lupus severity indexes than non-impoverished patients (**table 1**). Survival over the observation period was 85% in impoverished and 94% in non-impoverished participants (p=0.09). Linear regression models revealed associations between poverty status (p=0.002), younger age at onset (p=0.02), residence in an area with greater poverty level in 2016 (p=0.04), and higher glucocorticoid dose (p< 0.001), and greater LSI.

A.

District		Poverty headcount rate 2006	Poverty headcount rate 2016

Cataracts (%)	0	2	0.32	1
Pulmonary Fibrosis (%)	2	1	0.61	1
DVT/Thrombosis (%)	2	10	0.03	8
Diabetes (%)	4	5	0.80	5
Hyperlipidemia (%)	21	29	0.33	26
Glucocorticoid (%)	85	57	<0.01	66
Glucocorticoid dose	11.2 (11.9)	5.4 (7.9)	<0.01	7.4 (9.8)
Antimalarial (%)	96	91	0.22	92
DMARD (%)	62	45	0.06	50
District poverty (%)	29	24	<0.01	26

Values are expressed as % for categorical variables and mean ± standard deviation (SD) for continuous variables. Categorical variables compared using Fisher's exact test; continuous variables compared using the two-sample T-test or Mann Whitney U Test. DMARDs include non-biologic agents (azathioprine, cyclophosphamide, mycophenolate mofetil, mycophenolic acid, sirolimus, tacrolimus) and biologic agents (anakinra, abatacept, belimumab, rituximab, tocilizumab). Antimalarial drugs include hydroxychloroquine or chloroquine. Glucocorticoid doses are expressed in prednisone equivalent doses. District poverty % reflects data as of 2016.

Conclusion: In this predominantly African ancestry SLE cohort, poverty associated with early onset SLE, higher Lupus Severity Index, and heavier reliance on glucocorticoid therapy. There were trends toward higher case fatality in impoverished participants. These data implicate socioeconomic stress in SLE disease burden and support further studies into the mechanis

SESSION INFORMATION

Session Date: Tuesday, November 14, 2023

Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster III

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: Systemic Lupus Erythematosus (SLE) is associated with epithelial defects and disrupted intestinal barrier, risking bacterial translocation, and promoting systemic inflammation, known as dysbiosis, which is associated with increased disease activity (1). *Enterococcus gallinarum* has been previously linked to gastrointestinal autoimmune diseases, like autoimmune hepatitis and primary sclerosing cholangitis. (2) However, little is known about E. gallinarum prevalence in SLE. Our objective was to analyze the frequency of E. gallinarum in stool samples from SLE individuals and examine its association with clinical and laboratory characteristics.

Methods: A cross-sectional, descriptive study was conducted at the University Hospital "Dr. José Eleuterio González" in northern Mexico. We included adult patients who met the current criteria for systemic lupus erythematosus (SLE) and had recent (< 3 months) routine paraclinical tests, including acute phase reactants. Patients with other autoimmune diseases, chronic infections, pregnancy, cancer, abdominal surgery, or gastrointestinal bleeding were excluded. Demographic and clinical data, as well as anti-nuclear antibodies and complement levels, were obtained from medical records. No participant

§ Chi-Square Test

had received antibiotics, probiotics, or synbiotics within 3 months prior to the study. DNA was extracted using the DNeasy PowerLyzer PowerSoil DNeasy kit from Qiagen (Hilden, Germany) according to the manufacturer's specifications. E. gallinarum was detected using endpoint polymerase chain reaction assay in both SLE patients and age- and sex-matched healthy controls.

Results: Sixty subjects with systemic lupus erythematosus (SLE) were included in the study, with the majority being women (51, 85%). The mean age was 41.79 (±16.6) years, and the average time since diagnosis was 107.03 months (±95.46). E. gallinarum and Enterococcus spp were detected in 7 (11.6%) cases. The most common MEX-SLEDAI parameter observed was arthritis, present in 34 (56.6%) cases, followed by acute cutaneous lupus in 23 (38.3%) cases. Detailed clinical manifestations and laboratory findings can be found in Table 1. A significant difference was found in E. gallinarum-positive patients regarding creatinine levels (0.98 vs. 0.72, p=0.032), erythrocyte sedimentation rate (11.14 vs. 19.49, p=0.031), and the frequency of serositis (57.14% vs. 7.54%, p=0.001). However, when analyzing erythrocyte sedimentation rate using the age-adjusted upper limit, the significance was no longer present (p=0.4). When comparing the prevalence of E. gallinarum in age and sex matched healthy controls (2.8%) with subjects with systemic lupus erythematosus (SLE) (10.3%), E. gallinarum was found to be slightly higher, approaching statistical significance (Table 2)

Conclusion: E. gallinarum was found to have a slightly higher prevalence in patients with systemic lupus erythematosus (SLE) compared to healthy controls, indicating a potential association with the disease. Significant associations were observed between E. gallinarum-positive SLE patients and certain clinical and laboratory parameters.

Machine Learning Approaches for Prediction of Renal Flares in Systemic Lupus Erythematosus: Knowledge-Driven Models Outperformed Data-Driven Models

Nursen Cetrez[1], Julius Lindblom[1], Raffaele Da Mutten[2], Dionysis Nikolopoulos[2] and Ioannis Parodis[1], [1]Karolinska Institutet, Stockholm, Sweden, [2]Karolinska Institutet and Karolinska University Hospital, Division of Rheumatology, Department of Medicine Solna, Stockholm, Sweden

SESSION INFORMATION

Session Date: Tuesday, November 14, 2023
Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster III
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Renal flares in patients with SLE result in significant nephron loss. Thus, identification of reliable early signals of impending renal flares is anticipated to improve the prognosis for these patients. Machine learning (ML) has witnessed growing utilisation in managing extensive, heterogeneous datasets, and non-linear relationships. In this study, we implemented two different approaches of ML algorithms to identify baseline clinical and laboratory determinants of renal flare occurrence in a large cohort of SLE.

Methods: We analysed data from five phase III trials (BLISS-52, BLISS-76, BLISS-NEA, BLISS-SC, EMBRACE) after exclusion of patients with baseline renal flare BILAG A or B (N=3169). Renal flares were defined as a change from C, D, or E to A or B in the renal domain of the classic BILAG index within a 52-week long follow-up. Following construction of panels of variables using either (i) knowledge or (ii) feature selection methods, we developed ML classifiers including extreme gradient boosting (XGBoost), least absolute shrinkage and selection operator (LASSO), random forest (RF), and multivariable logistic regression. A stratified split was applied to the data to partition the study population into a training (90%; N=2853) and a test set (10%; N=316). The training set was used in model development while the internal validation was developed by a 10 times 10-fold cross validation. The test set was used for external validation of the built model, and the performance of the models was demonstrated using area under the curve (AUC) of the receiver operating curves (ROC), accuracy with a 95% confidence interval (CI), sensitivity, and specificity metrics.Both approaches yielded final models that utilised the minimal number of features while maintaining optimal model performance.

Results: Of 3169 patients, 899 (28.3%) developed a renal flare during follow-up. XGBoost yielded the greatest accuracy both in the hypothesis-driven (0.97 and the data-driven approach (0.88), as well as the highest performance metrics (AUC: 0.97 and 0.91; sensitivity: 1.00 and 0.82; specificity: 0.94 and 0.94, respectively) and an adequate calibration on the test dataset. LASSO (accuracy: 0.95 and 0.86 ; AUC: 0.97 and 0.96; sensitivity: 1.00 and 0.86; specificity: 0.91 and 0.86, respectively) demonstrated similar performance. The final model successfully reduced the number of features to five parameters: renal BILAG C or D score, urine protein creatinine ratio, serum albumin, blood urea nitrogen, and C3 levels. These models exhibited encouraging performance, with AUC values of 0.88, 0.88, 0.88, and 0.87 for XGBoost, LASSO, logistic regression, and RF, respectively.

Conclusion: The knowledge-driven approach based on clinical expertise outperformed the unsupervised data-driven approach which solely relied on feature selection methods. Through utilisation of five routine clinical parameters, we developed a robust and highly accurate prediction tool for forecasting renal flares in patients with SLE. Our ML-based model holds substantial value in guiding clinical decision-making to personalise patient management and possesses potential for practical application in clinical settings.

SESSION INFORMATION

Session Date: Tuesday, November 14, 2023

Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster III

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: Systemic lupus erythematosus is a heterogenous autoimmune disease characterized by inflammatory damage to multiple organ systems. We have shown that the single-nucleotide polymorphism (SNP) rs1876453 is associated with decreased risk of lupus, with a preferential effect on anti-double stranded (ds) DNA antibodies. Since anti-dsDNA antibodies develop prior to clinically apparent disease and are associated with more severe disease, we hypothesized that the minor A allele at rs1876453 would delay disease onset and improve clinical outcomes. We demonstrated a delay in lupus onset associated with the SNP using a large lupus association study [Large Lupus Association Study 2 (LLAS2)], and herein we explore the effects of the SNP on clinical outcomes using a longitudinal inception cohort.

Methods: Subjects genotyped using the Illumina platform from a longitudinal inception cohort [Systemic Lupus International Collaborating Clinics (SLICC), n=977] were studied. Age of onset was determined, and damage, disease activity, steroid exposure, and survival were assessed.

Results: As with the subjects in the LLAS2 cohort, the median age of diagnosis for subjects with the protective A allele at rs1876453 was significantly greater in the SLICC cohort [median (IQR), 33 (20) for GG, 36 (20) for AG, and 50 (31.5) for AA, p = 0.0167]. Subjects with the protective allele had similar scores for damage at 5 years, but their likelihood of developing damage by then was greater (41.6% for AG/AA vs 31.8% for GG at Year 5, p = 0.0270). This was not due to more severe disease, since they had lower disease activity [median SLEDAI (IQR) 2.5 (3.6) for GA/AA, 3.3 (3.8) for GG; p = 0.0163] and comparable steroid exposure. Although this was likely due in part to their older age at disease onset, there was a trend towards early damage even in patients younger than age 50 (p = 0.0762). Despite their older median age, their mortality rates were lower (p = 0.0414).

Conclusion: The minor allele at rs1876453 is associated with delayed onset, reduced overall disease activity, and lower mortality despite the increased probability of early damage. This increased risk of early damage may result from older age at disease onset or from a specific pathogenic mechanism in subjects with the protective SNP who develop lupus and will require further study.

Fungal Infections in Hospitalized Patients of Systemic Lupus Erythematosus: A Nationwide Cohort Analysis

Saman Tanveer and Chun Pan, John H. Stroger Jr. Hospital of Cook County, Chicago, IL

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster III
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Immunosuppressive therapy is the cornerstone of management in patients with systemic lupus erythematosus (SLE). Patients on immunosuppressive therapy are at increased risk of developing opportunistic fungal infections. We conducted this analysis to describe the epidemiology of fungal infections in this cohort.

Methods: We analyzed the National Inpatient Sample (NIS) 2016-2020 for all patients with discharge diagnosis of SLE & Fungal infections (Histoplasmosis, Pneumocystosis, Cryptococcosis, Aspergillosis, Blastomycosis, candidiasis, Coccidioidomycosis) as primary or secondary diagnosis via ICD-10 codes. Frequencies, demographics and trends were determined and compared between hospitalized patients with SLE and without SLE. A p-value of ≤0.05 was considered statistically significant.

Results: In hospitalized SLE patients, there was higher risk of developing fungal infections in male gender and in Hispanics & Asian populations. Steroid use, concomitant HIV infection and the presence of leukemias & lymphomas in hospitalized SLE patients were significant predictors of fungal infection (Figure 1). There were also differences in the incidence of different fungal infections based on geographical areas in the US, with Blastomycosis being more common in the Midwest. From 2016 to 2020, there was a decline in the incidence rate of hospitalization per 100,000 for non-SLE patients with fungal infections whereas this rate remained steady for the SLE cohort (Figure 2).

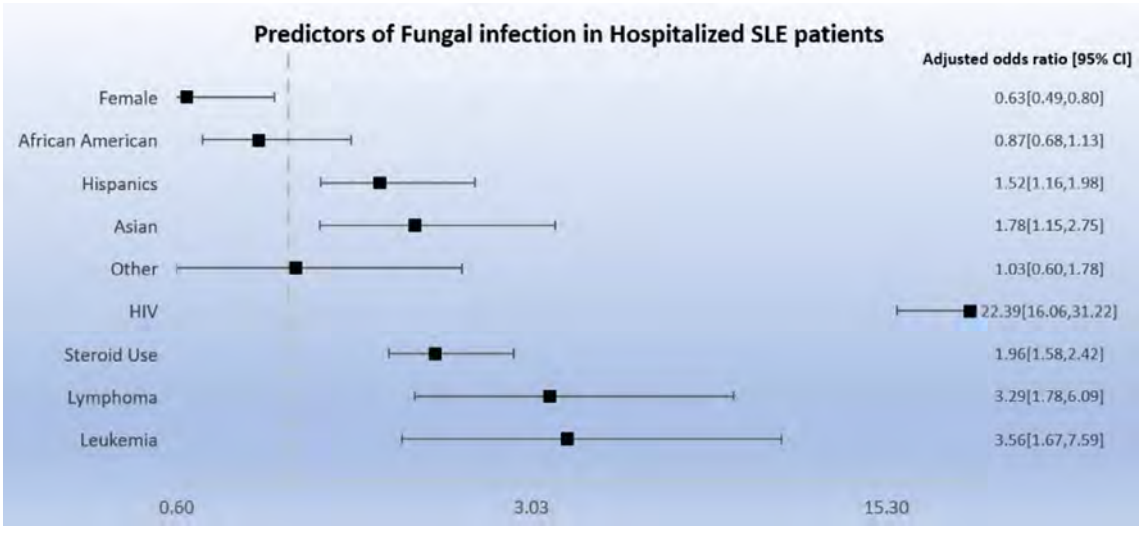

Figure 1 - Various predictors of fungal infections in hospitalized SLE patients (CI: Confidence Interval)

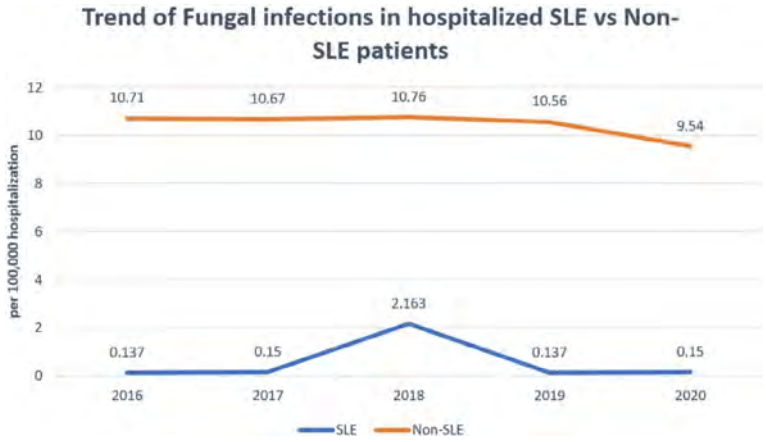

Figure 2 - Decrease in incidence rate of hospitalization per 100,000 for non-SLE patients with fungal infections; incidence rate of hospitalization per 100,000 for SLE patients with fungal infections has remained stable

Conclusion: The frequency of hospitalized SLE patients with fungal infections has remained stable between 2016 to 2020 compared to non-SLE patients for which this rate has decreased. This difference could be explained by the use of immunosuppressive therapy in SLE patients. Further studies can be done to explain the increased risk of fungal infections in hospitalized SLE patients who are males, Hispanics and Asians.

Utilization of Palliative Care in Hospitalized Patients with Systemic Lupus Erythematosus: A Nationwide Cohort Analysis

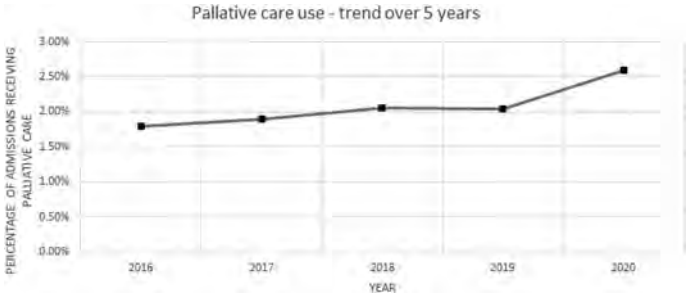
Saman Tanveer[1], Hema Pinnam[2], Fatima Tanveer[3] and Daksh Ahluwalia[1], [1]John H. Stroger Jr. Hospital of Cook County, Chicago, IL, [2]J.S.S. Medical College, Mysore, India, [3]CMH Lahore Medical College, Lahore, Pakistan

SESSION INFORMATION

Session Date: Tuesday, November 14, 2023
Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster III
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: We aimed to investigate trends in utilization of hospital palliative care services among hospitalized patients with systemic lupus erythematosus (SLE) and analyze its impact on length of hospital stay, hospital charges, and in-hospital mortality.

Methods: The National Inpatient Sample (NIS) 2016-2020 was used to identify hospitalizations for SLE, and these were further stratified based on inpatient palliative care use. Univariate logistic regression analysis was used for yearly trends, with year of admission as the independent variable and palliative care use as the dependent variable. Length of stay and total hospitalization charges were compared using multivariate linear regression, adjusting for potential confounders. A p-value of ≤ 0.05 was considered statistically significant.



Graph 1 - Increase in utilization of palliative care among hospitalized patients with SLE from 2016 to 2020

Results: The overall proportion of utilization of hospital palliative care services for patients with SLE over five years, ranging from 2016 to 2020, was 2.07%. There was a rise in the trend of utilization of palliative care services in patients with SLE, increasing from 1.8% in 2016 to 2.60% in 2020 (P-value for trend < 0.001). Older age, higher Charlson comorbidity index,

admission in urban teaching hospitals and large-size hospitals were associated with more frequent use of inpatient palliative care. Age less than 35 years, Black and Hispanic race were identified as independent predictors of lower use of inpatient palliative care. Patients with SLE who received palliative care services experienced a longer hospital stay (mean difference [MD]: 4.04 days, 95 % Confidence interval [CI]: 3.62-4.46 days, $p < 0.001$] as well as higher hospital charges (MD: $61287, 95% CI: $53914-$68660 $p < 0.001$), compared to SLE admissions that did not receive palliative care.

Conclusion: Utilization for palliative care services has increased over the last five years for hospitalized SLE patients, with a significant rise in utilization during the COVID-19 pandemic. Utilization of palliative care services is associated with increased length of stay in the hospital and increased hospitalization charges. Most importantly, significant disparities exist in palliative care utilization based on racial differences and medical comorbidities. Further efforts are needed for equitable access to palliative care in patients with rheumatological diseases.

Comparison of Disease Severity and Outcomes in Adolescent-Onset and Young Adult-Onset Systemic Lupus Erythematosus

Emma Materne[1], Baijun Zhou[1], Hyon K. Choi[2], Yuqing Zhang[3] and April Jorge[1], [1]Massachusetts General Hospital, Boston, MA, [2]Massachusetts General Hospital and Harvard Medical School, Lexington, MA, [3]Division of Rheumatology, Allergy, and Immunology, Department of Medicine, Massachusetts General Hospital, Boston, MA

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster III
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Adolescent-onset SLE is associated with more severe disease than adult-onset SLE, but young adults may also experience adverse outcomes. We sought to compare disease and damage-related outcomes between adolescent-onset and young adult-onset SLE.

Methods: We conducted a comparative cohort study to assess potential differences in outcomes between patients with adolescent-onset (ages 12-17) vs. young adult-onset (ages 18-23) SLE. Using observational data from a US multi-center electronic health record database, we identified patients with incident SLE (enrolled for ≥ 2 years prior to the first SLE code and met the SLE definition: > 2 SLE ICD codes > 30 days but < 2 years apart). We assessed demographics, SLE severity, early onset lupus nephritis (LN) and baseline comorbidities. We examined kidney outcomes including LN, chronic kidney disease (CKD), end-stage kidney disease (ESKD), transplantation. Among the subset with LN, we also assessed persistent proteinuria, defined as >500mg/day more than one year after LN onset among the subset with LN. We also assessed cardiovascular (CV) events (including major adverse cardiac events and venous thrombosis), psychiatric illness (including hospitalization for depression/suicidality), and SLICC damage index progression. Since LN can occur at SLE onset, kidney outcomes were compared using logistic regression; other outcomes were compared using cox regression to assess incidence rates and hazard ratios. We adjusted for sex, race/ethnicity, and geographic region.

Results: We identified 2866 patients with adolescent-onset and 5589 with young adult-onset SLE **(Table 1).** Adolescents were less likely to be non-Hispanic White (26 vs. 36%) than young adults. Adolescents had higher rates of moderate and severe SLE disease index scores and higher frequency of early onset LN compared to young adults (35 vs. 25%). Over

PY, person-years; MACE includes hospitalizations for myocardial infarction, stroke, and heart failure. *Adjusted for sex, race/ethnicity, and geographic region. Young-adult onset SLE is the reference group.

Morbidity and Damage Progression in Adolescent-Onset Versus Young Adult-Onset Systemic Lupus Erythematosus

2/3 of each group used hydroxychloroquine and glucocorticoids. Over mean 5.7 and 5.4 years follow up, LN was more common in adolescents than young-adult onset SLE patients (adjusted HR 1.43 (1.30-1.57), but CKD, ESRD, and kidney transplant were less frequent than in young adults **(Table 2)**. There was a trend towards a lower risk of persistent proteinuria in adolescents, but this outcome was frequent in both groups with LN (56 vs. 60%). Adolescent-onset SLE was associated with a lower risk of CV events, psychiatric outcomes, and damage accumulation than in young-adult onset SLE **(Table 3)**.

Conclusion: In this comparative cohort study of patients with adolescent and young adult-onset SLE, we found that adolescents have more severe disease at SLE onset, with a higher risk of LN, but they have a lower risk of kidney damage and overall damage progression than young adults, as well as a lower risk of CV and psychiatric morbidity. Among those with LN in both age groups of SLE onset, more than half had persistent proteinuria, which suggests the need to improve outcomes.

Assessing Lupus Disease Activity Following the Onset of End-Stage Kidney Disease Within a Single Tertiary Centre in South London

Samir Patel[1], Shounak Ghosh[2], Rajagopal Sankara Narayanan[3], Letizia Valisena[4], Deepak Nagra[1], Jonathan Dick[4], Kate Bramham[4], Patrick Gordon[5] and Chris Wincup[4], [1]King's College London, London, United Kingdom, [2]CMRI Hospital, Kolkata, India, [3]Narayana Medical College, Nellore, India, [4]King's College Hospital, London, United Kingdom, [5]NHS, London, United Kingdom

SESSION INFORMATION

Session Date: Tuesday, November 14, 2023

Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster III

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Table 1 - Mean values before and after the onset of ESKD (n=30)

	Before	After
SLEDAI-2K score	4.8	2.6
dsDNA titre (IU/mL)	64.6	25.2
C3 level (g/L)	0.96	1.03
C4 level (g/L)	0.26	0.3
Prednisolone dose equivalent (mg/day)	15.7	11.5

Background/Purpose: Lupus nephritis represents a severe manifestation of SLE and is associated with a risk of progression to end-stage kidney disease (ESKD) if untreated, leading to significant morbidity and high healthcare-related costs. Once patients with SLE reach ESKD and are initiated on renal replacement therapy (RRT), in the form of either dialysis or transplantation, it has previously been suggested that the disease becomes quiescent. However, our experience suggests that patients continue to exhibit active disease even after reaching ESKD. In this study we describe the temporal trends in disease activity for patients with SLE before and after ESKD from a single tertiary centre in South London. We also sought to identify whether there was a greater risk of ongoing disease activity across ethnic groups.

Methods: We conducted a retrospective observational study of consecutive adult patients with biopsy-proven lupus nephritis and ESKD who were under regular follow up in our unit from May 2004 to May 2023. Clinical electronic records were examined from the first point of entry until the end of the study period, transfer or death. Medication, SLE Disease Activity Index 2000 (SLEDAI-2K), dsDNA and complement levels were checked at 6-monthly intervals before and after the onset of ESKD. The primary outcome was disease activity using the SLEDAI-2K score, before and after the onset of ESKD. A SLEDAI-2K score ≤4 was considered low disease activity and >4 as active or flaring disease. Mean scores were compared using Wilcoxon's signed-rank test.

Results: Thirty patients were included (90% female, 67% of Black ethnicity, 20% Caucasian and 13% Asian) with a combined 369 years of follow up. The mean age at SLE diagnosis was 29 years (±11.7) and the mean interval from SLE diagnosis to ESKD was 11.8 years (±7.4). During this period 12 patients underwent renal transplantation, 18 patients received dialysis only and 7 patients died (4 with active SLE). SLEDAI-2K fell on average after the onset of ESKD although this did not reach statistical significance (Figures 1 and 2). Immunological markers of disease activity did appear to improve, as shown in Table 1. Of the 29 patients with >6 months of data after ESKD onset, 15 achieved consistently low disease activity within an average of 1.4 years (±2.5). However, 14 of the 29 patients exhibited active disease with an average time to flare of 2.6 years (±3.4). Nine of these 14 patients showed active disease within 18 months of ESKD onset and all were of Black

Figure 1 - Mean SLEDAI-2K Scores Before and After ESKD

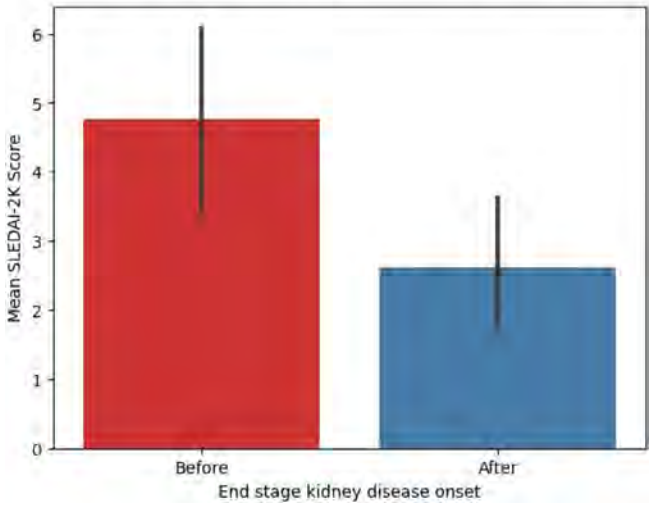

Figure 2 - SLEDAI-2K Scores In Relation To ESKD

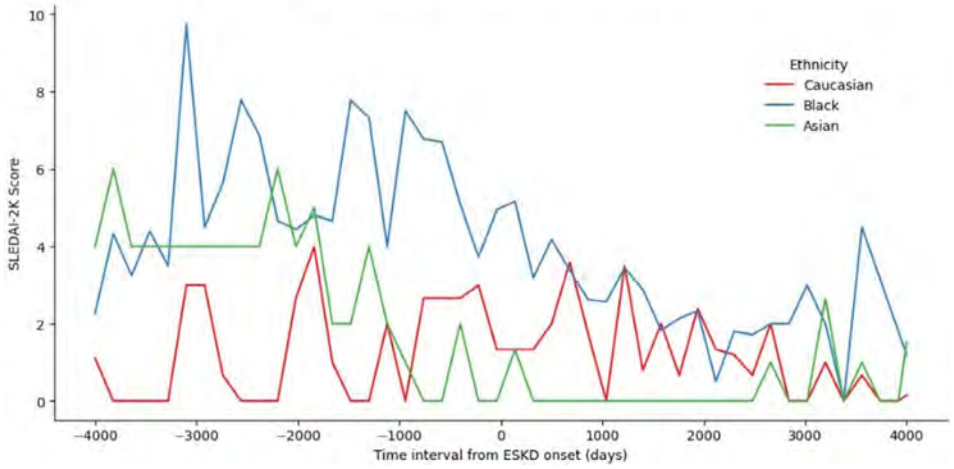

ethnicity. Clinical manifestations after ESKD involved rashes, synovitis, serositis, myocarditis and neuropsychiatric involvement. Five patients ultimately required induction therapy with cyclophosphamide or rituximab.

Conclusion: Despite a fall in mean SLEDAI scores after the onset of ESKD, SLE disease activity persisted or flared in 48% of cases, often within 18 months of ESKD diagnosis. Our cohort were primarily of Black ethnicities, who are known to have more frequent and aggressive renal involvement. Our data contradicts the notion that SLE "burns out" in ESKD and supports a need for vigilance in the monitoring of patients with SLE and ESKD, particularly in those of Black ethnicities and within the first 18 months of RRT.

Effect of SARS-CoV2 Infection on Disease Flares in Patients with Systemic Lupus Erythematosus: A Case-control Study

Chi Chiu Mok[1], Chris Cheung[2], Chi Hung To[3], Kar Li Kelly Chan[4] and SAU MEI TSE[5], [1]Tuen Mun Hospital, Hong Kong, Hong Kong, [2]Rutonjee Hospital, Hong Kong, Hong Kong, [3]Pok Oi Hospital, Hong Kong, Hong Kong, [4]Tuen Mun Hospital, Shatin, China, [5]Tuen Mun Hospital, Hong Kong, China

SESSION INFORMATION

Session Date: Tuesday, November 14, 2023
Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster III
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: To study the effect of SARS-CoV2 infection on disease flares in patients with systemic lupus erythematosus (SLE).

Methods: Patients who fulfilled the ACR or SLICC criteria for SLE and were followed in our rheumatology clinics were retrospectively studied. We identified patients who had documented COVID-19 (Omicron and its variants) between February and November 2022 and a group of SLE controls who did not have COVID-19 randomly matched for age, sex, and the time period of COVID-19 in a 1:2 ratio. The primary outcomes of interest were SLE flares (clinical or serological) within 90 days of SARS-CoV2 infection.SLE flares were assessed by the SELENA flare instruments, with modifications (mild/moderate or severe). The rates of SLE flares were compared between SARS-CoV2-infected SLE patients and controls.

Results: 91 SLE patients with COVID-19 (age 48.6±14.0 years; 95.6% women; SLE duration 14.2±8.3 years; 53% history of lupus nephritis) and 182 SLE controls not infected by COVID-19 (age 48.7±13.8 years; 95.6% women; SLE duration 15.2 ±9.0 years) were studied. Eleven of 90 (12.2%) SARS-CoV2-infected patients had serious manifestations (oxygen requirement, use of mechanical ventilator, lung infiltrates on imaging studies or admission to the intensive care unit). Patients with mild COVID-19 were treated symptomatically or oral anti-viral agents whereas those with serious COVID-19 was treated with intravenous remdesivir, dexamethasone, and/or biologic/targeted agents. One (1.1%) of our patients died and 7 (7.7%) patients developed severe complications. Within 90 days of SARS-CoV2 infection, 14 (15.4%) patients developed mild/moderate SLE flares, and 2 (2.2%) patients had severe SLE flares. The incidence of SLE flares in SARS-CoV2-infected patients was significantly higher than those without (17.6% vs. 5.5%; p=0.001). The changes in anti-dsDNA and complement C3 levels, however, were not significantly different between the two groups. Among SARS-CoV2-infected SLE patients, those with clinical SLE flares had significantly lower C3 values (p=0.004) but non-significantly higher anti-dsDNA titer (p=0.32) before SARS-CoV2 infection than those without SLE flares. Herpes zoster (HZ) reactivation occurred in 2 patients (2.2%) with COVID-19, which was numerically higher than those not infected by COVID-19 (2 patients, 1.1%; p=0.48). No particular risk factors were identified for HZ reactivation after COVID-19 infection.

Conclusion: In this retrospective case-control study, clinical flares within 90 days were significantly more common in patients infected with SARS-CoV2 than age and gender-matched non-infected SLE controls.SLE patients with lower C3 levels were more likely to flare after COVID-19. The results from our study support the hypothesis for a viral trigger for disease exacerbation in SLE.

Effect of SLE-DAS Remission on Quality of Life in Patients with Systemic Lupus Erythematosus: A Cross-sectional Validation Study

Fung Lam[1], Chi Hung To[1] and Chi Chiu Mok[2], [1]Pok Oi Hospital, Hong Kong, Hong Kong, [2]Tuen Mun Hospital, Hong Kong, Hong Kong

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster III
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: The SLE Disease Activity Score (SLE-DAS) has been developed and validated in Italian patients with SLE. The objective of this study was to evaluate the effect of disease remission as defined by SLE-DAS on health-related quality of life (HRQoL) in Chinese patients with SLE.

Methods: Consecutive patients who fulfilled the 1997 ACR or 2012 SLICC criteria for SLE between March and May 2023 were recruited from our clinics. Participants were asked to complete the validated Chinese version of the LupusPRO (v1.8) HRQoL questionnaire and Fatigue Severity Score (FSS) before consultation. Attending physicians were asked to grade the SLE disease activity according to the Physicians' Global Assessment (PGA [0-3]), SLE-DAS and SLEDAI-2K. Remission, mild, and moderate/severe disease activity of SLE was defined as SLE-DAS ≤2.08, < 2.08-≤7.64 and >7.64 respectively. SLE-DAS Boolean-based remission was defined as all clinical items of SLE-DAS equal to zero and prednisolone usage ≤5mg/day. The effects of SLE-DAS remission on LupusPRO were studied by statistical analyses.

Results: At interim, a total of 216 SLE patients were studied (age 45.8±13.6 years; 96.2% women; SLE duration 16.0 ±7.8 years). All were ethnic Chinese. At baseline visit, 84 (38.9%) patients had clinically active SLE, defined by a PGA score ≥0.5.Active organ manifestations, in decreasing order of frequency, were proteinuria (17.2%), mucocutaneous lesions (11.0%), leukopenia (7.9%), arthritis (4.7%) and thrombocytopenia (2.8%). The distribution of PGA score was: < 0.5 (60.6%); 0.5-1.0 (16.2%), ≥1.0-2.0 (19.0%) and 2.0-3.0 (3.70%).There were 135 (62.5%) patients who scored zero in the clinical SLEDAI-2K.A total of 135 (62.5%) patients had SLE-DAS≤2.08, and 132 (61.1%) patients achieved SLE-DAS Boolean-based remission; 34 (15.7%) and 47 (21.6%) patients, respectively, had SLE-DAS mild and moderate/severe activity. SLE-DAS correlated significantly with PGA (r=0.802, p< 0.001), SLEDAI-2K (r=0.798, p< 0.001) and LupusPRO score (r=-0.285, p< 0.001).Patients with SLE-DAS Boolean-based remission, compared to non-remission, had significantly higher total LupusPRO score (73.1±15.1 vs 65.9±17.4; p < 0.001), particularly in the domains of lupus symptoms (72.0±17.7 vs 61.5±20.7; p< 0.001), procreation (88.3±19.6 vs 76.8±28.9; p< 0.001), lupus medications (68.2±23.6 vs 58.2±28.2; p=0.003), physical health (81.2±18.9 vs 76.5±21.4; p=0.03), emotional (64.5±22.5 vs 57.0±25.3; p=0.01), and body image (80.3±22.7 vs 74.3±27.6, p=0.01).Similarly, significantly higher LupusPRO score was observed in patients who achieved clinical SLEDAI-2K=0 (vs >0) (72.7±15.4 vs 66.3±17.3; p=0.005) and PGA< 0.5 (vs ≥0.5) (73.5±15.4 vs 65.2±16.7; p< 0.001). SLEDAI-2K and PGA also correlated significantly with LupusPRO score (r=-0.247; p< 0.001; r=-0.265; p< 0.001 respectively), with similar correlation coefficients with the SLE-DAS.

Conclusion: SLE-DAS remission is associated with significantly better HRQoL in Chinese patients with SLE in this interim cross-sectional analysis.Similar performance of SLE-DAS was observed with the SLEDAI-2K and PGA.Further longitudinal studies on the sensitivity of the SLE-DAS to change in disease activity are in progress.

The Association Between Systemic Lupus Erythematosus (SLE) and Bone Mineral Density (BMD) Polygenic Risk Scores with Lumbar Spine BMD Z-score: A Retrospective Cohort Study

Vrati Mehra[1], Daniela Dominguez[2], Nicholas Gold[2], Andrea Knight[2], Deborah Levy[2], Fangming Liao[2], Eleanor Pullenayegum[2], Amer Shammas[2], etienne Sochett[2], Reza vali[2], Declan Webber[3], Earl Silverman[4] and Linda Hiraki[2], [1]The Hospital for Sick Children & University of Toronto, Toronto, ON, Canada, [2]The Hospital for Sick Children, Toronto, ON, Canada, [3]University of Toronto, Mississauga, ON, Canada, [4]Silverman, Toronto, ON, Canada

SESSION INFORMATION

Session Date: Tuesday, November 14, 2023

Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster III

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: Childhood-onset systemic lupus erythematosus patients < 18 years (cSLE) are at risk for reduced bone mineral density (BMD) due to disease activity and chronic glucocorticoid exposure. Genetics play a role in SLE susceptibility. Our aim was to assess the genetic contribution to BMD among a multi-ethnic cSLE cohort.

Methods: All patients were diagnosed and followed at the SickKids and had baseline Lumbar Spine (LS) BMD scan, defined as 1 month prior, or up to one year post cSLE diagnosis. The main outcome of interest was LS (L1-L4) BMD z scores. Two weighted polygenic risk scores (PRSs)- 1) BMD PRS 2) SLE PRS were calculated based on largest GWASs to date. Both PRSs were regressed with BMD z-scores in linear models adjusted for demographics, glucocorticoid exposure, height percentile, BMI, and an indicator for lupus nephritis and/or neuropsychiatric lupus.

Results: The study included 284 patients, 82% female, 29% of European, and 28% of East Asian ancestry. The median age of cSLE diagnosis was 13.5 years [IQR 11.1, 15.3]. In multivariate model, a higher BMD PRS was significantly associated with low BMD z-score (β: -0.75; 95%CI: -1.32, -0.18; *P*=0.01) as was prior steroids use (β: -0.34; 95%CI: -0.63, -0.04; *P*=0.02). No association was found between SLE PRS and LS BMD z-scores. Height percentile and BMI were significantly associated with BMD z-score, however presence of LN and/or NPSLE was not.

Conclusion: High BMD PRS was significantly associated with lower LS BMD z-score in cSLE patients at baseline. BMD PRS may be an effective tool to stratify cSLE patients.

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster III
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: The mortality in Systemic Lupus Erythematosus (SLE) varies largely across different countries most probably due to social, healthcare and ethnic differences. We need to identify demographic, clinical and serological predictors of mortality in SLE in our country, to improve the prognosis of SLE patients.

Objectives: To analyze the causes and identify predictive factors of mortality of SLE, and to assess the time evolution and chronological changes in Spain.

Methods: We performed a cross-sectional and retrospective study analyzing data from RELESSER cohort. Sociodemographic, clinical and serological variables, comorbidities and treatments, as well as indicators of disease activity, damage and severity were recorded. We excluded patients with lost information about the death variable and analyzed the differential features of deceased patients in comparisons with survivors through different time stages according to the date of diagnosis: until the 1980's; the 1990's and the first decade of the 21st century. Variables associated with mortality in univariate analysis were entered into different multivariate models to determine which ones were independently associated with the outcome of the disease in each decade.

Results: A total of 3665 patients were included, mostly caucasian female with similar general features regardless of the different time stages analyzed.18.4% until the 1980´s, the 5.97% in the 1990´s and up to 2.84% of the individuals in first decade of the 21st century, had died. The main age of death was similar in the different groups, around 55-58 years old (Table). The vascular events were the leading cause of death until the 1980´s, while in the last two decades, were infections.

The older age at diagnosis was predictor of mortality. Neither gender nor delay in diagnosis was independently associated with mortality, with the exception of the female sex, which behaved as a protective factor until the 1980´s.

The mortality predictors in our cohort were the presence of hypocomplementemia and organ damage until the 1980´s; thrombocytopenia, antiphospholipid syndrome and valve disease in the 1990´s; serositis, organ damage and depression in the first decade of the 21st century. Conversely, skin involvement was related to greater survival over the last two decades

Table. General Features

	Until 1980´s	1990´s	21st Century
N (3665)	539	1122	2004
Age at diagnosis, years, mean±SD	28.7 ± 12.6	33.4 ± 14.2	38.3 ± 15.3
Sex, female n (%)	491 (91.1%)	1025 (91.5%)	1770 (88.6%)
Caucasian race (%)	98.5%	96%	90.4%
Delay in diagnosis, months, mean±SD	20.8 ± 52.7	26.2 ± 53.6	28.9 ± 52.6
ACR criteria (≥ 4) (%)	98%	93.9%	88.1%
DECEASED n (%)	99 (18.4%)	67 (5.97%)	57 (2.84%)
Age of death, years, mean±SD	55.21 ± 15.59	57.74 ± 18.61	58.32 ± 19.73
Main cause of death	Vascular events	Infections	Infections

and comorbidities were associated with mortality in all periods of the study. The use of high doses of corticosteroids was predictor of mortality in each time stage, as well as the use of cyclophosphamide and rituximab from the year 2000. Antimalarial treatment was linked to improved survival in all the decades analyzed.

Conclusion: In the RELESSER cohort, the main cause of death in the last decades were infections. However, until the 1980´s, vascular events were predominant. Older age at diagnosis, use of corticosteroids and comorbidities were associated with significant increase in mortality in SLE, while antimalarial treatment was linked to improved survival. Data indicate that organ damage is a risk factor and skin involvement is a protective factor against mortality. Differentially, female sex until the 1980´s was independently associated with improved survival, and depression at the beginning of the 21st century was linked to mortality.

Predicting Remission and Low Disease Activity Attainment in Patients with Systemic Lupus Erythematosus

Raffaele Da Mutten[1], Nursen Cetrez[2], Julius Lindblom[2], Shereen Oon[3], Dionysis Nikolopoulos[1], Mandana Nikpour[4] and **Ioannis Parodis**[2], [1]Karolinska Institutet and Karolinska University Hospital, Division of Rheumatology, Department of Medicine Solna, Stockholm, Sweden, [2]Karolinska Institutet, Stockholm, Sweden, [3]St Vincent's Hospital, Fitzroy, Australia, [4]The University of Melbourne at St. Vincent's Hospital Melbourne, Departments of Medicine and Rheumatology, Melbourne, Australia

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster III
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Response to therapy in SLE varies significantly and presents a considerable challenge in terms of predictability. Development of predictive models with ability to accurately foresee attainment of remission or low disease activity would be of major clinical value.

Methods: We extracted 288 baseline features from five phase III trials of belimumab, comprising 3645 patients. Using a recursive regression and partitioning tree, the top 20 most important factors were identified. Next, clinical expertise was integrated to narrow down the features qualified for the final model to only three. To investigate a potentially differential predictive

ability of the model with different treatment regimens, we stratified the study population into placebo and belimumab recipients. Outcomes were attainment of sustained remission as defined by the Definitions of Remission in SLE (DORIS) criteria and sustained lupus low disease activity state (LLDAS), maintained through week 52. Remission or LLDAS was considered sustained if present at two or more consecutive visits. Different predictive models i.e., least absolute shrinkage and selection operator (LASSO), neural network (NNet), support vector machine (SVM), and extreme gradient boosting (XGBoost) were trained 10 times in a 10-fold cross-validation. Performance was assessed using 20% of the data not used in training. Area under the curve (AUC), confusion matrix, and calibration plots were generated.

Results: In total, 11% met the criteria for sustained LLDAS and 5% those for sustained remission. Lower urinary protein/creatinine ratio (UPCR), lower prednisone dose, and increasing C3 levels were the features yielding the greatest predictive ability. The largest AUC was achieved for predicting sustained LLDAS in the placebo group (LASSO with AUC: 0.80, sensitivity: 0.73, specificity: 0.67, accuracy 0.70) while the belimumab subgroup yielded inferior performance (LASSO with AUC: 0.71, sensitivity: 0.77, specificity: 0.57, accuracy: 0.67). Although calibration seemed satisfactory, class imbalance and the small positive sample size overall might be a reason underlying the superior performance of the first model. Sustained remission was more challenging to predict among belimumab-treated patients (NNet with AUC: 0.63, sensitivity: 0.62, specificity: 0.60, accuracy: 0.61) compared with the placebo group (LASSO with AUC: 0.76, sensitivity: 0.63, specificity: 0.63, accuracy: 0.63). Prediction of sustained LLDAS yielded superior results (LASSO with AUC: 0.76, sensitivity: 0.68, specificity: 0.65, accuracy: 0.67) compared with remission (SVM with AUC: 0.71, sensitivity: 0.61, specificity: 0.71, accuracy: 0.66).

Conclusion: The models developed to predict attainment of sustained remission or LLDAS yielded moderate sensitivity and specificity. Overall, sustained LLDAS was more precisely predicted than sustained remission and accuracy in the placebo population was superior to that in belimumab-treated patients. By reducing the complexity to only 3 factors (UPCR, prednisone dose, C3 levels), our approach enabled a quick estimation of the probability to attain sustained remission or LLDAS in this SLE population.

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster III
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: There is no information available regarding whether the patient's perception of disease activity aligns with current definitions of DORIS 2021 remission and Lupus Low Disease Activity State (LLDAS), nor whether there is concordance between the patient's perception and that of the physician.

Aim: To compare the SLE activity perceived by the patient using the Patient Acceptable Symptom State (PASS) question with the global assessment of activity by the physician, as well as with the definitions of LLDAS/DORIS2021.

Methods: Cross-sectional multicenter study of SLE patients from seven Spanish Rheumatology Departments. DORIS 2021 remission definition and LLDAS were applied and the rheumatologists were asked to classify the activity of the disease in 5 different categories: remission, SACQ, low, moderate or high activity. The patients were asked about their clinical SLE

Table 1. Patient demographics and disease characteristics.

	Number (%) or mean (± SD) (n = 503 patients)
Female gender	463 (92%)
Age at diagnosis (years)	40.7 (±21)

Prednisone	200 (39.7%)
Prednisone dose (mean ± SD)	5 (±6.27)
Antimalarials	366 (72.5%)
Immunosuppressants and/or biologic	219 (44%)

Abbreviations: SLE, systemic lupus erythematosus; ACR, American College of Rheumatology; SLEDAI, SLE disease activity index; PGA, physician global assessment; ANA, antinuclear antibody; ds DNA, double stranded DNA. SLICC/ACR-DI: Systemic Lupus International Collaborating Clinics (SLICC/American College of Rheumatology (ACR) damage index (SDI). (a) Ever present based on ACR criteria, LLDAS: Lupus Low Disease Activity State

condition through the PASS question: "Considering all the different ways your disease is affecting you, if you were to stay in this state for the next few months, do you consider your current state satisfactory?": PASS yes/PASS no. Statistical analysis: descriptive cross-sectional analysis. Analysis of the level of agreement between the PASS question and categorical classification (remission-low activity/ moderate-high activity) using Cohen's kappa.

Results: A total of 503 patients were included in the study (92% female, mean age 50.4 years). Table 1 shows in detail the patient´s characteristics at baseline. Of the 503 patient, 386 (77.4%) had an acceptable symptom state according to the PASS question. Mean (±SD) patient global assessment (PtGA) in a scale of 0-100 scale was 29.62 (±24.38) and mean (±SD) physician global assessment (PGA) in a scale of 0-3 was 0.46 (±0.59).A total of 236 (47.6%) patients met DORIS 2021 remission and 289 (59%) met LLDAS. According to the categorical classification of the rheumatologist: 435 (86.8%) patients were in remission or low disease; 56 (11.2%) in moderate activity and 10 (2%) in high activity state (Table 2). Among the patients who answered "yes" to the PASS question, 245 (65.5%) were in LLDAS and 220 (57.9%) were in remission according to the DORIS 2021 criteria. Mean PtGA in these patients was 19.7 (±18) and PGA 0.29 (±0.4). On the other hand, among non-PASS group, 71 (62.8%) patients were not in the LLDAS and 99 (87.6%) did not meet the criteria for DORIS 2021 remission state. Mean PtGA in these patients was 58 (±19) and PGA 1 (±0.7) (Table 3) Overall level of agreement between PASS question and categorical classification by the rheumatologist, was 82% (IC95%: 79.9, 82.9) with a Cohen's kappa of 0.43.

Table 2. SLE activity: patient and expert´s perspective

	Number (%) or mean (± SD) (n = 503 patients)
SLE disease state classification by expert	
Remission of SLE	205 (40.9%)
Serologically active, clinically inactive	74 (14.8%)
Low SLE activity	156 (31.1%)
Moderate SLE activity	56 (11.2%)
Severe SLE activity	10 (2%)
PGA at enrolment	0.46 (± 0.59)
Positive PASS question	386 (77.4%)
PtGA at enrolment	29.62 (±24.38)

Abbreviations: SLE, systemic lupus erythematosus; PGA, physician global assessment; PASS: Patient acceptable symptoms state; PtGA: patient global assessment.

Table 3. LLDAS and DORIS 2021 remission states according to PASS yes/no perspective by patient.

PASS (n, %)				**non-PASS (n, %)**			
LLDAS		**DORIS**		**LLDAS**		**DORIS**	
YES	NO	YES	NO	YES	NO	YES	NO
245 (65.5%)	129 (34.5%)	220 (57.9%)	160 (42.1%)	42 (37.2%)	71 (62.8%)	14 (12.4%)	99 (87.6%)
PtGA, mean, SD 19.76 (±18)				**PtGA, mean, SD** 58.04 (±19)			
PGA, mean, SD 0.29 (±0.4)				**PGA, mean, SD** 1.01 (±0.72)			

Abbreviations: PASS: Patient acceptable symptoms state; LLDAS: lupus low disease activity state; PGA: physician global assessment; PtGA: patient global assessment.

Conclusion: The majority of SLE patients reported being in an acceptable symptom state according to the PASS question, with similar results reported with the PtGA scale. SLE activity is similarly perceived by the physician perspective valued by the PGA and categorical classification. However, more than a third of patients in the PASS group were not in remission/LLDAS, and approximately 10-35% of the non-PASS group are in a state of remission/LLDAS. It seems that patient perspective is similar to the physician perspective in terms of subjective classification, but some differences are seen in terms of LLDAS and DORIS.

Identifying SLE Patients with Depression Using a Zero-Inflated Hidden Markov Model and Predicting Factors Associated with Transition from a Non-depressed State to a Depressed State

Yasmin Nariman[1], **Juan Pablo Diaz Martinez**[2], Kathleen Bingham[1], Patti Katz[3] and Zahi Touma[4], [1]University Health Network, Toronto, ON, Canada, [2]Schroeder Arthritis Institute, University Health Network, Toronto, ON, Canada, [3]University of California San Francisco, San Rafael, CA, [4]University of Toronto, Toronto, ON, Canada

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster III
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Depression is one of the most common neuropsychiatric disorders in patients with SLE. The Centre for Epidemiologic Studies Depression Scale (CES-D) has been used to determine depressive symptomatology with a score of 24 serving as the cut-off for depression in SLE. Instead of using this cut-off, we aimed to: 1) classify patients into one of two states representing being depressed or not using a hidden Markov model, and 2) identify socioeconomic factors that predict patients' transition from a non-depressed state to a depressed state.

Methods: Data from the Lupus Outcomes Study at the University of California, San Francisco were analysed. Depressive symptoms were assessed with the CES-D annually providing up to 6 waves of observation. Patients with at least 2 waves of data were included. Under a Bayesian perspective, a contiguous-time hidden Markov model was fitted to the data, assuming that patients can be divided into two different states (non-depressed and depressed) over time. We assumed that CES-D scores follow a zero-inflated negative binomial distribution (excess of zeroes and integer outcome), and its means depend linearly on clinically relevant factors (**Figure 2**). Moreover, we included socioeconomic factors (below poverty line, employment and higher education) that could potentially be associated with the transition between the non-depressed and the depressed state.

Results: 763 adults with SLE followed over 7 years were included. We found that the non-depressed state had a mean CES-D rate (μ_{ND}) of 6.05 (95% CrI 5.61 – 6.55) whereas the depressed state mean rate (μD) was 18.3 (95% CrI 17.7 – 18.9) (**Figure 1**). The mean CES-D score rate decreased (improvement of depressive symptoms) by 2% for one-unit increase in SF-36 bodily pain score (higher scores means less pain), and it increased (worsening of depressive symptoms)

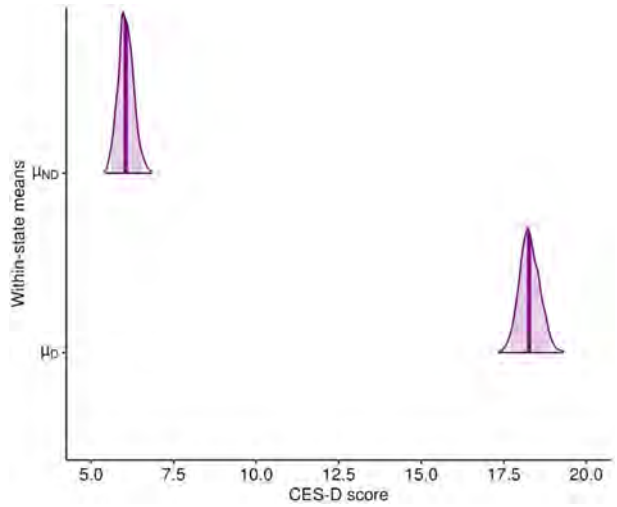

Figure 1. Posterior estimates for the within-state means of the two hidden states. X axis represents the distribution of the parameters of interest. Y axis represents the parameters where inference is made. The dark shaded region represents the point estimate from a frequentist point of view and the light shaded region represents the 95% uncertainty interval, i.e., with 95% of probability the estimate would lie in that region. As an example μ_ND represents the inference made on the unknown mean of the observed CES-D score given that it comes from the non-depressed state after adjusting for other clinical variables described in Figure 2.

by 12%, 26% and 28% for those with lupus related kidney disease, on anti-depressant, and current smokers versus those who did not smoke, respectively (**Figure 2**). Moreover, having higher education (college or more) decreased the rate of transitioning between the non-depressed state and the depressed state by 86% (**Figure 3**). For a patient who is not below the poverty line, nor employed and does not have higher education (i.e. transition covariates set to zero), the probability of transitioning between the non-depressed state and the depressed state was low (3%).

Conclusion: Using HMMs, we classified patients with SLE into two different states, depressed and non-depressed. Bodily pain, smoking, lupus related kidney disease and use of antidepressants drugs were associated with worsening depressive symptoms as measured by the CES-D. Transitioning between states was predicted by different factors over time, where higher education and employment significantly decreased the rate of transitioning between the non-depressed state and the depressed state.

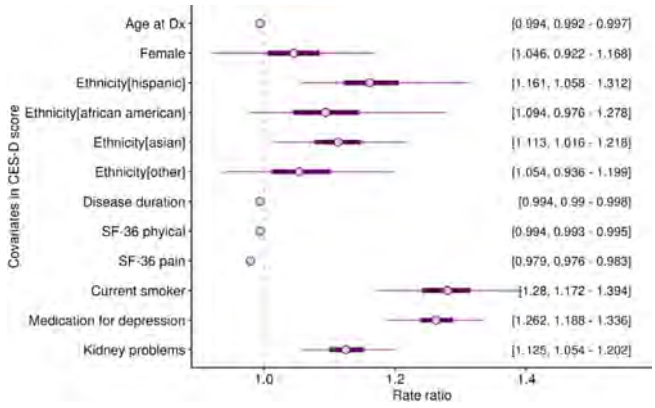

Figure 2. Posterior uncertainty intervals for the covariates in the CES-D score. X axis represents the rate ratio and Y axis represents the parameters where inference is made. For example, those who have kidney problems due to lupus have a 12.5% rate increase in their mean CES-D score compared to those without kidney problems. The dot on the graph represents the point estimate and the line represents the 95% CrI

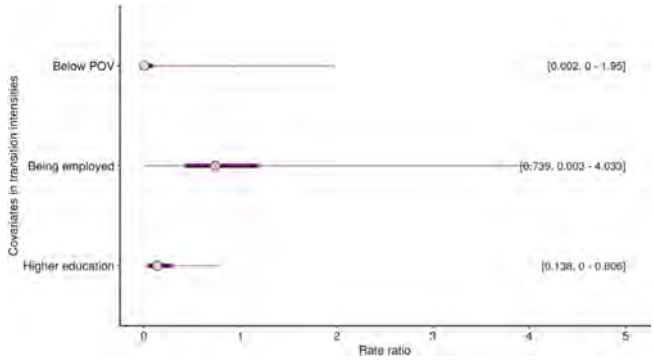

Figure 3. Posterior uncertainty intervals for the covariates in the transition between the non-depressed state and the depressed state X axis represents the hazard ratio and Y axis represents the parameters where inference is made. As an example, being below the POV had a protective effect (Rate ratio .002, 95% CrI 0 – 1.95), although this effect size was not significant. The dot on the graph represents the point estimate and the line represents the 95% CrI

An Electronic Health Record-Based Algorithm for Predicting Systemic Lupus Erythematosus Flares: Integrating Clinical Factors and Social Determinants of Health

Yu Huang[1], **Lixia Yao**[2], zhengkang Fan[3], Jingchuan Guo[1] and Jiang Bian[1], [1]University of Florida, Gainesville, FL, [2]Polygon Health Analytics LLC, Chalfont, PA, [3]University of Florida, Gainsville, FL

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster III
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Systemic lupus erythematosus (**SLE**) has a relapsing-remitting course, with patients experiencing disease activity flares over time. Flares and prolonged disease activity are associated with progressive multi-system organ damage, poor quality of life, high healthcare costs, and increased mortality. Disparities have also been widely reported in the health care access and health outcomes among patients with SLE, and social determinants of health (**SDoH**) are often considered as the root causes of health disparities. However, existing studies evaluating SLE flares and disease activities have not yet considered SDoH or patients' social risks. The objective of this study is to incorporate both patients' clinical characteristics and SDoH and develop an electronic health record (**EHR**)-based machine learning prediction algorithm for SLE flares to support real-time clinical decision-making, address social risks and SDoH, and ultimately reduce health disparities of SLE.

Methods: OneFlorida+ network is part of the national Patient-Centered Clinical Research Network (PCORnet), collating EHR data from 17 million residents in Florida, 2.1 million in Georgia, and 1.1 million in Alabama. We identified adult SLE patients using 2013-2021 OneFlorida+ data and spatiotemporally linked the cohort with 486 neighborhood SDoH (e.g., neighborhood unemployment rate and median income). A validated surrogate measure of SLE Disease Activity Score 2000 (SLEDAI-2K) based on the EHR data was calculated for each 30-day period over the baseline year and follow-up year.

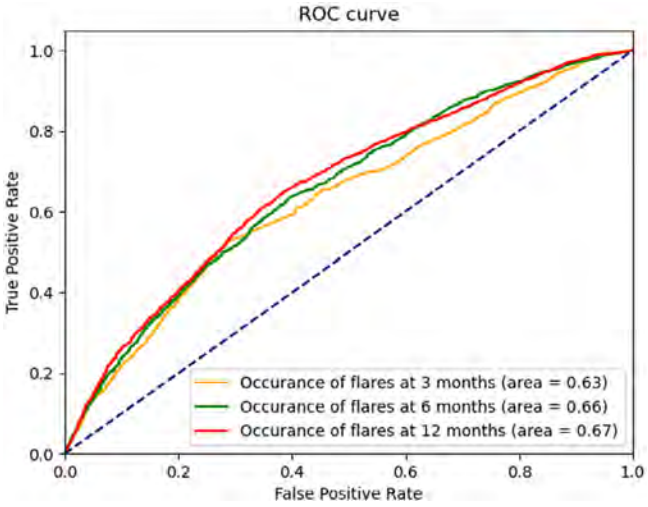

Figure. C statistics of gradient boosting machine algorithm to predict SLE flares.

The median score for the first 12 months was used to establish a baseline level of disease activity; and a flare was defined as an increase of at least 4 from the baseline score. We incorporated SDoH and patients' clinical characteristics (e.g., medical diagnoses, prescriptions, and lab results) collected at baseline year and employed a gradient boosting machine to predict the occurrence of flares at 3 months, 6 months and 12 months after baseline.

Results: We identified 33,151 eligible SLE patients; the mean age was 45 (std: 16) years, 89% were females, and 39%, 26%, and 25% were non-Hispanic White, non-Hispanic Black, and Hispanic race/ethnicity, respectively. Of the cohort, over one-third (39%) developed at least one flare during the follow-up year; 19%, 9%, 4%, and 6% experienced 1, 2, 3, and 3+ time(s) flares during the follow up year. Our algorithm showed a good utility for predicting individuals' risk of flares, achieving a C statistic (standard deviation) of 0.63 (0.01), 0.66 (0.01), and 0.67 (0.01) at the 3- month, and 6- month, and 12-month period, respectively (**Figure**).

Conclusion: By incorporating both SDoH and clinical data, our EHR-based algorithm shows promise for identifying likely flares in real-world patients with SLE. Future studies are needed to identify key SDoH causally associated with flares occurrence to identify intervention targets that improve both health outcomes and health disparities in patients with SLE.

Abstract Number: 2324

Leveraging ChatGPT for Real-World Systematic Lupus Erythematosus Data Curation from Electronic Health Records: A Feasibility Study

Lixia Yao, Liwam Gebru, Biruk Aweke, Jay Patel, Ernest Vina, David Fleece and Huanmei Wu, Temple University, Philadelphia, PA

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster III
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Epidemiologists, health services researchers, and health outcome investigators have begun utilizing real-world data (RWD) to gain valuable insights into disease patterns, treatment outcomes, and healthcare utilization and economics. Similarly, biopharmaceutical and medical device manufacturers utilize RWD to identify medical gaps, enhance patient care, and drive innovative therapeutic interventions. However, a significant portion (~80%) of essential clinical data is trapped in unstructured text within clinical notes, thereby remaining inaccessible in existing RWD for systemic lupus erythematosus (SLE).

Methods: To address this challenge, we leveraged the cutting-edge Natural Language Processing (NLP) model, ChatGPT 4.0, to analyze clinical notes to identify potential diagnosis of SLE. We evaluated:1) the adequacy of unstructured clinical notes in capturing essential clinical details (i.e., 22 clinical and immunologic variables) to support meeting the 2019 European League Against Rheumatism and American College of Rheumatology (EULAR/ACR) classification criteria for SLE; 2) the efficacy of the ChatGPT model in identifying those variables outlined in the EULAR/ACR criteria.

De-identified medical records were obtained from Temple University Health System's EHR system (Epic), comprised patients aged 18 years or above, with at least at least one rheumatology visit and one ICD-10-CM code of M32.* (SLE) between 1/1/2012 and 5/31/2022. Using a Python script, we conducted an automatic search for various mentions of SLE in rheumatology visit notes. We then identified those with a positive anti-nuclear antibody (ANA) test. A thorough manual review of the rheumatology notes were conducted to determine if patients met the EULAR/ACR classification criteria. Subsequently, we employed ChatGPT 4.0 to extract the EULAR/ACR clinical variables.

Results: The initial Python search yielded 16,124 rheumatology notes from 445 unique patients. The follow-up search for positive ANA tests returned 1,147 rheumatology notes from 187 unique patients. The manual review by trained medical professionals revealed that 116 of the 187 patients met the EULAR/ACR criteria. There was a remarkably high level of agreement between the assessments made by ChatGPT 4.0 and those made by trained medical professionals (830 out of

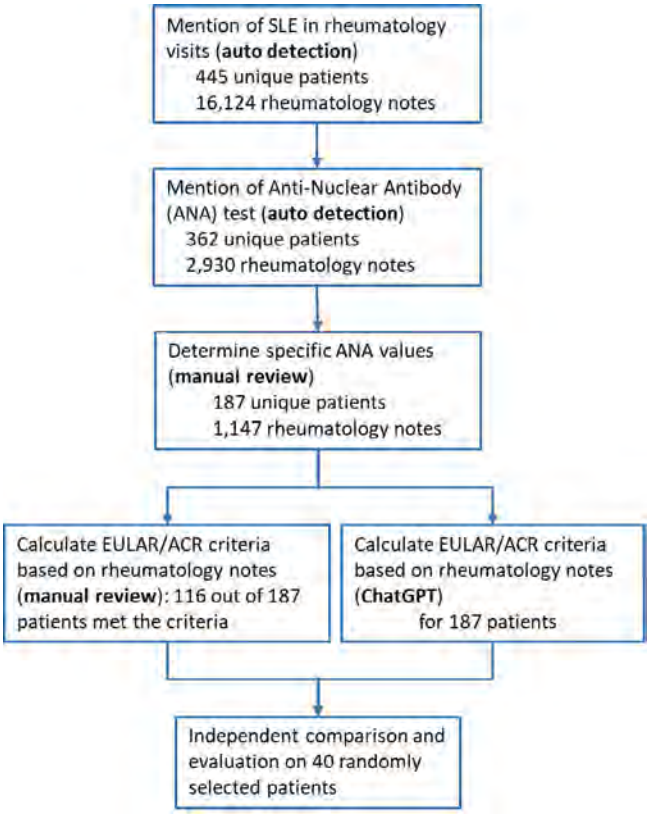

Figure 1. The overall study workflow

Table 1. Analysis of disagreements of annotations by medical professionals and ChatGPT

Clinical variables included in EULAR/ACR classification of SLE	Discrepancy between medical professional and chatGPT	Rightness by chatGPT	Rightness by medical professional
Alopecia	4	3	1
Oral ulcer	1	0	1
Subacute cutaneous or discoid lupus	8	3	5
Acute cutaneous lupus	5	3	2
Pleural or pericardial effusion	2	1	1
Joint involvement	12	10	2
Proteinuria	4	4	0
Antiphospholipid antibodies	4	2	2
Low C3 or low C4	1	1	0
Low C3 and low C4	3	1	2
anti-dsDNA antibody/anti-smith antibody	6	1	5
Total	50	29	21

880 clinical and immunologic variables across 40 randomly selected patients). Among the 50 annotations of disagreement (see Table 1), ChatGPT's interpretations were found to be accurate in 29 cases. In some cases, the differentiation between acute cutaneous lupus vs. subacute cutaneous lupus was not clearly documented in the visit notes. In other cases, ChatGPT and human annotators had to infer the classification based on certain patient-reported symptoms like rash and photosensitivity.

Conclusion: Our findings confirm that unstructured clinical notes contain sufficient clinical details into SLE patient care, including 22 clinical and immunologic variables specified in the established classification criterion for SLE. Moreover, the utilization of state-of-the-art NLP techniques has significant promise in identifying those with SLE, potentially enhancing existing SLE research using RWD.

Abstract Number: 2325

Longitudinal ANA Titers in SLE and ANA-associated Rheumatic Diseases

Emily Littlejohn[1], Lingxuan Kong[2], Lu Wang[2] and Emily Somers[2], [1]Cleveland Clinic, Cleveland, OH, [2]University of Michigan, Ann Arbor, MI

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: SLE – Diagnosis, Manifestations, & Outcomes Poster III
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Antinuclear antibodies (ANAs) are a hallmark of systemic lupus erythematosus (SLE) and also a marker of subclinical autoimmunity. While a seminal study using the US Department of Defense Serum Repository suggested a progressive accumulation of autoantibodies before the onset of SLE, there have been no large-scale studies to

Table 1. International Classification of Diseases (ICD) codes used for classifying ANA-associated diseases

Diagnosis	ICD-9	ICD-10
Lupus	710.0	M32.9, M 32.10
Scleroderma	710.1	M34.0, M34.1, M34.9
Sjogren's Syndrome	710.2	M35.0
Dermatomyositis	710.3	M33.9
Polymyositis	710.4	M33.20
Mixed Connective Tissue Disease	710.8	M35.1
Undifferentiated Connective Tissue Disease	710.9	M35.8, 35.9

assess changes in ANA titers within individuals over time. We performed this study to characterize longitudinal, intra-individual variation in ANAs in persons with SLE or other ANA-associated rheumatic diseases, as well as ANA-positive persons without rheumatic disease, in a large healthcare system in the Midwestern US.

Methods: We performed an exploratory analysis of electronic health record data from an academic health system between 1999-2020. Among the patients with at least one positive ANA, we screened their electronic medical records for ANA-associated rheumatic disease diagnoses, based on International Classification of Diseases (ICD) coding. We categorized the study population into four groups:(1) SLE according to ICD coding; (2) A "validated" SLE subset of patients enrolled in our institutions IRB-approved Lupus Cohort; (3) "Other" ANA-associated rheumatic disease, and (4) ANA-positive controls without a history of ANA-associated rheumatic disease. The ICD codes utilized are listed in Table 1.

For group comparisons, ANOVA was utilized for continuous variables, and chi-square test for categorical variables. Multivariable generalized linear mixed effects models were utilized for analyses with ANA positivity (binary) as the outcome. For analyses with ANA titer strength (magnitude of positivity) as the outcome, linear mixed effects models were used. As laboratory measurement of ANA titers is based on the detection of"doubling" of levels (eg, 1:80, 1:160, 1:320, etc.), we took a log transformation on the ANA titer to normalize the skewness in the distribution of the variable.

Results: SLE patients had a higher odds of a positive ANA titer compared to other ANA-associated rheumatic diseases [OR 2.05, 95% CI(1.77, 2.37)] (Figure 1). Compared to the ANA+ control group, the average ANA titer magnitude for the ANA-associated rheumatic diseases group was 0.44 units [95% CI (0.33, 0.55)] higher on the log scale controlling for age,

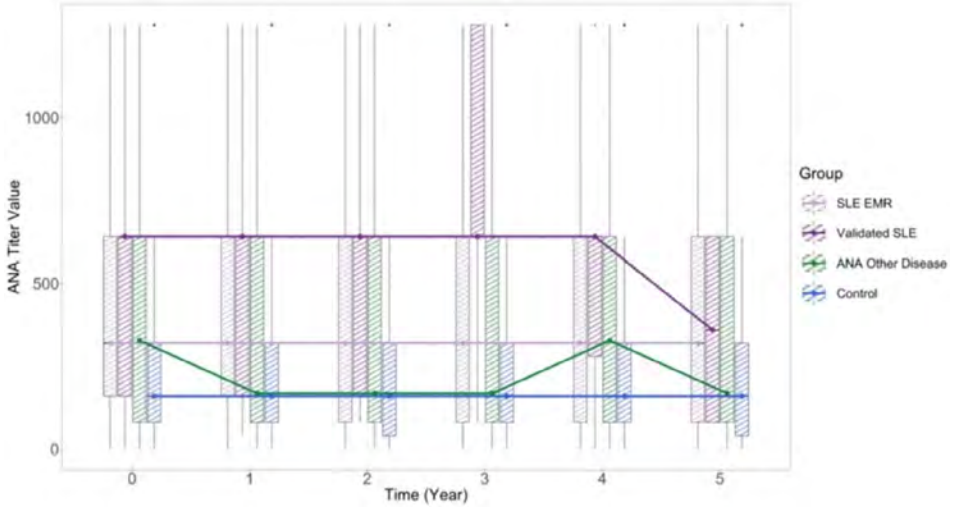

Figure 1. Boxplot of ANA titer among groups. (SLE-EMR, validated SLE patients, ANA-associated other rheumatic disease, ANA control group). Y-axis denotes the measure of ANA titer closest to each year point, X-axis denotes time (count in year), time is from baseline to 5-year follow-up. Dots and lines denote group median and its change over time. The upper and lower bound of each box is the 75% quantile and 25% quantile respectively.

Table 2. Results from linear mixed effects models, with log of ANA titer as the outcome.

Variable	Coefficient (95% CI)	P-value
Age	-0.0007 (-0.003, 0.002)	0.53
Female (Male referent)	0.18 (0.07, 0.29)	0.001**
Race (White referent)		
Black	0.07 (-0.04, 0.18)	0.20
Other/unknown	-0.01 (-0.17, 0.14)	0.86
Time (month)	-0.0002 (-0.002, 0.001)	0.74
Diagnostic group (ANA control referent)		
ANA other diagnosis	0.44 (0.33, 0.55)	<0.001***
SLE	0.77 (0.66, 0.88)	<0.001***
Time*ANA Other Disease	0.001 (-0.0007, 0.003)	0.21
Time*SLE	-0.003 (-0.004, -0.0008)	0.004**

sex and time, and 0.77 units [95% CI (0.66, 0.88)] higher for the SLE group, with both statistically significant (p< 0.001) (Table 2).

Longitudinally, in the validated SLE group, the likelihood of having a positive ANA decreased by 0.3% with each month [OR 0.997,95% CI (0.995, 0.998)]. ANA titer strength significantly decreased over time in the SLE group; after one year, the magnitude of ANA titer among patients in the SLE group was 0.033 units on the log scale lower than patients in the control group (95% CI 0.01, 0.04, p< 0.01).

Conclusion: Based on this large longitudinal dataset, ANA titers may be more dynamic than previously accepted in patients with SLE and ANA+ rheumatic diseases. Even in SLE, where titers were on average higher than for other ANA-associated diseases, declining ANA titers are seen over time, which might reflect aspects of disease states or flare risk that are beginning to be appreciated given accumulating evidence in other longitudinal studies.

Abstract Number: 2326

Efficacy and Safety of Voclosporin in Patients with Proteinuria > 2 G/g

Emily Littlejohn[1], Salem Almaani[2], Vanessa Birardi[3], Ernie Yap[4] and Christopher Collins[5], [1]Cleveland Clinic, Cleveland, OH, [2]Ohio State University Medical Center, Columbus, OH, [3]Aurinia Pharmaceuticals Inc, Edmonton, AB, Canada, [4]Aurinia Pharmaceuticals Inc., Edmonton, AB, Canada, [5]Formerly Aurinia Pharmaceuticals Inc., Copenhagen, Denmark

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: SLE – Treatment Poster III
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

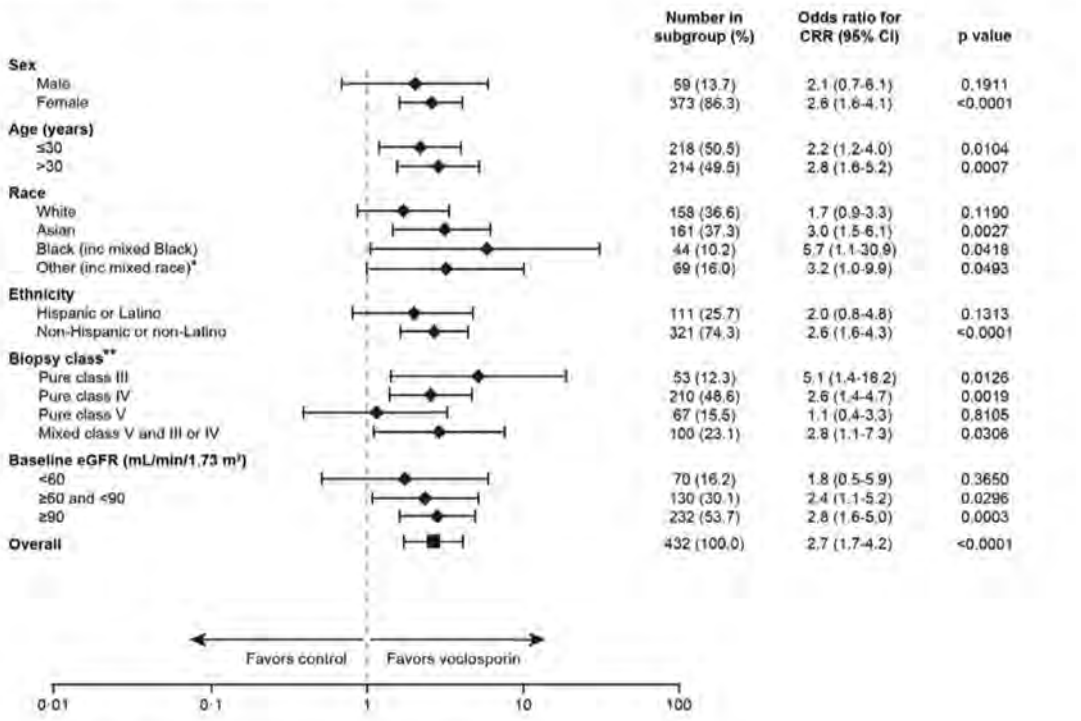
Background/Purpose: Proteinuria is the most common manifestation of lupus nephritis and is a mediator of progressive kidney damage. Early reductions in urine protein creatinine ratio (UPCR) have shown to be predictive of improved long-term outcomes in LN. However, recent studies with monoclonal antibody therapies have demonstrated a lack of efficacy in patients with moderate to high proteinuria (UPCR ≥2 to ≥3 g/g), potentially due to an increase in renal excretion of drug. In a pooled analysis of the Phase 2 AURA-LV and Phase 3 AURORA 1 studies, the addition of voclosporin to mycophenolate mofetil (MMF) and low-dose glucocorticoids resulted in earlier and greater reductions in proteinuria, regardless of baseline

demographics or disease characteristics. To further characterize the efficacy and safety of voclosporin in patients with moderate to high proteinuria, we have analyzed outcomes in patients with UPCR ≥2 g/g using the pooled dataset.

Methods: Both studies enrolled patients with biopsy-proven LN (Class III, IV, or V ± III/IV) within 6 months (or up to 2 years in AURORA 1) and proteinuria ≥1.5 g/g (≥2 g/g for Class V). Patients were randomized to voclosporin (23.7 mg BID) or placebo and treated for up to one year (48 weeks [AURA-LV], 52 weeks [AURORA 1]); all patients received MMF and low-dose glucocorticoids. For this post hoc analysis, complete renal response (CRR) rates were evaluated in patients with baseline UPCR ≥2 g/g. Complete renal response was defined as UPCR ≤0.5 g/g with stable renal function, low-dose steroids, and no rescue medication; partial renal response (PRR) was defined as a ≥50% reduction in UPCR from baseline. Adverse events (AEs) and measures of renal function were also assessed.

Results: Of the 268 and 266 patients included in the voclosporin and control arms of the pooled analysis, 217 and 215 patients had a baseline UPCR ≥2 g/g (mean [SD], 5.2 [3.4] vs. 4.6 [2.9] g/g). At one year, the change from baseline in least squares (LS) mean UPCR was significantly greater in the voclosporin arm (p=0.0003). A significantly greater percentage of voclosporin-treated patients achieved CRR at one year compared to the control arm (41.0% vs. 21.9%; odds ratio [OR] 2.48, p< 0.0001; Figure 1). Significantly more patients in the voclosporin arm (69.6%) than control arm (50.0%) achieved a PRR at one year (OR 2.3, p< 0.0001). Similar rates of AEs were reported in both arms. Measures of renal function, including mean eGFR, were similar and stable over one year of treatment (Figure 2, Table 1).

Figure 1. Complete Renal Response at One Year

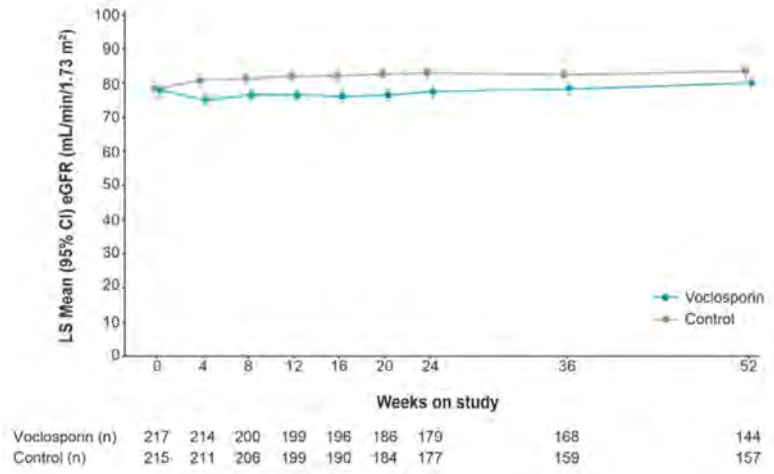


*Other races includes other or mixed races except Black race

**Two patients with Mixed Class III/IV and Mixed Class II/V disease are not included in the biopsy class subgroup analysis but are included in all other subgroup analyses and the overall analysis.

Post hoc analysis of patients with baseline UPCR ≥2 g/g includes pooled data from the 23.7 mg BID voclosporin arms and control arms in AURA-LV and AURORA 1. Analysis includes data from up to 48 weeks in AURA-LV and up to 52 weeks in AURORA 1. Complete renal response defined as UPCR of ≤0.5 g/g, eGFR ≥60 mL/min/1.73 m², or no decrease >20% from baseline, low-dose glucocorticoids, and no rescue medications. Odds ratio (OR) >1 demonstrates treatment benefit of voclosporin. CRR, complete renal response; estimated glomerular filtration rate; SD, standard deviation; UPCR, urine protein creatinine ratio.

Figure 2. LS Mean eGFR over Time



Post hoc analysis of patients with baseline UPCR ≥2 g/g includes pooled data from the 23.7 mg BID voclosporin arms and control arms of AURA-LV and AURORA 1. Data include up to 48 weeks from AURA-LV and up to 52 weeks from AURORA 1. Renal function was assessed with corrected eGFR (Chronic Kidney Disease Epidemiology Collaboration equation) using a prespecified ceiling of 90 mL/min/1.73 m². CI, confidence interval; eGFR, estimated glomerular filtration rate; LS Mean, least squares mean.

Table 1. Laboratory Parameters over Time

	Voclosporin n=217		Control n=215	
	Baseline	**One Year**	**Baseline**	**One Year**
Systolic BP, mean (SD) mmHg	126.0 (15.6)	120.0 (11.9)	125.8 (15.6)	118.2 (13.4)
Diastolic BP, mean (SD) mmHg	84.1 (11.3)	78.3 (8.8)	82.3 (11.6)	77.1 (10.4)
eGFR, mean (SD), mL/min/1.73 m²	77.7 (16.0)	79.8 (15.5)	78.0 (15.8)	83.1 (13.1)
UPCR, g/g	5.2 (3.4)	1.0 (1.7)	4.6 (2.9)	1.7 (1.9)
Magnesium, mean (SD) mg/dL	2.1 (0.2)	2.0 (0.2)	2.0 (0.2)	2.1 (0.2)
Potassium, mean (SD) mmol/L	4.1 (0.6)	4.2 (0.4)	4.0 (0.6)	3.9 (0.4)
Glucose, mean (SD) mg/dL	85.5 (24.6)	87.7 (21.3)	87.6 (37.5)	85.8 (11.8)
Creatinine, mean (SD) mg/dL	0.8 (0.3)	0.9 (0.3)	0.8 (0.3)	0.7 (0.3)

Post hoc analysis of patients with baseline UPCR ≥2 g/g includes pooled data from the 23.7 mg BID voclosporin arms and control arms of AURA-LV and AURORA 1. Data include up to 48 weeks from AURA-LV and up to 52 weeks from AURORA 1. Renal function assessed with corrected eGFR (Chronic Kidney Disease Epidemiology Collaboration equation) using a prespecified ceiling of 90 mL/min/1.73 m². BP, blood pressure; eGFR, estimated glomerular filtration rate; SD, standard deviation, UPCR, urine protein creatinine ratio.

Conclusion: Consistent with results from the overall pooled study population, patients with UPCR ≥2 g/g treated with voclosporin achieved significantly higher renal response rates than patients treated with MMF and low-dose glucocorticoids alone while renal function in both arms remained comparable. This is clinically relevant given the lack of safe and effective therapies for patients with high proteinuria.

Hydroxychloroquine Improves Low Complement Levels

Michelle Petri[1], Rebecca Jacobson[2], Andrea Fava[3] and Larry Magder[4], [1]Department of Medicine, Division of Rheumatology, Johns Hopkins University School of Medicine, Timonium, MD, [2]Johns Hopkins University School of Medicine, Baltimore, MD, [3]Johns Hopkins University, Baltimore, MD, [4]University of Maryland, Baltimore, MD

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: SLE – Treatment Poster III
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Low complement is associated with clinical disease activity and future organ damage in patients with systemic lupus erythematosus (SLE). Prior studies from Japan, although inconsistent, supported improvement in complement levels after hydroxychloroquine (HCQ) introduction. We studied HCQ whole blood levels and C3 and C4 levels in a US cohort.

Methods: In the first paired-visit analysis, to mimic the Japanese studies, we identified patients with low complement and low levels of HCQ in their blood.Then at their next clinic visit, we compared those whose HCQ whole blood levels increased to over 50 ng/mL to those whose HCQ whole blood levels did not with respect to changes in complement. In a second analysis, we considered all clinical visits in our cohort among patients who sometimes had low complement, and sometimes did not, and we examined the association between HCQ whole blood levels and low complement using conditional logistic regression.

Results: Although the numbers varied between analyses, approximately 68% of the patients included in these analyses were African American, and 93% were female. Table 1 shows the results of the analysis of paired visits with respect to C3.Among those whose HCQ whole blood levels increased to be above 50 ng/mL, there was a greater mean increase in mean C3 (p=0.022) compared to those whose HCQ whole blood levels did not increase.Similarly, with respect to C4, among those HCQ whole blood levels increased, there was a significantly greater probability of achieving normal C4 levels (p=0.0030) and of having a higher increase in mean C4 (p=0.0037) (Table 2).Table 3 shows the results considering all clinic visits among those with variable complement levels. In this analysis, we did not observe a strong relationship between HCQ whole blood levels and C3. However, there was a consistently higher probability of achieving normal C4 levels as HCQ whole blood levels increased.

Conclusion: Both C3 and C4 levels increased significantly with HCQ whole blood levels >50 ng/mL. The percentage of patients who achieved a normal C4 level with a HCQ whole blood level >50 ng/mL (44%) was statistically significant. Surprisingly, even a low HCQ whole blood level was able to achieve an increase in complement. In the second analysis, we found a strong dose response between HCQ whole blood levels and C4 (but not C3). Improving complement levels may be one mechanism by which HCQ prevents poor outcomes in SLE. As low complement is part of the SLEDAI, this effect can contribute to an SRI-4 response in clinical trials.

HCQ Whole Blood levels at 2nd visit (ng/mL)	Number (%) with complement in the normal range at 2nd visit	P-value[1]	Mean (SD) change in complement (mg/dL)	P-value[1]
<50 ng/mL (n=67)	9 (13%)	0.36	2.2 (12.9)	0.022
50+ ng/mL (n=84)	18 (21%)		8.3 (17.1)	

[1] Based on a GEE model to account for multiple measures from the same patient.

C3 changes between the two consecutive visits with a HCQ whole blood level of lower or higher than 50 ng/mL

HCQ Whole Blood levels at 2nd visit (ng/mL)	Number (%) with complement in the normal range on the 2nd visit	P-value[1]	Mean (SD) change in complement (mg/dL)	P-value[1]
<50 ng/mL (n=56)	9 (13%)	0.0030	0.7 (2.7)	0.0037
50+ ng/mL (n=61)	27 (44%)		3.0 (4.2)	

[1] Based on a GEE model to account for multiple measures from the same patient.

C4 changes between the two consecutive visits with a HCQ whole blood level of lower or higher than 50 ng/mL

HCQ Blood Level	Proportion (%) of visits with low C3	Odds Ratio (95% CI)	P-value[1]
HCQ<50 ng/mL (or patient reports no HCQ and HCQ was not measured	63/168 (38%)	1.00 (Ref)	
HCQ 50-199 ng/mL	33/88 (38%)	0.90 (0.63, 1.31)	0.59
HCQ 200-499 ng/mL	76/211 (36%)	0.74 (0.54, 1.00)	0.37
HCQ 500-999 ng/mL	100/302 (33%)	0.88 (0.67, 1.16)	0.37
HCQ 1000+ ng/mL	64/214 (30%)	0.88 (0.67, 1.16)	0.38
HCQ Blood Level	**Proportion (%) of visits with low C4**	**Odds Ratio (95% CI)**	**P-value[1]**
HCQ<50 ng/mL (or patient reports no HCQ and HCQ was not measured)	64/125 (51%)	1.00 (Ref)	
HCQ 50-199 ng/mL	36/72 (50%)	0.63 (0.41, 0.99)	0.045
HCQ 200-499 ng/mL	104/173 (40%)	0.55 (0.38, 0.80)	0.0015
HCQ 500-999 ng/mL	25/228 (20%)	0.39 (0.28, 0.54)	<0.0001
HCQ 1000+ ng/mL	24/147 (16%)	0.38 (0.28, 0.53)	<0.0001

BID, twice daily; BILAG-2004, British Isles Lupus Assessment Group 2004 index; BMI, body mass index; CLASI, Cutaneous Lupus Erythematosus Disease Area and Severity Index; CS, corticosteroids; MCS, mental component summary; PCS, physical component summary; PGA, Physician Global Assessment; PROMIS, Patient-Reported Outcomes Measurement Information System; QD, once daily; SD, standard deviation; SF-36, 36-Item Short Form Health Survey; SLEDAI-2K, SLE Disease Activity Index 2000.

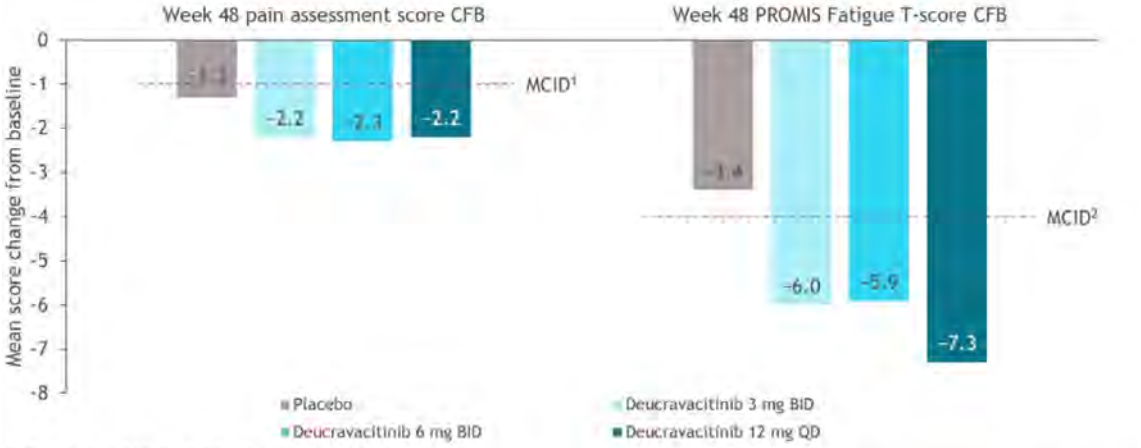
Background/Purpose: Deucravacitinib is a first-in-class, oral, selective, allosteric tyrosine kinase 2 (TYK2) inhibitor approved in the US, EU, and other countries for treatment of adults with moderate-to-severe plaque psoriasis who are candidates for systemic therapy. In PAISLEY, a 48-week, phase 2, randomized controlled trial that assessed deucravacitinib in patients with active systemic lupus erythematosus (SLE), a greater proportion of patients receiving deucravacitinib treatment achieved SLE Responder Index-4 (SRI[4]) responses at Weeks 32 and 48 vs placebo. Patient-reported outcomes (PROs) were collected as exploratory endpoints.

Table 2. Patients reporting clinically meaningful response at Week 48

Assessment	Placebo, n (%)	Deucravacitinib 3 mg BID, n (%)	Deucravacitinib 6 mg BID, n (%)	Deucravacitinib 12 mg QD, n (%)
Pain NRS score[a]	30 (33.3)	47 (51.6)	41 (44.1)	34 (38.2)
PROMIS Fatigue T-score[b]	20 (22.2)	33 (36.3)	34 (36.6)	32 (36.0)
SF-36 PCS score[c]	26 (28.9)	36 (39.6)	45 (48.4)	35 (39.3)
SF-36 MCS score[c]	25 (27.8)	33 (36.3)	27 (29.0)	29 (32.6)

[a]Patients achieving 1-point improvement.
[b]Patients achieving 4-point improvement.
[c]Patients achieving 2.5-point improvement, scores range from 0–50.
BID, twice daily; MCS, mental component summary; NRS, numeric rating scale; PCS, physical component summary; PROMIS, Patient-Reported Outcomes Measurement Information System; QD, once daily; SF-36, 36-Item Short Form Health Survey.

Figure 1. Mean changes from baseline on the pain NRS and in the PROMIS Fatigue T-score at Week 48



1. Salaffi F, et al. *Eur J Pain*. 2004;8:283-91.
2. Strand V, et al. *Lupus Sci Med*. 2020;7:e000373.

BID, twice daily; CFB, change from baseline; MCID, minimal clinically important difference; NRS, numeric rating scale; PROMIS, Patient-Reported Outcomes Measurement Information System; QD, once daily.

Methods: All patients met Systemic Lupus International Collaborating Clinics classification criteria, were seropositive for antinuclear antibody, anti-double-stranded DNA, or anti-Smith antibody, and had Systemic Lupus Erythematosus Activity Index 2000 total score ≥6 points and clinical score ≥4 points. Patients (N=363) were randomized 1:1:1:1 to placebo (n=90) or deucravacitinib 3 mg twice daily (BID; n=91), 6 mg BID (n=93), or 12 mg once daily (QD; n=89). Patients assessed pain levels on a numeric rating scale (NRS) and completed the Patient-Reported Outcome Measurement Information System (PROMIS) Fatigue 7a Short Form and 36-Item Short Form Health Survey (SF-36). Missing data were imputed using control-based pattern imputation. Results were descriptive.

Results: Baseline characteristics were comparable across groups (**Table 1)**. At Week 48, greater mean changes from baseline in pain and fatigue were reported with deucravacitinib 3 mg BID, 6 mg BID, and 12 mg QD vs placebo, including achievement of the minimal clinically important differences (MCID) of −1 and −4 for both pain and fatigue with all doses of deucravacitinib vs for pain only with placebo (**Figure 1**). Patients treated with deucravacitinib reported greater achievement of changes associated with MCID for pain (−1), fatigue (−4), and SF-36 MCS and PCS (−2.5) vs placebo (**Table 2**). Mean scores (SD) at Week 48 numerically improved with deucravacitinib 3 mg BID, 6 mg BID, and 12 mg QD vs placebo, respectively: Pain NRS: 3.6 (2.7), 3.7 (2.6), 3.6 (2.8), and 4.7 (2.7); PROMIS Fatigue: 52.4 (10.2), 52.6 (10.0), 51.9 (10.6), and 54.4 (10.9); SF-36 PCS: 44.7 (10.0), 44.6 (9.3), 45.1 (11.0), and 41.5 (10.5); and SF-36 MCS: 46.7 (12.6), 46.3 (13.1), 47.3 (12.6), and 45.2 (12.9).

Conclusion: Patients with SLE who received deucravacitinib reported improvements over patients who received placebo on pain and fatigue, and in health-related quality of life at Week 48.

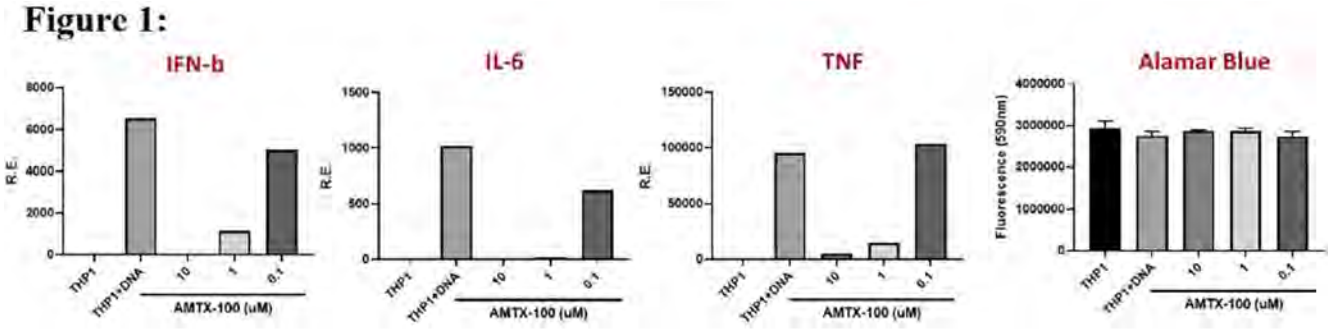
AMTX-100, a Nuclear Transport Inhibitor, Attenuates Inflammatory Cytokine Production in vitro and Following UV Mediated Skin Inflammation in a Mouse Model of Cutaneous Lupus Erythematosus in vivo

Xizhang Sun[1], Jie An[1], Ting Wang[1], Arpit Rathee[1], Vernon Alvarez[2], Matthew Gonda[3], Christian Lood[1] and Keith Elkon[1], [1]University of Washington, Seattle, WA, [2]Amytrx Therapeutics Inc., Nashville, TN, [3]Amytrx Therapeutics, Nashville, TN

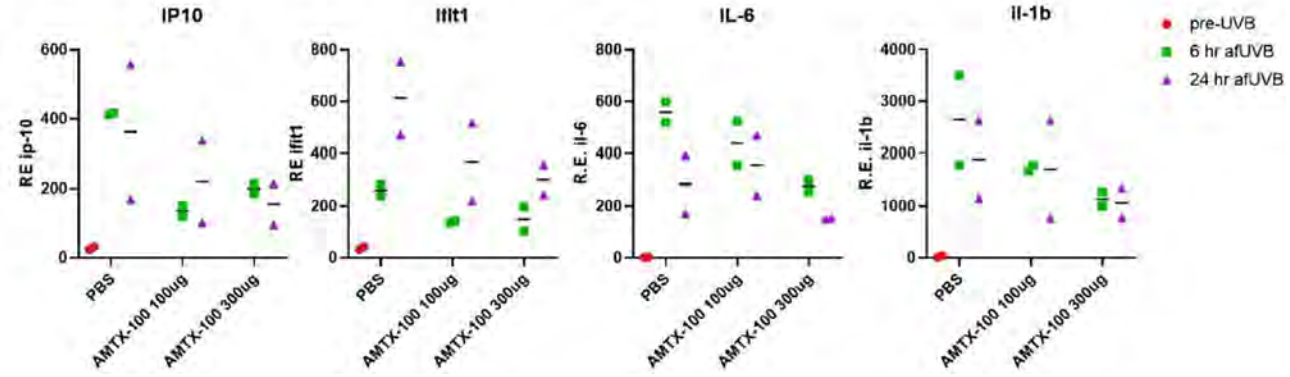
SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: SLE – Treatment Poster III
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Inflammatory stimuli induce transcription factors (TFs) such as NF-kB and interferon regulatory factors (IRFs). TFs are transported from cytosol to nucleus to activate genes encoding chemokines and cytokines. Nuclear transport of TFs is performed by importins that comprise a beta chain and different alpha chains that confer substrate specificity for TF nuclear localization sequences (NLS). The alpha-5-containing importin (Impα5) is of particular interest because it transports STAT1, NF-kB, and other stress responsive TFs containing a NLS. AMTX-100 is a 28 amino acid chimeric peptide containing a huFGF4 domain and NF-kB p50 NLS that function to facilitate leukocyte cell penetration and as a nuclear transport checkpoint inhibitor (NTCI), respectively. AMTX-100 is currently in a Phase 2b clinical trial to treat inflammation in eczema. Since Impα5 binds to the NLS of NF-kB p50 as well as STAT1 & 3, we examined the effects of AMTX-100 on inflammatory pathways and Type I interferons (IFN-I), in vitro and in vivo.



AMTX-100 inhibits IFN-b and inflammatory cytokine production in vitro. The THP-1 monocyte cell line was incubated with serial 10-fold dilution of AMTX-100 as shown on the X-axis. Left three panels: After 1 hr, cells were transfected with ds-DNA and 6 hrs later the cells were harvested and the RNA expression of IFN-b, IL-6 and TNF quantified by qPCR. The results are shown as expression of the cytokine relative to 18S RNA (R.E. on the Y-axis). Right Panel: The Alamar blue test for viability revealed that the AMTX-100 peptide was non-toxic at the doses used in these experiments.

Figure 2:



AMTX-100 attenuates the skin IFN and inflammatory response to UV light exposure. C57BL/6 mice were exposed to a single dose of 500 mJ of UV light on the shaved dorsum. As shown on the X-axis, mice received either saline (PBS) or 100 or 300 ug AMTX-100 peptide in PBS before and after UV exposure. Biopsies were obtained at time 0 and at 6 and 24 hr after UV exposure. RNA was extracted and the relative expression of representative ISGs (IP10 and Ifit1) and the inflammatory cytokines (IL-6 and IL-1b) shown on the Y axis. Relative expression of genes prior to UV is shown in orange.

Methods: The human monocyte cell line, THP-1 was transfected with 0.1 ug dsDNA in the presence or absence of AMTX-100 and cytokine mRNA expression quantified by qPCR. Neutrophils from healthy volunteers were isolated by density gradient and exposed to either PMA, the ionophore A23187 or immune complexes (IC) containing the lupus antigen SmRNP. NET formation was quantified by release of DNA and MPO as determined by fluorimetry. Female C57BL/6 (B6) mice aged 8-12 weeks were exposed to a single dose of UV (500mJ/cm^2) on the dorsal skin. Skin biopsies were obtained before and at 6 and 24 hr post UV exposure. Cytokine gene expression was determined by qPCR. Statistical significance between groups was determined by Student's t-test.

Results: In vitro studies with THP-1 cells revealed that 1 uM AMTX-100 inhibited IFN-b expression by 82% , and IL-6, TNF and IL-1b by 98%, 84% and 95% respectively (Fig. 1). In neutrophils incubated with NET-inducing stimuli, AMTX-100 (3 uM) inhibited DNA and MPO release by ~40% in PMA or A23187 stimulated cells but did not affect NET release induced by IC. To determine whether AMTX-100 attenuated the IFN-I response following UV induced inflammation of mouse skin, we applied either 100 or 300 ug AMTX-100 in saline onto the skin before and once daily after UV exposure. As shown in Fig. 2, ISGs, as well IL-1 and IL6 were all reduced in an apparent dose dependent fashion. Similar results were obtained in a second in vivo experiment (not shown).

Conclusion: We conclude that AMTX-100 reduces Type I IFN and NF-kB-dependent inflammatory cytokines from DNA activated human monocytes *in vitro*. While AMTX-100 had a modest inhibitory effect on NET formation in response to PMA and ionophore stimulation, it did not attenuate NET formation induced by ICs in vitro. When tested *in vivo* using the lupus-relevant UV skin exposure, we observed a dose-dependent inhibition of several NF-kB-dependent cytokines as well as ISGs. Since AMTX-100 is in clinical trials for inflammatory skin disease, these findings suggest a novel therapeutic approach utilizing importin NTCIs that may be useful for prevention or treatment of cutaneous lupus erythematosus.

SESSION INFORMATION

Session Date: Tuesday, November 14, 2023

Session Title: SLE – Treatment Poster III

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: Childhood-onset systemic lupus erythematosus (cSLE) is associated with symptoms such as fatigue, pain, and depressive symptoms that contribute to poor health-related quality of life. The Treatment and Education Approach for Childhood-Onset Lupus (TEACH; a cognitive behavioral therapy (CBT) program) has been shown in our prior work to significantly reduce fatigue and depressive symptoms when compared with standard care. The current study is a secondary data analysis of this recently completed trial which explores disease-related outcomes following TEACH, including disease activity, medication adherence, and health-related quality of life.

Methods: We conducted a randomized controlled trial of 59 youth ages 12-22 years meeting the ACR diagnostic classification criteria for SLE, from six rheumatology sites across the U.S. and Canada. Eligible participants had elevations in at least one target symptom area (e.g., fatigue, pain, or depression). Participants completed a baseline assessment, were randomized to 1) TEACH, a remotely delivered six-week CBT program with medical treatment as usual (TAU), or 2) TAU alone, then completed a post-assessment 8 weeks later. The current study explored: i) physician-reported disease activity via the Systemic Lupus Erythematosus Disease Activity Index 2000 (SLEDAI-2K) and a Visual Analog Scale (VAS, range 0-100); ii) medication adherence measured by the Medication Adherence Self-Report Inventory (MASRI, range 0-100%); and iii) health-related quality of life measured by Pediatrics Quality of Life – Adolescent version (PedsQL-A, 0-100). Independent samples *t*-tests compared changes from baseline to post-assessment between those who received TEACH+TAU vs. those who received TAU alone.

Results: Twenty-eight (47.5%) participants received TEACH+TAU, and 31 (52.5%) received TAU alone. Participant characteristics are shown in Table 1. At baseline, disease activity (SLEDAI-2K) and health-related quality of life (general core score) were higher in the TEACH+TAU group. The change in disease activity (SLEDAI-2K) scores between groups significantly

Table 1

Baseline Characteristics	TEACH+TAU group (n=28)	TAU alone group (n=31)	p-value
Age (mean)	16.9	16.6	0.61
Female sex, n (%)	26, (92.9%)	30, (96.8%)	0.50
Race, n (%)	African American/Black, 5 (25%) White, 10 (35.7%) Asian, 8 (28.6%) Multiracial, 5 (17.9%)	African American/Black, 6 (19.4%) White, 15 (48.4%) Asian, 9 (29%) Other, 1 (3.2%)	0.10

Medication Adherence (MASRI) (mean ± SD)	82.65 ± 16.41	83.90 ± 19.48	0.80
Health-related QOL (Peds QL-A)			
General core score (mean ± SD)	65.34 ± 15.63	51.30 ± 15.34	0.04
Rheumatology core score (mean ± SD)	68.63 ± 15.83	64.45 ± 16.07	0.53

Baseline characteristics of the TEACH+TAU group and TAU alone group.

Table 2

Disease-related Outcomes	Pre-post difference		Test statistic [95% CI], p-value
	TEACH+TAU	TAU alone	
Disease activity			
SLEDAI-2K	-2.11	0.67	T 2.47 [0.5-5.05], 0.02
Physician VAS	-9.81	1.21	T 2.24 [0.07-1.37], 0.03
Medication Adherence (MASRI)	7.5	2.22	T -1.27 [13.59-3.04], 0.21
Health-related QOL (Peds QL-A)			
General core score	14.05	10.03	T -0.93 [-12.92-4.89], 0.36
Rheumatology core score	12.81	10.07	T -.55 [-13.08-7.61], 0.59

Between group pre-post differences of disease-related outcomes.

Figure 3 A and B

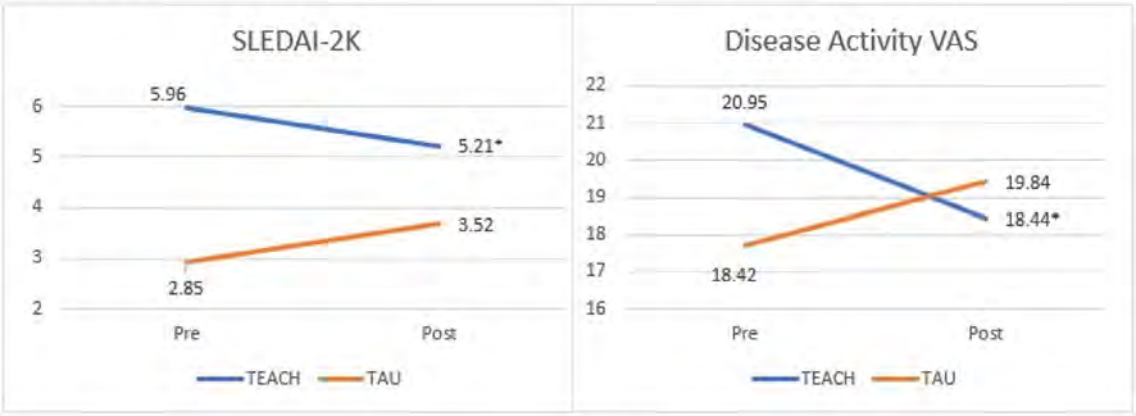

Figure 3A *Figure 3B*

Changes in SLEDAI-2K and Disease Activity VAS among TEACH and TAU participants from pre to post assessment.

differed, with the TEACH+TAU group demonstrating a significant decrease in disease activity scores ($t(40) = 2.47$, $p = 0.02$; Table 2, Figure 3A). There was also a statistically significant decrease in physician-reported disease activity VAS for the TEACH+TAU group vs the TAU group, ($t(38) = 2.24$, $p = 0.031$; Figure 3B). There were no other statistically significant differences between groups for changes in medication adherence or health-related quality of life.

Conclusion: TEACH may be associated with short-term improvement in disease activity, in addition to reducing depressive symptoms and fatigue. TEACH represents a promising treatment modality to mitigate mental health symptoms and improve disease outcomes. Future research will examine the long-term effectiveness of TEACH when implemented into real-world pediatric rheumatology clinics.

Molecular Predictors of Treatment Response in Two Trials of Abatacept in Systemic Lupus Erythematosus

Kevin Thomas[1], Miles Smith[1], Carla Guthridge[1], Nicolas Dominguez[1], Susan Macwana[1], Wade DeJager[1], Catriona Wagner[1], Peter Schafer[2], Stan Kamp[1], Betty Diamond[3], David Wofsy[4], Aikaterini Thanou[5], Cristina Arriens[6], Cynthia Aranow[3], Joan Merrill[1], Judith James[1] and Joel Guthridge[1], [1]Oklahoma Medical Research Foundation, Oklahoma City, OK, [2]Bristol Myers Squibb, Belle Mead, NJ, [3]Feinstein Institutes for Medical Research, Manhasset, NY, [4]University of California San Francisco, San Francisco, CA, [5]University of Oklahoma Health, Edmond, OK, [6]Oklahoma Medical Research Foundation and University of Oklahoma Health Sciences Center, Department of Arthritis & Clinical Immunology, Oklahoma City, OK

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: SLE – Treatment Poster III
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Abatacept (ABA) is a fusion protein that disrupts T cell co-stimulation by inhibiting interactions between CD28 and CD80/86. ABA is effective in RA, but SLE clinical trials have been disappointing. Exploratory analyses have suggested that ABA might benefit some SLE patients depending on disease severity or outcome definitions, but identification of reproducible predictors of response remains elusive. This study applied a systems-based approach to developing a predictive model of abatacept response in SLE.

Methods: Pre-treatment peripheral blood mononuclear cells were obtained from the screening visits of the Clarification of Abatacept Effects in SLE with Integrated Biologic and Clinical Approaches (ABC; n=19) and the Abatacept and Cyclophosphamide Combination Therapy for Lupus Nephritis (ACCESS; n=40) clinical trials evaluating ABA in SLE patients without

organ-threatening disease or lupus nephritis, respectively. Genomic DNA and total RNA were extracted from isolated T cells, B cells, and monocytes, followed by DNA methylation microarray and RNA sequencing analyses. Machine learning was applied to methylation data using generalized linear modeling and 40 bootstrapped re-samplings split between 70% training and 30% testing.

Results: A total of 29 ABA responders (R) and 30 non-responders (NR) were identified from both clinical trials. Bootstrapped models of all cell types separated responders and non-responders robustly, with an average AUC of 0.976 (Fig 1A-B). Four CpGs were shared in at least 80% of the re-samplings (Fig 1C), and a model using these 4 CpGs on T cells alone revealed an average ROC of 0.935 (Fig. 1D-E). Applying this model to B cells and monocytes yielded similarly robust results (Fig. 1F-G),

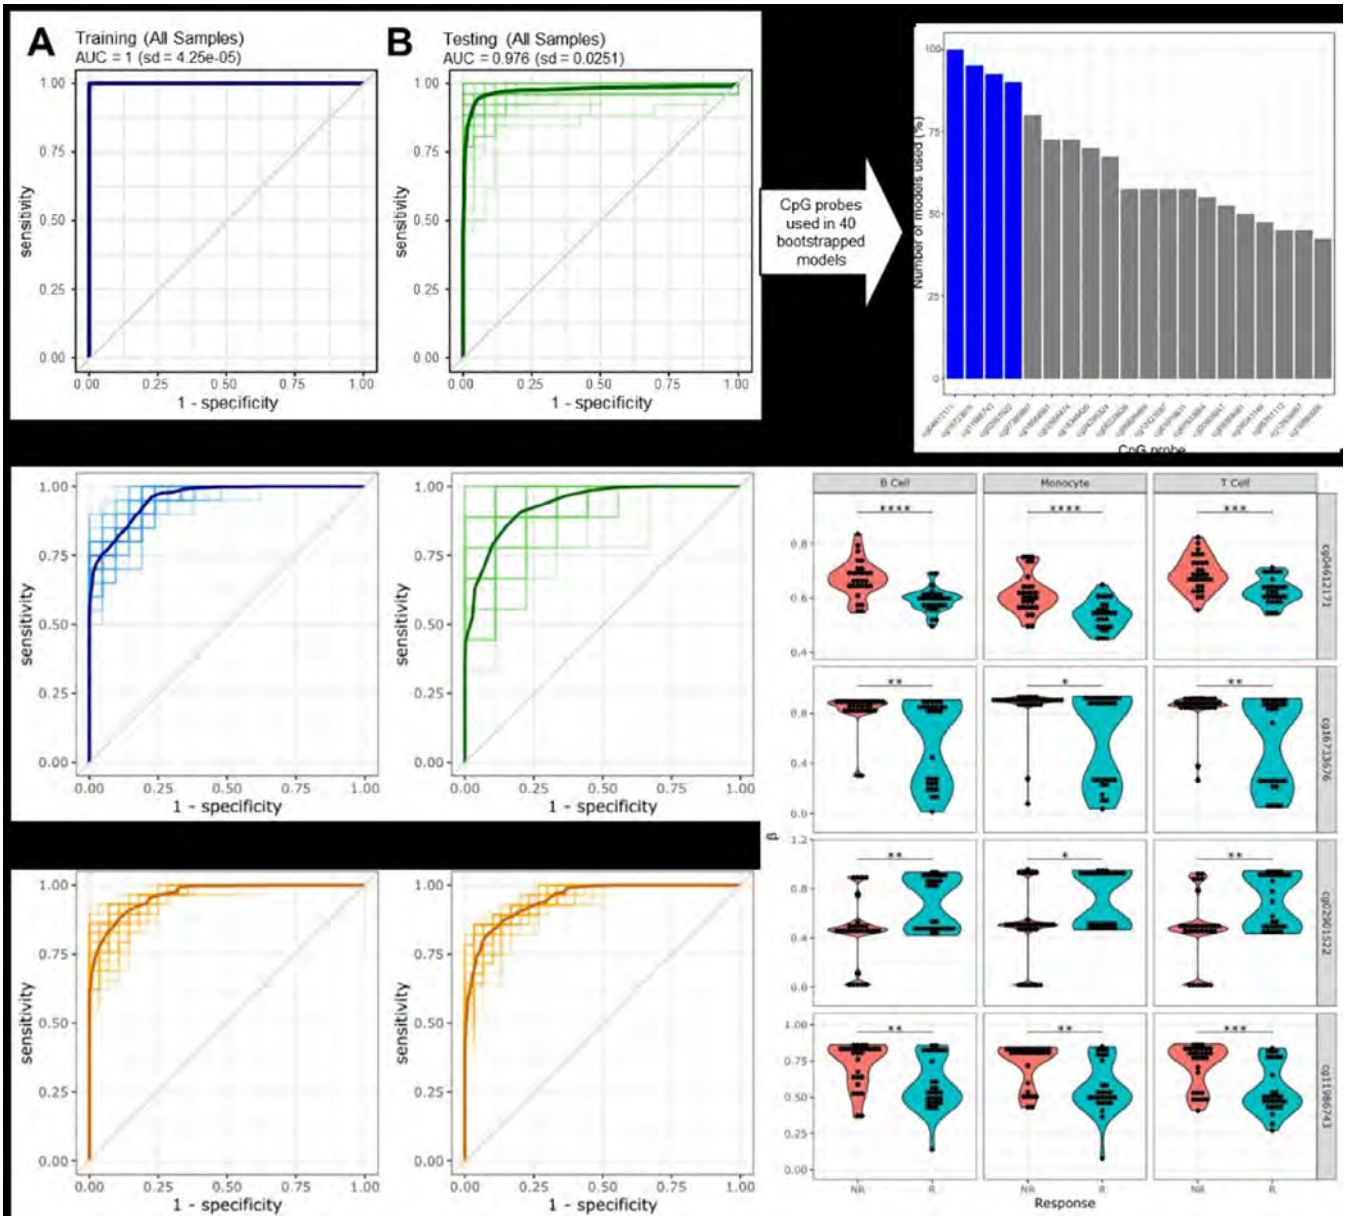

Figure 1. Machine learning identifies a 4-marker methylation signature distinguishing abatacept responders and non-responders at screening. ROC curves of 40 bootstrapped re-samplings of all cell type-specific epigenome profiles split between (A) 70% training and (B) 30% testing. (C) Percent of models using each of the top 20 most frequently utilized features across the models. (D-E) ROC curves of 40 bootstrapped re-samplings of T cell epigenome profiles. Models were developed with only the top 4 CpGs. (F-G) ROC curves of 40 models developed on T cells applied to B cells and monocytes. (H) Violin dot plots of methylation differences by abatacept response of the top 4 CpGs. Asterisks indicate significance of Benjamini-Hochberg corrected p-value of Mann-Whitney U-Tests: * < 0.05, ** < 0.01, *** < 0.001, **** < 0.0001.

and the 4 CpGs were differentially methylated in each cell type (Fig. 1H). In T cells, the 4 CpGs positively correlated with TCR activation, CTLA-4 regulation, and IL-2 production (Fig 2A-B), while BCR activity and phagosome activity and cytokine production are correlated with these CpGs in B cells and monocytes, respectively (Fig 2C-F). Unbiased principal component analysis on global T cell methylation profiles separated R and NR patients (Fig 3A), and most sites were hypermethylated in R patients (Fig 3C). The most hypermethylated transcription start sites revealed associations with cytokine storm and IL-17 signaling in NR patients (Fig 3D-E).

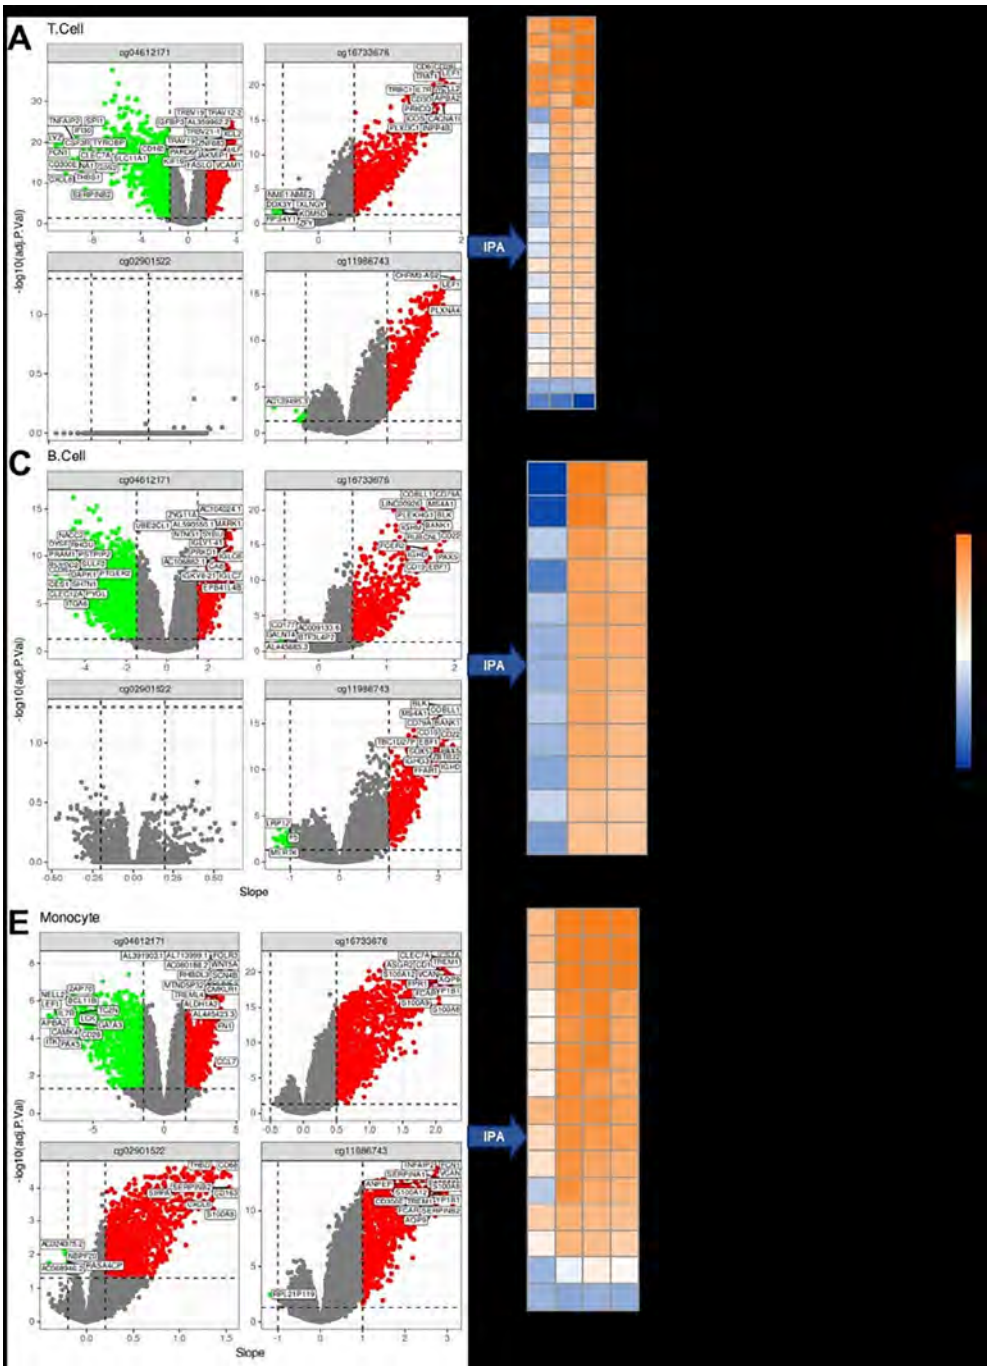

Figure 2. Correlation of RNA transcripts with methylation at CpGs predictive of abatacept response. Volcano plots and ingenuity pathway analysis (IPA) results of correlation analyses of methylation at each of the 4 predictive CpGs with RNA-seq data in (A-B) T cells, (C-D) B cells, and (E-F) monocytes. (A, C, E) The slope of each correlation is plotted on the x-axis, and the negative log transforms of p-values adjusted for multiple comparisons on the y-axis. (B, D, F) The most significantly correlated transcripts at each CpG of interest were input into IPA with previously noted cutoffs.

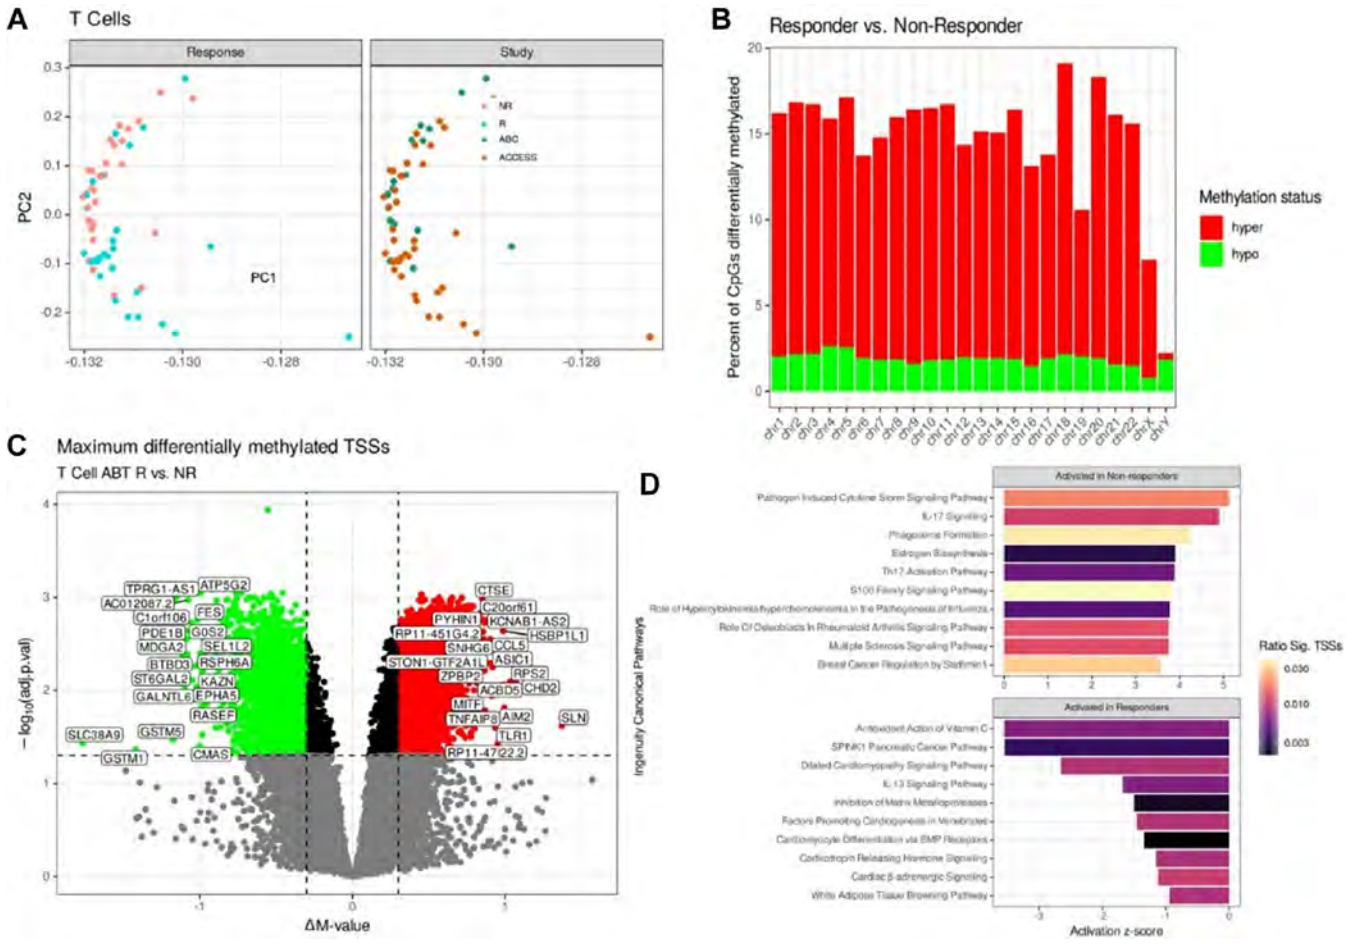

Figure 3. Global epigenetic landscape of T cells contributing to future abatacept response. (A) Principal component analyses of global DNA methylation profiles of T cells. (B) Bar graph of per-chromosome methylation comparison between T cells from abatacept responders and non-responders. (C) Volcano plot of maximum differential methylation at transcription start sites for annotated genes between T cells from abatacept responders and non-responders. (D) Bar graph of the top 10 canonical pathways from IPA by predicted activation in abatacept responders and non-responders. IPA results were filtered for Benjamini-Hochberg adjusted p-value < 0.05 by Fisher's exact test and selected for the top 10 positive and negative activation z-scores.

Conclusion: We determined a robust 4 CpG methylation signature that predicts ABA response across two disparate SLE trials. Parallel transcriptomic profiling linked this signature to cell lineage-specific activation pathways. Comparative epigenomic analysis of T cells revealed a hypomethylated signature in NR patients, likely driving continued proinflammatory responses despite abatacept treatment.

Dapirolizumab Pegol Efficacy by Subgroups in Patients with SLE: A Post Hoc Analysis of Phase 2b Clinical Trial Data

Anca Askanase[1], Christian Stach[2], Claire Brittain[3], George Stojan[4] and Richard Furie[5], [1]Columbia University Medical Center, New York, NY, [2]UCB Pharma, Monheim am Rheim, Germany, [3]UCB Pharma, Slough, United Kingdom, [4]UCB, Baltimore, MD, [5]Northwell Health, Manhasset, NY

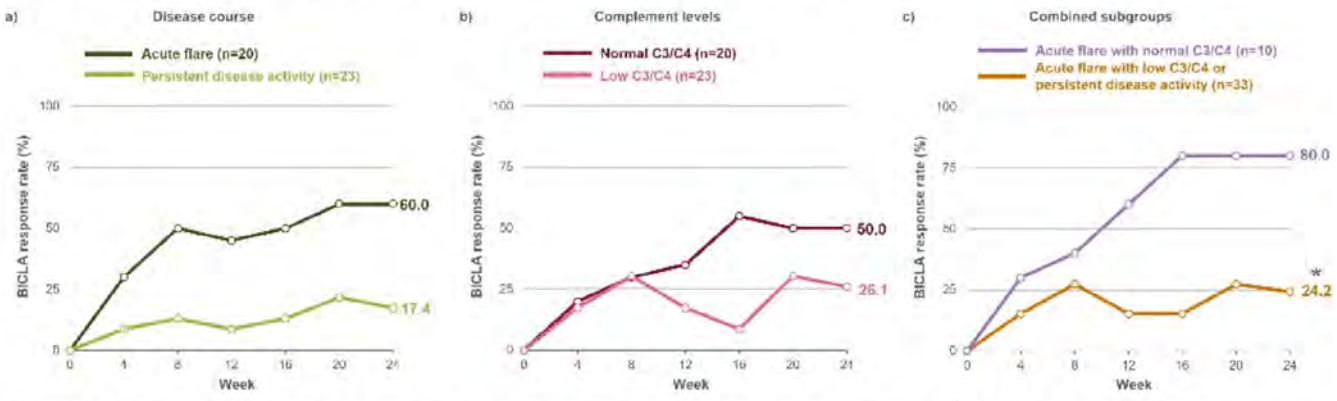
SESSION INFORMATION

Session Date: Tuesday, November 14, 2023
Session Title: SLE – Treatment Poster III
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Systemic lupus erythematosus (SLE) clinical trials are challenged by high standard of care plus placebo (SOC+PBO) response rates.[1] Previous post hoc analyses of the phase 2b RISE trial in SLE (NCT02804763) identified acute flare and normal complement as potential predictors of SOC+PBO response.[2] This analysis aims to evaluate the treatment effect of dapirolizumab pegol (DZP; a polyethylene glycol-conjugated antigen-binding fragment lacking a functional Fc domain that inhibits CD40L) in subgroups of patients (pts) from the phase 2b RISE trial based on the previously identified potential predictors of SOC+PBO response.[2,3]

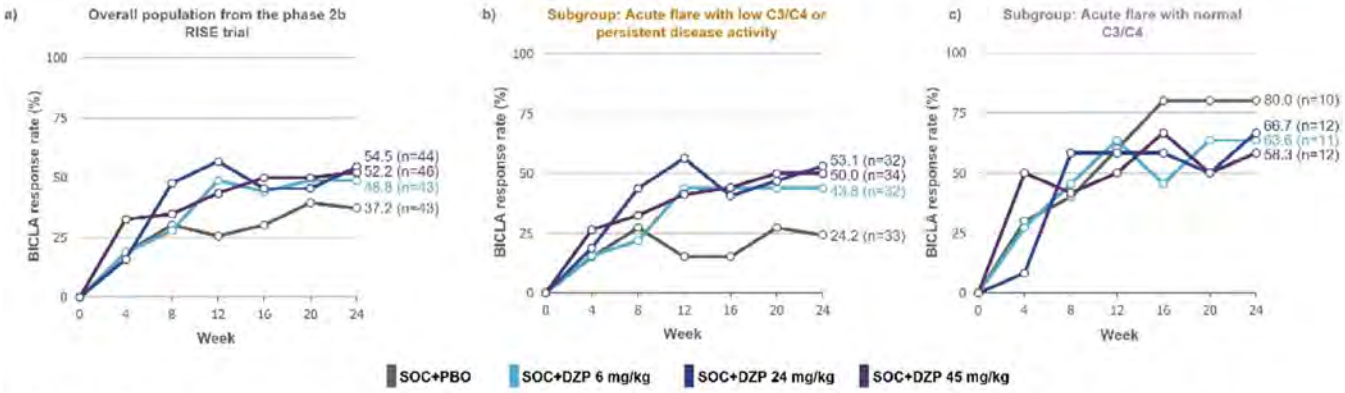
Methods: Post hoc analyses were performed on data from the phase 2b RISE trial, in which pts received PBO or DZP (6/24/45 mg/kg), alongside SOC, for 24 weeks (wks).[3] Adults with moderately to severely active SLE, receiving stable doses of corticosteroids, antimalarial or immunosuppressant drugs were included in the trial.[3] Pts from the trial were divided into subgroups based on previously identified potential predictors of SOC+PBO response.[2] Disease course at screening was defined using British Isles Lupus Assessment Group (BILAG) 2004 item level scores as acute flare (worsening/new symptoms) or persistent (symptoms rated as the same) based on the past 4 wks compared with the 4 wks prior to those. Low C3/C4 was defined as below the lower limit of normal at screening. Outcomes to Wk 24 were evaluated in subgroups and compared with the overall population. Outcomes assessed were BILAG-based Composite Lupus Assessment (BICLA) response, SLE Responder Index-4 (SRI-4) response, and change from baseline in Physician's Global Assessment (PGA).

Figure 1. BICLA response to Wk 24 in pts receiving SOC+PBO by subgroups



Full analysis set. *p=0.005 for the odds ratio (95% CI) of acute flare with low C3/C4 or persistent disease activity vs acute flare with normal C3/C4 at Wk 24 (0.1 [0.0, 0.5]). Missing data were imputed using modified non-responder imputation. **Abbreviations:** BICLA: British Isles Lupus Assessment Group-based Composite Lupus Assessment; CI: confidence interval; PBO: placebo; pts: patients; SOC: standard of care; Wk: Week.

Figure 2. BICLA response to Wk 24 in pts receiving SOC+PBO and SOC+DZP in the overall population and by combined subgroups



Full analysis set. Missing data were imputed using modified non-responder imputation. **Abbreviations:** BICLA: British Isles Lupus Assessment Group-based Composite Lupus Assessment; CI: confidence interval; DZP: dapirolizumab pegol; PBO: placebo; pts: patients; SOC: standard of care; Wk: Week.

Results: A higher proportion of pts receiving SOC+PBO with acute flare (vs persistent disease activity) and with normal C3/C4 (vs low C3/C4) achieved BICLA response at Wk 24 (**Figures 1a&1b**). When the subgroups were combined, a significantly higher proportion of pts receiving SOC+PBO with acute flare and normal C3/C4 achieved BICLA response at Wk 24 compared with pts receiving SOC+PBO with either acute flare with low C3/C4 or persistent disease activity (**Figure 1c**). BICLA responses to Wk 24 in the combined subgroups for pts receiving SOC+PBO and SOC+DZP are presented in **Figure 2b&2c**, alongside BICLA response in the overall population from the RISE trial in **Figure 2a**. Similar patterns were seen for SRI-4 response and change from baseline in PGA in the combined subgroups (data not shown). Baseline characteristics in the combined subgroups are presented in **Table 1**.

Table 1. Baseline characteristics of all pts in the phase 2b RISE trial by combined subgroups

	Acute flare with low C3/C4 or persistent disease activity (n=135)	Acute flare with normal C3/C4 (n=47)
Region, n (%)		
Western/Central Europe	24 (17.8)	4 (8.5)
Eastern Europe	26 (19.3)	18 (38.3)
North America	37 (27.4)	16 (34.0)
Latin America	48 (35.6)	9 (19.1)
Time since first diagnosis of SLE (years), mean (SD)	8.2 (7.1)	8.1 (7.0)
≥1 BILAG Grade A, n (%)	55 (40.7)	27 (57.4)
≥2 organ systems with BILAG Grade B and no organ system with BILAG Grade A, n (%)	80 (59.3)	20 (42.6)
SLEDAI-2K total score <10[a], n (%)	33 (24.4)	21 (44.7)
SLEDAI-2K total score ≥10[a], n (%)	101 (74.8)	25 (53.2)
Pts taking systemic corticosteroids, n (%)	121 (89.6)	38 (80.9)

Safety set. [a]SLEDAI-2K total score was calculated counting anti-dsDNA as positive if >10 iU. **Abbreviations:** BILAG: British Isles Lupus Assessment Group; dsDNA: double-stranded DNA; iU: international units; pts: patients; SD: standard deviation; SLE: systemic lupus erythematosus; SLEDAI-2K: SLE Disease Activity Index 2000.

Conclusion: Albeit in a limited sample size, pts with acute flare and normal complement were more likely to achieve response to SOC+PBO than pts with acute flare and low complement or persistent disease activity. These data suggest that SLE trial design may need to consider baseline clinical and serologic activity patterns to adequately assess treatment efficacy. **References:1.** Durcan L. Dapirolizumab Pegol Impacts Important Immunologic Pathways in SLE: Pharmacodynamic Analysis of B Cell and Type I Interferon Pathways from a Phase 2b Trial

Ioana Cutcutache[1], Alex Powlesland[1], Andrew Skelton[1], Yunyun Sun[1], Matthew Page[1], George Stojan[2], Peter Lipsky[3], Ania Skowera[1] and Christian Stach[4], [1]UCB Pharma, Slough, United Kingdom, [2]UCB, Baltimore, MD, [3]AMPEL BioSolutions, Charlottesville, VA, [4]UCB Pharma, Monheim am Rheim, Germany

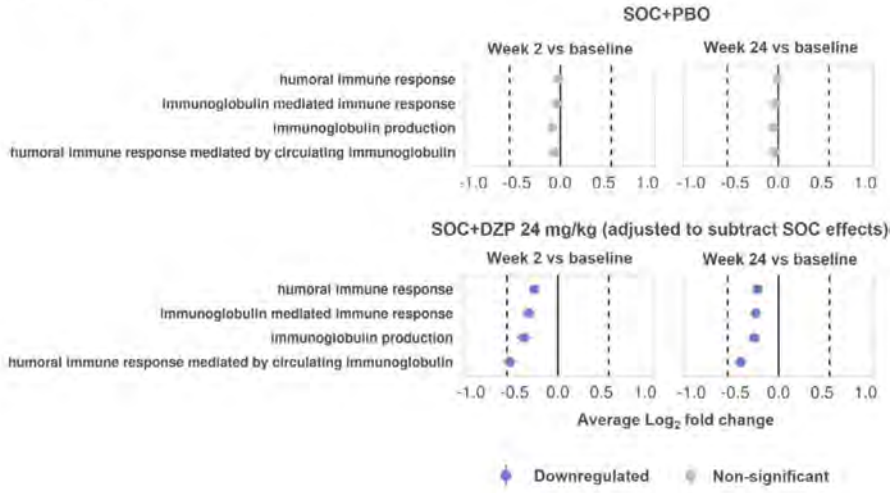
SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: SLE – Treatment Poster III
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: The pivotal role of CD40-CD40L interactions in systemic lupus erythematosus (SLE) pathogenesis stems from the orchestration of a range of immune and inflammatory responses involving B cells, T cells, antigen-presenting cells, and type I interferon (IFN) production.[1,2] Dapirolizumab pegol (DZP) is a polyethylene glycol-conjugated antigen-binding fragment lacking a functional Fc domain that inhibits CD40L.[3] This post hoc pharmacodynamic analysis explored the impact of DZP on B cell and type I IFN pathways using data from the phase 2b RISE trial in SLE (NCT02804763).[3]

Methods: In RISE, patients (pts) received placebo (PBO) or DZP (6/24/45 mg/kg) alongside standard of care (SOC) for 24 weeks (wks); adults with moderately to severely active SLE, receiving stable doses of SOC treatments, were included in the trial.[3] Analyses presented here used a subgroup of patients from RISE (n=131) that is analogous to the phase 3 trial population(NCT04294667);[4] results are shown for the PBO and DZP 24 mg/kg arms. RNA sequencing (RNAseq) was performed on available blood samples at baseline and Wks 2 and 24; samples were not available for all pts at all timepoints. Gene expression changes were analyzed and competitive gene set analyses were carried out on pathways relevant to SLE immunopathology, selected from Gene Ontology Biological Processes and augmented with gene signatures that discriminate immune cell types in SLE.[5,6] Differential expression results for DZP treatment were corrected for SOC effects. To assess effects of DZP on type I IFN biology, pts were stratified post hoc by baseline type I IFN expression levels using a 4-gene type I IFN signature.[7]

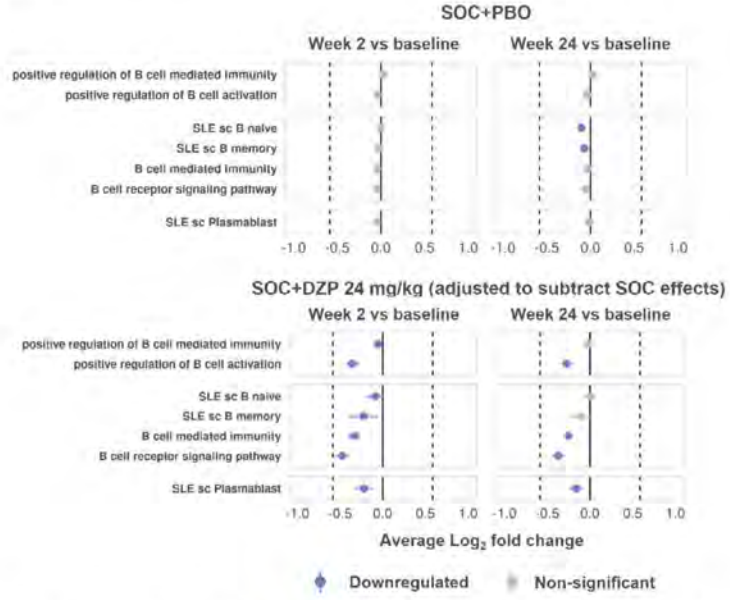
Results: DZP significantly downregulated genes related to immunoglobulin production compared with PBO, and this effect was observed as early as Wk 2 following a single dose (**Figure 1**). A similar trend was observed in clinical levels of autoantibodies (anti-dsDNA), which has been previously reported.[3]Compared with PBO, DZP also significantly downregulated genes that play a critical role in B cell biology, specifically those involved in B cell mediated immunity and B cell receptor

Figure 1. Effect of SOC+DZP compared with SOC+PBO on the expression of genes related to immunoglobulin production at Wk 2 and Wk 24



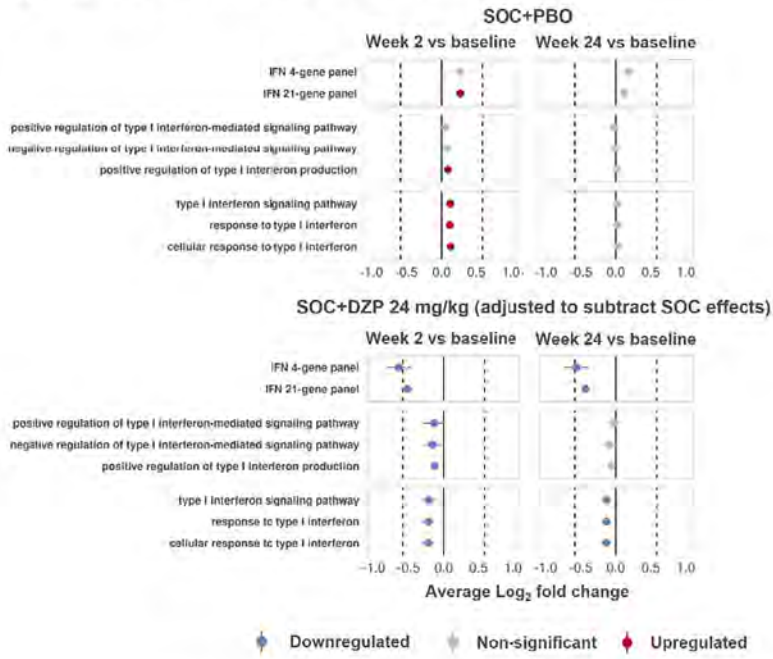
SOC+PBO: baseline: n=31; Wk 2: n=31; Wk 24: n=30. SOC+DZP 24 mg/kg: baseline: n=27; Wk 2: n=30; Wk 24: n=29. Each dot is a gene set, blue dots indicate statistically significant downregulated gene sets, grey dots represent non-significant changes. Dashed lines represent 1.5-fold change, block lines at 0 represent 1-fold change. Only significant datapoints after treatment with DZP 24 mg/kg are shown (FDR<0.05). **Abbreviations:** DZP: dapirolizumab pegol; FDR: false discovery rate; PBO: placebo; SOC: standard of care; Wk: Week.

Figure 2. Effect of SOC+DZP compared with SOC+PBO on the expression of genes related to B cell biology and regulators at Wk 2 and Wk 24



SOC+PBO: baseline: n= 31; Wk 2: n=31; Wk 24: n=30. SOC+DZP 24 mg/kg: baseline: n=27; Wk 2: n=30; Wk 24: n=29. Each dot is a gene set, blue dots indicate statistically significant downregulated gene sets, grey dots represent non-significant changes. Dashed lines represent 1.5-fold change, block lines at 0 represent 1-fold change. Only significant datapoints after treatment with DZP 24 mg/kg are shown (FDR<0.05). **Abbreviations:** DZP: dapirolizumab pegol; FDR: false discovery rate; PBO: placebo; sc: subcutaneous; SLE: systemic lupus erythematosus; SOC: standard of care: Wk: Week.

Figure 3. Effect of SOC+DZP compared with SOC+PBO on the expression of type I IFN gene signatures at Wk 2 and Wk 24 in pts with high type I IFN expression at baseline



SOC+PBO: baseline: n= 18; Wk 2: n=17; Wk 24: n=17. SOC+DZP 24 mg/kg: baseline: n=18; Wk 2: n=17; Wk 24: n=16. Each dot is a gene set, blue dots indicate statistically significant downregulated gene sets, red dots indicate statistically significant upregulated gene sets, and grey dots represent non-significant changes. Dashed lines represent 1.5-fold change, block lines at 0 represent 1-fold change. Only significant datapoints after treatment with DZP 24mg/kg are shown (FDR<0.05). **Abbreviations:** DZP: dapirolizumab pegol; FDR: false discovery rate; IFN: interferon; PBO: placebo; pts: patients; SOC: standard of care: Wk: Week.

signaling pathways (**Figure 2**). At baseline, 76/120 pts (63.3%) with RNAseq samples available across all treatment arms showed high type I IFN gene expression. In pts with high expression, DZP caused down-modulation of a variety of type I IFN gene signatures compared with PBO, with inhibitory effects observed as early as Wk 2 (**Figure 3**).

Conclusion: DZP exerts a broad suppressive effect on B cell biology, decreasing the expression of numerous gene sets involved in B cell activation and immunoglobulin production. Moreover, DZP decreases expression of type I IFN signatures in pts with high baseline type I IFN expression. The impacts of DZP were seen as early as Wk 2. These findings underscore the potent immunomodulatory role of DZP in SLE pathology.

Remission Attainment in Patients with Systemic Lupus Erythematosus Treated with Anifrolumab Compared with Placebo over a 4-Year Period

Ronald van Vollenhoven[1], Eric Morand[2], Richard A. Furie[3], Kenneth Kalunian[4], Raj Tummala[5], Gabriel Abreu[6], Hussein Al-Mossawi[7] and Catharina Lindholm[6], [1]Amsterdam University Medical Centers, Amsterdam, Netherlands, [2]Monash University, Centre for Inflammatory Diseases, Melbourne, Australia, [3]Donald and Barbara Zucker School of Medicine at Hofstra/Northwell, Great Neck, NY, [4]University of California San Diego, La Jolla, CA, [5]BioPharmaceuticals R&D, AstraZeneca, Gaithersburg, MD, [6]BioPharmaceuticals R&D, AstraZeneca, Gothenburg, Sweden, [7]BioPharmaceuticals R&D, AstraZeneca, Cambridge, United Kingdom

SESSION INFORMATION

Session Date: Tuesday, November 14, 2023

Session Title: SLE – Treatment Poster III

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: In patients with SLE, remission is an established therapeutic goal associated with reduced damage accrual and flares, and improved health-related quality of life.[1] Here, we evaluated attainment of DORIS (Definition of Remission in SLE) during anifrolumab treatment in the double-blind randomized phase 3 TULIP long-term extension (LTE) trial.[2]

Methods: Patients with moderate to severe SLE (1997 ACR criteria) despite standard therapy who completed the 52-week TULIP-1 or TULIP-2 trials (NCT02446912, NCT02446899) could reconsent to participatein the randomized, placebo-controlled, double-blind, 3-year extension (NCT02794285). Here, we analyzed patients randomized to receive intravenous anifrolumab 300 mg or placebo for the TULIP-1/TULIP-2 and LTE periods. DORIS attainment was defined as all the following: total clinical SLEDAI-2K score =0, physician global assessment (0–3) < 0.5, prednisone/equivalent dosage ≤5 mg/day, and no use of restricted medications (TULIP-1/TULIP-2 period only). Time to first DORIS was compared using Cox

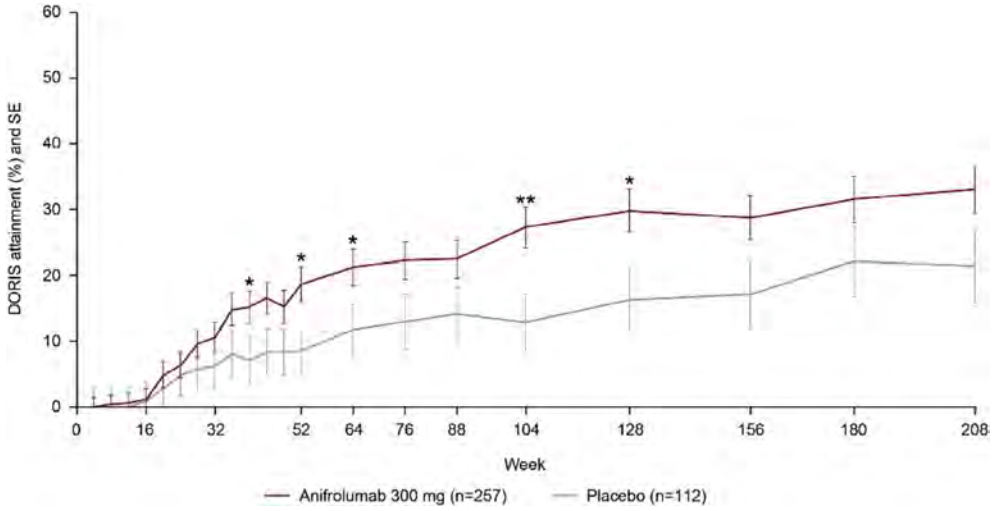

Figure. DORIS Attainment by Randomized Treatment in Patients With SLE in the TULIP and LTE Study Periods. DORIS attainment was defined as all the following: total clinical SLEDAI-2K score =0, physician global assessment (0–3) <0.5, prednisone/equivalent dosage ≤5 mg/day, and no use of restricted medications (TULIP-1 and TULIP-2 period only). Clinical SLEDAI-2K is a variant of the SLEDAI-2K, in which the serological descriptors (anti-dsDNA and complement) are omitted. DORIS attainment rates were calculated using a stratified Cochran–Mantel–Haenszel approach, with stratification factors of SLEDAI-2K at screening, Day 1 glucocorticoid dosage, type I interferon gene signature at screening, and study; response rates were compared using logistic regression. DORIS, Definition of Remission in SLE; LTE, long-term extension; SE, standard error. Nominal P: *<0.05; **<0.01.

regression. DORIS attainment rates were calculated using a Cochran–Mantel–Haenszel approach and compared using logistic regression. Total time and percentage of time in DORIS was analyzed using analysis of covariance. Patients who discontinuedinvestigational product prematurely and/or withdrew from the study due to lack of efficacy and/or disease worsening were considered nonresponders from that visit on. All *P*-values are nominal.

Results: Overall, 369 patients (anifrolumab 300 mg, n=257; placebo, n=112) who continued treatment in the LTE were analyzed for the 4-year TULIP+LTE period. Time to first DORIS remission was shorter in anifrolumab-treated patients compared with placebo (hazard ratio 1.49, 95% CI 1.04–2.19, *P*=0.034). DORIS remission attainment increased from TULIP baseline to Week 208; at the first LTE visit (Week 64), 21.2% of anifrolumab-treated patients achieved DORIS compared with 11.8% of the placebo group (odds ratio [OR] 2.1, 95% CI 1.0–4.1, *P*=0.036); a similar trend was seen up to Week 208 (33.0% vs 21.4%; OR 1.8, 95% CI 0.9–3.5, *P*=0.089) (Figure). Greater cumulative time (*P*=0.002) and percentage of time (*P*=0.002) were spent in DORIS by patients receiving anifrolumab compared with placebo. A greater proportion of patients treated with anifrolumab were in DORIS ≥20% of the time compared with placebo (OR 2.9, 95% CI 1.6–5.2, *P*=0.001) and ≥50% of the time (OR 2.3, 95% CI 1.1–5.0, *P*=0.030). Compared with placebo, anifrolumab-treated patients were more likely to sustain DORIS for ≥3 consecutive visits (OR 2.1, 95% CI 1.2–3.6, *P*=0.013) and ≥5 visits (OR 2.3, 95% CI 1.1–4.8, *P*=0.022).

Conclusion: Treatment with anifrolumab, in addition to standard therapy, was associated with more frequent, prolonged, and sustained DORIS remission attainment compared with placebo during the 4-year TULIP+LTE period. Our results suggest that DORIS, a definition of remission associated with improved clinical outcomes,[1] is an attainable therapeutic goal with long-term anifrolumab use.

Abstract Number: 2335

Defining a Basket Population for ANA+ Arthritis Trials

Jack Arnold[1], Md Yuzaiful Md Yusof[1], Lucy Carter[2], Zoe Wigston[1] and **Ed Vital**[1], [1]University of Leeds, Leeds, United Kingdom, [2]University of Leeds, Hartlepool, United Kingdom

SESSION INFORMATION

Session Date: Tuesday, November 14, 2023
Session Title: SLE – Treatment Poster III
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Musculoskeletal (MSK) manifestations are common in systemic lupus erythematosus (SLE) and other ANA-associated rheumatic musculoskeletal diseases (ANA-RMDs). Presently clinical trials recruit patients from individual diagnoses. Recruitment is often difficult, effect sizes are small and licensed therapies are only available to patients with the most common ANA-RMD, SLE.

Objectives:

1. To compare the symptom impact and immunophenotype of arthritis associated with a range of ANA-associated autoimmune diseases

2. To explore alternative classifications of the spectrum of ANA-associated arthritis to define basket populations for trials

3. To validate the MSK-BILAG across multiple diagnoses

Methods: We used analysis of flow cytometry for major subsets, gene expression (signatures for interferon, plasma blast, neutrophil, myeloid inflammation and erythropoiesis) and patient reported data from a mixed cohort of ANA-associated autoimmune diseases. 215 patients with MSK symptoms were included, 90 with SLE and 125 with an another diagnosis (UCTD, pSS, IM, MCTD and SSc).

The implications of legacy diagnosis membership were compared using QoL measures (SF36, EQ5D-5L, Patient VAS, ICECAP-A, FACIT-F, WPAI and ICECAP-A. Gaussian mixture modelling was used to explore alternative classifications more suitable for basket trials. The association of BILAG-MSK with physician VAS was tested in SLE and the non-SLE group.

Results: Legacy diagnosis was a poor indicator of the patient experience with Kruskal Wallis testing revealing only 2 significant differences (EQ5D Mobility and EQ5D-5l index domains) between diagnoses. Flow cytometric and gene expression data showed no significant differences between legacy diagnoses.

Better predictors of the patient experience were chromatin antibody positivity and non-European ancestry which were associated with worse EQ5D-5l index scores ($P < 0.05$ in both).

Preliminary gaussian mixture modelling analysis of this population based on variables identified as important within the principle component analysis identified 4 clusters. A biologically active MSK symptom dominant cluster (n=140), a biologically active non MSK symptom dominant cluster (n=43), a biologically and symptom quiescent cluster (n= 24) and a biologically and symptom quiescent cluster (n=65).

The application of the BILAG-MSK domain across ANA-RMDs correlated well with the Physician General Assessment scores of MSK disease activity suggesting it may be reasonable to apply this measure in any future basket trial.

Conclusion: Inflammatory arthritis is similar in both clinical impact and immune phenotype across ANA-associated RMDs, suggesting similar benefits of therapy for this feature within each disease. Machine learning reveals an alternative basket of patients suitable for clinical trials who have clinical synovitis, high symptom burden and consistently increased markers of immune activation, and a mixture of legacy diagnoses, who are more numerous than MSK SLE alone. A further smaller basket of patients have high symptom burden but little evidence of active inflammation.

SESSION INFORMATION

Session Date: Tuesday, November 14, 2023

Session Title: SLE – Treatment Poster III

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: LN is a severe complication of SLE, affecting 21%–48% of patients.[1] Development of noninvasive diagnostic tests for LN is ongoing; urinary biomarkers have good tissue proximity with minimal invasivity.[2] Anifrolumab, a type I IFN receptor mAb approved for the treatment of moderate to severe SLE,[3] is being evaluated in a phase 3 trial for patients with LN.[4] We conducted untargeted metabolomics profiling on urine samples from the phase 2 trial to identify markers associated with LN disease activity that were modulated by anifrolumab.

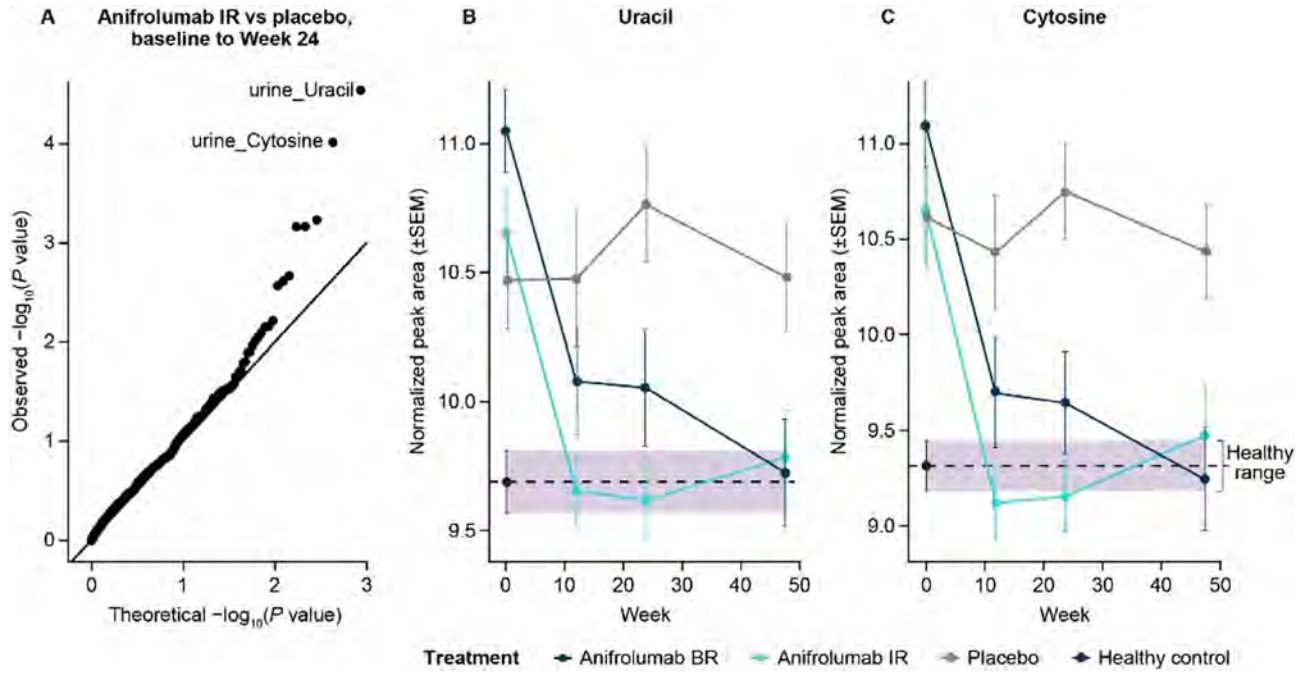

Figure: A. Untargeted urine metabolomics identified uracil and cytosine as the metabolites most impacted by anifrolumab treatment from BL to Week 24. B. Uracil and C. cytosine levels in urine were reduced by anifrolumab to within healthy ranges. BL, baseline; BR, basic regimen; IR, intensified regimen; SEM, standard error of the mean. For panel A, a linear mixed effects model evaluated the interaction of metabolite levels with treatment group and time.

Methods: The phase 2 TULIP-LN (NCT02547922) trial included adults with active LN (+ SLE per ACR 1997 criteria) who were randomized 1:1:1 to receive IV anifrolumab Q4W at standard SLE dosing (basic regimen [BR], 300 mg), intensified regimen (IR, 900 mg x3 doses, 300 mg thereafter), or placebo, in addition to standard therapy (including MMF and/or glucocorticoids). Metabolomics analysis (856 putatively identified metabolites) was conducted on patients with LN and healthy donors without renal involvement using an unbiased liquid chromatography–mass spectrometry-based approach in urine collected at baseline (BL) and Weeks 12, 24, and 48. Differentially modulated metabolites in the anifrolumab IR vs placebo groups were identified using a linear mixed effects model, adjusted for IFN gene signature (IFNGS, high/low) in blood and 24-hour urine protein–creatinine ratio (UPCR >3/≤3 mg/mg). Relationships between metabolite levels and serologic measures of disease activity (anti-dsDNA, complement C3), IFNGS, and UPCR were assessed with repeated measures correlation; nominal *P* values were adjusted for multiple comparisons (q).

Results: We analyzed urine metabolomics in 117 patients with LN (anifrolumab BR, n=36; IR, n=43; placebo, n=38) and 40 healthy donors. We identified 2 pyrimidine bases, uracil and cytosine, impacted by anifrolumab IR vs placebo from BL to Week 24 ($P< 0.05$; Figure A). Uracil and cytosine levels at BL were greater in patients with LN compared with healthy donors, and anifrolumab reduced their levels to within healthy ranges (Figures B, C). Within individual patients, uracil and cytosine levels correlated ($q< 0.05$) with IFNGS (R=0.59; R=0.65), anti-dsDNA levels (R=0.28; R=0.29), complement C3 levels (R=–0.19; R=–0.22), and UPCR (R=0.24; R=0.25).

Conclusion: Urine uracil and cytosine levels were elevated in patients with LN, consistent with studies showing upregulated pyrimidine metabolism in LN.[5] Uracil and cytosine levels were associated with IFNGS and measures of disease activity, indicating a previously unrecognized metabolomic link to type I IFN activity. Treatment with anifrolumab, in addition to standard therapy, normalized uracil and cytosine levels. Further studies are required to understand the role of uracil and cytosine in LN pathology, their association with type I IFN, and their potential as noninvasive biomarkers.

Safety and Tolerability of NIM-1324, an Oral, Once-daily LANCL2 Agonist, in a Randomized, Double-Blind, Placebo-Controlled Phase 1 Study in Normal Healthy Volunteers

Andrew Leber, Raquel Hontecillas, Nuria Tubau Juni and Josep Bassaganya-Riera, NIMML Institute, Blacksburg, VA

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: SLE – Treatment Poster III
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Systemic lupus erythematosus is a complex disease in which the immune system is dysfunctional at multiple levels including impaired regulatory responses, altered self-antigen processing and increased autoantibody production. LANCL2 is a novel therapeutic target that has been first targeted by a gut-restricted compound, omilancor, currently in clinical development for inflammatory bowel diseases. NIM-1324 functions through similar LANCL2-dependent immunometabolic mechanisms, increasing the suppressive capacity and stability of regulatory CD4+ T cells (Treg) while also supporting the metabolic demands of autophagy in phagocytes. The preclinical efficacy of NIM-1324 has been validated in NZB/W, MRL, and pristane-induced models of lupus and the preclinical safety has been demonstrated up to a NOAEL of 1,000 mg/kg/d.

Methods: Oral NIM-1324 was evaluated for safety and tolerability in normal healthy volunteers (n = 56) in a randomized, double-blind, placebo-controlled trial. Volunteers were randomized into five single ascending dose cohorts (250 – 1500 mg, p.o.) and three multiple ascending dose cohorts (250 – 1500 mg QD for seven days, p.o.). Safety and tolerability were assessed by adverse event (AE) reporting, vital signs, ECG, hematology, and clinical chemistry. Blood concentrations of NIM-1324 were measured. Whole blood gene expression and serum cytokines were analyzed as markers of target engagement.

Results: Single and seven-day dosing with NIM-1324 did not result in and SAEs or increases in total AE rates in individual dose cohorts and overall pooled active group relative to placebo. Oral NIM-1324 dosing did not result in any clinically significant findings by biochemistry, coagulation, ECG, hematology, or urinalysis. NIM-1324 was rapidly absorbed after oral dosing and did not accumulate over the seven-day dosing period. Plasma exposure of NIM-1324 was observed to scale in a dose-proportional manner within the range of 250 to 1000 mg/d. Using a whole blood transcriptomic signature developed during preclinical efficacy testing, NIM-1324 upregulated the mRNA expression of genes associated with mitochondrial metabolism and downregulated markers of phagocyte activation. The magnitude of effect in the 250 mg cohort was like those observed preclinically at maximally effective doses.

Conclusion: Oral treatment with NIM-1324 is well tolerated and safe in humans up to the tested limit dose of 1500 mg/d. Based on the observed safety, pharmacokinetics and target engagement profile, a first-in-patient clinical trial of NIM-1324 in systemic lupus erythematosus is currently planned.

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: SLE – Treatment Poster III
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Lupus nephritis (LN) is an autoantibody-mediated disease involving glomerular deposition of immune complexes containing pathogenic anti-C1q antibodies, leading to C1q binding and activation of the classical complement pathway. ANX009 is a subcutaneously administered antigen-binding fragment of a humanized antibody that inhibits C1q interaction with immune complexes. Plasma measures of classical complement activation (C4d/C4 ratio) strongly correlate with disease activity in LN patients, suggesting that these patients may benefit from anti-C1q therapy.

Methods: LN-01 is an ongoing, single-arm, phase 1b study evaluating safety and tolerability of ANX009 in patients (N≤8) with class III or IV LN and a diagnosis of systemic lupus erythematosus according to EULAR/ACR 2019 criteria. Patients also exhibited high plasma C4d/C4 ratio and urine protein creatinine ratio >0.5 g/g at study enrollment. Patients undergo an 8-week screening period, a 3-week treatment period, and an 11-week off-treatment follow-up period. Primary and secondary endpoints are the percentage of patients with treatment-emergent adverse events (TEAEs) and change in complement biomarkers, respectively.

Results: To date, 4 patients completed treatment, one patient discontinued treatment, and screening is ongoing. Among 3/5 patients, 29 TEAEs occurred. All AEs were non-serious, except fever of unknown diagnosis in one patient. Injection site reactions arose in 3/5 patients—mild, mostly erythema. C4d/C4 ratio decreased with treatment in all 5 patients and returned to baseline after treatment cessation. Inhibition of C1q also resulted in normalization of downstream complement markers of activation and consumption for the entire pathway.

Conclusion: In this interim analysis, ANX009 administered subcutaneously was well tolerated and demonstrated C1q target engagement and complement inhibition in 5/5 patients. Normalization of all downstream activation markers and primary components, notably C3 and C5b-9, suggests the classical pathway, not the alternative pathway, is a key driver of complement activation in these LN patients. These interim results support further study of anti-C1q therapy in LN patients.

Abstract Number: 2339

Fragility of Randomized Clinical Trials of Systemic Lupus Erythematosus and Lupus Nephritis Therapies

Gabriel Figueroa-Parra[1], Mike Putman[2] and Ali Duarte-Garcia[3], [1]Division of Rheumatology, Mayo Clinic, Rochester, MN, [2]Division of Rheumatology, Medical College of Wisconsin, Milwaukee, WI, [3]Mayo Clinic, Rochester, MN

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: SLE – Treatment Poster III
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Randomized controlled trials (RCTs) in systemic lupus erythematosus (SLE) for novel therapeutics have frequently failed to meet criteria for regulatory approval. Even among drugs that were recently approved, trials been mixed in their conclusions or have had small effect sizes for outcomes that matter. The Fragility Index (FI) is a recently described method for assessing the robustness of RCTs findings, which calculates the minimum number of patients whose status would be required to change from an event to a non-event to make the study lose statistical significance ($p< 0.05$). We aimed to assess the robustness of pivotal phase 3 RCTs for SLE and LN treatments using the FI, the reverse FI (RFI), and the fragility quotient (FQ) scores to aid the interpretation of these RCTs.

Methods: To identify all RCTs, we searched on ClinicalTrials.gov for all phase 3, placebo-controlled RCTs, including patients with active SLE or LN. Trials were excluded if they were unpublished, phase 2 or 4 RCTs, or terminated due to reasons other than futility. Data on pre-specified primary endpoints, total participants, participants within each trial arm, and the number of events in the intervention and placebo groups were obtained from the full publications. FI score was calculated using an online calculator (available at https://clincalc.com/Stats/FragilityIndex.aspx), the RFI was calculated for RCTs with non-statistically significant results by modifying the number of events in the intervention arm until a p-value < 0.05 is reached while keeping the total number of participants constant. The FQ score was calculated by dividing the FI (or RFI) score by the total sample size of the trial. We used descriptive statistics to present the results.

Results: We evaluated 20 RCTs (16 in SLE, 4 in LN). The mean FI/RFI score of the 20 studies was 13.6±6.6. There were 9 studies with statistically significant results (7 in SLE, 2 in LN), and the mean FI score was 10.2±6.2. Twelve studies showed non-statistically significant results (9 in SLE, 2 in LN) with a mean RFI score of 15.6±6.1. The lowest FI was for the ILLUMINATE-2 trial (score: 2, Tabalumab), and the highest FI was found in the BLISS-52 trial (score: 17, Belimumab). The lowest RFI (non-significant trials) was for the ILLUMINATE-1 trial (score: 4, Tabalumab), and the highest RFI was for the TULIP-1 trial (score: 27, Anifrolumab). The RCT that granted FDA approval to anifrolumab was the TULIP-2 trial, with a FI score of 11. Voclosporin trial (AURORA-1) had an FI score of 15. Regarding the belimumab studies, BLISS-52 had an FI score of 17, BLISS-76 had an FI score of 4, BLISS-SC had an FI score of 16, and BLISS-LN had a FI score of 3. The lowest FQ scores were found in the ILLUMINATE trials and the highest in the Rituximab trials (LUNAR & EXPLORER) and the early terminated LOTUS trial.

Conclusion: The evidence supporting the recent approval of therapies for patients with SLE and LN is derived mostly from fragile RCTs, both among trials that met thresholds for statistical significance and among those that did not.

Table 1. Fragility evaluation of phase 3, randomized placebo-controlled trials involving patients with active systemic lupus erythematosus (SLE)

Study drug, trial	First author, year	Condition	Primary endpoints	Sample size	Events in intervention	Events in Placebo	FI or RFI score	FQ score
Anifrolumab

Multi-targeted Therapy Better in Achieving Complete Response in Lupus Nephritis: A Systematic Review and Meta-analysis

Omer Pamuk[1], Bisma Shaikh[2], Saif Khan[3], Ali Abbas[4], Sarah Abi Doumeth[5] and sarfaraz Hasni[6], [1]University Hospitals Cleveland Medical Center, Cleveland, OH, [2]Jinnah Sindh Medical University, Karachi, Pakistan, [3]College of Medical and Dental Sciences, Birmingham, United Kingdom, [4]Alabama College of Osteopathic Medicine, Dothan, AL, [5]Case Western Reserve University/University Hospitals Cleveland Medical Center, Cleveland, OH, [6]Lupus Clinical Trials Unit, National Institute of Arthritis and Musculoskeletal and Skin Diseases, National Institutes of Health (NIH), Bethesda, MD

SESSION INFORMATION

Session Date: Tuesday, November 14, 2023

Session Title: SLE – Treatment Poster III

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: The overall management of SLE and Lupus Nephritis (LN) has significantly improved over the last four decades.Recently great therapeutic strides have been made in management of LN using newer agents alone or combination of older therapies. With the availability of increased number of options choosing the optimal treatment regimen for LN has become challenging. Identifying the treatment regimen most effective in achieving complete response while minimizing adverse events is crucial for improving patient outcomes.We performed a systematic review and meta-analysis of clinical trials to explore optimal treatment regimen for LN.

Methods: The systematic review and meta-analysis were performed using the Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) guidelines. The literature search was conducted using public databases, such as the Cochrane Library, Web of Science and PubMed. Only randomized controlled clinical trials with either active comparator or placebo arms were included. Studies were excluded if they were retrospective, with no comparative drug arm, or less than 20 subjects per treatment response arm. Due to lack of agreed upon outcome measures, complete response (CR) and partial response (PR) criteria were determined as per the definition used by individual studies. Severe adverse

reaction (SAE) frequencies were determined for each study for safety evaluation. Data from each study were evaluated for consistency. Publication bias was detected by using funnel plots. Forest plots were used to summarize data, generate frequencies, odds ratio (OR), relative risks (RR) and corresponding 95% confidence intervals (CI) for each subgroup. Heterogeneity was evaluated using the I^2statistic, and labelled as low (25%), moderate (50%) and high (75%). All analyses were performed using R Statistical Software meta package (v4.2.1; R Core Team 2022).

Results: 31 eligible studies comprising 5495 SLE patients were included in analyses, the study characteristic features are shown in Table 1. Overall significant OR for achieving CR was reported by 10 studies (Figure 1). The highest effect was reported from study by Bao et.al using a combination of tacrolimus(TAC) and mycophenolate mofetil (MMF) compared to cyclophosphamide (CYC) (OR=10.5, 95% CI 2.27; 48.76), another study using TAC+MMF combo reported OR=2.49, 95% CI 1.59;3.88. The study by Ginzler et.al reported OR= 5.06 (95% CI 1.6:16.02) in favor of using MMF. Studies using

Table 1. Main features of eligible clinical trials.

Study/year	Drug arms	Study design	Duration	Primary outcome
Furie 2022	OBI vs. Placebo	RCT-DB	104 weeks	Confirmed complete response
Zheng 2022	TAC vs. CYC	RCT-Open	24 weeks	Complete renal response
Ye 2022	TAC+MMF vs. CYC	RCT	72 weeks	Renal remission
Jayne 2021	ANIF vs. Placebo	RCT - DB	52 weeks	change in baseline 24-hour UPCR
Atisha-Fregoso 2021	RTX+BEL+CYC vs. RTX+CYC	RCT-Open	96 weeks	Safety (Phase II), Complete remission
Rovin 2021	VOC vs. Placebo	RCT-DB	52 weeks	Complete renal response
Furie 2020	BEL vs Placebo	RCT-DB	104 weeks	Primary efficacy renal response
Zhang 2020	MMF+TAC vs. MMF+CYC	RCT	6 months	Cystatin C, TGF-B levels
Rovin (low dose) 2019	VOC-low vs. Placebo	RCT-DB	48 weeks	Complete renal response
Rovin (high dose) 2019	VOC-High vs. Placebo	RCT-DB	48 weeks	Complete renal response
An 2019	CYC+MMF/AZA/LEF vs. CYC	RCT-Open	24 week	Complete remission
Sedhain 2018	MMF vs. CYC	RCT-Open	6 months	Treatment response
Mehra 2018	CYC-Low vs. CYC-High	RCT-Open	52 weeks	Complete renal response
Kamanamool 2018	TAC vs. MMF	RCT- Open	12 months	SLEDAI-2K
Rathi 2016	MMF vs. CYC-Low	RCT	24 weeks	Treatment response
Liu 2015	TAC+MMF vs. CYC	RCT- Open	24 week	Complete remission
Furie 2014	ABA 10/10 vs. Placebo	RCT-DB	12 months	Time to confirmed complete response
Furie 2014	ABA 30/10 vs. Placebo	RCT-DB	12 months	Time to confirmed complete response
Access 2014	ABA+CYC vs. EuroLN	RCT-DB	52 week	Complete response
Mok 2014	MMF vs. TAC	RCT-Open	6 months	Complete renal response
Mysler (Low) 2013	OCR-Low vs. Placebo	RCT-DB	48 week	Complete renal response
Mysler (High) 2013	OCR-High vs. Placebo	RCT-DB	48 week	Complete renal response
Rovin 2012	RTX vs. Placebo	RCT- DB	52/78 weeks	Complete renal response
Dooley 2011	MMF vs. AZA	RCT-DB	36-month	Time to treatment failure
Chen 2011	TAC vs. CYC	RCT-Open	6-month	Complete remission
Merrill 2010	RTX vs. Placebo	RCT- DV	52 weeks	Major clinical response
Appel 2009	MMF vs. CYC	RCT-Open	24 week	Change in UPCR and creatinine
Bao 2008	TAC+MMF vs. CYC	RCT-Open	9 months	Complete remission
Ginzler 2005	MMF vs. CYC	RCT-Open	24 week	Complete remission
Chan 2000	MMF vs. AZA	RCT	12 months	Complete remission
Austin 1986	CYC/AZA vs. PRD	RCT-Open	Not specified	Stable renal function

OBI: obinutuzumab, TAC: tacrolimus, CYC: cyclophosphamide, MMF: Mycophenolate, ANIF: anifrolumab, VOC: voclosporine, BEL: belimumab, AZA: azathioprine, LEF: leflunomide, ABA: abatacept, OCR: ocrelizumab, RTX: rituximab, PRD, prednisone

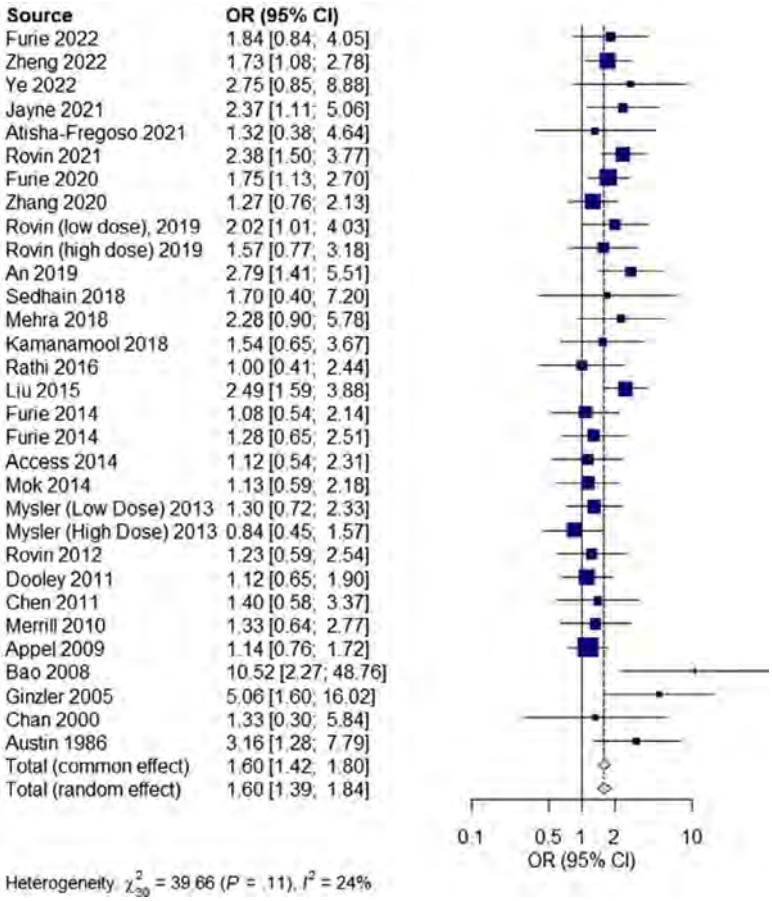

Figure 1. Odd ratios for complete remission in lupus nephritis studies.

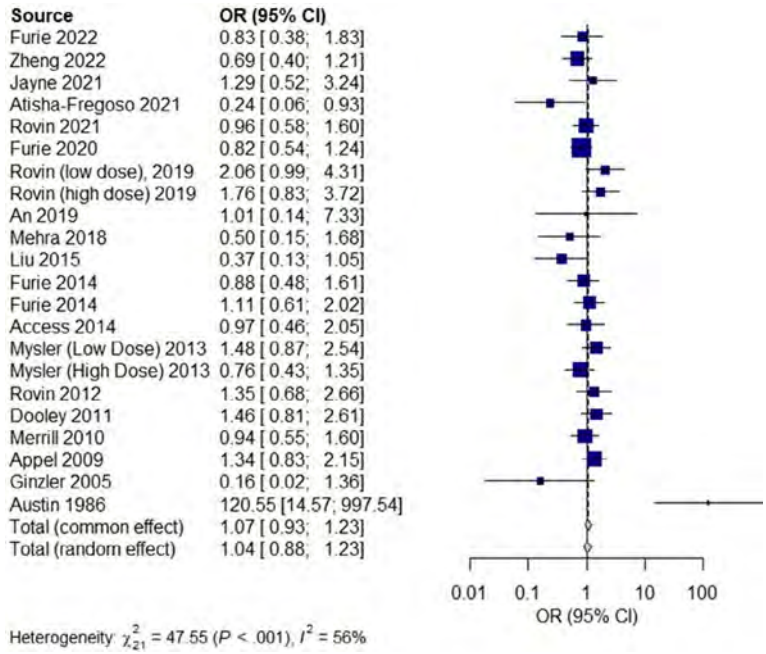

Figure 2. Odd ratios for severe adverse events in lupus nephritis trials.

CYC, voclosporin + MMF, and belimumab also reported significant OR for achieving CR. Data for the frequency of SAE were available in 22 studies. The frequency of SAE was not significantly different between treatments arms (OR: 1.07, 95%CI: 0.93-1.23, p >0.05)

Conclusion: Our meta-analysis suggests multi-target treatment strategies, by adding calcineurin inhibitors to MMF may be better for achieving complete response in LN. Furthermore, using this combination treatment did not seem to increase the risk of side effects. Heterogenous treatment response criteria and variable comparator arms were major limiting factors of this study.

SESSION INFORMATION

Session Date: Tuesday, November 14, 2023

Session Title: SLE – Treatment Poster III

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: Belimumab (BLM) is a monoclonal antibody that inhibits B-lymphocyte stimulating factor (BlyS), approved in 2011 as a treatment for systemic lupus erythematosus (SLE). We present the experience with BLM in this spanish cohort.

Methods: Descriptive, retrospective, multicenter study in patients diagnosed with SLE according to EULAR/ACR 2019, SLICC and/or ACR 1997 diagnostic criteria. Data regarding SLE patients treated with BLM were collected from medical records (2011-2023). Demographic features, analytical variables, SLEDAI, renal involvement, steroid dose, administration routes, efficacy, remission and safety were assessed.

Results: Five hundred and twenty one patients were included with a mean age at diagnosis of 35.1 (13.9) years. 85.8% were women. The mean age at BLM begins was 44.5 (13.3) years and the median time from SLE diagnosis to BLM begin was 6.5 (2.4-14.3) years. Regarding administration route 50.2% were on intravenous (IV), 34.6 % on subcutaneous (SC) and 15.2% change from IV to SC route. The mean time of follow-up was 24.0 (21.4) months.

Baseline characteristics are summarized in Table 1 and patients in remission are shown in figure 1.

The median number of pre-BLM cDMARD use was 2.0 (2.0-3.0), being hydroxychloroquine (HCQ) the most used (94.2%). 93 patients received bDMARD before BLM begins, being Rituximab (RTX) the most used (79.6%), and 59 patients were treated with IV cyclophosphamide (CFM) with a median of 6 (4.5-8) IV bolus received. 75.6% and 21.5% of patients were on treatment with HCQ and methotrexate when BLM was started respectively.

Table 1: Baseline characteristics of patients included in Belimumab Spanish registry.

Table 1: Baseline characteristics of patients included in Belimumab Spanish registry.

Age at SLE diagnosis (years)*	35.1 (13.9)
Age at BLM starts (years)*	44.5 (13.3)
Gender (female) n, (%)	447 (85.8)
Time from diagnosis until BLM start (years)**	6.5 (2.4-14.3)

- Methotrexate	280 (53.7)
- Azathioprine	182 (34.9)
- Mycophenolate mofetil/mycophenolic acid	153 (29.4)
- Leflunomide	59 (11.3)

* Mean (SD)
** Median (IQR)

The main reasons of starting BLM were musculoskeletal and mucocutaneous disorders (table1).

503 patients were on prednisone at the time of BLM begin with a median dose of 7.5 (5-10) mg. A statistically significant decrease in prednisone dose, SLEDAI and DNA was observed from baseline until the last follow up. In the other hand complement C3 and C4 raised (figure2).

One hundred and thirty seven patients (28.2%) had renal involvement. The median 24 hours proteinuria was 1.0 (0.5-2.4) grams and renal biopsy was done in 114 out of 137 patients, being class IV (42%), III (18.8%), II (12.5%) and V (10.7%) the most reported. 72.2% improve after BLM begins with last 24 hour proteinuria median of 0.2 (0.1-0.8) grams. Prior to BLM, most of them had been treated with MMF, RTX or CFM.

One hundred and and fitty one patients (29%) discontinued treatment mostly due to inefficacy (57.1%) and infections (12.2%). 133 patients developed infections, most of them mild, being urinary infection the most reported. 3 patients died, 8 had COVID and 3 presented neoplasms requiring discontinuation of the drug. The median time on treatment of patients that had to stop BLM was 12.0 (6-24) months.

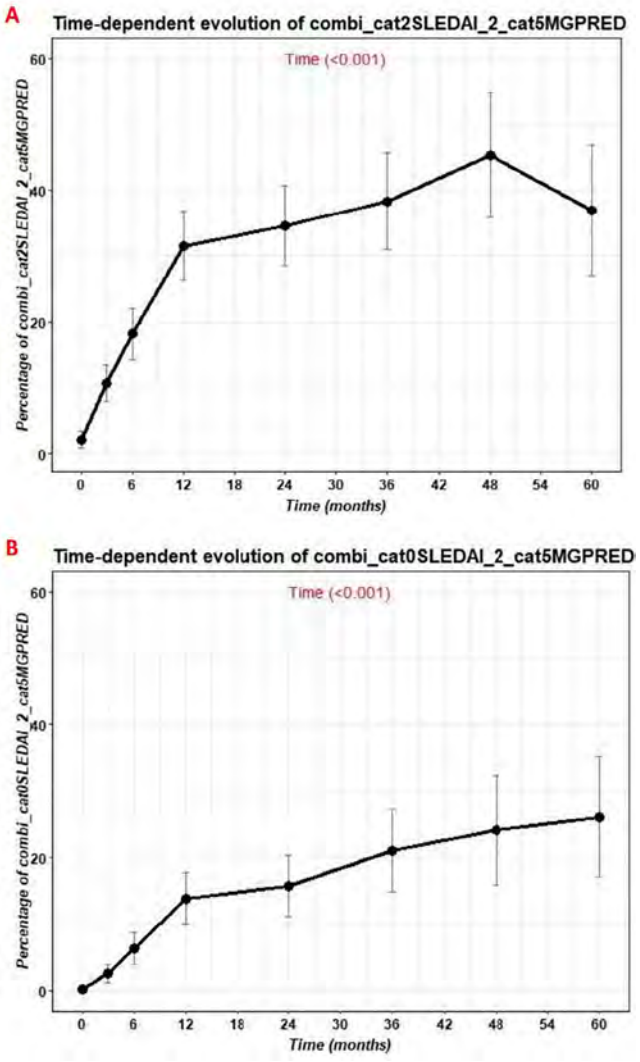

Figure 1: Remission define as SLEDAI ≤ 2 and ≤ 5 mg of prednisone (A) or SLEDAI ≤ 0 and ≤ 5 mg of prednisone (B).

Conclusion: Almost half of patients achieved remission after 4 years of BLM and a statistically significant improvement in prednisone dose reduction, SLEDAI, complement and antiDNA was demonstrated. Corticosteroids sparing effect with BLM was also observed.

BLM seems to be a good choice for patients with lupus nephritis since nearly three quarters of them normalized proteinuria values. No new safety alarms were reported.

This is the largest cohort of SLE patients treated with BLM reported in one country.

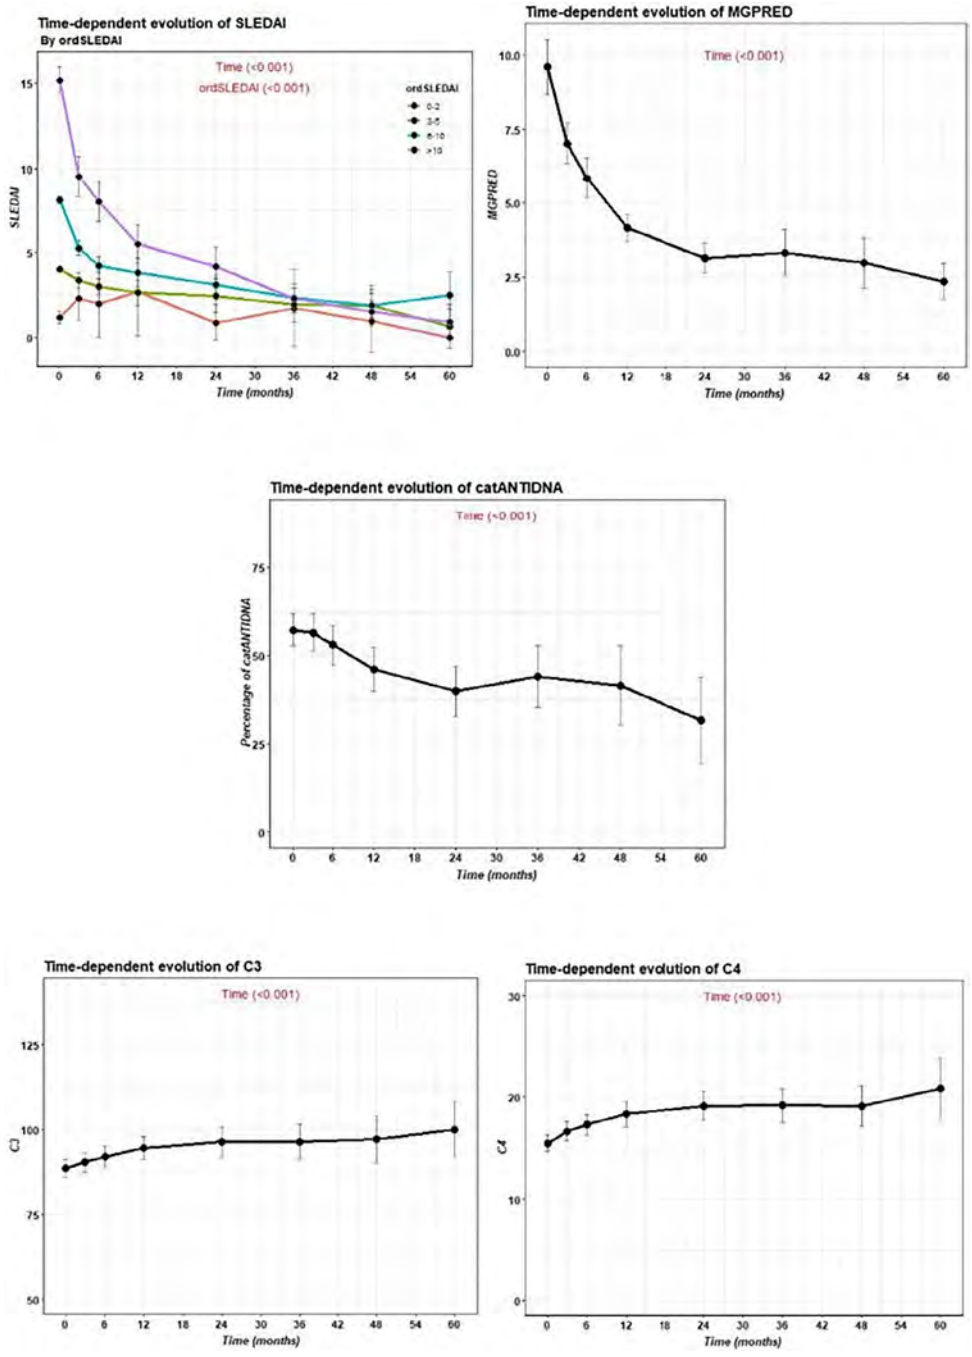

Figure 2: Time dependant evolution of SLEDAI, prednisone, antiDNA and complement C3 and C4.

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: SLE – Treatment Poster III
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Ianalumab (VAY736) is an afucosylated monoclonal antibody targeting the B cell activating factor receptor (BAFFR) that depletes B cells via enhanced antibody dependent cellular cytotoxicity with concurrent blockade of BAFF:BAFFR mediated survival signals. BAFF is commonly overexpressed in systemic lupus erythematosus (SLE) and strongly linked to autoimmune pathogenesis. Here we assessed changes within the transcriptomic and proteomic landscape of SLE patients pre- and post-treatment with ianalumab to characterize pharmacodynamic (PD) biomarkers and biological pathways linked to the disease activity and clinical response.

Methods: A phase 2 clinical trial (NCT03656562) evaluated the PD and preliminary clinical efficacy of ianalumab in patients with moderate to severe SLE; a multicenter randomized, parallel group, double blind, placebo controlled trial with patients on monthly s.c. injection of ianalumab 300 mg or placebo. Blood samples were collected at baseline and week (W) 28 post treatment from placebo (n=28) and ianalumab treated patients (n=25). Blood samples from 40 healthy volunteers were included for baseline transcriptomics analysis. Targeted cellular analysis was done by flow cytometry, serum protein profiles were generated using the SomaScan v4.1 assay and transcriptome analysis was done with total RNA obtained from whole blood using an Illumina Stranded kit. Treatment and placebo groups were compared over time using multivariate linear regression models to identify cellular markers, proteins and genes that were differentially modulated by ianalumab.

Results: The analysis of changes to cellular subsets upon ianalumab treatment demonstrated a strong and statistically significant reduction in total B cells which was confirmed by changes in transitional, naïve and memory B cells as well as plasmablasts/plasma cells without reductions in $CD4^+$ and $CD8^+$ T cells or NK cells **(Fig 1).** Assessment of SLE molecular drivers through blood transcriptomics versus healthy volunteers confirmed a disease signature driven by type 1 interferon (IFN) and innate immunity pathways, correlating with immunoglobulin genes. Upon ianalumab treatment, a strong reduction in B cell

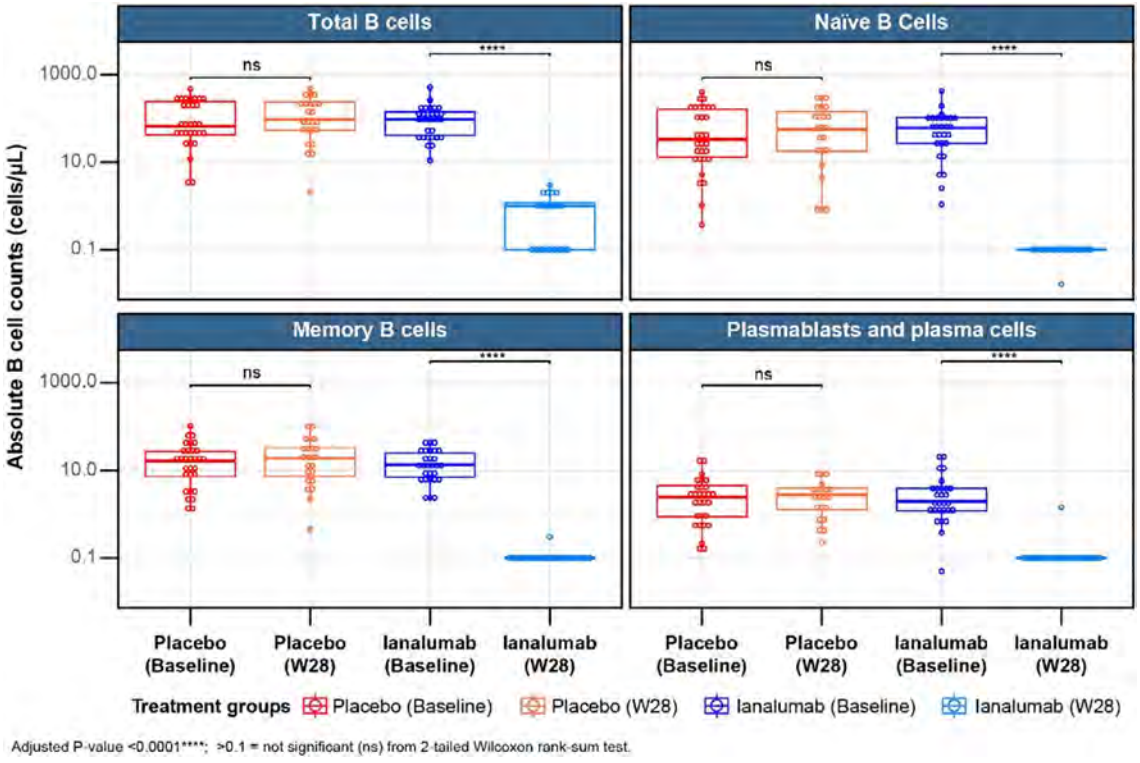

Fig 1. Depletion of B cell subsets (CD27+ memory cells and CD27high CD38high plasmablasts/plasma cells) upon ianalumab treatment measured by flow cytometry

related genes was seen at W28, accompanied by a significant decrease in IL-6 transcript and a modulation of the interferon gene signature (IFNGS) **(Fig 2)**. Broad serum protein profiling confirmed transcriptomics findings, showing reduction of multiple B cell markers on ianalumab treatment. Importantly, we observed that SRI-4 response to ianalumab was comparable in both baseline IFNGS-high and IFNGS-low patients, with a concomitant SLEDAI reduction.

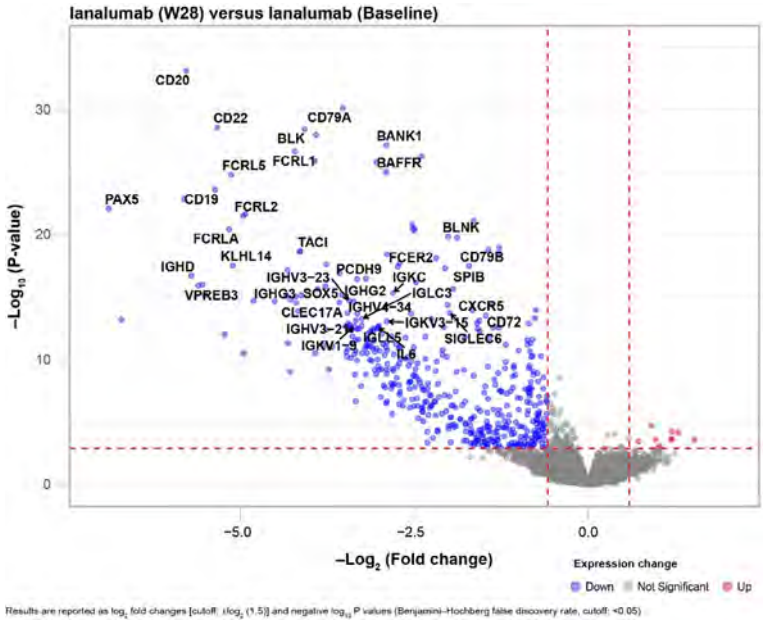

Fig 2. Volcano plot showing differentially expressed genes across time with ianalumab at W28 versus baseline

Conclusion: Ianalumab treatment of patients with SLE led to strong B cell depletion, including autoantibody-producing subsets, confirmed by transcriptomics and proteomics assessments. Initial evidence suggests that reductions in B cell numbers and autoantibodies levels observed clinically was accompanied by a decrease in IFNGS and clinical response to ianalumab was independent of baseline IFNGS status. Further molecular studies are ongoing to characterize the effects of ianalumab on these patients.

Hydroxychloroquine Discontinuation in the Real World: Reasons, Predictive Factors and Clinical Implications

Eduardo Mantovani Cardoso[1], Rachel Simon[1] and Vasileios Kyttaris[2], [1]Beth Israel Deaconess Medical Center / Harvard Medical School, Boston, MA, [2]BIDMC, Boston, MA

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: SLE – Treatment Poster III
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Systemic lupus erythematosus (SLE) is a complex autoimmune disease characterized by multisystemic involvement and difficult-to-predict disease flares. Hydroxychloroquine (HCQ) has long been recognized as a cornerstone of SLE management. However, the impact of discontinuing HCQ on disease activity and flare rates in SLE patients remains a subject of ongoing investigations. We aim to assess factors associated with flares in patients that discontinue HCQ.

Methods: This retrospective cohort study included SLE patients who met the 1997 ACR criteria for SLE. The study period was from 2012 to 2023. Patients were identified from our cohort and were required to have at least one year of follow-up before and after discontinuing HCQ. Thus, the time limit for discontinuation of HCQ was March 2022. Inclusion criteria stipulated consistent HCQ intake without erratic prescription patterns. HCQ discontinuation reason was documented. Patient data were collected on the electronic medical records through chart review. Local IRB approval was granted for it. We evaluated clinical and laboratory parameters historically (profile) and at the index visit, defined as within 3 months of HCQ discontinuation. Flares were evaluated 12 months before and after HCQ discontinuation according to the SLEDAI flare index. Statistical analysis was performed with STATA, group comparison by using t-test for continuous and a chi-square test for categorical variables.

Results: 42 patients were identified that met the established criteria. Ninety-five percent of patients were females. Blacks constituted 33% of the cohort and Hispanics 44%. The mean age at the index visit was 50 years old and were diagnosed, on average, 15 years before the index visit. Common clinical manifestations included mucocutaneous (69%), musculoskeletal (69%), and hematologic (69%). Class III/IV lupus nephritis was present in 21% and Class V in 17% of patients. The immunologic profile included dsDNA Ab positivity (76%), low C3 (67%), RNP antibody (38%), SSA Ab (36%), anticardiolipin Ab (33%), and Smith Ab (31%). ACR/EULAR 2019 classification criteria mean score was 24.4. 19%of patients had flared the

Table 1- Table 1- Clinical and serological profile of the SLE patients. Abbreviations: Ab: antibody, HCQ: hydroxychloroquine, LFT: liver function tests, RNP: ribonucleoprotein , dsDNA: double standed DNA,

year before HCQ discontinuation. The main reasons for discontinuation was retinal toxicity due to HCQ (57%), self-discontinuation (17%), and either other retinopathies or inability to perform eye exams (12%). At the index visit, mean C3 was 108 mg/dL and C4 20 mg/dL, and dsDNA Ab positivity in 38% (Table 1). 11/42 (26.1%) of patients flared the year after HCQ discontinuation, compared to 19% of flares the year before (p-value 0.433). Out of several parameters evaluated for association with flares, the strongest associations were: mean C3 at the index visit (79.4 mg/dL in flares versus 117.7 no flares, p-value < 0.001) and dsDNA positivity at index visit (83% flares versus 26% no flares, p-value 0.018). Other associations tested are available in Table 2.

Conclusion: In a cohort of 42 SLE patients that had high ACR/EULAR 2019 classification scores (>20), older age, and prolonged disease duration, flares within 1 year of HCQ discontinuation did not have a higher incidence than the year before HCQ discontinuation but were associated with lower C3 levels and positive dsDNA antibody.

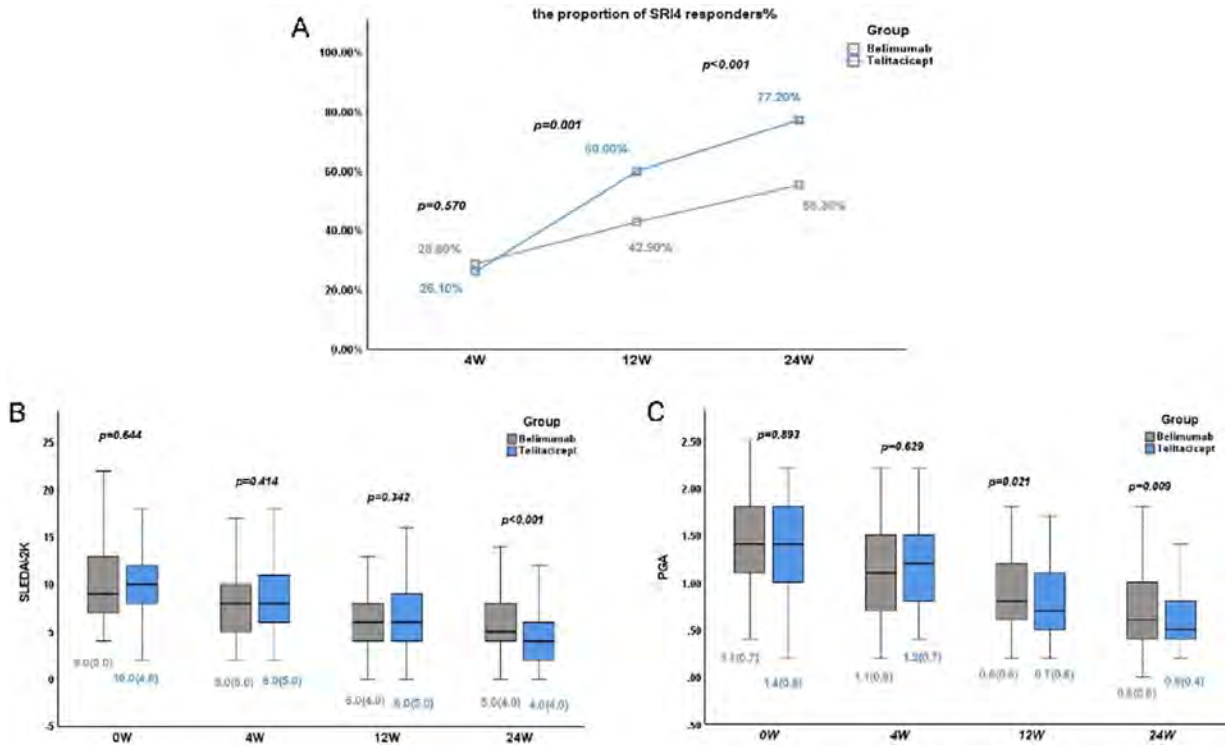
Telitacicept versus Belimumab for Patients with Active Systemic Lupus Erythematosus: A Retrospective, Multicenter, Real-world Observational Study

Zhu Chen[1], **Huizhi Jin**[1], Yujing Li[1], Guosheng Wang[1], Xiaomei Li[2], Zhijun Li[3], Lin Niu[4] and Haifeng Pan[5], [1]University of Science and Technology of China, Hefei, China, [2]University of Science and Technology of China, Department of Rheumatology and Immunology, The First Affiliated Hospital of USTC, Division of Life Sciences and Medicine, Hefei, China, [3]Bengbu Medical University, Bengbu, China, [4]Fuyang People's Hospital, Fuyang, China, [5]Anhui Medical University, Hefei, China

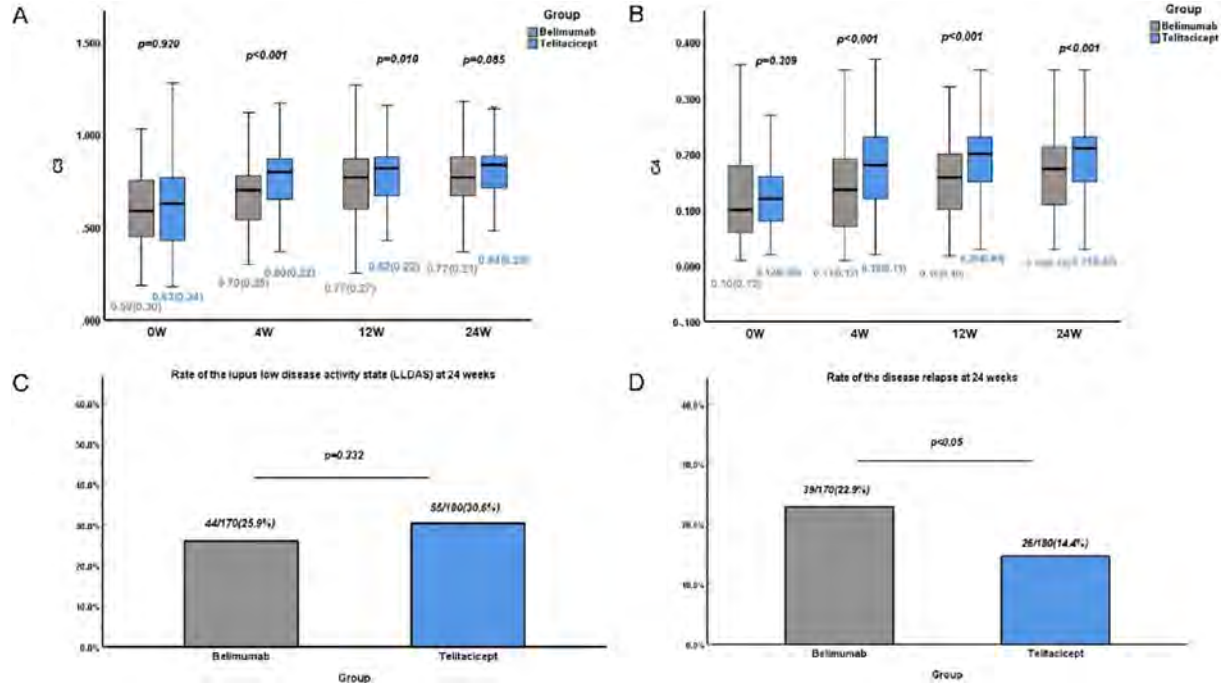
SESSION INFORMATION

Session Date: Tuesday, November 14, 2023
Session Title: SLE – Treatment Poster III
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: The past decade has witnessed the innovation of several biologics in the treatment of systemic lupus erythematosus (SLE), most of which target B cells, including B-cell activating factor/a proliferation-inducing ligand (BAFF/APRIL) inhibitors. Telitacicept is a TACI–immunoglobulin fusion protein that neutralizes the activity of BAFF and APRIL by competitively inhibiting the TACI site, thereby suppressing the development and survival of plasma cells and mature B cells. The aim of this study was to compare the efficacy and safety of two differentBAFF/APRIL inhibitors, telitacicept and belimumab, in treating patients with active SLE in real world clinical practice.



A-C Primary outcome in disease activity over a 24-week period following the introduction of BAFF/APRIL inhibitors after IPTW. (A) Comparison of changes in the proportion of SRI-4 responders after the treatment from 0 to 24 weeks between the belimumab and telitacicept groups. Comparison of changes in (B) Systemic Lupus Erythematosus Disease Activity Index 2000 (SLEDAI-2K) score and (C) Physician Global Assessment (PGA) score after the treatment from 0 to 24 weeks with median (IQR).



A-D Complement changes and other outcomes in disease activity over a 24-week period following the introduction of BAFF/APRIL inhibitors after IPTW. Comparison of changes in (A) C3 and (B) C4 between the belimumab and telitacicept groups after the treatment from 0 to 24 weeks with median (IQR). Comparison of the rate of (C) Lupus Low Disease Activity State (LLDAS) and (D) relapse between the two groups at 24 weeks.

Methods: Patients with active SLE who received telitacicept (n=72) or belimumab (n=103) from 2019 to 2022 at multiple centers in China were retrospectively reviewed, and the efficacy of telitacicept and belimumab was compared. Patients with renal and hematologic abnormalities were separately selected to confirm the treatment efficacy in these systems. Propensity score-based inverse probability of treatment weighting (IPTW) was used to reduce selection bias. Multivariable logistic regression analysis was used to identify the factors contributing to limited response.

Results: No significant between-group differences in patient characteristics were observed after adjustment by IPTW. The proportion of SLE Responder Index 4 responders at 12 and 24 weeks was significantly higher in the telitacicept group ($p < 0.05$). Consistently, patients who received telitacicept had a significantly greater decrease in the SLEDAI-2K score and Physician Global Assessment score at 24 weeks ($p < 0.05$). No significant between-group difference in kidney efficacy was observed, but telitacicept produced greater improvement in patients with anemia, leukopenia, and thrombocytopenia at 24 weeks. Importantly, the telitacicept group had a lower incidence of adverse events, especially upper respiratory tract infections, than the belimumab group after the start of therapy ($p < 0.05$).

Conclusion: Telitacicept showed better efficacy and safety than belimumab for patients with active SLE in multiple clinical centers. Further investigations in larger cohorts and head-to-head clinical trials are required to verify these findings.

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: SLE – Treatment Poster III
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Voclosporin is approved for the treatment of adults with active lupus nephritis. Addition of voclosporin to mycophenolate mofetil (MMF) and low-dose glucocorticoids in the Phase 3 global AURORA 1 and AURORA 2 studies led to significantly earlier and greater reductions in proteinuria and an improved estimated glomerular filtration rate (eGFR) slope over time.To characterize the long-term renal impact of voclosporin at the histologic level, we analyzed paired kidney biopsies from a subset of patients in these studies.

Methods: Patients in AURORA 1 had biopsy-proven lupus nephritis, urine protein creatinine ratio (UPCR) ≥1.5 g/g (≥2 g/g for Class V), and estimated glomerular filtration rate (eGFR) >45 mL/min/1.73 m^2. Patients were randomized to voclosporin or control for 1 year in AURORA 1 and continued the same blinded therapy for 2 additional years in AURORA 2; all patients received MMF and low-dose glucocorticoids. A subset of patients had a kidney biopsy prior to screening and a repeat biopsy after approximately 18-months of therapy. Histopathologic grading according to National Institutes of Health indices for lupus nephritis activity and chronicity was conducted by Arkana Laboratories. Efficacy outcomes and measures of renal function over time, including eGFR were assessed.

Table 1. Laboratory parameters, clinical outcomes, and activity and chronicity index scores over time

	Voclosporin n=16		Control n=10	
	Baseline	**Month 36**	**Baseline**	**Month 36**
CRR, % (n/n)	-	62.5% (10/16)	-	40.0% (4/10)
PRR, % (n/n)	-	81.3% (13/16)	-	70.0% (7/10)
UPCR, mean (SD) g/g	4.59 (2.5)	0.99 (1.4)	4.71 (2.6)	2.1 (4.6)
eGFR, mean (SD), mL/min/1.73 m^2	80.3 (16.4)	82.7 (15.4)	82.6 (12.3)	85.8 (13.3)
Urine protein, mean (SD) mg/dL	413.7 (277.2)	135.7 (264.0)	350.2 (234.1)	128.0 (284.7)
Magnesium, mean (SD) mg/dL	2.0 (0.1)	2.0 (0.2)	2.1 (0.1)	2.1 (0.2)
Potassium, mean (SD) mmol/L	4.0 (0.3)	4.3 (0.2)	3.9 (0.4)	4.1 (0.5)
Glucose, mean (SD) mg/dL	84.4 (9.0)	93.5 (7.9)	93.5 (38.5)	89.1 (15.3)
Creatinine, mean (SD) mg/dL	0.8 (0.3)	0.8 (0.4)	0.8 (0.2)	0.8 (0.3)
Systolic BP, mean (SD) mmHg	121.7 (9.05)	118.3 (10.4)	121.1 (14.9)	110.8 (4.8)
Diastolic BP, mean (SD) mmHg	79.6 (8.7)	74.7 (7.7)	80.4	76.9 (4.5)
Histology	**Baseline**	**Follow-up**	**Baseline**	**Follow-up**
Activity Index, mean (SD)	1.8 (3.0)	0.4 (1.0)	2.8 (3.2)	0.4 (1.0)
Chronicity Index, mean (SD)	3.8 (3.5)	4.1 (3.3)	2.9 (2.3)	2.8 (2.7)

Renal function assessed with corrected eGFR (Chronic Kidney Disease Epidemiology Collaboration equation) using a prespecified ceiling of 90 mL/min/1.73 m^2. Histopathologic grading based on the National Institutes of Health indices for lupus nephritis activity (scale 0-24) and chronicity (scale 0-12). BP, blood pressure; CRR, complete renal response (UPCR ≤0.5 g/g, stable eGFR > 60 mL/min/1.73 m2, low-dose steroids, and no rescue medication); eGFR, estimated glomerular filtration rate; PRR, partial renal response (>50% reduction from baseline in UPCR); SD, standard deviation; UPCR, urine protein creatinine ratio.

Results: Paired biopsy samples were collected from sixteen patients in the voclosporin arm and ten patients in the control arm. Baseline mean activity scores were similar between arms, with scores improving with treatment in both arms (Table 1). Mean chronicity scores were also similar between arms at baseline and remained stable over time in most patients. Measures of renal function remained stable in both arms over the 3-year follow-up. Voclosporin-treated patients had numerically greater mean reductions from baseline in UPCR year-on-year compared to patients in the control arm, although the difference was not statistically significant. On-going research involving the above patients and others from AURORA 2 using multiplex immunohistochemistry and RNA-sequencing has been performed, and data are currently being analyzed.

Conclusion: As expected, mean activity scores improved in both treatment arms. Importantly, exposure to voclosporin was not associated with chronic injury, with the mean index remaining stable at follow-up. Similar to the overall population, patients treated with voclosporin saw greater reductions in UPCR over 3 years of treatment; safety outcomes from this small subgroup were also consistent with outcomes in AURORA 1. Multiplex immunohistochemistry and sequencing data will further illuminate the cellular and molecular underpinnings of disease and response to treatment.

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: SLE – Treatment Poster III
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: A key treatment goal for patients (pts) with SLE is to reduce use of CS, due to their association with organ damage.[1] BEL is an approved treatment for active SLE and LN, in addition to standard therapy (ST).[1] BEL-treated pts were able to reduce CS dose and exhibited delayed organ damage progression during long-term extension studies (LTEs).[2–4] We evaluated use of SLE medications and change in organ damage over time in pts with SLE using data from three multicenter LTE studies.

Methods: This post hoc analysis pooled data from the LBSL02 LTE (Phase 2; GSK Study 112626),[2] BLISS-76 LTE (US pts only; Phase 3; GSK Study 112233),[3] and BLISS-52 + BLISS-76 LTE (excluding US pts from BLISS-76; Phase 3; GSK Study 112234)[4] studies. To enroll in LTEs, pts must have completed treatment through Week 72 of LBSL02 and BLISS-76, or Week 48 of BLISS-52; improvement in physician global assessment at Week 72 or 68 versus at first BEL dose was required in the LBSL02 LTE. Pts received BEL 10 mg/kg intravenously every 28 days plus ST at the start of each LTE, regardless of prior drug allocation. Maximum daily equivalent prednisone dose was summarized any time post–first BEL dose (in prior trial period or LTE) and in each year. SLICC/ACR Damage Index (SDI) score was assessed among eligible pts in the BLISS-76, and BLISS-52 + BLISS-76 LTE studies; the high disease activity (HDA) population (anti-dsDNA positive and low C3/C4); and the 5-year completer population (pts with ≥5 years of SDI data post–first BEL dose).

Results: Overall, 1304 pts enrolled in the LTE studies, 1299 (99.6%) received ≥1 dose of study drug (pooled safety population) and 604 (46.5%) completed their respective studies. Cumulative BEL-treated patient-years was 7040.1. At baseline (first BEL dose in prior trial period or LTE), 1054 (81.1%) pts received CS. Over time, the proportion of pts discontinuing CS (receiving an equivalent dose of 0 mg/day) increased; the proportion receiving >0 to ≤7.5 mg/day increased up to Year 4–5 (**Table 1**). Any use of CS decreased over time, while use of antimalarials and immunosuppressive/immunomodulatory agents remained stable (**Table 1**). At baseline, 580 (58.2%) and 416 (41.8%) pts had an SDI score of zero and ≥1, respectively. Mean (standard deviation [SD]) change over time in SDI score was similar and remained low for the total, HDA, and

Table 1. Use of SLE medication over time* (pooled safety population, N=1299; post hoc analysis). *Data are summarized at any time post–first BEL dose and in each year; †post–first BEL dose data include follow-up visits after the final dose of BEL; data from Year 0 up to last visit in the treatment period are shown by years of study participation; pts could be counted in more than one year interval; ‡CS were converted to a daily prednisone equivalent dose and the maximum dose was summarized in each interval; maximum daily prednisone dose applies to any time post–first BEL dose and for each year interval; baseline daily prednisone dose was calculated as the average daily dose for the 7 days pre–first BEL dose.

+3	0	0	1 (<1)	1 (<1)	2 (<1)	1 (<1)	1 (<1)	1 (<1)	0
+4	0	0	0	0	0	1 (<1)	1 (<1)	0	0

5-year completer populations (**Table 2**). Among the 5-year completer population, ≤20% had SDI worsening (change ≥0) compared with baseline in any study year (**Table 3**).

Conclusion: Over time, more BEL-treated pts were able to reduce their daily equivalent prednisone dose and exhibited low change in SDI. Limitations include the open-label nature of the studies, lack of control arm, and increased number of withdrawals at later years. These data are consistent with previous observations of the steroid sparing–effect of BEL, and delayed organ damage progression among a large population of BEL-treated pts.[2–5]

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: SLE – Treatment Poster III
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Belimumab (BEL) is approved for the treatment of active SLE, and lupus nephritis, with standard therapy.[1] The prevalence and severity of SLE tend to be higher in patients of Black and Asian race, and Hispanic ethnicity, compared with Caucasians.[2] This large integrated analysis investigated BEL efficacy by race and ethnicity in patients with SLE.

Methods: This Belimumab Summary of Lupus Efficacy (Be-SLE) post hoc analysis pooled data from five BEL trials: BLISS-76[3] (GSK study BEL110751); BLISS-52[4] (BEL110752); NEA[5] (BEL113750); BLISS-SC[6] (BEL112341); EMBRACE[7] (BEL115471; study in patients of self-identified Black race). Included patients received BEL (10 mg/kg/month intravenously or 200 mg/week subcutaneously) or placebo (PBO), plus standard therapy. The proportion of patients with SLE Responder Index-4 (SRI-4) response at Week 52, and time to first severe Safety of Estrogens in Lupus Erythematosus National Assessment (SELENA)-SLEDAI Flare Index (SFI) flare, SFI flare, and BILAG (1A/2B) flare over 52 weeks were analyzed by race (Asian, White, Black African ancestry) and ethnicity (Hispanic/Latino, non-Hispanic/Latino).

Results: Among 3086 patients (BEL, n=1869; PBO, n=1217), 35.7% (BEL, n=697; PBO, n=405) were Asian, 33.4% (BEL, n=596; PBO, n=436) were White, and 20.5% (BEL, n=405; PBO, n=229) were of Black African ancestry. For ethnicity, 27.4% (BEL, n=495; PBO, n=352) were Hispanic/Latino and 72.6% (BEL, n=1374; PBO, n=865) were not Hispanic/Latino. At Week 52, higher proportions of BEL-treated patients were SRI-4 responders and fewer BEL-treated patients experienced severe SFI flares in all subgroups versus PBO, with statistically significant differences in all subgroups except patients of Black African ancestry (**Table**). Greatest treatment differences were among Hispanic/Latino and White patients. Fewer BEL-treated patients experienced SFI and BILAG (1A/2B) flares in all subgroups versus PBO; however, statistical

significance was not reached for SFI in the Black African ancestry subgroup and for BILAG (1A/2B) among the White and Black African ancestry subgroups (**Table**).

Conclusion: BEL significantly increased SRI-4 response rates at Week 52 and decreased flares versus PBO in most subgroups by race and ethnicity, which was largely consistent with results from the overall populations of the primary trials. Numerical benefit only observed in Black African ancestry patients was consistent with the EMBRACE trial findings,[7] from which most patients in this subgroup originated. This analysis was limited by low power to detect statistically significant differences in the smallest subgroup. Collectively, this analysis in a large, diverse population of patients with SLE continues to support the efficacy of BEL

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: SLE – Treatment Poster III
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: BEL-treated patients (pts) in clinical trials and long-term extension (LTE) studies[1-7] experienced comparable incidence of infections versus those treated with standard therapy (ST) alone in clinical trials[1-4]; however, sample sizes were limited. We performed the most comprehensive analysis of infections among BEL-treated pts.

Methods: This post hoc analysis pooled data from three multicenter BEL LTE studies of adults with active SLE: LBSL02 LTE (Phase 2; GSK Study 112626),[5] BLISS-76 LTE (including US pts only; Phase 3; GSK Study 112233),[6] and BLISS-52 + BLISS-76 LTE (excluding US pts from BLISS-76; Phase 3; GSK Study 112234).[7] Eligibility for LTE studies required completion of treatment through Week 72 (LBSL02 and BLISS-76 trials), or Week 48 (BLISS-52 trial); improvement in physician global assessment at Week 72 or 68 versus at first BEL dose was also required in LBSL02 LTE. Pts received open-label BEL 10 mg/kg intravenously every 28 days plus ST at the start of each LTE for up to 8 years (BLISS-76 and BLISS-52 + BLISS-76 LTEs) or 13 years (LBSL02 LTE), regardless of prior study drug allocation. Adverse events (AEs) were assessed

Table 1. the most frequent infection of special interest; all subcategories generally remained stable over time. The rate of infections of special interest was 5.1 events per 100 PY; all subcategories remained stable over time(**Table 2**).

Conclusion: In this large, pooled population of BEL-treated pts, incidence of infections was generally stable up to 11 years with no new infection types or increase in severity. Limitations include the open-label nature of the studies, lack of control arm, inclusion of pts who had not withdrawn from prior study periods, and low numbers of pts at later years. Infection incidence rates were similar to or lower than in the GLADEL cohort study[8], and among pts receiving ST in the double-blind period of BEL clinical trials.[1-4]

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: SLE – Treatment Poster III
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Toll-like receptor (TLR)7 is a pattern recognition receptor whose ligands include nucleic acids and whose gain-of-function mutations have been reported to result insystemic lupus erythematosus (SLE). DS-7011a is an anti-TLR7 monoclonal antibody (mAb), which inhibits *in vitro* production of cytokines and antibodies stimulated by TLR7. A surrogate anti-TLR7 mAb improved survival and reduced autoantibody production in murine lupus models. DS-7011a

was generally safe and well tolerated and showed optimal pharmacokinetic (PK) and pharmacodynamic (PD) characteristics in a first-in-human (FIH), single ascending intravenous (IV) and subcutaneous (SC) dose studyin healthy volunteers (HV), including HV of Japanese descent [NCT05203692]. We report here the analysis of the PK and PD data from the non-Japanese HV (mainly Caucasian and African American) that were initially administered in this study IV doses of DS-7011a to select the doses for later SC administration to non-Japanese HV and IV administration to Japanese HV.

Methods: DS-7011a clinical PK and PD data from single ascending dose (SAD) IV cohorts (from 0.1 to 20 mg/kg, N = 34) of non-Japanese HV enrolled in the first stage of DS-7011a FIH study was used for PK/PD model development under blinded analysis. PK exposure of SC doses to non-Japanese HV was predicted by assuming human SC bioavailability identical to that observed in monkeys (55.6%). PK exposure of IV doses to Japanese HV was predicted by assuming mean body weight of 66 kg. Dose selection for three SAD SC cohorts of non-Japanese HV and one IV cohort of Japanese HV was informed by benchmarking simulated PK and PD profiles with selected IV reference doses (1, 3, and 10 mg/kg for SC cohorts of non-Japanese HV; 3 mg/kg for the IV cohort of Japanese HV) after interim review of blinded data.

Results: DS-7011a PK linearity started at 3 mg/kg after IV infusion, while the elimination of lower doses was accelerated by target-mediated disposition. DS-7011a PK profile after IV infusion was well described by a 2-compartment model, with parallel linear and saturable, non-linear clearance (CL). Weight was a covariate on linear CL and central volume, as higher weight resulted in increased CL and volume of distribution. DS-7011a showed *ex vivo* inhibition of TLR7-stimulated IL-6 production that was of large extent, early onset, and lasting duration at 3 mg/kg and above.*Ex vivo* IL-6 profile after DS-7011a IV infusion was adequately described by DS-7011a concentration-derived inhibition of *ex vivo* IL-6 production. By benchmarking simulated PK and IL-6 profile with IV reference dose data, SAD SC doses for non-Japanese HV were proposed as 100, 300, and 600 mg, and SAD IV dose for Japanese HV as 3 mg/kg.

Conclusion: Model prediction of SAD SC doses for non-Japanese HV and IV dose for Japanese HV is confirmed by emerging clinical PK data and demonstrates the value of model-informed dose selection for DS-7011a FIH. Additional analysis will be conducted to select DS-7011a dose for future treatment of SLE patients.

Upregulation of Both APRIL and BAFF in Systemic Lupus Erythematosus Suggests Non-Redundant Roles, Further Revealed by Dual Inhibition with Povetacicept (ALPN-303; TACI vTD-Fc)

Tiffany Blair, Elizabeth Repash, Armand Bankhead, Amanda Enstrom, Lawrence Evans, Susan Debrot, Allison Chunyk, Sherri Mudri, Stanford Peng and Stacey Dillon, Alpine Immune Sciences, Inc., Seattle, WA

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: SLE – Treatment Poster III
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

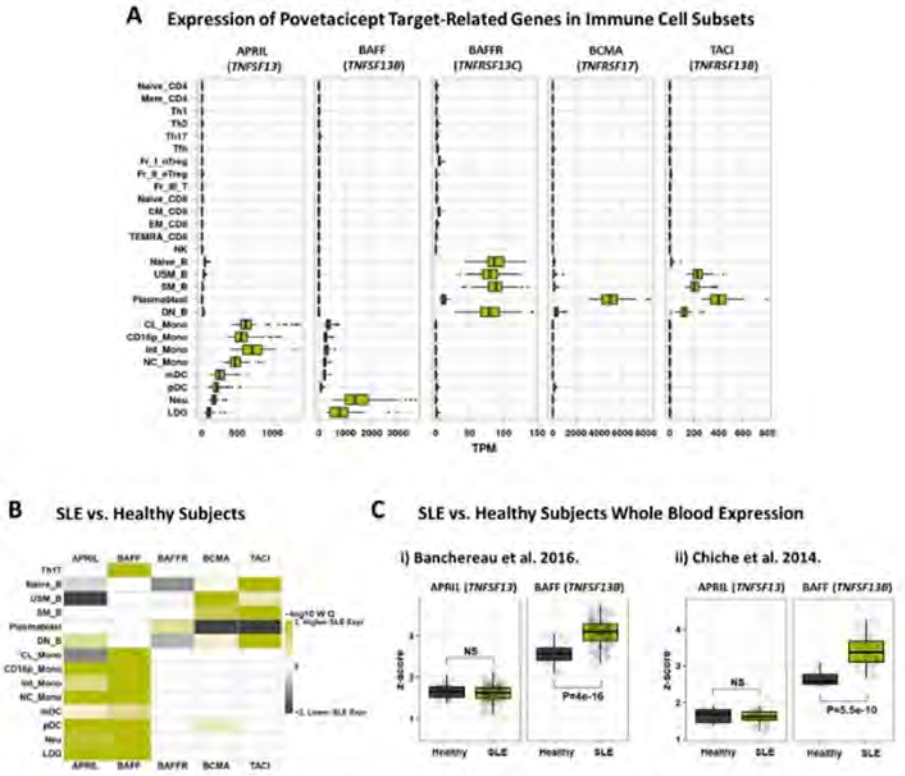

Figure 1: APRIL (*TNFSF13*) and BAFF (*TNFSF13B*) gene expression is upregulated in SLE. **A** Expression of povetacicept target-related genes from immune cell subsets sorted for RNASeq in healthy subjects[2]. **B** Transcript per million (TPM) values were $\log_2$ transformed and converted to z-scores for SLE vs. healthy comparison. Heatmap colors represent negative $\log_{10}$ q-values from Wilcoxon tests between SLE and healthy subjects. Positive (*green*) values represent higher SLE patient expression, and negative (*black*) values represent lower SLE patient expression. White values indicate either non-significance (q-values ≈ 1) or low expression (healthy subject median expression ≤ 10). TPM values displayed were upper quartile normalized. **C** BAFF expression in SLE vs. healthy subjects from publicly available transcriptional datasets from whole blood analyses: Banchereau et al., 2016[3] (SLE N=158) and Chiche et al., 2014[4] (SLE N=62).

Background/Purpose: B cell activating factor (BAFF) and a proliferation-inducing ligand (APRIL) are cytokines that signal through transmembrane activator and CAML interactor (TACI), B cell maturation antigen (BCMA), and/or BAFF-Receptor (BAFF-R) and play important roles in B cell development, proliferation, function, and survival. Therapeutic agents targeting BAFF and/or APRIL have demonstrated promising clinical potential in systemic lupus erythematosus (SLE), lupus nephritis,

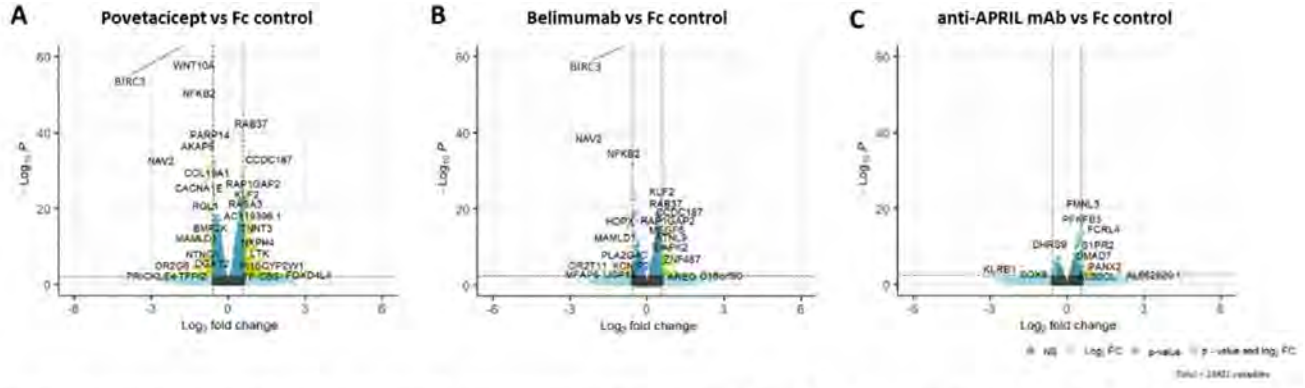

Figure 2: Povetacicept potently and more broadly downregulates genes associated with B cell activation than does anti-BAFF (belimumab) or anti-APRIL mAbs in primary human B cells stimulated with CD40L followed by BAFF+APRIL. Volcano plots demonstrate differentially expressed genes from B cells exposed to **A** povetacicept, **B** belimumab, or **C** anti-APRIL mAb vs Fc control in the presence of soluble BAFF and APRIL. Green dots represent differentially expressed genes that pass significance threshold with an adjusted p value > 0.005 and $\log_2$ fold cutoff value with an absolute value greater than 0.58. Light blue dots pass the p value cutoff but do not pass the $\log_2$ fold change threshold, dark blue dots represent genes that pass fold change cutoff, but not significantly, and gray dots pass neither $\log_2$ fold change nor p value cutoffs.

and other B cell-related diseases, but have generally targeted only BAFF, only APRIL, or predominantly BAFF. Due to the overlapping and non-redundant roles of BAFF and APRIL, more potent and/or complete inhibition of both cytokines is likely required for optimal efficacy. Povetacicept is an Fc fusion protein of a variant TACI domain engineered to have enhanced affinity for BAFF and APRIL, providing more potent dual inhibition of both BAFF and APRIL than wild type (WT) TACI-Fc or BAFF- or APRIL-specific antibodies. In preclinical mouse lupus models povetacicept suppressed autoantibodies, renal IgG deposition, and nephritis.[1]

Methods: Publicly available RNA Sequencing (RNA-Seq) datasets from healthy donors and SLE subjects were utilized to assess APRIL and BAFF gene expression.[2-4] Primary B cells isolated from healthy donor PBMCs were stimulated with CD40L for 72 hours, washed and then cultured for an additional 24 hours with 5 nM APRIL and 10 nM BAFF in the presence of either 100 nM of Fc control, povetacicept, anti-BAFF mAb (belimumab), or anti-APRIL mAb. Cultured B cells were then harvested for flow cytometry analysis or processed for bulk RNA-seq.

Results: In publicly available transcriptional datasets, SLE patients showed a significant elevation of only BAFF in whole blood compared to healthy adults, but specific analysis of cell types known to be associated with SLE pathogenesis revealed upregulation of both APRIL and BAFF (**Fig 1**). Genes associated with B cell activation, regulation of immunoglobulin production, and adaptive immunity were upregulated in primary B cells cultured with CD40L, BAFF, and APRIL. Povetacicept potently suppresses inflammatory pathways, significantly more broadly than mAbs targeting BAFF or APRIL alone (**Fig 2**).

Conclusion: Dual inhibition of both BAFF and APRIL may be required to achieve optimal suppression of pathogenic pathways associated with SLE and related diseases. When coupled with data from the literature, these results further support the clinical evaluation of dual BAFF/APRIL inhibitors such as povetacicept in SLE, as well as in other B cell- and/or autoantibody-related diseases. Clinical studies of povetacicept in autoimmune glomerulonephritis (NCT05732402) and cytopenias (NCT05757570) have been initiated; a study in SLE is in preparation.

Health Outcomes Among Patients (Pts) with SLE Initiating Belimumab (BEL) with and Without the Use of Immunosuppressants in the Previous 2 Years

Yan Chen[1], **Karen Worley**[2], Brendan Rabideau[1], Bernard Rubin[3], Benson Wu[1], Rose Chang[1] and Maral DerSarkissian[1], [1]Analysis Group, Boston, MA, [2]GlaxoSmithKline, US Value Evidence and Outcomes, Cincinnati, OH, [3]GlaxoSmithKline, US Medical Affairs and Immuno-inflammation, Durham, NC

SESSION INFORMATION

Session Date: Tuesday, November 14, 2023
Session Title: SLE – Treatment Poster III
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: BEL efficacy in pts with SLE has been previously demonstrated in clinical and real-world studies.[1] However, there are limited data on differences in outcomes for pts with SLE with different immunosuppressant (IS) treatment use before BEL initiation. This analysis assessed whether IS-naïve pts with SLE initiating BEL varied in their oral CS (OCS) use and clinical outcomes compared with those initiating BEL after the prior IS treatment.

Methods: This retrospective, longitudinal cohort study (GSK Study 217536) used data from the Komodo Health database of de-identified claims between Jan 2015 and Dec 2022. Eligible adults with SLE in the USA were identified from Jan 2017, allowing for ≥24 months of continuous enrollment before BEL initiation (index date). BEL initiators were categorized into 2 cohorts: BEL-0IS (pts who initiated BEL with no prior IS); BEL-1IS (pts who initiated BEL with 1 prior IS). Baseline (BL) was defined as 24 months pre-index. Pts were followed until the end of enrollment or up to 60 months post index. The incidence of SLE flares, organ damage (OD), OCS use, and healthcare resource utilization (HCRU) were stratified by BL moderate/severe disease severity and evaluated using descriptive statistics.

Results: At BL, of the 2719 BEL-0IS pts, 70.2% had moderate and 14.2% had severe SLE; of 4122 BEL-1IS pts, 78.9% had moderate, and 20.9% had severe SLE. BEL-1IS pts had higher BL flare rates (**Table**), partly due the moderate flare definition necessitating IS use. For both cohorts, BL OD was similar between pts with moderate (BEL-0IS: 67.6%; BEL-1IS: 68.4%) and severe SLE (BEL-0IS: 83.9%; BEL-1IS: 82.7%). All-cause BL HCRU was similar between pts with moderate SLE of both cohorts, but higher in BEL-1IS pts with severe SLE than in BEL-0IS pts. At 6 months post index, mean moderate flare rates (per-patient-year, PPY) were 2.2 for BEL-0IS and 4.7 for BEL-1IS in pts with moderate SLE, and 2.9 for BEL-0IS and 6.1 for BEL-1IS in pts with severe SLE; mean severe flare rates were 0.4 for BEL-0IS and 0.5 for BEL-1IS in pts with

Table. BL pt characteristics in the BEL-0IS and BEL-1IS cohorts stratified by disease severity. *Pts were classified into mutually exclusive groups of mild, moderate, or severe disease using a previously published algorithm, which is based on validated measures of SLE activity and the consensus of expert clinical opinion and considers medications of interest and HCRU associated with an SLE-related condition; †evaluated during the 24-month BL period excluding the index date; ‡SLE flare episodes were identified and classified by severity based on a previously published claims-based algorithm, which considers medications of interest and HCRU associated with an SLE diagnosis or SLE-related condition. SD, standard deviation.

	Moderate baseline SLE*		Severe baseline SLE*	
	BEL-0IS (N=1909)	BEL-1IS (N=3252)	BEL-0IS (N=386)	BEL-1IS (N=862)
Organ damage†, n (%)	1290 (67.6)	2223 (68.4)	324 (83.9)	713 (82.7)
SLE flares‡, pts with ≥1 flare, n (%)				
Mild	1727 (90.5)	3127 (96.2)	365 (94.6)	834 (96.8)
Moderate	1886 (98.8)	3252 (100.0)	361 (93.5)	860 (99.8)
Severe	254 (13.3)	490 (15.1)	301 (78.0)	724 (84.0)
All-cause HCRU†, mean ± SD (median)				
Inpatient visits	0.6 ± 1.4 (0.0)	0.6 ± 1.3 (0.0)	1.6 ± 2.6 (1.0)	1.9 ±2.8 (1.0)
Emergency department visits	1.1 ± 2.4 (0.0)	1.2 ± 2.6 (0.0)	2.5 ± 4.5 (1.0)	2.5 ± 4.8 (1.0)
OCS use at index, n (%)	1031 (54.0)	1916 (58.9)	264 (68.4)	632 (73.3)

moderate SLE, and 1.0 for BEL-0IS and 2.1 for BEL-1IS in pts with severe SLE. Notable difference persisted through 60 months post index. The median time to OD was 32.1 months for BEL-0IS and 26.7 months for BEL-1IS in pts with moderate SLE, and 22.7 months for BEL-0IS and 21.6 months for BEL-1IS in pts with severe SLE. In pts with BL OCS use, the median time to OCS discontinuation was 4.5 months for BEL-0IS and 8.9 months for BEL-1IS in pts with moderate BL SLE, and 6.2 months for BEL-0IS and 11.6 months for BEL-1IS in pts with severe BL SLE. Rates (PPY) of all-cause emergency room visits and inpatient stays were similar between pts with moderate SLE of both cohorts, but BEL-1IS pts with severe BL SLE had higher inpatient stay rates (0.7 vs 0.9).

Conclusion: While most BEL pts were able to discontinue OCS within 12 months post index, BEL-0IS pts were able to discontinue OCS in half the time of BEL-1IS pts. SLE flare rates were also notably lower in BEL-0IS pts, although some differences were observed in the cohorts during the BL. Future studies should further investigate optimal BEL placement in the SLE treatment pathway.

High Serum C-X-C Motif Chemokine Ligand 10 (CXCL10) Potentially Predicts New Onset of Systemic Sclerosis-Interstitial Lung Disease

Yehya Al-Adwi, Isabella Atzeni, Berber Doornbos-van der Meer, Marcel J van der Leij, Bart-Jan Kroesen, Alja Stel, Wim Timens, C.Tji Gan, Harry van Goor, Johanna Westra and Douwe J Mulder, University Medical Center Groningen, Groningen, Netherlands

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: Systemic Sclerosis & Related Disorders – Clinical Poster III: Translational Science
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Systemic sclerosis-interstitial lung disease (SSc-ILD) is the leading cause of death in SSc patients. There is an unmet need for predictive biomarkers of ILD to identify patients at risk, prior to clinical manifestations. Activated IFN-induced chemokines and proteins are implicated in the early inflammatory phase of SSc-ILD. CXCL10 is an IFN-induced chemokine that is important in the chemoattraction of CXCR3-expressing inflammatory cells in SSc-affected tissue.

Methods: One-hundred sixty-five SSc patients (SSc-ILD= 41) and 13 age- and sex-matched healthy controls were retrospectively followed for eight years. Furthermore, 15 SSc patients (SSc-ILD= 7) were prospectively recruited for bronchoalveolar lavage (BAL) procedure. CXCL10 mRNA and protein levels were measured on various levels (serum, BAL, and SSc-ILD lung tissues) by ELISA and nanoString transcriptomic assay. Spearman's correlations were performed between CXCL10 levels in serum and lungs. Kaplan-Meier analyses were performed to evaluate predictability of SSc-ILD using CXCL10 levels at baseline. Human primary lung fibroblasts were treated with BAL fluid or serum from SSc without ILD or SSc-ILD patients. After stimulation, inflammatory (IL-6 and CXCL10)/fibrotic (α-SMA and TGF-β) genes were assessed using qPCR.

TABLE 1: PATIENT CHARACTERISTICS AT BASELINE

	SSc patients without-ILD (n=124)	SSc patients with ILD (n=41)	HC (n=13)	P Value
AGE IN YEARS, MEDIAN (IQR)	61 (54-72)	65 (53-72)	53 (47-57)	p = 0·050
FEMALE, N (%)	102 (82·3)	28 (68·3)	8 (61·5)	p = 0·064
EXTENT OF SKIN INVOLVEMENT, n (%)				p = 0·312

lcSSc: limited cutaneous SSc; dcSSc: Diffuse cutaneous SSc; FVC: forced vital capacity, DL_{co}: capacity for diffusion of carbon monoxide, COPD: chronic obstructive pulmonary disease.

Results: At baseline, serum CXCL10 was significantly higher in SSc-ILD patients compared to SSc without ILD patients [Median (IQR): 126 (66-282) vs 79 (50-122), p=0.004] and healthy controls [Median (IQR): vs. 4 (4-9), p< 0.0001]. BAL fluid CXCL10 levels in SSc-ILD patients were not significantly higher than those in SSc without ILD [Median (IQR): 457 (42-725) vs 134 (72-333), p=0.2). However, BAL fluid CXCL10 levels significantly correlated with serum levels (r=0.7, p=0.007). The nanoString showed that CXCL10 gene expression is significantly higher in inflammatory lung tissue compared to fibrotic

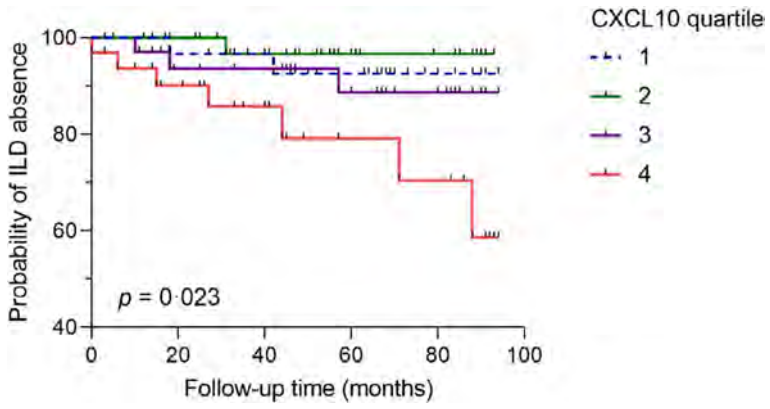

Figure 1: Capacity of CXCL10 to predict long-term ILD development. Kaplan-Meier survival curve according to baseline CXCL10 concentration quartiles. 1st quartile (N=34), 2nd quartile (N=35), 3rd quartile (N=35) and 4th quartile (N=34). CXCL10 levels in the 4th quartile significantly predicted the development of ILD in patients with SSc. p=0·023.

tissue (fold change=2.3, p=0.029). Kaplan-Meier survival analysis (figure 1) revealed that CXCL10 levels >3rd quartile at baseline in SSc patients significantly predicted new onset of ILD (p=0.023). The *in vitro* studies showed that CXCL10 and IL-6 were significantly overexpressed in lung fibroblasts treated with SSc-ILD BAL fluid or serum compared to SSc without

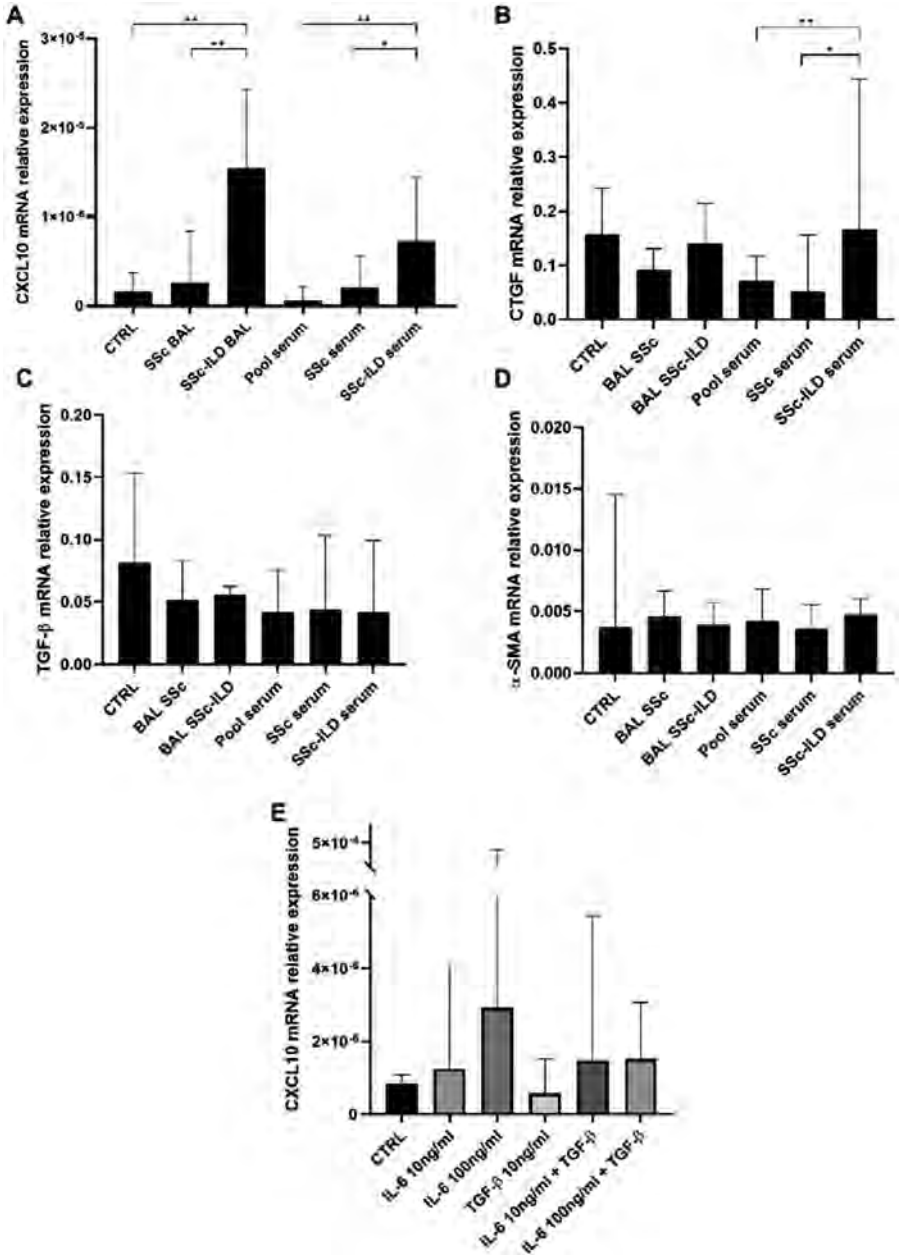

Figure 2: Stimulation of normal human lung fibroblasts with SSc fluids (A-D), or inflammatory or fibrotic cytokines (E). (A-D) 5% BAL supernatant from SSc without ILD (BAL SSc) or SSc-ILD (BAL SSc-ILD), or 1% serum from SSc without ILD (SSc serum) or SSc-ILD (SSc-ILD serum) or healthy control (Pool serum) was used to stimulate lung fibroblasts. (A) SSc-ILD BAL and serum significantly stimulated CXCL10 expression compared to SSc without ILD BAL (p = 0·0043) and serum (p = 0·0087). Also, SSc-ILD BAL significantly stimulated CXCL10 expression compared to CTRL (p = 0·0022) and SSc-ILD serum significantly stimulated CXCL10 compared to healthy serum (p = 0·0022). SSc-ILD serum significantly stimulated CTGF expression compared to SSc without ILD and pool sera (p = 0·026 and p = 0·0087, respectively). (C-D) No significant differences in TGF-β or α-SMA expression when treated with BAL or serum. The results are medians of three technical experiments (n=3) where 6 patients' biofluids were used (n=6). * $p < 0{\cdot}05$; ** $p < 0{\cdot}01$. (E) IL-6 (10ng/ml or 100ng/ml) or TGF-β (10ng/ml) or both were used to stimulate lung fibroblasts for 4h. IL-6 stimulated CXCL10 expression in a concentration-dependent manner. The higher concentration of IL-6 (100 ng/ml) showed increase of CXCL10 expression with a trend towards significance of p value = 0·055 vs CTRL. The results are medians with IQR of three technical experiments (n=3). CTRL: culture media without stimulant.

ILD [(CXCL10: p=0.0043; p=0.0087), (IL-6: p=0.0022; p=0.0043), respectively) and controls (all: p=0.0022). On the contrary, TGF-β and α-SMA expression did not change after treatment in all groups.

Conclusion: CXCL10 is a potential predictive biomarker for new onset of ILD in SSc patients. Further longitudinal studies with larger sample sizes are needed to verify the capability of CXCL10 to predict ILD. Additionally, our nanoString and *in vitro* data strongly suggest that CXCL10 may play a significant role in the early development of SSc-ILD which might be amenable to therapeutic interventions.

Role of Insulin-like Growth Factor Binding Protein-7 (IGFBP7) in Pulmonary Hypertension Pathogenesis and as a Biomarker Systemic Sclerosis-Associated Pulmonary Arterial Hypertension (SSc-PAH)

Ye Jin Jeong[1], Soumyaroop Bhattacharya[1], Maria de la Luz Garcia-Hernandez[2], Javier Rangel-Moreno[1], Qingfu Xu[3] and Benjamin Korman[1], [1]University of Rochester, Rochester, NY, [2]University of Rochester, West Henrietta, NY, [3]CanSino Biologic Inc., Tianjin, China

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: Systemic Sclerosis & Related Disorders – Clinical Poster III: Translational Science
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Systemic sclerosis (SSc, scleroderma) is an autoimmune connective tissue disease that causes autoimmunity, vascular dysfunction, and fibrosis of the skin, lungs, and other organs. Pulmonary arterial hypertension (PAH) is a severe complication of SSc which can cause right heart failure and is associated with a high rate of morbidity and mortality. Insulin-like growth factor binding protein 7 (IGFBP7) has been shown to be a biomarker for heart failure, and to be elevated in SSc skin. This study assessed IGFBP7 in pulmonary arteries from mice with pulmonary hypertension, and then looked at the potential role of IGFBP7 as a serum biomarker in both mice and patients with SSc-PAH.

Methods: Single cell RNA sequencing was performed on wild-type (WT) and TNF transgenic (TNF-Tg) mice with pulmonary hypertension. After identification of cell types with Seurat, differential gene expression analysis was performed and volcano plots were generated to identify the most differentially regulated genes in each cell type. Trajectory analysis was performed with Monocle, and pseudotime was assessed with Tradeseq. Lungs from WT and TNF-Tg mice were subsequently stained for IGFBP7 (n=6 per genotype) and its binding partner collagen 4a1. Serum from WT and TNF-Tg mice was collected over a time-series (n=4 per condition) and ELISA was performed to determine serum IGFBP7 levels. Blood from SSc patients with pulmonary arterial hypertension (SSc-PAH, n = 26), interstitial lung disease (SSc-ILD, n = 44), no lung disease (SSc-NL, n=44), or healthy control (HC, n =28) were collected and ELISA was performed to determine serum IGFBP7 levels.

Results: TNF-Tg mice develop progressive pulmonary hypertension as they age, making the model suitable for identification of potential disease severity biomarkers. Volcano plots from single cell RNA-sequencing demonstrated that IGFBP7 was among the most overexpressed genes in general capillary cells (Fig.1A), arteriovenous endothelial cells (Fig.1B), Col14+

fibroblasts (Fig.1C), Col13+ fibroblasts (Fig.1D), and myofibroblasts (Fig.1E). Gene expression was elevated across multiple cell types and pseudotime analysis showed IGFBP7 was the gene most elevated in TNG-Tg vs WT lungs across all lineages (Fig. 1F-G). Elevation of IGFBP7 was also observed at the protein level with immunofluorescence staining demonstrating an increased number of perivascular IGFBP7+ cells in close proximity to Col4A1+ cells. Serum concentration of IGFBP7 was elevated in the TNF-Tg mice compared to the WT and showed an increase over time (Fig.2B). To confirm the relevance of these findings in human SSc lung disease, ELISA was performed for IGFBP7 and showed that patients with SSc-PAH had significantly higher serum IGFBP7 concentration compared to controls or SSc patients with ILD or without lung disease.

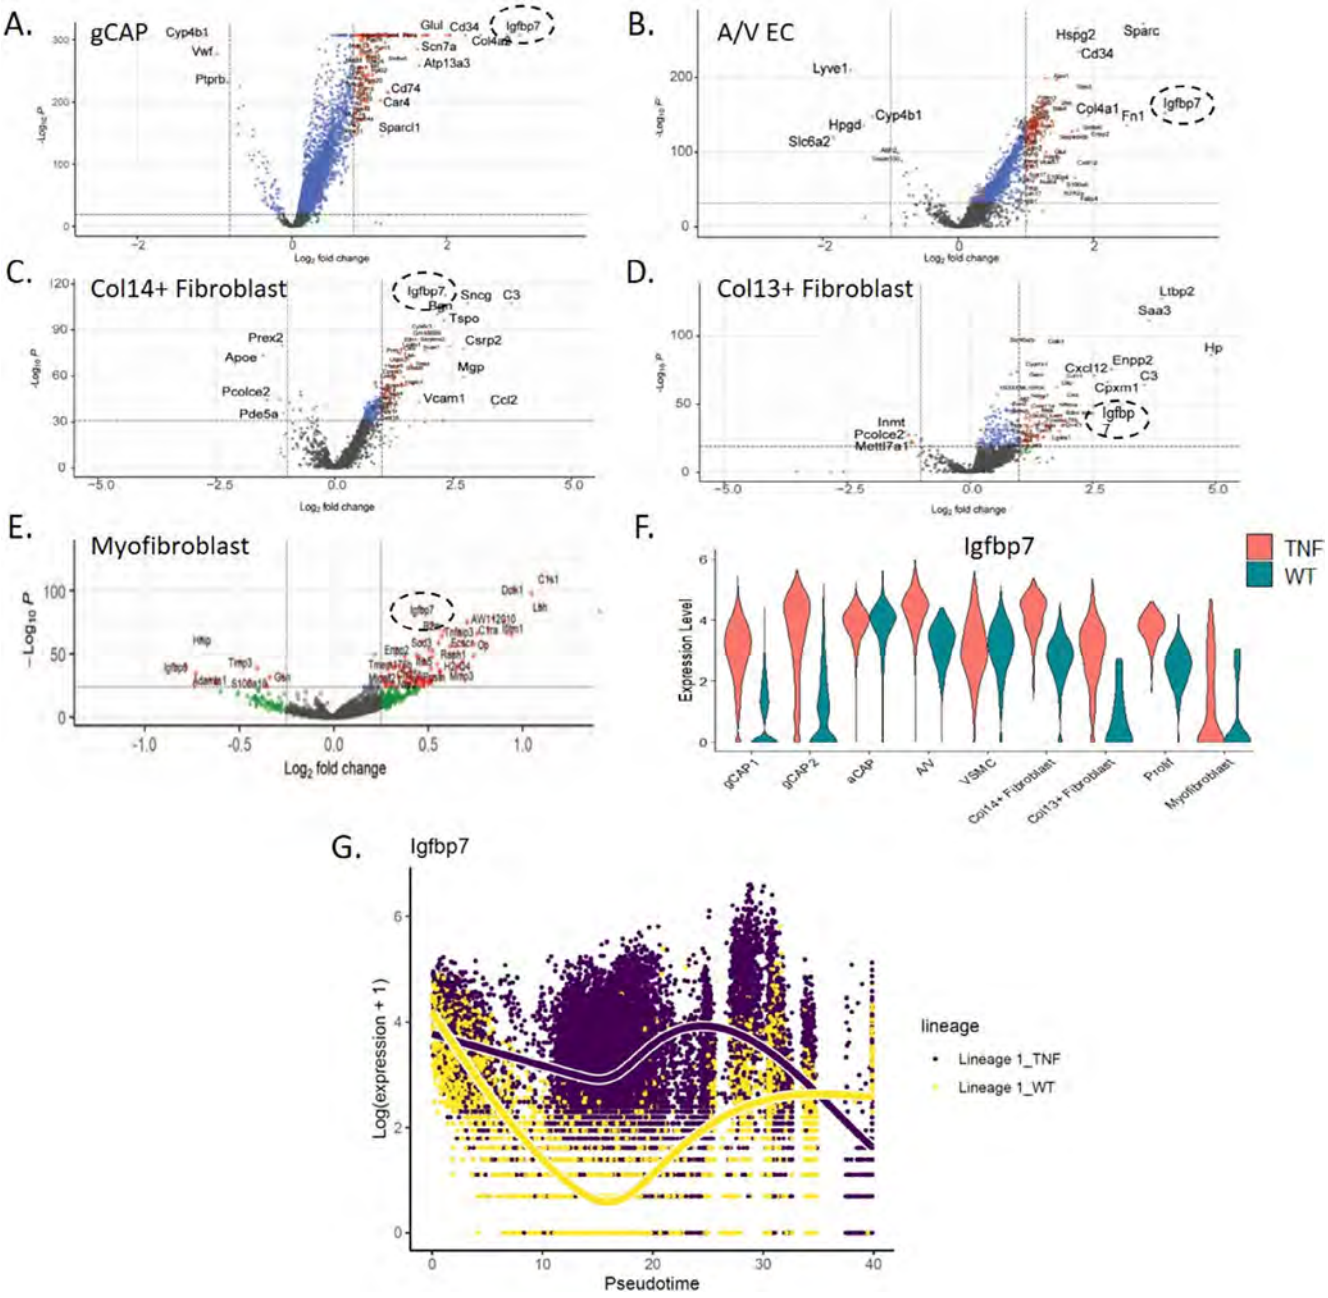

Figure 1. Single cell RNA sequencing of cells isolated from wild type (WT) and TNF transgenic mice (TNF). (A) General capillary endothelial cells, (B) Arteriovenous endothelial cells, (C) Collagen 14+ fibroblasts, (D) Collagen 13+ fibroblasts, and (E) Myofibroblasts. (F) Violin plot of individual cell type IGFBP7 expression and (G) Pseudotime analysis of Igfbp7 across all lineages.

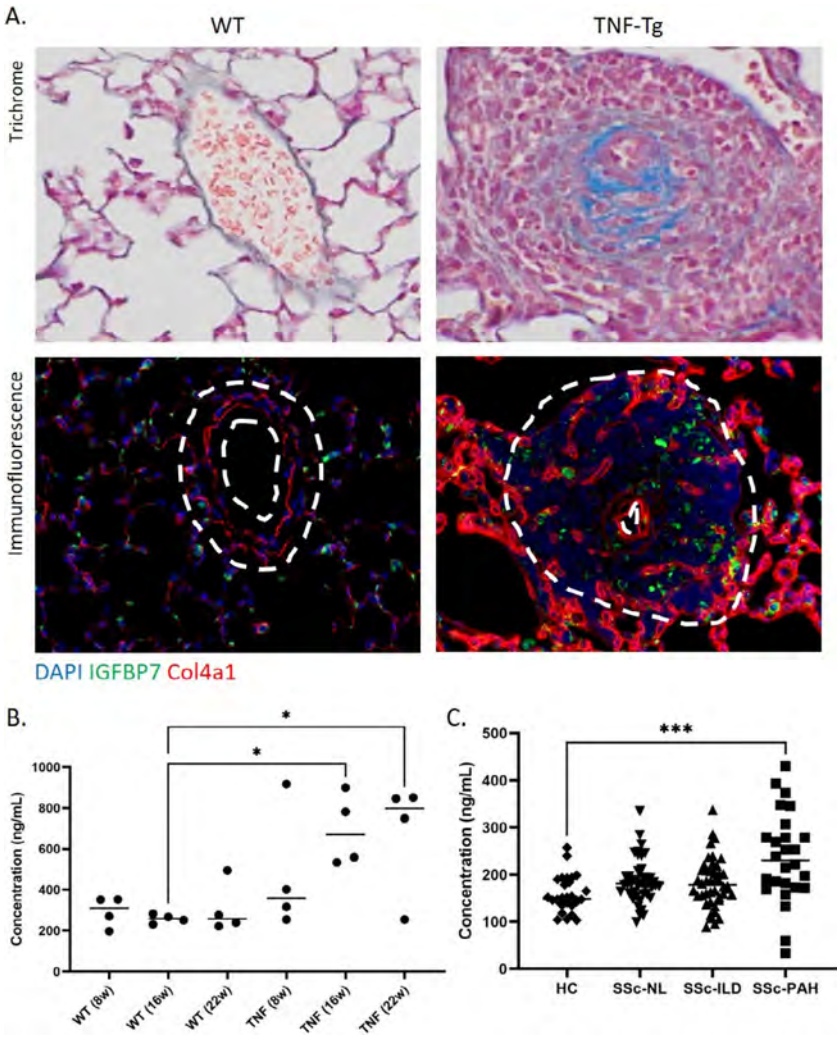

Figure 2. IGFBP7 protein level is elevated in tissue and serum. (A) Masson's trichrome (upper) and immunofluorescence staining (lower) images of pulmonary arteries from WT and TNF mice. Blood vessel lumen and adventitia are highlighted by white dashed lines. (B) Serum IGFBP7 concentration of the WT and TNF mice. *indicates p-value < 0.05. n=4 for per group. (C) Serum IGFBP7 concentration in patients with SSc associated PAH (SSc-PAH), SSc associated ILD (SSc-ILD), SSc with no lung disease (SSc-NL), or healthy control (HC). *** indicates p-value < 0.001. n=26 for PAH, n=44 for ILD, n=44 for NL, and n=28 for HC.

Conclusion: IGFBP7 is significantly upregulated in a TNF-Tg model of pulmonary hypertension across endothelial cells and fibroblasts, and serum levels increase as disease progresses. Patients with SSc-PAH have elevated levels of IGFBP7. Taken together, our data suggest that IGFBP7 is involved in PAH pathogenesis and may serve as a putative biomarker for SSc-PAH.

Abstract Number: 2354

Is Midkine a Novel Biomarker for Acro-osteolysis in Systemic Sclerosis?

Ganiat Adeogun[1], Venkateswara Gogulamudi[2], Meridith Balbach[1], Anthony Donato[2] and Tracy Frech[1], [1]Vanderbilt University Medical Center, Nashville, TN, [2]Salt Lake Veterans Affairs Medical Center, Salt Lake City, UT

SESSION INFORMATION

Session Date: Tuesday, November 14, 2023
Session Title: Systemic Sclerosis & Related Disorders – Clinical Poster III: Translational Science
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Acro-osteolysis is a hand complication in systemic sclerosis (SSc) characterized by the destruction of distal digital bone possibly related to repetitive ischemia-reperfusion injury. Diagnosis typically involves a thorough medical history, physical examination, and imaging studies. Unfortunately, there is no reliable serological marker to diagnose SSc acro-osteolysis. The growth factor midkine is expressed during bone formation and fracture repair, and it is upregulated in hypoxia to promote angiogenesis. This study aims to develop a noninvasive and reliable biomarker for acro-osteolysis in patients with SSc.

Methods: This study included SSc registry patients (IRB # 1618579) that had same day capillaroscopy, hand radiographs, and serum collection. Midkine levels were compared between SSc patients with and without acro-osteolysis detected on hand radiographs, and age-matched healthy controls. For all patients, plasma midkine concentrations were determined (MDK ELISA, Invitrogen, USA). An ANOVA test was used to assess differences between plasma midkine levels in SSc patients with acro-osteolysis, without acro-osteolysis and healthy controls.

Results: The clinical features of the 20 SSc patients are shown in Table 1. Most patients were white females with an antinuclear antibody (ANA), a SSc-specific autoantibody, limited cutaneous disease, and abnormal nailfold videocapillaroscopy (NVC). There were 10 SSc patients with acro-osteolysis on radiograph and 10 SSc patients without acro-osteolysis. These midkine levels were compared to 20 healthy control samples. The midkine levels were significantly higher in SSc patients with acro-osteolysis compared with no acro-osteolysis (p= 0.02) and healthy controls (p=0.01) (Figure 1). There were no significant differences between healthy controls and SSc patients without acro-osteolysis (p=0.18).

Conclusion: In this small, single-center study, serum level of midkine were significantly reduced in SSc patients with acro-osteolysis when compared to both healthy controls and SSc without acro-osteolysis. Higher levels were associated with intact digital tip on radiograph in SSc patients, which possibly indicates that this growth factor is necessary for maintaining

Proteome-based Stratification of Therapeutic Target Population for MT-6194 in Systemic Sclerosis with Pulmonary Arterial Hypertension

Yuuichi Ono[1], Akira Mogami[1], Ryuta Saito[2], Noriyasu Seki[1], Sho Ishigaki[3], Hiroshi Takei[3], Keiko Yoshimoto[3], Kenji Chiba[1], Tsutomu Takeuchi[4] and Yuko Kaneko[5], [1]Mitsubishi Tanabe Pharma Corporation, Yokohama, Japan, [2]Mitsubishi Tanabe Pharma Corporaion, Yokohama, Japan, [3]Keio University School of Medicine, Tokyo, Japan, [4]Keio University School of Medicine and Saitama Medical University, Tokyo, Japan, [5]Division of Rheumatology, Department of Internal Medicine, Keio University School of Medicine, Tokyo, Japan

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: Systemic Sclerosis & Related Disorders – Clinical Poster III: Translational Science
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: SSc-related pulmonary arterial hypertension (SSc-PAH) is the one of the leading causes of death in SSc. Early diagnosis and effective therapy for SSc-PAH may lead to improved outcomes. We have been developing MT-6194, a bispecific FynomAb targeting both human IL-17A and IL-6 receptor. To ensure that MT-6194 is used in appropriate patients, we attempted to stratify the patients using serum parameters.

Methods: SSc patients who met the 2013 ACR/EULAR classification criteria were eligible for study participation. We analyzed serum samples from 17 patients with diffuse cutaneous systemic sclerosis, 58 patients with limited cutaneous systemic sclerosis, and 38 healthy controls. PAH was defined as a mean pulmonary artery pressure of ≥25 mm Hg with pulmonary capillary wedge pressure of < 15 mm Hg by right-sided heart catheterization, and an absence of significant interstitial lung disease. The abundance ofserum proteins were analyzed using Proximity Extension Assay (PEA) technology (Olink).

Results: SSc patients were divided into 4 clusters according to their blood levels of IL-6 and IL-17A. SSc patients with high blood levels of both IL-6 and IL-17A had a high prevalence of PAH. We also identified 34 proteins that are upregulated in patients with high blood levels of both IL-6 and IL-17A, and that were significantly correlated with PAH prevalence. Unsupervised hierarchical clustering using the 34 proteins divided SSc patients into three clusters ("PAH cluster 1", "PAH cluster 2", and "PAH cluster 3" were defined). Almost all patients in "PAH cluster 3", where the identified proteins were highly elevated, had PAH. On the other hand, 4 of 30 patients in "PAH cluster 1", where the identified proteins were moderate elevated, had PAH, and there were no patients with PAH in "PAH cluster 2", which has low levels of identified proteins. A %FVC/%DLCO ratio > 1.6 is considered a risk factor for developing SSc-PAH. The %FVC/%DLCO ratio exceeded 1.6 not only in patients in "PAH cluster 3" but also in most patients in "PAH cluster 1". From these results, the 34 proteins can detect not only patients already suffering from PAH, but also patients at high risk of developing PAH. To identify predictive biomarkers of drug response, we evaluated the effects of MT-6194 on in vitro neutralization experiment using fibroblasts. As a result, eight molecules (IL-6, GDF15, LTBP2, CCL7, CHI3L1, EFEFMP1, PLAUR, and SPON1) were found to be upregulated in patients with high blood levels of both IL-6 and IL-17A, upregulated in fibroblast activation, and suppressed by MT-6194. The classification model using these biomarkers could classify not only "PAH cluster 3" but also "PAH cluster 1" with good performance.

Conclusion: Our study investigated the IL-6 and IL-17A-related classification of systemic sclerosis based on serum proteomics. Identified biomarkers stratified patients at increased risk of PAH. The 8-molecule signature identified in this study allowed us to select the appropriate patient population for MT-6194 treatment. Appropriately stratified clinical trials may yield additional treatment options for patients with systemic sclerosis.

Abstract Number: 2356

A Macrophage-Specific Mechanism for Mycophenolate Mofetil in the Treatment of Systemic Sclerosis

Emily Morris, Rezvan Parvizi, Patricia Pioli and Michael Whitfield, Geisel School of Medicine at Dartmouth, Hanover, NH

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: Systemic Sclerosis & Related Disorders – Clinical Poster III: Translational Science
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Systemic Sclerosis (SSc) is a rare autoimmune connective tissue disease characterized by inflammation and fibrosis. Treatment with mycophenolate mofetil (MMF), an inhibitor of lymphocyte guanine nucleotide synthesis that targets the enzyme inosine monophosphate dehydrogenase (IMPDH), is associated with clinical benefit in many SSc patients. Although MMF is thought to target lymphocytes exclusively, we have previously shown that MMF also reduces dermal myeloid cell numbers and CCL2 expression in the skin & sera of MMF-responsive SSc patients. Given macrophage

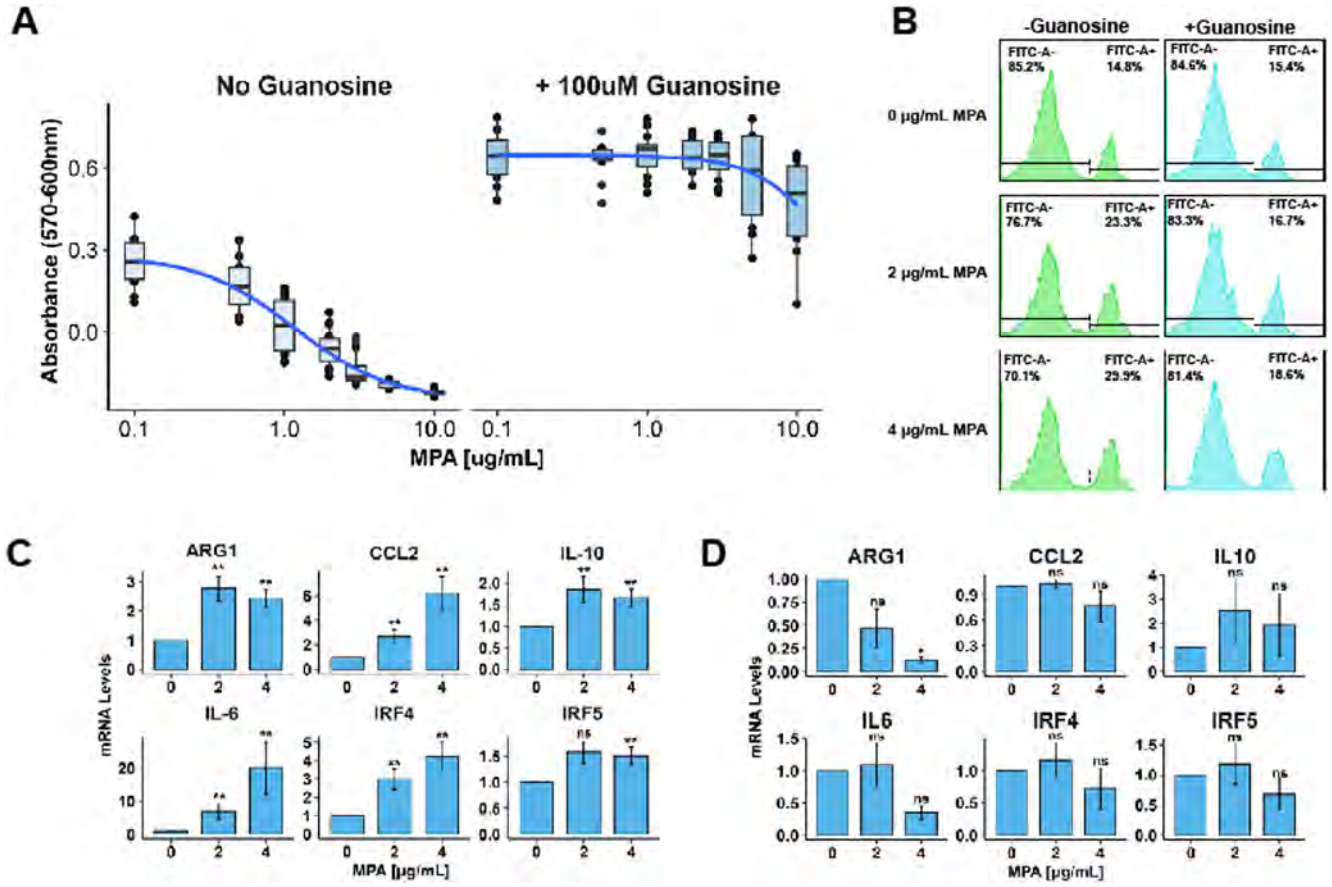

Figure 1: Mycophenolic acid reduces viability of primary human monocytes in vitro and upregulates mRNA expression of alternative activation markers through a guanosine dependent mechanism. (A) Primary human monocytes (n= 4 biological replicates; n = 4 technical replicates per biological replicate) were grown in the following concentrations of MPA for 7 days with or without guanosine supplementation (100µM): 0 µg/mL, 0.5 µg/mL, 1 µg/mL, 2 µg/mL, 3 µg/mL, 5 µg/mL, and 10µg/mL. A CellTiter Blue assay was performed viability of cells after 7 days in culture. Decreased absorbance indicates decreased mitochondrial function and viability; the average IC50 was 1.26 µg/mL MPA for unsupplemented monocytes. (B) Primary human monocytes were grown in 0 µg/mL, 2 µg/mL, or 4 µg/mL MPA for 4 days (n=3 biological replicates) with our without guanosine supplementation (100µM) and assessed for Annexin V (FITC) positivity via flow cytometry as an indicator of apoptosis; increasing concentrations of MPA induced higher levels of Annexin V positive monocytes only in the unsupplemented conditions (representative of 3 independent experiments). (C) and (D) Primary human monocytes were grown in 0 µg/mL, 2 µg/mL, or 4 µg/mL MPA for 4 days (n=4 biological replicates) without (C) and with (D) guanosine supplementation (100µM) for 4 days and assessed for mRNA expression of genes associated with classical and alternative activation. MPA dose-dependently upregulated expression of Arginase-1, CCL2, IL-10, IL-6, and IRF4 in unsupplemented monocytes (C). Supplementation with guanosine (D) consistently blocked this effect (significance of fold change in mRNA expression was assessed by Wilcoxon Ranked Sum test; * $p < 0.05$, ** $p < 0.005$).

plasticity, we hypothesized that, in addition to restricting macrophage skin infiltration, MMF might also mediate direct effects on dermal macrophage pro-fibrotic activation.

Methods: Clinical data from SSc patient cohorts were analyzed for myeloid gene signatures to identify changes in myeloid cell populations during MMF treatment. Primary human monocytes were cultured in clinically relevant serum concentrations of the active metabolite of MMF, mycophenolic acid (MPA), and analyzed for mRNA and surface marker expression, nitric oxide and cytokine production, cell viability and caspase activity in response to MPA. To assess MMF-mediated effects on pro-fibrotic macrophage activation, 3D tissue models of healthy and SSc skin were constructed and treated with or without MPA (0.5-10 µg/mL).

Results: SSc patients on MMF showed a significant decrease in myeloid cell populations in skin biopsies. The clinical target range for serum MPA levels are 1-3µg/mL for MMF patients; the IC_{50} of MPA in primary human monocytes in our experiments was found to be between 0.9-2.5 µg/mL (Fig. 1A), well within the clinical range. MPA dose-dependently induced

apoptosis in primary human monocytes at concentrations as low as 0.5 μg/mL (Fig. 1B). Intriguingly, a subset of monocytes not killed by MPA upregulated surface expression and mRNA levels of markers associated with alternative activation (Fig. 1C). MPA treatment of monocytes in 2D co-cultures with fibroblasts and 3D fabricated skin models showed similar results. Addition of guanosine to cultures significantly attenuated the ability of MPA to induce apoptosis in and modulate activation of monocytes (Fig. 1D).

Conclusion: We now demonstrate here that MMF inhibits primary human macrophage viability and alters macrophage function. Our work suggests that IMPDH activity is required for macrophage viability and mediates alternative activation, as treatment with guanosine rescues cell death and significantly attenuates macrophage phenotype. We thus propose that clinical benefit observed with MMF in the treatment of fibrotic diseases such as SSc may be attributable, at least in part, to effects on myeloid cells.

The Involvement of CCR3-CCL24 Axis in Endothelial to Mesenchymal Transition Process and Pulmonary Arterial Hypertension in Systemic Sclerosis Patients

Itzchak Amoyal[1], Tzipi Hornik-Lurie[2], Tali Zitman-Gal[1], Hilit Levy[3], **Ilan Vaknin**[3], Liat Drucker[4], Ishai Heusler[5], Yair Levy[1] and Shelly Tartakover Matalon[1], [1]Meir Medical Center, Autoimmune Research Laboratory, Kfar-Saba, Israel, [2]Meir Medical Center, Data Research Department, Kfar-Saba, Israel, [3]Chemomab Ltd, Tel Aviv, Israel, [4]Meir Medical Center, Oncogenetics Laboratory, Kfar Saba, Israel, [5]Meir Medical Center, Department of Obstetric and Genecology, Kfar-Saba, Israel

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: Systemic Sclerosis & Related Disorders – Clinical Poster III: Translational Science
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Systemic sclerosis (SSc) is an autoimmune disease characterized by vascular injury and extensive tissue fibrosis of the skin and internal organs. Endothelial cells (ECs), a predominant target of the autoimmune attack, may undergo proliferation arrest, apoptosis, or differentiation to myofibroblasts, leading to complications including pulmonary arterial hypertension (PAH). The differentiation of ECs into myofibroblasts through endothelial mesenchymal transition (EndMT) represents a critical step in the blood vessels remodeling. ECs in the dermal microvascular tissue of patients with SSc exhibit robust expression of CCR3, the cognate receptor of CCL24,which has been found to be elevated in the serum and skin biopsies of SSc patients. The objective of this study is to evaluate the association between serum CCL24 levels and clinical characteristics of SSc patients, as well as the involvement of the CCL24-CCR3 axis in EndMT process.

Methods: CCL24 levels were evaluated in the sera of 75 SSc patients using ELISA. In this cohort, Pearson correlation tests were conducted to determine the relationship between CCL24 levels and performance measures such as the 6-minute walk test (6MW test). To study the potential association of CCL24 and CCR3 with the processes underlying EndMT, we established an in-vitro system in which the combination of TGFβ TNFα induced EndMT in human umbilical vein endothelial cells (HUVECs) and explored the expression of CCR3 and the effect of CCL24 supplementation and anti CCL24 antibody to this

system. Studies included functional assessment of proliferation, cell death migration as well as evaluation of multiple markers of EndMT processes including αSMA, Vimentin, SNAIL, CD31 and VE-cadherin.

Results: The average level of CCL24 in the sera of patients with SSc with PAH (n=9) was significantly higher compared to the level of patients with SSc and without PAH (1136 vs 738 pg/ml, $p< 0.05$). Furthermore, a negative correlation was found between CCL24 levels and the 6MW test performance ($r=-0.3$, $p< 0.05$), reflecting reduced exercise capacity. The addition of TGFβ and TNFα resulted in EndMT in HUVECs, which was demonstrated by a significant increase in mesenchymal markers, reduced ECs markers, reduced cell number (52%, $p< 0.05$), and increased cell migration (112%, $p< 0.05$) relative to control. Furthermore, the EndMT process was associated with a significant increase in CCR3 levels (197%, $p< 0.05$). Notably, adding CCL24 in addition to TNFα and TGFβ further reduced cell count (from 52% to 33%, $p< 0.05$) and increased migration (from 112% to 127%, $p=0.07$). CCL24 neutralizing antibody (CM-101) completely inhibited cell migration and increased cell number.

Conclusion: This study provides evidence for the potential role of CCL24 in the pathogenesis of SSc and highlights its involvement in EndMT process resulting in disease complications such as PAH.

Neutrophil Extracellular Traps Induce Endothelial-to-Mesenchymal Transition and Associate with Vascular Complications in Scleroderma

Ramadan Ali[1], Wenying Liang[1], Claire Shiple[1], Rosemary Gedert[2], Suiyuan Huang[1], Cyrus Sarosh[1], Eliza Pei-Suen Tsou[1], Dinesh Khanna[1] and Jason Knight[1], [1]University of Michigan, Ann Arbor, MI, [2]University of Michigan, Onsted, MI

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: Systemic Sclerosis & Related Disorders – Clinical Poster III: Translational Science
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Systemic sclerosis (**SSc,** also known as scleroderma) is a disease characterized by fibrosis, autoimmunity, and vasculopathy. Many devastating complications such as digital ulcerations, scleroderma renal crisis, and pulmonary hypertension are the result of deranged vasculature. Neutrophils and neutrophil extracellular traps (**NETs**) have recently been revealed as drivers of diverse vasculopathies. Here, we investigated the potential role of NETs in SSc vascular complications.

Methods: Plasma from SSc patients (cohort 1: n=29, cohort 2: n=37) and healthy controls (n= 21) were evaluated for NET remnants (MPO-DNA complexes) and another marker of neutrophil activation (calprotectin) via ELISAs. For cohort 2, we compared diffuse SSc patients with known vascular complications (digital ulcers, pulmonary hypertension, and scleroderma renal crisis) to a cohort matched for age, sex, and disease duration but without vascular complications. To assess the effect of NETs on endothelial-to-mesenchymal transition (**EndoMT**), healthy human umbilical vein endothelial cells (**HUVECs**) or human dermal microvascular endothelial cells (**MVECs**) were treated with NETs (0.1-1 μg DNA/ml), TGF-β (10-100 ng/ml), or NETs + TGF-β. Gene expression of mesenchymal markers *ACTA2* and *S100A4* was measured by quantitative PCR.

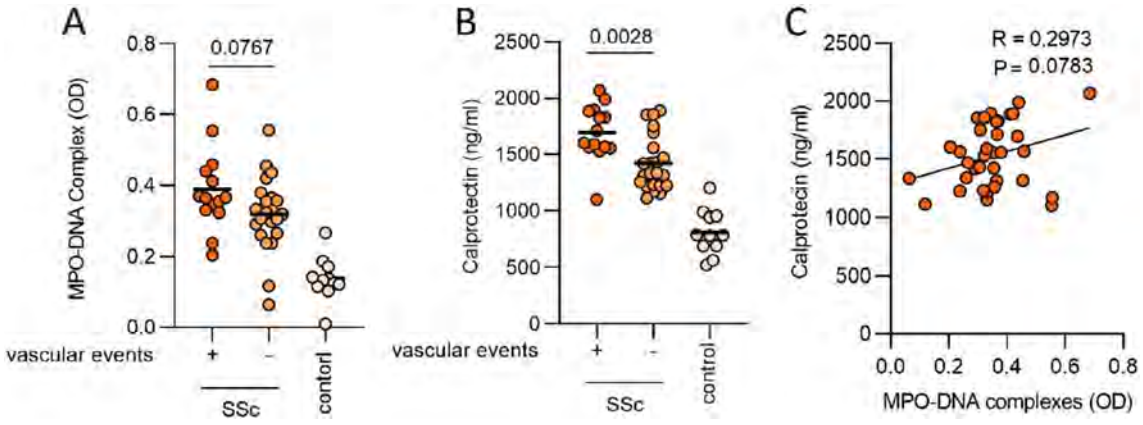

Fig 1: Plasma from SSc patients with vascular complications (n = 14), SSc patients without vascular complications (n = 23), and healthy controls (n = 11) were assessed for (A) MPO-DNA complexes and (B) calprotectin. Groups in A and B were compared by unpaired t-test, and Pearson correlation was computed for C.

Results: We tested cohort 1 (mixed SSc subtypes) and found higher levels of NET remnants in the plasma of patients with SSc compared to healthy controls (MPO-DNA complexes, mean 2.1 vs. 0.89 μg/ml, P=0.0018). At the same time, we found more plasma calprotectin in patients with diffuse SSc as compared with limited SSc (P=0.033). We then focused on patients with diffuse SSc (cohort 2), some with a history of vascular complications, and some without (**Figure 1**). We found more plasma calprotectin in patients with a history of vascular complications (P=0.0028); there was also a trend toward higher levels of NET remnants in the vascular patients although it missed statistical significance (P=0.0767). Interestingly, we found a positive correlation between circulating NETs and TGF-β (R=0.405, P=0.032), the latter a molecular determinant of fibrosis in SSc. We next assessed the potential role of NETs as inducers of EndoMT and the extent to which NETs might synergize with TGF-β in this induction. The combination of NETs and TGF-β (both at suboptimal concentrations) increased the expression of mesenchymal markers *ACTA2* (P=0.035) and *S100A4* (near significance at P=0.051) in HUVECs as compared with NETs or TGF-β alone. At higher concentrations (1 μg DNA/ml), NETs alone were also able to induce EndoMT (P=0.001). Notably, the addition of anti-NET therapies including anti-histone 4 (P=0.0007), DNase (P=0.034), and a neutrophil elastase inhibitor (P=0.0003) significantly reduced NET-mediated EndoMT (**Figure 2**).

Conclusion: Our data suggest that SSc patients with vascular complications have higher circulating markers of neutrophil activation than a matched cohort without vascular complications. Our data also suggest that NETs, similar to TGF-β, can contribute to EndoMT, and that anti-NET therapies might have potential for combatting EndoMT and vascular disease in SSc.

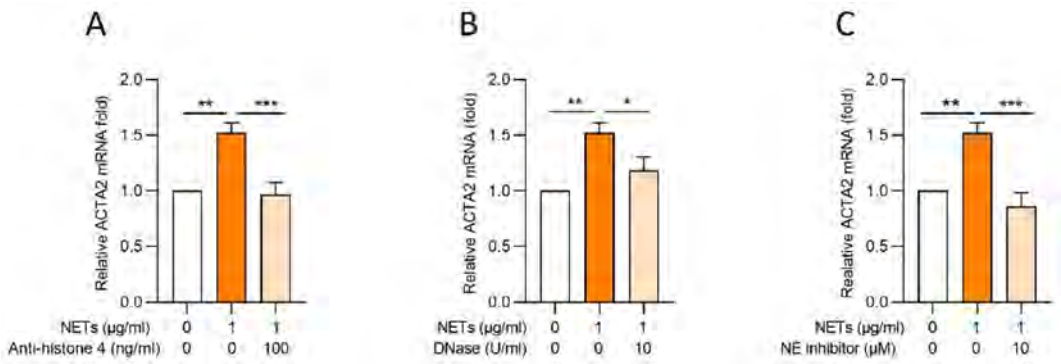

Fig 2: HUVECs were stimulated with NETs for 24 hours in the presence or absence of (A) anti-histone 4, (B) DNase, and (C) the NE inhibitor Sivelestat. The expression of mesenchymal markers was quantified by quantitative PCR. Groups were compared by unpaired ANOVA with correction for multiple comparisons.

Reversal of the Activation State of Pro-fibrotic CD206 Positive Macrophages by Therapeutic Peptide AUR300 in Systemic Sclerosis

Sandra Lopez[1], Bahja Ahmed Abdi[1], Linda Lei[1], Anas Al-Oweidi[1], Claire Macfadyen[1], Lydia Nagib[1], Sarah Ive[1], Anshul Kumar[1], Teresa Collins[1], Jennifer Cross[2], Christopher Denton[1], David Abraham[1], Clayton Yates[3], Charles Garvin[4], Henry Lopez[4], George Martin[5] and **Richard Stratton**[1], [1]University College London, London, United Kingdom, [2]Aurinia Pharmaceuticals Inc., Rockford, MD, [3]Tuskegee University, Tuskegee, AL, [4]Riptide Bioscience Inc., Valejo, CA, [5]Riptide Bioscience Inc., Bethesda, MD

SESSION INFORMATION

Session Date: Tuesday, November 14, 2023

Session Title: Systemic Sclerosis & Related Disorders – Clinical Poster III: Translational Science

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: A spectrum of macrophage activation is seen in human pathologic conditions; M2-like CD206 positive macrophages are pro-fibrotic and proresolution, while M1-like macrophages are proinflammatory, as identified by polarisation *in vitro*. CD206 positive macrophages are under study as potential targets for inflammatory fibrotic conditions

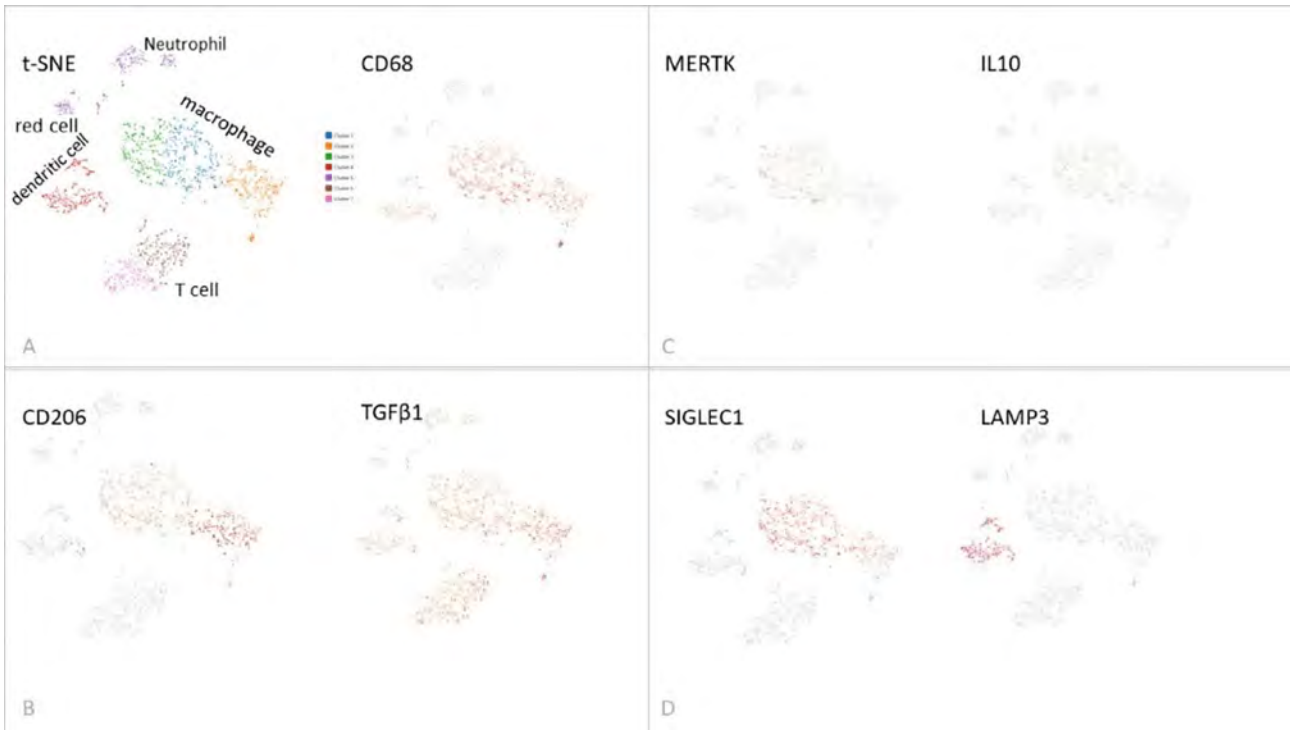

Figure 1 Single cell RNAseq of blister fluid derived cells from anti-Scl70 positive SSc patient. (A) Tissue derived immune cell populations and pan-macrophage marker CD68. (B) Pro-fibrotic CD206 cells. (C) Possible regulatory macrophages expressing MERTK and IL10. (D) Distinct tissue macrophage (SIGLEC1) and dendritic cell (LAMP3) cell populations.

including systemic sclerosis (SSc). We investigated SSc lesional macrophages by single cell profiling and Akoya Multiplex immunochemistry and evaluated the effects of AUR300, a novel peptide therapeutic that targets M2 macrophages via CD206, the mannose receptor.

Methods: Suction blister fluid-derived cells from lesional skin were profiled by 10X RNAseq matched to AKOYA antibody staining to characterise the tissue resident immune cells, including the CD206 positive macrophages of interest (n=12 SSc patients and controls).Tissue culture modelling with patients' blood monocyte-derived macrophages and disease fibroblasts (n=6 SSc cell lines), as well as bleomycin induced lung fibrosis as a model of organ involvement, were used to determine efficacy and mechanism of action of the therapeutic AUR300 peptide.Soluble CD206 (sCD206) (n=140 SSc and n=80 healthy control (HC) plasma samples) and cellular CD206 (n=17 SSc, n=9 HC macrophage lines) were investigated as potential biomarkers of SSc disease activity.

Results: CD206 positive macrophages were found in a spectrum of activation states varying from MERTK high CD206 low IL10 expressing regulatory cells, to CD206 high MERTK negative TGFβ expressing pathogenic cells (Figure 1) implicated in cross talk with fibroblasts, in the affected tissue and model systems. Exposure to disease microenvironments enhanced CD206 levels and triggered IL-6 release, reversed by the therapeutic AUR300 peptide ($p < 0.05$ for CD206, $p< 0.0013$ for IL-6, $p< 0.018$ for gel contraction, for effect of 10 μM AUR300) (Figure 2), which also attenuated inflammation and fibrosis in the bleomycin lung fibrosis model.Cross-talk with disease fibroblasts involved cytokines (IL-6, TSP-1) and growth factors (TGFβ and PDGF-BB) acting in concert. CD206 was elevated in plasma (HC 552±25, lcSSc 521±32, dcSSc 645±32, sCD206 pg/ml mean±SEM, $P< 0.026$ for dcSSc), tissue fluid (HC 31±3, SSc 48±6, pg/ml $P< 0.041$) and cells (HC 628, 485-729, SSc 663, 294-1932, median, range, fluorescence, P NS) as a biomarker, linked to severe resistant disease (highest in anti-Scl70 group).

Conclusion: In disease tissue, CD206 positive macrophages represent a spectrum of activation states, from pro-resolving MERTK IL-10 expressing cells, to pathogenic cells releasing profibrotic cytokines and growth factors in activating microenvironments. AUR300 reverses the activation state in SSc cell-based and murine *in vivo* models and represents a potential therapeutic for patients with strong CD206 positive signatures.

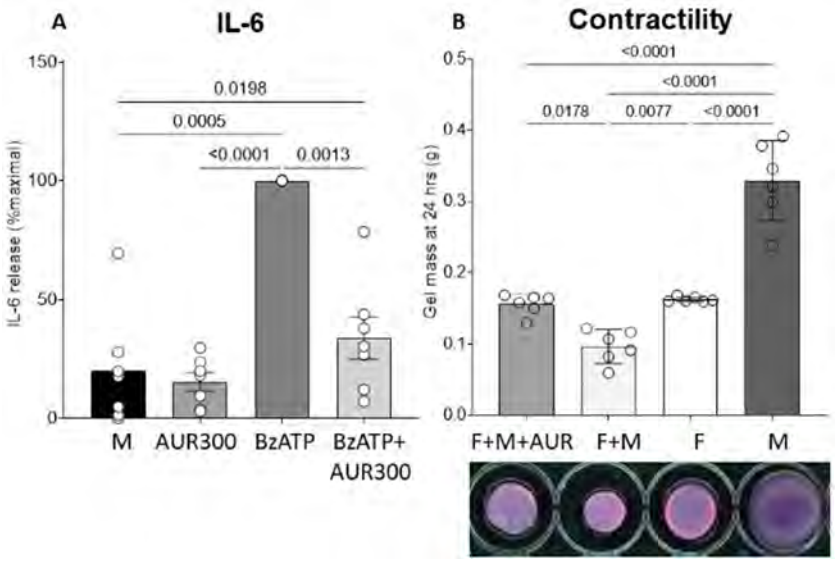

Figure 2 Effect of AUR300 on SSc macrophage activity in tissue culture models systems. (A) SSc blood monocyte-derived macrophage cultures were activated by stimulation with BzATP (0.1mM) with or without addition of AUR300 (10μM) which supressed the induction of IL-6 release. (B) In SSc macrophage-fibroblast co-cultures, macrophage induced fibroblast gel contraction was suppressed by the AUR300 compound (10μM). (AUR=AUR300 10μM, F= SSc fibroblasts, M=SSc macrophages,).

Session Date: Tuesday, November 14, 2023

Session Title: Systemic Sclerosis & Related Disorders – Clinical Poster III: Translational Science

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: Calcinosis may result from localised trans-differentiation of tissue resident stem cells in the subcutaneous layer of affected skin in systemic sclerosis (SSc), as a severe disabling manifestation linked to ischaemia and local trauma.Beyond SSc, inherited defects in Activin A responsive pathway (*ACTVAR1*) result in widespread calcinosis, as seen in Fibrodysplasia Ossificans Progessiva, where macrophages are implicated as the source of excess tissue Activin A.We investigated the possible induction of SSc calcinosis in a tissue culture model generated by stimulation of adipose derived mesenchymal stem cells (MSCs) with SSc patients' macrophages and explored the relevance of the Activin A pathway.

Methods: Clinical associations were screened in a database of well-characterised SSc patients with symptomatic calcinosis (n=28) and SSc without calcinosis (n=51). Human subcutaneous fat derived MSCs were cultured in osteogenic media, with or without SSc patients' monocyte-derived macrophages, with or without inhibitors, AUR300 10μM (peptide inhibitor of M2 macrophages) or SB431542 10μM (antagonist of Activin/ALK5 pathway). Cultures were stained with Alizarin red for osteogenesis on day 21. Macrophage secreted levels of Activin A under basal and ATP-stimulated conditions, were assayed by ELISA (Biotechne), as were plasma levels in n= 57 diffuse SSc patients (n=26 anti-Scl70, n=22 anti-RNA polymerase and 9 anti-U3RNP subgroup) and 21 healthy controls (HC).

Results: Most clinical characteristics did not differ significantly between patients with calcinosis and those without, including clinical subset, age, gender, disease duration, organ involvement or autoantibody subtype (all P values NS), whereas digital ulceration (DU) was associated with calcinosis (DU in 16/28 calcinosis and 13/51 no calcinosis, chi square P< 0.008). Notably, Activin A levels were increased in SSc patients' plasma samples when compared to controls, only in diffuse anti-Scl70 patient subgroup (plasma Activin A healthy controls 147, 80-249, anti-Scl70 SSc 261, 136-590 pg/ml, median, IQR, P< 0.05 Mann Whitney) (Figure 1A). Moreover, anti-Scl70 SSc patients' macrophages, released Activin A in tissue culture, enhanced by stimulation with BzATP (0.1 μM) and inhibited by AUR300 (10μM) (Figure 1B), and stimulated calcinosis in the MSC model, where addition of SSc macrophages (M) to the MSC cultures induced Alizarin red positive osteogenic foci

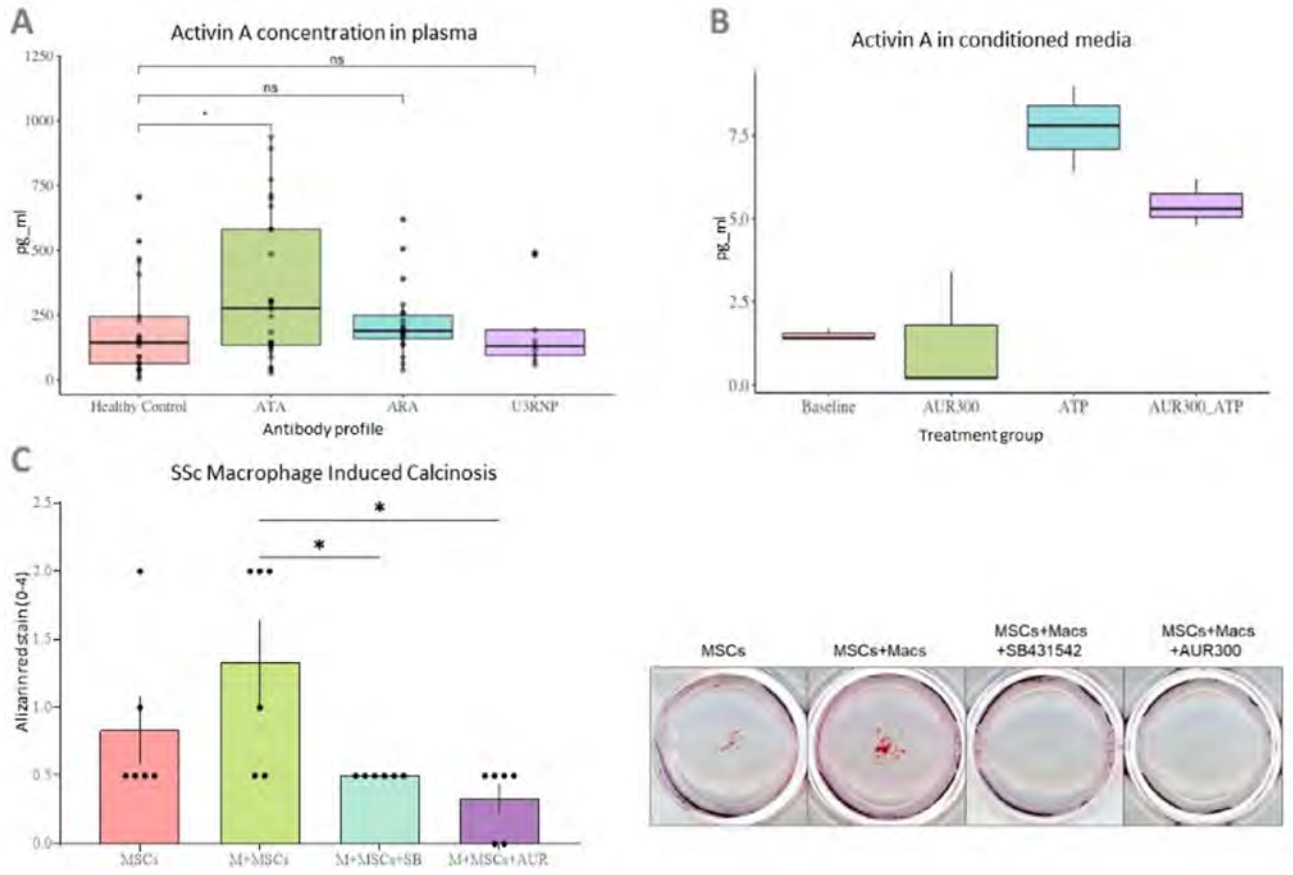

Figure 1 Role of activin A/ALK5 pathway in SSc macrophages induced calcinosis. (A) Plasma levels of Activin A are raised in diffuse SSc anti-Scl70 (ATA) group. (B) Release of Activin A by anti-Scl70 positive SSc patient's macrophages under basal and BzATP stimulated conditions: effect of peptide drug AUR300. (C) Role of activin A in anti-Scl70 SSc macrophage-induced MSC calcinosis model; antagonism by Activin/Alk5 signalling by inhibitor SB431542 and by M2 macrophage inhibitor. (ATP=0.1 μM BzATP, AUR=AUR300 10μM, M=macrophages, MSC=mesenchymal stem cells, SB=SB431542 10 μM, ARA=anti-RNA polymerase, ATA=anti-Scl70 subgroup, U3RNP=anti-U3RNP, *=P<0.05).

at 21 days, blocked by both AUR300 and SB431542 (MSCs 0.833+/-0.247, MSCs+M 1.33+/-0.307, MSCs+M+SB 0.5+/-0, MSCs+M+AUR300 0.33+/-0.105, Alizarin Red stain 0-4, P< 0.012 for AUR300 effect) (Figure 1C).

Conclusion: Calcinosis occurs in both diffuse and limited SSc subsets and across autoantibody subgroups and was associated with digital ulceration.Elevated plasma levels of Activin A, most notable in anti-Scl70 subgroup, is consistent with systemic upregulation of the Activin A pathway in SSc.Activated macrophages from SSc patients are a potential source of Activin A capable of stimulating MSCs via an osteogenic/calcinosis model.The AUR300 and SB431542 compounds as studied represent potential therapeutic inhibitors of this severe and currently resistant complication of SSc.

Optimal Combination of Circulating Biomarkers for Predicting the Progression of Interstitial Lung Disease in Patients with Systemic Sclerosis

Keina Yomono[1], Dinesh Khanna[2] and Masataka Kuwana[3], [1]Nippon Medical School University, Tokyo, Japan, [2]University of Michigan, Ann Arbor, MI, [3]Nippon Medical School Graduate School of Medicine, Tokyo, Japan

SESSION INFORMATION

Session Date: Tuesday, November 14, 2023

Session Title: Systemic Sclerosis & Related Disorders – Clinical Poster III: Translational Science

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: In patients with systemic sclerosis (SSc), progression of interstitial lung disease (ILD) is associated with an increased mortality. Since the course of SSc-ILD is highly variable, it is critical to predict the progression of ILD in clinical practice as well as in clinical trial setting. Previously reported risk factors for ILD progression include male, progression of skin thickness in diffuse cutaneous SSc (dcSSc), short SSc duration, anti-Scl-70, and elevated inflammatory markers and Krebs von den Lungen-6 (KL-6). The aim of this study was to examine performance of inflammatory markers and KL-6 to efficiently enrich patients who subsequently experience ILD progression in SSc patients using a single-center prospective cohort.

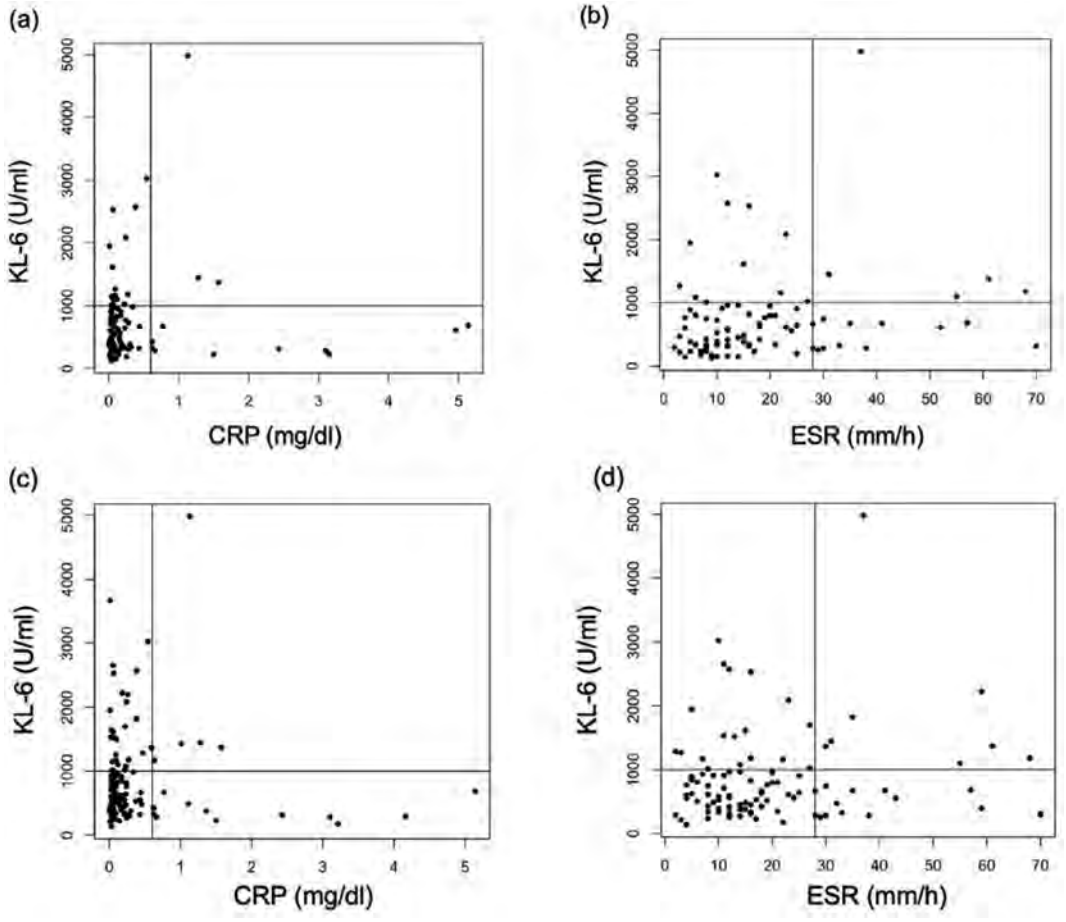

Figure 1. Scatter plot of CRP/ESR and KL-6 in dcSSc (a, b) and SSc-ILD cohorts (c, d).

Table 1. The AUC, sensitivity, and specificity of serum biomarkers and their combinations for predicting PF-ILD and PPF in dcSSc and SSc-ILD cohorts.

Methods: Two cohorts, including patients with dcSSc (n=109) and those with SSc-ILD (n=136), were selected from our prospective SSc registry. 87 patients with dcSSc and ILD were included in both cohorts. C-reactive protein (CRP) ≥6 mg/L and erythrocyte sedimentation rate (ESR) ≥28 mm/hour were used as increased inflammatory markers, and a cutoff point of increased KL-6 was provisionally set at 1,000 U/mL. ILD progression was defined as the first event developing progressive fibrosing ILD (PF-ILD) or progressive pulmonary fibrosis (PPF). Receiver Operating Characteristic Curve (ROC) analysis was conducted to determine the sensitivity, specificity and area under the curves (AUCs) and the Youden index was used to identify the appropriate cutoff. Cumulative rates free from ILD progression were assessed using Kaplan-Meier analysis and statistical comparisons were made using log-rank test.

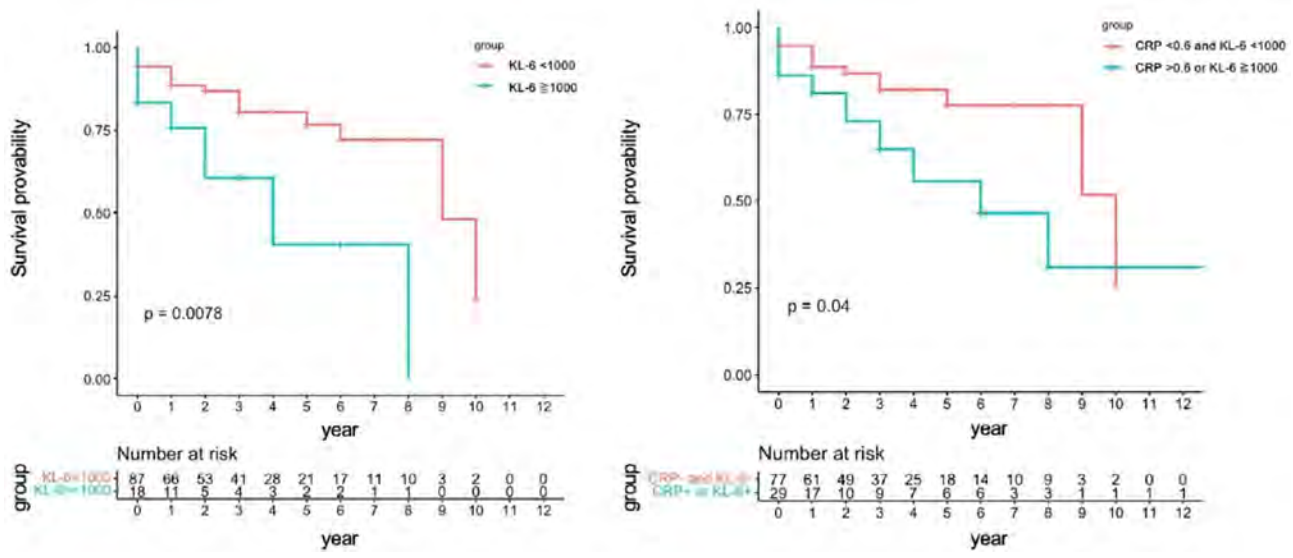

Figure 2. Kaplan-Meier analysis of cumulative PF-ILD-free survival rates in patients with dcSSc, stratified by the groups based on KL-6 or KL-6/CRP combination.

Results: Median disease duration at baseline was 15.0 and 23.5 months in dcSSc and SSc-ILD cohorts, respectively. In dcSSc cohort, 27 (25%) and 22 (20%) patients developed PF-ILD and PPF during median follow-up of 37 month, respectively; and 43 (31%) and 36 (26%) in SSc-ILD cohort developed PF-ILD and PPF during median follow-up of 43.5 months, respectively. There was no correlation between inflammatory markers and KL-6 (Figure 1). The specificity of CRP, ESR and KL-6 to predict ILD progression was favorable (74-88%), but sensitivity of CRP and ESR was low (9-15%). KL-6 provided better sensitivity (24-45%) (Table 1). The combination of CRP and KL-6 showed the best AUCs (0.54-0.62), with increased sensitivity (33-52%) while mainlining acceptable specificity (69-76%). Regardless of how ILD progression is defined, Kaplan-Meier analysis showed that the patients with increased KL-6 experienced ILD progression more frequently than those without. The same trend was observed for the KL-6/CRP combination (Figure 2). Optimal cut-offs of KL-6 to predict PF-ILD and PPF were found to be lower than provisional cut-off in dcSSc (∼610 U/mL) and SSc-ILD (820 U/mL) and the models using these data-driven cut-offs improved AUCs compared to provisional setting.

Conclusion: We propose use of combination of KL-6 and CRP in the inclusion criteria for enriching "at risk" patients in clinical trials for SSc, while optimal cut-off need to be further defined using different multicenter cohorts.

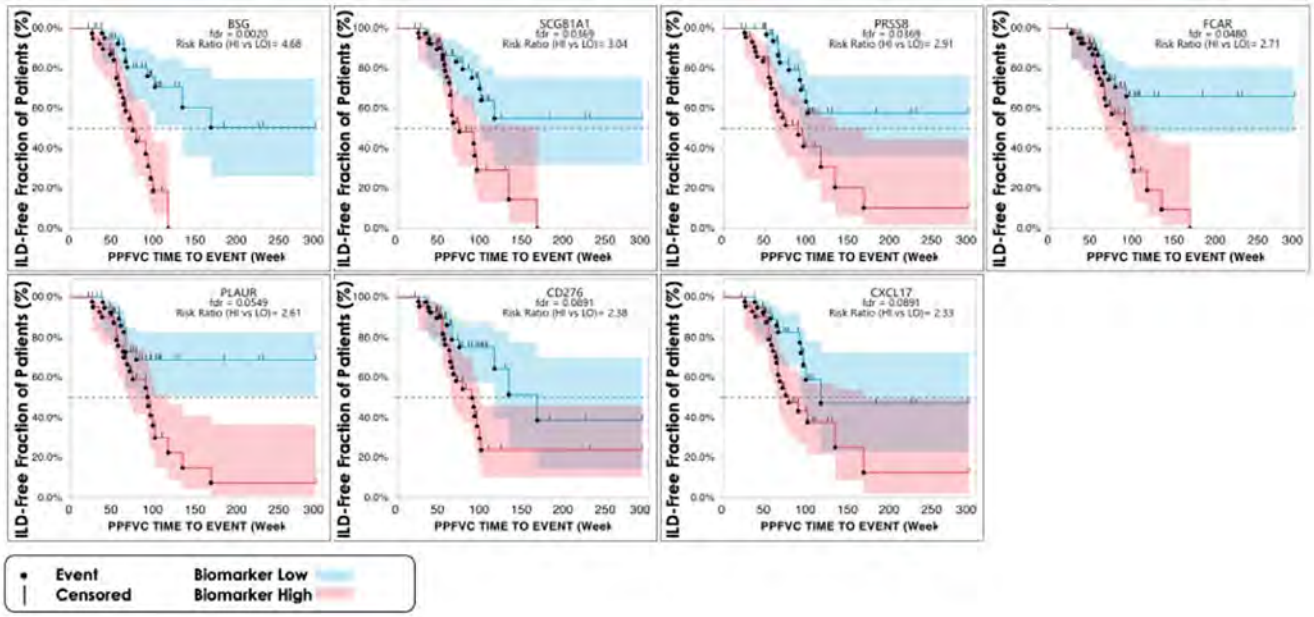
Identification of Protein Biomarkers Associated with the Severity and Risk of Progression of Interstitial Lung Disease in VEDOSS and Established Systemic Sclerosis Patients

Thierry Sornasse[1], Vishal Kakkar[2], Rebecca Ross[3], Sunhwa Kim[4] and Francesco Del Galdo[5], [1]AbbVie, Inc., North Chicago, IL, [2]University of Leeds, Leeds, United Kingdom, [3]Medicine and Health, University of Leeds, Leeds, United Kingdom, [4]AbbVie, Inc., South San Francisco, CA, [5]University of Leeds - Leeds Institute of Rheumatic and Muskuloskeletal Medicine, Leeds, United Kingdom

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: Systemic Sclerosis & Related Disorders – Clinical Poster III: Translational Science
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Pulmonary Fibrosis (PF) is one of the primary causes of systemic sclerosis (SSc)-related death. Hence, monitoring and predicting the course of PF in SSc remains a critical need in patient management. Furthermore, the stratification of patients based on their risk of PF progression should be improved the feasibility of clinical studies. Here, we explore the relationships of a subset of protein biomarkers (pBMs), initially identified as prognostic of disease worsening in progressing fibrosing interstitial lung disease (ILD) (Bowman WS et al *Lancet Respir Medicine* 2022), with the severity and risk of PF in Very Early Diagnosis of SSc (VEDOSS) and established limited (lcSSc) and diffuse cutaneous SSc (dcSSc).

Methods: Hundreds one patients (33 VEDOSS, 21 lcSSc, and 47 dcSSc) were selected from the ongoing SSc registry at the University of Leeds. Using a proximity extension assay, we determined the relative levels of 34 PF-ILD-related pBMs in the serum samples. Association with the presence of ILD at baseline was calculated using a t-test, with the severity of ILD



(Percent Predicted FVC) at baseline using Pearson's correlation, and with the risk of FVC decline using a Proportional Hazard model based on the median-dichotomized pBM levels at baseline. All 101 patients were combined for these analyses, and Benjamini-Hochberg FDR correction for multiple comparisons was applied.

Results: Out of 34 pBMs, we identified 8 BMs differentially expressed between VEDOSS, lcSSc, and dcSSc patients with or without ILD at baseline. AGER was lower in patients with ILD, suggesting a positive beneficial relation with ILD. Conversely, the remaining 7 pBMs (ITGB6, KRT19, PRSS8, SCGB3A2, IL1RN, SERPINB8, and HGF) were higher in patients with ILD, suggesting a potentially detrimental link with ILD. Consistent with these observations, AGER correlated positively with baseline ppFVC, while the other 5 pBMs correlated negatively with baseline ppFVC. Finally, we identified 7 pBMs (BSG, SCGB1A1, PLAUR, FCAR, PRSS8, CD276, and CXCL17) associated with the relative risk of ILD progression (figure 1; as defined by a reduction of ppFVC of 0.05/week). PRSS8 was the only pBM shared across the three analyses, suggesting a possible role of this peptidase in lung fibrosis.

Conclusion: In this pilot study, we confirmed the association of a subset of the pBMs identified by Bowman et al. with the presence, severity, and risks of progression of ILD in VEDOSS, lcSSc, and dcSSc patients. Notably, the pBMs associated with the presence and severity of lung fibrosis differed from those associated with the risk of progression. While these results could lead to useful biomarker tools for the stratification and monitoring of lung fibrosis in VEDOSS and SSc patients, we need to confirm these results in an additional group of prospectively recruited VEDOSS and established SSc.

Increase in Macrophage Infiltration in Scleroderma Esophageal Mucosa Is Associated with Motility and Mucosal Complications

Tai-Ju Lee[1], Ting-Yuan Lan[1], Ko-Jen Li[2], Song-Chou Hsieh[2] and Ping-Huei Tseng[3], [1]National Taiwan University Hospital Hsinchu Branch, Hsinchu City, Taiwan, [2]National Taiwan University Hospital, Taipei, Taiwan, [3]National Taiwan University Hospital, Taipei City, Taiwan

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: Systemic Sclerosis & Related Disorders – Clinical Poster III: Translational Science
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: The macrophage activation is elevated in systemic sclerosis (SSc) patients, and is implicated in pathogenesis of tissue inflammation, fibrosis, and the development of skin disease and interstitial lung disease. The gastroesophageal manifestations are common in SSc, with significant motility and mucosal complications. In this study, we aimed to investigate the potential influence of macrophages in SSc esophagus.

Methods: In this single-center observational study, we prospectively enrolled patients with SSc and primary gastroesophageal reflux disease (GERD) patients to the study. The SSc patients fulfilled the 2013 ACR/EULAR Classification Criteria. The primary GERD patients were examined by gastroenterologist and rheumatologist by clinical and serology tests to exclude possible autoimmune diseases and other structural gastrointestinal disorders.

The patients underwent a series of esophageal and gastric examinations including upper gastroendoscopy, high-resolution esophageal manometry, and middle-portion esophageal endoscopic mucosal biopsy. The erosive esophagitis was graded with Los Angeles classification and the diagnosis of motility disorder was classified according to Chicago Classification version 4.0.

The esophageal biopsy specimens were examined using light microscopy with hematoxylin-eosin stain, and immunohistochemical stains with CD117, Desmin, CD3, CD20, and CD68.

The statistical significance was calculated using Fisher's exact test for binomial parameters and Wilcoxon rank sum exact test for continuous and categorical data.

Immunohistochemical stains	SSc (n=22)	GERD (n=6)	p-value
CD117	0 (0%)	0 (0%)	
Desmin	12 (55%)	0 (0%)	0.024
CD3	22 (100%)	3 (50%)	0.002
CD20	2 (9.1%)	0 (0%)	>0.9
CD68	15 (68%)	0 (0%)	0.005

GERD, gastroesophageal reflux disease; SSc, systemic sclerosis

Systemic sclerosis (n=22)	CD68-positive (n=15)	CD68-negative (n=7)	p-value
UES Resting Pressure (mmHg)	39 (13, 45)	19 (13, 33)	0.3
UES IRP 0.2s (mmHg)	7.7 (5.9, 9.7)	11.7 (10.3, 15.1)	0.007
UES IRP 0.8s (mmHg)	13.5 (10.5, 18.4)	18.8 (16.6, 24.3)	0.052
LES Resting Pressure (mmHg)	13 (8, 18)	13 (8, 22)	0.7
LES IRP 4s (mmHg)	3.8 (0.0, 12.8)	1.6 (0.3, 11.3)	>0.9
Erosive esophagitis (LA grade)			0.3
0	4 (27%)	5 (71%)	
1	7 (47%)	1 (14%)	
2	3 (20%)	1 (14%)	
3	1 (6.7%)	0 (0%)	
Erosive esophagitis	11 (73%)	2 (29%)	0.074

IRP: integrated relaxation pressure; LA grade: Los Angeles classification grading; LES, lower esophageal sphincter; UES, upper esophageal sphincter

Results: From September 2021 to March 2023, 22 SSc patients and 6 primary gastroesophageal reflux disease patients completed the study. The median ages and female sex were similar across both groups. The rates of erosive esophagitis (59% vs. 33%, p = 0.4) and the LA gradings (p = 0.6%) were comparable. On immunohistochemical stains, the SSc patients exhibited increased T cell (100% vs. 50%, p = 0.006) and macrophage (68% vs. 0%, p = 0.008) infiltrations.

In SSc patients, the presence of esophageal macrophage infiltration was not associated with age, female sex, GERD and dysphagia symptoms, the proportion of the absent contractility on manometry, the interstitial lung disease, the functional vital capacity, or the diffusion of carbon monoxide. However, the macrophage infiltration is associated with a decreased upper esophageal sphincter relaxation pressure (7.7 vs. 11.7 mmHg, p = 0.007) and numerically higher rates of erosive esophagitis (73% vs. 29%, p = 0.074.)

Conclusion: In this study, we found a higher proportion of T cell and macrophage infiltrations in SSc patients compared with primary GERD individuals, irrespective of the mucosal complications. The macrophage infiltration in SSc patients was associated with decreased esophageal sphincter pressure and numerically higher incidence of erosive esophagitis. The observation supported the pathological role of macrophages in SSc and indicated its significance in developing esophageal mucosal and functional complications.

Session Title: Systemic Sclerosis & Related Disorders – Clinical Poster III: Translational Science

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: Despite recent advances in systemic sclerosis (SSc), there remains a paucity of clinically actionable biomarkers to assess disease severity and predict progression. Collagen triple helix repeat containing-1 (CTHRC1), a protein secreted during tissue-repair that regulates fibroblast function and vascular remodeling after arterial injury has been reported to be a marker for a subpopulation of fibroblasts uniquely found in lungs of SSc-ILD patients. The aim of this study was to determine whether serum levels of CTHRC1 are associated with specific disease manifestations and predict clinical outcomes in SSc.

Table 1: Demographic and clinical characteristics of SSc patients and healthy controls

		29 (7.7%)

Methods: Retrospective analysis of a prospectively collected longitudinal cohort was performed using a large, well characterized cohort of SSc patients, fulfilling the ACR/EULAR 2013 classification criteria, and healthy controls. Serum levels of CTHRC1 were measured by ELISA in 377 SSc patients and 40 healthy controls (Table 1). SSc patients were stratified by quartiles of CTHRC1 serum level for analysis. Quartile characteristics were compared using ANOVA/Chi-Square and mixed models were utilized to assess the association of CTHRC1 serum level with SSc disease manifestations and severity, including skin disease, interstitial lung disease (ILD), pulmonary arterial hypertension (PAH), and peripheral vascular disease. Survival analysis, as defined by time to death or lung transplantation, was assessed by Kaplan-Meier analysis between quartiles with long-rank test.

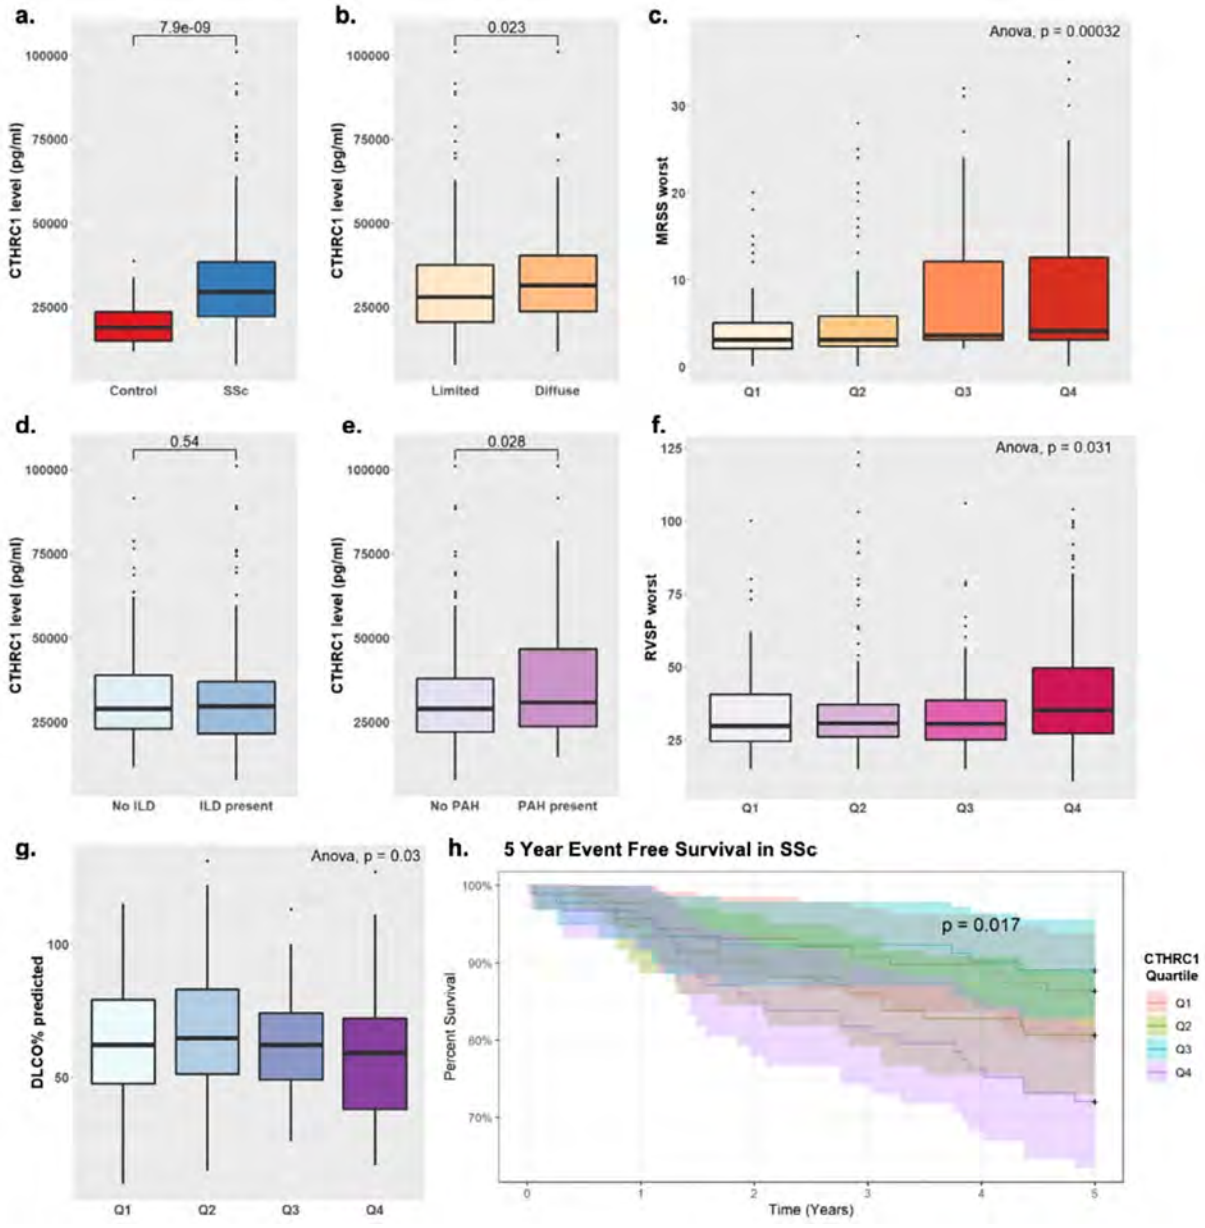

Figure 1: Serum CTHRC1 levels are elevated in SSc patients (a) and associated with skin disease severity (b-c), PAH severity (d-g) and 5 year event free survival (h). Q1 represents quartile of patients with lowest serum CTHRC1 level while Q4 represents highest.

Results: Serum CTHRC1 was significantly increased in SSc patients compared to healthy controls (Fig 1a). After controlling for age, sex, race, disease duration and SSc antibody status, elevated CTHRC1 was independently associated with skin disease severity ($p< 0.05$) and PAH (OR=1.43 per 10k pg elevation, p=0.005). Patient with diffuse skin disease had significantly higher CTHRC1 than limited skin disease (p=0.023) (Fig 1b) and elevated CTHRC1 was associated with both increased MRSS at time of serum measurement (p=0.003) and worst MRSS recorded (p=0.005) (Fig 1c). CTHRC1 was not associated with the presence of ILD, however was significantly elevated in subjects with PAH (Fig 1d-e). After controlling for covariates, higher CTHRC1 levels were significantly associated with markers of PAH severity, including decreased DLCO% predicted ($p< 0.001$) and elevated RVSP (p=0.003) at time of serum measurement as well as for worst recorded values (p=0.01) (Fig 1f-g). Elevated CTHRC1 serum level was associated with worse survival among SSc patients (Fig 1h).

Conclusion: Circulating CTHRC1 levels are increased in SSc patients and exhibit a significant association with more severe skin disease, PAH, and worse survival. While it remains to be determined whether CTHRC1 is directly implicated in the disease pathologic process, these findings suggest that circulating CTHRC1 may be further validated as a clinically actionable biomarker in SSc.

Decoding the Peripheral Immune Landscape of Systemic Sclerosis to Investigate Disease Stages and Interstitial Lung Disease Progression

Vasuki Ranjani Chellamuthu[1], Maria Noviani[2], Ahmad bin Mohamed Lajam[1], Andrea Hsiu Ling Low[2] and Salvatore Albani[1], [1]Translational Immunology Institute, SingHealth, Singapore, Singapore, [2]Department of Rheumatology and Immunology, Singapore General Hospital, Singapore, Singapore

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: Systemic Sclerosis & Related Disorders – Clinical Poster III: Translational Science
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Systemic sclerosis (SSc) is a heterogenous autoimmune disease characterized by fibrosis, vascular abnormalities and immune dysregulation. Characterization of peripheral blood immune signatures in relation to disease stages and progression remains insufficiently defined. Understanding these immune signatures may shed light to SSc pathogenesis underpinning distinct disease stages and states.

Methods: The study included a cohort of SSc patients (n=15), age and sex matched to healthy controls (n=7). We compared immune signatures of SSc patients at different stages ("very early diagnosis of SSc" (VEDOSS), early < 3 years and late >5 years from disease onset) and ILD status (stable vs progressive). Clinical and laboratory parameters were recorded for auto-antibody profile, immunosuppressive treatment and disease activity including ILD status. Peripheral blood mononuclear cells of SSc patients were analysed by high dimensional Mass Cytometry (CyTOF) approach employing 73 unique markers to identify perturbations in SSc immunome in comparison to healthy controls. A high throughput analytical and discovery platform, EPIC (Extended Polydimensional Immune Characterization) was deployed for multi-dimensional data analysis and clustering to identify significantly perturbed immune cell subsets.

Results: Unsupervised clustering revealed significant differences in T and NK cell subsets. Supervised analysis revealed activated CD4+ cells expressing CXCR4 and type 1 IFNs (IFI44 and IFI44L) to be significantly increased in SSc compared to healthy controls. This was particularly more pronounced in the late stage of disease and for patients with stable ILD. CXCR4 are known to mediate migration of lymphocytes, endothelial progenitor cells and stem cells and may play a key role in tissue fibrosis. Conversely, a decreased number of cytotoxic NK cells expressing CX3CR1 were found in SSc. CX3CR1 is a mediator of chemotaxis for immune cells and a significant decrease could potentially indicate impaired immunosurveillance in SSc patients. This subset was significantly decreased in the early and late stages of disease and in stable ILD state.

Conclusion: These findings shed light on the heterogeneity of SSc and provide insights into the differential characteristics of disease stages. Understanding the mechanism underlying SSc disease progression and immune perturbations will aid in early diagnosis and intervention. This could contribute to the development of targeted therapeutic strategies and better management of this debilitating disease. Further investigations are warranted to explore the functional significance of increased activated CD4 cells expressing CXCR4 and decreased cytotoxic NK cells expressing CX3CR1 in SSc, as well as to identify potential therapeutic targets that could mitigate disease progression and restore immune homeostasis in affected individuals.

Spatial Frequency Domain Imaging as a Novel Method to Quantify Longitudinal Skin Changes in Scleroderma

Hung Vo[1], Aarohi Mehendale[2], Anahita Pilvar[3], Eugene Kissin[4], Marcin Trojanowski[5], Michael York[6], Darren Roblyer[2] and Andreea Bujor[6], [1]Boston Medical Center, Peabody, MA, [2]Department of Biomedical Engineering, Boston University, Boston, MA, [3]Department of Electrical and Computer Engineering, Boston University, Boston, MA, [4]Boston University, Newton, MA, [5]Boston University School of Medicine, Boston, MA, [6]Boston University, Boston, MA

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: Systemic Sclerosis & Related Disorders – Clinical Poster III: Translational Science
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Systemic sclerosis (SSc) is an autoimmune disease characterized by excessive collagen deposition in the skin and internal organs, along with vascular dysfunction. The modified Rodnan skin score (mRSS) is the established gold standard for evaluating skin fibrosis in SSc. Nevertheless, mRSS is not objective, has significant interrater variability and may miss small but clinically significant changes. Spatial Frequency Domain Imaging (SFDI) is a non-invasive and optical technique that uses near-infrared light to generate widefield images of tissue optical properties (absorption (μ_a) and reduced scattering coefficients (μ_s')) at sub-surface depths. Our recent study showed that μ_s' is highly correlated with mRSS, suggesting that SFDI is a reliable method for assessing skin fibrosis in SSc patients (Fig. 1) (1). However, the sensitivity of SFDI to longitudinal changes has yet to be examined.

Methods: The SFDI data were collected from the left and right forearms in 2 healthy control (HC) subjects and 6 patients with diffuse SSc.Subjects were measured at two different time points, at least two months apart. Local forearm mRSS scores were performed by a trained physician, blinded to the SFDI measurements and using the averaging method. A rectangular region of interest (ROI) of dimensions 800 × 300 pixels (approx. 4.3 × 11.5 cm), aligned along the dorsal forearm was used

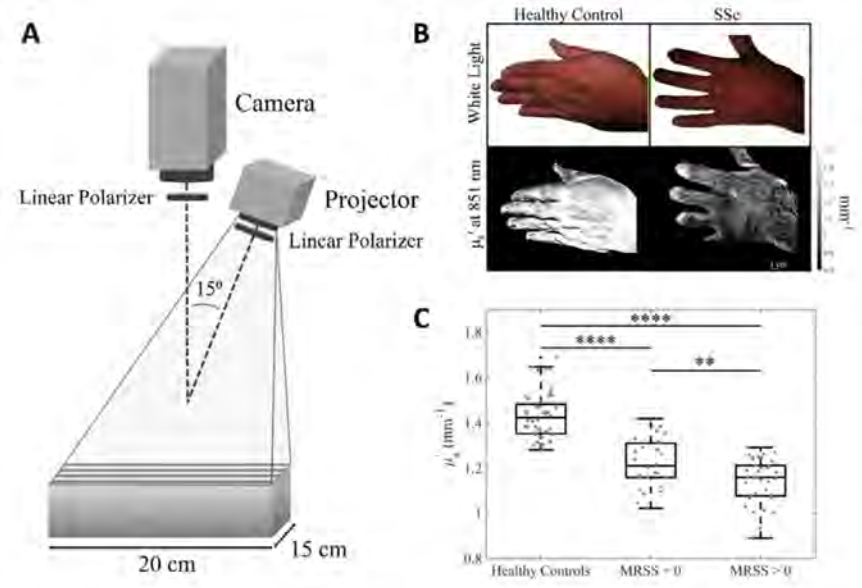

*Figure 1. A) Schematic diagram of a SFDI system. The target site is placed directly below the illumination source for data acquisition. B) The scleroderma patient exhibited a lower μ_s' value compared to the healthy subject at 851 nm as shown in the bottom row. C) μ_s' difference in healthy controls, versus mRSS = 0 and mRSS > 0 in SSc patients. ****p < 0.0001, **p ≤ 0.01. Panels A and C adapted from ref (1).*

Figure 1

to measure μ_s' at 851 nm .Differences between the sum of left and right forearms in each patient were plotted against differences in the sum ofμ_s' in each patient. Correlation between the absolute change of μ_s' versus absolute change of mRSS at the 2 time-points were evaluated using the Spearman test. A p-value < 0.05 was considered statistically significant. All data were analyzed with GraphPad Prism 9 software.

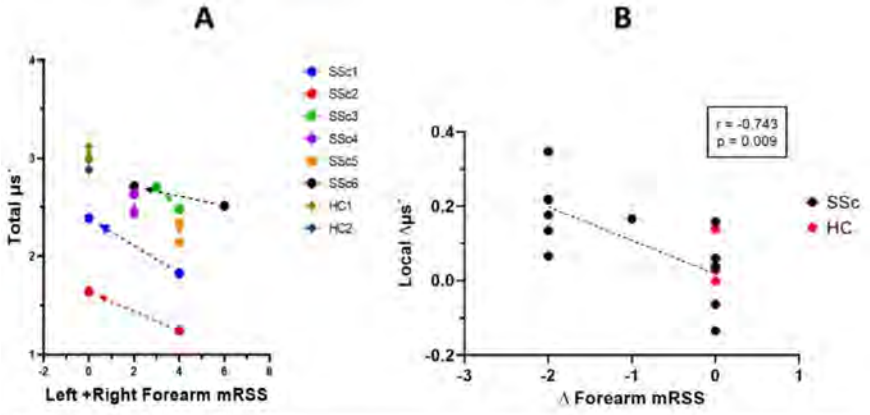

Figure 2. *A) Longitudinal associations of t1 and t2 total μ_s' (sum of left and R forearms) and t1 and t2 total mRSS (sum of left and R forearms) values for each individual patient. B) Correlation between the longitudinal change in μ_s' at each forearm and the corresponding change in mRSS at the same site r=-0.74 (**p < 0.01). t1-time of first measurements; t2-time of second measurements; SSc-scleroderma patient; HC- healthy controls*

Figure 2

Results: 83% of SSc patients were females, with a mean age of 44 ± 18.4 years. Mean disease duration was 4.3 ± 2.6 years and mean follow up interval between measurements was 23 months ± 4.8 months. In 3 patients the sum of forearm mRSS scores improved by 4 points (SSc1, 2 and 6), one patient had a modest improvement (1 point, SSc3), while two patients remained stable (SSc4 and 5, Fig 2A). No patient had an increase in the forearm skin score. As expected, the patients with no improvement showed minimal changes in the μs', similar to controls (0.0109 ± 0.1129 mm^{-1} in SSc compared to 0.0497 ± 0.0613 mm^{-1} in HC). However, when patients improved there was a proportionate increase in μs' that mirrored the degree of mRSS improvement (Fig 2A). Next we assessed correlation between change in mRSS and change in μs' at each site, and found a significant negative correlation ($r = -0.74$, $p < 0.01$, Fig 2B).

Conclusion: Our preliminary study indicates that SFDI is sensitive to longitudinal changes in the skin of SSc patients, further supporting this method as a highly promising new tool for scleroderma skin assessment and monitoring. Future studies are required to confirm these findings.

Characterization of the SFRP4+ PRG4+ Fibroblast Subpopulation in the Dermis of Healthy Skin and Its Relationship to SFRP4+ PRG4- Myofibroblasts in the Skin of Patients with Systemic Sclerosis

Banafsheh Nazari[1], Tracy Tabib[2] and Robert Lafyatis[2], [1]University of Pittsburgh, Atlanta, GA, [2]University of Pittsburgh, Pittsburgh, PA

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: Systemic Sclerosis & Related Disorders – Clinical Poster III: Translational Science
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Systemic sclerosis (SSc) is a debilitating autoimmune disease characterized by extensive fibrosis affecting multiple organs. The fibrosis arises from the excessive production of collagen by dysregulated myofibroblasts. Our recent single cell RNA-sequencing (scRNA-seq) studies have described several fibroblast subpopulations in the skin of SSc patients. We have previously shown that myofibroblasts derive from one of these populations that expresses secreted frizzled-related protein 2 (SFRP2) and DPP4, the most common subpopulation of dermal fibroblasts[1]. As these cells differentiate into myofibroblasts they show upregulated expression of another gene, secreted frizzled-related protein 4 (SFRP4). However, SFRP4 is also expressed by another fibroblast subpopulation found in healthy as well as SSc skin. ScRNA-seq indicates that this subpopulation also expresses PRG4. Thus, we sought to better understand the location of PRG4+ fibroblasts in healthy skin and their relationship to SFRP4+ myofibroblasts.

Methods: Dorsal forearm skin biopsies were obtained from a cohort of eight SSc patients and twelve healthy controls, following the approved protocol by the Institutional Review Board of the University of Pittsburgh School of Medicine. Paraffin-embedded skin samples were utilized for double and triple immunofluorescence staining, employing Tyramide

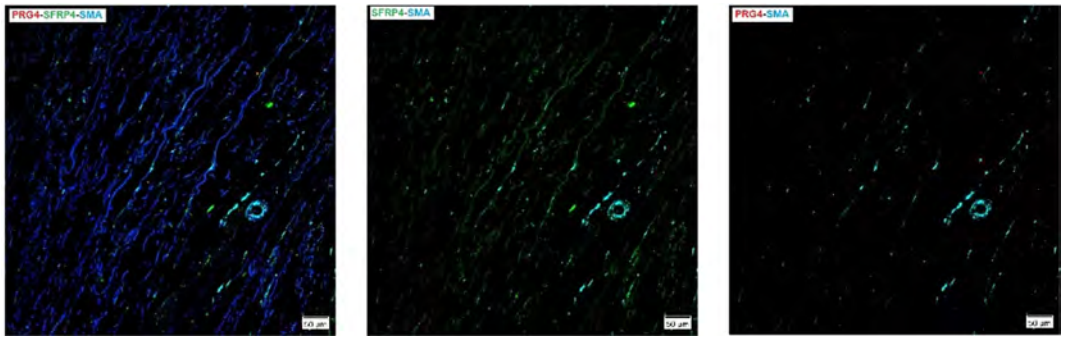

Figure 1 shows α-SMA+ SFRP4+ PRG4- myofibroblasts in the dermis of SSc patients

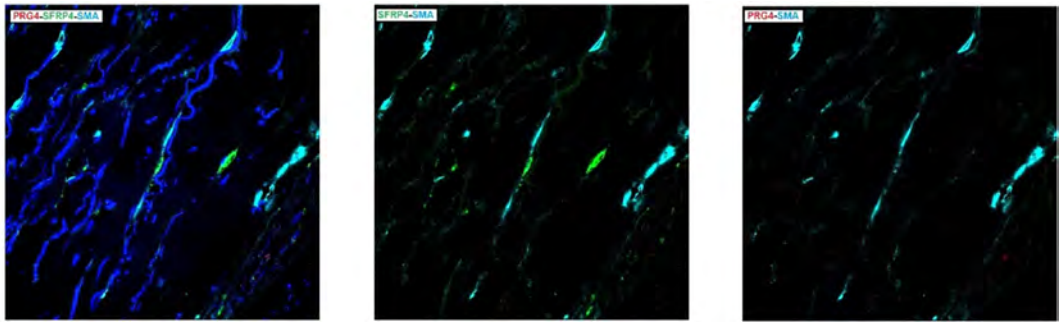

Figure 2 shows a higher magnification of α-SMA+ SFRP4+ PRG4- myofibroblast staining in the dermis of SSc patients

amplification and a range of antibodies targeting distinct fibroblast markers. High-resolution figures were generated using the Olympus FluoView 3000 confocal microscope.

Results: Our study uncovered a unique subpopulation of fibroblasts characterized by expression of proteoglycan 4 (PRG4) as well as (variable) expression of SFRP4 (and other markers). These cells were seen in both healthy and SSc skin. These cells were located in both papillary and reticular dermis. In contrast, myofibroblasts also expressed secreted frizzled-related protein 4 (SFRP4) and alpha-smooth muscle actin (α-SMA), while lacking the (PRG4) marker. Myofibroblasts were specifically identified in the deep dermis of SSc patients and were not observed in healthy skin.

Conclusion: This study clarifies the relationship between SFRP4-expressing fibroblast subpopulations. PRG4+ fibroblasts do not appear to be myofibroblast progenitors due to previous bioinformatics analyses, as well as their topological distribution in the skin. However, it is likely that they contribute to hydration of skin and intriguing to consider how they may contribute to loss of skin hydration and elasticity with aging, and possibly contribute to other skin pathology. This study also reinforces the importance of the distinct population of α-SMA+ SFRP4+ PRG4- myofibroblasts, which are key cells in driving skin fibrosis and tethering in SSc.

Is Skin Disease a Local Manifestation of Systemic Tissue Turnover? Serological Collagen Biomarkers Provide Important Information on Skin Diseases Arising from Mutations in Collagen Genes

Signe Holm Nielsen[1], Matej Anđelić[2], Dovile Sinkeviciute[1], Anne-Christine Bay-Jensen[1] and Morten Karsdal[1], [1]Nordic Bioscience, Herlev, Denmark, [2]Nordic Bioscience, Copenhagen, Denmark

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: Systemic Sclerosis & Related Disorders – Clinical Poster III: Translational Science
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Collagens are the main constituents of the skin. Genetic mutations in type VI, VII, and XVII collagen cause skin diseases, such as atopic dermatitis, epidermolysis bullosa, and bullous pemphigoid. These are all characterized as systemic diseases, with local manifestations. Novel collagen biomarkers hold the potential to detect skin manifestations, monitor the disease course, as well as improve our understanding of the pathophysiology. The objective of this study was to develop blood-based biomarkers of type VI, VII, and XVII collagen, and investigate their diagnostic potential for skin pathologies, including systemic sclerosis.

Methods: Three novel immunoassays targeting the N-terminal of type VI collagen (C6A6), an MMP-generated neo-epitope fragment of type VII collagen (C7M), and type XVII collagen (PRO-C17) were developed and used to measure the aforementioned analyte levels in serum from healthy donors (n=25), patients with atopic dermatitis (n=20) and systemic sclerosis (n=5).

Differences between biomarker levels in healthy donors and patients with atopic dermatitis, and systemic sclerosis, were calculated by a Mann-Whitney U test. The diagnostic accuracy was evaluated by the area under the receiver operating characteristics (AUROC) curve between the individual dermatological indications and healthy controls. An AUC=0.85 was considered clinically relevant.

Results: Patients with atopic dermatitis presented higher levels of C6A6, C7M, and PRO-C17 compared to healthy donors ($p < 0.001$, $p< 0.001$, and $p=0.0005$, respectively), where C7M was significantly elevated in patients with systemic sclerosis compared to healthy donors ($p=0.0019$). Neither C6A6 or PRO-C17 could separate between healthy donors and patients with systemic sclerosis. The diagnostic accuracy of C6A6 for separating patients with atopic dermatitis from healthy controls was AUC=1.00, while the C7M biomarker presented an AUC=0.912, and PRO-C17 presented an AUC=0.842. The C7M presented a diagnostic accuracy of an AUC=0.908 for separating healthy donors and patients with systemic sclerosis.

Conclusion: There was a clear link between collagen genetic components and serological biomarkers in skin diseases. This study highlights the possible use of novel non-invasive biomarkers of collagens to describe the disease in patients with atopic dermatitis. In addition, C7M may be a useful biomarker in systemic sclerosis. These biomarkers reflect the downstream effect of different genetic mutations leading to skin disease and may be useful to determine skin involvement in rheumatic diseases, including systemic sclerosis and psoriatic arthritis.

Session Date: Tuesday, November 14, 2023

Session Title: Systemic Sclerosis & Related Disorders – Clinical Poster III: Translational Science

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: Systemic sclerosis (SSc) is characterized by an initial inflammatory phase followed by fibrosis. Esophageal dysfunction in SSc is associated with Gastroesophageal Reflux Disease (GERD), which can lead to severe complications and contribute to fibrosis. SSc patients exhibit increased numbers of specific immune cells, such as CD14+ monocytes, fibrocytes, and tissue macrophages, which are correlated with disease severity and reduced survival. However, the role of macrophage populations in the esophagus and affected tissues remains poorly understood. This study aims to investigate the transcriptional heterogeneity of macrophages in the esophagus of SSc patients.

Methods: Esophageal biopsies were obtained from SSc patients, GERD patients without SSc, and healthy control patients. scRNA-Seq was performed on 20 samples and Cellular Indexing of Transcriptomes and Epitopes by Sequencing (CITE-Seq) was performed on 7 samples where CD45+ immune cells were isolated using fluorescence-activated cell sorting (FACS). Data were processed and analyzed using the 10X Genomics 3' v3.0 pipeline and the Seurat package.

Results: Analysis of the integrated immune cell data identified 16 individual clusters from about 45,000 cells, including T cells, B cells, and various myeloid cell subsets. Within the myeloid subsets (18% of CD45+), 10 distinct clusters were identified, including multiple dendritic cell subsets ($LAMP3^+$ ~5%) and macrophages. RNA expression analysis and protein expression confirmation revealed heterogeneity among macrophage subsets, characterized by differential expression of specific markers such as FABP4, CD11b, CD11c, and CCR2, and APOE as well as varying expression of HLA-antigens, indicating differences in antigen presentation capabilities. The number of macrophages was found to be increased up to 2-fold in SSc compared to GERD patients and healthy controls.

Conclusion: This is the first study to evaluate immune cells in the esophagus of SSc patients. We demonstrate the presence of diverse macrophage subsets within the esophagus of SSc patients, each potentially contributing to distinct functions and mechanisms in the pathogenesis of SSc. These findings underscore the importance of precisely identifying immune cell populations within affected organs and targeting specific subsets to effectively intervene in the inflammatory process of SSc. Future research will investigate the differential characteristics of these macrophage subsets compared to control and GERD patients.

Session Title: Vasculitis – ANCA-Associated Poster III: Biomarkers & Renal Outcomes

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: Immunoglobulin-A vasculitis (IgAV) and IgA nephropathy (IgAN) are inflammatory conditions that share pathophysiological mechanisms[1,2]. Similar features are also described between IgAV nephritis (IgAVN) and IgAN[3]. However, whether IgAV is an extension of IgAN or a different disease entity is still inconclusive[3]. The complement system plays a crucial role in the development of immune-mediated disorders, being specifically associated with renal pathology and clinical phenotypes in patients with IgAV[4]. In this regard, C5 signalling blockage is described as a novel strategy to modulate inflammatory diseases, such as different types of vasculitis[5].

Methods: The main objective of this study was to determine the role of *C5* as a potential genetic biomarker for discriminating between IgAV and IgAN. For that purpose, 9 tag genetic variants within *C5* (rs10760128, rs74971050, rs4310279, rs7868761, rs10818495, rs2159777, rs10156396, rs3815467 and rs16910280) were genotyped in the largest series of Caucasian patients diagnosed with IgAV ever assessed for genetic studies (n=407) and in 98 Caucasian patients diagnosed with IgAN. 35.4% of our patients were IgAVN.

Results: Similar genotype distribution were observed in IgAV patients compared to those with IgAN, when *C5*variants were analyzed independently (**Table 1**). In addition, no statistically significant allele differences were disclosed between patients with IgAV patients and those with IgAN (**Table 1**). Moreover, when we compared patients with IgAVN and patients with IgAN, we did not observe genotype nor allele statistical differences (**Table 1**). Similar results were disclosed when haplotype frequencies of *C5* were compared between patients with IgAV and those with IgAN, as well as between patients with IgAV-Nand patients with IgAN (data not shown).

Table 1. Genotype and allele frequencies of *C5* in patients with IgAV and those patients with IgAN and IgAVN.

Plasma and Urine Cytokine Profiles in Active ANCA-Associated Vasculitis

Salem Almaani[1], Huijuan Song[2], Stacy Ardoin[3], Lynn Fussner[2] and Brad Rovin[2], [1]Ohio State University Medical Center, Columbus, OH, [2]Ohio State University, Columbus, OH, [3]Nationwide Children's Hospital, Columbus, OH

SESSION INFORMATION

Session Date: Tuesday, November 14, 2023
Session Title: Vasculitis – ANCA-Associated Poster III: Biomarkers & Renal Outcomes
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: ANCA-associated vasculitis (AAV) is a multisystem autoimmune disease that often affects the kidneys. It is unclear why some patients with AAV have kidney involvement while others do not. To investigate the mechanisms underlying these phenotypes, this study examined plasma and urine cytokine profiles in patients with active renal and non-renal AAV (AAGN and NR-AAV, respectively), and healthy controls (HC).

Methods: Levels of 200 cytokines were measured in the plasma and urine of 6 patients with active AAGN, 9 patients with NR-AAV, and 3 HC using a human cytokine array. Urine cytokine levels were corrected to urine creatinine and an analyte-to-creatinine ratio was utilized for analysis. Levels in the three groups were compared using ANOVA. Analytes with false discovery rate (FDR)-corrected p-values < 0.05 were further compared using Tukey HSD post-hoc test.

Table 1. Patient Characteristics

GPA	52% (12/23)
MPA	35% (8/23)
EGPA	13% (3/23)
Serum Creatinine, average ±SD	3.6 ±2.9

*not available in one patient
** all had detectable ANCAs by ELISA
Abbreviations: ANCA: antineutrophil cytoplasmic antibodies. PR3: proteinase 3. MPO: myeloperoxidase. c-ANCA: cytoplasmic ANCA. P-ANCA: perinuclear ANCA. GPA: granulomatosis with polyangiitis. MPA: microscopic polyangiititis. EGPA: eosinophilic GPA

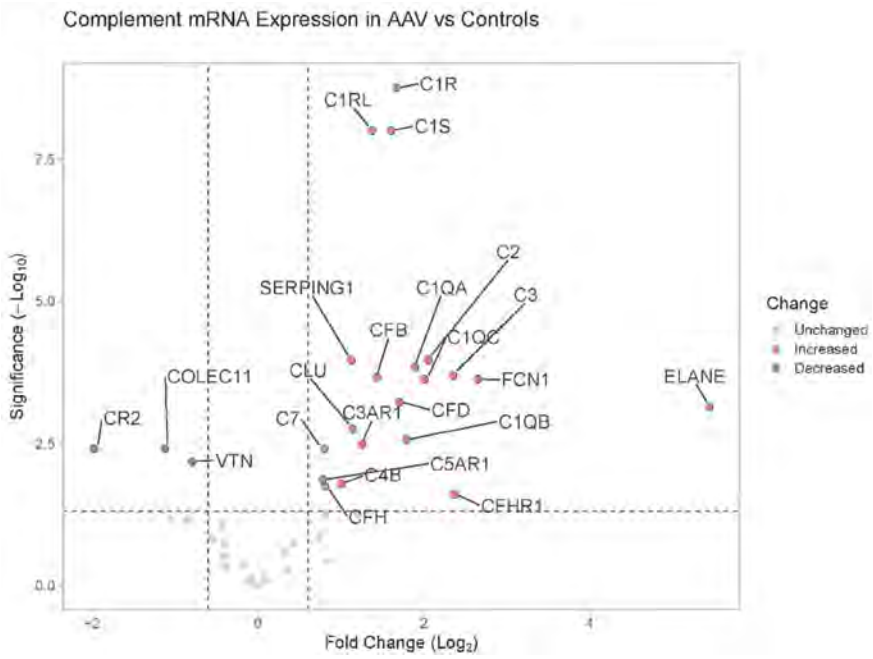

Figure 1. Difference in urine (a) and plasma (b) levels of cytokines in patients with active renal and non-renal vasculitis.

Results: Patient Characteristics are depicted in Table 1. Most cytokines measured were similar between HC and NR-AAV patients. Compared to patients with NR-AAV, patients with AAGN had higher levels of plasma and urine cytokines that are involved in involved in Th17 signaling (IL-17A, IL-17F, IL-17R, IL-23, IL-6), Th1 response (IL-12, GM-CSF, IFNg, TNFa), chemotaxis (especially for T-cells, monocytes, and dendritic cells - eotaxin-2, I-TAC, Lymphotactin, MCP-3, MIP-3a, CCL23), B and T-cell crosstalk (B7-1, CD40, CD40L), and angiogenesis (VEGFR1, FLT4, VEGF-C, VEGF-D, SDF1a) (Figure 1).

Conclusion: Compared to NR-AAV, AAGN is associated with an increase in plasma and urine levels of many pro-inflammatory cytokines. T-cell differentiation, signaling, and crosstalk seem to be the most prominent molecular processes that are active in patients with AAGN. These data suggest a prominent role of T-cells in AAGN which have the potential of being leveraged therapeutically.

Soluble Triggering Receptor Expressed on Myeloid Cell-1 Reflects the Cross-sectional Activity of Microscopic Polyangiitis and Granulomatosis with Polyangiitis

Jang Woo Ha[1], Jason Jungsik Song[2], Yong-Beom Park[2], Sung Soo Ahn[2] and Sang-Won Lee[3], [1]Yonsei University College of Medicine, Seodaemun-gu, Seoul, South Korea, [2]Yonsei University College of Medicine, Seoul, South Korea, [3]Yonsei University College of Medicine, Seoul, South Korea

SESSION INFORMATION

Session Date: Tuesday, November 14, 2023
Session Title: Vasculitis – ANCA-Associated Poster III: Biomarkers & Renal Outcomes
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: This study investigated whether the soluble triggering receptor expressed on myeloid cells-1 (sTREM-1) reflects the cross-sectional activity of microscopic polyangiitis (MPA) and granulomatosis with polyangiitis (GPA).

Methods: This study included 47 MPA and 32 GPA patients with well-documented clinical records and stored sera at diagnosis. The activity of vasculitis was assessed using the Birmingham vasculitis activity score (BVAS) The patients were arbitrarily divided into two groups according to BVAS at a frequency of 50% as the upper and lower halves of BVAS.

Results: The median age of the 79 patients was 67.0 years, and 58.2% were women. The median BVAS and sTREM-1 were 12.0 and 513.5 pg/mL. sTREM-1 was significantly correlated with BVAS along with five-factor score, short Form 36 health survey, and C-reactive protein. In the multivariable linear regression analysis, erythrocyte sedimentation rate (standardised β 0.241), and sTREM-1 (standardised β 0.288) were independently correlated with BVAS. Using the receiver operator characteristic curve, the cut-off of sTREM-1 for the upper half of BVAS was set as 474.1 pg/mL. When we divided patients into two groups based on sTREM-1 ≥474.1 pg/mL, MPA and GPA patients with sTREM-1 ≥474.1 pg/mL exhibited a significantly higher risk for the upper half of BVAS than those without (relative risk 5.932). In the multivariable logistic regression analysis with sTREM-1 ≥474 pg/mL, sTREM-1 ≥474 pg/mL (OR 5.662) was independently associated with the upper half of BVAS.

SIRPα Expression in Systemic Vasculitis

Shubhasree Banerjee[1], Eileen Rose[2], Sandip Panicker[2], Nader Khalidi[3], Curry Koening[4], Carol Langford[5], Paul Monach[6], Christian Pagnoux[7], Carol McAlear[1] and Peter Merkel[1], [1]University of Pennsylvania, Philadelphia, PA, [2]Electra Therapeutics, Inc., South San Francisco, CA, [3]McMaster University, Hamilton, ON, Canada, [4]University of Texas Dell Medical School, Austin, TX, [5]Cleveland Clinic, Cleveland, OH, [6]VA Boston Healthcare System, Boston, MA, [7]Mount Sinai Hospital, Toronto, ON, Canada

SESSION INFORMATION

Session Date: Tuesday, November 14, 2023
Session Title: Vasculitis – ANCA-Associated Poster III: Biomarkers & Renal Outcomes
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Signal regulatory protein alpha (SIRPα) is primarily found on myeloid cells, including macrophages and neutrophils. Upon binding to CD47, SIRPa signaling regulates various cellular functions, including phagocytosis, antigen presentation, cell proliferation, cellular fusion, and cell migration. Therefore, SIRPamay be involved in the pathogenesis of autoimmune diseases including systemic vasculitis. This study aimed to assess SIRPa expression in tissue samples from patients with vasculitis.

Methods: Immunohistochemical staining for SIRPα was performed on kidney, lung, and temporal artery (TA) biopsy samples from patients with granulomatosis with polyangiitis (GPA), microscopic polyangiitis (MPA), giant cell arteritis (GCA), and patients without vasculitis. Cells were grouped into 4 categories: i) monocytes/macrophages/dendritic cells; ii) neutrophils; iii) eosinophils; and iv) lymphocytes. Categories iii and iv were not analyzed because of positive isotype control staining and absence of SIRPα+ cells, respectively. A semiquantitative estimation of SIRPα+ cells in categories i and ii were reported

using the H-score system based on a visual estimate of the percentage of SIRPα+ cells and the staining intensities classified from 0 to 3 (H-score = 0 x [% with 0 intensity] + 1 x [% with 1 intensity] + 2 x [% with 2 intensity] + 3 x [% with 3 intensity]). Density of inflammatory infiltrate for individual cell categories were visually estimated and reported using an ordinal scale. Statistical analysis was done using GraphPad Prism 9.5.

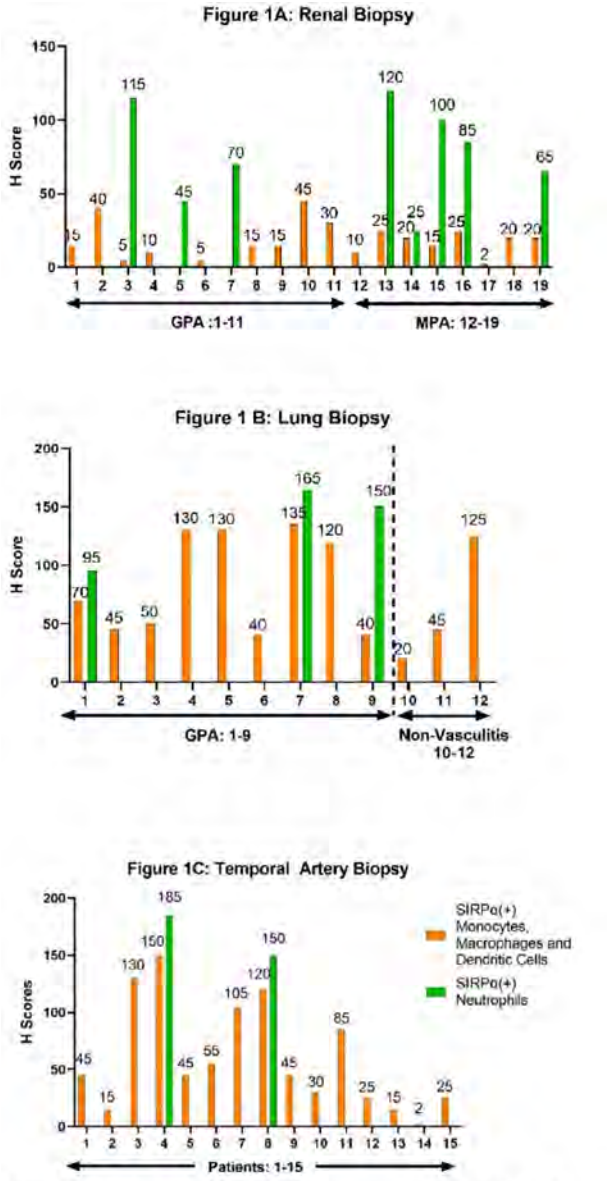

Figure 1: SIRPα expression on macrophages, monocytes, dendritic cells, and neutrophils, in tissues from patients with and without vasculitis.
Figure 1A: Three non-vasculitis kidney tissue samples had no SIRPα staining. Figure 1B: Non-vasculitis lung tissue samples (# 10, 11, 12 had macrophages and monocytes and thereby demonstrated SIRPα staining. Figure 1C: Three temporal artery biopsy samples without vasculitis had no SIRPα staining.

Figure 1: SIRPα expression on macrophages, monocytes, dendritic cells, and neutrophils, in tissues from patients with and without vasculitis. Figure 1A: Three non-vasculitis kidney tissue samples had no SIRPα staining. Figure 1B: Non-vasculitis lung tissue samples (# 10, 11, 12 had macrophages and monocytes and thereby demonstrated SIRPα staining. Figure 1C: Three temporal artery biopsy samples without vasculitis had no SIRPα staining.

Results: Samples from 43 patients (20 with GPA, 8 with MPA, and 15 with GCA) were included in the study. Tissue samples included kidney from 11 patients with GPA and 8 patients with MPA; lung from 9 patients with GPA; and TA from 15 patients with GCA. All renal biopsies demonstrated glomerulonephritis with crescents. Inflammation was found in all the lung tissue samples and 6/9 (67%) demonstrated granuloma formation. All 15 TA samples showed inflammation in the arterial wall consistent with the diagnosis of GCA and 9 (60%) demonstrated granuloma formation/multinucleated giant cell infiltration and disruption of the internal elastic lamina. **Figure 1** summarizes the data on SIRPa expression by tissue type. All tissue samples from patients with active vasculitis showed SIRPα staining. Due to absence of infiltrating immune cells, the kidney and TA samples from patients without vasculitis did not show any SIRPα staining. However, due to the presence of tissue-resident

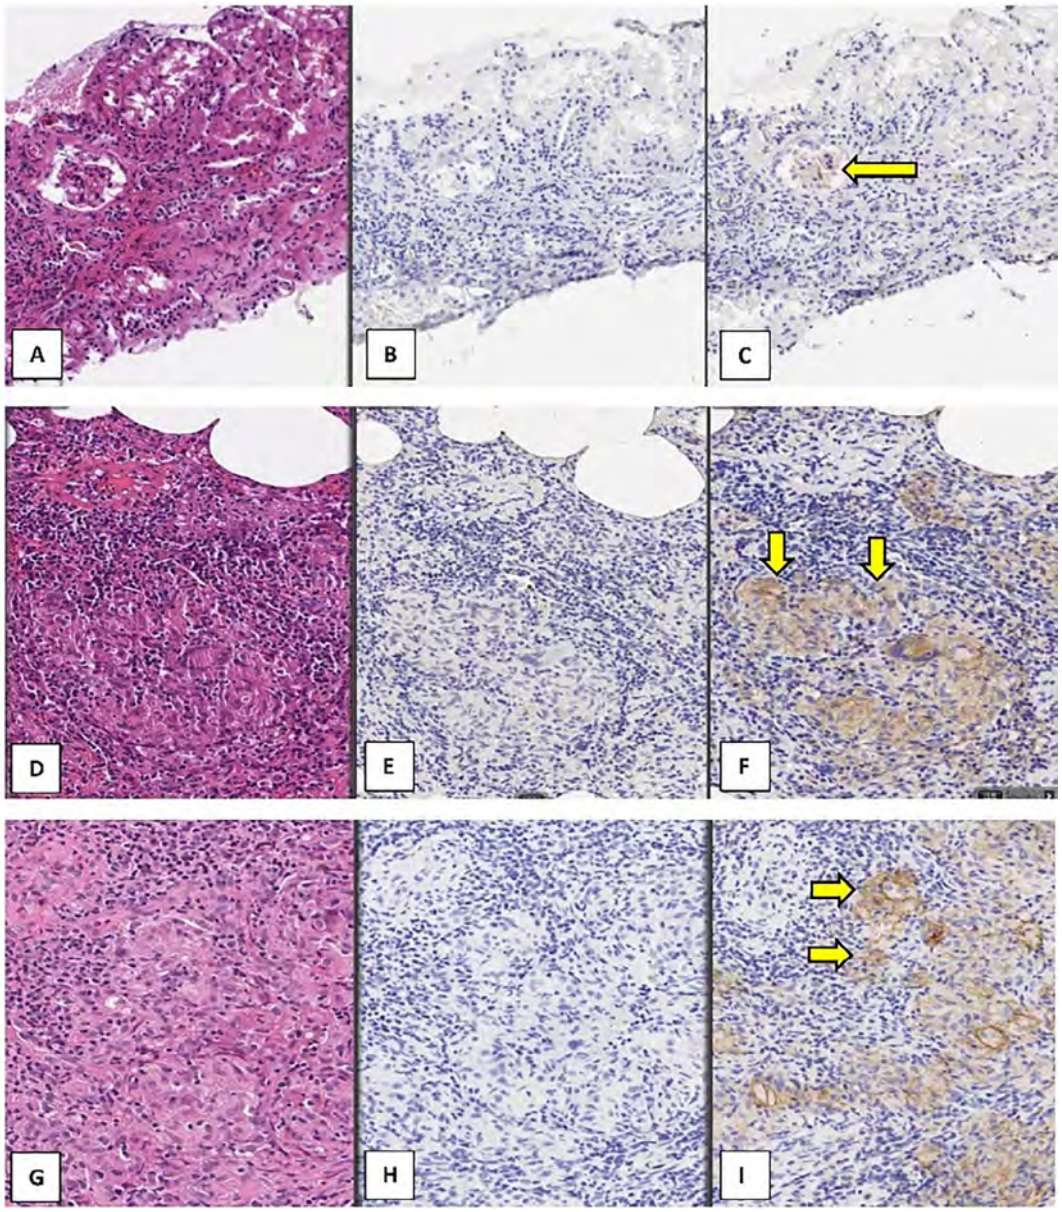

Figure 2: Tissue samples from patients with granulomatosis with polyangiitis, microscopic polyangiitis, and giant cell arteritis demonstrating SIRPα Expression. Figure: 2A-C: Renal biopsy from a patient with granulomatosis with polyangiitis; Figure 2D-F: Lung biopsy from a patient with granulomatosis with polyangiitis: Figure 2G-I: Temporal artery biopsy from a patient with giant cell arteritis. Figures A, D, and G: H&E staining; Figures B, E, and H: Control rabbit IgG monoclonal antibody (DA1E) stain which is the negative control stain for anti- SIRPα stain; Figures C, F , and I: anti-SIRPα antibody D613M stain. The yellow arrows demonstrate some areas of positive SIRPα stain. Magnification of all images was at 20X.

macrophages and monocytes, lung tissue from patients without vasculitis showed SIRPα staining. **Figure 2** provides examples of SIRPα staining in tissue samples from patients with vasculitis. **Figure 3** shows the overall density of inflammatory infiltrate of cell categories i and ii in the tissues.

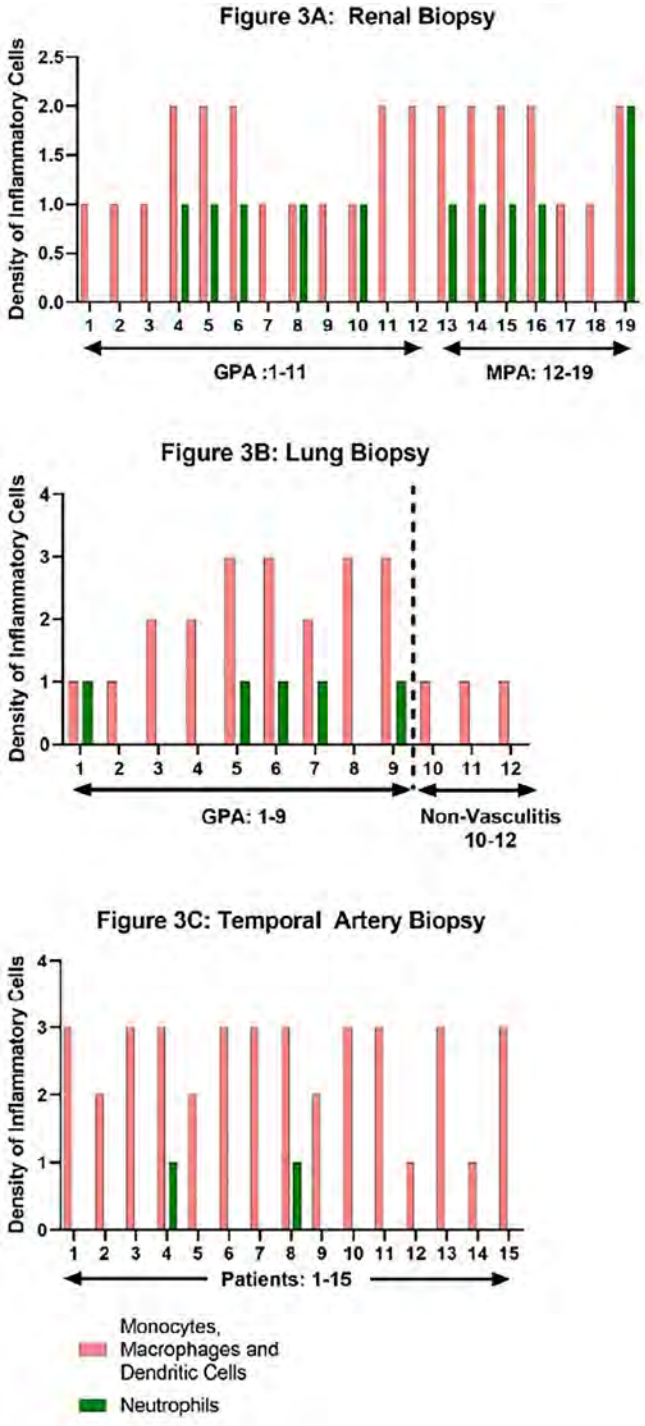

Figure 3: Density of infiltration of macrophages, monocytes, dendritic cells, and neutrophils, in tissues from patients with and without vasculitis. An ordinal scale ranging from 0 to 3+ (0 = none, 1+ = rare/mild, 2+ = moderate, 3+ = severe/dense inflammatory infiltrate) was used to represent the density of each cell type infiltrate. Figure 3A: Three non-vasculitis kidney tissue samples had no inflammatory infiltrate. Figure 1B: Non-vasculitis lung tissue samples (# 10, 11, 12) had infiltration of macrophages and monocytes. Figure 1C: Three temporal artery biopsy samples without vasculitis had no inflammatory infiltrate.

Conclusion: This study demonstrates high-level expression of SIRPα in macrophages and monocytes in affected tissues in systemic vasculitis. Some tissues also had SIRPα+ neutrophils. These findings pave the way for further studies exploring the role of the SIRPα/CD47 pathway in the pathogenesis of systemic vasculitis and the potential for blockade of SIRPα and/or the depletion of SIRPa+ cells as treatment of systemic vasculitis.

SESSION INFORMATION

Session Date: Tuesday, November 14, 2023

Session Title: Vasculitis – ANCA-Associated Poster III: Biomarkers & Renal Outcomes

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: ANCA-associated vasculitis (AAV) is a life-threatening disorder characterized by a relapsing-remitting disease course necessitating immunosuppression to control disease activity. Balancing the risks of infection against maintaining good disease control is crucial and yet often challenging. There is a lack of validated biomarkers to tailor immunosuppression to minimize therapy-related complications while maintaining a relapse-free period. The monitoring of Torque teno virus (TTV) has been successfully used in transplant medicine to predict the risk of organ rejection and infectious complications. However, the presence and role of TTV in association with clinical outcomes in AAV has yet to be reported.

Methods: Consecutive plasma samples (N=915) of 81 patients with AAV from the RAVE trial were used for assessment of the TTV load. Participants received either rituximab (RTX, N=40) or cyclophosphamide (CYC, N=41) followed by azathioprine (AZA). The TTV DNA was quantified using a real-time polymerase chain reaction method (TTV R-GENE®, BioMérieux) at multiple study visits. Change in TTV load and differences between non-relapsing and relapsing patients were investigated during a follow-up period of 1080 days.

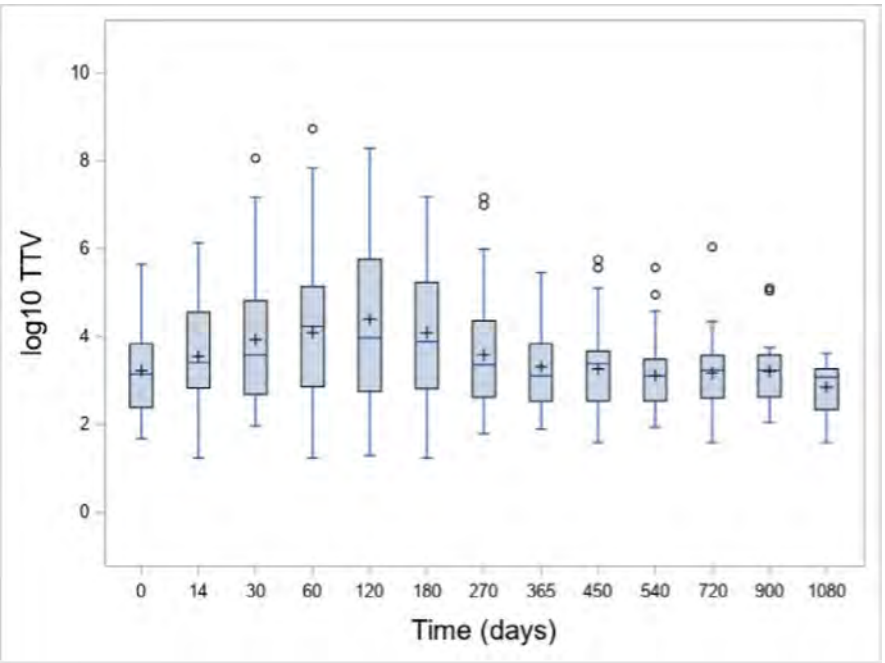

Figure 1. Change in TTV load after randomization in the study cohort of patients with ANCA-associated vasculitis. Box plots represent the interquartile range, while plus signs indicate the mean value.

Results: In total, 915 TTV quantifications were performed. At baseline, 72% (N=58) of patients had detectable TTV in the peripheral blood. The baseline median TTV load of all patients was 3 x 10^2 c/mL (interquartile range [IQR]: 0 – 3 x 10^3 c/mL). TTV load increased after initiation of immunosuppression and peaked at day 120 (median 2 x 10^3 c/mL, IQR: 2 x 10^2 – 5 x 10^5; Figure 1) and was detectable in 80% of the patients. Patients receiving RTX as a remission induction therapy showed a non-significant higher TTV load during the first 180 days in comparison to CYC/AZA-treated individuals at any visits. Patients with disease relapse had a lower TTV load at day 120 as compared to those without relapse (median 4 x

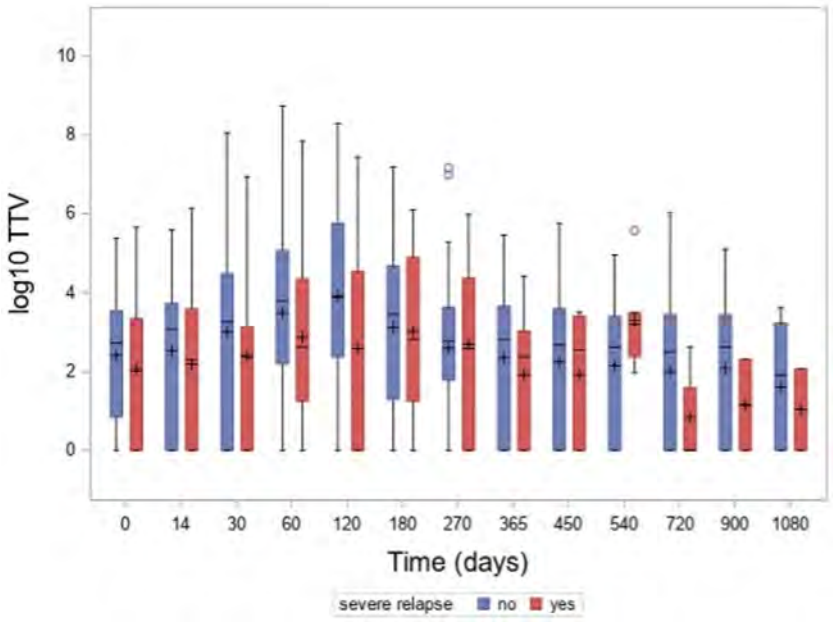

Figure 2. TTV load in the study cohort of ANCA-associated vasculitis patients with and without a disease relapse over time. Box plots represent the interquartile range, while plus signs indicate the mean value.

10^2 [IQR: 0 – 3 x 10^4] c/mL vs median 8 x 10^3 [IQR: 2 x 10^2 – 6 x 10^5] c/mL, p=0.036, respectively; Figure 2). For the 25 severe relapses, the median time to relapse was 339 (IQR: 232-516) days. Six relapses occured before 120 day, while 19 after day 120.

Conclusion: Among patients with AAV, TTV load reflects the intensity of immunosuppression and is associated with disease relapses. These results suggest that TTV might be a biomarker for the assessment of immunocompetence and identifying patients at risk of relapse in AAV.

SESSION INFORMATION

Session Date: Tuesday, November 14, 2023

Session Title: Vasculitis – ANCA-Associated Poster III: Biomarkers & Renal Outcomes

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: Interleukin 7 (IL-7) is a hematopoietic growth factor produced by stromal cells in the bone marrow and thymus, which is indispensable in maintaining immune cells. The transcriptome analysis using CD8 positive T cells demonstrated genes involved in the IL-7 receptor pathway were the poor prognostic factor in anti-neutrophil cytoplasmic antibody (ANCA)-associated vasculitis (AAV) (McKinney EF, Nat Med 2010;16:586–91). However, the clinical utility of the

serum IL-7 levels in AAV is unknown. We aimed to elucidate the clinical characteristics of patients with AAV with high serum IL-7 levels.

Methods: We retrospectively analyzed 60 patients newly diagnosed with AAV (granulomatosis with polyangiitis (GPA) and microscopic polyangiitis (MPA)) from March 2010 to April 2022 with preserved sera. We collected medical records from baseline variables at diagnosis, including clinical symptoms, laboratory data, treatments, and outcomes. Multiplex cytokine and chemokine bead assays were performed using preserved serum supernatants. Serum samples from 101 healthy donors were used to define the normal serum IL-7 levels. We compared clinical indices between the patients with and without high levels of IL-7 defined by the median levels of serum IL-7.

Results: The median serum levels of IL-7 were 8.3pg/mL (IQR: 5.3pg/mL - 15.1pg/mL) and 22.4pg/mL (IQR: 11.9pg/mL - 46.6pg/mL) in healthy donors and patients with AAV, respectively. The median levels of IL-7 (22.4pg/mL) divided the patients with AAV into two groups (30 patients for each group). The IL-7 high group had significantly higher total Birmingham Vasculitis Activity Score (BVAS), higher white blood cell count, higher neutrophil count, higher platelet count, higher CRP level, lower lymphocyte count, and lower IgG levels compared to the IL-7 low group (Table). The serum levels of IL-7 correlated with the total BVAS score significantly (ρ=0.28 (Spearman's rank correlation coefficient), p=0.028). No significant differences were shown in the type of ANCA (MPO-ANCA or PR3-ANCA) and the diseases (GPA or MPA). There were no

Table: Clinical characteristics of AAV with low and high levels of serum IL-7

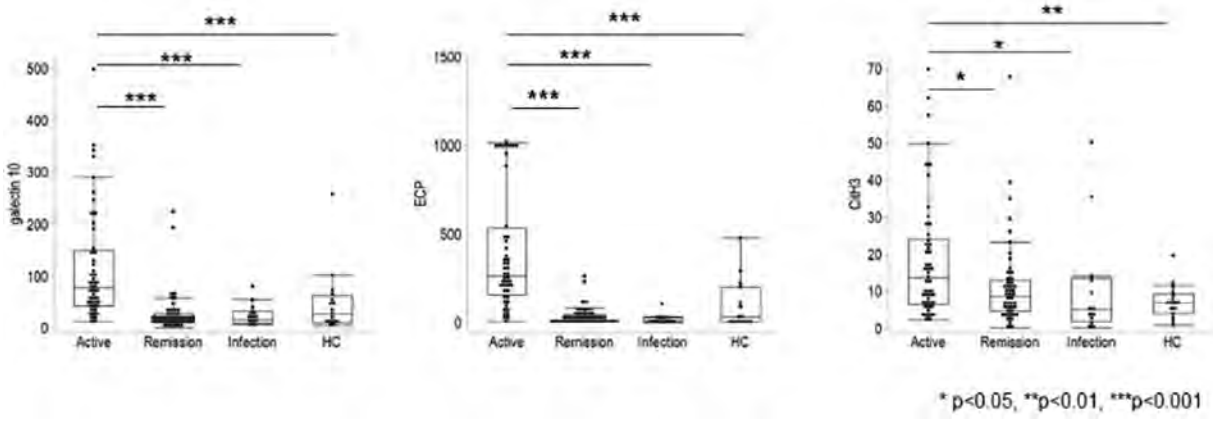
Eosinophil Activation as a Biomarker for Discriminating Active and Remission Phase in ANCA-Associated Vasculitis

Teppei Hashimoto[1], Kazuteru Noguchi[2], Yuko Minagawa[2], Takeo Abe[2], Masao Tamura[2], Tetsuya Furukawa[1], Naoto Azuma[2] and Kiyoshi Matsui[1], [1]Hyogo Medical University, Nishinomiya, Japan, [2]Hyogo Medical University, School of Medicine, Nishinomiya, Japan

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: Vasculitis – ANCA-Associated Poster III: Biomarkers & Renal Outcomes
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Antineutrophil cytoplasmic antibody (ANCA)-associated vasculitis (AAV) is a life-threatening disease requiring complex management due to a lack of suitable biomarkers. Elevated or persistently positive ANCA titer as an indicator of disease activity or relapse in patients with AAV remains controversial. ANCA can activate eosinophils to induce cell

Figure 1



The serum concentrations of galectin-10, ECP, and CitH3 in active AAV, in remission AAV, remission with infection AAV, and HC groups. *p < 0.05. **p < 0.01, ***P < 0.001; (Mann–Whitney U test)

death, which in turn releases histone-coated filamentous DNA, referred to as eosinophil extracellular traps (EETs). Eosinophils play an important role in eosinophilic granulomatosis with polyangiitis, and galectin-10, which is released from EETs, is useful as a biomarker. However, the role of eosinophils in granulomatosis with polyangiitis (GPA) and microscopic polyangiitis (MPA) remains unclear. Therefore, we investigated the association of galectin 10, eosinophil cationic protein (ECP), and citrullinated histone H3 (CitH3), which is a marker of EETs and neutrophil extracellular traps, with disease activity in GPA and MPA using Birmingham Vasculitis Activity Score (BVAS).

Methods: Serum concentrations of galectin-10, ECP, and CitH3 were retrospectively examined in 50 patients with AAV both in active and remission states, 13 patients with AAV in remission states with infection, and 16 age- and sex-matched healthy controls using ELISA kits. Additionally, the association between disease activity and conventional markers such as ANCA and CRP was also evaluated.

Results: The serum concentrations of galectin-10, ECP, and CitH3 in active AAV were significantly higher than those in remission AAV, remission with infection AAV, and HC groups (Figure 1). BVAS was associated with galectin-10 and ECP ($r=0.62$, $p< 0.001$ and $r=0.69$, $p< 0.001$, respectively), but only weakly associated with CitH3 ($r=0.21$, $p< 0.05$). ANCA titer was associated with the BVAS score ($r=0.71$, $p< 0.001$). Elevated serum galectin-10, ECP, and ANCA titers were identified as factors associated with the active phase using multivariate analysis with eosinophil count as a covariate. Receiver operating characteristic analyses for galectin-10, ECP, and ANCA titers for discriminating between active disease and remission revealed an area under the curve (AUC) of 0.886, with a sensitivity of 81.3% and specificity of 85%, AUC of 0.938, with a sensitivity of 83.3% and specificity of 95.1%, and AUC of 0.888, with a sensitivity of 69.4% and specificity of 93.5%, respectively.

Conclusion: Galectin-10 and ECP levels are elevated in patients with GPA and MPA, and can discriminate between active disease and remission independent of eosinophil counts. This suggests that the activation of both neutrophils and eosinophils is important for disease activity.

morbidity and mortality, has not been adequately studied in older adults with AAV and provides a more holistic assessment.

The objective of this study was to compare the impact of age and frailty on early (≤ 2 years of diagnosis) end-stage renal disease (ESRD), severe infection, and death in adults with incident AAV who are ≥ 75 years old vs 65-74 years old.

Methods: Patients ≥ 65 years were included from the 2002-2019 Mass General Brigham AAV cohort, a consecutive inception cohort. EGPA patients were excluded. Covariates including demographics, disease characteristics, and the Charlson comorbidity index were assessed at baseline. Disease activity at diagnosis was assessed using the Birmingham Vasculitis Activity Score (BVAS/GPA). Baseline frailty was measured using the claims-based frailty index (CFI); pre-established cut-offs defined degrees of frailty (robust, pre-frail, mildly frail, and moderately/severely frail).[1]

Death and ESRD (composite outcome) were ascertained from linkage to national registries and/or medical records. Severe infections were identified utilizing inpatient data or as a code in death certificate. The cumulative incidence of the death/ESRD and severe infections at 2-years were estimated. Kaplan-Meier curves for the probability of composite outcome and severe infection by age and frailty were generated. Multivariable analysis was performed to compare the association of age and frailty with death/ESRD and severe infections within 2 years of treatment initiation.

Results: There were 298 patients included. Most were female (61%), white (86%), MPO-ANCA+ (80%), and had renal involvement (72%). Patients ≥ 75 years old (n=156) had a median age of 81 years, while median age was 69 years in the 65-74 years group (**Table 1**).

The cumulative incidence at 2 years of death/ESRD (23.1% [95% CI 16.5, 29.7]) vs 5.6% [95% CI 1.8, 9.4]) and severe infection (34.0% [95% CI 26.5, 41.4] vs 12% [95% CI 6.6, 17.3]) were higher in AAV patients ≥ 75 vs 65-74 years old. In the multivariable analysis, age ≥ 75 years was associated with an increased risk of composite outcome (hazard ratio (HR) 4.22, 95% CI 1.94-9.15); frailty was not (HR 2.02, 95% CI 0.46,8.81) (**Table 2, Figure 1**). In contrast, both frailty (HR 8.9, 95% CI 2.20,36.90) and age ≥ 75 years (HR 2.90, 95 CI% 1.73, 4.47) appeared to be independent risk factors for severe infections at 2-year follow-up; the association with frailty appeared greater.

Conclusion: AAV patients aged ≥ 75 vs 65-74 years had a higher incidence of death/ESRD and severe infections. Older age was associated with death/ESRD and severe infection risk. Frailty was a strong risk factor, independent of age, for severe infection. These findings highlight the need for innovative considerations beyond age when assessing outcome risks in older adults with AAV.

Table 2. Univariable and multivariable analyses for factors associated with outcomes in older adults with AAV at 2 years ESRD = end-stage renal disease, CFI = Claims-based frailty index, BVAS = Birmingham Vasculitis Activity Score, CYC = cyclophosphamide aAdjusted for sex, frailty, pulmonary involvement, renal involvement, and BVAS/GPA. bAdjusted for age, sex, pulmonary involvement, renal involvement, and BVAS/GPA.

Session Date: Tuesday, November 14, 2023
Session Title: Vasculitis – ANCA-Associated Poster III: Biomarkers & Renal Outcomes
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: ANCA-associated vasculitis (AAV) commonly causes renal damage, leading to a spectrum of chronic kidney disease (CKD) and end-stage renal disease (ESRD). Quantitative descriptions of the longitudinal course of renal dysfunction in AAV have recently been published from the 2002-2017 Mass General Brigham (MGB) AAV cohort. We aimed to further investigate these findings in an expanded cohort with additional years of follow-up.

Table 1. Baseline Characteristics of the Study Cohort

	Overall (N=375)	Rapid decline (N=23, 6%)	Impaired (N=109, 29%)	Preserved (N=216, 58%)	Improvement (N=27, 7%)	p-value
Probability of group membership (mean, SD)	0.99 (0.96-1.0)	1.0 (1.0-1.0)	0.99 (0.86-0.99)	0.99 (0.97-0.99)	1.0 (0.99-1.0)

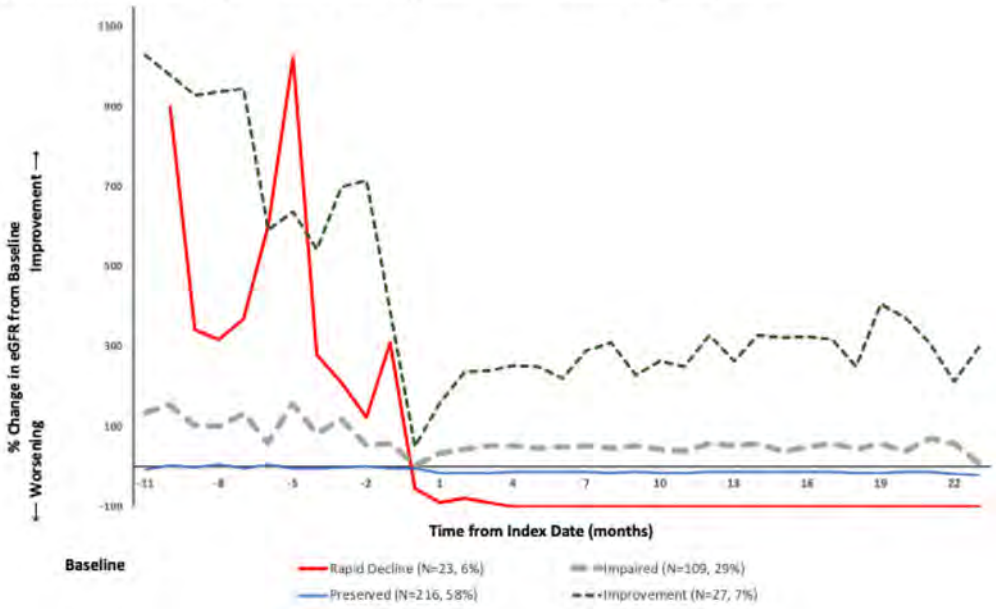
CKD III+ at 5 years	88 (48)	10 (100)	37 (69)	36 (34)	5 (38)	<0.001
Mortality						
Death	105 (28)	14 (61)	31 (28)	54 (25)	6 (23)	0.004
Follow-up time to death or censorship	5.7 (2.2-8.7)	5.2 (0.7-7.5)	5.7 (1.9-8.5)	5.7 (2.4-8.7)	5.9 (2.0-10)	0.01

CKD: Chronic kidney disease. ESRD: End-stage renal disease.
*Defined as (1) need for dialysis for >12 weeks, (2) dialysis until death if the patient died between 14-84 days of follow up, or (3) renal transplant.
** Among those with determined cause of ESRD.
***Among those who experienced ESRD.

Methods: We included patients from the MGB AAV cohort (2002-2022). A "baseline" measurement (±30 d from treatment initiation, the index date) of renal function was required along with one additional test. Renal function was assessed at up to monthly intervals, from -12 m to +24 m relative to the index date. Group-based trajectory modeling was used to identify distinct renal function trajectories. We assessed between-group differences (between all trajectory groups) with the chi-square and Kruskall-Wallis tests. Time to ESRD was compared using the log-rank test.

Figure: Observed Renal Trajectories in the Expanded Mass General Brigham Cohort



Results: We identified 4 renal trajectory groups among 375 patients: rapid decline (N=23 [6%]), impaired (N=109 [29%]), preserved (N=216 [58%]), and improvement (N=27 [7%]) (Figure). The median posterior probability of group membership was >0.98 in all groups, indicating excellent fit. Age, sex, race and ANCA type were not statistically different between groups. Renal vasculitis was found in all patients in the rapid decline (N=23 [100%]) and improvement (N=27 [100%]) groups, and in a majority of the impaired (N=92 [84%]), compared to a minority of the preserved group (N=100 [46%]; p< 0.001). Pulmonary vasculitis was more common among the rapid decline (N=13 [57%]) and preserved (N=131 [61%]) groups, compared to the impaired (N=41 [38%]) and improvement (N=10 [37%]) groups (p< 0.001). Otolaryngological and mucosal manifestations were most common in the preserved group (Table 1). The rapid decline group had the greatest baseline comorbidity, followed by the impaired group (p< 0.001; Table 1). Diabetes was equally common between groups, but there was a strong trend toward a higher rate of hypertension among the rapid decline and improvement groups vs the impaired and preserved groups (p=0.06). Disease activity by baseline Birmingham Vasculitis Activity Score was higher in the rapid decline (6 [4, 7]) and improvement (6 [4, 9]) groups, compared to the impaired (5 [4, 6.5]) and preserved (4 [3, 6]) groups (p< 0.001). ESRD occurred in 49 patients. In the rapid decline group, 22 patients (96%) experienced ESRD, compared to 11 (10%) in impaired, 15 (7%) in preserved and 1 (4%) in the improvement group (Table 2). ESRD occurred at a median of < 1 m from the index date in rapid decline vs 3.5 y (IQR 0, 6.8) in impaired and 2.5 y (IQR 0, 5.6) in the preserved group (log-rank p< 0.001). The cause of ESRD was active AAV in 91% of cases in the rapid decline, vs 45% in the impaired and 33% in the preserved group (p=0.01; Table 2).

Conclusion: We identified 4 distinct renal trajectory groups in an expanded AAV cohort. Trajectory groups were distinguished by variation in baseline comorbidity, rates of ESRD and CKD, and timing and cause of ESRD. Confirmation in a separate cohort will be required.

A Real-World Descriptive Study of Renal Outcomes Among Patients with ANCA-Associated Vasculitis Initiating Remission Induction Therapy

Sam Oh[1], Sushmitha Inguva[2], Pallavi Rane[2] and Brian Tumminello[3], [1]Amgen, Inc., South San Francisco, CA, [2]Amgen, Inc., Thousand Oaks, CA, [3]Amgen, Inc., San Juan Capistrano, CA

SESSION INFORMATION

Session Date: Tuesday, November 14, 2023
Session Title: Vasculitis – ANCA-Associated Poster III: Biomarkers & Renal Outcomes
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: ANCA-associated vasculitis (AAV) is a group of rare autoimmune diseases characterized by inflammation and necrosis of small- to medium-sized blood vessels, commonly affecting the kidneys. Clinical characteristics have been used to categorize AAV into different subtypes, including microscopic polyangiitis (MPA) and granulomatosis with polyangiitis (GPA). This study describes baseline characteristics and renal outcomes among patients with GPA or MPA who initiated remission induction therapy (RIT).

Methods: An observational retrospective cohort study using data from the MarketScan® Commercial and Medicare Supplemental claims database was conducted among patients diagnosed with GPA (ICD-10-CM M31.3, M31.30, M31.31) or MPA (M31.7) between April 1, 2016 and January 31, 2023. Patients must have been ≥18 years old on the GPA or MPA

diagnosis date (index date) and had ≥6 months of continuous medical and prescription enrollment prior to the index date (the baseline period). The study period was chosen to coincide with the availability of ICD-10 diagnosis codes for GPA and MPA. All available data prior to the index date were used to determine whether AAV diagnosis was prevalent based on the presence of claims for AAV prior to the index date, or presumptive incident based on the absence of AAV claims before the index date. Renal outcomes during follow-up were examined among the subset of presumed incident GPA or MPA patients initiating RIT, based on their first use of rituximab or cyclophosphamide. Renal outcomes included moderate-to-severe chronic kidney disease (CKD), defined as Stage 3 or higher, end-stage renal disease (ESRD), dialysis, and kidney transplant. The cumulative incidence for all available follow-up was estimated for each renal outcome.

Results: A total of 4,878 patients with GPA or MPA were identified. Among these, 33% (n=1,604) were prevalent cases, and 67% (n=3,274) were presumptive incident cases, with a higher proportion of prevalent cases among patients with GPA (35%, n=1,477) than MPA (18%, n=127). RIT was initiated among 23% (n=625) and 32% (n=185) of patients with presumptive incident GPA and MPA, respectively. These patients were primarily female (54% for GPA, and 68% for MPA) and age (mean ± standard deviation [SD]) at diagnosis was 51.9 ± 13.8 for GPA, and 57.7 ± 13.2 for MPA, respectively (Table 1). The prevalence of comorbidities between patients with GPA or MPA was generally similar, though comorbidities with renal or vascular involvement tended to be more frequent in patients with MPA than with GPA (Table 1). Claims for systemic steroids and immunosuppressive drugs were similar for patients with GPA (77% and 24%) and MPA (76% and 33%),

Table 1: Baseline and clinical characteristics of patients with presumptive incident AAV who initiated RIT

Characteristic	GPA or MPA (n = 810)	GPA (n = 625)	MPA (n = 185)
Mean age at diagnosis, years (SD)	53.2 (13.9)	51.9 (13.8)	57.7 (13.2)
Female patients (%)	465 (57.4%)	339 (54.2%)	126 (68.1%)
Selected comorbidities, n patients (%)			
Metabolic			
Hyperlipidemia	283 (34.9%)	205 (32.8%)	78 (42.2%)

Allergic rhinitis	128 (15.8%)	112 (17.9%)	16 (8.6%)
Renal/urologic			
Hematuria	220 (27.2%)	157 (25.1%)	63 (34.1%)
Proteinuria	181 (22.3%)	118 (18.9%)	63 (34.1%)
Glomerulonephritis	112 (13.8%)	76 (12.2%)	36 (19.5%)
Immune			
Rheumatoid arthritis	81 (10.0%)	63 (10.1%)	18 (9.7%)
Systemic lupus erythematosus	42 (5.2%)	27 (4.3%)	15 (8.1%)
Medications of interest, n patients (%)			
Systemic steroids	623 (76.9%)	482 (77.1%)	141 (76.2%)
Immunosuppressive drugs	214 (26.4%)	153 (24.5%)	61 (33.0%)
Mycophenolate mofetil	38 (4.7%)	29 (4.6%)	9 (4.9%)
Azathioprine	33 (4.1%)	23 (3.7%)	10 (5.4%)
Methotrexate	61 (7.5%)	49 (7.8%)	12 (6.5%)
Rituximab	95 (11.7%)	60 (9.6%)	35 (18.9%)
Cyclophosphamide	20 (2.5%)	13 (2.1%)	7 (3.8%)

AAV: ANCA-associated vasculitis. GPA: granulomatosis with polyangiitis. MPA: microscopic polyangiitis. RIT: remission induction therapy. SD: standard deviation.

Table 2: Cumulative incidence of selected renal outcomes among presumptive incident patients with GPA or MPA after initiating RIT

Outcome	Number of events	Patients at risk[1]	Cumulative incidence
Moderate to severe CKD (Stage 3 to 5)			
GPA or MPA	161	604	161 (26.7%)
GPA	128	491	128 (26.1%)
MPA	33	113	33 (29.2%)
End-stage renal disease			
GPA or MPA	74	758	74 (9.8%)
GPA	58	589	58 (9.8%)
MPA	16	169	16 (9.5%)
Dialysis			
GPA or MPA	89	722	89 (12.3%)
GPA	69	563	69 (12.3%)
MPA	20	159	20 (12.6%)
Kidney transplant			
GPA or MPA	22	801	22 (2.7%)
GPA	18	618	18 (2.9%)
MPA	4	183	4 (2.2%)

[1]Excludes patients who had claims for an outcome prior to initiating RIT.

CKD: chronic kidney disease. GPA: granulomatosis with polyangiitis. MPA: microscopic polyangiitis. RIT: remission induction therapy.

respectively. The cumulative incidences of CKD, dialysis, ESRD, and kidney transplant among patients with GPA or MPA were 27%, 12%, 10%, and 3%, respectively, and were similar across AAV subtypes (Table 2).

Conclusion: This study indicates that there remains a substantial burden of renal disease among patients with presumptive incident GPA or MPA after initiating RIT in a real-world setting.

Renal Survival Rate of ANCA-associated Vasculitis in Korea: A Nationwide Population-Based Study Using Claims Data

Chan-Bum Choi[1], Jung-Min Shin[2], Nayeon Choi[3] and Soorack Ryu[3], [1]Hanyang University Hospital for Rheumatic Diseases, Seoul, South Korea, [2]Nowon Eulji Medical Center, Eulji University School of Medicine, Seoul, South Korea, [3]Biostatistical Consulting and Research Lab, Medical Research Collaborating Center, Hanyang University, Seoul, South Korea

SESSION INFORMATION

Session Date: Tuesday, November 14, 2023

Session Title: Vasculitis – ANCA-Associated Poster III: Biomarkers & Renal Outcomes

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: ANCA-associated vasculitis (AAV) is a rare systemic autoimmune disease with varying reports of incidence rates and clinical manifestations. Renal involvement is one of the most common manifestations and it can potentially progress to end-stage renal disease (ESRD). This study investigated the incidence rate and renal survival rate of patients with AAV using national health database in Korea.

Methods: Data were collected from the Korean National Health Insurance Claims Database. Incident AAV cases, according to the previously validated case-finding algorithm of AAV, between January 2010 to December 2019 were identified. Inverse probability treatment weights based on propensity scores and Cox's regression analysis were used to calculate the renal survival rate of patients with AAV and compared to that of the patients with primary glomerulonephritis (PGN) and among disease subgroups.

Results: We identified a total of 2,048 AAV patients, consisting of 876 granulomatosis with polyangiitis (GPA), 646 eosinophilic granulomatosis with polyangiitis (EGPA) and 526 microscopic polyangiitis (MPA) and 57,549 patients with PGN. The percentage of patients with renal replacement treatment (RRT) in AAV was 20.5% (n=419), consisting of 18.7%, 4.5%, and 43% in GPA, EGPA and MPA, respectively. A total of 33,931 (59%) patients underwent RRT in PGN. The overall risk of ESRD was significantly lower in AAV group (hazard ratio [HR] 0.3, $p< 0.001$) compared to the PGN group after adjusting for age and sex. Among AAV subtypes, renal survival rate was superior in the order of EGPA, GPA and MPA (HR 0.08, 0.29, and 0.9, respectively and all p-values were < 0.001) compared to that of PGN.

Conclusion: A considerable number of AAV patients required RRT. Renal survival rate of AAV was favorable compared to PGN.

ANCA-associated Vasculitis and Renal Disease in a Multidisciplinary Outpatient Clinic in Northern Spain

Salma Al Fazazi[1], Fabricio Benavides[2], Vanesa Calvo Río[3], maria rodriguez Vidriales[2], clara escagedo Cagigas[2], monica renuncio garcia[2], luis martin penagos[4] and Ricardo Blanco[5], [1]Hospital Universitario Puerta Del Mar, Cádiz, Spain, [2]Hospital Universitario Marqués de Valdecilla, Santander, Spain, [3]Valdecilla Hospital, Santander, Spain, [4]Division of Nephrology, Immunopathology Group, Hospital Universitario Marqués de Valdecilla-DIVAL, Santander, Spain, [5]Hospital Universitario Marqués de Valdecilla, IDIVAL, Santander, Spain

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: Vasculitis – ANCA-Associated Poster III: Biomarkers & Renal Outcomes
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: The severity of clinical features and outcomes in previous series of patients reported with renal disease related to ANCA-associated vasculitis (AAV) vary greatly, probably due to selection bias.

To establish the actual clinical spectrum of renal disease due to AAV in a multidisciplinary outpatient clinic in Northern Spain.

Methods: Review of 132 patients classified as having AAV between 1994 to 2022; Granulomatosis with polyangiitis (GPA), Microscopic polyangiitis (MPA) or Eosinophilic Granulomatosis polyangiitis (EGPA) was classified according to 2022 ACR/EULAR classification criteria.

Results: Renal disease was observed in 82 of 132 (62.1%) AAV (38 men/44 women), median age 61.37 years (24-87 years). Table reflects the main clinical findings and outcomes.

Renal biopsy was performed in 44 patients (36 patients showing a pauci-immune crescentic glomerulonephritis). The remaining 38 patients were not biopsied due to patient disagreement, mild renal disease or contraindication for biopsy.

The most frequent ANCA antibody specificity was MPO (64.6%) followed by PR3 (26.8%) and double positivity in 3 patients (2 MPO and PR3 and 1 MPO and MBG).

43 patients were classified as MPA (52.4%), of those, 18 patients (21.9%) had renal limited vasculitis, 27 GPA (32.9%), and 4 EGPA (4.9%). The rest of the patients had other renal disease (5 microhematuria, 1 amyloidosis, 1 diabetes nephropathy and 1 nephroangiosclerosis).

Nephritic syndrome was the most common renal manifestation when the vasculitis was fully established (56.1%).

The most frequent therapies used were corticosteroids (68.3%), Cyclophosphamide (46.3%), Azathioprine (35.4%), Rituximab (34.1%) and mycophenolate mofetil (23.2%).

After a median follow-up of 6.23 years (7 days-22.9 years) the last median creatinine and glomerular filtration rate (GFR) was 1.4 mg/dl and 43 ml/min, respectively.

Renal function worsened compared to baseline in 78.3% of MPO positive and only in 33% of PR3 positive (p=0.005).

During the first 12 months follow-up, stabilization or normalization GFR (median GFR at 1 year: 50 ml/min) was observed in 47.1% with no statistical differences among ANCA groups (p=0.303).

Table. Main clinical findings and outcomes of patients with AAV and renal disease. Abbreviations: ANCA-associated vasculitis (AAV), Granulomatosis with polyangiitis (GPA), eosinophilic granulomatosis with polyangiitis (EGPA) or microscopic polyarteritis (MPA)

	AAV with renal disease (n=82)
Renal biopsy; n, (%)	44, (53.66%)
ANCA; n, (%)	
MPO	53, (64.6%)
PR3	22, (26.8%)
double positivity	3, (3.65%)
Diagnosis; n, (%)	
MPA	43, (52.4%)
GPA	27, (32.9%)
EGPA	4, (4.9%)
Other diseases	8, (9.8%)
Renal involvement; n, (%)	
nephritic syndrome	46 (56.1%)
proteinuria > 3.5 g/24h	3 (3.6%)
isolated hematuria	5 (6.1%)
Outcome; n, (%)	
dialysis	16, (19.5%)
total remission	25, (30.5%)
relapses	17, (20.7%)

Renal outcome at the end of follow-up was poorer in MPA than GPA or EGPA (76.3%, 47.4% and 50% respectively worsened GFR from baseline).

16 patients (19.5%) needed dialysis at any moment. Total remission was achieved in 25 patients (30.5%) while relapses were observed in 17 patients (20.7%).

Severe infectious was the main severe side-effect, reported in 26 patients (31.7%).

Conclusion: Most AAV patients had some grade of renal disease during follow-up and almost 20% ended up needing dialysis. Therefore this multi-systemic disease should be managed in a multidisciplinary way to establish an early diagnosis and adequate treatment, limiting chronic disease.

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: Vasculitis – ANCA-Associated Poster III: Biomarkers & Renal Outcomes
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: It is known that disease activity of ANCA-associated vasculitis (AAV) is decreased after dialysis. However, most studies have been conducted on Caucasians, and factors associated with relapse during dialysis have not been well-studied. Therefore, this study aimed to elucidate the clinical manifestation of AAV relapse during dialysis, and identify factors associated with relapse, in an Asian country.

Methods: We retrospectively reviewed the data of patients diagnosed with AAV who were on dialysis due to renal involvement during follow-up from July 2005 to March 2021 at a single tertiary center in Seoul, Korea. Diagnosis of AAV was based on the International Chapel Hill Consensus Conference on the Nomenclature of Systemic Vasculitides. The patients on dialysis at the time of AAV diagnosis or during follow-up period were included in our study. Cox regression analysis was performed with the relapse as the dependent variable for the univariable and multivariable analysis.

Results: A total of 38 patients were included in the present study. Median age of participants was 64.0 (52.5–71.3) years, 28 (73.7%) were female, and 92.1% had microscopic polyangiitis (MPA). At diagnosis, mean BVAS was 18.3 (± 4.0), and 66.3% of patients had pulmonary manifestations. Of them, 12 patients were relapsed during followed up for 59.7 (± 50.4) months after dialysis. Among patients who experienced relapse, 9 had diffuse alveolar hemorrhage (DAH), and interstitial

Table 1. Baseline characteristics of patients with or without relapse

	All (n = 38)	Relapse		p-value

Mean corticosteroid doses, mg/day	1.360 (1.155–1.602)	<0.001	1.381 (1.161–1.642)	<0.001
Cumulative cyclophosphamide doses, g	0.977 (0.908–1.051)	0.533		
Maintenance therapy	1.762 (0.529–5.873)	0.356		

HR: hazard ratio, CI: confidence interval,

BVAS: Birmingham Vasculitis Activity Score, DAH: diffuse alveolar hemorrhage, ENT: ear, nose, and throat, WBC: white blood cell count, Hb: hemoglobin, ESR: erythrocyte sedimentation rate, CRP: C-reactive protein

lung disease (ILD) aggravation (n = 2) and DAH (n =1) were found. There were no significant differences in age, sex, or mean BVAS at baseline between relapse and non-relapse group. Treatment regimen including cyclophosphamide, plasmapheresis, and maintenance therapy with azathioprine did not show statistical differences between the two groups. However, in univariable analysis, significant associations were observed between lung infiltration [HR 5.580 (1.168–26.659), p=0.031], DAH [HR 4.594 (1.449–14.562), p=0.010], corticosteroid pulse for induction [HR 0.281 (0.080–0.990), p=0.048], and mean corticosteroid doses [HR 1.360 (1.155–1.602), p< 0.001] with AAV relapse. Multivariable analysis showed that DAH [5.509 (1.569–19.339), p=0.008] and mean corticosteroid doses [1.381 (1.161–1.642), p< 0.001] were significantly associated with relapse.

Conclusion: Pulmonary manifestation, including DAH at baseline, was significantly associated with AAV relapse, and a significant association between mean corticosteroid doses and relapse was found.

Clinical Characteristics, Treatment Patterns, and Clinical Outcomes in Patients with Dual Positive Anti-Neutrophil Cytoplasmic Antibody and Anti-Glomerular Basement Membrane Antibody: A Single Center Experience

Zaina Shahid, Michael Lucke and Swati Arora, Allegheny Health Network, Pittsburgh, PA

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: Vasculitis – ANCA-Associated Poster III: Biomarkers & Renal Outcomes
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Knowledge of disease characteristics and long-term outcomes of dual-positive patients (DPP) exhibiting anti-neutrophil cytoplasmic antibodies (ANCA) and anti-glomerular basement membrane (GBM) antibodies is limited to small studies in European cohorts. Data regarding disease characteristics, treatment modalities, and disease outcomes from North American populations are limited to case reports.

Methods: We performed a comparative retrospective chart review from a single center of adult DPP with both ANCA and anti-GBM antibodies and Single-positive patients (SPP) with only anti-GBM antibodies presenting between 1/1/2014 – 2/8/2023. The follow-up period ranged from 1- 84 months. 9 DPP and 17 SPP were identified. 14 patients not meeting the clinical criteria for ANCA vasculitis or GBM disease as determined by treating physicians were excluded.

Results: 50% (n=6) of the patients with anti-GBM antibodies also tested positive for ANCA at the time of diagnosis. 5 of these patients had myeloperoxidase (MPO) antibodies, none had anti-proteinase-3 (PR-3) antibodies. The median age was 70 years for DPPand 67 years for SPP. DPP presented with acute renal failure (ARF) (n=5), pulmonary-renal syndrome (n=2), and isolated diffuse alveolar hemorrhage (DAH) (n=1). 6 SPP presented with ARF and 2 with pulmonary-renal syndrome. A similar number of DPP and SPP required dialysis at initial presentation however more SPP had GFR< 15 (n=5) as compared to DPP (n=4). Median serum creatinine was 8.5 mg/dL for SPP and 7.8 mg/dL for DPP. 11/12 patients underwent renal biopsy, 10/12 showed crescentic glomerulonephritis (CGN) and 8/12 had linear IgG staining on

immunofluorescence. Pulmonary disease was more severe in DPP with 2 patients requiring stay in the intensive care unit (ICU) and 1 patient requiring mechanical ventilation as compared to 1 SPP requiring ICU stay. DPP pulmonary diagnoses include pulmonary fibrosis (n=2), and pulmonary nodules (n=1), which were not seen in SPP. All 5 DPP requiring dialysis at presentation remained dialysis dependent.1 SPP requiring dialysis at diagnosis was able to stop dialysis after 11 months. All patients received plasmapheresis except for 2 SPP;1 with sepsis and 1 with 100% crescents. All patients received pulse dose steroids. DPP were mostly treated with rituximab (n=5) while most SPP patients received cyclophosphamide (n=4). DPP received maintenance immunosuppression with rituximab (n=2) and mycophenolate mofetil (n=2) for a duration ranging from 3-18 months. Only 1SPPreceived maintenance steroids over 4 years until renal transplant. 1 DPP and 1 SPP who did not receive immunosuppression due to comorbidities died. 5/6 DPP had no relapse in the study period. One patient who developed DAH2 years after initial presentation was successfully treated with steroids and Rituximab.

Table 1.

Clinical Characteristics	DPP ANCA/ GBM (n=6)	SPP Anti-GBM (n=6)
Age at presentation-years (Median, range)	70.5 (65-86)	67 (30-77)
Gender, n (%)		
Male	3 (50%)	4 (66.6%)
Female	3 (50%)	2 (33%)
Race, n (%)		
White or Caucasian	6 (100%)	5 (83%)
Black or African American	0	1 (16.7%)
Ethnicity, n (%)		
Not Hispanic or Latino	6 (100%)	6 (100%)
Hispanic or Latino	0 (0%)	0 (0%)
Antibody Profile, n (%)		
c-ANCA	5 (83%)	0 (0%)
P- ANCA	5 (83%)	0 (0%)
PR-3	0 (0%)	0 (0%)
MPO	5 (83%)	0 (0%)
C-ANCA/PR3	0 (0%)	0 (0%)
P-ANCA/MPO	4 (66%)	0 (0%)
C-ANCA/P-ANCA	4 (66%)	0 (0%)
GBM	6 (100%)	6 (100%)
GBM checked with ANCA	6 (100%)	5 (83%)
Disease manifestations, n (%)		
Renal	5 (83%)	6(100%)
GFR<15	4 (66%)	5 (83%)
GFR 15-29	0 (0%)	1 (16.7%)
GFR 30-59	1 (16%)	0 (0%)
GFR>60	1 (16%)	0 (0%)
Requiring dialysis at presentation	5 (83%)	5 (83%)
Pulmonary	4 (66%)	2 (33%)
Hemorrhage	3 (50%)	2 (33%)
Pulmonary nodules	1(16%)	0 (0%)
Pulmonary fibrosis	2 (33%)	0 (0%)
Requiring ICU stay	2 (33%)	1 (16%)
Requiring intubation	1 (16%)	0 (0%)
Constitutional	6 (100%)	2 (33%)
Polyarthralgia	2 (33%)	0 (0%)
ENT(sinus disease)	2 (33%)	0 (0%)

Conclusion: Half (50%) of this cohort of anti-GBM-positive patients also had positive ANCA serology, highlighting the importance of testing for both antibodies in CGN. DPP presented with mixed clinical features of ANCA vasculitis and anti-GBM disease. Patients with dual positivity may have an increased risk of disease relapse upon discontinuation of immunosuppression.

Major Cardiovascular Adverse Events in Patients with ANCA Vasculitis Compared with Hypertension Control Group

Lisa Rosenberg[1], Larabe Farrukh[1], Simrin Kooner[1], Moiz Ehtesham[1], Sumbal Wajid[1], Ruben Peredo-Wende[2] and Shannon Murawski[1], [1]Albany Medical Center, Albany, NY, [2]Stratton VA Medical Center, Albany, NY

SESSION INFORMATION

Session Date: Tuesday, November 14, 2023
Session Title: Vasculitis – ANCA-Associated Poster III: Biomarkers & Renal Outcomes
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Vascular damage from inflammation in ANCA vasculitis leads to a sustained procoagulant state causing accelerated atherosclerosis. A population-based cohort study found that the risk of cardiovascular disease is more than 3-fold higher in patients with ANCA-associated vasculitis. We hypothesize that those with ANCA vasculitis are more likely to have a major adverse cardiovascular event (MACE) compared to those in the hypertension control group.

Methods: We retrospectively reviewed patients with ANCA vasculitis (n=125) between 2017-2020. Charts were reviewed to assess cardiovascular (CV) risk factors which included history of smoking, hypertension, hyperlipidemia, diabetes mellitus and chronic kidney disease. Incidence of MACE such as myocardial infarction (MI), stroke, heart failure (HF) was calculated retrospectively after the diagnosis of ANCA vasculitis. Chi square and modified Poisson regression were used to calculate the incidence rate ratio (IRR) for MACE. We also retrospectively reviewed patients with hypertension without ANCA-associated vasculitis (n=100) between 2017-2020. The associations of each of the ANCA vasculitis categories and hypertension group with outcomes of MACE were examined by logistic regression. Minitab statistical software was used with significance accepted at $p < 0.05$.

Table 1

MACE	ANCA	Control	Odds Ratio	95% Confidence Interval
Stroke	EGPA	Hypertension	4.7647	(1.6858, 13.4671)
	GPA	Hypertension	10.2857	(4.4984, 23.5188)
	MPA	Hypertension	5.4000	(1.1196, 26.0439)
MI	EGPA	Hypertension	17.6000	(4.9577, 62.4804)
	GPA	Hypertension	8.7273	(2.7577, 27.6193)
	MPA	Hypertension	8.0000	(1.2122, 52.7971)
HF	EGPA	Hypertension	3.7251	(1.2344, 11.2419)
	GPA	Hypertension	6.7407	(2.8587, 15.8944)
	MPA	Hypertension	3.3704	(0.5912, 19.2155)

Table 2

MACE	ANCA	Size (Percentage)	Unadjusted IRR`	p-value	Adjusted IRR	p-value
Stroke	GPA	48 (62.3%)	1.00 (Reference)		1.00 (Reference)	
	EGPA	14 (37.8%)	0.61 (0.31 – 0.95)	0.03	0.65 (0.41 – 0.72)	0.04
	MPA	4 (36.4%)	0.68 (0.36 – 0.80)	0.02	0.67 (0.67 – 0.71)	0.01
MI	GPA	26 (33.7%)	1.00 (Reference)		1.00 (Reference)	
	EGPA	16 (43.2%)	1.28 (0.71 – 2.11)	0.31	1.34 (0.82 – 2.18)	0.23
	MPA	4 (36.4%)	1.07 (0.44 – 2.51)	0.86	1.18 (0.51 – 2.76)	0.71
HF	GPA	32 (41.5%)	1.00 (Reference)		1.00 (Reference)	
	EGPA	25 (67.6%)	1.23 (1.11 – 1.45)	0.04	1.21 (1.08 – 1.32)	0.04
	MPA	4 (36.4%)	0.87 (0.38 – 2.00)	0.75	1.05 (0.47 – 2.31)	0.89

Results: The mean age of the hypertension group was 62 years with a mean BMI of 30.1 kg/m². Females were 48%. The odds of having a stroke and MI were significantly higher amongst EGPA, GPA, and MPA patients than hypertension patients ($p< 0.05$). The odds of having HF were significantly higher amongst EGPA and GPA patients than hypertension patients ($p< 0.05$) [Table 1].

Of 125 total ANCA vasculitis patients, 77 (61.6%) had granulomatosis with polyangiitis (GPA), 37 (29.6%) had eosinophilic granulomatosis with polyangiitis (EGPA), and 11 (8.8%) had microscopic polyangiitis (MPA). Females were 68%. Mean age of the cohort was 58 years with a mean BMI of 29.4 kg/m². The unadjusted and adjusted (for age, gender, and CV risk factors) IRR for stroke was significantly lower in patients with EGPA and MPA vs. GPA ($p< 0.05$). The IRR for HF was significantly higher in EGPA vs. GPA ($p< 0.05$) [Table 2].

Conclusion: ANCA-associated vasculitis is a significant risk factor of MACE. The hypertension control group may not be a true matched control group. The ANCA vasculitis group may have other comorbidities including, diabetes, hyperlipidemia, chronic kidney disease, and tobacco abuse. More studies are needed to show that control of ANCA disease activity can decrease the risk of MACE and death. More studies are needed to show that treatment of modifiable risk factors including, glucocorticoid use, chronic kidney disease (CKD), proteinuria, respiratory infections, dyslipidemia, hypertension, metabolic syndrome, and insulin intolerance is necessary to optimize long-term outcomes.

SESSION INFORMATION

Session Date: Tuesday, November 14, 2023
Session Title: Vasculitis – ANCA-Associated Poster III: Biomarkers & Renal Outcomes
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: The aim of this study was to investigate the risk of major adverse cardiovascular events (MACE) in patients with ANCA-associated vasculitis (AAV).

Methods: We conducted a retrospective study using the ANCA-associated vasculitis Toulouse cohort (AAVT). The incidence of MACE, defined as myocardial infarction (MI) and/or stroke and/or death, as well as survival, were compared between groups using the Chapel Hill Consensus Conference classification criteria. We also applied Cox regression models adjusted for traditional cardiovascular risk factors and sex to assess the risk of MI, stroke and MACE occurrence.

Results: A total of 454 patients were included, including 266 (50%) with granulomatosis with polyangiitis (GPA), 167 (37%) with microscopic polyangiitis (MPA), and 61 (13%) with eosinophilic granulomatosis with polyangiitis (EGPA). Of these, 249 (55%) were men and 205 (45%) were women. The mean age at diagnosis was 61 (SD: 16.49) years, and the mean follow-up duration was 7.185 (SD: 6.72) years. We identified 19 MI and 13 strokes during the study period. The incidence rate of MACE was 23.77 per 1000 patient-years in the GPA group, compared to 35.51 per 1000 patient-years in the MPA group and 20.03 per 1000 patient-years in the EGPA group. The mean time to occurrence of a MACE was 8.07 (SD: 6.19) years in the GPA group, 4.59 (SD: 4.63) years in the MPA group and 13.58 (SD: 11.51) years in the GEPA group (p=0.0001). At 5 and 10 years from diagnosis, the probability of survival without MACE was 93.3% and 81.57%, respectively, in the GPA group, 83.98% and 67.15% in the MPA group, and 94.33% and 86.83% in the EGPA group (p=0.037). The incidence rate of MI was 4.10 per 1000 patient-years in the GPA group, compared to 8.44 per 1000 patient-years in the MPA group and 5.37 per 1000 patient-years in the EGPA group. The mean time to occurrence of an MI was 3.72 (SD: 5.74) years in the GPA group, compared to 3.04 (SD: 2) years in the MPA group and 7.52 (SD: 5.28) years in the EGPA group (p=0.0001). At 5 and 10 years from diagnosis, the incidence of MI was 2% and 3%, respectively, in the GPA group, 4% and 5% in the MPA group, and 2% and 5% in the EGPA group (p=0.48). The incidence rate of stroke was 4.08 per 1000 patient-years in the GPA group, compared to 5.26 per 1000 patient-years in the MPA group and 1.73 per 1000

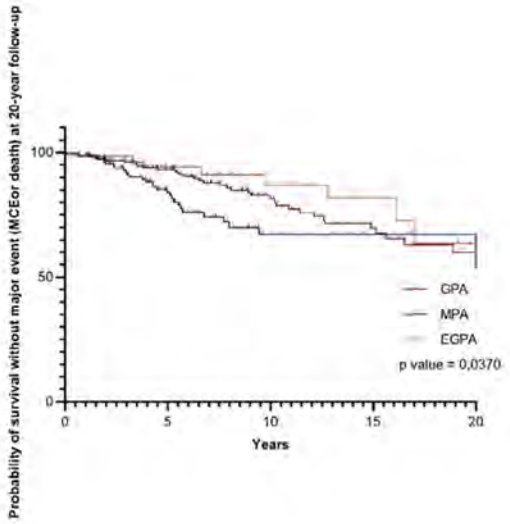

Figure 1. Kaplan Meier estimate of event-free survival where major adverse cardiovascular event were counted as events in ANCA-associated vasculitis.

patient-years in the EGPA group. The mean time to occurrence of a stroke was 7.19 (SD: 5.11) years in the GPA group, compared to 3 (SD: 2.14) years in the MPA group and 17.83 (SD not applicable) years in the EGPA group (0;0001). At 5 and 10 years from diagnosis the incidence of stroke was 1% and 2% respectively in the GPA group, 2% and 3% in the MPA group, and 0% in the EGPA group (p=0;49).

Conclusion: Patients classified as MPA appear to be at higher risk of MACE and have a lower probability of MACE-free survival.

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: Vasculitis – ANCA-Associated Poster III: Biomarkers & Renal Outcomes
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: The aim of this study was to investigate the relationship between ANCA specificity and the risk of major adverse cardiovascular events (MACE) in patients with ANCA-associated vasculitis (AAV).

Methods: We conducted a retrospective study using the ANCA-associated vasculitis Toulouse cohort (AAVT). The incidence of MACE, defined as myocardial infarction (MI) and/or stroke and/or death, as well as survival, were compared among patients according to their ANCA specificity. We also applied Cox regression models adjusted for traditional cardiovascular risk factors and sex to assess the risk of MI, stroke and MACE occurrence.

Results: A total of 402 patients were included, of whom 166 (41%) had anti-PR3 ANCA and 236 (59%) had anti-MPO ANCA. Among them, 220 (55%) were male and 182 (45%) were female. The mean age at diagnosis was 61.22 (SD: 16.05) years, and the mean follow-up duration was 7.51 (SD: 6.41) years. During the study period, 15 cases of MI and 12 cases of stroke were identified.

The incidence rate of MACE was 33.11 per 1000 patient-years in the anti-MPO ANCA group, compared to 21.37 per 1000 patient-years in the anti-PR3 ANCA group. The mean time to MACE occurrence was 3.29 (SD: 2.74) years in the anti-MPO ANCA group and 7.33 (SD: 5.68) years in the anti-PR3 ANCA group (p=0.0001). At 5 and 10 years from diagnosis, the probability of MACE-free survival was 89.39% and 68.77% respectively in the anti-MPO ANCA group, and 93.39% and 83.36% in the anti-PR3 ANCA group (p=0.0001) (figure 1).

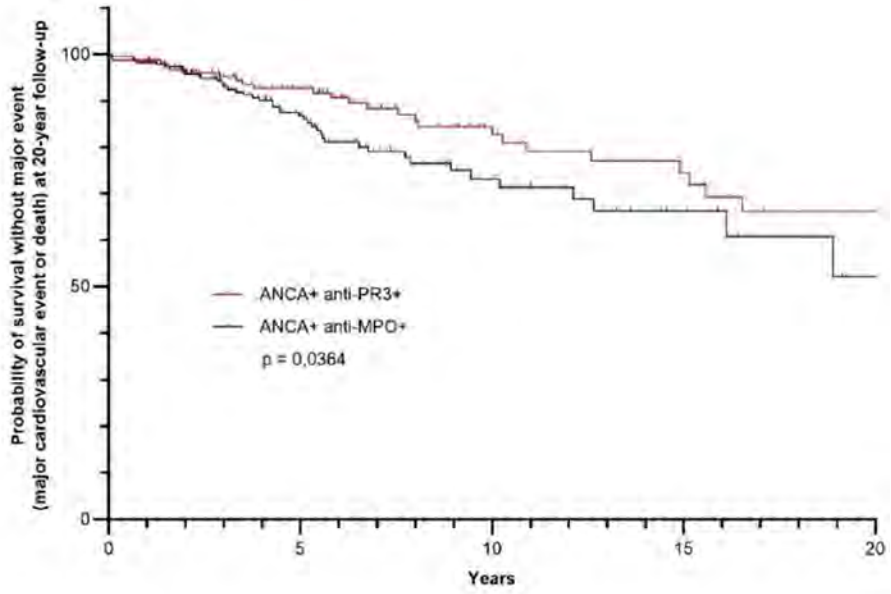

Figure 1. Kaplan Meier estimate of event-free survival where major adverse cardiovascular event were counted as events in ANCA-associated vasculitis.

The incidence rate of MI was 6.16 per 1000 patient-years in the anti-MPO ANCA group, compared to 4.09 per 1000 patient-years in the anti-PR3 ANCA group. The mean time to MI occurrence was 2.21 (SD: 1.81) years in the anti-MPO ANCA group, while it was 4.24 (SD: 6.11) years in the anti-PR3 ANCA group (p=0.0001). At 5 and 10 years from diagnosis, the incidence of MI was 4% in the anti-MPO ANCA group, compared to 2% and 3%, respectively, in the anti-PR3 ANCA group (p=0.31).

The incidence rate of stroke was 6.13 per 1000 patient-years in the anti-MPO ANCA group, compared to 2.72 per 1000 patient-years in the anti-PR3 ANCA group. The mean time to stroke occurrence was 4.39 (SD: 2.99) years in the anti-MPO ANCA group, while it was 7.69 (SD: 7.42) years in the anti-PR3 ANCA group (p=0.0009). At 5 and 10 years from diagnosis, the incidence of stroke was 2% and 3%, respectively, in the anti-MPO ANCA group, and 1% and 2% in the anti-PR3 ANCA group (p=0.18).

The Cox regression model found an association between the presence of anti-MPO ANCA and the risk of MACE (HR: 1.77; 95% CI: 1.13-2.8; p=0.0134). A similar trend was observed for the risk of stroke (HR: 3.05; 95% CI: 0.88-10.6; p=0.0795). There was no association found between the presence of anti-MPO ANCA and the risk of MI.

Conclusion: Patients with anti-MPO ANCA appear to be at higher risk of MACE.

Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster III

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: Manifestations of giant cell arteritis (GCA) include large vessel involvement (LVI) of the aorta and its branches. Aortic aneuryms are more common compared to the general population. GCA is complicated by an increased risk of infections, likely due to treatment and/or the systemic nature of the disease. There is limited information on the impact of

the disease phenotype on the risk of infection among patients with GCA. No previous study has investigated LVI in GCA as a risk factor for severe infections. Such investigations need to take into account demographics and comorbidities. The objective of this study was to assess the influence of age, sex, LVI and pre-existing comorbidities on the risk of severe infection in GCA.

Methods: Patients with biopsy-proven GCA, diagnosed between 2002 and 2010, were identified from a regional pathology register, and followed through the end of study December 2011.

Data on infections requiring hospitalization were obtained from linkage to the regional healthcare registry. Twenty categories of infections were identified based on ICD-10 codes.

Five categories of pre-existing comorbidities were based on diagnoses registered within four years before the date of GCA diagnosis, and the Charlson comorbidity index (CCI) was calculated. Information on LVI was obtained through structured review of all relevant radiological and clinic-physiological studies. LVI was defined as presence of aneurysm, ectasia, or stenosis of the aorta and/or its main branches or positive 18fluoro-2-deoxy-d-glucose positron emission tomography–computed tomography or other nuclear imaging methods indicating vasculitis. Patients with LVI findings after or ≤1 year before the GCA diagnosis were classified as having the LVI phenotype. Cox regression analysis was used to identify possible predictors of severe infections among patients with GCA. Patients were followed from time of GCA diagnosis and censored at death or migration from the region. Covariates were excluded from multivariate models based on co-linearity.

Results: Among 516 patients with biopsy-proven GCA (Table 1), 19.4% had confirmed LVI, and 12% had aortic involvement (aneurysm, ectasia, dissection or signs of vasculitis on nuclear imaging) with or without concomitant distributary artery affection. There were 118 patients with ≥1 severe infection during the study period.

HR: Hazard ratio, CI: Confidence interval; SD: Standard deviation; NA: Not applicable

Table 3

Table 3. Predictors of severe infections in patients with GCA – Cox regression, multivariate analysis

Variables	HR (95% CI)
Age, per SD	**1.82 (1.46 - 2.28)**
Male sex	1.45 (0.97 - 2.18)
Aortic involvement	**1.75 (1.04 - 2.94)**
Diabetes	**1.82 (1.16 - 2.84)**
Chronic obstructive pulmonary disease	**1.89 (1.18 - 3.03)**
Chronic kidney disease with renal failure	**2.90 (1.48 - 5.67)**
Proximal humeral fracture	**2.29 (1.08 - 4.86)**

SD: Standard deviation

Higher age at diagnosis and several pre-existing comorbidities, i.e. coronary artery disease, heart failure, diabetes, chronic obstructive pulmonary disease and renal failure were significant predictors for severe infections (Table 2). LVI overall and aortic involvement were associated with significantly increased risk of severe infections in age-adjusted analyses (Table 2**)**. In the multivariate analysis, aortic involvement was predictive of severe infections (Hazard ratio 1.75; 95% confidence interval 1.04-2.94, adjusted for age and comorbidities) (Table 3**)**.

Conclusion: In patients with GCA, age and specific pre-existing medical conditions are predictors of severe infections. LVI, in particular of the aorta, may also be associated with a higher risk for severe infection.

Increased Risk of Severe Infections in Early Giant Cell Arteritis: A Population- based Study

Nazanin Naderi[1], Aladdin Mohammad[2], Karin Wadström[3], Ulf Bergström[3] and **Carl Turesson**[3], [1]Lund University, Kristiandstad, Sweden, [2]Lund University, Lund, Sweden, [3]Lund University, Malmö, Sweden

SESSION INFORMATION

Session Date: Tuesday, November 14, 2023
Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster III
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Giant cell arteritis (GCA) is the most common type of vasculitis in adults aged 50 years or older. Although the substantial morbidity from infections in patients with GCA, partly due to immunosuppressive treatment, is well recognized, few studies have evaluated the incidence of severe infections compared to the general population. Even fewer have investigated the incidence of severe infection by time from GCA diagnosis compared to a reference population.

The objective of this study was to compare the risk of severe infection in different time intervals after GCA diagnosis to the general population.

Table 1

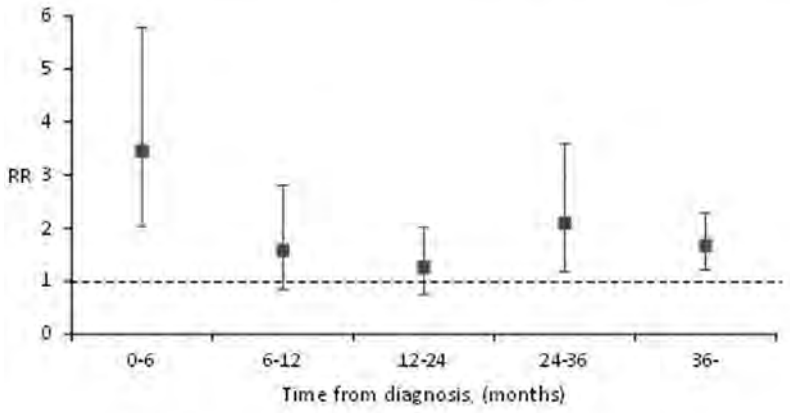
Table 1. Rates of severe infections in patients with giant cell arteritis and reference subjects

	Cases			Reference subjects		
Follow-up interval (months)	Infections (n)	Follow-up (pyr)	Rate/100 pyr (95% CI)	Infections (n)	Follow-up (pyr)	Rate/100 pyr (95% CI)
All severe infections						
0-6	37	250.5	14.8 (10.4; 20.4)	45	995.9	4.5 (3.3; 6.1)
6-12	21	240.2	8.7 (5.4; 13.4)	63	972.6	6.5 (5.0; 8.3)
12-24	40	441.7	9.1 (6.5; 12.3)	116	1806.7	6.4 (5.3; 7.7)
24-36	29	357.0	8.1 (5.4; 11.7)	65	1484.2	4.4 (3.4; 5.6)
36-	95	1011.4	9.4 (7.6; 11.5)	287	4155.0	6.9 (6.1; 7.8)

n; number; pyr: person years; CI: Confidence interval.

Methods: Patients with biopsy-proven GCA, diagnosed between 2002 and 2010 were retrieved from a regional pathology register. They were compared with four reference subjects per case from the corresponding area, matched for age, sex and area of residence. Data on infections requiring hospitalization were obtained from linkage of the cases and the references to the regional healthcare register, through 2011. Using ICD-10 codes, twenty categories of infections were identified. Patients and reference subjects were censored at death or migration from the area. Incidence rates of severe infections in patients with GCA and reference subjects, stratified by follow-up time (0-6 months, 6-12 months, 1-2 years, 2-3 years, > 3 years), were estimated by dividing the number of severe infections in each time interval with the corresponding follow-up time (in years). The follow-up time started at date of diagnosis for patients (index-date for reference subjects) and ended at death or December 31, 2011. Rate Ratios (RRs) regarding severe infections, stratified by category of follow-up time, were calculated for patients with GCA vs. reference subjects. The 95% confidence intervals (CI) for incidence rates and RRs were estimated using the Poisson distribution ratio.

Figure 1.
Incidence of severe infections in patients with GCA vs reference subjects



RR: Rate ratios. Whiskers indicate 95% confidence intervals

Figure 1

Results: Five hundred and sixteen patients with GCA were identified and compared to 3335 matched reference subjects. A total of 222 severe infections occurred in 118 patients with GCA. The cumulative incidence rate of severe infections was 8.5 % during the first year and 22.9 % over the entire follow-up.

The incidence rate in patients with GCA was highest during the first six months, 14.8/100 person-years (Table 1**)**.

During this period, the rate was significantly increased compared to reference subjects (RR 3.27; 95% CI 2.06; 5.11) (Figure 1**).**

The rate of severe infections was numerically higher than that for the general population during the entire follow-up, but the difference reached statistical significance only during the first six months and after > 2 years of follow-up (Table 1, Figure 1**)**.

Conclusion: The risk for severe infection is increased in patients with GCA compared to the general population, in particular during the first 6 months after diagnosis.

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster III
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Monitoring disease activity in giant cell arteritis (GCA) and polymyalgia rheumatica (PMR) remains challenging as standard inflammation parameters, i.e., C-reactive protein (CRP) and erythrocyte sedimentation rate (ESR), are not specific for rheumatic disease activity. Furthermore, tocilizumab (TCZ), meanwhile a cornerstone of GCA treatment, inhibits interleukin-6 (IL-6)-dependent synthesis of CRP. Calprotectin (CALPR) and serum amyloid A (SAA) are promising alternatives, especially since they are at least largely independent of IL-6. However, there are few prospective data on large cohorts. Our aim was to evaluate the value of CALPR and SAA for indicating disease activity in GCA/PMR.

Methods: In a prospective cohort study, CRP, ESR, CALPR, and SAA were measured repeatedly at each visit in 98 patients with confirmed GCA (N=81) or PMR (N=17). A total of 576 visits (=measurements) were performed with a mean of 5.9 ± 2.7 visits for each patient. Patients were classified as "active disease" by clinical evaluation according to current guidelines at 131 visits (=22.7% of all visits). TCZ was administered at 140 visits. To test the predictive power of patients' active status based on all measurements, we performed univariate logistic regression. For the resulting receiver operator curves (ROC), 99% confidence intervals of the area under the curve (AUC) were calculated based on a bootstrap approach (9999 replicates). Because patients were measured multiple times, we modeled the log value of all measurements using a mixed-effects model with the random factor "patient." These values were modeled using the numeric factors BMI and age and the binary factors sex (male/female), prednisolone (yes/no), MTX (yes/no), diagnosis (GCA/PMR), and active (yes/no).

Results: ROC analysis of examinations without TCZ showed the best AUC for CRP (0.76; 0.69-0.83), followed by SAA (0.74; 0.66-0.82), ESR (0.7; 0.63-0.78), and CALPR (0.66; 0.59-0.73). For visits with TCZ, SAA showed the best AUC (0.73; 0.5-0.9), then CRP (0.58; 0.41-0.77), CALPR (0.55; 0.32-0.74), and ESR (0.48; 0.31-0.68). In the adjusted model for visits without TCZ, CRP, ESR, and SAA showed highly significant mean change in active disease ($p > 0.001$), CALPR showed significant change ($p < 0.05$). For visits with TCZ, no parameter showed significant mean change with active disease.

Conclusion: SAA shows better AUC than the other seromarker in patients treated with TCZ. In patients without TCZ treatment, the AUC of CRP and SAA are almost equal. However, after multivariate regression, no significant effect is detectable for any of the tested parameters.

Session Date: Tuesday, November 14, 2023

Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster III

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: Age is the strongest risk factor of giant cell arteritis (GCA), implying a possible pathogenetic role of cellular senescence. So far, no studies have investigated adequately this question. The current study aims to identify the various senescent cell types in temporal artery biopsies (TABs) of GCA and polymyalgia rheumatica (PMR) patients by applying the novel multi-marker algorithm, define the secretory associated senescent phenotype (SASP) key molecules and explore possible implications of senescence in GCA pathogenesis.

Methods: Seventy five positive TABs from GCA patients and 22 negative from PMR patients were retrospectively analyzed. Senescent cells and their histologic origin were identified after staining for specific cellular markers including GL13, p21, vimentin, CD68, CD3 and aSMA, following the established multi-marker algorithm(1,2); IL-6 and MMP-9 were investigated as components of the (SASP) by triple co-staining. Twenty-four hour GCA or PMR artery culture supernatants were applied to primary skin fibroblasts with or without IL-6 blocking agent to explore the induction of IL-6 associated cellular senescence.

Results: Senescent cells were present in GCA arteries at higher proportion compared to PMR (9.50% vs 2.66% respectively, $p< 0.0001$) adjacent to the inflammatory cells and were mainly originated from fibroblasts (29.6%), macrophages (16.2%) and endothelial cells (14.3%) (Figure 1). IL-6 was expressed mainly by senescent fibroblasts and macrophages while MMP-9 by fibroblasts only (Figure 2). IL-6 positive senescent cells were associated with the extension of vascular wall

Figure 1. Detection of senescent cells in tissue artery biopsies of GCA patients. (A) Representative images for single GL13 staining with immunohistochemistry (upper panel) and immunofluorescence (lower panel) in TABs of GCA and PMR patients, showing higher proportion of GL13 positive cells adjacent to the inflammatory cells in GCA arteries compared to PMR. (B) Graphical representation of the proportion of GL13 positive senescent cells, after immunohistochemical evaluation by two independent readers and quantification analysis in 75 GCA and 22 PMR TABs (GCA vs PMR): 9.50% vs 2.66%, $p<0.001$. (C) Confirmation of senescent cells by co-staining for GL13 and p21WAF1/Cip1 in a TAB of a GCA compared to a PMR patient (representative image). (D) Electron micrographs of senescent cells in artery of GCA patients showing Lipofuscin (LF) granules in their cytoplasm (Di,ii). (E) Electron micrographs of cells in artery of PMR patient without lipofuscin granules (Ei,ii). Higher magnification of the area in the black box of (Ei). N: nucleus. Staining: uranyl acetate/lead citrate. Objectives (A) 20x, (C) 63x. Scale bars: 50μm (A) 10μm (C). 1μM (Di,ii, Eii), 2μM (Ei). ****$p < 0.0001$

Figure 2. Characterization of senescent cells per cell type in tissue artery biopsies of GCA patients. Representative images of double positive senescent cells after staining for GL13 and (A) Vimentin(+) (fibroblasts), (B) CD68(+) (macrophages), (C) CD34(+) (endothelial cells) or (D) aSMA (+) (smooth cells) in a TAB of one GCA and one PMR patient (double staining immunofluorescence). Squares depict magnified cells with presence of double positive staining. (E) Quantification analysis by two independent observers, showing significantly higher proportion of senescent fibroblasts (GL13(+)/Vimentin(+)), macrophages (GL13(+)/CD68(+)) and endothelial cells (GL13(+)/CD34(+)) in 13 GCA compared to 13 PMR biopsies. Objectives 20x. Scale bars: 50 μm. n.s. not significant, *$p < 0.05$, **$p < 0.01$, $p < 0.001$

Figure 3. Senescent cells in GCA express SASP that includes IL-6 and MMP-9. Representative images of IL-6 expression by senescent cells of different origin: (A) GL13(+)/Vimentin(+) (senescent fibroblasts, (B) GL13(+)/CD68(+) (senescent macrophages), (C) GL13(+)/CD34(+) (senescent endothelial cells)) and (D) GL13(+)/aSMA(+) (senescent smooth muscle cells) in a TAB of n=10 GCA and n=10 PMR patients (triple staining immunofluorescence). (E) Graphical representation of the proportion of IL-6 positive senescent cells in 10 GCA and 10 PMR biopsies, showing significantly higher proportion of IL- 6 positive senescent fibroblasts (GL13(+)/Vimentin(+)) and macrophages (GL13(+)/CD68(+)). Representative images of MMP-9 expression by GL13/vimentin double positive (senescent fibroblasts) cells in a TAB of one GCA and one PMR patient (triple stainingimmunofluorescence). (F-G) Graphical representation showing higher proportion of MMP-9 positive senescent fibroblast (GL13(+)/vimentin(+)) in the 3 GCA compared to 3 PMR specimens. Objectives (A), (D) 20x, (B), (C), 63x. Scale bars: (A), (D) 50 μm, (B), (C), 10μm. n.s. not significant, *$p < 0.05$, **$p < 0.01$

inflammation (adventitial limited disease vs transmural inflammation: 10.02% vs 4.37% respectively, p< 0.0001) (Figure 3). Giant cell arteritis but not PMR artery culture supernatant induced IL-6-associated senescence that was partially inhibited by IL-6 blockade.

Conclusion: Senescent cells with inflammatory phenotype are present in GCA arteries and are associated with the inflammatory burden of the vascular wall. These findings suggest a potential implication of senescent cells in disease pathogenesis by perpetuating inflammation and affecting vascular remodeling via IL-6 dependent mechanisms.

Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster III

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

	3 months	1 year	2 year	3 year	4 year	5 year
Total number of patients	1607	1284	872	532	281	126
Relapse	51	232	114	55	28	6
No relapse	1556	1052	758	477	253	120
Relapse rate	3,2%	18%	13%	10%	10%	4,8%
Number of relapses per patient	1=47 2=4	1=192 2=36 3=5 4=0 5=1	1=101 2=11 3=4	1=50 2=5	1=23 2=5	1=5 2=1
Percentage of patients with ≥ 1 relapse	8%	18%	13%	9%	18%	17%
Total number of relapses	55	284	135	60	33	7
Cumulative relapse rate		18% (232/1052)	27,9% (243/872)	37,6% (200/532)	44,8% (126/81)	42% (53/126)

Background/Purpose: The relapse rate of treated patients with giant cell arteritis (GCA) varied widely in observational series and randomized controlled trials. This study aimed to estimate the frequency and timing of relapse, the prevalence of multiple relapses, the characteristics of flares, and the predictors of relapse in a large cohort of Spanish patients with GCA.

Methods: All patients in the ARTESER (Registry of Giant Cell Arteritis Patients of the Spanish Society of Rheumatology) were reviewed. ARTESER is a multicentre observational retrospective longitudinal study conducted in 26 hospitals that included all consecutive patients diagnosed with GCA between 1 June 2013 and 29 March 2019. All cases were aged 50 years or older and had a confirmed diagnosis of GCA, that is, they met at least one of the following criteria: objective confirmation of the presence of vasculitis in a diagnostic test, at least three 1990 ACR criteria for GCA satisfied, and/or a diagnosis made based on the clinical judgment of the investigator. We diagnosed disease relapses if all the following criteria were satisfied: 1) reappearance of signs/symptoms of GCA and/or polymyalgia rheumatica (PMR); 2) resolution of signs/symptoms after increasing glucocorticoids; 3) presence of raised acute-phase reactants ESR and/or CRP, and 4) exclusion of other causes. The data were obtained by review of medical records.

Results: In total, 1675 patients were included. They were predominantly female (70.3%), with a mean (±SD) age at diagnosis of 76.9±8.1 years. Of them, 1284 patients were followed up for one or more years. During follow-up, 574 relapses were observed in 334 (26%) patients. One-year, 2-year, 3-year, and 4-year cumulative relapse rates were 18%, 27.9%, 37.6%, and 44.8%, respectively (see Table 1). Most relapses (81.2%) occurred within the first two years after diagnosis (55.3% in the first year and 26% during the second). The mean dose of prednisone at the first relapse was 13.95 mg/day (IQR25%-75%: 5-20 mg). Fifteen percent (34/232) of patients experienced > 1 flare within the first year of treatment and 10.5% (12/114) during the second year. The majority of flares corresponded to a minor relapse according to the EULAR consensus definitions for disease activity states in GCA (minor relapses 73% / major relapses 27%) In the multivariate analysis, we did not identify any clinical factor at diagnosis that was a predictor of relapse during the first three years of evolution: nor the age, sex, presence of cranial manifestations, severe ischemic complications, large vessel involvement, or a strong initial systemic inflammatory response. By contrast, the administration of intravenous (IV)methylprednisolone (MP) boluses was negatively associated with the occurrence of relapses (OR: 0.356, 95% CI 0.182 to 0.696; p< 0.01).

Conclusion: Relapses among patients with GCA are common, mainly during the first two years after diagnosis. Between 8 and 18% of patients had multiple relapses. Despite the relevance of this problem, we do not yet have any predictive factors to identify patients with a higher risk of flare. Induction treatment with high-dose IV MP boluses appears to decrease the risk of relapses.

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster III
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Polymyalgia rheumatica (PMR) is associated with giant cell arteritis (GCA) in 16 to 21% of cases. This raises the question of a pathophysiological continuum between PMR and GCA, especially since a study reported mature arterial wall dendritic cells (DC) in patients with GCA or PMR. There are 3 main types of DC: plasmacytoid DC (expressing CD123), conventional DC (cDC) expressing CD141 (cDC1) or CD1c (cDC2), and monocyte-derived DC (mo-DC) expressing CD209 and CD14.This study aimed to identify, localize and characterize the phenotype of arterial DC in PMR and GCA.

Methods: Using temporal artery biopsies (TAB) from patients with PMR, GCA and healthy controls, bulk RNA-sequencing and RT-PCR analyses were performed to assess the level of expression of myeloid DC genes (*CD141*, *CD1C*, *CD209*, *ITGAX*), DC maturation genes *(CD83, CD80/86, CCR7)* and mature DC chemokine expression *(CCL18, CCL19, CCL20, CCL21)*. Expression of markers of DC lineage (CD209), DC maturation state (CD83 and CCR7) and DC origin (CD14, CD68, CD1c, CD141) were also studied in TABs by immunofluorescence (IF).

Results: Forty-three patients were included (14 GCA, 15 PMR, 14 controls). TAB from GCA patients were characterized by a strong mature DC signature with high level of expression of DC associated genes (*CD1C*, *ITGAX* [coding CD11c] and *CD209 [coding DC-SIGN])*, DC maturation genes (*CD83, CCR7, CD80/CD86)* and DC chemokine genes *(CCL18, CCL19,*

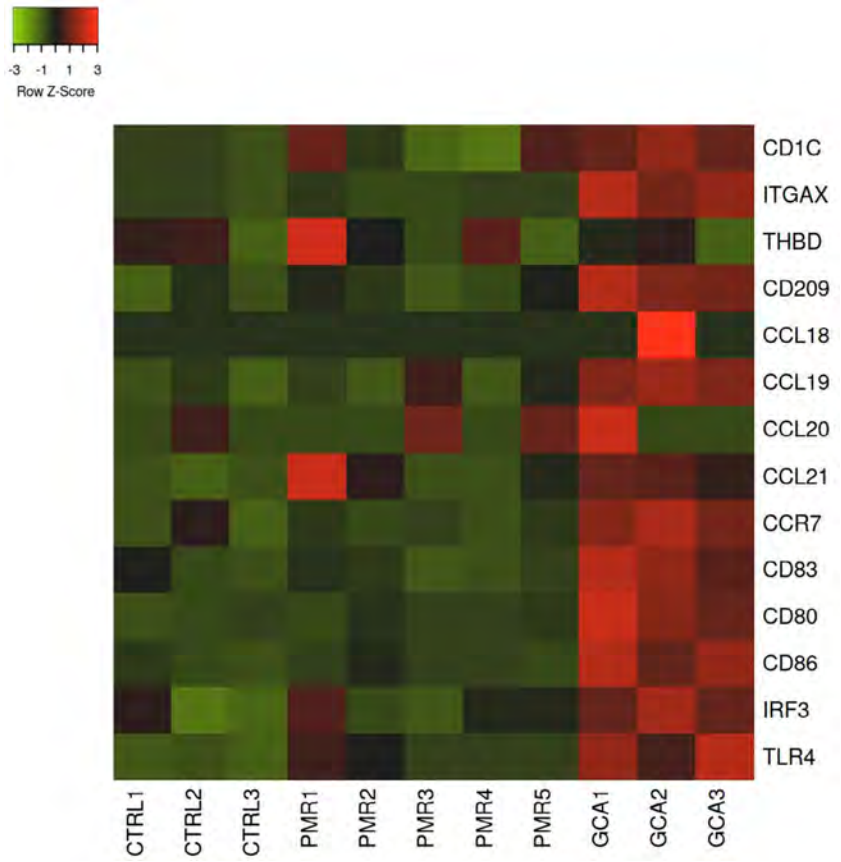

Figure 1: "DC signature" in GCA, PMR and control arteries. Myeloid dendritic cell genes are defined as genes that characterize human dendritic cells: CD1C (coding CD1c), THBD (coding CD141), CD209, ITGAX (coding CD11c). DC maturation associated genes are defined by the process in which antigen-activated dendritic cells acquire the specialized features of a mature conventional dendritic cell. Mature conventional dendritic cells upregulate the surface expression of MHC molecules, chemokine receptors and adhesion molecules, and increase the number of dendrites (cytoplasmic protrusions) in preparation for migration to lymphoid organs where they present antigen to T cells: CD83, CD80, CD86, CCR7, CCL18, CCL19, CCL20, CCL21, TLR4, IRF3.

CCL20). In PMR arteries, the DC signature was more heterogeneous: a few arteries expressed *CD1C* and *CD141* but none expressed DC maturation genes. Healthy arteries were characterized by the absence of expression of DC associated genes and mature DC genes (figure 1). In GCA arteries, IF analysis revealed that the three arterial layers were heavily infiltrated by $CD209^+$ cells. These cells also expressed CD14 and often CD68, thus fitting with mo-DC ($CD209^+CD14^+CD68^-$) or macrophages ($CD209^+CD14^+CD68^+$). Some of these cells expressed maturation markers of DC (CD83 and CCR7). However, no CD1c or CD141 cells were found in the arterial wall by IF. In PMR and control arteries, no DC were found by IF. Transcriptomic analysis revealed that GCA arteries expressed many genes involved in the differentiation of monocytes into mo-DC, including *CSF2*, *CYBA*, *IRF4*, *AHR*, *WNT5A*, and *FZD2*.

Conclusion: This work demonstrates the presence of mature $CD209^+CD83^+CCR7^+$ DCs within the arterial wall in GCA but not in PMR or healthy arteries. The phenotype of these DCs mainly fits with mo-DCs. In PMR, the DC signature is more heterogeneous without expression of DC maturation markers.

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster III
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Polymyalgia rheumatica (PMR) and giant cell arteritis (GCA) are frequently overlapping conditions. It is estimated that 16 to 21% of PMR patients have GCA. In PMR, the presence of cranial features of GCA easily lead the clinician to diagnose GCA. However, the diagnosis of isolated large vessel (LV) GCA is more challenging and requires the use of vascular imaging techniques that are costly and/or irradiating. It is currently not recommended to perform vascular imaging or temporal artery biopsy to rule out GCA in PMR patients without features of GCA. Therefore, the identification of biomarkers able to rule out GCA in PMR patients could be helpful to select PMR patients in whom these exams should be performed. The aim of this study was to assess the performance of several biomarkers to identify GCA in PMR patients.

Methods: Patients were prospectively enrolled at the Dijon University Hospital (France). At inclusion, all patients were free of glucocorticoids or immunosuppressive drugs. All isolated PMR patients fulfilled the 2012 ACR/EULAR classification criteria and GCA was ruled out by at least one exam evaluating the temporal arteries (biopsy and/or doppler US scan) and an evaluation of large vessels by angio-CT or ^{18}FDG-PET-CT. All PMR/GCA overlap patients fulfilled the 2022 ACR/EULAR classification criteria for GCA. For all patients, vascular remodeling markers (MMP2, MMP3, MMP9, ANGPTL4, ANGPTL6), endothelial markers (CD141, CD31, CD146, vWFA2, ICAM-1, VCAM-1), cytokines (IL-6, CXCL-9, IL-27, IL-11) and CD163 were determined by Luminex assay in serum samples. Mann-Whitney tests were performed to compare PMR and PMR/GCA patients. Receiving operator characteristic (ROC) with area under the curve (AUC) were used to assess the performance of the tested biomarkers. Optimal cut off were identified according to Youden Index.

Results: Fifty isolated PMR and 29 GCA/PMR patients were included. GCA/PMR patients had higher serum levels of CD141 ($p = 0.004$) and CXCL9 ($p = 0.004$) than isolated PMR patients. By contrast, serum levels of MMP3 ($p = 0.02$) and IL-6 ($p = 0.003$) were lower in GCA/PMR patients compared to isolated PMR patients. There was no difference between groups for the other markers. AUC were calculated for CD141, CXCL9, IL-6 and MMP3. Separately, none of them reached an AUC > 0.7. However, when combined, high accuracy performance was revealed for the CXCL9/IL-6 ratio, which was significantly increased in GCA/PMR patients ($p < 0.0001$) with an AUC of 0.75 (cutoff > 35.06) while the MMP3/CD141 ratio was significantly lower in GCA/PMR patients ($p < 0.0001$; AUC = 0.77, cutoff < 5.1).

Conclusion: This study demonstrated that combining serum markers such as MMP3/CD141 and CXCL9/IL-6 could help to discriminate between individuals with isolated PMR and those with GCA/PMR. These markers warrant prospective evaluation in larger cohorts of PMR and PMR/GCA patients.

SESSION INFORMATION

Session Date: Tuesday, November 14, 2023

Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster III

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: Imaging studies in patients with giant cell arteritis (GCA) and suspected large vessel vasculitis (LVV) are sensitive, increasingly available, and less aggressive than temporal artery biopsy. Positron emission tomography/computed tomography (PET/CT) with 18-fluorodeoxyglucose (18F-FDG) allows for the evaluation of mural inflammation in extracranial arteries and supports the diagnosis of LVV. This study aimed to analyze in which patients with GCA the use of 18F-FDG-PET/CT is useful for detecting LVV.

Methods: ARTESER is a large Spanish registry promoted by the Spanish Society of Rheumatology, including patients with a new diagnosis of GCA, from June 2013 to March 2019. A selection of patients who underwent an 18F-FDG-PET/CT was carried out. The main variable of the study was the presence of vasculitis detected by this imaging technique. The diagnosis of LVV was based on expert opinion. Demographic variables, comorbidities, acute phase reactants, cumulative dose of glucocorticoids prior to the test, and the number of days elapsed before performing the test were considered. The clinical phenotypes were defined as cranial or extracranial, depending on the main symptom at the moment of diagnosis. Results are presented as a bivariable model to analyze differences between patients with positive and negative results, a regression model to approach the association between variables in those with a positive test, and a ROC area under the curve analysis.

More than 101 days	24 (22.2)	23 (9.4)		47 (13.3)
Glucocorticoids received before the 18F-FDG-PET/CT, n (%)				
Glucocorticoids (oral or iv)	113 (85.6)	146 (59.6)	**<0.001**	259 (68.7)
No glucocorticoids	19 (14.4)	99 (40.4)		118 (31.3)

*p-value refers to the statistical difference between patients with the listed characteristics, to those who do not present them.

Results: From a total of 1675 GCA patients, included in ARTESER registry, 377 met the inclusion criteria of having an 18F-FDG-PET/CT done during the diagnostic process. **Table 1** shows the bivariable analysis. 67.4% of patients presented as a cranial-GCA phenotype and 29.1% as extracranial-GCA variant, 18 patients could not be classified as either phenotype. Sixty-five percent of patients in our registry had LVV, as detected by 18F-FDG-PET/CT (n=245). In those patients with a positive PET/TC, the vascular territory most frequently affected was the thoracic aorta (85.7%), followed by supra-aortic vessels (78.8%), and abdominal aorta (57.6%). Cardiovascular risk factors were more frequent in patients with a negative 18F-FDG-PET/CT **(Table 1)**. The regression model (**Table 2**) shows a negative association with a positive 18F-FDG-PET/CT for older patients, patients with diabetes mellitus and cardiovascular disease and, the *odds ratio* for having a positive 18F-FDG-PET/TC is lower, as days go by. No variables were found to have a positive association with a positive 18F-FDG-PET/TC. Depending on the cumulative dosage of glucocorticoids, 18F-FDG-PET/CT had an area under the curve of 0.74 **(Figure 1).**

Conclusion: Younger patients have a higher probability of presenting a LVV detected by 18F-FDG-PET/CT. Patients with cardiovascular risk factors (hypertension, diabetes mellitus, smoking), have a higher probability of a negative 18F-FDG-PET/CT. The most frequent large vessel affected was the thoracic aorta. As days go off, and the cumulative glucocorticoid

SESSION INFORMATION

Session Date: Tuesday, November 14, 2023

Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster III

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: Existing EULAR/ACR guidelines on polymyalgia rheumatica (PMR) are focused on the management by rheumatologists. However, there is no consensus regarding early referral and evaluation in secondary care for patients with suspected PMR. It is well known that important differential diagnosis such as giant cell arteritis may be missed in general practice. In addition, a recently conducted worldwide survey suggested a wide heterogeneity in the referral of patients with suspected PMR from primary to secondary care [1]. The aim of this project was to develop evidence-based guidelines for the early referral of patients with suspected PMR.

Methods: A task force formed by members from the international giant cell arteritis (GCA)/PMR study group consisting of 38 participants (29 rheumatologists, 4 general practitioners, 4 patients with PMR, and a health care professional) drafted the guideline. Task force activities were led in accordance with the EULAR standard operating procedures. After 3 virtual meetings during 2022, 70 clinical questions were initially identified. These were later reduced to 10 and finally 6 questions following the Population, Intervention, Comparator, Intervention (PICO) format. The protocol for the systematic literature review was published at the PROSPERO database, search were performed on February 14th 2023, and data extraction and evaluation were

Table 1. Questions for the systematic literature review in Population, Intervention, Comparator, Intervention format.

1: What is the diagnostic value of strategy A (I), compared with strategy B (C), to make an accurate diagnosis (O), in people with suspected PMR (P)?

A specific strategy cannot be defined. Therefore, the terms strategy A and strategy B is used. Search will focus on papers comparing different strategies for diagnosis.

2: What is the outcome (O) of patients with suspected PMR (P) undergoing screening for GCA (I) as compared to not undergoing screening (C)?

A specific outcome cannot be defined (glucocorticoid free survival, relapse free survival, vision loss, quality of life etc.). Search will focus on all available outcomes.

3: Is assessment with diagnostic strategy A for giant cell arteritis (GCA) efficient (I), compared to diagnostic strategy B (C), on the ability to diagnose GCA (O) in people with suspected PMR at diagnosis (P)?

A specific diagnostic strategy will not be defined. Therefore, the terms strategy A and strategy B is used. Search will focus on papers comparing different strategies including but not limited to ultrasound, PET-CT, MRI and clinical evaluation.

4: What is the value of shared care (I) compared to sole management in primary care (C), in patients with suspected PMR (P1) or established PMR (P2), on outcomes (O).

All available outcomes will be gathered.

5: What is the effect of initiating glucocorticoids before referral to secondary care (I), compared with not initiating glucocorticoids (C), on the ability to make an accurate diagnosis (O), in people with suspected PMR (P)?

6: Does a fast-track diagnostic pathway for PMR (I), compared to standard care (C), influence diagnostic accuracy of PMR (O) in people with suspected PMR referred to secondary care for evaluation (P)?

performed by two investigators. Full text papers with more than 20 participants with suspected PMR evaluating the 6 PICOs were included. The results of the SLR were discussed during 3 online meetings, formulating the draft of the guideline.

Results: The PICO questions are shown in Table 1. The SLR yielded 14 papers, concerning PICO 1, 3, 4, and 6 (Figure 1). For PICO 2 and 5 no studies were identified. Guideline draft included 3 overarching principles and 6 recommendations: mandatory evaluations of patients with suspected PMR in primary care before referral, which patients with suspected PMR to refer for evaluation in secondary care, when to start glucocorticoids in patients referred to secondary care for evaluation of suspected PMR, and when to use rapid refer strategies in patients suspected of PMR, which patients seen in secondary care with suspected PMR should be evaluated for GCA, and which patients could be managed in primary care after the diagnosis.

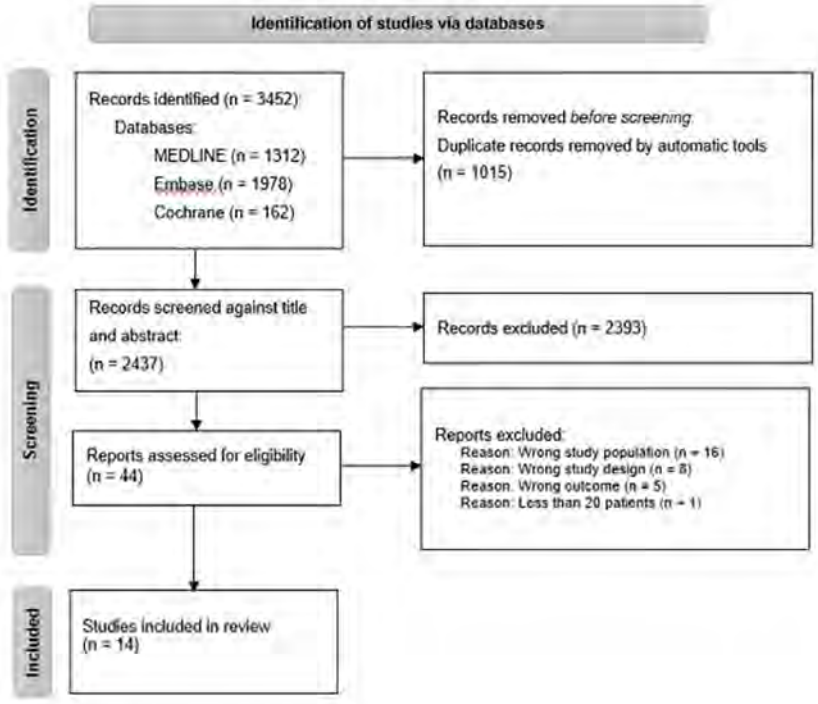

Figure 1. Prisma flow diagram of study selection

Conclusion: This is the first international consensus of the management of referral of patients with suspected PMR. The recommendations will ensure a more uniform management in the future, with a decreased risk of misdiagnosis. Moreover, the work will also define the future research agenda in the field.

Diagnostic Performance of a Newly-Launched Canadian Fast-Track Ultrasound Clinic Performed by Rheumatologists for Diagnosis of Giant Cell Arteritis

Jean-Charles Mourot[1], Sai Yan Yuen[2], Mihaela Popescu[3] and Nicolas Richard[4], [1]Université de Montréal, Mont-Royal, QC, Canada, [2]Maisonneuve-Rosemont Hospital, Mont-Royal, QC, Canada, [3]Maisonneuve Rosemont Hospital, Longueuil, QC, Canada, [4]Hopital Maisonneuve Rosemont, Montreal, QC, Canada

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster III
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Giant Cell Arteritis (GCA) poses diagnostic challenges for clinicians as there is no universal gold standard. We hypothesize that launching a Fast-Track Ultrasound (US) clinic by rheumatologists may spare the need for a biopsy. Therefore, we aimed to assess the diagnostic performance of temporal artery (TA) US in this setting.

Table 1 : Diagnostic performance of the ultrasound of the temporal and axillary arteries for GCA diagnosis

		Sensitivity		Specificity		PPV		NPV	
	N	%	95% CI	%	95% CI	%	95% CI	%	95% CI
Total	99	80.0	59.3-93.2	91.7	83.2-97.0	76.9	60.2-88.0	93.2	86.1-96.7
GCA Probability score									
Low risk	28	100.0	2.5-100	88.5	69.9-97.6	25.0	10.3-49.1	100.0	n/a
Medium risk	42	71.4	29.0-96.3	94.3	80.8-99.3	71.4	37.6-91.2	94.3	83.6-98.2
High risk	29	82.4	56.6-96.2	91.7	61.5-99.8	93.3	68.0-98.9	78.6	56.4-91.2
Disease course									
New-onset	88	78.3	56.3-92.5	90.8	81.0-96.5	75.0	57.6-86.9	92.2	84.4-92.3
Relapse	11	100.0	15.8-100	100.0	66.4-100	n/a	n/a	n/a	n/a
Biopsy	45	73.7	48.8-90.9	80.8	60.7-93.5	73.7	54.9-86.6	80.8	65.9-90.1

Methods: In this Canadian monocentric retrospective cross-sectional analysis, 106 subjects were identified from the Fast-Track clinic between 05/2020-05/2022 (99 after exclusion). Each subject had an US of the temporal and axillary arteries according to a standardized protocol for either suspicion of new-onset or relapse of GCA. The pretest probability was calculated using the *Southend probability score (*high, medium or low*)*. The sensitivity (Sn), specificity (Sp), positive predictive value (PPV) and negative predictive value (NPV) were calculated using the rheumatologist final diagnosis as the gold standard.

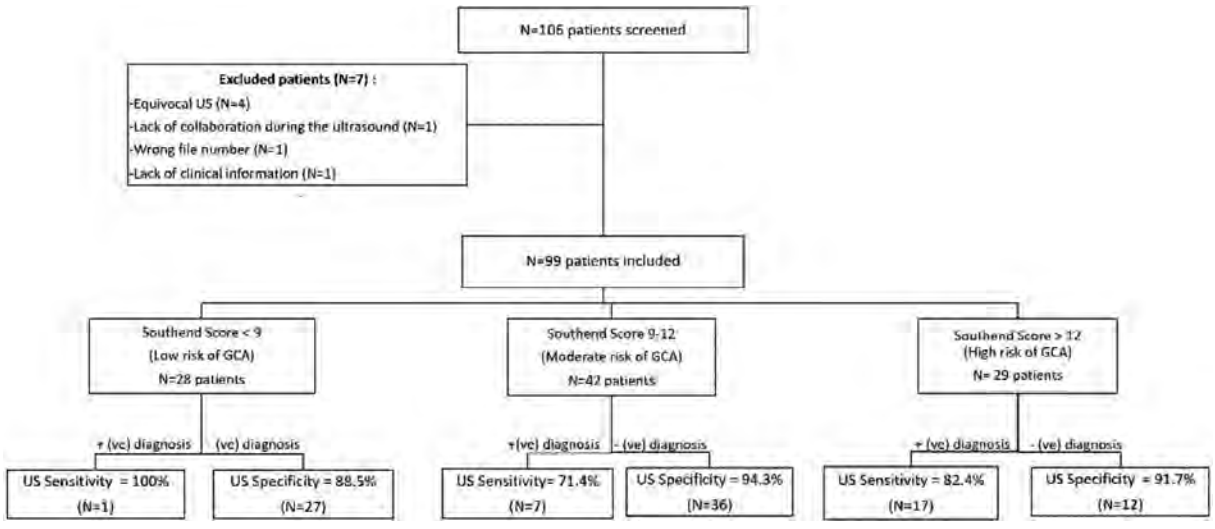

Figure 1 : Workflow of the exclusion criteria and summary of the diagnostic performance of US in GCA

Results: TA US demonstrated a sensitivity of 80.0% [95% confidence interval (CI) 59.3; 93.2%], a specificity of 91.7% (95% CI 83.2; 97.0%), a PPV of 76.9% (95% CI 60.2; 88.0%), and a NPV of 93.2% (95% CI 86.1; 96.7%). 30, 44, 29 subjects were at high, medium, and low risk, respectively. Of those subgroups, subjects at high risk had higher PPV with a lower NPV, while similar Sn/Sp were observed between all three subgroups (see Table).

Conclusion: Our findings confirm the validity of TA US as a diagnostic tool for GCA and highlight the importance of Fast-Track US clinics. Future studies will inform on the role of TA biopsy in the setting of increasing use of US.

SESSION INFORMATION

Session Date: Tuesday, November 14, 2023

Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster III

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: Environmental air pollution (AP) has been found to affect vascular inflammation and to contribute to the risk of onset and flare of autoimmune diseases[1,2]. Giant cell arteritis (GCA) has been reported to be more prevalent in urban than in rural areas[3], indicating a possible link between AP and disease onset. The objective of this study is to investigate whether there is an association between exposure to AP and the risk of developing GCA and its ischemic complications.

Methods: Charts of consecutive patients with GCA followed between June 2013 and December 2021 in three hospitals (Bozen, Milan, Verona) of Northern Italy were reviewed. Only patients who were resident in Italy at the time of diagnosis and who had confirmed GCA, a follow-up ≥ 6 months and precise information on disease onset were included. Data collection included demographics, clinical information, and ZIP code of residency. Patients were linked to their daily particulate matter (PM10, mass concentration, particles with aerodynamic diameter ≤10μm), exposure derived from a spatio-temporal interpolation process using a Bayesian hierarchical model that included 11 spatial and spatio-temporal predictors, such as meteorological variables and Aerosol Optical Depth. The model was cross-validated, showed good performance and provides a 1km x 1km spatial resolution for daily exposure to PM10. A case-crossover study with conditional logistic regression was conducted to investigate the acute effect of PM10 exposure on disease onset and the development of ischemic

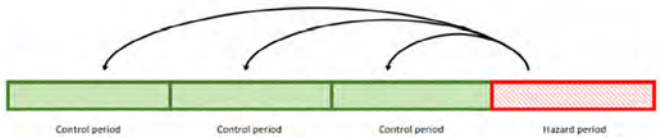
Figure 1. Case-crossover study design

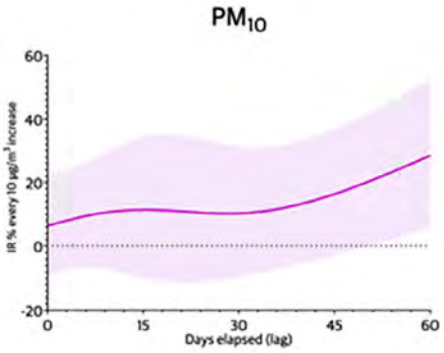


complications. Several lag exposures before symptoms onset were selected (hazard periods) and compared to 3 same-length periods prior to symptoms onset (control periods) (**Figure 1**).

Results: Two hundred and thirty-two patients were included. **Table 1** summarizes their main demographic and clinical features. **Figure 2** shows the exposure-response association between air pollutants and the risk of developing GCA. Incremental odds (%) of GCA every 10 µg/m³ increase in PM10 concentration at different lag-exposure were found. Specifically, the incremental risk (every 10 µg/m³ increase in PM10) for 60-day lag was27,08 (95% CI 5,81-52,63); at shorter lags we found no significant association. There was no significant difference after adjusting for seasonality. Fifty-nine patients (25%) suffered from a GCA-related ischemic complication. No significant association between exposure to PM10 and ischemic complications was found (p=.198).

Conclusion: Conclusion. Acute exposure to environmental AP PM10 seems to be associated with a higher risk of developing GCA but not with GCA-related ischemic complications. Further studies on larger cohorts are needed to confirm these preliminary results.

Figure 2. Exposure-response association between air pollutants and risk of GCA.



The curve was interpolated using the conditional logistic regression model. The curve was smoothed with restricted cubic splines with knots at 1, 7, 15, 30 and 60 days.

FDG Uptake in Limb Arteries at Diagnosis of Giant Cell Arteritis and Risk of Relapse: An Observational Cohort Study

Geoffroy Peyrac[1], Arthur Mageau[2], Augustin Gaudemer[2], Khadija Benali[1], Jean-Francois Alexandra[1], Andrey Strukov[1], Sebastien Ottaviani[1], Thomas Papo[2] and Karim Sacre[2], [1]Assistance Publique Hopitaux de Paris, Paris, France, [2]Université Paris Cité, Paris, France

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster III
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Steroids and anti-IL6 biotherapy are highly effective in obtaining remission in patients with giant cell arteritis (GCA) but the risk of relapses remains high, especially once treatments are withdrawn. Predictors of relapse in GCA are missing. We aimed to identify predictors of relapse in GCA.

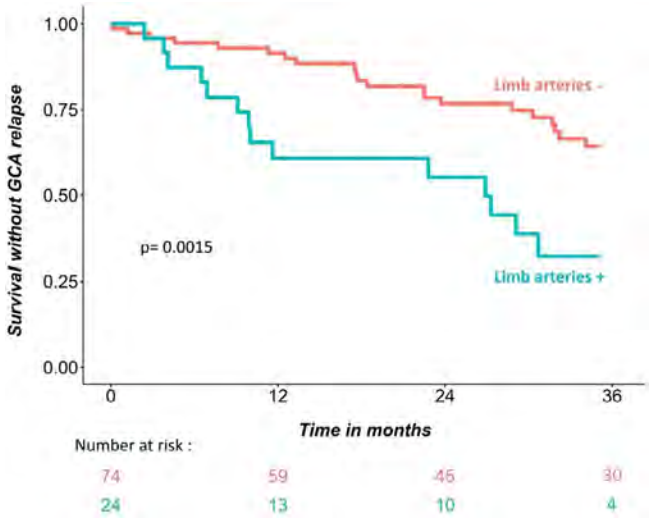

Figure 1Kaplan-Meier Curves of Study Population Patients with FDG uptake in limb arteries (limb arteries +) at diagnosis had higher rates of relapse than patients without FDG uptake in limb arteries (limb arteries -) at diagnosis (log-rank; p = 0.0015).

Methods: All consecutive patients admitted with a new diagnosis of GCA in our national center for rare immune-mediated inflammatory diseases (Bichat hospital, Paris, France) between January 2011 to December 2021 were eligible for this study. Patients were included if the 2022 American College of Rheumatology/EULAR classification criteria for GCA were met. GCA relapse was defined by the presence of recurrent or new-onset disease related symptoms, an increase of CRP value >10mg/L and the necessity for an increase in the prednisone dose. The primary outcome was the GCA relapse rate over the 36-months follow up. Factors associated with the primary outcome were identified and time to first relapse was studied with a multivariable Cox model.

Results: One hundred and eight patients (74 [69-81] years, 65% of women) with a new diagnosis of GCA were studied. At diagnosis, 87 (81%) patients had cranial symptoms. CRP was high (> 10 mg/L) in all but 5 cases (90%) with a median level of 64 [34-132] mg/L. GCA was biopsy-proven in 65 (64%) cases. Ninety-eight (91%) FDG/PET CT performed at diagnosis were available for a systematic review of FDG uptake in aorta, supra-aortic trunks, and limb (axillary and iliofemoral) arteries. Unequivocally strong linear large vessels wall FDG uptake was found in 74 (73%) cases. All patients received steroids given for 21.0 [18.0-28.5] months, associated with methotrexate or tocilizumab in 1 (1%) and 2 (2%) cases, respectively. During a median follow-up of 27.5 [11.4 - 35.0] months, 40 (37%) patients experienced GCA relapse. Univariate analysis showed that FDG uptake in limb arterie sat diagnosis was associated with GCA relapse: relapse occurred in 58% (n=14/24) of patients with FDG uptake in limb arteries and in 28% (n=21/74) of patients without FDG uptake in limb arteries(p=0.008). Multivariable Cox regression model, including age, gender, thickened aortic wall, FDG uptake in limb arteries and IV steroid pulse as covariates, showed that FDG uptake in limb arterie sat diagnosis was the unique identified risk factor for relapse (HR 3.05 [1.48-6.25], p=0.002) (Figure 1).

Conclusion: FDG uptake in limb arteries at diagnosis of GCA is associated with relapse. FDG/PET CT may help to better tailor therapy in GCA.

Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster III

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: Patients with Giant cell arteritis (GCA) face an elevated risk of aneurysm formation. Despite this, consensus regarding optimal aortic visualization methods and aneurysm monitoring frequency is still lacking. Low-frequency transducer ultrasound offers a potential solution, capable of visualizing the ascending aorta and aortic arch. We conducted a study to compare this ultrasound technique against Computed Tomography Angiography (CTA), the current gold standard for aortic evaluation.

Methods: We conducted our study at Martina Hansens Hospital in Bærum, Norway. We included patients diagnosed with GCA who also met the ACR/EULAR classification criteria for GCA. The ascending aorta's diameter was measured using both ultrasound and CTA. Aortic aneurysm was defined as an ascending aorta diameter of ≥40 mm. The Student's t-test was used to compare the results.

Results: Our pilot study included thirteen patients, twelve females, and one male, with an average disease duration of 4.6 years (95%CI 3.7-5.5). The mean diameter of the ascending aorta was 35.4 mm (95%CI 32.3-38.4) measured by ultrasound and 36.5 mm (95%CI 33.0-40.0) by CTA. The mean difference between the two methods was 1.15 mm (95%CI -0.07 to 2.38, p-value = 0.06). CTA identified four patients with an ascending aorta aneurysm, while ultrasound identified three. (Table 1). No aneurysms were found in the descending aorta by CTA.

Patient	Sex	Age	GCA type	Ultrasound measurements at the aortic root	CT measurements at the aortic root	Aneurysm	Years from GCA diagnosis to ultrasound/CT
1	Female	81	Mixed	28	27	No	4
2	Female	78	Cranial	31	30	No	5
3	Female	87	Mixed	31	34	No	4
4	Female	87	Mixed	32	32	No	8
5	Female	64	Cranial	33	38	No	5
6	Female	78	Mixed	34	34	No	5
7	Female	71	Mixed	34	34	No	2
8	Female	74	LV	34	34	No	4
9	Female	76	Mixed	38	39	No	6
10	Female	82	Mixed	40	41	Yes	4
11	Female	69	Mixed	42	42	Yes	4
12	Female	60	LV	46	48	Yes	4
13	Male	74	Mixed	37	42	Yes	4

LV; Large Vessel only involvement; Mixed: Large vessel and cranial vessels involvement

Conclusion: Our preliminary findings suggest that ultrasound provides results comparable to CTA in assessing the ascending aorta diameter in GCA patients. This positions ultrasound as a potential tool for monitoring aortic aneurysm development in this patient group.

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster III
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Applanation tonometry (ATn) is a non-invasive, point-of-care tool used to capture arterial pressure waveforms. It can measure arterial pulse wave velocity (PWV), a marker of arterial wall stiffness. Arterial inflammation increases vessel-wall stiffness and PWV, as previously demonstrated in patients with Takayasu arteritis. ATn on temporal arteries has not yet been studied, and it may help detect vasculitis in patients with active giant cell arteritis (GCA). The objective of this study is to investigate the feasibility of ATn on temporal arteries, assess the quality of the waveform/PWV obtained, and explore if PWV is increased in patients with GCA.

Methods: A cross-sectional study was performed in our quaternary vasculitis clinic from June to December 2022. Participants referred for suspected GCA, without prior temporal artery biopsy, were eligible. At baseline, participants had a clinical assessment, color doppler ultrasound (CDUS) and ATn of temporal arteries. ATn was performed by dedicated, blinded research personnel in a separate room. GCA specialists who completed the clinical assessment and CDUS were blinded to ATn results. Final diagnosis was established based on expert opinion at the 6-month follow-up. We used the Sphygmo Cor system to perform ATn. PWV were measured in five arterial segments on the right side: carotid to superficial temporal artery (C-S), carotid to parietal temporal artery (C-P), carotid to frontal temporal artery (C-F), superficial to parietal temporal artery (S-P), and superficial to frontal temporal artery (S-F). The quality of the waveform was confirmed visually. The coefficient of variation (CV = standard deviation/transit time) of the proximal and distal arterial points was assessed. A CV ≤ 6% denoted good capture quality as per the manufacturer's recommendations. Descriptives statistics were performed for baseline characteristics and ATn quality assessment. Mann-Whitney U test was used to explore a potential difference in PWV in patients with and without GCA.

Results: Fifteen participants were enrolled, including 3 patients with a final diagnosis of GCA who satisfied the 2022 ACR/EULAR classification criteria (Table 1). A total of 69 arterial segments were assessed (PWV measures could not be obtained in 1 C-F, 3 S-P and 2 S-F segments). Quality assessment of the ATn waveform was satisfactory for the C-S,

C-F, S-F arterial segments (Table 2). Parietal temporal arteries had a high proportion of low-quality waveforms, likely due to their small size relative to the probe. In patients with GCA, median PWV of the C-S, C-P, C-F and S-P segments were numerically but not statistically higher than in patients without GCA (Table 3).

Conclusion: ATn of temporal arteries is feasible, and PWV measures were of quality for 3 arterial segments (C-S, C-F, S-F). Median PWV was higher in patients with active GCA than in subjects without confirmed GCA; however, this study was underpowered to detect statistical difference. This proof-of-concept study allowed the identification of arterial segments that are now further evaluated in a larger trial of ATn in GCA (Clinicaltrials.gov id: NCT05703763).

Table 2: Quality assessment of the waveform obtained for 5 arterial segments in 15 participants undergoing applanation tonometry of temporal arteries.

ATn of 5 temporal artery segments	Results
Adequate signal quality, n (%)	
Carotid to superficial TA	N=15
Proximal waveform	15 (100)

Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster III
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: In recent years, Temporal Artery US (TAUS) incorporating Axillary Artery US (AAUS) has become a reliable alternative to biopsy for diagnosing GCA but studies have shown heterogenous results for its' diagnostic performance for this purpose (1,2). Published values for Intima-Media Thickness (IMT) exist which can differentiate an inflamed vessel from a normal one but have not yet been validated (Table 1). We aimed to establish what IMT values in each vascular territory could reliably support or refute a diagnosis of GCA.

Methods: We performed a prospective study of all newly diagnosed GCA patients (clinical diagnosis, verified by 2 rheumatologists after 6 months) who had a positive baseline vascular US (n= 57) presenting to our Rapid Access GCA clinic over 18 months. US of all 6 branches of the Superficial Temporal Arteries (STA) and both Axillary Arteries (AA) were performed on all patients using a GE P9 device. Sonographic abnormalities considered indicative of vasculitis in the temporal arteries included the halo sign and non-compressible arteries with a thickened IMT (3). In the axillary arteries, a halo sign and an

Table 1: IMT Cut-off values used to diagnose GCA on vascular US (4).

Vessel	IMT Cut-off Value
Common STA	0.42 mm
Frontal STA	0.34 mm
Parietal STA	0.29 mm
Axillary Artery	1.0 mm

Table 2: Baseline Intima-Media Thickness (IMT) values in each Superficial Temporal (STA) and Axillary Artery (AA) branch that give 100%, >95% and >90% sensitivity and specificity for a clinical diagnosis of GCA. Rt=right, Lt=left.

Vessel, IMT in mm	100% sensitivity	>95%	>90%	100% specificity	>95%	>90%
Rt Common STA	0.20	0.25	0.25	0.85	0.60	0.41
Rt Frontal STA	0.15	0.20	0.20	0.46	0.44	0.33
Rt Parietal STA	0.01	0.15	0.15	0.45	0.35	0.29
Rt Axillary Artery	0.40	0.49	0.50	2.70	1.10	0.91
Lt Common STA	0.20	0.30	0.30	0.75	0.65	0.44
Lt Frontal STA	0.15	0.20	0.20	0.55	0.43	0.35
Lt Parietal STA	0.15	0.18	0.20	0.55	0.35	0.26
Lt Axillary Artery	0.34	0.50	0.50	2.00	1.10	0.90

intima-media thickness of >1.0mm was considered positive. We performed Chi-Square test with ROC analysis to determine the sensitivity and specificity of each measured IMT value in each branch of the STA and AA.

Results: 66/124 patients had a clinical diagnosis of GCA at 6 months. 57 of these patients had a positive baseline vascular US. Our cohort consisted of 61% males (n=35) with a mean age of 74.4 years. Overall, US had a sensitivity of 86.4% and a specificity of 82.8% for a clinical diagnosis of GCA. Table 2 demonstrates the sonographically-defined IMT values in our cohort for each branch of the STA and AA which can irrefutably exclude (i.e. sensitivity 100%) or diagnose (i.e. specificity 100%) GCA.

Conclusion: Our data provides a template which can guide clinician-sonographers when interpreting vascular US images in cases of suspected GCA. The conventional method of identifying a halo with a non-compressible artery is somewhat limited due to conflicting results of its diagnostic performance in clinical studies to date. By incorporating IMT measurement into the routine US protocol for GCA, clinicians can attain increased diagnostic accuracy if the above thresholds are met.

A Retrospective Analysis of Prevalence of Positive Temporal Artery Biopsies in African American Patients with Giant Cell Arteritis (GCA) in a Large Academic Health Center

Leen Al saleh[1], Haya Haddad[2], sunita Dia[3] and Florina Constantinescu[2], [1]Medstar Washington Hospital Center, Alexandria, VA, [2]Medstar Washington Hospital Center, Washington, DC, [3]Spartanburg Regional Healthcare System, Greenville, SC

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster III
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Giant Cell Arteritis (GCA) is a systemic vasculitis reportedly more common in Caucasian older adults**.** Studies suggest that GCA is very rare in African American patients. There is paucity of data on positivity of temporal artery biopsy (TAB) in African American patients. The primary aim of our study is to assess the prevalence of positive TAB in AA patients in a large academic center. Our secondary outcome is to describe the presenting symptoms of GCA in AA patients.

Methods: We conducted retrospective chart reviews of patients who underwent TAB at a large academic health center between 2010 and 2021. Adult patients with self-reported race as AA were included in the study. Analyses were performed using Microsoft Excel.

Results: A total of 77 patients' charts were reviewed. Only 8 patients (10.4 %) had positive temporal artery biopsies. Their mean age was 79 years. In those patients with positive TAB, headache was reported in all cases, while only 4/8 patients presented with visual symptoms. Additionally, 3/8 patients reported jaw claudication and only 2/8 patients complained of scalp tenderness. The duration of steroid treatment prior to biopsy did not exceed 10 days.

Clinical suspicion was high enough after a multidisciplinary discussion to decide to treat 10/77 patients for GCA despite negative TAB. Vision changes were observed in 7/10 patients. 9/10 patients had elevated erythrocyte sedimentation rate (ESR). Only one patient presented with normal ESR, however, due to vision loss with evidence of ischemic optic neuropathy and concurrent cilioretinal artery occlusion, providers decided to treat for GCA. Notably, one patient had a PET scan that showed increased metabolic activity along the thoracic and abdominal aorta and was subsequently treated for extracranial GCA. In our study, rheumatology was consulted for 76.6% (59/77) of the patients, including all 18 patients who were treated for GCA; 8 with positive biopsies and 10 with negative biopsies.

The mean score for the 2022 ACR/EULAR GCA criteria was 8 among patients who had positive biopsies, while the mean score for GCA probability score (GCAPS) was 13. In contrast, patients with negative biopsies who continued to receive treatment for GCA had average scores on the ACR/EULAR and GCAPS of 5 and 11 respectively. Higher scores of ACR/EULAR and GCAPS were observed in the positive biopsy groups. Among the total cohort of 77 patients, 12 patients had symptoms of Polymyalgia Rheumatica. None of them had positive temporal artery biopsy, however 2 patients were treated as GCA cases despite negative biopsy results per provider high clinical suspicion.

Conclusion: Our study shows that the rate of positive TAB in African Americans is 10.4 % which is higher than 8.4% previously reported in the study by *Greuneret al*. Headache was found to be the most common presenting symptom of GCA in our cohort. In our study, a total of 23.4% (18 out of 77) of the patients were diagnosed and treated as GCA, 76.6% of them had negative biopsy and were not treated as GCA. Further research is needed to better stratify the risk of temporal artery inflammation in AA patients prior to the decision to pursue TAB.

Systole and Diastole Ultrasound Wall Thickness Shows Significant Differences That Affect the Diagnosis and Assessment of Giant Cell Arteritis

Emma Brugarolas[1], Elisa Fernandez-Fernandez[2], Irene Monjo[3] and Eugenio De Miguel[4], [1]Hospital Universitari de Bellvitge, Girona, Spain, [2]La Paz University Hospital, Madrid, Spain, [3]University Hospital La Paz, Madrid, Spain, [4]Hospital Universitario La Paz, Madrid, Spain

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster III
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: In the last few years, several cut-off points for the intima-media thickness (IMT) of temporal arteries (TA) and large vessels (LV) have been proposed for the ultrasound (US) diagnosis of giant cell arteritis (GCA). It has usually been recommended to use the average measure of the higher IMT, but there is currently a lack of consensus on this. We have observed some changes in the IMT measurements depending of if they are performed in systole or diastole. To confirm if there are differences in the IMT measurement taken in systole or diastole and if they are clinically relevant.

Methods: Observational study that included recorded videos of the US examination performed in consecutive patients referred to our GCA fast track clinic with suspicion of GCA. The gold standard diagnosis was the clinical diagnosis of the doctor after at least 6 months of follow-up. All the videos of every explored vessel (TA with their common trunk -CT- and their

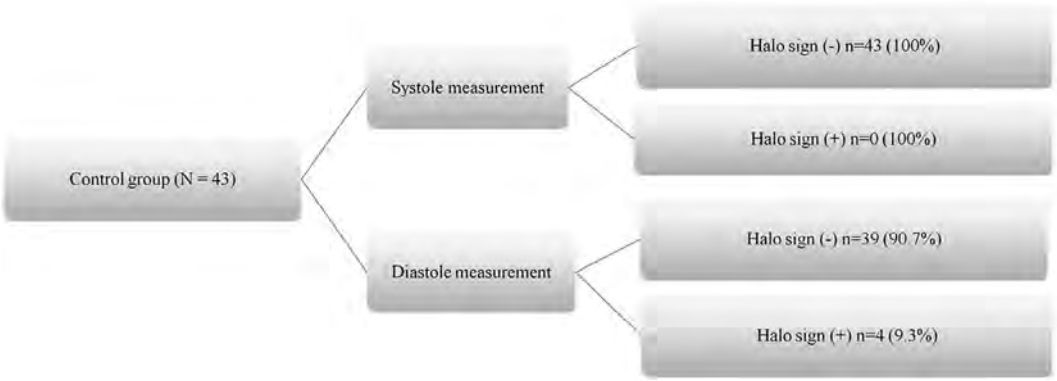
GCA = giant cell arteritis; N = number of patients; SD = standard deviation; TA temporal artery. Measures are showed in mm).

frontal -FR- and parietal -PAR-branches, subclavian -SC- and axillary -AA- arteries) were reviewed and the IMT of each of them was measured in systole and diastole peaks. We define an US result as positive with cut-off values of IMT ≥ 0.34 mm for FR and PAR, ≥ 0.42 mm for CT, and ≥ 1 mm for AA and SC. Demographic data were also collected. Reliability was tested by two independent readers in 40 patients using the of intraclass correlation coefficient mixed model absolute agreement (ICC).

Results: We have included 84 cases, 41 with GCA and 43 without GCA (controls). The mean values of age and sex, as well as the IMT in systole and diastole of each vessel are shown in Table 1. There were not significant differences in sex but patients without GCA were younger ($p < 0.01$). US IMT measurements in systolic and diastolic times showed statistically significant differences in all the explored vessels, both in patients with GCA and in the control non GCA group (Table 1). All the IMT measured in diastole showed higher and statistically significant values than those measured in systole, with a mean increment of measurement of 5.7% and 6.83 % in TA and 5.02% and 4.95% in LV, respectively in the GCA and control group. These results can have clinical relevance since if we used diastolic measurements, instead of systolic measurements, 4/43 (9.3%) cases in controls had halo sign in one isolated vessel (1 case in right FR, 1 in right CT, 1 in right SC, 1 in left SC) (Figure 1). However, in GCA patients, the number of patients with halo sign did not change, but the number of pathological vessels increased in 15 branches when the measurement was performed in diastole (2 in right FR, 3 in right PAR, 1 in right CT, 3 in left FR, 4 in left CT and 2 in right AA)(Fig 1), so it could influence the assessment of the disease with OGUS or other scores. The result of the interrater analysis, between two readers, revealed an ICC between 0.845 and 0.992 for the different arteries.



Conclusion: There are significant differences between the IMT measured in systolic and diastolic peaks, as in GCA as in normal controls, with higher values in diastole. The differences are relatively small but may increase the number of false positives in 9.3% cases in controls, and the number of affected vessels in the GCA group. This should be considered in the diagnosis and assessment of GCA.

Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster III

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: Around 20% of polymyalgia rheumatica (PMR) patients without clinical symptoms of giant cell arteritis (GCA) have subclinical GCA by image or byopsy[1]. However, there is not data about its natural evolution and how these patients should be treated.Our main objective was to compare the outcomes of patients with PMR and subclinical GCA with those with isolated PMR over a 2-year period.

Methods: We included PMR patients with a complete vascular ultrasound examination at basal visit, recruited from nine European rheumatology centers. We analyzed longitudinal data from baseline, 3, 6, 12, 18 and 24 months. Only patients followed for at least one year were included. All patients fulfilled the 2012 EULAR/ACR Provisional Classification Criteria for PMR. Patients were stratified into two groups: isolated PMR and PMR with subclinical GCA with ultrasound positive halo sign. The outcomes (relapses, prednisone use and treatments needed) were compared between groups, using Chi^2, student t test and logistic regression analysis. PMR relapse was defined as clinical and/or laboratory worsening after initial remission requiring change in treatment after excluding other causes. Relapses were classified as minor or major according to the EULAR definition[2].

Results: We included 150 PMR patients (50 with subclinical GCA, 100 withisolated PMR) with a median (IQR) follow-up of 22 (20; 24) months without significant differences betweenisolated PMR and subclinical GCA. 47 patients (29%) had a relapse, 31 (62%) in the PMR with subclinical GCA group and 16 (14.3%)in the isolated PMR group ($p< 0.001$).In patients with pure PMR all relapses were minor, whereas in patients with subclinical GCA there was one major relapse. Prednisone starting dose was significantly higher in patients with PMR with subclinical GCA than in patients with isolated PMR

	Pure PMR (n=100)	Subclinical GCA/PMR (n=50)	p
Age, mean ± SD years	71.7±8.4	74.1±7.8	0.080
Female sex, n (%)	66 (59%)	25 (50%)	0.302
CRP, mean ± SD mg/L	55.3±52.4	34.6±37.2	0.008
ESR, mean ± SD mm/hr	63.2±31.2	62.7±33.1	0.936
Follow-up time, median (IQR)	22.5 (21; 24)	22 (18; 25)	0.895
Relapses, n/n total (%)			
Total	16/112 (14.3%)	31/52 (59.6%)	0.001
Minor	16/112 (14.3%)	30/52 (57.7%)	0.001
Major	0	1 (2%)	
Glucocorticoid dose, mean ± SD mg of prednisone (or equivalent)			
Baseline	19.5±7.4	33.6±14.3	0.001
Month 3	10.0±5.2	15.2±7.9	0.001
Month 6	5.1±2.7	8.9±6.4	0.001
Month 12	2.4±3.4	7.5±13.5	0.016
Month 18	1.6±4.3	3.3±5.4	0.147
Month 24	0.4±4.9	1.6±6.6	0.296
Adjunctive DMARDs	13 (13%)	25 (50%)	0.001
Adjunctive biological therapy or new small molecules	2 (2%)	14 (28%)	0.001

(Table 1). Among patients with subclinical GCA, no differences were found in the prednisone starting dose between those who relapsed and those who did not (mean, 32.4±15.6 vs 35.5±12.1 mg, p=0.722). Patients who relapsed had a faster prednisone dose reduction in the first 3 months in compared to the non-relapsing patients (mean dose at 3 months, 13.0 ±7.4 vs 18.8±7.5 mg, p< 0.01). Five patients in the PMR with subclinical GCA group received tozilizumab therapy at diagnosis; one of them had a minor relapse. No differences were found between relapsing and non-relapsing patients with subclinical GCA regarding age, sex, CPR and ESR.

Conclusion: Patients with PMR and subclinical GCA had a significantly higher number of relapses during a 24-month follow-up than patients with isolated PMR (62 vs 16%). Our results suggest that patients with PMR with subclinical GCA should be treated in the same manner as patients with clinically overt GCA without ischemic symptoms.

SESSION INFORMATION

Session Date: Tuesday, November 14, 2023
Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster III
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: We recently found extracellular mitochondrial-derived N-formyl methionine in patients with giant cell arteritis (GCA. Extracellular mitochondria can be extruded by several mechanisms, including platelet activation, and are highly immunogenic, leading to formation of anti-mitochondrial antibodies (AMAs), such as anti-cardiolipin antibodies that have also been observed in GCA. The purpose of this study was to determine the presence of additional AMAs, including anti-mitofusin 1 (MFN1) antibodies, in patients with GCA. We also sought to determine whether extracellular mitochondria are capable of mediating platelet activation in patients with GCA.

Methods: Anti-MFN1 IgG levels were measured using an in-house ELISA in the plasma from patients with GCA (n=65 in remission, n=14 with active disease), and 30 healthy controls (HC). Ultrapure mitochondria, isolated from HepG2 cells, were incubated with plasma from 65 patients with GCA in remission, and 16 HC, and assessed for IgA and IgG binding to the mitochondrial outer membrane using flow cytometry. Mitochondria were also opsonized with patient (n=58) or healthy control (n=10) plasma (6%), and subsequently incubated with platelets to determine the capacity of plasma factors, including AMAs, to promote mitochondrial-mediated platelet activation.

Results: Levels of anti-MFN1 IgG antibodies, a specific AMA, were elevated both in active disease ($p< 0.0001$) and in remission ($p< 0.0001$) in patients with GCA (**Figure 1A**). No differences in levels of anti-MFN1 antibodies were found between patients in remission and active disease for GCA (**Figure 1B**).No association was observed between anti-MFN1 antibodies and ESR levels (**Figure 1C**). Though total levels of IgG AMA did not reach statistical significance (p=0.38) in GCA patients compared to HC, IgA AMA levels were significantly higher in patients with GCA as compared to healthy individuals (p=0.003, **Figure 2A**). Levels of IgA AMA correlated with levels of IgG AMA in patients with GCA (**Figure 2B**), but not with levels of anti-MFN1 (data not shown). Finally, to investigate a potential pathogenic role of AMAs in GCA, exogenous mitochondria, derived from HepG2 cells, were opsonized with patient plasma and, upon washing, incubated with platelets from healthy individual. Plasma from patients with GCA had enhanced capacity to promote mitochondrial-mediated platelet activation as measured by P-selectin expression on platelet cell surface by flow cytometry, as compared to plasma from HC ($p< 0.0001$, **Figure 3A**). Platelet levels of P-selectin were associated with levels of anti-MFN1 IgG in patients with GCA (r=0.43, p=0.0012, **Figure 3B**).

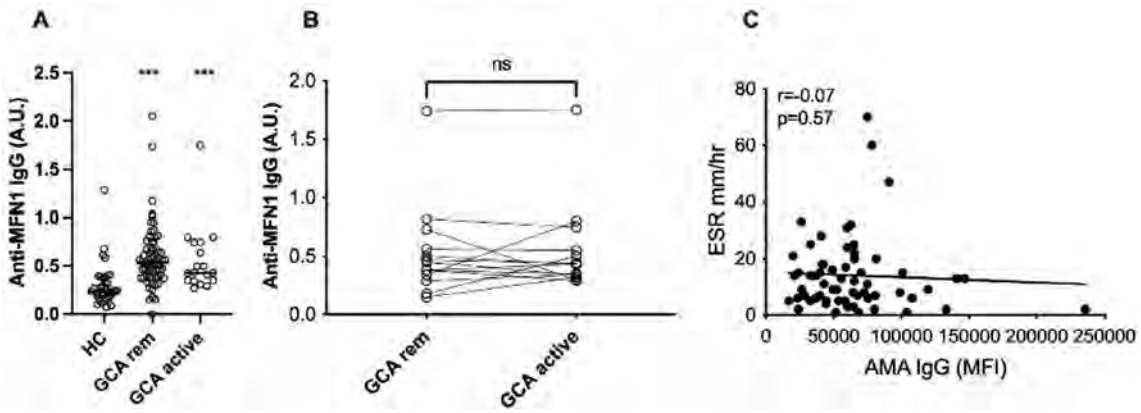

Figure 1. Anti-mitochondrial antibodies in giant cell arteritis. A) Levels of anti-MFN1 IgG antibodies were analyzed in the plasma of patients with giant cell arteritis (GCA) both in active disease and in remission (rem) and compared to healthy controls (HC). B) Anti-MFN1 IgG levels in patients at time-point of remission (rem) as well as matched active disease (active) as assessed by physician global assessment (PGA) in GCA. C) Correlation between levels of anti-MFN1 IgG antibodies and ESR. For statistical analyses, Mann-Whitney U test (A), Wilcoxon (B), and Spearman's correlation (C) were used. *** p<0.001.

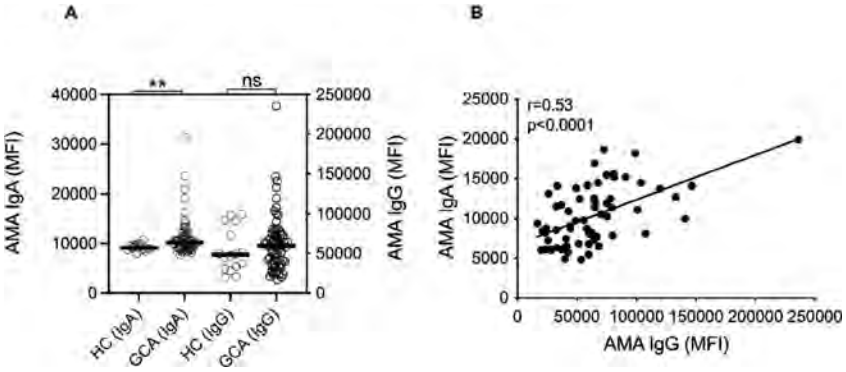

Figure 2. IgA and IgG anti-mitochondrial antibodies in giant cell arteritis. A) Levels of IgA and IgG anti-mitochondrial antibodies (AMA) were measured in the plasma of patients with giant cell arteritis (GCA) and health controls (HC) by flow cytometry. Results are presented as the mean fluorescence intensity (MFI). B) Correlation analysis between IgA AMA levels and IgG AMA levels in patients with GCA. Statistical analyses were done by Mann-Whitney U test (A) and Spearman's correlation (B). ** p<0.01.

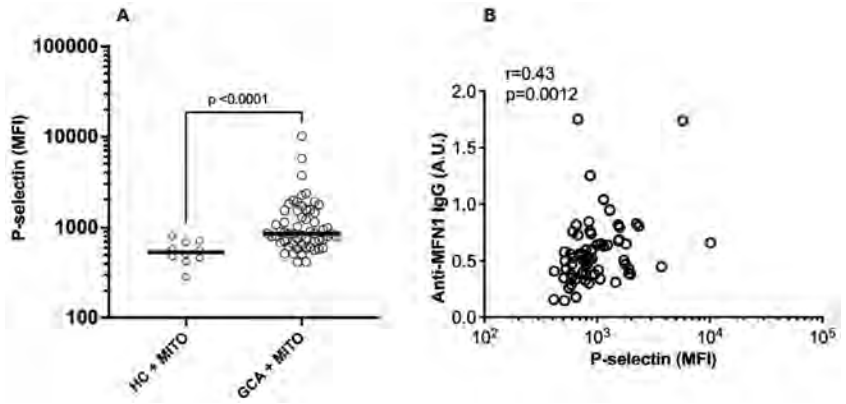

Figure 3. Mitochondrial-mediated platelet activation in giant cell arteritis. A) Platelet rich plasma (PRP) from a healthy individual was exposed to mitochondria (mito) in the presence of plasma of patients with giant cell arteritis (GCA, (n=58) and healthy controls (HC, n=10), and P-selectin expression on platelet measured by flow cytometry. Results are presented as the mean fluorescence intensity (MFI). B) Correlation analysis between levels of anti-MFN1 IgG and in vitro-induction of P-selectin on platelets in patients with GCA. Statistical analyses by Mann-Whitney U test (A) and Spearman's correlation (B).

Conclusion: We report the presence of AMAs in GCA. Presence of autoantibodies targeting mitochondria supports the hypothesis of antigenic mitochondrial components being present in GCA. Our data suggest that mitochondrial targeting by AMAs results in immune complex formation, potently activating platelets, possibly partaking in the thromboembolic morbidity and mortality of the disease. Targeting key drivers of mitochondrial extrusion in GCA could lead to new therapeutic interventions, including suppression of platelet activation.

Weyand[4], Matthew Koster[1] and Kenneth Warrington[1], [1]Mayo Clinic, Rochester, MN, [2]Mayo Clinic, Rochester, MN, Rochester, MN, [3]University of California Los Angeles, Los Angeles, CA, [4]Mayo Clinic School of Medicine and Stanford University, Rochester, MN

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster III
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Large vessel (LV) complications are known to occur in patients with giant cell arteritis (GCA). The magnitude of risk compared to the general population remains unclear.

In this study, we aimed to estimate the incidence of LV manifestations in a population-based cohort of patients with GCA compared with a non-GCA cohort from the same population.

Methods: The patient cohort included cases with incident GCA between 2000-2016 in defined geographical area. Incident LV complications were defined as aortic aneurysm, aortic dissection, stenosis in the aorta or any of its main branches diagnosed within 1 year prior to the diagnosis of GCA or anytime afterwards. A comparator cohort (age- and sex- matched) of individuals without GCA was assembled from the same population. Each subject was given an index date corresponding to an incidence date in the GCA cohort. All subjects were followed through December 31st, 2020, death, or migration. Cumulative incidence of large artery complications was adjusted for the competing risk of death. Cox proportional hazards models were used to assess the association of clinical characteristics with large artery complications.

Table 1. Large Vessel Complications in Patients with GCA Compared to Matched Comparators without GCA.

Event Type	HR (95% CI)*	HR (95% CI)**
Any Large Vessel Involvement	2.67 (1.59-4.51)	3.22 (1.83-5.68)
Large artery stenosis	2.98 (1.62-5.48)	4.20 (2.16-8.16)
Aortic Aneurysm/Dissection	2.41 (0.94-6.18)	1.86 (0.71-4.88)
Thoracic Aneurysm	13.46 (1.78-101.98)	--
Abdominal Aneurysm	1.08 (0.33-3.55)	--
*Age and sex adjusted **Adjusted for age, sex, hypertension, hyperlipidemia, diabetes mellitus, stroke, heart failure. Comorbid conditions were analyzed as time-dependent variables.		

Results: The patient cohort included 119 cases with GCA. Majority were female (88, 74%); mean age at diagnosis was 77.7 ± 8.1 years. Mean follow up for GCA cohort was 8.9 ± 4.7 years and 7.7 ± 4.9 years for the comparator cohort. LV complications occurred in 49 patients in the GCA cohort Vs 20 in non-GCA (HR: 2.67, 95% CI: 1.59-4.51). Large artery stenosis occurred in 40 patients in GCA cohort vs. 14 in non-GCA (HR: 2.98, 95% CI: 1.62-5.48). This included subclavian artery stenosis (17/40 GCA vs 1/14 non-GCA), axillary artery stenosis (9/40 GCA vs 0 non-GCA), vertebral artery stenosis (13/40 GCA Vs 3/14 non-GCA) and carotid artery stenosis (6/40 GCA Vs 4/14 non GCA).

On the other hand, aortic aneurysm/dissection occurred in 16 patients in the GCA cohort vs. 6 in non-GCA (HR: 2.41, 95% CI: 0.94-6.18). Furthermore, GCA was found to be a significant risk factor for the development of thoracic aortic aneurysm (HR: 13.46, 95% CI:1.78-101.98) but not for abdominal aortic aneurysm (HR: 1.08, 95% CI: 0.33-3.55) (Table 1). This elevated risk for any LV complication, large-artery stenosis and aneurysms persisted even when adjusted for age, sex, and comorbid conditions (Table 1). Interestingly, the incidence rates of any LV complication at 5 and 15 years were 27.8%

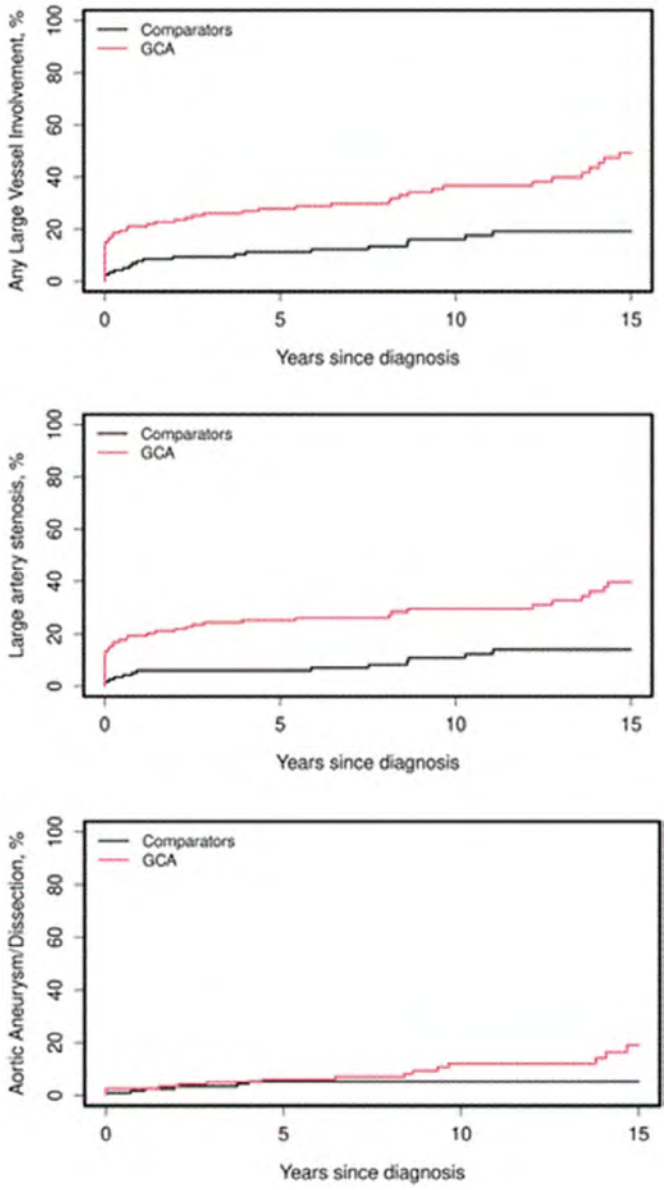

Figure 1. Cumulative incidence trends of any LV complication (upper panel), Large artery stenosis (middle panel) and Aortic aneurysm/dissection (lower panel) diagnosed within 1 year prior to incidence/index date or anytime thereafter during follow up.

(95% CI: 20.8-37.2%) and 49.2% (95% CI: 39.3-61.7%) respectively for the GCA cohort compared to 11.2% (95% CI: 6.7-18.7%) and 19.2% (95% CI: 12.5-29.4%) in the comparator cohort (Figure 1). Among individuals who developed LV complications, presence of GCA was not a significant predictor for death (HR: 0.82, 95% CI: 0.41-1.61).

Conclusion: In this study, large-artery stenosis and thoracic but not abdominal aortic complications were higher in patients with GCA. The pattern of involvement of large-artery and aortic manifestations differed in patients with GCA. Compared to the general population, the incidence of LV complications in patients with GCA increased over time which has implications for the long-term follow-up. GCA did not significantly increase risk of death in subjects with LV complications.

Immuno-permissive Antigen-presenting Cells in Giant Cell Arteritis

Shozo Ohtsuki[1], Chenyao Wang[2], Ryu Watanabe[3], Hui Zhang[3], Mitsuhiro Akiyama[3], Kenneth Warrington[4], Gerald J. Berry[3], Jorg Goronzy[4] and Cornelia M. Weyand[5], [1]Mayo Clinic College of Medicine and Science, Stanford University School of Medicine, Rochester, MN, [2]Mayo Clinic College of Medicine and Science, Rochester, MN, [3]Stanford University School of Medicine, Stanford, CA, [4]Mayo Clinic, Rochester, MN, [5]Mayo Clinic School of Medicine and Stanford University, Rochester, MN

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster III
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Giant cell arteritis (GCA) is a medium and large vessel vasculitis with pathognomonic granulomatous infiltrates in the vessel wall. During the early stages of vasculitis, the bone marrow accelerates myelopoiesis, providing critical effector cells that control T cell immunity via antigen-presenting function. GCA macrophages are distinguished from healthy cells by the low expression of the checkpoint molecules PD-L1 and CD155. Here, we have defined macrophage profiles of co-stimulatory and co-inhibitory ligands and have tested the functional implications of co-stimulation/co-inhibition on T cell differentiation.

Methods: Monocytes from the peripheral blood of GCA patients and age-matched controls were differentiated into monocyte-derived macrophages (MDM) with M-CSF and polarized with LPS/IFN-γ. Patients with granulomatosis with polyangiitis (GPA) served as disease controls. Ligand expression was measured by flow cytometry or by immunofluorescence staining in granulomatous tissue lesions. Cellular protein expression was analyzed by immunoblotting and immunoprecipitation.

Results: Compared to age-matched controls and GPA patients, MDM from GCA patients were strongly positive for CD80/CD86 but expressed low levels of PD-L1 (p=0.0035) and CD155 (p=0.0005). Healthy MDM were consistently double positive for PD-L1 and CD155, but GCA patients had a population of PD-L1^{low} CD155^{low} and of PD-L1^{neg} CD155^{low} MDM. Combined PD-L1/CD155 low expression was maintained in tissue macrophages in inflamed arteries. PD-L1 and CD155 mRNA transcripts were equally abundant in patients and controls and immunoblotting demonstrated similar amounts of total CD155 protein in GCA and control MDM. Subcellular mapping studies with organelle specific markers placed CD155

into the endoplasmic reticulum in GCA MDM and immunoprecipitation experiments confirmed that CD155 protein was retained by ER membranes (p=0.004 GCA vs. control). Transcriptomic studies identified an ER stress signature in GCA MDM, and tunicamycin-induced ER stress was sufficient to cause CD155 retention in healthy MDM (p=0.008). We explored whether the low surface expression of PD-L1 and CD155 had functional consequences. $CD155^{low}$ MDM shifted the differentiation of interacting $CD4^+$ T cells, favoring the expansion of poorly differentiated multifunctional memory T cells.Anti-CD155 blocking antibodies produced a similar bias in T cell differentiation (p< 0.001). Defective expression of the inhibitory ligands was resistant to immunosuppressive therapy and persisted in steroid treated patients.

Conclusion: Patients with GCA generate abnormal antigen-presenting cells that are characterized by the lack of inhibitory ligands. The defect is shared by at least two checkpoints, involving PD-L1- and CD155-dependent signaling. Underlying molecular defects map to the endoplasmic reticulum, which traps PD-L1 and CD155 in the cytosol and prevents surface translocation. $PD\text{-}L1^{low}$ $CD155^{low}$ macrophages function as immuno-permissive antigen-presenting cells, supporting the unopposed expansion of multifunctional, pro-inflammatory effector T cells.

The Use of the Southend GCA Probability Score (GCAPS) in Assessing the Risk of Giant Cell Arteritis in Australian Ophthalmological and General Medical Hospital Cohorts

Eloise Norman[1], Clare Fraser[2], Mitchell Lawlor[3] and **Anthony Sammel**[4], [1]Prince of Wales Hospital, Randwick, Australia, [2]Save Sight Institute, The University of Sydney, Sydney, Australia, [3]Sydney and Sydney Eye Hospital, Sydney, Australia, [4]The Prince of Wales Hospital, Sydney, Australia

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster III
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: The rate of positive temporal artery biopsies (TAB) in patients with suspected giant cell arteritis (GCA) varies widely, indicating the need for better pre-test probability evaluation. The Southend Probability Score (GCAPS) has been developed as a GCA risk stratification tool and low scores (< 10), can exclude the diagnosis without the need for further investigation. It has not been studied in ophthalmology specific hospitals, where patients may present with a higher frequency of ophthalmic symptoms and have a greater risk of vision loss if the diagnosis is missed.

Methods: Medical records of patients who underwent temporal artery biopsy (TAB) between 2010-2020 at the quaternary Sydney and Sydney Eye Hospital (SSEH) and 2010-2017 at the tertiary Prince of Wales Hospital (POWH) were reviewed and stratified into low (score < 10), intermediate (score 10-12) and high risk (score ≥13) according to the GCAPS score.

Results: Two hundred and thirty-three patients were assessed: 160 from SSEH and 73 from POWH. All 39 patients classified as low-risk had a negative TAB result (table 1). Amongst low-risk patients, the most reported symptoms were headache (69.2%) and cranial ischemia (38.5%), which included jaw claudication, transient monocular vision disturbance and diplopia.

The most frequently noted examination findings were temporal artery abnormalities (15.4%) and isolated relative-afferent pupillary defect (5.1%). None of the low-risk patients had findings consistent with arteritic anterior ischemic optic neuropathy.

Conclusion: The GCAPS reliably predicted negative biopsy results in all patients with a low-risk score. This study supports its use as a risk stratification tool in both ophthalmological and general medical settings and help to exclude the diagnosis and need for temporal artery biopsy in patients with GCAPS of less than 10.

Table 1: Characteristics and clinical features of patients with suspected giant cell arteritis risk stratified by Southend GCA Probability Score (GCAPS).

		Risk Category (Score)			
	All (n=233)	Low (n=39) GCAPS < 10	Intermediate (n=77) GCAPS 10-12	High (n=117) GCAPS ≥ 13	P-value[a]
% total		16.7	33.0	50.2	
Female, n (%)	148 (63.5)	26 (66.7)	47 (61.0)	75 (64.1)	0.824
Positive biopsy n (%)	63 (27.0)	0 (0.0)	14 (18.2)	49 (41.9)	<0.001

Weyand[5], Kenneth Warrington[1] and Matthew Koster[1], [1]Mayo Clinic, Rochester, MN, [2]Department of Quantitative Health Sciences, Mayo Clinic, Rochester, MN, [3]Mayo Clinic, Pueblo, CO, [4]Clinica Alemana de Santiago, Santiago, Chile, [5]Mayo Clinic School of Medicine and Stanford University, Rochester, MN

SESSION INFORMATION

Session Date: Tuesday, November 14, 2023

Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster III

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: Relapse is common in giant cell arteritis (GCA) with 40-75% of patients having at least one flare during course of disease. A clinically relevant question for both patients and providers is whether the initial symptoms at GCA diagnosis will be present at time of relapse or whether other clinical features may manifest. Given most cohorts describe both baseline and relapse symptoms in aggregate, evaluation of patient level concordance between initial symptoms and relapse has not been delineated. The purpose of this study was to evaluate the concordance between initial GCA symptoms at diagnosis and first relapse in patients with GCA.

Methods: Two previously described cohorts of patients with GCA were utilized. Cohort 1: 286 patients with biopsy-proven GCA treated with prednisone (no tocilizumab) and Cohort 2: 114 patients with biopsy-proven or imaging-proven GCA treated with tocilizumab. Clinical symptoms at diagnosis and first relapse were grouped into the following categories:

Table 1: Odds ratios for presence of symptoms at relapse associated with presence of given symptom at baseline. Cohort 1 (biopsy-proven, non-tocilizumab), Cohort 2 (tocilizumab treated)

Cohort 1 (n=183 patients with 1 or more relapses)					
	First relapse				
Baseline	*Constitutional*	*Musculoskeletal*	*Cranial*	*Visual*	*Large vessel*
Constitutional	1.85 (0.89, 3.86)	**0.54 (0.30, 0.98)**	1.21 (0.67, 2.18)	2.21 (0.23, 21.7)	0.84 (0.27, 2.60)
Musculoskeletal	0.91 (0.45, 1.84)	**3.94 (2.04, 7.62)**	**0.32 (0.17, 0.60)**	0.63 (0.09, 4.56)	3.76 (0.81, 17.5)
Cranial	0.88 (0.32, 2.38)	1.07 (0.45, 2.56)	2.30 (0.93, 5.67)	-	**0.14 (0.04, 0.46)**

LV	-	1.37 (0.47, 3.94)	0.42 (0.14, 1.23)	0.70 (0.06, 8.14)	3.09 (0.79, 12.1)

constitutional, musculoskeletal (MSK), cranial (non-visual), visual, and large-vessel (LV). Patients could have more than one category present at each time event. Odds ratios and conditional probabilities were calculated.

Results: In cohort 1 (C1), 183/286 (64%) patients had at least one relapse, whereas cohort 2 (C2) had 58/114 (51%) with at least one relapse. In C1, at first relapse 73% had symptoms in a single category, compared to 13% at baseline. At first relapse, 31% had cranial only, 30% MSK only, 9% constitutional only, 8% cranial plus constitutional, 7% cranial plus MSK. In C2, at first relapse 79% had symptoms in a single category, compared to 10% at baseline. At first relapse 33% had cranial only, 31% MSK only, 12% LV only, 9% cranial plus MSK. Odds ratios for presence of symptoms at first relapse based on presence of symptoms at baseline for C1 and C2 are shown in **Table 1**. In C1, patients with MSK symptoms at baseline were near 4 times more likely to have MSK features at first relapse but more than 3 times less likely to have cranial symptoms. Presence of LV symptoms at baseline resulted in a 48-fold increased odds of LV symptom at first relapse. In C2, patients with MSK at baseline had 9-fold greater odds of MSK at relapse but near 7-fold lower odds of cranial relapse symptoms. In C1, 21% and C2, 19% of patients went on to have new symptom categories at first relapse that were not present at baseline. Conditional probabilities of symptoms at first relapse according to presence or absence of baseline symptoms are shown in **Table 2**. No patient without visual symptoms at baseline developed visual symptoms at first relapse in either cohort. At first relapse new constitutional symptoms (17% C1, 4% C2), MSK (24% C1, 17% C2), cranial (33% C1, 11% C2), LV (2% C1, 12% C2) features were seen among patients that did not have these at baseline.

Conclusion: Relapse in GCA is common. Patients with MSK features at onset have greater odds of MSK but lower odds of cranial symptoms at relapse. New GCA symptoms not present at baseline occur in approximately 20% of first relapses, therefore providers should educate patients on the spectrum of GCA symptoms to be aware of, even beyond those present at a patient's diagnosis.

Table 2: Conditional probabilities of given symptom category at first relapse according to presence or absence of baseline symptom.

Cohort 1										
Probability	*Pr(Relapse 1 symptom | baseline = No)*					*Pr(Relapse 1 symptom | baseline = Yes)*				
Baseline symptom	*Con.*	*Msk.*	*Cran.*	*Vis.*	*LV*	*Con.*	*Msk.*	*Cran.*	*Vis.*	*LV*
Constitutional	**17%**	52%	48%	1%	8%	**27%**	37%	53%	3%	7%
Musculoskeletal	24%	**24%**	68%	3%	3%	22%	**55%**	40%	2%	10%
Cranial	25%	42%	**33%**	0%	25%	23%	43%	**53%**	3%	4%
Visual	23%	46%	49%	**0%**	8%	23%	37%	56%	**8%**	6%
LV	23%	45%	53%	2%	**2%**	19%	29%	33%	5%	**48%**
Cohort 2										
Probability	*Pr(Relapse 1 symptom | baseline = No)*					*Pr(Relapse 1 symptom | baseline = Yes)*				
Baseline symptom	*Con.*	*Msk.*	*Cran.*	*Vis.*	*LV*	*Con.*	*Msk.*	*Cran.*	*Vis.*	*LV*
Constitutional	**4%**	35%	54%	8%	19%	**3%**	47%	47%	3%	19%
Musculoskeletal	7%	**17%**	72%	7%	24%	0%	**66%**	28%	3%	14%
Cranial	0%	56%	**11%**	0%	33%	4%	39%	**57%**	6%	16%
Visual	5%	54%	46%	**0%**	22%	0%	19%	57%	**14%**	14%
LV	6%	38%	59%	6%	**12%**	0%	46%	38%	4%	**29%**

Values are percentages and represent the observed risk for the given symptom in those without (baseline=no) and with (baseline=yes) each symptom category at baseline. For example in cohort 1, 17% of patients without constitutional symptoms at baseline went on to have constitutional symptoms at first relapse, whereas 27% of patients with constitutional symptoms at baseline went on to have constitutional symptoms at first relapse.

SESSION INFORMATION

Session Date: Tuesday, November 14, 2023

Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster III

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: Glucocorticoids (GCs) are still the mainstay of treatment of Giant Cell Arteritis (GCA). Although GCs are highly effective in GCA, it is well documented the high burden of toxicity of GCs as well as the disease relapse during GC tapering. Therefore, patients with GCA may benefit from GC-sparing treatments. The aim of this retrospective study was to compare the efficacy and rapidity of TCZ and MTX as steroid-sparing agents in a real-life cohort of GCA patients.

Methods: A retrospective analysis was conducted including patients with newly diagnosed GCA from the Rheumatology Units of Udine and Rome. The diagnosis of GCA was based on the presence of symptoms and signs and confirmed by temporal artery biopsy, temporal artery ultrasound, or PET/CT imaging. The inclusion criterion was the treatment with TCZ or MTX as first steroid-sparing drug.

Results: 112 GCA patients (81 female) with a median age of 70 (IQ 65-75) years were collected. Thirty-one out of 112 (27.7%) patients were treated with TCZ (162mg/week), while 81/112 (72.3%) patients received MTX (up to 20mg/week) as a GC-sparing agent.

The median time of follow up in the TCZ and MTX group was 28 (18.5-44) and 67 (42-99) months (**p < 0.001**), respectively. At the last medical examination, 110/112 (98.2%) patients were in sustained remission, and 25/31 (80.6%) patients in TCZ group and 60/81 (74.1%) patients in MTX group were on steroid-free therapy.

At month 6 after GCA onset, 5/31 (16.1%) patients in TCZ group and none in MTX group were in GC-free sustained remission (**p-value=0.001**). Similarly, at month 12, 64.5% (20/31) and 11.1% (9/81) of patients were in sustained GC-free remission in TCZ and MTX group, respectively (**p-value < 0.001**). The median time to discontinued GCs was 10 (IQR 7-12) months (TCZ group) and 24 (IQR 18-45) months (MTX group) (**p-value < 0.001**).

During the follow up period, at least one relapse of the disease occurred in 7/31 (22.6%) in TCZ-treated and 43/81 (53.8%) in MTX-treated patients, respectively (**p-value=0.003**).

The number of overall complications (including infectious events, new-onset of hypertension, new-onset diabetes mellitus, fragility fractures, secondary osteoporosis, ischemic events and malignancies) was not statistically different between the two groups over the follow up, even if a trend towards a lower incidence of secondary osteoporosis was recorded, and the total number of adverse events under TCZ was numerically lower than on MTX (p-value=0.086).

Conclusion: TCZ allowed a faster discontinuation of steroid therapy and a lower relapse rate than MTX in GCA patients.

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster III
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: 2-[^{18}F]fluoro-2-deoxy-D-glucose(FDG) is the reference PET radiotracer for detecting inflammation in giant cell arteritis (GCA). C-X-C motif chemokine receptor 4 (CXCR4)-directed PET, however, allows for targeting leukocyte subsets, thereby providing a direct visualization of active inflammation. We aimed to report initial results from a Phase II trial applying chemokine receptor-targeted imaging in patients with newly diagnosed GCA (NCT05604482).

Methods: Nine treatment-naïve individuals with confirmed GCA underwent PET/CT imaging with both FDG and [^{68}Ga] PentixaFor (PXF). For each PET, a total of 13 arterial segments per patient were analyzed. In addition, eight joints were examined for concurrent polymyalgia rheumatica. We compared both scans on a visual (using PETVAS) and quantitative level

(by calculating the target-to-background ratio [TBR], with blood pool as reference). Flow cytometry determined quantitative CXCR4 expression on leukocytes in peripheral blood by calculating a normalized median fluorescence intensity (NMFI) scoring (with CXCR4 antibody isotype serving as control). Quantitative PET results were then correlated with NMFI.

Results: At the visual level, PETVAS of FDG (25.62 ± 5.61) was comparable with PXF (21.33 ± 3.5, P=0.07). The TBR of FDG (2.41 ± 0.96) was also not significantly different from that of PXF (1.8 ± 0.8, P=0.11). The interquartile ranges (IQR) for PEN (IQR, 0.48), however, were lower than for FDG (IQR, 1.5), suggesting lower scatter and improved accuracy for PXF-based quantitative read-outs. Comparable results were also recorded for joints (PEN: IQR, 0.25; FDG: IQR, 0.5). Flow cytometry showed broad expression of CXCR4 on leukocytes. Subpopulations with the highest CXCR4 expression were naive B and T cells, followed by basophils. NMFI and PXF-based quantification showed significant correlations with basophils in the aorta, with the most prominent association for the abdominal segment (r=0.85, P=0.03).

Conclusion: Quantification of the CXCR4-targeted PET radiotracer PXF was comparable to FDG for assessing vessel wall and joint inflammation. Thus, PXF PET may be incorporated for image-guided, anti-inflammatory strategies in patients with newly diagnosed GCA.

Session Date: Tuesday, November 14, 2023
Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster III
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Giant cell arteritis (GCA) affects large and medium size arteries. Biopsy was considered the gold standard in the diagnosis[1], but in the last years other techniques are being implemented like temporal and axillar arteries ultrasound (US) with a good performance being included in the 2022 ACR GCA classification criteria[2]. To improve the diagnosis of these patients a Pretest Probability Score (Southend) (PPS) has been developed[3],stratifying patients into 3 different risk groups. The aim was to study the performance of the different tools available for the diagnosis of GCA: PPS, vascular ultrasound, and biopsy of Temporal Artery.

Table 1. Descriptive analysis of the sample (n=97) comparing the main characteristics in GCA and non-GCA.

		GCA (n=23)		Non-GCA (n=74)		p
		n (%)	Mean (SD)	n (%)	Mean (SD)	
Age at diagnosis			77.35 (7.27)		74.32 (10.27)	0.262
Sex	Men	11 (47.83)		28 (37,84)		0.393
	Women	12 (52.17)		46 (62.16)		
Time symptoms to diagnosis (weeks)			5.26 (4.85)		16.79 (23.60)	0.030
Headache		20 (86.96)		39 (52.7)		0.003
Scalp hypersensitivity		9 (39.13)		6 (8.11)		0.001
Jaw claudication		14 (60.87)		7 (9.46)		< 0.001
Visual symptoms		11 (47.83)		20 (27.03)		0.062
Polymyalgia rheumatica		10 (43.48)		31 (41.89)		0.831
Temporal artery alteration	Right	7 (31.82)		3 (4.62)		< 0.001
	Left	4 (18.18)		4 (6.15)		
	Bilateral	7 (31.82)		7 (10.77)		
CRP mg/L			68.5 (57.66)		73.76 (87.82)	0.321
Positive ultrasound		21 (91.30)		6 (8.22)		0.415
Biopsy		21		34		
Positive biopsy		13 (61.90)		0 (0.00)		< 0.001
Pretest score	Low	0 (0.00)		26 (35.14)		< 0.001
	Medium	5 (21.74)		32 (43.24)		
	High	18 (78.26)		16 (21.62)		

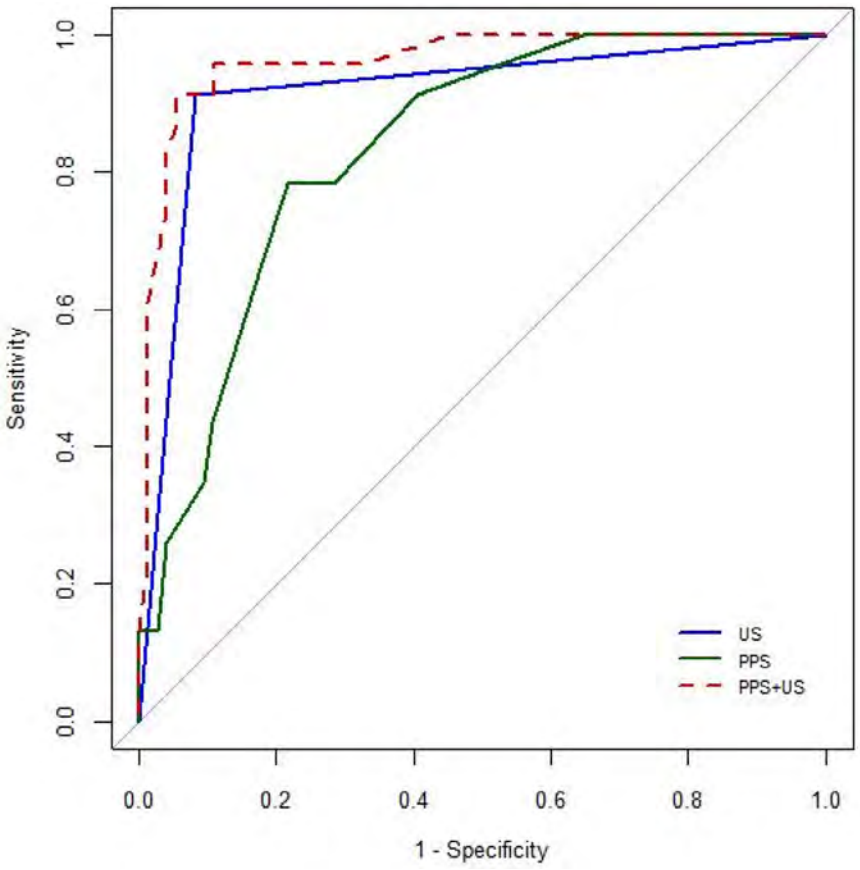

Figure 1. AUC of the different diagnostic tests studied (probability pretest score, ultrasound of temporal artery and combination).

Methods: Retrospective study of the patients referred to our Rheumatology Department with GCA suspicion from January 2019 to October 2022. Demographic and clinical variables including the ones from the PPS were collected.Exploration of the 3 branches of temporal artery and axillar artery bilaterally was performed by grey scale and Color Doppler US (Esaote MylabSix probe 10-22 Hz) evaluating the halo sign and the intima-media thicknes[4].PPS and US were carried out in all patients referred. Biopsy was performed in the necessary cases. Final GCA diagnosis was performed according to the rheumatologist decision (clinical diagnosis). A descriptive analysis of the sample was performed. Quantitative variables are expressed as mean (±SD) and qualitative ones as absolute frequencies and percentage. A comparative analysis was performed according to clinical diagnosis. The comparison of means was carried out using the Student's T or Mann-Whitney U test. The association between qualitative variables was analyzed using Chi-square test. The agreement between the different tests was analyzed using Kappa index. The predictive capacity of the different diagnostic tests is evaluated using ROC curves, providing their AUC, and the sensitivity and specificity values.

Results: Patients (97) with suspected GCA were included, 59.79% women, with a mean age of 74.4 (±9.69). Final diagnosis attending to clinical criteria and other tests was made in 23 patients (23.7%). In GCA compared with non GCA patients showed more frequently and statistical significance: headache, scalp hypersensitivity, facial pain, jaw claudication and changes on temporal artery. Ultrasound was positive in 91.3% (n=21) GCA patients, from them 61.90% had a positive biopsy (Table 1). Area under ROC curve (AUC), sensitivity and specificity for PPS were 0.83 (0.75-0.92), 78.3% and 78.4%, respectively, for US were 0.91 (0.84-0.99), 91.3% and 91.8%, and for biopsy, 0.81 (0.67-0.94), 61.9% and 100%. Data from the combination of PPS+US showed an AUC of 0.96 (0.92-1) (sensitivity 91.3% and specificity 94.5%). Combination of PPS+biopsy showed an AUC of 0.90 (sensitivity 71.4% and specificity 91.2%) (Figure 1).

Conclusion: The combination of US with PPS value improves the individual predictive capacity of each these diagnostic techniques.

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster III
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Patients with giant cell arteritis (GCA) can relapse despite glucocorticoids, methotrexate and tocilizumab treatment. The JAK/STAT signalling pathway is involved in the pathogenesis of GCA, and JAK inhibitors (JAKi) are a potential treatment alternative. Baricitinib showed positive results in a small uncontrolled study **(1)**.

The objective of this study is to evaluate the effectiveness of JAKi in GCA.

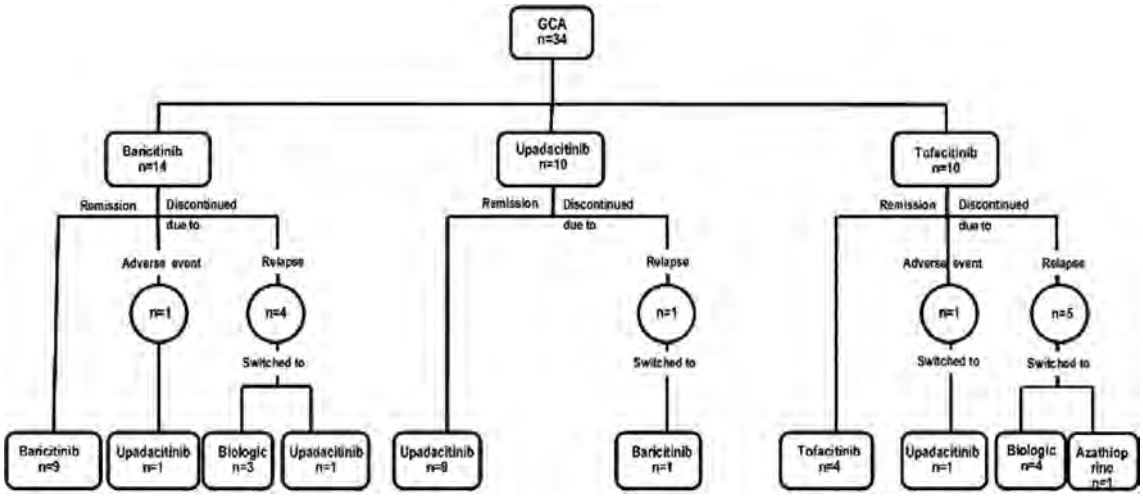
Methods: Real-world, retrospective clinical practice study of patients with GCA treated with JAKi. Outcomes assessed included disease relapse and safety. A literature search for other JAKi-treated GCA cases was conducted in PubMed, Embase and the Cochrane library from inception to 04/30/2023. We compared results of the previous baricitinib study **(1)** and the baricitinib recipients in our series.

Results: We present 34 patients (29 females[85%], mean age, 72.2 years, relapsing disease 34 [100%]) that received JAKi **.** The initial JAKi was baricitinib (n=14), tofacitinib (n=10) and upadacitinib (n=10) **(Table and Figure)**. After a median [IQR] follow-up of 9.5 [4.2-12.7] months, 22 (64.7%) achieved and maintained remission, and 12 (35.3%) patients discontinued

TABLE. Current series and literature review of patients with GCA treated with JAKi.

Reference	Cases	Sex	Age, mean±SD	JAKi	Previous csDMARDs	Previous bDMARDs	Follow-up (months), mean±SD	Outcome
Hershy. Br J Haematol. 2019	1	Female	75	Ruxolitinib	Methotrexate, mycophenolate mofetil	None	9	No data
Prigent. Clin Nucl Med. 2021	1	Female	76	Baricitinib	Methotrexate	Tocilizumab	12	Clinical improvement
Camellino. Ann Rheum Dis 2022	3	Female (3)	74±11.5	Baricitinib (3)	Methotrexate (2), hydroxychloroquine (1),sulfasalazine (1),cyclosporine (1), mycophenolate mophetil (1)	Tocilizumab (2)	8.5±4.9; no data(1)	Clinical improvement (1); no data (2)
Koster. Ann Rheum Dis. 2021	15	Female (11), male (4)	72.4±7.2	Baricitinib (15)	Methotrexate (2), Cyclophosphamide (1)	Sirukumab (1)	11.3±2.5	Clinical improvement (13);no improvement(1);no data (1)
Sanada. Rheumatology (Oxford). 2022	1	Female	72	Upadacitinib	Sulfasalazine	None	7.5	Clinical improvement
Current series	34	Female (29), male (5)	72.2±7.8	Baricitinib(14), tofacitinib(10), upadacitinib(10)	Methotrexate (20), hydroxychloroquine (3), leflunomide(1)	Tocilizumab (26),sarilumab(3),abatacept (6), azathioprine (2), ustekinumab (2)	9.7±7.2	Clinical improvement (22), no improvement(10)

Current series and literature review of patients with GCA treated with JAKi.



Flow chart of the 34 GCA patients treated with JAKi

the initial JAKi due to relapse (n=10, 29.4%) or severe adverse events (SAEs) (n=2, 5.9%) including liver dysfunction and dyspnea/palpitations. The 12 patients failing the initial JAKi were switched to an alternative [JAKi (n=4), biologic therapy (n=7) and azathioprine (n=1)]. The literature review identified another 21 GCA patients (17 females, mean age 74.2 years) treated with JAKi, mostly with baricitinib (n=18). Most of these patients benefited from JAKi therapy **(Table).** Patients in our series receiving baricitinib had longer disease duration (median [IQR]31 [12-51] vs 9 [7-21] months; p=0.001) and had received biologics (71% vs 6.7%; p< 0.001) more frequently than those in the previous baricitinib study **(1)**. Remaining baseline features were similar.

Conclusion: This real-world analysis suggest that JAKi could be effective in GCA, including patients failing other immunosuppressive therapies. The results of an ongoing phase 3 randomized controlled trial are awaited to confirm or rule out this observation.

Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster III

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: Tocilizumab (TCZ) is the only biologic therapy approved for giant cell arteritis (GCA). Clinical trial with TCZ in GCA was performed with intravenous (iv) TCZ in a phase 2 trial **(1)**, and with subcutaneous (sc) TCZ in the phase 3 GiACTA **(2)**. There is general agreement on the initial/maintenance dose, but duration of TCZ therapy is not well established. In GiACTA trial, after one year on TCZ, most patients had GCA relapse after withdrawal.

This study aims to assessthe predictive factors of relapse in GCA in a clinical practice scenario.

Methods: Multicentre observational study of 471 patients with GCA. The diagnosis of GCA was performed between 2016 and 2021 according to: **a)** ACR criteria, and/or **b)** temporal artery biopsy, and/or **c)** imaging techniques. Relapse was defined according to EULAR consensus definition **(3)**. From the 471 patients, we selected the patients who had available the data on relapse during follow-up. Multivariable study was conducted to identify the best set of predictors for the appearance of a relapse.

TABLE. Main features of the patients with GCA according to relapses.

	No relapsing GCA (n=342)	Relapsing GCA (n= 63)	p
Age at GCA diagnosis (mean±SD)	72±9	70±9	0.12
Women/Men (% de women)	246/96 (72)	47/16 (75)	0.57

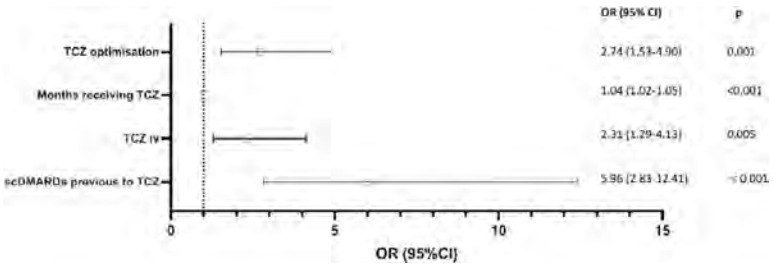
Optimization, n (%)	123 (39)	38 (62)	<0.001
Months receiving TCZ	27 [18-43]	4 [2-12]	<0.001

Abbreviations: bDMARDs: biologic disease-modifying antirheumatic drugs,GCA, CRP: C-reactive protein, giant cell arteritis, ESR: erythrocyte sedimentation rate, IQR: interquartile range [25th-75th], scDMARDs: synthetic conventional disease-modifying antirheumatic drugs, SD: standard deviation

Main features of the patients with GCA according to relapses.



Results: GCA relapses were observed in 63 of 405 (15%) patients for whom such data was available**(Table).** No significant differences were observed between the two groups in demographic, clinical and laboratory characteristics or in prednisone dose at initiation of TCZ. The set of variables associated with GCA relapses were prior use of synthetic conventional disease-modifying antirheumatic drugs (scDMARDs), use of iv.TCZ, shorter time on TCZ therapy and optimization of TCZ dose **(Figure).**

Conclusion: GCA relapse seems related mainly to TCZ schedule and was associated with iv TCZ, and a shorter treatment time and optimization.

Giant Cell Arteritis Is Associated with Worse Hospital Outcomes in Aortic Aneurysm/Dissection Hospitalizations: A Nationwide United States Population-Based Study

Artem Minalyan[1], Christopher Hino[1], Emily He[1], Osahon Idolor[2], Chinenye Osuorji[3], Nneka Chukwu[4], Ehizogie Edigin[1] and Vaneet Sandhu[5], [1]Loma Linda University Health, Loma Linda, CA, [2]Piedmont Athens Regional Hospital, Atlanta, GA, [3]Montefiore Medical Center/Albert Einstein College of Medicine, Bronx, NY, [4]Nuvance Health Internal Medicine Residency, Poughkeepsie, NY, [5]Loma Linda University, Loma Linda, CA

SESSION INFORMATION

Session Date: Tuesday, November 14, 2023
Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster III
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Giant Cell Arteritis (GCA) is a known risk factor for Aortic Aneurysm/Dissection (AAD). However, it is unclear if patients with GCA have worse hospital outcomes when hospitalized for AAD compared to patients without GCA hospitalized for AAD. We queried the largest inpatient hospitalization database in the United States (U.S.) to answer this question.

Methods: Data were abstracted from the National Inpatient Sample (NIS) from 2016 to 2020 Database. NIS is a nationally representative approximate 20-percent stratified sample of all discharges from U.S. community hospitals, excluding rehabilitation and long-term acute care hospitals. The numbers in the databases are weighted to optimize national estimates. The NIS was searched for hospitalizations for patients aged ≥ 50 years with a principal diagnosis of AAD ("I71") with and without a coexisting secondary diagnosis of GCA ("M315" and "M316") using ICD-10 codes. The principal diagnosis is the main reason for hospitalization. Any diagnosis other than the principal is a secondary diagnosis. Each hospitalization in the NIS has only 1 principal diagnosis and can have up to 40 secondary diagnoses. The chi-square test was used to compare baseline characteristics between the GCA and non-GCA groups. The primary outcome was inpatient mortality. Hospital length of stay (LOS) and total hospital charges were secondary outcomes. Multivariable logistic and linear regression analyses were used to adjust for confounders for the primary and secondary outcomes, respectively. We adjusted for age, gender, race, insurance type, income, Charlson co-morbidity index, and hospital characteristics. STATA version 16 was used for analysis. Since NIS contains publicly available depersonalized data, Institutional Review Board (IRB) review was waived.

Results: There were about 175 million hospitalizations in the combined 2016-2020 database. We obtained 314,215 hospitalizations for patients aged ≥ 50 years with a principal diagnosis of AAD. 685 (0.2%) of these had a secondary diagnosis of GCA, while 313,530 (99.8%) did not have co-existing GCA. The GCA group was older (mean age of 74.6 vs 71.8 years, $p < 0.0001$) and had more females (76.6% vs 29.5%, $p < 0.001$) compared to the non-GCA group. The GCA group had similar inpatient mortality compared to the non-GCA group (6.4% vs 6.6%, p=0.627). The GCA group had longer LOS (9.4 vs 5.5 days, $p < 0.0001$) and higher total hospital charges ($224,540 vs 180,356, p=0.002) compared to the non-GCA group. See table 1.

Conclusion: GCA patients admitted for AAD have worse hospital outcomes (longer LOS and higher total hospital charges) compared to non-GCA patients admitted for AAD. Adequate treatment of GCA to prevent complications such as AAD is needed. In addition, screening, early detection, and prompt management of AAD via a multidisciplinary approach are essential in optimizing the outcomes of GCA patients.

Table 1: Hospital outcomes of Aortic Aneurysm/Dissection hospitalizations with and without Giant Cell Arteritis

Hospital Outcomes	AAD with GCA (n=685)	AAD without GCA (n=313,530)	Adjusted odds ratio (95% CI)	P-value
Inpatient mortality, %	6.6	6.4	1.5 (0.3-6.9)	0.627
			Adjusted mean difference	
Hospital length of stay, days	9.4	5.5	7.7 (3.8-11.7)	<0.0001
Total Hospital charges, USD	224,540	180,356	177,239 (64,678-289,800)	0.002

Abbreviations: AAD: Aortic Aneurysm/Dissection hospitalizations, GCA: Giant cell arteritis, USD United States dollars, 95% CI: 95% Confidence Interval

Comparison of Clinical, Laboratory and Imaging Features of Relapses Between Takayasu and LV-GCA Patients. an Italian Monocentric Study

LUIGI BOIARDI[1], PIERLUIGI MACCHIONI[2], Francesco Muratore[3], Elena Galli[4], chiara marvisi[4], Giulia Besutti[1], Lucia Spaggiari[1], Annibale Versari[1] and Carlo Salvarani[5], [1]IRCCS REGGIO EMILIA, Reggio Emilia, Italy, [2]Azienda USL -IRCCS di Reggio Emilia, Reggio Emilia, Italy, [3]IRCCS di Reggio Emilia, Reggio Emilia, Italy, [4]Azienda Unità Sanitaria Locale-IRCCS Di Reggio Emilia, Reggio Emilia, Italy, [5]Azienda USL-IRCCS di Reggio Emilia, Reggio Emilia, Italy

SESSION INFORMATION

Session Date: Tuesday, November 14, 2023

Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster III

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: No previous study has compared clinical, laboratory and imaging features of relapses in Takayasu (TAK) and large vessel giant cell arteritis (LV-GCA). The aim of our study was to compare relapses characteristics in these 2 group of pts.

Methods: We retrospectively evaluated 171 pts LVV (119 LV-GCA and 52 TAK) seen at the Rheumatology Unit of Reggio Emilia Hospital (Italy) between 01.01.2005 and 31.12.2016 and followed-up for at least 2 years. Data of the pts collected at relapses included demographic, clinical, laboratory and imaging (PET/CT scan, MRI/CT angiography and/or arterial US). GCA was diagnosed according to ACR1990 criteria and LV-GCA in the presence of LVV involvement seen at CT and/or MRI and/or ultrasonography and/or PET examinations according to GIACTA criteria. TAK was diagnosed using Ishikawa's10 diagnostic criteria and its modification by Sharma et al. and ACR classification criteria for TAK. Disease-related signs/symptoms, ESR and CRP levels, and GC dosages were recorded at every follow-up visit. The presence of clinical disease relapses or long term remission were evaluated at every visit. We also evaluated the appearance of new structural lesions (SL) (stenosis, occlusion, and/or vessel dilatation at CTA/MRA and/or US examination) or new inflammatory lesions (IL)(new/increased FDG uptake at PET/TC or parietal thickening increase at US or CTA).

Results: During a median follow-up duration of 76 months we observed 86 TAK relapses and 89 LV-GCA relapses. TAK relapses presented more frequently carotidodynia (8.1 vs 1.1%, p = 0.032), chest pain (10.5 vs 1.1 %, p=0.009), large vessel vasculitis (89.4 vs 59.8%, p=0.001), had higher ESR (45+32 vs 32+29 p=0.009). TAK relapse caused the introduction of BIO therapy more frequently (48.8% vs 16.8%, p=0.001). LV-GCA relapses were characterized by cranial symptoms (16.9 vs 3.5, p=0.005), polymyalgia rheumatica (27.0 vs 0, p=0.001) and appeared after a shorter time from diagnosis (37.4+42 vs 52.8+48.3 months, p= 0.025). At vessel imaging TAK relapses had more anonymous artery involvement (30.7 vs 15.1 %, p =0.043), LV-GCA relapses had more thoracic and abdominal aorta involvement (89.6 vs 54.1, p< 0.001 and 45.8 vs 14.9, p=0001, respectively) At vessel imaging LV-GCA relapses had higher prevalence of IL (4.31 (1.98) vs 2.0 (1.84), p < 0.001). TAK relapses had higher new SL at common carotid artery (20.3 vs 1.9%, p =0.002), anonymous artery (9.5 vs 0, p=0.041) and subclavian artery (23.3 vs 1.9%, p=0.001). LV-GCA relapses had higher prevalence of common carotid(59.6 vs 28.4%, p=0.001) aortic (89.6 vs 56.8%, p< 0.001) and femoral (10.9 vs 1.5%, p=0.038) new IL.

Conclusion: TAK and LV-GCA relapses have different clinical, laboratory and imaging features. In particular TAK relapses were characterized by higher prevalence of new arterial SL while LV-GCA by new arterial IL.

Influence of Histological Tempol Artery Biopsy Findings on Outcomes of Biopsy-proven Giant Cell Arteritis in Italian Patients : A Long Single Center Follow-up Study

LUIGI BOIARDI[1], PIERLUIGI MACCHIONI[2], Francesco Muratore[3], Elena Galli[4], chiara marvisi[4], caterina Ricordi[4], federica Macaluso[1], alberto cavazza[4], Stefania Croci[4] and Carlo Salvarani[5], [1]IRCCS REGGIO EMILIA, Reggio Emilia, Italy, [2]Azienda USL -IRCCS di Reggio Emilia, Reggio Emilia, Italy, [3]IRCCS di Reggio Emilia, Reggio Emilia, Italy, [4]Azienda Unità Sanitaria Locale-IRCCS Di Reggio Emilia, Reggio Emilia, Italy, [5]Azienda USL-IRCCS di Reggio Emilia, Reggio Emilia, Italy

SESSION INFORMATION

Session Date: Tuesday, November 14, 2023

Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster III

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: Few studies have evaluted the influence of histological features of temporal artery biopsy (TAB) on disease outcome in giant cell arteritis (GCA) patients. Our aim was to investigate potential associations between TAB histological characterstics and outcomes of GCA in a long term single center retrospective follow-up study.

Methods: Two hundred and four Italian patients with biopsy-proven GCA resident in Reggio Emilia area (Italy) followed up for at least 12 months entered the study (median duration of FU 130 months(range 13-435 months). The following histological findings of TAB were recorded : localisation of inflammatory infiltrate (peri-adventitial and vasa vasorum small vessel vascultis (SVV+VVV), inflammation limited to adventitia (ILA), trans mural inflammation TMI), presence of giant cells (GC), presence of infiltrating neutrophils, plasma cells, histiocytes, eosinophils, presence of laminar necrosis (LN), vessel wall calcifications, luminal trombosis (LT) and intimal hyperplasia (IH). The severity of inflammation (SI) was graded on a semiquantitative scale (mild, moderate and severe), the severity of i IH (was graded as mild < 25% reduction in lumen diameter, moderate from 25% to 75%, and severe >75%).

The following data were recorded during follow up : presence of relapses, long term remission (LTR), cumulative steroid dose at 6, 12 months and at end of FU, duration of treatment and of LTR and mortality. Survival curve were compared with K-M method using log rank test.

Results: Relapses were recorded by 42.5% of the patients during a median FU period of 130 months (13-435). Factors which influenced the time of first relapse were : presence of GC (140 vs 207 months, p=0.025), presence of LT (91 vs 171 months, p=0.036) and histological subtype (80 vs 156 vs 249 months for SVV+VVV, ILA and TMI respectively, p=0.017). Fifty-seven % of patients were able to withdraw steroids for at least 12 month. Histological subtypes influenced the duration of treatment (SVV+VVV 2.7 months, ILA 17.9 months, TMI 32.0 months, p=0.019). Seventy % of patients died during the follow up period. Factors with impact on survival time were : SI severe vs mild infiltrate (107 months vs 155 months, p=0.006), presence of GC (112 vs 154 months, p=0.049), presence of LN (96 months vs 132 months, p=0.029), histological subtypes (TMI 115 months vs ILA 161 months vs SVV+VVV 195 months, p= 0.017).

Conclusion: Histological findings of TAB influenced survival time, first relapse time and duration of steroid treatment in GCA pts.

Effectiveness of Dose Spacing with Tocilizumab in Giant Cell Arteritis Treatment

Sharon Cowley[1], Colm Kirby[2], Patricia Harkins[3], Richard Conway[4], Grainne Murphy[5] and David Kane[6], [1]Tallaght University Hospital, Dublin, Dublin, Ireland, [2]Tallaght University Hospital, Dublin, Ireland, [3]St James's Hospital, Dublin, Ireland, [4]Trinity College Dublin, Dublin, Ireland, [5]Cork University Hospital, Cork, Ireland, [6]Tallaght University Hospital & Trinity College Dublin, Dublin, Ireland

SESSION INFORMATION

Session Date: Tuesday, November 14, 2023

Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster III

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: The only steroid sparing agent approved for treatment of Giant Cell Arteritis (GCA) is the anti-interleukin-6 receptor antagonist tocilizumab. There remains uncertainty regarding treatment duration of tocilizumab and the optimal approach to medication withdrawal.

Methods: Patients who met the 2022 ACR/EULAR GCA classification criteria with a clinical diagnosis of GCA were prospectively enrolled. As per ACR/ Vasculitis Foundation guidelines all patients with a new diagnosis of GCA were started on tocilizumab if there were no contraindications. All patients had a 26-week glucocorticoid taper as per the GiACTA protocol. Tocilizumab was administered weekly for the first 12 months, and then every-other-week for an additional 12 months. Relapse of disease on tocilizumab was managed with temporary increases in systemic glucocorticoids.

Results: 55 patients with newly-diagnosed GCA were included. Of these, 27 patients did not receive tocilizumab treatment for a variety of reasons; recent or active treatment for malignancy (7), history of diverticulitis (3), patient preference not to start (5), co-existing inflammatory condition for which other biologic treatment was preferred (1), patient frailty and/or recurrent infections (9), death before start of tocilizumab (1). 1 further patient only had one month of treatment before discontinuation for a drug reaction. 27 patients (49%) had weekly treatment with tocilizumab for 1 year. Of these only 17 had every second week tocilizumab at one year. 5 remained on a weekly dose due to previous visual loss and concern about preserving the remaining eye. 2 had other coexisting inflammatory diseases for which weekly dosing was required. 1 died of natural causes before dose spacing, and 2 stopped tocilizumab before spacing due to side effects. 27 patients had tocilizumab weekly for a mean of 15.7 months and 17 of had tocilizumab every-other-week at one year for a mean of 8.1 months. 2 patients (11.7%)

	Tocilizumab weekly (27)	Tocilizumab two-weekly (17)
Mean duration tocilizumab (months)	15.7	8.1
Number of minor relapses	1	1
Number of major relapses	0	2
Overall relapse free remission	26 (96%)	14 (82%)
Number of minor infections not requiring hospital admission	1	2
Number of major infections requiring hospital admission	1	0
Infection free remission	25 (92.5%)	15 (88%)

Figure 1: Results

had a major relapse on every-other-week tocilizumab (one aortic dissection and one with monocular visual loss). There were two minor relapses, one in the weekly dosing group and one in the two-weekly dosing group.

While on weekly tocilizumab, 1 patient had a minor infection treated in the community and 1 had a major infection (diverticulitis) requiring hospital admission. In the every-other-week tocilizumab group, two patient had minor infections treated in the community and no patient had a major infection requiring hospitalisation.

Conclusion: In a real-world prospective study cohort, only 49% (27/55) of patients were eligible for tocilizumab therapy (with GIACTA protocol steroid). 17/27 were eligible for dose reduction to every other week with 2/17 (11.7%) having major relapses of GCA at 24 months. In a real-life cohort tocilizumab therapy was only possible in 1 in 2 patients and when initiated was continued beyond the recommended period of 12 months in the majority of patients. Overall, 96% of patients in the weekly dosing group had relapse-free remission compared to 82% in the every-other-week treatment group. A dose reduction in tocilizumab after 12 months of weekly treatment maintained most patients in remission, had comparable safety outcomes and was cost effective.

Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster III

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: Visual loss is one of the most feared complications in giant cell arteritis (GCA). Some factors have been previously associated with visual loss, as lower levels of inflammatory markers, jaw claudication or thrombocytosis, although some of these studies showed contradictory results. Our objective was to identify predictive factors of visual involvement in a large cohort of patients with GCA.

Methods: ARTESER is a large Spanish multicenter registry promoted by the Spanish Society of Rheumatology, including patients with GCA diagnosis from June 2013 to March 2019. The following variables were collected at diagnosis per protocol: demographics, symptoms (including all visual manifestations reported by clinicians), laboratory test results, temporal artery biopsy and imaging techniques (ultrasound, PET, MRI, CT).Patients with and without visual involvement were compared in a bivariate analysis. Multivariate logistic regression model was performed to determine potential predictive factors of visual manifestations.

Table 1. Clinical, laboratory and imaging variables of patients with GCA according to presence of visual manifestations.

	All patients n=1636	Patients with visual symptoms n=599	Patients without visual symptoms n=1037	p
Demographics				
Female, n (%)	1151 (70.4%)	405 (67.6%)	746 (71.9%)	0.065
Age, mean (SD)	76.9 (8.10)	78.6 (7.56)	76.1 (8.18)	<0.001
Clinical variables				
Symptoms, duration up to diagnosis (months), mean (SD)	2.9 (5.67)	1.9 (5.22)	3.5 (5.84)	<0.001
Headache, n (%)	1307 (80.3%)	465 (77.9%)	842 (81.7%)	0.065
Jaw claudication, n (%)	590 (37.6%)	256 (44.7%)	334 (33.5%)	<0.001
Scalp tenderness, n (%)	446 (31.3%)	183 (31.5%)	283 (31.1%)	0.877
Upper limb claudication, n (%)	149 (10.1%)	53 (9.9%)	96 (10.2%)	0.885
Lower limb claudication, n (%)	153 (10.4%)	47 (8.8%)	106 (11.2%)	0.141
Polymyalgia rheumatica, n (%)	683 (43.5%)	190 (33.7%)	493 (48.9%)	<0.001
Fever, n (%)	355 (24%)	71 (13.2%)	284 (30.2%)	<0.001
Abnormal TA clinical examination, n (%)	807 (53.1%)	313 (56.3%)	494 (51.2%)	0.055
Smoking, n (%)	127 (8.3%)	46 (8.2%)	81 (8.3%)	0.112
Previous antiplatelet use, n (%)	308 (19.4%)	144 (24.9%)	164 (16.3%)	<0.001
Previous cardiovascular disease, n (%)	356 (22.6%)	142 (24.5%)	214 (21.5%)	0.164

Dyslipidemia, n (%)	783 (48.6%)	301 (51.5%)	482 (47%)	0.078
Temporal artery biopsy positive n=1204, n (%)	753 (62.5%)	302 (65.2%)	451 (60.9%)	0.128
Cranial-GCA, n (%)	1305 (79.8%)	515 (86%)	790 (76.2%)	<0.001
LV-GCA, n (%)	331 (55.3%)	84 (39.8%)	247 (63.6%)	<0.001
Mixed (cranial + LV) GCA, n (%)	197 (19%)	281 (17.2%)	84 (14%)	0.010
Imaging findings				
Positive FDG-PET/CT n=368, n (%)	240 (65.2%)	50 (48.5%)	190 (71.7%)	<0.001
Positive CT angiography n=184, n (%)	61 (33.2%)	16 (24.2%)	45 (38.1%)	0.055
Positive TA US n=701, n (%)	478 (68.2%)	179 (67.8%)	299 (68.4%)	0.865
Positive LV US n=177, n (%)	60 (33.9%)	24 (31.6%)	36 (35.6%)	0.572
Laboratory variables				
CRP (mg/L), mean (SD)	96.2 (177.2)	85 (190.69)	102.7 (171.29)	0.066
ESR (mm/h), mean (SD)	75.9 (33.57)	72.5 (32.41)	77.7 (34.07)	0.003
Haemoglobin (g/dL), mean (SD)	11.8 (1.61)	12 (1.59)	11.8 (1.62)	0.019
Platelets 10^3/L, mean (SD)	326.6 (180.03)	315.5 (142.97)	332 (200)	0.083

Abbreviations: GCA: giant cell arteritis; CRP: C-reactive protein; ESR: erythrocyte sedimentation rate; TA: temporal artery; US: ultrasound; LV: large-vessel; SD: standard deviation; CT: computed tomography

Table 2. Logistic regression analysis of factors associated with visual manifestations.

Variables	OR	95% CI
Female	0.887	0.670 - 1.173
Age	1.029	1.011 - 1.048
Jaw claudication	1.747	1.343 - 2.271
Polymyalgia rheumatica	0.498	0.383 - 0.648
Fever	0.393	0.274 - 0.563
Abnormal TA clinical examination	1.042	0.806 - 1.348
LV-GCA	0.724	0.512 - 1.023
ESR	0.993	0.989 - 0.998
Hb	0.971	0.883 - 1.069
Previous antiplatelet use	1.292	0.939 - 1.778
Hypertension	1.191	0.894 - 1.586
Diabetes Mellitus	1.358	0.994 - 1.854

Abbreviations: GCA: giant cell arteritis; ESR: erythrocyte sedimentation rate; LV: large-vessel; TA: temporal artery

Results: A total of 1636 GCA patients were included for analysis, of whom 599 (36.6%) presented visual involvement. The most frequent visual manifestation was anterior ischemic optic neuropathy (45.7%), followed by transient monocular vision loss (45.1%). Clinical, laboratory and imaging variables of patients with and without visual symptoms are shownin Table 1. Older age (OR 1.029; 95% CI 1.011-1.048), jaw claudication (OR 1.747; 95% CI 1.343-2.271) and diabetes mellitus (OR 1.358; 95% CI 0.994-1.854) were the only independent predictors of visual symptoms in our cohort. The presence of polymyalgia rheumatica (OR 0.498; 95% CI 0.383-0.648), fever (OR 0.393; 95% CI 0.274-0.563) and higher erythrocyte sedimentation rate (ESR) (OR 0.993; 95% CI 0.989-0.998) were associated with a reduced risk of developing visual involvement (Table 2).

Conclusion: One out of every three GCA patients present visual manifestations at diagnosis. Older age, jaw claudication and diabetes mellitus are independent predictors of visual manifestations, whereas polymyalgia rheumatica, fever and high ESR reduces the risk of visual involvement.

SESSION INFORMATION

Session Date: Tuesday, November 14, 2023

Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster III

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: Giant cell arteritis (GCA) is the most common vasculitis in North America and Western Europe. GCA is more likely to occur in women (1). However, there are scarce data on the epidemiology, clinical presentation, comorbidities, treatment and outcomes between men and women. Our aim was to assess the previous differential features between gender found in ARTESER registry.

Methods: ARTESER is a large Spanish multicenterepidemiological registry of GCA promoted by the Spanish Society of Rheumatology in which 26 national hospitals participated. Patients were included according to whether they met the 1990 ACR criteria, had a positive diagnostic test (biopsy or imaging test) or by the clinical judgement of the investigator. The recruitment period was between 2013 and 2019 and standardized data were included for all patients diagnosed with GCA in these centers. Differences between sexes were compared in a bivariate analysis.

Table 1. Main epidemiologic features and comorbidities at diagnosis.

	Total n=1675	Women n=1178	Men n=497
Annual incidence, Incidence rate x10^5 inhabitants ≥50 years (95% CI)	7.4 (6.6-8.3)	10.1 (8.1-11.5)	4.8 (3.8-5.9)
Age at diagnosis, years, mean (SD)	76.9 (8.1)	76.9 (8.0)	76.9 (8.3)
Comorbidity			
Arterial hypertension, n (%)	1079 (64.6)	749 (63.7)	330 (66.8)
Dyslipidemia, n (%)	801 (48.0)	563 (47.9)	238 (48.3)
Smoking status			
Former, n (%)	132 (8.4)	69 (6.3)	63 (13.4)
Current, n (%)	300 (19.1)	84 (7.7)	216 (46.0)
Never, n (%)	1135 (72.4)	944 (86.1)	191 (40.6)
Cardiovascular disease, n (%)	367 (22.0)	204 (17.4)	163 (33.1)
Diabetes mellitus, n (%)	351 (21.1)	217 (18.6)	134 (27.2)
Osteoporosis, n (%)	282 (17.0)	260 (22.3)	22 (4.5)
History of cancer, n (%)	204 (12.3)	109 (9.3)	95 (19.3)
Chronic kidney failure, n (%)	167 (10.0)	112 (9.6)	55 (11.2)
Obesity, n (%)	149 (9.0)	115 (9.8)	34 (7.0)
Alcohol consumption, n (%)	119 (7.1)	26 (2.2)	93 (18.9)

Results: A total of 1675 patients with GCA were included, 1178 women and 497 men. The annual incidence of GCA was higher in the female group (10.07; 95%CI: 8.7-11.5) than in the male group (4.83; 95%CI: 3.8-5.9) with a similar mean age at diagnosis and symptom onset between the two groups of 76.9 and 76.7 years, respectively. Among the comorbidities presented at diagnosis, male had a higher presentation of diabetes mellitus, tobacco use, alcohol consumption, cardiovascular disease and neoplasms than female, in which only osteoporosis was more frequent. The results are shown in **table 1.** Clinical manifestations were divided into cranial, extracranial and general. Among the cranial manifestations, headache (79.9%), temporal (49.2%) and visual (36.1%) disturbances were the most frequent. Polymyalgia rheumatica was the predominant extracranial manifestation (41.8%) and asthenia the most general symptom reported (52.2%). Main data are shown in **table 2.** We analyzed the distribution according to sex and observed a higher frequency of headache (p=0.028), polymyalgia rheumatica (p=0.003) and asthenia (p=0.035) in the female group. In contrast, we found a higher frequency of dysphasia in the male group (p=0.013) and visual symptoms, with no statistically significant differences in the latter. In terms of laboratory findings, elevated glomerular sedimentation rate (ESR) (p=0.039) and platelet count (p< 0.001) were higher in female. Treatment and outcome data are shown in **table 3.** Regarding the use of glucocorticoids and related adverse effects no differences between the two groups were detected. The use of conventional synthetic disease-modifying antirheumatic drugs (csDMARDs) was more frequent in males (p=0.005), but no differences were found regarding tocilizumab administration. There were no differences in the number of relapses or disease remission. However, the proportion of deaths during follow-up was higher in women (13.8% vs. 6.6%, p< 0.001).

Conclusion: GCA was more frequent in females, with more than twice as many cases as males. Some of the classic manifestations, such as headache, polymyalgia rheumatica and asthenia, were more common in women. In addition, women had higher ESR and platelet levels than men. The use of csDMARDs was higher in the male group but mortality was increased in females.

Table 2. Differences in clinical manifestations and laboratory abnormalities at diagnosis and during follow-up according to sex in ARTESER Registry.

SESSION INFORMATION

Session Date: Tuesday, November 14, 2023

Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster III

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

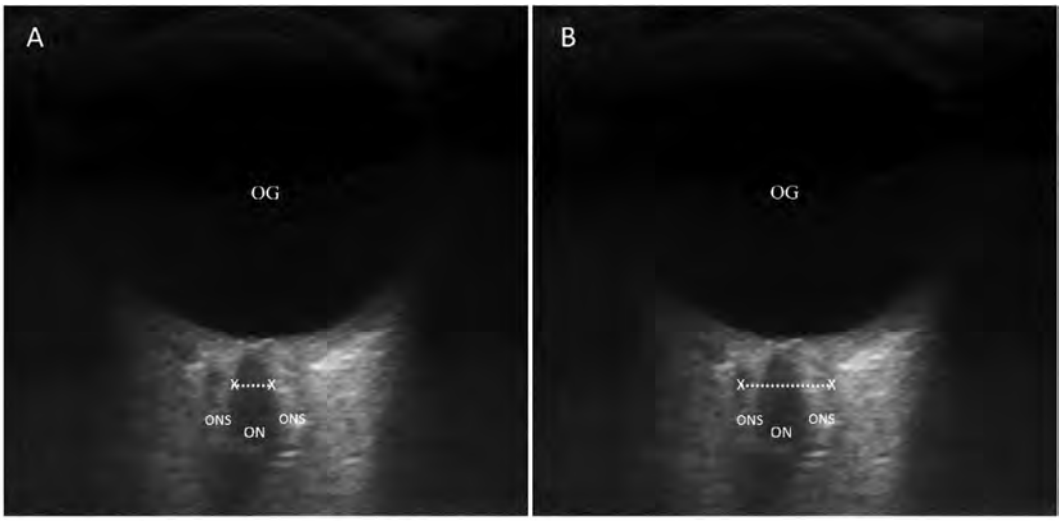
Background/Purpose: Confirming the diagnosis of giant cell arteritis (GCA) remains challenging. Available diagnostic tests have limited accuracy and availability. Recently, optic nerve sheath enhancement on magnetic resonance imaging has been reported in patients with GCA. Whether this finding can be documented on ultrasound is unknown. Optic nerve

(ON) ultrasound is non-invasive, easy to learn and does not require sophisticated equipment. This study aims to investigate if ON sheath measurement on ultrasound may be used to identify patients with active, new-onset GCA.

Methods: A cross sectional study was performed in our GCA Fast-Track clinic from June to December 2022. Adult patients were included if: (1) they were referred for suspected new-onset GCA, (2) had received < 14 days of glucocorticoids, and (3) had no prior history of intracranial hypertension, retinal disorder, or demyelinating disease. Study procedures were completed during the same visit: clinical assessment, bloodwork, ultrasound of temporal/axillary arteries and of the ON. Ultrasound measurements were performed for both eyes, 3mm distal to the posterior aspect of the ocular globe. Optic nerve sheath diameter (ONSD, includes ON and its sheath) and optic nerve diameter (OND) were measured. Optic nerve sheath thickness (ONST) was obtained by subtracting OND from ONSD (Figure 1). Final diagnosis of GCA was confirmed clinically after 6-month follow-up. Independent sample t-test was used to compare mean differences in ONSD, OND and ONST in patients with and without GCA at baseline. Paired-sample t-test was used to compare measurements between both eyes. Multivariable analysis was conducted for clinical baseline characteristics and ON ultrasound measurements. A significance level of 0.05 with Bonferroni correction (n=6) for multiple comparisons was used.

Results: A total of 30 participants were enrolled, including 9 participants with a final diagnosis of GCA (all of whom also satisfied 2022 ACR/EULAR classification criteria (Table 1)). Patients with GCA had a higher mean ONSD (5.98mm) compared to those without GCA (4.02mm); with a mean difference of 1.96mm (95% confidence interval [CI]: 1.11–2.82, p< 0.001). Mean ONST was higher in patients with GCA (3.01mm) than those without GCA (1.54mm), with a mean difference of 1.46mm (95%CI: 0.85–2.07, p< 0.001). Mean OND was numerically but not statistically higher in patients with GCA (Table 2). Paired measurement comparisons of ONSD, OND, ONST did not differ between the right and left eyes. On multivariable analysis, there was no significant association between age, sex, hypertension, diabetes, anterior ischemic optic neuropathy and ONSD, OND, ONST ultrasound measurements.

Conclusion: Patients with GCA had significantly wider optic nerve sheaths on ultrasound than patients without GCA. ON ultrasound may represent a novel, rapid, bedside diagnostic test in GCA. A large prospective cohort study is ongoing to confirm these findings and evaluate if ONSD-ONST are dynamic disease markers in GCA (ClinicalTrials.gov id: NCT05749094).



OG, ocular globe; ON, optic nerve; ONS, optic nerve sheath.
Panel A dotted line : measurement of the optic nerve diameter (OND), 3mm distal to the posterior aspect of the OG.
Panel B dotted line: measurement of the optic nerve sheath diameter (ONSD, includes the optic nerve and its sheath), 3mm distal to the posterior aspect of the OG.

Magnetic Resonance Imaging Reflects Disease Activity in the "Giant Cell Arteritis Treatment with Ultra-short Glucocorticoids and Tocilizumab" Trial (The GUSTO Trial)

Lisa Christ[1], Harald Bonel[2], Jennifer Cullmann[3], Luca Seitz[4], Lukas Butikofer[5], Franca Wagner[6] and Peter Villiger[7], [1]Department of Rheumatology and Immunology, Inselspital, Bern University Hospital, University of Bern, Bern, Switzerland, [2]Department of Diagnostic, Interventional and Pediatric Radiology (DIPR), Inselspital, Bern University Hospital, University of Bern, Bern, Switzerland; Campusradiologie, Lindenhofspital Bern, Bern, Switzerland, [3]Campusradiologie, Lindenhofspital Bern, Bern, Switzerland, [4]Rheumatology and Immunology, Inselspital University Hospital Bern, Bern, Switzerland, [5]CTU Bern, University of Bern, Bern, Switzerland, Bern, Switzerland, [6]University Institute of Diagnostic and Interventional Neuroradiology, Inselspital, Bern University Hospital and University of Bern, Bern, Switzerland, [7]Medical Center Monbijou, Rheumatology and Immunology, Bern, Switzerland

SESSION INFORMATION

Session Date: Tuesday, November 14, 2023

Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster III

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: Magnetic resonance imaging (MRI) is well established for diagnosing giant cell arteritis (GCA). Its role in monitoring disease activity has yet to be determined. We investigated vascular and musculoskeletal inflammation using MRI in the patients of the GUSTO trial.

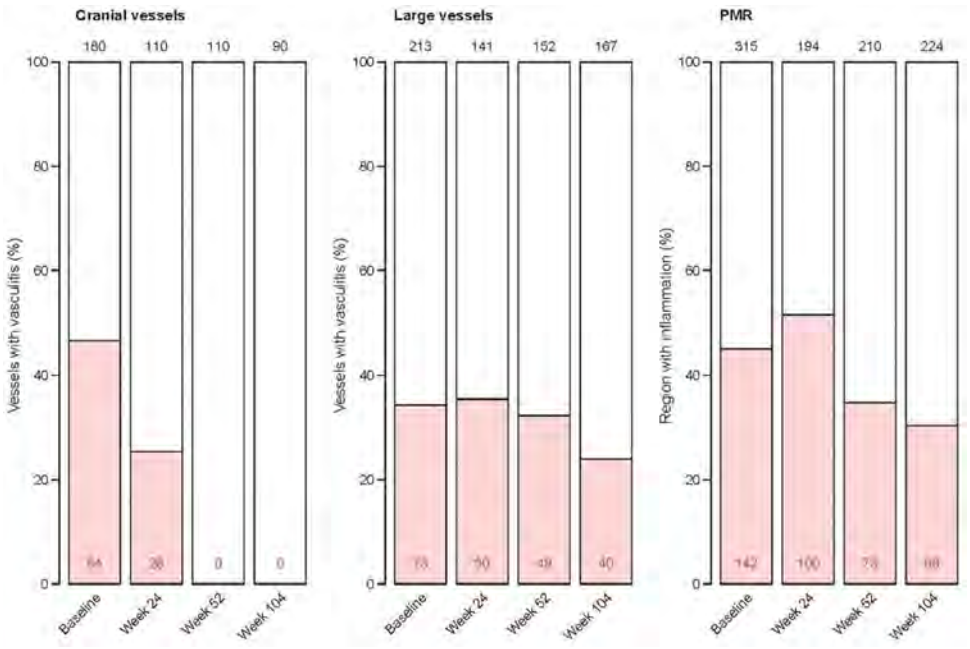

Figure 1: Proportion of segments with inflammatory findings (red numbers) summarized over all patients (black numbers=number of segments or regions assessed).

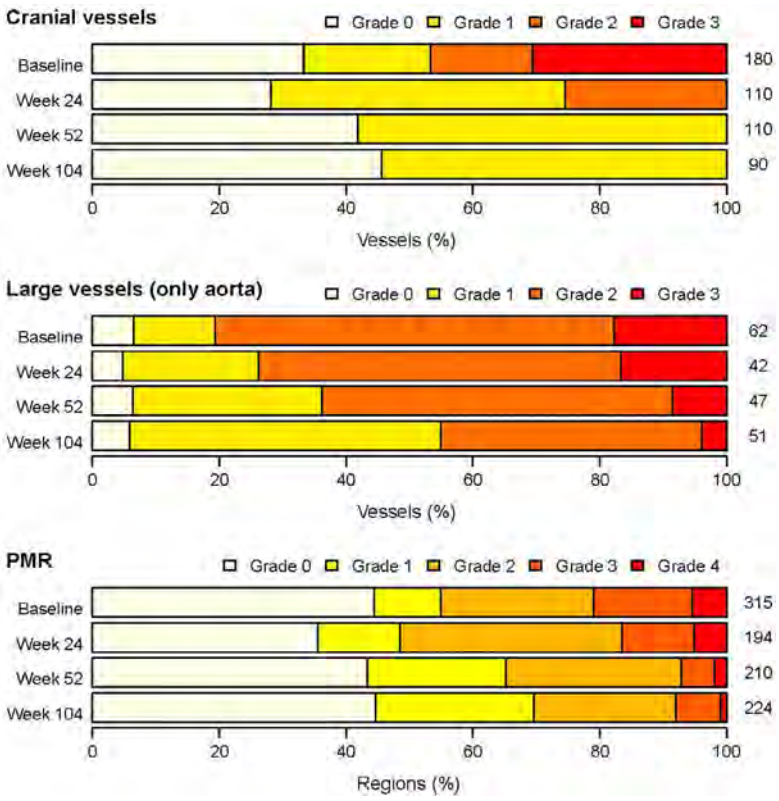

Figure 2: Grading of vessels and PMR findings summarized over all patients. Numbers refer to the total number of segments or regions assessed.

Methods: Eighteen patients with newly diagnosed GCA received 500 mg methylprednisolone intravenously for 3 consecutive days [1]. After that, GC treatment was discontinued, and a single dose of tocilizumab (TCZ) was administered intravenously, followed by weekly subcutaneous TCZ injections from day 10 until week 52. Cranial, thoracic and abdominal MR exams were performed at baseline (active, new-onset disease), and at weeks 24, 52 (remission on-treatment), and 104 (remission off-treatment). Polymyalgia rheumatica (PMR) findings as well as vasculitic disease extent and intensity were rated by experienced radiologistsand one board-certified neuroradiologist as previously reported (grade 0-3, grade ≥ 2 considered as vasculitis) [2,3]. Up to 10 cranial, 13 large vessel and 18 musculoskeletal segments were assessed.

Results: In total, 673 vascular segments and 943 musculoskeletal regions in 56 thoracic/abdominal MR and 490 vascular segments in 49 cranial MR scans of 18 patients were analyzed. Cranial vessels displayed dynamic changes. At weeks 52 and 104, no cranial vascular segment displayed vasculitic findings. Vasculitic signal alterations were still detectable in every 4th cranial segment at week 24. Large vessels, except for the ascending aorta, displayed no or only a slight decrease in vasculitic findings upon remission on- and off-treatment. PMR findings persisted in most patients. Results are displayed in Figures 1 - 3.

Conclusion: Whereas signals of cranial vessels normalized upon a 52-week treatment, large vessel signals and PMR findings persisted. Remission of vasculitic activity in cranial arteries took more than 24 weeks, which was longer than time to clinical symptom resolution and normalization of serum proteins but paralleled intima-media thickness measurements using ultrasound [4]. Thus, in contrast to large vessel signals and PMR findings, the dynamic of cranial vessel signals suggests that MRI of these arteries is a very promising monitoring tool for suspected relapse after 52 weeks of treatment.

Concordance Between the 1990 ACR Classification Criteria and the New 2022 ACR/EULAR 2022 Criteria in Giant Cell Arteritis

Julio Sanchez Martin[1], Julia Medina Valle[1], Javier Loricera[1], Maria Fe Garcia Reija[1] and Ricardo Blanco[2], [1]Hospital Universitario Marqués de Valdecilla, Santander, Spain, [2]Hospital Universitario Marqués de Valdecilla, IDIVAL, Santander, Spain

SESSION INFORMATION

Session Date: Tuesday, November 14, 2023

Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster III

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: Classification criteria for vasculitis, including giant cell arteritis (GCA) are under constant revision. In 2022, the American College of Rheumatology (ACR)/European League Against Rheumatism (EULAR) criteria were presented, renewing those published by ACR in 1990. They include wider range of clinical criteria and imaging tests, such as ultrasonography (US) and **Positron emission tomography** (PET), which has contributed to the diagnosis of a higher number of cases.

The objective of this study was to assess the concordance between recent 2022 ACR/EULAR giant cell arteritis classification criteria and the criteria of ACR 1990 **(1,2)**.

Methods: Observational study of patients diagnosed with GCA who underwent temporal artery biopsy (TAB) between 2016 and 2022 in an university hospital. Concordance between both sets of criteria were analyzed with Cohen's kappa index.

TABLE. Main characteristics according to TAB result

	Suspected diagnosis of GCA (n=191)	ACR 1990 Criteria (n=128)	ACR/EULAR 2022 Criteria (n=155)	Negative ACR1990 Criteria Positive ACR/EULAR 2022 Criteria (n=30)

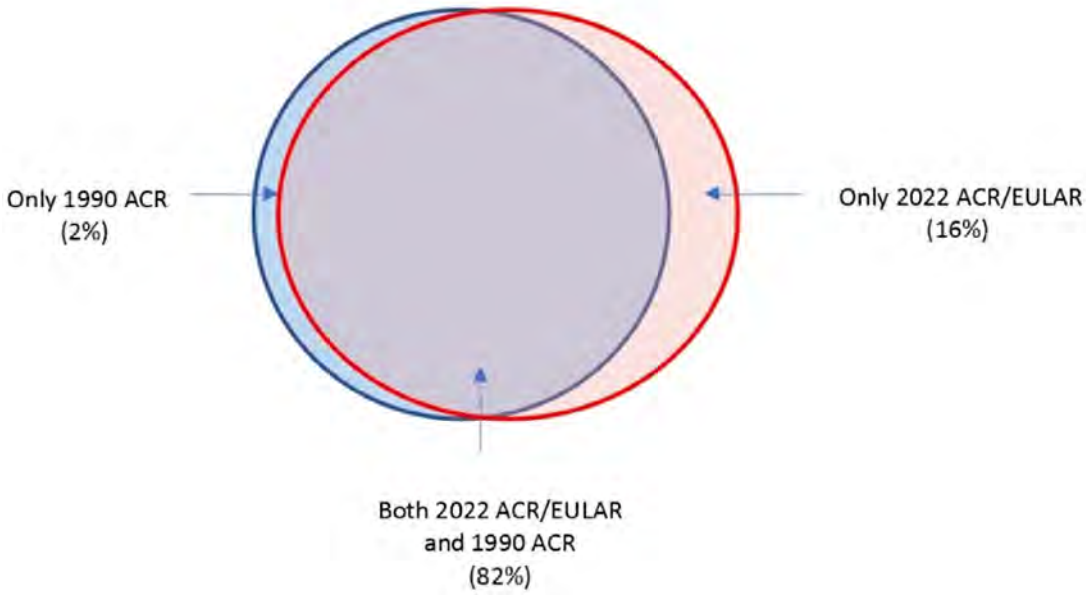
Abbreviations: ACR: American College of Rheumatology, CRP: C-reactive protein, ESR: erythrocyte sedimentation rate, EULAR: European League Against Rheumatism, FDG-PET: fluorodeoxyglucose positron emission tomography, GCA: giant cell arteritis, Hb: Hemoglobin, PmR: polymyalgia rheumatica, TA: temporal artery, TAB: temporal artery biopsy, US: ultrasound.

Figure. % of patients who met the different classification criteria.



Results: We present 191 patients (120 female/71 male) (mean±SD; 75±10 years). The main characteristics of the patients are shown in **Table**. The Kappa index between both criteria weighted by prevalence and bias was 0.654 (moderate-high degree of agreement). Global agreement of 83% was observed, with a higher specific agreement for negative results (88%) than for positive results (67%). Disagreement was observed in 16% of patients who were considered negative for ACR 1990 criteria but positive for ACR/EULAR 2022 criteria and in 2% who were considered positive for ACR 1990 criteria but negative for ACR/EULAR 2022. 2022 ACR/EULAR showed a higher sensitivity, and 27 additional patients were classified as GCA with these classification criteria.

Conclusion: Moderate-high concordance was found between 2022 ACR/EULAR and 1990 ACR classification criteria. However, the 2022 ACR/EULAR criteria consider a wider range of factors than the 1990 ACR criteria by introducing US and PET findings, thus increasing sensitivity and allowing a larger number of patients to be diagnosed. Cranial GCA was the most frequent phenotype observed.

SESSION INFORMATION

Session Date: Tuesday, November 14, 2023

Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster III

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: Giant cell arteritis (GCA) is the most common form of vasculitis in adults, necessitating prompt diagnosis to prevent severe complications. However, access to expert GCA ultrasonography is often limited to larger medical centers. The utilization of artificial intelligence (AI)-based assistance for ultrasound image classification holds significant potential. The development of such AI systems involves selecting a neural network architecture from a wide range of options, each with distinct characteristics, including limitations in processing image size, resolution, result quality, and resource

efficiency. This project aims to address the minimum resolution required for human experts to reliably classify ultrasound images of commonly affected arteries, distinguishing between GCA and normal.

Methods: In this study, a blinded classification task was conducted, involving 42 international experts from the OMERACT subgroup on ultrasound in large vessel vasculitis. A set of 250 vascular ultrasound images from both GCA patients and healthy individuals were presented to the experts. The image selection process initially comprised 10 B-mode scans each of the common temporal artery, its frontal branch, parietal branch, and the axillary artery (all in cross-section), as well as the axillary artery in longitudinal scan. These 50 images were presented in a random order at five distinct resolution levels: 32x32, 64x64, 128x128, 224x224, and 512x512 pixels (refer to Figure 1). The survey and image classification tasks were conducted using REDCap version 13.2.5, while data interim analysis was performed utilizing R (version 4.3.0).

Results: This interim analysis includes data from 30 study group members with an average of 10.5±6.4 years (mean±standard deviation) of experience in ultrasound in GCA. Across all artery categories, the proportion of images considered unclassifiable decreased as the image resolution increased. The mean percentage of unclassifiable images was 91% at 32x32 pixels and reduced to 26% at 512x512pixels (refer to Table 1). Similarly, lower image resolution resulted in less frequent correct classifications (see Figure 2). The chance of correct image classification was comparable at image resolutions of 512x512 pixels (highest resolution level) and 224x224 pixels (odds ratio = 0.99, p=0.891), while it was significantly lower at image sizes of 128x128 pixels (OR=0.79, p=0.01), 64x64 pixels (OR = 0.42, p< 0.001), and 32x32 pixels (OR=0.24, p< 0.001).

Conclusion: As the image resolution increases, the proficiency of human experts in GCA ultrasound improves, enabling more confident and accurate classification of vascular ultrasound images. At a resolution of 224x224 pixels and above, classification accuracy exceeded 50%. The best classification performance was achieved at a resolution of 512x512 pixels

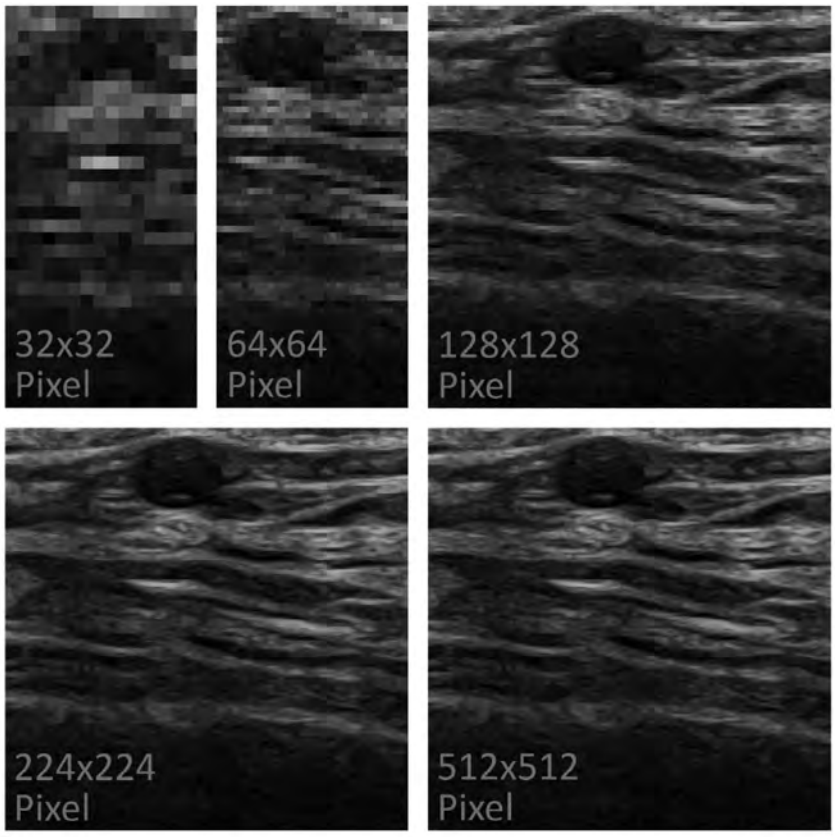

Figure 1: Shown is an exemplary ultrasound image of the common temporal artery (cross-section, B-mode), presented to study participants at five different resolution levels.

Table 1: Frequency of the selected response category "Meaningful classification is not possible" depending on the image resolution level.

Proportion of ultrasound images that were rated as unclassifiable by human experts at different resolution levels

Image resolution (pixels)	Overall		Vessel-specific proportions				
	Total number of images rated as unclassifiable (any vessel)	Proportion of images rated as unclassifiable (any vessel)	Axillary artery (Transverse section)	Axillary artery (Longitudinal section)	Common temporal artery (Transverse section)	Frontal branch (Transverse section)	Parietal branch (Transverse section)
32x32	1365/1500	91.00 %	91.33%	91.33%	88.33%	91.67%	92.33%
64x64	1228/1500	81.87 %	79.33%	84.33%	80.00%	85.00%	80.67%
128x128	835/1500	55.67 %	52.00%	57.00%	55.67%	62.67%	51.00%
224x224	484/1500	32.27 %	28.67%	26.67%	33.00%	42.33%	30.67%
512x512	394/1500	26.27 %	21.67%	19.00%	25.67%	37.67%	27.33%

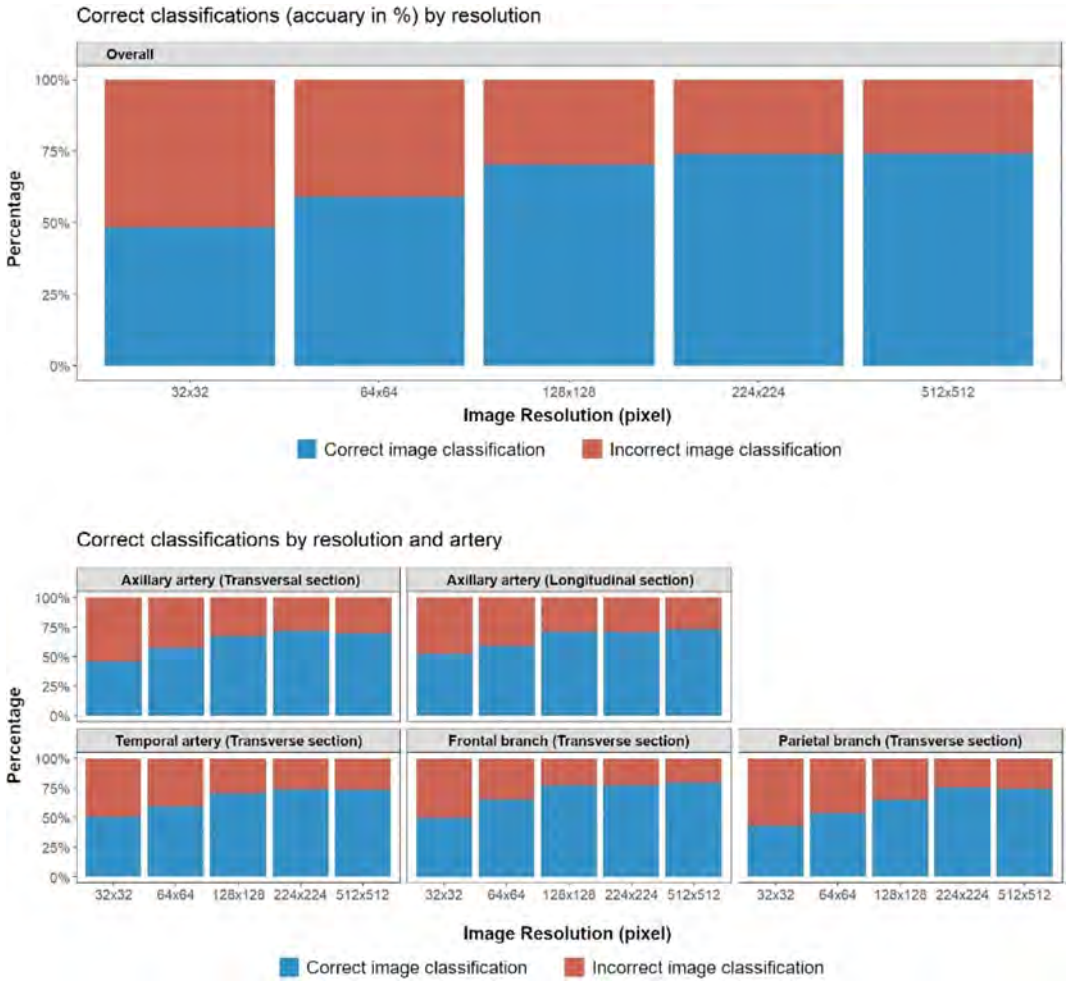

Figure 2: Frequency of correct image classification as "GCA patient" or "healthy individual" depending on image resolution level.

(74.13% of all single-image classifications correct). Yet given the comparable performance at a resolution level of 224x224 pixels (73.93% of all single-image classifications correct), this opens up a variety of perspectives in neural network architecture selection for the development of an AI based assistance for GCA ultrasound image classification.

Pregnancy Outcomes Among Patients with Vasculitis Using Administrative Claims Data

Amadeia Rector[1], Julia Simard[2], Gary Shaw[3] and Audra Horomanski[4], [1]Stanford University, San Francisco, CA, [2]Department of Epidemiology & Population Health, Stanford University School of Medicine, Stanford, CA, [3]Stanford University, Stanford, CA, [4]Stanford University, Palo Alto, CA

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: Plenary III
Session Type: Plenary Session
Session Time: 11:00AM–12:30PM

Background/Purpose: Systemic vasculitides are rare, heterogeneous, inflammatory disorders associated with high morbidity and mortality. Recent management and therapeutic advances have improved life expectancy and reproductive opportunities for vasculitis patients. Research on the risk of preterm delivery and maternal complications in these patients is limited. Therefore, we investigated pregnancy outcomes among patients with vasculitis leveraging large, administrative claims data.

Methods: Using administrative claims data from private health insurance providers we identified all pregnancies regardless of outcome for patients with and without vasculitis from 2007 to 2021. Vasculitis was defined as ≥2 ICD coded outpatient visits or ≥1 ICD coded inpatient visit occurring before the estimated last menstrual period (LMP). Vasculitis was further categorized by vessel size: large, medium, small, and variable based on Chapel Hill Consensus Conference criteria. As a referent population we included those without vasculitis or other rheumatic disease, defined as no ICD coded outpatient or inpatient visits for vasculitis, systemic lupus erythematosus, rheumatoid arthritis, systemic sclerosis, or juvenile idiopathic

Table 1. Pregnancy outcomes for patients without vasculitis and with vasculitis stratified by vessel size (2007-2021).

Characteristics	Non-vasculitis (n= 4,209,034)	All vasculitis (n= 665)	Large Vessel[1] (n= 60)	Medium vessel [2] (n= 160)	Small vessel [3] (n= 217)	Variable vessel [4] (n= 250)
Maternal age, median (IQR)[5]	31 (27, 35)	33 (29, 36)	35 (32, 37)	32 (26, 35)	33 (30, 37)	32 (28, 35)
Gestational age in weeks, mean (SD)	39 (16, 39)	38 (13, 42)	39 (11, 39)	38 (11, 41)	37 (11, 41)	39 (35, 39)
Observed time with vasculitis in years, mean (SD)[6]		2 (2.0)	1.8 (1.9)	2.7 (2.5)	1.6 (1.7)	1.9 (1.8)
Pregnancy outcomes						
Livebirth	3,044,907 (72%)	461 (69%)	44 (73%)	107 (67%)	136 (63%)	191 (76%)
Spontaneous abortion	810,512 (19%)	139 (21%)	13 (22%)	38 (24%)	55 (25%)	38 (15%)
Elective termination	191,903 (5%)	41 (6%)	<11	12 (8%)	14 (6%)	14 (6%)
Stillbirth, Mixed birth[7]	27,747 (<1%)	0	0	0	0	0
Ectopic & molar pregnancy	118,683 (3%)	24 (4%)	<11	<11	12 (6%)	<11
Unspecified abortion	15,282 (<1%)	0	0	0	0	0
Preterm delivery[8]	250,124 (6%)	62 (13%)	<11	<11	23 (17%)	28 (15%)

[1]Large vessel size includes Takayasu Arteritis
[2]Medium vessel size includes Polyarteritis Nodosa and Kawasaki Disease
[3]Small vessel size includes anti-neutrophil cytoplasmic antibody (ANCA)-associated vasculitides, Cryoglobulinemic Vasculitis, IgA Vasculitis, Hypocomplementemic Urticarial Vasculitis, and Primary Angiitis of the central nervous system (PACNS)
[4]Variable vessel size includes Behçet's disease and Cogan's syndrome
[5]Maternal age at delivery
[6]From observed date of Vasculitis diagnosis to estimated last menstrual period (LMP)
[7]Mixed birth is a Multifetal pregnancy resulting in stillbirth and livebirth
[8]Restricted to pregnancies that result in livebirth, mixed birth, or stillbirth

SD = Standard deviation

arthritis before LMP or during pregnancy. We described pregnancy outcomes in patients with vasculitis compared to the referent population. We also explored pregnancy characteristics and complications in patients with vasculitis stratified by parity (nulliparous vs multiparous).

Results: There were 665 pregnancies among 527 patients with vasculitis and 4,209,034 pregnancies among 2,932,379 patients from the referent population. Patients with vasculitis had a higher frequency of spontaneous abortion, elective termination, ectopic and molar pregnancy, and nearly two times as much preterm delivery compared to the referent population. Approximately 12% of pregnancies among patients with vasculitis were complicated by preeclampsia. Multiparous pregnancies compared to nulliparous had a slightly higher frequency of preterm delivery and were more often comorbid with gestational diabetes, pre-pregnancy hypertension, obesity, and hypothyroidism. Patients with small vessel vasculitis had higher frequencies of spontaneous abortion, preterm delivery, and comorbidities among vasculitis subtypes.

Conclusion: Pregnancies among patients with vasculitis had a higher frequency of spontaneous abortion and preterm delivery. Risk of maternal complications associated with vasculitis were observed to vary by vessel size and parity. These findings further the knowledge base and provide patients with up-to-date statistics on outcomes and complications.

Table 2. Pregnancy characteristics and complications for patients with vasculitis stratified by parity and vessel size (2007-2021).

The Role of β-catenin in Synovial Lining Fibroblast Differentiation

Sonia Presti[1], Gerald F.M. Watts[1], Junning Case[1], Zhu Zhu[2], Teri Bowman[1], Hung Nguyen[1], Gabriel Nigrovic[1], Ce Gao[1], Kartik Bhamidipati[1], Yuhong Li[1], Suppawat Kongthong[1], Fan Zhang[3], Anna Helena Jonsson[1], Accelerating Medicines Partnership Program (AMP RA/SLE) Network[4], STARS BWH[1], Michael Brenner[5], Shideh Kazerounian[1] and Kevin Wei[5], [1]Brigham and Women's Hospital, Boston, MA, [2]10x Genomics, St. Louis, MO, [3]University of Colorado, Aurora, CO, [4]National Institute of Arthritis and Musculoskeletal and Skin Diseases, Boston, MA, [5]Brigham and Women's Hospital and Harvard Medical School, Boston, MA

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: Plenary III
Session Type: Plenary Session
Session Time: 11:00AM–12:30PM

Background/Purpose: In healthy synovium, lining fibroblasts promote joint health by secreting proteoglycans that lubricate the joint cavity. In rheumatoid arthritis (RA), sublining fibroblasts undergo marked expansion while lining fibroblasts are relatively diminished[1–4]. We have previously demonstrated the role of vascular endothelial-derived Notch signaling as a driver of

perivascular sublining fibroblast differentiation[4]. Here, we seek to identify the transcriptional regulators of synovial lining fibroblast differentiation using synovial patient-derived organoids.

Methods: We developed two 3D tissue culture approaches to study fibroblast differentiation. First, we developed patient-derived organoids from synovial tissue explants that maintain fibroblast heterogeneity ex vivo. We leveraged an in vitro micromass system[5] to examine the stability and reversibility of fibroblast differentiation. Fibroblast differentiation in organoids were examined via confocal microscopy, histology, and single-cell RNA sequencing (scRNAseq). A targeted transcription factor screen was performed using siRNA and CRISPR gene-editing to identify candidate transcription factors driving fibroblast differentiation.

Results: Addition of a GSK3 inhibitor leads to compaction within patient-derived organoids, resembling a synovial lining-like layer **(Fig 1A-B)**. We identified cadherin-23 (CDH23), an atypical cadherin, as a novel cadherin that is specific to lining fibroblasts **(Fig 1C)**. Inhibition of GSK3 results in profound changes in gene expression, including upregulation of CDH23 and other lining fibroblast marker genes **(Fig 1E)**. This GSK3i-induced gene expression program is reversible suggesting active signaling is required to maintain this phenotype **(Fig 1F-G)**. We performed a targeted screen against transcription factors that are induced by GSK3 inhibition. This screen identified β-catenin as a necessary factor for mediating key transcriptional changes consistent with a lining-like phenotype in synovial fibroblasts **(Fig 2A)**. Consistent with β-catenin's potential role as a co-transcription factor, we observed increased β-catenin expression and nuclear localization in GSK3i-treated fibroblasts **(Fig 2B-C)**.

Conclusion: Inhibition of GSK3 induces a reversible lining-like phenotype in synovial fibroblasts. β-catenin is necessary for upregulation of lining fibroblast marker genes in the context of GSK3 inhibition. Further work is required to confirm direct transcriptional effects of β-catenin on synovial fibroblasts and upstream mechanisms. Understanding the mechanism underlying fibroblast differentiation could lead to identification of novel therapeutic targets for restoring synovial lining function in RA patients.

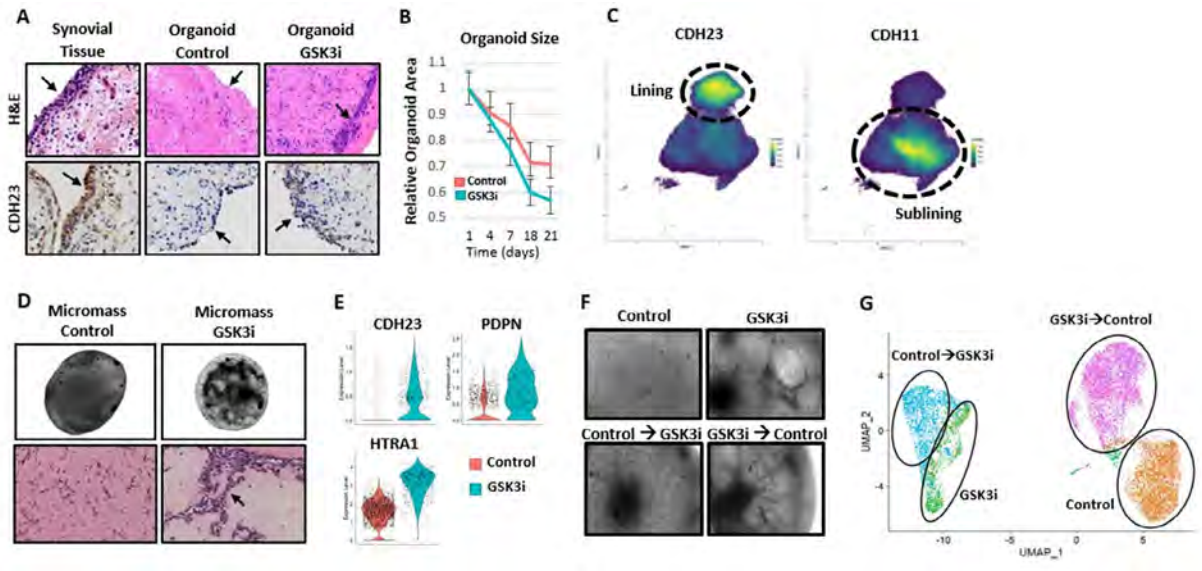

Figure 1: Synovial lining-like phenotype recapitulated in 3D culture. (A) IHC staining of synovial organoids displaying compaction and upregulation of CDH23 when treated with GSK3i, which resembles synovial lining. (B) Organoid size decreases more drastically when exposed to GSK3i indicating a compaction phenotype (C) Density plot of CDH23 and CDH11 mRNA expression in synovial fibroblasts from the Accelerating Medicines Partnership scRNAseq dataset (D) Micromass generated from synovial fibroblasts. (E) RNA expression of lining marker genes upregulated by GSK3 inhibition. (F) Live imaging of micromass that were either grown in control media, exposed to GSK3i, exposed to GSK3i after initially grown in control media, or grown in control media after initially exposed to GSK3i. (G) UMAP depicting scRNAseq data on micromass fibroblasts showing partial reversibility of GSK3i-induced transcriptional profile.

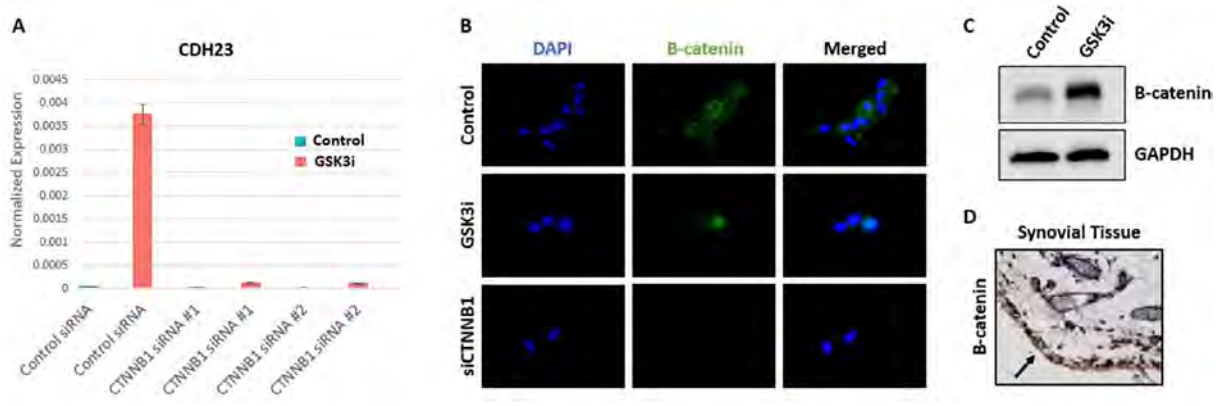

Figure 2: β-catenin is necessary for lining-like transcriptional changes in the context of GSK3 inhibition. (A) Normalized mRNA expression of CDH23 with siRNA knockdown against CTNNB1, which encodes β-catenin. (B) Immunofluorescent images of β-catenin (green) in synovial fibroblasts treated with either a GSK3 inhibitor or CTNNB1 siRNA. (C) Western blot showing upregulation of β-catenin in synovial fibroblasts treated with GSK3i. (D) High expression of β-catenin detected in synovial lining.

Degranulating PR3+ Myeloid Cells Characterize Proliferative Lupus Nephritis

Alessandra Ida Celia[1], Xiaoping Yang[2], Hana Minsky[2], Silvia Malvica[2], Michelle Petri[3], the Accelerating Medicines Partnership in RA/SLE[4], Avi Rosenberg[5] and Andrea Fava[2], [1]John Hopkins University of Medicine, Rome, Italy, [2]Johns Hopkins University, Baltimore, MD, [3]Department of Medicine, Division of Rheumatology, Johns Hopkins University School of Medicine, Timonium, MD, [4]Multiple, Multiple, [5]Department of Pathology, The Johns Hopkins University School of Medicine, Baltimore, MD

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: Plenary III
Session Type: Plenary Session
Session Time: 11:00AM–12:30PM

Background/Purpose: As part of the Accelerating Medicines Partnership (AMP), we discovered that urinary PR3, a neutrophil degranulation product, is associated with histological activity, indicating the involvement of neutrophil degranulation in proliferative LN, the most aggressive type of LN. Although mature neutrophils with classical polylobate nuclei are rare in LN kidney biopsies, recent evidence suggests that immature myeloid cells undergoing degranulation play a role in the

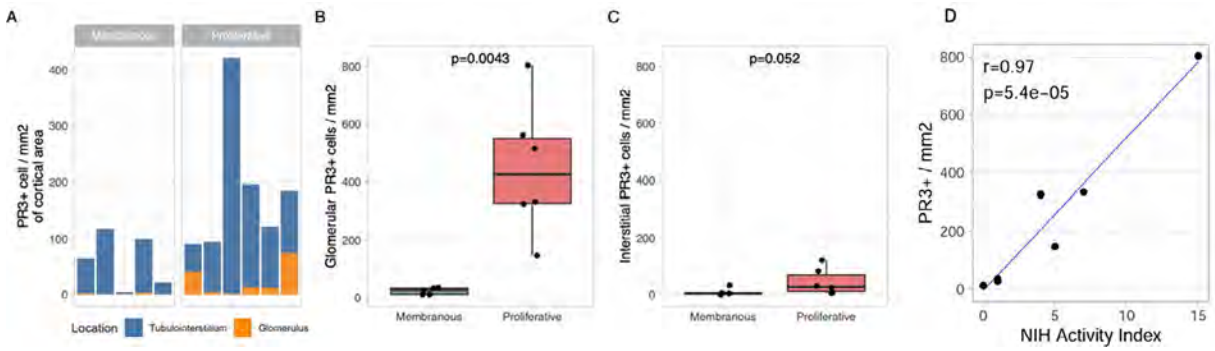

Figure1. Clinicopathological associations of intrarenal PR3+ cells. The majority of PR3+ cells were in the tubulointersitium (A). However, accounting for the smaller glomerular area, there was a higher density of PR3+ cells in the glomeruli (B-C). PR3+ cell abundance was higher in proliferative LN, especially in the glomeruli (A-C). Glomerular PR3+ cell density very strongly correlated with histological activity measured by the NIH Activity Index (Pearson's r=0.97, p=5*10-5; panel D. The analysis was limited to renal cortex.

pathogenesis of LN. Our aim is to investigate the presence of PR3+ cells in LN kidney, their association with histopathological features and to define their immunophenotype.

Methods: We performed multiplexed histology using serial immunohistochemistry (sIHC) on LN kidney biopsies to quantify the expression of PR3 and multiple cell lineage markers (20-plex). Image analysis including deconvolution, cell segmentation, glomerular annotation, and quantitative histology was performed using Indica HALO. The analysis was limited to renal cortex.

Results: A total of 11 patients with LN who underwent a clinically indicated kidney biopsy were enrolled: 6 (55%) with pure proliferative LN (ISN/RPS class III or IV) and 5 (45%) with pure membranous LN. PR3+ cells were identified in all biopsies (range 343-7625 per sample) and most of them did not show a polylobate nucleus. The majority of PR3+ cells were in the tubulointersitium **(Figure 1A).** However, when present, there was a higher density of PR3+ cells in the glomeruli due to their smaller area**(Figure 1A-C)**. PR3+ cell abundance was higher in proliferative LN, especially in the glomeruli **(Figure 1A-C)**. Glomerular PR3+ cell density very strongly correlated with histological activity measured by the NIH Activity Index (Pearson's r=0.97, $p=5*10^{-5}$; **Figure 1D)**. PR3+ cells displayed a unilobate nucleus (**Figure 2**). Most PR3+ cells coexpressed MPO. We identified 2 subsets of PR3+ cells based the coexpression of other lineage markers **(Figures 2 and 3**).

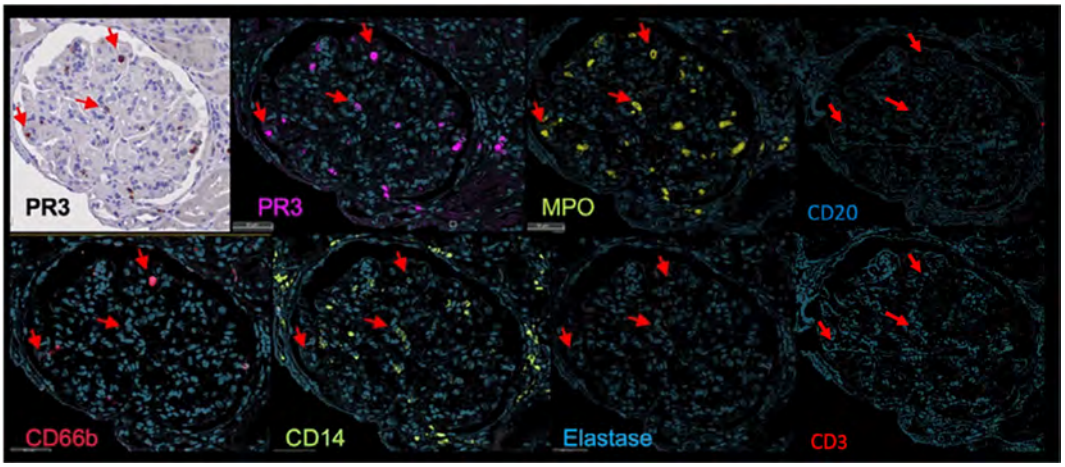

Figure2. Surface markers expression in PR3+ cells. The original and deconvoluted IHC images are shown for a representative glomerulus, with arrows indicating three identical representative cells. Markers indicated at the bottom with matching false colors.

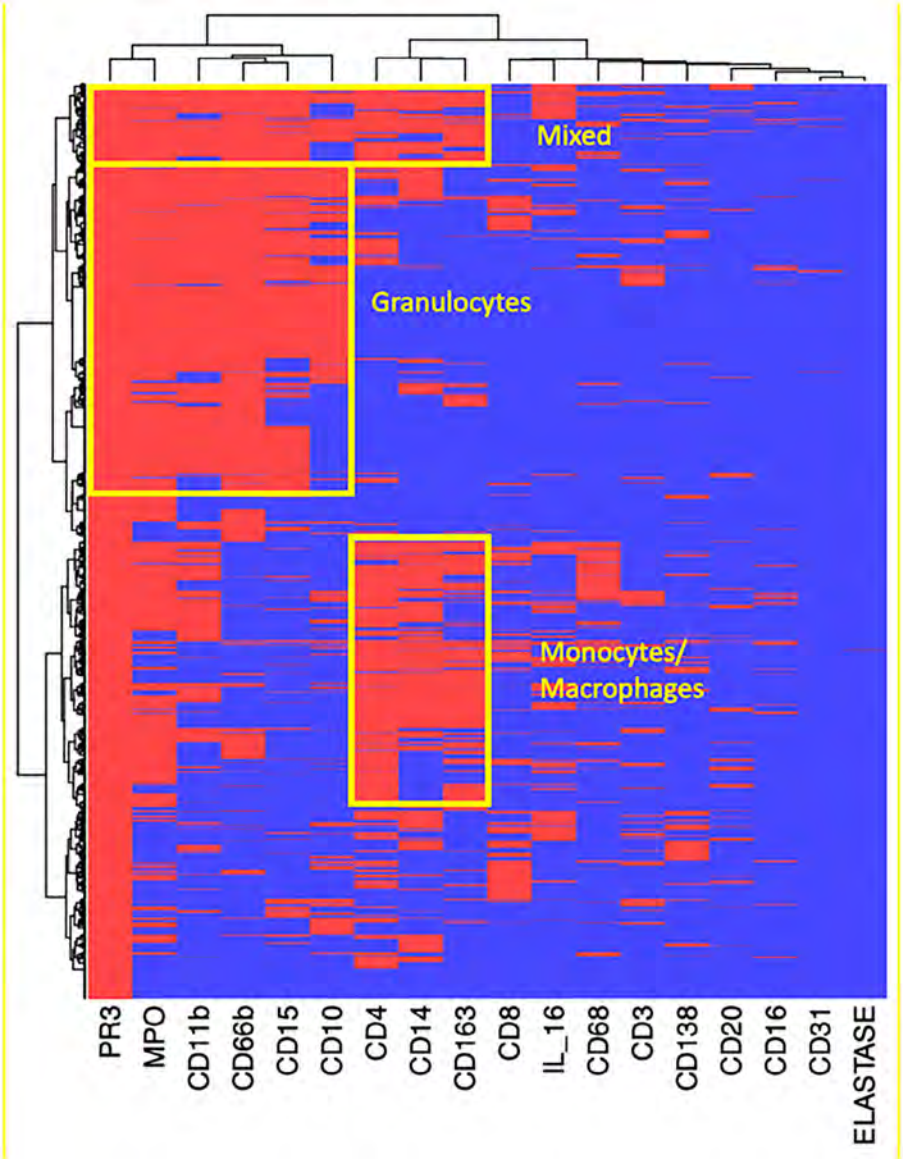

Figure3. Cell phenotypes Heatmaps displays the heterogeneity of marker coexpression at the single cell level fo PR3+ cells. Three distinct subsets of PR3+ cells infiltrating the kidney were identified. Data from one representative kidney biopsy (class IV lupus nephritis, NIH Activity Index 8/24, Chronicity Index 6/12).

One group coexpressed CD66b, CD11b, CD15, and (variably) CD10 indicating a degranulating phenotype (**Figure 3**). The other group expressed CD14, CD163, and CD4 indicating a phagocytic phenotype **(Figure 3).** The was a smaller subset with features of both groups.

Conclusion: PR3+ cells are abundant in LN, increased in proliferative LN and are strongly associated with histological activity thereby characterizing a more aggressive phenotype. This population densely infiltrated the glomeruli emphasizing a potential role in the endothelial pathogenic process. There were two subsets of kidney-infiltrating PR3+ cells characterized by a phagocytic or a degranulating phenotype; both were mononucleated suggesting a monocyte or nonsegmented neutrophil lineage. We previously showed the association between urinary PR3 and histological activity suggesting that intrarenal PR3+ cells are actively degranulating and therefore likely inducing kidney damage. These findings nominate PR3+ cells as a potential therapeutic target. Spatial transcriptomics and proteomic studies are ongoing to define the lineage and function of these cells.

Unclosing Premature Mortality Gap Among Gout Patients in the US General Population, Independent of Serum Urate and Atherosclerotic Cardiovascular Risk Factors

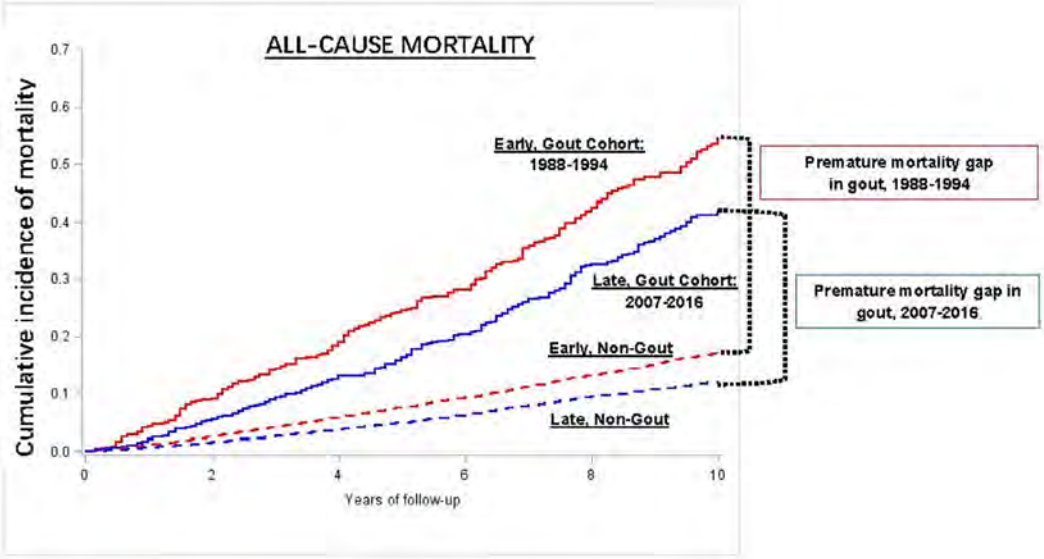
Natalie McCormick[1], Kehuan Lin[2], Chio Yokose[3], Na Lu[4], Yuqing Zhang[1] and Hyon K. Choi[5], [1]Massachusetts General Hospital, Boston, MA, [2]Channing Division of Network Medicine, Boston, MA, [3]Massachusetts General Hospital, Waltham, MA, [4]Arthritis Research Canada, Vancouver, BC, Canada, [5]Massachusetts General Hospital and Harvard Medical School, Lexington, MA

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: Plenary III
Session Type: Plenary Session
Session Time: 11:00AM–12:30PM

Background/Purpose: A recent UK study reported a transient increased cardiovascular risk after gout flare episodes [Cipolletta et al. *JAMA* 2022], which may translate to premature mortality for gout patients over the long term. Prior studies reported premature mortality in gout; however, it is unknown whether this mortality gap has improved over recent years at a national level.We prospectively evaluated the association between gout and the risk of all-cause and cardiovascular (CVD) mortality fully adjusting for serum urate (SU) and atherosclerotic cardiovascular disease (ASCVD) risk factors in the latest US general population data (as well as the UK).

Methods: Using nationally representative samples of US adults in the National Health and Nutrition Examination Survey (NHANES), linked prospectively with vital statistics data, we examined the independent association of prevalent gout with mortality risk and compared Early (NHANES III: 1988-1994 baseline) and Late cohorts (2007-2016 baseline), as well as key demographic subgroups defined by sex and self-reported race/ethnicity (Black vs. White).Hazard ratios (HRs) were calculated over 10 years adjusting for SU, ASCVD risk factors, cardiometabolic comorbidities, kidney function, and relevant medications. We replicated the Late cohort findings among incident gout in a nationwide UK cohort (2006-2010 baseline).

Results: US adults with gout had higher 10-year all-cause mortality rates than those without gout, in both the Early and Late cohorts, with similar magnitudes of excess mortality (**Figure**) and adjusted hazard ratios (HR) between the two cohorts (HR, 1.20; 1.03–1.40 and 1.19; 1.04–1.37, respectively; p for gout*time interaction=0.69).HRs changed minimally with further adjustment for SU (HR, 1.19; 1.02–1.38 and 1.19; 1.03–1.37, respectively) (**Table 1**).Late cohort findings were replicated among incident gout in the UK (adjusted HR, 1.61; 1.47–1.75).In both countries, associations were larger among women than men (HR 1.32 (1.10 to 1.58) in US and 1.90 (1.55 to 2.32) in UK; p for interaction=0.04) and prominent among Black individuals (**Table 2**).



Cumulative incidence of all-cause mortality by time period and gout status in the nationwide US cohort. Solid red line=Gout, Early Cohort (1988-1994), Dashed red line=Non-Gout, Early Cohort (1988-1994), Solid blue line=Gout, Late Cohort (2007-2016), Dashed blue line=Non-Gout, Late Cohort (2007-2016). The premature mortality gap in gout (difference between the solid and dashed lines) did not improve between the Early and Late cohorts.

Adjusted HR for cardiovascular mortality in the late US cohort was 1.39 (1.09–1.78); those for circulatory, cardiovascular, and coronary heart disease deaths among Britons with incident gout were 1.48 (1.24–1.76), 1.49 (1.20–1.85) and 1.59 (1.26–1.99), respectively.

Conclusion: Premature mortality in gout (beyond SU and ASCVD risk factors) has not improved over time in the US at a national level, despite improved survival in the general population, and is worse among women and possibly among Black individuals, among whom gout is already more prevalent compared to White individuals [PMID 35969396].Mortality gap was replicated among incident gout patients in the UK. This unclosing premature mortality gap suggests shortcomings in current gout care, particularly among women and possibly among Black patients and a potential role for targeted anti-inflammatory therapies such as daily colchicine for dual purposes of gout and CVD prevention, as is promoted in CVD prevention in European and Canadian cardiology guidelines.

Table 1. Association between prevalent gout and all-cause mortality according to Early and Late nationwide US cohorts.

	All		Early Cohort (NHANES III: 1988-1994 baseline)		Late Cohort (NHANES 2007–2016 baseline)		P for interaction
	Gout	Non-gout	Gout	Non-gout	Gout	Non-gout	
No. of deaths	439	4127	192	2418	247	1709	-
Person-years	10,060	293,432	3590	142,552	6470	150,881	-
Model 1	1.37 (1.24 to 1.52)	1.00 (ref)	1.31 (1.13 to 1.52)	1.00 (ref)	1.43 (1.25 to 1.64)	1.00 (ref)	0.30
Model 2	1.29 (1.16 to 1.42)	1.00 (ref)	1.25 (1.08 to 1.46)	1.00 (ref)	1.30 (1.13 to 1.50)	1.00 (ref)	0.42
Model 3	1.20 (1.08 to 1.33)	1.00 (ref)	1.20 (1.03 to 1.40)	1.00 (ref)	1.19 (1.04 to 1.37)	1.00 (ref)	0.69
Model 3 + SU	1.19 (1.08 to 1.32)	1.00 (ref)	1.19 (1.02 to 1.38)	1.00 (ref)	1.19 (1.03 to 1.37)	1.00 (ref)	0.63

Model 1 was adjusted for age (time scale), sex (male or female), race/ethnicity (White, Black, Hispanic, or Other), and NHANES cycle (III, 2007-2008, 2009-2010, 2011-2012, 2013-2014, or 2015-2016).
Model 2 was further adjusted for body mass index, education (some high school or lower, high school, college, graduate school or higher, or missing), smoking (former, current, never, or missing), alcohol consumption (times/month), and total cholesterol, HDL, systolic BP, diastolic BP (continuous), diuretic use, statin use, aspirin use, prescription use for hypertension, and for women, post-menopausal status (yes, no, or missing).
Model 3 was further adjusted for coronary heart disease (yes or no), diabetes (yes or no), and estimated glomerular filtration rate (continuous).
SU = serum urate

Romosozumab versus Denosumab in High-risk Patients Treated with Glucocorticoids: Interim 12-month Results from a Pilot Randomized Controlled Trial

Chi Chiu Mok[1], SAU MEI TSE[2], Kar Li Kelly Chan[3] and Wai Han Ma[1], [1]Tuen Mun Hospital, Hong Kong, Hong Kong, [2]Tuen Mun Hospital, Hong Kong, China, [3]Tuen Mun Hospital, Shatin, China

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: Plenary III
Session Type: Plenary Session
Session Time: 11:00AM–12:30PM

Background/Purpose: To compare the efficacy and safety of romozosumab (ROMO) and denosumab (DEN) in high-risk patients treated with glucocorticoids (GCs).

Methods: Adult patients (≥18 years) who were receiving prednisolone ≥5mg/day for ≥12 months and had moderate/high risk of osteoporotic fracture (history of fracture, DEXA T score ≤-2.5 [age ≥40 years] or Z scores ≤-3.0 [age < 40 years] or high 10-year major fracture risk by FRAX) were included. Participants were randomized to receive either ROMO (210mg SC monthly) or DEN (60mg SC every 6 months) for 12 months, followed by DEN for 2 more 6-month doses in both arms. The primary efficacy end point was the change in bone mineral density (BMD) at the lumbar spine from baseline to month 12.Secondary end points included BMD change at the non-dominant hip and femoral neck at month 12, change in bone turnover markers, new vertebral fractures, change in BMD at the hip and spine at month 24 and adverse events (AEs).

Results: 70 patients were recruited and 63(90%) completed the study (age 62.6±9.1 years; 96% women; 35 each assigned to ROMO or DEN).The mean prednisolone dose at entry was 6.6±3.5mg/day. Osteoporosis at spine/hip/femoral neck and a history of fragility fracture was present in 34(48.6%) and 35(50%) patients, respectively. Oral bisphosphonates were being used in 33(47%) patients prior to first dose of the study drugs. While the baseline demographics and osteoporosis risk factors were not significantly different between the two groups, ROMO-treated patients had lower hip/femoral neck BMD and serum vitamin D3 levels than those treated with DEN. At month 12, a significant increase in spine BMD was observed in both the ROMO (+7.3±4.5%; p< 0.001) and DEN (+2.3±3.1%; p< 0.001) groups of patients. The inter-group difference in spine BMD at month 12 was statistically significant after adjustment for baseline BMD values, age, sex, osteoporosis risk factors and the cumulative prednisolone doses in 12 months (p < 0.001).The corresponding increase in hip BMD were +1.6% ±3.3% (p=0.01) in the ROMO group and +1.6%±2.6% (p=0.003) in the DEN group. No significant inter-group difference in hip BMD was observed after adjustment for the same factors. The increase in femoral neck BMD from baseline to 12m was not significant in both groups. In DEN-treated patients, both serum CTX (-34.7±54.8%; p=0.002) and P1NP (-35.1 ±43.3%; p< 0.001) dropped significantly from baseline to 12m.However, in the ROMO group, a non-significant drop in CTX (-18.1±76.9%; p=0.18) but increase in P1NP (+1.7±70.3%; p=0.89) was observed. Only one new vertebral fracture developed in the ROMO group at 12m.The commonest AE was self-limiting injection site pain/redness, which was significantly more common in ROMO-treated patients. Post-injection musculoskeletal pain was reported in 2 and 3 patients in the ROMO and DEN group of patients, respectively. Mild hypocalcemia and hypercalcemia were observed in 2 DEN-treated patients. No serious AEs were reported. Complete 24-month data are pending in September 2023.

Conclusion: Romosozumab was superior to denosumab in raising the spine BMD at month 12 in chronic GC users with high fracture risk. Romosozumab may offer a new treatment option for GIOP in high-risk patients.

Session Title: Plenary III

Session Type: Plenary Session

Session Time: 11:00AM–12:30PM

Background/Purpose: Three-quarters of RA patients use glucocorticoids (GC) to manage RA symptoms. Prior work suggests recent GC use is associated with major adverse cardiovascular events (MACE) in RA, but these studies did not adequately consider the effect of prior GC exposure on current risk.

Methods: In this retrospective cohort study, we used national VA administrative data to identify RA patients with an initial VA rheumatology visit in 2010-2018 (index date) and a one-year lookback period prior to this. Exclusions included age < 40 or >90, non-RA rheumatologic disorder, prior MACE, or CHF. We used a Cox proportional hazards model to estimate the

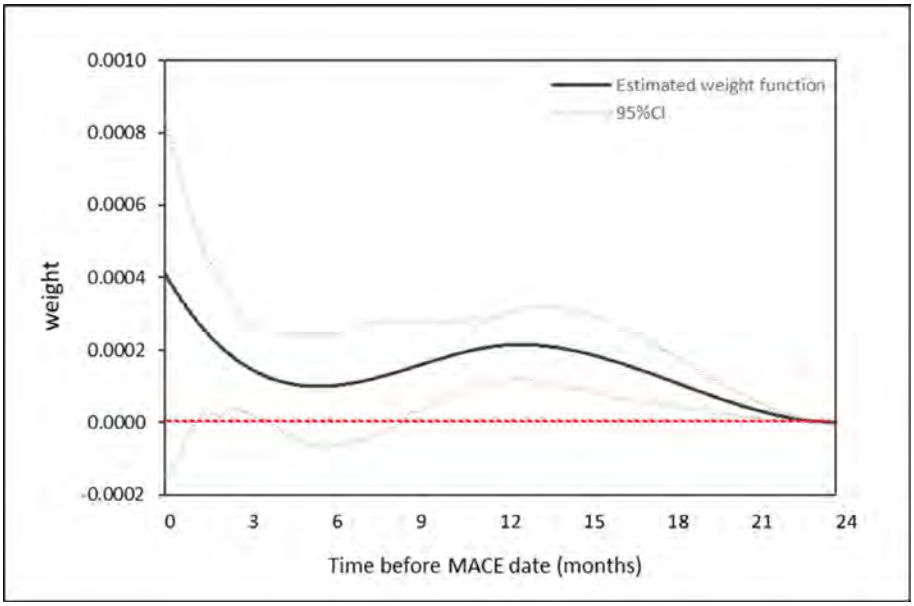

Table 1: Baseline characteristics by 5-year risk of major adverse cardiovascular events (MACE). Values are median and interquartile range (IQR) unless specified otherwise.

	Overall cohort (N= 18,882)	Low VARS (N= 4,675)	Medium VARS (N= 10,453)	High VARS (N= 3,754)

[3]Estimated using VARS-CV score

effect of time-varying cumulative weighted oral GC use (primary exposure) on risk of MACE defined as MI, stroke/TIA, cardiac arrest, coronary revascularization, or death from CV cause (primary outcome). We estimated the primary exposure using a weighted cumulative dose (WCD) model representing GC exposure as a weighted sum of past doses (Sylvestre et al, 2009). Weights estimated using cubic regression splines reflect the relative impact of GC exposure at different times. Since the time period over which prior GC exposure affects MACE risk is not well defined, we fit potential WCD models evaluating exposure over the 30 days, 90 days, 180 days, 1 year, 2 years, and 3 years prior to MACE. The best-fitting model, using a 2-year exposure window prior to MACE, was selected (**Fig 1**).

Results: Among 18,882 patients (mean age 62.5 years, 84% male), median 5-year MACE risk at baseline was 5.3%; 3,754 patients (19.9%) had high baseline MACE risk (**Table 1**). Incident MACE occurred in 4.1% of patients, with median time to MACE of 2.67 (IQR 1.26-4.45) years. **Table 2** shows adjusted hazard ratios (aHRs) for several temporal patterns of GC exposure compared to no use for the 2 years prior to MACE. Using 5mg, 7.5mg, and 10mg/day prednisone equivalent for 90 days prior to MACE is associated with a 13%, 19%, and 27% increase in MACE, respectively (aHR [95% CI] 1.13 [1.01-1.24], 1.19 [1.02-1.38], 1.27 [1.02-1.54]). aHRs and 95% CI for use of 5mg/day for 15 and 30 days prior to MACE were 1.03 (0.99-1.06) and 1.05 (0.99-1.11) respectively. Use of 5mg, 7.5mg, and 10mg for 30 days, with last use 1 year pre-MACE, were associated with 3%, 5%, and 7% increases in MACE (aHR [95% CI] 1.03 [1.02-1.05], 1.05 [1.03-1.07], 1.07 [1.04-1.10]. Similar use for 90 days was associated with 10%, 15%, and 21% increases, respectively (aHR [95% CI] 1.10 [1.05-1.15], 1.15 [1.08-1.23], 1.21 [1.11-1.32]).

Conclusion: In this national RA cohort, we observed a dose-, duration-, and recency-dependent relationship between previous GC use and MACE. GC doses as small as 5mg/day, durations as short as 30 days, and use as long as one year prior to MACE were all associated with an increased risk of MACE. Future work will examine the effect of time-varying covariate adjustment, and potential effect modification of prior GC exposure on risk associated with current use.

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: Abstracts: RA – Etiology & Pathogenesis
Session Type: Abstract Session
Session Time: 2:00PM–3:30PM

Background/Purpose: Identifying molecular signatures associated with anti-citrullinated protein antibody (ACPA) positive individuals who are 'at-risk' for future RA (At-Risk) and early RA (ERA) requires comprehensive datasets to integrate multi-omics platforms to define personalized mechanisms. In this study, we measured single cell epigenomic and transcriptomic profiles from peripheral blood mononuclear cells (PBMCs) of At-Risk individuals, ERA patients and controls (CON). We performed a cross-sectional analysis using a novel bioinformatic tool to integrate the large-scale multi-omics single cell data.

Methods: Three cohorts were studied including 26 At-Risk with elevated ACPA, 6 ERA, and 35 controls (CON). scRNA-seq and scATAC-seq data were paired for each participant (pt). Seurat and ArchR packages identified co-embedded clusters between scRNA and scATAC cells for each sample, which were annotated to identify cell types. Each cluster was processed through the Taiji pipeline (Nat Commun 2022;13:6221) to create regulatory networks and PageRanks for transcription factors (TFs). Groups were identified using K-means clustering with Pearson correlation as the distance metric. Chi-square test was applied and K-means group-specific TFs were identified by Wilcoxon test.

Results: 1613 clusters from 67 samples spanning 21 cell types were identified and grouped into 5 K-means groups displaying distinct TF regulatory patterns. 4 groups were enriched for individual cell lineages, such as CD4 and CD8 T cells, B cells and monocytes. Group 2 (G2) was multilineage and was significantly enriched in the At-Risk and ERA (8.2 clusters/pt)

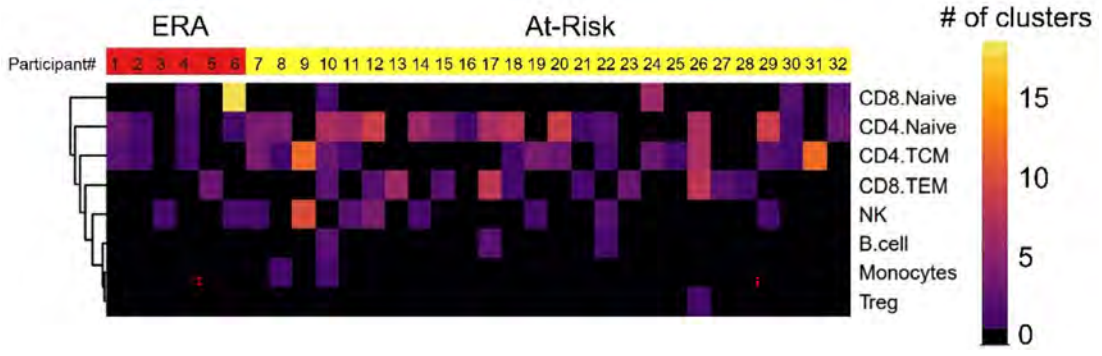

Figure 1. Heatmap across cell lineages of G2 clusters for participants in At-Risk and ERA . The color represents number of clusters for each participant in specific cell type. The horizontal axis shows the individual participants and the vertical axis shows the number clusters for each lineage. Some controls also displayed these clusters although the number was significantly less than At-Risk/ERA, particularly for certain T cell subsets.

compared to CON (5.5 clusters/pt) ($p< 0.001$). 344 TFs were G2-specific, such as embryonic development TFs SP7, FOXL2, and TFAP2C ($p< 0.001$ each). Reactome pathway analysis in G2 showed enrichment in RUNX2, SUMOylation, and YAP1 pathways, each of which have been previously implicated in RA. Remarkably, the G2 signatures were shared by multiple lineages in individual At-Risk and ERA participants. CD4 T naïve, CD4 TCM, and CD8 T naïve cells had greatest enrichment (47% vs 24% of total clusters in G2, $p< 0.0001$; 38% vs 22%, $p< 0.01$; 55% vs 27%, $p< 0.05$, respectively for At-Risk/ERA vs CON). In many cases, more than one cell lineage displayed the signature in an individual participant. Of interest, MAIT cells with the TF signature were only found in CON (49% vs. 0% in At-Risk/ERA, $p=0.01$). Figure 1 shows a heatmap illustrating the cell lineages with the At-Risk/ERA signature.

Conclusion: Distinctive TF profiles are enriched in PBMCs from ACPA+ At-Risk and ERA compared to controls, especially in CD8 and CD4 T cells. These TFs involve pathogenic pathways that have been identified in RA. Furthermore, PageRanks and pathways were similar between At-Risk and ERA suggesting that these mechanisms antedate classifiable disease. Moreover, the cell lineages with these TFs and pathways varied between individual participants, suggesting common mechanisms can occur across multiple cell types. These findings could explain the diversity of clinical responses in RA to targeted therapies because each patient can have an unique combination of pathogenic cell types displaying the RA TF signature.

SESSION INFORMATION

Session Date: Tuesday, November 14, 2023

Session Title: Abstracts: RA – Etiology & Pathogenesis

Session Type: Abstract Session

Session Time: 2:00PM–3:30PM

Background/Purpose: Synovial fibroblasts are a promising therapeutic target in rheumatoid arthritis (RA) where they can adopt inflammatory or destructive phenotypes and directly promote bone and cartilage degradation. In our prior analyses, we found that non-canonical Wnt activation induces robust inflammatory gene expression in these cells. Moreover, two Wnt modulators, RSPO3 and DKK3, are reciprocally expressed and form a transcriptional gradient associated with increased and decreased Wnt activation, respectively. Strikingly, RSPO3 and Wnt activation signatures are enhanced in

synovial fibroblasts in RA, suggesting the potential relevance of the Wnt pathway *in vivo*. Here, we explore the clinical impact of Wnt signaling in mouse models of inflammatory arthritis where we demonstrate that Wnt activation worsens the severity and prolongs the course of arthritis.

Methods: Single-cell RNA sequencing (scRNA-seq) libraries were generated from enzymatically digested, sort-purified CD45- synovial tissue dissected from K/BxN serum recipient mice at the indicated time points. To generate Wnt activation signatures, human RA synovial fibroblasts were stimulated *in vitro* with a combination of Wnt ligands, doses, and time points, and we performed RNA-seq and differential gene expression analysis. RSPO3 signatures were developed from scRNA-seq data of synovial fibroblasts from the Roche Fibroblast Network Consortium. In the antigen-induced arthritis (AIA) model, C57Bl/6 mice underwent subcutaneous (day -21) and knee intra-articular (day 0) injections of methylated BSA (mBSA) followed by knee intra-articular injections of PBS or Wnt5a (days 2 and 4). Knee diameters were measured using calipers, and synovial samples were collected at day 7 for scRNA-seq.

Results: Synovial tissues were processed at baseline, peak inflammation, resolving and resolved time points in K/BxN serum transfer recipient mice (Figure 1A). scRNA-seq analyses reveal reciprocal expression of RSPO3 and DKK3, similar to the pattern in human RA synovium (Figure 1B and 1C). Likewise, Wnt activation scores are enriched in cells that show high expression of the Wnt agonist RSPO3 (Figure 1D). Strikingly, RSPO3 and Wnt activation signatures are increased in synovial fibroblasts isolated at the peak of arthritis compared to those from control and resolution time points (Figure 1E). To determine how the activation of Wnt signaling would impact clinical arthritis, we used the AIA model where non-canonical Wnt5a ligand could be directly injected into the knee (Figure 2A). Strikingly, we found that Wnt activation induces a profound increase in the severity and duration of arthritis (Figure 2B) associated with increased expression of cytokines, chemokines, and other inflammatory mediators in synovial fibroblasts (Figure 2C).

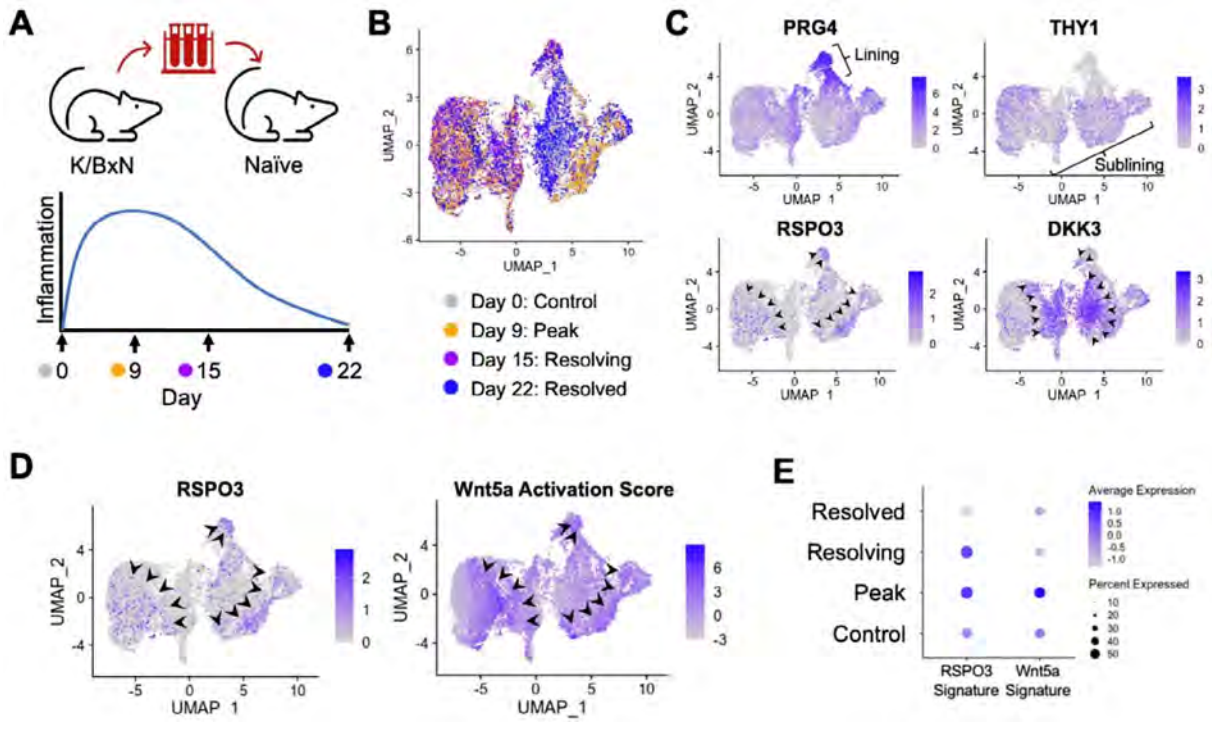

Figure 1: Stromal Wnt activation observed in rheumatoid arthritis is recapitulated in a murine model of inflammatory arthritis. A) Schematic depicting the methodology and time course of inflammation in the K/BxN serum transfer mouse model of inflammatory arthritis. (B) UMAP showing synovial fibroblasts from scRNA-seq analysis of joint tissues harvested at the indicated time points from C57BL/6 mice undergoing serum transfer arthritis. N=3 mice per time point. (C) UMAP of synovial fibroblasts depicting expression of the indicated genes. Arrowheads highlight regions of high expression of RSPO3 or DKK3. (D) UMAP showing the expression of RSPO3 alongside the non-canonical Wnt5a activation score, with arrowheads highlighting regions of high expression. (E) Dot plot exhibiting the level of expression of the RSPO3 and Wnt5a activation signatures at the indicated time points.

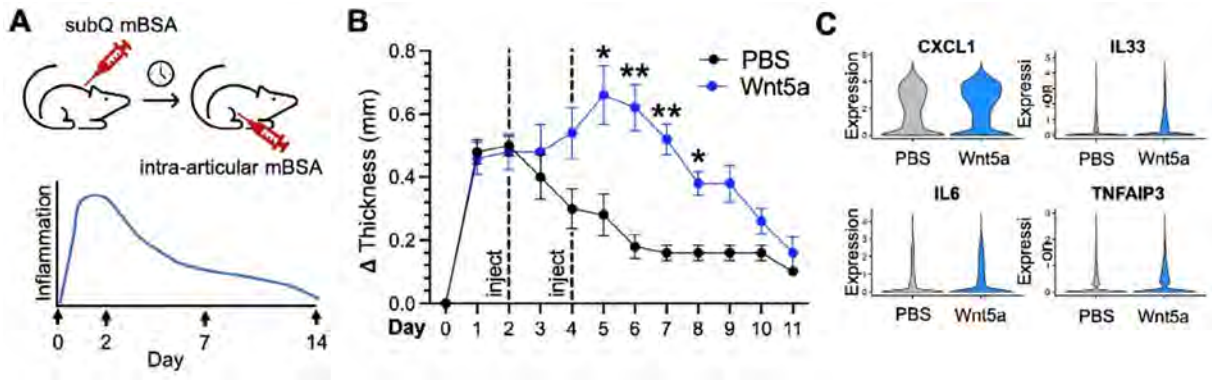

Figure 2: Wnt pathway activation increases the severity and duration of arthritis in a murine model of inflammatory arthritis. A) Schematic illustrating the methodology and time course of the antigen-induced arthritis (AIA) mouse model. Here, mice undergo subcutaneous (subQ) mBSA injection (day -21) followed by intra-articular mBSA injection in the knee (day 0). (B) Change in knee thickness over time in mice undergoing AIA with either Wnt5a (blue) or PBS control (black) knee intra-articular injection at days 2 and 4. N=11 mice each in PBS control and Wnt5a injection groups. (C) Violin plots depicting expression of the indicated genes derived from scRNA-seq of synovial tissue harvested at day 7 from AIA mice treated with PBS or Wnt5a. N=3 mice each in PBS control and Wnt5a injection groups.

Conclusion: Here, we demonstrate that stromal activation of Wnt signaling identified in human RA is recapitulated in mouse models of inflammatory arthritis and that non-canonical Wnt activation is associated with worsening severity of clinical arthritis. This work provides evidence supporting a new molecular target for treatments directed at synovial fibroblasts in RA.

Longitudinal Multi-Omics Single Cell Analysis Reveals Abatacept Treatment Shifts Peripheral Lymphocyte Subpopulations in Seropositive RA with Reduction of Mature B Cells and Retention of Transitional and Naive B Cells

Gregg Silverman[1], William Rigby[2], Helena Jun[1], Jasmine Shwetar[1], Katie Tumang[1], Sergei Koralov[3], Ellie Ivanova[1], David Mieles[1], Sladjana Skopelia-Gardner[4] and Kelly Ruggles[1], [1]NYU Grossman School of Medicine, New York, NY, [2]Hitchcock-Dartmouth Medicine Center, Hanover, NH, [3]NYU Grossman Schoolof Medicine, New York, NY, [4]Hitchcock-Dartmouth Medicine Center, Lebanon, NH

SESSION INFORMATION

Session Date: Tuesday, November 14, 2023

Session Title: Abstracts: RA – Etiology & Pathogenesis

Session Type: Abstract Session

Session Time: 2:00PM–3:30PM

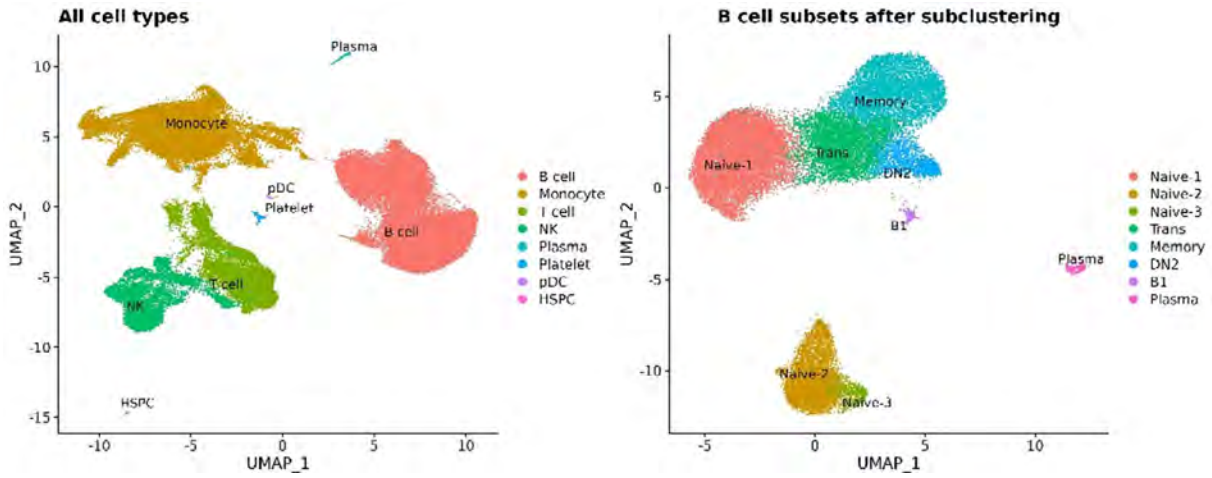

Figure 1. Cell type clustering based on UMAP analysis for 7 RA patients. Data pooled from samples obtained at baseline (0month), and 3 months and 6 months after abatacept initiation, with discontinuation after month 5 infusion, and follow-up at 9 months.

Background/Purpose: Biologic agents of diverse molecular mechanisms of action are approved for RA, but we do not have a full understanding of the implications of treatment and we do not know who will best respond to an agent. Abatacept (CTLA4-Ig) was designed to block a co-stimulation pathway involved in T-cell activation, yet other effects have been suspected. We therefore designed the open-label study, RA and memory B cells (RAMBA trial), to investigate the cellular and transcriptomic consequences of abatacept treatment.

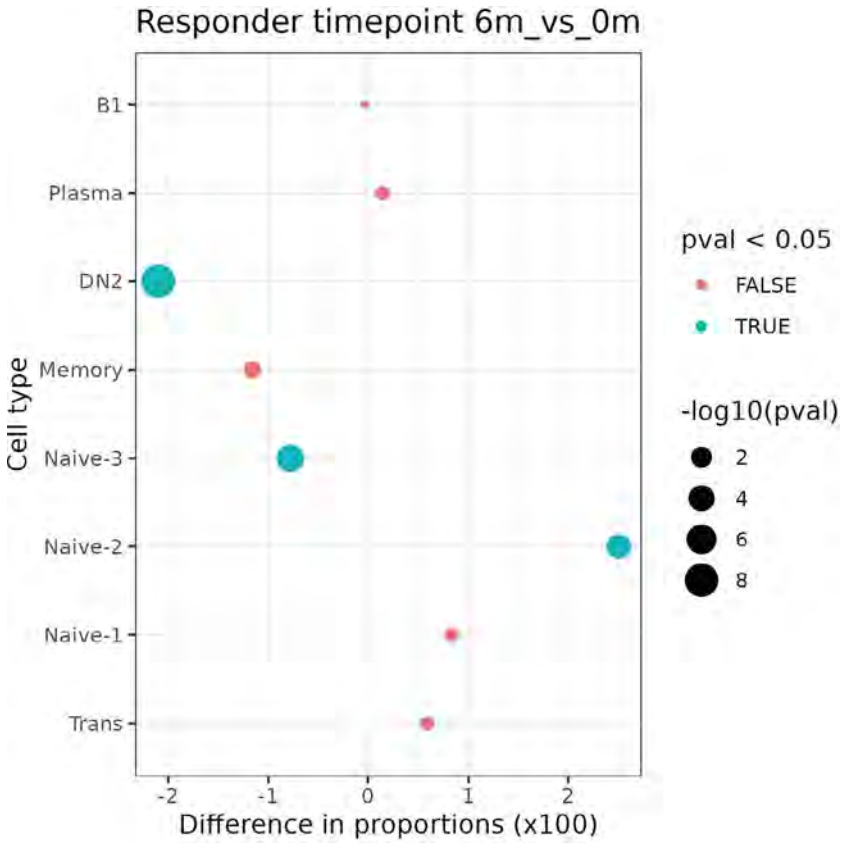

Figure 2. Distribution of B-cell subsets in clinical responders over time. Results are for Chi-squared test on the counts of responder B cell subsets between baseline and 6 month time points.

Methods: Biologic-naïve patients with seropositive RA were enrolled, and received the standard IV regimen of abatacept that was then discontinued after the month 5 infusion. Clinical evaluation and biospecimen collection were performed at baseline, 3, 6, and 9 months or when a flare occurred. In addition to routine clinical lab testing, autoantibody responses were evaluated in a multiplex assay with IgM-RF, and IgM- and IgG- to 4 ACPA fine specificities including CCP3. PBMCs or samples of negatively selected B-lineage cells were interrogated at a single cell level for high-dimensional surface phenotype and transcriptomic profiles, by Expanded Cellular Indexing of Transcriptomes and Epitopes (ExCITE) sequencing.

Results: 21 enrolled patients had two or more follow-up visits, with 18 completing to 9 months or post-treatment flare.12 patients achieved low disease activity by DAS28-CRP (< 3.2) or CDAI (< 10). Clinical responses were mirrored by reductions in serum RF and/or ACPA levels (not shown). Initial single cell analyses of 7 patients, of 70,790 PBMCs and 33,160 B-lineage cells Abatacept treatments induced increases in naïve CD4+ T cells over time (not shown). CD19+ B-lineage cells were resolved into 8 subsets (Fig.1). Treatment was associated with significant reductions of Naïve-3, and CD19+ sIgD- CD27- (DN2) B cells linked to autoimmune B-cell responses. In contrast, treatment was also associated with significant increases in the accumulation of Naïve-2 B cells, and a trend towards increases in the peripheral accumulation of transitional and Naïve-1 B cells (Fig.2).

Conclusion: Complete clinical response to abatacept in RA was associated with cellular shifts in peripheral B-cell subsets identified based on surface phenotype and transcriptomic profiles, with a return to a state dominated by newly emergent transitional and early naïve B cells. These findings elucidate previously unsuspected aspects of MOA of abatacept, that we postulate reflects a reversion in balance towards the preimmune natural state of clonal ignorance unaffected by autoimmune disease.

Supported in part by funds from BMS.

Acetylated Bacterial Proteins as Potent Antigens Inducing an Anti-modified Protein Antibody Response

Mikhail Volkov, Arieke Kampstra, Karin van Schie, Joanneke Kwekkeboom, Arnoud de Ru, Peter van Veelen, Thomas Huizinga, René Toes and Diane van der Woude, Leiden University Medical Center, Leiden, Netherlands

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: Abstracts: RA – Etiology & Pathogenesis
Session Type: Abstract Session
Session Time: 2:00PM–3:30PM

Background/Purpose: Gut-residing bacteria, such as *E.coli*, can acetylate their proteome under conditions of amine starvation. It is postulated that the (gut) microbiome is involved in the breach of immune tolerance to modified self-proteins leading to the anti-modified protein antibodies (AMPA), hallmarking seropositive RA. Our aim was to determine whether acetylated bacterial proteins can induce AMPA-responses cross-reactive to modified self-proteins and be recognized by human AMPA (hAMPA).

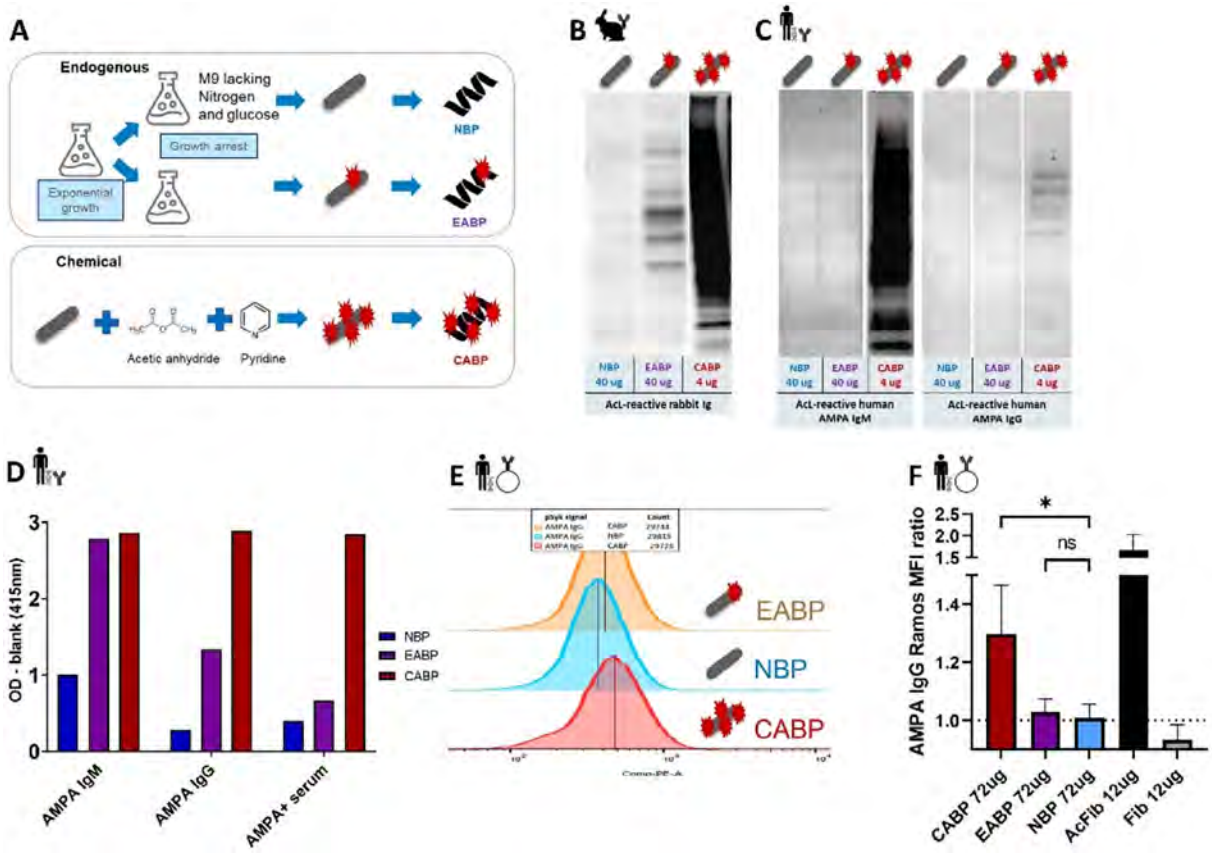

Figure 1. Recognition of acetylated bacterial antigens by hAMPA (A) Schematic overview of the generation of NBP, EABP and CABP. (B) Western blotting with NBP, EABP and CABP stained with anti-acetyllysine polyclonal rabbit antibody. (C) Western blotting with NBP, EABP and CABP stained with hAMPA mAbs, recognizing acetylated proteins: 7E4 IgG and 1E3 IgM. (D) ELISA with 1E3 IgM, 7E4 IgG and polyclonal IgG from an RA patient serum isolated with CAcP4 peptide. (E) pSyk MFI, visualizing BCR activation of Ramos B cells expressing 7E4 IgG after incubation with acetylated E. coli antigens. (F) Summary of three BCR activation experiments with 7E4 Ramos B cells. Statistical differences are indicated with asterisks, indicating p-value: * < 0.05, ** < 0.01, **** < 0.0001.

Methods: *E. coli*-bacteria were grown under amine starvation to generate endogenously acetylated bacterial proteins. Furthermore, *E. coli* proteins were acetylated chemically (Figure 1A). Recognition of these proteins by hAMPA was analysed by western blotting and ELISA; recognition by B cells carrying a modified protein-reactive B cell receptor (BCR) was analysed with a pSyk activation assay. C57BL/6 mice were immunized with (modified) bacterial protein fractions, and sera were analysed by ELISA (Figure 2A).

Results: Chemically modified bacterial protein fractions contained high levels of acetylated proteins (Figure 1B) and were readily recognized by hAMPA (Figure 1C) and able to activate B cells carrying modified protein-reactive BCRs (Figure 1E-F). Likewise, although expressing lower levels of acetylation, also endogenously acetylated protein fractions were recognized by hAMPA in ELISA (Figure 1D). Immunizing mice with chemically modifed protein fractions induced a strong cross-reactive AMPA response, targeting various modified antigens including citrullinated proteins (Figure 2B-C). Interestingly, highly acetylated bacterial proteins could induce an AMPA response even without an adjuvant (Figure 2D).

Conclusion: Acetylated bacterial proteins are recognizable by hAMPA and capable of inducing a cross-reactive AMPA response in mice. These observations provide first evidence for a novel mechanism, involving the (endogenous) acetylation of the bacterial proteome, allowing a breach of tolerance to modified proteins and the formation of cross-reactive AMPA.

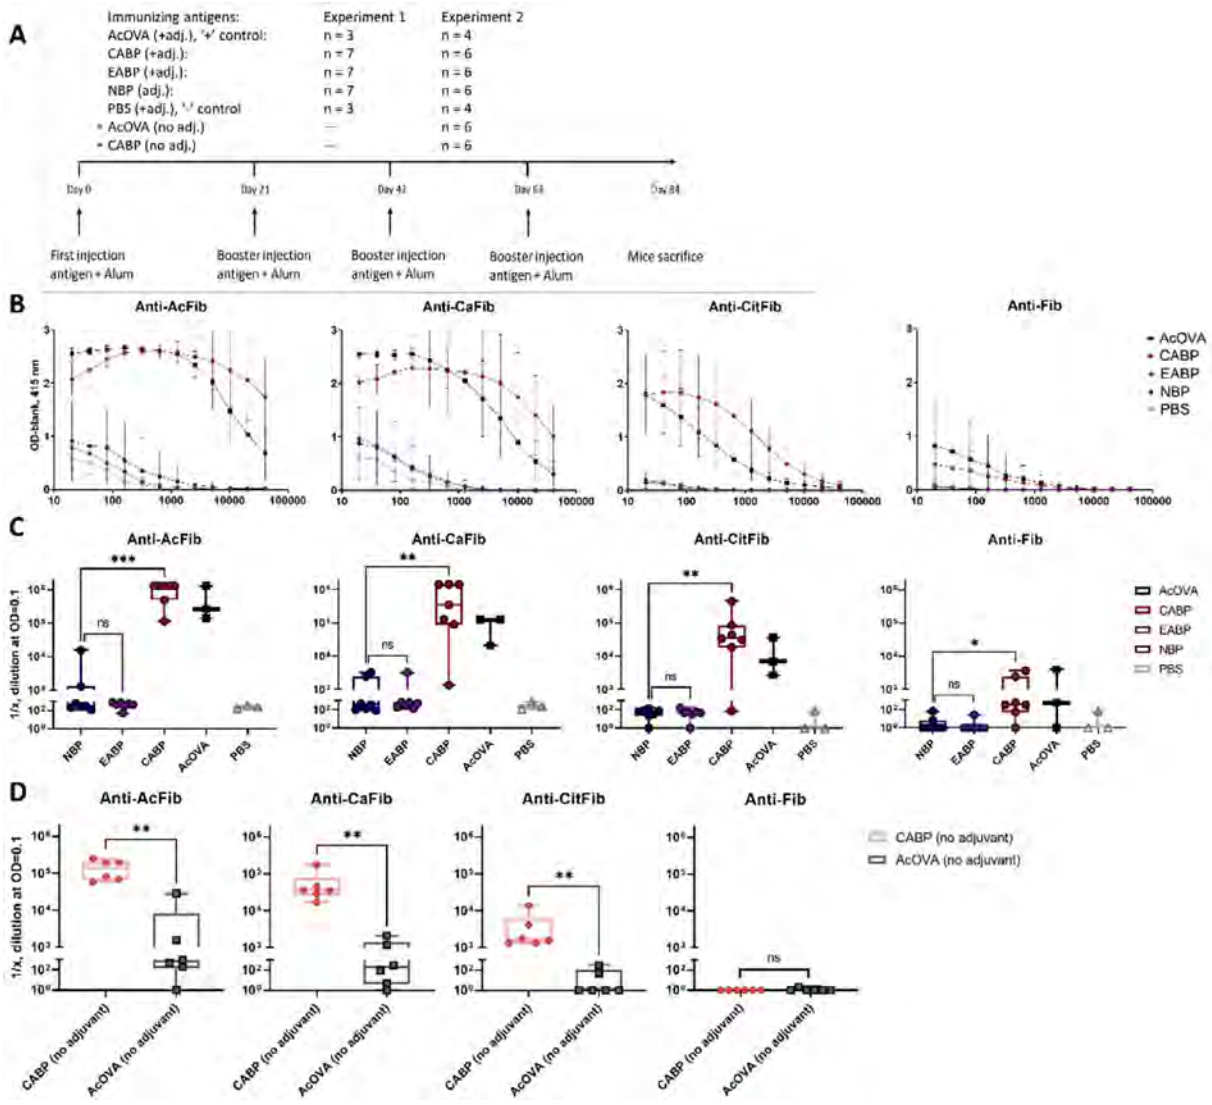

Figure 2. Immunization of mice with bacterial acetylation proteins (A) Immunization scheme of the performed mouse experiments. (B) Reactivity of titrated mouse serum to modified and unmodified versions of fibrinogen, per immunizing antigen. (C) Mice immunized with the antigens with the adjuvant: titers at OD = 0.1, as determined by ELISA to modified and native versions of fibrinogen. (D) Mice immunized with CABP or AcOVA without the adjuvant: reactivity of individual mouse serum samples to modified and unmodified versions of fibrinogen. Statistical differences are indicated with asterisks, indicating p-value: * < 0.05, ** < 0.01, **** < 0.0001. A-C: data are representative of two experiments. AcOVA: acetylated ovalbumin, CABP: chemically acetylated bacterial proteins; EABP: endogenously acetylated bacterial proteins; NBP: non-acetylated bacterial proteins; PBS: phosphate buffer saline.

SESSION INFORMATION

Session Date: Tuesday, November 14, 2023

Session Title: Abstracts: RA – Etiology & Pathogenesis

Session Type: Abstract Session

Session Time: 2:00PM–3:30PM

Background/Purpose: Single cell transcriptional profiling (scRNA-Seq) is valuable in identifying gene signatures and cell subpopulations associated with rheumatoid arthritis (RA). However prior studies have often overlooked important demographic confounders and not focused on non-remission and difficult to treat RA. The aim of this study is to identify peripheral blood mononuclear cells (PBMCs) of RA and disease-activity cell subsets and gene signatures in a diverse population of patients.

Figure 1 | A. Graphical Abstract. B. Figure 2 | A. Single cell UMAP projection of patients with rheumatoid arthritis and matched controls. B Differentially expressed genes between patients with RA and matched controls. C. Upsets pot of upregulated and downregulated genes. CD, Cluster differentiation; DCs, Dendritics cells; IFIT, Interferon Induced proteins with Tetratricopeptide repeats; IFITM, interferon-induced transmembrane; Tem: T effector memory, TEMRA: Terminally differentiated effector memory. RA Rheumatoid Arthritis

Methods: 10X Chromium single cell sequencing was performed on peripheral blood mononuclear cells (PBMC) from 18 early RA patients and 18 healthy controls matched on age, sex, race and ethnicity. Data were processed using standard CellRanger and Scanpy pipelines, with HarmonyPy for batch correction. Differential expression (DE) was computed using pseudobulk analysis and DESeq2. Pathway analysis was carried out with over-representation analysis (ORA). Mann-Whitney tests were used to assess differences in cell proportions between matched RA and control samples, as well as between RA patients with low disease activity or remission (DAS28-CRP< 3.2; n=9) versus moderate or high disease activity (DAS28 CRP≥3.2;n=7). Ligand-receptor interaction analysis was performed using Cellchatdb.

Results: The final dataset consisted of 22,159 genes across 125,698 cells. We identified 18 PBMC subsets, including 5 CD4+ T cell subsets, 3 CD8+ T cell subsets, 2 Natural Killer cell subsets, 3 B cell subsets, and 5 monocyte subsets (Figure 1). Within these subsets, IFIT CD4 T+ cells and IFITM3 monocytes were associated with Interferon-gamma response. 168 genes were DE between RA and matched controls (FDR≤0.05, foldchange >1.6). We identified up-regulation of pro-inflammatory genes associated with monocyte subsets and downregulation of inflammatory genes in gamma-delta T cells. Several genes associated with RA predisposition such as HLA-DRB5 and HLA-DQB1 were specifically downregulated in IFITM3 monocytes (Figure 2). Functional analysis and ORA highlighted significant enrichment of B cell activation and B cell receptor signaling pathways. Differences in cell subset proportions between patients with high and moderate activity, patients in low disease activity and remission, and healthy controls (n=18, Figure 3) were also observed. Non classical

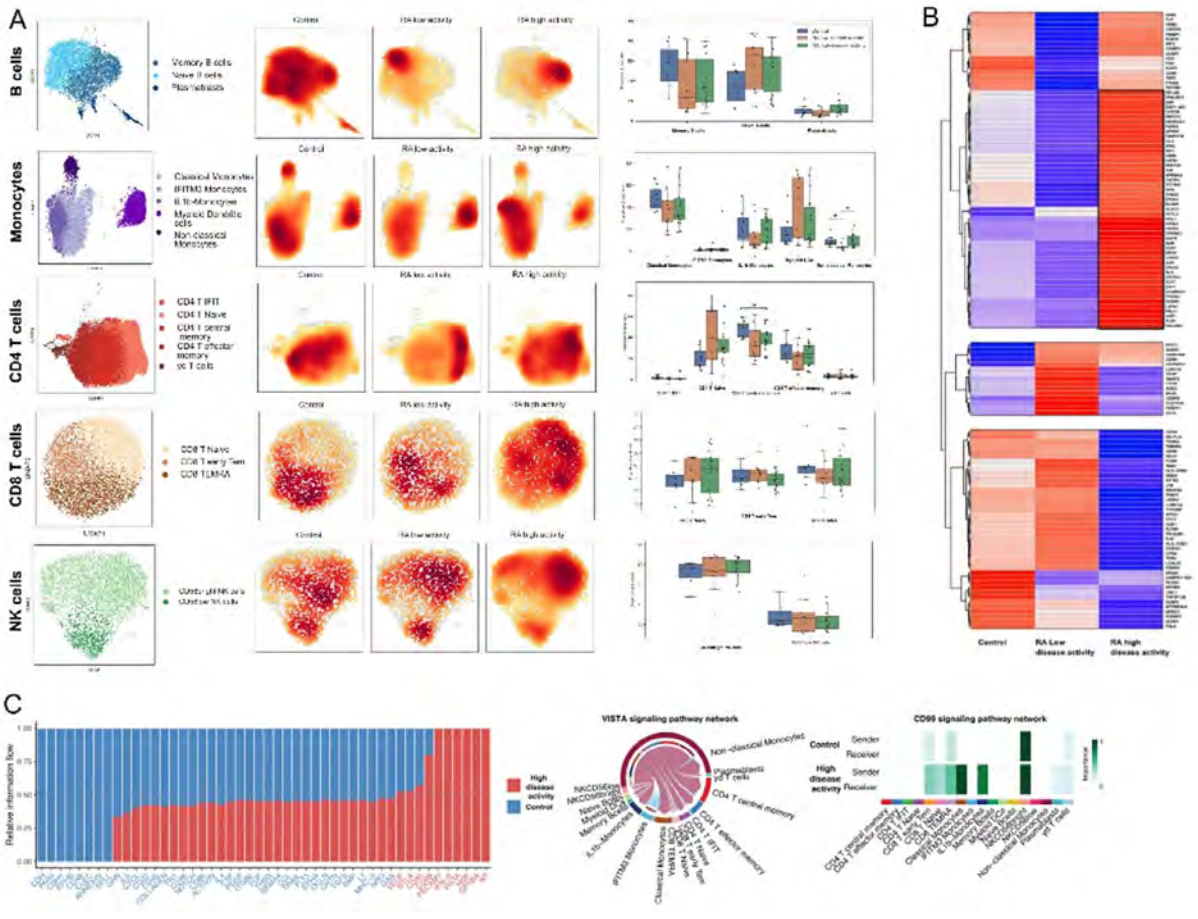

Figure 3 | A. Compositional, density and cell proportion analysis between control patients with low disease and high activity (Mann-Whitney - Wilcoxon p≤ 0.05). B. Genes expression heatmap between controls and RA with low and high disease activity and average expression across cell subtypes C. Communication pathway significantly up and downregulated in high disease activity and controls, overview of cell communication within the VISA and the CD99 pathway. CD, Cluster differentiation; DCs, Dendritics cells; IFIT, Interferon Induced proteins with Tetratricopeptide repeats; IFITM, interferon-induced transmembrane; Tem: T effector memory, TEMRA: Terminally differentiated effector memory. RA Rheumatoid Arthritis

monocytes and T central memory were decreased in patients with high disease activity compared to control and high disease activity (p=0.022; p=0.034). We also identified a specific signature of 49 genes, including IFNG, TNF, KLRD, EGR1, CBX6, CXCR4, JUN, and TLE3, that was significantly associated with disease activity. Finally, cell communication analysis between patients with high disease activity and controls revealed upregulation of IFN-II, VEGF, VISTA, BTLA, and CD40 pathway signaling.

Conclusion: Here we describe a dataset of scRNA-Seq PBMCs from a diverse population of patients with RA and matched healthy controls. We identify differentially expressed genes and cell subsets linked to disease activity, providing insights into RA pathophysiology and potentially new therapeutic targets.

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: Abstracts: RA – Etiology & Pathogenesis
Session Type: Abstract Session
Session Time: 2:00PM–3:30PM

Background/Purpose: Rheumatoid arthritis (RA) is an autoimmune disease characterized by immune infiltration of the synovial tissue lining joints. RA is clinically heterogenous, with patients having varied responses to therapies, likely reflecting distinct pathogenic mechanisms. To begin to define the heterogeneity in RA, a recent study showed that the fractional abundances of 5 cell types can help predict treatment response in some subsets of RA (1). With the goal of better understanding the spatial organization of cells in RA synovial tissues and mapping cell-cell interactions, we sought to take a key next step in defining RA heterogeneity and its relation to treatment response

Methods:

Spatial transcriptomic profiling

We used CosMx Spatial Molecular Imager to measure the RNA expression levels of 960 genes in 10 paraffin-embedded inflamed synovial tissue samples.

Cell segmentation and annotation

We developed a segmentation pipeline to map transcripts to cells, and then classified each cell into one of 10 major cell types. We used the single-cell RNA seq synovial atlas to map these cells further into fine-grained cell-states.

Niche detection and characterization

We performed spatial tissue segmentation to identify contiguous and transcriptionally homogeneous sections of the tissue called "niches". We split tissues into tiles and performed spatial clustering of the tiles to detect niches.

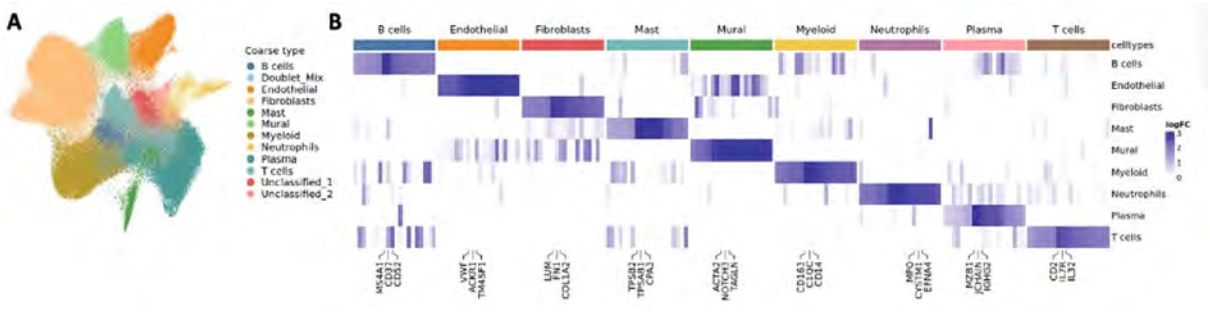
Results:

1. Identification of major and fine-grain cell types *in situ*. We segmented and labeled 333,966 high quality cells across 10 RA synovial tissue samples. We identified 10 major cell lineages (Figure 1A-B), including 2 absent in single-cell RNA-seq studies: mast cells and neutrophils. We subclassified cells into 54 subtypes and activation states based on prior definitions from the AMP single-cell RNA-seq atlas of inflamed synovium (1). We detected 2 cell states of mast cells (resting and activated) and 3 cell states of neutrophils (resting, activated, and proliferating) based on key gene expression markers.

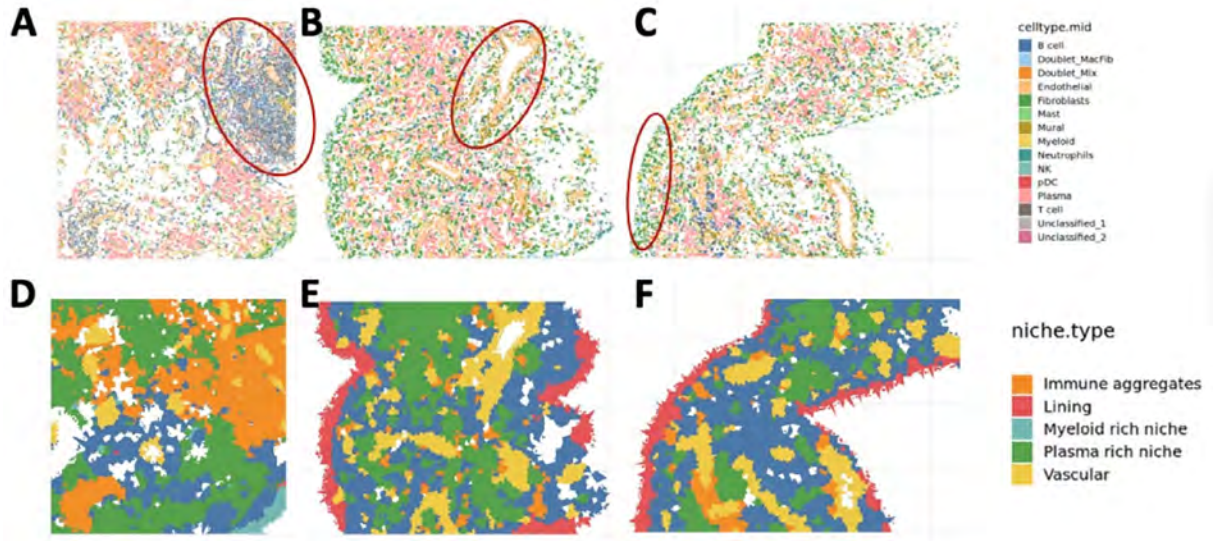
2. Quantification of anatomic niches. We mapped annotated cells into tissue space, where they organized into anatomic structures: vasculature (endothelial and mural cells), lining (lining fibroblasts and MERTK+ macrophages), and immune aggregates (T, B, and plasma cells) (Figure 2A-C). We quantified the boundaries of these niches and identified all niches in most samples. We next quantified the relative composition of niches within and across donors and observed significant heterogeneity of niches within samples (Figure 2D-F).

3. Validation with independent cohort. We validated our spatial organization results in an independent inflamed synovial tissue cohort from 3 patients with treatment naïve RA. Using our pipeline, we found similar proportions of cell types and organization of cells into the canonical niches defined in our spatial atlas (Figure 3A, B).

Conclusion: We established a draft spatial atlas of RA synovium and provided spatial context for 54 cell types, subtypes, and activation states observed in dissociated tissue assays. This atlas will serve as a reference to map the cellular organization in different cohorts as demonstrated and eventually enable us to compare the effects of different therapeutics on the RA tissue.



Identification of major cell types in situ (A) Cells projected in UMAP space, colored by their major cell type. (B) Heatmap of gene log fold-changes for each of the major cell types. Top 3 marker genes for each cluster are annotated on the x-axis.



Identification of anatomical niches (A-C) Cells in tissue space in active RA synovium. Each panel shows an FOV from a tissue sample. Session Title: Abstracts: Spondyloarthritis Including Psoriatic Arthritis – Basic Science

Session Type: Abstract Session

Session Time: 2:00PM–3:30PM

Background/Purpose: In spondylarthropathy (SpA), such as psoriatic arthritis (PsA) and ankylosing spondylitis (AS), arthritis is often associated with gut inflammation. After systemic β-1,3-glucan (curdlan) injection, ZAP70^{W163C} SKG mice develop IL23-dependent SpA-like spondylarthritis, ileitis and faecal dysbiosis with enrichment in Gram-negative pathobionts over commensals, recapitulating human SpA disease spectrum. Spondylitis in AS patients does not respond to anti-IL-23. To assess the interaction of intestinal dysbiosis and spondyloarthritis, we treated diseased SKG mice with anti-IL-23p19.

Methods: Specific-pathogen-free SKG or BALB/c control mice were injected i.p. with curdlan followed by anti-IL-23p19 antibody or isotype three weeks later. At eight weeks, ileum, ankle and sacroiliac joints were collected, paraffin-embedded for histology and scored for arthritis and ileitis. Tissue sections were analysed by fluorescence imaging using universal bacterial DNA EUB338 and non-sense EUB338 control probes, combined with anti-MPO or anti-IBA-1 antibodies for neutrophils and macrophages.

Results: At 8 weeks post-curdlan, isotype-treated SPF SKG mice developed ileitis, enthesitis, axial and peripheral arthritis while anti-IL-23p19-treated SKG mice had much less severe disease, and BALB/c mice remained healthy. In inflamed ileum of isotype-treated SKG mice, EUB338+ bacteria translocated from the lumen to the gut lamina propria, where they colocalised with infiltrating MPO+ neutrophils and IBA-1+ resident macrophages. In arthritic axial and ankle joints, EUB338+ bacterial DNA was detected in the blood vessels, tendon entheses, ligaments and the bone marrow, associated with bone and cartilage destruction. MPO+ neutrophils and IBA-1+ resident macrophages infiltrated the areas of inflammation. In anti-IL-23p19-treated SKG mice, bacterial signals were detected in entheses but not the bone marrow. No bacterial signal was detected in BALB/c tissues.

Conclusion: In SKG mice, curdlan triggers IL-23-dependent gut permeability and ileitis that allows mucosal invasion of bacteria, and dissemination of intestinal bacterial DNA to axial and peripheral joints' bone marrow and entheses through the vasculature, similar to reactive arthritis. While anti-IL-23 blocks bone marrow entry of bacterial DNA, it fails to limit the entheseal spread after disease onset. This suggests a potential mechanism by which inflammation is perpetuated in ankylosing spondylitis.

Session Title: Abstracts: Spondyloarthritis Including Psoriatic Arthritis – Basic Science

Session Type: Abstract Session

Session Time: 2:00PM–3:30PM

Background/Purpose: Synovial fibroblasts (FLS) are key contributors to joint inflammation and damage in patients with Rheumatoid (RA) and Psoriatic Arthritis (PsA). Recent studies have identified FLS subsets with distinct pro-inflammatory roles in RA. However, there is a scarcity of data regarding the contribution of FLS in PsA pathogenesis and overall lack of unifying nomenclature. Therefore, the aim is to identify the phenotypic and functional characteristics that define distinct FLS populations and function in RA vs PsA, with implication for disease pathogenesis and therapeutic response.

Methods: Single cell (Sc) RNAseq was performed on 88,953 RA and PsA FLS from intact synovial biopsies and FLS populations were defined by advanced bioinformatic analysis. Subsequently, multiparametric flow cytometric analysis (22 markers) was performed on RA and PsA patient synovial biopsies to examine FLS phenotype and function. Further characterization of differences in the invasive activity of RA and PsA FLS was conducted ex vivo through quantification of matrix metalloproteinases using MSD multiplex-assays/RT-PCR, whilst metabolism was assessed by Seahorse-XFe-technology. Additionally, flow cytometric analysis of key FLS activation/functional markers was performed on RA and PsA FLS across passages 0-3 (P0-3) to define phenotypic alterations once removed from the joint microenvironment.

Results: ScRNAseq analysis demonstrated 11 distinct FLS populations in RA and PsA, with differential frequency of clusters observed with $THY1^+$ FLS dominant in RA vs THY1- FLS dominant in PsA. Flow analysis of $PDPN^+$ FLS demonstrated significant increases in $HLADR^+$, YAP^+, $Cad11^+$, and $pS6^+$ FLS in RA (all $p< 0.05$), whilst PsA FLS demonstrated a significant increase in CD55 expression ($p=0.0079$). Further flow analysis identified 6 FLS populations that could be matched to 6 main populations in the scRNAseq. When compared directly between diseases, patients with RA displayed significant enrichment in $THY1^+CD34^-CD55^-FAP^+$ and $THY1^+CD34^+CD55^-FAP^+$ FLS ($p=0.0093$), while patients with PsA displayed enrichment in $THY1^+CD34^-CD55^+FAP^+$($p=0.02$) and $THY1^-CD34^-CD55^+FAP^+$ FLS ($p=0.0013$). HLADR and Cad11 were significantly higher in RA subpopulations, compared to increased metabolic markers in PsA subpopulations by flow cytometry. In parallel, single-cell analysis of these populations demonstrated immune/inflammatory responses in RA dominant populations in contrast to matrix degrading and metabolic markers in PsA populations. Expanded RA and PsA FLS (P0) confirmed these differences in matrix degrading/metabolic pathways, matching the single cell/flow cytometric analysis. While P0 FLS maintained similar phenotypic profiles to ex vivo FLS, once expanded to P3, FLS started to lose specific phenotypic characteristics. Specifically, the expression of HLADR and CD55 reduced across passages 0-3, while CD34 and CD54 increased, supporting their transient nature.

Conclusion: Distinct FLS populations with unique functional properties were identified in RA and PsA. However, once removed from the joint microenvironment, FLS subset stability appears transient with convergence towards common phenotypes.

Session Title: Abstracts: Spondyloarthritis Including Psoriatic Arthritis – Basic Science
Session Type: Abstract Session
Session Time: 2:00PM–3:30PM

Background/Purpose: Recent advances in understanding the biology of Ankylosing Spondylitis (AS) using innovative genomic and proteomic approaches offer the opportunity to address current challenges in AS diagnosis and management. Altered expression of genes, microRNAs (miRNAs), or proteins may contribute to immune dysregulation and play a significant role in the onset and persistence of inflammation in AS. The ability of exosomes to transport miRNAs across cells and alter the phenotype of recipient cells has implicated exosomes in perpetuating inflammation in AS. This study reports the first proteomic and miRNA profiling of plasma-derived exosomes in AS using comprehensive computational biology analysis.

Methods: Plasma samples from AS patients and healthy controls (HC) were isolated via ultracentrifugation and subjected to extracellular vesicle (EV) flow cytometry analysis to characterize exosome surface markers by a multiplex immunocapture assay. Cytokine profiling of plasma-derived exosomes and cell culture supernatants was performed. Next-generation sequencing was used to identify miRNA populations in exosomes enriched from plasma fractions. CD4+T cells were sorted, and the frequency and proliferation of CD4+T cell subsets were analyzed after treatment with AS-exosomes using flow cytometry.

Results: The expression of exosome-marker proteins CD63 and CD81 was elevated in the AS patients compared to HC ($q < 0.05$). Cytokine profiling in plasma-derived AS-exosomes demonstrated downregulation of interleukin (IL)-8 and IL-10 ($q < 0.05$). AS-exosomes co-cultured with HC CD4+ T cells induced significant upregulation of IFNα2 and IL-33 ($q < 0.05$). Exosomes from AS patients inhibited the proliferation of regulatory T cells (Treg), suggesting a mechanism for chronically activated T cells in this disease. Culture of CD4+T cells from healthy individuals in the presence of AS-exosomes reduced the proliferation of FOXP3+Treg cells and decreased the frequency of FOXP3+IRF4+Treg cells. miRNA sequencing identified 24 differentially expressed miRNAs found in circulating exosomes of AS patients compared with HC; 22 of which were upregulated, and 2 were downregulated.

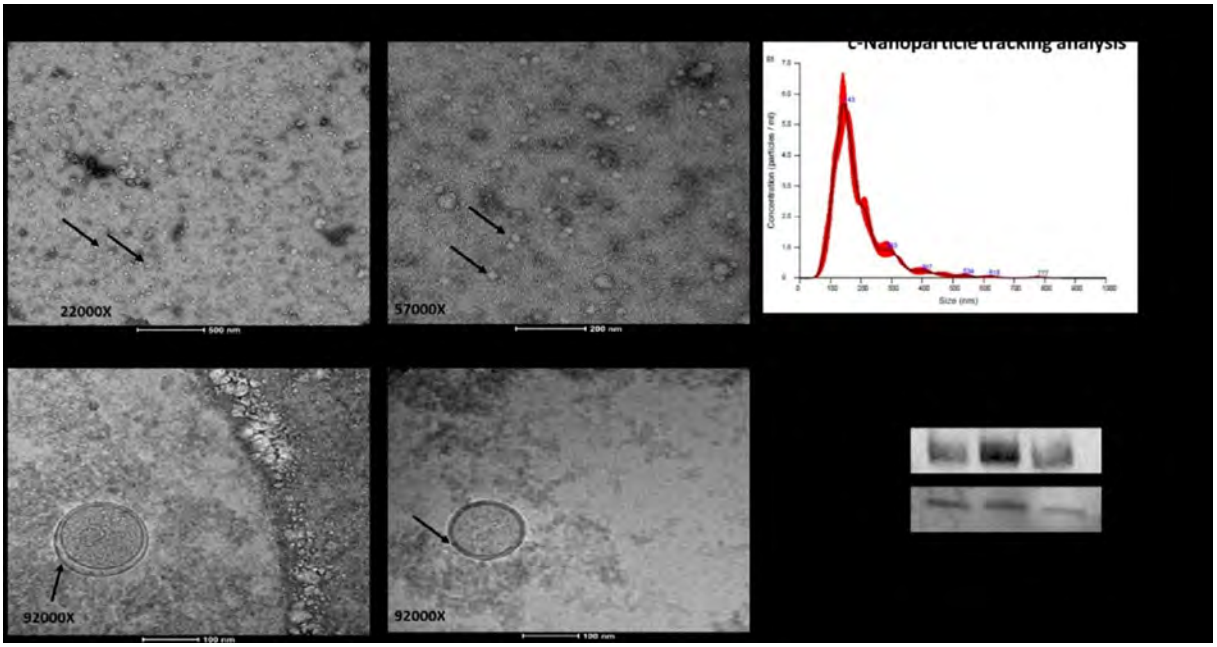

Figure 1. (a) Exosome characteristics with morphology, size, and markers. Exosomes display a round-shaped morphology in negative TEM. It is on 22000x magnification, demonstrating the density of isolated exosomes in plasma (b)and are bilayer and spherical by cryo-TEM imaging. (c) Exosome sizes can be determined using nanoparticle tracking. NTA was used to examine the exosome size and concentration, and the results showed that the exosomes had an average size of 147 nm. (d) Expression of the exosomal markers CD63 and CD9 was confirmed with Western blot.

Conclusion: Individuals with AS have different immunological and genetic profiles, as determined by evaluating the exosomes of these patients. The inhibitory effect of exosomes on Treg in AS suggests a mechanism contributing to chronically activated T cells in this disease.

SESSION INFORMATION

Session Date: Tuesday, November 14, 2023

Session Title: Abstracts: Spondyloarthritis Including Psoriatic Arthritis – Basic Science

Session Type: Abstract Session

Session Time: 2:00PM–3:30PM

Background/Purpose: Around 30% of the patients with psoriasis (PsO) develop psoriatic arthritis (PsA) overtime, suggesting the existence of a disease mediated skin-joint crosstalk. To date, it is still obscure why the inflammatory process in some patients with PsO is restrained to the skin, whereas in other patients it spreads to the joints. Using a pre-clinical model of PsA and PsO, we aimed to untangle the skin-joint axis and to address its role in PsA pathogenesis.

Methods: The IL-23 overexpression (IL-23OE) mouse model of PsO was performed in different genetic backgrounds of KAEDE-transgenic mice expressing a photo-convertible fluorescent reporter to assess cell trafficking from inflamed skin to the joints. Photoswitch from $KAEDE^{GREEN}$ to $KAEDE^{RED}$ of psoriatic skin lesions was obtained upon UV light irradiation. Skin-derived cell trafficking to the joints was detected by light sheet fluorescence microscopy (LSFM) and flow cytometry. Imaging flow cytometry was used to determine the immune nature of the migrating cells. Phenotypical characteristic of skin-derived migrating cells in joints was addressed by single-cell RNA-sequencing (scRNAseq) and functional assays. Data were validated in synovial biopsies from PsO and PsA patients by imaging mass cytometry.

Results: Psoriatic skin lesions were induced upon IL-23OE independently from the mouse strain, whereas the initiation of joint inflammation was dependent on the genetic background of the mice, as assessed by MRI scan and histological analysis. Immune cell migration from psoriatic skin to the joints was observed in both protected and non-protected mice from arthritis. ScRNAseq and computational analysis with RNA velocity approach indicates CD2+ MCHII+ monocytes as predominant cell type evading from the inflamed skin and entering the synovial tissue, with no frequency differences between PsO and PsA mice. No phenotypical differences were observed in the pre-differentiated stage of those monocytes in both, arthritis-protected and non-protected animals. However, once in the synovial tissue their further differentiation into macrophages resulted into two different phenotypes, with pro-inflammatory signatures in mice developing PsA. Interactome analyses between local differentiated skin-derived macrophages and tissue resident synovial cells highlighted the role of synovial sublining fibroblasts in shaping the fate of skin-derived macrophages into a protective phenotype without capacity to initiate the joint inflammatory process in PsO mice without arthritis. Imaging mass cytometry of synovial biopsies from patients with PsO and PsA identified niches of the synovial membrane that were either or not protected from inflammation by a similar fibroblastic fate as observed in the murine setting.

Conclusion: Skin derived monocytes play a major role in spreading the inflammation from psoriatic skin to the joints. However, it is upon interaction with the stromal-resident cells that the fate of the migrating monocytes is shaped towards joint protection or joint inflammation resembling PsA. These data might provide completely new diagnostic insights in assessing the risk of PsO patients to develop PsA.

Upregulation of RANKL in the Skin of Patients with Psoriatic Arthritis

Maria de la Luz Garcia-Hernandez[1], Takeshi Yoshida[2], Javier Rangel-Moreno[2], Alicia Lieberman[3], Ananta Paine[4], Joshua Weitz[2], Francisco Tausk[5], Lisa A Beck[2] and Christopher T Ritchlin[6], [1]University of Rochester, West Henrietta, NY, [2]University of Rochester, Rochester, NY, [3]University of Rochester, Batavia, NY, [4]ORNA Tx, Southborough, MA, [5]Universiy of Rochester, Rochester, NY, [6]University of Rochester Medical School, Allergy, Immunology & Rheumatology Division, Canandaigua, NY

SESSION INFORMATION

Session Date: Tuesday, November 14, 2023

Session Title: Abstracts: Spondyloarthritis Including Psoriatic Arthritis – Basic Science

Session Type: Abstract Session

Session Time: 2:00PM–3:30PM

Background/Purpose: Psoriatic arthritis (PsA) is a chronic inflammatory disease that affects the skin and joints. Circulating Osteoclast precursors (OCP) are elevated in the blood of PsA patients and express Dendritic Cell-Transmembrane Protein (DC-STAMP), a protein essential for cell-cell fusion. Receptor Activator of Nuclear Factor kB Ligand (RANKL) is a pivotal effector driving osteoclastogenesis and is elevated in psoriatic synovium. Herein, we examined skin from PsO and PsA patients to determine if events in the skin trigger the differentiation of monocytes to OCPs.

Methods: We collected lesional (L) and non-lesional (NL) skin biopsies from 23 patients with Ps and 16 patients with PsA. We applied immunofluorescence to visualize and enumerate DC-STAMP$^+$ monocytes, CD3$^+$ TNF$^+$ IL17$^+$ cells and RANKL expression by dermal-infiltrating immune cells and keratinocytes. We also evaluated RANKL expression in CD45$^-$ skin cell suspension by flow cytometry and the induction of RANKL in keratinocytes activated with IL-17 and TNF by western blot analysis.

Results: We found significantly higher RANKL mRNA expression (PsA: 16.67-fold vs PsO: 1.7-fold, p = 0.001) and infiltration by RANKL$^+$ cells in PsA compared to PsO skin (PsA: 4.8% vs PsO: 2% p = 0.022). In addition, 43.75% of PsA L skin have RANKL expression in the epidermal cells but not PsO lesional skin biopsies. Skin cell suspensions showed higher RANKL$^+$ non-hematopoietic cells in L skin, compared to NL skin. We also found an increased number of dermal DC-STAMP$^+$CD14$^+$ OCP in the dermis of PsA plaques. CD3$^+$ T and IL17$^+$ cells were less abundant in PsA, compared to PsO L skin. We detected a higher TNF concentration in sera from PsA patients than Ps. Furthermore, incubation with both TNF and IL17, but not TNF or IL-17 alone, strongly induced RANKL expression on keratinocytes.

Conclusion: We find infiltration of DC-STAMP$^+$CD14$^+$ OCP in the skin of PsA but not Ps patients. Also, increased systemic TNF levels in PsA patients combined with IL17 upregulates RANKL$^+$ protein expression by non-hematopoietic cells. Thus, expression of RANKL by monocytes and keratinocytes in plaques of PsA patients demonstrate the ability to promote RANKL-dependent priming of OCP.

Neutrophils Induce Contact-Dependent Expansion of Arthritogenic Th17 Cells and Are Necessary for Disease in Experimental Ankylosing Spondylitis

Hillary Struthers[1], Emily Vance[1], Kofi Asare-Konadu[1], Holly Rosenzweig[2] and Ruth Napier[1], [1]Oregon Health & Science University, Portland, OR, [2]VA Portland Healthcare System, Portland, OR

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: Abstracts: Spondyloarthritis Including Psoriatic Arthritis – Basic Science
Session Type: Abstract Session
Session Time: 2:00PM–3:30PM

Background/Purpose: Ankylosing spondylitis (AS) patients have irregular neutrophil responses, as indicated clinically by neutrophilia and increased neutrophil to lymphocyte ratios that positively associate with disease activity. $CD4^+$ T helper cells that produce IL-17 (Th17 cells) drive the pathogenesis of AS, and IL-17 blockade is an effective therapy for this disease. Yet, a causative connection between neutrophils and induction of pathogenic Th17 responses in AS remains unknown.

Methods: Arthritis was induced by intraperitoneal injection of 1.5mg zymosan to female SKG mice pre-treated with neutrophil-depleting mAb 1A8 or an isotype control, and onset and severity of peripheral arthritis and axial disease was measured clinically. Neutrophils and CD4+ T cells were isolated from the bone marrow and spleen, respectively, of naïve SKG and WT mice. Zymosan-stimulated neutrophils and TCR-activated CD4+ T cells were co-cultured, together or separated by a 0.4-um pore transwell. IL-17A in supernatants was quantified by ELISA after 72h of co-culture. N=2-4 mice/experiment/genotype, experiments were repeated 3 times each. Statistical significance was calculated by multiple unpaired parametric student T tests.

Results: SKG mice developed Th17 responses and clinical arthritis as early as 5d post-zymosan exposure (pze). SKG mice-deplete of neutrophils showed decreased Th17 responses and undetectable arthritis 5d pze; thereby revealing neutrophils as a requirement for the onset of AS. SKG T cells co-cultured with stimulated neutrophils at a 1:2 (T cell:neutrophil) ratio produced 4.5-fold more IL-17A than SKG T cells cultured in the absence of neutrophils. While SKG neutrophils increased IL-17A production in a dose-dependent manner, WT neutrophils did not. Collectively, these data indicate that neutrophils are alone sufficient to expand Th17 cells. Intriguingly, the capacity of co-cultured neutrophils to potentiate Th17 cells was mitigated when physically separated in transwell plates, indicating that neutrophil-induced Th17 expansion works through a contact-dependent mechanism.

Conclusion: Our study suggests that activated SKG neutrophils interact physically with CD4+ T cells to induce potent arthritogenic Th17 responses. Understanding the intersection between innate and adaptive cellular mechanisms in AS pathogenesis will elucidate novel therapeutic targets for treatment of disease.

Blockade of OX40/OX40L Signaling Using anti-OX40L Ameliorates Systemic Lupus Erythematosus

Junpeng Zhao[1], Liming Li[1], Xiwei Feng[1], Huiqi Yin[1] and Qianjin Lu[2], [1]Hospital for Skin Diseases, Institute of Dermatology, Chinese Academy of Medical Sciences and Peking Union Medical College, Nanjing, China, [2]Hospital for Skin Diseases, Institute of Dermatology, Chinese Academy of Medical Sciences and Peking Union Medical College, Changsha, China

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: Abstracts: SLE – Animal Models
Session Type: Abstract Session
Session Time: 2:00PM–3:30PM

Background/Purpose: Genetic variations in the OX40 ligand (OX40L) locus have been implicated in the susceptibility to systemic lupus erythematosus (SLE). Notably, the blockade of OX40L has demonstrated promising effects in mitigating renal damage and suppressing autoantibody production in NZB/W F1 mice, a commonly used model for SLE. Despite these encouraging findings, the precise mechanisms by which OX40L blockade exerts its delaying effect on the lupus phenotype remain elusive, warranting further investigation and exploration.

Methods: In the present study, we conducted an investigation to assess the effects of OX40L blockade using anti-OX40L in the MRL/lpr murine model of lupus, a well-established experimental system. The mice were categorized into three groups, each consisting of 9-11 individuals: IgG treatment, Cyclophosphamide (CTX) treatment, and anti-OX40L treatment. Following the respective treatments, the mice were sacrificed, and samples of serum, kidney, and spleen were collected for comprehensive outcome evaluation.

Subsequently, we explored the impact of anti-OX40L treatment on immunosuppression in 8-week-old C57BL/6J mice that were immunized with KLH. This was accomplished through the measurement of serum immunoglobulins (Igs) and flow cytometry analysis of splenocytes. Additionally, *in vitro* experimentation involving the treatment of anti-OX40L in $CD4^+$ T cells and $CD19^+$ B cells was conducted to elucidate the roles of OX40L in the pathogenesis of SLE.

Results: In the current study, we have made significant observations regarding the impact of blocking OX40L in MRL/lpr mice, a murine model of lupus. Notably, treatment with anti-OX40L resulted in a remarkable delay in disease progression, as evidenced by reduced production of anti-dsDNA antibodies, decreased proteinuria, and diminished Ig deposition in the kidney. Additionally, we observed lower frequencies of Th1 and Tfh cells in the spleen of anti-OX40L-treated mice compared to the IgG-treated group.

Furthermore, our *in vitro* experiments revealed that anti-OX40L treatment promoted the up-regulation of polyclonal $CD4^+$ T cell differentiation into regulatory T cells (Tregs). This finding suggests a potential mechanism through which anti-OX40L exerts its beneficial effects. In KLH-immunized mice, the administration of anti-OX40L resulted in decreased levels of immunoglobulins (Igs) and reduced numbers of plasmablast cells, further supporting the immunosuppressive effects of OX40L blockade.

Interestingly, we also found that blocking OX40/OX40L signaling inhibited the TLR7-mediated differentiation of antibody-secreting cells (ASCs) and antibody production. This effect was accompanied by the up-regulation of SPI-B, IRF8, and PAX5, as well as the down-regulation of Xbp-1 in B cells, indicating the involvement of multiple regulatory factors in this process.

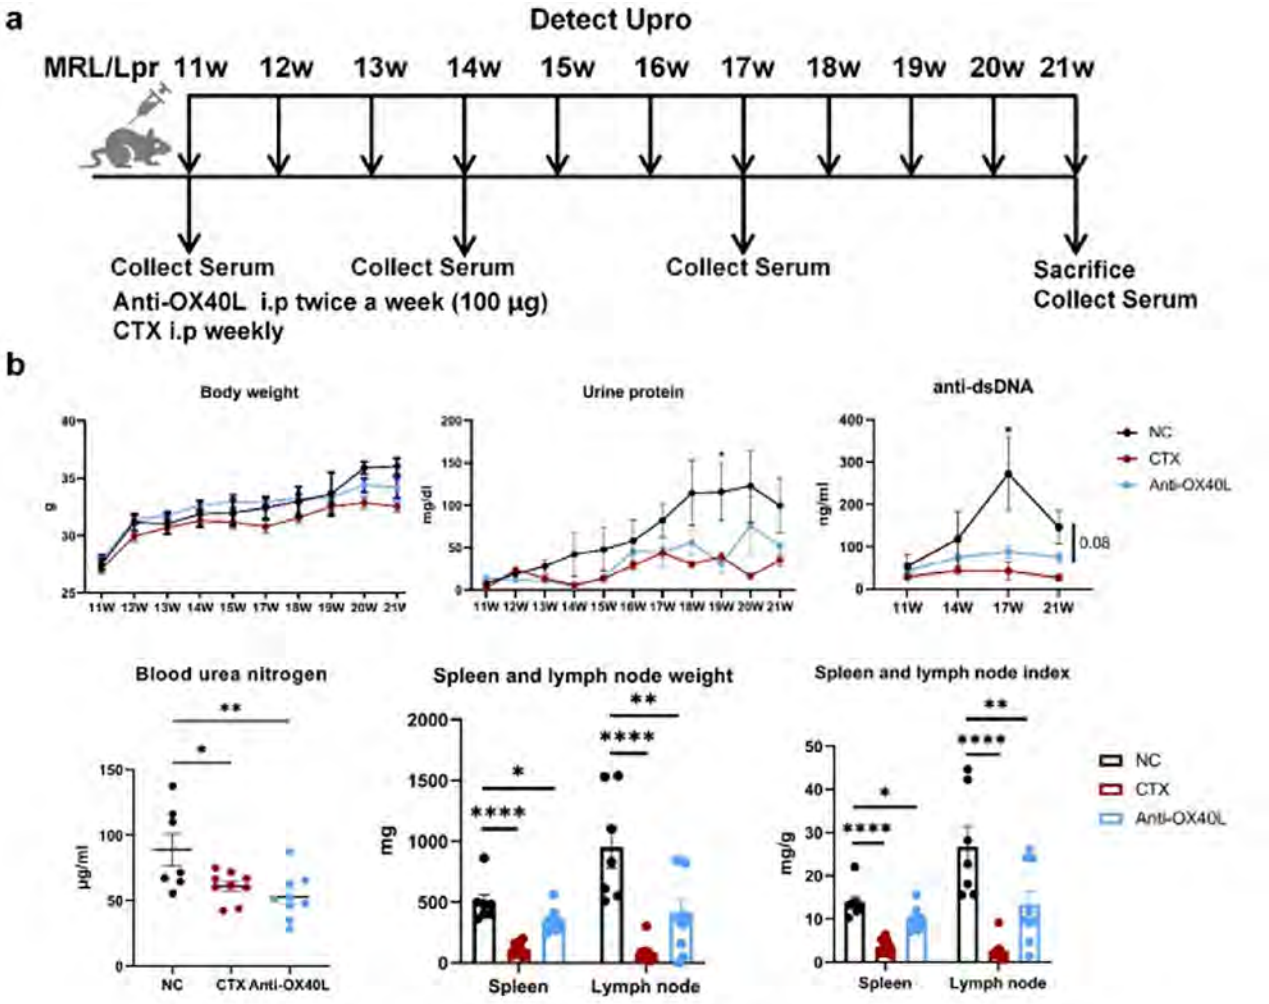

Fig. 1. Anti-OX40L ameliorates the lupus progression. **(a)** A schematic of the treatment of anti-OX40L in MRL/Lpr mice. **(b)** Body weight, urine protein, anti-dsDNA (IgG), blood urea nitrogen, spleen and lymph node weigh, as well as spleen and lymph node index were shown. Horizontal bars represent the mean ± SEM. n = 11 in MRL/Lpr group+ IgG isotype control (NC) (4 mice died); n = 10 in MRL/Lpr + CTX treated group (1 mouse died); n = 11 in MRL/Lpr + Anti-OX40L treated group (2 mice died). $*p < 0.05$, $**p < 0.01$, $***p < 0.001$, $****p < 0.0001$.

Conclusion: The results obtained from our study, along with the extensive evidence from previous investigations, underscore the potential of blocking OX40L as an effective strategy to mitigate disease progression and alleviate the pathological manifestations of SLE.

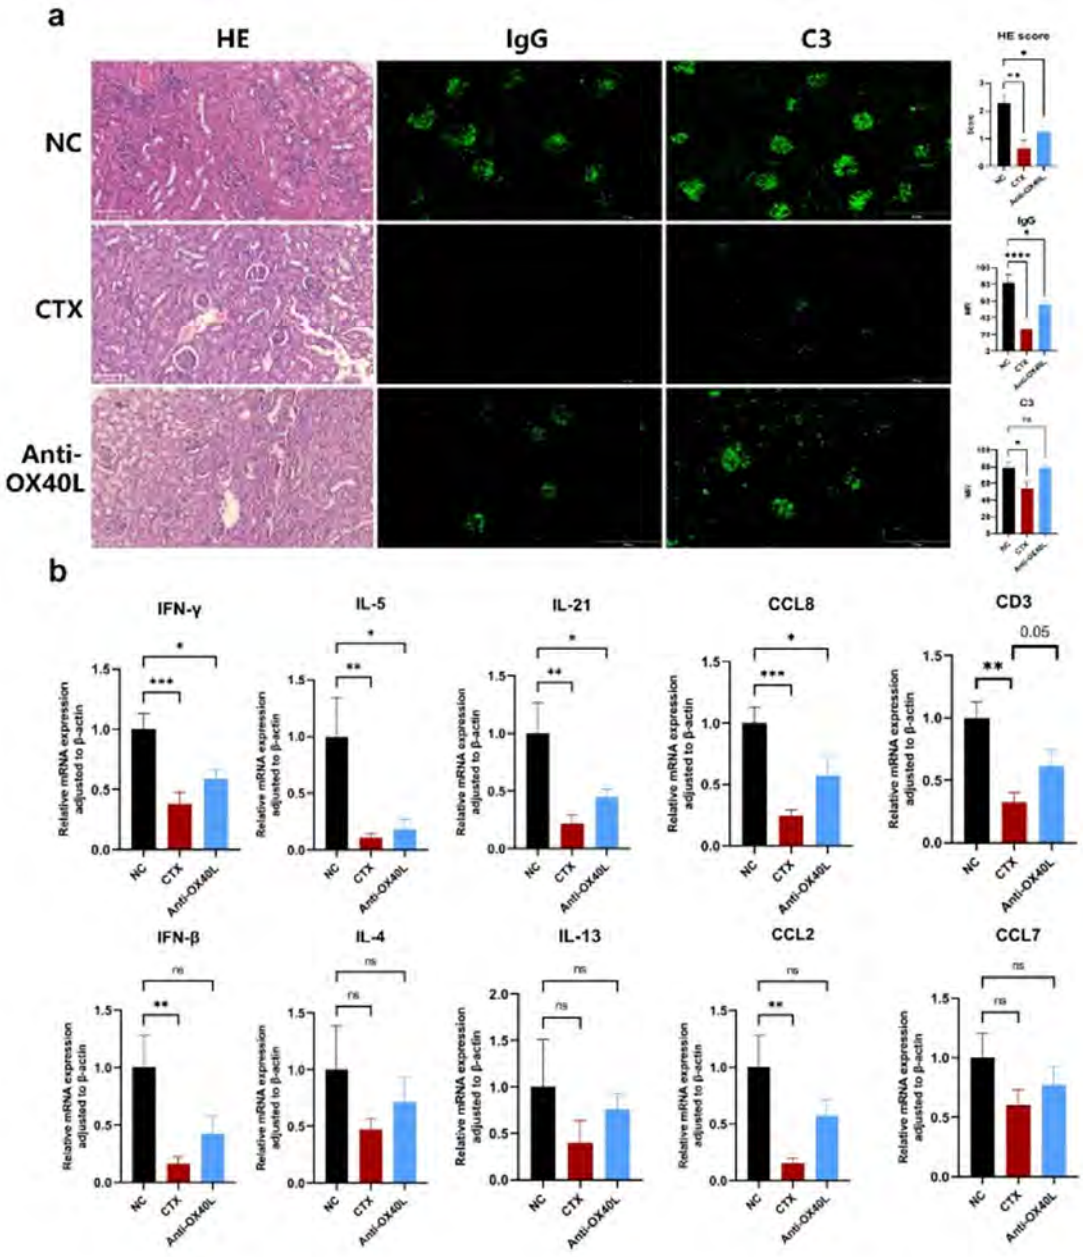

Fig. 2. Anti-OX40L improves histological damage, reduces immune-complex deposition, and controls inflammatory response in MRL/Lpr mice. **(a)** H&E staining, IgG and C3 deposition in the of kidney MRL/lpr mice. **(b)** Anti-OX40L treatment reduced renal mRNA levels of pro-inflammatory cytokines (INF-γ, IL-5, IL-21), chemokine (CCL8), and marker of inflammatory cell (CD3) in MRL/Lpr mice. Horizontal bars represent the mean ± SEM. n = 11 in MRL/Lpr group+ IgG isotype control (NC) (4 mice died); n = 10 in MRL/Lpr + CTX treated group (1 mouse died); n = 11 in MRL/Lpr + Anti-OX40L treated group (2 mice died). $*p < 0.05$, $**p < 0.01$, $***p < 0.001$.

SESSION INFORMATION

Session Date: Tuesday, November 14, 2023

Session Title: Abstracts: SLE – Animal Models

Session Type: Abstract Session

Session Time: 2:00PM–3:30PM

Background/Purpose: Regulatory T cells (Tregs) play an important role in maintaining immune system homeostasis. Antigen-specific Tregs potently and specifically suppress autoreactivity, suggesting their potential to be engineered to treat autoimmune diseases. Lupus nephritis (LN) is a severe manifestation of SLE associated with the presence of anti-Smith (Sm) autoantibodies as well as the HLA haplotypes DR15 and DR3, with the majority of patients DR15. Due to the strong association of LN with anti-Sm and HLA-DR15, we developed Sm-specific Tregs for potential treatment of LN.

Methods: We identified DR15-restricted Sm T cell epitopes using a physical affinity binding assay. T cell receptors (TCRs) specific for Sm epitopes were identified by co-culturing CD4+ T cells with dendritic cells from HLA-DR15+ healthy donors and Sm epitopes, and sequencing proliferating CD4+ T cells using high-throughput 10X single cell V(D)J sequencing. TCRs were ranked based on clonal expansion, cloned into a lentiviral vector then transduced onto primary SLE patient Tregs. Sm-specific Tregs were evaluated for suppression of T effector cell function in vitro and in a humanised model of LN created by the transfer of PBMCs from anti-Sm positive HLA-DR15+ SLE patient into NSG-MHC-null mice.

Results: The top three Sm epitopes identified were SmB/B'$_{58\text{-}72}$, SmB/B'$_{1\text{-}15,}$ and SmD3$_{43\text{-}57}$; the respective stability indices (SI) were 16.0, 1.4 and 1.2. Highly reactive TCRs specific for SmB/B'$_{58\text{-}72}$ were identified and the highest ranked SmB/B'$_{58\text{-}72}$ reactive TCR was cloned into a lentiviral vector then transduced onto primary SLE patient Tregs, resulting in Sm-Tregs. In *in vitro* co-cultures of SLE patient PBMCs with SmB/B'$_{58\text{-}72}$, Sm-Tregs, but not polyclonal Tregs induced 90% suppression of pro-inflammatory cytokine secretion (IFN-g (pg/mL): control 39.7±11.4, polyclonal Tregs 37.3±12.6, Sm-Tregs 2.7±1.0, $p< 0.05$; IL-17A (pg/mL): control 26.3±2.9, polyclonal Tregs 17.0±2.7, Sm-Tregs 2.4±0.6, $p< 0.01$) while Sm-Tregs produced significantly more IL-10 ($p< 0.01$). Transfer into NSG-MHC-null mice of Sm+ HLA-DR15+SLE patient PBMCs, but not healthy HLA-DR15+ PBMC, induced an LN phenotype characterised by proteinuria and histological glomerular necrosis. Treatment with Sm-Tregs halted the progression of functional and histological injury in this model (proteinuria: control 3.6±0.2, polyclonal Tregs 3.2±0.2, Sm-Tregs 1.2±0.2, $p< 0.01$; glomerular segmental necrosis: control 75.2±2.9%, polyclonal Tregs 61.2±6.3%, Sm-Tregs 14.4±1.9%, $p< 0.001$).

Conclusion: Antigen-specific Tregs generated against an immunodominant Sm peptide were highly efficient at suppressing Sm-specific T effector responses. HLDA-DR15+Sm+ SLE patient PBMC induced a model of LN, in which Sm-Tregs were therapeutic. Autologous Sm-Treg cell therapy is a promising treatment for LN, and other antigen-specific autoimmune diseases could be similarly targeted.

Targeting of Endothelial Dysfunction in Lupus Nephritis: Effect on Human Renal Endothelial Cell Gene Expression and Outcomes in Murine Lupus Nephritis

Dayvia Russell[1], Sandra Sanchez[2], Evelyn Bruner[2] and Jim Oates[2], [1]Ralph H. Johnson VA Medical Center, Charleston, SC, [2]Medical University of South Carolina, Charleston, SC

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: Abstracts: SLE – Animal Models
Session Type: Abstract Session
Session Time: 2:00PM–3:30PM

Background/Purpose: Lupus nephritis (LN) constitutes one of the most severe manifestations of systemic lupus erythematosus (SLE). Evidence points to endothelial nitric oxide synthase (eNOS) uncoupling, which induces oxidation-mediated changes in gene transcription, as a mechanism leading to chronic endothelial cell dysfunction (ECD) and damage in LN. Treatment with sepiapterin (L-Sep), which induces coupling of eNOS, restores endothelial function in lupus serum-treated endothelial cells. The aim of this study was to determine whether treatment with L-Sep could improve outcomes in a murine model of LN, and to better understand the protective mechanism of L-Sep by identifying genes involved in inflammatory redox pathways in human LN that are regulated by L-Sep.

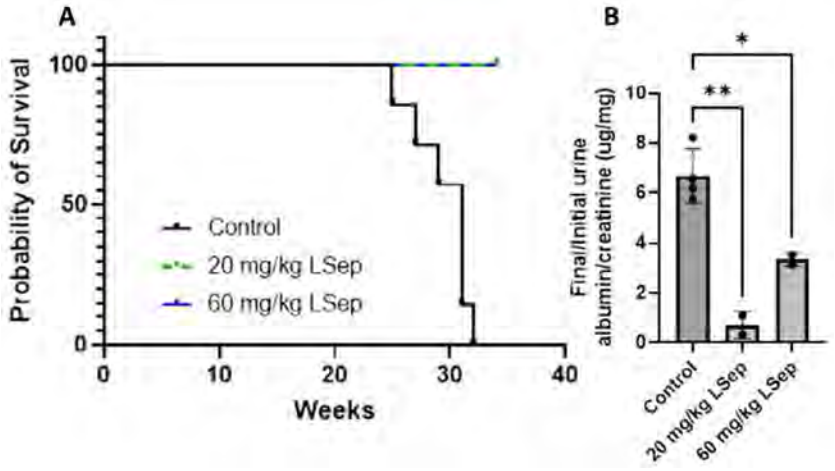

Figure 1. Survival and proteinuria in mice treated with vehicle or L-sepiapterin (LSep). Mice were treated (0, 20, or 60 mg/kg/day L-Sep) at the onset of trace proteinuria for five weeks. A) Survival (lack of death or severe illness requiring euthanasia) by age of mouse and treatment group B) 24-hour urine albumin/creatinine were collected at baseline and 5 weeks of therapy and reported as a ratio of 5wk/baseline values.

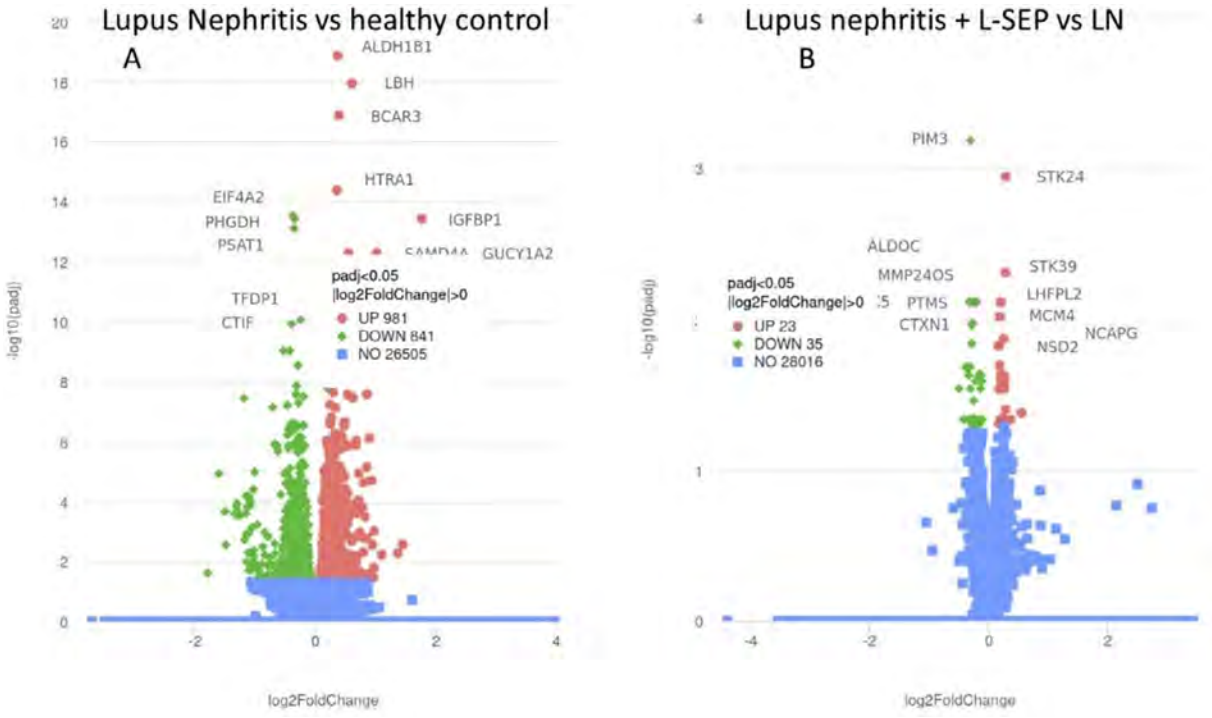

Figure 2. Volcano plot from human glomerular endothelial cell gene expression fold change versus -log10(p value adjusted). Human glomerular endothelial cells were treated with 10% serum for 3 hours. A) volcano plot of differential gene expression of cells treated with lupus nephritis (LN) flare serum versus healthy control serum (n=5) B) volcano plot of differential gene expression from cells treated with either LN flare serum or LN flare serum with L-Sep.

Methods: Female NZM2410/J mice, a model of lupus nephritis, were examined for the onset of trace proteinuria, at which time mice were randomized into treatments groups of vehicle, 20 mg/kg/day L-Sep, or 60 mg/kg/day L-Sep. Urine proteinuria was assessed weekly, and histopathological grading of kidneys using NIH activity and chronicity indices, along with C3 and IgG renal expression were examined after five weeks of treatment. Kaplan-Meier curves and log-rank test were applied to assess survival. One-way ANOVA with Tukey's multiple comparisons test was used to determine differences in proteinuria.

Human renal glomerular endothelial cells (HRGECs) were grown to confluence in media containing 10% human healthy control (HC) serum (n=5, negative for connective tissue disease), or lupus nephritis serum (n=5, class IV LN, collected at the time of induction of therapy) +/- 5 μM L-Sep. After three hours of culture, RNA was extracted, and RNA sequencing, using NovaSeq PE 150, was performed to determine differentially expressed genes between LN and HC treated cells and between LN and LN + LSep treated cells.

Results: Mice receiving L-Sep showed improved urine albumin/creatinine from five weeks/start of treatment compared to those receiving vehicle (p=0.001 for vehicle vs. 20 mg/kg L-Sep; p=0.017 for vehicle vs. 60 mg/kg L-Sep), along with enhanced survival as demonstrated by Kaplan-Meier curves and log rank test. Kidney sections from mice receiving L-Sep (n=3) had lower renal activity (0.0 ± 0.0 vs. 4.6 ± 1.1, p = 0.004) and chronicity scores (2.3 ± 2.1, p = 0.23) than mice treated with 20 (n=2) or 60 (n=2) mg/kg/day L-Sep.

RNA sequencing revealed that genes involved in oxidative-stress and hypertension were differentially upregulated in HRGECs cultured with LN serum compared to Healthy Control (HC) serum (STK24, padj= 0.001; STK39, padj= 0.005). PIM3, which increases eNOS expression, was the most significantly downregulated gene in LN compared to HC

(padj=0.0006). HRGECs treated with L-Sep had increased expression of syndecan-4 (SDC4) (padj=2.49E-11), a component of the glycocalyx that functions to protect ECs.

Conclusion: This study suggests L-Sep, a drug that restores eNOS coupling, may be beneficial in the treatment of LN, in part by preventing activity and fibrosis in the kidney. Differential gene expression analysis suggests that redox-regulated genes are increased with LN serum treatment, while L-Sep may improve endothelial barrier function by inducing syndecan 4 expression.

Intermittent Fasting Attenuates Cognitive Dysfunction in Murine Systemic Lupus Erythematosus

Yi Feng, Jiayu Qin, Lijuan Zheng, Hao Ren, Min Yang and Qin Huang, Department of Rheumatology, Nanfang Hospital, Southern Medical University, Guangzhou, China

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: Abstracts: SLE – Animal Models
Session Type: Abstract Session
Session Time: 2:00PM–3:30PM

Background/Purpose: Cognitive dysfunction is one of the most common manifestations of neuropsychiatric systemic lupus erythematosus (NPSLE) and severely affects patients' health-related quality of life. Intermittent fasting (IF) has been shown promising therapeutic effects in neurodegenerative diseases. In this study, we evaluated the impact of intermittent fasting on cognitive function in lupus-prone mice.

Methods: MRL/lpr mice, as an animal model for studying NPSLE, can spontaneously exhibit cognitive dysfunction. After 8 weeks of alternate-day fasting, novel object recognition and Morris water maze tests were used to assess cognitive manifestation. The number of microglia (IBA-1^{+}) was evaluated by immunofluorescence staining. Expression levels of IL-1β, IL-6 and TNF-α were detected by qRT-PCR. The blood-brain barrier permeability and autophagy levels were evaluated by western blotting.

Results: We found that IF improves cognitive function of MRL/lpr mice in the behavioral tests. IF also decreased hippocampal microglia activation and expression of inflammatory cytokines in MRL/lpr mice. In addition, we demonstrated that IF reduced blood-brain barrier permeability. Furthermore, IF inhibited mTOR signaling and increased autophagy levels.

Conclusion: These data indicate that IF improves cognitive function in lupus-prone mice.

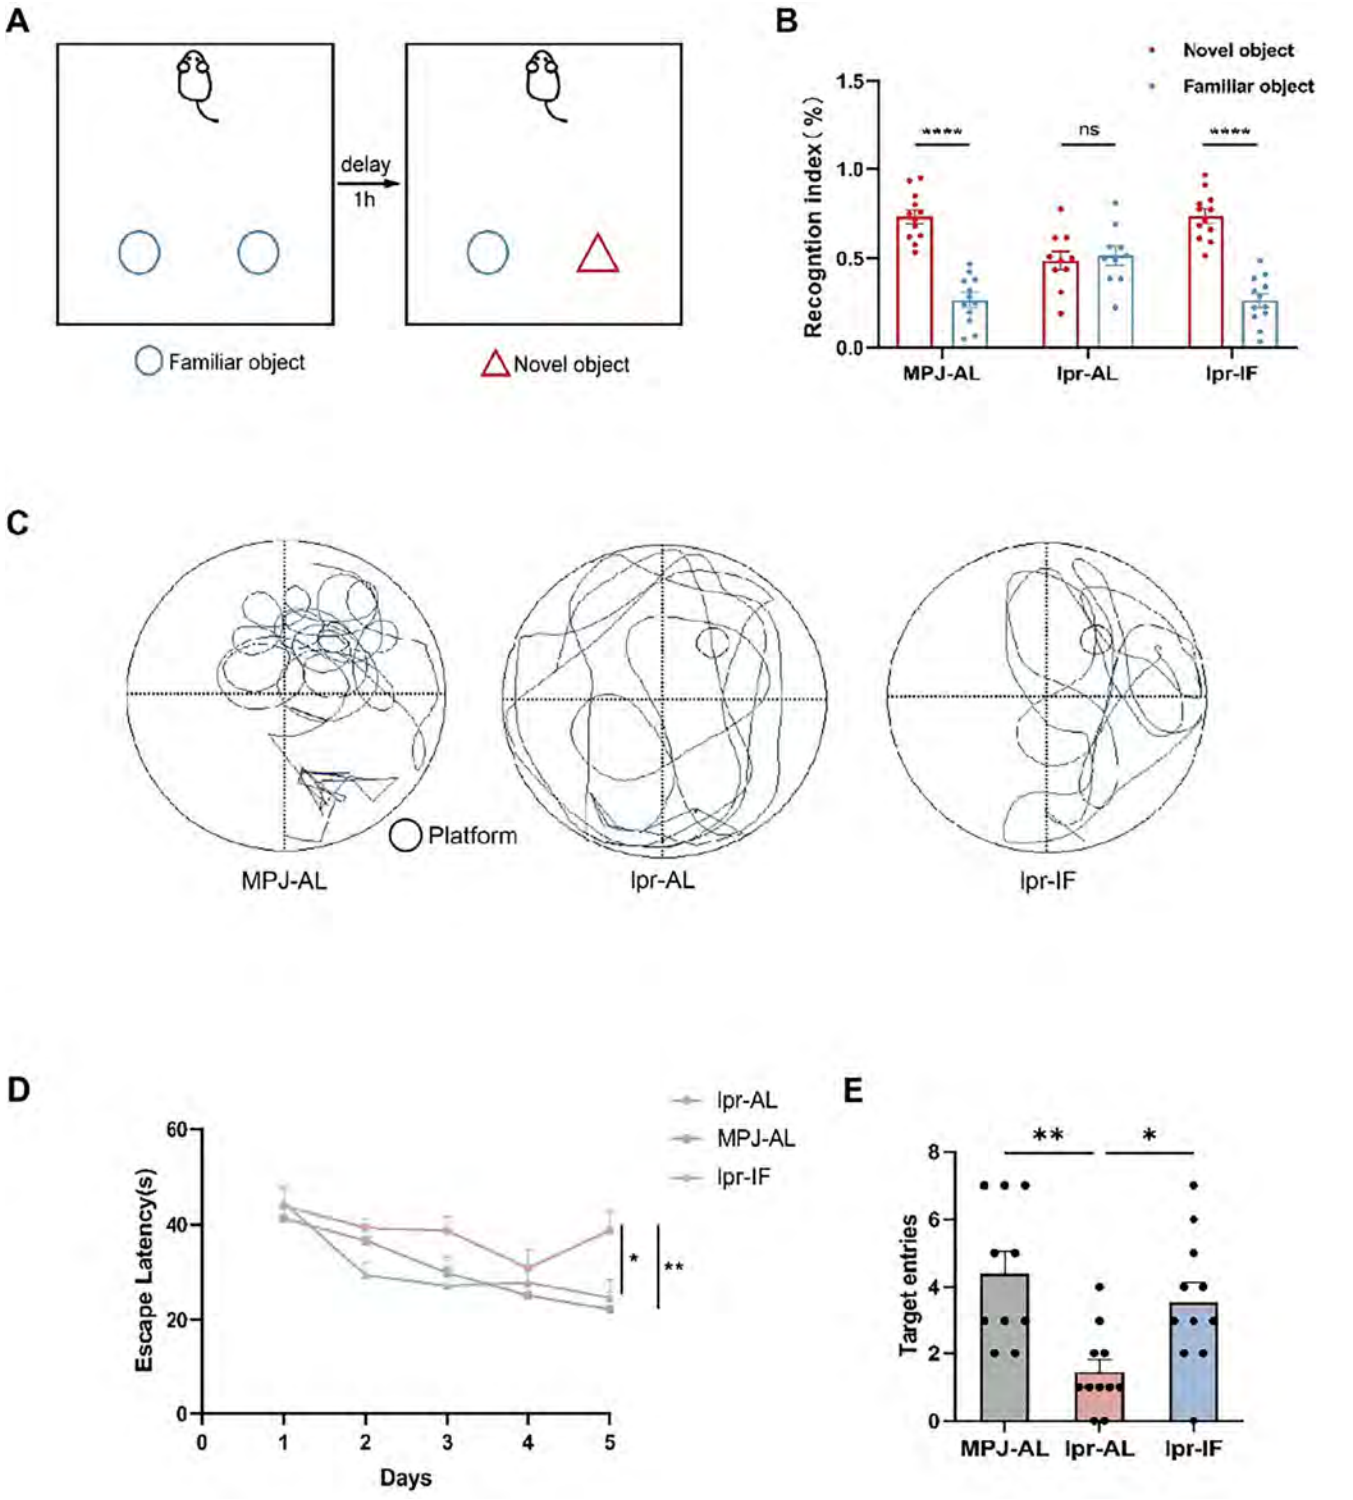

Fig.1 IF improves cognitive function of MRL/lpr mice.A:The experimental procedure of the novel object recognition test.B: The test recognition index of mice (n = 10-12 mice per group).C:The represent image of day6 in the Morris water maze test.D:The escape latency to the platform of day1-5.E:The target entries of day6.The data are represented as the mean ± standard error of the mean. *P < 0.05, **P < 0.01, ***P < 0.001 and ****P < 0.0001; NS, not significant.

Interleukin-6 Activates Glial Cells and Induces Cognitive Dysfunction in Murine Neuropsychiatric Lupus

Joshua Reynolds[1], Michelle Huang[1], Myriam Meineck[2], Tamara Möckel[2], Andreas Schwarting[2] and **Chaim Putterman**[1], [1]Albert Einstein College of Medicine, Bronx, NY, [2]University Medical Center of the Johannes Gutenberg University of Mainz, Mainz, Germany

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: Abstracts: SLE – Animal Models
Session Type: Abstract Session
Session Time: 2:00PM–3:30PM

Background/Purpose: Up to 50% of SLE patients experience neuropsychiatric involvement (neuropsychiatric lupus, or NPLSE) in the form of cognitive deficits, memory loss, depression, and anxiety. The pathogenic mechanisms of NPSLE have yet to be firmly established. Since current non-specific treatment regimens in NPSLE often fail to improve symptoms, identifying novel and more targeted interventions is necessary to improve patient care. Cerebrospinal fluid and serum levels of the inflammatory cytokine interleukin-6 (IL-6) are increased in NPSLE patients and lupus mice. Excessive IL-6, possibly entering the brain from the serum, could promote neuroinflammation by activating glial cells, including astrocytes and microglia. We aimed to assess this putative mechanism, hypothesizing that knocking out IL-6 in lupus mice would ameliorate NPSLE.

Methods: Female MRL/lpr mice exhibit severe lupus-like disease and neuropsychiatric deficits. To investigate the association of IL-6 with NPSLE, we compared serum levels of IL-6 with behavioral testing scores in 18-week-old MRL/lpr mice. Object placement (OP) and object recognition (OR) tests measured novelty preference to assess cognition and memory (increased scores indicate improved performance). Social preference (SP), Porsolt swim, tail suspension, and elevated plus maze (EPM) measured murine correlates of anxiety and depression. We repeated this battery in two separate cohorts of 14- to 18-week-old IL-6 knockout (KO; n = 7 + 8) and age-matched wildtype (WT; n = 7 + 8) MRL/lpr mice. Systemic disease was assessed by serum levels of anti-dsDNA antibodies. We measured gene expression of *gfap*, an astrocytic activation marker, and *aif1*, a microglial marker, in right-hemispheric cortical tissue by real-time qPCR. Results were compared between KO and WT using two-tail Mann-Whitney u- or Student's t-tests when appropriate, with a p-value threshold of 0.05.

Results: Elevated serum IL-6 correlated with worse spatial memory as measured by the OP task (n = 8; r = -0.76, p = 0.037; Fig 1A), but not with the depression or anxiety tasks. Serum anti-dsDNA antibody titers (Fig 1B) did not significantly differ between IL-6 KO mice and WT controls (p = 0.130). MRL/lpr IL-6 KO mice showed significantly increased novelty preference on OP (KO: 57.87 +/- 3.15; WT: 45.37 +/- 2.29, p = 0.002; Fig 1C) and OR (KO: 67.91 +/- 3.62; WT: 48.93 +/- 4.34; p = 0.003; Fig 1D). No difference was found on SP (p = 0.838), Porsolt swim (p = 0.161; Fig 1E), tail suspension (p = 0.325), or EPM (p = 0.890). Expression of both glial genes, *gfap* (KO: 1.03 +/- 0.15; WT: 1.49 +/- 0.16; p = 0.037) and *aif1* (KO: 0.59 +/- 0.05; WT: 0.84 +/- 0.09; p = 0.036), were decreased in whole cortex samples from IL-6 KO mice compared to WT (Fig 1F).

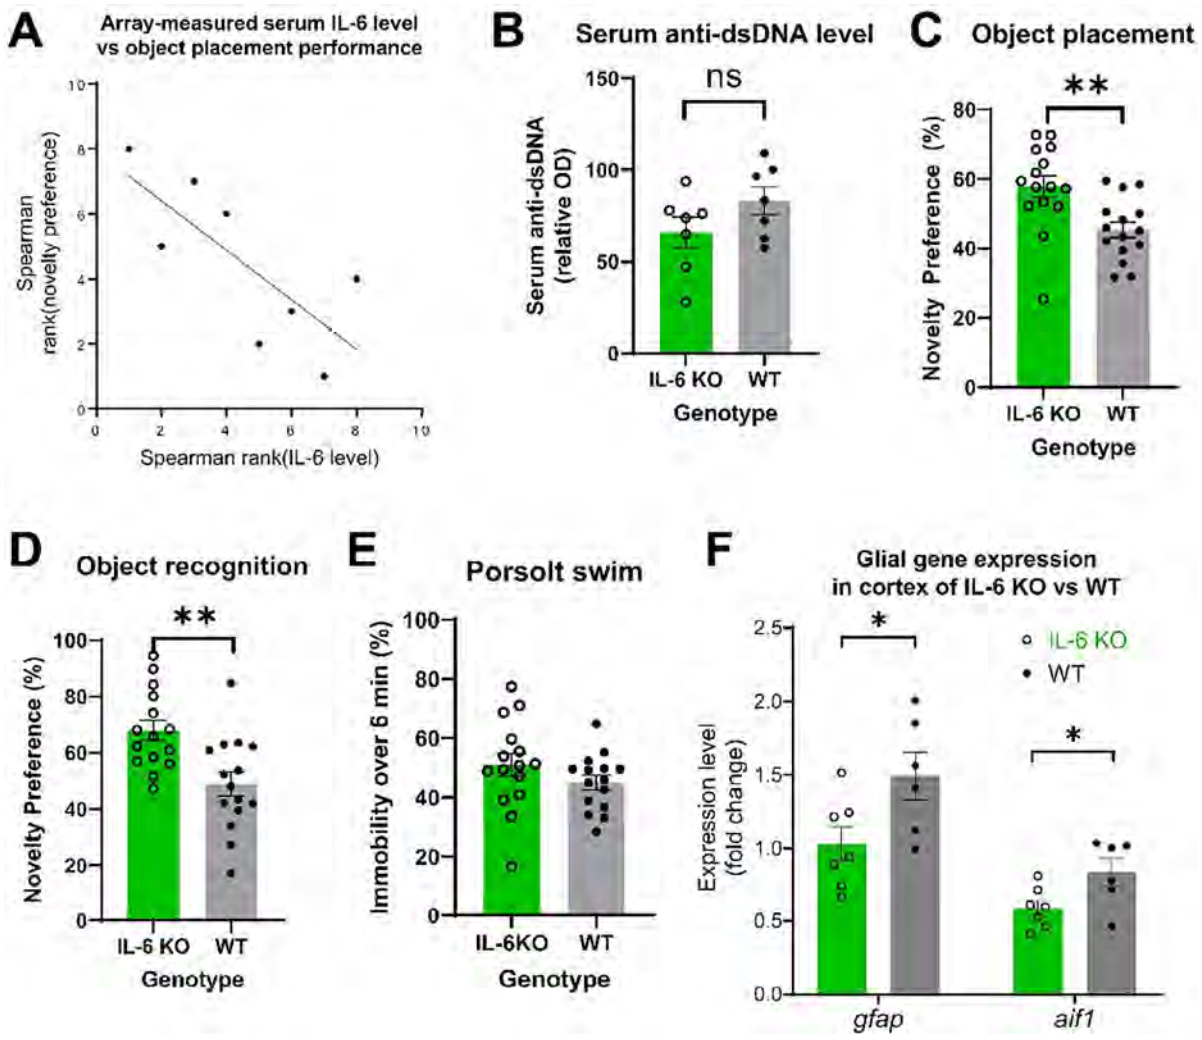

Figure 1. Role of IL-6 in murine neuropsychiatric lupus. To explore the pathogenic potential of IL-6 in NPSLE, we measured serum IL-6 in unmanipulated MRL/lpr mice (panel A). Cognitive and affective features of murine neuropsychiatric lupus were studied in IL-6 knockout (IL-6 KO) and littermate control (WT) MRL/lpr mice using a standard neurobehavioral battery (panel C-F). Object placement and object recognition tasks assess a mouse's preference for a novel object. Each task relies on intact spatial memory or identification memory, respectively; less novelty preference equates to worse cognitive performance. Porsolt swim is a validated measure of murine depressive-like behavior, wherein a mouse with worse disease spends more time immobile when placed in a tank of water (behavioral despair). A) There is a significant correlation between serum IL-6 levels and object placement novelty preference in unmanipulated MRL/lpr mice (n = 8; r = -0.76; p = 0.037). B) Systemic disease burden, as measured by serum anti-dsDNA antibody levels determined by ELISA (OD: optical density), did not differ between IL-6 KO and WT (n = 7; p = 0.1297). IL-6 KO lupus mice showed improved novelty preference on both object placement (C) (n = 15; p = 0.002) and object recognition (D) (n = 15; p = 0.003) tasks. E) Depressive-like behavior did not differ between genotypes (n = 15; p = 0.161). F) Whole cortex expression of astrocyte (gfap; n = 6-7; p = 0.037) and microglia (aif1; n = 6-7; p = 0.036) marker genes was significantly decreased in IL-6 KO lupus mice. * $p < 0.05$; ** $p < 0.01$; the "n" provided is the number of mice for each genotype.

Conclusion: In conclusion, we found that serum IL-6 levels correlate with worse cognition and memory in lupus mice. Moreover, knocking out IL-6 ameliorates those deficits without altering affective features or systemic disease. Whether pharmacologic inhibition of IL-6 would similarly attenuate murine NPSLE remains to be determined. IL-6 KO mice also demonstrated decreased cortical expression of inflammatory glial genes. Therefore, IL-6 may play a specific, glia-mediated role in the cognitive and memory deficits of NPSLE.

Abstract Number: 2448

UV Light Exposure Induces a Type I Interferon Dependent Activation and Migration of Inflammatory Dendritic Cells to Local Lymph Nodes

Xizhang Sun, Jaime Chao, Michael Gerner and Keith Elkon, University of Washington, Seattle, WA

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: Abstracts: SLE – Animal Models
Session Type: Abstract Session
Session Time: 2:00PM–3:30PM

Background/Purpose: Photosensitivity occurs in ~ 75% of lupus patients. Although ultraviolet (UV) light stimulates Type I interferon (IFN-I) in the skin, why lupus patients are sensitive to UV skin injury and how systemic immune responses are generated are poorly understood. Following skin inflammation in other contexts, DC migrate to draining lymph nodes (dLN) and activate adaptive immune cells. In virus infections that induce Type I interferon (IFN-I), a unique inflammatory DC subset (infl-cDC2) that are potent antigen presenting cells are generated. To explore the links between UV mediated skin inflammation and innate responses, we examined myeloid cell migration, including DC subsets (cDC1, cDC2, infl-cDC2) to dLNs in normal and a lupus prone mouse strain. We also examined the influence of Type-I IFN in migratory DC differentiation.

Methods: Mice were females aged 8-12 weeks of the strains C57BL/6 (B6); KiKR (photoactivatable); interferon receptor deficient (Ifnar KO); and Trex1 mutant mice (knock in of the lupus mutant allele, D18N, Trex1m). Mice were exposed to a single dose of UV (500mJ/cm^2) on the dorsal skin. In some experiments, the skin was painted with TRITC prior to UV to determine the origin of cells in the dLN. Brachial and axillary dLN were harvested at 1- or 2-days post UV exposure. Flow cytometry using the Symphony A3 cytometer identified myeloid cells as described previously. Statistical significance between groups was determined by Student's t-test.

Results: Skin painted with TRITC confirmed that skin derived DC migrated to dLN after UV. When compared to non-UV exposed mice and control non-draining LN, UV caused an increase in TRITC+CD64+ and TRITC+ Ly6Ghi (neutrophils) cells in dLN. UV of KiKR mouse skin revealed that both cDC1 and cDC2 cells migrated to dLN following UV. Higher numbers of neutrophils as well as CD64+ myeloid cells, that included monocytes as well as infl-cDC2 (CD26+MAR-1+), were detected in the dLN after UV, compared to non-UV exposed control mice (Fig.1). We observed a significant reduction of infl-cDC2 cells in Ifnar KO mice indicating that their development was IFN-I dependent. Finally, we quantified myeloid cell populations in the dLN of lupus-prone Trex1m mice. Although UV did not increase cDC1 nor cDC2 in dLN, we observed a significant increase in the infl-cDC2 in the dLN in this lupus prone strain (Fig.1). Curiously, monocyte and neutrophil migration to dLN were reduced in Trex1m mice compared to B6 after UV.

Figure 1:

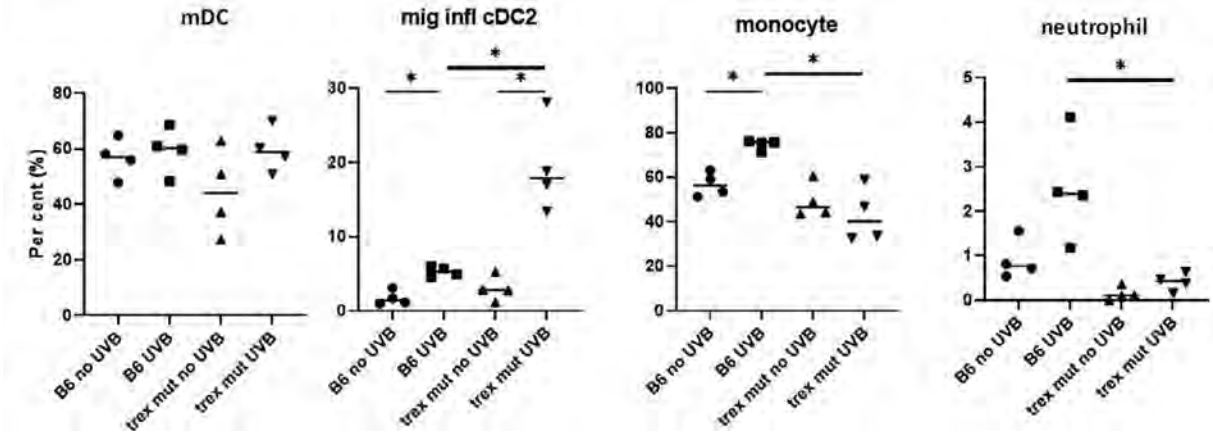

Fig 1. Percentage of cells in the draining Lymph Nodes (dLN). B6 or Trex1 mutant (mut) mice were exposed to 500 mJ/cm2 UV light on the dorsum. 48 hours after UV exposure, the brachial and axillary LN were harvested. The dissociated cells were analyzed by flow cytometry using 15 markers to distinguish different myeloid population on the Symphony A3 cytometer. The percentage of each cell type was calculated and comparisons made by Student's t test. mDC = migratory DC. * $p<0.05$.

Conclusion: We conclude that exposure of normal skin to UV light causes migration of many different types of myeloid cells to dLN, including skin-derived migratory DC, neutrophils, and monocytes. A subset of CD64+ infl-cDC2 is also induced and is dependent on UV-induced IFN-I. Of interest, Trex1m mice exhibit altered myeloid cell responses in the dLNs, including increased representation of infl-DCs and reduced neutrophil and monocyte cellularity. Overall, these findings show marked and non-equivalent IFN-I dependent effects of UV on myeloid cell responses in the dLN in wild type vs lupus-prone mice, implicating a link between IFN-I and the development of APCs that promote the adaptive immune response.

Cognitive Functioning Among Individuals with Systemic Lupus Erythematosus: A Population-Based Study

Laura Plantinga[1], C. Barrett Bowling[2], Charmayne Dunlop-Thomas[1], Courtney Hoge[1], Bradley Pearce[1], Cristina Drenkard[1] and S. Sam Lim[1], [1]Emory University, Atlanta, GA, [2]Duke University, Durham, NC

SESSION INFORMATION

Session Date: Tuesday, November 14, 2023
Session Title: Abstracts: Epidemiology & Public Health II
Session Type: Abstract Session
Session Time: 2:00PM–3:30PM

Background/Purpose: Studies of objectively measured cognitive dysfunction in SLE are often limited by small sample size, limited generalizability, and lack of diversity. We sought to comprehensively describe cognitive functioning and its correlates among participants recruited from a population-based, primarily Black U.S. cohort.

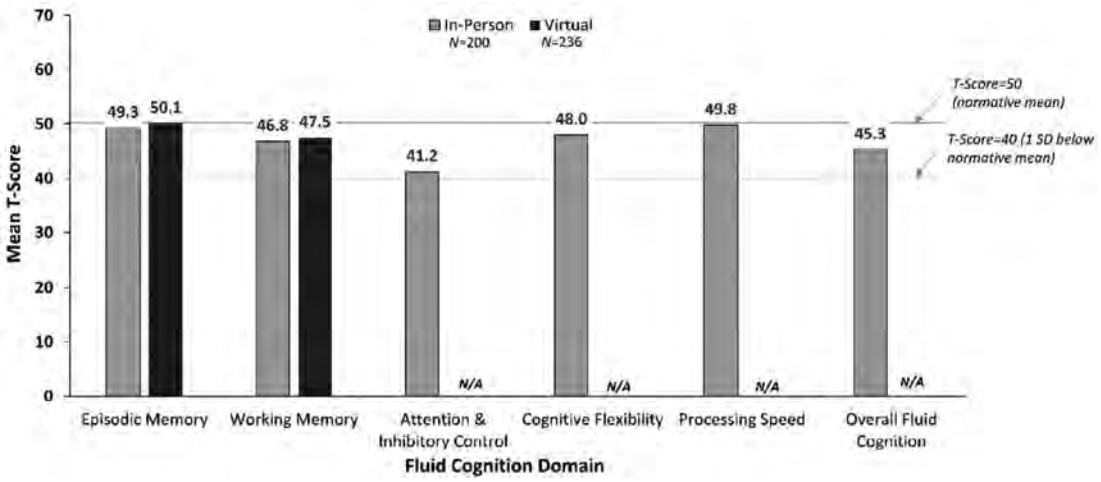

Figure 1. Mean fully adjusted* NIH Toolbox Fluid Cognition Battery T-scores among individuals with SLE, by visit type.

Methods: Participants (*n*=200; mean age, 42.6; 87.5% female, 86.5% Black, 5.0% Hispanic) completed in-person study visits (10/2019-5/2022), which included: (1) the NIH Toolbox Fluid Cognition Battery (episodic memory, working memory, attention and inhibitory control, cognitive flexibility, processing speed, overall composite measure; expressed as T-scores, adjusted for age, gender, race/ethnicity, and education); and (2) two brief screening tests, (a) a clock-drawing task (score range, 0-15; higher score=better performance) and (b) the Trail Making Test (TMT) B task (time in seconds, faster time=better performance). An additional 236 participants completed virtual study visits (10/2020-11/2021), which included NIH Toolbox episodic and working memory modules only. Descriptive statistics were calculated for all measures and the adjusted associations of various participant characteristics with the overall fluid cognition score were assessed with multivariable linear regression. Scatterplots and pairwise correlations were used to estimate relationships between cognitive functioning measures.

Results: The mean adjusted overall fluid cognition T-score was 45.3, ~0.5 SD below the general population mean; 31% participants scored < 40 (>1 SD below the mean), suggesting impairment. The mean score for attention and inhibitory control was nearly 1 SD below average (**Figure 1**). Adjusted fluid cognition T-scores were not associated with age, race, ethnicity, or gender, but those who had a high school education or less *vs*. having a college degree or higher had 5.3 points (>0.5

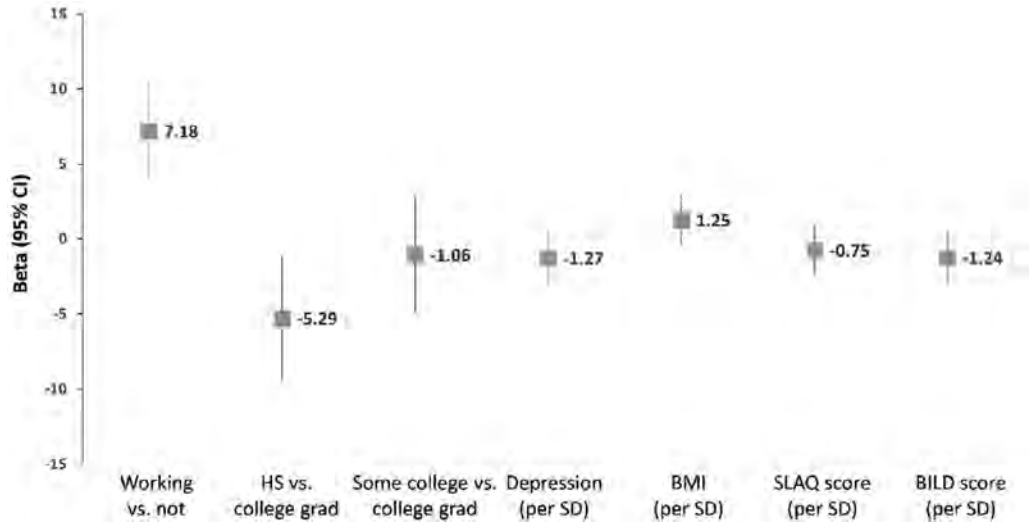

Figure 2. Adjusted differences in fluid cognition T-score by individual characteristics. HS, high school; BMI, body mass index; SLAQ, SLE Activity Questionnaire; BILD, Brief Index of Lupus Damage.

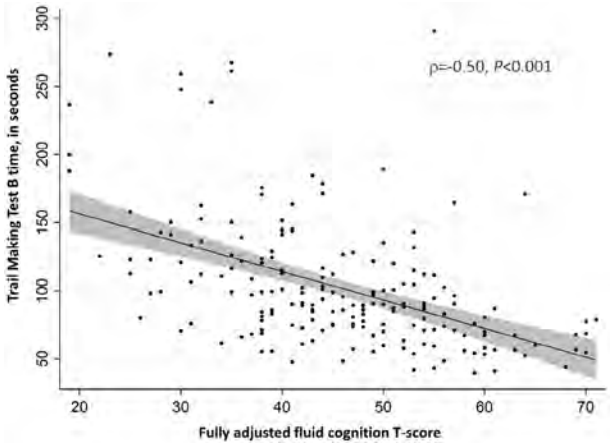

Figure 3. Scatterplot of Trail Making Test B time vs. fully adjusted fluid cognition T-Score. Line, fitted values; shaded area, 95% CI.

SD) lower score. Current working status was associated with a 7.2-point higher adjusted T-score, while higher depression, SLE activity, and SLE damage scores were associated with slightly lower T-scores (not statistically significant; **Figure 2**). Clock score (median=14, interquartile range, 13-15) was weakly correlated with fluid cognition T-score (r=0.17, *P*=0.01), while TMT B time (median=90.3, interquartile range, 71.9-121.1 s) was moderately correlated with fluid cognition T-score (**-Figure 3**). Moreover, 2.5% of individuals did not complete the TMT B within 300 s, suggesting impairment.

Conclusion: Our results suggest individuals with SLE commonly suffer from deficits in fluid cognition, particularly attention and inhibitory control. Higher educational attainment and working status may be protective against impairment, but reverse causality may contribute to this observed pattern. Additionally, we found that multi-domain measurement of global fluid cognition among these individuals may provide nuanced information beyond that available from screening tasks that are designed primarily to detect impairment among older adults. Together, these results inform potential interventions to support cognitive function among individuals with SLE.

Session Type: Abstract Session

Session Time: 2:00PM–3:30PM

Background/Purpose: Cigarette smoking, textile dust, and occupational inhalants all strongly interact with the Human Leukocyte Antigen (*HLA*) shared epitope for risk of seropositive RA. Recently, we found preceding respiratory tract diseases including asthma, sinusitis, and interstitial lung disease (ILD) are associated with increased risk of RA. In addition, the *MUC5B* promoter variant was found to increase risk of RA-ILD. Therefore, we aimed (1) to identify gene by respiratory tract disease interactions associated with developing RA and (2) to determine the interaction between *MUC5B* and respiratory tract diseases for RA risk.

Methods: In this case-control study using a single center biobank, we identified incident RA cases, all confirmed by ACR/EULAR criteria. We matched each RA case to four controls on age, sex, and electronic health record (EHR) duration at index date of RA diagnosis (or assigned date for controls). Genetic exposures included an overall genetic risk score (GRS) including all genetic factors previously associated with RA, an *HLA* GRS for RA, and the *MUC5B* promoter variant. We dichotomized the GRSs into "high" and "low" risk by the highest tertile in controls. We obtained preceding respiratory tract diseases from diagnosis codes (positive predictive value 86%). We estimated attributable proportions (AP) and multiplicative odds ratios (OR) with 95% confidence intervals (CI) for RA for each genetic and preceding respiratory disease using conditional logistic regression models, adjusting for age, sex, EHR duration, enrollment year, genetic ancestry by principal components, education, body mass index, and smoking status and pack-years.

Results: We identified 653 incident RA cases and 2,607 matched controls (mean age 54 years, 76% female, Table 1). The highest tertile of the overall GRS and the *HLA* GRS were each associated with increased RA risk (OR 2.28, 95% CI 1.89,2.74; OR 2.02, 95% CI 1.67,2.45). ILD and high *HLA* interacted synergistically for RA risk (OR for both factors 4.30, 95% CI 1.28,14.38 vs. neither; AP 0.51, 95% CI-0.16,1.18; Figure 1). Asthma and the *MUC5B* promoter variant also interacted synergistically for seropositive RA risk (OR for both factors 2.58, 95% CI 1.10,6.07 vs. neither; AP 0.62, 95% CI 0.24,1.00; Figure 2). Aside from these two synergistic interactions, each GRS exhibited a negative, or "antagonistic,"

Table 1. Characteristics of the 653 incident RA cases and 2,607 matched controls with GWAS data and at least 5 years of EHR history

Characteristic	RA cases (n=653)	Controls (n=2607)	p-value
Age, years, mean (SD)	54 (13)	54 (12)	*
Female sex, n (%)	494 (76)	1971 (76)	*
EHR history in years, median (IQR)	12 (9,17)	12 (8,16)	*
Education college or higher, n (%)**	377 (58)	1882 (72)	<0.001
BMI, kg/m², mean (SD)	29 (7)	28 (6)	<0.001
Smoking status, n (%)**			<0.001
Never	320 (49)	1526 (59)	
Past	274 (42)	949 (36)	
Current	59 (9)	132 (5)	
Smoking pack-years, mean (SD)**	10 (20)	6.6 (13)	<0.001

BMI = body mass index, CI = confidence interval, EHR = electronic health record, GWAS = genome-wide association study, IQR = interquartile range, kg = kilograms, m = meters, RA = rheumatoid arthritis, SD = standard deviation
*Matching factors
**As of biobank enrollment

Figure 1. High HLA genetic risk score (GRS) and interstitial lung disease (ILD) interact synergistically for RA risk (reference group=low GRS/ILD absent).

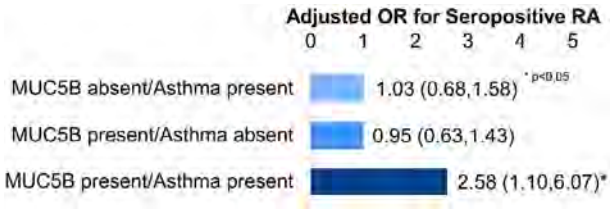

Figure 2. MUC5B promoter variant and asthma interact synergistically for seropositive RA risk (reference group=MUC5B absent/asthma absent).

multiplicative interaction with any respiratory tract disease and sinusitis for RA risk (multiplicative ORs 0.80, 95% CI 0.68,0.94 and 0.73, 95% CI 0.55,0.96, respectively, for the overall GRS).

Conclusion: In summary, ILD in the presence of *HLA* risk alleles and asthma in the presence of the *MUC5B* promoter variant were both synergistically associated with developing RA. Future studies should replicate these findings, as they may prove useful for RA screening (i.e. testing for *HLA* in individuals with ILD) and prevention (i.e. close monitoring for RA in people with asthma who have the *MUC5B* promoter variant).

SESSION INFORMATION

Session Date: Tuesday, November 14, 2023
Session Title: Abstracts: Epidemiology & Public Health II
Session Type: Abstract Session
Session Time: 2:00PM–3:30PM

Background/Purpose: Clonal hematopoiesis (CH), the clonal expansion of somatically mutated blood cells in people without hematologic malignancy, is found in ~10% of people age ≥ 70 years. CH genetic mutations confer selective advantage to stem cells. Several have been associated with aging and increased production of inflammatory cytokines, as well as with increased risk of cardiovascular disease (CVD) and malignancy. In population studies, somatic mutations in the epigenetic regulatory genes *DNMT3A, TET2,* and *ASXL1* predominate. We hypothesized that CH may be related to risk of rheumatoid arthritis (RA), which increases with age and is characterized by systemic inflammation.

Table 1. Characteristics of the UK Biobank study population with Whole Exome Sequencing Data (N= 189,947)[a]			
	RA n=1,592	No Incident RA N = 188,355	p[c]

[a] Restricted to unrelated individuals in 200K UK Biobank exomes tranche with unrelatedness defined as < 3rd degree relatedness
[b] Metrics represented as mean (standard deviation, SD) for continuous variables; % (n) for categorical variables. Clinical conditions occurring prior to enrollment.
[c] t-test or Chi square test, *p< 0.05, **p < 0.01, ***p < 0.001, ns= p> 0.05

Methods: We tested this hypothesis in the UK Biobank *Exomes* dataset. The UK Biobank prospective study consists of 502,543 adults recruited 2006-2010 from 22 UK centers. All participants provided consent for linkage to medical records and blood samples. At baseline visit, demographic and clinical variables were collected, as was blood for DNA. Both genome-wide genotyping and whole exome sequencing (WES) were performed on ~ 200,000 participants' DNA. We identified the 3 most common CH somatic mutations: *DNMT3A, TET2,* and *ASXL1*. We assessed both variant allele fraction (VAF) > 2% and >10%. We identified RA by a validated billing code algorithm and tested associations with incident RA (individuals without prevalent RA and not taking any RA disease-modifying drugs at enrollment). We compared baseline characteristics of individuals who developed incident RA to those who did not. Cox regression models estimated hazards ratios

Table 2. Clonal Hematopoiesis Mutation and Risk of Incident RA among unrelated Participants in the UK Biobank study population with Whole Exome Sequencing Data (N= 189,947)[a]			
		Incident RA vs. non-RA[a]	
	Model[b]	HR (95% CI)	p[c]

[a] Study population included 189,947 unrelated individuals in UK Biobank without RA at baseline. Logistic regression models were used for calculating the ORs for all cases
[b] Model 1 adjusted for age at baseline, sex, race, genotyping array and first 10 genetic principal components
Model 2 adjusted for covariates in model 1 and smoking status, body mass index, history of diabetes mellitus and cardiovascular disease at baseline
[c] *p< 0.05, **p < 0.01, ***p < 0.001, ns= p> 0.05
VAF: variant allele frequency; HR: hazard ratio; CI: confidence interval

(HR) for incident RA according to the presence of the 3 most common CH mutations. Model 1 adjusted for baseline age, sex, race, and 1st 10 genetic principal components. Model 2 additionally adjusted for baseline smoking, body mass index (BMI), CVD, and type 2 diabetes.

Results: We studied 189,947 unrelated individuals in UK Biobank without RA at baseline and identified 1,592 who developed incident RA. **Table 1** shows the baseline characteristics of those with and without incident RA. Those with incident RA were more likely to be female, more frequently reported a smoking history, had higher median BMIs, and were more likely to have prevalent CVD, type 2 diabetes, and hypercholesterolemia. *TET2* mutations were present in significantly higher proportions of the incident RA population. **Table 2** presents the results of adjusted regression models: *TET2* (VAF >2%) was associated with increased HR of developing RA (model 1 HR 1.60 [1.13, 2.27]). Further adjustment for lifestyle risk factors and comorbidities was associated with attenuated HR for RA (model 2 HR 1.49 [95%CI 1.03, 2.18]). Having *TET2* mutation with VAF >10% was also associated with increased RA risk (model 1 HR 1.54 [1.01, 2.34]).

Conclusion: The CH mutation *TET2* may be related to risk of RA, as it is for other diseases of inflammation and aging. As *TET2* increases interleukin-1beta (IL-1β) expression in mouse models, it may accelerate RA onset. *TET2* CH may also be related to the increased risk of cancer and CVD among patients with RA. These findings are being pursued and analyses replicated in other cohorts.

Assessment of Association Between Hydroxychloroquine Use and Toxic Retinopathy, Overall and by Indication, in a Large Cohort of Rheumatology Patients Within the US Department of Defense Military Healthcare System

Rachel Robbins[1], Toni Rush[2] and Jess Edison[3], [1]Walter Reed National Military Medical Center, Germantown, MD, [2]Health Research Tx, Pace, FL, [3]Uniformed Services University of the Health Sciences / National Capital Consortium-Walter Reed Bethesda, Bethesda, MD

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: Abstracts: Epidemiology & Public Health II
Session Type: Abstract Session
Session Time: 2:00PM–3:30PM

Background/Purpose: While generally believed to be a safe, well-established treatment, hydroxychloroquine (HCQ) use is associated with irreversible retinal toxicity requiring regular monitoring. The objective of the study was to assess the association between HCQ and retinopathy in a rheumatology cohort and by indication utilizing a large longitudinal database.

Methods: Between January 1, 2011, to December 31, 2019, all rheumatology patients 18 years of age and older were identified within the DoD healthcare system. Patients were assigned exposure status by defining hydroxychloroquine (HCQ) utilization accessing pharmacy dispensing data using an intent-to-treat approach. Prior toxic retinopathy was an exclusion criteria. Propensity score (PS) matching (1:1) was used to create study cohorts balanced on baseline covariates, including indication in the overall cohorts. In the indication specific analyses, PS estimation and matching were performed in cohorts stratified by indication. Cox proportional regression modeling was used to estimate the hazard ratios of toxic retinopathy after exposure to HCQ among overall rheumatology cohorts as well as for rheumatoid arthritis (RA) and systemic lupus erythematosus (SLE). All analyses were stratified by sex. A systematic algorithm was used to assign rheumatologic HCQ indication based on ICD-9/10 diagnostic codes assessed in claims data. Patients with diagnostic codes for a single rheumatologic condition were assigned that indication. If a patient had diagnostic codes for more than one rheumatologic condition, the indication with the most diagnostic codes was the defined indication. If one of the conditions was Sjögren's, then the condition other than Sjögren's, e.g., RA, was the assigned indication regardless of the count of diagnostic codes. SLE took precedence as the indication when diagnostic codes for both SLE and discoid lupus were present.

Results: All HCQ patients were matched to non-HCQ users. In the overall female cohort (n=88,120), patients had a mean age 55.7 (sd 16.6) and a median follow-up time 3.9 yr (IQR 1.9-6.2) and patients in the male cohort (n=19,946) had a mean age 60.8 (sd 16.0) and a median follow-up time 3.7 yr (IQR 1.8-6.1). In both cohorts, HCQ use was significantly associated (p< .0001) with retinopathy (Figure 1 & 2) with events occurring consistently more frequently in the HCQ cohorts. Female and male patients exposed to HCQ had a higher risk of retinopathy compared to non-exposed (HR 1.49, 95% 1.39,1.60; p< .0001; HR 1.47, 95% 1.26,1.72; p< .0001; respectively). For indications, HCQ use was significantly associated with retinopathy with variability seen within sex. The female RA cohort had an HR 1.41 (95% CI 1.28, 1.54; p< .0001) while the female SLE cohort had an HR 1.68 (95% CI 1.46, 1.94; p< .0001).A similar pattern was seen in the male cohorts, RA with HR 1.45 (95% CI 1.21, 1.74; p< .0001) and SLE with HR 2.02(95% CI 1.37, 2.96;p=0.0004) (Table 1).

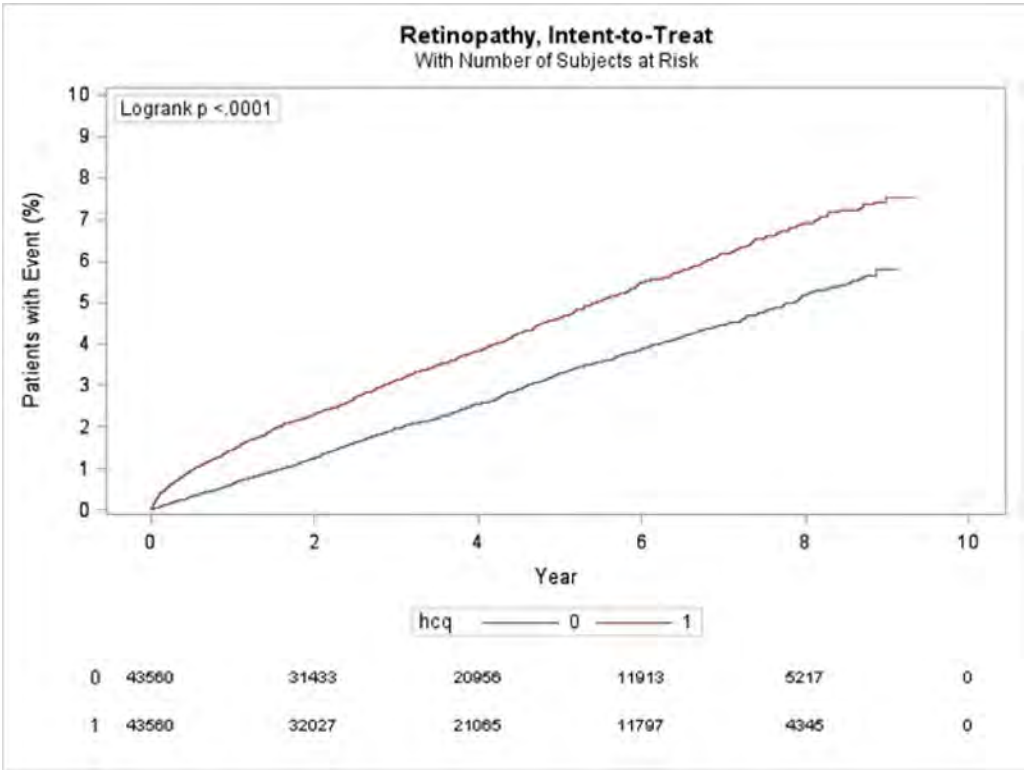

Figure 1.Kaplan Meier curve for Toxic Retinopathy in Overall Rheumatology Female Cohort by HCQ status

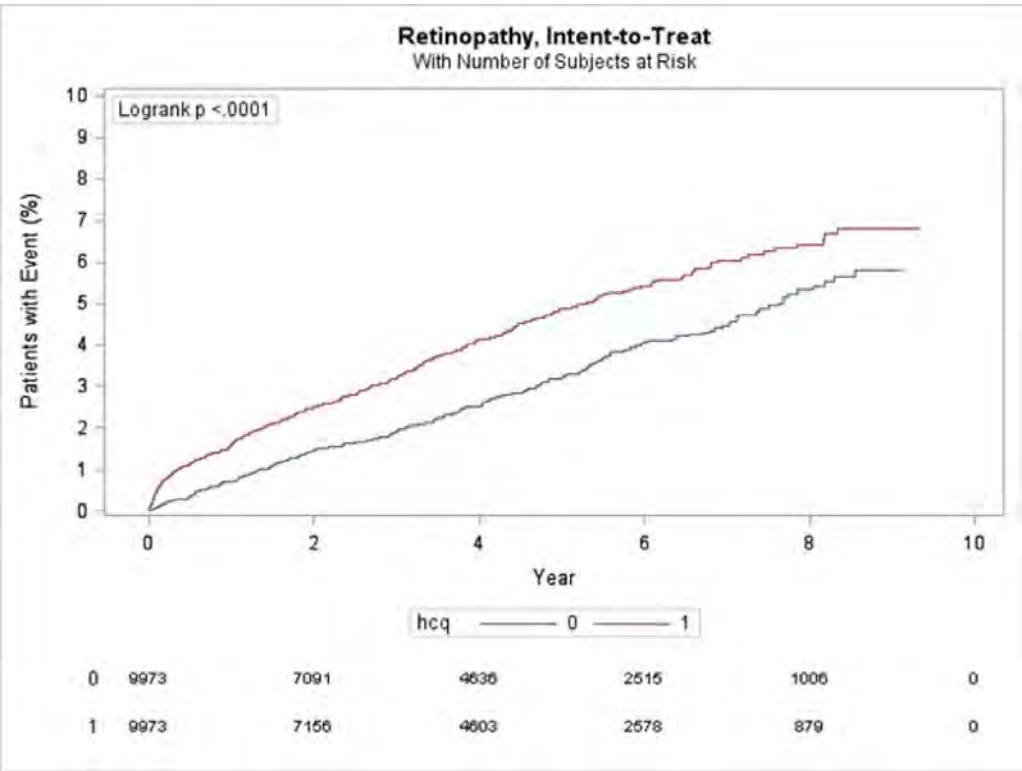

Figure 2. Kaplan Meier curve for Toxic Retinopathy in Overall Rheumatology Male Cohort by HCQ status

Conclusion: This uniquely large cohort of HCQ users reveals a risk of retinopathy that varies by sex and indication. The potential for serious ophthalmologic toxicity over the period studied emphasizes the importance of close ophthalmologic monitoring in the context of rheumatic disease where long term use is common.

Table 1.

Hazard Ratio of Toxic Retinopathy Associated with HCQ Utilization in a Cohort of Adult FEMALE Rheumatology MHS Patients DoD Database Jan 01, 2011 – Dec 31, 2019

		HCQ				Hazard Ratio

Abstract Number: 2453

Development of a Hydroxychloroquine Retinopathy Prediction Score

April Jorge[1], Ronald Melles[2], Baijun Zhou[1], Yuqing Zhang[3] and Hyon K. Choi[4], [1]Massachusetts General Hospital, Boston, MA, [2]Kaiser Permanente Northern California, Redwood City, CA, [3]Division of Rheumatology, Allergy, and Immunology, Department of Medicine, Massachusetts General Hospital, Boston, MA, [4]Massachusetts General Hospital and Harvard Medical School, Lexington, MA

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: Abstracts: Epidemiology & Public Health II
Session Type: Abstract Session
Session Time: 2:00PM–3:30PM

Background/Purpose: Hydroxychloroquine (HCQ) is an important medication for SLE and other rheumatic diseases, but its major adverse event is HCQ retinopathy. Weight-based HCQ dose is known to influence the risk of retinopathy, but other risk factors have also been identified. We explored predictive models for HCQ retinopathy and developed a clinical risk score.

Methods: We used a longitudinal cohort of incident HCQ users enrolled in the United States integrated health network Kaiser Permanente Northern California. HCQ retinopathy outcomes were obtained by masked expert-adjudication of optical coherence tomography screening studies, as previously described (Melles RB, Jorge A, *Ann Int Med* 2023). Among patients using HCQ for at least 5 years, we assessed candidate predictors at 5 years of use including the weight-based HCQ dose, cumulative dose in the first 5-years, age, sex, race/ethnicity, biometrics, indication for HCQ use, comorbidities including diabetes, liver disease, estimated glomerular filtration rate (eGFR), tamoxifen use, and use of inhibitors of cytochrome P450 CYP2D6, CYP2C8, or CYP3A4. We used Cox proportional hazards regression, using backwards stepwise selection to develop a parsimonious model, and an alternate method of random survival forest (RSF) to identify predictors of the 10-year risk of HCQ retinopathy (i.e., risk within 15 years from HCQ initiation). We created a comparator model using HCQ dose alone (weight-based dose at 5 years: > or ≤ 5 mg/kg). We assessed model discrimination with c-statistics, assessed model calibration using the Hosmer-Lemeshow statistic, and graphed deciles of predicted vs observed risk. We then developed an integer-based risk score from the optimal Cox model. Continuous variables were converted to categorical variables. We assessed net reclassification improvement and integrated discrimination improvement between the integer-based risk score and comparator model with HCQ dose alone.

Results: Of 4,151 patients who initiated HCQ and continued for ≥5 years, 119 developed HCQ retinopathy within 15 years (**Table 1**). The final Cox model had better discrimination than the RSF model and than HCQ dose alone (C-statistic 0.80 [95% CI 0.77-0.83] versus 0.62 (95% CI 0.53-0.70) for the RSF model and 0.72 [95% CI 0.68-0.77] for the HCQ dose-only model. From the identified predictors in this model, an integer-based risk score for 10-year risk of HCQ retinopathy was created: B-SAFE (Body weight [kg], Sex, Age, glomerular Filtration rate, Exposure (cumulative dose in first 5 years since initiation [g] and current weight-based dose [mg/kg/day]). The B-SAFE model c-statistic was 0.78 (95% CI 0.75=0.82) with acceptable calibration (**Figure 1**). Compared with the HCQ dose-only model, the net reclassification index was 0.34 (95% CI 0.20-0.46). The risk score ranged from 0-33 points and can identify patients with HCQ retinopathy risk ranging from < 1% to >20% (**Figure 2**).

Conclusion: In addition to weight-based HCQ dose, we identified additional predictors of HCQ retinopathy. These clinical and laboratory variables were incorporated into a novel risk score that performs better than HCQ dose alone in predicting the 10-year risk of HCQ retinopathy among long-term users.

Table 1. Characteristics of the Study Participants With and Without Incident Hydroxychloroquine Retinopathy Within 15 Years of Use, Assessed at 5 Years of Use

Characteristics	Overall (N =4151)	No Retinopathy During Follow-up (N= 4032)	Incident Retinopathy During Follow-up (N= 119)	P value
Age, years, mean (SD)	58.0 (14.1)	57.8 (14.1)	63.4 (11.6)	<0.001
Age category, n (%)				<0.001
Age <50	1119 (27.0)	1108 (27.5)	11 (9.2)	
Age 50-59	1037 (25.0)	1010 (25.0)	27 (22.7)

Endometriosis Increase Risk of Antiphospholipid Syndrome: A Propensity Score Matched Cohort Study

Zhiyong Chen[1], Shiow-Ing Wang[2], James Cheng-Chung Wei[3] and **Sheng-Ming Dai**[1], [1]Department of Rheumatology and Immunology, Shanghai Sixth People's Hospital, School of Medicine, Shanghai Jiao Tong University, Shanghai, China, [2]Institute of Medicine, College of Medicine, Chung Shan Medical University, Taichung, Taiwan, [3]Chung Shan Medical University Hospital, Department of Rheumatology, Taichung, Taiwan

SESSION INFORMATION

Session Date: Tuesday, November 14, 2023

Session Title: Abstracts: Epidemiology & Public Health II

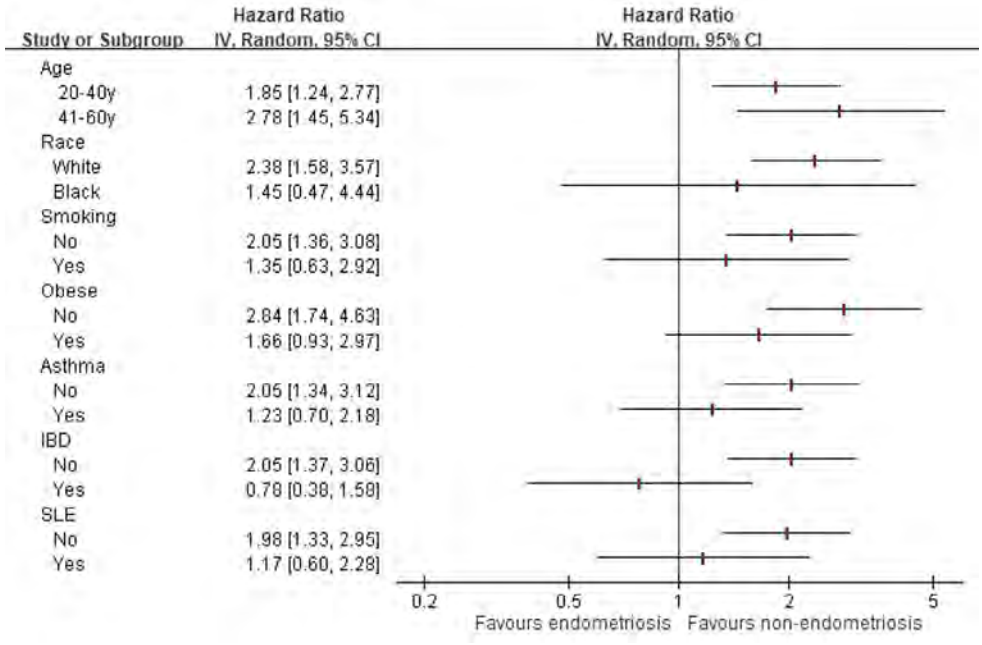
Session Type: Abstract Session

Session Time: 2:00PM–3:30PM

Background/Purpose: Patients with endometriosis have a variety of autoimmune abnormalities. Our objective was to investigate the risk of incident antiphospholipid syndrome (APS) in patients with endometriosis.

Methods: A retrospective cohort study was conducted using the US TriNetX (Cambridge, MA), a global federated health research network that provides real-time electronic medical record datasets. Propensity score matching was performed to adjust for demographic variables, comorbidities, and medication use. Cox proportional hazards models and subgroup analyses were used to estimate hazard ratios (HRs) for APS. The Kaplan–Meier method was used to plot the cumulative incidence curves. Subgroup analyses were also conducted, including age, obesity, and systemic lupus erythematosus (SLE). A sensitive analysis stratified by surgery confirmed endometriosis was performed.

Results: We identified50,078 patients with endometriosis among 16,602,603 female adults (20-60y) patients in the database. After propensity matching, 50,078 patients without endometriosis were analyzed for comparison. Compared to individuals without endometriosis, patients with endometriosis had a significantly higher risk of incident APS throughout the



Forest plot of subgroup analysis

course of endometriosis (log rank test, $p < 0.001$). The HRs ranged from 1.82 (APS within 30 days to 1 year after index date, 95% confidence intervals [CI] 1.40–2.53) to 2.44 (APS within 30 days to any time after the index date, 95% CI 1.65–3.61). In the subgroup analyses, an increased risk of APS was observed in all ages, white race, and subgroups without smoking, obesity, asthma, inflammatory bowel disease, and SLE (HR range 1.85–2.84). Sensitivity analyses revealed that risk of APS increased significantly in patients with surgery confirmed endometriosis, but not in patients without surgery confirmed endometriosis.

Conclusion: Patients with endometriosis had a significantly higher risk (up to 284%) of APS. Our study provides strong evidence for the screening of APS in patients with endometriosis.

Addressing Native American Health Disparities in Rheumatoid Arthritis by Training Primary Care Providers: Expanding the Reach of the RAE Initiative

Jennifer Mandal[1], Zara Izadi[1], Tabitha Carroway[1], Gwendolyn Grant[2], Mary Margaretten[1] and Jinoos Yazdany[1], [1]University of California San Francisco, San Francisco, CA, [2]Centura Health, Durango, CO

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: Abstracts: Healthcare Disparities in Rheumatology
Session Type: Abstract Session
Session Time: 2:00PM–3:30PM

Background/Purpose: The United States faces a critical shortage of rheumatology providers. This shortage is especially dire in rural areas, such as Navajo Nation, where primary care providers (PCPs) are often in the position of managing their patients' rheumatologic conditions with little or no specialist support. Rheumatology training programs for front-line PCPs are an important and under-utilized strategy to help address the workforce crisis. In 2021, the Rheumatology Access Expansion (RAE) Initiative launched the Rheumatoid Arthritis (RA) ECHO, a remote 12-week training program to teach Navajo Area PCPs about the diagnosis and management of RA. We successfully offered the RA ECHO curriculum three times on Navajo Nation from 2021-2022. For our fourth cohort (spring 2023), we greatly expanded our target audience, inviting healthcare workers serving American Indian communities all across the country. Here, we present data from the first four cohorts of the RA ECHO, including the impact of the program on PCPs' knowledge, confidence, and clinical behaviors related to the diagnosis and management of RA.

Methods: Between September 2021 and April 2023, we offered the RA ECHO Curriculum four times ("cohorts 1-4"). PCPs completed surveys before and after the course, including a RA medical knowledge test, as well as questions about their self-reported confidence in RA diagnosis and management on a Likert scale (1 = not at all confident, to 5 = extremely confident). Beginning with cohort 3, we also included questions about participants' self-reported changes in clinical behaviors related to RA (for example, the frequency with which they perform a screening joint exam for tenderness and synovitis, or check hepatitis serologies prior to starting immunosuppression). Pooling data across the cohorts, we used paired t-tests to assess mean changes in PCPs' knowledge and confidence scores post-intervention.

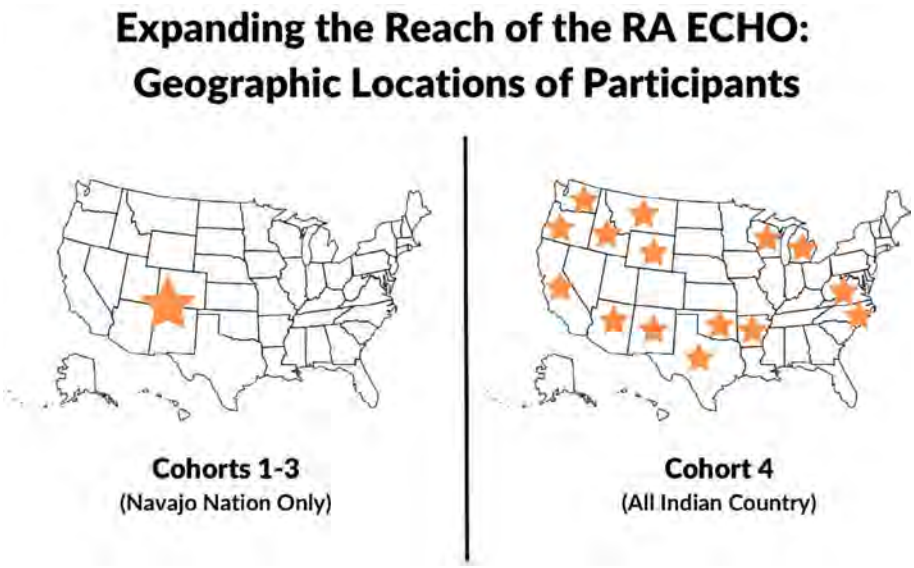

Figure 1: Geographic locations of PCP participants, separated by cohort.

Results: In total, 93 healthcare providers participated in the RA ECHO. Participants in cohorts 1-3 were all from Navajo Nation, while participants in cohort 4 came from 15 different states (Figure 1). Across all cohorts, paired pre- and post-intervention scores were available for a total of 32 and 34 PCPs for the knowledge and confidence surveys, respectively. Statistically significant improvements were observed in participants' knowledge (test scores increased by 26%, 95% CI: 19%-33%) and confidence (1.08 points on the Likert scale, 95% CI: 0.75-1.41) (Figure 2). Additionally, 79% of respondents

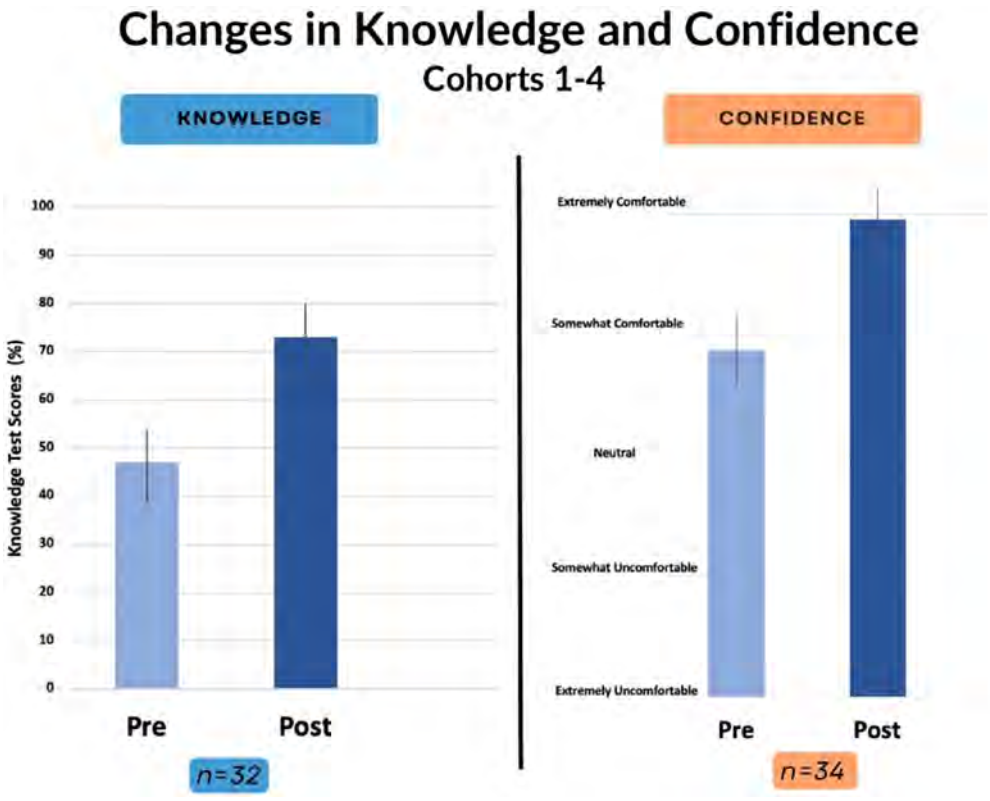

Figure 2: Changes in participants' knowledge and confidence related to RA diagnosis and management (pooled data for cohorts 1-4).

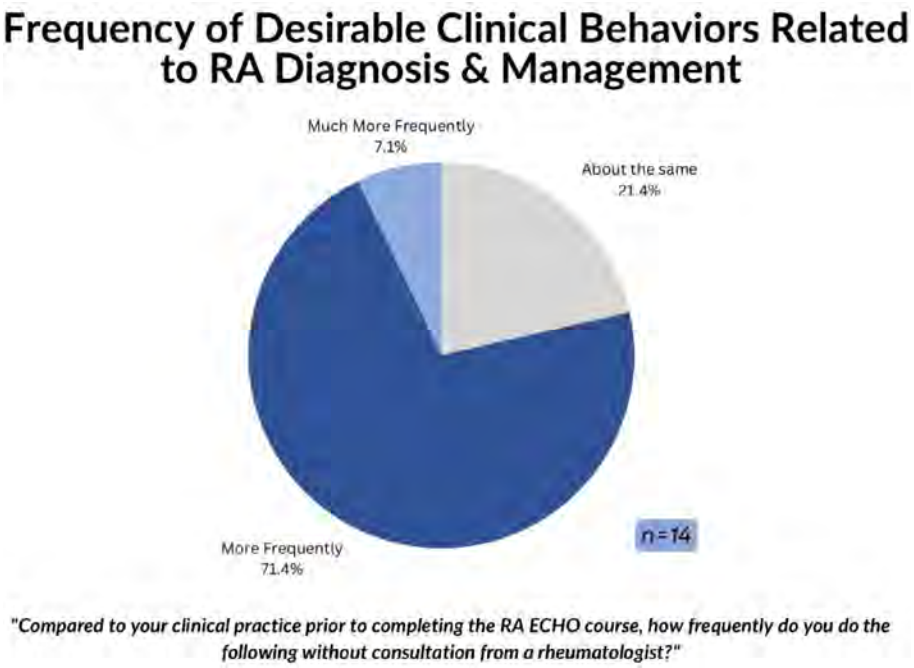

Figure 3: Self-reported changes in the frequency of desirable clinical behaviors related to RA diagnosis and management, from participants in cohorts 3 and 4.

reported performing desirable clinical behaviors related to RA diagnosis and management "more frequently" or "much more frequently" after completing the course (Figure 3).

Conclusion: Since 2021, the RAE Initiative has successfully trained 4 cohorts of PCPs through the RA ECHO Curriculum, and we've expanded the reach of the program far beyond Navajo Nation. Participants improved their medical knowledge, confidence, and self-reported frequency of desirable clinical behaviors related to the diagnosis and management of RA. Future research will focus on the impact of the RA ECHO on patient outcomes. The RA ECHO can serve as a scalable model for the development of similar programs in other communities with limited access to rheumatology providers.

Lupus Patient Navigator Program to Improve Healthcare Barriers for Minority Patients

Samiha Karim[1], Gary Link[1], Dulaney Wilson[1], Jim Oates[1], Gary Gilkeson[1], Jasvinder Singh[2] and Diane L. Kamen[1], [1]Medical University of South Carolina, Charleston, SC, [2]University of Alabama at Birmingham, Birmingham, AL

SESSION INFORMATION

Session Date: Tuesday, November 14, 2023
Session Title: Abstracts: Healthcare Disparities in Rheumatology
Session Type: Abstract Session
Session Time: 2:00PM–3:30PM

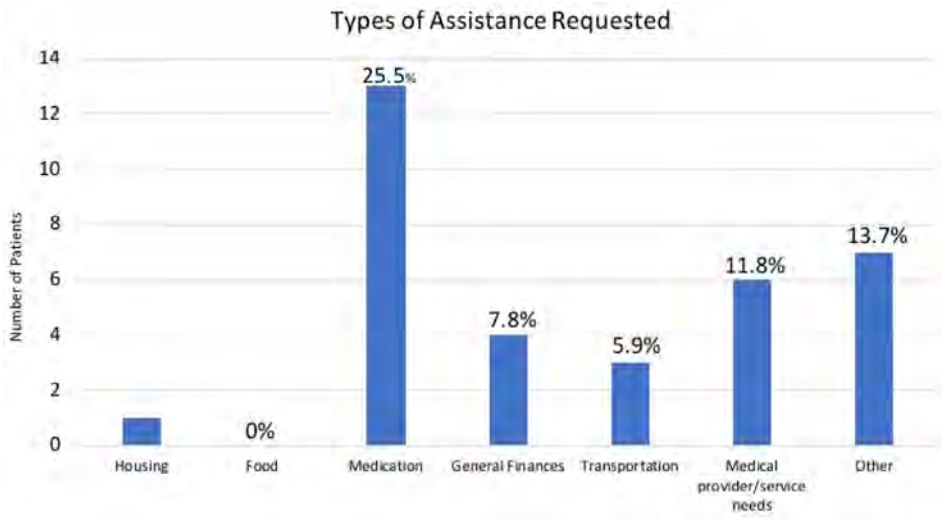

Figure 1. Participants in the LPNP requested multiple types of assistance from the PN during baseline visit. 56.9% patients asked for assistance, all of which asked for assistance for themselves rather than for their spouse or family. 25.5% requested assistance with medications followed by the other category, which included including help with appointment and medication reminders.

Background/Purpose: Despite recent progress in diagnosis and treatment of SLE minorities continue to bear the greater burden of disease with disproportionately higher morbidity and mortality. Barriers to care include access to preventive and specialty healthcare, economic resources, and health literacy. The goal of this study is to measure the impact and acceptability of a Lupus Patient Navigator Program (LPNP) providing interventions to reduce barriers to care for patients at high risk of poor outcomes.

Methods: Self-identified minority patients with SLE ≥18 years old at Medical University of South Carolina or University of Alabama were invited to participate if they were prescribed ≥1 immunosuppressant, and: 1) had ≥1 missed clinic or lab visit in the past 6 months, or 2) nonadherence to medical therapy, or 3) newly diagnosed SLE. The LPNP is modeled after the CDC STEPS to CARE toolkit. Participants had visits with the patient navigator (PN) every 3 months with monthly and as-

Table 1: There is a greater positive improvement in patient's QoL in those that are unemployed/disabled compared to employed/student.

Employment Effects on LupusPro Over 6 months

	Employed/Student	Unemployed/Disability	P-value

Coping	4.58±29.7	-1.11±16.5	0.46
Satisfaction with Care	-13.75±24.4	1.9±11.9	*0.014

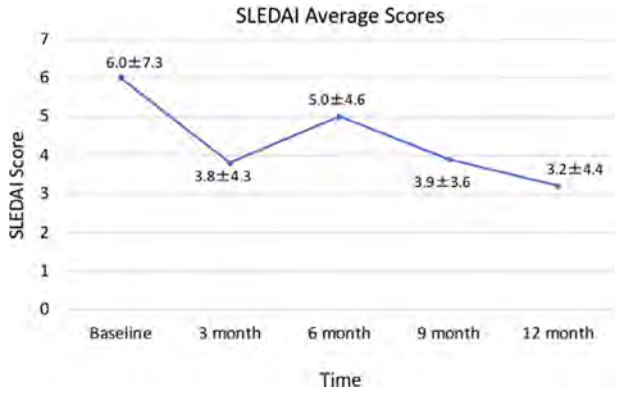

Figure 2. 42 patients at baseline visit completed SLEDAI questionnaires. SLEDAI scores from baseline to 1 year, visits are still ongoing. P-value 0.06 from baseline to 1 year.

needed check-ins by phone or email, with resources provided throughout the 12-month study duration. Patient-reported questionnaires included Type of Assistance Requested, LupusPRO for quality of life (QoL), SLEDAI, and Patient Satisfaction with Logistical Aspects of Navigation / Interpersonal Relationship with Navigator (PSN-L, PSN-I) Scales.

Results: 51 patients (96% female, 96% Black) with SLE completed at least 6-months, and 44 to date have completed 12-month assessments. Of the 51 patients, 90% were high school graduates, 86% had health insurance, 48% were unemployed/disabled, 33% were currently employed. A wide range of types of PN assistance were requested (**Figure 1**), with assistance with medications being most common at 25%. In addition, LupusPRO measures improved from baseline to the 6-month visit in most QoL domains. Results demonstrated a greater positive improvement in patient's QoL in those that are unemployed/disabled compared to employed participants (**Table 1**). SLEDAI scores from baseline to 1 year also improved from an average of 6.0 to 3.2 (**Figure 2**). Lastly, patients were satisfied with assistance received from the patient navigator in areas such as receiving/interpreting medical information and obtaining resources as indicated in the PSN-L, PSN-I Scales.

Conclusion: Implementation of a LPNP shows promise in addressing significant barriers to care for patients with SLE at high risk for poor outcomes, with participants to date reporting improved QoL and high satisfaction with the PN.

Ageism in Rheumatology: The Health Care Professional's Perspective

Aaron Smith[1], Pooja Achanta[1] and Una Makris[2], [1]UT Southwestern, Dallas, TX, [2]UT Southwestern Medical Center and Dallas VA, Dallas, TX

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: Abstracts: Healthcare Disparities in Rheumatology
Session Type: Abstract Session
Session Time: 2:00PM–3:30PM

Background/Purpose: Ageism (stereotypes, prejudice or discrimination based on age) is highly prevalent and has been linked to reduced lifespan, prolonged disability, and accelerated cognitive decline in older adults. Very little is known about ageism within the field of rheumatology. The aim of this study is to understand ageism among rheumatology health care professionals and to assess how ageism affects rheumatologic care.

Methods: An English language REDcap survey, distributed over social media and email, included Likert scaled, multiple-response and free response questions related to the clinical care of older adults and the validated Expectations Regarding Aging (ERA-12) scale where higher scores indicate reduced stereotypical beliefs regarding aging. Spearman's rank correlation coefficients were calculated for the ERA-12 scores and the responses to the other Likert questions to assess the effects of ageism on self-reported rheumatologic care decisions.

Have you received any training specific to the care of older adults?	123 (67%)		60 (33%)		0.13581	0.06678

*n=162 for questions presented only to prescribers, n (%)

Results: Over 3 months, 183 surveys were completed by respondents around the world but predominantly in the US. The survey respondent median age was between 45-64, 61% were women, 73% were white and 51% had been in practice for >11 years (Table 1). Most respondents were physicians (79%), specializing in rheumatology (86%), and practicing in academic medicine (65%). The most challenging aspects of caring for older adults were reported to be multi-complexity (90%), polypharmacy (79%), insufficient visit time (53%) and patient financial limitations (45%). The most frequently reported differences in the care of older adults included reduced use of NSAIDs (83%) and decreased use of opioids (42%), with a minority of providers reporting that they manage older and younger adults the same (18%) (Table 2). The median ERA-12 score was 36 out of 48 indicating that respondents on average disagreed with the stereotypes regarding aging but did not strongly disagree. Table 3 shows higher ERA-12 scores (less ageist beliefs) were associated with greater enjoyment of the care of older adults (p=0.0046) and awareness of the Geriatrics 5Ms (p=0.00063). Lower ERA-12 scores were associated with believing that older adults are more demanding of attention (p=0.0034) and more concerned about the risks of medical therapy (p=0.0046) than younger adults. Lower ERA-12 scores were also associated with a shift from disease modifying therapy to symptom relief in older adults (p=0.00037).

Conclusion: Increased stereotypical thinking regarding aging is associated with self-reported changes to patient counseling, medical decision making, and perception of patient goals. This suggests that our biases regarding aging may affect how we care for older patients. Knowledge of the Geriatrics 5Ms was correlated with increased ERA-12 scores suggesting that increased awareness of aging principles may reduce these stereotypes and ultimately improve care for older adults. Further studies to quantify the effects of ageism on patient care and to assess the patient perspective on ageism in rheumatology are needed to identify interventions that can improve outcomes for this patient population.

Abstract Number: 2458

The Impact of Social Inequities on Presentation of Childhood-Onset Systemic Lupus Erythematosus (cSLE) at a Large Tertiary Center

Emily Beil[1], Eyal Muscal[2], Abiodun Oluyomi[3], Omar Rosales[3], Danielle Guffey[4], Marietta DeGuzman[1], Cagri Yildirim-Toruner[5], Andrea Ramirez[3] and Erin Peckham-Gregory[3], [1]Baylor College of Medicine / Texas Children's Hospital, Houston, TX, [2]Division of Rheumatology, Department of Pediatrics, Baylor College of Medicine, Houston, TX, [3]Baylor College of Medicine, Houston, TX, [4]Institute for Clinical and Translational Research, Baylor College of Medicine, Houston, TX, [5]Baylor College of Medicine, Texas Children's Hospital, Houston, TX

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: Abstracts: Healthcare Disparities in Rheumatology
Session Type: Abstract Session
Session Time: 2:00PM–3:30PM

Background/Purpose: The prevalence of childhood-onset SLE (cSLE) differs by racial/ethnic group. Yet, the role of social determinants of health (SDoH) in disease severity is not understood. We hypothesized that in an urban center with a large, diverse catchment area, SDoH influence the severity of cSLE at diagnosis.

Methods: We completed an IRB-approved retrospective review of 136 children newly diagnosed with cSLE between 1/1/18-5/31/22 at Texas Children's Hospital (TCH). We abstracted demographic, clinical severity characteristics (SLEDAI at diagnosis, inpatient or ICU admission, CNS, CYC therapy) and SDoH variables such as State Area Deprivation Index

(ADI; higher quartiles indicate greater deprivation), insurance status, distance to care, pollution burden, food accessibility, and social work consultation. Statistical analyses performed in Stata v15.1 and ArcGIS Pro2.2.

Results: Mean age at diagnosis was 13.4 years ± 3 SD, with 82.4% female, 52.9% Hispanic White (HW) and 25.7% non-Hispanic Black (NHB). Fourteen patients (10.3%) were uninsured (UI) and 50% had Medicaid (M) or Children's Health Insurance Program (CHIP). Half were diagnosed during inpatient admission (14% in the ICU). Average SLEDAI at diagnosis was 12.5 ± 7.1

*Based on USDA 2019 Flag for low-access tract: a tract with at least 500 people or 33% of the population living more than 1 mile (urban areas) or 10 miles (rural areas) from the nearest supermarket, supercenter or large grocery store
**Based on 2020 Environmental Protection Agency State-Based pollution scores
Abbreviations: ADI: Area Deprivation Index, TCH: Texas Children's Hospital, FQHC: Federally Qualified Health Center

SD; 48.5% had SLEDAI ≥12 (severe disease). Average ADI (%) was 45.7 ± 25.2 SD. Twenty-five percent lived in a census tract with low-access to supermarkets. The median pollution burden score decile was 7 (IQR 5-9). Social work was consulted in 80.1% (Table 1).

SLEDAI scores were higher in NHB and Biracial (BR) patients at presentation (BR 17.1, NHB 14.8, HW 11.5, Asian (A) 10.6, Non-Hispanic White (NHW) 8.5; *P*=0.01), Table 2. CNS involvement was highest among NHB children (NHB 17.1%, BR 10%, A 9.1%, HW 0%, NHW 0%; *P*=0.004). CYC was most often used in NHB and BR patients (NHB 25.7%, BR 20%, A 9.1%, HW 2.8%, NHW 0%; *P*=0.003). HW patients had the highest ADI (HW 54.3, NHW 42.7, BR 37.6, NHB 37.5, A 28.5; *P*=0.001) and live in lower food accessible neighborhoods (HW 35.7%, NHW 25%, NHB 11.4%, BR 11.1%, A 9.1%; *P*=0.035). NHWs travel further to TCH (NHW 99.3 miles, A 26.2, NHB 25.2, HW 24.1, BR 20.7; P< 0.001), live in less polluted neighborhoods (burden score BR 8, HW 8, NHB 7, A 6, NHW 3; *P*=0.021), and were less likely to have a social work consult (BR 100%, NHB 85.7%, HW 81.9%, A 63.6%, NHW 37.5%; *P*=0.01).

Conclusion: In children with cSLE drawn from a large urban catchment area, we observed an impact of non-modifiable (e.g., race/ethnicity) and modifiable (e.g, insurance status, access to care, food accessibility) factors on disease severity at presentation. Next steps include geospatial mapping to identify high-risk neighborhoods with a discordant number of cSLE patients, and targeting modifiable risk factors in these communities to improve patient experiences and outcomes.

Abstract Number: 2459

Reporting of Race and Ethnicity in Lupus Publications in High-impact Rheumatology Journals

Idil Eroglu, Hailey Baker, Mario Felix and Lisa Suter, Yale School of Medicine, New Haven, CT

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: Abstracts: Healthcare Disparities in Rheumatology
Session Type: Abstract Session
Session Time: 2:00PM–3:30PM

Background/Purpose: Reporting of race and ethnicity as social constructs is critical to highlight equity and diversity of study participants, with the knowledge that socio-economic factors can affect systemic lupus erythematosus (SLE) outcomes[1-3]. Currently, reporting of race and ethnicity in rheumatology journals is not standardized. Studies often report majority White populations without discussing racial disparities or how inequities lead to worse outcomes[4]. Recent guidance on reporting of race and ethnicity by JAMA highlights the importance of specifying who identified participant race and ethnicity, including the federal Office of Management and Budget (OMB) minimum categories (American Indian or Alaska Native, Asian, Black, or African American, Native Hawaiian or Other Pacific Islander, and White), and reasons for assessing race. Reviewing current reporting practices on race and ethnicity in rheumatology journals is essential to potentially identify areas of improvement, especially in SLE which has high proportions of racial and ethnic disparities[5]. Here, we assess the reporting of race and ethnicity in recent high-impact rheumatology publications on SLE research to analyze for adherence to these reporting recommendations.

Methods: Using the Scimago Journal & Country Rank, we identified *Annals of Rheumatic Diseases* and *Arthritis and Rheumatology as* the two highest-ranked rheumatology journals according to the Scimago Journal Rank. We identified all studies involving human subject data published between January 2020 – December 2022 with at least one author based in the U.S. using the following search terms to identify our publications: systemic lupus erythematosus (Libman sacks or Libman-sacks), (lupus or lupovisceritis or erythematodes visceralis or SLE), (United Status or USA), "2020", "2021", "2022". Manuscripts were excluded if they did not involve human subjects. A single researcher (I.E.) reviewed all studies on reporting of race, ethnicity, and various other socioeconomic variables.

Results: A total of 103 articles met our inclusion criteria and six studies were excluded. There were 24 prospective cohort studies, 22 retrospective cohort/case-control studies, 20 randomized control trials, 5 cross-sectional studies, 22 laboratory studies with patient samples, 9 genomic analyses using patient sequences, and one machine learning study using patient data. Among included studies, 96 (93%) included any demographic data, 70 (68%) reported race, 59 (57%) reported ethnicity. Of those that reported race, 56 (80%) had majority White participants and only 4 studies met OMB minimum reporting

criteria for race. Only 13 studies (13%) mentioned that racial and ethnic categories were patient-reported. Additionally, we observed that 24 studies included any comorbidities and 16 studies included various other SES factors.

Conclusion: Reporting of race and ethnicity is not standardized across SLE research in high-impact rheumatology journals, and the majority of publications are not meeting the JAMA guidelines for reporting race and ethnicity.

Health Care Segregation, but Not Metropolitan Area Segregation, Magnifies Racial Disparities in Hospital Outcomes of Pediatric Lupus

Joyce Chang[1], Jessica Liu[1], Laura Berbert[1], Edie Weller[1], Gabrielle Alonzi[1], Emily Smitherman[2], Pooja Patel[3], Mary Beth Son[4] and Karen Costenbader[5], [1]Boston Children's Hospital, Boston, MA, [2]University of Alabama at Birmingham, Birmingham, AL, [3]Ann and Robert H. SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: Abstracts: Healthcare Disparities in Rheumatology
Session Type: Abstract Session
Session Time: 2:00PM–3:30PM

Background/Purpose: Racial disparities and hospital-level variation in pediatric SLE (pSLE) outcomes are well described, but it is not known how the racial and ethnic composition of the populations hospitals serve contributes to these disparities. Using de-identified data, we evaluated whether hospital minority composition, a measure of health care segregation, or metropolitan statistical area (MSA)-level racial or ethnic segregation modify racial disparities in pSLE outcomes.

Methods: We linked data from the Pediatric Health Information System (2006–2021) for patients 5-26 years old hospitalized for SLE to MSA-level 2020 U.S. Census and American Community Survey data. Primary outcomes assessed at the patient level were intensive care unit (ICU) stays and adverse renal outcomes (end stage renal disease, dialysis, or transplant). Hospital Black racial composition and Hispanic ethnic composition were based on % of all admissions (any indication) reported by each hospital. MSA segregation was measured by census-derived Dissimilarity Index (DI) for Black/Non-Hispanic White (NHW) or Hispanic/Non-Hispanic segregation, reflecting evenness of spatial distribution of two groups across census tracts within an MSA. We compared indices using mixed effects logistic models with hospital-level random effects, adjusted for calendar period, sociodemographics, severity indicators, and hospital volume. We stratified hospitals by above or below the median for Black or Hispanic composition and by high or low Black/NHW segregation.

Results: Of 8125 patients (at 47 hospitals), 2293 (28%) ever required ICU care and 698 (9%) had an adverse renal outcome (Table 1). Higher hospital Hispanic composition, but not Black racial composition, associated with lower overall odds of ICU stay (OR 0.99 [0.986-0.996] per % increase). Significant Black vs. NHW disparity in ICU care was observed only at hospitals with high Black racial composition, whereas Hispanic vs. NHW disparities in ICU stay did not differ by hospital Hispanic composition (Fig 1).

Similarly, the magnitude of Black vs. NHW disparity in renal outcomes was larger at hospitals with high Black racial composition (OR 2.0 [1.4-2.8] vs. 1.7 [1.1-2.4]). Moreover, disparities in renal outcomes for Hispanic White vs. NHW children were only observed at hospitals with high Black racial composition (Fig 2A). We observed the opposite for Hispanic composition, where Hispanic White, Asian, and American Indian/Other vs. NHW disparities were only apparent at hospitals with low Hispanic composition (Fig 2B).

MSA-level DI was not significantly associated with either outcome. Black vs. NHW disparities did not differ by high (DI >0.6) vs. low MSA Black/NHW segregation (Fig 1C, 2C). No MSAs met criteria for high Hispanic/Non-Hispanic segregation.

Table 1. Patient, Hospital, and Metropolitan Area-Level Characteristics of Hospitalized Children with SLE

Annualized Inpatient Admission Volume, median (min, max)		5338 (1787, 13825)
Annualized SLE Inpatient Volume, median (min, max)		77 (11, 864)
Hospital Black Racial Composition (%), median (min, max)		19 (2, 67)
Hospital Hispanic Ethnic Composition (%), median (min max)		12 (1, 59)
Metropolitan Area-Level Covariates[Ł]		N=41
Highly Segregated Dissimilarity Index (>0.6) (Black vs. Non-Hispanic White), n(%)		3620 (45)
Less Well Integrated Dissimilarity Index (≥0.3) (Hispanic vs. Non-Hispanic), n(%)		7485 (92)
ICE[ǂ] Race (Black vs. Non-Hispanic White), median (min, max)		0.53 (-0.003, 0.79)
ICE Ethnicity (Hispanic vs. Non-Hispanic), median (min, max)		0.64 (0.03, 0.85)
ICE Income (Highest 80%ile vs. Lowest 20%ile), median (min, max)		0.06 (-0.07, 0.42)

*Includes 94 individuals with hospital-reported American Indian race

^Black racial composition could be determined for N=46 out of 47 hospitals (one withdrew data); Hispanic ethnic composition could be determined for N=45 hospitals (one outlier excluded for incomplete reporting of ethnicity)

Ł N=41 hospital city names could be mapped to a metropolitan statistical area (MSA)

ǂ Index of Concentration at the Extremes (ICE) ranges from -1 to 1, with more positive values representing a higher proportion of residents belonging to the most privileged group relative to the least privileged group

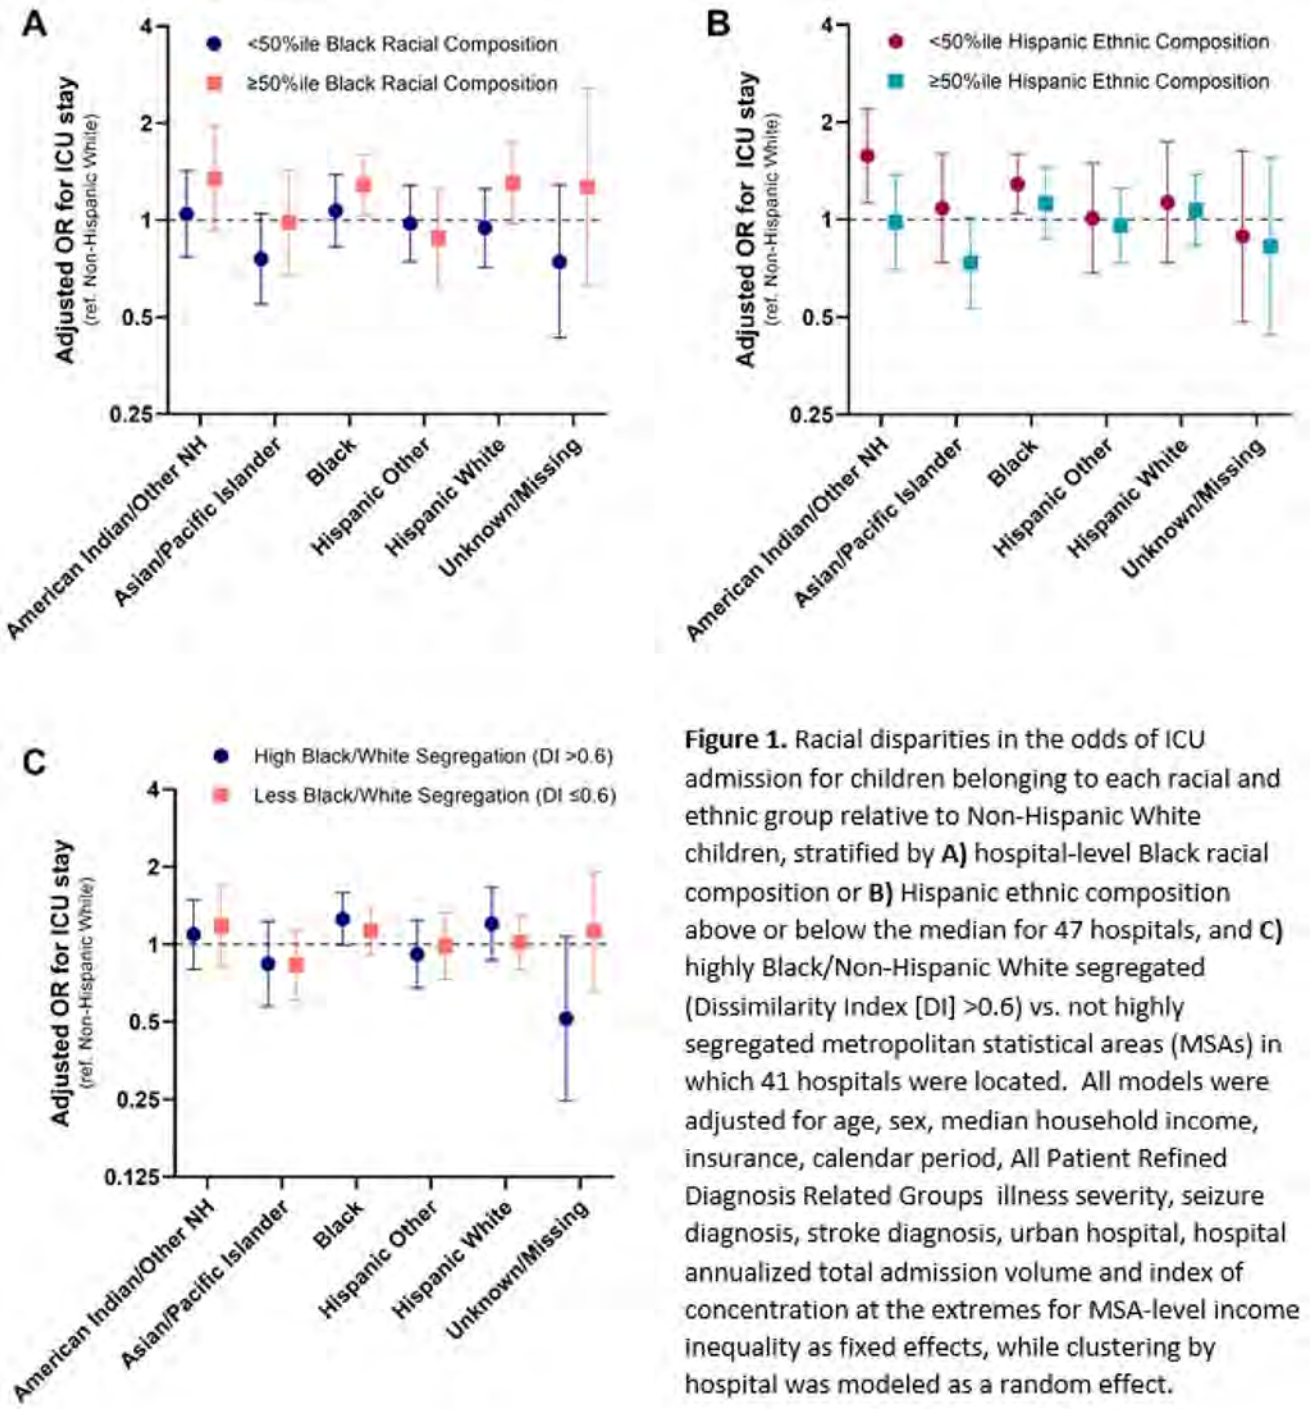

Figure 1. Racial disparities in the odds of ICU admission for children belonging to each racial and ethnic group relative to Non-Hispanic White children, stratified by **A)** hospital-level Black racial composition or **B)** Hispanic ethnic composition above or below the median for 47 hospitals, and **C)** highly Black/Non-Hispanic White segregated (Dissimilarity Index [DI] >0.6) vs. not highly segregated metropolitan statistical areas (MSAs) in which 41 hospitals were located. All models were adjusted for age, sex, median household income, insurance, calendar period, All Patient Refined Diagnosis Related Groups illness severity, seizure diagnosis, stroke diagnosis, urban hospital, hospital annualized total admission volume and index of concentration at the extremes for MSA-level income inequality as fixed effects, while clustering by hospital was modeled as a random effect.

Conclusion: Racial disparities in pSLE outcomes are magnified at hospitals serving a greater proportion of Black patients, which may reflect negative effects of health care segregation and inequitable hospital resources. Metropolitan level measures of segregation explain little variance in hospital outcomes, therefore linkages to small geographic units must be included in health care databases to understand local factors that contribute to poor outcomes.

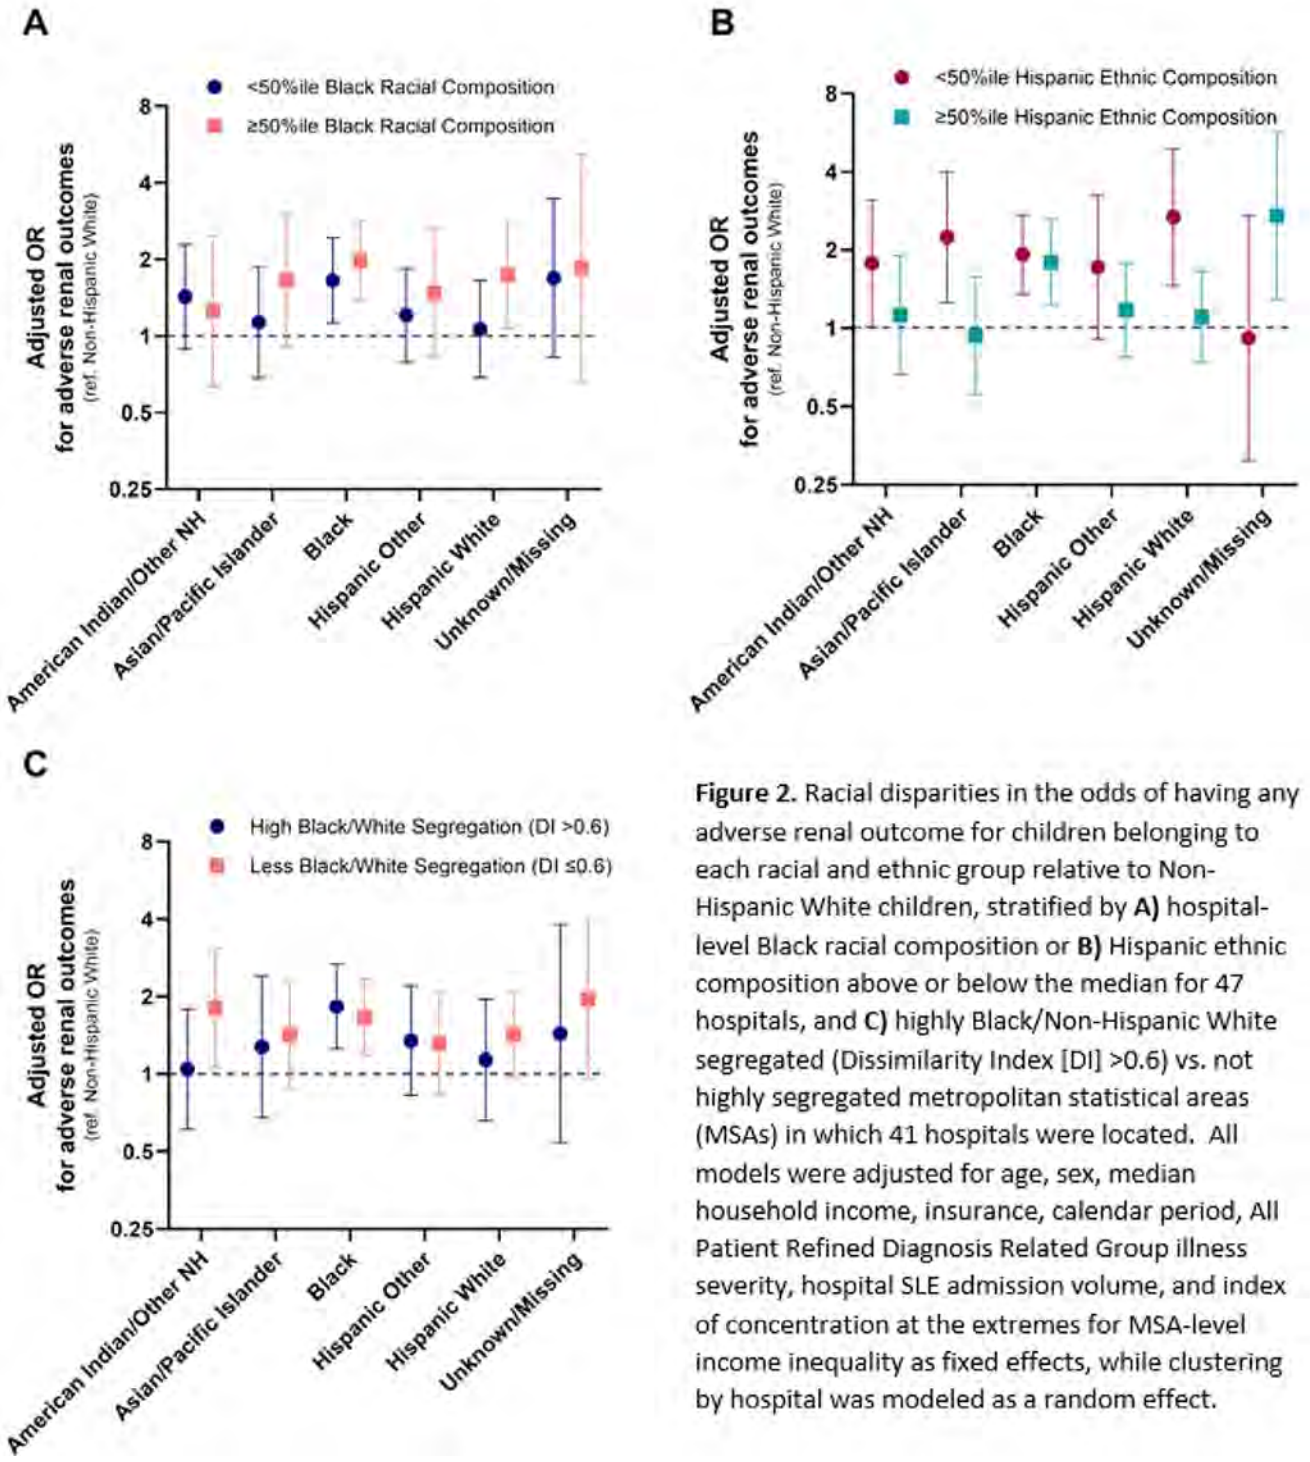

Figure 2. Racial disparities in the odds of having any adverse renal outcome for children belonging to each racial and ethnic group relative to Non-Hispanic White children, stratified by **A)** hospital-level Black racial composition or **B)** Hispanic ethnic composition above or below the median for 47 hospitals, and **C)** highly Black/Non-Hispanic White segregated (Dissimilarity Index [DI] >0.6) vs. not highly segregated metropolitan statistical areas (MSAs) in which 41 hospitals were located. All models were adjusted for age, sex, median household income, insurance, calendar period, All Patient Refined Diagnosis Related Group illness severity, hospital SLE admission volume, and index of concentration at the extremes for MSA-level income inequality as fixed effects, while clustering by hospital was modeled as a random effect.

SESSION INFORMATION

Session Date: Tuesday, November 14, 2023

Session Title: Abstracts: Muscle Biology, Myositis & Myopathies – Basic & Clinical Science I

Session Type: Abstract Session

Session Time: 2:00PM–3:30PM

Background/Purpose: Myositis is a heterogeneous family of diseases including dermatomyositis (DM), immune-mediated necrotizing myopathy (IMNM), antisynthetase syndrome (AS), and inclusion body myositis (IBM). Myositis-specific autoantibodies define different subtypes of myositis. For example, patients with anti-Mi2 autoantibodies targeting the CHD4/NuRD complex (a transcriptional repressor) have more severe muscle disease than other DM patients. This study aimed to define the transcriptional profile of muscle biopsies from anti-Mi2-positive DM patients.

Methods: RNA sequencing was performed on muscle biopsies (n=171) from patients with anti-Mi2-positive DM (n=18), DM without anti-Mi2 autoantibodies (n=32), AS (n=18), IMNM (n=54), and IBM (n=16) as well as 33 normal muscle biopsies. Genes specifically upregulated in anti-Mi2-positive DM were identified. Muscle biopsies were stained for human immunoglobulin and protein products corresponding to genes specifically upregulated in anti-Mi2-positive muscle biopsies.

Results: A set of 135 genes, including SCRT1 and MADCAM, was specifically overexpressed in anti-Mi2-positive DM muscle. This set was enriched for CHD4/NuRD-regulated genes and included genes that are not otherwise expressed in skeletal muscle. The expression levels of these genes correlated with anti-Mi2 autoantibody titers, markers of disease activity, and with the other members of the gene set. In anti-Mi2-positive muscle biopsies, immunoglobulin was localized to the nucleus, MADCAM protein was present in the cytoplasm of perifascicular fibers, and SCRT1 protein was localized to myofiber nuclei.

Conclusion: Based on these findings, we hypothesize that anti-Mi2 autoantibodies could exert a pathogenic effect by entering damaged myofibers, inhibiting the CHD4/NuRD complex, and subsequently derepressing the unique set of genes defined in this study.

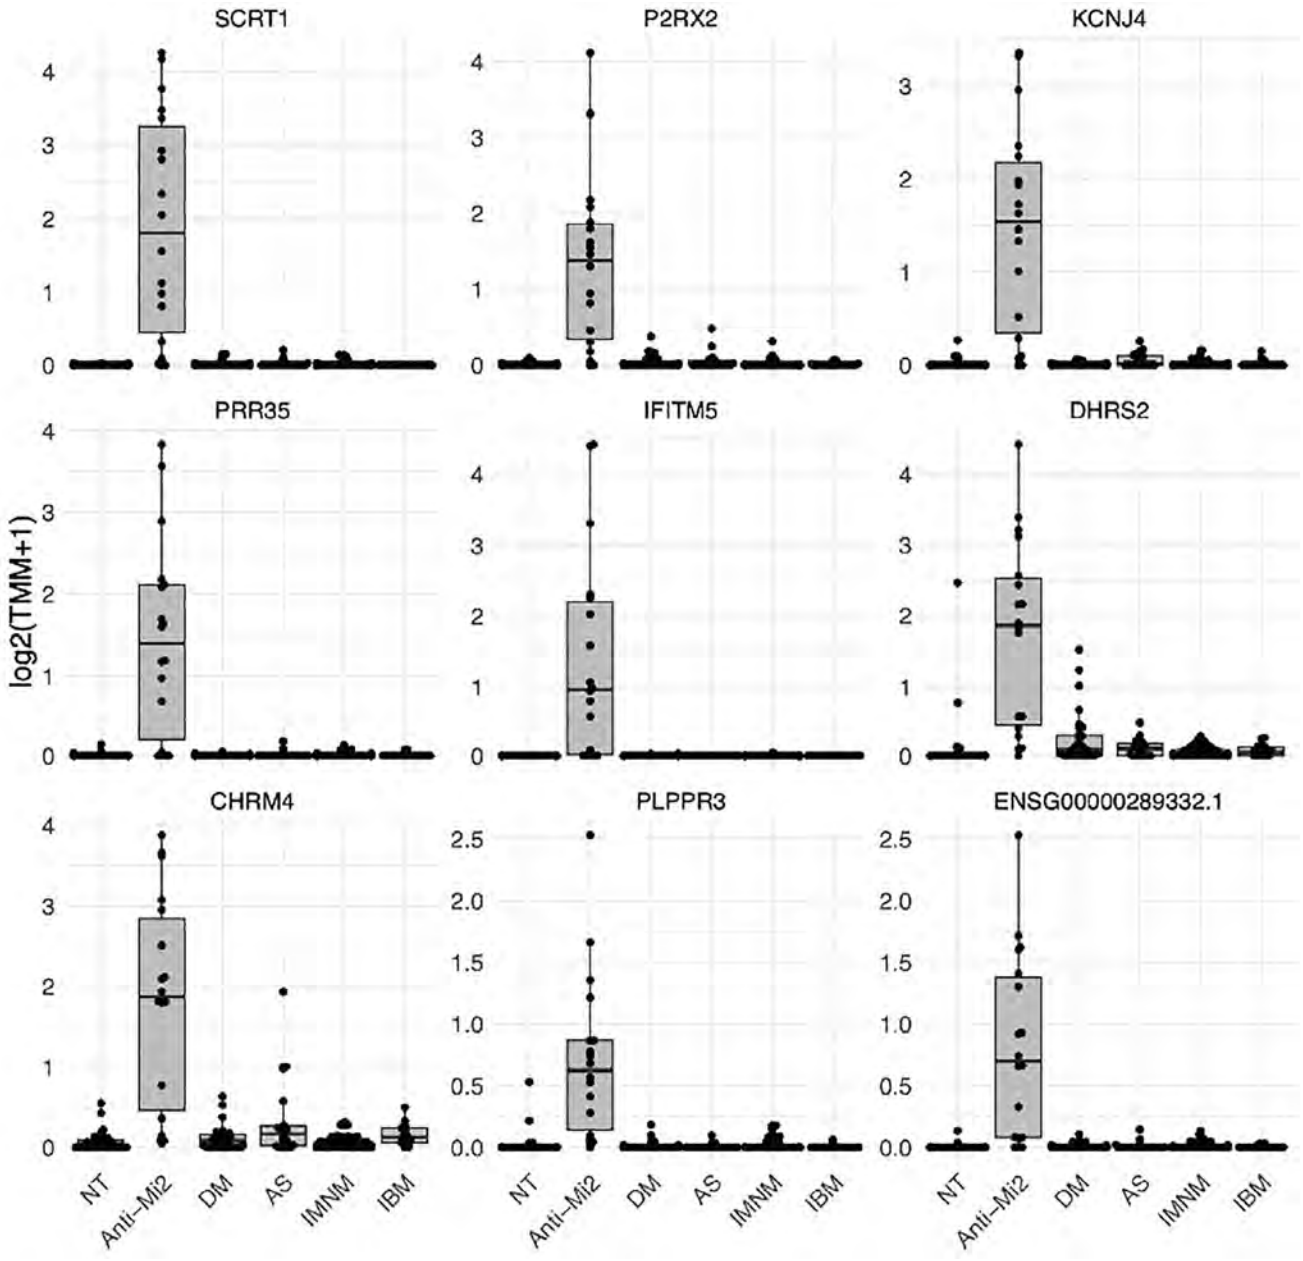

Figure 1. The most differentially overexpressed genes in anti-Mi2 dermatomyositis muscle compared to all the other muscle biopsies included in the study (histologically normal muscle biopsies [NT], non-anti-Mi2 dermatomyositis [DM], antisynthetase syndrome [AS], immune-mediated necrotizing myositis [IMNM], and inclusion body myositis [IBM]).

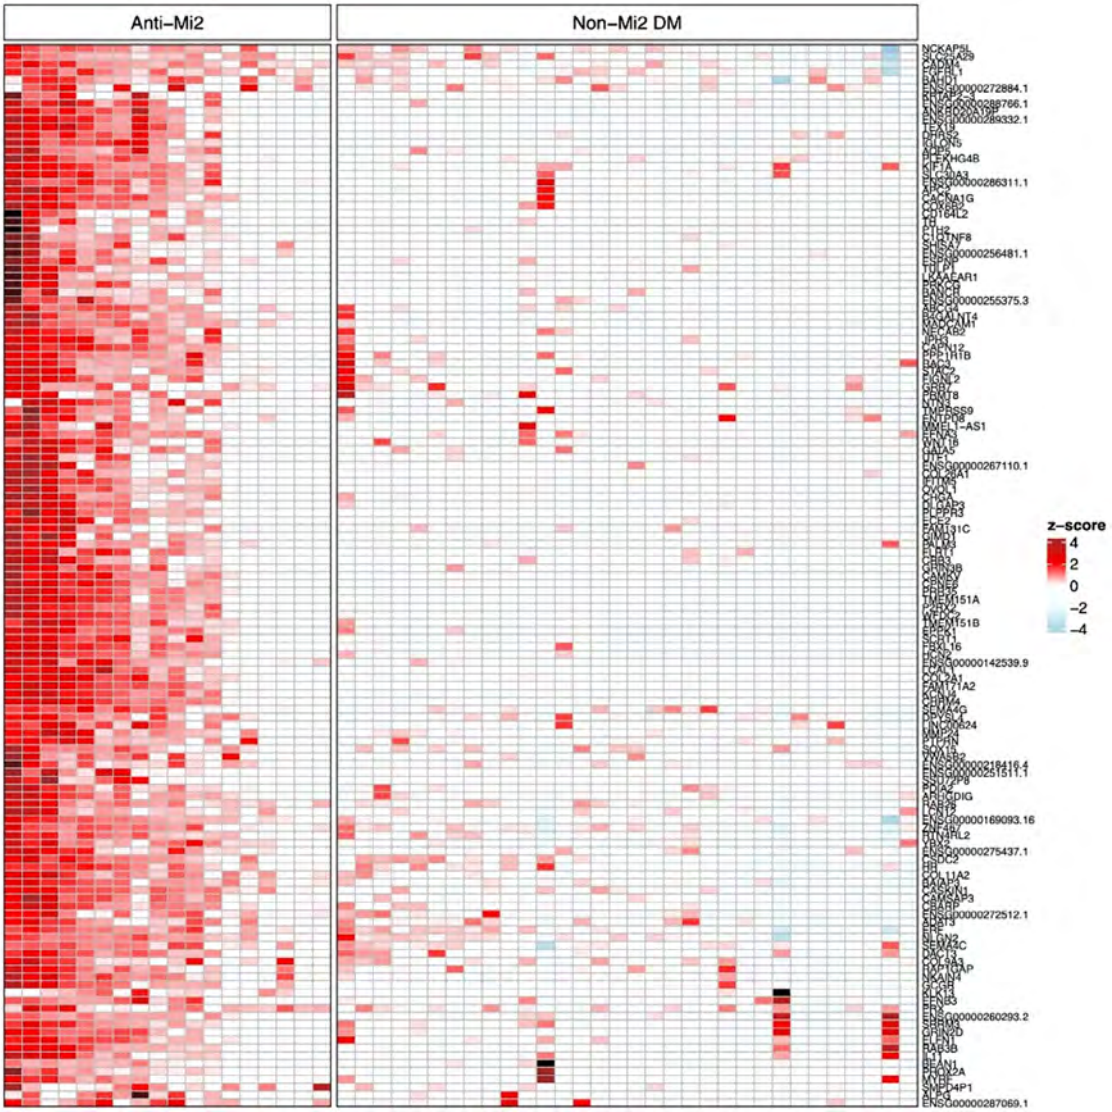

Figure 2. Normalized expression (z-score) of the specifically overexpressed genes in patients with anti-Mi2-positive dermatomyositis (DM) compared with non-Mi2-positive DM.

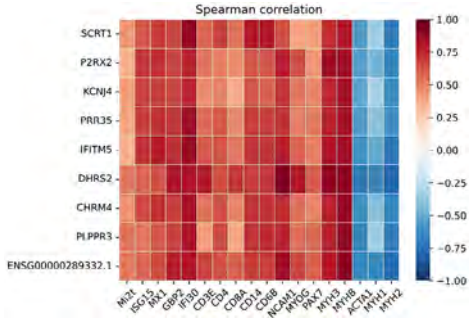

Figure 3. Correlation of the most differentially specifically overexpressed genes in patients with anti-Mi2-positive dermatomyositis and: titer of anti-Mi2 autoantibodies by ELISA (Mi2t), type 1 interferon-inducible genes (ISG15, MX1), type 2 interferon-inducible genes (GBP2, IFI30), T-cell markers (CD3E, CD4, CD8), macrophages (CD14, CD68), markers of muscle differentiation (NCAM1, MYOG, PAX7, MYH3, MYH8), and structural mature muscle proteins (ACTA1, MYH1, MYH2).

Mitochondrial-Mediated Neutrophil Activation in Dermatomyositis (DM) and Inclusion Body Myositis (IBM): Insights into Pathogenesis and Therapeutic Implications

Jorge Armando Gonzalez-Chapa[1], Jemima Albayda[2], Begum Horuluoglu[3], Despina Michailidou[1], Marina Barguil Macedo[1], Lisa Christopher-Stine[2], Ingrid Lundberg[4] and Christian Lood[1], [1]University of Washington, Seattle, WA, [2]Johns Hopkins University, Baltimore, MD, [3]Karolinska Institutet, Stockholm, Sweden, [4]Division of Rheumatology, Department of Medicine, Karolinska Institutet; Department of Gastroenterology, Dermatotology, Rhematology, Karolinska Universitetssjukhuset, Stockholm, Sweden

SESSION INFORMATION

Session Date: Tuesday, November 14, 2023

Session Title: Abstracts: Muscle Biology, Myositis & Myopathies – Basic & Clinical Science I

Session Type: Abstract Session

Session Time: 2:00PM–3:30PM

Background/Purpose: Dermatomyositis (DM) and inclusion body myositis (IBM) are characterized by muscle weakness and inflammation, with emerging evidence of mitochondrial and neutrophil involvement. Prior work from our group has demonstrated the important role of mitochondrial-derived danger-associated molecular patterns to promote neutrophil activation in inflammatory conditions. In the current study, we aimed to investigate whether patients with myopathies had elevated levels of extracellular mitochondrial biomarkers promoting neutrophil-mediated inflammation.

Methods: Plasma samples were obtained from patients with inclusion body myositis (IBM, n=46), dermatomyositis (DM, n=40), and healthy individuals (HC, n=40) from Karolinska Institutet, Stockholm, Sweden; Johns Hopkins, Baltimore, USA; and University of Washington, Seattle, USA. DM patients were further categorized based on the presence of autoantibodies towards MDA5 (n= 19) and TIF1-gamma (n=21). Plasma levels of neutrophil-derived calprotectin and neutrophil elastase (NE)-DNA complexes, as well as mitochondrial-derived GDF-15, and N-formyl methionine (fMET), which are valuable indicators of potential mitochondrial driven-pathological processes, cellular stress, and/or tissue damage, were measured using ELISA. Statistical analysis was performed using GraphPad Prism 9.4.0.

Results: Calprotectin levels were significantly elevated in DM patients, with the highest concentrations observed in those with MDA5 subtype **(Figure 1A)**. Patients with IBM had similar levels of calprotectin as compared to HC. In contrast, levels of neutrophil extracellular traps, NETs (NE-DNA), were elevated in both DM and IBM patients, as compared to HC **(Figure 1B)**. Both IBM and DM patients exhibited higher levels of mitochondrial-derived fMET and GDF-15 as compared to HC **(Figures 1C and D)**, supporting a role for mitochondrial dysfunction and extrusion in these myopathies. Levels of GDF-15 and fMET were strongly correlated in DM but surprisingly no association was found in IBM (**Figures 2A and B)**. Of note, consistent with other inflammatory conditions, levels of mitochondrial-derived fMET correlated strongly with neutrophil activation marker calprotectin in both IBM and DM (**Figures 2C and D**) suggesting that similar mechanisms, e.g. activation of neutrophils through fMET receptor FPR1, may operate in these subgroups of myopathies.

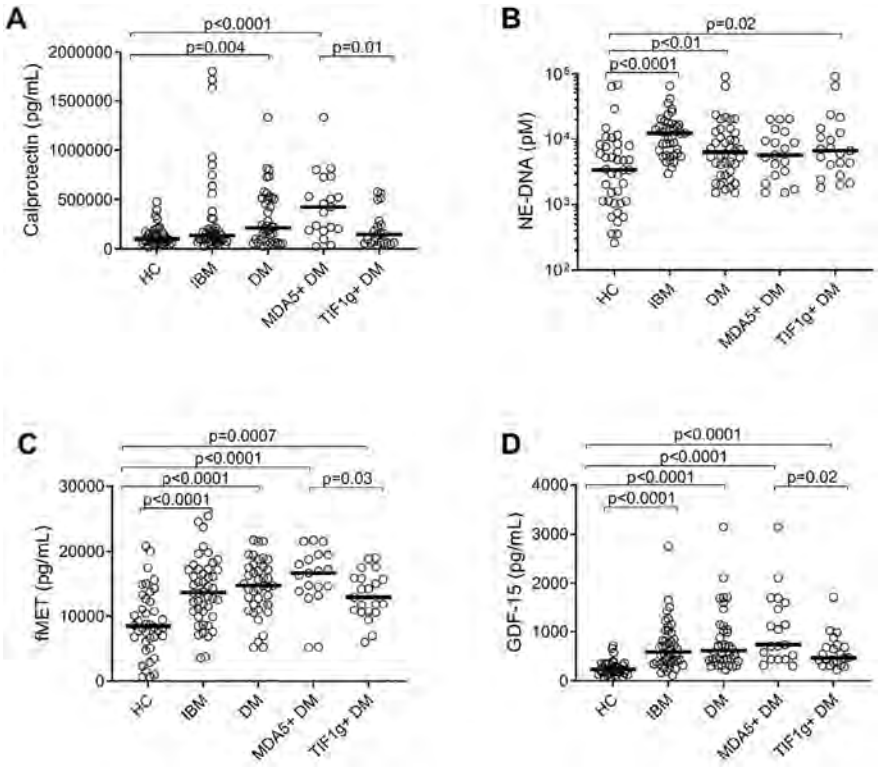

Figure 1. Neutrophil and mitochondrial biomarkers in IBM and DM. Levels of A) Calprotectin, B) NE-DNA, C) fMET, and D) GDF-15 in patients with Inclusion Body Myositis (IBM), Dermatomyositis (DM), and Healthy Controls (HC). DM patients were subdivided into MDA5 (n=19) and TIF-1 gamma (n=21) subgroups. Mann-Whitney U test was used for statistical analyses.

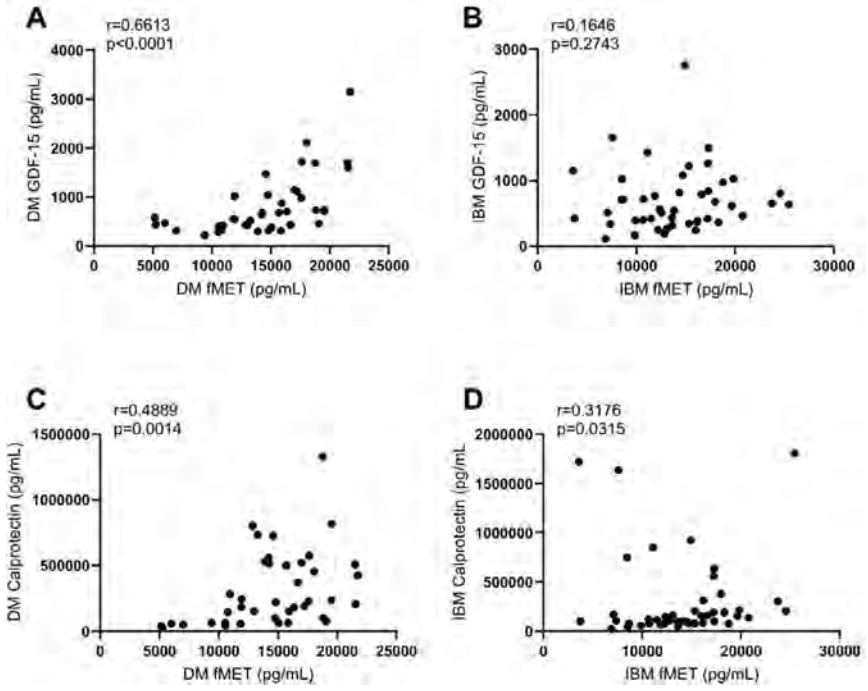

Figure 2. DM and IBM correlations between neutrophil and mitochondrial biomarkers Correlations between GDF-15 and fMET in A) DM and B) IBM patients. Correlations between calprotectin and fMET in C) DM and D) IBM patients. Spearman's correlation coefficient test.

Conclusion: Our findings reveal distinct biomarker profiles in DM and IBM, highlighting the potential roles of mitochondria and neutrophils in myopathies. The differences and similarities observed between the subgroups suggest that calprotectin and NETs may play distinct roles in DM and IBM, while elevated levels of mitochondrial-derived fMET and GDF-15 indicate the potential involvement of mitochondrial dysfunction suggesting a common pathological mechanism. Further studies are warranted to determine the role of mitochondria and neutrophils in disease pathogenesis, as well as their clinical implications in monitoring disease activity.

SESSION INFORMATION

Session Date: Tuesday, November 14, 2023

Session Title: Abstracts: Muscle Biology, Myositis & Myopathies – Basic & Clinical Science I

Session Type: Abstract Session

Session Time: 2:00PM–3:30PM

Background/Purpose: Antisynthetase syndrome (ASS) can be very severe affecting the lungs, the skin and the joints next to the muscles. ASS can take a refractory life-threatening course, necessitating the development of new treatment strategies. We recently reported the first case of successful rescue therapy of ASS with CD19-targeted CAR-T-cells [1]. Herein, we present efficacy and safety data for the first three patients with refractory ASS treated with autologous CD19 CAR-T-cells. The objective of this study was to test whether administration of CD19 CAR-T-cells is tolerable and effective in patients with severe refractory ASS.

Methods: Autologous CD19 CAR-T-cells were prepared and given as described previously [1,2,3]. All immunosuppressive treatments were stopped before CD19 CAR-T-cell administration. Tolerability was assessed by monitoring for Cytokine-Release Syndrome (CRS) and Immune-related effector Cell Neurotoxicity Syndrome (ICANS). Efficacy was assessed by CK levels, good response according 2016 ACR/EULAR total improvement score (TIS), imaging of muscles and lungs and successful cessation of all immunosuppressive treatments including glucocorticoids.

Results: Three ASS patients were treated with CD19 CAR-T-cells (table 1). All patients presented with active myositis and elevated CK levels. Patient 1 showed involvement of the muscles, skin and lungs, patient 2 showed involvement of muscles, skin, joints and lungs, patient 3 showed involvement of muscles and lungs. All patients did not respond to a minimum of 5 different immunosuppressive treatments (table 1). CAR-T-cell treatment was well-tolerated. Mild CRS (grade I) was observed in the first two patients. Patient 3 showed signs off increased O2 requirement (temporarily 10l/min by mask), chills and fever (39.0°C) defined as CRS grade II. All patients were treated with tocilizumab and CRS resolved quickly. Patient 2 had signs of mild self-limited ICANS (grade I discrete ataxia for a few days) two weeks after CAR-T treatment. Expansion of CAR-T-cells

Table 1 contains baseline demographic data from three antisynthetase syndrome patients treated with CD19 CAR T-cell therapy. Patient number one to three, age in years (ys), sex in female (F) and male (M). Disease duration in years (ys). Characterization of autoantibody positivity; data on lung involvement and oxygen requirement in liter per minute under rest; number (Nb.) of failed treatments (including CYC=cyclophosphamide, RTX=rituximab, OCR=ocrelizumab). Baseline muscle strength with a manual muscle test (MMT8) score of maximum 150. Baseline creatine kinase (CK) levels (norm value <170 U/l). Conditioning dose referred to 1x cyclophosphamide 1g/m2 and 3x fludarabine 25mg/m2. Maximum of CAR-T-cell expansion after administration of 1 million CAR-T-cells /kg body weight given as peak of CAR-T cells absolute and percent CAR+ of CD3+ T cells. Period of follow up in months after Car-T-cell application. Serconversion reached (yes/no) defined as disappearance of ASS specific antibodies (e.g. anti-Jo1). Efficacy criteria according to the 2016 ACR/EULAR total improvement score (TIS) 6 months after Car-T-cell therapy. Adverse events listed at Cytokine-release syndrome (CRS), application of tocilizumab regarding CRS in numbers of applications (Nb. Of applications) and Immune-related effector Cell Neurotoxicity Syndrome (ICANS) in grade 0-4.

paralleled with the complete depletion of circulating B cells. The first two patients experienced normalization of CK levels (patient 1: CK+150 days: 70 U/l, patient 2: CK+150 days: 99 U/l), major clinical improvement according to the 2016 TIS and could stop all immunosuppressive therapy. Follow-up CT scans of the lung done in patient 1 showed resolution of alveolar inflammation. Follow-up MRI of patient 1 and 2 revealed abrogation of inflammatory changes in the thigh muscles and hamstrings. At the latest follow up (365days and 150days) both patients were in drug-free remission, while patient 3 awaits follow up assessment.

Conclusion: Taken together, these data suggest that CD19 CAR-T-cell therapy provides a possibility to intercept with severe ASS leading to drug-free remission and resolution of muscle and lung inflammation.

B Cells in Anti-tRNA Synthetase Syndrome Patients Show an Activated, Interferon Responsive Signature

Erin Wilfong[1], Leslie Crofford[2] and Rachel Bonami[1], [1]Vanderbilt University Medical Center, Nashville, TN, [2]Vanderbilt University Medical Center, Melbourne, AR

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: Abstracts: Muscle Biology, Myositis & Myopathies – Basic & Clinical Science I
Session Type: Abstract Session
Session Time: 2:00PM–3:30PM

Background/Purpose: Autoantibodies directed against various tRNA synthetases defines the anti-tRNA synthetase syndrome (ARS). While it is unclear if the autoantibodies are directly pathogenic, the efficacy of rituximab in ARS implies that B cell dysregulation is critical in disease pathogenesis. We investigate how B cell transcriptomics varies in patients with active ARS versus healthy controls (HCs).

Methods: Ten patients with active ARS and HCs were identified from the MYSTIC cohort (VUMC IRB 141415). We thawed cryopreserved peripheral blood mononuclear cells (PBMCs) and isolated live CD19+ B cells using fluorescence activated cytometry sorting. Single cell RNA-Seq was performed using the 10X chromium platform with a target depth of 50,000 reads/cell. Data were de-multiplexed and processed using the CellRanger pipeline, and single-cell analysis was performed using Seurat v4.0.0. Immunoglobulin, MHC, and Y-chromosome genes were removed to prevent them driving transcriptionally defined clusters. B cell subset identities were assigned to clusters based on prior literature transcriptional profiles. Differential gene expression analysis comparing was performed in Seurat, subjected to GSEA pathway analysis, and visualized with CytoScape.

Results: Table 1 shows baseline participant characteristics. Eleven unique transcriptional clusters were identified and collapsed into five B cell subsets (transitional, naïve, activated, memory, plasmablast (**Fig. 1A**)) for downstream analysis based on isotype switching and gene expression (**Fig. 1B-C**). Initial visual examination of Jo-1 ARS, non-Jo-1 ARS, and healthy

control groups on UMAP plots suggested potential B cell subset skewing across participant groups (**Fig. 1D**). Jo-1 ARS patients showed an increase in naïve B cells, Non-Jo-1-ARS patients had increased activated B cells, and both ARS patient groups tended to have a lower frequency of memory B cells than HCs (**Fig. 1F**). Results of the GSEA analysis are shown in **Fig. 2**. Notably, the gene ontology term "defense response to symbiont," which contains the interferon genes IFI6, IFI44L, IFITM1, IFITM2, IRF7, ISG20, MX2, STAT1, was the most overrepresented term for transitional (FDR p=0.009) and activated (FDR p< 0.001) subsets. The Reactome term "Eph-ephrin signaling," which contains the critical B cell activation/migration genes ACTB, AP2M1, CDC42, CFL1, RAC1, and RHOA, was the most overrepresented term for memory cells (FDR p=0.01).

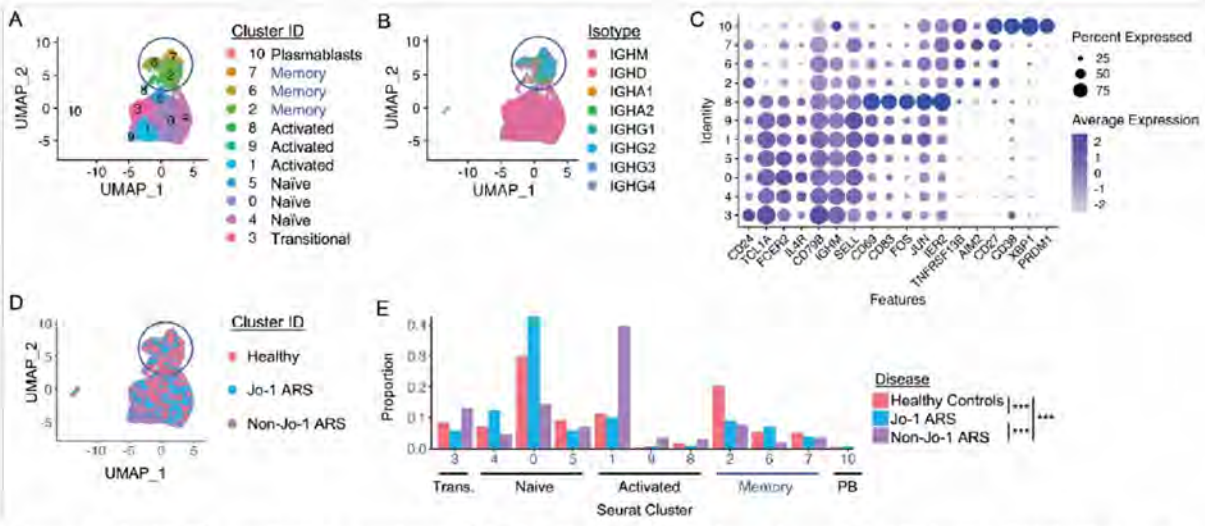

Figure 1. Anti-tRNA synthetase syndrome (ARS) patient subsets show skewed B cell cluster distribution from each other and healthy controls. Single-cell RNA-seq technology was used to profile 2,000-5,000 purified CD19+CD3- cells isolated from Jo1 ARS patients (n=5), non-Jo1 ARS patients (n=5), and healthy controls (n=5). Seurat was used to identify 11 clusters which were further grouped as naive, transitional, activated, memory, or plasmablast subsets based on manual inspection of isotype and gene expression profiles of each cluster. Blue circles highlight the memory subset. **A)** RNA-seq-based B cell subsets, **B)** BCR isotype, and **C)** manually selected gene expression profiles for cells grouped by B cell subset. **D)** UMAP is colored for each disease groups. **E)** Boxplots show the mean frequency of each B cell subset by disease group.

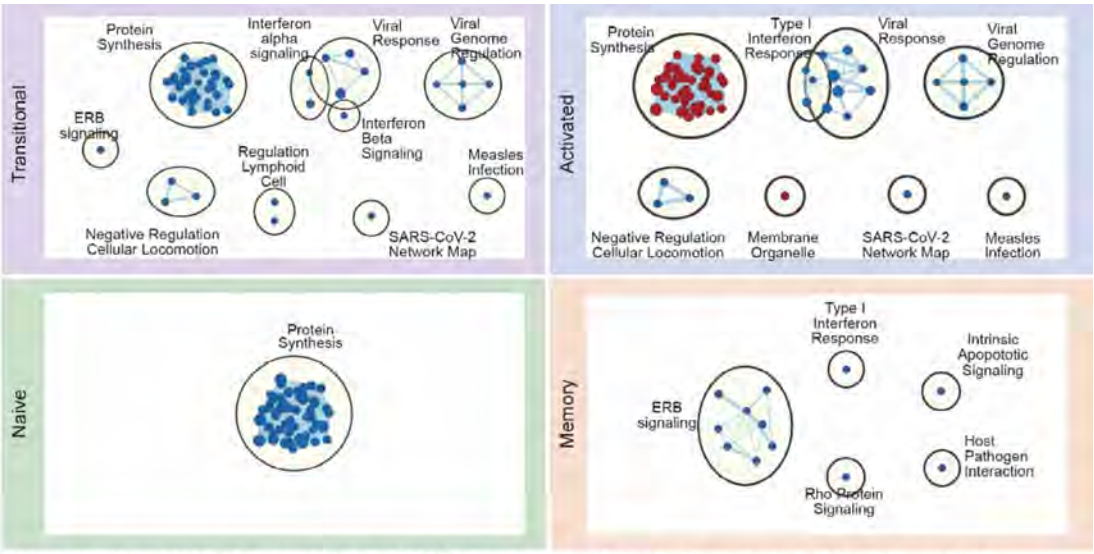

Figure 2. Annotated visualization of GSEA enrichment analysis. A rank list for differentially expressed genes for the transitional, naive, activated, and memory subsets was fed into the GSEA algorithm using an FDR Q-value of 0.1 and Jaccard overlap combined setting of 0.375. GSEA output files were visualized in CytoScape v.3.9.1 and automatically annotated using Enrichment Map and AutoAnnotate plugins.

Conclusion: B cell subset frequencies are skewed in ARS compared to HCs. ARS patients have altered B cell and interferon signaling compared to healthy controls. Future work will dissect how ARS B cell activation differs from normal immune responses.

Clonally Expanded B Cells in Anti-Histidyl-tRNA Synthetase Syndrome Patients Exhibit an Autoreactive-Prone Memory Phenotype and Bind Jo-1 Autoantigen

Lindsay Bass[1], Dena Liu[1], Alberto Cisneros[2], Jennifer Young-Glazer[2], Leslie Crofford[3], **Erin Wilfong**[2] and Rachel Bonami[2], [1]Vanderbilt University, Nashville, TN, [2]Vanderbilt University Medical Center, Nashville, TN, [3]Vanderbilt University Medical Center, Melbourne, AR

SESSION INFORMATION

Session Date: Tuesday, November 14, 2023
Session Title: Abstracts: Muscle Biology, Myositis & Myopathies – Basic & Clinical Science I
Session Type: Abstract Session
Session Time: 2:00PM–3:30PM

Background/Purpose: Anti-histidyl-tRNA synthetase syndrome (Jo-1 ARS) is defined by the presence of autoantibodies against histidyl tRNA synthetase (Jo-1). Clinically, Jo-1 ARS can involve multiple tissues including muscle, lung, skin, and joints. Previously, we identified that Jo-1 binding B cells show skewing towards specific phenotypic subsets in the peripheral blood of Jo-1 ARS patients, but the mechanisms that promote B cell recognition of Jo-1 autoantigen are unknown.

Methods: Five patients with active anti-Jo-1 ARS were identified from the Vanderbilt MYSTIC cohort (VUMC IRB 141415). We isolated live CD19+ B cells from cryopreserved peripheral blood mononuclear cells (PBMCs) using fluorescence activated cytometry sorting. Five-thousand cells were targeted for sequencing per sample. Single cell RNA-Seq, V(D)J sequencing, and Cite-Seq were performed using the 10X Chromium platform (5'-RNA, V(D)J, and CITE-Seq) demultiplexed and processed using the CellRanger pipeline and analyzed with Seurat v4.0.0. V(D)J gene identities and % somatic hypermutation were determined for B cell receptors (BCR) using IMGT/HighV-QUEST. Seurat was used to merge these outputs with RNA-seq and CITE-seq data to enable integrated analysis of BCRs with transcriptomic and phenotypic profiling. Clonally expanded BCRs were identified and recombinantly expressed as monoclonal antibodies. Total IgG, Jo-1, LPS, dsDNA, and insulin binding were measured by ELISA.

Results: Five B cell subsets (transitional, naïve, activated, memory, plasmablast) were assigned based on isotype switching and gene expression **(Fig. 1A-B)**. We identified 21 expanded clonotypes (defined as n ³ 3 per donor) amongst the five donors (**Fig. 1C**). Clonally expanded cells were CD27+ and CD21lo (**Fig. 2**) and were primarily IgM+ (non-class-switched) (**Fig. 3A**). Somatic hypermutation was highly variable and ranged from germline to very high (25%) (**Fig. 3B**). Recombinant expression of clonally expanded BCRs as IgG1 antibodies and ELISA binding studies revealed that 5/21 (24%) bound Jo-1. All Jo-1 binding clones exhibited some binding of dsDNA, LPS, or insulin, confirming polyreactivity. Multiple Jo-1 binding B cells expressed the VH4-34 heavy chain gene, which has been previously associated with autoimmunity.

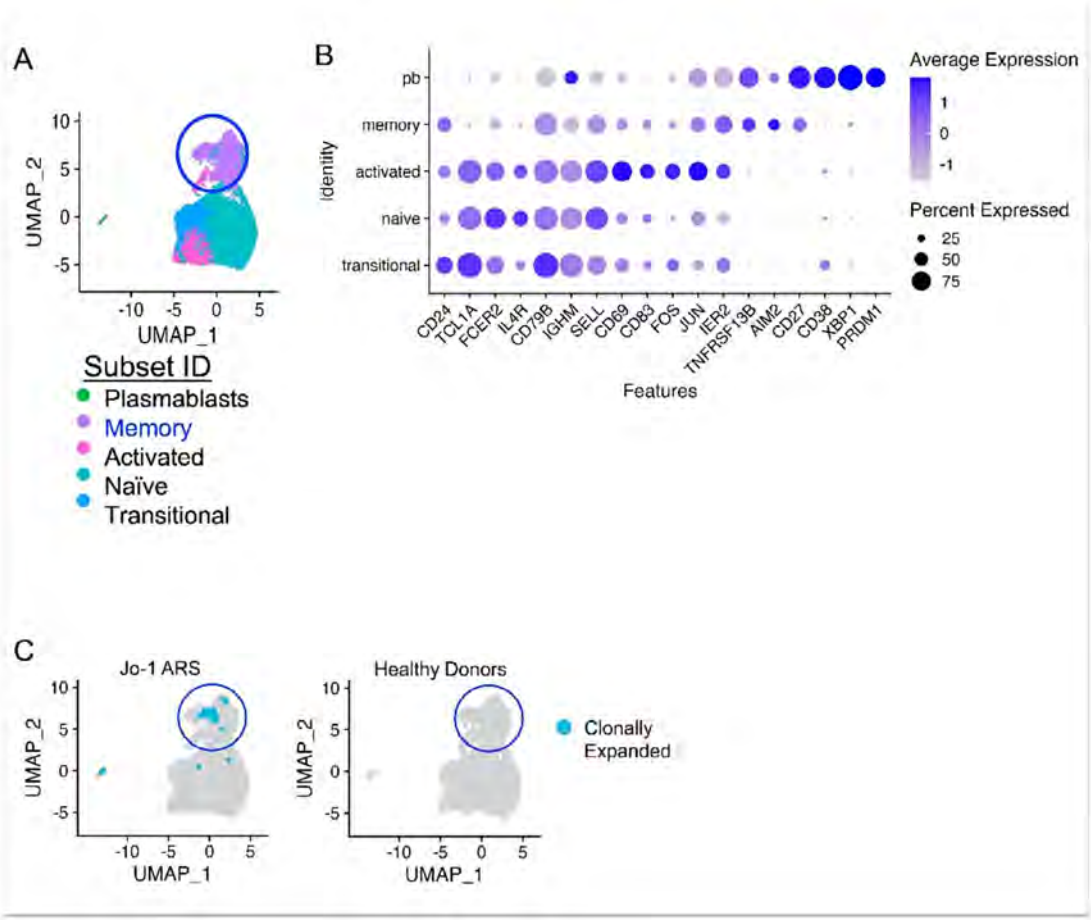

Figure 1. Transcriptionally defined memory B cell subsets and clonally expanded cells are identified in ARS patients. The 10X Genomics single-cell platform was used to perform transcriptomic (RNA-seq) profiling of purified B lymphocytes isolated from n=5 Jo-1 ARS patients, n=5 non-Jo-1 ARS patients, and n=5 healthy donors (age and sex-matched). A) Transcriptionally defined clusters and B) selected gene expression were identified using Seurat. C) Integrated Seurat/IMGT/HighV-QUEST analysis identified clonally expanded B cells (teal) through single-cell immune repertoire profiling (BCR-seq) in Jo-1 ARS (left) and healthy donors (right).

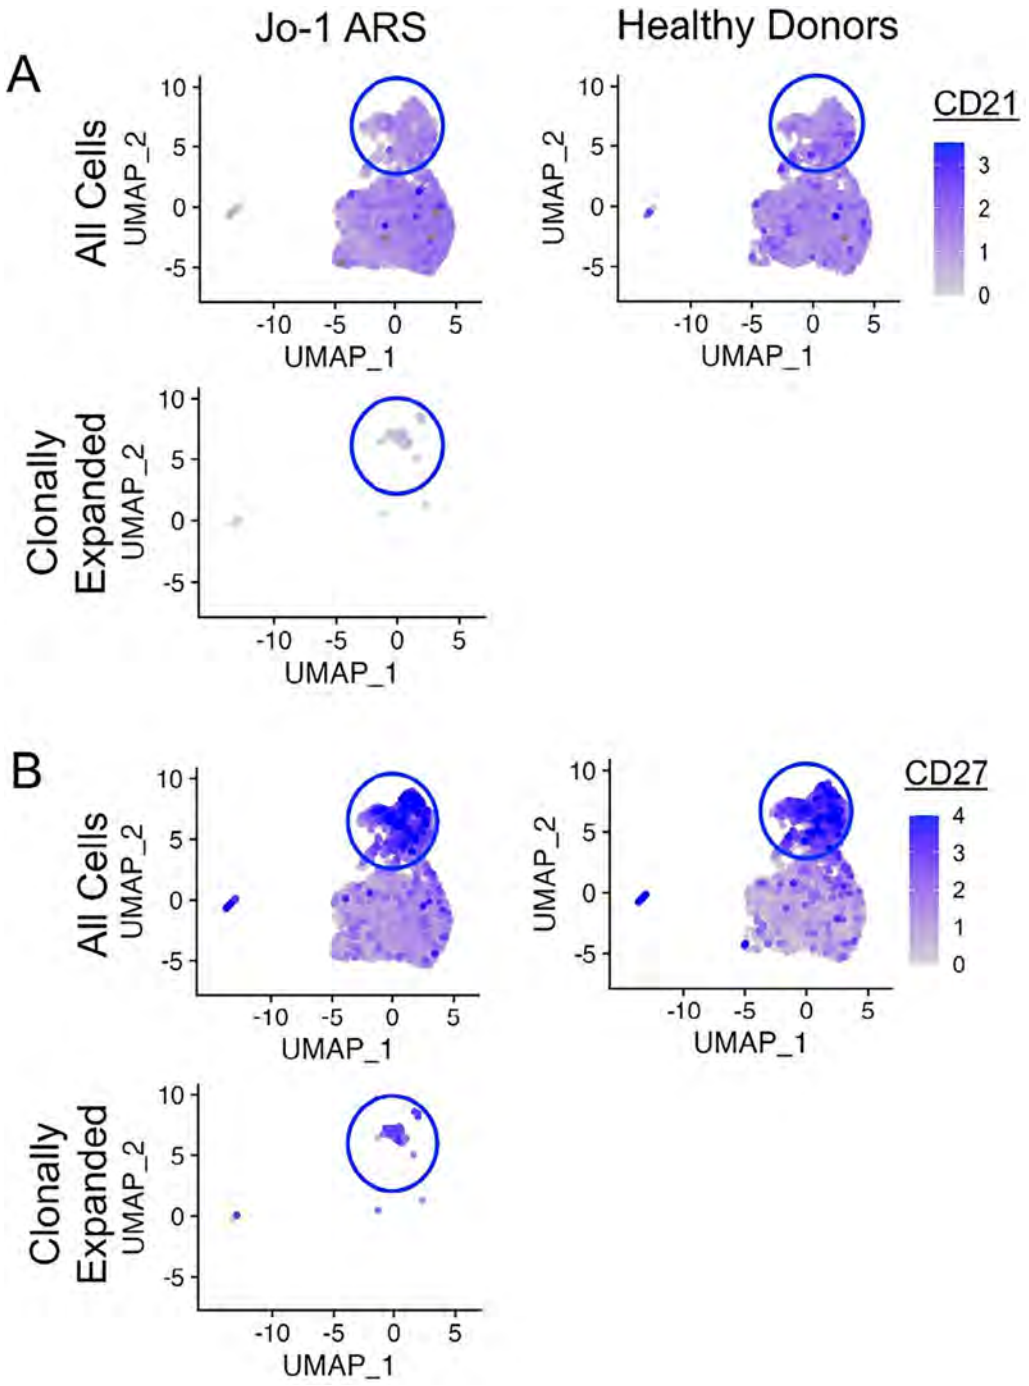

Figure 2. Clonally expanded B cells isolated from Jo-1 ARS patients exhibit an autoreactive-prone memory (CD21lo CD27+) phenotype. CITE-seq was used to measure A) CD21 and B) CD27 expression in total B cells (top panels) or clonally expanded B cells (bottom panels) in Jo-1 ARS or healthy donors. Heatmaps indicate expression levels.

Conclusion: Clonally expanded B cells in patients with Jo-1 ARS are enriched for anti-Jo1 B cells, which display an autoreactive-prone (CD21lo) memory phenotype. Somatic hypermutation analysis shows that germline recognition of Jo-1 autoantigen is possible, and that Jo-1-binding B cells can undergo extensive somatic hypermutation. Future studies will be required to determine if somatic hypermutation is associated with affinity maturation of Jo-1-binding B cells, and presumably enhanced pathogenicity.

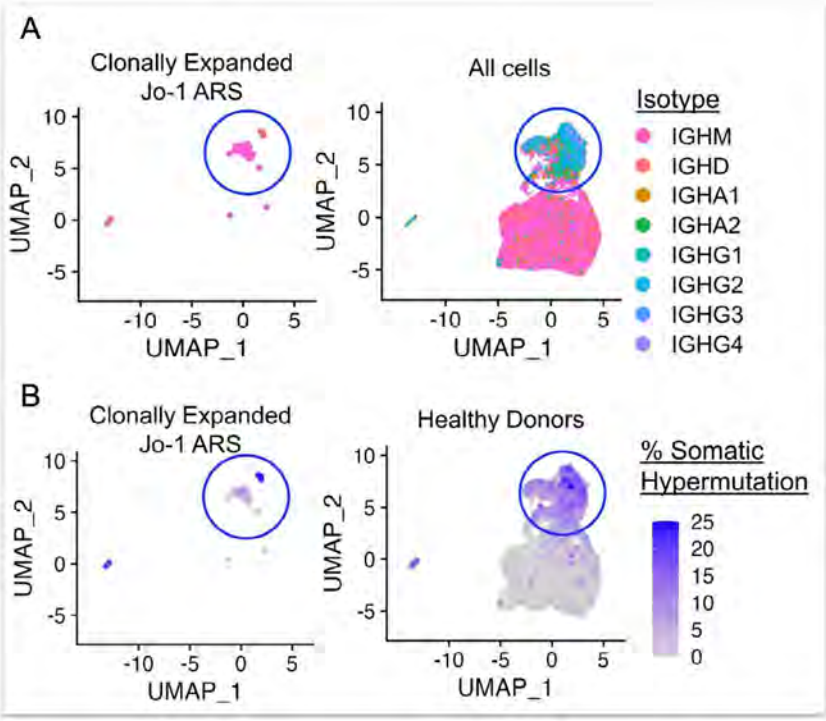

Figure 3. Clonally expanded B cells isolated from Jo-1 ARS patients underwent limited class switching and ranged from minimally to highly mutated BCRs. Integrated Seurat/IMGT/HighV-QUEST analysis of single-cell RNA-seq/BCR-seq data identified clonally expanded B cells from Jo-1 ARS patients (left) or total cells (right). A) isotype and B) percent variable heavy chain (VH) gene somatic hypermutation is shown. Heatmap indicates % somatic hypermutation.

Monoclonal Anti-MDA5 Autoantibodies Derived from a Patient with Dermatomyositis Target the Hel2i Domain of the MDA5 Protein

Eveline Van Gompel[1], Ragnhild Stålesen[2], Caroline Grönwall[2], Annika van Vollenhoven[2], Lena Israelsson[2], Ingrid Lundberg[3], Vivianne Malmström[2], Karine Chemin[4] and Vijay Joshua[2], [1]Karolinska Institutet - KU Leuven, Leuven, Belgium, [2]Karolinska Institutet, Stockholm, Sweden, [3]Division of Rheumatology, Department of Medicine, Karolinska Institutet; Department of Gastroenterology, Dermatology, Rhematology, Karolinska Universitetssjukhuset, Stockholm, Sweden, [4]Division of Rheumatology, Department of Medicine Solna, Center for Molecular Medicine, Karolinska University Hospital, Karolinska Institutet, Stockholm, Sweden

SESSION INFORMATION

Session Date: Tuesday, November 14, 2023

Session Title: Abstracts: Muscle Biology, Myositis & Myopathies – Basic & Clinical Science I

Session Type: Abstract Session

Session Time: 2:00PM–3:30PM

Background/Purpose: The strong clinical association between the anti-MDA5 autoantibodies and the development of severe lung disease in patients with dermatomyositis (DM) suggests an active role for the autoantibodies in the pathogenesis. The MDA5-specific autoreactive immune cells are understudied and it remains unclear if (and how) the autoantibodies contribute to the pathogenesis.

We aimed to get insight in the repertoire of the antigen-specific autoreactive B cells from patients with anti-MDA5(+) DM and confirm their antigen-specificity by producing anti-MDA5 monoclonal autoantibodies (mAb).

Methods: Circulating lymphocytes were available from MDA5(+) patients (n=3) at Karolinska Institutet (Sweden). All patients satisfy the EULAR/ACR IIM classification criteria. B cells were enriched using a negative selection kit and stained with a live/dead dye, with Streptavidin (SA)-PE-DL755 decoy probe to label non-specific B cells and with MDA5- SA-PE to label MDA5-specific B cells. Other B cell markers included CD19, IgD, CD27 and CD38. Single MDA5-SA-PE(+) B cells were index sorted using Influx (BD Bioscience) and recombinant mAbs were generated from the B cell receptor sequences as described previously and expressed as IgG1. Quality controls included SDS-PAGE, ELISA, and size-exclusion chromatography. Unspecific autoreactivity was assessed in a soluble membrane protein polyreactivity assay. MDA5-specificity of the produced mAbs was evaluated with ELISA and Western Blot. Apparent affinity was determined using a competition ELISA.

Results: Out of 234 MDA5(+)B cells sorted, 23 paired heavy and light chain sequences were selected to be expressed whereof 9 were originally IgGs, 3 IgAs and 11 IgMs. Two out of 23 mAbs were highly reactive towards the MDA5 protein in ELISA. The sequences originated from IgG-producing switched memory B cells (CD19+CD27loIgD-CD38+) and contained a low number of heavy and light variable region somatic hypermutations (SHM, 4 and 1 resp.). ELISA moreover showed that both mAbs specifically recognize the Hel2i domain of the MDA5 protein, but they differ in apparent affinity. Notably, one clone displayed sub-nanomolar apparent affinity, despite low SHM. The patient from whom the mAbs originated showed radiographic signs of ILD, had skin involvement and was lymphopenic.

Conclusion: We successfully cloned anti-MDA5 mAbs from two different B cell receptor sequences from an MDA5(+) patient with DM. Both mAbs specifically recognize the Hel2i domain of the MDA5 protein, but with different apparent affinity. These results are in line with previous findings, where we found the helicase domains to be the main immunogenic domains in 30 MDA5(+) serum samples. Therefore we hypothesize the anti-MDA5 autoantibodies potentially compete with the natural ligand of the MDA5 protein and interfere with the canonical function of MDA5 as a sensor of viral RNA. The successful production of anti-MDA5 mAbs allows us to further investigate this hypothesis, starting with setting up an *in vitro* competition assay to assess if the presence of anti-MDA5 mAbs can affect the downstream MDA5-signalling in lung fibroblasts.

Quadriceps Muscle Fat Composition but Not Muscle Energetics Is Associated with Knee Osteoarthritis: Initial Results from the Study of Muscle, Mobility, and Aging

Giovanna Distefano[1], Daniel Evans[2], Peggy Cawthon[2], John Lynch[2], Thomas Link[2], Philip Kramer[3], Stephanie Harrison[2], Bret Goodpaster[4], Jane Cauley[5], Theresa Mau[2], Paul Coen[4], Lauren Sparks[4] and **Nancy Lane**[6], [1]AventisHealth, Orlando, FL, [2]University of California San Francisco, San Francisco, CA, [3]Wake Forest, Winston-Salem, NC, [4]Aventis Health, Orlando, FL, [5]University of Pittsburgh, Pittsburgh, PA, [6]University of California, Hillsborough, CA

SESSION INFORMATION

Session Date: Tuesday, November 14, 2023
Session Title: Abstracts: Osteoarthritis II: Novel Insights from Observational Studies
Session Type: Abstract Session
Session Time: 2:00PM–3:30PM

Background/Purpose: Osteoarthritis (OA) remains the most common cause of joint pain and disability with age, and to date, effective treatments to reduce pain and slow disease progression remain elusive. Nonpharmacologic therapies, including physical therapy and walking, are reported to be effective in reducing knee pain and maintaining function in subjects with knee OA (KOA). Deep phenotyping of the thigh muscle was performed in older adults from the Study of Muscle, Mobility, and Aging (SOMMA) with the goal of determining the relationship between measures of muscle health and KOA in older adults.

Methods: Men and women aged >70 yrs. recruited from two study sites (University of Pittsburgh and Wake Forest University) based on their ability to walk ¼ mile at >= 0.6m/s and perform study related activities. Muscle mass and composition were assessed by MRI of the thigh, and D3Cr muscle mass by D3-creatine dilution. Knee extensor leg power was assessed using a Keiser exercise machine. Muscle mitochondrial energetics were assessed by P^{31} MRS (ATP_{max}) and high resolution respirometry of permeabilized myofibers collected from a muscle biopsy of the vastus lateralis (Oxidative phosphorylation, OXPHOS). At one-year post-enrollment, knee x-rays and standardized knee pain assessments were completed, and knee OA was defined by Kellgren and Lawrence (KL) grade >= 2. Participants were grouped NoKOA, NoPain; NoKOA, Pain; KOA, NoPain, and KOA, Pain. Differences between groups were assessed by ANOVA with parametric post-hoc tests and associations between participants with knee OA and muscle variables were analyzed by linear regression adjusted for age, gender, study site/technician, and race.

Table 1. Study Subject Characteristics (mean ± SD)

Variables	NoKOA, NoPAIN	NoKOA, Pain	KOA, NoPain	KOA, PAIN	P value
	(N= 212)	(N= 50)	(N= 203)	(N= 193)	
Age (Yrs.)	75.8±4.7	74.5 ± 4.0	76.6 ± 5.1	76.2 ± 5.1	0.04
Female, N (%)	109 (51.4)	29 (58.0)	113 (55.7)	125 (64.8)	0.05
BMI (kg/m^2)	26.2 ± 4.0	26.8 ± 4.6	27.9 ± 4.5	28.5 ± 4.2	<0.01
Walk speed from 400m walk in m/s	1.12 ± 0.16	1.10 ± 0.17	1.04 ± 0.18	1.01 ± 0.18	<0.01
% D3Cr muscle mass (kg)	0.31 ± 0.06	0.30 ± 0.08	0.29 ± 0.06	0.28 ± 0.07	<0.01
Mean Anterior Thigh Muscle Fat Infiltration (%)	0.067 ± 0.018	0.069 ±0.021	0.076 ±0.022	0.081 ± 0.023	<0.01
Total Thigh Fat Free Muscle vol (L)	9.09 ± 2.28	8.83 ± 2.28	9.19 ± 2.26	8.87 ± 2.29	0.52
P^{31} MRS (ATP_{max}) (mM/sec)	0.550 ± 0.1425	0.574 ± 0.177	0.53 ± 0.15	0.54 ± 0.15	0.41
OXPHOS (pmol/(s*mg))	61.4 ± 16.8	63.6 ± 23.0	62.1 ± 20.6	56.6 ± 17.0	0.02
Knee Extensor Leg Power (watts/kg)	5.3 ± 1.8	5.0 ± 1.8	4.7 ± 1.7	4.3 ± 1.5	<0.01

Table 2. Muscle mass, composition, function, and mitochondrial energetics in subjects with and without knee osteoarthritis

	D3Cr muscle mass (kg)	Mean Anterior Thigh muscle fat infiltration (%)	Total thigh fat free mass (L)	P^{31} MRS (ATP_{max}) (mM/sec)	OXPHOS (pmol/(s*mg))	Knee extensor leg power (watts/kg)
NoKOA, NoPain	0.0 (referent)	0.0 (referent)	0.0 (referent)	0.0 (referent)	0.0 (referent)	0.0 (referent)
NoKOA, Pain	-0.006 (-0.025, 0.013)	0.002 (-0.004, 0.008)	-0.127 (-0.509, 0.254)	0.018 (-0.029, 0.064)	2.81 (-2.59, 8.22)	-0.226 (-0.647, 0.195)

KOA,Pain	-0.022 (-0.034, -0.010)*	0.012 (0.008, 0.016)*	0.294 (0.047, 0.541)*	0.004 (-0.025, 0.034)	2.33 (-5.93, 1.28)	-0.774 (-1.05, -0.502)*

Data represent beta coefficients (95% CI). *p<0.05 when compared to No KOA ,No Pain group. All linear models are adjusted for age, gender, site or technician, and race,

Results: This analysis was performed on 658 SOMMA participants who had knee x-rays obtained, with a mean age of 76.1 yrs. Subjects with KOA tended to be older, with more anterior intramuscular fat, lower knee extension leg power and lower mitochondrial energetics (Table 1). After adjustment for age, gender, race, BMI and study site, KOA with and without pain groups showed lower % functional muscle mass by D_3Cr enrichment, lower knee extensor leg power, and greater anterior thigh intramuscular fat compared to the NoKOA, NoPain group (Table 2). No significant differences between groups were observed for the muscle mitochondrial energetics measures.

Conclusion: Older adults with KOA, with and without knee pain, have lower D3Cr muscle mass, lower knee extension leg power, similar mitochondrial function, and higher amounts of intramuscular fat than those without knee OA and without pain. The association of KOA with increased intramuscular fat is now under investigation.

Session Title: Abstracts: Osteoarthritis II: Novel Insights from Observational Studies

Session Type: Abstract Session

Session Time: 2:00PM–3:30PM

Background/Purpose: Since gut microbiome dysbiosis can cause inflammatory disorders by affecting host metabolism, we postulate that the gut microbiome and related metabolites could play a role in the pathogenesis of hand osteoarthritis. We characterised gut microbiome-related metabolites in people with symptomatic hand OA (SHOA) in two independent cohorts.

Methods: Using data collected from a large-sample community-based observational study (discovery cohort) (n=1,359), the Xiangya OA (XO) Study, we first performed shotgun metagenomic sequencing of stool samples for gut microbial function. We then performed targeted metabolomics analysis of plasma samples for metabolites related to altered microbial function in SHOA and compared the metabolites between participants with and those without SHOA. We also applied a multi-omics analysis approach to examine the associations between SHOA-related microbial function and SHOA-related plasma metabolites. Finally, we then replicated the findings from the XO Study among 71 SHOA patients and 71 age (±1 year), sex and BMI (±2 kg/m^2) matched controls (validation cohort) (Figure 1).

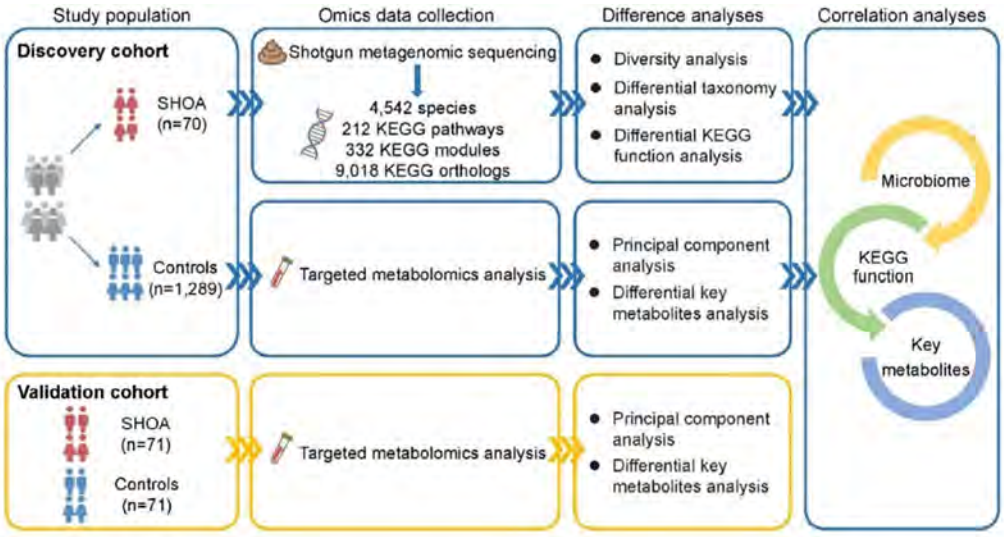

Figure 1. Summary of the present study. SHOA, symptomatic hand osteoarthritis; KEGG, Kyoto Encyclopedia of Genes and Genomes.

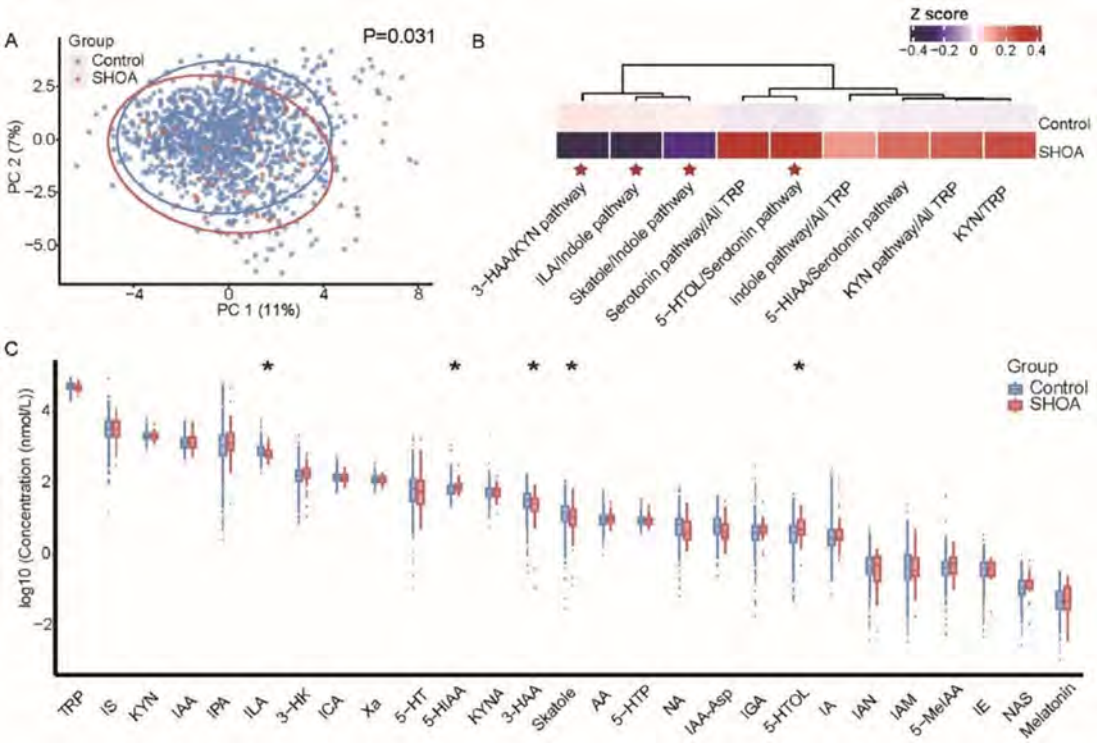

Figure 2. Associations of plasma tryptophan metabolites with SHOA in the discovery cohort. (A) Principal Component Analysis (PCA) plot compared the composition of plasma tryptophan metabolites between participants with SHOA and those without SHOA. Associations of ratios of tryptophan metabolites concentration in their related pathway (B) and individual plasma tryptophan metabolites (C) with SHOA adjusting for age, sex, body mass index, smoking status, alcohol consumption, and frequency of dietary intake of meat/eggs, dairy, and vegetables. Significant ratios are marked with red stars. SHOA, symptomatic hand osteoarthritis; TRP, tryptophan; KYN, kynurenine; ILA, indole-3-lactic acid; 3-HAA, 3-hydroxyanthranilic acid; 5-HIAA, 5-hydroxyindoleacetic acid; 5-HTOL, 5-hydroxytryptophol; 3-HK; 3-hydroxykynurenine; 5-HT, serotonin; 5-HTP, L-5-hydroxytryptophan; 5-MeIAA; 5-methoxy-3-indoleacetic acid; AA, anthranilic acid; IA; indole acrylic acid; IAA, indole-3-acetic acid; IAA-Asp, indole-3-acetyl-aspartate; IAM, indole-3-acetamide; IAN, indole-3-acetonitrile; ICA, indole-3-carboxaldehyde; IE, indole ethanol/tryptophol; IGA, 3-indoleglyoxylic acid; IPA, 3-indolepropionic acid; IS, indoxylsulfate; KYNA, kynurenic acid; NA, nicotinic acid; NAS, N-acetyl-5-hydroxytryptamine; Xa, xanthurenic acid.

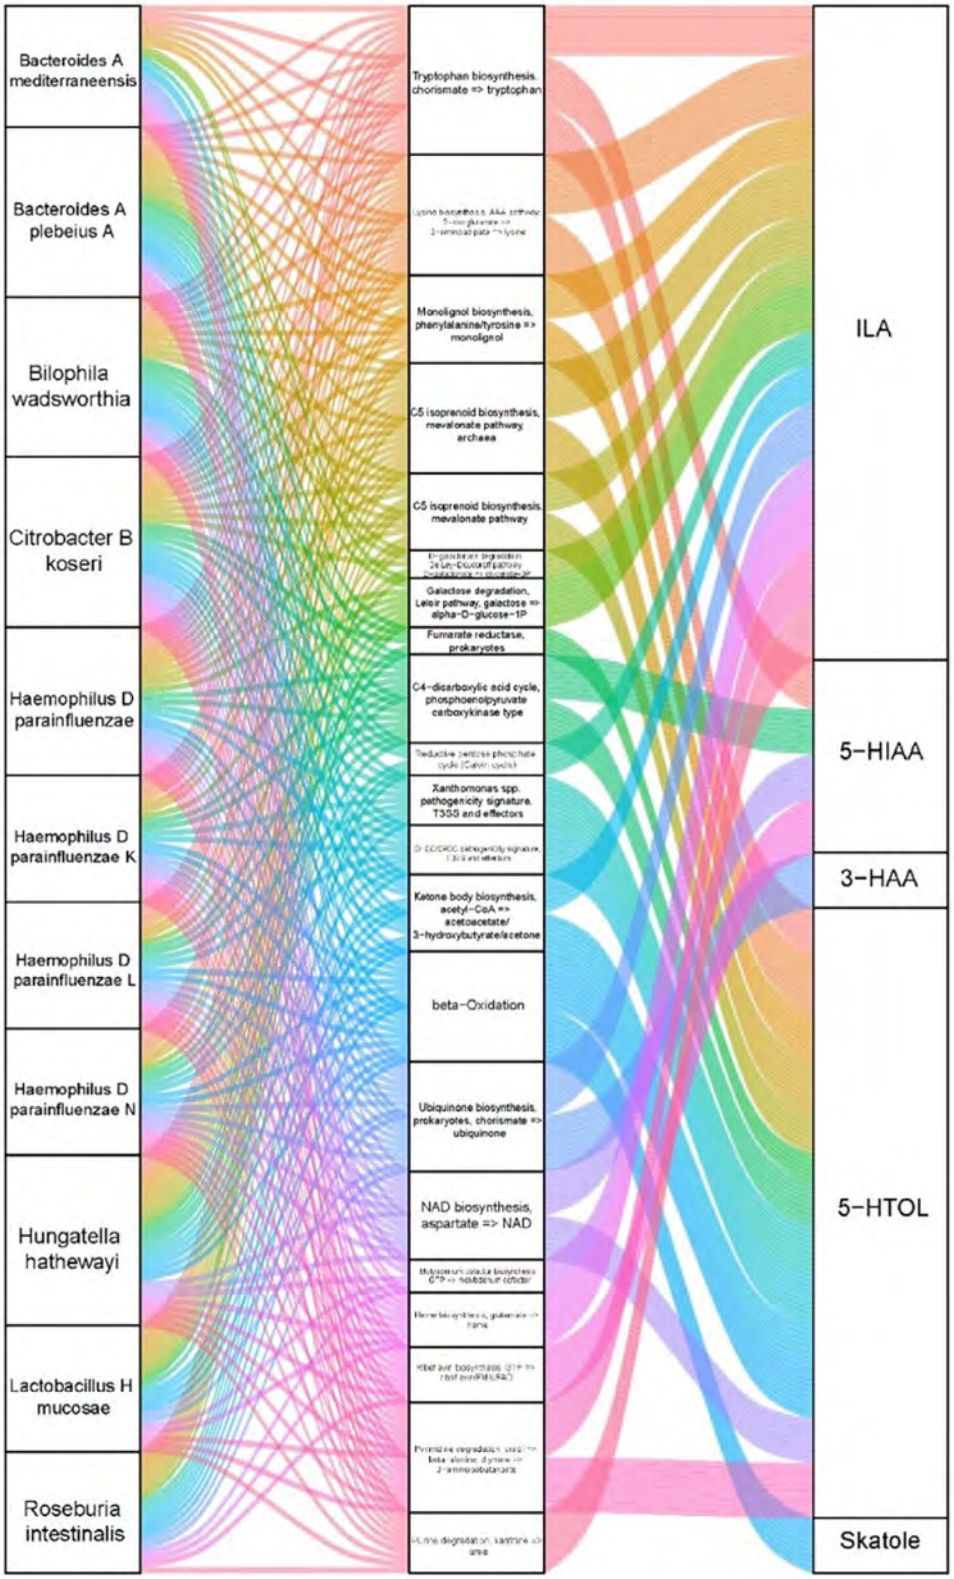

Figure 3. Correlations of microbial species to the microbial modules, and correlations of microbial modules to the tryptophan metabolites. The Sankey plot shows the significant correlations of classified microbial species with KEGG modules and KEGG modules with differential tryptophan metabolites. Shown are microbial species (left), KEGG modules (middle), and plasma tryptophan metabolites (right). The curved lines connecting the panels indicate the correlations, with colors corresponding to different modules. ILA, indole-3-lactic acid; 5-HIAA, 5-hydroxyindoleacetic acid; 3-HAA, 3-hydroxyanthranilic acid; 5-HTOL, 5-hydroxytryptophol.

Results: In the discovery cohort, compared with those without SHOA (n=70), participants with SHOA had significantly altered microbial functions related to tryptophan metabolism. Then we measured the plasma tryptophan metabolites and found that participants with SHOA had higher levels of 5-hydroxytryptophol and 5-hydroxyindoleacetic acid, but lower levels of indole-3-lactic acid (ILA), 3-hydroxyanthranilic acid and skatole (Figure 2). The multivariable-adjusted odd ratios of SHOA per one log10 unit increase for 5-HIAA, 5-HTOL, ILA, skatole, and 3-HAA were 8.97 (95% CI: 2.37 to 33.98), 3.44 (95% CI: 1.44 to 8.18), 0.19 (95% CI: 0.04 to 0.99), 0.51 (95% CI: 0.28 to 0.90) and 0.36 (95% CI: 0.19 to 0.70), respectively. Moreover, the multi-omics analysis suggested that the lower level of ILA in SHOA was related to the microbial function of tryptophan biosynthesis, which was further correlated with the microbiome species *Bacteroides A mediterraneensis* (Figure 3). Finally, we verified the associations between plasma tryptophan metabolites and SHOA in the validation cohort. Consistent with the findings in the discovery cohort, we observed a lower level of the ILA in the SHOA group compared with controls, with the multivariable adjusted ORs of SHOA per one log10 unit increase for ILA being 0.03 (95% CI: 0.002 to 0.46).

Conclusion: Alterations of the microbial function of tryptophan biosynthesis and tryptophan metabolites, especially lower levels of ILA, are associated with SHOA. Our novel findings suggest potential pathways and targets for further treatment of SHOA.

Associations Between Body Composition Measurements of Obesity and the Radiographic Progression of Hand Osteoarthritis: Data from the Dong-gu Study

Sung-Eun Choi[1], Hyemin Jeong[1], Dong-Jin Park[1], Ji-Hyoun Kang[2], Min-Ho Shin[3] and Shin-Seok Lee[1], [1]Chonnam National University Medical School & Hospital, Gwangju, South Korea, [2]Chonnam National University Hospital, Gwangju, South Korea, [3]Chonnam National University Medical School, Gwangju, South Korea

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: Abstracts: Osteoarthritis II: Novel Insights from Observational Studies
Session Type: Abstract Session
Session Time: 2:00PM–3:30PM

Background/Purpose: Previous studies have found that obesity is a risk factor for hand osteoarthritis (OA), but most have been cross-sectional studies and thus causality is uncertain. Longitudinal studies are instead needed to explore the association between obesity-related characteristics, including fat deposition/distribution and hand OA. The present study examined the association between changes in body composition measurements and the radiographic progression of hand OA in a longitudinal cohort.

Methods: In the Dong-gu Study population, 1,277 patients had hand radiographs at baseline and at the 4-year follow-up. X-rays of the hand joints were scored using a semi-quantitative grading method. Body composition was simultaneously measured in a bioelectrical impedance analysis using an InBody 520 analyzer. The relationship between changes in body composition measurements and the radiographic progression of hand OA was assessed in a multiple linear regression analysis.

Results: Total hand joint scores increased from 16.3 ± 5.74 at baseline to 18.8 ± 8.11 at year 4 (P < 0.001). Changes of body mass index, hip circumference (HC), waist-to-hip circumference (WHC), and fat mass were significantly associated with changes in the total hand joint scores (P = 0.012, P < 0.001, P = 0.017, P = 0.008, respectively). HC and WHC were significantly associated with radiographic progression of the hand joints, after adjusting for age, sex, physical activity, education status, smoking, alcohol consumption, hypertension, diabetes mellitus, dyslipidemia, chronic pulmonary disease, chronic liver disease, cardiovascular disease, cerebrovascular disease, and malignancy (P < 0.001, P = 0.001, respectively).

Conclusion: Changes in fat distribution were significantly associated with the radiographic progression of hand OA over 4 years, suggesting a role for the systemic effect of adipose tissue.

Low Serum Adiponectin Levels Were Associated with Radiographic Progression of Hand Osteoarthritis in a 6-year Follow-up of the Dong-gu Study

Sung-Eun Choi[1], Hyemin Jeong[1], Dong-Jin Park[1], Ji-Hyoun Kang[2], Min-Ho Shin[3] and Shin-Seok Lee[1], [1]Chonnam National University Medical School & Hospital, Gwangju, South Korea, [2]Chonnam National University Hospital, Gwangju, South Korea, [3]Chonnam National University Medical School, Gwangju, South Korea

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: Abstracts: Osteoarthritis II: Novel Insights from Observational Studies
Session Type: Abstract Session
Session Time: 2:00PM–3:30PM

Background/Purpose: The association between serum adiponectin levels and hand osteoarthritis (OA) has been studied cross-sectionally, but longitudinal studies on the radiographic progression of hand OA are lacking. Thus, we investigated the relationship between serum adiponectin levels and radiographic features of hand OA in a prospective longitudinal cohort.

Methods: A total of 1,356 subjects were enrolled from the Dong-gu study. Baseline serum adiponectin levels were measured by enzyme linked immunosorbent assay, and hand joint radiographs were assessed using a semi-quantitative grading system at the first visit and 6 years later. Multiple linear regression analysis was used to investigate the association between serum adiponectin levels and radiologic changes in hand OA.

Results: Total hand joint scores increased from 16.5 ± 5.74 at baseline to 19.4 ± 8.11 at year 6 ($p < 0.001$). The baseline adiponectin levels were negatively associated with the changes in total hand joint score ($p = 0.019$), subchondral cyst score ($p = 0.006$), and malalignment score ($p = 0.026$) after adjusting for age, gender, body mass index, smoking, alcohol consumption, education, physical activity, hypertension, diabetes mellitus, dyslipidemia, chronic pulmonary disease, chronic liver disease, cardiovascular disease, cerebrovascular disease, and malignancy. When serum adiponectin levels above and below the median were compared with the total score for hand OA based on the median radiographic scores, subjects with serum adiponectin levels below the median exhibited radiographic progression in hand joints after adjustment (odds ratio = 0.618, 95% confidence interval: 0.477–0.801, $p < 0.001$).

Conclusion: In this longitudinal population-based study, decreased serum adiponectin levels were associated with progression of radiographic hand OA.

Session Title: Abstracts: Osteoarthritis II: Novel Insights from Observational Studies

Session Type: Abstract Session

Session Time: 2:00PM–3:30PM

Background/Purpose: Hand osteoarthritis (HOA) is considered as a less severe disease with a better functional prognosis and a lower global burden than rheumatoid arthritis (RA). This paradigm may no longer be true considering the efficacy of targeted therapies in RA compared to the weak efficacy of therapies in the most severe form of HOA, namely erosive HOA (EHOA) (1).

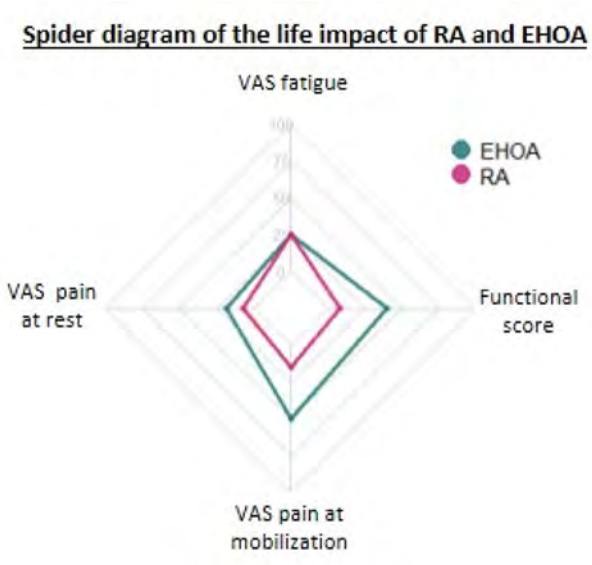

Figure 1: Spider diagram of the life impact of RA and EHOA VAS = visual analogical scale, EHOA = erosive hand osteoarthritis; RA : rheumatoid arthritis

Methods: We aimed to compare the burdens of established EHOA and RA. The objectives were to compare pain, functional impairment and the prevalence of comorbidities and of cardiovascular diseases (CVD).

This study involved EOHA patients, defined by at least 1 erosive joint according to the Verbruggen score (3)from inclusion visit of DIGital Cohort Osteoarthritis Design (DIGICOD), a French cohort of symptomatic HOA. RA patients fulfilling ACR/EULAR 2010 criteria at the 10th year visit were selected from the ESPOIR cohort (*Étude et Suivi des Polyarthrites Indifférenciées Récentes*), a French cohort of early RA (4).

Pain intensity at rest or mobilization (0-100mm visual analogical scale (VAS)³40/100), fatigue (VAS fatigue³25/100), function (normalized (0-100) scores of Health assessment questionnaire for RA, and AUStralian CANadian Osteoarthritis Hand Index for EHOA > 16.7) were analyzed and compared between EHOA and RA using logistic regression models adjusted on age, gender, BMI, comorbidities and socio-educational level. The risk to have ³ 2 comorbidities (among CVD, cancer, hemopathy, fracture) or at least 1 CVD (among high blood pressure, diabetes, dyslipidemia, myocardial infarction, stroke) were compared and adjusted on age, gender, BMI and socio-educational level. Odds ratios (OR) and their 95% confidence intervals (CIs) were reported (EOHA vs RA).

Results: We selected 138 EHOA patients and 379 with RA. The median [interquartile] age for EHOA patients was 67.3 [64.3; 72.2] years vs 48.6[39.9 ; 55.6] years for RA patients (p< 0.001). The disease duration, at the evaluation time, was 13.5 [7.0; 20.0] for EHOA and 10.5 years [10.3 ; 10.7] for RA patients. RA was anti-CCP antibodies positive for 56% of patients and in remission for 61%. RA patients received methotrexate (82%), biologics (37%) and corticosteroids (25%) while 20% of EHOA patients received oral non-steroidal anti-inflammatory drugs.

The number of painful joints in the hands was higher for EHOA than RA patients (4.0 [2.0;8.8] vs 0.0 [0.0;3.0], p< 0.001).

In the adjusted analysis, EHOA was associated with more pain at mobilization (OR = 3.13 95% CI [1.74 to 5.68] p< 0.001) and functional impairment (OR = 2.27 CI 95% [1.26 to 4.17], p = 0.007) (Figure 1). There was no difference for pain at rest and for fatigue.

For comorbidities, the proportions of EHOA patients with ³ 2 comorbidities were higher than RA patients (37.7% vs 27.5%). However, in adjusted analysis, the risk to have ³ 2 comorbidities was lower in EHOA than in RA (OR = 0.25 CI 95% [0.13 to 0.48]; p< 0.001) while there was no difference for CVD risk

Conclusion: After more than 10 years of disease duration, EHOA is associated with more pain and functional impairment but less comorbidities than RA. This study highlights the significant need for effective therapies EHOA.

Synovitis and the Risk of Incident Hand Osteoarthritis: Data from the Xiangya Osteoarthritis Study

ting Jiang[1], Qianlin Weng[1], Jiatian Li[2], Yuqing Zhang[3], Weiya Zhang[4], Michael Doherty[4], Tuo Yang[5], Zidan Yang[6], Ke Liu[1], Qiu Chen[1], Jie Wei[7], Guanghua Lei[2] and Chao Zeng[2], [1]Xiangya Hospital, Central South University, Changsha, China, [2]Department of Orthopaedics, Xiangya Hospital, Central South University, Changsha, China, [3]Division of Rheumatology, Allergy, and Immunology, Department of Medicine, Massachusetts General Hospital, Boston, MA, [4]Academic Rheumatology, Clinical Sciences Building, University of Nottingham, City Hospital, Nottingham, United Kingdom, [5]Department of Health Management Center, Xiangya Hospital, Central South University, Changsha, China, [6]Key Laboratory of Aging-related Bone and Joint Diseases Prevention and Treatment, Ministry of Education, Xiangya Hospital, Central South University, Changsha, China, [7]Health Management Center, Xiangya Hospital Central South University, Changsha, China

SESSION INFORMATION

Session Date: Tuesday, November 14, 2023

Session Title: Abstracts: Osteoarthritis II: Novel Insights from Observational Studies

Session Type: Abstract Session

Session Time: 2:00PM–3:30PM

Background/Purpose: Synovitis is a modifiable pathological lesion of hand osteoarthritis (HOA). Although synovitis has been related to the prevalence and symptoms of HOA, it remains unclear whether the presence of synovitis increases the risk of incident HOA. We aimed to examine the association between baseline synovitis and incident HOA.

Methods: We conducted a prospective cohort study among participants from the Xiangya OA (XO) Study. Rdiographic and ultrasound examinations were performed on both hands and reliability has been described in previous studies. Hands without baseline radiographic HOA (Kellgren-Lawrence grade $\geq$2 in any joint of a hand) or symptomatic HOA (Kellgren-Lawrence grade $\geq$2 plus self-reported symptoms in the same joint of a hand) were included in the analyses. Incident HOA was defined as the development of radiographic HOA or symptomatic HOA during the three-year follow-up. Hand synovitis was defined as grey-scale synovitis $\geq$2 grade by ultrasound. The inflammatory activity of the synovitis was assessed by the Power Doppler signal (PDS) detected in the synovium. We used generalized estimating equations to examine the relation of synovitis to the risk of incident radiographic and symptomatic HOA, respectively. We assessed the dose-response relationship between the synovitis load (number of hand joints affected by synovitis) and synovitis inflammatory activity (i.e., no synovitis, synovitis without PDS, and synovitis with PDS) at baseline and the risk of HOA. We quantified the impact of synovitis on incident HOA risk by population attributable fractions (PAF).

Results: Included in the analysis were 4,022 hands (2,280 participants) for incident radiographic HOA and 5,016 hands (2,600 participants) for incident symptomatic HOA, respectively (**Figure 1**). During three years of follow-up, 857 (21.3%) hands developed incident radiographic HOA and 111 (2.2%) hands developed symptomatic HOA. As shown in **Table 1**, baseline hand synovitis was associated with an increased risk of radiographic HOA (OR=2.69, 95% CI: 2.06-3.53, P <0.01) and symptomatic HOA (OR=1.73, 95% CI: 1.05-2.85, P=0.03). **Figure 2** shows there was a strong dose-response relationship between the number of hand joints with synovitis and the risk of radiographic and symptomatic HOA (P for trend <0.05). Compared with hands without synovitis, the risk of radiographic HOA was 2.6-fold higher among hands with synovitis but without PDS (OR=2.56, 95% CI: 1.95-3.36, P <0.01), and 10.4-fold higher among hands with both synovitis and PDS (OR=10.42, 95% CI: 1.51-71.81, P=0.03), with the P for trend being statistically significant. We could not assess the relationship between baseline synovitis activity and the risk of symptomatic HOA because of the limited sample size. Approximately 12.5% of incident radiographic HOA and 13.3% of incident symptomatic HOA were attributed to hand synovitis.

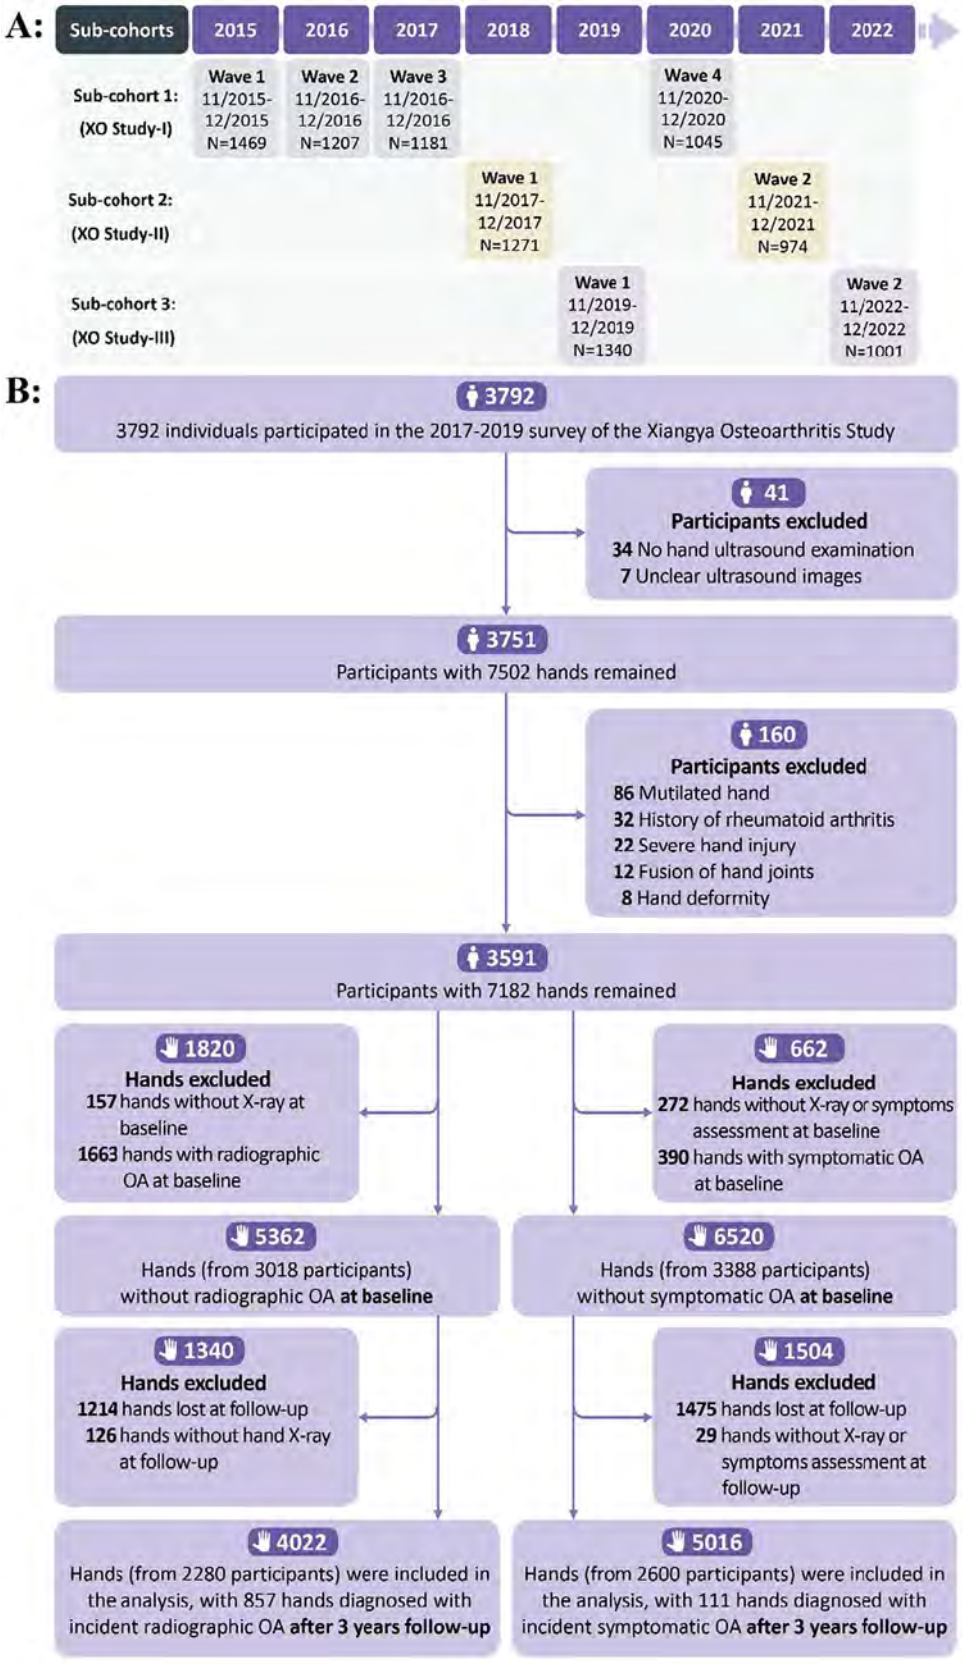

Figure 1. (A) diagram of examination cycles of the Xiangya Osteoarthritis Study (XO Study); (B) flow chart of participants in the study according to new onset of radiographic or symptomatic HOA. HOA, hand osteoarthritis.

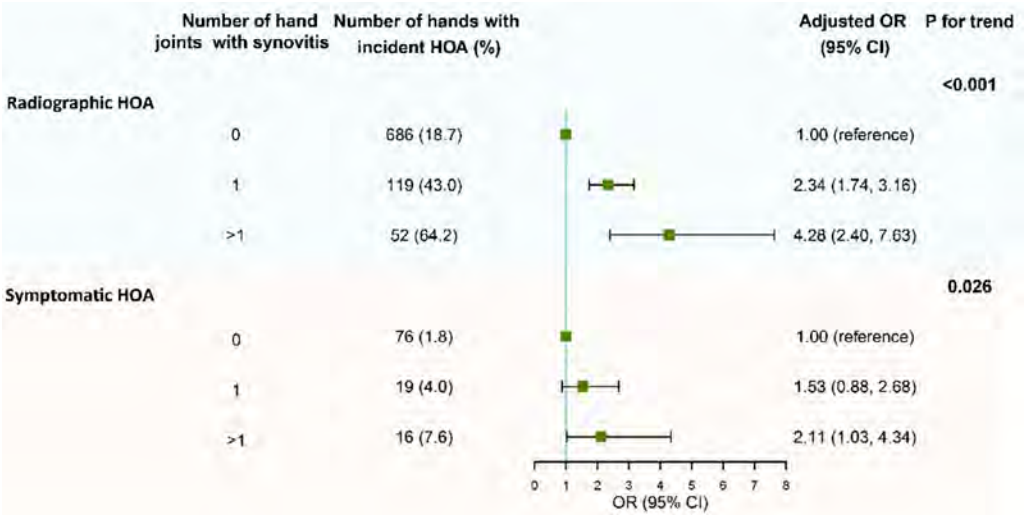

Figure 2. Associations between baseline synovitis load and incident radiographic or symptomatic HOA over three years of follow-up. Adjusted for age, sex, body mass index, smoking status, alcohol consumption, educational level, hand injury history and Kellgren/Lawrence grade at baseline. CI, confidence interval; HOA, hand osteoarthritis; OR, odds ratio.

Table 1. Associations between baseline hand synovitis and incident radiographic or symptomatic HOA over three years of follow-up

	Baseline hand synovitis	
	No	Yes
Incident radiographic HOA		
No, number (%)	2,978 (81.28)	187 (52.23)
Yes, number (%)	686 (18.72)	171 (47.77)
Crude OR (95% CI)	1.00 (reference)	3.97 (3.15, 5.00)
Adjusted OR (95% CI)[a]	1.00 (reference)	2.69 (2.06, 3.53)
Incident symptomatic HOA		
No, number (%)	4,251 (98.24)	654 (94.92)
Yes, number (%)	76 (1.76)	35 (5.08)
Crude OR (95% CI)	1.00 (reference)	2.99 (1.91, 4.70)
Adjusted OR (95% CI)[a]	1.00 (reference)	1.73 (1.05, 2.85)

CI, confidence interval; HOA, hand osteoarthritis; OR, odds ratio.

[a] Adjusted for age, sex, BMI, smoking status, alcohol consumption, educational level, hand injury history and Kellgren–Lawrence grade at baseline.

Conclusion: Synovitis is associated with an increased risk of both incident radiographic and symptomatic HOA in the general population. The strength of the associations increases with the load and inflammatory activity of synovitis. These results support synovitis as a risk factor for HOA and a prospective target for disease prevention.

Session Title: Abstracts: Pediatric Rheumatology – Clinical III: Potpourri

Session Type: Abstract Session

Session Time: 2:00PM–3:30PM

Background/Purpose: Over the last decade, lung disease (LD) has become an increasingly recognized complication of systemic juvenile idiopathic arthritis (sJIA). Children with sJIA-LD may be asymptomatic (diagnosed based on chest imaging) or present with a rapidly progressive disease course that can be fatal. Currently, the true burden of disease is unknown due

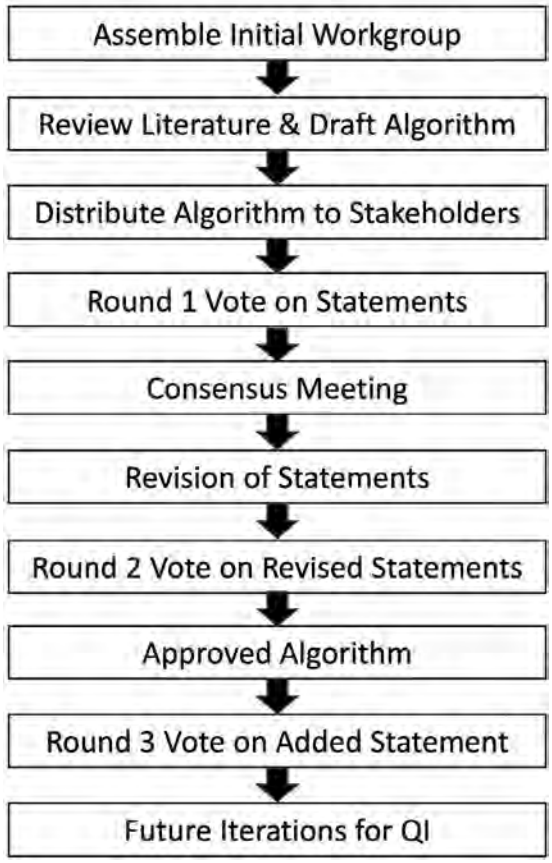

Figure 1. Steps used to develop the sJIA-LD screening algorithm. Through a modified Delphi approach, statements were voted upon, discussed, refined, and re-evaluated by a collaborative workgroup containing diverse stakeholders. Approved statements were rated as appropriate with a moderate or high level of consensus and were organized into the final version of the algorithm. sJIA-LD, systemic juvenile idiopathic arthritis lung disease; QI, quality improvement

to the variability of clinical symptoms and lack of a standardized approach to pulmonary screening in sJIA patients. Here, we sought to develop an algorithm to evaluate for LD in patients with sJIA at our institution.

Methods: A multidisciplinary workgroup was assembled and included members representing rheumatology (n=14), pulmonary (n=5), stem cell transplantation (n=1), and patients and their families (n=2). Four workgroup leaders drafted an initial algorithm based on review of the published literature and experience at our center. A modified Delphi approach was used to achieve agreement through 3 rounds of anonymous, asynchronous voting and a consensus meeting held in the Fall of 2022 (Figure 1). Approved statements were rated as appropriate by the workgroup with moderate or high levels of consensus. These approved statements were organized into the final version of the screening algorithm for LD in sJIA.

Results: The workgroup ultimately rated 21 statements as appropriate with a moderate or high level of consensus. The final algorithm recommends pulmonary screening for newly diagnosed sJIA patients with clinical features that the workgroup agreed may confer increased risk for LD (Figure 2). These "red flag" features include: baseline characteristics (young age

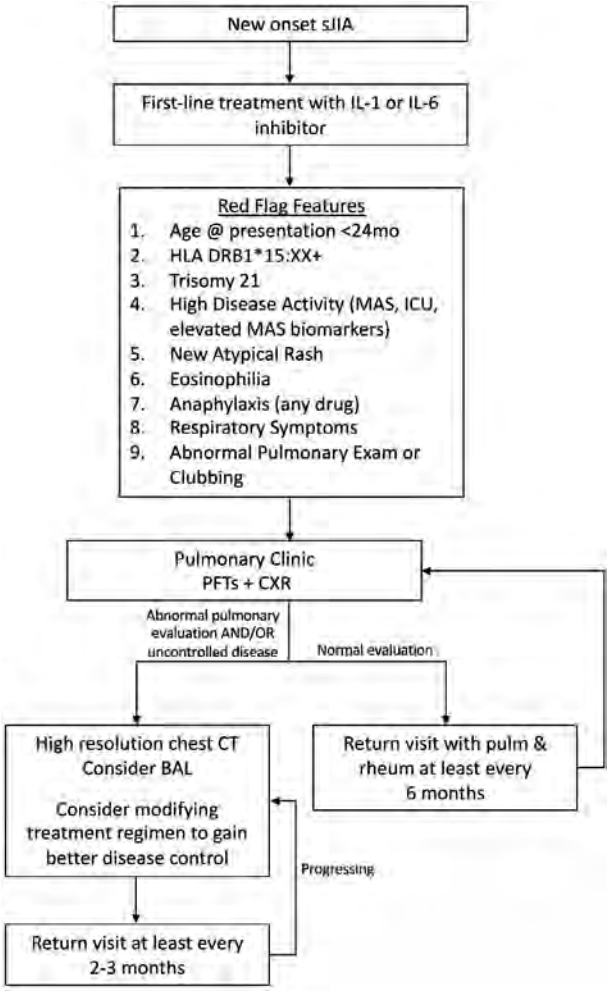

Figure 2. Pulmonary screening algorithm for lung disease in patients with sJIA. The approved algorithm outlines a consensus-based approach to pulmonary screening for LD in sJIA patients at our center. Patients with newly diagnosed sJIA and at least one red flag feature are referred for pulmonary evaluation and follow up. MAS biomarkers include CXCL9, IL-18, ferritin, sIL-2R. Eosinophilia is defined as two consecutive AEC >500/uL or a doubling of baseline AEC. PFTs include spirometry, lung volumes, DLCO, and 6-minute walk test. In younger children who cannot perform these PFTs, a 3-minute walk test can be used. This algorithm was developed for educational purposes only and for use in the Rheumatology and Pulmonary Programs at Boston Children's Hospital. Decisions about evaluation and treatment are the responsibility of the treating clinician and should always be tailored to individual clinical circumstances. sJIA, systemic juvenile idiopathic arthritis; ICU, intensive care unit; MAS, macrophage activation syndrome; AEC, absolute eosinophil count; sIL-2R, soluble IL-2 receptor; PFTs, pulmonary function tests; CXR, chest x-ray, CT, computed tomography; BAL, bronchoalveolar lavage; DLCO, diffusing capacity of the lungs for carbon monoxide

at sJIA disease onset, presence of HLA-DRB1*15 alleles, trisomy 21), high disease activity (history of MAS, sJIA-related ICU admission, elevated MAS biomarkers such as ferritin, soluble IL-2 receptor, IL-18 and CXCL9), respiratory symptoms or abnormal pulmonary examination findings, and features of drug hypersensitivity-like reactions (eosinophilia, new non-evanescent rash without identifiable cause, anaphylaxis to any drug). The presence of any red flag feature prompts an initial pulmonary evaluation, which includes pulmonary function tests (3-minute walk test for young children who cannot perform PFTs), chest x-ray, and referral to the pulmonary clinic. For patients with an abnormal initial pulmonary evaluation and/or persistently active sJIA disease, a high-resolution chest CT is recommended. Bronchoalveolar lavage should also be considered in these patients to evaluate for infectious causes of respiratory decline. The workgroup recommended that all patients with red flag features should be followed closely in the pulmonary clinic.

Conclusion: We used a multidisciplinary, consensus-based approach to develop a strategy to screen for LD in children with sJIA. This approach is intended to reduce practice variation and identify pulmonary complications earlier in the disease course when interventions may be more successful. The algorithm will form the foundation upon which iterative changes can be made as our understanding of sJIA-LD improves.

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: Abstracts: Pediatric Rheumatology – Clinical III: Potpourri
Session Type: Abstract Session
Session Time: 2:00PM–3:30PM

Background/Purpose: TNF inhibitors (TNFi) have dramatically changed the prognosis of Juvenile Idiopathic Arthritis (JIA). However, once achieved disease remission, it is not clear how and when withdraw the therapy. We aim to describe a multicentric cohort of JIA treated with Adalimumab or Etanercept who discontinued the treatment for persistent remission and identify factors associated with relapse.

Methods: In a multicentric Italian retrospective cohort study (Florence, Brescia, Trieste and Bari), medical records of patients with oligoarticular and polyarticular JIA were evaluated if they stopped therapy for persistent remission after the first course of TNFi. We collected demographic, clinical and laboratory data at onset and during biologic treatment.

Results: 136 patients were enrolled (102 female, median age at onset 3 years (R1-15)), of whom 76 (55.9%) had oligoarticular JIA, 55 (40.4%) uveitis and 99 (72.8%) ANA positivity. Adalimumab (59.3%) and Etanercept (40.7%) were started at a median age of 6 years (R1-16). Remission was achieved after a median time of 4 months (R 1-32) and TNFi were discontinued after a median time of 30 months (R 6-90), increasing the interval of administration in 76.5%, reducing the dose in 18.4% and abrupt discontinuation in16.9%. The 79.4% of patients relapsed after a median time of 5 months (R 0.5-66) and they were more likely female (X^2 5.9 p< 0.014), younger at onset (p< 0.001) and TNFi initiation (p 0.002), to have uveitis

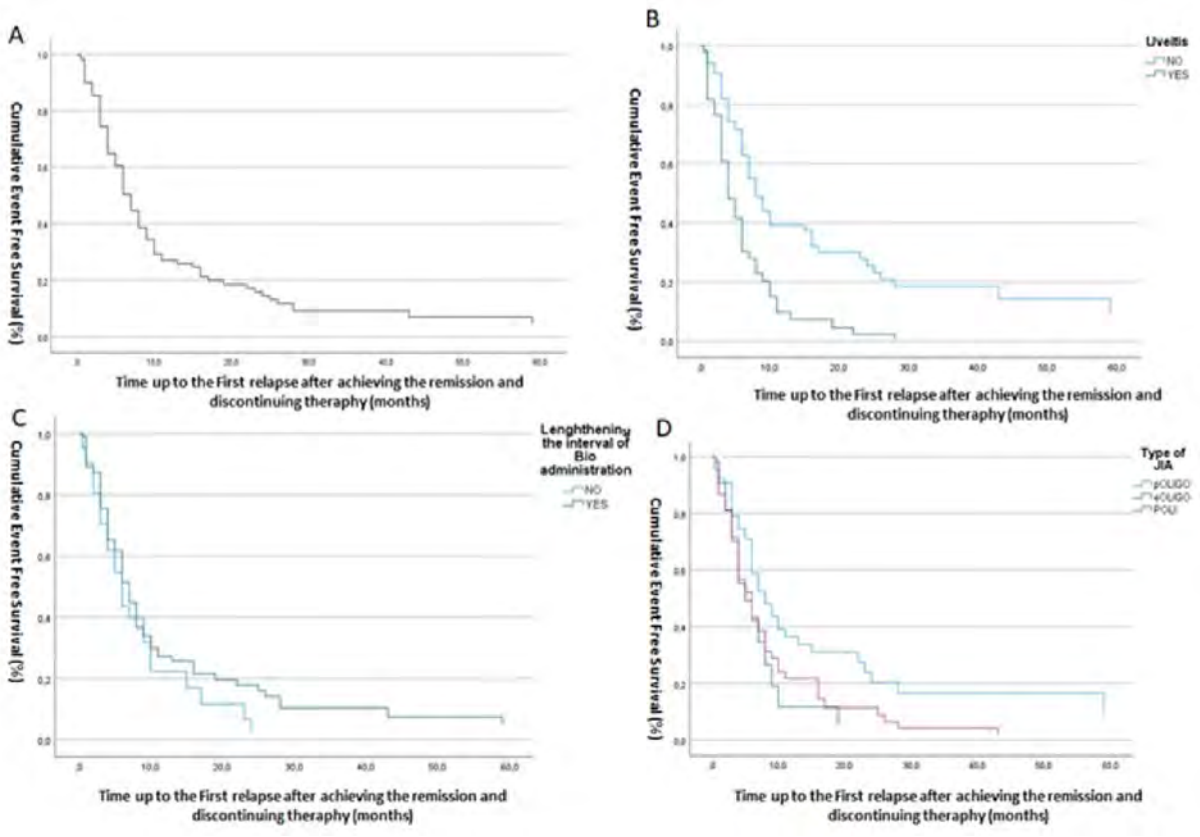

Figure 1: Survival functions from Cox regression, showing the time up to the first relapse after discontinuing therapy among enrolled patients (A), by uveitis (Log Rank $\chi_2$20.54 p0.025) (B), by drug withdrawal modality lengthening the interval of biologic administration (LogRank χ_2 30.3 p 0.001) (C), and by JIA subtypes (LogRank χ_2 31.9 p<0.001) (D)

(X^2 7.4 p< 0.006), longer time to TNFi initiation (p0.02), shorter time of weaning therapy (p0.005) and discontinued therapy not lengthening intervals of administration (X^2 5.2 p0.015). Moreover, patients with uveitis and who not lengthening the interval of administration have earlier relapse evaluated with Kaplan-Meier curve (Log Rank χ^2 = 16.4 p < 0.0001 and χ^2 = 6.95 p 0.008). Cox regression showed as independent predictors for time to relapse uveitis (HR 2.25 CI 1.41 – 3.57), age at onset (HR 0.907 CI 0.830-0.991), duration of tapering (HR 0.928 CI 0.875 -0.985) and to have a pOligo (HR 0.59 CI 0.361-0.978) (χ^2 = 32.9 p0.001). Stratifying the curve by uveitis, JIA categories and tapering modalities the curves showed respectively that patients with uveitis and who do not lengthened the interval of administration relapsed earlier compared to the others (respectively Log Rank χ^2 = 20.54 p0.025 and Log Rank χ^2 = 30.3 p0.001), while patients with pOligo relapse later compared to the other (Log Rank χ^2 = 31.9 p< 0.001)

Conclusion: Early age at onset, uveitis, duration of tapering and to have pOligo seem to be independent risk factors for earlier relapse after first Anti-TNF withdrawal.

Elevation of the IL-17 Cytokine Family Distinguishes Kawasaki Disease from Other Pediatric Inflammatory Disorders

Kailey Brodeur[1], Meng Liu[2], Yan Du[3], Lauren Henderson[1], Joyce Chang[1], Jane Newburger[1], Peter Nigrovic[1] and Pui Lee[4], [1]Boston Children's Hospital, Boston, MA, [2]Southern Medical University, Boston, MA, [3]Harvard medical school, Boston, MA, [4]Division of Immunology, Boston Children's Hospital, Boston, MA

SESSION INFORMATION

Session Date: Tuesday, November 14, 2023

Session Title: Abstracts: Pediatric Rheumatology – Clinical III: Potpourri

Session Type: Abstract Session

Session Time: 2:00PM–3:30PM

Background/Purpose: Kawasaki disease (KD) is a systemic vasculitis of young children that can lead to the development of coronary artery aneurysms (CAA) in up to 20% of patients. As KD shares overlapping clinical features with other pediatric inflammatory conditions, we aimed to identify diagnostic markers to distinguish KD using the proximity extension assay (PEA) proteomics platform that accurately quantifies protein targets in small volumes of biological fluids (Figure 1A).

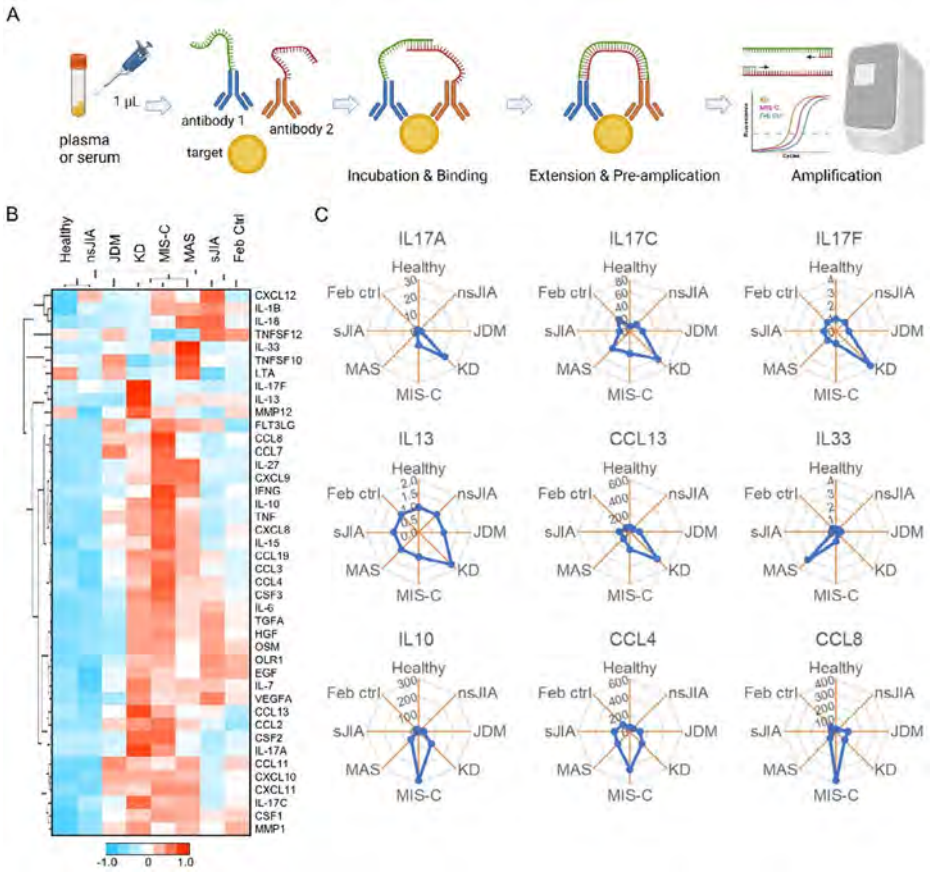

Figure 1. Profiling proinflammatory markers in pediatric inflammatory diseases using proximity extension assay (PEA). A) Schematic illustrating the key steps of PEA. B) Hierarchical clustering and heatmap display of normalized PEA data in healthy controls (n=30), febrile controls (n=26), and patients with Kawasaki disease (KD; n=23), multisystem inflammatory syndrome in children (MIS-C; n=25), macrophage activation syndrome (MAS, n=13), systemic- and non-systemic juvenile idiopathic arthritis (n=14 and n=10, respectively), and juvenile dermatomyositis (n=9). C) Radar plots of median expression values of key cytokines and chemokines upregulated in KD, MAS, and MIS-C. Units represent pg/mL in panel C.

Methods: We used PEA to profile proinflammatory mediators in plasma samples from healthy pediatric controls (n=30), febrile controls (n=26), and patients with KD (n=23), multisystem inflammatory syndrome in children (MIS-C; n=25), macrophage activation syndrome (MAS; n=13), systemic- and non-systemic juvenile idiopathic arthritis (n=14 and n=10, respectively), and juvenile dermatomyositis (n=9). We validated the key findings using serum samples from additional patients with KD (n=37) and febrile controls (n=28).

Results: High-fidelity proteomic profiling by PEA revealed distinct patterns of cytokine and chemokine expression across pediatric inflammatory diseases (Figure 1B). Although KD and MIS-C exhibited many similarities, KD differed from MIS-C and other febrile diseases in that most patients exhibited elevation in one or more members of the IL-17 cytokine family, IL-17A, IL-17C, and IL-17F (Figure 1C). In contrast, the MIS-C group showed elevated levels of IL-10, CCL4 and CCL8, while IL-33 elevation was specifically observed in the MAS group.

IL-17A, IL-17C, and IL-17F levels were significantly higher in patients with KD compared to those with MIS-C and febrile controls (Figure 2A). IL-17A was particularly sensitive and specific in discriminating KD from febrile controls with an area under the receiver operator characteristics (ROC) curve of 0.95 (95% CI: 0.89–1.00) in the derivation set and 0.91 (0.85–0.98) in the validation set. Concurrent elevation of all three IL-17-family cytokines was observed in >50% of KD patients (Figure 2B), including 19 of 20 with CAA, but was rare in other comparator groups. IL-17A and IL-17F levels were significantly higher in KD patients with CAA compared to those without CAA, whereas the levels of IL-1β, IL-6, and TNF were comparable between the groups.

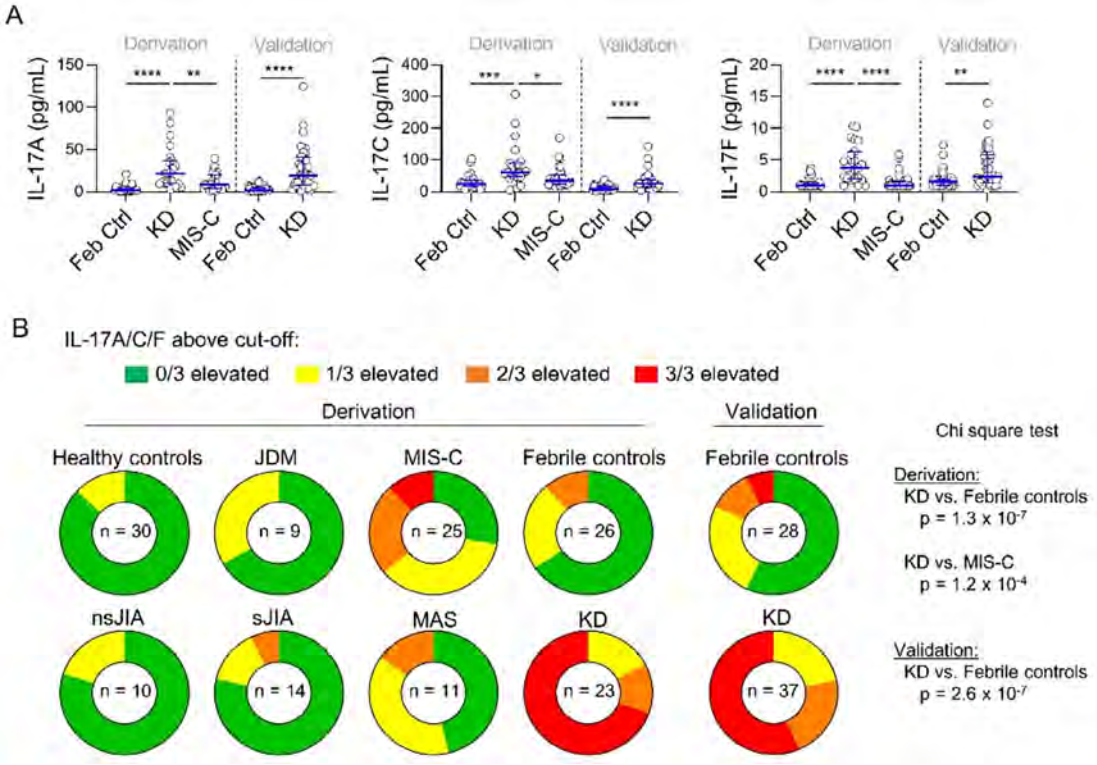

Figure 2. Identification of inflammatory mediators associated with KD. A) Comparison of IL-17 cytokine levels in febrile controls (n=26 in derivation cohort; n=28 in validation cohort), patients with KD (n=23 in derivation cohort; n=37 in validation cohort), and patients with MIS-C (n=25). Median and interquartile range are displayed by blue lines. B) Circle diagrams illustrating the proportion of patients with elevated levels of IL-17A, IL-17C, and/or IL-17F. Mann-Whitney U test was used for statistical analysis in panel A. Chi square test was used for panel B. * $p < 0.05$, ** $p < 0.01$, *** $p < 0.001$, **** $p < 0.0001$.

Conclusion: Data from a single center demonstrated that elevation of IL-17-family cytokines is a hallmark of KD and may help to distinguish this pediatric vasculitis from its clinical mimics. Future multicenter studies are needed to validate these findings.

SESSION INFORMATION

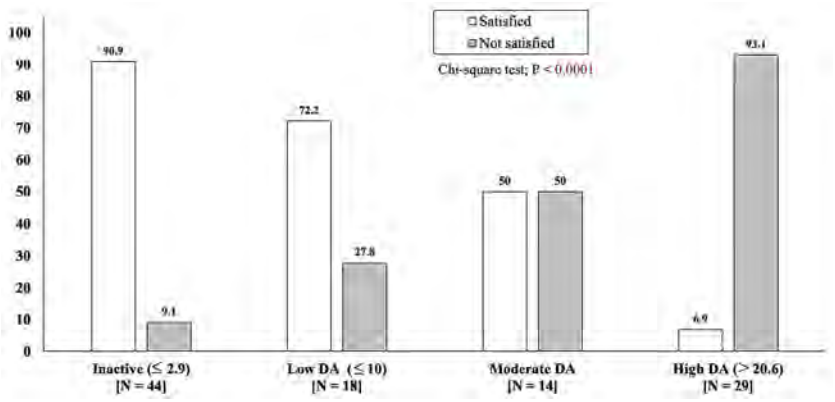
Session Date: Tuesday, November 14, 2023

Session Title: Abstracts: Pediatric Rheumatology – Clinical III: Potpourri

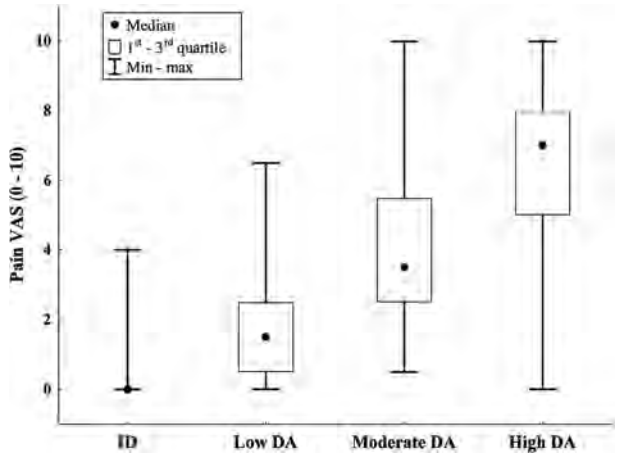
Session Type: Abstract Session

Session Time: 2:00PM–3:30PM

Background/Purpose: The systemic Juvenile Arthritis Disease Activity Score (sJADAS) is a composite disease activity (DA) score specifically validated for use in systemic JIA (sJIA), whose range is 0-50. The sJADAS10 is obtained as the simple sum of the scores of the following 5 items: 1) physician global assessment of overall DA, measured on a 10-cm visual analog scale (VAS), where 0 = no activity and 10 = maximum activity; 2) parent/patient global assessment of child's well-being, measured on a 10-cm VAS, where 0 = very well and 10 = very poor; 3) count of joints with active disease in a maximum of 10 joints; 4) ESR or CRP level, normalized to a 0-10 scale; and 5) modified Systemic Manifestation Score (mSMS), ranging from 0 to 10, where 0 = absence of systemic manifestations and 10 = maximum activity of systemic manifestations. Our aim was to develop and validate the cutoffs in the sJADAS10 that define the states of inactive disease (ID), low (or minimal) DA (LDA), moderate DA (MDA) and high DA (HDA) in sJIA.

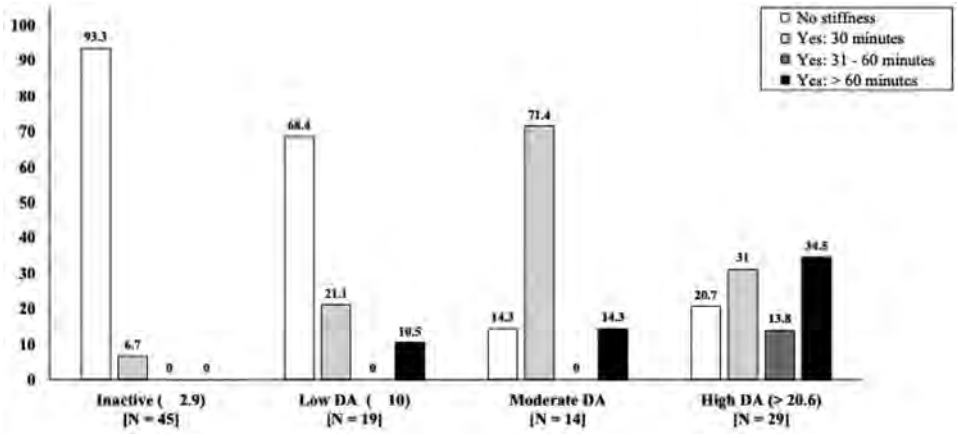


Discriminant Ability: sJADAS total score by category of Parent Acceptable Symptom State (PASS).



Discriminant Ability: sJADAS total score by level of pain VAS.

Methods: A multinational cross-sectional sample of 378 patients with definite or probable sJIA was enrolled. Each patient was categorized subjectively by the caring physician at study visit as being in the state of ID, LDA, MDA, or HDA. A total of 400 visits were collected, that were randomly divided into two samples: a developmental (n=240) and a validation sample (n=160). Optimal cutoff values were determined in the developmental sample against the subjective physician rating of DA state, that was used as external criterion, by multiple methods (calculation of percentiles of cumulative score distribution,



Relationship between sJADAS categories (as defined by the selected cutoff values) and categories of morning stiffness.

ROC curve analysis, Youden index, 90% fixed specificity and kappa agreement). The choice of final cutoffs was based on clinical and statistical grounds. Cutoff validation was conducted in the validation sample by assessing discriminative ability.

Results: The selected sJADAS10 cutoffs were < = 2.9 for ID, < = 10 for LDA, 10-20.6 for MDA, and >20.6 for HDA. In validation analyses, the cutoffs showed strong ability to discriminate among DA states defined subjectively by the parents, parents' satisfaction/dissatisfaction with illness outcome (Fig. 1), level of child's pain (Fig. 2), presence/absence of functional impairment, presence/absence of morning stiffness (Fig. 3), and normal/reduced quality of life.

Conclusion: We developed the cutoffs in the sJADAS10 that define the main DA states in sJIA. The cutoffs revealed good metrologic properties in the validation sample, and are therefore suitable for application in clinical practice and research.

SESSION INFORMATION

Session Date: Tuesday, November 14, 2023
Session Title: Abstracts: Pediatric Rheumatology – Clinical III: Potpourri
Session Type: Abstract Session
Session Time: 2:00PM–3:30PM

Background/Purpose: Autoinflammatory Type I Interferonopathies (IFNopathies) include SAVI (STING-associated vasculopathy with onset in infancy), CANDLE/PRASS (Chronic atypical neutrophilic dermatosis, with lipodystrophy and elevated temperature), and AGS (Aicardi-Goutieres syndrome). A high blood IFN-I signature/score correlates with disease activity and response to treatment[2] and is used together with a ratio (IFN-I score/NFKB score) to characterize patients with yet genetically uncharacterized diseases[3]. JAK inhibitors (JAKi), which block the signaling of the IFN receptor, have been the

mainstay of treatment,[1] but suppression of the IFN-I score is only achieved in a subset of CANDLE/PRAAS patients. We treated patients with ongoing active disease and elevated IFN-I scores with the anti- type I IFN receptor (IFNAR) monoclonal antibody, anifrolumab to achieve better disease control and reduce side effects from high-dose JAKi treatment.

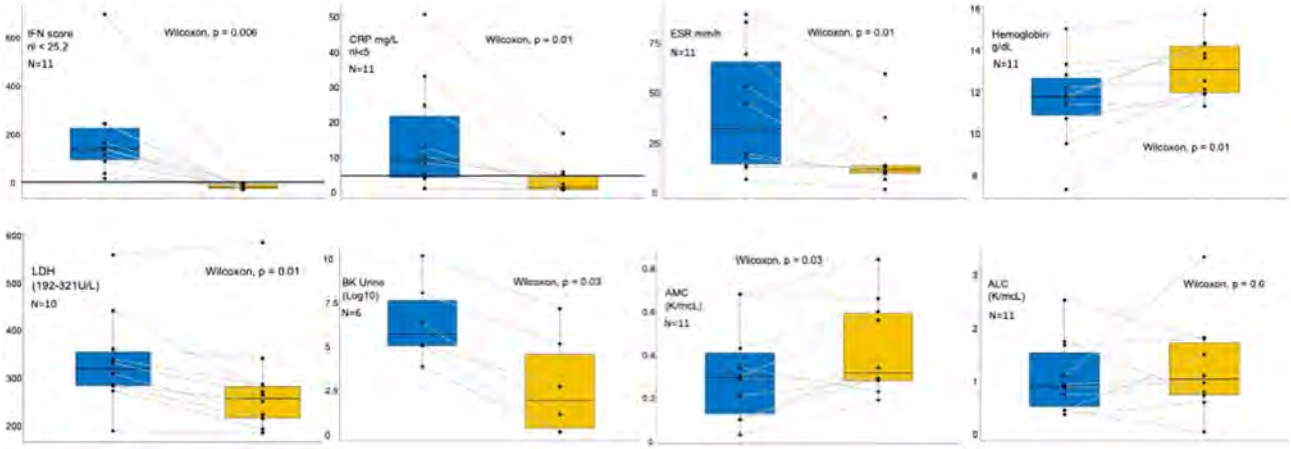
Methods: Pts (n=12), enrolled in NCT02974595, with type I IFNopathies (SAVI=3, CANDLE=6, Undifferentiated=3) and persistently elevated type I IFN score in the blood on optimized treatment with the JAKinhibitor, baricitinib, (n=11), were started on anifrolumab infusions every 4 wks (300 mg or 5.5 mg/kg) either as monotherapy (n=1) or in combination with the baseline JAKi treatment (n=11). The median length of treatment with anifrolumab (range 2-20, median 8 months). Table 1. All patients received zoster prophylaxis. Patient-reported outcomes (daily diaries and questionnaires, n=10) and clinical biomarkers, safety labs including BK viral titers were monitored (n=12).

Table 1: Characteristics of the IFNopathy cohort who received anifrolumab

	N=12
Age, Median (Range, yrs.)	17 (2-42)
Female, n (%)	4 (34%)
White, n (%)	10 (84%)
Interferonopathy type, (n)	SAVI (3) CANDLE (6) Undifferentiated (3)
Concomitant Baricitinib, n (%)	11 (92%)
Baricitinib dose at baseline, median (range, mg/day)	7 (4-12)
Baricitinib dose on anifrolumab, median (range, mg/day)	10 (60%)
Corticosteroid Use, n (%)	9 (75%)
Prednisone dose at baseline, median (range, mg/kg/day)*	0.2 (0.1-1)
Prednisone dose reduction on anifrolumab, n (% reduction)	6 (22%)
Anifrolumab	
Anifrolumab dose, every 28 days (range, mg)**	5.5/kg-300
Anifrolumab treatment duration, median (range, months)	8 (2-20)

*One patient is on methylprednisolone monthly infusion. The dose is reduced from 80 mg to 60 mg on anifrolumab.
**in patients >40kg the full dose of anifrolumab was administered

Figure 1:
Changes in the biomarkers before and after treatment with anifrolumab (n=11)
The blue box represent the value immediately before the first dose and the yellow box is the most recent lab value available on anifrolumab.
In one patient the recent labs were not available at the time of analysis. The same patient had IFN score measured in a different scale.
Paired Wilcoxon rank sum test was used for analysis.



Results: Treatment with anifrolumab resulted in a median change in IFN-I score from 142 to -16 and normalized in all patients treated (n=12) (Figure1). Clinical flares did not occur. The baricitinib dose was tapered down by median of 3 mg/day (0.2 mg/kg/day) in 10/11 pts of the starting dose. Pts on systemic steroids (n=9) could taper down by median of 0.5 mg/kg (n=7) or discontinued steroids (n=2). Inflammatory markers, CRP, and ESR significantly improved on anifrolumab (2/3 SAVI patients continue to have high CRP). Anemia resolved in all patients. Urine BK viral load dropped in (n=6) who had baseline high BK viral titers. Two pts on the combination of anifrolumab and JAKi developed systemic viral infections (Enterovirus n=1, Human Herpesvirus-6 =1 complicated with encephalopathy), and two patients had a long course of rhinovirus and parainfluenza infections that were resolved after tapering down the dose of JAKi and supportive therapy. Evaluation of cytokines and biomarkers is ongoing.

Conclusion: Anifrolumab effectively suppressed the IFN-1 signature/score in all patients, including in SAVI pts; this was associated with improved serum CRP and ESR in the context of tapering doses of baricitinib and corticosteroids. BK viral titers dropped. Long-term follow-up to assess treatment efficacy in controlling inflammatory organ manifestations and progression of organ damage is critical in determining the impact of IFN-I blockade on the diseases manifestations of the autoinflammatory interferonopathies.

SESSION INFORMATION

Session Date: Tuesday, November 14, 2023

Session Title: Abstracts: Pediatric Rheumatology – Clinical III: Potpourri

Session Type: Abstract Session

Session Time: 2:00PM–3:30PM

Background/Purpose: Children with rheumatic and autoimmune diseases are often treated with conventional or biologic disease-modifying antirheumatic drugs (cDMARDs and bDMARDs) to control disease. While effective, DMARDs may impact antibody responses to COVID-19 vaccination, leading to a risk of breakthrough infections. Here, we compared the effect of different treatments for rheumatic and autoimmune diseases on the antibody response to COVID-19 vaccination in children.

Methods: A prospective observational study was conducted across Canada. Serum or dried blood spots were collected from children with autoimmune or rheumatic diseases after each COVID-19 vaccine dose. Antibodies against the SARS-CoV-2 spike (SmT1) and receptor-binding domain (RBD) were measured using an automated ELISA platform and results are reported in binding antibody units per mL (BAU/mL). Children who had evidence of a SARS-CoV-2 infection prior to sample collection were excluded, except for the hybrid immunity analysis. The magnitude and kinetics of the antibody response after each vaccine dose were compared between treatment groups using mixed-effects linear regression models. Disease activity was measured in a subset of participants using the Childhood Health Assessment Questionnaire (CHAQ) and the Visual Analog Scale (VAS).

Results: For this interim analysis, 1751 potential participants were identified. Of these, 1748 were contacted and 192 enrolled in the study. Data are currently available for 126 participants, including from 94 individuals without evidence of prior COVID-19 infection. Participants contributed 1-6 samples, resulting in total of 187 samples collected pre-vaccination, and following 1-4 vaccine doses (Table 1). The median age of participants was 12 years and most patients had a primary diagnosis of either JIA (57%) or vasculitis (19%). There was a relatively even distribution between the three treatment groups (none, cDMARDs, and bDMARDs), with a slight over-representation of bDMARD-treated patients (42%).

Following the second dose of the COVID-19 vaccine, IgG responses were both reduced in magnitude and waned faster for participants treated with bDMARDs than for those treated with cDMARDs or who were treatment naïve (Figures 1 & 2). Post-dose 3, differences in the magnitude of response between treatment groups were attenuated, but responses continued to wane at a faster rate in those treated with bDMARDs (Figures 1 & 2). Differences between treatment groups were not significant, however, among children with evidence of a prior SARS-CoV-2 infection. After dose 4, antibody responses were similar in all treatment groups (Figures 1 & 2). As measured by CHAQ and VAS scores reported by parents and participants, vaccination was not associated with increased disease activity.

Conclusion: Antibody responses to COVID-19 vaccination in children with autoimmune and rheumatic diseases were lowest in individuals treated with bDMARDs, with third and fourth vaccine doses necessary to yield robust and durable antibody responses. Given that vaccination did not impact underlying disease activity, additional work is needed to optimize vaccine strategies in this population.

SESSION INFORMATION

Session Date: Tuesday, November 14, 2023

Session Title: Abstracts: RA – Diagnosis, Manifestations, & Outcomes III: Predicting & Optimizing Outcomes

Session Type: Abstract Session

Session Time: 2:00PM–3:30PM

Background/Purpose: Nintedanib and pirfenidone are antifibrotic drugs indicated for the treatment of idiopathic pulmonary fibrosis (IPF) and other forms of progressive pulmonary fibrosis. Antifibrotics have also been tested in RA-associated interstitial lung disease (ILD) within two recent randomized clinical trials (RCT). However, there are limited real-world studies regarding the use of antifibrotics, and none in RA-ILD. RA-ILD patients may be different from IPF patients since they often need concomitant immunosuppression for articular disease. Our aim was to investigate the tolerability and effectiveness of antifibrotics in a real-world cohort of patients with RA-ILD.

Methods: In this retrospective cohort study, we identified RA-ILD patients initiating antifibrotics at a large multi-hospital healthcare system. We used electronic query to find all patients with at least two RA diagnosis codes and a prescription for either nintedanib or pirfenidone (2014-2023). We then performed medical record review to confirm all patients met 2010 ACR/EULAR classification criteria for RA and had definite RA-ILD by Bongartz criteria. Data regarding adverse events (AEs), tolerability, pulmonary function test (PFT) results, and clinical data were collected. Drug retention was estimated using a Kaplan-Meier curve. A linear mixed model with random intercept was used to compare the within-patient trajectory of the percent predicted forced vital capacity (%FVC) within 18-months before to 18-months after antifibrotic initiation among those with these PFT data.

Results: We analyzed 74 patients with RA-ILD that initiated antifibrotics (mean age 67.8 years, 53% male); 40 patients initiated nintedanib and 34 initiated pirfenidone (**Table 1**). Median follow-up was 89 weeks (min 4, max 387). AEs were reported in 41 (55%) patients, with gastrointestinal (GI) AEs (n=30) being most common, followed by disease progression (n=6), rash (n=3), and hepatitis (n=2). The initial antifibrotic was discontinued in 34 (46%) patients due to: GI AEs (n=19), rash (n=3), transaminitis (n=2), and financial reasons (n=1). The median drug survival was 147.7 weeks (95%CI 79.1, NA; **Figure 1**). There was no difference in drug retention between nintedanib and pirfenidone (p=0.68). A second antifibrotic was prescribed in 14 patients, with 4 discontinuations. Change of %FVC trajectory was analyzed for 49 patients with available PFTs within 18 months pre- and post-antifibrotic (median number of PFT/patient = 4). There was a statistical difference in the estimated %FVC slope after initiation (-0.3% per year compared to -6.2% per year before initiation, p=0.031, **Figure 2**). Twenty-six patients (35%) died (17 due to ILD) and 4 (5%) had lung transplantation during follow-up.

Conclusion: In this first real-world study of antifibrotic use in RA-ILD, AEs were frequently reported, particularly GI, and discontinuation was common (46% compared to 20% for nintedanib and 24% for pirfenidone in their respective RCTs). However, antifibrotic initiation was associated with a modestly improved trajectory in %FVC. Death and/or lung transplant were frequent, emphasizing the need for additional safe and effective RA-ILD treatment options.

Table 1. Characteristics of patients with RA-ILD at initiation of initial antifibrotic medication. ACPA: anti-citrullinated peptides proteins, cs and bDMARDs: conventional and biologic disease modifying drugs, DLCO: diffusing lung capacity of the lungs for carbon monoxide, FVC: forced vital capacity, HRCT: high resolution computed tomography, ILD: Interstitial lung disease, NSIP: non-specific interstitial pneumonia, RA: rheumatoid arthritis, RF: rheumatoid factor, UIP: usual interstitial pneumonia.

Session Title: Abstracts: RA – Diagnosis, Manifestations, & Outcomes III: Predicting & Optimizing Outcomes

Session Type: Abstract Session

Session Time: 2:00PM–3:30PM

Background/Purpose: Measures of improvement and state of disease activity are well-established in rheumatoid arthritis (RA), whereas distinct classifiers for worsening ("flare") are lacking to date. Definitions of flare are highly warranted for novel treatment strategies that aim for drug tapering or withdrawal in patients on treatment target. We therefore aim to provide preliminary definitions of flare, based on the Simplified and Clinical Disease Activity Indices (SDAI, CDAI).(1)

Table 1 Baseline, three- and six-month data from the NOR-DMARD main analysis cohort and the Vienna RA validation cohort (no. of treatment cycles: 4256 and 2557, respectively); values are given in percent, or as mean and standard deviation

csDMARDs=conventional synthetic disease-modifying anti-rheumatic drug; btsDMARD=biologic/targeted synthetic disease-modifying anti-rheumatic drug; SDAI=Simplified Disease Activity Index; CDAI=Clinical Disease Activity Index; CRP=C-reactive protein; ESR=Erythrocyte sedimentation rate; SJC28=Swollen joint count of 28 joints; TJC=Tender joint count of 28 joints; PGA=Patient global assessment of disease activity; EGA=Evaluator global assessment of disease activity; HAQ=Health assessment questionnaire

Methods: We analysed RA treatment courses from the Norwegian DMARD registry (NOR-DMARD) and the Vienna RA cohort. In a receiver operating curve (ROC) analysis, we determined distinct cut points for absolute worsening in SDAI and CDAI based on a semiquantitative patient anchor (for details see legend figure 1). We separated the NOR-DMARD dataset into a training and test cohort by 8:2 random sampling. For internal validation, we performed bootstrapping in the training cohort and evaluated performance in the test cohort. We then validated the definitions externally in the independent Vienna RA cohort, and determined their performance on content, construct, longitudinal, and face validity.

Results: We analyzed 4256 treatment courses in the NOR-DMARD registry and 2557 in the Vienna RA cohort (table 1). The preliminary definitions for absolute changes in SDAI and CDAI for flare are an increase of 4.7 and 4.5, respectively (figure 1). These cut points performed well in the NOR-DMARD test cohort and the external validation cohort. When flaring, patients showed worsening in all disease activity core set variables, including both patient reported and objective measures (figure

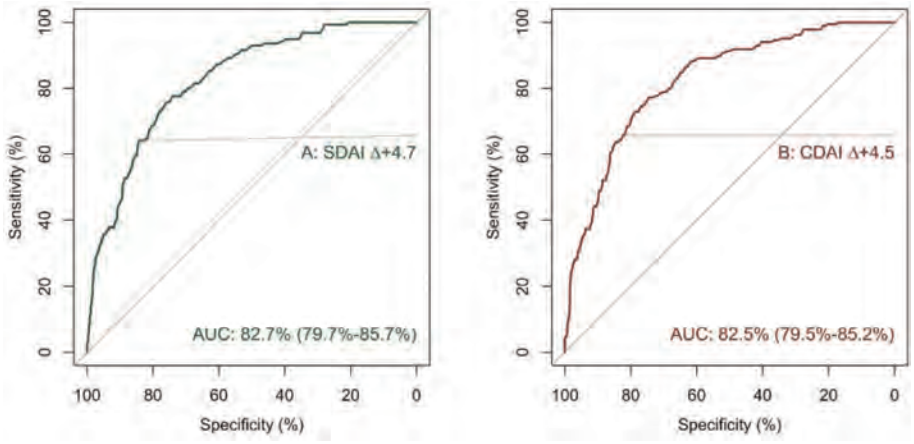

Figure 1 Receiver operating curves (ROC) to derive cut points for absolute changes in SDAI (A) and CDAI (B); based on a semiquantitative patient anchor from NOR-DMARD, where patients reported their perception of response to DMARD treatment compared to baseline on a five-point Likert scale (much worse – worse – unchanged – better – much better). Flare was defined as worsening of at least two points on the Likert scale, compared to the assessment at month three; 95%-confidence intervals for the area under the receiver operating curve (AUC) were estimated using bootstraps with 1000 resamples.

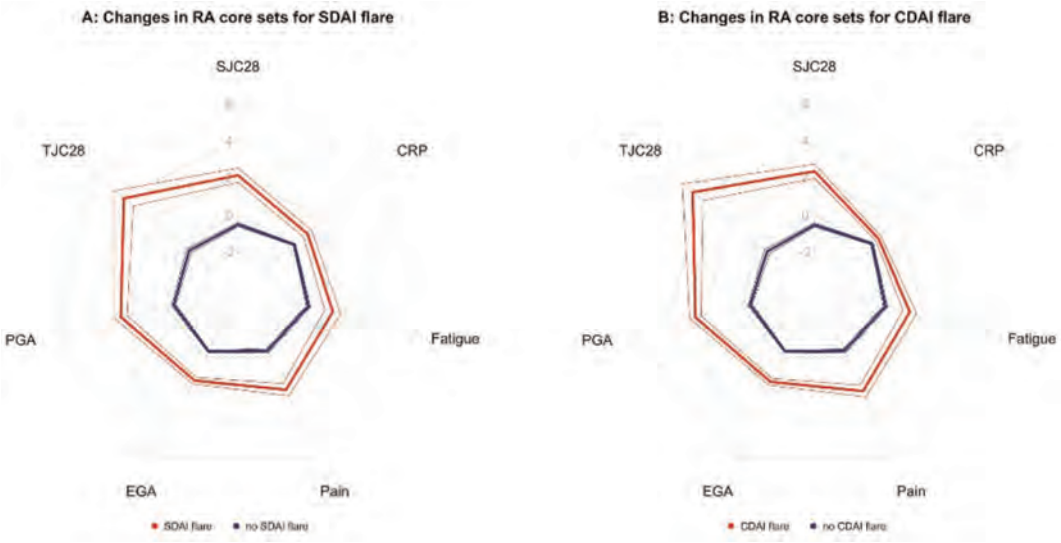

Figure 2 Content validity analysis; spider charts illustrate internal consistency of the novel definitions (A: SDAI Δ+4.7; B: CDAI Δ+4.5) across all rheumatoid arthritis core sets, tested in 1252 visits of 329 patients in the Vienna RA cohort; evaluator global (EGA), patient global (PGA), pain, and fatigue are given in cm; C-reactive protein (CRP) in mg/dl; thin borders mark 95%-confidence intervals

2), and were more frequently subjected to subsequent treatment changes (p< 0.001). Flares substantially impacted both functional and structural disease outcomes (increase in Health Assessment Questionnaire score, ΔHAQ,(2) for flare vs. no flare +0.44, p< 0.001; radiographic progression, Δmodified Sharp Score,(3) 43% higher after flare vs. no flare visits, 95%-CI 1.04-1.96, p< 0.001). This underlines clinical face and construct validity of the novel definitions.

Conclusion: We here provide novel preliminary definitions for flare in RA based on changes in SDAI and CDAI. In times of highly effective treatments available for RA, and consideration of treatment tapering or withdrawal, these definitions will be useful for guiding decision making in clinical practice and designing clinical trials.

Pre-pregnancy Gene Expression Signatures Among Women with Rheumatoid Arthritis May Represent Predictive Biomarkers for Subsequent Improvement or Worsening During Pregnancy

Matthew Wright[1], Mette Smed[2], Lee Nelson[3], Jørn Olsen[4], Merete Hetland[5], Nicholas Jewell[6], Vibeke Zoffmann[2] and **Damini Jawaheer**[1], [1]Northwestern University, Chicago, IL, [2]Juliane Marie Centre, Rigshospitalet, Copenhagen, Denmark, [3]Fred Hutchinson Cancer Center, Seattle, WA, [4]Aarhus University Hospital, Aarhus, Denmark, [5]Copenhagen Center for Arthritis Research, Rigshospitalet, Copenhagen, Denmark, [6]London School of Hygiene and Tropical Medicine, London, United Kingdom

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: Abstracts: RA – Diagnosis, Manifestations, & Outcomes III: Predicting & Optimizing Outcomes
Session Type: Abstract Session
Session Time: 2:00PM–3:30PM

Background/Purpose: Rheumatoid arthritis (RA) can improve naturally during pregnancy in a substantial proportion of women (50-75%), while it may worsen or remain unchanged in others. Thus far, there are no biomarkers to predict, at the pre-pregnancy stage, whether a woman with RA will improve or worsen during pregnancy. We examined pre-pregnancy gene

expression profiles among women with RA to identify prediction biomarkers for improvement/worsening during pregnancy. We also aimed to identify genes that demonstrated altered expression during pregnancy when RA improved or worsened.

Methods: Blood samples were collected before pregnancy (T0) and at the 3rd trimester (T3) from 19 women with RA and 14 healthy women enrolled in our prospective pregnancy cohort. RA improvement/worsening during pregnancy was assessed using the Clinical Disease Activity Index (CDAI). Total RNA from whole blood was sequenced to examine gene expression, and differences between groups or time-points were evaluated using differential expression analysis, using FDR < 0.05 and fold-change >=1.5 for significance. Co-expression network analysis and functional enrichment were also performed.

Results: Of the 19 women with RA, 14 improved during pregnancy ($RA_{improved}$) and 5 worsened ($RA_{worsened}$). At the T0 baseline, although both groups had similar disease activity (CDAI) [$RA_{improved}$ (mean±S.D.): 16.8±11.5 and $RA_{worsened}$: 16.9±7.6; p=0.9], their gene expression profiles were significantly different. The $RA_{improved}$ T0 gene expression signature showed increased expression of neutrophil-related genes. Additionally, one gene co-expression module related to B cell function was significantly correlated with the worsening of RA during pregnancy (r=0.65, FDR=$5E^{-5}$). This module was also significantly enriched (21-fold, FDR=$1.7E^{-118}$) in genes differentially expressed between the 2 RA groups at T0. At T3, the expression profile of the $RA_{improved}$ group became similar to those of the healthy women, and for most (86%) of the genes in the $RA_{improved}$ T0 RA signature, their T3 expression were no longer associated with the disease. In the $RA_{worsened}$ group, several genes became newly differentially expressed at T3, including some candidates known to be expressed in the RA synovium. Further, additional candidate genes (e.g. PADI4) previously reported to be involved in RA demonstrated longitudinal expression patterns that were associated with pregnancy, and those associations were influenced by clinical outcome during pregnancy.

Conclusion: Pre-pregnancy gene expression profiles in RA appear to be predictive of the subsequent improvement or worsening of RA during pregnancy, and they suggest that the $RA_{improved}$ and $RA_{worsened}$ groups may represent two distinct RA endotypes.

SESSION INFORMATION

Session Date: Tuesday, November 14, 2023

Session Title: Abstracts: RA – Diagnosis, Manifestations, & Outcomes III: Predicting & Optimizing Outcomes

Session Type: Abstract Session

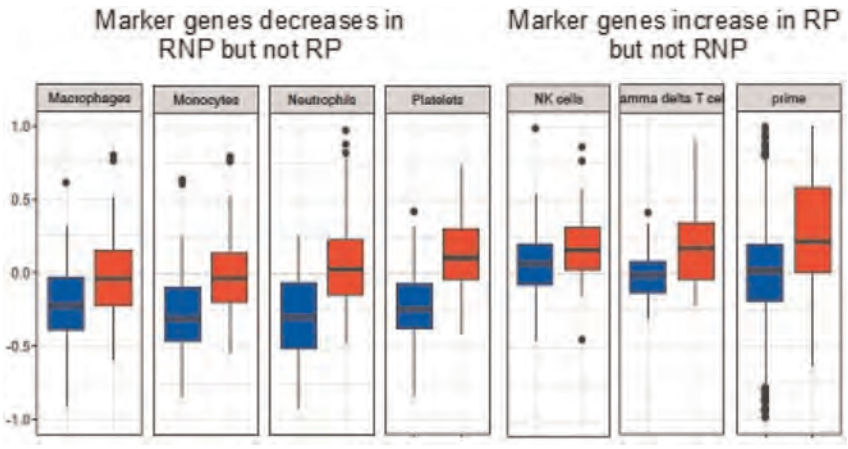
Session Time: 2:00PM–3:30PM

Background/Purpose: This study aimed to determine predictors of treatment response and radiographic progression following the initiation of biological disease-modifying antirheumatic medications (bDMARDs) in patients with rheumatoid arthritis (RA).

Methods: RNAseq was performed on peripheral blood mononuclear cells (PBMCs) taken before and 3 months after bDMARD initiation. Treatment response was defined as good EULAR response (change in DAS28 >1.2 if the DAS28 was >3.2) and radiographic progression was defined as increase in modified total sharp score (mTSS) of more than 0.5, 3.4, or 5.

Results: A total of 41 patients with RA were evaluated (meanage: 63.1 years; 75.6% are females). Radiographic progression was observed 60% of patients and was significantly less common in patients with a good EULAR response. Innate immune pathways, were significantly enriched at baseline in patients without radiographic progression, while genes atypical of immune cells, such as genes related to GO_mesoderm_developement, were upregulated in radiographic progressors, using various thresholds of mTSS change, suggesting enrichment of mesenchymal signature genes. In longitudinal analysis, Preinflammatory mesenchymal (PRIME) cell signature genes showed signifcant enrichment in radiographic progressors and poor treatment responders. In patients with no radiographic progression, innate immune cell, such as neutrophil, monocyte, and platelet, marker genes decreased significantly at 3 months compared to baseline, while they remained unchanged in patients with radiographic progression. On the other hand, in patients with radiographic progression, PRIME cell genes as well as NK and gdT cell genes increased significantly at 3 months compared to baseline, while they remained unchanged in those without radiographic progression (Figure 1).

Conclusion: PBMC innate immune gene signature are increased at baseline and decrease with treatment in patients no radiographic progression. On the other hand, PRIME cell genes are increased at baseline and increase further with treatment in patients with radiographic progression.



Gene expression changes after 3 months of treatment compared to baseline in radiographic nonprogressors (RNP; blue) and radiographic progressors (RP; red).

CD68 and Fibrinoid Necrosis Are Synovial Biomarkers of Severity in Early Rheumatoid Arthritis and Are Associated with a Better Response to Methotrexate: Analysis of the UCLouvain Brussels ERA Cohort

Francesco Natalucci[1], clement triaille[2], Emilie Sapart[2], Cécile VAN MULLEM[2], Tatiana Sokolova[3], Laurent MERIC de BELLEFON[2], Adrien NZEUSSEU TOUKAP[2], Christine GALANT[4], Bernard Lauwerys[5] and Patrick Durez[2], [1]UCLouvain University, Sermoneta, Italy, [2]Cliniques Universitaires Saint-Luc – Université catholique de Louvain (UCLouvain) – Institut de Recherche Expérimentale et Clinique (IREC), Rheumatology, Brussels, Belgium, [3]Université Catholique de Louvain, Brussels, Belgium, [4]Cliniques Universitaires Saint-Luc – Université catholique de Louvain (UCLouvain), Anatomie pathologique, Brussels, Belgium, [5]UCB Pharma, Brussels, Belgium

SESSION INFORMATION

Session Date: Tuesday, November 14, 2023

Session Title: Abstracts: RA – Diagnosis, Manifestations, & Outcomes III: Predicting & Optimizing Outcomes

Session Type: Abstract Session

Session Time: 2:00PM–3:30PM

Background/Purpose: Rheumatoid Arthritis (RA) is a chronic autoimmune disease with persistent synovial inflammation. Despite early diagnosis and the treatment-to-target strategy in ERA, the treatment response rate is not optimal. Analyzing synovial tissue in ERA may help to find useful biomarkers to optimize the remission rate. Therefore, this study aimed to analyze the histology features together with the presence and distribution of cells by immunohistochemistry (IHC) of ERA synovial biopsies, to better characterize the disease and identify the presence of predictive factors of treatment response.

Methods: According to ACR/EULAR 2010, ERA patients were enrolled as part of the UCLouvain Arthritis Cohort at Cliniques Universitaires Saint Luc, Brussels. All patients were naïve to steroids and DMARDs therapy. Patients underwent ultrasound (US)-guided or mini-arthroscopy synovial biopsy. After the biopsy, patients started DMARD therapy and were evaluated every 3-4 months. Synovial samples were analyzed for histology (Synovial Hyperplasia, Fibrinoid Necrosis, Hypervascularization, Inflammatory Infiltrate), pathotypes (lymphoid, myeloid, or pauci-immune), and IHC (CD3, CD20, CD138, and CD68) with a semiquantitative score from 0 to 3 for each feature.

Results: 140 patients were included. Clinical and demographic features are reported in Table 1. CD68 and Fibrinoid Necrosis score were strongly associated [r= 0,44 (0,27-0,56); p< 0,0001]. CD68 score showed a good correlation with CRP [r=0.31 (0.13-0.46); p=0.0013], DAS28 [r=0,26 (0,07-0,43); p=0,005], SDAI [r=0,28 (0,07-0,47); p=0,008] and CDAI

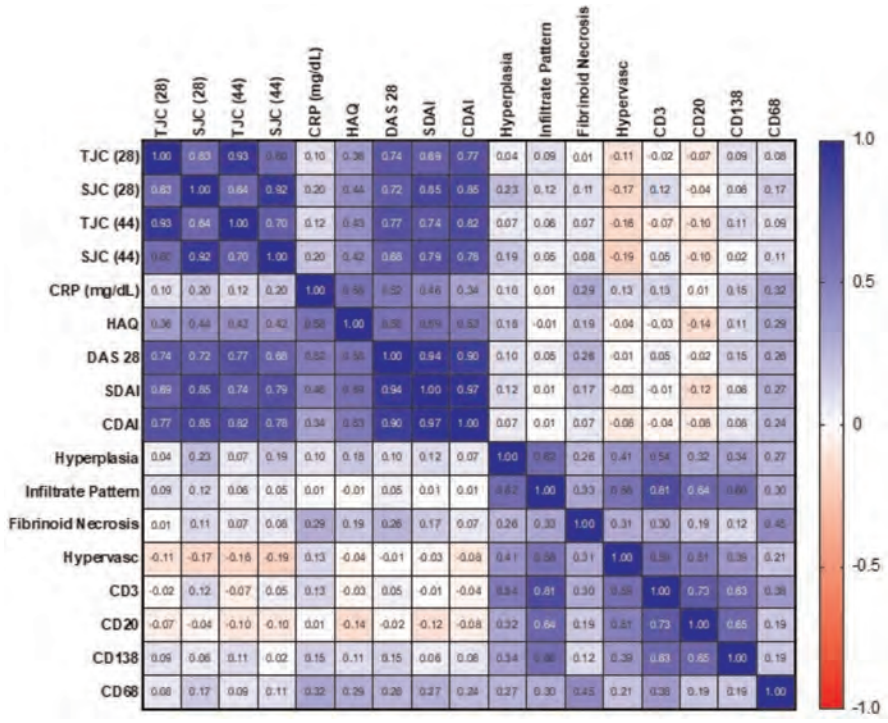

Figure 1. Correlation Matrix Each cell represents the r Spearman correlation value between clinical features and histology/IHC semiquantitative scores.

[r=0,25 (0,03-0,44); p=0,018]. The Fibrinoid Necrosis score showed a good correlation with CRP [r=0,29 (0,11-0,45); p=0,001] and DAS28 [r=0,26 (0,06-0,43); p=0,009].Based on the sum of the CD68 and Necrosis semiquantitative score [0-6], patients were then categorized as CD68Necrosis^{HIGH} (≥3) and CD68Necrosis^{LOW} (< 3). CD68Necrosis^{HIGH} patients had higher CRP values [2.5 mg/dL (4) *versus* 0.92 mg/dL (2.96); p=0.02], DAS28 [5.48 (1.6) *versus* 4.8 (1.7); p=0.03] and SDAI [33.10 (17.4) *versus* 25.65 (21.4); p=0.03). At three months of observation, CD68Necrosis^{HIGH} patients, compared to CD68Necrosis^{LOW} showed a greater fall of DAS28 [1.99 (2.06) *versus* 1.1 (2.27), p=0.03], SDAI [21.45 (IQR 23.3) *versus* 11.65 (IQR 17.5); p=0.003] and CDAI [16 [14.9] *versus* 10.5 (20.1), p=0.04].Moreover, CD68Necrosis^{HIGH} patients had a higher EULAR Moderate/Good Response rate compared to CD68Necrosis^{LOW} (90% versus 71.43%; p=0.036). CD68Necrosis score was then included in a predictive matrix model together with baseline disease features (SJC44 and DAS28) with

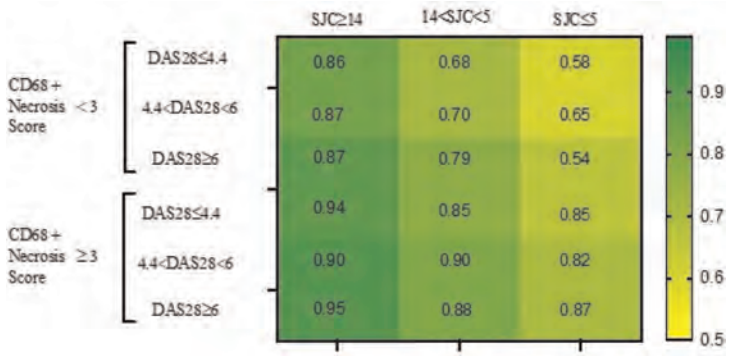

Figure 2. Three Months EULAR Moderate/Good Response Probability Prediction Matrix: The values reported expressing the 3 months predictive probability of reaching a Moderate/Good EULAR Response [0-1 = 0% - 100%] for each combination of included categorized variables. For example, a patient with CD68 + Necrosis Score <3, SJC ≥ 14, and DAS28 ≥ 6 has a 3-month predicted probability of reaching at least a Moderate EULAR Response of 87%.

a Moderate/Good EULAR Response Criteria at 3 months as the outcome (AUC 0.724, 95%CI [0.58-0.86]; p=0.0028, Figure 2). Classification into pathotypes did not identify patients with better responses to treatment or requiring therapy with bDMARDs/tsDMARDs.

Conclusion: The evaluation of Macrophages and Fibrinoid Necrosis in ERA synovial biopsies identifies patients with higher disease activity and with a better DAS28 fall at three months. The semiquantitative score can predict the achievement of EULAR Response Criteria, alone or with clinical baseline features.

Optimizing the Care of the Rheumatic Patient with Rheumatologist-Pharmacist Co-management

Ruchi Patel[1], Kristen Salava[1], Eric Newman[2], Joseph Chronowski[1], Dante Grassi[1], Hillary Harris[3], Amanda Young[1], Idorenyin Udoeyo[2], Lisa Schroeder[2], David Bulbin[4], David Pugliese[5] and Jonida Cote[6], [1]Geisinger Medical Center, Danville, PA, [2]Geisinger, Danville, PA, [3]Geisinger, Wilkes Barre, PA, [4]Geisinger Health System, Danville, PA, [5]Geisinger Health System, Wilkes-Barre, PA, [6]Geisinger Medical Center, Orefield, PA

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: Abstracts: RA – Diagnosis, Manifestations, & Outcomes III: Predicting & Optimizing Outcomes
Session Type: Abstract Session
Session Time: 2:00PM–3:30PM

Background/Purpose: More effective teamwork can improve patient care. We studied the effect of a Rheumatologist-Pharmacist Co-management program on the quality of care of rheumatology patients starting DMARDs.

Methods: The Rheumatologist-Pharmacist Co-management team used ACR guideline-driven protocols to manage rheumatic patients starting methotrexate (MTX).Interventions included Rheumatologist-Pharmacist visits, laboratory monitoring, medication tolerability assessment, treat-to-target (T2T) dose titration and disease monitoring. Electronic health record (EHR) data was compared for 3 groups -Rheumatologists at baseline, Rheumatologists at intervention and Co-management at intervention. Patient demographics, adherence with monthly visits and laboratories for the first 3 months after MTX initiation, MTX dose escalation, cumulative prednisone use within 6 months and biologic initiation within 12 months of MTX initiation were analyzed using appropriate statistical measures. Disease activity among the 3 groups was compared by descriptive analysis.

Results: Demographic evaluation showed that the Co-management group was more likely to be RF+ (80.6% vs 63.2% vs 72.4%) and had higher disease activity by CDAI (93.8% vs. 71.1% vs 75.6%) compared to the baseline and intervention period rheumatologist groups (Table 1). For the first 3 months post MTX intervention, the Co-management group was more adherent to all visits and all laboratories versus the baseline rheumatologist group (15% vs 2.2%, p=0.002; 70% vs 31.5%, p< 0.001) and the intervention rheumatologist group (15% vs 1.2%, p=0.001; 70% vs 24.8%, p< 0.001) (Table 2).When compared to the baseline and the intervention period rheumatologist groups, the Co-management group had a higher number of patients who escalated MTX dose to target (77.8% vs 36.6%, p< 0.001; 77.8% vs 34%, p< 0.001) and maximized MTX dose by 6 months (median 20mg vs 15 mg, p=0.01; 20 mg vs 15 mg, p=0.02).Additionally, the Co-management group had lower cumulative prednisone exposure (mean 144.6mg vs 493mg, p< 0.0001; 144.6mg vs 268.5mg, p< 0.58) and fewer patients

>10	20 (41.7%)	16 (61.5%)	3 (30.0%)		

(b) Chi-square test (c) Fisher's Exact test (d) Wilcoxon test (Mann-Whitney) *The values reflected are for patients who had a complete pre and post CDAI.

starting biologics by 12 months of MTX initiation (5% vs 17.6%, p=0.04) when compared to the baseline rheumatologist group. CDAI evaluation post intervention suggested a trend toward more patients with CDAI improvement (90% vs 64.6% vs 73.1%) and low disease activity (CDAI ≤ 10) (70% vs 58.3% vs 38.5%) achieved in the Co-management group vs rheumatologist managed groups respectively, however this analysis is underpowered due to the small Co-management population (Table 3).

Conclusion: Adherence to guideline-driven care is directly correlated with improved patient outcomes. In our study, despite having increased disease severity (higher RF+ and higher CDAI scores pre-intervention), the Co-management group had greater adherence with visits, laboratories and T2T disease management compared to the rheumatologist only groups. Additionally, they used less cumulative steroids within a 6-month period and had better control of their rheumatoid arthritis disease activity. Our Co-management care model shows improved care delivery when compared to usual care and is a model that can be easily replicated.

Abstract Number: 2485

Comparative Risk of Serious Psychiatric Events with Belimumab versus Oral Immunosuppressant Use in Patients with Systemic Lupus Erythematosus

April Jorge[1], Baijun Zhou[1], Yuqing Zhang[2] and Hyon K. Choi[3], [1]Massachusetts General Hospital, Boston, MA, [2]Division of Rheumatology, Allergy, and Immunology, Department of Medicine, Massachusetts General Hospital, Boston, MA, [3]Massachusetts General Hospital and Harvard Medical School, Lexington, MA

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: Abstracts: SLE – Treatment II: Nonrenal
Session Type: Abstract Session
Session Time: 2:00PM–3:30PM

Background/Purpose: In randomized placebo-controlled trials, including the phase 4 Belimumab Assessment of Safety in SLE study, belimumab use was associated with a higher incidence of serious depression and suicidality than placebo. (Sheikh S et al, Lancet Rheumatol. 2020). However, the comparative risk of psychiatric outcomes between belimumab versus oral immunosuppressants is unknown.

Methods: We conducted a comparative cohort study of adult patients with SLE who initiated treatment with belimumab versus an oral immunosuppressant (azathioprine [AZA], methotrexate [MTX], or mycophenolate [MMF]) between 2011-2021 using observational data from TriNetX, a United States multi-center electronic health records database. We excluded patients with lupus nephritis prior to the index date of treatment initiation. The outcomes of interest were hospitalization for depression and attempted suicide. We designed and emulated a hypothetical target trial to estimate the cumulative incidence and hazard ratios (HRs) of these outcomes associated with belimumab initiation versus each of the oral immunosuppressants. In three parallel analyses, we used propensity score overlap weighting to balance covariates, including age, sex, race/ethnicity, geographic region, year of initiation, use of concomitant SLE medications (glucocorticoids, hydroxychloroquine, rituximab, cyclophosphamide, other immunosuppressants), Charlson comorbidity index, SLE severity index, chronic kidney disease, healthcare utilization, and prior diagnoses of mood disorders. In a secondary population excluding patients with prior mood disorders, we also assessed the outcome of new onset depression. Patients were followed until the earliest of the outcome, death, end of the study period (August 31, 2021), or two years after treatment initiation. In a per-protocol analysis, patients were additionally censored for discontinuation of the assigned treatment or initiation of the comparator, and we adjusted for adherence to assigned treatment using inverse probability of treatment weighting.

Results: Of 91,425 patients with SLE, we compared 2,434 and 5,644 initiators of belimumab and AZA, (**Table 1**), 2,163 and 7,224 initiators of belimumab and MTX, and 2,431 and 6,350 initiators of belimumab and MMF, respectively. After propensity score overlap weighting, covariates were balanced in each comparison. 95% were female; the mean age was 44 years. Attempted suicide was rare, with fewer than 10 events in each treatment group. There were no differences in the risk of hospitalized depression among belimumab initiators and initiators of AZA or MTX (**Table 2**). The risk of hospitalization for depression was lower for belimumab than MMF users (HR 0.70 [95% CI 0.52-0.95]). There was no difference in the risk of new onset depression among patients without a prior history of mood disorders (**Table 3**).

Conclusion: In this multi-center observational SLE cohort, we found that belimumab use was not associated with an increased risk of serious psychiatric events compared with oral immunosuppressants for SLE. This provides real-world reassurance of the safety of this medication for the treatment of SLE.

Table 1. Baseline Characteristics of Belimumab and Azathioprine Initiators with Non-Renal Systemic Lupus Erythematosus

Prior mood disorder, n (%)	275 (11.3)	604 (10.7)	0.0191	11.7	11.7	<0.001

Covariates assessed within the six months prior to the index date. Non-renal lupus defined by meeting SLE definition (≥2 SLE ICD codes ≥2 months and ≤2 years apart) and not meeting lupus nephritis definition (defined by ≥1 LN code (ICD-10 M32.14) or ≥2 nephritis codes (e.g., ICD-9 580-586, 791.0 or ICD-10 N00, N04-5, N17-18, R80.9) prior to the index date. MTX, methotrexate. CKD, chronic kidney disease, defined by ≥1 ICD codes or GFR <60 on ≥2 occasions. ER, emergency room. SLE Severity Index is adapted from Garris algorithm for administrative data, based on ICD codes and not including medication dosing. Other oral immunosuppressant use includes leflunomide, sulfasalazine, cyclosporine, tacrolimus, abatacept, tocilizumab, TNF inhibitors, IL17 inhibitors, IL12/23 inhibitors, and JAK inhibitors

Table 2. Comparative Risk of Hospitalization for Depression with Belimumab versus Oral Immunosuppressant use

Treatment arms	Events (n)	Two-Year Cumulative Incidence (%)	Hazard Ratio (95% CI)
Per-protocol analysis			
Belimumab vs Azathioprine			
Azathioprine	236	5.5	1.00(ref)
Belimumab	74	4.7	0.85 (0.64-1.12)
Belimumab vs Methotrexate			
Methotrexate	241	4.4	1.00(ref)
Belimumab	70	4.3	0.97 (0.73-1.30)
Belimumab vs Mycophenolate

Abstract Number: 2486

Should SLE Patients Entering Clinical Trials Be Required to Have at Least One BILAG a And/or Two BILAG B Scores?

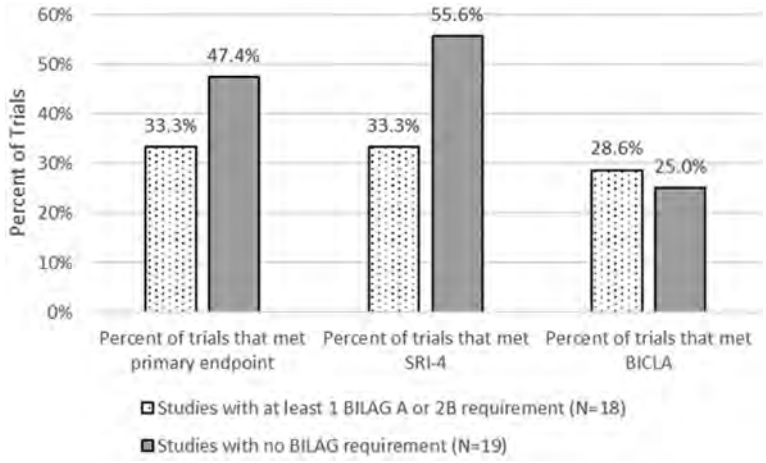
Ewa Olech[1] and Joan Merrill[2], [1]IQVIA, Rheumatology Consultants, PLLC, Las Vegas, NV, [2]Oklahoma Medical Research Foundation, Oklahoma City, OK

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: Abstracts: SLE – Treatment II: Nonrenal
Session Type: Abstract Session
Session Time: 2:00PM–3:30PM

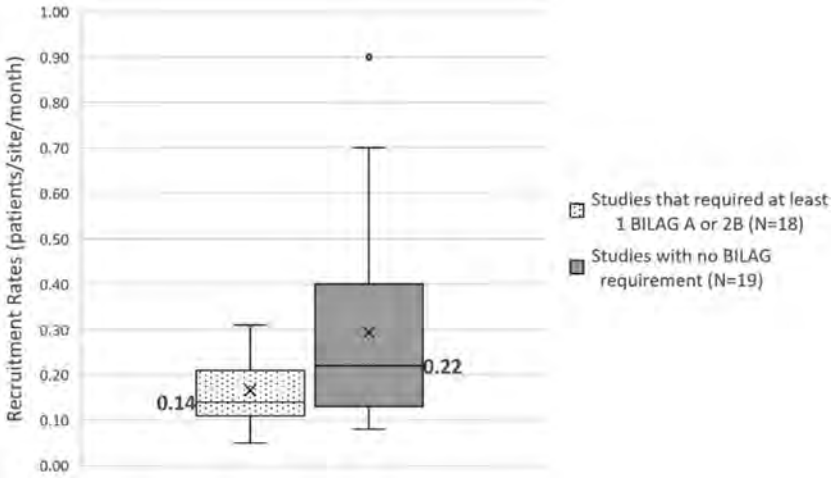
Background/Purpose: High placebo response rates have challenged interpretation of clinical trial results in SLE and may have contributed to failure of some effective treatments. One hypothesis to explain inflated placebo responses is that patients may not have sufficient disease activity at baseline. Most study designs require at entry a score of ≥6 on the SLE Disease Activity Index (SLEDAI). Some have attempted to enrich for more active disease by adding an additional inclusion criterion using BILAG: score of A (severe) in ≥1 organ system and/or B (moderate) in ≥2 organ systems (BILAG restricted studies). However, the impact of this requirement on enrollment and study outcomes, including placebo responses, has not previously been examined.

Methods: Data from all reported phase II & III SLE trials with ≥100 subjects enrolled, at least 24 weeks treatment duration, and SLE responder index (SRI) and/or BILAG-based combined lupus assessment (BICLA) results were analyzed. In studies that did not require BILAG 1A or 2B at entry (BILAG non-restricted studies), the proportion of patients who nevertheless had at least 1 BILAG A or 2B was examined. BILAG restricted trials were compared to non-restricted for meeting primary endpoints, SRI-4, BICLA, placebo responses, and recruitment rates.

Results: Of 40 trials that met the initial search criteria, 3 were excluded from the analysis for not allowing BILAG A at screening (2 trials) and for major changes in entry criteria during study (1 trial). Of the 37 remaining studies (21 phase II and 16 phase III), 18 were BILAG-restricted and 19 non-restricted. In non-restricted studies, the mean percent of patients with at least 1 BILAG A or 2B scores was 62.7%.



Impact of at least 1 BILAG A or 2B inclusion criterion on study results: comparison between trials with and without this requirement in meeting the primary endpoint, SRI-4 and BICLA (p=NS).



Impact of at least 1 BILAG A or 2B inclusion criterion on recruitment rates: comparison of recruitment rates between trials with and without this requirement (p = 0.047; Mann Whitney test)

Fifteen of 37 trials (41%) met the primary endpoint, including 6 of 18 (33%) restricted and 9 of 19 (47%) non-restricted studies (Figure 1). Of 36 studies with available SRI-4 data, this endpoint was met by 16 (44%) overall, 6 (33%) of 18 restricted and 10 (56%) of 18 non-restricted studies. Nineteen studies measured BICLA, which was met by 5 (26%) overall, including 4 (29%) of 14 restricted and 1 (25%) of 4 non-restricted.

Mean SRI-4 and BICLA placebo responses in all the studies were 43% and 36%: 44.3% and 36% in restricted studies, 41.7% and 35.9% in non-restricted studies.

Mean and median recruitment rates for all studies combined were 0.23 and 0.17 patients/site/month (p/s/m). BILAG restricted trials enrolled significantly slower than non-restricted with mean/median 0.17/0.14 p/s/m versus 0.29/0.22 p/s/m (p=0.047, Mann-Whitney test, Figure 2).

Conclusion: Phase II and III SLE studies that require at least 1 BILAG A or 2B at screening are not more likely to meet their primary endpoint. BILAG-restriction does not decrease placebo responses. Furthermore, this entry criterion decreases the eligible patient pool by almost 40% significantly slowing recruitment rates.

SESSION INFORMATION

Session Date: Tuesday, November 14, 2023

Session Title: Abstracts: SLE – Treatment II: Nonrenal

Session Type: Abstract Session

Session Time: 2:00PM–3:30PM

Background/Purpose: Ianalumab is a novel defucosylated human IgG1 mAb targeting the receptor for *B* cell *A*ctivating *F*actor belonging to the TNF *F*amily (BAFF-R) providing potent B cell depletion by enhanced antibody-dependent cellular cytotoxicity along with BAFF:BAFF-R signaling blockade.We report safety and efficacy of ianalumab in patients with active SLE.

Methods: This multi-center randomized, parallel group, double-blind placebo-controlled umbrella trial (NCT03656562) enrolled patients (19 Dec 2018 to 31 Jan 2022) having ANA ≥1:80 and meeting ≥4 of 11 ACR 1997 SLE classification criteria, with SLEDAI-2K score ≥6 and BILAG-2004 ≥1 A or ≥2 B scores that included activity in either mucocutaneous and/or musculoskeletal domains. This report is limited to interim analysis results for the fully enrolled ianalumab treatment cohort (active n=34; placebo n=33) completing 28-week blinded treatment period (monthly s.c. injection ianalumab 300 mg or placebo), with measured outcomes at baseline and weeks (w) 4, 8, 12, 16, 24 & 28. Primary w28 outcome was proportion patients meeting composite endpoint requirements consisting of those achieving SLE-Responder Index (SRI)-4 who also tapered predniso(lo)ne to ≤5 mg/d or ≤ baseline dose, whichever was lower, by w16 and kept within that range to w28.Secondary/exploratory outcomes included safety/tolerability, incidence BILAG-2004 moderate or severe flares (≥1 A or ≥2 B), proportion patients achieving Lupus Low Disease Activity State (LLDAS), patient and physician global assessments, and laboratory markers of B cell-associated autoimmune activity.

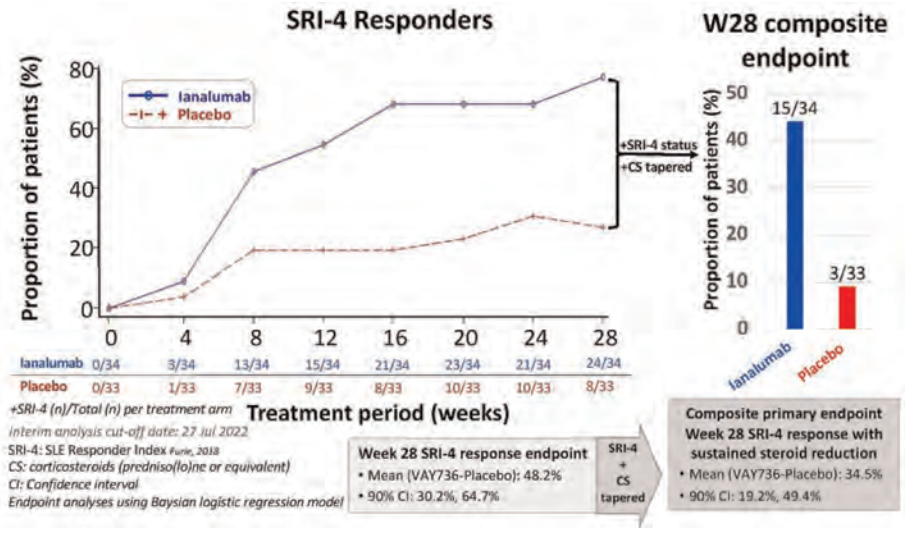

Figure 1. Primary endpoint: SRI-4 responders with sustained tapered corticosteroids

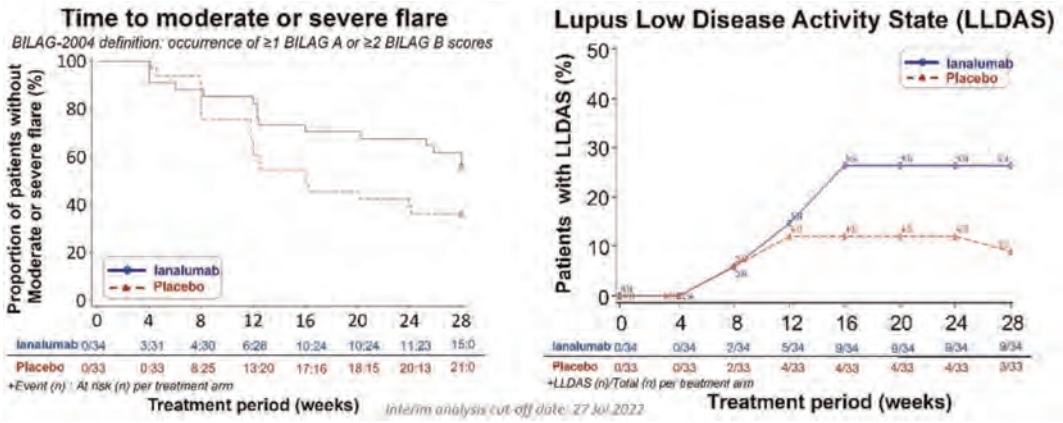

Figure 2. Ianalumab treatment effects on time to disease flare and achievement of LLDAS

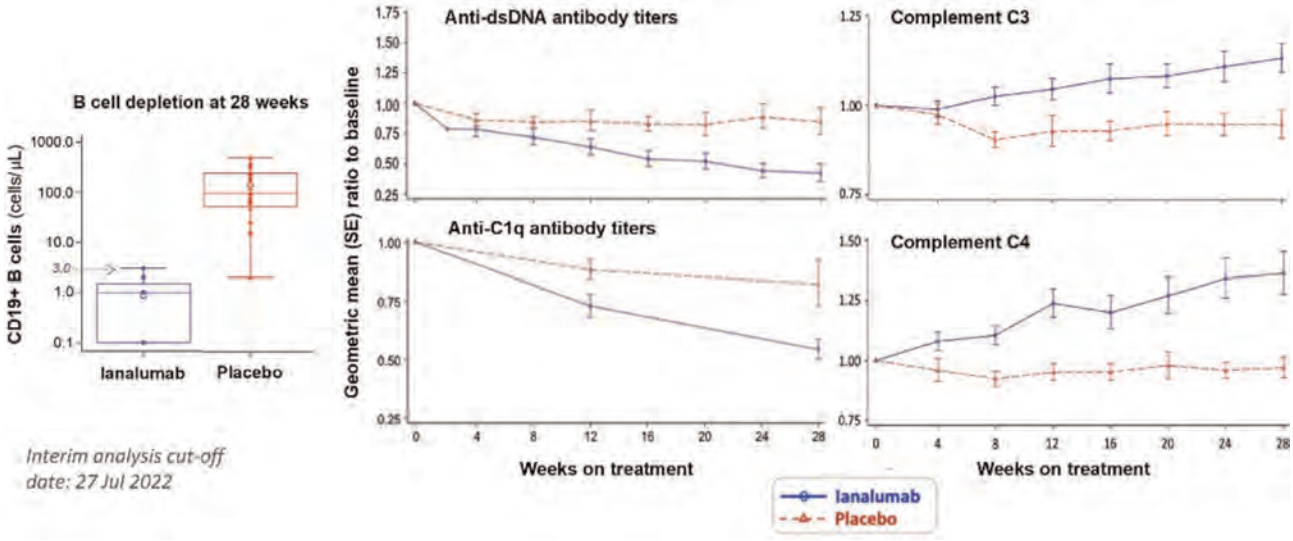

Figure 3. Ianalumab effects on laboratory markers of B cell autoimmune activity

Results: VAY736 was safe and well-tolerated with no drug-related SAE or dropouts, and one pandemic-related discontinuation in placebo arm. Baseline median(*range*) values for ianalumab and placebo arms, respectively, were: SLEDAI-2Kscore 10 (*6-32*) and10 (*4-18*), and predniso(lo)ne 10 mg (*0-30*) and 10 mg (*0-27.5*). Marked depletion of circulating CD19+ B cells was consistently achieved in all ianalumab-treated patients: w28 median 1 cell/uL; range *0-3* (Fig. 3). The mean w28 SRI-4 treatment effect of ianalumab (n=24) over placebo (n=8) was 48.2% (Fig. 1), and that also met the composite primary endpoint was 34.5% (ianalumab n=15; placebo n=3). Reduced incidence of moderate or severe flare was noted for patients treated with ianalumab 44% (n=15) vs placebo 64% (n=21). Benefits of ianalumab over placebo were observed for time-to-moderate or -severe flare and for achieving w28 LLDAS (Fig. 2). Therapeutic responses were also observed for ianalumab- vs placebo-treated subjects on laboratory markers of autoimmune activity (Fig. 3).

Conclusion: Potent B cell depletion was consistently achieved in ianalumab-treated SLE patients that was well tolerated, achieving the primary endpoint of SRI-4 response with sustained steroid reduction, along with substantial treatment benefits on overall SRI-4 response, LLDAS and reductions in moderate and severe flares, and on laboratory markers of autoimmune activity. These positive phase 2 study results support ongoing phase 3 development in lupus of the dual mechanisms of action of ianalumab (SIRIUS-SLE 1 & 2, and SIRIUS-LN).

SESSION INFORMATION

Session Date: Tuesday, November 14, 2023
Session Title: Abstracts: SLE – Treatment II: Nonrenal
Session Type: Abstract Session
Session Time: 2:00PM–3:30PM

Background/Purpose: ABBV-599 is a novel combination of elsubrutinib (ELS; a selective BTK inhibitor) and upadacitinib (UPA; a JAK inhibitor) that targets non-overlapping signaling pathways associated with systemic lupus erythematosus (SLE). The objective of this analysis is to report results from SLEek, a phase 2, randomized, placebo (PBO)-controlled, parallel-group, multicenter study evaluating efficacy and safety of ABBV-599 and UPA monotherapy in adults with moderately to severely active SLE (NCT03978520).

Methods: Patients (pts) were randomized 1:1:1:1:1 to once daily (QD) ABBV-599 high dose (HD; ELS 60 mg + UPA 30 mg), ABBV-599 low dose (LD; ELS 60 mg + UPA 15 mg), ELS 60 mg, UPA 30 mg, or PBO. The primary endpoint was the proportion of patients at W24 achieving SLE Responder Index-4 (SRI-4) and steroid dose ≤ 10 mg QD; additional efficacy and safety endpoints through W48 are also reported. The pre-specified 2-sided alpha level was 0.1.

Results: 341 patients were enrolled. After a planned interim analysis when 50% of pts reached W24, the ABBV-599LD and ELS 60 mg arms were discontinued for lack of efficacy (no safety concerns). Of 205 continuing pts (ABBV-599HD n = 68, UPA 30 mg n = 62, PBO n = 75), baseline characteristics were well balanced. The primary endpoint (proportion achieving SRI-4 and steroid dose ≤ 10 mg QD at W24 vs PBO) was met by ABBV-599HD and UPA 30 mg. Key secondary endpoints were also achieved at W48 in both groups (**Table**). Overall flares and time to first flare were substantially reduced in the ABBV-599HD and UPA 30 mg groups through W48 (**Figure**). Anti-double stranded DNA antibodies were significantly decreased with both treatments. TEAEs considered related to study drug were 42.6% ABBV-599HD, 32.3% UPA 30 mg,

ABBV-599HD, elsubrutinib 60 mg QD and UPA 30 mg QD; AO, as observed; PBO, placebo; SELENA, Safety of Estrogens in Lupus Erythematosus National Assessment; SLEDAI, Systemic Lupus Erythematosus Disease Activity Index; UPA, upadacitinib.

and 33.3% PBO. There were no malignancies or VTE. There were 3 non-fatal CV events (1 MI on PBO and 2 ruptured cerebral aneurysms [1 each on ABBV-599HD and UPA 30 mg]); all were assessed as unrelated to study drug by investigators. No new safety signals were observed beyond previously known data for UPA or ELS.

Conclusion: ABBV-599HD (ELS 60 mg + UPA 30 mg) and UPA 30 mg demonstrated significant improvements in SLE disease activity and flares with acceptable safety through 48 weeks.

SESSION INFORMATION

Session Date: Tuesday, November 14, 2023

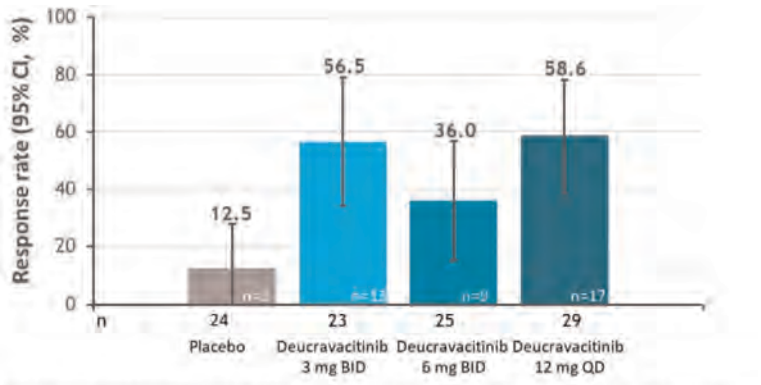
Session Title: Abstracts: SLE – Treatment II: Nonrenal

Session Type: Abstract Session

Session Time: 2:00PM–3:30PM

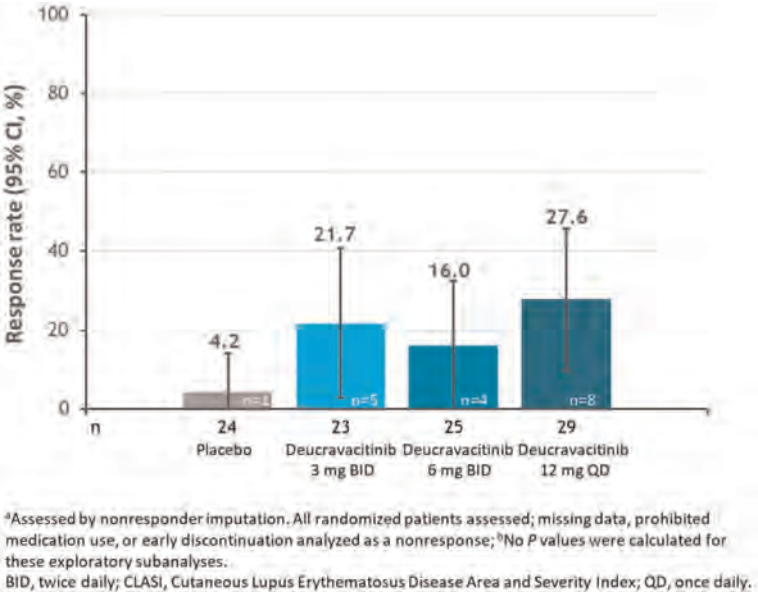
Background/Purpose: Deucravacitinib is a first-in-class, oral, selective, allosteric tyrosine kinase 2 inhibitor approved in multiple countries for the treatment of adults with plaque psoriasis. A 48-week, double-blind phase 2 trial (NCT03252587) in patients with SLE showed that deucravacitinib demonstrated greater efficacy compared with placebo across multiple endpoints, including the primary endpoint of Systemic Lupus Erythematosus Responder Index-4 (SRI[4]) at week 32 and the secondary endpoint of ≥50% reduction in CLASI activity (CLASI-50) for patients with moderate to severe skin involvement at baseline (CLASI score ≥10).[1] Here, we explored whether patients could sustain CLASI-50 over time and achieve 100% reduction in CLASI activity. CLASI-50 was also evaluated by SLE cutaneous manifestation subtype.

Methods: Patients with active SLE and a baseline CLASI score ≥10 who received placebo (n=24), deucravacitinib 3 mg twice daily (BID) (n=23), 6 mg BID (n=25), or 12 mg once daily (n=29) were included in these analyses. Exploratory outcomes were the proportion of patients that sustained CLASI-50 for the 5 consecutive visits from weeks 32 through 48, achieved 100% reduction in CLASI activity at week 48, and achieved CLASI-50 by SLE cutaneous manifestation subtype. For the subtype analysis, patients were classified as acute, subacute, chronic, or discoid at the discretion of investigators using SLICC classification criteria at screening without biopsy confirmation. Patients could be in ≥1 subcategory based on



[a]Assessed by nonresponder imputation. All randomized patients assessed; missing data, prohibited medication use, or early discontinuation analyzed as a nonresponse; [b]CLASI-50 is defined as a decrease of ≥50% from baseline in CLASI score at week 48 in patients with a CLASI score ≥10 at baseline; [c]No *P* values were calculated for these exploratory subanalyses; [d]A sustained response was defined as patients who were responders through 5 consecutive visits from weeks 32 through 48. Number of responders at each visit is the number of responders at that visit and at all previous visits from week 32.
BID, twice daily; CLASI, Cutaneous Lupus Erythematosus Disease Area and Severity Index; QD, once daily.

Figure 1. Sustained CLASI-50 response among patients with CLASI ≥10 at baseline (a, b, c, d)

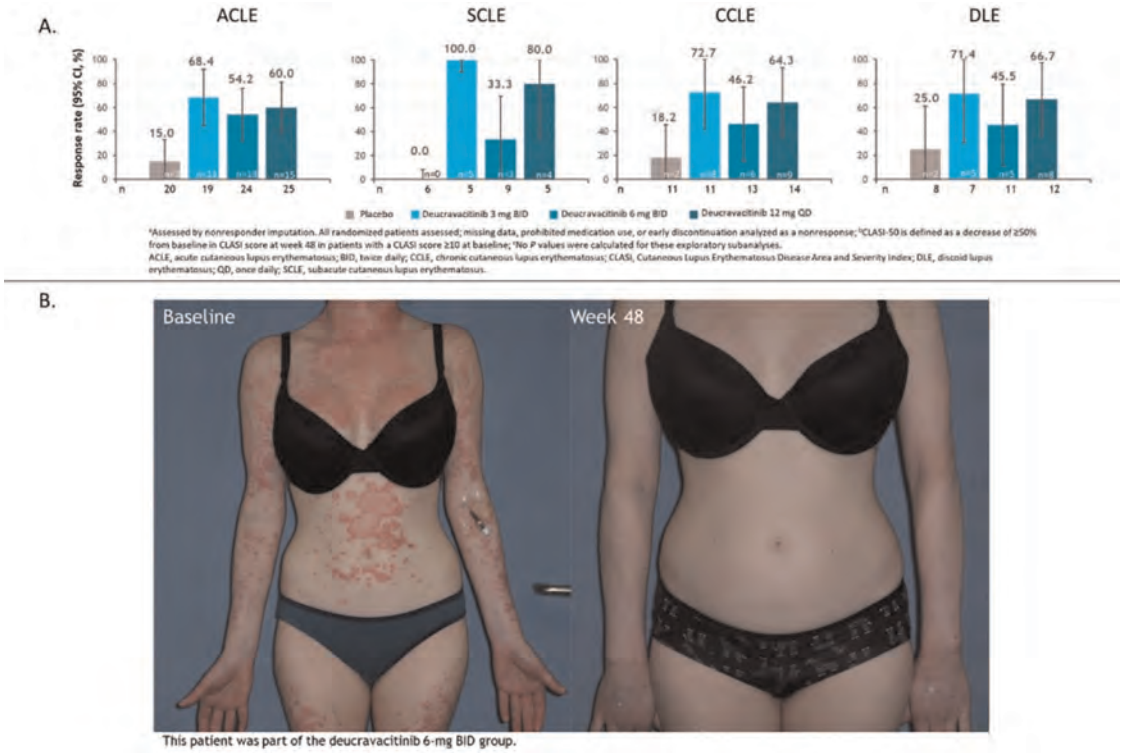


[a]Assessed by nonresponder imputation. All randomized patients assessed; missing data, prohibited medication use, or early discontinuation analyzed as a nonresponse; [b]No *P* values were calculated for these exploratory subanalyses.
BID, twice daily; CLASI, Cutaneous Lupus Erythematosus Disease Area and Severity Index; QD, once daily.

Figure 2. Proportion of patients with CLASI ≥10 at baseline achieving a 100% reduction in CLASI at week 48 (a, b)

classification criteria; all patients classified as discoid were included in the chronic subgroup. All analyses were descriptive.

Results: Among patients with a baseline CLASI score ≥10, a numerically higher proportion of patients treated with deucravacitinib had a sustained response for the 5 consecutive visits between weeks 32 and 48 compared with placebo (**Figure 1**). Furthermore, a higher proportion of these patients treated with deucravacitinib achieved 100% reduction in CLASI activity at



[a]Assessed by nonresponder imputation. ACLE, acute cutaneous lupus erythematosus; BID, twice daily; CCLE, chronic cutaneous lupus erythematosus; CLASI, Cutaneous Lupus Erythematosus Disease Area and Severity Index; DLE, discoid lupus erythematosus; QD, once daily; SCLE, subacute cutaneous lupus erythematosus.

This patient was part of the deucravacitinib 6-mg BID group.

Figure 3. Proportion of patients with CLASI ≥10 at baseline achieving CLASI-50 at week 48 by cutaneous manifestation subtype (a, b, c) (A) and exemplary patient photographic data (B)

week 48 (**Figure 2**). Analysis by cutaneous manifestation suggested that a numerically higher proportion of patients treated with deucravacitinib achieved CLASI-50 at week 48 compared with placebo in all subtypes assessed (**Figure 3**).

Conclusion: Among patients with moderate to severe skin involvement at baseline, more patients treated with deucravacitinib were able to achieve improvements in skin overall, and a greater proportion of patients were able to sustain a CLASI-50 response from weeks 32 through 48 compared with placebo. CLASI-50 achievement was more frequent among patients treated with deucravacitinib regardless of cutaneous subtype.

Safety and Efficacy of Mycophenolate Mofetil in New-onset Systemic Lupus Erythematosus with High Titer of Anti-dsDNA Antibody and Without Major Organ Involvement: A Multicenter Randomized Controlled Trial

Junna Ye[1], Yijun You[2], Zhuochao Zhou[2], Jingyi Wu[2], Fan wang[2] and Chengde Yang[2], [1]Ruijin Hospital affiliated to Shanghai Jiaotong University School of Medicine, Shanghai, China, [2]Ruijin Hospital, Shanghai Jiao Tong University School of Medicine, Shanghai, China

SESSION INFORMATION

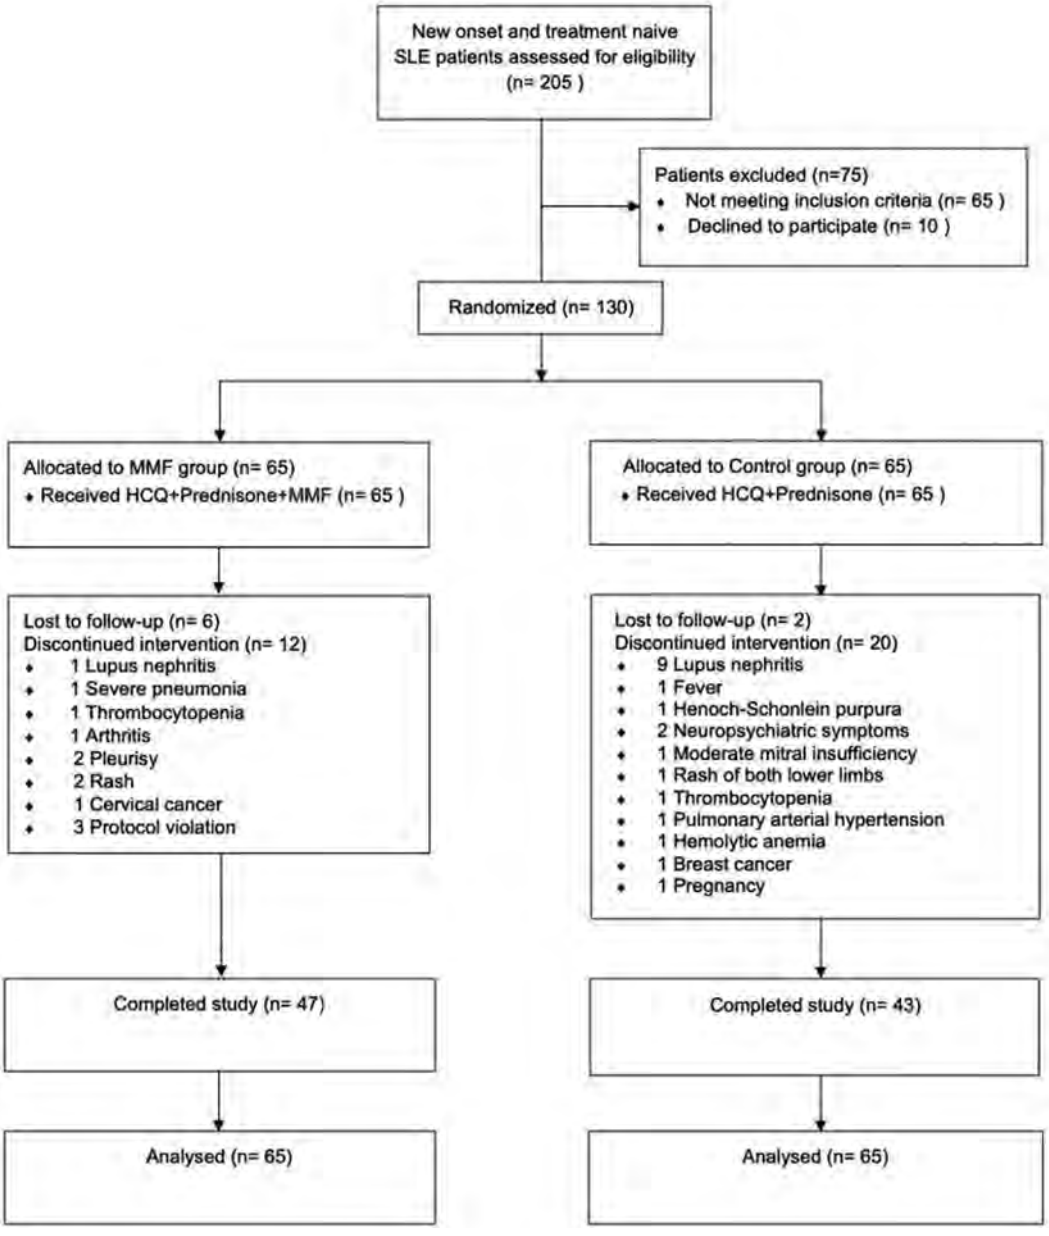
Session Date: Tuesday, November 14, 2023
Session Title: Abstracts: SLE – Treatment II: Nonrenal
Session Type: Abstract Session
Session Time: 2:00PM–3:30PM

Background/Purpose: Previous clinical trials of mycophenolate mofetil (MMF) in SLE were mainly focused on lupus nephritis (LN) (patients have been diagnosed with LN). In the pathogenesis of LN as well as other organ damages, anti-dsDNA antibody plays an important role.

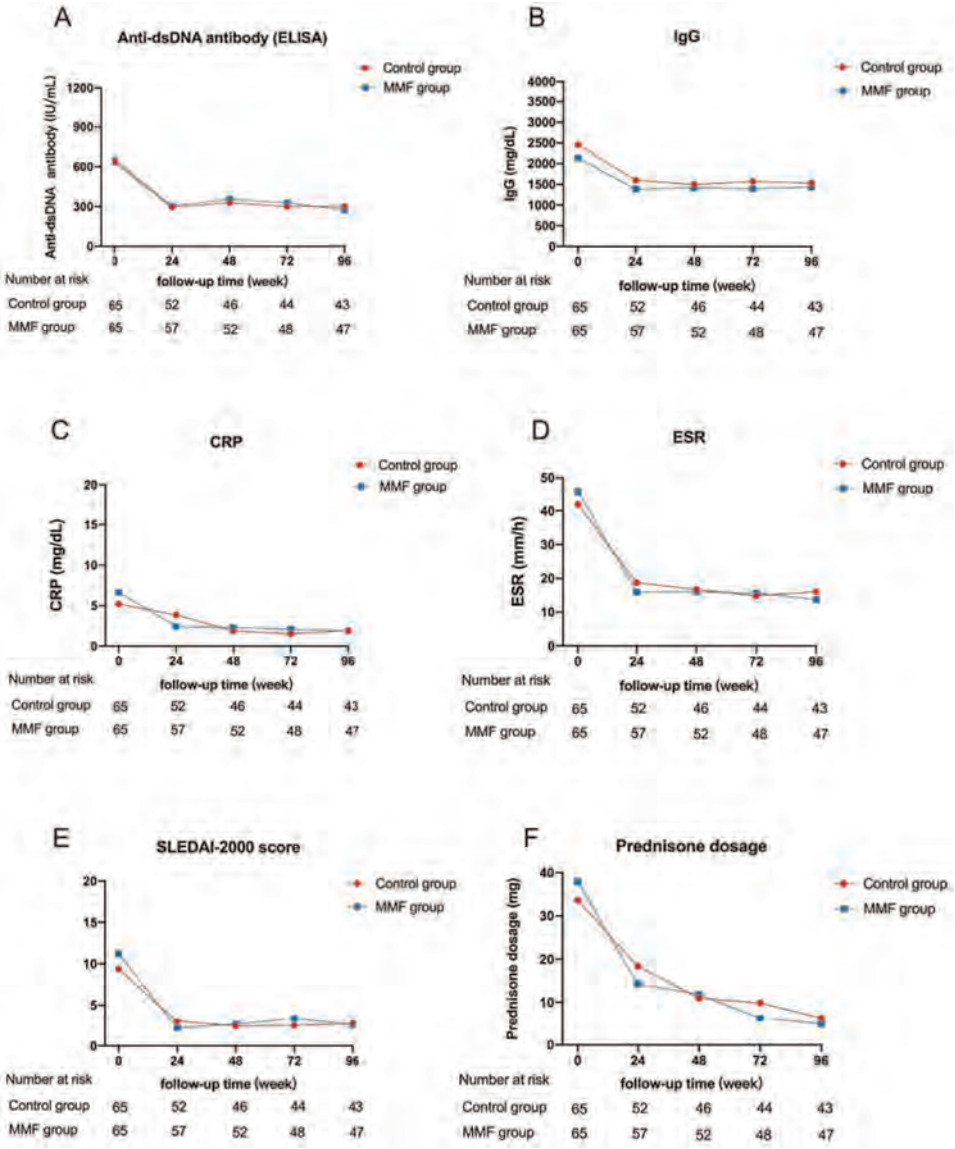
To assess the efficacy and safety of MMF plus hydroxychloroquine (HCQ) and prednisone compared with HCQ and prednisone alone in newly diagnosed and treatment-naïve SLE patients with high titer of anti-dsDNA antibody and without major organ involvement.

Methods: This investigator-initiated multicenter, open-label, randomized, controlled trial which enrolled 130 patients was conducted in three hospitals across China between September 2018 and September 2021. Inclusion criteria were newly diagnosed and treatment-naïve SLE patients with high titer of anti-dsDNA antibody (anti-dsDNA (ELISA) ≥ 300 IU/mL; (CLFT) ≥1:10) and without major organ involvement (brain, heart, liver, kidney, lung, muscle, and gastrointestinal tract).

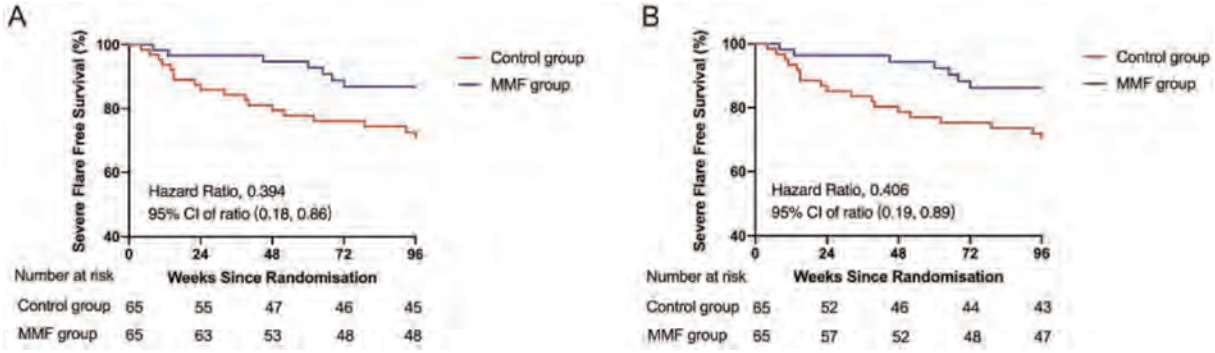
Participants were randomly assigned to received HCQ (5mg/kg/day) and prednisone (0.5mg/kg/day) (n=65) or HCQ (5mg/kg/day) and prednisone (0.5mg/kg/day) plus MMF 500mg twice daily (n=65).



Flowchart of this study.



Changes in clinical parameters in the control and MMF groups during the follow-up.



Severe flare-free survival was analyzed by Kaplan-Meier analysis with a log rank test in the ITT and PP populations.The intention-to-treat (ITT) population included all the eligible patients who had undergone randomization and received the treatment. The per protocol (PP) population included who were adherent to trial treatment excluded patients with major protocol violations.

The primary endpoint was the proportion of SLE patients having flares according to SELENA-SLEDAI Flare Index. The secondary outcome included the proportion of lupus low disease activity state (LLDAS) at week 96, short form-36 (SF-36) score before and after treatment, the proportion of adverse events, changes in SLEDAI-2000 score and prednisone dose.

Results: During the follow-up, 10.76% of patients in MMF group and 27.69% of patients in Control group showed severe flares (RR: 0.39, 95% CI: 0.17-0.87, p=0.014). 1.54% of patients in MMF group and 13.85% of patients in Control group manifested LN (RR: 0.11, 95% CI: 0.01-0.85, p=0.008). There was no significant differences in mild to moderate flares between the two groups (p=0.856). Besides, 33.85% of patients in MMF group and 16.92% of patients in Control group never had a relapse in the follow-ups (p=0.027). For the secondary outcomes, 41.54% patients in MMF group and 35.38% patients in Control group achieved LLDAS. SF-36 score of MMF group was better than Control group. Adverse events were reported in 49.23% patients in MMF group and 36.92% patients in Control group (p=0.157). Prednisone dosage was decreased gradually from baseline (mean [SD]: 33.66 [11.89] mg in Control group; 37.93 [13.56] mg in MMF group) to Week 96 (6.30 [6.82] in Control group; 4.88 [3.65] mg in MMF group) (prednisone dose change, p=0.087).

Conclusion: Low dose of MMF might decrease the rate of severe flare and lower the incidence of LN in new-onset SLE patients with high titer of anti-dsDNA antibody and without major organ involvement. Further research is needed to confirm efficacy of longer term outcomes in more diverse patient populations.

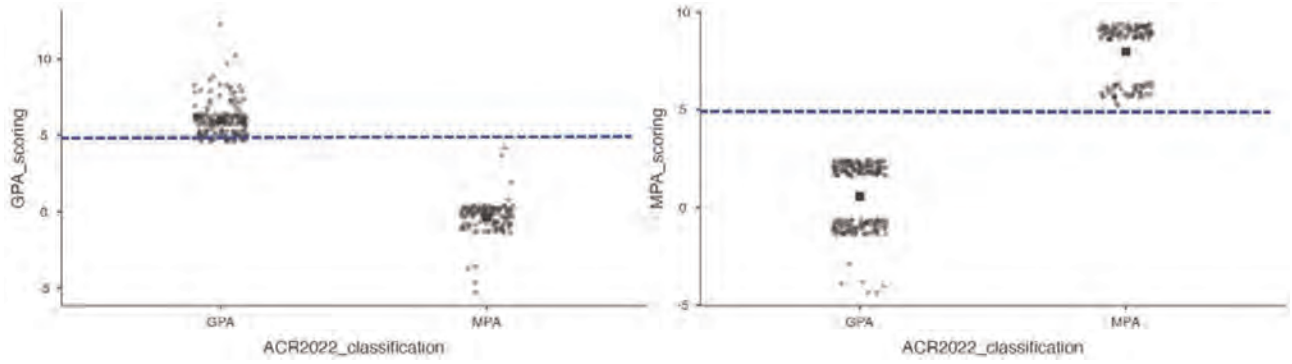
Alignment Between the Novel 2022 ACR/EULAR Classification Criteria for ANCA-associated Vasculitis (AAV), Clinical Diagnosis and Organ Manifestations in a European AAV Cohort

Stefan Krämer[1], Thomas Rauen[1], Kristian Vogt[1], Teresa Anslinger[1], Martin Busch[2], Tobias Schmitt[3], Raoul Bergner[4], Sebastian Mosberger[4] and **Thomas Neumann**[5], [1]RWTH, University Hospital Aachen, Department of Nephrology and Rheumatology, Aachen, Germany, [2]University Hospital Jena, Friedrich-Schiller University, Department of Internal Mediciine III, Jena, Germany, [3]University Hospital Jena, Friedrich Schiller University, Department of Nephrology, Jena, Germany, [4]Municipal Hospital Ludwigshafen, Department of Internal Medicine A, Nephrology and Rheumatology, Ludwigshafen, Germany, [5]Cantonal Hospital St. Gallen, Department of Rheumatology, St. Gallen, Switzerland

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: Abstracts: Vasculitis – ANCA-Associated II
Session Type: Abstract Session
Session Time: 2:00PM–3:30PM

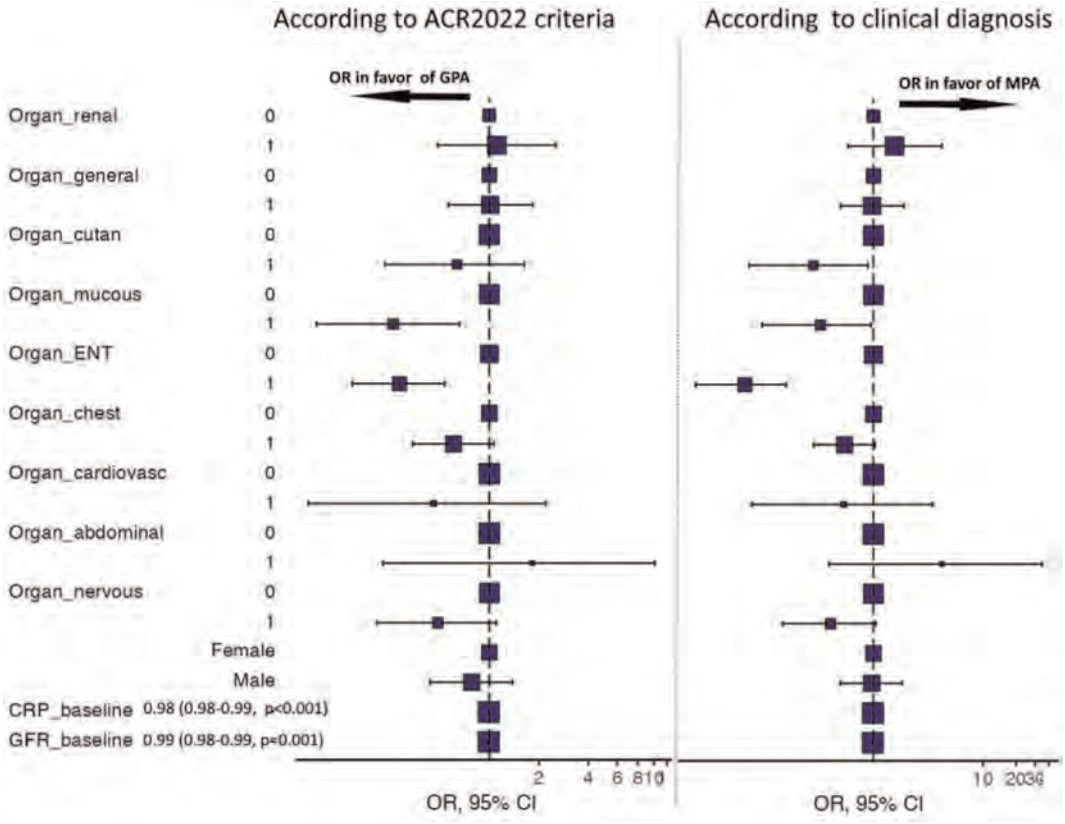
Background/Purpose: In 2022, ACR and EULAR proposed new classification criteria for granulomatosis with polyangiitis (GPA) and microscopic polyangiitis (MPA) based on a numerical item scoring system for different manifestations in ANCA-associated vasculitis (AAV) emphasizing the role of laboratory findings. Recently, a low concordance rate of only 73% in comparison with former nomenclature and algorithm for classification was reported in a Korean cohort of 65 GPA patients [1]. We thought to (i) retrospectively re-classify patients from our multicentric AAV cohort using to the 2022 ACR/EULAR criteria for GPA and MPA using a computational algorithm that involved existing clinical, laboratory and histological data, (ii) to compare these results to prior clinical diagnoses and (iii) to investigate the predictive power of organ manifestations for both, classification and diagnosis.



Clustering of ACR/EULAR 2022 criteria scores for GPA (left) and GPA classified cases (right)

Methods: Data of AAV patients from four tertiary referral centers (Germany and Switzerland) were collected between 2000 and 2021. Cases without conclusive ANCA status were excluded from computed analysis. The 2022 ACR/EULAR criteria were applied by algorithmically analyzing BVAS entries for organ manifestation, laboratory results for ANCA/ELISA testing and histological data for detection of granuloma and/or pauci-immune glomerulonephritis. Results were compared to previously reported diagnoses and clinical manifestations were analyzed by their odds ratio (OR) to be either diagnosed or classified as GPA or MPA.

Results: The final dataset included a total of 305 cases, 294 (96.4%) of Caucasian ethnicity, 161 males (52.8%), median age 61 years (IQR 50-70). Based on the 2022 ACR/EULAR criteria, 299 (98%) cases could be unambiguously categorized. The overall concordance was found to be higher in GPA with 93.1% (vs. 88.2% in MPA) as previously reported [2]. Within all cases classified as MPA, the ACR/EULAR itemized score sums up to an average of 7.99 points (±1.42) in MPA cases



OR for either MPA or GPA classification (left) and previous clinical diagnosis (right)

Literature

vs. -0.201 points (±1.36) for GPA cases (fig. 1). Classification as GPA sums up to an average score of 5.87 points (±1.21) vs. 0.548 points (±1.68). Overall, the distance of 9.41 points is higher in MPA cases, indicating a better selectivity as compared to GPA than vice versa with 5.32 points. ENT/mucous membrane involvement showed significant association with GPA for both classification and even more in clinical diagnosis (fig. 2). In addition to BVAS, baseline CRP (100 vs. 56 mg/L) and estimated GFR levels (57 vs. 36 ml/min/1.73 m²) were more elevated in GPA. GPA was more common among males than MPA.

Conclusion: The computational algorithm performed well to categorize 98% of all cases. Our findings demonstrated positive and negative concordance rates above 88% and suggest a higher specificity for GPA, but higher sensitivity for MPA classification criteria as well as better selectivity in MPA. Concerning clinical manifestations, ENT and mucous membrane involvement showed highest and significant association to GPA in our European cohort, reflecting their strong weighting in scoring.

The Impact of Neurologic Involvement in ANCA-Associated Vasculitis on Self-Reported Health-Related Quality of Life

Rula Hajj-Ali[1], Chao Zhang[2], Renee Borchin[3], Jenn Gordon[4], David Cuthbertson[3], Carol McAlear[5], Christine Yeung[5], David Badenoch[6], Cristina Burroughs[3] and Peter Merkel[5], [1]Cleveland Clinic, Cleveland, OH, [2]Cleveland Clinic Foundation, Cleveland, OH, [3]University of South Florida, Tampa, FL, [4]Vasculitis Patient Powered Research Network (VPPRN), Philadelphia, PA, [5]University of Pennsylvania, Philadelphia, PA, [6]Vasculitis Patient Powered Research Network (VPPRN), Los Angeles, CA

SESSION INFORMATION

Session Date: Tuesday, November 14, 2023
Session Title: Abstracts: Vasculitis – ANCA-Associated II
Session Type: Abstract Session
Session Time: 2:00PM–3:30PM

Background/Purpose: Neurologic involvement (NI) is a common manifestation in patients with ANCA-associated vasculitis (AAV) and can lead to chronic pain and disability. This project assessed the impact of NI on health-related quality of life (HRQoL) in AAV.

Methods: Retrospective analysis of data provided from 2014-2022 by patients ≥18 years old with AAV [eosinophilic granulomatosis with polyangiitis (EGPA), granulomatosis with polyangiitis (GPA), or microscopic polyangiitis (MPA)] enrolled in the Vasculitis Patient-Powered Research Network (VPPRN), an online registry. The VPPRN collects data regarding type of

PROMIS measures in patients with ANCA-associated vasculitis with (light blue) and without (dark blue) neurologic involvement: Compared to patients without neurologic involvement, patients with neurologic involvement had higher scores for fatigue, depression, sleep disturbance, and pain interference, and lower scores for anxiety, social role, and physical function

vasculitis, disease manifestations, information on how and when the diagnosis of vasculitis was established, and measures of HRQoL, including from multiple Patient-Reported Outcome Measurement Information System (PROMIS) domains. PROMIS measures generate T-scores with the mean T-score = 50 with a standard deviation of 10 in the reference population (U.S. general population). Data were analyzed according to NI involvement.

Results: Data from 1465 patients with AAV with available information on NI were included in this analysis; 901 of 1465 (61.5%) patients reported NI. Table 1 summarizes the demographic and clinical characteristics of patients with or without NI. Compared to patients without NI, those with NI were older at the time of diagnosis of AAV, were more likely to be diagnosed with GPA (vs. EGPA or MPA), be positive for ANCA, and more likely to have constitutional, musculoskeletal, skin, mucous membranes, ear/nose/throat, cardiovascular, pulmonary, and thrombotic manifestations of disease. The rate of renal involvement was the same among patients with or without NI. Patients with NI reported greater severity of vasculitis. There was no significant difference in the medications ever received among patients with NI vs patients with no NI.

Overall, patients with AAV reported reduced HRQoL in almost all domains compared to a reference population. Compared to patients without NI, patients with NI report higher scores for fatigue, depression, sleep disturbance, and pain interference, and lower scores for anxiety, social role, and physical function (Figure2).

Conclusion: NI, as reported directly by patients, is common in AAV, occurring in approximately two-thirds of patients. This rate is higher than has been reported through clinician-documented data, implying that physicians may be underappreciating the extent of NI in AAV. NI is more common in GPA, compared to EGPA or MPA. Patients with NI have involvement of more organ systems than patients without NI. NI in patients with AAV has a negative impact on multiple domains of illness and health-related quality of life. These patient-reported data are informative for clinicians and patients with AAV and should raise the awareness of the impairment in patients with NI in AAV

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: Abstracts: Vasculitis – ANCA-Associated II
Session Type: Abstract Session
Session Time: 2:00PM–3:30PM

Background/Purpose: Renal involvement in ANCA-associated vasculitides (AAV) is an organ- and life-threatening manifestation and therefore an important prognostic factor. However, the identification of predictive factors for renal failure remains a major challenge. Indeed, it may influence the intensity of induction treatment strategies. Furthermore, the benefit of plasma exchange (PLEX) has been questioned in recent years. The aim of this study is to describe the clinical outcome of patients requiring renal replacement therapy (RRT) at baseline and to identify clinical, biological and histological factors at baseline associated with their prognosis at one year.

Methods: This retrospective multicentre study included patients with anti-myeloperoxidase or proteinase 3 AAV with biopsy-proven renal involvement. Characteristics were evaluated stratified by dialysis requirement at baseline to identify determinants of renal prognosis. The primary composite outcome was the occurrence of death or end-stage renal disease at one year. Prognostic outcomes were modelized by generalized linear models to quantify the impact of predictors.

Results: Of the 395 patients enrolled, 106 (26.8%) were on dialysis at baseline. The mean age was 63.1±13.6 years and age was not associated with RRT at baseline (p=0.521). PR3-ANCA was associated to a greater prevalence of renal failure.

Among patients with dialysis at baseline, 61 (57.5%) achieved the one-year composite outcome of death or end-stage kidney disease (ESKD), whereas only 29 (10.0%) patients RRT-free at baseline reached the outcome at one year (p< 0,001). Thirty (28.3%) patients with RRT at baseline had an eGFR at one year superior to 30 mL/min/1,73m², with a null median of eGFR recuperation at one year (0,00 [IQR 0.00-31.5 mL/min/1,73m²]).

Among patients requiring dialysis at baseline, age at diagnosis was not associated with the composite outcome at one year in multivariate analysis (p=0.744). MPO-ANCA were associated with a higher prevalence of RRT or death at one year (OR 3,08; 95%CI 1.21–8.14; p = 0.02). In addition, Brix score at baseline was associated with worse renal prognosis at one year (OR 1.40; 95%CI 1.16–1.73; p=0.001).

Of the patients requiring dialysis at baseline, 80 (75.5%) underwent PLEX. Plasma exchanges were independently associated with a higher estimated glomerular filtration rate (eGFR) at one year of 9.15 mL/min/1.73m² [95%CI 0.26-18.04] (p=0.044). In addition, 41 (91.1%) of the surviving patients who were weaned from RRT at one year had received PLEX, whereas only 39 (63.9%) of the patients with the composite outcome (death or RRT at one year) had received PLEX (p=0.003). Thus, PLEX was associated with a reduced risk of one-year RRT or death in patients receiving dialysis at baseline (OR 0.24, 95%CI 0.06-0.82).

Conclusion: This study describes the clinical evolution of patients with AAV requiring RRT at baseline. It shows a strong association between plasma exchange and improvement in renal function with a higher rate of dialysis weaning. It opens perspectives for further studies in patients who benefit more from PLEX therapy.

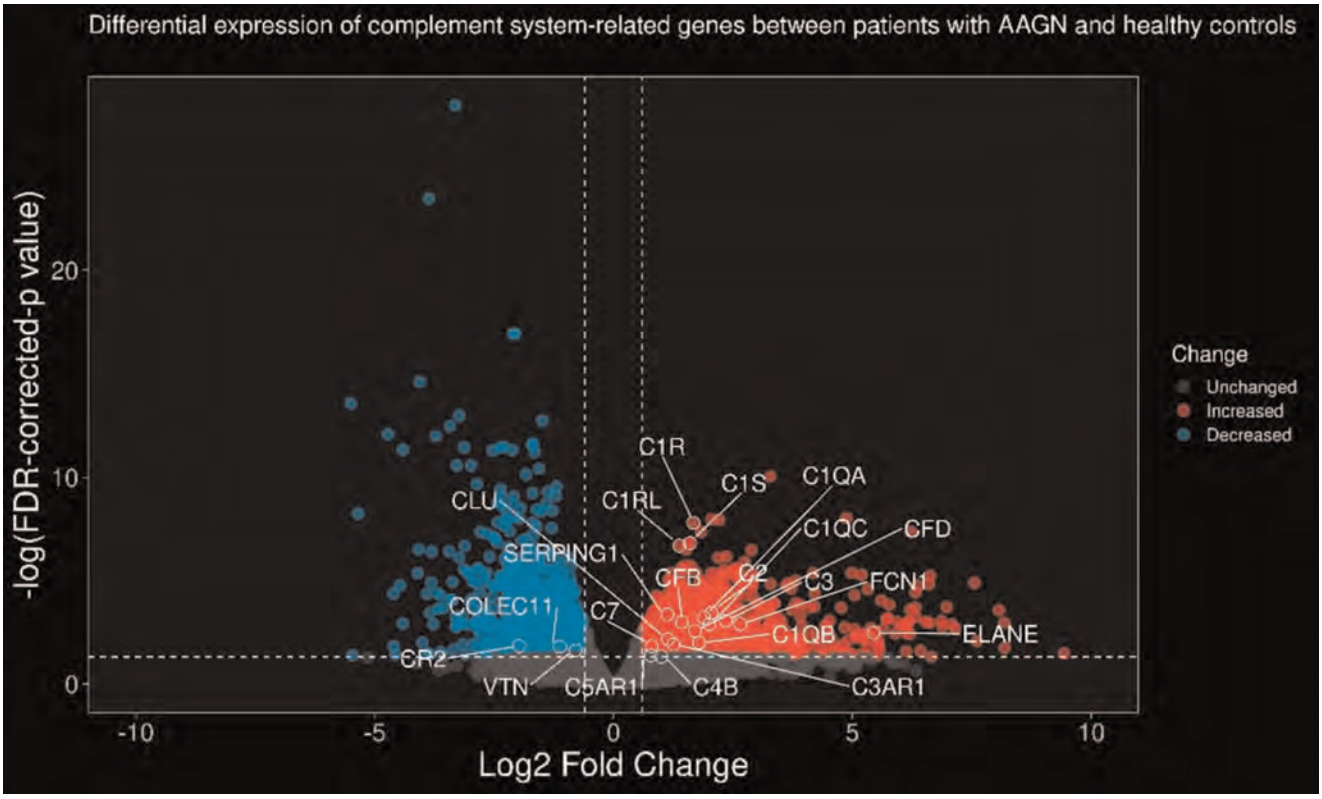
Session Date: Tuesday, November 14, 2023
Session Title: Abstracts: Vasculitis – ANCA-Associated II
Session Type: Abstract Session
Session Time: 2:00PM–3:30PM

Background/Purpose: The role of complement in patients with ANCA-associated vasculitis (AAV) has been increasingly appreciated and led to the use of complement system antagonists as a therapeutic strategy. However, it is unclear whether complement system activation occurs in affected organs such as the kidneys. This study aimed to characterize complement gene expression in patients with AAV with renal involvement (AAGN).

Table 1. Patient and Disease Characteristics

Age at biopsy, median (IQR)	58 (41-68)
% Female	59%
% White	95%
Newly diagnosed	95%
ANCA ELISA*	
anti-PR3	45% (10/22)
anti-MPO	45% (10/22)
both positive	5% (1/22)
negative	5% (1/22)
ANCA IIF	
c-ANCA	52% (12/23)
p-ANCA	30% (7/23)
*negative***	17% (4/23)
Phenotype	
GPA	52% (12/23)
MPA	35% (8/23)
EGPA	13% (3/23)
Serum Creatinine, average ±SD	3.6 ±2.9

*not available in one patient
** all had detectable ANCAs by ELISA
Abbreviations: ANCA: antineutrophil cytoplasmic antibodies. PR3: proteinase 3. MPO: myeloperoxidase. c-ANCA: cytoplasmic ANCA. P-ANCA: perinuclear ANCA. GPA: granulomatosis with polyangiitis. MPA: microscopic polyangiititis. EGPA: eosinophilic GPA



Complement mRNA expression of AAGN vs controls

Methods: Whole-tissue RNA-sequencing was performed on kidney biopsy samples of 23 patients with AAGN, and 5 healthy kidney donors. After quality control, differential expression (DGE) analysis was performed using generalized linear models correcting for number of genes and batch effects. This abstract describes mRNA expression of 42 complement system proteins, receptors, and regulators. For this analysis, differential expression was considered statistically if the FDR-corrected p-value < 0.05, and the absolute value of log2 fold change between groups was > 0.6 ($|\log_2 FC| > 0.6$).

Results: Patients' clinical and demographic characteristics are depicted in **Table 1**. Most patients were female (13/23), White (21/23), and had a median age of 58 years. Most patients had c-ANCAs and a granulomatosis with polyangiitis phenotype. DGE analysis (**Figure 1)** revealed increased abundance of mRNA coding for proteins participating in the classical (C1q, C1r, C1s, C2, C4B), alternative (CFB, CFD), and common (C3, C7) complement pathways. In addition, there was an increase in abundance of the anaphylatoxin receptors (C3AR, C5AR). mRNA abundance of complement regulators (CFH, CD55, CD46, CR1) were not different compared to controls except for CR2 which was decreased in patients with AAGN.

Conclusion: Analysis of mRNA expression in kidneys of patients with AAGN reveals increased abundance of members of the classical and alternative complement pathways, anaphylatoxin receptors, without a concomitant increase in mRNA expression of complement regulatory proteins. Along with our previous finding of increased complement activation products in urine of patients with active AAGN, these data strongly suggest intra-renal complement system activation in patients with AAGN.

Unbiased Proteomic Approach to Identify Novel Biomarkers of Disease Activity in ANCA- Associated Vasculitis

Natalie Atallah[1], Vahe Panossian[2], Xiaoqing Fu[1], Claire Cook[1] and **Zachary Wallace**[3], [1]Massachusetts General Hospital, Boston, MA, [2]American University of Beirut, Beirut, Lebanon, [3]Massachusetts General Hospital, Newton, MA

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: Abstracts: Vasculitis – ANCA-Associated II
Session Type: Abstract Session
Session Time: 2:00PM–3:30PM

Background/Purpose: Identifying novel biomarkers of disease activity could improve outcomes by facilitating personalized approaches to treatment decisions in ANCA-associated vasculitis. Biomarkers of disease activity used in day-to-day practice include PR3- or MPO-ANCA, CRP, and ESR, but these are unreliable. Few studies have examined a limited number of circulating proteins as biomarkers, identifying some candidates (e.g., BCA-1, MMP-3, TIMP-1). We previously leveraged a high-throughput, unbiased approach to investigate 92 potential biomarkers in AAV patients and identified 5 potential biomarkers: MCP3, TNFSF-14, OSM, Flt3L, and SCF. The objective of this study was to further investigate the association of 5 novel protein biomarkers with AAV disease activity.

Methods: Serum samples from n=78 patients with AAV were retrieved from a large biobank. We classified disease activity as "Active" or "Remission" at sample collection. The Olink high-throughput proteomic assay was used to measure circulating protein levels. Measurements of ESR, CRP, white blood cell (WBC) count and platelets collected for clinical purposes were extracted from the electronic medical record. We compared the levels of these potential biomarkers in active disease vs remission. Using the median value of each biomarker in the cohort as cut-off values, we determined the odds ratio

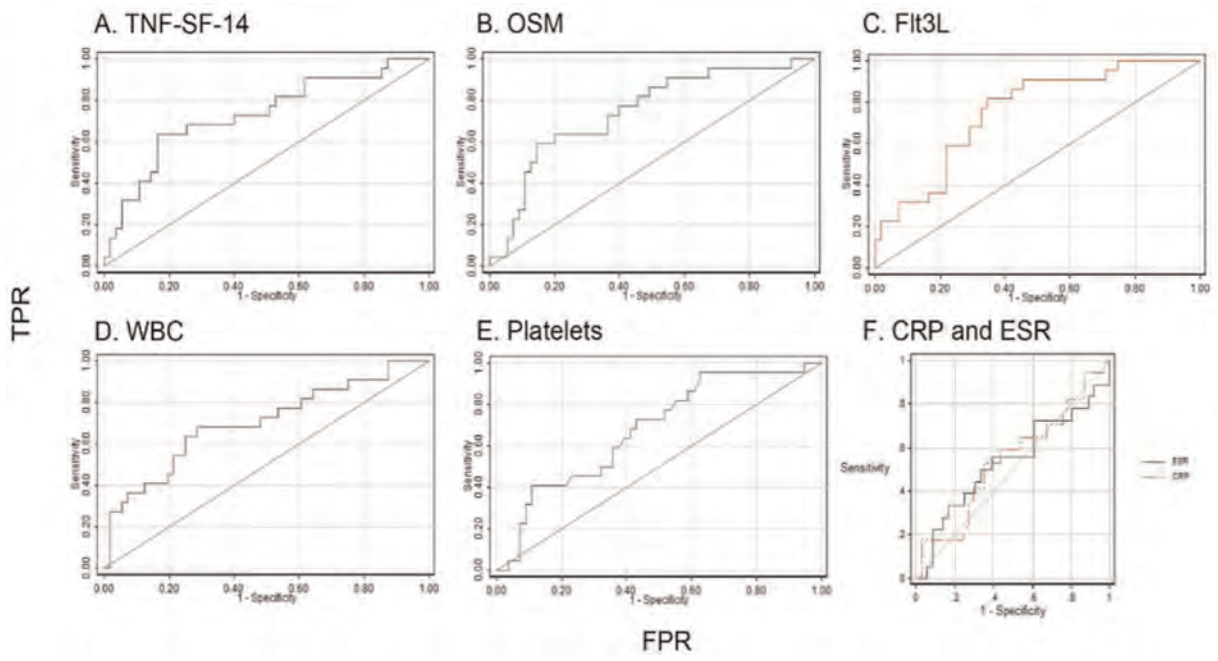

Figure 1: Receiver Operating Characteristic Curve (ROC) for the top performing biomarkers examining active vs inactive AAV disease. Note: TNF-SF-14=tumor necrosis factor super family-14; OSM=oncostatinM; Flt3L=FMS-like tyrosine kinase 3 ligand.

Table 1: AUC for top performing biomarkers in AAV disease status. Note: CI=confidence interval.

Biomarker	TNF-SF-14	OSM	Flt3L	WBC	Plt	CRP	ESR
AUC	0.731	0.745	0.757	0.703	0.680	0.549	0.547
CI	(0.601-0.862)	(0.622-0.867)	(0.644-0.871)	(0.566-0.840)	(0.551-0.809)	(0.376-0.721)	(0.372-0.722)

Table 2: Multivariate logistic regression for median biomarker levels and odds ratios for AAV active disease controlling for steroid use, ANCA type (PR3, MPO), age, and gender. Note: CI=confidence interval; MCP3=Monocyte chemotactic protein-3; SCF-Stem cell factor.

Biomarker	Odds Ratio (median cutoff, CI, p-value)
OSM	4.93 (≥ 6.96, 1.29-18.88, p=0.02)
TNF-SF-14	3.15 (≥ 7.07, 0.92-10.78, p=0.068)
MCP-3	1.38 (≥ 3.18, 0.48-.3.98, p=0.555)
Flt3L	0.11 (≥ 9.64, 0.03-0.46, p=0.002)
SCF	0.30 (≥ 10.13, 0.1-0.89, p=0.03)

(OR), the area under the receiver operating curve (AUC) of the association of abnormal biomarker with active disease, and a multivariate logistic regression to adjust for steroid use, sex, age and ANCA type.

Results: The mean age was 57.3 +/- 17.6, 55% were female, and 28% had active disease at sample collection. When comparing active disease vs remission, abnormal levels of OSM, TNF-SF-14, Flt3L, and SCF differentiated disease states: OR of 5.10 (p=0.005), 3.71 (p=0.017), 0.13 (p=0.001), and 0.34 (p=0.04), respectively. AUC analysis indicated that TNF-SF-14 (0.73, CI 0.60-0.86), OSM (0.75, CI 0.62-0.87), and Flt3L (0.76, CI 0.64-0.87) were more strongly associated with active disease than other biomarkers, including WBC (0.70, CI 0.57-0.84), platelets (0.68, CI 0.55-0.81), CRP (0.55, CI 0.38-0.72), and ESR (0.55, CI 0.37-0.72).After adjusting for steroid use, sex, age, and ANCA type, we found that only OSM and Flt3L differentiated active disease from remission.

Conclusion: Using a high-throughput, unbiased proteomics approach, we further investigated novel candidate markers differentiating active AAV disease from remission. These proteins likely reflect different states of immune activation during active disease and outperform conventional inflammatory markers (e.g., CRP, ESR) as well as WBC and platelets. Our study has certain limitations including sample size, a cross-sectional study design, and requires validation across diverse, longitudinal cohorts. The potential for biomarkers that accurately identify those individuals in remission compared to active disease may facilitate tailored, personalized therapeutic intervention, which avoids unnecessary exposure to the toxic side effects of immunomodulatory agents.

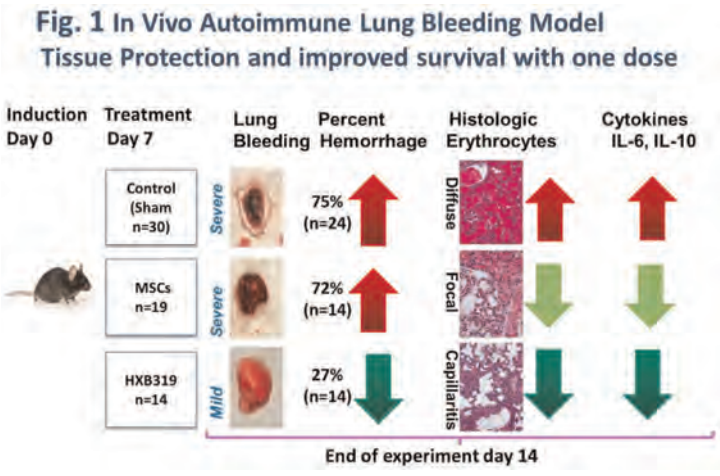
SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: Abstracts: Vasculitis – ANCA-Associated II
Session Type: Abstract Session
Session Time: 2:00PM–3:30PM

Background/Purpose: Mesenchymal stromal cells (MSCs) have been shown to be safe therapies in more than 100 human clinical trials. However, MSCs clinical efficacy is variable, and has been dependent on the severity of the inflammatory disease activity. MSC therapies have NOT been FDA approved for any disease indication, mostly due to lack of uniform potency and lack of specificity targeting the varying aspects of autoimmune diseases.

We developed a novel MSC-based cell therapy (HXB-319) that potently reduces inflammation and potentially halts organ damage in autoimmune pulmonary renal syndromes.

Methods: Using a combination of cytokines and growth factors that mimicked severe autoimmune disease microenvironment, we engineered a novel bone marrow derived MSC based cell therapy (HXB-319). We then verified its anti-inflammatory activity by flow cytometry, RT-PCR, and mass spectrophotometry *in vitro. Next, In vivo* efficacy was assessed by treating autoimmune induced DAH in C57Bl/6 mice by intraperitoneal (IP) injection of pristane. Seven days later, some mice were treated with either MSCs or HXB-319 ($2X10^6$ cells, IP). At day 14, peritoneal lavage fluid and lung tissue were sampled.

Results: HXB-319 cells showed significantly increased expression of anti-inflammatory genes (indoleamine 2,3-dioxygenase (IDO), TSG-6 and CD-274), and markers of angiogenesis (vascular endothelial growth factor A (VEGFA) and CD-146).



In vivo validation of HXB-319 mechanism of action

Table 1: Flow cytometry analysis of post mortem peritoneal lavage fluid of DAH model

Cell Population	DAH	MSC	HXB-319	Control
Neutrophils[a]	0.53 ± 0.05*	0.69 ± 0.10*	0.29 ± 0.10*¶^	0.004 ± 0.001
NK cells[a]	0.10 ± 0.02*	0.12 ± 0.03*	0.05 ± 0.01¶^	0.02 ± 0.01
Th17 $CD4^+$ $ROR\gamma T^{+c}$	83.3 ± 1.38*	77.8 ± 1.8*	75.0 ± 2.2*¶	59.0 ± 0.66
Th17 ($CD8^+ROR\gamma T$) $^{+c}$	92.3 ± 0.78*	86.9 ± 2.0*	82.3 ± 3.4*¶	59.7 ± 1.57
Tregs ($CD4^+FoxP3$) $^{+c}$	0.46 ± 0.67*	0.87 ± 0.10*¶	0.94 ± 0.15*¶^	0.29 ± 0.04
$FoxP3^+/ROR\gamma T^{+d}$	0.56 ± 0.09	1.14 ± 0.15*¶	1.27 ± 0.05*¶	0.48 ± 0.07

a data are millions of cells recovered from peritoneal lavage
b data are the dimensionless ratio of $CD3^+CD4^+$ cells compared to $CD3^+CD8^+$ cells
c data are the percentage of CD4 or CD8 cells that express the indicated cytosolic marker
d data are 100 times the dimensionless ratio of $CD3^+CD4^+FoxP3^+$ to $CD3^+CD4^+$ $ROR\gamma T^+$ cells
- significantly different from Control,
- ¶ significantly different from DAH,
- ^significantly different between the HXB-319 and MSCs

Protein pathway analysis of HXB-319 culture media (secretome) showed significant upregulation of protein pathways that reduce inflammation (IL1RN, IDO), and fibrosis with upregulation of HGF, c-MET signaling, matrix metalloproteinase secretion (MMP1, MMP13), and downregulation of TGF-β via Activin pathway, while inducing vascularization (VEGF).

Diffuse alveolar hemorrhage (DAH) model (C57bl/6 mouse induced by 0.5 cc IP pristane injection) was utilized for proof-of-concept *in vivo* studies. In the DAH model, the mortality is typically above 75% beyond 14 days after pristane injection.

When delivered *in vivo* to the DAH mice,HXB-319 significantly reduced lung inflammation and alveolar hemorrhage (27.2%) vs. naked MSC treatment (75%) (Fig.1). Pulmonary gene expression of IL-6 and 1L-10, and serum IL-1β levels were significantly reduced by HXB-319 when measured at day 14.

Peritoneal lavage fluid from DAH mice treated with HXB-319 showed reductions in total cells recovered, neutrophils, monocytes, and NK cells compared to mice given MSCs or untreated DAH mice, the reduction in neutrophils was the most statistically significant result (Table 1). DAH mouse treatment with HXB-319 cells, also significantly decreased the proportion of RORγT cells (Th17) in both CD4+ and CD8+ populations, and significantly increased the proportion of FoxP3+ cells among CD4+ cells (Tregs).

Conclusion: Novel HXB-319 cell therapy, phenotypically engineered to control inflammation, is a potent anti-inflammatory, anti-fibrotic, and angiogenic cell therapy. HXB-319 may suppress severe autoimmune disease activity, and end organ damage in DAH, particularly by excessive induction of anti inflammatory activity via IDO, and over expression of TSG-6, increased CD4+ Tregs and significant suppressive effects on neutrophil population.

Abstract Number: 2497

Factors Influencing Time to Diagnosis in U.S. Patients with Systemic Lupus Erythematosus

Joy Buie, Lupus Foundation of America, York, SC

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: Abstracts: Interprofessional OA & Lupus
Session Type: Abstract Session
Session Time: 2:00PM–3:30PM

Background/Purpose: Systemic lupus erythematosus (SLE) is a complex autoimmune disease defined by its heterogeneity and cycles of flares and remissions. Owing to non-specific or incomplete sequelae, diagnosing lupus represents a considerable clinical challenge. Despite increased awareness among physicians and patients, considerable diagnostic delays in SLE persist. The objective of this study was to identify factors contributing to delays in SLE diagnosis.

Methods: We performed cross-sectional analysis of 925 US patients with SLE registered in the Lupus Foundation of America Research Accelerated by You (RAY®) registry from October 2020 to May 2023. The Accelerated Failure Time model was used to ascertain factors influencing time to diagnosis. Demographics variables including age, sex, race as well as onset of first symptoms and time of diagnosis were evaluated. The potential effect of income, educational attainment and US region were also determined.

Results: All participants included in the analysis were ultimately diagnosed with lupus. The average duration from symptom onset and diagnosis is 6.29±0.277 SE years. Using a multivariable log-logistic AFT model, we observed that age (β=.019, p< .001), residence in the southern region (β=0.227, p=.024) and identification as American Indian/Alaska Native (β=0.651,p=.008) were associated with prolonged time to SLE diagnosis. Conversely, Asian (β=-0.545, p=.006) and Black/African American race (β=-.366, p=.002) showed association with a shorter time to diagnosis. Evaluation of income indicated a potential association with a shorter time to diagnosis (β=-0.049, p=0.063); however, it was not statistically significant.

Conclusion: Diagnostic delays remain a considerable issue for individuals eventually diagnosed with lupus. Factors such as race, regional location, and age may contribute to time to diagnosis. Additional research is needed to explore the relationship between these variables and the timing of SLE diagnosis.

Does Physical Activity Modify the Relationship Between Pain and Corticosteroid Injection Utilization in Adults with or at High Risk for Knee Osteoarthritis?

Sydney Liles[1], Daniel White[2], Thomas Bye[2] and Jason Jakiela[2], [1]University of Delaware, Elkton, MD, [2]University of Delaware, Newark, DE

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: Abstracts: Interprofessional OA & Lupus
Session Type: Abstract Session
Session Time: 2:00PM–3:30PM

Background/Purpose: Knee osteoarthritis (OA) is a leading global cause of pain and disability, with no current cure. Knee pain is the most common symptom and a driving factor for patients to seek treatment for knee OA. Exercise and Corticosteroid (CS) injections are mainstays of treatment for knee OA, however, increased utilization of CS injections may increase the risk of radiographic knee OA progression and cartilage loss. Given this, physical activity (PA) may be an ideal first-line treatment, however, it is unknown if PA modifies the utilization of CS in those with varying levels of pain. Therefore, the purpose of this study was to determine if PA modifies the relationship between knee pain and utilization of CS injections during a 5-year follow-up period in adults with or at high risk for knee OA.

Methods: We used data from the Osteoarthritis Initiative (OAI). Our exposure was visual analogue scale (VAS) knee pain severity over the past 30 days, dichotomized using a patient acceptable symptom state (PASS) value into high (≥ 4) vs low pain (< 4) at the 48-month visit (analytic baseline, BL). Our outcome was receiving a CS injection. Participants were asked, "In the past 6 months, have you received a CS injection?" at the 48-, 60-, 72-, 84-, 96-, and 108-month follow-up visits. PA at BL was measured using an Actigraph GT1M and was examined as an effect measure modifier between pain and CS injection. We used 6000 steps/day to stratify the sample, as this cutoff was previously found to be associated with

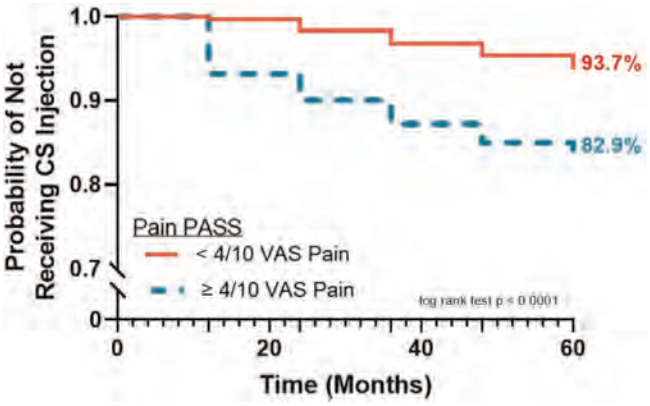

Figure 1: Kaplan-Meier survival curves for not receiving a CS injection by pain PASS exposure group in those who walked ≥ 6000 steps/day at baseline.

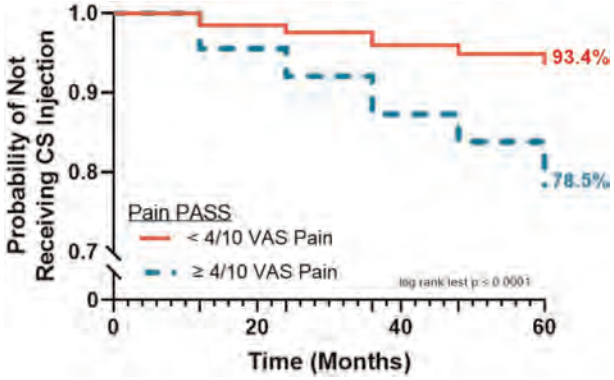

Figure 2: Kaplan-Meier survival curves for not receiving a CS injection by pain PASS exposure group in those who walked < 6000 steps/day at baseline.

Table 1: Hazard ratios and 95% confidence intervals for receiving a CS injection, by pain PASS exposure group, stratified by steps/day at baseline.

	CS Injection n/N (%)	HR [95% CI] (unadjusted)	HR [95% CI] (adjusted)
≥ 6000 steps/day			
Low pain (< 4/10)	32 / 523 (6.1%)	1.0 [REF]	1.0 [REF]
High pain (≥ 4/10)	54 / 321 (16.8%)	2.98 [1.92, 4.61]	1.48 [0.79, 2.78]
< 6000 steps/day			
Low pain (< 4/10)	36 / 580 (6.2%)	1.0 [REF]	1.0 [REF]
High pain (≥ 4/10)	90 / 444 (20.3%)	3.61 [2.45, 5.31]	2.72 [1.50, 4.94]

Note: models were adjusted for age, sex, BMI, race, education, comorbidity, function measured by the Knee Osteoarthritis Outcome Score (KOOS), and radiographic knee OA presence

developing functional limitation. We excluded participants who answered yes to the CS injection question at BL. We produced Kaplan-Meier survival curves for cumulative incidence of not receiving a CS injection and used Cox proportional hazards regression to calculate discrete-time hazard ratios (HR) and 95% confidence intervals (CI), adjusted for potential confounders.

Results: 1868 participants (mean age = 65.0 years old, 55% female, mean BMI = 28.5 kg/m^2) were included in the overall analytic sample. 212 participants received at least one CS injection over 5 years of follow-up. In the ≥ 6000 steps/day group, survival probability was 82.9% for those with high pain and 93.7% for those with low pain (Figure 1). In the < 6000 steps/day group, survival probability was 78.5% for those with high pain and 93.4% for those with low pain (Figure 2). Participants with ≥ 4/10 pain that walked < 6000 steps/day had a 2.72 times greater hazard of receiving a CS injection compared to those with < 4/10 pain (adjusted HR [95% CI] = 2.72 [1.50, 4.94]). Participants with ≥ 4/10 pain that walked ≥ 6000 steps/day had a 1.48 times greater hazard of receiving a CS injection compared to those with < 4/10 pain, which did not reach statistical significance (adjusted HR [95% CI] = 1.48 [0.79, 2.78]) (Table 1).

Conclusion: In adults with knee OA who walk less than 6000 steps per day, high pain is associated with greater corticosteroid utilization. However, in those who walk at least 6000 steps per day, pain is not related to CS injection utilization over the next 5 years. This initial look suggests that daily walking may modify the relationship between pain and receiving a CS injection, though further research is warranted.

Abstract Number: 2499

Influence of Adiposity on Physical Function, Physical Activity, and Self-Reported Symptom Severity for Individuals with Arthritis Prior to Beginning a Physical Activity Promotion Intervention

Scott Jamieson, Sara Wilcox and Christine Pellegrini, The University of South Carolina, Columbia, SC

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: Abstracts: Interprofessional OA & Lupus
Session Type: Abstract Session
Session Time: 2:00PM–3:30PM

Background/Purpose: Engagement in moderate-vigorous physical activity (MVPA) is recommended for individuals with obesity to promote weight loss and mitigate severity of chronic diseases associated with higher levels of adiposity. However, limited research has examined the role that weight status plays on physical function, physical activity, and symptoms severity for individuals with arthritis. Therefore, this study compared differences in physical activity; physical function; and arthritis pain, stiffness, fatigue, and self-efficacy between individuals with and without obesity.

Methods: Participants ≥18 years with a diagnosis of arthritis from an ongoing study aimed to evaluate a phone-based version of the Walk with Ease program were included. Physical function was assessed with the 30-second chair stand and 6-minute walk. Participants wore an ActiGraph GT9x Link for 7 days. Total minutes/week of MVPA (≥2020 counts/min) and steps/day were calculated among participants with >4 valid days (≥10 hours of wear time). Weight status was calculated using body mass index (BMI); a BMI ≥30 kg/m^2 indicated obesity and < 30 kg/m^2 indicated absence of obesity. Self-efficacy in arthritis care was assessed with the Arthritis Self-Efficacy Scale (ASES). Symptom severity for pain, fatigue, and stiffness was assessed using a visual analog scale (VAS). Independent t-tests were used to compare mean differences in physical function; physical activity; and self-reported measures of pain, stiffness, fatigue, and self-efficacy between participants with and without obesity.

Results: A total of 140 participants were included in the analysis (91.4% female, 60.7% African American, 63.0 ± 9.7 years, BMI 34.5 ± 8.1 kg/m^2). Differences between those with and without obesity are shown in Table 1. Participants without obesity were on average older than participants with obesity. Both groups were predominantly female and African American, with osteoarthritis the most common arthritis diagnosis for each. Participants without obesity were more physically active in terms of MVPA/week, steps/day, and walked a greater distance in the 6-minute walk test ($p< 0.05$). Participants without obesity also reported lower levels of fatigue and stiffness ($p< 0.05$). Pain ($p=0.059$) and ASES ($p=0.071$) approached significance such that participants without obesity reported higher levels of arthritis self-efficacy and lower levels of pain. No significant differences between groups were seen on the 30-second chair stand test ($p=0.969$).

Conclusion: Participants with obesity had greater impairments on the majority of tests administered along with lower levels of physical activity as compared to those without obesity. Additional coaching strategies are warranted encouraging adults with arthritis who are obese to engage in regular physical activity to assist with health-related outcomes.

Table 1: Demographics & Group Differences on Physical Activity, Physical Function, & Self-Reported Symptom Severity (n=140)

Demographics	BMI < 30 kg/m^2 (n=47)	BMI ≥ 30 kg/m^2 (n=93)	
Sex	89.4% Female	92.5% Female	
Race	53.2% African American	64.5% African American	
Age (years)	63.62 ± 9.75	62.74 ± 9.64	
BMI (kg/m^2)	26.29 ± 2.77	38.61 ± 6.70	
Arthritis dx:	48.9% Osteoarthritis	61.3% Osteoarthritis	
Measurement	**BMI < 30 kg/m^2**	**BMI ≥ 30 kg/m^2**	**p-value**
6-minute walk test (ft)	1422.95 ± 280.21	1229.64 ± 281.72	p<0.001
30-second chair stand test (repetitions)	8.91 ± 2.47	8.94 ± 3.22	p=0.969
MVPA (minutes/week)	86.10 ± 109.83	46.16 ± 57.88	p=0.005
Steps/day	4999.26 ± 2596.52	3727.75 ± 1865.95	p=0.001
VAS pain (mm)	34.16 ± 25.48	43.10 ± 26.55	p=0.059
VAS fatigue (mm)	33.35 ± 26.52	47.59 ± 29.45	p=0.006
VAS stiffness (mm)	38.07 ± 27.23	51.59 ± 26.03	p=0.005
Arthritis self-efficacy scale	6.47 ± 1.90	5.83 ± 1.99	p=0.071

Suicidal Ideation and Self-Efficacy in Systemic Lupus Erythematosus: Georgians Organized Against Lupus (GOAL) Cohort

Charmayne Dunlop-Thomas[1], Gaobin Bao[1], Jessica Williams[2], Hilton Mozee[1], Cristina Drenkard[1] and S. Sam Lim[1], [1]Emory University, Atlanta, GA, [2]Emory University School of Medicine, Atlanta, GA

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: Abstracts: Interprofessional OA & Lupus
Session Type: Abstract Session
Session Time: 2:00PM–3:30PM

Background/Purpose: Suicidal ideation is more common in SLE than in other chronic diseases. Targeted interventions are needed to reduce morbidity and mortality. Bandura's theory of self-efficacy notes the importance of individual perception of capabilities as predictors of health and well-being. Patients working with healthcare professionals to understand and manage symptoms is crucial. This study aimed to identify health and psychosocial factors associated with SI among patients with SLE, which could serve as possible targets for intervention by healthcare professionals. We explored the possible association between self-efficacy (SE) for managing symptoms and treatments and suicidal ideation (SI) among SLE patients from the Georgians Organized Against Lupus (GOAL) Cohort.

Methods: We examined data from the GOAL Cohort, a large population-based cohort of adults from metropolitan Atlanta, Georgia, who fulfilled three or more ACR classification criteria with a final SLE diagnosis by a board-certified rheumatologist. GOAL participants responded to validated self-administered tools on health outcomes. This study included participants with completed surveys between 2017- 2020. We explored the following measures: Patient Health Questionnaire-9, PROMIS Self-efficacy for managing medications and treatments (SEMMT) and PROMIS Self-efficacy for managing symptoms (SEMS), PROMIS depression, the Systemic Lupus Activity Questionnaire (SLAQ), and the Self-administered Brief Index of Lupus Damage (SA-BILD). We examined an individual SEMS question for further examination: I can work with my doctor

Table: Logistic Regression of Suicidal Ideation in SLE

		Univariable		Multivariable	
	Characteristics	**Odds Ratio**	**P value**	**Odds Ratio**	**P value**
Self-efficacy	***Adequate confidence in working with a doctor to manage symptoms (per 1 scale ↓)**	**1.73 (1.43-2.09)**	**<0.0001**	**1.64 (1.25-2.14)**	**<0.001**
	SEMMT (per 5 units ↓)	**1.39 (1.22-1.58)**	**<0.001**		
	SEMS (per 5 units ↓)	**1.56 (1.35-1.81)**	**<0.001**		
Socio-demo	Age at survey completion (per 10 units ↑)	0.86 (0.74-1.01)	0.071	1.23 (0.90-1.69)	0.20
	Disease duration (per 5 units ↑)	0.91 (0.81-1.01)	0.087	1.14 (0.95-1.36)	0.16
	Education years (per 3 units ↑)	0.88 (0.70-1.10)	0.25	1.25 (0.87-1.80)	0.22
	Organ damage (BILD score) (per 3 units ↑)	1.08 (0.92-1.28)	0.35	0.90 (0.67-1.22)	0.50
Health	Disease Activity (SLAQ score) (per 3 units ↑)	**1.34 (1.25-1.45)**	**<0.0001**	1.00 (0.89-1.13)	0.97
	PROMIS Depression T-score (per 5 units ↑)	**2.66 (2.23-3.17)**	**<0.0001**	**2.98 (2.36-3.77)**	**<0.001**

*SEMS individual question - adequate is defined as quite or very confident in working with a doctor to manage symptoms. Inadequate is defined as not at all, a little or somewhat confident in working with a doctor to manage symptoms. Abbreviations: SEMMT - PROMIS Self-efficacy for managing medications and treatments, SEMS - PROMIS Self-efficacy for managing symptoms, SA-BILD – Self-administered-Brief Index of Lupus Damage, SLAQ – Systemic Lupus Activity Questionnaire. Multivariable adjustments: socio-demographics (age, race, education, marital status, work status), insurance, disease duration, disease severity, and depression.

to manage my symptoms with response choices on a Likert scale from 1 (I am not at all confident) to 5 (I am very confident). Logistic regression was used to examine factors associated with SI.

Results: This study includes data from 967 SLE participants (94% women, mean age 32 years [SD 11.8], 82% Black, mean disease duration 15 years [SD 10.3], 14% uninsured). The mean disease activity and organ damage scores were 15 (SD 8.8) and 4 (SD 3.7), respectively. The t-scores for SEMMT and SEMS were 46 [SD 8.9] and 48 [SD 8.7], respectively. Ninety participants (9.4%) endorsed suicidal ideation.

Univariate analyses showed that lower SE, higher SLE activity and higher depression scores were significantly associated with SI. In the multivariate analysis, only lower SE related to working with doctors to manage symptoms remained significantly associated with suicidal ideation after controlling for other factors (Table).

Conclusion: In a population-based, predominantly Black SLE cohort with considerable disease activity, there was a significant proportion of suicidal ideation. After controlling for other risk factors, such as socio-demographics and disease status, those with low self-efficacy for working with doctors to manage symptoms were at higher risk for SI. Health professionals can consider assessing and addressing perceptions of self-management capabilities among patients with SLE in order to improve outcomes in this vulnerable population.

WITHDRAWN

SESSION INFORMATION

Session Date: **Tuesday, November 14, 2023**
Session Title: Abstracts: Interprofessional OA & Lupus
Session Type: Abstract Session
Session Time: 2:00PM–3:30PM

Background/Purpose: Systemic lupus erythematosus (SLE) is a common multisystem autoimmune disease with chronic inflammation. Many efficacy evaluation indicators of randomized clinical trials (RCTs) for SLE have been proposed but the comparability remains unknown. We aim to explore the preference and comparability of indicators reporting response rate and provide basis for primary outcome selection when evaluating the efficacy of SLE pharmaceutical treatment.

Methods: We systematically searched 3 databases and 3 registries to identify pharmacological intervention-controlled SLE RCTs. Relative discriminations between indicators were assessed by the Bayesian hierarchical linear mixed model.

Results: 33 RCTs met our inclusion criteria and we compared 8 of the most commonly used indicators reporting response rate (Figure 1). Systemic Lupus Erythematosus Disease Activity Index (SLEDAI)-4and Systemic Lupus Erythematosus Responder Index(SRI)-4 were considered the best recommended indicators reporting response rate to discriminate the pharmacological efficacy. Indicator preference was altered by disease severity, classification of drugs and outcome of trials, but SLEDAI-4 had robust efficacy in discriminating ability for most interventions. Of note, British Isles Lupus Assessment Group (BILAG) Index-based Combined Lupus Assessment (BICLA) showed efficacy in trials covering all-severity patients, as well as non-biologics RCTs. BILAG response and Physician's Global Assessment (PGA) response were more cautious

in evaluating disease changes. Serious adverse events (SAE) was often applied to evaluate the safety and tolerability of treatments rather than efficacy (Figure 2).

Conclusion: The impressionable efficacy discrimination ability of indicators highlights the importance of flexibility and comprehensiveness when choosing primary outcome(s) (Table 1). As for trials that are only evaluated by SLEDAI-4, attention should be paid to outcome interpretation to avoid the exaggeration of treatment efficacy.

Self-Reported Sleep Disorders Among Individuals with Systemic Lupus Erythematosus

Patti Katz[1], Maria Dall'Era[2], Jinoos Yazdany[3] and Kaleb Michaud[4], [1]University of California San Francisco, San Rafael, CA, [2]University of California San Francisco, San Francisco, CA, [3]University of California, General Department of Medicine, Division of Rheumatology, San Francisco, CA, [4]University of Nebraska Medical Center, Omaha, NE

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: Abstracts: Interprofessional OA & Lupus
Session Type: Abstract Session
Session Time: 2:00PM–3:30PM

Background/Purpose: Research in the general population has linked sleep disorders to poor outcomes such as lower pain thresholds, fatigue, cognitive impairment, depression, and cardiovascular disease – important health outcomes relevant to lupus, as well as higher levels of systemic inflammation, which may influence SLE disease activity and symptoms. SLE-specific studies have linked self-reported sleep problems with greater disease activity and symptoms and even risk of lupus onset. Some sleep disorders are more common among older individuals. We examine the prevalence of self-reported sleep disorders in two SLE cohorts, one with greater representation from older adults with SLE.

Methods: Data are from participants with physician-confirmed SLE in the California Lupus Epidemiology Study (CLUES) and the FORWARD Databank. In one data collection period in each study, we examined two sleep disorders: obstructive sleep apnea (OSA) using the validated STOP-Bang questionnaire and self-reported OSA diagnosis, and restless legs syndrome (RLS) using validated self-reported questions and self-reported RLS diagnosis. We examined the prevalence of OSA and RLS and the overlap between the two in each cohort. Unadjusted analyses identified significant associations between OSA and RLS and sociodemographic (age, sex, income, education), general health (smoking, obesity, comorbidities [Rheumatic Disease Comorbidity Index, RDCI), and SLE-related (SLE duration, self-reported disease activity [Systemic Lupus Activity Questionnaire, SLAQ], and damage [Brief Index of Lupus Damage, BILD], 0-10 pain rating, glucocorticoid use, use of immunosuppressive medications) characteristics. Multivariable analyses to identify independent associations of sleep disorders included all variables significant at $p \leq 0.10$ in unadjusted analyses.

Results: Mean age was 50 ± 14 years in CLUES and 61 ± 12 years in FORWARD (Table 1). Prevalence of each sleep disorder was higher in the older FORWARD cohort and considerably higher in both cohorts than in the general population (Table 1). In CLUES and FORWARD, 36.7% and 53.8% of participants, respectively, had at least one sleep disorder. In multivariable analyses, SLAQ, pain, and a higher number of comorbid conditions were the most consistent factors associated with sleep disorders (Tables 2 and 3).Obesity (BMI ≥30 kg/m2) was also associated with OSA.

Table 1. Subject characteristics

	CLUES (n = 248)	FORWARD (n = 336)	
Sociodemographic			
Age	49.9 ± 13.9	60.5 ± 7.5

RDCI = Rheumatic Disease Comorbidity Index; SLAQ = Systemic Lupus Activity Questionnaire; BILD = Brief Index of Lupus Damage

Conclusion: High proportions of individuals in both of these SLE cohort had sleep disorders; prevalence was greater in the older cohort. Factors associated with sleep disorders – comorbid conditions, disease activity, and pain – were similar in the two cohorts. Given the association of sleep disorders with poor health outcomes, increased awareness of and screening for sleep disorders among SLE patients may be beneficial, particularly among older adults who may be more likely to have sleep disorders and be more sensitive to the negative impacts of sleep disorders.

Cytokines Regulate the Fibrotic Response of Growth Factors in Joint Fibroblast-like Synoviocytes

Sofie Falkenløve Madsen[1], Mikkel Rathsach Andersen[2], Alexander Scheller Madrid[2], Signe Holm Nielsen[3], Morten Karsdal[3], Christian Thudium[3] and Anne-Christine Bay-Jensen[3], [1]University of Copenhagen, Herlev, Denmark, [2]Herlev-Gentofte Hospital, Gentofte, Denmark, [3]Nordic Bioscience, Herlev, Denmark

SESSION INFORMATION

Session Date: Tuesday, November 14, 2023
Session Title: Abstracts: Cytokines & Cell Trafficking
Session Type: Abstract Session
Session Time: 4:00PM–5:30PM

Background/Purpose: Rheumatoid arthritis (RA) and osteoarthritis (OA) are characterized by inflammation, joint swelling, stiffness, and pain. A fibroid phenotype has been identified in RA, where fibrosis is the key molecular feature, and inflammation is absent. Fibroblast-like synoviocytes (FLS) are located in the synovial membrane (SM), where they produce

extracellular matrix (ECM) components as a response to injury. The interplay between joint fibrosis and inflammation and its impact on ECM formation are poorly understood. We hypothesize that a fibro-inflammatory environment may affect the fibrotic response of FLS. Our objective was to characterize the fibrotic ECM profile of FLS in a fibro-inflammatory context to gain insights into the complex dynamics of fibrosis and inflammation in joint pathology.

Methods: Primary human FLS were isolated from the SM of patients undergoing total knee replacement surgery (n=8). The FLS were cultured in 0.4% fetal bovine serum DMEM with ficoll (to create a crowded environment) and ascorbic acid for 12 days. The growth factors, TGF-β1 [1 nM] and PDGF-AB [6 nM], and cytokines, IL-1β [0.5 nM] and TNF-α [0.5 nM] were added either alone or in combination. Non-treated FLS were used as control (w/o). Every 4 days, the supernatant was collected, and new treatments were added. PRO-C3, a type III collagen formation biomarker, was measured in the supernatant using a validated ELISA. 2-way ANOVA compared day-to-day differences with Tukey's multiple comparisons tests. In addition, the AUC for each patient was computed, and the treatment differences were compared using the Kruskal-Wallis test with Dunn's multiple comparisons tests.

Results: TGF-β increased the PRO-C3 formation from day 8 (D8) and PDGF from D4 compared to w/o ($p < 0.05$, Fig. 1A, 1B). Co-stimulation with TGF-β+IL-1β increased PRO-C3 on D4 compared to w/o ($p < 0.05$); however, it was not different from TGF-β or IL-1β alone (Fig. 1A). The AUC of co-stimulation with TGF-β+IL-1β were higher than w/o ($p < 0.05$, Fig. 1B).

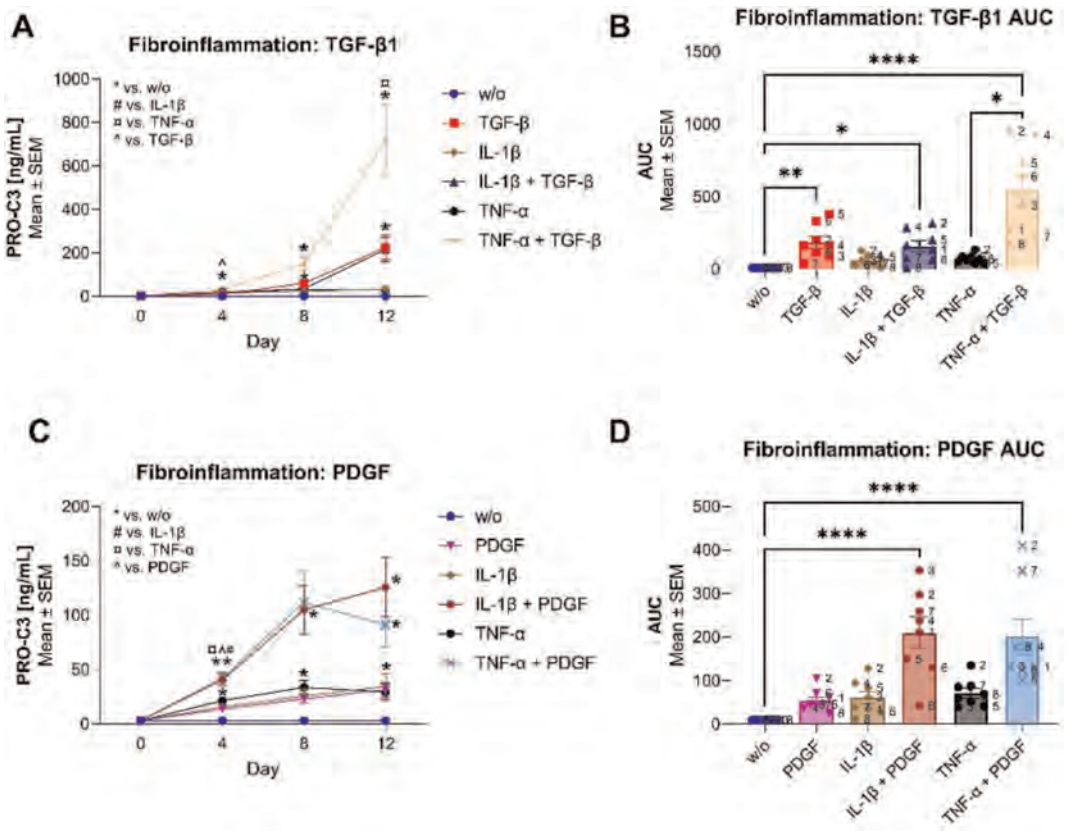

Figure 1 The effect of fibro inflammation on type III collagen formation (PRO-C3). A) PRO-C3 increases from single stimulation of TGF-β from D8, IL-1β on D4 and TNF-α on D4 and D8 compared to w/o. Co-stimulation of TGF-β+IL-1β increases PRO-C3 on D4 compared to w/o. Co-stimulation of TGF-β+TNF-α increases PRO-C3 compared to w/o from D4 and onwards, and to TGF-β on D4 and to TNF-α on D12. B) AUC increases from stimulation of TGF-β, TGF-β+IL-1β and TGF-β+TNF-α compared to w/o. Co-stimulation of TGF-β+TNF-α also increases AUC compared to TNF-α. No. indicates the different patients. C) PDGF and PDGF+IL-1β increases PRO-C3 from D4 and onwards compared to w/o. Co-stimulation of PDGF+IL-1β also increases PRO-C3 on D4 compared to PDGF and IL-1β. Co-stimulation of PDGF+TNF-α increases PRO-C3 compared to PDGF, TNF-α and w/o on D4, and to w/o on D12. D) Co-stimulation of PDGF+IL-1β and PDGF+TNF-α increases the AUC compared to w/o. No. indicates the different patients. A significance level of $p \leq 0.05$ was employed, and symbols denote the level * = $p<0.05$, ** =$p<0.01$, *** =$p<0.001$, **** =$p<0.0001$.

In contrast, co-stimulation with TGF-β+TNF-α increased PRO-C3 compared to w/o from D4 and onwards, and were higher than TGF-β on D4 and TNF-α on D12 ($p< 0.05$, Fig. 1A). The AUC of TGF-β+TNF-α was increased compared to w/o and TNF-α ($p< 0.0001$ and $p< 0.05$, respectively, Fig. 1B). Co-stimulation of PDGF+IL-1β, increased PRO-C3 from D4 and onwards compared to w/o, and to PDGF and IL-1β on D4 ($p< 0.05$, Fig. 1C). The AUC of the co-stimulation was increased compared with w/o ($p< 0.0001$, Fig. 1D). A similar trend was found for co-stimulation of PDGF+TNF-α. Here, PRO-C3 was increased on D4 and D12 compared to w/o and compared to PDGF and TNF-α on D4 ($p< 0.05$, Fig. 1C). The AUC of the co-stimulation was higher than w/o ($p< 0.0001$, Fig. 1D).

Conclusion: In conclusion, the combination of inflammatory cytokines and fibrotic growth factors induces a heightened fibrotic response, particularly increasing type III collagen formation, more than the fibrotic growth factors alone. These data suggest that the coexistence of fibrosis and inflammation could potentially influence the mechanisms driving joint damage in RA and OA. This underscores the potential need for therapeutic strategies targeting both fibrosis and inflammation in patients with arthritis.

Abstract Number: 2504

The Effect of Inflammatory Conditions on the Regulation of Canonical and Non-canonical NF-kB Pathways via Bcl11b

Sara Parsa[1], Saeid Rahmani[2], Nadine Davelaar[1], Adriana M.C.mus[1] and Erik Lubberts[1], [1]Erasmus Medical Center, Rotterdam, Netherlands, [2]Institute for Research in Fundamental Sciences, Tehran, Iran

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: Abstracts: Cytokines & Cell Trafficking
Session Type: Abstract Session
Session Time: 4:00PM–5:30PM

Background/Purpose: *Bcl11b*, a zinc finger bi-functional transcription factor, is highly expressed in various tissues during development and differentiation, including stromal cells. It has been shown that Bcl11b has an impact on Th17 responses. Recently we found using a bioinformatic analysis that *Bcl11b* is down-regulated in psoriatic skin. In addition to Bcl11b, other transcription factors, such as NF-kB, are also involved in immune-mediated diseases that can be activated by cytokine stimulation. However, the mechanism of activation and regulation of pathways related to these transcription factors has not been identified.

To investigate the role of *Bcl11b* in the regulation of NF-kB pathways in keratinocytes under naïve and inflammatory conditions.

Methods: : HaCaT keratinocytes were cultured and *Bcl11b* was knocked down in these cells using the CRISPRi approach. qPCR and WB were performed to analyze the RNA and protein levels of *Bcl11b*, control genes, and NF-kB pathway genes. In addition, the effect of IL-17A, IL-23, TNF, IL-23/TNF, and IL-17A/IL-23 on the activation of the canonical and non-canonical NF-kB pathways in HaCaT keratinocytes was investigated in the presence or absence of *Bcl11b*.

Results: To mimic the lower expression of Bcl11b that has been found in different autoimmune diseases, *Bcl11b* was knocked down in keratinocytes, which was confirmed using q-PCR and WB. Gene expression analysis and/or WB of NF-kB pathways including NF-kB1, TNF, NF-kB2, RELB, and NIK indicated an upstream role of *Bcl11b* in both the canonical and non-canonical NF-kB pathways. We further analyzed these pathways under inflammatory conditions. Cytokine stimulation showed that the IL-17A, IL-17/IL-23, and IL-23/TNF can rescue the down-regulation of *Bcl11b* expression. None of these cytokines are able to activate the canonical NF-kB pathway under Bcl11b knockdown condition. Interestingly, IL-17A and IL-23/TNF, but not IL-23 or TNF alone, are able to activate the non-canonical NF-kB pathway in the absence of Bcl11b.

Conclusion: Here, we showed for the first time the role of *Bcl11b* and its interaction with the canonical and non-canonical NF-kB pathways in keratinocytes. Our data suggest that pro inflammatory cytokines have different effects on *Bcl11b* dependent activation of NF-kB pathways. Since Bcl11b acts both directly, and indirectly to promoter regions, this may impact its effect on the NF-kB pathways in different inflammatory conditions. Further studies are warranted to unravel the interaction of Bcl11b and these two NF-kB pathways.

Discovery of First-in-Class IRAK4 Scaffolding Inhibitors for the Treatment of Inflammatory Disorders

Kate Byth[1], Rodney Morgan[2], Pierre Michelys[3], Kellie Demock[2], Geetha Kannan[2], Qing Chen[1], Brian Sanchez[2], Xiaokang Lu[2], Alissa Telling[2], Chuck Lesch[2], Carmen Yu[2], Sarah Bradley[2], Brian Andresen[1], Sherif Hassanien[2], Clarke Taylor[2], Zhilin Hou[2], Ken Borrelli[1], Anna Gardberg[1], Erika Munschy[1], Adam Schwaid[1], Anthony Opipari[2], Shifeng Pan[3] and Luigi Franchi[2], [1]Odyssey Therapeutics, Boston, MA, [2]Odyssey Therapeutics, Ann Arbor, MI, [3]Odyssey Therapeutics, San Diego, CA

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: Abstracts: Cytokines & Cell Trafficking
Session Type: Abstract Session
Session Time: 4:00PM–5:30PM

Background/Purpose: Interleukin-1 receptor-associated kinase 4 (IRAK4), is a key node that mediates inflammatory signaling in response to activation of toll-like receptor (TLR) and IL-1 receptor (IL-1R) activation making it an attractive target for treating inflammatory diseases. IRAK4 has multiple functions, including kinase activity and a scaffolding activity that bridges the interaction between MYD88 and IRAK1/2, which is a critical interaction for signal transduction from the myddosome. IRAK4 kinase inhibitors cannot block signaling in cells outside the myeloid compartment and reducing IRAK4 protein by targeted degradation fails to maximally block IRAK4 signaling. Thus, targeting scaffolding directly is an attractive approach to inhibit IRAK4 across a range of disease relevant cell types. Here, we describe compounds that bind to IRAK4, directly block scaffolding activity, and are effective at inhibiting IRAK4 signal transduction and cytokine production across a range of disease relevant cell types.

Methods: IRAK4 degraders, kinase inhibitors, and scaffolding inhibitors were tested for their ability to block scaffolding with recombinant proteins and in myeloid and non-myeloid cells and for their ability to inhibit cytokine production in primary cells responding to TLR ligands or IL-1 stimulation. The effect of scaffolding inhibitors in mice was determined by assessing TNF production following lipopolysaccharide (LPS) exposure, and chemokine production and neutrophil recruitment in a urate crystal model of gout.

Results: IRAK4 scaffolding inhibitors blocked recombinant IRAK4 binding both to IRAK1 and IRAK2 in vitro and in cells, whereas kinase inhibitors and protein degraders had no effect. To identify a relationship between scaffolding activity and proinflammatory signaling, the effect of these compounds on cytokine production was assessed in a panel of cells. In peripheral blood mononuclear cells (PBMCs) each compound blocked cytokine production. However, in certain disease relevant cell types, including fibroblasts, synoviocytes, osteoclasts, chondrocytes, and keratinocytes from healthy subjects or patients with inflammatory diseases only the scaffolding inhibitors blocked cytokine production in a robust fashion. Oral administration of the scaffolding inhibitor to mice dose-dependently reduced serum TNF produced in response to LPS and significantly reduced chemokine production and neutrophil recruitment in a model of gout.

Conclusion: Our data suggest that inhibiting IRAK4 scaffolding is an effective mechanism to inhibit IRAK4 signaling and unlike IRAK4 kinase inhibitors and degraders, has robust activity against disease relevant cell types. As such, blocking IRAK4 scaffolding represents a novel therapeutic approach to treat inflammatory diseases with the potential to achieve greater efficacy relative to previous approaches to drug this target.

Abstract Number: 2506

Role of TGF-β Activated Kinase 1 in Cytokine-Driven Juvenile Idiopathic Arthritis Synovial Fibroblasts Activation

Meena Afroze Shanta[1], Anil Singh[2], Paul Panipinto[3] and Salahuddin Ahmed[2], [1]College of Pharmacy and Pharmaceutical Science, Washington State University, Spokane, WA, [2]Washington State university, Spokane, WA, [3]Washington State University College of Pharmaceutical Science and Molecular Medicine, Spokane, WA

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: Abstracts: Cytokines & Cell Trafficking
Session Type: Abstract Session
Session Time: 4:00PM–5:30PM

Background/Purpose: Chronic synovitis is a debilitating manifestation of juvenile idiopathic arthritis (JIA). Synovial fibroblast is a major preparator of inflammatory arthritis and has not been well studied in JIA. Thus, we aimed to study the involvement of TGF-β activated kinase 1 (TAK1) in cytokine-driven JIA synovial fibroblasts (JIASFs) activation and subsequent induction of inflammatory arthritis.

Methods: JIASFs were isolated from the synovial fluids aspirated from the knees of deidentified JIA patients. JIASFs were treated with TNF-α and IL-1β (0-120 minutes) to study the phosphorylation of TAK1 and downstream signaling pathways. To investigate the overall impact of TAK1 inhibition, RNA sequencing (RNA-seq) analysis of JIASFs following IL-1β stimulation with and without TAK1 inhibitor- 5Z-7-oxozeaenol (5Z) was conducted. JIASFs treated with NG-25 (reversible TAK1 inhibitor) and 5Z (irreversible TAK1 inhibitor) were also examined for the expression of p-TAK1, p-p38, p-ERK, and p-JNK via Western blotting. To study the involvement of TAK1 in inducing JIASF aggressive and inflammatory phenotype, the

expression of COX-2, podoplanin, IL-6, IL-8, CXCL5, and CCL5 following 5Z treatment were determined dose-dependently via ELISA and Western blotting. The statistical value of $p< 0.05$ was considered statistically significant.

Results: RNA-seq analysis identified 2,076 differentially expressed genes significantly regulated by IL-1β (10 ng/mL; n=3, $p< 0.05$). A total of 502 genes, mostly involved in inflammation and aberrant cell proliferation, were upregulated by IL-1β, and 1,574 genes primarily responsible for controlled cell proliferation and homeostasis were downregulated by IL-1β. Among those 2,076 genes, 707 genes were significantly altered following 5Z (1 μM) treatment, of which 389 genes were significantly upregulated whereas 318 genes were significantly downregulated by 5Z treatment. Gene Ontology studies on RNA-seq revealed that 5Z suppressed the genes involved in cytokine signaling in the immune system, and inflammation, and restored the genes involved in the negative regulation of centriole replication, and regulation of the cell cycle process. Furthermore, the treatment with 5Z or NG-25 (0.01 to 1 μM) followed by IL-1β (10 ng/mL) stimulation revealed that 5Z significantly inhibited the p-TAK1 at 0.01 μM ($p < 0.001$, n = 3) and p-p38, p-JNK and p-ERK at 0.1 μM ($p < 0.0001$, n= 3). Whereas NG-25 significantly suppressed p-TAK1 at 1 μM ($p < 0.05$, n=3) and its downstream p-p38 and p-JNK at 0.1 μM and 0.5 μM, respectively. 5Z also significantly downregulated the expression of COX-2 (at 0.05 μM, $p< 0.01$, n=3), IL-8 and CXCL5 (at 0.01 μM, $p< 0.01$, n=3). The expression of podoplanin, IL-6 and CCL5 also went down following 5Z treatment (at 0.25 μM, n=3) indicating the overall potential of TAK1 inhibition to limit JIASFs ability to exacerbate arthritis.

Conclusion: Our preliminary findings delineate the critical role of TAK1 in cytokine-driven hyperplasia and invasiveness of JIASFs, and the inhibition of TAK1 *in vitro* promises cessation of JIASF- mediated expression of inflammatory markers.

ZCCHC6 Modulates the Global Phosphorylation Landscape in TNF-a-induced Rheumatoid Arthritis Synovial Fibroblasts

Anil Singh, Farheen Sultan Shaikh and Salahuddin Ahmed, Washington State university, Spokane, WA

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: Abstracts: Cytokines & Cell Trafficking
Session Type: Abstract Session
Session Time: 4:00PM–5:30PM

Background/Purpose: ZCCHC6, also known as TUT7 or TENT2, plays a crucial role in RNA processing and metabolism through its uridylyl transferase function. This function involves adding uridine residues to the 3' ends of RNA molecules, including mRNA and microRNAs and is important for regulating RNA stability, decay, and turnover. However, its role in pro-inflammatory cytokines, such as IL-1β and TNF-α induced inflammatory function, remains elusive.

Methods: To investigate the role of ZCCHC6 in TNF-α-induced inflammation, RNA-seq analysis was performed in human rheumatoid arthritis synovial fibroblasts (RASFs) treated with TNF-α alone or with ZCCHC6 knockdown using siRNA method. Mass Spectrometry based untargeted phospho-proteomics analysis was conducted to determine changes in the global phosphorylation landscape of RASFs treated with ZCCHC6 siRNA in the presence of TNF-α stimulation. Additionally, Gene Ontology studies, ELISA, quantitative RT-PCR, and Western blot analyses were performed to determine the effect on inflammatory responses in TNF-α-activated RASFs with or without ZCCHC6 knockdown. The experiments were carried out using at least three RASF donor lines, with statistical significance set at $p< 0.05$.

Results: ZCCHC6 knockdown in human RASFs resulted in the differential regulation of 835 genes in the presence of TNF-α. Out of these genes, 384 genes were upregulated, whereas 451 genes were downregulated by at least 2-fold (N=3, p< 0.05). ZCCHC6 exhibited anti-inflammatory effects in TNF-α-stimulated RASFs, as its knockdown by targeted siRNA by enhanced the phosphorylation of signaling proteins important in MAPK-activated pathways, including ASK1, cJun, pERK, p38, pP65, and SAPK/JNK proteins (N=3, p< 0.05). The MS-based phospho-proteomic analysis confirmed that ZCCHC6 knockdown selectively influenced the phosphorylation of 263 unique proteins (N=3, p< 0.05). Gene Ontology studies revealed the upregulation of key pathways, such as mRNA metabolism, apoptosis, DNA damage, and cellular localization. Further analysis demonstrated critical changes in the cellular activity of phosphorylation events that are tightly regulated by Protein Phosphatase 2A (PP2A), a serine/threonine phosphatase. A loss of ZCCHC6 inhibited the TNF-α-induced expression of three regulatory subunits of PP2A, including the structural subunit (A), catalytic subunit (C), and regulatory subunit (B).

Conclusion: This study unveils a novel axis involving ZCCHC6 and TNF-α in the progression of RA. TNF-α utilizes ZCCHC6 to mediate internal phosphorylation signaling events, positively influencing Protein Phosphatase activity, and driving the pathological processes underlying inflammation in RA.

Chronic IL-6 Trans-Signaling Enhances Stem Cell-Like Characteristics of Rheumatoid Arthritis Synovial Fibroblasts

Anil Singh and Salahuddin Ahmed, Washington State university, Spokane, WA

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: Abstracts: Cytokines & Cell Trafficking
Session Type: Abstract Session
Session Time: 4:00PM–5:30PM

Background/Purpose: Chronic exposure to IL-6 trans-signaling has been shown to significantly impact the characteristics of rheumatoid arthritis synovial fibroblasts (RASFs). Previous studies have demonstrated that this exposure increases heterogeneity markers, upregulates reprogramming factors, and transforms RASFs into cells with stem cell-like characteristics. Moreover, the transcription factor Ets2 has been identified as a crucial player in these effects, as it is upregulated and translocated to the nucleus of RASFs upon IL-6 trans-signaling stimulation.

Methods: To further explore the role of Ets2 in IL-6-induced inflammation, comprehensive analyses were performed. RNA-seq analysis was conducted on RASFs treated with IL-6 + IL6R, either alone or in combination with Ets2 knockdown using siRNA. Mass spectrometry-based untargeted phospho-proteomics analysis was utilized to evaluate global protein changes in RASFs. Additional RNA sequencing was carried out, and the data were evaluated using ELISA, quantitative RT-PCR, and Western blot analyses. The experiments involved multiple RASF donor lines, with statistical significance set at p< 0.05.

Results: Chronic IL-6 trans-signaling promotes stem cell-like characteristics in rheumatoid arthritis synovial fibroblasts (RASFs), as evidenced by the upregulation of Nanog, OCT4, Sox2, and Myc. This effect is also observed in normal synovial fibroblasts (NSFs), indicating a broader influence on cell differentiation. Proteomics analysis confirmed the upregulation of stemness markers and metabolic intermediates associated with glycolysis in IL-6 trans-stimulated RASFs. Inhibition of the

Ets2 transcription factor resulted in the downregulation of Nanog, Myc, and Sox2, suggesting that Ets2 drives the reprogramming of RASFs to a stem cell-like phenotype (N=3, $p< 0.05$). IL-6 trans-signaling induced the upregulation of CD90/Thy1, a marker of mesenchymal stem cells, which was reversed by Ets2 knockdown (N=3, $p< 0.05$). The downregulation of heterogeneity markers Thy1 and PDPN without Ets2 implies that IL-6 employs Ets2 to drive both inflammatory and differentiation functions in RASFs. RNA sequencing identified 506 differentially regulated genes (N=3, $p< 0.05$), with the enrichment of stem cell factors in the transcriptomics data. These findings shed light on the impact of chronic IL-6 trans-signaling on RASFs and highlight the role of Ets2 in regulating inflammatory and differentiation processes. Understanding these molecular events could lead to novel therapeutic strategies for rheumatoid arthritis.

Conclusion: To further explore the molecular changes induced by chronic IL-6 trans-signaling, we performed RNA sequencing on RASFs that were continuously stimulated with IL-6 + sIL6R. Our analysis identified 506 differentially regulated genes, with stem cell factors like Sox2, Myc, Oct4, Nanog, among others, showing enrichment in the transcriptomics data. The role of Ets2 as a key mediator in this process highlights its significance in regulating both inflammatory and differentiation functions.

Risk Factors and Mortality of Immune Checkpoint Inhibitor-Induced Flares of Pre-Existing Rheumatoid Arthritis: An Analysis Accounting for Competing Risk of Death and Immortal Time Bias

Kaitlin McCarter[1], Senada Arabelovic[1], Taylor Wolfgang[1], Xiaosong Wang[1], Kazuki Yoshida[1], Grace Qian[1], Emily Kowalski[1], Kathleen Vanni[1], Nicole LeBoeuf[1], Elizabeth Buchbinder[2], Lydia Gedmintas[1], Lindsey MacFarlane[1], Deepak Rao[1], Nancy Shadick[3], Ellen Gravallese[4] and Jeffrey Sparks[5], [1]Brigham and Women's Hospital, Boston, MA, [2]Dana-Farber Cancer Institute, Boston, MA, [3]Brigham and Women's Hospital, Boston, MA, [4]Brigham and Women's Hospital and Harvard Medical School, Boston, MA, [5]Division of Rheumatology, Inflammation, and Immunity, Brigham and Women's Hospital and Harvard Medical School, Boston, MA

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: Abstracts: Immunological Complications of Medical Therapy
Session Type: Abstract Session
Session Time: 4:00PM–5:30PM

Background/Purpose: Immune checkpoint inhibitors (ICI) stimulate the immune system to treat cancer but may cause flares of pre-existing immune-mediated inflammatory diseases. Risk factors for ICI-induced RA flares are unknown. Some studies suggest that flare of pre-existing autoimmune disease after ICI may portend a mortality benefit, perhaps as a marker of immune activity against cancer, but this has not been investigated for ICI-induced RA flares. Evaluating a post-baseline outcome such as RA flare could be prone to immortal time bias where patients must survive long enough to flare, falsely showing an association with mortality. Therefore, we studied risk factors and outcomes of ICI-induced RA flares, considering competing risk of death and immortal time bias in the analysis.

Methods: We performed a retrospective cohort study of patients with pre-existing RA initiating ICI for cancer treatment at a large healthcare system (2011-2022). We performed medical record review on patients with a RA diagnosis code prior to ICI initiation to confirm patients met 2010 ACR/EULAR RA criteria. We collected data on demographics, cancer, RA, RA disease activity/flares after ICI initiation, ICI disruption, and mortality. We analyzed baseline risk factors for RA flare after ICI

initiation taking into account competing risk of death using the Fine and Gray method. We performed a landmark analysis to limit the potential for immortal time bias, where baseline was 3 months after ICI initiation. Among those who survived at least 3 months, we examined whether RA flare within 3 months after ICI initiation was associated with mortality using Cox regression.

Results: Among 11,901 patients who initiated ICI for cancer treatment, we analyzed 100 pre-existing RA patients (mean age 70.3 years, 63% female, 89% on PD-1 monotherapy, 50% lung cancer). At ICI initiation, 71% were seropositive, 82% had remission/low RA disease activity, 24% were on glucocorticoids, 35% were on conventional DMARDs, and 10% were on b/tsDMARDs (**Table 1**). RA flares occurred in 46% (incidence rate 1.84 per 1000 person-days, 95%CI 1.30, 2.37); 31/100 flared within 3 months of baseline. 72% died during follow-up, 21/100 within 3 months of baseline. Seropositive RA had an adjusted sdHR of 1.95 (95%CI 1.02, 3.71) for RA flare compared to seronegative, accounting for competing risk of death (**Table 2**). Otherwise, there were no baseline factors associated with RA flare, including cancer type, baseline disease activity, RA duration, and deformities. 9/46 (20%) patients had their ICI discontinued/paused due to RA flares. In the

CI, confidence interval; DMARD, disease-modifying antirheumatic drug; ICI, immune checkpoint inhibitor; RA, rheumatoid arthritis; sdHR, subdistribution hazard ratio.

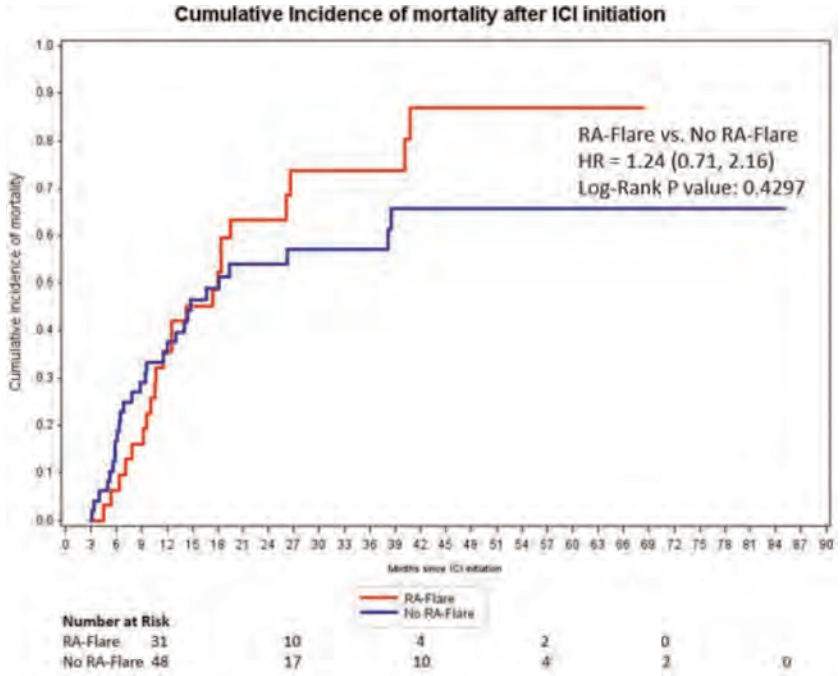

Figure 1. Cumulative incidence and hazard ratio for mortality by presence/absence of RA flare within 3 months of immune checkpoint inhibitor initiation. The landmark analysis was restricted to patients who survived at least 3 months after immune checkpoint inhibitor initiation (n=79). The model was adjusted for age, sex, cancer type (lung/melanoma/other), cancer duration, and Charlson comorbidity index.

landmark analysis among 79 patients who survived at least 3 months, RA flare in the first 3 months was not associated with lower mortality (adjusted HR 1.24, 95%CI 0.71, 2.16) compared to no RA flare (**Figure**).

Conclusion: RA flares and mortality were each common among pre-existing RA patients initiating ICI for cancer. Seropositivity was the only baseline factor associated with RA flare after accounting for the competing risk of death. RA flare after ICI may not have prognostic implications for mortality. Previous findings suggesting mortality benefit from flares of other autoimmune diseases after ICI may have been due to immortal time bias.

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: Abstracts: Immunological Complications of Medical Therapy
Session Type: Abstract Session
Session Time: 4:00PM–5:30PM

Background/Purpose: PD-1 immune checkpoint inhibitors are able to re-activate restrained anti-tumor T-cell responses in melanoma patients. However, PD-1 inhibition may also activate auto-reactive T-cells leading to immune-related adverse events (irAEs). Autoantibodies might also play a role in anti-PD-1 induced irAEs and could potentially be used to identify patients at risk of developing these irAEs. Therefore, we investigated the association between autoantibody-positivity and treatment toxicity and response in melanoma patients treated with anti-PD-1.

Methods: This multicenter, retrospective study included 143 advanced melanoma patients treated with anti-PD-1. Until six months after treatment initiation, toxicities grade ≥2 and recurrences/responses were captured. Autoantibody measurements, comprising IgM rheumatoid factor (RF), antinuclear antibodies (ANA), anti-cyclic citrullinated peptide antibodies (anti-CCP2), anti-thyroid peroxidase (anti-TPO) and anti-thyroglobulin (anti-Tg) were performed in an ISO15189 accredited laboratory at baseline and after three months of treatment.

Table 1. Association of baseline autoantibodies with immune-related adverse events (irAE). In each cell, n/N indicates the number of patients who developed the irAE (n) out of the total number of patients who were either positive or negative at baseline for the indicated antibody (N). Anti-CCP2: anti-cyclic citrullinated peptide antibodies, RF: rheumatoid factor, anti-TPO: thyroid peroxidase, anti-TG: anti-thyroglobulin, ANA: antinuclear antibodies

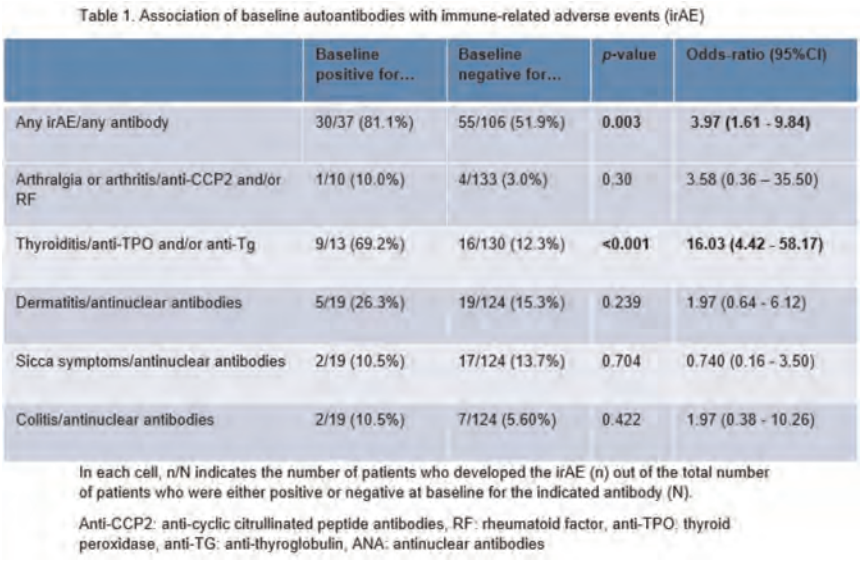

Table 1. Association of baseline autoantibodies with immune-related adverse events (irAE)

	Baseline positive for...	Baseline negative for...	p-value	Odds-ratio (95%CI)
Any irAE/any antibody	30/37 (81.1%)	55/106 (51.9%)	**0.003**	**3.97 (1.61 - 9.84)**
Arthralgia or arthritis/anti-CCP2 and/or RF	1/10 (10.0%)	4/133 (3.0%)	0.30	3.58 (0.36 – 35.50)
Thyroiditis/anti-TPO and/or anti-Tg	9/13 (69.2%)	16/130 (12.3%)	**<0.001**	**16.03 (4.42 - 58.17)**
Dermatitis/antinuclear antibodies	5/19 (26.3%)	19/124 (15.3%)	0.239	1.97 (0.64 - 6.12)
Sicca symptoms/antinuclear antibodies	2/19 (10.5%)	17/124 (13.7%)	0.704	0.740 (0.16 - 3.50)
Colitis/antinuclear antibodies	2/19 (10.5%)	7/124 (5.60%)	0.422	1.97 (0.38 - 10.26)

In each cell, n/N indicates the number of patients who developed the irAE (n) out of the total number of patients who were either positive or negative at baseline for the indicated antibody (N).

Anti-CCP2: anti-cyclic citrullinated peptide antibodies, RF: rheumatoid factor, anti-TPO: thyroid peroxidase, anti-TG: anti-thyroglobulin, ANA: antinuclear antibodies

Results: A total of 169 irAEs were experienced by 86 patients, the most common being thyroiditis (n=25), dermatitis (n=24), and sicca complaints (n=19). More irAE (30/37 [81%]) were observed in patients with pre-existing detectable autoantibodies than in patients without these autoantibodies (55/106 [52%], $p = 0.003$) (table 1). This was mainly due to the strong association of anti-thyroid antibodies and thyroid dysfunction (69% in anti-TPO and/or anti-Tg positive patients versus 12% in anti-TPO and/or anti-Tg negative patients, $p < 0.001$). No association between anti-CCP2, RF or ANA and arthritis, dermatitis, sicca or colitis was observed. The association with thyroid antibodies was strongest in female patients: of seropositive female patients 7/7 (100%) developed thyroiditis, compared to only 10/48 (21%) of anti-TPO and anti-Tg negative patients.

Seroconversion during anti-PD-1-treatment was only seen for thyroid antibodies. Here the combined positivity for anti-TPO and/or anti-Tg increased from 13/143 (9.1%) at baseline to 24/143 (17%) on treatment ($p = 0.003$). For the other autoantibodies the total number of seropositive patients stayed stable or decreased on treatment (table 2). Seroconversion of anti-Tg and/or anti-TPO was associated with thyroid dysfunction in female patients: 6/10 [60%] of seroconverted patients developed thyroid dysfunction compared to 3/38 [8%] patients that remained seronegative ($p = 0.001$). Autoantibody-positivity was not associated with disease recurrence ($p = 0.45$) or response ($p = 0.69$).

Table 2. Number of autoantibody-positive patients per antibody (RF, anti-CCP2, anti-TG, anti-TPO and ANA) at baseline and on treatment. Anti-CCP2: anti-cyclic citrullinated peptide antibodies, RF: rheumatoid factor, anti-TPO: thyroid peroxidase, anti-TG: anti-thyroglobulin, ANA: antinuclear antibodies

Autoantibody	Baseline (positive/total)	On treatment (positive/total)	Seroconversion (neg to pos)	Seroreversion (pos to neg)
RF	10/143 (6.99%)	10/143 (6.99%)	3	3
Anti-CCP2	0/143 (0%)	0/143 (0%)	0	0
Anti-Tg	7/143 (4.90%)	22/143 (15.4%)	15	0
Anti-TPO	7/143 (4.90%)	12/143 (8.39%)	6	1
ANA	19/143 (13.3%)	17/143 (11.9%)	2	4

Conclusion: Autoantibody-positivity prior to anti-PD-1 therapy is associated with the development of irAEs in melanoma patients, indicating that anti-PD-1 therapy not only leads to loss of tolerance to tumor antigens but also to nontumor autoantigens. Baseline positivity and seroconversion of anti-thyroid antibodies were associated with the development of thyroiditis.

Session Title: Abstracts: Immunological Complications of Medical Therapy

Session Type: Abstract Session

Session Time: 4:00PM–5:30PM

Background/Purpose: Rituximab (RTX) treatment significantly decreases the antibody response to COVID-19 vaccines, raising concerns about its use. However, unlike during the pandemic, most patients initiating RTX now, will receive COVID-19 vaccination before initiating RTX. Thus, the effect of RTX treatment on serological vaccine response in pre-vaccinated individuals remains unclear. We aimed to assess the antibody (abs) level and function by three different SARS-CoV-2 abs assays in COVID-19 vaccinated patients, depending on the timing of RTX treatment initiation, either before or after vaccination.

Methods: Patients treated with RTX at the Dep. of Rheumatology, Aarhus University Hospital, from 2017 to 2022 were eligible for inclusion (n=368). Patients were categorized based on the order of RTX treatment to their primary COVID-19 vaccination: *RTX pre* (RTX only prior to vaccination), *RTX pre+post* (RTX prior to and after vaccination), and *RTX post* (RTX only after vaccination). Additionally, we investigated the effect of vaccines administered ≥ 9 months since the last RTX treatment, "*RTX-free*" vaccinations. Serological response was evaluated by measuring 2 different SARS-CoV-2-IgGs (Spike and Nucleocapsid) and the concentration and activity of neutralizing antibodies. Blood donors (BDs) were enrolled as controls, n=113.

Results: We included 254 patients; 67% female, aged 62 years. The predominant diagnoses were ANCA-vasculitis (31%), rheumatoid arthritis (26%) and myositis (12%). Patients had on average four COVID-19 vaccinations and one infection, while BDs had respectively three and one.

The *RTX pre+post* group (n=132) had significantly lower concentrations of spike and neutralizing abs, neutralizing activity and seroconversion compared to the *RTX pre (n=54)* and *RTX post*group(n=68), Fig 1A-D. Only 65% of *RTX pre+post*developed neutralizing abs compared to 91% for the*RTX post* and 93% for the*RTX pre,* Fig 1C. There was no difference between the *RTX pre* or *RTX post* in seroconversion of the 3 abs measured (all p's ≥ 0.08).

Univariate and multivariate logistic regression analysis were performed with seroconversion of SARS-CoV-2-Spike IgG as the dependent variable, Table 1. The final model had number of "*RTX-free*" vaccinations (OR 1.93) and number of RTX infusions (OR 0.94) as the significant predictors.

There was a significant dose-dependent correlation between "*RTX-free*" vaccinations with both antibody concentrations and seroconversion (Fig 2A, P< 0.001). The patients with zero "*RTX-free*" vaccinations had a seroconversion rate of 50%, compared to 89% for patients with 3 "*RTX-free*" vaccinations and40-fold higher median ab levels.

Conclusion: Our study demonstrates that COVID-19 vaccination administered before initiating RTX will induce a superior serological response compared to vaccination after RTX treatment. This supports the continuous use of RTX in rheumatic diseases with an emphasis on administering vaccinations before initiating RTX. Additionally, our findings highlight the importance of timing vaccinations for individuals undergoing continuous RTX treatment. The concept of "*RTX-free*" vaccinations with a minimum gap of 9 months since last RTX treatment may be useful in guiding vaccination strategies.

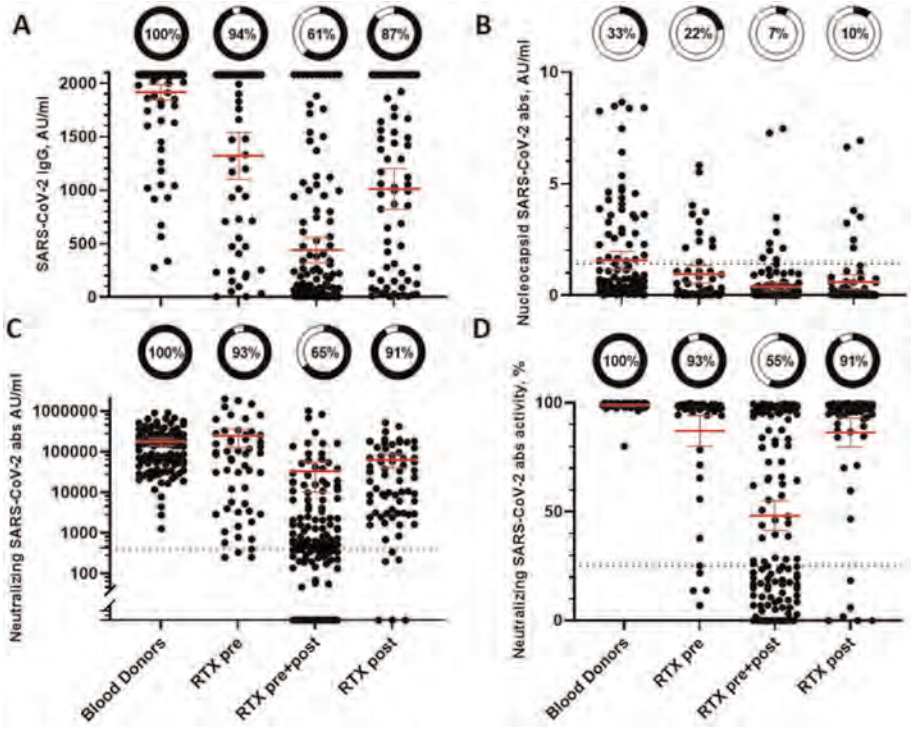

Figure 1. Concentrations of IgG (A), nucleocapside (B) and neutralizing (C) SARS-CoV-2 antibodies and neutralizing antibody activity (D) in Rituximab (RTX) treated patients and blood donors. RTX treated patients are divided according to sequence of primary COVID-19 vaccination and RTX treatment. ''RTX pre'' indicate RTX treatment were only given prior to vaccination, and not after. ''RTX pre+post'' RTX treatment were given prior to and after vaccination. ''RTX post'' RTX treatment were only given after primary COVID-19 vaccination. Pie charts indicate percentage of patients with measurabel antibodies/positive neutralizing antibody activity. Horizontal line indicate mean and whiskers 95% CI. Dotted lines indicate levels for positive test.

Targeted Therapies for Severe Immune-related Adverse Events of Immune Checkpoint Inhibitors Are Not Associated with a Worse Prognosis

Jacques-Eric Gottenberg[1], Nathanaël Sedmak[2], Pierre Tran Ba Loc[2], Thibaut Fabacher[2], Thibaut Bahougne[2], Cécile Arnold[2], Guillaume Desjeux[3], Hervé Servy[4], Nicolas Meyer[2], Erik Sauleau[2], Raphaele Seror[5] and Eden Sebbag[6], [1]Rheumatology Department, Strasbourg University Hospital, Strasbourg, France, [2]Hôpitaux Universitaires de Strasbourg, Strasbourg, France, [3]e-Health Services Sanoia, Gemenos, France, [4]e-Health Services Sanoia, La Ciotat, France, [5]University Hospital Paris Saclay, Le Kremlin-Bicêtre, France, [6]Université de Strasbourg, Strasbourg, France

SESSION INFORMATION

Session Date: Tuesday, November 14, 2023

Session Title: Abstracts: Immunological Complications of Medical Therapy

Session Type: Abstract Session

Session Time: 4:00PM–5:30PM

Background/Purpose: In about 10% of patients, the immune response to immune checkpoint inhibitors (ICI) exceeds the anti-tumor response and leads to autoimmune complications (immune-related Adverse Events, irAEs), which can sometimes be severe and require the use of targeted therapies. Two studies recently reported a deleterious impact of targeted therapies on the survival of patients with irAEs. This work aims at comparing overall survival in patients treated for an hospitalized irAE with a biological or targeted synthetic DMARD (b/tsDMARD), conventional synthetic DMARD or exclusively with corticosteroids.

Methods: All adults included in the French national health database who initiated ICI for any type of cancer between 2014 and 2019 were retrospectively analyzed, with a a one-year look-back and one year look-ahead period. The occurrence of an irAE during ICI treatment or in the 12 following months was defined by the combination of (1) hospitalization for a cause

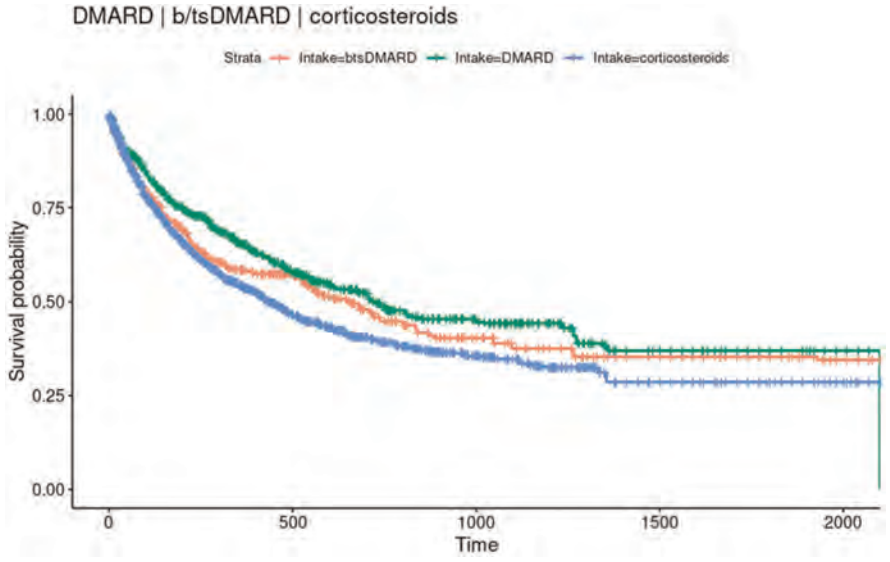

Figure. Overall survival in days in patients treated with a conventional DMARD (green), a b/tsDMARD (red), or corticosteroids (blue).

evoking an irAE of any nature, except endocrinopathy, and (2) initiation of corticosteroids, csDMARD or b/tsDMARD. Patients contributed from the time the 2 criteria were fulfilled until the end of follow-up or death. Treatment of IRAEs was considered as a time dependent variable with 3 classes: corticosteroids alone, csDMARD and b/tsDMARD. Because switches in treatment could occur during follow-up, propensity score (PS) was recalculated every 30 days using a multinomial logistic regression. PS included the current treatment, gender, age, type of cancer, ICI prescribed in monotherapy or as a combination, ICI year of beginning, time from cancer to initiation of ICI, use of corticosteroids, hospitalization in intensive care unit, type of irAE, number of LTDs, Charlson's index and FDep social deprivation index. Overall survival was compared between the three groups using a Cox model ponderated with overlap weights to ensure balance.

Results: 71,723 patients (men: 66.0%, median age: 66 years) initiating an ICI were analyzed. An hospitalized irAE occurred in 2575 patients at a median time of 232 days after ICI initiation and the 4 most frequent were gastrointestinal (inflammatory colitis, 1.7%), rheumatic (0.7%), cardiologic (0.5%) and pulmonary (0.4%). Global mortality was 66.0%. Median patient follow-up after irAE was 268 days. The weighted baseline populations consisted of 180 patients treated with b/tsDMARD, 263 patients treated with conventional DMARD and 341 patients exclusively with corticosteroids. Covariates were well-balanced between groups.

Overall mortality in patients treated with b/tsDMARD did not significantly differ from csDMARD (HR=1.13, CI=[0.97, 1.33]). Overall mortality in patients treated with corticosteroids was significantly higher than csDMARD (HR=1.30, CI=[1.04, 1.64]) but did not differ significantly from b/tsDMARD (HR=1.15, CI=[0.95, 1.39]).

Conclusion: In this large nationwide study, with one of the largest number of hospitalized irAEs and b/tsDMARD-treated patients, targeted therapies were not associated with a worse prognosis. The prognosis according to the underlying type of IRAEs is currently being investigated and will be presented at the meeting.

Latent Class Analysis Identifies 2 Clinical Phenotypes of Immune Checkpoint Inhibitor-induced Inflammatory Arthritis

Laura Cappelli[1], Jamie Perin[2], Clifton Bingham[3] and Ami Shah[4], [1]Johns Hopkins School of Medicine, Baltimore, MD, [2]Johns Hopkins University School of Medicine, Baltimore, MD, [3]Johns Hopkins University, Baltimore, MD, [4]Department of Medicine, Division of Rheumatology, Johns Hopkins University School of Medicine, Ellicott City, MD

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: Abstracts: Immunological Complications of Medical Therapy
Session Type: Abstract Session
Session Time: 4:00PM–5:30PM

Background/Purpose: : Immune checkpoint inhibitors (ICI) for cancer treatment can cause inflammatory arthritis (IA). ICI-IA is a heterogeneous entity affecting peripheral joints, tendons, and rarely the axial skeleton, and can be severe and persist even after ICI cessation. Since ICI-IA is a distinct entity with unique pathogenesis, applying categories of traditional IA is limited; thus, we used a data-driven approach to define clinically relevant subgroups within ICI-IA and examined differences between subgroups.

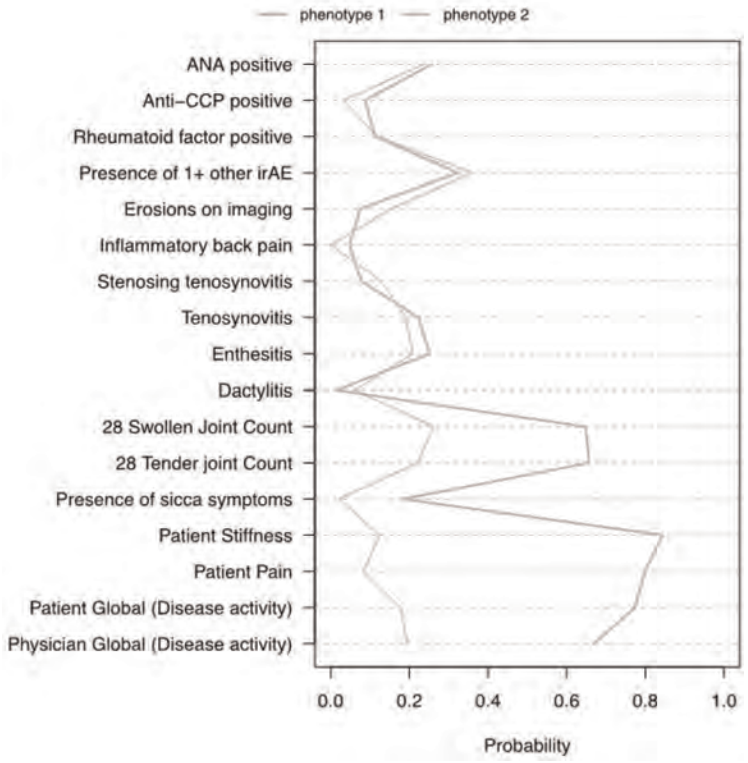

Figure 1. Predicted probabilities of features for two estimated phenotypes among 126 cancer patients receiving immune checkpoint inhibitors who developed inflammatory arthritis. For continuous variables (e.g. joint counts, disease activity ratings) probability is for being in the top 50% of values.

Table 1: Summary of inflammatory arthritis features by latent class group membership

			Phenotype 1 (N = 77)		Phenotype 2 (N = 49)		Difference

Small > large joints (count)	126	90 (71%)	77	48 (62%)	49	42 (86%)	**0.005**
Any hip or shoulder	126	34 (27%)	77	14 (18%)	49	20 (41%)	**0.007**

Methods: Participants were ³18 years old, treated with anti-PD-1, anti-PD-L1, and/or anti-CTLA-4 agents alone or in combination, and had ICI-IA diagnosed by a rheumatologist. We used information from the baseline rheumatology visit (patient reported symptoms, physical exam features, physician global arthritis rating, and laboratory studies) to cluster patients with latent class analysis (LCA). The Bayesian Information Criteria (BIC) was used to select the number of phenotypes with the lowest BIC. We then compared demographics, cancer type and treatments, and IA treatments and outcomes between

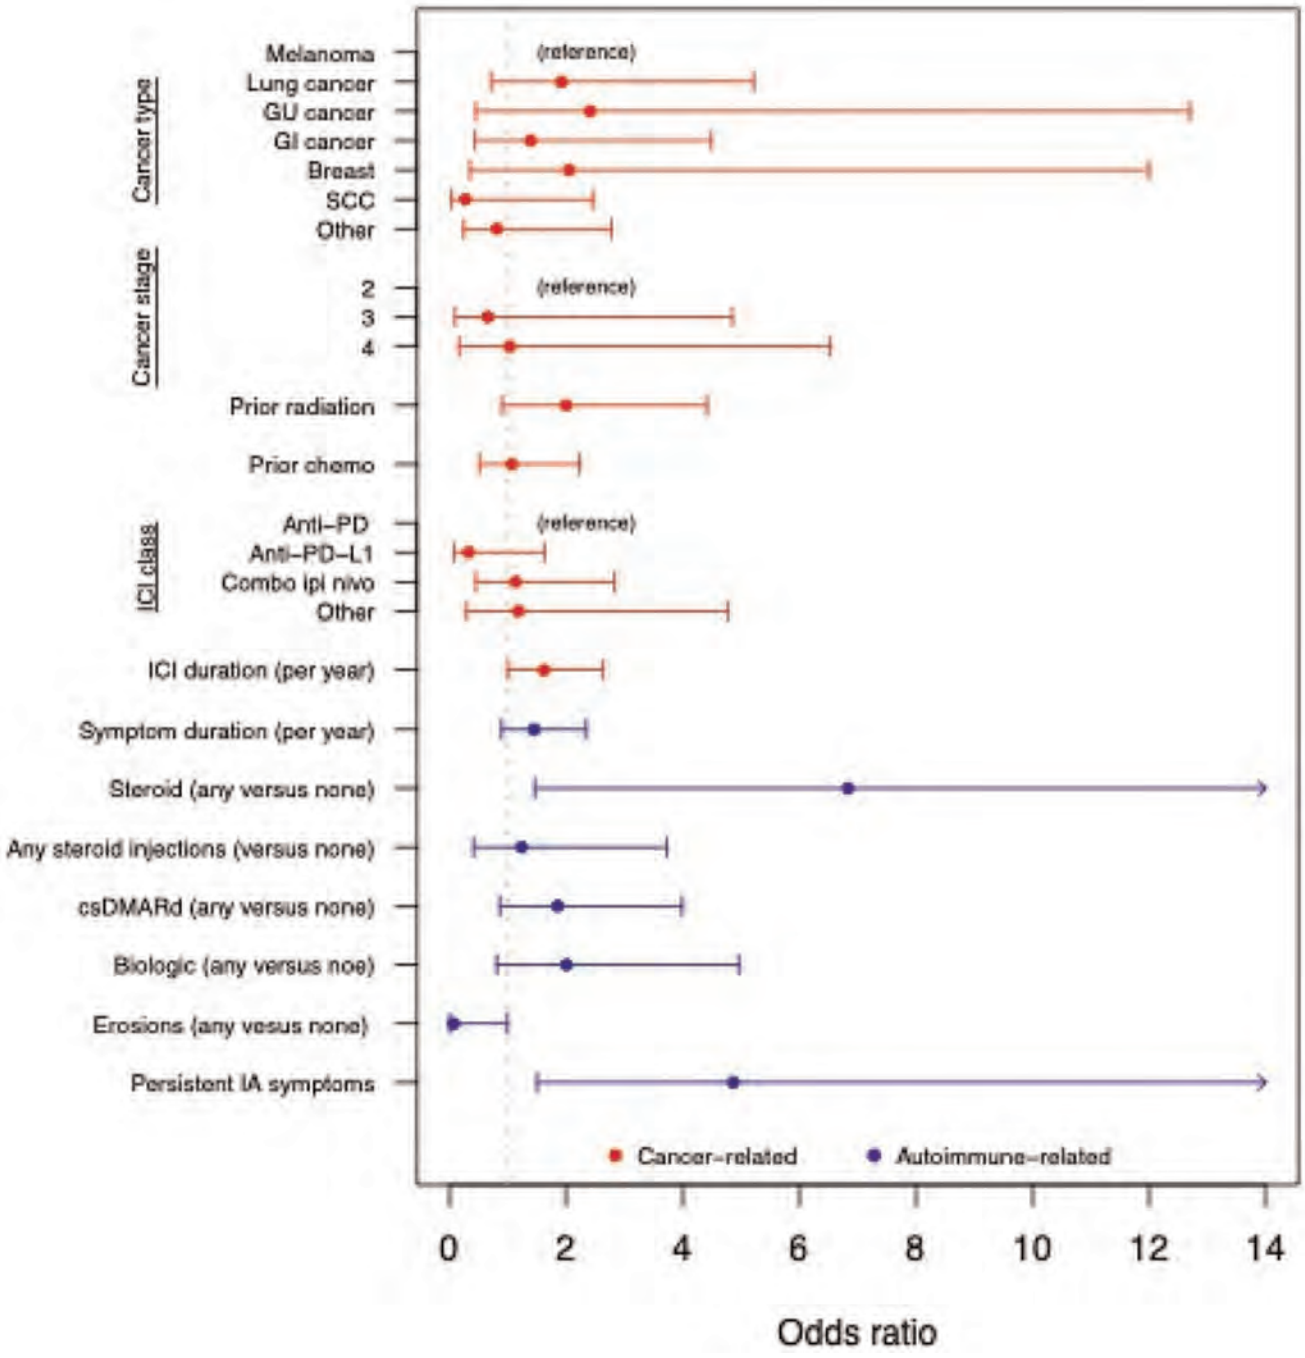

Figure 2: Associations between disease characteristics and latent class membership. Odds ratios greater than one are interpretable as a higher likelihood of being phenotype 2, the group with more severe IA symptoms. Odds ratios are adjusted for age and gender. Odds ratios in red represent potential risk factors for class membership (present before IA development) and those in blue represent IA-related outcomes that may be associated with class membership.

the estimated phenotypes. Next, we estimated the association between these features of interest and the likelihood of being in the group with the most severe IA symptoms using logistic regression.

Results: Of the 126 patients with ICI-IA, most participants were female (56%) and white (92%). Most patients had a moderate or high disease activity by CDAI. Mean CDAI was 16.98 (SD 10.2). Twenty variables were used to estimate latent classes. Two distinct phenotypes were indicated by the BIC; 77 patients are estimated to be the first phenotype and 49 in the second phenotype (Figure 1). The significantly different features of the phenotypes included higher levels of all components of the CDAI, more stiffness, and having more small and upper extremity joints involved for phenotype 2 (Table 1). Anti-CCP and RF positivity did not differ between groups. Patients in phenotype 2 were more likely to require steroids as compared to patients in phenotype 1 and were more likely to have persistent IA >6 months after ICI cessation (Figure 2). There was also a trend of longer ICI exposure prior to ICI-IA in phenotype 2, but no association with type of ICI or cancer.

Conclusion: Two separate phenotypes of ICI-IA were identified using LCA, the second having a more severe polyarthritis at baseline affecting the upper extremities. Those in the group with more severe features at baseline were more likely to need corticosteroids and to have persistent IA. There were no differences in terms of cancer type and treatment, thus future research can interrogate underlying genetic and immunologic differences between groups.

Myositis Triad Subset Is Associated with High Mortality in Immune Checkpoint Inhibitor- Induced Myositis

Selene Rubino[1], Grant Cannon[2], Brian Sauer[3], Jorge Rojas Jr[4], Greg Stoddard[1], Gary Kunkel[1], Jessica A Walsh[5], Bryant England[6], Ted R Mikuls[7], Joshua Baker[8] and Tawnie Braaten[1], [1]University of Utah, Salt Lake City, UT, [2]University of Utah and Salt Lake City VA, Salt Lake City, UT, [3]Salt Lake City VA/University of Utah, Salt Lake City, UT, [4]Puget Sound VA and University of Utah, Seattle, WA, [5]Salt Lake City Veterans Affairs Health and University of Utah Health, Division of Rheumatology, Salt Lake City, UT, [6]University of Nebraska Medical Center, Omaha, NE, [7]Division of Rheumatology and Immunology, University of Nebraska Medical Center, Omaha, NE, [8]University of Pennsylvania, Philadelphia, PA

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: Abstracts: Immunological Complications of Medical Therapy
Session Type: Abstract Session
Session Time: 4:00PM–5:30PM

Background/Purpose: Myositis is an infrequent but serious complication associated with immune check point inhibitor (ICI) treatment. Many patients with ICI-induced myositis will develop concurrent myocarditis and myasthenia gravis-like symptoms (ICI triad). We describe the prevalence and clinical characteristics of ICI-induced myositis and ICI triad among veterans receiving ICI.

Methods: Veterans enrolled in VHA who received ICI treatments between 6/6/2011 and 2/14/2023 were identified in the Corporate Data Warehouse. This analysis also employed data from the VA Central Cancer Registry for cancer diagnoses and Death Ascertainment File for all-cause mortality. Patients considered at high risk for ICI-induced myositis had medical records review via the Compensation and Pension Record Interchange (CAPRI) electronic medical records. Patients were

Table 1. Demographic characteristics of Veterans Treated with Immune Checkpoint Inhibitors (ICI)

Other	0 (0%)	1 (5%)	1969 (7.8%)	
Initial ICI infusion Class				
PD-1	30 (83.3%)	20 (83.3%)	21690 (73.5%)	p=0.36
PD-L1	3 (8.3%)	2 (8.3%)	6082 (20.6%)	
CTLA-4	2 (5.5%)	2 (8.3%)	1018 (3.4%)	
Combination Therapy	1 (2.8%)	0 (0%)	711 (2.4%)	

considered at high risk if they met at least one of the following criteria: a creatine kinase (CK) value over 10-times the upper limit of normal (312 U/L) within six months of first ICI, the term "myositis" in a discharge summary any time after first ICI and/or term "myositis" in a progress note within six months after first ICI. ICI-induced myositis was defined by the presence of a provider diagnosis of ICI-induced myositis in CAPRI and laboratory or imaging evidence of myositis in the absence of alternate etiologies such as STEMI or septic shock. Mortality follow-up data was calculated in months from ICI initiation. Univariate testing by the Bartlett's test and multivariate analysis by Cox regressions performed in Stata.

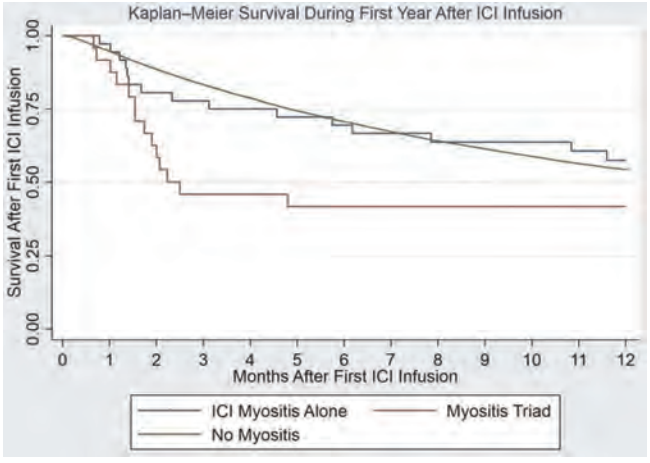

Figure 1. Kaplan-Meier Survival Curve of Veterans Treated with Immune Checkpoint Inhibitors by Myositis Category

Results: We identified 60 patients with ICI-induced myositis of which 24 (40%) had the ICI triad out of 29,561 treated with ICIs. All patients with ICI-induced myositis were male. Self-defined race, ethnicity, and smoking status were similar between veterans treated with ICI who did not develop myositis, those who developed myositis alone, or ICI triad. ICI triad patients were significantly older compared to myositis alone patients (76.6±7.5 vs 70±10 years, p< 0.001). While PD-1 use was higher in the ICI-induced myositis groups, this increase was not statistically significant (83.3% vs 73.5%, p=0.36) (Table 1).Genitourinary cancers were more common in ICI triad populations than myositis alone (50% vs 15.6%, p=0.002). ICI triad patients had increased mortality in the first year of treatment than myositis alone patients but this difference just outside range for statistically significant (HR 1.65 [0.77-3.5], p=0.077 by Cox). Myositis alone patients had no significant mortality differences in mortality compared to patients without myositis (HR 1.01 [0.61,1.68], p=0.967 by Cox (Figure 1). These results were not confounded by either age or genitourinary status.

Conclusion: The ICI triad is a severe subset of ICI-induced myositis which is associated with older age at initial ICI treatment. A signal for potential association with ICI triad subset was seen with genitourinary cancers that will require further investigation. A strong trend for increased early mortality in the ICI triad subset closely following ICI initiation was observed in comparison to patients with myositis alone and ICI-treated veterans without myositis.

SESSION INFORMATION

Session Date: Tuesday, November 14, 2023

Session Title: Abstracts: Miscellaneous Rheumatic & Inflammatory Diseases II

Session Type: Abstract Session

Session Time: 4:00PM–5:30PM

Background/Purpose: Mixed connective tissue disease (MCTD) is a heterogenous autoimmune disorder with overlapping clinical features of systemic lupus erythematosus (SLE), polymyositis/dermatomyositis, and systemic sclerosis (SSc). Despite its unique clinical characteristics, some patients may develop other rheumatic diseases during a follow-up period [1]. To better understand the heterogeneity of MCTD and to stratify the patients, we developed machine learning models

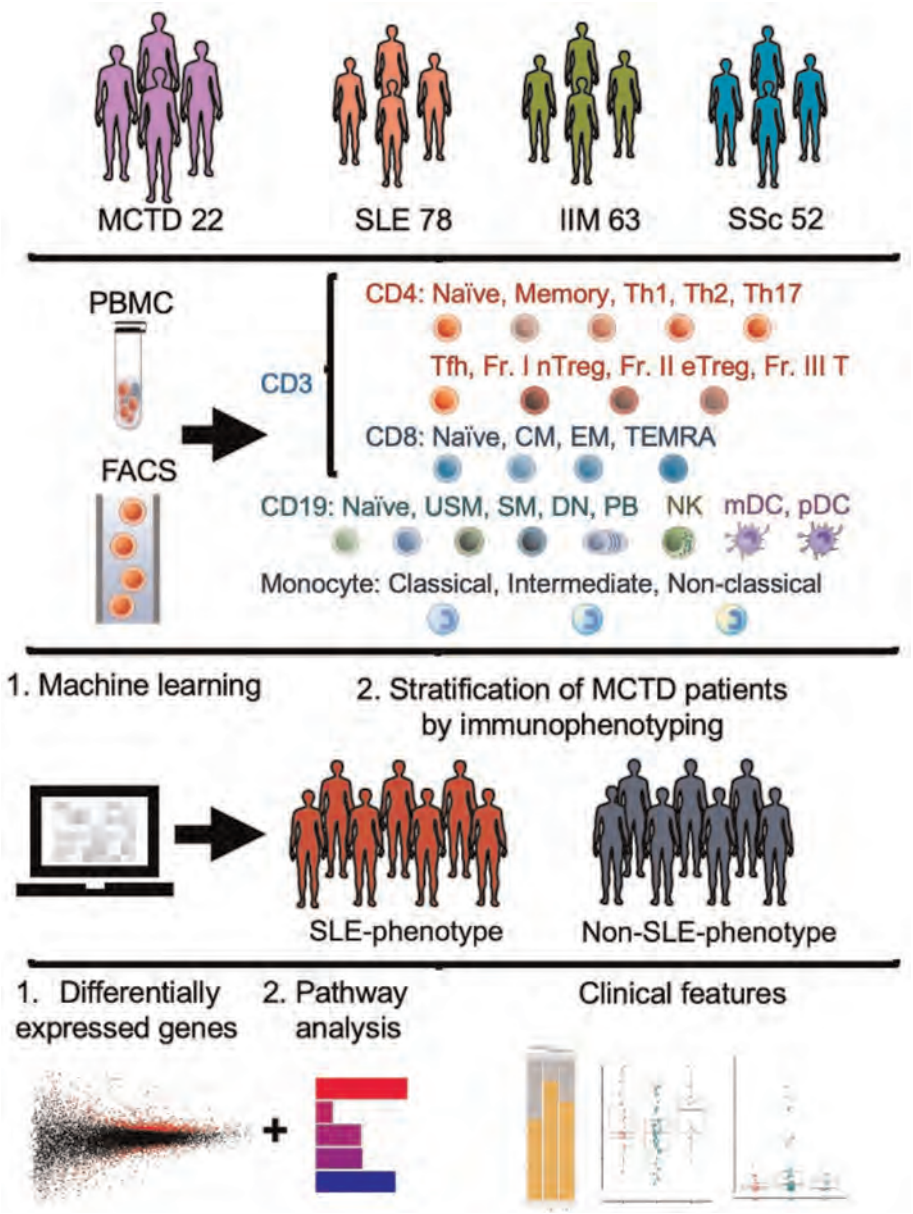

Figure 1. Workflow of this study

using immunophenotyping as a reference for SLE, idiopathic inflammatory myopathy (IIM), and SSc and identify differences in symptoms and transcriptome among the subgroups of MCTD.

Methods: We employed our large-scale database, Immune Cell Gene Expression Atlas from the University of Tokyo (ImmuNexUT) [2], to analyze the immunophenotyping (24 subsets) of patients with MCTD alongside SLE, IIM, and SSc. By utilizing the immunophenotyping data of SLE, IIM, and SSc, we developed machine learning models such as random forest, neural network, etc., to stratify MCTD patients. Following the stratification of the MCTD patients, we performed a transcriptome analysis, including a differentially expressed gene (DEG) analysis and pathway analysis. Finally, we compared the clinical features of the subgroup of MCTD patients (**Figure 1**).

Results: We enrolled a total of 215 patients with autoimmune diseases, consisting of 22 MCTD, 78 SLE, 63 IIM, and 52 SSc patients, and collected the data of immunophenotyping, bulk RNA-sequence on peripheral mononuclear blood cells, and clinical characteristics. We constructed machine learning models to classify patients with SLE, IIM, and SSc based on the

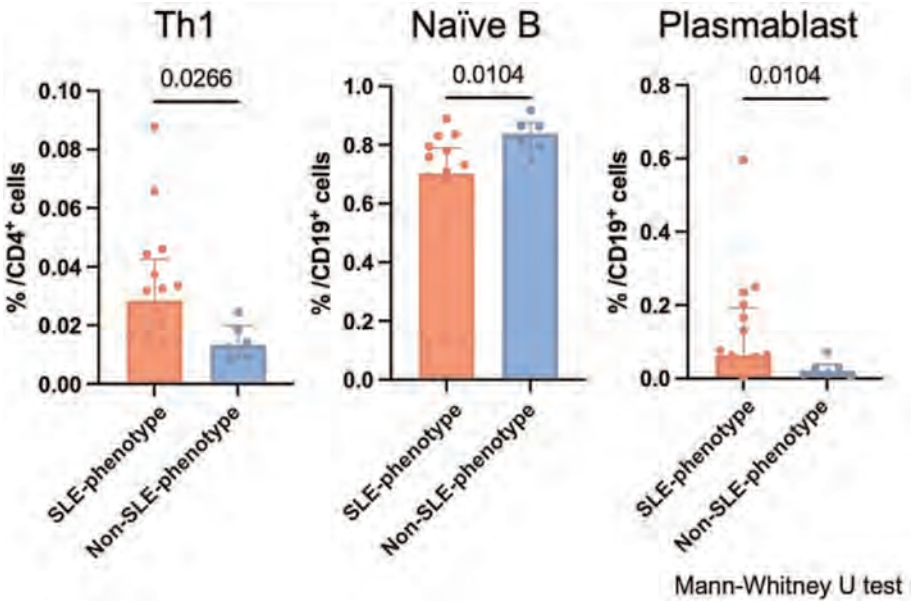

Figure 2. Comparison of immunophenotyping and clinical features of MCTD patients between SLE-phenotype and non-SLE-phenotype patients.

immunophenotyping and applied these models to the MCTD patients. Of the 22 patients with MCTD, 16 were classified as SLE-phenotype, and 6 were classified as non-SLE-phenotype (4 IIM-phenotype and 2 SSc-phenotype). Among the MCTD patients, SLE-phenotype patients had significantly higher proportions of Th1, naïve B cells, and plasmablast (p=0.03, 0.01, and 0.01, respectively) (**Figure 2**). Regarding clinical features, the proportions of having the SLE symptoms such as lymphadenopathy, malar rash, serositis, and cytopenia were significantly higher in SLE-phenotype patients (87.5% vs 33.3%, p=0.025). The number of DEGs across the cell types between SLE patients and MCTD patients (SLE-phenotype and non-SLE-phenotype) was comparable.

Conclusion: Our study suggested the potential stratification of MCTD patients based on their immunophenotyping. This approach may help distinguish clinical phenotypes in MCTD.

The Effect of Starting Prednisone Dose on the Treatment of Polymyalgia Rheumatica

Katrina Nguyen[1], Jennifer Du[1], Jiaxiao shi[2] and **Antony Lin**[1], [1]Kaiser SCAL, Fontana, CA, [2]SCPMG, Pasadena, CA

SESSION INFORMATION

Session Date: Tuesday, November 14, 2023
Session Title: Abstracts: Miscellaneous Rheumatic & Inflammatory Diseases II
Session Type: Abstract Session
Session Time: 4:00PM–5:30PM

Background/Purpose: Polymyalgia rheumatica (PMR) is a systemic inflammatory syndrome that is characterized by widespread pain and stiffness around the shoulders, pelvic girdle and neck. PMR is usually treated with oral glucocorticoids, most commonly prednisone. However, long-term use of prednisone has been associated with various serious side-effects. Some literature suggested minimum effective dose of prednisone is within the range of 12.5-25 mg of prednisone daily. However, there is limited data suggesting the ideal starting dose of prednisone. Our study is to evaluate the effect of starting prednisone dose on the treatment duration of PMR and to determine the ideal initial prednisone dose that will lead to the shortest time needed to achieve 12 months of prednisone-free period.

Methods: We performed a retrospective chart review on a cohort of 919 adult patients newly diagnosed with PMR who were started on prednisone between January 1, 2010 to December 31, 2018 from the Kaiser San Bernardino and Riverside, Southern California, USA. Patients were excluded if hey had prior conditions that require long-term glucocorticoid use before PMR diagnosed, existing diagnoses of giant cell arteritis, and patients who did not achieve 12 month of prednisone-free period. Potential risk factors (age, Duration and inflammatory markers) were also evaluated. The primary outcome was to compare the duration of prednisone treatment in groups with 4 different starting doses of prednisone. The secondary outcome was to evaluate the treatment duration in patients with added steroid-sparing agents and the incidence of re-treatment with prednisone after achieving 12-month prednisone-free period.

Results: Among 701 patients with PMR diagnosed and was treated with prednisone. Their mean age was 68.7 and 443 (63.2 %) were women. The mean ESR was 45.5. Prednisone at 15mg (n = 191) had the shortest duration (mean of 23.4 months) of treatment before achieving 12-month prednisone free period with p value of 0.019. Out of 191 patients giving prednisone 15mg daily, 171 (89.5%) were started by rheumatologists. Patients who were started at 10mg or less prednisone daily and required steroid-sparing agents (n = 7 out of 202) had the longest duration of treatment (with a mean of 94.3 months) with p value of 0.008. Our study also showed that the percentage of patients requiring re-treatment with prednisone decreased with higher starting doses of prednisone. However, this p-value was not significant.

Table 1. Durations of prednisone treatment (in months)

Duration of treatment		Prednisone dose, mg				
		≤10	11 - 15**	16 - 20**	21 - 80	p-value (p<0.05)
Total prednisone* (n = 701)	Mean ± Std. Dev, months	32.4 ± 34.4	23.4 ± 23.3	29.9 ± 28.1	28.4 ± 31.4	0.019[a]
	Median (IQR), months	20.8 (38.8)	13.8 (25.1)	19 (33.5)	13.8(35.3)	0.057[b]
Prednisone only (n = 658)	Mean ± Std. Dev, months	30.4 ± 32.5	23.3 ± 23.3	27.3 ± 25.5	27.4 ± 32.1	0.11
	Median (IQR), months	19.6 (33.8)	13.8 (25)	17.7 (29.8)	13.2 (32.5)	0.24
Prednisone + steroid sparing agents (n = 43)	Mean ± Std. Dev, months	94.3 ± 39.5	24.7 ± 26.8	55.2 ± 38.7	41.5 ± 20.1	0.0078
	Median (IQR), months	116.3 (61.5)	14.7 (42)	32.7 (61.6)	46.2 (28.2)	0.018

Conclusion: Based on a systemic literature review about PMR, our study has the largest study population with 701 patients. Out study showed the patients who were treated with medium dose of daily prednisone dose of 15mg achieved 12 months of prednisone-free period in the shortest time. Since the patients treated with both prednisone 10mg daily or less and steroid-sparing agents had a longer duration, we recommend against any starting daily doses of 10mg or less. Patients treated with high prednisone dose had the lowest rate of restarting prednisone after 12 months compared with the other dose groups. With the treatment duration appeared to be longer when taking prednisone 20mg or higher, this suggested that PMR may be a heterogenous diseases with various severity and co-morbid diseases.

The Relationship Between the NETosis Findings and Disease Activity in Behcet Disease

Erdem Bektas[1], Rabia Deniz[2], Zeliha Emrence[3], Sema Sırma Ekmekci[3], Neslihan Abacı[3], Shirkhan Amikishiyev[4], Yasemin Yalçınkaya[4], Bahar Artim Esen[4], Murat Inanç[5] and Ahmet Gul[6], [1]Istanbul University, Istanbul Faculty of Medicine, Department of Internal Medicine, Istanbul, Turkey, [2]University of Health Sciences, Basaksehir Cam and Sakura City Hospital, Department of Rheumatology, Istanbul, Turkey, [3]Istanbul University, Aziz Sancar Institute of Experimental Medicine, Department of Genetics, Istanbul, Turkey, [4]Istanbul University, Istanbul Faculty of Medicine, Department of Internal Medicine, Division of Rheumatology, Istanbul, Turkey, [5]Istanbul University, Istanbul, Turkey, [6]Division of Rheumatology, Department of Internal Medicine, Istanbul Faculty of Medicine, Istanbul University, Istanbul, Turkey

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: Abstracts: Miscellaneous Rheumatic & Inflammatory Diseases II
Session Type: Abstract Session
Session Time: 4:00PM–5:30PM

Background/Purpose: Behcet disease (BD) is a multisystemic inflammatory disease of unknown etiology. BD has been classified among the neutrophilic dermatosis, and neutrophil extracellular traps (NETs) have been claimed in the pathogenesis of BD [1]. We herein aimed to investigate the potential relationship between the NETosis findings and local and systemic disease activity in BD.

Methods: The study group was consisted of orally and/or systemically active BD patients who met the ISG criteria and healthy individuals. The patients with additional inflammatory conditions or using biologic agents were excluded. Serum and saliva samples were collected from the patients during their active (active oral ulcer and/or systemic manifestations) and remission (no manifestations, normal acute phase reactants) periods cross-sectionally. Some of them were followed also longitudinally. Cell-free DNA (cf-DNA), neutrophil elastase (NE), myeloperoxidase (MPO) and citrullinated histon-3 (cit-H3) levels were measured as NETosis findings, and the results were adjusted according to the peripheral blood neutrophil counts (as the amount of biomarker per 1 million neutrophils). Unadjusted and adjusted levels were evaluated.

Results: The study group consisted of 30 active and 18 inactive BD patients as well as 10 healthy controls. Serum samples were collected from all active patients, and saliva samples were obtained from 15 orally active patients, while 18 serum and 7 saliva samples were obtained when they were in remission. Demographic and cumulative clinical characteristics of the patients are shown in **Table 1**. In active BD, serum cf-DNA and serum NE levels were found to be high ($p \leq 0.001$, $p < 0.05$), whereas adjusted serum MPO and adjusted serum cit-H3 levels were found to be low ($p \leq 0.001$, $p \leq 0.01$). In inactive BD, serum NE level were higher than controls ($p < 0.05$), while serum MPO, adjusted serum MPO and adjusted serum cit-H3 levels were lower than controls ($p < 0.05$, $p \leq 0.001$, $p < 0.05$, respectively). No difference was found in salivary NETosis

Table 1. Demographic and cumulative clinical characteristics of the active and inactive patients. Data show median (IQR) or mean ± SD as appropriate. Abbreviations: BD, Behcet disease; CRP, c-reactive protein; ESR, erythrocyte sedimentation rate; IQR, interquartile range; N, number of available patients; n, number of meet criteria; SD, standard deviation; TNFi, tumor necrosis factor inhibitor

	Active BD (N=30)	Inactive BD (N=18)
Sex, male, n (%)	21 (70)	11 (61.1)
Age, year	34.5 (26.5-42)	36.5 ± 9.1
Follow-up period, month	54 (10.5-150)	48 (10.25-70.5)
HLA B51, n (%)	10/13 (76.9)	9/12 (75)
Smoking, n (%)	8 (26.7)	7 (38.9)
ISG criteria, n (%)	29 (96.7)	17 (94.4)
Involvements, n (%)		
Mucocutaneous	30 (100)	18 (100)
Arthritis	12 (40)	8 (44.4)
Uveitis	8 (26.7)	2 (11.1)
Neurologic	2 (6.7)	1 (5.6)
Gastrointestinal	1 (3.3)	0 (0)
Vascular	7 (23.3)	6 (33.3)
Other	1 (3.3)	1 (5.6)
Treatments, n (%)		
Naive	7 (23.3)	0 (0)
Colchicium	23 (76.7)	18 (100)
Azathioprine	7 (23.3)	10 (55.6)
Corticosteroid	3 (10)	9 (50)
TNFi	0 (0)	1 (5.6)
Laboratory values		
Neutrophil count, $10^3/\mu l$	6.5 ± 2.6	4.7 (3.4-6.6)
CRP, mg/l	7.5 (3.16-26.5)	2.44 (0.6-4.46)
ESR, mm/h	10.5 (7-23.25)	9 (3-15)

findings between patient groups and controls (**Figure 1**). Serum cf-DNA and saliva cf-DNA levels showed a decrease in longitudinal follow-up towards remission ($p \leq 0.01$, $p < 0.05$) (**Figure 2**). Serum cf-DNA and saliva cf-DNA positively correlated with C-reactive protein and erythrocyte sedimentation rate, while adjusted serum MPO and adjusted serum cit-H3 negatively correlated ($p < 0.05$).

Conclusion: NETosis findings showed changes in association with systemic and/or local activity of BD patients in relation to the disease manifestations. Especially, serum and saliva cf-DNA levels potentially indicated the local and systemic disease activity, and serum NE levels were high in both active and inactive periods. The mechanism of the low serum MPO and cit-H3 levels, particularly in the active patients warrants further investigation. Changes of the findings after adjustment of the results according to the peripheral blood neutrophil counts may indicate that the NETosis findings detected in serum could be related to high neutrophil turnover in the active phase of the disease. Further studies are needed to clarify the biomarker potential of NETosis findings in BD.

SESSION INFORMATION

Session Date: Tuesday, November 14, 2023

Session Title: Abstracts: Miscellaneous Rheumatic & Inflammatory Diseases II

Session Type: Abstract Session

Session Time: 4:00PM–5:30PM

Background/Purpose: Interstitial lung diseases with an autoimmune background (AIP) are a heterogeneous group of processes. There is an unmet need to identify those cases with a progressive fibrosing phenotype in order to tailor therapeutics. Both of inflammation and hypoxia enhance ATP externalisation and increase synthesis of extracellular adenosine. In turn, increased adenosine promotes postinjury fibrotic remodelling, via A2A or A2B receptors. Netrin-1, which is also triggered by hypoxia has been found to activate A2B receptors, and is up-regulated during experimental and human lung fibrosis. We have explored activation of the adenosine pathway in patients with different subtypes of AIP.

Methods: We conducted a cross-sectional study in patients from the NEREA Register of autoimmune IP cases and in lung tissues from the IIS-HUFJD biobank. We measured adenosine and its metabolite inosine in plasma using HPLC. Serum levels of netrin 1 were determined by ELISA. Immunodetection of A2A, A2B and alpha-SMA was performed in the lung specimens. A descriptive analysis was carried out, and comparison between categories was done with parametric tests.

Results: The population comprised 126 subjects (115 cases, 74% women, and 11 controls). There were 64 newly diagnosed patients and 51 prevalent cases. Predominant radiographic patterns were NSIP (32p) and UIP (23p), while underlying autoimmune conditions included 9p with RA, 5 MCTD, 4 ARS, 16 SSc, 6 pSS, 3 IIM, and overlapping syndromes. Twenty six patients fulfilled IPAF criteria, while 11 patients were unclassifiable. At the time of biomarkers determination, 44p were considered to have a fibrotic process. Presence of RA-defining autoAb was found in 24 patients. ANA test was + in 69 out of 81 cases. There was a positive correlation between adenosine and netrin 1 (r 0.3, p 0.004), but not with the markers of epithelial injury lactate dehydrogenase (LDH) and Krebs von den Lungen 6 (KL6). Netrin 1 was enhanced in the patient population in comparison to healthy controls (p 0.005). Levels of adenosine, inosine and netrin 1 were higher in women than in men, and also tended to be higher in patients with established disease as compared with newly diagnosed ones, while in contrast KL-6 levels dropped in established disease as regarded to newly diagnosed patients (p 0.05). Netrin 1 levels were higher in those patients with fibrotic disease (p 0.08), and in RF+ cases (p 0.011). In contrast, we could not observe significant differences as concerned radiographic patterns or clinical diagnosis.

In the lung specimens, A2B receptors were enriched at the fibrotic interstitial areas and in alveolar epithelial cells. On the other hand, scattered infiltrating cells and some endothelial layers showed activation of the A2A receptors.

Conclusion: On the whole, our findings suggest that a subgroup or patients with AIP up-regulate the adenosine/netrin-1 pathway, in this way promoting the development of a profibrotic remodelling via A2BR and possibly modulating processes of immune cell activation and migration via A2A signaling. The role of netrin 1 as biomarker of the progressive fibrosing phenotype in these patients needs to be confirmed with longitudinal studies.

SESSION INFORMATION

Session Date: Tuesday, November 14, 2023

Session Title: Abstracts: Miscellaneous Rheumatic & Inflammatory Diseases II

Session Type: Abstract Session

Session Time: 4:00PM–5:30PM

Background/Purpose: Behçet's disease (BD) is a chronic and recurrent vascular inflammatory disease with major manifestations including oral ulcers, genital ulcers, skin damage and ophthalmitis, and it can also affect the nervous system, gastrointestinal tract, cardiovascular system, joints, and other vital organs. PDE IV inhibition is an approved therapy for BD. Hemay005 is a novel PDE IV inhibitor for treating chronic inflammatory diseases. Hemay005 significantly inhibits the activation of T lymphocytes, which play a vital role in the pathogenesis of Bechet's disease. It also inhibits Th1 type proinflammatory cytokines TNF-α, IFN-γ, IL-2, IL-12, and IL-23. Improvements in the side effect /efficacy ratio vs Apremilast are anticipated to improve on the efficacy of Apremilast, which was side effect limited at doses >30mg.

Methods: This was a multi-centre, randomized, double-blind, placebo-parallel-controlled, phase II clinical study. The study included four periods: a screening period, a 12-week core treatment period, a 12-week extension treatment period, and an off-drug observation period. All subjects completed the extension treatment period, followed by a 4-week off-drug observation period. It was planned to enrol a total of 252 patients, with randomization at 2:2:1:1 ratio. The study was terminated early

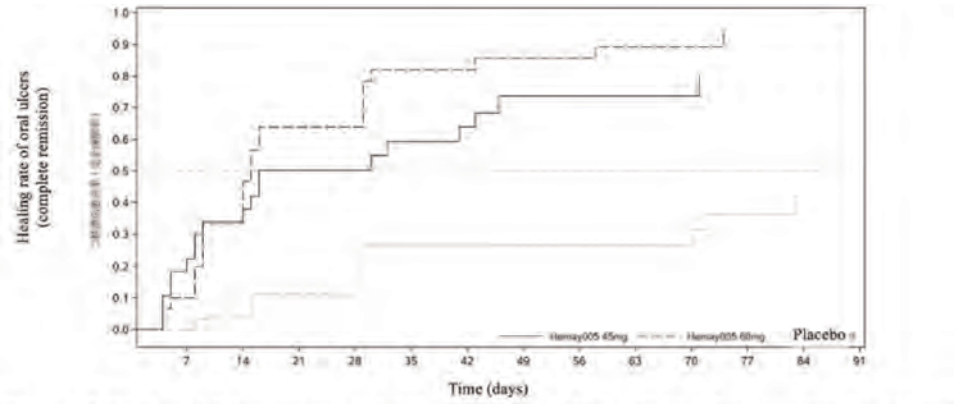

Figure 5 Kaplan-Meier curves - the time to first achieved complete remission of oral ulcer - FAS

Fig 1: Kaplan Meier curves: The time to first complete remission of oral ulcers -FAS

as the efficacy objective was achieved after 90 patients were recruited. The Area under the curve (AUC) for the number of oral ulcers in BD patients from baseline to Week 12 was the primary efficacy endpoint. Adverse Events were also recorded as primary safety endpoint.

Results: Overall, 90 subjects were recruited; 29 subjects were assigned to Hemay005 tablet 45 mg BID group, 31 to Hemay005 tablet 60 mg BID group, and 30 to placebo group. Results based on the FAS showed that the Hemay005 60 mg BID (1-sided, P <0.0001) and 45 mg BID (1-sided, P <0.0001) were statistically different from placebo in reducing the AUCs for the number of oral ulcers from baseline to Week 12. Analysis of the median healing time of oral ulcer estimated by KM was 16 days in 45 mg BID group, with 95% CI (8, 46); 15 days in 60 mg BID group, with 95% CI (9, 29); and the median healing time could not be estimated by KM method in placebo group Fig 1.

In the safety data set; (patients who received one dose or more of the drug or placebo), the incidence of TEAEs related to the study drug and leading to discontinuation of medication were higher in the 45 mg BID (6.9%) and 60 mg BID (6.7%)groups than that in the placebo group (0.0%) during the core treatment period. Most TEAEs reported during the core treatment period were mild; the incidence of severe TEAEs was dose-related, 3.3%, in the 60 mg BID and 0% in the 45 mg BID and placebo groups, respectively. No SAEs related to drug were reported throughout the study.

Table1 : The number of TEAS (MedDRA v 25); Percentages were calculated based on the number of subjects in the SS(Safety data set)

TEAEs reported in ≥ 5.0% of subjects in any treatment group, listed by SOC - SS

	45mg BID (N=29) n (%) E	60mg BID (N=30) n (%) E	Placebo (N=30) n (%) E
All TEAEs	26 (89.7) 129	29 (96.7) 186	21 (70.0) 75
Gastrointestinal disorders	20 (69.0) 52	20 (66.7) 58	12 (40.0) 19
Nervous system disorders	9 (31.0) 16	15 (50.0) 32	3 (10.0) 4
Infections and infestations	9 (31.0) 12	10 (33.3) 12	5 (16.7) 6
Musculoskeletal and connective tissue disorders	8 (27.6) 13	9 (30.0) 15	7 (23.3) 8
Metabolism and nutrition disorders	6 (20.7) 11	5 (16.7) 7	2 (6.7) 2
General disorders and administration site conditions	5 (17.2) 6	6 (20.0) 6	4 (13.3) 8
Investigations	3 (10.3) 7	8 (26.7) 31	11 (36.7) 14
Skin and subcutaneous tissue disorders	2 (6.9) 2	8 (26.7) 12	4 (13.3) 6
Respiratory, thoracic and mediastinal disorders	0	4 (13.3) 5	1 (3.3) 1
Cardiac Disorders	2 (6.9) 2	1 (3.3) 2	1 (3.3) 1
Reproductive system and breast disorders	2 (6.9) 3	1 (3.3) 1	0
Psychiatric disorders	0	3 (10.0) 3	1 (3.3) 1

Conclusion: Hemay005 60 mg BID and 45 mg BID for 12 weeks effectively reduced the AUC for the number of oral ulcers from baseline to Week 12 in BD patients. The study drug was safe and well-tolerated. A phase III clinical trial in patients with Bechet's disease is underway.

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: Abstracts: Miscellaneous Rheumatic & Inflammatory Diseases II
Session Type: Abstract Session
Session Time: 4:00PM–5:30PM

Background/Purpose: Sarcoidosis is a disease with heterogeneous clinical presentation and course. The objective of this study is the identification of clinical phenotypes using cluster analysis.

Methods: A model-based clustering relaying on 19 clinical variables was performed in a retrospective cohort of 342 sarcoidosis patients, diagnosed and follow-up from 1999 to 2019 in a hospital at Northern Spain. Chi-square test and ANOVA were used to compare categorical and continuous variables among groups. Two-sample t-tests and the partition of Pearson's chi-square statistic were used in pairwise comparisons. The Wasfi severity score was calculated and compared among clusters.

Results: Cluster analysis identified five groups: C1: erythema nodosum and articular involvement (n=55; 16.1%), C2: miscellaneous extrapulmonary sarcoidosis (n=49; 14.3%), C3: ocular and/or neurological involvement (n=83; 24.3%), C4: isolated hiliar adenopathy (n=17; 5.0%), and C5: parenchymal lung involvement with dyspnea (n=138; 40.4%). Lung involvement was predominant in all clusters, ranging from 89.9% (C5) to 100% (C1 and C4), except for C2 (55.1%). Extrapulmonary involvement was significantly higher in C2 (96.4%) and C3 (98.0%). Demographic and clinical characteristics are shown in **Table 1**. A significant low mean FEV1 was detected in C5 (90.5±21.8) versus C1 (102.0±22.9), C3 (102.3 ±17.6) and C4 (105.8±20.8). The cluster 5 had a significantly lower mean FVC (96.6±18.9) than the other clusters, ranging from 108.1±18.0 (C3) to 111.5±21.7 (C4). The prescription of systemic steroids and non-corticosteroid immunosuppressants was significantly higher in the clusters 1, 3 and 5**.** Chronicity rates were significantly higher in C3 (31.3%) and C5

(32.6%) compared to C1 (9.1%) and C4 (0%). The clusters 3 and 5 also showed significantly higher severity score values. According to the clusters identified in the present study, we proposed an individualized "treat to target" schedule by subgroups (**Figure 1)**.

Table 1. Demographic and clinical characteristics of the study population.

Characteristics	Whole cohort	C1	C2	C3	C4	C5	p- value	q-value

SESSION INFORMATION

Session Date: Tuesday, November 14, 2023
Session Title: Abstracts: Orthopedics, Low Back Pain, & Rehabilitation
Session Type: Abstract Session
Session Time: 4:00PM–5:30PM

Background/Purpose: Rates of total knee arthroplasty (TKA) in the United Stateshave risen, coupled with increasing demand for TKAs in younger patients.[1]Althoughrates of postoperative complications in TKA have decreased significantly,[2] they remaina significant concern for patients and clinicians. In light of these changing trends in TKA use and outcomes, we sought to understand how risk for adverse TKA outcomes changes with age using machine learning algorithms.

Methods: We studied patients undergoing TKA from the Pennsylvania Health Care Cost Containment Council (PHC4) Database, 2012-2018.Our primary variable of interest was age as a risk factor for the binary outcomes of 90-day readmission, 90-day mortality, 1-year revision, and the continuous outcome length of stay (LOS). Our model included patient-level demographics and covariates, including sex, race, discharge location, and insurance. We trained explainable boosting machines (EBMs)to predict risk (70% train:30% test) for the aforementioned outcomes.[3]For binary outcomes, we stratified the training data by outcome for balance. EBMs are highly accurate, interpretable models that are flexible in visualizing the dependent variables and handle collinearity well which is important in TKA. We report test AUROCs and R^2as evaluation metrics for predictive performance of the models, and further include partial dependency plots which explain the relationship of age with these outcomes.

Table 1: Cohort Characteristics by Outcome

* p-value < 0.05. ** p-value < 0.01. *** p-value < 0.001. p-value calculated via Chi-squared test, Fisher's exact test, and Wilcoxon rank sum test. p-values compares groups with and without the outcome for all the variables listed above.

HHC, health home care; IRF, inpatient rehabilitation facility; SNF, skilled nursing facility.

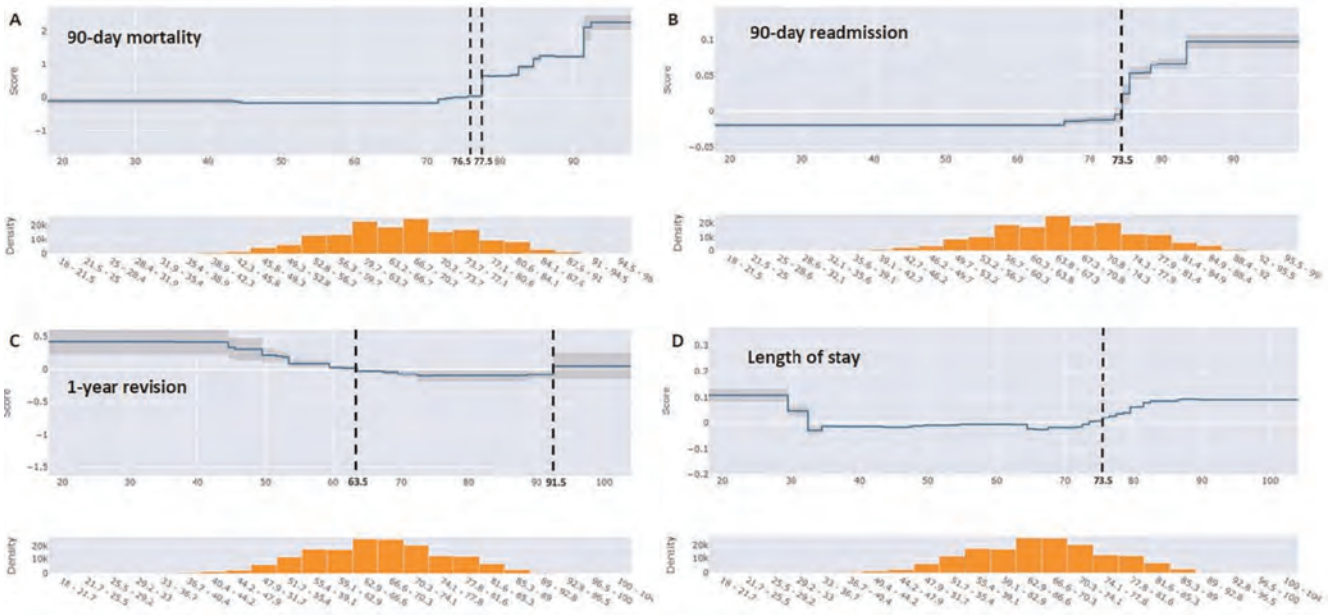

Figure 1: Partial dependency plots to understand the marginal effect of age (years) on (A) 90-day mortality, (B) 90-day readmission, (C) 1-year revision, and (D) length of stay from the supervised explainable boosting machine models. Y-axis score is shown in log scale. Vertical lines demonstrate where risk score is equal to 0, and show the age of the average contribution to risk.

Results: We had a cohort of 227,959TKA patients, with a median age of 65 years with 90.1% White and 55% Medicare-insured (Table 1).90-day readmission was observed in 7.49%, 90-day mortality in 0.22%, and 1-year revision in 0.79%. Predictive performance of adverse outcomes was strongest for 90-day mortality (AUROC=0.74), followed by 1-year revision (AUROC=0.64), 90-day readmission (AUROC=0.62), and LOS (RMSE=0.36, R^2=0.13). Age was among the most important factors for predicting all outcomes and its relationship with the outcomes is detailed in the partial dependency plots in Figure 1.Predicted risk of90-day mortality increases significantly after the age of 77.5 years, whereas90-day readmission increases after the age of 73.5 years, and LOS risk increases at 73.5 years. However, with 1-year revision the risk decreases after the age of 63.5 (Figure 1).

Conclusion: We determined that the effect of age as a risk factor for poor TKA outcomes changes dramatically at specific time points, thus demonstrating that there is a nonlinear relationship between age and TKA outcomes. Traditional regression models have always been understood to have a proportionate increase in risk as age increases. However, our study gives nuance to this understanding and can help physicians and patients in decision-making when trying to quantify risks related to aging as they consider TKA as a treatment option.

Diabetes Mellitus Impacts Primary Total Hip Arthroplasty Outcomes: A National Cohort Study

Sumanth Chandrupatla[1], Kranti Rumalla[2] and Jasvinder Singh[1], [1]University of Alabama at Birmingham, Birmingham, AL, [2]Northwestern School of Medicine, Chicago, IL

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: Abstracts: Orthopedics, Low Back Pain, & Rehabilitation
Session Type: Abstract Session
Session Time: 4:00PM–5:30PM

Background/Purpose: Primary total hip arthroplasty (THA) patients often have concomitant medical comorbidities. This study aims to identify the impact of diabetes mellitus (DM) on inpatient clinical and healthcare utilization outcomes in patients, and whether this association varies by the underlying primary diagnoses.

Methods: We identified patients over the age of 18 who underwent THA in the 2019 National Inpatient Sample (NIS). We stratified patients by primary diagnosis into hip osteoarthritis (OA; N=405691), avascular necrosis (AVN; N=17060), fracture (N=104265), inflammatory arthritis (IA; N=5720) (includes rheumatoid arthritis [RA], spondylarthritis [SpA], including ankylosing spondylitis, and psoriatic arthritis [PsA]), vs. other. We identified underlying diagnoses using primary diagnosis codes and diabetes and complications using secondary diagnosis codes. We performed multivariable-adjusted regression analyses for clinical and healthcare utilization outcomes as endpoints, adjusted for race, age, sex, hospital bed size, census region, and teaching status.

Results: Total cohort population was 591,891, with 101,385 classified as diabetic. Mean age was 68.75, mean length of stay (LOS) was 2.73 days, and 58.20% were female. Overall, DM was associated with increased LOS, non-routine discharge (i.e., to a facility), and acute renal failure (ARF) ($p \leq 0.05$ each). Patients in the OA or fracture cohorts with DM were more likely to have non-routine discharges ($p \leq 0.001$ each). DM was significantly associated with an increased risk of longer LOS and ARF in OA, fracture, and IA cohorts ($p \leq 0.03$ each). DM was associated with increased risk of blood transfusions ($p=0.031$), and a lower risk of pneumonia and prosthetic complications in the fracture cohort ($p \leq 0.016$ each).

Conclusion: DM was associated with increased healthcare utilization and ARF following primary THA, indicating associated healthcare resource and clinical burden. The variation in association of DM with outcomes post-primary THA for people with AVN or fractures, identifies differential effect in elective versus non-elective cases that needs further study.

Session Title: Abstracts: Orthopedics, Low Back Pain, & Rehabilitation

Session Type: Abstract Session

Session Time: 4:00PM–5:30PM

Background/Purpose: Osteoarthritis (OA) affects nearly 33 million adults in the US and total knee arthroplasty (TKA) is an effective treatment. Outcomes can vary by regional and hospital level disparities. We sought to determine patient characteristics and hospital level factors of extended hospital stays and increased costs in patients with knee OA who underwent primary TKA in a nationally representative sample.

Methods: We examined patients from the 2019 National Inpatient Sample (NIS) with OA who underwent primary TKA using the International Classification of Disease 10th Edition (ICD-10) Diagnosis and Procedure codes. Patient and regional characteristics were assessed. Primary outcomes were extended length of stay (eLOS) and increased hospital charges (IHC), determined as the upper quartile of each outcome. Multivariable analysis determined independent predictors for each outcome. Area Under the Curve (AUC) analysis assessed classification ability.

Results: 543,291 patients underwent TKA in 2019; 61.7% were female and 81.3% were white. Independent predictors of IHC include hospital bed size ($p < 0.001$), location & teaching status ($p < 0.001$), and hospital control ($p < 0.001$). South and West region hospitals a significantly higher adjusted odds ratio (aOR 1.54 & 2.79, $p < 0.001$) of IHC when compared to Northeastern region hospitals. Significant independent predictors of eLOS include race & ethnicity ($p < 0.001$), payer

Unit of change for age = 10; Unit of Change for Total Hospital Charge = $10,000
Significance was determined a priori at $p < 0.05$.

($p < 0.001$), and hospital control ($p < 0.001$). Multivariable models for eLOS and IHC had AUC C-statistic scores of 0.74 and 0.76, respectively, demonstrating a modest classification ability.

Conclusion: Patient race/ethnicity, payer, regional and hospital level characteristics impacted outcomes and costs for the OA patients who underwent primary TKA in 2019. A stronger emphasis to address regional, hospital-level, and racial disparities can improve outcomes for the thousands of OA patients who undergo TKA every year.

Figure-1: Multivariable prediction models of geographic and regional level characteristics demonstrating classification ability for extended length of stay and increased hospital charges

SESSION INFORMATION

Session Date: Tuesday, November 14, 2023

Session Title: Abstracts: Orthopedics, Low Back Pain, & Rehabilitation

Session Type: Abstract Session

Session Time: 4:00PM–5:30PM

Background/Purpose: Knee osteoarthritis (KOA) is a leading cause of pain and disability worldwide with no definitive treatment. There is a need to identify mechanisms that explain KOA progression so that targeted treatments can be developed. Increased forces while walking are associated with structural progression of KOA. Altered nociceptive signaling, a feature of KOA, could partially explain forces while walking. In this study, we aimed to characterize the relation of pain sensitization to ground reaction forces during walking. We hypothesized that lower pressure pain thresholds (PPTs) (i.e., greater

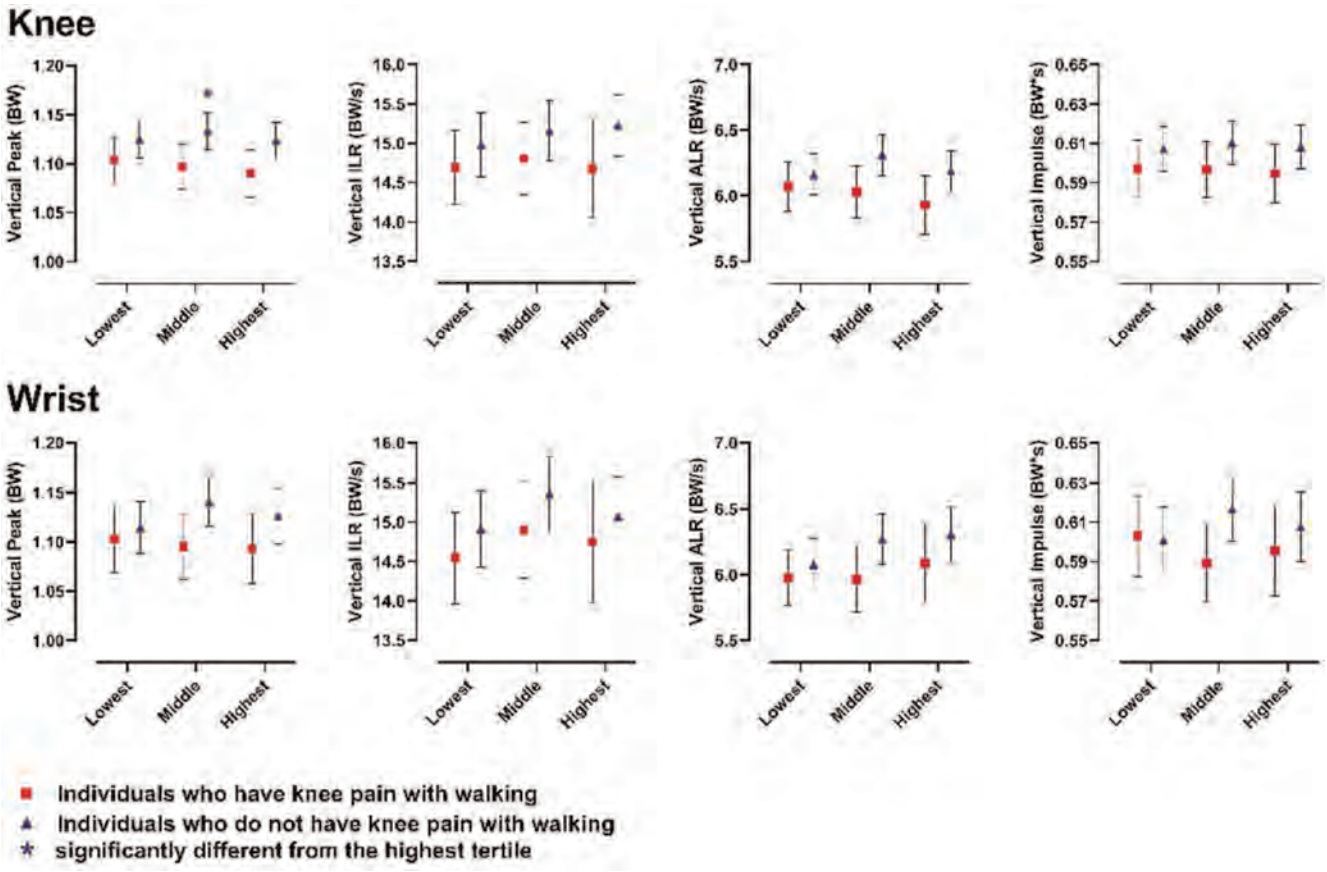
sensitization) would be associated with decreased vertical ground reaction forces (vGRF) in those with and without knee pain while walking.

Methods: We used data from the 12-year visit of the Multicenter Osteoarthritis (MOST) Study. MOST is a NIH-funded, prospective, cohort study of >3000 persons with or without KOA.

PPTs were assessed at the right wrist (unless contraindicated) and both patellae. For each trial, a hand-held pressure algometer with a 1 cm^2 tip was used to apply pressure at a rate of 0.5 kg/s. Pressure was recorded when pain was first perceived. PPTs for each anatomic site were determined as the average of three trials. Sex-specific tertiles were used to categorize PPTs because of known sex differences.

Three-dimensional force data were sampled (1000 Hz) while participants walked at a self-selected speed. With vGRF waveforms, we determined peak force, peak instantaneous loading rate (ILR), and average loading rate (ALR) during the first half of stance, as well as total impulse during stance (i.e., time integral). All vGRF metrics were averaged across at least 3 gait trials for each limb and normalized to body weight.

Generalized linear models, with generalized estimating equations to account for the correlation between limbs, characterized relations of PPT tertiles to vGRF metrics. Person-level covariates included age, sex, and race. Limb-level covariates included KOA status (Kellgren-Lawrence ≥2), knee pain severity (VAS; 0-100), and gait speed. For each vGRF metric, adjusted means and 95% confidence intervals were determined for each PPT tertile after stratifying by knee pain with walking. Knee pain was defined as at least mild pain in response to the question "how much pain do you have in your (right/left) knee while walking on a flat surface?"



Relation of sex-specific pressure pain threshold tertiles to vertical ground reaction force metrics during walking.

Results: 1944 MOST participants (57% female; 19% non-white; 38% with at least mild knee pain with walking), with a mean (SD) age of 62.4 (9.8) years and BMI of 29.9 (5.3) kg/m^2, were included. Of the 3399 limbs, 26% had KOA, and average walking speed and VAS were 1.31 (0.23) m/s and 12 (17), respectively.

All vGRF metrics are reported in Figure 1 by PPT tertile for those with and without knee pain with walking. Only the vGRF peak forces were significantly different between the middle and highest PPT knee tertiles; no other vGRF metrics differed across PPT tertiles. All vGRF metrics were numerically lower in those with knee pain with walking compared to those without knee pain with walking.

Conclusion: Pain sensitivity was not associated with limb-level loading in persons with or without knee pain during walking.

Comparing Patellar Tendon Characteristics Between Adults with and Without Knee Pain

Samantha Price[1], Karin Silbernagel[2], David Felson[3], Joshua Stefanik[4] and Patrick Corrigan[1], [1]Saint Louis University, St. Louis, MO, [2]University of Delaware, Avondale, PA, [3]Boston University, Boston, MA, [4]Northeastern University, Boston, MA

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: Abstracts: Orthopedics, Low Back Pain, & Rehabilitation
Session Type: Abstract Session
Session Time: 4:00PM–5:30PM

Background/Purpose: Knee pain is one of the most common types of joint pain leading to disability, limited physical activity, and reduced quality of life. While numerous risk factors for knee pain have been identified, extensor tendons have received limited attention. Altered patellar tendon structure and stiffness may contribute to knee pain through their effects on quadriceps muscle function and joint biomechanics. In this study, we aimed to determine if patellar tendon characteristics differed between adults with and without knee pain.

Comparing patellar tendon thickness (a), CSA (b), and shear wave speeds (c) between knees with and without pain.

Methods: Adults over the age of 45 with and without knee pain were recruited. Exclusion criteria included: history of traumatic knee joint injury in the past 6 months, knee joint injection in the past 3 months, knee replacement, or a diagnosis of rheumatoid arthritis, ankylosing spondylitis, psoriatic arthritis, reactive arthritis, lupus, gout, bone cancer, connective tissue disorders, or neurologic condition.

Patellar tendon characteristics were assessed bilaterally with a GE LOGIQ *e*10 ultrasound scanner immediately distal to the proximal enthesis. Participants were resting in a seated position with their hips and knees flexed to 90 degrees. Brightness mode was used to assess patellar tendon thickness and cross-sectional area (CSA). Shear wave elastography was performed to estimate patellar tendon shear wave speed, a surrogate measure of tendon stiffness. For each measure, three trials were acquired and averaged.

For analysis, we compared the most symptomatic limb in those with knee pain to a randomly selected limb in those without knee pain. The most symptomatic limb was defined as the limb with the highest VAS pain score (0-100). If VAS scores were identical, the Western Ontario and McMaster Universities Osteoarthritis Index (WOMAC) pain subscale was used to define the index knee. Patellar tendon thickness, CSA, and shear wave speeds were compared between groups using independent t-tests.

Results: A total of 42 adults were included, 24 with knee pain (VAS pain ≥1) and 18 without knee pain (VAS=0). Individuals with knee pain (14 female) had a mean (SD) age and BMI of 61 (10) years and 32.23 (5.28) kg/m^2, respectively. Individuals without knee pain (10 female) had a mean (SD) age and BMI of 63 (10) years and 30.95 (6.15) kg/m^2, respectively.

Mean (SD) patellar tendon thickness, CSA, and shear wave speeds for the entire sample were 3.25 (0.64) mm, 0.90 (0.22) cm^2, and 5.68 (1.79) m/s, respectively. Patellar tendon shear wave speeds were significantly slower in knees with pain compared to knees without pain (Figure 1). Patellar tendon thickness and CSA were not significantly different between groups (Figure 1).

Conclusion: Compared to knees without pain, those with knee pain have reduced patellar tendon stiffness. Further work in this area is needed to determine if treatments that target the patellar tendon are effective at reducing knee pain.

Single-cell RNA Sequencing Reveals the CRTAC1+ Population Actively Contributes to the Pathogenesis of Spinal Ligament Degeneration by Inducing Macrophage Activation

Yulong Tang[1], **Dachun Zhuo**[1], Li Jin[1], Qi Zhu[2], Yuanyuan Chen[3], Jiucun Wang[4] and Jing Liu[4], [1]Fudan University, Shanghai, China, [2]Guanghua Integrative Medicine Hospital, Shanghai, China, [3]Shanghai Sixth People's Hospital, Shanghai, China, [4]Shanghai, Shanghai, China

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: Abstracts: Orthopedics, Low Back Pain, & Rehabilitation
Session Type: Abstract Session
Session Time: 4:00PM–5:30PM

Background/Purpose: Spinal ligament degeneration is a chronic disease that affects the spine, ligaments, and associated bones, resulting in back pain and functional limitations in the world's aging population. Despite the significant burden on musculoskeletal medicine, there is a lack of research on preventive strategies for ligament degeneration. This study aims to establish a comprehensive transcriptomic atlas of ligament tissues and identify effective drug targets.

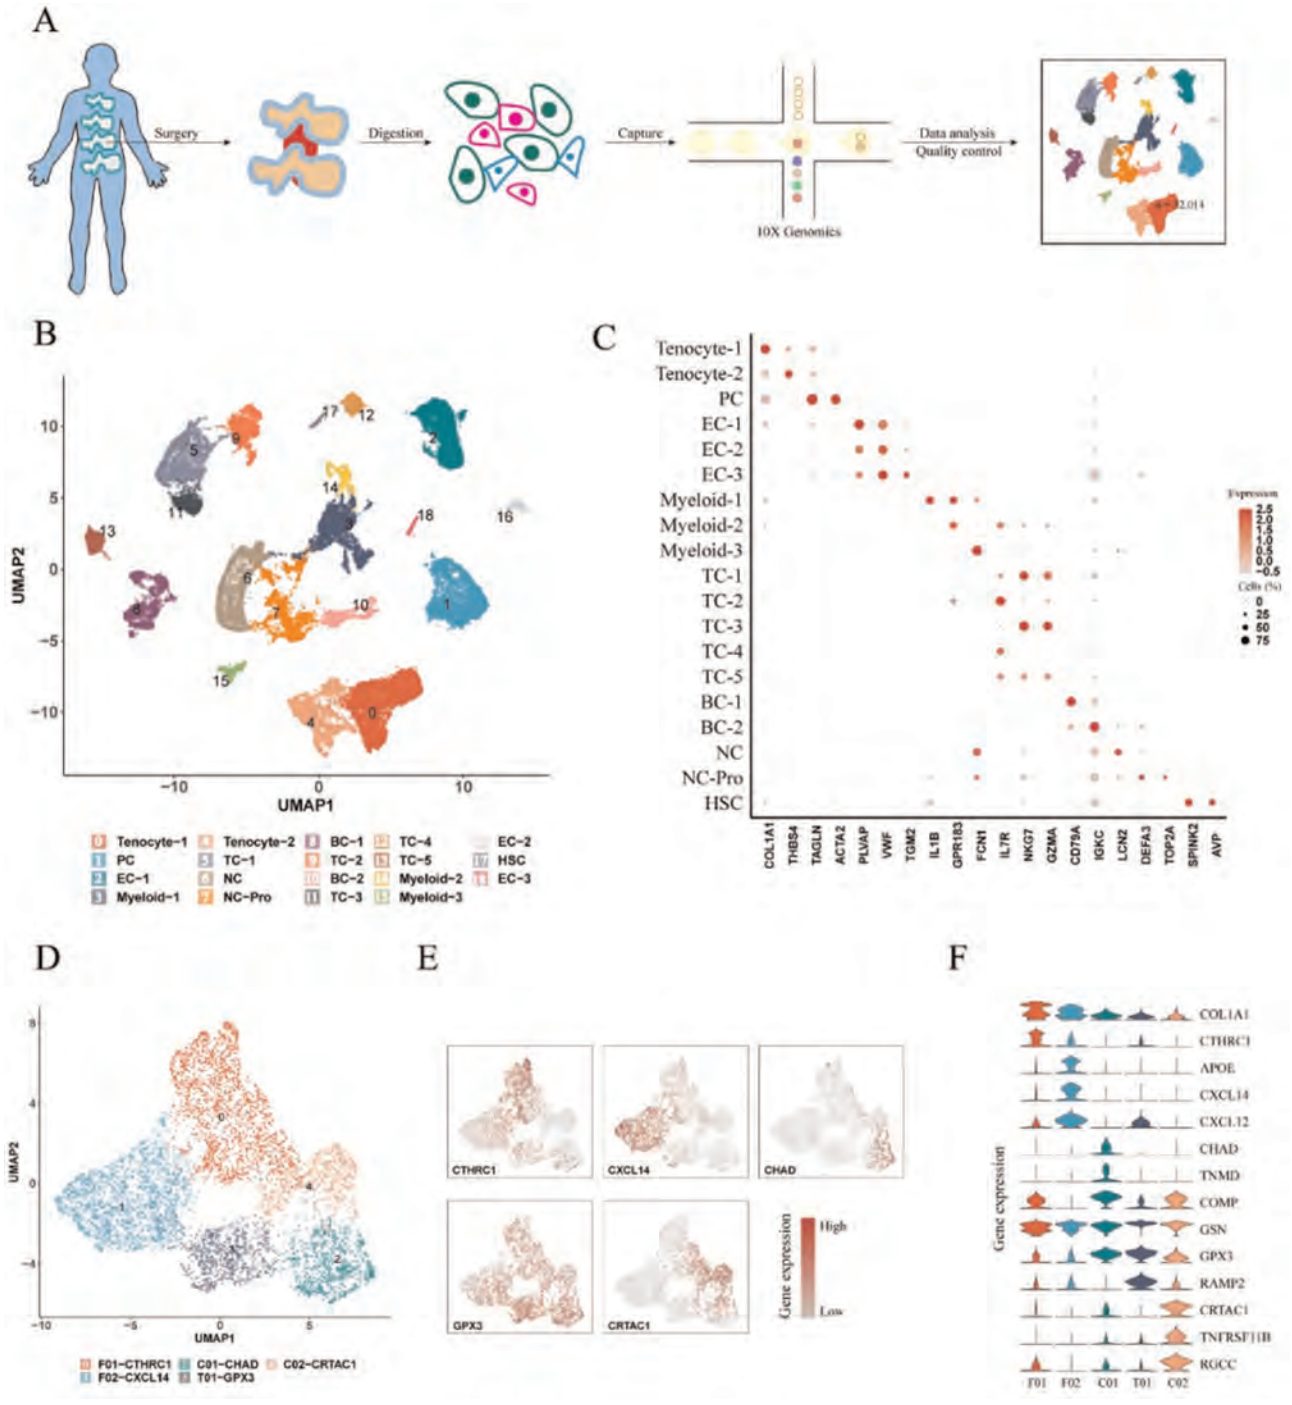

Figure 1 A, Workflow of ligament digestion and single-cell RNA sequencing. B, UMAP plot of total cells, 19 clusters were identified. C, Dotplot showed the marker genes of the 19 cell clusters. D, UMAP plot of stromal cell subpopulations. E, Feature plot of stromal cell subpopulations. F, Marker genes of the five stromal cell subpopulations.

Methods: Single-cell RNA sequencing was performed on six degenerative ligaments and three traumatic ligaments to decipher the heterogeneity of the tissues, followed by data analysis using various computational tools. Library preparation with 10X Genomics and sequencing on Illumina NextSeq instrument was performed. Immunohistochemistry and immunofluorescence analysis were performed to validate the molecular patterns and while in vitro models of primary ligament cells were isolated and utilized for the follow-up functional studies. Protein and mRNA levels were examined using western blot and

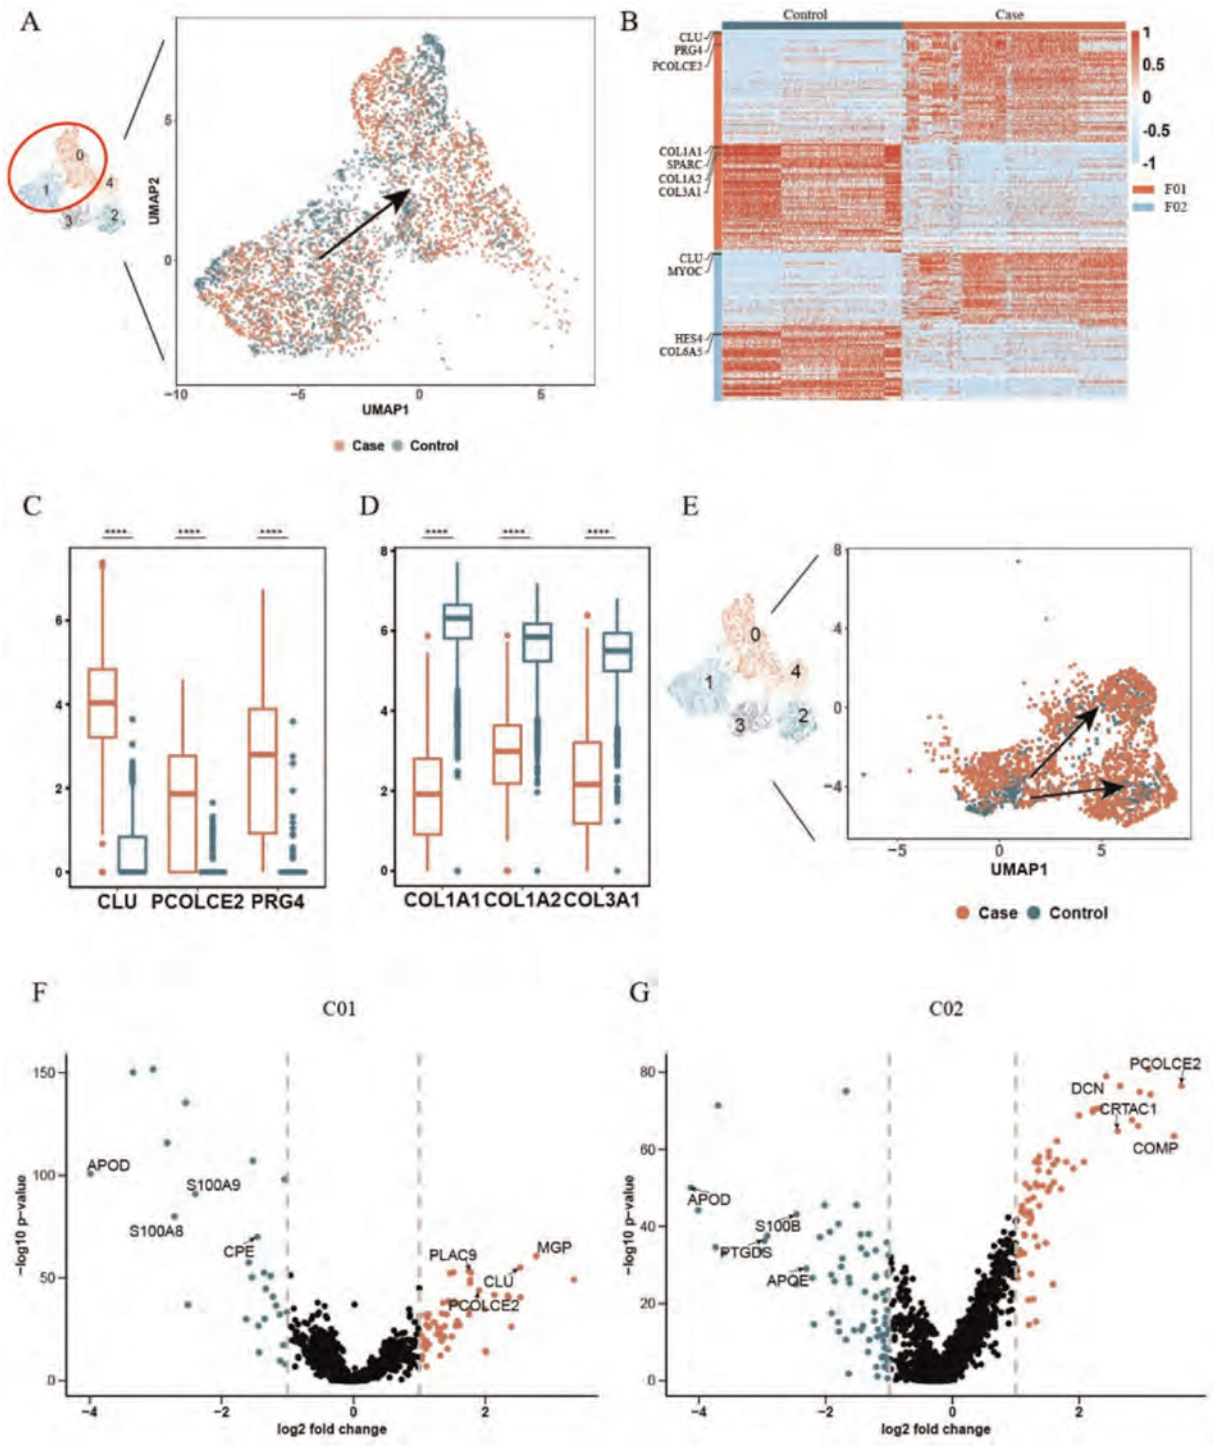

Figure 2 A, UMAP plot of the fibroblast-like cells. B, Heatmap of the differentially expressed genes of the two cell clusters. C, The expression level of chondrogenesis-related genes in fibroblast-like cells. D, The expression level of collagen-related genes in fibroblast-like cells. E, UMAP plot of the chondrocyte-like cells and tenocytes. F-G, Volcano plot showed the differentially expressed genes of the two chondrocyte-like cell clusters.

qPCR analysis. GW5074 (an inhibitor targeting ATF3) and si-ATF3 were used to silence ATF3 in ligament cells, and lentiviral transfection was conducted to overexpress ATF3. In addition, ligament cells were stimulated with recombinant SPP1 to evaluate its impact.

Results: After rigorous quality control, we obtained high-quality data from 32,014 cells for downstream analysis (Figure 1A). Our findings revealed distinct cell clusters comprising stromal and immune cells (Figures 1B-C). Stromal cells exhibited five cell subpopulations (Figures 1D-F), including GPX3+ tenocytes, two clusters of chondrocyte-like cells (CHAD+ and CRTAC1+), and two clusters of fibroblast-like cells (CTHRC1+ and CXCL14+). Notably, collagen degradation associated

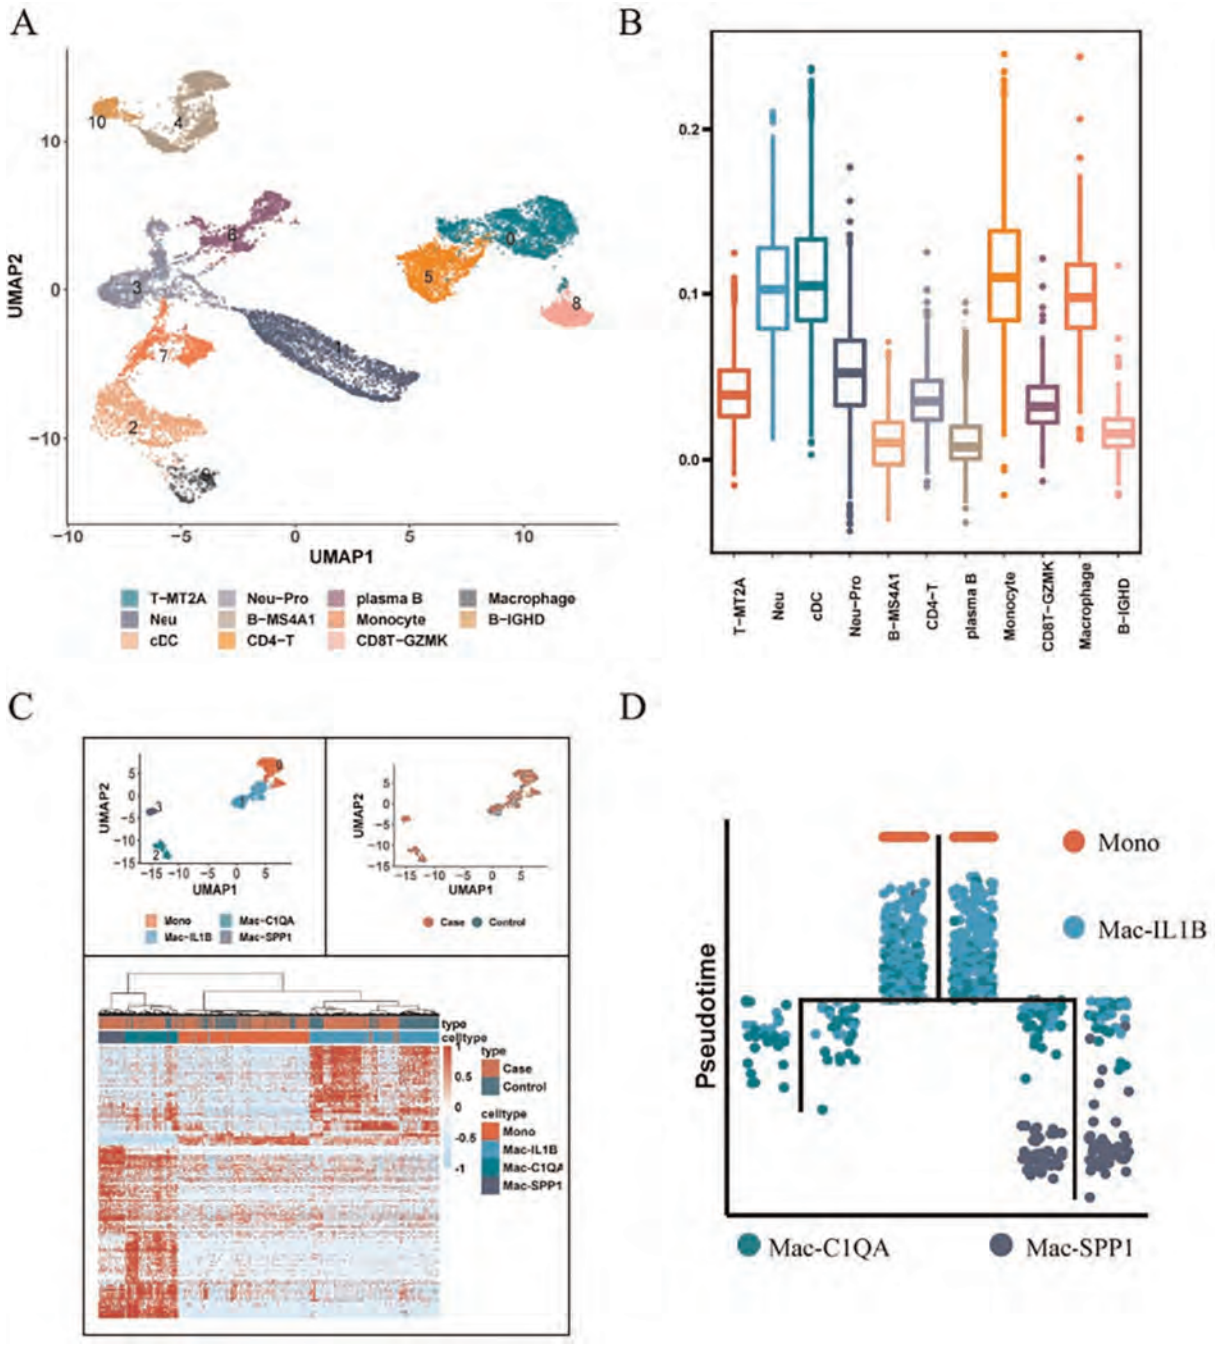

Figure 3 A, UMAP plot of immune cell subpopulations. B, The inflammation scores of the 11 immune cell subpopulations. C, UMAP plot of monocyte/macrophage subpopulations and Heatmap of the four cell clusters. D, Trajectory analysis of four cell clusters showed the evolutionary process of SPP1+ macrophage.

with CTHRC1+ fibroblast-like cells (Figures 2A-D) and ossification linked to CRTAC1+ chondrocyte-like cells (Figures 2E-G) were key features of ligament degeneration. Immune cells exhibited 11 cell subpopulations, including monocyte/macrophage, neutrophils, T cell, B cell, plasma B and cDC (Figure 3A). Among immune cells, myeloid cells demonstrated pathogenic activation, and degenerative ligaments showed enrichment of SPP1+ macrophages (Figures 3B-D). Further investigations unveiled the influence of ATF3, a core transcription factor, on the expression of CRTAC1/MGP/CLU in stromal cells, potentially mediating the interaction between SPP1+ macrophages and ligament degeneration (data not shown here).

Conclusion: SPP1+ macrophages contribute to the pathology of ligament degeneration through their interaction with the core transcription factor ATF3, resulting in enhanced expression of CRTAC1/MGP/CLU in stromal cells. Targeting SPP1+ macrophages and ATF3 in ligament stromal cells may hold promise for mitigating ligament degeneration.

Risk Factors for Bone Loss in Systemic Lupus Erythematosus

Nima Madanchi[1], Andrea Fava[2], Daniel Goldman[3], Larry Magder[4] and Michelle Petri[3], [1]Johns Hopkins University School of Medicine, Baltimore, MD, [2]Johns Hopkins University, Baltimore, MD, [3]Department of Medicine, Division of Rheumatology, Johns Hopkins University School of Medicine, Timonium, MD, [4]University of Maryland, Baltimore, MD

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: Abstracts: Osteoporosis & Metabolic Bone Disease – Basic & Clinical Science
Session Type: Abstract Session
Session Time: 4:00PM–5:30PM

Background/Purpose: Osteoporotic fractures are the most common damage item from the Systemic Lupus Erythematosus International Collaborating Clinics (SLICC)/American College of Rheumatology (ACR) Damage Index. Previous studies reported conflicting results on risk factors for osteoporosis in systemic lupus erythematosus (SLE). The role of vitamin D in osteoporosis in the general population and in SLE remains controversial. We conducted this study to evaluate the risk factors for bone loss in SLE.

Methods: We used a longitudinal cohort that included body mass index (BMI), 25-hydroxy vitamin D levels, complement levels, SLE disease activity index (SLEDAI), and prednisone dose historically and at each visit. 4283 bone density results from 1476 different patients were abstracted from the medical record and included in the statistical analysis. We estimated the association between various patient characteristics and spinal BMD using generalized estimating equations.

Results: A spinal T-score of -2.5 or lower was reported in 9.8% of the measurements. Univariate analysis (Table 1) showed that age, lower BMI, higher SLEDAI, mean prednisone dose, and a history of low C3 or C4 were associated with a spinal T-score of < -2.5. A multivariate analysis (Table 2) controlling for age, race, BMI, and mean prednisone dose showed higher risk of spinal osteoporosis with increasing age >40 years, Black race, mean SLEDAI >2, and history of any prednisone dose. BMI of >25 was protective. Sex, history of anti-DNA, or low C3/C4 were not associated with spinal osteoporosis in the multivariate analysis. The mean 25-hydroxy vitamin D, the first measured 25-hydroxy vitamin D, and the 25-hydroxy vitamin D level measured within 30 days prior to the bone density test were not associated with spinal osteoporosis (Table 3); but the mean 25-hydroxy vitamin D >50ng/ml was associated with lower mean spinal T-score.

Table 1. Number (%) with spinal osteoporosis and mean (DS) spinal T-scores in subgroups.

Predictor	Subgroups	Number of BMD measures	Number (%) -2.5 or lower	P-value[3]	Mean (SD) T-score	P-value[3]

Prior low C3[2]	No	1912	148 (8%)	0.041	-0.55 (1.40)	0.054
	Yes	1990	244 (12%)		-0.85 (1.36)	
Prior low C4[2]	No	2240	187 (8%)	0.0030	-0.65 (1.39)	0.53
	Yes	1662	205 (12%)		-0.77 (1.39)	

[1] Mean SLEDAI, vitamin D, and prednisone dose were defined as the mean from all cohort visits prior to the visit when BMD was measured.

[2] Prior anti-dsDNA, prior low C3 and prior low C4 were defined as the occurrence at any cohort visit prior to the visit when BMD was measured.

[3] P-values based on GEE to account for repeated observations on the same person.

Conclusion: Spinal osteoporosis in SLE was associated with age, African-American ethnicity, disease activity, and prednisone dose. Although African-Americans in the general population are protected against osteoporosis, in SLE they are at risk. Any prednisone dose – even low doses – increased osteoporosis. Vitamin D was not protective (and higher doses might have been harmful in the continuous analysis). Reduction of disease activity but without reliance on prednisone is key to osteoporosis reduction in SLE.

Table 2. Odds ratios for spinal osteoporosis based on multivariate analysis controlling for age, race, mean prednisone dose.

Predictor	Subgroups	Adjusted[1] Odds Ratio (95% CI)	Adjusted[1] p-values
Age	<40	1.00 (Ref. Group)	--

Current Trends in the Risk of Subsequent Fracture After Initial Fracture, and Post-Fracture Treatment Among Commercially Insured Postmenopausal Women in the United States

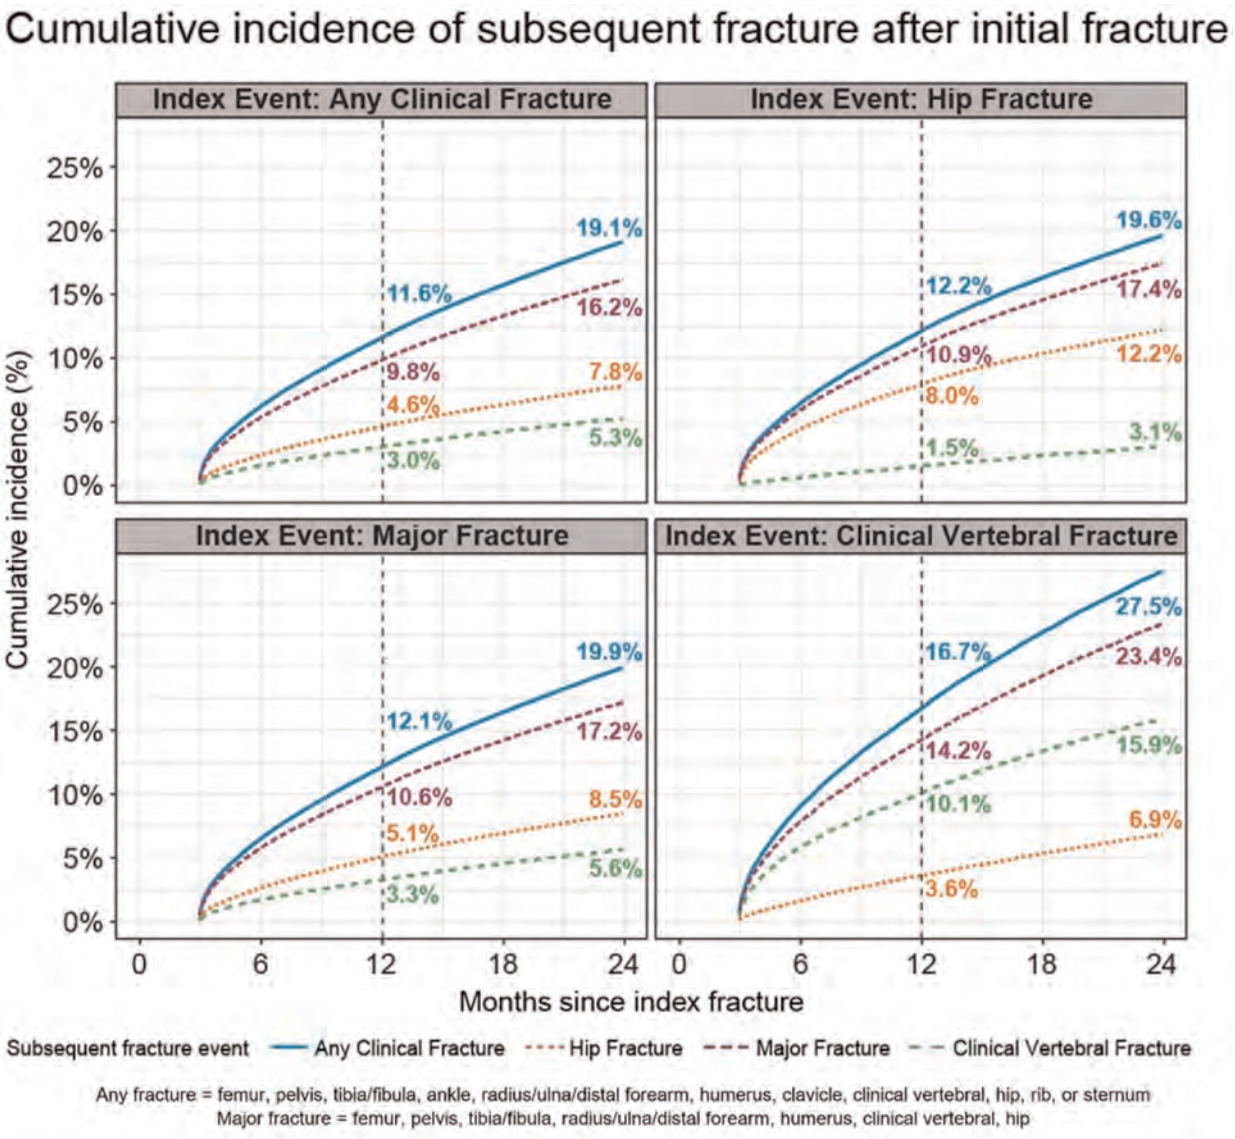
Min Kim[1], Vanessa C. Brunetti[1], Felicia Cosman[2], Jeffrey Curtis[3], E Michael Lewiecki[4], Matthew Phelan[5], Peter Samai[5], Michele McDermott[1], Tzu-Chieh Lin[1], M Alan Brookhart[6] and Kathleen Hurwitz[5], [1]Amgen, Inc., Thousand Oaks, CA, [2]Columbia University, New York, NY, [3]University of Alabama at Birmingham, Birmingham, AL, [4]New Mexico Clinical Research & Osteoporosis Center, Albuquerque, NM, [5]Target RWE, Durham, NC, [6]Department of Population Health Sciences, Duke University, Durham, NC

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: Abstracts: Osteoporosis & Metabolic Bone Disease – Basic & Clinical Science
Session Type: Abstract Session
Session Time: 4:00PM–5:30PM

Background/Purpose: Recent studies suggest that post-fracture pharmacologic management has been declining in the U.S. despite an increase in the burden of osteoporosis (OP). In light of this treatment gap, few studies have reported on the incidence of subsequent fracture risk among commercially insured postmenopausal women with a history of fracture.

Methods: We assembled a retrospective cohort of women aged ≥50 years from 2012-2021 using an administrative claims database of privately insured or employer-sponsored Medicare Advantage coverage. Osteoporotic fractures were identified by ≥1 insurance claims with a relevant diagnosis and/or procedure code for an open or closed fracture. Treatments for osteoporosis were identified by prescription fills or medical procedure claims. The cumulative incidence of a new, subsequent fracture at the same or a different anatomic site was estimated for any (clinical vertebral, hip, femur, pelvis, tibia, fibula, radius/ulna/distal forearm, humerus, clavicle, rib, sternum), major (any fracture excluding extremities, clavicle, rib, sternum), hip, and clinical vertebral fractures occurring ≥90 days of initial index fracture to up to 2 years. Women were followed from the index fracture for up to 2 years to estimate the cumulative incidence of any treatment uptake. All analyses used inverse probability weighting to adjust for differential censoring due to differences in demographics and clinical risk factors.

Results: Among the 483,564 women with any initial fracture (mean age 74.8), the 1-year cumulative incidence of a subsequent fracture at any site was 11.6%, which increased to 19.1% at 2 years (Figure). The same-site subsequent fracture risk was highest for women with an initial clinical vertebral fracture: 10.1% experienced a subsequent vertebral fracture at year 1 and 15.9% at year 2. Among women with an initial hip fracture, 12.2% and 19.6% experienced a subsequent fracture at any site after 1 and 2 years, respectively, while 8.0% and 12.2% experienced a subsequent hip fracture at 1 year and 2 years, respectively. Most patients did not receive pharmacological treatment one year (91.7%) and two years (89.4%) after their initial fracture.



Conclusion: Although clinical guidelines specify that OP is a lifelong, chronic disease requiring ongoing management, recent data over a 10-year period show that recurrent fracture rates within 2 years are high, while pharmacological treatment remains underutilized in this high-risk population.

Session Date: Tuesday, November 14, 2023

Session Title: Abstracts: Osteoporosis & Metabolic Bone Disease – Basic & Clinical Science

Session Type: Abstract Session

Session Time: 4:00PM–5:30PM

Background/Purpose: Although clinical trials have shown that denosumab (Dmab) significantly increases bone mineral density at key skeletal sites more than zoledronic acid (ZA), evidence from randomized trials evaluating fracture outcomes is lacking. This retrospective cohort study evaluated the comparative effectiveness of Dmab versus ZA in reducing fracture risk among women with postmenopausal osteoporosis (PMO) in the U.S.

Methods: Female Medicare fee-for-service beneficiaries ≥ 66 years of age who newly initiated Dmab (n=89,990) or ZA (n=36,861) between Jan 1, 2012 to Dec 31, 2018 with no prior history of osteoporosis treatment were followed from treatment initiation (index date) until the first instance of a given fracture outcome, treatment discontinuation (defined as the end of exposure according to usual dosing intervals + 60-day gap) or switch, Medicare disenrollment, death, end of available data (Dec 31, 2019), or 5 years post-index date. A doubly robust inverse-probability of treatment (weights estimated from multivariate logistic regression models) and censoring (weights estimated from multivariate Cox Proportional Hazards regression models) weighted function was used to estimate the relative risk (RR) associated with the use of Dmab compared with ZA for major osteoporotic (MOP; nonvertebral and hospitalized vertebral), hip, nonvertebral (NV; includes hip, humerus, pelvis, radius/ulna, other femur), non-hip, nonvertebral (NHNV), and hospitalized vertebral (HV) fractures for the overall study period and by year of follow-up.

Results: Over a maximum of 5 years of follow-up, Dmab reduced the risk of MOP by 26% (RR=0.74; 95% CI: 0.59-0.89), hip by 34% (0.66; 0.43-0.90), NV by 33% (0.67; 0.52-0.82), and NHNV by 31% (0.69; 0.50-0.88), and HV fractures by 10% (0.90; 0.56-1.24) compared with ZA (Figure). Over time, Dmab reduced the risk of MOP fractures by 9% (0.91; 0.83-0.99) at year 1, 12% (0.88; 0.80-0.96) at year 2, and 12% (0.88; 0.78-0.98) at year 3. An increase in the magnitude of fracture risk reduction with increasing duration of exposure was also observed for other NV outcomes.

Conclusion: In a cohort of over 125,000 treatment-naive women with PMO, we observed robust, clinically meaningful reductions in the risk of MOP, hip, NV, and NHNV fractures for patients on Dmab compared to ZA, with greater reductions in fracture risk with longer duration of exposure.

SESSION INFORMATION

Session Date: Tuesday, November 14, 2023
Session Title: Abstracts: Osteoporosis & Metabolic Bone Disease – Basic & Clinical Science
Session Type: Abstract Session
Session Time: 4:00PM–5:30PM

Background/Purpose: Osteoporotic fractures are a well-known complication in LT recipients, significantly impacting their quality of life. Specific risk factors for these fractures in LT recipients are poorly understood, and universal guidelines are lacking. We aimed to assess the incidence of osteoporotic fractures in end-stage lung disease patients pre- and post-LT, while also identifying potential risk factors for post-LT fractures.

Methods: This retrospective cohort study was conducted at a large international transplant center, including adult patients who underwent LT between January 1, 2010, and April 14, 2018. Patients who expired within the first year post-LT or had prior LT were excluded. Endpoints comprised the incidence of vertebral and non-vertebral osteoporotic fractures post-LT, as well as potential risk factors for post-LT fractures, as determined by clinicians. Secondary endpoints included evaluating the impact of osteoporosis medications. Logistic regression modeling was employed to examine the relationships between potential risk factors and post-LT fractures.

Table 1. Summary of study population characteristics.

Table 1. Summary of study population characteristics.

Variable		Total (N=786)
Age at time of transplant, Median [25th;75th]		61.0 [54.0;67.0]
Sex, N (%)		
Male		526 (67%)

*Post-transplant osteoporosis data shows newly diagnosed osteoporosis, excluding pre-transplant osteoporosis patients.

Results: Out of 911 patients who underwent LT, 786 patients met the study inclusion criteria (median age: 61; 67% male; 87% white). The most common indication for LT was idiopathic pulmonary fibrosis (49.1%) **(Table 1)**. Pre-LT, 186 patients (23.6%) had osteoporosis (T-score < -2.5), and ≥1 fracture occurred in 90 patients (11.4%), with vertebral fractures being the most common (53, 47.3%). Following LT, 185 patients (23.5%) developed new-onset osteoporosis, and 185 patients (23.5%) experienced at least one fracture, with 109 of these fractures (48.2%) being vertebral in nature. The median time to post-LT fracture was 655 days **(Table 2)**. Post-LT, 55.2% received osteoporosis medications, with the most prescribed

Table 3. Post-transplant fragility fracture predictors assessment.

Table 3. Post-transplant fragility fracture predictors assessment.

	Post-transplant fragility fracture	
Predictors	*Odds Ratio [95%CI]*	*p-value*
Age (IQR Increase)*	1.31 (1.02 – 1.69)	0.036
Sex (Female vs Male)	1.53 (0.98 – 2.39)	0.062
Smoking (Never vs Current/Former)	0.72 (0.45 – 1.14)	0.158
Alcohol (Yes vs No)	1.43 (0.93 – 2.20)	0.099
Pre-transplant osteopenia	1.13 (0.73 – 1.73)	0.594
Pre-transplant osteoporosis	2.04 (1.11 – 3.75)	0.021
Pre-transplant fragility fracture	0.89 (0.39 – 2.02)	0.777
Pre-transplant oral steroid use >3 months	0.89 (0.59 – 1.35)	0.895
Post-transplant biopsy-proven acute lung rejection in 1st year	1.19 (0.79 – 1.81)	0.400

CI: confidence interval, IQR: interquartile range
*Comparing age Q3 (67) to Q1 (51)

medications being alendronate (51.3%) and denosumab (33%). Notably, 14.5% of patients on bone metabolism medications experienced fractures either before or after LT.

A pre-LT diagnosis of osteoporosis was associated with a 2.04-fold increased odds of post-LT fractures compared to individuals with normal bone mass (95% CI 1.11-3.75, p=0.021). Compared to patients with age of 53 years (Q1), individuals aged 67 years (Q3) have 32% higher odds of experiencing post-LT fractures (95% CI: 1.03-1.69). Conversely, acute lung rejection episodes within the first year post-LT did not significantly increase the odds of post-LT fractures (95% CI 0.79-1.81, p=0.4) **(Table 3)**.

Conclusion: Osteoporosis and fractures remain significant comorbidities in LT recipients. Pre-LT osteoporosis and age is a strong predictor of post-LT fractures, highlighting the importance of proactive management. Notably, pre-LT fractures, osteopenia, and long term pre-LT steroid use were not associated with an increased risk of post-LT fractures. Acute lung rejection episodes post-LT did not contribute significantly to post-LT fractures. The high incidence of fractures among patients on bone metabolism medications underscores the need for effective prevention and management strategies for LT recipients. These findings emphasize the importance of ongoing vigilance and the development of universal LT osteoporosis management guidelines.

Session Title: Abstracts: Osteoporosis & Metabolic Bone Disease – Basic & Clinical Science

Session Type: Abstract Session

Session Time: 4:00PM–5:30PM

Background/Purpose: Patients with inflammatory rheumatic and musculoskeletal diseases (iRMDs) are at increased risk of osteoporosis and fragility fractures. For this population, whether proton pump inhibitor (PPI) intake contributes to that risk has not yet been definitively answered. Prior studies have yielded conflicting results, did not account for over-the-counter use of PPI, and major confounders were unmeasured. In addition, bone microarchitecture as a potential mediator of fracture risk has not been studied. We studied the effect of regular PPI intake on bone mineral density (BMD) and microarchitecture in patients with iRMDs.

Table. Bone mineral density and trabecular bone score in PPI users and non-users.

Table. Bone mineral density and trabecular bone score in PPI users and non-users.

	PPI use	No PPI use	Contrast	P-value
Crude (unadjusted)				
Left femoral neck T-score	-1.24 (-1.36 to -1.13)	-1.01 (-1.12 to -0.89)	-0.24 (-0.11 to -0.37)	<0.001
Lumbar spine T-score	-0.87 (-1.06 to -0.69)	-0.64 (-0.79 to -0.48)	-0.23 (-0.05 to 0.42)	0.01
Trabecular bone score	1.28 (1.24 to 1.31)	1.30 (1.26 to 1.33)	-0.02 (-0.06 to 0.02)	0.35
Adjusted				
Left femoral neck T-score	-1.24 (-1.36 to -1.13)	-1.08 (-1.27 to -0.88)	-0.17 (-0.35 to 0.01)	0.07
Lumbar spine T-score	-0.87 (-1.06 to -0.69)	-0.62 (-0.83 to -0.41)	-0.25 (-0.47 to -0.04)	0.02
Trabecular bone score	1.28 (1.24 to 1.31)	1.27 (1.24 to 1.31)	0.00 (-0.04 to 0.04)	0.97

Numbers are estimated marginal means and 95% confidence intervals.

Methods: Cross-sectional baseline data from the single center Rh-GIOP cohort were used. Briefly, patients with iRMDs were prospectively enrolled and assessed with DXA scans, laboratory testing, and bone-health-related questionnaires since 2015. Regular PPI and glucocorticoid (GC) use were ascertained by both chart review and patient self-report. Three co-primary outcomes (all reported as T-scores) were defined: BMD of the left femoral neck and the lumbar spine, and the trabecular bone score (TBS). The latter is a measure correlating with lumbar vertebrae's microarchitecture and is measured in a subset. Inverse probability of treatment weighting adjusted for the following confounders: age, sex, body mass index, iRMD type, C-reactive protein, current and cumulative GC dose, NSAID use, smoking, alcohol consumption, functional status (Health Assessment Questionnaire), disease duration, bisphosphonate use, chronic kidney disease stage, presence of diabetes mellitus, and frequency of exercise. We investigated whether dose-response relationships were present ("high dose" of >20mg/d vs. "low dose" of ≤20mg/d pantoprazole equivalent) and conducted an additional analysis with an interaction term for GC use. All analyses were based on linear regression models. Multiple imputation with 100 imputations was used to account for missing data (∼4%). A detailed prespecified statistical analysis plan with a gatekeeping procedure for statistical testing was followed.

Results: 1,495 patients (75.3% women; mean age 62.6 ± 13.1 years; 49.2% with regular PPI use [of those: 63.1% high dose]) were included. Most patients had a diagnosis of rheumatoid arthritis (37.5%), followed by 25.3% connective tissue diseases, 16% vasculitides, 14.2% spondyloarthropathies, and 7% others. 63.8% used GCs (median dose 5mg/d). In both adjusted and unadjusted analyses, PPI users had lower BMD at both the left femoral neck and the lumbar spine (**Table**). Interestingly, differences between PPI users and non-users were only present in the subset of patients concurrently using GCs (data not shown). There was no statistically significant difference in BMD when comparing high and low dose PPI users (all $P \geq 0.52$). TBS (n = 389) was similar in PPI users and non-users (**Table**).

Conclusion: Loss of BMD (seen at both lumbar spine and left femoral neck) rather than impairment of bone microarchitecture seems to be driving the increased fracture risk seen with PPI use in patients with iRMDs. The negative association between PPI use and BMD appears to be dependent on concurrent GC use.

SESSION INFORMATION

Session Date: Tuesday, November 14, 2023

Session Title: Abstracts: Osteoporosis & Metabolic Bone Disease – Basic & Clinical Science

Session Type: Abstract Session

Session Time: 4:00PM–5:30PM

Background/Purpose: Patients with systemic sclerosis (SSc) are at increased risk for osteoporosis (OP) and associated fragility fractures. However, the risks factors and mechanisms driving bone loss in patients with SSc remain elusive. The role of "general" factors such as higher age and low body mass index (BMI) is well established but their interplay with disease-specific factors is unclear. Thus, our objectives in the present study were i) to evaluate the prevalence of clinical OP and fragility fractures in a large population of SSc patients, and ii) to identify potential disease-specific factors for OP in this population. The findings presented in this abstract represent an extended analysis of our previously submitted work, in order to investigate the association between disease severity and osteoporosis in patients with systemic sclerosis.

Methods: This cross-sectional study was based on two large European prospective cohorts of SSc patients with retrospective collection of bone health data. OP was defined as the presence of a T-score below -2.5 at femoral neck or lumbar spine and/or a previous major osteoporotic fracture and/or the prescription of anti-osteoporotic therapy. Long-term therapy with glucocorticoids (GCs) was defined by a daily prednisone equivalent dose above 2.5 mg for more than 3 months. Age, female sex, BMI and treatment with proton pump inhibitors (PPIs) as predefined risk factors according to published evidence, as well as clinically relevant factors associated with a p-value < 0.05 in univariable analyses, after correction for multiple comparison, were implemented into a multivariable logistic regression model.

Results: A total of 932 patients fulfilling the ACR/EULAR 2013 classification criteria were included in the study, followed forward in time at two university hospitals: Lille (n=485) and Berlin (n=447). The two cohorts were studied separately. The prevalence of OP was 32% in Berlin and 23% in Lille (p=0.003), fragility fractures occurred in 22% and 18%, respectively.

Multivariable analysis in the Berlin cohort indicated that higher age (OR 1.05 [95%CI 1.03 to 1.07], p< 0.001), female sex (OR 2.70 [95%CI 1.29 to 5.65], p=0.009), diffuse skin extent (OR 5.03 [95%CI 2.50 to 10.10], p< 0.001), low BMI (OR 0.94 [95%CI 0.88 to 0.99], p=0.009), WHO-FC III-IV dyspnea (OR 2.06 [95%CI 1.16-3.67], p=0.014), receiving GCs (OR 1.78 [95%CI 1.10 to 3.17], p=0.026) or PPIs (OR 1.87 [95%CI 1.10 to 3.17], p=0.020) were associated with OP.

A. Berlin

Determinants	OR	Lower 95CI	Upper 95CI	p value
Age	1.05	1.03	1.07	<0.001
Female sex	2.7	1.29	5.65	0.009
BMI	0.94	0.88	0.99	0.009
Cutaneous diffuse	5.03	2.5	10.1	<0.001
mRSS	0.97	0.93	1	0.11
ILD	1.39	0.83	2.35	0.21
WHO-FC II-IV	2.06	1.16	3.67	0.014
PPIs use	1.87	1.1	3.17	0.02
GCs use	1.78	1.1	3.17	0.026

B. Lille

Determinants	OR	Lower 95CI	Upper 95CI	p value
Age	1.06	1.04	1.08	<0.001
Female sex	1.32	0.7	2.52	0.39
BMI	0.98	0.93	1.02	0.30
Cutaneous diffuse	0.99	0.53	1.84	0.98
ILD	1.00	0.55	1.81	0.99
ATA	2.22	1.18	4.16	0.013
DMARDs use	1.06	0.59	1.92	0.85
PPIs use	1.25	0.68	2.23	0.47
GCs use	4.48	2.42	8.26	<0.001

Figure 1. Factors associated with OP in two cohorts of SSc patients. (A) Berlin (n=447), (B) Lille (n=485). Forest plots indicate Odds ratio (OR) with lower and upper 95%CI (confidence interval). ATA: Anti-topoisomerase I antibodies; BMI: body mass index; DLCO: diffusing capacity for carbon monoxide; GCs: Glucocorticoids; ILD: interstitial lung disease; mRSS: modified Rodnan Skin Score; PPIs: Proton pump inhibitors; WHO-FC: WHO functional class.

In the Lille cohort, multivariable analysis confirmed the association of OP with higher age (OR 1.06 [95%CI 1.04 to 1.08], p< 0.001), GCs use (OR 4.48 [95%CI 2.42 to 8.26], p< 0.001), and with anti-topoisomerase I antibody positivity (OR 2.22 [95%CI 1.18 to 4.16], p=0.013).

Conclusion: Our data support a multifactorial etiopathogenesis of OP in SSc: besides common risk-factors for OP such as higher age, female sex, and BMI, several disease specific characteristics were associated with OP, such as SSc severity as reflected by diffuse skin extent and presence of antitopoisomerase I antibodies as well as severe dyspnea and SSc treatment (PPIs and GCs). These findings help to identify patients with SSc at particular risk for OP in clinical practice.

Real-world Evidence for Assessing Mortality Disparity Between the Patients with Rheumatoid Arthritis and the General Population in Japan: Results from the IORRA Study

Naohiro Sugitani[1], Eiichi Tanaka[2], Eisuke Inoue[3], Mai Abe[1], Eri Sugano[1], Kumiko Saka[1], Moeko Ochiai[4], Rei Yamaguchi[1], Katsunori Ikari[5], Ayako Nakajima[6], Hisashi Yamanaka[7] and Masayoshi Harigai[8], [1]Division of Rheumatology, Department of Internal Medicine, Tokyo Women's Medical University School of Medicine, Shinjunku-ku, Japan, [2]Division of Rheumatology, Department of Internal Medicine, Tokyo Women's Medical University School of Medicine, Tokyo, Japan, [3]Research Administration Center, Showa University, Shinagawa-ku, Japan, [4]Division of Rheumatology, Department of Internal Medicine, Tokyo Women's Medical University School of Medicine, Shinjunku-ku, Japan, [5]Tokyo Women's Medical University School of Medicine, Tokyo, Japan, [6]Center for Rheumatic Diseases, Mie University Hospital, Tsu city, Japan, [7]Sanno Medical Center, Tokyo, Japan, [8]Tokyo Women's Medical University, Division of Rheumatology, Department of Internal Medicine, Tokyo, Japan

SESSION INFORMATION

Session Date: Tuesday, November 14, 2023

Session Title: Abstracts: Patient Outcomes, Preferences, & Attitudes II: Patient Experience

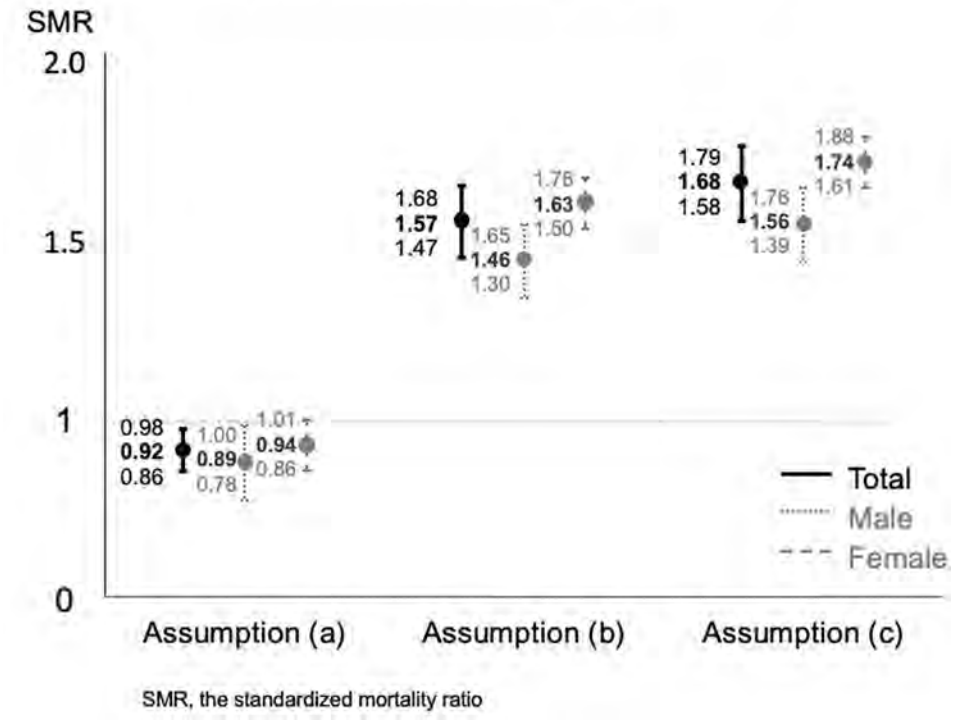
Session Type: Abstract Session

Session Time: 4:00PM–5:30PM

Background/Purpose: Patients with rheumatoid arthritis (RA) have been reported to have higher mortality rates than the general population. Our previous report showed that the standardized mortality ratio (SMR) of Japanese patients with RA registered in the Institute of Rheumatology, Rheumatoid Arthritis (IORRA) cohort between 2000 and 2007 was 1.46-1.90 (Nakajima A. Scand J Rheumatol 2010). Since the introduction of various biological disease-modifying anti-rheumatic drugs (bDMARDs) in Japan after 2007, the mortality rates have declined(Abhishek A. Rheumatology 2018), but it is unclear if the mortality disparity with the general population has decreased. Our study aims to investigate the mortality and its risk factors of Japanese patients with RA since 2007.

Methods: The IORRA cohort is an observational study of patients with RA established in 2000 at Tokyo Women's Medical University. We observed RA patients who participated in the IORRA survey from October 2007 to September 2020 until October 1, 2021. Since there is no National Death Registry in Japan, we obtained death reports from residual families who responded to our mail query, from affiliated hospitals' physicians, and from police if a dead patient was found outside of a hospital. The primary endpoint was to calculate SMR using the person-year method with the Japanese general population data as a reference from the Ministry of Health, Labour, and Welfare, Japan. Cases lost to follow-up were treated using

Figure. 1 The results of the standardized mortality ratio (SMR) analysis.



These are the results of the sensitivity analysis of the standardized mortality ratio (SMR). The adjusted SMRs were calculated by taking into account the supplementation of lost-to-follow-up cases. (a) Adjusted SMR assumed that all untraceable cases were alive. (b) Adjusted SMR assumed that the untraceable cases had the same mortality rate as tractable cases. (c) Adjusted SMR assumed that the untraceable cases were 1.65 times more likely to die than the traceable cases.

multiple imputation methods as a sensitivity analysis of SMR. The secondary endpoints were to examine the risk factors for death using the time-dependent Cox proportional hazards model.

Results: Among 10,613 patients with RA (female, 83.7%; mean age, 57.1±14.1 years; mean disease duration, 9.8 ±9.6 years; mean observation period, 9.4±4.2 years) who enrolled in the IORRA survey from October 2007 to September 2020, 3,284 (30.9%))were lost to follow up. During the observation period, which covered 99,364.8 person-years, 915 deaths were reported. The leading causes of death were malignancies (28%), respiratory involvement (22%), and cardiovascular disorders (12%). The SMR (95% confidence interval), assuming that all lost-to-follow-up patients were alive, was 0.92 (0.86-0.98). When it was assumed that lost-to-follow-up patients had the same mortality rate as the remaining patients, the SMR was 1.57 (1.47–1.68). Alternatively, when it was assumed that the mortality rate of lost-to-follow-up patients was 1.65 times as high as that of the remaining patients based on the previous report (Kauppi M, J Rheumatol 2005), the SMR was 1.68 (1.58-1.79) (Figure 1). Factors associated with increased mortality included male sex, older age, history of smoking, higher disease activity score in 28 joints (DAS28), higher Japanese version of the health assessment questionnaire (J-HAQ) score, corticosteroid use, and presence of interstitial lung disease. Conversely, factors associated with decreased mortality included methotrexate (MTX) use and bDMARDs use (Table 1).

Conclusion: The mortality in patients with RA has remained consistently poor since 2007 when compared to the general population. MTX and bDMARDs use may reduce the risk of death.

Table. 1 Risk factors associated with mortality in patients with rheumatoid arthritis based on clinical, medication, and comorbidities.

A Novel Approach for Mixed-methods Research Using Language Learning Models: A Report Using Patients' Perspectives on Barriers to Hip and Knee Replacement

Insa Mannstadt[1], Susan Goodman[1], Mangala Rajan[2], Sarah Young[3], Fei Wang[2], Iris Navarro-Millán[4] and Bella Mehta[5], [1]Hospital for Special Surgery, New York, NY, [2]Weill Cornell Medicine, New York, NY, [3]Binghamton University, Binghamton, NY, [4]Weill Cornell Medicine, Hospital for Special Surgery, New York, NY, [5]Hospital for Special Surgery, Weill Cornell Medicine, New York, NY

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: Abstracts: Patient Outcomes, Preferences, & Attitudes II: Patient Experience
Session Type: Abstract Session
Session Time: 4:00PM–5:30PM

Background/Purpose: While qualitative research techniques provide valuable insights into patient experiences and perceptions, analyzing textual data from interviews can be time consuming and require multiple analysts for concept triangulation. Triangulation in qualitative data analysis minimizes potential biases that stem from relying on a single investigator. This approach enhances the credibility and validity of the findings by corroborating information from various perspectives and investigators. The capability of Large Language Model (LLM) technology to identify patterns and themes in textual data offers potential for conducting independent analysis of patients perceptions of care. This study explored a novel approach to triangulation in mixed-methods research (MMR) by employing ChatGPT-4, an LLM, for analyzing data from interviews of patients with advanced arthritis facing barriers to joint replacement.

Methods: We compared the thematic analysis and survey generation between investigators and ChatGPT-4, an AI-powered natural language processing tool that utilizes Generative Pre-trained Transformer (GPT), a type of large language model (LLM), as its core model. We used qualitative data from an existing qualitative study that explored patient perceptions of barriers to joint replacement utilization. Textual data from six semi-structured interviews were analyzed by human investigators and ChatGPT-4 independently. Human investigators used NVivo software to analyze the data and generate the codes and themes that emerged. Once the analysis was completed and it was determined that thematic saturation had been achieved, we proceeded to utilize ChatGPT-4 to directly generate themes from the interview transcripts. Both, human investigators and ChatGPT-4 independently, used the themes to create a survey. We compared the investigator-generated themes and survey with those generated by ChatGPT-4.

Results: ChatGPT-4 generated analogous dominant themes and a comprehensive corresponding survey as the human investigators but in significantly less time. (**Table 1**) Human-led thematic analysis produced 6 themes and 30 survey questions, taking significant time. ChatGPT-4 generated the same themes in under 45 minutes and created 17 survey questions in less than 1 minute. Themes generated by ChatGPT-4 covered the same topics as human-generated themes. However,

Table 1: Comparison of human- and ChatGPT-4 generated themes and surveys regarding barriers to arthroplasty. Check marks indicate matched and italicized lines indicate unmatched questions between groups. *

Human-Generated Themes and Survey Questions	ChatGPT-4 Generated Themes and Survey Questions
Theme 1: Cost	**Theme 1: Financial barriers**
✓ Cost of a joint replacement	✓ How concerned are you about the cost of arthroplasty surgery?
✓ Cost of the co-pay for a joint replacement	✓ How concerned are you about copays for specialist visits related to arthroplasty surgery?
✓ Cost of a co-pay for physical therapy after joint replacement	
Theme 2: Physician	**Theme 2: Lack of trust in healthcare system**
✓ Finding a surgeon I trust	✓ How much trust do you have in your surgeon's expertise and success rate?
o Figuring out how to find a qualified and experienced surgeon	
o Finding a surgeon who understands what I need	
Theme 3: Trust/pride	**Theme 3: Personal responsibility and social isolation**
✓ Not having trust in any doctors or hospitals	✓ How much assistance and support do you think you will need during recovery from arthroplasty?
o Having someone I know have a bad result from a joint replacement	✓ How much caregiving responsibility do you have for family members?
o Already had a bad experience with a joint replacement	o How difficult do you find it to accept help during recovery from arthroplasty surgery?
o Already having bad experiences with other surgery or medical procedures	o How satisfied are you with the social support you currently receive?
o Having people to see me using a cane or walker	
Theme 4: Timing	**Theme 4: Lack of information**
✓ Not having enough information to decide about having a joint replacement	o How much information do you have about the specific procedures involved in arthroplasty surgery?
o Having a joint replacement is the last resort, and I think I should wait longer	
o Having many medical problems and having a joint replacement is not a priority now	
o Being too young to undergo joint replacement surgery	
o Being too old to undergo joint replacement surgery	
o Not doing everything I can do (like lose weight) to avoid having a joint replacement	
o Not having bad enough joint pain to have a joint replacement	
Theme 5: Procedure-specific concerns	**Theme 5: Fear and uncertainty about procedure**
✓ Fear that I will need another joint replacement after the first one because I am young	✓ How uncertain are you about the potential complications of arthroplasty surgery?
✓ Fear that a joint replacement will not help me walk and function better	✓ How fearful are you about undergoing arthroplasty surgery?
✓ Fear that the joint replacement will not improve my pain	✓ How skeptical are you about the long-term benefits of arthroplasty surgery for managing pain?
o Fear of needles	o How satisfied are you with current treatments for managing arthritis?
Theme 6: Recovery	**Theme 6: Challenges during recovery**
✓ Availability of someone to help me recover from a joint replacement	✓ How concerned are you about the healing process after arthroplasty surgery?
✓ Availability to take care of my family/friends while I undergo joint replacement surgery	✓ How accessible do you think comprehensive physical therapy services are for arthroplasty patients?
✓ Accessing transportation to get to physical therapy appointments	✓ How concerned are you about the need for multiple surgeries every 20 years?
✓ Finding good physical therapy centers in my community	o How concerned are you about the duration of recovery after arthroplasty surgery?
✓ Concerns about how hard the recovery after a joint replacement will be	
o Concern of being healthy enough to undergo joint replacement surgery	
o Taking care of myself after a joint replacement because my building doesn't have an elevator	

*Check marks signify that the question was successfully matched in the alternative method of survey generation, whereas circles indicate that the question was not matched.

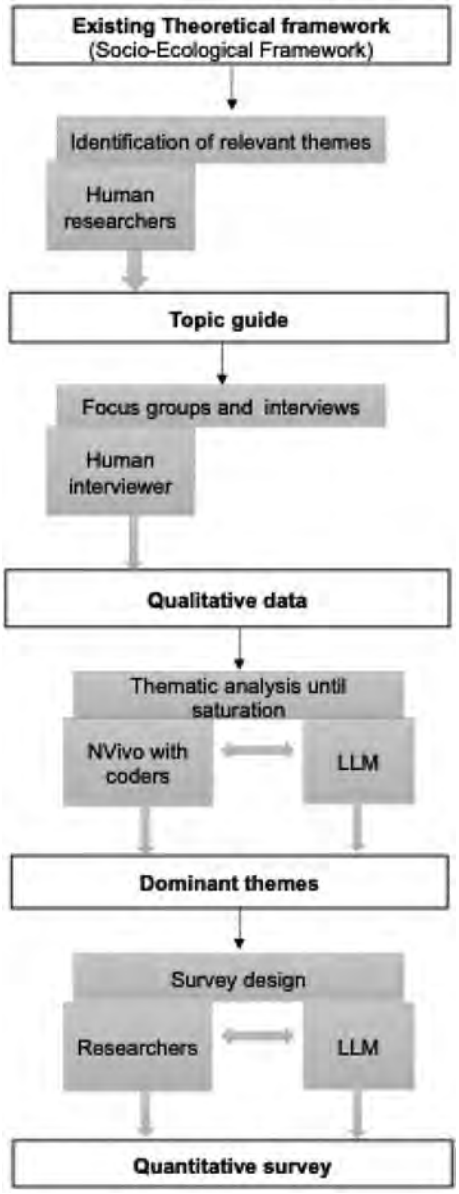

Figure 1: Mixed methods with Large Language Model (LLM) and human investigators for qualitative research

ChatGPT-4's survey questions were shorter and less specific compared to human-generated questions. The **Figure 1** mixed-methods flowchart proposes integrating LLMs alongside human investigators as a supplementary tool for the preliminary thematic analysis of qualitative data and survey generation.

Conclusion: The potential of ChatGPT-4 as a tool for assisting in triangulation was evident in both the qualitative portion of mixed methods research (MMR) by assisting with thematic analysis, and in the quantitative portion of MMR by facilitating survey development. This integration may improve the overall workflow efficiency of MMR. Given the novelty of LLM technology and the limited research on its embedded biases, investigators must consider the ethical and qualitative implications when using LLMs for research purposes.

Abstract Number: 2535

Strategies to Embrace Living with Lupus Fearlessly (SELF): A Promising Digital Intervention for Lupus Self-Management

Katherine Carpenter[1], **Melissa French**[2], Sarah Gilman[3], Sara Johnson[4], Patricia Castle[4], S. Sam Lim[5], Charmayne Dunlop-Thomas[5], Melicent Miller[1] and Mary Crimmings[1], [1]Lupus Foundation of America, Washington, DC, [2]Lupus Foundation of America, Alexandria, VA, [3]Wayfinder Health Strategies, Falls Church, VA, [4]Pro-Change Behavior Systems, Inc., Narragansett, RI, [5]Emory University, Atlanta, GA

SESSION INFORMATION

Session Date: Tuesday, November 14, 2023

Session Title: Abstracts: Patient Outcomes, Preferences, & Attitudes II: Patient Experience

Session Type: Abstract Session

Session Time: 4:00PM–5:30PM

Background/Purpose: The Lupus Foundation of America (LFA) has engaged in a 5-year cooperative agreement with the Centers for Disease Control and Prevention to implement a digital lupus self-management (SM) intervention based on the Transtheoretical Model of Change. Strategies to Embrace Living with Lupus Fearlessly (SELF) is designed to help users adopt 4 key lupus SM behaviors shown to have the highest impact on health and functional status: managing symptoms, managing stress, managing medications, and working with your healthcare team (each behavior includes 3-5 skills).

Methods: SELF offers user-tailored SM activities, symptom/medication trackers, a journal, links to LFA educators/peer support, and tailored text message tips. Onboarding and 90-day follow-up assessments collect demographics, stage of change for the 4 key SM behaviors , and patient-reported outcomes (PROs) such as measures of physical and mental health. Users select one SM behavior as a focus for a 2-week period. Activities are tailored to stage of change for that focus behavior. Users 'master a skill' if they improve from a skill-building stage at onboarding to a mastery stage at follow-up (Figure 1).

SELF was launched in January 2022 and promoted to people with lupus (PWL) via LFA and a patient registry. Utilization and outcomes were evaluated in January, 2023 for users who registered during the prior year.

Results: A total of 3,427 PWL registered for SELF, and 51% completed the onboarding assessment (n=1742) to gain access to the program.

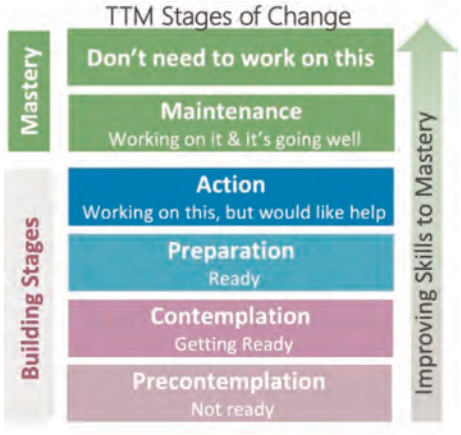

Figure 1. Transtheoretical Model of Change (TTM) is shown with stages of change and progression of improvement to mastery.

Table 1. User demographics are shown for three distinct groups: Enrollment disengagers (people who registered for SELF but did not complete the onboarding assessment), SELF users who did not complete a 90-day follow-up assessment and SELF users who completed a 90-day follow-up assessment.

	Enrollment Disengagers	SELF Users without Follow-up Assessment	SELF Users with Follow-up Assessment
N	1685	1569	173
Gender Identity	94.4% female 4.7% male 0.9% other	95.6% female 3.6% male 0.8% other	94.8% female 3.4% male 1.8% other
Age	46.5	45.9	51.4
Years Since Diagnosis	8.6	9.6	12.7
Race and Ethnicity			
White, non-Hispanic	51.7%	53.8%	44.2%
Black, non-Hispanic	21.8%	22.8%	38.4%
Hispanic	16.1%	13.9%	8.1%
Other/multi-racial	4.6%	4.8%	4.1%
Asian	2.3%	3.7%	2.9%
No answer	3.4%	1.0%	2.3%

Among SELF users for whom follow-up data were available (n=173), 46% (n=79) mastered 1 or more SM skills with many users mastering more (Figure 2); 52% experienced less fatigue ($p < .001$, $d = 0.33$); 37% reported better overall physical health ($p = .007$, $d = 0.22$); 41% reported better mental health ($p = .001$, $d = 0.28$); 59% improved medication adherence ($p = .004$, $d = 0.36$); and 59% improved doctor-patient communication ($p = .035$, $d = 0.16$). For those who did not complete a follow-up assessment (n-1569), the impact of SELF cannot be known, but users completed 8.1 SM activities on average (range = 0 - 224). Enrollment disengagers (n=1685) did not complete the onboarding assessment. The engagement groups were similar (demographics in Table 1), but those who completed follow-up assessments had a higher average age, longer duration since diagnosis, and a higher percentage of Black, non-Hispanic users.

Figure 2. Among SELF users who completed the follow-up assessment, 46% mastered one or more additional SM skills. Across the 4 key SM behaviors, SELF users improved the % of skills mastered from onboarding assessment to follow-up assessment in every category.

Conclusion: Improvements to SM skill development and PROs show that SELF is a promising program for building skills and impacting outcomes for PWL. Low engagement at onboarding and follow-up assessments indicates a need to ease response burden. While results need more study, it is notable that more users who completed the follow-up assessment were Black, a group historically experiencing greater health disparities.

Acknowledgement: The authors are grateful for the support of Kamil Barbour, Public Health Advisor for the Centers for Disease Control and Prevention.

Abstract Number: 2536

DMARD Adherence During the COVID-19 Pandemic and Association with Risk of COVID-19 Infection

Tanya Selvam, Kelli Peterman, Arezoo Haghshenas and Lucy Liu, Kaiser Permanente Northern California, Oakland, CA

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: Abstracts: Patient Outcomes, Preferences, & Attitudes II: Patient Experience
Session Type: Abstract Session
Session Time: 4:00PM–5:30PM

Background/Purpose: The COVID-19 pandemic affected medication adherence in patients with autoimmune disease (AD) due to their fear of contracting COVID-19, financial hardship, and medication shortage. We compared adherence to disease-modifying antirheumatic drugs (DMARDs) before, during, and after the COVID-19 pandemic among patients with AD and evaluated whether adherence affected the risk of contracting COVID-19.

Methods: This retrospective study included patients aged ≥18 years in a large integrated healthcare system during 2019-2021, who had ICD-coded diagnoses of AD and ≥2 DMARDs prescriptions dispensed by outpatient pharmacy. DMARDs were classified as synthetic (sDMARDs) or biologic (bDMARDs). Medication adherence was measured by the Medication Possession Ratio (MPR), with adherence defined as MPR ≥80%. Adherence during the pre-pandemic year (March 19, 2019 to March 18, 2020), pandemic year (March 19, 2020 to March 18, 2021), and vaccine era (March 19, 2021 to September 18, 2021) were compared using the Wilcoxon test. Multivariable logistic regression was used to examine the association of treatment adherence and risk of COVID-19, reporting odds ratios (OR) and 95% confidence intervals (CI), adjusted for age, sex, race and ethnicity, primary language, smoking, weight category, and presence of other chronic health conditions.

Results: The cohort included 7959 patients with AD; 77.2% were female, 46.4% were White, 21.3% Hispanic, 19.2% Asian/Pacific Islander (PI), and 10.7% Black race. The most common AD diagnoses were rheumatoid arthritis (62.8%), psoriatic arthritis (12.8%), and lupus (18.3%). The most commonly prescribed sDMARDs were methotrexate (51.5%), hydroxychloroquine (45.8%), and leflunomide (17.3%), while the most commonly prescribed bDMARDs were tofacitinib (14.3%), TNF inhibitors (7.7%), and abatacept (2.9%). The majority were receiving sDMARD monotherapy (69.8%), followed by combination sDMARD and bDMARD therapy (24.4%), bDMARD monotherapy (3.6%), and sDMARD triple therapy (3.6%). Of patients prescribed sDMARDs, 72% were adherent in the pre-pandemic year, 66% in the pandemic year, and 68% in the vaccine era. Of patients prescribed bDMARDs, 48% , 44%, and 53% were adherent in the pre-pandemic, pandemic, and

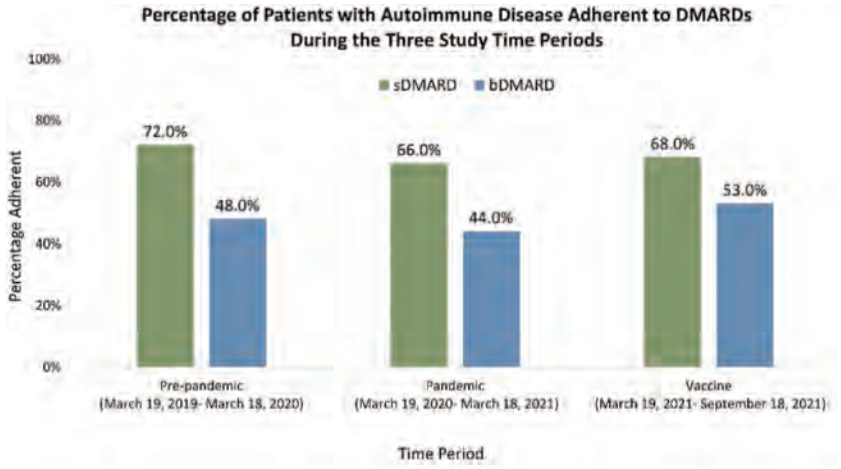

Figure 1. Percentage of Patients with Autoimmune Disease Adherent to DMARDs During the Three Study Time Periods

Table 1. Cohort Characteristics

Characteristics	N (%)
Female	6147 (77.2%)
Age (years)	
<40	1042 (13.1%)
40-49	1322 (16.6%)
50-59	2270 (28.5%)
60-69	1865 (23.4%)
70+	1460 (18.3%)
Race/Ethnicity	
Asian/Pacific Islander	1529 (19.2%)
Black	850 (10.7%)
Hispanic	1697 (21.3%)
Other/Unknown	192 (2.4%)
White	3691 (46.4%)
Rheumatologic Diagnosis	
Rheumatoid arthritis	4997 (62.8%)
Psoriatic arthritis	1022 (12.8%)
Spondyloarthritis	259 (3.3%)
SLE	1459 (18.3%)
Vasculitis	124 (1.6%)
Myositis	220 (2.8%)
Scleroderma	174 (2.2%)
Others	187 (2.5%)

vaccine era. Differences in adherence between the time periods were statistically significant ($p< 0.01$) for both sDMARDs and bDMARDs. Adherence to sDMARDs was associated with lower risk of COVID-19 infection (OR 0.73, 95% CI 0.60-0.88), adjusting for covariates. Similar findings were seen for adherence to bDMARDs (OR 0.56, 95% CI 0.34-0.94).

Conclusion: In a large population of patients with AD, medication adherence, particularly to bDMARDs, was low even pre-pandemic and decreased further during the pandemic, but subsequently increased in the vaccine era. Medication adherence was associated with lower risk of COVID-19 infection. These findings support efforts to reduce barriers to medication adherence, including addressing patient concerns regarding infection risk. Future studies should examine whether there is an association between poor medication adherence and severity of COVID-19 infection and outcomes.

Disclosure: T. Selvam: None; **K. Peterman**: None; **A. Haghshenas**: None; **L. Liu**: None.

Implementation of a Best Practice Advisory to Improve Infection Screening Prior to New Prescriptions of Biologics and Targeted Synthetic Drugs

Hailey Baker[1], Rebecca Fine[1], Fenn Suter[2], Heather Allore[3], Betty Hsiao[4], Vaidehi Chowdhary[5], Elizabeth Lavelle[6], Ping Chen[6], Richard Hintz[6], Lisa Suter[7] and Abhijeet Danve[8], [1]Yale New Haven Hospital, New Haven, CT, [2]Georgetown University, Washington, DC, [3]Yale University, Yale School of Medicine, New Haven, CT, [4]Yale-New Haven Medical Center, New Haven, CT, [5]Yale University, New Haven, CT, [6]Yale New Haven Health, New Haven, CT, [7]Yale School of Medicine, New Haven, CT, [8]Yale University School of Medicine, Glastonbury, CT

SESSION INFORMATION

Session Date: Tuesday, November 14, 2023

Session Title: Abstracts: Patient Outcomes, Preferences, & Attitudes II: Patient Experience

Session Type: Abstract Session

Session Time: 4:00PM–5:30PM

Background/Purpose: Biologic and targeted synthetic DMARDs (b/tsDMARDs) are widely used to treat patients with various autoimmune inflammatory diseases (ARD). Use of a b/tsDMARD in patients with pre-existing tuberculosis (TB), hepatitis B (HBV), or hepatitis C (HCV) can lead to significant morbidity and mortality. Many national and international societies recommend screening for one or all of these exposures prior to initiation of certain b/tsDMARDs. However, recommended timing intervals of screening are not clear and adherence to these recommendations varies widely. This quality improvement initiative focused on improving screening for TB, HBV, and HCV prior to new prescription of a b/tsDMARD using a best practice advisory (BPA) in the electronic health records (EHR).

Methods: Patients aged 18 years or older with at least one visit with a clinician (attending, fellow, or APRN) in the section of Rheumatology in the designated time frame were included. Upon a new prescription of a b/tsDMARD, clinicians were alerted via a BPA pop-up in the EHR about the last available results if any, for TB, HBV, and HCV, and allowed for quick ordering as appropriate. This BPA was implemented on December 1, 2020. Baseline screening proportions for TB (QuantiFERON), HBV, and HCV for patients prescribed a new b/tsDMARD from October 1, 2017 to November 30, 2020 (pre-BPA period) were compared with those of patients with prescriptions from December 1, 2020 to March 3, 2022 (post-BPA period).

Results: A total of 711 patients pre-BPA and 257 patients post-BPA implementation were included in the study. The BPA implementation was associated with statistically significant improvement in screening for TB, HBsAg, HBcAb, and HCV Ab or HCV viral load (Table 1). Partial hepatitis B testing (screening for HBcAb or HBsAg) was significantly changed by the BPA (pre-BPA 364 of 711 (51%) vs post-BPA 186 of 257 (72%), p=< 0.001). Complete hepatitis B testing (screening for both HBcAb and HBsAg) also improved after BPA implementation (pre-BPA 222 of 711 (31%) vs post-BPA 127 of 257 (49%), p< 0.001). A total of 154 patients (22%) in the pre-BPA and 117 patients (46%) in the post-BPA periods were appropriately screened for all three infectious diseases, which was statistically significant (p< 0.001). Multivariable logistic analysis revealed in the pre-BPA period, relative to attending physicians, fellows were significantly more likely to order testing (HBcAb p=< 0.001, HBsAb p=< 0.001, HBsAg p=0.005, partial Hep B testing p=0.006, complete Hep B testing p=< 0.001, HCV Ab or HCV RNA p=0.002, all four tests p=< 0.001) after accounting for multiple comparisons. In the pre-BPA period, each year of age decreased the adjusted odds of TB testing by 2% (OR 0.98; 95% CI 0.97, 1.0; p=0.006) and males had lower adjusted odds for HBcAb testing than females (OR 0.58; 95% CI 0.39, 0.85). In the post-BPA period, there were no statistically significant findings for any patient or clinician variable.

Conclusion: Implementation of a BPA in the EHR can improve infectious disease screening for patients with ARD initiating b/tsDMARDs and has potential to improve patient safety and eliminate screening discrepancies.

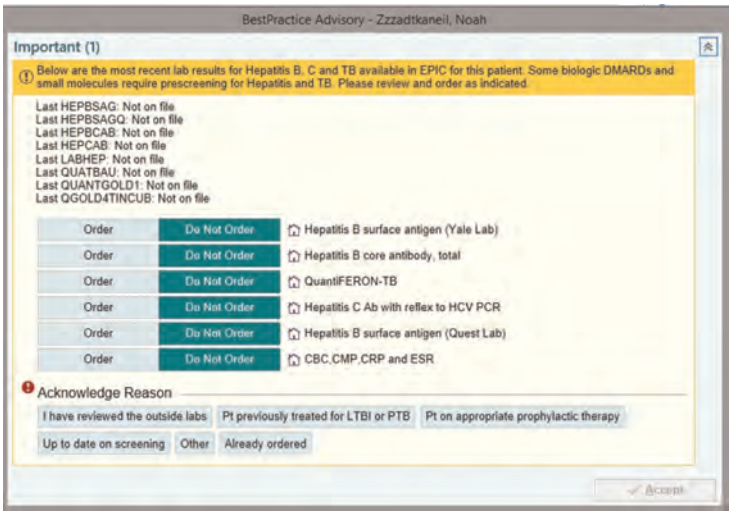

Figure 1 is a visualization of the finalized BPA after subsequent PDSA cycles identified areas of improvement in the clinical decision support system. This final version of the BPA includes seven lab result components at the top, five options for quick ordering of infectious disease screening, four lab components for general monitoring while on drug therapy (CBC, CMP, CRP, and ESR), and five acknowledgement reasons for why a clinician is or is not ordering the labs. TB= "Tuberculosis"; HCV="hepatitis C virus"; PCR= "polymerase chain reaction"; LTBI = "latent tuberculosis infection"; PTB = "pulmonary tuberculosis"; HEPBSAG= "Hepatitis B surface Antigen"; HEPBSAGQ= "Hepatitis B surface Antigen, Quest Diagnostics"; HEPBCAB="Hepatitis B core Antibody"; LABHEP= represents multiple test components for Hepatitis C; HEPCAB="Hepatitis C Antibody"; QUATBAU= "TB QuantiFERON Gold"; QUANTGOLD1= "TB QuantiFERON Gold"; QGOLD4TINCUB= "TB QuantiFERON Gold"

Table 1 includes descriptive statistics of the study population pre-BPA (10/1/2017 – 11/30/2020) and post-BPA (12/1/2020 – 3/3/2022) implementation. A Bonferroni correction was used to correct for multiple comparisons and reduce risk of false positive results, which is represented by the Q-values. BPA="best practice advisory"; TNF= "Tumor necrosis factor"; CTLA4= "cytotoxic T-lymphocyte associated protein 4"; IL-17= "Interleukin 17"; IL-6= "Interleukin 6"; JAK= "Janus kinase inhibitor". Inflammatory arthritides included rheumatoid arthritis, psoriatic arthritis, ankylosing spondylitis, and Adult-onset Still's disease. Connective tissue diseases included were systemic lupus erythematosus, Sjogren's syndrome, mixed connective tissue disease, and systemic sclerosis. Vasculitides included anti-neutrophil cytoplasmic autoantibody (ANCA)-associated vasculitis, Bechet's disease, giant cell arteritis, and Takayasu arteritis. The "Other" category included diagnoses for polymyalgia rheumatica and Familial Mediterranean Fever.

Table 1. Description of study population pre- and post-best practice advisory (BPA)

	Pre-BPA (N=711)	Post-BPA (N=257)	P-value	Q-value

Other N (%)	39 (5)	21 (8)		

Table 2 displays observed screening rates of TB, HBV, and HCV before and after the initiation of the BPA on 12/1/2020. Partial Hep B testing was defined as having either HBsAg or HBcAb, but not both. Complete Hep B testing was defined as having both HBsAg and HBcAb. To be considered as having testing of "All Four Tests" a patient had to have QuantiFERON Gold, HBsAg, HBcAb, and HCV Ab or HCV quantitative RNA performed within the specified time. We used a Bonferroni correction to correct for multiple comparisons and reduce risk of false positive results, which is represented by Q-values. BPA= "Best Practice Advisory"; TB= "Tuberculosis"; HBsAb= "Hepatitis B surface antibody"; HBcAb= "Hepatitis B core antibody"; HBsAg= "Hepatitis B surface antigen"; HCV= "Hepatitis C virus"; HBV= "Hepatitis B virus." *Q-value=<0.001 **Q-value=>0.9

Table 2. Comparison of screening rates of TB, HBV and HCV tests captured pre-BPA and post-BPA

	Pre-BPA (N=711)	Post-BPA (N=257)	P-value
TB, N (%)	467 (66)	210 (82)	<0.001*
HBsAb, N (%)	196 (28)	73 (28)	0.8**
HBcAb, N (%)	224 (32)	132 (51)	<0.001*
HBsAg, N (%)	362 (51)	181 (70)	<0.001*
HCV Ab or HCV RNA, N (%)	424 (60)	202 (79)	<0.001*
Partial Hep B, N (%)	364 (51)	186 (72)	<0.001*
Complete Hep B, N (%)	222 (31)	127 (49)	<0.001*
All four tests, N (%)	154 (22)	117 (46)	<0.001*

SESSION INFORMATION

Session Date: Tuesday, November 14, 2023

Session Title: Abstracts: Patient Outcomes, Preferences, & Attitudes II: Patient Experience

Session Type: Abstract Session

Session Time: 4:00PM–5:30PM

Background/Purpose: Psoriasis and type 2 diabetes mellitus (T2D) may share common underlying pathophysiology, in which the pathogenesis of psoriasis is mediated by NOD-like receptor family pyrin domain-containing inflammasome (NLRP)-dependent inflammatory pathways that is a target of sodium-glucose co-transporter 2 inhibitors (SGLT2i). The aim of the present study was to investigate whether treating psoriasis patients with concomitant T2D using SGLT2i improves clinical outcomes compared to similar line oral antidiabetic medications.

Methods: This was a population-based cohort study between 2014 and 2023 that included psoriasis patients with concomitant T2D from 92 hospitals across the United States. The risk of psoriasis-related comorbidities and general medical outcomes in patients treated with SGLT2i was compared with that in 1:1 propensity score-matched psoriasis patients with T2D on dipeptidyl peptidase 4 inhibitors (DPP4i). Hazard ratios (HRs) were estimated using Cox proportional hazards regression.

Results: After propensity-score matching, there were 17,085 patients with psoriasis and concomitant T2D on SGLT2i. Compared to those using DPP4i, patients on SGLT2i presented with a significantly lowered risk of incident cardiorenal complications including myocardial infarction (HR: 0.84, 95% CI: 0.74, 0.95), acute kidney failure (HR: 0.68, 95% CI: 0.63, 0.73), and chronic kidney disease (HR: 0.73, 95% CI: 0.69, 0.77), and a significantly lowered risk of incident emergency visits (HR: 0.82, 95% CI: 0.78, 0.85) over a mean follow-up period of six years. The risk of psoriatic arthritis (HR: 1.04, 95% CI: 0.98, 1.10), metabolic syndrome (HR: 1.15, 95% CI: 0.96, 1.39), stroke (HR: 0.93, 95% CI: 0.83, 1.04), amputation of the lower limb (HR: 0.78, 95% CI: 0.42, 1.47), and hospitalization (HR: 0.88, 95% CI: 0.76, 1.02) was not significantly different between SGLT2i and DPP4i users. Diabetic ketoacidosis (HR: 1.602, 95% CI: 1.21, 2.12) was a potential adverse event of SGLT2i.

Conclusion: Among patients with psoriasis and concomitant T2D, SGLT2i use was associated with a significantly decreased risk of incident cardiorenal events and emergency visits and did not trigger psoriasis-related comorbidities including psoriatic arthritis. Further research, including clinical trials are warranted to validate the findings.

SESSION INFORMATION

Session Date: Tuesday, November 14, 2023

Session Title: Abstracts: RA – Treatments III: Predictors of Response & Tapering

Session Type: Abstract Session

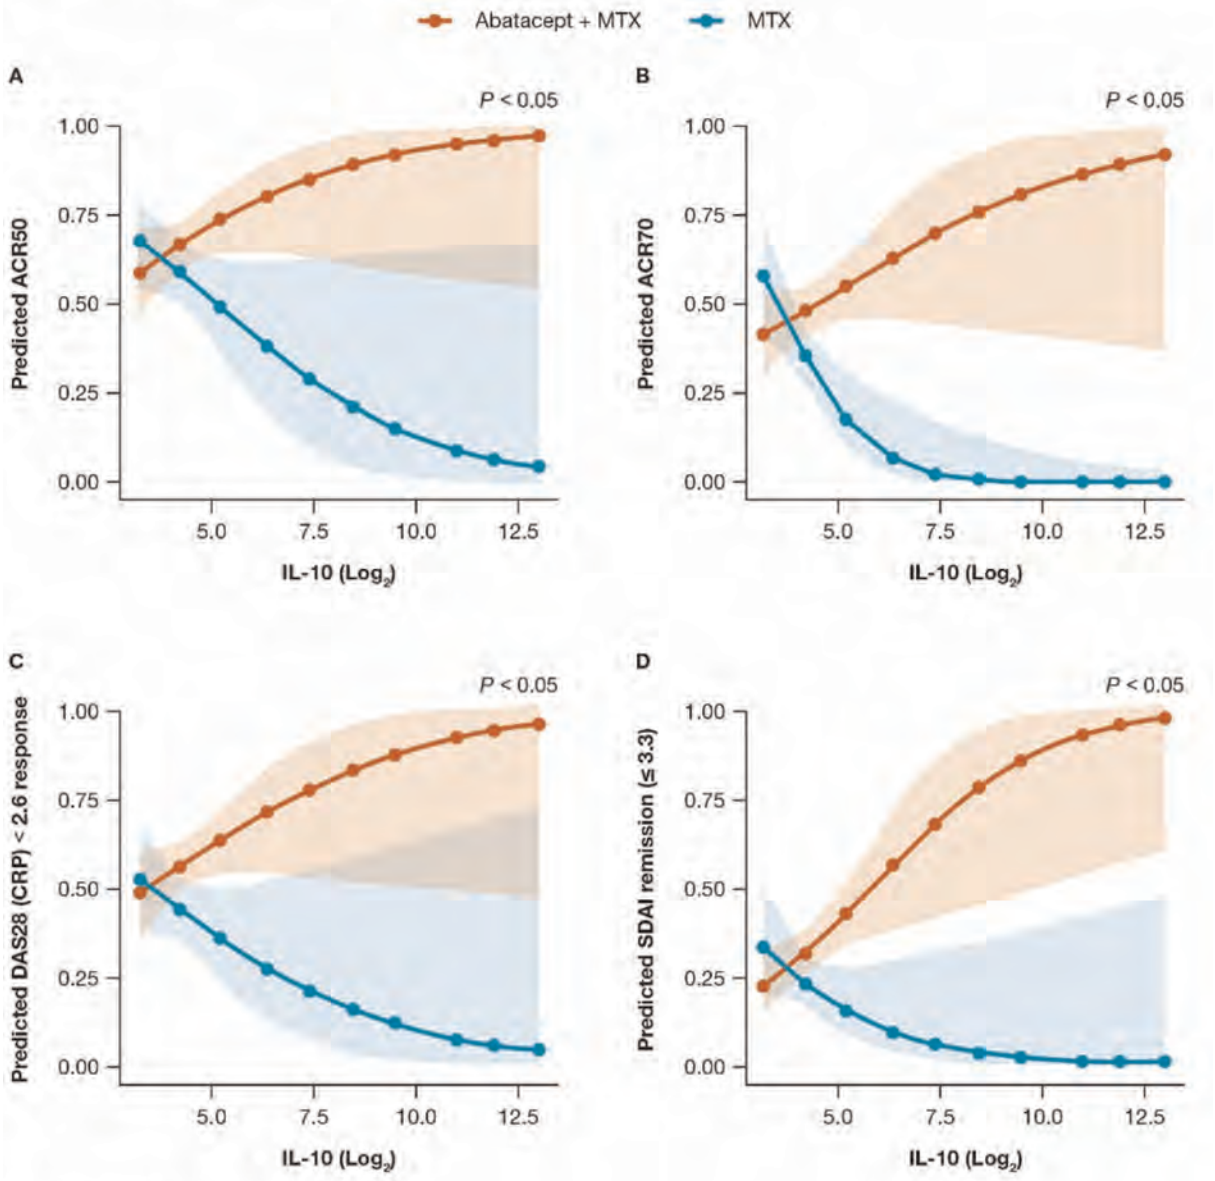
Session Time: 4:00PM–5:30PM

Background/Purpose: A key target of RA treatment is to achieve early and sustained remission in order to ensure lower levels of long-term structural joint damage and physical disability. Identifying predictive biomarkers may help guide treatment options to achieve this. Inflammatory biomarkers such as IL-10, a pleiotropic cytokine that drives B-cell responses and is associated with higher seropositivity for RF and anti-CCP in patients (pts) with RA,[1] may provide clinical value as predictive

biomarkers. We evaluated the association of baseline (BL) circulated biomarkers with disease activity (DA) measures and their ability to predict clinical response in MTX-naive, ACPA+ pts with early RA from a phase 3b study (AVERT-2; NCT02504268).[2]

Methods: Pts aged ≥ 18 years with early RA (≤ 6 months from diagnosis; ACR/EULAR 2010[3]) were randomized to abatacept + MTX or abatacept placebo + MTX (referred to as MTX). Serum samples were collected over a 56-week period, with endpoints assessed at weeks 24 and 52.A broad selection of 113 inflammatory and immune response–related proteins were analyzed using either the Olink Target 96 multiplex immunoassay inflammation panel or selected panels from Myriad Rules-Based Medicine. BL biomarker and clinical DA measures were analyzed using Spearman's correlation, with changes from BL in select biomarkers analyzed via repeated measures mixed-effects models. Logistic regression predicted response

Figure 1. Higher baseline IL-10 levels predicted greater response with abatacept + MTX versus MTX for (A) ACR50, (B) ACR70, (C) DAS28 (CRP) response, and (D) SDAI remission at week 52



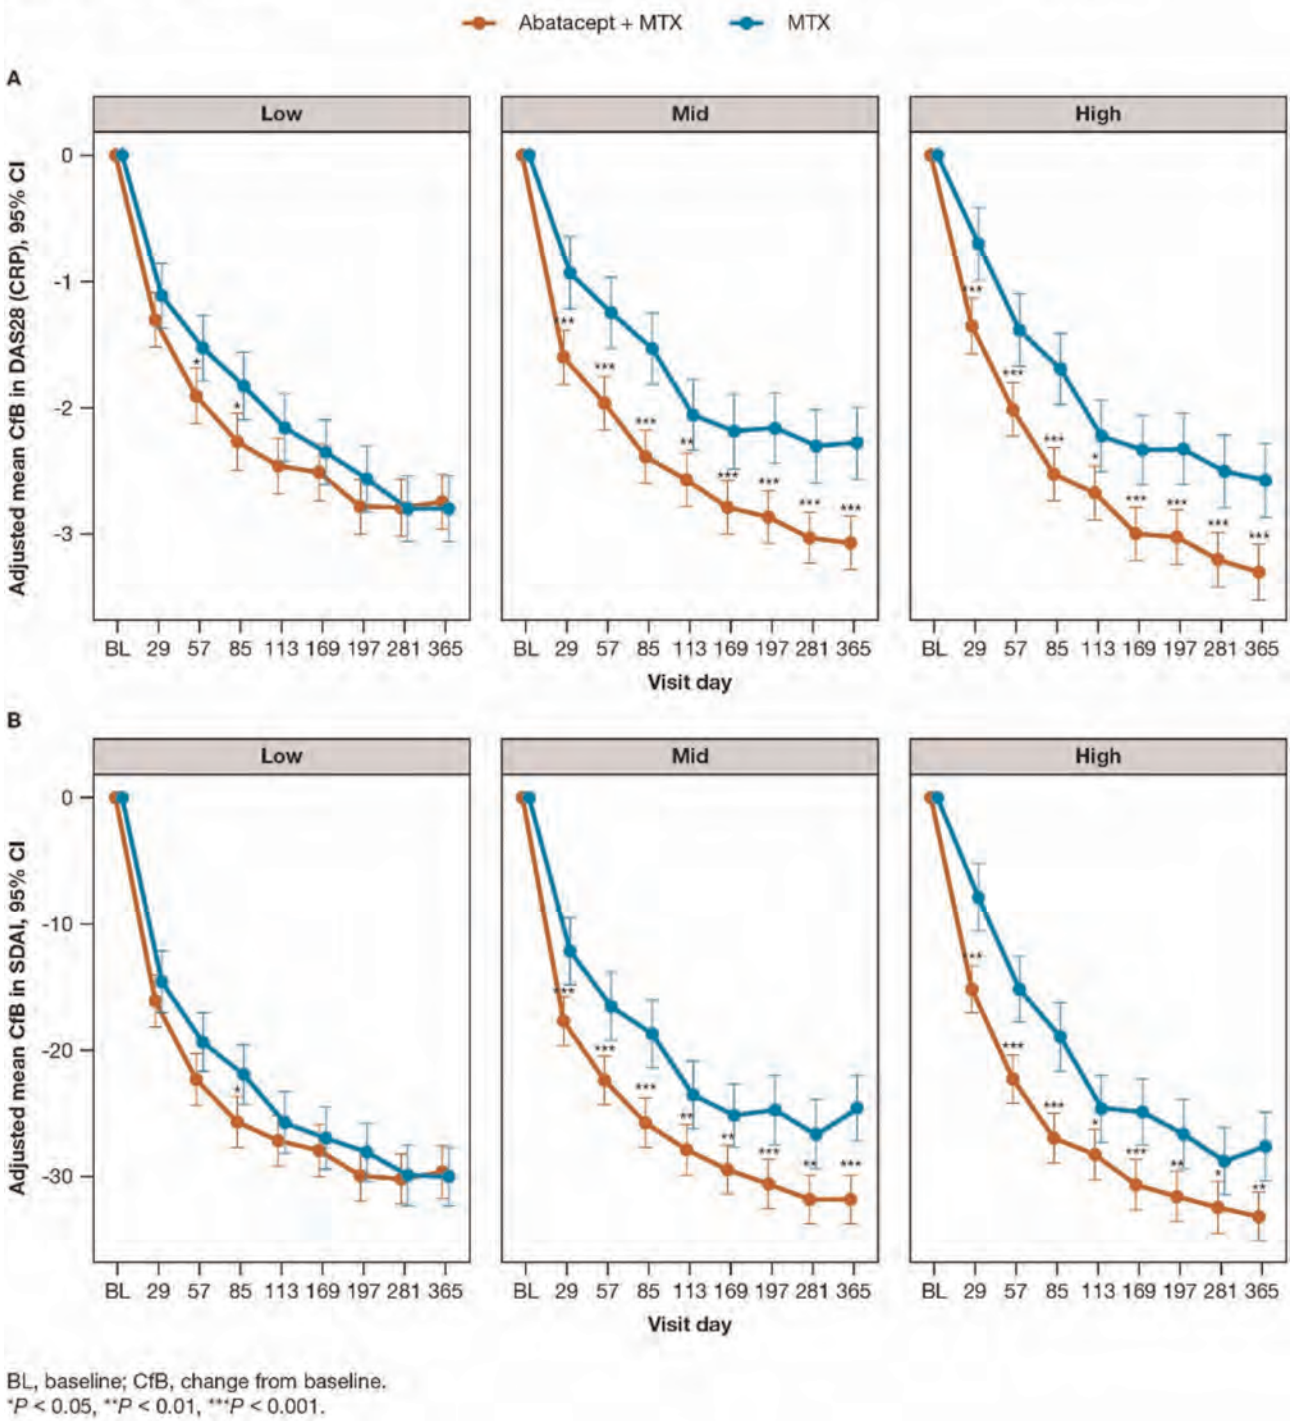
Shaded areas show 95% CIs.

ACR50/70, 50/70% improvement in ACR criteria.

to treatment with BL age, Simplified Disease Activity Index (SDAI), pain (measured via visual assessment scale), and ACPA positivity as covariates.

Results: Of 752 pts in the intent-to-treat population, 446 from the abatacept + MTX arm and 300 from the MTX arm were included in the biomarker analyses. BL characteristics were well-balanced between treatments. Of the 15 biomarkers significantly associated with ≥ 2 BL DA measures, at both weeks 24 and 52, pts receiving abatacept + MTX showed significantly

Figure 2. Higher baseline IL-10 tertile is associated with greater improvements in (A) DAS28 (CRP) and (B) SDAI over time for abatacept + MTX versus MTX



BL, baseline; CfB, change from baseline.
*$P < 0.05$, **$P < 0.01$, ***$P < 0.001$.

greater reductions in all biomarker levels compared with MTX ($P < 0.05$ to $P < 0.001$) with a change from BL in 13 biomarkers demonstrating significant associations with DA measure reduction ($P < 0.05$). Higher BL levels of IL-10 predicted greater clinical improvement, assessed by ACR and DAS28 (CRP) (< 2.6) responses and SDAI remission (≤ 3.3), with abatacept + MTX vs MTX ($P < 0.05$ at week 52) (**Figure 1**). Further, a higher BL IL-10 concentration tertile was significantly associated with greater improvements in DAS28 (CRP) and SDAI on abatacept + MTX vs MTX ($P < 0.05$ to $P < 0.001$ at days 29–365) (**Figure 2**).

Conclusion: Higher BL IL-10 levels predicted greater clinical response for pts treated with abatacept + MTX vs MTX. Increased IL-10 levels may reflect greater interactions between CD4+ T-helper cells and autoantibody-producing B cells. These findings may help clinicians to identify pts most likely to respond favorably to the abatacept mechanism of action. A prospective study is warranted to confirm whether screening for IL-10 in the clinical setting can help guide treatment options for pts with RA.

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: Abstracts: RA – Treatments III: Predictors of Response & Tapering
Session Type: Abstract Session
Session Time: 4:00PM–5:30PM

Background/Purpose: Rheumatoid arthritis (RA) is a remarkably heterogeneous autoimmune disease whose clinical outcomes with disease-modifying antirheumatic drugs (DMARDs) remain unpredictable. The aim of this study was to characterize the molecular landscape of RA patients by using a multi-omic approach involving transcriptomics and proteomics and their association with disease status and clinical response.

Methods: Peripheral blood mononuclear cells from 123 RA patients were profiled by RNAseq on Illumina platforms. The RA cohort included 49 patients taking conventional DMARDs and 74 biologics-naïve patients before receiving biologic (TNFi) or targeted-synthetic DMARDs (JAKinibs). Clinical outcomes were evaluated after 6 months of treatment following EULAR criteria. A consensus cluster approach was used to identify patients' subgroups based on their transcriptomic profile. In parallel, a panel of 92 inflammatory mediators was analyzed in the RA serum using the Olink platform.

Results: Unsupervised hierarchical clustering identified 3 subgroups of RA patients displaying differential expression of 7 gene modules defining distinctive biological pathways. Cluster 1 included the inflamed-myeloid group, showing high expression in myeloid and inflammation genes modules. Cluster 2 defined the healthy-like RA patients, displaying low levels of all gene modules. Cluster 3, identified the B-cells group, exhibiting high levels of B cell gene-modules. The analysis of the serum proteome among these clusters identified 34 proteins showing differential expression levels, where a signature of chemokines, interleukins, and growth factors was found increased in C1 compared with C2 and C3.

Clinically, C1 grouped RA patients with more severe disease activity, higher number of circulating monocytes and neutrophils, and larger disease evolution compared with C2 and C3. On the contrary, C2 involved patients with the lowest disease severity and evolution time and included few patients starting b- or ts-DMARDs. Lastly, C3 included patients with disease activity and evolution time like C2 but showed the highest number of circulating lymphocytes.

Regarding the response to DMARDs, C1 grouped RA patients with the highest percentage of response to TNFi. Clinical response of patients treated with JAKinibs was independent of the cluster where patients were allocated. That data suggests that clinical response to each drug might be associated with a deregulated expression of specific modules of genes and inflammatory proteins at baseline. Accordingly, correlation studies among DAS28 variation at 6 months and basal levels of different gene modules and proteins showed specificity depending on the drug analyzed.

Conclusion:

1. RA patients conform distinctive subgroups based on altered transcriptomic and proteomic profiles, directly linked to their clinical status.
2. Clinical effectiveness of TNFi and JAKinibs was divergent among these molecular clusters and associated with specific transcriptomic and proteomic profiles before starting such therapies.

SESSION INFORMATION

Session Date: Tuesday, November 14, 2023

Session Title: Abstracts: RA – Treatments III: Predictors of Response & Tapering

Session Type: Abstract Session

Session Time: 4:00PM–5:30PM

Background/Purpose: The identification of measures that help predict who is likely to benefit most from early escalation to biologic therapy would inform personalized care among patients with rheumatoid arthritis (RA) early in the course of the disease. While prior studies have assessed how body mass index (BMI) and adiposity might influence responses to therapy, these studies rarely have compared two active treatment strategies. We aimed to determine if BMI and circulating adipokines (peptide hormones produced by adipose tissue) can identify patients most likely to benefit from early initiation of tumor necrosis factor inhibitors (TNFi) as initial therapy compared to combination therapy with conventional DMARDs.

Methods: This is a secondary analysis of the Rheumatoid Arthritis Comparison of Active Treatments (RACAT) trial and the Treatment of Early Aggressive Rheumatoid Arthritis (TEAR) trial. Both trials evaluated strategies with conventional DMARDs (triple therapy) compared to strategies that included TNFi (etanercept), among patients with active RA. We compared response rates between TNFi and triple therapy among patients with different BMI (normal/underweight v. overweight/obese). Adipokines were also measured at enrollment in RACAT using validated assays and we explored the association

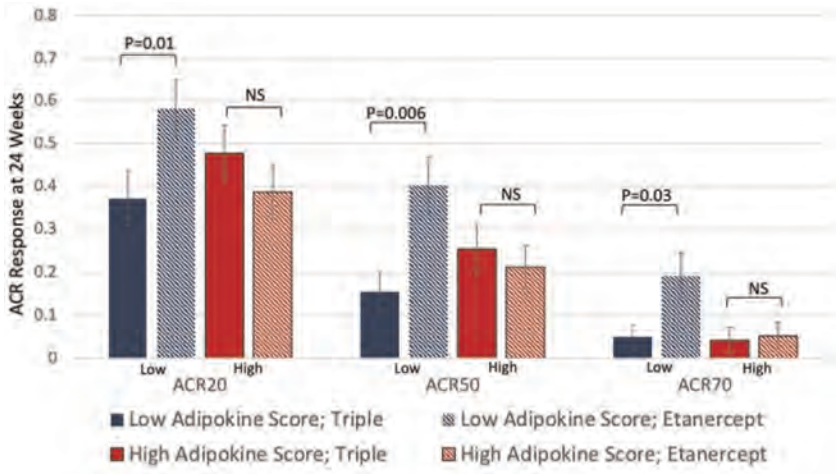

Figure 1: American College of Rheumatology Response rates in RACAT among 1) participants with a low adipokine score receiving triple therapy (blue solid bar); 2) participants with a low adipokine score receiving immediate etanercept (blue striped bar); 3) participants with a high adipokine score receiving triple therapy (red solid bar), and 4) participants with a high adipokine score receiving etanercept (red striped bar).

between an adipokine score (number of adipokines above/below the median, grouping those that directionally reflect greater adiposity) and response within the two treatment arms. Analyses were adjusted for age, sex, BMI, and baseline disease activity (DAS28).

Results: We included 306 participants that were eligible from RACAT and 601 from TEAR. In RACAT, greater change in DAS28 and greater ACR20 response was observed for TNFi initiators compared to triple therapy among participants that were normal or underweight (ACR 20: 64% v. 23%) while no differences between TNFi and triple therapy were observed among overweight and obese (p for interaction = 0.001) (Table). Similar patterns were observed in TEAR, though were more modest. The pattern in TEAR was similar among methotrexate-naïve initiators at baseline and methotrexate inadequate responders at 6-months (combined data are shown in Table). In RACAT, adipokine scores below the median (< 2) and a profile consistent with lower adiposity were associated with greater response to TNFi (ACR20: 58% v. 37%) (Figure). The addition of adipokines to the model resulted in better model fit compared to a model with BMI alone (p=0.01).

Conclusion: Low BMI and evidence of low adiposity based on adipokine profiles are both associated with a superior response to initiation of TNFi compared to the initiation of triple therapy. This is the first study, to our knowledge, to identify a meaningful difference between two active strategies based on weight and body habitus and may reflect phenotypic differences or pharmacodynamic effects. The results support earlier escalation to TNFi among thin patients that do not respond to methotrexate and have implications for future clinical trial design.

Session Date: Tuesday, November 14, 2023

Session Title: Abstracts: RA – Treatments III: Predictors of Response & Tapering

Session Type: Abstract Session

Session Time: 4:00PM–5:30PM

Background/Purpose: Recent randomized-controlled studies have suggested that tapering bDMARDs and/or csDMARDs after achieving sustained remission in patients with rheumatoid arthritis (RA) can be considered. However, the optimal tapering strategy is yet to be established, and it may differ between various circumstances. We investigated whether concomitant treatment of methotrexate (MTX) may influence the disease activity after tapering abatacept in patients with RA.

Methods: We utilized the data from the Korean College of Rheumatology Biologics and Targeted therapy Registry (KOBIO-RA) (NCT01965132). Patients were enrolled when initiating a bDMARD (defined as baseline) and were followed up annually thereafter. Follow-up data on disease activity, concomitant medications, and dose of bDMARDs were collected. We included patients who 1) were treated with abatacept at baseline and 2) had no missing data on the dose of abatacept and MTX. The observational unit in this study was a 1-year interval. Patients were divided into two groups according to whether the dose of abatacept was de-escalated or not compared with the preceding interval (tapering group vs. control group). The primary outcome of the study was DAS28-ESR-based remission in the 1-year interval. To minimize confounding by indication between the two groups, we used the marginal structural model in which inverse probability of treatment weights (IPTWs) for each interval was applied to control all baseline and time-varying confounders.

Table. Effect of tapering abatacept on disease activity with and without concomitant MTX treatment

Table. Effect of tapering abatacept on disease activity with and without concomitant MTX treatment

	OR (vs. control group)	95% CI	P for interaction
DAS28-remission			0.002
Without concomitant MTX	0.26	0.10 to 0.67	
With concomitant MTX	1.42	0.88 to 2.30	
DAS28-LDA			0.003
Without concomitant MTX	0.20	0.07 to 0.55	
With concomitant MTX	1.06	0.75 to 1.50	
Severe disability (HAQ > 2)			0.045
Without concomitant MTX	4.27	0.86 to 21.32	
With concomitant MTX	0.56	0.18 to 1.80	
SDAI-remission			0.446
Without concomitant MTX	0.50	0.15 to 1.62	
With concomitant MTX	0.85	0.46 to 1.57	

DAS, Disease activity score; HAQ, Health Assessment Questionnaire; LDA, Low disease activity; MTX, Methotrexate; OR, Odds ratio; SDAI, Simple Disease Activity Index

Results: A total of 505 intervals from 179 patients were analyzed. The mean (SD) age of the patients was 59.3 (12.9) years and 150 (83.8%) were females. Baseline DAS28-ESR was 5.7 (1.0) and the mean (SD) weekly dose of MTX was 12.5 (3.3) mg. Tapering abatacept was undergone in 146 (28.9%) intervals, with a mean dose quotient of 0.68. The DAS28-ESR measured in the interval before tapering abatacept was 3.4 (1.3) and DAS28 remission was achieved in only 51 (34.9%) intervals before tapering abatacept.

In the IPTW-applied pseudopopulation, the effect of tapering abatacept was significantly different based on concomitant use of MTX (P for interaction 0.002). In the subgroup of 1-year intervals without concomitant MTX, tapering abatacept significantly lower the odds for achieving DAS28-based remission, with an OR of 0.26 (95% CI 0.10 to 0.67). In contrast, with concomitant MTX, tapering abatacept did not have any significant effect (OR 1.42 [0.88 to 2.30]). This result was consistent when the effect of tapering abatacept was estimated using the outcome variable of achieving DAS28-low disease activity, or severe functional impairment (defined as HAQ >2). However, tapering abatacept with/without MTX did not significantly affect the odds for achieving SDAI-based remission (Table).

Conclusion: Tapering abatacept in the absence of concomitant MTX treatment is associated with a worse outcome in patients with RA.

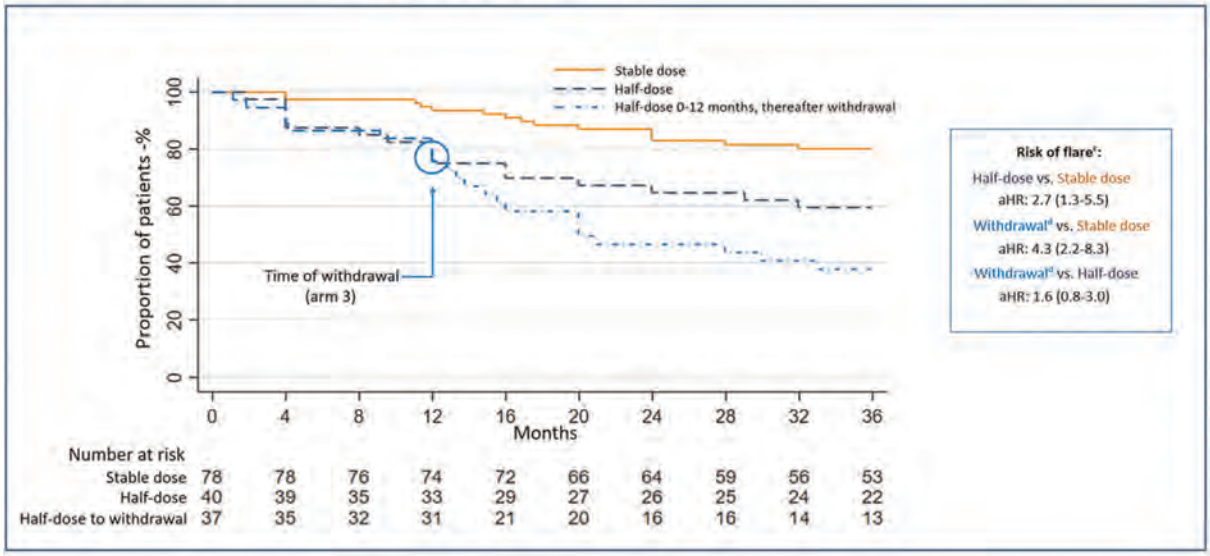
Session Title: Abstracts: RA – Treatments III: Predictors of Response & Tapering

Session Type: Abstract Session

Session Time: 4:00PM–5:30PM

Background/Purpose: Tapering of disease-modifying antirheumatic drugs (DMARDs) to achieve drug-free remission is a potential goal for the growing group of patients with rheumatoid arthritis (RA) in remission, although long-term effects of such strategies remain unclear. The purpose of this study was to compare the 3-year clinical and radiographic outcomes of three conventional synthetic DMARD (csDMARD) treatment strategies (continued stable treatment, half-dose treatment and tapering to withdrawal) among patients in sustained RA remission.

Figure 1: Proportions of patients without a flare[a] over the study period[b]



[a] Flare was defined as a combination of Disease Activity Score (DAS) above the cut-off for remission (1.6), a change in DAS of at least 0.6, and at least 2 swollen joints, or that both the treating physician and the patient agreed that a clinically significant flare had occurred.
[b] The analyses were performed in a per protocol population (all randomized patients meeting the study entry criteria were included in the analysis up until the date of a major protocol violation (nine patients) or censored when lost to follow-up (eight patients)).
[c] The risk of flare was analyzed by Cox Proportional Hazard Regression, adjusted for study centre.
[d] Half-dose 0-12 months, thereafter withdrawal.

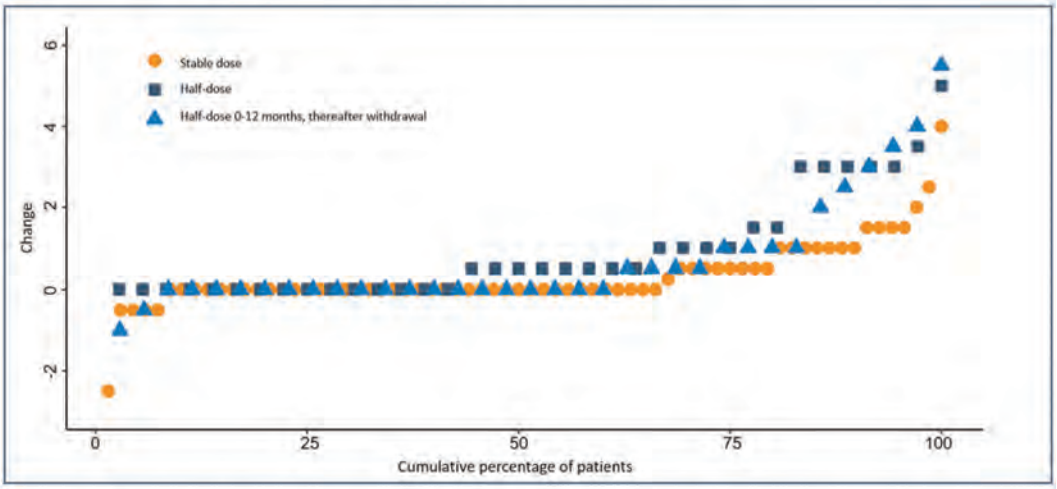
Methods: ARCTIC REWIND was a randomized, multicenter, open-label, clinical trial enrolling 160 RA patients in sustained remission for ≥1 year on stable csDMARD therapy (Lillegraven et al. JAMA 2021). Patients were randomized 2:1:1 to stable csDMARDs, half-dose csDMARDs, or half-dose csDMARDs for one year followed by withdrawal of all csDMARDs. The primary endpoint was absence of disease activity flare over 3 years. A flare was defined as a combination of DAS >1.6, an

Table: Remission at 12, 24 and 36 months[a]

	Remission, No./total No. (%)[b]				Absolute Risk Difference, % (95 % CI)[c]		
	Stable dose	Half-dose	Half-dose 0-12 months, thereafter withdrawal		Half-dose vs stable dose[d]	Half-dose 0-12 months, thereafter withdrawal vs stable dose[d]	Half-dose 0-12 months, thereafter withdrawal vs half- dose[d]
DAS remission				**DAS remission**			
12 months	71/77 (92%)	34/39 (87%)	29/36 (81%)	12 months[e]	-8.5 (-18.7-1.5)	NA	NA
24 months	64/73 (88%)	33/37 (89%)	33/35 (94%)	24 months	1.2 (-11.1-13.6)	6.0 (-5.0-17.0)	4.7 (-8.0-17.5)
36 months	64/67 (96%)	34/36 (94%)	31/34 (91%)	36 months	1.2 (-10.2-7.7)	-4.7 (-15.5-6.0)	-3.5 (-15.7-8.6)
ACR/EULAR 2011 Boolean remission				**ACR/EULAR 2011 Boolean remission**			
12 months	56/77 (73%)	25/39 (64%)	22/36 (61%)	12 months[e]	-11.3 (-26.2-3.5)	NA	NA
24 months	47/73 (64%)	21/37 (57%)	20/35 (57%)	24 months	-7.8 (-27.2-11.6)	-6.3 (-26.2-12.6)	1.0 (-21.5-23.4)
36 months	55/67 (82%)	25/36 (69%)	19/34 (56%)	36 months	-12.1 (-30.2-6.0)	-25.3 (-44.8—6.3)	-13.3 (-35.4-8.9)

[a] The analyses were performed in a per protocol population (all randomized patients meeting the study entry criteria were included in the analysis up until the date of a major protocol violation (nine patients in total). Furthermore, eight patients were lost to follow-up (one patient was lost to follow-up before 12 months, four patients were lost to follow-up before 24 months, and three patients were lost to follow-up before 36 months)).
[b] Crude remission rate.
[c] Absolute risk difference, calculated with mixed-effect logistic regression with random effects for both patient and study centre, in latter to account for the centre stratification.
[d] Reference group.
[e] The two groups using half-dose for the first year pooled in this analysis.
Abbreviation NA: Not applicable (same treatment the first 12 months).

Figure 2: Change in van der Heijde-modified Sharp score[a] at 36 months compared to baseline[b]



[a]The van der Heijde–modified Sharp scoring method assesses erosions in 16 joints of each hand and 6 joints of each foot, and the erosions are given a score of 1 to 5. Joint space narrowing is assessed in 15 joints for each hand and 6 joints for each foot. This gives scores for erosions on a scale from 0 to 280 and joint space narrowing on a scale from 0 to 168, thus the total van der Heijde–modified Sharp score ranges from 0 to 448, with higher scores indicating greater joint damage.
[b]The analyses were performed in a per protocol population (all randomized patients meeting the study entry criteria were included in the analysis up until the date of a major protocol violation (nine patients) or censored when lost to follow-up (eight patients)).

increase in DAS ≥0.6 units and ≥2 swollen joints, or if the physician and patient agreed that a clinically significant flare had occurred. Full-dose csDMARD treatment was reinstated upon flare. Secondary endpoints included remission (DAS, ACR/EULAR Boolean), and the 3-year change in radiographic joint damage (van der Heijde-Sharp score, vdHSS). Data were analyzed using Kaplan-Meier, Mann-Whitney test, Cox and mixed effect logistic regression, with stratification or adjustment for study center.

Results: Of 156 patients who received the allocated treatment strategy, 139 patients completed 3-years follow-up without major protocol violation. Mean baseline methotrexate dose/week was 19.0 mg in the stable group, 19.7 mg in the half-dose group, and 19.5 mg in the withdrawal group, and mean DAS at baseline was 0.8 in all groups. 80 % remained flare-free in the stable group, compared with 60 % in the half-dose group (adjusted HR (aHR) for flare 2.7 (95% CI: 1.3 to 5.5)), and 38 % in the tapering to withdrawal group (aHR for flare 4.3 (2.2 to 8.3)) (Figure 1). The aHR was 1.6 (0.8 to 3.0) in the tapering to withdrawal group compared to the half-dose group. A majority were in remission at 1, 2 and 3 years (Table), with the only significant group difference for ACR/EULAR Boolean remission at 3 years, with risk difference for tapering to withdrawal vs stable dose -25% (-45 to -6). Median (IQR) change in vdHSS after 3 years was 0.0 (0-0.5) in the stable group, 0.5 (0.0-1.3) in the half-dose group, and 0.0 (0.0-1.0) in the tapering to withdrawal group (Figure 2), with statistical significant difference between stable and half-dose group, $p< 0.01$. Sensitivity analyses in the full analysis population gave similar results.

Conclusion: These 3-year data show that 38% of patients in the tapering to withdrawal arm achieved long-term drug-free remission, indicating that this is a realistic option for some RA patients in sustained remission. The two tapering strategies were associated with an increased risk of flares compared to full-dose csDMARD, and the half-dose group had more radiographic change. However, there were no differences in DAS-remission at the end of the study period. Further research identifying prognostic factors for successful tapering is needed.

Microbial Metabolism of Methotrexate Contributes to Its Pharmacokinetics in Vivo

Diego Orellana, Mohana Mukherjee, Moriah Sandy, Peter Turnbaugh and Renuka Nayak, University of California San Francisco, San Francisco, CA

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: Abstracts: RA – Treatments III: Predictors of Response & Tapering
Session Type: Abstract Session
Session Time: 4:00PM–5:30PM

Background/Purpose: Methotrexate (MTX) is a first-line treatment drug used in rheumatoid arthritis (RA) patients. However, only 30-40% of patients tolerate the drug and achieve adequate therapeutic effects[1]. Risk factors such as smoking, age, and disease severity are associated with MTX non-responsiveness in patients[2]. Yet, these risk factors are limited in their ability to predict MTX non-responsiveness, and many of them are not modifiable. One hypothesis, pursued by our lab, is that the gut microbiome metabolizes MTX and interferes with its efficacy. This is significant because the gut microbiome can be both predictive and modifiable, and therefore can be leveraged to improve MTX efficacy and advance personalized medicine for patients with RA. In support of this hypothesis, we have previously shown that specific bacterial taxa and the abundance of bacterial genes are predictive of future MTX outcomes in RA patients[3].Yet, it remains to be seen whether the gut microbial community can directly affect MTX pharmacology and which microbes are responsible for MTX metabolism. Here, we examined the causal impact of the microbiome on MTX pharmacokinetics and surveyed the spectrum of RA-associated gut microbes that metabolize MTX.

Methods: To test the contribution of microbial metabolism of in MTX pharmacology *in vivo*, we orally dosed germ-free (GF) mice and specific-pathogen free mice (SPF) (N=6 per colonization state) with MTX 50 mg/kg. Plasma was collected at 0, 15, 30, 60, 120, 240, and 480 minutes; the concentration of MTX and its metabolites were quantified by HPLC-MS-MS (Sciex 6500 QTRAP). To survey the spectrum of RA-associated gut microbes that metabolize MTX, we collected stool samples from treatment-naïve RA patients (N= 5) and isolated individual strains on rich media. Each isolate was incubated with MTX 50 ug/mL or vehicle control (i.e., DMSO) for 72 hours and bacterial growth was measured by spectrometry (i.e., OD600). MTX metabolism was assessed by HPLC by: (1) quantifying a decrease in MTX levels and (2) detection of novel peaks.

Results: Peak plasma concentrations of MTX were significantly higher in GF mice as compared to SPF mice. In contrast, plasma concentrations of MTX metabolites were negligible in GF mice, whereas SPF mice showed increasing levels of MTX metabolites over 4 hours. To determine which RA-associated microbes might be responsible for MTX metabolism, we harvested 120 bacterial isolates from 5 RA patients. Of the profiled 120 isolates, 30.83% of isolates (37/120) metabolized MTX.

Conclusion: The presence of a microbiome in mice results metabolism of orally-administered MTX *in vivo* leading to altered pharmacokinetics. Furthermore, a significant percentage of isolates harvested from RA patient microbial communities are capable of metabolizing MTX *in vitro*. These findings support the overarching hypothesis that the gut microbiome contributes to MTX efficacy in RA patients.

SESSION INFORMATION

Session Date: Tuesday, November 14, 2023

Session Title: Abstracts: Spondyloarthritis Including Psoriatic Arthritis – Treatment III: AxSpA

Session Type: Abstract Session

Session Time: 4:00PM–5:30PM

Background/Purpose: While subcutaneous secukinumab (SEC) is approved for the treatment of axial spondyloarthritis (axSpA), some patients may benefit more from intravenous (IV) administration. This study investigated the long-term efficacy, safety, and tolerability of IV SEC in patients with active axSpA.

Methods: INVIGORATE-1 (NCT04156620) is a randomized, double blind, parallel group, phase 3 trial of patients with active axSpA (either radiographic [r]-axSpA or nonradiographic [nr]-axSpA). All patients had inflammatory back pain (ASAS criteria) for ≥6 months with onset before 45 years of age. Patients with r-axSpA fulfilled the modified New York criteria, and patients with nr-axSpA met ASAS criteria and had objective signs of inflammation at screening (positive MRI and/or elevated high-

sensitivity C-reactive protein (≥5 mg/L for nr-axSpA; ≥10 mg/L for r-axSpA). Patients were randomized 1:1 to receive IV SEC (6 mg/kg at baseline followed by 3 mg/kg every 4 weeks) or placebo (PBO) for 16 weeks. After Week 16, patients randomized to PBO were switched to IV SEC (3 mg/kg every 4 weeks), while patients randomized to SEC continued receiving IV SEC through Week 52. The primary endpoint was ASAS40 response at Week 16. Efficacy was assessed through Week 52 by the proportion of patients achieving ASAS40 response, ASDAS-CRP major improvement, and ASAS5/6 response, and by change from baseline in BASDAI, BASFI, and SF-36 PCS. Safety was evaluated through Week 60. Efficacy data through Week 16 are reported using nonresponder imputation; efficacy data from Week 20 through Week 52 are reported as observed.

Results: Demographics and baseline characteristics were balanced across treatment groups (**Table 1**). Among patients randomized to IV SEC (n=264) or PBO/IV SEC (n=262), 86.0% and 88.9% completed the entire study period, respectively. A total of 413 patients had r-axSpA and 113 patients had nr-axSpA. SEC treatment resulted in rapid and sustained improvement in ASAS40 response rates in patients randomized to SEC (**Figure 1**). By Week 24, patients who switched from PBO to SEC at Week 16 achieved comparable ASAS40 response rates to those of patients originally randomized to SEC. ASAS40 responses were maintained through Week 52 for both groups (SEC, 66.8%; PBO/IV SEC, 74.9% [observed data]). SEC treatment also resulted in rapid improvements in all other efficacy measures that were maintained through Week 52 (**Table 2**). Through Week 16, the incidences of adverse events (AEs; 38.6% vs 39.1%), serious AEs (2.7% vs 1.1%), and AEs leading to

ASAS, Assessment of SpondyloArthritis international Society; IV, intravenous.
Shaded area of the graph represents time points where data are reported as observed; unshaded area represents data reported using nonresponder imputation.
*P<.0001 vs placebo.

Figure 1. Proportions of patients with axSpA who achieved ASAS40 through Week 16 (nonresponder imputation) and through Week 52 (observed data).

treatment discontinuation (1.9% vs 0.4%) were similar for patients receiving SEC or PBO, respectively. Among patients receiving any IV SEC through the entire study period, 63.2%, 6.0%, and 3.5% reported any AE, serious AEs, and AEs leading to treatment discontinuation, respectively. One death occurred during SEC treatment due to a suspected myocardial infarction and was deemed not related to treatment.

Conclusion: IV SEC was safe and effective for treatment of adults with active axSpA over 52 weeks. The safety profile of IV SEC for patients with axSpA was consistent with that of previous reports for subcutaneous SEC, and no new safety signals were observed.

Anti-infliximab Antibodies as a Marker of Drug Survival and Tapering in Ankylosing Spondylitis Patients: 12 Years Follow-up

CLARISSA PIMENTEL, ANA CRISTINA MEDEIROS-RIBEIRO, ANDREA SHIMABUCO, PERCIVAL SAMPAIO-BARROS, JULIO CESAR MORAES, CLAUDIA SCHAINBERG, CELIO GONÇALVES, ELAINE LEON, LEONARD KUPPA, Sandra Pasoto, NADIA AIKAWA, CLOVIS SILVA, Eloisa Bonfa and CARLA SAAD, University of São Paulo, São Paulo, Brazil

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: Abstracts: Spondyloarthritis Including Psoriatic Arthritis – Treatment III: AxSpA
Session Type: Abstract Session
Session Time: 4:00PM–5:30PM

Background/Purpose: Tumor necrosis factor inhibitors (TNFi) therapies were one of the major advances in the treatment of Ankylosing Spondylitis (AS) patients. For infliximab, anti-drug antibodies (ADA) seem to contribute to drug failure but it is not known its long term influence on tapering, drug survival and switching. We aim to evaluate the frequency and long-term kinetics of anti-infliximab antibodies (anti-IFX) and its influence on drug survival, treatment failure, infusion reaction, tapering strategy and in subsequent treatment with a second TNFi.

Methods: A prospective cohort of 60 AS patients under infliximab (IFX) as their first biological therapy were evaluated retrospectively regarding clinical and laboratorial data, IFX levels and anti-IFX, both by ELISA, at baseline and after 6, 12-14, 22-24, 48-54, 96-102 weeks and immediately before the switching, treatment withdrawal or the end of the study. The switching group (to another TNFi), were further evaluated after 3 and 6 months. For the tapering group, additional clinical and laboratory data were assessed before tapering strategy and at tapering failure or withdrawal of the drug. Biological agent and anti-IFX antibodies quantification was performed according to the manufacturer's protocol of the kits (Promonitor® IFX and Promonitor ®anti-IFX).

Results: Anti-IFX were detected in 27 (45%) patients during follow-up and 85.1% in the first year. The concomitant use of methotrexate was negatively associated with anti-IFX (5.0 [18.5%] vs. 14.0 [42.4%]; p=0.048). Infusion reactions were more often observed in positive anti-IFX patients at 22-24 weeks (3.0 [21.4%] vs. 1.0 [2.2%]; p=0.020) and at 48-54 weeks (3 [20.0%] vs. 0 [0.0%]; p=0.034). Anti-IFX at 48-54 weeks was associated with treatment failure (7.0 [46.7%] vs. 4.0 [13.8%]; p=0.028) and lower overall IFX survival (54.9 months [CI 95% 26.3-83.4] vs. 148.9 months [CI 95% 123.5-174.4]; p< 0.001). Of note, for the tapering group (n=24) anti-IFX was associated with shorter survival of this strategy (9.9 months [IC 95% 4.0-15.8] vs 63.4 months [IC 95% 27.9-98.8]; p=0.004). In contrast, for patients who failed to IFX (n=29), anti-IFX positivity at the switching was related to a better clinical response to the second TNFi at 3 months (15.0 [83.3%] vs. 3.0 [27.3%]; p=0.005) and at 6 months (15 [83.3%] vs. 4 [36.4%]; p=0.017).

Conclusion: This study demonstrates that in spite of anti-IFX association with worse IFX performance, this marker was a predictor of 2nd TNFi good clinical response. We also provided novel data that anti-IFX is a parameter for reduced tapering survival, reinforcing its detection to guide clinical decision in these two treatment strategies. Additionally, concomitant use of methotrexate (MTX) may be recommended to reduce anti-IFX formation in AS.

Session Date: Tuesday, November 14, 2023

Session Title: Abstracts: Spondyloarthritis Including Psoriatic Arthritis – Treatment III: AxSpA

Session Type: Abstract Session

Session Time: 4:00PM–5:30PM

Background/Purpose: The EULAR task force recently published the difficult-to-treat (D2T) RA definition[1], however, a definition of D2T axSpA is still lacking. To date, we have little data concerning D2T axSpA, especially in real-world. One of the limitations of the D2T RA EULAR definition is the lack of a temporal criterion. The primary endpoint of this work was to study

Table 1 – Baseline characteristics of D2T axSpA and nD2T axSpA patients

Parameters	N	D2T axSpA n = 88	N	nD2T axSpA n = 223	p value
Men	88	44 (50.0)	223	126 (56.5)	0.30

Values are expressed as number (%) unless otherwise stated. axSpA: axial spondyloarthritis; BASDAI: Bath Ankylosing Spondylitis Disease Activity Index; bDMARD: biological disease modifying antirheumatic drug; BMI: body mass index; CRP: C-reactive protein; (n)D2T: (non) difficult-to-treat; HLA: human leukocyte antigen; IBD: inflammatory bowel disease; IQR: interquartile range; JAKi: Janus Kinase inhibitors; N: number of available observations; NA: not applicable; SD: standard deviation;

the characteristics of D2T axSpA patients using the EULAR definition applied to axSpA. The second endpoint was to study a sub-group of patients with a predefined more stringent definition including a temporal criterion.

Methods: A retrospective multicentric study was performed. Patients with axSpA (radiographic or non-radiographic) ≥18 years old starting a b/tsDMARDs with at least 2-year follow-up were included. D2T axSpA was defined as failure of ≥ 2 b/tsDMARDs with different mechanism of action (MoA) among TNF inhibitors, IL-17 inhibitors and JAK inhibitors. Very D2T axSpA was defined as failure of ≥ 2 b/tsDMARDs in strictly less than 2 years. D2T and Very D2T axSpA patient's characteristics were compared with non-D2T patients.

Results: 311 axSpA patients were included: 88 D2T axSpA (28.3%) and 223 non-D2T (nD2T) axSpA (71.7%) (**Table 1**). Proportion of r-axSpA patients was 71.2% in the D2T group and 60.3% in the nD2T group (p=0.10). Disease duration was significantly higher in the D2T group (p=0.006). Peripheral involvement was more prevalent in the D2T group with 34.9% of patients vs. 21.4% in the nD2T group (p=0.015). BASDAI level at baseline was higher in the D2T group with a mean of 63.7 vs 58.8 in the nD2T group (p=0.015). Fibromyalgia was found to be more frequent in the D2T group vs nD2T group (p < 0.001). Among D2T patients, 12 (14%) presented a contraindication to TNF or IL-17 inhibitors (multiple sclerosis, inflammatory bowel diseases, recurrent uveitis, solid cancer < 5 years).

12 patients (3.8%) were categorized as very D2T axSpA. axSpA patient's characteristics were compared between the three groups (Very D2T, remaining D2T and nD2T) and in case of significant result, pairwise comparisons were performed (**-Table 2**). When compared to nD2T, Very D2T patients had a higher CRP level at baseline (42.0 ± 31.3 *vs* 17.8 ± 23.1; p=0.010). Inflammatory bowel disease (IBD) prevalence at baseline was higher in the Very D2T group with 41.7% vs 3.1% in the nD2T group (p< 0.001). Uveitis at baseline was more frequent (45.5% vs 11%; p=0.020). None of the Very D2T patients had a diagnosis of fibromyalgia.

Table 2 – Characteristics of Very D2T axSpA, remaining D2T axSpA and nD2T patients: comparison two-by-two

axSpA: axial spondyloarthritis; CRP: C-reactive protein; IBD: inflammatory bowel disease; rD2T: remaining difficult-to-treat (total D2T population minus patients categorized as Very D2T)

Definition of Difficult-to-treat axSpA. 3 criteria needed.

- Failure of treatments according to either of the following options:
  - ≥ 2 b/tsDMARDs with different mechanisms of action within less than 2 years

Or

  - ≥ 1 b/tsDMARDs within less than 2 years and a contra-indication to one therapeutic class *(i.e. contra-indication to TNF inhibitors (multiple sclerosis, severe heart insufficiency).*

- Suggestive evidence of disease activity/progression, defined as ≥ 1 of the following:
  - o At least moderate activity (ASDAS-CRP 1.3 or BASDAI 4/10),
  - o Signs (including biology and imaging) and/or symptoms suggestive of active disease (articular or extra rheumatological: uveitis, psoriasis, inflammatory bowel disease),
  - o Inability to reduce or discontinue NSAIDs,
  - o Disease controlled, but with persistent ax-SpA symptoms causing reduced quality of life,
- Management of signs and/or symptoms is perceived as problematic by the rheumatologist and/or patient.

Figure 1 - Proposal of D2T axSpA definition

Conclusion: D2T axSpA was associated with a longer disease duration, higher BASDAI at baseline, higher prevalence of peripheral involvement and more frequent fibromyalgia. Very D2T patients represented a minim proportion of patients after applying a more stringent definition and might be independent from fibromyalgia, with higher CRP level at baseline and higher prevalence of IBD and uveitis. This study highlights some characteristics that may help practitioners better identify D2T axSpA patients. Pending a consensual definition by the European and American societies, we propose a definition of D2T axSpA (**Figure 1**).

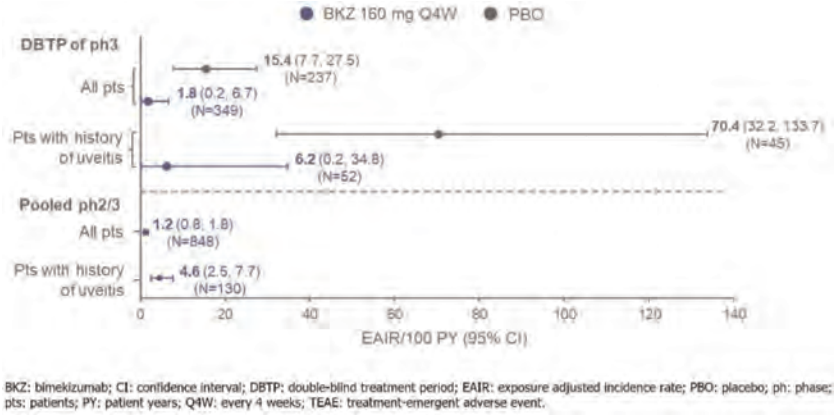
SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: Abstracts: Spondyloarthritis Including Psoriatic Arthritis – Treatment III: AxSpA
Session Type: Abstract Session
Session Time: 4:00PM–5:30PM

Background/Purpose: Acute anterior uveitis (’uveitis’), or ’iritis’, is a common extra-musculoskeletal manifestation among patients (pts) with axial spondyloarthritis (axSpA).[1] IL-17 has been implicated in the pathogenesis of uveitis; however, inhibition of IL-17A alone may not be optimal for the management of uveitis.[2] Here, we report the incidence of uveitis following inhibition of IL-17A in addition to IL-17F with bimekizumab (BKZ) in pts with axSpA.

Methods: Data were pooled for pts randomized to BKZ or placebo (PBO) in the double-blind treatment period (DBTP) of the phase (ph)3 studies BE MOBILE 1 (NCT03928704; non-radiographic [nr]-axSpA) and 2 (NCT03928743; radiographic [r]-axSpA i.e., ankylosing spondylitis).[3,4] Data were pooled separately for all pts treated with BKZ 160mg every 4 weeks (Q4W) in BE MOBILE 1, BE MOBILE 2, BE MOVING (NCT04436640; open-label extension [OLE] of BE MOBILE 1 and 2), and the ph2b study BE AGILE (NCT02963506; r-axSpA)[5] and its OLE BE AGILE 2 (NCT03355573). Uveitis treatment-

emergent adverse events (TEAEs) were identified using the preferred terms "autoimmune uveitis", "iridocyclitis", "iritis", and "uveitis", and were reported as both incidence and exposure adjusted incidence rates (EAIRs) per 100 pt years (PY) for all pts who received ≥1 BKZ dose.

Results: Baseline characteristics were reflective of a pt population with moderate to severe axSpA (**Table**). In the DBTP of BE MOBILE 1 and 2, uveitis TEAEs occurred in 11/237 pts randomized to PBO (4.6%; EAIR/100 PY [95% CI]: 15.4 [7.7, 27.5]) and 2/349 (0.6%; 1.8 [0.2, 6.7]) pts randomized to BKZ (% difference [95% CI]: 4.07 [1.71, 7.60]); **Figure**). In the 45 PBO-randomized (19.0%) and 52 BKZ-randomized (14.9%) pts with history of uveitis, uveitis TEAEs occurred in 20.0% (EAIR/100 PY [95% CI]: 70.4 [32.2, 133.7]) and 1.9% (6.2 [0.2, 34.8]) of pts, respectively. In the pooled ph2b/3 trial data, total BKZ exposure was 2,034.4 PY (N=848); 130 (15.3%) pts had history of uveitis. Uveitis TEAEs occurred in 25 pts overall (2.9%; EAIR/100 PY [95% CI]: 1.2 [0.8, 1.8]) and 14 pts with history of uveitis (10.8%; 4.6 [2.5, 7.7]; **Figure**). All uveitis TEAEs were mild/moderate; one event led to discontinuation.



BKZ: bimekizumab; CI: confidence interval; DBTP: double-blind treatment period; EAIR: exposure adjusted incidence rate; PBO: placebo; ph: phase; pts: patients; PY: patient years; Q4W: every 4 weeks; TEAE: treatment-emergent adverse event.

Figure. Pooled incidence of uveitis TEAEs (EAIR/100 PY [95% CI]) stratified by history of uveitis in patients randomized to BKZ 160 mg Q4W or PBO in the DBTP (Weeks 0–16) of the phase 3 trials BE MOBILE 1 and 2, and all patients treated with BKZ 160 mg Q4W in phase 2b/3 trials.

Table. Baseline characteristics

	Pooled phase 3		Pooled phase 2b/3
	PBO (N=237)	BKZ 160 mg Q4W (N=349)	BKZ 160 mg Q4W (N=848)
Age (years), mean (SD)	38.8 (12.1)	40.0 (11.8)	40.3 (11.9)
Male, n (%)	145 (61.2)	233 (66.8)	606 (71.5)
HLA-B27 positive, n (%)	187 (78.9)	294 (84.2)	717 (84.6)[a]
Caucasian, n (%)	200 (84.4)	286 (81.9)	746 (88.0)
r-axSpA, n (%)	111 (46.8)	221 (63.3)	604 (71.2)
Time since first axSpA symptoms (years), mean (SD)	10.3 (8.9)	12.4 (10.5)	12.4 (9.9)
History of uveitis, n (%)	45 (19.0)	52 (14.9)	130 (15.3)
Baseline concomitant synthetic DMARDs, n (%)	51 (21.5)	77 (22.1)	197 (23.2)

[a] n=6 missing. axSpA: axial spondyloarthritis; BKZ: bimekizumab; HLA-B27: human leukocyte antigen B27; PBO: placebo; Q4W: every 4 weeks; r-axSpA: radiographic axSpA; SD: standard deviation.

Conclusion: The incidence rate of uveitis TEAEs was lower to Wk 16 in axSpA pts randomized to BKZ 160 mg Q4W vs PBO. In the largest pool of ph2b/3 data available at the time of this report, the incidence rate of uveitis with BKZ 160 mg Q4W remained low at 1.2/100 PY.

Effect of Ixekizumab Treatment on MRI Structural Lesions in the Sacroiliac Joints of Patients with Radiographic Axial Spondyloarthritis; A Post-hoc Analysis of a Placebo and Active Controlled RCT

Walter P. Maksymowych[1], Robert Lambert[2], Eswar Krishnan[3], Baojin Zhu[3], Rebecca Bolce[3] and Mikkel Østergaard[4], [1]University of Alberta, Edmonton, AB, Canada, [2]Department of Radiology and Diagnostic Imaging, University of Alberta, Edmonton, AB, Canada, [3]Eli Lilly and Company, Indianapolis, IN, [4]Copenhagen Center for Arthritis Research, Center for Rheumatology and Spine Diseases, Centre for Head and Orthopaedics, Rigshospitalet; University of Copenhagen, Copenhagen, Denmark

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: Abstracts: Spondyloarthritis Including Psoriatic Arthritis – Treatment III: AxSpA
Session Type: Abstract Session
Session Time: 4:00PM–5:30PM

Background/Purpose: The effect of Ixekizumab (IXE) on structural lesions in the sacroiliac joints (SIJ) of patients (pts) with radiographic Axial Spondylarthritis (r-axSpA) assessed by magnetic resonance imaging (MRI) has not been analyzed. This analysis evaluated the effect of IXE versus placebo and active control, adalimumab (ADA), on structural lesions in SIJ assessed by MRI at week 16 in bio-naïve pts with r-axSpA.

Methods: COAST V (NCT02696785) is a phase 3, multicenter, randomized, double blind, placebo and active controlled study in bio-naïve adult pts (≥18 years) with active r-axSpA (1). Pts were randomly assigned 1:1:1:1 to placebo (PBO), 80 mg subcutaneous IXE, every 2 weeks (IXE Q2W) or 4 weeks (IXE Q4W), or 40 mg ADA Q2W (active reference group). Post-hoc analyses of pts with MRI available at baseline (BL) and week 16 for PBO, IXE Q2W, IXE Q4W and ADA groups are reported. Changes in MRI structural lesions were scored using the Spondyloarthritis Research Consortium of Canada

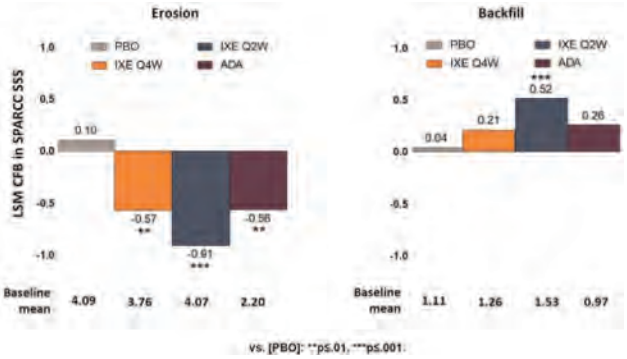

Figure 1: SPARCC SSS LSM Change from Baseline to Week 16

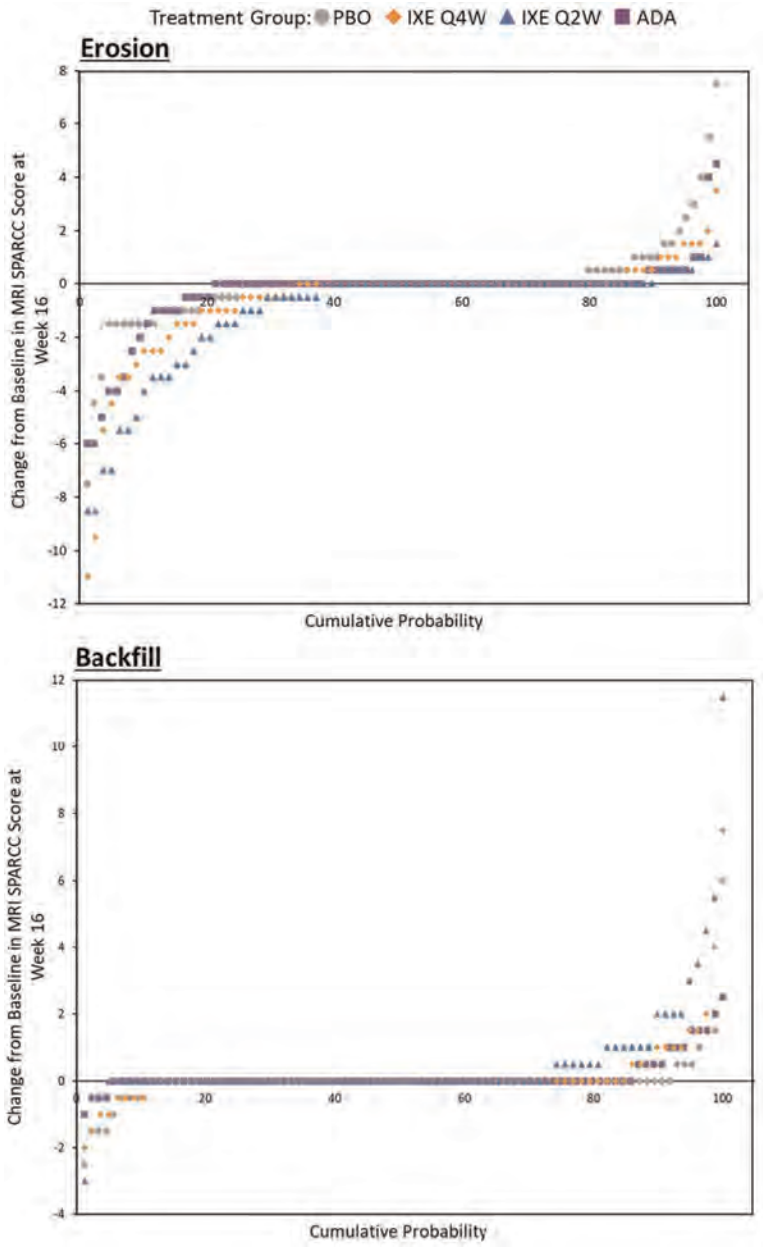

Figure 2: Cumulative Probability of Change from Baseline to Week 16 in SPARCC SSS

(SPARCC) sacroiliac joint structural scores (SSS) for erosion, backfill, fat lesion and ankylosis. For each of the 4 lesion types, analysis of covariance was utilized for treatment comparisons in observed cases after adjusting for BL values, BL SPARCC bone marrow edema (BME), and stratification factors (treatment, geographic region, BL CRP) and for backfill the analysis was also adjusted for BL erosion. Sensitivity analyses included adjustment of different factors and subsets of pts with less severe ankylosis scores. Subgroup analyses were conducted for changes in structural lesions by sex, HLA-B27 status, and SPARCC BME BL cutoffs ≥4, < 4.

Results: Of the 341 pts in the COAST V study, MRI scans were available for 325 pts at BL and week 16. At BL, the mean (std) scores for SPARCC SSS erosions for PBO, IXE Q4W, IXE Q2W and ADA were comparable. A significant decrease in SPARCC SSS erosion score, LSM (SEM), was observed in both IXE doses with the greatest decrease in IXE Q2W -0.91 (0.19). An increase in SPARCC SSS backfill score, LSM (SEM), was evident in both IXE doses, but a significant mean change was observed only in IXE Q2W 0.52 (0.12) (Figure 1). Cumulative probability of change from BL to week 16 in SPARCC SSS and sensitivity analyses confirmed the findings (Figure 2). SPARCC SSS erosions score, LSM (SEM), were significantly

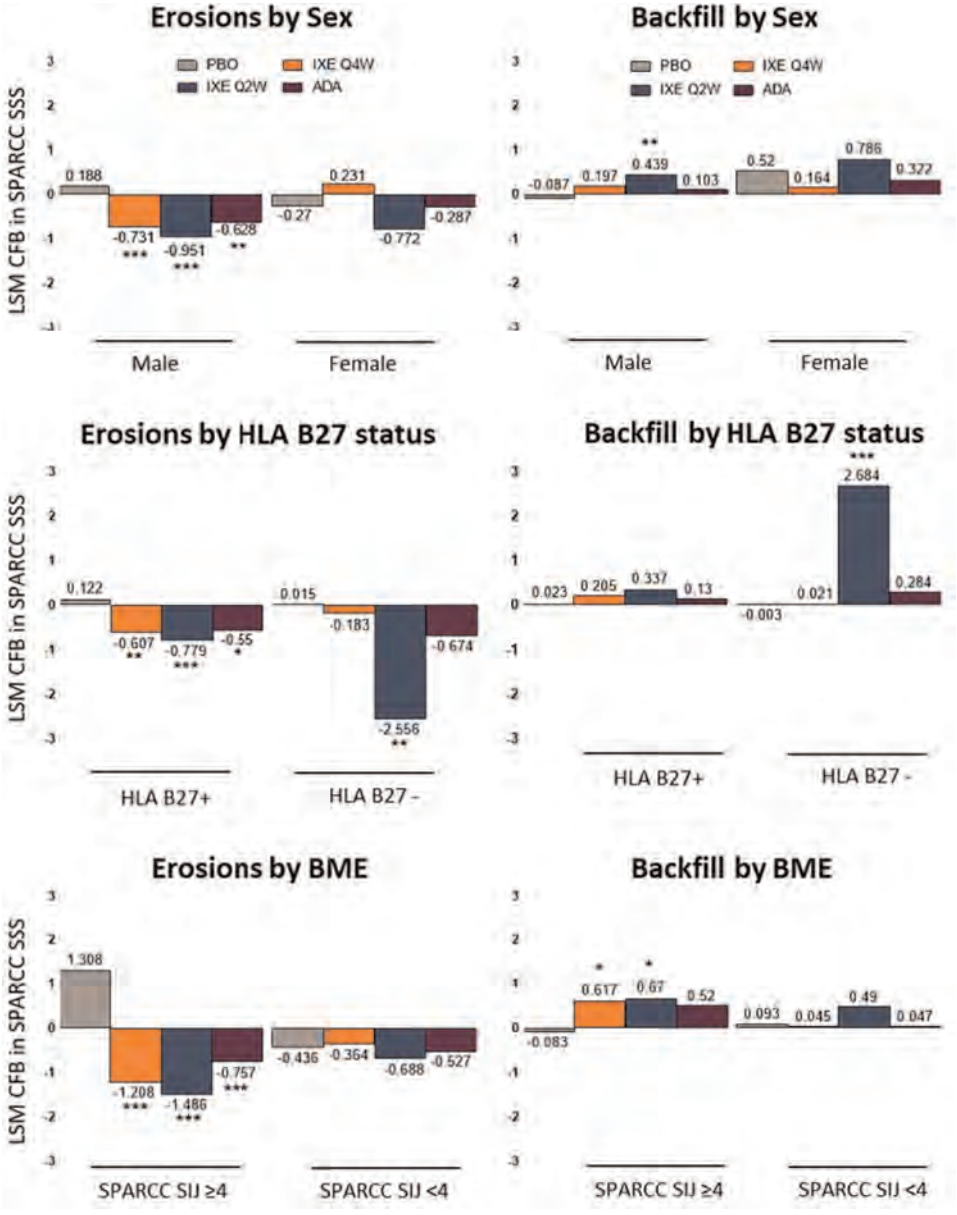

Figure 3: Subgroup Analyses for Changes in Structural Lesions

decreased in males for IXE Q4W -0.731 (0.199) and IXE Q2W -0.951 (0.207), in HLA B27 positive pts for IXE Q4W -0.607 (0.189) and IXE Q2W -0.779 (0.189), in HLA B27 negative pts for IXE Q2W -2.556 (0.656), and in pts with SPARCC SIJ BME ≥4 for IXE Q4W -1.208 (0.359) and IXE Q2W -1.486 (0.344) (Figure 3). SPARCC SSS backfill score, LSM (SEM), was significantly increased in males for IXE Q2W 0.439 (0.141), in HLA B27 negative pts for IXE Q2W 2.684 (0.434), and in pts with SPARCC SIJ BME ≥4 for IXE Q4W 0.617 (0.249) and IXE Q2W 0.67 (0.239).

Conclusion: In pts with bio-naïve r-axSpA, IXE treatment for 16 weeks decreased erosion scores and increased backfill scores, particularly in the IXE Q2W group, consistent with rapid tissue repair. Cumulative probability of change from BL to week 16 in SPARCC SSS and sensitivity analyses confirmed this. This documents that IXE may have an impact in structural damage progression and healing in pts with r-axSpA.

The Incidence of Uveitis in Patients with Axial Spondylarthritis Treated with Biologics or Targeted Synthetics: A Systematic Review and Network Meta-analysis

Zijing Yang[1], Maryam Adas[1], Bechman Katie[1], Deepak Nagra[1], Ali Soykan Uguzlar[1], Mark Russell[1], Nicky Wilson[2], Sophia Steer[1], Sam Norton[1] and James Galloway[1], [1]King's College London, London, United Kingdom, [2]King's College Hospital, London, United Kingdom

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: Abstracts: Spondyloarthritis Including Psoriatic Arthritis – Treatment III: AxSpA
Session Type: Abstract Session
Session Time: 4:00PM–5:30PM

Background/Purpose: Anterior uveitis (AU) is one of the commonly observed extraspinal manifestations in Axial spondyloarthritis (AxSpA). Data on the protective effects of targeted immunomodulatory therapies at reducing the frequency of AU flare is limited, particularly amongst more recently licensed drugs. The objective of this study was to investigate the incidence of AU in AxSpA patients treated with etanercept, anti-TNF, anti-IL17A and JAK inhibitors, and compare the protective effect between therapies.

Methods: Embase and MEDLINE were systematically searched to identify all RCTs assessing etanercept, anti-TNF, anti-IL17A and JAK inhibitors drugs in patients with AxSpA. The primary outcome of interest was AU events. Patient exposure years were calculated using a per-protocol analysis. Meta-analysis was performed to compare treatments with placebo. A fixed continuity correction of 0.1 was applied to each RCT arm with zero events. Crude incidence (IR) was calculated.

Relative risk between the treatment arm and placebo was estimated and expressed as incidence rate ratios (IRR). Network meta-analysis (NMA) was employed to allow indirect comparisons between the therapies.

Results: Forty-three studies with 9,184 participants met the inclusion criteria. The IR of AU per 100 patient-years were 1.0 [95% CI: 0.4, 1.8] for anti-TNF, 3.2 [1.2, 7.0] for etanercept, 2.2 [1.5, 3.0] for anti-IL17, 1.4 [0.5, 3.4] for JAK inhibitors, and 4.3 [3.3, 5.6] per 100-person years in the pooled placebo group. Compared with placebo, anti-TNF and JAK inhibitors

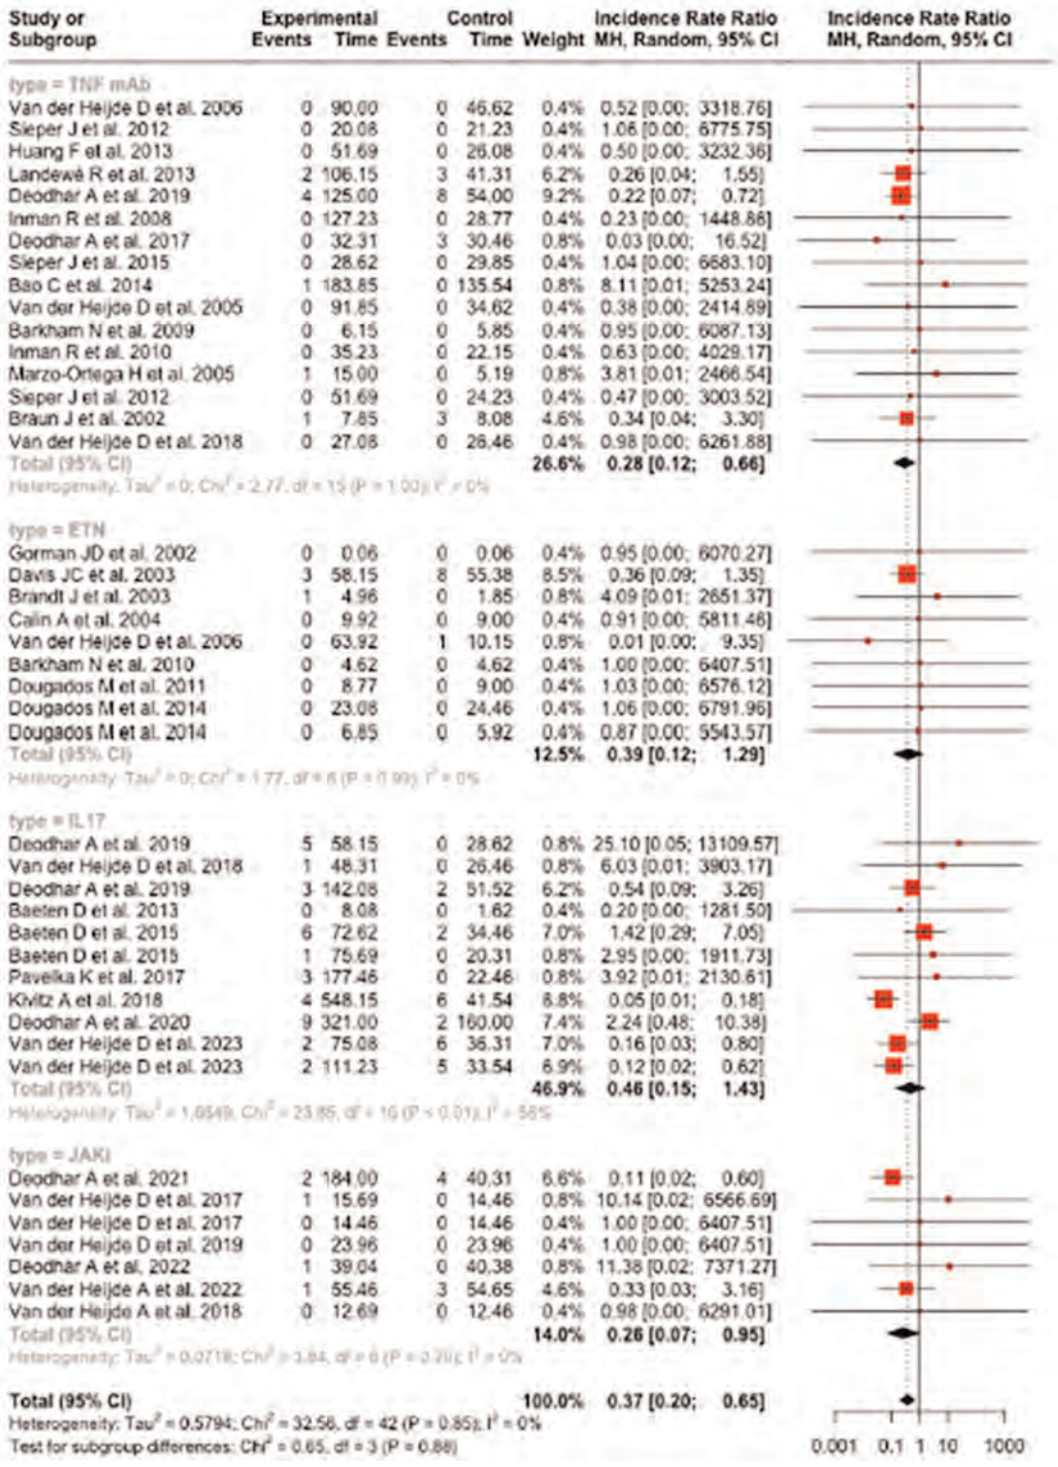

Figure 1. Pairwise meta-analysis, using a per protocol approach to calculated exposure.

had an IRR of uveitis: 0.28 [0.12, 0.66] for anti-TNF and 0.46 [0.07, 0.95] for JAK inhibitors. A lower but non-significant IRR was seen with etanercept (0.39 [0.12, 1.29]) and anti-IL17(0.46 [0.15, 1.43]) (Figure 1). Indirect comparisons between the treatment arms using network meta-analysis did not demonstrate any significant difference in risk of uveitis between different treatment arms.

Conclusion: Targeted immunomodulatory therapy is protective against AU flare. The greatest effects are seen with anti-TNF and JAK inhibitions, although indirect comparisons do not demonstrate any significant difference between treatment modalities.

SESSION INFORMATION

Session Date: Tuesday, November 14, 2023

Session Title: Abstracts: SLE – Diagnosis, Manifestations, & Outcomes III: Disease Activity

Session Type: Abstract Session

Session Time: 4:00PM–5:30PM

Background/Purpose: A key treatment goal in SLE management is the attainment of remission or LDA,[1] for which various definitions exist, including "Definitions of Remission in SLE" (DORIS),[2] and "Lupus LDA State" (LLDAS).[3]Using DORIS and LLDAS criteria, we evaluated remission or LDA attainment in patients with SLE treated with BEL, an approved treatment for active SLE and LN, with standard therapy.

Methods: This is a post hoc analysis of pooled data for adults with SLE from five trials: BLISS-76, BLISS-52, NEA, BLISS-SC, and EMBRACE (GSK Studies BEL110751, BEL110752, BEL113750, BEL112341, and BEL115471). Included patients received BEL (10 mg/kg/month intravenously or 200 mg/week [wk] subcutaneously) or placebo (PBO), plus standard therapy. Attainment of LLDAS and DORIS was compared between BEL and PBO using logistic regression adjusted for trial variance, in the overall population and in the following baseline patient subgroups: SLEDAI 2000 (SLEDAI-2K)score ³10; anti-dsDNA positivity; anti-dsDNA positivity or low complement C3/C4 levels; glucocorticoid (GC) dose (prednisone-equivalent) >7.5 mg/day.

Results: Among 1869 BEL and 1217 PBO patients analyzed, 94.4% were female, mean (standard deviation, SD) age was 37 (12) years. In the overall population, significantly greater attainment of remission was observed for BEL vs PBO at Wk 20 (odds ratio, OR [95% confidence interval, CI]: 1.59 [1.01, 2.50]; p=0.047) and Wk 28 (1.83 [1.20, 2.79]; p=0.005), and BEL superiority was maintained from Wk 48 (1.45 [1.07, 1.95]; p=0.016) to Wk 52 (**Figure**). Statistically significantly greater attainment of LLDAS with BEL vs PBO was first observed at Wk 24 (1.35 [1.04, 1.74]; p=0.022) and was maintained through Wk 52 (**Figure**). Similar results were observed for the baseline patient subgroups, with greater remission/LLDAS attainment with longer treatment, except for the GC >7.5 mg/day dose subgroup, where no significant difference in remission attainment was seen with BEL vs PBO (**Figure**). The earliest superiority of BEL in attaining remission was seen for patients with baselineSLEDAI-2K ³10 at Wk 20 (2.34 [1.11, 4.96]; p=0.026), which was maintained to Wk 52 (**Figure**). Superiority of BEL in attaining LLDAS was first seen at Wk 16 for patients with baselineSLEDAI-2K ³10 (1.65 [1.01, 2.69]; p=0.045),

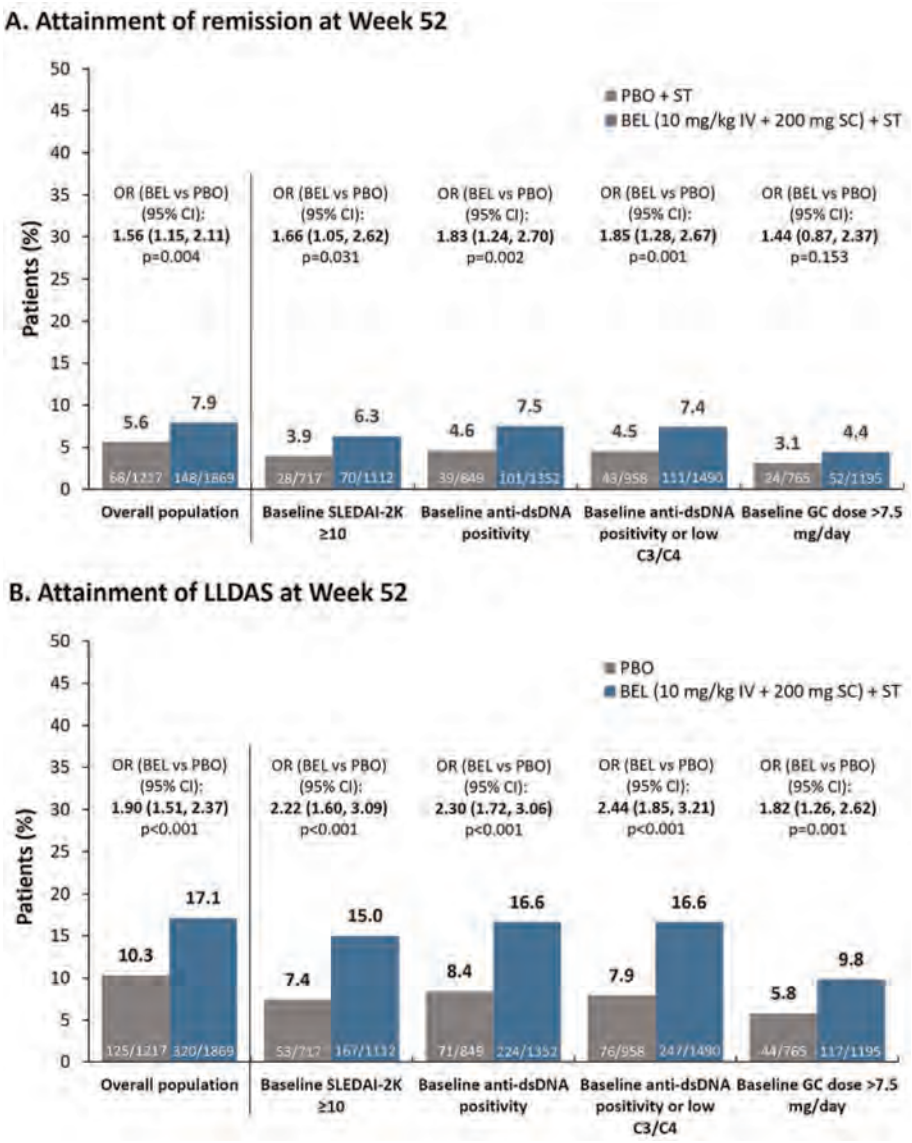

Figure. Remission* (A) and LLDAS† (B) rates in patients with SLE treated with BEL versus PBO, in the overall population, and in patient subgroups per baseline characteristics. Logistic regression (adjusted for the trials) was used for comparisons between BEL and PBO. *The DORIS remission definition requires a clinical SLEDAI-2K score=0 and a PGA score <0.5 (scale 0–3), while it allows serological activity and use of low-dose GCs (prednisone-equivalent <=5 mg/day) and immunosuppressive or biological agents at standard doses; †the LLDAS definition requires a SLEDAI-2K score <=4, excluding major organ activity and fever or new activity since the previous assessment, and PGA score <=1 (scale 0–3), and it allows a prednisone-equivalent dose <=7.5 mg/day and immunosuppressive or approved biological agents at standard doses. IV, intravenous; PGA, Physician Global Assessment; SC, subcutaneous; ST, standard therapy.

baseline anti-dsDNA positivity (1.48 [1.01, 2.18]; p=0.043), and baseline anti-dsDNA positivity/low C3/C4 (1.49 [1.04, 2.12]; p=0.029), and was maintained from Wk 24 (1.78 [1.20, 2.65]; p=0.004, 1.46 [1.05, 2.02]; p=0.025, and 1.49 [1.09, 2.02]; p=0.011, respectively) to Wk 52 (**Figure**).

Conclusion: In this large analysis, statistically significant differences in attainment of remission and LLDAS in favor of BEL vs PBO were seen as early as 24 wks after treatment, with 8% (vs 6%) and 17% (vs 10%) of BEL-treated patients achieving remission and LLDAS, respectively, at Wk 52. BEL appeared particularly beneficial for patients with baselineSLEDAI-2K ^{3}10 and baseline anti-dsDNA positivity/low C3/C4, in whom LLDAS was attained earlier than in the overall population.

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: Abstracts: SLE – Diagnosis, Manifestations, & Outcomes III: Disease Activity
Session Type: Abstract Session
Session Time: 4:00PM–5:30PM

Background/Purpose: Interstitial fibrosis in lupus nephritis (LN) is often infiltrated by immune cells. However, this is typically regarded as nonspecific "scar reaction" rather than active disease requiring treatment. In contrast, scar inflammation in kidney allografts is associated with chronic rejection and treated with immunosuppression. The objective of this study was to investigate the relationship between inflammatory fibrosis and kidney disease progression in LN.

Table 1. Clinical and demographic characteristics.

NIH Chronicity Index (mean (SD))	3.17 (2.50)

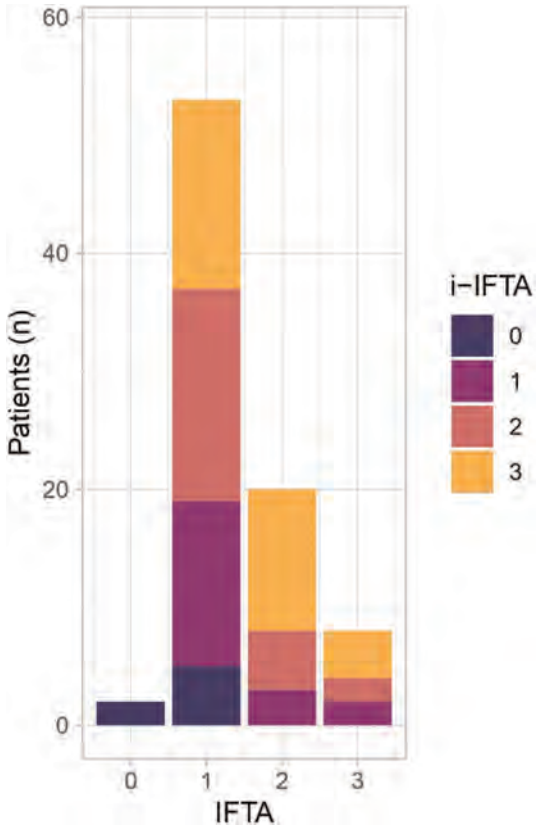

Figure 1. Distribution of i-IFTA groups according to the respective IFTA score. N=124.

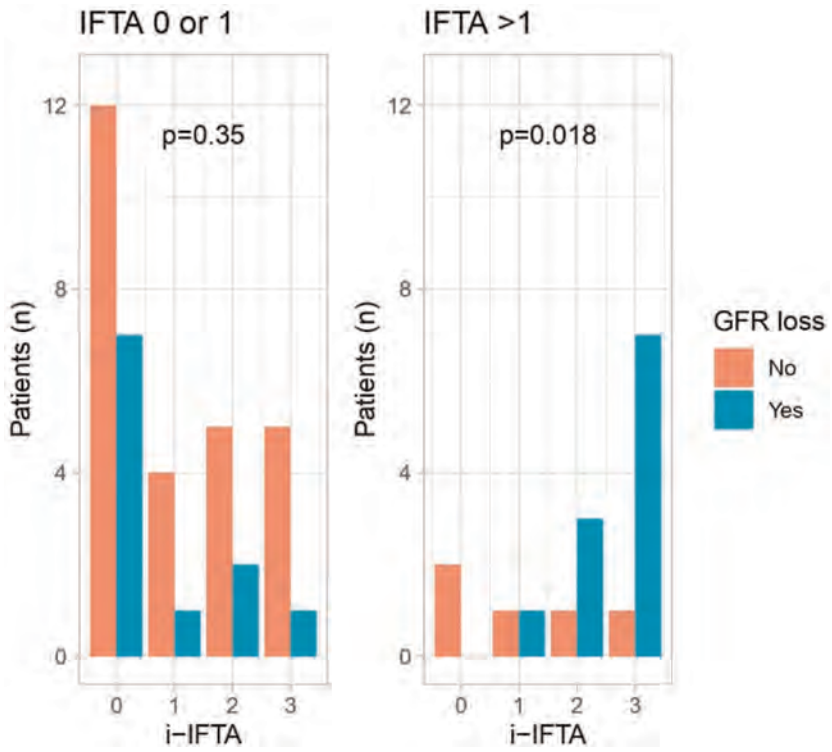

Figure 2. Significant GFR loss according to i-IFTA score. Bars display the frequency of GFR loss in patients with IFTA 0 or 1 (n=37) and IFTA >1 (n=16). Chi-square for trends.

Methods: Interstitial fibrosis and tubular atrophy (IFTA) were scored in 124 kidney biopsies from patients classified as LN according to the 2018 International Society of Nephrology/Renal Pathology Society criteria. Inflammation in areas of IFTA (i-IFTA) was graded 0-3 by 2 operators and reviewed by a senior renal pathologist based on extent according to the Banff Classification of Allograft Pathology (< 10%, 10-25%, 26-50%, >50%, respectively). Glomerular filtration rate (GFR) was estimated using the CKD-EPI equation. Significant GFR loss was defined as a decline of >15 ml/min at 3 years from biopsy or end-stage kidney disease (ESKD) by year 3 requiring dialysis or transplant.

Results: The clinical and demographic characteristics of the cohort are summarized in **Table 1.** IFTA was observed in 88/124 (71%) biopsies, and i-IFTA was identified in 76/88 (86%) cases. The distribution of i-IFTA grades according to the degree of IFTA is illustrated in **Figure 1**. Of the 53 IFTA cases with 3-year follow-up data available, significant GFR loss was observed in 22/53 (42%) cases. As expected, IFTA was associated with GFR loss (p for trend = 0.03). In patients with moderate-to-severe IFTA (grade 2 or 3), the degree of i-IFTA was associated with higher risk of significant GFR loss (**-Figure 2**). The risk of significant GFR loss in this subgroup was 0/2 (0%), 1/2 (50%), 3/4 (75%), and 7/8 (87.5%) for i-IFTA grades 0, 1, 2, and 3, respectively (p for trend = 0.018).

Conclusion: Inflammation in areas of IFTA is frequently observed in LN and exhibits substantial heterogeneity in its severity. For patients with baseline IFTA grades >1, the degree of i-IFTA emerged as a strong predictor of poor renal outcomes. These data support the routine scoring of i-IFTA in LN due to its prognostic implications and nominate i-IFTA as a potential therapeutic target.

Session Date: Tuesday, November 14, 2023

Session Title: Abstracts: SLE – Diagnosis, Manifestations, & Outcomes III: Disease Activity

Session Type: Abstract Session

Session Time: 4:00PM–5:30PM

Background/Purpose: There is increasing interest in adopting the principle of treating to target (T2T) in systemic lupus erythematosus (SLE). Remission and low disease activity states have been demonstrated to have protective associations with adverse outcomes such as flare, damage accrual and mortality. However, knowledge gaps remain in relation to the timing and impact of target attainment. In this study, we aimed to identify (i) the proportion of patients achieving the lupus low disease activity state (LLDAS) and the definition of remission in SLE (DORIS-remission) subsequent to a visit with clinically active disease, (ii) time to attainment of LLDAS and DORIS-remission, (iii) determinants of attaining these targets, and (iv) frequency and time to flare and damage accrual following target attainment.

Methods: Patients in the Asia Pacific Lupus Collaboration (APLC) cohort, followed between 2013 and 2020 who had any clinical disease activity according to the clinical domains of SLEDAI-2K and did not fulfill LLDAS or DORIS-remission were followed from their first time fulfilling these criteria. SELENA-SLEDAI flare index and the SLICC/ACR Damage Index were used to assess flare and damage accrual, respectively. We used Multivariable Cox regression models to analyse factors associated with attainment of LLDAS and DORIS-remission. Generalized estimating equation (GEE) models were used to identify factors associated with flare after attainment of target.

Results: 2852 patients (92.4% female) were followed for a median of 3.3 (1.1-5.7) years. The mean (standard deviations) SLEDAI and PGA at the first visit with clinical activity were 7.0±4.3 and 0.9±0.7, respectively. 1858 (65.2%) of the patients achieved LLDAS, with median (interquartile ranges) time to first attainment of LLDAS being 0.5 (0.3-1.2) years (Figure 1). The proportion and median time to first attainment of DORIS-remission were 49.3% and 0.7 (0.4-1.6) years, respectively. Multivariable Cox model showed that nephritis, positive anti-dsDNA and low complement were associated with a longer time to attainment of LLDAS and DORIS-remission, and in addition non-Asian ethnicity was associated with a longer time taken to attain DORIS-remission (Table 1). After the first attainment of LLDAS, 887/1852 (47.9%) of patients experienced flare(s) with a median time to first flare of 0.7 (0.3-1.4) years. 679/1405 (48.3%) patients had flare(s) after the first attainment of DORIS-remission within a median time of 0.8 (0.3-1.6) years (Figure 1). In multivariable GEE model, factors associated with flare post attainment of LLDAS included tapering of corticosteroids and immunosuppressants (Table 2). 110/960 (11.5%) and 77/750 (10.2%) patients had damage accrual within 24 months of first attainment of LLDAS and DORIS-remission, respectively (Figure 1).

Table 1. Multivariable Cox regression model for determinants of LLDAS or DORIS-remission attainment after the first visit with clinical activity

Model for LLDAS attainment			
Variables at first visit with clinical activity	**HR**	**95% CI**	**P value**
Nephritis	0.50	0.45-0.57	<0.001
Positive anti-dsDNA	0.79	0.72-0.87	<0.001
Low complements	0.84	0.76-0.92	<0.001
Immunosuppressants			
No immunosuppressant	Reference		
MMF/MPA	0.85	0.75-0.96	<0.001
Other immunosuppressant*	0.80	0.72-0.89	<0.001
Model for DORIS-remission attainment			
Variables at first visit with clinical activity	**HR**	**95% CI**	**P value**
Ethnicity			
Asian	Reference		
Non-Asian	0.71	0.60-0.83	<0.001
Nephritis	0.68	0.59-0.77	<0.001
Positive anti-dsDNA	0.80	0.71-0.89	<0.001
Low complements	0.72	0.64-0.80	<0.001
Immunosuppressants			
No immunosuppressant	Reference		
MMF/MPA	0.80	0.70-0.93	0.002
Other immunosuppressant*	0.69	0.61-0.78	<0.001

* Other immunosuppressants include Cyclophosphamide, Cyclosporin, Tacrolimus, Azathioprine, Methotrexate, Leflunomide

Abbreviation: LLDAS: lupus low disease activity state; DORIS: the definition of remission in SLE; anti-dsDNA: anti-double strain DNA; MMF: mycophenolate; MPA: mycophenolic acid

Table 2. Multivariable Generalized Estimating Equation Model for flare at the visit subsequent to LLDAS attainment

Variables	HR	95% CI	P value
Age at visit, per year	0.993	0.988-0.999	0.017
Time-adjusted mean SLEDAI at visit	1.07	1.04-1.10	<0.001
Cumulative duration of LLDAS, per day	0.9997	0.9996-0.9998	<0.001

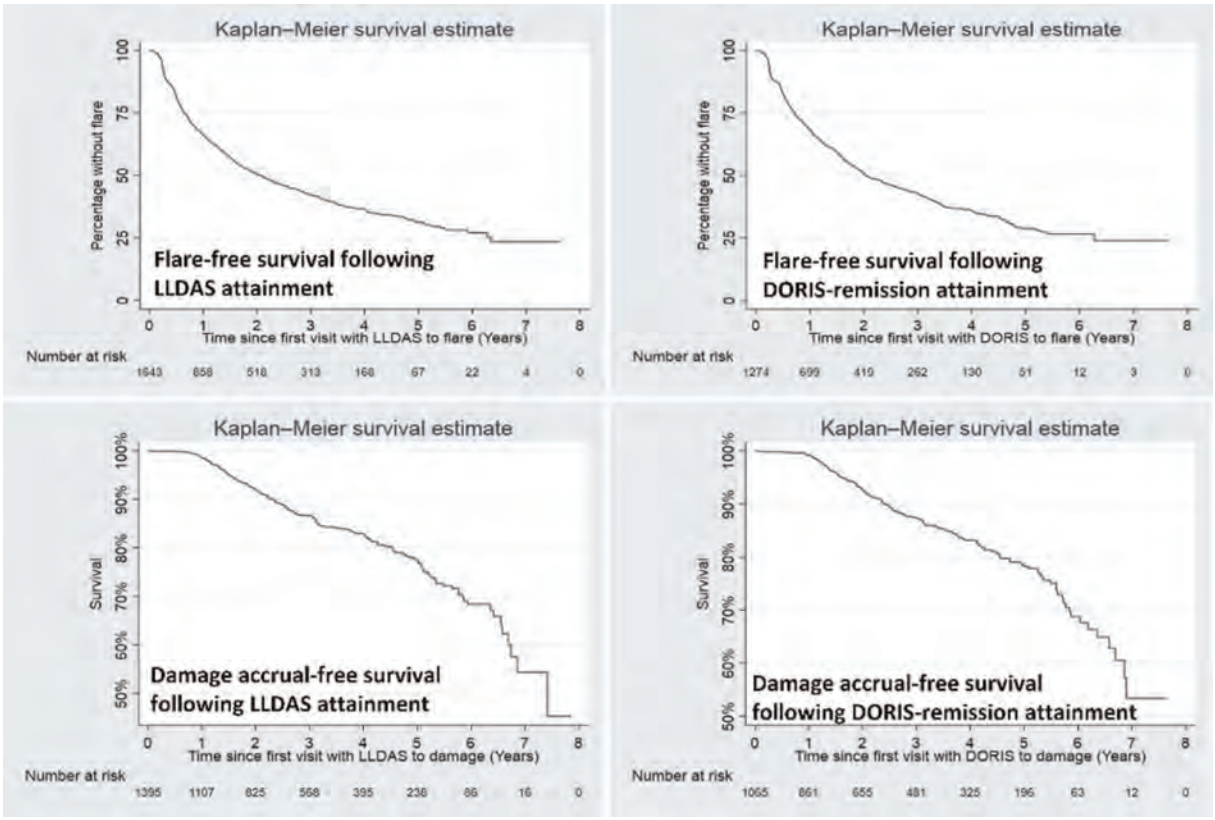
Tapering prednisolone or Immunosuppressants since achieving LLDAS	1.13	1.01-1.25	0.026



Flare-free and damage accrual-free survival after first attainment of LLDAS or DORIS-remission

Conclusion: In patients with clinically active disease, LLDAS and DORIS-remission are both achievable goals. However, flares still occur in almost 50% of patients, and 10-11.5% of patients still accrue damage over two years following LLDAS or DORIS-remission attainment, suggesting that further research is needed to inform monitoring and treatment adjustment in SLE patients to maintain states associated with optimal outcomes.

SESSION INFORMATION

Session Date: Tuesday, November 14, 2023

Session Title: Abstracts: SLE – Diagnosis, Manifestations, & Outcomes III: Disease Activity

Session Type: Abstract Session

Session Time: 4:00PM–5:30PM

Background/Purpose: SLE is marked by immune dysregulation linked to varied clinical disease activity. Using a unique confirmatory cohort of SLE patients, this study seeks to validate a recently refined Lupus Flare Risk Index (L-FRI; Munroe et al. Arthritis Rheumatol. 2023) reflecting altered immunity prior to clinical disease flare.

Methods: The L-FRI is the sum of log-transformed, standardized immune mediators, weighted by the Spearman r correlation coefficient for each preflare/prenonflare analyte vs. subsequent flare/nonflare hSLEDAI disease activity (flare is defined by the SELENA-SLEDAI Flare Index). SLE-associated plasma mediators (n=11) were evaluated by microfluidic immunoassay in 52 preflare and 52 prenonflare samples from patients with classified SLE. Hybrid SLEDAI (hSLEDAI) scores, clinical features, medication usage, and the presence of SLE-associated autoantibody (AutoAb) specificities, including dsDNA, chromatin, Ro/SSA, La/SSB, Sm, SmRNP, and RNP, were also compared at preflare (105 ± 62 days prior to flare) vs. prenonflare (105 ± 55 days prior to nonflare) time points. Data from this validation cohort were compared to development and merged development/validation cohorts.

Results: This validation (Val) cohort is enriched for African American (AA) SLE patients (44% preflare, 48% prenonflare vs. 11% preflare, 15% prenonflare in the development [Dev] cohort), with an associated increase in preflare hSLEDAI scores (4.0±3.4 preflare, 1.9±2.2 prenonflare, *p=0.0004* [Val] vs. 2.4±2.6 preflare, 2.8±3.8 prenonflare, *p=0.8953* [Dev]). Otherwise, after adjusting for multiple comparison, we did not observe differences with respect to clinical features, medication

Figure 2

usage, or number and type of SLE-associated AutoAbs in preflare vs. prenonflare samples. The L-FRI, informed by 11 mediators (**Fig. 1**), significantly ($p< 0.0001$) differentiated preflare vs. prenonflare samples in the Val cohort, similar to that of the Dev and combined (Com) cohorts (**Fig. 1**), with a large (>0.8) Cohen's effect size, AUC >0.7 ($p\leq0.0003$), and Spearman r ≥0.399 ($p< 0.0001$) vs. hSLEDAI scores at disease flare/nonflare (**Fig. 1**). The inclusion of 11 mediators in the L-FRI allows for varied differences between preflare vs. prenonflare across cohorts, yet with consistent differences in osteopontin, TNFRII, TNFRI, and TNF-α (**Table 1**). Furthermore, the L-FRI differentiates SLE patients at risk of imminent severe (S) and mild-moderate (M/M) flares vs. nonflare (**Fig. 2**), with increased L-FRI scores ($p\leq0.05$), effect size (≥1.3), and AUC (≥0.843, $p\leq0.0002$) in pre-severe flare samples across the Val, Dev, and Com cohorts (**Fig. 2**).

Conclusion: We verified the utility of the L-FRI, informed by 11 immune mediators, to identify SLE patients at risk of imminent lupus disease flare. Of particular interest is the ability of the L-FRI to differentiate future M/M vs. severe flare risk. A subset of mediators consistently enhanced the L-FRI to identify SLE patients who may benefit from early intervention strategies. Such an approach would be advantageous in prospective clinical trials for study participant recruitment and assessment, as well as improved management of lupus

SESSION INFORMATION

Session Date: Tuesday, November 14, 2023

Session Title: Abstracts: SLE – Diagnosis, Manifestations, & Outcomes III: Disease Activity

Session Type: Abstract Session

Session Time: 4:00PM–5:30PM

Background/Purpose: Serologically active clinically quiescent (SACQ) is a clinical state of systemic lupus erythematosus (SLE) characterized by high levels of serologic markers without clinical activity. SACQ patients are at potential risk of flares, even organ damage, and thus should be given closer monitoring according to the treat-to-target strategies. However, substantial phenotypic heterogeneity exists in SACQ patients hindering disease management. In this multi-center prospective study, we aimed to determine distinct subgroups among SACQ patients and identify their utility in organ damage prediction.

Methods: SACQ was defined as at least a 6-month period with persistent serologic activity (positive anti-dsDNA antibody, and/or hypocomplementemia), and without clinical activity. Partitioning around medoids (PAM) cluster analysis based on 18 independent components was performed to characterize the phenotypes. The flare was measured according to the SELENA-SLEDAI flare index. Organ damage is principally assessed using the SLICC damage index (SDI).

Results: Of 4107 enrolled SLE patients under standard treatment, 990 (17.1%) achieved the state as SACQ in 2.2 years. During the mean follow-up of 7246.8 patient years, 36.7% of SACQ patients experienced at least one flare in 1.7±0.8 years and 16.5% showed organ damage in 3.0±1.9 years. In SACQ patients, three distinct subgroups (Table) with markedly different features and outcomes were identified (Figure 1). Cluster 1 (n=219, 22.1%) was male, elderly patients, with neural involvement and hematological involvement, corresponding to the highest risk of organ damage accumulation (35.6%) (Figure 2). Cluster 2 (n=279, 28.2%) had the lowest rate of major organ involvements and autoantibodies positivity among the three subgroups and corresponded to mild risk of damage accrual (5.7%). Cluster 3 (n=492, 49.7%) was characterized by the highest proportion of lupus nephritis, corresponding to mild risk of flares (32.7%), moderate risk of organ damage (14.0%), and severe risk of renal damage (7.1%). For the management of SACQ, 224 patients tried tapering glucocorticoids. 86 (30.8%) patients in cluster 2 ("mild involvements" cluster) tapered glucocorticoids under tight control and 49 of them withdrawn successfully without flares. In contrast, only 31 (14.2%) patients in cluster 1 ("severe involvements" cluster) tried to withdraw glucocorticoids.

Table. Clinical features of the three clusters.

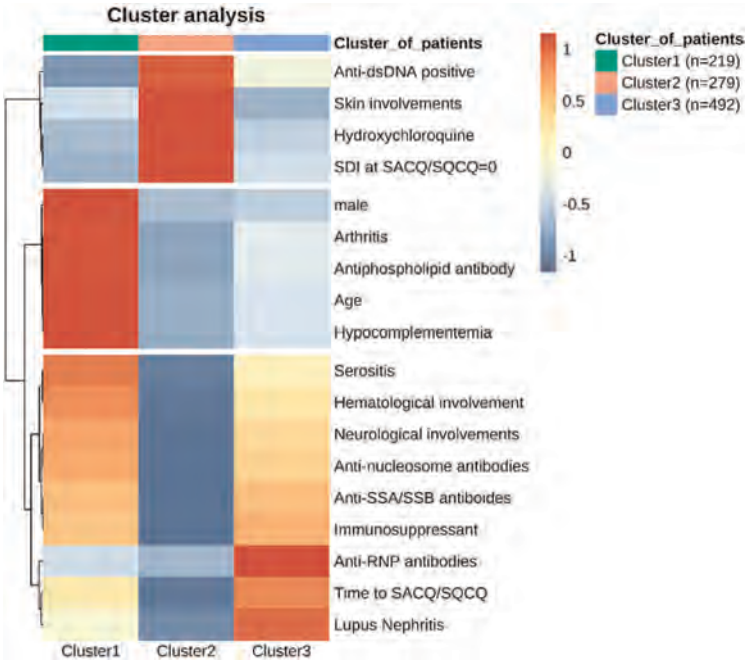

Figure 1. Heatmap of the cluster analysis.

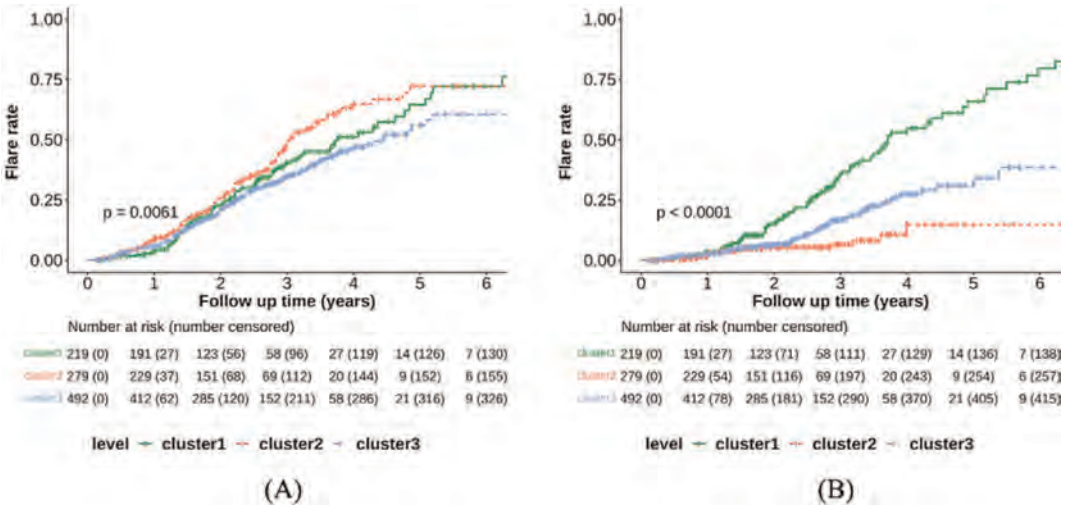

Figure 2. Cumulative probability of flares (A) and damage accrual rate (B) in the three clusters of SACQ patients

Conclusion: Our study distinguished three distinct clinical patterns and outcomes in SACQ patients. Low-dose glucocorticoid withdrawal under tight surveillance should be considered in SACQ patients without major organ involvement. Classification of SACQ patients into phenotypes with prognostic values may facilitate the individualized management of SACQ patients.

SESSION INFORMATION

Session Date: Tuesday, November 14, 2023

Session Title: Abstracts: SLE – Diagnosis, Manifestations, & Outcomes III: Disease Activity

Session Type: Abstract Session

Session Time: 4:00PM–5:30PM

Background/Purpose: SLE patients suffer high symptom burden at the end-of-life. However, the course of disease and treatment burden in the last year of life have not been described. Also, there remains few predictors to identify patients at risk of imminent death within a year that could trigger initiation of supportive care.

Methods: We collected data from SLE patients (ACR/SLICC criteria) prospectively between 2013 to 2020 from 13 Asia-pacific countries. Data at each visit included laboratory variables, SLEDAI and treatment. SLICC Damage Index (SDI) and 36-item Short Form Survey (SF-36) were administered annually. We captured causes of death, with each death possibly attributed to more than one cause. We computed a modified SLICC-frailty index that excluded Sjogren syndrome, hypothyroidism, BMI, hypertension and headache disorder. In order to build a model to identify patients in need of supportive care at the end-of-life, we used a generalized estimating equations (GEE) model that included variables at a given visit that could predict imminent death within a year. Next, we used GEE models to compare the course of disease in the last year of life versus before, with respect to (i) flares; (ii) use of immunosuppressive agents (IS); (iii) corticosteroid dose (CS); (iv) treatment escalation or tapering (any increase or decrease respecitvely, in IS/CS doses); (v) visit intervals; (vi) SF36 physical (PCS) and mental (MCS) scores.

Table 1. Multivariable Generalized Estimating Equation Model for Odds of Imminent Death Within One Year

	Odds Ratio (95% CI)	Standard coefficient	*p*
Age	1.02 (0.98-1.06)	0.02	0.32
Female vs male	1.89 (0.37-9.56)	0.63	0.44
Primary vs tertiary education	0.80 (0.24-2.73)	-0.22	0.72
Highest gross domestic product (GDP) category*	0.19 (0.07-0.49)	-1.68	<0.01
Anti-malarial (no vs yes)	1.29 (0.61-2.72)	0.25	0.51
Immunosuppressive therapy (no vs yes)	1.04 (0.54-1.98)	0.04	0.92
Prednisolone dose	1.00 (1.00-1.01)	<0.01	0.07
Haemoglobin	0.99 (0.98-1.00)	-0.01	0.07
Albumin	0.99 (0.95-1.03)	-0.01	0.61
Estimated glomerular filtration rate	1.00 (0.99-1.02)	<0.01	0.71
aPL positivity (no vs yes)	3.25 (1.13-9.37)	1.18	0.03
Disease duration	1.03 (0.97-1.08)	0.03	0.38
SLEDAI	1.04 (0.96-1.12)	0.04	0.35
SDI	1.52 (1.18-1.96)	0.42	<0.01
Frail*	0.55 (0.23-1.32)	-0.60	0.18

* GDP >$50000 per capita compared to <$20000 per capita

*Classified as frail on modified SLICC frailty index which excludes Sjogren syndrome, hypothyroidism, BMI, hypertension and headache disorder. Compared to other non-frail categories.

Results: We studied 4105 patients, of which 90 died at a median age of 43 (29.5-56.5) years and 7 (2-12) years after diagnosis. The most prevalent cause of death was infection (57/90, 63.3%) followed by SLE (40/90, 44.4%). The modified SLICC frailty index scores before death revealed that 73/90 (81.1%) were least fit or frail. In the last year of life, patients spent 56.9% of days on IS, the median CS dose was 10 (2.2-17.8) mg/day and visit interval was 85 (50-117) days; 41/90 (53.9%) had treatment escalated whereas 16/90 (21.1%) received treatment tapering.

A model that included age, sex, anti-malarial use, country gross domestic product (GDP), haemoglobin, albumin, CS dose, SDI, SLEDAI and modified SLICC frailty was not sensitive (65.6%) or specific (73.4%) in identifying patients who would demise in a year. (Table 1).

In multivariable GEE models, the odds of flare were higher in the last year of life (OR 1.59, 95% CI 1.09-2.31, p=0.016). Patients had higher odds of staying in low disease activity (LLDAS) before the last year of life (OR 3.63, 95% CI 2.17-6.05, p< 0.01). Patients had fewer days on IS in the year preceding death, as compared to other years (p= 0.047), but had higher daily CS doses (p< 0.01) and shorter visit intervals (p< 0.01). Patients in the last year of life received more treatment escalations (OR 2.30, 95% CI 1.29-4.13, p=0.005). There were no significant differences in treatment tapering, PCS or MCS scores before or during the year preceding death.

Conclusion: In the year leading up to demise, SLE patients suffer increased flares and higher treatment burden. Existing disease-related instruments, laboratory and clinical variables have limited utility in identifying patients who would die within a year. Our results highlight an urgent need to better identify and support SLE patients near the end-of-life.

SESSION INFORMATION

Session Date: Tuesday, November 14, 2023

Session Title: Abstracts: Vasculitis – Non-ANCA-Associated & Related Disorders II: Clinical

Session Type: Abstract Session

Session Time: 4:00PM–5:30PM

Background/Purpose: Patients with giant cell arteritis (GCA) are at increased risk of thoracic aortic aneurysm and dissection. This late complication of the disease is presumed to reflect damage from prior aortitis, however whether ongoing aortic inflammation contributes to aneurysm formation is largely unknown. The aim of this project was to investigate the clinicopathologic findings of patients with GCA who underwent thoracic aorta repair.

Methods: Patients who had thoracic aorta surgery at our institution between January 1, 2000, and December 31, 2021, were identified and screened for a prior diagnosis of GCA. The available data was manually abstracted from the medical records of all study subjects, and two cardiovascular pathologists reviewed available aorta tissue obtained during surgery. Grade 1 inflammation of the aorta was defined as inflammation limited to the peri-vasa vasorum or focal involvement, grade 2 was defined as inflammation beyond the peri-vasa vasorum or multifocal involvement but less than 50% of the medial thickness, grade 3 was defined as diffuse inflammation with involvement of equal or more than 50% of the medial thickness. Survival rates were estimated using Kaplan-Meier methods. Overall observed survival was compared with lifetable rates from the US population. The standardized mortality ratio was estimated as the ratio of the observed and expected number of deaths.

Results: Of the 4621 patients who underwent thoracic aorta surgery during the study period, 49 had a previous diagnosis of GCA (Table 1). Thirty-two (65%) were female, and 43 (88%) patients had either positive temporal artery biopsy or met the 1990 ACR or 2022 ACR/EULAR classification criteria for GCA. Forty-one patients had cranial symptoms at GCA diagnosis. All patients were considered in clinical remission at the time of aortic surgery. Ten (20%) patients had thoracic aortic dissection. Inflammatory markers (median [IQR]) were lower at the time of aortic surgery compared to initial diagnosis (erythrocyte sedimentation rate (mm/hr): 91 [54.0- 109.5] vs. 10 [5.0- 20.0]; C-reactive protein (mg/L): 76.5 [28.0- 139.0] vs. 3.1 [3.0- 8.0]). Histopathologic evaluation of the aortic tissue revealed active aortitis in most patients with GCA (40/49, 82%) after a median (IQR) of 6.0 (2.6- 10.3) years from GCA diagnosis. Healed aortitis was detected in 5 (10%) patients, and in 4 (8%) patients there was no evidence of active or healed aortitis. Nineteen (39%) patients were on immunosuppressive treatment at the time of aortic surgery. The detailed histopathologic re-evaluation of 43 out of 49 aortic samples revealed grade 1 aortitis in 17 (40%) patients, grade 2 in 12 (28%), and grade 3 in 5 (12%) (Table 2). The overall mortality compared to age and sex-matched general population was significantly increased with a standardized mortality ratio of 1.55 (95% CI, 1.05- 2.19) (Figure 1).

Conclusion: Histopathologic evaluation of the thoracic aorta obtained during surgery revealed active aortitis in most patients with GCA despite being considered in clinical remission several years after the initial diagnosis. Chronic, smoldering aortic inflammation likely contributes to the development of aortic aneurysm and dissection in GCA.

Table 1. Characteristics of the patients with giant cell arteritis who had thoracic aorta surgery.

	Total (n=49)	Active Aortitis (n=40)	Healed Aortitis (n=5)	No Evidence of Active or Healed Aortitis (n=4)
Age at GCA diagnosis, mean (SD) years	68.4 (7.66)	68.3 (7.52)	64.3 (7.90)	74.0 (7.12)
Age at aortic surgery, mean (SD) years	75.3 (7.25)	75.3 (7.42)	74.9 (7.90)	75.7 (6.42)
Sex, female	32 (65%)	28 (70%)	4 (80%)	0 (0%)
Race, white	48 (98%)	39 (98%)	5 (100%)	4 (100%)
Smoking, ever	27 (55%)	21 (53%)	3 (60%)	3 (75%)
Body mass index, mean (SD)	26.05 (4.22)	25.84 (3.93)	24.58 (5.80)	29.65 (4.77)
Polymyalgia rheumatica	20 (41%)	18 (45%)	0 (0%)	2 (50%)
Hypertension	43 (88%)	34 (85%)	5 (100%)	4 (100%)
Diabetes mellitus	6 (12%)	5 (13%)	0 (0%)	1 (25%)
Hyperlipidemia	37 (76%)	30 (75%)	4 (80%)	3 (75%)
Length of time between GCA diagnosis and aorta surgery, median (IQR) years	5.6 (2.5- 10.4)	6.0 (2.6- 10.3)	11.5 (9.5- 11.6)	1.9 (0.9- 2.6)
Follow-up duration, median (IQR) years	6.3 (2.8- 8.7)	6.4 (3.0- 8.6)	8.5 (2.5- 11.4)	4.3 (2.6- 8.9)
Positive Temporal Artery Biopsy	32/41 (78%)	27/35 (77%)	4/4 (100%)	1/2 (50%)
1990 ACR GCA Classification	39 (80%) [a]	33 (83%)	3 (60%)	3 (75%)
2022 ACR/EULAR GCA Classification	36 (73%) [b]	31 (78%)	4 (80%)	1 (25%)
Patients diagnosed with GCA at our institution	21 (43%)	19 (48%)	1 (20%)	1 (25%)
Duration of treatment with GCs prior to aortic surgery, median (IQR) years	2.0 (1.0- 3.9)	2.2 (1.0- 4.1)	2.5 (1.7- 6.3)	0.6 (0.4- 1.6)
Number of patients on immunosuppressive treatment at aortic surgery	19 (39%)	16 (40%)	1 (20%)	2 (50%)

[a] 6/10 patients who did not meet the 1990 ACR Criteria had limited data for at least one of the criteria questions.
[b] 7/13 patients who did not meet the 2022 ACR/EULAR Criteria had limited data for at least one of the criteria questions.

Table 2. Detailed histopathologic re-evaluation of 34 aorta specimens showing active aortitis.

Inflammatory Pattern	Total Active Aortitis (n=34)	Grade 1 Active Aortitis (n=17)	Grade 2 Active Aortitis (n=12)	Grade 3 Active Aortitis (n=5)
Granulomatous	15 (44%)	7 (41%)	6 (50%)	2 (40%)
Lymphoplasmacytic	12 (35%)	7 (41%)	4 (33%)	1 (20%)
Mixed (Both granulomatous and lymphoplasmacytic)	3 (9%)	0 (0%)	1 (8%)	2 (40%)
Other	4 (12%)	3 (18%) (lymphohistiocytic)	1 (8%) (predominantly granulomatous, focally suppurative)	0 (0%)

SESSION INFORMATION

Session Date: Tuesday, November 14, 2023

Session Title: Abstracts: Vasculitis – Non-ANCA-Associated & Related Disorders II: Clinical

Session Type: Abstract Session

Session Time: 4:00PM–5:30PM

Background/Purpose: Aortic aneurysms is a serious complication that can occur in patients with giant cell arteritis (GCA) **(1-2)**. Tocilizumab (TCZ) is approved for GCA. Nevertheless, to date, the usefulness of TCZ in aortic aneurysms has not been evaluated.

Our aim was to assess the role of TCZ in **a)** prevention of development of aneurysms, and **b)** impairment of aneurysm if present.

Methods: Observational, multicenter study of 196 patients with aortitis related to GCA treated with TCZ. Patients were diagnosed with GCA accordingly to **a)** American College of Rheumatology criteria, and/or **b)** positive biopsy of temporal artery, and/or **c)** the presence of imaging techniques consistent with LVV.

TABLE 1. Main features of 196 patients with aortitis related to GCA.

	Overall N=196	GCA-aortitis with aneurysm (n=10)	GCA-aortitis without aneurysm with imaging follow-up test (n=95)	p
General features

10	78/Female	Thoracic aorta	^{18}F-FDG PET/CT scan	3.9	Not performed	–	–	No

Abbreviations: CT-A: computed tomography angiography; ^{18}F-FDG PET/CT: ^{18}F-fluorodeoxyglucose positron emission tomography/computed tomography

Characteristics and outcome of aortic aneurysms in treatment with TCZ

Patients with GCA-aortitis were divided into two subgroups: **a)** with, and **b)** without aortic aneurysms.

Results: We studied 196 (148 women/48 men; mean age 71.3±9.5 years) patients with aortitis related to GCA treated with TCZ. Aortitis was confirmed by PET in all cases. Aortic aneurysms were present in 10 of 196 (5%) patients when TCZ was initiated.

Imaging in follow-up was present in these 10 patients and in 95 of the remaining 186 patients, that were finally studied. Main general features of both groups are shown in **TABLE 1.** No significant differences were observed between the two groups except for the median serum CRP value, which was higher in the group of patients with aneurysms. After a mean follow-up of 25±19 months, none of the 95 GCA-aortitis patients without aneurysm at TCZ initiation developed any aneurysm.

In **TABLE 2** are summarized the characteristics and follow-up of the 10 patients with aneurysms. Aneurysms were more frequently located in thoracic segment (n=5; 50%). Early surgery was required in 5 cases at TCZ initiation, and the usefulness of TCZ in these cases could not be assessed. From the remaining 5 patients, 3 patients experienced aneurysm growth despite TCZ therapy and a surgery was required during follow-up. The other 2 patients remained stable and did not require surgery due to the small size of the aneurysm.

Conclusion: Aortic aneurysms is a rare, but not exceptional complication in patients with aortitis related to GCA. In these patients, although TCZ could prevent the development of new aneurysms, it does not appear to prevent aneurysm growth.

Clinical Manifestations and Immunomodulatory Treatment in Patients with Relapsing Polychondritis

Roger Yang[1], Rennie Rhee[2], Kaitlin Quinn[3], Naomi Amudala[2], Peter Grayson[4], Peter Merkel[2], Marcela Ferrada[5] and **Shubhasree Banerjee**[2], [1]University of Pennsylvania, Montréal, QC, Canada, [2]University of Pennsylvania, Philadelphia, PA, [3]National Institute of Arthritis and Musculoskeletal and Skin Diseases (NIAMS), National Institutes of Health (NIH), Bethesda, MD, [4]National Institutes of Arthritis and Musculoskeletal and Skin Diseases (NIAMS), National Institutes of Health (NIH), Chevy Chase, MD, [5]NIH, Bethesda, MD

SESSION INFORMATION

Session Date: Tuesday, November 14, 2023

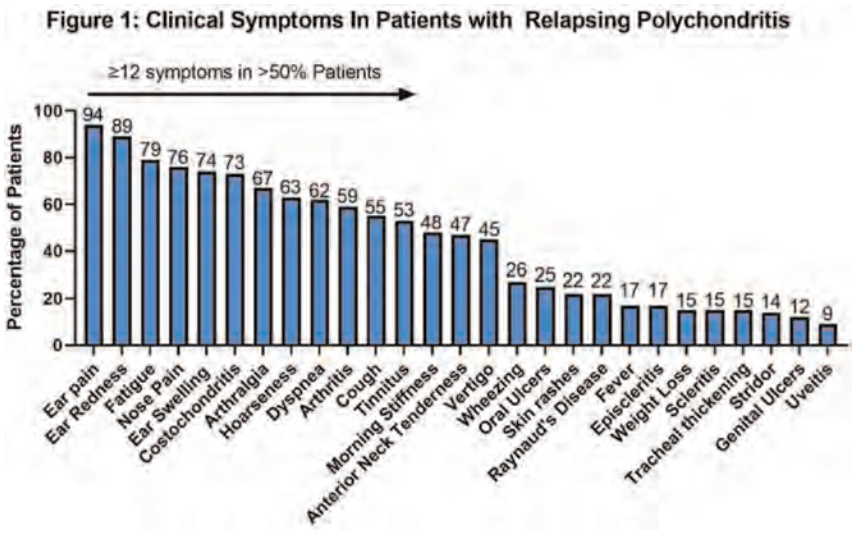
Session Title: Abstracts: Vasculitis – Non-ANCA-Associated & Related Disorders II: Clinical

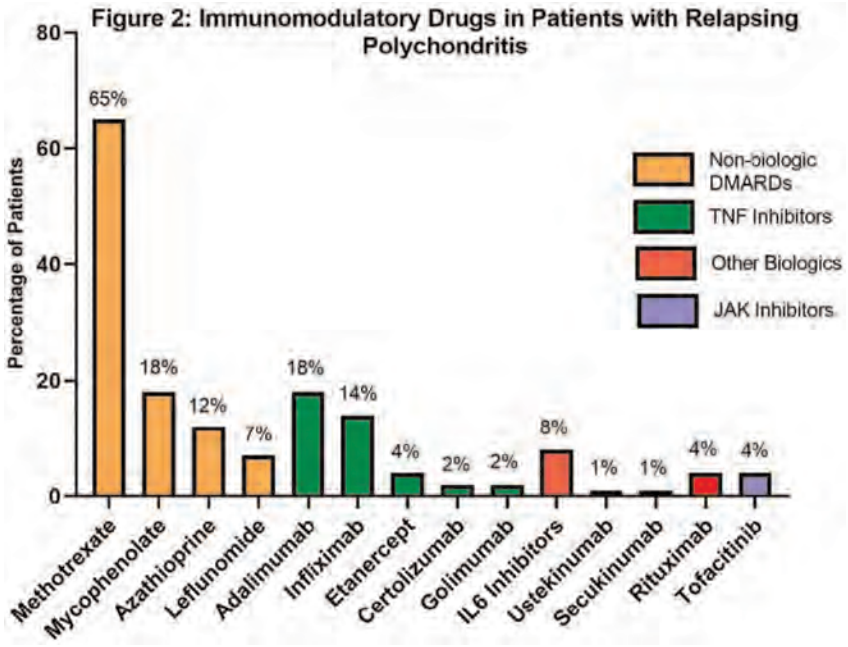
Session Type: Abstract Session

Session Time: 4:00PM–5:30PM

Background/Purpose: Relapsing polychondritis (RP) is a rare systemic inflammatory disease without standard treatment guidelines. This study aims to investigate the clinical characteristics, current treatment approaches, and association between clinical manifestations and immunomodulatory medication use in patients with RP.

Methods: This study included adult patients with physician-diagnosed RP enrolled in a multicenter prospective observational cohort. Data collected at baseline included demographics, clinical manifestations of RP ever experienced, disease damage indices, and immunomodulatory medications ever received. History of immunomodulatory treatment was categorized into three groups: I) no treatment or treatment only with glucocorticoids (GCs); II) treatment with non-biologic immunosuppressive (IS) drugs [other than Janus kinase inhibitors (JAKis)] with/ without GCs; III) treatment with JAKis and/or biologic IS with/without GCs/non-biologic IS. Chi-square test and logistic regression were used to determine the association between categorical and continuous independent variables.





Results: The study included 195 patients with RP. The clinical characteristics are detailed in **Figure 1**. Mean age was 49 (SD 13) years, with 86% (n=167) female, and 89% (n=174) Caucasians. Mean age at diagnosis was 43 (SD 13) years and mean disease duration was 5 (3-8) years.

All patients in the cohort had ear-nose-throat involvement and the majority (83%, n=163) had musculoskeletal manifestations. Clinical manifestations were heterogeneous and >50% (n=102) of patients had 12 or more symptoms (**Figure 1**). Permanent organ damage included sensorineural hearing loss in 26% (n=50), auricular deformity in 12% (n=23), saddle nose deformity 12% (n=23) and subglottic stenosis (SGS) in 9% (n=18). In subjects who underwent dynamic CT chest (n=162), tracheomalacia and bronchomalacia were found in 31% (n=50) and 20% (n=32), respectively.

Distribution per treatment group was: group I- 37 (19%) patients; group II- 55 (28%) patients; and group III- 103 (53%) patients. Most patients 95% (n=186) received treatment with GCs. The most frequently prescribed non-biologic drug was methotrexate in 65% (n=126) and the most prescribed class of biologic drugs was TNF inhibitors (29%, n=57) (**Figure 2**). Patients with arthritis were more likely to be in treatment group III (63%) compared to groups I and II (14% and 22%; P=0.01). Nasal inflammation was common in groups II and III (80% each) compared to group I (56%; P=0.02). Dry cough was associated with Group III (61%) vs Groups I and II (13% and 26%, P= 0.03). Patients with SGS were more likely to be in Group III (88%) vs group I and II (5%, P< 0.01). Tracheal thickening was also more common in Group III (76%) vs Groups I and II (16% and 8%; P=0.03).

Conclusion: Patients with RP have heterogeneous clinical presentations and are treated with a variety of immunosuppressive drugs. Arthritis, nasal inflammation, cough, SGS and tracheal thickening were associated with more frequent use of biologic drugs/JAKi or non-biologic IS. These findings highlight the absence of a consensus approach to treatment of RP and underscore the need for clinical trials and treatment guidelines in RP.

Risk of Gastrointestinal Perforation Among Patients with Giant Cell Arteritis Who Received Tocilizumab

Desh Nepal[1], Sebastian Sattui[2], Zachary Wallace[3] and Mike Putman[4], [1]Medical College of Wisconsin, Milwaukee, WI, [2]University of Pittsburgh, Pittsburgh, PA, [3]Massachusetts General Hospital, Newton, MA, [4]Division of Rheumatology, Medical College of Wisconsin, Milwaukee, WI

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: Abstracts: Vasculitis – Non-ANCA-Associated & Related Disorders II: Clinical
Session Type: Abstract Session
Session Time: 4:00PM–5:30PM

Background/Purpose: Exposure to the interleukin-6 inhibitor tocilizumab has been associated with an increased risk of gastrointestinal (GI) perforation in patients with rheumatoid arthritis. No studies to date have evaluated the risk of GI perforation in patients with giant cell arteritis (GCA) on treatment with tocilizumab. This study aimed to describe the incidence and risk factors associated with GI perforation among incident cases of GCA receiving treatment with tocilizumab.

Methods: We performed a retrospective cohort study of incident cases of GCA using the US-based TriNetX electronic health records database from 1/1/2010 to 4/23/2023. Patients were included if they had (1) 2 ICD-9CM/ICD10-CM codes for GCA separated by 30 days but within 1 year and (2) received any dose of prednisone within 30 days of the first GCA code. Gastrointestinal perforations were defined by ICD-9-CM/ICD-10-CM codes as described previously, and the incidence of gastrointestinal perforations as well as unadjusted incident rate ratios were calculated.1 Adjusted analysis using a Poisson regression was conducted. The clone-censor-weight approach was then used to account for immortal time bias. After cloning, censoring, and weighting using inverse probability of censoring, time-updated multivariable Cox proportional hazards models were used to calculate the hazard ratio (HR) and 95% confidence intervals for the risk of GI perforation.

Results: During the study period, 5,142 patients met the inclusion criteria (845 tocilizumab exposed and 4,297 tocilizumab unexposed), the majority of whom were female (3,624, 70.5%) and white (3,728, 72.5%) (Table 1). Incident GI perforations among tocilizumab exposed vs. unexposed were 2.0/1,000 person-years and 3.4/1,000 person-years, respectively, resulting in an incident rate ratio of 0.57 (95% CI 0.14-2.41). The adjusted rate ratio (RR) of GI perforation with tocilizumab use in a Poisson regression was RR 0.56 (95% CI 0.13-2.38). Factors associated with GI perforation included the history of diverticulitis (RR 3.51, 95% CI 1.55-7.96) and the use of intravenous methylprednisolone (RR 5.41, 95% CI 2.41-12.12). After implementing the clone-censor-weight approach, tocilizumab exposure was not associated with an increased risk of GI perforation (HR 1.05, 95% CI 0.30-1.65).

Conclusion: In this retrospective cohort study of patients with incident GCA, GI perforations were rare. When compared with steroid treatment, tocilizumab exposure was not associated with an increased risk of GI perforation. Risk factors for GI perforation included a history of diverticulitis and intravenous methylprednisolone use. These findings highlight the importance of judicious steroid use and will be useful for counseling patients considering initiation of IL-6 inhibitors.

SESSION INFORMATION

Session Date: Tuesday, November 14, 2023

Session Title: Abstracts: Vasculitis – Non-ANCA-Associated & Related Disorders II: Clinical

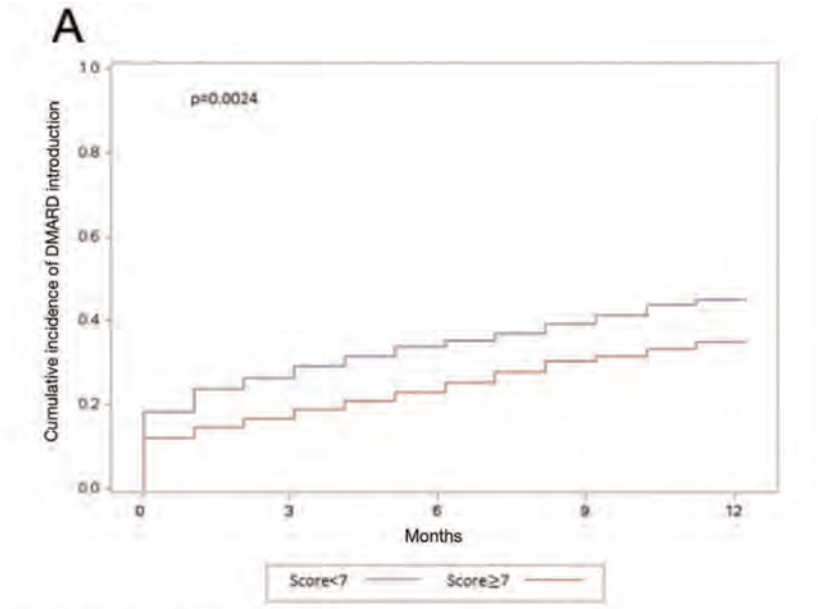
Session Type: Abstract Session

Session Time: 4:00PM–5:30PM

Background/Purpose: The 2022 classification criteria for giant cell arteritis (GCA) have been recently published. The aim of this study is to investigate whether the score obtained by summing clinical and laboratory items and the fulfillment of each item correlate with prognosis.

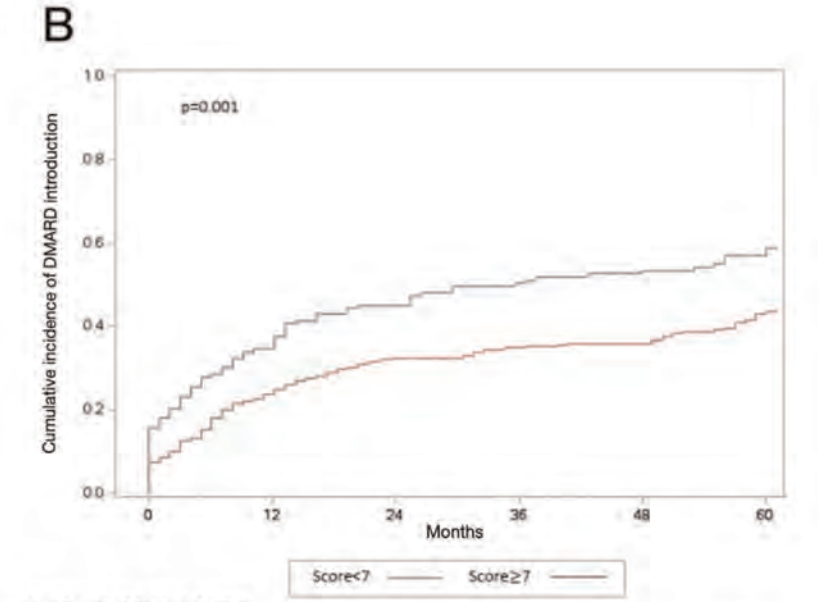
Methods: Data of GCA patients from centres belonging to the Italian Society of Rheumatology Vasculitis Group were retrospectively reviewed. Baseline clinical/laboratory items included in the 2022 GCA classification criteria were retrieved and summed to obtain a total score (from 0 to 16). Therapy-related complications, disease-related outcomes and need for disease-modifying drug (DMARD) introduction at baseline (only for visual loss [VL]), at 12 months and at 60 months were evaluated. Univariate and multivariate logistic analyses were performed.

Results: 873 patients (mean score, 8.1 ± 3.3; mean items fulfilled per-patient, 4.2 ± 1.6) were included. Follow-up data were available for all patients at 12 months and for 467 (53.4%) patients at 60 months. At GCA onset, 165 (18.9%) patients had VL. At 12 and 60 months, 41 (4.7%) and 28 (6.0%) patients developed ascending aorta aneurysm (AAA), 86 (9.9%) and



Number of subjects at risk (%)

Score<7	257 (100%)	189 (73.5%)	170 (66%)	156 (60.7%)	141 (55%)
Score≥7	616 (100%)	513 (83%)	475 (77%)	428 (69.5%)	401 (65%)



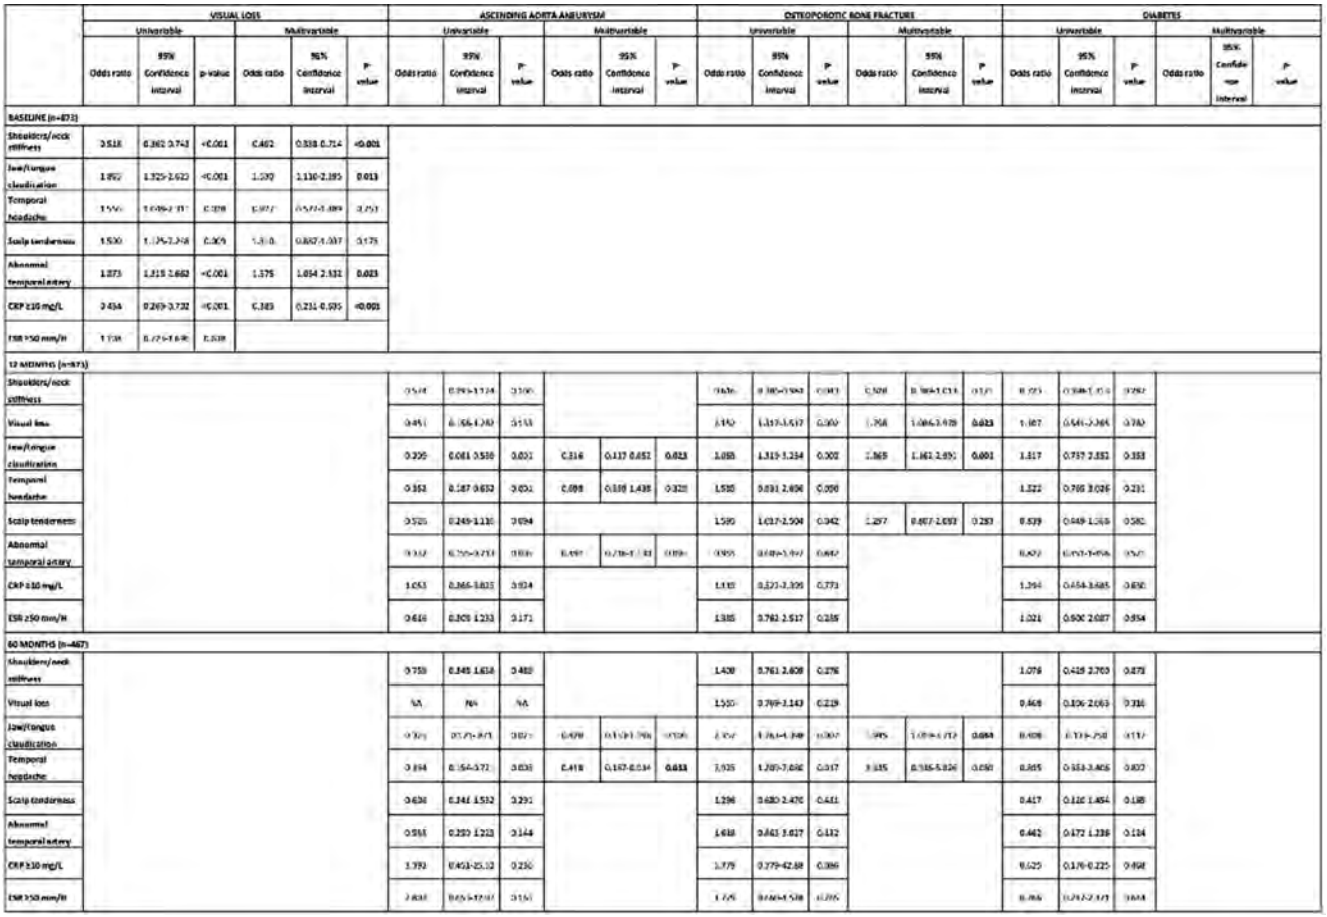
Number of subjects at risk (%)

Score<7	133 (100%)	87 (65.4%)	73 (55%)	66 (49.6%)	62 (46.6%)	55 (41%)
Score≥7	334 (100%)	254 (76%)	226 (67.6%)	217 (65%)	214 (64%)	188 (56%)

Figure legend. Cumulative incidence of DMARD introduction in patients with a score <7 (blue line) and in patients with a score ≥7 (red line) at 12 (A) and 60 months (B).

45 (9.6%) patients suffered from osteoporotic fractures (OF), 49 (5.6%) and 19 (4.1%) patients developed diabetes, respectively. 331 (38%) and 224 (48.0%) patients were prescribed ≥1 DMARD within 12 and 60 months, respectively.

Table legend. Univariate and multivariate logistic analyses evaluating the association of each item with different outcomes.



At univariate analysis, a higher score (excluding 'VL') was associated with VL (OR 1.551 [95%CI 1.439-1.672], p< 0.0001). A higher score was associated with AAA (OR 0.769 [0.687-0.860], p=0.0012; 0.814 [0.718-0.923], p=0.0014) at 12 and 60 months, OF (OR 1.102 [1.029-1.180], p=0.0057, 1.171 [1.064-1.290], p=0.0013) at 12 and 60 months, diabetes at 60 months (OR 0.856 [0.740-0.990], p=0.0364), and need for DMARD introduction at 12 (OR 0.948 [0.909-0.989], p=0.0135) and 60 months (OR 0.902 [0.853-0.955], p=0.0003). A score < 7 was associated with DMARD introduction at both timepoints (Figure).

At multivariate analysis, jaw/tongue claudication and temporal artery abnormality were directly associated with whereas polymyalgic symptoms and CRP ≥10 mg/L were inversely associated with VL. Jaw/tongue claudication was associated with a lower risk of AAA and higher risk of OF at 12 months and with a higher risk of OF at 60 months; headache with a lower risk of AAA at 60 months and VL with a higher risk of OF at 12 months (Table).

Conclusion: Considering only clinical and laboratory items, a higher score obtained from the 2022 GCA classification criteria is positively associated with VL and OF, and negatively with AAA and diabetes. A score < 7 is associated with a higher probability of receiving a DMARD. Cranial symptoms increase the risk of VL and OF but reduce the risk of AAA. PMR symptoms and high CRP levels are protective for VL.

SESSION INFORMATION

Session Date: Tuesday, November 14, 2023

Session Title: Abstracts: Vasculitis – Non-ANCA-Associated & Related Disorders II: Clinical

Session Type: Abstract Session

Session Time: 4:00PM–5:30PM

Background/Purpose: Immune checkpoint inhibitors (ICIs) have dramatically improved the prognosis for many cancers. The therapeutic effect of ICIs is based on their ability to release the brakes on lymphocyte activation. However, this brake release can cause immune-related adverse events (IrAEs) in up to 60-80% of cases. Few observations of ICI-induced large vessel vasculitis (LVV) have been reported. We aimed to describe the characteristics and outcomes of LVV occurring after or during ICI therapy.

Methods: We conducted a European, multicenter, retrospective study of patients who received at least one infusion of ICI and subsequently presented with LVV between March 2018 and January 2023. The diagnosis of giant cell arteritis (GCA) among LVV patients was based on the 2022 ACR/EULAR classification criteria. Remission was defined by the absence of manifestations attributable to active vasculitis and normal acute phase reactants.

Results: Nineteen patients were included (median age 70 (IQR 61-75) years). Previous history of PMR or GCA was noted in 4 (21%) patients. The two most common cancers treated with ICIs were melanoma (32%) and renal cell carcinoma (26%). Five (26%) patients received a combination of nivolumab and ipilimumab, 7 (37%) pembrolizumab, 6 (32%) nivolumab, and 1 (5%) atezolizumab. First LVV manifestations occurred after a median of 5 (IQR 3-19) ICI infusions and a median time of 4 (IQR 2-15) months since the first ICI infusion.

Six (32%) patients had cephalic manifestations, 6 (32%) had vascular manifestations, and 7 (37%) had both. Four patients (21%) had visual loss. Nine (47%) patients had PMR symptoms and 5 (26%) had other IrAEs, mainly hepatitis. 18F-FDG PET/CT showed hypermetabolism of the aorta or its main branches in 12 (63%) patients. Temporal artery biopsy was positive in 3/6 cases. Overall, 13 (68%) of patients fulfilled ACR/EULAR criteria for GCA.

ICIs were still being used at the onset of LVV in 16 patients, while they were discontinued prior to LVV in 3 patients. For patients still on ICIs, management consisted of definitive discontinuation of ICIs in 10 (53%) patients and temporary discontinuation or continuation of ICIs in 6 (32%) patients.

All patients received oral glucocorticoids. The median initial prednisone dose was 0.7 g/kg/d (IQR 0.7-1). Two (11%) patients received tocilizumab as first-line therapy.

Median follow-up after LVV diagnosis was 8 months (IQR 4-14). Remission was achieved in 18 (95%) patients. Three patients relapsed during prednisone tapering, at a median dose of 10 mg/d (IQR 5-15). Overall, 4 (21%) patients did not respond or relapsed during prednisone tapering, including 1/13 (8%) of patients who discontinued ICIs and 3/6 (50%) of patients who continued to receive ICIs. At the end of follow-up, 4/18 (22%) patients had died, 3 of cancer and 1 of acute coronary syndrome.

Conclusion: LVV is a rare IrAE that usually occurs early after the initiation of ICI. Unexplained elevations in acute phase reactants in ICI-treated patients should prompt clinicians to look for signs of LVV, as severe ischaemic manifestations such as visual loss may occur. Patients with ICI-induced LVV who were maintained on ICI or rechallenged had a more refractory or relapsing course.

Causal Associations Between Gut Microbiota and Rheumatic Diseases: A Mendelian Randomization Study

Ying Hu[1], **Hongyi He**[2], Yuqing Zhang[3], Houchen Lyu[4], Chao Zeng[2], Jie Wei[5] and Guanghua Lei[2], [1]Department of Epidemiology and Health Statistics, Xiangya School of Public Health, Central South University, Changsha, China, [2]Department of Orthopaedics, Xiangya Hospital, Central South University, Changsha, China, [3]Division of Rheumatology, Allergy, and Immunology, Department of Medicine, Massachusetts General Hospital, Boston, MA, [4]Chinese PLA General Hospital, Department of Orthopedics, Beijing, China, [5]Health Management Center, Xiangya Hospital Central South University, Changsha, China

SESSION INFORMATION

Session Date: Wednesday, November 15, 2023
Session Title: Abstracts: Epidemiology & Public Health III
Session Type: Abstract Session
Session Time: 9:00AM–10:30AM

Background/Purpose: Gut microbiota has been increasingly recognized as important and novel targets for rheumatic diseases. However, previous studies mostly examined the associations, leaving causality largely unknown, which hinders the clinical application of gut microbiota in preventing and treating rheumatic diseases.

Figure 1. Mendelian randomization results of the correlations between 141 gut microbiota taxa and 14 rheumatic diseases. The red color represents a detrimental effect, while blue represents a protective effect of the gut microbiota on the rheumatic disease. The shade of color represents the significance of associations. Statistically significant (FDR < 0·05) results are indicated by an asterisk (*).

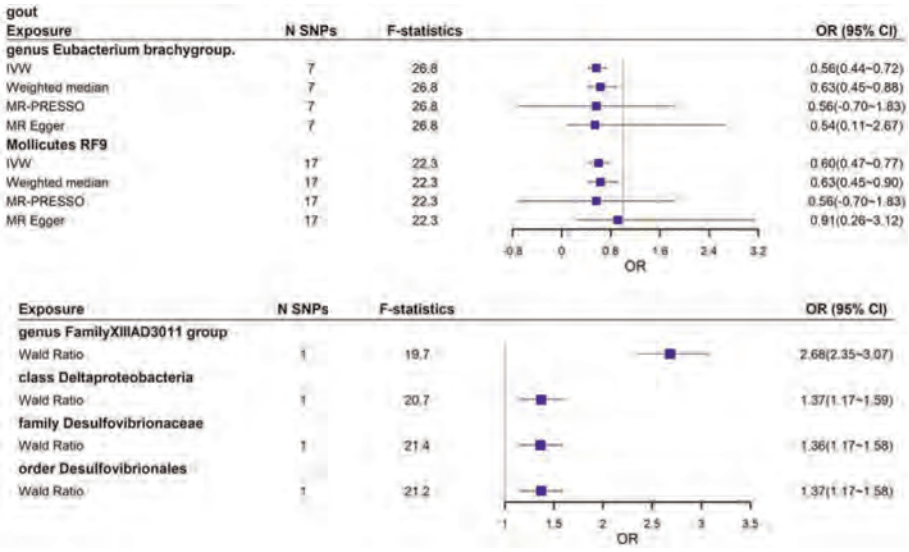

Figure 2. Forest plot for gout and ankylosing spondylitis N SNPs, number of genetic instruments; OR, odds ratio; CI, confidence interval; IVW, inverse-variance weighted; MR-PRESSO, MR pleiotropy residual sum and outlier. Wald ratio was calculated per SNP. If there were more than one SNP, IVW (primary), weighted median, and other MR methods were used to pool the result.

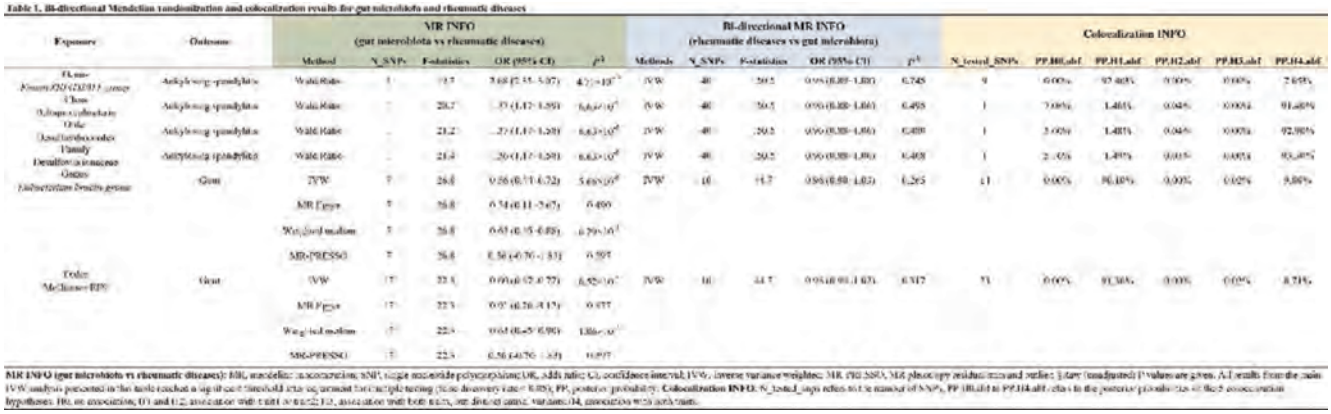
Methods: We performed Mendelian randomization (MR) analysis to investigate the causal associations between gut microbiota and rheumatic diseases. The genetic instruments for 141 gut microbiota taxa were extracted from the published genome-wide association study (GWAS) of individuals with European ancestry (N=18,340), and the summary statistics for 14 rheumatic diseases (sample size ranges from 6,190 to 417,596) were obtained from publicly available GWASs and the FinnGen database. Several MR methods (e.g., inverse-variance weighted and weighted median) were used to examine the causal association, and bi-directional MR and colocalization analyses were performed to examine the potential bi-directional causality and whether the gut microbiota and rheumatic disease share the same causal variant, respectively.

Results: Six pairs of relations between gut microbiota and rheumatic diseases remained statistically significant after multiple testing (FDR < 0.05), among which Genus *FamilyXIIIAD3011 group* (odds ratio [OR]=2.68, 95% CI=2.35-3.07), class Deltaproteobacteria (OR=1.37, 95% CI=1.17-1.59), family Desulfovibrionaceae (OR=1.36, 95% CI=1.17-1.58) and order Desulfovibrionales (OR=1.36, 95% CI=1.17-1.58) increased the risk of ankylosing spondylitis. Genus *Eubacterium brachy group* (OR=0.57, 95% CI=0.44-0.72), order Mollicutes RF9 (OR=0.61, 95% CI=0.48-0.77) decreased the risk of gout. Among them, the results were consistent across different MR methods. Using colocalization analysis, we identified that class

Table 1. Bi-directional Mendelian randomization and colocalization results for gut microbiota and rheumatic diseases



MR INFO (gut microbiota vs rheumatic diseases): MR, mendelian randomization; SNP, single nucleotide polymorphism; OR, odds ratio; CI, confidence interval; IVW, inverse-variance weighted; MR PRESSO, MR pleiotropy residual sum and outlier. P.raw (unadjusted) P values are given. All results from the main IVW analysis presented in the table reached a significant threshold after adjustment for multiple testing (false discovery rate< 0.05). PP, posterior probability. Colocalization INFO: N_tested_snps refers to the number of SNPs, PP.H0.abf to PP.H4.abf refers to the posterior probabilities of the 5 association hypotheses: H0, no association; H1 and H2, association with trait A (trait 1) and B, respectively, but distinct causal variants; H4, association with both traits, one shared causal variant.

Deltaproteobacteria, family Desulfovibrionaceae, and order Desulfovibrionales shared the same genetic variants with ankylosing spondylitis. No evidence of bi-directional causality was found between microbiota and rheumatic disease.

Conclusion: We identified and provided genetic evidence for six novel causal associations between gut microbiota taxa and rheumatic diseases. If confirmed by future animal studies or clinical trials, our results can serve as new clinical targets for rheumatic diseases and thus is conducive to the prevention and treatment of ankylosing spondylitis and gout.

SESSION INFORMATION
Session Date: Wednesday, November 15, 2023
Session Title: Abstracts: Epidemiology & Public Health III
Session Type: Abstract Session
Session Time: 9:00AM–10:30AM

Background/Purpose: Many patients with systemic autoimmune rheumatic diseases (SARDs) using immunomodulators have blunted humoral responses to COVID-19 vaccines. As such, the initial mRNA vaccine series is defined as 3 doses for this population and a 4th (or first "booster") dose was recommended by the CDC in October 2021. However, 4th dose uptake among patients with SARDs has been low. In the general population, a 4th vaccine dose reduces the risk of breakthrough infection; its effectiveness in SARDs receiving immunomodulators has not been established.

Methods: We conducted an emulated target trial in a large US healthcare system, comparing receiving vs. not receiving a 4th vaccine. Eligible patients had SARDs by a validated algorithm including immunomodulator use and were eligible (by CDC guidelines) to receive a 4th dose of BNT162b2 or mRNA-1273 between 1/16/22-6/11/22. We excluded recipients of Ad26.COV2.S. To account for temporal changes in COVID-19 variants and guidance on 4th dose eligibility, the study period was divided into 1-week intervals. Cases were included in a 1-week interval if they received a 4th mRNA dose in that interval; comparators were eligible for a 4th dose but had not yet received it before or during the interval and had similar duration from 3rd dose to account for waning. The index date for cases was the date of 4th dose; for comparators, it was a random date within the interval.

The primary outcome was COVID-19 infection (positive COVID-19 PCR or antigen test or positive COVID-19 flag in the electronic record). Follow-up ended at the earliest of: (1) COVID-19; (2) bivalent vaccine availability (9/1/22); (3) "deviation" from the assigned arm (i.e., 5th dose for cases, 4th dose for comparators); (4) or non-COVID death as a competing risk. The

propensity score (PS) for receiving the 4th dose was calculated weekly using logistic regression. We performed time-stratified, overlap PS-weighted Cox regressions to examine the relation of the 4th dose to the risk of each outcome.

Results: We included a total of 4,010 patients who received ≥3 mRNA vaccines and were eligible for a 4th during the study period; of this group, 2994 received a 4th dose and 1014 did not. Baseline covariates before and after overlap weighting are shown in Table 1. The mean age was 67 years, 72% were female, 88% were White, and most had RA (54%). The most common treatments were conventional synthetic DMARDs (58%) and biologic DMARDs (39%). Prior to the 3rd dose, 599 (14.9%) had had COVID-19.

The incidence of COVID-19 was lower in the 4th dose cohort than comparator cohort (14.8 vs 23.7 per 1000 person-months) (Table 2). The rate difference between the two cohorts was -8.85 (95% CI: -13.37 to -4.33) per 1000 person-months with an HR of 0.59 (95% CI: 0.47-0.74), favoring a 4th dose (Figure). The risk of hospitalization or death within

Table 1: Baseline characteristics of the study cohort, before and after propensity score overlap weighting.

	Before PS Overlap Weighting			After PS Overlap Weighting		
	4 doses	3 doses	Standardized difference	4 doses	3 doses	Standardized difference
Age (mean, SD)	67 (13)	67 (13)	0.72	67 (12)	67 (4)	< 0.001

tsDMARD	3.68	3.29	0.23	3.8	3.8	< 0.001
Oral glucocorticoid	14.1	13.7	0.15	14.5	14.5	< 0.001
Prior COVID-19 infection (%)	8.67	8.9	0.41	8.9	8.9	< 0.001
BNT162b2 as initial 2-dose series	33.8	33.6	0.28	33.8	33.8	< 0.001

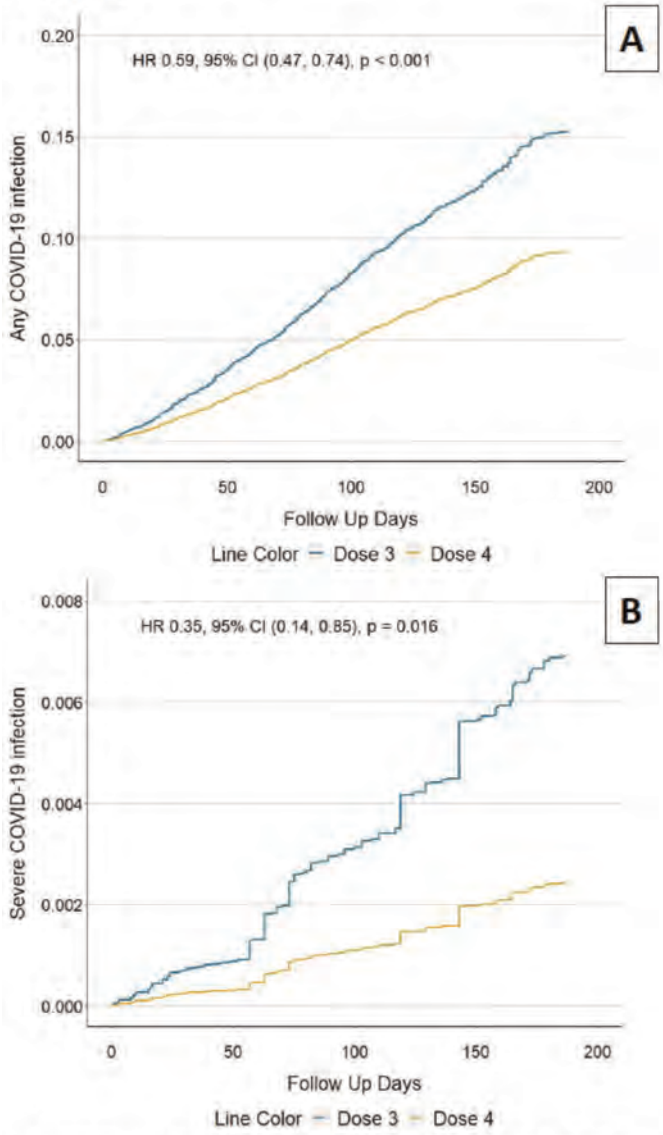
Variables shown were included as covariates in propensity score calculation. BMI: Body mass index. CCI: Charlson Comorbidity Index. bDMARD: biologic disease-modifying anti-rheumatic drug. csDMARD: conventional synthetic disease-modifying anti-rheumatic drug. tsDMARD: targeted synthetic disease-modifying anti-rheumatic drug.

Table 2: Frequency and risk of primary outcome (COVID-19 infection) and secondary outcomes (hospitalization or death within -3 to +14 or 30 days of positive COVID-19 test)

	Number of events		Median follow-up, d (IQR)		Incidence rate, per 1,000 person-months		Rate difference (95% CI), per 1,000 person-months	HR (95% CI)
Outcome	4 doses	3 doses	4 doses	3 doses	4 doses	3 doses	4 vs. 3 doses	4 vs. 3 doses
Primary analysis								
Any COVID-19 infection	196	2153	135 (112, 154)	65 (30, 156)	14.8	23.7	-8.85 (-13.37, -4.34)	0.59 (0.47, 0.74)
Secondary analysis								
Hospitalization/death within 14 days of positive COVID-19 test	10	160	136 (113, 157)	66 (31, 154)	0.36	0.93	-0.57 (-1.16, 0.02)	0.35 (0.14, 0.85)

HR: hazard ratio. IQR: interquartile range. CI: confidence interval.

Figure: Survival curves for those receiving a 4th dose vs not receiving a 4th dose of COVID-19 mRNA vaccine.



HR: hazard ratio. CI: confidence interval. **Panel A:** Survival curves for any COVID-19 infection in patients receiving a 4th vs no 4th dose of mRNA vaccine. **Panel B:** Survival curves for outcome of severe COVID-19 (hospitalization or death within 14 days) in patients receiving a 4th vs no 4th dose of mRNA vaccine.

14 days from COVID infection was lower in the 4th dose cohort than comparators (0.36 vs. 0.93 events/1000 person-months) with an HR of 0.35 (95% CI: 0.14-0.85).

Conclusion: In this emulated target trial, a 4th dose of mRNA vaccine reduced the risk of COVID-19 by 41% and severe COVID-19 by 65% among patients with SARDs using immunomodulators during the Omicron era. Patients with SARDs should be encouraged to receive at least 4 doses of mRNA vaccines.

The Problem of Pain in Rheumatology: A Population-based Study of Annual Trends in Pain Management Modalities in Patients with Autoimmune Rheumatic Diseases in the United States, 2007-2021

Titilola Falasinnu[1], Di Lu[2] and Matthew Baker[3], [1]Stanford School of Medicine, Palo Alto, CA, [2]Stanford School of Medicine, Stanford, CA, [3]Stanford University, Menlo Park, CA

SESSION INFORMATION
Session Date: Wednesday, November 15, 2023
Session Title: Abstracts: Epidemiology & Public Health III
Session Type: Abstract Session
Session Time: 9:00AM–10:30AM

Background/Purpose: Autoimmune rheumatic diseases (ARD) such as systemic lupus erythematosus (SLE) and rheumatoid arthritis (RA) are salient causes of disability, functional limitations, reduced quality of life and increased mortality. Pain remains the chief complaint among patients with ARD despite the advent of more effective therapies. Current guidelines recommend prioritizing non-opioid treatments in chronic pain. However, little is known about recent changes in the use of chronic pain treatment modalities in ARD. Such knowledge will be foundational for updating chronic pain treatment guidelines in rheumatology. The aim of this study is to examine annual trends among a national sample of privately insured adults diagnosed with ARD.

Methods: We used the IBM MarketScan Database (2007-2021) to identify patients in outpatient settings with ≥1 ARD diagnosis code by a specialist for ankylosing spondylitis (AS), psoriatic arthritis (PsA), RA, Sjogren's syndrome (SjS), systemic sclerosis (SSc), and SLE. Our primary outcome was opioid use and secondary outcomes were use of anticonvulsants, antidepressants, skeletal muscle relaxants, NSAIDS, topical pain medications and physical/occupational therapy. We extracted

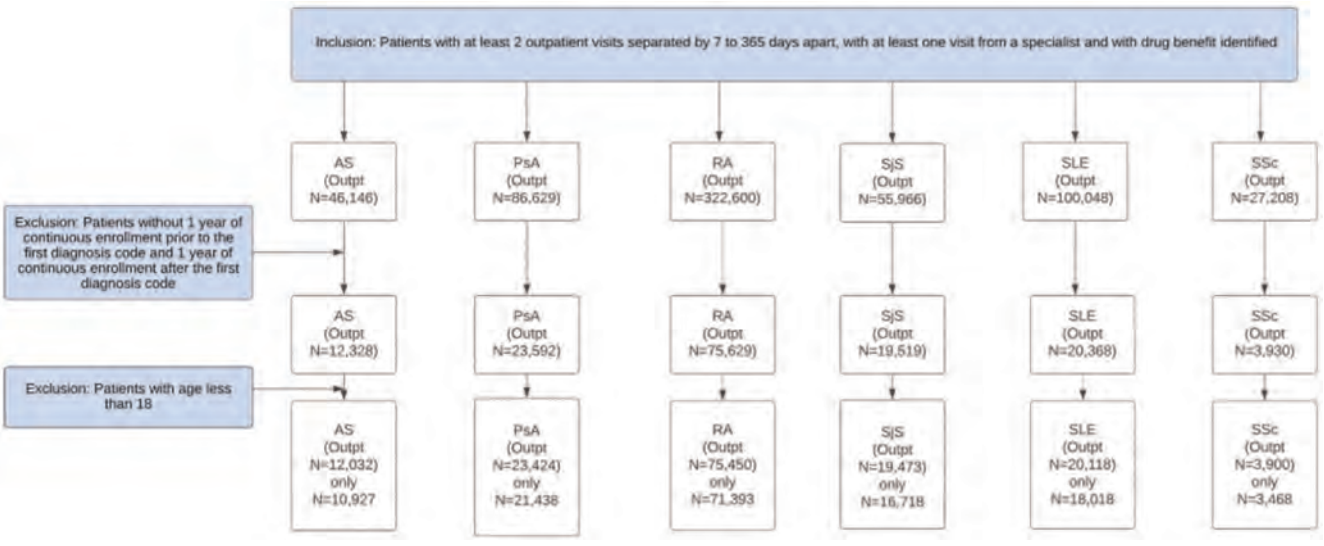

Figure 1. Consort Diagram

the proportion of patients who met the outcomes for each year. The numerator included patients receiving medications or non-pharmaceutical therapy within one year of their 1st ARD diagnosis. The denominator included patients with their 1st ARD diagnosis. We used logistic regression to estimate the association between calendar time and outcomes, adjusted for age, sex, and region. We included a spline knot to balance model fit by maximizing model likelihood and interpretation of results.

Results: There were 141,962 patients in our study (AS [n=10,927], PsA [n=21,438], RA [n=71,393], SjS [n=16,718], SLE [n=18,018], and SSc [n=3,468]) (Figure 1). Prevalence of opioid use increased from 26% in 2008 to 38% in 2014 and reduced to 24% in 2020. Prevalence of physical therapy use increased from 12% in 2008 to 24% in 2020. Prevalence of anticonvulsant use was 11% in 2008 and increased to 24% in 2020 (Figure 2). The odds of opioid use increased annually until 2014 by 3% [aOR, 1.03 (1.03, 1.04)] and decreased annually by 15% after 2014 [aOR, 0.85 (0.84, 0.86)] (Figure 3).

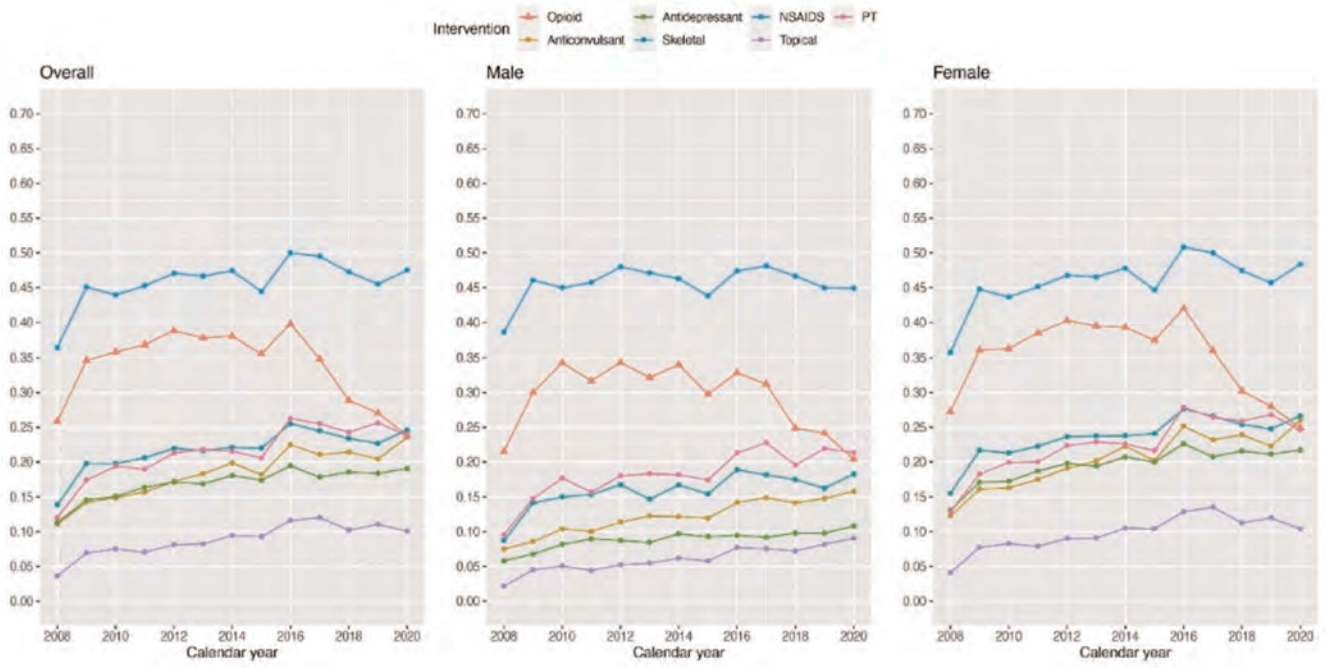

Figure 2. Trends of pain-related treatments among overall autoimmune patients, and stratified by sex

Outcomes	Unadjusted OR (95% CI)*	Adjusted OR (95% CI)**
Opioid (up to 2014)	1.03 (1.03, 1.04)	1.03 (1.03, 1.04)
Opioid (after 2014)	0.86 (0.85, 0.86)	0.85 (0.84, 0.86)
Anticonvulsant (up to 2014)	1.07 (1.06, 1.08)	1.08 (1.07, 1.09)
Anticonvulsant (after 2014)	1.00 (0.99, 1.01)	0.99 (0.99, 1.00)
Antidepressant (up to 2014)	1.05 (1.04, 1.05)	1.05 (1.04, 1.06)
Antidepressant (after 2014)	0.98 (0.97, 0.99)	0.98 (0.97, 0.99)
Skeletal (up to 2014)	1.04 (1.03, 1.05)	1.04 (1.04, 1.05)
Skeletal (after 2014)	0.97 (0.96, 0.98)	0.96 (0.96, 0.97)
NSAIDS (up to 2014)	1.02 (1.01, 1.03)	1.02 (1.02, 1.03)
NSAIDS (after 2014)	0.96 (0.95, 0.97)	0.96 (0.95, 0.96)
Topical (up to 2014)	1.09 (1.08, 1.10)	1.09 (1.07, 1.10)
Topical (after 2014)	0.98 (0.97, 0.99)	0.98 (0.97, 1.00)
PT (up to 2014)	1.05 (1.05, 1.06)	1.05 (1.04, 1.06)
PT (after 2014)	0.98 (0.98, 0.99)	0.99 (0.98, 1.00)

Abbreviation: OR, odds ratio.
*Per one-year increase
** Per one-year increase, adjusted for age, gender, and region.

Figure 3. Time trends of pain-related treatments among autoimmune patients

The odds of physical therapy use increased annually by 5% until 2014 [aOR, 1.05 (1.04, 1.06)] and with a slight decrease annually by 1% after 2014 [aOR, 0.99 (0.98, 1.00)]. The odds of anticonvulsant use increased annually by 8% until 2014 [aOR, 1.08 (1.07, 1.09)], with no statistically significant time trend after 2014 (aOR, 0.99 (0.99, 1.00). The use of topical analgesics increased annually by 9% up to 2014 [aOR, 1.09 (1.07, 1.10)], while the use of NSAIDs decreased annually by 4% after 2014 [aOR, 0.96 (0.95, 0.96)]. These trends did not differ by gender except for NSAID use before 2014 and topical analgesic use after 2014.

Conclusion: The use of various nonopioid pain management modalities has increased or stabilized in recent years, while opioid and NSAID use has declined since 2014. Future studies are needed to evaluate the effectiveness of these changes, and what possible effects they have had on outcomes such as quality of life, disability, and function.

Comparisons of the Risk of Serious Infections Associated with the Different Classes of Targeted Therapies Used in Psoriatic Arthritis Patients: A Nationwide Cohort Study from the French Health Insurance Database

Léa Bastard[1], pascal claudepierre[2], Laetitia Penso[3], Emilie Sbidian[4] and Laura PINA VEGAS[5], [1]Henri Mondor University Hospital (APHP) / Rheumatology Department, Créteil, France, [2]Universitary Henri Mondor Hospital, Creteil, France, [3]Université Paris Est Créteil, Créteil, France, [4]Hôpital Henri Mondor, Université Paris Est Créteil, Créteil, France, [5]Henri Mondor University Hospital (APHP), Rheumatology Department, Créteil, France

SESSION INFORMATION
Session Date: Wednesday, November 15, 2023
Session Title: Abstracts: Epidemiology & Public Health III
Session Type: Abstract Session
Session Time: 9:00AM–10:30AM

Background/Purpose: Targeted therapies have demonstrated their efficacy in the treatment of psoriatic arthritis (PsA), with an increased risk of serious infections. However, a comparison of this risk according to the different classes of drugs, in real world settings, remains an unmet need. This study aimed to assess and compare the risk of serious infections associated with different targeted therapies used in PsA from a national healthcare database.

Methods: This nationwide cohort study used data from the French National Health Insurance Database (*SNDS*), which covers over 98.8% of the French population.

All adults aged over 18 years with PsA registered in the SNDS were eligible for inclusion between January 1, 2015 and June 30, 2021. New users of targeted therapies (adalimumab, etanercept, golimumab, certolizumab, infliximab [TNF_i], secukinumab and ixekizumab [$IL17_i$], ustekinumab [$IL12/23_i$], and tofacitinib [JAK_i]) were included, defined as patients who had no previous prescriptions of targeted therapies in the year prior the index date. Patients with HIV infection, a history of cancer, transplant or serious infection were excluded. The follow-up period extended to December 31, 2021. The primary end point was the occurrence of a serious infection in a time-to-event analysis using propensity score-weighted Cox proportional hazards regression models, with adalimumab as comparator, estimating weighted hazard ratios ($_wHR$) with their corresponding 95% confidence intervals (CIs). Other drugs used as add-on therapies (csDMARDs, NSAIDs and prednisone) were considered as time-dependant covariables.

Results: Between 2015 and 2021, 12,071 new users of targeted therapies were included (mean age 48.7 ± 12.7 years; 6,909 [57.8%] women; median follow-up 13.2 [interquartile range: 6.4-31.5] months).

Among new users, 8,946 (74.1%) were treated with a TNF_i, 1,796 (14.9%) with an $IL17_i$, 1,177 (9.8%) with an $IL12/23_i$, and 152 (1.3%) with a JAK_i.

The total number of serious infections was 367, with an overall crude incidence rate of 17.0 (95%CI, 15.2-18.7) per 1,000 person-years. The most frequent serious infections were pulmonary infections (94 [0.8%] patients) (*Table 1*).

After inverse propensity weighting and adjustment for time-dependent covariables, risk of serious infection appeared significantly lower for patients receiving etanercept ($_wHR$, 0.70; 95%CI, 0.54-0.93) or ustekinumab ($_wHR$, 0.56; 95%CI, 0.36-0.89) than for those receiving adalimumab. No significant difference in the risk of serious infection was detected for the other targeted therapies (*Figure 1*). Concomitant use of systemic corticosteroids was associated with an increased risk of serious infection ($_wHR$, 1.85; 95%CI, 1.48-2.31).

Conclusion: Overall, the incidence of serious infections associated with targeted therapies used in PsA patients in real world settings is low. Compared with new users of adalimumab, this risk was lower among new users of etanercept and ustekinumab, with no difference among new users of the other TNF_i, $IL17_i$ or JAK_i. Given the numerous therapeutic options available for PsA treatment, these findings could assist physicians in optimizing their therapeutic strategies based on individual patients' characteristics.

Table 1. Serious infections and deaths events according to the targeted therapy used among psoriatic arthritis (PsA) patients between 2015 and 2021 in France. No., number; Mo., months; IQR, interquartile range; ENT, ear nose throat; NA, not applicable.

Events	No. (%) of events	Incidence rate, per 1000 person-years (95%CI)	Time before event, median (IQR), Mo.
Total (n= 12,071)			
Serious infections	367 (3.0)	17.0 (15.2-18.7)	9.5 (3.2-23.4)
Pulmonary infections	94 (0.8)	4.3 (3.5-5.2)	11.6 (3.8-30.4)
Gastrointestinal infections	90 (0.8)	4.2 (3.3-5.0)	9.6 (3.7-22.8)
Skin and subcutaneous tissues infections	73 (0.6)	3.4 (2.6-4.1)	9.4 (3.0-22.7)

Abstract Number: 2567

An Extended Interval Between mRNA COVID-19 Booster Vaccinations Is Associated with an Increased Humoral Immune Response in Patients with Inflammatory Rheumatic Diseases

Catherine Raptis[1], Christoph Berger[2], Christos Polysopoulos[1], Adrian Ciurea[3], Diego Andrey[4], Tanja Maletic[1], Myriam Riek[1], Almut Scherer[1], Isabell von Loga[1], Judith Safford[1], Kim Lauper[5], Burkhard Moeller[6], Nicolas Vuilleumier[4], Axel Finckh[7] and **Andrea Rubbert-Roth**[8], [1]SCQM Foundation, Zurich, Switzerland, [2]University Hospital Basel, Basel, Switzerland, [3]University Hospital Zurich, Zürich, Switzerland, [4]Geneva University Hospitals, Geneva, Switzerland, [5]Geneva University Hospitals, Genève, Switzerland, [6]Inselspital - University Hospital Bern, Bern, Switzerland, [7]HUG, Geneva, Switzerland, [8]Cantonal Hospital St. Gallen, St. Gallen, Switzerland

SESSION INFORMATION
Session Date: Wednesday, November 15, 2023
Session Title: Abstracts: Epidemiology & Public Health III
Session Type: Abstract Session
Session Time: 9:00AM–10:30AM

Background/Purpose: There is evidence that extending the interval between COVID-19 vaccination doses is associated with increased immunogenicity and neutralizing activity in healthy individuals (*1*, *2*). Previously, we reported higher humoral immune responses in patients with inflammatory rheumatic diseases (IRD) receiving mRNA-1273 vs BNT162b2 for their

2-dose primary immunization series (*3*). The same patients subsequently received a 3rd COVID-19 vaccine dose at varying intervals from the 2nd dose. The objectives of this study were to assess whether the interval or vaccine type (BNT162b2 vs mRNA-1273) affect the anti-SARS-CoV-2 Spike IgG levels up to 180 d post 3rd vaccine dose and the hazard of a positive SARS-CoV-2 test within 365 d post 3rd vaccine dose.

Methods: Patients from the Swiss cohort for patients with IRD (SCQM) who participated in the earlier phase of the study were recruited. They completed questionnaires using the mySCQM patient app and provided two self-collected capillary blood samples following the administration of the 3rd vaccine dose, that were tested for anti-S1-IgG levels. The analysis included patients who received a 3-dose homologous vaccination and reported no SARS-CoV-2 infection between the 2nd and 3rd doses. Mixed effects continuous outcome logistic regression and Cox proportional hazards regression models were employed to address the study aims. We adjusted for potential confounders at the time of the 1st vaccination.

Results: 344 IRD patients (67% female, mean age 52 y, 34% RA, 36% axSpA, 22% PsA, 8% UA) received their 3rd COVID-19 vaccination between 2021-08-13and 2022-03-04. The mean interval between the 2nd and 3rd vaccinations was 214 d (s.d. 25 d). The longer the interval to the booster dose was, the higher the antibody response to the 3rd dose up to 180 d post immunization. This result persisted after adjusting for confounders (Table 2). Indicatively, prolonging the vaccination interval by 30 d, led to a 1.9-fold increase (95% CI 1.2 – 3.0) of the odds of higher antibody levels post 3rd vaccination (Fig. 1).

Table 1. Patient demographics and clinical characteristics (n = 344)

	mRNA-1273	BNT162b2	All
Age at BL, years (mean (s.d.))	52.9 (10.8)	51.3 (12.9)	52.1 (12.9)
Females, n (%)	110 (67.1)	122 (67.8)	232 (67.4%)
Previous SARS-CoV-2 infection at BL, n (%)	15 (9.1)	20 (11.1)	35 (10.2)
Diagnosis, n (%)			
Rheumatoid Arthritis (RA)	57 (34.8)	61 (33.9)	118 (34.3)

of which combination therapy[x]	*1*	*2*	*3*
Interleukin inhibitors IL-1/IL-6/IL-17/IL-23	23 (14.0)	24 (13.3)	47 (13.7)
of which combination therapy[x]	*6*	*7*	*13*
PDE4i	2 (1.2)	0	2 (1.2)
Vaccine, 3-dose homologous n (%)			
BNT162b2			180 (52.3)
mRNA-1273*			164 (47.7)
Interval between 2nd and 3rd vaccination, days (mean (s.d.))	212 (24)	216 (25)	214 (25)

Patients on rituximab were excluded due to the high variability in the time since their last infusion.
[x]combination therapy = bDMARD with csDMARD and/or GC; *Available dosing info of 3rd mRNA-1273 vaccination: 31 patients ½ dose; 20 patients full dose; 113 patients NA

Table 2. The odds ratios of higher antibody levels and the hazard ratios of test-positive SARS-CoV-2 infection following the 3rd COVID-19 mRNA-based vaccination.

	Antibody model		Risk of test-positive infection model	
	OR (95% CI)	p value	HR (95% CI)	p value
Age	1.01 (0.97-1.05)	0.60	0.99 (0.98-1.01)	0.28
Past SARS-CoV-2 infection at BL	1.21 (0.42-3.48)	0.72	0.69 (0.39-1.22)	0.20
Sample time collection with respect to 3rd vaccination	0.95 (0.94-0.96)	<0.0001	N/A	N/A
mRNA-1273 vs BNT162b2	**3.3** (1.66-6.56)	**0.0007**	**0.64** (0.46-0.89)	**0.0085**
Interval between 2nd and 3rd vaccination*	**1.02** (1.01-1.04)	**0.0064**	1.0 (0.99-1.01)	0.64
Vaccine-age interaction	1.04 (0.98-1.11)	0.15	0.98 (0.96-1.01)	0.28

* Reported OR and HR are for an increase in interval of 1 day (for an increase in interval of 30 d see Fig. 1).

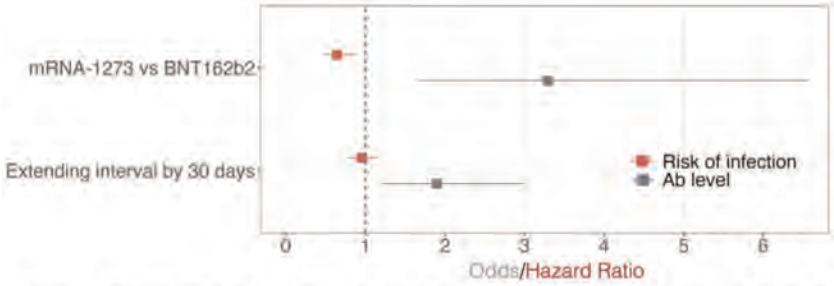

Figure 1. The odds ratios with 95% CI for higher anti-S1 antibody levels (Ab level) up to 180 d post 3-dose homologous mRNA vaccination (gray) and the hazard ratios with 95% CI for test-positive SARS-CoV-2 infection up to 365 d post 3-dose homologous mRNA vaccination (red).

154 patients reported a SARS-CoV-2 infection after the 3rd vaccine dose (between 2021-12-28and 2022-12-05, during the B.1.1.529 Omicron wave). We found no evidence of the vaccination interval affecting the hazard of test-positive SARS-CoV-2 infection up to 365 d post 3rd vaccination (Table 2).

After adjusting for confounders, the odds of higher anti-S1 levels were 3.3 times greater (95% CI 1.7 – 6.6; p< 0.001) in 3-dose homologous mRNA-1273 recipients compared toBNT162b2 recipients (Table 2, Fig. 1). Moreover, the hazard of a test-positive SARS-CoV-2 infection up to 365 d post 3rd vaccination was 36% lower (HR 0.64; 95% CI 0.46 – 0.89; p < 0.01) in 3-dose homologous mRNA-1273 vs BNT162b2 recipients (Table 2, Fig. 1).

Conclusion: A longer vaccination interval and a 3-dose homologous vaccination with mRNA-1273 were associated with higher anti-SARS-CoV-2 Spike IgG levels post 3rd vaccination in IRD patients. 3-dose homologous vaccination with mRNA-1273 was also associated with a lower risk of a test-positive SARS-CoV-2 infection post 3rd vaccination.

Abstract Number: 2568

First Breakthrough COVID-19 Infection Following Two SARS-CoV-2 Vaccinations Among Primary Systemic Vasculitis Patients

Michael Chen-Xu[1], Daniel Cooper[2], Rainer Döffinger[2], Dr Rachel Jones[3] and Rona Smith[2], [1]Unviersity of Cambridge, Cambridge, United Kingdom, [2]University of Cambridge, Cambridge, United Kingdom, [3]Addenbrooke's Hospital, Cambridge, United Kingdom

SESSION INFORMATION
Session Date: Wednesday, November 15, 2023
Session Title: Abstracts: Epidemiology & Public Health III
Session Type: Abstract Session
Session Time: 9:00AM–10:30AM

Background/Purpose: Primary systemic vasculitis (PSV) patients on immunosuppression are at higher risk of adverse outcomes following COVID-19 infection and often mount suboptimal vaccine responses to SARS-CoV-2 vaccination. The aim of this study was to investigate risk factors for first breakthrough COVID-19 infection after two vaccine doses in this patient group, from 02 January 2021 to 01 April 2023.

Methods: PSV patients enrolled in a prospective, UK-based multicentre observational cohort study investigating serological responses to SARS-CoV-2 vaccination (ethics reference: 20/EM/0180) were included if they had two SARS-CoV-2 vaccine doses. Patients were excluded if they had a previous history of documented COVID-19 infection or if their SARS-CoV-2 anti-nucleocapsid antibody titre (anti-N IgG) was >6104 median fluorescence intensity (MFI) indicating previous infection[1]. First symptomatic breakthrough SARS-CoV-2 infection (PCR or lateral flow positive) >14 days after a second SARS-CoV-2 vaccination was the outcome of interest. SARS-CoV-2 IgG spike antibody (anti-S IgG) and anti-N IgG titres were measured using a Luminex assay, and seroconversion was defined as an anti-S IgG titre >1896 MFI[1]. Clinical details were obtained via electronic health records.

[1]Smith et al. BMC Nephrol. 2022 May 31;23(1):199

Results: 252 PSV patients were identified, with 13 of these excluded (n = 9 had COVID-19 prior to or within 14 days of their second vaccination, n = 4 withdrew consent), leaving 239 eligible patients (48.5% male, median age 58.8 years) for the analysis, mainly consisting of ANCA-associated vasculitis (AAV) patients (Table 1). Median follow-up was 400 (range 78–756) days. During follow-up, 117 patients (49.0%) had a first breakthrough COVID-19 infection, representing a crude incidence rate of 12.0 per 10,000 person-days. 14 required inpatient admission (12.0%), with two being admitted to intensive care. One patient died of COVID-19. Median time from second vaccination to first breakthrough infection was 350 (interquartile range 285–442) days. Univariable and multivariable analyses of first breakthrough infection were conducted using the Fine and Gray method to adjust for the competing events of death and study withdrawal. In the fully-adjusted model, seroconversion and third and subsequent vaccinations i.e., boosters were associated with a lower hazard of breakthrough infection, with hazard ratios of 0.48 (95% confidence interval [CI] 0.27–0.85; p=0.012) and 0.43 (95% CI 0.32–0.59; p< 0.001) respectively. Chronic kidney disease was also associated with reduced hazard in fully-adjusted analysis (p=0.01). Patients with a history of malignancy (p=0.033), and those with IgA vasculitis and large vessel vasculitis (relative to AAV) were all at higher hazard for breakthrough infection (p=0.002, and p=0.009 respectively, Table 2)

Conclusion: In this cohort of PSV patients on immunosuppression who had two SARS-CoV-2 vaccinations, a third and subsequent vaccine doses were independently associated with reduced risk of breakthrough COVID-19 infection. Our study highlights the importance of booster vaccinations and support anti-S IgG titres as a correlate of protection against COVID-19 in this group of patients.

SESSION INFORMATION

Session Date: Wednesday, November 15, 2023

Session Title: Abstracts: Miscellaneous Rheumatic & Inflammatory Diseases III

Session Type: Abstract Session

Session Time: 9:00AM–10:30AM

Background/Purpose: To investigate the efficacy and safety of therapies currently in use and under evaluation for systemic Juvenile Idiopathic Arthritis (sJIA) and Adult-Onset Still's disease (AOSD).

Methods: A systematic review (SR) was performed. Medline, Embase, and the Cochrane Library databases were searched up to October 2022 for clinical trials (randomised, RCT, and quasi-controlled, CCT), longitudinal observational studies (retrospective, LOR, and prospective, LOP) and SRs published after 2013. The research question was formulated according to the PICO format. Population: sJIA (fulfilling ILAR criteria) or AOSD (fulfilling either Yamaguchi's and/or Fautrel's criteria) patients; Intervention: any pharmacological treatment (in use or under evaluation for sJIA/AOSD); Comparator: any other active drug or placebo; Outcomes: any relevant efficacy and safety outcome. The risk of bias (RoB) of the included clinical studies was assessed with the Cochrane RoB tool, while AMSTAR-2 was used to critically assess SRs.

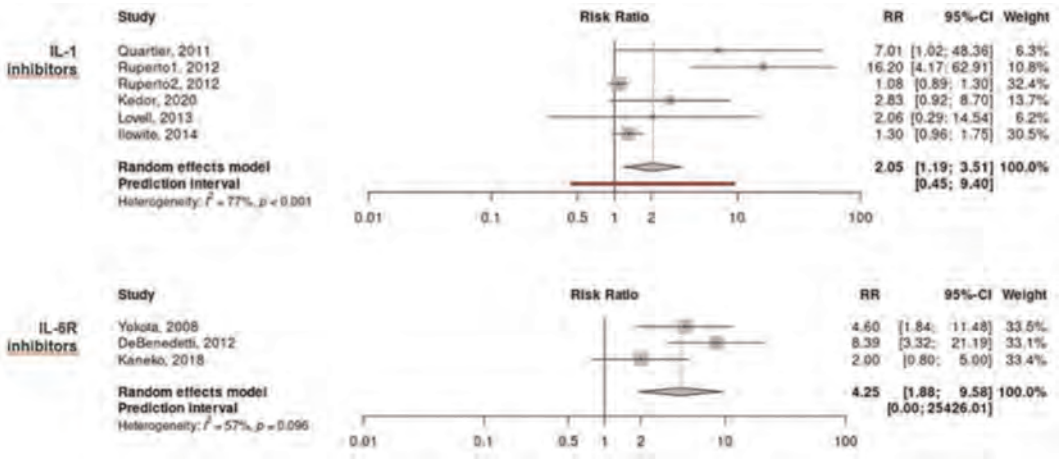

Figure: Meta-analysis of controlled clinical trials having assessed the efficacy of IL-1 and IL-6R inhibitors in Still's disease, based on ACR50 response.

Table: Studies having compared early (< 3 months) versus late (≥3 months) introduction of IL-1 and IL-6R inhibitors for the treatment of people with Still's disease.

		Study	Subtype	N	Time from disease onset to treatment start - months	Time of assessment	CID % (N)	other outcomes: %	Author, year
Comparison early vs late treatment	IL-1 (ANK)	LOR	sJIA	56	Early < 3 months	6 months	92 (35/37)	-	Pardeo 2021
					Late ≥ 3 months	6 months	37 (7/19)	-	
	IL-6 i (TCZ)	LOR	sJIA	23	Early 1 month (IQR 4)	12 months	54 (6/11)	ACR70: 91	Pacharapakornpon 2017
					Late 7.5 months (IQR 23)	12 months	0 (0/12)	ACR70: 50	

Results: Of 3,941 records, 115 full texts were finally included, representing 25 RCTs, 10 SRs published after 2013 and 80 LOR or LOP studies. Studies on glucocorticoids (GCs) and conventional synthetic DMARDs were mainly observational and displayed high RoB for the majority of them. Biologic DMARD (bDMARD) targeting IL-1 (IL-1i) or IL-6R (IL-6Ri) were the drugs with the highest level of evidence (6 clinical trials for IL-1i and 3 for IL-6Ri). A meta-analysis was conducted accordingly, using adapted ACR50 response as the outcome measure, and identified significant effect of both bDMARDs with RR 2.05 (95%CI 1.19, 3.51) and 4.25 (95%CI 1.88, 9.58) for IL1i and IL-6Ri respectively (Figure). Additionally, 2 retrospective longitudinal studies have demonstrated that the benefit of early bDMARD introduction, i.e. < 3 months, was associated with higher rates of clinically inactive disease (Table). This is consistent with data from other non-comparative studies in which clinically inactive disease (CID) achievement rates are between 59 to 100% when IL-1 or IL-6 inhibitors are initiated within 3 to 6 months, and 23 to 32% when they are started later on. Data on tsDMARDs (JAK-inhibitors), with promising findings, were limited to a few small case series.

Conclusion: Besides glucocorticoids, IL-1 and IL-6 inhibitors yielded the highest level of evidence for the treatment of sJIA and AOSD and their use early during the disease course was markedly efficacious.

SESSION INFORMATION

Session Date: Wednesday, November 15, 2023
Session Title: Abstracts: Miscellaneous Rheumatic & Inflammatory Diseases III
Session Type: Abstract Session
Session Time: 9:00AM–10:30AM

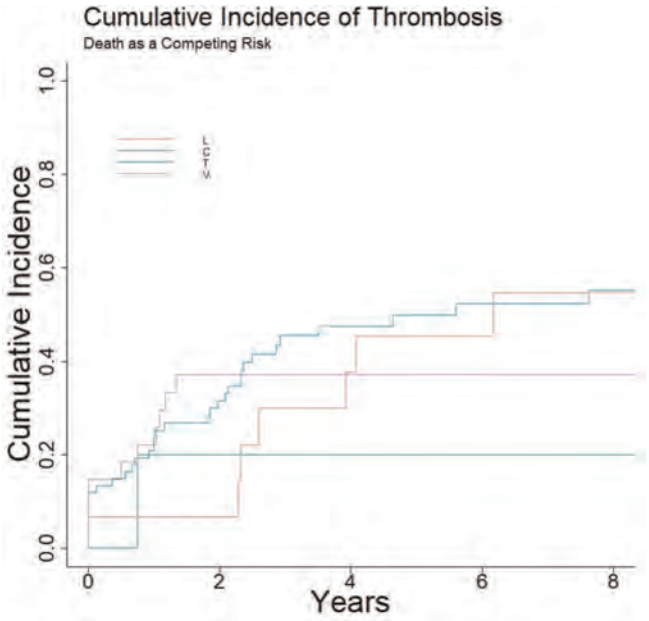
Background/Purpose: VEXAS (vacuoles, E1 enzyme, X-linked, autoinflammatory, somatic) syndrome, due to somatic mutations in the UBA1 gene, is an autoinflammatory disorder associated with an increased thrombotic risk. We investigated the frequency and characteristics of thrombotic events in patients with VEXAS syndrome, as well as their impact on survival.

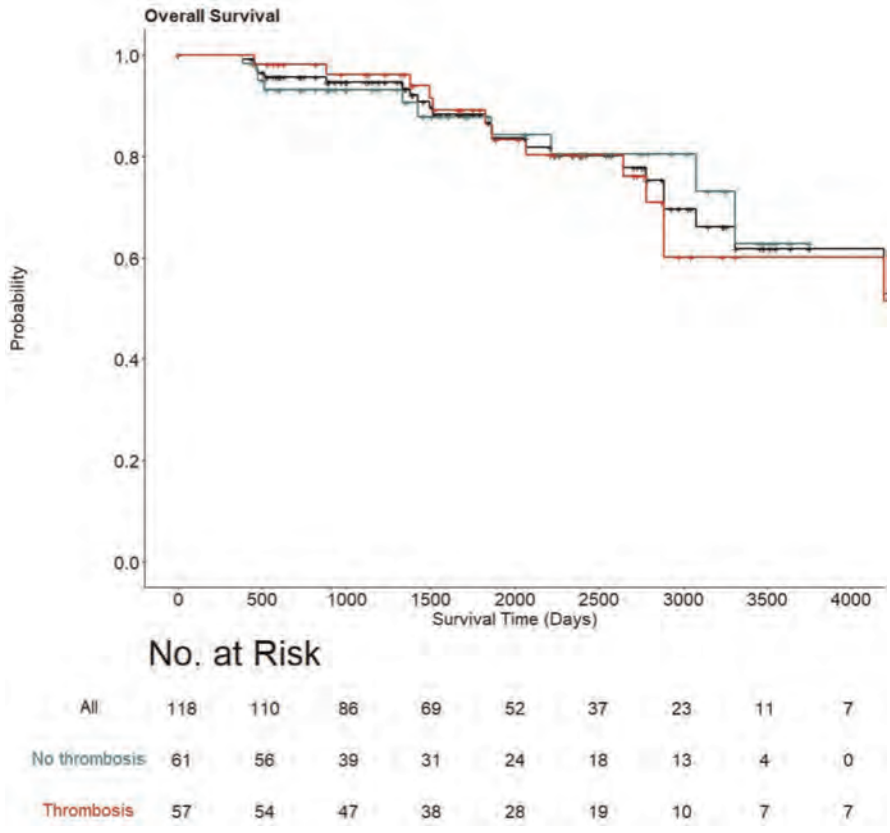
Methods: This retrospective, multi-center study utilized electronic medical records from the National Institutes of Health (NIH) Clinical Center and Mayo Clinic, along with referred outside records, to identify patients with VEXAS syndrome who had a confirmed *UBA1* somatic mutation and VEXAS clinical features. The time of symptom onset was used as the time of disease onset. Thrombosis was considered VEXAS disease onset if it occurred within two years of inflammatory symptom onset. SVT was excluded as a thrombotic event for analysis. Univariate and multivariate logistic regression analysis was used to identify predictors of thrombosis. Kaplan-Meier curve models were applied to estimate overall survival (OS). Statistical significance was $P < .05$. Lupus anticoagulant (LA) was assessed in 41 patients and other coagulation assays in 27.

Table 1. Demographic and clinical characteristics of patients with VEXAS syndrome and thrombotic events

Characteristic	Participants (N = 119)
Demographic characteristics	
Male sex, n (%)	119 (100)
Age (y), median (range)	64.5 (39.0, 86.0)
Somatic *UBA1* mutations	
p.Met41Val, n (%)	27 (23)
p.Met41Leu, n (%)	16 (13)
p.Met41Thr, n (%)	69 (58)
Splice motif mutation, n (%)	5 (4)
VEXAS phenotype	
Systemic symptoms (fever, fatigue, weight loss), n (%)	95 (80)
Skin involvement (rash), n (%)	89 (75)
Sweet's syndrome, n (%)	13 (11)
Inflammatory eye disease (episcleritis, uveitis), n (%)	35 (30)
Inner ear involvement (hearing loss, tinnitus, vertigo), n (%)	36 (30)
Chondritis (ear, nose), n (%)	50 (42)
Relapsing polychondritis, n (%)	49 (41)
Cardiac involvement (myocarditis, pericarditis, pericardial effusion), n (%)	7 (6)
Pulmonary involvement (lung infiltrates, pleural effusion), n (%)	60 (50)
Musculoskeletal involvement (arthritis, tenosynovitis), n (%)	76 (64)
Macrocytic anemia, n (%)	107 (90)
Myelodysplastic syndrome, n (%)	36 (30)
Plasma cell dyscrasia, n (%)	21 (18)
Venous thrombotic events	
DVT, n (%)	41 (34)
Proximal DVT, n (%)	27 (23)
Distal DVT, n (%)	12 (10)
PE, n (%)	17 (14)
Superficial thrombophlebitis, n (%)	23 (19)
Unprovoked event, n (%)	33 (28)
Recurrent event, n (%)	20 (17)
Event while on anticoagulation, n (%)	10 (8)
Time to event (mo), median (range)	33 (0, 553)
Arterial thrombotic events	
Stroke, n (%)	5 (4)
Myocardial infarction, n (%)	6 (5)
Recurrent event, n (%)	1 (1)
Time to event (mo), median (range)	29 (0, 232)

Results: A total of 119 VEXAS patients were included. All patients (100%) were male with a median age of 65 years (39-86 years). Hematologic manifestations included macrocytic anemia in 107 (90%), myelodysplastic syndrome (MDS) in 36 (30%), and plasma cell dyscrasia (PCD) in 21 (18%).





Of the 119 patients, 58/119 (49%) had a thrombotic event. Of those, 51 (43%) had VTE, and 9 (8%) had arterial events (AT), with a median time from disease onset of 33 and 29 months, respectively; seven patients (6%) had both venous and AT. The majority of VTE events were unprovoked 33 (28%) and over one-third 20 (17%) were recurrent, and 10 (8%) on anticoagulation (Table 1).

The cumulative incidence (CI) at a median follow-up of DVT, PE, and arterial thrombosis was 28.7%, 9.7%, and 8.7% respectively. CI at median follow-up of any thrombotic event was 22% for UBA1 M41L, 40% for M41T, and 37% for M41V, however, rising CI was seen with M41L over time while occurring early in M41T and M41V (Figure 1). The M41L UBA1 variant was positively associated with PE in univariate (OR: 4.58; p=0.02) and multivariate (OR: 16.94; p = 0.01) analyses but not with DVT or arterial thrombosis. The median OS from disease onset was 1740 days with no significant difference in OS between patients with (86.9%) or without (89.7%) thrombosis (Figure 2). In the univariate and multivariate Cox proportional hazard model, thrombosis was not associated with worse OS. The majority of VEXAS patients had high factor VIII levels (26/27; 96%) and VWF activity (16/27; 59%), while most had high VWF antigen (11/25; 44%), factor IX levels (12/27; 44%) and protein C activity (11/27; 41%). CRP and ESR were positively correlated with D-dimer and negatively correlated with VWF activity. LA was positive in 16/41 (40%) and correlated significantly with higher CRP (p< 0.01).

Conclusion: Patients with VEXAS syndrome are at high risk of VTE, which can recur despite anticoagulation therapy. Considering the high prevalence of thrombosis in VEXAS patients, it is crucial to assess their VTE risk carefully and consider prophylactic anticoagulation.

Session Date: Wednesday, November 15, 2023

Session Title: Abstracts: Miscellaneous Rheumatic & Inflammatory Diseases III

Session Type: Abstract Session

Session Time: 9:00AM–10:30AM

Background/Purpose: Immune checkpoint inhibitors (ICIs) are revolutionizing cancer treatment. However, ICIs often lead to immune-related adverse events (irAEs). Approximately 5% of patients treated with ICIs develop arthritis (here, ICI-arthritis). ICI-arthritis not only causes joint destruction but also necessitates the discontinuation of ICI therapy. Importantly, steroids,

Table 1. Information of peripheral blood samples

Table 1. Information of peripheral blood samples

Characteristic	No. (%)		
	Steroid-sensitive, n=19	Steroid-resistant, n=20	Neg control, n=11
Duration (Median with range; weeks)			N/A
From the first ICI infusion to sample donation	36.9 [6, 134.4]	31.1 [1.3, 244]	
From the last ICI infusion to sample donation	6.1 [0.4, 84.4]	6.6 [0.1, 126]	
From development of symptoms to sample donation	10 [1.6,132.6]	6.7 [0.1, 22.1]	
Systemic steroids <4 weeks prior to sample donation	1 (5)	0 (0)	N/A
DMARDs < 12 weeks prior to sample donation	2 (10)	1 (5)	N/A
ESR (Median; Range)	14 [4, 77]	39 [7, 113]	N/A
CRP (Median; Range)	2.7 [0.4, 78.4]	15.4 [0.8, 173.9]	N/A
CDAI (Median; Range)	15 [0.6, 48]	19 [3, 47]	N/A

the first-line therapy for irAEs, significantly abrogate the antitumor efficacy of ICIs. Therefore, it is critical to identify biomarkers which predict steroid resistance in irAE patients. This is particularly important in managing ICI-arthritis, because it requires long-term therapy, often with disease modifying anti-rheumatic drugs (DMARDs) in addition to systemic steroids.

Methods: Between 2019 and 2022, we enrolled 39 patients who newly developed joint pain and swelling following ICI therapy and were diagnosed with ICI-arthritis at the MD Anderson Rheumatology clinic. From the time of ICI-arthritis diagnosis, we prospectively followed these patients for one year. Simultaneously, at the time of ICI-arthritis diagnosis, we collected peripheral blood (PB) samples for serum cytokine analysis. PB samples were collected 13.4 ± 22.1 (mean ± SD) weeks after the onset of arthritis symptoms. We also collected PB samples from 11 healthy volunteers as negative controls. Levels of serum cytokines were measured by a multiplex assay. Mean differences were determined using unpaired t-test for two groups or one-way ANOVA test for three groups.

Results: Nineteen patients responded well to steroid monotherapy (here, steroid sensitive [SS] group) while twenty patients required DMARDs during the one-year followup (here, steroid resistant [SR] group). In both groups, ICI-arthritis developed primarily with PD-1 inhibitor monotherapy (74% in the SS group vs. 65% in the SR group). Fifteen patients in the SS group and 18 patients in the SR group exhibited RA-like polyarthritis. In the SR group, DMARDs were initiated 3.5 ± 3.0 months after the onset of arthritis symptoms. Hydroxychloroquine was the most commonly prescribed DMARD, followed by tocilizumab, methotrexate, and sulfasalazine. Compared to the SS group, patients in the SR group required higher doses of steroids (cumulative dose of prednisone: 1,921 ± 1,382 mg in the SR group vs. 613 ± 741 mg in the SS group; P=0.0008). A higher percentage of patients in the SS group tested positive for antinuclear antibody (10% in the SR group vs. 42% in the SS group). Characteristics of the samples were comparable between the SS and SR groups (Table 1). Serum analyses revealed that the level of interleukin (IL)-10 was higher in the SR group (14.5 ± 3.4 pg/mL in the SR group vs. 10.3 ± 5.6 pg/mL in the SS group; P=0.03). The level of serum IL-17A was higher in patients with SR arthritis, but the difference did not reach statistical significance (11.0 ± 10.9 pg/mL in the SR group vs. 5.0 ± 6.9 pg/mL in the SS group; P=0.14).

Conclusion: Th17 cells might play an important role in steroid resistance in ICI arthritis while Treg signatures might be enhanced as a compensatory mechanism. In-depth cellular, molecular, and immunologic analyses of Th17 cells will enable us to identify a biomarker predicting steroid resistance in ICI arthritis.

Autoantibody Profile of Autoimmune Driven Interstitial Lung Disease as Compared to Idiopathic Pulmonary Fibrosis and Association of Autoantibodies with Survival

Elena Joerns[1], Chad Newton[2], Stanislav Kolenikov[3], Jeffrey Sparks[4] and David Karp[5], [1]University of Texas Southwestern Medical Center, Dallas, TX, [2]UT Southwestern, Dallas, TX, [3]NORC at the University of Chicago, Columbia, MO, [4]Division of Rheumatology, Inflammation, and Immunity, Brigham and Women's Hospital and Harvard Medical School, Boston, MA, [5]UT Southwestern Medical Center, Dallas, TX

SESSION INFORMATION

Session Date: Wednesday, November 15, 2023

Session Title: Abstracts: Miscellaneous Rheumatic & Inflammatory Diseases III

Session Type: Abstract Session

Session Time: 9:00AM–10:30AM

Background/Purpose: The term interstitial pneumonia with autoimmune features (IPAF) describes patients with interstitial lung disease (ILD) and features of autoimmunity, that do not fulfill classification criteria for any of the defined rheumatic diseases (RD) or for other ILD subtypes. While cases of progressive ILD with clear autoimmune etiology such as those associated with RDs are usually treated with immunosuppression, IPAF, due to its heterogeneity and unclear pathophysiology, presents substantial difficulty in management. Our overarching hypothesis is that there are unique autoantibody profiles that can be identified in autoimmune forms of ILD reflecting the underlying inflammation-mediated damage. Understanding these signatures will allow us to identify an autoimmune endotype within poorly characterized ILD types such as IPAF with potential therapeutic implications.

Methods: We conducted a cross-sectional analysis of patients with RD-ILD (n=32) and idiopathic pulmonary fibrosis (IPF) (n=69) to evaluate autoantibodies correlating to autoimmune driven ILD (defined as RD-ILD). Autoantibody profiles were determined using a fluorescence-based multiplex assay for the detection of 124 IgM and IgG autoantibodies that detect autoantigens important in rheumatic diseases and ILD in the prior literature. T-test with False Discovery Rate (a=0.05) was performed to investigate significant mean differences between RD-ILD and IPF to identify autoantibodies characteristic of RD-ILD versus IPF, controlling for minimum detection level with censored regression methods. LASSO logistic regression was performed to identify autoantibodies predictive of RD-ILD subtype versus IPF subtype. A longitudinal cohort study

Autoantibody	HR (95% CI)	p-value
Matrigel IgM	1.5 (1.0-2.1)	0.045
Decorin bovine IgM	2.4 (1.2-4.8)	0.019
TNF-alpha IgM	1.4 (1.0-2.0)	0.044
TIF-1-gamma IgM	1.5 (1.0-1.3)	0.038
Prothrombin IgM	1.5 (1.1-2.2)	0.023
Ro52-SSA IgG	1.6 (1.9-2.3)	0.02

was performed to evaluate association of autoantibodies with lung disease progression (defined as relative forced vital capacity (FVC) decline of 10% or more, death, or lung transplant). Cox logistic regression was utilized to assess the association of autoantibodies with time to progression within each ILD subtype.

Results: Seven autoantibodies were selected by both FDR and LASSO methods, with additional autoantibodies selected by one of the other two methods. Ro-52 SSA IgG, U1snRNP IgG, nucleosome antigen IgM, SM-D1 IgM, proteoglycan IgM, and histone H1 IgG autoantibodies showed highest relevance score for association with RD-ILD versus IPF subtype (Figure 1).

In RD-ILD, 11 autoantibodies were significantly associated with faster progression, while in IPF, six autoantibodies were significantly associated with the outcome.

Conclusion: Several autoantibodies appear to be associated with RD-ILD more than IPF. Greater autoantibody level elevation in RD-ILD than in IPF emphasizes the lack of autoimmunity in the IPF patients. Different autoantibodies were associated with progression in RD-ILD and IPF, suggesting different mechanisms of damage. Autoantibodies predicting faster progression in IPF patients emphasized potentially undiagnosed autoimmune ILDs among IPF patients and the need for broad testing in a variety of ILDs. Knowledge of autoantibody profiles associated with autoimmune lung disease and progression in various ILD subtypes has implications for management decisions in ILD.

Prevalence of Pulmonary Hypertension in a Cohort of Patients with Interstitial Pneumonia with Autoimmune Features and Its Effect on Lung Disease Progression and Mortality

Michelle Ghebranious, Elena Joerns, Traci Adams and Trushil Shah, University of Texas Southwestern Medical Center, Dallas, TX

SESSION INFORMATION
Session Date: Wednesday, November 15, 2023
Session Title: Abstracts: Miscellaneous Rheumatic & Inflammatory Diseases III
Session Type: Abstract Session
Session Time: 9:00AM–10:30AM

Background/Purpose: Interstitial pneumonia with autoimmune features (IPAF) is a subset of interstitial lung disease (ILD) that manifests with interstitial pneumonia and features of autoimmunity while not meeting classification criteria for a defined rheumatic disease. Recent studies have examined the clinical characteristics, common comorbidities, and outcomes of IPAF patients, but little is known regarding the presence of pulmonary hypertension (PH) in this population. Given the known effect of PH on decreased functional capacity and increased mortality in patients with underlying ILD, we characterize the effect of PH on lung disease progression and mortality in a cohort of patients with IPAF.

Methods: Using a retrospective study design, we evaluated the prevalence of PH in an institutional cohort of patients with IPAF at the University of Texas Southwestern Medical Center. Included patients were identified as having pre-capillary PH on right heart catheterization as defined by the European Society of Cardiology 2022 guidelines. Descriptive statistics were used to describe baseline data including demographic factors, radiographic patterns, pulmonary function tests, and 6-minute walk distance. In addition, right heart catheterization (RHC) and echocardiogram (TTE) data were collected and used to stratify patients according to disease severity (severe = mean pulmonary artery pressure (mPAP) ≥30 mmHg and pulmonary vascular resistance (PVR) ≥4 WU). Using Cox logistic regression, we evaluated the association of clinical variables on time to relative forced vital capacity (FVC) decline of ≥10% and survival.

Results: A cohort of 173 IPAF patients was analyzed, of which 46 patients (26.6%) met criteria for pre-capillary PH by RHC. Clinical characteristics of the patients with PH are summarized in Table 1. Among the patients with PH by RHC (n=46), 21 (46%) were classified as having mild or moderate PH, and 25 (54%) with severe PH. The average time between IPAF and PH diagnosis was 2.35 (SD ± 2.1) years. Following diagnosis, 92% of patients with severe PH were followed in PH clinic and started on treatment. There was not a statistically significant association between the severity of PH, being followed in PH clinic, or the number of PH medications and time to relative FVC decline ≥10% or mortality (Table 2). A trend was observed as patients with more severe PH had a faster decline in FVC of 10% or more (Figure 1).

Conclusion: PH was prevalent in our cohort of patients with IPAF and the severity of PH was associated with lung function decline and mortality, although this was not statistically significant. Clinicians taking care of patients with IPAF should be aware of the high prevalence of PH and its possible association with clinical outcomes in this population. Thus, a high index of suspicion for the condition should be maintained when a patient with IPAF is evaluated, and further screening and workup should be considered if PH is suspected.

Table 1: Baseline Characteristics of IPAF Patients at Time of PH Diagnosis

Table 1: Baseline Characteristics of IPAF Patients at Time of PH Diagnosis (n=46)				
Age, years	62.7 ± 11.1			
Sex	Male: 12 (26%)		Female: 34 (74%)

Are Patients Classified as IPAF More Likely to Also Meet SLE Criteria by 2019 EULAR/ACR Than by SLICC?: An Abstract

Gabriela Martinez Zayas[1], David Karp[1] and Elena Joerns[2], [1]UT Southwestern Medical Center, Dallas, TX, [2]University of Texas Southwestern Medical Center, Dallas, TX

SESSION INFORMATION

Session Date: Wednesday, November 15, 2023

Session Title: Abstracts: Miscellaneous Rheumatic & Inflammatory Diseases III

Session Type: Abstract Session

Session Time: 9:00AM–10:30AM

Background/Purpose: Interstitial pneumonia with autoimmune features (IPAF) is a research classification proposed by the European Respiratory Society and American Thoracic Society Task Force for those patients with forms of interstitial lung disease (ILD) that have autoimmune features but that do not classify as having systemic rheumatic diseases such as systemic lupus erythematous (SLE).(1)

In 2012 the Systemic Lupus International Collaborating Clinics (SLICC) published criteria to identify and classify patients with SLE. (2) Subsequently, in 2019 the European Alliance of Association of Rheumatology/American College of Rheumatology (EULAR/ACR) published updated criteria SLE criteria. Sensitivities were similar, but 2019 EULAR/ACR criteria had superior specificity. (3)

We hypothesized that patients initially classified as IPAF may meet SLE by 2019 ACR/EULAR criteria more frequently than by SLICC criteria. The purpose of our study was to review data of patients classified as IPAF and assess if there is a difference in classification of SLE by both sets of criteria.

Methods: This observational, single-center cohort study included consecutive patients who had initially been classified as having IPAF between December 1st, 2005-August 31st, 2019. Two authors (GM-Z, EKJ) independently and retrospectively reviewed patients' charts and assigned SLE criteria by SLICC or 2019 EULAR/ACR classifications. Fisher's exact test was used to assess for significant difference in number of patients' meeting SLE criteria by SLICC criteria versus 2019 EULAR/ACR criteria.

Results: A total of 197 patients that had been initially classified as IPAF were included. Out of these 197 patients, 12 met SLE criteria by SLICC and 23 by 2019 EULAR/ACR. All but three patients that met SLE criteria SLICC also met 2019 EULAR/ACR criteria. The difference in eligibility for these three patients was due to lymphopenia (Figure 1). The most frequent SLE inclusion characteristics by either criteria and by 2019 EULAR/ACR criteria alone are shown in Figures 1 and 2, respectively. The difference in meeting SLE criteria between groups was statistically significant ($p< 0.001$, Table 1).

Conclusion: The difference in the number of patients originally classified as IPAF that met SLE criteria by SLICC and by 2019 EULAR/ACR upon re-review in 2023 was statistically significant (12 vs 23 patients, respectively, $p < 0.001$, Table 1). Based on our results, we conclude that 2019 ACR/EULAR criteria are superior for SLE classification in patients with ILD. ILD may be an underrecognized manifestation of SLE. Patients with ILD who have features seen in SLE, particularly dsDNA/Smith, arthritis and serositis should undergo full work-up to evaluate for other SLE clinical characteristics.

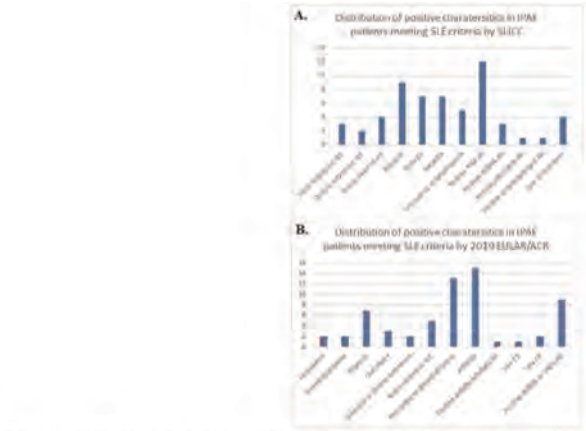

Figure 1. The figure shows the distribution of positive characteristics in IPAF patients meeting SLE criteria by A) SLICC and by B) 2019 EULAR/ACR. Characteristics that were not met by any patients were omitted from the figure. Abbreviations: IPAF: interstitial pneumonia with autoimmune features; SLE=systemic lupus erythematous; SLICC: Systemic Lupus International Collaborating Clinics; EULAR/ACR European Alliance of Association of Rheumatology/American College of Rheumatology; Ab=antibodies.

Figure 1. The figure shows the distribution of positive characteristics in IPAF patients meeting SLE criteria by A) SLICC and by B) 2019 EULAR/ACR

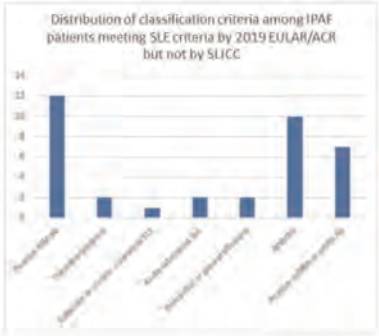

Figure 2. The figure shows the distribution of classification criteria among IPAF patients that met SLE criteria by 2019 EULAR/ACR but not by SLICC. Characteristics that were not met by any patients were omitted from the figure. Abbreviations: IPAF: interstitial pneumonia with autoimmune features; SLE=systemic lupus erythematous; SLICC: Systemic Lupus International Collaborating Clinics; EULAR/ACR European Alliance of Association of Rheumatology/American College of Rheumatology; Ab=antibodies.

Figure 2. The figure shows the distribution of classification criteria among IPAF patients that met SLE criteria by 2019 EULAR/ACR but not by SLICC.

SESSION INFORMATION

Session Date: Wednesday, November 15, 2023

Session Title: Abstracts: Muscle Biology, Myositis & Myopathies – Basic & Clinical Science II

Session Type: Abstract Session

Session Time: 9:00AM–10:30AM

Background/Purpose: Adult-onset idiopathic inflammatory myopathy (IIM) is associated with an increased cancer risk within three years prior to or following IIM onset. The International Guideline for Idiopathic Inflammatory Myopathy-Associated Cancer Screening recommends individual patient risk stratification into "high", "moderate", and "standard" according to IIM subtype, antibody profile, and clinical features[1]. Application in a real-world IIM cohort could assess the accuracy of this risk stratification approach and guide future amendments.

Methods: The MyoProsp study recruited a UK-based cohort with adult onset IIM within 2 years of diagnosis between 2016 and 2020. Comprehensive demographic, disease activity, IIM subtype, myositis-specific/associated autoantibody (MSA/MAA), and cancer data (primary cancer site, date of diagnosis) were collected. Estimated cancer risk of each participant ("high", "moderate", and "standard") according to the International Guideline for Idiopathic Inflammatory Myopathy-Associated Cancer Screening was identified. "High disease activity" (a high risk factor) was defined as physician global and patient global assessment scores greater than 75 (range 0-100). As defined in the guideline, participants with two or more "high risk factors" (see Table 1) were assigned as high cancer risk; those with one "high risk factor" or two or more "intermediate risk factors" were assigned as moderate cancer risk; the remaining were assigned as standard risk. The concordance of risk stratification and actual cancer diagnosis was calculated across the cohort.

Results: Two hundred and ninety participants (72% female, mean age 54 years at time of recruitment) were included in the analysis (see Table 1 for a profile of IIM subtypes and presence of cancer risk factors). One hundred and twenty three participants (42%) fulfilled criteria for high cancer risk, 116 (40%) moderate risk, and 51 (17%) standard risk. Seventeen cancers (6% of whole cohort) were detected within the cohort, of which five (29%) were breast cancer, two (12%) cancer of unknown primary, two stomach (12%), and one (6%) each of bladder, endometrial, kidney, lung, lymphoma, oesophagus, ovarian, and prostate. The "high risk" group displayed the highest proportions of cancers (n=14, 11%), followed by the "moderate risk" group (n=3, 3%; one each of breast, endometrial, and kidney cancer); no participant with "standard risk" had a cancer diagnosis.

Table 1 – Demographics, profile of risk factors, and cancer diagnoses stratified by cancer risk category

Variable		Total cohort N = 290	Cancer risk group†		
			High N = 123	Moderate N = 116	Standard N = 51
Cancer diagnosis N (%)		17 (5.9)	14 (11.4)	3 (2.6)	0 (0.0)
Mean age / years (SD)		54.1 (14.8)	56.7 (13.3)	55.6 (14.1)	32.4 (6.1)

	Inflammatory arthropathy	66 (22.8)	36 (29.3)	24 (20.7)	6 (11.8)
	Interstitial lung disease	94 (32.4)	31 (25.2)	37 (31.9)	26 (51.0)

IIM = idiopathic inflammatory myopathy
DM = dermatomyositis
PM = polymyositis
IMNM = immune-mediated necrotising myopathy
CADM = clinically amyopathic dermatomyositis
ASyS = anti-synthetase syndrome
CTD = connective tissue disease
NXP2 = nuclear matrix protein 2
TIF1-gamma = transcriptional intermediary factor 1
SAE1 = small ubiquitin-like modifier-1 activating enzyme
HMGCR = 3-hydroxy 3-methylutaryl coenzyme A reductase
MDA5 = melanoma differentiation-associated gene 5
SRP = signal recognition particle
MAA = myositis-associated autoantibody (PM-Scl, Ku, RNP, Ro/La [SSA/B])
† According to The International Guideline for Idiopathic Inflammatory Myopathy-Associated Cancer Screening – recommendations 5, 6, 7, and 8
* Defined as physician global and patient global assessment scores greater than 75 (range 0-100).

Conclusion: Risk stratification recommended by The International Guideline for Idiopathic Inflammatory Myopathy-Associated Cancer Screening clearly and appropriately stratified cancer risk in a real-world IIM cohort, thus demonstrating clinical utility. Future research should focus on investigating the impact of risk stratification upon stage at time of cancer diagnosis and outcomes, including survival.

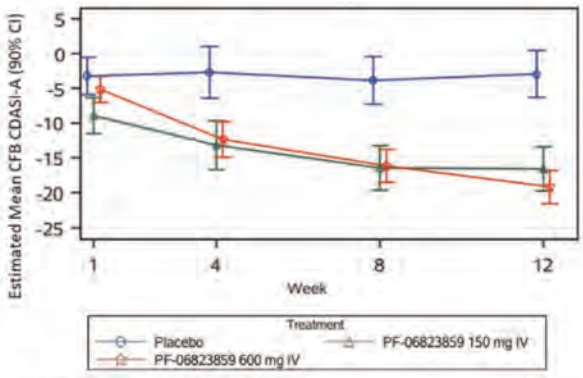
SESSION INFORMATION
Session Date: Wednesday, November 15, 2023
Session Title: Abstracts: Muscle Biology, Myositis & Myopathies – Basic & Clinical Science II
Session Type: Abstract Session
Session Time: 9:00AM–10:30AM

Background/Purpose: Interferon (IFN) dysregulation is a key feature in the pathogenesis of Dermatomyositis (DM). PF-06823859 is a potent, selective, humanized IgG1 neutralizing antibody directed against IFNb. We examined the onset of efficacy of PF-06823859 in patients (pts) with moderate-to-severe refractory DM.

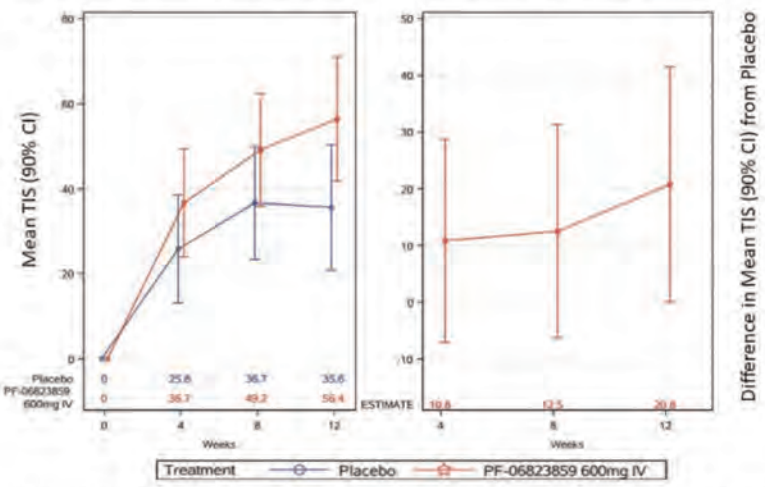
Methods: This double-blind, placebo (PBO)-controlled, Phase 2 study (NCT03181893) enrolled adult pts (18–75 years) with moderate-to-severe refractory DM.Pts with skin disease predominant (SP) DM and Cutaneous Dermatomyositis Disease Area and Severity Index activity [CDASI-A] score ≥14 who had failed ≥1 standard of care systemic treatment were randomized to PBO, PF-06823859 150 mg or 600 mg (intravenous administration on Day 0, wks 4 and 8). Pts with muscle disease predominant (MP) DM who met 1 of the following: (1) Manual Muscle Testing (MMT-8) ≤136/150 and Physician Global Assessment (PhGA) ≥3 cm on a 0–10 cm visual analogue scale (VAS) or (2) sum of PhGA, Patient Global Assessment (PtGA), Extra-muscular Global Assessment ≥10 cm (0–10 cm VA for each) and refractory disease, were randomized to PBO or IV PF-06823859 600 mg(Day 0, wks 4 and 8). Onset of efficacy was evaluated in the SP cohort using the CDASI-A, 5D-itch, Dermatology Quality of Life Index (DLQI), and SF-36 change from baseline to Wk 12. In the MP cohort, onset of efficacy was evaluated using the Total Improvement Score (TIS), Manual Muscle Testing (MMT-8), creatine kinase (CK) levels, PtGA, Health Assessment Questionnaire Disability Index (HAQ-DI) and FACIT-Fatigue change from baseline to Wk 12.

Change from Baseline of CDASI Activity Score (CDASI-A) in Skin Predominant Dermatomyositis Participants in Phase 2 Study C0251002 Receiving PF-06823859. Note: Lower CDASI-A score is better (improvement of disease)



Longitudinal ANCOVA Model, with baseline value as a covariate, treatment, visit as factor variables and treatment by visit as unstructured interaction effect

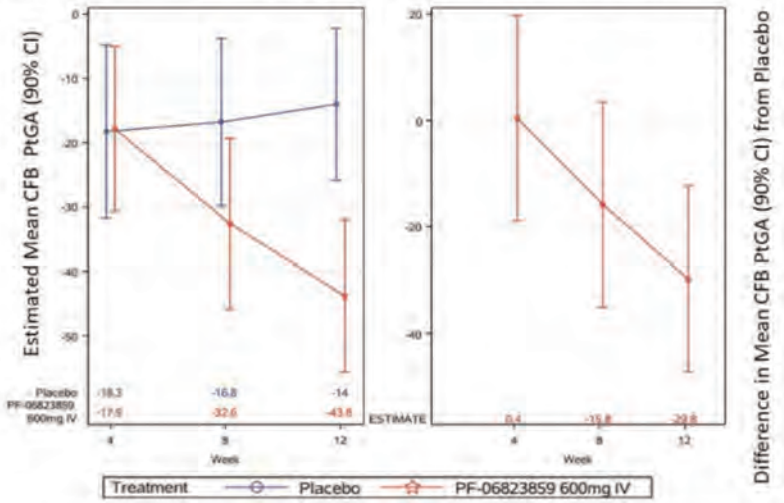
Total Improvement Score (TIS) in Muscle Predominant Dermatomyositis Participants in Phase 2 Study C0251002 Receiving PF-06823859 Following Sensitivity Analysis. Note: Higher TIS is better (improvement in disease)



MMRM Model with treatment, visit as factor variables, treatment by visit as unstructured interaction effect

Results: SP and MP cohorts had 57 and 18 pts respectively. In the SP cohort, differentiation from PBO in CDASI-A was observed at Wk 4 for both 150 mg (PBO-adjusted CFB -13.19 [p=0.0006]) and 600 mg (PBO-adjusted CFB -12.35 [p=0.0004]) doses. A reduction in CFB 5D-itch was observed for the 600 mg dose at Wk 1 (PBO-adjusted CFB 5D-itch 600 mg [p=0.0359]). PBO-adjusted CFB in DLQI and SF-36 mental component were observed for 150 and 600 mg (p=0.024, p=0.016 and p=0.009, p=0.0398, respectively) at Wk 4. In the MP cohort, a numerical advantage was observed in TIS scores at 600 mg compared to PBO with increasing trends from Wks 4-12 (PBO-adjusted CFB [p=0.0497] at Wk 12) following a sensitivity analysis that removed affected data following use of a prohibited medication by one pt. Significant reduction in CK and HAQ-DI was observed at Wk 4 and 8, respectively (PBO-adjusted CFB for 600 mg CK [p=0.044] and HAQ-DI [p=0.035]). A numerical differentiation in PtGA started at Wk 1 and reached significance at Wk 8 (PBO-adjusted CFB 600 mg [p=0.0470]). A numerical advantage in MMT-8 and FACIT-F were observed starting at Wk 4, but did not reach statistical significance.

Change from Baseline in Patient Global Assessment (PtGA) in Muscle Predominant Dermatomyositis Participants in Phase 2 Study C0251002 Receiving PF-06823859. Note: lower PtGA score is better (improvement of disease)



Longitudinal ANCOVA Model, with baseline value as a covariate, treatment, visit as factor variables and treatment by visit as unstructured interaction effect

Conclusion: PF-06823859 induced rapid improvement in 5D-itch (Wk 1), followed by CDASI-A, DLQI, and SF-36 (mental component) at Wk 4 in DM pts with SP disease. Rapid improvement in MP DM was observed at Wk 1 for PtGA, and at Wk 4 for MMT-8 and CK. The inhibition of IFNβ activity by PF-06823859 is a promising treatment in DM, with a more rapid onset of efficacy potentially allowing a faster taper of steroids than current DM therapies.

Frequency of Atherosclerotic Cardiovascular Disease Following a Diagnosis of Idiopathic Inflammatory Myopathy: Data from a Large National Registry

Astia Allenzara[1], Carolina Alvarez[2], Amanda Nelson[3] and Galen Foulke[4], [1]University of North Carolina, Chapel Hill, NC, [2]University of North Carolina at Chapel Hill, Miami, FL, [3]University of North Carolina at Chapel Hill, Chapel Hill, NC, [4]Penn State MS Hershey Medical Center, Hershey, PA

SESSION INFORMATION
Session Date: Wednesday, November 15, 2023
Session Title: Abstracts: Muscle Biology, Myositis & Myopathies – Basic & Clinical Science II
Session Type: Abstract Session
Session Time: 9:00AM–10:30AM

Background/Purpose: Idiopathic inflammatory myopathies confer an increased risk of morbidity from cardiovascular disease. Prior work has noted more than double risk of cardiovascular events for patients with dermatomyositis (DM) and polymyositis (PM) when compared to the general population. Furthermore, in a single center study of patients with DM, one-fifth of hospitalizations were associated with an atherosclerotic cardiovascular (ASCVD) diagnosis or procedure. We investigated the incidence of new-onset ASCVD after International Classification of Disease (ICD) diagnosis code of DM, PM, dermatopolymyositis (DPM) or juvenile dermatomyositis (JDM).

Methods: This retrospective analysis used the TriNetX database, a national federated research network of de-identified data enrolling over 150 million patients. Patients were identified by entry of two ICD codes separated by at least 6 months, according to their first diagnosis code (i.e., DM, PM, DPM, or JDM). Patients with an ASCVD code that preceded the diagnosis code were excluded as we wanted to capture a new ASCVD event. We defined an ASCVD event as an ICD code entry for myocardial infarction, ischemic stroke, transient ischemic attack or peripheral arterial disease. Logistic regression modeling the odds of ASCVD outcome were used to produce adjusted odds ratios (OR) and 95% confidence intervals (95% CI) for differences among diagnosis codes.

Results: A total of 35,649 patients were identified, of whom 26% were male and the mean age at first IIM diagnosis code was 54 (table 1). In the sample, half of the patients had hypertension. The majority of patients (79%) were not on a cholesterol medication, and 20% had a prior dispensation for a statin medication. The ASCVD outcome occurred in 30% of patients with PM, 24% in patients with DM, 15% of patients with DPM and 4% of patients with JDM. The median time to ASCVD

Table 1: Demographics	n or mean or median	% or ±SD or (IQR)
Male, n %	9321	26.1
Age at first diagnosis, mean ± SD years, range=1 – 88	54.4	±17.2
Comorbidity history by 2 ICD codes within 90 days		
Overweight or obesity	8729	24.5
Obesity	6783	19.0
Hypertension	18194	51.0
Diabetes	8697	24.4
Smoking	6042	16.9
Alcohol	320	0.9
Cholesterol med history (not mutually exclusive)		
Statin	7025	19.7
Ezetimibe	622	1.7
PCSK9	162	0.5
Number of cholesterol meds per person		
None	28246	79.2
1	7012	19.7
2	376	1.1
all 3	15	0.0
ICD Diagnosis		
PM	16900	47.4
DM	10153	28.5
DPM	6501	18.2
JDM	2025	5.7
DM and PM same date	70	0.2
ASCVD at any time after diagnosis	8682	24.4
Median years to ASCVD (95% CI) after IIM diagnosis	12.4	(11.9, 13.6)

Abbreviations: SD=standard deviation, IQR= interquartile range, ICD=International Classification of Disease, PM=polymyositis, DM=dermatomyositis, DPM= dermatopolymyositis, IIM=Idiopathic inflammatory myopathy, JDM=Juvenile dermatomyositis, PCSK9=Proprotein convertase subtilisin/kexin type, CI= Confidence interval

event was 9.7 years for PM, 14.2 years for DM, and 16.7 years for DPM (Figure 1). There were higher odds of ASCVD outcome for all PM, DM, DPM patients compared to JDM (table 2). Compared to DM, patients with PM had 26% higher odds of ASCVD (table 2).

Conclusion: ASCVD is an important comorbidity that affects patients with IIM. Given the median time to event of 12 years, it appears to be a long-term complication after myositis diagnosis in patients who do not have concomitant ASCVD. This study also highlights the need for further evaluation into the use of the DPM code which represents a subset of patients seen in the US who have a longer time to ASCVD event compared to patients with ICD codes for DM or PM. Future study should investigate the shorter time-to-event observed in PM than other IIM. Additional study should evaluate whether special screening or intervention are necessary to reduce risk for ASCVD in IIM.

Table 2: Logistic regression modeling ICD diagnosis association with odds of ASCVD

Diagnosis type risk factor	*aOR (95% CI)*
PM (vs JDM)	**2.37 (1.77, 3.18)**
DM (vs JDM)	**1.88 (1.40, 2.52)**

SESSION INFORMATION

Session Date: Wednesday, November 15, 2023

Session Title: Abstracts: Muscle Biology, Myositis & Myopathies – Basic & Clinical Science II

Session Type: Abstract Session

Session Time: 9:00AM–10:30AM

Background/Purpose: Sporadic inclusion body myositis (sIBM) is a subset of autoimmune inflammatory myopathies (AIM) that is often challenging to diagnose. The objective of this study was to use machine learning and a comprehensive profile of autoantibodies to: 1) examine sIBM endotypes, 2) differentiate sIBM from AIM. The primary goal was to identify an approach that would facilitate earlier and more precise diagnosis.

Table 1. Baseline Characteristics and Autoantibody Profiles of the Four sIBM Clinical Clusters

	Entire cohort (n=75)	Cluster 1 (n=22)	Cluster 2 (n=23)	Cluster 3 (n=23)	Cluster 4 (n=7)	P-value[1]	Adj. p-value[2]
Male, % (n)	62.2 (46)	0	100 (23)	100 (23)	0	**<0.001**	**<0.001**
Age, mean (SD) yrs	68.3 (9.2)	67.4 (8.3)	68.3 (9.9)	69.7 (9.9)	66.3 (8.3)	0.759	1.000

1. Other autoimmune inflammatory myopathies included dermatomyositis, polymyositis, anti-synthase syndrome, immune-mediated necrotizing myositis, overlap myositis and other.
Abbreviations: NPV, negative predictive value; PPV, positive predictive value

Methods: Clinical and demographic information were obtained on sIBM patients and AIM disease comparators. Baseline sera from these patients were tested for conventional and novel autoantibodies that included anti-NT5c1A/Mup44 and anti-mitofusin (MFN)-1 and -2) using an addressable laser bead immunoassay, a multiplexed autoimmune liver disease array, and antinuclear antibodies (ANA) on HEp-2 substrates by an indirect immunofluorescence assay (IFA). Agglomerative hierarchical clustering based on clinical features (creatine kinase level, dysphagia, knee extension weakness, quadriceps atrophy, grip strength, and disease severity (graded by expert)) was performed to identify clinical sub-phenotypes of sIBM. Seven classification algorithms were trained using K-fold cross validation to differentiate sIBM from AIM based on the

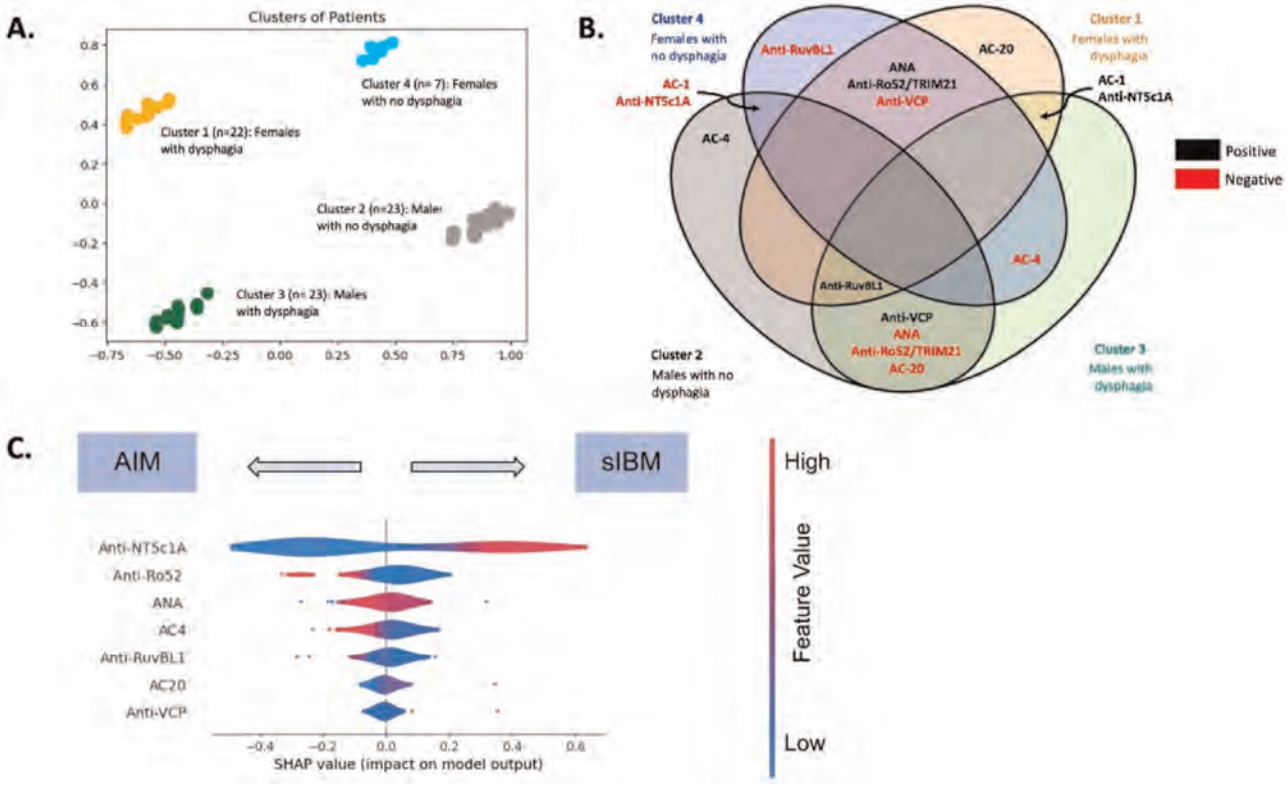

Figure 1. A) Four sIBM cluster identified by agglomerative hierarchical clustering based on clinical features (creatine kinase level, dysphagia, knee extension weakness, quadriceps atrophy, grip strength, and disease severity (graded by expert)). B) Autoantibody profile associated with each sIBM cluster determined by SHapley Additive exPlanation (SHAP). C) SHAP plots for the most important autoantibodies using Extreme Gradient Boosting machine learning model to differentiate sIBM from AIM (autoimmune inflammatory myopathies). Autoantibodies that had a frequency of less than 10% of the entire cohort are not shown on the SHAP plots.

autoantibodies and performance was assessed. SHapley Additive exPlanation (SHAP) plots identified the most important associated with each sIBM cluster and model used to different between sIBM vs. AIM.

Results: 75 sIBM patients were included in the cluster analysis (mean age 68.3 years (SD 9.2), 62.2% male) (**Table 1**). Four sIBM clinical clusters were identified: 1) females with dysphagia (n=22), 2) males with no dysphagia (n=23), 3) males with dysphagia (n=23), 4) females with no dysphagia (n=7) (**Figure 1a**). Based on the SHAP analysis, ANA and anti-Ro52/TRIM21 were more likely to be positive among female clusters (1 and 4), while anti-VCP was more likely to be positive among male clusters (2 and 3) (**Figure 1b**). Positive AC-1 (homogeneous pattern) and anti-NT5c1A were more likely to be found in clusters with dysphagia (1 and 3). Anti-RuvBL1 was less likely to be found among females with no dysphagia (cluster 4). Machine learning analysis based on autoantibody profile alone included an additional 17 sIBM patients (total 92) sIBM and 129 AIM disease controls. All the machine learning models used to differentiate sIBM vs. AIM, based on autoantibody profile alone, demonstrated high specificity (75.9%-89.7%) with fair sensitivity (57.6%-71.3%), accuracy (73.3%-77.8%) and F1 score (65.6%-71.1%) (**Table 2**). SHAP analysis revealed that positive anti-NT5c1A, AC-20 (cytoplasmic [speckled]) pattern, anti-VCP, but negative anti-Ro52/TRIM21, ANA, AC-4 (nuclear [fine speckled]) pattern, and anti-RuvBL1, favored a diagnosis of sIBM over AIM (**Figure 1c**).

Conclusion: In this comprehensive machine learning analysis of autoantibodies, ANA, anti-NT5c1A, anti-Ro52/TRIM21, anti-VCP, and anti-RuvBL1 were important biomarkers for both assessing sIBM clinical endotypes and differentiating sIBM from other AIMs. Future studies to study other novel biomarkers and validate our findings in larger cohorts are needed.

Validation of PROMIS in Adult and Pediatric Patients with Idiopathic Inflammatory Myopathies

Emma Austenfeld[1], Sara Sabbagh[1], Melodee Liegl[1], Ke Yan[1], Julie Fuller[2], Kelly Rouster-Stevens[3], Lisa Rider[4] and Adam Schiffenbauer[4], [1]Medical College of Wisconsin, Wauwatosa, WI, [2]UT Southwestern and Scottish Rite for Children, Dallas, TX, [3]Emory University/Children's Healthcare of Atlanta, Norcross, GA, [4]NIEHS, NIH, Bethesda, MD

SESSION INFORMATION
Session Date: Wednesday, November 15, 2023
Session Title: Abstracts: Muscle Biology, Myositis & Myopathies – Basic & Clinical Science II
Session Type: Abstract Session
Session Time: 9:00AM–10:30AM

Background/Purpose: This study aimed to validate the Patient Reported Outcome Measurement Information System (PROMIS) tools in patients with adult and juvenile idiopathic inflammatory myopathies (IIM/JIIM) to better assess quality of life (HR-QoL).

Table 1: Demographics, clinical, and autoantibody subgroups in patient populations

	Juvenile-Onset (N=85) Median (IQR) or n/N, %	Adult-Onset (N=50) Median (IQR) or n/N, %
Age at enrollment (years)	13.0 (8.5-17.0)	49.5 (36.5-58.3)
Disease duration (years)	2.8 (1.0-7.7)	1.6 (0.9-9.4)
Female	53/85, 62%	38/50, 76%
Race		
Caucasian	63/83, 76%	29/47, 62%
African American	11/83, 13%	11/47, 23%
Asian	4/83, 5%	2/47, 4%
Other	5/83, 6%	5/47, 11%
Ethnicity (Hispanic or Latino)	12/83, 14%	5/48, 10%
Diagnosis		
JDM/DM*	82/85, 97%	40/50, 80%
MSA		
anti-NXP2(MJ)	24/70, 34%	12/44, 27%
anti-p155/140	19/70, 27%	7/44, 16%
anti-MDA5	12/70, 17%	2/38, 5%
anti-synthetase‡	4/71, 6%	12/48, 25%
anti-Mi2	2/71, 3%	4/48, 8%
MAA positive †	24/72, 33%	7/48, 15%

JDM: Juvenile Dermatomyositis, DM: Dermatomyositis, JPM: Juvenile Polymyositis, PM: Polymyositis, MAA: Myositis Associated Autoantibody, MSA: Myositis Specific Autoantibody, NXP2: nuclear matrix protein-2, MDA5: melanoma differentiation associated protein-5, SRP: signal recognition particle
* non-JDM/DM subgroup included polymyositis and immune mediated necrotizing myositis
‡ anti-Jo-1, anti-PL7, anti-PL12, or anti-KS.
† MAAs included La/Ro, Ro, PMSCL, U1RNP, or U1RNP/Sm.
Antibody testing for signal recognition particle (SRP) was also performed; no patients tested positive.

Methods: Seventy-four children and 11 adults with juvenile-onset IIM (mean age 13 years, 62% female) and 50 adult-IIM patients (mean age 50 years, 76% female) with probable or definite Bohan and Peter criteria for IIM enrolled in a myositis natural history study (Table 1). Patients ≥ 18 years of age (n=61) completed PROMIS57, while patients < 18 years (n=49) and/or their parents (n=70) completed PROMIS49. PROMIS domains (Physical Function (PF), Pain Interference (PI), Fatigue, Social Role (SR), Peer Relations (PR), Anxiety, Depression, and Sleep Disturbance) were analyzed for content validity or

Table 2: PROMIS scores in myositis patients vs. healthy controls

Domains of PROMIS 49 – Patient	**Mean ± SD**	**p-value**
Physical Function T-score	44.3 ± 9.8	p < 0.001
Pain Interference T-score	49.6 ± 12.2	ns
Fatigue T-score	49.5 ± 12.6	ns
Peer Relations T-score	50.2 ± 11.3	ns
Anxiety T-score	47.0 ± 11.0	ns
Depression T-score	44.9 ± 10.9	p = 0.002*
Domains of PROMIS 49 – Parent		
Physical Function T-score	42.1 ± 9.9	p < 0.001
Pain Interference T-score	49.8 ± 11.2	ns
Fatigue T-score	51.7 ± 13.2	ns
Peer Relations T-score	49.2 ± 10.2	ns
Anxiety T-score	48.9 ± 11.5	ns
Depression T-score	45.7 ± 10.3	p < 0.001*
Domains of PROMIS 57		
Physical Function T-score	39.9 ± 8.5	p < 0.001
Pain Interference T-score	55.8 ± 10.6	p < 0.001
Fatigue T-score	55.1 ± 11.1	p < 0.001
Social Role T-score	45.6 ± 9.3	p < 0.001
Anxiety T-score	52.5 ± 9.5	p = 0.043
Depression T-score	50.0 ± 8.9	ns
Sleep Disturbance T-score	52.1 ± 9.0	ns

p-values are based on comparison with the PROMIS healthy reference population (T-scores = 50).
**Study participants reported less depression than general population.*

internal consistency and construct validity, using Pearson's r and Cronbach's α. Construct validity of PROMIS was examined in the correlation of PROMIS scores with HAQ/CHAQ and SF-36 as previously studied instruments of HR-QoL.

Results: When compared to the PROMIS healthy reference population, both JIIM patients and their parents reported significantly lower PF, while adult IIM patients reported lower PF, lower SR, and higher PI, Fatigue, and Anxiety scores (Table 2). Pediatric Anxiety scores increased with age (r=0.324, p=0.023), and adult female patients had higher Anxiety scores than adult males (53.9 vs 48.3, p=0.029); there were no other differences in PROMIS scores by demographics. In paired analysis of parent and patient PROMIS scores, parents reported lower PF (p< 0.001), and greater Fatigue (p=0.023) and Anxiety (p=0.032) than their children. All three PROMIS instruments demonstrated "Excellent" or "Good" internal consistency (Cronbach α=0.895 - 0.986) in all domains. None of the PROMIS instruments exhibited floor or ceiling effects, as the majority of patients scored within 2 standard deviations of the mean for all of the domains. PROMIS exhibited strong construct validity using both the HAQ and CHAQ disability index, especially in the PF, PI, and Fatigue domains (r=0.51 - 0.78, p< 0.001). PROMIS57 scores also showed significant correlations with many related SF-36 domains, including PF, PI, and Fatigue (r=|0.840| - 0.85, p< 0.001).

Conclusion: As the first study to analyze many domains of PROMIS in adults with IIM, patients with JIIM, and parents of children with JIIM, our findings emphasize the perceived burden of disease between these populations and suggest that parents perceive poorer health status than their children. Our findings of PROMIS demonstrated excellent internal consistency and correlations with related domains on the HAQ/CHAQ and SF-36. These findings support the incorporation of PROMIS into assessments of IIM/JIIM populations and emphasize the importance of PROMIS to address comprehensive well-being for pediatric and adult patients with these chronic conditions.

High-intensity Resistance Training Improves Quality of Life, Muscle Endurance and Strength in Patients with Myositis

Kasper Jensen[1], Per Aagaard[2], Charlotte Suetta[3], Jakob Nielsen[2], Rune Bech[4], Henrik Schrøder[1], Casper Simonsen[1], Jan Christensen[1] and Louise Pyndt Diederichsen[5], [1]University Hospital of Copenhagen, Rigshospitalet, Copenhagen, Denmark, [2]University of Southern Denmark, Odense, Denmark, [3]Bispebjerg Hospital, Copenhagen, Denmark, [4]Zealand University Hospital, Koege, Dragør, Denmark, [5]University Hospital of Copenhagen, Rigshospitalet, Dragør, Denmark

SESSION INFORMATION
Session Date: Wednesday, November 15, 2023
Session Title: Abstracts: Muscle Biology, Myositis & Myopathies – Basic & Clinical Science II
Session Type: Abstract Session
Session Time: 9:00AM–10:30AM

Background/Purpose: Myositis is associated with muscle impairment, which impacts quality of life. The purpose of this study was to investigate the effects of high-intensity strength training on quality of life, functional capacity, muscle strength and disease-related measures in patients with myositis.

Methods: Using a randomized control trial design (**NCT04486261**), 32 patients with established and stable myositis, were randomly allocated to 16 weeks of high-intensity strength training (HRT) or 16 weeks of baseline activity levels (CON). The primary outcome was quality of life (Short Form-36, SF-36) - physical component summary (PCS). Secondary outcomes

included SF36 - mental component summary (MCS), functional capacity measures (e.g., 2-minute walk test (2MWT), 30-s Sit-To-Stand (30-STS), Timed-Up-&-GO (TUG) and Functional Index 3 (FI3)), maximal leg extensor power (LEP) and disease-related measures (Physician Global Activity (PhGA), Patient Global Activity (PtGA), Extramuscular Global Assessment (EMGA), Creatine Kinase (CK), Health Assessment Questionnaire (HAQ), Physician Global Damage (PhGD), Patient Global Damage (PtGD), and Manual Muscle Testing 8 (MMT8)).

Results: The primary outcome PCS showed an improvement in favour of HRT with a between-group difference of 5.33 (0.61;10.05) (p=0.03). Further, FI3 showed a between-group difference with greater gains of HRT (11.49 (3.37;19.60) (p=0.04)). Within-group increases in other functional capacity measures were observed with HRT (30-s STS, 6.5%, p=0.03; TUG, 12.9%, p< 0.0001; 2MWT, 4.9%, p=0.008; LEP, 14.2%, p=0.04). HRT also resulted in a between-group improvement in MMT8 (1.30 (0.09;2.51) (p=0.04)). Finally, IMACS's physician global damage decreased by 27.7% (p=0.02), and patient global damage decreased by 47.2% (p=0.03), within the HRT group (**Table 1**).

Conclusion: Improvement in physical component of quality of life was observed following 16 weeks of strength training in myositis patients. Likewise, improvements in muscle endurance by FI3 and strength by MMT8 were significantly higher in TRAIN compared to CON. No increases in disease activity or damage were observed. These results indicate that high-intensity strength training is well tolerated and positively impacts patients with established myositis.

Data are presented as means and 95% confidence intervals in parentheses. HRT: high-intensity resistance trained; CON: control; 2MWT: 2-minute walk test; 30 STS: 30 second Sit To Stand; TUG: Timed Up and Go; FI3: Functional Index 3; LEP: Leg Power; PhGA: physician global activity; PtGA: patient global Activity; EMGA: Extramuscular global assessment; MMT8: Manual muscle testing 8; HAQ: Health assessment questionnaire; CK: Creatine kinase; PhGD: physician global damage; PtGD: patient global damage. Bold font means significant. Significant levels set at p=0.05.

Proteomic Signatures in Pre-Rheumatoid Arthritis Suggest Evolving Biological Pathways in Different Stages of Disease Development That May Inform Prediction and Prevention Strategies

Samir Rachid Zaim[1], Adam Savage[1], Mark Gillespie[1], Christy Bennett[1], lynne Becker[1], LauraKay Moss[2], Marie Feser[2], Jess Edison[3], Ted R Mikuls[4], Michael Holer[2], kevin Deane[2] and Xiao-Jun Li[1], [1]Allen Institute for Immunology, Seattle, WA, [2]University of Colorado Anschutz Medical Campus, Aurora, CO, [3]Walter Reed Military Medical Center, Bethesda, MD, [4]Division of Rheumatology and Immunology, University of Nebraska Medical Center, Omaha, NE

SESSION INFORMATION

Session Date: Wednesday, November 15, 2023

Session Title: Abstracts: RA – Diagnosis, Manifestations, and Outcomes IV: Pre-RA & RA Diagnosis

Session Type: Abstract Session

Session Time: 11:00AM–12:30PM

Background/Purpose: Rheumatoid arthritis (RA) includes a stage of development that can be termed 'pre-RA' and defined as the presence of abnormal biomarkers and/or other features (e.g. articular symptoms) prior to the development of clinically-apparent synovitis (i.e. Clinical RA). In pre-RA, multiple interventions are being evaluated to prevent, delay or modulate future Clinical RA. However, the biologic pathways during the various stages of development in pre-RA are incompletely understood, and this 'gap' limits the ability to predict Clinical RA in at-risk populations as well as target the key pathways during disease development. To address this gap, we evaluated samples from the pre-RA period, and controls, from the Department of Defense Serum Repository (DoDSR) to test the hypothesis that proteomic testing can identify evolving biologic features in pre-RA that can ultimately be used to improve prediction for future Clinical RA and identify potential stage-specific targets for preventive interventions.

Table 1. Characteristics of individuals with RA and controls without RA

Table 1. Characteristics of individuals with RA and controls without RA

	RA Subjects	Healthy Controls	P value

*Mann-Whitney test. [#]Fisher's exact test.

Methods: We evaluated 197 proteins on the Olink platform in serum from the DoDSR from the pre-RA period from 213 individuals with confirmed RA and 215 controls without RA (**Table 1**). Samples were also tested for ACPA and rheumatoid factor (RF) using anti-CCP3, RF-IgA and RF-IgM ELISA assays (Werfen).We applied linear mixed effect models and Mann-Whitney testing to evaluate participant-specific trajectories for pre-RA and controls in discrete time periods prior to RA diagnosis (i.e. pre-RA), and to identify biologic pathways through KEGG analyses. All p-values were adjusted for multiple testing with false discovery rate (FDR).

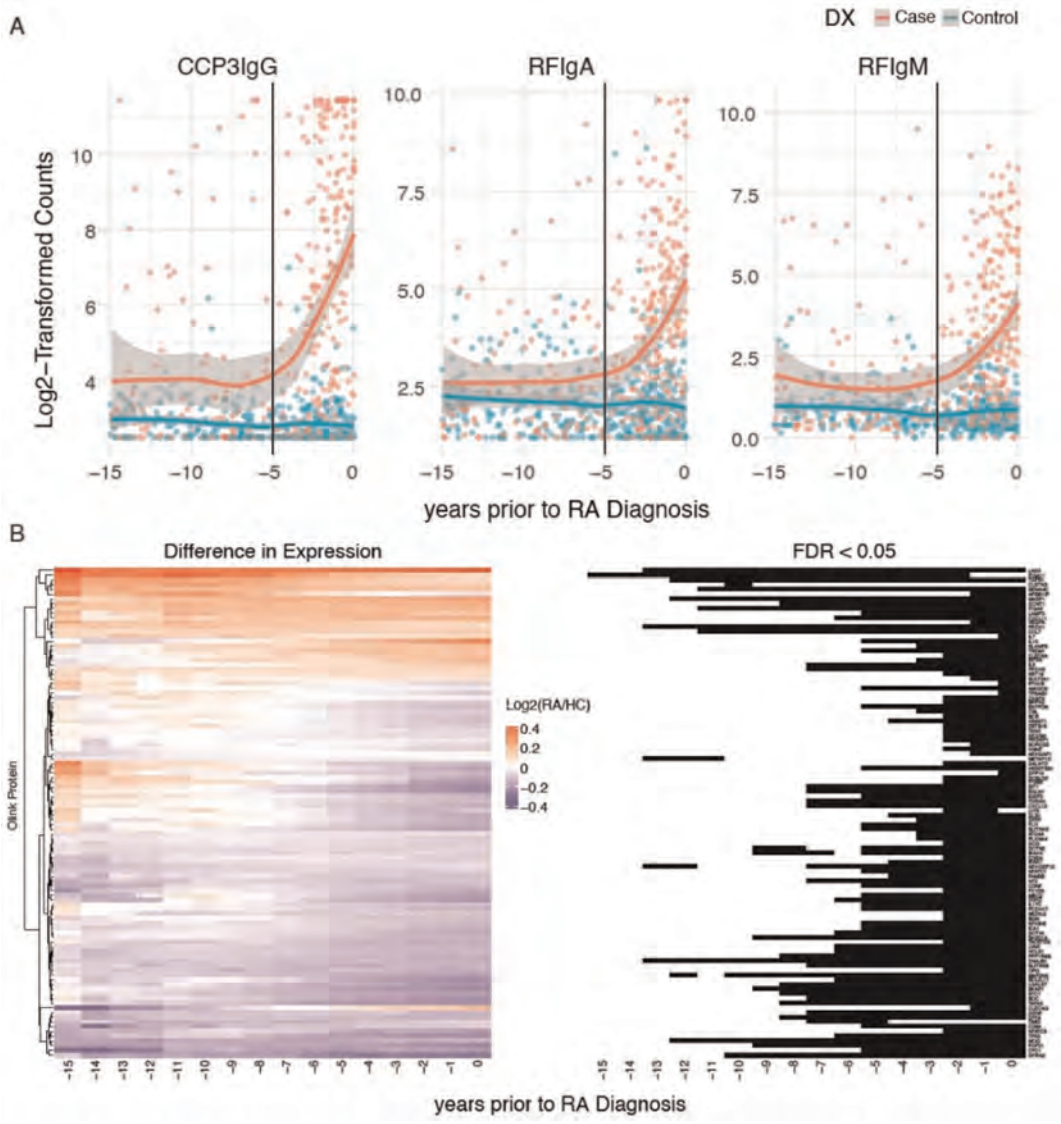

Figure 1. Autoantibody and proteomic findings in pre-RA. Panel A: Autoantibody levels for CCP3, RFIgA, and RFIgM for each sample from -15 to 0 years prior to RA diagnosis. LOESS regression curves were fit to show cohort trajectory, with confidence bands shown in gray. Overall, these autoantibodies increase in level with an inflection point of rise in RA cases ~5 years prior to diagnosis. Panel B: Heatmaps showing longitudinal signatures of 104 proteins that were differentially expressed between samples from the pre-RA period in individuals who developed RA compared to controls. Panel B/left side: Each cell denotes the Log2 fold change differences between individuals with RA and controls. Red cells denote higher normalized protein expression in RA, and blue/purple cells represent lower expression in RA. Panel B/right side: Each black cell denotes a protein that was differentially expressed in pre-RA samples versus controls at each time point and significant at a false-discovery rate (FDR) < 0.05. Overall, the differential expression of proteins appears to be in 'stages' with potential inflection point for many proteins approximately 5 years prior to the diagnosis of RA.

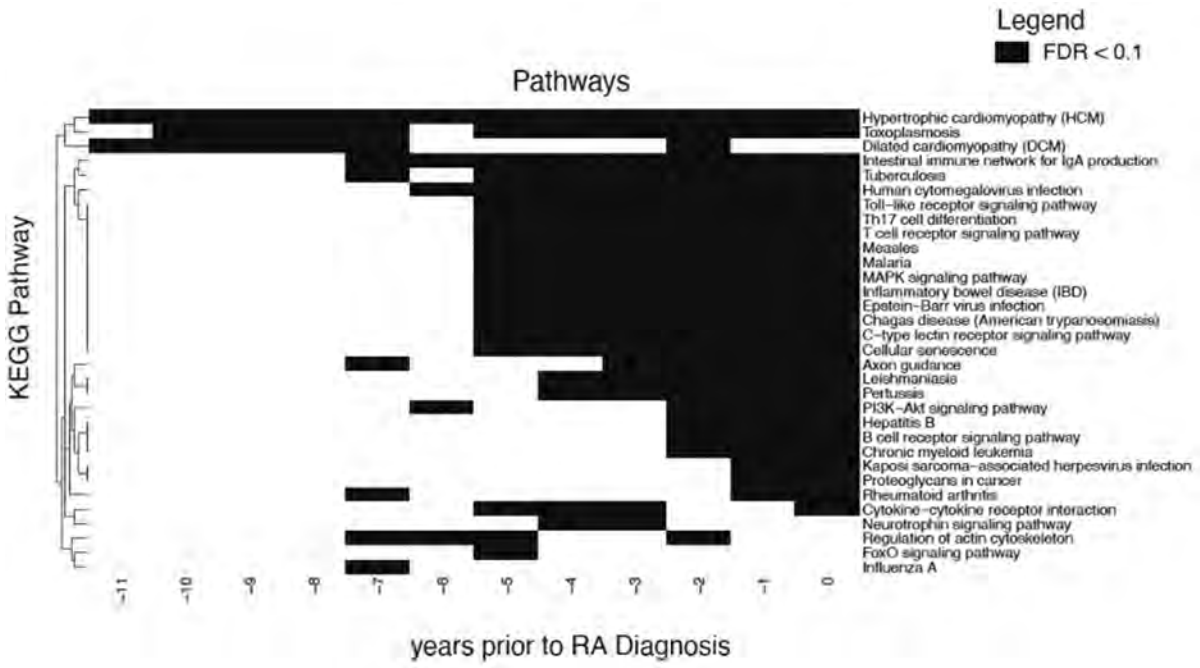

Figure 2. Biologic pathway enrichment in specific years prior to RA diagnosis. We applied KEGG analyses of the proteins that were differentially expressed in individuals in the pre-RA period compared to controls. The black cells indicate the enriched pathways in the pre-RA period in individuals with RA compared to controls, and significant at a false-discovery rate (FDR) <0.1. Overall, the pathways were differentially expressed at various time points in pre-RA, including a number of pathways predominately present <=5 years prior to RA diagnosis.

Results: Anti-CCP3, RFIgA, and RFIgM were significantly elevated in individuals in pre-RA compared to controls, with the highest levels observed ≤5 years prior to diagnosis (**Fig 1A**). We further identified 104 proteins that were differentially expressed in pre-RA samples compared to controls (**Fig 1B**). Of these, 60/104 proteins (e.g. IL7, IL10, NFKBIE) were differentially expressed ≤5 years prior to RA diagnosis in pre-RA samples vs controls, and enriched 21 biologic pathways including infection-related (e.g. Epstein-Barr virus, Malaria), mucosal (e.g. IBD) and cellular signaling pathways (e.g. Toll-like receptor and MAPK signaling). In contrast, only 2 proteins were differentially expressed >5 years prior to RA diagnosis. The remaining 42/104 proteins (e.g. LAG3, IL6, TGFB1) were differentially expressed over both time periods and enriched 10 pathways.

Conclusion: Our findings suggest that autoantibody and protein biomarkers evolve in pre-RA in distinct stages. In particular, the protein biomarkers may identify biologic pathways that are relevant to certain time points in pre-RA evolution. Notably, several pathways associated with infections and/or mucosal processes enriched in the period ≤5 years prior to clinical RA suggests these factors may play a role in increasing autoantibody levels and the transition from pre-RA to Clinical RA. These findings can be explored in future studies to improve prediction of future RA, as well as identify specific processes and pathways that could be targeted with preventive interventions.

Session Type: Abstract Session

Session Time: 11:00AM–12:30PM

Background/Purpose: Production of ACPA following T and B cell interactions is a hallmark of ACPA+ RA. Recently identified peripheral helper T (Tph) cells have B cell-helper functions coupled with a migratory program targeting inflamed peripheral non-lymphoid tissues. Tph cells are expanded in the inflamed joint and blood of ACPA+ RA patients. However, it is not known whether immune dysregulation with an expansion of Tph cells occurs in a pre-disease stage of RA (i.e., ACPA+ at-risk individuals [ARI]).

Methods: We analyzed peripheral blood mononuclear cells (PBMC) from two independent and ethnically distinct cohorts to identify cell populations associated with serum ACPA positivity as well as eventual progression to classified RA. First, we employed mass cytometry with 38 markers in PBMCs from ARI, ACPA+ early RA patients, and healthy controls in a Japanese cohort (n = 17 in each group). Data were analyzed by computational analyses and biaxial gating. Next, the findings identified in the Japanese cohort were evaluated by flow cytometric analysis of PBMCs from a US-based cohort that included 11 healthy controls and 11 ACPA+ individuals who all subsequently developed RA (pre-RA), of which 9 had available post-RA diagnosis PBMC (post-RA), allowing for longitudinal analyses.

Results: In the Japanese cohort, FlowSOM analysis of CD4$^+$ T cells identified 10 metaclusters (i.e., cell populations). Of those, two metaclusters were significantly increased in ARI and RA compared to controls (**Figure 1A**). One of these metaclusters showed a high level of PD-1 expression and lack of CXCR5 expression, consistent with Tph cells (**Figure 1B**). t-SNE clustering visualized Tph cells composed of two distinct subpopulations based on HLA-DR expression (**Figure 1C**). Biaxial gating revealed that HLA-DR$^+$ Tph cells were significantly increased in ARI ($p = 0.002$) and RA ($p < 0.001$) compared to controls, while HLA-DR$^-$ Tph cells were increased only in RA (**Figure 1D**). In ARI, the frequency of HLA-DR$^+$ Tph cells was higher in 'progressors' (i.e., ARI who developed RA within one year after PBMC collection) compared to non-progressors ($p = 0.032$, **Figure 1E**). The FlowSOM analysis of B cells identified 15 metaclusters, and one of these metaclusters was significantly expanded in ARI and RA compared to controls (**Figure 2A**). Heatmap indicated that this metacluster was IgM$^+$IgD$^+$CD38$^+$CD27$^-$CXCR5$^-$ cells (CXCR5$^-$CD38$^+$ mature naïve B cells) (**Figure 2B**). Biaxial gating confirmed their expansion in ARI and RA ($p = 0.002$, $p < 0.001$, respectively; **Figure 2C**). In the US-based cohort, HLA-DR$^+$ Tph cells and CXCR5$^-$CD38$^+$ mature naïve B cells were also increased in pre-RA compared to controls ($p = 0.047$, $p = 0.040$, respectively; **Figure 3AB**). The frequencies of HLA-DR$^+$ Tph cells and CXCR5$^-$CD38$^+$ mature naïve B cells did not significantly differ between pre-RA and post-RA visits (**Figure 3CD**).

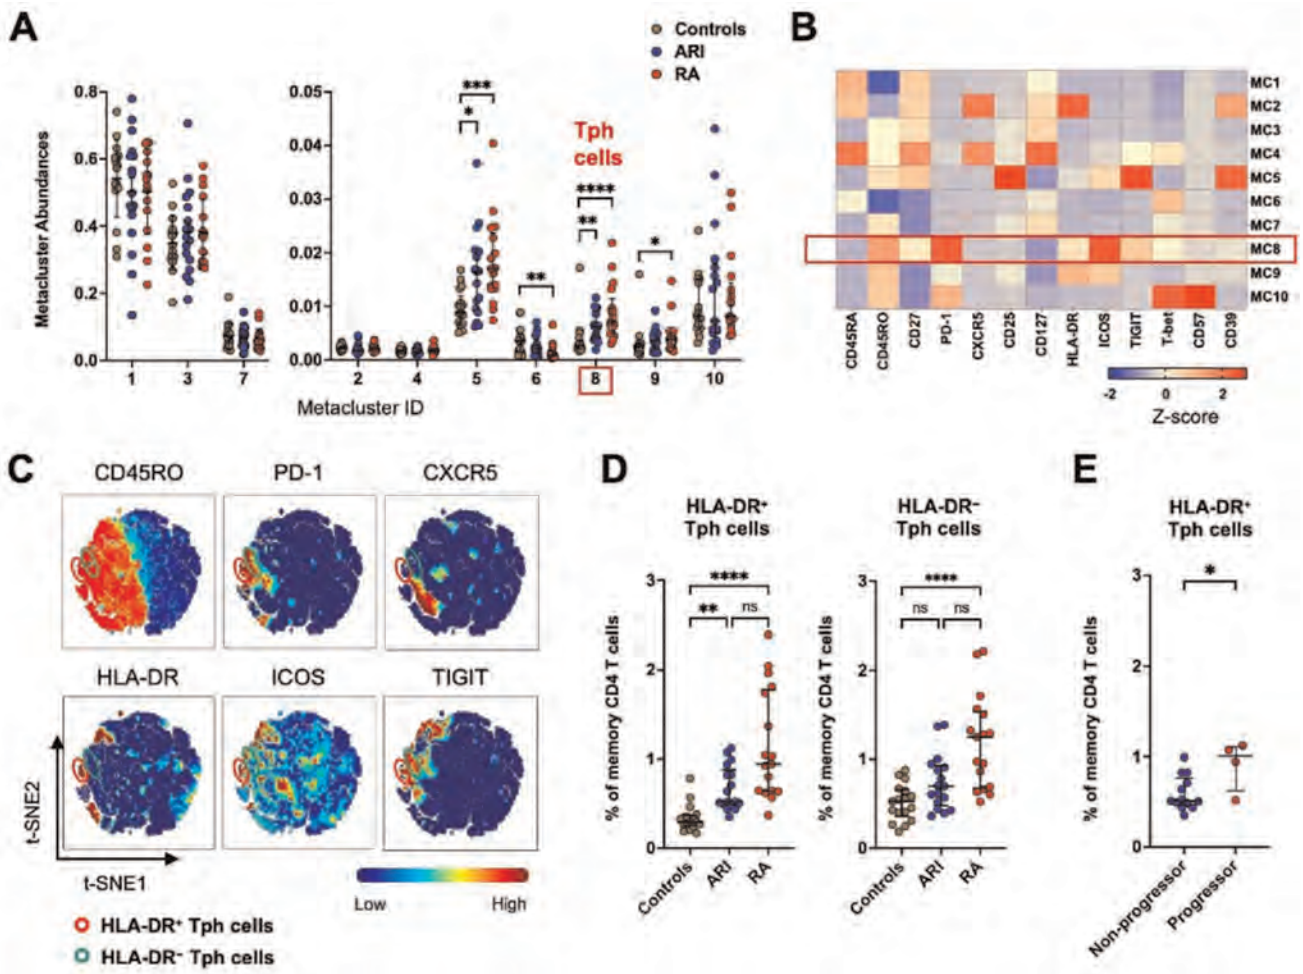

Figure 1. Identification of expanded HLA-DR⁺ Tph cells in blood of ACPA+ at-risk individuals and early RA patients in the Japanese at-risk cohort. (A) Abundance of FlowSOM metaclusters of CD4+ T cells. (B) Heatmap of normalized expression of mass cytometry markers in each metacluster (MC). (C) Visualization of CD4⁺ T cells by t-SNE, showing HLA-DR⁺ Tph cells (red circle) and HLA-DR⁻ Tph cells (green circle). (D) Frequencies of HLA-DR⁺ Tph cells and HLA-DR⁻ Tph cells. (E) Frequency of HLA-DR⁺ Tph cells in ARI who developed RA within one year after PBMC collection (progressor, n=4) and those who did not develop RA within that period (non-progressor, n=13). *P < 0.05, **P < 0.01, ***P < 0.001, ****P < 0.0001 by Kruskal-Wallis test and Dunn's multiple comparisons test in A and D, and by Mann-Whitney test in E. Error bars show median with interquartile range. ARI, at-risk individuals; ns, not significant; Tph, peripheral helper T.

Conclusion: The expansion of HLA-DR$^+$ Tph cells and CXCR5$^-$CD38$^+$ mature naïve B cells in ACPA+ individuals, including those who develop classified RA, and the association of the former sub-type with 'progressors' supports a key role of these cells in ACPA positivity as well as a transition from pre-RA to classified RA. These cell sub-types may identify a mechanistic target for treatment and prevention in RA.

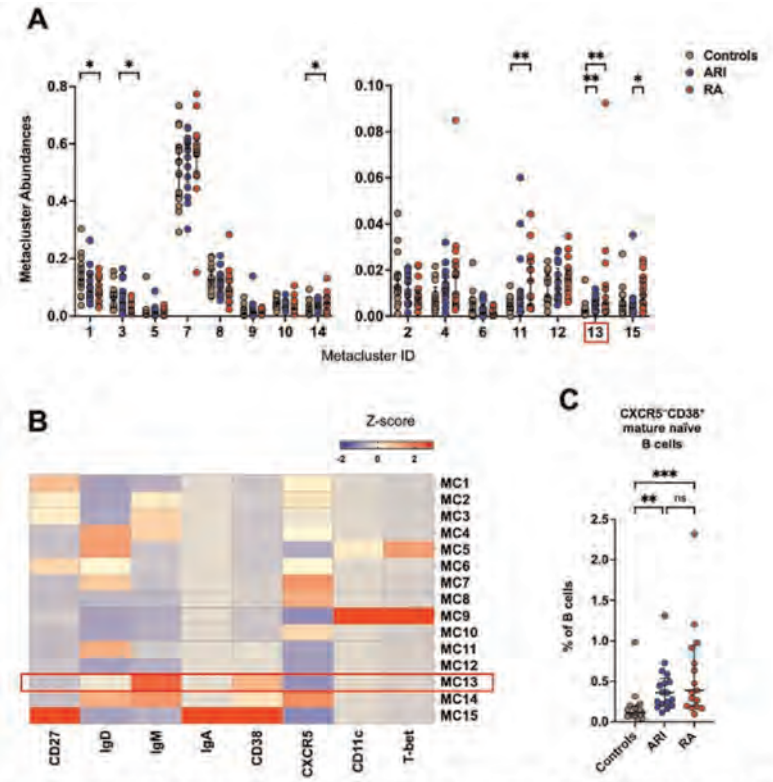

Figure 2. Expansion of CXCR5⁻CD38⁺ mature naïve B cells in blood of ACPA+ at-risk individuals and early RA patients in the Japanese at-risk cohort. (A) Abundance of FlowSOM metaclusters of B cells. (B) Heatmap of normalized expression of mass cytometry markers in each metacluster (MC). (C) Frequency of CXCR5⁻CD38⁺ mature naïve B cells by biaxial gating. *P < 0.05, **P < 0.01, ***P < 0.001 by Kruskal-Wallis test and Dunn's multiple comparisons test. Error bars show median with interquartile range. ARI, at-risk individuals.

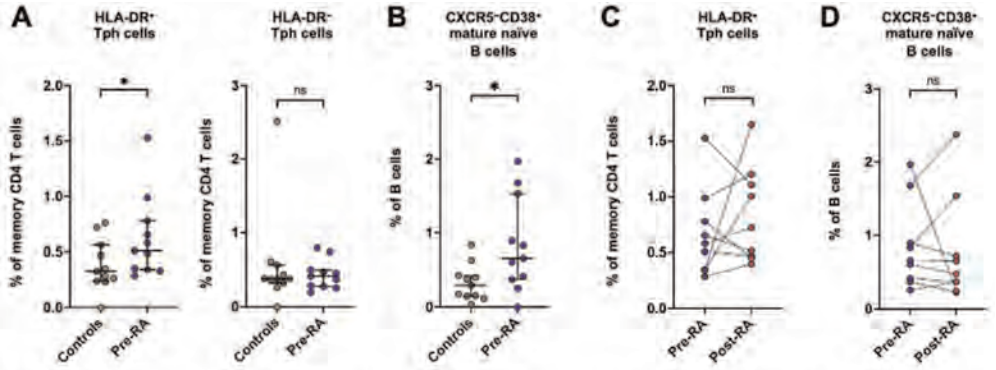

Figure 3. Cross-sectional and longitudinal analyses of T cell and B cell subsets in the US-based at-risk cohort. (A) Frequencies of HLA-DR⁺ Tph cells and HLA-DR⁻ Tph cells in memory CD4⁺ T cells. (B) Frequency of CXCR5⁻CD38⁺ mature naïve B cells. (C) Longitudinal change in frequency of HLA-DR⁺ Tph cells. (D) Longitudinal change in frequency of CXCR5⁻CD38⁺ mature naïve B cells. Comparison between HC and Pre-RA was performed by Mann-Whitney test, and comparison between Pre-RA and Post-RA was performed by Wilcoxon matched-pairs signed rank test. *P < 0.05. Error bars show median with interquartile range.

SESSION INFORMATION

Session Date: Wednesday, November 15, 2023

Session Title: Abstracts: RA – Diagnosis, Manifestations, and Outcomes IV: Pre-RA & RA Diagnosis

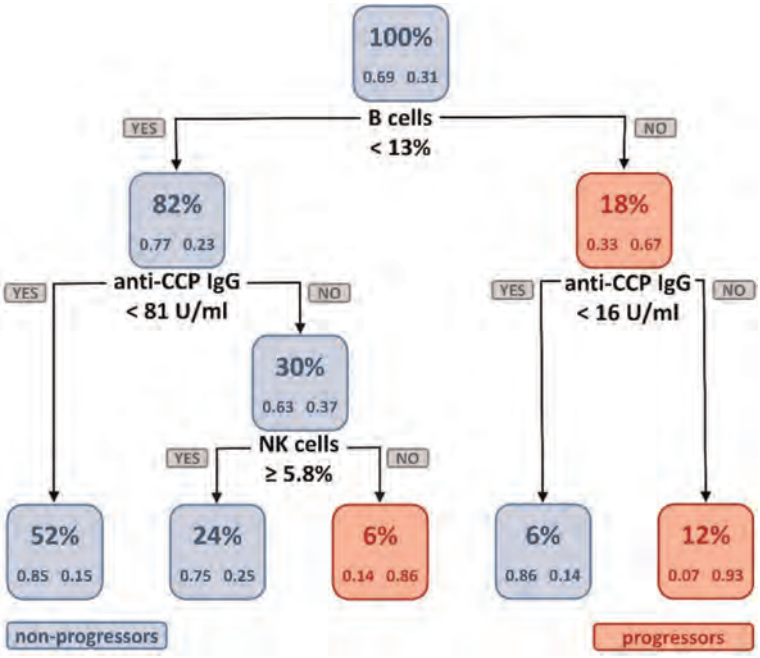
Session Type: Abstract Session

Session Time: 11:00AM–12:30PM

Background/Purpose: The positivity of antibodies against citrullinated proteins (ACPA) substantially increases the risk of developing rheumatoid arthritis (RA). The definition of individuals with arthralgia at risk of progression to RA (clinically suspect arthralgia, CSA) was established by EULAR based on clinical characteristics irrespective of the ACPA. Dysregulation of lymphocyte subpopulations (including B and NK cells) was previously described in early and established RA. We aimed to propose the predictive model for progression to arthritis based on peripheral lymphocyte subsets and ACPA in at-risk individuals with arthralgia.

Methods: Individuals from the At Risk of RA (ARRA) prospective observational cohort were defined at baseline as having arthralgia without arthritis on the examination of 66 joints and being either ACPA+ and/or meeting the EULAR definition of CSA. The percentage (%) of B cells, T cells, NK cells, NK-T cells, and γδ-T cells were detected within the peripheral blood lymphocyte population using flow cytometry. A logistic regression model was constructed to discriminate between progressors to arthritis and non-progressors and evaluated using ROC curves. Moreover, a classification decision tree was built to find segments with the highest risk of progression to arthritis.

Results: Out of 191 at-risk individuals with a median of 14 months follow-up and symptom duration 13 months at inclusion, 36 developed clinical arthritis (progressors) within a median of 9 months follow-up. For the construction of predictive models, 81 individuals who have not yet progressed to arthritis (non-progressors) with symptom duration longer than 12 months were included. A logistic regression model with baseline age, body mass index, % of peripheral blood lymphocyte subpopulations, and anti-CCP and anti-MCV serum levels as predictors was constructed for the discrimination between progressors and non-progressors. The resulting predictive model for arthritis development showed in a total cohort that high anti-CCP IgG levels, high % of B cells, and low % of NK cells increase the probability of developing arthritis, particularly in ACPA+ individuals, but not in the subset of ACPA- individuals. Evaluation of this model using the ROC curve showed AUC=0.732 ($p< 0.001$). When the identical set of predictors was applied to ACPA+ individuals, AUC was even higher (AUC=804,$p< 0.001$). However, we were not able to construct a well-performing model in ACPA- individuals. The CSA definition appears of no predictive value in our cohort. The proposed classification decision tree (Figure 1) showed, that individuals with B cells over 13% and anti-CCP IgG over 16 U/ml have a higher risk (93%) of progression to arthritis.



Classification decision tree

Conclusion: We propose here a predictive model to distinguish at-risk individuals with arthralgia who progress to arthritis from non-progressors based on baseline levels of lymphocyte subpopulations and ACPA levels, especially applicable in ACPA-positive individuals. The final model includes B cells and NK cells, which are involved in the pathogenesis of RA. This is a preliminary model that requires further validation in larger at-risk of RA cohorts.

SESSION INFORMATION

Session Date: Wednesday, November 15, 2023

Session Title: Abstracts: RA – Diagnosis, Manifestations, and Outcomes IV: Pre-RA & RA Diagnosis

Session Type: Abstract Session

Session Time: 11:00AM–12:30PM

Background/Purpose: We attempted to replicate and expand previous findings of an increased abundance of Prevotellaceae in early untreated Rheumatoid Arthritis (RA) or its preclinical stages, in first-degree relatives of RA patients (FDRs).[1]

Methods: FDRs from the SCREEN-RA cohort (Evaluation of a SCREENing strategy for RA)[2] were categorized in four groups:

- Controls: healthy asymptomatic FDRs
- High genetic risk: asymptomatic FDRs with two shared epitope (SE) copies
- Autoimmunity: asymptomatic FDRs with RA-associated autoimmunity
- Symptomatic: clinically suspect arthralgias (CSA) or untreated new-onset RA

Fecal samples were collected and immediately frozen. DNA was extracted and V3-V4 16S regions were sequenced on a MiSeq platform. Output was processed with DADA2 pipeline on R, using Silva 138v database. Cells counts (cytometry) and calprotectin (ELISA) were obtained for each fecal sample. Microbial community composition and differential analysis were conducted using non-parametric tests, such as PERMANOVA, Wilcoxon and Kruskal-Wallis, or Aldex2 R-package to account for data compositionality.

Results: A total of 372 individuals were included (Table 1). Groups had similar age, gender, and BMI. We found no group-wise clustering of 16S sequence variants (PERMANOVA, R2 = 0.0073, p = 0.81) (Figure 1A) and we found no group-differences in Prevotellaceae abundance (Figure 1B; Kruskal-Wallis p = 0.14). Results were similar after fecal cell counts correction (not shown). Aldex2 found no significant differences between groups regarding other bacterial families.

Table 1 Legend SD: Standard Deviation. N: Negative. L: Low positivity (1 to 3x the norm). H: High positivity (>=3x the norm). ACPA: Anti-Citrullinated Protein Antibodies. RF: Rheumatoid Factor. Anti-ra33: anti-Ra33 autoantibodies. CSA: Clinical Suspect Arthralgia according to the EULAR definition – score ranges from 1 to 7, with cutoffs at 3 or 4. Shared Epitope: a group of MHC-II alleles conferring higher risk for RA. NA: Not Assigned.

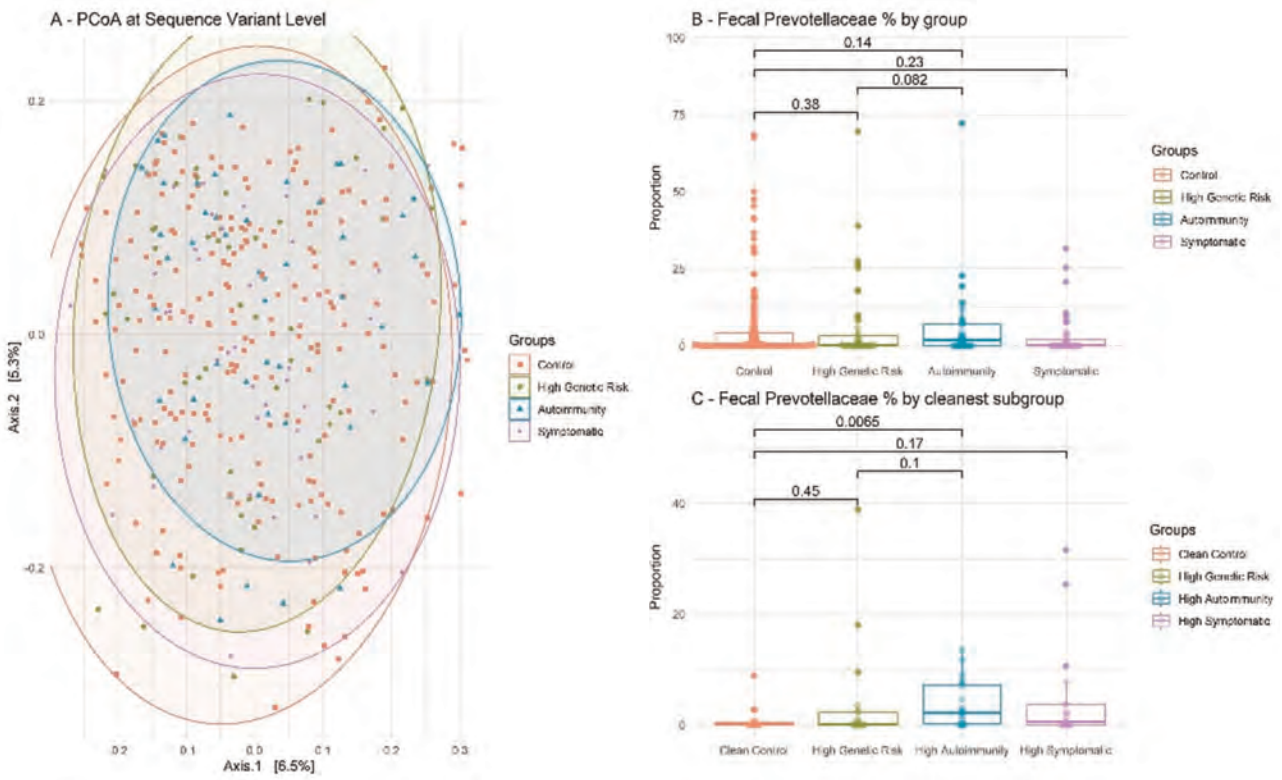

Figure 1: Microbiota 16S profiling by risk group, SCREEN-RA cohort A - PCoA : Principal Coordinate Analysis, performed at the Amplicon Sequence Variant level. On this figure, the more distant two point are, the more different they are in terms of 16S gene composition, based on Bray-Curtis index. B – Percentages of 16S sequences attributed to Prevotellaceae bacteria, per group. Wilcoxon test. C – Same panel as B, but restricted to cleaner subgroups, with high auto-antibody titers and/or high CSA scores. For readability Y-axis was cut (grey dotted line).

In a predefined subgroup analysis, selecting the most pronounced phenotypes in each group (i.e. highest autoantibody titers or arthralgia scores, n = 4x20) reproduced published results regarding Prevotellaceae (Figure 1C – Wilcoxon $p < 0.01$).

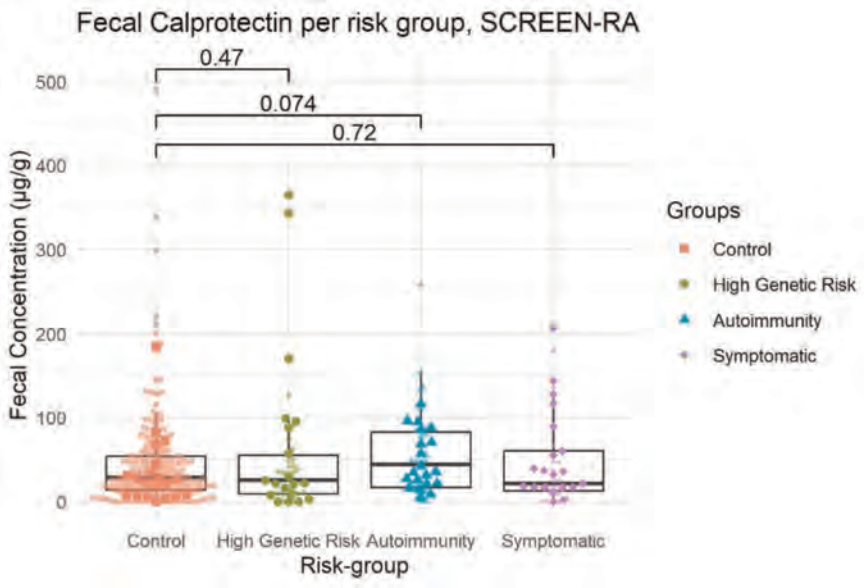

Figure 2: Fecal calprotectin by risk group, SCREEN-RA cohort Measured with ELISA in fresh frozen stool. Bold points are subjects presented on panel 1C.

Examining biomarkers of mucosal inflammation, we found a trend for fecal calprotectin elevation in the autoimmunity stage compared to controls (p = 0.074), which was no longer apparent in the symptomatic stage.

Specific bacterial cell counts, or abundances, failed to identify intestinal 'dysbiosis' in pre-clinical stages of RA and are most likely not usable as clinical biomarkers under these conditions. Still, a comparison of the most pronounced phenotypes retrieved the previously reported association, which suggests a weak signal in a distinct subgroup of patients. Accounting for lifestyle characteristics, such as diet, use of antibiotics or probiotics, may reduce confounding. Potentially increased fecal calprotectin in asymptomatic RA autoimmunity could suggests an ongoing low grade mucosal inflammation of the intestine.

Conclusion: Prevotellaceae abundance, or bacterial cell counts, are associated with RA-autoimmunity only in the most pronounced phenotypes of preclinical RA stages. But in the larger overall FDR population, specific bacterial taxa were not associated with pre-clinical RA stages.

Session Title: Abstracts: RA – Diagnosis, Manifestations, and Outcomes IV: Pre-RA & RA Diagnosis
Session Type: Abstract Session
Session Time: 11:00AM–12:30PM

Background/Purpose: Rheumatoid arthritis (RA) has a 'pre-RA' period definable as elevations of antibodies to citrullinated protein antibodies (ACPA) before clinically-apparent inflammatory arthritis (i.e. Clinical RA). ACPA elevations are highly associated with the future development of Clinical RA; in addition, biomarkers such as cytokines and chemokines in the pre-RA period may improve the prediction of future Clinical RA as well as identify biologic pathways related to disease development that could ultimately be targeted with preventive interventions. In this study, we evaluated 45 cytokines and chemokines in cohort of ACPA+ individuals without Clinical RA at baseline.

Methods: Through testing of first-degree relatives of patients with established RA, health-fair screening and clinic referral evaluations, we identified 85 ACPA+ individuals (CCP3, Werfen) who had no history or physical examination evidence of inflammatory arthritis. All ACPA+ individuals were followed prospectively for Clinical RA development. We tested their

baseline serum samples for 45 cytokines and chemokines (Table 2) using a Luminex platform and evaluated differences in log-transformed levels between ACPA+ individuals who did (or did not) later develop Clinical RA, including standard p-values as well as false discovery rate (FDR) corrected p-values to account for multiple comparisons.

Results: 85 ACPA+ individuals were followed longitudinally for a median of 639 days, and 23/85 (27%) developed Clinical RA ('Converters') a median of 589 days after their baseline visit (**Table 1**). At their baseline visit, the Converters had higher rates of positivity for RF-IgM and IgA than Nonconverters. In addition, Converters had higher levels of MCP1, IP10, IFN-

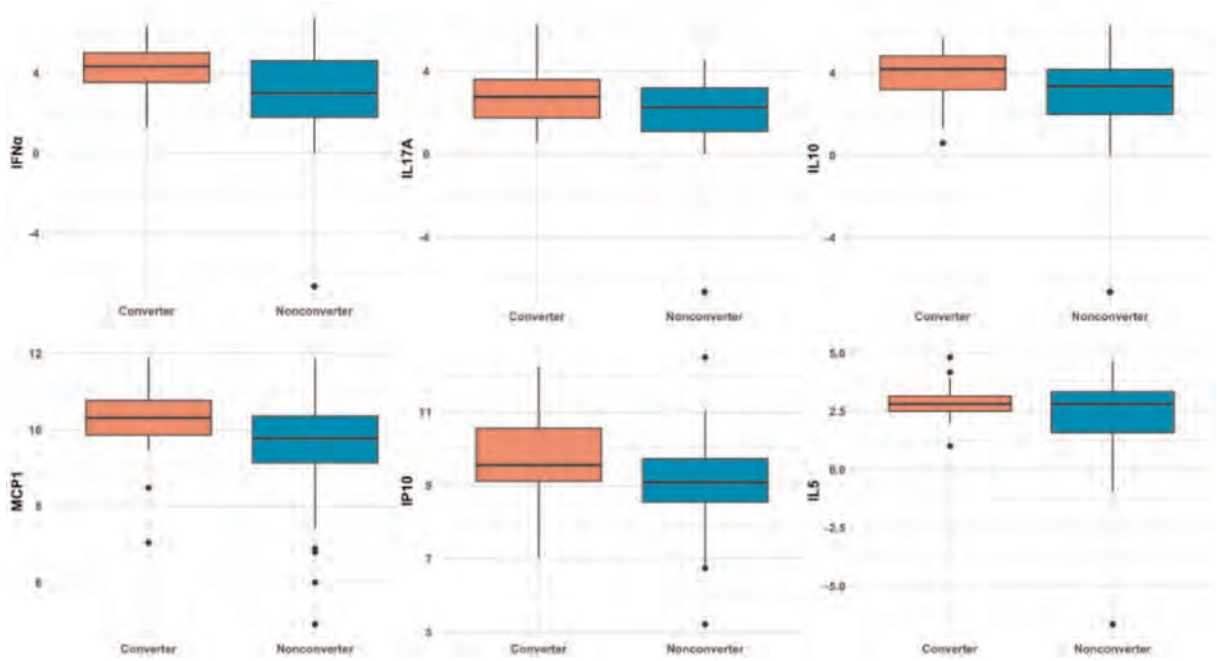

Figure 1. Multiple cytokines and chemokines are elevated at baseline in ACPA+ individuals who later develop Clinical RA (i.e. Converters) compared to ACPA+ individuals who do not (i.e. Nonconverters). IFN-alpha, IL17A, IL10, MCP1, IP10 and IL5 are all elevated in Converters compared to Nonconverters at a standard p-value of <0.05; however, only IFN-alpha remained significant at false discovery rate (FDR) corrected p-value of <0.05, although there were trends for elevations of IL17A and and IL10 (FDR p<0.10). These latter 3 cytokines have multiple biologic roles; their elevations may indicate a role for viral infections, mucosal and/or innate processes in the transition from ACPA+ state to Clinical RA.

alpha, IL10, IL17A and IL5 at a standard p< 0.05 level (Figure 1). Of these, IFN-alpha was significantly elevated in Converters compared to Nonconverters at an FDR-corrected p-value of < 0.05, with trends of higher levels of IL10 and IL17A in Converters vs Nonconverters (FDR p< 0.1).

Conclusion: Multiple cytokines and chemokines are elevated at baseline in ACPA+ individuals who develop clinical RA in a median of 589 days compared to those who do not. The most significant difference was the elevation of IFN-alpha, with trends of IL10 and IL17A. These 3 cytokines have multiple immunologic effects and in particular their elevations may indicate a role for viral infections and/or mucosal and innate immunologic processes in the transition from ACPA+ state to Clinical RA. Future studies will evaluate whether these cytokines improve the ability to predict future RA, as well as role of these cytokines and related biologic processes in the evolution from pre- to Clinical RA.

A Novel Blood-Based Assay Differentiates Seropositive and Seronegative Rheumatoid Arthritis from Healthy Individuals and Those with Other Inflammatory Diseases or Osteoarthritis

Peter C. Taylor[1], Jenya Antonova[2], Jennifer Geis[3], Katharine Dilger[3], David Chernoff[4], Diana Abdueva[3], Nancy Shadick[5] and Michael Weinblatt[6], [1]Nuffield Department of Orthopedics, Rheumatology and Musculoskeletal Sciences, University of Oxford, Oxford, United Kingdom, [2]Compass Strategy and Research, Inc., San Francisco, CA, [3]Aqtual Inc., Hayward, CA, [4]Chernoff Consulting, Sausalito, CA, [5]Brigham and Women's Hospital, Boston, MA, [6]Harvard Medical School, Waban, MA

SESSION INFORMATION
Session Date: Wednesday, November 15, 2023
Session Title: Abstracts: RA – Diagnosis, Manifestations, and Outcomes IV: Pre-RA & RA Diagnosis
Session Type: Abstract Session
Session Time: 11:00AM–12:30PM

Background/Purpose: Non-invasive differentiation of seropositive and seronegative rheumatoid arthritis (RA) from other conditions has been limited in the current practice. We aimed to evaluate the clinical feasibility of a novel blood-based assay to differentiate RA patents from healthy controls and those with other conditions, including osteoarthritis (OA) and inflammatory conditions.

Methods: We acquired plasma samples from 89 individuals meeting 2010 ACR/EULAR classification criteria for RA (89 samples), 29 healthy controls (66 samples), 12 individuals with osteoarthritis (12 samples) or 61 individuals with an inflammatory condition (62 samples; Table 1). Samples were processed via chromatin enrichment assay that enables access to tissue and disease specific genetic signatures. A machine learning algorithm (involving 5-repeat 10-fold cross-validation training and testing), trained to identify synovial signatures in blood plasma, was used to generate the probabilistic estimates for the presence and absence of RA.

For RA vs non-RA, we report the area under the curve (AUC), mean (standard deviation; SD) sensitivity, overall specificity, positive likelihood ratio and negative likelihood ratio. For comparator conditions, we report specificity alone.

Table 2. Test performance in differentiation individuals with RA from those who were healthy or had health conditions adjacent to rheumatoid arthritis

	Number of RA / Non-RA	Performance Averages Across 5-repeats				
		AUC	Sensitivity, %	Specificity, %	Positive Likelihood Ratio	Negative Likelihood Ratio
RA vs. Non-RA						
For all:	89 / 140	0.991 (0.0007)	90.8 (0.94)	96.1 (0.64)	24.13 (4.495)	0.10 (0.001)

Table 1. Sample description

	Number of samples	Number of patients	White, % (race known**)	Female, %	Age, Median (Q1, Q3)
Overall, including:	229	191*	63.3% (n=188)	67.9%	56.0 (40.0, 66.0)
Rheumatoid Arthritis* **	89	89	58.4% (n=89)	86.5%	58.0 (48.0, 68.0)
Non-RA:	140	102	67.7% (n=99)	51.8%	51.0 (34.0, 65.0)
Healthy controls	66	29*	42.3% (n=26)	53.6%	41.0 (34.2, 51.8)
Ankylosing spondylitis	13	13	84.6% (n=13)	30.8%	59.0 (36.0, 63.0)
Crohn's Disease	11	10	80.0% (n=10)	30.0%	59.0 (37.2, 70.0)
Psoriasis	18	18	66.7% (n=18)	50.0%	44.5 (33.0, 56.8)
Psoriatic arthritis	10	10	70.0% (n=10)	50.0%	65.5 (63.0, 71.8)
Ulcerative colitis	10	10	70.0% (n=10)	50.0%	27.0 (23.2, 68.0)
Osteoarthritis	12	12	91.7% (n=12)	91.7%	75.5 (23.2, 41.0)

* One patient did not have demographic characteristics recorded but was included in the sample because plasma and healthy status were known.
** Race was known for some patients, the number of which is indicated in parentheses.
*** Among RA patients, 70% were seropositive, 30% were seronegative and 96% were biologic-naïve

Results: Table 1 describes the study sample. RA subjects were 70% seropositive, 30% seronegative, 96% biologic-naïve (Table 1).The test distinguished RA from non-RA with the following overall accuracy: AUC 0.991 (0.0007), sensitivity 90.8% (0.94%), and overall specificity 96.1% (0.64%), positive likelihood ratio 24.13 (4.495) and negative likelihood ratio 0.10 (0.001). For seronegative RA, the results included sensitivity 83.7% (2.03%), positive likelihood ratio 21.46 (3.99), and negative likelihood ratio 0.17 (0.002). In comparator groups, specificity was 80.0% (0 %) for psoriatic arthritis, 88.3% (4.56%) for osteoarthritis, 92.2% (3.04%) for psoriasis, 95.4% (4.21%) for ankylosing spondylitis, and 100% (0%) for healthy controls, Crohn's disease, and ulcerative colitis (Table 2).

Conclusion: A novel non-invasive assay differentiated individuals with RA from healthy controls and those with other inflammatory conditions without RA with high sensitivity and overall specificity. In comparator cohorts, the assay demonstrated high specificity for all groups, including healthy controls, osteoarthritis, and other inflammatory conditions. The sensitivity was maintained in seronegative individuals. Further research is needed to confirm these results in an independent study.

Note: Both Dr. Shadick and Dr. Weinblatt are last authors.

SESSION INFORMATION
Session Date: Wednesday, November 15, 2023
Session Title: Abstracts: SLE – Diagnosis, Manifestations, & Outcomes IV: Outcomes & Comorbidity
Session Type: Abstract Session
Session Time: 11:00AM–12:30PM

Background/Purpose: Frailty, conceptualized as an accumulation of deficits across multiple physiological systems, was first examined in SLE in 2017 using the Fried Frailty Phenotype criteria and showed associations with functional decline, cognitive impairment, and mortality. Frailty in SLE has since been measured with other methods, including the recently-developed Systemic Lupus International Coordinating Clinics (SLICC) Frailty Index. We examined the agreement between 3 frailty measurement methods and the associations of frailty by each measure with outcomes.

Methods: Data were from the California Lupus Epidemiology Study (CLUES), a longitudinal cohort with rheumatologist-confirmed SLE. Data are collected annually. In Year 3 (n=256), frailty was measured in 3 ways: SLICC Frailty Index (SLICC-FI), Short Physical Performance Battery (SPPB; n=166), and FRAIL scale (Figure 1). We also examined PROMIS Physical Function score ≤40 (1 SD below population mean) as a proxy for frailty (PF40). Kappa (k) analyses assessed agreement between frailty measures. Linear and logistic regressions examined cross-sectional associations between frailty and hospitalizations in the previous 12 months, cognitive impairment (≤ -1.5 SD below age- and education-adjusted norms on the Controlled Word Association Test, COWAT), distance walked in 6 minutes (6MWT), self-reported disease damage (Brief Index of Lupus Damage, BILD), disability (Short Valued Life Activities questionnaire, SVLA), fatigue (PROMIS Fatigue), and depressive symptoms (Patient Health Questionnaire, PHQ-8). Longitudinal outcomes examined were hospitalization, functional decline (SVLA score worsening ≥ 0.5 SD), and an increase in BILD ≥2 points at any point during the subsequent 3 years.

Results: Mean age was 48±14 years, SLE duration 19±11 years. The cohort was 90% female. Racial/ethnic representation was 37% Asian, 10% Black, 23% Hispanic, and 30% White (non-overlapping categories). Prevalence of frailty varied by measurement method: SLICC-FI, 45.9%; SPPB, 10.8%; FRAIL scale ≥3, 17.5%; FRAIL scale ≥2, 33.3%; PF40, 23.6%. Agreement among frailty measures was weak to moderate, with highest agreement between FRAIL≥2 and PF40 (k = 0.63), SLICC-FI and FRAIL≥2 (k = 0.62), and SLICC-FI and PF40 (k = 0.50). FRAIL≥3 and PF40 were significantly associated with all cross-sectional outcomes, FRAIL≥2 with all except hospitalization, SLICC-FI with all except cognitive impairment, and SPPB with SVLA, PHQ, 6MWD, and fatigue (Table 1). SLICC-FI was significantly associated with all longitudinal

Figure 1. Components of the three frailty measures: Short Physical Performance Battery, FRAIL scale, and SLICC Frailty Index

	Short Physical Performance Battery [1]	FRAIL scale [2]	SLICC Frailty Index [3]
General	Performance based	Questionnaire	Based primarily on SDI, SLEDAI, and SF-36 subscales
Components	• Standing balance • Time to complete 5 chair stands • Time to complete 4-meter walk	• Fatigue • Difficulty walking up 10 steps • Difficulty walking several hundred yards • Presence of ≥5 of 11 illnesses • Weight loss	48 health "deficits" identified • 14 related to organ damage • 14 reflect active inflammation • 6 reflect comorbid conditions •14 related to function, mobility, health attitude, and mental health
Scoring	Each component is scored 0 – 4, for a total score range of 0 – 12, with higher scores reflecting better status	Each component can receive 1 point. Points are summed for total score ranging from 0 – 5.	Each deficit is scored 0 – 1. The total number of deficits is summed and divided by 48.
Frailty definitions	Robust, ≥ 10 Pre-frail, 8 or 9 Frail, ≤7	Robust, 0 Prefrail, 1 or 2 Frail, ≥3 We also assessed FRAIL score ≥2.	Robust, 0 – 0.03 Less fit, >0.03 – 0.10 Least fit, >0.10 – 0.21 Frail, >0.21

Abbreviations: FRAIL = Fatigue, Resistance, Ambulation, Illnesses, and Loss of weight; SLICC = Systemic Lupus International Coorcinating Clinics; SDI = SLICC Damage Index; SLEDAI = Systemic Lupus Erythematosus Disease Activity Index; SF-36 = Short Form 36.

* (OR, 95% CI) from logistic regression analysis

† (β, p-value) from linear regression analysis

Notes: c-statistic of 0.5 means no explanatory power greater than chance. Bolding represents statistical significance at $p<0.05$

FRAIL = Fatigue, Resistance, Ambulation, Illnesses, and Loss of weight ; PROMIS = Patient Reported Outcomes Measurement Information System; SLICC = Systemic Lupus International Coordinating Clinics Damage Index ; SPPB = Short Physical Performance Battery

Definitions of outcomes

Hospitalized: Report at Year 3 interview of any hospitalization during the previous 12 months

Cognitive impairment: ≤ -1.5 SD below age- and education-adjusted norms on the Controlled Word Association Test, COWAT

BILD = Brief Index of Lupus Damage. Self-reported validated measure of SLE damage

PHQ = Patient Health Questionnaire-8 depressive symptoms score. Scores ≥10 are suggestive of moderate-severe depression.

SVLA = Short Valued Life Activities disability questionnaire. Scores range from 0 – 3, with higher scores indicating more disability.

PROMIS = Patient Reported Outcomes Measurement Information System 4-item Fatigue scale. Population mean ± SD, 50 ± 10

6MWD = Six-minute walk distance, meters

Table 2. Association of frailty measures with longitudinal outcomes

Frailty definition		Longitudinal outcomes		
		Any follow-up hospitalization	Any SVLA decline	BILD increase
FRAIL scale ≥3	OR (95% CI)	1.8 (0.9, 3.5)	1.7 (0.8, 3.7)	2.2 (0.9, 4.9)

	c (95% CI)	0.54 (0.48, 0.60)	**0.58 (0.51, 0.65)**	**0.65 (0.56)**

* (OR, 95% CI) from logistic regression analysis.
† (β, p-value) from linear regression analysis
Note: c-statistic of 0.5 means no explanatory power greater than chance.

FRAIL = Fatigue, Resistance, Ambulation, Illnesses, and Loss of weight ; PROMIS = Patient Reported Outcomes Measurement Information System; SLICC = Systemic Lupus International Coordinating Clinics Damage Index ; SPPB = Short Physical Performance Battery

Definitions of outcomes
Follow-up hospitalization: Report of any hospitalization during follow-up period (Years 4, 5, or 6)
SVLA decline = Short Valued Life Activities disability questionnaire. Worsening of score ≥ 0.5 SD from Year 3 at Year 4, 5, or 6
BILD = Brief Index of Lupus Damage. Increase in score ≥2 points during follow-up period

outcomes, FRAIL≥2 with follow-up hospitalizations and SVLA decline, and PF40 with SVLA decline and BILD increase (Table 2).

Conclusion: Agreement between measures of frailty in SLE is moderate at best. The SLICC-FI was a robust predictor of all SLE cross-sectional and longitudinal outcomes examined in this study except cognitive impairment. The simple FRAIL≥2 performed almost as well. The PROMIS PF, which may already be incorporated into many studies or clinical workflows, also performed well and may be used as a reasonable proxy for frailty. These data should inform selection of frailty measures for future studies in SLE.

SESSION INFORMATION

Session Date: Wednesday, November 15, 2023

Session Title: Abstracts: SLE – Diagnosis, Manifestations, & Outcomes IV: Outcomes & Comorbidity

Session Type: Abstract Session

Session Time: 11:00AM–12:30PM

Background/Purpose: Many studies of cancer risk in SLE are limited by small sample size or use of administrative data, which rely on billing code diagnoses instead of clinical data. We produced updated estimates cancer risk in the largest-ever cohort of clinically confirmed incident SLE patients.

Methods: Adults with SLE were enrolled (within 15 months of diagnosis) into the SLICC Inception Cohort, across 32 centres. Individuals were followed with annual assessments, where detailed data was collected on Disease Activity Index-2000 (SLEDAI-2K), lupus drugs in the past year, and documentation of cancer diagnoses (by the examining physician at yearly intervals).

We performed univariate and multivariate Cox regression, with baseline demographics (age at SLE onset, race/ethnicity, sex), and time-dependent variables for medications (antimalarials, biologics and other immunosuppressives, corticosteroids), smoking, and SLEDAI-2K. As well as cancer over-all, we evaluated risk factors for the most common cancer types.

Results: Of 1848 new-onset SLE patients enrolled between 1999-2011, 1675 had at least one follow-up; these were the sample for the current analysis. End date was the first of death, last visit, or end of study interval for this analysis (June 21,2021). Baseline demographics are shown in Table 1.

Over 16493 years of follow-up (median follow up, 10 years) 72 cancers occurred (incidence 4. 4 events per 1,000 patient-years). This included 16 breast cancers, 10 non-melanoma skin, 10 lung, 6 hematological, 6 prostate, 5 melanoma, 3 cervical, 3 renal, 3 head and neck, 3 thyroid, 2 gastric, 2 uterine, and one each rectal, sarcoma, thymoma. Adjusted and

Table 1. Baseline characteristics of the SLE sample

Baseline characteristics	No Cancer (N=1603)	Cancer (N=72)	Overall (N=1675)
Female sex	1434 (89.5)	53 (73.6)	1487 (88.8)
White race/ethnicity	778 (48.5)	49 (68.1)	827 (49.4)
Mean age at SLE diagnosis, years (SD)	34.1 (13.0)	45.5 (15.0)	34.6 (13.3)
Mean SLE duration, months (SD)	5.6 (4.2)	5.4 (3.7)	5.6 (4.2)
Ever top quartile SLE activity, N (%)	541 (33.7)	18 (25.0)	559 (33.4)
Ever smoking, N (%)	533 (33.3)	34 (47.2)	567 (33.9)
Ever cigarettes 15+/day, N (%)	131 (8.2)	18 (25.0)	149 (8.9)
Ever steroids, N (%)	1198 (74.7)	51 (70.8)	1249 (74.6)
Ever cyclophosphamide, N (%)	139 (8.7)	4 (5.6)	143 (8.5)
Ever azathioprine (Imuran), N (%)	462 (28.8)	21 (29.2)	483 (28.8)
Ever methotrexate, N (%)	188 (11.7)	9 (12.5)	197 (11.8)
Ever mycophenolate, N (%)	243 (15.2)	9 (12.5)	252 (15.0)
Ever antimalarial, N (%)	1264 (78.9)	53 (73.6)	1317 (78.6)
Ever NSAID, N (%)	321 (20.0)	11 (15.3)	332 (19.8)
Ever aspirin, N (%)	303 (18.9)	17 (23.6)	320 (19.1)
Ever biologic, N (%)	40 (2.5)	0 (0.0)	40 (2.4)
Ever dsDNA antibody, N (%)	536 (33.4)	15 (20.8)	551 (32.9)

unadjusted hazard ratios (HR) are shown in Table 2. Multivariate analyses of all cancer types (analyzed together) suggested a higher risk of cancer among patients of older age, males, and those who smoked more than 15 cigarettes a day.

In the multivariate analyses specifically for breast cancer, age at SLE diagnoses remained a risk factor, and antimalarials were associated with a decreased risk. This effect of antimalarials was not clearly seen for any other cancer type. For non-melanoma skin cancer, both age at SLE diagnosis and cyclophosphamide (albeit with a wide confidence interval) were associated with risk. For hematologic cancers, older age was a risk factor in univariate analyses (hazard ratio, HR 1.06, 95% confidence interval, CI 1.01 , 1.12) as was highest quartile of SLEDAI-2k (HR 10.3, 95% CI 1.31 , 81.7), but due to the low number of hematologic cancers, multivariate estimates were less precise and confidence intervals included the null value for all variables.

Conclusion: Our updated analyses of this large, international inception SLE cohort continues to illustrate how different cancer types in SLE might be associated with specific risk factors. Additional follow-up is still needed to precisely determine the potential effects of disease activity (particularly for hematologic malignancies) and medications on cancer risk in SLE.

Table 2. Hazard Ratio (HR) for cancer in SLE (Cox regression analysis)

ALL CANCERS	Unadjusted HR (95% CI)	Adjusted HR (95% CI)[a]
Age at SLE diagnosis (years)	**1.06 (1.04, 1.07)**	**1.05 (1.03, 1.06)**

SESSION INFORMATION

Session Date: Wednesday, November 15, 2023

Session Title: Abstracts: SLE – Diagnosis, Manifestations, & Outcomes IV: Outcomes & Comorbidity

Session Type: Abstract Session

Session Time: 11:00AM–12:30PM

Background/Purpose: Chronic glucocorticoid (GC) morbidity is rarely captured as a standardized clinical outcome in pediatric rheumatic conditions. The pediatric glucocorticoid toxicity index (pGTI) (Brogan et al. 2022) is a new, pediatric-specific tool to measure GC toxicity in research and clinical care. Common clinically important toxicities are organized into domains

and weighted according to severity. We used the pGTI to quantify and identify risk factors for GC toxicity in children with pediatric-onset systemic lupus erythematosus (pSLE) with or without lupus nephritis (LN).

Methods: We conducted a single-center cohort study of patients with pSLE, stratified by LN. We included patients with rheumatology visits since January 2016 and ³6 months of systemic GC treatment and followed them through March 2023. We scored change in GC toxicity using a modified version of the pGTI, including steroid toxicity items in 12/15 subdomains, at visits every 6 months (+/-2) for up to 3 years. Glucose metabolism, dyslipidemia, and bone density domains could not be assessed due to sparse data. Index date was the visit at which GC were initiated. Positive scores indicate new/worsening toxicity and negative scores indicate improvement. We also calculated the Cumulative Worsening Score (CWS), an endpoint of the pGTI representing a continuous summation of any GC toxicity accrued over time. Mixed effects linear regression was used to estimate associations of baseline factors and GC exposure with CWS over time.

Table 1. Baseline characteristics of children with SLE by history of nephritis

	No nephritis (N=29)	With nephritis (N=48)
Demographic Characteristics		
Age at SLE diagnosis (years), median [IQR]	13.8 [11.4 - 16.2]	13.9 [11.9 - 16.4]
Disease duration at index visit (months), median [IQR]	0.0 [0.0 - 1.0]	0.0 [0.0 - 1.0]
Female, n (%)	25 (86%)	37 (77%)
Race		
Asian	3 (10%)	8 (17%)
Black	4 (14%)	11 (23%)
Other*	6 (21%)	9 (19%)
White	15 (52%)	14 (29%)
Unknown	1 (3%)	6 (13%)
Hispanic ethnicity	8 (28%)	13 (27%)
Insurance status		
Public	12 (41%)	22 (46%)
Private	17 (59%)	25 (52%)
Uninsured	0 (0%)	1 (2%)
Calendar year of index visit		
Before 2016	12 (41%)	19 (40%)
2016-2022	17 (59%)	29 (60%)
BMI at index visit		
Normal	25 (86%)	35 (73%)
≥ 85 and <95%ile	3 (10%)	9 (19%)
≥ 95ile	1 (3%)	4 (8%)
Disease Features		
SLEDAI-2K score at index visit, median [IQR]†	8.5 [5.0 - 14.5]	20.0 [14.0 - 24.0]
Nephritis Class		
Class III/IV	N/A	36 (75%)
Mixed Class III/IV and V	N/A	6 (13%)
Class V	N/A	4 (8%)
Unavailable	N/A	2 (4%)
Serositis	8 (28%)	16 (33%)
Neurologic Manifestations	6 (21%)	10 (21%)
Anti-dsDNA antibody positive	23 (79%)	45 (94%)
Medication use within 30 days of index visit		
Cyclophosphamide	3 (10%)	12 (25%)
Rituximab	6 (21%)	6 (13%)
Mycophenolate	3 (10%)	18 (38%)
Other non-biologic DMARD^	7 (24%)	8 (17%)

The index visit date was defined by the first encounter at which oral glucocorticoids were initiated for SLE. BMI = body mass index; SLEDAI-2K = Systemic Lupus Erythematosus Disease Activity Index 2000. *Other includes Middle Eastern. †Index SLEDAI-2K scores were missing for 1 non-nephritis and 7 nephritis patients. ^Includes azathioprine, leflunomide, methotrexate, calcineurin inhibitors, and JAK-STAT inhibitors.

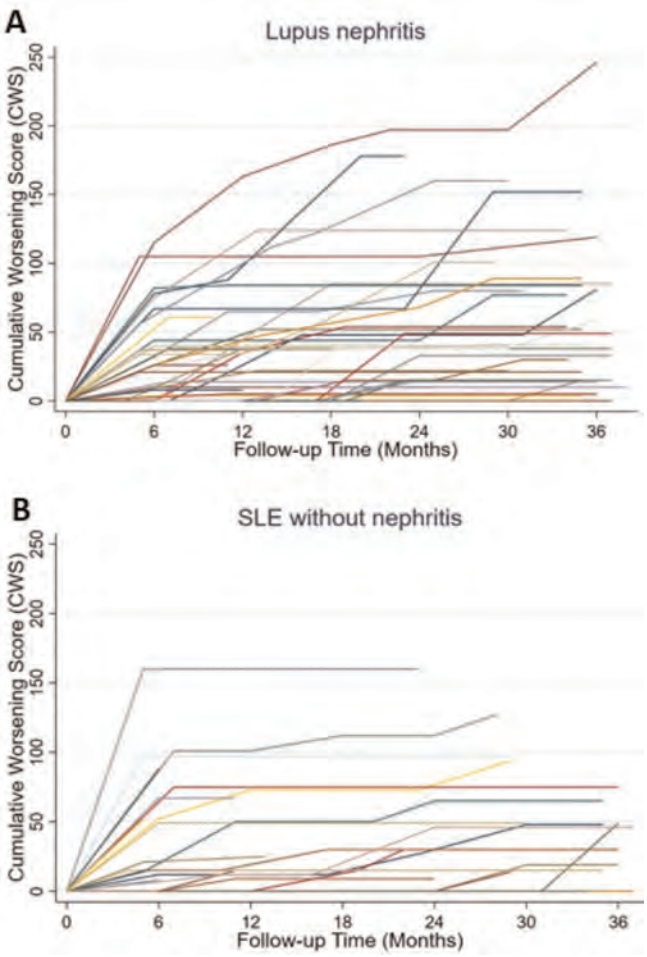

Figure 1. Individual Cumulative Worsening Score (CWS) trajectories over three years of follow-up in pediatric SLE patients (A) with (n=48) and (B) without nephritis (n=29). CWS is a continuous summation of any glucocorticoid (GC) toxicity accrued after the index visit. Each line represents the score trajectory of an individual patient. Following discontinuation of GCs, if there was no GC use during subsequent visit intervals, then further increase in toxicity could not be reliably attributed to GC use and did not contribute to the CWS.

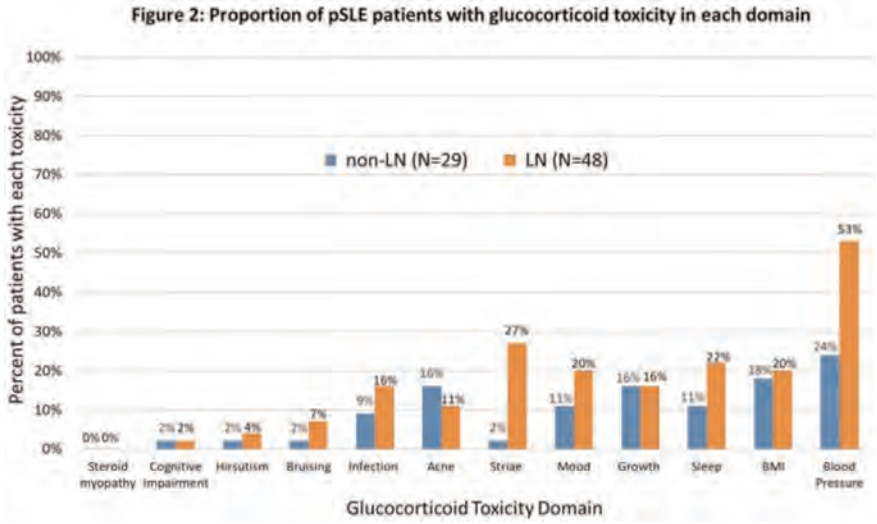

Figure 2. Proportion of patients with pediatric SLE (stratified by presence of LN) with new or worsening toxicity for each pediatric glucocorticoid toxicity subdomain at any time during follow-up.

Results: We included 425 visits by 77 pSLE patients (median 6 visits/patient [IQR 5-7]), of which 48 had LN (Table 1). In both groups, the most common toxicity was worsening blood pressure; this was more pervasive in the LN group (53% vs. 24% of patients), which also exhibited greater damage (24% vs. 8% developed hypertensive emergency or posterior reversible encephalopathy syndrome). Increased body mass index (BMI), sleep disturbance, and growth delay were also common. Compared to LN patients, those without LN had similar or less frequent toxicity in every subdomain except for acne (Fig 2). Median CWS at month 12 was 15 (IQR [0-47]; N = 47) in the LN subgroup and 15 (IQR [0-67]; N = 22) in those without LN. 46% of patients with LN and 34% without accrued new/worsening toxicity beyond 12 months (Fig 1).

Cumulative dose associated with greater CWS (1.5 unit increase in CWS for every 1000 mg higher cumulative prednisone dose, 95% CI [0.03 – 2.8]), adjusted for time, but there was large between-subject variance. Of baseline factors in Table 1, younger age of onset, need for initial treatment with rituximab, and baseline BMI >95th%ile were significantly associated with higher CWS over time.

Conclusion: Patients with pSLE exhibit significant GC toxicity captured by the pGTI, particularly in blood pressure, BMI, sleep, and growth subdomains. This cohort also demonstrated substantial between-subject variability in toxicity. We will further assess the construct validity and feasibility of the pGTI in upcoming multicenter analyses. Standardized, pediatric-specific assessment of GC toxicity may help facilitate reduction in GC-associated morbidity in children with SLE.

SESSION INFORMATION
Session Date: Wednesday, November 15, 2023
Session Title: Abstracts: SLE – Diagnosis, Manifestations, & Outcomes IV: Outcomes & Comorbidity
Session Type: Abstract Session
Session Time: 11:00AM–12:30PM

Background/Purpose: SLE has one of the highest 30-day hospital readmission rates among chronic conditions[1]. Frailty is common[2] and associated with hospitalization[3] in SLE, but whether frailty is associated with worse outcomes after hospital admission, including readmissions, is unknown. Our objective was to evaluate the association between frailty status and risk of readmissions, inpatient mortality at readmissions, and cost of admission among patients with SLE.

Methods: Using ICD-10 codes, we identified adults >18 years of age within the National Readmissions Database who had a primary or secondary diagnosis of SLE and were hospitalized between January and June 2018. We excluded patients who died during the index hospitalization, had an elective hospitalization, were transferred from another hospital, or were missing length of stay (LOS) or total cost values. Using the validated claims-based Hospital Frailty Risk Score[4], we categorized individuals as either frail (score≥5) or non-frail (score<5) at the time of index hospitalization. Age, sex, insurance type, household income, Elixhauser Comorbidity Index (ECI), and LOS were extracted from the dataset. Primary outcome was readmission rates following discharge from the index hospitalization. Secondary outcomes included inpatient mortality, and the economic burden of hospitalizations. We compared baseline characteristics and primary and secondary outcomes between frail and non-frail patients with SLE using descriptive statistics. We used Cox proportional hazard models to estimate the association between frailty and risk of readmissions, after adjustment for relevant covariates.

Table 1: Baseline Patient, Hospital, and Hospitalization Characteristics of Patients with SLE at Time of Index Admission by Frailty Status

Outcomes at Index Hospitalization	Non-frail patients	Frail patients	P-Value
N	21,353	18,385

($1-$45,999)			
2. 26th to 50th percentile	26.5%	27.1%	
($46,000-$58,999)			
3. 51st to 75th percentile	23.0%	22.8%	
($59,000-$78,999)			
4. 76th to 100th percentile	18.7%	17.8%	
($79,000 or more)			
Teaching Status			
1. Metropolitan non-teaching	20.9%	20.4%	<0.01
2. Metropolitan teaching	93.8%	73.7%	
3. Non-metropolitan non-teaching	5.3%	5.9%	
Bed size			
1. Small	14.4%	14.5%	0.20
2. Medium	26.5%	26.1%	
3. Large	59.1%	59.4%	
Elixhauser Index *	8.53	14.14	<0.01
Length of stay	3 (2-5)	5 (3-9)	<0.01
Comorbid Conditions			
Hypertension	43.40%	47.05%	<0.01
Heart Failure	12.81%	24.15%	<0.01
Diabetes mellitus	19.11%	26.56%	<0.01
COPD	26.24%	31.42%	<0.01

*Elixhauser Index ranges from -7 to +12.

Table 2: Longitudinal Hospitalization-Related Outcomes in Frail and Non-frail Patients with SLE

Outcomes	Non-frail patients	Frail patients	P-Value
Readmission	43.10%	59.80%	<0.01
Inpatient mortality	0.27%	2.88%	<0.01
Length of Stay > 7 days	9.11%	28.89%	<0.01
Average days to readmission	87.7	77.1	<0.01
Cost of hospitalization			
Median	$7,991.00	$11,087.00	<0.01
Interquartile Range	$4,755 - $14,010	$6,359 - $20,978	

Results: We identified 39,738 patients with SLE admitted during the study period. Over a median follow-up of 9 months, frail patients with SLE (n = 18,385, 46.3%) were older with Medicare/Medicaid coverage and had higher ECI scores and longer LOS compared to non-frail patients with SLE (n = 21,353, 53.7%) (**Table 1**). Frail patients with SLE had more prolonged hospitalizations defined by LOS > 7 days with higher costs per hospitalization. Readmission rates in frail patients with SLE were significantly higher. At index hospitalization, frail patients had significantly higher inpatient mortality and fewer days-to-readmission on average (**Table 2**). In multivariable Cox proportional hazard analysis, frailty was independently associated with a 10% higher risk of readmission after adjustment for covariates (**Table 3**).

Conclusion: Among patients with SLE who were hospitalized, frailty is associated with more readmissions, higher mortality, and greater economic burden of hospitalization as compared to non-frail SLE patients. Assessing frailty status may help risk stratify patients with SLE at higher risk for readmission. Further research is needed to determine strategies to reduce frailty in patients with SLE in order to decrease readmission rates and other adverse health outcomes.

Table 3: Cox Proportional Hazard Analysis Evaluating Risk of Readmission by Frailty Risk Score.

Variable	Hazard Ratio (95% Confidence interval)	P-value
Frailty risk score	1.10 (1.06-1.13)	<0.01
Age	1.00 (1.00-1.00)	<0.01
Female	0.95 (0.92-1.00)	0.03
Median Household Income	1.01 (0.99-1.02)	0.44
Hospital Teaching Status	0.99 (0.97-1.02)	0.68

Under Assault: Ongoing Brain Dysfunction Identified on Resting State-functional MRI (rs-fMRI) in SLE Patients in Clinical Remission

Meggan MacKay, an vo, Erik Anderson, Cynthia Aranow, Betty Diamond and David Eidelberg, Feinstein Institutes for Medical Research, Manhasset, NY

SESSION INFORMATION
Session Date: Wednesday, November 15, 2023
Session Title: Abstracts: SLE – Diagnosis, Manifestations, & Outcomes IV: Outcomes & Comorbidity
Session Type: Abstract Session
Session Time: 11:00AM–12:30PM

Background/Purpose: There is substantial evidence that the brain is targeted early in SLE, likely from disease inception. Data from mouse models and human studies suggest that SLE-related pathogenic mechanisms contribute to brain injury through blood brain barrier disruption, autoantibody and cytokine-mediated injury and microglial synaptic pruning (1). It is unknown whether SLE-related brain abnormalities improve or persist during clinical disease remission. We used rs-fMRI to identify a candidate SLE-related functional network (SLE-Net) and measure individual SLE-Net expression levels in SLE and healthy control (HC) subjects.

Methods: rs-fMRI scans were obtained on 25 SLE and 14 HC enrolled in a prospective observational study. SLE subjects were determined to be in clinical remission (SLE-R; n=9), defined as no disease activity and off all SLE medications except Plaquenil for ≥3 years, or not in remission (SLE-NR).

Results: An automated algorithm, blind to group, was applied to rs-fMRI data. For independent components (IC) selection, logistic regression analysis was applied to each of 1,000 bootstrap iterations, revealing three component patterns (IC4 [hippocampus, parahippocampal gyrus, putamen, globus pallidus], IC20 [insula], and IC21 [motor, premotor cortex]), for which the SLE and HC groups differed significantly based on their respective subject scores ($p < 0.05$). The IC weights (coefficients), 0.35, 0.63, and 0.7, respectively, were determined with a second bootstrap procedure to identify the combination

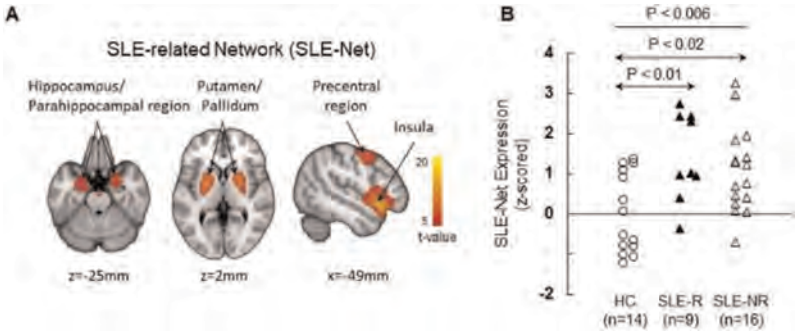

Figure 1. SLE-Net. A. SLE-Net identified in rs-fMRI scans from 25 SLE and 14 age- and gender-matched HC (p=0.001; Student t-test). SLE-Net characterized by bilateral contributions from the hippocampus and parahippocampal gyrus, insula, putamen, globus pallidus, motor and premotor cortex. B. SLE-Net expression levels (z-scored) for 9 SLE-R (filled triangles), 16 SLE-NR (open triangles), and 14 HC (open circles). SLE-Net expression differed across groups (p<0.006; ANOVA), with abnormal increases in both SLE-R and SLE-NR (p<0.02; post-hoc tests).

best discriminating SLE from HC. This resulted in a composite SLE-Net, for which the corresponding expression levels accurately discriminated the two groups (P< 0.005; permutation test, 5,000 iterations) (Fig. 1A). Regions contributing to SLE-Net were among the hypermetabolic regions previously identified in SLE with FDG PET (2). SLE-Net expression in individual subjects (Fig. 1B) were elevated in SLE compared to HC (P=0.006). In an exploratory analysis, we used the same approach to identify a candidate SLE-R-specific network (SLE-RNet). Despite the small n (9), a significant SLE-RNet was identified that discriminated SLE-R from HC (p < 0.005; Student t-test). The topography of SLE-RNet was closely related to that of SLE-Net (r=0.93, p< 0.001; voxel-wise correlation with SLE-Net).

Conclusion: In the absence of additional SLE-R subjects for validation, the SLE-NET is considered preliminary. However, our data support the hypothesis that there may be ongoing brain dysfunction despite the appearance of clinical remission and this may impact treatment considerations. 1. N. Kello, E. Trends, Sociodemographic and Clinical Factors Associated with Avascular Necrosis and Related Arthroplasties in Hospitalized Patients with Systemic Lupus Erythematosus and Rheumatoid Arthritis

Rashmi Dhital[1], Neha Singh[2], Brian Pedersen[2] and Christie M. Bartels[3], [1]UC San Diego, San Diego, CA, [2]University of California San Diego, San Diego, CA, [3]University of Wisconsin, School of Medicine and Public Health, Madison, WI

SESSION INFORMATION
Session Date: Wednesday, November 15, 2023
Session Title: Abstracts: SLE – Diagnosis, Manifestations, & Outcomes IV: Outcomes & Comorbidity
Session Type: Abstract Session
Session Time: 11:00AM–12:30PM

Background/Purpose: Avascular necrosis (AVN) can be a debilitating complication of autoimmune diseases and steroid treatment, with a higher prevalence in systemic lupus erythematosus (SLE) (0.8-33%) compared to rheumatoid arthritis (RA) (0.4%-12). AVN frequently leads to progressive joint destruction necessitating arthroplasty. Limited research exists on trends following the introduction of newer steroid-sparing agents as well as sociodemographic and clinical factors associated with AVN. We aimed to analyze rates, trends, and characteristics associated with AVN and AVN-related joint arthroplasties among SLE and RA hospitalizations using the largest publicly available all-payer inpatient US database, the National Inpatient Sample (NIS).

Methods: This cross-sectional study used NIS data (2000-2019) to identify hospitalized adults (≥18 years) with diagnoses of SLE and RA, and those with concomitant AVN diagnoses using validated International Classification of Disease (ICD) codes. AVN was further grouped into whether or not they had arthroplasties to examine trends. We compared SLE and RA hospitalizations with and without AVN, and arthroplasties using STATA and the Joinpoint regression program to calculate annual percent change (APC).

Results: From 2000-2019, there were 3,295,384 SLE and 8,983,521 RA hospitalizations, among which 43,339 (1.3%) and 44,148 (0.5%) had concomitant AVN (herein referred to as SLE-AVN and RA-AVN, respectively; **Table 1**). Of the SLE-AVN and RA-AVN, 16,941 (39%) and 25,509 (57%) underwent arthroplasties, respectively (**Table 1, Figure 1**). We observed an uptrend in RA-AVN (APC: 1.10*), with a decrease in the proportions of arthroplasties (APC: -0.82*; **Figure 2**). In contrast, there was an initial increase followed by a tendency to decline in SLE-AVN (APC 2000-2011: 1.96* APC 2011-2019 -2.05), with a decrease in the proportion of arthroplasties over time (APC -2.03*, **Figure 2**). Hospitalizations with AVN were younger [SLE (mean age: 43 vs 52 without), RA (mean age: 60 vs 68 without)] and more often Black race [SLE (41% Black with AVN, 26% without), RA (17% with AVN vs 10% without); Table 1]. SLE-AVN patients had higher rates of antiphospholipid syndrome (5% vs 3%) and end-stage renal disease (11% vs 9%); RA-AVN patients had higher nicotine use (15% vs 12%) compared to those without AVN. Among SLE-AVN and RA-AVN, encounters with arthroplasty (**Table 1**) were less likely to be Black (34% vs 46% in SLE-AVN and 13% vs 23% in RA-AVN) or have Medicaid coverage (15% vs 24% for SLE-AVN, and 9% vs 15% for RA-AVN) or most comorbidities than those without.

	SLE (N= 3,295,384)		SLE-AVN (N= 43,339)		RA (N= 8,983,521)		RA-AVN (N= 44,148)

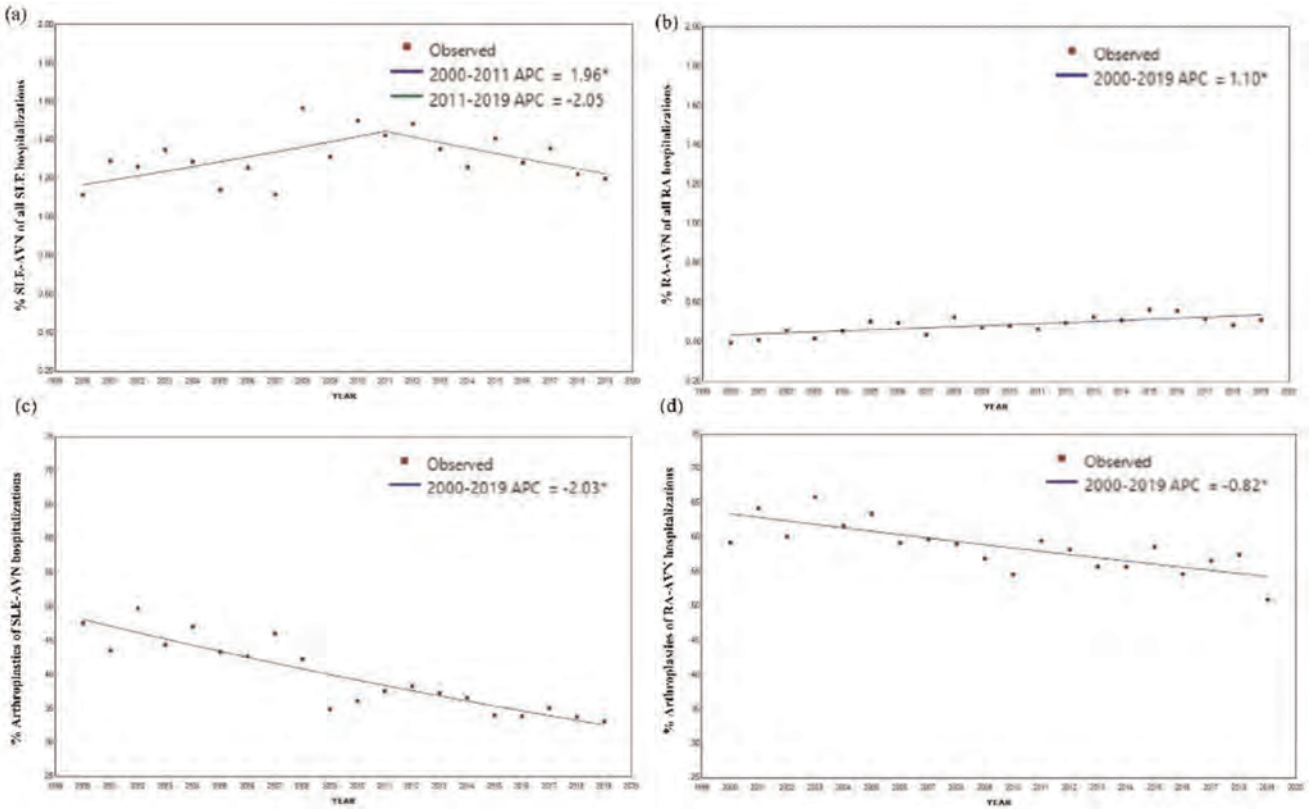
Avascular necrosis (AVN) and related arthroplasties per 100,000 hospitalized adults with systemic lupus erythematosus (SLE) and rheumatoid arthritis (RA), National Inpatient Sample, 2000-2019. Green represents RA, orange represents SLE, arthroplasties are represented by lighter shading.



Trends of avascular necrosis (AVN) and AVN-associated arthroplasties among hospitalized adults with systemic lupus erythematosus (SLE) and rheumatoid arthritis (RA), National Inpatient Sample, 2000-2019. (a) The percentage of AVN among SLE hospitalizations shows an initial significant uptrend (APC 1.96*) with a peak around 2011 (b) The percentage of AVN among RA hospitalizations shows a modest significant uptrend over time (APC 1.10*), however, rates are lower compared to SLE-AVN. (c) AVN-related arthroplasties in both SLE-AVN (APC -2.03*) and (d) RA-AVN (APC -0.82*) show a significant decline over time. The rate of change from 2000 to 2019 was calculated using Joinpoint regression software and expressed as Annual Percent Change (APC). *Indicates significant difference at alpha = 0.05 level.

Conclusion: We report an initial increasing trend of SLE-AVN followed by a tendency to decline, which may relate to newer steroid-sparing therapies (i.e., Belimumab approval in 2011). There was an overall declining trend of AVN-associated arthroplasties in both SLE and RA. AVN hospitalizations were more likely to be younger and of the Black race. Yet, arthroplasty was less likely in encounters with patients who were Black or had Medicaid coverage. Our data indicate potential healthcare disparities that may influence surgical access. Further research should examine sociodemographic and treatment differences impacting AVN and arthroplasty rates.

Comparison of SLE and RA hospitalizations with and without diagnoses of AVN and with and without AVN-associated arthroplasties (hip, knee, shoulder), National Inpatient Sample, 2000-2019 *SLE: systemic lupus erythematosus, RA: rheumatoid arthritis, AVN: avascular necrosis, SEM: standard error of mean APS: Antiphospholipid syndrome ESRD: End-stage renal disease IHD: Ischemic heart disease PVD: Peripheral vascular disease HF: Heart failure, CMP: cardiomyopathy Differences in variables between groups are significant with $p < 0.05$ except for: SLE without AVN vs SLE with AVN: hypertension; SLE-AVN without and with arthroplasty: sex, COPD, hyperlipidemia, alcohol-related disorders; RA without AVN vs RA with AVN: sex, ESRD, alcohol-related disorders; RA-AVN without and with arthroplasty: sex, hypertension, nicotine dependence

FT011 for the Treatment of Systemic Sclerosis. Results from a Phase II Study

Christopher Denton[1], Wendy Stevens[2], Nicole Kruger[3], Michelle Papadimitriou[4], Fay Khong[4], Michelle Bradney[3], Darren Kelly[4] and Robert Lafyatis[5], [1]University College London, London, United Kingdom, [2]Department of Rheumatology, St Vincent's Hospital Melbourne, Fitzroy, Australia, [3]Certa Therapeutics, Melbourne, Australia, [4]Certa Therapeutics and Melbourne University, Melbourne, Australia, [5]University of Pittsburgh, Pittsburgh, PA

SESSION INFORMATION
Session Date: Wednesday, November 15, 2023
Session Title: Abstracts: Systemic Sclerosis & Related Disorders III: Clinical Trials
Session Type: Abstract Session
Session Time: 11:00AM–12:30PM

Background/Purpose: Systemic Sclerosis (SSc) is an autoimmune disease characterized by vascular damage, inflammation, and fibrosis of the skin and organs, with no approved disease modifying treatments. The available treatment options are limited to systemic sclerosis-associated interstitial lung disease to slow the decline in lung function. Accordingly, there remains a serious unmet medical need for safe and effective therapeutics for the SSc population. FT011, a G protein-coupled receptor 68 (GPR68) proton sensing antagonist is being developed as a novel inhibitor of pro-fibrotic and inflammatory pathways.

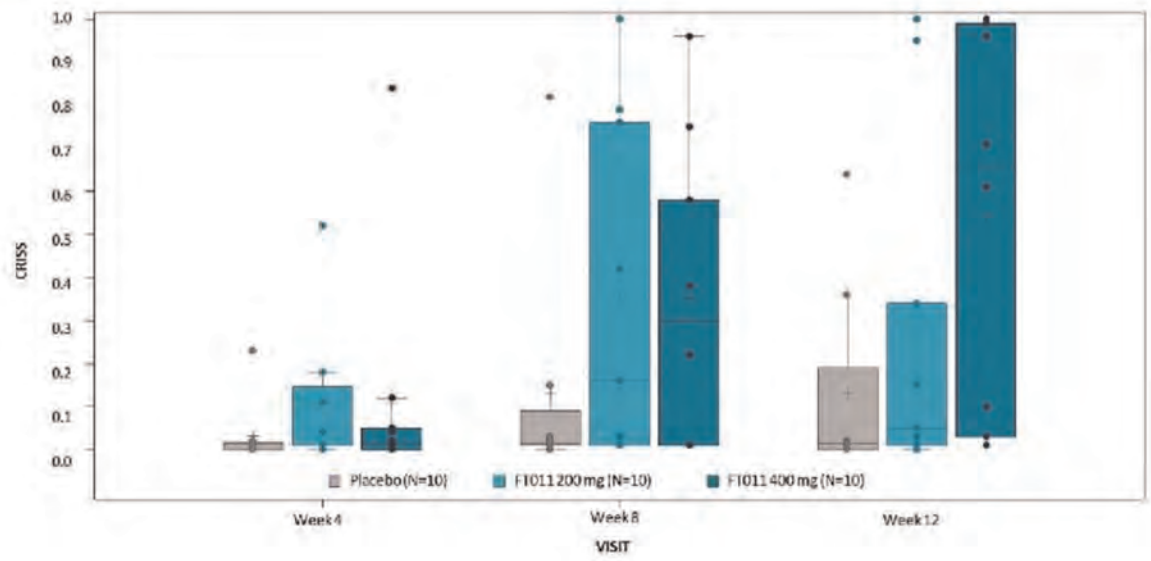
Methods: This was a Phase II, multi-center, randomized, double blind, placebo-controlled study of the pharmacokinetics, pharmacodynamic effects, and safety, of oral FT011 in patients with diffuse SSc (dSSc). The study randomized 30 participants (n = 10/group) to placebo, FT011 200 mg or FT011 400 mg taken once daily (OD) for 12 weeks. ClinicalTrials.gov Identifier: NCT04647890

Results: Patients were a mean age of 51 years, white and the majority (73%) female. Treatment with FT011 400 mg OD for 12 weeks resulted in significant and clinically meaningful improvements in the American College of Rheumatology Combined Response Index in Diffuse Cutaneous Systemic Sclerosis (ACR-CRISS) score and its composites.

By week 12, 60% of patients in the FT011 400 mg arm were classified as clinical responders with improvement in ACR-CRISS (defined by predicted probability ≥0.60)[1] vs 10.0% in the placebo arm (nominal p-value = 0.046). Median ACR-CRISS score was 0.660 vs 0.015, FT011 400 mg vs placebo, respectively. The mean ACR-CRISS score was 0.542 in the FT011 400 mg arm vs 0.131 in the placebo arm (nominal p-value = 0.019) (Figure 1).

FT011 also led to significant and clinically meaningful improvements across multiple efficacy measures including % predicted Forced Vital Capacity (FVC), Scleroderma Health Assessment Questionnaire-Disability Index (SHAQ-DI) and physician global assessments (Table 1).

Figure 1: Longitudinal Plots of Composite Response Index in Diffuse Cutaneous Systemic Sclerosis Scores Over Time



Notes: CRISS: Composite Response Index in Diffuse Cutaneous Systemic Sclerosis. IQR: Interquartile Range. The CRISS score is ranged from 0.0 to 1.0 where higher scores indicate greater improvement. Symbol inside the box: Mean. Horizontal line inside the box: Median. Bottom and top of box: 25th and 75th percentiles, respectively. Bottom and top whiskers: Extreme value within 1.5 IQR. Circle: individual participant's value.

Table 1: Efficacy Measure Changes from Baseline to Week 12

	Placebo	FT011 400 mg	FT011 400mg - Placebo	Nominal P-value
Parameter Visit	LS mean (95%CI)		LS Mean difference (95%CI)	
# mRSS	-1.8 (-4.57, 0.97)	-3.25 (-5.87, -0.62)	-1.45 (-5.27, 2.38)	0.443
ǂ % Predicted FVC	-1.64 (-5.49, 2.21)	4.9 (1.23, 8.56)	6.54 (1.23, 11.85)	0.018
# SHAQ-DI	0.0273 (-0.145, 0.200)	-0.2636 (-0.428, -0.100)	-0.291 (-0.529, -0.053)	0.019
ǂ Patient Global Assessment	8.14 (-5.60, 21.88)	9.03 (-3.70, 21.76)	0.89 (-18.01, 19.79)	0.924
# Physician Global Assessment	-4.83 (-19.52, 9.86)	-28.19 (-41.29, -15.10)	-23.36 (-43.03, -3.69)	0.022

Notes: ǂ Positive value indicates improvement and # Negative value indicates improvement. A formal sample size calculation for efficacy endpoints was not conducted for this study; the results are considered exploratory.

50% of patients in the FT011 400 mg arm exceeded the % predicted FVC minimally important clinically difference (MICD) (defined as a change of >3.3 - 5.3%)[2] vs no patients in the placebo arm meeting these criteria. Furthermore, 60% of patients in the FT011 400 mg arm met the MICD for SHAQ-DI (defined as a change of –0.13)[3] vs 22% in the placebo arm.

Compared to placebo, FT011 demonstrated numerically larger improvements from baseline to week 12 for mRSS and patient global assessment, however this was not significant.

FT011 was safe and well tolerated, with no differences in drug-related treatment-emergent adverse events between placebo and active treatment groups. There were no serious adverse events reported, nor any adverse events resulting in study drug interruption, withdrawal, or discontinuation.

Conclusion: These results demonstrate promising efficacy and safety data for FT011 OD after 12 weeks of treatment and therefore warrants a confirmatory phase III study to assess its potential to improve this debilitating condition.

SESSION INFORMATION
Session Date: Wednesday, November 15, 2023
Session Title: Abstracts: Systemic Sclerosis & Related Disorders III: Clinical Trials
Session Type: Abstract Session
Session Time: 11:00AM–12:30PM

Background/Purpose: The SENSCIS trial enrolled patients with SSc-ILD without a requirement for them to have evidence of recent progression. During the trial, nintedanib reduced the rate of decline in FVC (mL/year) versus placebo. The open-label extension of the SENSCIS trial, SENSCIS-ON, assessed changes in FVC in patients treated with nintedanib over the longer term. We assessed the trajectory of FVC decline in patients who received placebo in the SENSCIS trial and then nintedanib in SENSCIS-ON.

Methods: In the SENSCIS trial, patients with SSc-ILD were randomized to receive nintedanib or placebo double-blind until the last patient reached week 52 but for ≤100 weeks. Patients who completed the SENSCIS trial on treatment (nintedanib or placebo) and attended a follow-up visit were eligible to enter SENSCIS-ON. The protocol allowed an off-treatment period between SENSCIS and SENSCIS-ON of ≤12 weeks. We calculated the trajectory of FVC in patients who received placebo in SENSCIS and initiated nintedanib in SENSCIS-ON. The baseline measurement in SENSCIS-ON was considered the anchor measurement (time point 0) (Figure 1). FVC was measured at time points before the anchor measurement (when patients were receiving placebo in SENSCIS or were off treatment between SENSCIS and SENSCIS-ON) and at time points after the anchor measurement (when patients were receiving open-label nintedanib in SENSCIS-ON). Analyses were descriptive and based on observed FVC values.

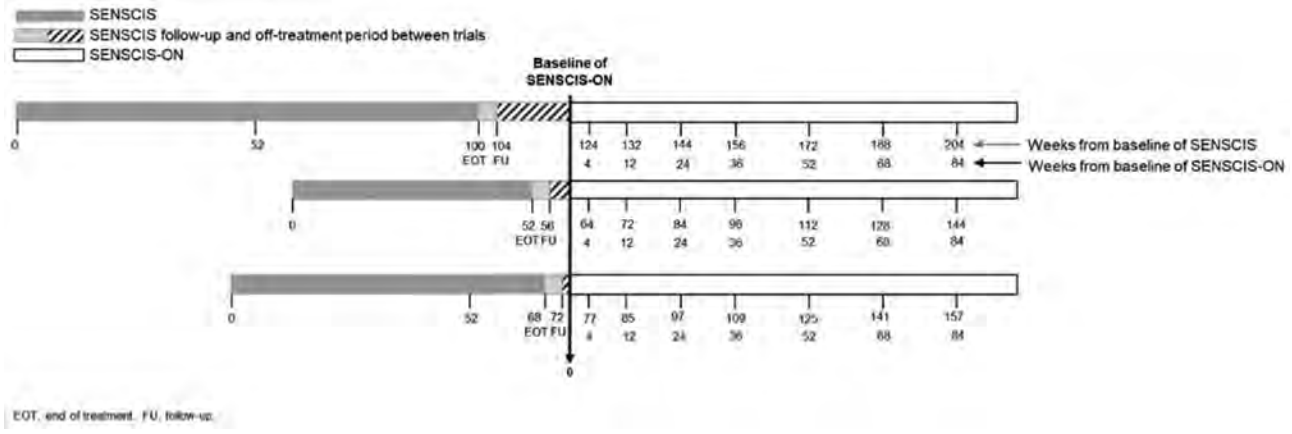

Figure 1. Method for pooling FVC data in SENSCIS and SENSCIS-ON

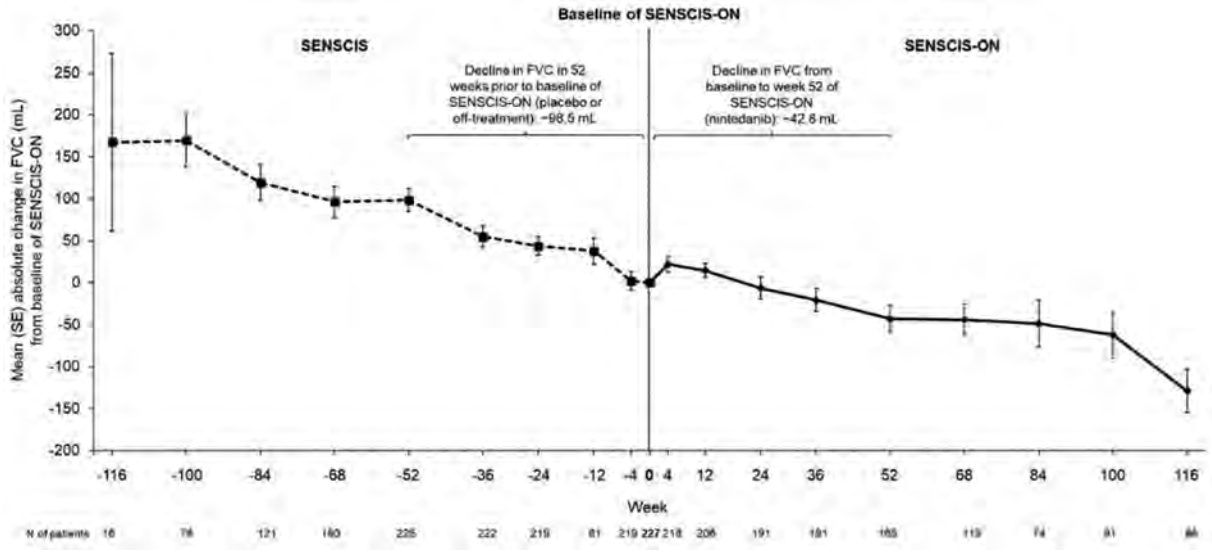

Figure 2. Trajectory of FVC in patients who received placebo in the SENSCIS trial followed by nintedanib in SENSCIS-ON

Results: In total, 231 patients received placebo in SENSCIS and then nintedanib in SENSCIS-ON. In these patients, mean (SD) FVC was 2593 (833) mL at baseline of SENSCIS and 2441 (833) mL at baseline of SENSCIS-ON. The mean decline in FVC in the 52 weeks prior to baseline of SENSCIS-ON (when patients were receiving placebo in SENSCIS or were off treatment) was −98.5 mL (Figure 2). The mean decline in FVC from baseline of SENSCIS-ON to week 52 of SENSCIS-ON (when patients were receiving nintedanib) was −42.8 mL (Figure 2).

Conclusion: In patients who received placebo in the SENSCIS trial, the decline in FVC over 52 weeks was reduced by approximately 57% following initiation of open-label nintedanib in SENSCIS-ON. These analyses illustrate the progressive nature of SSc-ILD in the population enrolled in SENSCIS and the effectiveness of nintedanib on slowing the progression of SSc-ILD.

A Randomized Controlled Trial to Compare the Efficacy and Safety of Tacrolimus with Mycophenolate Mofetil in Patients with Systemic Sclerosis - Interstitial Lung Disease (INSIST TRIAL)

Shefali Khanna Sharma[1], Jithin Mathew[1], Chirag Kopp[1], Varun Dhir[2], Sahajal Dhooria[3], Anindita Sinha[1] and Sanjay Jain[1], [1]Post Graduate Institute of Medical Education and Research, Chandigarh, India, [2]PGIMER, CHD, INDIA, Chandigarh, India, [3]PGI CHANDIGARH, Chandigarh, India

SESSION INFORMATION

Session Date: Wednesday, November 15, 2023
Session Title: Abstracts: Systemic Sclerosis & Related Disorders III: Clinical Trials
Session Type: Abstract Session
Session Time: 11:00AM–12:30PM

Background/Purpose: Interstitial lung disease in systemic sclerosis(SSc-ILD) is heterogeneous with limited therapeutic options. Mycophenolate mofetil (MMF) is the most commonly used first line agent for SSc-ILD. Tacrolimus has shown promising efficacy in few small case series, and large cohorts of patients with non-SSC-ILD1,but has never been evaluated in the setting of a clinical trial in scleroderma.

Methods: In this single center open labelled, prospective, two-arm parallel group, randomized controlled pilot study (INSIST) conducted between November 2021 to December 2022, patients with progressive ILD (FVC decline >10%) due to SSc, aged between 18-65 years, disease duration < 10 years, without concomitant inflammatory myositis, with an FVC of 40-85%, and not having received active immunosuppression other than prednisolone < 10mg/day in the last 6 months were randomized to receive either MMF (target dose 2gm/day) or tacrolimus (Max dose-0.075 mg/kg/day; target trough levels-4- 10ng/ml) for 24 weeks. The primary endpoint was the difference in change in FVC% at 24 weeks; secondary outcomes included absolute change in FVC, skin scores, 6-minute walk distance, Mahler's transitional dyspnea index, ACR-CRISS and revised CRISS responses and adverse outcomes. (Trial Reg: CTRI/2021/11/037864)

Results: 25 out of 26 patients (13 in each group) completed 24 weeks follow up. Majority had Anti-Scl 70 positivity (73%) and limited skin disease. At 24 weeks, the mean change in FVC was 4.4% (10.6) and 6.92%(8.4) in the MMF and tacrolimus groups respectively (difference 2.52%, 95% CI (-10.3 to 5.18); p-0.500). All patients on tacrolimus and 85% of patients on MMF had stabilization (ΔFVC% -5% TO 5%) or improvement (ΔFVC% >10%) in lung function. Secondary outcomes were similar between two groups. Subgroup analyses stratified by ILD type, skin involvement at baseline, and early vs late SSc

Table 1: Primary and Secondary outcomes at 24 weeks

	MMF (n=13)	Tacrolimus (n=13)	P value
Change in FVC (% predicted), mean (SD)	+ 4.4 (10.6)	+ 6.92 (8.4)	Difference 2.52%, 95% CI (-10.3 to 5.18); p-0.500
Absolute change in FVC (ml), mean (SD)	+130.7 (164.6)	+176.8 (305.5)	0.636
Change in mRSS , median (IQR)	-1 (-3 to -0.5)	-1 (-1 to -0.5)	0.209
Change in 6MWD (metres), mean (SD)	63.15 (56.72)	32.67 (27.53)	0.094
Change in SGRQ score, mean (SD)	-14.83 (12.40)	-12.97 (11.78)	0.698
Focal Score TDI, median (IQR)	3 (2-4)	3 (2-4)	0.979
Change in SF-36 PCS, mean (SD)	5.59 (4.89)	4.72 (12.91)	0.823
Change in SF-36 MCS, mean (SD)	3.46 (7.86)	5.58 (5.54)	0.446
Change in PGA, median (IQR)	-2.0 (-2.5 to -1.5)	-2.0 (-2 to -1)	0.364
Change in HAQ-DI, median (IQR)	-0.23 (-0.25 to -0.19)	-0.125 (-0.25 to -0.125)	0.393
ACR-CRISS Improvement, n (%)	5 (38.5)	3 (23.1)	0.395
Revised ACR-CRISS responders; n (%)	10 (76.9)	7 (53.9)	0.416

FVC: Forced Vital Capacity; 6MWD- 6 minute walk distance; mRSS- Modified Rodnan Skin Score; SGRQ- St. George Respiratory Questionnaire; HAQ-DI- Health Assessment Questionnaire-Disability Index; TDI- Transitional Dyspnea Index; SF-36- Short Form 36; PCS- Physical component summary; MCS- Mental Component Summary; CRISS - Composite Response Index in Systemic Sclerosis

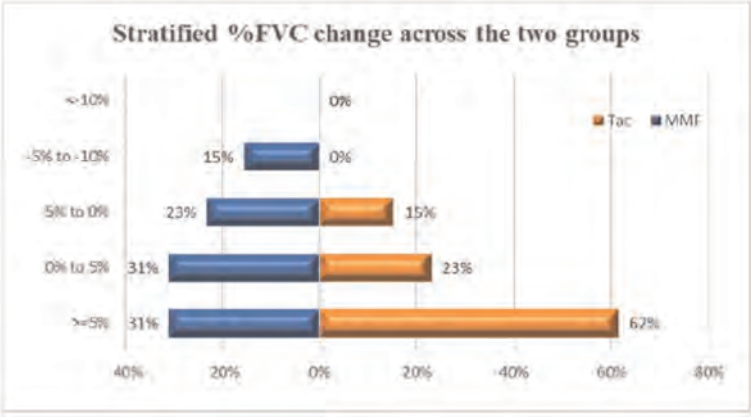

Figure 1: Changes in FVC% stratified by magnitude of change

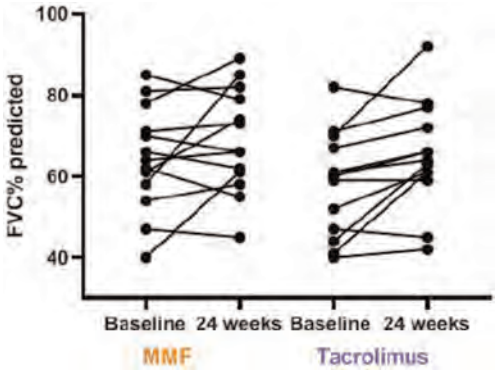

Figure 2: FVC changes at individual level between baseline and week 24 in both groups

yielded similar results. The mean tacrolimus levels were 4.9 ng/ml(1.47) and the median dose needed to achieve these levels was 4mg/d. No serious adverse events were noted in either group. Gastrointestinal disturbances was noted in 23% of patients of mycophenolate and new onset hypertension, minor infection and diarrhea in 1 patient each in the tacrolimus arm. Notably, tacrolimus did not result in renal dysfunction or renal crises.

Conclusion: Tacrolimus resulted in comparable improvement to MMF across primary and secondary outcome measures at 24 weeks with a favorable safety profile in patients with SSc ILD. Larger studies with longer follow up are needed to investigate the role of calcineurin inhibitors in SSc.

SESSION INFORMATION

Session Date: Wednesday, November 15, 2023
Session Title: Abstracts: Systemic Sclerosis & Related Disorders III: Clinical Trials
Session Type: Abstract Session
Session Time: 11:00AM–12:30PM

Background/Purpose: Tocilizumab (TCZ), rituximab (RTX), mycophenolate mofetil (MMF), and cyclophosphamide (CYC) are the immunosuppressants (IS) with the current best evidence for the treatment of systemic sclerosis-associated interstitial lung disease (SSc-ILD)[1-4]. However, limited information is available from comparison studies, and these treatments have often been tested in diverse populations. This study aimed to compare the effectiveness of TCZ, RTX, MMF, and CYC in SSc-ILD patients from the EUSTAR database.

Methods: We included SSc patients from the EUSTAR database who fulfilled the following criteria: 1/ radiologically confirmed ILD; 2/ database record on the use of TCZ, RTX, MMF, or CYC; 3/ baseline and follow-up lung function associated with the treatment period. The primary endpoint was the change of forced vital capacity (FVC) % predicted from baseline to follow-up. Secondary endpoints included changes in diffusing capacity (DLCO) % predicted, modified Rodnan Skin Score (mRSS), and categorical changes in lung function tests and mRSS. Missing data were processed using multiple imputations with chained equations. Selection bias of the medications was reduced to a minimum using propensity score-based inverse probability of treatment weighting (IPTW). For paired therapy comparisons, we used average treatment effects (ATE). Subgroup analysis included previous IS use, background IS, and treatment duration (less than 18 months).

Results: 995 patients with 1050 treatment observations were included in this study. TCZ patients had more arthritis, higher baseline FVC and DLCO, more reticular change in chest CT, and less ground glass opacity. RTX and CYC patients had more elevations of C-reaction protein, and TCZ and RTX patients had higher baseline mRSS, more digital ulcers, and fewer IS naive cases (Table 1).

The median follow-up time was 11 months (interquartile range: 8-14 months). After IPTW, the changes of FVC % predicted were not significantly different between the four treatment arms by the Kruskal Wallis test (P=0.058, Figure 1). Among paired comparisons, only the treatment difference between CYC vs. RTX was significant (mean difference of FVC % predicted, 2.29; 95% CI, 0.18-4.40; P=0.034, Table 2).

In the multivariate logistic regression, only CYC was associated with stable or improved FVC among the four agents. The treatment differences in change of FVC% predicted among the four groups were not significant in patients with previous IS, background IS, or treatment duration > 18 months. Interestingly, MMF showed better FVC responses in patients with previous IS than in IS naive patients [Mean adjusted change of FVC % predicted (95% CI): 1.90 (0.36 to 3.45) vs. -0.04 (-1.35 to 1.26), P=0.047].

Conclusion: In this first large real-world observational study, the treatment effectiveness on FVC change of SSc-ILD patients was not statistically different between TCZ, RTX, MMF, and CYC. CYC showed clinically marginal but statistically significantly better effectiveness in some sub-analyses. Head-to-head randomized clinical trials on IS with longer follow-up are needed for SSc-ILD.

Table1. Patient parameters pre- and post-IPTW. IPTW, inverse probability of treatment weighting; CYC, cyclophosphamide; MMF, mycophenolate mofetil; RTX, rituximab; TCZ, tocilizumab; CRP, C-reaction protein; DU, digital ulcer; SRC, scleroderma renal crisis; ACA, anti-centromere antibody; ATA, anti-topoisomerase I antibody; ESR, erythrocyte sediment rate; LVEF, left ventricular ejection fraction; RHC, right heart catheter; PH, pulmonary hypertension; FVC, forced vital capacity; DLCO, diffusing capacity of the lungs for carbon monoxide; HRCT, high-resolution computational tomography; GGO, ground-glass opacity; AZA, azathioprine; LEF, leflunomide; MTX, methotrexate.

Session Title: Abstracts: Systemic Sclerosis & Related Disorders III: Clinical Trials

Session Type: Abstract Session

Session Time: 11:00AM–12:30PM

Background/Purpose: Lower gastrointestinal tract (GIT) complications are common in patients with systemic sclerosis (SSc), associate with a high disease burden, and current treatment alternatives are limited. Patients with SSc have also an altered intestinal microbiota composition. This provides a rational for the investigation of fecal microbiota transplantation (FMT) in SSc patients with lower GIT symptoms. In this randomized mutlicenter double-blind clinical trial (RCT) we assessed the safety and efficacy of a standardized intestinal microbiota infusion in SSc patients with lower GIT symptoms.

Methods: Patients with SSc and moderate to severe bloating and/or diarrhea assessed by the UCLA SCTC GIT score 2.0 were enrolled in a multicenter, double-blind, randomized, placebo-controlled phase 2 trial. Patients were randomized to receive FMT with an intestinal infusion of a standardized fecal microbiota culture (ACHIM) or placebo at weeks 0 and 2. At week 12, all patients received a FMT infusion and were followed in an open lable phase until week 20. The primary outcome was change between baseline and week 12 in UCLA GIT score item diarrhea or bloating measured as the average marginal effect (AME), depending on which was the worst symptom at baseline; evaluated separately for each patient. Comprehensive predefined subgroup analyses were conducted. Secondary outcomes were safety and tolerability and total UCLA GIT score. Other outcome measures included the change in UCLA GIT score from week 12 to week 20.

Results: A total of 65 patients were randomized to receive FMT or placebo. Baseline characteristics in the groups were comparable (Table). There was no significant difference in the change in lower GIT symptoms from week 0 to week 12 between the groups (AME=0.17 (-0.12, 0.47), p=0.25) and no significant differences in any of the predefined subgroup analyses (Figure 1A-C and 2). Similarly, no significant difference was observed in the total GIT score between the two groups (AME=0.09 (-0.04, 0.23), p=0.17). Furthermore, during the open lable period, there was no statistical difference in change

Table: Baseline characteristics of patients included in the randomized double-blimd placebo controlled ReSScue trial

Parameter	FMT with ACHIM (N=33)	Placebo (N=34)
Age, y (SD)	58 (11.5)	60 (11.7)
Female, n (%)	33 (100)	29 (85)
Worst symptom Bloating, n (%)	22 (67)	22 (65)
Disease duration, y (SD)	9 (7)	10 (8)
Limited cutaneous SSc, n (%)	31 (94)	28 (85)
FVC% (SD)	95 (13.7)	90 (19.2)
Immunosuppressives, n (%)	3 (9)	5 (15)
Proton pump inhibitors n (%)	27 (82)	21 (62)
Calcium channel blocker, n (%)	18 (58)	20 (59)
Total UCLA GIT score	0.9 (0.5)	0.7 (0.3)
UCLA GIT scale Diarrhea	0.8 (0.7)	0.5 (0.5)
UCLA GIT scale Bloating	1.8 (0.8)	1.7 (0.7)

between the ACHIM and the placebo group (AME= -0.04 (-0.32, 0.23), p=0.077) shown in Figure 1D. Participants treated with ACHIM, 16 (37%) and with placebo 19 (42%) experienced any side effects. These were in general mild and short-lasting, with abdominal pain as the most frequent side effect present in 5 (15%) in ACHIM and 2 (6%) in placebo. Time to resolved pain was 2days in both groups. One patient experienced an intramural perforation during gastroscopy and needed IV antibiotics but fully recovered.

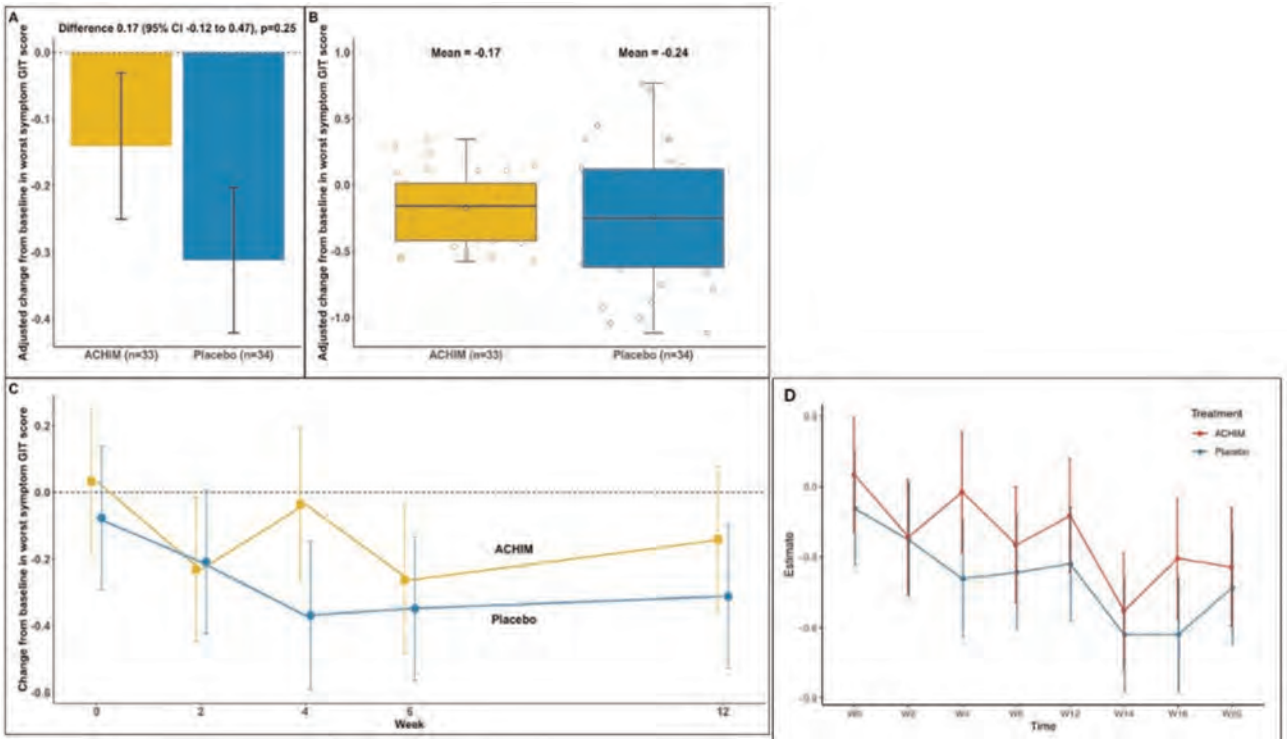

Figure 1: Change in worst symptom GIT score between baseline and week 12. Panel A shows the marginal means of the adjusted changes in the worst symptom GIT score over 12 weeks together with their standard errors for ACHIM and placebo groups as well as the adjusted between-group difference estimated from the primary model. Panel B shows the box-plots of the predicted (adjusted) individual changes in worst symptom GIT score over 12 weeks for both treatment groups given by the primary model. Panel C shows the mean change from baseline to 12 weeks in the worst symptom GIT score. The bars indicate 95% confidence intervals. Panel D shows the mean change from baseline to 20 weeks in the worst symptom GIT score. The bars indicate 95% confidence intervals

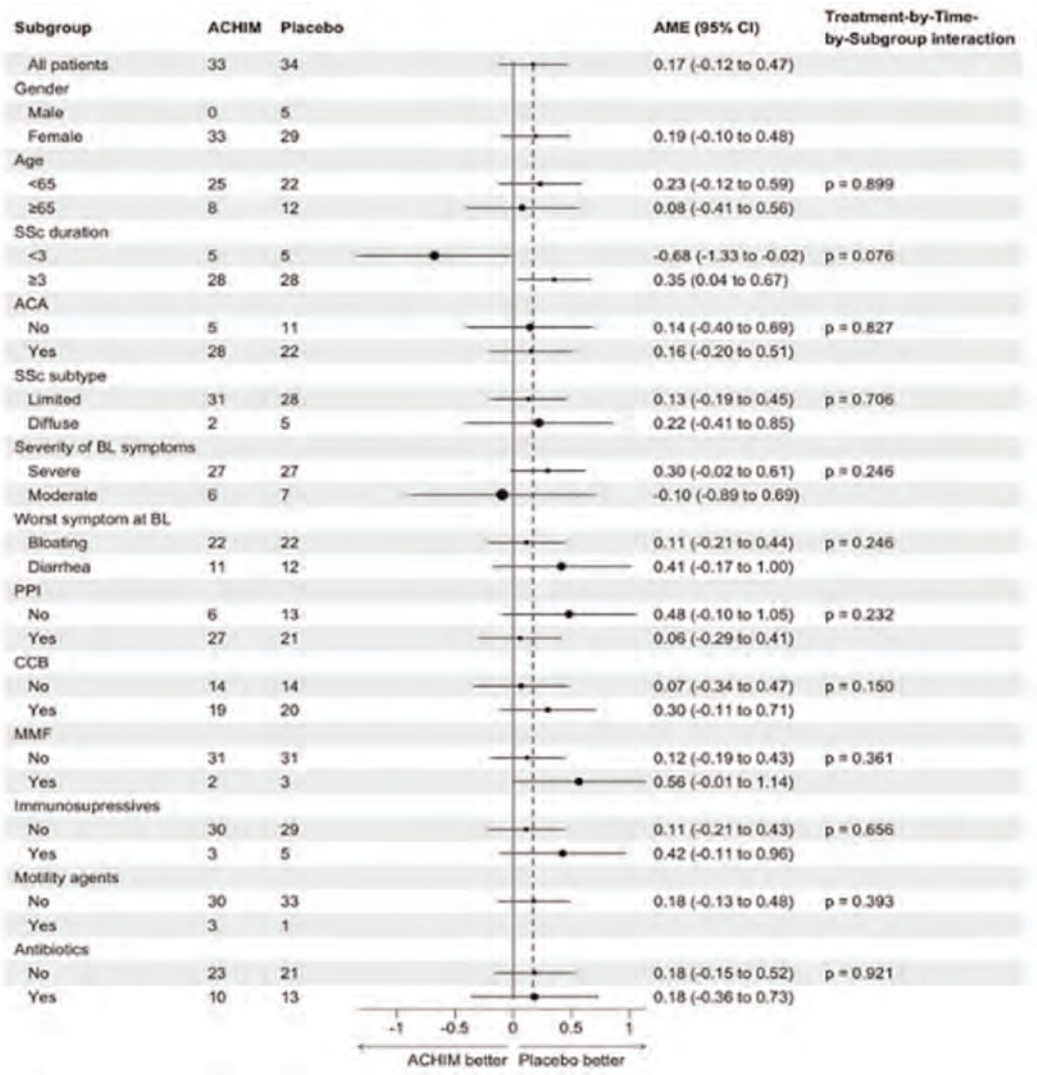

Figure 2: Pre-specified subgroup analyses of the change in the worst symptom GIT score from baseline to week 12 (primary endpoint) based on baseline characteristics and concomitant medication.

Conclusion: We were unable to find indications that FMT improves lower GIT symptoms in SSc patients, but the treatment was found to be safe.

SESSION INFORMATION

Session Date: Wednesday, November 15, 2023

Session Title: Abstracts: Systemic Sclerosis & Related Disorders III: Clinical Trials

Session Type: Abstract Session

Session Time: 11:00AM–12:30PM

Background/Purpose: CD19-targeting CAR-T-cells showed remarkable improvements in autoimmune diseases including refractory lupus erythematodes (1,2) and inflammatory myopathy (3). Moreover, first data of a patient with diffuse Systemic Sclerosis (SSc) were recently reported (4). Here we present 6 months follow up data of the first three patients with severe diffuse SSc who received CAR-T-cell treatment.

Methods: T-cells were acquired by peripheral blood apheresis and transfected with a lentiviral vector encoding a CAR against CD19 (Miltenyi Biotec) using the CliniMacs Prodigy system (Miltenyi Biotec). Infusion of CAR-T-cells was performed upon lymphodepletion with fludarabine (25 mg/m^2 on days -5, -4, -3) and cyclophosphamide (1g/m2 on day -3, 50% dose reduction in patient 3 due to renal insufficiency) as single infusion. Immunosuppression was stopped before CAR-T-cell infusion. Outcomes were assessed before baseline and 6 months after CAR-T-cell infusion.

Results: Three SSc patients were treated with CAR-T-cells with a follow up of 6 months: patient 1 (male, baseline data: 60 yrs, disease duration 2 years (first non-Raynaud symptom), mRSS 24, myocardial- and lung fibrosis, anti RNAP3-antibodies), patient 2: male, 37 yrs, mRSS 27, disease duration 1.5 yrs, lung- and myocardial fibrosis, digital ulcerations (DU), anti-Scl70 antibodies) and patient 3 (female,38 yrs, disease duration 1.5 yrs, mRSS 32, scleroderma renal crisis, DU, anti-Scl70 antibodies). All patients had failed state of the art SSc treatments. The CAR-T-cell procedure was well tolerated: Patient 1 developed mild CRS (grade I; fever) and an episode of respiratory tract infection three months after CAR-T infusion, treated outpatient with antibiotics. B-cells were completely absent in peripheral blood within 7 days after CAR-T

cells administration in all patients. ANA titres were reduced by 10-fold in patients 2 and 3, patient 1 converted to negative ANA status within 3 months and anti-RNAP III antibodies turned negative. mRSS improved in all three patients until six-months follow up (median 6 points (5-7)). 2 patients suffered from multiple digital ulcerations despite bosentan- treatment before CAR-T cells, which were no longer detectable on follow up. All patients reported improvement of hand function (median reduction of Cochin Hand function scale of 8 points (8-20). Improvement of HAQ-DI ranged from 0.5 to 1.38 points and of EUSTAR activity from 3.62 to 4.37 points. Lung function parameters remained stable in patients 1 and 3 and improved in patient 2 (FVC increase by 390 ml (8%)). Myocardial ^{68}Ga-FAPI-04-uptake declined in patients 1 and 2 by 30% and 35% respectively. B-cells recurred after 84 days in patient 1 and 2 without signs of disease activity.

Conclusion: These data on the first three SSc patients receiving CD19 CAR-T cell treatment show that the procedure is well tolerated and can lead to stabilization of SSc disease activity without additional immunosuppression on 6 months follow up.

SESSION INFORMATION
Session Date: Wednesday, November 15, 2023
Session Title: Abstracts: Vasculitis – Non-ANCA-Associated & Related Disorders III: Innovation
Session Type: Abstract Session
Session Time: 11:00AM–12:30PM

Background/Purpose: Giant cell arteritis (GCA) is a vasculitis in which Th17 cells have been identified in excess in lesions and in the blood of patients. While the efficacy of secukinumab has recently been reported in a phase II study, the role of interleukin-17 (IL-17) in the pathophysiology of GCA is not clearly understood. The aim of this study was to investigate the role of IL-17 in the pathogenesis of GCA.

Methods: Vascular myofibroblasts (MFs) were obtained from cultures of healthy arteries in MATRIGEL as previously described. After 3-6 doubling passages, MFs were treated with IL-17 (50 ng/mL), interferon-gamma (IFN-γ, 50 ng/mL), secukinumab (20 μg/mL) or the association of IL-17 and IFN- γ or IL-17 and secukinumab for 24 hours. mRNA expression was analyzed by RNA sequencing and RT-PCR. Proliferation was analyzed by impedancemetry and migration was assessed by scratch-wound healing assays. Fresh fragments of temporal artery biopsies (TAB) were prospectively

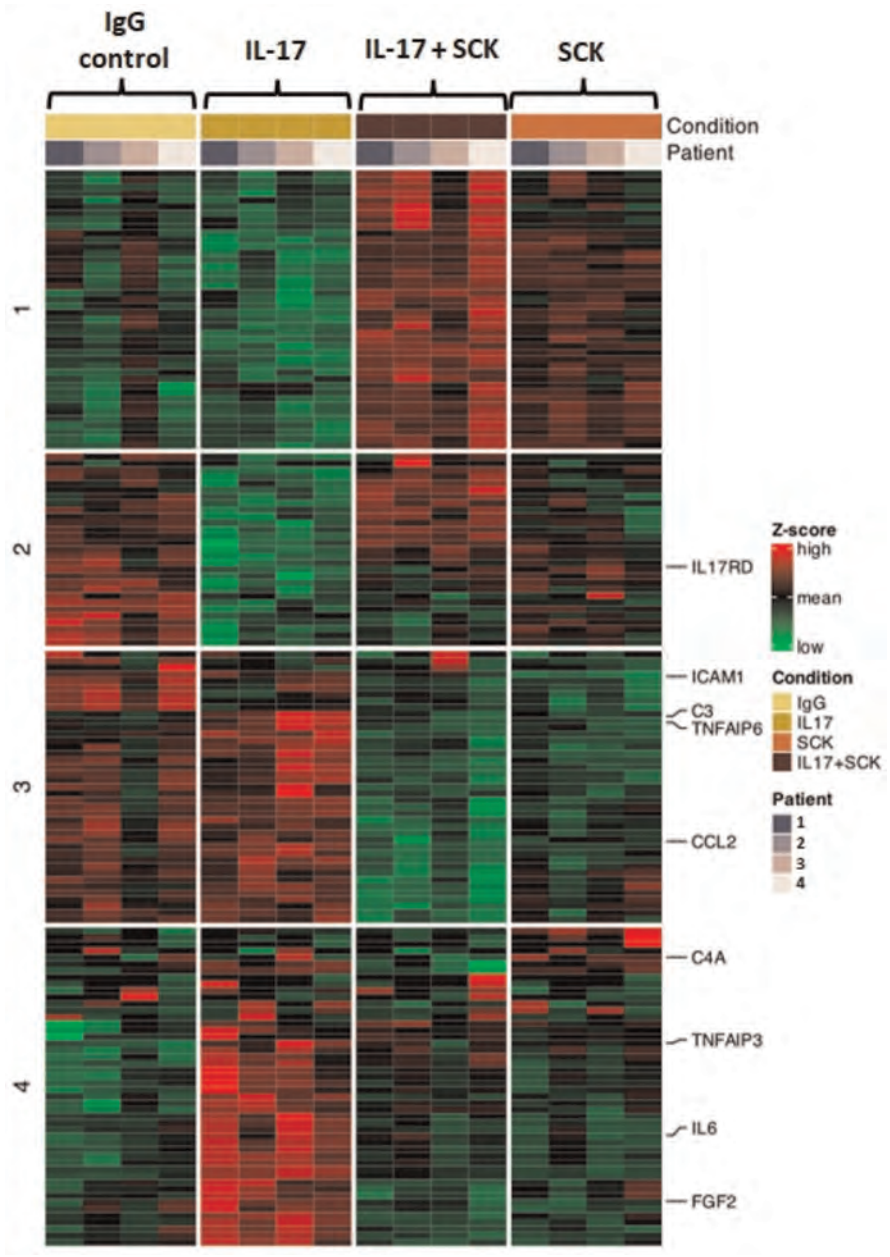

Figure 1: transcriptomic analysis (RNA sequencing) of MF cultivated during 24 hours with IL-17, secukinumab (SCK), IL-17 and SCK or IgG control.

collected, cut in 1-mm sections and cultured for 5 days in MATRIGEL®, as previously described, in the presence of IL-17, secukinumab or IgG control. Then, arterial sections were collected, homogenized and analyzed by RT-PCR.

Results: The transcriptome of MFs was dramatically modified when IL-17 was added to the culture, with increased expression of genes involved in vascular inflammation (*CCL2*, *IL6*), NFkB pathway activation (*TNFAIP6*, *TNFAIP3*), leukocyte adhesion (*ICAM1*), complement activation (*C3*, *C4A*) and MF proliferation (*FGF2*) (Figure 1). These changes were reversed in the presence of secukinumab (**Figure 1**).

RT-PCR analysis of 8 MF lines showed that in the presence of IL-17, the mRNA expression of the genes encoding for IL1-β, IL-6, IL-12p35, VEGF-A, GM-CSF, CCL2 and CCL20 was increased ($P < 0.01$). There was no significant effect on the mRNA expression of IL-23p19, IL-12p40, collagen alpha chains 1 and 3, PDGFA, PDGFB, CXCL9 or CXCL10. The addition

of IFN-γ to the culture increased the expression level of chains of the IL-17 receptor (*IL17RA* and *IL17RC*), creating a synergistic effect in the presence of IFN-γ and IL-17, thus resulting in a sharp rise in the expression of genes encoding for IL-1β, IL-6, IL-12p35, GM-CSF, VEGF-A, CCL2 and CCL20.

The study of MF migration and proliferation revealed that IL-17 had no direct effect on these MF functions.

Ex-vivo cultures of TAB revealed that treatment with IL-17 increased the expression of mRNA encoding for IL-6, VEGF-A, GM-CSF, CCL2 and CCL20 in negative TAB (n=8; $P< 0.05$) whereas treatment with secukinumab decreased the expression of mRNA encoding for IL-6 and CCL20 in positive TAB (n=12; $P < 0.05$).

Conclusion: IL-17 increases vascular inflammation and has a direct effect on MF synergistically with IFN-γ, which increases the production of pro-inflammatory cytokines (IL-1B, IL-6, GM-CSF), chemokines leading to the recruitment of T cells (CCL20) and monocytes (CCL2), and growth factors involved in neoangiogenesis (VEGF). In contrast, IL-17 does not appear to have a direct effect on MF proliferation and migration. These data explain why blocking the IL-17 signaling pathway could be useful in the treatment of GCA.

Abstract Number: 2600

Clonal Hematopoiesis Is Associated with Giant Cell Arteritis

SESSION INFORMATION

Session Date: **Wednesday, November 15, 2023**
Session Title: Abstracts: Vasculitis – Non-ANCA-Associated & Related Disorders III: Innovation
Session Type: Abstract Session
Session Time: 11:00AM–12:30PM

Background/Purpose: Giant cell arteritis (GCA) is an age-related vasculitis of large and medium vessels. Prior population studies have identified an association between GCA and hematologic malignancy (HM). Clonal hematopoiesis describes the age-related expansion of blood cells carrying somatic mutations that drive development of HM, most frequently in the epigenetic modifiers *DNMT3A, TET2*, and *ASXL1*. When the variant allele fraction (VAF) is ≥ 0.02, the terms clonal hematopoiesis of indeterminant potential (CHIP) and clonal cytopenia of uncertain significance (CCUS) are used to refer to patients without and with unexplained cytopenia, respectively. Individuals with CHIP/CCUS, especially mutated in *TET2*, develop many other age-related inflammatory-spectrum disorders including ischemic cardiovascular disease, non-alcoholic fatty liver disease, and gout. How the presence of CHIP, CCUS, or specific somatic mutation genotypes may influence the developmental and/or clinical outcomes in GCA is not well understood.

Methods: We analyzed sequenced exomes of 470960 UK Biobank participants for the presence of CH and used multivariable Cox regression to associate the presence of CHIP, CCUS, and the top three mutated genes with incident GCA. We then performed CH-panel targeted sequencing of DNA from blood samples from 114 patients with GCA recruited from a large academic health system who had a positive temporal artery biopsy, positive imaging, or met 1990 ACR classification criteria for clinical diagnosis GCA, of which 99% met 2022 ACR/EULAR classification criteria post-hoc. Abstraction of clinical data from the electronic medical record was performed to test association of *TET2* with development of GCA-associated vision loss and to determine HM outcomes.

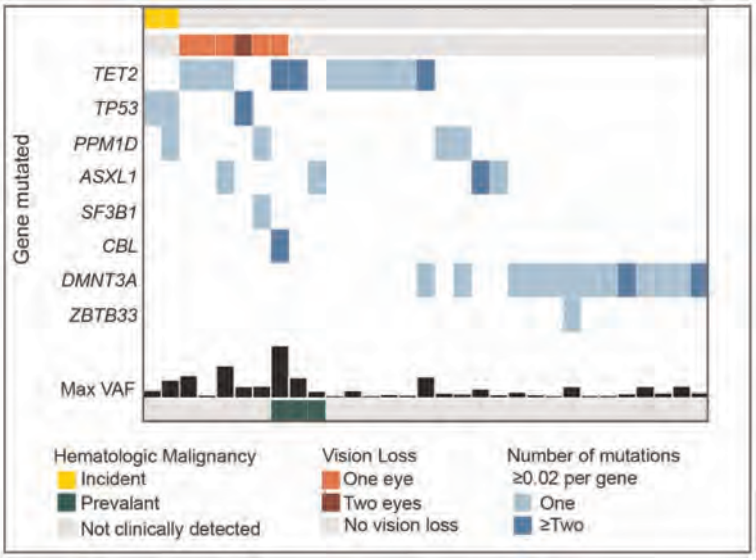

Figure 1: Co-mutation plot of adverse outcomes of hematologic malignancy and vision loss in individuals with GCA and CH. Each column represents one individual. Rows show mutated genes, color coded by number of mutations, and the maximum variant allele frequency (VAF) of largest mutation.

Results: We identified 779 UKB participants with incident GCA, of which 11.8% had CHIP/CCUS. CHIP/CCUS had a 1.48-fold increase in risk of incident GCA compared to UKB participants without CH. GCA risk was highest among individuals with CCUS (HR 2.98, p =0.0018) and with *TET2*-mutated CHIP/CCUS (HR 2.02, p =0.0012). Within the institutional GCA cohort, somatic mutations were detected in 27.2%, most commonly in *DNMT3A* (41.9%) and *TET2* 35.5%). *TET2*-mutated GCA was associated with vision loss (n = 4, OR 4.33, p = 0.047) (Figure 1). Overall, adverse outcomes (vision loss or incident HM) were associated with clones with larger VAF (median VAF 0.161 vs 0.049, p = 0.004). Cytopenia was common before and after GCA diagnosis, but few individuals underwent diagnostic evaluation for HM (7.2%) with abnormalities detected in most cases (87.5%). Compared to diagnosis of GCA, we observed prevalent HM in individuals with *TET2* (n =2) and *ASXL1* mutations (n=1) and incident HM only among individuals with *TP53*-mutant CH (n=2) (Figure 1).

Conclusion: CH increases risk for development of GCA in a genotype-specific fashion, with greatest risk being conferred by the presence of mutations in *TET2*. *TET2* mutations likewise increase the risk of GCA-associated vision loss. Features associated in large population studies with increased risk of HM, namely CCUS and larger clone size, were also associated with increased development of GCA and adverse outcomes, respectively.

Identification of Giant Cell Arteritis Using Plasma Proteome Profiles Integrated with Machine Learning

kevin cunningham[1], **Jaeyun Sung**[2], Benjamin Hur[2], VINOD GUPTA[2], Matthew Koster[2], Cornelia M. Weyand[3], David Cuthbertson[4], Nader Khalidi[5], Curry Koening[6], Carol Langford[7], Carol McAlear[8], Paul Monach[9], Larry Moreland[10], Christian Pagnoux[11], Rennie Rhee[8], Philip Seo[12], Peter Merkel[8] and Kenneth Warrington[2], [1]University of Minnesota, Minneapolis, MN, [2]Mayo Clinic, Rochester, MN, [3]Mayo Clinic School of Medicine and Stanford University, Rochester, MN, [4]University of South Florida, Tampa, FL, [5]McMaster University, Hamilton, ON, Canada, [6]University of Texas Dell Medical School, Austin, TX, [7]Cleveland Clinic, Cleveland, OH, [8]University of Pennsylvania, Philadelphia, PA, [9]VA Boston Healthcare System, Boston, MA, [10]University of Colorado, Denver, CO, [11]Mount Sinai Hospital, Toronto, ON, Canada, [12]Johns Hopkins University, Baltimore, MD

SESSION INFORMATION

Session Date: Wednesday, November 15, 2023
Session Title: Abstracts: Vasculitis – Non-ANCA-Associated & Related Disorders III: Innovation
Session Type: Abstract Session
Session Time: 11:00AM–12:30PM

Background/Purpose: The availability of diagnostic laboratory tests and specific biomarkers of disease activity for giant cell arteritis (GCA) remains an area of unmet need. The purpose of this study was to utilize a high-throughput screening array to identify plasma proteins that 1) differentiate patients with GCA from controls; and 2) associate with disease activity in GCA.

Methods: This study included patients with GCA (n = 30) from a multi-institutional prospective longitudinal cohort study and 30 age-/sex-/race-matched healthy controls (**Figure 1**). Most patients with GCA were taking glucocorticoids at the time of sample collection (**Figure 1**). Plasma samples were collected from patients with GCA at two separate visits: 1) during active disease; and 2) during inactive disease. An aptamer-based, multiplex microarray platform (SomaScan® Assay, SomaLogic) measured semi-quantitative abundances of 7,289 proteins in relative fluorescence units (RFUs). Linear regression models identified differentially-abundant proteins between patients with GCA (at active or inactive disease state) compared with controls while adjusting for potential confounders ($P < 0.01$). Gene Ontology (GO) Biological Processes identified enriched functional categories of the differentially-abundant proteins. Proteins associated with disease activity (Physician Global Assessment, PGA) in patients with active GCA were also identified. A random forest model was trained on plasma proteomes to develop a classifier that distinguishes GCA (active or inactive state) from controls.

	GCA*, Active disease (n = 30)	GCA, Inactive disease (n = 30)	Controls (n = 30)

[1]Giant Cell Arteritis, [2]Trimethoprim-sulfamethoxazole, [3]Not applicable or not available.

Figure 1. Study design overview. Plasma samples were collected from 30 patients with GCA and 30 healthy controls. For each patient with GCA, one sample was collected at a time of active disease (physician global assessment [PGA] > 0) and another at a time of inactive disease (PGA = 0). Proteome profiling was performed on all samples using an aptamer-based, multiplex microarray platform. Proteins were compared between patients with GCA and controls to identify differentially-abundant proteins and enriched biological functions. The confounding factors adjusted for during linear regression modeling were age, sex, smoking status, and use of prednisone, aspirin, and methotrexate. A machine learning technique (random forests) was trained on the plasma proteome profiles to build a classifier that distinguishes between GCA and controls.

Figure 2

	Active GCA vs. Controls	Inactive GCA vs. Controls
Accuracy	98.3%	98.3%
Sensitivity	100%	96.7%
Specificity	96.7%	100%
PPV	96.7%	100%
NPV	100%	96.7%

Figure 2. Differences in plasma proteins between patients with GCA and healthy controls form the basis of a novel machine learning approach for identifying GCA. Plasma proteins found to have significantly higher (A) or lower (B) relative fluorescence unit (RFU) abundances in active GCA and inactive GCA compared with controls (P-value of the corresponding regression coefficient < 0.01). The intersection of the Venn diagram indicates proteins having higher (or lower) RFUs in both disease states. (C) Top 5 enriched (i.e., statistically over-represented) GO Biological Processes from proteins higher in active GCA and inactive GCA compared with controls. Enriched GO terms are rank-ordered in descending order based on modified one-tailed Fisher's exact test P-values. (D) A total of 31 proteins were significantly associated with physician's global assessment (PGA) in active GCA (P-value < 0.05 and |Spearman's rho| > 0.4): 4 and 27 proteins had positive and negative correlations with PGA, respectively. (E) Random forest classifiers could differentiate patients with GCA from controls with high accuracy (> 98%) in 5-fold cross-validation.

Results: 509 and 618 differentially-abundant proteins were identified between active GCA compared with healthy controls (**Figure 2A**) and inactive GCA compared with controls (**Figure 2B**), respectively. Among these, 100 and 159 proteins had significantly higher abundances in active GCA and inactive GCA, respectively. The observed enriched biological processes are shown in **Figure 2C**: 'Regulation of protein metabolic process' and immune-related processes were the most highly

enriched functions of plasma proteins found higher in active GCA. Interestingly, processes involving apoptosis, nucleotide metabolism, and EGFR, ErbB, and neurotrophin signaling were also significantly enriched. A paired analysis between active and inactive visits found 219 differentially abundant proteins. In addition, 31 proteins were found to be associated with disease activity (PGA) in patients with active GCA (**Figure 2D**). A random forest classifier correctly predicted active GCA vs. controls with an accuracy of 98.3% (sensitivity: 100%; specificity: 96.7%) in 5-fold cross-validation (**Figure 2E**). Similarly, in the case of inactive GCA vs. controls, a random forest classifier distinguished these two phenotypes at 98.3% accuracy (sensitivity: 96.7%; specificity: 100%).

Conclusion: Plasma proteome profiling in two different disease states of GCA produced highly accurate classification for distinguishing active and inactive disease states from controls. These results demonstrate the strong potential of integrating plasma proteomes with machine learning for future approaches to identify GCA. Future studies should include validating these findings in a larger independent cohort.

Spatially Resolved Cellular Signatures Predict Corticosteroid Treatment Response in Giant Cell Arteritis

Cecilia Ansalone[1], Sam McAllister[2], Ethan Pickerill[3], Lin Zhang[3], Annie Peacock[2], Dominic McGovern[4], Holly Leslie[5], Victoria Kellior[2], Evelyn Qian[2], David Gemperline[3], Aysin Tulunay Virlan[2], Sylvia Wright[6], Paul Cauchi[6], Timothy Beckman[6], Lisa Hutton[6], John Cole[1], Isabella Wulur[3], Robert Benschop[3], Nigel Jamieson[5], Carl Goodyear[1] and Neil Basu[1], [1]University of Glasgow, Glasgow, United Kingdom, [2]University of Glasgow - School of Infection & Immunity, Glasgow, United Kingdom, [3]Eli Lilly and Company, Indianapolis, IN, [4]University of Glasgow - School of Medicine, Glasgow, United Kingdom, [5]University of Glasgow - School of Cancer Sciences, Glasgow, United Kingdom, [6]NHS Greater Glasgow and Clyde, Glasgow, United Kingdom

SESSION INFORMATION
Session Date: Wednesday, November 15, 2023
Session Title: Abstracts: Vasculitis – Non-ANCA-Associated & Related Disorders III: Innovation
Session Type: Abstract Session
Session Time: 11:00AM–12:30PM

Background/Purpose: Corticosteroids (CS) remain the mainstay of giant cell arteritis (GCA) therapy. Between ~30-70% patients relapse following CS taper and are consequently at risk of high toxicity due to prolonged CS exposure. Predictors of CS treatment response would enable a stratified approach to management but have yet to be established. Existing

mechanistic GCA research has mostly focussed upon a putative role for $CD4^+$ T cells in treatment non-response, however, GCA is characterised by a more expansive immune landscape. This study is the first to comprehensively characterise the spatial immunobiology of GCA and associate this with CS treatment response.

Methods: Archival formalin-fixed paraffin-embedded (FFPE) GCA temporal artery biopsies (TAB) from patients who fulfilled ACR GCA criteria were linked to their clinical record and sub-grouped according to those who fulfilled the EULAR definition for sustained remission (SR) at 1 year (n=6) and those who did not (non-response; NR, n=6). Non-GCA TAB (n=4) were included as controls. Tissue sections were analysed for the whole transcriptome atlas on the Nanostring GeoMx Digital Spatial Profiler. Specific topographic areas of interest (AOI) were defined by immunofluorescence in the adventitia, media, and intima layers within which $CD45^+$ (leukocytes), $CD68^+$ (macrophages and giant cells; Mϕ and GCs), $CD31^+$ (endothelial cells), and $CD45^-CD68^-CD31^-$ (stroma). Several bioinformatic tools were used to determine transcriptomic differences, including GeoMx NGS pipeline, DESeq2 package, Searchlight2 software, Gene Set Enrichment Analysis (GSEA), and CIBERSORT. The results informed a 28-plex antibody panel for spatial phenotypic cell analysis, which was applied to sections sourced from corresponding TABs using a PhenoCycler System (CODEX).

Results: Spatial transcriptomic analysis identified 2,275 differentially expressed genes between GCA and controls. The most significantly upregulated genes were immunoglobulin genes and genes associated with pathological Mϕ. GCA SR cases had greater $CD45^+$ and $CD68^+$ infiltrates towards the intima layer than NR cases. Differential expression signature analysis showed fundamental differences among $CD68^+$ adventitial/media Mϕ, intima Mϕ, and GCs. Deconvolution analysis indicated a mix of monocyte, M1 and M2 Mϕ in the adventitial transcriptomic signature, while a mainly M0 undifferentiated phenotype was observed in intima Mϕ and GCs. Notably, SR cases expressed an increased plasma cell molecular signature when compared to NR cases, both in adventitial $CD45^+$ AOI and stroma. In contrast, NR adventitial $CD45^+$ AOI demonstrated a pronounced $CD4^+$ T cell signature associated with INFγ response and other inflammatory pathways, including TNF and IL-6 signalling. CODEX imaging analysis revealed clear and abundant $CD138^+CD38^+$ plasma cells in the adventitia layer, which were visible in 6/6 of SR cases and only 1/5 of NR case.

Conclusion: Spatial analysis of GCA TAB tissue collected at diagnosis revealed strong plasma cell and pathological Mϕ signatures that correlated with CS treatment response at 1 year. In contrast, CS treatment non-response was characterised by a $CD4^+$ T cell signature.

SESSION INFORMATION

Session Date: Wednesday, November 15, 2023
Session Title: Abstracts: Vasculitis – Non-ANCA-Associated & Related Disorders III: Innovation
Session Type: Abstract Session
Session Time: 11:00AM–12:30PM

Background/Purpose: Giant cell arteritis (GCA) is a large vessel vasculitis in adults that commonly involves the aorta and branching arteries, resulting in multiple symptoms including vision loss. IL-6 has been identified as key to GCA pathogenesis, and treatment with IL6 receptor (IL-6R) antibody, tocilizumab, induces steroid-free disease remission in many patients with GCA. Not all patients with GCA have favorable clinical response to tocilizumab. A relatively common SNP in IL-6R, Asp358Ala, results in increased solubilization of the IL-6R that then binds the ubiquitous IL-6 co-receptor, gp130, leading to more pro-inflammatory soluble IL-6 signaling, known as trans signaling. This contrasts with classical membrane bound IL-6R signaling, found on hepatocytes and lymphocytes, that results in anti-inflammatory effects and release of C-reactive protein. We hypothesized that the Asp358Ala IL-6R variant in patients with GCA impact IL-6 mediated T cell activity and response to tocilizumab.

Methods: Samples and clinical data were obtained from patients who met the 2022 ACR/EULAR Classification Criteria for GCA. Genetic sequencing was completed to identify GCA patients with the Asp358Ala variant. Serum from patients was used to quantitate serum soluble IL-6R levels by ELISA. Peripheral blood mononuclear cells (PBMCs) evaluated for

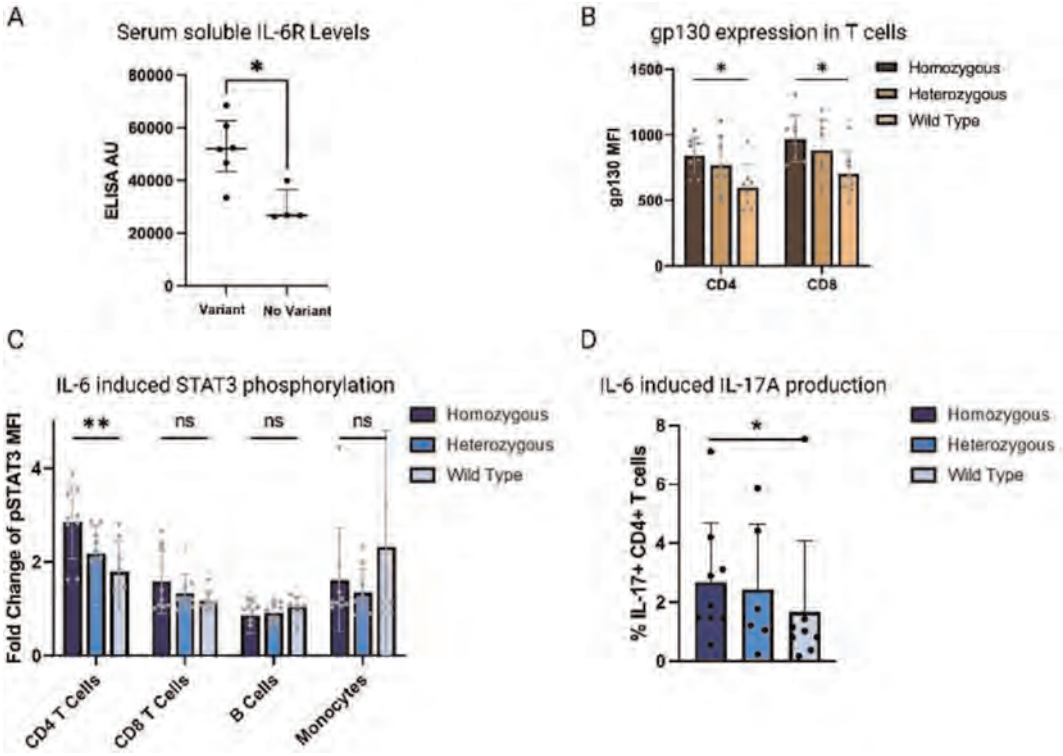

Figure 1. A) Serum samples from GCA patients were measured by ELISA for soluble IL-6R levels. sIL-6R levels from patients with the Asp358Ala variant (homozygous and heterozygous) were compared to those without the variant. B) PBMCs were analyzed by flow cytometry for gp130 expression on different T cell subsets. C) PBMCs were stimulated with IL-6 (100ng/ml) for 15mins and then analyzed for STAT3 phosphorylation. C) PBMCs from patients with GCA were stimulated with 50ng/ml of IL-6 and costimulatory molecules (CD3, CD28, anti-IL4, and anti-IFNy) for 3 days and then re-stimulated with PMA/Ionomycin.

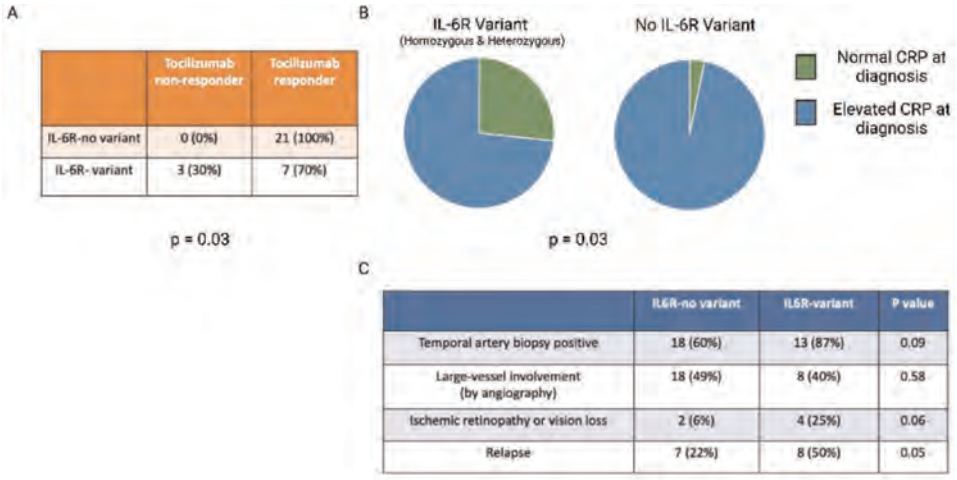

Figure 2. Clinical characteristics of a prospective observational cohort of patients with GCA. A) Tocilizumab non-response was identified as clinical signs or symptoms of active disease following treatment with tocilizumab. Response and non-response was compared between GCA patients with and without the IL6-R variant (Asp358Ala) B) CRP at time of diagnosis was compared between GCA patients with and without the IL6-R variant (Asp358Ala), normal range was determined by clinical laboratory standards. 3) Prospective chart review as conducted to identify clinical characteristics and complications commonly associated with GCA, before, during, or after treatment with tocilizumab.

expression of IL-6R and its co-receptor, gp130, using flow cytometry. The same PBMCs were stimulated ex vivo with IL-6 and evaluated for downstream targets of IL-6, STAT3 phosphorylation and IL-17A expression, also using flow cytometry. Clinical symptoms, laboratory values, and response to tocilizumab was identified by chart review. Active disease was defined by clinical signs and symptoms.

Results: Patients with GCA and the Asp358Ala IL-6R variant had increased serum soluble IL-6 receptor levels (Fig 1A) as well as higher lymphocyte expression of surface gp130 (Fig 1B). When stimulated ex vivo with IL-6, CD4+ T cells in patients with Asp358Ala had increased STAT3 phosphorylation and IL17A expression (Fig 1C and 1D). Similar associations were not seen in other leukocyte subsets or in CD4+ T cells from healthy controls by variant status. Clinically, patients with the Asp358Ala SNP had a higher likelihood of treatment failure to tocilizumab (Fig 2A), lower CRP values at diagnosis (Fig 2B), and a higher rate of relapse (Fig 2C).

Conclusion: The Asp358Ala IL6R variant may result in increased pro-inflammatory trans IL-6 signaling via increased soluble IL-6R and surface gp130 expression, leading to more robust STAT3 phosphorylation and IL-17A production in T cells. IL-6R inhibition via tocilizumab in patients with the Asp358Ala variant may be insufficient to achieve disease control. This variant may be a useful biomarker to predict treatment response to tocilizumab and to identify patients who may respond more favorably to alternative therapeutic approaches.

Session Title: Abstracts: Vasculitis – Non-ANCA-Associated & Related Disorders III: Innovation

Session Type: Abstract Session

Session Time: 11:00AM–12:30PM

Background/Purpose: Takayasu's arteritis (TAK) is characterized by persistent vascular inflammation involving aorta and its main branches, which is an important prosenescent factor that in turn amplifies local inflammation via senescence-associated secretory phenotype (SASP). In this study, we aimed to explore the pathogenic role of vascular smooth muscle cells (VSMCs) senescence and the relevant prosenescent pathway in TAK.

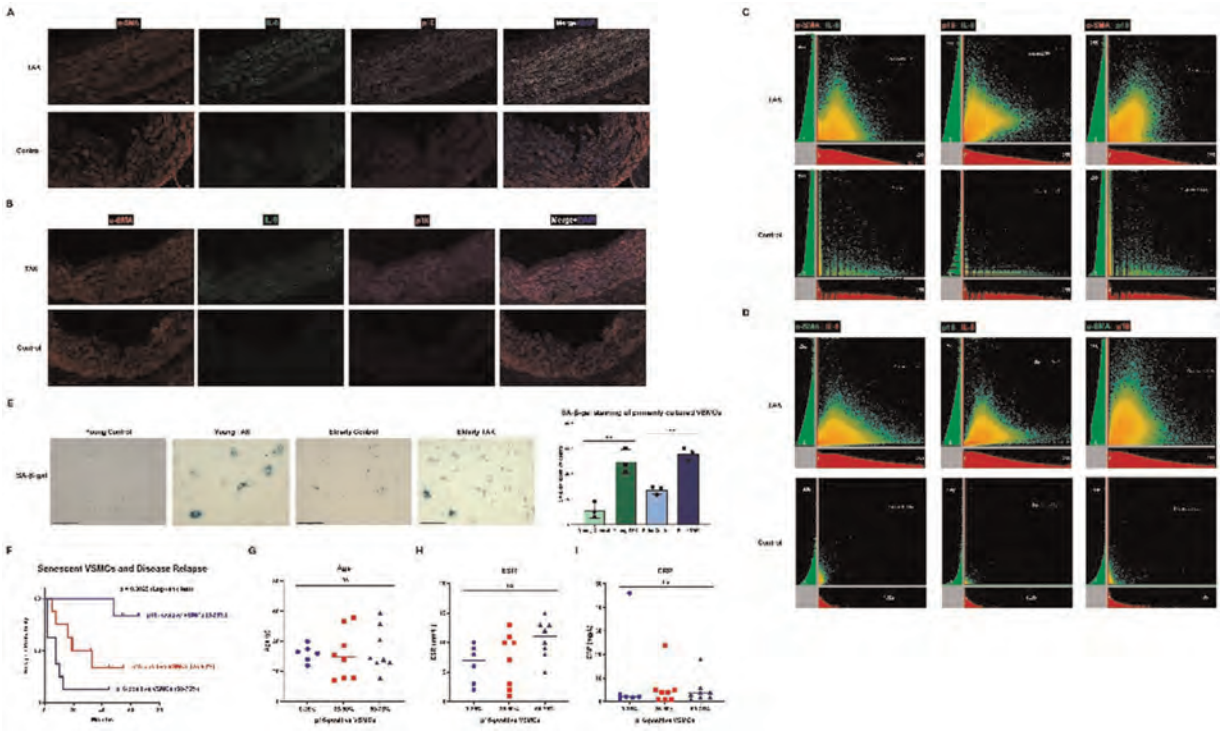

Figure 1. Premature VSMCs senescence in TAK patients and its association with disease parameters

Methods: Cellular senescence markers were tested in vascular samples from patients with TAK using immunofluorescence, western blot and SA-β-gal staining. The key prosenescent inflammatory cytokine and its downstream intracellular events were investigated in a series of in-vitro and ex-vivo experiments including coculture experiments, RNA-Seq, gene knock-down, mitochondrial assays, co-immunoprecipitation, and tissue culture.

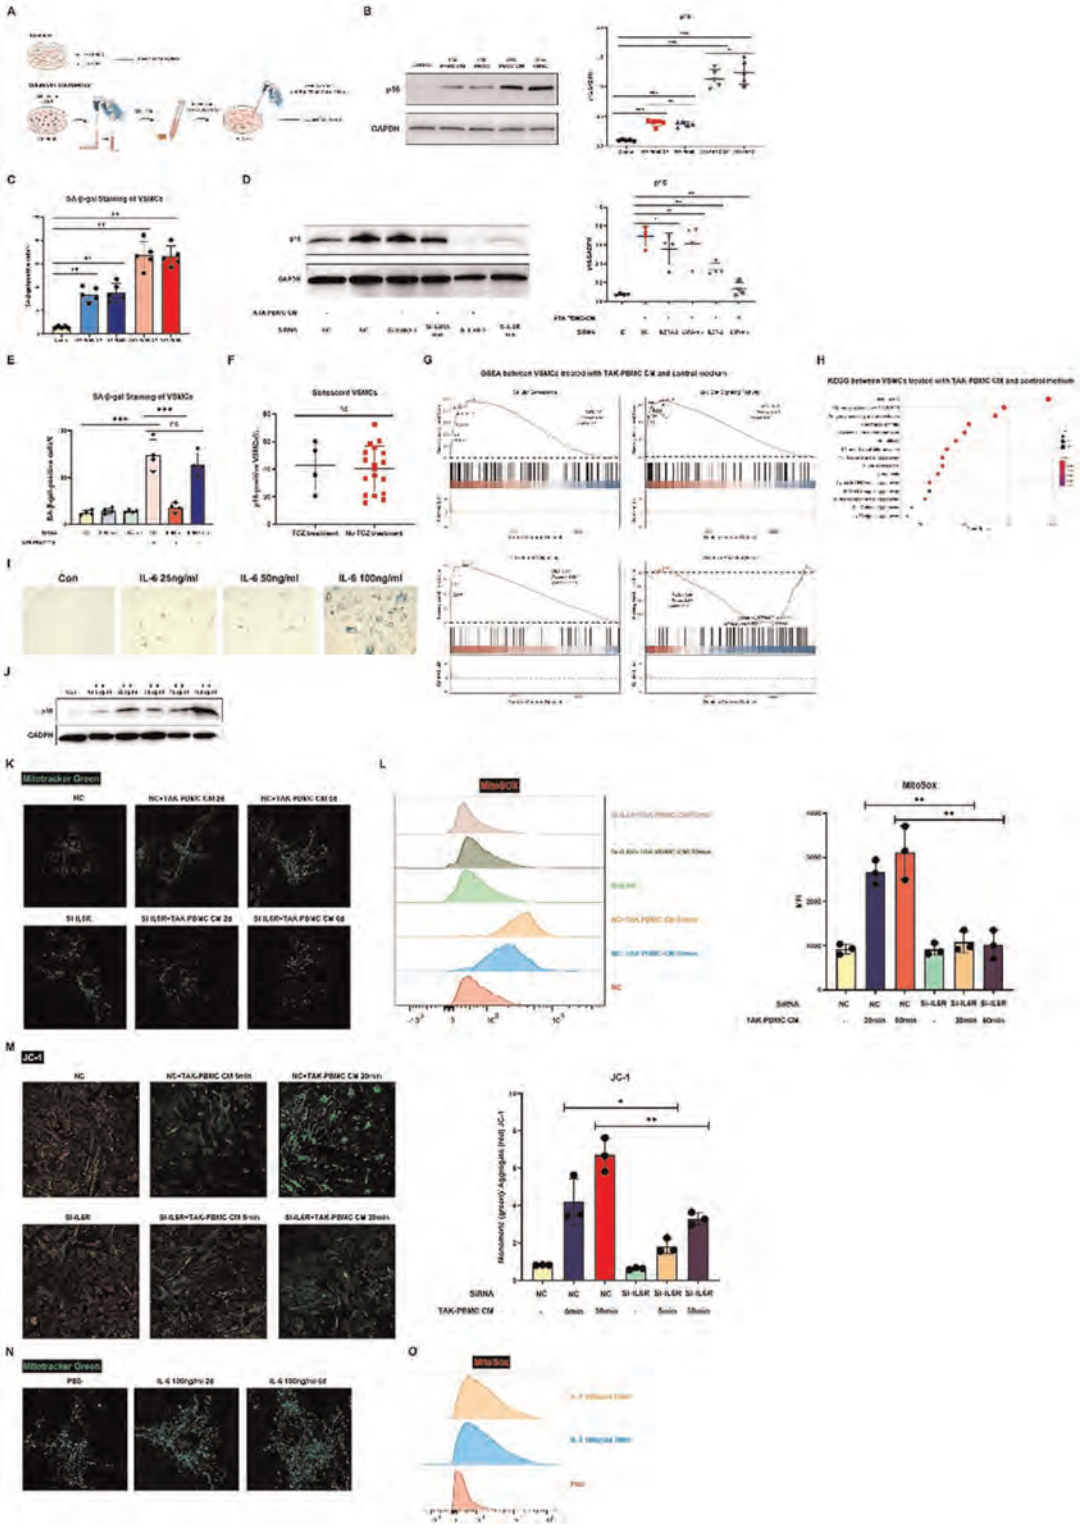

Figure 2. Prosenescent effects and senescence-associated mitochodrial dysfunctions driven by TAK inflammatory milieu via IL-6 signaling

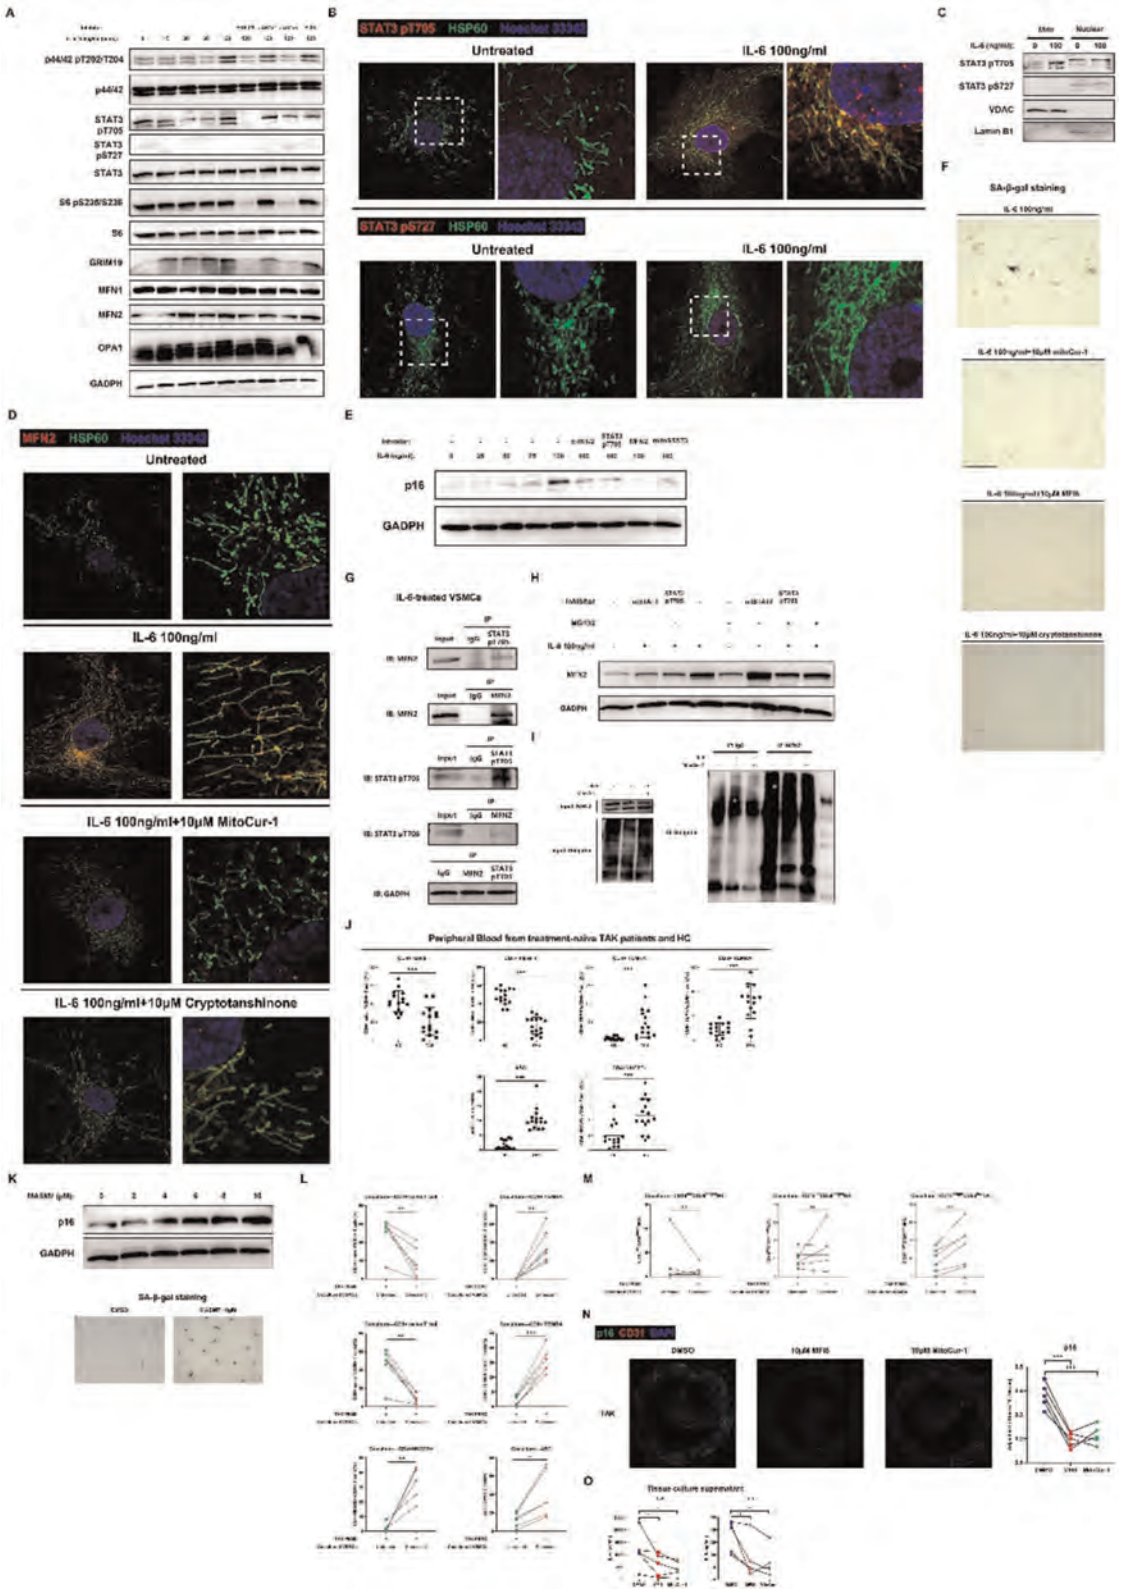

Figure 3. IL-6-induced prosenescent noncanonical mitochondrial-localized phosphorylated STAT3 (Tyr705) interact with MFN2 and prevented it from proteasomal degradation in VSMCs, resulting mitochondrial elongation in VSMCs. Coculture with senescent VSMCs lead to an immunosenescence-like and cytotoxic phenotype switch in cocultured TAK PBMCs. MitoCur-1 or MFI8 treatment ameliorates VSMCs senescence in ex vivo-cultured arteries from TAK patients.

Results: The features of premature VSMCs senescence, including upregulated p16 expression, more intense SA-β-gal staining, and SASP consisting of increased interleukin-6 (IL-6) and IL-8 expression, were detected in TAK patients, compared with age- and sex-matched control subjects (Figure 1). Treatment with conditioned medium of peripheral blood mononuclear cell (PBMC) from patients (TAK-PBMC CM) and coculture with TAK-PBMC exerted similar prosenescent effects on VSMCs via IL-6 signaling. RNA-Seq suggested that cellular senescence and IL-6-STAT3 pathway were upregulated, while oxidative phosphorylation pathway was downregulated in TAK-PBMC CM-treated VSMCs. TAK-PBMC CM treatment induced multiple senescence-associated mitochondrial dysfunctions that can be significantly improved by IL-6 receptor knockdown (Figure 2). IL-6-induced noncanonical mitochondrial localization of phosphorylated STAT3 (Tyr705) prevented mitofusin 2 (MFN2) from proteasomal degradation, and subsequently promoted mitochondrial elongation and cellular senescence in VSMCs. In addition, coculture with MFN2 activator MASM7-induced senescent VSMCs led to an immunosenescence-like and cytotoxic phenotype switch in TAK-PBMC that can be detected in treatment-naïve patients, including decreased frequencies of naïve T cells, increased frequencies of TEMRA cells, age-associated B cells and $CD16^{bright}CD56^{dim}$ NK cells, and upregulated NKG2D expression in CD4+ T cells (Figure 3). Of clinical relevance, although no significant difference of ESR and CRP levels was observed among patients with various senescent VSMCs proportions, patients with higher percentage of senescent VSMCs were more likely to relapse (Figure 1). However, senescent VSMCs proportions in vascular samples were comparable between patients taking long-term tocilizumab treatment (>1 year) and those receiving other therapies, which is contradicting our expectation. Instead, treatment with mitoCur-1 (mitochondrial STAT3 inhibitor) or MFI8 ameliorated (MFN2 inhibitor) VSMCs senescence in ex vivo cultured arteries of patients with TAK (Figure 3).

Conclusion: VSMCs of patients with TAK exhibited the features of cellular senescence. IL-6-mitochondrial STAT3-MFN2 signaling is an important driver of VSMCs senescence. This may provide new insights into the mechanisms governing inflammation in TAK.

Analysis of 245,388 Diverse Participants in the NIH All of Us Cohort Identifies VEXAS Resiliency in UBA1 M41L Somatic Mutation Carriers

Robert Corty[1] and Alexander Bick[2], [1]Vanderbilt University Medical Center, Nashville, TN, [2]Vanderbilt University, Nashville, TN

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: Late-Breaking Poster
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: VEXAS syndrome is a recently-discovered systemic auto-inflammatory disease caused by somatic mutation at position 41 in the X-linked gene *UBA1*.[1] First, 25 older men with M41T, M41V, or M41L with variant allele fraction (VAF) 35-80% were reported among quaternary referral populations of severely ill patients. A later study of 163,096 patients participating in a regional health system research cohort found 8 older men with the same *UBA1* M41X mutations, with VAF 9-74%.[2] Nearly all had severe anemia and macrocytosis, and five had a clinical diagnosis of VEXAS. This study population was >96% White and more than half of participants were >60 years old. Thus, there is a critical unmet need to define the prevalence and clinical consequences of somatic *UBA1* M41L mutation in a racially and geographically diverse population.

Methods: We analyzed 245,388 individuals with clinical-grade whole genome sequencing data in the NIH All of Us cohort v7 data release.[3] Somatic variants in *UBA1* were identified with *Mutect2* [4], annotated with *Annovar* [5], and filtered in R version 4.2.2 [6] based on published pragmatic guidelines.[7] VEXAS-associated SNOMED codes, laboratory abnormalities, and medications were defined by literature search of symptoms of confirmed cases.[1,2,8] Controls were identified in a 10:1 ratio based on matching age and sex.

Results: 74 participants in the NIH All of Us cohort harbor somatic mutation *UBA1* M41L and none have the other well-described variants, M41V or M41T. The M41L mutation was more common among women than men (n = 62 vs 12, $p < 0.001$) and no effect of age ($p = 0.17$) or ancestry ($p > 0.4$) was observed. The cases are age 20 to 83 and have VAF 4.5% to 33%. Their ancestry is 51% European, 27% African, and 19% admixed/Latino. The number of VEXAS-associated diagnosis codes was similar between cases and controls (4.3 vs 3.6, $p = 0.77$), but cases had an increased rate of asthma (27% vs 18%, $p < 0.001$), Tietze's syndrome (8% vs 2%, $p < 0.001$), and neutropenia (7% vs 2%, $p = 0.005$). The minimum observed hemoglobin was similar between cases and controls (11.5 vs 11.4 mg/dL) as was the maximum mean corpuscular volume (91.7 vs 91.4). Interestingly, cases were much more likely to be prescribed systemic steroids than matched controls (55% vs 0%, $p < 0.001$).

Conclusion: We describe the largest cohort of people with somatic mutation M41L in the *UBA1* gene and the largest cohort of women with a VEXAS-associated mutation. The diagnosis codes and laboratory values do not comport with the severe, systemic illness that has characterized our understanding of VEXAS to date. However, these cases were prescribed systemic steroids at a much higher rate than matched controls and are enriched for a few idiopathic inflammatory diagnoses suggesting an incompletely-appreciated inflammatory syndrome. These cases are younger, healthier, have lower VAF, and much better represent the demographic and geographic diversity of the United States than previous reports. We

hypothesize that many of the cases reported here will not develop VEXAS due to either somatic reversion or haplosufficiency of *UBA1*. Further characterization of the genetic and clinical trajectories in these individuals may permit strategies for risk stratification, monitoring, and treatment.

Table 1: Demographic characteristics of participants with somatic mutation M41L in UBA1 closely mirror their matched controls.

	case (n = 74)	control (n = 740)
age (mean (SD))	48.3 (16.3)	48.3 (16.2)
sex = Male (%)	12 (16%)	120 (16%)
genetic ancestry (%)		
African	20 (27%)	179 (24%)
American/Admixed	14 (19%)	164 (22%)
European	38 (51%)	367 (50%)
ethnicity (%)		
Hispanic or Latino	15 (20%)	164 (22%)
Not Hispanic or Latino	57 (77%)	557 (75%)

Figure 1: Participants with with somatic mutation M41L in UBA1 reside in geographically diverse parts of the United States.

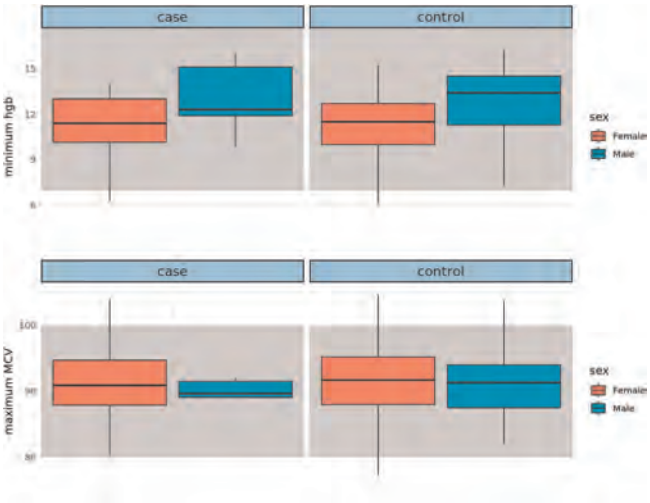

Figure 2: Participants with with somatic mutation M41L in UBA1 have similar minimum hemoglobin concentration and maximum mean corpuscular volume (MCV) as compared to matched controls.

Mutational Analysis of UNC93B1 Identifies Regulatory Regions Mutated in Human SLE

John Huizar[1], Victoria Rael[2], Julian Yano[2], Leianna Slayden[3], Madeleine Weiss[4], Robert Saxton[4], Bo Liu[5], Olivia Majer[6] and Gregory Barton[7], [1]UCSF, San Francisco, CA, [2]Division of Immunology and Molecular Medicine, Department of Molecular and Cell Biology, UC Berkeley, Berkeley, CA, [3]HHMI at UC Berkeley, Berkeley, CA, [4]UC Berkeley, Berkeley, CA, [5]Institut Pasteur of Shanghai, Chinese Academy of Sciences, Shangai, China, [6]Max Planck Institute for Infection Biology, Berlin, Germany, [7]UC Berkeley / HHMI, Berkeley, CA

SESSION INFORMATION

Session Date: Tuesday, November 14, 2023

Session Title: Late-Breaking Poster

Session Type: Poster Session C

Session Time: 9:00AM–11:00AM

Background/Purpose: Endosomal nucleic acid-sensing toll-like receptors 3, 7 and 9 are key innate immune sensors of dsRNA, ssRNA and ssDNA, respectively, whose activities must be tightly regulated to prevent systemic autoimmune or autoinflammatory disease (TLR7, TLR9) or virus-associated immunopathology (TLR3). The 12-pass transmembrane protein UNC93B1 chaperones nascent TLR3, TLR7 and TLR9 molecules from the ER to endosomes that support ligand recognition and signaling. Release from UNC93B1 is required for TLR3 and TLR9 signaling, whereas a persistent association between UNC93B1 and TLR7 is important for limiting TLR7 responses to endogenous nucleic acids.

Methods: Here we undertook a systematic scanning mutagenesis screen of all cytosolic and endosomal loops of UNC93B1 in murine RAW macrophages, totaling 93 mutated single or triplet amino acid residues.

Results: We identified both negative and positive regulatory regions - in particular, 21, 31 and 17 of these mutations yielded a 2-fold or higher enhancement of TNFa production downstream of TLR3, TLR7 or TLR9, respectively. The number and effect size of negative regulatory UNC93B1 mutations was noted to be highest for TLR7 responses.

We were subsequently contacted by several groups of clinicians who had identified patients with coding mutations in UNC93B1, including: (i) a family of 3 adolescent siblings and with pediatric onset isolated cutaneous tumid lupus, harboring a heterozygous T93I mutation; (ii) an adolescent girl with pediatric onset extended oligoarticular JIA, chillblain and tumid lupus rashes and an ataxic/dystonic movement disorder with CNS basal ganglia calcifications reminiscent of Aicardis-Goutieres syndrome, harboring a heterozygous R336C mutation not present in either of her parents; and (iii) a young man diagnosed at age 10 with SLE complicated by aggressive class IV nephritis, harboring a homozygous G590E mutation. When introduced in to human THP-1 monocytes and murine RAW macrophages, these mutations enhanced cytokine responses to TLR7 (expressed in mouse and human cells), TLR8 (human cells only), and to a lesser extent TLR3 (mouse cells only) stimulation, phenocopying mutants in the same UNC93B1 regions from our original screen. Knock-in mice have been generated for all three human variant alleles, and to date analysis of Unc93b1^(R336C) mice has revealed a 30% reduction in body weight, splenomegaly, expansion of Age-Associated B cells and plasma cells, monocytes and neutrophils, and titers of serum ANA IgG comparable to TLR7.1 transgenic animals.

Conclusion: Altogether our results implicate the UNC93B1-TLR7/8 axis in human monogenic autoimmune disease and provide a functional resource and analysis pipeline to assess the impact of yet-to-be-reported UNC93B1 mutations.

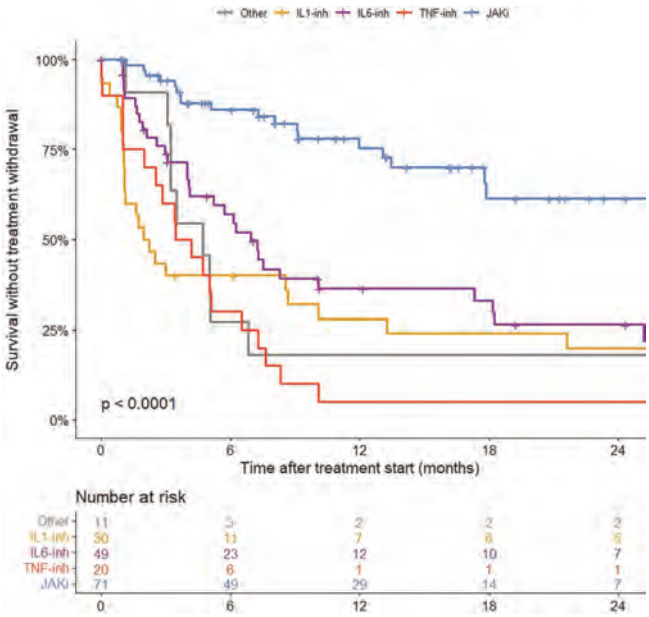
SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: Late-Breaking Poster
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: VEXAS (vacuoles, E1 enzyme, X-linked, autoinflammatory, somatic) syndrome is a monogenic disease of adults due to acquired somatic mutations of the *UBA1* gene. Patients present with a broad range of inflammatory and hematological manifestations, and the prognosis is severe. Due to its recent description, the therapeutic management is poorly codified and only based on small retrospective studies. The aim of this study was to evaluate the efficacy and safety of targeted therapies in a cohort of patients with VEXAS syndrome.

Methods: Multicenter retrospective study conducted within the French national VEXAS study registry between November 2020 and August 2023 including patients with genetically proven VEXAS syndrome who had received at least one targeted therapy. CR was defined by clinical remission, CRP < 10 mg/L and corticosteroid therapy less than 10 mg/day; partial response (PR) by clinical remission, CRP and corticosteroid therapy decreased by 50%; and no response by persistence of clinical activity and/or biological inflammatory syndrome and/or inability to decrease corticosteroid therapy.

Results: One hundred and ten patients (male 99%, median age 71 (68-79) years) who had received 194 targeted therapies were included. Treatments received were JAK inhibitor (JAKi) in 40% (n=78, ruxolitinib in 87%) of cases, anti-interleukin (IL)-6 antibody in 26% (n=51, tocilizumab in 92%), anti-IL-1 in 17% (n=33, anakinra in 91%), anti-TNFa in 10% (n=20), and another targeted therapy in 6% (n=12). Fifty-three patients (48%) received more than one targeted therapy. The main clinical features of VEXAS syndrome at the initiation of targeted therapy were constitutional symptoms (82%), skin involvement (76%) and inflammatory arthralgias (60%). Myelodysplastic syndrome was present in 28% of cases, without indication for specific hematological treatment. Median CRP at treatment initiation was 39 (19-57) mg/L and median prednisone dose received was 20 (10-35) mg/day. At 3 months, overall response (CR and PR) was 24% (CR 19% and PR 5%) with JAKi, 32% (CR 20% and PR 12%) with anti-IL-6, 9% with anti-IL-1, and 0% with anti-TNF or another targeted therapy. At 6 months, the overall response was 30% (CR 26% and PR 4%) with JAKi and 26% (CR 20% and PR 6%) with anti-IL-6. Corticosteroid withdrawal was similar between JAKi and anti-IL-6. Compared to JAKi, other therapies had significantly higher risk of treatment withdrawal during follow-up (P< 0.001, Figure 1). Treatment was stopped in 28% (n=22) of cases under JAKi with a median delay of 7.2 (3.4-12.4) months and in 69% of cases under anti-IL-6 with a median delay of 5.1 (2-9.1) months.



Survival without treatment withdrawal according to the targeted therapy used

The causes of discontinuation were primary failure, secondary failure, serious adverse event or death respectively in 43%, 14%, 19% and 19% with JAKi, 46%, 11%, 31% and 9% with anti-IL-6, 50%, 4%, 35% and 8% with anti-IL-1, and 74%, 5%, 16% and 5% with anti-TNFa.

Conclusion: This large multicenter cohort is the first to compare the efficacy and safety of targeted therapies in VEXAS syndrome. This study confirms the benefit of JAKi and tocilizumab with similar response rates, whereas the other targeted therapies appear to have lower efficacy. These results need to be confirmed in prospective therapeutic trials.

EP-104IAR (Extended-Release Fluticasone Propionate for Injectable Suspension): Topline and Key Secondary Results from a Phase 2 Randomized, Double-blind, Vehicle-Controlled Trial in Subjects with Knee Osteoarthritis

James Helliwell[1], **Amanda Malone**[1], Mark Kowalski[2], Asger Reinstrup Bihlet[3], Claire Miller[4], Alejandro Castillo Mondragon[5], Yanqi Li[6], Christine Dobek[7], Vik Peck[1], Mike Wilmink[8] and Lee Simon[9], [1]Eupraxia Pharmaceuticals, Victoria, BC, Canada, [2]Eupraxia Pharmaceuticals, Winchester, VA, [3]NBCD A/S, Soeborg, Denmark, [4]NBCD A/S, Copenhagen, Denmark, [5]NBCD, Copenhagen, Denmark, [6]NBCD A/S, Soborg, Denmark, [7]Eupraxia Pharmaceuticals, Edmonton, AB, Canada, [8]OrthoArizona, Phoenix, AZ, [9]SDG LLC, Cambridge, MA

SESSION INFORMATION

Session Date: Tuesday, November 14, 2023
Session Title: Late-Breaking Poster
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: EP-104IAR is being developed to treat OA symptoms. Previous results from non-clinical studies evaluating local joint safety in beagle dogs, in contrast to other corticosteroid preparations, indicated that the prolonged local residence time of EP-104IAR had no impact on cartilage health.[1] Safety and PK data from a Phase 1 trial in 24 OA knee patients were consistent with nonclinical findings and supported continued development of EP-104IAR.[2] This report describes the results of a Phase 2b trial in subjects with Knee OA.

Methods: Subjects were randomized 1:1 to a single intraarticular dose of EP-104IAR 25 mg, or vehicle and followed for 24 weeks. Males and females, ≥40 years, with a diagnosis of primary knee OA, Kellgren-Lawrence Grade 2-3 and symptoms (WOMAC Pain scores ≥ 4.0 to ≤9.0 (out of 10)) were enrolled. Subjects recorded weekly WOMAC Pain and monthly

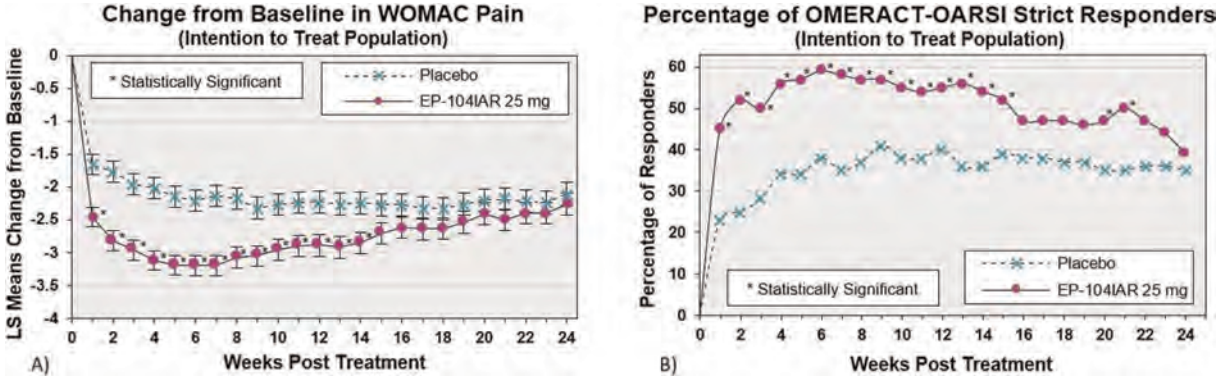

Figure 1: A) Least-squares mean change from baseline (and standard error) for the primary efficacy end point of Western Ontario and McMaster Universities Osteoarthritis Index (WOMAC)-A (pain) (n = 318). B) Percent of patients classified as OMERACT-OARSI strict responders (OMERACT-OARSI strict responder defined as a subject with a greater than 2-point change from baseline and a 50% reduction in baseline pain) (n=318).

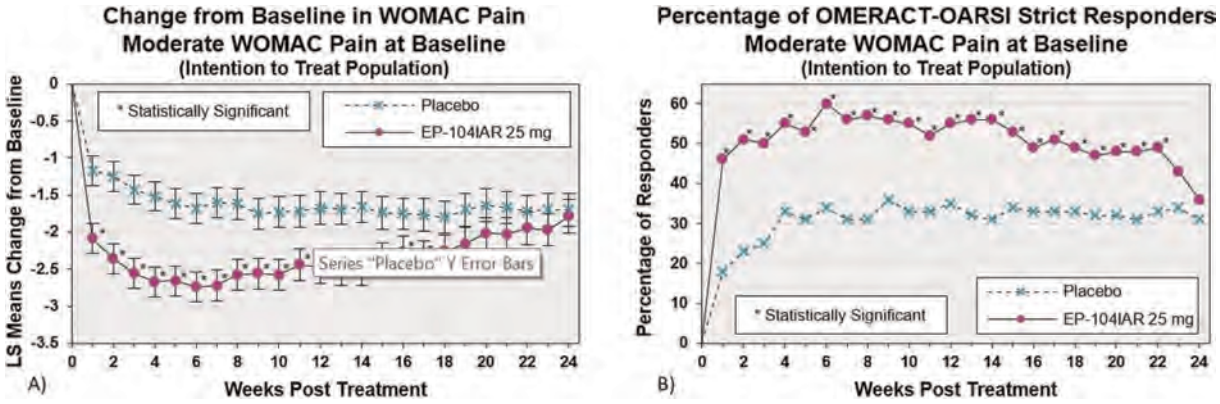

Figure 2: A) Least-squares mean change from baseline (and standard error) for the exploratory efficacy end point of Western Ontario and McMaster Universities Osteoarthritis Index (WOMAC)-A (pain) in the moderate sub-population (n = 214). B) Percent of patients classified as OMERACT-OARSI strict responders (OMERACT-OARSI strict responder defined as a subject with a greater than 2-point change from baseline and a 50% reduction in baseline pain) in the moderate sub-population (n=214). Moderate was defined as having an average baseline WOMAC-A score on entry between 3.5-6.5. Patients who's screening WOMAC-A scores were ≥4 but dropped below 4 on the day of injection were still eligible for the trial (potentially resulting in an average baseline pain <4).

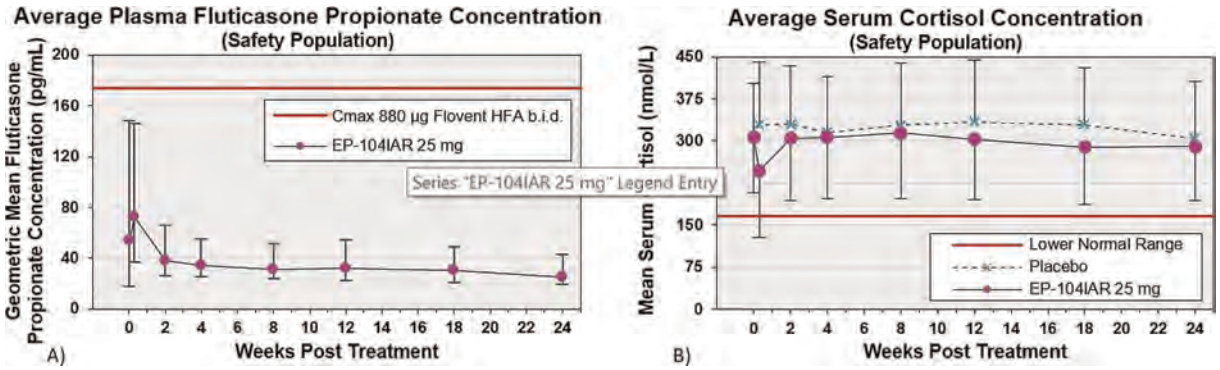

Figure 3: A) Geometric Mean ± SE plasma fluticasone concentrations following a single injection of EP-104IAR (n=163 received EP-104IAR). Red line demarcates the average Cmax fluticasone concentrations with b.i.d. dosing of 880 µg Flovent HFA. B) Geometric Mean ± SE serum cortisol concentrations. Red line demarcates lower bound of normal cortisol range (n=318).

WOMAC Total measurements on a diary device. Safety assessments included adverse events (AEs), vital signs, laboratory evaluations, and knee examinations. The primary endpoint was the change from baseline between treatments in WOMAC® Pain at Week 12.

Results: 318 subjects were dosed (163 EP-104IAR, 155 vehicle), median age = 64 years, 57.5% female. 68% had moderate OA pain (average baseline WOMAC Pain 3.5-6.5). Participants treated with EP-104IAR had significantly higher pain relief compared to vehicle in WOMAC Pain at Week 12 (change from baseline: -2.89 EP-104IAR, -2.23 vehicle; 95%CI -1.1, -0.2, p=0.004). This significant difference persisted until Week 14 in the full population and until Week 17 in subjects with moderate pain. A similar pattern was observed in the OMERACT-OARSI Strict Responders analysis: in allcomers % of OMERACT-OARSI Strict Responders was statistically different until Week 15 while in moderates there was statistical significance to Week 22 (both $p < 0.05$). Most AEs were mild/moderate. There were no EP-104IAR-related serious AEs or withdrawals. Mean serum cortisol and glucose values were similar in both treatment arms, no subjects developed adrenal insufficiency.

Conclusion: A single dose of EP-104IAR provided clinically and statistically significant pain relief for 14 weeks compared to vehicle. In subjects with moderate pain, significant pain-relief persisted for 17 weeks. Responder analyses in subjects with moderate pain demonstrated that clinically meaningful differences persisted for the majority of the study. This suggests EP-104IAR could offer clinically meaningful and safe benefit for substantially longer than any other currently marketed corticosteroids.

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: Late-Breaking Poster
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: There is an unmet need for treatments of knee OA. Diacerein is recommended for alleviating pain in OA patients for its anti-inflammatory effect by blocking interleukin-1β. Previous trials showed a small beneficial effect of diacerein on pain and joint space narrowing (JSN) in OA patients. However, none specifically targeted patients with an inflammatory OA phenotype who might benefit most from this therapy. Therefore, this trial aimed to determine the effect of diacerein on knee pain and effusion-synovitis over 24 weeks in patients with symptomatic knee OA and MRI-detected effusion-synovitis.

Methods: The DIaCerein for Knee osteoarthritis with EffusioN-Synovitis (DICKENS) study was a multicentre, randomised, double-blinded, placebo-controlled trial over 24 weeks. Patients aged 40-64 years who had significant knee pain (defined as a 0-100mm visual analogue scale (VAS) ≥ 40 mm) and MRI-detected effusion-synovitis were randomised to receive either diacerein (50 mg twice daily for the first 2 weeks, increasing to 100 mg twice daily afterwards if gastrointestinal side-effects acceptable) or identical placebo. Those with severe knee OA (Grade 3 JSN using the Osteoarthritis Research Society International (OARSI) atlas) were excluded. The primary outcome was improvement in knee pain on a 0-100mm VAS at 24 weeks. Secondary outcomes included improvements in effusion-synovitis, knee pain, function, and stiffness by the WOMAC, leg strength, and quality of life (the Assessment of Quality of Life (AQoL-8D) and the 5 level EuroQoL-5-dimensional version (EQ-5D-5L)). Pre-specified stratification analyses were conducted by effusion-synovitis (grade 1 or 2/3) at baseline.

Results: 262 patients (mean ± SD age 54.9±6.1 years, 147 females) were enrolled, and 88.5% completed the trial. At baseline, mean ± SD knee VAS pain (0-100) was 54.8±18.3, and median (interquartile range) effusion-synovitis volume was 4.6 (2.3 to 9.8) ml. After 24 weeks, there was no significant difference in changes in knee pain (VAS pain: -19.9 vs -18.6, p=0.77; WOMAC pain: -76.9 vs -70.4, p=0.64) or WOMAC function (-253.2 vs -234.0, p=0.68) and stiffness scores (-37.5 vs -31.4, p=0.34) between the diacerein and placebo groups. Between-group difference in change in effusion-synovitis volume was statistically significant (diacerein vs placebo: +0.4 ml vs -1.1 ml, p=0.002). There were no significant between-group differences in other secondary outcomes, except that improvement in AQoL-8D (0.03 vs 0.07, p=0.02) was significantly higher in the placebo group. Pre-specified analyses showed no between-group differences in change in knee symptoms in patients with either grade 1 or 2/3 effusion-synovitis at baseline. Adverse events were more frequent in the diacerein group, especially diarrhoea (38.6% vs 22.3%) and coloured urine (10.6% vs none).

Conclusion: In patients with symptomatic knee OA and effusion-synovitis, 50-100 mg twice daily of diacerein, compared to placebo, did not significantly improve knee pain or effusion-synovitis over 24 weeks. These findings do not support the use of diacerein in treating patients with knee OA and effusion-synovitis.

Improvement in Clinical and Patient-Reported Outcomes for Refractory Juvenile-Onset Systemic Sclerosis (jSSc) 6 Months to 2 Years After Autologous Stem Cell Transplantation (ASCT)

Kathryn Torok[1], Paulina Horvei[1], Franziska Rosser[1], Kirsten Rose-felker[2], Vibha Sood[2], Adam Olsen[2], Nicole Hogue[2], Vickie Vandergrift[2], Lauren Farver[2], Devin Mcguire[2], Jonathan Li[3], Haley Havrilla[2], Jessie Alexander[4], Shawna McIntyre[2] and Paul Szabolcs[1], [1]University of Pittsburgh; UPMC Children's Hospital of Pittsburgh, Pittsburgh, PA, [2]UPMC Children's Hospital of Pittsburgh, Pittsburgh, PA, [3]University of Pittsburgh Medical Center, Pittsburgh, PA, [4]Stanford Children's Hospital, Palo Alto, CA

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: Late-Breaking Poster
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Juvenile-onset systemic sclerosis (jSSc) is an inflammatory, fibrotic, and vasculopathic disease that causes severe multi-organ dysfunction leading to significant morbidity and early mortality.When patients with adult SSc are refractory to available immunomodulatory therapies clinical studies support the use of autologous stem cell transplant (ASCT), but data is limited in jSSc. Herein, we report the outcomes of five jSSc patients 6 months to 2 years after receiving ASCT.

Methods: All patients were referred to our multidisciplinary pediatric scleroderma center, had disease refractory to ≥3 immunomodulatory therapies, and met criteria for ASCT by severity of lung or skin disease, or both (Table 1). Our ASCT protocol began with stem cell mobilization with cyclophosphamide and filgrastim, collected via pheresis. Conditioning chemoradiation was then administered per an IRB-approved individual treatment plan (Patients 1-3) or per our clinical trial NCT03630211 (Patients 4-5) with rituximab, anti-thymocyte globulin (ATG), total body irradiation 600 cGy with lung and kidney shielding, and cyclophosphamide or thiotepa +/- alemtuzumab. CD34+ selected cryopreserved autologous peripheral blood stem cell graft was infused on day 0. Antimicrobial prophylaxis and viral monitoring (EBV, CMV, adenovirus) followed institutional standards. Corticosteroids were discontinued by week 5 post-ASCT. Clinical outcomes and patient reported measures were collected at baseline (pre-ASCT), 6, 12 and 24 months-post ASCT.

Results: All 5 patients engrafted, with median neutrophil engraftment on day 10.8 (range 10-11) and median platelet engraftment (>50K) on day 18.8 (range 16-20). Patients globally improved across physician-measured and patient reported outcomes (Table 2). There was an average overall disease HAQ VAS improvement of 75% (range: 48-99%). In the skin/musculoskeletal domain, all 5 patients met the mRSS MCID by their 6-month visit, with an average of 87% improvement (range 74-100%), sustained at 1 and 2 years follow-up. In the gastrointestinal domain, four patients displayed improvement in their GIT by a mean 55% (range 38-68%) and one remained unchanged. Three had repeat lower esophageal manometry with an average improvement of 15 mmHg (range: 5-26 mmHg) associated with an average reduction in esophageal acid exposure by 67%. In the pulmonary domain, FVC overall remained relatively stable, however DLCO improved by >10% among two patients and 5-10% among two other patients. Global function, measured by the CHAQ from a rheumatology standpoint, demonstrated a significant mean reduction among all patients in CHAQ at 6 months by -0.60, surpassing the MCID threefold, and from a BMT standpoint, the performance functional score increased from a mean score of 68 (range: 50-80) to 86 (range: 70-100) toward healthy status.

Table 1. Baseline juvenile systemic sclerosis (jSSc) patient characteristics prior to autologous stem cell transplant (ASCT).

ID	Race	Ethnicity	Sex	Age at Onset (years)	Age at time of ASCT (years)	Disease Duration at time of ASCT (years)	Disease Subtype	Treatment Prior to ASCT	Major organ manifestations	Auto-antibody positivity	mRSS
Patient 1	White	Non-Hispanic	M	15	18	3	dcSSc	Cytoxan, Rituximab, Mycophenolate mofetil, Methotrexate	Progressive mod-severe ILD (DLCO 35%, FVC 52%), Mod-severe mRSS, joint contracture small to large joints, RP, GI esophageal dysmotility	Scl-70	24
Patient 2	Black	Non-Hispanic	F	7	15	8	lcSSc	Cytoxan, Mycophenolate mofetil, Methotrexate	Progressive ***severe*** ILD (DLCO 28%, FVC 48%), Skin thickening minimal after Cytoxan; GI esophageal dysmotility	ANA only	5
Patient 3	White	Hispanic	F	13	21	7	Overlap	Cytoxan, IVIG, Rituximab, Mycophenolate mofetil, Methotrexate, Baricitinib	Progressive skin thickening, weakness myositis, joint contracture small to large joints; restrictive lung disease from muscle weakness and ST; GI esophageal dysmotility	PM-Scl	23
Patient 4	White	Hispanic	F	11	18	7	dcSSc	Rituximab, Mycophenolate mofetil, IVIG, Prednisone	Progressive skin thickening, recent onset ILD, joint limitation, fatigue/endurance, mod-server RP with recurrent digital ulcers	Scl-70	28
Patient 5	Black	Non-Hispanic	F	16	18	2	Overlap	Rituximab, Mycophenolate mofetil, IVIG, Prednisone	Severe GI disease (TPN dependent), progressive skin thickening, myositis/myopathy, PHTN	U3-RNP	28

Abbreviations: dcSSc (diffuse cutaneous systemic sclerosis); lcSSc (limited cutaneous systemic sclerosis); Overlap (overlap SSc and dermatomyositis); Scl-70 (scleroderma-70 anti-topoisomerase antibody); PM-Scl (polymyositis-scleroderma overlap antibody); U3-RNP (U3 – ribonucleoprotein antibody, fibrillarin) ; ILD (interstitial lung disease); PHTN (pulmonary arterial hypertension)

Abbreviations: ASCT (autologous stem cell transplant); mRSS (modified Rodnan skin score); VAS (Visual Analog Scale); HAQ (Health Assessment Questionnaire); CHAQ (Childhood Health Assessment Questionnaire); LES (lower esophageal sphincter); GIT (scleroderma gastrointestinal tract instrument); FVC (forced vital capacity); DLCO (diffusing capacity for carbon monoxide); GLI2012 prediction equations used for both FVC and DLCO; KPS (Karnofsky Performance Scale); LPS (Lansky Play-Performance Scale). KPS and LPS scales are 0 to 100; higher number reflects normal function/ healthy status.

* Indicates a patient reported outcome. VAS scale on HAQ, GIT, CHAQ are 0 to 3; higher number reflects more interference of disease with function.

Conclusion: Among our cohort of refractory jSSc patients with moderate-severe disease, ASCT was a safe and effective intervention that provided sustained global disease modifying improvement throughout 2 years after transplant. Most notable improvements were in skin, gastrointestinal, pulmonary, and patient-reported functional domains.

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: Late-Breaking Poster
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Tapering of tumor necrosis factor inhibitor (TNFi) treatment in patients who have reached sustained remission is debated in current guidelines, and further data are needed regarding the long-term consequences of such strategies. Our aim was to assess the 3-year effect of tapering to withdrawal of TNFi versus continued stable TNFi on disease activity flare and remission status.

Methods: ARCTIC REWIND was a randomized, multicenter, open-label, non-inferiority trial including RA patients in sustained remission for ^{3}12 months on stable TNFi therapy, with no swollen joints at inclusion. Patients were randomized 1:1 to taper to withdrawal of TNFi (four months half-dose, thereafter withdrawal) or continue stable TNFi therapy, with scheduled visits every four months for 3 years. Full-dose TNFi therapy was reinstated if a flare occurred. The primary endpoint of the current study was disease activity flare over 3 years. A flare was defined as a combination of DAS >1.6 (loss of remission status), an increase in DAS ≥0.6 units (change above minimal detectable change) and ≥2 swollen joints, or if the physician and patient agreed that a clinically significant flare had occurred. Secondary endpoints included remission status (ACR/EULAR Boolean 2.0 and DAS), medication use and adverse events (AE). Flare-free survival was analyzed by Kaplan-Meier, flare by center adjusted Cox regression, and remission status by logistic regression adjusted for baseline status, analyzed in a per protocol population.

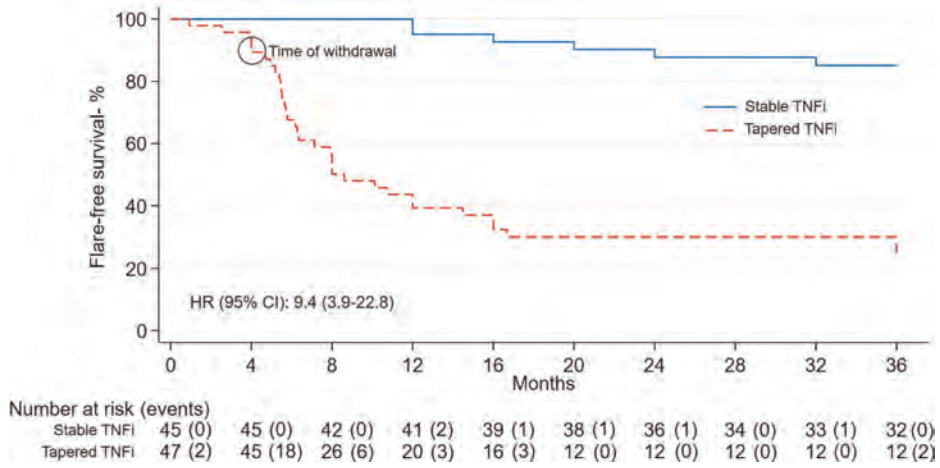

Figure 1: Proportions of patients without a flare over the study period

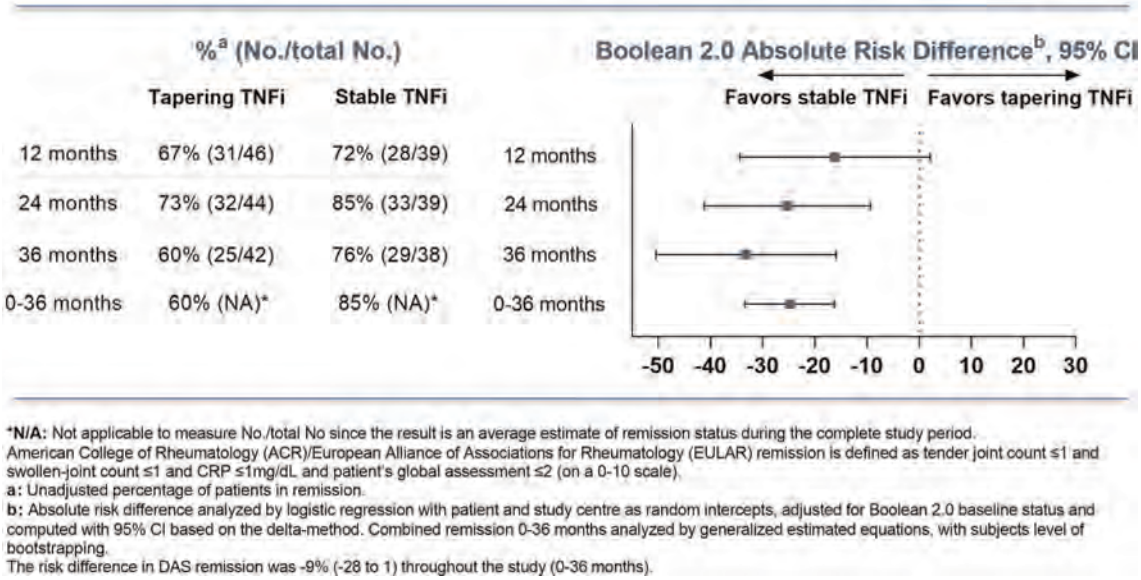

*N/A: Not applicable to measure No./total No since the result is an average estimate of remission status during the complete study period.
American College of Rheumatology (ACR)/European Alliance of Associations for Rheumatology (EULAR) remission is defined as tender joint count ≤1 and swollen-joint count ≤1 and CRP ≤1mg/dL and patient's global assessment ≤2 (on a 0-10 scale).
a: Unadjusted percentage of patients in remission.
b: Absolute risk difference analyzed by logistic regression with patient and study centre as random intercepts, adjusted for Boolean 2.0 baseline status and computed with 95% CI based on the delta-method. Combined remission 0-36 months analyzed by generalized estimated equations, with subjects level of bootstrapping.
The risk difference in DAS remission was -9% (-28 to 1) throughout the study (0-36 months).

Figure 2: ACR/EULAR Boolean 2.0 remission status

Table: Medication use

% (No./total No.)	Tapering TNFi	Stable TNFi
bDMARD/tsDMARD treatment at 3-year follow-up[1]:		
• No bDMARD/JAKi	29% (12/42)	0% (0/38)
• Same TNFi as baseline	62% (26/42)	89% (34/38)
• Other TNFi	10% (4/42)	5% (2/38)
• JAKi	0% (0/42)	5% (2/38)
csDMARD co-medication increase at 3-years follow-up compared to baseline[1]	8% (3/42)	3% (1/38)
Glucocorticoids during the study:		
- ≥1 treatment period with systemic glucocorticoids	23% (11/47)	13% (6/45)
- ≥1 intraarticular glucocorticoids injections	46% (21/47)	23% (10/45)

[1]The analyses were performed in patients that completed 3-years follow up in a per-protocol population

Abbrevations:
bDMARD: biological disease-modifying antirheumatic drug
tsDMARD: targeted synthetic disease-modifying antirheumatic drug
csDMARD: conventional synthetic disease-modifying antirheumatic drug
JAKi: Janus Kinase inhibitor

Results: Of 99 randomized patients, 92 received the allocated therapy, and 80 (87%) completed 3-year follow-up. Mean baseline DAS was 0.8 in the tapering TNFi group, and 0.9 in the stable TNFi group. csDMARD co-medication was used by 89% in the tapering group and 91% in the stable group. After 3 years, 25% (95% CI: 13 to 38) remained flare-free in the tapering TNFi group compared to 85% (70 to 93) in the stable TNFi group (Fig 1), with corresponding hazard ratio for flare of 9.4 (3.9 to 22.8). Most patients regained DAS remission within the next visit after a flare (81% in tapering group, 67% in stable group). We observed significantly lower Boolean 2.0 remission rates in the tapering TNFi group than the stable TNFi group throughout the study period (Fig 2), adjusted risk difference 0-36 months -25% (-33 to -16), p< 0.001 (Boolean 1.0 revealed similar results). Systemic glucocorticoids (≥1 treatment period during the study) were used by 23% in the tapering TNFi group and 13% in the stable TNFi group during the study, and 10% switched to other types of TNFi or JAK inhibitor treatment in the tapering group, and 11% in the stable group (Table). AE/serious AE occurred in 81%/21% of the patients in the tapering group, and 89%/11% of the patients in the stable group.

Conclusion: A large majority of RA patients in remission tapering TNFi to withdrawal experienced a flare within 3 years, while a minority of patients receiving stable TNFi treatment flared over the same time period. Even though most patients regained remission within the next visit after a flare, TNFi tapering was associated with significantly lower Boolean 2.0 remission rates throughout the study. These findings do not support tapering of TNFi treatment among RA patients in sustained remission.

Early Clinical Development of CIT-013, a First in Class NETosis Inhibitor, in a Randomized Phase I Dose Escalation Study in Healthy Volunteers Demonstrating Potent Inhibition of LPS Induced Neutrophil Extracellular Trap Formation

Leonie Middelink[1], Renato Chirivi[2], Helmuth van Es[2], Eric Meldrum[2], Peter van Zandvoort[2], Tirza Bruurmijn[2], Matthijs Moerland[3] and **Patrick Round**[2], [1]Middelinc., Utrecht, Netherlands, [2]Citryll BV, Oss, Netherlands, [3]CHDR, Leiden, Netherlands

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: Late-Breaking Poster
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Aberrant Neutrophil Extracellular Traps (NETs) production contributes to the pathophysiology of multiple inflammatory and autoimmune diseases such as Rheumatoid arthritis (RA) Hidradenitis suppurativa (HS), Systemic Lupus Erythematosus and ANCA-Associated Vasculitis. Here we report the first in human studies of a humanized

monoclonal antibody (CIT-013) with high affinity for citrullinated histones H2A and H4. CIT-013 inhibits NET formation and accelerates the clearance of NETs and netting neutrophils to lower NET tissue burden in vivo with significant anti-inflammatory consequences in pre-clinical studies (Chirivi et al 2021; DOI 10.1038/s41423-020-0381-3).

The objectives of the studies were:

- Part A: to assess safety, tolerability, andpharmacokinetics (PK) of intravenous (IV) single ascending doses of CIT-013.
- Part B: to assess safety, tolerability, PK, and pharmacodynamics (PD) by inducing systemic NET formation by nano-dosing lipopolysaccharide (LPS) after single IV doses of CIT-013.
- Part C: to evaluate safety, tolerability, bioavailability, and PK of single subcutaneous (SC) doses of CIT-013.

Methods: The study was a randomized, double-blind, placebo-controlled, phase I study with a single dose of CIT-013 in healthy volunteers. In part A, single ascending doses of 0.1, 0.3, 1.0, 1.8 and 3.0 mg/kg CIT-013 or placebo were administered IV. In part B, 0.3 or 0.9 mg/kg CIT-013 or placebo were given IV before 2ng/kg LPS. LPS will trigger the innate immune system resulting in measurable circulating NET components in the blood. In part C, 50 or 100 mg CIT-013 or placebo was administrated SC. Endpoints were safety, tolerability, and PK in all three parts, plus PD in part B.

Results: In total 73 healthy volunteers were dosed (Figure 1) and no severe, or Serious Adverse Events (SAEs) were reported. In part A, IV administration of CIT-013 was well tolerated up to 0.3 mg/kg alone, and 0.9 mg/kg with premedication. Dose limiting toxicity was seen at doses greater than 0.9 mg/kg with chest discomfort associated with elevated cytokines, CRP and temperature as the most common AEs. CIT-013 given SC at 50 mg or 100 mg was well tolerated. The only AEs of note were mild injection site reactions. PK was consistent with what would be expected from an IgG1 human monoclonal antibody with a half-life of approximately 7 days. The bioavailability of 100 mg given SC was 66% compared to IV administration and equated to approximately 0.7 mg/kg given IV (Figure 2). CIT-013 markedly reduced LPS induced levels of systemic NET components, equally well at 0.3 and 0.9 mg/kg, demonstrating effective target engagement (Figure 3).

Conclusion: CIT-013 is well tolerated up to 0.3 mg/kg intravenously and up to 0.9 mg/kg with pre-medication. Dose limiting toxicity was seen when given intravenously, with chest discomfort associated with elevated cytokines, CRP and temperature which was markedly reduced by subcutaneous administration. Near complete inhibition of circulating NET components at 0.3 and 0.9 mg/kg CIT-013 in the LPS challenge study showed effective target engagement. These data form the basis for further development of CIT-013 in RA and HS.

Part /Cohort	N	Gender		Age (years)		BMI (kg/m²)	
		Male	Female	mean	SD	mean	SD

SESSION INFORMATION

Session Date: Tuesday, November 14, 2023
Session Title: Late-Breaking Poster
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: LNK01001 is a selective oral JAK1 inhibitor in clinical development for treating autoimmune and inflammatory diseases, including rheumatoid arthritis (RA). Here, we report the 24-week efficacy and safety results of LNK01001 in patients with moderate to severe active RA who had an inadequate response to csDMARDs.

Methods: Eligible participants aged 18 to 75 with a diagnosis of moderate to severe active RA who met ACR/EULAR 2010 criteria and had an inadequate response to csDMARDs, were randomized (1: 1: 1) to receive LNK01001 12mg or 24mg twice daily (BID), or placebo for 12 weeks, followed by a 12-week extension treatment with LNK01001 12mg or 24mg. The primary endpoint was the proportion of patients achieving an ACR20 response at Week 12.

Results: All 156 patients randomized were included in the analysis. The mean age was 52.4 years, and 76.9% were female, mean DAS28-CRP score was 5.884. Baseline characteristics were similar across treatment groups. At week 12, a significantly higher proportion of patients achieved ACR20, ACR50 and ACR70 in LNK01001 12 mg and 24 mg groups compared with the placebo group (ACR20: 60.0% [95%CI: 45.2, 73.6], 73.1% [95%CI: 59.0, 84.4], vs 31.5% [95%CI: 19.5, 45.6], both doses $p< 0.01$; ACR50: 40.0% [95%CI: 26.4, 54.8], 42.3% [95%CI: 28.7, 56.8], vs 9.3% [95%CI: 3.1, 20.3], both doses $p< 0.001$; and ACR70: 12.0% [95%CI: 4.5, 24.3], 23.1% [95%CI: 12.5, 36.8], vs 1.9% [95%CI: 0.0, 9.9], both doses $p < 0.05$). A statistically significant difference was reached as early as Week 1 in ACR20 for both doses of LNK01001 vs placebo (18.0% [95%CI: 8.6, 31.4], 23.1% [95%CI: 12.5, 36.8], vs 0% [95%CI: 0, 6.6], both doses $p < 0.01$). Disease activity reduction measured by DAS28-CRP and functional ability improvement of HAQ-DI were significant in patients treated with LNK01001 compared to patients treated with placebo (-2.518, -2.614, vs -1.263, both doses $p < 0.0001$; and -0.64, -0.73, vs -0.34, both doses $P < 0.01$). During extension treatment, the proportion of patients achieving ACR20/50/70, DAS28 (≤ 3.2 and < 2.6), SDAI (≤ 11 and ≤ 3.3) and CDAI (≤ 10 and ≤ 2.8) response increased steadily over time. At week 24, 91.1% (95%CI: 78.8, 97.5) and 90.7% (95%CI: 77.9, 97.4) of patients achieved ACR20 in LNK01001 12mg and 24mg group, respectively.

The most frequently reported TEAE in patients receiving LNK01001 was hyperlipidemia. No serious infection, malignancy, venous thromboembolism or major adverse cardiovascular events were reported up to 24 weeks.

Conclusion: Treatment with LNK01001 12 mg or 24 mg BID up to 24 weeks in patients with moderate to severe active RA and an inadequate response to csDMARDs were generally safe, and well tolerated with most TEAEs being mild to moderate. Both doses were superior to placebo in reducing the severity of rheumatoid arthritis over a period of 12 weeks across multiple efficacy end points.

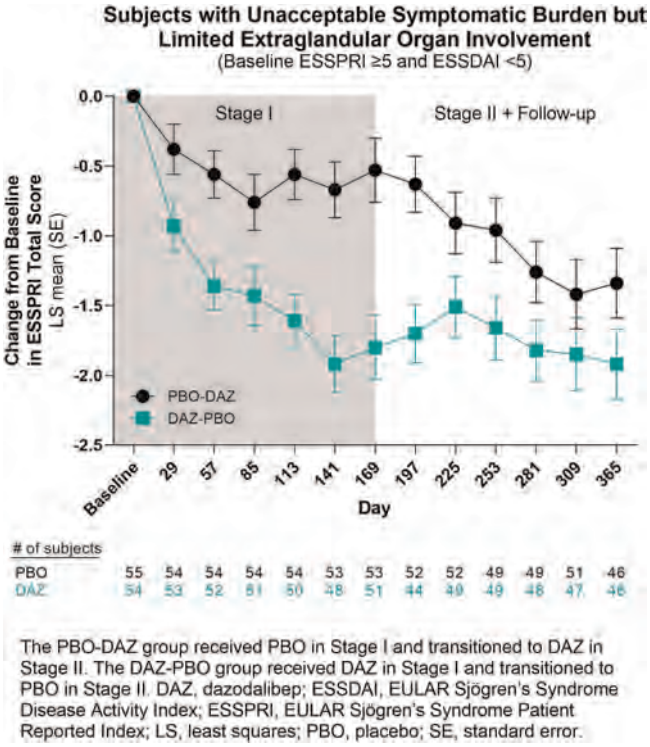
SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: Late-Breaking Poster
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Dazodalibep (DAZ) is a non-antibody fusion protein that acts as a CD40L antagonist and blocks costimulatory signals between immune cells, including T cells, B cells, and antigen-presenting cells. Previously, we reported that the primary endpoint, the change from baseline to Day 169 in the EULAR Sjögren's Syndrome Patient Reported Index (ESSPRI), was achieved in the population of subjects with unacceptable symptomatic burden but limited extraglandular organ involvement (NCT04129164).[1] Here, we report the efficacy and safety of DAZ therapy in this population through the crossover period of the study.

Methods: We performed a randomized, double-blind, placebo-controlled, crossover study to evaluate DAZ therapy in adult subjects with Sjögren's Disease having an ESSPRI score ≥ 5 and EULAR Sjögren's Syndrome Disease Activity Index score < 5. Eligible subjects were randomized 1:1 to receive intravenous DAZ 1500 mg or PBO Q2W x 3 doses, and then Q4W x 4 additional doses (Stage I). Starting on Day 169, subjects initially randomized to DAZ transitioned to PBO Q4W x 5 doses (DAZ-PBO) and subjects randomized to PBO were switched to DAZ Q4W x 5 doses (PBO-DAZ); all were then followed for 12 weeks (Stage II).



Adjusted mean change from baseline in ESSPRI total score.

Treatment-emergent AEs in Stage II Preferred term, n (%)	PBO-DAZ N=52	DAZ-PBO N=48
Nasopharyngitis	2 (3.8)	6 (12.2)
COVID-19	9 (17.3)	5 (10.2)
Arthralgia	1 (1.9)	3 (6.1)
Constipation	0	3 (6.1)
Gastroesophageal reflux disease	0	3 (6.1)
Urinary Tract Infection	2 (3.8)	3 (6.1)
Headache	4 (7.7)	1 (2.0)

The PBO-DAZ group received PBO in Stage I and transitioned to DAZ in Stage II. The DAZ-PBO group received DAZ in Stage I and transitioned to PBO in Stage II. AE, adverse event; DAZ, dazodalibep; PBO, placebo.

Most frequently reported treatment-emergent AEs occurring in ≥5% of subjects.

Results: A total of 109 eligible subjects were randomized (DAZ, N=54; PBO, N=55), with 102 (93.6%) completing Stage I and 94 (86.2%) completing Stage II. In the PBO-DAZ group, the change from baseline in ESSPRI total score (LS mean ± SE) improved from –0.5 ± 0.2 at Day 169 to –1.3 ± 0.3 at Day 365. In the DAZ-PBO group, the change from baseline in ESSPRI total score achieved during Stage I was sustained during the crossover period through Day 365 (Day 169: –1.8 ± 0.3; Day 365: –1.9 ± 0.3). In the PBO-DAZ group, the proportion of subjects achieving an ESSPRI response (≥1 point or ≥15% improvement in ESSPRI total score) at Day 169 was 32.7% (18/55) and continued improvement was observed during the crossover period (Day 365: 50.0% [26/52]). In the DAZ-PBO group, the proportion of subjects achieving an ESSPRI response at Day 169 was 66.7% (36/54) and this treatment effect was largely sustained through the crossover period (Day 365: 57.1% [28/49]). During Stage II, the subjects in the PBO-DAZ group exhibited improvement in the Functional Assessment of Chronic Illness Therapy-Fatigue score, and Patient's Global Impression of Severity score during the crossover period.

In Stage II, 66 of 101 subjects reported an AE (DAZ-PBO: 32 [65.3%]; PBO-DAZ: 34 [65.4%]) and the majority were mild/moderate in severity. Two SAEs were reported in two subjects in the DAZ-PBO group (urinary tract infection, invasive ductal breast carcinoma), and one SAE was reported in the PBO-DAZ group (atrial flutter). One subject in the PBO-DAZ group discontinued the study during Stage II due to an AE (rash).

Conclusion: The results during Stage II provide further evidence of the clinical efficacy of DAZ in Sjögren's disease and support the primary endpoint result. DAZ was generally safe and well tolerated in Stage II, although larger trials of DAZ therapy for this indication are warranted to further explore its safety profile and confirm its clinical efficacy.

Abstract Number: L11

Risk of Cardiovascular Events According to Biological Agent Exposure in Patients with Ankylosing Spondylitis: A Korean Population-based Study

Oh Chan Kwon, Hye Sun Lee, Juyeon Yang, Yong-Beom Park and Min-Chan Park, Yonsei University College of Medicine, Seoul, South Korea

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: Late-Breaking Poster
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Patients with ankylosing spondylitis (AS) have a higher risk of cardiovascular events than controls. Although biological disease-modifying anti-rheumatic drugs (bDMARDs) are efficacious in treating AS, their effect on risk of cardiovascular events remains unclear. This study evaluated the risk of cardiovascular events according to tumour necrosis factor inhibitors (TNFis) and interleukin-17 inhibitors (IL-17is) exposures in patients with AS.

Methods: We extracted the data of 43,502 patients diagnosed with AS from 2010 onwards and without prior history of cardiovascular events from the Korean nationwide database. Cardiovascular events were defined as incident myocardial infarctions or strokes. Patients were followed-up through 2021. We used multivariable time-dependent Cox models to estimate the adjusted hazard ratios [HRs] and 95% confidence intervals [CIs] for cardiovascular events, comparing TNFis exposure (vs. bDMARDs non-exposure) and IL-17is exposure (vs. bDMARDs non-exposure and vs. TNFis exposure).

Results: The incidence rates of cardiovascular events in periods of bDMARDs non-exposure, TNFis exposure, and IL-17is exposure were 18.66, 8.92, and 12.87 per 10,000 person-years, respectively. TNFis exposure (vs. bDMARDs non-exposure) was significantly associated with a lower risk of cardiovascular events (adjusted HR 0.697, 95% CI 0.499–0.974), whereas IL-17is exposure (vs. bDMARDs non-exposure) was not (adjusted HR 0.958, 95% CI 0.133–6.888). The risk of cardiovascular events did not differ between IL-17is and TNFis exposures (adjusted HR 1.373, 95% CI 0.188–10.029).

Table 1. Characteristics of the study population

	N = 43,502
Demographics

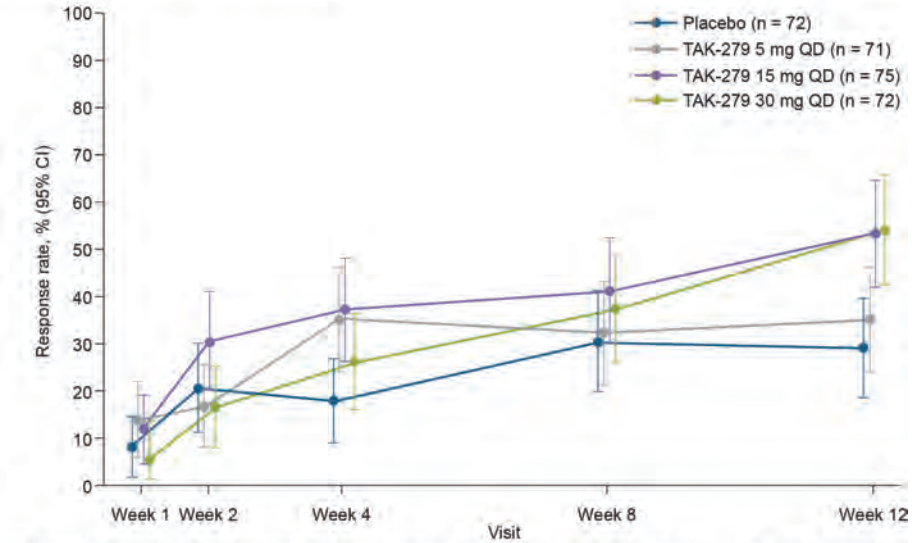
SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: Late-Breaking Poster
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: TYK2 mediates signaling by key cytokines involved in the pathogenesis of immune-mediated inflammatory diseases such as psoriatic arthritis (PsA) and psoriasis (PsO). TAK-279 is a highly selective, oral, allosteric TYK2 inhibitor shown to be clinically effective with an acceptable safety profile in a phase 2b trial in patients with moderate-to-severe PsO (Armstrong *et al*. AAD 2023).The current study evaluated efficacy and safety of TAK-279 in patients with active PsA treated over 12 weeks.

Methods: This phase 2b randomized, multicenter, double-blind, placebo (PBO)-controlled, dose-ranging study (NCT05153148) was conducted at 45 sites in North America and Europe. Eligible patients were aged ≥ 18 years, with PsA symptoms for ≥ 6 months prior to screening, met CASPAR criteria, and had ≥ 3 tender and ≥ 3 swollen joint counts (TJC/SJC) at enrollment despite prior NSAID, DMARD or biologic treatment. Patients were randomized 1:1:1:1 to receive oral TAK-279 5 mg, 15 mg, 30 mg, or PBO, once daily for 12 weeks. Primary endpoint: ACR 20 response at Week 12. Secondary endpoints at Week 12 included: ACR 50, ACR 70, PASI 75 responses (in patients with ≥ 3% BSA), change from baseline in TJC/SJC, physician global assessment (PhGA) of PsA, and safety.

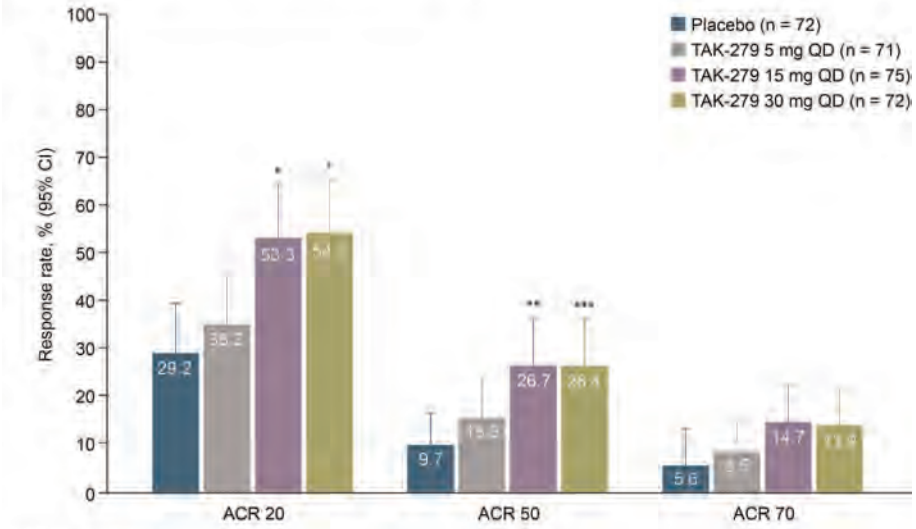
Results: In total, 290 patients were randomized and treated; 245 completed 12 weeks' treatment. Baseline characteristics were generally comparable across groups (except for a lower mean TJC in the 30 mg group); 58.6% had BSA ≥ 3% (of which mean baseline PASI score was 6.2), and 32.1% had prior biologic use (20.7% TNFis). Mean baseline hsCRP was 7.0 mg/L; 45.9% had hsCRP ≥ 3 mg/L. The primary endpoint was met with a significantly greater proportion of patients achieving ACR 20 with TAK-279 15 mg and 30 mg vs PBO (53.3% and 54.2% vs 29.2%, both $p = 0.002$; **Figure 1**). ACR

Figure 1. ACR 20 response over time.



The ACR20 is a composite measure defined as both improvement of 20% in the number of tender and number of swollen joints, and a 20% improvement in three of the following five criteria: patient global assessment of psoriatic arthritis, physician global assessment of psoriatic arthritis, patient global assessment of psoriatic arthritis pain, Health Assessment Questionnaire - Disability Index and high-sensitivity C-reactive protein.
CI, confidence interval.

Figure 2. ACR 20/50/70 responses at Week 12.



*ACR 20: $p = 0.002$ versus placebo.
p values for ACR 50 are nominal: **$p = 0.005$, ***$p = 0.009$ versus placebo.
CI, confidence interval; QD, once daily.

Table 1. Safety overview.

	Placebo (n = 72)	TAK-279 5 mg QD (n = 71)	TAK-279 15 mg QD (n = 75)	TAK-279 30 mg QD (n = 72)

Aphthous ulcer	0	0	1 (1.3)	6 (8.3)
Dermatitis allergic	0	1 (1.4)	1 (1.3)	4 (5.6)
Rash maculo-papular	0	0	2 (2.7)	4 (5.6)

*TEAEs occurring at ≥ 5% by preferred term in any treatment arm.
CPK, creatine phosphokinase; QD, once daily; TEAE, treatment-emergent adverse event; URTI, upper respiratory tract infection.

50 response rates were also higher in the TAK-279 15 mg and 30 mg groups vs PBO ($p = 0.005$ and $p = 0.009$, respectively**; Figure 2).** PASI 75 response was highest in the 30 mg group vs other doses and PBO (45.7% [30 mg] and 28.3% [15 mg] vs 15.4% [PBO]; $p = 0.002$ and $p = 0.101$, respectively). A numerically higher proportion of patients treated with TAK-279 15 mg and 30 mg achieved ACR 70 than with PBO (**Figure 2**). Numerical reductions were observed in mean change from baseline in

the TJC/SJC in all groups, with higher reductions with the 15 mg and 30 mg doses vs PBO and 5 mg TAK-279. Improvements from baseline were seen in PhGA of PsA in all TAK-279 groups vs PBO (5 mg [p = 0.016]; 15 mg [p = 0.004]; 30 mg [p = 0.003]). Safety outcomes are summarized in **Table 1**. Nasopharyngitis, upper respiratory tract infections, headache and rash were the most common treatment-emergent adverse events (TEAEs) in TAK-279-treated patients. No opportunistic infections, major adverse cardiovascular events or differences in mean laboratory parameters of interest were observed, compared with PBO. Serious and grade 3 or higher TEAEs occurred infrequently and at a similar rate in the TAK-279 and PBO groups.

Conclusion: TAK-279 was well tolerated and demonstrated superior dose-dependent efficacy to PBO over 12 weeks of treatment in patients with active PsA. Its safety profile was consistent with that observed in the phase 2b PsO study.

An Open-label, Multicenter, Phase 1/2 Study to Assess Safety, Efficacy and Cellular Kinetics of YTB323, a Rapid Manufacturing CAR-T Cell Therapy Targeting CD19 on B Cells, for Severe Refractory Systemic Lupus Erythematosus: Preliminary Results

Josefina Cortés Hernández[1], Pere Barba[2], Mònica Linares Alberich[3], Ozana Fischer[4], Beata Kovacs[4], Thomas Calzascia[4], David Pearson[4], Ana-Laura Jordán Garrote[5], Tiina Kirsilä[4], Richard Siegel[4], Tamas Shisha[4], Giulio Cavalli[4] and Peter Gergely[4], [1]Vall d'Hebron Institute of Research (VHIR) and Hospital Universitari Vall d'Hebron, Universitat Autonoma de Barcelona, Barcelona, Catalonia, Spain, [2]Vall d'Hebron Institute of Oncology and Hospital Universitari Vall d'Hebron, Universitat Autonoma de Barcelona, Barcelona, Catalonia, Spain, [3]Banc de Sang i Teixits, Hospital Universitari Vall d'Hebron, Barcelona, Catalonia, Spain, [4]Novartis Biomedical Research, Basel, Basel-Stadt, Switzerland, [5]Novartis Farmacéutica, Barcelona, Catalonia, Spain

SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: Late-Breaking Poster
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Systemic lupus erythematosus (SLE) is characterized by pathogenic autoreactive B cells producing autoantibodies against multiple self-antigens. Recently, a series of clinical cases suggested that traditionally manufactured anti-CD19 chimeric antigen receptor T cell (CAR-T cell) therapies show potential to promote full clinical remission in severe refractory SLE (srSLE).[1,2] This is the first clinical trial to evaluate the preliminary safety and efficacy of anti-CD19 CAR-T cell therapy in patients with srSLE. YTB323 is a novel, rapidly manufactured, autologous CAR-T cell therapy that has shown preserved T cell stemness and enhanced CAR-T cell efficacy in hematological malignancies.[3]

Table 1: Patient baseline characteristics and exposure

Parameter	Patient 1	Patient 2	Patient 3
Age (years), sex, race	50, male, white	48, female, white	38, female, white
Lymphodepleting therapy	cyclophosphamide, fludarabine	cyclophosphamide, fludarabine	cyclophosphamide, fludarabine
YTB323 infusion	25-Apr-2023 (day 1)	08-Jun-2023 (day 1)	12-Jul-2023 (day 1)
Diagnosis (year)	SLE (2013)	SLE (2012)	SLE (2002), LN (2012)
Follow-up duration from YTB323 dosing (days)	106	62	28
Major organ involvement	pleuritis, vasculitis, arthritis, constitutional symptoms, skin rash, proteinuria	LN (Class III/IV), arthritis, pericarditis, skin rash	LN (Class IV-V), arthritis
Disease activity SLEDAI-2K	22	14	12
Urine protein/creatinine ratio (g/mol)	130.49 (H)	156.69 (H)	155.24 (H)

Normal ranges (local lab) for urine protein/creatinine ratio: 0-22.6. Values were within normal range, unless otherwise stated.
H, high; LN, lupus nephritis; SLE, systemic lupus erythematosus; SLEDAI-2K, SLE Disease Activity Index 2000.

Figure 1: Adverse events by patients and severity over time

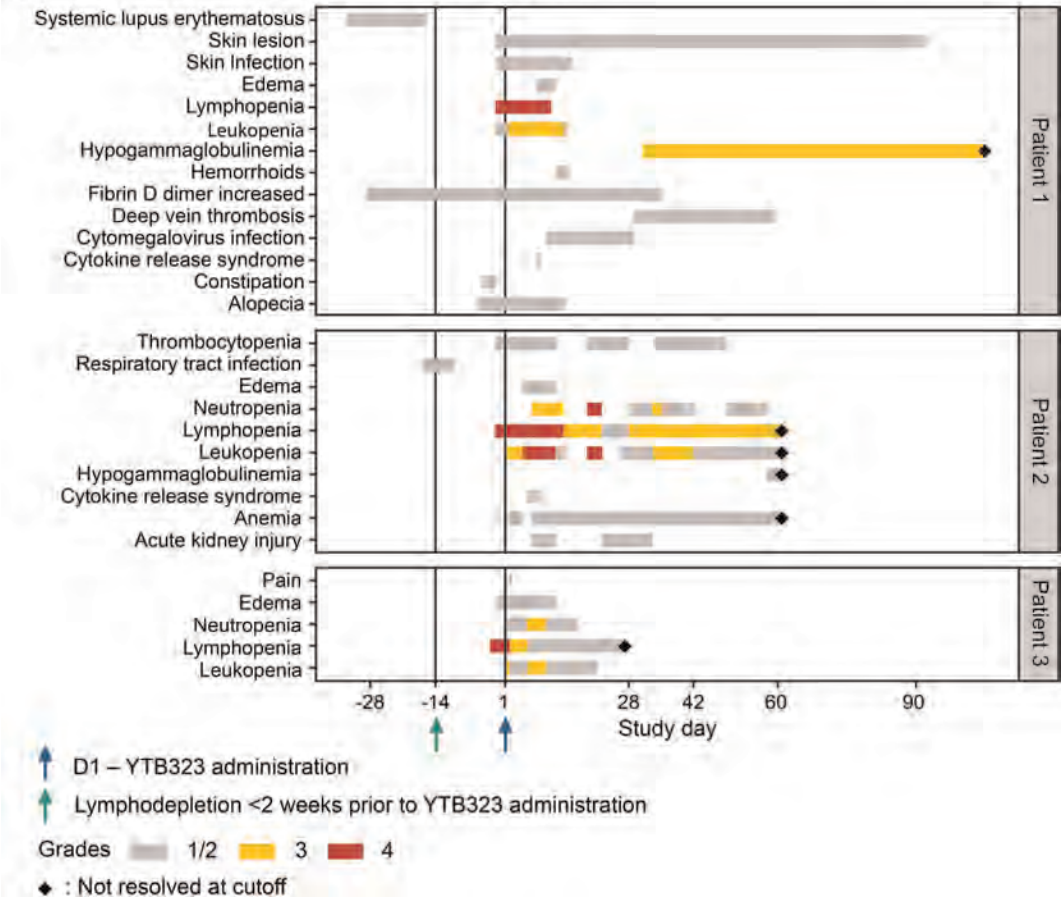

Figure 2: Individual efficacy parameters over time

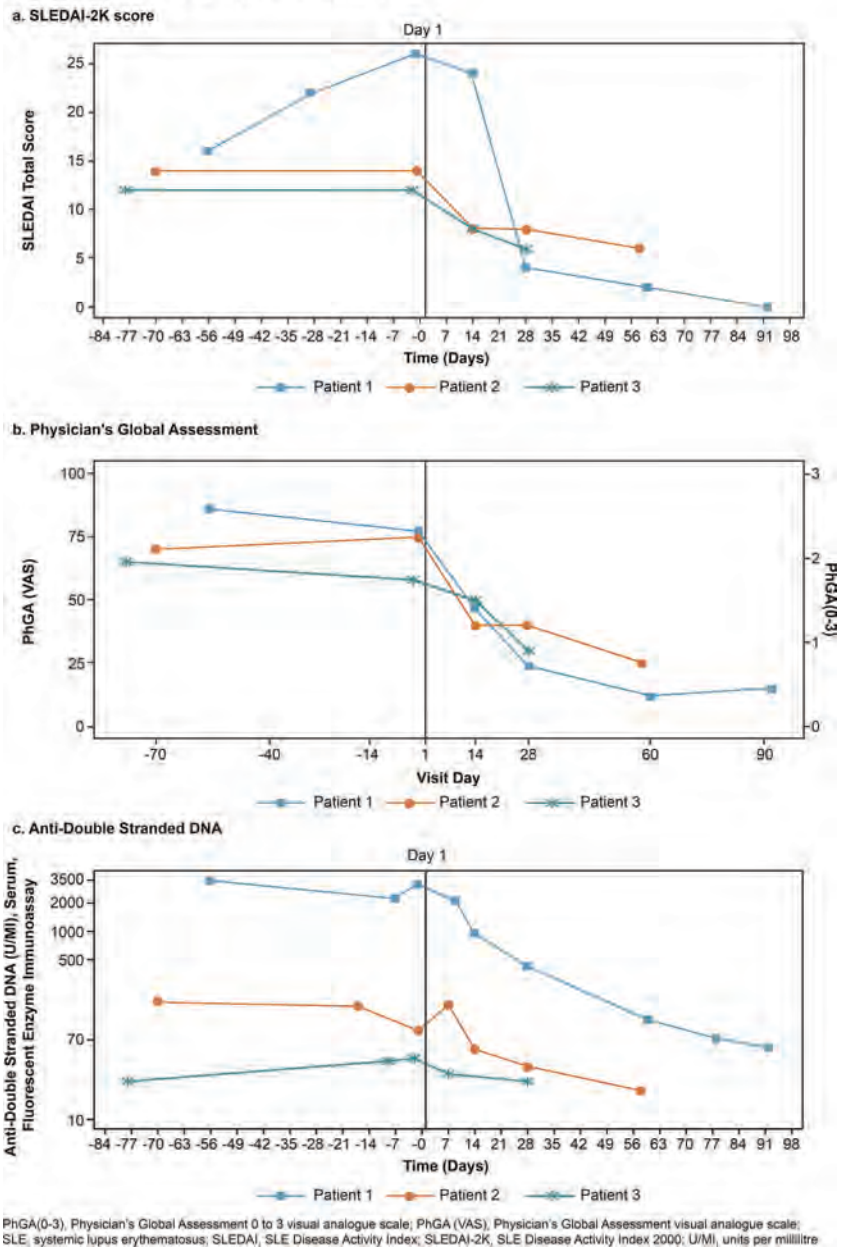

PhGA(0-3), Physician's Global Assessment 0 to 3 visual analogue scale; PhGA (VAS), Physician's Global Assessment visual analogue scale; SLE, systemic lupus erythematosus; SLEDAI, SLE Disease Activity Index; SLEDAI-2K, SLE Disease Activity Index 2000; U/Ml, units per millilitre

Methods: An open-label, single-arm, multicenter phase 1/2 study, CYTB323G12101 (NCT05798117), to assess the safety, efficacy and cellular kinetics of YTB323 in participants with srSLE is currently ongoing. A sentinel cohort of patients with srSLE (n=3), dosed with $12.5x10^6$ cells at least 28 days apart, was enrolled. The primary endpoint was safety as measured by vital signs, adverse events, laboratory parameters and ECG evaluation. CAR-T cell kinetics were monitored by quantitative PCR and flow cytometry. Further relevant endpoints included changes from baseline levels in circulating B and T cells, autoantibody and complement levels, disease activity scores and renal outcome measures.

Results: Baseline characteristics of patients are summarized in **Table 1**. Adverse events are shown in **Figure 1**. No serious adverse events or deaths were reported. Following screening, the first patient experienced a worsening of disease during immunosuppressant washout prior to receiving lymphodepletion therapy. No immune effector cell-associated neurotoxicity syndrome (ICANS) occurred. A grade 1 cytomegalovirus reactivation occurred in one patient, which was subsequently resolved. Two patients had cytokine release syndrome (grade 1 or 2); both responded well to tocilizumab treatment and fully recovered. As expected,

grade 3 and 4 transient lymphodepletion-related cytopenias were observed in all patients. Grade 2 or 3 hypogammaglobulinemia was observed in two patients; neither event required intravenous immunoglobulin treatment. Cellular kinetics studies showed peak expansion (T_{max}) at 13 and 18 days post-infusion for the two patients with available data characterizing the expansion phase. Transient T cell and sustained B cell depletion were observed in all patients. Preliminary efficacy data **(Figure 2)** suggest substantial decreases in SLE Disease Activity Index (SLEDAI) **(Figure 2a)** and Physician's Global Assessment (PhGA) **(Figure 2b)**, in line with improvements in relevant disease biomarkers such as dsDNA **(Figure 2c)**, complement levels and proteinuria.

Conclusion: Preliminary data from this clinical trial including the first three sentinel patients suggest favorable safety, CAR-T cell expansion, B cell depletion and initial efficacy, supporting continuation of the study to evaluate YTB323 in srSLE.

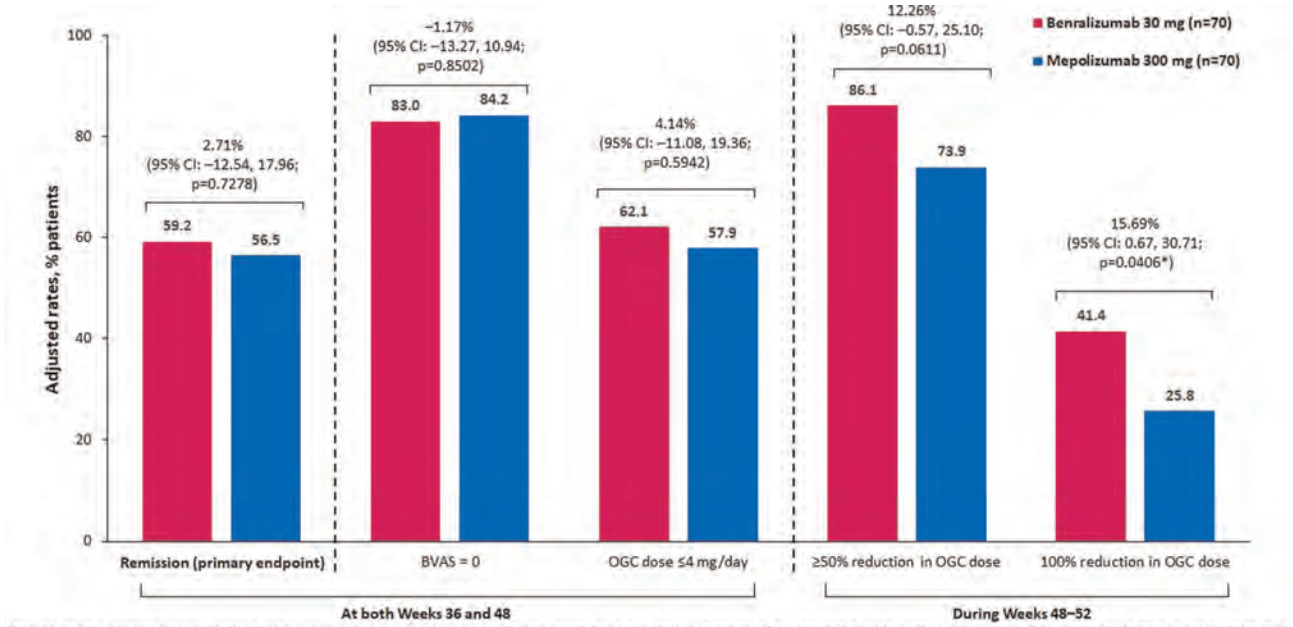
SESSION INFORMATION
Session Date: Tuesday, November 14, 2023
Session Title: Late-Breaking Poster
Session Type: Poster Session C
Session Time: 9:00AM–11:00AM

Background/Purpose: Eosinophilic inflammation is a key pathophysiological mechanism of eosinophilic granulomatosis with polyangiitis (EGPA). Oral glucocorticoids (OGCs) and immunosuppressants remain the basis for the standard of care (SoC),but their long-term use is associated withsignificantadverse effects, and relapses are frequently seen. The MANDARA

trial compared the efficacy and safety of benralizumab (a monoclonal antibody against the IL-5 receptor) and mepolizumab (an anti-IL-5 agent, and the only approved drug for EGPA) in patients with EGPA receiving SoC.

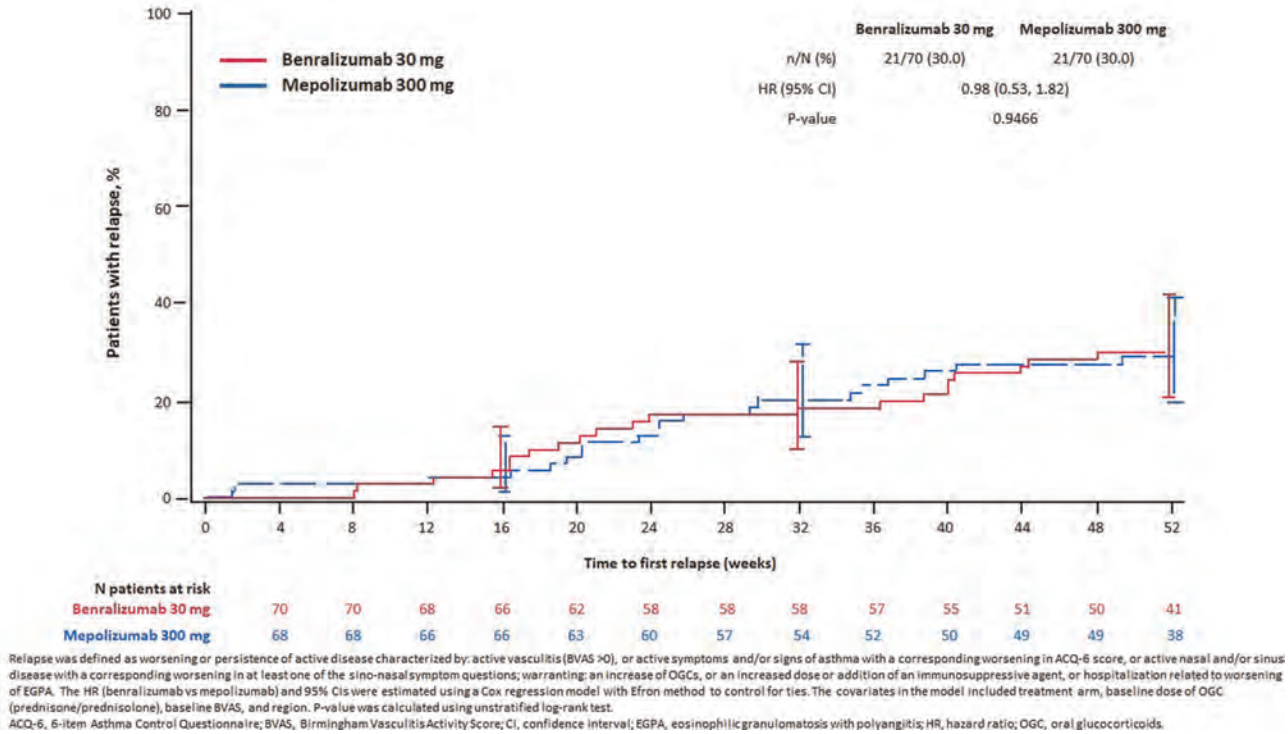
Methods: MANDARA was a randomized, active-controlled, parallel-group, multicenter, 52-week double-blind with open-label extension, Phase III non-inferiority study (NCT04157348). Patients (≥18 years) with documented EGPA based on asthma and blood eosinophilia plus ≥2 additional features of EGPA, and a history of relapsing/refractory disease requiring stable OGCs (≥7.5 mg prednisone/prednisolone daily) ± stable immunosuppressive therapy for ≥4 weeks before randomization, were included. Benralizumab 1 x 30 mg or mepolizumab 3 x 100 mg were administered by subcutaneous injection every 4 weeks for 52 weeks, and OGC was tapered if disease was controlled. The primary endpoint was the proportion of patients achieving remission (defined as Birmingham Vasculitis Activity Score [BVAS] = 0 and OGC dose ≤4 mg/day) at both Weeks 36 and 48. Secondary endpoints included accrued and maintained remission, OGC use, other clinical benefits, time to first relapse, and safety.

Results: 140 patients were randomized (mean [standard deviation; SD] age 52.3 [14.1] years; 60.0% women) to benralizumab (n=70) or mepolizumab (n=70). The adjusted remission rate at both Weeks 36 and 48 was 59.2% for the benralizumab group and 56.5% for the mepolizumab group (difference: 2.71%; 95% confidence interval [CI]: –12.54, 17.96; p=0.7278), confirming non-inferiority of benralizumab to mepolizumab (using the predefined margin of –25%; **Figure 1**). Secondary efficacy endpoints are shown in **Table 1**. The proportion of patients who relapsed was the same for benralizumab vs mepolizumab (both 30.0%; **Figure 2**). The mean (SD) OGC dose was 11.02 (5.25) mg/day at baseline. At Weeks 48–52, 86.1% vs 73.9% in the benralizumab and mepolizumab groups, respectively, had a reduction in OGC dose of ≥50% from baseline, and 41.4% vs 25.8% were fully tapered off OGC. Adverse events (AEs) were reported in 90.0% of benralizumab and 95.7% of mepolizumab recipients, most commonly COVID-19 (21.4% vs 27.1%), headache (17.1% vs 15.7%), and arthralgia (17.1% vs 11.4%). Serious AEs were reported in 5.7% of benralizumab and 12.9% of mepolizumab recipients. No benralizumab and 2 mepolizumab recipients experienced AEs leading to discontinuation of treatment.



*Nominal p-value. Patients received double-blind treatment with either one SC injection of benralizumab 30 mg plus three SC injections of mepolizumab placebo, or three SC injections of mepolizumab 100 mg plus one SC injection of benralizumab placebo every 4 weeks from baseline to Week 48. Remission was defined as BVAS=0 and OGC dose ≤4 mg/day (patients achieving remission who had, at any subsequent visit, a BVAS=1 that did not require an increase in OGC dose >4 mg/day or any other significant clinical intervention/investigation, were considered to be in continued remission). Remission rates and the between-treatment differences were estimated using marginal standardization method in a logistic regression model. The covariates in the model included treatment arm, baseline dose of OGC (prednisone/prednisolone), baseline BVAS and region (North America, Rest of World, and Japan). Baseline was defined as the last measurement on or prior to the date of randomization. The non-inferiority margin was predefined at –25%. P-values are shown for the superiority test. During the double-blind period of the study if patients reached BVAS=0 after Week 4 their OGCs were allowed to be tapered according to standard practice.
BVAS, Birmingham Vasculitis Activity Score; CI, confidence interval; OGC, oral glucocorticoid; SC, subcutaneous.

Figure 1. Efficacy outcomes and between-treatment differences in rates during the double-blind treatment period



Relapse was defined as worsening or persistence of active disease characterized by: active vasculitis (BVAS >0), or active symptoms and/or signs of asthma with a corresponding worsening in ACQ-6 score, or active nasal and/or sinus disease with a corresponding worsening in at least one of the sino-nasal symptom questions; warranting: an increase of OGCs, or an increased dose or addition of an immunosuppressive agent, or hospitalization related to worsening of EGPA. The HR (benralizumab vs mepolizumab) and 95% CIs were estimated using a Cox regression model with Efron method to control for ties. The covariates in the model included treatment arm, baseline dose of OGC (prednisone/prednisolone), baseline BVAS, and region. P-value was calculated using unstratified log-rank test.
ACQ-6, 6-item Asthma Control Questionnaire; BVAS, Birmingham Vasculitis Activity Score; CI, confidence interval; EGPA, eosinophilic granulomatosis with polyangiitis; HR, hazard ratio; OGC, oral glucocorticoids.

Figure 2. Time to first relapse

Table 1. Secondary endpoints during the double-blind treatment period

	Treatment	Patients with accrued remission duration up to Week 52, n (%)					Comparison between groups	
		0 weeks	>0 to < 12 weeks	12 to < 24 weeks	24 to <36 weeks	≥36 weeks	OR (95% CI)	P value
Accrued remission up to Week 52								
Remission	Benralizumab (n=70)	9 (12.9)	12 (17.1)	8 (11.4)	21 (30.0)	20 (28.6)	1.36 (0.75, 2.48)	0.3142
	Mepolizumab (n=70)	15 (21.4)	10 (14.3)	8 (11.4)	19 (27.1)	18 (25.7)		
Achieved remission by Week 24 and maintained remission until Week 52								
		Patients, n (%)			Adjusted remission rates, %		Difference in remission rates (95% CI)	P value
Remission	Benralizumab (n=70)	28 (40.0)			42.1		5.54 (−9.30, 20.37)	0.4643
	Mepolizumab (n=70)	27 (38.6)			36.5			
Achieved clinical benefit								
		Patients, n (%)			Adjusted response rates, %		Difference in response rates (95% CI)	P value
Clinical benefit (OGC dose ≤4 mg/day threshold)	Benralizumab (n=70)	66 (94.3)			94.4		4.60 (−4.22, 13.41)	0.3068
	Mepolizumab (n=70)	63 (90.0)			89.8			
Clinical benefit (OGC dose ≤7.5 mg/day threshold)	Benralizumab (n=70)	68 (97.1)			97.3		−1.13 (−5.85, 3.59)	0.6390
	Mepolizumab (n=70)	69 (98.6)			98.5			
Achieved complete response								
		Patients, n (%)			Adjusted response rates, %		Difference in response rates (95% CI)	P value
Complete response (OGC dose ≤4 mg/day threshold)	Benralizumab (n=70)	43 (61.4)			62.5		7.90 (−7.32, 23.12)	0.3088
	Mepolizumab (n=70)	39 (55.7)			54.6			
Complete response (OGC dose ≤7.5 mg/day threshold)	Benralizumab (n=70)	45 (64.3)			64.9		6.93 (−8.42, 22.28)	0.3762
	Mepolizumab (n=70)	41 (58.6)			57.9			

Secondary endpoints are not multiplicity-protected. All p-values are nominal. ORs and 95% CIs for benralizumab versus mepolizumab were estimated using a proportional odds model, with covariates including treatment arm, baseline OGC dose, baseline BVAS, and region. Rates and the difference in rates (benralizumab minus mepolizumab) and 95% CIs, were estimated using marginal standardization method from a logistic regression model, with covariates including treatment arm, baseline OGC dose, baseline BVAS, and region. Remission was defined as BVAS=0 and OGC dose ≤4 mg/day (patients achieving remission who had, at any subsequent visit, a BVAS=1 that did not require an increase in OGC dose >4 mg/day or any other significant clinical intervention/investigation, were considered to be in continued remission). Daily dose of OGCs: Baseline is defined as the last measurement on or prior to the date of randomization. Clinical benefit was defined as any of the following: remission (BVAS=0 and OGC dose ≤4 mg/day or ≤7.5 mg/day) at any time during the double-blind treatment period; ≥50% reduction in average daily OGC dose during Weeks 48 through 52; relapse free during the double-blind treatment period. Complete response was defined as all of the following: remission (BVAS=0 and OGC dose ≤4 mg/day or ≤7.5 mg/day) at any time during the double-blind treatment period; ≥50% reduction in average daily OGC dose during Weeks 48 through 52; relapse free during the double-blind treatment period.
BVAS, Birmingham Vasculitis Activity Score; CI, confidence interval; OGC, oral glucocorticoids; OR, odds ratio.

Conclusion: This study demonstrated non-inferiority of benralizumab vs mepolizumab over 52 weeks in patients with relapsing/refractory EGPA receiving SoC and provides evidence for the efficacy and utility of benralizumab, with more benralizumab-treated patients being fully tapered off OGC. Both study drugs were well tolerated with a similar proportion of patients reporting AEs.

AR882, an Efficacious and Selective URAT1 Inhibitor for Patients with Chronic Gouty Arthritis and Subcutaneous Tophi: Results from a Global, Prospective, Proof-of-Concept Trial Using Dual Energy Computed Tomography

Robert Keenan[1], James Cheng-Chung Wei[2], Sarah Morris[3], Pamella Mundell[3], Wen Wei[3], Ke Shi[3], Zancong Shen[3], Vijay Hingorani[4], Shunqi Yan[3], Bahram Kiani[5] and Litain Yeh[3], [1]Arthrosi Therapeutics, Inc., Chapel Hill, NC, [2]Chung Shan Medical University, Taichung, Taiwan (Republic of China), [3]Arthrosi Therapeutics, Inc., San Diego, CA, [4]Vanguard Healthsciences, Inc., San Diego, CA, [5]Wake Forest University School of Medicine, Winston-Salem, NC

SESSION INFORMATION
Session Date: Wednesday, November 15, 2023
Session Title: Late-Breaking Abstracts
Session Type: Late-Breaking Abstract Session
Session Time: 7:30AM–9:00AM

Background/Purpose: AR882 is a novel and selective URAT1 inhibitor currently in clinical stage development for the treatment of gout and tophaceous gout and has demonstrated robust and sustained serum urate (sUA) lowering in a 3-month Phase 2b trial. This proof-of-concept trial evaluates the effect of AR882 versus allopurinol on the reduction of clinically visible tophi in patients with gout using caliper measurements and Dual Energy Computer Tomography (DECT).

Methods: The phase 2 global trial recruited 42 gout patients with subcutaneous tophi. The patients were randomized into three treatment groups to receive once-daily AR882 75 mg, once-daily AR882 50 mg + allopurinol, or once-daily allopurinol up to 300 mg at a 1:1:1 ratio. Tophi measurements with calipers were completed every 4 weeks for 6 months; patients were imaged with DECT at baseline and 6 months. The primary efficacy endpoint was sUA change at month 3. Secondary endpoints included resolution of target tophus area and change from baseline in target tophus crystal volume at month 6. Safety assessments, including vital signs and electrocardiograms, were collected throughout the study.

Results: In the Intent-to-Treat population, the mean baseline sUA level ranged between 9.1-9.6 mg/dL across treatment groups. At month 3, the mean sUA levels were reduced to 4.5 (±1.2), 4.7 (±1.4), and 6.1 (±2.0) mg/dL, respectively for 75 mg, 50 mg + allopurinol and allopurinol. In the 75 mg AR882 group, 86% and 64% of patients achieved sUA < 6 and < 5 mg/dL, respectively; in the 50 mg AR882 + allopurinol group, 77% and 69% of patients achieved sUA levels < 6 and

Table 1. Mean (SD) sUA reduction, response rates and complete resolution of at least one target tophus.

Treatment	N	Baseline	sUA levels at Month 3 (ITT)		sUA (mg/dL) response, % at Month 3 (ITT)				n/N, % of subjects with ≥1 tophus completely resolved (Month 6)
		sUA mg/dL	sUA mg/dL	% change	< 6	< 5	< 4	< 3	
AR882 75 mg	14	9.1 (1.3)	4.5 (1.2)	-49.6 (12.5)	86	64	43	7	4/14 (29%)
AR882 50 mg + allopurinol	13	9.6 (1.2)	4.7 (1.4)	-49.9 (15.1)	77	69	23	8	1/13 (8%)
allopurinol	13	9.5 (2.0)	6.1 (2.0)	-34.9 (20.1)	46	23	15	8	1/13 (8%)

ITT: Intent-to-Treat population

Table 2. Mean (SE) change in DECT crystal volumes at Month 6.

Treatment	Visit	N	Crystal volume, cm^3	Absolute change, cm^3	Percent change
AR882 75 mg	Baseline	12	15.6 (9.9)		
	Month 6	11	8.7 (5.0)	-8.3 (5.8)	-30.7 (17.7)
AR882 50 mg + allopurinol	Baseline	12	4.7 (2.0)		
	Month 6	9	3.2 (1.8)	-0.9 (0.5)	-31.5 (13.9)
Allopurinol	Baseline	13	11.5 (5.8)		
	Month 6	13	10.3 (4.5)	-1.2 (3.8)	-16.8 (25.5)

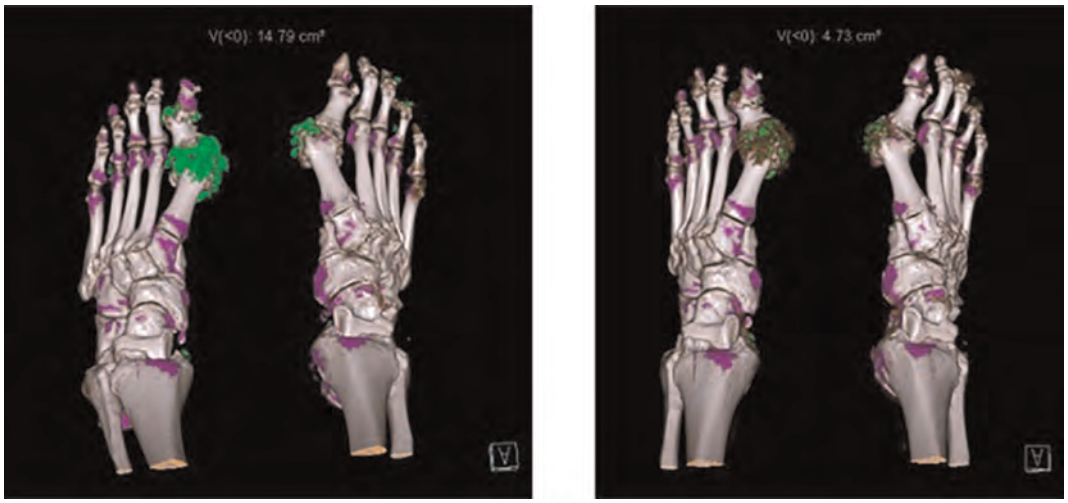

Figure 1. DECT image of gouty arthritis showing 68% reduction in total urate crystal volume from baseline (left) to Month 6 after taking AR882 75 mg once daily.

< 5 mg/dL, respectively. This was compared to patients in the allopurinol group, where 46% and 23% of patients achieved sUA levels < 6 and < 5 mg/dL, respectively (Table 1).

At Month 6, 4 patients (29%) in the AR882 75 mg group showed complete resolution of at least one tophus, compared to 1 patient (8%) in AR882 50 mg + allopurinol and 1 patient (8%) in allopurinol groups. The AR882 75 mg group showed a greater reduction of total urate crystal volume (-30.7%, -8.3 cm^3) vs. combination (-31.5%, -0.9 cm^3) or allopurinol (-16.8%, -1.2 cm^3) from baseline to month 6 on DECT (Table 2). Figure 1 shows a 68% decrease in total urate crystal volume of the feet and ankles after AR882 75 mg once daily treatment for 6 months.

There were no serious adverse events related to AR882 treatment. No kidney or liver abnormalities were observed. The most frequently reported adverse event was gout flare, mild or moderate adverse events including diarrhea, headache, and upper respiratory infection. Gout flare rate appeared less in the AR882 treatment groups than in the allopurinol group.

Conclusion: In this global study, six-month treatment of AR882 demonstrated safe and efficacious sUA lowering, tophus resolution and total crystal volume dissolution in gout patients with various demographics and baseline characteristics. AR882 may offer improved efficacy and better safety compared to existing therapies in the treatment of patients with gout, including those with both clinically visible and subclinical crystal deposition.

Withdrawal of Immunosuppressant and Low-dose Steroids in IgG4-RD Patients with Stable Disease (WInS IgG4-RD): An Investigator-initiated, Multi-center, Open-label, Randomized Controlled Trial

Linyi Peng[1], Yuxue nie[1], Jiaxin Zhou[1], Lijun Wu[2], Fang Wang[3], Xiaomei Chen[4], Jieqiong Li[1], Yu Peng[1], Hui Lu[1], Lidan Zhao[1], Mengtao Li[1], Yan Zhao[1], Xiaofeng Zeng[5], Yunyun Fei[1] and Wen Zhang[1], [1]Peking Union Medical College Hospital, Department of Rheumatology and Clinical Immunology, National Clinical Research Center for Dermatologic and Immunologic Diseases, State Key Laboratory of Complex Severe and Rare Diseases, Beijing, China, [2]Xinjiang Uygur Autonomous Region People's Hospital, XinJiang, China, [3]Beijing Hospital, Beijing, China, [4]Xinjiang Uygur Autonomous Region People's Hospital, Wulumuqi, China, [5]Peking Union Medical College Hospital, Chinese Academy of Medical Science & Peking Union Medical College, Beijing, China

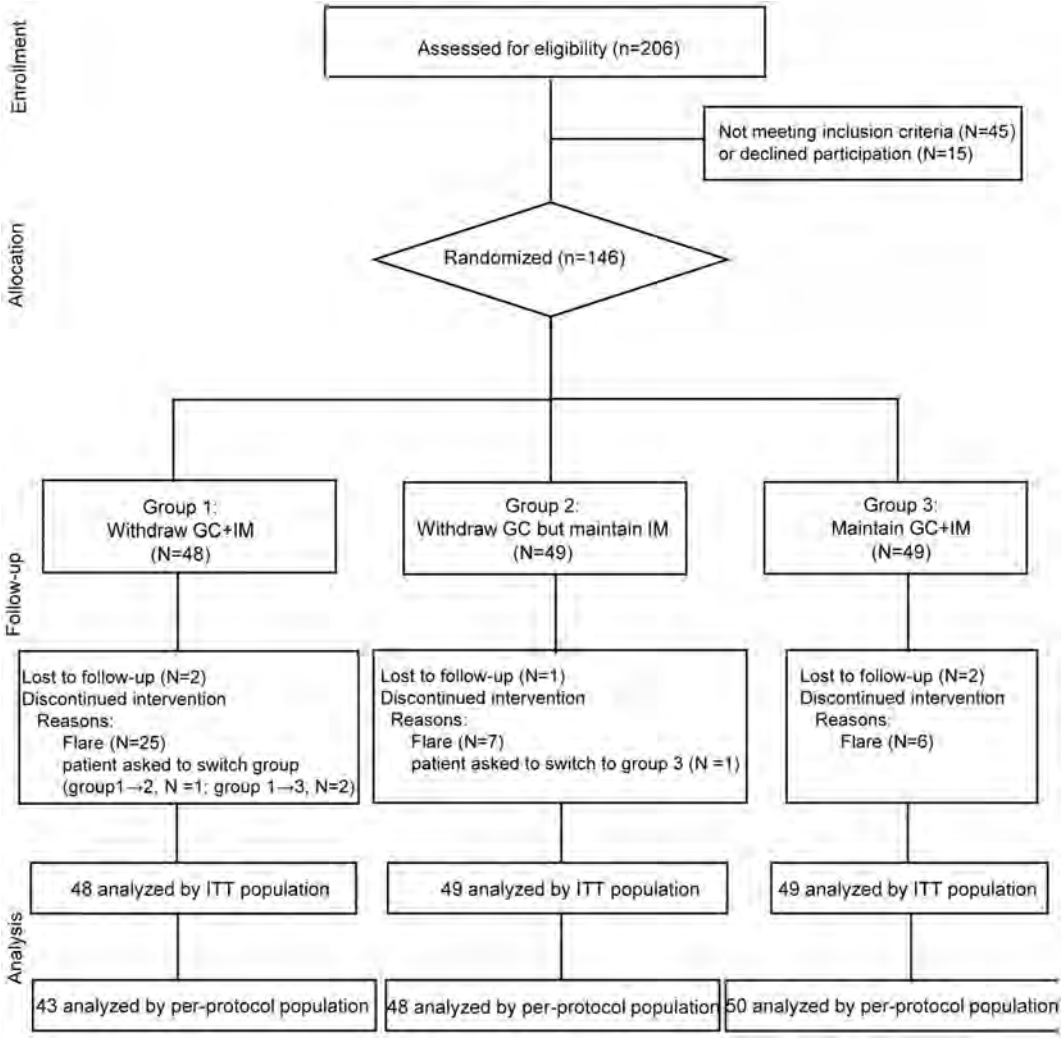
SESSION INFORMATION
Session Date: Wednesday, November 15, 2023
Session Title: Late-Breaking Abstracts
Session Type: Late-Breaking Abstract Session
Session Time: 7:30AM–9:00AM

Background/Purpose: IgG4-related disease (IgG4-RD) is a fibroinflammatory disease. Remission induction treatment with glucocorticoid (GC) is usually effective, but its tendency of relapse makes the strategy for maintenance treatment a challenge. The WInS IgG4-RD (withdraw immunosuppressants and steroid in stable IgG4-RD) trial tested whether discontinuation of GC and immunosuppressive agent (IM) were feasible in stable IgG4-RD.

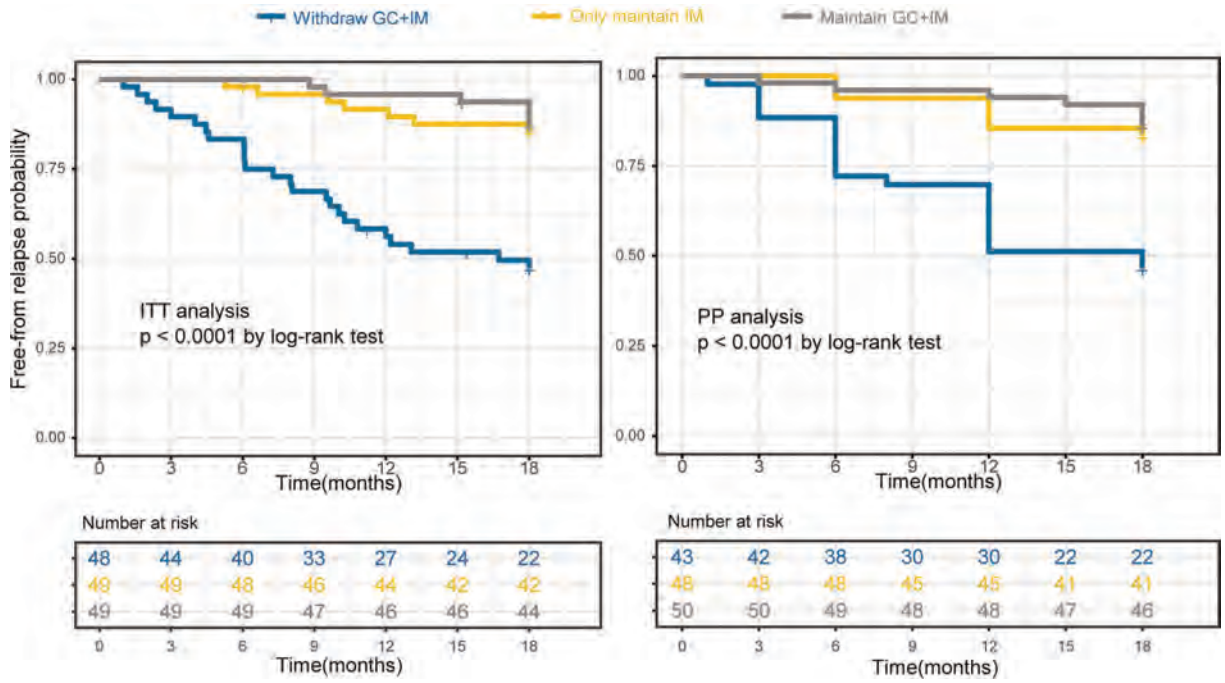
Methods: The WInS IgG4-RD trial was a multicentre, open-label, randomised controlled trial. IgG4-RD patients receiving GC+IM as maintenance treatment with clinically quiescent disease for at least 12 months were randomised (1:1:1) into three groups: (1) Group 1: withdraw GC+IM; (2) Group 2: withdraw GC but maintain IM; (3) Group 3: maintain GC +IM. The primary endpoint was the relapse rate of disease within 18 months. The secondary endpoints include the changes of responder index (RI), physician's global assessment (PGA), serum IgG4 and IgG, as well as adverse events.

Results: One hundred and forty-six patients were randomised, with 48 patients in Group 1, and 49 patients in Group 2 and Group 3 respectively. Within the 18-month follow-up period, disease relapse occurred in 25/48 (52.1%) patients in Group 1 versus 7/49 (14.2%) in Group 2 and 6/49 (12.2%) in Group 3 ($p< 0.001$). The changes in RI and PGA were significantly higher in Group 1 than Group 2 ($p< 0.001$) or Group 3 ($p< 0.001$).

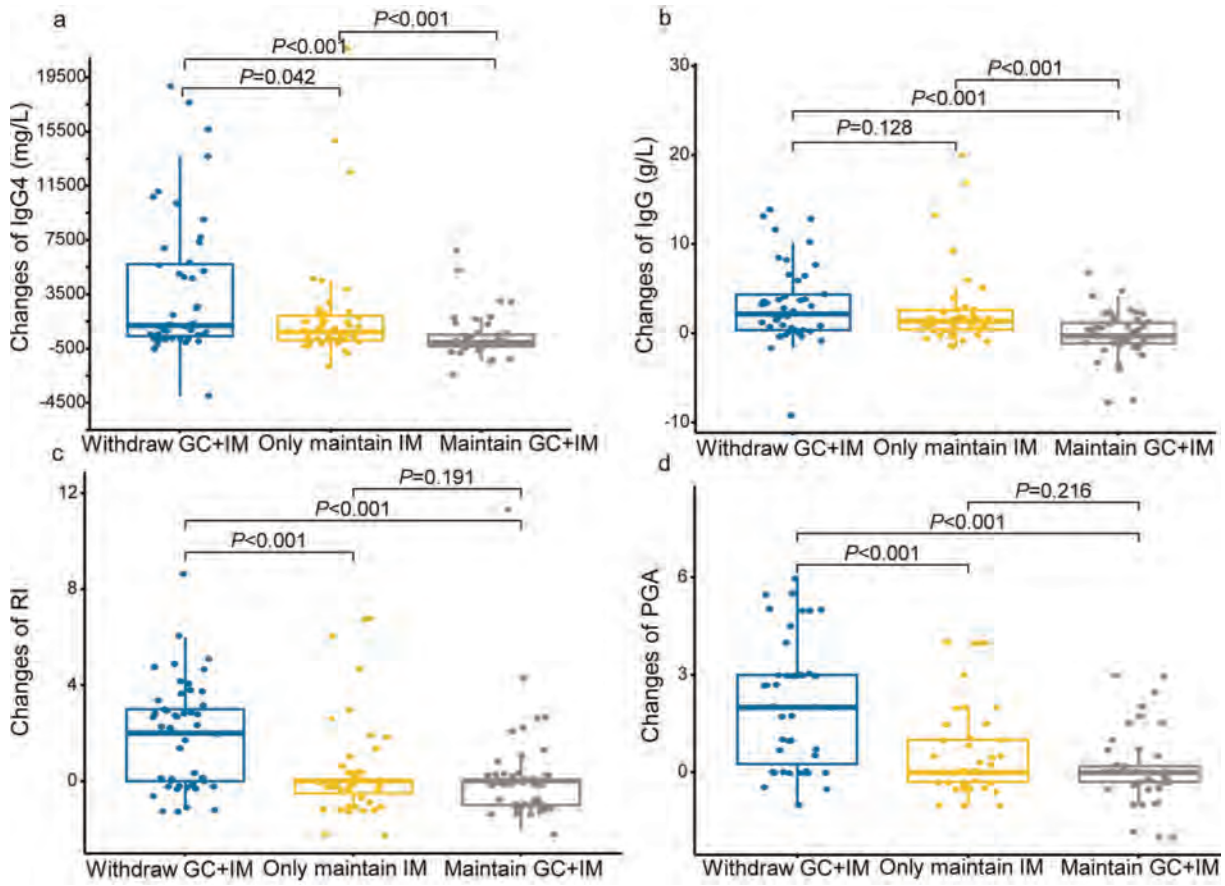
Conclusion: The maintenance of IMs, with or without low-dose GC, was found to be superior to withdraw GC+IM in preventing relapse for long-time stable IgG4-RD.



Flowchart of WInS IgG4-RD study



The occurrence of relapse during follow-up is presented as a Kaplan-Meier curve of cumulative probability (Figure 2), where there were significant differences among the three groups by both ITT and PP analysis (both overall p<0.001).



Changes of IgG4(a), IgG (b), IgG4-RD RI (3c), PGA (figure 3d) at baseline of the study and the endpoints by intention-to-treat analysis. RI, Responder index; PGA, physician's global assessment.

Safety, Tolerability, and Exploratory Efficacy of Afimetoran, a TLR7/8 Inhibitor, in Patients with Cutaneous Lupus Erythematosus: A Phase 1b Randomized, Double-Blind, Placebo-Controlled Study

Fareeda Hosein[1], Stanislav Ignatenko[2], Kristina Chadwick[1], Lin Zhu[1], Frédéric Baribaud[1], Thanh Bach[1], Hazem Karabeber[1], Michelle Dawes[1], Leon Carayannopoulos[1] and Gopal Krishna[1], [1]Bristol Myers Squibb, Princeton, NJ, [2]Charité Research Organisation GmbH, Berlin, Germany

SESSION INFORMATION
Session Date: Wednesday, November 15, 2023
Session Title: Late-Breaking Abstracts
Session Type: Late-Breaking Abstract Session
Session Time: 7:30AM–9:00AM

Background/Purpose: Over 50 years have passed since the last therapy was approved for cutaneous lupus erythematosus (CLE).[1] Parenteral administration, off-label use, or toxicity with long-term use of some existing therapies illustrate a key unmet need to identify novel treatments for CLE. Toll-like receptors (TLR) are implicated in SLE pathobiology, which make these receptors candidate targets for CLE therapies.[2] Afimetoran is a first-in-class, orally bioavailable, potent, and selective small molecule inhibitor of TLR7 and TLR8. This phase 1b, randomized, double-blind, placebo-controlled study (NCT04493541) investigated the safety, tolerability, and exploratory efficacy of afimetoran in patients with CLE.

Methods: Patients were aged 18–65 years, diagnosed with either SLE according to EULAR/ACR 2019 classification criteria[3] or had biopsy-proven CLE, had a modified CLE Disease Area and Severity Index-Activity (CLASI-A) score of ≥ 6, were antinuclear antibody positive, and had no evidence of retinal toxicity. Stable doses of oral corticosteroids and/or antimalarials at baseline were permitted. Patients were randomized 2:1 to once-daily oral afimetoran (30 mg) or placebo for 16 weeks and monitored for 4 weeks after stopping treatment. The primary endpoints were safety and tolerability; efficacy was an exploratory endpoint.

Results: 13 patients were randomized (afimetoran, n = 8; placebo, n = 5); 12 patients completed 16 weeks of treatment and 1 discontinued from the afimetoran arm due to an adverse event (AE) of symptomatic COVID-19 infection. Baseline patient characteristics were generally balanced, though the patients in the afimetoran arm had higher baseline CLASI-A scores and a higher proportion of current smokers vs placebo (**Table 1**). The primary objective was met: afimetoran demonstrated a favorable safety profile and was well tolerated vs placebo. Further, there were no serious AEs or safety signals among laboratory tests, vital signs, or electrocardiography. Overall, AEs were mild or moderate and resolved by the end of the study without intervention (**Table 2**). The proportion of patients with reported AEs was lower for patients treated with afimetoran vs placebo (62.5% vs 80.0%, **Table 2**). Compared with placebo, patients treated with afimetoran showed a greater reduction in CLASI-A scores as early as week 4 (first CLASI-A assessment point) which continued through the 16 weeks of active treatment and persisted for 4 weeks after end of treatment (**Figure 1**).

Table 1. Baseline demographics and clinical characteristics

	Afimetoran (n = 8)	Placebo (n = 5)	Total (n = 13)
Age, mean (SD), years	46.0 (11.1)	51.2 (12.4)	48.0 (11.4)

Systemic lupus erythematosus	3 (37.5)	3 (60.0)	6 (46.2)
Anti-dsDNA antibody or anti-Smith antibody, n (%)	3 (37.5)	4 (80.0)	7 (53.8)
CLASI-A score, mean (min, max)	15.0 (6, 25)	11.6 (9, 16)	13.7 (6, 25)

dsDNA, double stranded deoxyribonucleic acid; CLASI-A, Cutaneous Lupus Erythematosus Disease Area and Severity Index-Activity.

Table 2. Safety summary for placebo vs afimetoran

Event, n (%)	Afimetoran (n = 8)	Placebo (n = 5)
Deaths	0	0
AE	5 (62.5)	4 (80.0)
Serious AEs	0	0
AEs leading to discontinuation[a]	1 (12.5)	0
Drug-related AE[b,c]	2 (25.0)	2 (40.0)
Non-serious AE	5 (62.5)	4 (80.0)
Infections and infestations	3 (37.5)	1 (20.0)
Nervous system disorders	1 (12.5)	2 (40.0)
Injury/procedural complications	1 (12.5)	2 (40.0)
General and administration site disorders	2 (25.0)	0
Gastrointestinal disorders	1 (12.5)	1 (20.0)
Psychiatric disorders	1 (12.5)	0
Respiratory, thoracic, and mediastinal disorders	1 (12.5)	0
Blood and lymphatic system disorder	0	1 (20.0)
Musculoskeletal and connective tissue disorders	0	1 (20.0)

Data (n) represent the number of patients within the afimetoran or placebo arm with an event.

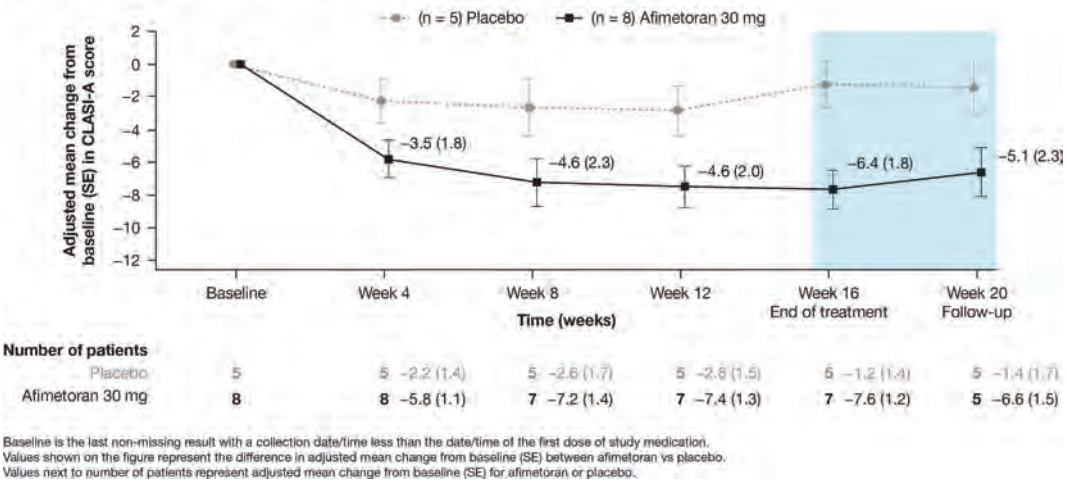
[a]Patient discontinuation at week 8 attributed to symptomatic COVID-19.

[b]Drug-related AEs were investigator assessed at each site.

[c]Drug related AEs were reported during the blinded treatment period, however after unblinding those patients were in the placebo group.

AE, adverse event.

Figure 1. Mean change from baseline in CLASI-A with afimetoran vs placebo



Baseline is the last non-missing result with a collection date/time less than the date/time of the first dose of study medication.
Values shown on the figure represent the difference in adjusted mean change from baseline (SE) between afimetoran vs placebo.
Values next to number of patients represent adjusted mean change from baseline (SE) for afimetoran or placebo.

Conclusion: Afimetoran demonstrated a favorable safety profile and was well tolerated vs placebo in patients with CLE. These results provide the first clinical evidence to suggest that afimetoran may offer a clinical benefit as indicated by an early and sustained clinical response vs placebo as measured by CLASI-A. As such, these results support the continued clinical investigation of afimetoran in lupus, including the ongoing phase 2b study in SLE (NCT04895696).

Session Title: Late-Breaking Abstracts
Session Type: Late-Breaking Abstract Session
Session Time: 7:30AM–9:00AM

Background/Purpose: Primary Sjögren's syndrome (pSS) is a complex autoimmune disease with significant heterogeneity. Our study aimed to clarify the etiology and molecular variation of the target organ, salivary glands (SGs), in pSS by stratifying them into distinguishable subgroups, which could inform treatment choices in pSS.

Methods: Large-scale transcriptomic profiling of SGs was conducted on 396 pSS, 87 non-pSS, and 44 early-pSS individuals from a multicenter consecutive Chinese cohort. Unsupervised clustering methods were used for molecular classification and integrated analyses were performed to elucidate comprehensive clinical and biological features, immune-metabolic and genetic characteristics. Lymphoma risk and treatment response for pSS subgroups was also predicted for pSS subtypes.

Results: Three distinct subtypes were identified both in established and early-pSS, including "pauci-immune/C1", "cold-immune/C2", and "hot-immune/C3". Pauci-immune/C1 exhibited a similar biologic pattern to non-pSS. The cold-immune/C2 displayed dramatic activation of classical adaptive immune and depressed metabolism, along with mitochondrial dysfunction and cGAS-STING-NFkB signaling overactivity. "Hot-immune/C3" had an innate immune inclination and

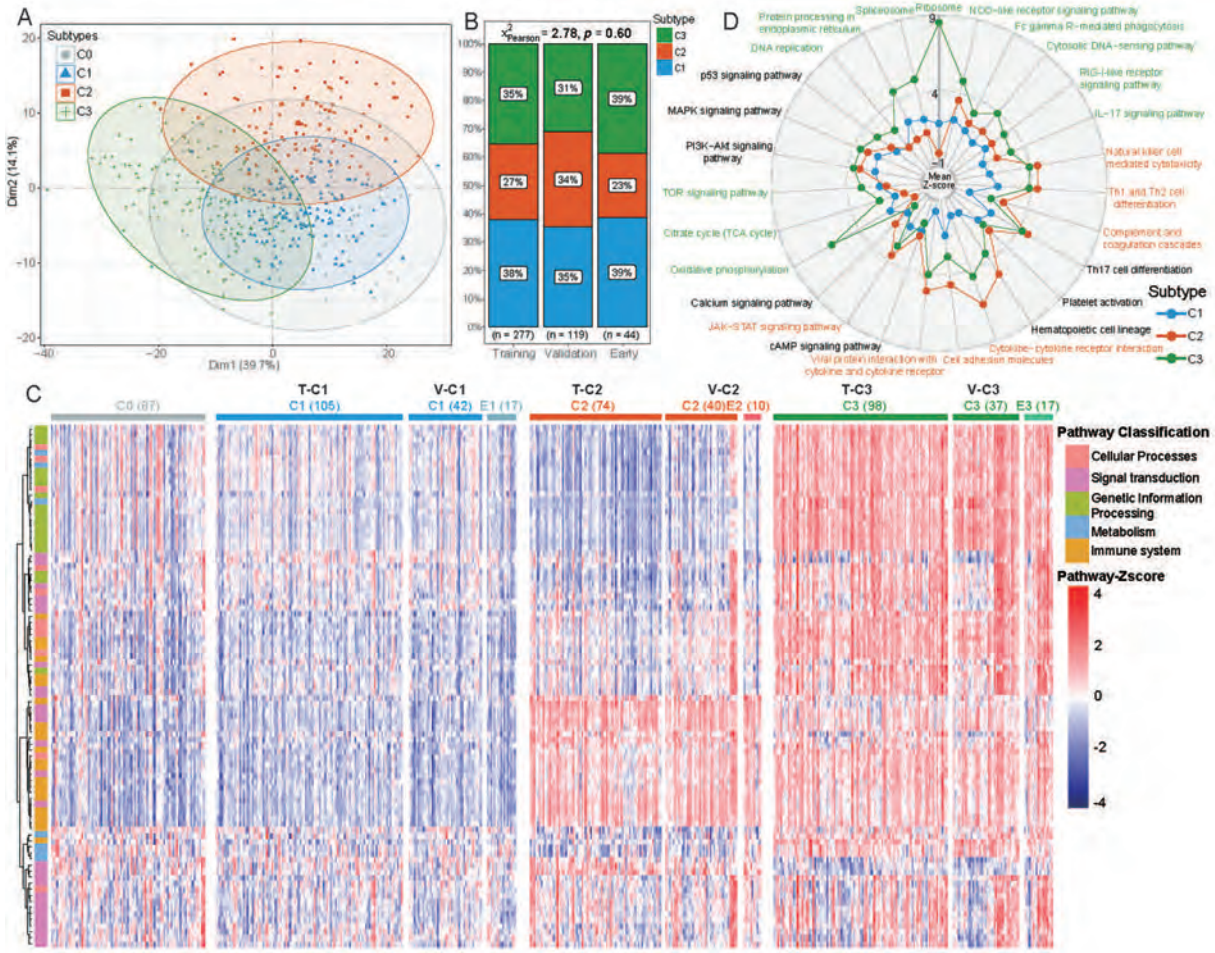
Overview of this study We recruited 527 participants based on respective criteria, including 87 non-pSS (C0), 44 early-pSS, and 396 pSS. Using an unsupervised clustering approach on the transcriptomic data of SGs, we identified three distinct molecular subtypes in pSS and early-pSS. We then conducted extensive downstream analysis on their clinical and biological and immune features, immune-metabolic and genetic characteristics, and disease diagnosis, prognosis, and treatment response prediction. pSS, primary Sjogren's syndrome; PIM, pauci-immune; CIM, cold-immune; HIM, heat-immune; ICI, immune cell infiltration; mIHC, multiplex immunohistochemistry; eQTL, expression quantitative trait loci; bDMARDs, biologic disease-modifying anti-rheumatic drugs; tsDMARDs, targeted synthesis disease-modifying anti-rheumatic drugs.

predominantly active metabolism processes, especially for oxidative phosphorylation (OXPHOS). Among the three subtypes, C2 had a higher lymphoma risk with the highest immune cell and endothelial cell infiltration in SGs. Based on the distinct features of each group, we matched them with approved or exploratory treatment options the patient most likely would benefit from, including conventional medicine, JAK inhibitors, and biologics.

Conclusion: Overall, our findings provide a comprehensive and in-depth molecular landscape of SGs in pSS, shedding light on the disease heterogeneity and promoting the development of precise clinical intervention strategies for pSS patients.



Molecular classifications and biological features of pSS subtypes (A) A PCA plot to show 3 groups of pSS patients (C1, C2, C3) by hierarchical pathway-based clustering. Non-pSS cases were overlaid using the same algorithm (C0, grey dots). (B) The scale map showing the distribution of 3 pSS subgroups in the Training set, Validation set and early-pSS cohorts without significant difference (Chi-Square test, p =0.60). (C) A heatmap generated from transcriptomic information via hierarchical pathway-based clustering based on z-score levels, including pSS Training set: 277/70%, pSS Validation set: 119/30%, 44 early-pSS patients, and 87 non-pSS cohorts, illustrating the distribution of five categories of pathways across the ten subtypes (non-pSS/C0 (87), T-C1(105), V-C1(42), E1(17), T-C2(74), V-C2 (40), E2(10), T-C3(98), V-C3(37) and E3(17)). T-C represents the clustering pSS subtypes in the Training set; V-C represents the clustering pSS subtypesthe in the Validation set; E represents the clustering early-pSS subtypes. (D) Representative significant pathways for each cluster. A radar plot showing the mean pathway z-scores in three pSS subtypes; C1 (blue), C2 (red), and C3 (green).

A Phase 3 Study of Repeat Injection of TLC599 in Osteoarthritis of the Knee: Benefits to 52 Weeks

George Spencer-Green[1], David Hunter[2], Thomas Schnitzer[3], Sheue-Fang Shih[4], Tien-Tzu Tai[4], Cathy Kao[4] and Siao-Ning Huang[4], [1]Taiwan Liposome Company, Cambridge, MA, [2]Sydney Musculoskeletal Health, University of Sydney, St Leonards, New South Wales, Australia, [3]Northwestern University Feinberg School of Medicine, Chicago, IL, [4]Taiwan Liposome Company, Taipei, Taiwan (Republic of China)

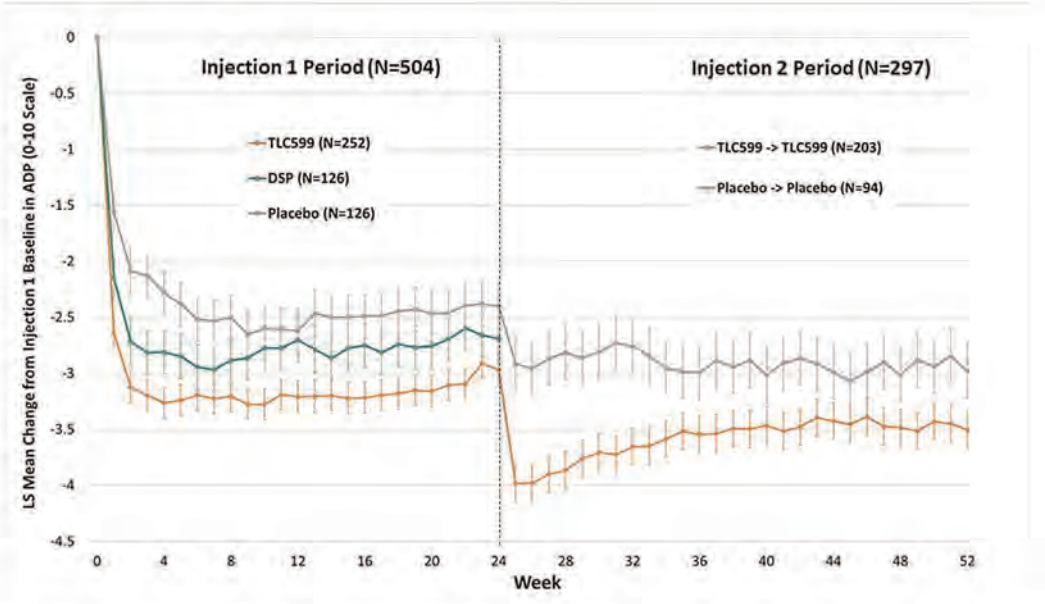
SESSION INFORMATION
Session Date: Wednesday, November 15, 2023
Session Title: Late-Breaking Abstracts
Session Type: Late-Breaking Abstract Session
Session Time: 7:30AM–9:00AM

Background/Purpose: In osteoarthritis (OA) of the knee, intraarticular injections of corticosteroids can relieve pain, reduce inflammation, and improve mobility, but the effect is not predictable, and the duration of pain relief can be short. The benefit of repeat injection has not been established. TLC599 is a liposomal formulation of dexamethasone sodium phosphate (DSP) intended for administration by local injection to provide sustained relief of pain of OA of the knee. The current study was conducted to confirm earlier phase 2 results demonstrating pain relief in OA patients over 24 weeks (*Hunter et al., 2022*), and to study the benefit of repeat injection over one year.

Methods: The study was a Phase 3, randomized, double-blinded, 3-armed, placebo- and active-controlled study to evaluate the efficacy and safety of TLC599 in single or repeat doses, in patients with K-L Grade 2-3 OA of the knee and average daily pain (ADP) from screening diary completion in the index knee of 5-9 (on a scale of 0-10). A total of 506 patients were randomized in a 2:1:1 ratio to receive an injection of TLC599 12 mg, DSP 4 mg, or saline placebo. At Week 24, eligible patients in the TLC599 and placebo arms received a second blinded injection of the same treatment, while patients in the DSP arm received a blinded injection of TLC599. Efficacy and safety were assessed through Week 52. Among other efficacy parameters, ADP and Western Ontario and McMaster Universities Osteoarthritis Index (WOMAC) pain were assessed using Mixed Models for Repeated Measures (MMRM) and Analysis of Covariance (ANCOVA), respectively.

Results: With respect to WOMAC pain, TLC599 was numerically superior to placebo at all time points through week 24, and statistically superior ($p < 0.05$) at Week 12, the primary endpoint. For ADP, TLC599 was numerically and statistically superior ($p < 0.05$) to placebo at all time points during Injection 1 period (Figure). Additionally, at Week 12, the reduction in ADP for

Change from Injection 1 Baseline in Average Daily Pain (ADP) Score of Patients Who Received the First Injection through Week 24 (N=504) and Patients Who Received a Repeat Injection from Week 24 through Week 52 (N=297)



Note: Observed data are used. LS Mean (SE) was calculated using MMRM.

Change from Injection 1 Baseline in Average Daily Pain (ADP) Score of Patients Who Received the First Injection through Week 24 (N=504) and Patients Who Received a Repeat Injection from Week 24 through Week 52 (N=297)

TLC599 was superior to DSP ($p< 0.05$). A total of 203 patients who received an initial injection of TLC599 and 94 patients who received an initial injection of placebo were eligible and received repeat doses of TLC599 or placebo. The mean reduction in ADP from the injection 1 baseline for TLC599 was numerically superior to placebo at all time points through Week 52 and statistically superior through Week 34. TLC599 was generally well tolerated, with the number and type of adverse events similar among all three treatment groups. At Weeks 1 and 25 (after the second injection), there was a transient reduction in mean morning serum cortisol levels in patients who received TLC599, but this returned to normal by Weeks 2 and 26. There were no signs or symptoms of adrenal insufficiency in any patient.

Conclusion: TLC599 demonstrated a benefit over placebo in ADP and WOMAC pain in patients with OA of the knee after a single injection that was sustained to 24 weeks. A second injection of TLC599 at Week 24 provided further benefit to Week 52. These results provide additional information about the benefits of repeat steroid injection in OA of the knee and suggest that TLC599 may provide prolonged benefit and offer an alternative treatment for the management of OA knee pain.

Telitacicept, a Human Recombinant Fusion Protein Targeting and Neutralizing B Lymphocyte Stimulator (BlyS) and a Proliferation-Inducing Ligand (APRIL), in Rheumatoid Arthritis (RA) Patients with an Inadequate Response to Methotrexate (MTX): A Randomized, Double-Blind, Phase 3 Study

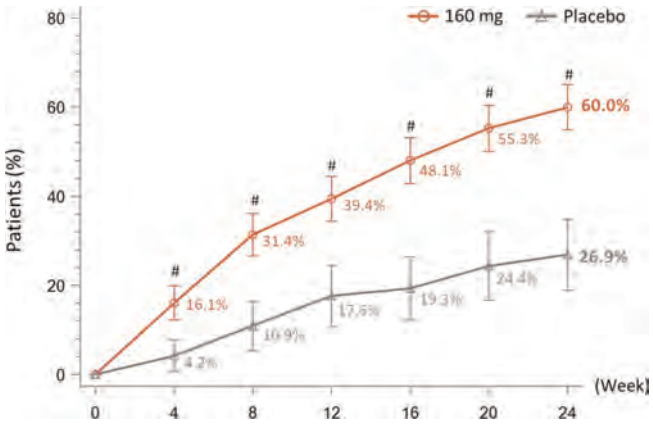
Li Wang[1], Dong Xu[2], Jianmin Fang[3], **Qing Zuraw**[4] and Fengchun Zhang[1], [1]Peking Union Medical College Hospital, Beijing, China, [2]Peking Union Medical College Hospital, Dong Cheng District, China, [3]RemeGen Co, Ltd., Yantai, China, [4]RemeGen Biosciences, Inc., San Francisco, CA

SESSION INFORMATION
Session Date: Wednesday, November 15, 2023
Session Title: Late-Breaking Abstracts
Session Type: Late-Breaking Abstract Session
Session Time: 7:30AM–9:00AM

Background/Purpose: Telitacicept is a recombinant fusion protein targeting and neutralizing BLyS and APRIL. This phase 3, randomized, double-blind study evaluated the efficacy and safety of telitacicept 160 mg versus placebo in RA patients with an inadequate response to MTX.

Methods: This was a 24-week, randomized, double-blind, placebo-controlled, phase 3 study with an open label treatment follow up period from week 25 to 48 (NCT03016013). Patients with moderate-to-severe RA with an inadequate response to MTX were randomized 3:1 to receive either telitacicept 160 mg or placebo QW for 24 weeks. After Week 24, patients in the placebo arm were switched to telitacicept 160 mg QW for an additional 24 weeks. The primary efficacy endpoint was the proportion of patients achieving an ACR20 response at Week 24. Secondary efficacy endpoints included response rates for ACR50 and ACR70, individual components of the ACR response, DAS28-ESR, and radiographic joint damage as measured by the mTSS at Week 24.

Results: A total of 479 patients were randomized to receive telitacicept 160 mg (N=360) or placebo (N=119). Baseline demographics and disease characteristics were similar between the two groups, with the exception of CRP level which was higher for telitacicept versus placebo (22.856 mg/L vs. 17.287 mg/L). The primary endpoint was met with significantly more patients in the telitacicept 160 mg group achieving an ACR20 response at Week 24 compared with the placebo group



ACR20 Response Rate Through Week 24 (NRI, FAS). #P<0.001 vs. Placebo. NRI, missing data were imputed as non-response. FAS, full analysis set.

FAS, full analysis set.

AE, n (%)	Telitacicept 160 mg (N=360)	Placebo (N=119)
TEAE	287 (79.7)	92 (77.3)
SAE	23 (6.4)	8 (6.7)
TEAE leading to discontinuation from study treatment	14 (3.9)	4 (3.4)
Death	0 (0)	0 (0)
Infections and infestations* (SOC)	148 (41.1)	50 (42.0)
Upper respiratory tract infection	88 (24.4)	28 (23.5)
Urinary tract infection	26 (7.2)	10 (8.4)
Bronchitis	12 (3.3)	1 (0.8)
Herpes zoster	2 (0.6)	4 (3.4)
Serious infections	8 (2.2)	4 (3.4)

Summary of Adverse Events Through Week 24 AE, adverse event; TEAE, treatment-emergent adverse event; SAE, serious adverse event; SOC, system organ class. *AEs with an incidence of ≥3% in any group were listed.

(60.0% vs 26.9%, P< 0.001) (Figure 1). At Week 24, the proportion of patients achieving an ACR50 response was significantly higher in the telitacicept 160 mg group compared with placebo (21.4% vs. 5.9%, P< 0.001) and the reductions from baseline in the DAS28-ESR as well as the individual components of the ACR criteria were significantly greater for patients receiving telitacicept compared with placebo (Table 1). Significantly more patients in the telitacicept 160 mg group showed no radiographic progression (△mTSS ≤0) at Week 24 compared with placebo (90.2% vs 66.4%, P< 0.001). Additionally, patients in the telitacicept 160 mg group showed significantly less progression of joint damage (as measured by mTSS, joint space narrowing score, erosion score) from baseline to Week 24 (Table 1). The incidences of treatment-emergent adverse events (TEAEs), serious adverse events (SAEs), TEAEs leading to discontinuation from study treatment, and infections were similar between the telitacicept 160 mg group and placebo group (Table 2). No patient deaths occurred during the study.

Conclusion: These phase 3 study results demonstrate the efficacy (e.g., responses in the ACR20, ACR50, and DAS28-ESR; and no radiographic progression measured by mTSS) and safety of telitacicept in treating moderate-to-severe RA patients with an inadequate response to MTX.

You Can't Get This from a Doctor: The Role of Support Groups for Adults Aged 25-55 Living with Arthritis

Eileen Davidson, Global Healthy Living Foundation, Burnaby, BC, Canada

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Patient Perspectives Poster
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Living with a rheumatic condition comes with unique concerns specific to mental and social health like struggling with fatigue, anxiety, depression, and isolation, all while experiencing chronic pain and complications from being immunocompromised. Since my rheumatoid arthritis (RA) diagnosis eight years ago, I am no stranger to such feelings. The Covid-19 pandemic heightened these concerns, and had a large impact on my well-being and the well-being of many other people living with arthritis.

Intervention: Peer support groups for people with arthritis to meet with each other in person is an effective approach to combating anxiety and loneliness. With support from the Arthritis Society Canada's Community Action Grant, and using my skills and connections as a patient advocate to create a support group, I created an in-person support group to be held at a Vancouver, Canada arthritis clinic. "The Arthritis Social Hour" was designed for people with any form of arthritis between the ages of 25-55, an age group often without programs designed for them. The aim of this group was to provide a safe space for patients to express their concerns, share their journey, and learn from each other and qualified professionals in a fun, easy to understand and engaging environment.

Maintenance: Across ten in-person support group sessions held from February 8 to April 5, eighteen unique patients attended, many attending multiple sessions. Some patients reported never having met another person with arthritis in their age range, including someone who had been living with RA for 30 years. Patients new to Canada, who did not know anyone living with the condition and were newly diagnosed without current medical help, were able to receive guidance on where to seek care for their arthritis. Some patients met with an occupational therapist or physiotherapist for the first time at the in-person sessions. These providers offered long-term advice on how to exercise or self-manage arthritis.

Quality of Life: As people with lived experience, we speak a unique language together that can often not be provided elsewhere. Connecting with others living through similar experiences can foster transformative moments in our disease journeys. Such encounters lead us to feeling part of a community that understands and relates to the struggles that come with living with arthritis, especially as younger to middle-aged adults.

Hosting a support group reminded me how important it is for patients to connect with each other, to support each other, and learn together.

Since hosting the event, I have been able to reduce my own feelings of isolation and loneliness as a person living with arthritis.

THEMES	SPEAKERS
Medications Sleep Mental Health Work Diet Nordic Walking Poles Fatigue Relationships Covid-19 Art Exercise Yoga Advocacy	Physiotherapist Researchers Occupational Therapists Rheumatologists Patient Advocates Certified Yoga Therapist Kinesiologists Expressive Arts Therapist

The majority of my appointments are no longer than 20 minutes, which is not enough time for deep conversations on topics important to me. The opportunity to sit for two hours talking with other patients and professionals provided me with an incredibly invaluable amount of information and resources from my local community, which has broadened my abilities to self-manage my condition.

The Arthritis Social Hour continues to meet once a month to connect more people. The group's size and popularity is growing, along with my skills as a leading patient advocate.

Patient Centered Care: The Complete Picture

Chisa Nosamiefan, South Weymouth, MA

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Patient Perspectives Poster
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: My recollection is that in l997 there about, I began to feel sick and I experienced these symptoms, night sweats, pain in my chest, breathlessness, always being tired, and I was loosing weight. This persisted over a span of five years. My doctor's interpretation of my symptoms was unexplained fevers, pericarditis, pleurisy, fatigue, unintentional weight loss. Initially, the diagnosis was unclear, and the treatment focused on managing the symptoms. Eventually, I was diagnosed with mixed connective tissue disorder and later with lupus.

Intervention: My healthcare team headed by my exceptional rheumatologist was able to step me down from clinically critical to medically stable but lupus continued to ravage other areas of my life which kept me unwell.

To address this, I applied a patient-centered therapy approach to my non-clinical symptoms of lupus. I identified and addressed various issues that didn't necessarily show up in my blood work but still impacted their health and well-being.

Maintenance: The first four issues I addressed were as follows:

1. Stress factors: By listing my assumed or real stresses, I was able to alleviate a significant level of stress. I made adjustments in my lifestyle and eliminated unnecessary sources of stress, considering my reduced income due to not being able to work.
2. Diet and Exercise: Educating myself about nutrition and eating habits led to changes in my diet, gradually reducing sugar, salt, and fried food. This change in diet resulted in reduced fatigue and enabled me to start exercising. Water aerobics, a low-impact exercise, became a fun activity for I began.
3. Support system: I recognized that relying solely on my family for support and care was not feasible, as my family members were also affected by lupus in a secondary sense. I intentionally built a support system that included emotional, spiritual, instrumental, informational, and appraisal support. I found a network of caring and knowledgeable individuals, including fellow patients, doctors, friends, and empaths, who provided the support I needed.
4. Hobby, Interest, or Amusement: Lupus had taken away my enjoyment in life, so I decided to explore new hobbies. I began visiting different neighboring towns and cities, engaging in sightseeing, taking pictures of historic architecture and water views, and people-watching from my car. This allowed me to find amusement and have fun without requiring extensive physical activity.

Quality of Life: Gradually over time there was a significant change in the quality of my life. I learned how to distress, I was going to the gym for the first time in my adult life, I had a new social community and I was out and about. More importantly I believe that the application of precision patient centered therapy to my non clinical lupus symptoms impacted my clinical symptoms. I had fewer flares and no more lupus related hospitalization.

The Labalaba Foundation inspired by my approach, adapted this patient centered approach in their programs for lupus patients self care management.

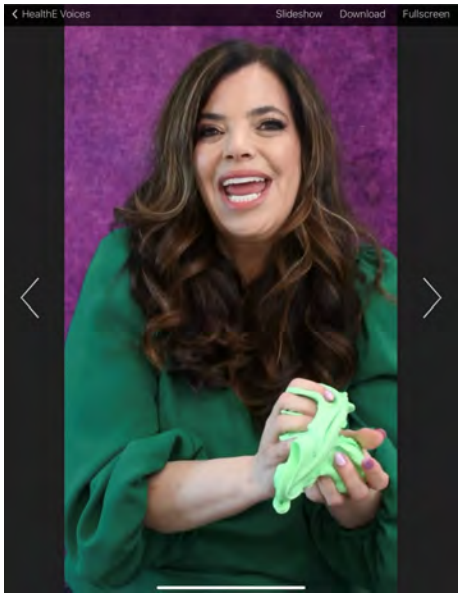
Lupus with Slime: Improve QOL and Increase ROM in SLE with Slime

Amanda Greene, Los Angeles, CA

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Patient Perspectives Poster
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: In 1983, over forty years ago, I was diagnosed with Systemic Lupus Erythematosus (SLE). I was immediately prescribed high dose corticosteroids. My body and disease flared. After 16 months, the rheumatologist and internist decided to start to taper my medication dosage. I was stabilized at 20, 15, 12.5 and 10m milligram daily doses. However, the side effects were still drastic, and I wanted to see how well I would do at a lower dose. So together with my doctors, I started a slow (super slow) taper process. Eventually, I was taking 2.5 milligrams of steroids a day. After three months, we discussed another tapering. It took another three months, in 1989 I took my last dose of corticosteroids. At the



While living with Lupus using slime has a positive impact on both my physical and mental health.

Stepping into slime requires strength, stability and balance.

time, my doctors thought I would have a potential future need for another round of corticosteroids, as most people living with lupus do. My prognosis at the time of diagnosis was a life expectancy of 5-7 years based on my symptoms and lab work.

Intervention: During the intervention, and while I was in lockdown, I was struggling to balance my mental and physical health, when I discovered how slime could help me stretch my mind and body. I quickly realized how much I needed the tactile sensation and distraction; the slime had helped me regain my sense of play and I was captivated by the autonomous sensory meridian response (ASMR) that popping slime provided. With some practice, I was doing tricks and I saw my outstretched arms and shoulders above my head, even better I was not wincing in agony. My Range Of Motion (ROM) was increasing with each session and I was thoroughly enjoying my self, while the slime was providing me with quality occupational therapy, I was improving my Quality of Life (QOL) and the impact on my state of mind which is evident in the "countless smiles that smile has brought to my face." Slime has had a such positive impact on my life that I am using less prescription pain and anxiety medication to help maintain my healthy "flare free" state while living and thriving with SLE for 40 years and still striving.

Stretching slime, opens up my ROM and I have discovered countless smiles and reduced anxiety due to the essential oils that enhance the sensations and tactile joy.

Maintenance: Due to my use of slime as a tool for my mental and physical health, I am using less prescription pain and anxiety medication to maintain a healthy state of aging with while living with SLE and I am a proud "adult slimer" who has found a way to quantify my playtime as being truly good for my health.

Quality of Life: Due to my use of slime as a tool for my mental and physical health, I am using less prescription pain and anxiety medication to maintain a healthy state of aging with while living with SLE and I am a proud "adult slimer" who has found a way to quantify my playtime as being truly good for my health.

Bouncing Back: How I Found My Running Shoes Using a Rebounder for My Psoriatic Arthritis

Ashley Krivohlavek, University of Oklahoma, Claremore, OK

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Patient Perspectives Poster
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: When I was diagnosed with psoriatic arthritis (PsA) nine years ago, I thought my running days were behind me. Since high school, I have loved exercising. Cardio, specifically running, had always been my favorite because it cleared my head and invigorated me, preparing me mentally and physically for the day ahead. I built a running routine that fits my life well. I started by getting up ten minutes earlier than normal to ensure I had enough time to work out. Once I established the routine of getting up earlier, I gradually increased the minutes (five to ten minutes at a time) to where I am now. I also find that laying out workout clothes and shoes the night before helps keep me from missing my workout. I have also found that rewarding myself before and/or after my workout with something like coffee keeps me interested and excited about doing it. Given that my family has a history of heart disease and diabetes, I was proud that I was establishing a lifelong habit of and love for exercise. However, when my joints started becoming inflamed and painful from PsA about nine years ago, it looked like my running days were over. My rheumatologist recommended light workouts such as yoga and tai chi, so I incorporated them into my new routine, but I really missed running and runner's high. I began researching how I could run without further trauma to my joints.

Intervention: I began by researching workouts online and found several that included run-in-place examples. These run-in place examples were on a rebounder (mini trampoline). The constant impact on my feet, ankles, knees, and hips prevented me from running as I had before my PsA diagnosis. I was interested to try running on the rebounder and see if it gave me the

same benefits as regular running. I bought a rebounder and began practicing. Once I got comfortable running in place, I started doing other things on the rebounder, such as jumping jacks and squats. I also found a free Tabata timer app and created a high-intensity interval training (HIIT) routine (Table 1). I showed it to my rheumatologist, who approved my routine and reminded me to wear running shoes while on the rebounder, hydrate before and after, listen to my body, and slow down if needed. I had found my way back to running without adding more trauma to my joints.

Maintenance: Since starting my HIIT routine, I have added weights and core training to my regimen. In addition, I have increased my endurance by doing a longer HIIT routine and added a day of yoga and Pilates to my weekly schedule (Table 2). I plan to continue increasing the amount of time I do my HIIT routine and gradually adding heavier weights.

Quality of Life: I like to say that rebounding gave me back my running shoes. It fosters the same love of running I had before PsA and builds my physical strength while providing mental clarity. My rebounder helped teach me that I could still have autonomy over my body, even when PsA continues to occasionally surprise me with new physical and mental disruptions.

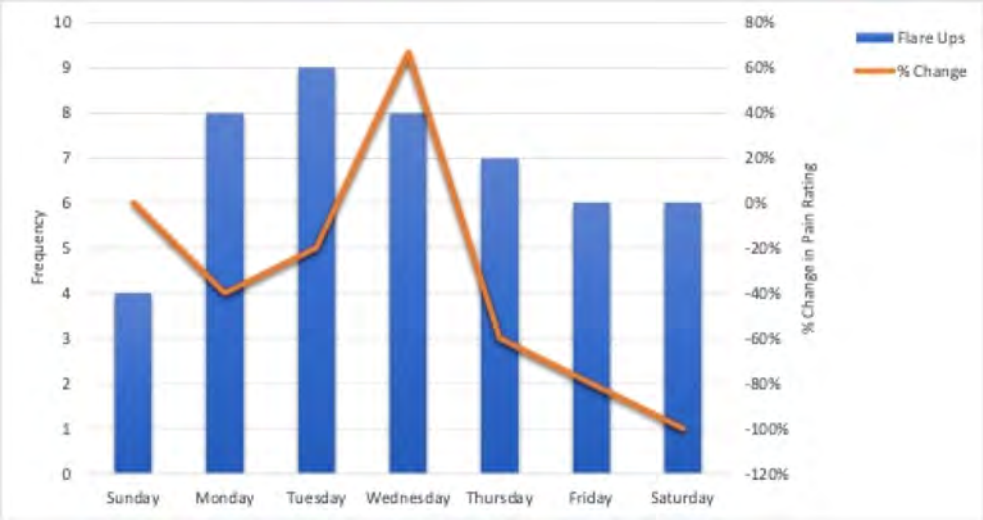
Relief Redefined: A Patient's Journey to Reducing the Impact of Her PsA Flare Ups

Caitlin West, Advocate, Coatesville, PA

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Patient Perspectives Poster
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: I was diagnosed with Psoriatic Arthritis (PsA) ten years ago, at 25. I had been dealing with stiffness and chronic fatigue for most of my life. Growing up I was actively accident prone (falling off horses, rock climbing falls, a skiing accident or two). I didn't think much of my pain growing up as I was so tough on my body. However, the pain I was experiencing, at 25, was unnatural. Approximately a couple months after my relocation from Santa Monica, CA to Houston, TX, I was unable to move my hands and morning inflammation lead to stiffness which severely limited my mobility for 1.5 hours. I was taking 6 Advil (200 mg) around 3x a day. A couple months later psoriasis' began to appear all over my face, neck, shoulders, and chest.

My primary doctor thought I had stressed induced eczema and possibly lupus. She was able to help expediate my dermatologist appointment. By the time I had my dermatology appointment my fingers swelled to the point of looking like sausage links, my face was swollen and bloated, and I had a hard time standing up or sitting down. The dermatologist was confident that I



Average daily flare ups and the % change in pain rating

had psoriasis and naturally with the visibility of my joint inflammation + chronic pain, she was also confident that I had PsA. Within a month I was able to get into a rheumatologist and time to diagnosis was relatively short. I was on Remicade infusions within a couple weeks after my visit. My dosage was 500 mg every 4 weeks and eventually reducing the frequency to every 8 weeks (present day). I do not pair Remicade with other drugs, outside of steroid injections and meloxicam 15mg (as needed).

Intervention: Novel therapy circuit inspired by over-the-counter therapeutic devices

1 out of 4 arthritis individuals experience daily debilitating pain and +80% are dissatisfied with their pain management options during these times (MEDSurvey April 2023). Therapeutic devices mainly encompass one technology (i.e. infrared light, TENS, PEMF), bulky and obvious (i.e. wires, straps, and gadgets to keep the device in place), and expensive! Personally, I spent ~$300 / device and have four devices. I was determined to create a better solution; obtaining flare up relief had to be easier and less frustrating.

Through experimentation, I found using infrared light, electric stimulation, and hot/cold therapies in a specific manner + routines resulted in a reduction of intensity of my flare ups. For 84 days (42 pre and 42 test period) I tracked my: back spasms and sharp pain (back, knees and hips). In the pretest and test period I continued my workout routine which includes swimming and biking 4x a week. During the test period I created a routine of 3 days /week (min.) where I utilized the novel therapy combination: 5 mins infrared light, 10 mins electric simulation, 5 mins hot/cold therapy with reduced intensity of infrared light.

Maintenance:

The Result: -45% reduction in flare up intensity (95% CI $p < 0.03$)

Reference chart

Quality of Life: I have noticed a significant improvement in my quality of life since the introduction of my novel therapy. The pain and discomfort which used to interfere with my daily routine has significantly reduced. My mood has lifted considerably, and I find myself feeling more optimistic and energetic.

Disclosure: C. West: None.

Dana's Data Dashboard: Applying a Familiar Framework for Efficient and Effective Health Management

Dana Guglielmo, Los Angeles, CA

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Patient Perspectives Poster
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: As a researcher and data analyst, I enjoy the meticulous attention to detail that my work requires. I love the process of collecting, analyzing, and interpreting data to find patterns to ultimately improve population health. My passion for public health comes from my own health battles: I have rheumatoid arthritis and several other chronic conditions. These require ongoing maintenance, including doctor appointments, medications, labs, prior authorizations, referrals, and more. I started seeing more specialists in my 20s, and with each new specialist it became increasingly challenging to remember all of the complex and intricate details of my health management plan. I felt overwhelmed trying to stay on top of all of the moving parts, and I realized I needed to make a change.

Intervention: I applied a familiar framework to my health management by turning it into a research project! The first step was getting organized, so I created a spreadsheet to manage my health information. Although it accomplished my immediate goal of getting organized, the spreadsheet was very plain and I did not use it often. I decided to turn it into a Dashboard (Figure 1). In the research world, a "Dashboard" is any data visualization platform that distills large amounts of complex information into a user-friendly data snapshot. I'm a fun and vibrant person, and the design needed to match this. I added colors, icons, clickable dropdown buttons, and optimized it for use on a computer or mobile device. I embedded links to different apps - for example, clicking an address pulls up real-time directions.

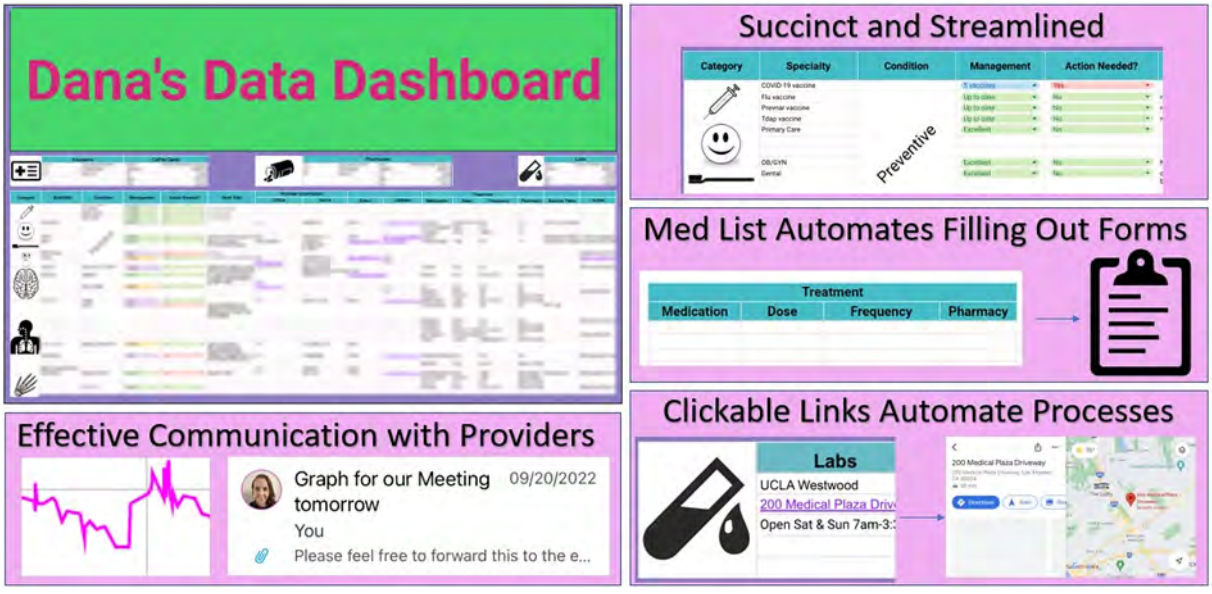

Figure 1. Dana's Data Dashboard: a snapshot of the numerous features and benefits of my dashboard.

Figure 2. Proactive instead of reactive health management: finally getting my routine rheumatology labs completed on schedule!

Figure 3. Portable, adaptable, and user-friendly: demonstrating that I can manage my health anytime and anywhere (even in a tree!) at Santa Ynez Falls, Los Angeles California.

Maintenance: My dashboard greatly improved my health management in several ways: (1) My approach changed from reactive to proactive (Figure 2). I now stay on top of appointments, medication refills, labs, prior authorizations, etc. long before they are due. (2) My communication with my health care team substantially improved. I can communicate large amounts of accurate health data efficiently, concisely, and effectively. I can articulate my thoughts much more clearly. For example, if I want to demonstrate a pattern I've noticed, I present it in a graph. (3) I am significantly more confident about my health management. Visualizing my progress allows me to come up with creative ideas and solutions to problems efficiently - just like a research project! (4) Most importantly, these changes have led to reduced stress levels and a decrease in symptoms of my arthritis and other chronic conditions.

Quality of Life: Dana's Data Dashboard transformed my health management. Not only can I manage my health anytime and anywhere (Figure 3), but it has enabled me to "zoom out on the graph." Instead of focusing on the day-to-day never-ending list of tasks, I can see the bigger picture: I am finally managing my health effectively. The final piece of any research project is disseminating findings in a way that can help others - hence this abstract! My hope is that this abstract will provide inspiration for others to work with their medical team to utilize their own strengths and interests to translate their health management into an area of their life in which they can excel and thrive.

Disclosure: D. Guglielmo: None.

How "Coming Out" About My Lupus Diagnosis Allowed Me to Connect With Patients, Get Involved With Research, and Spread Awareness

Jamie Chieh Lo, School of Medicine, I-Shou University, Keelung, Taiwan

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Patient Perspectives Poster
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Ever since I started medical school, I have been advised to not talk about my experiences with SLE. Family, friends, and even professors have warned me that discussing such topics may have negative implications on my future career.

Initially, I was skeptical. However, I soon found out that many young people, particular physicians, are extremely reluctant to openly discuss their chronic conditions, because they were worried about employers viewing them as a liability.

Intervention: In order to spread awareness about lupus, I ventured out of the private patient support groups and started with a Facebook post explaining my diagnosis to family and friends, more than 4 years after my first rheumatologist visit.

I also started to post regularly about both my personal journey and educational content about lupus on my Instagram account with more than 13000 followers. Friends and strangers alike messaged me to exchange experiences (as well as morbid jokes that will make healthy peers quite uncomfortable). I was also able to convince a few who were experiencing mysterious symptoms to see a rheumatologist. In one case, lupus nephritis was diagnosed early, and treatment was initiated before any further damage occurred!

The author presenting at the HBV Patient Session, AASLD The Liver Meeting 2022

Encouraged by the response I received, I felt empowered to go further in my advocacy and started sharing my experiences with another stigmatized condition: CHB. With CHB, managing lupus is more challenging since the treatments I am on, like steroids and rituximab, carry a high risk of causing HBV reactivation.

However, as a young "healthy" carrier, I was ineligible for costly antiviral medications under Taiwanese National Health Insurance (NHI), even though I had an off-the-charts viral load, mildly abnormal liver function, and was at risk of infecting my patients. I shared my story at multiple international hepatitis meetings, and with the effort of fellow advocates, eventually NHI agreed to start covering antivirals for immunosuppressed patients like me.

Maintenance: In recent years, Taiwan has seen an upsurge of patient-led advocacy efforts. As a result, many new drugs are now available for oncology and rare disease patients, and we are beginning to see the same trend in rheumatology. Patients have also become more health-literate, thanks to improved access to high-quality educational materials in Mandarin.

As a bilingual medical student, I also joined the translation task force of the COVID-19 Global Rheumatology Alliance. Over the past 3 years, we have translated the adult and pediatric versions of our vaccine survey into dozens of languages and disseminated them worldwide. I am also working on several other projects in autoimmunity and viral hepatitis, and was able to present my research at several international conferences.

Quality of Life: Inspired by the feedback I've received and progress that has been made, I no longer view myself as a "liability". Instead, I strongly believe that my lived experience as both a medical student and a patient are valuable assets when it comes to patient care, research, and advocacy.

In the future, I hope to become a rheumatologist who conducts research that meets patients' needs, as well as an advocate for a more inclusive workplace environment for young professionals living with chronic illness.

Disclosure: J. Lo: None.

Finding Gratitude in Adversity: The Impact of Finding the Right Rheumatologist

Yaideliz Acevedo, Global Healthy Living Foundation, Newark, NJ

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Patient Perspectives Poster
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: I recall sitting in the doctor's office with my one-month-old baby in his stroller, hearing the words "You have rheumatoid arthritis." At 21, I had no understanding of this condition, and my primary care doctor didn't take the time to talk to me about it. I didn't perceive it as too serious, but after my first visit with a rheumatologist, I felt worse than before. He assured me that I would be fine, but left the room before I could ask any questions or seek comfort in understanding my disease. This made me feel frustrated because I felt I would receive the same standard care as everyone else.

Because of this, I decided not to take the prescribed medication, hoping the condition would pass.. However, my condition deteriorated to the point where I couldn't care for myself, let alone my son.

Intervention: This realization prompted me to seek answers and take control of my health. I started on my own research journey and found a rheumatologist who took me seriously and took the time to answer my questions. She emphasized the importance of adhering to the treatment plan. This marked a turning point for me, igniting a desire to be proactive in my care.

Around that time I also found CreakyJoints. CreakyJoints is an international digital community for people living with arthritis who seek education, support, advocacy, and patient-centered research. The articles and personal stories available on the CreakyJoints.org website provided invaluable insights and answered questions I thought no one could address. To this day, I keep a 'bucket list' of ideas to try from those articles. Whenever doubts, concerns, or questions arose, I turned to CreakyJoints for guidance. It became my go-to resource and has prompted many great conversations about integrative treatments with my rheumatologist.

Through CreakyJoints, I discovered patient advocacy opportunities and ArthritisPower, a patient-centered research registry. Inspired to be a voice for others facing similar challenges, I embraced the chance to advocate for the rheumatoid arthritis (RA) community. By fostering a closer relationship with my doctor, I gained better control over my flares and realized that a fulfilling life with this disease was possible. Lifestyle changes and the insights I gained from my experiences allowed me to manage my RA effectively.

Maintenance: I'm still navigating how to thrive with the disease. Currently employed as a certified medical assistant at a cancer center, I cherish the open line of communication and trust I've developed with my rheumatologist. Participating in various projects with CreakyJoints has been transformative. Connecting with individuals across the world who share similar conditions has provided immense support and learning opportunities. We help one another while gaining insights into our conditions and sharing ideas that may work for some but not others. Being part of this community has given me a voice and the chance to advocate for those who may feel unheard.

Quality of Life: Finding the right rheumatologist inspired me to become an active member of the chronic disease community and explore integrative treatments. Embracing this journey has led to a significantly improved quality of life, and I am profoundly grateful for the experiences I have gained.

Disclosure: Y. Acevedo: None.

Number: PP09

Practicing Mindfulness to Improve Quality of Life

Vanessa Patino-Lydia, Global Healthy Living Foundation, Hallandale, FL

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Patient Perspectives Poster
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: I've been living with symptoms of PSA and fibromyalgia for over 15 years. Four years ago, after flareup that severely impacted my mobility where I was unable to walk up/down stairs, get in/out of car, I was diagnosed with non-radial axial spondylarthritis. My quality of life was compromised and my future outlook felt grim.

Intervention: I began learning about spondylarthritis: what to expect, treatments, prognosis and ways to ease the pain. In the past my approach to rheumatic disease has been to just deal with the pain, ignore it, and keep pushing through, but this time I knew I had to do something drastically different. I needed to build a better relationship with my body. I tried complementary strategies to medical treatment such as meditation, reading, journaling, resting, leaving job, reducing commitments, massage, walking/movement, aqua therapy, and gluten- and sugar-free diets. Certainly all of these complementary approaches helped, but the real change occurred when I made a mental shift from thinking of my condition as "something I have to fix or change" to "something that I have to make peace with."

My rheumatologist recommended mindfulness training and a trusted friend recommended the Mindfulness Based Stress Reduction (MBSR) class, specifically. Over the course of six months, I began doing it in a self-directed way by watching videos, reading, reflecting, and practicing mindfulness activities, specifically:

- Body scanning and breathwork

- Building Awareness and slowing down
- Perspective changing
- Responding vs. reacting
- Not judging, self-love (loving kindness)
- Individualized choice
- Asking for what I need from family, from doctors

Maintenance: I still wake up tired with neck, hip, and back pain from my inflammatory arthritis. Mornings tend to be slow moving for me, and I don't commit to doing too much in the first two hours after I wake up. But now I have built awareness of this into my life. I look forward to my internal body scan as part of my daily mindfulness meditation routine. Fatigue is something I still experience, but what I tell myself about such things is different. These don't make me less than. They are my body's way of communicating with me. Am I going to listen? Am I going to advocate for myself? It is an ongoing process of befriending my body.

Quality of Life: I am much more aware of how I engage with my life and with stressors. My nervous system feels more relaxed, my heart rate is lower and I'm living with increased ease of wellbeing. This means more movement, presence with nature, getting outside, engaging in social activities and feeling more connected, less isolated. I am even planning a family trip overseas and working with my rheumatologist to have medications with me in case I have a flare up. Mindfulness helps me experience less suffering over pain (Table). I am less focused on needing to find a solution and instead focused on knowing that healing is within me.

Table. Observed Shifts in Quality of Life as a Result of Practicing Mindfulness

Shifting from this... **Focus on Emotional and Physical Toll of Living with Rheumatic Disease**	*To this...* **Mindful Adaptations to Healing**
Suffering: fearful of future and unknown, fearful of pain and loss of mobility	Listening to body and giving it what it needs: heat, cold, rest, stretching. Better sleep equals rest equals better mood and a feeling of having internal resources to cope with whatever comes up
Feeling defeated: depressed about what can't do anymore	Awareness of intrusive thoughts. Accepting what is, what's changed, showing love to myself.
Working harder: feeling behind not good enough which increased stress response	Mindful adaptation: shifting goals, realistic expectations, releasing judgement and having patience
Feeling guilty: Saying no to extra activities, social activities	More choice: Being intentional about time and energy and saying no to what I don't want to do.
Limited movement: Saying no to physical activity time and car travel	Knowing I am worth making adjustments: using back rest, heated seats for road trips, preparing medications, building in recovery time
Not making plans because can't commit	Being OK with change of plans
Grieving loss of self.	Living life even if it looks different: Freedom of Beginner's mind and trusting self Renewed personal outlook/sense of self

Disclosure: V. Patino-Lydia: None.

Saved by Plants: How a Necessary Lifestyle Change Led to a Happier Life with Decreased Rheumatoid Arthritis Pain and Fatigue

Shelley Fritz, Global Healthy Living Foundation, Nyack, NY

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Patient Perspectives Poster
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: After my RA diagnosis over eleven years ago, I was optimistic that the first biologic DMARD I took would slow the progression of my RA and ease symptoms. I spent the next decade switching medications to find better options, all while taking steroids between biologics to continue to have a decent quality of life. Weight gain came quickly and stayed. I began having gastrointestinal problems like microscopic colitis, but the moment that sent me racing for a healthier lifestyle was when I was diagnosed with non-alcoholic fatty liver disease (NAFLD).

Intervention: After a doctor told me I had fatty liver in 2022, I began exercising more regularly. I still had pain and fatigue, but my lab work showed low inflammation levels. Since 2015, I've been tracking my pain, sleep, and fatigue using patient-reported outcome measures available in the ArthritisPower app. Beginning in 2020, when I felt more isolated after a big move away from family and friends and the pandemic began, I also started tracking my satisfaction in social activities. I've been gluten-free and dairy-free for over a decade, but in January of 2023, I added one more change to determine how my diet might have an impact on my pain, fatigue, and sleep. This was because I always seemed to feel worse after eating processed foods and red meat, which are considered high-inflammatory foods.

Because I needed more information first, I researched low-inflammatory foods and diet plans. It was important for me to find a plan I could easily adhere to while keeping my meals free of gluten and dairy. I read that the Mediterranean diet is plant-based at its core, and I wondered if this diet plan would help me minimize inflammation and feel better. So, I made the decision to fully implement the Mediterranean diet and try it for four months (Table).

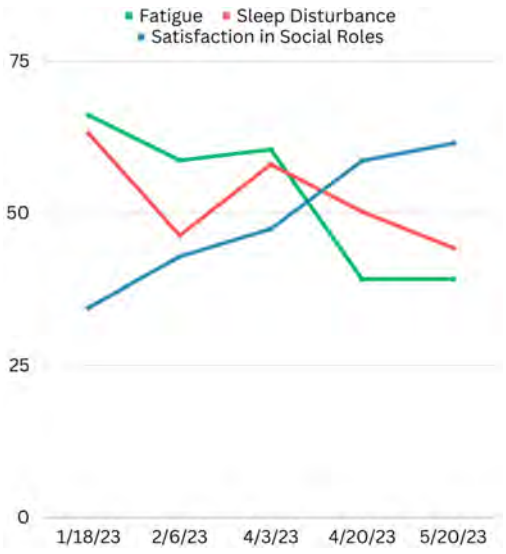

Figure 1: ArthritisPower data shows decreases in fatigue and sleep disturbance and increase in satisfaction with social roles.

Figure 2: Data from ArthritisPower app shows decrease in social isolation from January-May 2023

Within the first week of my Mediterranean diet, I felt major changes in my body. I had more energy and less fatigue. I continued tracking my symptoms over four months and found that my pain, fatigue, and sleep disturbance decreased noticeably on my ArthritisPower Health Picture (Figures 1 and 2). In addition, my desire to reach out to friends and socialize improved.

Table. My Mediterranean Diet

	Meal Examples			
Day	Breakfast	Lunch	Dinner	Snacks
1	Berries	Salad: asparagus, walnuts,	Salmon, artichokes, green beans	Roasted pistachios
2	Scrambled eggs with asparagus	Edamame hummus almond wrap	Roasted cauliflower with pistachios	Carrots with hummus
3	Fresh fruit bowl	Spaghetti squash with cannellini beans	Edamame pasta with chicken	Cashews
4	Omelet with spinach	Salad of vegetables and beans	Mahi Mahi with olives, capers, Greek-style potatoes	Apricot
5	Spinach and eggs with berries	Lentil soup	Black bean quinoa bowl	Celery and hummus
6	Berries and non-dairy yogurt	Roasted eggplant with non-dairy yogurt sauce	Shrimp with tomatoes and feta	Almonds
7	Frittata with red pepper and broccoli	Sauteed zucchini with lemon-basil dressing	Grilled chicken kebobs with Greek salad	Papaya

Maintenance: Eating healthy fats and avoiding foods that increase inflammation have been key to helping me feel better. I learned that blood work never tells the whole story. Before implementing the diet, I felt terrible even though my C-reactive protein (CRP) and erythrocyte sedimentation rate were lower than ever. Having a visual to represent how I feel helps me to communicate to my doctor that my medications are indeed working well now and that my dietary changes have helped me to feel as good as my blood work looked. The slight increase in fatigue and sleep disturbance in April reflects the two weeks I paused the new diet.

Quality of Life: Adhering to the diet helped me to make major improvements in my well-being. Today I have normal liver levels, more energy, less fatigue, less pain, and more inclination to socialize with family and friends. Managing RA is not only about effective medications; patients may need to also make lifestyle changes to support their treatment plan. There are limitations to the diet as it is high in healthy fats and may not help with weight loss, so continuing daily exercise and using portion control are essential.

Disclosure: S. Fritz: None.

We Suffered For Decades, But Then She Was Born

Ian Stedman[1] and Barbara Stedman[2], [1]Canadian Autoinflammatory Network, Vaughan, ON, Canada, [2]Canadian Autoinflammatory Network, Turkey Point, ON, Canada

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Patient Perspectives Poster
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: I was born in 1981; my mother in 1949; and my grandmother in 1926. Our story runs at least four generations deep, that we know of.

I began visiting my family doctor at 2 years of age for various issues, including swollen joints, bloodshot eyes, unexplained rashes, fevers, and debilitating headaches. My symptoms lasted from a half day to three days, with no patterns or triggers. My mother had the same challenges, as did her mother.

My childhood was defined by an endless search for answers. We rushed from specialist to specialist and spent long hours in waiting rooms to endure never-ending tests. I was prescribed anti-inflammatories, antihistamines, pain meds, but never accurately diagnosed. Doctors treated my symptoms, yet never suggested they might be connected.

By my late teens I lost interest in continuing the "specialist shuffle". I took the medicines I was prescribed and adjusted my lifestyle as needed. I missed school. I missed sports. I missed activities with friends. I accepted that my normal was not everyone's.

Intervention: Everything changed in 2012 when our first daughter was born. Like many babies, she had a rash at birth. Hers was different though. Like mine, it would go away and come back. It covered her body and sometimes her face, and she even experienced joint problems. Although I had given up looking for answers ten years earlier, it became clear that I didn't have that right anymore.

Image of skin on daughter's legs and left arm.

Image of author's legs.

My diagnostic odyssey re-started, I spent nights reading medical journals to no avail. Desperate, I searched online for images of rashes and found a blog. The blogger described his diagnosis and posted pictures of his rash. It looked like ours! I headed back to the journals, made a plan, visited more specialists, then had my eureka moment - I think we have Muckle Wells Syndrome! I searched for physicians who knew this rare disease and cold emailed a rheumatologist at our children's hospital. That rheumatologist responded within hours and asked me to obtain a referral.

Back to the hospital for more questions and tests. This time our blood was sent for genetic analysis and three months later we confirmed that we have Muckle Wells Syndrome (MWS). We learned that if left untreated, MWS can cause amyloidosis and sometimes lead to death.

Maintenance: Luckily, effective therapies were available. My mother, daughter and I now take an anti-IL-1b monoclonal antibody every 8 weeks. Our symptoms went away overnight and my daughter does have to live the same life that we did. I was in complete disbelief after that first dose and struggled for months to accept our "new normal". I feared it might be temporary, so I took nothing for granted.

Quality of Life: Treatment has changed our lives. It transformed my sense of what I am capable of and inspired me to think deeply about what I am responsible for. I am lifted each morning knowing that I am no longer limited by my health. I joined the board of a national rare disease advocacy group, which broadened my perspectives. I went back to University, earned my PhD in law and became a professor. I have testified before Canada's House of Commons Committee on Health and even co-founded a not-for-profit to help bring awareness to these diseases. MWS is merely one of 60+ gene mutations that have been described in the field of autoinflammation. Everyone should know them!

Disclosure: I. Stedman: None; **B. Stedman**: None.

Sjögren's-Fatigue: Non-Therapeutic Lifestyle Adjustments to Help Manage My Most Problematic Symptom

Lisa Rubenstein, Sjögren's Foundation, Los Angeles, CA

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Patient Perspectives Poster
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: I was diagnosed with Sjögren's disease in 2015. I sought help from a rheumatologist after experiencing hand pain. I also had dry eyes and dry mouth but thought the level of dryness was "normal." At the time, my health was so good that I did not even have a primary care provider. Since then, my disease has progressed to include comorbidities of orthostatic hypotension, Raynaud's phenomenon, and peripheral neuropathy. I now see five specialists on a regular basis. My Sjögren's symptoms have also worsened and fatigue is the symptom that affects my quality of life the most.

My fatigue takes different forms. I never feel rested and always wake up feeling tired. There are times when I feel as if I've literally hit a wall and need to immediately sit down and take a break. At times I can't even lift my arms.

Intervention: Unfortunately, at this time there is no medicine approved for Sjögren's that treats fatigue. I knew I had to do something to manage my fatigue to maintain and improve my quality of life. I started keeping a journal of when the fatigue worsened. I tracked the level of fatigue, frequency, time of day, activities during that day and the previous day, and level of stress. I tried to identify what activities would increase fatigue and what activities might lessen it. I found that my peak energy is early in the day and decreases significantly by midday. Stress definitely increases all of my Sjögren's symptoms, including fatigue. Debilitating fatigue occurs most often when my schedule is overloaded. As long as the fatigue is not debilitating, I found that exercise can temporarily make the fatigue go away.

Maintenance: Based on my analysis, I now schedule all appointments for the morning. I limit errands to 1-2 each day and do them in the morning. For the first time in my life, I hired house cleaners. I would rather save my energy for more fun activities! I stay active and exercise regularly, where I again try to schedule this for the morning. I also know that I should not plan other activities like laundry or errands on days with a heavy workout. I take a 1-2 hour break midday, then decide what else to accomplish the rest of the day based on my energy level after the break. I rarely go out in the evening.

Quality of Life: Despite my Sjögren's, I still do quite a bit of traveling, both in the United States and internationally. I understand that a trip will result in an enormous amount of fatigue. I do not schedule any appointments or events for a week after I return. I accept this as the price I pay to pursue my interests and continue to travel.

Although fatigue is still my most challenging symptom, scheduling my activities to minimize fatigue has reduced its impact on my life to a more tolerable level. I've accepted that I have a constant level of fatigue. I continue to do the activities I enjoy most – running and traveling among them. I'm not going to let my Sjögren's and fatigue stop me from living a fulfilling life.

Disclosure: L. Rubenstein: None.

Number: PP13

My Four Pillars of Wellness: How Sleep, Diet, Exercise and Stress Reduction Enable Me to Define My Life and not let Sjögren's Define Me

Susan Barajas, Sjögren's Foundation, Los Angeles, CA

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Patient Perspectives Poster
Session Type: Poster Session A
Session Time: 9:00AM–11:00AM

Background/Purpose: Being diagnosed with Sjögren's has been a life changing event for me.I was diagnosed in 2013 after suffering from various odd ailments. Ultimately, extreme fatigue, muscle pain and weakness led to my diagnosis. I spent 6 weeks with my legs feeling like I had just run a marathon. I was always on the move, played competitive tennis and had a corporate full-time career. I was a woman on-the-go…until I wasn't. My internist confirmed something was amiss and that I had positive ANA and SSB antibodies, and, subsequently sent me for a lip biopsy and to a rheumatologist for further evaluation, which confirmed my Sjögren's diagnosis.

Intervention: I was fortunate to have connected with a rheumatologist who was well-versed in Sjögren's and is deeply involved in rheumatic disease research. She immediately started me on 300mg of plaquenil, which took several weeks to kick in. In an effort to stay on top of things I began making adjustments based on the 4 main pillars of my wellness: sleep, diet, exercise and stress reduction. I developed a strict sleep routine and equipped my bedroom with the essentials for

restful sleep. I began working with a nutritionist and, on my doctor's recommendation, went gluten free and reduced my dairy and sugar intake, though I still love dark chocolate M&M's! It has been amazing to see the impact my diet changes have had on my inflammation. Keeping my body moving is key, even when I just want to curl up under a blanket. My exercise of choice is walking, and my preference is to be outdoors as much as possible. Lastly, I transitioned from my full-time corporate career to a more fulfilling career where I can manage my own calendar and stress. We call it Lisa 2.0.

Maintenance: Being diagnosed with a progressive disease only stressed the importance of keeping my health at the forefront of everything I do. With this in mind, those same pillars are my playbook – every single day. Maintenance for me is staying ahead of my disease. Sjögren's is truly a game of whack-a-mole. Sjögren's affects my bladder, nerves, eyes, and digestive tract. As these issues pop up, they need to be addressed immediately and I've had to endure numerous treatments as part of these processes. I don't let my guard down and I am open and honest about what I can and cannot do. I've become comfortable accepting that "no" is a complete and acceptable sentence and I'm intentional with my energy and how I use it throughout the day. I'm aware of my productive times of the day and how to operate in low gear when I need to. I've been intentional in choosing doctor's that are familiar with Sjögren's and are compassionate to the complexities of this disease. Being surrounded by an amazing team of doctors has been critical to my health.

Quality of Life: I'm not going to lie and say this is all easy. I've completely adjusted my life to accommodate this disease. It affects everyone around you, and, let's face it, it's an invisible disease which makes it hard for people to understand that you feel sick when you look fine. I try not to focus on what I can't do, and instead put my energy into the things I can do. When something new pops up, I allow myself a little time to mourn and move on. Life has changed and I need to keep moving forward. I have confidence in my medical team and my 4 pillars have served me well. I don't allow Sjögren's to define me.

Disclosure: S. Barajas: None.

Putting Lived Experience into Action: Flipping the Script on Living with a Chronic Disease

Natasha Trehan[1] and Naomi Abrahams[2], [1]University of Ottawa, Take a Pain Check Foundation, Toronto, ON, Canada, [2]University of Ottawa, Ottawa, ON, Canada

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Patient Perspectives
Session Type: Patient Perspectives
Session Time: 4:00PM–5:00PM

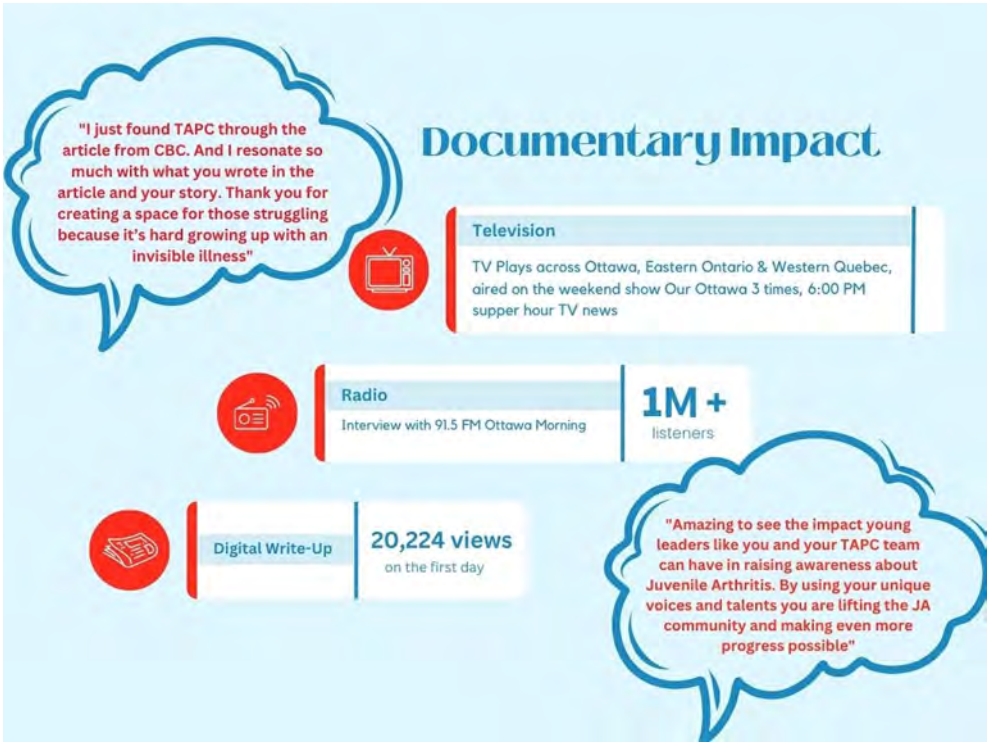
Background/Purpose: Naomi was diagnosed with Juvenile Idiopathic Arthritis (JIA) at the age of 18, after enduring 3 years of misdiagnoses. Similarly, Natasha received a diagnosis of the same condition at the age of 13. Despite their distinct timelines, they lived with the challenges of chronic autoimmune disease. To seek support, they sought out communities where they could connect with others who shared similar lived experiences. However, this proved difficult at times, prompting them to take the initiative in creating their own inclusive and supportive spaces.

Intervention: Recognizing a gap in the chronic illness community, Natasha decided to create an online platform for youth with rheumatic diseases. "I wanted to make sure other young people would never have to feel alone and go through the experience I had." This led her to create Take a Pain Check (TAPC), a non-profit organization which supports, empowers,

and provides an inclusive space where youth with rheumatic diseases feel understood. They run ambassador programs, chronic illness-related events, host podcasts, and monthly hangouts. TAPC has brought together a global network of healthcare professionals and patients to raise awareness and advocate for young people with invisible disabilities. To combine their passion for research and experiences with JIA, they joined the Choice Research Lab as patient partners. The lab focuses on patient engagement, valuing patient voices in research and shared decision-making. As patient partners, they represent young people's perspectives within the healthcare system, from diagnosis in adolescence into adulthood, influencing knowledge translation. Naomi emphasized the value of her role in a TAPC podcast episode, "Being a patient partner enables me to use both my knowledge and experience as a researcher and respondent to participate in research promotion that values lived experience."

Maintenance: Their commitment to raising awareness about arthritis has garnered recognition from the broadcaster Canadian Broadcasting Corporation (CBC) leading them to produce a documentary "If it weren't for my friends, I wouldn't have survived". The documentary emphasizes the importance of self-advocacy, finding and building a community, patient engagement and the role of friendship during one's diagnosis. Having a friend who has a similar condition can alleviate the burden of navigating it alone. This resource provides insight on obtaining support, advocating and raising awareness. Following the documentary, TAPC saw a 20% increase in followers.

Quality of Life: Arthritis is often wrongly perceived as a disease that only affects older individuals. They are determined to challenge this misconception and break down the associated stigma. Through their advocacy work, they aim to create positive change and increase awareness. They are committed to advocating for themselves and others in the chronic disease community. They hope to inspire others and expand inclusive advocacy measures in both research and social media. Their ultimate goal is to empower those affected by chronic conditions and to foster a more understanding and accepting society.



The Impact

Toward a Frontier Beyond the Barriers of Position and Prejudice

Noriko Okochi[1], Eiji Oishi[2], Yuki Kojima[3], Noro Takashi[3], Mika Ishiguro[3], Toshiko Ito-Ihara[4] and YOSHIHIRO ARIMURA[5], [1]Rheumatic Disease and Vasculitis Support Network Japan, Institute of Neuropsychiatry, Tokyo, Japan, [2]Rheumatic Disease and Vasculitis Support Network Japan, UBE Frontier University, Yamaguchi, Japan, [3]Rheumatic Disease and Vasculitis Support Network Japan, Shinagawa-Ku, Tokyo, Japan, [4]Kyoto Prefectural University of Medicine, Rheumatic Disease and Vasculitis Support Network Japan, Kyoto, Japan, [5]Kyorin University School of Medicine, Kichijoji Asahi Hospital, Rheumatic Disease and Vasculitis Support Network Japan, Mitaka-Shi, Tokyo, Japan

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Patient Perspectives
Session Type: Patient Perspectives
Session Time: 4:00PM–5:00PM

Background/Purpose: In Japan, firm boundaries exist between people from different walks of life surrounding diseases.

【Patients】

Some patients are unable to assert themselves before doctors who are knowledgeable and socially authoritative, and they are treated as they are told. It appears as if it is taboo to express to a medical professional one's desire for self-fulfillment by putting off treatment. They feel sorry for their family members, lower their self-esteem, and are unable to say what they want to prioritize in their lives.

【Caregivers of children with illnesses】

In Japan, where interaction with neighbors is decreasing, many families are isolated in child-rearing. This is even more difficult when the child has an incurable disease. Only the caregiver is responsible for the child's protection. The caregiver's personal feelings, history, and life are rarely shared with the patients themselves or with health professionals.

【Health care professionals】

It is difficult to fully interact with patients in the small amount of time available for consultation. Doctors experience many conflicts during treatment and feel helpless if their patients' conditions worsen. They may have to deal with complaints from patients because they are frustrated by their lack of success in treatment.

【Researcher】

There is a delay in the practice of patients actively participating in research. Patients have a victimized sense of being "experimented on" when asked to cooperate in drug development. Researchers and pharmaceutical companies are seen as the bad guys. Communication is not open and transparent.

The strong boundaries created by these positions have caused divisions within our society.

Intervention: It was against this cultural background that we launched the non-profit organization named Rheumatic Disease and Vasculitis Support Network in Japan. We had to resolve a number of conflicts in order to create a framework that was different from the previous Japanese patient associations.We were encouraged by many people's comments when we presented our work at the ACR in 2021.

Activities created by people from many perspectives

Maintenance: Patients, Caregivers, Health care professionals, and researchers know each other, accept each other, and work hand in hand together on various projects.

In April 2022, we exhibited a booth at the Japan College of Rheumatology. There, many doctors and researchers who support the organization joined the group. Occupational therapists and psychologists joined the group when making a video on rehabilitation.While conducting awareness-raising activities, we were contacted from overseas and exchanged views with an Indonesian patient group. I feel empowered, hopeful, and joyful by the expansion of encounters.

Quality of Life: Although patient association activities are not active in Japan, we believe that many people are encouraged by these activities.In fact, in the course of our activities to date, we have received hopeful responses from many patients and caregivers. We are working to overcome the divisions created by the strong boundaries of position. We hope that this organization will be a beacon of hope in the area of rheumatic diseases and vasculitis.

Peer Health Coaches Help Scleroderma Patients Cope with Isolation

Mary Alore[1], Yen Chen[2] and Susan Murphy[3], [1]Troy, MI, [2]University of Michigan, Ann Arbor, MI, [3]University of Michigan, Plymouth, MI

SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Patient Perspectives
Session Type: Patient Perspectives
Session Time: 4:00PM–5:00PM

Background/Purpose: In 2011, I felt extremely isolated with my new diagnosis of diffuse systemic sclerosis and sought support online and in support groups. In addition to being confusing, the misinformation I found about the disease was even scarier and more isolating than my diagnosis. I then sought social support through my rheumatologist at the University of Michigan who put me in contact with a few other patients who had asked him for similar social support. Since then, my focus

has been on supporting and educating fellow scleroderma patients as a mentor. I have worked one-on-one with over 100 scleroderma patients and concluded that patients need peer support for their mental and physical wellbeing.

Intervention: In my work as a Peer Mentor with the Michigan Medicine Scleroderma Program, I received the opportunity to become a Peer Health Coach for the RENEW study. After meeting with 45 participants, I learned that almost all patients were lonely and isolated in their disease, just like I was ten years ago.

In addition to being diagnosed with scleroderma, you receive a new status – isolated. You've never heard of scleroderma prior to the diagnosis, nor has anyone you know. Also, the physicians you have been trying to get a diagnosis from over the last year are not familiar with scleroderma either. Plus, you get the reaction, "But you don't look sick!" Through the RENEW study, health coaches met with patients virtually nine times over 12 weeks. Coaches led patients through goal-focused health-related learning modules and provided guidance, experience, and social support. As a health coach, I could offer real-life, lived experience and provide the support that was unavailable from family, friends, physicians, or therapists.

Maintenance: Patients need support and are seeking it. A trained health coach with a goal-setting framework helps them be less isolated and feel that they are not alone. Peer support is crucial for helping individuals change behaviors, like improving mental clarity and outlook, as well as motivating them to achieve health goals.

Quality of Life: I am able to discuss the health coaching experience from both the health coach and patient perspective to help reinforce the positive outcomes of peer social support. This is a valuable part of patient care that is missing in health systems.

RENEW Study logo

Utilizing Support Networks to Improve Patient Outcomes

Brian Vogel, Lupus and Allied Diseases Association, Inc., San Diego, CA

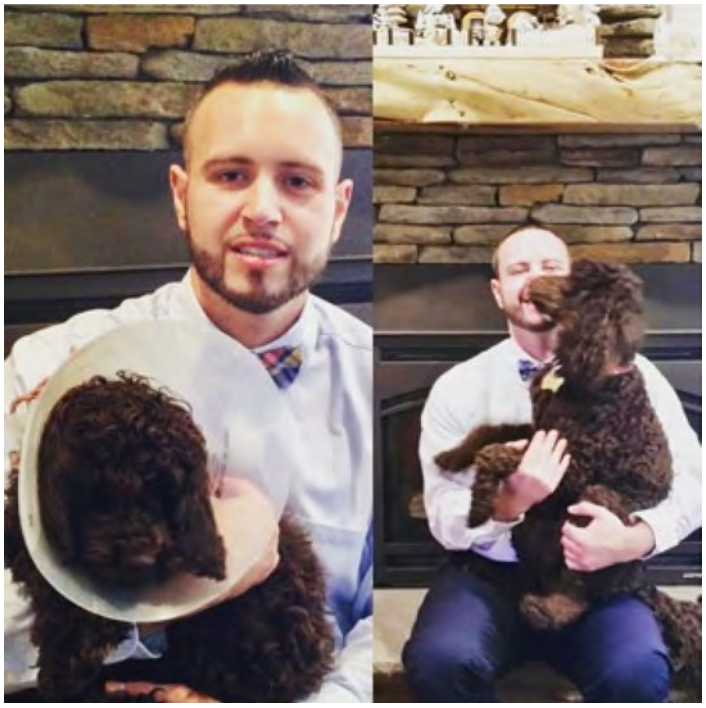
SESSION INFORMATION
Session Date: Sunday, November 12, 2023
Session Title: Patient Perspectives
Session Type: Patient Perspectives
Session Time: 4:00PM–5:00PM

Background/Purpose: In 2006, I realized I was gay and identified as LGBTQIA but did not come out. In 2008, I began experiencing chronic widespread pain, fatigue, and joint inflammation. I was referred to a rheumatologist due to a positive antinuclear antibody (ANA) test and misdiagnosed with juvenile rheumatoid arthritis. I began a medication regimen but no improvement. I consulted another rheumatologist and started a hydroxychloroquine (HCQ) and prednisone regimen. In 2010, I was diagnosed with Idiopathic Thrombocytopenia (ITP) and consulted with an oncologist when my platelets dropped dangerously low. After several failed intravenous immunoglobulin therapy (IVIG) infusions, I consulted a new oncologist and received a ten-week rituximab infusion treatment that raised my platelets. In 2011, I was formally diagnosed with Systemic Lupus Erythematosus (SLE). In 2013, I came out to my family and friends. I've tried numerous treatments between 2011-2022. SLE stabilized since February 2022 on current treatment.

Intervention: In 2017, my mom reached out to LADA and I volunteered at LADA's Annual Lupus Charity Golf Classic. I met other people with lupus and other autoimmune diseases for the first time. I then participated in LADA's Lupus Education Symposium. We learned a lot about the importance of clinical trials, patient empowerment, and care partnering from experts in the field. We then attended Annual Awareness Day at the State Capitol, as constituents of LADA, to meet with various legislators in the Senate and Assembly. I told my own story for the first time and shared my story with SLE. I will never forget the feeling of validation when seeing my story resonate with others. This feeling sparked a sense of empowerment and passion for advocating. I now share more on social media along with details of my story. When I moved to San Diego, I joined gay sports leagues to meet other gay men. It's allowed me to make new friends and connections that are essential parts of my support networks. They significantly improve my SLE outcomes regarding my social, physical, and psychological well-being. Support networks became an essential component of coping with my SLE.

Maintenance: Through joining gay sports leagues, I've cultivated a tribe of friends in San Diego that are lifelong friends and connections. LADA has indeed steered me down a road to advocacy and self-empowerment as well as amplified my support networks. I've made lifelong friends and connections around the country that have become part of support network and certainly improved my outcomes coping with SLE. They've created a close-knit Lupus community that I can rely on when I need support and questions answered. In April 2020, I became LADA Board Member. I continue my advocacy efforts alongside LADA working with people with Lupus through raising my voice and sharing my journey.

My family at the 19th Annual Lupus Charity Golf Classic 2019



My care partner poodle "Charlie" and I

Our golf team "Don't Drink and Drive"

Quality of Life: In 2013, I earned my Bachelor of Science degree. In November of 2020, I relocated to warmer climate and now live in San Diego. I've since changed careers and team of doctors. I've established strong healthy support networks in San Diego while maintaining LADA relationships. I'm eating healthier and exercising regularly. As a result of these things, I'm experiencing reduced disease activity and better quality of life.

Disclosure: B. Vogel: None.
